Clearly, $W_c[t_0,t_1]$ is at least positive semidefinite. If $W_c[t_0,t_1]$ is positive semidefinite, we simply write $W_c[t_0,t_1]\geq 0$ or, equivalently, $W_c[t_0,t_1]$ is singular or not of full rank. If $W_c[t_0,t_1]$ is strictly positive definite, we simply write $W_c[t_0,t_1]>0$ or, equivalently, $W_c[t_0,t_1]$ is nonsingular or of full rank. The Gramian criterion states that the state $x(t_0)$ is completely controllable at t_0 if and only if there exists some $t_1>t_0$ such that $W_c[t_0,t_1]>0$. The following lemma, whose proof is given in Appendix A, plays a key role in establishing Propositions 2.6 and 2.7.

LEMMA 2.5. *In the* FDLCP *system* (1)*, assume that the entries of* $A(t)$ *are piecewise continuous with respect to* t*,* $B(t)$ *belongs to* $L_\infty[0,h]$*, and* $\Phi(t,0) = P(t,0)e^{Qt}$ *is a Floquet factorization. If* $W_c[t_0, t_0+kh] \geq 0$ *with* $k \geq 1$ *being an integer larger than or equal to the degree of the minimal polynomial of the monodromy matrix* $\Phi(h,0) = e^{Qh}$*, there exists a left eigenvector* $\mathbf{a}^H$ *of* Q *such that for any integer* $v \geq 1$*,* $\mathbf{a}^H W_c[t_0, t_0+vh]\mathbf{a} = 0$*.*

PROPOSITION 2.6. *In the* FDLCP *system* (1)*, assume that the entries of* $A(t)$ *are piecewise continuous with respect to* t *and* $B(t)$ *belongs to* $L_\infty[0,h]$*. Let* $W_c[0,kh]$ *be defined as in* (5) *with the integer* k *defined in Lemma* 2.5*. Then the following three assertions are equivalent to each other.*

(a) *The system is completely controllable;*

(b) *The system is completely controllable over* $[0,kh)$*;*

(c) $W_c[0,kh]$ *is positive definite; that is,* $W_c[0,kh] > 0$*.*

Combining Lemma 2.5 and Proposition 2.6, the following result follows readily. Proposition 2.7 is important in deriving a controllability criterion based on Floquet factorizations.

PROPOSITION 2.7. *In the* FDLCP *system* (1)*, assume that the entries of* $A(t)$ *are piecewise continuous in* t*,* $B(t)$ *belongs to* $L_\infty[0,h]$*, and* $\Phi(t,0) = P(t,0)e^{Qt}$ *is a Floquet factorization. Then the system* (1) *is not completely controllable if and only if there exists a left eigenvector* $\mathbf{a}^H$ *of* Q *such that* $\mathbf{a}^H W_c[0,h]\mathbf{a} = 0$*. Here,* $W_c[0,h]$ *is given in* (5) *as appropriate.*

3. Harmonic framework for controllability in FDLCP systems. Now we establish controllability criteria through harmonic analysis on the system matrices of FDLCP systems. These results can be viewed as counterparts to the controllability criteria we frequently employ in LTI continuous-time systems. In view of this similarity, the results can be useful in clarifying structural characteristics of FDLCP systems, which have not been well examined by means of the conventional time-domain approaches [27].

3.1. Controllability criteria via Floquet factorizations. Now we state a controllability criterion by use of Floquet factorizations of FDLCP systems.

THEOREM 3.1. *In the* FDLCP *system* (1)*, suppose that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t) \in L_{\mathrm{CAC}}[0,h]$*. Also assume that* $\Phi(t,0) = P(t,0)e^{Qt}$ *is a Floquet factorization. Then the system* (1) *is completely controllable if and only if for any* $s \in \mathcal{C}$

$$\mathbf{a}^H[\ sI - Q \ \big|\ \cdots, \hat{B}_{-2}, \hat{B}_{-1}, \hat{B}_0, \hat{B}_1, \hat{B}_2, \cdots\ ] \neq 0 \quad \forall \mathbf{a} \neq 0 \in \mathcal{C}^n, \tag{6}$$

where n *is the dimension of the state matrix* $A(t)$ *and* $\{\hat{B}_\mu\}_{\mu=-\infty}^{\infty}$ *is the Fourier coefficient sequence of the matrix* $\hat{B}(t)(= P^{-1}(t,0)B(t))$*.*

Proof. The assumptions on $A(t)$ and $B(t)$ guarantee by Lemma 2.2 that $\hat{B}(t) \in L_{\mathrm{CAC}}[0,h]$. This in particular means that the Fourier series $\sum_\mu \hat{B}_\mu e^{j\mu\omega_h t}$ of $\hat{B}(t)$ uniformly converges to $\hat{B}(t)$ so that it is meaningful to replace $\hat{B}(t)$ with its Fourier series in the following.

(Necessity) Assume that the system (1) is completely controllable but the condition (6) fails. That is, for some $s_0 \in \mathcal{C}$, there exists a vector $\mathbf{a} \neq 0 \in \mathcal{C}^n$ such that

$$\mathbf{a}^H[\ s_0 I - Q \ \big|\ \cdots, \hat{B}_{-2}, \hat{B}_{-1}, \hat{B}_0, \hat{B}_1, \hat{B}_2, \cdots\ ] = 0.$$

It is easy to see that s_0 is an eigenvalue of Q with $\mathbf{a}^H$ being a corresponding left eigenvector. Taking into account that $\mathbf{a}^H \hat{B}_\mu = 0$ for all μ, we observe the deductions

$$\mathbf{a}^H e^{-Qt}\hat{B}(t) = \mathbf{a}^H e^{-s_0 t}\hat{B}(t) = \left\{ \sum_\mu \mathbf{a}^H \hat{B}_\mu e^{j\mu\omega_h t} \right\} e^{-s_0 t} = 0 \quad \forall t \geq 0,$$

which lead to $\mathbf{a}^H W_c[0, kh]\mathbf{a} = 0$ by the definition (5) with k given in Lemma 2.5. Then Proposition 2.6 implies that the system is not completely controllable. This yields a contradiction.

(Sufficiency) Assume that the condition (6) is true but the system is not completely controllable. Proposition 2.7 tells us that there exist an eigenvalue s_0 of Q and a left eigenvector $\mathbf{a}^H \neq 0$ such that $\mathbf{a}^H W_c[0, h]\mathbf{a} = 0$. This implies that $\mathbf{a}^H e^{-Qt}\hat{B}(t) = \mathbf{a}^H e^{-s_0 t}\hat{B}(t) = 0$ for all $t \in [0, h)$, or $\mathbf{a}^H \hat{B}(t) = 0$ for all $t \in [0, h)$. Again, replacing $\hat{B}(t)$ in the previous equation with its Fourier series $\sum_\mu \hat{B}_\mu e^{j\mu\omega_h t}$, it is trivial to derive that $\mathbf{a}^H \hat{B}_\mu = 0$ for all μ. This, together with the fact that $\mathbf{a}^H$ is a left eigenvector of Q, implies that (6) fails at s_0. ∎

Unfortunately, however, there is still an obstacle in implementing Theorem 3.1. That is, one must know the Floquet factorization of the state transition matrix of the FDLCP system. How to determine Floquet factorizations in closed form for general FDLCP systems is still an open problem, although there are numerous numeric procedures [26] for the derivation of the Floquet factorizations; for instance, directly via piecewise constant approximation [10] or indirectly but approximately analytic via Chebyshev polynomial expansion [35]. Therefore, a natural question is: can we develop any controllability criteria without the state transition matrices of FDLCP systems? This question is answered in the next section.

3.2. Controllability criteria via Fourier analysis. Based on Theorem 3.1, let us consider how to express the condition (6) without involving the state transition matrix of the FDLCP system considered.

THEOREM 3.2. *In the* FDLCP *system* (1)*, suppose that* $A(t) \in L_{\mathrm{PCD}}[0, h]$ *and* $B(t) \in L_{\mathrm{CAC}}[0, h]$*. Then the system* (1) *is completely controllable if and only if for each* $s \in \mathcal{C}_f$

$$\underline{a}^H [\ s\underline{I} + \underline{E}(j0) - \underline{A} \mid \underline{B}\ ] \neq 0 \quad \forall \underline{a} \neq 0 \in l_E, \tag{7}$$

where $\underline{A} = \mathcal{T}\{A(t)\}$ *and* $\underline{B} = \mathcal{T}\{B(t)\}$*, respectively. Also,* $\underline{I} = \mathcal{T}\{I\}$*.*

Proof. Assume in the proof discussion that a Floquet simplex for the state transition matrix $\Phi(t, 0)$ of the system (1) is meant whenever Floquet factorizations of $\Phi(t, 0)$ are mentioned. This will cause no loss of generality by Lemma 2.1 in the following arguments.

(Necessity) Assume that the system (1) is completely controllable but the condition (7) fails. Thus, there exist some $s_0 \in \mathcal{C}_f$ and a nonzero vector $\underline{a} \in l_E$ such that $\underline{a}^H [\ s_0\underline{I} + \underline{E}(j0) - \underline{A} \mid \underline{B}\ ] = 0$. By the harmonic Floquet similarity formulas of Lemma 2.2, the equation can be rewritten as

$$\underline{a}^H \underline{P} [\ s_0\underline{I} + \underline{E}(j0) - \underline{Q} \mid \underline{P}^{-1}\underline{B}\ ] \begin{bmatrix} \underline{P}^{-1} & 0 \\ 0 & \underline{I} \end{bmatrix} = 0.$$

Since the last operator matrix in the above equation is invertible on $l_2 \oplus l_2$, we obtain simply

$$\underline{a}^H \underline{P} [\ s_0\underline{I} + \underline{E}(j0) - \underline{Q} \mid \hat{\underline{B}}\ ] = 0. \tag{8}$$

Now, for our purpose, define $0 \neq \underline{a}^H \underline{P} =: [\cdots, a_{-1}^H, a_0^H, a_1^H, \cdots]$ with $a_k \in \mathcal{C}^n$. Apparently, there is at least one (vector) entry $a_k \neq 0$ since $\underline{a} \neq 0$ and $\underline{P}$ is invertible on l_E by Lemma 2.2. Note that $s_0\underline{I} + \underline{E}(j0) - \underline{Q}$ is block-diagonal. Then from (8) it follows that

$$a_k^H[(s_0 + jk\omega_h)I - Q] = 0 \quad \forall k \in \mathcal{Z}. \tag{9}$$

Revoking the Floquet simplex assumption that all eigenvalues of Q are located in $\mathcal{C}_f$ and the comment just after Lemma 2.1, we can conclude that for any integer $k \neq 0$, the matrix $(s_0 + jk\omega_h)I - Q$ must be invertible at any $s_0 \in \mathcal{C}_f$. This, together with (9), gives that $a_k = 0$ for any $k \neq 0$. Note again that not all a_k are zeros. Then the above observation means that $a_0 \neq 0$ but $a_k = 0$ for any $k \neq 0$. Using this fact back to (8), we obtain immediately after simple multiplications that $a_0^H[\ s_0 I - Q \ \big|\ \cdots, \hat{B}_{-1}, \hat{B}_0, \hat{B}_1, \cdots\ ] = 0$, $a_0 \neq 0$, which says from Theorem 3.1 that the system (1) is not completely controllable. However, this is contradictory to the assumption that the system is completely controllable.

(Sufficiency) Assume that the condition (7) holds but the system (1) is not completely controllable. By Theorem 3.1, there exist a scalar $s_0 \in \mathcal{C}$ and a nonzero vector $\alpha_0 \in \mathcal{C}^n$ satisfying

$$\alpha_0^H[\ s_0 I - Q \ \big|\ \cdots, \hat{B}_{-2}, \hat{B}_{-1}, \hat{B}_0, \hat{B}_1, \hat{B}_2, \cdots\ ] = 0.$$

However, by the Floquet simplex assumption this cannot be true unless $s_0 \in \mathcal{C}_f$. Hence, there is no need to consider any s_0 that is located beyond the fundamental strip $\mathcal{C}_f$.

Now we define the infinite-dimensional vector $\underline{\alpha}^H := [\cdots, 0^H, \alpha_0^H, 0^H, \cdots]$. Clearly, $\underline{\alpha}$ is nonzero and $\underline{\alpha} \in l_E$. Based on the matrix expressions of $s\underline{I} + \underline{E}(j0) - \underline{Q}$ and $\hat{\underline{B}}$, it is straightforward to see that $\underline{\alpha}^H[\ s_0\underline{I} + \underline{E}(j0) - \underline{Q} \ \big|\ \hat{\underline{B}}\ ] = 0$, which can be written by the harmonic Floquet similarity formulas of Lemma 2.2 as $\underline{a}^H[s_0\underline{I} + \underline{E}(j0) - \underline{A} \,|\, \underline{B}] = 0$ with $\underline{a} := \underline{P}^{-H}\underline{\alpha}$. By Lemma 2.2, l_E is $\underline{P}^{-H}$-invariant so that $\underline{a} \neq 0$ belongs to l_E. However, this means that the condition (7) does not hold at $s_0 \in \mathcal{C}_f$ with $\underline{a}$ thus defined. This is contradictory to the assumption on (7). □

THEOREM 3.3. *In the* FDLCP *system* (1)*, suppose that* $A(t) \in L_{\mathrm{PCD}}[0, h]$ *and* $B(t) \in L_{\mathrm{CAC}}[0, h]$. *Then the system* (1) *is completely controllable if and only if for each* $\lambda_i \in \Lambda$ *and any eigenvector* $\underline{a} \in \mathcal{N}(\lambda_i\underline{I} + \underline{E}(j0) - \underline{A}) \subset l_E$*, one of the following two conditions is satisfied.*

(a) $\underline{a}^H \underline{e}(\underline{A} - \underline{E}(j0), t)\underline{B} \neq 0$ *for all* $t \in [0, \infty)$*;*

(b) $\underline{a}^H[\underline{B}, (\underline{A} - \underline{E}(j0))\underline{B}, (\underline{A} - \underline{E}(j0))^2\underline{B}, \cdots] \neq 0$.

Proof. The proof can be given by repeating arguments similar in form to those in LTI continuous-time systems, based on Theorem 3.2. Here only a sketched proof for (a) is provided.

(Necessity) Assume that the system is completely controllable but the condition (a) fails. That is, there exist $\lambda_i \in \Lambda$ and an associated eigenvector $\underline{a} \in \mathcal{N}(\lambda_i\underline{I} + \underline{E}(j0) - \underline{A})$ such that $\underline{a}^H \underline{e}(\underline{A} - \underline{E}(j0), t)\underline{B} = 0$ for all $t \in [0, \infty)$. This, in particular, says that $\underline{a}^H\underline{B} = 0$ if we note that $\underline{e}(\underline{A} - \underline{E}(j0), 0) = \underline{I}$. These facts yield that $\underline{a}^H[\lambda_i\underline{I} + \underline{E}(j0) - \underline{A} \,|\, \underline{B}] = 0$, which means that the system is not completely controllable by Theorem 3.2. This brings us a contradiction.

(Sufficiency) Assume that the condition (a) is satisfied but the system is not completely controllable. Theorem 3.2 says that $\lambda_i \in \Lambda$ and an associated eigenvector $\underline{a} \in \mathcal{N}(\lambda_i\underline{I} + \underline{E}(j0) - \underline{A})$ such that $\underline{a}^H[\lambda_i\underline{I} + \underline{E}(j0) - \underline{A} \,|\, \underline{B}] = 0$, from which it follows

that $\underline{a}^H(\underline{A}-\underline{E}(j0))^i\underline{B}=0$ for all $i=0,1,2,\ldots$. By the definition of $\underline{e}(\underline{A}+\underline{E}(j0),t)$, it follows immediately that $\underline{a}^H\underline{e}(\underline{A}-\underline{E}(j0),t)\underline{B}=0$ for all $t\in[0,\infty)$. We are led to a contradiction. □

Combining Theorem 3.3 with Proposition 2.3, it is obvious that under the assumptions of Theorem 3.3, the system (1) is completely controllable if and only if for each $\lambda_i\in\Lambda$ and any eigenvector $\underline{a}\in\mathcal{N}(\lambda_i\underline{I}+\underline{E}(j0)-\underline{Q})\subset l_E$, one of the following two conditions is satisfied: (a) $\underline{a}^H\underline{e}(\underline{Q}-\underline{E}(j0),t)\hat{\underline{B}}\neq 0$ for all $t\in[0,\infty)$; (b) $\underline{a}^H[\hat{\underline{B}},(\underline{Q}-\underline{E}(j0))\hat{\underline{B}},(\underline{Q}-\underline{E}(j0))^2\hat{\underline{B}},\cdots]\neq 0$.

Remark 1. Theorems 3.2 and 3.3 can be viewed as operator-valued counterparts in the FDLCP setting to the controllability criteria in the LTI continuous-time systems; for instance, Theorem 3.2 is the harmonic version of the famous PBH criterion. In this sense we say that FDLCP systems are essentially LTI whenever controllability is considered. Moreover, some intuitive observations indicate readily that installing an h-periodic state feedback in an FDLCP system does not affect controllability between the open- and closed-loop systems. Though this conclusion is already well known in the FDLCP field, it is interesting to notice that such a controllability invariance may follow more easily by the harmonic framework.

The significance of the controllability conditions suggested in Theorem 3.3 is mainly theoretical. This is especially true for condition (b). It is worth mentioning that condition (a) of Theorem 3.3 is useful in tackling what we called the harmonic Lyapunov equation [42]. To avoid distracting the reader's attention, we do not pursue this topic in this paper.

3.3. Corollaries of Theorem 3.2. Similar to what we have encountered in testing the controllability conditions of Theorem 3.1, it is hard to numerically implement the results of Theorem 3.2 if we mention that $s\underline{I}+\underline{E}(j0)-\underline{A}$ is infinite-dimensional and unbounded, even though no state transition matrix is involved in the criterion. As we will see from Corollaries 3.4 and 3.5, the controllability conditions in Theorem 3.2 can reduce to some numerically implementable conditions if $A(t)$, $B(t)$, and/or the Floquet factorizations of the FDLCP system (1) have specific features.

To simplify our statements, we denote the submatrix of $[s\underline{I}+\underline{E}(j0)-\underline{A}\,|\,\underline{B}]$ consisting of the central $(2N+1)$ blockwise rows in $[s\underline{I}+\underline{E}(j0)-\underline{A}\,|\,\underline{B}]$ by $[s\underline{I}+\underline{E}(j0)-\underline{A}\,|\,\underline{B}]_N$.

3.3.1. An equivalent statement of Theorem 3.2.

COROLLARY 3.4. *In the* FDLCP *system* (1)*, suppose that* $A(t)\in L_{\mathrm{PCD}}[0,h]$ *and* $B(t)\in L_{\mathrm{CAC}}[0,h]$. *Then the system* (1) *is completely controllable if and only if for each* $s\in\mathcal{C}_f$ *and each* $N=0,1,2,\ldots$

$$\mathbf{a}^H[\ s\underline{I}+\underline{E}(j0)-\underline{A}\ \mid\ \underline{B}\ ]_N\neq 0\quad\forall\mathbf{a}\neq 0\in\mathcal{C}^{(2N+1)n},$$

where the integer n *is the dimension of the state matrix* $A(t)$.

In Corollary 3.4, the controllability criteria claimed on infinite-dimensional operators are converted into a group of infinitely many finite-dimensional conditions. At first glance, the latter may be equally difficult to test. However, in some cases due to the skew strip matrix expressions of $\underline{E}(j0)-\underline{A}$ and $\underline{B}$ only finitely many finite-dimensional conditions need to be tested.

3.3.2. A special case of Theorem 3.2. If Floquet factorizations of the FDLCP system (1) possesses some specific features, the criteria of Theorem 3.2 may be expressed in finite-dimensional forms.

COROLLARY 3.5. *In the* FDLCP *system* (1), *suppose that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t) \in L_{\mathrm{CAC}}[0,h]$. *Assume that* $\Phi(t,0) = \tilde{P}(t,0)e^{\tilde{Q}t}$ *is a Floquet factorization satisfying*

$$\tilde{P}(t,0) = \sum_{|k|\le N_p} \tilde{P}_k e^{jk\omega_h t}, \quad \lambda(\tilde{Q}) \subset \bigcup_{|k|\le N_q} \{\mathcal{C}_f + jk\omega_h\}$$

for some integers $N_p \ge 0$ *and* $N_q \ge 0$. *Then, the* FDLCP *system* (1) *is completely controllable if and only if for each* $s \in \mathcal{C}$

$$\mathbf{a}^H[\ s\underline{I} + \underline{E}(j0) - \underline{A} \mid \underline{B}\ ]_{N_p+N_q} \ne 0 \quad \forall \mathbf{a} \ne 0 \in \mathcal{C}^{(2(N_p+N_q)+1)n}, \tag{10}$$

where the integer n *is the dimension of the state matrix* $A(t)$.

Proof. Since $A(t) \in L_{\mathrm{CPD}}[0,h] \subset L_{\mathrm{CAC}}[0,h]$ and $B(t) \in L_{\mathrm{CAC}}[0,h]$, Theorem 3.2 applies and it follows that the system (1) is completely controllable if and only if for any $s \in \mathcal{C}_f$

$$\underline{a}^H[\ s\underline{I} + \underline{E}(j0) - \underline{A} \mid \underline{B}\ ] \ne 0 \quad \forall \underline{a} \ne 0 \in l_E. \tag{11}$$

Again note that (11) holds over $s \in \mathcal{C}_f$ if and only if it is true over $s \in \mathcal{C}$. The necessity is obvious. In the following, we turn to show the sufficiency.

First, let us verify that under the assumptions about the Floquet factorization $\tilde{P}(t,0)e^{\tilde{Q}t}$, any eigenvector associated with an eigenvalue of $\underline{E}(j0) - \underline{A}$ has at most $2(N_p + N_q) + 1$ consecutive nonzero entries while all other entries are zeros.

To this end, we write $\Phi(t,0) = P(t,0)e^{Qt}$ to be the Floquet simplex derived via the technique suggested in the proof of Lemma 2.1 so that (3) holds. With this Floquet simplex, it follows that for each eigenvalue λ of $\underline{Q} - \underline{E}(j0)$, any associated eigenvector must be of the form $\underline{x} = [\cdots, x^T, \cdots]^T \in l_E$, with $x \ne 0 \in \mathcal{C}^n$. By Lemma 2.2, one can assert that λ is also an eigenvalue of $\underline{A} - \underline{E}(j0)$ with an associated eigenvector $\underline{P}\,\underline{x} \in l_E$. Since $P(t,0)$ contains at most $N_p + N_q$ harmonics, it follows that only entries in the $2(N_p+N_q)+1$ skew lines along the main diagonal line of $\underline{P}$ are possibly nonzero. This, together with the specific structure of $\underline{x}$, leads to the desired assertion.

Second, we mention that (11) fails only if $\underline{a}$ is an eigenvector of $\underline{A} - \underline{E}(j0)$. In other words, we can examine (11) by testing it over all eigenvectors of $\underline{A} - \underline{E}(j0)$.

Finally, taking into account the structure features of eigenvectors of $\underline{A} - \underline{E}(j0)$ under the assumptions about the Floquet factorization, we see that for each eigenvector of $\underline{A} - \underline{E}(j0)$, only the $2(N_p + N_q) + 1$ consecutive blockwise rows in $\underline{A} - \underline{E}(j0)$ corresponding to the $2(N_p + N_q) + 1$ consecutive nonzero entries in the eigenvector are significant with regard to linear independence of vectors. Based on the above arguments, if (10) is satisfied, then we can conclude that for each eigenvector of the operator $\underline{A} - \underline{E}(j0)$, (11) is true. ∎

It can be understood from the proof of Corollary 3.5 that the exact formula for Floquet factorizations involved in Corollary 3.5 is not necessary, except for the integers N_p and N_q. Indeed, N_q always exists. Therefore, if $\tilde{P}(t,0)$ contains only finitely many harmonics, it is always possible to fix an integer N satisfying $N \ge N_p + N_q$. If for each $s \in \mathcal{C}$, $\mathbf{a}^H[s\underline{I} + \underline{E}(j0) - \underline{A} \mid \underline{B}]_N \ne 0$ for all $\mathbf{a} \ne 0 \in \mathcal{C}^{(2N+1)n}$, then (10) holds. In this sense, we must point out that the Floquet factorization assumption is not a big obstacle in implementing the controllability criterion of Corollary 3.5.

3.3.3. Noncontrollability criterion derived from Theorem 3.2. Corollaries 3.4 and 3.5 are claimed in the sense of controllability of FDLCP systems. In contrast, the corollary given below provides sufficient conditions for noncontrollability.

COROLLARY 3.6. *In the* FDLCP *system* (1)*, suppose that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t) \in L_{\mathrm{CAC}}[0,h]$*. If for some* $s \in \mathcal{C}_f$ *there exists a vector sequence* $\{\mathbf{a}_\mu\}_{\mu=-\infty}^{\infty}$ *with* $\mathbf{a}_\mu \in \mathcal{C}^n$ *and* $\mathbf{a}_\mu \neq 0$ *for some* μ *such that*

$$\mathbf{a}_\mu^H[\ (s+j\mu\omega_h)\mathbf{I}-\mathbf{A}\ \big|\ \mathbf{B}\ ]=0 \quad \forall \mu \in \mathcal{Z}, \tag{12}$$

then the system (1) *is not completely controllable. In the above,* $\mathbf{I}$ *and* $\mathbf{A}$ *are defined as follows:*

$$\mathbf{I}=[\cdots,0,I,0,\cdots], \quad \mathbf{A}=[\cdots,A_{-1},A_0,A_1,\cdots],$$

where $\{A_\mu\}_{\mu=-\infty}^{\infty}$ *is the Fourier coefficient sequence of* $A(t)$*.* $\mathbf{B}$ *is defined similarly to* $\mathbf{A}$ *but in terms of the Fourier coefficients of* $B(t)$*.*

Proof. By the assumption on $\{\mathbf{a}_\mu\}_{\mu=-\infty}^{\infty}$, there exists at least one vector, say $\mathbf{a}_\mu$, satisfying $\mathbf{a}_\mu \neq 0$. Let us define an infinite-dimensional vector $\underline{a}^H := [\cdots,\mathbf{a}_\mu^H,\cdots]$ with $\mathbf{a}_\mu$ being situated at the μth position in $\underline{a}$. Obviously, $\underline{a}$ is nonzero and belongs to l_E. Bearing this in mind, arranging the conditions (12) according to $\underline{a}$, it follows readily that $\underline{a}^H[s\underline{I}-\underline{A}\,|\,\underline{B}]=0$. This implies by Theorem 3.2 that the system is not completely controllable. □

In less rigorous words, Corollary 3.6 says that some linear dependence among the Fourier coefficients of $A(t)$ and $B(t)$ of the FDLCP system (1) can be a structural reason why the system loses controllability, as is already known in LTI cases. Needless to say, other coefficients' linear dependence may also result in non-controllability. The linear dependence among the Fourier coefficients of $A(t)$ and $B(t)$ described in Corollary 3.6 is just one of the simplest cases. In other words, linear independence of the n infinite-dimensional row vectors in $[s\mathbf{I}-\mathbf{A}\,|\,\mathbf{B}]$ is a necessary condition for controllability of the FDLCP system (1).

4. Controllability decomposition of FDLCP systems. From the results of the previous sections, one can see that FDLCP systems are essentially LTI when controllability is concerned. It is well known [11], [21], [39] that an LTI state-space model can always be decomposed according to controllable/uncontrollable modes through a state coordinate transform. It is natural to consider whether or not such controllability decompositions exist in FDLCP systems. Indeed, as a first answer to such a decomposition question, the canonical structure theorems of [21] ensure that controllability canonical decompositions for general dynamic systems are possible and the state coordinate transform can be determined in a pointwise fashion in time (i.e., for each fixed instant t of time, the dynamic system concerned is viewed as an LTI one and thus decomposed accordingly). For FDLCP systems, it is claimed that the state coordinate transform needed can be continuous in time by Theorem 6 of [21] (without proof).

However, in many FDLCP systems merely keeping continuity during the state coordinate transform is not enough to validate harmonic analysis due to convergence issues. There is another decomposition method given in [37] for general linear continuous-time time-varying systems by means of the so-called Doležal theorem with a continuous and differentiable state coordinate transform, under the assumption that the rank of the controllability Gramian is independent of t. This rank assumption is true in FDLCP systems and brings us with periodic transformed systems by applying the Doležal theorem to suitable sequences of Gramians as shown by [4]. In general, the Doležal theorem results in a transformed FDLCP system that has a periodic state matrix, which may be hard to handle when such a controllability decomposition is utilized.

In this section, we show that controllability decompositions for FDLCP systems are also available via state coordinate transforms that possess fairly strong analytic properties, which are highly expected in system analysis and synthesis if the harmonic approach is adopted, while a constant state matrix is attained in the decomposed FDLCP system. How to exploit these analytic features of the controllability canonical decompositions for poles/zeros analysis, positive realness of the so-called harmonic frequency response operators [41] and the harmonic state operators [43], and H_2/H_∞ performance synthesis in FDLCP systems is left for subsequent papers.

4.1. Decomposition algorithm. First, we write $\Phi(t,0) = P(t,0)e^{Qt}$ to be a Floquet factorization for the FDLCP system (1), and then we observe that the FDLCP system given by

$$\Sigma : \dot{z} = Qz + \hat{B}(t)u \tag{13}$$

with $\hat{B}(t) = P^{-1}(t,0)B(t)$ is equivalent to the system (1) in the sense of controllability, after introducing the Floquet state coordinate transform $z = P(t,0)x$ to the system (1).

Second, we form the following approximate FDLCP model for the system (13) by piecewise constant treatment upon all the entries of $\hat{B}(t)$. That is, we have

$$\Sigma_\kappa : \dot{\zeta} = Q\zeta + \hat{B}(\kappa,t)u \tag{14}$$

with

$$\hat{B}(\kappa,t) := \hat{B}(t_{k-1}) \quad \forall t \in [t_{k-1}, t_k),\ k = 1,2,\ldots,\kappa,$$

with $0 = t_0 < t_1 < t_2 < \cdots < t_\kappa = h$. That is, the union of all the subintervals $[t_0,t_1),\ [t_1,t_2),\cdots,[t_{\kappa-1},t_\kappa)$ forms $[0,h)$. Obviously, if $\hat{B}(t)$ is continuous in t, the piecewise constant treatment on $\hat{B}(t)$ is well defined for any subinterval sequences since the set of piecewise constant functions is dense in the set of piecewise continuous functions in the norm sense of $\sup_{t\in[0,h)} ||\cdot||$. For simplicity, the subintervals sequence $\{[t_0,t_1),[t_1,t_2),\cdots,[t_{\kappa-1},t_\kappa)\}$ is called a segmentation of $[0,h)$ and denoted by $\mathcal{S}(\kappa)$. With a bit of abuse of notation we use $\kappa \to \infty$ to mean $\max_{k=1,2,\ldots,\kappa} |t_{k-1} - t_k| \to 0$ in the following. Hence, we obtain by the definition of $\hat{B}(\kappa,t)$ that $\lim_{\kappa\to\infty} \hat{B}(\kappa,t) = \hat{B}(t)$.

Third, let us define the following matrix:

$$\hat{B}_\kappa = [\, e^{-Qt_0}\hat{B}(t_0), e^{-Qt_1}\hat{B}(t_1), \cdots, e^{-Qt_{\kappa-1}}\hat{B}(t_{\kappa-1})\,].$$

Now let $\gamma(\kappa) := \operatorname{rank}[\hat{B}_\kappa, Q\hat{B}_\kappa, \cdots, Q^{n-1}\hat{B}_\kappa]$ and choose $\gamma(\kappa)$ column vectors that are linearly independent from $[\hat{B}_\kappa, Q\hat{B}_\kappa, \cdots, Q^{n-1}\hat{B}_\kappa]$. Based on these $\gamma(\kappa)$ column vectors, one can always construct $\gamma(\kappa)$ orthonormal vectors $\epsilon_\kappa^{(1)}, \epsilon_\kappa^{(2)}, \cdots, \epsilon_\kappa^{(\gamma(\kappa))}$ by Lemma 1 of [8, p. 25]. Then add other $n - \gamma(\kappa)$ more orthonormal vectors $\epsilon_\kappa^{(\gamma(\kappa)+1)}, \cdots, \epsilon_\kappa^{(n)}$ such that $\epsilon_\kappa^{(1)}, \epsilon_\kappa^{(2)}, \cdots, \epsilon_\kappa^{(n)}$ form an orthonormal base for the Euclidean space $\mathcal{C}^n$. For our purpose, let us write

$$T_\kappa := [\epsilon_\kappa^{(1)}, \cdots, \epsilon_\kappa^{(\gamma(\kappa))} |\, \epsilon_\kappa^{(\gamma(\kappa)+1)}, \cdots, \epsilon_\kappa^{(n)}] =: [T_{1\kappa} |\, T_{2\kappa}]. \tag{15}$$

It should be pointed out that $T_\kappa^H = T_\kappa^{-1}$ by the definition of T_κ.

Finally, noncontrollability of the system (1) is connected to that of its approximate models defined in (14). This noncontrollability connection is significant in determining

a controllability canonical decomposition which we will deal with in the next section. A detailed proof of the results in Proposition 4.1 is given in Appendix B.

PROPOSITION 4.1. *In the* FDLCP *system* (1)*, assume that the entries of* $A(t)$ *are piecewise continuous in* t*, while the entries of* $B(t)$ *are continuous in* t*. Then the approximate* FDLCP *system* (14) *is well defined for any segmentation* $\mathcal{S}(\kappa)$*. Moreover, the system* (1) *is not completely controllable if and only if for any* $\mathcal{S}(\kappa)$ *the approximate system* (14) *is not completely controllable.*

4.2. Controllability canonical decomposition theorem. Based on the algorithm for constructing T_κ and the Floquet factorization of the state transition matrix, we can claim the following controllability canonical decomposition theorem for the FDLCP system (1), whose proof is a bit lengthy and thus found in Appendix C.

THEOREM 4.2. *In the* FDLCP *system* (1)*, suppose that the entries of* $A(t)$ *are piecewise continuous in* t*, while the entries of* $B(t)$ *are continuous in* t*. Assume that the pair* $(A(\cdot), B(\cdot))$ *is not completely controllable. If the segmentation* $\mathcal{S}(\kappa)$ *on* $[0, h)$ *is fine enough in the sense of* $\kappa \to \infty$*, then the state coordinate transform* $\tilde{x} = T_\kappa P(t, 0)x$ *transforms the* FDLCP *system* (1) *into a controllability canonical form given by*

$$\dot{\tilde{x}} = \begin{bmatrix} Q_c & Q_{12} \\ 0 & Q_{\bar{c}} \end{bmatrix} \tilde{x} + \begin{bmatrix} B_c(t) \\ 0 \end{bmatrix} u, \tag{16}$$

where Q_c*,* Q_{12}*, and* $Q_{\bar{c}}$ *are constant matrices of appropriate dimensions, while* $B_c(t)$ *is* h*-periodic and continuous in* t *and the pair* $(Q_c, B_c(\cdot))$ *is completely controllable. Moreover,* T_κ *defined in* (15) *can be chosen independently of the segmentation* $\mathcal{S}(\kappa)$ *as long as* κ *is large enough. Hence,* Q_c*,* Q_{12}*,* $Q_{\bar{c}}$*, and* $B_c(t)$ *are also independent of the segmentation* $\mathcal{S}(\kappa)$*.*

When the assumptions on $A(t)$ and $B(t)$ are strengthened mildly, some excellent analytic properties about $P(t, 0)$, $P^{-1}(t, 0)$, and $\hat{B}(t)$ follow from the results in [41]. This, together with the fact that T_κ is a constant matrix, implies the assertions of Corollary 4.3.

COROLLARY 4.3. *In the* FDLCP *system* (1)*, suppose that* $A(t) \in L_{\mathrm{PCD}}[0, h]$ *and* $B(t) \in L_{\mathrm{CAC}}[0, h]$*, and that the pair* $(A(\cdot), B(\cdot))$ *is not completely controllable. If the segmentation* $\mathcal{S}(\kappa)$ *on* $[0, h)$ *is fine enough, i.e.,* $\kappa \to \infty$*, then the state coordinate transform* $x = T_\kappa P(t, 0)\tilde{x}$ *transforms the* FDLCP *system* (1) *into a controllability canonical form given by* (16)*. Moreover, it holds that*

(a) $B_c(t) \in L_{\mathrm{CAC}}[0, h]$*;*

(b) $T_\kappa P(t, 0)$ *is absolutely continuous with respect to* t *and invertible uniformly over* $t \in [0, h)$*;*

(c) *The first-order derivatives of* $T_\kappa P(t, 0)$ *and* $P^{-1}(t, 0)T_\kappa^{-1}$ *are piecewise continuous in* t*.*

5. Controllability of numeric examples. To illustrate the main results obtained in the paper, we investigate controllability of the following 5-periodic differential state-space equation [10] as the first example, in which different constant input matrices $B(t)$ (i.e., b_1, b_2, b_3, and b_4 are constants) are considered in two cases:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \end{bmatrix} = \begin{bmatrix} 0 & -\frac{13\pi}{30} & \frac{2\pi}{5}\cos^2(\frac{2\pi t}{5}) & \frac{\pi}{5}\sin(\frac{4\pi t}{5}) \\ \frac{13\pi}{30} & 0 & -\frac{\pi}{5}\sin(\frac{4\pi t}{5}) & \frac{2\pi}{5}\cos^2(\frac{2\pi t}{5}) \\ 0 & 0 & 0 & -\frac{13\pi}{30} \\ 0 & 0 & \frac{13\pi}{30} & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix} u.$$

For the state matrix $A(t)$ we have the following Floquet factorization:

$$P(t,0) = \begin{bmatrix} \cos(\frac{2\pi t}{5}) & -\sin(\frac{2\pi t}{5}) & \sin(\frac{2\pi t}{5}) & 0 \\ \sin(\frac{2\pi t}{5}) & \cos(\frac{2\pi t}{5}) & 0 & \sin(\frac{2\pi t}{5}) \\ 0 & 0 & \cos(\frac{2\pi t}{5}) & -\sin(\frac{2\pi t}{5}) \\ 0 & 0 & \sin(\frac{2\pi t}{5}) & \cos(\frac{2\pi t}{5}) \end{bmatrix},$$

$$Q = \begin{bmatrix} 0 & -\frac{\pi}{30} & 0 & 0 \\ \frac{\pi}{30} & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{13\pi}{30} \\ 0 & 0 & \frac{13\pi}{30} & 0 \end{bmatrix}.$$

Case A. Let us investigate controllability when $B(t) = [0,0,0,1]^T$. By means of the sufficient rank criterion suggested in [33], the so-called controllability matrix is

$$\begin{bmatrix} 0 & -\frac{\pi}{5}\sin(\frac{4\pi t}{5}) & \begin{pmatrix} -\frac{26\pi^2}{75}\cos^2(\frac{2\pi t}{5}) \\ -\frac{4\pi^2}{25}\cos(\frac{4\pi t}{5}) \end{pmatrix} & \frac{2019\pi^3}{4500}\sin(\frac{4\pi t}{5}) \\ 0 & -\frac{2\pi}{5}\cos^2(\frac{2\pi t}{5}) & \frac{\pi^2}{3}\sin(\frac{4\pi t}{5}) & \begin{pmatrix} \frac{338\pi^2}{1500}\cos^2(\frac{2\pi t}{5}) \\ +\frac{252\pi^3}{750}\cos(\frac{4\pi t}{5}) \end{pmatrix} \\ 0 & \frac{13\pi}{30} & 0 & -\frac{2197\pi^3}{27000} \\ 1 & 0 & -\frac{169\pi^2}{900} & 0 \end{bmatrix},$$

whose rank is 4 for $t = 1.25$, for instance, after tedious computations. Then one can assert by Theorem 3 of [33] that the given FDLCP system is completely controllable.

Since the Floquet factorization is available, we can also test controllability for Case A through Theorem 3.1. Note that $\hat{B}(t) = P^{-1}(t,0)B(t)$ possesses only nonzero harmonic waves within the third order. Then, dropping all zero harmonic blocks we obtain

$$[sI - Q | \hat{B}_{-3}, \hat{B}_{-2}, \hat{B}_{-1}, \hat{B}_0, \hat{B}_1, \hat{B}_2, \hat{B}_3]$$
$$= \left[\begin{array}{cccc|ccccccc} s & \frac{\pi}{30} & 0 & 0 & \frac{1}{4} & 0 & -\frac{1}{4} & 0 & -\frac{1}{4} & 0 & \frac{1}{4} \\ -\frac{\pi}{30} & s & 0 & 0 & -\frac{j}{4} & 0 & \frac{j}{4} & 0 & -\frac{j}{4} & 0 & \frac{j}{4} \\ 0 & 0 & s & \frac{13\pi}{30} & 0 & 0 & \frac{j}{2} & 0 & -\frac{j}{2} & 0 & 0 \\ 0 & 0 & -\frac{13\pi}{30} & s & 0 & 0 & \frac{1}{2} & 0 & -\frac{1}{2} & 0 & 0 \end{array}\right],$$

which has rank 4 for all $s \in \mathcal{C}$. Hence, Theorem 3.1 says also that the FDLCP system considered is completely controllable. It should be pointed out that the criterion in [33] is merely sufficient but the controllability conditions in Theorem 3.1 are necessary and sufficient.

Case B. Let us investigate controllability when $B(t) = [0,1,0,0]^T$. By means of the rank criterion of [33], the corresponding controllability matrix is

$$\begin{bmatrix} 0 & \frac{13\pi}{30} & 0 & -(\frac{13\pi}{30})^3 \\ 1 & 0 & -(\frac{13\pi}{30})^2 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

whose rank is $2 < 4$. Then Theorem 3 of [33] cannot tell us whether the given FDLCP system is completely controllable. Fortunately, however, we test controllability through Theorem 3.1. The corresponding controllability matrix is

$$[sI - Q|\hat{B}_{-1}, \hat{B}_0, \hat{B}_1] = \left[\begin{array}{cccc|ccc} s & \frac{\pi}{30} & 0 & 0 & \frac{j}{2} & 0 & -\frac{j}{2} \\ -\frac{\pi}{30} & s & 0 & 0 & \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & s & \frac{13\pi}{30} & 0 & 0 & 0 \\ 0 & 0 & -\frac{13\pi}{30} & s & 0 & 0 & 0 \end{array}\right].$$

It follows readily that $\operatorname{rank}[sI - Q|\hat{B}_{-1}, \hat{B}_0, \hat{B}_1] < 4$ for $s = \pm\frac{13\pi}{30}j$. This implies by Theorem 3.1 that the system is not completely controllable.

We can also draw the noncontrollability conclusion by Corollary 3.6 for Case B, which does not depend on the Floquet factorization. We notice that the Fourier coefficients of the state matrix $A(t)$ possess only harmonic waves up to the second order and the input matrix $B(t)$ is constant. Then, we can construct the matrix $[(s + j\mu\omega_h)\mathbf{I} - \mathbf{A}|\mathbf{B}]$ as defined in Corollary 3.6 as follows, where all zero harmonic blocks are dropped for brevity:

$$\left[\begin{array}{cccccccccc|c} 0 & 0 & -\frac{\pi}{10} & -\frac{\pi j}{10} & s + j\mu\omega_h & \frac{13\pi}{30} & -\frac{\pi}{5} & 0 & 0 & 0 & -\frac{\pi}{10} & \frac{\pi j}{10} & b_1 \\ 0 & 0 & -\frac{\pi j}{10} & -\frac{\pi}{10} & -\frac{13\pi}{30} & s + j\mu\omega_h & 0 & -\frac{\pi}{5} & 0 & 0 & \frac{\pi j}{10} & -\frac{\pi}{10} & b_2 \\ 0 & 0 & 0 & 0 & 0 & 0 & s + j\mu\omega_h & \frac{13\pi}{30} & 0 & 0 & 0 & 0 & b_3 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{13\pi}{30} & s + j\mu\omega_h & 0 & 0 & 0 & 0 & b_4 \end{array}\right],$$

from which it is straightforward to see that $\operatorname{rank}[(s + j\mu\omega_h)\mathbf{I} - \mathbf{A}|\mathbf{B}] < 4$ for some $s \in \mathcal{C}$ and $\mu \in \mathcal{Z}$ whenever $b_3 = b_4 = 0$. Hence, it is possible to construct a number sequence such that Corollary 3.6 is satisfied. In other words, in this case the system is not completely controllable.

We stress that regarding the two cases of the first numeric example, one can apply the necessary and sufficient controllability conditions in Corollary 3.5, in which only the Fourier coefficient matrices of $A(t)$ and $B(t)$ are involved. However, since the state matrix $A(t)$, which is 4×4 in dimension, possesses harmonic waves up to the second order and thus the conditions of Corollary 3.5 must be examined by working on some matrices of big size, it seems inappropriate to give the detailed arguments in this paper due to the limited space.

To show how to apply the results of Corollary 3.4, we consider controllability of the π-periodic lossy Mathieu differential equation [29], [38] given by

$$\ddot{y}(t) + 2\zeta\dot{y}(t) + (1 - 2\beta\cos(2t))y(t) = u(t),$$

where ζ is the damping ratio. The lossy Mathieu differential equation can be equivalently expressed by the following FDLCP state-space modeling:

$$A(t) = \left[\begin{array}{cc} 0 & 1 \\ -1 + 2\beta\cos(2t) & -2\zeta \end{array}\right], \quad B(t) = \left[\begin{array}{c} 0 \\ 1 \end{array}\right].$$

We notice that the Fourier coefficients of the state matrix $A(t)$ do not possess any harmonic waves higher than the first order and that the input matrix $B(t)$ is constant. Then, we can construct $[s\underline{I} + \underline{E}(j0) - \underline{A}]_{N=0}$ as follows, where all zero harmonic blocks are dropped:

$$\left[\begin{array}{cccccc|c} 0 & 0 & s & -1 & 0 & 0 & 0 \\ -\beta & 0 & 1 & s - 2\zeta & -\beta & 0 & 1 \end{array}\right].$$

Forming a 2×2 matrix by the 4th and 7th columns in $[s\underline{I} + \underline{E}(j0) - \underline{A}]_{N=0}$, we can see that its determinant is -1 no matter how the variables s, β, and ζ are taken. It follows that $\operatorname{rank}[s\underline{I} + \underline{E}(j0) - \underline{A}]_{N=0} = 2$ for all $s \in \mathcal{C}$.

Similarly, we have $[s\underline{I} + \underline{E}(j0) - \underline{A}]_{N=1}$ given by

$$\left[\begin{array}{cccccccccc|ccc}
0 & 0 & s+j\omega_h & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-\beta & 0 & 1 & s+j\omega_h-2\zeta & -\beta & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & s & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -\beta & 0 & 1 & s-2\zeta & -\beta & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & s-j\omega_h & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -\beta & 0 & 1 & s-j\omega_h-2\zeta & -\beta & 0 & 0 & 0 & 1
\end{array}\right].$$

Forming a 6×6 matrix by the 4th, 6th, 8th, 11th, 12th, and 13th columns in $[s\underline{I} + \underline{E}(j0) - \underline{A}]_{N=1}$, we obtain a matrix whose determinant is $(-1)^k$ ($k > 0$ is an integer) no matter what s, β, and ζ are taken. It follows that $\operatorname{rank}[s\underline{I} + \underline{E}(j0) - \underline{A}]_{N=1} = 6$ for all $s \in \mathcal{C}$.

We can repeat the above arguments for all $N = 2, 3, \ldots$. In particular, it is always possible to fix a corresponding square matrix whose determinant is 1 or -1. Hence, one can conclude that the conditions of Corollary 3.4 hold for each $N = 0, 1, 2, \ldots$ over $s \in \mathcal{C}$, β, and ζ. It follows that the lossy Mathieu equation is completely controllable.

One can also investigate controllability of the lossy Mathieu equation by means of the rank criterion suggested in [33], which also leads to the lossy Mathieu equation being completely controllable. In both numeric examples, the system matrices $A(t)$ and $B(t)$ contain only finitely many harmonic waves so that the system matrices are analytic. Note 9.4 of [31] indicates that under the analytic assumption the controllability criterion of [33] can also be necessary.

We must add that the numeric examples are relatively simple, for example, compared with those given in [26]. Performance of the theoretical results in practical and complicated systems still needs to be evaluated but is left as one of our future works.

6. Conclusion. In this paper, controllability of a large class of FDLCP systems is considered from a harmonic analysis point of view for the first time, to the best knowledge of the author. Major contributions of this study include an operator-valued PBH controllability criterion claimed in the FDLCP setting and its derivations; that is, Theorems 3.1–3.3. Numeric implementable algorithms for these controllability criteria are also worked out in Corollaries 3.4, 3.5, and 3.6, which are directly applicable via Floquet factorizations of the FDLCP systems and/or Fourier coefficients of the systems matrices. Compared with controllability criteria existing in the literature, the methodology adopted here is highly intuitive and heuristic and keeps some mathematical convenience of their LTI counterparts in the FDLCP setting. Another achievement of this study is a novel controllability canonical decomposition algorithm summarized in Theorem 4.2, which provides us with decomposed FDLCP modeling with a constant state matrix through state coordinate transforms of strong analytic properties; see Corollary 4.3. The results are significant since the paper has succeeded in establishing a harmonic framework in the FDLCP field to exploit the well-developed LTI analysis and synthesis tools relevant to controllability/observability characteristics.

Needless to say, one can simply assert similar results about observability of FDLCP systems through the duality principle [19, pp. 79–103]. However, to avoid any redundancy in the paper, the author paid no attention to observability directly or indirectly. We hope this treatment is allowable for the sake of simplicity.

Appendix A. Proof of lemmas.

Proof of Lemma 2.1. The existence assertion of Floquet simplices can follow from the main branch formula and relevant properties about matrix logarithm theory [40, pp. 55–58]. Here we provide an alternative proof for (a) that is constructive and given by modifying the proof of Theorem 8.1.3 of [23]. This alternative proof also paves a way for showing assertion (b).

To see assertion (a), let $\Xi(\cdot)$ be a fundamental matrix of $A(\cdot)$. That is, $\dot{\Xi}(t) = A(t)\Xi(t)$, a.e. $t \geq 0$. By the properties of the fundamental matrix, $\det(\Xi(t)) \neq 0$ for all $t \geq 0$. Now let $\Theta(t) = \Xi(t+h)$. Then $\dot{\Theta}(t) = A(t+h)\Xi(t+h) = A(t)\Theta(t)$, a.e. for $t \geq 0$, which means that $\Theta(\cdot)$ is also a fundamental matrix of $A(\cdot)$. Also note that $\det(\Theta(t)) \neq 0$ for all t. These facts imply by Theorem 6.7.2 of [23] that $\Xi(t+h) = \Xi(t)M$ for all $t \geq 0$ with some nonsingular matrix M. This implies by Lemma 8.1.1 of [23] that there exists a complex matrix $\tilde{Q}$ such that $M = e^{\tilde{Q}h}$. Then the arguments in the later part of the proof of Theorem 8.1.3 of [23] say that $\tilde{P}(t,0)e^{\tilde{Q}t}$, with $\tilde{P}(t,0) =: \Xi(t)e^{-\tilde{Q}t}$ being h-periodic, is a Floquet factorization for $\Phi(t,0)$.

Next, we express $\tilde{Q}$ through its Jordan canonical form $\tilde{Q} = S\tilde{J}S^{-1}$ with S being a nonsingular matrix, and $\tilde{J} = \operatorname{diag}[\tilde{J}_1, \tilde{J}_2, \cdots, \tilde{J}_\alpha]$, where $\tilde{J}_i$ $(i = 1, 2, \ldots, \alpha)$ is an $n_i \times n_i$ Jordan block defined in the obvious fashion corresponding to an eigenvalue $\tilde{\lambda}_i$ of $\tilde{Q}$. It is straightforward to see that

$$e^{\tilde{Q}t} = Se^{\tilde{J}t}S^{-1}, \tag{17}$$

where $e^{\tilde{J}t} = \operatorname{diag}[e^{\tilde{J}_1 t}, e^{\tilde{J}_2 t}, \cdots, e^{\tilde{J}_\alpha t}]$ and

$$e^{\tilde{J}_i t} = e^{\tilde{\lambda}_i t} \begin{bmatrix} 1 & t & \frac{t}{2} & \cdots & \frac{t^{n_i-1}}{(n_i-1)!} \\ 0 & 1 & t & \cdots & \frac{t^{n_i-2}}{(n_i-2)!} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \end{bmatrix}. \tag{18}$$

Write $\tilde{\lambda}_i = \lambda_i + jk_i\omega_h$, $k_i \in \mathcal{Z}, i = 1, 2, \ldots, \alpha$, with $\lambda_i \in \mathcal{C}_f$, which are always possible. In particular, (18) means that $e^{\tilde{J}_i h} = e^{J_i h}$ for each i, where J_i is a Jordan block in terms of λ_i. From (17), we have that $e^{\tilde{Q}h} = Se^{Jh}S^{-1} = e^{SJS^{-1}h} = e^{Qh}$, in which $Q := SJS^{-1}$ and $J := \operatorname{diag}[J_1, J_2, \cdots, J_\alpha]$. Clearly, Q has eigenvalues λ_1, $\lambda_2, \cdots, \lambda_\alpha$ located in $\mathcal{C}_f$.

Now, let us repeat the arguments in the later part of the proof of Theorem 8.1.3 of [23] but in terms of $M = e^{Qh}$. Then we can draw the conclusion that there exists an h-periodic matrix $P(t,0) =: \Xi(t)e^{-Qt}$ such that $P(t,0)e^{Qt}$ is a Floquet factorization of $\Phi(t,0)$ with $\lambda(Q) \subset \mathcal{C}_f$; in other words, $\Phi(t,0) = P(t,0)e^{Qt}$ is a Floquet simplex.

To see assertion (b) under the assumption of (2), let us observe that

$$P(t,0) = \Xi(t)e^{-Qt} = \Xi(t)e^{-\tilde{Q}t}e^{\tilde{Q}t}e^{-Qt} = \tilde{P}(t,0)e^{\tilde{Q}t}e^{-Qt}. \tag{19}$$

On the other hand, (17) yields that

$$\begin{aligned} e^{\tilde{Q}t} &= Se^{\tilde{J}t}S^{-1} = S\operatorname{diag}[e^{\tilde{J}_1 t}, e^{\tilde{J}_2 t}, \cdots, e^{\tilde{J}_\alpha t}]S^{-1} \\ &= S\ \operatorname{diag}[e^{jk_1\omega_h t}I_{n_1}, e^{jk_2\omega_h t}I_{n_2}, \cdots, e^{jk_\alpha\omega_h t}I_{n_\alpha}]\operatorname{diag}[e^{J_1 t}, e^{J_2 t}, \cdots, e^{J_\alpha t}]S^{-1} \\ &= S\ \operatorname{diag}[e^{jk_1\omega_h t}I_{n_1}, e^{jk_2\omega_h t}I_{n_2}, \cdots, e^{jk_\alpha\omega_h t}I_{n_\alpha}]\ S^{-1}S\operatorname{diag}[e^{J_1 t}, e^{J_2 t}, \cdots, e^{J_\alpha t}]S^{-1} \\ &= S\ \operatorname{diag}[e^{jk_1\omega_h t}I_{n_1}, e^{jk_2\omega_h t}I_{n_2}, \cdots, e^{jk_\alpha\omega_h t}I_{n_\alpha}]\ S^{-1}S\,e^{Jt}S^{-1} \\ &= S\ \operatorname{diag}[e^{jk_1\omega_h t}I_{n_1}, e^{jk_2\omega_h t}I_{n_2}, \cdots, e^{jk_\alpha\omega_h t}I_{n_\alpha}]\ S^{-1}e^{Qt}, \end{aligned}$$

where I_{n_i} denotes the $n_i \times n_i$ identity matrix.

Using the last equation in the above back to (19), we have

$$\begin{aligned} P(t,0) &= \tilde{P}(t,0) S \operatorname{diag}[e^{jk_1\omega_h t} I_{n_1}, e^{jk_2\omega_h t} I_{n_2}, \cdots, e^{jk_\alpha\omega_h t} I_{n_\alpha}]\, S^{-1} \\ &= \tilde{P}(t,0) S \sum_{i=1}^{\alpha} \operatorname{diag}[0, \cdots, 0, e^{jk_i\omega_h t} I_{n_i}, 0, \cdots, 0]\, S^{-1} \\ &= \tilde{P}(t,0) \sum_{i=1}^{\alpha} e^{jk_i\omega_h t} \{S \operatorname{diag}[0, \cdots, 0, I_{n_i}, 0, \cdots, 0]\, S^{-1}\} \\ &=: \tilde{P}(t,0) \sum_{i=1}^{\alpha} e^{jk_i\omega_h t} S_i, \end{aligned}$$

where the definition of S_i is obvious. Clearly S_i is a constant matrix for each i. The last equation, together with the assumption on $\tilde{P}(t,0)$, yields that

$$P(t,0) = \sum_{|k| \le N_p} \tilde{P}_k e^{jk\omega_h t} \sum_{i=1}^{\alpha} e^{jk_i\omega_h t} S_i,$$

which implies the desired assertion if we denote $N_q = \max\{k_1, k_2, \cdots, k_\alpha\}$. □

Proof of Lemma 2.5. Without loss of generality, we prove only the case of $t_0 = 0$. The proof is accomplished by modifying the arguments in the proof for Lemma 3 of [2]. First, we observe by Lemma 1 of [2] that

$$W_c[t_0, t_0 + ih] = W_c[t_0, t_0 + (i-1)h] + e^{-Q(i-1)h} W_c[t_0, t_0 + h] e^{-Q^T(i-1)h},$$

where $i = 1, 2, \ldots, k$. Using this, it is straightforward to see that

$$W_c[t_0, t_0 + kh] = \sum_{i=1}^{k} e^{-Q(i-1)h} W_c[t_0, t_0 + h] e^{-Q^T(i-1)h}. \tag{20}$$

Clearly, $W_c[t_0, t_0 + kh] \ge 0$ implies that there exists at least one nonzero vector $\alpha \in \mathcal{C}^n$ satisfying $\alpha^H W_c[t_0, t_0 + kh]\alpha = 0$. Interpreting this term by term in the right-hand side of (20), we obtain

$$0 = \alpha^H W_c[t_0, t_0 + kh]\alpha = \sum_{i=0}^{k-1} \alpha^H e^{-Qih} W_c[t_0, t_0 + h] e^{-Q^T ih} \alpha.$$

Note that each term in the summation of the above equation is nonnegative. Then it follows that $\alpha^H e^{-Qih} W_c[t_0, t_0 + h] e^{-Q^T ih} \alpha = 0$ for any $i = 1, 2, \ldots, k-1$. Also, $W_c[t_0, t_0 + h]$ is symmetric and nonnegative, and its square root $W_c^{1/2}[t_0, t_0 + h]$ exists [12]. We obtain that $W_c^{1/2}[t_0, t_0 + h] e^{-Q^T ih} \alpha = 0$ for any $i = 1, 2, \ldots, k-1$ and thus

$$W_c[t_0, t_0 + h] e^{-Q^T ih} \alpha = 0 \quad \forall i = 1, 2, \ldots, k-1. \tag{21}$$

Let $a(z)$ be a polynomial of minimal degree for $e^{-Q^T h}$ at α; that is, $a(e^{-Q^T h})\alpha = 0$. It is easy to see by the Cayley–Hamilton theorem about the characteristic equations of matrices that $a(z)$ always exists and the degree of $a(z)$ is less than or equal to the

dimension of $e^{-Q^T h}$. Factorizing $a(z)$ in the form of $a(z) = (z - \lambda)b(z)$ with λ being a root of $a(z) = 0$ and the degree of $b(z)$ being strictly less than that of $a(z)$, we can assert that

$$0 = (e^{-Q^T h} - \lambda I)b(e^{-Q^T h})\alpha := (e^{-Q^T h} - \lambda I)\mathbf{a}, \tag{22}$$

where $\mathbf{a} = b(e^{-Q^T h})\alpha$. Then $b(e^{-Q^T h})\alpha \neq 0$ (otherwise $b(z)$ is also a polynomial of minimal degree for $e^{-Q^T h}$ at α but of degree strictly less than that of $a(z)$, which is impossible). The fact of (22) means that λ is actually an eigenvalue of $e^{-Q^T h}$ and $\mathbf{a} \neq 0$ is an associated eigenvector; or, equivalently, $\mathbf{a}^T \neq 0$ is a left eigenvector of Q.

Now we show that $W_c[t_0, t_0 + h]\mathbf{a} = 0$. Note that k is larger than or equal to the degree of the minimal polynomial and that the degree of $b(z)$ must be strictly less than k. Based on these facts, it follows by (21) that $W_c[t_0, t_0 + h]\mathbf{a} = \sum_i b_i W_c[t_0, t_0 + h]e^{-Q^T ih}\alpha = 0$, where b_i are the coefficients of $b(z)$. Recalling that $e^{-Q^T h}\mathbf{a} = \lambda\mathbf{a}$, simple manipulations on the right-hand side of (20), in which k is replaced with v, lead to the desired assertion. □

Appendix B. Proofs for propositions.

Proof of Proposition 2.6. The proof is completed in two steps.

Step 1. It is shown that the system (1) is completely controllable at t_0 if and only if $W_c[t_0, t_0 + kh] > 0$. The sufficiency is obvious. To see the necessity, assume that the system (1) is completely controllable at t_0; or, equivalently, there is $t_1 > t_0$ such that $W_c[t_0, t_1] > 0$.

Case (i) $t_1 = t_0 + kh$. The necessity assertion follows readily.

Case (ii) $t_1 < t_0 + kh$. Note by segmenting the integral interval $[t_0, t_0 + kh]$ that

$$W_c[t_0, t_0 + kh] = W_c[t_0, t_1] + \int_{t_1}^{t_0+kh} \Phi(t_0, \tau)B(\tau)B^T(\tau)\Phi^T(t_0, \tau)d\tau > 0$$

since $W_c[t_0, t_1] > 0$ and the integral in the above equation is at least positive semi-definite.

Case (iii) $t_1 > t_0 + kh$. Note that $W_c[t_0, t_1] > 0$ always implies $W_c[t_0, t_2] > 0$ as long as $t_2 \geq t_1$. Hence, in this case we lose no generality by assuming that $t_1 = t_0 + vh$ for some integer $v > k$. Now we show that $W_c[t_0, t_0 + vh] > 0$ entails $W_c[t_0, t_0 + kh] > 0$. To see this, suppose that $W_c[t_0, t_0 + kh] \geq 0$ under $W_c[t_0, t_0 + vh] > 0$. However, Lemma 2.5 says that if $W_c[t_0, t_0 + kh] \geq 0$, then there exists a left eigenvector $\mathbf{a}^H \neq 0$ of Q such that $\mathbf{a}^H W_c[t_0, t_0 + vh]\mathbf{a} = 0$ for any integer $v \geq 1$. This is contradictory to $W_c[t_0, t_0 + vh] > 0$.

Step 2. It is shown that the system (1) is completely controllable if and only if $W_c[0, kh] > 0$.

(Necessity) Assume that the system (1) is completely controllable. Then, the system (1) is completely controllable at each $t_0 \in [0, \infty)$. In particular, the system is completely controllable at $t_0 = 0$. This, together with the results in Step 1, implies that $W_c[0, kh] > 0$.

(Sufficiency) Assume that $W_c[0, kh] > 0$. It is shown that the system (1) is completely controllable; that is, $W_c[t_0, t_0 + kh] > 0$ for any $t_0 \in [0, \infty)$. To this end, we observe that

$$W_c[\mu h, \mu h + kh] = \int_{\mu h}^{\mu h+kh} \Phi(\mu h, \tau)B(\tau)B^T(\tau)\Phi^T(\mu h, \tau)d\tau$$

$$
\begin{aligned}
&= \int_0^{kh} \Phi(\mu h, \tau' + \mu h) B(\tau' + \mu h) B^T(\tau' + \mu h) \Phi^T(\mu h, \tau' + \mu h) d\tau' \\
&= \int_0^{kh} \Phi(\mu h, 0) \Phi^{-1}(\tau' + \mu h, 0) B(\tau' + \mu h) \\
&\qquad \cdot B^T(\tau' + \mu h) \Phi^{-T}(\tau' + \mu h, 0) \Phi^T(\mu h, 0) d\tau' \qquad (23) \\
&= \int_0^{kh} P(\mu h, 0) e^{-Q\tau'} P^{-1}(\tau' + \mu h, 0) B(\tau' + \mu h) \\
&\qquad \cdot B^T(\tau' + \mu h) P^{-T}(\tau' + \mu h, 0) e^{-Q^T\tau'} P^T(\mu h, 0) d\tau' \\
&= \int_0^{kh} e^{-Q\tau'} P^{-1}(\tau', 0) B(\tau') B^T(\tau') P^{-T}(\tau', 0) e^{-Q^T\tau'} d\tau' = W_c[0, kh] > 0,
\end{aligned}
$$

where we used the fact that $P(\mu h, 0) = P(0, 0) = I$. The above equation implies that the system is completely controllable at $t_0 = \mu h$ for each integer $\mu \geq 0$. Note by the Gramian criterion that if a system is completely controllable at time t_0, then it is completely controllable at any $t \leq t_0$. Since μ is arbitrary, the desired assertion follows. □

Proof of Proposition 4.1. By the assumptions on $A(t)$ and $B(t)$ and the Floquet theorem, it can be shown that $\hat{B}(t) = P^{-1}(t, 0)B(t)$ is continuous in t. Hence, the approximate FDLCP system (14) is well defined for each segmentation $\mathcal{S}(\kappa)$ in the sense described in the paragraph below (14).

Now let us observe the following arguments, by means of Proposition 2.7.

$$
\begin{aligned}
&\text{The FDLCP system (1) is not completely controllable} \\
&\Leftrightarrow \beta^H \int_0^h e^{-Q\tau} \hat{B}(\tau) \hat{B}^T(\tau) e^{-Q^T\tau} d\tau \beta = 0, \quad \exists \beta \neq 0 \in \mathcal{C}^n \\
&\Leftrightarrow \beta^H e^{-Qt} \hat{B}(t) = 0 \quad \forall t \in [0, h), \ \exists \beta \neq 0 \in \mathcal{C}^n \\
&\Rightarrow \beta^H e^{-Qt} \hat{B}(t_{k-1}) = 0 \quad \forall t \in [t_{k-1}, t_k), \ \forall \mathcal{S}(\kappa), \ \exists \beta \neq 0 \in \mathcal{C}^n \\
&\Leftrightarrow \beta^H \sum_{k=1}^{\kappa} \int_{t_{k-1}}^{t_k} e^{-Q\tau} \hat{B}(t_{k-1}) \hat{B}^T(t_{k-1}) e^{-Q^T\tau} d\tau \beta = 0 \quad \forall \mathcal{S}(\kappa), \ \exists \beta \neq 0 \in \mathcal{C}^n \\
&\Leftrightarrow \beta^H \sum_{k=1}^{\kappa} \int_{t_{k-1}}^{t_k} e^{-Q\tau} \hat{B}(\kappa, \tau) \hat{B}^T(\kappa, \tau) e^{-Q^T\tau} d\tau \beta = 0 \quad \forall \mathcal{S}(\kappa), \ \exists \beta \neq 0 \in \mathcal{C}^n \\
&\Leftrightarrow \text{The system (14) is not completely controllable for any } \mathcal{S}(\kappa). \qquad (24)
\end{aligned}
$$

A sufficiency assertion, that is, $\Leftarrow$, in the third relationship in (24) can also be derived. This is because noncontrollability of the approximate system (14) tells us that there exists $\beta \neq 0 \in \mathcal{C}^n$ so that $\beta^H e^{-Qt} \hat{B}(t)$ vanishes almost everywhere in $[0, h)$ as long as $\kappa \to \infty$. □

Appendix C. Proof of Theorem 4.2. The proof will be completed in 4 steps.

Step 1. It is shown that T_κ of (15) can transform the state matrix Q of the system (14) into a state matrix in the form of (16) with a specific segmentation $\mathcal{S}(\kappa)$ when $\kappa \to \infty$.

Note that the pair $(A(\cdot), B(\cdot))$ is not completely controllable. Then, Proposition 4.1 says that the system (14) is not completely controllable, no matter how large κ is taken. From this noncontrollability and Proposition 2.7, the approximate FDLCP system (14) defined via $\mathcal{S}(\kappa)$ is not completely controllable if and only if there exists

$\beta \neq 0 \in \mathcal{C}^n$ such that

$$\begin{aligned}
&\beta^H \int_0^h e^{-Q\tau}\hat{B}(\kappa,\tau)\hat{B}^H(\kappa,\tau)e^{-Q^T\tau}d\tau\beta = 0\\
&\Leftrightarrow \beta^H e^{-Qt}\hat{B}(\kappa,t) = 0 \quad \forall t \in [0,h)\\
&\Leftrightarrow \beta^H e^{-Qt}\hat{B}(t_{k-1}) = 0 \quad \forall t \in [t_{k-1},t_k),\ k = 1,2,\ldots,\kappa,\\
&\Leftrightarrow \beta^H e^{-Q(t+t_{k-1})}\hat{B}(t_{k-1}) = 0 \quad \forall t \in [0,t_k - t_{k-1}),\ k = 1,2,\ldots,\kappa,\\
&\Leftrightarrow \beta^H e^{-Qt}e^{-Qt_{k-1}}\hat{B}(t_{k-1}) = 0 \quad \forall t \in \Big[0, \min_{k=1,2,\ldots,\kappa} |t_k - t_{k-1}|\Big)\\
&\Leftrightarrow \beta^H e^{-Qt}\hat{B}_\kappa = 0 \quad \forall t \in \Big[0, \min_{k=1,2,\ldots,\kappa} |t_k - t_{k-1}|\Big)\\
&\Leftrightarrow \beta^H e^{-Qt}\hat{B}_\kappa = 0 \quad \forall t \geq 0, \qquad (25)
\end{aligned}$$

which implies that the constant pair $(Q, \hat{B}_\kappa)$ is not completely controllable. This tells us that there exists a left eigenvector β_κ^H of Q such that

$$\beta_\kappa^H[\lambda I - Q, \hat{B}_\kappa] = 0. \qquad (26)$$

Now we show that such a left eigenvector β_κ^H is related to some uncontrollable modes of Q, which can be "extracted" by applying the linear transformation T_κ on Q. To see this, we define

$$\mathcal{E}_\kappa := \{\eta \in \mathcal{C}^n : \eta^H[\hat{B}_\kappa, Q\hat{B}_\kappa, \cdots, Q^{n-1}\hat{B}_\kappa] = 0, \eta \neq 0\}. \qquad (27)$$

Clearly, $\mathcal{E}_\kappa$ is nonempty since at least $\beta \in \mathcal{E}_\kappa$ by (25).

Note in (15) that each column vector in $T_{1\kappa}$ is orthogonal to any column vectors in $T_{2\kappa}$. This implies that column vectors of $T_{2\kappa}$ form a base for $\mathcal{E}_\kappa$. Furthermore, we notice that $Q^H\eta \in \mathcal{E}_\kappa$ for any $\eta \in \mathcal{E}_\kappa$, which follows from the definition of $\mathcal{E}_\kappa$ and the Cayley–Hamilton theorem about characteristic polynomials of square matrices. These facts say that each vector in $Q^H T_{2\kappa}$ must belong to $\mathcal{E}_\kappa$. Therefore, we have $T_{2\kappa}^H Q T_{1\kappa} = 0$ and then it follows that

$$T_\kappa^H Q T_\kappa = \begin{bmatrix} X_\kappa & Y_\kappa \\ 0 & Z_\kappa \end{bmatrix} \qquad (28)$$

for some matrices X_κ, Y_κ, and Z_κ of compatible dimensions. Note that Z_κ is square. For an eigenvalue $\lambda(Z_\kappa)$ and a corresponding left eigenvector $\hat{\eta}_\kappa^H$, we construct an augmented vector

$$\eta_\kappa := \begin{bmatrix} 0 \\ \hat{\eta}_\kappa \end{bmatrix} \in \mathcal{C}^n.$$

Then, it follows readily that $\lambda(Z_\kappa)$ is also an eigenvalue of Q with a left eigenvalue $T_\kappa\eta_\kappa$ since

$$\eta_\kappa^H T_\kappa^{-1} Q\, T_\kappa = \eta_\kappa^H \begin{bmatrix} X_\kappa & Y_\kappa \\ 0 & Z_\kappa \end{bmatrix} = \begin{bmatrix} 0 & \hat{\eta}_\kappa^H Z_\kappa \end{bmatrix} = \begin{bmatrix} 0 & \hat{\eta}_\kappa^H \lambda(Z_\kappa) \end{bmatrix} = \lambda(Z_\kappa)\eta_\kappa^H.$$

Let $\beta_\kappa := T_\kappa\eta_\kappa$ and we must show that such a β_κ satisfies (26). To this end, we observe that

$$\beta_\kappa^H \hat{B}_\kappa = \eta_\kappa^H T_\kappa^H \hat{B}_\kappa = \eta_\kappa^H \begin{bmatrix} T_{1\kappa}^H \\ T_{2\kappa}^H \end{bmatrix} \hat{B}_\kappa = \eta_\kappa^H \begin{bmatrix} *(\gamma(\kappa), m\kappa) \\ 0(n-\gamma(\kappa), m\kappa) \end{bmatrix} = 0, \qquad (29)$$

where $0(n-\gamma(\kappa), m\kappa)$ follows from the definition of $T_{2\kappa}$ and the fact that the column vectors in $\hat{B}_\kappa$ are a linear combination of $\epsilon_\kappa^{(1)}, \cdots, \epsilon_\kappa^{(\gamma(\kappa))}$. Based on (29) and the fact that β_κ is a left eigenvector of Q, we obtain (26). In other words, we can conclude from (26) and (29) that eigenvalues in $\lambda(Z_\kappa)$ are uncontrollable modes of the approximate system (14). Note by (28) that $\lambda(Z_\kappa) \subset \lambda(Q)$. It follows that eigenvalues in $\lambda(Z_\kappa)$ are uncontrollable modes of the system (1).

Step 2. We show that T_κ defined in (15) can be taken independently of $\mathcal{S}(\kappa)$ that is taken appropriately as long as $\kappa \to \infty$.

Let us construct consecutive segmentations as follows. First, segment $[0, h)$ into κ_1 subintervals $[t_0, t_1)$, $[t_1, t_2), \cdots, [t_{\kappa_1-1}, t_{\kappa_1})$, which form $\mathcal{S}(\kappa_1)$. In the ensuing segmentation $\mathcal{S}(\kappa_2)$, we partition $[0, h)$ into κ_2 subintervals, each of which is constructed by segmenting one of the subintervals in $\mathcal{S}(\kappa_1)$. Thus, each ending point of a subinterval in $\mathcal{S}(\kappa_1)$, i.e., $t_0, t_1, \cdots, t_{\kappa_1}$, also appears as an ending point of some subinterval contained in $\mathcal{S}(\kappa_2)$. In such a way, we can obtain a sequence of consecutive segmentations $\mathcal{S}(\kappa_1)$, $\mathcal{S}(\kappa_2), \cdots$, satisfying $0 < \kappa_1 < \kappa_2 < \cdots$, and define the approximate systems Σ_{κ_1}, $\Sigma_{\kappa_2}, \cdots$ as in (14) and $\hat{B}_{\kappa_1}$, $\hat{B}_{\kappa_2}, \cdots$ as introduced in (25).

Clearly, $\hat{B}_{\kappa_{i-1}}$ is contained in $\hat{B}_{\kappa_i}$ as a submatrix for any i. Thus

$$\operatorname{rank}[\hat{B}_{\kappa_i}, Q\hat{B}_{\kappa_i}, \cdots, Q^{n-1}\hat{B}_{\kappa_i}] \geq \operatorname{rank}[\hat{B}_{\kappa_{i-1}}, Q\hat{B}_{\kappa_{i-1}}, \cdots, Q^{n-1}\hat{B}_{\kappa_{i-1}}],$$

which means in turn that

$$\cdots \subseteq \mathcal{E}_{\kappa_i} \subseteq \cdots \subseteq \mathcal{E}_{\kappa_2} \subseteq \mathcal{E}_{\kappa_1}, \tag{30}$$

where $\mathcal{E}_{\kappa_i}$ is defined as in (27) but in terms of Q and $\hat{B}_{\kappa_i}$. From (30), it follows that $\cdots \leq \dim(\mathcal{E}_{\kappa_i}) \leq \cdots \leq \dim(\mathcal{E}_{\kappa_2}) \leq \dim(\mathcal{E}_{\kappa_1})$. In view of this, we turn to show that if the system (1) is not completely controllable, there exists an integer $\kappa_1 > 0$ that is large enough such that for all $\kappa_i \geq \kappa_1$ it holds that

$$\dim(\mathcal{E}_{\kappa_i}) = \dim(\mathcal{E}_{\kappa_1}) =: \gamma \geq 1, \tag{31}$$

with γ being an integer.

By contradiction, suppose that (31) is not true; i.e., for some large $\kappa_1 > 0$, one has that $\dim(\mathcal{E}_{\kappa_1}) = 0$. It means by definition of $\mathcal{E}_{\kappa_1}$ that $\operatorname{rank}[\hat{B}_{\kappa_1}, Q\hat{B}_{\kappa_1}, \cdots, Q^{n-1}\hat{B}_{\kappa_1}] = n$, which says that the constant pair $(Q, \hat{B}_{\kappa_1})$ is completely controllable. Thus, for any nonzero vector $b \in \mathcal{C}^n$, $b^T e^{-Qt}\hat{B}_{\kappa_1} \neq 0\ \forall t \geq 0$. If we interpret this along subintervals in $\mathcal{S}(\kappa_1)$ (i.e., we argue similarly to those in (25) but in the sense of being controllable), it follows that at least on one subinterval, say $[t_{k-1}, t_k)$ in $\mathcal{S}(\kappa_1)$, it holds that $b^T e^{-Qt}\hat{B}(\kappa_1, t) \neq 0$. Hence, we obtain that

$$\begin{aligned} & b^T \int_0^h e^{-Q\tau}\hat{B}(\kappa_1, \tau)\hat{B}^T(\kappa_1, \tau)e^{-Q^T\tau}d\tau \\ = & \sum_{k=0,1,\ldots,\kappa_1-1} b^T \int_{t_{k-1}}^{t_k} e^{-Q\tau}\hat{B}(t_{k-1})\hat{B}^T(t_{k-1})e^{-Q^T\tau}d\tau\, b > 0. \end{aligned}$$

Again noticing that in the approximate system Σ_{κ_1} of (14), $W_c[0, vh] = W_c[0, h] + W_c[h, vh]$ with v be any positive integer, we can assert that $W_c[0, vh] > 0$. Hence, Proposition 2.7 says that the approximate system Σ_{κ_1} is completely controllable.

Let us return to (30) and notice that $\dim(\mathcal{E}_{\kappa_i}) \geq 0$ for any κ_i. Then $\dim(\mathcal{E}_{\kappa_1}) = 0$ tells us that for any $\kappa_i > \kappa_1$, $\dim(\mathcal{E}_{\kappa_i}) = 0$. By repeating the arguments in the

previous paragraph but in terms of $\hat{B}_{\kappa_i}$, one can assert that the approximate system Σ_{κ_i} (14) defined on $\mathcal{S}(\kappa_i)$ is completely controllable for each $\kappa_i > \kappa_1$. Bearing this in mind, Proposition 4.1 yields that the system Σ of (13) is also completely controllable or, equivalently, the FDLCP system (1) is completely controllable. However, this is a contradiction.

In summary, (31) indicates that there exist orthonormal vectors $\epsilon_1, \cdots, \epsilon_\gamma$, which are determined during $\mathcal{S}(\kappa_1)$, and available orthonormal vectors for $\mathcal{S}(\kappa_i)$ uniformly over $\kappa_i > \kappa_1$ as well. That is, $\epsilon_1, \cdots, \epsilon_\gamma$ form a base for each $\mathcal{E}_{\kappa_i}$, $\kappa_i > \kappa_1$, while $\epsilon_1, \cdots, \epsilon_n$ form a base for $\mathcal{C}^n$ by including $n-\gamma$ more orthonormal vectors $\epsilon_{\gamma+1}, \cdots, \epsilon_n$. Based on such a base, we have that T_{κ_1} defined in (15) can satisfy (28) for any $\kappa_i \geq \kappa_1$.

Step 3. It is shown that T_{κ_1} defined in Step 2 transforms $\hat{B}(t)$ of the system (13) into the input matrix of the system (16); that is,

$$T_{\kappa_1}^{-1}\hat{B}(t) = \begin{bmatrix} B_*(t) \\ 0 \end{bmatrix}, \tag{32}$$

where $B_*(t)$ is a $\gamma \times m$ h-periodic matrix. Note that $\hat{B}_{\kappa_1}$ is contained in $\hat{B}_{\kappa_i}$ as a submatrix for any $\kappa_i > \kappa_1$. Therefore, for any $\kappa_i > \kappa_1$ we have from (29) that

$$\begin{aligned} T_{\kappa_1}^{-1}\hat{B}_{\kappa_i} = T_{\kappa_1}^H \hat{B}_{\kappa_i} &= \left[\frac{*(\gamma, m\kappa_i)}{0(n-\gamma, m\kappa_i)}\right] \\ &= \left[T_{\kappa_1}^H e^{-Q\tau_0}\hat{B}(\tau_0), \cdots, T_{\kappa_1}^H e^{-Q\tau_{\kappa_i-1}}\hat{B}(\tau_{\kappa_i-1})\right] \\ &= \left[T_{\kappa_1}^H e^{-Q\tau_0} T_{\kappa_1} T_{\kappa_1}^H \hat{B}(\tau_0), \cdots, T_{\kappa_1}^H e^{-Q\tau_{\kappa_i-1}} T_{\kappa_1} T_{\kappa_1}^H \hat{B}(\tau_{\kappa_i-1})\right] \\ &= \left[e^{-T_{\kappa_1}^H Q T_{\kappa_1}\tau_0} T_{\kappa_1}^H \hat{B}(\tau_0), \cdots, e^{-T_{\kappa_1}^H Q T_{\kappa_1}\tau_{\kappa_i-1}} T_{\kappa_1}^H \hat{B}(\tau_{\kappa_i-1})\right] \\ &= \left[e^{-Q_{\kappa_1}\tau_0} T_{\kappa_1}^H \hat{B}(\tau_0), \cdots, e^{-Q_{\kappa_1}\tau_{\kappa_i-1}} T_{\kappa_1}^H \hat{B}(\tau_{\kappa_i-1})\right], \end{aligned} \tag{33}$$

where $T_{\kappa_1}^H Q T_{\kappa_1}$ satisfies (28) in form, and thus we have

$$Q_{\kappa_1} := \begin{bmatrix} X_{\kappa_1} & Y_{\kappa_1} \\ 0 & Z_{\kappa_1} \end{bmatrix}.$$

Furthermore, it is evident by trivial manipulations that

$$e^{-Q_{\kappa_1}\tau_k} = \begin{bmatrix} e^{-X_{\kappa_1}\tau_k} & *(\cdot) \\ 0 & e^{-Z_{\kappa_1}\tau_k} \end{bmatrix}, \quad k = 0, 1, \ldots, \kappa_i - 1.$$

Using $e^{-Q_{\kappa_1}\tau_k}$ $(k = 0, 1, \ldots, \kappa_i - 1)$ back to (33) and denoting $T_{\kappa_1} = [T_{1\kappa_1} \,|\, T_{2\kappa_1}]$ in the same sense as we express T_κ in (15), we obtain

$$\left[\frac{*(\gamma, m\kappa_i)}{0(n-\gamma, m\kappa_i)}\right] = \left[\cdots, \begin{bmatrix} e^{-X_{\kappa_1}\tau_k} & *(\cdot) \\ 0 & e^{-Z_{\kappa_1}\tau_k} \end{bmatrix} \begin{bmatrix} T_{1\kappa_1}^H \\ T_{2\kappa_1}^H \end{bmatrix} \hat{B}(\tau_k), \cdots\right].$$

Comparing the corresponding entries in the lower halves of the left and right sides of the above equation, it is easy to see that

$$e^{-Z_{\kappa_1}\tau_k} T_{2\kappa_1}^H \hat{B}(\tau_k) = 0(n-\gamma, m) \quad \forall k = 0, 1, \ldots, \kappa_i - 1.$$

Note that $e^{-Z_{\kappa_1}\tau_k}$ is always invertible. Then it follows readily that $T_{2\kappa_1}^H \hat{B}(\tau_k) = 0(n-\gamma, m)$ for any $k = 0, 1, \ldots, \kappa_i - 1$. Based on this, it follows readily that

$$T_{\kappa_1}^H \hat{B}(\tau_k) = \left[\frac{*(\gamma, m)}{0(n-\gamma, m)}\right] \quad \forall k = 0, 1, \ldots, \kappa_i - 1.$$

We mention that τ_k $(k = 0, 1, \ldots, \kappa_i - 1)$ can be taken in $[0, h)$ arbitrarily as long as $\kappa_i \geq \kappa_1$ with κ_1 being sufficiently large. This implies nothing but (32).

Step 4. By letting $T_\kappa = T_{\kappa_1}$ and denoting $Q_c = X_{\kappa_1}$, $Q_{12} = Y_{\kappa_1}$, $Q_{\bar{c}} = Z_{\kappa_1}$, and $B_c(t) = B_*(t)$, it follows that the state coordinate transform $z = T_\kappa \tilde{x}$ transforms Σ to the form of (16). The assertion that the pair $(Q_c, B_c(\cdot))$ is completely controllable follows from the fact that γ given in (31) is the biggest one when κ_1 is sufficiently large. This completes the proof. ∎

LOCAL CONTROLLABILITY FOR A "SWIMMING" MODEL*

A. Y. KHAPALOV†

Abstract. We study the local controllability of a mathematical model of an abstract object which "swims" in the two-dimensional (2D) nonstationary Stokes fluid. We assume that this object consists of finitely many subsequently connected small sets ("thick points"), each of which can act upon any of the adjacent sets in a rotation fashion with the purpose of generating its fish- or snake-like motion. We regard the magnitudes of the respective rotation forces, entering the system's equations as coefficients, as multiplicative (or bilinear) controls. The structural integrity of the object is maintained by the elastic forces acting between the aforementioned adjacent sets according to Hooke's law. Models like this are of a interest in biology and engineering applications dealing with propulsion systems in fluids.

Key words. swimming model, coupled systems, multiplicative control, local controllability, nonstationary Stokes equation

1. Introduction: Model and its wellposedness.

1.1. Model description. The subject of our interest in this paper is the study of the swimming phenomenon (see, e.g., the classical works [12], [2]) from the controllability theory viewpoint. We would like to approach this issue by investigating the local controllability properties of an abstract object which applies fish- or snake-like motion to *"swim" in a fluid* (as *opposed to* bodies that are drifting or being pushed/pulled in a fluid by external forces). This object (we also call it an "apparatus" below) can be viewed as a very simplified model of a living organism (see [12], [15], [2], [3], [4], [16], and the references therein) or a "mechanical device (such as a robotic fish or eel, e.g., [5], [13], [14], and the references therein).

Modeling philosophy. It appears that the issue of modeling for the swimming phenomenon should be perceived as a variety of models of different levels of complexity describing various objects that can *propel themselves* in a fluid. Such objects can be modeled as solid bodies or not, can have different geometries, and can employ different "swimming techniques" (such as "snake-like" or "rowing"). Numerous approaches, currently available in the literature in this respect, reflect the interests and preferences of researchers using them, also imposing the respective limitations ("tradeoffs") on the resulting form of the equations involved.

For example, a number of models employ only the finite systems of ODEs to describe the positions of certain points of the swimming object at hand and avoid the use of fluid equations, replacing them with friction forces acting upon the aforementioned points (e.g., [14] and the references therein). On the other end of this spectrum, there are sophisticated infinite dimensional swimming models focusing on detailed study of the interaction between the solid bodies and the surrounding medium (see, e.g., [12], [2], and the references therein). However, in the latter case it can be more difficult to

†Department of Mathematics, Washington State University, Pullman, WA 99164-3113 (khapala@wsu.edu). The work of this author was supported in part by NSF grant DMS-0504093.

construct a swimming model as a "solvable" system of coupled differential equations containing an equation which describes the *progress of the position of the body (such as, e.g., its center of mass) in the fluid*. This equation is critical if one wants to study the issue of controllability for the swimming phenomenon, which is our goal in this paper.

In this respect, we would like to begin with a "reasonably good starting model" which should, on the one hand, be simple enough from the mathematical viewpoint, while, on the other hand, be adequate enough to represent (at least some of the) principal elements and difficulties arising in the context of swimming processes (so that the developed controllability methodology could later be carried over to more complex models in various fluids). This model, in our opinion, should include (a) a fluid equation (and there are many of these available), (b) an equation describing the motion of the swimming object, and (c) the coupling between them. In this paper we employ the following approach (see Figures 1–3).

1. *We model a swimming object (an "apparatus") as a collection of "small" sets of nonzero measure ("thick" points) in the nonstationary two-dimensional* (2D) *Stokes fluid, which are linked to each other by the set of internal forces, satisfying the third law of Newton*. Some of these forces serve to maintain the structural integrity of the object, while the others excite its swimming motion in the fluid. (Thus, our swimming object and its motion can also be viewed as a version of the classical problem in mechanics about the motion of a system of particles, linked by internal forces, when they are placed in a "resisting" medium.)

2. Since the sum of all internal forces, defining the force acting upon the center of mass of the object at hand, is zero, *no actual motion (of the center of mass) occurs, if the object is not in the fluid*. However, when such an object is placed in the fluid, the interaction with the latter can result in its swimming motion. The variety of these motions is the goal of our study.

3. To further simplify the model *we identify the "thick" points forming the body of the object with the parts of the fluid they "occupy,"* which seems a reasonable assumption if such "points" are "small" and stay away from each other. This assumption allows us to avoid dealing with the mathematics of solid bodies in fluids at this point. (Note that in many theoretical works a solid body is viewed as a limit of a sequence of fluids of increasing density occupying its volume.)

Our modeling approach can be viewed as one derived from the approach developed by Peskin, Fauci, and others (see also the references in [15], [3], [4], [16]) in computational mathematical biology, where an object in a fluid is modeled as *an immaterial curve (immersed boundary), identified with the fluid, further discretized* for computational purposes *on some grid*. In turn, *our model* (1.1)–(1.3) *can be viewed as such an already discretized immaterial curve supported on the respective cells of the aforementioned grid*; see Figures 1–3.

The equations (1.1)–(1.3) below resemble, in particular, the equations (2.9) in [15, p. 223], where an object in a fluid is modeled as a collection of countably many points linked by internal forces instead of our finitely many "thick" points (which allows us to "replace" the δ-functions in the limit description of the forcing term in [15] with the integral terms in (1.2) and a finite sum in (1.3) involving "more analysis-friendly" characteristic functions). In [4, p. 93], e.g., the swimming object is represented as an immaterial curve (immersed boundary), which requires the use of a more sophisticated δ-function.

More precisely, we consider the following model, consisting of two *coupled* systems of equations—one for the nonstationary 2D Stokes fluid and another for the *position*

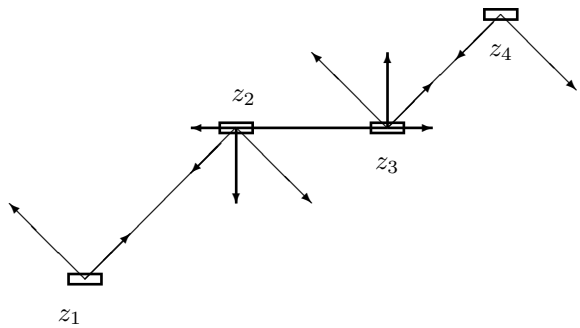

FIG. 1. *The case* $n = 4$.

of the apparatus in it:

$$\frac{\partial y}{\partial t} = \nu \Delta y + F(y, z, v) - \nabla p \quad \text{in} \quad Q_T = \Omega \times (0, T), \tag{1.1}$$

$$\text{div } y = 0 \text{ in } Q_T, \quad y = 0 \quad \text{in } \Sigma_T = \partial\Omega \times (0, T), \quad y\,|_{t=0} = y_0 \text{ in } \Omega,$$

$$\frac{dz_i}{dt} = \frac{1}{\text{mes}\,\{S_r(0)\}} \int_{S_r(z_i(t))} y(x,t)dx, \quad z_i(0) = z_{i0}, \quad i = 1, \dots, n, \quad n > 2, \tag{1.2}$$

where for $t \in [0, T]$

$$\begin{aligned} z(t) = (z_1(t), \dots, z_n(t)),\ z_i(t) \in R^2,\ \ i = 1, \dots, n, \quad v(t) = (v_1(t), \dots, v_{n-1}(t)) \in R^{n-1}, \\ F(y,z,v) = \sum_{i=2}^{n+1} \xi_{i-1}(x,t) \left[k_{i-1} \frac{(\| z_i(t) - z_{i-1}(t) \|_{R^2} - l_{i-1})}{\| z_i(t) - z_{i-1}(t) \|_{R^2}} (z_i(t) - z_{i-1}(t)) \right. \\ \left. + k_{i-2} \frac{(\| z_{i-2}(t) - z_{i-1}(t) \|_{R^2} - l_{i-2})}{\| z_{i-2}(t) - z_{i-1}(t) \|_{R^2}} (z_{i-2}(t) - z_{i-1}(t)) \right] \\ + \sum_{i=2}^{n+1} \xi_{i-1}(x,t) \left(v_{i-1}(t) A \left(z_i(t) - z_{i-1}(t) \right) + v_{i-2}(t) A \left(z_{i-2}(t) - z_{i-1}(t) \right) \right). \end{aligned} \tag{1.3}$$

In the above, Ω is a bounded domain in R^2 with boundary $\partial\Omega$ of class C^2, $y = (y_1(x,t), y_2(x,t))$ and $p(x,t)$ are, respectively, the velocity and the pressure of the fluid at point $x = (x_1, x_2) \in \Omega$ at time t, and ν is a kinematic viscosity constant. Also, to simplify the Σ-notation in (1.3) and below, throughout the paper we use two auxiliary fictitious points z_0 and z_{n+1} as $z_0(t) = z_1(t), z_n(t) = z_{n+1}(t)$, and we set accordingly $v_0 = v_n = k_0 = k_n = l_0 = l_n = 0$ (see below for more details).

Let us explain the terms in (1.1)–(1.3).

Apparatus. The swimming object in (1.1)–(1.3) is modeled as a collection of finitely many points with flexible immaterial internal links (or, say, which have a "negligible affect" on the swimming process), each of which is surrounded by *"very small immaterial"* support (i.e., identified with the fluid it occupies); see Figure 1.

Thus, *as a "mechanical device,"* our apparatus can be viewed as a *sequence of floating platforms connected by flexible links positioned above the surface of fluid*.

At any given moment of time the apparatus is represented by a "broken-line" structure, formed by an ordered sequence of "thick points" $S_r(z_1(t)), \dots, S_r(z_n(t))$, where $z_i(t), i = 1, \dots, n$, are points in Ω (the apparatus's "skeleton"). Accordingly,

in (1.3) the ξ_i's denote the respective characteristic functions of the $S_r(z_i(t))$'s:

$$\xi_i(x,t) = \begin{cases} 1 & \text{if } x \in S_r(z_i(t)), \\ 0 & \text{if } x \in \Omega \backslash S_r(z_i(t)), \end{cases} \qquad i = 1, \dots, n. \tag{1.4a}$$

We assume that (a) $S_r(0)$ is the given open set with its center of mass at the origin (if treated as a plate with uniform mass density) and (b)

$$S_r(0) = \{x \mid -r < x_1 < r,\ \alpha(x_1) < x_2 < \beta(x_1)\}, \tag{1.4b}$$

where α and β are the given continuously differentiable functions. Alternatively, $S_r(0)$ may consist of finitely many nonoverlapping sets similar to (1.4b), namely, of the form

$$\{x \mid -r \le r_* < x_1 < r^* \le r,\ \alpha_*(x_1) < x_2 < \beta_*(x_1)\}$$

or

$$\{x \mid -r \le r_{**} < x_2 < r^{**} \le r,\ \alpha_{**}(x_2) < x_1 < \beta_{**}(x_2)\}.$$

$S_r(a)$ denotes the set $S_r(0)$ shifted to point a.

Forces. The term $F(y,z,v)$ in (1.3) represents the *internal forces* (their sum is zero) generated by the apparatus, acting in turn as *external forces* upon the fluid in the fluid equation (1.1) (see also Remark 1.2 below). We assume that all the apparatus's forces act through the immaterial links attached to the centers of mass of sets $S_r(z_i(t))$, i.e., to the points $z_i(t)$, and then transmitted as such to all points in their respective supports. The latter points will create a pressure upon the surrounding fluid, thus acting as external forces upon it.

Each of the points $z_i(t)$ can force any of the adjacent points to "rotate" about it. In turn, by the third Newton law, the affected point will act back upon $z_i(t)$ with the opposite force. For example, $z_1(t)$ can act upon $z_2(t)$ with the force perpendicular to the vector $z_2(t) - z_1(t)$ and $z_2(t)$ will act back with the opposite force. These two forces, being transmitted to their respective supports, provide two terms in the last line in (1.3), namely,

$$\xi_1(x,t)v_1(t)A\left(z_2(t) - z_1(t)\right) + \xi_2(x,t)v_1(t)A\left(z_1(t) - z_2(t)\right),$$

where

$$A = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

The magnitudes and directions of the applied rotation forces (shown in Figure 2) are determined by the coefficients $v_i, i = 1, \dots, n-1$, which we regard as *bilinear or multiplicative* controls (see, e.g., [1], [6], [7], [8]).

The structural integrity of the apparatus is preserved by the elastic forces (shown in Figure 3) which act according to Hooke's law when the distances between any two adjacent points $z_i(t)$ and $z_{i-1}(t), i = 2, \dots, n$, deviate from the respective given values

$$l_{i-1} > 0, \quad i = 2, \dots, n, \tag{1.5}$$

as described in the first two lines in (1.3), where the given parameters $k_i > 0,\ i = 1, \dots, n-1$, characterize the rigidity of the links $z_{i-1}(t)z_i(t),\ i = 2, \dots, n$. (For the auxiliary points/links we set $k_0 = k_n = l_0 = l_n = 0$.)

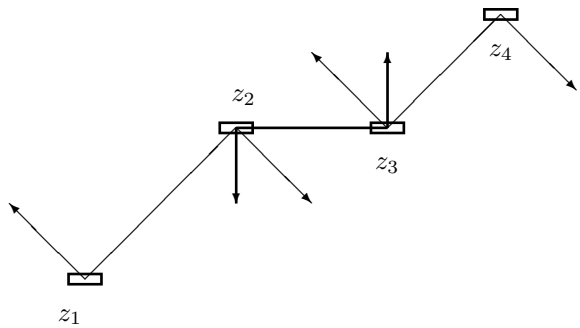

FIG. 2. *Controlling rotation forces,* $n = 4$.

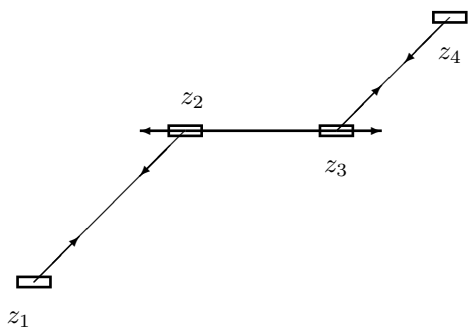

FIG. 3. *Elastic forces,* $n = 4$.

Remark 1.1.

- Note that, when the adjacent points in the apparatus share the same position in space (at some moments of time or on some time-interval), the forcing term F in (1.3) and hence the model (1.1)–(1.3) become undefined. While this situation seems physically plausible, even if, prior to this, the solution to this system exists on some "small" time-interval, it does not necessarily have to happen. The former issue, namely, the existence on some "small" time-interval $(0, T)$, is addressed below in the next section. The latter issue can be viewed as the issue of *controllability*, namely, when one tries to select multiplicative controls v_i with the purpose of ensuring that the apparatus is *"swimming" in the desirable fashion, while avoiding the aforementioned ill-defined situation.*
- Assuming that the set $S_r(0)$ in (1.4a)–(1.4b) is "small," we model all the apparatus's forces in (1.3) as of the same vector-value within their respective supports.

Apparatus's motion. The *dynamics of the "thick points"* $z_i(t)\xi_i(x,t), i = 1, \ldots, n$, are determined by the average motion of the fluid within their respective supports $S_r(z_i(t))$'s as described in (1.2).

Remark 1.2. Internal forces and conservation of momentums.

- We want to emphasize that all forces in (1.3) satisfy the third Newton law and their sum is equal to zero. Thus, they are *internal with respect to the apparatus and cannot move its center of mass without interaction with the fluid.* This is the principal feature of a "swimming-by-itself-device."
- The third Newton law ensures that the linear momentums generated by the apparatus's forces are conserved (see, e.g., [17]). However, the rotation forces

produce, in general, a nonzero torque. This means that the conservation of the angular momentums should hold in a more general framework, which also takes into account some "additional control forces" (from an "engine" such as, e.g., a "watch-and-hand" mechanism with its mutually counterrotating parts), also internal with respect to the apparatus, that generate the corresponding "negating" torques.

1.2. Existence and uniqueness. Let $\dot{J}(\Omega)$ denote the linear space of infinitely differentiable 2D vector functions $\phi(x) \in R^2$ which have compact support in Ω and are *solenoidal* (or *divergence-free*), that is, div $\phi = 0$ in Ω. By $H(\Omega)$ we denote the completion of this space in the norm

$$\| \phi \|_{H(\Omega)} = \left(\int_\Omega (\| \phi_{x_1} \|^2_{R^2} + \| \phi_{x_2} \|^2_{R^2}) dx \right)^{1/2}.$$

We decompose (e.g., [11], [18]) the vector space $(L^2(Q_T))^2$ into two orthogonal subspaces $J_0(Q_T)$ and $G(Q_T)$ assuming that for almost all $t \in (0,T)$ the elements of the former belong to the completion $J_0(\Omega)$ of $\dot{J}(\Omega)$ in the norm of $(L^2(\Omega))^2$ and the elements of the latter to its orthogonal complement $G(\Omega)$.

ASSUMPTION 1.1. *Assume that*

$$\| z_i(0) - z_{i-1}(0) \|_{R^2} = \mu_{i-1} > 0, \quad i = 2, \dots, n; \qquad \bar{S}_r(z_i(0)) \subset \Omega, \quad i = 1, \dots, n, \tag{1.6}$$

where "–" stands for closure, and the set $S_r(0)$ is such that

$$\int_{(S_r(0) \bigcup S_r(h)) \setminus (S_r(0) \bigcap S_r(h))} dx = \int_\Omega | \xi(x) - \xi(x-h) | \, dx \le C_0 \| h \|_{R^2} \qquad \forall h, \| h \|_{R^2} \in (0, h_0) \tag{1.7}$$

for some positive constants h_0 and C_0, where $\xi(x)$ is the characteristic function of $S_r(0)$.

Conditions (1.6) simply mean that our apparatus lies in Ω and that the positions of any two adjacent points forming it are distinct at time $t = 0$. Condition (1.7) is not difficult to satisfy—it holds, e.g., for rectangles and disks.

Throughout the paper we assume that $y_0 \in H(\Omega) \bigcap (H^2(\Omega))^2$. We have the following result from [9].

THEOREM 1.1. *Let $y_0 \in H(\Omega) \bigcap (H^2(\Omega))^2$; $T^* > 0; v_i \in L^\infty(0, T^*), k_i > 0, i = 1, \dots, n-1$; and $z_{i0} \in \Omega, i = 1, \dots, n$ be given, and let Assumption* 1.1 *hold. Then there exists a $T = T(z_{10}, \dots, z_{n0}, \| v_1 \|_{L^\infty(0,T^*)}, \dots, \| v_{n-1} \|_{L^\infty(0,T^*)}, \Omega) \in (0, T^*)$ such that the system* (1.1)–(1.3) *admits a unique solution $\{y, p, z\}$ on $(0,T)$, $\{y, \nabla p, z\} \in J_0(Q_T) \times G(Q_T) \times [C([0,T]; R^2)]^n$. Moreover, $y \in C([0,T]; H(\Omega))$, $y_t, y_{x_i x_j} \in (L^2(Q_T))^2$, $p_{x_i} \in L^2(Q_T)$, where $i, j = 1, 2$, and equations in* (1.1) *and* (1.2) *are satisfied almost everywhere, while*

$$z_i(t) \ne z_{i+1}(t), \quad i = 1, \dots, n-1; \qquad \bar{S}_r(z_i(t) \subset \Omega, \quad t \in [0,T], \quad i = 1, \dots, n. \tag{1.8}$$

Remark 1.3.

- Condition (1.7) is used in the proof of Theorem 1.1 (as a form of the Lipschitz condition).
- Condition (1.8) means that for the solution of (1.1)–(1.7), whose existence is established in Theorem 1.1, we can guarantee that on some "small" time-interval $[0,T]$ any two adjacent points $z_i(t)$ and $z_{i+1}(t)$ in the apparatus do

not share the same point in space, while our swimming device stays "sufficiently away" from the boundary of Ω. The former allows us to maintain the wellposedness (both mathematical and "physical"—the validity of Hooke's law) of the elastic forces in (1.3), while the latter implies that we do not have to deal with any "complications" arising when some of the "thick points" "hit" $\partial\Omega$.

- On the other hand, Theorem 1.1 allows sharing of the same space for some portions of supports of the aforementioned thick points (recall that they are assumed to be immaterial and "parts of the fluid"). At no extra cost, we could equally make the assumption (1.6) more strict to exclude the latter possibility by assuming that μ_i's (and l_i's) strictly exceed $2r$ or even to assume that (1.6) (and then (1.8)) holds with a margin exceeding $2r$ for all $z_i(t)$'s (*not only adjacent*), while modifying the statement of Theorem 1.1 accordingly.

The duration of the time-interval $(0,T)$ in Theorem 1.1 is not quite of local nature. Namely, based on suitable a priori estimates, the value of T is selected small enough to guarantee that condition (1.8) holds on $(0,T)$ for the given choice of data in (1.1)–(1.3). This solution can be extended further in time as long as (1.8) holds.

2. Local controllability: Problem formulation and main results.

2.1. Problem formulation. In this paper we would like to analyze the *"local" swimming capabilities* of model (1.1)–(1.7) in the following sense.

For the given initial datum of this model, namely,

$$\{y_0,\ z_i(0),\ \ i=1,\dots,n\}, \tag{2.1a}$$

denote by

$$\{y^*(x,t),\ z_i^*(t),\ \ i=1,\dots,n\} \tag{2.1b}$$

the solution pair to (1.1)–(1.7) generated by the zero controls $v_i=0,\ i=1,\dots,n-1$ (as long as (1.8) holds).

We also distinguish the following equilibrium initial state for system (1.1)–(1.7):

$$\begin{aligned}\{y_0=0,\ \ z_i(0),\ i=1,\dots,n,\ \ \text{such that}\ \ l_{i-1}=&\parallel z_i(0)-z_{i-1}(0)\parallel_{R^2},\\ &i=2,\dots,n\},\end{aligned} \tag{2.2a}$$

in which case the fluid "rests" and the apparatus does not move for any $t>0$, that is,

$$\{y^*(x,t)\equiv 0,\quad z_i^*(t)\equiv z_i(0),\ \ i=1,\dots,n\},\ \ t\geq 0. \tag{2.2b}$$

We intend to approach the general issue of local controllability for (1.1)–(1.7) by asking first a "rather simple" question.

Given the equilibrium initial datum (2.2a) *in* (1.1)–(1.7)*, can we move at least one point, say, z_i, in the skeleton of the apparatus anywhere within some neighborhood of its initial equilibrium position $z_i(0)$ at some preassigned moment $T>0$?*

We will call this problem the *local controllability problem with respect to z_i near equilibrium* at time T. However, the question of main interest, associated with the actual motion of any object, is the following.

Given the equilibrium initial datum (2.2a) *in* (1.1)–(1.7)*, can we move the "center of mass" of our apparatus, namely, the point*

$$z_c(t)=\frac{1}{n}\sum_{i=1}^{n} z_i(t),$$

anywhere within some neighborhood of its initial equilibrium position

$$z_c(0) = \frac{1}{n}\sum_{i=1}^{n} z_i(0)$$

at some preassigned moment $T > 0$*?*

We will call this problem the *local controllability problem with respect to* $z_c(0)$ *near equilibrium* at time T.

In the case of the general (not necessarily equilibrium) initial conditions (2.1a), the motion of the apparatus, associated with the zero-controls v_i's, is a "drifting" (uncontrolled) motion (2.1b), generated, on the one hand, by the given initial fluid condition y_0 and, on the other hand, by the elastic forces in the first two lines on the right in (1.3) trying to return the apparatus to its natural equilibrium position, that is, when the distances between the adjacent points z_i's are exactly l_i's. In this case, our goal is to investigate the *local controllability of system* (1.1)–(1.7) *near the "drifting" trajectory* $z_i^*(t)$, $i = 1, \dots, n$.

Given the initial datum in (1.1)–(1.7)*, can we move at least one point, say,* z_i*, of the apparatus or its center of mass* z_c *anywhere within some neighborhood, respectively, of* $z_i^*(T)$ *or of*

$$z_c^*(T) = \frac{1}{n}\sum_{i=1}^{n} z_i^*(T),$$

along its uncontrolled drifting trajectory (2.1a)–(2.1b) *for some* $T > 0$*?*

We will call these two problems the *local controllability problems near the drifting positions, respectively, of* $z_i^*(T)$ *and of* $z_c^*(T)$.

Our strategy in this paper is centered around the following propositions.

PROPOSITION 2.1. *Assume that in* (1.1)–(1.7) *only two controls are active, say,* v_j *and* v_l*, where* $j \neq l$ *and* $j, l \in \{1, \dots, n-1\}$*, while* $v_k = 0$ *for* $k = 1, \dots, n-1, k \neq j, l$*. Assume further that* v_j *and* v_l *are independent of time. Then, if for some* $i \in \{1, \dots, n\}$ *there exists a* $T > 0$ *such that the matrix*

$$\left(\frac{dz_i(T)}{dv_j} \mid_{v_m' s = 0}, \frac{dz_i(T)}{dv_l} \mid_{v_m' s = 0} \right) \tag{2.3}$$

is nondegenerate, then the system (1.1)–(1.7) *is locally controllable near its drifting position* $z_i^*(T)$ *in* (2.1b)*. Namely, there is an* $\varepsilon > 0$ *such that*

$$B_\varepsilon(z_i^*(T)) \subset \{z_i(T) \mid v_j, v_l \in R,\ v_k = 0 \text{ for } k = 1, \dots, n-1, k \neq j, l\}. \tag{2.4}$$

In particular, for the initial equilibrium position (2.2a) *condition* (2.3) *implies the local controllability with respect to* z_i *near equilibrium at time* T.

In other words, (2.4) means that the set of all possible positions of $z_i(T)$ when controls v_i run over R will include some ε-neighborhood of $z_i^*(T)$.

In (2.3) and anywhere below the subscript, $v_m' s = 0$ indicates that the corresponding expressions are calculated for $v_m = 0, m = 1, \dots, n-1$.

Proof of Proposition 2.1. This is an immediate consequence of the inverse function theorem, which, in view of (2.3), implies that the mapping

$$R^2 \ni (v_j, v_l) \ \rightarrow \ z_i(T) \in R^2,$$

defined on some (open) neighborhood of the origin, has the inverse mapping, defined on some (open) neighborhood of $z_i^*(T)$; that is, (2.4) holds. □

Clearly, the same argument implies a similar result for the motion of the center of mass $z_c(t)$.

PROPOSITION 2.2. *Assume that in* (1.1)–(1.7) *only two controls are active, say,* v_j *and* v_l*, where* $j \neq l$ *and* $j, l \in \{1, \dots, n-1\}$*, while* $v_k = 0$ *for* $k = 1, \dots, n-1, k \neq j, l$*. Assume further that* v_j *and* v_l *are independent of time. Then, if there exists a* $T > 0$ *such that the matrix*

$$\left(\frac{dz_c(T)}{dv_j} \mid_{v'_m s=0}, \frac{dz_c(T)}{dv_l} \mid_{v'_m s=0} \right) \tag{2.5}$$

is nondegenerate, then the system (1.1)–(1.7) *is locally controllable near its drifting position of the center of mass* $z_c^*(T)$*. Namely, there is an* $\varepsilon > 0$ *such that*

$$B_\varepsilon(z_c^*(T)) \subset \{z_c(T) \mid v_j, v_l \in R,\ v_k = 0 \text{ for } k = 1, \dots, n-1, k \neq j, l\}.$$

In particular, for the initial equilibrium position (2.2a) *we have the local controllability with respect to* z_c *near equilibrium at time* T*.*

Our *main results* below deal with the conditions under which the matrices in (2.3) and (2.5) in Propositions 2.1 and 2.2 are nondegenerate (the general scheme of our proofs is described in the beginning of section 3). They involve various assumptions on the initial position of the apparatus. To formulate them, we will need to introduce some notation first.

Let 2D vector functions $\omega_k \in J_0(\Omega) \bigcap H(\Omega)$ and real numbers $-\lambda_k, k = 1, \dots$ ($\lambda_k > 0, \lambda_k \to \infty$ as $k \to \infty$), denote, respectively, the orthonormalized in $(L^2(\Omega))^2$ eigenfunctions and eigenvalues of the spectral problem associated with (1.1):

$$\begin{aligned} \nu \Delta \omega_k \ - \ \nabla p_k &= -\lambda_k \omega_k \quad \text{in} \quad \Omega, \\ \operatorname{div} \omega_k = 0 \ \text{ in } \ \Omega, \quad \omega_k &= 0 \quad \text{in } \ \partial\Omega. \end{aligned}$$

Then the unique solution to (1.1), described in Theorem 1.1, admits the following *implicit* representation:

$$\begin{aligned} y(x,t) = &\sum_{k=1}^{\infty} e^{-\lambda_k t} \left(\int_\Omega y_0^T \omega_k dq \right) \omega_k(x) \\ &+ \sum_{k=1}^{\infty} \int_0^t e^{-\lambda_k (t-\tau)} \left(\int_\Omega F^T(y, z, v) \omega_k dq d\tau \right) \omega_k(x). \end{aligned} \tag{2.6}$$

(Here and below, where appropriate, we use $q = (q_1, q_2)$ to denote the space variable in the internal integration.)

The series in (2.6) and the series obtained from it by differentiation once with respect to t and twice with respect to the spatial variables converge in $(L^2(\Omega))^2$ uniformly for $t \geq 0$ (e.g., [11], [18]).

Denote the projection of the sum of two rotation forces in the last line of (1.3), generated at the initial moment $t = 0$ by the unit control input $v_j = 1$, on the *divergence-free* space $J_0(\Omega)$ by

$$F_j(x) = F_{j,1}(x) + F_{j,2}(x), \quad j = 1, \dots, n-1, \tag{2.7a}$$

where

$$F_{j,1}(x) = \sum_{k=1}^{\infty} \left[\int_{\Omega} \left(\xi_j(q,0) A(z_{j+1}(0) - z_j(0))\right)^T \omega_k(q) dq \right] \omega_k(x)$$

$$= \sum_{k=1}^{\infty} \left[\left(A(z_{j+1}(0) - z_j(0))\right)^T \int_{S_r(z_j(0))} \omega_k(q) dq \right] \omega_k(x), \tag{2.7b}$$

$$F_{j,2}(x) = \sum_{k=1}^{\infty} \left[\int_{\Omega} \left(-\xi_{j+1}(q,0) A(z_{j+1}(0) - z_j(0))\right)^T \omega_k(q) dq \right] \omega_k(x)$$

$$= -\sum_{k=1}^{\infty} \left[\left(A(z_{j+1}(0) - z_j(0))\right)^T \int_{S_r(z_{j+1}(0))} \omega_k(q) dq \right] \omega_k(x). \tag{2.7c}$$

Here we used the fact that $\{\omega_k\}_{k=1}^{\infty}$ form an orthonormalized basic in $J_0(\Omega) \subset (L^2(\Omega))^2$.

ASSUMPTION 2.1. *Let the* $[2 \times 2]$*-matrix*

$$\left(\int_{S_r(z_i(0))} F_j(x) dx, \ \int_{S_r(z_i(0))} F_l(x) dx \right) \tag{2.8}$$

be nondegenerate for some $i \in \{1, \dots, n\}$ *and* $l, j \in \{1, \dots, n-1\}$.

THEOREM 2.3. *Let* $i \in \{1, \dots, n\}$, $l, j \in \{1, \dots, n-1\}$, *and Assumption* 2.1 *hold. Then there exists a* $T^* > 0$ *such that the matrix* (2.3) *is nondegenerate for any* $T \in (0, T^*]$ *and Proposition* 2.1 *holds. Namely, we have the local controllability of system* (1.1)–(1.7) *near its drifting position* $z_i^*(T)$. *In particular, for the equilibrium position* (2.2a)–(2.2b) *condition* (2.8) *implies the local controllability with respect to* z_i *near equilibrium at time* T.

The argument of Theorem 2.3 establishes that

$$\frac{dz_i(t)}{dv_j} \mid_{v'_m s=0} = \frac{t^2}{2\text{mes}\{S_r(0)\}} \int_{S_r(z_i(0))} F_j(x) dx + t^2 O(t), \ \ j = 1, \dots, n-1, \tag{2.9}$$

which allows us to apply (2.8) to ensure that (2.3) in Proposition 2.1 is nondegenerate.

Condition (2.8) holds for any point $z_i, i = 2, \dots, n-1$, in the original position of the swimming apparatus with controls acting in the adjacent links $A(z_{i+1}(0) - z_i(0))$ and $A(z_i(0) - z_{i-1}(0))$ (i.e., for $i = j, l = i-1 = j-1$), provided (a) that these links are *nonparallel* and (b) that the thick points forming it are *sufficiently small disks*. This conclusion is based on the following lemma.

LEMMA 2.4. *Let* $S_r(0)$ *be a disk of radius* r. *Then*

$$\frac{1}{\text{mes}\{S_r(0)\}} \int_{S_r(z_j(0))} F_j dx = \frac{1}{2} A(z_{j+1}(0) - z_j(0)) \ + \ g(r), \ \ j = 1, \dots, n-1, \tag{2.10a}$$

$$\frac{1}{\text{mes}\{S_r(0)\}} \int_{S_r(z_{j+1}(0))} F_j dx = -\frac{1}{2} A(z_{j+1}(0) - z_j(0)) \ + \ g(r), \ \ j = 1, \dots, n-1, \tag{2.10b}$$

where $\| g(r) \|_{R^2} \leq Cr$ as $r \to 0+$ *for some positive constant* C.

Due to (2.9), at no extra cost, Theorem 2.3 implies the respective statement for the center of mass $z_c(t)$.

THEOREM 2.5. *Let $l, j \in \{1, \dots, n-1\}$, and the matrix*

$$\sum_{i=1}^{n} \left(\int_{S_r(z_i(0))} F_j(x)dx, \ \int_{S_r(z_i(0))} F_l(x)dx \right)$$

is nondegenerate. Then there exists a $T^* > 0$ such that for any $T \in (0, T^*]$ Proposition 2.2 *holds. Namely, we have the local controllability of system* (1.1)–(1.7) *with respect to the position of center of mass $z_c(T)$ near its drifting position $z_c^*(T)$. In particular, for the equilibrium position* (2.2a)–(2.2b) *we have the local controllability with respect to z_c near equilibrium at time T.*

Discussion of Theorems 2.3 and 2.5. Note that the two columns in (2.8) multiplied by $\text{mes}^{-1}\{S_r(0)\}$ describe the "average" forces induced respectively by the forces $F_j(x)$ and $F_l(x)$ over the region $S_r(z_i(0))$. Thus, the sufficient conditions for the local controllability near the drifting position $z_i^*(T)$ in Theorem 2.3 require that these average forces are not colinear. Respectively, for the local controllability of the center of mass z_c Theorem 2.5 requires that the sums of such average forces over all "thick points" in the skeleton of the apparatus generated respectively by the unit controls $v_l = 1$ and $v_j = 1$ are not colinear as well.

Remark 2.1. Supports of $F_j(x)$'s . In spite of the fact that the rotation forces in (1.3) have only local supports this does not have to be so for their projections (as in (2.7a)–(2.7b)) on the solenoidal part $J_0(\Omega)$ of $(L^2(\Omega))^2$, associated with incompressible fluids (see section 6 for more details).

Recall now that the space $(L^2(\Omega))^2$ is the direct sum of the spaces $J_0(\Omega)$ and $G(\Omega)$. In (2.7a)–(2.7c) we denoted the projections of the functions

$$\xi_j(x,0)\,(A(z_{j+1}(0) - z_j(0))) \quad \text{and} \quad -\xi_{j+1}(x,0)\,(A(z_{j+1}(0) - z_j(0)))\,, \quad j = 1, \dots, n-1$$

on $J_0(\Omega)$ by $F_{j,1}(x)$ and $F_{j,2}(x)$. Denote now the projections of the aforementioned functions on the space $G(\Omega)$, respectively, by $F_{j,1}^{\perp}(x)$ and $F_{j,2}^{\perp}(x)$. Since (e.g., [11, p. 28]; [18, p. 15])

$$J_0(\Omega) = \{u \in (L^2(\Omega))^2, \ \text{div}\, u = 0, \ \gamma_\nu u\,|_{\partial\Omega} = 0\}, \tag{2.11}$$

$$G(\Omega) = \{u \in (L^2(\Omega))^2, \ u = \nabla p, \ p \in H^1(\Omega)\}, \tag{2.12}$$

where ν is the unit vector normal to the boundary $\partial\Omega$ (pointing outward) and $\gamma_\nu u\,|_{\partial\Omega}$ is the restriction of $u \cdot \nu$ to $\partial\Omega$, we have

$$F_{j,1}^{\perp}(x) = \nabla w_{j,1}(x), \quad F_{j,2}^{\perp}(x) = \nabla w_{j,2}(x), \quad j = 1, \dots, n-1,$$

for some functions $w_{j,1}, w_{j,2} \in H^1(\Omega), j = 1, \dots, n-1$. Thus,

$$F_{j,1}(x) = \xi_j(x,0)\,(A(z_{j+1}(0) - z_j(0))) - \nabla w_{j,1}(x), \tag{2.13}$$

$$F_{j,2}(x) = -\xi_{j+1}(x,0)\,(A(z_{j+1}(0) - z_j(0))) - \nabla w_{j,2}(x). \tag{2.14}$$

Furthermore, $w_{j,1}$ and $w_{j,2}$ solve the following two generalized Neumann problems:

$$\Delta w_{j,1} = \ \text{div}\ \xi_j(x,0)\,(A(z_{j+1}(0) - z_j(0))) \quad \text{in } \Omega, \quad \frac{\partial w_{j,1}}{\partial \nu}\,|_{\partial\Omega} = 0, \tag{2.15}$$

$$\Delta w_{j,2} = \ -\text{div}\ \xi_{j+1}(x,0)\,(A(z_{j+1}(0) - z_j(0))) \quad \text{in } \Omega, \quad \frac{\partial w_{j,2}}{\partial \nu}\,|_{\partial\Omega} = 0. \tag{2.16}$$

Indeed, (2.15), e.g., can be obtained by applying divergence to (2.13) and recalling that $F_{j,1} \in J_0(\Omega)$, which in particular implies that $\mathrm{div} F_{j,1} = 0$. In turn, the boundary condition in (2.15) follows from (2.13) by recalling that, due to (2.11), $\gamma_\nu F_{j,1} \mid_{\partial\Omega} = 0$ and that $\xi_j(x,0)$ vanishes outside of $S_r(z_j(0))$, which provides $\gamma_\nu \nabla w_{j,1} \mid_{\partial\Omega} = \frac{\partial w_{j,1}}{\partial \nu} \mid_{\partial\Omega} = 0$.

Our qualitative analysis of solutions to (2.15) and (2.16) in section 6 led us to Lemma 2.4. In this section we also (see Remark 6.1) derived certain qualitative estimates and formulas which can be used to verify sufficient conditions for controllability in Theorems 2.3 and 2.5 (i.e., not only for the circular support as in Lemma 2.4).

3. Preliminary results. Our plan to prove Theorem 2.3 is as

1. We intend to use Propositions 2.1 and 2.2 involving derivatives $\frac{dz_i(T)}{dv_j}, i = 1, \dots, n, j = 1, \dots, n-1$. In order to evaluate them, in section 3 we differentiate the implicit solution formula (2.6) with respect to v_j's.
2. In section 4 the results of section 3 are presented as a vector Volterra equation for the aforementioned $\frac{dz_i(T)}{dv_j}$'s and suitable asymptotic analysis is used to qualitatively evaluate them for "small" T's.
3. Making use of all of the above to obtain the qualitative estimates for the terms in (2.8), we complete the proof of Theorem 2.3 in section 5.

In this section we intend to derive a number of auxiliary formulas. Everywhere below, for simplicity of calculations we assume that $S_r(0)$ has the form of (1.4b).

3.1. Solution formula. Let us rewrite (2.6) as

$$
\begin{aligned}
y(x,t) = &\sum_{k=1}^{\infty} e^{-\lambda_k t} \left(\int_\Omega y_0^T \omega_k dx \right) \omega_k(x) \\
&+ \sum_{i=2}^{n+1} \left(P_i(x,t) + v_{i-1}(t) Q_i(x,t) + v_{i-2}(t) R_i(x,t) \right),
\end{aligned} \tag{3.1}
$$

where *here and below we always assume* that (besides all other imposed assumptions, if there are such) T is selected "sufficiently small" as in Theorem 1.1 to ensure the wellposednesss of system (1.1)–(1.7) at hand on $[0,T]$, and

(3.2)

$$
\begin{aligned}
P_i(x,t) = \sum_{k=1}^{\infty} \Bigg(\int_0^t e^{-\lambda_k (t-\tau)} \Bigg[& k_{i-1} \frac{(\| z_i(\tau) - z_{i-1}(\tau) \|_{R^2} - l_{i-1})}{\| z_i(\tau) - z_{i-1}(\tau) \|_{R^2}} (z_i(\tau) - z_{i-1}(\tau))^T \\
& + k_{i-2} \frac{(\| z_{i-2}(\tau) - z_{i-1}(\tau) \|_{R^2} - l_{i-2})}{\| z_{i-2}(\tau) - z_{i-1}(\tau) \|_{R^2}} (z_{i-2}(\tau) - z_{i-1}(\tau))^T \Bigg] \\
& \times \left(\int_\Omega \xi_{i-1}(q,\tau) \omega_k dq \right) d\tau \Bigg) \omega_k(x),
\end{aligned}
$$

(3.3)

$$
Q_i(x,t) = \sum_{k=1}^{\infty} \left(\int_0^t e^{-\lambda_k (t-\tau)} \left(A(z_i(\tau) - z_{i-1}(\tau)) \right)^T \left(\int_\Omega \xi_{i-1}(q,\tau) \omega_k dq \right) d\tau \right) \omega_k(x),
$$

(3.4)

$$
R_i(x,t) = \sum_{k=1}^{\infty} \left(\int_0^t e^{\lambda_k (t-\tau)} \left(A(z_{i-2}(\tau) - z_{i-1}(\tau)) \right)^T \left(\int_\Omega \xi_{i-1}(q,\tau) \omega_k dq \right) d\tau \right) \omega_k(x).
$$

3.2. Differentiation with respect to v_j's. We assume from now on that the functions $v_j, j = 1, \dots, n-1$, are constant in time. Below we formally differentiate various expressions with respect to $v_j, j = 1, \dots, n-1$. The validity of these calculations will be discussed in the next section (see the subsection 4.2).

3.2.1. Derivatives of z_i's. In view of (1.2) and (1.4a)–(1.4b), for any $t \in [0, T]$,

$$\begin{aligned} z_i(t) &= z_{i0} + \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \int_{S_r(z_i(\tau))} y(x,\tau) dx d\tau \\ &= z_{i0} + \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \int_{z_{i,1}(\tau)-r}^{z_{i,1}(\tau)+r} \int_{z_{i,2}(\tau)+\alpha(x_1-z_{i,1}(\tau))}^{z_{i,2}(\tau)+\beta(x_1-z_{i,1}(\tau))} y(x,\tau) dx_2 dx_1 d\tau. \end{aligned} \tag{3.5}$$

Denote $z_i(t) = (z_{i,1}(t), z_{i,2}(t))$. Then differentiating (3.5) with respect to v_j, we obtain

$$\begin{aligned} \frac{dz_i(t)}{dv_j} &= \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \int_{z_{i,1}(\tau)-r}^{z_{i,1}(\tau)+r} \\ &\times \left(y(x_1, z_{i,2}(\tau) + \beta(x_1 - z_{i,1}(\tau)), \tau) \left(\frac{dz_{i,2}(\tau)}{dv_j} - \beta'(x_1 - z_{i,1}(\tau)) \frac{dz_{i,1}(\tau)}{dv_j} \right) \right. \\ &\left. - y(x_1, z_{i,2}(\tau) + \alpha(x_1 - z_{i,1}(\tau)), \tau) \left(\frac{dz_{i,2}(\tau)}{dv_j} - \alpha'(x_1 - z_{i,1}(\tau)) \frac{dz_{i,1}(\tau)}{dv_j} \right) \right) dx_1 d\tau \\ &+ \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \frac{dz_{i,1}(\tau)}{dv_j} \int_{z_{i,2}(\tau)+\alpha(r)}^{z_{i,2}(\tau)+\beta(r)} y(z_{i,1}(\tau) + r, x_2, \tau) dx_2 d\tau \\ &- \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \frac{dz_{i,1}(\tau)}{dv_j} \int_{z_{i,2}(\tau)+\alpha(-r)}^{z_{i,2}(\tau)+\beta(-r)} y(z_{i,1}(\tau) - r, x_2, \tau) dx_2 d\tau \\ &+ \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \int_{S_r(z_i(\tau))} \frac{dy(x,\tau)}{dv_j} dx d\tau. \end{aligned} \tag{3.6}$$

3.2.2. Derivatives of y. Making use of (3.1), we obtain

$$\begin{aligned} \frac{dy}{dv_j} |_{v'_m s=0} &= \frac{d}{dv_j} \left(\sum_{i=2}^{n+1} (P_i + v_{i-1} Q_i + v_{i-2} R_i) \right) |_{v'_m s=0} \\ &= Q_{j+1} |_{v'_m s=0} + R_{j+2} |_{v'_m s=0} + \sum_{i=2}^{n+1} \left(\frac{d}{dv_j} P_i + v_{i-1} \frac{d}{dv_j} Q_i + v_{i-2} \frac{d}{dv_j} R_i \right) |_{v'_m s=0} \\ &= Q_{j+1} |_{v'_m s=0} + R_{j+2} |_{v'_m s=0} + \sum_{i=2}^{n+1} \left(\frac{d}{dv_j} P_i \right) |_{v'_m s=0} . \end{aligned} \tag{3.7}$$

3.2.3. Derivatives of P_i's. Making use of (3.2), while noticing that

$$\int_\Omega \xi_{i-1}(x,\tau) \omega_k dx = \int_{z_{i-1,1}(\tau)-r}^{z_{i-1,1}(\tau)+r} \int_{z_{i-1,2}(\tau)+\alpha(x_1-z_{i-1,1}(\tau))}^{z_{i-1,2}(\tau)+\beta(x_1-z_{i-1,1}(\tau))} \omega_k(x) dx_2 dx_1,$$

we obtain

$$\frac{d}{dv_j}P_i(x,t)\mid_{v'_m s=0}$$

$$=\sum_{k=1}^{\infty}\left[\int_0^t e^{-\lambda_k(t-\tau)}\left\{k_{i-1}\Theta_{1,i,j}(\tau)+k_{i-2}\Theta_{2,i,j}(\tau)\right\}\left(\int_\Omega \xi_{i-1}(q,\tau)\omega_k dq\right)d\tau\right]\omega_k(x)\mid_{v'_m s=0}$$

$$+\sum_{k=1}^{\infty}\left(\int_0^t e^{-\lambda_k(t-\tau)}\Theta_{3,i}(\tau)\;\Theta_{4,i,j}(\tau)d\tau\right)\omega_k(x)\mid_{v'_m s=0},$$

(3.8)

where

$$\Theta_{1,i,j}(\tau)=\left(\frac{dz_i(\tau)}{dv_j}-\frac{dz_{i-1}(\tau)}{dv_j}\right)^T\left(1\;-\;\frac{l_{i-1}}{\parallel z_i(\tau)-z_{i-1}(\tau)\parallel_{R^2}}\right)$$

$$+\,l_{i-1}\left(z_i(\tau)-z_{i-1}(\tau)\right)^T\frac{1}{\parallel z_i(\tau)-z_{i-1}(\tau)\parallel^3_{R^2}}$$

$$<\frac{dz_i(\tau)}{dv_j}\;-\;\frac{dz_{i-1}(\tau)}{dv_j},z_i(\tau)-z_{i-1}(\tau)>_{R^2},$$

$$\Theta_{2,i,j}(\tau)=\left(\frac{dz_{i-2}(\tau)}{dv_j}-\frac{dz_{i-1}(\tau)}{dv_j}\right)^T\left(1-\frac{l_{i-2}}{\parallel z_{i-2}(\tau)-z_{i-1}(\tau)\parallel_{R^2}}\right)$$

$$+\,l_{i-2}(z_{i-2}(\tau)-z_{i-1}(\tau))^T\frac{1}{\parallel z_{i-2}(\tau)-z_{i-1}(\tau)\parallel^3_{R^2}}$$

$$<\frac{dz_{i-2}(\tau)}{dv_j}\;-\;\frac{dz_{i-1}(\tau)}{dv_j},z_{i-2}(\tau)-z_{i-1}(\tau)>_{R^2},$$

$$\Theta_{3,i}(\tau)=k_{i-1}\left(\frac{(\parallel z_i(\tau)-z_{i-1}(\tau)\parallel_{R^2}\,-l_{i-1})}{\parallel z_i(\tau)-z_{i-1}(\tau)\parallel_{R^2}}(z_i(\tau)-z_{i-1}(\tau))^T\right)$$

$$+\,k_{i-2}\left(\frac{(\parallel z_{i-2}(\tau)-z_{i-1}(\tau)\parallel_{R^2}\,-l_{i-2})}{\parallel z_{i-2}(\tau)-z_{i-1}(\tau)\parallel_{R^2}}(z_{i-2}(\tau)-z_{i-1}(\tau))^T\right),$$

$$\Theta_{4,i,j}(\tau)=\int_{z_{i-1,1}(\tau)-r}^{z_{i-1,1}(\tau)+r}\omega_k\left(x_1,z_{i-1,2}(\tau)+\beta(x_1-z_{i-1,1}(\tau))\right)$$

$$\times\left(\frac{dz_{i-1,2}(\tau)}{dv_j}-\beta'(x_1-z_{i-1,1}(\tau))\frac{dz_{i-1,1}(\tau)}{dv_j}\right)dx_1$$

$$-\int_{z_{i-1,1}(\tau)-r}^{z_{i-1,1}(\tau)+r}\omega_k\left(x_1,z_{i-1,2}(\tau)+\alpha(x_1-z_{i-1,1}(\tau))\right)$$

$$\times\left(\frac{dz_{i-1,2}(\tau)}{dv_j}-\alpha'(x_1-z_{i-1,1}(\tau))\frac{dz_{i-1,1}(\tau)}{dv_j}\right)dx_1$$

$$+\,\frac{dz_{i-1,1}(\tau)}{dv_j}\int_{z_{i-1,2}(\tau)+\alpha(r)}^{z_{i-1,2}(\tau)+\beta(r)}\omega_k(z_{i-1,1}(\tau)+r,x_2)dx_2$$

$$-\,\frac{dz_{i-1,1}(\tau)}{dv_j}\int_{z_{i-1,2}(\tau)+\alpha(-r)}^{z_{i-1,2}(\tau)+\beta(-r)}\omega_k(z_{i-1,1}(\tau)-r,x_2)dx_2.$$

To better understand the terms in the second sum in (3.8), denote

$$V_i(\tau)=\Theta_{3,i}(\tau)\mid_{v'_m s=0}.$$

Then we can rewrite, e.g., the term in the second sum in (3.8) associated with the factor $\frac{dz_{i-1,2}(\tau)}{dv_j}$ in the first line in the expression for $\Theta_{4,i,j}(\tau)$ as

$$\int_0^t \frac{dz_{i-1,2}(\tau)}{dv_j}\left[\sum_{k=1}^{\infty} e^{-\lambda_k(t-\tau)}\{(\Phi_1(\tau))(V_i(\tau)\omega_k)\}\right] d\tau\omega_k(x) \mid_{v'_m s=0}, \tag{3.9}$$

where we denoted

$$(\Phi_1(t))(\psi) = \int_{z_{i-1,1}(t)-r}^{z_{i-1,1}(t)+r} \psi(x_1, z_{i-1,2}(t) + \beta(x_1 - z_{i-1,1}(t)))dx_1.$$

Note that $\Phi_1(t) \in H^{-1}(\Omega)$ for any $t \in [0,T]$, where the space $H^{-1}(\Omega)$ is dual of $H_0^1(\Omega)$; namely, it is the space of all linear bounded functionals on $H_0^1(\Omega)$. (As usual, we endow the latter space with the norm $\|\psi\|_{H_0^1(\Omega)} = \{\int_\Omega(\psi_{x_1}^2 + \psi_{x_2}^2)dx\}^{1/2}$.)

Indeed, regardless of t, for any $\psi \in H_0^1(\Omega)$, due to the continuous embedding of $H_0^1(a,b)$ into $C[a,b]$ for any finite interval $[a,b]$, for any $t \in [0,T]$ we have

$$\mid (\Phi_1(t))(\psi) \mid \leq \int_{z_{i-1,1}(t)-r}^{z_{i-1,1}(t)+r} \mid \psi(x_1, z_{i-1,2}(t) + \beta(x_1 - z_{i-1,1}(t))) \mid dx_1$$

$$\leq C_1 \int_{z_{i-1,1}(t)-r}^{z_{i-1,1}(t)+r} \| \psi(x_1,\cdot) \|_{H_0^1(\{\xi|(x_1,\xi)\in\Omega\}} dx_1 \leq \sqrt{2r}C_1 \| \psi \|_{H_0^1(\Omega)},$$

where C_1 is a positive constant. Thus, for any $t \in [0,T]$,

$$\| \Phi_1(t) \|_{H^{-1}(\Omega)} = \sup_{\|\psi\|_{H_0^1(\Omega)}=1, \psi\in H_0^1(\Omega)} \mid (\Phi_1(t))(\psi) \mid \leq \sqrt{2r}C_1. \tag{3.10}$$

In the next subsection we will need the following observation.

Remark 3.1. Consider any vector $\kappa \in R^2$. Then, similar to the derivation of (3.10), we can show that for any $t \in [0,T]$ the expression

$$(\Phi_1(t)\kappa)(\phi) = (\Phi_1(t))(\kappa^T\phi), \quad \text{where } \phi \in (H_0^1(\Omega))^2,$$

defines a linear bounded functional on $(H_0^1(\Omega))^2$ and

$$\sup_{\|\phi\|_{(H_0^1(\Omega))^2}=1, \phi\in(H_0^1(\Omega))^2} \mid (\Phi_1(t)\kappa)(\phi) \mid \leq \| \kappa \|_{R^2} \| \Phi_1(t) \|_{H^{-1}(\Omega)} \leq \sqrt{2r}C_1 \| \kappa \|_{R^2}.$$

On the other hand, if $\phi \in H(\Omega) \subset (H_0^1(\Omega))^2$, then it admits the following representation:

$$\phi = \sum_{k=1}^{\infty} a_k\omega_k, \quad \| \phi \|_{H(\Omega)} = \| \phi \|_{(H_0^1(\Omega))^2} = \left(\sum_{k=1}^{\infty} \frac{\lambda_k}{\nu} a_k^2\right)^{1/2}.$$

In this case, we can introduce the space $H'(\Omega)$ of linear bounded functionals $\mathbf{\Phi}$ on $H(\Omega)$ making use of the duality product

$$\mathbf{\Phi}(\phi) = \sum_{k=1}^{\infty} a_k b_k, \quad \text{where } b_k = \mathbf{\Phi}(\omega_k), \quad k = 1, \ldots,$$

with the norm

$$\| \mathbf{\Phi} \|_{H'(\Omega)} = \left(\sum_{k=1}^{\infty} \frac{\nu}{\lambda_k} b_k^2 \right)^{1/2},$$

equivalent to the regular one on this space (i.e., analogous to that in (3.10)). Thus, in particular, for any $\kappa \in R^2$ we have for any $t \in [0,T]$

$$\begin{aligned} \sum_{k=1}^{\infty} \frac{\nu}{\lambda_k} \{(\Phi_1(t)\kappa)(\omega_k)\}^2 \;&\le\; C_* \left(\sup_{\|\phi\|_{H(\Omega)}=1, \phi \in H(\Omega)} | \, (\Phi_1(t)\kappa)(\phi) \, | \right)^2 \\ \le\; C_* \left(\sup_{\|\phi\|_{(H_0^1(\Omega))^2}=1, \phi \in (H_0^1(\Omega))^2} | \, (\Phi_1(t)\kappa)(\phi) \, | \right)^2 \;&\le\; C_* \left(\sqrt{2r} C_1 \, \| \, \kappa \, \|_{R^2} \right)^2, \end{aligned} \tag{3.11}$$

where $C_* > 0$ is some (generic) constant.

3.3. Kernels. Let us now consider in detail the contribution of (3.9) to the expression in (3.6), multiplied by $\operatorname{mes}\{S_r(0)\}$, when $v_m' s = 0$, namely,

$$\begin{aligned} &\int_0^t \int_0^\tau \frac{dz_{i-1,2}(s)}{dv_j} \int_{S_r(z_i(\tau))} \left[\sum_{k=1}^{\infty} e^{-\lambda_k(\tau - s)} \{(\Phi_1(s) V_i(s))(\omega_k)\} \omega_k(x) \right] dx ds d\tau \\ &= \int_0^t \frac{dz_{i-1,2}(s)}{dv_j} \left\{ \int_s^t \int_{S_r(z_i(\tau))} \left[\sum_{k=1}^{\infty} e^{-\lambda_k(\tau - s)} \{(\Phi_1(s) V_i(s))(\omega_k)\} \omega_k(x) \right] dx d\tau \right\} ds. \end{aligned}$$

In the above, the factor at $\frac{dz_{i-1,2}(s)}{dv_j}$ can be regarded as a 2D kernel $K(t,s)$, $(t,s) \in (0,T) \times (0,T)$, vanishing for $s > t$.

LEMMA 3.1. *The kernel K is an element of $(L^\infty((0,T) \times (0,T)))^2$.*

Proof of Lemma 3.1. Indeed, for almost all $(s,\tau) \in (0,T) \times (0,T)$,

$$\begin{aligned} \| \, K(t,s) \, \|_{R^2}^2 &= \| \int_s^t \int_{S_r(z_i(\tau))} \left[\sum_{k=1}^{\infty} e^{-\lambda_k(\tau - s)} \{(\Phi_1(s) V_i(s))(\omega_k)\} \omega_k(x) \right] dx d\tau \, \|_{R^2}^2 \\ &\le\; T \operatorname{mes}\{S_r(0)\} \sum_{k=1}^{\infty} \left(\int_s^t e^{-2\lambda_k(\tau - s)} d\tau \right) \{(\Phi_1(s) V_i(s))(\omega_k)\}^2 \\ &\le\; CT \sum_{k=1}^{\infty} \frac{1}{\lambda_k} \{(\Phi_1(s) V_i(s))(\omega_k)\}^2 \;\le\; \hat{C} T \left(\sqrt{2r} C_1 \, \| \, V_i \, \|_{C([0,T];R^2)} \right)^2 \end{aligned} \tag{3.12}$$

for some (generic) positive constants C and $\hat{C}$, while C_1 is from (3.11) in Remark 3.1. In (3.12) we also used the following type of estimate, employing Bessel's inequality:

$$\begin{aligned} \left\| \int_\omega \left(\sum_{k=1}^{\infty} a_k \omega_k(x) \right) dx \, \right\|_{R^2}^2 &= \| \int_\Omega \left(\sum_{k=1}^{\infty} a_k \omega_k(x) \right) \xi_\omega(x) dx \, \|_{R^2}^2 \\ \le\; \left\| \sum_{k=1}^{\infty} a_k \omega_k \right\|_{(L^2(\Omega))^2}^2 &\| \, \xi_\omega \, \|_{L^2(\Omega)}^2 = \left(\sum_{k=1}^{\infty} a_k^2 \right) \operatorname{mes}\{\omega\}, \end{aligned}$$

where $\xi_\omega(x)$ is the characteristic function of a set $\omega \subset \Omega$. This ends the proof of Lemma 3.1. □

The assertion of Lemma 3.1 can be established for all other kernels associated with $\frac{dz_i(s)}{dv_j}$'s in (3.8) and (3.6).

4. Volterra equations for $\frac{dz_i(\tau)}{dv_j}$'s. Below we will deal only with the terms $\frac{dz_i(t)}{dv_j}\,|_{v'_m s=0}$. Therefore, to simplify further notation, we will *omit the subscript* $|_{v'_m s=0}$ *from now on.*

4.1. Volterra equations. Equation (3.6) can be rewritten as the following vector Volterra equation:

$$\begin{pmatrix} \frac{dz_1(t)}{dv_j} \\ \vdots \\ \frac{dz_n(t)}{dv_j} \end{pmatrix} + \int_0^t \mathbf{B}_j(t,s) \begin{pmatrix} \frac{dz_1(s)}{dv_j} \\ \vdots \\ \frac{dz_n(s)}{dv_j} \end{pmatrix} ds = \begin{pmatrix} \Xi_{1j}(t) \\ \vdots \\ \Xi_{nj}(t) \end{pmatrix}, \quad j = 1, \dots, n-1, \quad t \in [0,T], \tag{4.1}$$

where

$$\Xi_{ij}(t) = \frac{1}{\operatorname{mes}\{S_r(0)\}} \int_0^t \int_{S_r(z_i(\tau))} (Q_{j+1} + R_{j+2})\, dx d\tau \,|_{v'_m s=0}$$

and $\mathbf{B}_j(t,s)$, $j = 1, \dots, n-1$, are, respectively, the vector and matrix functions defined by (3.6) along (3.7)–(3.12). We will need the following asymptotic result.

LEMMA 4.1.

$$\Xi_{ij}(t) = \frac{t^2}{2\operatorname{mes}\{S_r(0)\}} \left[\sum_{k=1}^{\infty} \left(\int_{S_r(z_i(0))} \omega_k dx\right)\left(\int_{S_r(z_j(0))} \omega_k^T(x) dx\right)\right] A(z_{j+1}(0) - z_j(0))$$

$$+ \frac{t^2}{2\operatorname{mes}\{S_r(0)\}} \left[\sum_{k=1}^{\infty} \left(\int_{S_r(z_i(0))} \omega_k dx\right)\left(\int_{S_r(z_{j+1}(0))} \omega_k^T(x) dx\right)\right] A(z_j(0) - z_{j+1}(0)) + t^2 O(t) \tag{4.2}$$

as $t \to 0+$, where $i = 1, \dots, n$, $j = 1, \dots, n-1$, and $O(t)$ stands for a vector function whose R^2-norm tends to zero as $t \to 0+$.

Proof of Lemma 4.1. *Step* 1. In view of (3.3) and (3.4), we have

$$\operatorname{mes}\{S_r(0)\}\Xi_{ij}(t)$$

$$= \int_0^t \int_0^\tau \int_\Omega \left[\sum_{k=1}^{\infty} e^{-\lambda_k(\tau - s)} \left(\int_\Omega (A(z_{j+1}(s) - z_j(s)))^T \xi_j(q,s)\omega_k dq\right)\omega_k(x)\right] \xi_i(x,\tau) dx ds d\tau$$

$$+ \int_0^t \int_0^\tau \int_\Omega \left[\sum_{k=1}^{\infty} e^{\lambda_k(\tau - s)} \left(\int_\Omega (A(z_j(s) - z_{j+1}(s)))^T \xi_{j+1}(q,s)\omega_k dq\right)\omega_k(x)\right] \xi_i(x,\tau) dx ds d\tau. \tag{4.3}$$

Step 2. We will further deal with the first term in (4.3). Let us show that the following representation holds for the expression in the square brackets in this term:

$$\mathbf{W}(s,\tau) = \left\| \sum_{k=1}^{\infty} e^{-\lambda_k(\tau - s)} \left(\int_\Omega (A(z_{j+1}(s) - z_j(s)))^T \xi_j(q,s)\omega_k dq\right)\omega_k \right.$$

$$\left. - \sum_{k=1}^{\infty} \left(\int_\Omega (A(z_{j+1}(0) - z_j(0)))^T \xi_j(q,0)\omega_k dq\right)\omega_k \right\|^2_{(L^2(\Omega))^2} \le O(t) \tag{4.4}$$

as $t \to 0+$ uniformly over $0 \le s \le \tau \le t$.

Indeed,

$$\begin{aligned}\mathbf{W}(s,\tau) &\le 2\sum_{k=1}^{\infty} e^{-2\lambda_k(\tau-s)} \\ &\times \left[\int_\Omega \left((A(z_{j+1}(s)-z_j(s)))^T\xi_j(q,s) - (A(z_{j+1}(0)-z_j(0)))^T\xi_j(q,0)\right)\omega_k dq\right]^2 \\ &+ 2\sum_{k=1}^{N}(e^{-\lambda_k(\tau-s)}-1)^2\left(\int_\Omega (A(z_{j+1}(0)-z_j(0)))^T\,\xi_j(q,0)\omega_k dq\right)^2 \\ &+ 2\sum_{k=N+1}^{\infty}(e^{-2\lambda_k(\tau-s)}-1)^2\left(\int_\Omega (A(z_{j+1}(0)-z_j(0)))^T\,\xi_j(q,0)\omega_k dq\right)^2.\end{aligned} \tag{4.5}$$

Step 3. Due to Bessel's inequality,

$$\begin{aligned}&\left\|\sum_{k=1}^{\infty}\left(\int_\Omega (A(z_{j+1}(0)-z_j(0)))^T\,\xi_j(q,0)\omega_k dq\right)\omega_k\right\|^2_{(L^2(\Omega))^2} \\ &= \sum_{k=1}^{\infty}\left(\int_\Omega (A(z_{j+1}(0)-z_j(0)))^T\,\xi_j(q,0)\omega_k dq\right)^2 \le \|\,\xi_j(\cdot,0)\,(A(z_{j+1}(0)-z_j(0)))\,\|^2_{(L^2(\Omega))^2}.\end{aligned}$$

Therefore for every $\varepsilon>0$ there is an $N=N(\varepsilon)$ such that the last sum on the right in (4.5) can be made smaller than $\varepsilon/3$ regardless of $0\le s\le\tau\le t$.

In turn, for this $N(\varepsilon)$, determined by ε, there is a $t_*=t_*(\varepsilon)>0$ such that, by continuity of the exponential function, the second sum on the right in (4.5) can be made smaller than $\varepsilon/3$ as well for any $0\le s\le\tau\le t\le t_*$.

Step 4. Now recall that continuity of solutions in time in Theorem 1.1 yields that

$$\|\,A(z_{j+1}(s)-z_j(s)) - A(z_{j+1}(0)-z_j(0))\,\|_{R^2} = O(s)$$

as $s\to 0+$. In turn, (1.7) implies that for any $k=1,\dots,n$

$$\begin{aligned}&\|\,\xi_k(\cdot,s)-\xi_k(\cdot,0)\,\|^2_{L^2(\Omega)} \\ &= \int_{(S_r(z_k(s)))\bigcup(S_r(z_k(0)))\setminus(S_r(z_k(s))\bigcap S_r(z_k(0)))} dx = O(\|\,z_k(s)-z_k(0)\,\|_{R^2}) = O(s)\end{aligned} \tag{4.6}$$

as $s\to 0+$. Therefore, for any selected-above ε there is a $t_{**}=t_{**}(\varepsilon)>0$ such that the first term on the right in (4.5) can be made smaller than $\varepsilon/3$ for any $0\le s\le\tau\le t\le t_{**}$. Indeed,

$$\begin{aligned}&\sum_{k=1}^{\infty} e^{-2\lambda_k(\tau-s)}\left[\int_\Omega \left((A(z_{j+1}(s)-z_j(s)))^T\xi_j(q,s) - (A(z_{j+1}(0)-z_j(0)))^T\xi_j(q,0)\right)\omega_k dq\right]^2 \\ &\le \sum_{k=1}^{\infty}\left[\int_\Omega \left((A(z_{j+1}(s)-z_j(s)))^T\xi_j(q,s) - (A(z_{j+1}(0)-z_j(0)))^T\xi_j(q,0)\right)\omega_k dq\right]^2 \\ &\le \|\,\xi_j(\cdot,s)(A(z_{j+1}(s)-z_j(s))) - \xi_j(\cdot,0)(A(z_{j+1}(0)-z_j(0)))\,\|_{(L^2(\Omega))^2} = O(s)\end{aligned}$$

as $s\to 0+$ uniformly over $0\le s\le\tau\le t$.

Combining all of the above, we obtain that $\mathbf{W}(s,\tau)$ in (4.4), (4.5) can be made smaller than $\varepsilon > 0$ for any $t \in [0, \min\{t_*, t_{**}\}]$, which yields (4.4).

Step 5. Applying (4.6) to $\xi_i(x,\tau)$ in the first term in (4.3) and making use of (4.4) yields the assertion of Lemma 4.1 for the first term in (4.2). The proof for the second term is similar. This ends the proof of Lemma 4.1. □

4.2. Auxiliary estimates. It is well known (e.g., [10]) that (as a special form of the Fredholm equation) (4.1) admits a unique solution in $(L^2(0,T))^{2n}$. This will allow us to prove, making use of the classical methods, that dz_i/dv_j's indeed exist in $(L^2(0,T))^2$, and all the above calculations leading to (4.1) are valid. (Namely, one needs, based on (3.5), to write the Volterra equations for the expressions $\Delta z_i/\Delta v_j$'s and then pass to the limit as Δv_j tend to zero to obtain (4.1).)

Furthermore, it is easy to see that there exists a ("small") $T_1 > 0$ such that for any $T \in (0, T_1]$

$$\left\| \left(\frac{dz_1}{dv_j}, \dots, \frac{dz_n}{dv_j} \right) \right\|_{(L^2(0,T))^{2n}} \le C \parallel (\Xi_{1j}, \dots, \Xi_{nj}) \parallel_{(L^2(0,T))^{2n}}, \tag{4.7}$$

where $C > 0$ is a (generic) positive constant independent of $T \in [0, T_1]$.

Moreover, since in (4.1) the integral terms, with $(L^2(0,T))^2$-derivatives dz_i/dv_j's in them and the right-hand sides, are actually continuous functions (which can be shown, in particular, making use of Lemma 3.1), we have

$$\left(\frac{dz_1}{dv_j}, \dots, \frac{dz_n}{dv_j} \right) \in C([0,T]; R^{2n}),$$

and, similar to (4.7), there exists a ("small") $T_2 \in [0, T_1]$ such that for any $T \in (0, T_2]$

$$\left\| \left(\frac{dz_1}{dv_j}, \dots, \frac{dz_n}{dv_j} \right) \right\|_{C([0,T];R^{2n})} \le C \parallel (\Xi_1, \dots, \Xi_n) \parallel_{C([0,T];R^{2n})}, \tag{4.8}$$

where, to simplify notation, we again used the generic notation C for the constant.

Applying (4.2) and (4.8) to (4.1), we obtain that

$$\left\| \left(\frac{dz_1}{dv_j}, \dots, \frac{dz_n}{dv_j} \right) \right\|_{C([0,T];R^{2n})} \le Lt^2 \tag{4.9}$$

for some constant $L > 0$ as $t \to 0+$.

5. Proof of Theorem 2.3: The inverse function theorem. From (4.1), making use of (4.2), (4.9), and (2.7a)–(2.7b), we derive that

$$\frac{dz_i(t)}{dv_j} = \frac{t^2}{2\mathrm{mes}\,\{S_r(0)\}} \int_{S_r(z_i(0))} F_j(x)dx + t^2 O(t) \tag{5.1}$$

for $j = 1, \dots, n-1$, $t \in [0,T]$.

Thus, the matrix

$$\left(\frac{dz_i(t)}{dv_j}, \frac{dz_i(t)}{dv_l} \right)$$

is not degenerate under Assumption 2.1 of Theorem 2.3 for sufficiently small t. We can now select any such "small" number t as a $T > 0$ in Proposition 2.1 and obtain the statement of Theorem 2.3 from this proposition. This ends the proof of Theorem 2.3. □

6. Proof of Lemma 2.4 and supports of F_j's. Let us show first (see Remark 2.1) that the projections $F_{j,1}(x)$ and $F_{j,2}(x)$ in (2.7a)–(2.7c) of the respective rotation forces in (1.3) with supports in $S_r(z_j(0))$ and $S_r(z_{j+1}(0))$ can have support beyond these two sets in Ω.

For example, let $F_{j,1}(x)$ be supported only in $S_r(z_j(0))$. Then, as a divergence-free function on Ω, it is orthogonal to any function of type ∇p in $(L^2(\Omega))^2$. Since the latter functions include all constant vectors, this yields that

$$\int_{S_r(z_j(0))} F_{j,1}(x)dx = 0.$$

In turn, since

$$F_{j,1}(x) \ + \ \nabla w_{j,1} = (A(z_{j+1}(0) - z_j(0)))\, \xi_j(x,0),$$

and $\nabla w_{j,1}$ is orthogonal to $F_{j,1}$ in $(L^2(\Omega))^2$,

$$\int_\Omega \parallel F_{j,1}(x) \parallel^2_{R^2} dx = (A(z_{j+1}(0) - z_j(0)))^T \int_{S_r(z_j(0))} F_{j,1}(x)dx = 0$$

or $F_{j,1}(x) \equiv 0$, and hence

$$\nabla w_{j,1} = \xi_j(x,0)\,(A(z_{j+1}(0) - z_j(0)))\,,$$

which means that $w_{j,1} \notin H^1(\Omega)$, contradicting (2.12).

Proof of Lemma 2.4. We will prove (2.10a) (the proof of (2.10b) is similar). Without loss of generality, we can assume that some neighborhoods of $S_r(z_j(0))$ and $S_r(z_{j+1}(0))$ do not overlap. We use below the traditional notation $y = (y_1, y_2)$ for a space variable to complement $x = (x_1, x_2)$, where it is necessary. (Since the proof below does not use (1.1)–(1.3), this should not cause confusion.)

Step 1: Green's formula. Our plan is to evaluate the vector columns in (2.8)/(2.9) by making use of (2.13)–(2.16) and the generalized version of the classical Green's formula representing solutions of the boundary problems (2.15), (2.16).

Consider the spectral problem

$$\Delta\theta = \alpha\theta, \quad \frac{\partial\theta}{\partial\nu} \mid_{\partial\Omega} = 0.$$

Denote by $\{\alpha_k\}_{k=1}^\infty$ its *negative* eigenvalues and by $\{\theta_k\}_{k=1}^\infty$ denote their respective orthonormalized in $L^2(\Omega)$ eigenfunctions. Then any solution to (2.15) admits the following representation:

$$w_{j,1}(x) = \sum_{k=1}^\infty \frac{1}{\sqrt{-\alpha_k}} \left(\int_\Omega \xi_j(q,0)\,(A(z_{j+1}(0) - z_j(0)))^T \frac{\nabla\theta_k}{\sqrt{-\alpha_k}} dq \right) \theta_k(x) \ + \ K,$$

where K is any number. (Note that $\{\frac{\nabla\theta_k}{\sqrt{-\alpha_k}}\}_{k=1}^\infty$ is an orthonormal sequence in $(L^2(\Omega))^2$.) Since in (2.13) we deal only with $\nabla w_{j,1}$, without loss of generality we can further assume that $K = 0$.

Let $g_{j,n}(x), n = 1, \ldots$, be a sequence of uniformly bounded infinitely many times differentiable functions vanishing on $\partial\Omega$ which converge to $\xi_j(x,0)$ in $L^2(\Omega)$. Consider now the boundary problem (2.15) with div $g_{j,n}\,(A(z_{j+1}(0) - z_j(0)))$'s in place

of div $\xi_j(x,0)\,(A(z_{j+1}(0)-z_j(0)))$ on the right. Denote by $w_{j,1,n}$ the following particular sequence of solutions to this new boundary problem:

$$w_{j,1,n}(x)=\sum_{k=1}^{\infty}\frac{1}{\sqrt{-\alpha_k}}\left(\int_\Omega g_{j,n}(q)\,(A(z_{j+1}(0)-z_j(0)))^T\,\frac{\nabla\theta_k}{\sqrt{-\alpha_k}}dq\right)\theta_k(x),\quad n=1,\dots.$$

Note that $w_{j,1,n}\to w_{j,1}$ as $n\to\infty$ in $H^1(\Omega)$ and hence in $L^2(\partial\Omega)$, due to the continuous embedding of the former space into the latter (see (6.3) below and also recall that we picked $K=0$).

Recall now that the classical Green's formula yields for $w_{j,1,n}$'s

$$\begin{aligned}
2\pi w_{j,1,n}(x)&=-\int_{\partial\Omega}w_{j,1,n}(\eta)\frac{\partial}{\partial\nu}\left(\ln\frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2}}\right)d\eta\\
&\quad-\int_\Omega\Delta w_{j,1,n}(y)\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\\
&=-\int_{\partial\Omega}w_{j,1,n}(\eta)\frac{\partial}{\partial\nu}\left(\ln\frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2}}\right)d\eta\\
&\quad-\int_\Omega\operatorname{div}g_{j,n}(y)\,(A(z_{j+1}(0)-z_j(0)))\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\\
&=-\int_{\partial\Omega}w_{j,1,n}(\eta)\frac{\partial}{\partial\nu}\left(\ln\frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2)}}\right)d\eta\\
&\quad+\int_\Omega g_{j,n}(y)\,(A(z_{j+1}(0)-z_j(0)))^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy,
\end{aligned}$$

where in the last step we used integration by parts. Here and below, when we write ∇ within some integral we mean that the corresponding differentiation is conducted with respect to the integration variables.

Everywhere in this section we understand the improper integral over the given domain E for a function with a discontinuity at x as the limit of the integrals over $E\backslash B_s(x)$ as $s\to 0+$, where $B_s(x)$ is a disk of radius s with center at x. In particular, by switching to the polar coordinates near the "bad point" (x_1,x_2), one can show the last integral in the above is well defined, even if $g_{j,n}$ is replaced by any measurable bounded function.

Making use of the above, we can pass to the limit in the space $L^2(\Omega)$ as $n\to\infty$ in the last two lines in the above expression for $w_{j,1,n}$'s , which gives the following formula:

$$\begin{aligned}
2\pi w_{j,1}(x)&=-\int_{\partial\Omega}w_{j,1}(\eta)\frac{\partial}{\partial\nu}\left(\ln\frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2)}}\right)d\eta\\
&\quad+\int_{S_r(z_j(0))}(A(z_{j+1}(0)-z_j(0)))^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy.
\end{aligned}\tag{6.1a}$$

Analogously,

$$
\begin{aligned}
2\pi w_{j,2}(x) = &- \int_{\partial\Omega} w_{j,2}(\eta) \frac{\partial}{\partial \nu} \left(\ln \frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2)}} \right) d\eta \\
&- \int_{S_r(z_{j+1}(0))} (A(z_{j+1}(0)-z_j(0)))^T \nabla \left(\ln \frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}} \right) dy.
\end{aligned} \tag{6.1b}
$$

For the first column in (2.8) we have for $j = i$ (see (2.7a), (2.14)):

$$
\begin{aligned}
\int_{S_r(z_j(0))} F_j dx &= \int_{S_r(z_j(0))} F_{j,1}(x)dx \; + \; \int_{S_r(z_j(0))} F_{j,2}(x)dx \\
&= \int_{S_r(z_j(0))} F_{j,1}(x)dx \; - \; \int_{S_r(z_j(0))} \nabla w_{j,2}(x)dx.
\end{aligned} \tag{6.2}
$$

To evaluate (6.2), we intend to evaluate the gradients of the terms in (6.1a)–(6.1b) and their integrals over required $S_r(z_j(0))$ and $S_r(z_{j+1}(0))$, and then to use (2.13). Since the integration with respect to x in (2.10a) is taken over $S_r(z_j(0))$, *everywhere below we consider only* $x \in S_r(z_j(0))$.

Step 2: Evaluation of the integrals of the gradients of the first terms in (6.1a)–(6.1b) over $S_r(z_j(0))$.

We begin with the gradient of the first term on the right in (6.1a). Recall first that

$$
\| w_{j,1} \|_{L^2(\partial\Omega)} \leq \; L_0 \, \| w_{j,1} \|_{H^1(\Omega)}, \tag{6.3}
$$

where L_0 depends on the $\partial\Omega$.

Recall that in Step 1, we selected

$$
w_{j,1}(x) = \sum_{k=1}^{\infty} \frac{1}{\sqrt{-\alpha_k}} \left(\int_\Omega \xi_j(q,0) \, (A(z_{j+1}(0)-z_j(0)))^T \, \frac{\nabla\theta_k}{\sqrt{-\alpha_k}} dq \right) \theta_k(x).
$$

Hence, taking into account that $\{\frac{\nabla\theta_k}{\sqrt{-\alpha_k}}\}_{k=1}^{\infty}$ is an orthonormal sequence in $(L^2(\Omega))^2$, we derive from Bessel's inequality that

$$
\| w_{j,1} \|_{H^1(\Omega)} \leq \; C \, \| A(z_{j+1}(0)-z_j(0)) \|_{R^2} \;\; \mathrm{mes}^{1/2} \{S_r(0)\}, \tag{6.4}
$$

where C denotes a (generic) positive constant.

Furthermore, for $i, j = 1, 2, i \neq j$, and $x \neq y$,

$$
\frac{\partial}{\partial y_i} \left(\ln \frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}} \right) = \frac{x_i - y_i}{(x_1-y_1)^2+(x_2-y_2)^2}, \tag{6.5}
$$

$$
\frac{\partial^2}{\partial y_i \partial x_i} \left(\ln \frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}} \right) = \frac{-(x_i-y_i)^2+(x_j-y_j)^2}{((x_1-y_1)^2+(x_2-y_2)^2)^2}, \tag{6.6}
$$

$$
\frac{\partial^2}{\partial y_i \partial x_j} \left(\ln \frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}} \right) = \frac{-2(x_i-y_i)(x_j-y_j)}{((x_1-y_1)^2+(x_2-y_2)^2)^2}. \tag{6.7}
$$

Denote next by d_0 the shortest distance between the set $S_r(z_j(0)) \bigcup S_r(z_{j+1}(0))$ and $\partial\Omega$:

$$
d_0 = \inf_{x \in S_r(z_j(0)) \bigcup S_r(z_{j+1}(0)), y \in \partial\Omega} \sqrt{(x_1-y_1)^2+(x_2-y_2)^2}. \tag{6.8}
$$

Note first that, since $S_r(z_j(0))$ is strictly separated from $\partial\Omega$, all the denominators in (6.5)–(6.7) are well defined for $x \in S_r(z_j(0))$ and $y \in \partial\Omega$. Therefore, in view of (6.5)–(6.7), we have the following estimate:

$$\left\| \nabla_x \frac{\partial}{\partial \nu} \left(\ln \frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2}} \right) \right\|_{R^2} \le \frac{C_0}{d_0^4}, \quad x \in S_r(z_j(0)), \ \ y \in \partial\Omega,$$

where C_0 is a positive constant and ∇_x means that the gradient is taken with respect to x (while $\frac{\partial}{\partial \nu}$ is taken with respect to y). Denote

$$\nabla_x \frac{\partial}{\partial \nu} \left(\ln \frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2}} \right) = (h_1(x,y), h_2(x,y)).$$

Therefore, for the gradient of the first term in (6.1a), we have

$$\begin{aligned}
&\left\| \int_{S_r(z_j(0))} \nabla \int_{\partial\Omega} w_{j,1}(\eta) \frac{\partial}{\partial \nu} \left(\ln \frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2}} \right) d\eta dx \right\|_{R^2} \\
&= \left[\left(\int_{S_r(z_j(0))} \int_{\partial\Omega} w_{j,1}(\eta) h_1(x,\eta) d\eta dx \right)^2 + \left(\int_{S_r(z_j(0))} \int_{\partial\Omega} w_{j,1}(\eta) h_2(x,\eta) d\eta dx \right)^2 \right]^{1/2} \\
&\le \left(\left(\max_{x \in S_r(z_j(0)),\ y \in \partial\Omega} \mid h_1(x,y) \mid \right)^2 \right. \\
&\qquad \left. + \left(\max_{x \in S_r(z_j(0)),\ y \in \partial\Omega} \mid h_2(x,y) \mid \right)^2 \right)^{1/2} \int_{S_r(z_j(0))} \int_{\partial\Omega} \mid w_{j,1}(\eta) \mid d\eta dx \\
&\le \frac{2C_0}{d_0^4} \int_{S_r(z_j(0))} \| w_{j,1} \|_{L^2(\partial\Omega)} \operatorname{mes}^{1/2} \{\partial\Omega\} dx \\
&\le 2L_0 \frac{C_0}{d_0^4} \| w_{j,1} \|_{H^1(\Omega)} \operatorname{mes}^{1/2} \{\partial\Omega\} \int_{S_r(z_j(0))} dx \\
&\le \frac{2L_0 C C_0}{d_0^4} \| A(z_{j+1}(0) - z_j(0)) \|_{R^2} \operatorname{mes}^{3/2} \{S_r(0)\} \operatorname{mes}^{1/2} \{\partial\Omega\},
\end{aligned} \tag{6.9}$$

where we used (6.3) and (6.4) in the last two steps. Analogously,

$$\begin{aligned}
&\left\| \int_{S_r(z_j(0))} \nabla \int_{\partial\Omega} w_{j,2}(\eta) \frac{\partial}{\partial \nu} \left(\ln \frac{1}{\sqrt{(x_1-\eta_1)^2+(x_2-\eta_2)^2}} \right) d\eta dx \right\|_{R^2} \\
&\qquad \le \frac{C}{d_0^4} \| A(z_{j+1}(0) - z_j(0)) \|_{R^2} \operatorname{mes}^{3/2} \{S_r(0)\} \operatorname{mes}^{1/2} \{\partial\Omega\},
\end{aligned} \tag{6.10}$$

where C is a (generic) positive constant.

Step 3: Evaluation of the integral of the gradient of the second term in (6.1b) over $S_r(z_j(0))$. Denote next by d_1 the distance between the set $S_r(z_j(0))$ and $S_r(z_{j+1}(0))$:

$$d_1 = \inf_{x \in S_r(z_j(0)), y \in S_r(z_{j+1}(0))} \sqrt{(x_1-y_1)^2+(x_2-y_2)^2}.$$

Then for $d_1 > 0$, similar to (6.9), (6.10) from (6.1b), it follows that

$$\left\| \int_{S_r(z_j(0))} \nabla \int_{S_r(z_{j+1}(0))} (A(z_{j+1}(0) - z_j(0)))^T \nabla \left(\ln \frac{1}{\sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}} \right) dy dx \right\|_{R^2}$$
$$\leq \frac{C}{d_1^4} \parallel A(z_{j+1}(0) - z_j(0)) \parallel_{R^2} \ \mathrm{mes}^2 \{S_r(0)\},$$

(6.11)

where C is a (generic) positive constant.

Step 4: Evaluation of the integral of the gradient of the second term in (6.1a) over $S_r(z_j(0))$. Without loss of generality, we can assume that the origin of our space coordinate system is located at $z_j(0)$, i.e., $S_r(z_j(0)) = S_r(0)$.

Consider any point $x = (x_1, x_2) \in S_r(0)$ and introduce the following function of x (or, more precisely, of $\parallel x \parallel_{R^2}$):

$$\rho(x) = \frac{1}{2} \min\{\parallel x \parallel_{R^2}, r - \parallel x \parallel_{R^2}\}.$$

Let $B_{\rho(x)}(x)$ be the disk of radius $\rho(x)$ with center at x:

$$B_{\rho(x)}(x) = \{(y_1, y_2) \mid (x_1 - y_1)^2 + (x_2 - y_2)^2 < \rho^2(x)\}.$$

Note that $B_{\rho(x)}(x) \subset S_r(0)$ for any $x \in S_r(0)$.

To simplify further notation, denote

$$A(z_{j+1}(0) - z_j(0)) = b = (b_1, b_2).$$

Then, from (6.1a),

$$\int_{S_r(0)} b^T \nabla \left(\ln \frac{1}{\sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}} \right) dy$$
$$= \int_{S_r(0) \setminus B_{\rho(x)}(x)} b^T \nabla \left(\ln \frac{1}{\sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}} \right) dy$$
$$+ \int_{B_{\rho(x)}(x)} b^T \nabla \left(\ln \frac{1}{\sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}} \right) dy.$$

Now note that, in view of (6.5),

$$\int_{B_{\rho(x)}(x)} \left(\ln \frac{1}{\sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}} \right)_{y_1} dy$$
$$= \lim_{s \to 0+} \int_{B_{\rho(x)}(x) \setminus B_s(x)} \frac{x_1 - y_1}{(x_1 - y_1)^2 + (x_2 - y_2)^2} dy \tag{6.12}$$
$$= - \lim_{s \to 0+} \int_0^{2\pi} \int_s^{\rho(x)} \cos\zeta \, d\rho \, d\zeta = 0.$$

These and similar calculations for the integration with respect to y_2 within the disk $B_\rho(x)$ yield that

$$\int_{B_{\rho(x)}(x)} b^T \nabla \left(\ln \frac{1}{\sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}} \right) dx = 0.$$

Thus,

$$\begin{aligned}&\int_{S_r(0)} b^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\\ &=\int_{S_r(0)\setminus B_{\rho(x)}(x)}\left(b_1\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}+b_2\frac{x_2-y_2}{(x_1-y_1)^2+(x_2-y_2)^2}\right)dy.\end{aligned}\tag{6.13}$$

We intend now to calculate the gradient of the second term in (6.1a) represented as in (6.13), assuming that $S_r(z_j(0))=S_r(0)$ is as in (1.4b) (recall that we can assume that $z_j(0)$ is the origin).

Fix any $x=(x_1,x_2)\in S_r(0)$.

Due to our selection of h for the given x, for "small" Δx_1,

$$B_{\rho((x_1+\Delta x_1,x_2))}((x_1+\Delta x_1,x_2))\subset S_r(0).$$

Furthermore, notice that, as in the second equality in (6.12),

$$\int_{B_{\rho((x_1+\Delta x_1,x_2))}((x_1+\Delta x_1,x_2))\setminus B_{\rho(x)}((x+\Delta x_1,x_2))}\left(\ln\frac{1}{\sqrt{(x_1+\Delta x_1-y_1)^2+(x_2-y_2)^2}}\right)_{y_1}dy=0.$$

Taking this into account, we obtain from (6.13)

$$\begin{aligned}&\frac{\partial}{\partial x_1}\int_{S_r(0)} b^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\\ &=\lim_{\Delta x_1\to 0}\frac{1}{\Delta x_1}\left(\int_{S_r(0)\setminus B_{\rho((x_1+\Delta x_1,x_2))}((x_1+\Delta x_1,x_2))} b^T\nabla\right.\\ &\qquad\times\left(\ln\frac{1}{\sqrt{(x_1+\Delta x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\\ &\left.-\int_{S_r(0)\setminus B_{\rho(x)}(x)} b^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\right)\\ &=\lim_{\Delta x_1\to 0}\frac{1}{\Delta x_1}\left(\int_{S_r(0)\setminus B_{\rho(x)}((x_1+\Delta x_1,x_2))} b^T\nabla\left(\ln\frac{1}{\sqrt{(x_1+\Delta x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\right.\\ &\left.-\int_{S_r(0)\setminus B_{\rho(x)}(x)} b^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dy\right)\\ &=b_1\frac{\partial}{\partial x_1}\left(\int_{S_r(0)\setminus B_\rho(x)}\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}dy\right)\\ &+b_2\frac{\partial}{\partial x_1}\left(\int_{S_r(0)\setminus B_\rho(x)}\frac{x_2-y_2}{(x_1-y_1)^2+(x_2-y_2)^2}dy\right),\end{aligned}$$

where $\rho=\rho(x)$ *in the last line is now treated as independent of* x *when calculating the derivatives.*

Let us calculate the derivative in the first term in the last expression. To simplify notation, we will also further write ρ instead of $\rho(x)$.

$$\begin{aligned}
&\frac{\partial}{\partial x_1}\int_{S_r(0)\setminus B_\rho(x)}\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}dy\\
&=\frac{\partial}{\partial x_1}\left\{\int_{-r}^{x_1-\rho}\int_{\alpha(y_1)}^{\beta(y_1)}\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}dy_2dy_1\right.\\
&\quad+\int_{x_1+\rho}^{r}\int_{\alpha(y_1)}^{\beta(y_1)}\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}dy_2dy_1\\
&\quad+\int_{x_1-\rho}^{x_1+\rho}\left[\int_{\alpha(y_1)}^{x_2-\sqrt{\rho^2-(x_1-y_1)^2}}\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}dy_2\right.\\
&\quad\left.\left.+\int_{x_2+\sqrt{\rho^2-(x_1-y_1)^2}}^{\beta(y_1)}\frac{x_1-y_1}{(x_1-y_1)^2+(x_2-y_2)^2}dy_2\right]dy_1\right\}\qquad(6.14)\\
&=\int_{S_r(0)\setminus B_\rho(x)}\frac{-(x_1-y_1)^2+(x_2-y_2)^2}{((x_1-y_1)^2+(x_2-y_2)^2)^2}dy\;+\;2\int_{x_1-\rho}^{x_1+\rho}\frac{(x_1-y_1)^2}{\rho^2\sqrt{h^2-(x_1-y_1)^2}}dy_1\\
&=\int_{S_r(0)\setminus B_\rho(x)}\frac{-(x_1-y_1)^2+(x_2-y_2)^2}{((x_1-y_1)^2+(x_2-y_2)^2)^2}dy\;+\;\pi.
\end{aligned}$$

Similar calculations also yield

$$\begin{aligned}
&\frac{\partial}{\partial x_2}\int_{S_r(0)\setminus B_\rho(x)}\frac{x_2-y_2}{(x_1-y_1)^2+(x_2-y_2)^2}dy\\
&=\int_{S_r(0)\setminus B_\rho(x)}\frac{-(x_2-y_2)^2+(x_1-y_1)^2}{((x_1-y_1)^2+(x_2-y_2)^2)^2}dy\;+\;\pi,\qquad(6.15)\\
&\frac{\partial}{\partial x_j}\int_{S_r(0)\setminus B_\rho(x)}\frac{x_i-y_i}{(x_1-y_1)^2+(x_2-y_2)^2}dy\\
&=-\int_{S_r(0)\setminus B_\rho(x)}2\frac{(x_i-y_i)(x_j-y_j)}{((x_1-y_1)^2+(x_2-y_2)^2)^2}dy,\quad i\neq j,i,j=1,2.\qquad(6.16)
\end{aligned}$$

Then, since we assumed that $S_r(0)$ is a disk, due to the symmetry of quadratic function,

$$\int_{S_r(0)}\int_{S_r(0)\setminus B_\rho(x)}\frac{-(x_i-y_i)^2+(x_j-y_j)^2}{((x_1-y_1)^2+(x_2-y_2)^2)^2}dydx=0,\quad i,j=1,2,\;\;i\neq j,\qquad(6.17)$$

while due to the antisymmetry of the linear functions,

$$\int_{S_r(0)}\int_{S_r(0)\setminus B_\rho(x)}\frac{(x_i-y_i)(x_j-y_j)}{((x_1-y_1)^2+(x_2-y_2)^2)^2}dydx=0,\quad i,j=1,2,\;\;i\neq j.\qquad(6.18)$$

Hence, in view of (6.14)–(6.16),

$$\int_{S_r(0)}\nabla\int_{S_r(0)\setminus B_\rho(x)}b^T\nabla\left(\ln\frac{1}{\sqrt{(x_1-y_1)^2+(x_2-y_2)^2}}\right)dydx=\pi\ \mathrm{mes}\,\{S_r(0)\}b.\qquad(6.19)$$

Step 5: An approximation formula for (2.8). In view of (6.9)–(6.11) and (6.19), we obtain from (6.1a) that for "small" r's

$$\begin{aligned}(6.20)\qquad &\left\| \int_{S_r(z_j(0))} \nabla w_{j,1} dx \; - \; \frac{\text{mes}\,\{S_r(0)\}}{2} A(z_{j+1}(0) - z_j(0)) \right\|_{R^2} \\ &\leq \; \frac{C}{\min\{d_0^4, d_1^4\}} \parallel A(z_{j+1}(0) - z_j(0)) \parallel_{R^2} \; \text{mes}^{3/2}\,\{S_r(0)\},\end{aligned}$$

where, again, C is a (generic) positive constant. Now, also making use of (6.1a)–(6.1b), (6.9)–(6.11), (6.20), and (2.13)–(2.16), we obtain (2.10a) from (6.2), taking into account that d_0 and d_1 do not decrease as $r \to 0+$. This ends the proof of Lemma 2.4. □

Remark 6.1. Note that we essentially used the assumption that $S_r(0)$ is a disk only to establish (6.17)–(6.18). The qualitative estimates and formulas (6.9)–(6.16) can be used to analyze the sufficient conditions of controllability in Theorems 2.3 and 2.5 along with formulas like (6.2) in other cases as well.

Acknowledgment. The author wishes to thank the referee for numerous helpful comments and suggestions that resulted in substantial changes to the original version of the manuscript.

NULL CONTROLLABILITY WITH VANISHING ENERGY FOR DISCRETE-TIME SYSTEMS IN HILBERT SPACE*

AKIRA ICHIKAWA†

Abstract. In this paper null controllability with vanishing energy is considered for discrete-time systems in Hilbert space. As in the case of continuous time systems, necessary and sufficient conditions in terms of an algebraic Riccati equation are given. Then necessary and sufficient conditions involving the spectrum of the system operator are given. Reachability and controllability with vanishing energy are also considered, and necessary and sufficient conditions for them are given. Finally applications to sampled-data systems, systems with impulse control, and periodic systems are discussed.

Key words. discrete-time systems, null controllability, optimal regulator, Riccati equation

1. Introduction.

Consider the linear system

$$\dot{x} = Ax + Bu,\ x(0) = x_0 \in H, \tag{1.1}$$

where A is the infinitesimal generator of a strongly continuous semigroup $S(t)$ in a Hilbert space H, u is a control in some Hilbert space U, and $B \in L(U, H)$ is the space of bounded linear operators from U into H. For each locally square integrable function $u : [0, \infty) \to U$, define the solution in the mild sense

$$x(t; x_0, u) = S(t)x_0 + \int_0^t S(t - r)Bu(r)dr,\ t \geq 0.$$

We denote by $|\cdot|$ the norm of vectors and by $\sigma(A)$ the spectrum of the operator A. The following definitions are introduced in [8].

DEFINITION 1.1. (a) *The system* (1.1) *is said to be null controllable with vanishing energy* (*NCVE for short*) *if for each initial* $x(0) = x_0$ *there exists a sequence of pairs* (T_N, u_N), $0 < T_N \uparrow \infty$, $u_N \in L_2(0, T_N; U)$ *such that* $x(T_N; x_0, u_N) = 0$ *and*

$$\lim_{N\to\infty} \int_0^{T_N} |u_N(t)|^2 dt = 0. \tag{1.2}$$

(b) *The system* (1.1) *is said to be exactly controllable with vanishing energy* (*ECVE*) *if for any pair* (x_0, x_1) *of initial and final states there exists a sequence of pairs* (T_N, u_N), $0 < T_N \uparrow \infty$, $u_N \in L_2(0, T_N; U)$ *such that* $x(T_N; x_0, u_N) = x_1$ *and* (1.2) *holds.*

(A, B) is said to be NCVE (ECVE) if the system (1.1) is NCVE (ECVE). The following theorem gives necessary and sufficient conditions.

THEOREM 1.2. *(A, B) is NCVE if and only if*
(a) *it is null controllable on some interval $[0, \tau]$, and*
(b) *$X = 0$ is the unique solution of the algebraic Riccati equation (ARE)*

$$A^*X + XA - XBB^*X = 0$$

in the class of nonnegative operators.

Priola and Zabczyk [8] showed that condition (b) is necessary and sufficient for NCVE when (A, B) is null controllable on some interval $[0, \tau]$. The necessity of (a) was then shown by van Neerven [7].

Under the following two assumptions Priola and Zabczyk [8] obtained more explicit necessary and sufficient conditions.

Hypothesis 1. There exists a sequence $\{\lambda_n\} \subset \sigma(A)$ such that λ_n is isolated in $\sigma(A)$ and

$$\lim_{n\to\infty} \mathrm{Re}(\lambda_n) = s(A) = \sup\{\mathrm{Re}(\lambda) : \lambda \in \sigma(A)\}.$$

Hypothesis 2. There exist $S(t)$-invariant subspaces H_s and H_u such that
(a) $H = H_s \oplus H_u$,
(b) A on H_s is exponentially stable, and
(c) the set of all generalized eigenvectors of A contained in H_u is linearly dense in H_u.

THEOREM 1.3. *Suppose that Hypotheses 1 and 2 hold. Then (A, B) is NCVE if and only if*
(a) *(A, B) is null controllable on some interval $[0, \tau]$, and*
(b) *$\mathrm{Re}(\lambda) \le 0$ for any $\lambda \in \sigma(A)$.*

THEOREM 1.4. *Suppose that Hypotheses 1 and 2 hold. Suppose further that $S(t)$ is a strongly continuous group on H. Then (A, B) is ECVE if and only if*
(a) *(A, B) is exactly controllable on some interval $[0, \tau]$, and*
(b) *$\mathrm{Re}(\lambda) = 0$ for any $\lambda \in \sigma(A)$.*

The proof of Theorem 1.2 is based on the theory of optimal quadratic control. For the proof of necessity of Theorem 1.3 the relation between the Riccati equation and the controllability Gramian of the pair $(-A, B)$ is used, while for sufficiency the Riccati equation is directly used. Theorem 1.4 is a consequence of Theorem 1.3 and the fact that $(-A, -B)$ is also NCVE.

If we fix $x_0 = 0$ in (b) of Definition 1.1, (A, B) is said to be reachable with vanishing energy (RVE). It is easy to see that (A, B) is ECVE if and only if it is NCVE and RVE. Suppose that $S(t)$ is a strongly continuous group, and let P_T be the controllability operator defined by

$$P_T x = \int_0^T S(t)BB^*S^*(t)x dt.$$

It is coercive (positive and boundedly invertible) for $T \ge \tau$, if (A, B) is exactly controllable on $[0, \tau]$. The control with minimum norm in $L_2(0, T; U)$ such that $x(T; 0, u) = x_1$ is given by

$$\hat{u}_T = B^*S^*(T - t)P_T^{-1}x_1$$

[8] and its norm by

$$\| \hat{u}_T \|_2 = \langle x_1, P_T^{-1}x_1 \rangle^{\frac{1}{2}}. \tag{1.3}$$

LEMMA 1.5. *(A, B) is RVE if and only if*

(a) *(A, B) is exactly controllable on some interval $[0, \tau]$, and*

(b) *$P_T^{-1} \to 0$ strongly as $T \to \infty$.*

Proof. The proof of necessity of (a) is based on the Baire category theorem and is similar to that of Theorem 1.2(a) given in [7]. The rest follows from (1.3). □

In this paper we shall establish the discrete-time versions of the theorems above. It is important in its own right but also useful when we consider sampled-data systems with zero-order hold, systems with impulse control, and periodic systems. In the discrete-time case the proof of necessity of Theorem 1.3 is more involved, since the Riccati equation is more complicated for discrete-time systems. Lemma 2.5 in section 2 fills this gap and enables us to extend Theorem 1.3. The extension of Theorem 1.4 requires the invertibility of A. It is also useful to introduce RVE. In section 2 we give preliminaries concerning necessary notions of discrete-time systems. In section 3 we consider necessary and sufficient conditions for NCVE and extend Theorems 1.2 and 1.3. In section 4 we introduce RVE and extend Theorem 1.4. Finally in section 5 we apply NCVE and ECVE results to sampled-data systems, systems with impulse control, and periodic systems.

2. Preliminaries. Consider the discrete-time system

$$x(k+1) = Ax(k) + Bu(k),\ x(0) = x_0, \tag{2.1}$$

where $A \in L(H)$, $B \in L(U, H)$, $x \in H$, and $u \in U$. We collect basic definitions and some useful results for (2.1) as in the finite dimensional case [1].

DEFINITION 2.1. (a) *(A, B) is null controllable on $[0, K]$ if for any x_0 there is a sequence of control inputs $u = \{u(0), u(1), \dots, u(K-1)\}$ such that $x(K; x_0, u) = 0$.*

(b) *(A, B) is reachable on $[0, K]$ if for every state x_1 there is a sequence of control inputs $u = \{u(0), u(1), \dots, u(K-1)\}$ such that $x(K; 0, u) = x_1$.*

(c) *(A, B) is exactly controllable on $[0, K]$ if for every pair (x_0, x_1) there is a sequence of control inputs $u = \{u(0), u(1), \dots, u(K-1)\}$ such that $x(K; x_0, u) = x_1$.*

LEMMA 2.2. (a) *(A, B) is reachable on $[0, K]$ if and only if it is exactly controllable on $[0, K]$. In this case it is null controllable on $[0, K]$.*

(b) *If A is invertible and (A, B) is null controllable on $[0, K]$, then (A, B) is exactly controllable on $[0, K]$.*

LEMMA 2.3. *The following statements are equivalent:*

(a) *(A, B) is null controllable on $[0, K]$.*

(b) *$R(A^K) \subset R(M_K)$, where $M_K = [B, AB, \dots, A^{K-1}B]$ is the reachability operator.*

(c) *$|M_K^* x| \geq a|(A^*)^K x|$ for some $a > 0$.*

If these conditions hold, the operator $\begin{bmatrix} B^* \\ \lambda I - A^* \end{bmatrix}$ is 1 to 1 for any nonzero λ.

Proof. Consider the response of the system (2.1) with initial condition x_0 and control $u = \{u(0), u(1), \dots, u(K-1)\}$. Then

$$x(K; x_0, u) = A^K x_0 + \sum_{j=0}^{k-1} A^{k-j-1} B u(j),$$

and the second term on the right-hand side lies in $R(M_K)$, the range of M_K. Hence (a) is equivalent to (b). The equivalence of (b) and (c) follows from Corollary 3.5 of [3]. If there exists a nonzero q such that $B^* q = 0$ and $\lambda q = A^* q$, it contradicts to (c) with $x = q$. □

LEMMA 2.4. *Suppose A is exponentially stable* [5], i.e., $|A^k| \le M\rho^k$, $0 < \rho < 1$, and that (A, B) is exactly controllable on $[0, K]$. Then there exists a coercive operator Y such that

$$Y = AYA^* + BB^*.$$

Y is called the controllability Gramian of (A, B).

Proof. By Lemma 2.2 (A, B) is reachable on $[0, K]$. Hence $M_K = [B, AB, \dots, A^{K-1}B]$ is onto and $M_K M_K^* \ge aI$ for some $a > 0$. Define

$$Y = \lim_{k\to\infty} M_k M_k^* = \lim_{k\to\infty} \sum_{j=0}^{k-1} A^j BB^* (A^*)^j.$$

The right-hand side converges in the uniform operator topology, and $Y \ge M_K M_K^* \ge aI$. Hence Y is coercive. Moreover

$$Y = BB^* + A\sum_{j=0}^{\infty} A^j BB^* (A^*)^j A^* = BB^* + AYA^*. \qquad \square$$

LEMMA 2.5. *Suppose A is invertible and (A, B) is exactly controllable on $[0, K]$. Then $(A^{-1}, A^{-1}B)$ is exactly controllable on $[0, K]$. If A^{-1} is exponentially stable, then the inverse of its controllability Gramian Y exists and satisfies the following ARE:*

$$X = A^*XA - A^*XB(I + B^*XB)^{-1}B^*XA. \tag{2.2}$$

Proof. Since (A, B) is exactly controllable on $[0, K]$, so is $(A^{-1}, A^{-1}B)$. In fact

$$\begin{aligned}&[A^{-1}B, A^{-1}(A^{-1}B), \dots, (A^{-1})^{K-1}(A^{-1}B)]\\ &= (A^{-1})^K [A^{K-1}B, \dots, AB, B].\end{aligned}$$

Now by definition

$$Y = A^{-1}Y(A^{-1})^* + A^{-1}BB^*(A^{-1})^*,$$

which implies

$$AYA^* = Y + BB^*.$$

By Lemma 2.4, Y is coercive and hence invertible. As in Lemma 3.18 in [4], we obtain

$$\begin{aligned}(A^{-1})^* Y^{-1} A^{-1} &= (Y + BB^*)^{-1}\\ &= Y^{-1}(I + BB^*Y^{-1})^{-1}\\ &= Y^{-1}[I - (I + BB^*Y^{-1})^{-1}BB^*Y^{-1}]\\ &= Y^{-1}[I - B(I + B^*Y^{-1}B)^{-1}B^*Y^{-1}]\\ &= Y^{-1} - Y^{-1}B(I + B^*Y^{-1}B)^{-1}B^*Y^{-1},\end{aligned}$$

where for the second equality we have used the equality $Y + BB^* = (I + BB^*Y^{-1})Y$, and for the fourth equality the familiar identity $M(I + NM)^{-1} = (I + MN)^{-1}M$ is used. Hence we obtain

$$Y^{-1} = A^*Y^{-1}A - A^*Y^{-1}B(I + B^*Y^{-1}B)^{-1}B^*Y^{-1}A,$$

and Y^{-1} is a coercive solution of the ARE (2.2). $\square$

3. Null controllability with vanishing energy. Consider the system (2.1)

$$x(k+1) = Ax(k) + Bu(k),\ x(0) = x_0.$$

We shall define NCVE for this system.

DEFINITION 3.1. *(A, B) is NCVE if for each x_0 there exists a sequence of pairs (k_N, u_N), k_N a positive integer $\uparrow \infty$, $u_N \in l_2(0, k_N - 1; U)$, such that $x(k_N; x_0, u_N) = 0$ and*

$$\lim_{N\to\infty} \| u_N \|_2 = 0,$$

where $l_2(0, k_N - 1; U)$ is the set of vectors $u = \{u(0), u(1), \dots, u(k_N - 1)\}$, $u(k) \in U$, with norm

$$\| u \|_2 = \left(\sum_{k=0}^{k_N - 1} |u(k)|^2 \right)^{\frac{1}{2}}.$$

LEMMA 3.2. *If (A, B) is NCVE, then (A, B) is null controllable on some interval $[0, K]$.*

Proof. The proof is based on the Baire category theorem and similar to the proof of Theorem 3.1 in [7]. □

First we shall prove the following.

THEOREM 3.3. *(A, B) is NCVE if and only if*

(a) *(A, B) is null controllable on some interval $[0, K]$, and*

(b) *$X = 0$ is the unique solution of the ARE* (2.2)

$$X = A^*XA - A^*XB(I + B^*XB)^{-1}B^*XA$$

in the class of nonnegative operators.

We modify Hypotheses 1 and 2 as follows.

Hypothesis 3. There exists a sequence $\{\lambda_n\} \subset \sigma(A)$ such that λ_n is isolated in $\sigma(A)$ and

$$\lim_{n\to\infty} |\lambda_n| = s(A) = \sup\{|\lambda| : \lambda \in \sigma(A)\}.$$

Hypothesis 4. There exist A-invariant subspaces H_s and H_u such that

(a) $H = H_s \oplus H_u$,

(b) (b) A on H_s is exponentially stable, and

(c) the set of all generalized eigenvectors of A contained in H_u is linearly dense in H_u.

Under Hypotheses 3 and 4 we shall prove the following.

THEOREM 3.4. *(A, B) is NCVE if and only if*

(a) *(A, B) is null controllable on some interval $[0, K]$, and*

(b) *$|\lambda| \le 1$ for any $\lambda \in \sigma(A)$.*

Proof of Theorem 3.3. We shall follow the proof of Theorem 1.2 in [8]. We first show necessity. Consider the quadratic cost associated with (2.1) on $[0, k_N - 1]$:

$$J(u; x_0, k_N, Q) = \sum_{k=0}^{k_N - 1} |u(k)|^2 + \langle x(k_N), Qx(k_N) \rangle,$$

where $Q \geq 0$. It is known [6], [9], [10] that the optimal control minimizing the cost function is given by the feedback law

$$\bar{u}(k) = -[I + B^*X(k+1)B]^{-1}B^*X(k+1)Ax(k),$$

where $X(k) = X(k; k_N, Q)$ is the sequence of nonnegative operators defined by the Riccati equation

$$\begin{aligned} X(k) &= A^*X(k+1)A - A^*X(k+1)B[I + B^*X(k+1)B]^{-1}B^*X(k+1)A, \\ X(k_N) &= Q. \end{aligned} \tag{3.1}$$

Moreover,

$$J(\bar{u}; x_0, k_N, Q) = \langle x_0, X(0; k_N, Q)x_0 \rangle.$$

Now we consider the case $Q = qI$, $q > 0$, and let $q \to \infty$. Since (A, B) is null controllable on $[0, K]$, for each x_0 and $k_N \geq K$ there exists a control $u \in l_2(0, k_N - 1; U)$ such that $x(k_N; x_0, u) = 0$. Let u_N be the control with minimum norm among them. Then it is given by $u_N = -\bar{M}_N^*(\bar{M}_N\bar{M}_N^*)^{-1}A^{k_N}x_0$, where $\bar{M}_N = [A^{k_N-1}B, \ldots, AB, B]$. Since (A, B) is NCVE, $\lim_{N\to\infty} \| u_N \|_2^2 = 0$ for each x_0, and hence there exists a constant $a > 0$ such that $\| u_N \|_2^2 \leq a|x_0|^2$. Notice that

$$J(\bar{u}; x_0, k_N, qI) = \langle x_0, X(0; k_N, qI)x_0 \rangle \leq J(u_N; x_0, k_N, qI) = \| u_N \|_2^2 \leq a|x_0|^2,$$

which yields $X(0; k_N, qI) \leq aI$. Since $X(0; k_N, qI)$ is monotone increasing in q, there exists a limit as $q \to \infty$, denoted by $X(0; k_N)$, i.e., $X(0; k_N) = \lim_{q\to\infty} X(0; k_N, qI)$. Let $\bar{u}_q$ be the optimal control for $J(u; x_0, k_N, qI)$. Then it is uniformly bounded in q. Hence there exists a subsequence q_j such that $\bar{u}_{q_j}$ converges weakly to some limit $\bar{u}_\infty$. Then $x(k_N; x_0, \bar{u}_\infty) = 0$ and $\| \bar{u}_\infty \|_2^2 \leq \langle x_0, X(0; k_N)x_0 \rangle \leq \| u_N \|_2^2$. But u_N is the control with minimum norm, and hence $\| \bar{u}_\infty \|_2^2 = \langle x_0, X(0; k_N)x_0 \rangle = \| u_N \|_2^2$. Now suppose that (A, B) is null controllable on $[0, K]$, $K \leq k_N$. Since $X(k; k_N, qI) = X(0; k_N - k, qI)$, the following limit exists:

$$\lim_{q\to\infty} X(k; k_N, qI) = \lim_{q\to\infty} X(0; k_N - k, qI) \equiv X(k; k_N) \text{ for } k \leq k_N - K.$$

Moreover, from (3.1), $X(k; k_N)$, $k \leq k_N - K$, satisfies the Riccati equation

$$\begin{aligned} X(k) &= A^*X(k+1)A - A^*X(k+1)B[I + B^*X(k+1)B]^{-1}B^*X(k+1)A, \\ X(k_N - K) &= X(k_N - K; k_N). \end{aligned}$$

Since $\langle x_0, X(0; k_N)x_0 \rangle = \| u_N \|_2^2$, $X(0; k_N)$ is decreasing in N and has a nonnegative limit

$$X_\infty = \lim_{N\to\infty} X(0; k_N).$$

For $k \leq N - K$ we know $X(k; k_N) = X(0; k_N - k)$, and hence $\lim_{N\to\infty} X(k; k_N) = X_\infty$. Letting $N \to \infty$ in the Riccati equation above we see that X_∞ satisfies the ARE (2.2). Recall that (A, B) is NCVE, and hence

$$\langle x_0, X_\infty x_0 \rangle \leq \langle x_0, X(0; k_N)x_0 \rangle = \| u_N \|_2^2 \to 0$$

and $X_\infty = 0$. Now let X be any nonnegative solution of the ARE (2.2). We shall show that $X \le X_\infty$ to conclude $X = 0$. For this purpose consider the Riccati difference equation (3.1) with $Q = X$. Then $X(k) = X$ is a solution. Thus

$$J(\bar{u}_X; x_0, k_N, X) = \langle x_0, Xx_0\rangle \le J(\bar{u}_q; x_0, k_N, qI) = \langle x_0, X(0; k_N, qI)x_0\rangle$$

for $q \ge \| X \|$, where $\bar{u}_X$ and $\bar{u}_q$ denote the optimal controls for the corresponding cost functions. Now passing to the limit $q \to \infty$ and to the limit $N \to \infty$ we obtain $\langle x_0, Xx_0\rangle \le \langle x_0, X(0; k_N)x_0\rangle$ and $\langle x_0, Xx_0\rangle \le \langle x_0, X_\infty x_0\rangle$, respectively. Thus we have shown $X = 0$, which completes the proof of necessity. □

To show sufficiency we recall that $\| u_N \|_2^2 = \langle x_0, X(0; k_N)x_0\rangle \to \langle x_0, X_\infty x_0\rangle$. But by condition (b) $X_\infty = 0$, and hence $\| u_N \|_2 \to 0$ and (A, B) is NCVE.

Proof of Theorem 3.4. We shall follow the proof of Theorem 1.3 in [8]. To show necessity we suppose that $|\lambda| > 1$ for some $\lambda \in \sigma(A)$. Then by Hypothesis 3 there exists an isolated element $\mu \in \sigma(A)$, with $|\mu| > 1$. Consider the spectral Riesz projection P_1 associated with μ

$$P_1 x = \frac{1}{2\pi i}\int_\gamma (\lambda I - A)^{-1} x d\lambda,\ x \in H,$$

where γ is a circle containing μ in its interior and $\sigma(A)/\{\mu\}$ in its exterior. Using projections P_1 and $P_2 = I - P_1$, we can split (2.1) into two subsystems in E_1 and E_2, respectively:

$$x_1(k+1) = A_1 x_1(k) + B_1 u(k),$$
$$x_2(k+1) = A_2 x_2(k) + B_2 u(k),$$

where $E_i = P_i H$, A_i is the restriction of A to E_i, and $B_i = P_i B$. The subspaces E_i are A-invariant and $H = E_1 \oplus E_2$. Since (2.1) is null controllable, (A_1, B_1) and (A_2, B_2) are null controllable. Since $\sigma(A_1) = \{\mu\}$, it is invertible, and (A_1, B_1) is exactly controllable by Lemma 2.2. Hence $(A_1^{-1}, A_1^{-1}B_1)$ is exactly controllable. Since A_1^{-1} is exponentialy stable, by Lemma 2.4 it possesses a coercive controllability Gramian Y

$$Y = A_1^{-1} Y (A_1^{-1})^* + A_1^{-1} B_1 B_1^* (A_1^{-1})^*.$$

By Lemma 2.5, $X_1 = Y^{-1}$ is a coercive solution of the ARE

$$X = A_1^* X A_1 - A_1^* X B_1 (I + B_1^* X B_1)^{-1} B_1^* X A_1.$$

Then $X = I_H X_1 P_1$ is a nontrivial nonnegative solution of the ARE for (2.2), where I_H is the injection of E_1 into H. This contradicts Theorem 3.3 and hence $|\lambda| \le 1$ for any $\lambda \in \sigma(A)$.

To show sufficiency let X be any nonnegative solution of the ARE (2.2). Since $H = H_s \oplus H_u$, it is suficient to show $X = 0$ on both H_s and H_u. As in the proof of Theorem 3.3 consider (3.1) with $Q = X$, and recall the inequality

$$\langle x_0, Xx_0\rangle = J(\bar{u}_X; x_0, k_N, X) \le J(0; x_0, k_N, X) = \langle A^{k_N} x_0, XA^{k_N} x_0\rangle \to 0,\ x_0 \in H_s.$$

Hence $Xx_0 = 0$ for any $x_0 \in H_s$. To show $Xx_0 = 0$ for any $x_0 \in H_u$, let $\lambda \in \sigma(A)$ with $|\lambda| \le 1$, which corresponds to an eigenvector p, i.e., $Ap = \lambda p$. Then

$$\begin{aligned}\langle p, Xp\rangle &= \langle p, A^*XAp\rangle - \langle p, A^*XB(I + B^*XB)^{-1}B^*XAp\rangle \\ &= |\lambda|^2[\langle p, Xp\rangle - \langle p, XB(I + B^*XB)^{-1}B^*Xp\rangle]. \qquad (3.2)\end{aligned}$$

If $|\lambda| < 1$, then (3.2) yields $Xp = 0$. If $|\lambda| = 1$, then it yields $B^*Xp = 0$. In this case we obtain $Xp = \lambda A^*Xp$ from the ARE (2.2). Hence

$$\begin{bmatrix} B^* \\ \frac{1}{\lambda}I - A^* \end{bmatrix} Xp = 0.$$

By Lemma 2.3 the operator above is one to one and hence $Xp = 0$. Thus for any eigenvector of A we have shown $Xp = 0$. We shall show that $Xq = 0$ for any generalized eigenvector of A, which would then conclude $X = 0$. Now let $q \in N((\lambda I - A)^2)$, i.e., $(\lambda I - A)^2 q = 0$. Then $q_1 = (\lambda I - A)q$ satisfies $(\lambda I - A)q_1 = 0$. Repeating the arguments above we conclude $Xq_1 = 0$. Hence $XAq = \lambda Xq$, and from the ARE (2.2) we obtain

$$\begin{aligned} \langle q, Xq\rangle &= \langle q, A^*XAq\rangle - \langle q, A^*XB(I + B^*XB)^{-1}B^*XAq\rangle \\ &= |\lambda|^2[\langle q, Xq\rangle - \langle q, XB(I + B^*XB)^{-1}B^*Xq\rangle]. \end{aligned}$$

This is the same with (3.2) and hence $Xq = 0$. Repeating this process we conclude $Xq = 0$ for any generalized eigenvector of A satisfying $(\lambda I - A)^k q = 0$. Hence $X = 0$ on H_u. Thus $X = 0$ on H, and by Theorem 3.3 (A, B) is NCVE. □

In [7] the reproducing kernel Hilbert space associated with the controllability operator was introduced, and Theorem 1.2 was extended to the case where H is a Banach space. The extension of Theorem 3.3 to a Banach space is also possible using the Riccati equation directly.

4. Exact controllability with vanishing energy. First we introduce RVE, which is useful to consider ECVE.

DEFINITION 4.1. *(A, B) is RVE if for each x_1 there exists a sequence of pairs (k_N, u_N), $k_N \uparrow \infty$, $u_N \in l_2(0, k_N - 1; U)$, such that $x(k_N; 0, u_N) = x_1$ and*

$$\lim_{N\to\infty} \| u_N \|_2 = 0.$$

LEMMA 4.2. *Suppose (A, B) is RVE. Then $0 \notin \sigma_p(A^*)$. If A is invertible, then (A, B) is RVE if and only if $(A^{-1}, A^{-1}B)$ is NCVE.*

Proof. Suppose $0 \in \sigma_p(A^*)$ and $A^*h = 0$, with $|h| = 1$. If (A, B) is reachable on $[0, K]$, then for some sequence $u = (u_j)$

$$\sum_{j=0}^{K-1} A^{K-j-1}Bu_j = h.$$

Then

$$\begin{aligned} 1 = \langle h, h\rangle &= \left\langle h, \sum_{j=0}^{K-1} A^{K-j-1}Bu_j \right\rangle \\ &= \sum_{j=0}^{K-1} \langle B^*(A^*)^{K-j-1}h, u_j\rangle \\ &= \langle B^*h, u_{K-1}\rangle \le |B^*h||u_{K-1}|. \end{aligned}$$

Hence $|u_{K-1}| \ge \frac{1}{|B^*h|}$, and (A, B) cannot be RVE. Now assume that A is invertible. Then the system (2.1) can be written as

$$x(k) = A^{-1}x(k + 1) - A^{-1}Bu(k).$$

Thus if (A, B) is RVE, then by redefining u and x we can easily see that

$$\tilde{x}(k+1) = A^{-1}\tilde{x}(k) + A^{-1}B\tilde{u}(k)$$

is NCVE. The converse is also true, since we can reverse the arguments. □

From Lemma 4.2 we immediately obtain the following.

THEOREM 4.3. *Suppose A is invertible and A^{-1} satisfies Hypotheses* 3 *and* 4. *Then (A, B) is RVE if and only if*

(a) *(A, B) is exactly controllable on some interval $[0, K]$, and*

(b) *$|\lambda| \geq 1$ for any $\lambda \in \sigma(A)$.*

Now we are ready to extend Theorem 1.4.

THEOREM 4.4. *Suppose A and A^{-1} satisfy Hypotheses* 3 *and* 4. *Then (A, B) is ECVE if and only if*

(a) *(A, B) is exactly controllable on some interval $[0, K]$, and*

(b) *$|\lambda| = 1$ for any $\lambda \in \sigma(A)$.*

Proof. Note that (A, B) is ECVE if and only if it is NCVE and RVE. Hence the proof follows from Theorems 3.4 and 4.3. □

5. Applications. In this section we apply our theorems to sampled-data systems, systems with impulse control, and periodic systems. First we consider a sampled-data system with zero-order hold [2]

$$\dot{x} = Ax + Bu,$$

where A is the infinitesimal generator of a strongly continuous semigroup $S(t) \in L(H)$, $B \in L(U, H)$, and u is a control given by

$$u(t) = u(k\tau), k\tau \leq t < (k+1)\tau.$$

Then at times $k\tau$ we have the following:

$$\begin{aligned} x((k+1)\tau) &= S(\tau)x(k\tau) + \int_0^\tau S(r)Bdru(k\tau) \\ &\equiv A_d x(k\tau) + B_d u(k\tau). \end{aligned}$$

The sampled-data system is said to be NCVE (ECVE) if it is NCVE (ECVE) in the sense of Definition 1.1 with $T_N = N\tau$. Note that the sampled-data system is NCVE (ECVE) if and only if (A_d, B_d) is NCVE (ECVE). Hence, if A_d satisfies Hypotheses 3 and 4, then by Theorem 3.4 the sampled-data system is NCVE if and only if

(a) (A_d, B_d) is null controllable on some interval $[0, K]$, and

(b) $|\lambda| \leq 1$ for any $\lambda \in \sigma(A_d)$.

If $S(t)$ is a group and $S(\tau)^{-1}$ satisfies Hypotheses 3 and 4, then the sampled-data system is ECVE if and only if

(a) (A_d, B_d) is exactly controllable on some interval $[0, K]$, and

(b) $|\lambda| = 1$ for any $\lambda \in \sigma(A_d)$.

Next we consider the system (1.1) with impulse control $u(k-1)\delta(t-k\tau)$ at time $k\tau$, $k \geq 1$. Then the state $x(k\tau)$ after the impulse $u(k-1)\delta(t-k\tau)$ satisfies

$$x((k+1)\tau) = S(\tau)x(k\tau) + Bu(k).$$

LEMMA 5.1. *The system* (1.2) *with impulse control is NCVE if and only if $(S(\tau), B)$ is NCVE.*

LEMMA 5.2. *Suppose $S(t)$ is a group and $S(\tau)^{-1}$ satisfies Hypotheses* 3 *and* 4. *Then the system* (1.2) *with impulse control is ECVE if and only if $(S(\tau), B)$ is ECVE.*

Proof. Note that the system (1.2) with impulse control is ECVE if and only if it is NCVE and RVE. Let $K\tau \le T < (K+1)\tau$, and consider the controllability operator

$$\begin{aligned} P_T^{imp} &= S(T-K\tau)\left(\sum_{j=1}^{K} S(\tau)^{K-j}BB^*(S(\tau)^*)^{K-j}\right)S^*(T-K\tau) \\ &= S(T-K\tau)P_{K\tau}^{imp}S^*(T-K\tau). \end{aligned}$$

Hence $(P_T^{imp})^{-1} \to 0$ strongly if and only if $(P_{K\tau}^{imp})^{-1} \to 0$ strongly, and as in Lemma 1.5 the assertion follows. □

Now we have the following.

THEOREM 5.3. (1) *The system* (1.2) *with impulse control is NCVE if and only if*

(a) *$(S(\tau), B)$ is null controllable on some interval $[0, K]$, and*

(b) *$|\lambda| \le 1$ for any $\lambda \in \sigma(S(\tau))$.*

(2) *Suppose $S(t)$ is a group and $S(\tau)^{-1}$ satisfies Hypotheses* 3 *and* 4. *Then the system* (1.2) *with impulse control is ECVE if and only if*

(a) *$(S(\tau), B)$ is exactly controllable on some interval $[0, K]$, and*

(b) *$|\lambda| = 1$ for any $\lambda \in \sigma(S(\tau))$.*

Finally consider the T-periodic system

$$\dot{x} = A(t)x + B(t)u,\ x(t_0) = x_0, 0 \le t_0 < T, \tag{5.1}$$

where $A(t)$ is T-periodic and generates an evolution operator $S(t,s)$, and $B(t)$ is T-periodic and strongly continuous. Then

$$\begin{aligned} x((k+1)T+t_0) &= S(T+t_0,t_0)x(kT+t_0) + \int_{t_0}^{T+t_0} S(T+t_0,r)B(r)u(k,r)dr \\ &\equiv S(T+t_0,t_0)x(kT+t_0) + B_d u(k), \end{aligned} \tag{5.2}$$

where we have used the property $S((k+1)T+t_0, kT+r) = S(T+t_0, r)$, and $u(k,r) = u(kT+r)$, for $t_0 \le r < t_0+T$, $u(k) = u(k,\cdot) \in L_2(t_0, t_0+T; U)$, and B_d is a bounded linear operator in $\mathcal{L}(L_2(t_0, t_0+T; U), H)$. Notice that the periodic system is NCVE if and only if $(S(T+t_0,t_0), B_d)$ is NCVE. Then by Theorem 3.4 the periodic system is NCVE if and only if

(a) it is null controllable on some interval $[t_0, \tau]$, and

(b) $|\lambda| \le 1$ for any $\lambda \in \sigma(S(T+t_0,t_0))$.

Suppose $S(t,s)$ is a two-parameter group so that $S(T+t_0,t_0)$ is boundedly invertible.

LEMMA 5.4. *The periodic system* (5.1) *is ECVE if and only if the discrete-time system* (5.2) *is ECVE.*

Proof. Consider the controllability operator

$$P_L x = \int_{t_0}^{L} S(L,r)B(r)B(r)^*S^*(L,r)x\,dr.$$

Let $KT+t_0 \le L < (K+1)T+t_0$. Then $\alpha P_{(K+1)T} \ge P_L \ge \beta P_{KT}$ for some $\alpha > 0$ and $\beta > 0$. Hence $P_L^{-1} \to 0$ strongly if and only if $(P_{KT})^{-1} \to 0$ strongly. By a periodic version of Lemma 1.5 the assertion follows. □

LEMMA 5.5.

$$S(T+t_0,t_0) = S(t_0,0)S(T,0)S(t_0,0)^{-1}$$

and $\sigma(S(T+t_0,t_0)) = \sigma(S(T,0))$.

Suppose further $S(T+t_0,t_0)^{-1}$ satisfies Hypotheses 3 and 4. Then from Theorem 4.4 we obtain the following.

THEOREM 5.6. *The periodic system* (5.1) *is ECVE if and only if*

(a) *it is exactly controllable on some interval* $[t_0,\tau]$, *and*

(b) $|\lambda| = 1$ *for any* $\lambda \in \sigma(S(T,0))$.

Acknowledgment. The author thanks the anonymous referees for careful reading of the mauscript and many helpful comments on the paper.

IDENTIFIABILITY OF PIECEWISE CONSTANT CONDUCTIVITY IN A HEAT CONDUCTION PROCESS*

SEMION GUTMAN† AND JUNHONG HA‡

Abstract. We study the identification and identifiability problems for heat conduction in a nonhomogeneous rod. The identifiability results are established for two different sets of observations. Given a sequence of distributed type observations, the identifiability is proved for conductivities in a piecewise smooth class of functions. In the case of observations taken at finitely many points the identifiability is established for piecewise constant conductivities. Such conductivities can be uniquely identified using the proposed marching algorithm.

Key words. identification, identifiability, piecewise constant conductivity

AMS subject classifications. 35R30, 93B30

1. Introduction.

Consider the heat conduction in a nonhomogeneous insulated rod of a unit length, with the ends kept at zero temperature at all times. Our main interest is in the identification and identifiability of the discontinuous conductivity (thermal diffusivity) coefficient $a(x)$, $0 \le x \le 1$. The identification problem consists of finding a conductivity $a(x)$ in an admissible set K for which the temperature $u(x,t)$ fits given observations in a prescribed sense. Under a wide range of conditions one can establish the continuity of the objective function $J(a)$ representing the best fit to the observations. Then the existence of the best fit to data conductivity follows if the admissible set K is compact in the appropriate topology. However, such an approach usually does not guarantee the uniqueness of the found conductivity $a(x)$. Establishing such a uniqueness is referred to as the identifiability problem. If the conductivity is identifiable and one can design an algorithm for its reconstruction, then we say that a is constructively identifiable.

From physical considerations the conductivity coefficients $a(x)$ are assumed to be in

$$A_{\rm ad} = \{a \in L^\infty(0,1) : 0 < \nu \le a(x) \le \mu\}. \tag{1.1}$$

The temperature $u(a) = u(x,t;a)$ inside the rod satisfies

$$\begin{array}{ll} u_t - (a(x)u_x)_x = 0, & Q = (0,1)\times(0,T), \\ u(0,t) = u(1,t) = 0, & t \in (0,T), \\ u(x,0) = g(x), & x \in (0,1), \end{array} \tag{1.2}$$

where $g \in L^2(0,1)$. In general, the solution of (1.2) is understood in the weak sense. According to [11] for any $a \in A_{\rm ad}$ there exists a unique weak solution $u(a) \in L^2(0,1;H_0^1(0,1)) \cap C([0,1];L^2(0,1))$, and so the map $a \to u(a)$ is well defined. Moreover, this map is continuous from $A_{\rm ad}$ equipped with the $L^2(0,1)$ topology into

$C([0,T];L^2(0,1))$. In fact, in [11] these results are established for multidimensional parabolic problems.

The identification (parameter estimation) problem for (1.2) is as follows: Find a conductivity $a \in A_{\rm ad}$ such that the solution $u(a)$ of (1.2) fits a given observation z of the heat conduction process. For example, given $z \in L^2(0,1)$ one defines

$$J(a) = \|u(x,T;a) - z(x)\|_{L^2(0,1)}. \tag{1.3}$$

Then the parameter estimation problem for (1.2) is reduced to the minimization of the objective function J over the admissible set $A_{\rm ad}$ or its subset $K_{\rm ad}$: Find $\overline{a} \in K_{\rm ad} \subset A_{\rm ad}$ such that

$$J(\bar{a}) = \inf\{J(a) : a \in K_{\rm ad}\}. \tag{1.4}$$

The above-mentioned properties of the solutions $u(a)$ imply that the objective function $J(a)$ is continuous on $A_{\rm ad} \cap L^2(0,1)$. Therefore the identification problem (1.4) has a solution if $A_{\rm ad}$ is compact in $L^2(0,1)$. One such choice is $K_{\rm ad} = \{a \in A_{\rm ad} \cap H^1(0,1) : \|a\|_{H^1} \le \text{constant}\}$; see [8]. However, $a \in H^1(0,1)$ implies that the conductivity is continuous. Therefore this choice of $K_{\rm ad}$ is not suitable for the study of the identification problems with discontinuous coefficients.

To overcome this difficulty we have shown in [5] (in a multidimensional case) that one can take for $K_{\rm ad}$ the set of functions in $A_{\rm ad}$ which have a uniformly bounded variation. Such a set $K_{\rm ad}$ is compact in $L^2(0,1)$, and the existence of solutions to the identification problem (1.4) follows. See [5] for additional details and numerical experiments for 2D parameter identification problems. A variety of identification problems is studied in [1] under very general assumptions on the problem's parameters.

The identifiability questions for partial differential equations are much more difficult, and there are just a few available results. Suppose that one is given an observation $z(t) = u(p,t;a)$ of the heat conduction process (1.2) for $t_1 < t < t_2$ at some observation point $0 < p < 1$. From the series solution for (1.2) and the uniqueness of the Dirichlet series expansion (see section 2), one can, in principle, recover all of the eigenvalues of the associated Sturm–Liouville problem. If one also knows the eigenvalues for the heat conduction process with the same coefficient a and different boundary conditions, then the classical results of Gelfand and Levitan [4] show that smooth coefficients $a(x)$ can be uniquely identified from the knowledge of the two spectral sequences. Also, if the entire spectral function is known (i.e., the eigenvalues and the values of the derivatives of the normalized eigenfunctions at $x = 0$), then the conductivity is identifiable as well. However, such results have little practical value, since the observation data $z(t)$ always contain some noise, and therefore one cannot hope to adequately identify more than just the few first eigenvalues of the problem.

A different approach is taken in [6, 12, 13, 14]. These works show that one can identify a constant conductivity a in (1.2) from the measurement $z(t)$ taken at one point $p \in (0,1)$. These works also discuss problems more general than (1.2), including problems with a broad range of boundary conditions, nonzero forcing functions, as well as elliptic and hyperbolic problems. In [7, 3] and references therein identifiability results are obtained for elliptic and parabolic equations with discontinuous parameters in a multidimensional setting. A typical assumption there is that one knows the normal derivative of the solution at the boundary of the region for every Dirichlet boundary input.

The main result of this paper is contained in Theorem 4.6. This theorem describes and justifies the marching algorithm for the unique identification of piecewise constant conductivities from observations of (1.2) given at finitely many points $p_k \in (0,1)$. We

start by recalling some basic properties of (1.2) in section 2. Identifiability results for countably many distributed observations are given in section 3. Identifiability of piecewise constant conductivities a is discussed in section 4. Numerical results for the identifiability algorithms described in this paper require an extensive exposition, and they will be presented elsewhere.

2. Auxiliary results. In this section we collect some well-known results for the solutions $u(x,t;a)$ of (1.2), as well as for its associated Sturm–Liouville problem. Since such results are scattered in the literature, some brief proof outlines are included as well. See [2, 9, 10, 11] for a detailed discussion.

DEFINITION 2.1. *Function $a(x)$ is said to belong to the class $\mathcal{PS}_N$ if*

(i) *$a \in A_{\rm ad} = \{a \in L^\infty(0,1) : 0 < \nu \le a(x) \le \mu\}$ for some positive constants ν and μ;*

(ii) *function a is piecewise smooth; that is, there exists a finite sequence of points $0 = x_0 < x_1 < \cdots < x_{N-1} < x_N = 1$ such that both $a(x)$ and $a'(x)$ are continuous on every open subinterval (x_i, x_{i+1}), $i = 0, \dots, N-1$, and both can be continuously extended to the closed intervals $[x_i, x_{i+1}]$, $i = 0, \dots, N-1$. For definiteness, we assume that a and a' are continuous from the right, i.e., $a(x) = a(x+)$ and $a'(x) = a'(x+)$ for all $x \in [0,1)$. Also let $a(1) = a(1-)$.*

DEFINITION 2.2. $\mathcal{PS} = \cup_{N=1}^\infty \mathcal{PS}_N$.

Everywhere in the following the conductivities a are assumed to be in $\mathcal{PS}$. If $a \in \mathcal{PS}_N$, then the regularity conditions on a and the uniqueness of the weak solutions imply that for any $t > 0$ the weak solution $u(x,t;a)$ of (1.2) satisfies the equation in the classical sense on any subinterval (x_i, x_{i+1}), $i = 0, \dots, N-1$. Also u satisfies the matching conditions for the continuity of the solution and its conormal derivative at $x_i \in (0,1)$, $i = 1, 2, \dots, N-1$:

$$
\begin{aligned}
&u_t - (a(x)u_x)_x = 0, \quad x \ne x_i, \quad t \in (0,T),\\
&u(0,t) = u(1,t) = 0, \quad t \in (0,T),\\
&u(x_i+,t) = u(x_i-,t),\\
&a(x_i+)u_x(x_i+,t) = a(x_i-)u_x(x_i-,t),\\
&u(x,0) = g(x), \quad x \in (0,1),
\end{aligned}
\tag{2.1}
$$

where $g \in L^2(0,1)$; see [11, 16].

Denote by $\|\cdot\|$, $\langle \cdot, \cdot \rangle$ the norm and the inner product, respectively, in $H = L^2(0,1)$.

THEOREM 2.3. *Let $a \in \mathcal{PS}$. Then*

(i) *the associated Sturm–Liouville problem*

$$
\begin{aligned}
&(a(x)v(x)')' = -\lambda v(x), \quad x \ne x_i,\\
&v(0) = v(1) = 0,\\
&v(x_i+) = v(x_i-),\\
&a(x_i+)v_x(x_i+) = a(x_i-)v_x(x_i-)
\end{aligned}
\tag{2.2}
$$

has infinitely many eigenvalues

$$0 < \lambda_1 < \lambda_2 < \cdots \to \infty.$$

The eigenvalues $\{\lambda_k\}_{k=1}^\infty$ and the corresponding orthonormal set of eigenfunctions $\{v_k\}_{k=1}^\infty$ satisfy

(2.3)

$$\lambda_k = \inf \left\{ \frac{\int_0^1 a(x)[v'(x)]^2 dx}{\int_0^1 [v(x)]^2 dx} \ : \ v \in H_0^1(0,1), \ \langle < v, v_j \rangle = 0, \ j = 1, 2, \dots, k-1 \right\},$$

$$\lambda_k = \int_0^1 a(x)[v_k'(x)]^2 dx. \tag{2.4}$$

The normalized eigenfunctions $\{v_k\}_{k=1}^{\infty}$ *form a basis in* $L^2[0,1]$.

(ii) *Each eigenvalue is simple. For each eigenvalue* λ_k *there exists a unique continuous, piecewise smooth normalized eigenfunction* $v_k(x)$ *such that* $v_k'(0+) > 0$, *and the function* $a(x)v_k'(x)$ *is continuous on* $[0,1]$.

(iii) *Eigenvalues* $\{\lambda_k\}_{k=1}^{\infty}$ *satisfy the inequality*

$$\nu\pi^2 k^2 \le \lambda_k \le \mu\pi^2 k^2.$$

(iv) *The first eigenfunction* v_1 *satisfies* $v_1(x) > 0$ *for any* $x \in (0,1)$.

(v) *The first eigenfunction* v_1 *has a unique point of maximum* $q \in (0,1)$: $v_1(x) < v_1(q)$ *for any* $x \ne q$.

(vi) *For any fixed* $t > 0$ *the solution* u *of* (2.1) *is given by*

$$u(x,t;a) = \sum_{k=1}^{\infty} \langle g, v_k\rangle e^{-\lambda_k t} v_k(x),$$

and the series converges uniformly and absolutely on $[0,1]$.

(vii) *For any* $p \in (0,1)$ *the function*

$$z(t) = u(p,t;a), \quad t > 0,$$

is real analytic on $(0,\infty)$.

Proof. (i) The proof is standard; see, e.g., [10].

(ii) On any subinterval (x_i, x_{i+1}) the coefficient $a(x)$ has a bounded continuous derivative. Therefore, on any such interval the initial value problem $(a(x)v'(x))'+\lambda v = 0,\ v(x_i) = A,\ v'(x_i) = B$ has a unique solution. Suppose that two eigenfunctions $w_1(x)$ and $w_2(x)$ correspond to the same eigenvalue λ_k. Then they both satisfy the condition $w_1(0) = w_2(0) = 0$. Therefore their Wronskian is equal to zero at $x = 0$. Consequently, the Wronskian is zero throughout the interval (x_0, x_1), and the solutions are linearly dependent there. Thus $w_2(x) = Cw_1(x)$ on (x_0, x_1), $w_2(x_1-) = Cw_1(x_1-)$, and $w_2'(x_1-) = Cw_1'(x_1-)$. The linear matching conditions imply that $w_2(x_1+) = Cw_1(x_1+)$ and $w_2'(x_1+) = Cw_1'(x_1+)$. The uniqueness of solutions implies that $w_2(x) = Cw_1(x)$ on (x_1, x_2), etc. Thus $w_2(x) = Cw_1(x)$ on $(0,1)$, and each eigenvalue λ_k is simple. In particular λ_1 is a simple eigenvalue. The uniqueness and the matching conditions also imply that any solution of $(a(x)v'(x))' + \lambda v = 0,\ v(0) = 0,\ v'(0) = 0$ must be identically equal to zero on the entire interval $(0,1)$. Thus no eigenfunction $v_k(x)$ satisfies $v_k'(0) = 0$. Assuming that the eigenfunction v_k is normalized in $L^2(0,1)$, it leaves us with the choice of its sign for $v_k'(0)$. Letting $v_k'(0) > 0$ makes the eigenfunction unique.

(iii) The eigenvalues of (2.3) satisfy the min-max principle

$$\lambda_k = \min_{V_k} \max \left\{ \frac{\int_0^1 a(x)[v'(x)]^2 dx}{\int_0^1 [v(x)]^2 dx} \ : \ v \in V_k \right\},$$

where V_k varies over all subspaces of $H_0^1(0,1)$ of finite dimension k; see [10]. Therefore $a(x) \le b(x),\ x \in [0,1]$ implies $\lambda_k^{(a)} \le \lambda_k^{(b)}$. Since the eigenvalues of (2.3) with $a(x) = 1$ are $\pi^2 k^2$, the required inequality follows.

(iv) Recall that $v_1(x)$ is a continuous function on $[0,1]$. Suppose that there exists $p \in (0,1)$ such that $v_1(p) = 0$. Let $w_l(x) = v_1(x)$ for $0 \le x < p$ and $w_l(x) = 0$ for $p \le x \le 1$. Let $w_r(x) = v_1(x) - w_l(x),\ x \in [0,1]$. Then w_l, w_r are continuous, and, moreover, $w_l, w_r \in H_0^1(0,1)$. Also

$$\int_0^1 w_l(x)w_r(x)dx = 0 \quad \text{and} \quad \int_0^1 a(x)w_l'(x)w_r'(x)dx = 0.$$

Suppose that w_l is not an eigenfunction for λ_1. Then

$$\int_0^1 a(x)[w_l'(x)]^2dx > \lambda_1 \int_0^1 [w_l(x)]^2dx.$$

Since

$$\int_0^1 a(x)[w_r'(x)]^2dx \ge \lambda_1 \int_0^1 [w_r(x)]^2dx,$$

we have

$$\lambda_1 = \frac{\int_0^1 a(x)[v_1'(x)]^2dx}{\int_0^1 [v_1(x)]^2dx} = \frac{\int_0^1 a(x)([w_l'(x)]^2 + [w_r'(x)]^2)dx}{\int_0^1 ([w_l(x)]^2 + [w_r(x)]^2)dx}$$

$$> \frac{\int_0^1 (\lambda_1[w_l(x)]^2 + \lambda_1[w_r(x)]^2)dx}{\int_0^1 ([w_l(x)]^2 + [w_r(x)]^2)dx} = \lambda_1.$$

This contradiction implies that w_l (and w_r) must be an eigenfunction for λ_1. However, $w_l(x) = 0$ for $p \le x \le 1$, and as in (ii) it implies that $w_l(x) = 0$ for all $x \in [0,1]$, which is impossible. Since $v_1'(0) > 0$ the conclusion is that $v_1(x) > 0$ for $x \in (0,1)$.

(v) From part (i), any eigenfunction v_k is continuous and satisfies

$$(a(x)v_k'(x))' = -\lambda_k v_k(x)$$

for $x \ne x_i$. Also the function $a(x)v_k'(x)$ is continuous on $[0,1]$ because of the matching conditions at the points of discontinuity $x_i,\ i = 1, 2, \dots, N-1$ of a. The integration gives

$$a(x)v_k'(x) = a(p)v_k'(p) - \lambda_k \int_p^x v_k(s)ds$$

for any $x, p \in (0,1)$.

Let $p \in (0,1)$ be a point of maximum of v_k. If $p \ne x_i$, then $v_k'(p) = 0$. If $p = x_i$, then $v_k'(x_i-) \ge 0$ and $v_k'(x_i+) \le 0$. Therefore $\lim_{x\to p} a(x)v_k'(x) = 0$ and $v_k'(p+) = v_k'(p-) = 0$ since $a(x) \ge \nu > 0$. In any case for such a point p we have

$$a(x)v_k'(x) = -\lambda_k \int_p^x v_k(s)ds, \quad x \in (0,1). \tag{2.5}$$

Since $v_1(x) > 0,\ a(x) > 0$ on $(0,1)$, (2.5) implies that $v_1'(x) > 0$ for any $0 \le x < p$ and $v_1'(x) < 0$ for any $p < x \le 1$. Since the derivative of v_1 is zero at any point of maximum, we have to conclude that such a maximum p is unique.

(vi) We prove only the convergence part. Note that

$$\nu\|v_k'\|^2 \le \int_0^1 a(x)[v_k'(x)]^2 dx = \lambda_k \|v_k\|^2 = \lambda_k.$$

Thus

$$\|v_k'\| \le \frac{\sqrt{\lambda_k}}{\sqrt{\nu}}$$

and

$$|v_k(x)| \le \int_0^x |v_k'(s)| ds \le \|v_k'\| \le \frac{\sqrt{\lambda_k}}{\sqrt{\nu}}.$$

Bessel's inequality implies that the sequence of Fourier coefficients $\langle g, v_k\rangle$ is bounded. Therefore, denoting by C various constants and using the fact that the function $s \to \sqrt{s}e^{-\sigma s}$ is bounded on $[0,\infty)$ for any $\sigma > 0$, one gets

$$|\langle g, v_k\rangle e^{-\lambda_k t} v_k(x)| \le C\frac{\sqrt{\lambda_k}}{\sqrt{\nu}} e^{-\frac{\lambda_k t}{2}} e^{-\frac{\lambda_k t}{2}} \le C e^{-\frac{\lambda_k t}{2}}.$$

From (iii) of this theorem $\lambda_k \ge \nu\pi^2 k^2$. Thus

$$\sum_{k=1}^{\infty} |\langle g, v_k\rangle e^{-\lambda_k t} v_k(x)| \le C\sum_{k=1}^{\infty} e^{-\frac{\nu\pi^2 k^2 t}{2}} \le C\sum_{k=1}^{\infty} \left(e^{-\frac{\nu\pi^2 t}{2}}\right)^k < \infty.$$

(vii) Let $t_0 > 0$ and $p \in (0,1)$. From (vi), the series $\sum_{k=1}^{\infty}\langle g, v_k\rangle e^{-\lambda_k t_0} v_k(p)$ converges absolutely. Therefore $\sum_{k=1}^{\infty}\langle g, v_k\rangle e^{-\lambda_k s} v_k(p)$ is analytic in the part of the complex plane $\{s \in \mathbf{C} : \text{Re } s > t_0\}$, and the result follows. □

Series of the form $\sum_{k=1}^{\infty} C_k e^{-\lambda_k t}$ are known as the Dirichlet series. The following lemma shows that the Dirichlet series representation of a function is unique.

LEMMA 2.4. *Let $\mu_k > 0$, $k = 1, 2, \ldots$, be a strictly increasing sequence. Suppose that $T_1 \ge 0$ and $\sum_{k=1}^{\infty} |C_k| < \infty$. If*

$$\sum_{k=1}^{\infty} C_k e^{-\mu_k t} = 0 \quad \textit{for all} \quad t \in (T_1, T_2),$$

then $C_k = 0$ for $k = 1, 2, \ldots$.

The result follows at once from the observation that the series $\sum_{k=1}^{\infty} C_k e^{-\mu_k z}$ converges uniformly in the Re $z > 0$ region of the complex plane, implying that it is an analytic function there. See Chapter 9 of [15] for additional results on Dirichlet series.

Remark. According to Theorem 2.3(vi) for each fixed $p \in (0,1)$ the solution $z(t) = u(p,t;a)$ of (2.1) is given by a Dirichlet series. However, Lemma 2.4 is not directly applicable since the coefficients $C_k = \langle g, v_k\rangle v_k(p)$ are only square summable. Nevertheless, the conclusion of Lemma 2.4 remains valid, since the exponents μ_k in the Dirichlet series are the eigenvalues λ_k which satisfy the growth condition stated in Theorem 2.3(iii). This allows one to conclude (Theorem 2.3(vii)) that the solution $z(t)$ is a real analytic function on $(0,\infty)$, and the uniqueness of such a representation follows. Thus it would be a mistake to simply refer to the standard results such as Lemma 2.4 for the uniqueness of the Dirichlet series representation to justify the paper's conclusions.

3. Identifiability by distributed measurements. Suppose that one is given some observations of the heat conduction process (2.1) with an unknown conductivity $a(x)$ and that they coincide with the observations of the model process

$$\begin{aligned} &u_t^m - (a^m(x)u_x^m)_x = 0, \quad x \neq x_i^m, \quad t \in (0,T),\\ &u^m(0,t) = u^m(1,t) = 0, \quad t \in (0,T),\\ &u^m(x_i^m+,t) = u^m(x_i^m-,t),\\ &a^m(x_i^m+)u_x^m(x_i^m+,t) = a^m(x_i^m-)u_x^m(x_i^m-,t),\\ &u^m(x,0) = g(x), \quad x \in (0,1), \end{aligned} \tag{3.1}$$

where g is the same as in (2.1). The conductivity a is said to be identifiable in some class of functions $\mathcal{M}$ if the coincidence of the measurements of the observed and the model processes implies that $a = a^m$, provided $a, a^m \in \mathcal{M}$.

THEOREM 3.1. *Let $\{\psi_n\}_{n=1}^\infty$ be a complete orthonormal set in $H = L^2(0,1)$. Suppose that nonzero initial data $g \in H$ and the observations $z_n(t) = \langle u(x,t;a), \psi_n\rangle$ for $n = 1,2,\dots$ and $0 \le T_1 < t < T_2$ of the heat conduction process (2.1) are given. Then the conductivity $a(x) \in A_{\rm ad}$ is constructively identifiable in the class of piecewise smooth functions $\mathcal{PS}$.*

Proof. To show the identifiability of a we give an algorithm for its reconstruction from the data $z_n(t)$, $n = 1,2,\dots$, guaranteeing the uniqueness in each step. Using Theorem 2.3(vi) we have

$$z_n(t) = \sum_{k=1}^{\infty} \langle g, v_k\rangle e^{-\lambda_k t}\langle v_k, \psi_n\rangle \tag{3.2}$$

for each $n = 1,2,\dots$ and $0 \le T_1 < t < T_2$.

Fix an $n > 0$. Since $\psi_n \in H$ and $\{v_k\}_{k=1}^\infty$ form a basis in H, the Bessel inequality implies that the sequence of the Fourier coefficients $\{\langle v_k, \psi_n\rangle\}_{k=1}^\infty$ is bounded. From Theorem 2.3(vi) one concludes that the above series converges absolutely. Note that some products $\langle g, v_k\rangle\langle v_k, \psi_n\rangle$ may be equal to zero. The zero value products present a difficulty, since we would not know how to associate the sequence of exponents recovered from (3.2) with the (unknown) eigenvalues λ_k: Some eigenvalues may be missing from the sequence. Define (possibly empty) subsets $Q_n \subset \mathbf{N}$ by

$$Q_n = \{k \in \mathbf{N} \ : \ \langle g, v_k\rangle\langle v_k, \psi_n\rangle \neq 0\}, \quad n = 1,2,\dots.$$

For $Q_n \neq \emptyset$ reindex (3.2) so that there would be no vanishing coefficients:

$$z_n(t) = \sum_{l=1}^{\infty} C_{l,n} e^{-\mu_{l,n} t}, \quad t \in (T_1, T_2). \tag{3.3}$$

By Theorem 2.3(vii) the solutions $z_n(t)$ are real analytic. Therefore, since all of the coefficients $C_{l,n} \neq 0$, one can uniquely determine them and the sequences $\mu_{l,n}$, $l = 1,2,\dots$. Recall that $\{\mu_{l,n}\}_{l=1}^\infty \subset \{\lambda_k\}_{k=1}^\infty$ for any n with a nonempty Q_n so each $\mu_{l,n} \ge \lambda_1 > 0$. For each n such that $Q_n \neq \emptyset$ let

$$\gamma_n = \min\{\mu_{l,n} \ : \ l \in \mathbf{N}\}.$$

Define

$$\gamma = \min\{\gamma_n \ : \ Q_n \neq \emptyset\}$$

and

$$A_n = \begin{cases} C_{1,n} & \text{if} \quad \gamma_n = \gamma, \quad Q_n \neq \emptyset, \\ 0 & \text{if} \quad \gamma_n > \gamma, \quad Q_n \neq \emptyset, \\ 0 & \text{if} \quad Q_n = \emptyset. \end{cases} \tag{3.4}$$

Let

$$w(x) = \sum_{n=1}^{\infty} A_n \psi_n(x). \tag{3.5}$$

We claim that w is a nonzero multiple of some eigenfunction v_J of (2.1). Indeed, let J be the smallest index for which $\langle g, v_J \rangle \neq 0$. Such an index exists since $g \neq 0$, and the eigenfunctions form a basis in H. Now, since $v_J \neq 0$ and $\{\psi_n\}_{n=1}^{\infty}$ also form a basis in H, there exists $n \in \mathbf{N}$ such that $\langle v_J, \psi_n \rangle \neq 0$. Thus $\langle g, v_J \rangle \langle v_J, \psi_n \rangle \neq 0$ and $\gamma \leq \lambda_J$. The choice of J implies that $\gamma = \lambda_J$. By the definition $A_n = \langle g, v_J \rangle \langle v_J, \psi_n \rangle$ for nonzero products. Therefore

$$\begin{aligned} w(x) &= \sum_{n=1}^{\infty} \langle g, v_J \rangle \langle v_J, \psi_n \rangle \psi_n(x) \\ &= \langle g, v_J \rangle \sum_{n=1}^{\infty} \langle v_J, \psi_n \rangle \psi_n(x) = \langle g, v_J \rangle v_J(x) \end{aligned}$$

as claimed.

Now we show that the set of points $y \in (0,1)$ where $w'(y) = 0$ is finite. Assuming the opposite, and since w is a nonzero multiple of v_J, there exists a sequence $y_j \in (0,1)$ such that $v_J'(y_j) = 0$ and $\lim_{j \to \infty} y_j = c \in [0,1]$. The continuity of $a(x)v_J'(x)$ implies that $v_J'(c) = 0$. From $(a(x)v_J'(x))' = -\gamma v_J(x)$ one gets

$$0 = a(y_{j+1})v_J'(y_{j+1}) - a(y_j)v_J'(y_j) = -\gamma \int_{y_j}^{y_{j+1}} v_J(s)ds \tag{3.6}$$

and concludes that v_J cannot be strictly positive or strictly negative on (y_j, y_{j+1}). Let $\zeta_j \in (y_j, y_{j+1})$ be such that $v_J(\zeta_j) = 0$. Then $\lim_{j \to \infty} \zeta_j = c \in [0,1]$ and $v_J(c) = 0$. Now we have both $v_J(c) = 0$ and $v_J'(c) = 0$. But then the uniqueness of the Cauchy problem for the second order linear equations, and the matching conditions (see the proof of Theorem 2.3(ii)) imply that $v_J(x) = 0$ for all $x \in [0,1]$, which is impossible.

Let q be a point of maximum of w. Note that w may have several maxima, unless it is a multiple of v_1. In any case, (2.5) implies

$$a(x)w'(x) = -\gamma \int_q^x w(s)ds, \quad x \in (0,1). \tag{3.7}$$

Then, outside of the finite sets $\{x_i\}$ and $\{y_j\}$, the conductivity $a(x)$ is uniquely determined from (3.7) by

$$a(x) = -\gamma \frac{\int_q^x w(s)ds}{w'(x)}.$$

Because a is assumed to be in $\mathcal{PS}$, it can be uniquely extended to the entire interval $[0,1]$. □

Remark 1. In an application one can choose $\psi_n = \sqrt{2}\sin \pi n x$ and the initial condition $g(x) > 0$ on $(0,1)$. Then $\langle g, v_1\rangle\langle v_1, \psi_1\rangle \neq 0$, since $v_1(x) > 0$ on $(0,1)$ by Theorem 2.3(iv). Thus $J = 1$ in this case, and $w(x) = \langle g, v_1\rangle v_1(x)$ in the above algorithm. Also, one can see from (3.6) that there is only one point $y_1 = q \in (0,1)$ where $v_1'(q) = 0$, and it is the point of maximum of $v_1(x)$ on $(0,1)$. Indeed, if there were two such points, then by (3.6) $v_1(x)$ would have to become negative between them, which would contradict $v_1(x) > 0$ on $(0,1)$.

Remark 2. Since the system $\{\psi_n\}_{n=1}^{\infty}$ is complete, the conditions of Theorem 3.1 imply that for any $t > 0$ one knows $u(x,t;a)$ almost everywhere on $[0,1]$. Since $u(x,t;a)$ is continuous in x and analytic in t, Theorem 3.1, in fact, assumes that the solution is known in $[0,1]\times(0,T)$ or (equivalently) in $[0,1]\times(0,\infty)$. Thus, Theorem 3.1 can be stated under any of these conditions. However, a practical reconstruction of the conductivity a directly from the equation $u_t = (au_x)_x$ is extremely unstable. The algorithm presented in the above theorem does not reconstruct the entire solution u but just the first eigenfunction of the associated Sturm–Liouville problem. Its stability properties will be studied elsewhere.

4. Identifiability of piecewise constant conductivities from finitely many observations. The identifiability is sought within the following set.

DEFINITION 4.1. *Let $\mathcal{PC} \subset \mathcal{PS}$ be the class of piecewise constant conductivities, and let $\mathcal{PC}_N = \mathcal{PC} \cap \mathcal{PS}_N$.*

Functions $a \in \mathcal{PC}_N$ have the form $a(x) = a_i$ for $x \in [x_{i-1}, x_i)$, $i = 1, 2, \dots, N$. In this case the governing system (2.1) is

$$\begin{aligned} &u_t - a_i u_{xx} = 0, \quad x \in (x_{i-1}, x_i), \quad t \in (0,T),\\ &u(0,t) = u(1,t) = 0, \quad t \in (0,T),\\ &u(x_i+,t) = u(x_i-,t),\\ &a_{i+1}u_x(x_i+,t) = a_i u_x(x_i-,t),\\ &u(x,0) = g(x), \quad x \in (0,1), \end{aligned} \tag{4.1}$$

where $g \in L^2(0,1)$ and $i = 1, 2, \dots, N-1$. The associated Sturm–Liouville problem is

$$\begin{aligned} &a_i v''(x) = -\lambda v(x), \quad x \in (x_{i-1}, x_i),\\ &v(0) = v(1) = 0,\\ &v(x_i+) = v(x_i-),\\ &a_{i+1}v'(x_i+) = a_i v'(x_i-) \end{aligned} \tag{4.2}$$

for $i = 1, 2, \dots, N-1$.

We are interested only in the first eigenfunction v_1 of (4.2). Let λ_1 be the first eigenvalue. Suppose that $p^* \in (x_{i-1}, x_i)$. Then v_1 can be expressed on (x_{i-1}, x_i) as

$$v_1(x) = A\cos\left(\sqrt{\frac{\lambda_1}{a_i}}(x - p^*) + \gamma\right), \quad A > 0, \quad -\frac{\pi}{2} < \gamma < \frac{\pi}{2}.$$

The range for γ in the above representation follows from the fact that $v_1(p^*) = A\cos\gamma > 0$ by Theorem 2.3(iv).

The identifiability of piecewise constant conductivities is based on the following three lemmas.

LEMMA 4.2. *Suppose that $\delta > 0$. Assume $Q_1, Q_3 \geq 0$, $Q_2 > 0$, and $0 < Q_1 + Q_3 < 2Q_2$. Let*

$$\Gamma = \left\{(A,\omega,\gamma) \ : \ A > 0, \quad 0 < \omega < \frac{\pi}{2\delta}, \quad -\frac{\pi}{2} < \gamma < \frac{\pi}{2}\right\}.$$

Then the system of equations

$$A\cos(\omega\delta-\gamma)=Q_1,\quad A\cos\gamma=Q_2,\quad A\cos(\omega\delta+\gamma)=Q_3$$

has a unique solution $(A,\omega,\gamma)\in\Gamma$ *given by*

$$\omega=\frac{1}{\delta}\arccos\frac{Q_1+Q_3}{2Q_2},\quad \gamma=\arctan\left(\frac{Q_1-Q_3}{2Q_2\sin\omega\delta}\right),\quad A=\frac{Q_2}{\cos\gamma}.$$

Proof. For $(A,\omega,\gamma)\in\Gamma$ one has $A>0$ and $\cos\gamma>0$. Therefore

$$\frac{\cos(\omega\delta-\gamma)}{\cos\gamma}=\cos(\omega\delta)+\sin(\omega\delta)\frac{\sin\gamma}{\cos\gamma}=\frac{Q_1}{Q_2}, \tag{4.3}$$

$$\frac{\cos(\omega\delta+\gamma)}{\cos\gamma}=\cos(\omega\delta)-\sin(\omega\delta)\frac{\sin\gamma}{\cos\gamma}=\frac{Q_3}{Q_2}. \tag{4.4}$$

Adding (4.3) and (4.4) yields

$$\cos\omega\delta=\frac{Q_1+Q_3}{2Q_2}.$$

Since $0<\omega\delta<\frac{\pi}{2}$ and $0<(Q_1+Q_3)/2Q_2<1$ the above equation is uniquely solvable. Now subtracting (4.4) from (4.3) yields

$$\tan\gamma=\frac{Q_1-Q_3}{2Q_2\sin\omega\delta},$$

which is also uniquely solvable, since $-\pi/2<\gamma<\pi/2$. Finally, we have $A=Q_2/\cos\gamma$. □

LEMMA 4.3. *Suppose that* $\delta>0,\ 0<p\le x_1<p+\delta<1,\ 0<\omega_1,\omega_2<\pi/2\delta$. *Let* $w(x),\ v(x),\ x\in[p,p+\delta]$ *be such that*

$$w(x)=A_1\cos\omega_1x+B_1\sin\omega_1x,$$
$$v(x)=A_2\cos\omega_2x+B_2\sin\omega_2x.$$

Suppose that

$$v(x_1)=w(x_1),\quad \omega_1^2v'(x_1)=\omega_2^2w'(x_1),$$
$$v'(x_1)>0,\quad v(x_1)>0.$$

Then

(i) *conditions* $v(p+\delta)=w(p+\delta),\ v'(p+\delta)\ge0$, *and* $\omega_1\le\omega_2$ *imply* $\omega_1=\omega_2$;

(ii) *conditions* $v(p+\delta)=w(p+\delta),\ w'(p+\delta)\ge0$, *and* $\omega_1\ge\omega_2$ *imply* $\omega_1=\omega_2$.

Proof. Since $v(x_1)>0,\ v'(x_1)>0$ we have

$$v(x)=A\sin[\omega_2(x-x_1)+\gamma],\quad 0<\gamma<\frac{\pi}{2},$$

where $A>0$. The matching conditions for $w(x)$ at x_1 imply

$$\begin{aligned}w(x)&=A\sin\gamma\cos\omega_1(x-x_1)+A\frac{\omega_1}{\omega_2}\cos\gamma\sin\omega_1(x-x_1)\\&=A\sin[\omega_1(x-x_1)+\gamma]+A\left[\frac{\omega_1}{\omega_2}-1\right]\cos\gamma\sin\omega_1(x-x_1).\end{aligned}$$

Thus

$$\begin{aligned} v(p+\delta) - w(p+\delta) &= A\left[1 - \frac{\omega_1}{\omega_2}\right]\cos\gamma \sin\omega_1(p+\delta-x_1) \\ &+ A\sin[\omega_2(p+\delta-x_1)+\gamma] - A\sin[\omega_1(p+\delta-x_1)+\gamma] \\ &= A\frac{\omega_2-\omega_1}{\omega_2}\cos\gamma\sin\omega_1(p+\delta-x_1) \\ &+ 2A\sin\frac{\omega_2-\omega_1}{2}(p+\delta-x_1)\cos\left[\frac{\omega_2+\omega_1}{2}(p+\delta-x_1)+\gamma\right]. \end{aligned}$$

Observe that $0 < p+\delta-x_1 \le \delta$. Thus $\sin\omega_1(p+\delta-x_1) > 0$.

For $\omega_2 > \omega_1$ and $v'(p+\delta) \ge 0$ one has

$$\cos[\omega_2(p+\delta-x_1)+\gamma] = \frac{1}{\omega_2}v'(p+\delta) \ge 0.$$

Therefore

$$\frac{\omega_2+\omega_1}{2}(p+\delta-x_1)+\gamma < \omega_2(p+\delta-x_1)+\gamma \le \frac{\pi}{2}$$

and

$$\cos\left[\frac{\omega_2+\omega_1}{2}(p+\delta-x_1)+\gamma\right] > \cos[\omega_2(p+\delta-x_1)+\gamma] \ge 0.$$

Thus $v(p+\delta) - w(p+\delta) > 0$, and the conclusion (i) of the lemma follows.

The case $\omega_2 < \omega_1$ and $w'(p+\delta) \ge 0$ is reduced to the already established one by interchanging ω_1 with ω_2 and w with v. □

LEMMA 4.4. *Let $\delta > 0$, $0 < \eta \le 2\delta$, $\omega_1 \ne \omega_2$, with $0 < \omega_1\delta, \omega_2\delta < \pi/2$. Also let $A, B > 0$, $0 \le p < p+\eta \le 1$, and*

$$\begin{aligned} w(x) &= A\cos[\omega_1(x-p)+\gamma_1], \\ v(x) &= B\cos[\omega_2(x-p-\eta)+\gamma_2], \end{aligned}$$

with $|\gamma_1|, |\gamma_2| < \pi/2$.

Then the system

$$w(q) = v(q), \tag{4.5}$$

$$\omega_2^2 w'(q) = \omega_1^2 v'(q), \tag{4.6}$$

$$w(q) > 0, \quad v(q) > 0 \tag{4.7}$$

admits at most one solution q on $[p, p+\eta]$. This unique solution q can be computed as follows:

If $\gamma_1 \ge 0$, then

$$q = p + \frac{1}{\omega_1}\left[\arctan\left(\omega_1\sqrt{\left|\frac{B^2-A^2}{A^2\omega_2^2 - B^2\omega_1^2}\right|}\right) - \gamma_1\right]. \tag{4.8}$$

If $\gamma_2 \le 0$, then

$$q = p + \eta + \frac{1}{\omega_2}\left[-\arctan\left(\omega_2\sqrt{\left|\frac{B^2-A^2}{A^2\omega_2^2 - B^2\omega_1^2}\right|}\right) - \gamma_2\right]. \tag{4.9}$$

Otherwise, compute q_1 and q_2 according to (4.8) *and* (4.9) *and discard the one that does not satisfy the conditions of the lemma.*

Proof. Let $\alpha > 0$ and

$$\mathbf{c}(t;\alpha) = \begin{pmatrix} \cos t \\ \alpha \sin t \end{pmatrix}, \quad t \in \mathbf{R}.$$

Vector function $\mathbf{c}(t,\alpha)$ traverses the ellipse $\mathcal{E}(1,\alpha)$ centered in the origin with the x semiaxis equal to 1 and the y semiaxis equal to α. This function can be rewritten as

$$\mathbf{c}(t;\alpha) = \mathbf{P}(\alpha)\mathbf{M}(t)\mathbf{e}_1,$$

where

$$\mathbf{M}(t) = \begin{pmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{pmatrix}, \quad \mathbf{P}(\alpha) = \begin{pmatrix} 1 & 0 \\ 0 & \alpha \end{pmatrix}, \quad \mathbf{e}_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Note that $\mathbf{M}(t)$ is the counterclockwise rotation in $\mathbf{R}^2$ by the angle t, $\mathbf{P}(\alpha)$ is the α-contraction (expansion) in $\mathbf{R}^2$ along the y axis, and $\mathbf{e}_1$ is the standard basis vector along the x axis. Furthermore

$$\mathbf{c}(t_1 + t_2;\alpha) = \mathbf{P}(\alpha)\mathbf{M}(t_1)\mathbf{M}(t_2)\mathbf{e}_1. \tag{4.10}$$

With this notation system (4.5)–(4.6) is

$$A\mathbf{c}(\omega_1(q-p)+\gamma_1; 1/\omega_1) = B\mathbf{c}(\omega_2(q-p-\eta)+\gamma_2; 1/\omega_2)$$

or

$$\mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1(q-p)+\gamma_1]A\mathbf{e}_1 = \mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2(q-p-\eta)+\gamma_2]B\mathbf{e}_1. \tag{4.11}$$

If q is a solution of (4.5)–(4.6), then the vectors in the right and the left sides of (4.11) are identical. Thus they belong to the intersection of the ellipses $\mathcal{E}(A, A/\omega_1)$ and $\mathcal{E}(B, B/\omega_2)$, and this intersection is not empty. In general the ellipses intersect in four points: one in each quadrant.

Suppose that $q^* \neq q$ is another solution of (4.5)–(4.6) on $[p, p+\eta]$. We can assume that $q^* = q + \tau$ for some $\tau > 0$, $0 < \omega_1\tau, \omega_2\tau < \pi$. System (4.5)–(4.6) at $x = q^*$ is

$$\mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1(q+\tau-p)+\gamma_1]A\mathbf{e}_1 = \mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2(q+\tau-p-\eta)+\gamma_2]B\mathbf{e}_1. \tag{4.12}$$

Using (4.10) and $\mathbf{P}(\alpha)\mathbf{P}(\alpha^{-1}) = \mathbf{I}$ the right side of (4.12) can be written as

$$\begin{aligned}
&\mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2(q+\tau-p-\eta)+\gamma_2]B\mathbf{e}_1 = \mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2\tau]\mathbf{M}[\omega_2(q-p-\eta)+\gamma_2]B\mathbf{e}_1 \\
&= \mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2\tau]\mathbf{P}(\omega_2)\mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2(q-p-\eta)+\gamma_2]B\mathbf{e}_1 \\
&= \mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2\tau]\mathbf{P}(\omega_2)\mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1(q-p)+\gamma_1]A\mathbf{e}_1.
\end{aligned}$$

Similarly the left side of (4.12) can be written as

$$\begin{aligned}
&\mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1(q+\tau-p)+\gamma_1]A\mathbf{e}_1 = \mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1\tau]\mathbf{M}[\omega_1(q-p)+\gamma_1]A\mathbf{e}_1 \\
&= \mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1\tau]\mathbf{P}(\omega_1)\mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1(q-p)+\gamma_1]A\mathbf{e}_1.
\end{aligned}$$

Let $\mathbf{v} = \mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1(q-p)+\gamma_1]A\mathbf{e}_1$ and

$$\mathbf{D} = \mathbf{P}(\omega_2^{-1})\mathbf{M}[\omega_2\tau]\mathbf{P}(\omega_2) - \mathbf{P}(\omega_1^{-1})\mathbf{M}[\omega_1\tau]\mathbf{P}(\omega_1).$$

Then (4.12) is $\mathbf{D}\mathbf{v} = \mathbf{0}$. Since $\mathbf{v} \neq \mathbf{0}$ we must have $\det(\mathbf{D}) = 0$. Note that

$$\begin{aligned}\det(\mathbf{D}) &= \frac{1}{\omega_1\omega_2}\left[2\omega_1\omega_2 - (\omega_1^2+\omega_2^2)\sin\omega_1\tau\sin\omega_2\tau - 2\omega_1\omega_2\cos\omega_1\tau\cos\omega_2\tau\right]\\ &= \frac{1}{\omega_1\omega_2}\left[2\omega_1\omega_2 - \frac{1}{2}(\omega_1+\omega_2)^2\cos(\omega_1-\omega_2)\tau + \frac{1}{2}(\omega_1-\omega_2)^2\cos(\omega_1+\omega_2)\tau\right].\end{aligned}$$

Let us define $f(\tau)$ on $[0,\pi/\omega_1)\cap[0,\pi/\omega_2)$ as

$$f(\tau) = 2\omega_1\omega_2 + \frac{1}{2}(\omega_1-\omega_2)^2\cos(\omega_1+\omega_2)\tau - \frac{1}{2}(\omega_1+\omega_2)^2\cos(\omega_1-\omega_2)\tau.$$

Function f is smooth on $(0,\pi/\omega_1)\cap(0,\pi/\omega_2)$, and its first and second derivatives are

$$\begin{aligned}f'(\tau) &= -\frac{1}{2}(\omega_1-\omega_2)^2(\omega_1+\omega_2)\sin(\omega_1+\omega_2)\tau + \frac{1}{2}(\omega_1+\omega_2)^2(\omega_1-\omega_2)\sin(\omega_1-\omega_2)\tau,\\ f''(\tau) &= (\omega_1-\omega_2)^2(\omega_1+\omega_2)^2\sin\omega_1\tau\sin\omega_2\tau.\end{aligned}$$

Since $f(0) = f'(0) = 0$, $f''(\tau) > 0$, and $f'(\tau) > 0$ on $(0,\pi/\omega_1)\cap(0,\pi/\omega_2)$, we conclude that $f(\tau) > 0$ for all $\tau \in (0,\pi/\omega_1)\cap(0,\pi/\omega_2)$. Thus $\det(\mathbf{D}) = 0$ if and only if $\tau = 0$. This contradicts the assumption $\tau > 0$. Therefore the solution q of (4.5)–(4.7) is unique on $[p, p+\eta]$.

To obtain formulas (4.8) and (4.9) notice that the ellipses $\mathcal{E}(A, A/\omega_1)$ and $\mathcal{E}(B, B/\omega_2)$ are given by

$$x^2 + \omega_1^2 y^2 = A^2 \quad \text{and} \quad x^2 + \omega_2^2 y^2 = B^2.$$

At the intersection points we have

$$y^2 = \frac{B^2-A^2}{\omega_2^2-\omega_1^2} \quad \text{and} \quad x^2 = \frac{A^2\omega_2^2 - B^2\omega_1^2}{\omega_2^2-\omega_1^2}.$$

The polar angle of the intersection point in the first quadrant is

$$\zeta = \arctan\sqrt{\left|\frac{B^2-A^2}{A^2\omega_2^2 - B^2\omega_1^2}\right|}.$$

Since $w(q) = v(q) > 0$ the intersection points corresponding to the solution q are in either the first or the fourth quadrants, and $0 \le \zeta < \pi/2$.

If $w'(p) \le 0$, then $\gamma_1 \ge 0$. Therefore $0 \le \gamma_1 \le \omega_1(q-p)+\gamma_1$. In this case the intersection point is in the first quadrant. Accordingly $\tan[\omega_1(q-p)+\gamma_1] = \omega_1\tan\zeta$. Thus

$$q = p + \frac{1}{\omega_1}\left[\arctan\left(\omega_1\sqrt{\left|\frac{B^2-A^2}{A^2\omega_2^2 - B^2\omega_1^2}\right|}\right) - \gamma_1\right].$$

If $v'(p+\eta) \ge 0$, then $\gamma_2 \le 0$ and $\omega_2(q-p-\eta)+\gamma_2 \le \gamma_2 \le 0$. In this case the intersection point is in the fourth quadrant. Accordingly $\tan[\omega_2(q-p-\eta)+\gamma_2] = -\omega_2\tan\zeta$ and one gets (4.9). ∎

Now we would like to define a class of piecewise constant conductivities with sufficiently separated points of discontinuity.

DEFINITION 4.5. *By the definition of $a \in \mathcal{PC}$ there exists $N \in \mathbf{N}$ and a finite sequence $0 = x_0 < x_1 < \cdots < x_{N-1} < x_N = 1$ such that a is a constant on each subinterval (x_{n-1}, x_n), $n = 1, \ldots, N$. Let $\sigma > 0$. Define*

$$\mathcal{PC}(\sigma) = \{a \in \mathcal{PC} \ : \ x_n - x_{n-1} \geq \sigma, \quad n = 1, 2, \ldots, N\}.$$

Note that $a \in \mathcal{PC}(\sigma)$ attains at most $N = [[1/\sigma]]$ distinct values $a_i, 0 < \nu \leq a_i \leq \mu$.

The following theorem is our main result. It describes and justifies the marching algorithm for the unique identification of piecewise constant conductivities in the class $\mathcal{PC}(\sigma)$.

THEOREM 4.6. *Given $\sigma > 0$ let an integer M be such that*

$$M \geq \frac{3}{\sigma} \quad \textit{and} \quad M > 2\sqrt{\frac{\mu}{\nu}}.$$

Suppose that the initial data $g(x) > 0$, $0 < x < 1$, and the observations $z_m(t) = u(p_m, t; a), p_m = m/M$ for $m = 1, 2, \ldots, M-1$ and $0 \leq T_1 < t < T_2$ of the heat conduction process (4.1) *are given. Then the conductivity $a \in A_{\mathrm{ad}}$ is constructively identifiable in the class of piecewise constant functions $\mathcal{PC}(\sigma)$.*

First, we present the marching algorithm for the unique identification of the conductivity a and then justify it. The algorithm marches from the left end $x = 0$ to a certain observation point $p_{l-1} \in (0, 1)$ and identifies the values a_n and the discontinuity points x_n of the conductivity a on $[0, p_{l-1}]$. Then the algorithm marches from the right end point $x = 1$ to the left until it reaches the observation point $p_{l+1} \in (0, 1)$ identifying the values and the discontinuity points of a on $[p_{l+1}, 1]$. Finally, the values of a and its discontinuity are identified on the interval $[p_{l-1}, p_{l+1}]$. The overall goal of the algorithm is to determine the number $N - 1$ of the discontinuities of a on $[0, 1]$, the discontinuity points x_n, $n = 1, 2, \ldots, N-1$, and the values a_n of a on $[x_{n-1}, x_n]$, $n = 1, 2, \ldots, N$ ($x_0 = 0$, $x_N = 1$). As a part of the process the algorithm determines certain functions $H_n(x)$ defined on intervals $[x_{n-1}, x_n]$, $n = 1, 2, \ldots, N$. The resulting function $H(x)$ defined on $[0, 1]$ is a multiple of the first eigenfunction v_1.

MARCHING ALGORITHM.

(i) Represent the data $z_m(t)$ as

$$z_m(t) = \sum_{k=1}^{\infty} c_{k,m} e^{-\lambda_k t}, \quad m = 1, 2, \ldots, M-1, \quad 0 \leq T_1 < t < T_2, \tag{4.13}$$

and use it to uniquely identify the first eigenvalue λ_1 and the coefficients $G_m = c_{1,m}$, $m = 1, 2, \ldots, M-1$. Let $G_0 = G_M = 0$.

(ii) Find l, $0 < l < M$, such that $G_l = \max\{G_m : m = 1, 2, \ldots, M-1\}$ and $G_m < G_l$ for any $0 \leq m < l$.

(iii) Let $i = 1$, $m = 0$.

(iv) Use Lemma 4.2 to find A_i, ω_i, and γ_i from the system

$$\begin{cases} A_i \cos(\omega_i \delta - \gamma_i) = G_m, \\ A_i \cos \gamma_i = G_{m+1}, \\ A_i \cos(\omega_i \delta + \gamma_i) = G_{m+2}. \end{cases} \tag{4.14}$$

Let

$$H_i(x) = A_i \cos(\omega_i (x - p_{m+1}) + \gamma_i).$$

(v) If $m+3 \geq l$, then go to step (viii). If $H_i(p_{m+3}) \neq G_{m+3}$, or $H_i(p_{m+3}) = G_{m+3}$ and $H_i'(p_{m+3}) \leq 0$, then a has a discontinuity x_i on interval $[p_{m+2}, p_{m+3})$. Proceed to the next step (vi). If $H_i(p_{m+3}) = G_{m+3}$ and $H_i'(p_{m+3}) > 0$, then let $m := m+1$ and repeat this step (v).

(vi) Use Lemma 4.2 to find A_{i+1}, ω_{i+1}, and γ_{i+1} from the system

$$\begin{cases} A_{i+1}\cos(\omega_{i+1}\delta - \gamma_{i+1}) = G_{m+3}, \\ A_{i+1}\cos\gamma_{i+1} = G_{m+4}, \\ A_{i+1}\cos(\omega_{i+1}\delta + \gamma_{i+1}) = G_{m+5}. \end{cases} \tag{4.15}$$

Let

$$H_{i+1}(x) = A_{i+1}\cos(\omega_{i+1}(x - p_{m+4}) + \gamma_{i+1}).$$

(vii) Use the formulas in Lemma 4.4 to find the unique discontinuity point $x_i \in [p_{m+2}, p_{m+3})$. The parameters and functions used in Lemma 4.4 are defined as follows. Let $p = p_{m+2}$, $\eta = \delta$. To avoid confusion we are going to use the notation Ω_1, Ω_2, Γ_1, Γ_2 for the corresponding parameters ω_1, ω_2, γ_1, γ_2 required in Lemma 4.4. Let $\Omega_1 = \omega_i$, $\Omega_2 = \omega_{i+1}$. For $w(x)$ use function $H_i(x)$ recentered at $p = p_{m+2}$; i.e., rewrite $H_i(x)$ in the form

$$w(x) = H_i(x) = A\cos(\Omega_1(x - p_{m+2}) + \Gamma_1), \quad |\Gamma_1| < \pi/2.$$

For $v(x)$ use function H_{i+1} recentered at $p + \eta = p_{m+3}$; i.e.,

$$v(x) = H_{i+1}(x) = B\cos(\Omega_2(x - p_{m+3}) + \Gamma_2), \quad |\Gamma_2| < \pi/2.$$

Let $i := i+1$, $m := m+3$. If $m < l$, then return to step (v). If $m \geq l$, then go to the next step (viii).

(viii) Do steps (iii)–(vii) in the reverse direction of x, advancing from $x = 1$ to $x = p_{l+1}$. Identify the values and the discontinuity points of a on $[p_{l+1}, 1]$, and determine the corresponding functions $H_i(x)$.

(ix) Using the notation introduced in (vii) let $H_j(x)$ be the previously determined function H on interval $[p_{l-2}, p_{l-1}]$. Recenter it at $p = p_{l-1}$; i.e., $w(x) = H_j(x) = A\cos(\Omega_1(x - p_{l-1}) + \Gamma_1)$. Let $H_{j+1}(x)$ be the previously determined function H on interval $[p_{l+1}, p_{l+2}]$. Recenter it at p_{l+1}: $v(x) = H_{j+1}(x) = B\cos(\Omega_2(x - p_{l+1}) + \Gamma_2)$. If $\Omega_1 = \Omega_2$, then stop; otherwise, use Lemma 4.4 with $\eta = 2\delta$ and the above parameters to find the discontinuity $x_j \in [p_{l-1}, p_{l+1}]$. Stop.

Proof. To prove Theorem 4.6 we need to justify the marching algorithm and to show the uniqueness of the identification in each step.

(i) Using Theorem 2.3(vi) we get

$$z_m(t) = \sum_{k=1}^{\infty} g_k e^{-\lambda_k t} v_k(p_m), \quad m = 1, 2, \ldots, M-1, \quad 0 \leq T_1 < t < T_2, \tag{4.16}$$

where $g_k = \langle g, v_k \rangle$ for $k = 1, 2, \ldots$. By Theorem 2.3(iv) $v_1(x) > 0$ on interval $(0, 1)$. Since g is positive on $(0, 1)$ we conclude that $g_1 v_1(p_m) > 0$. According to Theorem 2.3(vii) each observation $z_m(t)$ is a real analytic function. Thus one can uniquely determine the nonzero coefficients in (4.16) and the corresponding exponents. In particular, one determines the first eigenvalue λ_1 and the values of

$$G_m = g_1 v_1(p_m) > 0, \quad p_m = m/M, \ m = 1, 2, \ldots, M-1. \tag{4.17}$$

Because of the zero boundary conditions we can let $G_0 = G_M = 0$. The crucial point is that the numbers $\{G_m\}_{m=1}^{M-1}$ are not arbitrary but are the values (up to a nonzero multiplicative constant g_1) of the still-undetermined eigenfunction v_1.

(ii) Let index l be defined as in (ii) of the marching algorithm. By Theorem 2.3(v) there exists a unique point q^* of maximum of v_1 on $(0,1)$. Note that $q^* \in (p_{l-1}, p_{l+1})$. Thus $G_{l+1} \le G_l$ and $G_m < G_l$ for $m > l+1$. Also $v_1'(p_m-) > 0$ for $m = 1, 2, \dots, l-1$ and $v_1'(p_m-) < 0$ for $m = l+1, l+2, \dots, M-1$.

(iii) Start at the left end point $p_0 = 0$ and work on interval $[0, x_1]$, where x_1 is the first discontinuity point of a.

(iv) Let $\delta = 1/M$. Since $\sigma \ge 3\delta$ and $a \in \mathcal{PC}(\sigma)$ we conclude that $[0, p_2) \subset [0, x_1)$ and $a = a_1$ on $[0, x_1)$. To apply Lemma 4.2 we just need to check the conditions for Q_1, Q_2, Q_3 required there.

We have $Q_1 = G_0 = 0,\ Q_2 = G_1 = g_1 v_1(p_1) > 0\ , Q_3 = G_2 = g_1 v_1(p_2) > 0$. Let

$$\omega_1 = \sqrt{\frac{\lambda_1}{a_1}}.$$

By Theorem 2.3(iii) $0 < \lambda_1 \le \mu\pi^2$. Since $0 < \nu \le a_1$ we have

$$0 < \omega_1\delta < \sqrt{\frac{\mu\pi^2}{\nu}}\frac{1}{2}\sqrt{\frac{\nu}{\mu}} = \frac{\pi}{2}.$$

This inequality and $v_1(x) > 0$ on $(0,1)$ imply that the first eigenfunction v_1 of (4.2) can be represented on $(0, x_1)$ as

$$v_1(x) = C_1 \cos(\omega_1(x - p_1) + \gamma_1)$$

for some $(C_1, \omega_1, \gamma_1) \in \Gamma$, where Γ was defined in Lemma 4.2.

Also $Q_1 + Q_3 = g_1 C_1(\cos(\omega_1\delta + \gamma_1) + \cos(\omega_1\delta - \gamma_1)) = 2g_1 C_1 \cos(\omega_1\delta)\cos\gamma_1 < 2G_1 = 2Q_2$ since $0 < \omega_1\delta < \pi/2$; hence $0 < \cos(\omega_1\delta) < 1$. Now Lemma 4.2 guarantees a unique solution of the system

$$\begin{cases} g_1 C_1 \cos(\omega_1\delta - \gamma_1) = G_0, \\ g_1 C_1 \cos\gamma_1 = G_1, \\ g_1 C_1 \cos(\omega_1\delta + \gamma_1) = G_2. \end{cases} \tag{4.18}$$

It also gives formulas for the computation of $A_1 = g_1 C_1$, γ_1, ω_1 from the known values of G_0, G_1, and G_2. Thus one can determine $a_1 = \lambda_1/\omega_1^2$ and obtain

$$H_1(x) = g_1 C_1 \cos(\omega_1(x - p_1) + \gamma_1) = g_1 v_1(x) \tag{4.19}$$

for $x \in [0, x_1)$.

(v) Let a_i be the value of a on the part of the interval $[p_{m+1}, p_{m+2})$ adjacent to $[p_{m+2}, p_{m+3})$. By construction this value and the associated function $H_i(x) = g_1 v_1(x)$ are already determined by the algorithm. If there is no discontinuity of a on interval $[p_{m+2}, p_{m+3})$, then a has the same value a_i on interval $[p_{m+2}, p_{m+3})$ as well. Therefore $H_i(x) = g_1 v_1(x)$ on this interval, and we must have $G_{m+3} = H_i(p_{m+3})$ by (4.17). If one has $G_{m+3} \ne H_i(p_{m+3})$, then the implication is that there is a discontinuity of a on $[p_{m+2}, p_{m+3})$, and one proceeds to step (vi).

On the other hand, if $G_{m+3} = H_i(p_{m+3})$, then one cannot, in general, conclude that there is no discontinuity of a on $[p_{m+2}, p_{m+3})$. However, since we have $m + 3 < l$

then (ii) of the proof implies that $v_1'(p_{m+3}-) > 0$. Then the assumption $a = a_i$ on $[p_{m+2}, p_{m+3})$ implies $H_i'(p_{m+3}) = g_1 v_1'(p_{m+3}-)$. Therefore the equality $G_{m+3} = H_i(p_{m+3})$ together with $H_i'(p_{m+3}) \le 0$ lead to a contradiction. The conclusion is that $G_{m+3} = H_i(p_{m+3})$ and $H_i'(p_{m+3}) \le 0$ imply a discontinuity of a on $[p_{m+2}, p_{m+3})$, and one proceeds to step (vi).

Finally, one uses Lemma 4.3 to conclude that $m+3 < l$, $G_{m+3} = H_i(p_{m+3})$, and $H_i'(p_{m+3}) > 0$ imply that there is no discontinuity of a on $[p_{m+2}, p_{m+3})$. Indeed, suppose that there is a discontinuity point x_i of a on interval $[p_{m+2}, p_{m+3})$. Then $a = a_i$ on $[p_{m+1}, x_i)$ and $a = a_{i+1}$ on $[x_i, p_{m+3}]$. We are going to use the notation x_i, Ω_1, Ω_2 for the corresponding variables x_1, ω_1, and ω_2 used in Lemma 4.3. Let $p = p_{m+2}$, $p + \delta = p_{m+3}$, $\Omega_1 = \sqrt{\lambda_1/a_i}$, $\Omega_2 = \sqrt{\lambda_1/a_{i+1}}$, and

$$w(x) = H_i(x) = g_1 v_1(x) = A_1 \cos \Omega_1 x + B_1 \sin \Omega_1 x, \quad x \in [p, x_i),$$
$$v(x) = g_1 v_1(x) = A_2 \cos \Omega_2 x + B_2 \sin \Omega_2 x, \quad x \in [x_i, p+\delta].$$

Note that the condition $\Omega_1^2 v'(x_i) = \Omega_2^2 w'(x_i)$ is just the matching condition (4.2) at $x = x_i$. Since $m+3 < l$, the maximum q^* of v_1 satisfies $q^* > p_{m+3}$. Because w is a positive multiple of v_1, it implies $w(x_i) > 0$ and $w'(x_i) > 0$. Therefore $v(x_i) > 0$ and $v'(x_i) > 0$. Because v is a positive multiple of v_1, we have $v'(p+\delta) > 0$. The condition $v(p+\delta) = w(p+\delta)$ means $v(p_{m+3}) = g_1 v_1(p_{m+3}) = G_m = H_i(p_{m+3}) = w(p_{m+3})$.

Suppose that $\Omega_1 < \Omega_2$. We have $v(p+\delta) = w(p+\delta)$ and $v'(p+\delta) > 0$. According to Lemma 4.3(i), this is impossible.

Suppose that $\Omega_1 > \Omega_2$. We have $v(p+\delta) = w(p+\delta)$ and $w'(p+\delta) = H_i'(p_{m+3}) > 0$. According to Lemma 4.3(ii), this is also impossible.

Thus the conclusion is that there is no point of discontinuity of a on $[p_{m+2}, p_{m+3})$ in this case. By assigning $m := m+1$ one advances to the next observation interval $[p_{m+3}, p_{m+4})$ and repeats the analysis of (v).

(vi) Since it is already determined that there is a discontinuity point on interval $[p_{m+2}, p_{m+3})$, the assumption $a \in \mathcal{PC}(\sigma)$ implies that a is constant on $[p_{m+3}, p_{m+5}]$. This value a_{i+1} of a can be uniquely determined from the system in (vi) similarly to the argument presented in (iv). Note that $H_{i+1}(x) = g_1 v_1(x)$ on $[p_{m+3}, p_{m+5}]$.

(vii) One knows that the discontinuity $x_i \in [p_{m+2}, p_{m+3})$ as well as the values a_i and a_{i+1} of a on the adjacent intervals $[p_{m+1}, p_{m+2}]$ and $[p_{m+3}, p_{m+4}]$ together with the corresponding functions $H_i(x)$ and $H_{i+1}(x)$. According to Lemma 4.4 one can determine the unique location of the discontinuity x_i by the formulas given there.

(viii) The advance of the algorithm from $x = 1$ to $x = p_{l+1}$ is justified by reducing it to (iii)–(vii) using the change of variables $z = 1 - x$.

(ix) Lemma 4.4 is applicable with $\eta = 2\delta$. Note that there can be only one discontinuity of a on $[p_{l-1}, p_{l+1}]$, since $2\delta < \sigma$. The values of a as well as the corresponding functions H_j and H_{j+1} are already known on the adjacent intervals. The discontinuity of a exists on $[p_{l-1}, p_{l+1})$ if $\omega_j \ne \omega_{j+1}$. □

The marching algorithm of Theorem 4.6 requires measurements of the system at a possibly large number of observation points. Our next theorem shows that if a piecewise constant conductivity a is known to have just one point of discontinuity x_1, and its values a_1 and a_2 are known beforehand, then the discontinuity point x_1 can be determined from just one measurement of the heat conduction process.

THEOREM 4.7. *Let $p \in (0,1)$ be an observation point, $g(x) > 0$ on $(0,1)$, and the observation $z_p(t) = u(x_p, t; a)$, $t \in (T_1, T_2)$, of the heat conduction process (4.1) be given. Suppose that the conductivity $a \in A_{\rm ad}$ is piecewise constant and has only one (unknown) point of discontinuity $x_1 \in (0,1)$. Given positive values $a_1 \ne a_2$ such that*

$a(x) = a_1$ for $0 \le x < x_1$ and $a(x) = a_2$ for $x_1 \le x < 1$, the point of discontinuity x_1 is constructively identifiable.

Proof. Arguing as in the previous theorem,

$$z_p(t) = \sum_{k=1}^{\infty} g_k e^{-\lambda_k t} v_k(p), \quad 0 \le T_1 < t < T_2,$$

where $g_k = \langle g, v_k \rangle$ for $k = 1, 2, \ldots$. Since $g_1 v_1(p) > 0$, the uniqueness of the Dirichlet series representation implies that one can uniquely determine the first eigenvalue λ_1 and the value of $G_p = g_1 v_1(p)$.

Without loss of generality one can assume that $a_1 > a_2$. In this case we show that the first eigenvalue λ_1 is strictly increasing as a function of $x_1 \in [0, 1]$. Indeed, suppose that

$$0 \le x_1^a < x_1^b \le 1;$$

that is,

$$a(x) = \begin{cases} a_1, & 0 < x < x_1^a \\ a_2, & x_1^a < x < 1 \end{cases} \quad \text{and} \quad b(x) = \begin{cases} a_1, & 0 < x < x_1^b \\ a_2, & x_1^b < x < 1. \end{cases}$$

By Theorem 2.3(i)

$$\lambda_1^b = \frac{\int_0^1 b(x)[v'_{1,b}(x)]^2 dx}{\int_0^1 [v_{1,b}(x)]^2 dx} > \frac{\int_0^1 a(x)[v'_{1,b}(x)]^2 dx}{\int_0^1 [v_{1,b}(x)]^2 dx} \ge \inf_{v \in H_0^1(0,1)} \frac{\int_0^1 a(x)[v'(x)]^2 dx}{\int_0^1 [v(x)]^2 dx} = \lambda_1^a$$

provided that the derivative $v'_{1,b}(x)$ of the first eigenfunction $v_{1,b}(x)$ is not identically zero on (x_1^a, x_1^b). But, from $(b(x)v'_{1,b}(x))' = -\lambda_1^b v_{1,b}(x)$, the assumption $v'_{1,b}(x) = 0$ on (x_1^a, x_1^b) implies $v_{1,b}(x) = 0$ on (x_1^a, x_1^b), and this is impossible, since $v_{1,b}(x) > 0$ on $(0, 1)$. Thus there exists a unique conductivity of the type sought in the theorem for which its first eigenvalue is equal to λ_1; i.e., a is identifiable.

Now the unique discontinuity point x_1 of a can be determined as follows. Let

$$\omega_1 = \sqrt{\frac{\lambda_1}{a_1}}, \quad \omega_2 = \sqrt{\frac{\lambda_1}{a_2}}.$$

Then the first eigenfunction v_1 is given by

$$v_1(x) = \begin{cases} A \sin \omega_1 x, & 0 < x < x_1, \\ B \sin \omega_2 (1 - x), & x_1 < x < 1, \end{cases} \tag{4.20}$$

for some $A, B > 0$. The matching conditions at x_1 give

$$A \sin \omega_1 x_1 = B \sin \omega_2 (1 - x_1) \quad \text{and} \quad \frac{A}{\omega_1} \cos \omega_1 x_1 = \frac{B}{\omega_2} \cos \omega_2 (1 - x_1).$$

Since $v_1(x_1) > 0$ we have $0 < \omega_1 x_1 < \pi$ and $0 < \omega_2(1 - x_1) < \pi$. Therefore x_1 satisfies

$$\frac{1}{\omega_1} \cot \omega_1 x = \frac{1}{\omega_2} \cot \omega_2 (1 - x).$$

The existence and the uniqueness of the solution x_1 of the above nonlinear equation follows from the monotonicity and the continuity of the cotangent functions. Practically, the value of x_1 can be found by a numerical method. ∎

5. Conclusions. The prevalent approach to parameter identification (estimation) problems is to find such parameters from the best fit to data minimization. However, such an approach usually does not guarantee the uniqueness of the identified parameters. The identifiability problem consists of finding sufficient conditions assuring such a uniqueness, and there have been just a few results for the identifiability in distributed parameter systems.

In this paper we have shown that in some cases a variable conductivity in a 1D heat conduction process can be uniquely identified from observations of this process. The identifiability has been established for two sets of observations. In one case it is assumed that the conductivity is piecewise smooth, and we are given a sequence of distributed observations of the form $z_n(t) = \langle u(x,t;a), \psi_n \rangle$ for $n = 1, 2, \ldots$ on a finite time interval, where functions $\{\psi_N\}_{n=1}^{\infty}$ form a basis in $H = L^2(0,1)$. An algorithm for the conductivity identification is proposed. Its numerical study will be reported elsewhere.

In the second case it is assumed that the conductivity is piecewise constant with sufficiently separated points of discontinuity. The observations of the process are taken at equidistant points $p_m \in (0,1)$. The total number of points needed for the unique conductivity identification can be computed from a priori known parameters of the process. A marching algorithm for the conductivity identification is presented and justified.

In both cases the plant does not require a special external input for its identifiability; i.e., it is modeled by $u_t = (au_x)_x$ rather than by $u_t = (au_x)_x + f(x,t)$. It will be of interest to extend the developed methods to vibration and steady-state processes.

Our current research shows that the methods described in this paper can be extended to identifiability problems for heat conduction processes admitting various boundary (e.g., periodic) inputs and to other cases. A numerical implementation shows that the marching algorithm achieves a perfect identification for observations with low noise levels. These results will be presented elsewhere.

AN ABELIAN LIMIT APPROACH TO A SINGULAR ERGODIC CONTROL PROBLEM*

ANANDA WEERASINGHE†

Abstract. We consider an ergodic stochastic control problem for a class of one-dimensional Itô processes where the available control is an added bounded variation process. The corresponding infinite horizon discounted control problem was solved in [A. Weerasinghe, *SIAM J. Control Optim.*, 44 (2005), pp. 389–417]. Here, we show that as the discount factor approaches zero, the optimal strategies derived in [A. Weerasinghe, *SIAM J. Control Optim.*, 44 (2005), pp. 389–417] "converge" to an optimal strategy for the ergodic control problem. Under different assumptions, two types of optimal strategies were derived. Also, the Abelian limit relationships among the ergodic control problem, the infinite horizon discounted control problem, and the finite time horizon control problem are established here. A solution to a constrained optimization problem is obtained as an application.

Key words. ergodic control, local-time processes, diffusions with reflecting boundaries

1. Introduction.

Consider a weak solution to the one-dimensional stochastic differential equation

$$X_x(t) = x + \int_0^t \mu(X_x(s-))ds + \int_0^t \sigma(X_x(s-))dW(s) + A(t), \tag{1.1}$$

where x is a real number, and $\{W(t) : t \geq 0\}$ is a standard Brownian motion adapted to a right continuous filtration $\{\mathfrak{F}_t : t \geq 0\}$ on a probability space $(\Omega, \mathfrak{F}, P)$. The σ-algebra $\mathfrak{F}_0$ contains all the null sets in $\mathfrak{F}$ and the Brownian increments $W(t+s)-W(t)$ are independent of $\mathfrak{F}_t$ for all $t \geq 0$ and $s \geq 0$. The control process $A(\cdot)$ is $\{\mathfrak{F}_t\}$-adapted, right continuous with left limits, and of bounded variation on finite time intervals. Also, $A(0) = 0$.

We further assume that there is a $\delta_0 > 0$ so that for each $X_x(\cdot)$ and $0 < \alpha < \delta_0$, there exists a sequence of stopping times (τ_n) satisfying $\lim_{n\to\infty} \tau_n = \infty$ and

$$\begin{aligned} &\text{(i)} \quad E_x \int_0^{T\wedge\tau_n} [|\mu(X_x(s-)| + \sigma^2(X_x(s-))]ds < \infty \text{ for each } T > 0, \text{ and} \\ &\text{(ii)} \quad \lim_{n\to\infty} E_x[|X_x(\tau_n)|e^{-\alpha\tau_n} I_{[\tau_n<\infty]}] = 0. \end{aligned} \tag{1.2}$$

The first condition helps us to make sense of (1.1) and the second condition will be used in verifying the Abelian limits described below. Throughout this article, we closely rely on several results obtained in [28], and the above two conditions imply the assumption (1.2) in [28].

The quintuple $((\Omega, \mathfrak{F}, P), (\mathfrak{F}_t), W, A, X_x)$ is called an admissible control system if the corresponding state process X_x satisfies (1.1) and (1.2). Let $\mathcal{U}$ denote the collection of all such admissible systems and let $C : \mathbf{R} \to \mathbf{R}$ be a running cost

function. We shall study the ergodic stochastic control problem with optimal value λ_0 defined by

$$\lambda_0 \triangleq \inf_{\mathcal{U}} \limsup_{T\to\infty} \frac{1}{T} E_x \int_0^T [C(X_x(s))ds + d|A|(s)]. \tag{1.3}$$

Notice that λ_0 is a constant which is independent of the initial value x, since an initial jump does not alter the above lim sup value for a given state process X_x.

Our goal here is to characterize an optimal control with a Markovian state process X that achieves the value λ_0 and to relate it to the value functions of the family of discounted control problems defined by

$$V_\alpha(x) \equiv \inf_{\mathcal{U}} E_x \int_0^\infty e^{-\alpha s}[C(X_x(s))ds + d|A|(s)], \tag{1.4}$$

as well as to the value functions of the family of finite horizon control problems

$$V_0(x,T) \equiv \inf_{\mathcal{U}} E_x \int_0^T [C(X_x(s))ds + d|A|(s)]. \tag{1.5}$$

It turns out that under the assumptions (1.6)–(1.8) below, $V_0(x,T)$ remains the same even when the infimum is taken over all processes $X_x(\cdot)$ which satisfy (1.1) together with the condition $E|X_x(t)| < \infty$ for each t in $[0,T]$. This is because we can extend such a process $X_x(\cdot)$ to $[0,\infty)$ as an admissible process by taking $A(t) \equiv 0$ for all $t > T$, and then using the results outlined in section 3 below.

Throughout this article, we make the basic assumptions (1.6), (1.7), and (1.8) below. Here μ', σ', and C' denote the derivatives of μ, σ, and C, respectively.

(1.6) (i) The functions μ and σ are continuously differentiable on $\mathbf{R}$, $\mu'(x) \le 0$ for all x, $\inf_{\mathbf{R}} \sigma(x) > 0$, and $x\mu(x) < 0$ for all $x \neq 0$.

(1.7) (ii) $$\int_{-\infty}^0 \frac{\mu(x)-x}{\sigma^2(x)}dx = \int_0^\infty \frac{x-\mu(x)}{\sigma^2(x)}dx = \infty.$$

(iii) The cost function C is continuously differentiable on $\mathbf{R}$, decreasing on $(-\infty,0)$, increasing on $(0,\infty)$, $C(0) = 0$, and satisfies one of the following conditions:

(1.8) either (a) $\liminf_{|x|\to\infty} \dfrac{C(x)}{|x|} > 0$ or (b) $\limsup_{|x|\to\infty} \dfrac{C(x)}{|x|} < \infty$.

The condition $C(0) = 0$ is made for convenience. If $C(0)$ is any other value, then it only shifts the value functions of (1.3)–(1.5) by an appropriate constant. The diffusion coefficient $\sigma(\cdot)$ is allowed to be an unbounded function subject to the above conditions (1.6) and (1.7).

Under assumption (1.6), the ordinary differential equation $\dot{x} = \mu(x)$ has a unique global, asymptotically stable equilibrium point at the origin. The cost function $C(\cdot)$ also has its unique minimum at the origin, and it increases as x moves away from the origin. Therefore, our study concerns the long term stability of a randomly perturbed stable dynamical system with a minimal control effort.

The qualitative nature of the optimal policies depends on the growth rates of $|\mu'(x)|$ and $|C'(x)|$. Therefore, we introduce a function H defined by

$$H(x) = \mu'(x) + |C'(x)| \qquad \text{for all } x \text{ in } \mathbf{R}. \tag{1.9}$$

The basic relationships among $\lambda_0, V_\alpha(x)$, and $V_0(x,T)$ are known as the "Abelian limit relations" (see [13]). These relations (which hold uniformly over the compact sets) are described by

$$\text{(a)} \quad \lim_{\alpha\to 0} \sup_{|x|\le K} |\alpha V_\alpha(x) - \lambda_0| = 0 \quad \text{and} \quad \text{(b)} \quad \lim_{T\to\infty} \sup_{|x|\le K} \left| \frac{V_0(x,T)}{T} - \lambda_0 \right| = 0 \tag{1.10}$$

for each $K > 0$.

We will establish these limits in this article. In an interesting article, Karatzas [13] derived optimal strategies for (1.3), (1.4), (1.5) and established the Abelian relations (1.10) when the drift coefficient μ is identically zero and the diffusion coefficient σ is a constant. In the symmetric case, where μ is an odd function and σ and C are even functions, an optimal strategy for (1.3) was obtained in [27]. In both of these articles, first a smooth solution to the corresponding Hamilton–Jacobi–Bellman (HJB) equation was obtained and then a verification lemma was used to prove the optimality of the chosen candidate for optimal control.

Here we develop a different approach. Using the properties of the value function $V_\alpha(x)$ of (1.4) derived in [28], we first establish that $\lim_{\alpha\to 0} \alpha V_\alpha(x)$ exists and is equal to a constant Λ_0, and we also show that $\Lambda_0 \le \lambda_0$, where λ_0 is the value of (1.3). Finally, to describe the derivation of an optimal strategy, let the initial point be at the origin. In this case, the optimal state process for $V_\alpha(0)$ derived in [28] induces a probability measure ν_α on $C[0,\infty)$. Under our assumptions, ν_α converges weakly (through a subsequence) to a probability measure ν_0 on $C[0,\infty)$ as α tends to zero. Thereafter, we derive an admissible strategy $((\Omega,\mathfrak{F},P),(\mathfrak{F}_t),W,A^*,X_0^*)$ in $\mathcal{U}$ so that the corresponding state process X_0^* induces the measure ν_0 on $C[0,\infty)$. It turned out that the corresponding value for the ergodic cost criteria is indeed Λ_0. Hence, Λ_0 is equal to the optimal value λ_0, and the above strategy $((\Omega,\mathfrak{F},P),(\mathfrak{F}_t),W,A^*,X_0^*)$ is optimal for (1.3). A complete solution to a constrained optimization problem is derived in section 6 by applying the results in section 4.

In [3], Arisawa and Lions considered an ergodic stochastic control problem in a compact state space. Hence, their cost function is bounded. In their model, there is no added bounded variation process, but the drift and diffusion coefficients are controlled. Their aim was to analyze the solution to the HJB equation and to establish the uniform convergence of the Abelian limits described in (1.10). But they did not derive any optimal strategies. This work complements their results and shows that uniform convergence on the compact sets for the Abelian limits in (1.10) is the best possible when the state space is noncompact.

In [16], the authors used a controlled martingale formulation for the cost structures in (1.3), (1.4), and (1.5) when there is no added bounded variation process. They related these problems with linear programming problems over a space of measures and proved the existence of optimal Markovian controls. Problem (1.4) is considered in [17] when the drift term is linear and the cost function is convex. There, the optimal control is a local-time process which is similar to our results in section 4. In a series of articles [1], [2], Alvarez considered singular control problems for diffusions with an absorbing barrier at the origin and with an added increasing control process.

He used the connection between stochastic control and optimal stopping to derive optimal strategies. In [8], the existence theorems for optimal policies for the ergodic control problem of multidimensional diffusions were developed. A higher-dimensional singular control problem for the standard Brownian motion was treated in [24]. For a discussion on singular control problems and related references, we refer to [11].

This article is organized as follows: Section 2 gathers the preliminary results regarding the value functions defined in (1.4) and (1.5). Our main theorem of section 3 is Theorem 3.1. It shows that under certain assumptions, zero control policy is optimal for the ergodic control problem (1.3). It also establishes the Abelian relation (1.10a). In section 4, under a different set of assumptions, we derive an optimal control policy which can be described in terms of local-time processes. The corresponding optimal state process is a reflecting diffusion on a finite interval. We also establish the limit (1.10a) for this case. Section 5 is devoted to the proof of the Abelian limit (1.10b). We apply the results obtained in section 4 to find an optimal policy for a constrained minimization problem in section 6. The main results in this article are Theorems 3.1, 4.1, 5.1, and 6.3. Next, we describe a motivating example from finance.

Example 1 (foreign exchange rates). Consider the currency exchange rate that governs the transactions between two countries (which we label as "domestic" and "foreign"). We assume that the economies of both countries are stable. Hence, in the absence of interventions, the currency exchange rate resembles a dynamical system which fluctuates around a stable equilibrium point. In the presence of uncertainty, it is common practice to model currency exchange rates using stochastic differential equations (see Chapter 7 of [21] and also [10], [12], [15], [19], [20], [25], [26]). Here we consider the problem of a central bank which would like to keep the exchange rate as close as possible to a target value through minimal intervention.

In a pioneering work [15], Krugman introduced a model where the exchange rate takes values in an exogenously given target interval, which is commonly called the "target zone" or the "target band." In recent years, exchange rate target zones have been an area of intense research activity in finance [10], [12], [19], [20], [25], [26]. When the exchange rate is high, the central bank may intervene by reducing the money supply by selling the foreign currency reserves or by adjusting the domestic interest rates. The central bank may also intervene appropriately when the exchange rate is low. To keep the exchange rate within the target band, the central bank may intervene while the exchange rate is still within the target band and there is empirical evidence to support this claim [7]. Such an optimal intervention policy with jumps within the target band is derived for a target zone exchange rate model using impulse controls in [12].

For a detailed discussion of Krugman's model, its underlying assumptions, its implications and drawbacks, and for modifications to accompany empirical data, we refer to [26]. One important prediction of Krugman's original model is that the long term distribution of the logarithm of the exchange rate within the target band must be U-shaped. This implies that in the long run, the logarithm of the exchange rate must spend most of its time near the end points of the target band. However, empirical data rejected this fact, and, as described in [26], there is a "hump"-shaped distribution within the band. In a detailed discussion about an extension of Krugman's model to agree with data, Svensson [26] pointed out that the logarithm of the exchange rate within the target band displays a "mean reversion behavior," and this is an important property of target zone exchange rates. This property also supports the "hump"-shaped long run distribution of the logarithm of the exchange rate.

In [20], a discrete impulse control intervention coupled with a continuous domestic interest rate control policy is used to derive an optimal target band. In [10], a similar problem for a geometric Brownian motion with a cost function $C(x) = x^2$ is considered. The authors also allow a fixed cost and a cost proportional to the size of the intervention. They derive an optimal intervention policy and the explicit form of the value function.

In this model, we consider a target value or a benchmark for the exchange rate which we simply assume to be at 1. The controlled state process $X_x(\cdot)$ represents the logarithm of the exchange rate. The central bank would like to keep the $X_x(\cdot)$ process near the origin. Here, there is no a priori assigned target band. We assume that $X_x(\cdot)$ satisfies (1.1) and the drift and diffusion coefficients μ and σ satisfy (1.6) and (1.7). Hence, $X_x(\cdot)$ clearly shows the mean reversion behavior around the origin as observed in [26]. The bounded variation control process $A(\cdot)$ represents the changes in the exchange rate due to central bank interventions. The corresponding total variation process $|A|(\cdot)$ represents the cumulative cost incurred by the central bank interventions. There is also a running cost associated with the deviation of the exchange rate from its benchmark, and this running cost function satisfies the assumption (1.8).

With our model, the central bank would like to know the answers to the following two important questions:

1. What optimal intervention policy will minimize the long term average cost criteria? Furthermore, to what extent will such an optimal intervention policy verify the validity of a target band for the exchange rate?

2. Suppose that the central bank insists on the intervention policy not to exceed the long term average intervention cost above a given target value $m > 0$ (i.e., $\limsup_{T\to\infty} \frac{E|A|(T)}{T} \le m$). What would be an optimal intervention policy which minimizes the long term average running cost $\limsup_{T\to\infty} \frac{1}{T} E \int_0^T C(X_x(s))ds$? Under what conditions on μ, σ, and $C(\cdot)$ does this constrained problem lead to a target zone model?

Sections 3 and 4 provide answers to question 1. Question 2 will be analyzed in section 6. In section 3, we derive a set of sufficient conditions for the optimality of zero intervention policy. Hence, there is no optimal target band under these conditions. With a different set of assumptions on μ, σ, and C, we prove the existence of an optimal target band in section 4. We also derive an optimal intervention policy. In section 6, under the given constraint on the long term average intervention rate, we provide an optimal target band and also an optimal intervention policy.

2. Preliminaries. Here we develop some results related to the value functions of the control problems in (1.3), (1.4), and (1.5). They will be important in establishing Abelian limits in (1.10). Throughout this section, we assume the conditions (1.6), (1.7), and (1.8).

PROPOSITION 2.1. *Let $\lambda_0, V_\alpha(x)$, and $V_0(x,T)$ be as in* (1.3), (1.4), *and* (1.5). *Then the following hold:*

(i) *For each $T > 0$ and $0 < \alpha < \delta_0$, the quantities $\lambda_0, V_\alpha(x)$, and $V_0(x,T)$ are finite. Also, for each $K > 0$, there is a constant M_K so that*

$$\sup_{0<\alpha<\delta_0} \sup_{|x|\le K} \alpha V_\alpha(x) \le M_K.$$

(ii) *For each $T > 0$, $0 < \alpha < \delta_0$, and x, y in $\mathbf{R}$, $|V_\alpha(x,T) - V_\alpha(y,T)| \le |x-y|$ and $|V_\alpha(x) - V_\alpha(y)| \le |x-y|$.*

(iii) $\limsup_{\alpha\to 0} \alpha V_\alpha(x) \le \lambda_0$ *and* $\limsup_{T\to\infty} \frac{1}{T} V_0(x,T) \le \lambda_0$, *where* λ_0 *is the value of the ergodic control problem* (1.3).

Proof. Given $K > 0$ and $|x| < K$, we pick an interval $[a,b]$ so that $a < -K < K < b$. Consider the reflected diffusion process on $[a,b]$, which is given by

$$X_x(t) = x + \int_0^t \mu(X_x(s))ds + \int_0^t \sigma(X_x(s))dW(s) + L_a(t) - L_b(t). \tag{2.1}$$

Here L_a and L_b are local-time processes of X_x at a and b, respectively. In comparison with (1.1), $A(t) = L_a(t) - L_b(t)$ and $|A|(t) = L_a(t) + L_b(t)$ for all $t \ge 0$. Consider the solution to the differential equation

$$\begin{aligned} \frac{\sigma^2(x)}{2} Q''(x) + \mu(x)Q'(x) &= \gamma \quad \text{for all } x \text{ in } (a,b), \\ Q'(a) = -1 \quad &\text{and} \quad Q'(b) = 1, \end{aligned} \tag{2.2}$$

where $\gamma > 0$ is a constant which will be chosen appropriately. Notice that (2.2) is a first order equation in $Q'(\cdot)$, and it can be solved using the boundary condition $Q'(a) = -1$. Then, for each x in $[a,b]$, we obtain

$$Q'(x)e^{2\int_0^x \rho(u)du} + e^{-2\int_a^0 \rho(u)du} = \gamma \int_a^x \frac{2}{\sigma^2(y)} e^{2\int_0^y \rho(u)du} dy.$$

In the above equation, $\rho(x) = \frac{\mu(x)}{\sigma^2(x)}$ for all x in $[a,b]$. Now we choose the positive constant γ so that it satisfies

$$\gamma \int_a^b \frac{2}{\sigma^2(y)} e^{2\int_0^y \rho(u)du} dy = e^{2\int_0^b \rho(u)du} + e^{-2\int_a^0 \rho(u)du}; \tag{2.3}$$

then it enforces $Q'(\cdot)$ to satisfy the other boundary condition $Q'(b) = 1$ in (2.2). The solution to (2.2) is unique up to a constant and we consider the solution

$$Q(x) = \int_a^x u(y)dy,$$

where

$$u(x) = e^{-2\int_0^x \rho(u)du} \left[\gamma \int_a^x \frac{2}{\sigma^2(y)} e^{2\int_0^y \rho(u)du} dy - e^{-2\int_a^0 \rho(u)du} \right].$$

Here the constant γ satisfies (2.3). Next, we apply Itô's lemma to $Q(X_x(t))$ and obtain

$$E|A|(T) = E[L_a(T) + L_b(T)] = \gamma T + Q(x) - E[Q(X_x(T))]. \tag{2.4}$$

At this point, using (2.3) together with (2.4), we can derive the following limit (independent of the initial point x):

$$\lim_{T\to\infty} \frac{E|A|(T)}{T} = \gamma = \frac{e^{2\int_0^b \rho(u)du} + e^{-2\int_a^0 \rho(u)du}}{\int_a^b \frac{2}{\sigma^2(y)} e^{2\int_0^y \rho(u)du} dy}, \tag{2.5}$$

which will be used in section 6.

Let $M_1 > 0$ be a constant so that

$$\sup_{[a.b]} [|C(x)| + |Q(x)|] < M_1. \tag{2.6}$$

This combined with (2.4) yields $E|A|(T) < \gamma T + 2M_1$. Therefore, we can conclude $V_0(x,T) \leq (M_1+\gamma)T + 2M_1$ and $\lambda_0 \leq \limsup_{T\to\infty} \frac{1}{T} E\int_0^T [C(X_x(s))ds + d|A|(s)] \leq (M_1+\gamma)$. Consequently, $V_0(x,T)$ and λ_0 are finite. Next, by (1.4), we have the inequality

$$V_\alpha(x) \leq E\int_0^\infty e^{-\alpha t}[C(X_x(s))ds + d|A|(s)] \leq \frac{M_1}{\alpha} + E\int_0^\infty e^{-\alpha t} d|A|(t).$$

Hence, using integration by parts and the estimate for $E|A|(T)$, we obtain

$$V_\alpha(x) \leq \frac{M_1}{\alpha} + \alpha\int_0^\infty e^{-\alpha t}(\gamma t + 2M_1)dt \leq \frac{M_1}{\alpha} + \frac{\gamma}{\alpha} + 2M_1.$$

Consequently, $V_\alpha(x)$ is also finite and the following uniform estimate holds:

$$\sup_{0<\alpha<\delta_0} \sup_{[a,b]} \alpha V_\alpha(x) \leq M_0 \equiv (M_1 + \gamma + 2M_1\delta_0).$$

Hence, part (i) follows.

For any admissible process X_x, introduce the cost functional

$$J(x, X_x, T) = E\int_0^T [C(X_x(t))dt + d|A|(t)].$$

For a given $\epsilon > 0$ and any $T > 0$, we pick a process X_x so that $V_0(x,T) + \epsilon > J(x, X_x, T)$. Then for any y, consider the process $\tilde{X}_y(0-) = y$ and with an initial jump to the point x so that $\tilde{X}_y(0) = x$. Thereafter it satisfies $\tilde{X}_y(t) \equiv X_x(t)$ for all $t > 0$. Hence we observe that $J(y, \tilde{X}_y, T) = |x-y| + J(x, X_x, T)$ and consequently $V_0(y,T) < |x-y| + J(x, X_x, T) < |x-y| + V_0(x,T) + \epsilon$.

Since ϵ is arbitrary and x and y are arbitrary points, we obtain

$$|V_0(x,T) - V_0(y,T)| \leq |x-y|. \tag{2.7}$$

By Theorems 4.3 and 5.5 of [28], V_α satisfies $|V'_\alpha(x)| \leq 1$ for all x and hence $|V_\alpha(x) - V_\alpha(y)| \leq |x-y|$. Thus, part (ii) follows.

To prove part (iii), we can alter an argument from classical analysis (see [23, p. 107]). We pick any constant K_1 so that $K_1 > \lambda_0$. Then there is an admissible process $X_x(.)$ so that

$$\limsup_{T\to\infty} \frac{J(x, X_x, T)}{T} < K_1. \tag{2.8}$$

Introduce a Borel measure ν on $[0,\infty)$, induced by the distribution function F, where F is defined by $F(T) = J(x, X_x, T)$ for all $T > 0$. Hence, $\nu([0,T]) = F(T)$ for all $T > 0$. Also, introduce the function G on $[0,\infty)$ by $G(T) = \frac{F(T)}{T+1}$ for $T > 0$. Therefore,

$$\begin{aligned} \alpha\int_0^\infty e^{-\alpha t} d\nu(t) &= \alpha^2\int_0^\infty e^{-\alpha t} F(t)dt \qquad \text{(by integration by parts)} \\ &= \alpha^2\int_0^\infty e^{-\alpha t}(t+1)G(t)dt = \int_0^\infty e^{-y}(y+\alpha)G\left(\frac{y}{\alpha}\right)dy. \end{aligned} \tag{2.9}$$

By (2.8), $G(t) < K_1$ for all $t > T_0 > 1$ and $||G||_\infty = \sup_{[0,\infty)} |G(t)| < \infty$. Hence, by (2.9),

$$\begin{aligned}
\alpha V_\alpha(x) &= \alpha \int_0^\infty e^{-\alpha t} d\nu(t) \\
&= \int_0^{\alpha T_0} e^{-y}(y+\alpha) G\left(\frac{y}{\alpha}\right) dy + \int_{\alpha T_0}^\infty e^{-y}(y+\alpha) G\left(\frac{y}{\alpha}\right) dy \\
&< \alpha^2 (T_0^2 + T_0)||G||_\infty + K_1 \int_0^\infty e^{-y}(y+\alpha) dy \\
&< \alpha^2 (T_0^2 + T_0)||G||_\infty + K_1(1+\alpha).
\end{aligned}$$

Consequently, $\limsup_{\alpha \to 0} \alpha V_\alpha(x) \le K_1$. Since $K_1 > \lambda_0$ is arbitrary this implies that $\limsup_{\alpha \to 0} \alpha V_\alpha(x) \le \lambda_0$. Next $V_0(x,T) \le F(T)$ for all $T > 0$ and by (2.8), we obtain $\limsup_{T\to\infty} \frac{V_0(x,T)}{T} \le \limsup_{T\to\infty} \frac{F(T)}{T} < K_1$. But $K_1 > \lambda_0$ is arbitrary. Hence $\limsup_{T\to\infty} \frac{V_0(x,T)}{T} \le \lambda_0$ and the proof of part (iii) is complete. □

3. Optimality of the zero control. First we introduce the state process $Z_x(\cdot)$ which corresponds to zero control policy, namely, $A(t) \equiv 0$ for all t in (1.1). Let $Z_x(\cdot)$ be a weak solution (see [14]) to

$$Z_x(t) = x + \int_0^t \mu(Z_x(s)) ds + \int_0^t \sigma(Z_x(s)) dW(s), \tag{3.1}$$

where $W(t)$ is a one-dimensional Brownian motion. The existence of $Z_x(t)$ for all $t \ge 0$ and the finiteness of the first moment $E|Z_x(t)|$ for each $t \ge 0$ are obtained in section 4 of [28] (see also Chapter 5, Theorem 5.15 in [14]). The main theorem in this section is the following.

THEOREM 3.1. *Assume* (1.6), (1.7), (1.8) *and that* $H(x) \le 0$ *for all* x, *where* H *is given in* (1.9). *Then the following hold:*

(i) $\lim_{\alpha \to 0} \alpha V_\alpha(x) = \Lambda_0$ *exists, where* Λ_0 *is a constant. Moreover, this limit converges uniformly over compact sets.*

(ii) *The process* $Z_x(.)$ *of* (3.1) *is an optimal process which corresponds to the zero control policy for the ergodic control problem in* (1.3). *Its value* $\lambda_0 = \Lambda_0$, *where* Λ_0 *is the limit in part* (i).

This theorem implies that under the above set of assumptions, there is no optimal target band for the exchange rates related to question 1 of our example on foreign exchange rates in section 1. Furthermore, an optimal policy for the central bank is not to intervene at all.

To prove this theorem, first we describe some results related to the value function $V_\alpha(x)$, which were developed in sections 3 and 4 of [28]. Let $Y(\cdot)$ be the weak solution to

$$Y(T) = x + \int_0^T [\sigma(Y(t))\sigma'(Y(t)) + \mu(Y(t))] dt + \int_0^T \sigma(Y(t)) dB(t), \tag{3.2}$$

where $\{B(t) : t \ge 0\}$ is a Brownian motion. The existence and uniqueness of a weak solution to (3.2) follows from Theorem 5.15 of Chapter 5 in [14]. This process was also introduced in (3.1) of [28]. Next we consider the function W_∞ introduced in

Lemma 4.2 of [28] and relabel it as W_α to specify its dependence on α. Then, by Lemma 4.2 of [28], $W_\alpha(x)$ has the stochastic representation

$$W_\alpha(x) = E_x \int_0^{\tau_\infty} e^{-\int_0^t (\alpha - \mu'(Y(s)))ds} C'(Y(t))dt, \tag{3.3}$$

where τ_∞ is the explosion time of the $Y(\cdot)$ process. Next, the assumption $H(x) \leq 0$ for all x implies that $|C'(x)| < (\alpha - \mu'(x))$ for all x. Using this estimate in (3.3), we obtain $|W_\alpha(x)| < 1$ for all x. Furthermore, as in Lemma 4.2 of [28], W_α satisfies

$$\frac{\sigma^2(x)}{2} W''_\alpha(x) + (\sigma(x)\sigma'(x) + \mu(x))W'_\alpha(x) - (\alpha - \mu'(x))W_\alpha(x) + C'(x) = 0 \tag{3.4}$$

for all x and $|W_\alpha(x)| < 1$ for all x. Theorem 4.3 of [28] also implies the following representation for the value function V_α:

$$V_\alpha(x) = \frac{\sigma^2(0)}{2\alpha} W'_\alpha(0) + \int_0^x W_\alpha(u)du. \tag{3.5}$$

Next, we prove a technical lemma.

LEMMA 3.2. *Let W_α be as in* (3.3) *above. Then the following results hold.*

(i) $\lim_{\alpha \to 0} W_\alpha(x)$ *exists for all x. Let $W_0(x) \triangleq \lim_{\alpha \to 0} W_\alpha(x)$; then $W_0(x)$ has the stochastic representation*

$$W_0(x) = E_x \int_0^{\tau_\infty} e^{\int_0^t \mu'(Y(s))ds} C'(Y(t))dt. \tag{3.6}$$

(ii) $W_0(\cdot)$ *also satisfies*

$$\frac{\sigma^2(x)}{2} W''_0(x) + (\sigma(x)\sigma'(x) + \mu(x))W'_0(x) + \mu'(x)W_0(x) + C'(x) = 0 \tag{3.7}$$

and $|W_0(x)| \leq 1$ for all x.

(iii)

$$\lim_{\alpha \to 0} W'_\alpha(0) = W'_0(0). \tag{3.8}$$

Proof. Consider the representation (3.3) for W_α. Since $H(x) \leq 0$ for all x, we obtain

$$|C'(Y(t))|e^{-\int_0^t (\alpha - \mu'(Y(s)))ds} \leq -\mu'(Y(t)) \cdot e^{-\int_0^t (\alpha - \mu'(Y(s)))ds}.$$

Notice that $-\int_0^{\tau_\infty} e^{\int_0^t \mu'(Y(s))ds} \cdot \mu'(Y(t))dt = 1 - e^{\int_0^{\tau_\infty} \mu'(Y(s))ds} \leq 1$. Now using (3.3) and the dominated convergence theorem, it follows that $\lim_{\alpha \to 0} W_\alpha(x) \equiv W_0(x)$ exists and W_0 has the representation (3.6). Hence, part (i) follows.

Next, we integrate (3.4) twice and obtain

$$\frac{\sigma^2(0)}{2} \cdot W'_\alpha(0) \cdot \int_0^x \frac{2}{\sigma^2(r)} dr = W_\alpha(x) - W_\alpha(0) + 2\int_0^x \frac{\mu(r)}{\sigma^2(r)} \cdot W_\alpha(r)dr + 2\int_0^x \frac{C(r)}{\sigma^2(r)} dr - 2\alpha \int_0^x \int_0^r \frac{W_\alpha(u)}{\sigma^2(u)} dudr.$$

Since $\lim_{\alpha\to 0} W_\alpha(x) \equiv W_0(x)$ exists and $|W_\alpha(x)| < 1$ for all x, we obtain that the right-hand side of the above equation converges as α tends to zero and $|W_0(x)| \le 1$ for all x. Therefore, $\lim_{\alpha\to 0} W'_\alpha(0)$ exists and we label it β. Hence,

$$\frac{\sigma^2(0)}{2} \cdot \beta \cdot \int_0^x \frac{2}{\sigma^2(r)} dr = W_0(x) - W_0(0) + \int_0^x \frac{2\mu(r)}{\sigma^2(r)} \cdot W_0(r) dr + \int_0^x \frac{2C(r)}{\sigma^2(r)} dr.$$

By differentiating this equation, we obtain $W'_0(0) = \beta$ and W_0 satisfies the differential equation (3.7). Hence, the proofs of parts (ii) and (iii) are complete. □

Now we are ready to prove Theorem 3.1.

Proof of Theorem 3.1. By (3.5), we can write

$$\alpha V_\alpha(x) = \Lambda_\alpha + \alpha \int_0^x W_\alpha(u) du \tag{3.9}$$

for all x, where

$$\Lambda_\alpha = \frac{\sigma^2(0)}{2} W'_\alpha(0). \tag{3.10}$$

Next, we let

$$\Lambda_0 = \frac{\sigma^2(0)}{2} W'_0(0). \tag{3.11}$$

Using part (iii) of Lemma 3.2, we have $\lim_{\alpha\to 0} \Lambda_\alpha = \Lambda_0$. Since $|W_\alpha(x)| < 1$ for all x, using (3.9) we obtain $|\alpha V_\alpha(x) - \Lambda_0| \le |\Lambda_\alpha - \Lambda_0| + \alpha|x|$. Then $\lim_{\alpha\to 0} \alpha V_\alpha(x) = \Lambda_0$ and the convergence is uniform on compact sets. Thus, the proof of part (i) is complete.

To prove part (ii), we consider the process $Z_x(\cdot)$ in (3.1) and first show that $\limsup_{T\to\infty} \frac{1}{T} E \int_0^T C(Z_x(t)) dt = \Lambda_0$. Under the assumptions of this section, the $Z_x(\cdot)$ process is also optimal for the discounted control problem (1.4) as shown in [28]. Hence,

$$V_\alpha(x) = E \int_0^\infty e^{-\alpha t} C(Z_x(t)) dt = \int_0^\infty e^{-\alpha t} E[C(Z_x(t))] dt.$$

Now we can apply the classical Abelian limit theorem [23, p. 117] to obtain

$$\lim_{\alpha\to 0} \alpha V_\alpha(x) = \lim_{T\to\infty} \frac{1}{T} E \int_0^T C(Z_x(t)) dt.$$

This theorem also guarantees the existence of the ergodic limit on the right-hand side of the above equation. Consequently, $\lim_{T\to\infty} \frac{1}{T} E \int_0^T C(Z_x(t)) dt = \Lambda_0$. By part (iii) of Proposition 2.1, we know that $\Lambda_0 \le \lambda_0$, where λ_0 is the value of (1.3). Therefore, we can conclude $Z_x(\cdot)$ is an optimal process for (1.3) and $\lim_{\alpha\to 0} \alpha V_\alpha(x) = \Lambda_0 = \lambda_0$. This completes the proof. □

Remarks.

1. It should be noted that if the process $Z_x(\cdot)$ has a stationary distribution π, then the limit Λ_0 is equal to $\int_{-\infty}^{\infty} C(y)\pi(dy)$.

2. Under the assumptions of Theorem 3.1, one can show that the process $Z_x(\cdot)$ is also optimal for the finite-horizon problem with the value function $V_0(x, T)$ in (1.5). Here we sketch the proof.

Let $Q(x,T) = E\int_0^T C(Z_x(t))dt$ be the payoff from $Z_x(\cdot)$ in (3.1), which corresponds to zero control. Then Q satisfies $\frac{\sigma^2(x)}{2}Q_{xx} + \mu(x)Q_x + C(x) = Q_t$ for all x and $t > 0$. Also, $Q(x,0) = 0$. Now let $U(x,T) = Q_x(x,T)$; then U satisfies

$$\frac{\sigma^2(x)}{2}U_{xx} + (\sigma(x)\sigma'(x) + \mu(x))U_x + \mu'(x)U + C'(x) = U_t$$

for all x and $t > 0$, and $U(x,0) = 0$. By Itô's lemma (with the same notation as in (3.6)), U has the stochastic representation

$$U(x,T) = E\int_0^{\tau_\infty \wedge T} e^{\int_0^t \mu'(Y(s))ds} C'(Y(t))dt.$$

Thus, as in the proof of Theorem 3.1, $|U(x,T)| \le 1$ since $H(x) \le 0$. Now, for any given process $X_x(\cdot)$, by applying Itô's lemma to $Q(X_x(t), T-t)$, we obtain

$$Q(x,T) \le E\int_0^T [C(X_x(s))ds + d|A|(s)].$$

Hence, $Q(x,T) = V_0(X,T)$ and $Z_x(\cdot)$ is optimal for the finite time horizon problem (1.5).

4. Optimality of a reflected diffusion. In this section, we assume the following conditions (4.1) and (4.2) in addition to the basic assumptions (1.6)–(1.8). Let the function H be as in (1.9). We assume the existence of a constant $\alpha_0 > 0$ which satisfies the following:

(4.1) (i) For each $0 \le \alpha < \alpha_0$, there exist two points $\theta_\alpha < 0 < \beta_\alpha$ so that $H(x) > \alpha$ outside $[\theta_\alpha, \beta_\alpha]$. Furthermore, if $\alpha > 0$, then $H(x) < \alpha$ in $(\theta_\alpha, \beta_\alpha)$. Finally, if $\alpha = 0$, then $\{x : H(x) \le 0\} = [\theta_0, \beta_0]$.

(4.2) (ii) For each $0 < \alpha < \alpha_0$, there are two constants $\epsilon_\alpha > 0$ and $M_\alpha > 0$ so that $H(x) + \epsilon_\alpha\mu'(x) > (1+\epsilon_\alpha)\alpha$ for all $|x| > M_\alpha$.

Remarks.

1. Without loss of generality, we assume that $\alpha_0 < \delta_0$, where δ_0 is given in (1.2).
2. By (4.1), $H(0) \le 0$ and $\theta_\alpha \le \theta_0 < 0 < \beta_0 \le \beta_\alpha$ for each $0 \le \alpha < \alpha_0$.
3. By (4.2), it follows that $\lim_{x\to\infty} C(x) + \mu(x) = +\infty$ and $\lim_{x\to-\infty} C(x) - \mu(x) = +\infty$.
4. For each α in $(0, \alpha_0)$, the above assumptions imply those of section 5 in [28], and hence we can use the results related to $V_\alpha(x)$ in there.

Our main theorem in this section is the following.

THEOREM 4.1. *Assume* (4.1) *and* (4.2), *in addition to the basic assumptions* (1.6)–(1.8). *Then the following hold:*

(i) $\lim_{\alpha\to 0} \sup_{|x|\le K} |\alpha V_\alpha(x) - \lambda_0| = 0$ *for each* $K > 0$.

(ii) *There exist two points* a^* *and* b^* *so that the corresponding reflected diffusion process on the state space* $[a^*, b^*]$ *(if the initial point is outside this interval, then there will be an initial jump to the nearest point of the interval) is an optimal state process for the ergodic control problem* (1.3). *Hence the optimal control policy here is given by the difference of two local-time processes at* a^* *and* b^*.

This theorem verifies the existence of an optimal target band for our example on exchange rates in section 1 under the above set of assumptions. In this case, the optimal intervention policy of the central bank involves local-time processes of the exchange rate as described in the above theorem.

First we gather the necessary technical results in Lemma 4.2.

LEMMA 4.2. *Assume the same assumptions as in Theorem* 4.1. *Let* l_0 *be any limit point of the set* $\{\alpha V_\alpha(0)\}$ *as* α *tends to zero. Then there exist two points* a^*, b^* *and a continuously differentiable function* W_0 *defined on* $\mathbf{R}$ *satisfying the following conditions:*

(i) $-\infty < a^* \le \theta_0 < \beta_0 \le b^* < +\infty$, *where* θ_0 *and* β_0 *are given in* (4.1).

(ii) W_0 *satisfies* $\frac{\sigma^2(x)}{2} W_0'(x) + \mu(x) W_0(x) + C(x) = l_0$ *for* $a^* < x < b^*$.

(iii) $W_0(x) = -1$ *for all* $x \le a^*$, $W_0(x) = +1$ *for all* $x \ge b^*$, *and* $|W_0(x)| \le 1$ *for all* x.

(iv) *The value of* l_0 *can be identified by the formula*

$$l_0 = \frac{e^{2\int_0^{b^*} \rho(u)du} + e^{-2\int_{a^*}^0 \rho(u)du}}{2D} + \int_{a^*}^{b^*} C(u)\phi(u)du,$$

where $D = \int_{a^*}^{b^*} \frac{1}{\sigma^2(x)} e^{2\int_0^x \rho(u)du} dx$, $\rho(x) = \frac{\mu(x)}{\sigma^2(x)}$ *on* $[a^*, b^*]$, *and the density function* ϕ *is given by* $\phi(x) = \frac{1}{D}\frac{1}{\sigma^2(x)} e^{2\int_0^x \rho(u)du}$ *on* $[a^*, b^*]$.

Proof. Using [28, Proposition 5.4, (5.28), and Theorem 5.5], we obtain the following representation for the value function V_α: $V_\alpha(x) = V_\alpha(0) + \int_0^x W_\alpha(u)du$. Here, we write W_α for the function W in [28, Proposition 5.4] to represent the dependence on α. We also observe that

$$V_\alpha(x) = \frac{\sigma^2(0)}{2\alpha} W_\alpha'(0) + \int_0^x W_\alpha(u)du. \tag{4.3}$$

Furthermore, by [28, Proposition 5.4 and Theorem 5.5], for each α, there exist two points a_α^*, b_α^* and a C^1 function W_α so that $a_\alpha^* < \theta_0 < \beta_0 < b_\alpha^*$ and W_α satisfies

$$\frac{\sigma^2(x)}{2} W_\alpha''(x) + (\sigma(x)\sigma'(x) + \mu(x)) W_\alpha'(x) - (\alpha - \mu'(x)) W_\alpha(x) + C'(x) = 0 \tag{4.4}$$

for $a_\alpha^* < x < b_\alpha^*$. Also,

$$W_\alpha(a_\alpha^*) = -1, \quad W_\alpha(b_\alpha^*) = 1, \quad |W_\alpha(x)| < 1 \text{ on } (a_\alpha^*, b_\alpha^*), \tag{4.5}$$

and

$$\begin{aligned} W_\alpha'(a_\alpha^*) = W_\alpha'(b_\alpha^*) = 0, \quad W_\alpha(x) = -1 \text{ for } x \le a_\alpha^*, \\ W_\alpha(x) = 1 \text{ for } x \ge b_\alpha^*. \end{aligned} \tag{4.6}$$

This solution W_α was obtained in [28] by deriving a solution to an optimal stopping problem. For details, we refer to [28]. Now consider the limit point l_0 of the set $\{\alpha V_\alpha(0)\}$ as α tends to zero. Then there is a decreasing sequence $\{\alpha_n\}$ so that $\lim_{n\to\infty} \alpha_n = 0$ and $\lim_{n\to\infty} \alpha_n V_{\alpha_n}(0) = l_0$. By part (iii) of Proposition 2.1, it follows that $l_0 \le \lambda_0$. Hence, there is a constant $C_0 > 0$ so that $0 < \alpha_n V_{\alpha_n}(0) < C_0$ for all n. Notice that $[\theta_0, \beta_0] \subseteq [a_{\alpha_n}^*, b_{\alpha_n}^*]$. We intend to show that there is a finite $K > 0$

so that $[a^*_{\alpha_n}, b^*_{\alpha_n}] \subseteq [-K, K]$ for all α_n. Next, by integrating (4.4) over $[0, b^*_{\alpha_n}]$, we obtain

$$C(b^*_{\alpha_n}) + \mu(b^*_{\alpha_n}) - \frac{\sigma^2(0)}{2} W'_{\alpha_n}(0) = \alpha_n \int_0^{b^*_{\alpha_n}} W_{\alpha_n}(x)dx < \alpha_n b^*_{\alpha_n}.$$

Hence,

$$\begin{aligned} \int_0^{b^*_{\alpha_n}} [H(x) - \alpha_n]dx &= C(b^*_{\alpha_n}) + \mu(b^*_{\alpha_n}) - \alpha_n b^*_{\alpha_n} \\ &< \frac{\sigma^2(0)}{2} W'_{\alpha_n}(0) = \alpha_n V_{\alpha_n}(0) < C_0, \end{aligned} \tag{4.7}$$

where C_0 is a constant independent of n. But, from (4.2), $\int_0^\infty [H(x) - \alpha_n]dx = \infty$ for each n. Hence, by picking $n = 1$, we have a constant $K_1 > 0$ so that $\int_0^x [H(x) - \alpha_1]dx > C_0$ for all $x > K_1$. However, using (4.7) we obtain $\int_0^{b^*_{\alpha_n}} [H(x) - \alpha_1]dx < \int_0^{b^*_{\alpha_n}} [H(x) - \alpha_n]dx < C_0$. Consequently,

$$\beta_0 \le b^*_{\alpha_n} < K_1 \qquad \text{for all } n. \tag{4.8}$$

Similarly, by integrating (4.4) over $[a^*_{\alpha_n}, 0]$, we obtain

$$\int_{a^*_{\alpha_n}}^0 [H(x) - \alpha_n]dx = C(a^*_{\alpha_n}) - \mu(a^*_{\alpha_n}) - \alpha_n |a^*_{\alpha_n}| < \alpha_n V_{\alpha_n}(0) < C_0 \tag{4.9}$$

for all n. Then, using (4.2) and following an argument similar to that above, we obtain a constant $K_2 > 0$ so that

$$-K_2 < a^*_{\alpha_n} \le \theta_0 \qquad \text{for all } n. \tag{4.10}$$

Now we let $K = \max\{K_1, K_2\}$. Then by (4.8) and (4.10), we obtain

$$[a^*_{\alpha_n}, b^*_{\alpha_n}] \subseteq [-K, K] \qquad \text{for all } n. \tag{4.11}$$

In the rest of the proof we show that $\{W_{\alpha_n}\}$ and $\{W'_{\alpha_n}\}$ are equicontinuous families and conclude that $\{W_{\alpha_n}\}$ converges (possibly through a subsequence) to the desired function W_0 which satisfies parts (ii) and (iii) of the lemma. For this, we consider the sequence of functions (W_{α_n}) defined on $[-K, K]$. By integrating (4.4), we have

$$\frac{\sigma^2(x)}{2} W'_{\alpha_n}(x) = \alpha_n V_{\alpha_n}(0) + \alpha_n \int_0^x W_{\alpha_n}(u)du - C(x) - \mu(x) \cdot W_{\alpha_n}(x).$$

Using the facts that $\inf_{[-K,K]} \sigma^2(x) > 0$, $|W_{\alpha_n}(x)| \le 1$ for all x, the functions μ, σ, and C are bounded on $[-K, K]$, and $0 < \alpha_n V_{\alpha_n}(0) < C_0$ for all n, we obtain

$$\sup_n \sup_{[-K,K]} |W'_{\alpha_n}(x)| < C_1, \qquad \text{where } C_1 \text{ is a constant.} \tag{4.12}$$

Now, using (4.4) and (4.12) together with the same reasoning as above, we conclude

$$\sup_n \sup_{[a^*_{\alpha_n}, b^*_{\alpha_n}]} |W''_{\alpha_n}(x)| < C_2, \tag{4.13}$$

where $C_2 > 0$ is a constant. Here, at the end points $a^*_{\alpha_n}$ and $b^*_{\alpha_n}$, we considered the one-sided limits $W''_{\alpha_n}(a^*_{\alpha_n}+)$ and $W''_{\alpha_n}(b^*_{\alpha_n}-)$. Next, using (4.12), (4.13), and the fact that $W''_{\alpha_n}(x) = 0$ outside $[a^*_{\alpha_n}, b^*_{\alpha_n}]$, we conclude that $\{W_{\alpha_n}\}$ and $\{W'_{\alpha_n}\}$ are equicontinuous families on $[-K, K]$. By (4.11), we can pick a subsequence of (α_n), so that $(a^*_{\alpha_n})$ and $(b^*_{\alpha_n})$ converge to limit points a^* and b^*, respectively. Furthermore, these limit points are inside $[-K, K]$. Since $\{W_{\alpha_n}\}$ and $\{W'_{\alpha_n}\}$ are equicontinuous families on $[-K, K]$ (through a further subsequence, if necessary), using the Arzelà–Ascoli theorem, we can conclude that there exists a continuously differentiable function W_0 on the interval $[-K, K]$ which satisfies the following:

$$\lim_{\alpha_n \to 0} W_{\alpha_n}(x) = W_0(x) \qquad \text{and} \qquad \lim_{\alpha_n \to 0} W'_{\alpha_n}(x) = W'_0(x).$$

Furthermore, $-K \le a^* \le \theta_0 < \beta_0 \le b^* \le K$. Now by integrating (4.4) and letting α_n tend to zero in the resulting integral equation, we obtain that W_0 satisfies the differential equation in part (ii) of the lemma. To derive part (iii), we only need to extend W_0 to all $\mathbf{R}$, so that $W_0(x) = -1$ for $x \le -K$ and $W_0(x) = 1$ for $x \ge K$. Now, the equicontinuity of $\{W_{\alpha_n}\}$ and $\{W'_{\alpha_n}\}$ implies part (iii).

Next, similar to the argument in (2.2) and (2.3), we can solve the first order differential equation in part (ii) with the boundary condition $W_0(a^*) = -1$ and then use the other boundary condition $W_0(b^*) = 1$ to obtain the formula for l_0. Hence, the proof of part (iv) is complete. □

Remarks. In the following proof of the theorem, we show that $l_0 = \lambda_0$. Hence, we obtain the uniqueness of l_0 as well as the existence of the limit $\lim_{\alpha \to 0} \alpha V_\alpha(0)$.

Proof of Theorem 4.1. Introduce the function Q by

$$Q(x) = \int_0^x W_0(u)du,$$

where W_0 is as in the previous lemma. Let a^* and b^* be also as in the previous lemma. Next, consider the reflected diffusion process X^*_x on the interval $[a^*, b^*]$, given by (4.14). This process is positive recurrent on the interval $[a^*, b^*]$ and its ergodic limit for the cost functional can be derived explicitly as given below (see also [9, Chapter II, sec. 6]). In the following discussion, we simply assume x is in $[a^*, b^*]$, since an initial jump to the set $\{a^*, b^*\}$ does not alter the cost functional in (1.3). Let

$$X^*_x(t) = x + \int_0^t \mu(X^*_x(s))ds + \int_0^t \sigma(X^*_x(s))ds + A^*(t), \tag{4.14}$$

where

$$A^*(t) = L_{a^*}(t) - L_{b^*}(t) \qquad \text{and} \qquad |A^*|(t) = L_{a^*}(t) + L_{b^*}(t). \tag{4.15}$$

The processes L_{a^*} and L_{b^*} are local-time processes of X^*_x at the points a^* and b^*, respectively. Clearly, X^*_x is an admissible process for (1.3). We apply Itô's lemma to $Q(X^*_x(T))$ and use Lemma 4.2 to obtain

$$Q(X^*_x(T)) = Q(x) + l_0 T - E\int_0^T [C(X^*_x(t))dt + d|A^*|(t)].$$

Consequently, $\lim_{T\to\infty} \frac{1}{T} E\int_0^T [C(X^*_x(t))dt + d|A^*|(t)] = l_0$. Therefore, $l_0 \ge \lambda_0$ and the value of l_0 is given in part (iv) of Lemma 4.2. However, $l_0 \le \lambda_0$ from Proposition 2.1. Therefore, $l_0 = \lambda_0$ and the above X^*_x process is an optimal state process. Furthermore, every limit point of $\{\alpha V_\alpha(0)\}$ is equal to λ_0. Consequently, $\lim_{\alpha\to 0} \alpha V_\alpha(0) = \lambda_0$. Using part (ii) of Proposition 2.1, we obtain $\lim_{\alpha\to 0} \sup_{|x|\le K} |\alpha V_\alpha(x) - \lambda_0| = 0$ for each $K > 0$. Hence, the proofs of both parts (i) and (ii) of Theorem 4.1 are complete. □

5. Asymptotics for $V_0(x,T)$. In this section, we intend to prove the following theorem, which describes the long term behavior of $V_0(x,T)$ defined in (1.5).

THEOREM 5.1. *Under the assumptions of Theorem* 3.1 *or* 4.1, *the following Abelian limit holds:*

$$\lim_{T\to\infty} \sup_{|x|\le K} \left| \frac{V_0(x,T)}{T} - \lambda_0 \right| = 0 \quad \textit{for each } K > 0. \tag{5.1}$$

Proof. It suffices to show $\liminf_{T\to\infty} \frac{V_0(0,T)}{T} \ge \lambda_0$, because this together with parts (ii) and (iii) of Proposition 2.1 implies (5.1). First, we observe that a given process $X_x(\cdot)$ which satisfies (1.1) on $[0,T]$ with the condition $E\int_0^T [C(X_x(t))dt + d|A|(t)] < \infty$ can be extended to $[0,\infty)$ as an admissible process for (1.3), simply by using the zero control policy on $[T,\infty)$. Hence

$$X_x(T+s) = X_x(T) + \int_T^{T+s} \mu(X_x(u))du + \int_T^{T+s} \sigma(X_x(u))dW(u),$$

where $\{W(t) : t \ge 0\}$ is a Brownian motion. Since we have observed that the process corresponding to zero control policy is an admissible process in section 3, it easily follows that $X_x(\cdot)$ is also an admissible process. Second, we have observed that $\limsup_{T\to\infty} \frac{V_0(0,T)}{T} \le \lambda_0$ in the Proposition 2.1. Thus, if we take a constant $M_1 > \lambda_0$, then there is a $T_0 > 0$ so that

$$V_0(0,T) < M_1 T \tag{5.2}$$

for all $T > T_0$. Because of this fact, it suffices to consider the collection of admissible processes $X_0(\cdot)$ which satisfy (1.1) together with

$$E\int_0^T [C(X_0(t))dt + d|A|(t)] < M_1 T. \tag{5.3}$$

Next, we establish that the quantity $\frac{E|X_0(T)|}{T}$ is bounded for such an admissible process $X_0(\cdot)$ as $T \to \infty$. For this consider the even C^2 function ϕ defined by

$$\phi(x) = \frac{1}{8}(3 + 6x^2 - x^4)I_{[|x|<1]} + |x|I_{[|x|\ge 1]}.$$

Here, I_A denotes the indicator function of the set A. Then $0 \le \phi'(x) \le 1$ for $x \ge 0$ and $1 + \phi(x) \ge |x|$ for all x. Also, ϕ is nonnegative and $\phi'(x)\mu(x) \le 0$ for all x. Now, we use the generalized Itô lemma [18, p. 285] together with the above facts to obtain

$$E\phi(X_0(T)) \le E\int_0^T \frac{\sigma^2(X_0(s))}{2}\phi''(X_0(s))I_{[-1,1]}(X_0(s))ds + E|A|(T).$$

Since we can find a constant $C_2 > 0$ so that $\sup_{[-1,1]} \left[\sigma^2(x)|\phi''(x)|\right] \le C_2$ and by (5.3), for each $T > \max\{T_0, 1\}$, we obtain

$$E|X_0(T)| \le 1 + E\phi(X_0(T)) \le C_2 T + E|A|(T) + 1 < (M_1 + C_2 + 1)T. \tag{5.4}$$

Notice that the constants M_1 and C_2 are independent of the process $X_0(\cdot)$. Hence, the quantity $\frac{E|X_0(T)|}{T}$ remains bounded as $T \to \infty$. Next, by the dynamic programming

principle (or applying the generalized Itô lemma), we derive

$$\begin{aligned}\alpha V_\alpha(0) \le \alpha E \int_0^{T\wedge\tau_n} e^{-\alpha s}[C(X_0(s))ds + d|A|(s)] \\ + E[e^{-\alpha(T\wedge\tau_n)}\alpha V_\alpha(X_0(T\wedge\tau_n))].\end{aligned} \tag{5.5}$$

Here (τ_n) is a sequence of stopping times which satisfy the assumption (1.2). From the proofs of Theorems 3.1 and 4.1 (see (3.9), (3.10), and (4.3)), $V_\alpha(x)$ has the representation

$$\alpha V_\alpha(x) = \Lambda_\alpha + \alpha\int_0^x W_\alpha(u)du, \tag{5.6}$$

where $\lim_{\alpha\to 0}\Lambda_\alpha = \lambda_0$ and $|W_\alpha(x)| \le 1$ for all x. Hence, $\alpha V_\alpha(x) \le \Lambda_\alpha + \alpha|x|$ for all x. Combining this with (5.5), we obtain

$$\begin{aligned}\Lambda_\alpha[1 - E(e^{-\alpha(T\wedge\tau_n)})] \le \alpha E\int_0^T [C(X_0(s))ds + d|A|(s)] \\ + \alpha E|X_0(T\wedge\tau_n)|e^{-\alpha(T\wedge\tau_n)}.\end{aligned} \tag{5.7}$$

Notice that $E[|X_0(T\wedge\tau_n)|e^{-\alpha(T\wedge\tau_n)}] \le E[|X_0(\tau_n)|e^{-\alpha\tau_n}I_{[\tau_n<T]}] + E[|X_0(T)|e^{-\alpha T}]$. Now keeping $\alpha > 0$ fixed and letting (τ_n) tend to infinity and using (1.2), we derive $\lim_{n\to\infty} E[|X_0(\tau_n)|e^{-\alpha\tau_n}I_{[\tau_n<T]}] = 0$. Therefore,

$$\begin{aligned}\Lambda_\alpha[1 - e^{-\alpha T}] &\le \alpha E\int_0^T [C(X_0(s))ds + d|A|(s)] + \alpha E|X_0(T)|e^{-\alpha T} \\ &\le \alpha E\int_0^T [C(X_0(s))ds + d|A|(s)] + \alpha K e^{-\alpha T}.\end{aligned}$$

We have used (5.4) in the last inequality and here $K = (M_1 + C_2 + 1)$, where the constants M_1 and C_2 are as in (5.4). Thus, K is independent of α as well as the process $X_0(\cdot)$. Therefore, $\Lambda_\alpha[1 - e^{-\alpha T}] \le \alpha V_0(0,T) + \alpha K e^{-\alpha T}$. Consequently,

$$\Lambda_\alpha\frac{1 - e^{-\alpha T}}{\alpha T} \le \frac{V_0(0,T)}{T} + \frac{K}{T}e^{-\alpha T}.$$

We choose $\alpha = \frac{\delta}{T}$, where $0 < \delta < 1$ as in the argument in section (vi) of [3] for large $T > 0$. Thus,

$$\Lambda_\alpha\frac{1 - e^{-\delta}}{\delta} \le \frac{V_0(0,T)}{T} + \frac{K}{T}e^{-\delta}.$$

Since $\lim_{\alpha\to 0}\Lambda_\alpha = \lambda_0$, first we let δ tend to zero and then let T tend to infinity to obtain $\lambda_0 \le \liminf_{T\to\infty}\frac{V_0(0,T)}{T}$ as desired. This completes the proof. □

6. A constrained optimization problem. In this section, we address a constrained optimization problem which can be solved by using our results in section 4. For the purposes of this section, we need to strengthen the assumption (1.7) by the following assumption:

$$\int_{-\infty}^0 \frac{1 + \mu(x)}{\sigma^2(x)}dx = \int_0^\infty \frac{1 - \mu(x)}{\sigma^2(x)}dx = \infty. \tag{6.1}$$

At the end of this section, in Theorem 6.4, we will describe the results we can obtain when we replace (6.1) by the assumption (1.7). We will introduce further assumptions on μ, σ, and C after we describe the constrained optimization problem.

Consider the collection $\mathcal{U}$ of all admissible control systems used in the ergodic control problem (1.3). Let $\mathcal{U}_0$ be the subcollection of $\mathcal{U}$ obtained by enforcing μ and σ to also satisfy (1.6) and (6.1). Let $m > 0$ be any fixed positive real number. Here, we address the following constrained minimization problem:

$$\text{Minimize} \qquad \limsup_{T\to\infty} \frac{1}{T} E \int_0^T C(X_x(s))ds \tag{6.2}$$

subject to

$$\limsup_{T\to\infty} \frac{E|A|(T)}{T} \le m \tag{6.3}$$

over all admissible systems in $\mathcal{U}_0$. Notice that an initial jump does not affect our cost criteria or the constraint. Therefore, throughout this section, we simply consider the initial point x to be the origin and omit the dependence on x in our notation. To be more precise, for each $m > 0$, we define

$$\mathcal{U}_m = \left\{ ((\Omega, \mathfrak{F}, P), (\mathfrak{F}_t), W, A, X) \in \mathcal{U}_0 : \limsup_{T\to\infty} \frac{E|A|(T)}{T} \le m \right\}. \tag{6.4}$$

The collection $\mathcal{U}_m$ is nonempty, since the zero control policy developed in section 3 is there. The constrained minimization problem is to find the value function and characterize an optimal policy for

$$\inf_{\mathcal{U}_m} \limsup_{T\to\infty} \frac{1}{T} E \int_0^T C(X(s))ds. \tag{6.5}$$

We intend to characterize an optimal strategy that achieves the infimum in (6.5). We develop a "Lagrange multiplier"-type method by introducing an unconstrained optimization problem whose cost criteria includes a "penalty rate" $p > 0$. This penalty rate can be considered as the Lagrange multiplier variable. For each $p > 0$, we can obtain an optimal strategy for the unconstrained problem from the results in section 4. Furthermore, we also obtain an explicit formula for the derivative of the value with respect to p. Then we show that there exists a unique value for p, say p^*, where the corresponding optimal control A^* of the unconstrained problem satisfies $\lim_{T\to\infty} \frac{E|A^*|(T)}{T} = m$. This enables us to conclude that the same control policy is also optimal for the constrained minimization problem (6.5). At the end of this section, we also point out that if we assume (1.7) instead of (6.1), we can solve the constrained minimization problem with the same optimal policy only when $m > \gamma_0$, where γ_0 is a constant explicitly given in Theorem 6.4.

In a continuous-time setting, the idea of using both Lagrange multipliers and Kuhn–Tucker characterization of optimal policies for constrained stochastic control problems is considered in [6]. A problem of finite-fuel singular control with dynamic constraints for the control process is addressed in [5]. The Lagrange multiplier method was applied to a stochastic control problem with terminal conditions in [22, p. 241]. When the state space is a finite interval, a similar constrained optimization problem and an application to dynamic power control in wireless communication are addressed in [4] and we are motivated by their work.

Let $p > 0$ be a positive constant which represents the penalty rate. For each $p > 0$, we let

$$\Gamma(p) = \inf_{\mathcal{U}_0} \limsup_{T\to\infty} \frac{1}{T} E\left[\int_0^T C(X(s))ds + p \cdot |A|(T)\right]. \tag{6.6}$$

Introduce the function $C_p : \mathbf{R} \to [0, \infty)$ by

$$C_p(x) = \frac{C(x)}{p} \qquad \text{for all } x. \tag{6.7}$$

Notice that

$$\frac{\Gamma(p)}{p} = \inf_{\mathcal{U}_0} \limsup_{T\to\infty} \frac{1}{T} E\left[\int_0^T \frac{C(X(s))}{p} ds + |A|(T)\right] \tag{6.8}$$

and the function C_p satisfies the assumption (1.8). Similar to the definition of H in (1.9), for each $p > 0$, we define the function $H_p : \mathbf{R} \to \mathbf{R}$ by

$$H_p(x) = \mu'(x) + \frac{|C'(x)|}{p}. \tag{6.9}$$

We make the following additional assumptions throughout this section. They will enable us to use the results in section 4. For each $p > 0$, we assume there exists a constant $\alpha_0(p) > 0$ which satisfies the conditions below.

(6.10) (i) For each $0 \le \alpha < \alpha_0(p)$, there exist two points $\theta_\alpha(p) < 0 < \beta_\alpha(p)$ so that $H_p(x) > \alpha$ outside the interval $[\theta_\alpha(p), \beta_\alpha(p)]$. Furthermore, if $\alpha > 0$, then $H_p(x) < \alpha$ in $(\theta_\alpha(p), \beta_\alpha(p))$. Finally, if $\alpha = 0$, then $\{x : H_p(x) \le 0\} = [\theta_0(p), \beta_0(p)]$.

(6.11) (ii) For each $p > 0$, $\lim_{|x|\to\infty} \frac{\alpha_0(p) - \mu'(x)}{|C'(x)|} = 0$.

(6.12) (iii) $C(x) > 0$ for all $x \neq 0$.

Remarks. Assumption (6.10) is similar to (4.1) in section 4, and (6.11) clearly implies (4.2). Condition (6.12) enables us to simplify the proofs.

Examples. The following examples of μ, σ, and C satisfy all the assumptions in this section:

(i) Let $\mu(x) = -\theta x^3$ for some $\theta > 0$, $\sigma(x) = 1 + x^2$ and $C(x) = x^{2n}$ for any $n \ge 2$.

(ii) Let $\mu(x) = -\theta x$ for some $\theta > 0$, $\sigma(x) = \sigma_0$, where $\sigma_0 > 0$ is a constant. Let $C(\cdot)$ be any C^2 convex function which has a unique minimum at zero, $C(0) = 0$ and $\lim_{|x|\to\infty} |C'(x)| = \infty$.

When μ, σ, and C satisfy all the assumptions in this section, then for each $p > 0$, μ, σ, and C_p clearly satisfy all the assumptions of Theorem 4.1. Therefore, for each $p > 0$, $\frac{\Gamma(p)}{p}$ is finite and there is a finite interval $[a^*(p), b^*(p)]$ so that the corresponding reflecting diffusion process $X_p^*(\cdot)$ which satisfies (2.1) on this interval is an optimal process. The corresponding optimal bounded variation control process $A_p^*(\cdot)$ satisfies

$$A_p^*(t) = L_{a^*(p)}(t) - L_{b^*(p)}(t) \qquad \text{for all } t > 0, \tag{6.13}$$

where $L_{a^*(p)}(\cdot)$ and $L_{b^*(p)}(\cdot)$ are local time processes of $X_p^*(\cdot)$ at the end points $a^*(p)$ and $b^*(p)$, respectively. By Lemma 4.2, we know that $a^*(p)$ and $b^*(p)$ satisfy

$$-\infty < a^*(p) \leq \theta_0(p) < 0 < \beta_0(p) \leq b^*(p) < \infty. \tag{6.14}$$

It is known (see [9]) that the reflected diffusion $X_p^*(\cdot)$ on the finite interval $[a^*(p), b^*(p)]$ has a unique stationary probability distribution with the probability density ϕ given below in (6.16). Therefore,

$$\lim_{T\to\infty} \frac{1}{T} E \int_0^T C(X_p^*(s))ds = \int_{a^*(p)}^{b^*(p)} C(u)\phi(u)du. \tag{6.15}$$

The density function ϕ is given by

$$\phi(x) = \frac{1}{D}\frac{1}{\sigma^2(x)} e^{2\int_0^x \rho(u)du}, \tag{6.16}$$

where $\rho(x) = \frac{\mu(x)}{\sigma^2(x)}$ on the interval $[a^*(p), b^*(p)]$ and the normalization constant $D > 0$ is given by

$$D = \int_{a^*(p)}^{b^*(p)} \frac{1}{\sigma^2(x)} e^{2\int_0^x \rho(u)du} dx. \tag{6.17}$$

Also, we can use the limit in (2.5) for (6.13) to obtain

$$\lim_{T\to\infty} \frac{E|A_p^*|(T)}{T} = \frac{e^{2\int_0^{b^*(p)} \rho(u)du} + e^{-2\int_{a^*(p)}^0 \rho(u)du}}{2D}, \tag{6.18}$$

where the constant $D > 0$ is given in (6.17).

Consequently, $\Gamma(p)$ has the representation

$$\Gamma(p) = \lim_{T\to\infty} \frac{1}{T} E \int_0^T C(X_p^*(s))ds + p \cdot \lim_{T\to\infty} \frac{E|A_p^*|(T)}{T}. \tag{6.19}$$

Our next lemma shows the differentiability of $\Gamma(p)$ and computes the derivative explicitly.

LEMMA 6.1. *For each $p > 0$, consider the value function $\Gamma(p)$ defined in* (6.6). *Then the following statements are true:*

(i) $\Gamma(\cdot)$ *is a differentiable, strictly increasing function and its derivative is given by*

$$\Gamma'(p) = \lim_{T\to\infty} \frac{E|A_p^*|(T)}{T}, \tag{6.20}$$

where $A_p^*(\cdot)$ is the optimal control process described in (6.13).

(ii) $\Gamma(\cdot)$ *satisfies $0 < p \cdot \Gamma'(p) < \Gamma(p)$ for each $p > 0$ and $\lim_{p\to 0} \Gamma(p) = 0$.*

(iii) *The function $\frac{\Gamma(p)}{p}$ is strictly decreasing on $(0, \infty)$.*

Proof. We introduce the function $F(a, b)$ on the set $\{(a, b) \in \mathbf{R}^2 : a < 0 < b\}$ by

$$F(a,b) = \frac{e^{2\int_0^b \rho(u)du} + e^{-2\int_a^0 \rho(u)du}}{\int_a^b \frac{2}{\sigma^2(x)} e^{2\int_0^x \rho(u)du} dx}, \tag{6.21}$$

where ρ is as in (6.16). Notice that $\rho > 0$ on $(-\infty, 0)$ and $\rho < 0$ on $(0, \infty)$. Using this fact, a direct computation yields

$$\frac{\partial F}{\partial a}(a,b) > 0 \quad \text{and} \quad \frac{\partial F}{\partial b}(a,b) < 0 \quad \text{when} \quad a < 0 < b. \tag{6.22}$$

By (6.18), for each $p > 0$, we observe that

$$F(a^*(p), b^*(p)) = \lim_{T\to\infty} \frac{E|A_p^*|(T)}{T}. \tag{6.23}$$

Next, consider $0 < p < q$. By (6.6), it is clear that $\Gamma(p) \le \Gamma(q)$. Since the optimal strategy (X_p^*, A_p^*) for $\Gamma(p)$ is also an admissible strategy for $\Gamma(q)$, using the definitions of $\Gamma(p)$, $\Gamma(q)$ and (6.23), we obtain

$$0 \le \Gamma(q) - \Gamma(p) \le (q-p) \cdot F(a^*(p), b^*(p)).$$

Similarly, (X_q^*, A_q^*) is optimal for $\Gamma(q)$ and is an admissible strategy for $\Gamma(p)$ and hence

$$0 < (q-p) \cdot F(a^*(q), b^*(q)) \le \Gamma(q) - \Gamma(p).$$

Combining these two inequalities, we obtain

$$0 < F(a^*(q), b^*(q)) \le \frac{\Gamma(q) - \Gamma(p)}{q-p} \le F(a^*(p), b^*(p)) \quad \text{when} \ \ 0 < p < q. \tag{6.24}$$

Notice that (6.24) also implies that $F(a^*(p), b^*(p))$ is a decreasing function in the variable p. Now let $p_0 > 0$ be fixed. Let $\delta_1 > 0$ be such that $0 < \delta_1 < p_0$. Then by (6.24), for all $0 < |h| < \delta_1$, we have

$$F(a^*(p_0+\delta_1), b^*(p_0+\delta_1)) \le \frac{\Gamma(p_0+h) - \Gamma(p_0)}{h} \le F(a^*(p_0-\delta_1), b^*(p_0-\delta_1)). \tag{6.25}$$

Clearly, (6.25) implies the continuity of $\Gamma(\cdot)$ at p_0, and it also shows that if $\lim_{p\to p_0} F(a^*(p), b^*(p)) = F(a^*(p_0), b^*(p_0))$, then $\Gamma(\cdot)$ is differentiable at p_0 and $\Gamma'(p_0) = F(a^*(p_0), b^*(p_0))$. Notice that if $a^*(\cdot)$ and $b^*(\cdot)$ are continuous at $p = p_0$, then by (6.21), $\lim_{p\to p_0} F(a^*(p), b^*(p)) = F(a^*(p_0), b^*(p_0))$ holds. Therefore, to prove part (i) of the lemma, it suffices to show the continuity of the functions $a^*(\cdot)$ and $b^*(\cdot)$. Here, we prove the continuity of $b^*(\cdot)$. The proof of the continuity of $a^*(\cdot)$ is very similar, and therefore we omit it.

By parts (ii) and (iii) of Lemma 4.2 (notice that $l_0 = \lambda_0$ there, as shown in the proof of Theorem 4.1), we have

$$\frac{C(b^*(p))}{p} + \mu(b^*(p)) = \frac{C(a^*(p))}{p} - \mu(a^*(p)) = \frac{\Gamma(p)}{p}. \tag{6.26}$$

First we show that $b^*(\cdot)$ is bounded on the interval $[p_0 - \delta_1, p_0 + \delta_0]$ and notice that $b^*(p) > 0$ by (6.14). By the monotonicity of $\Gamma(\cdot)$, (6.9), and by (6.26), we have

$$\frac{\Gamma(p_0+\delta_1)}{p_0-\delta_1} \ge \frac{\Gamma(p)}{p} = \int_0^{b^*(p)} H_p(u)du \ge \int_0^{b^*(p)} H_{p_0+\delta_1}(u)du.$$

But (6.11) implies that $\int_0^\infty H_{p_0+\delta_1}(u)du = \infty$. Therefore, we can conclude that $b^*(\cdot)$ is a bounded function on $[p_0-\delta_1, p_0+\delta_1]$. Now consider a sequence (q_n) in $(p_0-\delta_1, p_0+\delta_1)$

such that $\lim_{n\to\infty} q_n = p_0$. Now let m_0 be any limit point of the bounded sequence $(b^*(q_n))$. Then $m_0 \geq 0$ by using (6.14). By (6.26) and by the continuity of $\Gamma(\cdot)$, we obtain $\frac{C(m_0)}{p_0} + \mu(m_0) = \frac{\Gamma(p_0)}{p_0} > 0$ and consequently $m_0 > 0$. But $b^*(p_0) > 0$ and also satisfies $\frac{C(b^*(p_0))}{p_0} + \mu(b^*(p_0)) = \frac{\Gamma(p_0)}{p_0} > 0$. By (6.10), we have $H_{p_0}(x) \leq 0$ on $[0, \beta_0(p_0)]$ and $H_{p_0}(x) > 0$ on $(\beta_0(p_0), \infty)$. Therefore, $\{x \geq 0 : \frac{C(x)}{p_0} + \mu(x) > 0\} \subseteq (\beta_0(p_0), \infty)$ and $\frac{C(x)}{p_0} + \mu(x)$ is strictly increasing on $(\beta_0(p_0), \infty)$ and hence $m_0 = b^*(p_0)$. This implies that $b^*(\cdot)$ is continuous at $p = p_0$. A similar proof yields the continuity of $a^*(\cdot)$ at $p = p_0$. Consequently, we have $\lim_{p\to p_0} F(a^*(p), b^*(p)) = F(a^*(p_0), b^*(p_0))$. This together with (6.25) implies that $\Gamma(\cdot)$ is differentiable at p_0, and its derivative is given by $\Gamma'(p_0) = F(a^*(p_0), b^*(p_0)) > 0$. Hence, the proof of part (i) is complete.

To prove part (ii), using (6.15)–(6.19), (6.23), and the above result we can write

$$\Gamma(p) = \int_{a^*(p)}^{b^*(p)} C(u)\phi(u)du + p \cdot \Gamma'(p),$$

where ϕ is given in (6.16). By (6.12) and (6.16), it is clear that the above integral is strictly positive. Therefore, $\Gamma(p) > p \cdot \Gamma'(p) > 0$ holds. To show $\lim_{p\to 0} \Gamma(p) = 0$, we consider the reflecting diffusion process described in (2.1) with $a = -\sqrt{p}$ and $b = \sqrt{p}$ on the interval $[-\sqrt{p}, \sqrt{p}]$ and obtain the following upper bound for $\Gamma(p)$:

$$0 < \Gamma(p) \leq \max\{C(\sqrt{p}), C(-\sqrt{p})\} + p \cdot F(-\sqrt{p}, \sqrt{p}).$$

Clearly, $\lim_{p\to 0^+} \max\{C(\sqrt{p}), C(-\sqrt{p})\} = 0$. A direct computation shows that $\lim_{p\to 0^+} \sqrt{p} \cdot F(-\sqrt{p}, \sqrt{p}) = \frac{\sigma^2(0)}{2}$. Therefore, $\lim_{p\to 0^+} p \cdot F(-\sqrt{p}, \sqrt{p}) = 0$ and, consequently, $\lim_{p\to 0} \Gamma(p) = 0$. This completes the proof of part (ii).

For the proof of part (iii), consider $0 < p < q$. Then the optimal strategy (X_p^*, A_p^*) for $\Gamma(p)$ is also an admissible strategy for $\Gamma(q)$, and therefore, by using (6.15)–(6.19), we obtain

$$\begin{aligned}
\frac{\Gamma(p)}{p} &> \int_{a^*(p)}^{b^*(p)} \frac{C(u)}{q}\phi(u)du + F(a^*(p), b^*(p)) \\
&= \lim_{T\to\infty} \frac{1}{T} E\left[\int_0^T C_q(X_p^*(t))dt + |A_p^*|(T)\right] \\
&\geq \frac{\Gamma(q)}{q}.
\end{aligned}$$

This completes the proof of the lemma. □

In our next lemma, we derive the second order properties of the function $\Gamma(\cdot)$. We show that $\Gamma(\cdot)$ is a strictly concave function and its derivative $\Gamma'(\cdot)$ takes all the values in the interval $(0, \infty)$.

LEMMA 6.2. *The functions $a^*(\cdot)$, $b^*(\cdot)$, and $\Gamma(\cdot)$ satisfy the following conditions:*

(i) *The functions $a^*(\cdot)$ and $b^*(\cdot)$ are differentiable and their derivatives satisfy $\frac{da^*}{dp} < 0$ and $\frac{db^*}{dp} > 0$.*

(ii) *$\lim_{p\to 0^+} a^*(p) = \lim_{p\to 0^+} b^*(p) = 0$, $\lim_{p\to\infty} a^*(p) = -\infty$, and $\lim_{p\to\infty} b^*(p) = \infty$.*

(iii) *$\Gamma(\cdot)$ is a twice differentiable function which is strictly concave on $(0, \infty)$. Furthermore, $\lim_{p\to 0^+} \Gamma'(p) = \infty$ and $\lim_{p\to\infty} \Gamma'(p) = 0$.*

Proof. Introduce the function

$$U(p,x) = \frac{C(x)}{p} + \mu(x)$$

for $p > 0$ and $x > 0$. Then $U(p, b^*(p)) = \frac{\Gamma(p)}{p}$ by (6.26) and $\frac{\partial U}{\partial x}(p,x) = H_p(x)$ by (6.9). We notice that $b^*(p) > \beta_0(p) > 0$ by (6.14) and by the argument below (6.26). Hence, $\frac{\partial U}{\partial x}(p, b^*(p)) = H_p(b^*(p)) > 0$. Therefore, we can use the implicit function theorem to conclude that $b^*(\cdot)$ is differentiable at p. Now, by differentiating $\Gamma(p)$ with respect to p using (6.26), we obtain

$$p \cdot H_p(b^*(p)) \cdot \frac{db^*}{dp}(p) + \mu(b^*(p)) = \Gamma'(p). \tag{6.27}$$

By the previous lemma, $\Gamma'(p) > 0$ and $\mu(b^*(p)) < 0$ by (1.6). Also, $H_p(b^*(p)) > 0$ as we noted above. Hence, we conclude that $\frac{db^*}{dp}(p) > 0$. A similar proof yields $\frac{da^*}{dp}(p) < 0$. This completes the proof of part (i).

Consequently, $b^*(\cdot)$ is a strictly increasing function on $(0,\infty)$ and thus the limit $\lim_{p\to 0^+} b^*(p)$ exists. Let $\lim_{p\to 0^+} b^*(p) = b_0$. By (6.26), we obtain $\Gamma(p) = C(b^*(p)) + p \cdot \mu(b^*(p))$. Using Lemma 6.1 and letting p tend to zero, we can conclude that $b_0 \geq 0$ and $C(b_0) = 0$. By (6.12), it follows that $b_0 = 0$. A similar proof shows $\lim_{p\to 0^+} a^*(p) = 0$.

Next, we intend to show $\lim_{p\to\infty} b^*(p) = \infty$. Since $b^*(\cdot)$ is strictly increasing, we let $b_\infty = \lim_{p\to\infty} b^*(p)$. If b_∞ is finite, using (1.6) and (1.8) we obtain

$$0 < \Gamma(p) = C(b^*(p)) + p \cdot \mu(b^*(p)) < C(b_\infty) + p \cdot \mu(b^*(1))$$

for all $p > 1$. If b_∞ is finite, then the right-hand side of the above expression tends to $-\infty$ as p tends to infinity, which is a contradiction. Hence $b_\infty = \infty$. The proof of $\lim_{p\to -\infty} a^*(p) = -\infty$ is similar, and this completes the proof of part (ii).

To prove part (iii), using (6.23) and Lemma 6.1, we obtain the representation

$$\Gamma'(p) = F(a^*(p), b^*(p)) \quad \text{for } p > 0. \tag{6.28}$$

Since $F(\cdot,\cdot)$ is differentiable, using the proof of part (i) of this lemma, we have that $\Gamma(\cdot)$ is twice differentiable and its second derivative is given by

$$\Gamma''(p) = \frac{\partial F}{\partial a}(a^*(p), b^*(p)) \cdot \frac{da^*}{dp}(p) + \frac{\partial F}{\partial b}(a^*(p), b^*(p)) \cdot \frac{db^*}{dp}(p).$$

Now using (6.22) and the above part (i) of the lemma, it is evident that $\Gamma''(p) < 0$. Next, using (6.21), (6.28), and part (ii) of this lemma, we obtain $\lim_{p\to 0^+} \Gamma'(p) = \infty$. To compute $\lim_{p\to\infty} \Gamma'(p)$, again we use (6.21), (6.28), the fact that $F(a^*(p), b^*(p))$ is a decreasing function in the variable p, and the concavity of $\Gamma(\cdot)$. Then we can conclude that

$$\lim_{p\to\infty} \Gamma'(p) = F(-\infty,\infty) = \frac{e^{2\int_0^\infty \rho(u)du} + e^{-2\int_{-\infty}^0 \rho(u)du}}{\int_{-\infty}^\infty \frac{2}{\sigma^2(x)} e^{2\int_0^x \rho(u)du} dx}. \tag{6.29}$$

By (1.6), we obtain $0 < \int_{-\infty}^0 \rho(u)du \leq \infty$ and $-\infty \leq \int_0^\infty \rho(u)du < 0$. If $\int_{-\infty}^0 \rho(u)du = \infty$ and $\int_0^\infty \rho(u)du = -\infty$, then by (6.29) clearly $\lim_{p\to\infty} \Gamma'(p) = 0$. Next consider

the case $\int_0^\infty \rho(u)du$ to be convergent. Let $\int_0^\infty \rho(u)du = -L$, where L is a positive constant. Then, by (6.1), $\int_0^\infty \frac{1}{\sigma^2(r)}dr = \infty$. Therefore, the numerator of the right-hand side of (6.29) is less than 2, while the denominator is greater than or equal to $2e^{-2L}\int_0^\infty \frac{1}{\sigma^2(r)}dr$. Hence, the denominator is infinite and, consequently, $\lim_{p\to\infty}\Gamma'(p) = 0$. If the integral $\int_{-\infty}^0 \rho(u)du$ is convergent, a similar proof shows $\lim_{p\to\infty}\Gamma'(p) = 0$. This completes the proof. □

Remarks. The assumption (6.1) is used only in the proof of $\lim_{p\to\infty}\Gamma'(p) = 0$. If we assume (1.7) instead of (6.1), our conclusion for the limit $\lim_{p\to\infty}\Gamma'(p)$ will be given by the right-hand side of (6.29).

Next, we present the main theorem of this section.

THEOREM 6.3. *Assume* (1.6), (1.8), (6.1), *and* (6.10)–(6.12). *Then for any positive constant* $m > 0$, *the constrained optimization problem* (6.5) *has an optimal strategy of the type described in part* (ii) *of Theorem* 4.1*: Namely, there exist two points* $a_0^* < 0$ *and* $b_0^* > 0$ *so that the reflecting diffusion process described in* (4.14) *and* (4.15) *on the state space* $[a_0^*, b_0^*]$ *is an optimal state process.*

Proof. Let $m > 0$ be a constant. Then by Lemma 6.2, there is a unique constant $p^* > 0$ so that $\Gamma'(p^*) = m$. Consider the optimal strategy (X_p^*, A_p^*) for (6.6) with $p = p^*$. Then, using Lemma 6.1, we can write

$$\Gamma(p^*) = \lim_{T\to\infty}\frac{1}{T}E\left[\int_0^T C(X_{p^*}^*(u))du\right] + p^*\cdot m. \tag{6.30}$$

Now consider any admissible control system in $\mathcal{U}_m$ with the corresponding state process $X(\cdot)$ and the control process $A(\cdot)$, where $\mathcal{U}_m$ is given in (6.4). Then (X, A), which satisfies (1.1), is also an admissible strategy for $\Gamma(p^*)$ and the following inequalities hold:

(6.31)

$$\begin{aligned}\limsup_{T\to\infty}\frac{1}{T}E\int_0^T C(X(u))du + p^*\cdot m &\geq \limsup_{T\to\infty}\frac{1}{T}E\left[\int_0^T C(X(u))du\right]\\ &\quad + p^*\cdot\limsup_{T\to\infty}\frac{E|A|(T)}{T}\\ &\geq \limsup_{T\to\infty}\frac{1}{T}E\left[\int_0^T C(X(u))du + p^*\cdot|A|(T)\right]\\ &\geq \Gamma(p^*).\end{aligned}$$

Therefore, by (6.30) and (6.31), we conclude that

$$\limsup_{T\to\infty}\frac{1}{T}E\int_0^T C(X(u))du \geq \limsup_{T\to\infty}\frac{1}{T}E\int_0^T C(X_{p^*}^*(u))du.$$

Hence, (X_{p^*}, A_{p^*}) is an optimal policy for the constrained optimization problem (6.5). This completes the proof. □

When we replace assumption (6.1) by (1.7), we can obtain a partial solution to the constrained optimization problem. To describe it, first we introduce the nonnegative constant γ_0 by $\gamma_0 \equiv F(-\infty, \infty)$. Here, $F(-\infty, \infty)$ is defined as in the right-hand side of (6.29). Then we have the following result.

THEOREM 6.4. *Assume* (1.6)–(1.8) *and* (6.10)–(6.12). *Let* γ_0 *be the constant defined above. Then for each* $m > \gamma_0$, *the conclusion of Theorem* 6.3 *holds.*

Proof. By Lemma 6.2, $\Gamma'(\cdot)$ is a strictly increasing function whose range is (γ_0, ∞). Then for a given $m > \gamma_0$, there exists a unique $p^* > 0$ so that $\Gamma'(p^*) = m$. Now, the rest of the proof is identical to that of Theorem 6.3. □

COMPARISON RESULTS AND ESTIMATES ON THE GRADIENT WITHOUT STRICT CONVEXITY*

A. CELLINA†

Abstract. In this paper we establish a comparison result for solutions to the problem

$$\text{minimize} \int_\Omega f(\nabla u(x))\,dx \quad \text{on } \{u : u - u_0 \in W_0^{1,1}(\Omega)\}.$$

Key words. strict convexity, comparison theorem, bounded slope condition

AMS subject classification. 49K20

DOI. 10.1137/060655869

1. Introduction. This paper deals with properties of solutions to minimization problems of the kind

$$\text{minimize} \int_\Omega f(\nabla u(x))\,dx \quad \text{on } \{u : u - u_0 \in W_0^{1,1}(\Omega)\}. \tag{1}$$

More precisely, we are interested in establishing a comparison result among solutions and an estimate on the gradient of a solution, derived from the boundary datum.

A comparison result is a statement of the kind, "for w and v solutions, $w \le v$ on $\partial\Omega$ implies $w \le v$ on Ω." In this generality, the only possible condition for the validity of this statement is the assumption of strict convexity on the Lagrangian f. However, rarely a comparison result is needed in this full generality: in general, one of the two solutions, w or v, belongs to a special class of solutions, as the affine functions (sometimes one is the function identically zero), and one aims at results for this more restricted class of problems. As an example, the first step in the proof of the existence of solutions for the minimal surface problem in parametric form depends on obtaining a priori bounds on the solution based on comparing the unknown solution with a constant solution [5].

The following example shows, however, that even when one of the solutions is an affine function (in particular, a constant), without the assumption of strict convexity, the comparison result is false.

Example 1. Let Ω be the interval $[-1, 1]$; let

$$f(\xi) = \begin{cases} 0, & |\xi| \le 1, \\ (|\xi| - 1)^2, & |\xi| > 1, \end{cases}$$

and consider the problem

$$\text{minimize} \int_{[-1,1]} f(u'(x))\,dx; \qquad u \in W_0^{1,1}([-1, 1]).$$

*Received by the editors March 31, 2006; accepted for publication (in revised form) December 6, 2006; published electronically May 14, 2007.

Both functions $v(x) \equiv 0$ and $w(x) = -|x| + 1$ are solutions, and $w \leq v$ at $\partial\Omega$, but it is not true that $w \leq v$ on Ω.

Still, non–strictly convex Lagrangians do appear in the literature, frequently arising from the convexification of nonconvex Lagrangians: well-known examples, originating from problems of optimal design, are the Lagrangians in [1], [6], [7], [8].

This paper aims at dropping the requirement of strict convexity of f: its purpose is to introduce a class of solutions (to be used instead of the affine functions) such that the corresponding comparison theorem holds true without any requirement of strict convexity. The main property of this class of solutions is that it automatically reduces to the affine functions when f is strictly convex.

As a further motivation for the present study, notice that a comparison theorem involving affine functions is the main tool for the estimates on the gradient of a solution w to problem (1) provided by the bounded slope condition. In the situation described by this condition, affine functions of a given slope K bound the boundary datum u^0, and one is able to show that the same K bounds $\|\nabla w(x)\|$. Example 1 shows, again, that this result cannot possibly be true without the assumption of strict convexity of f. In fact, here the affine function identically zero bounds the boundary datum, with $K = 0$, but it is not true that, for the solution $w(x) = -|x| + 1$, one has $\|\nabla w(x)\| = 0$. In section 3 we prove a new result of the bounded slope condition type. When the Lagrangian f is strictly convex, the new condition we introduce reduces to the classical bounded slope condition, and the estimate on the gradient it provides is the classical estimate.

For a discussion of affine functions as solutions to variational problems, see [3]. In [9], Mariconda and Treu present a comparison theorem for variational problems of general form; their results, in particular, generalize those of [2] and will be used in the present paper. The book [5] contains several references to classical results connected with the bounded slope condition.

2. A comparison theorem. For K a subset of $\mathbb{R}^N$, K^c is its complement; m is the N-dimensional Lebesgue measure, while $m_{(N-1)}$ is the $(N-1)$-dimensional Lebesgue measure; the Hausdorff N-dimensional measure is H^N. The unit ball of $\mathbb{R}^N$ is B. A direction is a vector of unit norm; for a vector $v \in \mathbb{R}^N$, we will frequently use the notation $v = (v_1, \hat{v})$, where $\hat{v}$ is the $N-1$ vector consisting of the components from 2 to N of v. We denote by I_K the *indicator function* of the set K. The notation f^* denotes the *polar* or the *Legendre–Fenchel conjugate* of f. For f a convex function, $Dom(f)$ is the effective domain of f and $\partial f(x)$ is the subdifferential computed at x. For the notions of convex analysis we refer to [11]. When u and v are in $W^{1,1}(\Omega)$, by saying that at $\partial\Omega$ we have $v \geq u$ we mean, as usual, that $(u-v)^+ \in W_0^{1,1}(\Omega)$.

For $\theta \in Dom(\partial f^*)$, we will consider the functions

$$\left(I_{\partial f^*(\theta)}\right)^*(x) = \sup_{k \in \partial f^*(\theta)} \{\langle k, x\rangle\}$$

and

$$-\left(I_{\partial f^*(\theta)}\right)^*(-x) = -\sup_{z \in \mathbb{R}^N} \{\langle -x, z\rangle - I_{\partial f^*(\theta)}(z)\} = \inf_{k \in \partial f^*(\theta)} \{\langle k, x\rangle\}.$$

As an example, for the Lagrangian (see [8])

$$f(\xi) = \begin{cases} \sqrt{2}\|\xi\|, & \|\xi\| \leq \sqrt{2}, \\ 1 + \frac{1}{2}\|\xi\|^2, & \|\xi\| \geq \sqrt{2}, \end{cases} \tag{2}$$

we obtain that $\left(I_{\partial f^*(\theta)}\right)^*(x)$ is the family of maps

$$\left(I_{\partial f^*(\theta)}\right)^*(x) = \begin{cases} 0, & \|\theta\| \le \sqrt{2}, \\ \sqrt{2}\langle \frac{\theta}{\|\theta\|}, x\rangle \chi_{\{x:\langle\theta,x\rangle\ge 0\}}, & \|\theta\| = \sqrt{2}, \\ \langle\theta, x\rangle, & \|\theta\| > \sqrt{2}. \end{cases}$$

Next Theorem 1 shows that the functions defined above are solutions to the minimum problem (1), among those functions satisfying the same boundary conditions. In it, we assume the following growth assumption: $Dom(f^*)$ is open. The following proposition discusses how general this assumption is.

PROPOSITION 1. *Let f be an extended valued, convex, lower semicontinuous function with superlinear growth; then $Dom(f^*) = \mathbb{R}^N$.*

However, the Lagrangian $f(t) = |t| - \sqrt{|t|}$, whose polar is $f^*(p) = \frac{1}{4}\frac{1}{1-|p|}$ for $p \in (-1, 1)$, satisfies the condition $Dom(f^*)$ open, without being of superlinear growth.

It is convenient to use the following notation.

DEFINITION 1. *For $\theta \in Dom(f^*)$, $x^0 \in \mathbb{R}^N$, and $r \in \mathbb{R}$, set*

$$h^+_{\theta,x^0,r}(x) = \left(I_{f^*(\theta)}\right)^*(x - x^0) + r \quad \text{and} \quad h^-_{\theta,x^0,r}(x) = -\left(I_{f^*(\theta)}\right)^*(-x - x^0) + r.$$

THEOREM 1. *Let $Dom(f^*)$ be open. For $\theta \in Dom(f^*)$, $x^0 \in \mathbb{R}^N$, and $r \in \mathbb{R}$, the maps $h^+_{\theta,x^0,r}(x)$ and $h^-_{\theta,x^0,r}(x)$ are solutions to the minimum problem (1), among those u in*

$$\mathcal{S}^+_{\theta,x^0,r} = \left\{u \in W^{1,1}(\Omega) : u - h^+_{\theta,x^0,r} \in W^{1,1}_0(\Omega)\right\}$$

and

$$\mathcal{S}^-_{\theta,x^0,r} = \left\{u \in W^{1,1}(\Omega) : u - h^-_{\theta,x^0,r} \in W^{1,1}_0(\Omega)\right\},$$

respectively.

Proof. The proof is presented for $h^+_{\theta,x^0,r}$. For brevity, we set $h_\theta = h^+_{\theta,x^0,r}$.

The function h_θ, a supremum of convex functions, is convex; since $Dom(f^*)$ is open, $\partial f^*(\theta)$ is bounded; this implies that h_θ is finite on $\mathbb{R}^N$, and hence locally Lipschitzian and differentiable a.e. Let x be a point where it is differentiable, and let $\delta(x)$ be its gradient at x. The set $K(x) = \{k \in \partial f^*(\theta) : \langle k, x - x^0\rangle = \sup_{v\in\partial f^*(\theta)}\langle v, x - x^0\rangle\}$ is nonempty, compact, and convex.

(a) We claim that $\delta(x) \in K(x)$.

In fact, fix any h; let $k_t \in K(x + th)$ be such that $h_\theta(x + th) = \langle k_t, x + th - x^0\rangle + r$ and choose a sequence $t_i \to 0$ such that (k_{t_i}) converge to some k^*_h. Since the map $K(\cdot)$ has closed graph, we have $k^*_h \in K(x)$.

From the definition we have

$$\langle k_{t_i} - k^*_h, x - x^0\rangle \le 0 \quad \text{and} \quad \langle k_{t_i} - k^*_h, x - x^0 + t_i h\rangle \ge 0$$

so that, recalling that $k_{t_i} - k^*_h \to 0$, we obtain

$$\left\langle \frac{k_{t_i} - k^*_h}{t_i}, x - x^0 \right\rangle \to 0.$$

Hence,

$$\begin{aligned} \langle \delta(x), t_i h\rangle + t_i\|h\| o(t_i\|h\|) &= h_\theta(x + t_i h) - h_\theta(x) \\ &= t_i \left\langle \frac{k_{t_i} - k^*_h}{t_i}, x - x^0 \right\rangle + t_i\langle k_{t_i}, h\rangle = t_i\langle k^*_h, h\rangle + t_i o(t_i), \end{aligned}$$

so that

$$\langle \delta(x), h\rangle = \langle k_h^*, h\rangle. \tag{3}$$

In particular, choosing $h = x - x^0$, we obtain $\langle \delta(x) - k_0, x - x^0\rangle = 0$.

Then, in the case $\delta(x) \notin K(x)$, there exist $x^\perp \neq 0$ and $\varepsilon > 0$ such that $\langle x^\perp, x - x^0\rangle = 0$ and $\sup_{k\in K(x)}\langle k, x^\perp\rangle = \langle \delta(x), x^\perp\rangle - \varepsilon$. Take $h = x^\perp$ in (3), and notice that $k^*_{x^\perp} \in K(x)$: we have

$$\sup_{k\in K(x)} \langle k, x^\perp\rangle < \langle \delta(x), x^\perp\rangle = \langle k_h^*, x^\perp\rangle \leq \sup_{k\in K(x)} \langle k, x^\perp\rangle.$$

Hence, $\delta(x) \in K(x)$.

(b) Since $\delta(x) \in K(x) \subset \partial f^*(\theta)$, it follows that $\theta \in \partial f(\delta(x))$. Hence

$$f(\nabla u(x)) \geq \langle \theta, \nabla u(x) - \delta(x)\rangle + f(\delta(x)),$$

and hence

$$\int_\Omega f(\nabla u(x))\,dx - \int_\Omega f(\nabla h_\theta(x))\,dx \geq \int_\Omega \langle \theta, \nabla u(x) - \nabla h_\theta(x)\rangle\,dx.$$

Since $u \in \mathcal{S}_\theta$, the right-hand side equals zero, ending the proof. □

Remarks. In the case in which f is strictly convex, $\partial f^*(\theta)$ is single-valued and the maps h_θ^+ and h_θ^- are affine maps.

In general, we have proved that, a.e. in Ω,

$$\langle \nabla h_\theta, x - x^0\rangle = \sup_{v\in\partial f^*(\theta)} \langle v, x - x^0\rangle. \tag{4}$$

For the comparison theorem we shall need the following lemma: it is a modification of the classical statement saying that Sobolev functions are absolutely continuous on a.e. parallel to a given line. A general discussion of these results is presented in [10] and the lemma follows from these results.

LEMMA 1. *Let Ω be open and convex and let η be in $W^{1,1}(\Omega)$; let $B(x^*, \rho) \subset \Omega$ and, for $x \in B(x^*, \rho)$, set $\tilde{x}(t) = x^0 + (x - x^0)e^t$, $t \leq 0$; then, for a.e. $x \in B(x^*, \rho)$, as long as $\tilde{x}(t) \in \Omega$ and $\|\tilde{x}(t) - x^0\| \geq \delta > 0$,*

(i) *the map $t \to \eta(\tilde{x}(t))$ is absolutely continuous, and*

(ii) *for a.e. t, we have $\frac{d}{dt}\eta(\tilde{x}(t)) = \langle \nabla\eta(\tilde{x}(t)), \tilde{x}(t) - x^0\rangle$.*

The following is the comparison result.

THEOREM 2. *Let Ω be convex, let f be a (possibly extended valued) lower semicontinuous, convex function such that $Dom(f^*)$ is open. Let w be a solution to the problem of minimizing the functional*

$$\mathcal{J}(u) = \int_\Omega f\left(\nabla u(x)\right) dx$$

on $\{u : u - u^0 \in W_0^{1,1}(\Omega)\}$.

Assume that for $\theta \in Dom(f^*)$, $x^0 \in (\Omega)^c$, and $r \in \mathbb{R}$, we have $h^+_{\theta,x^0,r} \geq w$ on $\partial\Omega$. Then $h^+_{\theta,x^0,r} \geq w$ on Ω.

Remarks. Notice that any affine function $\ell(x) = \langle a, x\rangle + b$ can be written as $\ell(x) = \langle a, x - x^0\rangle + r$ with $x^0 \notin \Omega$ and $r = b + \langle a, x^0\rangle$.

Notice also that Example 1 shows that the analogous theorem, where we had an affine function ℓ (in particular, $\ell(x) \equiv 0$) instead of the convex function $h^+_{\theta,x^0,r}$, would be false.

Finally notice that the functions $u(x) \equiv 0$ and $h^+_{0,0,-1}(x) = -1 + |x|$ are solutions to the problem of Example 1; still, $h^+_{0,0,-1} \geq u$ on $\partial\Omega$, but it is not true that $h^+_{0,0,-1} \geq u$ on Ω. Here, the point $x^0 = 0 \in \Omega$, opposite to our assumptions.

Example 2. Consider the problem

$$\text{minimize} \int_{[-1,1]} f(u'(x))\,dx; \quad u^0 = \varepsilon(x-1); \quad u - u^0 \in W^{1,1}_0([-1,1]),$$

where f is defined in (2) and $\varepsilon > 0$ is small. The best upper bound for a solution w is

$$w(x) \leq \sup\left\{ \left(I_{\partial f^*(0)}\right)^* (x+1) + 2\varepsilon, \left(I_{\partial f^*(\sqrt{2})}\right)^* (x-1) \right\} = \sup\left\{ 2\varepsilon, \sqrt{2}(x-1) \right\}.$$

The proof of Theorem 2 is partially based on the following general lemma.

LEMMA 2. *Let Ω be open, bounded, and convex, let η be in $W^{1,1}(\Omega)$, and assume that there exists a point $x^* \in \Omega$ and a set of directions Z^+ having $H^{N-1}(Z^+) > 0$, such that, on the intersection of the half lines $\{x^* + \lambda z : z \in Z^+ \text{ and } \lambda \geq 0\}$ with Ω, we have $\eta \geq \delta > 0$. Then $\eta \notin W^{1,1}_0(\Omega)$.*

Proof. (a) Let D be the diameter of Ω. There exists ρ such that $B(x^*, 3\rho) \subset \Omega$. For $\xi^i \in \partial B$, set $t^i(z) = \frac{z - \langle z, \xi^i \rangle \xi^i}{\langle z, \xi^i \rangle}$; set $R = \frac{3\rho^2}{D^2 + \rho D}$ (so that, in particular, $3\rho - RD \geq 0$); set $Z^i = \{z \in \partial B : \|t^i(z)\| \leq R\}$. Choose finitely many ξ^i so that the corresponding sets Z^i cover ∂B: since $H^{N-1}(Z^+) > 0$, for at least one of them (say, $i = \hat{i}$), one has $H^{N-1}(Z^+ \cap Z^{\hat{i}}) > 0$. We will call Z^* the set $Z^+ \cap Z^{\hat{i}}$: we have

$$H^{N-1}(Z^*) > 0. \tag{5}$$

The half line $\{x^* + \lambda \xi^{\hat{i}} : \lambda \geq 0\}$ meets $\partial\Omega$ at one point, where we set the origin, so that $\xi^{\hat{i}} = -\frac{x^*}{\|x^*\|}$; moreover, we set the x_1 axis to be the half line from the origin through x^*: in this notation we obtain that $x^* = (x^*_1, \hat{0})$ and that $z \in Z^*$ implies

$$\frac{\|\hat{z}\|}{|z_1|} \leq R \quad \text{and} \quad |z_1| \geq \frac{1}{\sqrt{1+R^2}}.$$

It is convenient to call Ω^* the intersection of the half lines $\{x^* + \lambda z : \lambda \geq 0; z \in Z^*\}$ with Ω, and $\partial\Omega^*$ the intersection of the same half lines with $\partial\Omega$.

(b) The map $Z(x) = \frac{x - x^*}{\|x - x^*\|}$ is Lipschitzian on $\Omega \setminus B(x^*, \rho)$, since

$$\left| \frac{x^1 - x^*}{\|x^1 - x^*\|} - \frac{x^2 - x^*}{\|x^2 - x^*\|} \right| \leq \|x^1 - x^2\| \left(\frac{1}{\rho} + \frac{D}{\rho^2} \right).$$

Hence, from the equality $Z^* = Z(\partial\Omega^*)$, we obtain that

$$H^{N-1}(Z^*) \leq \left(\frac{1}{\rho} + \frac{D}{\rho^2} \right) H^{N-1}(\partial\Omega^*)$$

and, from (5), we conclude that

$$H^{N-1}(\partial\Omega^*) > 0. \tag{6}$$

On $\Omega^* \setminus B(x^*, \rho)$ we have $|x_1 - x_1^*| \geq \rho |z_1| \geq \frac{\rho}{\sqrt{1+R^2}}$ so that

$$\left\| \frac{\hat{x}^1 - \hat{x}^*}{x_1^1 - x_1^*} - \frac{\hat{x}^2 - \hat{x}^*}{x_1^2 - x_1^*} \right\| \leq \frac{1}{|x_1^1 - x_1^*|} \|\hat{x}^1 - \hat{x}^2\| + \frac{\|\hat{x}^2 - \hat{x}^*\|}{|x_1^1 - x_1^*||x_1^2 - x_1^*|} |x_1^1 - x_1^2|$$
$$\leq \frac{\sqrt{1+R^2}}{\rho} \|\hat{x}^1 - \hat{x}^2\| + D \frac{1+R^2}{\rho^2} |x_1^1 - x_1^2| \leq L \|x^1 - x^2\|.$$

The above shows that the map $\hat{T}(x) = \frac{\hat{x} - \hat{x}^*}{x_1 - x_1^*}$ is Lipschitzian on $\Omega \setminus B(x^*, \rho)$.

(c) The half line $\{x = x^* + \lambda z : \lambda \geq 0\}$ can as well be described by $\{x : \frac{\hat{x} - \hat{x}^*}{x_1 - x_1^*} = \hat{t} = \frac{\hat{z}}{z_1}\}$: there exists a unique point $b(\hat{t})$ on its intersection with $\partial\Omega$. We will prove the Lipschitzianity of this map. Consider two points $b^1 = b^1(\frac{\hat{x}^1 - \hat{x}^*}{x_1^1 - x_1^*})$ and $b^2 = b^2(\frac{\hat{x}^2 - \hat{x}^*}{x_1^2 - x_1^*})$ in $\partial\Omega$, such that $b_1^1 < b_1^2 < x_1^*$. The half line $b^1 + \lambda(b^2 - b^1)$ meets the plane $\{x_1 = x_1^*\}$ at the point $(x_1^*, \hat{b}^1 + \frac{x_1^* - b_1^1}{b_1^2 - b_1^1}(\hat{b}^2 - \hat{b}^1))$: it cannot be that this point is in $B(x^*, 3\rho)$, since, otherwise, a half line issued from a point in the interior of a convex set would meet its boundary in two distinct points. Hence we must have that $\|\hat{b}^1 + \frac{x_1^* - b_1^1}{b_1^2 - b_1^1}\hat{b}^2 - \hat{b}^1\| \geq 3\rho$, i.e., since $\|\hat{b}^1\| \leq RD$, that $\frac{\|\hat{b}^2 - \hat{b}^1\|}{b_1^2 - b_1^1} \geq \frac{3\rho - RD}{D}$. We have obtained that

$$|b_1^2 - b_1^1| = b_1^2 - b_1^1 \leq \frac{D}{3\rho - RD} \|\hat{b}^2 - \hat{b}^1\| = M \|\hat{b}^2 - \hat{b}^1\|. \tag{7}$$

In particular, since $b_1(\hat{0}) = 0$, we have also obtained that $|b_1| \leq M\|\hat{b}\| \leq MRD = \frac{RD^2}{3\rho - RD} = \rho$, so that $|b_1(\hat{t}) - x_1^*| \geq 2\rho$.

The equalities

$$\frac{\hat{z}^1}{z_1^1} = \frac{\hat{b}^1}{b_1^1 - x_1^*} \qquad \text{and} \qquad \frac{\hat{z}^2}{z_1^2} = \frac{\hat{b}^2}{b_1^2 - x_1^*}$$

yield

$$\hat{b}^1 - \hat{b}^2 = \left(\frac{\hat{z}^1}{z_1^1} - \frac{\hat{z}^2}{z_1^2} \right) (b_1^1 - x_1^*) + \frac{\hat{z}^2}{z_1^2} (b_1^1 - b_1^2)$$

so that (7) gives

$$(1 - MR) \|\hat{b}^1 - \hat{b}^2\| \leq \left\| \frac{\hat{z}^1}{z_1^1} - \frac{\hat{z}^2}{z_1^2} \right\| |b_1^1 - x_1^*| \leq \left\| \frac{\hat{z}^1}{z_1^1} - \frac{\hat{z}^2}{z_1^2} \right\| D;$$

hence we have both

$$\|\hat{b}^1 - \hat{b}^2\| \leq \frac{D}{1 - MR} \left\| \frac{\hat{z}^1}{z_1^1} - \frac{\hat{z}^2}{z_1^2} \right\|$$

and

$$|b_1^1 - b_1^2| \leq \frac{MD}{1 - MR} \left\| \frac{\hat{z}^1}{z_1^1} - \frac{\hat{z}^2}{z_1^2} \right\|,$$

which show that the map $\hat{t} \to b(\hat{t})$ is Lipschitzian (call β its Lipschitz constant).

(d) On $\Omega^* \setminus B(x^*, \rho)$, define the map

$$\Lambda(x) = \frac{x_1 - x_1^*}{b_1(\frac{\hat{x} - \hat{x}^*}{x_1 - x_1^*}) - x_1^*}.$$

We have that $\Lambda(x) = 1$ when $x = b(\frac{\hat{x}-\hat{x}^*}{x_1-x_1^*})$, so that the level set $\Lambda(x) = 1$ is $\partial\Omega^*$. We already know that $|b_1(\frac{\hat{x}-\hat{x}^*}{x_1-x_1^*}) - x_1^*| > 2\rho$ and that $b_1(\hat{t})$ is Lipschitzian. From (b) above, $x \to \hat{t}(x)$ is Lipschitzian. Hence, $\Lambda(x)$ is Lipschitzian and its Jacobian, $J\Lambda$, is bounded.

Consider the sets $\Lambda^{-1}(\lambda)$, which we shall call $(\partial\Omega)_\lambda$, and $(\Omega)_{\lambda^*} = \cup_{\lambda^* \le \lambda < 1}(\partial\Omega)_\lambda$. For x in it, from the equality $x_1 - x_1^* = \lambda(b_1 - x_1^*)$, we obtain $\|x - x^*\| \ge \lambda 2\rho$; hence, whenever $\frac{1}{2} \le \lambda^* \le \lambda \le 1$, we have that $\|x - x^*\| \ge \rho$, so that $(\Omega)_{\lambda^*} \subset \Omega^* \setminus B(x^*, \rho)$. For any set $V \subset \Omega_{\lambda^*}$, the coarea theorem yields

$$\int_{\Omega^*_{\lambda^*}} \chi_V(x) J\Lambda(x)\, dx = \int_{\lambda^*}^1 \left(\int_{(\partial\Omega)_\lambda \cap V} dH^{N-1} \right) d\lambda.$$

Hence, whenever $\int_{\Omega_{\lambda^*}} \chi_V(x) J\Lambda(x)\, dx < \varepsilon$ (ε and V to be fixed later), we must have $m(\{\lambda : H^{N-1}((\partial\Omega)_\lambda \cap V) \le \sqrt{\varepsilon}\}) \ge 1 - \lambda^* - \sqrt{\varepsilon}$, so that, for some λ_ε: $\lambda_\varepsilon - \lambda^* \le 2\sqrt{\varepsilon}$, we must have

$$H^{N-1}((\partial\Omega)_{\lambda_\varepsilon} \cap V) < \sqrt{\varepsilon}. \tag{8}$$

(e) Let $\psi_n \in C_c^\infty(\Omega)$, $\psi_n \to \eta$ in $W^{1,1}(\Omega)$. Fix any $\tilde{\lambda}$ with $\lambda^* \le \tilde{\lambda} < 1$. For $x \in \Omega^*_{\lambda^*}$, consider the Lipschitzian map $\hat{T}(x) = \frac{\hat{x}-\hat{x}^*}{x_1-x_1^*}$ and call $\hat{T}^* = \hat{T}(Z^*)$. We have

$$\begin{aligned}\int_{\Omega_{\lambda^*}} \|\nabla\psi_n(x)\| J\hat{T}(x)\, dx &\ge \int_{\Omega_{\tilde{\lambda}}} \left\langle \nabla\psi_n(x), \frac{x - x^*}{\|x - x^*\|} \right\rangle J\hat{T}(x)\, dx \\ &= \int_{\hat{T}^*} \left(\int_{\hat{T}^{-1}(\hat{t}) \cap \Omega_{\tilde{\lambda}}} \left\langle \nabla\psi_n(x), \frac{x - x^*}{\|x - x^*\|} \right\rangle dH^1 \right) d\hat{t}.\end{aligned}$$

The set $\hat{T}^{-1}(\hat{t}) \cap \Omega_{\tilde{\lambda}}$ is described by $\{x = x^* + \lambda(b(\hat{t}) - x^*) : \tilde{\lambda} < \lambda < 1\}$ and can be parametrized setting $\lambda = e^\tau$, so that $\tilde{x}(\tau) = x^* + (b(\hat{t}) - x^*)e^\tau$, $\tilde{x}'(\tau) = \tilde{x}(\tau) - x^*$, and $dH^1 = \|\tilde{x}(\tau) - x^*\| d\tau$. Hence

$$\begin{aligned}\int_{\Omega_{\lambda^*}} \|\nabla\psi_n(x)\| J\hat{T}(x)\, dx &\ge \int_{\hat{T}^*} \left(\int_0^{\ln\tilde{\lambda}} \langle \nabla\psi_n(\tilde{x}(\tau)), \tilde{x}(\tau) - x^* \rangle\, d\tau \right) d\hat{t} \\ &= \int_{\hat{T}^*} \left(\int_0^{\ln\tilde{\lambda}} \frac{d}{d\tau}\psi_n(\tilde{x}(\tau))\, d\tau \right) d\hat{t} = \int_{\hat{T}^*} \psi_n(x^* + \tilde{\lambda}(b(\hat{t}) - x^*))\, d\hat{t}.\end{aligned} \tag{9}$$

We wish to estimate the last integral by suitably choosing $\tilde{\lambda}$. Set $V_n = \{x \in \Omega_{\lambda^*} : |\psi_n(x) - \eta(x)| \ge \frac{\delta}{2}\}$: we know that, in particular, ψ_n converges to η in measure and, since $J\Lambda$ is bounded, we obtain that

$$\int_{\Omega_{\lambda^*}} \chi_{V_n} J\Lambda(x)\, dx = \varepsilon_n \to 0,$$

and hence, by (8), that there exist λ_n, such that at once we have $\lambda_n - \lambda^* \le 2\sqrt{\varepsilon_n}$ and $H^{N-1}((\partial\Omega)_{\lambda_n} \cap V_n) < \sqrt{\varepsilon_n}$. Since $H^{N-1}(\partial\Omega)_{\lambda_n} = \lambda_n^{N-1} H^{N-1}(\partial\Omega^*)$, we obtain

$$H^{N-1}((\partial\Omega)_{\lambda_n} \setminus V_n) \ge \lambda_n^{N-1} H^{N-1}(\partial\Omega^*) - \sqrt{\varepsilon_n}. \tag{10}$$

There exists n^* such that for every $n \ge n^*$ we have

$$H^{N-1}((\partial\Omega)_{\lambda_n} \setminus V_n) \ge \frac{1}{2}(\lambda^*)^{N-1} H^{N-1}(\partial\Omega^*) = C > 0. \tag{11}$$

(f) Recall that, for $x \in (\partial\Omega)_{\lambda_n} \setminus V_n$, we have both $|\psi_n(x)-\eta(x)| \le \frac{\delta}{2}$ and $\eta(x) \ge \delta$, inferring that $\psi_n(x) \ge \frac{\delta}{2}$ there. Call $\hat{T}_n = \{\hat{T}(x) : x \in (\partial\Omega)_{\lambda_n} \setminus V_n\}$: we also obtain that $(\partial\Omega)_{\lambda_n} \setminus V_n = \{b_n(\hat{t}) : \hat{t} \in \hat{T}_n\}$, where $b_n(\hat{t}) = x^* + \lambda_n(b(\hat{t}) - x^*)$. Hence, we have

$$\int_{\hat{T}_n} \psi_n(x^* + \lambda_n(b(\hat{t}) - x^*))\, d\hat{t} \ge \frac{\delta}{2} m_{(N-1)}(\hat{T}_n).$$

On the other hand, the map b_n is Lipschitzian, since, from the conclusion of (c) above, so is b, and its Lipschitz constant is bounded by β, the Lipschitz constant of b, so that $H^{N-1}((\partial\Omega)_{\lambda_n} \setminus V_n) = H^{N-1}(b_n(\hat{T}_n)) \le \beta m_{(N-1)}(\hat{T}_n)$. Hence, for $n \ge n^*$, we have

$$m_{(N-1)}(\hat{T}_n) \ge \frac{1}{\beta} H^{N-1}(\partial\Omega)_{\lambda_n} \setminus V_n \ge \frac{1}{\beta} C$$

and, from (9), we conclude

$$\begin{aligned}
\int_{\Omega_{\lambda_n}} \|\nabla\eta(x)\| J\hat{T}(x)\, dx &\ge \int_{\Omega_{\lambda_n}} \|\nabla\psi_n(x)\| J\hat{T}(x)\, dx - \int_{\Omega_{\lambda_n}} \|\nabla\eta(x) - \nabla\psi_n(x)\| J\hat{T}(x)\, dx \\
&\ge \int_{\hat{T}_n} \psi_n(x^* + \lambda^*(b(\hat{t}) - x^*))\, d\hat{t} - \int_{\Omega} \|\nabla\eta(x) - \nabla\psi_n(x)\| J\hat{T}(x)\, dx \\
&\ge \frac{\delta}{2}\frac{1}{\beta} C - \int_{\Omega} \|\nabla\eta(x) - \nabla\psi_n(x)\| J\hat{T}(x)\, dx,
\end{aligned}$$

so that

$$\int_{\Omega_{\lambda^*}} \|\nabla\eta(x)\| J\hat{T}(x)\, dx = \lim_{n\to\infty} \int_{\Omega_{\lambda_n}} \|\nabla\eta(x)\| J\hat{T}(x)\, dx \ge \frac{\delta}{2}\frac{1}{\beta} C.$$

However, as $\lambda^* \to 1$, we have $m(\Omega_{\lambda^*}) \to 0$, so the previous estimate contradicts the integrability of $\nabla\eta$. □

Proof of Theorem 2. For brevity, set $h_\theta = h^+_{\theta,x^0,r}$. Let $\eta = (w - h_\theta)^+$, so that $\eta \in W^{1,1}_0(\Omega)$. Set $E^+ = \{x : \eta(x) > 0\}$: we wish to prove that $m(E^+) = 0$.

(a) Consider $v = w - \eta$: we have

$$\nabla v(x) = \begin{cases} \nabla u(x), & x \in (E^+)^c, \\ \nabla h_\theta(x), & x \in E^+. \end{cases}$$

Since $w - v \in W^{1,1}_0(\Omega)$, from the above we obtain

$$0 = \int_\Omega \langle\theta, \nabla w(x) - \nabla v(x)\rangle dx = \int_{E^+} \langle\theta, \nabla w(x) - \nabla h_\theta(x)\rangle dx.$$

Moreover, $\nabla h_\theta(x) \in \partial f^*(\theta)$, so that $\theta \in \partial f(\nabla h_\theta(x))$, and the convexity of f implies

$$\begin{aligned}
&\int_\Omega (f(\nabla w(x)) - f(\nabla v(x)))dx \\
&= \int_{E^+} (f(\nabla w(x)) - f(\nabla h_\theta(x))\, dx \ge \int_{E^+} \langle\theta, \nabla w(x) - \nabla h_\theta(x)\rangle dx = 0.
\end{aligned}$$

On the other hand, w is a minimum, so that

$$0 \ge \int_\Omega (f(\nabla w(x)) - f(\nabla v(x)))dx = \int_{E^+} (f(\nabla w(x)) - f(\nabla h_\theta(x)))dx,$$

so that we conclude that

$$\int_{E^+} (f(\nabla w(x)) - f(\nabla h_\theta(x)))dx = 0.$$

Adding the equalities, we have

$$\int_{E^+} (f(\nabla w(x)) - f(\nabla h_\theta(x)) + \langle \theta, \nabla w(x) - \nabla v(x)\rangle)\, dx = 0.$$

Since the integrand is nonnegative, we obtain that, for a.e. $x \in E^+$,

$$f(\nabla w(x)) - f(\nabla h_\theta(x)) + \langle \theta, \nabla w(x) - \nabla v(x)\rangle = 0.$$

(b) The previous equality can be rewritten as

$$\langle \theta, \nabla w\rangle - f(\nabla w) = \langle \theta, \nabla v\rangle - f(\nabla h_\theta).$$

Since $\theta \in \partial f(\nabla h_\theta(x))$, as is well known we have $\langle \theta, \nabla v\rangle - f(\nabla h_\theta) = f^*(\theta)$, so that also $\langle \theta, \nabla w\rangle - f(\nabla w) = f^*(\theta)$; then we obtain that $\theta \in \partial f(\nabla w)$ and finally that, a.e. on E^+,

$$\nabla w(x) \in \partial f^*(\theta),$$

and hence that, recalling (4), a.e. on E^+, we have

$$\langle \nabla w(x), x - x^0\rangle \le \sup_{k \in \partial f^*(\theta)} \{\langle k, x - x^0\rangle\} = \langle \nabla h_\theta(x), x - x^0\rangle.$$

We have obtained that, a.e. on Ω,

$$\langle \nabla \eta(x), x - x^0\rangle \le 0. \tag{12}$$

In addition, from the assumption on f^*, we obtain that there exists K such that, a.e. on E^+, $\|\nabla w(x)\| \le K$. This inequality will be used in (f).

(c) To show that $m(E^+) = 0$, we shall prove that the assumption that there exist $\delta > 0$ and $E^+_\delta \subset E^+$ such that $m(E^+_\delta) > 0$ and $\eta(x) \ge \delta$ on E^+_δ leads to a contradiction.

Let x^* be a point of density of E^+_δ and let ρ^* be such that $B(x^*, \rho^*) \subset \Omega$. Then, on a.e. line connecting $x \in B(x^*, \rho^*)$ and x^0, the map η is absolutely continuous. The estimate (12) implies that on any such segment (x, x^0), we have that $\eta \ge \delta$, and one would like to conclude that $\eta \notin W^{1,1}_0(\Omega)$, the contradiction we seek. The reasoning to show this contradiction is based on some version of the Fubini–Tonelli theorem, and has been used in [2] and [9]. In the present situation, however, x^0 can belong to $\partial\Omega$ and, in this case, knowing that $\eta \ge \delta$ on segments of the form (x, x^0), does not by itself prevent η from being in $W^{1,1}_0(\Omega)$. It is this case we are going to examine in some detail.

Consider $x^0 \in \partial\Omega$; let $H = \{x : \langle h, x - x^0\rangle = 0\}$ be a supporting plane to Ω through x^0, and set $H^- = \{x : \langle h, x - x^0\rangle < 0\}$ with $\Omega \subset H^+$. Let $\tilde{x}^2$ be in H^-; for $\lambda \in (0, 1)$, set $x^*_\lambda = x^0 + \lambda(x^* - x^0)$ and $\tilde{x}^2_\lambda = x^0 + \lambda(\tilde{x}^2 - x^0)$. Let $x^1_\lambda = \alpha x^*_\lambda + (1-\alpha)\tilde{x}^2_\lambda$ be the intersection of the segment $(x^*_\lambda, \tilde{x}^2_\lambda)$ with H, described by

$$\alpha = \frac{\langle h, x^0 - \tilde{x}^2_\lambda\rangle}{\langle h, x^*_\lambda - \tilde{x}^2_\lambda\rangle} = \frac{\langle h, x^1_\lambda - \tilde{x}^2_\lambda\rangle}{\langle h, x^*_\lambda - \tilde{x}^2_\lambda\rangle}.$$

Since

$$\frac{\langle h, x^1_\lambda - \tilde{x}^2_\lambda\rangle}{\langle h, x^*_\lambda - \tilde{x}^2_\lambda\rangle} = \frac{\langle h, x^0 - \tilde{x}^2\rangle}{\langle h, x^* - \tilde{x}^2\rangle},$$

α is independent on λ. Consider the expression

$$\frac{\|x^*_\lambda - \tilde{x}^2_\lambda\|}{\|x^*_\lambda - x^1_\lambda\|}\left(1 - e^{-\frac{\delta}{2K\|\tilde{x}^2_\lambda - x^0\|}}\right).$$

As λ decreases to zero, the ratio

$$\frac{\|x^*_\lambda - \tilde{x}^2_\lambda\|}{\|x^*_\lambda - x^1_\lambda\|} = \frac{1}{1-\alpha} > 1$$

does not change, while $(1 - e^{-\frac{\delta}{2K\|\tilde{x}^2_\lambda - x^0\|}}) \uparrow 1$. Hence, we can assume to have chosen $\lambda > 0$ such that

$$\frac{\|x^*_\lambda - \tilde{x}^2_\lambda\|}{\|x^*_\lambda - x^1_\lambda\|}\left(1 - e^{-\frac{\delta}{2K\|\tilde{x}^2_\lambda - x^0\|}}\right) = \ell > 1.$$

Having fixed λ, in what follows we will call x^* the point x^*_λ and $\tilde{x}^2$ the point $\tilde{x}^2_\lambda$. For x^2 in a small neighborhood of $\tilde{x}^2$, the unique intersection of the segment (x^2, x^*) with H will be denoted by $x^1_{x^2}$. We notice that, since the original point x^* was of density for E^+_δ and a.e. segment (x^0, x) with x in E^+_δ belongs to E^+_δ, we obtain that the point x^* just fixed is again of density for E^+_δ.

Set $x_{x^2}(t) = x^2 + e^t(x^* - x^2)$ and $t(x^2) = -\frac{\delta}{2K\|x^2 - x^0\|}$. In particular, for $x^2 = \tilde{x}^2$, we have

$$\|x_{\tilde{x}^2}(t(\tilde{x}^2)) - x^*\| = \|x^* - x^1_{\tilde{x}^2}\|\frac{\|x^* - \tilde{x}^2\|}{\|x^* - x^1_{\tilde{x}^2}\|}\left(1 - e^{-\frac{\delta}{2K\|\tilde{x}^2 - x^0\|}}\right) = \ell\|x^* - x^1_{\tilde{x}^2}\|.$$

By continuity, there exists $r > 0$ so that $x^2 \in B(\tilde{x}^2, r)$ implies

$$\frac{\|x^* - x^2\|}{\|x^* - x^1_{x^2}\|}\left(1 - e^{-\frac{\delta}{2K\|x^2 - x^0\|}}\right) \geq \frac{1}{2} + \frac{\ell}{2} > 1.$$

In other words, for every $x^2 \in B(\tilde{x}^2, r)$, $\|x_{x^2}(t(x^2)) - x^*\| > \|x^* - x^1(x^2)\|$, i.e., the segment $(x^*, x_{x^2}(t(x^2)))$ intersects H. Equivalently, the map $x_{x^2}(t)$ takes values in Ω on some interval $(\alpha_{x^2}, 0)$ with $\alpha_{x^2} \geq t(x^2)$.

(d) Since x^* is a point of density of E^+_δ, we have that $m(x^* + rB \cap E^+_\delta) = (1 - \varepsilon(r))m(x^* + rB)$, and by the coarea theorem we obtain

$$\int_0^r H^{(N-1)}(x^* + s\partial B \cap E^+_\delta)\, ds = m(x^* + rB \cap E^+_\delta) = (1 - \varepsilon(r))m(x^* + rB)$$
$$= \int_0^r (1 - \varepsilon(r))H^{(N-1)}(x^* + s\partial B)\, ds = \int_0^r (1 - \varepsilon(r))s^{N-1}N\omega_N\, ds,$$

so that there exist $r_\nu \downarrow 0$ such that $H^{(N-1)}(x^* + r_\nu\partial B \cap E^+_\delta) \geq (1 - \varepsilon(r_\nu))r_\nu^{N-1}N\omega_N$.

For brevity, when $x \neq x^*$, we will use the notation $z(x) = \frac{x - x^*}{\|x - x^*\|}$. Consider $Z = z(B(\tilde{x}^2, r))$. We have that

$$\frac{H^{(N-1)}(Z)}{N\omega_N} = L > 0.$$

Since $H^{(N-1)}(x^* + r_\nu Z) = r_\nu^{(N-1)} N\omega_N L$, whenever $\varepsilon(r_\nu) < L$, we have that

$$H^{(N-1)}(x^* + r_\nu Z \cap E_\delta^+) = M_\nu > 0.$$

Fix one such ν; set Z^+ to be the subset of Z defined by $x^* + r_\nu Z^+ = x^* + r_\nu Z \cap E_\delta^+$, so that $H^{(N-1)}(x^* + r_\nu Z^+) = M_\nu$, i.e.,

$$H^{(N-1)}(Z^+) = \frac{M_\nu}{r_\nu^{N-1}} > 0. \tag{13}$$

(e) Define β_{x^2} by the equation $x^* - (x^2 + e^{\beta_{x^2}}(x^* - x^2)) = r_\nu$. For almost every $z \in Z^+$, the map $\eta(x_{x^2}(t))$ is absolutely continuous on $(\alpha_{x^2}, \beta_{x^2})$ and we can write

$$\begin{aligned}
&\eta(x_{x^2}(\beta_{x^2}) = \eta(x_{x^2}(t)) + \int_t^{\beta_{x^2}} \frac{d}{ds}\eta(x_{x^2}(s))\, ds \\
&= \eta(x_{x^2}(t)) + \int_t^{\beta_{x^2}} \langle \nabla\eta(x_{x^2}(s)), x'_{x^2}(s)\rangle\, ds \\
&= \eta(x_{x^2}(t)) + \int_t^{\beta_{x^2}} \langle \nabla\eta(x_{x^2}(s)), [(x_{x^2}(s) - x^0) + (x^0 - x^2)]\rangle\, ds.
\end{aligned}$$

Recalling that $\eta(x_{x^2}(\beta_{x^2}) \geq \delta$; that, for $x \in E^+$, we have $\langle \nabla\eta(x), x - x^0\rangle \leq 0$; that $\|\nabla\eta(x)\| \leq K$; and that $-t \leq -t(x^2) = \frac{\delta}{2K\|x^2 - x^0\|}$, we obtain

$$\delta \leq \eta(x_{x^2}(\beta_{x^2})) \leq \eta(x_{x^2}(t)) + (-t)K\|x^0 - x^2\| \leq \eta(x_{x^2}(t)) + \frac{\delta}{2},$$

so that $\eta(x_{x^2}(t)) \geq \frac{\delta}{2}$.

Hence, we have obtained that $\eta \geq \frac{\delta}{2}$ on the intersection of Ω with the set of half lines $x^* + \lambda Z^+$ issuing from x^*, where $H^{(N-1)}(Z^+) > 0$. Applying Lemma 2 we obtain that $\eta \notin W_0^{1,1}(\Omega)$, a contradiction. □

3. The bounded slope condition. The bounded slope condition is imposed on the boundary datum u_0: classically, under the assumption of strict convexity on f, it demands the existence, for every $x^0 \in \partial\Omega$, of two vectors k^+ and k^- (depending on x^0) such that, for every $x \in \partial\Omega$, one has

$$u_0(x^0) + \langle k^-, x - x^0\rangle \leq u_0(x) \leq u_0(x^0) + \langle k^+, x - x^0\rangle$$

and, in addition, the existence of K such that

$$K \geq \sup_{x^0 \in \partial\Omega} \max\{\|k^-\|, \|k^+\|\}.$$

Its purpose is to infer that, for a solution w to problem (1), one has $\|\nabla w(x)\| \leq K$ for almost every $x \in \Omega$.

Example 1 shows that this result, the proof of which depends on a comparison theorem, cannot possibly be true without the assumption of strict convexity of the Lagrangian f. Our present aim is to be able to provide estimates for the gradient of a solution in those cases, as the examples mentioned in this paper, where the Lagrangian f is non–strictly convex on a bounded set and becomes strictly convex for large values of ξ. In it, the notation $\|A\| = \sup_{a\in A}\{\|a\|\}$ will be used.

THEOREM 3. *Let Ω be an open, bounded, and convex set; let f be an extended valued, lower semicontinuous convex function, such that $Dom(f^*)$ is open; assume that for every $x^0 \in \partial\Omega$ there exist $\theta^+(x^0)$ and $\theta^-(x^0)$ such that, for every $x \in \partial\Omega$,*

$$u_0(x^0) + (I_{\partial f^*(\theta_)})^*(x - x^0) \le u_0(x) \le u_0(x^0) + (I_{\partial f^*(\theta+)})^*(x - x^0).$$

In addition, assume that there is K such that

$$K \ge \sup_{x^0 \in \partial\Omega} \max\{\|\partial f^*(\theta^+(x^0))\|, \|\partial f^*(\theta^-(x^0))\|\}.$$

Furthermore, assume that when $\|\xi\| > K$, f is strictly convex at ξ. If $w \in C(\Omega) \cap W^{1,1}(\Omega)$ is a solution to problem (1), then w is Lipschitzian and, for a.e. $x \in \Omega$, we have

$$\|\nabla w(x)\| \le K.$$

For the problem in Example 2, we obtain, for a solution w, the bound $|w'(x)| \le \sqrt{2}$, independent of ε.

Proof. The proof is a minor modification of the proof of Theorem 4.1 of [2]. ∎

LINEAR QUADRATIC DIFFERENTIAL GAMES: SADDLE POINT AND RICCATI DIFFERENTIAL EQUATION*

MICHEL C. DELFOUR†

Abstract. Zhang [*SIAM J. Control Optim.*, 43 (2005), pp. 2157–2165] recently established the equivalence between the finiteness of the *open loop value* of a two-player zero-sum linear quadratic (LQ) game and the finiteness of its open loop lower and upper values. In this paper we complete and sharpen the results of Zhang for the finiteness of the lower value of the game by providing a set of necessary and sufficient conditions that emphasizes the *feasibility condition*: $(0,0)$ is a solution of the open loop lower value of the game for the zero initial state. Then we show that, under the assumption of an open loop saddle point in the time horizon $[0,T]$ for all initial states, there is an open loop saddle point in the time horizon $[s,T]$ for all initial times s, $0 \le s < T$, and all initial states at time s. From this we get an *optimality principle* and adapt the *invariant embedding approach* to construct the decoupling symmetrical matrix function $P(s)$ and show that it is an $H^1(0,T)$ solution of the matrix Riccati differential equation. Thence an open loop saddle point in $[0,T]$ yields closed loop optimal strategies for both players. Furthermore, a necessary and sufficient set of conditions for the existence of an open loop saddle point in $[0,T]$ for all initial states is the convexity-concavity of the utility function and the existence of an $H^1(0,T)$ symmetrical solution to the matrix Riccati differential equation. As an illustration of the cases where the open loop lower/upper value of the game is $-\infty/+\infty$, we work out two informative examples of solutions to the Riccati differential equation with and without blow-up time.

Key words. linear quadratic differential game, saddle point, value of a game, Riccati differential equation, open loop and closed loop strategies, conjugate point, blow-up time

1. Introduction.

We consider the *two-player zero-sum game* with *linear dynamics* and a *quadratic utility function* over a *finite time horizon*. The min sup problem was studied in 1969 by [5]. The fundamental theory of closed loop linear quadratic (LQ) games was given in 1979 by Bernhard [4] followed by the seminal book of Başar and Bernhard [1] in 1991 and 1995. A very nice paper by Zhang [10] in 2005 established the equivalence between the finiteness of the open loop value of a two-player zero-sum LQ game and the finiteness of its open loop lower and upper values.

In this paper we complete and sharpen the results of [10] for the finiteness of the lower value of the game by providing a set of necessary and sufficient conditions (Theorem 2.2) that emphasizes the *feasibility condition*: $(0,0)$ is a solution of the open loop lower value of the game for the zero initial state. A similar feasibility condition holds for the finiteness of the open loop upper value and value of the game. It also recasts the results in the more intuitive state-adjoint state framework.

Then we show that, under the assumption of an open loop saddle point in the time horizon $[0,T]$ for all initial states, there is a unique open loop saddle point in

the time horizon $[s,T]$ for all initial times s, $0 \le s < T$, and all initial states at time s (Theorem 5.2(iii)). From this we get an *optimality principle* and adapt the *invariant embedding approach* of Bellman in the style of Lions [9] to construct the decoupling symmetrical matrix function $P(s)$ (Theorem 2.9) and show that it is an $H^1(0,T)$ solution of the matrix Riccati differential equation. Thence an open loop saddle point in $[0,T]$ yields closed loop optimal strategies for both players who achieve a closed loop-closed loop saddle point in the sense of Bernhard [4]. Furthermore, a necessary and sufficient set of conditions for the existence of an open loop saddle point in $[0,T]$ for all initial states is the convexity-concavity of the utility function and the existence of a symmetrical $H^1(0,T)$ solution to the matrix Riccati differential equation (Theorem 2.10). As an illustration of the cases where the open loop lower/upper value of the game is $-\infty/+\infty$, we work out two informative examples of solutions to the Riccati differential equation with and without blow-up time.

2. Definitions, notation, and main results.

2.1. System, utility function, values of the game. Given a finite dimensional Euclidean space $\mathbf{R}^d$ of dimension $d \ge 1$, the *norm* and *inner product* will be denoted by $|x|$ and $x \cdot y$, respectively, irrespective of the dimension d of the space. Given $T > 0$, the norm and inner product in $L^2(0,T;\mathbf{R}^n)$ will be denoted $\|f\|$ and (f,g). The norm in the Sobolev space $H^1(0,T;\mathbf{R}^n)$ will be written $\|f\|_{H^1}$.

Consider the following two-player zero-sum game over the finite time interval $[0,T]$ characterized by the quadratic *utility function*

$$C_{x_0}(u,v) \stackrel{\text{def}}{=} Fx(T)\cdot x(T) + \int_0^T Q(t)x(t)\cdot x(t) + |u(t)|^2 - |v(t)|^2\,dt, \tag{2.1}$$

where x is the solution of the linear differential system

$$\frac{dx}{dt}(t) = A(t)x(t) + B_1(t)u(t) + B_2(t)v(t) \quad \text{a.e. in } [0,T], \quad x(0) = x_0, \tag{2.2}$$

x_0 is the *initial state* at time $t = 0$, $u \in L^2(0,T;\mathbf{R}^m)$, $m \ge 1$, is the strategy of the first player, and $v \in L^2(0,T;\mathbf{R}^k)$, $k \ge 1$, is the strategy of the second player. We assume that F is an $n \times n$ matrix and that A, B_1, B_2, and Q are matrix functions of appropriate order that are measurable and bounded a.e. in $[0,T]$. Moreover, $Q(t)$ and F are symmetrical. It will be convenient to use the following compact notation and drop the "a.e. in $[0,T]$" wherever no confusion arises:

$$C_{x_0}(u,v) = Fx(T)\cdot x(T) + \int_0^T Qx\cdot x + |u|^2 - |v|^2\,dt, \tag{2.3}$$

$$x' = Ax + B_1u + B_2v \quad \text{in } [0,T], \quad x(0) = x_0. \tag{2.4}$$

The above assumptions on F, A, B_1, B_2, and Q will be used throughout this paper.

Remark 2.1. The more general quadratic structure involving cross terms and different quadratic weights $N_1u\cdot u$ and $N_2v\cdot v$ on u and v (cf., for instance, Bernhard [4, section 2, p. 53]),

$$\int_0^T (x,u,v)\cdot \begin{bmatrix} Q & S & T \\ S^* & N_1 & 0 \\ T^* & 0 & -N_2 \end{bmatrix} \begin{bmatrix} x \\ u \\ v \end{bmatrix} dt,$$

can be brought back to the simpler form (2.1)–(2.2) by the following change of variables:

$$\begin{bmatrix} x \\ u \\ v \end{bmatrix} = \begin{bmatrix} I & 0 & 0 \\ -N_1^{-1}S^* & N_1^{-1/2} & 0 \\ N_2^{-1}T^* & 0 & N_2^{-1/2} \end{bmatrix} \begin{bmatrix} x \\ \bar{u} \\ \bar{v} \end{bmatrix},$$

where $N_1(t)$ and $N_2(t)$ are symmetrical positive definite matrices such that

$$\begin{aligned} &\exists \nu_1 > 0 \text{ such that } \forall u \in \mathbf{R}^m \text{ and almost all } t, \quad N_1(t)u \cdot u \geq \nu_1 |u|^2, \\ &\exists \nu_2 > 0 \text{ such that } \forall v \in \mathbf{R}^k \text{ and almost all } t, \quad N_2(t)v \cdot v \geq \nu_2 |v|^2. \end{aligned} \tag{2.5}$$

This yields the simpler initial structure with the system and the utility function

$$x' = \bar{A}x + \bar{B}_1\bar{u} + \bar{B}_2\bar{v}, \quad \int_0^T \bar{Q}x \cdot x + |\bar{u}|^2 - |\bar{v}|^2 \, dt$$

by introducing the new matrices

$$\begin{aligned} &\bar{A} = A - B_1N_1^{-1}S^* + B_2N_2^{-1}T^*, \quad \bar{B}_1 = B_1N_1^{-1/2}, \quad \bar{B}_2 = B_2N_2^{-1/2}, \\ &\bar{Q} = Q - SN_1^{-1}S^* + TN_2^{-1}T^*. \end{aligned}$$

The matrix functions N_1, N_2, S, and T are all assumed to be measurable and bounded.

DEFINITION 2.1. *Let x_0 be an initial state in $\mathbf{R}^n$ at time $t = 0$.*

(i) *The game is said to achieve its* open loop lower value *(resp.,* upper value*) if*

$$v^-(x_0) \stackrel{\text{def}}{=} \sup_{v \in L^2(0,T;\mathbf{R}^k)} \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v) \tag{2.6}$$

$$\textit{(resp., } v^+(x_0) \stackrel{\text{def}}{=} \inf_{u \in L^2(0,T;\mathbf{R}^m)} \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u,v)\textit{)} \tag{2.7}$$

is finite. By definition $v^-(x_0) \leq v^+(x_0)$.

(ii) *The game is said to achieve its* open loop value *if its open loop lower value $v^-(x_0)$ and upper value $v^+(x_0)$ are achieved and $v^-(x_0) = v^+(x_0)$. The* open loop value *of the game will be denoted by $v(x_0)$.*

(iii) *A pair $(\bar{u}, \bar{v})$ in $L^2(0,T;\mathbf{R}^m) \times L^2(0,T;\mathbf{R}^k)$ is an* open loop saddle point *of $C_{x_0}(u,v)$ in $L^2(0,T;\mathbf{R}^m) \times L^2(0,T;\mathbf{R}^k)$ if for all u in $L^2(0,T;\mathbf{R}^m)$ and all v in $L^2(0,T;\mathbf{R}^k)$*

$$C_{x_0}(\bar{u},v) \leq C_{x_0}(\bar{u},\bar{v}) \leq C_{x_0}(u,\bar{v}). \tag{2.8}$$

In general, (ii) *does not necessarily imply* (iii)*, but we shall see that it does for LQ games.*

DEFINITION 2.2. *Associate with $x_0 \in \mathbf{R}^n$ the sets and the functions*

$$V(x_0) \stackrel{\text{def}}{=} \left\{ v \in L^2(0,T;\mathbf{R}^k) : \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v) > -\infty \right\}, \tag{2.9}$$

$$U(x_0) \stackrel{\text{def}}{=} \left\{ u \in L^2(0,T;\mathbf{R}^m) : \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u,v) < +\infty \right\}, \tag{2.10}$$

$$J^-_{x_0}(v) \stackrel{\text{def}}{=} \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v), \quad J^+_{x_0}(u) \stackrel{\text{def}}{=} \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u,v). \tag{2.11}$$

By definition, $V(x_0) \neq \varnothing$ if and only if $v^-(x_0) > -\infty$, and $U(x_0) \neq \varnothing$ if and only if $v^+(x_0) < +\infty$.

2.2. Saddle points of the game and solution of the Riccati differential equation. In the literature, an important issue is the connection between the existence of a symmetrical solution to the *matrix Riccati differential equation*

$$P' + PA + A^*P - PRP + Q = 0 \text{ a.e. in } [0,T], \quad P(T) = F, \tag{2.12}$$

where $R = B_1B_1^* - B_2B_2^*$, and the existence of either an open or closed loop[1] lower value, upper value, or saddle point of the game. For instance, in the closed loop case, quoting Bernhard [4] in his introduction,

> "It has long been known that, for the two-person, zero-sum differential game with linear dynamics, quadratic payoff, fixed end-time, and free end-state (*standard LQ game*), the existence of a solution to a Riccati equation is a sufficient condition for the existence of a saddle point within the class of instantaneous state feedback strategies (cf. [8], [7]), and therefore within any wider class (cf. [3])."

Similarly, we quote Zhang [10] in his introduction,

> "(a) if the Riccati differential equation admits a solution, then, the game admits a closed loop-closed loop saddle point,"

where he refers to [4].

In the open loop case, the above statements are incomplete (cf. Example 2.2), even under the assumptions

$$F \geq 0 \text{ and } Q(t) \geq 0 \text{ a.e. in } [0,T]$$

used in [4] that necessarily imply the convexity of $C_{x_0}(u,v)$ with respect to u and $V(x_0) = L^2(0,T;\mathbf{R}^k)$ for all $x_0 \in \mathbf{R}^n$. Even when the solution of the Riccati differential equation (2.12) is $H^1(0,T)$ or bounded (Remark 2.5), it is also *necessary* that the utility function be convex in u and concave in v (Theorem 2.10) to get an open loop-open loop saddle point.

This leaves the cases where either the open loop lower or upper value of the game explodes. In such cases the solution of the Riccati differential equation might have a blow-up time as illustrated in Example 2.1 (cf. Bernhard [4, Example 5.1, p. 67]:

> "The following game has a saddle point that *survives* a conjugate point,"

where he means a closed loop-closed loop saddle point). The conjugate point corresponds to a *blow-up time* of the solution of the Riccati equation (2.12), where the solution is not of the $H^1(0,T)$ type. Finally, an open loop saddle point yields closed loop optimal strategies that achieve a closed loop-closed loop saddle point (Theorem 2.9), but the *converse is not necessarily true*. It is informative to first detail the example of Bernhard.

Example 2.1. Consider the dynamics and utility function in the time interval $[0,2]$:

$$x'(t) = (2-t)\,u(t) + t\,v(t) \text{ a.e. in } [0,2], \quad x(0) = x_0, \tag{2.13}$$

$$C_{x_0}(u,v) = \frac{1}{2}|x(2)|^2 + \int_0^2 |u(t)|^2 - |v(t)|^2\,dt. \tag{2.14}$$

Here $A = 0$, $B_1(t) = 2-t$, $B_2(t) = t$, $F = 1/2$, $Q = 0$, and $R = B_1B_1^* - B_2B_2^* = 4(1-t)$. It is shown in [4] that the Riccati equation reduces to

$$P' - 4(1-t)P^2 = 0, \quad P(2) = 1/2 \quad \Rightarrow P(t) = \frac{1}{2(t-1)^2}.$$

[1] The reader is referred to Bernhard [4] for the *closed loop* definitions.

Its solution is positive and blows up at $t = 1$. It is not an element of $H^1(0,2)$. We now show that there is no open loop saddle point in the time interval $[0,2]$. For the open loop lower value of the game, the minimization with respect to u has a unique solution for all (x_0, v) since the utility function $u \mapsto C_{x_0}(u,v)$ is convex and bounded below by $-\|v\|^2_{L^2}$. The minimizer is completely characterized by the coupled system

$$\begin{cases} x'(t) = (2-t)\,\hat{u}(t) + t\,v(t) \text{ a.e. in } [0,2], & x(0) = x_0, \\ p'(t) = 0 \text{ a.e. in } [0,2], & p(2) = \dfrac{1}{2}x(2), \\ \hat{u}(t) = -(2-t)\,p(t). \end{cases}$$

From this

$$x(2) = \frac{3}{7}\left[x_0 + \int_0^2 s\,v(s)\,ds\right] \quad \text{and} \quad p(t) = \frac{1}{2}x(2)$$

and

$$\begin{aligned} J^-_{x_0}(v) &\stackrel{\text{def}}{=} \inf_{u \in L^2(0,2;\mathbf{R})} C_{x_0}(u,v) \\ &= C_{x_0}(\hat{u},v) = \frac{1}{2}x(2)^2 + \frac{1}{4}\,x(2)^2 \int_0^2 (2-t)^2\,dt - \int_0^2 |v(t)|^2\,dt \\ &= \frac{7}{6}x(2)^2 - \int_0^2 |v(t)|^2\,dt = \frac{3}{14}\left[x_0 + \int_0^2 s\,v(s)\,ds\right]^2 - \int_0^2 |v(t)|^2\,dt. \end{aligned}$$

It is readily seen that $J^-_{x_0}$ is concave in v and that the supremum with respect to v of $J^-_{x_0}(v)$ exists. Indeed, from the first order condition,[2]

$$\forall v,\ \frac{1}{2}dJ^-_{x_0}(\hat{v};v) = \frac{3}{14}\left[x_0 + \int_0^2 s\,\hat{v}(s)\,ds\right]\int_0^2 s\,v(s)\,ds - \int_0^2 \hat{v}(t)\,v(t)\,dt = 0,$$

there is a unique stationary point $\hat{v}(t) = t\,x_0/2$, the expression of the Hessian

$$\begin{aligned} \frac{1}{2}d^2J^-_{x_0}(\hat{v};v;v) &= \frac{3}{14}\left[\int_0^2 s\,v(s)\,ds\right]^2 - \int_0^2 |v(t)|^2\,dt \\ &\le \frac{3}{14}\left[\int_0^2 s^2\,ds\right]\left[\int_0^2 |v(s)|^2\,ds\right] - \int_0^2 |v(t)|^2\,dt \\ &\le \left[\frac{3}{14}\,\frac{2^3}{3} - 1\right]\int_0^2 |v(t)|^2\,dt = -\frac{3}{7}\int_0^2 |v(t)|^2\,dt \le 0 \end{aligned}$$

is negative, and the open loop lower value of the game is $v^-(x_0) = J^-_{x_0}(\hat{v}) = (x_0)^2/2$.

However, the open loop upper value of the game is $v^+(x_0) = +\infty$ for all $x_0 \in \mathbf{R}$. Indeed pick the sequence of controls $\{v_n\}$, $n \ge 1$, $v_n(t) = 0$ in $[0,1]$, and $v_n(t) = n$ in

[2]Given a real function f defined on a Banach space B, the *first directional semiderivative* at x in the direction v (when it exists) is defined as $df(x;v) \stackrel{\text{def}}{=} \lim_{t \searrow 0} \frac{f(x+tv)-f(x)}{t}$. When the map $v \mapsto df(x;v) : B \to \mathbf{R}$ is linear and continuous, it defines the *gradient* $\nabla f(x)$ as an element of the dual B^* of B. The *second order bidirectional derivative* at x in the directions (v,w) (when it exists) is defined as $d^2f(x;v,w) \stackrel{\text{def}}{=} \lim_{t \searrow 0} \frac{df(x+tw;v)-df(x;v)}{t}$. When the map $(v,w) \mapsto d^2f(x;v,w) : B \times B \to \mathbf{R}$ is bilinear and continuous, it defines the *Hessian operator* $Hf(x)$ as a continuous linear operator from B to B^*.

$[1,2]$. The corresponding sequence of states at time $t=2$ is

$$x_n(2) = x_0 + \int_0^2 (2-t)\,u(t)\,dt + n\int_1^2 t\,dt = \left[x_0 + \int_0^2 (2-t)\,u(t)\,dt\right] + \frac{3}{2}n.$$

Denote by X the square bracket that does not depend on n. Then

$$\begin{aligned} C_{x_0}(u,v_n) &= \frac{1}{2}\left|X + \frac{3}{2}n\right|^2 + \int_0^2 |u(t)|^2\,dt - \int_1^2 n^2\,dt \\ &= \frac{1}{8}n^2 + \frac{3}{2}n\,X + \frac{X^2}{2} + \int_0^2 |u(t)|^2\,dt \to +\infty \text{ as } n \to +\infty. \end{aligned}$$

Thus for all $x_0 \in \mathbf{R}$ and $u \in L^2(0,T;\mathbf{R})$

$$\sup_{v\in L^2(0,T;\mathbf{R})} C_{x_0}(u,v) = +\infty \quad \Rightarrow v^+(x_0) = +\infty \quad \text{and} \quad U(x_0) = \varnothing.$$

Therefore, whatever the initial state x_0 is, $C_{x_0}(u,v)$ has no open loop saddle point.

We now consider the example of Zhang [10] of a game without open loop saddle point. We show that the solution of the Riccati differential equation (2.12) is unique, strictly positive, and *infinitely differentiable*.

Example 2.2. Consider the utility function and linear dynamics

$$C_{x_0}(u,v) = \int_0^1 2x^2 + u^2 - v^2\,dt, \quad x' = x + u + v, \quad x(0) = x_0 \tag{2.15}$$

given by Zhang [10]. Here $A = B_1 = B_2 = 1$, $F = 0$, and $Q = 2$. Now $R = B_1B_1^* - B_2B_2^* = 0$, and the associated Riccati differential equation (2.12) reduces to

$$P' + 2P + 2 = 0 \text{ in } [0,1], \quad P(1) = 0.$$

It has a unique infinitely differentiable solution $P(t) = e^{2(1-t)} - 1$ that is strictly positive in $[0,1)$.

We now extend the result of Zhang [10] on the nonexistence of an open loop saddle point from the initial state $x_0 = 0$ to any initial state. For all $x_0 \in \mathbf{R}$ the open loop lower value $v^-(x_0)$ of the game is finite, but the open loop upper value $v^+(x_0)$ is $+\infty$. Indeed for each $v \in L^2(0,T;\mathbf{R})$

$$\begin{aligned} &\inf_{u\in L^2(0,T;\mathbf{R})} C_{x_0}(u,v) \le C_{x_0}(-v,v) = \int_0^1 2\left(x_0\,e^t\right)^2\,dt = \left(e^2-1\right)(x_0)^2 \\ &\quad \Rightarrow v^-(x_0) = \sup_{v\in L^2(0,T;\mathbf{R})} \inf_{u\in L^2(0,T;\mathbf{R})} C_{x_0}(u,v) \le \left(e^2-1\right)(x_0)^2. \end{aligned}$$

By definition of the sup,

$$\begin{aligned} v^-(x_0) &= \sup_{v\in L^2(0,T;\mathbf{R})} \inf_{u\in L^2(0,T;\mathbf{R})} C_{x_0}(u,v) \\ &\ge \inf_{u\in L^2(0,T;\mathbf{R})} C_{x_0}(u,0) = \inf_{u\in L^2(0,T;\mathbf{R})} \int_0^1 2x^2 + u^2\,dt \ge 0 \\ &\quad \Rightarrow \forall x_0 \in \mathbf{R}, \quad 0 \le v^-(x_0) \le \left(e^2-1\right)(x_0)^2. \end{aligned}$$

For the open loop upper value, associate with each $u \in L^2(0,T;\mathbf{R})$ the sequence of functions $v_n(t) = -u(t) + n$, $n \geq 1$. The corresponding sequence of states is

$$
\begin{aligned}
x_n(t) &= e^t x_0 + n \int_0^t e^{t-s}\, ds = e^t x_0 + n(e^t - 1),\\
C_{x_0}(u, v_n) &= n^2 \int_0^1 2(e^t - 1)^2 - 1\, dt + 2n \int_0^1 u(t)\, dt\\
&\quad + \int_0^1 (e^t x_0)^2\, dt + 2n\, x_0 \int_0^1 e^t\, (e^t - 1)\, dt\\
&= n^2 \int_0^1 1 + 2e^{2t} - 4e^t\, dt + 2n \int_0^1 u(t)\, dt\\
&\quad + \int_0^1 (e^t x_0)^2\, dt + 2n\, x_0\, (e-1)^2\\
&\geq (e-2)^2 n^2 + 2n \left[x_0\, (e-1)^2 + \int_0^1 u(t)\, dt \right] + \int_0^1 (e^t x_0)^2\, dt\\
&\Rightarrow \sup_{v \in L^2(0,T;\mathbf{R})} C_{x_0}(u, v) \geq C_{x_0}(u, v_n) \to +\infty
\end{aligned}
$$

as n goes to infinity. Therefore for all $x_0 \in \mathbf{R}^n$ and all $u \in L^2(0,T;\mathbf{R})$,

$$
\sup_{v \in L^2(0,T;\mathbf{R})} C_{x_0}(u, v) = +\infty \quad \Rightarrow v^+(x_0) = +\infty \quad \text{and} \quad U(x_0) = \varnothing,
$$

and there is no open loop saddle point.

2.3. Properties of the utility function, convexity, concavity, and saddle points. We use a state-adjoint state equation approach to characterize the existence of the open loop upper and lower values as well as the open loop saddle point of the quadratic utility function.

The utility function $C_{x_0}(u, v)$ is infinitely differentiable and, since it is quadratic, its Hessian of second order derivatives is independent of the point (u, v). Indeed,

$$
\frac{1}{2} dC_{x_0}(u, v; \bar{u}, \bar{v}) = Fx(T) \cdot \bar{y}(T) + (Qx, \bar{y}) + (u, \bar{u}) - (v, \bar{v}), \tag{2.16}
$$

where x is the solution of (2.4) and $\bar{y}$ is the solution of

$$
\bar{y}' = A\bar{y} + B_1 \bar{u} + B_2 \bar{v}, \quad \bar{y}(0) = 0. \tag{2.17}
$$

It is customary to introduce the adjoint system

$$
p' + A^* p + Qx = 0, \quad p(T) = Fx(T) \tag{2.18}
$$

and rewrite expression (2.16) for the gradient in the following form:

$$
\frac{1}{2} dC_{x_0}(u, v; \bar{u}, \bar{v}) = (B_1^* p + u, \bar{u}) + (B_2^* p - v, \bar{v}). \tag{2.19}
$$

As predicted, the Hessian is independent of (u, v):

$$
\frac{1}{2} d^2 C_{x_0}(u, v; \bar{u}, \bar{v}; \tilde{u}, \tilde{v}) = F\tilde{y}(T) \cdot \bar{y}(T) + (Q\tilde{y}, \bar{y}) + (\tilde{u}, \bar{u}) - (\tilde{v}, \bar{v}), \tag{2.20}
$$

where $\bar{y}$ is the solution of (2.17) and $\tilde{y}$ is the solution of

$$\tilde{y}' = A\tilde{y} + B_1\tilde{u} + B_2\tilde{v}, \quad \tilde{y}(0) = 0. \tag{2.21}$$

In particular, for all x_0, u, v, $\bar{u}$, and $\bar{v}$

$$d^2C_{x_0}(u, v; \bar{u}, \bar{v}; \bar{u}, \bar{v}) = 2\, C_0(\bar{u}, \bar{v}), \tag{2.22}$$

and this yields the following characterizations of the u-convexity, v-concavity, and (u, v)-convexity-concavity under the assumptions of section 2.1 on the matrix F and the matrix functions A, B_1, B_2, and Q. Note that the matrices F and $Q(t)$ are symmetrical, but they are not necessarily positive semidefinite.

LEMMA 2.1. *Let F be an $n \times n$ matrix and A, B_1, B_2, and Q be bounded measurable matrix functions of appropriate dimensions, and assume that F and $Q(t)$ are symmetrical for almost all t. Then the following statements are equivalent.*

(i) *The map $u \mapsto C_0(u, 0) : L^2(0, T; \mathbf{R}^m) \to \mathbf{R}$ is convex.*
(ii) *For all $u \in L^2(0, T; \mathbf{R}^m)$, $C_0(u, 0) \geq 0$.*
(iii) $\inf_{u \in L^2(0,T;\mathbf{R}^m)} C_0(u, 0) = C_0(0, 0)$.
(iv) *For all v and x_0 the map $u \mapsto C_{x_0}(u, v) : L^2(0, T; \mathbf{R}^m) \to \mathbf{R}$ is convex.*

COROLLARY 2.1. *The following statements are equivalent.*

(i) *The map $v \mapsto C_0(0, v) : L^2(0, T; \mathbf{R}^k) \to \mathbf{R}$ is concave.*
(ii) *For all $v \in L^2(0, T; \mathbf{R}^k)$, $C_0(0, v) \leq 0$.*
(iii) $\sup_{v \in L^2(0,T;\mathbf{R}^k)} C_0(0, v) = C_0(0, 0)$.
(iv) *For all u and x_0, the map $v \mapsto C_{x_0}(u, v) : L^2(0, T; \mathbf{R}^k) \to \mathbf{R}$ is concave.*

COROLLARY 2.2. *The following statements are equivalent.*

(i) *The map, $(u, v) \mapsto C_0(u, v) : L^2(0, T; \mathbf{R}^m) \times L^2(0, T; \mathbf{R}^k) \to \mathbf{R}$ is (u, v)-convex-concave; that is,*

$$\begin{aligned} &\forall v \in L^2(0, T; \mathbf{R}^k), \quad u \mapsto C_0(u, v) \text{ is convex, and} \\ &\forall u \in L^2(0, T; \mathbf{R}^m), \quad v \mapsto C_0(u, v) \text{ is concave.} \end{aligned} \tag{2.23}$$

(ii) *The pair $(0, 0)$ is a saddle point of $C_0(u, v)$:*

$$\sup_{v \in L^2(0,T;\mathbf{R}^k)} C_0(0, v) = C_0(0, 0) = \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_0(u, 0). \tag{2.24}$$

(iii) $\sup_{v \in L^2(0,T;\mathbf{R}^k)} C_0(0, v) = C_0(0, 0) = \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_0(u, 0)$.
(iv) *For all x_0 the map $(u, v) \mapsto C_{x_0}(u, v) : L^2(0, T; \mathbf{R}^m) \times L^2(0, T; \mathbf{R}^k) \to \mathbf{R}$ is (u, v)-convex-concave; that is,*

$$\begin{aligned} &\forall v \in L^2(0, T; \mathbf{R}^k), \quad u \mapsto C_{x_0}(u, v) \text{ is convex, and} \\ &\forall u \in L^2(0, T; \mathbf{R}^m), \quad v \mapsto C_{x_0}(u, v) \text{ is concave.} \end{aligned} \tag{2.25}$$

2.4. Saddle point and coupled state-adjoint state system. We first obtain necessary and sufficient conditions for the existence of a saddle point of the game and introduce the *coupled (state-adjoint state) system* (cf. Notation 2.1 on page 758) that will also arise in the characterization of the open loop lower and upper values of the game in section 2.5. Theorem 2.4 in section 2.5 will later complete this theorem with the equivalent condition that the value $v(x_0)$ of the game is finite.

THEOREM 2.1. *The following conditions are equivalent.*

(i) *There exists an open loop* saddle point *of $C_{x_0}(u, v)$.*

(ii) *There exists a solution* $(\hat{u}, \hat{v})$ *in* $L^2(0,T;\mathbf{R}^m) \times L^2(0,T;\mathbf{R}^k)$ *of the system*

$$\forall u \in L^2(0,T;\mathbf{R}^m),\ \forall v \in L^2(0,T;\mathbf{R}^k), \quad dC_{x_0}(\hat{u},\hat{v};u,v) = 0, \tag{2.26}$$

and C_{x_0} *is convex-concave in the sense of* (2.25).

(iii) *There exists a solution* $(x,p) \in H^1(0,T;\mathbf{R}^n)^2$ *of the* coupled system

$$\begin{cases} x' = Ax - B_1B_1^*p + B_2B_2^*p, & x(0) = x_0, \\ p' + A^*p + Qx = 0, & p(T) = Fx(T), \end{cases} \tag{2.27}$$

$$\hat{u} = -B_1^*p, \quad \hat{v} = B_2^*p, \tag{2.28}$$

and

$$\sup_{v \in L^2(0,T;\mathbf{R}^k)} C_0(0,v) = C_0(0,0) = \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_0(u,0). \tag{2.29}$$

Under any one of the above conditions, the value of the game is given by

$$v(x_0) = C_{x_0}(\hat{u},\hat{v}) = p(0) \cdot x_0. \tag{2.30}$$

Proof. (i) $\Rightarrow$ (ii). Let $(\bar{u},\bar{v})$ in $L^2(0,T;\mathbf{R}^m) \times L^2(0,T;\mathbf{R}^k)$ be an open loop saddle point of $C_{x_0}(u,v)$ in $L^2(0,T;\mathbf{R}^m) \times L^2(0,T;\mathbf{R}^k)$. Then by Definition 2.1

$$\sup_{L^2(0,T;\mathbf{R}^k)} C_{x_0}(\bar{u},v) = C_{x_0}(\bar{u},\bar{v}) = \inf_{L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,\bar{v}). \tag{2.31}$$

Since $C_{x_0}(u,v)$ is infinitely differentiable, the minimizing point $\bar{u}$ of $C_{x_0}(u,\bar{v})$ with respect to u is characterized by the first order condition $dC_{x_0}(\bar{u},\bar{v};u,0) = 0$ for all u and the second order condition $d^2C_{x_0}(\bar{u},\bar{v};u,0;u,0) \geq 0$ for all u. Since $d^2C_{x_0}(\bar{u},\bar{v};u,0;u,0)$ is independent of $(\bar{u},\bar{v})$ and x_0, $C_{x_0}(u,v)$ is convex in u for all x_0 and all v. A similar argument for the maximum yields $dC_{x_0}(\bar{u},\bar{v};,w) = 0$ and $d^2C_{x_0}(\bar{u},\bar{v};0,w;0,w) \leq 0$ for all w and the concavity of $C_{x_0}(u,v)$ in v.

(ii) $\Rightarrow$ (i). By assumption $C_{x_0}(\hat{u},\hat{v})$ is convex-concave and infinitely differentiable and there is a solution to the two first order conditions. By [6, Proposition 1.6], there exists a saddle point.

(ii) $\Leftrightarrow$ (iii). This follows from the previous computations of the gradient and Corollary 2.2.

Finally, we compute the value

$$\begin{aligned} C_{x_0}(\hat{u},\hat{v}) &= Fx(T) \cdot x(T) + (Qx,x) + \|B_1^*p\|^2 - \|B_2^*p\|^2 \\ &= p(T) \cdot x(T) - (p' + A^*p, x) + ([B_1B_1^* - B_2B_2^*]p, p) \\ &= p(0) \cdot x(0) + (p, x' - Ax + ([B_1B_1^* - B_2B_2^*]p) = p(0) \cdot x_0. \end{aligned}$$ ∎

NOTATION 2.1. *It will be useful to introduce the set* $\mathcal{N}_{x,p}$ *of all solutions* (y,q) *of the homogeneous coupled system*

$$\begin{cases} y' = Ay - B_1B_1^*q + B_2B_2^*q, & y(0) = 0, \\ q' + A^*q + Qy = 0, & q(T) = Fy(T). \end{cases} \tag{2.32}$$

Thus the coupled system has a solution up to an additive pair of $\mathcal{N}_{x,p}$.

2.5. Necessary and sufficient conditions for games with finite values. The quadratic character of the problem yields surprising equivalences that reduce the complexity of its solution. We start with the open loop lower value of the game.

THEOREM 2.2. *The following conditions are equivalent.*

(i) *There exist* $\hat{u}$ *in* $L^2(0,T;\mathbf{R}^m)$ *and* $\hat{v}$ *in* $L^2(0,T;\mathbf{R}^k)$ *such that*

$$C_{x_0}(\hat{u},\hat{v}) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,\hat{v}) = \sup_{v\in L^2(0,T;\mathbf{R}^k)} \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v). \tag{2.33}$$

(ii) *The open loop lower value* $v^-(x_0)$ *of the game is finite.*

(iii) *There exists a solution* $(x,p)\in H^1(0,T;\mathbf{R}^n)\times H^1(0,T;\mathbf{R}^n)$ *of the* coupled system (2.27) *such that* $B_2^*p\in V(x_0)$*, the solution pairs* $(\hat{u},\hat{v})$ *and the open loop lower value are given by the expressions*

$$\hat{u} = -B_1^*p, \quad \hat{v} = B_2^*p, \quad \textit{and} \quad v^-(x_0) = C_{x_0}(\hat{u},\hat{v}) = p(0)\cdot x_0, \tag{2.34}$$

and

$$\sup_{v\in V(0)} \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u,v) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u,0) = C_0(0,0). \tag{2.35}$$

Proof. The proof of this main theorem will be given in sections 3 and 3.3. □

Remark 2.2. The above necessary and sufficient conditions for the finiteness of the open loop value of the game complete the results of Zhang [10] by introducing the new *feasibility condition* (2.35) that is equivalent to saying that the open loop lower value of the game is zero and that $(0,0)$ is a solution for the zero initial state. It also recasts the results in the more intuitive state-adjoint state framework. Condition (2.35) is equivalent to the convexity of $C_{x_0}(u,v)$ with respect to u and the concavity of $J^-_{x_0}(v) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v)$ with respect to $v\in V(x_0)$.

Theorem 2.2 has a counterpart for the upper value $v^+(x_0)$ of the game.

THEOREM 2.3. *The following conditions are equivalent.*

(i) *There exist* $\hat{u}$ *in* $L^2(0,T;\mathbf{R}^m)$ *and* $\hat{v}$ *in* $L^2(0,T;\mathbf{R}^k)$ *such that*

$$C_{x_0}(\hat{u},\hat{v}) = \sup_{v\in L^2(0,T;\mathbf{R}^k)} C_{x_0}(\hat{u},v) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} \sup_{v\in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u,v). \tag{2.36}$$

(ii) *The open loop upper value* $v^+(x_0)$ *of the game is finite.*

(iii) *There exists a solution* $(x,p)\in H^1(0,T;\mathbf{R}^n)\times H^1(0,T;\mathbf{R}^n)$ *of the* coupled system (2.27) *such that* $-B_1^*p\in U(x_0)$*, the solution pairs* $(\hat{u},\hat{v})$ *and the open loop upper value are given by the expressions*

$$\hat{u} = -B_1^*p, \quad \hat{v} = B_2^*p, \quad \textit{and} \quad v^+(x_0) = C_{x_0}(\hat{u},\hat{v}) = p(0)\cdot x_0, \tag{2.37}$$

and

$$\inf_{u\in U(0)} \sup_{v\in L^2(0,T;\mathbf{R}^k)} C_0(u,v) = \sup_{v\in L^2(0,T;\mathbf{R}^k)} C_0(0,v) = C_0(0,0). \tag{2.38}$$

Condition (2.38) says that $C_{x_0}(u,v)$ is concave with respect to v and that $J^+_{x_0}(u) = \sup_{v\in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u,v)$ is convex with respect to $u\in U(x_0)$.

Finally, the necessary and sufficient condition for the finiteness of the value $v(x_0)$ of the game can now be obtained from the above two theorems and Theorem 2.1(iii).

THEOREM 2.4. *The following conditions are equivalent.*

(i) *There exists an open loop* saddle point *of* $C_{x_0}(u,v)$.
(ii) *The open loop value* $v(x_0)$ *of the game is finite.*
(iii) *There exists a solution* $(x,p) \in H^1(0,T;\mathbf{R}^n) \times H^1(0,T;\mathbf{R}^n)$ *of the* coupled system (2.27)*, the solution pair* $(\hat{u},\hat{v})$ *is given by the expressions* (2.28)*, and the convexity-concavity* (2.29) *is verified.*

Under any one of the above conditions, the open loop value is given by expression (2.30).

Proof. (i) ⇒ (ii). Since the utility function has a saddle point, the value of the game is finite. (ii) ⇒ (iii). From Theorems 2.2 and 2.3 there exists a solution to the coupled system (2.27), and the convexity-concavity condition (2.29) readily follows from (2.38) and (2.35). (iii) ⇒ (i). This follows from Theorem 2.1. □

Remark 2.3. The common necessary condition for the finiteness of the lower value $v^-(x_0)$, value $v(x_0)$, and upper value $v^+(x_0)$ of the game is the existence of a solution of the coupled system (2.27). The difference is in the respective *feasibility conditions* (2.35), (2.29), and (2.38): $v^-(0) = 0$, $v(0) = 0$, and $v^+(0) = 0$.

We conclude with the enlightening result proved by Zhang [10, Thm. 4.1] that has shed new light on the characterization of a game with finite value. One of the consequences is that only three cases can occur: (i) $v^+(x_0)$ finite and $v^-(x_0) = -\infty$, (ii) $v^+(x_0) = +\infty$ and $v^-(x_0)$ finite, or (iii) $v(x_0)$ finite.

THEOREM 2.5. *Given* $x_0 \in \mathbf{R}^n$*, the following statements are equivalent.*
(i) *There exists an open loop saddle point of* $C_{x_0}(u,v)$.
(ii) *The open loop value of the game of* $C_{x_0}(u,v)$ *is finite.*
(iii) *Both the open loop lower and upper values of* $C_{x_0}(u,v)$ *are finite.*

Proof. (i) ⇒ (ii) ⇒ (iii) are obvious. It remains to prove that (iii) ⇒ (i). From condition (2.35) of Theorem 2.2 and condition (2.38) of Theorem 2.3 we get condition (2.29) of Theorem 2.4. Finally, both Theorems 2.2 and 2.3 give the existence of a pair $(x,p) \in H^1(0,T;\mathbf{R}^n) \times H^1(0,T;\mathbf{R}^n)$ solution of the coupled system (2.27). Therefore by Theorem 2.4 the utility function has a saddle point. □

2.6. Games with finite values for each initial state. In this section we sharpen the results of the previous section when the open loop lower value, value, or upper value of the game is finite for *all initial states* $x_0 \in \mathbf{R}^n$. In each case this global assumption yields the *uniqueness of solution.*

THEOREM 2.6. *The following conditions are equivalent.*
(i) *For each* $x_0 \in \mathbf{R}^n$*, there exist* $\hat{u}$ *in* $L^2(0,T;\mathbf{R}^m)$ *and* $\hat{v}$ *in* $L^2(0,T;\mathbf{R}^k)$ *such that*

$$C_{x_0}(\hat{u},\hat{v}) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,\hat{v}) = \sup_{v\in L^2(0,T;\mathbf{R}^k)} \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v). \tag{2.39}$$

(ii) *For each* $x_0 \in \mathbf{R}^n$*, the open loop lower value* $v^-(x_0)$ *of the game is finite.*
(iii) *For each* $x_0 \in \mathbf{R}^n$*, there exists a unique pair* $(x,p) \in H^1(0,T;\mathbf{R}^n)^2$ *solution of the* coupled system (2.27) *such that* $B_2^* p \in V(x_0)$*, there exists a unique pair* $(\hat{u},\hat{v})$ *that verifies* (2.28)*, and*

$$\sup_{v\in V(0)} \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u,v) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u,0) = C_0(0,0). \tag{2.40}$$

Remark 2.4. The uniqueness under condition (i) was originally given by Zhang et al. in [11] by a different argument. Our short and transparent proof seems to be new. The same proof can readily be used in the context of optimal control [9].

Proof. (i) ⇒ (ii) is obvious. (ii) ⇒ (iii). This follows from Theorem 2.2 where condition (2.40) is condition (2.35). We need only show the uniqueness of the solution to the coupled system (2.27). By linearity, this amounts to proving that the solution (y, q) of the homogeneous system (2.32) such that $B_2^* q \in V(0)$ is $(0, 0)$. Given an arbitrary x_0, consider the expression

$$\begin{aligned} q(0) \cdot x_0 &= q(T) \cdot x(T) - \int_0^T q' \cdot x + q \cdot x' \, dt \\ &= Fx(T) \cdot y(T) + \int_0^T Qx \cdot y + B_1^* p \cdot B_1^* q - B_2^* p \cdot B_2^* q \, dt \\ &= \frac{1}{2} dC_{x_0}(\hat{u}, \hat{v}; -B_1^* q, B_2^* q) = 0 \end{aligned}$$

from (2.16), (2.27), (2.34), and the fact that $B_2^* q \in V(0)$. Since this identity is true for all $x_0 \in \mathbf{R}^n$, $q(0) = 0$. But now we can look at the coupled system (2.32) as a linear differential system in (x, p) with zero initial condition $(y(0), q(0)) = (0, 0)$ whose unique solution is $(y, q) = (0, 0)$. This proves uniqueness. (iii) ⇒ (i). This follows, again from Theorem 2.2, since the conditions are verified for each $x_0 \in \mathbf{R}^n$. □

We readily have the dual result.

THEOREM 2.7. *The following conditions are equivalent.*

(i) *For each $x_0 \in \mathbf{R}^n$, there exist $\hat{u}$ in $L^2(0, T; \mathbf{R}^m)$ and $\hat{v}$ in $L^2(0, T; \mathbf{R}^k)$ such that*

(2.41)
$$C_{x_0}(\hat{u}, \hat{v}) = \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_{x_0}(\hat{u}, v) = \inf_{u \in L^2(0,T;\mathbf{R}^m)} \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u, v).$$

(ii) *For each $x_0 \in \mathbf{R}^n$, the open loop upper value $v^+(x_0)$ of the game is finite.*

(iii) *For each $x_0 \in \mathbf{R}^n$, there exists a unique pair $(x, p) \in H^1(0, T; \mathbf{R}^n)^2$ solution of the* coupled system (2.27) *such that $-B_1^* p \in U(x_0)$, there exists a unique pair $(\hat{u}, \hat{v})$ that verifies* (2.28)*, and*

$$\inf_{u \in U(0)} \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_0(u, v) = \sup_{v \in L^2(0,T;\mathbf{R}^k)} C_0(0, v) = C_0(0, 0). \tag{2.42}$$

Finally, by combining the last two theorems, we get the saddle point case.

THEOREM 2.8. *The following conditions are equivalent.*

(i) *For each $x_0 \in \mathbf{R}^n$, there exists an open loop* saddle point *of $C_{x_0}(u, v)$.*

(ii) *For each $x_0 \in \mathbf{R}^n$, the open loop value $v(x_0)$ of the game is finite.*

(iii) *For each $x_0 \in \mathbf{R}^n$, there exists a unique pair $(x, p) \in H^1(0, T; \mathbf{R}^n)^2$ solution of the* coupled system (2.27)*, there exists a unique pair $(\hat{u}, \hat{v})$ that verifies* (2.28)*, and the convexity-concavity condition* (2.29) *is verified.*

2.7. Open loop saddle point and Riccati differential equation. Under the assumption of the finiteness of the open loop value of the game in $[0, T]$ for each initial state, we can *unexpectedly* use *invariant embedding* and introduce a *decoupling symmetrical matrix* solution of the *matrix Riccati differential equation* (2.12).

THEOREM 2.9. *Assume that the open loop value $v(x_0)$ is finite for all $x_0 \in \mathbf{R}^n$.*

(i) *There exists a unique symmetrical solution with elements in $H^1(0, T)$ of the matrix Riccati differential equation*

$$P' + PA + A^* P - PRP + Q = 0, \quad P(T) = F, \tag{2.43}$$

where $R = B_1B_1^* - B_2B_2^*$. *Moreover,*

$$\hat{p}(t) = P(t)\,\hat{x}(t),\ 0 \le t \le T, \text{ and } C_{x_0}(\hat{u},\hat{v}) = P(0)x_0 \cdot x_0, \tag{2.44}$$

where $(\hat{x},\hat{p}) \in H^1(0,T;\mathbf{R}^n)^2$ *is the unique solution of the coupled system* (2.27).

(ii) *The optimal strategies of the two players are closed loop*

$$\hat{u} = -B_1^*P\hat{x} \quad \text{and} \quad \hat{v} = B_2^*P\hat{x}, \tag{2.45}$$

and they achieve a closed loop-closed loop saddle point in the sense of [4].

(iii) *For all* $x_0 \in \mathbf{R}^n$ *the function* $C_{x_0}(u,v)$ *is convex-concave.*

Proof. For the proof, see section 5.3. □

The existence of a symmetrical solution to the matrix Riccati differential equation (2.43) implies that, for all $x_0 \in \mathbf{R}^n$, there exists a solution $(\hat{x},\hat{p}) \in H^1(0,T;\mathbf{R}^n) \times H^1(0,T;\mathbf{R}^n)$ of the coupled system (2.27). However, as we have seen in Example 2.2, this is not sufficient to get an open loop saddle point of the utility function $C_{x_0}(u,v)$.

THEOREM 2.10. *A set of necessary and sufficient conditions for the existence of an open loop saddle point of the utility function* $C_{x_0}(u,v)$ *for all* $x_0 \in \mathbf{R}^n$ *is*

(a) *the utility function* $C_{x_0}(u,v)$ *is convex in* u *and concave in* v *for some* x_0, *and*

(b) *there exists a (unique) symmetrical solution in* $H^1(0,T)$ *to the matrix Riccati differential equation* (2.43).

Proof. For the proof, see section 5.4. □

Remark 2.5. The method of *completion of the squares* (cf., for instance, Başar and Bernhard [1, Chap. 9, Thm. 9.4]) can also be used here to obtain

$$\sup_{v\in L^2(0,T;\mathbf{R}^k)} \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v) \le P(0)x_0 \cdot x_0 \le \inf_{u\in L^2(0,T;\mathbf{R}^m)} \sup_{v\in L^2(0,T;\mathbf{R}^k)} C_{x_0}(u,v).$$

So it would be tempting to conclude that there is a saddle point *without* condition (a). But, as illustrated in Example 2.2 where we show that $U(x_0) = \varnothing$ for all x_0, condition (a) is really necessary. In order to get a saddle point, both $v^-(x_0)$ and $v^+(x_0)$ must be finite. Therefore the open loop lower value of the game will be finite if (b) is verified and $V(x_0) \neq \varnothing$; the open loop upper value of the game will be finite if (b) is verified and $U(x_0) \neq \varnothing$.

3. Open loop lower value of the game. We review the three steps: existence and characterization of a minimizer for $v \in V(x_0)$, formulation of the resulting maximization problem with respect to v, and, finally, existence and characterization of the pair that achieves the finite open loop lower value of the game.

3.1. Existence and characterization of the minimizers.

THEOREM 3.1. *Given* $x_0 \in \mathbf{R}^n$ *and* $v \in L^2(0,T;\mathbf{R}^k)$, *the following statements are equivalent.*

(i) *There exists* $\hat{u} \in L^2(0,T;\mathbf{R}^m)$ *such that*

$$C_{x_0}(\hat{u},v) = J_{x_0}^-(v) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v). \tag{3.1}$$

(ii) $\inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,v) > -\infty$ *(that is,* $v \in V(x_0)$*).*

(iii) *There exists a pair* $(x,p) \in H^1(0,T;\mathbf{R}^n)\times H^1(0,T;\mathbf{R}^n)$ *solution of the system*

$$\begin{cases} x' = Ax - B_1B_1^*p + B_2v, & x(0) = x_0, \\ p' + A^*p + Qx = 0, & p(T) = Fx(T), \end{cases} \tag{3.2}$$

$$\hat{u}(t) = -B_1^*(t)p(t), \quad J_{x_0}^-(v) = p(0)\cdot x_0 + \int_0^T B_2^*p\cdot v - |v|^2\,dt, \tag{3.3}$$

and

$$\inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u,0) \geq 0. \tag{3.4}$$

(iv) *The convexity inequality* (3.4) *is verified and*

$$\forall q \in N_p, \quad x_0\cdot q(0) + \int_0^T v\cdot B_2^*q\,dt = 0, \tag{3.5}$$

where

$$N_p \overset{\text{def}}{=} \left\{q \in H^1(0,T;\mathbf{R}^n) : \forall (y,q) \in N_{x,p}\right\} \tag{3.6}$$

and $N_{x,p}$ *denotes the set of all solutions* (y,q) *of the homogeneous system*

$$\begin{cases} y' = Ay - B_1\,B_1^*q, & y(0) = 0, \\ q' + A^*q + Qy = 0, & q(T) = Fy(T). \end{cases} \tag{3.7}$$

Proof. The proof follows from the following lemma, the computation of first and second order derivatives (2.19) and (2.22) in section 2.3, and the equivalent condition of Lemma 2.1(ii) for the u-convexity of $C_0(u,v)$.

LEMMA 3.1. *Let* U *be a Hilbert space,* $M : U \to U$ *a continuous linear self-adjoint compact operator,* $f \in U$, c *a constant, and* $j(u) = c + 2(f,u) + ([I+M]u,u)$.

(i) *Then the following conditions are equivalent.*

(a)

$$\exists \hat{u} \in U, \quad j(\hat{u}) = \inf_{u\in U} j(u), \tag{3.8}$$

(b)

$$\inf_{u\in U} j(u) > -\infty, \tag{3.9}$$

(c)

$$\exists \hat{u} \in U \text{ such that } [I+M]\hat{u} + f = 0, \text{ and} \tag{3.10}$$

$$\forall u \in U, \quad ([I+M]u,u) \geq 0. \tag{3.11}$$

(ii) *Condition* (3.10) *is equivalent to*

$$\forall w \in \ker[I+M], \quad (f,w) = 0. \tag{3.12}$$

(iii) *Condition* (3.11) *is equivalent to the convexity of* j.

We omit the proof of the lemma. □

NOTATION 3.1. *Given* $x_0 \in \mathbf{R}^n$ *such that* $V(x_0) \neq \varnothing$ *and* $v \in V(x_0)$, *denote by* $\mathcal{P}(v,x_0)$ *the set of all solutions* (x,p) *of system* (3.2). *It is readily checked that for all* $p \in \mathcal{P}(v,x_0)$, $\mathcal{P}(v,x_0) = p + N_p$.

3.2. Some intermediary results.

THEOREM 3.2.

(i) *The sets $N_{x,p}$, N_p, and $B_2^* N_p$ are finite dimensional linear subspaces of $H^1(0,T;\mathbf{R}^n)^2$, $H^1(0,T;\mathbf{R}^n)$, and $L^2(0,T;\mathbf{R}^k)$, respectively. $\mathcal{P}(v,x_0)$ is a finite dimensional affine subspace of $H^1(0,T;\mathbf{R}^n)$.*

(ii) *If $V(x_0) \neq \varnothing$ for some $x_0 \in \mathbf{R}^n$, then $V(x_0)$ is a closed affine subspace of $L^2(0,T;\mathbf{R}^k)$, $V(0)$ is a nonempty closed linear subspace of $L^2(0,T;\mathbf{R}^k)$,*

$$V(0) = (B_2^* N_p)^\perp, \tag{3.13}$$

$$\forall v \in V(x_0), \quad V(x_0) = v + V(0). \tag{3.14}$$

(iii) *Given $v \in V(x_0)$ and $p \in \mathcal{P}(v,x_0)$, define*

$$v^* \stackrel{\text{def}}{=} v + P_{V(0)}(B_2^* p - v), \tag{3.15}$$

where $P_{V(0)}$ is the orthogonal projection onto $V(0)$ in $L^2(0,T;\mathbf{R}^k)$. Then v^* is independent of the choice of p, v^* is unique in $V(x_0) \cap B_2^* \mathcal{P}(v,x_0)$, and there exists $p^* \in \mathcal{P}(v,x_0)$ such that $v^* = B_2^* p^*$. If, in addition, $B_2^* p - v \in V(0)^\perp$, then $v = v^* = B_2^* p^*$.

Analogues of Theorems 3.1 and 3.2 hold for the open loop upper value.

Remark 3.1. This theorem due to Zhang [10] is a key result in the proof of the existence of a maximizer of the inf problem. We have added part (i) to show that the subspace $B_2^* N_p$ is finite dimensional and hence closed. This is critical in the proof of part (ii). The proof essentially uses the arguments of [10].

Proof of Theorem 3.2. (i) From system (3.7), $N_{x,p}$ is a closed linear subspace of $H^1(0,T;\mathbf{R}^n)^2$ as the kernel of the continuous linear map

$$\begin{aligned}&(x,p) \mapsto \mathcal{A}(x,p) \stackrel{\text{def}}{=} (-x' + Ax - B_1 B_1^* p, -x(0), p' + A^* p + Qx, Fx(T) - p(T))\\ &: H^1(0,T;\mathbf{R}^n)^2 \to \left(L^2(0,T;\mathbf{R}^n) \times \mathbf{R}^n\right)^2.\end{aligned}$$

We now use the fact that a topological vector space is finite dimensional if and only if every closed bounded set is compact. Indeed, let K be a closed bounded subset of points (y,q) in $N_{x,p}$ for the $L^2(0,T;\mathbf{R}^n)^2$-topology. Since all the matrices in system (3.7) are bounded, the right-hand sides are bounded and the derivatives (y',q') are also bounded in $L^2(0,T;\mathbf{R}^n)^2$ and, a fortiori, in $H^1(0,T;\mathbf{R}^n)^2$. Since the injection of $H^1(0,T;\mathbf{R}^n)^2$ into $L^2(0,T;\mathbf{R}^n)^2$ is compact, then the closure of K in $L^2(0,T;\mathbf{R}^n)^2$ is compact. But, by assumption, we already know that K is closed. Thence K is compact in $L^2(0,T;\mathbf{R}^n)^2$ and $N_{x,p}$ is finite dimensional.

(ii) Since $V(x_0) \neq \varnothing$, then, by definition, for all v_1, v_2 in $V(x_0)$, condition (ii) of Theorem 3.1 is verified and condition (iii) is also verified for some pairs (x_1,p_1) and (x_2,p_2) verifying the system (3.2). Therefore, for any $\alpha \in \mathbf{R}$, the pair $(x_\alpha,p_\alpha) = (\alpha x_1 + (1-\alpha)x_2, \alpha p_1 + (1-\alpha)p_2)$ is also a solution of system (3.2) for x_0 and $v_\alpha = \alpha v_1 + (1-\alpha)v_2 \in V(x_0)$. Identity (3.14) follows from the fact that $V(x_0)$ is an affine subspace. Moreover, from (3.14), $V(x_0) \neq \varnothing$ necessarily implies that $V(0) \neq \varnothing$. Finally, from condition (3.5) with $x_0 = 0$

$$v \in V(0) \quad \Leftrightarrow \quad \forall q \in N_p, \quad \int_0^T v \cdot B_2^* q \, dt = 0 \quad \Leftrightarrow \; v \in (B_2^* N_p)^\perp,$$

and $V(0) = (B_2^* N_p)^\perp$, a nonempty closed linear subspace.

(iii) Given p_1, p_2 in $\mathcal{P}(v, x_0)$, $p_2 - p_1 \in N_p$ and

$$v + P_{V(0)}(B_2^* p_2 - v) - (v + P_{V(0)}(B_2^* p_1 - v)) = P_{V(0)}(B_2^*(p_2 - p_1)) = 0,$$

since $B_2^* N_p = V(0)^\perp$. So v^* is independent of the choice of $p \in \mathcal{P}(v, x_0)$. Since $V(x_0)$ is affine, then for all $v \in V(x_0)$,

$$\begin{aligned} v^* &= v + P_{V(0)}(B_2^* p - v) \in v + V(0) = V(x_0), \\ v^* - B_2^* p &= v - B_2^* p - P_{V(0)}(v - B_2^* p) \in V(0)^\perp = B_2^* N_p \\ \Rightarrow\ \exists q \in N_p &\text{ such that } v^* - B_2^* p = B_2^* q \quad \Rightarrow\ v^* = B_2^*(p+q) \in B_2^* \mathcal{P}(v, x_0), \end{aligned} \tag{3.16}$$

and $v^* \in V(x_0) \cap B_2^* \mathcal{P}(v, x_0)$. This element is unique since for v_1^* and v_2^* in $V(x_0) \cap B_2^* \mathcal{P}(v, x_0)$, $v_2^* - v_1^* \in V(0) \cap B_2^* N_p = V(0) \cap V(0)^\perp = \{0\}$. Finally, if $B_2^* p - v \in V(0)^\perp$, then from (3.16) we get $v = v^*$. □

3.3. Existence and characterization of maximizers. Assume that $v^-(x_0)$ is finite. By definition of $V(x_0)$, it is not empty and

$$v^-(x_0) = \sup_{v \in L^2(0,T;\mathbf{R}^k)} \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u, v) = \sup_{v \in V(x_0)} J_{x_0}^-(v), \tag{3.17}$$

where $V(x_0)$ is a closed affine subspace of $L^2(0, T; \mathbf{R}^k)$ and by (3.3) and condition (3.5)

$$J_{x_0}^-(v) = \inf_{u \in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u, v) = p(0) \cdot x_0 + \int_0^T B_2^* p \cdot v - |v|^2 \, dt, \tag{3.18}$$

or, equivalently,

$$J_{x_0}^-(v) = Fx(T) \cdot x(T) + \int_0^T Q(t)x(t) \cdot x(t) + |B_1^*(t)p(t)|^2 - |v(t)|^2 \, dt \tag{3.19}$$

for all solutions (x, p) of system (3.2). Define the equivalence class $[(x, p)] = (x, p) + N_{x,p}$. Then for each pair $v \in V(x_0)$, $[(x, p)]$ is the unique solution in $H^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n)/N_{x,p}$ of system (3.2). Thus the map

$$v \mapsto [(x, p)] : V(x_0) \to \frac{H^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n)}{N_{x,p}} \tag{3.20}$$

is affine and continuous, and the map

$$\begin{aligned} &(x, p) \mapsto (x(T), x, p) \\ &: H^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n) \to \mathbf{R}^n \times L^2(0, T; \mathbf{R}^n) \times L^2(0, T; \mathbf{R}^n) \end{aligned} \tag{3.21}$$

is continuous and compact.

So we are back to a continuous linear quadratic function $J_{x_0}^-(v)$ that is to be maximized over the closed affine subspace $V(x_0)$. The state is now the pair (x, p) solution of (3.2), but the structure is the same. Lemma 3.1 readily extends to the case of a sup over a closed affine subspace and the following conditions are equivalent:

(a)

$$\exists \hat{v} \in V(x_0), \quad J_{x_0}^-(\hat{v}) = \sup_{v \in V(x_0)} J_{x_0}^-(v), \tag{3.22}$$

(b)

$$\sup_{v\in V(x_0)} J^-_{x_0}(v) < +\infty, \tag{3.23}$$

(c)

$$\exists \hat v \in V(x_0) \text{ such that } [I+M]\hat v + f \in V(0)^\perp, \text{ and} \tag{3.24}$$

$$\forall w \in V(0), \quad ([I+M]w, w) \le 0 \tag{3.25}$$

for the new compact operator M corresponding to the new state (x,p).

It remains to compute the directional derivative of $J^-_{x_0}(v)$ at $v \in V(x_0)$ in the direction $w \in V(0)$. By direct computation from formula (2.19)

$$\frac{1}{2} dC_{x_0}(-B_1^* p, v; 0, w) = \int_0^T (B_2^* p - v)\cdot w\, dt, \tag{3.26}$$

which is independent of $p \in \mathcal{P}(v, x_0)$ for all $w \in V(0)$ by Theorem 3.1(iv). Hence

$$dJ^-_{x_0}(v; w) = dC_{x_0}(-B_1^* p, v; 0, w) = 2\int_0^T (B_2^* p - v)\cdot w\, dt, \quad \forall p \in \mathcal{P}(v, x_0). \tag{3.27}$$

As for the second order derivative,

$$\begin{aligned} &\frac{1}{2} d^2 C_{x_0}(-B_1^* p, v; 0, w; 0, w') \\ &= Fy_{w'}(T)\cdot y_w(T) + \int_0^T Qy_{w'}\cdot y_w + B_1^* q_{w'}\cdot B_1^* q_w - w'\cdot w\, dt \end{aligned} \tag{3.28}$$

$$\begin{aligned} \Rightarrow \frac{1}{2} d^2 J^-_{x_0}(v; w; w) &= \frac{1}{2} d^2 C_{x_0}(-B_1^* p, v; 0, w; 0, w) \\ &= \frac{1}{2} J_0^-(w) = \frac{1}{2} \inf_{u\in L^2(0.T;\mathbf{R}^m)} C_0(u, w), \end{aligned} \tag{3.29}$$

where the last term must be negative or zero for all $w \in V(0)$. But, from Theorem 3.1(iii), $C_0(u, 0)$ is convex in u. By using the equivalent condition of Lemma 2.1(ii) for the u-convexity of $C_0(u, 0)$, we finally get the two-part condition

$$\sup_{v\in V(0)} \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u, v) \le 0 \le \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u, 0).$$

This condition is equivalent to condition (2.35) since $C_0(0, 0) = 0$.

Proof of Theorem 2.2. (i) $\Rightarrow$ (ii) is obvious. (ii) $\Rightarrow$ (iii). From the previous discussion, the finiteness of $v^-(x_0)$ is equivalent to

$$\exists \hat v \in V(x_0) \text{ such that } dJ^-_{x_0}(\hat v; w) = 2\int_0^T (B_2^* \hat p - \hat v)\cdot w\, dt = 0, \quad \forall w \in V(0),$$

$$d^2 J^-_{x_0}(\hat v; w; w) = 2 \inf_{u\in L^2(0.T;\mathbf{R}^m)} C_0(u, w) \le 0, \quad \forall w \in V(0).$$

The second order condition combined with the fact that $V(x_0) \neq \varnothing$ (Theorem 3.1(iii)) yields condition (2.35). The first order condition says that $B_2^*\hat p - \hat v \in V(0)^\perp$. By Theorem 3.2(iii) there exists $\hat p^* \in \mathcal{P}(\hat v, x_0)$ such that $\hat v = B_2^* \hat p^*$, where $(\hat x^*, \hat p^*)$ is a solution of (3.2). Since $\hat v = B_2^* \hat p^*$, system (2.27) has a solution unique up to an

element of $\mathcal{N}_{x,p}$. After substitution of $\hat{v} = B_2^* \hat{p}^*$ in (3.2), $(\hat{x}^*, \hat{p}^*)$ becomes a solution of the coupled system (2.27). This also yields the identities (2.34). (iii) $\Rightarrow$ (i). By assumption $\hat{v} = B_2^* p \in V(x_0)$. The existence of a solution (x, p) to system (2.27) yields the existence of a solution to system (3.2) of Theorem 3.1(iii) with $\hat{u} = -B_1^* p$ as a minimizer. For all $v \in V(x_0)$,

$$J_{x_0}^-(v) = J_{x_0}^-(B_2^* p) + dJ_{x_0}^-(B_2^* p; v - B_2^* p) + \frac{1}{2} d^2 J_{x_0}^-(B_2^* p; v - B_2^* p; v - B_2^* p).$$

The second order term is negative by condition (2.35) since, by assumption, $B_2^* p \in V(x_0)$ and hence $v - B_2^* p \in V(0)$ for all $v \in V(x_0)$. As for the first order term, recall that, in view of (2.34), for all $w \in V(0)$

$$dJ_{x_0}^-(B_2^* p; w) = \int_0^T (B_2^* p - v) \cdot w \, dt = 0.$$

Thus $dJ_{x_0}^-(B_2^* p; v - B_2^* p) = 0$ since $v - B_2^* p \in V(0)$: $B_2^* p$ is a maximizer of $J_{x_0}^-$. ∎

4. Invariant embedding and convexity-concavity. Consider the LQ game on the time interval $[s, T]$, $0 \le s < T$, with initial state $h \in \mathbf{R}^n$ at time s:

$$C_h^s(u, v) \stackrel{\text{def}}{=} Fx(T) \cdot x(T) + \int_s^T Qx \cdot x + |u|^2 - |v|^2 \, dt, \tag{4.1}$$

$$x' = Ax + B_1 u + B_2 v \quad \text{a.e. in } [s, T], \quad x(s) = h. \tag{4.2}$$

DEFINITION 4.1. *Let $h \in \mathbf{R}^n$ be an initial state at time s, $0 \le s < T$.*

(i) *The game is said to achieve its* open loop lower value *(resp.,* upper value*) if*

$$v_s^-(h) \stackrel{\text{def}}{=} \sup_{v \in L^2(s.T; \mathbf{R}^k)} \inf_{u \in L^2(s.T; \mathbf{R}^m)} C_h^s(u, v) \tag{4.3}$$

$$(\textit{resp.}, \; v_s^+(h) \stackrel{\text{def}}{=} \inf_{u \in L^2(s.T; \mathbf{R}^m)} \sup_{v \in L^2(s, T; \mathbf{R}^k)} C_h^s(u, v)) \tag{4.4}$$

is finite.

(ii) *The game is said to achieve its* open loop value *if its open loop lower value $v_s^-(h)$ and upper value $v_s^+(h)$ are achieved and $v_s^-(h) = v_s^+(h)$. The open loop value of the game will be denoted by $v_s(h)$.*

(iii) *A pair $(\bar{u}, \bar{v})$ in $L^2(s, T; \mathbf{R}^m) \times L^2(s, T; \mathbf{R}^k)$ is an* open loop saddle point *of $C_h^s(u, v)$ if for all u in $L^2(s, T; \mathbf{R}^m)$ and all v in $L^2(s, T; \mathbf{R}^k)$*

$$C_h^s(\bar{u}, v) \le C_h^s(\bar{u}, \bar{v}) \le C_h^s(u, \bar{v}). \tag{4.5}$$

The first result is that, if the $C_{x_0}(u, v)$ is convex, concave, or convex-concave for some x_0, so is $C_h^s(u, v)$ for all $h \in \mathbf{R}^n$ and all s, $0 \le s < T$.

THEOREM 4.1.

(i) *If, for all $(x_0, v) \in \mathbf{R}^n \times L^2(0, T; \mathbf{R}^k)$, the map $u \mapsto C_{x_0}(u, v)$ is convex, then for all s, $0 \le s < T$, and all $(h, v) \in \mathbf{R}^n \times L^2(s, T; \mathbf{R}^k)$ the map $u \mapsto C_h^s(u, v)$ is convex.*

(ii) *If, for all $(x_0, u) \in \mathbf{R}^n \times L^2(0, T; \mathbf{R}^m)$, the map $v \mapsto C_{x_0}(u, v)$ is concave, then for all s, $0 \le s < T$, and all $(h, u) \in \mathbf{R}^n \times L^2(s, T; \mathbf{R}^m)$ the map $v \mapsto C_h^s(u, v)$ is concave.*

Proof. We prove only (i). From (2.20)–(2.22) for all $(u,v) \in L^2(0,T;\mathbf{R}^m) \times L^2(0,T;\mathbf{R}^k)$,

$$\begin{aligned} &\forall \bar{u} \in L^2(0,T;\mathbf{R}^m), \quad d^2C_{x_0}(u,v;\bar{u},0;\bar{u},0) \\ &\qquad = F\bar{y}(T)\cdot\bar{y}(T) + (Q\bar{y},\bar{y}) + (\bar{u},\bar{u}) \geq 0, \end{aligned} \tag{4.6}$$

where $\bar{y}$ is the solution of

$$\bar{y}' = A\bar{y} + B_1\bar{u}, \quad \bar{y}(0) = 0. \tag{4.7}$$

To prove the same result on $[s,T]$, associate with each $\bar{u} \in L^2(s,T;\mathbf{R}^m)$ its extension by zero $\tilde{\bar{u}}$ from $[s,T]$ to $[0,T]$. Therefore

$$\forall \bar{u} \in L^2(s,T;\mathbf{R}^m), \quad F\bar{y}(T)\cdot\bar{y}(T) + \int_0^T Q\bar{y}\cdot\bar{y} + \tilde{\bar{u}}\cdot\tilde{\bar{u}}\,dt \geq 0, \tag{4.8}$$

where $\bar{y}$ is the solution of

$$\bar{y}' = A\bar{y} + B_1\tilde{\bar{u}}, \quad \bar{y}(0) = 0. \tag{4.9}$$

Notice that, since $\tilde{\bar{u}}$ is zero in $[0,s]$, $\bar{y} = 0$ in $[0,s]$ and $\bar{y}$ is also the solution of

$$\bar{y}' = A\bar{y} + B_1\bar{u}, \quad \bar{y}(s) = 0 \tag{4.10}$$

$$\Rightarrow \forall \bar{u} \in L^2(s,T;\mathbf{R}^m), \quad F\bar{y}(T)\cdot\bar{y}(T) + \int_s^T Q\bar{y}\cdot\bar{y} + \bar{u}\cdot\bar{u}\,dt \geq 0. \tag{4.11}$$

Hence for all $h \in \mathbf{R}^n$, all $(u,v) \in L^2(s,T;\mathbf{R}^m)\times L^2(s,T;\mathbf{R}^k)$, and all $\bar{u} \in L^2(s,T;\mathbf{R}^m)$,

$$\begin{aligned} d^2C_h^s(u,v;\bar{u},0;\bar{u},0) &= F\bar{y}(T)\cdot\bar{y}(T) + \int_s^T Q\bar{y}\cdot\bar{y} + \bar{u}\cdot\bar{u}\,dt \\ &= d^2C_{x_0}(0,0;\tilde{\bar{u}},0;\tilde{\bar{u}},0) \geq 0. \end{aligned}$$

Thus for all s and all (h,v), the map $u \mapsto C_h^s(u,v)$ is convex. ∎

5. Decoupling and Riccati differential equation in the saddle point case.

5.1. Open loop saddle point optimality principle. At this juncture, it is important to notice that the necessary conditions (2.35) and (2.38) associated with the respective finiteness of the lower and upper values of the game on $[0,T]$ do not generally survive on $[s,T]$. However the convexity-concavity condition (2.29) does.

THEOREM 5.1. *Assume that $v(x_0)$ is finite for some $x_0 \in \mathbf{R}^n$, let $x(\cdot;x_0), p(\cdot;x_0)$ be a solution of the coupled system (2.27) in $[0,T]$, and let s, $0 \leq s < T$.*

(i) *The value $v_s(x(s;x_0))$ of the game is finite.*

(ii) *The restriction of (x,p) to $[s,T]$ is a solution of the coupled system*

$$\begin{cases} x_s' = Ax_s - B_1B_1^*p_s + B_2B_2^*p_s \text{ a.e. in } [s,T], & x_s(s) = x(s;x_0), \\ p_s' + A^*p_s + Qx_s = 0, & p_s(T) = Fx_s(T), \end{cases} \tag{5.1}$$

the restrictions $(u_s,v_s) = (u|_{[s,T]}, v_{[s,T]})$ of the controls (u,v) on $[0,T]$ to $[s,T]$ verify

$$u_s = -B_1^*p_s \text{ and } v_s = B_2^*p_s, \quad v_s(x(s;x_0)) = p_s(s)\cdot x(s;x_0), \tag{5.2}$$

$$v(x_0) = v_s(x(s;x_0)) + \int_0^s Qx\cdot x + |u|^2 - |v|^2\,dt, \tag{5.3}$$

and

$$\sup_{v\in L^2(s,T;\mathbf{R}^k)} C_0^s(0,v) = C_0^s(0,0) = \inf_{u\in L^2(s,T;\mathbf{R}^m)} C_0^s(u,0). \tag{5.4}$$

Proof. From Theorem 2.4 on $[s,T]$, part (i) is equivalent to part (ii), and thus it is sufficient to prove part (ii). From Theorem 4.1, the convexity-concavity conditions on $[0,T]$ survive on $[s,T]$, and we get (5.4). Moreover, if $(x(\cdot;x_0),p(\cdot;x_0))$ is a solution of the coupled system (2.27) in $[0,T]$ with initial state x_0 at time 0 and the controls (u,v) verify identities (2.28), then the restrictions $(x_s,p_s)=(x|_{[s,T]},p|_{[s,T]})$ are a solution to the coupled system (5.1), and the restrictions $(u_s,v_s)=(u|_{[s,T]},v_{[s,T]})$ of the controls on $[0,T]$ verify (5.2). Thus, by the analogue of Theorem 2.4, we get the finiteness of the value of the game on $[s,T]$. □

THEOREM 5.2. *Assume that $v(x_0)$ is finite for all $x_0\in\mathbf{R}^n$.*

(i) *The solution (x_s,p_s) of the coupled system* (5.1) *and the controls (u_s,v_s) on $[s,T]$ in* (5.2) *are unique.*

(ii) *The map*

$$x_0 \mapsto X(s)x_0 \stackrel{\text{def}}{=} x(s;x_0) : \mathbf{R}^n \to \mathbf{R}^n \tag{5.5}$$

is a linear bijection, where $x(\cdot;x_0),p(\cdot;x_0)$ is the unique solution of the coupled system (2.27) *in $[0,T]$.*

(iii) *For all $h\in\mathbf{R}^n$, the utility function $C_h^s(u,v)$ has a unique open loop saddle point $(\hat u_s,\hat v_s)\in L^2(s,T;\mathbf{R}^m)\times L^2(s,T;\mathbf{R}^k)$, and there exists a unique solution $(\hat x_s,\hat p_s)$ of the coupled system*

$$\begin{cases} \hat x_s' = A\hat x_s - B_1B_1^*\hat p_s + B_2B_2^*\hat p_s \ \text{a.e. in } [s,T], & \hat x_s(s)=h,\\ \hat p_s' + A^*\hat p_s + Q\hat x_s = 0 \ \text{a.e. in } [s,T], & \hat p_s(T) = F\hat x_s(T), \end{cases} \tag{5.6}$$

$$\text{such that } \hat u_s = -B_1^*\hat p_s \text{ and } \hat v_s = B_2^*\hat p_s. \tag{5.7}$$

Proof. (i) Assume that the pair $(\hat u_s,\hat v_s)$ is a saddle point of $C^s_{\hat x(s)}$ on the time interval $[s,T]$. Denote by $(\hat x_s,\hat p_s)$ the corresponding solution to the coupled system (5.1). Consider the new pair on the interval $[0,T]$,

$$\tilde u \stackrel{\text{def}}{=} \begin{cases} \hat u & \text{in } [0,s],\\ \hat u_s & \text{in } [s,T], \end{cases} \quad \tilde v \stackrel{\text{def}}{=} \begin{cases} \hat v & \text{in } [0,s],\\ \hat v_s & \text{in } [s,T], \end{cases} \tag{5.8}$$

and the corresponding solution $(\tilde x,\tilde p)$ to the state-adjoint state system (2.4)–(2.18). If it can be shown that the pair $(\tilde u,\tilde v)$ is a saddle point of $C_{x_0}(u,v)$ on $[0,T]$, then by uniqueness of the saddle point on $[0,T]$ we can conclude that $(\tilde u,\tilde v)=(\hat u,\hat v)$ and hence $(\hat u_s,\hat v_s)=(\hat u|_{[s,T]},\hat v|_{[s,T]})$. From this we get the uniqueness of the saddle point of $C^s_{\hat x(s)}$ on $[s,T]$ and the uniqueness of solution to the coupled system (5.1). The first remark is that $\tilde x(s)=\hat x(s)$ and from (5.3)

$$\begin{aligned} C_{x_0}(\hat u,\hat v) = v(x_0) &= \int_0^s Q\hat x\cdot\hat x + |\hat u|^2 - |\hat v|^2\,dt + v_s(\hat x(s))\\ &= \int_0^s Q\hat x\cdot\hat x + |\hat u|^2 - |\hat v|^2\,dt + F\hat x_s(T)\cdot\hat x_s(T) + \int_s^T Q\hat x_s\cdot\hat x_s + |\hat u_s|^2 - |\hat v_s|^2\,dt\\ &\Rightarrow C_{x_0}(\hat u,\hat v) = C_{x_0}(\tilde u,\tilde v). \end{aligned}$$

Yet, this is not sufficient to conclude that $(\tilde{u},\tilde{v})$ is a saddle point of $C_{x_0}(u,v)$. We must show that

$$\sup_{v\in L^2(0,T;\mathbf{R}^k)} C_{x_0}(\tilde{u},v) = C_{x_0}(\tilde{u},\tilde{v}) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_{x_0}(u,\tilde{v}). \tag{5.9}$$

The second remark is that, since $(\tilde{u}-\hat{u},\tilde{v}-\hat{v})$ is equal to $(0,0)$ on $[0,s]$, $(\hat{u}_s-\hat{u},\hat{v}_s-\hat{v})$ is a saddle point of $C_0^s(u_s,v_s)$. Combining this with the fact that, by (5.4), $(0,0)$ is also a saddle point of $C_0^s(u_s,v_s)$, the pairs $(\hat{u}_s-\hat{u},0)$ and $(0,\hat{v}_s-\hat{v})$ are also saddle points of $C_0^s(u_s,v_s)$ and $C_0^s(\hat{u}_s-\hat{u},0) = C_0^s(0,\hat{v}_s-\hat{v}) = 0$. The third remark is that

$$C_{x_0}(\hat{u},\tilde{v}) = C_{x_0}(\hat{u},\hat{v}) + dC_{x_0}(\hat{u},\hat{v};0,\tilde{v}-\hat{v}) + C_0(0,\tilde{v}-\hat{v}) = C_{x_0}(\hat{u},\hat{v}) + C_0(0,\tilde{v}-\hat{v}).$$

But, since $\tilde{v}-\hat{v}$ is equal to 0 on $[0,s]$,

$$C_0(0,\tilde{v}-\hat{v}) = C_0^s(0,\hat{v}_s-\hat{v}) = 0 \quad \Rightarrow C_{x_0}(\hat{u},\tilde{v}) = C_{x_0}(\hat{u},\hat{v}) = C_{x_0}(\tilde{u},\tilde{v}).$$

We now prove the second part of identity (5.9):

$$C_{x_0}(u,\tilde{v}) = C_{x_0}(\hat{u},\tilde{v}) + dC_{x_0}(\hat{u},\tilde{v};u-\hat{u},0) + C_0(u-\hat{u},0). \tag{5.10}$$

Since $(0,0)$ is a saddle point of $C_0(u,v)$,

$$\inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u-\hat{u},0) = \inf_{u\in L^2(0,T;\mathbf{R}^m)} C_0(u,0) = 0.$$

It remains to prove that for all $u\in L^2(0,T;\mathbf{R}^m)$, $dC_{x_0}(\hat{u},\tilde{v};u-\hat{u},0) = 0$. First observe that

$$\begin{aligned} dC_{x_0}(\hat{u},\tilde{v};u-\hat{u},0) &= dC_{x_0}(\hat{u},\hat{v};u-\hat{u},0) + dC_0(0,\tilde{v}-\hat{v};u-\hat{u},0) \\ &= dC_0(0,\tilde{v}-\hat{v};u-\hat{u},0). \end{aligned}$$

Since $(0,\hat{v}_s-\hat{v})$ is a saddle point of C_0^s on $[s,T]$, there exists a pair (ξ,π) solution of the coupled system

$$\begin{cases} \xi' = A\xi - B_1B_1^*\pi + B_2B_2^*\pi \text{ a.e. in } [s,T], & \xi(s) = 0, \\ \pi' + A^*\pi + Q\xi = 0, & \pi(T) = F\xi(T), \end{cases} \tag{5.11}$$

$$0 = -B_1^*\pi, \quad \hat{v}_s - \hat{v} = B_2^*\pi. \tag{5.12}$$

The first equation can also be written

$$\xi' = A\xi + B_2(\hat{v}_s-\hat{v}) \text{ a.e. in } [s,T], \quad \xi(s) = 0.$$

Denote by $\tilde{\xi}$ the solution of the state equation (2.4) on $[0,T]$ corresponding to the initial state 0 and the control pair $(0,\tilde{v}-\hat{v})$:

$$\tilde{\xi}' = A\tilde{\xi} + B_2(\tilde{v}-\hat{v}) \text{ a.e. in } [0,T], \quad \tilde{\xi}(0) = 0.$$

Then observe that, since the restriction of $\tilde{v}-\hat{v}$ to $[0,s]$ is 0, $\tilde{\xi} = 0$ on $[0,s]$ and $\tilde{\xi} = \xi$ on $[s,T]$. Denoting by y the solution of

$$y' = Ay + B_1(u-\hat{u}) \text{ a.e. in } [0,T], \quad y(0) = 0,$$

we get the expression (cf. (2.16) and (2.19) for the directional derivative)

$$\begin{aligned} dC_0(0,\tilde{v}-\hat{v};u-\hat{u},0) &= F\tilde{\xi}(T)\cdot y(T)+\int_0^T Q\tilde{\xi}\cdot y+0\cdot(u-\hat{u})+(\tilde{v}-\hat{v})\cdot 0\,dt \\ &= F\tilde{\xi}(T)\cdot y(T)+\int_0^T Q\tilde{\xi}\cdot y\,dt = F\tilde{\xi}(T)\cdot y(T)+\int_s^T Q\tilde{\xi}\cdot y\,dt \\ &= F\xi(T)\cdot y(T)+\int_s^T Q\xi\cdot y\,dt = \int_s^T B_1^*\pi\cdot(u-\hat{u})\,dt = 0, \end{aligned}$$

since $B_1^*\pi = 0$ on $[s,T]$ from (5.12). This establishes the second part of expression (5.9). The proof of the first part is dual to the proof of the second part. This yields the uniqueness and completes the proof of part (i).

(ii) The map (5.5) is clearly linear (and continuous). Assume that it is not bijective; then there exists some $x_0 \in \mathbf{R}^n$, $x_0 \neq 0$, such that $\hat{x}(s) = 0$. The restriction of $(\hat{x},\hat{p})$ to the interval $[s,T]$ is a solution of the system

$$\text{(5.13)}\qquad \begin{cases} \xi' = A\xi - B_1B_1^*\pi + B_2B_2^*\pi \text{ a.e. in } [s,T], & \xi(s) = 0 = \hat{x}(s), \\ \pi' + A^*\pi + Q\xi = 0 \text{ a.e. in } [s,T], & \pi(T) = F\xi(T). \end{cases}$$

But from part (i) the unique solution of system (5.13) is $(0,0)$. Hence

$$\begin{aligned} &(\hat{x},\hat{p}) = (0,0) \text{ in } [s,T] \quad \Rightarrow (\hat{x}(s),\hat{p}(s)) = (0,0) \\ \Rightarrow &\begin{cases} \hat{x}' = A\hat{x} - B_1B_1^*\hat{p} + B_2B_2^*\hat{p} \text{ a.e. in } [0,s], & \hat{x}(s) = 0, \\ \hat{p}' + A^*\hat{p} + Q\hat{x} = 0 \text{ a.e. in } [0,s], & \hat{p}(s) = 0, \end{cases} \\ &\Rightarrow (\hat{x},\hat{p}) = (0,0) \text{ in } [0,s] \quad \Rightarrow x_0 = \hat{x}(0) = 0. \end{aligned}$$

This contradicts our initial conjecture that $x_0 \neq 0$, and we conclude that the linear map (5.5) is injective and, a fortiori, bijective.

(iii) From part (i) for each $h \in \mathbf{R}^n$ and each s, $0 \leq s < T$, there exists a unique $h_0 \in \mathbf{R}^n$ such that $h = X(s)h_0$. But $C_{h_0}(u,v)$ has a unique open loop saddle point in $[0,T]$. From part (i), $C^s_{X(s)h_0}(u,v)$ has a unique open loop saddle point in $[s,T]$. The result now follows from the fact that $h = X(s)h_0$. The equations and the identities follow from Theorem 5.1(ii). □

Remark 5.1. The proof of part (i) is not trivial. It is one of the key elements needed to get the result of part (iii) that says that $C^s_h(u,v)$ has a saddle point for all initial state h and all initial times s.

5.2. Decoupling of the coupled system. We need the following lemma.

LEMMA 5.1. *Assume that the open loop saddle point value $v(x_0)$ is finite for all $x_0 \in \mathbf{R}^n$. Let s, $0 \leq s < T$, and $(\hat{x}_s,\hat{p}_s)$ be the unique solution of the coupled system* (5.6) *with initial state h at time s. Then the map $P(s)$*

$$\text{(5.14)}\qquad h \mapsto P(s)h \stackrel{\text{def}}{=} \hat{p}_s(s) : \mathbf{R}^n \to \mathbf{R}^n$$

is linear, continuous, and symmetrical.

Proof. By definition, $P(s)$ is linear and continuous. For the symmetry, let (x,p) and $(\bar{x},\bar{p})$ be the solutions of the coupled system (5.6) for the respective initial states

h and $\bar{h}$ at time s. By symmetry of F, $Q(t)$, and $B_1(t)B_1^*(t) - B_2(t)B_2^*(t)$,

$$\begin{aligned} P(s)h\cdot\bar{h} = p(s)\cdot\bar{x}(s) &= p(T)\cdot\bar{x}(T) - \int_s^T p'\cdot\bar{x} + p\cdot\bar{x}'\,dt \\ &= Fx(T)\cdot\bar{x}(T) - \int_s^T -(A^*p+Qx)\cdot\bar{x} + p\cdot(A\bar{x} - B_1B_1^*\bar{p} + B_2B_2^*\bar{p})\,dt \\ &= Fx(T)\cdot\bar{x}(T) + \int_s^T Qx\cdot\bar{x} + p\cdot(B_1B_1^* - B_2B_2^*)\bar{p}\,dt = P(s)\bar{h}\cdot h, \end{aligned}$$

and $P(s)^* = P(s)$. □

Remark 5.2. At this juncture the matrix Riccati differential equation can be readily obtained from Lemma 3.1 in [4] since, from Theorem 5.2(ii), the matrix function $X(s)$ is invertible for all s. However, in view of Lemma 5.1, we use invariant embedding to get more a priori information on the decoupling matrix function $P(s)$.

THEOREM 5.3. *Assume that $v(x_0)$ is finite for all $x_0 \in \mathbf{R}^n$.*

(i) *Given the solution of the coupled system* (2.27) *in* $[0,T]$ *for* $x_0 \in \mathbf{R}^n$,

$$\hat{p}(s) = P(s)\hat{x}(s), \quad 0 \le s \le T. \tag{5.15}$$

(ii) *The elements of the matrix function P are $H^1(0,T)$-functions, the elements of the matrix functions*

$$A_P \overset{\text{def}}{=} A - RP, \quad R \overset{\text{def}}{=} B_1B_1^* - B_2B_2^* \tag{5.16}$$

belong to $L^\infty(0,T)$, and the closed loop system

$$\hat{x}' = [A - (B_1B_1^* - B_2B_2^*)\,P]\,\hat{x} \text{ a.e. in } [0,T], \quad \hat{x}(0) = x_0, \tag{5.17}$$

has a unique solution in $H^1(0,T;\mathbf{R}^n)$. For all (t,s), $0 \le s \le t \le T$, the fundamental matrix solution $\Phi_P(t,s)$ associated with the closed loop system (5.17) *and its inverse $\Phi_P(t,s)^{-1}$ are continuous in $\{(t,s) : 0 \le s \le t \le T\}$. For all pairs $0 \le s \le t \le T$*

$$\frac{\partial}{\partial s}\Phi_P(t,s) + \Phi_P(t,s)A_P(s) = 0 \text{ a.e. in } [0,t], \quad \Phi_P(t,t) = I. \tag{5.18}$$

(iii) *For all h and $\overline{h}$ in $\mathbf{R}^n$*

$$\begin{aligned} h\cdot P(s)\,\overline{h} &= \Phi_P(T,s)h\cdot F\Phi_P(T,s)\bar{h} \\ &\quad + \int_s^T \Phi_P(t,s)h\cdot[Q(t) + P(t)R(t)P(t)]\,\Phi_P(t,s)\bar{h}\,dt. \end{aligned} \tag{5.19}$$

Proof. (i) From Theorems 5.1 and 5.2(i)

$$\hat{x}_s = \hat{x}|_{[s,T]}, \quad \hat{p}_s = \hat{p}|_{[s,T]} \quad \Rightarrow \hat{p}(s) = \hat{p}_s(s) = P(s)\hat{x}_s(s) = P(s)\hat{x}(s),$$

and we get (5.15). The closed loop system is obtained by direct substitution of the identity (5.15) for $\hat{p}$ into the first equation of the coupled system (2.27) in $[0,T]$.

(ii) Associate with the solution of the coupled system (2.27) in $[0,T]$ the matrix function

$$\Lambda(s)x_0 \overset{\text{def}}{=} \hat{p}(s;x_0), \quad \forall x_0 \in \mathbf{R}^n,\ 0 \le s \le T. \tag{5.20}$$

From (5.15) in part (i) and the invertibility of $X(s)$

$$\Lambda(s)x_0 \overset{\text{def}}{=} P(s)X(s)x_0, \quad \forall x_0 \in \mathbf{R}^n,\ 0 \le s \le T$$
$$\Rightarrow\ \Lambda(s) = P(s)X(s),\ \Rightarrow\ P(s) = \Lambda(s)X(s)^{-1}, \quad 0 \le s \le T.$$

Since $X(s)$ is invertible and the elements of the matrices X and Λ are $H^1(0,T)$-functions,

$$P'(s) = \Lambda(s)'X(s)^{-1} - \Lambda(s)X(s)^{-1}X(s)'X(s)^{-1}. \tag{5.21}$$

In particular the elements of the matrix function P are $H^1(0,T)$-functions. Then the matrix function $A_P(t)$ in (5.16) belongs to $L^\infty(0,T)$, and the closed loop system (5.17) has a unique solution in $H^1(0,T;\mathbf{R}^n)$. From this Φ_P has the usual properties of a fundamental matrix solution Φ_P in $\{(t,s) : 0 \le s \le t \le T\}$, $\Phi_P(t,0) = \Phi_P(t,s)\Phi_P(s,0)$, and

$$\frac{\partial \Phi_P}{\partial s}(t,s) + \Phi_P(t,s)A_P(s) \text{ a.e. in } [0,T], \quad \Phi_P(t,t) = I. \tag{5.22}$$

(iii) Let (ψ,φ) (resp., $(\overline{\psi},\overline{\varphi})$) be the solution of the coupled system (5.1) for the initial state h (resp., $\overline{h}$). Then by direct computation

$$h \cdot \overline{\psi}(s) = \varphi(T) \cdot F\overline{\varphi}(T) + \int_s^T \varphi(t) \cdot Q(t)\,\overline{\varphi}(t) + \psi(t) \cdot R(t)\,\overline{\psi}(t)\,dt,$$
$$h \cdot P(s)\,\overline{h} = \Phi_P(T,s)h \cdot F\Phi_P(T,s)\bar{h} + \int_s^T \Phi_P(t,s)h \cdot [Q(t) + P(t)R(t)P(t)]\,\Phi_P(t,s)\bar{h}\,dt. \tag{5.23}$$

□

5.3. Proof of Theorem 2.9. (i) From identity (5.21) in the proof of part (ii) of Theorem 5.3 a straightforward computation yields that the matrix function P is a solution of the matrix Riccati differential equation (2.43). This solution is unique. Indeed if $\bar{P}$ is another solution of the Riccati equation, the closed loop system with $\bar{P}$ has a unique solution $\bar{x}$ and it is easy to check that $\bar{p} = \bar{P}\bar{x}$ is a solution of the associated adjoint equation. But there is a unique solution to the coupled system. By definition of P via invariant embedding we get that $\bar{P} = P$. (ii) and (iii) The proof follows from identities (2.34) and (2.35) in Theorem 2.2.

5.4. Proof of Theorem 2.10. From Theorem 2.9 we get (a) and (b). Conversely, from (a) if P is a solution of the Riccati differential equation, the closed loop system has a unique solution x_P and $p_P = Px_P$ is the solution of the adjoint system. It is then easy to check that the pair (x_P, p_P) is indeed a solution of the coupled system (2.27) in $[0,T]$. Finally from the convexity-concavity property (b) we get the existence of the open loop saddle point.

OPTIMAL CONTROL OF A NUTRIENT-PHYTOPLANKTON-ZOOPLANKTON-FISH SYSTEM*

MARCUS R. GARVIE† AND CATALIN TRENCHEA‡

Abstract. We consider the mathematical formulation, analysis, and numerical solution of an optimal control problem for a nonlinear "nutrient-phytoplankton-zooplankton-fish" reaction-diffusion system. We study the existence of optimal solutions, derive an optimality system, and determine optimal solutions. In the original spatially homogeneous formulation [M. Scheffer, *Oikos*, 62 (1991), pp. 271–282] the dynamics of plankton were investigated as a function of parameters for nutrient levels and fish predation rate on zooplankton. In our paper the model is spatially extended and the parameter for fish predation treated as a multiplicative control variable. The model has implications for the biomanipulation of food-webs in eutrophic lakes to help improve water quality. In order to illustrate the control of irregular spatiotemporal dynamics of plankton in the model we implement a semi-implicit (in time) finite element method with "mass lumping" and present the results of numerical experiments in two space dimensions.

Key words. chaos, optimal control, biomanipulation, predator-prey interaction, finite element method

1. Introduction.

1.1. Model equations.

In this paper we study the following nutrient-phytoplankton-zooplankton-fish reaction-diffusion system:

$$\begin{cases} \dfrac{\partial A}{\partial \tau} = D_A \Delta A + \widehat{r}\dfrac{n}{n+h_n}A - cA^2 - pZ\dfrac{A}{A+h_a}, \\ \dfrac{\partial Z}{\partial \tau} = D_Z \Delta Z + peZ\dfrac{A}{A+h_a} - \widehat{m}Z - F\dfrac{Z^2}{Z^2+h_Z^2}, \end{cases} \tag{1.1}$$

where A is phytoplankton biomass, Z is zooplankton biomass, D_a and D_z are the diffusion coefficients of phytoplankton and zooplankton, respectively, and n is the nutrient level of the system. F is the rate of zooplankton biomass consumed by fish per unit volume of water per day (average predation rate times the density of fish). It is important to note that in our formulation $F \equiv F(x,t)$, i.e., F is defined at every point in the lake and at every point in time. For definitions of the positive parameters c, e, $\widehat{m}$, $\widehat{r}$, p, h_a, h_z, and h_n, see [39]. The symbol τ denotes time in days, and $\Delta = \sum_{i=1}^{d} \partial^2/\partial X_i^2$ is the usual Laplacian operator in $d = 2$ or 3 space dimensions. The grazing rate of zooplankton on phytoplankton is of a type II functional response, while the predation rate of fish on zooplankton is of type III [17]. In the absence of zooplankton the phytoplankton are assumed to grow logistically.

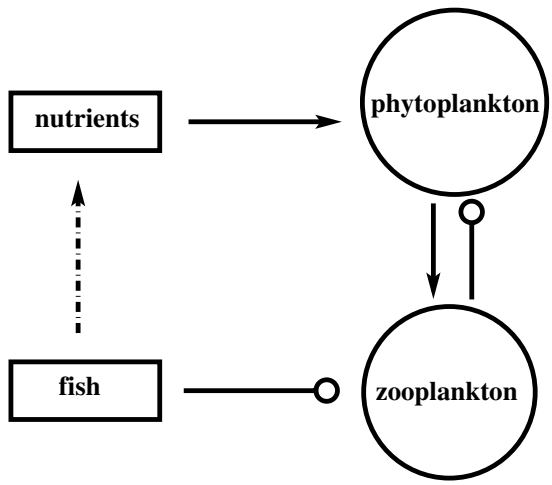

FIG. 1.1. *Interactions incorporated into a nutrient-plankton-fish model. Arrows indicate positive effects, circles indicate negative effects (redrawn from* [39]*).*

The nutrient-phytoplankton-zooplankton-fish model was originally formulated as a system of ordinary differential equations (ODEs) by Scheffer [39] and has since been spatially extended (see, for example, [32, 29, 30, 33, 34, 45]).

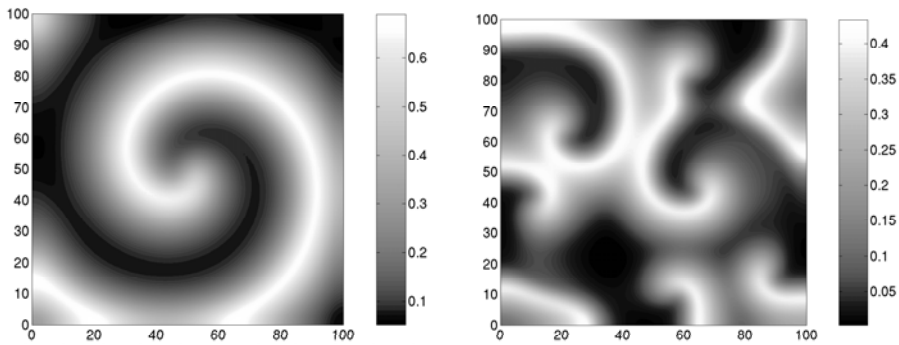
The reaction-diffusion system models a simple food-web in lakes where planktivorous fish feed on zooplankton, and the zooplankton feed on phytoplankton (algae). The basic interactions in the model are illustrated in Figure 1.1. The model is "minimal" in the sense that only a few important interactions are taken into account. For example, the positive effect that fish have on the nutrients of the system is omitted in this model (indicated by the dotted arrow in Figure 1.1). Nevertheless, such minimal predator-prey systems display a wide range of ecologically relevant behavior, for example, spiral waves [34], target waves [41], diffusion-induced instability [30], and chaos [36, 34]. See [31] for a historical overview of modeling plankton dynamics and pattern formation mechanisms.

It is simpler to work with equations that have been scaled to nondimensional form; thus after letting $N := n/(n + h_n)$ in (1.1) we define dimensionless phytoplankton densities, zooplankton densities, spatial coordinates, and time via

$$u = \frac{cA}{\widehat{r}N}, \quad v = \frac{cZ}{\widehat{r}eN}, \quad x_i = \frac{kX_i}{L}, \quad t = R_0\tau$$

(cf. [33] and [34]), where R_0 is the characteristic (or typical) growth rate of phytoplankton, k is a factor related to the scale of expected patchy patterns, and L is the maximum diameter of the lake in the coordinate direction x_2, or x_3. Note that in the case of a square domain, L is the side length. We also rescale the parameters via

$$r = \frac{R}{R_0}, \qquad a = \frac{C_1K}{C_2R_0}, \qquad b = \frac{K}{C_2}, \qquad m = \frac{M}{R_0},$$
$$f = \frac{F}{C_3R_0}, \qquad g = \frac{K}{C_3A}, \qquad d_1 = \frac{k^2D_A}{L^2R_0}, \qquad d_2 = \frac{k^2D_Z}{L^2R_0},$$



(a) (b)

FIG. 1.2. *Numerical solution v of (1.2) at time $t = 1000$ with $d_1 = d_2 = 0.05$, $f = 0$, $g = 10$, solved on a space-time grid of $101 \times 101 \times 12000$. A semi-implicit (in time) Galerkin finite element method with piecewise linear continuous basis functions was employed with homogeneous Neumann boundary conditions. In both cases initial data of the form $u_0 = A(x/100) + B$, $v_0 = C(100 - y)/100 + D$ was employed with the following parameter values:* (a) $A = 0.02$, $B = 0.19$, $C = 0.02$, $D = 0.31$, $r = 1$, $a = b = 5$, $m = 0.5$; (b) $A = 0.2$, $B = 0.1$, $C = 0.2$, $D = 0.1$, $r = 1$, $a = b = 20$, $m = 0.8$.

which leads to the dimensionless system

$$\begin{cases} \dfrac{\partial u}{\partial t} = d_1 \Delta u + ru(1-u) - \dfrac{auv}{1+bu}, \\ \dfrac{\partial v}{\partial t} = d_2 \Delta v + \dfrac{auv}{1+bu} - mv - f\dfrac{gv^2}{1+g^2v^2}. \end{cases} \tag{1.2}$$

Any 2-component reaction-diffusion system with reaction kinetics close to a super critical Hopf bifurcation, with equal diffusion coefficients, can be transformed into a generic reaction-diffusion system of "λ-ω" form [40]. Thus as spiral wave solutions of λ-ω reaction-diffusion systems have been proved to exist [9], for appropriate parameter values and initial data we also expect spiral wave solutions to exist for system (1.1). In Figure 1.2 we present snapshots at $t = 1000$ for the uncontrolled system (1.2) representing spiral wave solutions that persist indefinitely (Figure 1.2(a)) or, after initialization, rapidly break up into irregular patterns (Figure 1.2(b)). In both cases we checked that this behavior persists up to $t = 10{,}000$. This behavior is important to our study as we apply controls that drive the system from the unstable regime to form regular patterns.

In this paper we consider the above model in the context of eutrophication of lakes. Eutrophication is the process where excessive input of nutrients in lakes leads to high levels of phytoplankton (algae) and hence degraded water quality (see [6, 18] and the references therein). The most common approach to improving water quality in this situation is to either reduce the external nutrient loading or enhance zooplankton by reducing planktivorous fish, thereby reducing algal biomass. We focus on the latter approach ("top-down" control), where the nutrient level in the system is determined by a parameter. In practice, planktivorous fish can be reduced by fish removal, or by piscivore[1] stocking. This manipulation of the food-web is called biomanipulation and

[1]Species that feed on fish.

is an important approach for improving water quality in eutrophic lakes (e.g., [23, 25, 28, 38, 44, 50]). Evidence from the limnological literature supports the hypothesis that the most effective biomanipulation strategy for improving water quality is the partial removal of fish, and that there may be an optimum harvesting rate of planktivorous fish [11, 21, 48, 49]. This observation helped motivate the work in this paper, where we consider the optimal control of phytoplankton u and zooplankton v densities, where f is the distributed control. We aim to minimize the quadratic cost functional

$$J(u,v,f) = \frac{1}{2}\int_Q \left(|u-\bar{u}|^2 + |v-\bar{v}|^2\right) dxdt + \frac{\alpha}{2}\int_Q \left|\frac{\partial f}{\partial t}\right|^2 dxdt, \tag{1.3}$$

where $(\bar{u},\bar{v})$ are the desired phytoplankton-zooplankton densities, and $Q = \Omega \times (0,T)$ is the space-time domain of interest. The first two terms in (1.3) measure, with respect to the L^2-norm in space and time, the difference between the given target densities $(\bar{u},\bar{v})$ and the state densities (u,v). The last term in (1.3) reflects the fact that we want to avoid changing the control (adding or removing fish) too often. The constant α can be chosen to adjust the relative importance of this cost. We assume the state equations (1.2) are augmented with appropriate initial and boundary conditions. Note that as there is no forcing in the first equation of (1.2), the control of phytoplankton must result indirectly through the coupling with the second equation. Furthermore, the forcing in (1.2) enters not merely as an additive inhomogeneous source term, but rather in a multiplicative manner. Additionally, as the control f is a *rate*, it is strictly nonnegative.

We emphasize that although this work has implications for the control of eutrophication in lakes, the main focus of this work is on the rigorous mathematical analysis of the optimal control problem. We do not provide practical implementational details for the improvement of water quality in lakes, but we do provide a theoretical basis on which such a task would be based. We also remark that the mathematical problem and results from numerical simulations may provide insights into the field situation.

It is important to distinguish between the mathematical (optimal control) problem and the practical problem in the field. Mathematically, we assume that f can be manipulated at every point in space and time. However, from a practical point of view, we only have direct control of the net density of fish in the lake at any instant. For example, fish released into a lake may distribute themselves uniformly throughout the lake, or move in schools. Nevertheless, there is significant overlap between the mathematical problem and the field situation, for example, in the case where we wish to reduce the (net) algal growth. In addition to improving water quality we are also interested in the more fundamental aim of maintaining a stable equilibrium between the plankton, thus avoiding the extinction of one or more species.

The aim of this paper is to undertake the mathematical analysis of the optimal control problem introduced above, namely, to minimize (1.3) subject to (1.2). We also provide some numerical results that illustrate the theoretical results. We remark that there are few optimal control studies in the literature for interacting species involving space and time (e.g., [1, 2, 3, 8, 13, 24, 26]) or for reaction-diffusion equations applied in other contexts (e.g., [5, 7, 12, 19, 43]).

2. Mathematical preliminaries.

2.1. Local analysis. We present some details of the local dynamics of the reaction-diffusion system for the state equations (1.2). This is important for deriving necessary conditions on the system parameters for the kinetics to possess biologically

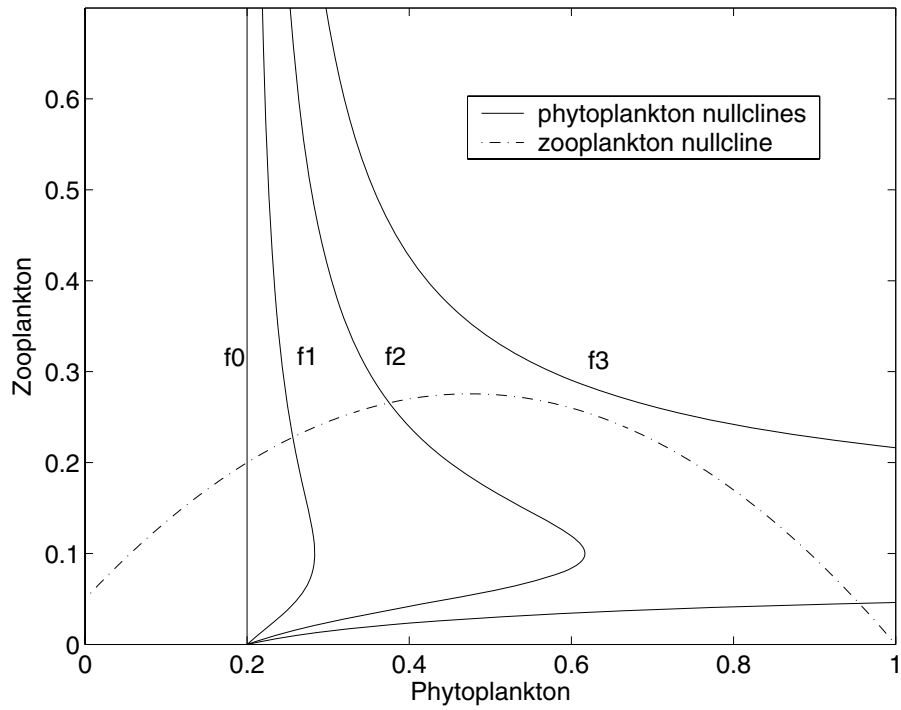


FIG. 2.1. *Nullclines for the local kinetics of* (1.2) *with* $r = 1$, $a = b = 20$, $m = 0.8$, $g = 10$, *for fish predation rates* $f_0 = 0$ *(limit cycle, no fish),* $f_1 = 0.1$ *(limit cycle),* $f_2 = 0.25$ *(limit cycle), and* $f_3 = 0.4$ *(phytoplankton dominance).*

meaningful equilibria. Furthermore, this acts as a guide in the appropriate choice of parameters for the numerical simulation of optimal solutions.

The local dynamics can be analyzed by considering the nullclines ("zero-isoclines") of this system, which are the solution curves for

$$v = \psi(u) := \frac{r}{a}(1-u)(1+bu),$$
$$u = \phi(v) := \frac{g^2 m v^2 + fgv + m}{(a-bm)g^2v^2 - bfgv + a - bm}, \tag{2.1}$$

corresponding to the first and second equations of (1.2). It is easy to show that there are saddle points at $(0,0)$ and $(0,1)$, and a stationary point (u_s, v_s) (stable or unstable) corresponding to the coexistence of phytoplankton and zooplankton. Note that for positive u_s and v_s we must have

$$m < \frac{a}{1+b}, \tag{2.2}$$

which follows from the restriction $0 < u_s < 1$. The nullclines are illustrated in Figure 2.1 for a specific parameter set and increasing predation rate. With no fish present, or a low fish predation rate, there is a limit cycle in the reaction kinetics surrounding the unstable stationary point, while at higher predation rates the system is dominated by a phytoplankton-only state [33, 39]. In general there are no closed

form expressions for u_s and v_s and consequently the analysis must be done numerically in each case. However, in the special case with no fish present, the analysis is straightforward and is briefly outlined below.

With $f = 0$ the intersection of the nullclines $v = \psi(u)$ and $u = \phi(v)$ in (2.1) intersect at (u_s, v_s), where

$$u_s = \frac{m}{a - bm}, \quad v_s = \frac{r}{a}(1 - u_s)(1 + bu_s). \tag{2.3}$$

To find conditions that guarantee limit cycle kinetics in the positive quadrant of phase space we first prove the existence of a positively invariant region in the sense of [47, Definition 1.1.4] that contains (u_s, v_s), and then apply standard theory of dynamical systems. We claim that the trapezoidal region $\Sigma \in [0, \infty)^2$ defined by

$$\Sigma := \left\{(u, v) \,:\, u \leq l, \quad v - \frac{l}{m}(r + m) + u \leq 0, \quad u \geq 0, \quad v \geq 0\right\}, \quad l > 1, \tag{2.4}$$

is positively invariant. To see this, first observe that the reaction kinetics do not point out of Σ along $u = 0$, $v = 0$, and $u = l$. To show that this is also true along the line $v = \frac{l}{m}(r + m) - u$, set $G(u, v) := v - \frac{l}{m}(r + m) + u$ and denote the outward normal to Σ along this line by $\nabla G := (\partial G/\partial u, \partial G/\partial v)^T = (1, 1)^T$. Then denoting the vector of reaction kinetics by $\widehat{\mathbf{f}} = (\widehat{f}, \widehat{g})^T$, observe that

$$\nabla G \cdot \widehat{\mathbf{f}}|_{v = \frac{l}{m}(r+m) - u} \leq (r + m)(u - l) \leq 0,$$

which proves the assertion. We derive a simple condition that ensures the critical point given by (2.3) is either an unstable node or an unstable focus, and thus by the Poincaré–Bendixson theorem [47, Theorem 1.1.19] there exists a limit cycle solution surrounding this point. Define

$$A := \begin{pmatrix} \widehat{f}_u & \widehat{f}_v \\ \widehat{g}_u & \widehat{g}_v \end{pmatrix}\Big|_{(u_s, v_s)};$$

direct calculation then leads to

$$\operatorname{tr} A := mr\left[\frac{(b + 1)}{a} - \frac{2}{(a - bm)}\right], \quad |A| = \frac{mr}{a}\left[a - (b + 1)m\right].$$

Now from (2.2) we have $|A| > 0$, and with the condition

$$m < \frac{a(b - 1)}{b(b + 1)}, \tag{2.5}$$

it also follows that $\operatorname{tr} A > 0$. Thus if (2.5) is satisfied, then the critical point (u_s, v_s) is an unstable node or focus (e.g., [46, p. 107]), as required. Thus, to summarize, in the special case with $f = 0$, if the system parameters satisfy (2.5), then there exists a limit cycle solution in the positive quadrant of phase space surrounding the unstable stationary state given by (2.3) (note that condition (2.5) implies condition (2.2)). It is easy to check that (2.5) is satisfied for the parameter sets in Figure 1.2, and also for the numerical results of the uncontrolled problem in section 4.

2.2. Well-posedness of the state equations. We use results from semigroup theory and the abstract theoretical setup of Morgan [35], which is based on the kinetics satisfying a Lyapunov-type condition, to infer the global existence and uniqueness of classical solutions of the state equations (1.2).

Before proving well-posedness of the equations we need to establish the formal setting and restate the fish-plankton system with appropriate initial and boundary data. Let Ω be a bounded and open subset of $\mathbb{R}^d$, $d \leq 3$, with a boundary $\partial\Omega$ of class C^{2+s}, $s > 0$, i.e., $\partial\Omega$ is a $(d-1)$-dimensional $C^{2+\nu}$ manifold on which Ω lies locally on one side. The model problem is formulated as follows:

Find the phytoplankton $u(\mathbf{x}, t)$ and zooplankton $v(\mathbf{x}, t)$ densities such that

$$\frac{\partial u}{\partial t} = d_1 \Delta u + ru(1-u) - \frac{auv}{1+bu} \qquad \text{in} \quad Q := \Omega \times (0,T), \tag{2.6a}$$

$$\frac{\partial v}{\partial t} = d_2 \Delta v + \frac{auv}{1+bu} - m\, v - f\frac{gv^2}{1+g^2v^2} \qquad \text{in} \quad Q, \tag{2.6b}$$

$$u(\mathbf{x},0) = u_0(\mathbf{x}), \qquad v(\mathbf{x},0) = v_0(\mathbf{x}), \quad \mathbf{x} \in \Omega \tag{2.6c}$$

$$\frac{\partial u}{\partial \boldsymbol{\nu}} = \frac{\partial v}{\partial \boldsymbol{\nu}} = 0 \quad \text{on} \quad \partial\Omega \times (0,T), \tag{2.6d}$$

where the parameters a, b, m, and g are real and strictly positive, and $\boldsymbol{\nu}$ denotes the outward normal to $\partial\Omega$. We assume that the control $f \equiv f(\mathbf{x}, t)$ is a Lipschitz continuous function on Q, which we denote by $f \in \mathrm{Lip}(Q)$, and that the initial data is bounded, i.e., $u_0(\mathbf{x}), v_0(\mathbf{x}) \in L^\infty(\Omega)$. It will be convenient to denote the vector of reaction kinetics by $\widehat{\mathbf{f}}(\mathbf{u}) := (\widehat{f}(\mathbf{u}), \widehat{g}(\mathbf{u}))^T$, where $\mathbf{u} := (u, v)^T$.

THEOREM 2.1. *Let $f \in \mathrm{Lip}(Q)$ and $u_0(\mathbf{x}), v_0(\mathbf{x}) \in L^\infty(\Omega)$. Then there exists a unique nonnegative classical solution of the fish-plankton system* (2.6a)–(2.6d) *for all $(\mathbf{x}, t) \in \Omega \times [0, \infty)$. Furthermore, if $d_1 = d_2$ and the initial data is chosen in the positively invariant region $\Sigma \in [0, \infty)^2$ given by* (2.4)*, then $(u, v) \in \Sigma$ for all $(\mathbf{x}, t) \in \Omega \times [0, \infty)$.*

Proof. Local existence of solutions is based on well-known semigroup theory (see, for example, Pazy [37] or Henry [20]). From Proposition 1 in [22] it follows immediately that (2.6a)–(2.6d) has a unique noncontinuable classical solution (u, v) for $(\mathbf{x}, t) \in \Omega \times [0, T_{max})$. Moreover, if $T_{max} < \infty$, then

$$\lim_{t \uparrow T_{max}} \sup_{\mathbf{x} \in \Omega} \{|u(\mathbf{x}, t)| + |v(\mathbf{x}, t)|\} = \infty. \tag{2.7}$$

To prove the nonnegativity of solutions observe that the reaction kinetics satisfy

$$\widehat{f}(0, v),\ \widehat{g}(u, 0) \geq 0 \quad \forall u, v \geq 0,$$

and the initial data $(u_0(\mathbf{x}), v_0(\mathbf{x}))$ is in $[0, \infty)^2$ for all (or almost every) $\mathbf{x} \in \Omega$. Thus by a maximum principle (see, e.g., [42, Lemma 14.20]) the solution $(u(\mathbf{x}, t), v(\mathbf{x}, t))$ lies in $[0, \infty)^2$ for all $\mathbf{x} \in \Omega$ and for all $t > 0$ for which the solution of (2.6a)–(2.6d) exists. In other words $[0, \infty)^2$ is positively invariant for the system. Proving global existence of solutions from local existence in the equal diffusion case is straightforward. The invariant region yields an L^∞ a priori bound [42] which contradicts nonglobal existence as solutions either exist for all time or blow up in the sup-norm in finite time (see (2.7)) [4]. The proof of global existence results in the distinct diffusion coefficient case requires additional theory as the only admissible invariant regions are products of intervals [42]. We apply the theoretical framework of Morgan [35] to prove global

existence and uniqueness, which involves verifying "intermediate sum" conditions and polynomial growth conditions on the kinetics.

We first define a so-called Lyapunov-type function given by

$$H(\mathbf{u}) := h_1(u) + h_2(v), \quad \text{where} \quad h_1(u) = u, \quad h_2(v) = v.$$

Then with $a_{11} = a_{22} = a_{21} = \mu = q = 1$, $K_2 = K_4 = K_6 = 0$, $K_1 = K_5 = r$, $K_3 = \max\{r, a/b\}$ the following conditions are easily verified for all $\mathbf{u} \in [0,\infty)^2$, corresponding to conditions (H1), (H3), (H4)(i), (H5), and (H6) in [35], respectively:

$$\begin{gathered} a_{11}h_1^{'}(u)\widehat{f}(\mathbf{u}) \leq K_1(H(\mathbf{u}))^{\mu} + K_2, \\ a_{21}h_1^{'}(u)\widehat{f}(\mathbf{u}) + a_{22}h_2^{'}(v)\widehat{g}(\mathbf{u}) \leq K_1(H(\mathbf{u}))^{\mu} + K_2, \\ h_1^{'}(u)\widehat{f}(\mathbf{u}),\ h_2^{'}(v)\widehat{g}(\mathbf{u}) \leq K_3(H(\mathbf{u}))^{q} + K_4, \\ \nabla H(\mathbf{u}) \cdot \widehat{\mathbf{f}}(\mathbf{u}) \leq K_5 H(\mathbf{u}) + K_6. \end{gathered}$$

Thus Theorems 3.2 and 2.2 in [35] hold, which implies $T_{max} = \infty$, i.e., we have global existence of nonnegative, classical solutions. ∎

3. The optimal control problem. Let Ω be a bounded, open subset of $\mathbb{R}^2$ with smooth boundary $\partial\Omega$ and let the set of all possible target densities $L^2_{\text{loc}}(0,T;L^2(\Omega))$ be denoted by $\mathcal{T}_{ad}$. There are no particular requirements on the target densities $(\bar{u},\bar{v})$ other than the fact that the cost functional (1.3) must be bounded. The target densities need not to be solutions of (2.6a)–(2.6d).

Let $\mathcal{U}_{ad}$ be the set of admissible controls

$$\mathcal{U}_{ad} = \{f \in \text{Lip}(Q);\ 0 \leq f(x,t)\ \forall (x,t) \in Q\}.$$

Given $T > 0$, $u_0, v_0 \in H^1(\Omega) \cap L^\infty(\Omega)$, and $(\bar{u},\bar{v}) \in \mathcal{T}_{ad}$, then (u,v,f) is said to be an admissible element if $u, v \in L^2(0,T;H^1(\Omega))$, $f \in \mathcal{U}_{ad}$, the functional $J(u,v,f)$ is bounded, and (u,v,f) satisfies (2.6a)–(2.6d). Let $\mathcal{A}_{ad}$ be the set of admissible states and controls. With this notation, the formulation of the optimal control problem is given by the following:

$$\text{(P)} \qquad \begin{array}{l} \text{Given } T > 0,\ u_0, v_0 \in H^1(\Omega) \cap L^\infty(\Omega), \text{ and } (\bar{u},\bar{v}) \in \mathcal{T}_{ad}, \\ \text{find } (u^*,v^*,f^*) \in \mathcal{A}_{ad} \text{ such that } J(u^*,v^*,f^*) \leq J(u,v,f) \\ \forall (u,v,f) \in \mathcal{A}_{ad}. \end{array}$$

THEOREM 3.1. *Given $u_0, v_0 \in H^1(\Omega) \cap L^\infty(\Omega)$ and $(\bar{u},\bar{v}) \in \mathcal{T}_{ad}$, there exists a solution (u^*,v^*,f^*) of the optimal control problem* (P).

Proof. The admissible set is bounded and nonempty, e.g., the system (2.6a)–(2.6d) has a solution for $f = 0$ (see [14]). Let $\{(u_n,v_n,f_n)\}_n$ be a minimizing sequence in $\mathcal{A}_{ad}$. The sequence $\{\frac{\partial f_n}{\partial t}\}$ is bounded in $L^2(0,T;L^2(\Omega))$, and therefore with a subsequence, again indexed by n, we have

$$f_n \to f^* \qquad \text{weakly in } H^1([0,T];L^2(\Omega)).$$

On the other hand, from (2.6a)–(2.6b) we have

$$\|u_n(t)\|^2_{L^2(\Omega)} + \|v_n(t)\|^2_{L^2(\Omega)} + \int_0^t \left(d_1\|\nabla u_n(t)\|^2_{L^2(\Omega)} + d_2\|\nabla v_n(t)\|^2_{L^2(\Omega)}\right) dt \leq C$$

for all $t \in [0,T]$. Here and in what follows we denote by C a positive constant independent of u, v, f, and n. Next we multiply system (2.6a)–(2.6b) by $(-\Delta u_n, -\Delta v_n)$ and integrate over $(0,t)$ to get, after some calculation involving Gronwall's lemma,

$$\|\nabla u_n(t)\|^2_{L^2(\Omega)} + \|\nabla v_n(t)\|^2_{L^2(\Omega)} + \int_0^t \left(d_1 \|\Delta u_n(s)\|^2_{L^2(\Omega)} + d_2 \|\Delta v_n(s)\|^2_{L^2(\Omega)} \right) dt \le C,$$

$$\left\| \frac{d}{dt} u_n(t) \right\|^2_{L^2(\Omega)} + \left\| \frac{d}{dt} v_n(t) \right\|^2_{L^2(\Omega)} \le C \quad \forall t \in [0,T].$$

Using the classical Lions–Aubin compactness lemma [27] and Ascoli's theorem [10], and noting that the injection of $H^1(\Omega)$ into $L^2(\Omega)$ is compact, we infer that $\{u_n\}, \{v_n\}$ are compact in $L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$. Thus selecting further subsequences, if necessary, we have

$$\begin{aligned}
&u_n \to u^*,\ v_n \to v^* && \text{strongly in } L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega)),\\
&u_n \to u^*,\ v_n \to v^* && \text{weakly in } L^2(0,T;H^2(\Omega)),\\
&\frac{d}{dt}u_n \to \frac{d}{dt}u^*,\ \frac{d}{dt}v_n \to \frac{d}{dt}v^* && \text{weakly in } L^2(0,T;L^2(\Omega)).
\end{aligned}$$

Moreover we have that

$$\begin{aligned}
&u_n(1-u_n) \to u^*(1-u^*) && \text{strongly in } L^2(0,T;L^2(\Omega)),\\
&\frac{u_n v_n}{1+bu_n} \to \frac{u^* v^*}{1+bu^*} && \text{strongly in } L^2(0,T;L^2(\Omega)),\\
&f_n \frac{v_n^2}{1+g^2 v_n^2} \to f^* \frac{{v^*}^2}{1+g^2 {v^*}^2} && \text{weakly in } L^2(0,T;L^2(\Omega)).
\end{aligned}$$

Letting n go to ∞ we see that (u^*, v^*, f^*) satisfies the system (2.6a)–(2.6d) and $J(u^*, v^*, f^*) = \inf_{\mathcal{A}_{ad}} J$. ∎

3.1. First-order necessary conditions. We show that the optimal solution must satisfy the first-order necessary condition associated with the optimal control problem (P).

We introduce the tangential (contingent) cone to $\mathcal{A}_{ad}$ at $(u,v,f) \in \mathcal{A}_{ad}$:

$$\begin{aligned}
\operatorname{Tan} \mathcal{A}_{ad}(u,v,f) = \Bigg\{ & (y,z,h) \,|\, y,z \in L^2(Q), h \in \operatorname{Tan} \mathcal{U}_{ad}(f) \quad \text{and}\\
& \frac{\partial y}{\partial t} = d_1 \Delta y + ry(1-2u) - \frac{av}{(1+bu)^2} y - \frac{au}{1+bu} z \text{ in } Q,\\
& \frac{\partial z}{\partial t} = d_2 \Delta z + \frac{av}{(1+bu)^2} y + \left(\frac{au}{1+bu} - m - \frac{2gvf}{(1+g^2v^2)^2} \right) z - \frac{gv^2 h}{1+g^2v^2} \text{ in } Q,\\
& \frac{\partial y}{\partial \nu} = \frac{\partial z}{\partial \nu} = 0 \qquad \text{on } \partial\Omega \times (0,T),\\
& y(x,0) = z(x,0) = 0 \qquad \text{in } \Omega \Bigg\}.
\end{aligned} \tag{3.1}$$

Recall that if

$$J(u^*, v^*, f^*) = \inf_{(u,v,f) \in \mathcal{A}_{ad}} J(u,v,f)$$

and the functional $J(u,v,f)$ is Gâteaux differentiable, then necessarily

$$\partial J(u^*,v^*,f^*)(y,z,h) \geq 0 \quad \forall (y,z,h) \in \operatorname{Tan} \mathcal{A}_{ad}(u^*,v^*,f^*), \tag{3.2}$$

where $\partial J(u^*,v^*,f^*)$ denotes the Gâteaux derivative of J at $(u^*,v^*,f^*) \in \mathcal{A}_{ad}$. Applying the optimum principle given by (3.2), it follows that

$$\int_Q \left[(u^*-\bar{u})y + (v^*-\bar{v})z + \alpha \frac{\partial f^*}{\partial t}\frac{\partial h}{\partial t} \right] dxdt \geq 0 \quad \forall (y,z,h) \in \operatorname{Tan} \mathcal{A}_{ad}(u^*,v^*,f^*). \tag{3.3}$$

THEOREM 3.2. *Let $u_0, v_0 \in H^1(\Omega) \cap L^\infty(\Omega)$. The mapping $(u,v) = (u(f), v(f))$ from $\mathcal{U}_{ad}$ to $L^2(0,T;H^1(\Omega))$, defined as the solution of the system* (2.6a)–(2.6d)*, has a Gâteaux derivative $(D(u,v)/Df)\cdot h$ in every direction $h \in \operatorname{Tan}\mathcal{U}_{ad}(f)$. Furthermore, $(y(h),z(h)) = (D(u,v)/Df)\cdot h$ is the classical solution of problem* (3.1).

Proof. Let $h \in \operatorname{Lip}(Q)$ be such that $f + \lambda h \in \mathcal{U}_{ad}$ for all $\lambda \in \mathbb{R}$ sufficiently small and let (u_f, v_f) and $(u_{f+\lambda h}, v_{f+\lambda h})$ denote the solutions of (2.6a)–(2.6d) with fish predation rates f and $f+\lambda h$, respectively. To simplify the notation in this proof we use $\|\cdot\|$ to denote $\|\cdot\|_{L^2(\Omega)}$.

We need to prove that

$$\lim_{\lambda \to 0} \frac{1}{\lambda} \left\{ \|u_{f+\lambda h} - u_f - \lambda y(h)\|_{L^2(0,T;H^1(\Omega))} + \|v_{f+\lambda h} - v_f - \lambda z(h)\|_{L^2(0,T;H^1(\Omega))} \right\} = 0.$$

We set $\widetilde{u} = u_{f+\lambda h} - u_f - \lambda y(h)$, $\widetilde{v} = v_{f+\lambda h} - v_f - \lambda z(h)$ so that $(\widetilde{u}, \widetilde{v})$ satisfies the system

$$\frac{\partial \widetilde{u}}{\partial t} = d_1 \Delta \widetilde{u} + r\widetilde{u} - r\Lambda_1 - a\Lambda_2 \qquad \text{in } Q, \tag{3.4a}$$

$$\frac{\partial \widetilde{v}}{\partial t} = d_2 \Delta \widetilde{v} + a\Lambda_2 - m\widetilde{v} - g\Lambda_3 \qquad \text{in } Q, \tag{3.4b}$$

$$\frac{\partial \widetilde{u}}{\partial \nu} = \frac{\partial \widetilde{v}}{\partial \nu} = 0 \qquad \text{on } \partial\Omega \times (0,T), \tag{3.4c}$$

$$\widetilde{u}(x,0) = \widetilde{v}(x,0) = 0 \qquad \text{in } \Omega, \tag{3.4d}$$

where

$$\Lambda_1 = u_{f+\lambda h}^2 - u_f^2 - 2\lambda y u_f, \quad \Lambda_2 = \frac{u_{f+\lambda h}v_{f+\lambda h}}{1+bu_{f+\lambda h}} - \frac{u_f v_f}{1+bu_f} - \lambda \frac{v_f y}{(1+bu_f)^2} - \lambda \frac{u_f z}{1+bu_f},$$

$$\Lambda_3 = (f+\lambda h)\frac{v_{f+\lambda h}^2}{1+g^2 v_{f+\lambda h}^2} - f\frac{v_f^2}{1+g^2v_f^2} - \lambda \frac{2v_f f}{(1+g^2v_f^2)^2} z - \lambda \frac{v_f^2 h}{1+g^2v_f^2}.$$

Now we multiply (3.4a)–(3.4b) by $\widetilde{u}$ and $\widetilde{v}$, respectively, and get

$$\frac{d}{dt}\left(\|\widetilde{u}\|^2 + \|\widetilde{v}\|^2\right) + \left(\|\nabla\widetilde{u}\|^2 + \|\nabla\widetilde{v}\|^2\right) \leq C\left(\|\widetilde{u}\|^2 + \|\widetilde{v}\|^2 + \|\Lambda_1\|^2 + \|\Lambda_2\|^2 + \|\Lambda_3\|^2\right).$$

We denote $\widehat{u} = u_{f+\lambda h} - u_f$, $\widehat{v} = v_{f+\lambda h} - v_f$ and use the fact that (u_f, v_f) is a classical solution to (2.6a)–(2.6d), yielding

$$\int_\Omega \Lambda_1^2\, dx = \int_\Omega \left(\widehat{u}^2 + 2u_f\widetilde{u}\right)^2 dx \leq 2\|\widehat{u}\|_{L^4(\Omega)}^4 + C\|\widetilde{u}\|^2,$$

$$\int_\Omega \Lambda_2^2\, dx \leq C\int_\Omega \left(\widehat{u}^4 + \widehat{v}^4 + \widetilde{u}^2 + \widetilde{v}^2\right) dx,$$

$$\int_\Omega \Lambda_3^2\, dx \leq C\int_\Omega \left(\widehat{v}^4 + \widehat{v}^6 + \widetilde{v}^2 + \lambda^2 h^2 \widehat{v}^2\right) dx \leq C\int_\Omega \left(\widehat{v}^4 + \widetilde{v}^2 + \lambda^4\right) dx.$$

Hence from the above estimates and the Gronwall inequality, this leads to

$$\|\widetilde{u}(t)\|^2 + \|\widetilde{v}(t)\|^2 + \int_0^T \left(\|\nabla\widetilde{u}(s)\|^2 + \|\nabla\widetilde{v}(s)\|^2\right) ds \\ \leq C\left(\lambda^4 + \int_0^T (\|\widehat{u}\|^2\|\widehat{u}\|^2_{H^1(\Omega)} + \|\widehat{v}\|^2\|\widehat{v}\|^2_{H^1(\Omega)})\, dt\right) \quad \forall t \in [0,T].$$

To estimate the norm of $\widehat{u}, \widehat{v}$ in $L^2(0,T;H^1(\Omega))$ we note that

$$\frac{\partial\widehat{u}}{\partial t} = d_1\Delta\widehat{u} + r\widehat{u} - r\widehat{u}(\widehat{u}+2u_f) - a\left(\frac{\widehat{v}(\widehat{u}+u_f)}{1+b(\widehat{u}+u_f)} - \frac{\widehat{u}v_f}{(1+bu_f)[1+b(\widehat{u}+u_f)]}\right),$$

$$\frac{\partial\widehat{v}}{\partial t} = d_2\Delta\widehat{v} + a\left(\frac{\widehat{v}(\widehat{u}+u_f)}{1+b(\widehat{u}+u_f)} - \frac{\widehat{u}v_f}{(1+bu_f)[1+b(\widehat{u}+u_f)]}\right) - m\widehat{v} \\ + g\left(f\frac{\widehat{v}(\widehat{v}+2v_f)}{(1+g^2v_f^2)(1+g^2(\widehat{v}+v_f)^2)} + \lambda h\frac{(\widehat{v}+v_f)^2}{1+g^2(\widehat{v}+v_f)^2}\right),$$

$$\frac{\partial\widehat{u}}{\partial\nu} = \frac{\partial\widehat{v}}{\partial\nu} = 0 \qquad \text{on } \partial\Omega\times(0,T),$$

$$\widehat{u}(x,0) = \widehat{v}(x,0) = 0 \qquad \text{in } \Omega.$$

We then easily obtain

$$\|\widehat{u}(t)\|^2 + \|\widehat{v}(t)\|^2 + \int_0^t \left(\|\nabla\widehat{u}(s)\|^2 + \|\nabla\widehat{v}(s)\|^2\right) ds \leq C\lambda^2\int_0^t \|h(s)\|^2 ds \quad \forall t\in[0,T].$$

From the last two results we obtain the estimate

$$\int_0^T \left(\|\widetilde{u}\|^2_{H^1(\Omega)} + \|\widetilde{v}\|^2_{H^1(\Omega)}\right) dt \leq C\lambda^4,$$

from which our claim follows. The proof of the regularity of y and z is similar to the proof of Theorem 2.1. □

The Gâteaux derivative gives useful information about the sensitivity of the system (2.6a)–(2.6d) at a particular point (u,v) in a particular direction h, but complete information requires the solution of (3.1) for every direction h. Fortunately, in order to minimize the functional we need only an integral over all these directions, which can be obtained by solving a single adjoint equation.

THEOREM 3.3. *Let $u_0, v_0 \in H^1(\Omega)\cap L^\infty(\Omega)$ and $(\bar{u},\bar{v}) \in \mathcal{T}_{ad}$ be given. If (u^*,v^*,f^*) is an optimal solution for* (P)*, then we have*

$$\int_Q \left(\frac{gv^{*2}k}{1+g^2v^{*2}}(f-f^*) + \alpha\frac{\partial f^*}{\partial t}\left(\frac{\partial f}{\partial t} - \frac{\partial f^*}{\partial t}\right)\right) dxdt \geq 0 \quad \forall f\in\mathcal{U}_{ad}, \tag{3.5}$$

where (p,k) is the unique classical solution of the adjoint equation

(3.6a)

$$\frac{\partial p}{\partial t} + d_1\Delta p + rp(1-2u^*) - a\frac{v^*}{(1+bu^*)^2}p + a\frac{v^*}{(1+bu^*)^2}k = u^* - \bar{u} \text{ in } Q,$$

$$\frac{\partial k}{\partial t} + d_2\Delta k + a\frac{u^*}{1+bu^*}k - mk - 2\frac{gf^*v^*}{(1+g^2v^{*2})^2}k - a\frac{u^*}{1+bu^*}p = v^* - \bar{v} \text{ in } Q,$$

$$\frac{\partial p}{\partial\nu} = \frac{\partial k}{\partial\nu} = 0 \qquad \text{on } \partial\Omega\times(0,T),$$

(3.6b)
$$p(x,T) = k(x,T) = 0 \qquad in\ \Omega.$$

Proof. Let (u^*, v^*, f^*) be an optimal solution. From the optimality condition (3.3) and (3.1) and from (3.6a)–(3.6b), we have after integration by parts

$$\begin{aligned}
0 &\leq \int_Q \left[(u^* - \bar{u})y + (v^* - \bar{v})z + \alpha \frac{\partial f^*}{\partial t}\frac{\partial h}{\partial t}\right] dxdt \\
&= \int_Q \left\{ y\left[\frac{\partial p}{\partial t} + d_1\Delta p + rp(1-2u^*) - a\frac{v^*}{(1+bu^*)^2}p + a\frac{v^*}{(1+bu^*)^2}k\right]\right. \\
&\left. + z\left(\frac{\partial k}{\partial t} + d_2\Delta k + a\frac{u^*}{1+bu^*}k - mk - \frac{2gf^*v^*}{(1+g^2{v^*}^2)^2}k - a\frac{pu^*}{1+bu^*}\right) + \alpha\frac{\partial f^*}{\partial t}\frac{\partial h}{\partial t}\right\} dxdt \\
&= \int_Q p\left[-\frac{\partial y}{\partial t} + d_1\Delta y + ry(1-2u^*) - a\frac{v^*}{(1+bu^*)^2}y - a\frac{u^*}{1+bu^*}z\right] dxdt + \int_\Omega yp\Big|_0^T dx \\
&+ \int_Q k\left[-\frac{\partial z}{\partial t} + d_2\Delta z - \frac{2gf^*v^*}{(1+g^2{v^*}^2)^2}z + a\frac{u^*}{1+bu^*}z - mz + a\frac{v^*}{(1+bu^*)^2}y\right] dxdt \\
&+ \int_\Omega zk\Big|_0^T dx + \alpha\int_\Omega \frac{\partial f^*}{\partial t}\frac{\partial h}{\partial t}\, dxdt \\
&= \int_Q k\frac{g{v^*}^2}{1+g^2{v^*}^2}h\, dxdt + \alpha\int_\Omega \frac{\partial f^*}{\partial t}\frac{\partial h}{\partial t}\, dxdt,
\end{aligned}$$

and therefore (3.5). ∎

4. Numerical results. To illustrate the theoretical results of the optimal control problem in the previous section we present results of numerical experiments in two space dimensions. The state equations and adjoint equations were solved using a "lumped mass," semi-implicit (in time) Galerkin finite element method with piecewise linear continuous basis functions. We showed previously that this approach was highly effective in solving the forward-in-time equations of a similar predator-prey system [15].

The control was updated using a variable-step gradient algorithm based on the fully discrete optimality condition (see (4.4) below). At each iteration of the gradient algorithm the method requires the sequential solution of the discrete state and adjoint equations (see (4.1) and (4.3) below). In practice one cannot solve these systems simultaneously. The discrete state equations are solved by marching forward in time starting from an initial condition, while the discrete adjoint equations are solved by marching backward in time (from T) starting from a terminal condition. For further details, see [16].

We employed a (uniform) right-angled triangulation Ω^h of the square $\Omega = [0, L] \times [0, L]$, with space steps h, and numerically solved the optimal control problem up to time T with uniform time steps Δt. We introduce S^h, the standard finite element space

$$S^h := \{v \in C(\overline{\Omega}) \ :\ v|_\tau \quad \text{is linear } \forall \tau \in \Omega^h\} \subset H^1(\Omega).$$

Let $\{x_i\}_{i=0}^J$ be the set of nodes of the triangulation. We introduce $\pi^h : C(\overline{\Omega}) \mapsto S^h$, the Lagrange interpolation operator, such that $\pi^h v(x_j) = v(x_j)$ for all $j = 0, \ldots, J$. In order to formulate our finite element approximation of the reaction-diffusion system we define a discrete L^2 inner product on $C(\overline{\Omega})$ given by $(u, v)^h := \int_\Omega \pi^h(u(x)v(x))\, dx$,

which approximates the usual L^2 inner product (u, v). Given $\mathbf{f}_h \in \mathrm{Lip}(\Omega)$ and $u_0, v_0 \in H^1(\Omega) \cap L^\infty(\Omega)$, $(\mathbf{u}_h, \mathbf{v}_h)$ is a solution of the fully discrete, semi-implicit (in time) fish-plankton system if $u_h^{(n)}, v_h^{(n)} \in S^h$ satisfies the system

$$
\begin{aligned}
&\frac{1}{\Delta t}\left(u_h^{(n)} - u_h^{(n-1)}, \chi_h\right)^h + d_1\left(\nabla u_h^{(n)}, \nabla \chi_h\right) \\
&= \left(r u_h^{(n)}(1 - |u_h^{(n-1)}|) - \frac{a u_h^{(n-1)} v_h^{(n)}}{1 + b|u_h^{(n-1)}|}, \chi_h\right)^h, \\
&\frac{1}{\Delta t}\left(v_h^{(n)} - v_h^{(n-1)}, \chi_h\right)^h + d_2\left(\nabla v_h^{(n)}, \nabla \chi_h\right) \\
&= \left(\frac{a u_h^{(n-1)} v_h^{(n)}}{1 + b|u_h^{(n-1)}|} - m v_h^{(n)} - \frac{g f_h^{(n)} v_h^{(n-1)2}}{1 + g^2 v_h^{(n-1)2}}, \chi_h\right)^h
\end{aligned}
\tag{4.1}
$$

for all $\chi_h \in S^h$, $n = 1, 2, \ldots, N$, with initial densities $u_h^{(0)} = \pi^h u_0(x)$, $v_h^{(0)} = \pi^h v_0(x)$. The discrete cost functional used in the optimal control problem is given by

$$
\mathcal{J}_h^N(\mathbf{u}_h, \mathbf{v}_h, \mathbf{f}_h) = \frac{\Delta t}{2}\sum_{n=1}^{N}\left(\|u_h^{(n)} - \bar{u}^{(n)}\|^2 + \|v_h^{(n)} - \bar{v}^{(n)}\|^2\right) + \frac{\alpha}{2\Delta t}\sum_{n=1}^{N}\|f_h^{(n)} - f_h^{(n-1)}\|^2. \tag{4.2}
$$

Thus we can now formulate the fully discrete optimal control problem as follows:

($\mathrm{P}^{h,\Delta t}$) Given $\Delta t = T/N$, $h = L/J$, $u_0, v_0 \in H^1(\Omega) \cap L^\infty(\Omega)$ and $(\bar{u}, \bar{v}) \in \mathcal{T}_{ad}$, find $(\mathbf{u}_h, \mathbf{v}_h, \mathbf{f}_h) \in S^h \times S^h \times S^h$ such that (4.1) is satisfied for $n = 1, 2, \ldots, N$ and the cost functional (4.2) is minimized.

To complete the fully discrete optimality system we also need the following fully discrete adjoint system: The adjoint functions $p_h^{(n)}, k_h^{(n)} \in S^h$ satisfy

$$
\begin{aligned}
&-\frac{1}{\Delta t}\left(p_h^{(n)} - p_h^{(n-1)}, \chi_h\right)^h + d_1\left(\nabla p_h^{(n-1)}, \nabla \chi_h\right) \\
&= \left(r(1 - 2|u_h^{(n)}|)p_h^{(n-1)} - a\frac{v_h^{(n)}}{(1+b|u_h^{(n)}|^2)^2}p_h^{(n-1)} + a\frac{v_h^{(n)}}{1+b|u_h^{(n)}|^2}k_h^{(n-1)} - u_h^{(n)} - \bar{u}^{(n)}, \chi_h\right)^h \\
&-\frac{1}{\Delta t}\left(k_h^{(n)} - k_h^{(n-1)}, \chi_h\right)^h + d_2\left(\nabla k_h^{(n-1)}, \nabla \chi_h\right) \\
&= \left(a\frac{u_h^{(n)}}{1+b|u_h^{(n)}|^2}p_h^{(n-1)} + a\frac{u_h^{(n)}}{1+b|u_h^{(n)}|^2}k_h^{(n-1)} - m k_h^{(n-1)} - g f_h^{(n)}\frac{2v_h^{(n)}}{1+g^2 v_h^{(n)2}} - v_h^{(n)} - \bar{v}^{(n)}, \chi_h\right)^h
\end{aligned}
\tag{4.3}
$$

for all $\chi_h \in S^h$, $n = 1, 2, \ldots, N$, with the terminal conditions $p_h^{(N)} = k_h^{(N)} = 0$. The fully discrete optimality condition is

$$
\begin{aligned}
0 \le\ &\Delta t \sum_{n=1}^{N-1}\left(\tilde{f}_h^{(n)}, g\frac{v_h^{(n)2}}{1 + g^2 v_h^{(n)2}}k_h^{(n-1)} - \alpha\frac{f_h^{(n+1)} - 2f_h^{(n)} + f_h^{(n-1)}}{\Delta t}\right) \\
&- \frac{\alpha}{\Delta t}\left(\tilde{f}_h^{(0)}, f_h^{(1)} - f_h^{(0)}\right) + \left(\tilde{f}_h^{(n)}, \Delta t g\frac{v_h^{(N)2}}{1 + g^2 v_h^{(N)2}}k_h^{(n-1)} + \alpha\frac{f_h^{(N)} - f_h^{(N-1)}}{\Delta t}\right)
\end{aligned}
\tag{4.4}
$$

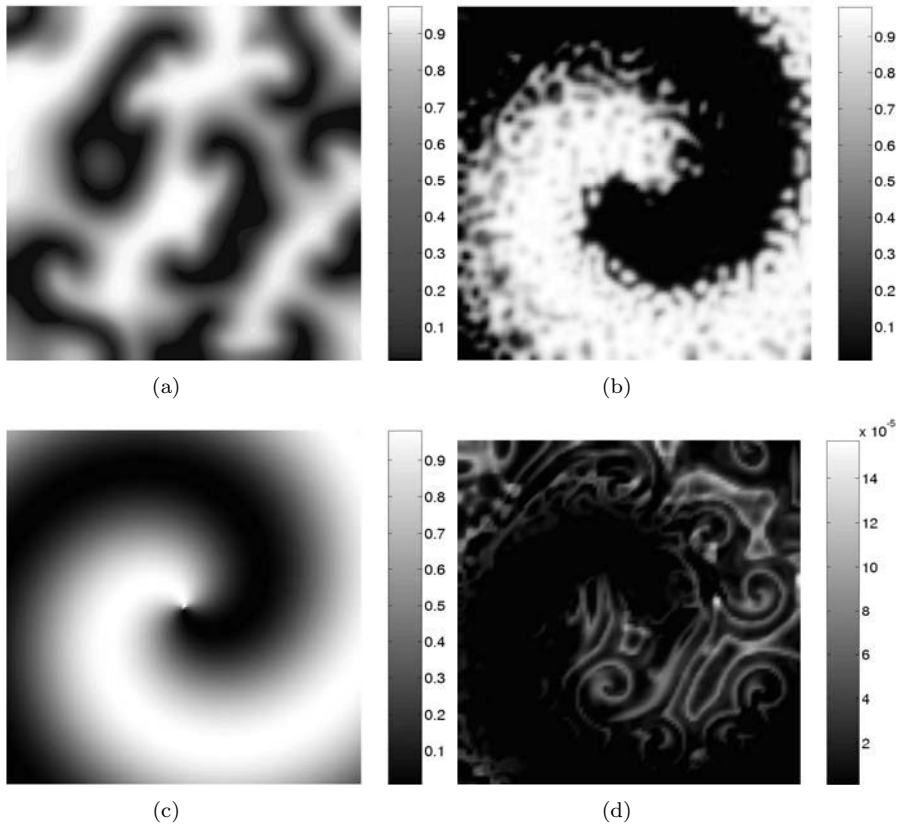

FIG. 4.1. *Uncontrolled* (a)*, optimally controlled* (b)*, target* (c)*, and the control* f (d) *for phytoplankton densities* u *at time* $T = 100$ *for* (1.2)*. Parameter values:* $d_1 = d_2 = 0.05$*,* $r = 1$*,* $a = b = 20$*,* $m = 0.8$*,* $g = 10$*,* $\alpha = 10^{-5}$*. For details of initial data, see text.*

for all $\tilde{\mathbf{f}}_h \in \mathrm{Tan}\mathcal{U}_{ad}(\mathbf{f}_h)$.

In the numerical experiments we chose the domain $\Omega = [0, 100] \times [0, 100]$ and initial conditions of the optimal control problem to be the freely evolving ($f = 0$) system (1.2) at time $t = 1000$, with parameter values and initial data corresponding to Figure 1.2(b) (see caption). The target functions are one-armed Archimedean spirals with period of rotation equal to 20 and are given by

$$\bar{u}(R, \theta, t) = 0.495 \cos(\theta + R/12 + \pi t/10) + 0.495,$$
$$\bar{v}(R, \theta, t) = 0.21 \sin(\theta + R/12 + \pi t/10) + 0.22,$$

where $R := \sqrt{(x-50)^2 + (y-50)^2}$ and $\theta := \arctan[(y-50)/(x-50)]$. The numerical results for the optimal control of phytoplankton densities u are shown in Figure 4.1 at time $T = 100$. A plot of the reduction in cost functional with increasing iteration count suggests the near optimality of the system (see [16]). The results show that at time $T = 100$ the controlled system is close to the desired state, and that we were successful in driving the system from a disordered state to an ordered one.

5. Conclusions. The mathematical formulation, analysis, and numerical solution of an optimal control problem for a nonlinear plankton-fish reaction-diffusion

system was presented. The model was discussed in the context of biomanipulation of eutrophic lakes. After considering the local dynamics of the system and proving the global existence and uniqueness of the classical solutions of the state equations, we presented the mathematical analysis of the plankton-fish optimal control problem. Numerical solutions were obtained with the aid of a semi-implicit Galerkin finite element method with piecewise linear continuous basis functions. The numerical results illustrate the ability of a variable step-size gradient algorithm to drive the plankton dynamics from a chaotic regime to an (arbitrary) ordered state. The time taken to achieve the ordered distribution of phytoplankton in nondimensional units was $t = 100$, which with an assumed maximum growth rate for phytoplankton in eutrophic conditions of $R_0 = 0.5$ per day [39] gives the time taken to achieve this state to be $\tau = 200$ days. The theoretical results in this paper provide the basis for a numerical analysis of the optimal control problem [16]. Furthermore, our results can be generalized in numerous ways to include, for example, convection driven flows, forcing via nutrient inputs, and stochastic influences. We leave these tasks for future work.

INEXACT CENTRAL PATH FOLLOWING ALGORITHMS FOR OPTIMAL CONTROL PROBLEMS*

MARTIN WEISER† AND PETER DEUFLHARD‡

Abstract. A new approach to the numerical solution of optimal control problems including control and state constraints is presented. Like hybrid methods, the approach aims at combining the advantages of direct and indirect methods. Unlike hybrid methods, however, our method is directly based on interior point concepts in function space—realized via an adaptive multilevel scheme applied to the complementarity formulation and numerical continuation along the central path. An adaptive stepsize control with respect to the duality gap parameter is worked out in the framework of affine invariant inexact Newton methods. Finally, the performance of our new type of algorithm is documented by a simple example within the range of our present theory, and by the successful treatment of the well-known intricate windshear problem outside this range.

Key words. numerical optimal control, interior point methods in function space, affine invariant Newton methods

1. Introduction.

In the last decade, the numerical solution of optimal control problems has reached a high level of sophistication. Present methods are able to treat important classes of large-scale real-life problems in science and engineering. Two types of method are in common use:

- *direct methods*, mostly based on some *robust collocation* including an ad hoc parametrization of the controls (see Bock and Plitt [8] or, for more recent publications, the nice survey paper by Hager [23] or his more specialized work on a Runge–Kutta approach [22]);
- *indirect methods*, typically based on either *multiple shooting* techniques (see Bulirsch [9], Stoer and Bulirsch [34], Deuflhard [16, 17], and Bock [7]) or *adaptive collocation methods* (see Ascher, Christiansen, and Russell [2], Ascher and Bader [4], and Ascher, Mattheij, and Russell [3]).

Whenever the necessary Euler–Lagrange conditions give a sufficient description of the problem, then indirect methods lead to a provably optimal solution [9]. However, they require rather detailed a priori knowledge about the sequence of optimal subtrajectories and a significant amount of problem-specific analytical preparation. In contrast to that, direct methods may dispense of this severe constraint, but they have a tendency to lead to nonoptimal solutions now and then. For this reason, *hybrid methods* seem to be the state of the art (see von Stryk and Bulirsch [39] and Bulirsch et al. [12]): in a first step, some direct method, wherein the control variables are parameterized

ad hoc, supplies a rough idea about the optimal subarc sequence; then, in the second step, an indirect method is employed to finally solve the problem to high accuracy.

The present paper advocates a *unified function space approach* realizing ideas of both direct and indirect methods in infinite dimension rather than in finite dimension—as opposed to the above hybrid methods. There are several possibilities of such an extension. In a recent monograph Pytlak [32] proposed an approach that he claims is a function space approach. However, in our wording above, that approach is of the "robust collocation" type, leaving a considerable gap between the presented theory and the rather heuristic algorithmic realization. A genuine function space SQP method has been analyzed by Alt and Malanowski [1]. The solution of the infinite-dimensional QP subproblems, however, is not addressed.

The present paper advocates a function space interior point (IP) approach realized as a *nested* reduction of mesh size and duality gap parameter. The simultaneous progress in mesh refinement and duality gap reduction eliminates the need for warm start capabilities, which IP methods are lacking. The extension of IP-type methods from finite to infinite dimension is not at all straightforward: after all, the concept of logarithmic barrier functions is no longer useful in the infinite-dimensional setting (cf. Jarre [26]). A first attempt in this direction has been made by Ito, Kelley, and Sachs [25] in 1995. An approach closer to our present suggestion, and, in fact, in the same spirit, was recently published by M. Ulbrich and S. Ulbrich in [36] as well as with coauthor Heinkenschloss in [37].

The present paper is based on the *complementarity* version of IP methods, including the *central path* concept, which carries over naturally to infinite dimension. In the opinion of the authors, forged in a PDE environment, a function space–oriented approach is a convenient means to exploit similarity of the solution on different discretization levels. In particular, it allows for a natural use of adaptive multilevel methods—a technique well established in PDE applications. Compared with the indirect methods, the benefit of such an approach is the avoidance of human preparatory work, as opposed to the PDE aspect, where typically a fast solution is the focus. Compared with the direct methods, adaptive multilevel techniques establish appropriate grids using a posteriori error estimates. Of course, mixtures of tools are possible and have been worked out, e.g., by Schulz [33]. It seems worth mentioning that the method we suggest herein differs clearly from his finite-dimensional multigrid techniques, where the adaptive refinement of the *control variables* is done in the *outer loop*, as opposed to our infinite-dimensional technique, where the refinement is performed in the *innermost loop*. Recent suggestions by Ulbrich [35] concerning a semismooth Newton method represent a true alternative to our method as suggested below. In certain situations, this method is equivalent to a primal-dual active set strategy. A comparison of these methods with IP methods in a finite-dimensional setting has been published by Bergounioux et al. [5].

The paper is organized as follows. In section 2, we motivate the central path in function space as the mathematical concept. In section 3, details of an algorithm based on this concept are worked out. The basic scheme is an adaptive Newton-continuation method along the central path, realized as an inexact continuation method (predictor) with an inexact Newton method (corrector). Affine invariant norms are used to control the iteration process towards the numerical solution (see Volkwein and Weiser [38], Potra [31], or the research monograph by Deuflhard [18]). Our computational approach actually *exploits function space* via an *adaptive multilevel refinement* of all variables, *including the controls*. Its present realization is done within the setting of collocation methods. An adaptive stepsize control along the central path is

worked out as the infinite-dimensional extension of finite-dimensional suggestions due to Deuflhard [17]. An intriguing feature of our suggested algorithm is that it requires only the solution of *linear* operator equations in each step. In section 4, we give two numerical examples, a first one, which is covered by our theoretical frame, and a second one, which exceeds this frame. The second one is a well-known intricate optimal control problem, the abort landing in the presence of windshear (cf. Miele et al. [30] and Bulirsch, Montrone, and Pesch [10, 11]). Even though our approach does not need any cumbersome analytic preparation, our numerical results are in full agreement with those obtained by multiple shooting [11].

2. Central path continuation in function space. On the time interval $\Omega = [0,1]$ we consider the optimal control problem

$$\min J(x) \quad \text{subject to} \quad \begin{aligned} c(x) &= 0 \quad \text{a.e.},\\ r(x) &= 0,\\ g(x) &\geq 0 \quad \text{a.e.} \end{aligned} \tag{2.1}$$

with a partitioning of the variable $x = (u, y) \in X = L_\infty^{n_u}(\Omega) \times (W_\infty^1)^{n_y}(\Omega)$ into controls and states, a Lagrange-type cost functional

$$J(x) = \int_0^1 \tilde{f}(x(t))\, dt\,,$$

ODEs with boundary conditions

$$c(x) = \begin{bmatrix} \bar{c}(x) \\ y(0) - y_0 \end{bmatrix}, \quad \bar{c}(x)(t) = \tilde{c}(x(t)) - \dot{y}(t)\,,$$
$$r(x) = \tilde{r}(y(1))$$

as equality constraints, and pointwise state and control constraints

$$g(x)(t) = \begin{bmatrix} \tilde{g}_u(u(t)) \\ \tilde{g}_y(y(t)) \end{bmatrix}.$$

For the whole paper we will restrict the discussion to the fixed time interval Ω and hence simplify the notation by omitting it from the function spaces. We assume all the functions $\tilde{f} : \mathbb{R}^{n_u} \times \mathbb{R}^{n_y} \to \mathbb{R}$, $\tilde{c} : \mathbb{R}^{n_u} \times \mathbb{R}^{n_y} \to \mathbb{R}^{n_y}$, $\tilde{r} : \mathbb{R}^{n_y} \to \mathbb{R}^{n_r}$, $\tilde{g}_u : \mathbb{R}^{n_u} \to \mathbb{R}^{n_\eta^u}$, and $\tilde{g}_y : \mathbb{R}^{n_y} \to \mathbb{R}^{n_\eta^y}$ to be twice Lipschitz continuously differentiable on arbitrary bounded sets. This implies that also $J : X \to \mathbb{R}$, $c : X \to L_\infty^{n_y} \times \mathbb{R}^{n_y}$, $r : X \to \mathbb{R}^{n_r}$, and $g : X \to L_\infty^{n_\eta^u} \times (W_\infty^1)^{n_\eta^y}$ are twice Lipschitz continuously differentiable (see [40]).

The inequality constraints can also be written as $g(x) \in K$, where $K = \{z \in L_\infty^{n_\eta^u} \times (W_\infty^1)^{n_\eta^y} : z(t) \geq 0 \text{ a.e.}\}$ is the closed convex cone of nonnegative functions. Its dual cone is given by $K^+ = \{\zeta \in (L_\infty^{n_\eta^u} \times (W_\infty^1)^{n_\eta^y})^* : \langle \zeta, z \rangle \geq 0 \text{ for all } z \in K\}$.

Note that state constrained problems (i.e., $n_\eta^y > 0$) in general are notoriously difficult to solve, and that both analysis and numerics are usually much more demanding than for control constrained problems ($n_\eta^y = 0$). This extends to this article, where most of the theoretical results are valid only for control problems. State constrained problems are nevertheless included in the setting as far as possible because numerical experience suggests that the algorithm presented here performs reasonably well for such problems.

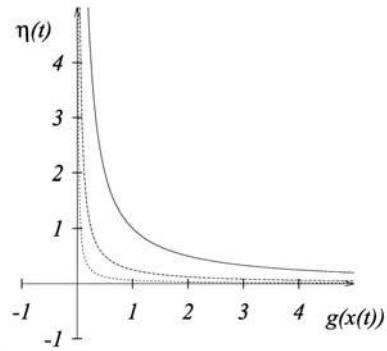

FIG. 2.1. *Zero level sets of the smoothed complementarity function* (2.8) *for* $\mu \in \{1, 1/4, 1/16\}$.

The aim of the IP method presented here is to approximate Kuhn–Tucker points x_*. These are feasible points characterized by the existence of Lagrange multipliers $\lambda_c \in (L_\infty^{n_y})^* \times \mathbb{R}^{n_y}$, $\lambda_r \in \mathbb{R}^{n_r}$, and $\eta \in K^+$, such that the following conditions are satisfied:

$$J'(x_*) - c'(x_*)^*\lambda_c - r'(x_*)^*\lambda_r - g'(x_*)^*\eta = 0 \in X^*, \tag{2.2}$$
$$c(x_*) = 0\,, \quad r(x_*) = 0,$$
$$g(x_*) \geq 0\,, \quad \eta \geq 0\,, \quad \langle \eta, g(x_*)\rangle = 0. \tag{2.3}$$

Under certain assumptions (see, e.g., [28, 29]) these conditions are necessary for x_* to be a local solution of (2.1), such that Kuhn–Tucker points are promising candidates for solutions of (2.1).

If $g(x_*)$ and η are sufficiently smooth, condition (2.3) is equivalent to *pointwise complementarity* in the sense that

$$\eta(t)g(x)(t) = 0, \quad \eta(t) \geq 0, \quad g(x)(t) \geq 0 \quad \text{for almost all } t \in \Omega. \tag{2.4}$$

Informally, the idea of *interior point methods* is to replace the unwieldy complementarity condition (2.4) with a relaxed substitute condition of the type

$$\eta(t)g(x)(t) = \mu \quad \text{for } \mu > 0\,, \tag{2.5}$$

where μ is the *duality gap* parameter. μ may also be interpreted as a regularization parameter (see Figure 2.1) or a barrier parameter in the primal IP formulation. The connection between (2.4) and (2.5) is via a homotopy with respect to μ, the *central path*. Since (2.5) allows solutions with g and η both positive as well as g and η both negative, the additional *feasibility condition*

$$\eta(t) \geq 0, \quad g(x)(t) \geq 0 \tag{2.6}$$

has to be satisfied, such that the central path is well-defined. For $\mu \to 0$ we arrive at the condition (2.4)—see Figure 2.1.

Replacing condition (2.4) with a condition of the type

$$\Psi(g(x), \eta; \mu) = 0 \quad \text{for } \mu > 0, \tag{2.7}$$

where the feasibility of the central path is guaranteed by the construction of Ψ, leads to so-called *complementarity methods*. Thus, infeasible intermediate iterates can be accepted—a feature which increases the overall robustness of the method. Throughout the paper we specify Ψ to be defined by pointwise application $\Psi(g(x),\eta;\mu)(t) = \psi(g(x)(t),\eta(t);\mu)$ of the Fischer–Burmeister function [21]

$$\psi(a,b;\mu) = a + b - \sqrt{a^2+b^2+2\mu}\,, \tag{2.8}$$

the zero level set of which is characterized by the IP conditions (2.5) and (2.6). Different complementarity functions are studied, e.g., in [13, 14, 15, 27].

For ease of writing, we introduce the extended variables $v = (x, \lambda_c, \lambda_r, \eta)$. Defining the Lagrangian as

$$L(v) = J(x) - \langle \lambda_c, c(x)\rangle - \lambda_r^T r(x) - \langle \eta, g(x)\rangle,$$

the adjoint equation (2.2) can be written as $\partial_x L(x,\lambda_c,\lambda_r,\eta) = 0$. Relaxing the necessary conditions (2.2)–(2.3) by (2.7), we arrive at the formulation

$$F(v;\mu) = \begin{bmatrix} \partial_x L(x,\lambda_c,\lambda_r,\eta) \\ -c(x) \\ -r(x) \\ \Psi(g(x),\eta;\mu) \end{bmatrix} = 0 \tag{2.9}$$

defining the central path $v(\mu)$. This formulation will actually be treated numerically by a continuation method. In order to justify this approach, we have to establish the existence of the central path in appropriate function spaces and to study under which conditions convergence to a KKT point can be shown. This is the topic of the following two subsections.

Notation. Some variables and operators are constructed such that they have a natural block partitioning corresponding to the components u and y of x. The individual blocks are denoted by the corresponding component as a superscript, e.g.,

$$g(x) = \begin{bmatrix} g^u(u) \\ g^y(y) \end{bmatrix} \quad \text{and} \quad \Psi(g(x),\eta) = \begin{bmatrix} \Psi^u(g^u(u),\eta^u) \\ \Psi^y(g^y(y),\eta^y) \end{bmatrix}.$$

2.1. Existence of the central path. Existence of the central path can be shown by using the implicit function theorem. For this to be applicable to (2.9), however, F has to be continuously Fréchet-differentiable. For both the IP condition (2.5) and the complementarity condition (2.7) to be well-defined and continuously differentiable, the multiplier η has to be sufficiently regular, i.e., $\eta \in L_\infty$. This is not covered by the necessary conditions (2.3) stating only $\eta \in K^+$, and, in general, does not hold for the solution η_*. In the presence of *state* constraints, their Lagrange multipliers usually contain Dirac distributions at touch points and boundary points of state constrained subarcs.

During the homotopy, however, i.e., for $\mu > 0$, the multipliers are indeed contained in L_∞. In [42], existence of the central path and boundedness of the Lagrange multipliers $\eta(\mu) \in L_\infty \times L_\infty \subset (L_\infty \times W^1_\infty)^*$ associated with central path solutions $x(\mu)$ is shown for $\mu > 0$; see Theorem 2.1.

As it turns out, the appropriate setting to show existence of the central path is to consider F mapping

$$V \times \mathbb{R}_+ = (L_\infty^{n_u} \times (W_\infty^1)^{n_y}) \times (\mathbb{R}^{n_y} \times L_\infty^{n_y}) \times \mathbb{R}^{n_r} \times (L_\infty^{n_\eta^u} \times L_\infty^{n_\eta^y}) \times \mathbb{R}_+$$

into

$$Z = (L_1^{n_u} \times (W_1^1)^{n_y})^* \times (\mathbb{R}^{n_y} \times L_\infty^{n_y}) \times \mathbb{R}^{n_r} \times (L_\infty^{n_\eta^u} \times L_\infty^{n_\eta^y}).$$

The following theorem has been compiled from Theorems 3.3 and 3.4 given in [42]. It proves that the homotopy can be performed for $\mu > 0$ in this setting.

THEOREM 2.1. *Suppose there are an open bounded set $D \subset V$ and $v_0 \in D$ and $\mu_0 > 0$ with $F(v_0; \mu_0) = 0$. Assume there are constants $\beta > 0$ and $\alpha > 0$, such that the following conditions hold uniformly for all $v = (x, \lambda_c, \lambda_r, \eta) \in D$ and $0 < \mu \le \mu_0$.*

1. *The state equation satisfies the following* inf-sup *condition:*

$$\inf_{\xi \in \mathbb{R}^{n_r}} \sup_{\delta u \in L_1^{n_u}} \frac{\xi^T \partial_y r(x) \partial_y c(x)^{-1} \partial_u c(x) \delta u}{|\xi| \, \|\delta u\|_{L_1^{n_u}}} \ge \beta.$$

2. *A strengthened Legendre–Clebsch-type condition holds:*

$$\xi^T M_u(t) \xi \ge \alpha |\xi|^2$$

for all $\xi \in \mathbb{R}^{n_u}$ and almost all $t \in \Omega$. Here,

$$M_u(t) := \partial_u^2 \tilde{f}(x(t)) - \partial_u^2 \tilde{c}(x(t))^T \lambda_c(t) - (\tilde{g}^u)''(u(t))^T \eta^u(t)$$
$$+ (\tilde{g}^u)'(u(t))^T \partial_\eta \psi(\tilde{g}^u(u(t)), \eta^u(t); \mu)^{-1} \partial_g \psi(\tilde{g}^u(u(t)), \eta^u(t); \mu)(\tilde{g}^u)'(u(t)).$$

3. *The augmented second derivative of the Lagrangian is positive definite on the nullspace of the state equation:*

$$\langle \xi, (\partial_x^2 L(v) + g'(x)^* \partial_\eta \Psi(g(x), \eta)^{-1} \partial_g \Psi(g(x), \eta) g'(x)) \xi \rangle \ge \alpha \|\xi\|^2_{L_2^{n_u} \times (W_2^1)^{n_y}}$$

for all $\xi \in \ker c'(x)$.

Then there exist a maximal open interval $I \subset R_+$ around μ_0 and a continuously differentiable central path $v : I_\mu \to D$ with the following properties:

1. *$v(\mu_0) = v_0$.*
2. *$F(v(\mu); \mu) = 0$ for all $\mu \in I_\mu$.*
3. *$\operatorname{dist}(v(I_\mu), \partial D) = 0$ or $\inf I_\mu = 0$ holds.*

In the presence of state constraints, the associated multipliers η^y may rapidly increase in order to approximate Dirac distributions occurring in the solution ${\eta^y}_*$. Therefore, convergence of $v(\mu)$ to a KKT point cannot be expected in the setting of Theorem 2.1. This is reflected by massive grid refinements in the vicinity of critical points and numerical difficulties for very small μ when $\eta(\mu)$ approximates Dirac measures. Nevertheless, numerical experience suggests that convergence may actually occur in a weaker norm.

In contrast, proving convergence to a KKT point requires stronger assumptions and in particular the more restricted setting of control constrained problems. This is addressed in section 2.2 below.

2.2. Convergence for control constrained problems. In order to prove convergence of $v(\mu)$ to a KKT point, we need at least to bound $\eta^y(\mu)$ in L_∞ and therefore restrict our attention to the control constrained case $n_\eta^y = 0$. Moreover, proving convergence needs a more subtle setup than Theorem 2.1. We therefore introduce the notion of nearly active sets.

DEFINITION 2.2. *For some $\rho > 0$ and functions $u \in L_\infty^{n_u}$ and $\eta \in L_\infty^{n_\eta^u}(\Omega)$, define the characteristic function $\chi^A = \chi^A(t; u, \eta, \mu)$ of the nearly active set vector Ω^A componentwise as*

$$\chi_i^A(t) = \begin{cases} 1, & \tilde{g}_i^u(u_i(t)) \le \rho \eta_i^u(t), \\ 0, & \text{otherwise.} \end{cases}$$

The corresponding characteristic function χ^I of the nearly inactive set vector Ω^I is defined as $\mathbf{1} - \chi^A$, where $\mathbf{1} \in L_\infty^{n_\eta^u}$ is the constant function with value 1.

Compared to Theorem 2.1 above, the strengthened Legendre–Clebsch-type condition is only required to hold on a smaller subspace, but the inf-sup condition needs to hold on a larger one. The difference is just the nearly active set. The following theorem is compiled from [42, Thms. 3.6, 3.8, 3.10].

THEOREM 2.3. *Suppose $n_\eta^y = 0$, i.e., there are no state constraints. Assume that the following conditions are satisfied.*

1. *The feasible region $D_u := \{u \in L_\infty^{n_u} : g(u) \ge 0\}$ is bounded.*
2. *The state contribution function in the state equation is linearly bounded:*

$$|\tilde{c}(u, y)| \le \text{const}(1 + |u|^p + |y|) \quad \text{for all } (u, y) \in \mathbb{R}^{n_u} \times \mathbb{R}^{n_y}.$$

Then there is a bounded set $D_y \subset (W_\infty^1)^{n_y}$ such that for all $\mu > 0$ every solution v of $F(v; \mu) = 0$ satisfies $u \in D_u$ and $y \in D_y$.

If, in addition, there is a constant $\beta > 0$ and some $\mu_0 > 0$ such that the equality constraints and nearly active control constraints satisfy the inf-sup *condition*

$$\inf_{h \in \mathbb{R}^{n_r}, \xi \in L_p^{n_\eta^u}} \sup_{\delta u \in L_q^{n_u}} \frac{h^T \partial_y r(x) \partial_y c(x)^{-1} \partial_u c(x) \delta u + \langle \chi^A \xi, g'(u) \delta u \rangle}{(|h| + \|\chi^A \xi\|_{L_p^{n_\eta^u}}) \, \|\delta u\|_{L_q^{n_u}}} \ge \beta \tag{2.10}$$

with $(p, q) = (\infty, 1)$ and $(p, q) = (2, 2)$ uniformly for central path solutions v with $x \in D_u \times D_y$ and $\mu \le \mu_0$, then there is a bounded set $D_0 \subset V$ such that $v \in D_0$. Define $D = \bigcup_{v \in D_0} S(v, \epsilon)$ for some $\epsilon > 0$, where $S(v, \epsilon)$ is the open ball around v with radius ϵ.

Suppose there is a constant $\alpha > 0$, such that the following conditions hold uniformly for all central path solutions $v = v(\mu) \in D$ with $F(v(\mu); \mu) = 0$ and $0 < \mu \le \mu_0$.

3. *The augmented second derivative of the Lagrangian,*

$$M = \partial_x^2 L(v) + g'(x)^* \partial_\eta \Psi(g(x), \eta)^{-1} \partial_g \Psi(g(x), \eta) g'(x),$$

satisfies the following positivity conditions:

$$\begin{aligned} &\langle \xi, M\xi \rangle \ge \alpha \|\xi\|^2_{L_2^{n_u} \times (W_2^1)^{n_y}} && \text{for } \xi \in \ker c'(x) \cap \ker \chi^A g'(u), \\ &\langle \xi, M\xi \rangle \ge 0 && \text{for } \xi \in \ker c'(x). \end{aligned}$$

Then the central path $v(\mu)$ converges to a Kuhn–Tucker point $v(0) \in D$:

$$\|v(\mu) - v(0)\|_V \le \text{const} \sqrt{\mu}.$$

The numerical scheme, however, carries further than the currently available theory. Even our key example in section 4.2 falls out of the present analytic setting, since it involves state constraints as well. However, in this case, the *adaptive multilevel algorithm* to be worked out in section 3 produces successively sharper local peaks on successively finer meshes—thus realizing a multilevel approximation of the Dirac distribution. For an illustration of this effect see Figure 4.7 below.

3. Numerical algorithm. For the numerical computation of the solution point $v(0)$ we employ a Newton-type continuation method following the central path $v(\mu)$ defined by (2.9). When applied to $F(v) = 0$ and $AF(Bv) = 0$, where A and B are invertible linear transformations, Newton's method generates equivalent sequences of iterates. This *invariance* property should be inherited by numerical algorithms and accompanying convergence theory. Unfortunately, full invariance is impossible due to the necessity of measuring convergence in some appropriate norm. Fixing $B = I$ one obtains affine covariant (error-oriented) methods [19], whereas setting $A = I$ yields affine contravariant (residual-oriented) methods [24]. Coupling $A = B^*$ results in affine conjugate (energy-oriented) methods for convex unconstrained optimization problems [20]. For an in-depth treatment of affine invariance we refer to the research monograph [18].

3.1. Affine invariant norms. Neither of the above-mentioned invariance classes reflects the structure of the optimization problem (2.1). A new class of affine invariance and a corresponding invariant norm for equality constrained problems ($n_\eta = 0$) that has been worked out by Volkwein and Weiser [38] needs to be adapted to the L_∞ setting and to include inequality constraints as well. Due to the pointwise nature of the constraints we have to restrict ourselves to *pointwise* transformations when studying affine invariance.

DEFINITION 3.1. *For $(z_a, z_c, z_r, z_\eta) \in Z$ and $(v, \mu) \in V \times \mathbb{R}_+$ we define*

(3.1)
$$\|(z_a, z_c, z_r, z_\eta)\|^2_{(v,\mu)} := \|\phi\|_\infty + \|\xi_{\lambda_c}\|^2_{L_\infty} + |\xi_{\lambda_r}|^2 + \|\xi_\eta\|^2_{L_\infty} + \|z_c\|^2_{L_\infty} + |z_r|^2 + \|z_\eta\|^2_{L_\infty}$$

with ξ and ϕ given by

$$F'(v;\mu)(\xi_x, \xi_{\lambda_c}, \xi_{\lambda_r}, \xi_\eta)^T = (z_a, 0, 0, 0)^T \tag{3.2}$$

and

$$\phi(t) = \xi_x(t)^T \partial_x^2 L(v;\mu)(t)\xi_x(t). \tag{3.3}$$

Equation (3.2) *defines the subspace $\mathcal{N}(v;\mu) \subset V$.*

For the easily computable expression (3.1) to be a norm we have to modify the assumptions on the problem slightly compared to Theorem 2.3. Instead of augmenting the Hessian of the Lagrangian with the almost inactive part of the IP regularization when requesting pointwise positivity, we directly assume positivity of the Hessian itself. This will in general be only a slight modification because the augmentation is rather small and bounded for $\mu \to 0$. The positivity is not required to hold on the nullspace $\mathcal{N}(v;\mu)$ of the almost active constraints, but rather on the nullspace of state equation and regularized complementarity condition. Again, these subspaces are rather close to each other, in particular for $\mu \to 0$.

In this section we will need the following properties of $\partial_v F$ shown in [42, Thms. 3.2 and 3.8].

LEMMA 3.2. *Assume that Theorem* 2.3 *holds. Then there is a constant C such that the following estimates hold uniformly for all $v \in D$ and $\mu > 0$:*

$$\|\partial_v F(v;\mu)^{-1}\| \le C, \quad \|\partial_v F(v_1;\mu) - \partial_v F(v_2;\mu)\| \le \frac{C}{\sqrt{\mu}}\|v_1 - v_2\|.$$

THEOREM 3.3. *Assume Theorem* 2.3 *holds and there is some $\alpha > 0$ such that*

$$\langle \xi_x, \partial_x^2 L(v;\mu)\xi_x\rangle \ge \alpha \|\xi_x\|^2_{L_2 \times W_2^1} \tag{3.4}$$

for all $\xi \in \mathcal{N}(v;\mu)$. Then (3.1) *defines a norm on Z that is invariant under pointwise invertible transformations of X. Moreover, this norm is equivalent to the usual norm on Z.*

Proof. For brevity we will omit any function arguments. First we will show that $\partial_u^2 L \succeq \alpha$ for almost all $t \in \Omega$. From this we will conclude that there is a constant $c > 0$, such that $\|\phi\|_{L_\infty} \geq c\|\xi_x\|_{L_\infty}^2$ for all $\xi \in \mathcal{N}(v;\mu)$. Due to the bounded invertibility of $F'(v;\mu)$ as asserted by Lemma 3.2, it is then obvious that (3.1) defines a norm that is indeed equivalent to the usual norm of Z.

Let us approximate the effect of an impulse control at $t \in \Omega$ by a constant control with shrinking support, i.e., $\chi_{[t-\epsilon,t+\epsilon]}$. Since the homogeneous terminal condition $\partial_y r(x)y = 0$ has to be satisfied by the associated state, we need to complement the approximate impulse control with some compensation $\epsilon\tilde{u}_{t,\epsilon}$. Note that due to (2.10), $\tilde{u}_{t,\epsilon}$ can be chosen to be uniformly bounded in L_∞ for all t and ϵ. We define $\hat{u}_\epsilon = \chi_{[t-\epsilon,t+\epsilon]} + \epsilon\tilde{u}_{t,\epsilon}$ with associated state $\hat{y}_\epsilon$ and multipliers such that $\hat{\xi}_\epsilon \in \mathcal{N}(v;\mu)$. From standard ODE theory it follows that $\|\hat{y}_\epsilon\|_{L_\infty} \leq c\|\hat{u}_\epsilon\|_{L_1} = c\epsilon$. From (3.4) we know that

$$\begin{aligned}\langle \hat{u}_\epsilon, \partial_u^2 L \hat{u}_\epsilon\rangle &= \langle \hat{\xi}_{x\epsilon}, \partial_x^2 L \hat{\xi}_{x\epsilon}\rangle - \langle \hat{y}_\epsilon, \partial_y^2 L \hat{y}_\epsilon\rangle - 2\langle \hat{u}_\epsilon, \partial_{yu} L \hat{y}_\epsilon\rangle \\ &\geq \alpha\|\hat{\xi}_{x\epsilon}\|_{L_2\times W_2^1}^2 - c\|\hat{y}_\epsilon\|_{L_\infty}^2 - c\|\hat{y}_\epsilon\|_{L_\infty}\|\hat{u}_\epsilon\|_{L_1} \\ &\geq 2\alpha\epsilon - c\epsilon^2\end{aligned}$$

for some generic constant c independent of ϵ, and hence $\partial_u^2 L \succeq \alpha$ for almost all $t \in \Omega$.

Now assume that for any $\epsilon > 0$ there is some $\xi_\epsilon \in \mathcal{N}(v;\mu)$ with control and state component u_ϵ and y_ϵ, respectively, such that

$$\|\phi_\epsilon\|_{L_\infty} \leq \epsilon\|\xi_\epsilon\|_{L_\infty}^2 \tag{3.5}$$

and $\|u_\epsilon\|_{L_\infty} = 1$. From (3.4) we know that

$$\begin{aligned}\|y_\epsilon\|_{L_\infty}^2 &\leq c\|u_\epsilon\|_{L_1}^2 \leq c\|\xi_\epsilon\|_{L_2}^2 \leq \frac{c}{\alpha}\|\phi_\epsilon\|_{L_2} \\ &\leq \frac{c}{\alpha}\|\phi_\epsilon\|_{L_\infty} \leq \epsilon\frac{c}{\alpha}\|\xi_\epsilon\|_{L_\infty}^2 \leq \epsilon\frac{c}{\alpha}\|y_\epsilon\|_{L_\infty}^2 + \epsilon\frac{c}{\alpha}\|u_\epsilon\|_{L_\infty}^2\end{aligned}$$

for some generic constant c independent of ϵ. For sufficiently small ϵ we have $\epsilon c/\alpha < 1$ and may conclude that $(1 - \epsilon c/\alpha)\|y_\epsilon\|_{L_\infty}^2 \leq c\epsilon/\alpha\|u_\epsilon\|_{L_\infty}^2$ and hence $\|y_\epsilon\|_{L_\infty}^2 \leq c\epsilon$. Using the boundedness of $\partial_x^2 L$, we obtain

$$\phi_\epsilon = u_\epsilon^T \partial_u^2 L u_\epsilon + y_\epsilon^T \partial_y^2 L y_\epsilon + 2u_\epsilon^T \partial_{yu} L y_\epsilon \geq \alpha|u_\epsilon|^2 - c\epsilon - c\sqrt{\epsilon}|u_\epsilon|$$

for almost all $t \in \Omega$. For all sufficiently small ϵ this implies $\|\phi_\epsilon\|_{L_\infty} \geq c\|\xi_x\|_{L_\infty}^2$ for some constant c independent of ϵ, which contradicts (3.5).

Now we turn to affine invariance. Let us consider a transformation $\hat{x} = B^{-1}x$ of X. With the pointwise transformation $D = \mathrm{diag}(B, I, I, I)$ the transformed problem is $D^*\hat{F}(\hat{v};\mu) = F(B\hat{x}, \lambda_c, \lambda_r, \eta)$ with derivative $\partial_{\hat{v}}\hat{F}(\hat{v};\mu) = D^*\partial_v F(v;\mu)D$. Computing the norm of $(\hat{z}_a, \hat{z}_c, \hat{z}_r, \hat{z}_\eta) = (B^* z_a, z_c, z_r, z_\eta)$, we obtain

$$\begin{aligned}(\hat{\xi}_x, \hat{\xi}_{\lambda_c}, \hat{\xi}_{\lambda_r}, \hat{\xi}_\eta) &= \partial_{\hat{v}}\hat{F}(\hat{v};\mu)^{-1}(B^* z_a, z_c, z_r, z_\eta) \\ &= D^{-1}\partial_v F(v;\mu)^{-1}(z_a, z_c, z_r, z_\eta) \\ &= (B^{-1}\xi_x, \xi_{\lambda_c}, \xi_{\lambda_r}, \xi_\eta)\end{aligned}$$

and

$$\begin{aligned}\hat{\phi}(t) &= \hat{\xi}_a(t)^T \partial_{\hat{x}}^2 \hat{L}(\hat{v};\mu)(t)\hat{\xi}_a(t)\\ &= \xi_a(t)^T B(t)^{-T} B(t)^T \partial_x^2 L(v;\mu)(t)B(t)B(t)^{-1}\xi_a(t)\\ &= \phi(t).\end{aligned}$$

Since all terms in the sum (3.1) coincide, the norm is invariant. If B was not a pointwise transformation, $\hat{\phi}$ could not be defined in a pointwise manner. This is the reason why the invariance class has to be restricted to pointwise transformations. ∎

Formulating convergence results in terms of local norms, the norms need to be Lipschitz continuous with respect to the evaluation point to which they are attached.

THEOREM 3.4. *There are constants $\gamma_v(\mu)$ and $\gamma_\mu(\mu)$ independent of v such that*

$$\big|\|z\|_{(v_1,\mu)} - \|z\|_{(v_2,\mu)}\big| \le \gamma_v(\mu)\|\partial_v F(v_1;\mu)(v_1 - v_2)\|_{(v_1,\mu)}\|z\|_{(v_1,\mu)} \tag{3.6}$$

and

$$\big|\|z\|_{(v,\mu_1)} - \|z\|_{(v,\mu_2)}\big| \le \gamma_\mu(\mu)|\mu_1 - \mu_2|\|z\|_{(v,\mu_1)} \tag{3.7}$$

for all $z \in Z$.

Proof. With $z = (z_a, z_c, z_r, z_\eta)$ and $\hat{z} = (z_a, 0, 0, 0)$ we define $\xi_i = \partial_v F(v_i;\mu)^{-1}\hat{z} \in \mathcal{N}(v_i;\mu)$ for $i = 1, 2$. Using the Lipschitz continuity and bounded invertibility of $\partial_v F$ as given by Lemma 3.2, we first obtain

$$\begin{aligned}\|\xi_1 - \xi_2\| &= \|(\partial_v F(v_1;\mu)^{-1} - \partial_v F(v_2;\mu)^{-1})\hat{z}\|\\ &\le \|F(v_2;\mu)^{-1}(\partial_v F(v_1;\mu) - \partial_v F(v_2;\mu))\partial_v F(v_1;\mu)^{-1}\hat{z}\|\\ &\le c\|\partial_v F(v_1;\mu) - \partial_v F(v_2;\mu)\|\|\hat{z}\|\\ &\le \frac{c}{\sqrt{\mu}}\|v_1 - v_2\|\|\hat{z}\|_{(v_1,\mu)} \qquad (3.8)\end{aligned}$$

for some generic constant c independent of μ and v_i. Second we have

$$\begin{aligned}|\xi_{x1}^T\partial_x^2 L(v_2;\mu)\xi_{x1}| &= |\xi_{x1}^T\partial_x^2 L(v_1;\mu)\xi_{x1}| + |\xi_{x1}^T(\partial_x^2 L(v_2;\mu) - \partial_x^2 L(v_1;\mu))\xi_{x1}|\\ &\le |\xi_{x1}^T\partial_x^2 L(v_1;\mu)\xi_{x1}| + |\xi_{x1}|^2|\partial_x^2 L(v_2;\mu) - \partial_x^2 L(v_1;\mu)|\end{aligned}$$

for almost all $t \in \Omega$ and hence

$$\|\xi_{x1}^T\partial_x^2 L(v_2;\mu)\xi_{x1}\|_{L_\infty} \le \left(1 + \frac{c}{\sqrt{\mu}}\|v_2 - v_1\|\right)\|\phi_1\|_{L_\infty}. \tag{3.9}$$

Writing the norm induced by (3.1) on $\mathcal{N}(v;\mu)$ as $\|\cdot\|_v$ (note that the expression does not depend on μ), we utilize (3.9) and (3.8) in order to obtain

$$\begin{aligned}\|\hat{z}\|_{(v_2,\mu)} &= \|\xi_2\|_{v_2}\\ &\le \|\xi_1\|_{v_2} + c\|\xi_2 - \xi_1\|\\ &\le \left(\|\xi_{x1}^T\partial_x^2 L(v_2;\mu)\xi_{x1}\|_{L_\infty} + \|(\xi_{\lambda_c 1}, \xi_{\lambda_r 1}, \xi_{\eta 1})\|_{L_\infty}^2\right)^{1/2} + c\|\xi_2 - \xi_1\|\\ &\le \left(\sqrt{1 + \frac{c}{\sqrt{\mu}}\|v_2 - v_1\|}\,\|\phi_1\|_{L_\infty} + \|(\xi_{\lambda_c 1}, \xi_{\lambda_r 1}, \xi_{\eta 1})\|_{L_\infty}^2\right)^{1/2} + c\|\xi_2 - \xi_1\|\\ &\le \left(1 + \frac{c}{\sqrt{\mu}}\|v_2 - v_1\|\right)^{1/4}\|\xi_1\|_{v_1} + \frac{c}{\sqrt{\mu}}\|v_1 - v_2\|\|\hat{z}\|_{(v_1,\mu)}\\ &\le \left(1 + \frac{c}{\sqrt{\mu}}\|v_1 - v_2\|\right)\|\hat{z}\|_{(v_1,\mu)}\end{aligned}$$

for some generic constant c independent of μ. This and the bounded invertibility of $\partial_v F(v;\mu)$ imply

$$\begin{aligned}\big|\|z\|_{(v_2,\mu)} - \|z\|_{(v_1,\mu)}\big| \le \big|\|\hat z\|_{(v_2,\mu)} - \|\hat z\|_{(v_1,\mu)}\big| \\ \le \frac{c}{\sqrt{\mu}}\|\partial_v F(v_1;\mu)(v_1-v_2)\|_{(v_1,\mu)}\|\hat z\|_{(v_1,\mu)}\end{aligned}$$

and verify the claim (3.6) for $\gamma_v = c\mu^{-1/2}$. The corresponding estimate (3.7) can be shown analogously. ∎

Remark. We would like to point out that for local norms with structures simpler than the one considered here, useful analytical bounds for γ_v can be found in terms of a corresponding affine invariant Lipschitz constant. In the affine contravariant setting $\|\cdot\|_v = \|\cdot\|$, $\gamma_v = 0$ is trivially obtained, $\gamma_v \le \omega$ holds in the affine covariant case $\|\cdot\|_v = \|F'(v)^{-1}\cdot\|$, and $\gamma_v \le \frac{\omega}{2}$ in the affine conjugate case $\|\cdot\|_v = \|F'(v)^{-1/2}\cdot\|$. Based on an assumption similar to (3.12), a rather crude estimate of $\gamma_v \le \frac{3}{2}\omega$ was derived in [38] for equality constrained problems. Numerical experience with computational estimates suggests that even if available, the analytical bounds are often too large to describe the actual norm variation correctly. Therefore, using computational estimates may be advantageous. For the norm (3.1), however, no analytical quantitative estimate is known up to now, such that we have to resort to computational estimates (see (3.29) below).

Remark. Recently, Potra [31] employed an affine invariant norm for proving $\mathcal{O}(\sqrt{n}L)$-iteration complexity of an IP algorithm applied to finite-dimensional horizontal linear complementarity problems, which include linear and linear-quadratic optimization problems. In the notation of the current paper, that author uses a diagonal scaling like $D := \sqrt{\partial_w \psi^{-1} \partial_\eta \psi}$. A similar norm has been used to analyze the convergence rate of an IP method applied to infinite-dimensional optimal control problems in a restricted setting with bang-bang control [41].

3.2. Adaptive central path following. Once the central path homotopy is theoretically established, a numerical continuation scheme for following the path towards the solution $v(0)$ must be developed. For *numerical* pathfollowing, an adaptive tangential predictor/Newton-type corrector algorithm is worked out. The method is applied directly to the infinite-dimensional function space formulation, involving discretization only in the innermost loop when solving linear subproblems. Since a reduction of the discretization error is expensive, we substitute both the tangential predictor and the Newton corrector by their inexact counterparts and aim for linear convergence only—in the spirit of complexity estimates of [20].

As illustrated in Figure 3.1, the local convergence domain of the Newton corrector can be expected to collapse for $\mu \to 0$ as a consequence of an ever increasing Lipschitz constant $\omega(\mu)$. Nevertheless, Theorem 2.3 provides a qualitative upper bound on the error incurred by a premature termination at $\mu_{\text{final}} > 0$ of the numerical continuation along the central path in the order of $\mathcal{O}(\mu_{\text{final}}^{1/2})$. Experience shows that feasible and acceptably suboptimal solutions can indeed be obtained by following the central path up to some $\mu_{\text{final}} > 0$—see section 4.

Inexact Newton corrector. The corrector operates with constant duality gap parameter; thus we drop μ in order to simplify notation and write $F'(v)$ instead of $\partial_v F(v;\mu)$. Due to the prohibitive cost of reducing the discretization error, we cannot strive for highly accurate Newton corrections. Instead, we will employ an *inexact*

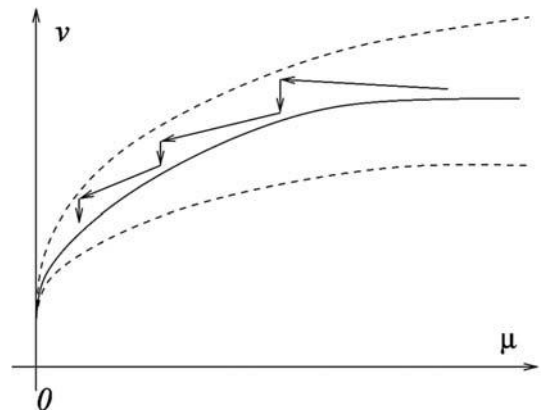

FIG. 3.1. *Inexact tangential continuation along the central path including local convergence domain of Newton's method.*

Newton method, where an *inner residual* remains:

$$F'(v^k)\delta v^k = -F(v^k) + r^k, \qquad v^{k+1} = v^k + \delta v^k\,. \tag{3.10}$$

The relative accuracy δ_k of the *inexact Newton correction* δv^k, given by

$$\delta_k := \frac{\|r^k\|_{v^k}}{\|F(v^k)\|_{v^k}}\,, \tag{3.11}$$

will play a crucial role. In actual computation, the inexact simplified Newton correction $\overline{\delta v}^{k+1}$ approximating the exact simplified Newton correction

$$F'(v^k)\overline{\Delta v}^{k+1} = -F(v^{k+1})$$

will also be used. Again, an inner residual $\overline{r}^{k+1}$ remains:

$$F'(v^k)\overline{\delta v}^{k+1} = -F(v^{k+1}) + \overline{r}^{k+1}.$$

In view of convergence of Newton's method, we need to have a Lipschitz constant for $\partial_v F$ formulated in the affine invariant norm. This affine invariant Lipschitz condition comprises two usual assumptions for Newton convergence theorems: that F' is Lipschitz continuous, and that $F'(v^k)$ has a bounded inverse (cf. [18]).

LEMMA 3.5. *If* (3.4) *holds for* $\mu > 0$*, then there exists an affine invariant Lipschitz constant* $\omega(\mu) \le c(1 + \mu^{-1/2})$*, such that*

$$\|F'(v_1) - F'(v_2)\|_\zeta \le \omega(\mu)\|F'(v_1)(v_1 - v_2)\|_{v_1} \tag{3.12}$$

for all v_1, v_2 *such that* $\zeta \in \mathrm{co}\{v_1, v_2\} \subset D$.

Proof. The bound on ω is a direct consequence of the corresponding Lipschitz estimate for the complementarity function ψ (see [42, Theorem 3.2]) and the equivalence of the norms $\|\cdot\|_{v_1}$ and $\|\cdot\|$ on Z. ∎

THEOREM 3.6. *Let* V *be a Banach space and* $D \subset V$ *an open set. Let* Z *be a Banach space equipped with a family of equivalent local norms* $\|\cdot\|_v$ *parameterized*

over D. Assume $F : D \to Z$ is a continuously differentiable function. Let γ_v and ω be constants such that the local norms $\|\cdot\|_v$ on Z satisfy

$$|\|r\|_{v_1} - \|r\|_{v_2}| \le \gamma \|F'(v_1)(v_1 - v_2)\|_{v_1} \|r\|_{v_1} \quad \text{for all } r \in Z, \tag{3.13}$$

and the affine invariant Lipschitz condition

$$\|(F'(\xi) - F'(v))(\xi - v)\|_\zeta \le \omega \|F'(v)(\xi - v)\|_v^2 \tag{3.14}$$

holds for all collinear $v, \xi, \zeta \in V$ such that the convex hull $\mathrm{co}\{v, \xi, \zeta\}$ is contained in D. Let $\Theta < 1$ and

$$\mathcal{L}(v) := \Big\{ \xi \in D : \|F(\xi)\|_\xi \le \Big(1 + \frac{\gamma_v \Theta}{2\omega}\Big) \|F(v)\|_v \Big\}.$$

Assume that $v^0 \in D$ and that the level set $\mathcal{L}(v^0)$ is closed. If $\omega \|F(v^0)\|_{v_0} < 2\Theta$ and the relative error δ_k in computing the Newton correction is controlled such that

$$\frac{1 + \delta_k}{2} \omega \|F'(v^k)\delta v^k\|_{v^k} + (1 + \gamma_v \|F'(v^k)\delta v^k\|_{v^k})\delta_k \le \Theta \tag{3.15}$$

(which is possible for all k), then the iterates are well-defined for all $k \in \mathbb{N}$ and stay in $\mathcal{L}(v^0)$, and the residuals converge to zero at a rate of

$$\|F(v^{k+1})\|_{v^{k+1}} \le \Theta \|F(v^k)\|_{v^k}. \tag{3.16}$$

Furthermore, if the inexact simplified Newton correction is computed with relative accuracy $\overline{\delta_{k+1}}$,

$$\|F'(v^k)\overline{\delta v^{k+1}}\|_{v^k} \le (1 + \overline{\delta_{k+1}}) \Big(\frac{\delta_k}{1 - \delta_k} + \frac{\omega}{2} \|F'(v^k)\delta v^k\|_{v^k} \Big) \|F'(v^k)\delta v^k\|_{v^k} \tag{3.17}$$

holds.

Proof. By induction, let $\mathcal{L}(v^k)$ be closed and $\omega \|F(v^k)\|_{v^k} < 2$. Then

$$F(v^k + s\delta v^k) = F(v^k) + \int_0^s F'(v^k + t\delta v^k)\delta v^k \, dt \tag{3.18}$$

$$= (1 - s)F(v^k) + sr^k + \int_0^s (F'(v^k + t\delta v^k) - F'(v^k))\delta v^k \, dt \tag{3.19}$$

for all $s \in [0, 1]$ with $\mathrm{co}\{v^k, v^k + s\delta v^k\} \subset D$.

Using the Lipschitz continuity (3.14) of F' and the norm continuity (3.13), for $\sigma \in [0, s]$ we have

$$\begin{aligned}
&\|F(v^k + s\delta v^k)\|_{v^k + \sigma\delta v^k} \\
&\quad \le (1 - s)\|F(v^k)\|_{v^k + \sigma\delta v^k} + s\|r^k\|_{v^k + \sigma\delta v^k} \\
&\qquad + \int_0^s \|(F'(v^k + t\delta v^k) - F'(v^k))\delta v^k\|_{v^k + \sigma\delta v^k} \, dt \\
&\quad \le (1 - s)(1 + \sigma\gamma_v \|F'(v^k)\delta v^k\|_{v^k})\|F(v^k)\|_{v^k} \\
&\qquad + s(1 + \sigma\gamma_v \|F'(v^k)\delta v^k\|_{v^k})\|r^k\|_{v^k} + \int_0^s t\omega \|F'(v^k)\delta v^k\|_{v^k}^2 \, dt \\
&\quad = (1 + \sigma\gamma_v \|F'(v^k)\delta v^k\|_{v^k})((1 - s)\|F(v^k)\|_{v^k} + s\delta_k \|F(v^k)\|_{v^k}) \\
&\qquad + \frac{s^2}{2} \omega \|F'(v^k)\delta v^k\|_{v^k}^2.
\end{aligned} \tag{3.20}$$

From (3.11) we have

$$(1-\delta_k)\|F(v^k)\|_{v^k} \le \|F'(v^k)\delta v^k\|_{v^k} = \|F(v^k) - r^k\|_{v^k} \le (1+\delta_k)\|F(v^k)\|_{v^k}\,. \tag{3.21}$$

Thus we arrive at

$$\begin{aligned}\frac{\|F(v^k + s\delta v^k)\|_{v^k+s\delta v^k}}{\|F(v^k)\|_{v^k}} \\ \le (1+s\gamma_v\|F'(v^k)\delta v^k\|_{v^k})(1-s+s\delta_k) + \frac{1+\delta_k}{2}s^2\omega\|F'(v^k)\delta v^k\|_{v^k}\,.\end{aligned}$$

The ultimate goal is to establish a contraction property for the undamped Newton method ($s=1$). Thus we have to require

$$(1+\gamma_v\|F'(v^k)\delta v^k\|_{v^k})\delta_k + \frac{1+\delta_k}{2}\omega\|F'(v^k)\delta v^k\|_{v^k} \le \Theta < 1\,,$$

which is the accuracy condition (3.15). Defining $\chi := \gamma_v\|F'(v^k)\delta v^k\|_{v^k}$ and using $s \le 1$ and (3.15), we have

$$\begin{aligned}\frac{\|F(v^k + s\delta v^k)\|_{v^k+s\delta v^k}}{\|F(v^k)\|_{v^k}} &\le (1+s\chi)(1-s+s\delta_k) + \frac{1+\delta_k}{2}s^2\omega\|F'(v^k)\delta v^k\|_{v^k} \\ &= (1+s\chi)(1-s) + (1+s\chi)s\delta_k + \frac{1+\delta_k}{2}s^2\omega\|F'(v^k)\delta v^k\|_{v^k} \\ &\le (1+s\chi)(1-s) + s\Theta \\ &= 1 - s + s\Theta + s(1-s)\chi \\ &\le 1 + \frac{\chi}{4}\,.\end{aligned} \tag{3.22}$$

From (3.15) we infer $\|F'(v^k)\delta v^k\|_{v^k} \le 2\Theta/\omega$, and hence

$$\|F(v^k + s\delta v^k)\|_{v^k+s\delta v^k} \le \left(1 + \frac{\gamma_v\Theta}{2\omega}\right)\|F(v^k)\|_{v^k}$$

holds. Since D is open and $\mathcal{L}(v^k) \subset D$ is closed, $\mathrm{co}\{v^k, v^k + \delta v^k\} \not\subset D$ implies the existence of some $s^* \in [0,1)$ with $\mathrm{co}\{v^k, v^k + s^*\delta v^k\} \subset D$ but $v^k + s^*\delta v^k \notin \mathcal{L}(v^k)$, i.e.,

$$\|F(v^k + s^*\delta v^k)\|_{v^k+s^*\delta v^k} > \left(1 + \frac{\gamma_v\Theta}{2\omega}\right)\|F(v^k)\|_{v^k}\,,$$

which is a contradiction. Thus, $v^{k+1} \in D$. Furthermore, setting $s=1$ in (3.22) yields

$$\|F(v^{k+1})\|_{v^{k+1}} \le \Theta\|F(v^k)\|_{v^k} \tag{3.23}$$

and therefore $\mathcal{L}(v^{k+1}) \subset \mathcal{L}(v^k)$. Since $\mathcal{L}(v^k)$ is closed, every Cauchy sequence in $\mathcal{L}(v^{k+1})$ converges to a limit point in $\mathcal{L}(v^k)$, which is, by continuity of the norm, also contained in $\mathcal{L}(v^{k+1})$. Hence, $\mathcal{L}(v^{k+1})$ is closed. Moreover, $\omega\|F(v^{k+1})\|_{v^{k+1}} \le \omega\Theta^{k+1}\|F(v^0)\|_{v^0} < 2\Theta^{k+2} < 2\Theta$, such that (3.15) can be satisfied in the next iteration by choosing a sufficiently small δ_{k+1}.

Inserting $\sigma = 0$, $s = 1$ into (3.20) yields

$$\begin{aligned}\|F'(v^k)\overline{\delta v^{k+1}}\|_{v^k} &\le (1+\overline{\delta_{k+1}})\|F(v^{k+1})\|_{v^k} \\ &\le (1+\overline{\delta_{k+1}})\left(\delta_k\|F(v^k)\|_{v^k} + \frac{\omega}{2}\|F'(v^k)\delta v^k\|_{v^k}^2\right) \\ &\le (1+\overline{\delta_{k+1}})\left(\frac{\delta_k}{1-\delta_k} + \frac{\omega}{2}\|F'(v^k)\delta v^k\|_{v^k}\right)\|F'(v^k)\delta v^k\|_{v^k}\,,\end{aligned}$$

which completes the proof. ∎

The boundedness of $F'(v^k)$ as provided by Theorem 2.3 now provides linear convergence of the iterates towards the solution $v(\mu)$.

COROLLARY 3.7. *Suppose that Theorems* 2.3 *and* 3.3 *hold and* (3.4) *is satisfied. If the Newton iteration is controlled according to* (3.15)*, the iterates v^k converge linearly to $v(\mu)$.*

Proof. Under the given conditions, Theorem 3.3 and Lemma 3.5 provide the assumptions of Theorem 3.6 with D given by Theorem 2.3, such that the inexact Newton iteration is well-defined and the residuals converge to 0 according to (3.16). Due to (3.10), (3.11), and the equivalence of $\|\cdot\|_v$ and $\|\cdot\|$ we have $\|\delta v^k\| \le \|F'(v^k)^{-1}\|\|F(v^k) - r^k\| \le c(1+\delta_k)\|F(v^k)\|_{v^k}$ with a constant c independent of μ. From (3.15) we infer $\delta_k < 2$ and with (3.16) holding obtain $\|\delta v^k\| \le 2c\Theta^k\|F(v^0)\|_{v^0}$. Finally,

$$\|v^k - v(\mu)\| \le 2c\|F(v^0)\|_{v^0}\frac{\Theta^k}{1-\Theta}$$

proves r-linear convergence. ∎

Inexact prediction step. From numerical experience, we expect more or less constant reduction factors for μ, translating into constantly decreasing continuation stepsizes. In order to avoid this biased stepsize behavior, the predictor is formulated in terms of $\tau = -\log\mu$. The inexact tangential predictor $\hat{v}(\tau)$ is defined by

$$F'(v_0;\tau_0)\phi = -\partial_\tau F(v_0;\tau_0) + r\,, \quad \hat{v}(\tau) = v_0 + (\tau - \tau_0)\phi\,, \tag{3.24}$$

where again a residual r remains.

LEMMA 3.8. *Assumptions of Theorem* 3.6. *Let γ_τ and β be nonnegative constants such that the local norm $\|\cdot\|_{(v,\tau)}$ satisfies*

$$\big|\|\rho\|_{(v_1,\tau_1)} - \|\rho\|_{(v_0,\tau_0)}\big| \le \gamma_\tau(\tau_1 - \tau_0)\|\rho\|_{(v_0,\tau_0)} \tag{3.25}$$

and

$$\|F(v_1;\tau_1)\|_{(v_0,\tau_0)} \le \|F(v_0;\tau_0)\|_{(v_0,\tau_0)} + \|r\|_{(v_0,\tau)}(\tau_1 - \tau_0) + \beta(\tau_1 - \tau_0)^2 \tag{3.26}$$

for all $\rho \in Z_\infty$, v_0, v_1 such that $F'(v_0;\tau_0)(v_1 - v_0) = -(\tau_1 - \tau_0)(\partial_\mu F(v_0;\tau_0) + r)$, and $\mathrm{co}\{v_0, v_1\} \subset D$. Then the inexact Newton corrector with starting point v_1 converges to the central path $v(\tau)$ for all stepsizes $\Delta\tau = \tau_1 - \tau_0$ satisfying

$$(1 + \gamma_\tau\Delta\tau)(\|F(v_0;\tau_0)\|_{(v_0,\tau_0)} + \|r\|_{(v_0,\tau_0)}\Delta\tau + \beta\Delta\tau^2) < \frac{2}{\omega}\,. \tag{3.27}$$

Proof. Combining the convergence condition $\omega\|F(v;\tau)\|_{(v,\tau)} < 2$ from Theorem 3.6 with assumptions (3.25) and (3.26) yields the result. ∎

Note that since (3.27) represents a monotone convex function of $\Delta\tau$, the maximum permitted stepsize can be easily computed by an ordinary Newton method starting from $\sqrt{2/(\omega\beta)}$.

Remark. Again, the constant γ_τ is needed because of the inexactness of the tangential predictor. In exact Newton continuation algorithms (see Deuflhard [17]), the change of local norms can be subsumed under the second order term β.

Computable Lipschitz estimates. For actual computation we need easily computable estimates of the theoretical quantities ω, γ_v, γ_τ, and β to be inserted into

conditions (3.15) and (3.27). From (3.17) and (3.6), (3.21), respectively, we derive the computable estimates

$$[\omega]_k = \frac{2}{\|F'(v^k)\delta v^k\|_{v^k}} \left(\frac{\|F'(v^k)\overline{\delta v^{k+1}}\|_{v^k}}{(1+\overline{\delta_{k+1}})\|F'(v^k)\delta v^k\|_{v^k}} - \frac{\delta_k}{1-\delta_k} \right) \leq \omega \tag{3.28}$$

and

$$[\gamma_v]_k = \frac{d\Big(\Phi\big(\delta_{k+1}, \|F'(v^{k+1})\delta v^{k+1}\|_{v^{k+1}}\big), \Phi\big(\overline{\delta_{k+1}}, \|F'(v^k)\overline{\delta v^{k+1}}\|_{v^k}\big)\Big)}{(1+\delta_{k+1})\|F'(v^{k+1})\delta v^{k+1}\|_{v^{k+1}}\|F'(v^k)\delta v^k\|_{v^k}} \leq \gamma_v, \tag{3.29}$$

where $\Phi(a,b) = [\frac{b}{1+a}, \frac{b}{1-a}]$ denotes the inaccuracy interval and

$$d(A,B) = \inf_{a\in A, b\in B} |a-b|$$

is the usual set distance. Furthermore, computable estimates for γ_τ and β can be derived from (3.25) and (3.26) as

$$[\gamma_\tau] = \frac{d\Big(\Phi\big(\delta_2, \|F'(v_2;\tau_2)\delta v_2\|_{(v_2;\tau_2)}\big), \Phi\big(\overline{\delta_2}, \|F'(v_1;\tau_1)\overline{\delta v_2}\|_{(v_1;\tau_1)}\big)\Big)}{(1+\delta_2)\|F'(v_2;\tau_2)\delta v_2\|_{(v_2;\tau_2)}(\tau_2-\tau_1)} \leq \gamma_\tau \tag{3.30}$$

and

$$[\beta] = \max\{0, \tilde{\beta}\} \leq \beta, \tag{3.31}$$

where

$$\tilde{\beta} = \frac{d\Big(\Phi\big(\overline{\delta_2}, \|F'(v_1;\tau_1)\overline{\delta v_2}\|_{(v_1,\tau_1)}\big), \Phi\big(\delta_1, \|F'(v_1;\tau_1)\delta v_1\|_{(v_1,\tau_1)}\big)\Big)}{(\tau_2-\tau_1)^2} - \frac{\|r\|_{(v_1,\tau_1)}}{\tau_2-\tau_1},$$

respectively. Of course, *reliable* estimates are obtained only if δ_k is sufficiently small, which imposes additional accuracy requirements on the computation of the predictor and corrector.

Since the computable estimates are based on *local sampling* only, they are necessarily too small. Therefore, the computed continuation stepsize $\Delta\tau$ is larger than intended and may even be too large for the corrector to converge. In this case, a *stepsize reduction* has to be performed on the basis of updated estimates. In view of computational efficiency, an early detection of violation of the theoretical assumptions is preferable. Putting it all together, we arrive at the following inexact continuation algorithm.

ALGORITHM 3.9.

initialize $v, \tau, [\omega], [\beta], [\gamma_\tau], [\gamma_v]$

choose δ_{cor}, $\rho < 1$, $\Theta < 1$

1: *while* $\tau < \tau_{\mathrm{final}}$*:*

compute predictor $\partial_v F(v;\tau)\hat{v} = -\partial_\tau F(v;\tau) + r$ *without mesh refinement*

choose $\delta_{\mathrm{TOL}} < 2/[\omega]$

compute a stepsize $\Delta\tau > 0$ *such that*

$(1 + [\gamma_\tau]\Delta\tau\|\partial_v F(v;\tau)\hat{v}\|_{(v,\tau)})(\|F(v;\tau)\|_{(v,\tau)} + \Delta\tau\|r\|_{(v,\tau)} + [\beta]\Delta\tau^2) \leq \rho^3\delta_{\mathrm{TOL}}$

update $[\beta]$ *according to* (3.31)

if $\|F(v+\Delta\tau\hat{v};\tau+\Delta\tau)\|_{(v,\tau)} > \rho^2\delta_{\mathrm{TOL}}$ *go to* 1:

update $[\gamma_\tau]$ *according to* (3.30)
if $\|F(v+\Delta\tau\hat{v},\tau+\Delta\tau)\|_{(v+\Delta\tau\hat{v},\tau+\Delta\tau)}$
$> \rho^{-1}(1+[\gamma_\tau]\Delta\tau\|\partial_v F(v;\tau)\hat{v}\|_{(v,\tau)})(\|F(v;\tau)\|_{(v,\tau)}+\Delta\tau\|r\|_{(v,\tau)})$ *go to* 1:
initialize corrector $v_0 \leftarrow v+\Delta\tau\hat{v}$
while $\|F(v_k;\tau+\Delta\tau)\|_{(v_k,\tau+\Delta\tau)} > \delta_{\mathrm{cor}}\delta_{\mathrm{TOL}}$
if not in first Newton iteration
compute $\partial_v F(v_{k-1};\tau+\Delta\tau)\overline{\delta v} = -F(v_k;\tau+\Delta\tau)+\bar{r}$ *without refinement*
update $[\omega]$ *according to* (3.28)
if (3.17) *is violated go to* 1:
compute corrector $\partial_v F(v_k;\tau+\Delta\tau)\delta v = -F(v_k;\tau+\Delta\tau)+r$ *satisfying* (3.15)
update $[\gamma_v]$ *according to* (3.29)
$v_{k+1} = v_k+\delta v$
advance $v \leftarrow v_k$, $\tau \leftarrow \tau+\Delta\tau$

Termination of this stepsize reduction scheme has been studied in [40]. In actual computation, the estimated values $[\gamma_v]$ and $[\gamma_\mu]$ are very small, which suggests that using analytical bounds as mentioned in section 3.1 would be inefficient. Instead, the continuation algorithm mainly depends on $[\omega]$ and $[\beta]$.

Solution of linear subproblems. Applying Newton continuation methods in function space requires solving a *sequence of linear perturbed saddle point problems* of the same structure as the nonlinear complementarity problem (2.9). In principle, any standard linear BVP solver technique can be employed. If there is a stable direction for the initial value problem, a multiple shooting discretization of the state equation is certainly appropriate for the linear problem. For the numerical example in section 4 and further ones in [40], a Gauss collocation method has been employed. A fixed but arbitrary polynomial order p has been used for the states and $p-1$ for the controls, with p in the range $4, 5, 6$. The successive grid adaptation is based on a not very sophisticated ad hoc error estimator comparing approximations of different order. Standard band and sparse solvers have been used to solve the finite-dimensional linear systems. These and related algorithmic issues will be worked out to a higher level of sophistication in the near future.

4. Numerical examples. This section is devoted to numerical examples for the function space–oriented IP method developed above. In all the examples shown below, the continuation process has been run until either the memory requirement induced by successive refinement or insufficient accuracy of the linear system solver induced by increasing condition numbers limited the progress on the central path.

4.1. A simple class of optimal control problems. First we turn to a class of simple problems which are covered by Theorems 2.1 and 2.3:

$$\min \int_0^1 \left(\tilde{f}^y(y(t)) + \frac{\alpha}{2}|u(t)|^2\right) dt$$

$$\text{subject to} \quad \dot{y}(t) = Ay(t)+Bu(t),$$
$$y(0) = y_0,$$
$$a \le u(t) \le b.$$

Since the case of vector-valued controls is notationally more complex but provides no additional insight, we restrict the presentation to scalar controls.

THEOREM 4.1. *Suppose that on arbitrary bounded sets in* $\mathbb{R}^{n_y}$, $\tilde{f}^y$ *is convex and twice Lipschitz continuously differentiable,* $\alpha > 0$, $a < b$, $A \in \mathbb{R}^{n_y \times n_y}$, *and* $B \in \mathbb{R}^{n_y}$.

Assume there are v_0 and $\mu_0 > 0$ such that $F(v_0; \mu_0) = 0$. Then the central path $v(\mu)$ converges to a Kuhn–Tucker point $v(0) \in D$ at a rate of

$$\|v(\mu) - v(0)\| \leq \text{const}\, \sqrt{\mu}.$$

Proof. We start with Theorem 2.3, choosing

$$\rho < \frac{1}{\mu_0} \left(\frac{b-a}{2} \right)^2 \tag{4.1}$$

for separating nearly active and nearly inactive constraints. Obviously, conditions 1 and 2 are satisfied. Since no terminal boundary conditions are given, the inf-sup condition (2.10) simplifies to

$$\inf_{\xi \in L_p^2} \sup_{\delta u \in L_q^1} \frac{\langle \chi^A \xi, g'(u) \delta u \rangle}{\|\chi^A \xi\|_{L_p^2} \|\delta u\|_{L_q^1}} \geq \beta.$$

Assume that for a central path solution (v, μ) with $\mu \leq \mu_0$, the lower constraint $u \geq a$ is nearly active at t, i.e., $\rho \eta^a(t) \geq u(t) - a$. For simplicity, we will omit the argument t in the following. Together with (4.1) and the IP condition $\eta^a(u-a) = \mu = \eta^b(b-u)$ holding for all central path solutions, this implies

$$\begin{aligned} b - u = b - a - (u - a) &\geq b - a - \sqrt{\rho \eta^a (u-a)} = b - a - \sqrt{\rho \mu} \\ &\geq b - a - \frac{b-a}{2} = \frac{b-a}{2} > \sqrt{\rho \mu} = \sqrt{\rho \eta^b (b-u)}. \end{aligned}$$

Squaring and dividing by $b-u$ finally yields $b - u > \rho \eta^b$, which implies that the upper constraint $u \leq b$ is nearly inactive whenever the lower constraint is nearly active. Analogously, the converse can be shown, such that at most one of the two constraints is active. Always choosing the nearly active constraint whenever possible, we see that

$$\inf_{\xi \in L_p^2} \sup_{\delta u \in L_q^1} \frac{\langle \chi^A \xi, g'(u) \delta u \rangle}{\|\chi^A \xi\|_{L_p^2} \|\delta u\|_{L_q^1}} \geq \inf_{\xi \in L_p^1} \sup_{\delta u \in L_q^1} \frac{\langle \xi, \delta u \rangle}{\|\xi\|_{L_p^1} \|\delta u\|_{L_q^1}} \geq 1$$

for both $(p, q) = (\infty, 1)$ and $(p, q) = (2, 2)$, which confirms the inf-sup condition.

Now we verify the assumptions of Theorem 2.1 on the whole space $D = V$. Assumption 1 is trivially inapplicable due to $n_r = 0$. The Legendre–Clebsch condition 2 is obviously satisfied due to $\alpha > 0$ and the linearity of the constraints, as is the positive definiteness of $\partial_x^2 L(v)$.

Finally, the remaining assumptions of Theorem 2.3, conditions 3 and 4, are satisfied uniformly for $v \in D$ as their counterparts from Theorem 2.1. Thus, Theorem 2.3 can be applied and yields the claim. ∎

For a brief discussion on how to extend the argumentation to more complex nonlinear problems we refer to [42].

As an illustrative example of the problem class studied in Theorem 4.1 we choose

$$\begin{aligned} \min \int_0^1 \left(t^2 y(t)^2 + \frac{\alpha}{2} u(t)^2 \right) dt \\ \text{subject to} \qquad \ddot{y}(t) = u(t), \\ y(0) = 1,\ \dot{y}(0) = 0, \\ -1 \leq u(t) \leq 1 \end{aligned} \tag{4.2}$$

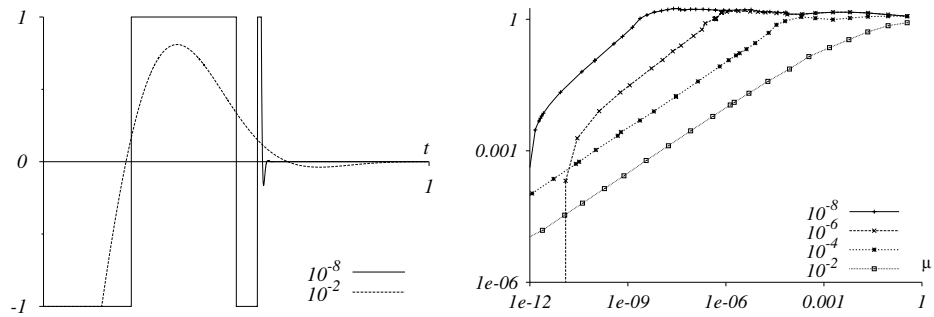

FIG. 4.1. *The control u of problem* (4.2) *for different values of α. Left: numerical solutions. Right: the approximate error $\|u(\mu) - u(\mu_{\text{final}})\|_{L_\infty}$.*

with control regularization values $\alpha = 10^{-2}, 10^{-4}, 10^{-6}, 10^{-8}$. Rewriting (4.2) as a system of two first order ODEs, the example is covered by Theorem 4.1. Clearly visible in Figure 4.1 is the convergence of order $\mathcal{O}(\sqrt{\mu})$ in the control, which is the most critical variable. The quantitative value of μ where this asymptotics sets in depends, of course, on the control regularization parameter α. For $\alpha \to 0$ we approach the bang-bang case, for which no convergence in L_∞ can be expected at all.

4.2. Abort landing in the presence of windshear. Here we will consider a well-known intricate optimal control problem, the abort landing in the presence of windshear. Our numerical results are based on the precise model given in [6]. The problem is of Chebyshev type, maximizing the minimal altitude. The optimal solution consists of control and state constrained subarcs as well as touch points and singular subarcs, which makes the problem difficult to tackle by means of the maximum principle. It contains a third order state constraint and a nondifferentiable wind model based on spline representation—and is therefore not covered by the theoretical presentation in [42]. Nevertheless, as will be reported now, already the first version of our algorithm developed herein worked satisfactorily.

Originally, the problem has been modeled by Miele et al. [30]; as for the numerical solution, these authors seem to have applied a *robust collocation* method based on a finite-dimensional parametrization of the control and combined with a gradient restoration technique to find the corresponding optimal finite-dimensional solution. Their paper does not present any numerical results for the control, which is the most sensitive and numerically critical variable.

As preparation for the application of *multiple shooting*, Bulirsch, Montrone, and Pesch [10] required 11 pages to present a brief outline of the analytic derivation of the necessary conditions. In contrast to that, the method we propose here does not require any analytical preprocessing—thus saving considerable human effort. In a second paper [11], the application of the multiple shooting method has been described along with the homotopy necessary to obtain the correct switching structure. In 1995, Berkmann and Pesch [6] solved the same problem even more accurately and claimed that "a competing direct method is unlikely to be able to produce solutions with such high resolution." In fact, our direct function space method did require a substantial computational effort to reach a comparably high accuracy. A comparison of computing times, however, would be too early, since our first focus was on developing a working algorithm within the rather new conceptual frame. There is enough space left for

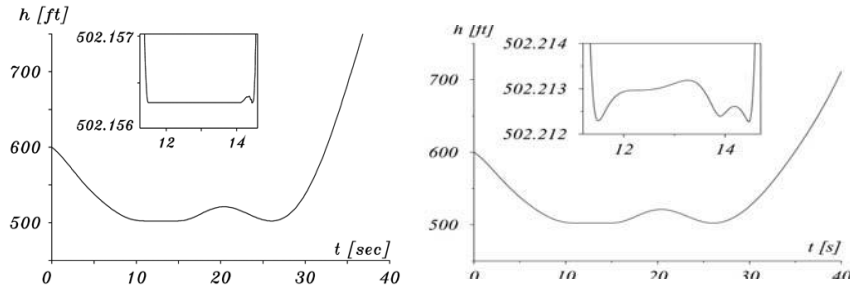

FIG. 4.2. *Altitude h for windshear problem. Left: multiple shooting result from* [6]. *Right: central path result at $\mu = 2.1 \cdot 10^{-4}$ (this paper).*

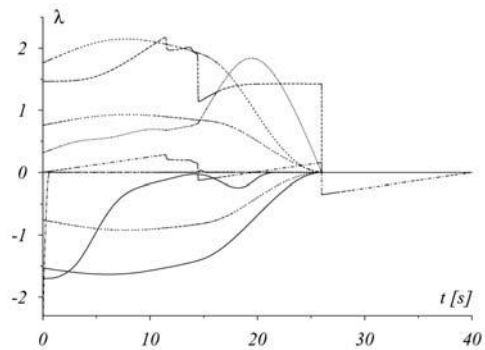

FIG. 4.3. *Lagrange multipliers λ_i corresponding to equality constraints (scaled).*

perfecting our algorithm, which will be filled in the near future.

Figure 4.2 shows a comparison of our altitude results with those obtained in [6]. The agreement is perfect within the interval up to the last touch point $t^* = 25.997$s. Beyond that point, there exists a continuum of optimal solutions. This can be understood from the fact that for $t > t^*$ all relevant Lagrange multipliers vanish (Figure 4.3) and none of the inequality constraints is active. Only the multiplier corresponding to the Chebyshev reformulation of the minimization problem does not vanish.

As already mentioned above, the most critical variable is the control u, the angle of attack rate. That is why we present its rather complex behavior in Figure 4.4. As can be seen, our results once again are in perfect agreement with the multiple shooting results from [6] at least in the relevant interval $[0, t^*]$. Only one slight deviation occurs before $t = t^*$, the reason for which is not yet clear. The second deviation, the downward spike starting at t^*, can be attributed to the nonuniqueness of the solution. In the interval $[t^*, 1]$, both methods happen to choose different, but equivalent, solutions. The pronounced peak of u at t^* reflects the tendency of the IP method to drive a previously actively constrained state variable towards the interior of the feasible set. Of course, this peak could have been suppressed by adding some penalty term ϵu^2 to the cost functional on the interval $[t^*, 1]$, without changing the uniquely determined part of the solution in the interval $[0, t^*]$.

In passing we note that Pytlak [32] has also attacked this problem using his method and documented his results, but he obtained a control behavior quite different from the one given in Figure 4.4.

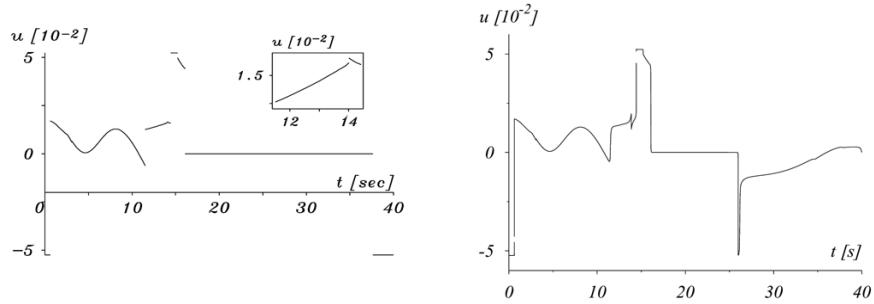

FIG. 4.4. *Control u for windshear problem. Left: multiple shooting result from* [6]. *Right: central path result at $\mu = 2.1 \cdot 10^{-4}$ (this paper).*

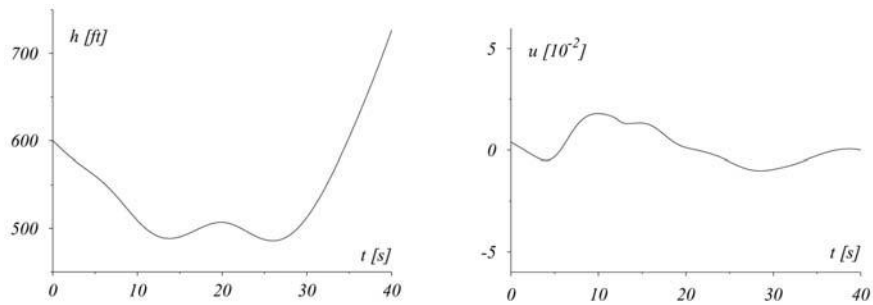

FIG. 4.5. *Initial trajectory for windshear problem. Left: altitude h. Right: control u.*

As for the obtained functional value (minimum altitude $h_{\min}$), Bulirsch, Montrone, and Pesch [11] report an improvement of 10ft over Miele et al. [30]. On top of that, Berkmann and Pesch [6] achieved a further improvement of $2.7 \cdot 10^{-6}$ ft to a value of $h_{\min} = 502.1562810$ ft. Our method led to an even better minimal altitude of $h_{\min} = 502.210661$ ft. In order to assess this value, we solved the initial value problem in both forward and backward directions using the computed control from our algorithm. As a numerical integrator we selected the MATLAB implementation of Dormand–Prince RK45. In the forward direction we obtained $h_{\min} = 502.210433$ ft, in the backward direction $h_{\min} = 502.210438$ ft. This seems to confirm that our results are an improvement even over [6]—within the discretization error level, of course.

In order to shed some light on the performance of our new algorithm, we next give some details about the continuation process with respect to the duality gap parameter μ and the adaptive multilevel scheme.

The computations were started on a uniform initial grid with mesh size $h_0 = 1/25$. On this grid, the nonlinear KKT equations $F(v; 1) = 0$ with dimension 2748 have been solved using a Newton method with damping. The corresponding initial trajectory is depicted in Figure 4.5.

An illustration of the adaptive continuation process along the central path is given in Figure 4.6. Assuming a convergence of the form

$$J(v(\mu)) - J(v(0)) \sim \mu^{\alpha}\,, \tag{4.3}$$

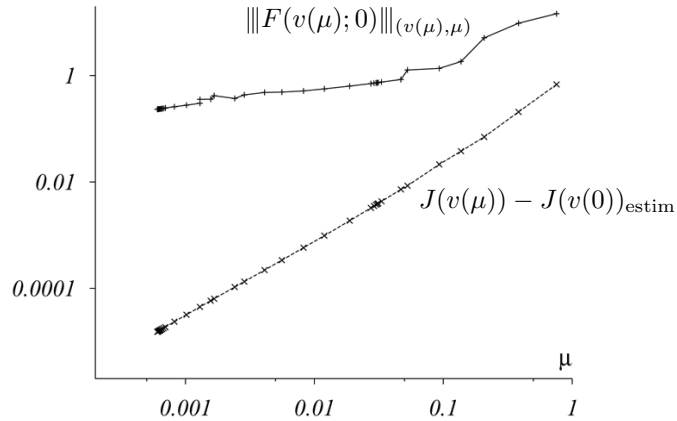

FIG. 4.6. *Central path continuation for windshear problem.*

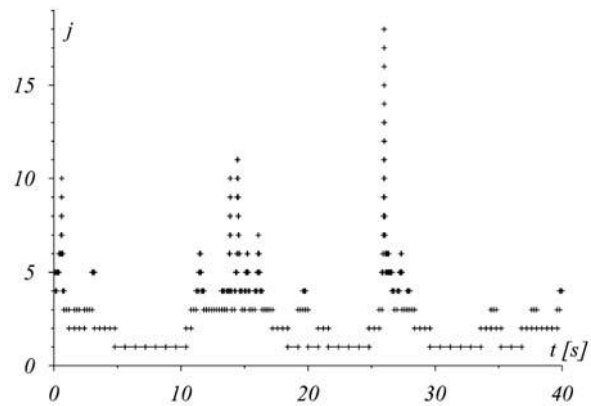

FIG. 4.7. *Adaptive mesh refinement in windshear problem.*

a simple parameter fitting yields $J(v(0))_{\text{estim}} \approx 5.022118$ and $\alpha \approx 1.44$. The log-log scale indicates that (4.3) is indeed quite reasonable.

Finally, the adaptive mesh refinement structure for this problem is presented in Figure 4.7. Successive refinement led to mesh sizes

$$h_j = 2^{-j} h_0 \,.$$

Obviously, the highly dynamic structure of the solution is captured reasonably well by the adaptive refinement procedure.

Conclusion. In this paper we present a direct function space method for optimal control problems based on the complementarity formulation of IP methods. The new method essentially dispenses with any analytical preprocessing—thus saving considerable human effort. In its algorithmic realization, function space is exploited via an adaptive multilevel method in combination with an adaptive central path following algorithm. A theoretical justification of the algorithm has been achieved only for control constrained problems. However, numerical results for a well-known intricate

optimal control problem with both control and state constraints seem to indicate that a much wider class of problems should be tractable by our algorithm. Even though a lot remains to be done both in theoretical justification and in algorithmic realization, we are confident to have opened a promising alternative path towards the numerical solution of complex optimal control problems from science and engineering.

Acknowledgments. The authors gratefully acknowledge invaluable helpful discussions with F. Tröltzsch on a former version of the paper. Moreover, they would like to thank H. Maurer and C. Helmberg for helpful comments.

DIFFERENTIAL GAMES WITH ASYMMETRIC INFORMATION*

P. CARDALIAGUET†

Abstract. We investigate a two-player zero-sum differential game in which the players have asymmetric information on the random terminal payoff. We prove that the game has a value and characterize this value in terms of *dual* solutions of some Hamilton–Jacobi equation. We also explain how to adapt the results to differential games where the initial position is random.

Key words. differential game, asymmetric information, viscosity solution

DOI. 10.1137/060654396

1. Introduction.

In this paper we investigate a two-player zero-sum differential game in which the players have asymmetric information on the random terminal payoff. The dynamics of the game is given by

$$\left\{\begin{array}{ll} x'(t) = f(x(t), u(t), v(t)) , & u(t) \in U,\ v(t) \in V, \\ x(t_0) = x_0, \end{array}\right. \tag{1}$$

where U and V are compact subsets of some finite dimensional spaces, and $f : \mathbb{R}^N \times U \times V \to \mathbb{R}^N$ is Lipschitz continuous. We consider a finite horizon problem with a terminal time denoted by T. The game starts at time $t_0 \in [0, T]$ from the initial position x_0.

The description of the game involves $I \times J$ terminal payoffs (where $I, J \geq 1$): $g_{ij} : \mathbb{R}^N \to \mathbb{R}$ for $i = 1, \ldots, I$ and $j = 1, \ldots, J$, a probability $p = (p_i)_{i=1,\ldots,I}$ belonging to the set $\Delta(I)$ of probabilities on $\{1, \ldots, I\}$ and a probability $q = (q_j)_{j=1,\ldots,J}$ of the set $\Delta(J)$ of probabilities on $\{1, \ldots, J\}$.

The game is played in two steps: At time t_0, a pair (i, j) is chosen at random among $\{1, \ldots, I\} \times \{1, \ldots, J\}$ according to the probability $p \otimes q$; the choice of i is communicated to player 1 only, while the choice of j is communicated to player 2 only.

Then the players control system (1) in order for player 1 to minimize the terminal payoff $g_{ij}(x(T))$ and for player 2 to maximize it. We assume that both players observe their opponent's control. Note, however, that the players do not know which g_{ij} they are actually optimizing, because they have only a part of the information on the 91A05 pair (i, j). They can nevertheless try to guess their missing information by observing what their opponent is doing. Indeed, in order to use his information a player necessarily reveals at least a part of it, and any piece of information he reveals can be later exploited by his opponent.

As usual we introduce two value functions associated to this game. We have to take special care of the way we define the strategies of the players, since this definition has to represent the lack of symmetry in the knowledge of the players.

†Université de Bretagne Occidentale, Laboratoire de Mathématiques, UMR 6205, 6 Av. Le Gorgeu, BP 809, 29285 Brest, France (pierre.cardaliaguet@univ.brest.fr).

The upper value is given by

$$V^+(t_0,x_0,p,q) = \inf_{(\alpha_i)\in(\mathcal{A}_r(t_0))^I} \sup_{(\beta_j)\in(\mathcal{B}_r(t_0))^J} \sum_{i=1}^{I}\sum_{j=1}^{J} p_i q_j \mathbf{E}_{\alpha_i\beta_j}\left(g_{ij}\left(X_T^{t_0,x_0,\alpha_i,\beta_j}\right)\right) ,$$

where the $\alpha_i \in \mathcal{A}_r(t_0)$ (for $i = 1,\dots,I$) are I random strategies for player 1, the $\beta_j \in \mathcal{B}_r(t_0)$ (for $j = 1,\dots,J$) are J random strategies for player 2, and $\mathbf{E}_{\alpha_i\beta_j}(g_{ij}(X_T^{t_0,x_0,\alpha_i,\beta_j}))$ is the payoff associated with the pair of strategies (α_i,β_j) for the terminal payoff g_{ij}: These notions are explained in the next section. The key point in the definition is that player 1 chooses his strategy α_i $(i = 1,\dots,I)$ according to the value of the index i only, while player 2 has a strategy (β_j) which depends only upon the index j. This reflects the asymmetry of information of the players. The sum $\sum_i \sum_j p_i q_j \dots$ is the expectation of the payoff when the pair (i,j) is chosen according to the probability $p \otimes q$, where $p = (p_1,\dots,p_I)$ and $q = (q_1,\dots,q_J)$.

The lower value is defined by the symmetric formula:

$$V^-(t_0,x_0,p,q) = \sup_{(\beta_j)\in(\mathcal{B}_r(t_0))^J} \inf_{(\alpha_i)\in(\mathcal{A}_r(t_0))^I} \sum_{i=1}^{I}\sum_{j=1}^{J} p_i q_j \mathbf{E}_{\alpha_i\beta_j}\left(g_{ij}\left(X_T^{t_0,x_0,\alpha_i,\beta_j}\right)\right) .$$

Obviously we have

$$V^-(t_0,x_0,p,q) \le V^+(t_0,x_0,p,q)$$

for any $(t_0,x_0) \in [0,T]\times\mathbb{R}^N$, any probability $p \in \Delta(I)$ on $\{1,\dots,I\}$, and any probability $q \in \Delta(J)$ on $\{1,\dots,J\}$. Our aim is to show that the equality holds, i.e., that the game has a value, and to provide a PDE characterization of the value.

The game studied in this paper is strongly inspired by *repeated games* with a lack of information introduced by Aumann and Maschler; see [2, 22] for a general presentation. Repeated games with a lack of information on one side (i.e., $I = 1$ or $J = 1$) or on both sides (i.e., $I, J \ge 2$) have a value [2, 18], in the sense that the averaged n-stage games converge to a limit as $n \to +\infty$. This value can be characterized in terms of the value of the "nonrevealing game." In this paper, we prove the existence of a value for differential games with a lack of information on both sides. However, we show in the companion paper [10] that the characterization in terms of a game without information does not hold. In that respect, our game is close to stochastic games with incomplete information, as studied in [21], for instance. Although it is known that stochastic games with a lack of information on one side have a value when the game is controlled by the informed player only [21], the general case is still open.

There are several proofs of Aumann and Maschler's result. In order to show that our game has a value, we use a strategy of proof initiated by De Meyer in [12] and later developed in [13, 14, 17]. We first note that the maps $V^+ = V^+(t,x,p,q)$ and $V^- = V^-(t,x,p,q)$ are convex in p and concave in q (Lemma 3.2). This leads us to introduce, for a generic map $w : [0,T]\times\mathbb{R}^N\times\Delta(I)\times\Delta(J) \mapsto \mathbb{R}$, the convex Fenchel conjugate w^* of w with respect to the variable p and its concave conjugate $w^\sharp$ with respect to q: for all $(t,x,\hat{p},q) \in [0,T]\times\mathbb{R}^N\times\mathbb{R}^I\times\Delta(J)$

$$w^*(t,x,\hat{p},q) = \sup_{p\in\Delta(I)} p.\hat{p} - w(t,x,p,q)$$

and for all $(t,x,p,\hat{q}) \in [0,T]\times\mathbb{R}^N\times\Delta(I)\times\mathbb{R}^J$

$$w^\sharp(t,x,p,\hat{q}) = \inf_{q\in\Delta(J)} q.\hat{q} - w(t,x,p,q) .$$

Then the proof of the equality $V^+ = V^-$ runs as follows: We first check (Lemma 4.2) that V^{-*} satisfies a subdynamic programming principle and thus (Corollary 4.3) that $(t,x) \mapsto V^{-*}(t,x,\hat{p},q)$ is a viscosity subsolution of the (dual) Hamilton–Jacobi (HJ) equation

$$w_t + H^*(x, Dw) = 0 \text{ in } [0,T] \times \mathbb{R}^N \tag{2}$$

for any $(\hat{p},q) \in \mathbb{R}^I \times \Delta(J)$. The map H^* is defined through the standard Hamiltonian H of the game

$$H(x,\xi) = \inf_{u\in U} \sup_{v\in V} f(x,u,v).\xi = \sup_{v\in V} \inf_{u\in U} f(x,u,v).\xi$$

via the relation by $H^*(x,\xi) = -H(x,-\xi)$. Note that we assume that Isaacs' condition holds. We recall that the notion of viscosity solutions was introduced by Crandall and Lions in [11] and first used in the framework of differential games in [15] (see also [3, 4] for a general presentation). We also establish a symmetric result for $V^{+\sharp}$ (Corollary 4.4): For any $(p,\hat{q}) \in \Delta(I) \times \mathbb{R}^J$, the map $(t,x) \mapsto V^{+\sharp}(t,x,p,\hat{q})$ is a viscosity supersolution of the same equation (2). A new comparison principle (Theorem 5.1) then implies that $V^+ \le V^-$. Since inequality $V^+ \ge V^-$ is obvious, the game has a value: $V^+ = V^-$. We also have the following characterization of this value: $\mathbf{V} := V^+ = V^-$ is the unique Lipschitz continuous function which is convex in p, concave in q, such that $(t,x) \mapsto \mathbf{V}^*(t,x,\hat{p},q)$ is a subsolution of the HJ equation (2), while $(t,x) \mapsto \mathbf{V}^\sharp(t,x,p,\hat{q})$ is a supersolution of (2). We call such a function the *dual solution* to the Hamilton–Jacobi equation

$$\begin{cases} w_t + H(x,Dw) = 0 & \text{in } [0,T) \times \mathbb{R}^N, \\ w(T,x) = \sum_{ij} p_i q_j g_{ij}(x) & \text{in } \mathbb{R}^N. \end{cases}$$

We discuss this terminology below.

We explain in section 6 how to adapt our approach to differential games with a lack of information on the initial positions. As previously, the game is played in two steps. At time t_0, the initial position of the game is chosen at random among $I \times J$ possible initial positions x^0_{ij} according to a probability $p \otimes q$, where $p \in \Delta(I)$ and $q \in \Delta(J)$; the index i is communicated to player 1, while the index j is communicated to player 2. Then the players control system (1) in order, for player 1, to minimize a terminal payoff $g(x(T))$ and, for player 2, to maximize it. The key assumption is that the players observe their opponent's behavior but not the state of the system $x(\cdot)$. We prove that this game has a value, which can be characterized as the unique dual solution of some HJ equation in $[0,T] \times \mathbb{R}^{NIJ}$.

Although there have been several attempts to formalize differential games with lack of information [5, 6, 7, 8], there are only very few papers in which a game is proved to have a value; see in particular [19], [20], which discuss interesting examples. In [9] we consider a game with a lack of information on the current position, but with symmetric information. To the best of our knowledge, our result is the first one showing the existence of a value for differential games with asymmetry in the information in a general setting.

The kind of characterization proposed in this paper for the value function (as a dual solution of some Hamilton–Jacobi equations) is also new. It relies upon a new comparison principle (Theorem 5.1) stating the following: Assume that w_1 and w_2 defined on $[0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J)$ are convex in p, concave in q, that $(t,x) \mapsto w_1^\sharp(t,x,p,\hat{q})$ is a supersolution of the dual HJ equation (2) for any $(p,\hat{q})$, and that

$(t,x) \mapsto w_2^*(t,x,\hat{p},q)$ is a subsolution of this HJ equation for any $(\hat{p},q)$. If futhermore $w_1(T,x,p,q) \leq w_2(T,x,p,q)$ for any (x,p,q), then $w_1 \leq w_2$.

Note that the function w_2, for instance, is a kind of supersolution for our problem. For this reason we call it a dual supersolution of the orginal HJ equation

$$w_t + H(x, Dw) = 0 \text{ in } [0,T] \times \mathbb{R}^N, \tag{3}$$

and we see the HJ equation (2) as a dual one. Let us recall that, although the Fenchel conjugate of a supersolution of (3) is a subsolution of the dual equation (2) (see [1]), the converse does not hold in general. In fact we show through several examples in [10] that the value function $\mathbf{V} := V^+ = V^-$ of our game is *not* a solution of the original HJ equation (3), nor are its Fenchel conjugates $\mathbf{V}^*$ and $\mathbf{V}^\sharp$ solutions of the dual one (2). The particular structure of our problem leads us to replace the classical notion of sub- and supersolutions by a weaker one, involving families of sub- and supersolutions in some dual spaces (see also Lemma 5.4, where an equivalent definition for a dual subsolution is discussed).

We complete this introduction by describing the organization of the paper. In section 2, we introduce the main notations: In particular we explain the notions of random strategies and define the value functions of our game. Section 3 is mainly devoted to the proof of the convexity properties of the value functions. In section 4 we show that V^{-*} satisfies a subdynamic programming principle and is a subsolution of the dual HJ equation and give the corresponding results for $V^{+\sharp}$. Section 5 is devoted to the comparison principle and to the existence of a value. In the last section, we extend our results to differential games with a lack of information on the initial position.

2. Definition of the value functions.

Notations. Throughout the paper, $x.y$ denotes the scalar product in the space $\mathbb{R}^N$, $\mathbb{R}^I$, or $\mathbb{R}^J$ (depending on the context) and $|\cdot|$ the Euclidean norm. The ball of center x and radius r will be denoted by $B_r(x)$. If E is a set, then $\mathbf{1}_E$ is the indicatrix function of E (equal to 1 if E and to 0 outside of E). The set $\Delta(I)$ is the set of probability measures on $\{1,\dots,I\}$, always identified with the simplex of $\mathbb{R}^I$:

$$p = (p_1,\dots,p_I) \in \Delta(I) \quad \Leftrightarrow \quad \sum_{i=1}^{I} p_i = 1 \text{ and } p_i \geq 0 \text{ for } i = 1,\dots,I\,.$$

The set $\Delta(J)$ of probability measures on $\{1,\dots,J\}$ is defined symmetrically.

The dynamics of the game is given by

$$\begin{cases} x'(t) = f(x(t),u(t),v(t))\,, & u(t) \in U,\ v(t) \in V, \\ x(t_0) = x_0. \end{cases} \tag{4}$$

Throughtout the paper we assume that

$$\begin{cases} \text{(i)} & U \text{ and } V \text{ are compact subsets of some finite dimensional spaces;} \\ \text{(ii)} & f : \mathbb{R}^N \times U \times V \to \mathbb{R}^N \text{ is bounded, continuous, and uniformly} \\ & \text{Lipschitz continuous with respect to the } x \text{ variable;} \\ \text{(iii)} & \text{for } i = 1,\dots,I \text{ and } j = 1,\dots,J,\ g_{ij} : \mathbb{R}^N \to \mathbb{R} \text{ is Lipschitz} \\ & \text{continuous and bounded.} \end{cases} \tag{5}$$

We also assume that Isaacs' condition holds:

$$H(x,\xi) := \inf_{u\in U} \sup_{v\in V} f(x,u,v).\xi = \sup_{v\in V} \inf_{u\in U} f(x,u,v).\xi \tag{6}$$

for any $(x,\xi) \in \mathbb{R}^N \times \mathbb{R}^N$. We note that the Hamilton–Jacobi equation naturally associated with the dynamics is the so-called primal Hamilton–Jacobi equation

$$w_t + H(x, Dw) = 0 \qquad \text{in } [0,T) \times \mathbb{R}^N. \tag{7}$$

For any $t_0 < t_1 \le T$, the set of open-loop controls for player 1 on $[t_0,t_1]$ is defined by

$$\mathcal{U}(t_0,t_1) = \{u : [t_0,t_1] \mapsto U \text{ Lebesgue measurable}\} .$$

If $t_1 = T$, we simply set $\mathcal{U}(t_0) := \mathcal{U}(t_0,T)$. Open-loop controls on the interval $[t_0,t_1]$ for player 2 are defined symmetrically and denoted by $\mathcal{V}(t_0,t_1)$ (and by $\mathcal{V}(t_0)$ if $t_1 = T$).

If $u \in \mathcal{U}(t_0)$ and $t_0 \le t_1 < t_2 \le T$, we denote by $u_{|_{[t_1,t_2]}}$ the restriction of u to the interval $[t_1,t_2]$. We note that $u_{|_{[t_1,T]}}$ belongs to $\mathcal{U}(t_1)$.

For any $(u,v) \in \mathcal{U}(t_0) \times \mathcal{V}(t_0)$ and any initial position $x_0 \in \mathbb{R}^N$, we denote by $t \mapsto X_t^{t_0,x_0,u,v}$ the solution to (4).

Next we introduce the notions of pure and mixed strategies. The definition of mixed strategies involves a set $\mathcal{S}$ of (nontrivial) probability spaces, which has to be stable by a finite product. To fix the ideas we choose from now on

$$\mathcal{S} = \{([0,1]^n, B([0,1]^n), \mathcal{L}^n) \text{ for some } \ n \in \mathbb{N}^*\} \ ,$$

where $B([0,1]^n)$ is the class of Borel sets and $\mathcal{L}^n$ is the Lebesgue measure on $\mathbb{R}^n$. As the reader can easily check, the results presented in this paper do not depend on this particular choice of $\mathcal{S}$.

DEFINITION 2.1 (pure and random strategies). *A pure strategy for player* 1 *at time* t_0 *is a map* $\alpha : \mathcal{V}(t_0) \mapsto \mathcal{U}(t_0)$ *which satisfies the following conditions:*

(i) α *is a measurable map from* $\mathcal{V}(t_0)$ *to* $\mathcal{U}(t_0)$*, where* $\mathcal{U}(t_0)$ *and* $\mathcal{V}(t_0)$ *are endowed with the Borel* σ*-field associated with the* L^1 *distance;*

(ii) α *is nonanticipative with delay; i.e., there is some* $\tau > 0$ *such that, for any* $v_1, v_2 \in \mathcal{V}(t_0)$*, if* $v_1 \equiv v_2$ *a.e. on* $[t_0,t]$ *for some* $t \in (t_0, T-\tau)$*, then* $\alpha(v_1) \equiv \alpha(v_2)$ *a.e. on* $[t_0, t+\tau]$.

A random strategy for player 1 *is a pair* $((\Omega_\alpha, \mathcal{F}_\alpha, \mathbf{P}_\alpha), \alpha)$*, where* $(\Omega_\alpha, \mathcal{F}_\alpha, \mathbf{P}_\alpha)$ *belongs to the set of probability spaces* $\mathcal{S}$ *and* $\alpha : \Omega_\alpha \times \mathcal{V}(t_0) \mapsto \mathcal{U}(t_0)$ *satisfies the following conditions:*

(i) α *is a measurable map from* $\Omega_\alpha \times \mathcal{V}(t_0)$ *to* $\mathcal{U}(t_0)$*, with* Ω_α *endowed with the* σ*-field* $\mathcal{F}_\alpha$ *and* $\mathcal{U}(t_0)$ *and* $\mathcal{V}(t_0)$ *with the Borel* σ*-field associated with the* L^1 *distance;*

(ii) *there is some delay* $\tau > 0$ *such that, for any* $v_1, v_2 \in \mathcal{V}(t_0)$*, any* $t \in (t_0, T-\tau)$*, and any* $\omega \in \Omega_\alpha$*,*

$$v_1 \equiv v_2 \text{ on } [t_0,t) \ \Rightarrow \ \alpha(\omega, v_1) \equiv \alpha(\omega, v_2) \text{ on } [t_0, t+\tau) \ .$$

We denote by $\mathcal{A}(t_0)$ the set of pure strategies and by $\mathcal{A}_r(t_0)$ the set of random strategies for player 1. By abuse of notations, an element of $\mathcal{A}_r(t_0)$ is simply noted α—instead of $((\Omega_\alpha, \mathcal{F}_\alpha, \mathbf{P}_\alpha), \alpha)$—the underlying probability space being always denoted by $(\Omega_\alpha, \mathcal{F}_\alpha, \mathbf{P}_\alpha)$. Let us point out the inclusion $\mathcal{A}(t_0) \subset \mathcal{A}_r(t_0)$.

In order to take into account the fact that player 1 knows the index i of the terminal payoff, a strategy for player 1 is actually an I-uplet $\hat{\alpha} = (\alpha_1, \dots, \alpha_I) \in (\mathcal{A}_r(t_0))^I$.

Pure and random strategies for player 2 are defined symmetrically: At time t_0, a pure strategy β is a measurable map which is nonanticipative with delay from $\mathcal{U}(t_0)$ to $\mathcal{V}(t_0)$, while a random strategy is a map $\beta : \Omega_\beta \times \mathcal{U}(t_0) \mapsto \mathcal{V}(t_0)$, where $(\Omega_\beta, \mathcal{F}_\beta, \mathbf{P}_\beta)$ belongs to $\mathcal{S}$, which satisfies the conditions:

(i) β is measurable from $\Omega_\beta \times \mathcal{U}(t_0)$ to $\mathcal{V}(t_0)$;

(ii) there is some delay $\tau > 0$ such that, for any $u_1, u_2 \in \mathcal{U}(t_0)$, any $t \in (t_0, T-\tau)$, and any $\omega \in \Omega_\beta$,

$$u_1 \equiv u_2 \text{ on } [t_0, t) \;\Rightarrow\; \beta(\omega, u_1) \equiv \beta(\omega, u_2) \text{ on } [t_0, t+\tau) \; .$$

The set of pure and random strategies for player 2 are denoted by $\mathcal{B}(t_0)$ and $\mathcal{B}_r(t_0)$, respectively. Elements of $\mathcal{B}_r(t_0)$ are denoted simply by β and the underlying probability space by $(\Omega_\beta, \mathcal{F}_\beta, \mathbf{P}_\beta)$. Since player 2 knows the index j of the terminal payoff, a strategy for player 2 is a J-uplet $\hat{\beta} = (\beta_1, \dots, \beta_J) \in (\mathcal{B}_r(t_0))^J$.

Let us now comment upon these definitions of strategies. In the recent literature on differential games, one generally uses "nonanticipative strategies" or "Varayia–Roxin–Elliott–Kalton" strategies, i.e., pure strategies without delay (see [3, 15], for instance). In this setting, no measurability condition is required upon the strategy. We have chosen here to work with "nonanticipative strategies with delay" because using these strategies allows us to put the game under normal form: See Lemma 2.2 below; standard nonanticipative strategies do not enjoy this crucial property. The introduction of random strategies is new in the context of differential games, in which one usually has the existence of a value in pure strategies provided Isaacs' condition (6) holds. In the game considered in this paper, the players have to hide their private information. To do this they have to use some randomness in their strategies. From a technical point of view, this randomness is the key argument for the convexity properties of the value functions to hold; see the proof of Lemmas 3.2 and 4.1 in particular. The measurability requirement of a random strategy with respect to ω is necessary to be able to define an expectation. The joint measurability in (i) of the definition is a technical requirement needed in the proof of the dynamic programming. One also has to face such a difficulty for stochastic differential games; see [16], for instance.

LEMMA 2.2. *For any pair $(\alpha, \beta) \in \mathcal{A}_r(t_0) \times \mathcal{B}_r(t_0)$ and any $\omega := (\omega_1, \omega_2) \in \Omega_\alpha \times \Omega_\beta$, there is a unique pair $(u_\omega, v_\omega) \in \mathcal{U}(t_0) \times \mathcal{V}(t_0)$ such that*

$$\alpha(\omega_1, v_\omega) = u_\omega \text{ and } \beta(\omega_2, u_\omega) = v_\omega \; . \tag{8}$$

Furthermore the map $\omega \to (u_\omega, v_\omega)$ is measurable from $\Omega_\alpha \times \Omega_\beta$ endowed with $\mathcal{F}_\alpha \otimes \mathcal{F}_\beta$ into $\mathcal{U}(t_0) \times \mathcal{V}(t_0)$ endowed with the Borel σ-field associated with the L^1 distance.

Notations. Given any pair $(\alpha, \beta) \in \mathcal{A}_r(t_0) \times \mathcal{B}_r(t_0)$, we denote by $(X_t^{t_0,x_0,\alpha,\beta})$ the map $(t, \omega) \mapsto X_t^{t_0,x_0,u_\omega,v_\omega}$ defined on $[t_0, T] \times \Omega_\alpha \times \Omega_\beta$, where (u_ω, v_ω) satisfies (8). We also define the expectation $\mathbf{E}_{\alpha\beta}$ as the integral over $\Omega_\alpha \times \Omega_\beta$ against the probability measure $\mathbf{P}_\alpha \otimes \mathbf{P}_\beta$. In particular, if $\phi : \mathbb{R}^N \to \mathbb{R}$ is some bounded continuous map and $t \in (t_0, T]$, we have

$$\mathbf{E}_{\alpha\beta}\left(\phi\left(X_t^{t_0,x_0,\alpha,\beta}\right)\right) := \int_{\Omega_\alpha \times \Omega_\beta} \phi\left(X_t^{t_0,x_0,u_\omega,v_\omega}\right) d\mathbf{P}_\alpha \otimes \mathbf{P}_\beta(\omega) \; , \tag{9}$$

where (u_ω, v_ω) is defined by (8). Note that (9) makes sense because, the map $(u, v) \mapsto X_t^{t_0,x_0,u,v}$ being continuous in L^1, the map $\omega \mapsto \phi\left(X_t^{t_0,x_0,u_\omega,v_\omega}\right)$ is measurable in $\Omega_\alpha \times \Omega_\beta$ and bounded. If either α or β is a pure strategy, then we simply drop α or β in the expectation $\mathbf{E}_{\alpha\beta}$, which then becomes $\mathbf{E}_\beta$ or $\mathbf{E}_\alpha$.

Proof of Lemma 2.2. The existence of (u_ω, v_ω) is simply due to the delay and proved in detail in [9]. We show here only the measurability of $\omega \to (u_\omega, v_\omega)$. For this we argue by induction by proving that the map $\omega \to (u_\omega, v_\omega)_{|[t_0,t_0+n\tau]}$ from $\Omega_\alpha \times \Omega_\beta$ into $L^1([t_0, t_0 + n\tau])$ is measurable, where τ denotes the minimum of the delays for α and β (see condition (ii) in Definition 2.1).

Let us start with $n = 1$. It is enough to show that, for any Borel subsets B_1 and B_2 of $\mathcal{U}(t_0, t_0 + \tau)$ and $\mathcal{V}(t_0, t_0 + \tau)$, the set

$$\Omega := \{\omega \in \Omega_\alpha \times \Omega_\beta \mid (u_\omega, v_\omega)_{|[t_0,t_0+\tau)} \in B_1 \times B_2\}$$

is measurable. Let us fix $\hat{u}$ and $\hat{v}$ in $\mathcal{U}(t_0)$ and $\mathcal{V}(t_0)$. Since $\alpha(\omega_1, \cdot)$ and $\beta(\omega_2, \cdot)$ are nonanticipative with delay τ, the restrictions of $\alpha(\omega_1, \hat{v})$ and $\beta(\omega_2, \hat{u})$ to $[t_0, t_0 + \tau]$ do not depend on $\hat{u}$ and $\hat{v}$. Hence $(u_\omega, v_\omega) \equiv (\alpha(\omega, \hat{v}), \beta(\omega, \hat{u}))$ a.e. in $[t_0, t_0 + \tau)$. Therefore

$$\Omega = \{\omega_1 \in \Omega_\alpha \mid \alpha(\omega_1, \hat{v})_{|[t_0,t_0+\tau)} \in B_1\} \times \{\omega_2 \in \Omega_\beta \mid \beta(\omega_2, \hat{u})_{|[t_0,t_0+\tau)} \in B_2\} ,$$

which is measurable since α and β are measurable. So the result holds true for $n = 1$.

Let us now assume that $\omega \to (u_\omega, v_\omega)_{|[t_0,t_0+n\tau]}$ from $\Omega_\alpha \times \Omega_\beta$ into $L^1([t_0, t_0 + n\tau])$ is measurable, and let us show that this still holds true for $n+1$. It is again enough to show that, for any Borel subsets B_1 and B_2 of $\mathcal{U}(t_0, t_0+(n+1)\tau)$ and $\mathcal{V}(t_0, t_0+(n+1)\tau)$, the set

$$\Omega := \{\omega \in \Omega_\alpha \times \Omega_\beta \mid (u_\omega, v_\omega)_{|[t_0,t_0+(n+1)\tau)} \in B_1 \times B_2\}$$

is measurable. Let us fix again $\hat{u}$ and $\hat{v}$ in $\mathcal{U}(t_0)$ and $\mathcal{V}(t_0)$. For any $(u, v) \in \mathcal{U}(t_0, t_0 + n\tau) \times \mathcal{V}(t_0, t_0+n\tau)$, we denote by $\tilde{u}$ and $\tilde{v}$ the maps equal to u and v on $[t_0, t_0+n\tau]$ and to $\hat{u}$ and $\hat{v}$ on $[t_0+n\tau, T]$. Note that $(u, v) \mapsto (\tilde{u}, \tilde{v})$ is continuous from L^1 to L^1. Since α and β are nonanticipative with delay τ, $u_\omega \equiv \alpha(\omega_1, \widetilde{v_\omega})$ on $[t_0, t_0 + (n + 1)\tau)$ and $v_\omega \equiv \beta(\omega_1, \widetilde{u_\omega})$ on $[t_0, t_0 + (n + 1)\tau)$. Therefore Ω is the preimage of the set $B_1 \times B_2$ by the map $\omega \to (\alpha(\omega_1, \widetilde{v_\omega}), \beta(\omega_2, \widetilde{u_\omega}))$, which is measurable as the composition of the measurable maps $\omega \mapsto (u_\omega, v_\omega)_{|[t_0,t_0+n\tau]}$, the map $(u, v) \mapsto (\tilde{u}, \tilde{v})$, and the maps α and β. Hence Ω is measurable, and the result is proved. □

We now define the payoff associated with a strategy $\hat{\alpha}$ of player 1 and a strategy $\hat{\beta}$ of player 2.

Definition of the payoff: Let $(p, q) \in \Delta(I) \times \Delta(J)$, $(t_0, x_0) \in [0, T) \times \mathbb{R}^N$, $\hat{\alpha} = (\alpha_i)_{i=1,\dots,I} \in (\mathcal{A}_r(t_0))^I$, and $\hat{\beta} = (\beta_j) \in (\mathcal{B}_r(t_0))^J$. We set

$$\mathcal{J}(t_0, x_0, \hat{\alpha}, \hat{\beta}, p, q) = \sum_{i=1}^{I} \sum_{j=1}^{J} p_i q_j \mathbf{E}_{\alpha_i \beta_j} \left(g_{ij} \left(X_T^{t_0, x_0, \alpha_i, \beta_j} \right) \right) , \tag{10}$$

where $\mathbf{E}_{\alpha_i \beta_j}$ is defined by (9). Note that $\hat{\alpha}$ does not depend on j, while $\hat{\beta}$ does not depend on i, which formalizes the asymmetry of information.

Definition of the value functions: The upper value function is given by

$$V^+(t_0, x_0, p, q) = \inf_{\hat{\alpha} \in (\mathcal{A}_r(t_0))^I} \sup_{\hat{\beta} \in (\mathcal{B}_r(t_0))^J} \mathcal{J}(t_0, x_0, \hat{\alpha}, \hat{\beta}, p, q),$$

while the lower value function is defined by

$$V^-(t_0, x_0, p, q) = \sup_{\hat{\beta} \in (\mathcal{B}_r(t_0))^J} \inf_{\hat{\alpha} \in (\mathcal{A}_r(t_0))^I} \mathcal{J}(t_0, x_0, \hat{\alpha}, \hat{\beta}, p, q) .$$

Let us emphasize that, because of the special form of the payoff, the value functions defined above *cannot* be recasted in terms of usual value functions of a zero-sum differential game with perfect information. For instance, they do not satisfy the standard dynamic programming principle, as we show in the companion paper [10].

3. Convexity properties of the value functions. The main result of this section is Lemma 3.2, which states that the value functions V^+ and V^- are convex in p and concave in q. We also investigate some regularity properties of the value functions.

LEMMA 3.1 (regularity of V^+ and V^-). *Under assumption* (5), V^+ *and* V^- *are Lipschitz continuous.*

Proof. We first note that the Lipschitz continuity of V^- and V^+ with respect to p and q just comes from the boundness of the g_{ij}. Using standard arguments, one easily shows that, for any $t_0 \in [0,T]$, $(u,v) \in \mathcal{U}(t_0) \times \mathcal{V}(t_0)$, the map

$$x \to g_{ij}\left(X_T^{t_0,x,u,v}\right)$$

is Lipschitz continuous with a Lipschitz constant independant of $t_0 \in [0,T]$. Hence for any pair of strategies $(\hat{\alpha},\hat{\beta}) \in (\mathcal{A}_r(t_0))^I \times (\mathcal{B}_r(t_0))^J$ the map

$$x \to \mathcal{J}(t,x,\hat{\alpha},\hat{\beta},p,q) = \sum_{i=1}^{I}\sum_{j=1}^{J} p_i q_j \mathbf{E}_{\alpha_i\beta_j}\left(g_{ij}(X_T^{t_0,x,\alpha_i,\beta_j})\right)$$

is C-Lipschitz continuous for some constant C independent of $t \in [0,T]$, of $p \in \Delta(I)$, and of $q \in \Delta(J)$. From this one easily deduces that V^+ and V^- are C-Lipschitz continuous with respect to x (see, for instance, [15]).

We now consider the time regularity of V^- and V^+. We do only the proof for V^-, since the case of V^+ can be treated similarly. Let $x_0 \in \mathbb{R}^N$, $(p,q) \in \Delta(I)\times\Delta(J)$, and $t_0 < t_1 < T$ be fixed. Let $\hat{\beta} = (\beta_j) \in (\mathcal{B}_r(t_0))^J$ be ϵ-optimal for $V^-(t_0,x_0,p,q)$ and $\alpha \in \mathcal{A}_r(t_1)$. Let us define, for any $j = 1,\dots,J$, $\tilde{\beta}_j \in \mathcal{B}_r(t_1)$ and $\alpha' \in \mathcal{A}_r(t_0)$ by setting (for some $\bar{u} \in U$ fixed)

$$\tilde{\beta}_j(\omega,u) = \beta_j(\omega,\tilde{u}), \text{ where } \tilde{u}(t) = \begin{cases} \bar{u} & \text{if } t \in [t_0,t_1), \\ u & \text{otherwise} \end{cases}$$

for any $\omega \in \Omega_{\tilde{\beta}_j} := \Omega_{\beta_j}$ and $u \in \mathcal{U}(t_1)$, and

$$\alpha'(\omega,v) = \begin{cases} \bar{u} & \text{if } t \in [t_0,t_1), \\ \alpha(\omega, v_{|_{[t_1,T]}}) & \text{otherwise} \end{cases} \qquad \forall \omega \in \Omega_{\alpha'} := \Omega_\alpha,\ \forall v \in \mathcal{V}(t_0)\ .$$

We note that, for any $\alpha \in \mathcal{A}_r(t_1)$ and $j = 1,\dots,J$, we have

$$\left|X_t^{t_0,x_0,\alpha',\beta_j} - X_t^{t_1,x_0,\alpha,\tilde{\beta}_j}\right| \le M|t_0 - t_1|e^{L(t-t_1)} \qquad \forall t \ge t_1$$

(where $M = \|f\|_\infty$ and f is L-Lipschitz continuous), because the pair (u_ω, v_ω) satisfying

$$\alpha'(\omega_1, v_\omega) = u_\omega \text{ and } \beta_j(\omega_2, u_\omega) = v_\omega$$

is given by $u_\omega = \bar{u}$ and $v_\omega = \beta_j(\omega_2,\bar{u})$ on $[t_0,t_1]$ and coincides on $[t_1,T]$ with the pair (u'_ω, v'_ω) satisfying

$$\alpha(\omega_1, v'_\omega) = u'_\omega \text{ and } \tilde{\beta}_j(\omega_2, u'_\omega) = v'_\omega \text{ on } [t_1,T]\ .$$

Therefore, for any $\hat\alpha = (\alpha_i) \in (\mathcal{A}_r(t_1))^I$, we have

$$\begin{aligned}
&\mathcal{J}(t_1, x_0, \hat\alpha, (\tilde\beta_j), p, q)\\
&\quad \geq\ \mathcal{J}(t_0, x_0, \hat\alpha', \hat\beta, p, q) - LM|t_0 - t_1|e^{L(T-t_1)}\\
&\quad \geq\ \inf_{\hat\alpha" \in (\mathcal{A}_r(t_0))^I} \mathcal{J}(t_0, x_0, \hat\alpha", \hat\beta, p, q) - LM|t_0 - t_1|e^{L(T-t_1)}\\
&\quad \geq\ V^-(t_0, x_0, p, q) - \epsilon - LM|t_0 - t_1|e^{L(T-t_1)}
\end{aligned}$$

(where L is also a Lipchitz constant for the g_i), because $\hat\beta$ is ϵ-optimal for $V^-(t_0, x_0, p, q)$. Since this holds for any $\hat\alpha = (\alpha_i) \in (\mathcal{A}_r(t_1))^I$ and any $\epsilon > 0$, we get

$$V^-(t_1, x_0, p, q) \geq V^-(t_0, x_0, p, q) - LM|t_0 - t_1|e^{L(T-t_1)}\ .$$

The reverse inequality can be proved in a similar way: We choose some ϵ-optimal strategy $\hat\beta = (\beta_j) \in (\mathcal{B}_r(t_1))^J$ for $V^-(t_1, x_0, p, q)$, and we extend it to a strategy $(\tilde\beta_j) \in (\mathcal{B}_r(t_0))^J$ by setting (for some $\bar v \in V$ fixed)

$$\tilde\beta_j(\omega, u) = \begin{cases} \bar v & \text{if } t \in [t_0, t_1),\\ \beta_j(\omega, u_{|_{[t_1,T]}}) & \text{otherwise} \end{cases} \qquad \forall \omega \in \Omega_{\tilde\beta_j} := \Omega_{\beta_j},\ \forall u \in \mathcal{U}(t_0)\ .$$

Then similar estimates as above show that for any $\hat\alpha \in (\mathcal{A}_r(t_0))^I$ we have

$$\mathcal{J}(t_0, x_0, \hat\alpha, (\tilde\beta_j), p, q) \geq V^-(t_1, x_0, p, q) - \epsilon - LM|t_0 - t_1|e^{L(T-t_1)}$$

from the ϵ-optimality of $\hat\beta$ for $V^-(t_1, x_0, p, q)$. Then we get

$$V^-(t_0, x_0, p, q) \geq V^-(t_1, x_0, p, q) - LM|t_0 - t_1|e^{L(T-t_1)}\ . \qquad \square$$

LEMMA 3.2 (convexity properties of V^- and V^+). *For any $(t, x) \in [0, T) \times \mathbb{R}^N$, the maps $V^+ = V^+(t, x, p, q)$ and $V^- = V^-(t, x, p, q)$ are convex in p and concave in q on $\Delta(I)$ and $\Delta(J)$, respectively.*

Remark. This result is well known for repeated games with a lack of information. The procedure we use in the proof is usually called "splitting"; see [22], for instance.

Proof of Lemma 3.2. We do only the proof for V^+; the proof for V^- can be achieved by reversing the roles of the players. One first easily checks that

$$V^+(t_0, x_0, p, q) = \inf_{(\alpha_i) \in (\mathcal{A}_r(t_0))^I} \sum_{j=1}^J q_j \sup_{\beta \in \mathcal{B}_r(t_0)} \left[\sum_{i=1}^I p_i \mathbf{E}_{\alpha_i \beta} \left(g\left(X_T^{t_0, x_0, \alpha_i, \beta} \right) \right) \right]\ .$$

Hence $q \to V^+(t, x, p, q)$ is concave for any (t, x, p).

We now prove the convexity of V^+ with respect to p. Let $(t, x, q) \in [0, T) \times \mathbb{R}^N \times \Delta(J)$, $p^0, p^1 \in \Delta(I)$, $\lambda \in (0, 1)$, and let $\hat\alpha^0 = (\alpha_i^0) \in (\mathcal{A}_r(t))^I$ and $\hat\alpha^1 = (\alpha_i^1) \in (\mathcal{A}_r(t))^I$ be ϵ-optimal for $V^+(t, x, p^0, q)$ and $V^+(t, x, p^1, q)$, respectively ($\epsilon > 0$). Let us set $p^\lambda = (1 - \lambda)p^0 + \lambda p^1$. We can assume without loss of generality that $p_i^\lambda \neq 0$ for any i (because if $p_i^\lambda = 0$, then $p_i^0 = p_i^1 = 0$, so that this index i plays no role in our computation). We now define the strategy $\hat\alpha^\lambda = (\alpha_i^\lambda) \in (\mathcal{A}_r(t))^I$ by setting

$$\Omega_{\alpha_i^\lambda} = [0, 1] \times \Omega_{\alpha_i^0} \times \Omega_{\alpha_i^1},\ \mathcal{F}_{\alpha_i^\lambda} = B([0, 1]) \otimes \mathcal{F}_{\alpha_i^0} \otimes \mathcal{F}_{\alpha_i^1},\ \mathbf{P}_{\alpha_i^\lambda} = \mathcal{L}^1 \otimes \mathbf{P}_{\alpha_i^0} \otimes \mathbf{P}_{\alpha_i^1}$$

(where $B([0, 1])$ is the Borel σ-field and $\mathcal{L}^1$ the Lebesgue measure on $[0, 1]$) and

$$\alpha_i^\lambda(\omega_1, \omega_2, \omega_3, v) = \begin{cases} \alpha_i^0(\omega_2, v) & \text{if } \omega_1 \in [0, \frac{(1-\lambda)p_i^0}{p_i^\lambda}),\\ \alpha_i^1(\omega_3, v) & \text{if } \omega_1 \in [\frac{(1-\lambda)p_i^0}{p_i^\lambda}, 1] \end{cases}$$

for any $(\omega_1, \omega_2, \omega_3) \in \Omega_{\alpha_i^\lambda}$ and $v \in \mathcal{V}(t)$. We note that $(\Omega_{\alpha_i^\lambda}, \mathcal{F}_{\alpha_i^\lambda}, \mathbf{P}_{\alpha_i^\lambda})$ belongs to the set of probability spaces $\mathcal{S}$ and that α_i^λ belongs to $\mathcal{A}_r(t_0)$ for any $i = 1, \dots, I$.

The interpretation of the strategy $\hat{\alpha}^\lambda$ is the following: If the index i is chosen according to the probability p^λ, then player 1 chooses α_i^0 with probability $\frac{(1-\lambda)p_i^0}{p_i^\lambda}$ and α_i^1 with probability $1 - \frac{(1-\lambda)p_i^0}{p_i^\lambda} = \frac{\lambda p_i^1}{p_i^\lambda}$. Hence the probability for the strategy α_i^0 to be chosen is $p_i^\lambda \frac{(1-\lambda)p_i^0}{p_i^\lambda} = (1-\lambda)p_i^0$, while the strategy α_i^1 appears with probability $p_i^\lambda \frac{\lambda p_i^1}{p_i^\lambda} = \lambda p_i^1$. Therefore

$$\begin{aligned}
\sup_{\hat{\beta}} \mathcal{J}(t,x,\hat{\alpha}^\lambda,\hat{\beta},p^\lambda,q) &= \sum_j q_j \sup_\beta \sum_i p_i^\lambda \mathbf{E}_{\alpha_i^\lambda,\beta}\left(g_{ij}(X_T^{t,x,\alpha_i^\lambda,\beta})\right) \\
&= \sum_j q_j \sup_\beta \sum_i p_i^\lambda \left[\frac{(1-\lambda)p_i^0}{p_i^\lambda}\mathbf{E}_{\alpha_i^0,\beta}\left(g_{ij}(X_T^{t,x,\alpha_i^0,\beta})\right) + \frac{\lambda p_i^1}{p_i^\lambda}\mathbf{E}_{\alpha_i^1,\beta}\left(g_{ij}(X_T^{t,x,\alpha_i^1,\beta})\right)\right] \\
&\le (1-\lambda)\sum_j q_j \sup_\beta \sum_i p_i^0 \mathbf{E}_{\alpha_i^0,\beta}\left(g_{ij}(X_T^{t,x,\alpha_i^0,\beta})\right) \\
&\qquad + \lambda \sum_j q_j \sup_\beta \sum_i p_i^1 \mathbf{E}_{\alpha_i^1,\beta}\left(g_{ij}(X_T^{t,x,\alpha_i^1,\beta})\right) \\
&\le (1-\lambda)V^+(t,x,p^0,q) + \lambda V^+(t,x,p^1,q) + \epsilon,
\end{aligned}$$

because $\hat{\alpha}^0$ and $\hat{\alpha}^1$ are ϵ-optimal for $V^+(t,x,p^0,q)$ and $V^+(t,x,p^1,q)$, respectively. Therefore

$$\begin{aligned}
V^+(t,x,p^\lambda,q) &\le \sup_{\hat{\beta}} \mathcal{J}(t,x,\hat{\alpha}^\lambda,\hat{\beta},p^\lambda,q) \\
&\le (1-\lambda)V^+(t,x,p^0) + \lambda V^+(t,x,p^1) + \epsilon\,,
\end{aligned}$$

which proves the desired claim because ϵ is arbitrary. □

The convexity properties of the value functions lead one naturally to consider their Fenchel conjugates. Let $w : [0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J) \mapsto \mathbb{R}$ be some function. We denote by w^* its convex conjugate with respect to variable p:

$$w^*(t,x,\hat{p},q) = \sup_{p \in \Delta(I)} \hat{p}.p - w(t,x,p,q) \qquad \forall (t,x,\hat{p},q) \in [0,T] \times \mathbb{R}^N \times \mathbb{R}^I \times \Delta(J)\,.$$

In particular V^{-*} and V^{+*} denote the convex conjugate with respect to the p-variable of the functions V^- and V^+.

For a function $w = w(t,x,\hat{p},q)$ defined on the dual space $[0,T] \times \mathbb{R}^N \times \mathbb{R}^I \times \Delta(J)$, we also denote by w^* its convex conjugate with respect to $\hat{p}$ defined on $[0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J)$:

$$w^*(t,x,p,q) = \sup_{\hat{p} \in \mathbb{R}^I} p.\hat{p} - w(t,x,p,q) \qquad \forall (t,x,p,q) \in [0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J)\,.$$

In a symmetric way, we denote by $w^\sharp = w^\sharp(t,x,p,\hat{q})$ the concave conjugate with respect to q of w:

$$w^\sharp(t,x,p,\hat{q}) = \inf_{q \in \Delta(J)} \hat{q}.q - w(t,x,p,q) \qquad \forall (t,x,p,\hat{q}) \in [0,T] \times \mathbb{R}^N \times \Delta(I) \times \mathbb{R}^J\,.$$

4. The subdynamic programming. The main result of this section is that $V^{+\sharp}$ and V^{-*} are subsolutions of the dual HJ equation. To fix the ideas, we study here the case of V^{-*} and deduce at the very end of the section the symmetric results for $V^{+\sharp}$.

LEMMA 4.1 (reformulation of V^{-*}). *We have*

$$V^{-*}(t,x,\hat{p},q) = \inf_{(\beta_j)\in(\mathcal{B}_r(t_0))^J} \sup_{\alpha\in\mathcal{A}_r(t_0)} \max_{i\in\{1,\dots,I\}} \left\{ \hat{p}_i - \sum_{j=1}^J q_j \mathbf{E}_{\alpha\beta_j}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j})\right)\right\}. \tag{11}$$

Proof of Lemma 4.1. Let us note for later use that

$$\begin{aligned} V^-(t,x,p,q) &:= \sup_{\beta_j}\inf_{\alpha_i}\sum_{i,j} p_i q_j \mathbf{E}_{\alpha_i\beta_j}\left(g_{ij}(X_T^{t,x,\alpha_i,\beta_j})\right) \\ &= \sup_{\beta_j}\sum_i p_i \inf_\alpha \sum_j q_j \mathbf{E}_{\alpha\beta_j}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j})\right), \end{aligned} \tag{12}$$

because player 1 can choose—and indeed chooses—his strategy $\hat{\alpha}=(\alpha_i)$ such that α_i minimizes $\sum_j q_j \mathbf{E}_{\alpha\beta_j}\left(g_{ij}(X_T^{t,x,\alpha_i,\beta_j})\right)$.

Let us denote by $z = z(t,x,\hat{p},q)$ the right-hand side of equality (11). We first claim that

$$z \text{ is convex with respect to } \hat{p}. \qquad \square \tag{13}$$

Proof of (13). The proof mimics the proof of the convexity of V^+. Let $(t,x,q)\in[0,T)\times\mathbb{R}^N\times\Delta(J)$, $\hat{p}^0,\hat{p}^1\in\mathbb{R}^I$, $\lambda\in(0,1)$, and let $(\beta_j^0)\in(\mathcal{B}_r(t))^J$ and $(\beta_j^1)\in(\mathcal{B}_r(t))^J$ be ϵ-optimal for $z(t,x,\hat{p}^0,q)$ and $z(t,x,\hat{p}^1,q)$, respectively ($\epsilon>0$). Let us set $\hat{p}^\lambda = (1-\lambda)\hat{p}^0+\lambda\hat{p}^1$. We define the strategies $\beta_j^\lambda\in\mathcal{B}_r(t)$ by setting

$$\Omega_{\beta_j^\lambda} = [0,1]\times\Omega_{\beta_j^0}\times\Omega_{\beta_j^1},\ \mathcal{F}_{\beta_j^\lambda} = B([0,1])\otimes\mathcal{F}_{\beta_j^0}\otimes\mathcal{F}_{\beta_j^1},\ \mathbf{P}_{\beta_j^\lambda} = \mathcal{L}^1\otimes\mathbf{P}_{\beta_j^0}\otimes\mathbf{P}_{\beta_j^1},$$

and

$$\beta_j^\lambda(\omega_1,\omega_2,\omega_3,u) = \begin{cases} \beta_j^0(\omega_2,u) & \text{if } \omega_1\in[0,(1-\lambda)),\\ \beta_j^1(\omega_3,u) & \text{if } \omega_1\in[(1-\lambda),1]\end{cases}$$

for any $(\omega_1,\omega_2,\omega_3)\in\Omega_{\beta_j^\lambda}$ and $u\in\mathcal{U}(t)$. Then $(\Omega_{\beta_j^\lambda},\mathcal{F}_{\beta_j^\lambda},\mathbf{P}_{\beta_j^\lambda})$ belongs to $\mathcal{S}$ and $(\beta_j^\lambda)\in(\mathcal{B}_r(t_0))^J$. For any $\alpha\in\mathcal{A}_r(t)$, we have by using the convexity of the map $(s_i)\mapsto\max_i\{s_i\}$:

$$\begin{aligned} &\max_i\left\{\hat{p}_i^\lambda - \sum_j q_j\mathbf{E}_{\alpha,\beta_j^\lambda}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j^\lambda})\right)\right\} \\ &= \max_i\left\{(1-\lambda)\left(\hat{p}_i^0 - \sum_j q_j\mathbf{E}_{\alpha\beta_j^0}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j^0})\right)\right)\right. \\ &\qquad\left. +\lambda\left(\hat{p}_i^1 - \sum_j q_j\mathbf{E}_{\alpha\beta_j^1}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j^1})\right)\right)\right\} \\ &\le (1-\lambda)\sup_\alpha\max_i\left\{\hat{p}_i^0 - \sum_j q_j\mathbf{E}_{\alpha\beta_j^0}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j^0})\right)\right\} \\ &\qquad +\lambda\sup_\alpha\max_i\left\{\hat{p}_i^1 - \sum_j q_j\mathbf{E}_{\alpha\beta_j^1}\left(g_{ij}(X_T^{t,x,\alpha,\beta_j^1})\right)\right\} \\ &\le (1-\lambda)z(t,x,\hat{p}^0,q) + \lambda z(t,x,\hat{p}^1,q) + \epsilon, \end{aligned}$$

because β^0 and β^1 are ϵ-optimal for $z(t,x,\hat{p}^0,q)$ and $z(t,x,\hat{p}^1,q)$, respectively. Hence

$$\begin{aligned} z(t,x,\hat{p}^\lambda,q) &\le \sup_\alpha \max_i \left\{ \hat{p}_i^\lambda - \sum_j q_j \mathbf{E}_{\alpha,\beta_j^\lambda} \left(g_{ij}(X_T^{t,x,\alpha,\beta_j^\lambda}) \right) \right\} \\ &\le (1-\lambda) z(t,x,q^0) + \lambda z(t,x,q^1) + \epsilon \,, \end{aligned}$$

which proves the desired claim because ϵ is arbitrary.

Next we show that $V^{-*} = z$. Indeed we have by definition of z:

$$\begin{aligned} z^*(t,x,p,q) &= \sup_{\hat{p}} p.\hat{p} - \inf_{(\beta_j)} \max_i \left\{ \hat{p}_i - \inf_\alpha \sum_j q_j \mathbf{E}_{\alpha\beta_j} \left(g_{ij}(X_T^{t,x,\alpha,\beta_j}) \right) \right\} \\ &= \sup_{(\beta_j)} \sup_{\hat{p}} \min_i \left\{ p.\hat{p} - \hat{p}_i + \inf_\alpha \sum_j q_j \mathbf{E}_{\alpha\beta_j} \left(g_{ij}(X_T^{t,x,\alpha,\beta_j}) \right) \right\} . \end{aligned}$$

In this last expression, the $\sup_{\hat{p}}$ is attained by

$$\hat{p}_i = \inf_\alpha \sum_j q_j \mathbf{E}_{\alpha\beta_j} \left(g_{ij}(X_T^{t,x,\alpha,\beta_j} \right) \,,$$

for which all of the arguments of the $\min_i$ are equal. Hence

$$\begin{aligned} z^*(t,x,p,q) &= \sup_{\beta_j} \sum_i p_i \inf_\alpha \sum_j q_j \mathbf{E}_{\alpha\beta_j} \left(g_{ij}(X_T^{t,x,\alpha,\beta_j}) \right) \\ &= V^-(t,x,p,q) \end{aligned}$$

because of (12). Since we have proved that z is convex with respect to $\hat{p}$, we get by duality $V^{-*} = z^{**} = z$. □

LEMMA 4.2 (subdynamic principle for V^{-*}). *We have for any* $(t_0,x_0,\hat{p},q) \in [0,T) \times \mathbb{R}^N \times \mathbb{R}^I \times \Delta(J)$ *and any* $t_1 \in (t_0,T]$

$$V^{-*}(t_0,x_0,\hat{p},q) \le \inf_{\beta \in \mathcal{B}(t_0)} \sup_{\alpha \in \mathcal{A}(t_0)} V^{-*}(t_1, X_{t_1}^{t_0,x_0,\alpha,\beta}, \hat{p}, q) \,.$$

Proof. Let us denote by $V_1^{-*}(t_0,t_1,x_0,\hat{p},q)$ the right-hand side of the above inequality. Arguing as in Lemma 3.1 one can prove that V_1^{-*} is Lipschitz continuous with respect to x. We also note that player 1 can play in pure strategies in V^{-*}, namely,

$$V^{-*}(t,x,\hat{p},q) = \inf_{(\beta_j) \in (\mathcal{B}_r(t))^J} \sup_{\alpha \in \mathcal{A}(t)} \max_{i \in \{1,\dots,I\}} \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\beta_j} \left[g_{ij}(X_T^{t,x,\alpha,\beta_j}) \right] \right\} \tag{14}$$

for any $(t,x,\hat{p},q) \in [0,T) \times \mathbb{R}^N \times \mathbb{R}^I \times \Delta(J)$. Indeed, we have from Lemma 4.1 that

$$\begin{aligned} &V^{-*}(t,x,\hat{p},q) = \\ &\inf_{(\beta_j) \in (\mathcal{B}_r(t_0))^J} \sup_{\alpha \in \mathcal{A}_r(t_0)} \max_{i \in \{1,\dots,I\}} \left\{ \hat{p}_i - \sum_{j=1}^J q_j \mathbf{E}_{\alpha\beta_j} \left(g_{ij}(X_T^{t,x,\alpha,\beta_j}) \right) \right\} . \end{aligned}$$

Hence the inequality "$\geq$" in (14) is obvious because $\mathcal{A}(t) \subset \mathcal{A}_r(t)$. To prove the reverse inequality we first note that, for any $\alpha \in \mathcal{B}_r(t_0)$ and for any $\omega_1 \in \Omega_\alpha$, $\alpha(\omega_1, \cdot)$ belongs to $\mathcal{A}(t_0)$. Let us fix $(\beta_j) \in (\mathcal{B}(t))^J$. We have, from the convexity of $(s_i) \mapsto \max_i\{s_i\}$,

$$\begin{aligned}
&\sup_{\alpha\in\mathcal{A}_r(t)} \max_i \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\alpha\beta_j}(g_{ij}(X_T^{t,x,\alpha,\beta_j})) \right\} \\
&\quad \leq \sup_{\alpha\in\mathcal{A}_r(t)} \int_{\Omega_\alpha} \max_i \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\beta_j}(g_{ij}(X_T^{t,x,\alpha(\omega_1,\cdot),\beta_j})) \right\} dP_\alpha(\omega_1) \\
&\quad \leq \sup_{\alpha\in\mathcal{A}_r(t)} \sup_{\omega_1\in\Omega_\alpha} \max_i \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\beta_j}(g_{ij}(X_T^{t,x,\alpha(\omega_1,\cdot),\beta_j})) \right\} \\
&\quad \leq \sup_{\alpha\in\mathcal{A}(t)} \max_i \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\beta_j}(g_{ij}(X_T^{t,x,\alpha,\beta_j})) \right\}.
\end{aligned}$$

Taking the infimum over $(\beta_j) \in (\mathcal{B}(t))^J$ gives (14).

Let $\epsilon > 0$ and $\beta^0 \in \mathcal{B}(t_0)$ be some pure ϵ-optimal strategy for $V_1^{-*}(t_0, t_1, x_0, \hat{p}, q)$. For any $x \in \mathbb{R}^N$, we can find some ϵ-optimal strategy $\hat{\beta}^x = (\beta_j^x) \in \mathcal{B}_r(t_1)$ for player 2 in the game $V^{-*}(t_1, x, \hat{p}, q)$. From the Lipschitz continuity of the map

$$y \to \sup_{\alpha\in\mathcal{A}(t)} \max_{i\in\{1,\ldots,I\}} \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\beta_j^x} \left[g_{ij}(X_T^{t,y,\alpha,\beta_j^x}) \right] \right\},$$

and of $y \to V^{-*}(t_1, y, \hat{p}, q)$, β^x is also (2ϵ)-optimal for $V^{-*}(t_1, y, \hat{p}, q)$ if $y \in B_r(x)$ for some radius $r > 0$. Using the fact that f is bounded, one can show that the reachable states from (t_0, x_0) by using the differential equation (1) is bounded and contained in some ball $B_R(0)$. Let us set $M = \|f\|_\infty$, and let us fix $\sigma > 0$ small such that $M\sigma \leq r/2$. Then we choose $(x_l)_{l=1,\ldots,l_0}$ such that $\bigcup_{l=1}^{l_0} B_{r/2}(x_l)$ contains the ball $B_R(0)$. Let $(E_l)_{l=1,\ldots,l_0}$ be a Borel partition of $B_R(0)$ such that, for any l, $E_l \subset B_{r/2}(x_l)$. We set

$$\beta_j^l = \beta_j^{x_l},\ \Omega_j^l = \Omega_{\beta_j^l},\ \mathcal{F}_j^l = \mathcal{F}_{\beta_j^l},\ \text{and } \mathbf{P}_j^l = \mathbf{P}_{\beta_j^l}$$

for $j = 1, \ldots, J$ and $l = 1, \ldots, l_0$. We choose some delay $\tau \in (0, \sigma]$ common to all of the strategies β_j^l.

We note for later use that, if for some controls $(u, v) \in \mathcal{U}(t_0) \times \mathcal{V}(t_0)$ and for some l, we have $X_{t_1-\tau}^{t_0,x_0,u,v} \in E_l$, then

$$|X_{t_1-\tau}^{t_0,x_0,u,v} - X_{t_1}^{t_0,x_0,u,v}| \leq \|f\|_\infty \tau \leq M\sigma \leq r/2\,,$$

so that $X_{t_1}^{t_0,x_0,u,v}$ belongs to $B_r(x_l)$. In particular $(\beta_j^l)_j$ is (2ϵ)-optimal for V^+ at $(t_1, X_{t_1}^{t_0,x_0,u,v}, \hat{p}, q)$. To summarize

$$X_{t_1-\tau}^{t_0,x_0,u,v} \in E_l \ \Rightarrow\ (\beta_j^l)_j \text{ is } (2\epsilon)\text{-optimal for } V^{-*} \text{ at } (t_1, X_{t_1}^{t_0,x_0,u,v}, \hat{p}, q). \tag{15}$$

Let us now define a new strategy $\hat{\beta} = (\beta_j) \in (\mathcal{B}_r(t_0))^J$ in the following way: Set

$$\Omega_{\beta_j} = \Pi_{l=1}^{l_0} \Omega_j^l,\ \mathcal{F}_{\beta_j} = \mathcal{F}_j^1 \otimes \ldots \otimes \mathcal{F}_j^{l_0}, \text{and } \mathbf{P}_{\beta_j} = \mathbf{P}_j^1 \otimes \ldots \otimes \mathbf{P}_j^{j_0},$$

and, for any $\omega = (\omega^1, \dots, \omega^{l_0}) \in \Omega_{\beta_j}$ and $u \in \mathcal{U}(t_0)$, set

$$\beta_j(\omega, u)(t) = \begin{cases} \beta^0(u)(t) & \text{if } t \in [t_0, t_1), \\ \beta_j^l(\omega^l, u_{|_{[t_1,T]}})(t) & \text{if } t \in [t_1, T] \text{ and } X_{t_1-\tau}^{t_0,x_0,u,\beta^0(u)} \in E_l. \end{cases}$$

Then $(\Omega_{\beta_j}, \mathcal{F}_{\beta_j}, \mathbf{P}_{\beta_j})$ belongs to $\mathcal{S}$ and $\hat{\beta} = (\beta_j) \in (\mathcal{B}_r(t_0))^J$.

For any pure strategy $\alpha \in \mathcal{A}(t_0)$, we have

$$g_{ij}(X_T^{t_0,x_0,\alpha,\beta_j}) = \sum_{l=1}^{l_0} g_{ij}\left(X_T^{t_1, X_{t_1}^{t_0,x_0,\alpha,\beta^0}, \tilde{\alpha}, \beta_j^l}\right) \mathbf{1}_{\{X_{t_1-\tau}^{t_0,x_0,\alpha,\beta^0} \in E_l\}},$$

where $\tilde{\alpha} \in \mathcal{A}(t_1)$ is a restriction of α to the time interval $[t_1, T]$ defined by

$$\tilde{\alpha}(v) = \alpha(v') \qquad \forall v \in \mathcal{V}(t_1), \text{ where } v'(t) = \begin{cases} \bar{v}(t) & \text{if } t \in [t_0, t_1], \\ v(t) & \text{otherwise,} \end{cases}$$

the controls $(\bar{u}, \bar{v})$ being the pair associated with (α, β^0) as in (8). Hence

$$\max_{i \in \{1,\dots,I\}} \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\beta_j} \left(g_{ij}(X_T^{t_0,x_0,\alpha,\beta_j}) \right) \right\} =$$

$$\max_{i \in \{1,\dots,I\}} \left\{ \hat{p}_i - \sum_j q_j \sum_{l=1}^{l_0} \left(\int_{\Omega_j^l} g_{ij}\left(X_T^{t_1, X_{t_1}^{t_0,x_0,\alpha,\beta^0}, \tilde{\alpha}, \beta_j^l}\right) d\mathbf{P}_j^l(\omega^l) \right) \mathbf{1}_{O^l} \right\}$$

(where we have set $O^l = \{X_{t_1-\tau}^{t_0,x_0,\alpha,\beta^0} \in E_l\}$)

$$\leq \sum_{l=1}^{l_0} \sup_{\alpha' \in \mathcal{B}(t_1)} \max_{i \in \{1,\dots,I\}} \left\{ \hat{p}_i - \sum_j q_j \left(\int_{\Omega_j^l} g_{ij}\left(X_T^{t_1, X_{t_1}^{t_0,x_0,\alpha,\beta^0}, \alpha', \beta_j^l}\right) d\mathbf{P}_j^l(\omega^l) \right) \right\} \mathbf{1}_{O^l}$$

(because of the convexity of the map $s = (s_i) \mapsto \max\{s_i\}$)

$$\leq \sum_{l=1}^{l_0} \left(V^{-*}\left(t_1, X_{t_1}^{t_0,x_0,\alpha,\beta^0}, \hat{p}, q\right) + 2\epsilon \right) \mathbf{1}_{O^l}$$

(because of (15))

$$= V^{-*}\left(t_1, X_{t_1}^{t_0,x_0,\alpha,\beta^0}, \hat{p}, q\right) + 2\epsilon$$

$$\leq V_1^{-*}(t_0, t_1, x_0, \hat{p}, q) + 3\epsilon \,,$$

because β^0 is ϵ-optimal for $V_1^{-*}(t_0, t_1, x_0, \hat{p}, q)$.

From this we conclude easily that

$$V^{-*}(t_0, x_0, \hat{p}, q) \leq V_1^{-*}(t_0, t_1, x_0, \hat{p}, q) \,. \qquad \square$$

COROLLARY 4.3 (V^{-*} is a subsolution of HJ). *For any $(\hat{p}, q) \in \mathbb{R}^I \times \Delta(J)$, the map $(t, x) \mapsto V^{-*}(t, x, \hat{p}, q)$ is a viscosity subsolution of the dual Hamilton–Jacobi equation:*

$$w_t + H^*(x, Dw) = 0 \text{ in } [0, T] \times \mathbb{R}^N \,, \tag{16}$$

where H is defined by (6) *and $H^*(x, \xi) = -H(x, -\xi)$.*

Remark. From the definition of H, we have

$$H^*(x,\xi) := \sup_{u\in U}\inf_{v\in V} f(x,u,v).\xi = \inf_{v\in V}\sup_{u\in U} f(x,u,v).\xi. \tag{17}$$

Proof of Corollary 4.3. It is well known that a function satisfying a subdynamic programming principle is a subsolution of the associated HJ equation when the game is played with classical nonanticipative strategies (see [15]). We give a short proof of this fact in the framework of nonanticipative strategies with delay. Let $(\hat{p},q)\in\mathbb{R}^I\times\Delta(J)$ be fixed, and let ϕ be a smooth test function such that

$$\phi(t,x)\geq V^{-*}(t,x,\hat{p},q) \qquad \forall (t,x)\in[0,T]\times\mathbb{R}^N\ , \tag{18}$$

with an equality at (t_0,x_0), where $t_0\in[0,T)$. For any $v\in V$, let us define the pure strategy $\beta\in\mathcal{B}(t_0)$ by setting

$$\beta(u)(t) = v \qquad \forall u\in\mathcal{U}(t_0),\ t\in[t_0,T]\ .$$

Let us fix $\epsilon>0$ and $h>0$ small.

Since V^{-*} satisfies the subdynamic programming principle of Lemma 4.2, there is some strategy $\alpha_h\in\mathcal{A}(t_0)$ such that

$$V^{-*}(t_0,x_0,\hat{p},q)\leq V^{-*}(t_0+h,X_{t_0+h}^{t_0,x_0,\alpha_h,\beta},\hat{p},q)+\epsilon h\ . \tag{19}$$

Let us set $u_h(s)=\alpha_h(v)(s)$ and $x_h(s)=X_s^{t_0,x_0,\alpha_h,\beta}=X_s^{t_0,x_0,u_h,v}$. Then

$$x_h(t_0+h)=x_0+\int_{t_0}^{t_0+h} f(x_h(s),u_h(s),v)ds = x_0+\int_{t_0}^{t_0+h} f(x_0,u_h(s),v)ds+h\epsilon(h),$$

where $\epsilon(h)\mapsto 0$ as $h\to 0^+$. From (18) and (19) we have

$$\begin{aligned}
0 \ &\leq\ V^{-*}(t_0+h,X_{t_0+h}^{t_0,x_0,\alpha_h,\beta},\hat{p},q)-V^{-*}(t_0,x_0,\hat{p},q)+\epsilon h\\
&\leq\ \phi\left(t_0+h,x_0+\int_{t_0}^{t_0+h} f(x_0,u_h(s),v)ds+h\epsilon(h)\right)ds-\phi(t_0,x_0)+\epsilon h\\
&\leq\ h\phi_t(t_0,x_0)+\int_{t_0}^{t_0+h} D\phi(t_0,x_0).f(x_0,u_h(s),v)ds+h\epsilon_1(h)+\epsilon h\\
&\leq\ h\phi_t(t_0,x_0)+h\sup_{u\in U} D\phi(t_0,x_0).f(x_0,u,v)+h\epsilon_1(h)+\epsilon h
\end{aligned}$$

where $\epsilon_1(h)\mapsto 0$ as $h\to 0^+$. Dividing the last inequality by $h>0$ and letting $h\to 0^+$ gives

$$\phi_t(t_0,x_0)+\sup_{u\in U} D\phi(t_0,x_0).f(x_0,u,v)\geq -\epsilon\ .$$

Then we let $\epsilon\to 0^+$, take the minimum over $v\in V$, and use (17) to get the desired inequality:

$$\phi_t(t_0,x_0,p)+H^*(x_0,D\phi(t_0,x_0))\geq 0\ . \qquad \square$$

To state the symmetric results for $V^{+\sharp}$, we need only to note that

$$-V^+(t,x,p,q)=\sup_{\hat{\alpha}\in(\mathcal{A}_r(t_0))^I}\inf_{\hat{\beta}\in(\mathcal{B}_r(t_0))^J}\sum_{i=1}^I\sum_{j=1}^I p_iq_j\mathbf{E}_{\alpha_i\beta_j}\left((-g_{ij})\left(X_T^{t_0,x_0,\alpha_i,\beta_j}\right)\right)\ ,$$

which is of the same form as V^- when one changes the roles of the players. In particular the convex Fenchel conjugate of $(-V^+)$ with respect to q, i.e., $-V^{+\sharp}(-\hat{q})$, satisfies a subdynamic programming principle and is therefore a subsolution of some associated Hamilton–Jacobi equation. From this we easily deduce the following.

COROLLARY 4.4 ($V^{+\sharp}$ is a supersolution of HJ). *For any* $(t_0, t_1, x_0, p, \hat{q}) \in [0,T] \times [0,T] \times \mathbb{R}^N \times \Delta(I) \times \mathbb{R}^J$, *we have*

$$V^{+\sharp}(t_0, x_0, p, \hat{q}) \geq \sup_{\alpha \in \mathcal{A}(t_0)} \inf_{\beta \in \mathcal{B}(t_0)} V^{+\sharp}(t_1, X_{t_1}^{t_0,x_0,\alpha,\beta}, p, \hat{q}) \ .$$

Hence $V^{+\sharp}$ *is a supersolution of the dual Hamilton–Jacobi equation* (16).

Remark. We use here Isaacs' assumption (6). Indeed, if V^{-*} is a subsolution of the HJ equation (16) with $H^*(x,\xi) = \inf_u \sup_v f(x,u,v).\xi$, $V^{+\sharp}$ is actually a supersolution of (16) with a Hamiltonian H^* defined by $H^*(x,\xi) = \sup_v \inf_u f(x,u,v).\xi$.

5. Existence of the value and solutions of the primal/dual HJ equations. In this section we prove that our game has a value: $V^+ = V^-$. This value can be characterized in terms of dual solutions of some HJ equations.

The key argument for this is the following comparison principle, which we state for later use for a general Hamiltonian H. We assume that $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ is continuous, and we suppose that there is a constant C such that, for any $x_1, x_2 \in \mathbb{R}^N$ and $\theta \geq 0$,

$$|H(x_1, \theta(x_1 - x_2)) - H(x_2, \theta(x_1 - x_2))| \leq C|x_1 - x_2|(1 + \theta|x_1 - x_2|) \ . \tag{20}$$

Let us point out that the map H defined by (6) satisfies the above assumptions under conditions (5) on the dynamics.

Recall that, for any map $w = w(t,x,p,q)$ defined on $[0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J)$, w^* denotes the convex Fenchel conjugate of w with respect to p, while $w^\sharp$ denotes its concave Fenchel conjugate with respect to q.

We now consider a Hamilton–Jacobi equation of the form:

$$z_t + H(x, Dz) = 0 \ . \tag{21}$$

We say that a function $w : [0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J) \mapsto \mathbb{R}$ is a *dual subsolution of* (21) if w is Lipschitz continuous, convex with respect to p, and concave with respect to q and if, for any $(p, \hat{q}) \in \Delta(I) \times \mathbb{R}^J$, $(t,x) \mapsto w^\sharp(t,x,p,\hat{q})$ is a supersolution of the dual HJ equation

$$z_t + H^*(x, Dz) = 0 \ , \tag{22}$$

where $H^*(x,\xi) = -H(x,-\xi)$. In a symmetric way, w is a *dual supersolution of the HJ equation* (21) if w is Lipschitz continuous, convex with respect to p, and concave with respect to q and if, for any for any $(\hat{p}, q) \in \mathbb{R}^I \times \Delta(J)$, $(t,x) \mapsto w^*(t,x,\hat{p},q)$ is a subsolution of the dual HJ equation (22). We say that w is a *dual solution of* (21) if w is at the same time a dual subsolution and a dual supersolution of (21).

THEOREM 5.1 (comparison principle). *Let* $w_1, w_2 : [0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J) \mapsto \mathbb{R}$ *be, respectively, a dual subsolution and a dual supersolution of the HJ equation* (21). *We assume that for any* $(x,p,q) \in \mathbb{R}^N \times \Delta(I) \times \Delta(J)$, $w_1(T,x,p,q) \leq w_2(T,x,p,q)$. *Then* $w_1 \leq w_2$ *in* $[0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J)$.

Remarks.

1. We cannot compare $w_1^\sharp$ and w_2^* at time $t = T$. So this result is *not* an application of the classical comparison principle.

2. It is known that, if w_2 is a supersolution of the HJ equation (21), then w_2^* is a subsolution of the dual HJ equation (22) (see, for instance, [1]). The converse does not hold true in general, and so we cannot rephrase the assumptions in term of sub- and supersolutions of (21) for w_1 and w_2. However, it turns out that w_2, for instance, is a supersolution at "some suitable points," related with its convexity property with respect to p. We explain this more precisely in Lemma 5.4 below.
3. The result can be extended to bounded uniformly continuous subsolutions by standard techniques (see [3], for instance).

The comparison principle is proved at the end of the section. Let us now state the main result of this paper.

THEOREM 5.2 (existence of the value). *Assume that conditions* (5) *on f and on the g_i hold and that Isaacs' assumption* (6) *is satisfied. Then we have*

$$V^+(t,x,p,q) = V^-(t,x,p,q) \qquad \forall (t,x,p) \in [0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J)\ .$$

Proof of Theorem 5.2. From Lemma 3.1, V^- and V^+ are Lipschitz continuous. From Lemma 3.2, we know that V^+ and V^- are convex with respect to p and concave with respect to q. Corollary 4.3 states that, for any $(\hat{p},q) \in \mathbb{R}^I \times \Delta(J)$, $V^{-*}(\cdot,\cdot,\hat{p},q)$ is a subsolution of the dual HJ equation (16). Hence V^- is a dual supersolution of (7). Corollary 4.4 states that $V^{+\sharp}(\cdot,\cdot,p,\hat{q})$ is a supersolution of the HJ equation (16) for any $(p,\hat{q}) \in \Delta(I) \times \mathbb{R}^J$ and therefore a dual subsolution of (7). Since $V^+(T,\cdot,p,q) = V^-(T,\cdot,p,q) = \sum_{i,j} p_i q_j g_{ij}$, the comparison principle states that $V^+ \le V^-$. But the reverse inequality always holds. Hence $V^- = V^+$ and the game has a value. □

The above proof also shows the following.

COROLLARY 5.3 (characterization of the value). *Under the assumptions of Theorem* 5.2*, the value function $V := V^+ = V^-$ is the unique dual solution of the HJ equations* (7)*, such that $V(T,x,p,q) = \sum_{ij} p_i q_j g_{ij}(x)$.*

We complete this section by an equivalent formulation of the notion of dual supersolution. Although the result is not needed in the rest of the text, we think that it can help to enlighten the notion.

LEMMA 5.4. *Let $w : [0,T] \times \mathbb{R}^N \times \Delta(I) \times \Delta(J) \mapsto \mathbb{R}$ be Lipschitz continuous, convex with respect to p, and concave with respect to q. Then the following statements are equivalent:*

(i) *w is a dual supersolution of* (21)*;*

(ii) *for any $q \in \Delta(J)$, for any test function $\phi = \phi(t,x,p)$ which is $\mathcal{C}^1$ and convex in p and such that*

$$(t,x,p) \mapsto w(t,x,p,q) - \phi(t,x,p)$$

has a strict global minimum at some point $(t_0,x_0,p_0) \in [0,T) \times \mathbb{R}^N \times \Delta(I)$, we have

$$\phi_t(t_0,x_0,p_0) + H(x_0, D\phi(t_0,x_0,p_0)) \le 0\ . \tag{23}$$

Remarks.

1. This result means that a dual supersolution of (21)—originally defined in terms of subsolution of the dual HJ equation—is indeed a supersolution of the primal HJ equation (21) in weak sense. However, it is not a classical supersolution. For instance, if $I = 1$, $f = f(u,v)$, and $g_j(x) = a_j.x$ for some

$a_j \in \mathbb{R}^N$ $(j = 1, \dots, J)$, then we prove in [10] that

$$V^+(t,x,p) = V^-(t,x,p) = (T-t)Cav(h)(p) + \sum_j p_j x.a_j,$$

where $h(p) = H(\sum_j p_j a_j)$ and $Cav(h)$ is the concave hull of h with respect to $p \in \Delta(I)$. Then

$$V_t^- + H(DV^-) = -Cav(h)(p) + h(p) \geq 0\ ,$$

with a strict inequality in general. In particular, V^- is not a classical supersolution of the primal HJ equation.

2. Note carefully that we require the minimum $w(t,x,p,q) - \phi(t,x,p)$ at (t_0,x_0,p_0) to be *strict*. This point is absolutely crucial for the equivalence. It is related with similar definition in repeated games, where some function has to be tested only at extreme points (see [17]). Let us point out that a general minimum of $w - \phi$ cannot be made artificially strict by substracting $\epsilon|(t,x,p) - (t_0,x_0,p_0)|^2$ to ϕ (as is usually done in viscosity solutions) because one then loses the convexity of ϕ with respect to p.
3. A symmetric result holds for subsolutions: w is a dual subsolution of (21) if and only if, for any $p \in \Delta(I)$, for any test function $\phi = \phi(t,x,q)$ which is $\mathcal{C}^1$ and concave in q and such that $w - \phi$ has a strict global maximum at some point $(t_0,x_0,q_0) \in [0,T) \times \mathbb{R}^N \times \Delta(J)$, we have

$$\phi_t(t_0,x_0,q_0) + H(x_0, D\phi(t_0,x_0,q_0)) \geq 0\ .$$

Proof of Lemma 5.4. Let us first assume that w is a dual supersolution of (21). Let $q \in \Delta(J)$, $\phi = \phi(t,x,p)$ be a test function which is $\mathcal{C}^1$ and convex in p and such that $w - \phi$ has a strict global minimum at some point $(t_0,x_0,p_0) \in [0,T) \times \mathbb{R}^N \times \Delta(I)$. This means that

$$w(t,x,p,q) \leq \phi(t,x,p) + w(t_0,x_0,p_0,q) - \phi(t_0,x_0,p_0) \tag{24}$$

for any $(t,x,p) \in [0,T] \times \mathbb{R}^N \times \Delta(I)$, with an equality only at (t_0,x_0,p_0). By using the fact that the minimum of $w - \phi$ is strict and the standard perturbation argument (consisting in replacing ϕ by $\phi + \epsilon|p|^2$ if necessary), we can assume that ϕ is strictly convex in p. Then, for any $\hat{p} \in \mathbb{R}^I$, p being the unique element of the subdifferential of $\phi^*(t_0,x_0,\cdot)$ at $\hat{p}$, $\phi^*(\cdot,\cdot,\hat{p})$ is differentiable at (t_0,x_0), and one easily checks that

$$\phi_t^*(t_0,x_0,\hat{p}) = -\phi_t(t_0,x_0,p) \text{ and } D\phi^*(t_0,x_0,\hat{p}) = -D\phi(t_0,x_0,p)\ . \tag{25}$$

Let $\hat{p}_0$ belong to the subdifferential with respect to p of w at (t_0,x_0,p_0). Then inequality (24) shows that $\hat{p}_0$ belongs to the subdifferential of ϕ with respect to p at (t_0,x_0,p_0). Since w and ϕ are convex in p, we have

$$w^*(t_0,x_0,\hat{p}_0,q) = p_0.\hat{p}_0 - w(t_0,x_0,p_0,q) \text{ and } \phi^*(t_0,x_0,\hat{p}_0) = p_0.\hat{p}_0 - \phi(t_0,x_0,p_0)\ .$$

Thus

$$w(t_0,x_0,p_0,q) - \phi(t_0,x_0,p_0) = w^*(t_0,x_0,\hat{p}_0,q) - \phi^*(t_0,x_0,\hat{p}_0)\ . \tag{26}$$

We note that (24) can be rewritten as

$$p.\hat{p}_0 - w(t,x,p,q) \geq p.\hat{p}_0 - \phi(t,x,p) - w(t_0,x_0,p_0,q) + \phi(t_0,x_0,p_0)$$

for all $(t,x,p) \in [0,T] \times \mathbb{R}^N \times \Delta(I)$. Taking the sup over $p \in \Delta(I)$ and taking into account (26) gives

$$w^*(t,x,\hat{p}_0,q) \geq \phi^*(t,x,\hat{p}_0) + w^*(t_0,x_0,\hat{p}_0,q) - \phi^*(t_0,x_0,\hat{p}_0) \ .$$

Therefore $(t,x) \mapsto w^*(t,x,\hat{p}_0,q) - \phi^*(t,x,\hat{p}_0)$ has a maximum at (t_0,x_0). Since w^* is a subsolution of the dual HJ equation, we have

$$\phi^*_t(t_0,x_0,\hat{p}_0) + H^*(x_0, D\phi^*(t_0,x_0,\hat{p}_0)) \geq 0 \ ,$$

which implies the desired inequality (23) thanks to (25).

Conversely, let us assume that (ii) holds. Let ϕ be a $\mathcal{C}^1$ test function such that $(t,x) \mapsto w^*(t,x,\hat{p}_0,q) - \phi(t,x)$ has a local minimum at (t_0,x_0) for some $(\hat{p}_0,q) \in \mathbb{R}^I \times \Delta(I)$. Without loss of generality, we can assume that this minimum is a global one and that $\phi(t_0,x_0) = w^*(t_0,x_0,\hat{p}_0,q)$ (see [3]). Let $\tilde{\phi}(t,x,\hat{p}) = \phi(t,x)$ if $\hat{p} = \hat{p}_0$ and $\tilde{\phi}(t,x,\hat{p}) = +\infty$ otherwise. Then $\tilde{\phi} \geq w^*(\cdot,\cdot,\cdot,q)$ on $[0,T] \times \mathbb{R}^N \times \mathbb{R}^I$, with an equality at $(t_0,x_0,\hat{p}_0)$. Thus, by duality,

$$p.\hat{p}_0 - \phi(t,x) = \tilde{\phi}^*(t,x,p) \leq w^{**}(t,x,p,q) = w(t,x,p,q)$$

for any $(t,x,p) \in [0,T] \times \mathbb{R}^N \times \Delta(I)$, with an equality at (t_0,x_0,p_0) for any $p_0 \in \partial w^*(t_0,x_0,\hat{p}_0,q)$ (where $\partial w^*(t_0,x_0,,\hat{p}_0,q)$ denotes the superdifferential of the convex function $\hat{p} \mapsto w^*(t_0,x_0,\hat{p},q)$ at $\hat{p}_0$). Hence $(t,x,p) \mapsto w(t,x,p,q) - (p.\hat{p}_0 - \phi(t,x))$ has a minimum at (t_0,x_0,p_0) for any $p_0 \in \partial w^*(t_0,x_0,\hat{p}_0,q)$. In order to get a *strict* minimum, we have to introduce some perturbation term. Let $\gamma > 0$, $\epsilon > 0$, and $(t_\epsilon,x_\epsilon,p_\epsilon)$ be a point of minimum of $w - \psi_{\epsilon,\gamma}$, where

$$\psi_{\epsilon,\gamma}(t,x,p) = p.\hat{p}_0 + \epsilon|p|^2 - \phi(t,x) - \gamma|(t,x) - (t_0,x_0)|^2 \ .$$

Then $(t_\epsilon,x_\epsilon,p_\epsilon)$ converges (up to some subsequence) to (t_0,x_0,p_0) for some $p_0 \in \partial w^*(t_0,x_0,\hat{p}_0,q)$ as $\epsilon \to 0^+$ (we use here the penalization term in γ). Moreover, we have

$$\begin{array}{rcl} \tilde{\psi}(t,x,p) & := & \psi_{\epsilon,\gamma}(t,x,p) - \epsilon|p-p_\epsilon|^2 - \epsilon|(t,x)-(t_\epsilon,x_\epsilon)|^2 \\ & < & \psi_{\epsilon,\gamma}(t,x,p) \\ & \leq & w(t,x,p) - w(t_\epsilon,x_\epsilon,p_\epsilon) + \tilde{\psi}(t_\epsilon,x_\epsilon,p_\epsilon) \end{array}$$

for any $(t,x,p) \neq (t_\epsilon,x_\epsilon,p_\epsilon)$, with an equality at $(t_\epsilon,x_\epsilon,p_\epsilon)$. This means that $w - \tilde{\psi}$ has a strict minimum at $(t_\epsilon,x_\epsilon,p_\epsilon)$. Since $\tilde{\psi}$ is still convex in p we get from assumption (ii) that

$$\tilde{\psi}_t(t_\epsilon,x_\epsilon,p_\epsilon) + H(x_\epsilon, D\tilde{\psi}(t_\epsilon,x_\epsilon,p_\epsilon)) \leq 0 \ .$$

Using the definition of $\tilde{\psi}$ and letting $\epsilon \to 0^+$, we then obtain

$$\phi_t(t_0,x_0) + H^*(x_0, D\phi(t_0,x_0)) \geq 0 \ ,$$

which proves that w is a dual supersolution of (21). □

Proof of Theorem 5.1. We follow the proof of Theorem 3.7, p. 152, in [3]. Let us argue by contradiction, by assuming that there is some (t_1,x_1,p_1,q_1) such that $w_1(t_1,x_1,p_1,q_1) > w_2(t_1,x_1,p_1,q_1)$. This means that, for some $\sigma > 0$, we have

$$\sup_{t,x,p,q} \ w_1(t,x,p,q) - w_2(t,x,p,q) - \sigma(T-t) \ > \ 0 \ . \tag{27}$$

We now use the standard method of separation of variables. In order to avoid burdensome details, we do the proof under the additional assumption that there is some $R > 0$ such that $w_1(t,x,p,q) \leq w_2(t,x,p,q)$ for any (t,x,p,q) with $|x| \geq R$. This assumption can be omitted by using penalization arguments at infinity (see [3] for the details). Let $\epsilon > 0$ be fixed. From our assumption, the map

$$(28) \qquad (t,x,s,y,p,q) \mapsto w_1(t,x,p,q) - w_2(s,y,p,q) - \frac{1}{\epsilon}|(t,x)-(s,y)|^2 - \sigma(T-t)$$

has a maximum over $[0,T]\times\mathbb{R}^N\times\Delta(I)\times\Delta(J)$, and we denote by $(t_\epsilon, x_\epsilon, s_\epsilon, y_\epsilon, p_\epsilon, q_\epsilon)$ such a point of maximum. From the usual arguments in [3], we have $t_\epsilon < T$ and $s_\epsilon < T$ for small ϵ, because $w_1(T,x,p,q) \leq w_2(T,x,p,q)$ and w_1 and w_2 are Lipschitz continuous. Moreover

$$(29) \qquad \lim_{\epsilon\to 0^+} \frac{1}{\epsilon}|(t_\epsilon,x_\epsilon)-(s_\epsilon,y_\epsilon)|^2 = 0\ .$$

Since, for $(s,y)=(s_\epsilon,y_\epsilon)$, $(t_\epsilon,x_\epsilon,q_\epsilon)$ is a maximum in (28), we have

$$(30) \qquad \begin{aligned} w_1(t,x,p_\epsilon,q) \leq\ & w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon) + w_2(s_\epsilon,y_\epsilon,p_\epsilon,q) - w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon) \\ & + \frac{1}{\epsilon}\left(|(t,x)-(s_\epsilon,y_\epsilon)|^2 - |(t_\epsilon,x_\epsilon)-(s_\epsilon,y_\epsilon)|^2\right) + \sigma(t_\epsilon - t) \end{aligned}$$

for any (t,x,q), with an equality at $(t_\epsilon,x_\epsilon,q_\epsilon)$. Let $\hat{q}_\epsilon$ belong to the superdifferential $\partial_q^+ w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon)$ of w_2 with respect to q at $(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon)$. Then the above inequality shows that $\hat{q}_\epsilon \in \partial_q w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon)$. From the concavity of w_1 and w_2 with respect to q, we have

$$w_1^\sharp(t_\epsilon,x_\epsilon,p_\epsilon,\hat{q}_\epsilon) = q_\epsilon.\hat{q}_\epsilon - w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon)$$

and

$$w_2^\sharp(s_\epsilon,y_\epsilon,p_\epsilon,\hat{q}_\epsilon) = q_\epsilon.\hat{q}_\epsilon - w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon)$$

so that

$$(31) \qquad w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon) - w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon) = w_2^\sharp(s_\epsilon,y_\epsilon,p_\epsilon,\hat{q}_\epsilon) - w_1^\sharp(t_\epsilon,x_\epsilon,p_\epsilon,\hat{q}_\epsilon)\ .$$

Combining (30) with (31) then gives

$$\begin{aligned} q.\hat{q}_\epsilon - w_1(t,x,p_\epsilon,q) \geq\ & \\ & w_1^\sharp(t_\epsilon,x_\epsilon,p_\epsilon,\hat{q}_\epsilon) + q.\hat{q}_\epsilon - w_2(s_\epsilon,y_\epsilon,p_\epsilon,q) - w_2^\sharp(s_\epsilon,y_\epsilon,p_\epsilon,\hat{q}_\epsilon) \\ & - \frac{1}{\epsilon}\left(|(t,x)-(s_\epsilon,y_\epsilon)|^2 - |(t_\epsilon,x_\epsilon)-(s_\epsilon,y_\epsilon)|^2\right) - \sigma(t_\epsilon - t)\ . \end{aligned}$$

Taking the infimum over q in the above expression then gives

$$\begin{aligned} w_1^\sharp(t,x,p_\epsilon,\hat{q}_\epsilon) \geq\ & \\ & w_1^\sharp(t_\epsilon,x_\epsilon,p_\epsilon,\hat{q}_\epsilon) - \frac{1}{\epsilon}\left(|(t,x)-(s_\epsilon,y_\epsilon)|^2 - |(t_\epsilon,x_\epsilon)-(s_\epsilon,y_\epsilon)|^2\right) - \sigma(t_\epsilon - t)\ . \end{aligned}$$

So $(t,x) \mapsto w_1^\sharp(t,x,p_\epsilon,\hat{q}_\epsilon) - \left(-\frac{|(t,x)-(s_\epsilon,y_\epsilon)|^2}{\epsilon} + \sigma t\right)$ has a minimum at (t_ϵ,x_ϵ). Since $w_1^\sharp(\cdot,\cdot,p_\epsilon,\hat{q}_\epsilon)$ is a supersolution of the HJ equation (21), we get

$$(32) \qquad \sigma + \frac{2}{\epsilon}(s_\epsilon - t_\epsilon) + H^*\left(x_\epsilon, \frac{2}{\epsilon}(y_\epsilon - x_\epsilon)\right) \leq 0\ .$$

We now argue in a symmetric way for w_2. Since $(s_\epsilon, y_\epsilon, p_\epsilon)$ is a maximum in (28), we have

$$w_2(s,y,p,q_\epsilon) \geq w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon) + w_1(t_\epsilon,x_\epsilon,p,q_\epsilon) - w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon) \\ - \frac{1}{\epsilon}\left(|(t_\epsilon,x_\epsilon)-(s,y)|^2 - |(t_\epsilon,x_\epsilon)-(s_\epsilon,y_\epsilon)|^2\right) \tag{33}$$

for any $(s,y,p) \in [0,T]\times\mathbb{R}^N\times\Delta(I)$. Let $\hat{p}_\epsilon$ belong to the subdifferential $\partial_p^- w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon)$ of w_1 with respect to p at $(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon)$. Then the above inequality shows that $\hat{p}_\epsilon \in \partial_p^- w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon)$. Therefore we have as above

$$w_2(s_\epsilon,y_\epsilon,p_\epsilon,q_\epsilon) - w_1(t_\epsilon,x_\epsilon,p_\epsilon,q_\epsilon) = w_1^*(t_\epsilon,x_\epsilon,\hat{p}_\epsilon,q_\epsilon) - w_2^*(s_\epsilon,y_\epsilon,\hat{p}_\epsilon,q_\epsilon)\ .$$

Then we get from (33):

$$w_2^*(s,y,\hat{p}_\epsilon,q_\epsilon) \leq w_2^*(s_\epsilon,y_\epsilon,\hat{p}_\epsilon,q_\epsilon) + \frac{1}{\epsilon}\left(|(t_\epsilon,x_\epsilon)-(s,y)|^2 - |(t_\epsilon,x_\epsilon)-(s_\epsilon,y_\epsilon)|^2\right)$$

for any $(s,y) \in [0,T]\times\mathbb{R}^N$, with an equality at (s_ϵ,y_ϵ). Since $w_2^*(\cdot,\cdot,\hat{p}_\epsilon,q_\epsilon)$ is a subsolution of the HJ equation (21), this gives

$$\frac{2}{\epsilon}(s_\epsilon - t_\epsilon) + H^*\left(y_\epsilon, \frac{2}{\epsilon}(y_\epsilon - x_\epsilon)\right) \geq 0\ . \tag{34}$$

Computing the difference between (32) and (34) and using the assumption (20) on H (recall that $H^*(x,\xi) = -H(x,-\xi)$) gives

$$-\sigma + C|x_\epsilon - y_\epsilon|\left(1 + \frac{2|x_\epsilon - y_\epsilon|}{\epsilon}\right) \geq 0\ ,$$

which is in contradiction with (29) as $\epsilon \to 0^+$. □

6. The case of a lack of information on the initial position. In this section we investigate a two-player zero-sum differential game in which the players have some private information on the random initial position. The dynamics of the game is still given by

$$x'(t) = f(x,u(t),v(t))\ , \qquad u(t)\in U,\ v(t)\in V, \tag{35}$$

where U, V, and f satisfy (5). The terminal time of the game is denoted by T, and the payoff is a terminal payoff $g(x(T))$, where $g : \mathbb{R}^N \to \mathbb{R}$ is Lipschitz continuous and bounded. The game starts at time $t_0 \in [0,T]$.

The description of the game involves $I \times J$ initial positions x_{ij}^0, $i = 1,\dots,I$, $j = 1,\dots,J$, a probability $p \in \Delta(I)$, and a probability $q \in \Delta(J)$. As before, the game is played in two steps: At time t_0, the pair (i,j) is chosen according to the probability $p \otimes q$; the index i is communicated to player 1 only and the index j to player 2 only.

Then the players control system (35) with initial position x_{ij}^0 in order for player 1 to minimize the terminal payoff $g(x(T))$ and for player 2 to maximize it. The players observe their opponent's behavior and try to deduce from this behavior their missing information. They cannot compute the actual position of the system in general.

As before we define the upper and lower value functions associated to this game. For this we introduce the new state of the system: $\mathbf{x} = (x_{ij})$, which denotes the $I \times J$-uplet of possible positions. The upper value is given for $t_0 \in [0,T)$, $\mathbf{x}^0 = (x_{ij}^0) \in \mathbb{R}^{NIJ}$,

$p \in \Delta(I)$, and $q \in \Delta(J)$ by

$$V^+(t_0, \mathbf{x}^0, p, q) = \inf_{(\alpha_i)\in(\mathcal{A}_r(t_0))^I} \sup_{(\beta_j)\in(\mathcal{B}_r(t_0))^J} \sum_{i=1}^{I}\sum_{j=1}^{J} p_i q_j \mathbf{E}_{\alpha_i\beta_j}\left(g\left(X_T^{t_0,x_{ij}^0,\alpha_i,\beta_j}\right)\right),$$

where $t \to X_t^{t_0,x_{ij}^0,\alpha_i,\beta_j}$ is the random solution to (35) with initial position x_{ij}^0 at time t_0 when the players play the random strategies α_i and β_j (see section 2). The lower value is defined by the symmetric formula:

$$V^-(t_0, \mathbf{x}^0, p, q) = \sup_{(\beta_j)\in(\mathcal{B}_r(t_0))^J} \inf_{(\alpha_i)\in(\mathcal{A}_r(t_0))^I} \sum_{i=1}^{I}\sum_{j=1}^{J} p_i q_j \mathbf{E}_{\alpha_i\beta_j}\left(g\left(X_T^{t_0,x_{ij}^0,\alpha_i,\beta_j}\right)\right).$$

Obviously we have

$$V^-(t_0, \mathbf{x}^0, p, q) \le V^+(t_0, \mathbf{x}^0, p, q)\ \forall (t_0, \mathbf{x}^0, p, q) \in [0,T] \times \mathbb{R}^{NIJ} \times \Delta(I) \times \Delta(J).$$

Our main result is that the equality holds.

THEOREM 6.1. *Assume that f, U, and V satisfy* (5), *that the payoff $g : \mathbb{R}^N \to \mathbb{R}$ is Lipschitz continuous and bounded, and that the following generalized Isaacs condition holds:*

$$\mathbf{H}(\mathbf{x}, \xi) = \inf_{u\in U}\sup_{v\in V} \sum_{i=1}^{I}\sum_{j=1}^{J} f(x_{ij}, u, v).\xi_{ij} = \sup_{v\in V}\inf_{u\in U} \sum_{i=1}^{I}\sum_{j=1}^{J} f(x_{ij}, u, v).\xi_{ij} \tag{36}$$

for any $\mathbf{x} = (x_{ij}) \in \mathbb{R}^{NIJ}$ and $\xi = (\xi_{ij}) \in \mathbb{R}^{NIJ}$.

Then the game has a value:

$$V^-(t_0, \mathbf{x}^0, p, q) = V^+(t_0, \mathbf{x}^0, p, q)\ \forall (t_0, \mathbf{x}^0, p, q) \in [0,T] \times \mathbb{R}^{NIJ} \times \Delta(I) \times \Delta(J).$$

Furthermore this value is the dual solution of the HJ equation

$$\begin{cases} z_t + \mathbf{H}(\mathbf{x}, Dz) = 0 & \text{in } [0,T) \times \mathbb{R}^{NIJ}, \\ z(T, \mathbf{x}, p, q) = \sum_{i=1}^{I}\sum_{j=1}^{J} p_i q_j g(x_{ij}) & \text{for } \mathbf{x} = (x_{ij}) \in \mathbb{R}^{NIJ}. \end{cases} \tag{37}$$

Proof of Theorem 6.1. The proof is mainly the same as the proof of Theorem 5.2 and Corollary 5.3, and we give only an outline of it. We first note that V^+ and V^- are Lipschitz continuous in their arguments, convex in p, and concave in q as in Lemmas 3.1 and 3.2. Then, following Lemma 4.1, one proves that

$$V^{-*}(t, \mathbf{x}^0, \hat{p}, q) = \inf_{(\beta_j)\in(\mathcal{B}_r(t_0))^J} \sup_{\alpha\in\mathcal{A}_r(t_0)} \max_{i=1,\dots,I} \left\{ \hat{p}_i - \sum_j q_j \mathbf{E}_{\alpha\beta_j}\left[g\left(X_T^{t,x_{ij}^0,\alpha,\beta_j}\right)\right]\right\}$$

for any $t \in [0,T]$, $\mathbf{x}^0 = (x_{ij}^0) \in \mathbb{R}^{NIJ}$, $\hat{p} \in \mathbb{R}^I$, and $q \in \Delta(J)$. Using this, one obtains as in Lemma 4.2 that V^{-*} satisfies the subdynamic programming principle

$$V^{-*}(t_0, \mathbf{x}^0, \hat{p}, q) \le \inf_{\beta\in\mathcal{B}(t_0)} \sup_{\alpha\in\mathcal{A}(t_0)} V^{-*}(t_1, \mathbf{X}_{t_1}^{t_0,\mathbf{x}^0,\alpha,\beta}, \hat{p}, q)$$

for any $0 \le t_0 < t_1 \le T$, $\mathbf{x}^0 \in \mathbb{R}^{NIJ}$, $\hat{p} \in \mathbb{R}^I$, and $q \in \Delta(J)$, where

$$\mathbf{X}_{t_1}^{t_0,\mathbf{x}^0,\alpha,\beta} = \left(X_{t_1}^{t_0,x_{ij}^0,\alpha,\beta}\right)_{\substack{i=1,\dots,I\\ j=1,\dots,J}}.$$

Hence $V^{-*}(\cdot,\cdot,\hat{p},q)$ is a subsolution of the dual HJ equation

$$z_t + \mathbf{H}^*(x, Dz) = 0 \qquad \text{in } [0,T]\times\mathbb{R}^{NIJ}$$

for any $(\hat{p},q)$, which means that V^- is a dual supersolution of (37). One proves in the same way that V^+ is a dual subsolution of (37). The comparison Theorem 5.1 then implies that $V^+ \le V^-$. Since the inequality $V^- \le V^+$ is obvious, we get the equality and the characterization of the value function. □

A MODEL FOR REVERSIBLE INVESTMENT CAPACITY EXPANSION*

AMAL MERHI† AND MIHAIL ZERVOS†

Abstract. We consider the problem of determining the optimal investment level that a firm should maintain in the presence of random price and/or demand fluctuations. We model market uncertainty by means of a geometric Brownian motion, and we consider general running payoff functions. Our model allows for capacity expansion as well as for capacity reduction, with each of these actions being associated with proportional costs. The resulting optimization problem takes the form of a singular stochastic control problem that we solve explicitly. We illustrate our results by means of the so-called Cobb–Douglas production function. The problem that we study presents a model in which the associated Hamilton–Jacobi–Bellman equation admits a classical solution that conforms with the underlying economic intuition but does not necessarily identify with the corresponding value function, which may be identically equal to ∞. Thus, our model provides a situation that highlights the need for rigorous mathematical analysis when addressing stochastic optimization applications in finance and economics, as well as in other fields.

Key words. singular stochastic control, investment capacity expansion, variational inequalities

1. Introduction.

We consider the problem of determining the optimal capacity level of a given investment project operating within a random economic environment in a dynamical way. In particular, we consider an investment project that yields payoff at a rate that is dependent on its installed capacity level and on an underlying economic indicator such as the price of or the demand for the project's unique output commodity, which we model by a geometric Brownian motion. The project's capacity level can be increased or decreased at any time and at given proportional costs. The objective is to determine the project's capacity level that maximizes the associated expected, discounted payoff flow.

Irreversible capacity expansion models have attracted considerable interest in the literature; e.g., see Davis et al. [6] (see also Davis [5]), Kobila [10], Øksendal [11], Wang [12], Chiarolla and Haussmann [4], Bank [2], and the references therein. Recently, Bentolila and Bertola [3] and Abel and Eberly [1] considered models involving both expansion and reduction of a project's capacity level. These authors assume that the rate at which the project yields payoff is modelled by a constant elasticity Cobb–Douglas production function. Our model considers many more general running payoff functions that include the whole family of the Cobb–Douglas production functions as special cases and allow for the situation where a running cost proportional to the project's installed capacity (reflecting, e.g., labor costs) is also included (see Examples 1 and 2). Also, Guo and Pham [7] consider a related partially reversible investment model with entry decisions and a general running payoff function. The model that these authors consider is fundamentally different from the ones considered

by Bentolila and Bertola [3] and Abel and Eberly [1], or the one that we study here, because, e.g., it is one-dimensional instead of two-dimensional.

Our analysis, which leads to results of an explicit analytic nature, involves the derivation of tight conditions for the project's value function to be finite. The fact that simple choices for the project's running payoff function lead to unique solutions to the associated free-boundary problem that conform with standard economic intuition but are associated with value functions that are identically equal to infinity presents a most interesting feature of our analysis (see Remark 3; also, note that this pathological situation does not arise in the context of the special cases studied by Bentolila and Bertola [3] and Abel and Eberly [1]). Indeed, this possibility stresses the fact that treating optimization models related to investment decision making in a "formal" way, which is often the case in the economics literature, can lead to erroneous conclusions and can suggest the adoption of potentially disastrous policies.

The paper is organized as follows. Section 2 is concerned with a rigorous formulation of the investment decision model that we study. In section 3, we derive tight sufficient conditions, which conform with economic intuition, for the associated optimization problem to possess a finite value function. Assumptions 1 and 2 summarize all of the assumptions that we make about the problem data in the paper. We also establish a number of estimates that we use in our subsequent analysis. Section 4 is concerned with the proof of a verification theorem that provides sufficient conditions for the value function of our control problem to be identified with a solution to the associated dynamic programming or Hamilton–Jacobi–Bellman equation. In section 5, we solve the optimization problem considered. Finally, we illustrate our results by a number of examples in section 6.

2. Problem formulation. We fix a probability space $(\Omega, \mathcal{F}, P)$ equipped with a filtration $(\mathcal{F}_t)$ satisfying the usual conditions of right continuity and augmentation by P-negligible sets and carrying a standard, one-dimensional $(\mathcal{F}_t)$-Brownian motion W. We denote by $\mathcal{A}$ the family of all càglàd, $(\mathcal{F}_t)$-adapted, increasing processes ξ such that $\xi_0 = 0$.

We consider an investment project that produces a given commodity, and we assume that the project's capacity, namely its rate of output, can be controlled at any given time. We denote by Y_t the project's capacity at time t, and we model cumulative capacity increases (resp., decreases) by a process $\xi^+ \in \mathcal{A}$ (resp., $\xi^- \in \mathcal{A}$). In particular, given any times $0 \leq s \leq t$, $\xi^+_{t+} - \xi^+_s$ and $\xi^-_{t+} - \xi^-_s$ are the total capacity increase and decrease, respectively, incurred by the project management's decisions during the time interval $[s, t]$. The project's capacity process Y is therefore given by

$$Y_t = y + \xi^+_t - \xi^-_t, \quad Y_0 = y \geq 0, \tag{1}$$

where $y \geq 0$ is the project's initial capacity. Note that the project's capacity process Y is a finite variation process because it is the difference of two increasing processes. Also, the assumptions that the processes $\xi^{\pm}$ are càglàd and $\xi^{\pm}_0 = 0$ imply that $Y_0 = y$. We make the assumption that the project's management controls only the project's capacity level. Accordingly, we denote by Π_y the set of all admissible decision strategies, which is defined by

$$\Pi_y = \left\{(\xi^+, \xi^-) : \ \xi^+, \xi^- \in \mathcal{A}, \text{ and } Y_t \geq 0, \text{ for all } t \geq 0\right\}.$$

We assume that all randomness associated with the project's operation can be captured by a state process X that satisfies the SDE

$$dX_t = bX_t\,dt + \sqrt{2}\sigma X_t\,dW_t, \quad X_0 = x > 0, \tag{2}$$

for some constants b and σ. In practice, X_t can be the price of one unit of the output commodity or an economic indicator reflecting, e.g., the output commodity's demand, at time t.

To simplify the notation, we define

$$\mathcal{S} = \left\{(x,y) \in \mathbb{R}^2 :\ x > 0,\ y \geq 0\right\},$$

so that $\mathcal{S}$ is the set of all possible initial conditions.

With each decision policy $(\xi^+, \xi^-) \in \Pi_y$ we associate the performance criterion

$$\begin{aligned} J_{x,y}(\xi^+,\xi^-) = E\Bigg[&\int_0^\infty e^{-rt} h(X_t, Y_t)\,dt \\ &- K^+ \int_{[0,\infty[} e^{-rt}\,d\xi_t^+ - K^- \int_{[0,\infty[} e^{-rt}\,d\xi_t^- \Bigg], \end{aligned} \tag{3}$$

where $h : \mathcal{S} \to \mathbb{R}$ is a given function, and $r > 0$ and K^+, K^- are constants. Here, h models the running payoff resulting from the project's operation, and K^+ (resp., K^-) models the costs associated with increasing (resp., decreasing) the project's capacity level.

As it stands in (3), the performance index $J_{x,y}$ is not necessarily well-defined because the random variable inside the expectation may not be integrable or even well-defined. To address this issue, we define

$$U_T = \int_0^T e^{-rt} h(X_t, Y_t)\,dt - K^+ \int_{[0,T]} e^{-rt}\,d\xi_t^+ - K^- \int_{[0,T]} e^{-rt}\,d\xi_t^- \quad \text{for } T \geq 0. \tag{4}$$

In the next section (see Lemma 4, in particular), we are going to impose assumptions on h such that U_T is well-defined, for all $T > 0$, and *either*

$$U_\infty = \lim_{T\to\infty} U_T \text{ exists in } \mathbb{R},\ P\text{-a.s.}, \quad \text{and} \quad U_\infty \in L^1(\Omega, \mathcal{F}, P), \tag{5}$$

in which case we naturally define

$$J_{x,y}(\xi^+,\xi^-) = E\left[U_\infty\right], \tag{6}$$

as in (3), *or* there exists an $(\mathcal{F}_t)$-adapted process Z such that

$$U_T \leq Z_T,\ \text{for all } T \geq 0, \quad \text{and} \quad \limsup_{T\to\infty} E\left[Z_T\right] = -\infty, \tag{7}$$

in which case we define

$$J_{x,y}(\xi^+,\xi^-) = -\infty. \tag{8}$$

The objective is to maximize the performance index $J_{x,y}$ thus defined over all admissible decision strategies $(\xi^+, \xi^-) \in \Pi_y$. The value function of the resulting optimization problem is defined by

$$v(x,y) = \sup_{(\xi^+,\xi^-)\in\Pi_y} J_{x,y}(\xi^+,\xi^-). \tag{9}$$

3. Assumptions and preliminary estimates. The purpose of this section is to establish conditions on the problem data under which our control problem is well-posed and its value function is finite and to prove certain estimates that we will need. Before we address these issues, we first discuss an ODE that will play an instrumental role in the solution of our control problem.

Every solution of the homogeneous ODE

$$\sigma^2 x^2 u''(x) + bxu'(x) - rw(x) = 0$$

is given by

$$u(x) = Ax^n + Bx^m$$

for some $A, B \in \mathbb{R}$. Here, the constants $m < 0 < n$ are the solutions of the quadratic equation

$$\sigma^2\lambda^2 + (b - \sigma^2)\lambda - r = 0, \tag{10}$$

given by

$$m, n = \frac{-(b-\sigma^2) \pm \sqrt{(b-\sigma^2)^2 + 4\sigma^2 r}}{2\sigma^2}. \tag{11}$$

Now, let $k :]0, \infty[\to \mathbb{R}$ be any measurable function such that

$$E\left[\int_0^\infty e^{-rt}\,|k(X_t)|\,dt\right] < \infty \quad \text{for all } x > 0. \tag{12}$$

This integrability condition is equivalent to

$$\int_0^x s^{-m-1}|k(s)|\,ds + \int_x^\infty s^{-n-1}|k(s)|\,ds < \infty, \quad \text{for all } x > 0,$$

and the function $R^{[k]} :]0, \infty[\to \mathbb{R}$ defined by

$$R^{[k]}(x) = \frac{1}{\sigma^2(n-m)}\left[x^m \int_0^x s^{-m-1}k(s)\,ds + x^n \int_x^\infty s^{-n-1}k(s)\,ds\right] \tag{13}$$

is a special solution to the nonhomogeneous ODE

$$\sigma^2 x^2 u''(x) + bxu'(x) - rw(x) + k(x) = 0 \tag{14}$$

and satisfies

$$R^{[k]}(x) = E\left[\int_0^\infty e^{-rt}k(X_t)\,dt\right]. \tag{15}$$

Furthermore,

$$\text{if } k \text{ is increasing, then } R^{[k]} \text{ is increasing,} \tag{16}$$

and

$$\text{if } k \text{ is increasing, then } \lim_{x\downarrow 0}\frac{k(x)}{r} \geq 0 \;\Leftrightarrow\; \lim_{x\downarrow 0} R^{[k]}(x) \geq 0. \tag{17}$$

All of these results are proved in Knudsen, Meister, and Zervos [9]. For future reference, we also note that, given any $\lambda \in \mathbb{R}$,

$$E\left[\int_0^\infty e^{-rt} X_t^\lambda \, dt\right] = x^\lambda \int_0^\infty e^{\left[\sigma^2\lambda^2 + (b-\sigma^2)\lambda - r\right]t} E\left[e^{-\sigma^2\lambda^2 t + \sqrt{2}\sigma\lambda W_t}\right] dt$$

$$= \begin{cases} \infty, & \text{if } \lambda \le m \text{ or } \lambda \ge n, \\ -x^\lambda / \left[\sigma^2\lambda^2 + (b-\sigma^2)\lambda - r\right] & \text{if } \lambda \in]m, n[. \end{cases} \tag{18}$$

We are going to need the following estimate that is related to the definitions above.

LEMMA 1. *Given any $\lambda \in]0, n[$, there exist constants $\varepsilon_1, \varepsilon_2 > 0$ such that*

$$E\left[e^{-rt}\bar{X}_t^\lambda\right] \le \frac{\sigma^2\lambda^2 + \varepsilon_2}{\varepsilon_2} x^\lambda e^{-\varepsilon_1 t} \quad \textit{and} \quad E\left[\sup_{t\ge 0} e^{-rt}\bar{X}_t^\lambda\right] \le \frac{\sigma^2\lambda^2 + \varepsilon_2}{\varepsilon_2} x^\lambda,$$

where $\bar{X}_t = \sup_{s\le t} X_s$.

Proof. Since n is the positive solution of the quadratic equation (10), it follows that there exist $\varepsilon_1, \varepsilon_2 > 0$ such that

$$r - \varepsilon_1 > 0 \quad \text{and} \quad \sigma^2\lambda^2 + (b-\sigma^2)\lambda - (r-\varepsilon_1) = -\varepsilon_2.$$

Given such parameters, we define

$$V = \sup_{t\ge 0}\left[-\frac{\sigma^2\lambda^2 + \varepsilon_2}{\sqrt{2}|\sigma|\lambda} t + W_t\right],$$

we calculate

$$\begin{aligned} e^{-rt}\bar{X}_t^\lambda &= x^\lambda e^{-\varepsilon_1 t} e^{-(r-\varepsilon_1)t} \sup_{s\le t} \exp\big((r-\varepsilon_1)s - (\sigma^2\lambda^2 + \varepsilon_2)s + \sqrt{2}\sigma\lambda W_s\big) \\ &= x^\lambda e^{-\varepsilon_1 t} \sup_{s\le t}\left[\exp\big(-(r-\varepsilon_1)(t-s)\big) \exp\left(-(\sigma^2\lambda^2 + \varepsilon_2)s + \sqrt{2}\sigma\lambda W_s\right)\right] \\ &\le x^\lambda e^{-\varepsilon_1 t} e^{\sqrt{2}|\sigma|\lambda V}, \end{aligned}$$

and we observe that

$$\sup_{t\ge 0} e^{-rt}\bar{X}_t^\lambda \le x^\lambda e^{\sqrt{2}|\sigma|\lambda V}.$$

Since V is exponentially distributed with parameter $2(\sigma^2\lambda^2 + \varepsilon_2)/(\sqrt{2}|\sigma|\lambda)$ (see Karatzas and Shreve [8, Exercise 3.5.9]), the two bounds follow by a simple integration. ∎

The following assumptions on the data of the control problem formulated in section 2 will ensure that the associated free-boundary problem has a unique solution that conforms with economical intuition.

Assumption 1. $r > 0$, and the function h is C^3 and satisfies

$$\int_0^x s^{-m-1}|h(s,y)|\, ds + \int_x^\infty s^{-n-1}|h(s,y)|\, ds < \infty$$

for all $(x, y) \in \mathcal{S}$. If we define

$$H(x,y) = h_y(x,y), \quad \text{for } x, y > 0, \tag{19}$$

then, given any $y > 0$,

$$H_x(x,y) > 0, \text{ for all } x > 0, \quad \text{and} \quad \lim_{x\to\infty} H(x,y) = \infty, \tag{20}$$

and, given any $x > 0$,

$$H_y(x,y) < 0 \quad \text{for all } y > 0. \tag{21}$$

Also, $K^+ + K^- > 0$, and

$$\int_0^x s^{-m-1}\left[|H(s,y)| + |H_y(s,y)|\right] ds + \int_x^\infty s^{-n-1}\left[|H(s,y)| + |H_y(s,y)|\right] ds < \infty$$

for all $x, y > 0$.

It is worth observing that (20) and (21) in this assumption have a natural economic interpretation. Indeed, we can think of $H(x,y)\Delta y$ as the *additional* running payoff that we are faced with if we increase the project's capacity level from y to $y + \Delta y$, for small Δy, and the underlying state process X assumes the value x. In view of this observation, (20) reflects the idea that, given y, a small amount of extra capacity should be associated with increasing values of additional running payoff as the value of x, which, e.g., models the price of or the demand for the project's output commodity, is increasing. Similarly, (21) reflects the fact that, for a given value x of the underlying state process, the extra running payoff resulting from a small amount of additional capacity is decreasing as the level of the already installed capacity y increases. Also, the assumption that $K^+ + K^- > 0$, which is an indispensable one, is a most realistic one. Indeed, the inequality $K^+ + K^- < 0$ gives rise to the unrealistic scenario where the project's management can realize arbitrarily high profits by just sequentially increasing and then decreasing the project's capacity by the same amount sufficiently fast.

At this point, we should also observe that (20) and (21) in Assumption 1 exclude the special case that arises when the running payoff function h does not depend on the capacity level y, i.e., when $h(x,y) = \tilde{h}(x)$, for some function $\tilde{h}$. In this case, it is plainly optimal to never change the project's capacity level. However, the qualitative nature of this strategy is fundamentally different from any of the forms that our analysis allows the optimal strategy to have, which is reflected in our assumptions.

The following additional assumptions will ensure that the value function of the control problem considered is finite and identifies with the solution of the associated Hamilton–Jacobi–Bellman equation. Apart from (26), which can be justified by straightforward economic considerations such as the ones discussed above, the conditions in the assumption are of a technical nature.

Assumption 2. $K^+ > 0$, and there exist constants

$$\alpha > 0, \quad \beta \in]0,1[, \quad \vartheta \in]0, K^+ \wedge (K^+ + K^-) \wedge n[, \quad \text{and } C > 0, \tag{22}$$

where $n > 0$ is as in (11), such that

$$\frac{\alpha}{1-\beta} < n, \tag{23}$$

$$-C(1+y) \le h(x,y) \le C(1 + x^{n-\vartheta} + x^\alpha y^\beta) + r(K^+ - \vartheta)y, \quad \text{for all } (x,y) \in \mathcal{S}, \tag{24}$$

$$-C \le H(x,y) \equiv h_y(x,y) \le \beta C x^\alpha y^{-(1-\beta)} + r(K^+ - \vartheta) \quad \text{for all } x, y > 0. \tag{25}$$

Also,

$$h_x(x,y) \geq 0 \quad \text{for all } (x,y) \in \mathcal{S}. \tag{26}$$

Remark 1. Note that we could have replaced the upper bound in (25) by

$$H(x,y) \leq \begin{cases} C\left(1 + x^{\alpha} y^{-(1-\beta)}\right), & \text{for all } x > 0 \text{ and } y < y_1, \\ \beta C x^{\alpha} y^{-(1-\beta)} + r(K^+ - \vartheta), & \text{for all } x > 0 \text{ and } y \geq y_1, \end{cases}$$

for some constant $y_1 > 0$. Depending on the problem data, such a significant relaxation could result in an optimal policy such as the one depicted by Figure 5 that would qualitatively enrich the class of optimal capacity control strategies (see also Example 3 in section 6). However, we decided against such a relaxation because this would complicate both the presentation and the analysis of our results.

Example 1. A choice for the running payoff function h that has been widely considered in the literature is the so-called Cobb–Douglas production function given by

$$h(x,y) = x^{\alpha} y^{\beta} \quad \text{for some constants } \alpha > 0 \text{ and } \beta \in]0,1[. \tag{27}$$

It is straightforward to verify that this function satisfies all of our assumptions if and only if the parameters α and β satisfy the inequality (23).

Example 2. A choice for the running payoff function h that is a variation of the Cobb–Douglas function and incorporates a running cost proportional to the project's installed capacity is given by

$$h(x,y) = (x+\eta)^{\alpha}(y+\zeta)^{\beta} - Ky \quad \text{for some constants } \alpha, \beta, \eta, \zeta, K > 0. \tag{28}$$

This choice satisfies our assumptions if and only if

$$\alpha, \beta \in]0,1[, \quad \frac{\alpha}{1-\beta} < n, \quad \text{and} \quad \beta \eta^{\alpha} \zeta^{-(1-\beta)} < K + rK^+. \tag{29}$$

To see this claim, fix any $\vartheta > 0$ such that

$$\alpha < n - \vartheta \quad \text{and} \quad \beta \eta^{\alpha} \zeta^{-(1-\beta)} < K + r(K^+ - \vartheta),$$

and observe that there exist constants $\Gamma_1, \Gamma_2, \Gamma_3 > 1$ such that

$$(x+\eta)^{\alpha} \leq \Gamma_1(1 + x^{\alpha}), \quad (y+\zeta)^{\beta} \leq \Gamma_2(1 + y^{\beta}), \quad \text{and} \quad \Gamma_1\Gamma_2 y^{\beta} < \Gamma_3 + r(K^+ - \vartheta)y,$$

because $\alpha, \beta \in]0,1[$. In view of these inequalities, we can see that

$$\begin{aligned} h(x,y) &\leq \Gamma_1\Gamma_2\left(1 + x^{\alpha} + x^{\alpha} y^{\beta}\right) + \Gamma_1\Gamma_2 y^{\beta} \\ &\leq \Gamma_1\Gamma_2\Gamma_3\left(1 + x^{\alpha} + x^{\alpha} y^{\beta}\right) + r(K^+ - \vartheta)y, \end{aligned}$$

and we check that Assumption 1 and (23), (24), and (26) in Assumption 2 all hold true. To verify (25) in Assumption 2, we note that, given a constant $C > 1$,

$$\frac{\partial}{\partial x}\left[H(x,y) - \beta C x^{\alpha} y^{-(1-\beta)}\right] < 0$$

is equivalent to

$$\left(\frac{x}{x+\eta}\right)^{1-\alpha} < C\left(\frac{y+\zeta}{y}\right)^{1-\beta},$$

which is true for all $x, y > 0$. It follows that (25) is satisfied if it is true for $x = 0$, i.e., if

$$\beta\eta^{\alpha}(y+\zeta)^{-(1-\beta)} \leq K + r(K^{+} - \vartheta), \quad \text{for all } y \geq 0,$$

which is true when the associated parameters satisfy (29).

To see that if the last inequality in (29) is not true, then the upper bound in (25) does not hold, we argue by contradiction. Indeed, if there are constants $C, \vartheta > 0$ such that (25) is satisfied, then we can pass to the limit as $x \downarrow 0$ to obtain

$$\beta\eta^{\alpha}(y+\zeta)^{-(1-\beta)} \leq K + r(K^{+} - \vartheta) \quad \text{for all } y > 0.$$

However, this inequality cannot be true for all $y > 0$ if the last inequality in (29) above does not hold.

It is a straightforward exercise to show that the bounds in (24)–(25) imply the following estimates.

LEMMA 2. *With reference to the notation in* (13)*, the bounds provided by* (24) *and* (25) *in Assumption* 2 *imply that there exists a constant* $C_1 > 0$ *such that*

$$-C_1(1+y) \leq R^{[h(\cdot,y)]}(x) \leq C_1\left(1 + y + x^{n-\vartheta} + x^{\alpha}y^{\beta}\right), \quad \textit{for all } (x,y) \in \mathcal{S},$$
$$-C_1 \leq R^{[H(\cdot,y)]}(x) \leq C_1\left(1 + x^{\alpha}y^{-(1-\beta)}\right) \quad \textit{for all } (x,y) \in \mathcal{S}.$$

As we have remarked above, bounds such as the ones appearing in Assumption 2 are essential for the value function to be finite. Indeed, we can prove the following result.

LEMMA 3. *Consider the control problem formulated in section* 2 *that arises if the running payoff function* h *is defined by* (27) *in Example* 1*, and suppose that* $\frac{\alpha}{1-\beta} > n > \alpha$*. Then, under any well-posed definition of the performance index* $J_{x,y}$ *that is consistent with* (3)*,* $v(x,y) = \infty$ *for every initial condition* $(x,y) \in \mathcal{S}$*.*

Proof. Consider the strategy defined by

$$\tilde{\xi}_t^{+} = \bar{X}_t^{(n-\alpha)/\beta} \quad \text{and} \quad \tilde{\xi}_t^{-} = 0, \quad \text{for all } t \geq 0, \tag{30}$$

where $\bar{X}_t = \sup_{s \leq t} X_s$. With regard to (18), we can see that this strategy is associated with

$$E\left[\int_0^{\infty} e^{-rt} X_t^{\alpha} \tilde{Y}_t^{\beta}\, dt\right] \geq E\left[\int_0^{\infty} e^{-rt} X_t^{n}\, dt\right] = \infty. \tag{31}$$

Now, let us assume that $\frac{\alpha}{1-\beta} > n > \alpha$. If we define $\lambda = \frac{n-\alpha}{\beta} > 0$, then such an assumption implies that $\lambda < n$. In view of this observation, we can use the first estimate in Lemma 1, the monotone convergence theorem, and the integration by parts formula to see that the strategy given by (30) satisfies

$$\begin{aligned} E\left[\int_{[0,\infty[} e^{-rt}\, d\tilde{\xi}_t^{+}\right] &= \lim_{T\to\infty} E\left[r\int_0^T e^{-rt}\tilde{\xi}_t^{+}\, dt + e^{-rT}\tilde{\xi}_{T+}^{+}\right] \\ &= \lim_{T\to\infty}\left(r\int_0^T E\left[e^{-rt}\bar{X}_t^{\lambda}\right] dt + E\left[e^{-rT}\bar{X}_T^{\lambda}\right]\right) \\ &\leq r\frac{\sigma^2\lambda^2 + \varepsilon_2}{\varepsilon_1\varepsilon_2}x^{\lambda} \\ &< \infty. \end{aligned}$$

However, this calculation, (30), and (31) imply that

$$E\left[\int_0^\infty e^{-rt}X_t^\alpha \tilde{Y}_t^\beta\,dt - \int_{[0,\infty[} e^{-rt}\,d\tilde{\xi}_t^+ - \int_{[0,\infty[} e^{-rt}\,d\tilde{\xi}_t^-\right]$$

is well-defined and equal to ∞, which proves the result. □

We can now prove that our assumptions are sufficient for the optimization problem considered to be well-posed and for its value function to be finite.

LEMMA 4. *Suppose that the running payoff function h satisfies* (24) *in Assumption* 2 *and that $K^+, K^+ + K^- > 0$. Given any initial condition $(x,y) \in \mathcal{S}$,* (5)–(8) *provide a well-posed definition of the performance criterion $J_{x,y}$, and the following statements hold true:*

(a) *Given any admissible strategy $(\xi^+,\xi^-) \in \Pi_y$, $J_{x,y}(\xi^+,\xi^-) \in \mathbb{R}$ if and only if*

$$E\left[\int_0^\infty e^{-rt}Y_t\,dt + K^+\int_{[0,\infty[} e^{-rt}\,d\xi_t^+ + |K^-|\int_{[0,\infty[} e^{-rt}\,d\xi_t^-\right] < \infty. \tag{32}$$

(b) *Condition* (32) *implies that*

$$\liminf_{T\to\infty} e^{-rT}E\left[Y_{T+}\right] = 0. \tag{33}$$

(c) $v(x,y) \in \mathbb{R}$.

Proof. Fix any initial condition $(x,y) \in \mathcal{S}$ and any admissible strategy $(\xi^+,\xi^-) \in \Pi_y$. Since ξ^+, ξ^- are increasing càglàd processes with $\xi_0^+ = \xi_0^- = 0$, we can use the integration by parts formula to calculate

$$\begin{aligned} &-K^+\int_{[0,T]} e^{-rt}\,d\xi_t^+ - K^-\int_{[0,T]} e^{-rt}\,d\xi_t^- \\ &\qquad = -r\int_0^T e^{-rt}\left[K^+\xi_t^+ + K^-\xi_t^-\right]dt - e^{-rT}\left[K^+\xi_{T+}^+ + K^-\xi_{T+}^-\right]. \end{aligned} \tag{34}$$

With regard to (1) and the inequality $K^+ + K^- > 0$, we can see that

$$-K^+\xi_t^+ - K^-\xi_t^- \le -K^+\left(\xi_t^+ - \xi_t^-\right) = -K^+Y_t + K^+y, \tag{35}$$

which, combined with (34), implies that

$$\begin{aligned} &-K^+\int_{[0,T]} e^{-rt}\,d\xi_t^+ - K^-\int_{[0,T]} e^{-rt}\,d\xi_t^- \\ &\qquad \le -rK^+\int_0^T e^{-rt}Y_t\,dt - e^{-rT}K^+Y_{T+} + K^+y. \end{aligned} \tag{36}$$

However, this inequality and (24) in Assumption 2 imply that the random variables U_T defined by (4) satisfy

$$\begin{aligned} U_T &\le K^+y + \int_0^T e^{-rt}\left[h(X_t,Y_t) - rK^+Y_t\right]dt \\ &\le K^+y + C\int_0^T e^{-rt}\left(1 + X_t^{n-\vartheta}\right) - \hat{Z}_T, \end{aligned} \tag{37}$$

where

$$\hat{Z}_T = \int_0^T e^{-rt}\left[r\vartheta Y_t - CX_t^{\alpha}Y_t^{\beta}\right] dt \quad \text{for } T \geq 0.$$

With reference to (18), we note that

$$\begin{aligned} I_1(x) &:= E\left[C\int_0^{\infty} e^{-rt}\left(1 + X_t^{n-\vartheta}\right) dt\right] \\ &= \frac{C}{r} - \frac{Cx^{n-\vartheta}}{\sigma^2(n-\vartheta)^2 + (b-\sigma^2)(n-\vartheta) - r} \in]0,\infty[. \end{aligned} \tag{38}$$

Now, suppose that the strategy $(\xi^+, \xi^-) \in \Pi_y$ is associated with

$$E\left[\int_0^{\infty} e^{-rt} Y_t\, dt\right] = \infty. \tag{39}$$

With regard to (23) in Assumption 2 and (18), we observe that

$$I_2(x) := E\left[\int_0^{\infty} e^{-rt} X_t^{\alpha/(1-\beta)}\, dt\right] < \infty. \tag{40}$$

Therefore, given any constant $\mu > 0$,

$$E\left[\int_0^{\infty} e^{-rt} Y_t \mathbf{1}_{\left\{Y_t < \mu X_t^{\alpha/(1-\beta)}\right\}}\, dt\right] \leq \mu I_2(x) < \infty. \tag{41}$$

It follows that (39) is true if and only if

$$E\left[\int_0^{\infty} e^{-rt} Y_t \mathbf{1}_{\left\{Y_t \geq \mu X_t^{\alpha/(1-\beta)}\right\}}\, dt\right] = \infty. \tag{42}$$

Now, let any $\mu > 0$ such that $r\vartheta - C\mu^{-(1-\beta)} > 0$, where the constants $\vartheta, C > 0$ and $\beta \in]0,1[$ are as in Assumption 2, and note that

$$\begin{aligned} E\left[\hat{Z}_T\right] \geq\ & -C\mu^{\beta} E\left[\int_0^T e^{-rt} X_t^{\alpha/(1-\beta)} \mathbf{1}_{\left\{Y_t < \mu X_t^{\alpha/(1-\beta)}\right\}}\, dt\right] \\ & + \left(r\vartheta - C\mu^{-(1-\beta)}\right) E\left[\int_0^T e^{-rt} Y_t \mathbf{1}_{\left\{Y_t \geq \mu X_t^{\alpha/(1-\beta)}\right\}}\, dt\right]. \end{aligned}$$

In view of (41)–(42) and the monotone convergence theorem, the right-hand side of this inequality tends to ∞ as $T \to \infty$, which implies that $\lim_{T\to\infty} E[\hat{Z}_T] = \infty$. However, this conclusion, (37), and (38) imply that there exists a process Z such that (7) is satisfied and, therefore, $J_{x,y}(\xi^+, \xi^-) = -\infty$.

To proceed further, let us assume that

$$E\left[\int_0^{\infty} e^{-rt} Y_t\, dt\right] < \infty, \tag{43}$$

which is necessary for condition (32) to be satisfied. Since Y is a finite variation process, its sample paths can have at most countable discontinuities. Using Fubini's theorem, we can see that this observation and (43) imply that

$$\int_0^{\infty} e^{-rt} E\left[Y_{t+}\right] dt = E\left[\int_0^{\infty} e^{-rt} Y_{t+}\, dt\right] = E\left[\int_0^{\infty} e^{-rt} Y_t\, dt\right] < \infty,$$

which proves that (32) implies (33) and establishes part (b) of the lemma.

Now, using Hölder's inequality, we calculate

$$E\left[\int_0^\infty e^{-rt}X_t^\alpha Y_t^\beta\,dt\right] \le I_2^{1-\beta}(x)\left(E\left[\int_0^\infty e^{-rt}Y_t\,dt\right]\right)^\beta < \infty, \tag{44}$$

where $I_2(x)$ is given by (40). This inequality, (38), (43), and the bounds in (24) in Assumption 2 imply that

$$\begin{aligned} E\Big[\int_0^\infty e^{-rt}\,|h(X_t,Y_t)|\,dt\Big] &\le E\left[\int_0^\infty e^{-rt}\left[C\left(1+X_t^{n-\vartheta}+X_t^\alpha Y_t^\beta\right)+\left\{r(K^+-\vartheta)\vee C\right\}Y_t\right]dt\right] \\ &< \infty, \end{aligned}$$

which, combined with the dominated convergence theorem, implies that

$$\lim_{T\to\infty} E\left[\int_0^T e^{-rt}h(X_t,Y_t)\,dt\right] = E\left[\int_0^\infty e^{-rt}h(X_t,Y_t)\,dt\right] \in \mathbb{R}. \tag{45}$$

This observation gives rise to two possibilities. The first one is associated with the inequality

$$E\left[\int_{[0,\infty[} e^{-rt}\,d\xi_t^+ + \int_{[0,\infty[} e^{-rt}\,d\xi_t^-\right] < \infty.$$

In this case, $\lim_{T\to\infty} U_T$ exists, P-a.s., and belongs to $L^1(\Omega,\mathcal{F},P)$, and so $J_{x,y}(\xi^+,\xi^-)$ is finite and is given by (6). The second possibility is associated with

$$E\left[\int_{[0,\infty[} e^{-rt}\,d\xi_t^+ + \int_{[0,\infty[} e^{-rt}\,d\xi_t^-\right] = \infty,$$

which, combined with (43) and (33), implies that

$$E\left[\int_{[0,\infty[} e^{-rt}\,d\xi_t^+\right] = E\left[\int_{[0,\infty[} e^{-rt}\,d\xi_t^-\right] = \infty. \tag{46}$$

If $K^- < 0$, then we can use (1) and the integration by parts formula to calculate

$$\begin{aligned} K^-\int_{[0,T]} e^{-rt}\,d\xi_t^- &= K^-\int_{[0,T]} e^{-rt}\,d\xi_t^+ + |K^-|\int_{[0,T]} e^{-rt}\,dY_t \\ &= K^-\int_{[0,T]} e^{-rt}\,d\xi_t^+ + r|K^-|\int_0^T e^{-rt}Y_t\,dt \\ &\quad + |K^-|e^{-rT}Y_{T+} - |K^-|y \\ &\ge K^-\int_{[0,T]} e^{-rt}\,d\xi_t^+ - |K^-|y, \end{aligned}$$

which implies that

$$\begin{aligned} E\Big[K^+\int_{[0,T]} e^{-rt}\,d\xi_t^+ + K^-\int_{[0,T]} e^{-rt}\,d\xi_t^-\Big] \\ \ge (K^+ + K^-)E\left[\int_{[0,T]} e^{-rt}\,d\xi_t^+\right] - |K^-|y. \end{aligned}$$

This inequality, the assumption that $K^+ + K^- > 0$, (46), and the monotone convergence theorem imply that

$$\lim_{T\to\infty} E\left[K^+ \int_{[0,T]} e^{-rt}\, d\xi_t^+ + K^- \int_{[0,T]} e^{-rt}\, d\xi_t^-\right] = \infty. \tag{47}$$

On the other hand, if $K^- \geq 0$, then (46) plainly implies (47). However, (45) and (47) imply that $\lim_{T\to\infty} E[U_T] = -\infty$, and so (7) is satisfied for $Z = U$ and $J_{x,y}(\xi^+, \xi^-) = -\infty$.

The analysis above establishes the well-posedness of the definition of $J_{x,y}$ given by (5)–(8) as well as parts (a) and (b) of the lemma. To prove part (c) of the lemma, we first note that the first bound in Lemma 2 and (18) imply that

$$R^{[h(\cdot,y)]}(x) = E\left[\int_0^\infty e^{-rt} h(X_t, y)\, dt\right] \in \mathbb{R}.$$

However, this shows that our performance criterion is finite for the strategy that involves no capacity changes at any time, which proves that $v(x,y) > -\infty$. To show that $v(x,y) < \infty$, consider any admissible decision strategy $(\xi^+, \xi^-) \in \Pi_y$ such that $J_{x,y}(\xi^+, \xi^-) > -\infty$. With reference to (43) and (44),

$$\begin{aligned} &E\left[\int_0^\infty e^{-rt}\left[r\vartheta Y_t - CX_t^\alpha Y_t^\beta\right] dt\right] \\ &\qquad \geq r\vartheta E\left[\int_0^\infty e^{-rt} Y_t\, dt\right] - CI_2^{1-\beta}(x)\left(E\left[\int_0^\infty e^{-rt} Y_t\, dt\right]\right)^\beta \\ &\qquad \geq -\frac{(1-\beta)r\vartheta}{\beta}\left(\frac{\beta C}{r\vartheta}\right)^{1/(1-\beta)} I_2(x), \quad \text{for all } T > 0, \end{aligned} \tag{48}$$

the second inequality following because, given any constants $\kappa, \lambda > 0$ and $\beta \in]0,1[$,

$$\kappa Q - \lambda Q^\beta \geq -\frac{(1-\beta)\kappa}{\beta}\left(\frac{\beta\lambda}{\kappa}\right)^{1/(1-\beta)}, \quad \text{for all } Q \geq 0,$$

in particular, for $Q = E\left[\int_0^\infty e^{-rt} Y_t\, dt\right]$. However, (37), (38), and (48) imply that

$$J_{x,y}(\xi^+, \xi^-) \leq I_1(x) + K^+ y + \frac{(1-\beta)r\vartheta}{\beta}\left(\frac{\beta C}{r\vartheta}\right)^{1/(1-\beta)} I_2(x),$$

which proves that $v(x,y) < \infty$ because the right-hand side of this inequality is finite and independent of ξ^+ and ξ^-. □

4. The Hamilton–Jacobi–Bellman (HJB) equation. The problem described in the previous section has the structure of a singular stochastic control problem. With regard to standard theory of singular control, we expect that its value function can be identified with a solution $w : \mathcal{S} \to \mathbb{R}$ to the HJB quasi-variational inequalities

$$\begin{aligned} &\max\{\sigma^2 x^2 w_{xx}(x,y) + bx w_x(x,y) - rw(x,y) + h(x,y), \\ &\qquad w_y(x,y) - K^+,\ -w_y(x,y) - K^-\} = 0, \quad x, y > 0, \end{aligned} \tag{49}$$

$$\max\{\sigma^2 x^2 w_{xx}(x,0) + bx w_x(x,0) - rw(x,0) + h(x,0),\ w_y(x,0) - K^+\} = 0, \quad x > 0, \tag{50}$$

where $w_y(x,0) := \lim_{y\downarrow 0} w_y(x,y)$.

To obtain some qualitative understanding of the origins of this equation, we observe that, at time 0, the project's management has to choose between three options. The first one is to wait for a short time Δt and then continue optimally. With respect to Bellman's principle of optimality, this option is associated with the inequality

$$v(x,y) \geq E\left[\int_0^{\Delta t} e^{-rt}h(X_t,y)\,dt + e^{-r\Delta t}v(X_{\Delta t},y)\right].$$

Applying Itô's formula to the second term in the expectation and dividing by Δt before letting $\Delta t \downarrow 0$, we obtain

$$\sigma^2x^2v_{xx}(x,y) + bxv_x(x,y) - rv(x,y) + h(x,y) \leq 0. \tag{51}$$

The second option is to increase capacity immediately by $\varepsilon > 0$ and then continue optimally. This action is associated with the inequality

$$v(x,y) \geq v(x,y+\varepsilon) - K^+\varepsilon.$$

Rearranging terms and letting $\varepsilon \downarrow 0$, we obtain

$$v_y(x,y) - K^+ \leq 0. \tag{52}$$

Assuming that $y > 0$, the final option is to decrease capacity immediately by $\varepsilon > 0$ and then continue optimally. This option yields the inequality

$$v(x,y) \geq v(x,y-\varepsilon) - K^-\varepsilon,$$

which, in the limit as $\varepsilon \downarrow 0$, implies that

$$-v_y(x,y) - K^- \leq 0. \tag{53}$$

Since these three are the only options available, we expect that one of them should be optimal, so that one of the inequalities (51)–(53) should hold with equality if $y > 0$, while one of the inequalities (51)–(52) should hold with equality if $y = 0$. However, this observation combined with (51)–(53) implies that the value function v should identify with a solution w to (49)–(50).

The following result is concerned with *sufficient* conditions under which the value function v of the control problem considered identifies with a solution to (49)–(50). We impose some of these conditions, (58)–(59) in particular, which are not standard in similar "verification" theorems, with a hindsight relative to our analysis in the next section.

THEOREM 5. *Suppose that the running payoff function h satisfies* (24) *in Assumption* 2 *and that $K^+, K^+ + K^- > 0$. Also, assume that the HJB equation* (49)–(50) *has a C^2 solution $w : \mathcal{S} \to \mathbb{R}$ such that*

$$-C_2\left(1 + y + x^{\alpha/(1-\beta)}\right) \leq w(x,y), \quad \textit{for all } (x,y) \in \mathcal{S}, \tag{54}$$

for some constant $C_2 > 0$. The following statements hold true:

(a) *$v(x,y) \leq w(x,y)$ for all initial conditions $(x,y) \in \mathcal{S}$.*

(b) *Given any initial condition $(x,y) \in \mathcal{S}$, suppose that there exists a decision strategy $(\xi^{o+}, \xi^{o-}) \in \Pi_y$ such that, if Y^o is the associated capacity process, then*

$$(X_t, Y_t^o) \in \left\{(x,y) \in \mathcal{S} :\ \sigma^2x^2w_{xx}(x,y) + bxw_x(x,y) - rw(x,y) + h(x,y) = 0\right\}, \tag{55}$$

Lebesgue-a.e., P-a.s.,

$$\int_{[0,T]} e^{-rs}\left[w_y(X_t,Y_t)-K^+\right]d\xi_s^{o+}=0,\quad \textit{for all } T\geq 0,\ P\textit{-a.s.}, \tag{56}$$

$$\int_{[0,T]} e^{-rs}\left[w_y(X_t,Y_t)+K^-\right]d\xi_s^{o-}=0,\quad \textit{for all } T\geq 0,\ P\textit{-a.s.}, \tag{57}$$

and

$$Y_t^o+X_t^\alpha (Y_t^o)^\beta+\xi_t^{o+}\leq C_3(y)\left(1+\bar{X}_t^{n-\varepsilon_3}\right),\quad \textit{for all } t\geq 0,\ P\textit{-a.s.}, \tag{58}$$

$$w(X_t,Y_t^o)\leq C_3(y)\left(1+\bar{X}_t^{n-\varepsilon_3}\right),\quad \textit{for all } t\geq 0,\ P\textit{-a.s.}, \tag{59}$$

where $\bar{X}_t=\sup_{s\leq t}X_s$, $\varepsilon_3\in\,]0,\vartheta[$ *is a constant, and* $C_3(y)>0$ *is a constant depending on the initial condition* y *only. Then* $v(x,y)=w(x,y)$ *and* (ξ^{o+},ξ^{o-}) *is the optimal strategy.*

Proof. (a) Fix any initial condition (x,y) and any admissible strategy $(\xi^+,\xi^-)\in\Pi_y$ such that $J_{x,y}(\xi^+,\xi^-)>-\infty$, so that $J_{x,y}(\xi^+,\xi^-)=E[U_\infty]$ (see (5)–(6)). Using Itô's formula and the fact that X has continuous sample paths, we obtain

$$\begin{aligned}
&e^{-rT}w(X_T,Y_{T+})\\
&\quad=w(x,y)+\int_0^T e^{-rt}\left[\sigma^2X_t^2w_{xx}(X_t,Y_t)+bX_tw_x(X_t,Y_t)-rw(X_t,Y_t)\right]dt\\
&\qquad+\int_{[0,T]} e^{-rt}\left[w_y(X_t,Y_t)\,d\xi_t^+-w_y(X_t,Y_t)\,d\xi_t^-\right]+M_T\\
&\qquad+\sum_{0\leq t\leq T} e^{-rt}\left[w(X_t,Y_{t+})-w(X_t,Y_t)-w_y(X_t,Y_t)\Delta Y_t\right],
\end{aligned}$$

where

$$M_T=\sqrt{2}\sigma\int_0^T e^{-rt}X_tw_x(X_t,Y_t)\,dW_t,\quad T\geq 0. \tag{60}$$

Recalling the definition of U_T in (4), this implies that

$$\begin{aligned}
&U_T+e^{-rT}w(X_T,Y_{T+})-w(x,y)\\
&=\int_0^T e^{-rt}\left[\sigma^2X_t^2w_{xx}(X_t,Y_t)+bX_tw_x(X_t,Y_t)-rw(X_t,Y_t)+h(X_t,Y_t)\right]dt\\
&\quad+\int_{[0,T]} e^{-rt}\left[w_y(X_t,Y_t)-K^+\right]d\left(\xi^+\right)_t^c\\
&\quad+\int_{[0,T]} e^{-rt}\left[-w_y(X_t,Y_t)-K^-\right]d\left(\xi^-\right)_t^c\\
&\quad+M_T+\sum_{0\leq t\leq T} e^{-rt}\left[w(X_t,Y_{t+})-w(X_t,Y_t)-K^+\Delta Y_t\right]\mathbf{1}_{\{\Delta Y_t>0\}}\\
&\quad+\sum_{0\leq t\leq T} e^{-rt}\left[w(X_t,Y_{t+})-w(X_t,Y_t)+K^-\Delta Y_t\right]\mathbf{1}_{\{\Delta Y_t<0\}}.
\end{aligned}$$

Observing that

$$\begin{aligned}
&\left[w(X_t,Y_{t+})-w(X_t,Y_t)-K^+\Delta Y_t\right]\mathbf{1}_{\{\Delta Y_t>0\}}\\
&\qquad=\mathbf{1}_{\{\Delta Y_t>0\}}\int_0^{\Delta Y_t}\left[w_y(X_t,Y_t+u)-K^+\right]du
\end{aligned}$$

and

$$\begin{aligned}\left[w(X_t,Y_{t+})-w(X_t,Y_t)+K^-\Delta Y_t\right]\mathbf{1}_{\{\Delta Y_t<0\}}&\\ =\mathbf{1}_{\{\Delta Y_t<0\}}\int_0^{|\Delta Y_t|}\left[-w_y\left(X_t,Y_t-|\Delta Y_t|+u\right)-K^-\right]du,&\end{aligned}$$

we can see that, since w satisfies the HJB equation (49)–(50),

$$U_T+e^{-rT}w(X_T,Y_{T+})\le w(x,y)+M_T. \tag{61}$$

Now, in view of (36) and the assumption $K^+>0$,

$$-e^{-rT}Y_{T+}\ge-\int_{[0,T]}e^{-rt}\,d\xi_t^+-\frac{|K^-|}{K^+}\int_{[0,T]}e^{-rt}\,d\xi_t^--y,$$

which, combined with assumption (54), implies that

$$e^{-rT}w(X_T,Y_{T+})\ge-C_{21}\left(1+\int_{[0,T]}e^{-rt}\,d\xi_t^++\int_{[0,T]}e^{-rt}\,d\xi_t^-+e^{-rT}X_T^{\alpha/(1-\beta)}\right)$$

for some constant $C_{21}=C_{21}(y)>0$. Combining this inequality with

$$\int_0^T e^{-rt}h(X_t,Y_t)\,dt\ge-C\int_0^T e^{-rt}Y_t\,dt-\frac{C}{r}\left(1-e^{-rT}\right),$$

which follows from (24) in Assumption 2, we can see that (61) implies

$$\begin{aligned}\inf_{T\ge0}M_T\ge-C_{22}\Bigg(1+\int_0^\infty e^{-rt}Y_t\,dt+\int_{[0,\infty[}e^{-rt}\,d\xi_t^+&\\ +\int_{[0,\infty[}e^{-rt}\,d\xi_t^-+\sup_{T\ge0}e^{-rT}\bar X_T^{\alpha/(1-\beta)}\Bigg),&\end{aligned}$$

where $C_{22}=C_{22}(x,y)>0$ is a constant and $\bar X_t=\sup_{s\le t}X_s$. Recalling the assumption that $\frac{\alpha}{1-\beta}\in]0,n[$, we can see that the second bound in Lemma 1 and (32) in Lemma 4 imply that the random variable on the right-hand side of this inequality has finite expectation. It follows that the stochastic integral M defined by (60) is a supermartingale, and therefore $E[M_T]\le0$, for all $T>0$. Taking expectations in (61), we therefore obtain

$$E[U_T]\le w(x,y)+e^{-rT}E\left[-w(X_T,Y_{T+})\right]. \tag{62}$$

Furthermore, since

$$U_T\ge-C_{22}\left(1+\int_0^\infty e^{-rt}Y_t\,dt+\int_{[0,\infty[}e^{-rt}\,d\xi_t^++\int_{[0,\infty[}e^{-rt}\,d\xi_t^-\right),\quad\text{for all } T\ge0,$$

and the random variable on the right-hand side of this inequality has finite expecta-

tion, Fatou's lemma implies that

$$J_{x,y}(\xi^+,\xi^-) \leq \liminf_{T\to\infty} E\left[U_T\right], \tag{63}$$

while (54) implies that

$$\begin{aligned}\liminf_{T\to\infty} e^{-rT}E\left[-w(X_T,Y_{T+})\right] \leq{}& \lim_{T\to\infty} e^{-rT}C_2 + C_2 \liminf_{T\to\infty} e^{-rT}E\left[Y_{T+}\right]\\ &+ C_2 \lim_{T\to\infty} e^{-rT}E\left[\bar{X}_T^{\alpha/(1-\beta)}\right]\\ ={}& 0,\end{aligned} \tag{64}$$

the equality being true thanks to the first bound in Lemma 1 and (33). However, (62)–(64) imply that $J_{x,y}(\xi^+,\xi^-) \leq w(x,y)$, which establishes part (a) of the theorem.

(b) If $(\xi^{\mathrm{o}+},\xi^{\mathrm{o}-})$ is as in the statement of the theorem, then we can see that the monotone convergence theorem, the integration by parts formula, (58), and the first estimate in Lemma 1 imply that

$$\begin{aligned}&E\left[\int_0^\infty e^{-rt}Y_t^{\mathrm{o}}\,dt + \int_{[0,\infty[} e^{-rt}\,d\xi_t^{\mathrm{o}+}\right]\\ &\qquad= \lim_{T\to\infty} E\left[\int_0^T e^{-rt}Y_t^{\mathrm{o}}\,dt + r\int_0^T e^{-rt}\xi_t^{\mathrm{o}+}\,dt + e^{-rT}\xi_{T+}^{\mathrm{o}+}\right]\\ &\qquad\leq (1+r)C_3(y)\left(\frac{1}{r} + \int_0^\infty e^{-rt}E\left[\bar{X}_t^{n-\varepsilon_3}\right]dt\right) + \lim_{T\to\infty} e^{-rT}E\left[\bar{X}_T^{n-\varepsilon_3}\right]\\ &\qquad< \infty,\end{aligned}$$

which, combined with (1), implies that (32) in Lemma 4 is satisfied, and, therefore,

$$J_{x,y}(\xi^{\mathrm{o}+},\xi^{\mathrm{o}-}) = E\left[\lim_{T\to\infty} U_T^{\mathrm{o}}\right] \in \mathbb{R}, \tag{65}$$

where U^{o} is defined as in (4). Furthermore, we can verify that (61) holds with equality, i.e.,

$$U_T^{\mathrm{o}} + e^{-rT}w(X_T,Y_{T+}^{\mathrm{o}}) = w(x,y) + M_T^{\mathrm{o}}, \tag{66}$$

where the stochastic integral M^{o} is defined as in (60). In view of (24) in Assumption 2 and (58), there exist constants $C_{31} > 0$ and $C_{32} = C_{32}(y) > 0$ such that

$$\begin{aligned}\sup_{T\geq 0}\int_0^T e^{-rt}h(X_t,Y_t^{\mathrm{o}})\,dt &\leq C_{31}\left(1 + \int_0^\infty e^{-rt}\left[X_t^{n-\vartheta} + X_t^{\alpha}(Y_t^{\mathrm{o}})^{\beta} + Y_t^{\mathrm{o}}\right]dt\right)\\ &\leq C_{32}\left(1 + \int_0^\infty e^{-rt}\bar{X}_t^{n-\varepsilon_3}\,dt\right).\end{aligned} \tag{67}$$

With reference to (1), the assumption $K^+ + K^- > 0$, the integration by parts formula,

and (58), we can see that there exists a constant $C_{33} = C_{33}(y) > 0$ such that

$$\begin{aligned}
\sup_{T\geq 0}\left(-K^+\int_{[0,T]} e^{-rt}\,d\xi_t^{o+} - K^-\int_{[0,T]} e^{-rt}\,d\xi_t^{o-}\right)& \\
&\leq \sup_{T\geq 0} K^-\left(\int_{[0,T]} e^{-rt}\,d\xi_t^{o+} - \int_{[0,T]} e^{-rt}\,d\xi_t^{o-}\right)\\
&\leq |K^-|\sup_{T\geq 0}\int_{[0,T]} e^{-rt}\,dY_t^o\\
&\leq |K^-|\sup_{T\geq 0} e^{-rT}Y_{T+}^o + r|K^-|\int_0^\infty e^{-rt}Y_t^o\,dt\\
&\leq |K^-|\sup_{T\geq 0} e^{-rT}Y_{T+}^o + C_{33}\left(1+\int_0^\infty e^{-rt}\bar{X}_t^{n-\varepsilon_3}\,dt\right). \qquad (68)
\end{aligned}$$

Moreover, (58)–(59) imply that

$$\sup_{T\geq 0} e^{-rT}Y_{T+}^o + \sup_{T\geq 0} e^{-rT}w(X_T, Y_{T+}^o) \leq 2C_3(y)\left(1+\sup_{T\geq 0} e^{-rT}\bar{X}_T^{n-\varepsilon_3}\right). \qquad (69)$$

Now, (18) implies that

$$E\left[\int_0^\infty e^{-rt}\bar{X}_t^{n-\varepsilon_3}\,dt\right] < \infty, \qquad (70)$$

while the second estimate in Lemma 1 implies that

$$E\left[\sup_{T\geq 0} e^{-rT}\bar{X}_T^{n-\varepsilon_3}\right] < \infty. \qquad (71)$$

However, (66) and the estimates (67)–(71) imply that $E\left[\sup_{T\geq 0} M_T^o\right] < \infty$, which proves that the stochastic integral M^o is a submartingale. Taking expectations in (66), we therefore obtain

$$E\left[U_T^o\right] \geq w(x,y) + e^{-rT}E\left[-w(X_T, Y_T^o)\right]. \qquad (72)$$

Furthermore, the estimates (67)–(71) imply that the random variables U_T^o, indexed by $T \geq 0$, are all bounded from above by a random variable with finite expectation. This observation, (65), and Fatou's lemma imply that

$$J_{x,y}(\xi^{o+}, \xi^{o-}) \geq \limsup_{T\to\infty} E\left[U_T^o\right]. \qquad (73)$$

Finally, (59) and the first estimate in Lemma 1 imply that

$$\begin{aligned}
\limsup_{T\to\infty} e^{-rT}E\left[-w(X_T, Y_T^o)\right] &\geq -\lim_{T\to\infty} C_3(y)\left(e^{-rT} + E\left[e^{-rT}\bar{X}_T^{n-\varepsilon_3}\right]\right)\\
&= 0,
\end{aligned}$$

which, combined with (72) and (73), implies that $J_{x,y}(\xi^{o+}, \xi^{o-}) \geq w(x,y)$. However, this inequality and part (a) of this theorem complete the proof. □

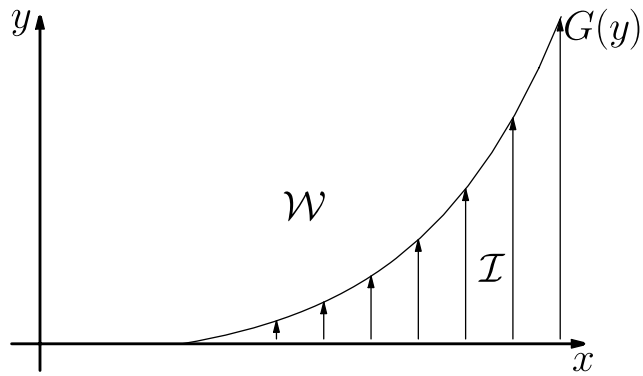

FIG. 1. *A possible optimal capacity control strategy. In this case, it is never optimal to decrease the project's capacity.*

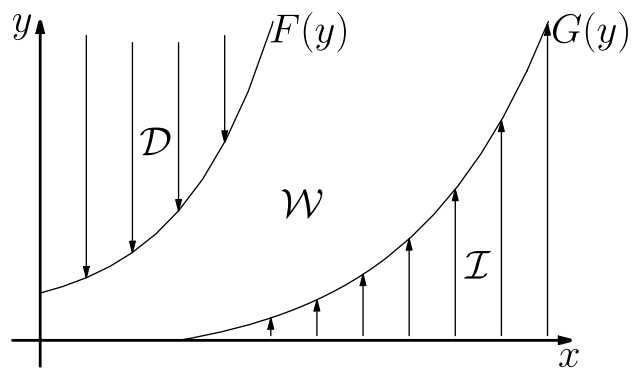

FIG. 2. *A possible optimal capacity control strategy. In this case, increasing the project's capacity, waiting, and decreasing the project's capacity are all parts of the optimal strategy. Also, the point* y^* *defined by* (74) *is strictly positive.*

5. The solution of the control problem. We can now derive an explicit solution to the control problem formulated in section 2 by constructing an appropriate solution w to the HJB equation (49)–(50). With respect to the heuristic arguments in section 4 that led to the derivation of this equation, we start by conjecturing that the optimal strategy is characterized by three disjoint open subsets of $]0,\infty[\times\mathbb{R}_+$: the "wait" region $\mathcal{W}$ where (51) holds with equality, the "investment" region $\mathcal{I}$ where (52) holds with equality, and the "disinvestment" region $\mathcal{D}$ where (53) holds with equality. Also, we conjecture that each of the regions $\mathcal{W}$, $\mathcal{I}$, $\mathcal{D}$ is connected. In particular, we expect that, depending on the problem data, the optimal strategy can take any of the forms depicted by Figures 1–4. Note that one can envisage other possibilities such as the one depicted by Figure 5. However, our assumptions do not allow for the optimality of other such cases under any admissible choice of the problem data (see also Remark 1 in section 3 and Example 3 in section 6).

With regard to Figures 1–4, we denote by $\mathbb{F}$ and $\mathbb{G}$ the boundaries separating the regions $\mathcal{D}$, $\mathcal{W}$ and $\mathcal{W}$, $\mathcal{I}$, respectively, so that

$$\mathbb{F} = \overline{\mathcal{D}} \cap \overline{\mathcal{W}} \quad \text{and} \quad \mathbb{G} = \overline{\mathcal{W}} \cap \overline{\mathcal{I}},$$

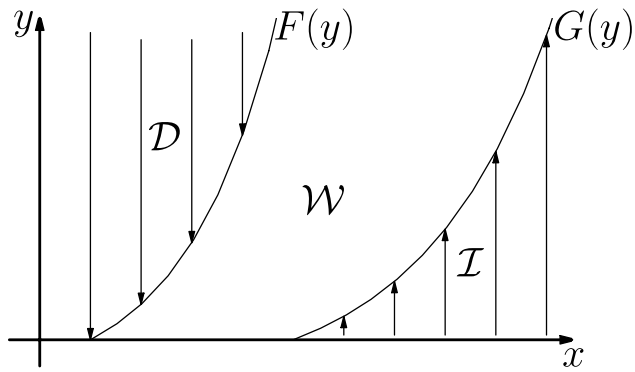

FIG. 3. *A possible optimal capacity control strategy. In this case, increasing the project's capacity, waiting, and decreasing the project's capacity all belong to the set of optimal tactics. Also,* $y^* = 0$*, where* y^* *is defined by* (74)*,* $F(0) > 0$*, and* $\{(x, 0) : \ x \leq F(0)\}$ *is a subset of the "wait" region* $\mathcal{W}$*.*

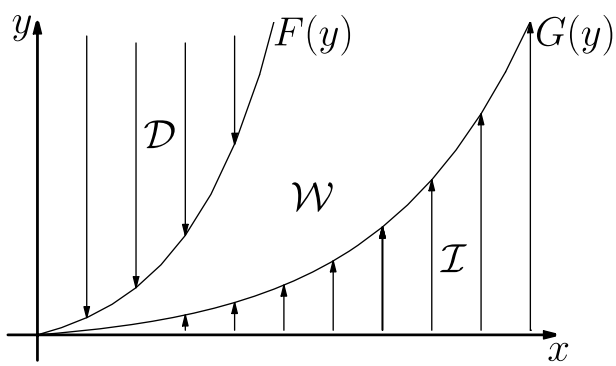

FIG. 4. *A possible optimal capacity control strategy. This case arises when the running payoff function* h *identifies with the Cobb–Douglas production function and* $K^- < 0$*.*

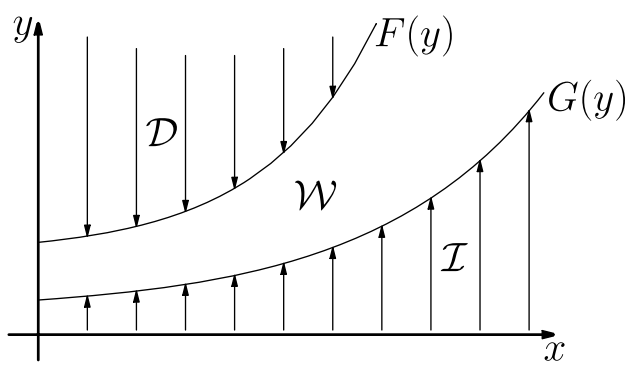

FIG. 5. *A possible optimal capacity control strategy. This case* cannot *arise under our assumptions.*

where $\overline{\mathcal{W}}$, $\overline{\mathcal{I}}$, and $\overline{\mathcal{D}}$ are the closures of $\mathcal{W}$, $\mathcal{I}$, and $\mathcal{D}$ in $\mathbb{R}^2_+$, respectively. Furthermore, we define

$$y^* = \inf\{y \geq 0 : \text{ there exists } x > 0 \text{ such that } (x,y) \in \mathbb{F}\}, \tag{74}$$

with the usual convention that $\inf \emptyset = \infty$. We will prove that

$$\begin{gathered}\text{there exists an increasing function } G : [0,\infty[\to [0,\infty[\text{ such that} \\ \mathbb{G} = \{(G(y), y) : \ y \geq 0\},\end{gathered} \tag{75}$$

and, if $y^* < \infty$, then

$$\begin{gathered}\text{there exists an increasing function } F : [y^*,\infty[\to [0,\infty[\text{ such that} \\ \mathbb{F} \cap (\mathbb{R}_+ \setminus \{0\})^2 = \{(F(y), y) : \ y > y^*\}.\end{gathered} \tag{76}$$

Given such a characterization of $\mathbb{F}$ and $\mathbb{G}$,

$$\begin{aligned}\overline{\mathcal{W}} = & \left\{(x,y) \in \mathbb{R}^2_+ : \ y \leq y^* \text{ and } x \in [0, G(y)]\right\} \\ & \cup \left\{(x,y) \in \mathbb{R}^2_+ : \ y > y^* \text{ and } x \in [F(y), G(y)]\right\}, \\ \overline{\mathcal{I}} = & \left\{(x,y) \in \mathbb{R}^2_+ : \ G(y) \leq x\right\},\end{aligned}$$

while if $y^* < \infty$, then

$$\overline{\mathcal{D}} = \left\{(x,y) \in \mathbb{R}^2_+ : \ y \geq y^* \text{ and } x \in [0, F(y)]\right\}.$$

In view of this structure, it is worth noting that if $y^* = 0$ and $0 < F(0) < G(0)$ (see Figure 3), then $\{(x,0) : \ x < G(0)\} \subset \mathcal{W}$, so that the segment $]0, F(0)]$ is part of the "wait" region $\mathcal{W}$.

Inside the region $\mathcal{W}$, w satisfies the differential equation

$$\sigma^2 x^2 w_{xx}(x,y) + bx w_x(x,y) - rw(x,y) + h(x,y) = 0. \tag{77}$$

In view of the discussion regarding the solvability of (14) in section 3, every solution to this equation is given by

$$w(x,y) = A(y)x^n + B(y)x^m + R(x,y) \tag{78}$$

for some functions A and B. Here, the constants $m < 0 < n$ are given by (11), while the function $R \equiv R^{[h(\cdot,y)]}$ is given by

$$R(x,y) = \frac{1}{\sigma^2(n-m)}\left[x^m \int_0^x s^{-m-1} h(s,y)\, ds + x^n \int_x^\infty s^{-n-1} h(s,y)\, ds\right]. \tag{79}$$

For $y \in [0, y^*] \cap \mathbb{R}$, we must have $B(y) = 0$. This choice is supported by the heuristic observation that, for fixed capacity level $y \geq 0$, the problem's value function should remain bounded as the value x of the underlying state process tends to 0. Also, it eventually turns out that (58)–(59) in the verification theorem, Theorem 5, cannot be satisfied if $B(y) \neq 0$. To determine $A(y)$ and $G(y)$ when $y \in [0, y^*] \cap \mathbb{R}$, we postulate that $w(\cdot, y)$ is C^2 at the free-boundary point $G(y)$. In particular, we postulate that

$$\lim_{x \uparrow G(y)} w_y(x,y) = \lim_{x \downarrow G(y)} w_y(x,y) \quad \text{and} \quad \lim_{x \uparrow G(y)} w_{yx}(x,y) = \lim_{x \downarrow G(y)} w_{yx}(x,y). \tag{80}$$

Since w satisfies

$$w_y(x,y) = K^+, \quad \text{for } (x,y) \in \mathcal{I}, \tag{81}$$

which implies that

$$w_{xy}(x,y) = 0, \quad \text{for } (x,y) \in \mathcal{I}, \tag{82}$$

this requirement yields the system of equations

$$A'(y)G^n(y) = K^+ - R_y(G(y),y), \tag{83}$$

$$A'(y)G^n(y) = -\frac{1}{n}G(y)R_{xy}(G(y),y). \tag{84}$$

Equating the right-hand sides of these equations and using the definition of R in (79), we obtain

$$G^m(y)\int_0^{G(y)} s^{-m-1}H(s,y)\,ds - \sigma^2 nK^+ = 0, \tag{85}$$

where H is the function defined by (19). Using the identity $\sigma^2 mn = -r$, which follows from the definition of the constants m, n in (11), we can see that $G(y)$ should satisfy

$$q(G(y),y) = 0, \tag{86}$$

where

$$q(x,y) = \int_0^x s^{-m-1}\left[H(s,y) - rK^+\right]ds, \quad (x,y) \in \mathcal{S}. \tag{87}$$

Furthermore, adding (83) and (84) side by side and using (79) and (85), we obtain

$$\begin{aligned} A'(y) &= \frac{1}{2}G^{-n}(y)\left[K^+ - R_y(G(y),y) - \frac{1}{n}G(y)R_{xy}(G(y),y)\right] \\ &= -\frac{1}{\sigma^2(n-m)}\int_{G(y)}^{\infty} s^{-n-1}\left[H(s,y) - rK^+\right]ds. \end{aligned} \tag{88}$$

The following result, whose proof is developed in the appendix, is concerned with the solvability of (86).

LEMMA 6. *Suppose that Assumption* 1 *is true. Given any* $y \geq 0$*, the equation* $q(x,y) = 0$ *has a unique solution* $x = x(y) > 0$ *if and only if* $\inf_{x>0} H(x,y) < rK^+$*. If we define*

$$\tilde{y}_* = \inf\left\{y \geq 0 : \inf_{x>0} H(x,y) < rK^+\right\}, \tag{89}$$

then (86) *uniquely defines a function* $\tilde{G} :]\tilde{y}_*, \infty[\to]0, \infty[$ *that is* C^1*, is strictly increasing, and satisfies*

$$H(\tilde{G}(y),y) - rK^+ > 0 \quad \textit{for all } y > \tilde{y}_*. \tag{90}$$

Furthermore, if (25) *in Assumption* 2 *is also true, then* $\tilde{y}_* = 0$ *and*

$$\begin{aligned} &C_4^{-\frac{1-\beta}{\alpha}} y^{\frac{1-\beta}{\alpha}} \leq \tilde{G}(y), \quad \textit{for all } y \geq 0 \\ &\qquad\qquad \Leftrightarrow \quad \tilde{G}^{[-1]}(x) \leq C_4 x^{\frac{\alpha}{1-\beta}}, \quad \textit{for all } x \geq \tilde{G}(0), \end{aligned} \tag{91}$$

where $\tilde{G}(0) := \lim_{y \downarrow 0} \tilde{G}(y)$, $\tilde{G}^{[-1]} : [\tilde{G}(0), \infty[\to \mathbb{R}_+$ *is the inverse function of* $\tilde{G}$, *and* $C_4 > 0$ *is a constant.*

Now, let us consider the case where $\mathcal{D} \neq \emptyset$ and the point y^* defined by (74) is finite (see Figures 2–4). For $y > y^*$, w is given by (77) for x such that $(x, y) \in \mathcal{W}$, by (81) for x such that $(x, y) \in \mathcal{I}$, and by

$$w_y(x, y) = -K^- \tag{92}$$

for x such that $(x, y) \in \mathcal{D}$. Plainly, C^2 continuity of w inside $\mathcal{D}$ implies that

$$w_{xy}(x, y) = 0 \quad \text{for } (x, y) \in \mathcal{D}. \tag{93}$$

To determine $A(y)$, $B(y)$, $F(y)$, and $G(y)$, we postulate that $w(\cdot, y)$ is C^2 at both of the free-boundary points $F(y)$ and $G(y)$. With regard to (78), (81)–(82), (92)–(93), the definition (79) of $R(x, y)$, and the identity $\sigma^2 mn = -r$, this requirement yields

$$A'(y) = -\frac{1}{\sigma^2(n-m)} \int_{F(y)}^{\infty} s^{-n-1} \left[H(s, y) + rK^-\right] ds, \tag{94}$$

$$A'(y) = -\frac{1}{\sigma^2(n-m)} \int_{G(y)}^{\infty} s^{-n-1} \left[H(s, y) - rK^+\right] ds, \tag{95}$$

$$B'(y) = -\frac{1}{\sigma^2(n-m)} \int_{0}^{F(y)} s^{-m-1} \left[H(s, y) + rK^-\right] ds, \tag{96}$$

$$B'(y) = -\frac{1}{\sigma^2(n-m)} \int_{0}^{G(y)} s^{-m-1} \left[H(s, y) - rK^+\right] ds, \tag{97}$$

where H is defined by (19). These calculations imply that the points $F(y)$ and $G(y)$ should satisfy the system of equations

$$f(F(y), G(y), y) = 0, \tag{98}$$

$$g(F(y), G(y), y) = 0, \tag{99}$$

where

$$f(x_1, x_2, y) = \int_0^{x_1} s^{-m-1} \left[H(s, y) + rK^-\right] ds - \int_0^{x_2} s^{-m-1} \left[H(s, y) - rK^+\right] ds, \tag{100}$$

$$g(x_1, x_2, y) = \int_{x_1}^{\infty} s^{-n-1} \left[H(s, y) + rK^-\right] ds - \int_{x_2}^{\infty} s^{-n-1} \left[H(s, y) - rK^+\right] ds. \tag{101}$$

In the appendix, we prove the following result that is concerned with the solvability of the system of equations (98) and (99).

LEMMA 7. *Suppose that Assumption* 1 *holds. Given* $y \geq 0$, *the system of equations* (98) *and* (99) *has a unique solution* $(x_1, x_2) = (x_1(y), x_2(y))$ *such that* $0 < x_1 < x_2$ *if and only if* $\inf_{x>0} H(x, y) < -rK^-$. *Moreover, if we define*

$$\bar{y}^* = \inf \left\{ y \geq 0 : \inf_{x>0} H(x, y) < -rK^- \right\}, \tag{102}$$

with the usual convention that $\inf \emptyset = \infty$, *then, if* $\bar{y}^* < \infty$, *the system of equations* (98) *and* (99) *uniquely defines two functions* $\bar{F}, \bar{G} :]\bar{y}^*, \infty[\to]0, \infty[$ *that are* C^1, *are*

strictly increasing, and satisfy $\bar{F}(y) < \bar{G}(y)$*, for all* $y > \bar{y}^*$*,*

$$\bar{F}(\bar{y}^*) := \lim_{y \downarrow \bar{y}^*} \bar{F}(y) = 0, \quad \text{if } \bar{y}^* > 0, \tag{103}$$

$$\bar{F}(0) := \lim_{y \downarrow 0} \bar{F}(y) \leq \lim_{y \downarrow 0} \bar{G}(y) =: \bar{G}(0), \quad \text{if } \bar{y}^* = 0, \tag{104}$$

$$H(\bar{F}(y), y) + rK^- < 0 \quad \text{and} \quad H(\bar{G}(y), y) - rK^+ > 0 \quad \text{for all } y > \bar{y}^*. \tag{105}$$

Furthermore, if (25) *in Assumption* 2 *also holds, then*

$$\begin{aligned} &C_4^{-\frac{1-\beta}{\alpha}} y^{\frac{1-\beta}{\alpha}} \leq \bar{G}(y), \quad \text{for all } y \geq \bar{y}^* \\ &\qquad\qquad \Leftrightarrow \quad \bar{G}^{[-1]}(x) \leq C_4 x^{\frac{\alpha}{1-\beta}}, \quad \text{for all } x \geq \bar{G}(\bar{y}^*), \end{aligned} \tag{106}$$

where $\bar{G}^{[-1]} : [\bar{G}(0), \infty[\to \mathbb{R}_+$ *is the inverse function of* $\bar{G}$ *and the constant* $C_4 > 0$ *is the same constant as in Lemma* 6*.*

In light of the results above and in the presence of (25) in Assumption 2, $\tilde{y}_* = \infty$, where $\tilde{y}_*$ is defined by (89), and the point $\bar{y}^*$ defined by (102) identifies with the point y^* in (74). Also, the functions $F : [y^*, \infty[\to [0, \infty[$ and $G : [0, \infty[\to [0, \infty[$ separating the three possible regions, as conjectured in (75)–(76), are given by

$$F = \bar{F}, \text{ if } y^* < \infty, \tag{107}$$

$$G = \tilde{G}, \text{ if } y^* = \infty, \quad \text{and} \quad G(y) = \begin{cases} \tilde{G}(y), & \text{for } y \in [0, y^*], \\ \bar{G}(y), & \text{for } y > y^*, \end{cases} \text{ if } y^* < \infty, \tag{108}$$

where $\tilde{G}$ is as in Lemma 6, $\bar{F}$, $\bar{G}$ are as in Lemma 7, and $y^* \equiv \bar{y}^*$, where $\bar{y}^*$ is given by (102).

The results above completely determine the boundaries of the three possible regions. To specify w inside the "wait" region $\mathcal{W}$, we still have to solve (88) and (94)–(97). To this end, it is straightforward to see that if the associated integrals are finite, then the function

$$A(y) = \frac{1}{\sigma^2(n-m)} \int_y^\infty \int_{G(u)}^\infty s^{-n-1} \left[H(s,u) - rK^+ \right] ds\, du > 0, \quad y \geq 0, \tag{109}$$

satisfies (88) as well as (94) and (95). In this expression, the inequality follows thanks to (90) or the second inequality in (105), depending on the case, and the assumption that $H(\cdot, y)$ is increasing. It is worth noting that adding a constant on the right-hand side of (109) would yield a further solution to (88). However, it turns out that (109) gives the *only* solution of (88) that renders w compatible with the requirements of the verification theorem that we proved in section 4.

If $y^* < \infty$, then

$$B(y) = -\frac{1}{\sigma^2(n-m)} \int_{y^*}^y \int_0^{F(u)} s^{-m-1} \left[H(s,u) + rK^- \right] ds\, du > 0, \quad y > y^*, \tag{110}$$

satisfies (96) or (97). Here, the positivity of B follows from the first inequality in (105) and the assumption that $H(\cdot, y)$ is increasing. As above, we have set a possible additive constant to zero because the resulting function w can be identified with the value function of the control problem for *no other* choice.

With reference to (81), w must satisfy

$$w(x,y) = w(x, G^{[-1]}(x)) - K^+ \left(G^{[-1]}(x) - y \right), \quad \text{for } (x,y) \in \mathcal{I},$$

where $G^{[-1]} : [G(0), \infty[\to \mathbb{R}_+$ is the inverse function of G. Also, if $\mathcal{D} \neq \emptyset$, then (92) implies that w should satisfy

$$w(x,y) = w(x, \Phi(x)) - K^-(y - \Phi(x)), \quad \text{for } (x,y) \in \mathcal{D},$$

where the function $\Phi :]0, \infty[\to \mathbb{R}_+$ is defined by

$$\Phi(x) = \begin{cases} F^{[-1]}(x), & \text{if } x \geq F(y^*), \\ 0, & \text{if } y^* = 0 \text{ and } F(0) > x, \end{cases} \tag{111}$$

in which expression $F^{[-1]} : [F(y^*), \infty[\to \mathbb{R}_+$ is the inverse function of F. Summarizing, we have two possibilities. If the point $y^* \equiv \bar{y}^*$ as in (74) or (102) is equal to ∞, then

$$w(x,y) = \begin{cases} A(y)x^n + R(x,y), & \text{for } (x,y) \text{ such that} \\ & 0 < x \leq G(y), \\ w(x, G^{[-1]}(x)) - K^+(G^{[-1]}(x) - y) & \text{for } (x,y) \text{ such that } G(y) < x. \end{cases} \tag{112}$$

On the other hand, if $y^* < \infty$, then

$$w(x,y) = \begin{cases} w(x, \Phi(x)) - K^-(y - \Phi(x)), & \text{for } (x,y) \text{ such that} \\ & y > y^* \text{ and } x < F(y), \\ A(y)x^n + R(x,y), & \text{for } (x,y) \text{ such that} \\ & y \in [0, y^*] \cap \mathbb{R} \text{ and } x \leq G(y), \\ A(y)x^n + B(y)x^m + R(x,y), & \text{for } (x,y) \text{ such that} \\ & y > y^* \text{ and } F(y) \leq x \leq G(y), \\ w(x, G^{[-1]}(x)) - K^+(G^{[-1]}(x) - y) & \text{for } (x,y) \text{ such that } G(y) < x. \end{cases} \tag{113}$$

It is worth noting that if $y^* = 0$ and $F(0) > 0$, then (78) and (110) imply that

$$w(x,0) = A(0)x^n + R(x,0), \quad \text{for } 0 < x \leq G(0),$$

which is consistent with the associated expression resulting from (113).

The next result, which we prove in the appendix, is concerned with proving that the construction above indeed provides a solution to the HJB equation (49)–(50), as well as with certain estimates that we will need.

LEMMA 8. *Suppose that Assumptions* 1 *and* 2 *hold. The function w given by* (112)–(113)*, where F, G and A, B are as in* (107)*,* (108) *and* (109)*,* (110)*, respectively, is C^2 and satisfies the HJB equation* (49)–(50)*. Also, w satisfies*

$$w(x,y) \leq C_5 \left(1 + y + G^{n-\varepsilon_4}(y) + G^{\alpha}(y)y^{\beta} + x^{n-\varepsilon_4}\right), \text{ for all } (x,y) \in \mathcal{S}, \tag{114}$$

for some constants $C_5 > 0$ and $\varepsilon_4 \in]0, n[$, as well as (54) *in the verification theorem, Theorem* 5.

Remark 2. A careful inspection of the proof of this result reveals that, had we perturbed the expressions on the right-hand sides of (109) and (110) by additive constants, we still would have obtained a further solution to the HJB equation (49)–(50).

However, such a solution would not satisfy an estimate such as the one provided by (114) that plays a fundamental role in the proof of the verification theorem, Theorem 5.

We can now prove the main result of the paper.

THEOREM 9. *Consider the capacity control problem formulated in section* 2*, and suppose that Assumptions* 1 *and* 2 *hold. The value function* v *identifies with the function* w *given by* (112)–(113)*, where* F*,* G *and* A*,* B *are as in* (107)*,* (108) *and* (109)*,* (110)*, respectively. The optimal capacity process* Y^{o} *reflects the joint process* (X, Y^{o}) *along the boundaries* G *and* F *in the positive and in the negative* y*-direction, respectively, and can be constructed as follows.*

(a) *If* $y^* = \infty$*, then* Y^{o} *is given by*

$$Y_t^{\mathrm{o}} = y\mathbf{1}_{\{t\le\tau_0\}} + G^{[-1]}\left(\sup_{s\le t} X_s\right)\mathbf{1}_{\{\tau_0<t\}},$$

where $\tau_0 = \inf\{t \ge 0 :\ X_t \ge G(y)\}$ *and* $G^{[-1]} : [G(0), \infty[\to \mathbb{R}_+$ *is the inverse function of* G*.*

(b) *If* $y^* < \infty$*, we first define*

$$\hat{y} = \begin{cases} \Phi(x), & \text{if } y > \Phi(x), \\ y & \text{otherwise,} \end{cases} \qquad \tau_0 = \inf\{t \ge 0 :\ X_t \ge G(\hat{y})\}$$

and

$$Y_t^{(1)} = y\mathbf{1}_{\{t=0\}} + \hat{y}\mathbf{1}_{\{0<t\le\tau_0\}} + G^{[-1]}\left(\sup_{s\le t} X_s\right)\mathbf{1}_{\{\tau_0<t\}},$$

where Φ *is defined by* (111)*. We then recursively define the* $(\mathcal{F}_t)$*-stopping times* τ_n *and the processes* $Y^{(n)}$ *by*

$$\tau_{2k+1} = \inf\left\{t > 0 :\ X_t < \hat{F}\left(Y_t^{(2k+1)}\right)\right\},$$
$$Y_t^{(2k+2)} = Y_t^{(2k+1)}\mathbf{1}_{\{t\le\tau_{2k+1}\}} + \Phi\left(\inf_{\tau_{2k+1}<s\le t} X_s\right)\mathbf{1}_{\{\tau_{2k+1}<t\}}$$

for $k = 0, 1, \ldots,$ *where*

$$\hat{F}(y) = \begin{cases} 0, & \text{if } y < y^*, \\ F(y), & \text{if } y \ge y^*, \end{cases}$$

and by

$$\tau_{2k} = \inf\left\{t > 0 :\ X_t > G\left(Y_t^{(2k)}\right)\right\},$$
$$Y_t^{(2k+1)} = Y_t^{(2k)}\mathbf{1}_{\{t\le\tau_{2k}\}} + G^{[-1]}\left(\sup_{\tau_{2k}<s\le t} X_s\right)\mathbf{1}_{\{\tau_{2k}<t\}}$$

for $k = 1, 2, \ldots$*. The optimal capacity process* Y^{o} *is given by* $Y_t^{\mathrm{o}} = Y_t^{(n)}$ *for* $t < \tau_n$ *and* $n \ge 1$*.*

Proof. In view of Lemma 8, we have to show only that the process Y^{o} satisfies (55)–(59) in the verification theorem, Theorem 5. To this end, we first make the

following comments on the construction of Y^{o}. If $y^* = \infty$, then the boundary F does not exist, and $Y^{\mathrm{o}} = Y^{(1)}$ is all we need because it reflects the joint process $(X, Y^{(1)})$ along the boundary G in the positive y-direction. On the other hand, if $y^* < \infty$, then the boundary F becomes part of the picture and we need to define Y^{o} in a recursive way. If the initial condition (x, y) is in the interior of the "disinvestment" region $\mathcal{D}$, then the process $Y^{(1)}$ has a jump of size $-(y - \Phi(x))$ at time 0, which instantaneously repositions the joint process $(X, Y^{(1)})$ in the closure of the "wait" region $\mathcal{W}$. Similarly, if the initial condition (x, y) is in the interior of the "investment" region $\mathcal{I}$, then the process $Y^{(1)}$ has a jump of size $G^{[-1]}(x) - y$ at time 0, which instantaneously repositions $(X, Y^{(1)})$ in the closure of the "wait" region. After time 0, the process $Y^{(1)}$ reflects the joint process $(X, Y^{(1)})$ along the boundary G in the positive y-direction, and $(X, Y^{(1)})$ enters the interior of the "disinvestment" region $\mathcal{D}$ after time τ_1 with positive probability. The process $Y^{(2)}$ is the same as $Y^{(1)}$ up to time τ_1, $Y^{(2)}_{\tau_1} \equiv Y^{(1)}_{\tau_1} > y^*$, and $X_{\tau_1} = F(Y^{(2)}_{\tau_1})$. Beyond time τ_1, $Y^{(2)}$ reflects the joint process $(X, Y^{(2)})$ along the boundary F in the negative y-direction. As a result, the process $(X, Y^{(2)})$ is kept outside the interior of $\mathcal{I} \cup \mathcal{D}$ at all times up to τ_2, after which time it enters the interior of the "investment" region $\mathcal{I}$ with positive probability. The process $Y^{(3)}$ is the same as $Y^{(2)}$ up to time τ_2 and $X_{\tau_2} = G(Y_{\tau_2})$. After τ_2, $Y^{(3)}$ reflects $(X, Y^{(3)})$ along the boundary G in the positive y-direction. It follows that the process $(X, Y^{(3)})$ does not enter the interior of $\mathcal{I} \cup \mathcal{D}$ up to time τ_3. Iterating this construction, which ensures that $Y^{(n)}_t = Y^{(n+1)}_t$, for all $t \in [0, \tau_{n+1}]$ and $n \geq 1$, and observing that $\lim_{n\to\infty} \tau_n = \infty$, we can see that Y^{o}_t is defined for all $t \geq 0$ and that (55) is satisfied. Also, if $\xi^{\mathrm{o}+}$ and $\xi^{\mathrm{o}-}$ are the increasing processes providing the minimal decomposition of Y^{o} into $Y^{\mathrm{o}} = y + \xi^{\mathrm{o}+} - \xi^{\mathrm{o}-}$, then both (56) and (57) hold.

To proceed further, we note that the construction of Y^{o} implies that

$$Y^{\mathrm{o}}_t \leq y\mathbf{1}_{\{\bar{X}_t \leq G(y)\}} + G^{[-1]}(\bar{X}_t)\mathbf{1}_{\{\bar{X}_t > G(y)\}}, \tag{115}$$

where $\bar{X}_t = \sup_{s\leq t} X_s$. Combining this inequality with the definition (108) of G and the estimates in (91) and (106), we can see that

$$Y^{\mathrm{o}}_t \leq y\mathbf{1}_{\{\bar{X}_t \leq G(y)\}} + C_4 \bar{X}_t^{\alpha/(1-\beta)}\mathbf{1}_{\{\bar{X}_t > G(y)\}} \tag{116}$$

and

$$\xi^{\mathrm{o}+}_t \leq C_4 \bar{X}_t^{\alpha/(1-\beta)}. \tag{117}$$

Now, we can use (116), the observation that

$$G(Y^{\mathrm{o}}_t) \leq G(y)\mathbf{1}_{\{\bar{X}_t \leq G(y)\}} + \bar{X}_t\mathbf{1}_{\{\bar{X}_t > G(y)\}},$$

which follows immediately from (115), to see that, e.g.,

$$\begin{aligned} G^\alpha\left(Y^{\mathrm{o}}_t\right)\left(Y^{\mathrm{o}}_t\right)^\beta &\leq G^\alpha(y)y^\beta\mathbf{1}_{\{\bar{X}_t \leq G(y)\}} + C_4^\beta \bar{X}_t^{\alpha/(1-\beta)}\mathbf{1}_{\{\bar{X}_t > G(y)\}} \\ &\leq G^\alpha(y)y^\beta + C_4^\beta \bar{X}_t^{\alpha/(1-\beta)}. \end{aligned}$$

In view of this and similar calculations involving the other terms, as well as the estimate (114) and the fact that $\alpha < \frac{\alpha}{1-\beta} < n$ (see Assumption 2), we can conclude that (116)–(117) imply that the estimates (58)–(59) hold true, and the proof is complete. □

6. Examples. We can illustrate our main results by means of the special cases that we now consider.

COROLLARY 10. *Suppose that h is given by* (27) *in Example* 1, *and $K^+, K^+ + K^- > 0$. If $\frac{\alpha}{1-\beta} < n$, then $v < \infty$, while if $\frac{\alpha}{1-\beta} > n > \alpha$, then $v \equiv \infty$, where n is the positive solution of* (10). *In the former case, the following hold true:*

(a) *If $K^- \geq 0$, then $y^* = \infty$,*

$$G(y) = \left[-\frac{rK^+(\alpha - m)}{m\beta}\right]^{1/\alpha} y^{(1-\beta)/\alpha}, \tag{118}$$

and the optimal strategy can be depicted by Figure 1.

(b) *If $K^- < 0$, then $y^* = 0$ and*

$$\lim_{y \downarrow 0} F(y) = \lim_{y \downarrow 0} G(y) = 0, \tag{119}$$

and the optimal strategy can be depicted by Figure 4.

Proof. As we have observed in Example 1, Assumptions 1 and 2 are satisfied and $v < \infty$ if and only if $\frac{\alpha}{1-\beta} < n$. Also, if $\frac{\alpha}{1-\beta} > n > \alpha$, then we have proved in Lemma 3 that $v \equiv \infty$.

The condition distinguishing the two cases follows from a simple inspection of (102), while showing (118) involves elementary calculations. To see (119), we observe that the system of equations (100)–(101), which specifies F and G, is equivalent to

$$\frac{\beta}{\alpha - m} y^{-(1-\beta)} \left[G^{\alpha-m}(y) - F^{\alpha-m}(y)\right] = -\frac{r}{m}\left[K^+ G^{-m}(y) + K^- F^{-m}(y)\right], \tag{120}$$

$$\frac{\beta}{n - \alpha} y^{-(1-\beta)} \left[G^{\alpha-n}(y) - F^{\alpha-n}(y)\right] = \frac{r}{n}\left[K^+ G^{-n}(y) + K^- F^{-n}(y)\right]. \tag{121}$$

Since $m < 0 < \alpha, 1 - \beta$ and F, G are increasing, the right-hand side of (120) remains bounded as $y \downarrow 0$, and $\lim_{y \downarrow 0} y^{-(1-\beta)} = \infty$. It follows that (120) cannot be true unless (119) is satisfied, and the proof is complete. □

Remark 3. In the context of the special case considered in Corollary 10, it is worth noting that the solution w to the HJB equation (49)–(50) that we have constructed following intuition based on economical considerations is finite for all $\alpha \in]0, n[$ and $\beta \in]0, 1[$. Had we adopted a *formal* approach, this observation would have suggested the adoption of the capacity expansion strategy that keeps the process (X, Y) inside the "wait" region $\mathcal{W}$ that is determined by the functions F and G provided by the unique solution to the associated free-boundary problem. However, such a formal approach would have led us to wrong conclusions because

$$w(x, y) < \infty = v(x, y), \quad \text{for all } (x, y) \in \mathcal{S},$$

if $\frac{\alpha}{1-\beta} > n$.

Remark 4. In the special case of Corollary 10 arising when $\alpha = 1 - \beta$ and $K^- < 0$, we can verify that (120) and (121) are satisfied by the functions

$$F(y) = \kappa y \quad \text{and} \quad G(y) = \nu y, \quad \text{for } y \geq 0,$$

where κ and ν are constants satisfying the system of algebraic equations

$$\frac{1 - \alpha}{\alpha - m}\left[\nu^{\alpha-m} - \kappa^{\alpha-m}\right] = -\frac{r}{m}\left[K^+ \nu^{-m} + K^- \kappa^{-m}\right], \tag{122}$$

$$\frac{1 - \alpha}{n - \alpha}\left[\nu^{-(n-\alpha)} - \kappa^{-(n-\alpha)}\right] = \frac{r}{n}\left[K^+ \nu^{-n} + K^- \kappa^{-n}\right]. \tag{123}$$

Abel and Eberly [1] considered this special case with $r > b$, which satisfies our assumptions thanks to the equivalence $r > b \Leftrightarrow n > 1$, and have proved that the system of equations (122)–(123) has a unique solution such that $0 < \kappa < \nu$.

The following special case follows from our general results and (29).

COROLLARY 11. *Suppose that* $K^+, -K^-, K^+ + K^- > 0$, *consider the running payoff function* h *given by* (28) *in Example* 2, *and assume that the associated parameters satisfy* (29). *The following cases hold true:*

(a) *If* $-rK^- \in \left]\left(\beta\eta^\alpha\zeta^{-(1-\beta)} - K\right) \vee 0, rK^+\right[$, *then* $y^* = 0$, $0 < \lim_{y\downarrow 0} F(y) < \lim_{y\downarrow 0} G(y)$, *and the optimal strategy can be depicted by Figure* 3.

(b) *If* $\beta\eta^\alpha\zeta^{-(1-\beta)} > K$ *and* $-rK^- \in \left]0, \beta\eta^\alpha\zeta^{-(1-\beta)} - K\right[$, *then*

$$y^* = \left(\frac{\beta\eta^\alpha}{K - rK^-}\right)^{\frac{1}{1-\beta}} - \zeta > 0,$$

$\lim_{y\downarrow y^*} F(y) = 0$, $\lim_{y\downarrow 0} G(y) > 0$, *and the optimal strategy can be depicted by Figure* 2.

We conclude with the following example that does not satisfy the requirements imposed on the problem data by Assumptions 1 and 2.

Example 3. Suppose that the running payoff function h is given by $h(x, y) = (x + \eta)^\alpha y^\beta$, for some constants $\eta > 0$ and $\alpha, \beta \in]0, 1[$, such that $\frac{\alpha}{1-\beta} < n$. Using the same arguments as the ones in Example 2, we can check that Assumption 1 and (23), (24), and (26) in Assumption 2 all hold true. However, this payoff function does not satisfy the upper bound required by (25) in Assumption 2. Furthermore, if we assume that $K^+, -K^-, K^+ + K^- > 0$, then we can check that the points y_* and y^* defined as in Lemmas 6 and 7 are given by

$$0 < y_* = \left(\frac{\beta\eta^\alpha}{rK^+}\right)^{\frac{1}{1-\beta}} < \left(\frac{\beta\eta^\alpha}{-rK^-}\right)^{\frac{1}{1-\beta}} = y^*.$$

It follows that, at least formally, this example provides a case in which a strategy such as the one depicted by Figure 5 is optimal.

Appendix. Proof of selected results.

Proof of Lemma 6. Suppose that (20) in Assumption 1 is satisfied. Fix any $y \geq 0$, and suppose that $\inf_{x>0} H(x, y) - rK^+ \geq 0$. In this case, $H(x, y) - rK^+ > 0$, for all $x > 0$, because $H(\cdot, y)$ is a strictly increasing function. This implies that $q(x, y) > 0$, for all $x > 0$, and, therefore, the equation $q(x, y) = 0$ has no solution $x > 0$.

Now, fix any $y \geq 0$, and assume that $\inf_{x>0} H(x, y) < rK^+$. Recalling the assumption that $H(\cdot, y)$ is strictly increasing, we define

$$x^\dagger = x^\dagger(y) := \inf\left\{x > 0 : \ H(x, y) - rK^+ > 0\right\} > 0,$$

and we observe that

$$\frac{\partial}{\partial x} q(x, y) = x^{-m-1}\left[H(x, y) - rK^+\right] \begin{cases} < 0, & \text{for all } x \in]0, x^\dagger[, \\ > 0 & \text{for all } x > x^\dagger. \end{cases} \tag{124}$$

Combining the fact that $q(\cdot, y)$ is strictly decreasing in $]0, x^\dagger[$ and strictly increasing in $]x^\dagger, \infty[$, with $q(0, y) = 0$, we can see that $q(x, y) < 0$ for all $x \leq x^\dagger$. In particular, $q(x^\dagger, y) < 0$. Therefore, if $q(x, y) = 0$ has a solution $x > 0$, then this must satisfy $x > x^\dagger$. Also, given that it exists, this solution is unique because $q(\cdot, y)$ is strictly

increasing in $]x^{\dagger}, \infty[$. To prove that the required solution indeed exists, it suffices to show that $\lim_{x\to\infty} q(x,y) = \infty$. The assumption that $\lim_{x\to\infty} H(x,y) = \infty$ implies that, given any constant $M > 0$, there exists $\gamma > x^{\dagger}$ such that $H(x,y) - rK^{+} \geq M$ for all $x \geq \gamma$. However, given any such choice of these constants, we calculate

$$\begin{aligned}\lim_{x\to\infty} q(x,y) &= \lim_{x\to\infty} \left[q(\gamma,y) + \int_{\gamma}^{x} s^{-m-1} \left[H(s,y) - rK^{+} \right] ds \right] \\ &\geq \lim_{x\to\infty} \left[q(\gamma,y) + \frac{M}{m}\gamma^{-m} - \frac{M}{m}x^{-m} \right] = \infty.\end{aligned}$$

If (21) in Assumption 1 also holds and the point $\tilde{y}_*$ defined as in (89) is finite, then $\inf_{x>0} H(x,y) < rK^{+}$ for all $y > \tilde{y}_*$. It follows that (86) uniquely defines a continuous function $\tilde{G} :]\tilde{y}_*, \infty[\to]0, \infty[$. Moreover, the arguments above regarding the solvability of $q(x,y) = 0$ imply (90).

To see that $\tilde{G}$ is C^1 and strictly increasing, we differentiate $q(\tilde{G}(y), y) = 0$ with respect to y to obtain

$$\tilde{G}'(y) = -\tilde{G}^{m+1}(y) \left[H(\tilde{G}(y), y) - rK^{+} \right]^{-1} \int_{0}^{\tilde{G}(y)} s^{-m-1} H_y(s,y)\, ds > 0 \tag{125}$$

for all $y > \tilde{y}_*$. The inequality here follows thanks to (90) and (21) in Assumption 1.

Now, suppose that (25) in Assumption 2 also holds, and observe that this implies that

$$\inf_{x>0} H(x,y) < rK^{+} \quad \text{for all } y > 0.$$

However, this inequality implies that $\tilde{y}_* = 0$. Finally, with regard to (25) in Assumption 2 and (124) above, we calculate

$$\frac{\partial}{\partial x} q(x,y) \leq x^{-m-1} \left[\beta C x^{\alpha} y^{-(1-\beta)} - r\vartheta \right].$$

Combining this inequality with $q(0,y) = 0$, we can see that, given any $y > 0$, $\tilde{G}(y)$ is greater than or equal to the strictly positive solution of the equation

$$\int_{0}^{z} s^{-m-1} \left[\beta C s^{\alpha} y^{-(1-\beta)} - r\vartheta \right] ds = 0,$$

which yields

$$\tilde{G}(y) \geq \left(-\frac{r\vartheta(\alpha - m)}{\beta C m} \right)^{\frac{1}{\alpha}} y^{\frac{1-\beta}{\alpha}} \quad \text{for all } y > 0.$$

However, this implies (91). □

Proof of Lemma 7. Suppose that Assumption 1 holds. We develop the proof in a number of steps.

Step 1. To study the solvability of the system of equations (98) and (99), we first prove that (98) uniquely defines a mapping $L : (\mathbb{R}_{+} \setminus \{0\})^2 \to]0, \infty[$ such that

$$f(x_1, L(x_1,y), y) = 0 \quad \text{and} \quad L(x_1,y) > x_1. \tag{126}$$

To this end, fix any $x_1 > 0$, $y > 0$, and observe that

$$f(x_1, x_1, y) = -\frac{1}{m} r \left(K^{+} + K^{-} \right) x_1^{-m} > 0. \tag{127}$$

Given $M > 0$, observe that the assumption that $\lim_{x\to\infty} H(x,y) = \infty$, for all $y > 0$, implies that there exists a constant $\gamma > x_1$ such that $H(x,y) - rK^+ \geq M$ for all $x \geq \gamma$. For such a choice of parameters, since $m < 0$, we calculate

$$\begin{aligned}
\lim_{x_2\to\infty} f(x_1,x_2,y) &= \lim_{x_2\to\infty}\Big[-\int_{x_1}^{\gamma} s^{-m-1}\left[H(s,y)-rK^+\right]ds \\
&\quad -\int_{\gamma}^{x_2} s^{-m-1}\left[H(s,y)-rK^+\right]ds - \frac{r}{m}\left(K^+ + K^-\right)x_1^{-m}\Big] \\
&\leq \lim_{x_2\to\infty}\left[f(x_1,\gamma,y) - M\int_{\gamma}^{x_2} s^{-m-1}\,ds\right] \\
&= \lim_{x_2\to\infty}\left[f(x_1,\gamma,y) - \frac{M}{m}\gamma^{-m} + \frac{M}{m}x_2^{-m}\right] \\
&= -\infty. \qquad (128)
\end{aligned}$$

Also, it is straightforward to calculate

$$\frac{\partial f}{\partial x_2}(x_1,x_2,y) = -x_2^{-m-1}\left[H(x_2,y)-rK^+\right]\begin{cases} >0, & \text{for all } x_2 \in]0,x^\dagger[, \\ <0, & \text{for all } x_2 > x^\dagger, \end{cases} \qquad (129)$$

where

$$x^\dagger = x^\dagger(y) := \inf\left\{x > 0 :\ H(x,y) - rK^+ > 0\right\}.$$

Combining the fact that $f(x_1,\cdot,y)$ is strictly increasing in the interval $[x_1, x^\dagger[$, if $x_1 < x^\dagger$, and strictly decreasing in the interval $]x^\dagger \vee x_1, \infty[$, with (128) and (127), we can conclude that the equation $f(x_1,x_2,y) = 0$ has a unique solution $x_2 = L(x_1,y)$ which satisfies (126) as well as

$$H(L(x_1,y),y) - rK^+ > 0. \qquad (130)$$

For future reference, we also note that differentiation of $f(x_1,L(x_1,y),y) = 0$ with respect to x_1 yields

$$\frac{\partial}{\partial x_1}L(x_1,y) = \frac{x_1^{-m-1}\left[H(x_1,y)+rK^-\right]}{L^{-m-1}(x_1,y)\left[H(L(x_1,y),y)-rK^+\right]}, \qquad (131)$$

while differentiation of $f(x_1,L(x_1,y),y) = 0$ with respect to y gives

$$\frac{\partial}{\partial y}L(x_1,y) = -L^{m+1}(x_1,y)\left[H(L(x_1,y),y)-rK^+\right]^{-1}\int_{x_1}^{L(x_1,y)} s^{-m-1}H_y(s,y)\,ds. \qquad (132)$$

Step 2. To prove that the system of equations (98) and (99) has a unique solution (x_1,x_2) such that $0 < x_1 < x_2$ we have to show that there exists a unique $x_1 > 0$ such that $g(x_1,L(x_1,y),y) = 0$. To this end, we first observe that the calculation

$$g(x_1,L(x_1,y),y) = \int_{x_1}^{L(x_1,y)} s^{-n-1}\left[H(s,y)-rK^+\right] + \frac{1}{n}r\left(K^+ + K^-\right)x_1^{-n}$$

and the assumptions $\lim_{x\to\infty} H(x,y) = \infty$, $K^+ + K^- > 0$ imply that

(133) there exists a constant $N > 0$ such that $g(x_1,L(x_1,y),y) > 0$ for all $x_1 \geq N$.

Now, with regard to (131), we calculate

$$\frac{\partial}{\partial x_1} g(x_1, L(x_1,y), y) = x_1^{-m-1} \left[L^{m-n}(x_1,y) - x_1^{m-n}\right] \left[H(x_1,y) + rK^-\right]. \tag{134}$$

Since $L(x_1,y) > x_1$ and $m < n$, $L^{m-n}(x_1,y) - x_1^{m-n} < 0$. It follows that if $\inf_{x>0} H(x,y) \geq -rK^-$, then $g(\cdot, L(\cdot,y), y)$ is decreasing, which, combined with (133), implies that the equation $g(x_1, L(x_1,y), y) = 0$ cannot have a solution $x_1 > 0$. Therefore, we must have $\inf_{x>0} H(x,y) < -rK^-$. Assuming that this condition holds, we recall that $H(\cdot,y)$ is strictly increasing, we define

$$x^\ddagger = x^\ddagger(y) := \inf\left\{x > 0 : \ H(x,y) + rK^- > 0\right\},$$

and we observe that

$$g(\cdot, L(\cdot,y), y) \text{ is strictly increasing in }]0, x^\ddagger[\text{ and strictly decreasing in }]x^\ddagger, \infty[. \tag{135}$$

Furthermore, under this condition, there exist $\varepsilon > 0$ and $\delta < x^\ddagger$ such that $H(x_1,y) + rK^- \leq -\varepsilon$ for all $x_1 \leq \delta$. For such a choice of parameters, we calculate

$$\begin{aligned} &\lim_{x_1 \downarrow 0} \int_{x_1}^\infty s^{-n-1} \left[H(s,y) + rK^-\right] ds \\ &\qquad \leq \lim_{x_1 \downarrow 0} \left[\frac{\varepsilon}{n}\delta^{-n} - \frac{\varepsilon}{n} x_1^{-n} + \int_\delta^\infty s^{-n-1} \left[H(s,y) + rK^-\right] ds\right] \\ &\qquad = -\infty. \end{aligned} \tag{136}$$

In view of this, (130), and the assumption that $H(\cdot,y)$ is increasing,

$$\begin{aligned} &\lim_{x_1 \downarrow 0} g(x_1, L(x_1,y), y) \\ &\qquad = \lim_{x_1 \downarrow 0} \left[\int_{x_1}^\infty s^{-n-1} \left[H(s,y) + rK^-\right] ds - \int_{L(x_1,y)}^\infty s^{-n-1} \left[H(s,y) - rK^+\right] ds\right] \\ &\qquad \leq \lim_{x_1 \downarrow 0} \int_{x_1}^\infty s^{-n-1} \left[H(s,y) + rK^-\right] ds \\ &\qquad = -\infty. \end{aligned} \tag{137}$$

However, combining (133) with (135) and (137), we can see that the equation $g(x_1, L(x_1,y), y) = 0$ has a unique solution $x_1 > 0$, which also satisfies

$$H(x_1,y) + rK^- < 0. \tag{138}$$

Step 3. Summarizing the analysis above, under the assumption that the point $\bar{y}^*$ defined as in (102) is finite, the system of equations (98) and (99) uniquely defines two continuous functions $\bar{F}, \bar{G} :]\bar{y}^*, \infty[\to]0, \infty[$ that satisfy $\bar{F}(y) < \bar{G}(y)$, for all $y > \bar{y}^*$, as well as (105). Also, (103)–(104) follow from a simple continuity argument combining the definition of $\bar{y}^*$ and (138).

Step 4. Now, assuming that $\bar{y}^* < \infty$, we consider any point $y > \bar{y}^*$. Differentiating the equation $g(\bar{F}(y), L(\bar{F}(y),y), y) = 0$ with respect to y, using (131), and observing

that $\bar{G}(y) = L(\bar{F}(y), y)$, we calculate

$$\begin{aligned}\bar{F}'(y) = & -\bar{F}^{m+1}(y)\bar{G}^{-n}\left[\bar{G}^{-(n-m)}(y) - \bar{F}^{-(n-m)}(y)\right]^{-1}\left[H(\bar{F}(y), y) + rK^{-}\right]^{-1} \\ & \times \int_{\bar{F}(y)}^{\bar{G}(y)} \left[\left(\frac{\bar{G}(y)}{s}\right)^{n} - \left(\frac{\bar{G}(y)}{s}\right)^{m}\right] \frac{1}{s} H_y(s, y)\, ds > 0, \end{aligned} \tag{139}$$

the inequality following thanks to assumption (21), the first inequality in (105), and the fact that $m < 0 < n$. Also, differentiating the equation $f(\bar{F}(y), L(\bar{F}(y), y), y) = 0$ with respect to y, and using (132) and (139), we calculate

$$\begin{aligned}\bar{G}'(y) = & -\bar{F}^{-n}(y)\bar{G}^{m+1}\left[\bar{G}^{-(n-m)}(y) - \bar{F}^{-(n-m)}(y)\right]^{-1}\left[H(\bar{G}(y), y) - rK^{+}\right]^{-1} \\ & \times \int_{\bar{F}(y)}^{\bar{G}(y)} \left[\left(\frac{\bar{F}(y)}{s}\right)^{n} - \left(\frac{\bar{F}(y)}{s}\right)^{m}\right] \frac{1}{s} H_y(s, y)\, ds > 0, \end{aligned}$$

the inequality following thanks to (105) and (21). However, these calculations show that $\bar{F}$ and $\bar{G}$ are both C^1 and strictly increasing.

Step 5. Finally, suppose that (25) in Assumption 2 is also true. With reference to the equation $f(\bar{F}(y), \bar{G}(y), y) = 0$, we calculate

$$\begin{aligned} 0 = & -\int_{\bar{F}(y)}^{\bar{G}(y)} s^{-m-1}\left[H(s, y) - rK^{+}\right] ds - \frac{1}{m} r\left(K^{+} + K^{-}\right)\bar{F}^{-m}(y) \\ \geq & -\left[\frac{\beta C}{\alpha - m}\bar{G}^{\alpha-m}(y) y^{-(1-\beta)} + \frac{r\vartheta}{m}\bar{G}^{-m}(y)\right] \\ & + \left[\frac{\beta C}{\alpha - m}\bar{F}^{\alpha-m}(y) y^{-(1-\beta)} - \frac{1}{m} r\left(K^{+} + K^{-} - \vartheta\right)\bar{F}^{-m}(y)\right]. \end{aligned}$$

Since $\vartheta < K^{+} + K^{-}$ by assumption, the second term on the right-hand side of this expression is strictly positive. Therefore, we must have

$$\frac{\beta C}{\alpha - m}\bar{G}^{\alpha-m}(y) y^{-(1-\beta)} + \frac{r\vartheta}{m}\bar{G}^{-m}(y) > 0.$$

This inequality can be true only if $\bar{G}(y)$ is strictly greater than the unique strictly positive solution of the equation

$$\frac{\beta C}{\alpha - m} z^{\alpha-m} y^{-(1-\beta)} + \frac{r\vartheta}{m} z^{-m} = 0,$$

which yields

$$\bar{G}(y) \geq \left(-\frac{r\vartheta(\alpha - m)}{\beta C m}\right)^{\frac{1}{\alpha}} y^{\frac{1-\beta}{\alpha}} \quad \text{for all } y > \bar{y}^{*}.$$

However, this implies (106).

Proof of Lemma 8. We develop the proof along a series of steps.

Step 1. We first prove (114). Consider (109), and note that the upper bound in (25) in Assumption 2 implies that

$$0 < A(y) \leq \frac{\beta C}{\sigma^2 (n - m)(n - \alpha)} \int_{y}^{\infty} u^{-(1-\beta)} G^{-(n-\alpha)}(u)\, du. \tag{140}$$

Recalling the inequalities $\alpha < \frac{\alpha}{1-\beta} < n$, we fix any $\varepsilon_0 > 0$ such that

$$\varepsilon_0 < n - \frac{\alpha}{1-\beta} < n - \alpha.$$

Using the fact that G is increasing and the estimate provided by (91) and (106), we calculate

$$\begin{aligned}\int_y^\infty u^{-(1-\beta)} G^{-(n-\alpha)}(u)\,du &\le G^{-\varepsilon_0}(y) \int_y^\infty u^{-(1-\beta)} G^{-(n-\alpha-\varepsilon_0)}(u)\,du \\ &\le \frac{\alpha C_4^{(1-\beta)(n-\alpha-\varepsilon_0)/\alpha}}{(1-\beta)(n-\varepsilon_0)-\alpha} G^{-\varepsilon_0}(y) y^{1-\frac{(1-\beta)(n-\varepsilon_0)}{\alpha}},\end{aligned}$$

which implies that

$$\int_y^\infty u^{-(1-\beta)} G^{-(n-\alpha)}(u)\,du \le \frac{\alpha C_4^{(1-\beta)(n-\alpha-\varepsilon_0)/\alpha}}{(1-\beta)(n-\varepsilon_0)-\alpha} G^{-\varepsilon_0}(y) \quad \text{for all } y \ge 1. \tag{141}$$

Also, the fact that G is increasing implies that

$$\begin{aligned}G^n(y) \int_y^1 u^{-(1-\beta)} G^{-(n-\alpha)}(u)\,du &\le G^\alpha(y) \int_y^1 u^{-(1-\beta)}\,du \\ &\le \frac{1}{\beta} G^\alpha(1) \quad \text{for all } y < 1.\end{aligned} \tag{142}$$

However, (140)–(142) imply that

$$\begin{aligned}A(y)x^n &\le A(y)G^n(y) \\ &\le \frac{\beta C}{\sigma^2(n-m)(n-\alpha)} \left[\frac{\alpha C_4^{(1-\beta)(n-\alpha-\varepsilon_0)/\alpha}}{(1-\beta)(n-\varepsilon_0)-\alpha} G^{n-\varepsilon_0}(y) \mathbf{1}_{\{y\ge 1\}} \right. \\ &\quad \left. + \left(\frac{\alpha C_4^{(1-\beta)(n-\alpha-\varepsilon_0)/\alpha}}{(1-\beta)(n-\varepsilon_0)-\alpha} G^{n-\varepsilon_0}(1) + \frac{1}{\beta} G^\alpha(1) \right) \mathbf{1}_{\{y<1\}} \right] \\ &= C_{51} \left(1 + G^{n-\varepsilon_0}(y)\right), \quad \text{for all } y \ge 0 \text{ and } x \le G(y),\end{aligned} \tag{143}$$

where $C_{51} > 0$ is a constant.

If $y^* < \infty$, then (110), the assumption that $K^+ + K^- > 0$, the lower bound in (25) in Assumption 2, and the fact that F is increasing imply that, given any $y > y^*$,

$$\begin{aligned}B(y) &\le -\frac{C + rK^+}{\sigma^2 m(n-m)} \int_{y^*}^y F^{-m}(u)\,du \\ &\le -\frac{C + rK^+}{\sigma^2 m(n-m)} y F^{-m}(y).\end{aligned}$$

In light of this calculation and the fact that $m < 0$, we can see that

$$\sup_{x \in [F(y), G(y)]} B(y)x^m \le B(y)F^m(y) \le C_{52} y, \quad \text{for all } y > y^*, \tag{144}$$

where $C_{52} > 0$ is a constant. Since R is increasing in x (see (26) in Assumption 2 and (16)), the upper bound in Lemma 2 implies that

$$\begin{aligned}\sup_{x\leq G(y)} R(x,y) &\leq R(G(y),y)\\ &\leq C_1\left(1+y+G^{n-\vartheta}(y)+G^{\alpha}(y)y^{\beta}\right) \quad \text{for all } y\geq 0.\end{aligned}$$

However, combining this estimate with (143) and (144), we can see that w satisfies

$$w(x,y)\leq C_{53}\left(1+y+G^{n-\varepsilon_0\wedge\vartheta}(y)+G^{\alpha}(y)y^{\beta}\right), \quad \text{for all } (x,y)\in\overline{\mathcal{W}}, \tag{145}$$

for some constant $C_{53} > 0$. With regard to the structure of w provided by (112)–(113), this inequality and the estimates provided by (91) and (106) imply that

$$\begin{aligned}w(x,y) &\leq w(x,G^{[-1]}(x))+K^{+}y\\ &\leq C_{53}\left(1+G^{[-1]}(x)+x^{n-\varepsilon_0\wedge\vartheta}+x^{\alpha}\left[G^{[-1]}(x)\right]^{\beta}\right)+K^{+}y\\ &\leq C_{54}\left(1+y+x^{n-\varepsilon_0\wedge\vartheta}+x^{\alpha/(1-\beta)}\right), \quad \text{for } (x,y)\in\mathcal{I}, \qquad (146)\end{aligned}$$

for some constant $C_{54} > 0$. Also, since $\Phi(x) \leq y$, for all $(x,y) \in \mathcal{D}$, and G is increasing,

$$\begin{aligned}w(x,y) &\leq w(x,\Phi(x))+|K^{-}|y\\ &\leq C_{53}\left(1+\Phi(x)+G^{n-\varepsilon_0\wedge\vartheta}(\Phi(x))+G^{\alpha}(\Phi(x))\Phi^{\beta}(x)\right)+|K^{-}|y\\ &\leq C_{55}\left(1+y+G^{n-\varepsilon_0\wedge\vartheta}(y)+G^{\alpha}(y)y^{\beta}\right), \quad \text{for } (x,y)\in\mathcal{D}, \qquad (147)\end{aligned}$$

where $C_{55} > 0$ is a constant. However, in view of the assumption $\frac{\alpha}{1-\beta} < n$, if we choose any

$$\varepsilon_4 \in \left]0, \varepsilon_0\wedge\vartheta\wedge\left(n-\frac{\alpha}{1-\beta}\right)\right[\quad \text{and} \quad C_5 \geq C_{53}\vee C_{54}\vee C_{55},$$

then we can see that (145)–(147) imply (114).

Step 2. To show that w satisfies (54), we first observe that the positivity of A, B and the lower bound in Lemma 2 imply that

$$w(x,y)\geq -C_1(1+y) \quad \text{for all } (x,y)\in\overline{\mathcal{W}}. \tag{148}$$

This estimate and the definition of w in $\mathcal{I}$, provided by (112)–(113), imply that

$$\begin{aligned}w(x,y) &\geq -(C_1+K^{+})G^{[-1]}(x)-C_1\\ &\geq -(C_1+K^{+})C_4x^{\alpha/(1-\beta)}-C_1, \quad \text{for all } (x,y)\in\mathcal{I}, \qquad (149)\end{aligned}$$

the second inequality following thanks to (91) and (106). Also, if $y^{*} < \infty$, then (148) and the definition of w in $\mathcal{D}$, given by (113), imply that

$$\begin{aligned}w(x,y) &\geq -C_1(1+\Phi(x))-|K^{-}|\max\{y,\Phi(x)\}\\ &\geq -(C_1+|K^{-}|)y-C_1. \qquad (150)\end{aligned}$$

However, (148)–(150) establish (54).

Step 3. With reference to the construction of w, we will show that w is C^2 if we prove that w_x, w_{xx}, and w_{yy} are continuous along the free boundaries F and G. To this end, we calculate

$$\begin{aligned} w_x(x,y) &= w_x\left(x, G^{[-1]}(x)\right) + \left[w_y\left(x, G^{[-1]}(x)\right) - K^+\right] \frac{dG^{[-1]}(x)}{dx} \\ &= w_x\left(x, G^{[-1]}(x)\right), \quad \text{for } (x,y) \in \mathcal{I}, \end{aligned} \tag{151}$$

and

$$\begin{aligned} w_{xx}(x,y) &= w_{xx}\left(x, G^{[-1]}(x)\right) + w_{xy}\left(x, G^{[-1]}(x)\right) \frac{dG^{[-1]}(x)}{dx} \\ &= w_{xx}\left(x, G^{[-1]}(x)\right), \quad \text{for } (x,y) \in \mathcal{I}, \end{aligned} \tag{152}$$

the second equalities following thanks to (80) that have been among the requirements leading to the equations specifying the function G. However, these calculations and the structure of w provided by (112)–(113) show that w_x and w_{xx} are continuous along G.

Now, if $y^* > 0$ and $y \in [0, y^*] \cap \mathbb{R}$, we can use (79) and (88) to calculate

$$\begin{aligned} \lim_{x \uparrow G(y)} w_{yy}(x,y) &= A''(y)G^n(y) + R_{yy}(G(y), y) \\ &= \frac{G^{-1}(y)}{\sigma^2(n-m)}\left[G'(y)\left[H(G(y),y) - rK^+\right]\right. \\ &\quad \left. + G^{m+1}(y)\int_0^{G(y)} s^{-m-1} H_y(s,y)\, ds\right] \\ &= 0, \end{aligned} \tag{153}$$

the last equality following thanks to (125). Also, if $y^* < \infty$ and $y > y^*$, we can use (79), (95), and (97) to calculate

$$\begin{aligned} \lim_{x \uparrow G(y)} w_{yy}(x,y) &= A''(y)G^n(y) + B''(y)G^m(y) + R_{yy}(G(y), y) \\ &= 0. \end{aligned} \tag{154}$$

However, combining (153) and (154) with the fact that $w_{yy}(x,y) = 0$, for $(x,y) \in \mathcal{I}$, we conclude that w_{yy} is continuous along G.

Showing that w_x, w_{xx}, and w_{yy} are continuous along F involves similar arguments.

Step 4. By construction, we will prove that w satisfies the HJB equation (49)–(50) if we show that

$$\sigma^2 x^2 w_{xx}(x,y) + bx w_x(x,y) - rw(x,y) + h(x,y) \le 0, \quad \text{for } (x,y) \in \mathcal{I}, \tag{155}$$

$$w_y(x,y) + K^- \ge 0, \quad \text{for } (x,y) \in \mathcal{I},\ y > 0, \tag{156}$$

$$w_y(x,y) - K^+ \le 0, \quad \text{for } (x,y) \in \mathcal{W}, \tag{157}$$

$$w_y(x,y) + K^- \ge 0, \quad \text{for } (x,y) \in \mathcal{W},\ y > 0, \tag{158}$$

and, if $\mathcal{D} \neq \emptyset$,

$$\sigma^2 x^2 w_{xx}(x,y) + bx w_x(x,y) - rw(x,y) + h(x,y) \le 0, \quad \text{for } (x,y) \in \mathcal{D}, \tag{159}$$

$$w_y(x,y) - K^+ \le 0 \quad \text{for } (x,y) \in \mathcal{D}. \tag{160}$$

It is straightforward to see that either of (156) or (160) is equivalent to $K^+ + K^- \geq 0$, which is true by assumption. Recalling that $H \equiv h_y$, we can easily verify that, since $y \leq G^{[-1]}(x)$, for all $(x, y) \in \mathcal{I}$, (151) and (152) imply that (155) is equivalent to

$$\int_y^{G^{[-1]}(x)} \left[H(x,u) - rK^+\right] du \geq 0 \quad \text{for } (x,y) \in \mathcal{I}.$$

However, this inequality follows immediately from the assumption that $H(x,\cdot)$ is strictly decreasing, for all x, and (90) together with the second inequality in (105). Similarly, we can show that if $\mathcal{D} \neq \emptyset$, then (159) is equivalent to

$$\int_{\Phi(x)}^{y} \left[H(x,u) + rK^-\right] du \leq 0, \quad \text{for } (x,y) \in \mathcal{D},$$

where Φ is defined by (111). However, we can see that this inequality is true once we combine the first inequality in (105) with the assumption that $H(x,\cdot)$ is strictly decreasing, for all x, and the assumption that $H(\cdot, 0)$ is strictly increasing.

Now, suppose that $y^* < \infty$, and fix any $y > y^*$. Since $w_y(F(y), y) = -K^-$ and $w_y(G(y), y) = K^+$, we will prove that both (157) and (158) are satisfied if we show that

$$w_{yx}(x,y) \geq 0 \quad \text{for all } x \in]F(y), G(y)[. \tag{161}$$

To this end, we consider the transformation of the independent variable $x > 0$ provided by $z = \ln x$, and we write $w(x,y) = u(\ln x, y)$ for some function $u = u(z,y)$. It follows that (161) is true if and only if

$$u_{yz}(z,y) \geq 0 \quad \text{for all } z \in]\ln F(y), \ln G(y)[. \tag{162}$$

Now, since $w = w(x,y)$ satisfies (77) for $x \in]F(y), G(y)[$, u_y satisfies

$$\sigma^2 u_{yzz}(z,y) + \left(b - \sigma^2\right) u_{yz}(z,y) - r u_y(z,y) + H(e^z, y) = 0 \text{ for } z \in]\ln F(y), \ln G(y)[.$$

Recalling that H_x is continuous and $H_x(\cdot, y) \geq 0$ (see Assumption 1), we can differentiate this equation with respect to z to obtain

$$\begin{aligned}\sigma^2 (u_{yz})_{zz}(z,y) + \left(b - \sigma^2\right)(u_{yz})_z(z,y) - r u_{yz}(z,y) &= -e^z H_x(e^z, y) \\ &\leq 0 \text{ for } z \in]\ln F(y), \ln G(y)[.\end{aligned}$$

This inequality and the maximum principle imply that $u_{yz}(\cdot, y)$ does not have a negative minimum in the interval $]\ln F(y), \ln G(y)[$, and so

$$\begin{aligned}\inf_{z \in]\ln F(y), \ln G(y)[} u_{yz}(z,y) &\geq \min_{z = \ln F(y), \ln G(y)} 0 \wedge u_{yz}(z,y) \\ &= \min_{z = F(y), G(y)} 0 \wedge w_{yx}(x,y) \\ &= 0.\end{aligned}$$

However, this calculation implies (162).

To proceed further, fix any $y \in [0, y^*] \cap \mathbb{R}$. Using the definition of R in (79), the expression for $A'(y)$ provided by (88), and the fact that $G(y)$ satisfies (86), we can

see that if we define $\overline{u}(x,y) = w_y(x,y) - K^+$, then

$$\overline{u}_x(x,y) = \frac{1}{\sigma^2(n-m)}\left[-mx^{m-1}\int_x^{G(y)} s^{-m-1}\left[H(s,y) - rK^+\right]ds + nx^{n-1}\int_x^{G(y)} s^{-n-1}\left[H(s,y) - rK^+\right]ds\right] \quad \text{for } x \in]0, G(y)[.$$

This calculation and the assumption that $H(\cdot, y)$ is strictly increasing imply that $\overline{u}_x(x,y) = w_{yx}(x,y) > 0$, for all $x \in [x^\dagger(y), G(y)[$, where $x^\dagger(y) \in]0, G(y)[$ is the unique point such that $H\left(x^\dagger(y), y\right) - rK^+ = 0$ (see Lemma 6). This observation and the boundary condition $w_y\left(G(y), y\right) = K^+$ imply that

$$w_y(x,y) - K^+ < 0 \quad \text{for all } x \in [x^\dagger(y), G(y)[. \tag{163}$$

Furthermore, since

$$\sigma^2 x^2 \overline{u}_{xx}(x,y) + bx\overline{u}_x(x,y) - r\overline{u}(x,y) = -\left[H(x,y) - rK^+\right] \geq 0, \quad \text{for } x \in]0, x^\dagger(y)[,$$

the maximum principle implies that the function $x \mapsto \overline{u}(x,y) = w_y(x,y) - K^+$ has no positive maximum in the interval $]0, x^\dagger(y)[$, and so

$$\sup_{x \in]0, x^\dagger(y)[}\left[w_y(x,y) - K^+\right] \leq \max_{x=0, x^\dagger(y)} 0 \vee \left[w_y(x,y) - K^+\right] = 0, \tag{164}$$

the equality following thanks to (163) and the fact that

$$\lim_{x \downarrow 0} w_y(x,y) = \lim_{x \downarrow 0} R_y(x,y) = \lim_{x \downarrow 0} \frac{H(x,y)}{r} \in [-K^-, K^+[. \tag{165}$$

The second equality here holds true because of (17), while the inclusion follows from the context (see Lemmas 6 and 7). However, (163) and (164) establish (157). Finally, if we define $\underline{u}(x,y) = w_y(x,y) + K^-$, then (165) and the assumption that $H(\cdot, y)$ is increasing imply that

$$\sigma^2 x^2 \underline{u}_{xx}(x,y) + bx\underline{u}_x(x,y) - r\underline{u}(x,y) = -\left[H(x,y) + rK^-\right] \leq 0 \text{ for all } x \in]0, G(y)[.$$

This calculation and the maximum principle imply that the function $x \mapsto \underline{u}(x,y) = w_y(x,y) + K^-$ has no negative minimum inside $]0, G(y)[$, and so

$$\inf_{x \in]0, G(y)[}\left[w_y(x,y) + K^-\right] = \min_{x=0, G(y)} 0 \wedge \left[w_y(x,y) + K^-\right],$$

which, combined with (165) and the boundary condition $w_y(G(y), y) + K^- = K^+ + K^- > 0$, proves (158), and the proof is complete. □

Acknowledgments. We would like to acknowledge the stimulating environment of the Isaac Newton Institute for Mathematical Sciences in Cambridge, where this research was completed while we were participants in the Developments in Quantitative Finance programme. We are grateful for several fruitful discussions with other participants in the programme. We would also like to thank two anonymous referees, whose comments led to an improvement of the paper.

EXACT CONTROLLABILITY OF A NONLINEAR KORTEWEG–DE VRIES EQUATION ON A CRITICAL SPATIAL DOMAIN*

EDUARDO CERPA†

Abstract. We consider the boundary controllability problem for a nonlinear Korteweg–de Vries equation with the Dirichlet boundary condition. We study this problem for a spatial domain with a critical length for which the linearized control system is not controllable. In order to deal with the nonlinearity, we use a power series expansion of second order. We prove that the nonlinear term gives the local exact controllability around the origin provided that the time of control is large enough.

Key words. controllability, Korteweg–de Vries equation, power series expansion

1. Introduction.

Let $L > 0$ be fixed. Let us consider the following Korteweg–de Vries (KdV) control system with the Dirichlet boundary condition

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y + y\partial_x y = 0, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = u(t), \end{cases} \tag{1.1}$$

where the state is $y(t,\cdot) : [0,L] \to \mathbb{R}$ and the control is $u(t) \in \mathbb{R}$. This is a well-known example of a nonlinear dispersive partial differential equation. This equation has been introduced by Korteweg and de Vries in [14] to describe approximately long waves in water of relatively shallow depth. A very good book to understand both physical motivation and deduction of the KdV equation is the book by Whitham [23].

We are concerned with the exact controllability properties of (1.1). In [17] Rosier has proved that this control system is locally exactly controllable around the origin provided that the length of the spatial domain is not critical. This was done using multiplier techniques and the Hilbert Uniqueness Method (HUM) method introduced by Lions (see [15]).

THEOREM 1.1 (see [17, Theorem 1.3]). *Let $T > 0$, and assume that*

$$L \notin N := \left\{ 2\pi \sqrt{\frac{k^2 + kl + l^2}{3}};\ k, l \in \mathbb{N}^* \right\}. \tag{1.2}$$

Then there exists $r > 0$ such that, for every $(y_0, y_T) \in L^2(0,L)^2$ with $\|y_0\|_{L^2(0,L)} < r$ and $\|y_T\|_{L^2(0,L)} < r$, there exist $u \in L^2(0,T)$ and

$$y \in C([0,T], L^2(0,L)) \cap L^2(0,T,H^1(0,L))$$

satisfying (1.1), *$y(0,\cdot) = y_0$, and $y(T,\cdot) = y_T$.*

Moreover, Rosier proved that the linearized control system of (1.1) around the origin, which is given by

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y = 0, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = u(t), \end{cases} \tag{1.3}$$

is not controllable if $L \in N$. Indeed, there exists a finite-dimensional subspace of $L^2(0,L)$, denoted by M, which is unreachable for the linear system. More precisely, for every nonzero state $\psi \in M$, for every $u \in L^2(0,T)$, and for every $y \in C([0,T],L^2(0,L)) \cap L^2(0,T,H^1(0,L))$ satisfying (1.3) and $y(0,\cdot) = 0$, one has $y(T,\cdot) \neq \psi$.

Remark 1.2. If one is allowed to use more than one boundary control input, there is no critical spatial domain, and the exact controllability holds for any $L > 0$. More precisely, let us consider the nonlinear control system

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y + y\partial_x y = 0, \\ y(t,0) = u_1(t), \quad y(t,L) = u_2(t), \quad \partial_x y(t,L) = u_3(t), \end{cases} \tag{1.4}$$

where the controls are $u_1(t), u_2(t)$, and $u_3(t)$. As has been pointed out by Rosier in [17], for every $L > 0$ the system (1.4) with $u_1 \equiv 0$ is locally exactly controllable in $L^2(0,L)$ around the origin. Moreover, using all three control inputs, Zhang proved in [24] that for every $L > 0$ the system (1.4) is exactly controllable in the space $H^s(0,L)$ for any $s \geq 0$ in a neighborhood of a given smooth solution of the KdV equation.

Recently, Coron and Crépeau in [8] have proved Theorem 1.1 for the critical lengths $L = 2k\pi$, with $k \in \mathbb{N}^*$ satisfying

$$\nexists (m,n) \in \mathbb{N}^* \times \mathbb{N}^*, \quad \text{with} \quad m^2 + mn + n^2 = 3k^2 \quad \text{and} \quad m \neq n. \tag{1.5}$$

For these values of L, the subspace M of missed directions is one-dimensional and is generated by the function $f(x) = 1 - \cos(x)$. Their method consists, first, in moving along this direction by performing a power series expansion of the solution and then in using a fixed point theorem.

Remark 1.3. The condition (1.5) has been communicated to the author by Coron and Crépeau. They pointed out that if it is not satisfied, then the dimension of the missed directions subspace is higher than one, and the proof given in [8] does not work anymore.

In this paper, we follow the method of Coron and Crépeau to investigate the case of critical lengths for which the subspace M is two-dimensional. The set of lengths for which it holds is denoted by N'. We will see in section 2 that N' contains an infinite number of lengths.

This paper is organized as follows. First, in section 2, we study the linearized control system (1.3), and we provide a complete description of the space M in terms of the length L of the spatial domain $(0,L)$. Then, in section 3, we prove in the case $L \in N'$ that the nonlinear term $y\partial_x y$ allows us to reach all of the missed directions provided that the time of control is large enough. We give an explicit expression of the minimal time required by our method. Finally, in section 4, we get the local exact controllability by means of a fixed point theorem; i.e., we prove our main result.

THEOREM 1.4. *Let $L \in N'$. There exists $T_M > 0$ such that for any $T > T_M$ there exist $C > 0$ and $r > 0$ such that for every $(y_0, y_T) \in L^2(0,L)^2$ with $\|y_0\|_{L^2(0,L)} < r$ and $\|y_T\|_{L^2(0,L)} < r$ there exist $u \in L^2(0,T)$ with*

$$\|u\|_{L^2(0,T)} \leq C(\|y_0\|_{L^2(0,L)} + \|y_T\|_{L^2(0,L)})^{1/2} \tag{1.6}$$

and

$$y \in C([0,T],L^2(0,L)) \cap L^2(0,T,H^1(0,L))$$

satisfying (1.1), $y(0,\cdot) = y_0$, *and* $y(T,\cdot) = y_T$.

Remark 1.5. The power 1/2 in the estimate (1.6) comes, as we will see, from performing a power series expansion of second order to deal with the nonlinearity. The same estimate holds with power 1/3 for the critical lengths studied in [8] (third-order expansion) and with power 1 for the noncritical lengths studied in [17] (first-order expansion).

Remark 1.6. In order to complete the study of the exact controllability of system (1.1), it is necessary to investigate the case where the dimension of the space M is bigger than 2. An approach would be to use the exact controllability of the nonlinear equation around nontrivial stationary solutions proved by Crépeau (in [10] for the domains $(0, 2\pi k)$ and in [11] for any other domain $(0, L)$) and then to apply the method introduced in [5] (see also [1, 2]), that is, the return method (see [3, 4]), together with quasi-static deformations (see also [9]). With such a method, one should obtain the exact controllability of (1.1) for a large time. However, it seems that the minimal time required with this approach is far from being optimal.

Remark 1.7. In Theorem 1.4, we get the local controllability for (1.1) provided that the time of control is large enough. However, we may wonder if this condition on the time is really necessary. This is an interesting open problem since one knows that even if the speed of propagation of the KdV equation is infinite, it may exist a minimal time of control. This is, for example, the case of a nonlinear control system for the Schrödinger equation studied by Beauchard and Coron in [2]. They proved the local controllability of this system along the ground state trajectory for a large time. More recently, Coron proved in [6] and [7, Theorem 9.8] that this local controllability does not hold in small time, even if the Schrödinger equation has an infinite speed of propagation.

Remark 1.8. In [1, 2], there appear Schrödinger linear control systems which are not controllable. One could apply the method used in this paper to prove the local controllability of the corresponding nonlinear control systems. The main difficulty is that in those cases the subspace of missed directions for the linear system is not finite-dimensional.

Remark 1.9. Concerning the stabilization of the KdV equation, some results in the case of periodic boundary conditions can be found in [13] (damping distributed all along the domain), [20] (damping distributed with localized support), and [19] (boundary damping). In the case of the Dirichlet boundary condition, exponential decay of the solution has been obtained in [16] by adding a localized damping term (see also [18] for a generalization of this result). However, the decay rate is unknown. A natural open problem is to design for the control system (1.1) (or the linearized one (1.3)) stabilizing feedback laws which give us an explicit decay rate. This kind of result, even with a prescribed arbitrarily large decay rate, has been obtained in [12, 22] for a general class of second-order (in time) systems including the wave equation and platelike systems. It uses the fact that these systems are time-reversible. This is not the case of the control system (1.1).

2. Linearized control system. We first recall some properties proved by Rosier in [17]. Let $L > 0$ and $T > 0$. In order to study the following linear KdV equation:

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y = f, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = u(t), \\ y(0,\cdot) = y_0, \end{cases} \tag{2.1}$$

we define the space $\mathcal{B} := C([0,T],L^2(0,L)) \cap L^2(0,T,H^1(0,L))$ endowed with the norm

$$\|y\|_{\mathcal{B}} = \max_{t\in[0,T]} \|y(t)\|_{L^2(0,L)} + \left(\int_0^T \|y(t)\|^2_{H^1(0,L)} dt\right)^{1/2}.$$

Let A denote the operator $Aw = -w' - w'''$ on the domain $D(A) \subset L^2(0,L)$ defined by

$$D(A) := \left\{w \in H^3(0,L);\, w(0) = w(L) = w'(L) = 0\right\}.$$

One can see that both A and its adjoint A^* are closed and dissipative. Hence A generates a strongly continuous semigroup of contractions. Using this fact and the multiplier method, Rosier proved the following existence and uniqueness result.

PROPOSITION 2.1 (see [17, Propositions 3.2 and 3.7]). *There exist unique continuous linear maps* Ψ *and* δ

$$\begin{array}{rcl} \Psi : L^2(0,L)\times L^2(0,T)\times L^1(0,T,L^2(0,L)) & \longrightarrow & \mathcal{B}, \\ (y_0,u,f) & \longmapsto & \Psi(y_0,u,f), \\ \delta : L^2(0,L)\times L^2(0,T)\times L^1(0,T,L^2(0,L)) & \longrightarrow & L^2(0,T), \\ (y_0,u,f) & \longmapsto & \delta(y_0,u,f), \end{array}$$

such that, for $y_0 \in D(A)$, $u \in C^2([0,T])$, *with* $u(0) = 0$, *and* $f \in C^1([0,T],L^2(0,L))$, *then* $\Psi(y_0,u,f)$ *is the unique classical solution of* (2.1) *and*

$$\delta(y_0,u,f) = \partial_x \Psi(y_0,u,f)(\cdot,0).$$

The function $\Psi(y_0,u,f)$ is called the mild solution or simply the solution of (2.1) in the context of this paper.

Now we focus our attention on the domains of critical length. In particular, we describe the space M of unreachable states for the linear control system (1.3). Let $L \in N$. There exists a finite number of pairs $\{(k_j,l_j)\}_{j=1}^n \subset \mathbb{N}^*\times\mathbb{N}^*$, with $k_j \geq l_j$, such that

$$L = 2\pi\sqrt{\frac{k_j^2 + k_j l_j + l_j^2}{3}}. \tag{2.2}$$

From the work of Rosier in [17], we know that for each $j \in \{1,\dots,n\}$ there exist two nonzero real-valued functions $\varphi_1^j = \varphi_1^j(x)$ and $\varphi_2^j = \varphi_2^j(x)$ such that $\varphi^j := \varphi_1^j + i\varphi_2^j$ is a solution of

$$\left\{\begin{array}{l} -ip(k_j,l_j)\varphi^j + \varphi^{j\prime} + \varphi^{j\prime\prime\prime} = 0, \\ \varphi^j(0) = \varphi^j(L) = 0, \\ \varphi^{j\prime}(0) = \varphi^{j\prime}(L) = 0, \end{array}\right. \tag{2.3}$$

where, for $(k,l) \in \mathbb{N}^*\times\mathbb{N}^*$, $p(k,l)$ is defined by

$$p(k,l) := \frac{(2k+l)(k-l)(2l+k)}{3\sqrt{3}(k^2+kl+l^2)^{3/2}}.$$

Easy computations lead to

$$\begin{aligned} \varphi_1^j &= C\left(\cos(\gamma_1^j x) - \frac{\gamma_1^j - \gamma_3^j}{\gamma_2^j - \gamma_3^j}\cos(\gamma_2^j x) + \frac{\gamma_1^j - \gamma_2^j}{\gamma_2^j - \gamma_3^j}\cos(\gamma_3^j x)\right), \\ \varphi_2^j &= C\left(\sin(\gamma_1^j x) - \frac{\gamma_1^j - \gamma_3^j}{\gamma_2^j - \gamma_3^j}\sin(\gamma_2^j x) + \frac{\gamma_1^j - \gamma_2^j}{\gamma_2^j - \gamma_3^j}\sin(\gamma_3^j x)\right), \end{aligned} \tag{2.4}$$

where C is a constant and the numbers γ_m^j, with $m = 1, 2, 3$, are the three roots of $x^3 - x + p(k_j, l_j) = 0$. One can easily verify that these roots are given by

$$\gamma_1^j = -\frac{2\pi}{L}\left(\frac{2k_j + l_j}{3}\right), \quad \gamma_2^j = \gamma_1^j + \frac{2\pi k_j}{L}, \quad \gamma_3^j = \gamma_2^j + \frac{2\pi l_j}{L}. \tag{2.5}$$

Moreover, by choosing the constant C, we can assume that

$$\|\varphi_1^j\|_{L^2(0,L)} = \|\varphi_2^j\|_{L^2(0,L)} = 1.$$

Roughly speaking, the functions φ_1^j and φ_2^j for $j = 1, \dots, n$ are unreachable states for the linear KdV control system (1.3) since the following functions:

$$y_1(t,x) = \mathrm{Re}(e^{-ip(k_j,l_j)t}\varphi^j(x)) \quad \text{and} \quad y_2(t,x) = \mathrm{Im}(e^{-ip(k_j,l_j)t}\varphi^j(x))$$

are solutions of (1.3) with $u(t) \equiv 0$, but they do not satisfy the next observability inequality leading to the exact controllability

$$\|y(0,x)\|_{L^2(0,L)} \le C\|\partial_x y(t,0)\|_{L^2(0,T)}.$$

Let us define the following subspaces of $L^2(0,L)$:

$$M := \langle\{\varphi_1^1, \varphi_2^1, \dots, \varphi_1^n, \varphi_2^n\}\rangle \quad \text{and} \quad H := M^\perp.$$

Remark 2.2. If $p(k_j, l_j) = 0$ for some $j \in \{1, \dots, n\}$, then $\varphi_1^j = \varphi_2^j = 1 - \cos(x)$. It occurs when $k_j = l_j$, i.e., if $L = 2\pi k_j$. If k_j satisfies the condition (1.5), then the space M is one-dimensional. This is the case treated in [8]. It corresponds, for example, to the length $L = 2\pi$.

Remark 2.3. If $p(k_j, l_j) \neq 0$, it is easy to see that $\varphi_1^j \perp \varphi_2^j$. Moreover, for distinct $j_1, j_2 \in \{1, \dots, n\}$, $\varphi_m^{j1} \perp \varphi_s^{j2}$ for $m, s = 1, 2$. Let us give some examples. The pair $(2, 1)$ defines a critical length for which the space M is two-dimensional. The pair $(11, 8)$ defines a critical length for which the space M is four-dimensional since the pairs $(11, 8)$ and $(16, 1)$ define the same critical length.

At this point, we can state the following controllability result which follows directly from the work of Rosier in [17, Propositions 3.3 and 3.9].

THEOREM 2.4. *Let $T > 0$. For every $(y_0, y_T) \in H \times H$, there exist $u \in L^2(0,T)$, and $y \in \mathcal{B}$ satisfying* (1.3)*, $y(0,\cdot) = y_0$, and $y(T,\cdot) = y_T$.*

Now let us define the set N' by

$$N' := \left\{ 2\pi\sqrt{\frac{k^2 + kl + l^2}{3}}; (k,l) \in \mathbb{N}^* \times \mathbb{N}^* \text{ satisfying } k > l \text{ and } (2.7) \right\} \tag{2.6}$$

$$\forall m, n \in \mathbb{N}^*\backslash\{k\},\ k^2 + kl + l^2 \neq m^2 + mn + n^2. \tag{2.7}$$

It is easy to see that N' is the set of critical lengths for which the space of unreachable states is two-dimensional. Indeed, let $L \in N'$; from (2.7) there exists a unique pair $(k_1, l_1) := (k, l)$ satisfying (2.2), and since $k_1 > l_1$, $p(k_1, l_1) > 0$, and therefore the functions φ_1^1, φ_2^1 are orthogonal.

Let us follow the proof of Proposition 8.3 in [7] in order to see that N' contains an infinite number of elements. Let $q \ge 1$ be an integer satisfying

$$\forall m, n \in \mathbb{N}^*\backslash\{q\}, \quad m^2 + mn + n^2 \neq 7q^2. \tag{2.8}$$

Let us consider the critical length L_q defined by the pair $(2q, q)$, that is,

$$L_q := 2\pi\sqrt{\frac{(2q)^2 + 2q^2 + q^2}{3}} = 2\pi q\sqrt{\frac{7}{3}}.$$

From (2.8), it is easy to see that $L_q \in N'$. One can verify that (2.8) holds for $q = 1, 2, 3$, and therefore $L_1, L_2, L_3 \in N'$. Moreover, the following lemma says that the set N' contains an infinite number of lengths L_q.

LEMMA 2.5. *There are infinitely many positive integers q satisfying* (2.8).

Proof. Let $q > 3$ be a prime integer which does not satisfy (2.8), that is, such that

$$\exists m, n \in \mathbb{N}^* \backslash \{q\}, \quad m^2 + mn + n^2 = 7q^2. \tag{2.9}$$

From (2.9) one gets

$$-3mn = (m-n)^2 \pmod q, \quad mn = (m+n)^2 \pmod q. \tag{2.10}$$

It is easy to see that $m + n \neq 0 \pmod q$, and consequently from (2.10) we have

$$-3 = \left((m+n)^{-1}(m-n)\right)^2 \pmod q; \tag{2.11}$$

that is, -3 is a square modulo q. Let us introduce the Legendre symbol, where s is a prime and $x \in \mathbb{Z}$ is an integer not divisible by s:

$$\left(\frac{x}{s}\right) := \begin{cases} 1 & \text{if } x \text{ is a square modulo } s, \\ -1 & \text{if } x \text{ is not a square modulo } s. \end{cases}$$

We have the quadratic reciprocity law due to Gauss for every prime integer $z > 2$, $s > 2$ (see [21, Chapter 3])

$$\left(\frac{s}{z}\right) = \left(\frac{z}{s}\right)(-1)^{\epsilon(z)\epsilon(s)}, \tag{2.12}$$

where

$$\epsilon(z) = \begin{cases} 0 & \text{if } z = 1 \pmod 4, \\ 1 & \text{if } z = -1 \pmod 4. \end{cases}$$

From [21, Chapter 3], we also have that for every x, y coprime to s

$$\left(\frac{xy}{s}\right) = \left(\frac{x}{s}\right)\left(\frac{y}{s}\right) \tag{2.13}$$

and for every $s > 2$ prime integer

$$(-1)^{\epsilon(s)} = \left(\frac{-1}{s}\right). \tag{2.14}$$

Using (2.12), (2.14), (2.13), and (2.11) with $s = q$, $z = 3$, and since $\epsilon(3) = 1$, one obtains

$$\left(\frac{q}{3}\right) = \left(\frac{3}{q}\right)(-1)^{\epsilon(q)} = \left(\frac{3}{q}\right)\left(\frac{-1}{q}\right) = \left(\frac{-3}{q}\right) = 1;$$

that is, $q = 1 \pmod 3$.

Hence, if $q > 3$ is a prime integer such that $q = 2 \pmod 3$, then q satisfies (2.8). As there are two possible nonzero congruences modulo 3, the Dirichlet density theorem (see [21, Chapter 4]) says that (2.8) holds on a set of prime integers of density 1/2. In particular, there are infinitely many positive integers q satisfying (2.8). □

From now on and until the end of this paper, we consider $L \in N'$. From (2.7), for each $L \in N'$ we can define a unique

$$p := \frac{(2k+l)(k-l)(2l+k)}{3\sqrt{3}(k^2+kl+l^2)^{3/2}},$$

and the space M is then defined by

$$M := \langle \varphi_1, \varphi_2 \rangle = \{\alpha\varphi_1 + \beta\varphi_2 \,;\, \alpha, \beta \in \mathbb{R}\},$$

where φ_1 and φ_2 are given by (2.4) with γ_m^j replaced by γ_m, where γ_1, γ_2, and γ_3 are the three roots of $x^3 - x + p = 0$. From (2.3) we also have that φ_1 and φ_2 satisfy

$$\begin{cases} \varphi_1' + \varphi_1''' = -p\,\varphi_2, \\ \varphi_1(0) = \varphi_1(L) = 0, \\ \varphi_1'(0) = \varphi_1'(L) = 0, \end{cases} \tag{2.15}$$

and

$$\begin{cases} \varphi_2' + \varphi_2''' = p\,\varphi_1, \\ \varphi_2(0) = \varphi_2(L) = 0, \\ \varphi_2'(0) = \varphi_2'(L) = 0. \end{cases} \tag{2.16}$$

Now we investigate the evolution of the projection on the subspace M of a solution of (1.3). Let us consider $(y, u) \in \mathcal{B} \times L^2(0,T)$ satisfying (1.3). Let us multiply (2.15) by y and integrate on $[0, L]$. Using integrations by parts we get

$$\frac{d}{dt}\left(\int_0^L y(t,x)\varphi_1(x)dx\right) = -p\int_0^L y(t,x)\varphi_2(x)dx. \tag{2.17}$$

Similarly, multiplying (2.16) by y, we get

$$\frac{d}{dt}\left(\int_0^L y(t,x)\varphi_2(x)dx\right) = p\int_0^L y(t,x)\varphi_1(x)dx. \tag{2.18}$$

Hence, from (2.17) and (2.18), we obtain

$$\int_0^L y(t,x)\varphi_1(x)\,dx = \int_0^L y(0,x)(\cos(p\,t)\varphi_1(x) - \sin(p\,t)\varphi_2(x))\,dx, \tag{2.19}$$

$$\int_0^L y(t,x)\varphi_2(x)\,dx = \int_0^L y(0,x)(\sin(p\,t)\varphi_1(x) + \cos(p\,t)\varphi_2(x))\,dx. \tag{2.20}$$

From (2.19) and (2.20), we see that the projection on M of $y(t,\cdot)$, denoted by $P_M(y(t,\cdot))$, only turns in this two-dimensional subspace and therefore conserves its $L^2(0,L)$-norm. The period of this rotation is $2\pi/p$. Furthermore, we see that if the initial condition $y(0,\cdot)$ lies in H, the solution does too for every time t. Combining this rotation with Theorem 2.4, we obtain the following proposition.

PROPOSITION 2.6. *Let $y_0, y_1 \in L^2(0,L)$ be such that*

$$\|P_M(y_0)\|_{L^2(0,L)} = \|P_M(y_1)\|_{L^2(0,L)}.$$

Then there exists $t^* \leq \frac{2\pi}{p}$ and $u \in L^2(0,t^*)$ such that the solution $y = y(t,x)$ of (1.3), with $y(0,\cdot) = y_0$, satisfies $y(t^*,\cdot) = y_1$.

Proof. Let $y_M = y_M(t,x)$ be the solution of (1.3), with $y_M(0,\cdot) = P_M(y_0)$ and without control ($u \equiv 0$). We know that there exists a time $0 < t^* \leq \frac{2\pi}{p}$ such that $y_M(t^*,\cdot) = P_M(y_1)$. On the other hand, from Theorem 2.4 there exists a control $u_H \in L^2(0,t^*)$ such that the corresponding solution $y_H = y_H(t,x)$ of (1.3) satisfies

$$y_H(0,\cdot) = P_H(y_0) \in H \quad \text{and} \quad y_H(t^*,\cdot) = P_H(y_1).$$

Then $y(t,x) := y_H(t,x) + y_M(t,x)$ satisfies (1.3), with $u = u_H$, $y(0,\cdot) = y_0$, and $y(t^*,\cdot) = y_1$, which ends the proof of this proposition. ∎

3. Motion in the missed directions. Let us first explain the general idea of the method. Let $y = y(t,x)$ be a solution of (1.1) with control $u = u(t)$. We consider a power series expansion of (y,u) with the same scaling on the state and on the control

$$\begin{aligned} y &= \epsilon y_1 + \epsilon^2 y_2 + \epsilon^3 y_3 \ldots, \\ u &= \epsilon u_1 + \epsilon^2 u_2 + \epsilon^3 u_3 \ldots. \end{aligned}$$

In this way, we see that the nonlinear term is given by

$$y\partial_x y = \epsilon^2 y_1 \partial_x y_1 + \epsilon^3 y_1 \partial_x y_2 + \epsilon^3 y_2 \partial_x y_1 + (\text{higher terms}),$$

and therefore, for a small ϵ, we have the expansion of second order $y \approx \epsilon y_1 + \epsilon^2 y_2$, where y_1 and y_2 are given by

$$\begin{cases} \partial_t y_1 + \partial_x y_1 + \partial_x^3 y_1 = 0, \\ y_1(t,0) = y_1(t,L) = 0, \\ \partial_x y_1(t,L) = u_1(t), \end{cases}$$

and

$$\begin{cases} \partial_t y_2 + \partial_x y_2 + \partial_x^3 y_2 = -y_1 \partial_x y_1, \\ y_2(t,0) = y_2(t,L) = 0, \\ \partial_x y_2(t,L) = u_2(t), \end{cases}$$

respectively. The strategy consists first in proving that the expansion to the second order of $y = y(t,x)$, i.e., $\epsilon y_1 + \epsilon^2 y_2$, can reach all of the missed directions and then in using a fixed point argument to prove that it is sufficient to get Theorem 1.4. This is a classical approach to study the local controllability of a finite-dimensional control system, and it has been applied in [8] to prove the local exact controllability around the origin of the control system (1.1) for some critical domains.

Now we see that we can "enter" into the subspace M. More precisely, the result we prove is the following one.

PROPOSITION 3.1. *Let $T > 0$. There exists $(u,v) \in L^2(0,T)^2$ such that if $\alpha = \alpha(t,x)$ and $\beta = \beta(t,x)$ are the solutions of*

$$\begin{cases} \partial_t \alpha + \partial_x \alpha + \partial_x^3 \alpha = 0, \\ \alpha(t,0) = \alpha(t,L) = 0, \\ \partial_x \alpha(t,L) = u(t), \\ \alpha(0,\cdot) = 0, \end{cases} \tag{3.1}$$

and

$$\begin{cases} \partial_t\beta + \partial_x\beta + \partial_x^3\beta = -\alpha\partial_x\alpha, \\ \beta(t,0) = \beta(t,L) = 0, \\ \partial_x\beta(t,L) = v(t), \\ \beta(0,\cdot) = 0, \end{cases} \tag{3.2}$$

then

$$\alpha(T,\cdot) = 0 \quad \textit{and} \quad \beta(T,\cdot) \in M\backslash\{0\}.$$

Proof. In order to study the trajectory $\beta = \beta(t,x)$, we set $\beta = \beta^u + \beta^v$, where $\beta^u = \beta^u(t,x)$ and $\beta^v = \beta^v(t,x)$ are the solutions of

$$\begin{cases} \partial_t\beta^u + \partial_x\beta^u + \partial_x^3\beta^u = -\alpha\partial_x\alpha, \\ \beta^u(t,0) = \beta^u(t,L) = 0, \\ \partial_x\beta^u(t,L) = 0, \\ \beta^u(0,\cdot) = 0, \end{cases} \tag{3.3}$$

and

$$\begin{cases} \partial_t\beta^v + \partial_x\beta^v + \partial_x^3\beta^v = 0, \\ \beta^v(t,0) = \beta^v(t,L) = 0, \\ \partial_x\beta^v(t,L) = v(t), \\ \beta^v(0,\cdot) = 0, \end{cases} \tag{3.4}$$

respectively. If $u \in L^2(0,T)$ is given, by Theorem 2.4 one can find $v \in L^2(0,T)$ such that

$$\beta^v(T,\cdot) = -P_H(\beta^u(T,\cdot))$$

and thus $\beta(T,\cdot) = P_M(\beta^u(T,\cdot))$. From this fact, one sees that the proof of Proposition 3.1 can be reduced to prove

$$\exists u \in L^2(0,T) \quad \text{such that} \quad \alpha(T,\cdot) = 0 \quad \text{and} \quad P_M(\beta^u(T,\cdot)) \neq 0. \tag{3.5}$$

Let $u \in L^2(0,T)$. Let us multiply (3.3) by φ_1 and integrate the resulting equality on $[0,L]$. Then, using integration by parts, (2.15), and the boundary and initial conditions in (3.3), one gets

$$\frac{d}{dt}\left(\int_0^L \beta^u(t,x)\varphi_1(x)dx\right) = -p\int_0^L \beta^u(t,x)\varphi_2(x)dx + \frac{1}{2}\int_0^L \alpha^2(t,x)\varphi_1'(x)dx.$$

In a similar way, if we now multiply (3.3) by φ_2, we get

$$\frac{d}{dt}\left(\int_0^L \beta^u(t,x)\varphi_2(x)dx\right) = p\int_0^L \beta^u(t,x)\varphi_1(x)dx + \frac{1}{2}\int_0^L \alpha^2(t,x)\varphi_2'(x)dx.$$

If we call

$$\eta_k(t) := \int_0^L \beta^u(t,x)\varphi_k(x)dx \quad \text{for } k = 1,2,$$

we can write the system

$$\left\{ \begin{array}{l} \begin{pmatrix} \dot\eta_1(t) \\ \dot\eta_2(t) \end{pmatrix} = \begin{pmatrix} 0 & -p \\ p & 0 \end{pmatrix} \begin{pmatrix} \eta_1(t) \\ \eta_2(t) \end{pmatrix} + \begin{pmatrix} \frac{1}{2}\int_0^L \alpha^2(t,x)\varphi_1'(x)dx \\ \frac{1}{2}\int_0^L \alpha^2(t,x)\varphi_2'(x)dx \end{pmatrix}, \\ \eta_1(0) = 0, \quad \eta_2(0) = 0. \end{array} \right. \tag{3.6}$$

The solution of (3.6) is given by

$$\begin{pmatrix} \eta_1(t) \\ \eta_2(t) \end{pmatrix} = \begin{pmatrix} \cos(p\,t) & -\sin(p\,t) \\ \sin(p\,t) & \cos(p\,t) \end{pmatrix} \begin{pmatrix} I_1(t) \\ I_2(t) \end{pmatrix},$$

where

$$I_1(t) := \frac{1}{2}\int_0^t \int_0^L \alpha^2(s,x)(\cos(ps)\varphi_1'(x) + \sin(ps)\varphi_2'(x))dx\,ds,$$
$$I_2(t) := \frac{1}{2}\int_0^t \int_0^L \alpha^2(s,x)(-\sin(ps)\varphi_1'(x) + \cos(ps)\varphi_2'(x))dx\,ds.$$

If we work with complex numbers calling $\varphi := \varphi_1 + i\varphi_2$, we get

$$\eta_1(t) + i\eta_2(t) = \frac{1}{2}e^{ip\,t}\int_0^t \int_0^L e^{-ips}\alpha^2(s,x)\varphi'(x)dx\,ds.$$

Now let us assume that (3.5) fails to be true; i.e., let us suppose that

$$\forall\, u \in L^2(0,T), \quad \eta_1(T) = \eta_2(T) = 0 \quad \text{or} \quad \alpha(T,\cdot) \neq 0. \tag{3.7}$$

If we define

$$U_{ad} := \left\{ u \in L^2(0,T)\,;\ \text{the solution } \alpha \text{ of (3.1) satisfies } \alpha(T,\cdot) = 0 \right\},$$

then condition (3.7) implies that

$$\forall\, u \in U_{ad}, \quad \int_0^T \int_0^L e^{-ips}\alpha^2(s,x)\varphi'(x)dx\,ds = 0. \tag{3.8}$$

Let $\alpha_1 = \alpha_1(t,x)$ and $\alpha_2 = \alpha_2(t,x)$ be two solutions of (3.1) such that

$$\alpha_1(T,\cdot) = \alpha_2(T,\cdot) = 0.$$

Now, for $(\rho_1,\rho_2) \in \mathbb{R}^2$, let $\alpha := \rho_1\alpha_1 + \rho_2\alpha_2$ and $u := \alpha_x(\cdot,L)$. By linearity, we see that $\alpha = \alpha(t,x)$ is a solution of (3.1) and $u \in U_{ad}$. Consequently, (3.8) implies that, for every $(\rho_1,\rho_2) \in \mathbb{R}^2$,

$$\rho_1^2 \int_0^T \int_0^L e^{-ips}\alpha_1^2(s,x)\varphi'(x)dx\,ds + 2\rho_1\rho_2 \int_0^T \int_0^L e^{-ips}\alpha_1(s,x)\alpha_2(s)\varphi'(x)dx\,ds + \rho_2^2 \int_0^T \int_0^L e^{-ips}\alpha_2^2(s,x)\varphi'(x)dx\,ds = 0.$$

Looking at the coefficient of $\rho_1\rho_2$, we get

$$\int_0^T \int_0^L e^{-ips}\alpha_1(s,x)\alpha_2(s,x)\varphi'(x)dx\,ds = 0. \tag{3.9}$$

Let t_1, t_2 be such that $0 < t_1 < t_2 < T$. We choose the trajectories $\alpha_1 = \alpha_1(t,x)$ and $\alpha_2 = \alpha_2(t,x)$ such that

$$\alpha_2 \text{ is not identically equal to } 0, \tag{3.10}$$

$$\alpha_2(t,x)|_{([0,t_1]\cup[t_2,T])\times[0,L]} = 0 \quad \text{and} \quad \alpha_1(t,x)|_{[t_1,t_2]\times[0,L]} = \mathrm{Re}(e^{\lambda t} y_\lambda(x)), \tag{3.11}$$

where $\lambda \in \mathbb{C}\backslash\{\pm ip\}$ and $y_\lambda = y_\lambda(x)$ is a complex-valued function which satisfies

$$\begin{cases} \lambda y_\lambda + y_\lambda' + y_\lambda''' = 0, \\ y_\lambda(0) = y_\lambda(L) = 0. \end{cases} \tag{3.12}$$

If $\lambda \neq \pm ip$, one can see that $\mathrm{Re}(y_\lambda), \mathrm{Im}(y_\lambda) \in H$, and then by Theorem 2.4 there exists such a trajectory $\alpha_1 = \alpha_1(t,x)$.

Let us introduce the operator $\tilde{A}w = -w' - w'''$ on the domain $D(\tilde{A}) \subset L^2(0,L)$ defined by

$$D(\tilde{A}) := \left\{ w \in H^3(0,L);\, w(0) = w(L) = 0, w'(0) = w'(L) \right\}.$$

It is not difficult to see that $i\tilde{A}$ is a self-adjoint operator on $L^2(0,L)$ with compact resolvent. Hence, the spectrum $\sigma(\tilde{A})$ of $\tilde{A}$ consists only of eigenvalues. Furthermore, the spectrum is a discrete subset of $i\mathbb{R}$.

If we take λ such that $(-ip+\lambda) \notin \sigma(\tilde{A})$, the operator $(\tilde{A} - (-ip+\lambda)I)$ is invertible, and thus, there exists a unique complex-valued function $\phi_\lambda = \phi_\lambda(x)$ solution of

$$\begin{cases} (-ip+\lambda)\phi_\lambda + \phi_\lambda' + \phi_\lambda''' = y_\lambda \varphi', \\ \phi_\lambda(0) = \phi_\lambda(L) = 0, \\ \phi_\lambda'(0) = \phi_\lambda'(L). \end{cases} \tag{3.13}$$

We multiply (3.13) by $\alpha_2(t,x)e^{(-ip+\lambda)t}$, integrate on $[0,L]$, and use integrations by parts together with (3.1), and the boundary and initial conditions in (3.13) to get

$$e^{-ip\,t}\int_0^L e^{\lambda t} y_\lambda \alpha_2(t,x)\varphi'(x)dx = \frac{d}{dt}\left(\int_0^L e^{(-ip+\lambda)t}\phi_\lambda(x)\alpha_2(t,x)dx\right) - e^{(-ip+\lambda)t}\phi_\lambda'(L)\partial_x\alpha_2(t,x)\Big|_{x=0}^{L}.$$

Then let us integrate this equality on $[0,T]$ and use the fact that $\alpha_2(0,\cdot) = 0$ and $\alpha_2(T,\cdot) = 0$. We obtain

$$\int_0^T\int_0^L e^{-ip\,t}e^{\lambda t} y_\lambda \alpha_2(t,x)\varphi'(x)dx\,dt = -\phi_\lambda'(L)\int_0^T e^{(-ip+\lambda)t}\left(\partial_x\alpha_2(t,L) - \partial_x\alpha_2(t,0)\right)dt. \tag{3.14}$$

On the other hand, by (3.9) and (3.11), it follows that

$$\int_0^T\int_0^L e^{-ip\,t}\mathrm{Re}(e^{\lambda t} y_\lambda)\alpha_2(t,x)\varphi'(x)dx\,dt = 0, \tag{3.15}$$

and, since one can also take a trajectory $\tilde{\alpha}_1 = \tilde{\alpha}_1(t,x)$ such that

$$\tilde{\alpha}_1(t,x)|_{[t_1,t_2]\times[0,L]} = \mathrm{Im}(e^{\lambda t} y_\lambda(x)),$$

one deduces from (3.9) that

$$\int_0^T \int_0^L e^{-ip\,t}\mathrm{Im}(e^{\lambda t} y_\lambda)\alpha_2(t,x)\varphi'(x)dx\,dt = 0. \tag{3.16}$$

Therefore, from (3.15) and (3.16), one gets

$$\int_0^T \int_0^L e^{-ip\,t} e^{\lambda t} y_\lambda \alpha_2(t,x)\varphi'(x)dx\,dt = 0,$$

and consequently from (3.14), for every $\lambda \neq \pm ip$ such that $(-ip+\lambda) \notin \sigma(\tilde{A})$, one has

$$\phi'_\lambda(L)\int_0^T e^{(-ip+\lambda)t}\left(\partial_x\alpha_2(t,L) - \partial_x\alpha_2(t,0)\right)dt = 0. \tag{3.17}$$

Let $a \in \mathbb{R}\backslash[-1/\sqrt{3}, 1/\sqrt{3}]$. We take $\lambda = 2ai(4a^2-1)$. Let

$$y_\lambda(x) = Ce^{(-\sqrt{3a^2-1}-ai)x} + (1-C)e^{(\sqrt{3a^2-1}-ai)x} - e^{2aix}, \tag{3.18}$$

where

$$C = \frac{e^{2aiL} - e^{(\sqrt{3a^2-1}-ai)L}}{e^{(-\sqrt{3a^2-1}-ai)L} - e^{(\sqrt{3a^2-1}-ai)L}}.$$

One easily checks that such a $y_\lambda = y_\lambda(x)$ satisfies (3.12) and $y_\lambda \neq 0$. Let us define

$$\Sigma := \left\{ a \in \mathbb{R}\backslash[-1/\sqrt{3}, 1/\sqrt{3}]\,;\, \lambda \notin \sigma(\tilde{A}), (\lambda - ip) \notin \sigma(\tilde{A}) \right\},$$

where $\lambda = 2ai(4a^2-1)$. Then the function $S : \Sigma \to \mathbb{C}$, $S(a) = \phi'_\lambda(L)$ is continuous. Now we use the fact that S is not identically equal to the function 0 (the proof of this statement will be given in Lemma 3.6 at the end of this section). Then there exist $\widehat{a} \in \Sigma$ and $\epsilon > 0$ such that, for every $a \in \Sigma$ with $|a - \widehat{a}| < \epsilon$, $S(a) \neq 0$. From (3.17) one gets

$$\forall\, a \in \Sigma, \quad |a-\widehat{a}| < \epsilon, \quad \int_0^T e^{(-p+2a(4a^2-1))i\,t}\left(\partial_x\alpha_2(t,L) - \partial_x\alpha_2(t,0)\right)dt = 0,$$

and since the function $\beta \in \mathbb{C} \mapsto \int_0^T e^{\beta t}\left(\partial_x\alpha_2(t,L) - \partial_x\alpha_2(t,0)\right)dt \in \mathbb{C}$ is holomorphic, it follows that

$$\forall\, \beta \in \mathbb{C}, \quad \int_0^T e^{\beta t}\big(\partial_x\alpha_2(t,L) - \partial_x\alpha_2(t,0)\big)dt = 0,$$

which implies that $\partial_x\alpha_2(t,0) - \partial_x\alpha_2(t,L) = 0$ for every t. In summary, one has that $\alpha_2 = \alpha_2(t,x)$ satisfies

$$\begin{cases} \partial_t\alpha_2 + \partial_x\alpha_2 + \partial_x^3\alpha_2 = 0, \\ \alpha_2(t,0) = \alpha_2(t,L) = 0, \\ \partial_x\alpha_2(t,0) = \partial_x\alpha_2(t,L), \\ \alpha_2(0,\cdot) = 0, \\ \alpha_2(T,\cdot) = 0. \end{cases} \tag{3.19}$$

If we multiply (3.19) by α_2, integrate on $[0, L]$, and use integration by parts together with the boundary conditions, we obtain that

$$\frac{d}{dt}\int_0^L |\alpha_2(t,x)|^2 dx = 0,$$

which, together with $\alpha_2(0,\cdot) = 0$, implies that

$$\alpha_2(t,x) = 0 \quad \forall\, x \in [0,L],\ \forall\, t \in [0,T]. \tag{3.20}$$

But this is in contradiction with (3.10). Thus, we have proved (3.5) and therefore Proposition 3.1. □

From now on, for each $T_c > 0$, we denote by $(u_c, v_c) \in L^2(0,T)^2$ the controls given by Proposition 3.1 and by (α_c, β_c) the corresponding trajectories. Let us define $\tilde{\varphi}_1 := \beta_c(T_c, \cdot)$. Let us notice that, by scaling the controls, we can assume that $\|\tilde{\varphi}_1\|_{L^2(0,L)} = 1$. We will prove now that in any time $T > \pi/p$, we can reach all of the states lying in M.

PROPOSITION 3.2. *Let $T > \pi/p$. Let $\psi \in M$. There exists $(u,v) \in L^2(0,T)^2$ such that if $\alpha = \alpha(t,x)$ and $\beta = \beta(t,x)$ are the solutions of* (3.1) *and* (3.2)*, then*

$$\alpha(T,\cdot) = 0 \quad \textit{and} \quad \beta(T,\cdot) = \psi.$$

Proof. Let $\hat{T} > 0$ be such that $T = (\pi/p) + \hat{T}$. Let T_c be such that $0 < T_c < \hat{T}$. Let $T_a := T - T_c$. If we take in (3.1) and (3.2) the controls

$$(u^1, v^1)(t) = \begin{cases} (0,0) & \text{if } t \in (0, T_a), \\ (u_c(t - T_a), v_c(t - T_a)) & \text{if } t \in (T_a, T), \end{cases}$$

we obtain that $\beta^1(T,\cdot) = \tilde{\varphi}_1$, where $\beta^1 = \beta^1(t,x)$ is the corresponding solution of (3.2). Now we use the rotation showed in section 2 (see, in particular, (2.19) and (2.20)) in order to reach other states lying in M. Let us define $\tilde{\varphi}_2 := \beta^2(T,\cdot)$, where $\beta^2 = \beta^2(t,x)$ is defined by the controls

$$(u^2, v^2)(t) = \begin{cases} (0,0) & \text{if } t \in (0, T_a - \frac{\pi}{2p}), \\ (u_c(t - T_a + \frac{\pi}{2p}), v_c(t - T_a + \frac{\pi}{2p})) & \text{if } t \in (T_a - \frac{\pi}{2p}, T - \frac{\pi}{2p}), \\ (0,0) & \text{if } t \in (T - \frac{\pi}{2p}, T). \end{cases}$$

In a similar way, the controls

$$(u^3, v^3)(t) = \begin{cases} (0,0) & \text{if } t \in (0, T_a - \frac{\pi}{p}), \\ (u_c(t - T_a + \frac{\pi}{p}), v_c(t - T_a + \frac{\pi}{p})) & \text{if } t \in (T_a - \frac{\pi}{p}, T - \frac{\pi}{p}), \\ (0,0) & \text{if } t \in (T - \frac{\pi}{p}, T) \end{cases}$$

allow us to define $\tilde{\varphi}_3 := \beta^3(T,\cdot)$. Notice that $\tilde{\varphi}_3 = -\tilde{\varphi}_1$.

Let T_θ be such that $0 < T_\theta < \min\{\pi/(2p), \hat{T} - T_c\}$, and let $T_b := (\pi/p) + T_\theta$. Let us define $\tilde{\varphi}_4 := \beta^4(T,\cdot)$, where $\beta^4 = \beta^4(t,x)$ is the solution of (3.2), with

$$(u^4, v^4)(t) = \begin{cases} (0,0) & \text{if } t \in (0, T_a - T_b), \\ (u_c(t - T_a + T_b), v_c(t - T_a + T_b)) & \text{if } t \in (T_a - T_b, T - T_b), \\ (0,0) & \text{if } t \in (T - T_b, T). \end{cases}$$

We have thus proved that we can reach the missed directions $\{\tilde{\varphi}_k\}_{k=1}^4$. Let us now define the cones

$$\begin{aligned} M_1 &:= \{d_1\tilde{\varphi}_1 + d_2\tilde{\varphi}_2; d_1 > 0, d_2 \geq 0\},\\ M_2 &:= \{d_1\tilde{\varphi}_2 + d_2\tilde{\varphi}_3; d_1 > 0, d_2 \geq 0\},\\ M_3 &:= \{d_1\tilde{\varphi}_3 + d_2\tilde{\varphi}_4; d_1 > 0, d_2 \geq 0\},\\ M_4 &:= \{d_1\tilde{\varphi}_4 + d_2\tilde{\varphi}_1; d_1 > 0, d_2 \geq 0\}. \end{aligned}$$

By construction of these cones, one has that $M = \cup_{k=1}^4 M_k$.

Remark 3.3. It is easy to see that if one chooses T_c, T_θ such that $T_c < T_\theta$, then the supports of the trajectories $\alpha^k = \alpha^k(t,x)$ for $k = 1, \dots, 4$ are disjoint.

For each $w = (w_1, w_2) \in \mathbb{R}^2$, let us define

$$\rho_w := \sqrt{w_1^2 + w_2^2} \quad \text{and} \quad z_w := (w_1\varphi_1 + w_2\varphi_2)/\rho_w \in M.$$

We have that $z_w \in M_i$ for some $i \in \{1, \dots, 4\}$, and hence there exist $d_{1w} > 0$ and $d_{2w} \geq 0$ such that $z_w = d_{1w}\tilde{\varphi}_i + d_{2w}\tilde{\varphi}_{i+1}$. If we take the control

$$(u_w, v_w) = (d_{1w}^{1/2}u^i + d_{2w}^{1/2}u^{i+1}, d_{1w}v^i + d_{2w}v^{i+1})$$

and use the fact that the trajectories α^k for $k = 1, \dots, 4$ are disjoints, then we see that the corresponding solution $\beta_w = \beta_w(t,x)$ of (3.2) satisfies $\beta_w(T, \cdot) = z_w$.

Finally, let $\psi \in M$. With $R := \|\psi\|_{L^2(0,L)}$ we can write $\psi = Rz_w$ for a $(w_1, w_2) \in \mathbb{R}^2$ such that $w_1^2 + w_2^2 = 1$. It is easy to see that the control $(u, v) = (R^{1/2}u_w, Rv_w)$ allows us to reach the state ψ, and so the proof of this proposition is ended. □

Remark 3.4. The proof of Proposition 3.2 is the only part which needs a time large enough. Hence, Theorem 1.4 holds for $T_M := \pi/p$.

Remark 3.5. In [8] an expansion to the second order is not sufficient, and the authors must go to the third order to enter into the subspace of missed directions. Since in their case this subspace is one-dimensional and since they use an odd order expansion, one can reach all of the missed states with a scaling argument. Our case is different. We can also enter into the subspace of missed directions in any time, but, in order to reach all of these states, our method needs a time large enough.

It remains to prove the following lemma to complete the proof of Proposition 3.1.

LEMMA 3.6. *The function S is not identically equal to* 0.

Proof. Let $a \in \Sigma$ and $\lambda = 2ai(4a^2 - 1)$. Let $\mu \in \mathbb{C}$, and let $y_\mu = y_\mu(x)$ be a solution of

$$\begin{cases} \mu y_\mu + y'_\mu + y'''_\mu = 0,\\ y_\mu(0) = y_\mu(L) = 0. \end{cases}$$

We multiply (3.13) by y_μ and integrate by parts on $[0, L]$. Thus, we get

$$(\lambda - ip + \mu)\int_0^L \phi_\lambda y_\mu dx - \phi'_\lambda(L)\big(y'_\mu(L) - y'_\mu(0)\big) = \int_0^L y_\lambda \varphi' y_\mu dx. \tag{3.21}$$

From now on, we set $\mu = \mu(a) := -\lambda + ip$. With this choice we obtain from (3.21)

$$-S(a)\big(y'_\mu(L) - y'_\mu(0)\big) = \int_0^L y_\lambda \varphi' y_\mu dx.$$

Therefore, if we prove that the function

$$a \in \Sigma \longrightarrow J(a) := \int_0^L y_\lambda \varphi' y_\mu dx \in \mathbb{C}$$

is not identically equal to 0, the proof of this lemma is ended. Let $b \in \mathbb{R}$ be such that $\mu = 2bi(4b^2 - 1)$. We take the function y_μ given by

$$y_\mu(x) = De^{(-\sqrt{3b^2-1}-bi)x} + (1-D)e^{(\sqrt{3b^2-1}-bi)x} - e^{2bix}, \tag{3.22}$$

where

$$D = \frac{e^{2biL} - e^{(\sqrt{3b^2-1}-bi)L}}{e^{(-\sqrt{3b^2-1}-bi)L} - e^{(\sqrt{3b^2-1}-bi)L}}.$$

In the next computations, we use the fact that $e^{i\gamma_1 L} = e^{i\gamma_2 L} = e^{i\gamma_3 L}$ (see (2.5)) and the following formula:

$$\int_0^L e^{(v+iw)x}\varphi' = \frac{\big(1+\gamma_1^2 - 2p/\gamma_1\big)\big(1 - e^{(v+iw+i\gamma_1)L}\big)(vi-w)}{(vi-w)^3 - (vi-w) + p}, \tag{3.23}$$

which holds if $v + iw \neq -i\gamma_m$ for $m = 1, 2, 3$.

We want to show that as $a \to \infty$, the following expression diverges, which is in contradiction with the fact that $J(a) \equiv 0$:

$$R(a) := \frac{(e^{(-\sqrt{3a^2-1}-ai)L} - e^{(\sqrt{3a^2-1}-ai)L})(e^{(-\sqrt{3b^2-1}-bi)L} - e^{(\sqrt{3b^2-1}-bi)L})}{1+\gamma_1^2 - 2p/\gamma_1} J(a).$$

In fact, by using (3.23), one computes explicitly $J(a)$, and thus one sees that, as a tends to infinity, the dominant term of $R(a)$ is given by

$$\begin{aligned}
Z(a) := e^{(\sqrt{3a^2-1}+\sqrt{3b^2-1})L}\Big\{ & \frac{(e^{(-ai-bi)L} - e^{(ai+bi+\gamma_1 i)L})(-2a-2b)}{(-2a-2b)^3 - (-2a-2b) + p} \\
& + \frac{e^{(-ai-bi)L}(-i\sqrt{3a^2-1} - i\sqrt{3b^2-1} + a + b)}{(-i\sqrt{3a^2-1} - i\sqrt{3b^2-1} + a + b)^3 - (-i\sqrt{3a^2-1} - i\sqrt{3b^2-1} + a + b) + p} \\
& - \frac{e^{(ai+bi+\gamma_1 i)L}(i\sqrt{3a^2-1} + i\sqrt{3b^2-1} + a + b)}{(i\sqrt{3a^2-1} + i\sqrt{3b^2-1} + a + b)^3 - (i\sqrt{3a^2-1} + i\sqrt{3b^2-1} + a + b) + p} \\
& + \frac{e^{(ai+bi+\gamma_1 i)L}(i\sqrt{3a^2-1} + a - 2b)}{(i\sqrt{3a^2-1} + a - 2b)^3 - (i\sqrt{3a^2-1} + a - 2b) + p} \\
& - \frac{e^{(-ai-bi)L}(-i\sqrt{3b^2-1} - 2a + b)}{(-i\sqrt{3b^2-1} - 2a + b)^3 - (-i\sqrt{3b^2-1} - 2a + b) + p} \\
& + \frac{e^{(ai+bi+\gamma_1 i)L}(i\sqrt{3b^2-1} - 2a + b)}{(i\sqrt{3b^2-1} - 2a + b)^3 - (i\sqrt{3b^2-1} - 2a + b) + p} \\
& - \frac{e^{(-ai-bi)L}(-i\sqrt{3a^2-1} + a - 2b)}{(-i\sqrt{3a^2-1} + a - 2b)^3 - (-i\sqrt{3a^2-1} + a - 2b) + p}\Big\}.
\end{aligned}$$

Using that as $a \to \infty$, $b \to -\infty$ and $a+b \sim -p/(24a^2)$, we obtain the following asymptotical expression for the right-hand factor of $Z(a)$:

$$\frac{-(e^{\frac{p}{24a^2}iL} - e^{-\frac{p}{24a^2}iL+i\gamma_1 L})}{12a^2} \sim \begin{cases} -\frac{(1-e^{i\gamma_1 L})}{12a^2} & \text{if } e^{i\gamma_1 L} \neq 1, \\ -\frac{ipL}{144a^4} & \text{if } e^{i\gamma_1 L} = 1. \end{cases}$$

One can see that in both cases $Z(a)$ diverges as $a \to \infty$, and therefore $R(a)$ does, which implies that $J(a)$ is not identically equal to 0. It ends the proof of this lemma. □

4. Proof of Theorem 1.4.

4.1. Existence and uniqueness results. Let us recall the existence property proved by Coron and Crépeau in [8] for the following nonlinear KdV equation:

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y + y\partial_x y = f, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = u(t), \\ y(0,\cdot) = y_0. \end{cases} \tag{4.1}$$

Proposition 4.1 (see [8, Proposition 14]). *Let $L > 0$ and $T > 0$. There exist $\epsilon > 0$ and $C > 0$ such that, for every $f \in L^1(0,T,L^2(0,L))$, $u \in L^2(0,T)$, and $y_0 \in L^2(0,L)$ such that*

$$\|f\|_{L^1(0,T,L^2(0,L))} + \|u\|_{L^2(0,T)} + \|y_0\|_{L^2(0,L)} \leq \epsilon,$$

there exists at least one solution of (4.1) which satisfies

$$\|y\|_{\mathcal{B}} \leq C(\|f\|_{L^1(0,T,L^2(0,L))} + \|u\|_{L^2(0,T)} + \|y_0\|_{L^2(0,L)}). \tag{4.2}$$

For the uniqueness, one has the following.

Proposition 4.2 (see [8, Proposition 15]). *Let $T > 0$, and let $L > 0$. There exists $C > 0$ such that for every $(y_{01}, y_{02}) \in L^2(0,L)^2$, $(u_1, u_2) \in L^2(0,T)^2$, and $(f_1, f_2) \in L^1(0,T,L^2(0,L))^2$ for which there exist solutions $y_1 = y_1(t,x)$ and $y_2 = y_2(t,x)$ of (4.1), one has the following estimates:*

$$\int_0^T \int_0^L |\partial_x y_1(t,x) - \partial_x y_2(t,x)|^2 dxdt \leq e^{C(1+\|y_1\|^2_{L^2(0,T,H^1(0,L))} + \|y_2\|^2_{L^2(0,T,H^1(0,L))})} \cdot \left(\|u_1 - u_2\|^2_{L^2(0,T)} + \|f_1 - f_2\|^2_{L^1(0,T,L^2(0,L))} + \|y_{01} - y_{02}\|^2_{L^2(0,L)} \right),$$

$$\int_0^L |y_1(t,x) - y_2(t,x)|^2 dx \leq e^{C(1+\|y_1\|^2_{L^2(0,T,H^1(0,L))} + \|y_2\|^2_{L^2(0,T,H^1(0,L))})} \cdot \left(\|u_1 - u_2\|^2_{L^2(0,T)} + \|f_1 - f_2\|^2_{L^1(0,T,L^2(0,L))} + \|y_{01} - y_{02}\|^2_{L^2(0,L)} \right)$$

for every $t \in [0,T]$.

4.2. Settings and a technical lemma. Until the end of this paper, we adopt some important notations. Let us denote, for $D > 0$ and $R > 0$,

$$B_R^D := \left\{ \xi \in L^2(0,D) \,;\, \|\xi\|_{L^2(0,D)} \leq R \right\}$$

and recall that for each $w = (w_1, w_2) \in \mathbb{R}^2$, we write $\rho_w := \sqrt{w_1^2 + w_2^2}$ and $z_w := (w_1\varphi_1 + w_2\varphi_2)/\rho_w$. We also write $(u_w, v_w) \in L^2(0,T)$ the controls defined in section 3 in order to drive the solutions $\beta_w = \beta_w(t,x)$ from zero at $t = 0$ to z_w at $t = T$.

By the work of Rosier in [17], we know that for each $y_0 \in L^2(0,L)$ there exists a continuous linear affine map (it is a consequence of applying the HUM method to prove Theorem 2.4)

$$\Gamma_0 : h \in H \subset L^2(0,L) \longmapsto \Gamma_0(h) \in L^2(0,T)$$

such that the solution of

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y = 0, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = \Gamma_0(h), \\ y(0,\cdot) = P_H(y_0) \end{cases}$$

satisfies $y(T,\cdot) = h$. Moreover, there exist constants $D_1, D_2 > 0$ such that

$$\forall y_0 \in L^2(0,L),\ \forall h \in H, \quad \|\Gamma_0(h)\|_{L^2(0,T)} \le D_1(\|h\|_{L^2(0,L)} + \|y_0\|_{L^2(0,L)}), \tag{4.3}$$

$$\forall y_0 \in L^2(0,L),\ \forall h, g \in H, \quad \|\Gamma_0(h) - \Gamma_0(g)\|_{L^2(0,T)} \le D_2\|h - g\|_{L^2(0,L)}. \tag{4.4}$$

Let $y_0 \in L^2(0,L)$ be such that $\|y_0\|_{L^2(0,L)} < r$, $r > 0$ to be chosen later. Let us define the functions G and F

$$\begin{aligned} G : L^2(0,L) &\longrightarrow L^2(0,T), \\ z = P_H(z) + w_1\varphi_1 + w_2\varphi_2 &\mapsto G(z) = \Gamma_0(P_H(z)) + \rho_w^{1/2}u_w + \rho_w v_w, \end{aligned}$$

$$\begin{aligned} F : B_{\epsilon_1}^T \cap L^2(0,T) &\longrightarrow L^2(0,L), \\ u &\longmapsto F(u) = y(T,\cdot), \end{aligned}$$

where $y = y(t,x)$ is the solution of

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y + y\partial_x y = 0, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = u(t), \\ y(0,\cdot) = y_0, \end{cases} \tag{4.5}$$

and ϵ_1 is small enough so that the function F is well defined. It holds if $\epsilon_1 + r < \epsilon$, where ϵ is given by Proposition 4.1. The map F is even continuous according to Proposition 4.2. Let $y_T \in L^2(0,L)$ be such that $\|y_T\| < r$. Let Λ_{y_0,y_T} denote the map

$$\begin{aligned} \Lambda_{y_0,y_T} : B_{\epsilon_2}^L \cap L^2(0,L) &\longrightarrow L^2(0,L), \\ z &\longmapsto \Lambda_{y_0,y_T}(z) = z + y_T - F \circ G(z), \end{aligned}$$

where ϵ_2 is small enough so that Λ_{y_0,y_T} is well defined (ϵ_2 exists according to Proposition 4.1 and to the continuity of G).

Let us notice that if we find a fixed point $\tilde{z} \in L^2(0,L)$ of the map Λ_{y_0,y_T}, then we will have $F \circ G(\tilde{z}) = y_T$, and this means that the control $u := G(\tilde{z}) \in L^2(0,T)$ drives the solution of (4.5) from y_0 at $t = 0$ to y_T at $t = T$.

Let us assert the following technical result which will be needed to study the map Λ_{y_0,y_T}.

LEMMA 4.3. *There exist $\epsilon_3 > 0$ and $C_3 > 0$ such that for every $z, y_0 \in B^L_{\epsilon_3}$ the following estimate holds:*

$$\|z - F(G(z))\|_{L^2(0,L)} \leq C_3(\|y_0\|_{L^2(0,L)} + \|z\|^{3/2}_{L^2(0,L)}).$$

Proof. Let $z, y_0 \in L^2(0,L)$. Let $w = (w_1, w_2) \in \mathbb{R}^2$ be such that $z = P_H(z) + \rho_w z_w$. Let $y = y(t,x)$ be a solution of

$$\begin{cases} \partial_t y + \partial_x y + \partial_x^3 y + y\partial_x y = 0, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = G(z), \\ y(0,\cdot) = y_0. \end{cases} \tag{4.6}$$

From (4.3) and since $\rho_w \leq \|z\|_{L^2(0,L)}$, one deduces that if $\|z\|_{L^2(0,L)}$ is smaller than 1 (and therefore $\|z\|_{L^2(0,L)} \leq \|z\|^{1/2}_{L^2(0,L)}$), then there exists a constant D_3 such that

$$\|G(z)\|_{L^2(0,T)} \leq D_3(\|y_0\|_{L^2(0,L)} + \|z\|^{1/2}_{L^2(0,L)}). \tag{4.7}$$

Remark 4.4. Let us notice that the controls u_w, v_w in the definition of the map G drive the solution β_w from the origin at $t = 0$ to the state z_w at $t = T$, with $\|z_w\|_{L^2(0,L)} = 1$, and therefore they are uniformly bounded.

By using (4.2) and (4.7), one can find $\epsilon_2, C_2 > 0$ such that for every $z, y_0 \in B^L_{\epsilon_2}$ the unique solution of (4.6) satisfies

$$\|y\|_{\mathcal{B}} \leq C_2(\|y_0\|_{L^2(0,L)} + \|z\|^{1/2}_{L^2(0,L)}). \tag{4.8}$$

Let $\tilde{y} = \tilde{y}(t,x)$, $\alpha_w = \alpha_w(t,x)$, $\beta_w = \beta_w(t,x)$, and $\beta^0 = \beta^0(t,x)$ be the solutions of

$$\begin{cases} \partial_t \tilde{y} + \partial_x \tilde{y} + \partial_x^3 \tilde{y} = 0, \\ \tilde{y}(t,0) = \tilde{y}(t,L) = 0, \\ \partial_x \tilde{y}(t,L) = \Gamma_0(P_H(z)), \\ \tilde{y}(0,\cdot) = P_H(y_0), \end{cases}$$

$$\begin{cases} \partial_t \alpha_w + \partial_x \alpha_w + \partial_x^3 \alpha_w = 0, \\ \alpha_w(t,0) = \alpha_w(t,L) = 0, \\ \partial_x \alpha_w(t,L) = u_w(t), \\ \alpha_w(0,\cdot) = 0, \end{cases}$$

$$\begin{cases} \partial_t \beta_w + \partial_x \beta_w + \partial_x^3 \beta_w = -\alpha_w \partial_x \alpha_w, \\ \beta_w(t,0) = \beta_w(t,L) = 0, \\ \partial_x \beta_w(t,L) = v_w(t), \\ \beta_w(0,\cdot) = 0, \end{cases}$$

$$\begin{cases} \partial_t \beta^0 + \partial_x \beta^0 + \partial_x^3 \beta^0 = 0, \\ \beta^0(t,0) = \beta^0(t,L) = 0, \\ \partial_x \beta^0(t,L) = 0, \\ \beta^0(0,\cdot) = P_M(y_0), \end{cases}$$

respectively. Let us define

$$\phi := y - \tilde{y} - \rho_w^{1/2}\alpha_w - \rho_w \beta_w - \beta^0.$$

We have that $\phi = \phi(t,x)$ satisfies

$$\begin{cases} \partial_t\phi + \partial_x\phi + \partial_x^3\phi + \phi\partial_x\phi = -\partial_x(\phi a) - b, \\ \phi(t,0) = \phi(t,L) = 0, \\ \partial_x\phi(t,L) = 0, \\ \phi(0) = 0, \end{cases}$$

where

$$\begin{aligned} a &:= \tilde{y} + \rho_w^{1/2}\alpha_w + \rho_w\beta_w + \beta^0, \\ b &:= \tilde{y}\partial_x\tilde{y} + \partial_x(\tilde{y}(\rho_w^{1/2}\alpha_w + \rho_w\beta_w + \beta^0)) + \rho_w^{3/2}\partial_x(\alpha_w\beta_w) \\ &\quad + \rho_w^2\beta_w\partial_x(\beta_w) + \rho_w^{1/2}\partial_x(\alpha_w\beta^0) + \rho_w\partial_x(\beta_w\beta^0) + \beta^0\partial_x\beta^0. \end{aligned}$$

It is easy to see that there exists $C_4 > 0$ such that for every $z, y_0 \in B^L_{\epsilon_2}$

$$\|\phi\|_{\mathcal{B}} \le C_4(\|y_0\|_{L^2(0,L)} + \|z\|^{1/2}_{L^2(0,L)}), \tag{4.9}$$

$$\|a\|_{\mathcal{B}} \le C_4(\|y_0\|_{L^2(0,L)} + \|z\|^{1/2}_{L^2(0,L)}), \tag{4.10}$$

$$\|b\|_{L^1(0,T,L^2(0,L))} \le C_4(\|y_0\|_{L^2(0,L)} + \|z\|^{3/2}_{L^2(0,L)}). \tag{4.11}$$

One can also prove that there exists $C_5 > 0$ such that for every $f, g \in \mathcal{B}$

$$\|\partial_x(fg)\|_{L^1(0,T,L^2(0,L))} \le C_5\|f\|_{\mathcal{B}}\|g\|_{\mathcal{B}}. \tag{4.12}$$

By (4.2), (4.11), and (4.12), there exists $C_6 > 0$ such that

$$\|\phi\|^2_{\mathcal{B}} \le C_6(\|\phi\|^2_{\mathcal{B}}\|a\|^2_{\mathcal{B}} + \|y_0\|^2_{L^2(0,L)} + \|z\|^3_{L^2(0,L)});$$

i.e., one has

$$\|\phi\|^2_{\mathcal{B}}(1 - C_6\|a\|^2_{\mathcal{B}}) \le C_6(\|y_0\|^2_{L^2(0,L)} + \|z\|^3_{L^2(0,L)}),$$

which, together with (4.10), implies the existence of ϵ_3 and C_7 such that for every $z, y_0 \in B^L_{\epsilon_3}$

$$\|\phi\|_{\mathcal{B}} \le C_7(\|y_0\|_{L^2(0,L)} + \|z\|^{3/2}_{L^2(0,L)}). \tag{4.13}$$

Finally, from (4.13) and using that $\|\beta^0(0)\|_{L^2(0,L)} = \|\beta^0(T)\|_{L^2(0,L)}$ (β^0 turns only in the subspace M), one obtains with $C_3 := C_7 + 1$

$$\begin{aligned} \|z - F\circ G(z)\|_{L^2(0,L)} &\le \|z - F\circ G(z) + \beta^0(T)\|_{L^2(0,L)} + \|\beta^0(T)\|_{L^2(0,L)} \\ &= \|\phi(T)\|_{L^2(0,L)} + \|\beta^0(0)\|_{L^2(0,L)} \\ &\le \|\phi\|_{\mathcal{B}} + \|y_0\|_{L^2(0,L)} \\ &\le C_7(\|y_0\|_{L^2(0,L)} + \|z\|^{3/2}_{L^2(0,L)}) + \|y_0\|_{L^2(0,L)} \\ &\le C_3(\|y_0\|_{L^2(0,L)} + \|z\|^{3/2}_{L^2(0,L)}), \end{aligned}$$

which ends the proof of Lemma 4.3. ∎

4.3. Fixed point in the subspace H. For $w = (w_1, w_2) \in \mathbb{R}^2$ fixed, let us study the map $\Pi := P_H \circ \Lambda_{y_0,y_T}(\cdot + \rho_w z_w)$ on the subspace H (recall that $\rho_w z_w = w_1\varphi_1 + w_2\varphi_2$):

$$\begin{array}{rcl} \Pi : H & \longrightarrow & H, \\ h & \longmapsto & \Pi(h) = h + P_H(y_T) - P_H(F \circ G(h + \rho_w z_w)). \end{array}$$

In order to prove the existence of a fixed point of the map Π, we will apply the Banach fixed point theorem to the restriction of Π to the closed ball $B_R^L \cap H$, with $R > 0$ small enough. By using Lemma 4.3 we see that

$$\begin{array}{rcl} \|\Pi(h)\|_{L^2(0,L)} & \leq & \|y_T\|_{L^2(0,L)} + \|h + \rho_w z_w - F \circ G(h + \rho_w z_w)\|_{L^2(0,L)} \\ & \leq & \|y_T\|_{L^2(0,L)} + C_3(\|y_0\|_{L^2(0,L)} + \|h + \rho_w z_w\|^{3/2}_{L^2(0,L)}) \\ & \leq & C_3'(\|y_0\|_{L^2(0,L)} + \|y_T\|_{L^2(0,L)} + \rho_w^{3/2}) + C_3\|h\|^{3/2}_{L^2(0,L)} \\ & \leq & C_3'(2r + \rho_w^{3/2}) + C_3\|h\|^{3/2}_{L^2(0,L)}, \end{array}$$

where $C_3' := C_3 + 1$. Hence, if we choose R such that $R^{3/2} \leq \frac{R}{2C_3}$ and r, ρ_w such that

$$C_3'(2r + \rho_w^{3/2}) \leq \frac{R}{2},$$

then it follows that

$$\|\Pi(h)\|_{L^2(0,L)} \leq R \quad \text{and so} \quad \Pi(B_R^L \cap H) \subset (B_R^L \cap H).$$

It remains to prove that the map Π is a contraction. Let $g, h \in B_R^L \cap H$. Let $y = y(t,x)$, $q = q(t,x)$, $\tilde{y} = \tilde{y}(t,x)$, and $\tilde{q} = \tilde{q}(t,x)$ be the solutions of the following problems:

$$\left\{ \begin{array}{l} \partial_t y + \partial_x y + \partial_x^3 y + y\partial_x y = 0, \\ y(t,0) = y(t,L) = 0, \\ \partial_x y(t,L) = G(g + \rho_w z_w), \\ y(0,\cdot) = y_0, \end{array} \right.$$

$$\left\{ \begin{array}{l} \partial_t q + \partial_x q + \partial_x^3 q + q\partial_x q = 0, \\ q(t,0) = q(t,L) = 0, \\ \partial_x q(t,L) = G(h + \rho_w z_w), \\ q(0,\cdot) = y_0, \end{array} \right.$$

$$\left\{ \begin{array}{l} \partial_t \tilde{y} + \partial_x \tilde{y} + \partial_x^3 \tilde{y} = 0, \\ \tilde{y}(t,0) = \tilde{y}(t,L) = 0, \\ \partial_x \tilde{y}(t,L) = \Gamma_0(g), \\ \tilde{y}(0,\cdot) = P_H(y_0), \end{array} \right.$$

$$\left\{ \begin{array}{l} \partial_t \tilde{q} + \partial_x \tilde{q} + \partial_x^3 \tilde{q} = 0, \\ \tilde{q}(t,0) = \tilde{q}(t,L) = 0, \\ \partial_x \tilde{q}(t,L) = \Gamma_0(h), \\ \tilde{q}(0,\cdot) = P_H(y_0), \end{array} \right.$$

repsectively. Let us define $\phi := y - \tilde{y}$, $\psi := q - \tilde{q}$, and $\gamma := \phi - \psi$. One sees that γ satisfies

$$\left\{ \begin{array}{l} \partial_t \gamma + \partial_x \gamma + \partial_x^3 \gamma + \gamma\partial_x \gamma = -\partial_x(\gamma a) - b, \\ \gamma(t,0) = \gamma(t,L) = 0, \\ \partial_x \gamma(t,L) = 0, \\ \gamma(0) = 0, \end{array} \right. \tag{4.14}$$

where

$$a := \tilde{y} + \psi \quad \text{and} \quad b := \partial_x \left(q(\tilde{y} - \tilde{q})\right) + (\tilde{y} - \tilde{q})\partial_x(\tilde{y} - \tilde{q}).$$

It is easy to see that there exists a constant $C_8 > 0$ such that

$$\|b\|_{L^1(0,T,L^2(0,L))} \leq C_8 \left(\|q\|_{\mathcal{B}} + \|\tilde{y}\|_{\mathcal{B}} + \|\tilde{q}\|_{\mathcal{B}}\right) \|\tilde{y} - \tilde{q}\|_{\mathcal{B}}, \tag{4.15}$$

$$\|\partial_x(a\gamma)\|_{L^1(0,T,L^2(0,L))} \leq C_8 \left(\|q\|_{\mathcal{B}} + \|\tilde{y}\|_{\mathcal{B}} + \|\tilde{q}\|_{\mathcal{B}}\right) \|\gamma\|_{\mathcal{B}}. \tag{4.16}$$

By using Proposition 4.2, (4.15), and (4.16) we get the existence of $C_9 > 0$ such that

$$\|\gamma\|_{\mathcal{B}}^2 \leq C_9(\|q\|_{\mathcal{B}} + \|\tilde{y}\|_{\mathcal{B}} + \|\tilde{q}\|_{\mathcal{B}})^2(\|\tilde{y} - \tilde{q}\|_{\mathcal{B}}^2 + \|\gamma\|_{\mathcal{B}}^2). \tag{4.17}$$

In addition, since $w := \tilde{y} - \tilde{q}$ satisfies the following linear equation:

$$\begin{cases} \partial_t w + \partial_x w + \partial_x^3 w = 0, \\ w(t,0) = w(t,L) = 0, \\ \partial_x w(t,L) = \Gamma_0(g) - \Gamma_0(h), \\ w(0,\cdot) = 0, \end{cases}$$

there exists $C_{10} > 0$ such that

$$\|\tilde{y} - \tilde{q}\|_{\mathcal{B}} \leq C_{10}\|\Gamma_0(g) - \Gamma_0(h)\|_{L^2(0,T)},$$

and so, from (4.4), one gets

$$\|\tilde{y} - \tilde{q}\|_{\mathcal{B}} \leq C_{10}D_2\|g - h\|_{L^2(0,L)}. \tag{4.18}$$

Moreover, it is easy to see that there exists a constant $C_{11} > 0$ such that

$$\|q\|_{\mathcal{B}} + \|\tilde{q}\|_{\mathcal{B}} + \|\tilde{y}\|_{\mathcal{B}} \leq C_{11}(\|y_0\|_{L^2(0,L)} + \|h\|_{L^2(0,L)} + \|g\|_{L^2(0,L)} + \rho_w^{1/2}). \tag{4.19}$$

Thus, using (4.17)–(4.19) we see that if R, ρ_w, r are small enough, it follows that

$$\|\gamma\|_{\mathcal{B}} \leq \tfrac{1}{2}\|g - h\|_{L^2(0,L)}.$$

Therefore, we have

$$\begin{array}{rcl} \|\Pi(g) - \Pi(h)\|_{L^2(0,L)} & \leq & \|g - F \circ G(g + \rho_w z_w) - h + F \circ G(h + \rho_w z_w)\|_{L^2(0,L)} \\ & = & \|\gamma(T)\|_{L^2(0,L)} \leq \|\gamma\|_{\mathcal{B}} \\ & \leq & \frac{1}{2}\|g - h\|_{L^2(0,L)}, \end{array}$$

which implies the existence of a unique fixed point $h(y_0, y_T, w_1, w_2) \in B_R^L \cap H$ of the map $\Pi|_{B_R^L \cap H}$. Moreover, the more precise proposition follows.

PROPOSITION 4.5. *There exist $R_0 > 0$, $D > 1$ such that for every $0 < R < R_0$, for every $y_0, y_T \in B_{R/D}^L$, $(w_1, w_2) \in \mathbb{R}^2$, with $\rho_w < R/D$, there exists a unique $h(y_0, y_T, w_1, w_2) \in B_R^L \cap H$ fixed point of the map $\Pi|_{B_R^L \cap H}$.*

4.4. Fixed point in the subspace M. We now apply the Brouwer fixed point theorem to the restriction of the map

$$\begin{array}{rcl} \tau : M & \longrightarrow & M, \\ w_1\varphi_1 + w_2\varphi_2 & \to & P_M(\rho_w z_w + y_T - F \circ G(\rho_w z_w + h(y_0, y_T, w_1, w_2))) \end{array}$$

to the closed ball $B^L_{\hat{R}} \cap M$, with $\hat{R}$ small enough. Using Lemma 4.3, the continuity (in a neighborhood of $0 \in (L^2(0,L))^2 \times \mathbb{R}^2$) of the map $(y_0, y_T, w_1, w_2) \longmapsto h(y_0, y_T, w_1, w_2)$ and choosing r small enough, we get the existence of a radius $\hat{R} > 0$ such that $\tau(B^L_{\hat{R}} \cap M) \subset B^L_{\hat{R}} \cap M$. This inclusion and the continuity of the map τ allow us to apply the Brouwer fixed point theorem. Therefore, there exists $(\tilde{w}_1, \tilde{w}_2) \in \mathbb{R}^2$, with $\tilde{w}_1^2 + \tilde{w}_2^2 \leq \hat{R}^2$, such that $\tilde{h} := h(y_0, y_T, \tilde{w}_1, \tilde{w}_2)$ satisfies

$$P_M(y_T - F \circ G(\tilde{h} + \tilde{w}_1\varphi_1 + \tilde{w}_2\varphi_2)) = 0. \tag{4.20}$$

Using the fact that

$$\Pi(\tilde{h}) = P_H(\tilde{h} + y_T - F \circ G(\tilde{h} + \tilde{w}_1\varphi_1 + \tilde{w}_2\varphi_2)) = \tilde{h},$$

we obtain

$$P_H(y_T - F \circ G(\tilde{h} + \tilde{w}_1\varphi_1 + \tilde{w}_2\varphi_2)) = 0,$$

which together with (4.20) implies that

$$y_T = F \circ G(\tilde{h} + \tilde{w}_1\varphi_1 + \tilde{w}_2\varphi_2),$$

which ends the proof of Theorem 1.4. Let us remark that from our proof it follows that if r is chosen small enough, one can take $\hat{R} := rD$, where $D > 0$ is given by Proposition 4.5. By using this proposition one obtains the estimate (1.6).

Acknowledgments. I thank Jean-Michel Coron for having attracted my attention to this problem, for his constant support, and for fruitful discussions. I also thank Emmanuelle Crépeau for interesting remarks.

SWITCHING GAMES OF STOCHASTIC DIFFERENTIAL SYSTEMS*

SHANJIAN TANG† AND SHUI-HUNG HOU‡

Abstract. A two-player, zero-sum, switching game is formulated for general stochastic differential systems and is studied using a combined dynamic programming and viscosity solution approach. The existence of the game value is proved. For the proof of the related dynamic programming principle (DDP) for the lower and upper value functions, the measurability problem, of the same kind as mentioned in the paper of Fleming and Souganidis, is also encountered, and we are able to get around it via a delicate adaptation of their technique. Moreover, the traditional direct method to prove the time continuity of lower and upper value functions also gives rise to a serious measurability problem. To get around the new difficulty, a subtle dynamic programming argument is developed to obtain the time continuity, which in return is used to derive the DDP for random intermediate times from the DDP with deterministic intermediate times.

Key words. stochastic differential games, dynamic programming inequalities, switching strategies, value function, viscosity solution

1. Introduction.

Consider a differential game of the following stochastic differential system on Wiener space $(\Omega, \mathcal{F}, P)$:

$$\begin{cases} dy(t) = f(t, y(t), a(t), b(t))\,dt + g(t, y(t), a(t), b(t))\,dw(t), \quad t \in (s, 1], \\ y(s) = x \end{cases} \tag{1.1}$$

with the cost functional

$$\begin{aligned} J_{s,x}(a(\cdot), b(\cdot)) = E_{sx}\Bigg\{ \int_s^1 f^0(t, y(t), a(t), b(t))\,dt + h(y(1)) \\ + \sum_{i \geq 1} k(\theta_i, a_{i-1}, a_i) - \sum_{j \geq 1} l(\tau_j, b_{j-1}, b_j) \Bigg\}. \end{aligned} \tag{1.2}$$

Here f, g, f^0, and h are given maps; $w(\cdot)$ is the coordinate process in Ω, and its natural filtration is denoted by $\mathcal{F}_t$. The subscript sx of the expectation operator E indicates that the underlying mathematical expectation is taken under the condition that the underlying system state process $y(\cdot)$ takes the value x at time s. The first player chooses the control a from a given finite set A to minimize the payoff (1.2), and each

of his instantaneous actions is related with one positive cost k, while the second player chooses the control b from a given finite set B to maximize the payoff (1.2), and each of his instantaneous actions is associated with the other positive cost l.

For differential switching games, a key point in connecting value functions with the corresponding Isaacs' equations is to prove the following fact: It is the best way for a player to keep his underlying switching position for some time of a positive length, whenever he is not on his switching set. In the deterministic case, such an assertion is easy to understand from the following almost obvious fact: If he is not on his switching set, a player will keep away from the set for some deterministic time interval of a positive length, as the system state evolves continuously. See Yong [10] for details. In the stochastic case, the situation becomes complicated due to the nature of diffusion: Even if he is not on his switching set, it is possible for a player to arrive at his switching set in an arbitrarily short time. That is, if he is not on his switching set, although the system state still evolves continuously, a player can keep away from the switching set only for some *random* (rather than deterministic, in general) time interval, *almost surely* (rather than uniformly, in general) of a positive length. Then the intuition of the dynamic programming principle for the underlying switching game suggests that if he is not on his switching set, the optimal action of a player has to vary with different events, even within a very short deterministic time period. We show in section 3 by using arguments quite different from the deterministic case that, whenever he is not on his switching set, a player's best action is to keep his underlying switching position, *before he escapes from a sufficiently small ball centered at the current state*, within some deterministic time interval of a positive length.

It has been widely recognized that the dynamic programming method is both easy and efficient for the study of deterministic optimal control and differential games within the framework of viscosity solutions. The general nonsmooth feature of inf-sup functions is no longer a difficulty in view of the notion of viscosity solutions. However, applications of dynamic programming to optimal stochastic controls and stochastic differential games still encounter difficulties; the reader is referred to Bertsekas and Shreve [1] and Fleming and Souganidis [6] for detail. It was noticed by Fleming and Souganidis [6], in the study of classical stochastic differential games, that the conventional proof of the dynamic programming principle for the lower and upper value functions encounters a serious measurability issue. In this paper, we observe that the traditional direct approach to show the time continuity of lower and upper value functions also gives rise to a serious measurability problem. The difficulty is circulated using a dynamic programming argument.

In this paper, the coefficients of differential games are allowed to grow linearly, and a powerful simple test function is given to prove the uniqueness of unbounded viscosity solutions for the associated Isaacs' system of variational inequalities.

The rest of our paper is organized as follows. Section 2 is devoted to the formulation of our stochastic switching game, the definitions of some restrictive class of admissible controls, and strategies to be used in the following sections. Several useful dynamic programming results and the time continuous properties are established in section 3. The existence of the value is proved for our game in section 4.

There are some related papers which remain to be mentioned. For the optimal switching problem, the reader is referred to Capuzzo Dolcetta and Evans in [2] in the deterministic case, and to Evans and Friedman [4], Tang and Yong [7] and the references therein in the stochastic case. For the switching game, the reader is referred to Yong [10] in the deterministic case with the dynamic programming approach and the notion of viscosity solution, and to Yamada [8, 9] in the stochastic and infinite

time-horizon case with an analytical approach rather than the dynamic programming approach.

2. Preliminaries. Let $A = \{1, 2, \dots, m\}, B = \{1, 2, \dots, n\}$, and X be a finite-dimensional Euclidean space. Let $f : [0,1] \times X \times A \times B \to X, g : [0,1] \times X \times A \times B \to X \times W, f^0 : [0,1] \times X \times A \times B \to \mathbb{R}, k : [0,1] \times A \times A \to \mathbb{R}_+ \equiv [0, \infty)$, and $l : [0,1] \times B \times B \to \mathbb{R}_+$ be continuous functions satisfying the following hypotheses.

Hypothesis 1. There exists a constant $L > 0$ such that for all $x, \widehat{x} \in X, t \in [0,1], a \in A$, and $b \in B$,

$$\begin{aligned}
&|f(t,x,a,b) - f(t,\widehat{x},a,b)| + |g(t,x,a,b) - g(t,\widehat{x},a,b)| \le L|x - \widehat{x}|,\\
&|f(t,x,a,b)| + |g(t,x,a,b)| \le L(1 + |x|),\\
&|f^0(t,x,a,b) - f^0(t,\widehat{x},a,b)| + |h(x) - h(\widehat{x})| \le L|x - \widehat{x}|,\\
&|f^0(t,0,a,b)| + |h(0)| \le L.
\end{aligned}$$

Hypothesis 2. For all $a, \widehat{a}, \widetilde{a} \in A, a \ne \widehat{a} \ne \widetilde{a}$, and $0 \le s \le t \le 1$,

$$\begin{aligned}
&k(t,a,\widetilde{a}) < k(t,a,\widehat{a}) + k(t,\widehat{a},\widetilde{a}),\\
&k(t,a,\widehat{a}) > 0, k(t,a,a) = 0,\\
&k(t,a,\widetilde{a}) \le k(s,a,\widetilde{a}).
\end{aligned}$$

Hypothesis 3. For all $b, \widehat{b}, \widetilde{b} \in B, b \ne \widehat{b} \ne \widetilde{b}$, and $0 \le s \le t \le 1$,

$$\begin{aligned}
&l(t,b,\widetilde{b}) < l(t,b,\widehat{b}) + l(t,\widehat{b},\widetilde{b}),\\
&l(t,b,\widehat{b}) > 0, l(t,b,b) = 0,\\
&l(t,b,\widetilde{b}) \le l(s,b,\widetilde{b}).
\end{aligned}$$

For $s, \hat{s} \in [0,1]$ such that $s < \hat{s}$, let

$$\Omega_{s,\hat{s}} = \{\omega \in C([s,\hat{s}]; \mathbb{R}^d) : \omega(s) = 0\}. \tag{2.1}$$

Denote by $\mathcal{F}_{s,\hat{s}}$ the topological σ-field of $\Omega_{s,\hat{s}}$ and consider the Wiener space $(\Omega_{s,\hat{s}}, \mathcal{F}_{s,\hat{s}}, P_{s,\hat{s}})$. Let

$$\Omega_s = \Omega_{s,1}, \quad P_s = P_{s,1}, \quad \mathcal{F}_s = \mathcal{F}_{s,1}, \tag{2.2}$$

and

$$\begin{cases}
\omega_1 = \omega|_{[s,\hat{s}]},\\
\omega_2 = (\omega - \omega(\hat{s}))|_{[\hat{s},1]},\\
\Pi\omega = (\omega_1, \omega_2).
\end{cases} \tag{2.3}$$

We see that the map $\Pi : \Omega_s \to \Omega_{s,\hat{s}} \times \Omega_{\hat{s}}$ induces an identification

$$\Omega_s = \Omega_{s,\hat{s}} \times \Omega_{\hat{s}}. \tag{2.4}$$

Moreover, the inverse of Π is defined in an evident way: $\Omega_s = \Pi^{-1}(\Omega_{s,\hat{s}}, \Omega_{\hat{s}})$. Finally, we have

$$P_s = P_{s,\hat{s}} \otimes P_{\hat{s}}.$$

Define

$$w(r,\omega)=\omega(r),\quad (\omega,r)\in\Omega_s\times[s,1]. \tag{2.5}$$

Then $\{w(r), r\in[s,1]\}$ is a standard Wiener process.

DEFINITION 2.1. *An admissible switching process for player* I *(resp.,* II*) on* $[s,1]$ *with initial value* a_0 *(resp.,* b_0*) is defined to be a pair of sequences* $\{a_i,\theta_i\}_{i\geq 0}$ *(resp.,* $\{b_i,\tau_i\}_{i\geq 0}$*) such that each* θ_i *(resp.,* τ_i*) is an* $\mathcal{F}_{s,\cdot}$*-stopping time, with*

$$s=\theta_0\leq\theta_1\leq\cdots\leq 1\quad \text{a.s.}$$
$$(\text{resp., } s=\tau_0\leq\tau_1\leq\cdots\leq 1\quad \text{a.s.}),$$

each a_i *(resp.,* b_i*) is* $\mathcal{F}_{s,\theta_i}$*- (resp.,* $\mathcal{F}_{s,\tau_i}$*-) measurable with values in* A *(resp.,* B*), and*

$$E\sum_{i\geq 1}k(\theta_i,a_{i-1},a_i)<\infty\quad\left(\text{resp., } E\sum_{j\geq 1}l(\tau_j,b_{j-1},b_j)<\infty\right).$$

Denote by $\mathcal{A}^a[s,\hat{s}]$ *(resp.,* $\mathcal{B}^b[s,\hat{s}]$*) the totality of the admissible switchings for player* I *(resp.,* II*) on* $[s,\hat{s}]$ *with the initial value* a *(resp.,* b*).*

We shall identify $\{a_i,\theta_i\}_{i\geq 0}\in\mathcal{A}^a[s,1]$ with

$$a(r)=\sum_{i\geq 1}a_{i-1}\chi_{[\theta_{i-1},\theta_i)}(r),\quad r\in[s,1].$$

Note that in the case of $\theta_1=\theta_2$ the term $a_1\chi_{[\theta_1,\theta_2)}(r)$ will be void, but we still keep it in the above expression. This is due to the fact that the sequence $\{a_i,\theta_i\}$ with or without (a_1,θ_1) represents two different switching controls and their costs are different. A similar identification will also be used for $\{b_i,\tau_i\}\in\mathcal{B}^b[t,1]$.

Following Elliott and Kalton [3] and Fleming and Souganidis [6], we define in the switching game an admissible strategy as follows.

DEFINITION 2.2. *For* $s\in[0,1]$ *and* $a\in A$ *(resp.,* $b\in B$*), an admissible strategy* $\alpha^{a,s}$ *(resp.,* $\beta^{b,s}$*) with the initial value* a *(resp.,* b*) for player* I *(resp.,* II*) on* $[s,1]$ *is a mapping* $\alpha^{a,s}:\cup_{b\in B}\mathcal{B}^b[s,1]\to\mathcal{A}^a[s,1]$ *(resp.,* $\beta^{b,s}:\cup_{a\in A}\mathcal{A}^a[s,1]\to\mathcal{B}^b[s,1]$*) such that*

$$b(r)=\widehat{b}(r)\quad(\text{resp., } a(r)=\widehat{a}(r))\quad\text{a.s. }\forall r\in[s,\hat{s}]$$

implies

$$\alpha^{a,t}[b(\cdot)](r)=\alpha^{a,t}[\widehat{b}(\cdot)](r)\quad(\text{resp., } \beta^{b,t}[a(\cdot)](r)=\beta^{b,t}[\widehat{a}(\cdot)](r))$$

for $r\in[s,\hat{s}]$.

We denote all admissible strategies with the initial value a (resp., b) for player I (resp., II) on $[s,1]$ by $\Gamma^a[s,1]$ (resp., $\Delta^b[s,1]$). We adopt the convention that

$$\begin{aligned}&\mathcal{A}^a[1,1]=a,\quad \Gamma^a[1,1]=a,\\ &\mathcal{B}^b[1,1]=b,\quad \Delta^b[1,1]=b.\end{aligned} \tag{2.6}$$

Set for $(s,x)\in[0,1]\times X$,

(2.7)

$$V_{a,b}(s,x)=\inf_{\alpha\in\Gamma^a[s,1]}\sup_{b(\cdot)\in\mathcal{B}^b[s,1]}J_{s,x}(\alpha(b(\cdot)),b(\cdot)),\quad V(s,x)=(V_{a,b}(s,x))_{a\in A,b\in B};$$

$$U^{a,b}(s,x)=\sup_{\beta\in\Delta^b[s,1]}\inf_{a(\cdot)\in\mathcal{A}^a[s,1]}J_{s,x}(a(\cdot),\beta(a(\cdot))),\quad U(s,x)=(U^{a,b}(s,x))_{a\in A,b\in B}.$$

The matrix-valued functions V and U are called the lower and the upper value function, respectively. If $V = U$, we say that the above stochastic switching game has a value. Our aim is to study the existence of the value of our stochastic switching game. U and V should satisfy the dynamic programming principle. However, the conventional proof leads to serious technical problems related to measurability issues, which have been noticed by Fleming and Souganidis [6] in the study of classical stochastic differential games . To circumvent these problems, we borrow the techniques of Fleming and Souganidis [6] and introduce in the following the concepts of restrictive class of admissible strategies, π-admissible switching processes, and π-admissible strategies.

Consider $s \in [0,1]$, $\hat{s} \in (s,1)$, and $b(\cdot) \in \mathcal{B}^b[s,1]$. For $P_{s,\hat{s}}$-a.s. $\omega_1 \in \Omega_{s,\hat{s}}$, the map $b(\omega_1) : [\hat{s},1] \times \Omega_{\hat{s}} \to B$ defined by

$$b(\omega_1)(\omega_2)(r) = b(\omega_1,\omega_2)(r), \quad r \in [\hat{s},1],$$

is an admissible control for player II, i.e., $b(\omega_1) \in \mathcal{B}^{b(\hat{s})}[\hat{s},1]$.

DEFINITION 2.3. *Let $\alpha \in \Gamma^a[\hat{s},1]$. If for $\forall s \in (0,\hat{s})$ and $\forall b(\cdot) \in \mathcal{B}^b[s,1], b \in B$, the map $(\tau,\omega) \mapsto \alpha[b(\omega_1)](\omega_2)(\tau)$ is $\mathcal{B}([\hat{s},\tau]) \otimes \mathcal{F}_{s,\tau}$-measurable for every $\tau \in [\hat{s},1]$, then α is called an r-strategy with initial value a for player* I *on $[s,1]$. The set of r-strategies with initial value a on $[s,1]$ of player* I *is denoted by $\Gamma_1^a[s,1]$.*

Similarly, we define r-strategies with initial value $b \in B$ on $[s,1]$ for player II and denote their collection by $\Delta_1^b[s,1]$.

Set

(2.8)
$$V_{a,b}^1(s,x) = \inf_{\alpha \in \Gamma_1^a[s,1]} \sup_{b(\cdot) \in \mathcal{B}^b[s,1]} J_{s,x}(\alpha(b(\cdot)), b(\cdot)), \quad V^1(s,x) = (V_{a,b}^1(s,x))_{a \in A, b \in B};$$

$$U_1^{a,b}(s,x) = \sup_{\beta \in \Delta_1^b[s,1]} \inf_{a(\cdot) \in \mathcal{A}^a[s,1]} J_{s,x}(a(\cdot), \beta(a(\cdot))), \quad U_1(s,x) = (U_1^{a,b}(s,x))_{a \in A, b \in B}.$$

The matrix-valued functions V^1 and U_1 are called the r-lower and the r-upper value function, respectively.

Let $\pi_s = \{s = t_0 < t_1 < \cdots < t_M = 1\}$ be a partition of $[s,1]$, and denote by $||\pi_s|| = \max_{1 \le i \le M}(t_i - t_{i-1})$ its mesh. The notions of π-admissible switching processes and π-admissible strategies are then defined as follows.

DEFINITION 2.4. *Let $a(\cdot) = \{a_i, \theta_i\}_{i \ge 0} \in \mathcal{A}^a[s,1]$. If each θ_i is a π_s-valued stopping time, then it is called a π-admissible switching process with initial value $a \in A$ on $[s,1]$ for player* I. *The set of π-admissible switching processes with initial value $a \in A$ on $[s,1]$ for player* I *is denoted by $\mathcal{A}_\pi^a[s,1]$. The π-admissible switching processes with initial value $b \in B$ on $[s,1]$ for player* II *are defined in a similar way, and their collection is denoted by $\mathcal{B}_\pi^b[s,1]$.*

DEFINITION 2.5. *$\alpha \in \Gamma^a[s,1]$ is called a π-admissible strategy with initial value $a \in A$ on $[s,1]$ for player* I, *if it satisfies the following properties:* (1) *$\forall b(\cdot) \in \mathcal{B}^b[s,1], b \in B$, $\alpha[b(\cdot)] \in \mathcal{A}_\pi^a[s,1]$.* (2) *Fix $b \in B$. If $s \in [t_{i_0}, t_{i_0+1})$, then $\alpha[b_1(\cdot)]|_{[s,t_{i_0+1})} = \alpha[b_2(\cdot)]|_{[s,t_{i_0+1})}$ $\forall\, b_1(\cdot), b_2(\cdot) \in \mathcal{B}^b[s,1]$.* (3) *If $b(\cdot) = \bar{b}(\cdot)$ on $[s,t_i)$, then $\alpha[b(\cdot)](t_i) = \alpha[\bar{b}(\cdot)](t_i), P_s$-a.s. for $i \in \{i_0+1, \ldots, M\}$. The collection of π-admissible strategies with initial value $a \in A$ on $[s,1]$ for player I is denoted by $\Gamma_\pi^a[s,1]$. The π-admissible strategies with initial value $b \in B$ on $[s,1]$ for player* II *are defined in a similar way, and their collection is denoted by $\Delta_\pi^b[s,1]$.*

It is crucial, in our case of the switching game, that $\alpha[b(\cdot)](t_i)$ in Definition 2.5 is required to be independent of $b(t_i)$ for $\alpha \in \Gamma_\pi^a[s,1]$ and $i = i_0+1, \ldots, M$. Definition 2.5 differs from Fleming and Souganidis' in that $\alpha[b(\cdot)]|_{[s,t_{i_0+1})}$ may depend on $b(s-)$

even if $\alpha \in \Gamma_\pi^a[s,1]$, and this is due to the fact that the initial position of a player is crucial in our switching game.

According to the definitions of $V_{a,b}^1(s,x), U_1^{a,b}(s,x), V_{a,b}(s,x)$, and $U^{a,b}(s,x)$, we have immediately the following two relations:

$$V_{a,b}(s,x) \le V_{a,b}^1(s,x) \text{ and } U_1^{a,b}(s,x) \le U^{a,b}(s,x). \tag{2.9}$$

Next, let us introduce some operators. For any $m \times n$ matrix-valued function $W(\cdot,\cdot) = (W^{a,b}(\cdot,\cdot))$ defined on $[0,1] \times X$, we define for $(a,b,s,x) \in A \times B \times [0,1] \times X$

$$\begin{aligned} M^{a,b}[W](s,x) &= \min_{\hat{a} \ne a} \{W^{\hat{a},b}(s,x) + k(s,a,\hat{a})\}, \\ M_{a,b}[W](s,x) &= \max_{\hat{b} \ne b} \{W^{a,\hat{b}}(s,x) - l(s,b,\hat{b})\}. \end{aligned} \tag{2.10}$$

The two operators are called obstacle operators. According to the definitions, for any $(a,b,s,x) \in A \times B \times [0,1] \times X$, the following are true:

$$\begin{aligned} M_{a,b}[V](s,x) \le V_{a,b}(s,x) \le M^{a,b}[V](s,x), \\ M_{a,b}[V^1](s,x) \le V_{a,b}^1(s,x) \le M^{a,b}[V^1](s,x), \\ M_{a,b}[U](s,x) \le U^{a,b}(s,x) \le M^{a,b}[U](s,x), \\ M_{a,b}[U_1](s,x) \le U_1^{a,b}(s,x) \le M^{a,b}[U_1](s,x). \end{aligned} \tag{2.11}$$

Before closing this section, we state without proof the following result on the continuity in the space variable of the costs and the value functions.

PROPOSITION 2.1. (1) *For any $a(\cdot) \in \mathcal{A}^a[s,1], b(\cdot) \in \mathcal{B}^b[s,1], \alpha \in \Gamma^a[s,1]$, and $\beta \in \Delta^b[s,1]$, the functions $J_{sx}(\alpha[b(\cdot)], b(\cdot))$ and $J_{sx}(a(\cdot), \beta[a(\cdot)])$, $(s,x) \in [0,T] \times X$, grow linearly, are Lipschitz continuous in the space variable x, and are Hölder-continuous in the time variable s, uniformly with respect to the other variable s and x, respectively, and uniformly as well with respect to the four parameters: $\alpha, a(\cdot), \beta$, and $b(\cdot)$.*

(2) *The functions V, V^1, U, and U_1 grow linearly and are Lipschitz continuous in the space variable x, uniformly with respect to the time variable s.*

The time continuity of value functions turns out to be a measurability issue and will be considered in the next section.

3. Dynamic programming and time continuity of various value functions. In this section, we use the Bellman dynamic programming principle to study the time continuity and the dynamics of various value functions related to our game.

PROPOSITION 3.1. (1) *The lower value function $V^1(\cdot,\cdot)$ satisfies the following suboptimality condition: For any $(a,b) \in A \times B$, $x \in X$, and $0 \le s < \hat{s} \le 1$,*

(3.1a)

$$\begin{aligned} V_{a,b}^1(s,x) \le \inf_{\alpha \in \Gamma_1^a[s,1]} \sup_{b(\cdot) \in \mathcal{B}^b[s,1]} E_{sx} \Bigg\{ & \int_s^{\hat{s}} f^0(r, y(r), \alpha[b(\cdot)](r), b(r))\, dr \\ & + \sum_{\theta_i \le \hat{s}} k(\theta_i, a_{i-1}, a_i) - \sum_{\tau_j \le \hat{s}} l(\tau_j, b_{j-1}, b_j) + V_{\alpha[b(\cdot)](\hat{s}), b(\hat{s})}^1(\hat{s}, y(\hat{s})) \Bigg\}, \end{aligned}$$

where $\{a_i, \theta_i\}$ and $\{b_j, \tau_j\}$ are associated with $\alpha[b(\cdot)]$ and $b(\cdot)$, respectively, and $\alpha[b(\cdot)](\hat{s}) = \alpha[b(\cdot)](\hat{s}+0), b(\hat{s}) = b(\hat{s}+0)$.

(2) *The upper value function $U_1(\cdot,\cdot)$ satisfies the following superoptimality condition: For any $(a,b) \in A \times B$, $x \in X$, and $0 \le s < \hat{s} \le 1$,*

(3.1b)

$$U_1^{a,b}(s,x) \geq \sup_{\beta\in\Delta_1^b[s,1]}\inf_{a(\cdot)\in\mathcal{A}^a[s,1]} E_{sx}\Big\{\int_s^{\hat{s}} f^0(r,y(r),a(\cdot),\beta[a(\cdot)](r))\,dr + \sum_{\theta_i\leq\hat{s}} k(\theta_i,a_{i-1},a_i) - \sum_{\tau_j\leq\hat{s}} l(\tau_j,b_{j-1},b_j) + U_1^{a(\hat{s}),\beta[a(\cdot)](\hat{s})}(\hat{s},y(\hat{s}))\Big\},$$

where $\{a_i,\theta_i\}$ *and* $\{b_j,\tau_j\}$ *are associated with* $a(\cdot)$ *and* $\beta[a(\cdot)]$*, respectively, and* $\beta[a(\cdot)](\hat{s}) = \beta[a(\cdot)](\hat{s}+0), b(\hat{s}) = b(\hat{s}+0)$.

Proof of Proposition 3.1. We prove only the inequality (3.1a); the inequality (3.1b) can be proved in the same manner.

Let (s,x,a,b) be fixed, and let $W_{a,b}(s,x)$ be the right-hand side of (3.1a). Then, $\forall\varepsilon>0$, there exists $\alpha\in\Gamma_1^a[s,1]$ such that

(3.2)

$$W_{a,b}(s,x) \geq E_{sx}\Big\{\int_s^{\hat{s}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr + \sum_{\theta_i\leq\hat{s}} k(\theta_i,a_{i-1},a_i) - \sum_{\tau_j\leq\hat{s}} l(\tau_j,b_{j-1},b_j) + V^1_{\alpha[b(\cdot)](\hat{s}),b(\hat{s})}(\hat{s},y(\hat{s}))\Big\} - \varepsilon$$

for every $b(\cdot)\in\mathcal{B}^b[s,1]$. Also, for each $\hat{a}\in A,\hat{b}\in B,\xi\in X$,

$$V^1_{\hat{a},\hat{b}}(\hat{s},\xi) = \inf_{\alpha\in\Gamma_1^{\hat{a}}[\hat{s},1]}\sup_{b(\cdot)\in\mathcal{B}^{\hat{b}}[\hat{s},1]} J_{\hat{s}\xi}(\alpha[b(\cdot)],b(\cdot)); \tag{3.3}$$

thus there exists $\alpha_\xi^{\hat{a},\hat{b}}\in\Gamma_1^{\hat{a}}[\hat{s},1]$ for which

$$V^1_{\hat{a},\hat{b}}(\hat{s},\xi) \geq \sup_{b(\cdot)\in\mathcal{B}^{\hat{b}}[\hat{s},1]} J_{\hat{s}\xi}(\alpha_\xi^{\hat{a},\hat{b}}[b(\cdot)],b(\cdot)) - \varepsilon. \tag{3.4}$$

Next let $\{A_i : i=1,2,\dots\}$ be a partition of X by Borel sets, and choose $\xi_i\in A_i (i=1,2,\dots)$. If the diameter of the A_i's is sufficiently small, then for $i=1,2,\dots$ and $w\in A_i$,

(3.5)

$$|J_{\hat{s}w}(\alpha[b(\cdot)],b(\cdot)) - J_{\hat{s}\xi_i}(\alpha[b(\cdot)],b(\cdot))| < \varepsilon \quad \text{for any } b(\cdot)\in\mathcal{B}^{\hat{b}}[\hat{s},1] \text{ and } \alpha\in\Gamma_1^{\hat{a}}[\hat{s},1],$$

and

$$|V^1_{\hat{a},\hat{b}}(\hat{s},w) - V^1_{\hat{a},\hat{b}}(\hat{s},\xi_i)| < \varepsilon. \tag{3.6}$$

Now we use the strategies α and $\alpha_{\xi_i}^{\hat{a},\hat{b}}, i=1,\dots,\hat{a}\in A,\hat{b}\in B$, to construct a new admissible strategy $\widetilde{\alpha}\in\Gamma_1^a[s,1]$ as follows: For $(r,\omega)\in[s,1]\times\Omega_s$ and $b(\cdot)\in\mathcal{B}^b[s,1]$, we define

(3.7)

$$\alpha[b(\cdot)](\omega)(r) = \begin{cases} \alpha[b(\cdot)](\omega)(r) & \text{if } r<\hat{s},\\ \sum_{i=1}^\infty\sum_{\hat{a}\in A,\hat{b}\in B}\chi_{\{b(\hat{s})=\hat{b},\alpha[b(\cdot)](\hat{s})=\hat{a}\}}\chi_{A_i}(y_{sx}(\hat{s}))\alpha_{\xi_i}^{\hat{a},\hat{b}}[b(\omega_1)](\omega_2)(r) & \text{if } r\geq\hat{s},\end{cases}$$

where $\omega=(\omega_1,\omega_2)\in\Omega_{t,\hat{s}}\times\Omega_{\hat{s}}$ and $b(\omega_1)(\cdot)\in\mathcal{B}^{b(\hat{s})}[\hat{s},1]$ is given by $b(\omega_1)(\omega_2)(r) = b(\omega_1,\omega_2)(r)$.

Consequently for any $b(\cdot) \in \mathcal{B}^b[s,1]$, using (3.2), (3.4), and (3.6), we obtain

$$
\begin{aligned}
W_{a,b}(s,x) \geq & E_{sx}\Bigg\{\int_s^{\hat{s}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\
& + \sum_{\theta_i \leq \hat{s}} k(\theta_i, a_{i-1}, a_i) - \sum_{\tau_j \leq \hat{s}} l(\tau_j, b_{j-1}, b_j) \\
& + \sum_{i=1}^{\infty} \sum_{\hat{a}\in A, \hat{b}\in B} \chi_{\{\alpha[b(\cdot)](\hat{s})=\hat{a}, b(\hat{s})=\hat{b}\}} \chi_{A_i}(y_{s,x}(\hat{s})) V^1_{\hat{a},\hat{b}}(\hat{s}, y(\hat{s}))\Bigg\} - \varepsilon \\
\geq & E_{sx}\Bigg\{\int_s^{\hat{s}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\
& + \sum_{\theta_i \leq \hat{s}} k(\theta_i, a_{i-1}, a_i) - \sum_{\tau_j \leq \hat{s}} l(\tau_j, b_{j-1}, b_j) \\
& + \sum_{i=1}^{\infty} \sum_{\hat{a}\in A, \hat{b}\in B} \chi_{\{\alpha[b(\cdot)](\hat{s})=\hat{a}, b(\hat{s})=\hat{b}\}} \chi_{A_i}(y_{s,x}(\hat{s})) V^1_{\hat{a},\hat{b}}(\hat{s}, \xi_i)\Bigg\} - 2\varepsilon.
\end{aligned} \tag{3.8}
$$

On the other hand, for $y_{sx}(\hat{s}) \in A_i, i = 1,2,\ldots$ and $\forall\, b(\cdot) \in \mathcal{B}^{\hat{b}}[\hat{s},1]$, we derive from (3.4) and (3.5) that

$$
V^1_{\hat{a},\hat{b}}(\hat{s},\xi_i) \geq J_{\hat{s}\xi_i}(\alpha^{\hat{a},\hat{b}}_{\xi_i}[b(\cdot)], b(\cdot)) - \varepsilon \geq J_{\hat{s}y_{sx}(\hat{s})}(\alpha^{\hat{a},\hat{b}}_{\xi_i}[b(\cdot)], b(\cdot)) - 2\varepsilon. \tag{3.9}
$$

Combining the above inequalities, we have

$$
\begin{aligned}
W_{a,b}(s,x) \geq & E_{sx}\Bigg\{\int_s^{\hat{s}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\
& + \sum_{\theta_i \leq \hat{s}} k(\theta_i, a_{i-1}, a_i) - \sum_{\tau_j \leq \hat{s}} l(\tau_j, b_{j-1}, b_j) \\
& + \sum_{i=1}^{\infty} \chi_{A_i}(y_{s,x}(\hat{s})) E_{\hat{s}y_{sx}(\hat{s})}\Bigg\{\int_{\hat{s}}^1 f^0(r,y(r),\widetilde{\alpha}[b(\cdot)](r),b(r))\,dr \\
& + \sum_{\theta_i > \hat{s}} k(\theta_i, a_{i-1}, a_i) - \sum_{\tau_j > \hat{s}} l(\tau_j, b_{j-1}, b_j) + h(y(1))\Bigg\}\Bigg\} - 4\varepsilon.
\end{aligned} \tag{3.10}
$$

Therefore,

$$
W_{a,b}(s,x) \geq \; J_{sx}(\widetilde{\alpha}, b(\cdot)) - 4\varepsilon,
$$

which in turn implies

$$
W_{a,b}(s,x) \geq \; V^1_{a,b}(s,x) - 4\varepsilon,
$$

and the result now follows. □

From Proposition 3.1, we can obtain the following time continuity of V^1 and U_1.

PROPOSITION 3.2. *There exists $L > 0$ such that for any $a \in A, b \in B, x \in X$, and $s,t \in [0,1]$*

$$
\begin{aligned}
|V^1_{a,b}(s,x) - V^1_{a,b}(t,x)| \; &\leq L(1+|x|)\sqrt{|s-t|}, \\
|U_1^{a,b}(s,x) - U_1^{a,b}(t,x)| \; &\leq L(1+|x|)\sqrt{|s-t|}.
\end{aligned} \tag{3.11}
$$

Proof of Proposition 3.2. We prove only the $\frac{1}{2}$-Hölder continuity of the r-lower value function V^1 in the time variable the $\frac{1}{2}$-Hölder continuity of the r-upper value function U_1 in the time variable can be proved in the same way.

Suppose that $s < t$. First, we prove the following:

$$V^1_{a,b}(s,x) - V^1_{a,b}(t,x) \le L(1+|x|)\sqrt{t-s}. \tag{3.12}$$

From Proposition 3.1 and Hypothesis 3, we derive

$$\begin{aligned}
&V^1_{a,b}(s,x)\\
&\le \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}\left\{\int_s^t f^0(r,y(r),a,b(r))\,dr - \sum_{\tau_j\le t} l(\tau_j,b_{j-1},b_j) + V^1_{a,b(t)}(t,y(t))\right\}\\
&\le \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}\left\{\int_s^t f^0(r,y(r),a,b(r))\,dr - \sum_{\tau_j\le t} l(t,b_{j-1},b_j) + V^1_{a,b(t)}(t,y(t))\right\}\\
&\le \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}\left\{\int_s^t f^0(r,y(r),a,b(r))\,dr - l(t,b,b(t)) + V^1_{a,b(t)}(t,y(t))\right\}\\
&\le \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}\left\{\int_s^t f^0(r,y(r),a,b(r))\,dr + V^1_{a,b}(t,y(t))\right\}.
\end{aligned} \tag{3.13}$$

Note that in the last step, we have used the relation (2.11). We then have

$$\begin{aligned}
&V^1_{a,b}(s,x) - V^1_{a,b}(t,x)\\
&\le \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}\left\{\int_s^t f^0(r,y(r),a,b(r))\,dr + V^1_{a,b}(t,y(t)) - V^1_{a,b}(t,x)\right\},
\end{aligned} \tag{3.14}$$

which proves (3.12) by the uniformly Lipschitz continuity of $V^1_{a,b}(t,x)$ in x and the following estimate:

$$E|y_{sx}(t) - x| \le L(1+|x|)\sqrt{t-s}.$$

Second, we prove the following:

$$V^1_{a,b}(s,x) - V^1_{a,b}(t,x) \ge -L(1+|x|)\sqrt{t-s}. \tag{3.15}$$

In fact, for any $\widehat{b}(\cdot) \in \mathcal{B}^b[t,1]$ and $\alpha \in \Gamma^a_1[s,1]$, we define

$$b(r) = \begin{cases} b, & r \in [s,t),\\ \widehat{b}(r), & r \in [t,1], \end{cases}$$

and

$$\begin{aligned}
&\widehat{\alpha}(\omega_1)[\widehat{b}(\cdot)](r) = \alpha[b(\cdot)](\omega_1)(r), \quad r \in [t,1],\\
&\widehat{\alpha}(\omega_1)[\widehat{b}(\cdot)](t-0) = a.
\end{aligned} \tag{3.16}$$

Then we see that $b(\cdot) \in \mathcal{B}^b[s,1]$ and $\widehat{\alpha}(\omega_1) \in \Gamma_1^a[s,1]$, a.s. It follows that

(3.17)
$$\begin{aligned} &J_{sx}(\alpha[b(\cdot)], b(\cdot)) \\ &\geq E_{sx}\Big\{\int_s^t f^0(r, y(r), \alpha[b(\cdot)](r), b(r))\,dr + l(t,a,a(t)) + J_{tx}(\alpha(\omega_1)[b(\cdot)], \widehat{b}(\cdot)) \\ &\quad + \int_t^1 [f^0(r, y(r), \widehat{\alpha}(\omega_1)[\widehat{b}(\cdot)](r), \widehat{b}(r)) - f^0(r, y(r), \widehat{\alpha}(\omega_1)[\widehat{b}(\cdot)](r), b(r))]\,dr\Big\}. \end{aligned}$$

Here we have used Hypothesis 2. Then we see that

(3.18)
$$\begin{aligned} &\sup_{b(\cdot)\in\mathcal{B}^b[s,1]} J_{sx}(\alpha[b(\cdot)], b(\cdot)) \\ &\geq \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}[V^1_{\alpha[b(\cdot)](t),b}(t,x) + l(t,a,\alpha[b(\cdot)](t))] - L(1+|x|)\sqrt{t-s} \\ &\geq V^1_{a,b}(t,x) - L(1+|x|)|s-t|^{1/2}, \end{aligned}$$

which implies (3.15). □

Remark 3.1. It is still true to replace in Proposition 3.1 the deterministic time $\hat{s} \in (s,1]$ with a stopping time τ which takes its values in $(s,1]$. In fact, in this version of Proposition 3.2, it is sufficient to note that, for any $(x,a,b) \in X \times A \times B$, the two random variables $V^1_{a,b}(\tau,x)$ and $U_1^{a,b}(\tau,x)$ may be sufficiently approximated by

$$\sum_{i=0}^{N-1} V^1_{a,b}(t_i,x)\chi_{[t_i,t_{i+1})}(\tau) \quad \text{and} \quad \sum_{i=0}^{N-1} U_1^{a,b}(t_i,x)\chi_{[t_i,t_{i+1})}(\tau),$$

respectively, by letting N be sufficiently large. Here we have used the following notation:

$$t_i = \frac{i(1-s)}{N}, \quad i = 0,1,\ldots,N.$$

For $(s,x,\delta) \in [0,1] \times X \times (0,\infty)$ and $(a(\cdot),b(\cdot)) \in \mathcal{A}^a[s,1] \times \mathcal{B}^b[s,1]$, define

$$\tau^\delta_{s,x}(a(\cdot),b(\cdot)) := \inf\Big\{t \in [s,T] : |y_{s,x}^{a(\cdot),b(\cdot)}(t) - x| \geq \delta\Big\} \wedge T,$$

where $y_{s,x}^{a(\cdot),b(\cdot)}$ is the solution of the system (1.1) corresponding to $(a(\cdot),b(\cdot)) \in \mathcal{A}^a[s,1] \times \mathcal{B}^b[s,1]$, which will occasionally be abbreviated as y_{sx} or simply y to simplify the notation. It is easy to see that $\tau^\delta_{s,x}(a(\cdot),b(\cdot))$ is a stopping time for any triplet $(s,x,\delta) \in [0,1] \times X \times [0,\infty)$ and any pair $(a(\cdot),b(\cdot)) \in \mathcal{A}^a[s,1] \times \mathcal{B}^b[s,1]$. To simplify the notation, we shall simply write τ^δ for $\tau^\delta_{s,x}(a(\cdot),b(\cdot))$ when the dependence on $(s,x,a(\cdot),b(\cdot))$ is not confused from the context. We also have

$$|y_{s,x}^{a(\cdot),b(\cdot)}(t \wedge \tau^d) - x| \leq \delta$$

for $s \leq t \leq 1, a(\cdot) \in \mathcal{A}^a[s,1]$, and $b(\cdot) \in \mathcal{B}^b[s,1]$. Moreover, we have

$$\lim_{\hat{s}\to s+} \sup_{a(\cdot)\in\mathcal{A}^a[s,1], b(\cdot)\in\mathcal{B}^b[s,1]} \frac{P(\{\hat{s} \geq \tau^\delta\})}{\hat{s}-s} = 0.$$

In fact, we have

$$P(\{\tau^\delta \le \hat{s}\}) = P\left(\left\{\sup_{s\le t\le \hat{s}} |y_{s,x}^{a(\cdot),b(\cdot)}(t) - x| \ge \delta\right\}\right) \le \sum_{i=1}^{N} P_{s,x}^{\delta,i}(a(\cdot),b(\cdot)),$$

where N is the dimension of the state space X, for $i = 1,\dots,N$, e_i is the unit vector of X whose ith component is one, and

$$P_{s,x}^{\delta,i}(a(\cdot),b(\cdot)) := P\left(\left\{\sup_{s\le t\le \hat{s}} \langle e_i, y_{s,x}^{a(\cdot),b(\cdot)}(t) - x\rangle \ge \delta N^{-\frac{1}{2}}\right\}\right).$$

Define

$$f_{s,x}^{\delta} := \sup\{|f(t,y,a,b)| : (t,a,b) \in [s,1]\times A\times B, |y-x|\le\delta\}$$

and

$$g_{s,x}^{\delta} := \sup\{|g(t,y,a,b)| : (t,a,b) \in [s,1]\times A\times B, |y-x|\le\delta\}.$$

For $\theta \in X$, from Itô's formula, it follows that the process

$$\begin{aligned} &Z_{s,x}^{\delta,\theta}(t;a(\cdot),b(\cdot)) \\ &:= \exp\left\{\left\langle \theta, y_{s,x}(t\wedge\tau^\delta) - x - \int_s^{t\wedge\tau^\delta} f(r,y_{s,x}(r),a(r),b(r))\,dr\right\rangle \right. \\ &\quad \left. -\frac{1}{2}\int_s^{t\wedge\tau^\delta} |g^*(r,y_{s,x}(r),a(r),b(r))e_i|^2\,dr\right\}, \quad t\in[s,1], \end{aligned}$$

is a continuous martingale, and $E[Z_{s,x}^{\delta,\theta}(t;a(\cdot),b(\cdot))] = 1$ for any $(t,a(\cdot),b(\cdot),\theta) \in [s,T]\times\mathcal{A}^a[s,1]\times\mathcal{B}^b[s,1]\times X$. Therefore, using Doob's inequality, we have for $h := \hat{s}-s, \lambda>0, \delta_0\ge\delta>0, a(\cdot)\in\mathcal{A}^a[s,1]$, and $b(\cdot)\in\mathcal{B}^b[s,1]$

$$\begin{aligned} &P_{s,x}^{\delta,i}(a(\cdot),b(\cdot)) \\ &\le P\left(\left\{\sup_{s\le t\le\hat{s}} Z_{s,x}^{\delta,\lambda e_i}(t;a(\cdot),b(\cdot)) \ge \exp\left[\lambda(\delta N^{-\frac{1}{2}} - hf_{s,x}^{\delta_0}) - \frac{1}{2}\lambda^2 h|g_{s,x}^{\delta_0}|^2\right]\right\}\right) \\ &\le \exp\left[-\lambda(\delta N^{-\frac{1}{2}} - hf_{s,x}^{\delta_0}) + \frac{1}{2}\lambda^2 h|g_{s,x}^{\delta_0}|^2\right]. \end{aligned}$$

As h is sufficiently small, take

$$\lambda = \frac{\delta N^{-\frac{1}{2}} - hf_{s,x}^{\delta_0}}{h|g_{s,x}^{\delta_0}|^2},$$

and we further have

$$P_{s,x}^{\delta,i}(a(\cdot),b(\cdot)) \le \exp\left\{\frac{-|\delta N^{-\frac{1}{2}} - hf_{s,x}^{\delta_0}|^2}{2h|g_{s,x}^{\delta_0}|^2}\right\}.$$

Hence,

$$\begin{aligned}
&\lim_{\hat{s}\to s+} \sup_{a(\cdot)\in\mathcal{A}^a[s,1],b(\cdot)\in\mathcal{B}^b[s,1]} \frac{P(\{\tau^\delta \le \hat{s}\})}{\hat{s}-s} \\
&\le \lim_{\hat{s}\to s+} \sup_{a(\cdot)\in\mathcal{A}^a[s,1],b(\cdot)\in\mathcal{B}^b[s,1]} h^{-1}\sum_{i=1}^{N} P^{\delta,i}_{s,x}(a(\cdot),b(\cdot)) \\
&\le \lim_{h\to 0} Nh^{-1}\exp\left\{\frac{-|\delta N^{-\frac{1}{2}} - hf^{\delta_0}_{s,x}|^2}{2h|g^{\delta_0}_{s,x}|^2}\right\} = 0.
\end{aligned}$$

The desired result then follows.

PROPOSITION 3.3. (1) *The r-lower value function $V^1(\cdot,\cdot)$ satisfies the following: Suppose at $(a,b,s,x)\in A\times B\times[0,1]\times X$*

$$V^1_{a,b}(s,x) > M_{a,b}[V^1](s,x). \tag{3.19a}$$

Then there exist a deterministic time $s_0 > s$ and a sufficiently small number $\delta_0 > 0$, such that for all $\hat{s}\in[s,s_0]$ and $\delta\in(0,\delta_0]$,

$$V^1_{a,b}(s,x) \le E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(r,y^{a,b}(r),a,b)\,dr + V^1_{a,b}(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta))\right\}. \tag{3.19b}$$

Here we have abbreviated $\tau^\delta_{s,x}(a,b)$ as τ^δ.

(2) *The r-upper value function $U_1(\cdot,\cdot)$ satisfies the following: Suppose at $(a,b,s,x)\in A\times B\times[0,1]\times X$*

$$U^{a,b}_1(s,x) < M^{a,b}[U_1](s,x). \tag{3.20a}$$

Then there exist a deterministic time $s_0 > s$ and a sufficiently small number $\delta_0 > 0$, such that for all $\hat{s}\in[s,s_0]$ and $\delta\in(0,\delta_0]$,

$$U^{a,b}_1(s,x) \ge E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(r,y^{a,b}(r),a,b)\,dr + U^{a,b}_1(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta))\right\}. \tag{3.20b}$$

Here we have abbreviated $\tau^\delta_{s,x}(a,b)$ as τ^δ.

Remark 3.2. Proposition 3.3 can be viewed as a stochastic version of Theorem 3.2 by Yong [10]. However, it is by no means trivial and is of stochastic nature in its formulation. The upper limits of the integrals in (3.19b) and (3.20b) are more complicated than the deterministic counterparts: The former are a deterministic time $\hat{s} > s$ which is sufficiently close to the initial time s, stopped by the first time of the system state process $y^{a,b}_{s,x}$ (steered by both players I and II with constant actions $a\in A$ and $b\in B$, respectively) escaping from a sufficiently small ball centered at the initial state x, while the latter are simply a deterministic time $\hat{s} > s$ which is sufficiently close to the initial time s. Obviously, both coincide. Our proof below is quite different from the deterministic case and is of stochastic nature; it includes a delicate analysis.

Proof of Proposition 3.3. We prove only statement (1); the proof of statement (2) is similar.

If statement (1) were not true, then there would exist sequences $\hat{s}\to s, \delta\to 0+$, and $\varepsilon\to 0+$ such that

$$V^1_{a,b}(s,x) - \varepsilon > E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(s,y(s;a,b),a,b)\,ds + V^1_{a,b}(\hat{s}\wedge\tau^\delta, y(\hat{s}\wedge\tau^\delta;a,b))\right\}. \tag{3.21}$$

On the other hand, using Proposition 3.2 and the idea exposed in Remark 3.1, we can show the following analogy to Proposition 3.1 (1):

$$\begin{aligned} V^1_{a,b}(s,x) \le \inf_{\alpha\in\Gamma^a_1[s,1]} \sup_{b(\cdot)\in\mathcal{B}^b[s,1]} E_{sx}\Big\{ & \int_s^{\hat{s}\wedge\tau^\delta_{a(\cdot),b(\cdot)}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\ & + \sum_{\theta_i\le\hat{s}\wedge\tau^\delta_{a(\cdot),b(\cdot)}} k(\theta_i,a_{i-1},a_i) - \sum_{\tau_j\le\hat{s}\wedge\tau^\delta_{a(\cdot),b(\cdot)}} l(\tau_j,b_{j-1},b_j) \\ & + V^1_{\alpha[b(\cdot)](\hat{s}),b(\hat{s})}(\hat{s}\wedge\tau^\delta_{a(\cdot),b(\cdot)}, y(\hat{s}\wedge\tau^\delta_{a(\cdot),b(\cdot)}))\Big\}, \end{aligned}$$

where $\{a_i,\theta_i\}$ and $\{b_j,\tau_j\}$ are associated with $\alpha[b(\cdot)]$ and $b(\cdot)$, respectively; $\alpha[b(\cdot)](\hat{s}) = \alpha[b(\cdot)](\hat{s}+0), b(\hat{s}) = b(\hat{s}+0)$, and $\tau^\delta_{a(\cdot),b(\cdot)} := \tau^\delta_{s,x}(a(\cdot),b(\cdot))$. Therefore, we have

$$\begin{aligned} V^1_{a,b}(s,x) \le \sup_{b(\cdot)\in\mathcal{B}^{b,s}} E_{sx}\Big\{ & \int_s^{\hat{s}\wedge\tau^\delta_{a,b(\cdot)}} f^0(r,y(r),a,b(r))\,dr \\ & - \sum_{\tau_j\le\hat{s}\wedge\tau^\delta_{a,b(\cdot)}} l(\tau_j,b_{j-1},b_j) + V^1_{a,b(\hat{s})}(\hat{s}\wedge\tau^\delta_{a,b(\cdot)}, y(\hat{s}\wedge\tau^\delta_{a,b(\cdot)}))\Big\}. \end{aligned} \tag{3.22}$$

Furthermore, by definition, we conclude that there exists $b^\varepsilon(\cdot)\in\mathcal{B}^b[s,1]$ such that

$$\begin{aligned} V^1_{a,b}(s,x) - \varepsilon \le E_{sx}\Big\{ & \int_s^{\hat{s}\wedge\tau^\delta_{a,b^\varepsilon(\cdot)}} f^0(r,y(r),a,b^\varepsilon(r))\,dr \\ & - \sum_{\tau^\varepsilon_j\le\hat{s}\wedge\tau^\delta_{a,b^\varepsilon(\cdot)}} l(\tau^\varepsilon_j,b^\varepsilon_{j-1},b^\varepsilon_j) + V^1_{a,b^\varepsilon(\hat{s})}(\hat{s}\wedge\tau^\delta_{a,b^\varepsilon(\cdot)}, y(\hat{s}\wedge\tau^\delta_{a,b^\varepsilon(\cdot)}))\Big\}, \end{aligned} \tag{3.23}$$

where $\{\tau^\varepsilon_j,b^\varepsilon_j\} = b^\varepsilon(\cdot)$.

Set

$$\begin{aligned} B_1 &:= \{\omega : b^\varepsilon(r\wedge\tau^\delta_{a,b^\varepsilon(\cdot)},\omega) \ne b \text{ for some } r\in[s,\hat{s}\wedge\tau^\delta_{a,b^\varepsilon(\cdot)}]\}, \\ B_1^c &:= \Omega\backslash B_1 = \{\omega : b^\varepsilon(r\wedge\tau^\delta_{a,b^\varepsilon(\cdot)},\omega) = b\ \forall\, r\in[s,\hat{s}\wedge\tau^\delta_{a,b^\varepsilon(\cdot)}]\}. \end{aligned}$$

Note that B_1 and B_1^c depend on $(\delta,\hat{s})$. Then the two inequalities (3.21) and (3.23) yield

$$E[\chi_{B_1}] > 0 \text{ for sufficiently small positive } \delta \text{ and } \hat{s}. \tag{3.24}$$

Combining (3.21) and (3.23), we have

$$\text{(I)} + \text{(II)} + \text{(III)} > 0, \tag{3.25}$$

where

(3.26)

$$\begin{aligned}
\text{(I)} &= E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)}} f^0(r,y(r;a,b^{\varepsilon}(\cdot)),a,b^{\varepsilon}(r))\,dr - \int_s^{\hat{s}\wedge\tau^{\delta}_{a,b}} f^0(r,y(r;a,b),a,b)\,dr\right\}\\
&\le C((\hat{s}-s)(1+|x|+\delta))E\chi_{B_1},\\
\text{(II)} &= E_{sx}\left\{-\sum_{\tau^{\varepsilon}_j\le\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)}} l(\tau^{\varepsilon}_j,b^{\varepsilon}_{j-1},b^{\varepsilon}_j)\right\} \le -E_{sx}\left\{\sum_{\tau^{\varepsilon}_j\le\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)}} l(\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)},b^{\varepsilon}_{j-1},b^{\varepsilon}_j)\right\},\\
\text{(III)} &= E_{sx}[V^1_{a,b^{\varepsilon}(\hat{s})}(\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)},y(\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)};a,b^{\varepsilon}(\cdot))) - V^1_{a,b}(\hat{s}\wedge\tau^{\delta}_{a,b},y(\hat{s}\wedge\tau^{\delta}_{a,b};a,b))]\\
&= E_{sx}\Big\{[V^1_{a,b^{\varepsilon}(\hat{s})}(\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)},y(\hat{s}\wedge\tau^{\delta}_{a,b^{\varepsilon}(\cdot)};a,b^{\varepsilon}(\cdot)))\\
&\qquad - V^1_{a,b}(\hat{s}\wedge\tau^{\delta}_{a,b},y(\hat{s}\wedge\tau^{\delta}_{a,b};a,b))]\chi_{B_1}\Big\}.
\end{aligned}$$

Hence, noting Propositions 2.1 and 3.2, we have

$$\begin{aligned}
0 &\le \text{(I)} + \text{(II)} + \text{(III)}\\
&\le \{M_{a,b}[V^1](s,x) - V^1_{a,b}(s,x) + C[\sqrt{\hat{s}-s}(1+|x|)+\delta]\}E\chi_{B_1}
\end{aligned}\tag{3.27}$$

for some positive constant C, which implies that

$$M_{a,b}[V^1](s,x) - V^1_{a,b}(s,x) \ge -C\sqrt{\hat{s}-s}(1+|x|)+\delta. \tag{3.28}$$

Letting $\delta\to 0+$ and $\varepsilon\to 0+$, we have

$$M_{a,b}[V^1](s,x) \ge V^1_{a,b}(s,x),$$

which contradicts (3.19a). □

Note that the time continuity of V^1 and U_1 given by Proposition 3.2 is used in the proof of Proposition 3.3.

Denote by $C^{0,1}(X,\mathbb{R}^{m\times n})$ the totality of $\mathbb{R}^{m\times n}$-valued uniformly Lipschitz continuous functions on X. For $\varphi(\cdot)=(\varphi_{a,b}(\cdot))_{a\in A,b\in B}\in C^{0,1}(X,\mathbb{R}^{m\times n})$, define

(3.29a)

$$\begin{aligned}
F_{a,b}(s,\hat{s})\varphi(x) = \sup_{\hat{b}\in B}\inf_{a(\cdot)\in\mathcal{A}^a[s,\hat{s}]} E_{sx}\Big\{&\varphi_{a(\hat{s}-),\hat{b}}(y(\hat{s})) + \int_s^{\hat{s}} f^0(r,y(r),a(r),\hat{b})\,dr\\
&+\sum_{s\le\theta_i<\hat{s}} k(\theta_i,a_{i-1},a_i) - l(s,b,\hat{b})\Big\},\quad (a,b,x)\in A\times B\times X;\\
F(s,\hat{s})\varphi = (F_{a,b}(s,\hat{s})\varphi)_{a\in A,b\in B}&
\end{aligned}$$

and

(3.29b)

$$\begin{aligned}
G^{a,b}(s,\hat{s})\varphi(x) = \inf_{\hat{a}\in A}\sup_{b(\cdot)\in\mathcal{B}^b[s,\hat{s}]} E_{sx}\Big\{&\varphi_{\hat{a},b(\hat{s}-)}(y(\hat{s})) + \int_s^{\hat{s}} f^0(r,y(r),\hat{a},b(r))\,dr\\
&+k(s,a,\hat{a}) - \sum_{s\le\tau_j<\hat{s}} l(\tau_j,a_{j-1},a_j)\Big\},\quad (a,b,x)\in A\times B\times X;\\
G(s,\hat{s})\varphi = (G^{a,b}(s,\hat{s})\varphi)_{a\in A,b\in B}&.
\end{aligned}$$

It is easily shown that $F(s,\hat{s})$ and $G(s,\hat{s})$ are self-mappings on $C^{0,1}(X,\mathbb{R}^{m\times n})$. Therefore, the function $V^\pi : [0,1]\times X \to C^{0,1}(X,\mathbb{R}^{m\times n})$ given by

(3.30a)
$$V^\pi(1,x) = (V^\pi_{a,b}(1,x))_{a\in A, b\in B}, \quad V^\pi_{a,b}(1,x) \equiv h(x) \text{ for } (a,b)\in A\times B, \text{ with } x\in X;$$
$$V^\pi(s,x) = F(s,t_{i_0+1}) \prod_{i=i_0+2}^{M} F(t_{i-1},t_i)h(x), \quad x\in X, \quad \text{if } s\in[t_{i_0},t_{i_0+1}),$$

is well defined. Let $V^\pi_{a,b}(s,x)$ be the (a,b)-component of the matrix $V^\pi(s,x)$. Similarly, define $U_\pi = (U^{a,b}_\pi)_{a\in A,b\in B} : [0,1]\times X \to C^{0,1}(X,\mathbb{R}^{m\times n})$ as follows:

(3.30b)
$$U_\pi(1,x) = (U^{a,b}_\pi(1,x))_{a\in A,b\in B}, \quad U^{a,b}_\pi(1,x) \equiv h(x) \text{ for } (a,b)\in A\times B, \text{ with } x\in X;$$
$$U_\pi(s,x) = G(s,t_{i_0+1}) \prod_{i=i_0+2}^{M} G(t_{i-1},t_i)h(x), \ x\in X, \quad \text{if } s\in[t_{i_0},t_{i_0+1}).$$

We have the following.

PROPOSITION 3.4. *For $(a,b,s,x)\in A\times B\times[0,1]\times X$ and $\hat{s}\in\pi\cap[s,1]$, we have*

$$\begin{aligned} V^\pi_{a,b}(s,x) = \inf_{\alpha\in\Gamma^a[s,1]} \sup_{b(\cdot)\in\mathcal{B}^b_\pi[s,1]} E_{sx}\Bigg\{ &\int_s^{\hat{s}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\ &+ \sum_{s\le\theta_i<\hat{s}} k(\theta_i,a_{i-1},a_i) - \sum_{s\le\tau_j<\hat{s}} l(\tau_j,b_{j-1},b_j) \\ &+ V^\pi_{\alpha[b(\cdot)](\hat{s}-),b(\hat{s}-)}(\hat{s},y(\hat{s}))\Bigg\}, \end{aligned} \tag{3.31a}$$

where $b(\cdot)=\{b_j,\tau_j\}$ and $a(\cdot)=\alpha[b(\cdot)]=\{a_i,\theta_i\}$, and

$$\begin{aligned} U^{a,b}_\pi(s,x) = \sup_{\beta\in\Delta^b[s,1]} \inf_{a(\cdot)\in\mathcal{A}^a_\pi[s,1]} E_{sx}\Bigg\{ &\int_s^{\hat{s}} f^0(r,y(r),a(r),\beta[a(\cdot)](r))\,dr \\ &+ \sum_{s\le\theta_i<\hat{s}} k(\theta_i,a_{i-1},a_i) - \sum_{s\le\tau_j<\hat{s}} l(\tau_j,b_{j-1},b_j) \\ &+ U^{a(\hat{s}-),\beta[a(\cdot)](\hat{s}-)}_\pi(\hat{s},y(\hat{s}))\Bigg\}, \end{aligned} \tag{3.31b}$$

where $a(\cdot)=\{a_i,\theta_i\}$ and $b(\cdot)=\beta[a(\cdot)]=\{b_j,\tau_j\}$.

Proof of Proposition 3.4. We prove only (3.31a) here; the proof of (3.31b) is identical and therefore will be omitted.

For $a(\cdot)\in\mathcal{A}^a[s,1]$ and $b(\cdot)\in\mathcal{B}^b[s,1]$, set

$$\begin{aligned} \widehat{J}_{sx}(a(\cdot),b(\cdot)) = E_{sx}\Bigg\{ &\int_s^{\hat{s}} f^0(r,y(r),a(r),b(r))\,dr \\ &+ \sum_{s\le\theta_i<\hat{s}} k(\theta_i,a_{i-1},a_i) - \sum_{s\le t_j<\hat{s}} l(t_j,b_{j-1},b_j) \\ &+ V^\pi_{a(\hat{s}-),b(\hat{s}-)}(\hat{s},y(\hat{s}))\Bigg\}. \end{aligned} \tag{3.32}$$

The desired result can be derived from the following assertion: For $(a,b,s,x)\in A\times B\times[0,1]\times X$ and $\forall\varepsilon>0$, there exist $\beta_\varepsilon\in\Delta^b_\pi[s,1]$ and $\alpha_\varepsilon\in\Gamma^a[s,1]$ such that

$$V^\pi_{a,b}(s,x) \ge \widehat{J}_{sx}(\alpha_\varepsilon[b(\cdot)],b(\cdot)) - \varepsilon \quad \forall b(\cdot)\in\mathcal{B}^b_\pi[s,1] \tag{3.33}$$

and

$$V^{\pi}_{a,b}(s,x) \le \widehat{J}_{sx}(a(\cdot),\beta_\varepsilon[a(\cdot)]) + \varepsilon \quad \forall a(\cdot) \in \Gamma^a[s,1]. \tag{3.34}$$

In fact, the inequality (3.33) implies (3.31a) with the equality sign replaced by "$\ge$." On the other hand, for any $\alpha \in \Gamma^a[s,1]$, the pair of strategies of $\beta_\varepsilon \in \Delta^b_\pi[s,1]$ and $\alpha \in \Gamma^a[s,1]$ define a pair of switching processes $a_\varepsilon(\cdot) \in \mathcal{A}^a[s,1]$ and $b_\varepsilon \in \mathcal{B}^b_\pi[s,1]$ such that

$$\widehat{J}_{sx}(a_\varepsilon(\cdot),\beta_\varepsilon) = \widehat{J}_{sx}(\alpha, b_\varepsilon(\cdot)), \tag{3.35}$$

and this gives the other inequality in (3.31a). We invite the reader to see Fleming and Souganidis [6] for the details of the proof.

We conclude the proof by establishing (3.33) and (3.34). For $\varphi \in C^{0,1}(X,\mathbb{R}^{m\times n})$, define

$$\begin{aligned}\psi_{a,b}(s,x,\hat{s},\varphi,\widetilde{b}) = \inf_{a(\cdot)\in\mathcal{A}^a[s,\hat{s})} E_{sx}\Bigg\{ & \varphi_{a(\hat{s}-),\widetilde{b}}(y(\hat{s})) + \int_s^{\hat{s}} f^0(r,y(r),a(r),\widetilde{b})\,dr \\ & + \sum_{s\le\theta_i<\hat{s}} k(\theta_i,a_{i-1},a_i) - l(s,b,\widetilde{b})\Bigg\}.\end{aligned} \tag{3.36}$$

Here $y_{sx}(\cdot)$ is the solution of (1.1) with $b(r) = \widetilde{b}, r \in [s,\hat{s}]$.

$$F_{a,b}(s,\hat{s})\varphi(x) = \sup_{\widetilde{b}\in B} \psi_{a,b}(s,x,\hat{s},\varphi,\widetilde{b}). \tag{3.37}$$

If $s \in [t_{i_0}, t_{i_0+1})$ for $i_0 \in \{0,1,\dots,M-1\}$, let $D_M = h, D_j = F(t_j,t_{j+1})D_{j+1}$, for $j = i_0+1,\dots,M-1$, and $D_{s,i_0} = F(t,t_{i_0+1})D_{i_0+1}$. Thus,

$$D_{s,i_0}(x) = V^{\pi}_{a,b}(s,x), \tag{3.38}$$

and, in particular,

$$D_{i_0}(x) = V^{\pi}_{a,b}(t_{i_0},x). \tag{3.39}$$

We partition X into Borel sets $\{A_i : i = 1,2,\dots\}$ of diameter less than δ, where δ is to be specified later, and we choose $x_i \in A_i$. Given $\gamma > 0$, we can choose δ small enough and $\widetilde{b}^a_{i(j-1)} \in B$ for $i = 1,2,\dots$ and $j = i_0+1,\dots,M$ such that

$$\psi_{a,b}(t_{j-1},x_i,t_j,D_j,\widetilde{b}^a_{i(j-1)}) > F_{a,b}(t_{j-1},t_j)D_j(x_i) - \gamma, \tag{3.40a}$$

and thus

$$\begin{aligned}E_{t_{j-1}x_i}\Bigg\{ & D_j^{a(t_j-),\widetilde{b}^a_{i(j-1)}}(y(t_j)) + \int_{t_{j-1}}^{t_j} f^0(r,y(r),a(r),\widetilde{b}^a_{i(j-1)})\,dr \\ & + \sum_{t_{j-1}\le\theta_i<t_j} k(\theta_i,a_{i-1},a_i) - l(t_{j-1},b,\widetilde{b})\Bigg\} > D^{a,b}_{j-1}(x_i) - \gamma \quad \forall a(\cdot) \in \mathcal{A}^a[t_{j-1},t_j].\end{aligned} \tag{3.40b}$$

We also choose $a^{\tilde{b}}_{i(j-1)}(\cdot) \in \mathcal{A}^a(t_{j-1}, t_j)$ such that, for $a(\cdot) = a^{\tilde{b}}_{ij}(\cdot)$ and $b(r) = \widetilde{b}, r \in (t_{j-1}, t_j]$,

$$\begin{aligned} & E_{t_{j-1}x_i}\Big\{ D_j^{a(t_j-),\tilde{b}}(y(t_j; a^{\tilde{b}}_{i(j-1)}(\cdot), \widetilde{b})) + \int_{t_{j-1}}^{t_j} f^0(r, y(r), a^{\tilde{b}}_{i(j-1)}(r), \widetilde{b})\, dr \\ & \qquad + \sum_{t_{j-1} \le \theta_i < t_j} k(\theta_i, a_{i-1}, a_i) - l(t_{j-1}, b, \widetilde{b}) \Big\} \\ & < \quad \psi_{a,b}(t_{j-1}, x_i, t_j, D_j, \widetilde{b}) + \gamma = D_j^{a,b}(x_i) + \gamma, \end{aligned} \tag{3.41}$$

where for $j = i_0 + 1$ we replace t_{i_0} by s. Here $y_{t_j x_i}(\cdot; a^{\tilde{b}}_{ij}(\cdot), \widetilde{b})$ is the solution of (1.1) with the initial data (t_{j-1}, x_i) and on the switchings $a(\cdot) = a^{\tilde{b}}_{ij}(\cdot)$ and $b(\cdot) \equiv \widetilde{b}$.

We need to introduce more notations. As before, we identify $\omega \in \Omega_s$ with the pair $(\omega_{1j}, \omega_{2j})$ for $j = i_0 + 2, \dots, M$, where $\omega_{1j} = \omega|_{[s,t_{j-1}]}$ and $\omega_{2j} = \omega - \omega_{t_{j-1}}|_{[t_{j-1},1]}$. With this identification, the Wiener measure P_s on Ω_s can be regarded as the product measure $P_{1j} \otimes P_{2j}$ of the two probability measures P_{1j} and P_{2j}, which are defined on the two measure spaces $(\Omega_{s,t_{j-1}}, \mathcal{F}_{s,t_{j-1}})$ and $(\Omega_{t_{j-1}}, \mathcal{F}_{t_{j-1}})$, respectively. In view of this identification, we will be writing

$$E^{P_{2j}} \equiv E_{t_{j-1}x_i}. \tag{3.42}$$

The strategies $\alpha_\varepsilon \in \Gamma^a[s,1]$ and $\beta_\varepsilon \in \Delta^b_\pi[s,1]$ are defined as follows. Let $(a, b, s, x) \in A \times B \times [0,1) \times X$ be fixed. For $a(\cdot) \in \mathcal{A}^a[s,1]$, we define

$$\begin{cases} \beta_\varepsilon[a(\cdot)](r) = b\chi_{[s,s)} + \chi_{[s,t_{i_0+1})}(r) \displaystyle\sum_{i=1}^{\infty} \widetilde{b}^a_{ii_0}\chi_{A_i}(x) \\ \qquad\qquad + \displaystyle\sum_{j=i_0+1}^{M-1} \chi_{[t_j,t_{j+1})}(r) \sum_{\substack{\tilde{a}\in A \\ i=1}}^{\infty} \widetilde{b}^{\tilde{a}}_{ij}\chi_{A_i}(y_{sx}(t_j))\chi_{\{a(t_j-)=\tilde{a}\}}, r \in [s,1), \\ \beta_\varepsilon[a(\cdot)](1) = \beta_\varepsilon[a(\cdot)](1-), \end{cases} \tag{3.43}$$

where the random variable $y_{sx}(\cdot)$ is defined successively on intervals $[s, t_{i_0+1}]$, $[t_j, t_{j+1}]$, $j = i_0 + 1, \dots, M-1$, as the solution to (1.1) with $b(r) = \beta_\varepsilon[a(\cdot)](r)$. Note that $\forall a(\cdot) \in \mathcal{A}^a[s,1]$ and $r \in (s,1)$, $\beta_\varepsilon[a(\cdot)](r)$ depends only on $a(\cdot)|_{[s,r)}$ and is independent of $a(r)$. For $b(\cdot) \in \mathcal{B}^b[s,1]$, we define

$$\begin{cases} \alpha_\varepsilon[b(\cdot)](r) = \chi_{[s,s)} \displaystyle\sum_{i=1}^{\infty} \widetilde{a}^b_{ii_0}\chi_{A_i}(x) + \chi_{[s,t_{i_0+1})}(r) \sum_{\tilde{b}\in B, i=1}^{\infty} \widetilde{a}^{\tilde{b}}_{ii_0}(r)\chi_{A_i}(x)\chi_{\{b(s)=\tilde{b}\}} \\ \qquad\qquad + \displaystyle\sum_{j=i_0+1}^{M-1} \chi_{[t_j,t_{j+1})}(r) \sum_{\tilde{b}\in B, i=1}^{\infty} \widetilde{a}^{\tilde{b}}_{ij}(r)\chi_{A_i}(y_{sx}(t_j))\chi_{\{b(r)=\tilde{b}\}}, r \in [s,1); \\ \alpha_\varepsilon[b(\cdot)](1) = \alpha_\varepsilon[b(\cdot)](1-), \end{cases} \tag{3.44}$$

where again $y_{sx}(\cdot)$ is defined successively on intervals $[s, t_{i_0+1}]$, $[t_j, t_{j+1}]$, $j = i_0 + 1, \dots, M-1$, as the solution to (1.1) with $a(r) = \alpha_\varepsilon[b(\cdot)](r)$. Note that for any $b(\cdot) \in \mathcal{B}^b[s,1]$ and $r \in [s,1]$, $\alpha_\varepsilon[b(\cdot)](r)$ depends on $b(r)$.

For either $a(\cdot) \in \mathcal{A}^a[s,1]$ and $b(\cdot) = \beta_\varepsilon[a(\cdot)]$ or $b(\cdot) \in \mathcal{B}^b_\pi[s,1]$ and $a(\cdot) = \alpha_\varepsilon[b(\cdot)]$, we have

$$
\begin{aligned}
&V^\pi_{a,b}(s,x) - \widehat{J}_{sx}(a(\cdot),b(\cdot)) \\
&= E^{P_s} \sum_{t_{i_0+1} \le t_j \le \hat{s}} \Big\{ D_{j-1}^{a(t_{j-1}-),b(t_{j-1}-)}(y_{sx}(t_{j-1})) \\
&\quad + E^{P_s}\Big[-\int_{t_{j-1}}^{t_j} f^0(r, y_{sx}(r), a(r), b(r))\, dr - \sum_{t_{j-1} \le \theta_i < t_j} k(\theta_i, a_{i-1}, a_i) \\
&\quad + \sum_{t_{j-1} \le \tau_j < t_j} l(\tau_j, b_{j-1}, b_j) - D_j^{a(t_j-),b(t_j-)}(y_{sx}(t_j)) \;\Big|\; \mathcal{F}_{s,t_{j-1}} \Big] \Big\}.
\end{aligned} \tag{3.45}
$$

To obtain (3.33) and (3.34), it suffices to show that the following statements hold:

$$
\begin{aligned}
&D_{j-1}^{a(t_{j-1}-),b(t_{j-1}-)}(y_{sx}(t_{j-1})) \;\ge \\
&E^{P_s}\Big[\int_{t_{j-1}}^{t_j} f^0(r, y_{sx}(r), a(r), b(r))\, dr + \sum_{t_{j-1} \le \theta_i < t_j} k(\theta_i, a_{i-1}, a_i) \\
&- \sum_{t_{j-1} \le \tau_j < t_j} l(\tau_j, b_{j-1}, b_j) + D_j^{a(t_j-),b(t_j-)}(y_{sx}(t_j)) \;\Big|\; \mathcal{F}_{s,t_{j-1}} \Big] - \varepsilon(t_j - t_{j-1}), \\
&\qquad P_s\text{-a.s.} \quad \forall\, b(\cdot) \in \mathcal{B}^b_\pi[s,1] \text{ and } a(\cdot) = \alpha_\varepsilon[b(\cdot)]
\end{aligned} \tag{3.46}
$$

and

$$
\begin{aligned}
&D_{j-1}^{a(t_{j-1}-),b(t_{j-1}-)}(y_{sx}(t_{j-1})) \\
&\le E^{P_s}\Big[\int_{t_{j-1}}^{t_j} f^0(r, y_{sx}(r), a(r), b(r))\, dr + \sum_{t_{j-1} \le \theta_i < t_j} k(\theta_i, a_{i-1}, a_i) \\
&- \sum_{t_{j-1} \le \tau_j < t_j} l(\tau_j, b_{j-1}, b_j) + D_j^{a(t_j-),b(t_j-)}(y_{sx}(t_j)) \;\Big|\; \mathcal{F}_{s,t_{j-1}} \Big] + \varepsilon(t_j - t_{j-1}), \\
&\qquad P_s\text{-a.s.} \quad \forall\, a(\cdot) \in \mathcal{A}^a[s,1] \text{ and } b(\cdot) = \beta_\varepsilon[a(\cdot)].
\end{aligned} \tag{3.47}
$$

They can be derived from (3.41) and (3.40b), separately. □

It is easy to see that $V^\pi_{a,b}(s,x)$ and $U^{a,b}_\pi(s,x)$ grow in a linear way in the state variable $x \in X$, uniformly with respect to $(a,b,s) \in A \times B \times [0,T]$ and the partition π. Analogous to the first part of the proof of Proposition 3.2, we can also show some time continuity of V^π and U_π. These properties are summarized into the following.

PROPOSITION 3.5. *There is a positive constant L such that for $s \in [0,1], t \in \pi \cap [s,1]$, $a \in A, b \in B, x \in X$, and $y \in X$ we have*

$$
\begin{aligned}
&|V^\pi_{a,b}(s,x)| + |U^{a,b}_\pi(s,x)| \le L(1+|x|), \\
&|V^\pi_{a,b}(s,x) - V^\pi_{a,b}(s,y)| + |U^{a,b}_\pi(s,x) - U^{a,b}_\pi(s,y)| \le L|x-y|, \\
&|V^\pi_{a,b}(s,x) - V^\pi_{a,b}(t,x)| + |U^{a,b}_\pi(s,x) - U^{a,b}_\pi(t,x)| \le L(1+|x|)\sqrt{t-s}.
\end{aligned} \tag{3.48}
$$

Next we assume that $\pi_i = \{j/2^i\}_{j=0}^{2^i}, i = 0,1,2,\ldots$. Then $||\pi_i|| = 1/2^i$, and, from the definition of V^{π_i} and $U_{\pi_i}, i = 0,1,2,\ldots$, and Proposition 3.4, we have

$$
V^{\pi_0}_{a,b} \le V^{\pi_1}_{a,b} \le \cdots \le V^{\pi_i}_{a,b} \le \cdots \le V_{a,b}, \quad (a,b) \in A \times B \tag{3.49a}
$$

and

$$U^{a,b}_{\pi_0} \geq U^{a,b}_{\pi_1} \geq \cdots \geq U^{a,b}_{\pi_i} \geq \cdots \geq U^{a,b}, \quad (a,b) \in A \times B. \tag{3.49b}$$

PROPOSITION 3.6. *For $(a,b) \in A \times B$, let $v_{a,b} = \lim_{i\to\infty} V^{\pi_i}_{a,b}$ and $v := (v_{a,b})_{a\in A, b\in B}$. Then, for $s,t \in [0,1]$ and $x,y \in X$, we have*

$$\begin{aligned} v_{a,b}(s,x) &\leq V_{a,b}(s,x), \\ |v_{a,b}(s,x)| &\leq L(1+|x|), \\ |v_{a,b}(s,x) - v_{a,b}(t,x)| &\leq L(1+|x|)\sqrt{|t-s|}, \\ |v_{a,b}(s,x) - v_{a,b}(s,y)| &\leq L|x-y|. \end{aligned} \tag{3.50a}$$

Similarly, let $u^{a,b} = \lim_{i\to\infty} U^{a,b}_{\pi_i}$ and $u := (u^{a,b})_{a\in A, b\in B}$. Then, for $s,t \in [0,1]$ and $x,y \in X$,

$$\begin{aligned} u^{a,b}(s,x) &\geq U^{a,b}(s,x), \\ |u^{a,b}(s,x)| &\leq L(1+|x|), \\ |u^{a,b}(s,x) - u^{a,b}(t,x)| &\leq L(1+|x|)\sqrt{|t-s|}, \\ |u^{a,b}(s,x) - u^{a,b}(s,y)| &\leq L|x-y|. \end{aligned} \tag{3.50b}$$

Proof of Proposition 3.6. First, we prove (3.50a). Assume, without loss of generality, that $s < t$. Let $\{t_i\}_{i=1}^{\infty} \subset \cup_{i=0}^{\infty}\pi_i \cap [t,1]$ and $\lim_{i\to\infty} t_i = t$. Then we have from Proposition 3.5 that

$$\begin{aligned} &|v_{a,b}(s,x) - v_{a,b}(t,x)| \\ &\leq |v_{a,b}(s,x) - v_{a,b}(t_i,x)| + |v_{a,b}(t_i,x) - v_{a,b}(t,x)| \\ &\leq L(1+|x|)(\sqrt{t_i - s} + \sqrt{t_i - t}), \quad i = 1,2,\ldots. \end{aligned} \tag{3.51}$$

This concludes the $\frac{1}{2}$-Hölder continuity in the time variable of $v_{a,b}$. Its linear growth and uniform Lipschitz continuity in the space variable x is straightforward.

In an identical way, we can show (3.50b). ∎

Passing to the limit $\|\pi\| \to 0$ in Proposition 3.4, we obtain that two functions v and u satisfy the following dynamic programming principle.

PROPOSITION 3.7. *For $(a,b,s,x) \in A \times B \times [0,1] \times X$ and $\hat{s} \in \cup_{i=0}^{\infty}\pi_i \cap [s,1]$, we have*

$$\begin{aligned} v_{a,b}(s,x) = \lim_{i\to\infty} \inf_{\alpha\in\Gamma^a[s,1]} \sup_{b(\cdot)\in\mathcal{B}^b_{\pi_i}[s,1]} E_{sx}\Bigg\{ &\int_s^{\hat{s}} f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\ &+ \sum_{s\leq\theta_j<\hat{s}} k(\theta_j,a_{j-1},a_j) - \sum_{s\leq\tau_j<\hat{s}} l(\tau_j,b_{j-1},b_j) \\ &+ v_{\alpha[b(\cdot)](\hat{s}-),b(\hat{s}-)}(\hat{s},y(\hat{s}))\Bigg\}, \end{aligned} \tag{3.52a}$$

where $b(\cdot) = \{b_j,\tau_j\}$ and $a(\cdot) = \alpha[b(\cdot)] = \{a_j,\theta_j\}$, and

$$\begin{aligned} u^{a,b}(s,x) = \lim_{i\to\infty} \sup_{\beta\in\Delta^b[s,1]} \inf_{a(\cdot)\in\mathcal{A}^a_{\pi_i}[s,1]} E_{sx}\Bigg\{ &\int_s^{\hat{s}} f^0(r,y(r),a(r),\beta[a(\cdot)](r))\,dr \\ &+ \sum_{s\leq\theta_j<\hat{s}} k(\theta_j,a_{j-1},a_j) - \sum_{s\leq\tau_j<\hat{s}} l(\tau_j,b_{j-1},b_j) \\ &+ u^{a(\hat{s}-),\beta[a(\cdot)](\hat{s}-)}(\hat{s},y(\hat{s}))\Bigg\}, \end{aligned} \tag{3.52b}$$

where $a(\cdot) = \{a_j,\theta_j\}$ and $b(\cdot) = \beta[a(\cdot)] = \{b_j,\tau_j\}$.

Proof of Proposition 3.7. We only derive the equality (3.52a) from the equality (3.31a) in Proposition 3.4. The proof of the equality (3.52b) is similar.

Since $\hat{s} \in \cup_{i=0}^{\infty} \pi_i \cap [s,1]$, we have $\hat{s} \in \pi_i \cap [s,1]$ when i is sufficiently large. From Proposition 3.4, we have that, when i is sufficiently large,

$$\begin{aligned} V_{a,b}^{\pi_i}(s,x) = \inf_{\alpha \in \Gamma^a[s,1]} \sup_{b(\cdot) \in \mathcal{B}_{\pi_i}^b[s,1]} E_{sx} \Big\{ & \int_s^{\hat{s}} f^0(r, y(r), \alpha[b(\cdot)](r), b(r))\, dr \\ & + \sum_{s \le \theta_j < \hat{s}} k(\theta_j, a_{j-1}, a_j) - \sum_{s \le \tau_j < \hat{s}} l(\tau_j, b_{j-1}, b_j) \\ & + V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) \Big\}, \end{aligned} \tag{3.53}$$

where $b(\cdot) = \{b_j, \tau_j\}$ and $a(\cdot) = \alpha[b(\cdot)] = \{a_j, \theta_j\}$.

Set, for any $C > 0$,

$$O_C(x) := \{y : |y - x| \le C\}, \quad O_C^c(x) := \{y : |y - x| > C\}.$$

It is easy to see from Propositions 3.5 and 3.6 that

$$\begin{aligned} & E_{sx} |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| \\ & \le E_{sx} \{ \chi_{O_C^c(x)}(y(\hat{s})) |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| \} \\ & \quad + E_{sx} \{ \chi_{O_C(x)}(y(\hat{s})) |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| \} \\ & \le \{ E_{sx} |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))|^2 \}^{\frac{1}{2}} \{ P(O_C^c(x)) \}^{\frac{1}{2}} \\ & \quad + E_{sx} \{ \chi_{O_C(x)}(y(\hat{s})) |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| \}. \end{aligned} \tag{3.54}$$

From Propositions 3.5 and 3.6, we have that, for any given positive constant C,

$$\lim_{i \to \infty} V^{\pi_i}(\hat{s}, y) = v(\hat{s}, y) \quad \text{uniformly in } y \in O_C(x),$$

which implies that

$$\lim_{i \to \infty} E_{sx} \{ \chi_{O_C(x)}(y(\hat{s})) |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| \} = 0. \tag{3.55}$$

Moreover,

$$E_{sx} |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))|^2 \le L(1 + E_{sx}|y(\hat{s})|^2). \tag{3.56}$$

Since

$$\begin{aligned} & E_{sx}|y(\hat{s})|^2 \le L(1 + |x|^2), \\ & P(O_C^c(x)) \le C^{-2} E_{sx}|y(\hat{s}) - x|^2 \le LC^{-2}(1 + |x|^2), \end{aligned} \tag{3.57}$$

we see that

$$0 \le \overline{\lim_{i \to \infty}} \sup_{\alpha, b(\cdot)} E_{sx} |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| \le LC^{-2}(1 + |x|^2)$$

for an arbitrary sufficiently large positive number C, and therefore

$$\lim_{i \to \infty} \sup_{\alpha, b(\cdot)} E_{sx} |V_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}^{\pi_i}(\hat{s}, y(\hat{s})) - v_{\alpha[b(\cdot)](\hat{s}-), b(\hat{s}-)}(\hat{s}, y(\hat{s}))| = 0. \tag{3.58}$$

The last equality implies (3.52a) immediately. □

Note that

$$v_{a,b}(1,x) = u^{a,b}(1,x) = h(x), \quad (a,b,x) \in A \times B \times X. \tag{3.59}$$

It follows from Proposition 3.7 that, for $(a,b,s,x) \in A \times B \times [0,1] \times X$,

$$\begin{aligned} v_{a,b}(s,x) = \lim_{i\to\infty} \inf_{\alpha\in\Gamma^a[s,1]} \sup_{b(\cdot)\in\mathcal{B}^b_{\pi_i}[s,1]} E_{sx}\Big\{ & \int_s^1 f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\ & + \sum_{s\le\theta_j<1} k(\theta_j,a_{j-1},a_j) - \sum_{s\le\tau_j<1} l(\tau_j,b_{j-1},b_j) + h(y(1))\Big\}, \end{aligned} \tag{3.60a}$$

where $b(\cdot) = \{b_j,\tau_j\}$ and $a(\cdot) = \alpha[b(\cdot)] = \{a_j,\theta_j\}$, and

$$\begin{aligned} u^{a,b}(s,x) = \lim_{i\to\infty} \sup_{\beta\in\Delta^b[s,1]} \inf_{a(\cdot)\in\mathcal{A}^a_{\pi_i}[s,1]} E_{sx}\Big\{ & \int_s^1 f^0(r,y(r),a(r),\beta[a(\cdot)](r))\,dr \\ & + \sum_{s\le\theta_j<1} k(\theta_j,a_{j-1},a_j) - \sum_{s\le\tau_j<1} l(\tau_j,b_{j-1},b_j) + h(y(1))\Big\}, \end{aligned} \tag{3.60b}$$

where $a(\cdot) = \{a_j,\theta_j\}$ and $b(\cdot) = \beta[a(\cdot)] = \{b_j,\tau_j\}$. From the above two formulas, we have

$$M_{a,b}[v](s,x) \le v_{a,b}(s,x) \le M^{a,b}[v](s,x), \quad (a,b,s,x) \in A \times B \times [0,1] \times X, \tag{3.61a}$$

and

$$M_{a,b}[u](s,x) \le u^{a,b}(s,x) \le M^{a,b}[u](s,x), \quad (a,b,s,x) \in A \times B \times [0,1] \times X. \tag{3.61b}$$

In view of the time continuity given by Proposition 3.6, the deterministic time $\hat{s}$ may be replaced in Proposition 3.7 with an arbitrary stopping time which takes values in $[s,1]$. That is, we have the following.

PROPOSITION 3.8. *For $(a,b,s,x) \in A \times B \times [0,1] \times X$ and any stopping time τ which take values in $[s,1]$, we have*

$$\begin{aligned} v_{a,b}(s,x) = \lim_{i\to\infty} \inf_{\alpha\in\Gamma^a[s,1]} \sup_{b(\cdot)\in\mathcal{B}^b_{\pi_i}[s,1]} E_{sx}\Big\{ & \int_s^\tau f^0(r,y(r),\alpha[b(\cdot)](r),b(r))\,dr \\ & + \sum_{s\le\theta_j<\tau} k(\theta_j,a_{j-1},a_j) - \sum_{s\le\tau_j<\tau} l(\tau_j,b_{j-1},b_j) \\ & + v_{\alpha[b(\cdot)](\tau-),b(\tau-)}(\tau,y(\tau))\Big\}, \end{aligned} \tag{3.62a}$$

where $b(\cdot) = \{b_j,\tau_j\}$ and $a(\cdot) = \alpha[b(\cdot)] = \{a_j,\theta_j\}$, and

$$\begin{aligned} u^{a,b}(s,x) = \lim_{i\to\infty} \sup_{\beta\in\Delta^b[s,1]} \inf_{a(\cdot)\in\mathcal{A}^a_{\pi_i}[s,1]} E_{sx}\Big\{ & \int_s^\tau f^0(r,y(r),a(r),\beta[a(\cdot)](r))\,dr \\ & + \sum_{s\le\theta_j<\tau} k(\theta_j,a_{j-1},a_j) - \sum_{s\le\tau_j<\tau} l(\tau_j,b_{j-1},b_j) \\ & + u^{a(\tau-),\beta[a(\cdot)](\tau-)}(\tau,y(\tau))\Big\}, \end{aligned} \tag{3.62b}$$

where $a(\cdot) = \{a_j,\theta_j\}$ and $b(\cdot) = \beta[a(\cdot)] = \{b_j,\tau_j\}$.

Proceeding similarly as in the proof of Proposition 3.3, we derive from Proposition 3.8 the following.

PROPOSITION 3.9. (1) *The lower value function* $v(\cdot,\cdot) := (v_{a,b})_{a\in A, b\in B}$ *satisfies the following: Suppose at* $(a,b,s,x) \in A\times B\times[0,1]\times X$,

$$v_{a,b}(s,x) > M_{a,b}[v](s,x) \quad (\text{resp., } v_{a,b}(s,x) < M^{a,b}[v](s,x)). \tag{3.63a}$$

Then there exist a deterministic time $s_0 > s$ *and a sufficiently small number* $\delta_0 > 0$, *such that for all* $\hat{s} \in [s, s_0]$ *and* $\delta \in (0, \delta_0]$,

(3.63b)

$$v_{a,b}(s,x) \leq \ (\text{resp., } \geq)\ E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(r, y^{a,b}(r), a, b)\, dr + v_{a,b}(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta))\right\}.$$

Here we have abbreviated $\tau^\delta_{s,x}(a,b)$ *as* τ^δ.

(2) *The upper value function* $u(\cdot,\cdot) := (u^{a,b})_{a\in A, b\in B}$ *satisfies the following: Suppose at* $(a,b,s,x) \in A\times B\times[0,1]\times X$,

$$u^{a,b}(s,x) < M^{a,b}[u](s,x) \quad (\text{resp., } u^{a,b}(s,x) > M_{a,b}[u](s,x)). \tag{3.64a}$$

Then there exist a deterministic time $s_0 > s$ *and a sufficiently small number* $\delta_0 > 0$, *such that for all* $\hat{s} \in [s, s_0]$ *and* $\delta \in (0, \delta_0]$,

(3.64b)

$$u^{a,b}(s,x) \geq \ (\text{resp., } \leq)\ E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(r, y^{a,b}(r), a, b)\, dr + u^{a,b}(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta))\right\}.$$

Here we have abbreviated $\tau^\delta_{s,x}(a,b)$ *as* τ^δ.

4. Viscosity solutions, uniqueness result, dynamic programming equations, and existence of the game value. In this section, we shall introduce the generalized notion of viscosity solution for our Isaacs' system of variational inequalities. The value functions defined in sections 2 and 3 turn out to be its viscosity sub- or supersolutions. We then prove the uniqueness of the viscosity solution and establish the existence of the value of our stochastic switching game.

Define for $(a,b,t,x,q,Q) \in A\times B\times[0,1]\times X\times X\times\mathcal{S}$,

$$H^{a,b}(t,x,q,Q) := \ f^0(t,x,a,b) + < q, f(t,x,a,b) > + \frac{1}{2}\mathrm{tr}(Qgg^*(t,x,a,b)). \tag{4.1}$$

Here $\mathcal{S}$ is the set of all real symmetric transformations in X. Let $C^{1,2}([0,1)\times X)$ be the set of all continuous functions which are continuously differentiable in t and twice continuously differentiable in x.

Associated with our stochastic switching game is the following Isaacs' system of quasi-variational inequalities where W is to be solved:

(1) For $(a,b,t,x) \in A\times B\times[0,1]\times X$,

$$M_{a,b}[W](t,x) \leq W_{a,b}(t,x) \leq M^{a,b}[W](t,x); \tag{4.2}$$

(2) for $(a,b,t,x) \in A\times B\times[0,1]\times X$ such that $W_{a,b}(t,x) > M_{a,b}[W](t,x)$,

$$\frac{\partial}{\partial t}W_{a,b}(t,x) + H^{a,b}(t,x,\nabla W_{a,b}(t,x), \nabla^2 W_{a,b}(t,x)) \geq 0; \tag{4.3}$$

(3) for $(a,b,t,x) \in A \times B \times [0,1] \times X$ such that $W_{a,b}(t,x) < M^{a,b}[W](t,x)$,

$$\frac{\partial}{\partial t} W_{a,b}(t,x) + H^{a,b}(t,x,\nabla W_{a,b}(t,x), \nabla^2 W_{a,b}(t,x)) \le 0; \tag{4.4}$$

(4) the terminal condition

$$W_{a,b}(1,x) = h(x), \quad (a,b,x) \in A \times B \times X. \tag{4.5}$$

DEFINITION 4.1. *An $\mathbb{R}^{m\times n}$-valued continuous function $W = (W_{a,b})_{a\in A, b\in B}$ on $[0,T]\times X$ is called a viscosity sub- (resp., super-) solution of* (4.2)–(4.5) *if it satisfies* (4.2) *and* (4.5)*, and moreover, for any $\varphi(\cdot,\cdot) \in C^{1,2}([0,1)\times X)$ and $(a,b) \in A \times B$, whenever $W_{a,b}(\cdot,\cdot) - \varphi(\cdot,\cdot)$ attains a local maximum (resp., minimum) at $(t_0,x_0) \in [0,1)\times X$ and*

$$W_{a,b}(t_0,x_0) > M_{a,b}[W](t_0,x_0) \quad (\text{resp., } W_{a,b}(t_0,x_0) < M^{a,b}[W](t_0,x_0)),$$

we have

$$\frac{\partial}{\partial t}\varphi(t_0,x_0) + H^{a,b}(t_0,x_0,\nabla\varphi(t_0,x_0),\nabla^2\varphi(t_0,x_0)) \ge 0$$
$$\left(\textit{resp.,}\ \frac{\partial}{\partial t}\varphi(t_0,x_0) + H^{a,b}(t_0,x_0,\nabla\varphi(t_0,x_0),\nabla^2\varphi(t_0,x_0)) \le 0\right).$$

An $\mathbb{R}^{m\times n}$-valued function $W = (W_{a,b})_{a\in A,b\in B}$ on $[0,T]\times X$ is called a viscosity solution of (4.2)–(4.5) *if it is both a viscosity sub- and supersolution of* (4.2)–(4.5).

Propositions 3.3 and 3.9 imply the following result.

PROPOSITION 4.1. (1) *The r-lower and r-upper value functions V^1 and U_1 are viscosity sub- and supersolutions of* (4.2)–(4.5), respectively.

(2) The functions $v = (v_{a,b})$ and $u = (u^{a,b})$ defined in Proposition 3.6 *are viscosity solutions of* (4.2)–(4.5).

Proof of Proposition 4.1. We now prove that the r-lower value function V^1 is a viscosity subsolution of (4.2)–(4.5). From the definition, it follows that $V^1_{a,b} = h$ for $(a,b) \in A \times B$. In view of (2.11), we see that V^1 satisfies (4.2).

Consider $\varphi(\cdot,\cdot) \in C^{1,2}([0,1)\times X)$ and $(a,b) \in A\times B$. Assume that $V^1_{a,b}(\cdot,\cdot) - \varphi(\cdot,\cdot)$ attains a local maximum at $(s,x) \in [0,1)\times X$ and

$$V^1_{a,b}(s,x) > M_{a,b}[V^1](s,x).$$

From Proposition 3.3, we see that there exist a deterministic time $s_0 > s$ and a sufficiently small number $\delta_0 > 0$, such that for all $\hat{s} \in (s,s_0]$ and $\delta \in (0,\delta_0]$, we have

$$V^1_{a,b}(s,x) \le E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(r,y^{a,b}(r),a,b)\,dr + V^1_{a,b}(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta))\right\}.$$

Here we have abbreviated $\tau^\delta_{s,x}(a,b)$ as τ^δ. For sufficiently small $\hat{s} \in [s,s_0]$ and $\delta \in (0,\delta_0]$, we have

$$V^1_{a,b}(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta)) - \varphi(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta)) \le V^1(s,x) - \varphi(s,x). \tag{4.6}$$

Therefore,

$$E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta} f^0(r,y^{a,b}(r),a,b)\,dr + \varphi(\hat{s}\wedge\tau^\delta, y^{a,b}(\hat{s}\wedge\tau^\delta)) - \varphi(s,x)\right\} \ge 0.$$

From Itô's formula, we conclude that

$$E_{sx}\int_s^{\hat{s}\wedge\tau^\delta}\left[\frac{\partial}{\partial t}\varphi(r,y^{a,b}(r))+H^{a,b}(r,y^{a,b}(r),\nabla\varphi(r,y^{a,b}(r)),\nabla^2\varphi(r,y^{a,b}(r)))\right]dr\geq 0.$$

Noting (see the arguments following Remark 3.1) that

$$\lim_{\hat{s}\to s+}\frac{P(\{\tau^\delta\leq\hat{s}\})}{\hat{s}-s}=0,$$

we have

$$\begin{aligned}0&\leq\lim_{\hat{s}\to s+}(\hat{s}-s)^{-1}E_{sx}\left\{\int_s^{\hat{s}\wedge\tau^\delta}\left[\frac{\partial}{\partial t}\varphi(r,y^{a,b}(r))+H^{a,b}(\cdots)\right]dr\right\}\\&=\lim_{\hat{s}\to s+}(\hat{s}-s)^{-1}E_{sx}\left\{\chi_{\{\hat{s}\leq\tau^\delta\}}\int_s^{\hat{s}}\left[\frac{\partial}{\partial t}\varphi(r,y^{a,b}(r))+H^{a,b}(\cdots)\right]dr\right\}\\&=\frac{\partial}{\partial t}\varphi(s,x)+H^{a,b}(s,x,\nabla\varphi(s,x),\nabla^2\varphi(t,x)).\end{aligned}$$

Concluding the above, we see that V^1 is a viscosity subsolution.

Noting (3.59), (3.61a), and (3.61b), we can prove all other assertions in Proposition 4.1 in an identical way. □

Let us introduce the following sets, which are adopted from Evans and Ishii [5]. For function $v:[0,1]\times X\to[-\infty,+\infty]$ and $(s,z)\in[0,1)\times X$, define

$$\begin{aligned}\wp^{2,+}v(s,z):=\Big\{&(p,q,Q)\in\mathbb{R}\times X\times\mathcal{S}:v(t,x)\\&\leq v(s,z)+p(t-s)+\langle q,x-z\rangle+\tfrac{1}{2}\langle Q(x-z),x-z\rangle\\&\quad+o(|t-s|+|x-z|^2)\text{ as }[0,1]\times X\ni(t,x)\to(s,z)\Big\},\end{aligned}\tag{4.7}$$

$$\begin{aligned}\bar{\wp}^{2,+}v(s,z):=\Big\{&(p,q,Q)\in\mathbb{R}\times X\times\mathcal{S}:\exists(t_i,x_i)\in[0,1]\times X,\\&(p_i,q_i,Q_i)\in\wp^{2,+}v(t_i,x_i),\\&(t_i,x_i,v(t_i,x_i),p_i,q_i,Q_i)\to(s,z,v(s,z),p,q,Q)\Big\}.\end{aligned}\tag{4.8}$$

Define for $(s,z)\in[0,1)\times X$

$$\wp^{2,-}v(s,z)=-\wp^{2,+}(-v)(s,z)\text{ and }\bar{\wp}^{2,-}v(s,z)=-\bar{\wp}^{2,+}(-v)(s,z).\tag{4.9}$$

The following result is standard.

PROPOSITION 4.2. *An $\mathbb{R}^{m\times n}$-valued function $W=(W_{a,b})_{a\in A,b\in B}$ on $[0,T]\times X$ is a viscosity sub- (resp., super-) solution of* (4.2)–(4.5) *if and only if it satisfies* (4.2) *and* (4.5)*, and moreover, for any $(t,x,a,b)\in[0,1)\times X\times A\times B$, whenever $(p,q,Q)\in\bar{\wp}^{2,+}W_{a,b}(t,x)$ (resp., $\bar{\wp}^{2,-}W_{a,b}(t,x)$) and*

$$W_{a,b}(t_0,x_0)>M_{a,b}[W](t_0,x_0)\quad(\text{resp., }W_{a,b}(t_0,x_0)<M^{a,b}[W](t_0,x_0)),$$

we have

$$p+H^{a,b}(t,x,q,Q)\geq 0\text{ (resp., }p+H^{a,b}(t,x,q,Q)\leq 0).\tag{4.10}$$

Now let us make a further assumption that will play an important role in the proof of the uniqueness result.

Hypothsis 4. For any loop $\{a_i, b_i\}_{i=1}^{j+1} \subset A \times B$, with the properties that

$$\begin{aligned} &j \le mn, \quad a_{j+1} = a_1, \quad b_{j+1} = b_1, \\ &\text{and either} \quad a_{i+1} = a_i \quad \text{or} \quad b_{i+1} = b_i \quad \forall\, 1 \le i \le j, \end{aligned} \tag{4.11}$$

we have

$$\sum_{i=1}^{j} k(s, a_i, a_{i+1}) - \sum_{i=1}^{j} l(s, b_i, b_{i+1}) \neq 0 \quad \forall s \in [0,1]. \tag{4.12}$$

THEOREM 4.1. *Assume Hypotheses* 1–4. *If* W *and* $\widehat{W}$ *are continuous viscosity sub- and supersolutions of* (4.2)–(4.5), *respectively, and satisfy for* $(t, x, y, a, b) \in [0,1] \times X \times X \times A \times B$ *the following:*

$$\begin{aligned} &|W_{a,b}(t,x)| + |\widehat{W}_{a,b}(t,x)| \le C(1 + |x|), \\ &|W_{a,b}(t,x) - W_{a,b}(t,y)| + |\widehat{W}_{a,b}(t,x) - \widehat{W}_{a,b}(t,y)| \le C|x - y|, \end{aligned} \tag{4.13}$$

then

$$W_{a,b}(t,x) \le \widehat{W}_{a,b}(t,x) \quad \forall (t,x,a,b) \in [0,1] \times X \times A \times B. \tag{4.14}$$

Proof of Theorem 4.1. We prove the theorem by contradiction. So suppose that $\exists (\bar{a}, \bar{b}, \bar{t}, \bar{x}) \in A \times B \times (0,1) \times X$ such that

$$W_{\bar{a},\bar{b}}(\bar{t}, \bar{x}) - \widehat{W}_{\bar{a},\bar{b}}(\bar{t}, \bar{x}) = \eta > 0. \tag{4.15}$$

Consider the following test function:

$$\psi(t,x,y) = \frac{|x-y|^2}{2\varepsilon} + \alpha e^{-\beta t}(1 + |x|^2 + |y|^2), \quad (t,x,y) \in [0,1] \times X \times X, \tag{4.16}$$

with parameters $\alpha > 0$ and $\beta > 0$. We choose a sufficiently small $\alpha > 0$ such that it does not depend on the parameter $\beta > 0$ and that it satisfies the following:

$$\psi(\bar{t}, \bar{x}, \bar{x}) < \frac{\eta}{2} \quad \forall \beta > 0. \tag{4.17}$$

Now consider the function

$$\Psi^{a,b}(t,x,y) = W_{a,b}(t,x) - \widehat{W}_{a,b}(t,y) - \psi(t,x,y), \quad (a,b,t,x,y) \in A \times B \times [0,1] \times X \times X. \tag{4.18}$$

From (4.13), (4.15), and (4.17), we see that there is a point $(a_0, b_0, t_0, x_0, y_0) \in A \times B \times [0,1] \times X \times X$ such that

$$\Psi^{a_0,b_0}(t_0, x_0, y_0) = \max_{\substack{a \in A \\ b \in B}} \sup_{t,x,y} \Psi^{a,b}(t,x,y) \ge \Psi^{\bar{a},\bar{b}}(\bar{t}, \bar{x}, \bar{x}) \ge \frac{\eta}{2}. \tag{4.19}$$

At this stage, we have the following two conclusions.

Conclusion 1. Following the arguments of Yamada [9, pp. 424–425], we can show the following assertion: Without loss of generality, we may assume that

$$M_{a_0,b_0}[W](t_0, x_0) < W_{a_0,b_0}(t_0, x_0), \quad M^{a_0,b_0}[\widehat{W}](t_0, y_0) > \widehat{W}_{a_0,b_0}(t_0, y_0). \tag{4.20}$$

Otherwise, we have

$$M_{a_0,b_0}[W](t_0,x_0)=W_{a_0,b_0}(t_0,x_0)\quad\text{or}\quad M^{a_0,b_0}[\widehat{W}](t_0,y_0)=\widehat{W}_{a_0,b_0}(t_0,y_0). \tag{4.21}$$

Consequently, there is $b_1\in B$ or $a_1\in A$ such that

$$W_{a_0,b_0}(t_0,x_0)=W_{a_0,b_1}(t_0,x_0)-l(t_0,b_0,b_1) \tag{4.22}$$

or

$$\widehat{W}_{a_0,b_0}(t_0,y_0)=\widehat{W}_{a_1,b_0}(t_0,y_0)+k(t_0,a_0,a_1). \tag{4.23}$$

On the other hand, from (4.19), we have

$$\Psi^{a_0,b_0}(t_0,x_0,y_0)\geq\Psi^{a_1,b_0}(t_0,x_0,y_0), \tag{4.24}$$

which implies immediately

$$W_{a_0,b_0}(t_0,x_0)-\widehat{W}_{a_0,b_0}(t_0,y_0)\geq W_{a_1,b_0}(t_0,x_0)-\widehat{W}_{a_1,b_0}(t_0,y_0). \tag{4.25}$$

Therefore, we have

$$\begin{aligned}0\geq&W_{a_0,b_0}(t_0,x_0)-W_{a_1,b_0}(t_0,x_0)-k(t_0,a_0,a_1)\\ \geq&\widehat{W}_{a_0,b_0}(t_0,y_0)-\widehat{W}_{a_1,b_0}(t_0,y_0)-k(t_0,a_0,a_1),\end{aligned} \tag{4.26}$$

which shows the following:

$$W_{a_0,b_0}(t_0,x_0)=W_{a_1,b_0}(t_0,x_0)+k(t_0,a_0,a_1) \tag{4.27}$$

if (4.23) is true. In summary, there is $b_1\in B$ or $a_1\in A$ such that either (4.22) or (4.27) is true. Moreover, we have

$$W_{a_0,b_0}(t_0,x_0)-\widehat{W}_{a_0,b_0}(t_0,y_0)=W_{a_1,b_0}(t_0,x_0)-\widehat{W}_{a_1,b_0}(t_0,y_0), \tag{4.28}$$

from which it follows that

$$\Psi^{a_0,b_0}(t_0,x_0,y_0)=\Psi^{a_1,b_0}(t_0,x_0,y_0)=\max_{\substack{a\in A\\ b\in B}}\sup_{t,x,y}\Psi^{a,b}(t,x,y). \tag{4.29}$$

Symmetrically, we have

$$\Psi^{a_0,b_0}(t_0,x_0,y_0)=\Psi^{a_0,b_1}(t_0,x_0,y_0)=\max_{\substack{a\in A\\ b\in B}}\sup_{t,x,y}\Psi^{a,b}(t,x,y). \tag{4.30}$$

Set $(\tilde{a}_1,\tilde{b}_1):=(a_0,b_0)$. We can repeat the above argument to start from the pair of parameters $(\tilde{a}_2,\tilde{b}_2)$—which is $(a_1,\tilde{b}_1)$ or $(\tilde{a}_1,b_1)$—to find a new pair of parameters (a_2,b_2) such that either

$$W_{\tilde{a}_2,\tilde{b}_2}(t_0,x_0)=W_{\tilde{a}_2,b_2}(t_0,x_0)-l(t_0,\tilde{b}_2,b_2) \tag{4.31}$$

or

$$W_{\tilde{a}_2,\tilde{b}_2}(t_0,x_0)=W_{a_2,\tilde{b}_2}(t_0,x_0)+k(t_0,\tilde{a}_2,a_2) \tag{4.32}$$

is true. Moreover,

$$\Psi^{\tilde{a}_2,b_2}(t_0,x_0,y_0)=\Psi^{a_2,\tilde{b}_2}(t_0,x_0,y_0)=\max_{\substack{a\in A\\ b\in B}}\sup_{t,x,y}\Psi^{a,b}(t,x,y). \tag{4.33}$$

Then we can continue the procedure until we find a loop $\{\tilde{a}_i,\tilde{b}_i\}_{i=1}^{j+1}$ which satisfies the properties (4.11). Summing up (4.31)–(4.32) for the loop, we get

$$\sum_{i=1}^{j}k(s,\tilde{a}_i,\tilde{a}_{i+1})-\sum_{i=1}^{j}l(s,\tilde{b}_i,\tilde{b}_{i+1})=0. \tag{4.34}$$

Then we get a contradiction to Hypothesis 4.

Conclusion 2. On the maximum point (a_0,b_0,t_0,x_0,y_0), we have the following properties:

(i) There is a constant $C_{\alpha,\beta}$, which depends on positive α,β such that $|x_0|+|y_0|\le C_{\alpha,\beta}$;

(ii) from (4.13) and the following inequality:

$$2\Psi^{a_0,b_0}(t_0,x_0,y_0)\ge\Psi^{a_0,b_0}(t_0,x_0,x_0)+\Psi^{a_0,b_0}(t_0,y_0,y_0),$$

we obtain $|x_0-y_0|\le\varepsilon C_{\alpha,\beta}$. Hence, $|x_0-y_0|\to 0$ as $\varepsilon\to 0$, while keeping α and β fixed;

(iii) since $\Psi^{a_0,b_0}(1,x_0,y_0)\le h(x_0)-h(y_0)\le C|x_0-y_0|$, we conclude from (4.19) that $t_0\in[0,1)$ whenever $\varepsilon>0$ is sufficiently small.

A simple computation gives rise to the following:

$$\begin{aligned}
\partial_t\psi(t,x,y)&=-\beta\alpha e^{-\beta t}(1+|x|^2+|y|^2),\\
\partial_x\psi(t,x,y)&=\frac{(x-y)}{\varepsilon}+2\alpha e^{-\beta t}x,\\
\partial_y\psi(t,x,y)&=\frac{(y-x)}{\varepsilon}+2\alpha e^{-\beta t}y,\\
\partial^2_{(x,y)}\psi(t,x,y)&=\frac{1}{\varepsilon}\begin{pmatrix}I&-I\\-I&I\end{pmatrix}+2\alpha e^{-\beta t}\begin{pmatrix}I&0\\0&I\end{pmatrix}.
\end{aligned} \tag{4.35}$$

Then, applying Theorem 9 of Evans and Ishii [5] to the function

$$W_{a_0,b_0}(t,x)+(-\widehat{W}_{a_0,b_0})(t,y)-\psi(t,x,y)$$

at the point (t_0,x_0,y_0), we can find $p_1,p_2\in\mathbb{R}$ and $Q_1,Q_2\in\mathcal{S}$ such that

$$\begin{aligned}
&(p_1,\partial_x\psi(t_0,x_0,y_0),Q_1)\in\bar{\wp}^{2,+}W_{a_0,b_0}(t_0,x_0),\\
&(p_2,\partial_y\psi(t_0,x_0,y_0),Q_2)\in\bar{\wp}^{2,+}(-\widehat{W}_{a_0,b_0})(t_0,y_0),\\
&p_1+p_2=\partial_t\psi(t_0,x_0,y_0),\\
&\begin{pmatrix}Q_1&0\\0&Q_2\end{pmatrix}\le\partial^2_{(x,y)}\psi(t_0,x_0,y_0)+\varepsilon\Big(\partial^2_{(x,y)}\psi(t_0,x_0,y_0)\Big)^2.
\end{aligned} \tag{4.36}$$

By the definitions of viscosity sub- and supersolutions, and in view of (4.20), we have

$$\begin{aligned}
p_1+H^{a,b}\left(t_0,x_0,\frac{(x_0-y_0)}{\varepsilon}+2\alpha e^{-\beta t_0}x_0,Q_1\right)&\ge 0,\\
-p_2+H^{a,b}\left(t_0,y_0,-\frac{(y_0-x_0)}{\varepsilon}-2\alpha e^{-\beta t_0}y_0,-Q_2\right)&\le 0.
\end{aligned} \tag{4.37}$$

Thus, we have (see (4.36))

$$\begin{aligned}
&\beta\alpha e^{-\beta t_0}(1+|x_0|^2+|y_0|^2)\\
&\le H^{a,b}\left(t_0,x_0,\frac{(x_0-y_0)}{\varepsilon}+2\alpha e^{-\beta t_0}x_0,Q_1\right)\\
&\quad - H^{a,b}\left(t_0,y_0,-\frac{(y_0-x_0)}{\varepsilon}-2\alpha e^{-\beta t_0}y_0,-Q_2\right)\\
&\le \frac{1}{2}\mathrm{tr}[(g^*Q_1g)(t_0,x_0,a_0,b_0)+(g^*Q_2g)(t_0,y_0,a_0,b_0)]\\
&\quad + \left[\left\langle\frac{x_0-y_0}{\varepsilon},f(t_0,x_0,a_0,b_0)-f(t_0,y_0,a_0,b_0)\right\rangle\right.\\
&\quad \left.+2\alpha e^{-\beta t_0}\Big(\langle x_0,f(t_0,x_0,a_0,b_0)\rangle+\langle y_0,f(t_0,y_0,a_0,b_0)\rangle\Big)\right]\\
&\quad + f^0(t_0,x_0,a_0,b_0)-f^0(t_0,y_0,a_0,b_0).
\end{aligned}$$

Set

$$\begin{aligned}
\text{(I)} &:= \frac{1}{2}\mathrm{tr}[(g^*Q_1g)(t_0,x_0,a_0,b_0)+(g^*Q_2g)(t_0,y_0,a_0,b_0)]\\
\text{(II)} &:= \left\langle\frac{x_0-y_0}{\varepsilon},f(t_0,x_0,a_0,b_0)-f(t_0,y_0,a_0,b_0)\right\rangle\\
&\quad + 2\alpha e^{-\beta t_0}\left(\langle x_0,f(t_0,x_0,a_0,b_0)\rangle+\langle y_0,f(t_0,y_0,a_0,b_0)\rangle\right)\\
\text{(III)} &:= f^0(t_0,x_0,a_0,b_0)-f^0(t_0,y_0,a_0,b_0).
\end{aligned}$$

We now estimate (I), (II), and (III) separately. It is immediate that

$$\begin{aligned}
&\partial^2_{(x,y)}\psi(t_0,x_0,y_0)+\varepsilon\Big(\partial^2_{(x,y)}\psi(t_0,x_0,y_0)\Big)^2\\
&\le \frac{3}{\varepsilon}\begin{pmatrix} I & -I\\ -I & I\end{pmatrix}+4\alpha e^{-\beta t_0}\begin{pmatrix} I & -I\\ -I & I\end{pmatrix}\\
&\quad +(4\varepsilon\alpha^2e^{-2\beta t_0}+2\alpha e^{-\beta t_0})\begin{pmatrix} I & 0\\ 0 & I\end{pmatrix}.
\end{aligned}\tag{4.38}$$

Then we have

$$\begin{aligned}
\text{(I)} &\le \frac{C}{\varepsilon}|x_0-y_0|^2+C\alpha e^{-\beta t_0}|x_0-y_0|^2\\
&\quad + C(2\varepsilon\alpha^2e^{-2\beta t_0}+\alpha e^{-\beta t_0})(1+|x_0|^2+|y_0|^2),\\
\text{(II)} &\le \frac{C}{\varepsilon}|x_0-y_0|^2+C\alpha e^{-\beta t_0}(1+|x_0|^2+|y_0|^2),\\
\text{(III)} &\le C|x_0-y_0|.
\end{aligned}\tag{4.39}$$

Hence, we have

$$\begin{aligned}
&\beta\alpha e^{-\beta t_0}(1+|x_0|^2+|y_0|^2)\\
&\le \frac{C}{\varepsilon}|x_0-y_0|^2+C|x_0-y_0|+C\alpha e^{-\beta t_0}(|x_0-y_0|^2+1+|x_0|^2+|y_0|^2)\\
&\quad + C(2\varepsilon\alpha^2e^{-2\beta t_0}+\alpha e^{-\beta t_0})(1+|x_0|^2+|y_0|^2).
\end{aligned}\tag{4.40}$$

Letting $\varepsilon \to 0$, we get

$$(4.41)\quad \beta\alpha e^{-\beta t}(1+2|x|^2) \le C\alpha e^{-\beta t}(1+2|x|^2) + C(2\varepsilon\alpha^2 e^{-2\beta t} + \alpha e^{-\beta t})(1+2|x|^2)$$

for some $(t,x) \in [0,1] \times X$, which immediately implies $\beta \le C + C\alpha$. Since we can choose β to be sufficiently large so that $\beta > C + \alpha C$, we arrive at a contradiction. Hence, (4.14) is proved. □

Remark 4.1. Note that the stochastic nature leads to the corresponding Isaacs' system of variational inequalities involving a second-order differential operator, and thus the proof of the uniqueness of the viscosity solutions necessarily involves the computation of the second-order differentials of the chosen test function, say, ψ in our proof. Due to this feature, the test function used by Yong [10] does not seem to carry over to our case. Here we use a different test function. It is both simpler and more powerful in proving the uniqueness of unbounded viscosity solutions, as is shown in the above proof.

THEOREM 4.2. *Let Hypotheses* 1–4 *be satisfied. Then our stochastic differential switching game described by* (1.1) *and* (1.2) *has a value. The function* $V^1 = v = V = U = u = U^1$ *is the unique viscosity solution of* (4.2)–(4.5).

Proof of Theorem 4.2. From Proposition 4.1, we see that V^1 is a viscosity subsolution and v is a viscosity supersolution, while u is a viscosity subsolution and U^1 is a viscosity supersolution. From Theorem 4.1, it follows immediately that

$$V^1_{a,b}(t,x) \le v_{a,b}(t,x) \text{ and } u^{a,b}(t,x) \le U_1^{a,b}(t,x), \quad (t,x,a,b) \in [0,1] \times X \times A \times B.$$

In view of Proposition 3.6, we have

$$V^1_{a,b} \le v_{a,b} \le V_{a,b}, \quad U_1^{a,b} \ge u^{a,b} \ge U^{a,b}, \quad (a,b) \in A \times B.$$

Combining these inequalities with (2.9), we have

$$V^1_{a,b} = v_{a,b} = V_{a,b}, \quad U_1^{a,b} = u^{a,b} = U^{a,b}, \quad (a,b) \in A \times B.$$

In short form, we have

$$V^1 = v = V, \quad U_1 = u = U.$$

From Proposition 4.1, we also know that u and v are two viscosity solutions of (4.2)–(4.5). By Theorem 4.1, we have $u = v$.

Concluding the above, we have

$$V^1 = v = V = U_1 = u = U.$$

Therefore, our stochastic differential switching game described by (1.1) and (1.2) has a value, and the function $V^1 = v = V = U = u = U^1$ is the unique viscosity solution of (4.2)–(4.5). □

A BIRKHOFF CONTRACTION FORMULA WITH APPLICATIONS TO RICCATI EQUATIONS*

JIMMIE LAWSON† AND YONGDO LIM‡

Abstract. In this paper we show that the symplectic Hamiltonian operators on a Hilbert space give rise to linear fractional transformations on the open convex cone of positive definite operators that contract a natural invariant Finsler metric, the Thompson or part metric, on the convex cone. More precisely, the constants of contraction for the Hamiltonian operators satisfy the classical Birkhoff formula: the Lipschitz constant for the corresponding linear fractional transformations on the cone of positive definite operators is equal to the hyperbolic tangent of one fourth the diameter of the image. By means of the close connections between Hamilitonian operators and Riccati equations, this result and the associated machinery are applied to obtain convergence results for discrete algebraic Riccati equations and Riccati differential equations.

Key words. Riccati equation, Birkhoff formula, contraction, symplectic group, control theory, Lie semigroup, Hamiltonian operator, positive definite operator

1. Introduction.

Connections between linear control theory, the Riccati equation, and the symplectic group are well known; see, for example, Hermann [13], Shayman [22], Jurdjevic [14, Chapter 8], and [23], and the references cited in those sources. In this paper we focus particularly on connections to the symplectic subsemigroup, which consists of those symplectic transformations that are sometimes called Hamiltonian. In [15] we studied in some detail this subsemigroup of symplectic operators in the infinite dimensional setting and its close connection to Riccati differential equations arising in linear control systems. The canonical triple factorization of symplectic Hamiltonian operators and their action via linear fractional transformation on the open convex cone $\mathcal{P}_0$ of positive definite operators on a Hilbert space have played key roles in the study of Riccati equations via Lie semigroup theory. In this paper we study the contraction property of symplectic Hamiltonian operators acting on the convex cone $\mathcal{P}_0$ for the natural *invariant* Finsler metric (Thompson's part metric), and apply it to finite- and infinite dimensional discrete algebraic Riccati equations and Riccati differential equations.

One of our main results is the Birkhoff theorem (section 5) for symplectic Hamiltonian operators with respect to Thompson's metric $p(X, Y)$: each symplectic Hamiltonian $g = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$, regarded as the self map on $\mathcal{P}_0$ given by the linear fractional transformation

$$g.X = (AX + B)(CX + D)^{-1},$$

satisfies the contraction formula

$$\sup_{\substack{X,Y\in\mathcal{P}_0\\ X\neq Y}} \frac{p(g(X),g(Y))}{p(X,Y)} = \tanh\left(\frac{\operatorname{diam}(g)}{4}\right),$$

where $\operatorname{diam}(g)$ denotes the diameter of the image $g(\mathcal{P}_0)$ for the Thompson's metric. The diameter is completely determined by $\operatorname{diam}(g) = p(BD^{-1}, AC^{-1})$ when both BD^{-1} and AC^{-1} are positive definite; otherwise $\operatorname{diam}(g) = \infty$ (Theorem 5.8). This beautiful and important formula had its origin with Birkhoff [4] for Möbius transformations with positive entries with respect to the Riemannian metric $p(a,b) = |\log a - \log b|$ on the positive reals. Liverani and Wojtkowski [18] and Lim [16] have generalized it to fractional transformations on the symmetric cone of positive definite matrices and on symmetric cones arising from Euclidean Jordan algebras with respect to the invariant Finsler metric associated with the spectral norm. In the linear setting, the Birkhoff formula for positive linear maps on Banach spaces for Hilbert's projective (pseudo)metric [5] is well known, with many applications in analysis [4], [8], [17]; see also [20], [21] and the references therein. It has also found applications in control theory, primarily in filtering theory; see, e.g., [3], [7].

In the connections between linear control theory, the Riccati equation, and symplectic Hamiltonians, the contraction property of symplectic Hamiltonians with explicitly given contraction coefficient is applied to the iterative method of solution for discrete algebraic Riccati equations,

$$X = A^*XA - A^*XB(R + B^*XB)^{-1}B^*XA + H,$$

and to the asymptotic behavior of solutions of the Riccati differential equation,

$$\dot{K}(t) = R(t) + A(t)K(t) + K(t)A^*(t) - K(t)S(t)K(t),$$

on an arbitrary Hilbert space. Bougerol [6] has proved that symplectic Hamiltonian matrices are contractions for the standard Riemannian metric on the symmetric space of positive definite matrices and given applications to Kalman filtering theory (cf. [12], [9]). However, in the Riemannian metric case, there is no explicit formula for the contraction coefficient of Hamiltonian matrices. In section 7, we prove that under the invertiblity condition of A and $BR^{-1}B^*$, the discrete Riccati equation has a unique positive solution X_∞ approached by any iteration $X_n \in \mathcal{P}_0$ with the rate of convergence determined by the *computable* Birkhoff constant with respect to Thompson's part metric. Using the *best estimation* given by the Birkhoff constant on the Lie wedge of the symplectic Hamiltonian semigroup studied in section 6, we prove in section 8 that, under the uniform boundedness condition $S^{1/2}(t)R(t)S^{1/2}(t) \geq \mu I$, the solution $K(t)$ of the Riccati differential equation with $K(0) \in \mathcal{P}_0$ is exponentially attracting for Thompson's part metric. These results, obtained mainly from the Birkhoff formula and the invariant Finsler metric, provide new techniques for study of Riccati equations, even for the finite dimensional case, where illustrative numerical experiments can be calculated.

2. Symplectic Hamiltonian operators. In this section we review some basic material on the algebraic structure of the symplectic Lie group and the associated symplectic Hamiltonian semigroup from [15].

Let E be a real Hilbert space with inner product $\langle\cdot,\cdot\rangle\colon E\times E\to\mathbb{R}$, and let $V_E = E\oplus E$. We denote members of V_E by column vectors $\left[\begin{smallmatrix} x\\ y\end{smallmatrix}\right]$, where $x, y \in E$. The

standard symplectic form Q on V_E is defined by

$$Q\left(\begin{bmatrix} x_1 \\ y_1 \end{bmatrix}, \begin{bmatrix} x_2 \\ y_2 \end{bmatrix}\right) := \langle x_1, y_2\rangle - \langle y_1, x_2\rangle.$$

We denote by $\mathrm{End}(V_E)$ (resp., $\mathrm{End}(E)$) the set of bounded linear operators on V_E (resp., E), and by $\mathrm{GL}(V_E)$ (resp., $\mathrm{GL}(E)$) those that are invertible. We shall always assume that the topology is generated by the operator norm. For a bounded linear transformation A on E, let A^* denote the unique linear operator such that $\langle Ax, y\rangle = \langle x, A^*y\rangle$ for all x, y in E. We call A^* the *adjoint* of A. We say that A is *symmetric* if $A^* = A$. A bounded symmetric operator A on E is *positive semidefinite* if $\langle x, Ax\rangle \geq 0$ for all $x \in E$. We denote by $\mathcal{P}$ (resp., $\mathcal{P}_0$) all positive semidefinite (resp., positive semidefinite invertible) bounded operators on E.

For (V_E, Q) a standard sympletic space, the symplectic Lie group is defined by

$$\mathrm{Sp}(V_E) := \{M \in \mathrm{GL}(V_E) \colon \forall x, y \in V_E,\ Q(Mx, My) = Q(x, y)\}$$

and has the following characterizations.

Proposition 2.1 (see Proposition 2.5 of [15]). *Let $M \in GL(V_E)$. The following are equivalent:*

1. *$M \in Sp(V_E)$; i.e., M preserves $Q(\cdot, \cdot)$.*
2. *$M^*JM = J$, where $J = \left[\begin{smallmatrix} 0 & I \\ -I & 0 \end{smallmatrix}\right] \in End(V_E)$.*
3. *If M has block matrix form $\left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$, then*
   (a) *A^*C, B^*D are symmetric;*
   (b) *$A^*D - C^*B = I$.*

Members of $\mathrm{Sp}(V_E)$ viewed as linear operators on V_E are called *linear sympletic maps.*

Recall that the symplectic Lie algebra $\mathfrak{sp}(V_E)$ consists of all $X \in \mathrm{End}(V_E)$ such that $\exp(tX) \in \mathrm{Sp}(V_E)$ for all $t \in \mathbb{R}$.

Proposition 2.2. *Let $X \in End(V_E)$. The following are equivalent:*

1. *$X \in \mathfrak{sp}(V_E)$.*
2. *$X^*J + JX = 0$.*
3. *If $X = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$, then*
   (a) *B and C are symmetric;*
   (b) *$D = -A^*$.*

We consider four subsets of $\mathrm{Sp}(V_E)$:

$$\mathcal{S} = \left\{\begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathrm{Sp}(V_E) : D \text{ is invertible, } B^*D \in \mathcal{P},\ CD^* \in \mathcal{P}\right\},$$

$$\mathcal{S}_1 = \left\{\begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathrm{Sp}(V_E) : D \text{ is invertible, } B^*D \in \mathcal{P}_0,\ CD^* \in \mathcal{P}\right\},$$

$$\mathcal{S}_2 = \left\{\begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathrm{Sp}(V_E) : D \text{ is invertible, } B^*D \in \mathcal{P},\ CD^* \in \mathcal{P}_0\right\},$$

$$\mathcal{S}_0 = \mathcal{S}_1 \cap \mathcal{S}_2.$$

We define

$$\Gamma^U = \left\{\begin{bmatrix} I & B \\ 0 & I \end{bmatrix} : B \in \mathcal{P}\right\}, \qquad \Gamma_0^U = \left\{\begin{bmatrix} I & B \\ 0 & I \end{bmatrix} : B \in \mathcal{P}_0\right\},$$

$$\Gamma^L = \left\{ \begin{bmatrix} I & 0 \\ C & I \end{bmatrix} : C \in \mathcal{P} \right\}, \qquad \Gamma_0^L = \left\{ \begin{bmatrix} I & 0 \\ C & I \end{bmatrix} : C \in \mathcal{P}_0 \right\}.$$

We further define a group H of block diagonal matrices by

$$H = \left\{ \begin{bmatrix} A^* & 0 \\ 0 & A^{-1} \end{bmatrix} : A \in \mathrm{GL}(E) \right\}.$$

THEOREM 2.3. *We have that $\mathcal{S}$ is a subsemigroup of $Sp(V_E)$ and $\mathcal{S}\mathcal{S}_i\mathcal{S} \subseteq \mathcal{S}_i$ for $i = 0, 1, 2$; i.e., $\mathcal{S}_i$ is a semigroup ideal. We alternatively have that $\mathcal{S} = \Gamma^U H \Gamma^L$, $\mathcal{S}_1 = \Gamma_0^U H \Gamma^L$, $\mathcal{S}_2 = \Gamma^U H \Gamma_0^L$, and $\mathcal{S}_0 = \Gamma_0^U H \Gamma_0^L$. Furthermore these "triple decompositions" are unique: the multiplication mapping from $\Gamma^U \times H \times \Gamma^L$ to $\mathcal{S}$ is a homeomorphism.*

Proof. The proof follows from Theorem 6.7 and [15, Lemmas 6.4, 6.5]. See also [6], [9]. □

The unique triple factorization of a symplectic Hamiltonian $M = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix} \right] \in \mathcal{S}$ is given by

$$M = \begin{bmatrix} I & BD^{-1} \\ 0 & I \end{bmatrix} \begin{bmatrix} (D^{-1})^* & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ D^{-1}C & I \end{bmatrix}.$$

This factorization occurs more generally for any member $M \in \mathrm{Sp}(V_E)$ with invertible $(2,2)$-entry. The semigroup $\mathcal{S}$ of the preceding theorem is called the *sympletic semigroup*, and members of $\mathcal{S}$ are sometimes called *Hamiltonian* operators of $\mathrm{Sp}(V_E)$.

3. Fractional transformations and compressions. In this section we show that Hamiltonians arise exactly as compressions of the open convex cone of positive definite operators under the canonical fractional transformation action.

We consider the lower block triangular subgroup $\mathbf{P}$ of $\mathrm{Sp}(V_E)$ given by

$$\mathbf{P} := \left\{ \begin{bmatrix} A & 0 \\ C & D \end{bmatrix} \in \mathrm{Sp}(V_E) : A, C, D \in \mathrm{End}(E) \right\}.$$

We note from Proposition 2.1 that such a lower triangular block matrix is in $\mathrm{Sp}(V_E)$ if and only if $A^* = D^{-1}$ and $A^*C = D^{-1}C$ is symmetric. We denote by $\mathcal{M}$ the homogeneous space

$$\mathcal{M} := \mathrm{Sp}(V_E)/\mathbf{P}.$$

In the finite dimensional setting, $\mathbf{P}$ is a parabolic subgroup and the homogeneous space is a flag manifold of $\mathrm{Sp}(V_E)$. The set $\mathrm{Sym}(E)$ of symmetric operators in $\mathrm{End}(E)$ is embedded into $\mathcal{M}$ as a dense open subset (see Lemma 9.2 of [15]):

$$X \mapsto \left[\begin{smallmatrix} I & X \\ 0 & I \end{smallmatrix} \right] \mathbf{P} \in \mathcal{M}.$$

If $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathrm{Sp}(V_E)$ and $X \in \mathrm{Sym}(E)$ such that $CX + D$ is invertible, then

$$M \begin{bmatrix} I & X \\ 0 & I \end{bmatrix} \mathbf{P} = \begin{bmatrix} I & (AX + B)(CX + D)^{-1} \\ 0 & I \end{bmatrix} \mathbf{P}.$$

This defines the (partial) action by fractional transformations of $\mathrm{Sp}(V_E)$ on $\mathrm{Sym}(E) \subseteq \mathcal{M}$:

$$M.X = (AX + B)(CX + D)^{-1} \quad \text{if } (CX + D)^{-1} \text{ exists.} \tag{3.1}$$

For $X, Y \in \mathrm{Sym}(E)$, we define

$$X < Y :\Longleftrightarrow Y - X \in \mathcal{P}_0,$$
$$X \leq Y :\Longleftrightarrow Y - X \in \mathcal{P}.$$

The order $\leq$ is sometimes called the *Loewner order*. For $X \leq Y$ (resp., $X < Y$) we define the order intervals

$$[X, Y] = \{Z \in \mathrm{Sym}(E) : X \leq Z \leq Y\},$$
$$(X, Y) = \{Z \in \mathrm{Sym}(E) : X < Z < Y\},$$

respectively.

PROPOSITION 3.1 (see Propositions 9.6 and 9.7 of [15]). *The sets* $\{(-(1/n)A, (1/n)A) : n \in \mathbb{N}\}$ *form a basis of open sets at* 0 *in* $Sym(E)$ *for any* $A \in \mathcal{P}_0$. *For an element* $A \in Sym(E)$, *the following are equivalent:*

1. $A \in \mathcal{P}$;
2. $A + X$ *is invertible for all* $X \in \mathcal{P}_0$;
3. $A + rI$ *is invertible for all* $r > 0$.

PROPOSITION 3.2 (see Propositions 9.6 and 9.9 of [15]). *Each order interval* $[A, B] = \{X \in Sym(E) : A \leq X \leq B\}$ *for* $A \leq B$ *is closed in* $\mathcal{M}$, *the interior of* $[A, B]$ *is equal to* (A, B), *and the closure* $\overline{\mathcal{P}}$ *of* $\mathcal{P}$ *in* $\mathcal{M}$ *has interior* $\mathcal{P}_0$.

Let us call a member of $\mathrm{Sp}(V_E)$ a *compression* if it carries $\mathcal{P}_0$ into itself under the action of fractional transformation (3.1).

LEMMA 3.3. *If* $M = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right] \in Sp(V_E)$ *is a compression and the image of* $0_E \in \mathrm{Sym}(E) \subseteq \mathcal{M}$ *under* M *is in* $\mathcal{P}$, *then* M *belongs to the sympletic semigroup* $\mathcal{S}$.

Proof. The image of 0_E under M is BD^{-1}. This means that D is invertible, and hence M has a triple decomposition in $\mathrm{Sp}(V_E)$ of the form

$$M = \begin{bmatrix} I & BD^{-1} \\ 0 & I \end{bmatrix} \begin{bmatrix} (D^{-1})^* & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ D^{-1}C & I \end{bmatrix}.$$

Since $0_E \in \mathcal{M}$ corresponds to $\mathbf{P}$ in $\mathrm{Sp}(V_E)/\mathbf{P}$, we conclude that the last two factors of M applied to it return 0_E. Thus, by (3.1),

$$M.0_E = \begin{bmatrix} I & BD^{-1} \\ 0 & I \end{bmatrix}.0 = BD^{-1}.$$

Since the latter is in $\mathcal{P}$ by hypothesis, we conclude that BD^{-1} is positive semidefinite, and hence that the first factor of M is in $\mathcal{S}$. The second factor is trivially in $\mathcal{S}$.

Let $X \in \mathcal{P}_0$. Then

$$\begin{bmatrix} I & 0 \\ D^{-1}C & I \end{bmatrix}.X = \begin{bmatrix} D^* & 0 \\ 0 & D^{-1} \end{bmatrix} \begin{bmatrix} I & -BD^{-1} \\ 0 & I \end{bmatrix} M.X,$$

where the right-hand side must be in $\mathrm{Sym}(E) \subseteq \mathcal{M}$. It follows that $D^{-1}CX + I$ is invertible for all $X \in \mathcal{P}_0$. Since X is invertible, $(D^{-1}CX + I)X^{-1} = D^{-1}C + X^{-1}$ is invertible for all $X \in \mathcal{P}_0$. It then follows from Proposition 3.1 that $D^{-1}C$ is in $\mathcal{P}$. Thus the third factor of M is also in $\mathcal{S}$. ∎

THEOREM 3.4. *Let* $M \in Sp(V_E)$. *The following are equivalent:*

1. $M.\mathcal{P}_0 \subseteq \overline{\mathcal{P}}$;
2. M *is a compression;*

3. $M \in \mathcal{S}$.

Proof. If $M.\mathcal{P}_0 \subseteq \overline{\mathcal{P}}$, then since M is a homeomorphism, it must carry $\mathcal{P}_0$ into $\text{int}\overline{\mathcal{P}}$, which by Proposition 3.2 is $\mathcal{P}_0$. Thus M is a compression. The converse is immediate. Hence items 1 and 2 are equivalent.

It turns out that elements of $\mathcal{S}$ carry $\mathcal{P}_0$ into itself (Proposition 7.1 of [15]). Conversely suppose that $M.\mathcal{P}_0 \subseteq \mathcal{P}_0$. Define $M_n = M \circ t_n$, where t_n has matrix representation $\left[\begin{smallmatrix} I & (1/n)I \\ 0 & I \end{smallmatrix}\right]$. Since $t_n.0 = (1/n)I$, we conclude that $M_n.0 \in \mathcal{P}_0$. Hence by the preceding lemma, $M_n \in \mathcal{S}$.

Let $A := M.I$. By hypothesis we may write the result in this form with $A \in \mathcal{P}_0$. Since A is in the open order interval $(0, 2A)$, we have for n large enough that $M_n.I \in (0, 2A)$. Since M_n is order-preserving (Proposition 3.5), we have

$$0 \leq M_n.0 \leq M_n.I \leq 2A.$$

Since the interval $[0, 2A]$ is closed in $\mathcal{M}$ (Proposition 3.2), we conclude that

$$M.0 = \lim_n M_n.0 \in [0, 2A].$$

We can now apply the preceding lemma to M to conclude that $M \in \mathcal{S}$. □

PROPOSITION 3.5 (see Proposition 9.10 of [15]). *Members of the symplectic semigroup $\mathcal{S}$ satisfy the following monotonicity properties:*

1. *For $g \in \mathcal{S}$ and $X, Y \in \mathcal{P}_0$, $X \leq Y$ if and only if $g(X) \leq g(Y)$.*
2. *For $g \in \mathcal{S}$ and $X, Y \in \mathcal{P}$, $X \leq Y$ implies $g(X) \leq g(Y)$.*

4. Hamiltonian operators and the standard sector. There is an alternative context in which Hamiltonian operators arise naturally. We consider the quadratic form $\mathcal{Q}$ on the symplectic space (V_E, Q),

$$\mathcal{Q}(w) = \langle x, y \rangle, \qquad w = \begin{bmatrix} x \\ y \end{bmatrix} \in V_E,$$

and the *standard sector* of the symplectic space (V_E, Q), which is defined by

$$\mathcal{C} = \{w \in V_E : \mathcal{Q}(w) \geq 0\}.$$

By $\mathcal{C}^\circ$ we denote the interior of $\mathcal{C}$:

$$\mathcal{C}^\circ = \{w \in V_E : \mathcal{Q}(w) > 0\}.$$

By continuity $g(\mathcal{C}^\circ) \subset \mathcal{C}^\circ$ for any $\mathcal{Q}$-monotone g. Each member of H, the subgroup of block diagonals in $\text{Sp}(V_E)$, acts as an $\mathcal{Q}$-isometry.

The following is immediate from the triple decompositions of $\mathcal{S}$ and $\mathcal{S}_0$ (Theorem 2.3) and the preservation of (strict) $\mathcal{Q}$-monotonicity under composition.

THEOREM 4.1. *Each member of $\mathcal{S}$ (resp., $\mathcal{S}_0$) is $\mathcal{Q}$-monotone (resp., strictly $\mathcal{Q}$-monotone). Furthermore, each member of $\mathcal{S}$ (resp., $\mathcal{S}_0$) increases (resp., strictly increases) the quadratic form.*

Remark. The quadratic form $\mathcal{Q}$ and the associated sector $\mathcal{C}$ define two natural closed subsemigroups in $\text{Sp}(V_E)$ containing the symplectic semigroup $\mathcal{S}$: the subsemigroup of (strictly) monotone maps and the subsemigroup of (strictly) symplectic maps (strictly) increasing the quadratic form. It turns out that these are all the same in the finite dimensional case [19].

We derive an explicit relationship between the action of symplectic Hamiltonians on the sector $\mathcal{C}^\circ$ and the Möbius action of fractional transformation on the positive definite cone $\mathcal{P}_0$.

LEMMA 4.2. *Let* $\left[\begin{smallmatrix} x \\ y \end{smallmatrix}\right] \in \mathcal{C}^\circ$. *Then there exists a positive definite operator* P *on* E *such that* $y = Px$. *In particular,*

$$\mathcal{C}^\circ = \left\{ \begin{bmatrix} x \\ Px \end{bmatrix} : x \neq 0, P \in \mathcal{P}_0 \right\}.$$

Proof. Let W be the subspace generated by x and y. If x and y are linearly dependent, then $y = \lambda x$ for some $\lambda > 0$, so we may take $P = \lambda I$. Suppose that W is two-dimensional. Then it is enough to construct a positive definite operator A on W sending x into y by observing that $P := \begin{bmatrix} A & 0 \\ 0 & I_{W^\perp} \end{bmatrix}$ is positive definite.

Suppose that $x = (x_1, x_2), y = (y_1, y_2) \in \mathbb{R}^2$ such that $l := x_1y_1 + x_2y_2 > 0$. We will solve the equations $ax_1 + bx_2 = y_1, bx_1 + dx_2 = y_2$ with $a > 0, ad > b^2$.

Case 1. If $x_1 = 0$, then take $b = y_1/x_2, d = y_2/x_2 > 0$, and a (positive) large enough. If $x_2 = 0$, then take $b = y_2/x_1, a = y_1/x_1 > 0$, and d large enough.

Case 2. $x_1 \neq 0$ and $x_2 \neq 0$: If $x_1x_2 > 0$, then take

$$b < \min\left\{ \frac{y_1}{x_2}, \frac{y_1y_2}{l} \right\}, \quad a = \frac{(y_1 - bx_2)}{x_1}, \quad d = \frac{(y_2 - bx_1)}{x_2}.$$

If $x_1x_2 < 0$, then take $b > \max\{y_1/x_2, y_1y_2/l\}$, $a = (y_1 - bx_2)/x_1$, and $d = (y_2 - bx_1)/x_2$. ∎

A *slice* of the sector $\mathcal{C}^\circ$ consists of sets of the form

$$\mathcal{P}_x = \left\{ P_x := \begin{bmatrix} Px \\ x \end{bmatrix} : P \in \mathcal{P}_0 \right\}.$$

The preceding lemma shows that the sector $\mathcal{C}^\circ$ is the disjoint union of slices.

PROPOSITION 4.3. *Let* $g = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right] \in \mathcal{S}$. *Then for* $P > 0$,

$$g(P_x) = (g.P)_{(CP+D)x}.$$

Proof. We calculate that

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} Px \\ x \end{bmatrix} = \begin{bmatrix} (AP + B)x \\ (CP + D)x \end{bmatrix} = \begin{bmatrix} (AP + B)(CP + D)^{-1}y \\ y \end{bmatrix} = \begin{bmatrix} (g.P)y \\ y \end{bmatrix},$$

where $y = (CP + D)x$. ∎

5. Contractions and the Birkhoff formula. In this section, we show that each element of $\mathcal{S}$ (resp., $\mathcal{S}_0$) is a contraction (resp., strict contraction) of $\mathcal{P}_0$ for a natural invariant metric on it, with an explicit contraction constant given by the Birkhoff formula.

For $A, B \in \mathcal{P}_0$, we define

$$M(A/B) := \inf\{t > 0 : A \leq tB\},$$
$$m(A/B) := \sup\{t > 0 : tB \leq A\}.$$

Then $M(A/B) = m(B/A)^{-1}$. *Thompson's metric* (sometimes called the *part metric*) on $\mathcal{P}_0$ is defined by

$$p(A, B) = \log(\max\{M(A/B), M(B/A)\});$$

see, e.g., [24], [25], [20].

LEMMA 5.1. *The set $\mathcal{P}_0$ becomes a complete metric space with respect to the metric p, and the metric p induces the topology of $\mathcal{P}_0$.*

Proof. The space $\mathrm{Sym}(E)$ of symmetric operators equipped with the operator norm is a Banach space satisfying that $0 \le A \le B$ implies $\|A\| \le \|B\|$. It follows from Proposition 3.1 that for $A, B \in \mathcal{P}_0$ there exists $t \in \mathbb{R}$ such that $A \le tB$. It then follows from Lemma 3 of [24] that the Thompson metric p is indeed a metric and is complete on $\mathcal{P}_0$, and by Proposition 1.1 of [21] that the Thompson metric induces the same topology. □

LEMMA 5.2. *The metric p is invariant under the block diagonal group H and inversion $j(A) = A^{-1}$.*

Proof. The lemma follows directly from the observations

$$\forall D \in \mathrm{GL}(E), M(D^*AD/D^*BD) = M(A/B), \quad M(A^{-1}/B^{-1}) = M(B/A),$$

where the last equality follows from the fact that inversion on $\mathcal{P}_0$ is order-reversing (cf. Proposition 9.8 of [15]). □

A map $\gamma : [0, 1] \to \mathcal{P}_0$ is said to be a *minimal geodesic* for the metric p if, whenever $0 \le t_1 \le t_2 \le 1$, we have

$$p(\gamma(t_1), \gamma(t_2)) = (t_2 - t_1)p(\gamma(0), \gamma(1)).$$

PROPOSITION 5.3 (see Proposition 1.10 of [20]). *Let $A, B \in \mathcal{P}_0$. Then*

$$\gamma(t) = A^{1/2}(A^{-1/2}BA^{-1/2})^t A^{1/2}$$

is a minimal geodesic curve from A to B with respect to p.

For $X \in \mathrm{Sym}(E)$, the *order unit norm* for the order unit I is given by

$$\|X\| = \inf\{t > 0 : -tI \le X \le tI\}.$$

LEMMA 5.4. *On $\mathrm{Sym}(E)$ we have the following:*

1. *The order unit norm agrees with the operator norm on $\mathrm{Sym}(E)$.*
2. *For $X \in \mathcal{P}_0$, $m(X/I) = \|X^{-1}\|^{-1}$.*
3. *The map $X \mapsto m(X/I)$ is continuous on $\mathcal{P}$.*

Proof. Part 1. Let us temporarily denote the order unit norm by $\|X\|_{or}$. Then

$$|\langle x, Xx\rangle| \le \|x\|(\|X\|\,\|x\|) = \|X\|\langle x, Ix\rangle = \langle x, \|X\|Ix\rangle$$

implies that $\|X\|_{or} \le \|X\|$. For $\|x\| = 1$ and $X \ge 0$, we have

$$\|X^{1/2}x\|^2 = \langle X^{1/2}x, X^{1/2}x\rangle = \langle x, Xx\rangle \le \langle x, \|X\|_{or}Ix\rangle = \|X\|_{or}.$$

It follows that $\|X\| \le \|X^{1/2}\|^2 \le \|X\|_{or}$. We then have for arbitrary symmetric X

$$\|X\|^2 = \|X^*X\| = \|X^2\| = \|X^2\|_{or} \le \|X\|_{or}^2,$$

since $-tI \le X \le tI$ implies that $t^2I - X^2 = (tI + X)^{1/2}(tI - X)(tI + X)^{1/2} \ge 0$.

2. For $X \in \mathcal{P}_0$, we have directly that

$$\begin{aligned} m(X/I) &= \sup\{t > 0 : tI \le X\} = \sup\{t > 0 : (1/t)I \ge X^{-1}\} \\ &= \sup\{(1/s) > 0 : X^{-1} \le sI\} = \|X^{-1}\|^{-1}. \end{aligned}$$

3. It follows from part 2 that the function $X \mapsto m(X/I)$ is continuous on $\mathcal{P}_0$. For $X \in \mathcal{P}$, let $0 \le X_n \to X$. Then for $\varepsilon > 0$, $X_n + \varepsilon I \to X + \varepsilon I$ in $\mathcal{P}_0$, which in turn implies $m(X_n + \varepsilon I/I) \to m(X + \varepsilon I/I)$. Since $m(A + \varepsilon I/I) = m(A/I) + \varepsilon$ for $A \in \mathcal{P}$, the desired conclusion follows. □

Remarks. (1) The map $X \mapsto m(X/I)$ on $\mathcal{P}_0$ is one of special interest; it agrees with the smallest eigenvalue function in the finite dimensional case.

(2) For $X \in \mathcal{P}_0$, $||X|| = M(X/I)$, and hence $p(I, X) = \max\log\{||X||, ||X^{-1}||\}$. Thus for $X, Y \in \mathcal{P}_0$,

$$p(X, Y) = p(I, X^{-1/2}YX^{-1/2}) = \log\max\{||X^{-1/2}YX^{-1/2}||, ||X^{1/2}Y^{-1}X^{1/2}||\}.$$

Identifying the tangent bundle $T\mathcal{P}_0$ of $\mathcal{P}_0$ with $\mathcal{P}_0 \times \mathrm{Sym}(E)$, we define a Finsler structure on $\mathcal{P}_0$ by

$$|X|_A := ||A^{-1/2}XA^{-1/2}||$$

for $A \in \mathcal{P}_0$, $X \in \mathrm{Sym}(E)$. Then it is easy to see that $|\cdot|_A$ is a norm on the tangent space $\mathrm{Sym}(E)$ at A.

THEOREM 5.5 (see Theorem 1.1 of [21]). *Let $A, B \in \mathcal{P}_0$. Then*

$$p(A, B) = \inf\left\{\int_0^1 |\psi'(t)|_{\psi(t)}dt\right\},$$

where the infimum is taken over all piecewise C^1 maps ψ from $A = \psi(0)$ to $B = \psi(1)$. In particular,

$$p(A, B) = \int_0^1 |\gamma'(t)|_{\gamma(t)}dt,$$

where $\gamma(t) = A^{1/2}(A^{-1/2}BA^{-1/2})^tA^{1/2}$.

For notational convenience, we denote for $A \in \mathcal{P}$ and $D \in \mathrm{GL}(E)$,

$$\begin{aligned} t_A &:= \begin{bmatrix} I & A \\ 0 & I \end{bmatrix} \in \Gamma^U, \\ \tilde{t}_A &:= \begin{bmatrix} I & 0 \\ A & I \end{bmatrix} \in \Gamma^L, \\ h_D &:= \begin{bmatrix} D^* & 0 \\ 0 & D^{-1} \end{bmatrix} \in H. \end{aligned}$$

Then under the action of fractional transformation (3.1),

$$t_A(B) = A + B, \quad h_D(B) = D^*BD, \quad \tilde{t}_A(B) = (A + B^{-1})^{-1} = (jt_Aj)(B)$$

for $B \in \mathcal{P}_0$, where $j(A) = A^{-1}$, the inversion operator on $\mathcal{P}_0$.

PROPOSITION 5.6. *Let $X, Y \in \mathcal{P}_0$ and let $D \in \mathrm{GL}(E)$. Then*

$$t_X \circ h_D \circ \tilde{t}_Y = h_{Y^{-1/2}D} \circ t_{Y^{1/2}(D^{-1})^*XD^{-1}Y^{1/2}} \circ \tilde{t}_I \circ h_{Y^{1/2}}.$$

Proof. The proof is straightforward. □

Set $\infty := \left[\begin{smallmatrix} 0 & I \\ -I & 0 \end{smallmatrix}\right]\mathbf{P} \in \mathcal{M}$. It is easy to see that for $g \in \mathrm{Sp}(V_E)$, $g \cdot \infty = \infty$ if and only if g is an upper triangular block matrix.

LEMMA 5.7. *Let $0 < A \le B$. If $X, Y \in [A, B]$, then $p(X, Y) \le p(A, B)$.*

Proof. Suppose that $p(X, Y) = \log M(X/Y)$. Since $A \le X \le M(X/A)A \le M(X/A)Y$, we have $M(X/Y) \le M(X/A)$. The fact $A \le X$ implies that $m(X/A) \ge 1$ and hence $M(A/X) = m(X/A)^{-1} \le 1$. Thus $M(X/A) \ge 1$. Therefore

$$p(X, Y) = \log M(X/Y) \le \log M(X/A) = p(A, X). \tag{5.1}$$

Now, $X \le B \le M(B/A)A$ implies that $M(X/A) \le M(B/A)$ and hence by (5.1)

$$p(X, A) = \log M(X/A) \le \log M(B/A) \le p(B, A).$$

Therefore $p(X, Y) \le p(A, B)$. Similarly, we have that $p(X, Y) \le p(A, B)$ when $p(X, Y) = \log M(X/Y)$. □

THEOREM 5.8. *Let $g \in \mathcal{S}_0$. Then $g(\mathcal{P}_0) = (g(0), g(\infty))$, $g(\overline{\mathcal{P}}) = [g(0), g(\infty)] \subseteq \mathcal{P}_0$, and the diameter $\Delta(g)$ of $g(\mathcal{P}_0)$ for the metric p is the distance $p(g(0), g(\infty))$. If $g \in \mathcal{S} \setminus \mathcal{S}_0$, then $\Delta(g) = \infty$.*

Proof. Let $g = t_X \circ h_D \circ \tilde{t}_Y \in \mathcal{S}_0$. By Theorem 2.3, $X, Y \in \mathcal{P}_0$. Then $g(0) = X$ and $g(\infty) = X + D^*Y^{-1}D$. Suppose that $Z \in (X, X + D^*Y^{-1}D)$. Then $Z = X + A = X + D^*Y^{-1}D - B$ for some $A, B \in \mathcal{P}_0$. Note that $A = D^*Y^{-1}D - B$, so $A < D^*Y^{-1}D$. Since the inversion j is order-reversing on $\mathcal{P}_0$ (cf. Proposition 9.8 of [15]), $W := (DA^{-1}D^* - Y)^{-1} \in \mathcal{P}_0$. This implies that $Z = X + A = g(W) \in g(\mathcal{P}_0)$. Conversely, suppose that $Z \in g(\mathcal{P}_0)$. Then $Z = g(W) = X + D^*(Y + W^{-1})^{-1}D$ for some $W \in \mathcal{P}_0$. It is obvious that $X < Z$. Since $W^{-1} \in \mathcal{P}_0$, we have that $Y^{-1} > (Y + W^{-1})^{-1}$. Thus $D^*Y^{-1}D > D^*(Y + W^{-1})^{-1}D$. This implies that

$$g(\infty) - Z = (X + D^*Y^{-1}D) - (X + D^*(Y + W^{-1})^{-1}D) > 0.$$

Therefore $Z \in (g(0), g(\infty))$. So, $g(\mathcal{P}_0) = (g(0), g(\infty))$. The second assertion follows from this, Proposition 3.1, the fact that g acts as a homeomorphism on $\mathcal{M}$, and our computation of $g(0)$ and $g(\infty)$.

That the diameter of $g(\mathcal{P}_0) = (g(0), g(\infty))$ is the Thompson distance $p(g(0), g(\infty))$ follows from the preceding lemma.

Suppose that $g = t_A \circ h_D \circ \tilde{t}_B \in \mathcal{S} \setminus \mathcal{S}_0$. Then by Theorem 2.3 either A or B lies in $\mathcal{P} \setminus \mathcal{P}_0$. Suppose that $A \in \mathcal{P} \setminus \mathcal{P}_0$. Pick $C \in g(\mathcal{P}_0)$ with $C > 0$. Let $Y_n = g(\frac{1}{n}I) \in \mathcal{P}_0$. Then $Y_n \to g(0) = A$. Since $g(0) = A \in \mathcal{P} \setminus \mathcal{P}_0$, for each $k > 0$, there exists $n_k > 0$ such that $Y_{n_k} \notin [\frac{1}{k}C, kC]$, that is, $Y_{n_k} \not\le kC$ or $\frac{1}{k}C \not\le Y_{n_k}$. By definition, $M(C/Y_{n_k}) \ge k$ or $M(Y_{n_k}/C) \ge k$. Therefore $\log k \le p(C, Y_{n_k}) \to \infty$, and hence $\Delta(g) = \infty$. Similarly, if $g(\infty) = B \in \mathcal{P} \setminus \mathcal{P}_0$, then $\Delta(g) = \infty$. □

LEMMA 5.9. *Let $A, X \in \mathcal{P}_0$. Then*

$$|(I + A)^{-1}U(I + A)^{-1}|_{X+(I+A^{-1})^{-1}} \le \left(\sqrt{m(X/I)} + \sqrt{1 + m(X/I)}\right)^{-2} |U|_A$$

for all $U \in \mathrm{Sym}(E)$.

Proof. First, we show that

$$(I + A)X(I + A) + A^2 + A \ge \left(\sqrt{m(X/I)} + \sqrt{1 + m(X/I)}\right)^2 A.$$

It immediately follows from $m(X/I)I \le X$ that

$$m(X/I)(I+A)^2 = m(X/I)(I+A)I(I+A) \le (I+A)X(I+A).$$

We then have

$$\begin{aligned}
&(I+A)X(I+A) + A^2 + A \\
&\ge m(X/I)(I+A)^2 + A^2 + A \\
&= (m(X/I)+1)A^2 + m(X/I)I + (2m(X/I)+1)A \\
&\ge 2\sqrt{m(X/I)(m(X/I)+1)}A + (2m(X/I)+1)A \\
&= (\sqrt{m(X/I)} + \sqrt{1+m(X/I)})^2 A,
\end{aligned}$$

where the second inequality follows from the fact that the square of $\sqrt{m(X/I)+1}A - \sqrt{m(X/I)}I$ is positive semidefinite.

Set $k := (\sqrt{m(X/I)} + \sqrt{1+m(X/I)})^{-2}$. Then $-tI \le kA^{-1/2}UA^{-1/2} \le tI$ for some $t > 0$, or equivalently $(-t/k)A \le U \le (t/k)A$. From the first paragraph, we obtain that

$$-t\big((I+A)X(I+A) + A^2 + A\big) \le \frac{-t}{k}A \le U \le \frac{t}{k}A \le t((I+A)X(I+A) + A^2 + A).$$

Since $(I+A)^{-1}(A^2+A)(I+A)^{-1} = (I+A^{-1})^{-1}$, this implies that

$$-t(X + (I+A^{-1})^{-1}) \le (I+A)^{-1}U(I+A)^{-1} \le t(X + (I+A^{-1})^{-1})$$

and hence

$$-tI \le (X + (I+A^{-1})^{-1})^{-1/2}(I+A)^{-1}U(I+A)^{-1}(X + (I+A^{-1})^{-1})^{-1/2} \le tI.$$

Therefore from the definition of the order unit norm,

$$||(X+(I+A^{-1})^{-1})^{-1/2}(I+A)^{-1}U(I+A)^{-1}(X+(I+A^{-1})^{-1})^{-1/2}|| \le k||A^{-1/2}UA^{-1/2}||,$$

and the lemma follows immediately. □

LEMMA 5.10. *Let $X \in \mathcal{P}_0$ and let $0 < \alpha < \beta$. Then*

$$M(X + \beta I/X + \alpha I) \ge \frac{m(X/I) + \beta}{m(X/I) + \alpha} \ge 1.$$

In particular,

$$M\left(X + \frac{\beta}{\beta+1}I/X + \frac{\alpha}{\alpha+1}\right) \ge \frac{m(X/I) + \frac{\beta}{\beta+1}}{m(X/I) + \frac{\alpha}{\alpha+1}} \ge 1.$$

Proof. If $X + \beta I \le t(X + \alpha I)$ for $t > 0$, then

$$m(X/I) + \beta = m(X + \beta I/I) \le m(t(X+\alpha I)/I) = t(m(X/I) + \alpha). \qquad \square$$

Let us introduce the Lipschitz constant (the least coefficient of contraction) of $g \in \mathcal{S}$,

$$N(g) = \sup_{\substack{A,B \in \mathcal{P}_0 \\ A \ne B}} \frac{p(g(A), g(B))}{p(A,B)}.$$

Note that $N(g_1g_2) \le N(g_1)N(g_2)$.

THEOREM 5.11. *Let $g \in \mathcal{S}$. Then*

$$N(g) = \tanh\left(\frac{\Delta(g)}{4}\right).$$

Proof. Let $g \in \mathcal{S}_0$. Note that $N(g) = N(h \circ g \circ h')$ for any $h, h' \in H$ by the H-invariance of the metric. By Proposition 5.6, we may assume that $g = t_X \circ \tilde{t}_I$ for some $X \in \mathcal{P}_0$. Then $g(0) = X, g(\infty) = X + I$, and hence $\Delta(g) = p(X, X+I) = \log M(X+I/X) = \log(1+M(I/X)) = \log(1+\frac{1}{m(X/I)})$. A straightforward calculation yields

$$\begin{aligned}\tanh\left(\frac{\Delta(g)}{4}\right) &= \tanh\left(\frac{1}{4}\log\left(1+\frac{1}{m(X/I)}\right)\right)\\ &= \frac{(1+\frac{1}{m(X/I)})^{\frac{1}{4}} - (1+\frac{1}{m(X/I)})^{-\frac{1}{4}}}{(1+\frac{1}{m(X/I)})^{\frac{1}{4}} + (1+\frac{1}{m(X/I)})^{-\frac{1}{4}}}\\ &= \left(\sqrt{m(X/I)} + \sqrt{1+m(X/I)}\right)^{-2}. \qquad (5.2)\end{aligned}$$

Furthermore, for the differential of the mapping $g(Y) = X + (I + Y^{-1})^{-1}$, we have

$$\mathrm{d}g(A)(U) = (I+A^{-1})^{-1}(A^{-1}UA^{-1})(I+A^{-1})^{-1} = (I+A)^{-1}U(I+A)^{-1}$$

for $A \in \mathcal{P}_0, U \in \mathrm{Sym}(E)$.

Let $A, B \in \mathcal{P}_0$, and let $\gamma(t) = A^{\frac{1}{2}}(A^{-\frac{1}{2}}BA^{-\frac{1}{2}})^tA^{\frac{1}{2}}$ be the minimal geodesic curve passing from A to B. Then by Lemma 5.9,

$$\begin{aligned}p(g(A), g(B)) &\le \int_0^1 |(g\circ\gamma)'(t)|_{g(\gamma(t))}dt\\ &= \int_0^1 |\mathrm{d}g(\gamma(t))(\gamma'(t))|_{g(\gamma(t))}dt\\ &= \int_0^1 |(I+\gamma(t))^{-1}\gamma'(t)(I+\gamma(t))^{-1}|_{X+(I+\gamma(t)^{-1})^{-1}}dt\\ &\le (\sqrt{m(X/I)} + \sqrt{1+m(X/I)})^{-2}\int_0^1 |\gamma'(t)|_{\gamma(t)}dt\\ &= (\sqrt{m(X/I)} + \sqrt{1+m(X/I)})^{-2}p(A,B),\end{aligned}$$

where in the last equality we have used the fact that the distance $p(A, B)$ is equal to the Finsler length of the geodesic curve $\gamma(t)$. Therefore

$$N(g) \le \left(\sqrt{m(X/I)} + \sqrt{1+m(X/I)}\right)^{-2}.$$

To show that equality holds, it is enough to show that

$$\left(\sqrt{m(X/I)} + \sqrt{1+m(X/I)}\right)^{-2} \le \sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{p(g(\alpha I), g(\beta I))}{p(\alpha I, \beta I)}.$$

By Lemma 5.10, we obtain that

$$\begin{aligned}\sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{p(g(\alpha I), g(\beta I))}{p(\alpha I, \beta I)} &= \sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{p(X+(I+\alpha^{-1}I)^{-1}), X+(I+\beta^{-1}I)^{-1})}{p(\alpha I, \beta I)} \\ &= \sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{\log M\left(X+\frac{\beta}{\beta+1}I/X+\frac{\alpha}{\alpha+1}I\right)}{\log\frac{\beta}{\alpha}} \\ &\geq \sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{\log\frac{m(X/I)+\frac{\beta}{\beta+1}}{m(X/I)+\frac{\alpha}{\alpha+1}}}{\log\frac{\beta}{\alpha}} = \sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{\log\frac{g(\beta)}{g(\alpha)}}{\log\frac{\beta}{\alpha}},\end{aligned}$$

where $g = \left[\begin{smallmatrix} 1+m(X/I) & m(X/I) \\ 1 & 1 \end{smallmatrix}\right] \in \mathrm{SL}(2,\mathbb{R})$ is the usual Möbius transformation on $\mathbb{R}$. By the Birkhoff formula on the positive reals [4],

$$\begin{aligned}\sup_{\substack{\alpha,\beta\in\mathbb{R}^+\\ \alpha<\beta}} \frac{\log\frac{g(\beta)}{g(\alpha)}}{\log\frac{\beta}{\alpha}} &= \tanh\left(\frac{\Delta(g)}{4}\right) \\ &= \tanh\left(\frac{1}{4}\log\left(1+\frac{1}{m(X/I)}\right)\right) \\ &\overset{5.2}{=} \left(\sqrt{m(X/I)}+\sqrt{1+m(X/I)}\right)^{-2}.\end{aligned}$$

This shows that the Birkhoff formula holds for $\mathcal{S}_0$.

It follows from previous result that every member of $\mathcal{S}_0$ is a strict contraction. By definition we have that the operator $g_n := \left[\begin{smallmatrix} I & 0 \\ (1/n)I & I \end{smallmatrix}\right]$ is in $\mathcal{S}_2$, the operator $h_n := \left[\begin{smallmatrix} I & (1/n)I \\ 0 & I \end{smallmatrix}\right]$ is in $\mathcal{S}_1$, and $g_n, h_n \to e$, the identity element of $\mathrm{Sp}(V_E)$. Then for any $g \in \mathcal{S}$, $g_n h_n g \to g$ and $g_n h_n g \in \mathcal{S}_0$ since $\mathcal{S}_1$ and $\mathcal{S}_2$ are ideals by Theorem 2.3 and $\mathcal{S}_0 = \mathcal{S}_1 \cap \mathcal{S}_2$ by definition. It follows from standard continuity arguments and the density of $\mathcal{S}_0$ in $\mathcal{S}$ that all members of $\mathcal{S}$ are contractions.

Define $\sigma : \mathcal{S} \to \mathbb{R}^+ = [0,\infty)$ by

$$\sigma(t_A h_D \tilde{t}_B) = \left(\sqrt{m(Q/I)}+\sqrt{1+m(Q/I)}\right)^{-2}, \quad \text{where } Q = B^{1/2}(D^{-1})^* A D^{-1} B^{1/2}.$$

Then σ is well defined from the unique triple factorization of $\mathcal{S}$ (Theorem 2.3) and is continuous by Lemma 5.4. By Proposition 5.6 and the calculation above, $\sigma(g) = N(g) = \tanh\left(\frac{\Delta(g)}{4}\right)$ for any $g \in \mathcal{S}_0$. Let $g = t_A h_D \tilde{t}_B \in \mathcal{S} \setminus \mathcal{S}_0$. Then either A or B is not invertible; thus $m(B^{1/2}(D^{-1})^* A D^{-1} B^{1/2}/I) = 0$, and hence $\sigma(g) = 1$. By Theorem 5.8, $\tanh(\Delta(g)/4) = 1$. For small positive ϵ, pick $g_\epsilon \in \mathcal{S}_0$ sufficiently close to the identity such that $\sigma(g) - \epsilon \leq \sigma(g_\epsilon g)$. Then

$$\sigma(g) - \epsilon \leq \sigma(g_\epsilon g) = N(g_\epsilon g) \leq N(g_\epsilon) N(g) \leq N(g) \leq 1,$$

which shows that $N(g) = 1 = \sigma(g) = \tanh(\Delta(g)/4)$. Thus the Birkhoff formula holds for $\mathcal{S} \setminus \mathcal{S}_0$, which completes the proof. □

We refer the reader to the references [6] and [12] for applications of contraction results to Riccati transformations and control. There it is shown that the Riccati transformation of linear filtering/control theory is a contraction on the space of positive definite matrices. The metric used there is the standard Riemannian metric on

the symmetric space of positive definite matrices. Since we extend these results to the infinite dimensional case as well, it has been necessary to substitute the Thompson metric for the Riemannian metric. We have sharpened the results in another sense by calculating the constant of contraction, the one given by the Birkhoff formula. These formulas have been derived in the finite dimensional case in [18].

6. The Birkhoff formula on the Lie wedge. For the symplectic semigroup $\mathcal{S}$, which is a closed subsemigroup of the symplectic Lie group $\mathrm{Sp}(V_E)$, the Lie wedge of $\mathcal{S}$,

$$\mathfrak{L}(\mathcal{S}) := \{X \in \mathfrak{g} : \exp(tX) \in S \ \forall \ t \geq 0\},$$

which is the tangent object of $\mathcal{S}$ in the Lie algebra, is explicitly described as follows.

PROPOSITION 6.1 (see Proposition 8.1 of [15]). *The symplectic semigroup $\mathcal{S}$ has Lie wedge*

$$\mathfrak{L}(\mathcal{S}) = \left\{ \begin{bmatrix} A & B \\ C & -A^* \end{bmatrix} : B, C \geq 0 \right\}.$$

Setting

$$\mathfrak{h} = \left\{ \begin{bmatrix} A & 0 \\ 0 & -A^* \end{bmatrix} : A \in \mathrm{End}(V_E) \right\},$$
$$W = \left\{ \begin{bmatrix} 0 & R \\ S & 0 \end{bmatrix} : R, S \geq 0 \right\},$$

we have $\mathfrak{L}(\mathcal{S}) = \mathfrak{h} \oplus W$. In particular, $\mathfrak{h}$ is the Lie subalgebra of the subgroup H of block diagonal matrices.

We recall the Birkhoff constant map

$$N : \mathcal{S} \to [0,1], \quad N(g) = \tanh\Big(\frac{\triangle(g)}{4}\Big) = \sup_{\substack{X,Y>0 \\ X \neq Y}} \frac{p(g(X), g(Y))}{p(X,Y)},$$

and define

$$f : \mathfrak{L}(\mathcal{S}) \to [0,\infty), \quad \begin{bmatrix} A & R \\ S & -A^* \end{bmatrix} \mapsto \sqrt{m(S^{1/2}RS^{1/2}/I)}.$$

Then f is a continuous, homogeneous, Ad_H-invariant function and is an extension of the map $X \mapsto m(X/I)$ on $\mathcal{P}$.

THEOREM 6.2. *We have* $\log \circ N \circ \exp \leq -2f$ *on* $\mathfrak{L}(\mathcal{S})$.

Proof. Let $\left[\begin{smallmatrix} 0 & R \\ S & 0 \end{smallmatrix}\right] \in W^\circ$, the interior of W, i.e., $R, S > 0$. Then

$$\exp \begin{bmatrix} 0 & R \\ S & 0 \end{bmatrix} = \begin{bmatrix} S^{-1/2} & 0 \\ 0 & S^{1/2} \end{bmatrix} \cdot \exp \begin{bmatrix} 0 & S^{1/2}RS^{1/2} \\ I & 0 \end{bmatrix} \cdot \begin{bmatrix} S^{1/2} & 0 \\ 0 & S^{-1/2} \end{bmatrix},$$

and it follows by homogeneity of the Thompson metric that

$$N\left(\exp \begin{bmatrix} 0 & R \\ S & 0 \end{bmatrix} \right) = N\left(\exp \begin{bmatrix} 0 & S^{1/2}RS^{1/2} \\ I & 0 \end{bmatrix} \right).$$

Setting $X = S^{1/2}RS^{1/2}$ and $g = \exp \left[\begin{smallmatrix} 0 & X \\ I & 0 \end{smallmatrix}\right]$, we have

$$g = \begin{bmatrix} \cosh X^{1/2} & X^{1/2} \sinh X^{1/2} \\ X^{-1/2} \sinh X^{1/2} & \cosh X^{1/2} \end{bmatrix}$$

and therefore

$$g(0) = X^{1/2} \sinh X^{1/2} (\cosh X^{1/2})^{-1} = X^{1/2} \tanh X^{1/2}, \qquad g(\infty) = X^{1/2} \coth X^{1/2}.$$

Then

$$\begin{aligned} \triangle(g) &= p(g(0), g(\infty)) \\ &= p(X^{1/2} \tanh X^{1/2}, X^{1/2} \coth X^{1/2}) \\ &= p(I, \coth^2 X^{1/2}) \\ &= \log M(\coth X^{1/2}/I)^2 \\ &\le \log \coth^2 m(X^{1/2}/I), \end{aligned}$$

where the third equality follows from the homogeneity of the metric, the fourth from $\coth X^{1/2} \ge I$, and the last inequality from the fact that for $t > 0$, $tI \le X$ implies $t^n I \le X^n$ and hence $(\exp t)I \le \exp X$ and consequently $(\coth t)I \ge \coth X$. By direct computation we have

$$N(g) = \tanh \left(\frac{\triangle(g)}{4} \right) \le \tanh \left(\frac{1}{2} \log \coth m(X^{1/2}/I) \right) = e^{-2m(X^{1/2}/I)} = e^{-2\sqrt{m(X/I)}}.$$

By continuity of $N(\cdot)$ and $m(\cdot/I)$, the asserted inequality holds for arbitrary members of W.

Finally, the assertion of the inequality on all of $\mathfrak{L}(S)$ follows from the preceding, from the fact that both sides of the inequality reduce to 0 on $\mathfrak{h}$, from the Lie–Trotter product formula, and from the multiplicative property of the Birkhoff constant function: $N(gh) \le N(g)N(h)$. □

Remark. In the finite dimensional case, the inequality in Theorem 6.2 becomes an equality on W: $\log \circ N \circ \exp = -2f$. This follows from the fact that

$$|| \coth X|| = \coth ||X^{-1}||^{-1}, \quad X > 0.$$

Set $R = \left\{ \left[\begin{smallmatrix} 0 & X \\ I & 0 \end{smallmatrix}\right] : X > 0 \right\} \subseteq W^\circ$, the interior of W.

THEOREM 6.3. *We have*

$$\mathcal{S}_0 = \Gamma_0^U H \Gamma_0^L = H(\exp R)H = H(\exp W^\circ).$$

Proof. The first equality follows by Theorem 2.3. We have observed in the proof of Theorem 6.2 that $\exp W^\circ \subseteq H(\exp R)H$ and hence $H \exp W^\circ \subseteq H(\exp R)H$. Since W° is Ad_H-invariant, $(\exp R)H \subseteq H \exp W^\circ$, and therefore $H(\exp R)H \subseteq H \exp W^\circ$, the third equality is proved.

Let $X > 0$. Then

$$\begin{aligned} \exp \begin{bmatrix} 0 & X \\ I & 0 \end{bmatrix} &= \begin{bmatrix} \cosh X^{1/2} & X^{1/2} \sinh X^{1/2} \\ X^{-1/2} \sinh X^{1/2} & \cosh X^{1/2} \end{bmatrix} \\ &= \begin{bmatrix} I & X^{1/2} \tanh X^{1/2} \\ 0 & I \end{bmatrix} \begin{bmatrix} (\cosh X^{1/2})^{-1} & 0 \\ 0 & \cosh X^{1/2} \end{bmatrix} \begin{bmatrix} I & 0 \\ X^{-1/2} \tanh X^{1/2} & I \end{bmatrix} \\ &\in \mathcal{S}_0 = \Gamma_0^U H \Gamma_0^L \end{aligned}$$

because $X^{1/2}\tanh X^{1/2} > 0$ and $X^{-1/2}\tanh X^{1/2} > 0$. The ideal property of $\mathcal{S}_0$ implies that $H(\exp R)H \subseteq \mathcal{S}_0$. However, the explicit triple decomposition and Proposition 5.6 imply that

$$\exp\begin{bmatrix} 0 & X \\ I & 0 \end{bmatrix} \in H \cdot \begin{bmatrix} 0 & (\sinh X^{1/2})^2 \\ I & 0 \end{bmatrix}\begin{bmatrix} I & 0 \\ I & I \end{bmatrix} \cdot H,$$

and thus each element in the right-hand side belongs to $H(\exp R)H$. Suppose that $g \in \mathcal{S}_0 = \Gamma_0^U H \Gamma_0^L$. Then by Proposition 5.6, $g = h_{D_1}\left[\begin{smallmatrix} I & A \\ 0 & I \end{smallmatrix}\right]\left[\begin{smallmatrix} I & 0 \\ I & I \end{smallmatrix}\right]h_{D_2}$ for some $A > 0$ and $D_i \in \mathrm{GL}(E)$. Set $X = [\log(A^{1/2} + (A+I)^{1/2})]^2$. Then $X > 0$, and by direct computation $\sinh X^{1/2} = A^{1/2}$, so that $g \in H(\exp R)H$. □

7. Discrete algebraic Riccati equations. The discrete algebraic Riccati equation (DARE) arises in the context of minimizing a quadratic cost for discrete-time linear time-invariant systems (see, for example, [23, Chapter 8.4]). We consider (DARE) on a Hilbert space E:

$$X = A^*XA - A^*XB(R + B^*XB)^{-1}B^*XA + H, \tag{7.1}$$

where R and H are symmetric and positive definite [10].

It will be convenient to work with a simpler form of (DARE). We begin with the following result.

LEMMA 7.1.

1. *If $A + B$ is invertible, then $A(A+B)^{-1}B = A - A(A+B)^{-1}A$.*
2. *$B(I + B^*XB)^{-1} = (I + BB^*X)^{-1}B$.*

Proof. For the first assertion move the longer term from the right-hand side to the left, factor, and simplify. For the second eliminate the inverses by moving the expressions to the other side of the equation. □

Lemma 7.1 can be used to show that (DARE) is equivalent to

$$X = A^*X(I + GX)^{-1}A + H, \qquad G = BR^{-1}B^*. \tag{7.2}$$

Indeed,

$$\begin{aligned}
& X - XB(R + B^*XB)^{-1}B^*X \\
= \quad & X - XBR^{-1/2}(I + R^{-1/2}B^*XBR^{-1/2})^{-1}R^{-1/2}B^*X \\
\overset{C=BR^{-1/2}}{=} \quad & X - XC(I + C^*XC)^{-1}C^*X \\
\overset{Lemma\ 7.1(2)}{=} \quad & X - X(I + CC^*X)^{-1}CC^*X \\
\overset{G=CC^*}{=} \quad & X - X(I + GX)^{-1}GX \\
\overset{Lemma\ 7.1(1)}{=} \quad & X - X\Big(I - (I + GX)^{-1}\Big) \\
= \quad & X(I + GX)^{-1}.
\end{aligned}$$

THEOREM 7.2. *If A is invertible and $G = BR^{-1}B^*$ is positive definite, then* (DARE) *has a unique positive definite solution X_∞ and the iteration*

$$X_{n+1} = H + A^*X_n(I + GX_n)^{-1}A$$

starting at any point $X_0 \in \mathcal{P}_0$ converges to X_∞ with

$$p(X_\infty, X_n) \le \frac{L^n}{1-L}p(X_1, X_0),$$

where $\Lambda = H^{-1/2}A^*G^{-1/2}$, $L = \tanh\left((1/4)\log\|I + \Lambda\Lambda^*\|\right)$.

Proof. We note that positive definite solutions of (DARE) correspond to positive definite fixed points of the map

$$X \mapsto A^*X(I + GX)^{-1}A + H \tag{7.3}$$

on $\mathcal{P}_0$. Under the fractional transformation, the mapping (7.3) becomes

$$X \mapsto H + A^*X(I + GX)^{-1}A = \begin{bmatrix} I & H \\ 0 & I \end{bmatrix} \begin{bmatrix} A^* & 0 \\ 0 & A^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ G & I \end{bmatrix} .X.$$

The operator of the right-hand side,

$$\begin{bmatrix} I & H \\ 0 & I \end{bmatrix} \begin{bmatrix} A^* & 0 \\ 0 & A^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ G & I \end{bmatrix}, \tag{7.4}$$

belongs to $\mathcal{S}_0$ and hence is a strict contraction for Thompson's metric p by Theorems 5.11 and 5.8. By completeness of the metric, it has a unique fixed point on the positive definite cone $\mathcal{P}_0$, and therefore (DARE) has a unique positive definite solution. Obviously the solution X_∞ is represented as a limit of iteration $X_{n+1} = H + A^*X_n(I + GX_n)^{-1}A$ with initial point in $\mathcal{P}_0$. Set $X_\infty = \lim_{n\to\infty} X_n$, $X_0 > 0$. The p-diameter of the map $X \mapsto H + A^*X(I + GX)^{-1}A$ is computed from Theorem 5.8:

$$\Delta = p(H, H + A^*G^{-1}A) = p(I, I + \Lambda\Lambda^*) = \log||I + \Lambda\Lambda^*||,$$

where $\Lambda =: \Lambda(H, R, A, B) = H^{-1/2}A^*G^{-1/2}$. Then its contraction constant is

$$L := \tanh\left(\frac{\Delta}{4}\right) = \tanh\left(\frac{\log||I + \Lambda\Lambda^*||}{4}\right),$$

and the error bound may be estimated by $p(X_\infty, X_n) \le \frac{L^n}{1-L}\, p(X_1, X_0)$. ∎

Remark. We observe that the unique positive definite solution $S(H, R, A, B)$ in the above theorem depends on the parameters H, R, A, B, where H, R vary over the positive definite operators and A, B over invertible operators on E. This defines the solution map of DARE

$$S : \mathcal{P}_0 \times \mathcal{P}_0 \times \mathrm{GL}(E) \times \mathrm{GL}(E) \to \mathcal{P}_0, \quad (H, R, A, B) \to S(H, R, A, B).$$

In the finite dimensional case it is shown in [2] that the solution map is continuous and extends to the set of singular A. Under the additional condition that A is stable (leaves the unit ball invariant) but without the invertibility condition of $G = BR^{-1}B^*$, (DARE) has a unique positive definite solution (Corollary 5.7 of [11]).

Remark. In [9] (DARE) is called the *standard symplectic form* (SSF) when both H and G are invertible, which is the case of Theorem 7.2; that is, the associated symplectic Hamiltonian (7.4) is in $\mathcal{S}_0$. An efficient numerical method is developed, the so-called *structure-preserving doubling* (SDP) algorithm, which requires the fact that the (positive) powers of the associated symplectic Hamiltonian Z remain in SSF (Theorem 2.1 of [9]). We have already obtained the semigroup property (even ideal property) of $\mathcal{S}_0$ in Theorem 2.3. The SDP algorithm produces the sequence $Z^{2^k}, k = 1, 2, \ldots$, and the rate of convergence is estimated in terms of eigenvalues of the associated symplectic pencil (Theorem 3.1 of [9]; see also [10]).

Remark. The unique positive definite solution of (DARE) or (7.3) lies in the open order interval

$$(H, H + A^*G^{-1}A).$$

Thus it is more effective to begin the iteration method starting at a point in this interval. There are three positive definite operators lying in the interval. The harmonic-geometric-arithmetic inequalities of the positive definite operators $A, B > 0$ (cf. [1]),

$$2(A^{-1} + B^{-1})^{-1} \leq A\#B := A^{1/2}(A^{-1/2}BA^{-1/2})^{1/2}A^{1/2} \leq \frac{A+B}{2},$$

imply that the open order interval $(H, H+A^*G^{-1}A)$ contains the harmonic, geometric, and arithmetic means of H and $H + A^*G^{-1}A$:

$$2(H^{-1} + (H + A^*G^{-1}A)^{-1})^{-1}, \quad H\#(H + A^*G^{-1}A), \quad H + \frac{A^*G^{-1}A}{2}.$$

One can also show that $\frac{1}{2}(H + H\#(H + 4A^*G^{-1}A))$ lies in the interval $(H, H + A^*G^{-1}A)$.

8. Stability of Riccati differential equations. We consider the control system given by the *basic group control equation* (BGCE) on $\mathrm{Sp}(V_E)$:

$$\dot{g}(t) = u(t)g(t), \tag{BGCE}$$

where $u : \mathbb{I} \to \mathfrak{sp}(V_E)$, $\mathbb{I}$ a (finite or infinite) subinterval of $\mathbb{R}$, is called a *steering* or *control* function. In the case that E is finite dimensional, we assume that $u(\cdot)$ belongs to the class of measurable functions from $\mathbb{I}$ into $\mathfrak{sp}(V_E)$, which are locally bounded, that is, bounded on every finite subinterval, and in the case of general E we assume that $u(\cdot)$ is a regulated function, that is, a function that on each finite subinterval of its domain is a uniform limit of piecewise constant functions. A solution of (BGCE), called a *trajectory*, is an absolutely continuous function $x(\cdot)$ from $\mathbb{I}$ into G such that the equation (BGCE) holds a.e., where a.e. means on the complement of a set of measure 0 in the finite dimensional setting and the complement of a countable set otherwise. The solution for initial condition $g(0) = \mathrm{id}_{V(E)}$ is called the *fundamental solution* of the basic group control equation and denoted $\Phi(t)$. By right invariance the general solution to (BGCE) with initial condition $g(t_0) = g_0$ is then given by $g(t) = \Phi(t)(\Phi(t_0))^{-1}g_0$.

Proposition 8.1 (see [15, Proposition 8.3]). *Each solution $\Phi(t)$ for $t \geq 0$ of the basic group control equation on $Sp(V_E)$,*

$$\dot{g}(t) = u(t)g(t), \quad g(0) = id_{V(E)}, \quad u(t) \in \mathfrak{L}(\mathcal{S}),$$

is contained in the semigroup $\mathcal{S}$; i.e., the attainable set is contained in $\mathcal{S}$. If $\Phi(s) \in \mathcal{S}_i$ for some s and some $i = 0, 1$, or 2, then $\Phi(t) \in \mathcal{S}_i$ for all $t > s$.

We return to the material on the Lie wedge of the symplectic semigroup at the beginning of section 6. Note that $\mathfrak{L}(S) = \mathfrak{h} \oplus W$ has interior $\mathfrak{h} \oplus W^\circ$ in $\mathfrak{sp}(V_E)$, where

$$W^\circ = \left\{ \begin{bmatrix} 0 & R \\ S & 0 \end{bmatrix} : R, S > 0 \right\}.$$

Since the exponential function is locally a homeomorphism in a neighborhood $N(0)$ of the 0-matrix, we conclude that members of $(\mathfrak{h} + W^\circ) \cap N(0)$ are carried by the exponential map into the interior of $\mathcal{S}$. Since for any $Y \in \mathfrak{sp}(V_E)$, $\exp(Y) = (\exp(1/n)Y)^n$

and $\mathcal{S}$ is a subsemigroup, we conclude that $\exp(\mathfrak{h} + W^\circ)$ is carried into the interior of $\mathcal{S}$. It follows readily from the homeomorphic triple decomposition of Theorem 2.3 that the interior of $\mathcal{S}$ is contained in $\mathcal{S}_0$ (indeed they are equal), so $\exp(\mathfrak{h}+W^\circ) \subseteq \mathcal{S}_0$.

We need the following elementary lemma.

LEMMA 8.2. *Let $\Phi : \mathbb{R}^+ \times X \to X$ be a continuous semiflow of the nonnegative reals on a Hausdorff space X. Set $\phi_t(x) = \Phi(t, x)$. If ϕ_t has exactly one fixed point for each $t = 1/2^n$, $n \in \mathbb{N}$, then the fixed point is a common one for all ϕ_t, $t \in \mathbb{R}^+$.*

Consider on the Hilbert space E the Riccati differential equation

$$\text{(RDE)} \qquad \dot{K}(t) = R(t) + A(t)K(t) + K(t)A^*(t) - K(t)S(t)K(t), \quad K(t_0) = K_0,$$

where the coefficient functions are locally bounded and measurable in the finite dimensional case and regulated otherwise. It was shown in [15, section 5] that the solution of equation (RDE) for the case that $R(t), S(t), K_0 \geq 0$ arises through the fundamental solution of basic control equation (BGCE) acting by fractional transformations on $\mathcal{P} \subseteq \mathcal{M}$:

$$K(t) = \Phi(t)(\Phi(t_0))^{-1}(K_0), \qquad \text{where } u(t) = \begin{bmatrix} A(t) & R(t) \\ S(t) & -A(t)^* \end{bmatrix}.$$

In the case of constant coefficients with $R, S > 0$, then for $t > 0$, $\Phi(t) = \exp(tM)$ lies in $\mathcal{S}_0$ (as we have seen), where $M = \left[\begin{smallmatrix} A & R \\ S & -A^* \end{smallmatrix}\right]$. It follows that for each $t > 0$, $\exp(tM)$ is a strict contraction on $\mathcal{P}_0$ by Theorems 5.8 and 5.11 and hence has a unique fixed point. Hence by the preceding Lemma 8.2 we conclude that there is a common fixed point P^* for all ϕ_t, $t \geq 0$. Hence the vector field, given by (RDE), must have a 0-vector at P^*, i.e., the algebraic Riccati equation (ARE)

$$R + AK + KA^* - KSK = 0, \qquad R, S > 0,$$

must have a unique positive definite solution. (Note that another solution would yield another fixed point for the ϕ_t.) We have thus rederived from our machinery the following familiar result.

PROPOSITION 8.3. *The ARE*

$$R + AK + KA^* - KSK = 0, \qquad R, S > 0,$$

has a unique positive definite solution.

Recall the homogeneous function defined on the Lie wedge $\mathfrak{L}(\mathcal{S})$,

$$f : \mathfrak{L}(\mathcal{S}) \to [0, \infty), \qquad \begin{bmatrix} A & R \\ S & -A^* \end{bmatrix} \mapsto \sqrt{m(S^{1/2}RS^{1/2}/I)}.$$

COROLLARY 8.4. *Let $\Phi(t)$ be the fundamental solution of the basic control equation*

$$\dot{g}(t) = u(t)g(t), \quad g(0) = \mathrm{id}_{V(E)}, \quad u(t) \in \mathfrak{L}(\mathcal{S}).$$

If there exists $\mu > 0$ such that $u(t) \in f^{-1}([\mu, \infty))$ for all $t \geq 0$, then $N(\Phi(t)) \leq e^{-2t\mu}$ for each $t \geq 0$.

Proof. The density of the set of piecewise constant controls yields that $\Phi(t)$ is a limit of finite products of elements of the form

$$\exp(\alpha_1 X_1) \exp(\alpha_2 X_2) \cdots \exp(\alpha_n X_n),$$

where $\sum_{i=1}^{n} \alpha_i = t$ and $\alpha_i \geq 0, X_i \in f^{-1}([\mu, \infty))$ for $i = 1, 2, \ldots, n$. Theorem 6.2 ensures that

$$N(\exp \alpha_i X_i) \leq e^{-2f(\alpha_i X_i)} = e^{-2\alpha_i f(X_i)} \leq e^{-2\alpha_i \mu}$$

and hence

$$N(\exp(\alpha_1 X_1) \exp(\alpha_2 X_2) \cdots \exp(\alpha_n X_n)) \leq e^{-2\alpha_1 \mu} e^{-2\alpha_2 \mu} \cdots e^{-2\alpha_n \mu} = e^{-2t\mu}.$$

By continuity (see the last part of the proof of Theorem 5.11), $N(\Phi(t)) \leq e^{-2t\mu}$. ∎

Example. Let $u(t) = \left[\begin{smallmatrix} A(t) & R(t) \\ S(t) & -A(t)^* \end{smallmatrix}\right] \in \mathfrak{L}(\mathcal{S})$. Then $u(t) \in f^{-1}([\mu, \infty))$ for all $t \geq 0$ if and only if $m(S^{1/2}(t)R(t)S^{1/2}(t)/I) \geq \mu^2$ for all $t \geq 0$, and this includes the case when $S(t)$ is invertible and $R(t) \geq \mu^2 S^{-1}(t)$ for all $t \geq 0$.

The next theorem shows that under general conditions two solutions of the Riccati differential equation (RDE) exponentially converge toward each other.

THEOREM 8.5. *Let $K_1(t), K_2(t)$ be two solutions with initial values $K_1(t_0) = K_1 > 0$ and $K_2(t_0) = K_2 > 0$ of the Riccati differential equation*

$$\dot{K}(t) = R(t) + A(t)K(t) + K(t)A^*(t) - K(t)S(t)K(t), \text{ where } R(t), S(t) \geq 0.$$

If there exists $\mu > 0$ and $t_1 \geq t_0$ such that $m(S(t)^{1/2}R(t)S(t)^{1/2}/I) \geq \mu^2$ for all $t \geq t_1$, then

$$p(K_1(t), K_2(t)) \leq e^{-2(t-t_1)\mu} p(K_1, K_2)$$

for $t \geq t_1$.

Proof. Let $u(t) = \left[\begin{smallmatrix} A(t) & R(t) \\ S(t) & -A(t)^* \end{smallmatrix}\right]$. Since $R(t), S(t) \geq 0$, then $u(t) \in \mathfrak{L}(\mathcal{S}), t \geq t_0$. Let $\Phi(t)$ be the fundamental solution of the basic group control equation

$$\dot{g}(t) = u(t)g(t), g(0) = \mathrm{id}_{V_E}.$$

Then

$$K_1(t) = \Phi(t)\Phi(t_0)^{-1}(K_1) = \Phi(t)\Phi(t_1)^{-1}\Phi(t_1)\Phi(t_0)^{-1}(K_1)$$

and $K_2(t) = \Phi(t)\Phi(t_1)^{-1}\Phi(t_1)\Phi(t_0)^{-1}(K_2)$. Note that $\Psi(t) := \Phi(t+t_1)\Phi(t_1)^{-1}$ is the fundamental solution of the basic group control equation

$$\dot{g}(t) = u(t + t_1)g(t), \qquad g(0) = \mathrm{id}_{V(E)}.$$

By assumption,

$$u(t + t_1) \in f^{-1}([\mu, \infty)) = \left\{ \left[\begin{array}{cc} A & R \\ S & -A^* \end{array}\right] \in \mathcal{L}(S) : m(S^{1/2}RS^{1/2}) \geq \mu^2 \right\},$$

and by the previous corollary $N(\Psi(t)) \leq e^{-2t\mu}$ for all $t \geq 0$. Similarly, $\Phi(t_1)\Phi(t_0)^{-1} \in \mathcal{S}$, a contraction. Therefore for $t \geq t_1$

$$\begin{aligned} p(K_1(t), K_2(t)) &= p(\Psi(t - t_1)\Phi(t_1)\Phi(t_0)^{-1}(K_1), \Psi(t - t_1)\Phi(t_1)\Phi(t_0)^{-1}(K_2)) \\ &\leq e^{-2(t-t_1)\mu} p(\Phi(t_1)\Phi(t_0)^{-1}(K_1), \Phi(t_1)\Phi(t_0)^{-1}(K_2)) \\ &\leq e^{-2(t-t_1)\mu} p(K_1, K_2). \end{aligned}$$ ∎

There has been extensive study of conditions for the existence of a (positive definite) solution K to the ARE

$$R + AK + KA^* - KSK = 0, \quad R, S > 0;$$

see, for example [23, Chapter 8.4]. The preceding allows one to draw results in the converse direction.

COROLLARY 8.6. *If K^* is the unique positive definite solution for the constant coefficient ARE, then all solutions of the corresponding Riccati differential equation $\dot{K} = R + AK + KA^* - KSK$, $R, S > 0$, that enter the space of positive definite operators converge exponentially toward K^*.*

Proof. We consider a trajectory of the given Riccati differential equation that takes on a value $K_0 > 0$ at some time t_0. Then the trajectory satisfies (RDE) with initial condition K_0 at time t_0. Since K^* satisfies ARE, the value of the Riccati differential equation at K^* is 0, and thus the solution through K^* is constant. Since the coefficients R, S are constant and positive definite, the appropriate boundedness condition of the previous theorem for $S^{1/2}RS^{1/2}$ is satisfied. Hence the first trajectory converges exponentially toward the second trajectory with constant value K^*. ∎

ERROR ESTIMATES FOR THE NUMERICAL APPROXIMATION OF A DISTRIBUTED CONTROL PROBLEM FOR THE STEADY-STATE NAVIER–STOKES EQUATIONS*

EDUARDO CASAS†, MARIANO MATEOS‡, AND JEAN-PIERRE RAYMOND§

Abstract. We obtain error estimates for the numerical approximation of a distributed control problem governed by the stationary Navier–Stokes equations, with pointwise control constraints. We show that the L^2-norm of the error for the control is of order h^2 if the control set is not discretized, while it is of order h if it is discretized by piecewise constant functions. These error estimates are obtained for local solutions of the control problem, which are nonsingular in the sense that the linearized Navier–Stokes equations around these solutions define some isomorphisms, and which satisfy a second order sufficient optimality condition. We establish a second order necessary optimality condition. The gap between the necessary and sufficient second order optimality conditions is the usual gap known for finite dimensional optimization problems.

Key words. optimal control, stationary Navier–Stokes equations, numerical approximation, error estimates

1. Introduction.

The goal of this paper is to derive some error estimates for the numerical approximation of a distributed optimal control problem governed by the steady-state Navier–Stokes equations, with pointwise control constraints. More precisely we consider the following problem:

$$\text{(P)} \qquad \inf\Big\{F(\mathbf{u},\mathbf{y}) \mid \mathbf{u}\in U_{ad} \text{ and } (\mathbf{u},\mathbf{y}) \text{ satisfies (1.2)}\Big\},$$

where

$$F(\mathbf{u},\mathbf{y}) = \frac{1}{2}\int_\Omega |\mathbf{y}(x)-\mathbf{y}_d(x)|^2dx + \frac{N}{2}\int_\omega |\mathbf{u}(x)|^2dx, \tag{1.1}$$

$$-\nu\Delta\mathbf{y} + (\mathbf{y}\cdot\nabla)\mathbf{y} + \nabla p = \mathbf{f} + \mathcal{C}\mathbf{u} \text{ in } \Omega, \quad \operatorname{div}\mathbf{y} = 0 \text{ in } \Omega, \quad \mathbf{y} = 0 \text{ on } \Gamma, \tag{1.2}$$

$\mathcal{C}$ is a localization operator, $\omega\subset\Omega$, $N>0$, $\nu>0$, and

$$U_{ad} = \Big\{\mathbf{u}\in L^2(\omega;\mathbb{R}^m) \mid \alpha\le\mathbf{u}(x)\le\beta \text{ for almost every (a.e.) } x\in\omega\Big\}.$$

In this setting, Ω is a bounded open and connected subset in $\mathbb{R}^d$, of class C^2, with $d=2$ or $d=3$, and ω is a nonempty open subset in Ω. We can easily show that

problem (P) admits at least one solution. On one hand, uniqueness of solution to problem (P) is not necessarily guaranteed even if (1.2) has a unique solution (which is not necessarily the case). On the other hand, we can only hope to obtain error estimates for solutions to problem (P) which are locally unique. Local uniqueness can be proved for solutions satisfying first order and sufficient second order optimality conditions. When first order optimality conditions in qualified form are satisfied by a local solution $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ of problem (P), we have

$$\bar{\mathbf{u}} = \mathrm{Proj}_{[\alpha,\beta]}\left(-\frac{1}{N}\mathcal{C}^*\bar{\mathbf{\Phi}}\right),$$

where $\mathrm{Proj}_{[\alpha,\beta]}$ is a projection operator and $\bar{\mathbf{\Phi}}$ is the adjoint state associated with $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$. Thus, even if $\bar{\mathbf{\Phi}}$ is regular, because of the projection operator $\mathrm{Proj}_{[\alpha,\beta]}$ (due to control constraints), $\bar{\mathbf{u}}$ is only a Lipschitz function.

Assuming that $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ satisfies first order and sufficient second order optimality conditions, we can define a discrete control problem (P_h) by discretizing the state equation (1.2) with a finite element method (here h is the mesh size of the underlying triangulation, and we assume that the family of triangulations is regular; see section 4). We consider two cases, the case where the control set in (P_h) is still U_{ad}, and the case where the control set U_{ad}^h is the set of functions in U_{ad} which are piecewise constant on the elements of the triangulation. We show that there exists $\hat{h}$ such that, for all $0 < h \leq \hat{h}$, the discrete control problem (P_h) admits at least one local solution $\bar{\mathbf{u}}_h$ in a ball $B_\rho(\bar{\mathbf{u}})$. We prove that the corresponding sequences $\{\bar{\mathbf{u}}_h\}_h$ strongly converge to $\bar{\mathbf{u}}$ in L^2 (see Theorem 4.11). When the control set in (P_h) is U_{ad}, we show that

$$\|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2} \leq Ch^2, \tag{1.3}$$

while if the control set is U_{ad}^h, we prove that

$$\|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2} \leq Ch \tag{1.4}$$

(see Theorem 4.18). To the best of our knowledge both results are new. For numerical computations it seems easier to solve $(\mathrm{P_h})$ when the control set is discretized, that is, when controls belong to U_{ad}^h. However, it is also possible to solve it without a priori discretizing the control set (see, e.g., [16]).

Before comparing our results with the ones existing in the literature, let us make some comments. Knowing that $\bar{\mathbf{u}}$ is a Lipschitz function, the error estimate (1.4), obtained when the discrete control set is defined with piecewise constant functions, is consistent with estimates obtained by approximating Lipschitz functions by piecewise constant functions. The result obtained in (1.3) is more surprising. Indeed, as we are going to see, this kind of result is already known for problems without control constraints. But in that case the optimal control belongs to H^2, and the error estimate is then directly derived from error estimates for the adjoint state. Here we obtain the same order of error estimate, but with control constraints. As far as we know, this kind of result was not previously known. Moreover, our method is quite general, and it can be used in some other problems, provided that we are able to obtain error estimates for the discrete state and discrete adjoint equations.

Let us come back to the existing results in the literature. For optimal control problems of the steady-state Navier–Stokes equations with a distributed control and a slightly different functional, Gunzburger, Hou, and Svobodny have proved error

estimates similar to (1.3) in the case when there is no control constraints and when the control acts everywhere in Ω (see [13, end of section 5.2]). But for a distributed control localized in Ω, the error estimate is only of order $h^{3/2-\varepsilon}$ (see [13, end of section 5.3]). To prove these estimates they do not assume that the optimal solution $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$, which they want to approximate, satisfies a sufficient second order optimality condition. But they assume that the optimality system satisfied by $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is regular, in the sense that the corresponding linearized optimality system defines some isomorphism. This approach is the extension—to optimality systems of control problems—of the classical one used in the numerical approximation of the steady-state Navier–Stokes equations; see, e.g., [12]. This method has been used in the literature for other similar problems [17] and for the boundary control of the stationary Navier–Stokes equations [14, 15]. Observe that the estimates are not the same if the boundary of the domain where the control is applied is empty or nonempty [14, Theorem 4.6 and the assumptions in Theorem 3.5]. In any case this method cannot be used for problems with control constraints. Another approach used more recently for problems without control constraints is the one by Deckelnick and Hinze [10], which is based on the Kantorovich convergence theorem of the Newton method. In that case a second order sufficient optimality condition is needed, but the Kantorovich convergence theorem is proved only for systems of equations and not for generalized equations. Thus this method cannot be used for problems with control constraints.

For problems with control constraints the obtention of both optimality conditions and error estimates is more complicated. Indeed even if the nonlinear Navier–Stokes equations are well posed, the linearized ones are not necessarily well posed. Thus in general one can obtain optimality conditions only in nonqualified form, that is, optimality conditions of Fritz–John type. Such optimality conditions for optimal control problems of the stationary Navier–Stokes equations have been obtained by Abergel and Casas [1]; see also Casas [3]. Optimality conditions in qualified form, that is, optimality conditions of Karush–Kuhn–Tucker type, may be obtained either by assuming that data of the problem are small enough with respect to the viscosity parameter ν (see, e.g., Roubiček and Tröltzsch [19], Tröltzsch and Wachsmuth [21], De Los Reyes [18]) or by assuming some qualification condition of the set of feasible controls as in Gunzburger, Hou, and Svobodny [15, condition (2.7)] or in [1].

Here, since we are mainly interested in the numerical approximation of control problem (P), we assume that the local optimal solution $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ we want to approximate is a nonsingular solution, that is, that the linearized Navier–Stokes equations about $\bar{\mathbf{y}}$ define some isomorphism. As already mentioned, this is the classical assumption used in the numerical approximation of the Navier–Stokes equations (see, e.g., [12, p. 297]). Thanks to this assumption we derive a necessary optimality condition of the form

$$J''(\bar{\mathbf{u}})\mathbf{v}^2 \geq 0 \qquad \forall\, \mathbf{v} \in C_{\bar{\mathbf{u}}}, \tag{1.5}$$

where $C_{\bar{\mathbf{u}}}$ is the set of directions belonging to the tangent cone at $\bar{\mathbf{u}}$ to U_{ad} satisfying $J'(\bar{\mathbf{u}})\mathbf{v} = 0$; see Theorem 3.6 and Corollary 3.7 (here $J(\mathbf{u}) = F(\mathbf{u}, \mathbf{y}_{\mathbf{u}})$, where $\mathbf{y}_{\mathbf{u}}$ is the unique solution to (1.2) corresponding to $\mathbf{u}$, when $\mathbf{u}$ belongs to some ball $B_\rho(\bar{\mathbf{u}})$). The weakest sufficient optimality condition we can state is the following:

$$J''(\bar{\mathbf{u}})\mathbf{v}^2 > 0 \qquad \forall\, \mathbf{v} \in C_{\bar{\mathbf{u}}} \text{ such that } \ \mathbf{v} \neq 0. \tag{1.6}$$

Under this condition, and assuming that the first order optimality conditions are in qualified form, we prove that $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is the unique local solution to (P) in some ball

$B_\rho(\bar{\mathbf{u}})$. (See Theorem 3.8. Notice that we cannot hope to prove such a result without assuming that $\bar{\mathbf{u}}$ satisfies the first order optimality conditions in qualified form and condition (1.6).) This local uniqueness result is essential to carry out some numerical analysis of the control problem. The discrete state equation is stated in section 4. The well posedness of the discrete state equation is performed in Theorem 4.8, and error estimates are obtained in Lemma 4.10. The discrete adjoint equation is studied in section 4.3. Its well posedness and error estimates are proved in Lemmas 4.12 and 4.13. Error estimates for the control problem are obtained in section 4.4.

Let us finally mention that in the case of control problems governed by scalar semilinear elliptic equations, this approach to derive error estimates has been developed by Arada, Casas, and Tröltzsch [2], Casas [4, 5], Casas, Mateos, and Tröltzsch [6], and Casas and Raymond [7].

2. Assumptions and preliminary results. Let us recall that Ω is a bounded open and connected subset in $\mathbb{R}^d$, of class C^2, with $d = 2$ or $d = 3$, and that ω is a nonempty open subset in Ω. We assume that $M : \omega \to \mathbb{R}^{d\times m}$ is a Lipschitz function, with $1 \le m \le d$ ($\mathbb{R}^{d\times m}$ denotes the space of $d \times m$ real matrices). Let us consider the linear operator $\mathcal{C} \in \mathcal{L}(L^2(\omega;\mathbb{R}^m), L^2(\Omega;\mathbb{R}^d))$, defined by $(\mathcal{C}\mathbf{u})(x) = M(x)\mathbf{u}(x)\chi_\omega(x)$, where χ_ω is the characteristic function of ω. In the functional $F : L^2(\Omega;\mathbb{R}^d) \times L^2(\omega;\mathbb{R}^m) \longmapsto \mathbb{R}$, defined in (1.1), we assume that $N > 0$ and $\mathbf{y}_d \in L^{\bar r}(\Omega;\mathbb{R}^d)$, for some $\bar r > d$, are given fixed. For $\mathbf{u} \in L^2(\omega;\mathbb{R}^m)$, we denote by u_j the components of $\mathbf{u}$, that is, $\mathbf{u} = (u_j)_{1\le j\le m}$. For $1 \le j \le m$, let $-\infty \le \alpha_j < \beta_j \le +\infty$ be extended real numbers, and set

$$U_{ad} = \Big\{\mathbf{u} \in L^2(\omega;\mathbb{R}^m) \mid \alpha_j \le u_j(x) \le \beta_j \text{ for a.e. } x \in \omega,\ 1 \le j \le m\Big\}.$$

In the case when $\alpha_j = -\infty$, this means that the corresponding constraint is absent. The same convention is adopted if $\beta_j = \infty$.

In (1.2) we assume that $\nu > 0$ and $\mathbf{f} \in L^{\bar r}(\Omega;\mathbb{R}^d)$.

To study (1.2) we have to introduce some function spaces and operators. Throughout the following we set $\mathbf{H}^1(\Omega) = H^1(\Omega;\mathbb{R}^d)$, $\mathbf{H}^1_0(\Omega) = H^1_0(\Omega;\mathbb{R}^d)$, $\mathbf{H}^{-1}(\Omega) = (\mathbf{H}^1_0(\Omega))'$, $\mathbf{L}^p(\Omega) = L^p(\Omega;\mathbb{R}^d)$, and $\mathbf{W}^{s,p}(\Omega) = W^{s,p}(\Omega;\mathbb{R}^d)$ for $1 \le p \le \infty$ and $s > 0$. We introduce different spaces of divergence-free vector fields:

$$\mathbf{V}^0_n(\Omega) = \Big\{\mathbf{u} \in \mathbf{L}^2(\Omega) \mid \text{ div } \mathbf{u} = 0 \ \text{ in } \Omega,\ \mathbf{u}\cdot\mathbf{n} = 0 \text{ in } H^{-1/2}(\Gamma)\Big\},$$
$$\mathbf{V}^1_0(\Omega) = \mathbf{H}^1_0(\Omega) \cap \mathbf{V}^0_n(\Omega),$$

where $\mathbf{n}$ is the outward unit normal to Γ. The dual space of $\mathbf{V}^1_0(\Omega)$ with respect to the pivot space $\mathbf{V}^0_n(\Omega)$ is denoted by $\mathbf{V}^{-1}(\Omega)$. Thus we have

$$\mathbf{V}^1_0(\Omega) \hookrightarrow \mathbf{V}^0_n(\Omega) \hookrightarrow \mathbf{V}^{-1}(\Omega),$$

with dense and continuous imbeddings. The orthogonal projector from $\mathbf{L}^2(\Omega)$ onto $\mathbf{V}^0_n(\Omega)$ will be denoted by P. The operator P can be extended to a bounded operator from $\mathbf{H}^{-1}(\Omega)$ to $\mathbf{V}^{-1}(\Omega)$. For notational simplicity this extension will still be denoted by P.

Let us consider the bilinear form on $\mathbf{H}^1_0(\Omega)$ defined by

$$a(\mathbf{y},\mathbf{z}) = \nu \int_\Omega \nabla\mathbf{y} : \nabla\mathbf{z}\, dx = \nu \sum_{i,j=1}^{d} \int_\Omega \partial_{x_i} y_j\, \partial_{x_i} z_j,$$

and the trilinear form on $b : \mathbf{L}^4(\Omega) \times \mathbf{H}_0^1(\Omega) \times \mathbf{L}^4(\Omega)$ defined by

$$b(\mathbf{y}, \mathbf{z}, \mathbf{\Phi}) = \int_\Omega (\mathbf{y} \cdot \nabla)\mathbf{z} \cdot \mathbf{\Phi}\, dx.$$

We define $A \in \mathcal{L}(\mathbf{H}_0^1(\Omega), \mathbf{H}^{-1}(\Omega))$ by

$$\big\langle A\mathbf{y}, \mathbf{z}\big\rangle_{\mathbf{H}^{-1}(\Omega),\mathbf{H}_0^1(\Omega)} = a(\mathbf{y}, \mathbf{z}) \qquad \forall\, \mathbf{z},\, \mathbf{y} \in \mathbf{H}_0^1(\Omega),$$

and the nonlinear operator B from $\mathbf{H}_0^1(\Omega)$ to $\mathbf{H}^{-1}(\Omega)$ by

$$\big\langle B(\mathbf{y}), \mathbf{z}\big\rangle_{\mathbf{H}^{-1}(\Omega),\mathbf{H}_0^1(\Omega)} = b(\mathbf{y}, \mathbf{y}, \mathbf{z}) \qquad \forall\, \mathbf{z},\, \mathbf{y} \in \mathbf{H}_0^1(\Omega).$$

Equation (1.2) is equivalent to the variational problem

$$\begin{aligned} &\text{Find } \mathbf{y} \in \mathbf{V}_0^1(\Omega) \quad \text{such that} \\ &a(\mathbf{y}, \mathbf{z}) + b(\mathbf{y}, \mathbf{y}, \mathbf{z}) = (\mathbf{f} + \mathcal{C}\mathbf{u}, \mathbf{z}) \quad \forall\, \mathbf{z} \in \mathbf{V}_0^1(\Omega), \end{aligned} \tag{2.1}$$

or to the weak formulation

$$\mathbf{y} \in \mathbf{V}_0^1(\Omega), \quad \big\langle A\mathbf{y} + B(\mathbf{y}), \mathbf{z}\big\rangle_{\mathbf{H}^{-1}(\Omega),\mathbf{H}_0^1(\Omega)} = \big\langle \mathbf{f} + \mathcal{C}\mathbf{u}, \mathbf{z}\big\rangle_{\mathbf{H}^{-1}(\Omega),\mathbf{H}_0^1(\Omega)} \quad \forall \mathbf{z} \in \mathbf{V}_0^1(\Omega).$$

This last equation is equivalent to

$$\mathbf{y} \in \mathbf{V}_0^1(\Omega), \quad PA\mathbf{y} + PB(\mathbf{y}) = P(\mathbf{f} + \mathcal{C}\mathbf{u}) \quad \text{in } \mathbf{V}^{-1}(\Omega),$$

which we shall simply write in the form

$$\mathbf{y} \in \mathbf{V}_0^1(\Omega), \quad A\mathbf{y} + B(\mathbf{y}) = \mathbf{f} + \mathcal{C}\mathbf{u} \quad \text{in } \mathbf{V}^{-1}(\Omega). \tag{2.2}$$

We know that, for all $\mathbf{u} \in L^2(\omega; \mathbb{R}^m)$, equation (2.1), or equivalently (2.2), admits at least one solution $\mathbf{y} \in \mathbf{V}_0^1(\Omega)$. The pressure appearing in (1.2) is the unique function in

$$L_0^2(\Omega) = \left\{ v \in L^2(\Omega) : \int_\Omega v(x)\, dx = 0 \right\},$$

obeying

$$\nabla p = (I - P)(\mathbf{f} + \mathcal{C}\mathbf{u} + \nu\Delta\mathbf{y} - (\mathbf{y} \cdot \nabla)\mathbf{y}). \tag{2.3}$$

It is a consequence of [12, Chapter 1, Lemma 2.1].

The following properties are well known. For all $\mathbf{y} \in \mathbf{L}^4(\Omega)$ obeying $\operatorname{div} \mathbf{y} = 0$ in Ω, and $\mathbf{z}, \mathbf{w} \in \mathbf{H}_0^1(\Omega)$

$$b(\mathbf{y}, \mathbf{z}, \mathbf{w}) = -b(\mathbf{y}, \mathbf{w}, \mathbf{z}) \quad \text{and} \quad b(\mathbf{y}, \mathbf{z}, \mathbf{z}) = 0. \tag{2.4}$$

The next lemma follows directly from Green's formula.

LEMMA 2.1. *For all $\mathbf{y} \in \mathbf{H}_0^1(\Omega)$, the operators $B'(\mathbf{y}) \in \mathcal{L}(\mathbf{H}_0^1(\Omega), \mathbf{H}^{-1}(\Omega))$ and $B'(\mathbf{y})^* \in \mathcal{L}(\mathbf{H}_0^1(\Omega), \mathbf{H}^{-1}(\Omega))$ satisfy*

$$\langle B'(\mathbf{y})\mathbf{z}, \mathbf{\Phi}\rangle = b(\mathbf{y}, \mathbf{z}, \mathbf{\Phi}) + b(\mathbf{z}, \mathbf{y}, \mathbf{\Phi})$$

and

$$\langle B'(\mathbf{y})^*\mathbf{\Phi}, \mathbf{z}\rangle = \int_\Omega (\nabla \mathbf{y})^T \mathbf{\Phi}\cdot \mathbf{z}\, dx - b(\mathbf{y}, \mathbf{\Phi}, \mathbf{z}) - \int_\Omega (\operatorname{div} \mathbf{y})\, \mathbf{\Phi}\cdot \mathbf{z}\, dx$$

for all $\mathbf{z}$, $\mathbf{\Phi} \in \mathbf{H}_0^1(\Omega)$. *Moreover,* $B'' \in \mathcal{L}(\mathbf{H}_0^1(\Omega)\times \mathbf{H}_0^1(\Omega), \mathbf{H}^{-1}(\Omega))$ *obeys*

$$\langle B''(\mathbf{y}, \mathbf{z}), \mathbf{\Phi}\rangle = b(\mathbf{y}, \mathbf{z}, \mathbf{\Phi}) + b(\mathbf{z}, \mathbf{y}, \mathbf{\Phi}) \quad \forall\, \mathbf{z}, \mathbf{y}, \mathbf{\Phi} \in \mathbf{H}_0^1(\Omega).$$

The following regularity result will be used throughout this paper. It is an immediate consequence of the classical result by Cattabriga [8].

THEOREM 2.2. *There exists a constant* $C > 0$ *such that if* $\mathbf{u} \in L^2(\omega; \mathbb{R}^m)$ *and if* $\mathbf{y} \in \mathbf{V}_0^1(\Omega)$ *is a solution to* (2.2), *then*

$$\|\mathbf{y}\|_{\mathbf{V}_0^1(\Omega)} \le C(\|\mathbf{f}\|_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|_{L^2(\omega;\mathbb{R}^m)}).$$

There exists a constant $C_r > 0$ *such that if* $\mathbf{u} \in L^r(\omega; \mathbb{R}^m)$, $\mathbf{f} \in \mathbf{L}^r(\Omega)$ *with* $2 \le r < \infty$ *and* $\mathbf{y} \in \mathbf{V}_0^1(\Omega)$ *is a solution to* (2.2) *and* p *the associated pressure, then* $\mathbf{y} \in \mathbf{W}^{2,r}(\Omega)$, $p \in \mathbf{W}^{1,r}(\Omega)$, *and*

$$\|p\|_{\mathbf{W}^{1,r}(\Omega)} + \|\mathbf{y}\|_{\mathbf{W}^{2,r}(\Omega)} \le C_r(1 + \|\mathbf{f}\|^7_{\mathbf{L}^r(\Omega)} + \|\mathbf{u}\|^7_{L^r(\omega;\mathbb{R}^m)}). \tag{2.5}$$

Proof. The estimate of $\|\mathbf{y}\|_{\mathbf{V}_0^1(\Omega)}$ is classical. Using this estimate, since $d \le 3$, we can write

$$\|\mathbf{y}\|_{\mathbf{L}^6(\Omega)} \le C\|\mathbf{y}\|_{\mathbf{V}_0^1(\Omega)}$$

and

$$\|\mathbf{y}\otimes\mathbf{y}\|_{(\mathbf{L}^3(\Omega))^d} \le C\|\mathbf{y}\|^2_{\mathbf{V}_0^1(\Omega)}.$$

Thus, from estimates for the Stokes equation, we successively deduce

$$\|\mathbf{y}\|_{\mathbf{W}^{1,3}(\Omega)} \le C(\|\mathbf{y}\otimes\mathbf{y}\|_{(\mathbf{L}^3(\Omega))^d} + \|\mathbf{f}\|_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|_{L^2(\omega;\mathbb{R}^m)})$$

$$\le C(\|\mathbf{f}\|^2_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|^2_{L^2(\omega;\mathbb{R}^m)} + 1)$$

and

$$\|\mathbf{y}\|_{\mathbf{H}^2(\Omega)} \le C(\|\mathbf{y}\|_{\mathbf{W}^{1,3}(\Omega)}\|\mathbf{y}\|_{\mathbf{L}^6(\Omega)} + \|\mathbf{f}\|_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|_{L^2(\omega;\mathbb{R}^m)})$$

$$\le C(\|\mathbf{f}\|^3_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|^3_{L^2(\omega;\mathbb{R}^m)} + 1).$$

Therefore

$$\|(\mathbf{y}\cdot\nabla)\mathbf{y}\|_{(\mathbf{L}^3(\Omega))^d} \le C\|\mathbf{y}\|_{\mathbf{H}^1(\Omega)}\|\mathbf{y}\|_{\mathbf{H}^2(\Omega)} \le C(\|\mathbf{f}\|^4_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|^4_{L^2(\omega;\mathbb{R}^m)} + 1),$$

which yields

$$\|\mathbf{y}\|_{\mathbf{W}^{2,r}(\Omega)} \le C(\|\mathbf{f}\|^4_{\mathbf{L}^r(\Omega)} + \|\mathbf{u}\|^4_{L^r(\omega;\mathbb{R}^m)} + 1)$$

if $2 \le r \le 3$. Next we have

$$\|(\mathbf{y}\cdot\nabla)\mathbf{y}\|_{(\mathbf{L}^r(\Omega))^d} \le C_r\|\mathbf{y}\|_{\mathbf{H}^2(\Omega)}\|\mathbf{y}\|_{\mathbf{W}^{2,3}(\Omega)} \le C(\|\mathbf{f}\|^7_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}\|^7_{L^2(\omega;\mathbb{R}^m)} + 1)$$

if $3 \le r < \infty$, which provides the desired estimate. ∎

It is well known that the solution of (1.2) is unique when ν is large enough with respect to the right-hand side; see, for instance, Temam [20]. Since this is a strong assumption we are interested in the solutions of (1.2) for which the equation is locally unique. These solutions, called nonsingular solutions, are defined below.

DEFINITION 2.3. *A function $\mathbf{y} \in \mathbf{V}_0^1(\Omega)$ is a nonsingular solution of* (1.2)*, or equivalently* (2.2)*, if $P(A + B'(\mathbf{y}))$ is an isomorphism from $\mathbf{V}_0^1(\Omega)$ into $\mathbf{V}^{-1}(\Omega)$. If, moreover, $A\mathbf{y} + B(\mathbf{y}) = \mathbf{f} + \mathcal{C}\mathbf{u}$ in $\mathbf{V}^{-1}(\Omega)$, with $\mathbf{u} \in L^2(\omega;\mathbb{R}^m)$, we will also say that the pair $(\mathbf{u},\mathbf{y})$ is a nonsingular solution of* (1.2).

Remark 2.4. For a nonsingular solution $(\mathbf{u},\mathbf{y})$ of (1.2), the condition $P(A + B'(\mathbf{y})) \in \mathrm{isom}(\mathbf{V}_0^1(\Omega),\mathbf{V}^{-1}(\Omega))$ corresponds to the one stated in [12, Chapter 4, condition (3.4)], which is used to get the error estimates for the approximation of the Navier–Stokes equations.

The following theorem is a straightforward consequence of the implicit function theorem and will be useful in what follows.

THEOREM 2.5. *Let $(\bar{\mathbf{u}},\bar{\mathbf{y}}) \in L^2(\omega;\mathbb{R}^m)\times\mathbf{V}_0^1(\Omega)$ be a nonsingular solution of* (1.2)*; then there exist an open neighborhood $\mathcal{O}(\bar{\mathbf{u}})$ of $\bar{\mathbf{u}}$ in $L^2(\omega;\mathbb{R}^m)$, an open neighborhood $\mathcal{O}(\bar{\mathbf{y}})$ of $\bar{\mathbf{y}}$ in $\mathbf{V}_0^1(\Omega)$, and a mapping G from $\mathcal{O}(\bar{\mathbf{u}})$ to $\mathcal{O}(\bar{\mathbf{y}})$ of class C^∞ such that, for all $\mathbf{u} \in \mathcal{O}(\bar{\mathbf{u}})$, $G(\mathbf{u}) = \mathbf{y}_\mathbf{u}$ is the unique solution in $\mathcal{O}(\bar{\mathbf{y}})$ to* (2.2)*. Moreover, if $\mathbf{z}_\mathbf{v} = G'(\mathbf{u})\mathbf{v} \in \mathbf{V}_0^1(\Omega)$ and $\mathbf{w} = G''(\mathbf{u})\mathbf{v}^2 \in \mathbf{V}_0^1(\Omega)$, then $\mathbf{z}_\mathbf{v}$ and $\mathbf{w}$ satisfy the equations*

$$A\mathbf{z}_\mathbf{v} + B'(\mathbf{y}_\mathbf{u})\mathbf{z}_\mathbf{v} = \mathcal{C}\mathbf{v} \quad \text{in } \mathbf{V}^{-1}(\Omega), \tag{2.6}$$

$$A\mathbf{w} + B'(\mathbf{y}_\mathbf{u})\mathbf{w} + B''(\mathbf{z}_\mathbf{v},\mathbf{z}_\mathbf{v}) = 0 \quad \text{in } \mathbf{V}^{-1}(\Omega), \tag{2.7}$$

and $P(A + B'(\mathbf{y}_\mathbf{u}))$ is an isomorphism from $\mathbf{V}_0^1(\Omega)$ into $\mathbf{V}^{-1}(\Omega)$ for all $\mathbf{u} \in \mathcal{O}(\bar{\mathbf{u}})$.

LEMMA 2.6. *Let $(\bar{\mathbf{u}},\bar{\mathbf{y}})$ be as in Theorem* 2.5*, and let $\bar{p}$ be the associated pressure (the solution of* (2.3) *corresponding to $\bar{\mathbf{y}}$). Let $(\mathbf{u}_k)_k$ be a sequence in $\mathcal{O}(\bar{\mathbf{u}})$ weakly converging to $\bar{\mathbf{u}}$ in $L^2(\omega;\mathbb{R}^m)$. Let $\mathbf{y}_k$ be the solution to* (1.2) *in $\mathcal{O}(\bar{\mathbf{y}})$ corresponding to $\mathbf{u}_k$, and let p_k be the associated pressure. Then $(\mathbf{y}_k)_k$ converges to $\bar{\mathbf{y}}$ in $\mathbf{V}_0^1(\Omega)$, and $(p_k)_k$ converges to $\bar{p}$ in $L_0^2(\Omega)$.*

Proof. The proof is an easy consequence of Theorem 2.2 and of formula (2.3). ∎

3. Analysis of the control problem. The existence of a solution of problem (P) can be obtained by the usual approach of taking a minimizing sequence, which is bounded in $L^2(\omega;\mathbb{R}^m)\times\mathbf{V}_0^1(\Omega)$, and passing to the limit; see, for instance, [18] for a detailed proof. In this section we will derive the first and second order optimality conditions for a local solution $(\bar{\mathbf{u}},\bar{\mathbf{y}})$ in $U_{ad}\times\mathbf{V}_0^1(\Omega)$.

3.1. First order optimality conditions. Let us precisely define local solutions of (P).

DEFINITION 3.1. *We shall say that $(\bar{\mathbf{u}},\bar{\mathbf{y}}) \in U_{ad}\times\mathbf{V}_0^1(\Omega)$ is a local solution of* (P) *if and only if $(\bar{\mathbf{u}},\bar{\mathbf{y}})$ satisfies* (1.2) *and there exist neighborhoods $\mathcal{O}(\bar{\mathbf{u}})$ of $\bar{\mathbf{u}}$ in $L^2(\omega;\mathbb{R}^m)$ and $\mathcal{O}(\bar{\mathbf{y}})$ of $\bar{\mathbf{y}}$ in $\mathbf{V}_0^1(\Omega)$ such that $F(\bar{\mathbf{u}},\bar{\mathbf{y}}) \le F(\mathbf{u},\mathbf{y})$ for all pairs $(\mathbf{u},\mathbf{y}) \in (U_{ad}\cap\mathcal{O}(\bar{\mathbf{u}}))\times\mathcal{O}(\bar{\mathbf{y}})$ satisfying* (1.2).

The following theorem was proved by Abergel and Casas [1] for a slightly different functional, but the proof can be repeated for our problem step by step, just by doing the obvious modifications.

THEOREM 3.2. *Let* $(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \in U_{ad} \times \mathbf{V}_0^1(\Omega)$ *be a local solution of* (P)*; then there exist a real number* $\bar{\lambda}$ *and some elements* $\bar{\mathbf{\Phi}} \in \mathbf{W}^{2,\bar{r}}(\Omega)$ *and* $\bar{\pi}, \bar{p} \in W^{1,\bar{r}}(\Omega)$ *such that*

$$\bar{\lambda} + \|\bar{\mathbf{\Phi}}\|_{\mathbf{V}_0^1(\Omega)} > 0, \tag{3.1}$$

$$-\nu\Delta\bar{\mathbf{y}} + (\bar{\mathbf{y}}\cdot\nabla)\bar{\mathbf{y}} + \nabla\bar{p} = \mathbf{f} + \mathcal{C}\bar{\mathbf{u}} \text{ in } \Omega,\ \operatorname{div}\bar{\mathbf{y}} = 0 \text{ in } \Omega,\ \bar{\mathbf{y}} = 0 \text{ on } \Gamma, \tag{3.2}$$

$$-\nu\Delta\bar{\mathbf{\Phi}} + (\nabla\bar{\mathbf{y}})^T\bar{\mathbf{\Phi}} - (\bar{\mathbf{y}}\cdot\nabla)\bar{\mathbf{\Phi}} + \nabla\bar{\pi} = \bar{\lambda}(\bar{\mathbf{y}} - \mathbf{y}_d) \text{ in } \Omega, \tag{3.3}$$

$$\operatorname{div}\bar{\mathbf{\Phi}} = 0 \text{ in } \Omega,\ \bar{\mathbf{\Phi}} = 0 \text{ on } \Gamma, \tag{3.4}$$

$$\int_\omega (\mathcal{C}^*\bar{\mathbf{\Phi}} + \bar{\lambda}N\bar{\mathbf{u}})\cdot(\mathbf{u} - \bar{\mathbf{u}})\,dx \geq 0\ \forall\,\mathbf{u} \in U_{ad}. \tag{3.5}$$

These conditions for optimality are of Fritz–John type, and we are interested in the cases where $\bar{\lambda}$ can be chosen equal to one. Gunzburger, Hou, and Svobodny [14] introduced an assumption on U_{ad} for the local solution $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$. The control set U_{ad} is said to have the property (C) at $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ if the system

$$-\nu\Delta\mathbf{\Phi} + (\nabla\bar{\mathbf{y}})^T\mathbf{\Phi} - (\mathbf{y}\cdot\nabla)\mathbf{\Phi} + \nabla\pi = \bar{\lambda}(\bar{\mathbf{y}} - \mathbf{y}_d) \text{ in } \Omega,\ \operatorname{div}\mathbf{\Phi} = 0 \text{ in } \Omega,\ \mathbf{\Phi} = 0 \text{ on } \Gamma,$$

admits at least a nonzero solution $(\mathbf{\Phi}, \pi) \in \mathbf{V}_0^1(\Omega) \times L_0^2(\Omega)$, and if for any nonzero solution $(\mathbf{\Phi}, \pi)$ we can find $\mathbf{u} \in U_{ad}$ such that

$$\int_\omega \mathcal{C}^*\mathbf{\Phi}\cdot(\mathbf{u} - \bar{\mathbf{u}})\,dx < 0.$$

It is obvious that if U_{ad} has the property (C) at $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$, then (3.2)–(3.5) hold with $\bar{\lambda} = 1$.

Here we will make a different assumption which will be crucial in what follows, in particular for the numerical analysis. We consider only local solutions $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ of (P) such that $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is a nonsingular solution of (2.2). In that case we shall say that $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is a *local nonsingular solution* of (P). For such a local nonsingular solution we can apply Theorem 2.5 and define the control problem

$$\inf\Big\{J(\mathbf{u}) \mid \mathbf{u} \in U_{ad} \cap \mathcal{O}(\bar{\mathbf{u}})\Big\}, \tag{$\mathrm{P}_{\mathcal{O}(\bar{\mathbf{u}})}$}$$

where $J : \mathcal{U} \longmapsto \mathbb{R}$ is given by $J(\mathbf{u}) = F(\mathbf{u}, G(\mathbf{u}))$. Then $\bar{\mathbf{u}}$ is a local solution of $(\mathrm{P}_{\mathcal{O}(\bar{\mathbf{u}})})$. Let us study the differentiability properties of J.

THEOREM 3.3. *Function* J *is of class* C^∞ *in* $\mathcal{O}(\bar{\mathbf{u}})$*, and for every* $\mathbf{u} \in \mathcal{O}(\bar{\mathbf{u}})$ *and* $\mathbf{v} \in L^2(\omega;\mathbb{R}^m)$ *we have*

$$J'(\mathbf{u})\mathbf{v} = \int_\omega (\mathcal{C}^*\mathbf{\Phi}_\mathbf{u} + N\mathbf{u})\cdot\mathbf{v}\,dx, \tag{3.6}$$

$$J''(\mathbf{u})\mathbf{v}^2 = \int_\Omega (|\mathbf{z}_\mathbf{v}|^2 - 2(\mathbf{z}_\mathbf{v}\cdot\nabla)\mathbf{z}_\mathbf{v}\cdot\mathbf{\Phi}_\mathbf{u})dx + N\int_\omega |\mathbf{v}|^2 dx, \tag{3.7}$$

where $\mathbf{z}_\mathbf{v}$ *is the solution of* (2.6) *and* $\mathbf{\Phi}_\mathbf{u} \in \mathbf{V}_0^1(\Omega)$ *satisfies*

$$\begin{cases} -\nu\Delta\mathbf{\Phi}_\mathbf{u} + (\nabla\mathbf{y}_\mathbf{u})^T\mathbf{\Phi}_\mathbf{u} - (\mathbf{y}_\mathbf{u}\cdot\nabla)\mathbf{\Phi}_\mathbf{u} + \nabla\pi_\mathbf{u} = \mathbf{y}_\mathbf{u} - \mathbf{y}_d \text{ in } \Omega, \\ \operatorname{div}\mathbf{\Phi}_\mathbf{u} = 0 \text{ in } \Omega,\ \mathbf{\Phi}_\mathbf{u} = 0 \text{ on } \Gamma. \end{cases} \tag{3.8}$$

The proof follows easily from Theorem 2.5. The only delicate point is the definition of $\mathbf{\Phi}_\mathbf{u}$. Let us remark that (3.8) is equivalent to the equation $A^*\mathbf{\Phi}_\mathbf{u} +$

$B'(\mathbf{y_u})^*\mathbf{\Phi_u} = \mathbf{y_u} - \mathbf{y}_d$ in $\mathbf{V}^{-1}(\Omega)$, and due to Theorem 2.5 the operator $P(A^* + B'(\mathbf{y_u})^*)$ is an isomorphism from $\mathbf{V}_0^1(\Omega)$ into $\mathbf{V}^{-1}(\Omega)$.

By using the previous theorem we get the following result.

THEOREM 3.4. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \in U_{ad} \times \mathbf{V}_0^1(\Omega)$ be a local nonsingular solution of* (P)*, and let $\bar{p}$ be the associated pressure; then there exist some elements $\bar{\mathbf{\Phi}} \in \mathbf{V}_0^1(\Omega)$ and $\bar{\pi} \in L_0^2(\Omega)$ such that* (3.2)–(3.5) *hold with $\bar{\lambda} = 1$.*

Proof. It is enough to take into account that $J'(\bar{\mathbf{u}})(\mathbf{u} - \bar{\mathbf{u}}) \geq 0$ for all $\mathbf{u} \in U_{ad}$ and to use (3.6). ∎

Using the first order necessary conditions we can deduce some extra regularity for the optimal control, the state, and the adjoint state.

THEOREM 3.5. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ be a local nonsingular solution of* (P) *and let $\bar{\mathbf{\Phi}}$ be the adjoint state as defined by* (3.3)–(3.4) *with $\bar{\lambda} = 1$. Then $\bar{\mathbf{y}}, \bar{\mathbf{\Phi}} \in \mathbf{W}^{2,\bar{r}}(\Omega)$, $\bar{p}, \bar{\pi} \in W^{1,\bar{r}}(\Omega)$, and $\bar{\mathbf{u}} \in C^{0,1}(\bar{\omega}; \mathbb{R}^m)$.*

Proof. Taking into account that $\mathcal{C}\bar{\mathbf{u}} \in \mathbf{L}^2(\Omega)$ and the assumption on $\mathbf{f}$, it is enough to apply Theorem 2.2 to deduce that $\bar{\mathbf{y}}$ belongs to $\mathbf{H}^2(\Omega)$ and that $\bar{\mathbf{\Phi}}$ belongs to $\mathbf{W}^{2,\bar{r}}(\Omega)$. On the other hand, $\bar{\mathbf{\Phi}} \in \mathbf{W}^{2,\bar{r}}(\Omega) \subset C^{0,1}(\bar{\Omega}; \mathbb{R}^d)$ because $\bar{r} > d$. Now using the Lipschitz property of the function M defining $\mathcal{C}$ and the representation of the optimal control deduced from (3.5), we obtain

$$\bar{u}_j(x) = \mathrm{Proj}_{[\alpha_j, \beta_j]}\left(-\frac{1}{N}(\mathcal{C}^*\bar{\mathbf{\Phi}})_j(x)\right) \quad \text{for a.e. } x \in \omega, \tag{3.9}$$

which gives the desired regularity for $\bar{\mathbf{u}}$. Now still using Theorem 2.2, we obtain the regularity of $\bar{\mathbf{y}}$. ∎

3.2. Second order optimality conditions. To perform the numerical analysis of the problem as well as the analysis of the algorithms of optimization, second order sufficient conditions are required. These sufficient conditions should be as unrestrictive as possible. One way of measuring this is to compare them with the necessary second order conditions and check if the gap is small. This is the reason why we first introduce the second order necessary conditions.

Second order conditions have to be written for directions $\mathbf{v} \in T_{U_{ad}}(\bar{\mathbf{u}})$ such that $J'(\mathbf{u})\mathbf{v} = 0$, where $T_{U_{ad}}(\bar{\mathbf{u}})$ is the tangent cone at $\bar{\mathbf{u}}$ to U_{ad}. To characterize these directions, we introduce $\bar{\mathbf{d}}(x) = \mathcal{C}^*\bar{\mathbf{\Phi}}(x) + N\bar{\mathbf{u}}(x)$ for $x \in \omega$, and the following conditions:

$$v_j(x) = 0 \text{ if } \bar{d}_j(x) \neq 0, \tag{3.10}$$

$$v_j(x) \geq 0 \text{ if } -\infty < \alpha_j = \bar{u}_j(x) \text{ and } \bar{d}_j(x) = 0, \tag{3.11}$$

$$v_j(x) \leq 0 \text{ if } \bar{u}_j(x) = \beta_j < \infty \text{ and } \bar{d}_j(x) = 0. \tag{3.12}$$

Now we define the cone

$$C_{\bar{\mathbf{u}}} = \Big\{\mathbf{v} \in L^2(\omega; \mathbb{R}^m) \mid \mathbf{v} \text{ satisfies (3.10)–(3.12)}\Big\}.$$

Notice that

$$\begin{aligned} &J'(\bar{\mathbf{u}})\mathbf{v} = \int_\omega \bar{\mathbf{d}}(x) \cdot \mathbf{v}(x)\, dx \;\forall\, \mathbf{v} \in L^2(\omega; \mathbb{R}^m), \\ &\bar{\mathbf{d}}(x) \cdot \mathbf{v}(x) = 0 \text{ for a.e. } x \in \omega \text{ and all } \mathbf{v} \in C_{\bar{\mathbf{u}}}. \end{aligned} \tag{3.13}$$

THEOREM 3.6. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ be a nonsingular local solution of* (P)*. Then*

$$J''(\bar{\mathbf{u}})\mathbf{v}^2 \geq 0 \quad \forall\, \mathbf{v} \in C_{\bar{\mathbf{u}}}.$$

Proof. We sketch the proof in the case where $-\infty < \alpha_j < \beta_j < \infty$ for all $1 \le j \le m$. The modifications for the other cases are obvious. Take $\mathbf{v} \in C_{\bar{\mathbf{u}}}$, and for $\varepsilon < \min\{(\beta_j - \alpha_j)/2 : \ 1 \le j \le m\}$ define

$$v_{j,\varepsilon}(x) = \begin{cases} 0 & \text{if } \alpha_j < \bar{u}_j(x) < \alpha_j + \varepsilon, \\ 0 & \text{if } \beta_j - \varepsilon < \bar{u}_j(x) < \beta_j, \\ \mathrm{Proj}_{[-\frac{1}{\varepsilon}, \frac{1}{\varepsilon}]}(v_j(x)) & \text{otherwise.} \end{cases}$$

It is clear that $|v_{j,\varepsilon}(x)| \le |v_j(x)|$ and that $v_{j,\varepsilon}(x) \to v_j(x)$ for a.e. $x \in \omega$ as $\varepsilon \to 0$, and hence $\mathbf{v}_\varepsilon \to \mathbf{v}$ in $L^2(\omega; \mathbb{R}^m)$. A simple inspection convinces us that $\mathbf{v}_\varepsilon \in C_{\bar{\mathbf{u}}}$. Let us check that $\bar{\mathbf{u}} + \rho \mathbf{v}_\varepsilon \in U_{ad}$ for every $0 < \rho < \varepsilon^2$. If $\bar{d}_j(x) \ne 0$, then $v_{j,\varepsilon}(x) = 0$. So $\bar{u}_j(x) + \rho v_{j,\varepsilon}(x) = \bar{u}_j(x) \in [\alpha_j, \beta_j]$. For $\bar{d}_j(x) = 0$, we have the following:

(1) If $\bar{u}_j(x) = \alpha_j$, then $v_j(x) \ge 0$ and $v_{j,\varepsilon}(x) \ge 0$. So clearly $\alpha_j \le u_j(x) + \rho v_{j,\varepsilon}(x)$. For the other inequality we write $u_j(x) + \rho v_{j,\varepsilon}(x) \le \alpha_j + \varepsilon^2 \frac{1}{\varepsilon} \le \frac{\alpha_j + \beta_j}{2} < \beta_j$. If $\bar{u}_j(x) = \beta_j$, the argument is completely analogous.

(2) If $\alpha_j < \bar{u}_j(x) < \alpha_j + \varepsilon$, then $\bar{u}_j(x) + \rho v_{j,\varepsilon}(x) = \bar{u}_j(x) \in [\alpha_j, \beta_j]$. The same applies if $\beta_j - \varepsilon < \bar{u}_j(x) < \beta_j$.

(3) If $\alpha_j + \varepsilon \le \bar{u}_j(x) \le \beta_j - \varepsilon$, then on the left side, $\bar{u}_j(x) + \rho v_{j,\varepsilon}(x) \ge \alpha_j + \varepsilon - \varepsilon^2 \frac{1}{\varepsilon} = \alpha_j$, and on the right side $\bar{u}_j(x) + \rho v_{j,\varepsilon}(x) \le \beta_j - \varepsilon + \varepsilon^2 \frac{1}{\varepsilon} = \beta_j$.

Thus $\bar{\mathbf{u}} + \rho \mathbf{v}_\varepsilon$ belongs to U_{ad}. Making a second order Taylor expansion of J at $\bar{\mathbf{u}}$ and taking into account that it is a local minimum for $\rho < \varepsilon^2$ small enough, there exists $0 < \theta_\rho < \rho$ such that

$$0 \le J(\bar{\mathbf{u}} + \rho \mathbf{v}_\varepsilon) - J(\bar{\mathbf{u}}) = \rho J'(\bar{\mathbf{u}}) \mathbf{v}_\varepsilon + \frac{\rho^2}{2} J''(\bar{\mathbf{u}} + \theta_\rho \mathbf{v}_\varepsilon) \mathbf{v}_\varepsilon^2.$$

Since $\mathbf{v}_\varepsilon \in C_{\bar{\mathbf{u}}}$, (3.13) implies that $J'(\bar{\mathbf{u}}) \mathbf{v}_\varepsilon = 0$. Therefore the above inequality leads to $J''(\bar{\mathbf{u}} + \theta_\rho \mathbf{v}_\varepsilon) \mathbf{v}_\varepsilon^2 \ge 0$. Now we must take the limit as $\rho \to 0$ to get $J''(\bar{\mathbf{u}}) \mathbf{v}_\varepsilon^2 \ge 0$. Next it is enough to take the limit as $\varepsilon \to 0$. To do this, let us recall the expression of $J''(\bar{\mathbf{u}})$ provided by (3.7):

$$J''(\bar{\mathbf{u}}) \mathbf{v}_\varepsilon^2 = \int_\Omega (|\mathbf{z}_{\mathbf{v}_\varepsilon}|^2 - 2(\mathbf{z}_{\mathbf{v}_\varepsilon} \cdot \nabla) \mathbf{z}_{\mathbf{v}_\varepsilon} \cdot \boldsymbol{\Phi}_{\bar{\mathbf{u}}}) \, dx + N \int_\omega |\mathbf{v}_\varepsilon|^2 dx$$

$$\longrightarrow \int_\Omega (|\mathbf{z}_{\mathbf{v}}|^2 - 2(\mathbf{z}_{\mathbf{v}} \cdot \nabla) \mathbf{z}_{\mathbf{v}} \cdot \boldsymbol{\Phi}_{\bar{\mathbf{u}}}) \, dx + N \int_\omega |\mathbf{v}|^2 dx = J''(\bar{\mathbf{u}}) \mathbf{v}^2 \quad \text{as } \varepsilon \to 0. \qquad \square$$

The following result is an obvious consequence of the previous theorem and the expression of J'' given by (3.7).

COROLLARY 3.7. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ be a nonsingular local solution of* (P) *and let $\bar{\boldsymbol{\Phi}}$ be the corresponding adjoint state. Then*

$$\int_\Omega (|\mathbf{z}|^2 - 2(\mathbf{z} \cdot \nabla) \mathbf{z} \cdot \bar{\boldsymbol{\Phi}}) dx + N \int_\omega |\mathbf{v}|^2 dx \ge 0 \tag{3.14}$$

for every $(\mathbf{v}, \mathbf{z})$ satisfying the linearized state equation (2.6) *and $\mathbf{v} \in C_{\bar{\mathbf{u}}}$.*

To state second order sufficient conditions we will *not* suppose that $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is a nonsingular solution of the Navier–Stokes equations (1.2). The result we are going to state is the following.

THEOREM 3.8. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{\boldsymbol{\Phi}}) \in L^2(\omega; \mathbb{R}^m) \times \mathbf{V}_0^1(\Omega) \times \mathbf{V}_0^1(\Omega)$ satisfy* (3.2)–(3.5) *with $\bar{\lambda} = 1$. Let us suppose that*

$$\int_\Omega (\mathbf{z}^2 - 2(\mathbf{z} \cdot \nabla) \mathbf{z} \cdot \bar{\boldsymbol{\Phi}}) dx + N \int_\omega \mathbf{v}^2 dx > 0 \tag{3.15}$$

for every $(\mathbf{v},\mathbf{z}) \neq (0,0)$ *satisfying the linearized state equation* (2.6) *and* $\mathbf{v} \in C_{\bar{\mathbf{u}}}$. *Then there exist* $\varepsilon > 0$ *and* $\mu > 0$ *such that*

$$F(\bar{\mathbf{u}},\bar{\mathbf{y}}) + \frac{\mu}{2}\left(\|\mathbf{u}-\bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{y}-\bar{\mathbf{y}}\|^2_{\mathbf{L}^2(\Omega)}\right) \leq F(\mathbf{u},\mathbf{y})$$

for every $(\mathbf{u},\mathbf{y})$ *satisfying* (1.2), $\mathbf{u} \in U_{ad}$, *and* $\|\mathbf{u}-\bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{y}-\bar{\mathbf{y}}\|^2_{\mathbf{L}^2(\Omega)} \leq \varepsilon^2$.

Proof. Let us suppose the theorem is false. In that case, for all $k \in \mathbb{N}$, there exists $(\mathbf{u}_k,\mathbf{y}_k)$ satisfying (1.2), $\mathbf{u}_k \in U_{ad}$,

$$\|\mathbf{u}_k-\bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{y}_k-\bar{\mathbf{y}}\|^2_{\mathbf{L}^2(\Omega)} < \frac{1}{k^2},$$

and

$$F(\bar{\mathbf{u}},\bar{\mathbf{y}}) + \frac{1}{k}\left(\|\mathbf{u}_k-\bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{y}_k-\bar{\mathbf{y}}\|^2_{\mathbf{L}^2(\Omega)}\right) > F(\mathbf{u}_k,\mathbf{y}_k). \tag{3.16}$$

Since the sequence $\{\mathbf{u}_k\}_{k=1}^\infty$ is bounded in $L^2(\omega;\mathbb{R}^m)$, Theorem 2.2 implies that $\{\mathbf{y}_k\}_{k=1}^\infty$ is bounded in $\mathbf{H}^2(\Omega)\cap\mathbf{V}_0^1(\Omega)$. Let us set

$$\rho_k = \sqrt{\|\mathbf{u}_k-\bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{y}_k-\bar{\mathbf{y}}\|^2_{\mathbf{L}^2(\Omega)}},\ \mathbf{v}_k = \frac{\mathbf{u}_k-\bar{\mathbf{u}}}{\rho_k},\ \mathbf{z}_k = \frac{\mathbf{y}_k-\bar{\mathbf{y}}}{\rho_k}.$$

Clearly $\|\mathbf{v}_k\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}_k\|^2_{\mathbf{L}^2(\Omega)} = 1$, and hence there exist weakly convergent subsequences in $L^2(\omega;\mathbb{R}^m)$ and $\mathbf{L}^2(\Omega)$, still indexed by k, such that $\mathbf{v}_k \rightharpoonup \mathbf{v}$, $\mathbf{z}_k \rightharpoonup \mathbf{z}$. We are going to check that the pair $(\mathbf{v},\mathbf{z})$ satisfies the linearized equation (2.6) and $\mathbf{v} \in C_{\bar{\mathbf{u}}}$.

The pair $(\mathbf{v}_k,\mathbf{z}_k)$ satisfies the equation

$$\begin{cases} -\nu\Delta\mathbf{z}_k + (\bar{\mathbf{y}}\cdot\nabla)\mathbf{z}_k + (\mathbf{z}_k\cdot\nabla)\mathbf{y}_k + \nabla\pi_k = \mathcal{C}\mathbf{v}_k \text{ in } \Omega, \\ \operatorname{div}\mathbf{z}_k = 0 \text{ in } \Omega,\ \mathbf{z}_k = 0 \text{ on } \Gamma, \end{cases} \tag{3.17}$$

where $\pi_k = (\bar{p}-p_k)/\rho_k$, which is equivalent to the variational formulation

$$a(\mathbf{z}_k,\mathbf{z}) + b(\bar{\mathbf{y}},\mathbf{z}_k,\mathbf{z}) + b(\mathbf{z}_k,\mathbf{y}_k,\mathbf{z}) = (\mathcal{C}\mathbf{v}_k,\mathbf{z})\ \forall\,\mathbf{z} \in \mathbf{V}_0^1(\Omega). \tag{3.18}$$

Taking $\mathbf{z} = \mathbf{z}_k$ and using (2.4), we obtain

$$a(\mathbf{z}_k,\mathbf{z}_k) = (\mathcal{C}\mathbf{v}_k,\mathbf{z}_k) - \int_\Omega (\mathbf{z}_k\cdot\nabla)\mathbf{y}_k\cdot\mathbf{z}_k dx.$$

Using the equality $\|\mathbf{v}_k\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}_k\|^2_{\mathbf{L}^2(\Omega)} = 1$ and the imbedding $\mathbf{H}^1(\Omega)\subset\mathbf{L}^4(\Omega)$, we obtain

$$\nu\|\mathbf{z}_k\|^2_{\mathbf{H}^1(\Omega)} \leq \|\mathcal{C}\| + \|\mathbf{y}_k\|_{\mathbf{H}^1(\Omega)}\|\mathbf{z}_k\|^2_{\mathbf{L}^4(\Omega)} \leq C(1+\|\mathbf{z}_k\|^2_{\mathbf{L}^4(\Omega)}),$$

because $(\mathbf{y}_k)_k$ is bounded in $\mathbf{H}^1(\Omega)$. From the well-known interpolation inequality when $d=3$ (see Temam [20, Lemma 3.5, p. 296]),

$$\|\zeta\|_{L^4(\Omega)} \leq \sqrt{2}\|\zeta\|^{1/4}_{L^2(\Omega)}\|\zeta\|^{3/4}_{H^1(\Omega)}\quad \forall\zeta \in H_0^1(\Omega),$$

and the bound $\|\mathbf{z}_k\|_{\mathbf{L}^2(\Omega)} \leq 1$, it follows that

$$\|\mathbf{z}_k\|^2_{\mathbf{H}^1(\Omega)} \leq C\left(1+\|\mathbf{z}_k\|^{3/2}_{\mathbf{H}^1(\Omega)}\right).$$

Thus the sequence $\{\mathbf{z}_k\}$ is bounded in $\mathbf{V}_0^1(\Omega)$, and therefore $\{\mathbf{z}_k\}$ converges strongly to $\mathbf{z}$ in $\mathbf{L}^2(\Omega)$. Now we can take the limit in (3.18), and we obtain that $(\mathbf{v}, \mathbf{z})$ satisfies (2.6).

Let us now check that $\mathbf{v} \in C_{\bar{\mathbf{u}}}$. The sign condition (3.11)–(3.12) is satisfied by $v_{k,j}$, and this is conserved when we pass to the weak limit because the set of functions satisfying these sign conditions is closed and convex in $L^2(\omega; \mathbb{R}^m)$. On the other hand, using condition (3.16), for all k, we have

$$\begin{aligned}\frac{\rho_k}{k} &> \frac{F(\bar{\mathbf{u}} + \rho_k \mathbf{v}_k, \bar{\mathbf{y}} + \rho_k \mathbf{z}_k) - F(\bar{\mathbf{u}}, \bar{\mathbf{y}})}{\rho_k} \\ &= \frac{1}{2} \int_\Omega \frac{|\bar{\mathbf{y}} + \rho_k \mathbf{z}_k - \mathbf{y}_d|^2 - |\bar{\mathbf{y}} - \mathbf{y}_d|^2}{\rho_k} dx + \frac{N}{2} \int_\omega \frac{|\bar{\mathbf{u}} + \rho_k \mathbf{v}_k|^2 - |\bar{\mathbf{u}}|^2}{\rho_k} dx \\ &= \frac{1}{2} \int_\Omega (2(\bar{\mathbf{y}} - \mathbf{y}_d) + \rho_k \mathbf{z}_k) \cdot \mathbf{z}_k \, dx + \frac{N}{2} \int_\omega (2\bar{\mathbf{u}} + \rho_k \mathbf{v}_k) \cdot \mathbf{v}_k \, dx.\end{aligned}$$

Since $\|\mathbf{v}_k\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}_k\|^2_{\mathbf{L}^2(\Omega)} = 1$, $\rho_k < 1/k$ converges to 0, $\mathbf{z}_k \to \mathbf{z}$ in $\mathbf{L}^2(\Omega)$, and $\mathbf{v}_k \rightharpoonup \mathbf{v}$ weakly in $L^2(\omega; \mathbb{R}^m)$, we can pass to the limit when k tends to infinity, and we get

$$\int_\Omega (\bar{\mathbf{y}} - \mathbf{y}_d) \cdot \mathbf{z} \, dx + N \int_\omega \bar{\mathbf{u}} \cdot \mathbf{v} \, dx \le 0,$$

which is exactly

$$\int_\omega \bar{\mathbf{d}}(x) \cdot \mathbf{v}(x) \le 0.$$

The sign condition (3.5) implies that $\bar{d}_j(x) v_j(x) \ge 0$ for a.e. $x \in \omega$; therefore the above inequality is equivalent to

$$\sum_{j=1}^m \int_\Omega |\bar{d}_j(x) v_j(x)| \, dx \le 0.$$

Thus if $\bar{d}_j(x) \ne 0$, $v_j(x) = 0$, $1 \le j \le m$, and hence $\mathbf{v} \in C_{\bar{\mathbf{u}}}$.

Making a second order Taylor expansion of F at $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$, with condition (3.16), we obtain

$$\frac{1}{\rho_k} \left(\partial_{\mathbf{u}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \mathbf{v}_k + \partial_{\mathbf{y}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \mathbf{z}_k\right) + \frac{1}{2} \int_\Omega |\mathbf{z}_k|^2 \, dx + \frac{N}{2} \int_\omega |\mathbf{v}_k|^2 \, dx < \frac{1}{k}. \tag{3.19}$$

Notice that the pair $(\mathbf{v}_k, \mathbf{z}_k)$ satisfies (3.17), but does not satisfy the linearized equation (2.6). Thus $\frac{1}{\rho_k} \left(\partial_{\mathbf{u}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \mathbf{v}_k + \partial_{\mathbf{y}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \mathbf{z}_k\right)$ is not equal to $\int_\omega \bar{\mathbf{d}}(x) \cdot \mathbf{v}_k(x) dx$. We can write (3.17) as follows:

$$\begin{aligned}&-\nu \Delta \mathbf{z}_k + (\bar{\mathbf{y}} \cdot \nabla) \mathbf{z}_k + (\mathbf{z}_k \cdot \nabla) \bar{\mathbf{y}} + \nabla \pi_k = \mathcal{C} \mathbf{v}_k - (\mathbf{z}_k \cdot \nabla)(\mathbf{y}_k - \bar{\mathbf{y}}) \text{ in } \Omega, \\ &\operatorname{div} \mathbf{z}_k = 0 \text{ in } \Omega, \ \mathbf{z}_k = 0 \text{ on } \Gamma.\end{aligned}$$

Since

$$\partial_{\mathbf{u}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \mathbf{v}_k + \partial_{\mathbf{y}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \mathbf{z}_k = \int_\Omega (\bar{\mathbf{y}} - \mathbf{y}_d) \cdot \mathbf{z}_k dx + N \int_\omega \bar{\mathbf{u}} \cdot \mathbf{v}_k dx,$$

using the adjoint state $\bar{\mathbf{\Phi}}$ and making an integration by parts, we get that

$$\int_\Omega (\bar{\mathbf{y}} - \mathbf{y}_d) \cdot \mathbf{z}_k dx = \int_\Omega \bar{\mathbf{\Phi}} \cdot (\mathcal{C}\mathbf{v}_k - (\mathbf{z}_k \cdot \nabla)(\mathbf{y}_k - \bar{\mathbf{y}}))\, dx,$$

and therefore

$$\frac{1}{\rho_k} (\partial_{\mathbf{u}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}})\mathbf{v}_k + \partial_{\mathbf{y}} F(\bar{\mathbf{u}}, \bar{\mathbf{y}})\mathbf{z}_k) = \frac{1}{\rho_k} \int_\omega \bar{\mathbf{d}}(x) \cdot \mathbf{v}_k(x) dx - \int_\Omega (\mathbf{z}_k \cdot \nabla)\mathbf{z}_k \cdot \bar{\mathbf{\Phi}} dx.$$

Since $\mathbf{v}_k$ satisfy the sign condition, we have $\bar{\mathbf{d}}(x) \cdot \mathbf{v}_k(x) \geq 0$; therefore (3.19) leads to

$$-2 \int_\Omega (\mathbf{z}_k \cdot \nabla)\mathbf{z}_k \cdot \bar{\mathbf{\Phi}} dx + \int_\Omega |\mathbf{z}_k|^2 dx + N \int_\omega |\mathbf{v}_k|^2 dx < \frac{2}{k} \quad \forall k.$$

Taking the inferior limit in this inequality we deduce

$$\int_\Omega (|\mathbf{z}|^2 - 2(\mathbf{z} \cdot \nabla)\mathbf{z} \cdot \bar{\mathbf{\Phi}}) dx + N \int_\omega |\mathbf{v}|^2 dx \leq 0.$$

Since $\mathbf{v} \in C_{\bar{\mathbf{u}}}$ and the pair $(\mathbf{v}, \mathbf{z})$ satisfies the linearized equation (2.6), this is possible only if $(\mathbf{v}, \mathbf{z}) = (0, 0)$.

The sequence $\{\mathbf{z}_k\}_{k=1}^\infty$ converges strongly in $\mathbf{L}^2(\Omega)$ and weakly in $\mathbf{V}_0^1(\Omega)$. Since $\bar{\mathbf{\Phi}} \in \mathbf{L}^\infty(\Omega)$, by passing to the limit when k tends to infinity, we obtain

$$-2 \int_\Omega (\mathbf{z}_k \cdot \nabla)\mathbf{z}_k \cdot \bar{\mathbf{\Phi}} dx + \int_\Omega |\mathbf{z}_k|^2 dx \to -2 \int_\Omega (\mathbf{z} \cdot \nabla)\mathbf{z} \cdot \bar{\mathbf{\Phi}} dx + \int_\Omega |\mathbf{z}|^2 dx = 0.$$

The last three relations imply that $\mathbf{v}_k \to 0$ strongly in $L^2(\omega; \mathbb{R}^m)$. So we have proved that $(\mathbf{v}_k, \mathbf{z}_k) \to 0$ strongly in $L^2(\omega)^m \times \mathbf{L}^2(\Omega)$, which contradicts the fact that

$$\|\mathbf{v_k}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z_k}\|^2_{\mathbf{L}^2(\Omega)} = 1.$$

The proof is complete. □

The sufficient condition (3.15) is the best possible. Actually the gap between (3.15) and the second order necessary condition (3.14) is the same as in finite dimension. In the case of nonsingular solutions we have the following result analogous to Theorem 3.6.

COROLLARY 3.9. *Let us assume that* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ *is a nonsingular solution of* (1.2) *and* $(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{\mathbf{\Phi}})$ *satisfies* (3.2)–(3.5) *with* $\bar{\lambda} = 1$. *Then* (3.15) *is equivalent to* $J''(\bar{\mathbf{u}})\mathbf{v}^2 > 0$ *for every* $\mathbf{v} \in C_{\bar{\mathbf{u}}} \setminus \{0\}$.

This corollary is an immediate consequence of (3.7) and the fact that $\mathbf{z} = \mathbf{z_v}$ if $(\mathbf{v}, \mathbf{z})$ satisfies (2.6).

To make the numerical analysis of control problem (P), we will use the following equivalent condition to (3.15), which may seem stronger but is not, as we will see below. Given $\tau > 0$, let us define a bigger cone than $C_{\bar{\mathbf{u}}}$ in the following way:

$$v_j(x) = 0 \quad \text{if } |\bar{d}_j(x)| > \tau, \tag{3.20}$$

$$v_j(x) \geq 0 \quad \text{if } -\infty < \alpha_j = \bar{u}_j(x) \text{ and } |\bar{d}_j(x)| \leq \tau, \tag{3.21}$$

$$v_j(x) \leq 0 \quad \text{if } \bar{u}_j(x) = \beta_j < \infty \text{ and } |\bar{d}_j(x)| \leq \tau, \tag{3.22}$$

and

$$C^\tau_{\bar{\mathbf{u}}} = \Big\{ \mathbf{v} \in L^2(\omega; \mathbb{R}^m) \mid \mathbf{v} \text{ satisfies (3.20)–(3.22)} \Big\}.$$

THEOREM 3.10. *Let* $(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{\mathbf{\Phi}}) \in L^2(\omega;\mathbb{R}^m) \times \mathbf{V}_0^1(\Omega) \times \mathbf{V}_0^1(\Omega)$ *satisfy* (3.2)–(3.5) *with* $\bar{\lambda} = 1$. *Then the condition* (3.15) *is equivalent to the existence of* $\delta > 0$ *and* $\tau > 0$ *such that*

$$\int_\Omega (|\mathbf{z}|^2 - 2(\mathbf{z}\cdot\nabla)\mathbf{z}\cdot\bar{\mathbf{\Phi}})\,dx + N\int_\omega |\mathbf{v}|^2\,dx \geq \delta\left(\|\mathbf{v}\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}\|^2_{\mathbf{L}^2(\Omega)}\right) \tag{3.23}$$

for every $(\mathbf{v},\mathbf{z})$ *satisfying the linearized state equation* (2.6) *and* $\mathbf{v} \in C^\tau_{\bar{\mathbf{u}}}$.

Proof. Notice that $C_{\bar{\mathbf{u}}} = C^0_{\bar{\mathbf{u}}} \subseteq C^\tau_{\bar{\mathbf{u}}}$; therefore (3.23) implies (3.15).

Suppose that (3.15) holds and (3.23) is false. In that case, for every $k \in \mathbb{N}$ there exists a pair $(\mathbf{v}_k, \mathbf{z}_k)$ satisfying the linearized state equation (2.6), $\mathbf{v}_k \in C^{1/k}_{\bar{\mathbf{u}}}$, and

$$\int_\Omega (|\mathbf{z}_k|^2 - 2(\mathbf{z}_k\cdot\nabla)\mathbf{z}_k\cdot\bar{\mathbf{\Phi}})dx + N\int_\omega \mathbf{v}_k^2 dx < \frac{1}{k}\left(\|\mathbf{v}_k\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}_k\|^2_{\mathbf{L}^2(\Omega)}\right). \tag{3.24}$$

We can suppose that $\|\mathbf{v}_k\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}_k\|^2_{\mathbf{L}^2(\Omega)} = 1$; otherwise we can redefine $\mathbf{v}_k = \mathbf{v}_k/\rho_k$ and $\mathbf{z}_k = \mathbf{z}_k/\rho_k$, with $\rho_k = (\|\mathbf{v}_k\|^2_{L^2(\omega;\mathbb{R}^m)} + \|\mathbf{z}_k\|^2_{\mathbf{L}^2(\Omega)})^{1/2}$. Then there exist two weakly convergent subsequences in $L^2(\omega;\mathbb{R}^m)$ and $\mathbf{L}^2(\Omega)$, still indexed by k, such that $\mathbf{v}_k \rightharpoonup \mathbf{v}$ and $\mathbf{z}_k \rightharpoonup \mathbf{z}$. Repeating the argument of the proof of Theorem 3.8, we deduce that the pair $(\mathbf{v},\mathbf{z})$ satisfies the linearized equation (2.6) and $\{\mathbf{z}_k\}_{k=1}^\infty$ is bounded in $\mathbf{V}_0^1(\Omega)$. Thus $\{\mathbf{z}_k\}_{k=1}^\infty$ converges strongly in $\mathbf{L}^4(\Omega)$. Let us prove that $\mathbf{v} \in C_{\bar{\mathbf{u}}}$. The sign condition (3.11)–(3.12) is again trivial since every $\mathbf{v}_k$ satisfies it. To check condition (3.10) we are going to prove that if $|\bar{d}_j(x)| \neq 0$, then $v_j(x) = 0$. Let us fix $\varepsilon > 0$ and define $\omega_\varepsilon = \{x \in \omega : |d_j(x)| > \varepsilon\}$. Notice that $\int_{\omega_\varepsilon} v_{j,k}(x)\bar{d}_j(x)dx \to \int_{\omega_\varepsilon} v_j(x)\bar{d}_j(x)dx$ when k tends to infinity. From the definition of $C^{1/k}_{\bar{\mathbf{u}}}$ it follows that for $k > 1/\varepsilon$ all the terms of the sequence $\{\int_{\omega_\varepsilon} v_{j,k}(x)\bar{d}_j(x)dx\}_k$ are 0, and so the limit is also 0. Since $\mathbf{v}$ satisfies the sign condition (3.5), this can happen only if $v_j(x) = 0$ almost everywhere in ω_ε. Since ε is arbitrarily small, we conclude that $v_j(x) = 0$ for a.e. x such that $|\bar{d}_j(x)| \neq 0$, and so $\mathbf{v} \in C_{\bar{\mathbf{u}}}$.

Finally, taking the lower limit in (3.24) we obtain that

$$\int_\Omega (\mathbf{z}^2 - 2(\mathbf{z}\cdot\nabla)\mathbf{z}\cdot\bar{\mathbf{\Phi}})dx + N\int_\omega \mathbf{v}^2 dx \leq 0.$$

We complete the proof by arguing as at the end of the proof of Theorem 3.8. ∎

COROLLARY 3.11. *Let us assume that* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ *is a nonsingular solution of* (1.2) *and* $(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{\mathbf{\Phi}})$ *satisfies* (3.2)–(3.5) *with* $\bar{\lambda} = 1$. *Then* (3.15) *is equivalent to the existence of* $\delta > 0$ *and* $\tau > 0$ *such that*

$$J''(\bar{\mathbf{u}})\mathbf{v}^2 \geq \delta\|\mathbf{v}\|^2_{L^2(\omega;\mathbb{R}^m)} \quad \forall\, \mathbf{v} \in C^\tau_{\bar{\mathbf{u}}}. \tag{3.25}$$

This a consequence of Theorem 3.10 and the expression of $J''(\bar{\mathbf{u}})$ stated in (3.7).

4. Numerical approximation of the control problem.

4.1. Numerical analysis of the state equation. Let $\mathbf{X}_h \subset \mathbf{H}_0^1(\Omega)$ and $M_h \subset L_0^2(\Omega)$ be two finite dimensional spaces satisfying the assumptions (H1)–(H3) stated below.

(H1) (Approximation property of $\mathbf{X}_h$). There exists an operator $r_h \in \mathcal{L}(\mathbf{H}^2(\Omega) \cap \mathbf{H}_0^1(\Omega), \mathbf{X}_h)$ such that

$$\begin{aligned}
&\text{(a) } \|\mathbf{y} - r_h\mathbf{y}\|_{\mathbf{H}_0^1(\Omega)} \le Ch\|\mathbf{y}\|_{\mathbf{H}^2(\Omega)} \ \forall\, \mathbf{y} \in \mathbf{H}^2(\Omega) \cap \mathbf{H}_0^1(\Omega),\\
&\text{(b) } \|\mathbf{y} - r_h\mathbf{y}\|_{\mathbf{L}^2(\Omega)} \le Ch^2\|\mathbf{y}\|_{\mathbf{H}^2(\Omega)} \ \forall\, \mathbf{y} \in \mathbf{H}^2(\Omega) \cap \mathbf{H}_0^1(\Omega),\\
&\text{(c) } \|\mathbf{y} - r_h\mathbf{y}\|_{\mathbf{L}^\infty(\Omega)} \le Ch^{2-d/2}\|\mathbf{y}\|_{\mathbf{H}^2(\Omega)} \ \forall\, \mathbf{y} \in \mathbf{H}^2(\Omega) \cap \mathbf{H}_0^1(\Omega),\\
&\text{(d) } \|\mathbf{y}_h\|_{\mathbf{L}^\infty(\Omega)} \le Ch^{-d/2}\|\mathbf{y}_h\|_{\mathbf{L}^2(\Omega)} \ \forall\, \mathbf{y}_h \in \mathbf{X}_h.
\end{aligned}$$

(H2) (Approximation property of M_h). There exists an operator $s_h \in \mathcal{L}(L_0^2(\Omega), M_h)$ such that

$$\|p - s_h p\|_{L_0^2(\Omega)} \le Ch\|p\|_{H^1(\Omega)} \ \forall\, p \in H^1(\Omega) \cap L_0^2(\Omega).$$

(H3) (Uniform inf-sup condition). For each $p_h \in M_h$ there exists $\mathbf{y}_h \in \mathbf{X}_h$ such that

$$(p_h, \operatorname{div} \mathbf{y}_h) = \|p_h\|^2_{L_0^2(\Omega)} \quad \text{and} \quad \|\mathbf{y}_h\|_{\mathbf{H}_0^1(\Omega)} \le C\|p_h\|_{L_0^2(\Omega)},$$

where $C > 0$ is independent of h, p_h, and $\mathbf{y}_h$.

Remark 4.1. Assumptions (H1)(b), (H1)(c), and (H1)(d) are needed to establish uniform convergence for the approximation of the state and the adjoint state (cf. Lemmas 4.10 and 4.13). In particular, if we use the finite element method when the family of triangulations is quasi-uniform, the above assumptions are satisfied for the Taylor–Hood finite element method and for the (P1-Bubble, P1) finite element method (see [12, p. 98, Lemma A.7 on p. 103, and Chapter 2]). The quasi-uniformity condition can be relaxed in some cases. For instance, Eriksson [11] gives some conditions on a locally refined family of triangulations in order to have an inverse inequality similar to (H1)(d).

Assumption (H3) is equivalent to the classical inf-sup condition. See Girault–Raviart [12, Remark II.1.4].

For $\rho > 0$, $\bar{\mathbf{y}} \in \mathbf{H}_0^1(\Omega)$, $\bar{p} \in L_0^2(\Omega)$, and $\bar{\mathbf{u}} \in L^2(\omega; \mathbb{R}^m)$, let us set

$$\begin{aligned}
B_\rho(\bar{\mathbf{y}}) &= \Big\{\mathbf{y} \in \mathbf{H}_0^1(\Omega) \mid \|\mathbf{y} - \bar{\mathbf{y}}\|_{\mathbf{H}_0^1(\Omega)} \le \rho\Big\},\\
B_\rho(\bar{p}) &= \Big\{p \in L_0^2(\Omega) \mid \|p - \bar{p}\|_{L_0^2(\Omega)} \le \rho\Big\},\\
B_\rho(\bar{\mathbf{u}}) &= \Big\{\mathbf{u} \in L^2(\omega; \mathbb{R}^m) \mid \|\mathbf{u} - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)} \le \rho\Big\}.
\end{aligned}$$

For all $\mathbf{u} \in L^2(\omega; \mathbb{R}^m)$, we define a discrete state equation in $\mathbf{X}_h \times M_h$, associated with (1.2), as follows:

$$\begin{aligned}
&\text{Find } (\mathbf{y}_d, p_h) \in \mathbf{X}_h \times M_h \text{ satisfying}\\
&a(\mathbf{y}_h, \mathbf{w}_h) + b(\mathbf{y}_h, \mathbf{y}_h, \mathbf{w}_h) - (p_h, \operatorname{div} \mathbf{w}_h) = (\mathbf{f} + \mathcal{C}\mathbf{u}, \mathbf{w}_h) \ \forall\, \mathbf{w}_h \in \mathbf{X}_h,\\
&(\lambda_h, \operatorname{div} \mathbf{y}_h) = 0 \ \forall\, \lambda_h \in M_h.
\end{aligned} \tag{4.1}$$

For a given $\mathbf{u} \in L^2(\omega;\mathbb{R}^m)$, this equation does not necessarily have a unique solution $\mathbf{y}_h$. Our main objective in this section is to show that there exist $\rho_1 > 0$ and $\rho_2 > 0$ independent of h, such that, for all $\mathbf{u} \in B_{\rho_2}(\bar{\mathbf{u}})$, (4.1) admits a unique solution in $B_{\rho_1}(\bar{\mathbf{y}}) \times B_{\rho_1}(\bar{p})$. Let T be the bounded linear operator from $\mathbf{H}^{-1}(\Omega)$ to $\mathbf{V}_0^1(\Omega) \times L_0^2(\Omega)$ defined by $T\mathbf{g} = (\mathbf{z}, q)$, where $(\mathbf{z}, q)$ is the solution of

$$-\nu\Delta\mathbf{z} + \nabla q = \mathbf{g} \text{ in } \Omega,\ \operatorname{div}\mathbf{z} = 0 \text{ in } \Omega,\ \mathbf{z} = 0 \text{ on } \Gamma.$$

Let $\mathcal{F}$ be the nonlinear mapping from $L^2(\omega;\mathbb{R}^m) \times \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ into $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ defined by

$$\mathcal{F}(\mathbf{u}, \mathbf{y}, p) = (\mathbf{y}, p) + T[B(\mathbf{y}) - (\mathbf{f} + \mathcal{C}\mathbf{u})].$$

Notice that $\mathcal{F}(\mathbf{u}, \mathbf{y}, p) = 0$ if and only if $A\mathbf{y} + B(\mathbf{y}) = \mathbf{f} + \mathcal{C}\mathbf{u}$ in $\mathbf{V}^{-1}(\Omega)$ and $p \in L_0^2(\Omega)$ satisfies $\nabla p = (I - P)(\mathbf{f} + \mathcal{C}\mathbf{u} + \nu\Delta\mathbf{y} - (\mathbf{y}\cdot\nabla)\mathbf{y})$. The operator $\partial_{(\mathbf{y},p)}\mathcal{F}(\mathbf{u}, \mathbf{y}, p)$ belongs to $\mathcal{L}(\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega))$ and is defined by

$$\partial_{(\mathbf{y},p)}\mathcal{F}(\mathbf{u}, \mathbf{y}, p)(\mathbf{z}, q) = (\mathbf{z}, q) + T[B'(\mathbf{y})\mathbf{z}].$$

Observe that $\partial_{(\mathbf{y},p)}\mathcal{F}(\mathbf{u}, \mathbf{y}, p)$ does not depend on $\mathbf{u} \in L^2(\omega;\mathbb{R}^m)$ and $p \in L_0^2(\Omega)$.

LEMMA 4.2. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \in L^2(\omega;\mathbb{R}^m) \times \mathbf{V}_0^1(\Omega)$ be a solution of (1.2), with associated pressure $\bar{p}$. Then $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is a nonsingular solution if and only if $\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$.*

Proof. Let us assume that $(\bar{\mathbf{u}}, \bar{\mathbf{y}}) \in L^2(\omega;\mathbb{R}^m) \times \mathbf{V}_0^1(\Omega)$ is a nonsingular solution of (1.2). Let $(\hat{\mathbf{y}}, \hat{p})$ be in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$. We have to check that there exists a unique pair $(\mathbf{y}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ such that $(\mathbf{y}, p) + T[B'(\bar{\mathbf{y}})\mathbf{y}] = (\hat{\mathbf{y}}, \hat{p})$. Let $(\mathbf{y}_0, p_0) \in \mathbf{V}_0^1(\Omega) \times L_0^2(\Omega)$ be the unique solution of the equation

$$-\nu\Delta\mathbf{y}_0 + B'(\bar{\mathbf{y}})\mathbf{y}_0 + \nabla p_0 = -B'(\bar{\mathbf{y}})\hat{\mathbf{y}} \text{ in } \Omega,\ \operatorname{div}\mathbf{y}_0 = 0 \text{ in } \Omega,\ \mathbf{y}_0 = 0 \text{ on } \Gamma.$$

Set $\mathbf{y} = \mathbf{y}_0 + \hat{\mathbf{y}}$ and $p = p_0 + \hat{p}$. The equality $(\mathbf{y}, p) + T[B'(\bar{\mathbf{y}})(\mathbf{y})] = (\hat{\mathbf{y}}, \hat{p})$, i.e., $T[-B'(\bar{\mathbf{y}})\mathbf{y}_0 - B'(\bar{\mathbf{y}})\hat{\mathbf{y}}] = (\mathbf{y}_0, p_0)$, follows from the definition of T and of $(\mathbf{y}_0, p_0)$. So we have proved the surjectivity of $\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})$. For the injectivity let us assume that $(\mathbf{y}, p) + T[B'(\bar{\mathbf{y}})\mathbf{y}] = (0, 0)$. This implies that $A\mathbf{y} + B'(\bar{\mathbf{y}})\mathbf{y} = 0$ in $\mathbf{V}^{-1}(\Omega)$; then $\mathbf{y} = 0$ and therefore $p = 0$ too.

Conversely, let us assume that $\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$. Let $\mathbf{g} \in \mathbf{V}^{-1}(\Omega)$. Let $(\hat{\mathbf{y}}, \hat{p}) \in \mathbf{V}_0^1(\Omega) \times L_0^2(\Omega)$ be the solution of the equation

$$-\nu\Delta\hat{\mathbf{y}} + \nabla\hat{p} = \mathbf{g}.$$

Let $(\mathbf{y}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ be the solution of the equation

$$\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})(\mathbf{y}, p) = (\hat{\mathbf{y}}, \hat{p}).$$

It is easy to check that $\mathbf{y} \in \mathbf{V}_0^1(\Omega)$ is the unique solution of $A\mathbf{y} + B'(\bar{\mathbf{y}})\mathbf{y} = \mathbf{g}$. ∎

Let T_h be the bounded linear operator from $\mathbf{H}^{-1}(\Omega)$ to $\mathbf{X}_h \times M_h$ defined by $T_h\mathbf{g} = (\mathbf{z}_h, q_h)$, where $(\mathbf{z}_h, q_h) \in \mathbf{X}_h \times M_h$ is the solution of

$$\begin{aligned} &a(\mathbf{z}_h, \mathbf{w}_h) - (q_h, \operatorname{div}\mathbf{w}_h) = (\mathbf{g}, \mathbf{w}_h)\ \forall\, \mathbf{w}_h \in \mathbf{X}_h, \\ &(\lambda_h, \operatorname{div}\mathbf{z}_h) = 0\ \forall\, \lambda_h \in M_h. \end{aligned}$$

Let $\mathcal{F}_h$ be the nonlinear mapping from $L^2(\omega;\mathbb{R}^m) \times \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ into $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ defined by

$$\mathcal{F}_h(\mathbf{u}, \mathbf{y}, p) = (\mathbf{y}, p) + T_h[B(\mathbf{y}) - (\mathbf{f} + \mathcal{C}\mathbf{u})].$$

Remark 4.3. Notice that if $\mathcal{F}_h(\mathbf{u},\mathbf{y},p)=0$, then $(\mathbf{y},p)$ belongs to $\mathbf{X}_h\times M_h$ and is a solution of (4.1). Conversely if $(\mathbf{y},p)\in\mathbf{X}_h\times M_h$ is a solution of (4.1), then $\mathcal{F}_h(\mathbf{u},\mathbf{y},p)=0$.

Now we want to prove that if $\bar{\mathbf{y}}$ is nonsingular and if $\|\mathbf{y}-\bar{\mathbf{y}}\|_{\mathbf{H}_0^1(\Omega)}$ is small enough, then $\partial_{(\mathbf{y},p)}\mathcal{F}_h(\mathbf{u},\mathbf{y},p)$ is an automorphism in $\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)$. For that we make the following additional and usual assumptions concerning the approximation results for the Stokes problem.

(S1) $\lim_{h\to 0}\|(T-T_h)\mathbf{g}\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}=0\ \forall\,\mathbf{g}\in\mathbf{H}^{-1}(\Omega)$.

(S2) $\|(T-T_h)\mathbf{g}\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\le Ch\|\mathbf{g}\|_{\mathbf{L}^2(\Omega)}\ \forall\,\mathbf{g}\in\mathbf{L}^2(\Omega)$.

Before proving the desired property of $\partial_{(\mathbf{y},p)}\mathcal{F}_h(\mathbf{u},\mathbf{y},p)$, we establish several lemmas.

LEMMA 4.4. *There exists $C>0$ independent of h such that*

$$\|T_h\|_{\mathcal{L}(\mathbf{H}^{-1}(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}\le C.$$

Proof. We want to estimate $\sup\{\|T_h\mathbf{g}\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\mid\|\mathbf{g}\|_{\mathbf{H}^{-1}(\Omega)}\le 1\}$. Recall that $T_h\mathbf{g}$ is the solution $(\mathbf{z}_h,q_h)$ to the discrete Stokes problem

$$\begin{aligned}&a(\mathbf{z}_h,\mathbf{w}_h)-(q_h,\operatorname{div}\mathbf{w}_h)=(g,\mathbf{w}_h)\ \forall\,\mathbf{w}_h\in\mathbf{X}_h,\\&(\lambda_h,\operatorname{div}\mathbf{z}_h)=0\ \forall\,\lambda_h\in M_h.\end{aligned}$$

Taking $\mathbf{w}_h=\mathbf{z}_h$, we obtain $\|\mathbf{z}_h\|_{\mathbf{H}_0^1(\Omega)}\le C\|\mathbf{g}\|_{\mathbf{H}^{-1}(\Omega)}$. The estimate for the pressure q_h follows from inf-sup condition (H3). Indeed if we take $\mathbf{w}_h$ such that $(q_h,\operatorname{div}\mathbf{w}_h)=\|q_h\|^2_{L_0^2(\Omega)}$ and $\|\mathbf{w}_h\|_{\mathbf{H}_0^1(\Omega)}\le C\|q_h\|_{L_0^2(\Omega)}$, it is clear that $\|q_h\|_{L_0^2(\Omega)}\le C\|g\|_{\mathbf{H}^{-1}(\Omega)}$. ∎

We will need the following standard result.

LEMMA 4.5. *Let X be a Banach space, $A\in\mathcal{L}(X)$ invertible and $B\in\mathcal{L}(X)$. If $\|A-B\|_{\mathcal{L}(X)}<1/\|A^{-1}\|_{\mathcal{L}(X)}$, then B is invertible. If $\|A-B\|_{\mathcal{L}(X)}<1/(2\|A^{-1}\|_{\mathcal{L}(X)})$, then $\|B^{-1}\|_{\mathcal{L}(X)}\le 2\|A^{-1}\|_{\mathcal{L}(X)}$.*

Proof. $A^{-1}B=I-A^{-1}(A-B)$. Since $\|A^{-1}(A-B)\|\le\|A^{-1}\|\,\|A-B\|<1$, we have that $A^{-1}B$ is invertible and so is B.

$B^{-1}A=(I-A^{-1}(A-B))^{-1}=\sum_{k=1}^{\infty}(A^{-1}(A-B))^k$. So $\|B^{-1}\|\le\|A^{-1}\|/(1-\|A^{-1}(A-B)\|)\le 2\|A^{-1}\|$. ∎

LEMMA 4.6. *Let $\bar{\mathbf{y}}\in\mathbf{V}_0^1(\Omega)$ be a nonsingular solution of (2.2). Then for every $\varepsilon>0$ there exist $h_\varepsilon>0$ and $\rho_\varepsilon>0$ such that*

$$\|T[B'(\bar{\mathbf{y}})]-T_h[B'(\mathbf{y})]\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}<\varepsilon$$

for all $0<h<h_\varepsilon$ and all $\mathbf{y}\in B_{\rho_\varepsilon}(\bar{\mathbf{y}})$.

Proof. With classical calculations we can write

$$\begin{aligned}&\|T[B'(\bar{\mathbf{y}})]-T_h[B'(\mathbf{y})]\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}\\&\le\|(T-T_h)[B'(\bar{\mathbf{y}})]\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}+\|T_h[B'(\bar{\mathbf{y}})-B'(\mathbf{y})]\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}\\&\le\sup_{\|\mathbf{z}\|_{\mathbf{H}_0^1(\Omega)}\le 1}\|(T-T_h)[B'(\bar{\mathbf{y}})\mathbf{z}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\&+\sup_{\|\mathbf{z}\|_{\mathbf{H}_0^1(\Omega)}\le 1}\|T_h[(B'(\bar{\mathbf{y}})-B'(\mathbf{y}))\mathbf{z}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}.\end{aligned}$$

Since $\bar{\mathbf{y}}\in\mathbf{H}^2(\Omega)$, $B'(\bar{\mathbf{y}})\mathbf{z}$ belongs to $\mathbf{L}^2(\Omega)$, and due to assumption (S2) we have

$$\begin{aligned}&\sup_{\|\mathbf{z}\|_{\mathbf{H}_0^1(\Omega)}\le 1}\|(T-T_h)[B'(\bar{\mathbf{y}})\mathbf{z}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\&\le Ch\sup_{\|\mathbf{z}\|_{\mathbf{H}_0^1(\Omega)}\le 1}\|B'(\bar{\mathbf{y}})\mathbf{z}\|_{\mathbf{L}^2(\Omega)}\le Ch\|\bar{\mathbf{y}}\|_{\mathbf{H}^2(\Omega)}.\end{aligned}$$

On the other hand, using Lemma 4.4 we have

$$\begin{aligned}
&\sup_{\|\mathbf{z}\|_{\mathbf{H}_0^1(\Omega)}\le 1} \|T_h[(B'(\bar{\mathbf{y}})-B'(\mathbf{y}))\mathbf{z}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&\le \|T_h\|_{\mathcal{L}(\mathbf{H}^{-1}(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))} \sup_{\|\mathbf{z}\|_{\mathbf{H}_0^1(\Omega)}\le 1} \|(B'(\bar{\mathbf{y}})-B'(\mathbf{y}))\mathbf{z}\|_{\mathbf{H}^{-1}(\Omega)}\\
&\le C\|\bar{\mathbf{y}}-\mathbf{y}\|_{\mathbf{H}_0^1(\Omega)}.
\end{aligned}$$

Taking h_ε and ρ_ε small enough, we obtain the desired result. ∎

THEOREM 4.7. *Let $(\bar{\mathbf{u}},\bar{\mathbf{y}})\in L^2(\omega;\mathbb{R}^m)\times\mathbf{V}_0^1(\Omega)$ be a nonsingular solution of (2.2) and $\bar p$ the associated pressure. There exist $h_0>0$ and $\rho_0>0$ such that for all $0<h<h_0$ and all $\mathbf{y}\in B_{\rho_0}(\bar{\mathbf{y}})$, $\partial_{(\mathbf{y},p)}\mathcal{F}_h(\mathbf{u},\mathbf{y},p)$ is an automorphism in $\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)$, and*

$$\|\partial_{(\mathbf{y},p)}\mathcal{F}_h(\mathbf{u},\mathbf{y},p)^{-1}\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}\le 2\|\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)^{-1}\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}.$$

Proof. The proof is a straightforward consequence of the previous lemmas. Take

$$\varepsilon=\frac{1}{2\|\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)^{-1}\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}},$$

and set $(h_0,\rho_0)=(h_\varepsilon,\rho_\varepsilon)$, where $(h_\varepsilon,\rho_\varepsilon)$ is the pair corresponding to ε and defined in Lemma 4.6. For every $0<h<h_0$ and all $\mathbf{y}\in B_{\rho_0}(\bar{\mathbf{y}})$, we have

$$\begin{aligned}
&\|\partial_{(\mathbf{y},p)}\mathcal{F}(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)-\partial_{(\mathbf{y},p)}\mathcal{F}_h(\mathbf{u},\mathbf{y},p)\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}=\\
&\|T[B'(\bar{\mathbf{y}})]-T_h[B'(\mathbf{y})]\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega),\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}<\varepsilon,
\end{aligned}$$

and the result follows from Lemma 4.5. ∎

THEOREM 4.8. *Let $(\bar{\mathbf{u}},\bar{\mathbf{y}})$ be as in Theorem 4.7; then there exist $\rho_1>0$, $\rho_2>0$, and $h_1>0$ such that for all $0<h<h_1$ and $\mathbf{u}\in B_{\rho_2}(\bar{\mathbf{u}})$, the equation $\mathcal{F}_h(\mathbf{u},\mathbf{y}_h,p_h)=0$ admits a unique solution in $B_{\rho_1}(\bar{\mathbf{y}})\times B_{\rho_1}(\bar p)$.*

Proof. Let ρ_0 and h_0 be the positive constants given by Theorem 4.7. For $\rho\le\rho_0$, $h\le h_0$, and $\mathbf{u}\in B_{\rho^2}(\bar{\mathbf{u}})$, we define the mapping $\Psi_{\mathbf{u}}$ from $B_\rho(\bar{\mathbf{y}})\times B_\rho(\bar p)$ into $\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)$ by

$$\Psi_{\mathbf{u}}(\mathbf{y},p)=(\mathbf{y},p)-\left[\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)\right]^{-1}\mathcal{F}_h(\mathbf{u},\mathbf{y},p).$$

It is clear that any fixed point of $\Psi_{\mathbf{u}}$ is a solution of $\mathcal{F}_h(\mathbf{u},\mathbf{y},p)=0$. Let us show that $\Psi_{\mathbf{u}}$ is a strict contraction if ρ is small enough.

(i) First, we show that $\Psi_{\mathbf{u}}$ is a mapping from $B_\rho(\bar{\mathbf{y}})\times B_\rho(\bar p)$ into itself. With the identity $\mathcal{F}(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)=0$, and a Taylor formula we obtain

$$\begin{aligned}
&\|\Psi_{\mathbf{u}}(\mathbf{y},p)-(\bar{\mathbf{y}},\bar p)\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&=\|\left[\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)\right]^{-1}\left\{\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)(\mathbf{y}-\bar{\mathbf{y}},p-\bar p)\right.\\
&\qquad\left.+[-\mathcal{F}_h(\mathbf{u},\mathbf{y},p)+\mathcal{F}_h(\mathbf{u},\bar{\mathbf{y}},\bar p)]+[-\mathcal{F}_h(\mathbf{u},\bar{\mathbf{y}},\bar p)+\mathcal{F}(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)]\right\}\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&\le C\|\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)(\mathbf{y}-\bar{\mathbf{y}},p-\bar p)\\
&\qquad-\int_0^1\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\mathbf{y}_\theta,p_\theta)(\mathbf{y}-\bar{\mathbf{y}},p-\bar p)d\theta\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&\qquad+C\|\mathcal{F}_h(\mathbf{u},\bar{\mathbf{y}},\bar p)-\mathcal{F}(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&\le C\int_0^1\|\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\mathbf{y}_\theta,p_\theta)-\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}},\bar{\mathbf{y}},\bar p)\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}d\theta\\
&\qquad\times\|(\mathbf{y}-\bar{\mathbf{y}},p-\bar p)\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&\qquad+C\|(T_h-T)[B(\bar{\mathbf{y}})-\mathbf{f}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}+\ C\|(T-T_h)[\mathcal{C}\bar{\mathbf{u}}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}\\
&\qquad+C\|T_h[\mathcal{C}(\bar{\mathbf{u}}-\mathbf{u})]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)},
\end{aligned}$$

where $(\mathbf{y}_\theta, p_\theta) = (\bar{\mathbf{y}} + \theta(\mathbf{y} - \bar{\mathbf{y}}), \bar{p} + \theta(p - \bar{p}))$.

Let us estimate each of the terms. Using the definition of $\mathcal{F}_h$ and Lemma 4.4 we get

$$\begin{aligned}
&\|\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \bar{\mathbf{y}} + \theta(\mathbf{y} - \bar{\mathbf{y}}), \bar{p} + \theta(p - \bar{p})) - \partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))} \\
&\quad = \|T_h[B'(\bar{\mathbf{y}} + \theta(\mathbf{y} - \bar{\mathbf{y}})) - B'(\bar{\mathbf{y}})]\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))} \\
&\quad \le C\|B'(\mathbf{y} - \bar{\mathbf{y}})\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega),\mathbf{H}^{-1}(\Omega))} \le C\|\mathbf{y} - \bar{\mathbf{y}}\|_{\mathbf{H}_0^1(\Omega)}. \qquad (4.2)
\end{aligned}$$

With assumption (S2) we have

$$\|(T_h - T)[B(\bar{\mathbf{y}}) - \mathbf{f}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \le Ch(\|\bar{\mathbf{y}}\|_{\mathbf{H}^2(\Omega)} + \|\mathbf{f}\|_{\mathbf{L}^2(\Omega)}),$$

and

$$\|(T - T_h)[\mathcal{C}\bar{\mathbf{u}}]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \le Ch\|\bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}.$$

Finally, from Lemma 4.4 it follows that

$$\|T_h[\mathcal{C}(\bar{\mathbf{u}} - \mathbf{u})]\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \le C\|\bar{\mathbf{u}} - \mathbf{u}\|_{L^2(\omega;\mathbb{R}^m)}.$$

Collecting these estimates all together, we have proved that there exists a constant $\hat{C} > 0$ independent of h and ρ such that

$$\|\Psi_{\mathbf{u}}(\mathbf{y}, p) - (\bar{\mathbf{y}}, \bar{p})\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \le \hat{C}(h + \rho^2).$$

We choose $\hat{\rho}_1 \le \min\{\rho_0, 1/(2\hat{C})\}$, $\hat{\rho}_2 = \hat{\rho}_1^2$, and $\hat{h}_1 = \min\{h_0, \hat{\rho}_1/(2\hat{C})\}$. It is clear that for all $0 < h < \hat{h}_1$ and all $\mathbf{u} \in B_{\hat{\rho}_2}(\bar{\mathbf{u}})$, $\Psi_{\mathbf{u}}$ is a mapping from $B_{\hat{\rho}_1}(\bar{\mathbf{y}}) \times B_{\hat{\rho}_1}(\bar{p})$ into itself.

(ii) Now we look for conditions to have a strict contraction. Take $(\mathbf{y}_1, p_1)$, $(\mathbf{y}_2, p_2) \in B_{\hat{\rho}_1}(\bar{\mathbf{y}}) \times B_{\hat{\rho}_1}(\bar{p})$, $0 < h < \hat{h}_1$, and $\mathbf{u} \in B_{\hat{\rho}_2}(\bar{\mathbf{u}})$. Classical calculations lead to

$$\begin{aligned}
&\| \Psi_{\mathbf{u}}(\mathbf{y}_1, p_1) - \Psi_{\mathbf{u}}(\mathbf{y}_2, p_2)\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \\
&= \Big\| (\mathbf{y}_1 - \mathbf{y}_2, p_1 - p_2) \\
&- \left[\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})\right]^{-1} \Big\{ \mathcal{F}_h(\mathbf{u}, \mathbf{y}_1, p_1) - \mathcal{F}_h(\mathbf{u}, \mathbf{y}_2, p_2) \Big\} \Big\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \\
&= \Big\| \left[\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})\right]^{-1} \Big\{ \partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})(\mathbf{y}_1 - \mathbf{y}_2, p_1 - p_2) \\
&- \int_0^1 \partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \mathbf{y}_1 + \theta(\mathbf{y}_2 - \mathbf{y}_1), p_1 + \theta(p_2 - p_1))(\mathbf{y}_1 - \mathbf{y}_2, p_1 - p_2) d\theta \Big\} \Big\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)}.
\end{aligned}$$

The norm $\| \left[\partial_{(\mathbf{y},p)}\mathcal{F}_h(\bar{\mathbf{u}}, \bar{\mathbf{y}}, \bar{p})\right]^{-1} \|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}$ can be estimated by a constant C independent of h; see Theorem 4.7. To estimate the expression in brackets we can repeat the argument of inequalities (4.2), since $\mathbf{y} = \mathbf{y}_1 + \theta(\mathbf{y}_2 - \mathbf{y}_1) \in B_{\hat{\rho}_1}(\bar{\mathbf{y}})$. There then exists $\tilde{C} > 0$ independent of $\hat{\rho}_1$ and h such that

$$\|\Psi_{\mathbf{u}}(\mathbf{y}_1, p_1) - \Psi_{\mathbf{u}}(\mathbf{y}_2, p_2)\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \le \tilde{C}\hat{\rho}_1^2.$$

Choosing $\rho_1 = \min\left\{\rho_0, 1/(2\hat{C}), 1/\sqrt{2\tilde{C}}\right\}$, $\rho_2 = \rho_1^2$, and $h_1 = \min\left\{h_0, \rho_1/(2\hat{C})\right\}$, we have established that, for all $0 < h < h_1$ and all $\mathbf{u} \in B_{\rho_2}(\bar{\mathbf{u}})$, $\Psi_{\mathbf{u}}$ is a strict contraction in $B_{\rho_1}(\bar{\mathbf{y}}) \times B_{\rho_1}(\bar{p})$. ∎

Remark 4.9. We have proved that, for all $0 < h < h_1$ and all $\mathbf{u} \in B_{\rho_2}(\bar{\mathbf{u}})$, the equation $\mathcal{F}_h(\mathbf{u}, \mathbf{y}_h, p_h) = 0$ admits a unique solution $(\mathbf{y}_h(\mathbf{u}), p_h(\mathbf{u}))$ in $(B_{\rho_1}(\bar{\mathbf{y}}) \times B_{\rho_1}(\bar{p})) \cap (\mathbf{X}_h \times M_h)$, and that $\partial_{(\mathbf{y},p)}\mathcal{F}_h(\mathbf{u}, \mathbf{y}_h(\mathbf{u}), p_h(\mathbf{u}))$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$. Therefore the mapping G_h from $B_{\rho_2}(\bar{\mathbf{u}})$ into $(B_{\rho_1}(\bar{\mathbf{y}}) \times B_{\rho_1}(\bar{p})) \cap (\mathbf{X}_h \times M_h)$ defined by $G_h(\mathbf{u}) = (\mathbf{y}_h(\mathbf{u}), p_h(\mathbf{u}))$, obeys $\mathcal{F}_h(\mathbf{u}, G_h(\mathbf{u})) = 0$, and the implicit function theorem implies that it is of class C^∞ in the interior of the ball $B_{\rho_2}(\bar{\mathbf{u}})$. Notice that G_h is not an approximation of G because $G(\mathbf{u}) = \mathbf{y}_\mathbf{u}$ is a velocity field, while $G_h(\mathbf{u})$ stands for a velocity field and a pressure.

4.2. Discretization of the control problem. For simplicity throughout the following we assume that ω is a polygonal domain. But we could consider a more general situation if we take into account the error we introduce by approximating ω by a polygonal domain.

For $h > 0$, let $\mathcal{T}_h$ be a triangulation of ω. Although the discretization of the control can be done independently of the discretization of the state equation, in practice, when we use the finite element method to approximate the state and adjoint state equation, the same family of triangulations is used. Some assumptions must be made on the family of triangulations in order to have the inverse estimate of assumption (H1)(d). We will suppose that the family is quasi-uniform (see, e.g., [9, p. 135]): In this case $h = \max_{T \in \mathcal{T}_h} \rho(T)$, where $\rho(T)$ is the diameter of the set T. We denote by $\sigma(T)$ the diameter of the largest ball contained in T. We assume there exist two positive constants ρ and σ such that

$$\frac{\rho(T)}{\sigma(T)} \le \sigma, \qquad \frac{h}{\rho(T)} \le \rho$$

hold for all $T \in \mathcal{T}_h$ and all $0 < h$.

In the following we would like to treat in the same way the cases when the control set is discretized and when it is not. We shall see that we obtain better estimates when the control set is not discretized. For that we set

$$U_h = \Big\{ \mathbf{u} \in L^2(\omega; \mathbb{R}^m) \mid u_i|_T \in P_0(T) \ \forall\, T \in \mathcal{T}_h \Big\},$$
$$U_{ad}^h = \Big\{ \mathbf{u} \in U_h \mid \alpha_i \le u_i \le \beta_i \ \forall\ 1 \le i \le d \Big\}.$$

In the discrete control problem stated below, the case when the control set is not discretized corresponds to the choice $U_{ad,h} = U_{ad}$, while the case when the control set is discretized corresponds to $U_{ad,h} = U_{ad}^h$.

We can now define the discrete control problem associated with (P) in the following way:

$$(\mathrm{P}_h) \qquad \inf\Big\{ F(\mathbf{u}, \mathbf{y}) \mid (\mathbf{u}, \mathbf{y}, p) \in U_{ad,h} \times \mathbf{X}_h \times M_h \text{ and } (\mathbf{u}, \mathbf{y}, p) \text{ satisfies (4.1)} \Big\}.$$

Let us recall that $(\mathbf{u}, \mathbf{y}, p)$ satisfies (4.1) if and only if

$$\mathcal{F}_h(\mathbf{u}, \mathbf{y}, p) = 0. \tag{4.3}$$

Our aim is to study the existence of local minima of problems (P_h) which approximate the local minima of (P). This can be proved for nonsingular local solutions of (P). Let us start by proving some error estimates for the state equation. Given a nonsingular solution $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ of (1.2), let $h_1 > 0$ and $\rho_2 > 0$ be given by Theorem 4.8.

By using the function G_h from $B_{\rho_2}(\bar{\mathbf{u}})$ into $(B_{\rho_1}(\bar{\mathbf{y}}) \times B_{\rho_1}(\bar{p})) \cap (\mathbf{X}_h \times M_h)$ introduced at the end of the previous section in Remark 4.9, we set $(\mathbf{y}_{\mathbf{u}}^h, p_{\mathbf{u}}^h) = G_h(\mathbf{u}) = (\mathbf{y}_h(\mathbf{u}), p_h(\mathbf{u}))$. Now we have the following result.

LEMMA 4.10. *Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ be as in Theorem 4.7. There exists a constant $C > 0$ such that, for all $\mathbf{u}$, $\hat{\mathbf{u}} \in \bar{B}_{\rho_2}(\bar{\mathbf{u}})$, and $0 < h < h_1$, the following estimates hold:*

$$\|\mathbf{y}_{\mathbf{u}} - \mathbf{y}_{\mathbf{u}}^h\|_{\mathbf{L}^2(\Omega)} \le Ch^2 \|\mathbf{y}_{\mathbf{u}}\|_{\mathbf{H}^2(\Omega)}, \tag{4.4}$$

$$\|\mathbf{y}_{\mathbf{u}} - \mathbf{y}_{\hat{\mathbf{u}}}^h\|_{\mathbf{H}_0^1(\Omega)} + \|p_{\mathbf{u}} - p_{\hat{\mathbf{u}}}^h\|_{L_0^2(\Omega)} \le C(h + \|\mathbf{u} - \hat{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}). \tag{4.5}$$

Moreover, if $\mathbf{u}_h \in B_{\rho_2}(\bar{\mathbf{u}})$ and $\mathbf{u}_h \rightharpoonup \mathbf{u}$ weakly in $L^2(\omega;\mathbb{R}^m)$, then $\mathbf{y}_{\mathbf{u}_h}^h \to \mathbf{y}_{\mathbf{u}}$ in $C(\bar{\Omega};\mathbb{R}^d)$.

Proof. (i) The estimate (4.4) directly follows from usual estimates for the approximation of the Navier–Stokes equations by a finite element method. See, for instance, Girault–Raviart [12, Theorem IV.4.2].

(ii) To prove (4.5), let us write

$$\|\mathbf{y}_{\mathbf{u}} - \mathbf{y}_{\hat{\mathbf{u}}}^h\|_{\mathbf{H}_0^1(\Omega)} \le \|\mathbf{y}_{\mathbf{u}} - \mathbf{y}_{\mathbf{u}}^h\|_{\mathbf{H}_0^1(\Omega)} + \|\mathbf{y}_{\mathbf{u}}^h - \mathbf{y}_{\hat{\mathbf{u}}}^h\|_{\mathbf{H}_0^1(\Omega)},$$
$$\|p_{\mathbf{u}} - p_{\hat{\mathbf{u}}}^h\|_{L_0^2(\Omega)} \le \|p_{\mathbf{u}} - p_{\mathbf{u}}^h\|_{L_0^2(\Omega)} + \|p_{\mathbf{u}}^h - p_{\hat{\mathbf{u}}}^h\|_{L_0^2(\Omega)}.$$

Usual finite element estimates [12, estimate (4.7)] give us

$$\|\mathbf{y}_{\mathbf{u}} - \mathbf{y}_{\mathbf{u}}^h\|_{\mathbf{H}_0^1(\Omega)} + \|p_{\mathbf{u}} - p_{\mathbf{u}}^h\|_{L_0^2(\Omega)} \le Ch.$$

If $\mathbf{u}$ belongs to the interior of $B_{\rho_2}(\bar{\mathbf{u}})$, from the definition of G_h it follows that

$$G_h'(\mathbf{u})\mathbf{v} = -[\partial_{(\mathbf{y},p)} \mathcal{F}_h(\mathbf{u}, \mathbf{y}_{\mathbf{u}}^h, p_{\mathbf{u}}^h)]^{-1} T_h[\mathcal{C}\mathbf{v}].$$

Hence, with Lemma 4.4 and Theorem 4.7 we obtain

$$\begin{aligned}
&\|G_h(\mathbf{u}) - G_h(\hat{\mathbf{u}})\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \\
&= \left\| \int_0^1 [\partial_{(\mathbf{y},p)} \mathcal{F}_h(\mathbf{u}_\theta, \mathbf{y}_{\mathbf{u}_\theta}^h, p_{\mathbf{u}_\theta}^h)]^{-1} T_h[\mathcal{C}(\mathbf{u} - \hat{\mathbf{u}})] \right\|_{\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)} \\
&\le C\|\mathbf{u} - \hat{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)},
\end{aligned}$$

where $\mathbf{u}_\theta = \hat{\mathbf{u}} + \theta(\mathbf{u} - \hat{\mathbf{u}})$. Collecting the previous estimates, the proof of (4.5) is complete.

(iii) Let $(\mathbf{u}_h)_h$ be a sequence in $B_{\rho_2}(\bar{\mathbf{u}}) \cap U_{ad}$, weakly converging to $\mathbf{u}$ in $L^2(\omega;\mathbb{R}^m)$. Due to Theorem 2.2, $\mathbf{y}_{\mathbf{u}}$ belongs to $\mathbf{W}^{2,\bar{r}}(\Omega)$ and $\{\mathbf{y}_{\mathbf{u}_h}\}_h$ is bounded in $\mathbf{W}^{2,\bar{r}}(\Omega)$. Thus it converges to $\mathbf{y}_{\mathbf{u}}$ in $\mathbf{L}^p(\Omega)$ for all $2 \le p < \infty$, and the sequence $\{\mathbf{y}_{\mathbf{u}_h} \otimes \mathbf{y}_{\mathbf{u}_h}\}_h$ converges to $\mathbf{y}_{\mathbf{u}} \otimes \mathbf{y}_{\mathbf{u}}$ in $(\mathbf{L}^p(\Omega))^d$ for all $2 \le p < \infty$. The function $\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}}$ satisfies the equation

$$A(\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}}) = \operatorname{div}\big((\mathbf{y}_{\mathbf{u}} \otimes \mathbf{y}_{\mathbf{u}_h}) - (\mathbf{y}_{\mathbf{u}_h} \otimes \mathbf{y}_{\mathbf{u}})\big) + \mathcal{C}(\mathbf{u}_h - \mathbf{u}) \quad \text{in } \mathbf{V}^{-1}(\Omega).$$

Let p satisfy $d < p < 6$. From classical estimates for the Stokes equations it follows that

$$\begin{aligned}
&\|\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}}\|_{\mathbf{W}^{1,p}(\Omega)} \le C\|\operatorname{div}\big((\mathbf{y}_{\mathbf{u}} \otimes \mathbf{y}_{\mathbf{u}_h}) - (\mathbf{y}_{\mathbf{u}_h} \otimes \mathbf{y}_{\mathbf{u}})\big) + \mathcal{C}(\mathbf{u}_h - \mathbf{u})\|_{\mathbf{W}^{-1,p}(\Omega)} \\
&\le C\big(\|(\mathbf{y}_{\mathbf{u}} \otimes \mathbf{y}_{\mathbf{u}_h}) - (\mathbf{y}_{\mathbf{u}_h} \otimes \mathbf{y}_{\mathbf{u}})\|_{\mathbf{L}^p(\Omega)} + \|\mathcal{C}(\mathbf{u}_h - \mathbf{u})\|_{\mathbf{W}^{-1,p}(\Omega)}\big).
\end{aligned}$$

Since $\mathbf{W}^{1,p}(\Omega) \hookrightarrow \mathbf{L}^\infty(\Omega)$, and $\mathbf{L}^2(\Omega)$ is compactly embedded in $\mathbf{W}^{-1,p}(\Omega)$ (because $p < 6$), it is clear that $\{\mathbf{y}_{\mathbf{u}_h}\}_h$ tends to $\mathbf{y}_{\mathbf{u}}$ in $\mathbf{L}^\infty(\Omega)$.

We have

$$\|\mathbf{y}^h_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}}\|_{\mathbf{L}^\infty(\Omega)} \le \|\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}}\|_{\mathbf{L}^\infty(\Omega)} + \|\mathbf{y}^h_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{L}^\infty(\Omega)}$$
$$\le \|\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}}\|_{\mathbf{L}^\infty(\Omega)} + \|\mathbf{y}^h_{\mathbf{u}_h} - r_h\mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{L}^\infty(\Omega)} + \|r_h\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{L}^\infty(\Omega)}.$$

From (H1)(c) and (H1)(d) we deduce that

$$\|\mathbf{y}_{\mathbf{u}_h} - r_h\mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{L}^\infty(\Omega)} \le Ch^{2-d/2}\|\mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{H}^2(\Omega)},$$

and

$$\|r_h\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}^h_{\mathbf{u}_h}\|_{\mathbf{L}^\infty(\Omega)} \le Ch^{-d/2}\|r_h\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}^h_{\mathbf{u}_h}\|_{\mathbf{L}^2(\Omega)}$$
$$\le Ch^{-d/2}\|r_h\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{L}^2(\Omega)} + Ch^{-d/2}\|\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}^h_{\mathbf{u}_h}\|_{\mathbf{L}^2(\Omega)}.$$

With (H1)(b) and (4.4) we have

$$\|r_h\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{L}^2(\Omega)} \le Ch^2\|\mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{H}^2(\Omega)},$$
$$\|\mathbf{y}_{\mathbf{u}_h} - \mathbf{y}^h_{\mathbf{u}_h}\|_{\mathbf{L}^2(\Omega)} \le Ch^2\|\mathbf{y}_{\mathbf{u}_h}\|_{\mathbf{H}^2(\Omega)}.$$

Collecting together these estimates and the previous convergence result we have proved that $\{\mathbf{y}^h_{\mathbf{u}_h}\}_h$ converges to $\mathbf{y}_{\mathbf{u}}$ in $\mathbf{L}^\infty(\Omega)$. □

THEOREM 4.11. *Let us assume that* (P) *has a nonsingular local minimum* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$. *Then there exists* $h_2 > 0$ *such that, for all* $0 < h < h_2$, (P_h) *has at least one solution. If, furthermore,* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ *is a strict local minimum of* (P), *then* (P_h) *has a local minimum* $(\bar{\mathbf{u}}_h, \bar{\mathbf{y}}_h)$ *in a neighborhood of* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ *for all* $0 < h < h_2$ *and the following identities hold:*

$$\lim_{h\to 0} J_h(\bar{\mathbf{u}}_h) = J(\bar{\mathbf{u}}),\ \lim_{h\to 0}\|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|_{\mathbf{L}^2(\omega)} = 0,\ \textit{and}\ \lim_{h\to 0}\|\bar{\mathbf{y}} - \bar{\mathbf{y}}_h\|_{\mathbf{H}^1_0(\Omega)} = 0,$$

where $J_h(\bar{\mathbf{u}}_h) = F(\bar{\mathbf{u}}_h, \bar{\mathbf{y}}_h)$.

Proof. Let us start by proving that the set of feasible pairs $(\mathbf{u}, \mathbf{y})$ for problem (P_h) is nonempty for h small enough. We prove it only in the case when $U_{ad,h} = U^h_{ad}$. The case when $U_{ad,h} = U_{ad}$ is obvious.

Since $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is a nonsingular local minimum, with the aid of Theorem 4.8 we derive the existence of $\rho \le \rho_2$ such that

$$J(\bar{\mathbf{u}}) \le J(\mathbf{u}) \quad \forall \mathbf{u} \in U_{ad} \cap B_\rho(\bar{\mathbf{u}}). \tag{4.6}$$

Let us define $\Pi_h\bar{\mathbf{u}} \in U_h$ by

$$\Pi_h\bar{\mathbf{u}}|_T = \frac{1}{|T|}\int_T \bar{\mathbf{u}}(x)dx. \tag{4.7}$$

It is clear that $\Pi_h\bar{\mathbf{u}} \in U_{ad,h}$. Let us prove that it belongs to $B_\rho(\bar{\mathbf{u}})$ if h is small enough. Since $\bar{\mathbf{u}}$ is Lipschitz continuous (see Theorem 3.5), we can write

$$\int_\omega (\Pi_h\bar{u}_i(s) - \bar{u}_i(s))^2 ds = \sum_{T\subset\omega}\int_T \left(\frac{1}{|T|}\int_T \bar{u}_i(x)dx - \bar{u}_i(s)\right)^2 ds$$
$$= \sum_{T\subset\omega}\int_T (\bar{u}_i(x_T) - \bar{u}_i(s))^2 ds \le |\omega|\|\bar{\mathbf{u}}\|^2_{W^{1,\infty}(\omega;\mathbb{R}^m)}h^2.$$

Therefore if

$$h_2 = \min\left\{h_1, \frac{\rho}{\|\bar{\mathbf{u}}\|_{W^{1,\infty}(\omega;\mathbb{R}^m)}|\omega|^{1/2}}\right\},$$

then $\Pi_h\bar{\mathbf{u}}$ belongs to $U_{ad,h}\cap B_\rho(\bar{\mathbf{u}})$ for all $h\le h_2$. Now setting $\mathbf{u}_h=\Pi_h\bar{\mathbf{u}}$ and $(\mathbf{y}^h_{\mathbf{u}_h},p^h_{\mathbf{u}_h})=G_h(\mathbf{u}_h)$, we have that $(\mathbf{u}_h,\mathbf{y}^h_{\mathbf{u}_h},p^h_{\mathbf{u}_h})$ satisfies (4.3) and $(\mathbf{u}_h,\mathbf{y}^h_{\mathbf{u}_h})$ is a feasible pair for (P_h) for any $h\le h_2$.

Since the set of feasible points of (P_h) is nonempty and closed, and F_h is continuous, convex on $U_{ad,h}\times\mathbf{X}_h$, and coercive with respect to $\mathbf{u}\in U_{ad,h}$, then (P_h) has at least one solution.

Now let us assume that $(\bar{\mathbf{u}},\bar{\mathbf{y}})$ is a strict local solution of (P) in $(U_{ad}\cap B_\rho(\bar{\mathbf{u}}))\times B_\rho(\bar{\mathbf{y}})$. We consider the problems

$$(\mathrm{Q}_h)\begin{cases}\min J_h(\mathbf{u}),\\ \mathbf{u}\in U_{ad,h}\cap B_\rho(\bar{\mathbf{u}}),\end{cases}$$

where $J_h(\mathbf{u})=F(\mathbf{u},\mathbf{y}^h_{\mathbf{u}})$ with $(\mathbf{y}^h_{\mathbf{u}},p^h_{\mathbf{u}})=G_h(\mathbf{u})$, G_h being defined in Remark 4.9. Above we have proved that $U_{ad,h}\cap B_\rho(\bar{\mathbf{u}})$ is nonempty for $h\le h_2$. Observe that $U_{ad,h}\cap B_\rho(\bar{\mathbf{u}})$ is convex, bounded, and closed in $L^2(\omega;\mathbb{R}^m)$, the mapping $\mathbf{u}\mapsto\int_\omega|\mathbf{u}|^2$ is lower semicontinuous for the weak topology of $L^2(\omega;\mathbb{R}^m)$, and from Remark 4.9 it follows that the mapping $\mathbf{u}\mapsto\int_\Omega|\mathbf{y}^h_{\mathbf{u}}-\mathbf{y}_d|^2$ is continuous for the weak topology of $L^2(\omega;\mathbb{R}^m)$. Therefore (Q_h) has at least one solution $\bar{\mathbf{u}}_h$. From any subsequence of $\{\bar{\mathbf{u}}_h\}_h$, we can extract another subsequence, still indexed by h to simplify the notation, converging weakly in $L^2(\omega;\mathbb{R}^m)$ to some $\tilde{\mathbf{u}}\in B_\rho(\bar{\mathbf{u}})$. Let us check that $\tilde{\mathbf{u}}=\bar{\mathbf{u}}$. Let us take again $\mathbf{u}_h=\Pi_h\bar{\mathbf{u}}\in U_{ad,h}\cap B_\rho(\bar{\mathbf{u}})$ for all $h<h_2$. By passing to the limit when h tends to zero, with the convergence result stated in Lemma 4.10, we can write

$$J(\tilde{\mathbf{u}})\le\liminf_{h\to0}J_h(\bar{\mathbf{u}}_h)\le\limsup_{h\to0}J_h(\bar{\mathbf{u}}_h)\le\limsup_{h\to0}J_h(\Pi_h\bar{\mathbf{u}})=J(\bar{\mathbf{u}}).$$

Since $\tilde{\mathbf{u}}\in B_\rho(\bar{\mathbf{u}})$ and the inequality in (4.6) is strict for $\mathbf{u}\ne\bar{\mathbf{u}}$, the above inequality implies that $\tilde{\mathbf{u}}=\bar{\mathbf{u}}$. Thus we have

$$\lim_{h\to0}J_h(\bar{\mathbf{u}}_h)=J(\bar{\mathbf{u}}),$$

and still with Lemma 4.10, we deduce that

$$\lim_{h\to0}\int_\omega|\bar{\mathbf{u}}_h|^2=\int_\omega|\bar{\mathbf{u}}|^2.$$

Therefore the subsequence $\{\bar{\mathbf{u}}_h\}_h$ converges to $\bar{\mathbf{u}}$ in $L^2(\omega;\mathbb{R}^m)$. Since $\bar{\mathbf{u}}$ is the only cluster point for the weak topology of $L^2(\omega;\mathbb{R}^m)$ of the original sequence $\{\bar{\mathbf{u}}_h\}_h$, it is clear that the convergence properties stated in the theorem hold for the whole sequence $\{\bar{\mathbf{u}}_h\}_h$. The convergence of the corresponding states is a consequence of Lemma 4.10. Finally, the strong convergence $\bar{\mathbf{u}}_h\to\bar{\mathbf{u}}$ in $L^2(\omega;\mathbb{R}^m)$ implies that $\bar{\mathbf{u}}_h$ belongs to the interior of the ball $B^h_\rho(\bar{\mathbf{u}})$, which implies that $(\bar{\mathbf{u}}_h,\bar{\mathbf{y}}_h)$ is a local minimum of (P_h). ∎

4.3. Discrete adjoint equation. We define the discrete adjoint state $(\boldsymbol{\Phi}^h_{\mathbf{u}},\pi^h_{\mathbf{u}})\in\mathbf{X}_h\times M_h$ associated with a control $\mathbf{u}\in B_{\rho_2}(\bar{\mathbf{u}})$ as the solution to the problem

$$\begin{aligned}&a(\boldsymbol{\Phi}^h_{\mathbf{u}},\mathbf{w}_h)+b(\mathbf{y}^h_{\mathbf{u}},\mathbf{w}_h,\boldsymbol{\Phi}^h_{\mathbf{u}})+b(\mathbf{w}_h,\mathbf{y}^h_{\mathbf{u}},\boldsymbol{\Phi}^h_{\mathbf{u}})-(\pi^h_{\mathbf{u}},\operatorname{div}\mathbf{w}_h)\\ &=(\mathbf{y}^h_{\mathbf{u}}-\mathbf{y}_d,\mathbf{w}_h)\quad\forall\,\mathbf{w}_h\in\mathbf{X}_h,\\ &(\lambda_h,\operatorname{div}\boldsymbol{\Phi}^h_{\mathbf{u}})=0\quad\forall\,\lambda_h\in M_h.\end{aligned}\tag{4.8}$$

LEMMA 4.12. *Let* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ *be as in Theorem* 4.7. *There exist* $0 < h_3 \le h_2$ *and* $0 < \rho_3 \le \rho_2$ *such that, for all* $\mathbf{u} \in B_{\rho_3}(\bar{\mathbf{u}})$ *and all* $0 < h \le h_3$, *the system* (4.8) *admits a unique solution* $(\boldsymbol{\Phi}_{\mathbf{u}}^h, \pi_{\mathbf{u}}^h) \in \mathbf{X}_h \times M_h$.

Proof. (i) For $\mathbf{y} \in \mathbf{H}_0^1(\Omega)$, consider the mapping $\mathcal{G}_{\mathbf{y}}$ from $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ into itself defined by

$$\mathcal{G}_{\mathbf{y}}(\boldsymbol{\Phi}, \pi) = (\boldsymbol{\Phi}, \pi) + T[B'(\mathbf{y})^* \boldsymbol{\Phi}].$$

As in Lemma 4.2, we can easily show that $\mathcal{G}_{\mathbf{y}}$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ if and only if $\mathbf{y}$ is a nonsingular solution of (2.2). Thus $\mathcal{G}_{\bar{\mathbf{y}}}$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$. We also introduce the mapping $\mathcal{G}_{\mathbf{y},h}$ from $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ into itself defined by

$$\mathcal{G}_{\mathbf{y},h}(\boldsymbol{\Phi}, \pi) = (\boldsymbol{\Phi}, \pi) + T_h[B'(\mathbf{y})^* \boldsymbol{\Phi}].$$

Arguing as in the proof of Theorem 4.7, we can assume that h_0 is chosen so that, for all $0 < h < h_0$ and all $\mathbf{y} \in B_{\rho_0}(\bar{\mathbf{y}})$, $\mathcal{G}_{\mathbf{y},h}$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$. In particular, according to estimate (4.5), there exist $0 < h_3 \le h_2$ and $0 < \rho_3 \le \rho_2$ such that, for all $0 < h \le h_3$ and all $\mathbf{u} \in B_{\rho_3}(\bar{\mathbf{u}})$, $\mathcal{G}_{\mathbf{y}_{\mathbf{u}}^h,h}$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ and

$$\|\mathcal{G}_{\mathbf{y}_{\mathbf{u}}^h,h}^{-1}\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))} \le 2\|\mathcal{G}_{\bar{\mathbf{y}}}^{-1}\|_{\mathcal{L}(\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega))}.$$

Without loss of generality we can also assume that $\mathcal{G}_{\mathbf{y}(\mathbf{u})}$ is an automorphism in $\mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ for all $\mathbf{u} \in B_{\rho_3}(\bar{\mathbf{u}})$.

(ii) Now we are going to show that $(\boldsymbol{\Phi}_{\mathbf{u}}^h, \pi_{\mathbf{u}}^h) \in \mathbf{X}_h \times M_h$ is a solution of (4.8) if and only if

$$\mathcal{G}_{\mathbf{y}_{\mathbf{u}}^h,h}(\boldsymbol{\Phi}_{\mathbf{u}}^h, \pi_{\mathbf{u}}^h) = (\mathbf{z}_h, q_h), \tag{4.9}$$

where $(\mathbf{z}_h, q_h) \in \mathbf{X}_h \times M_h$ is the solution of the discrete Stokes problem,

$$\begin{aligned} &a(\mathbf{z}_h, \mathbf{w}_h) - (q_h, \operatorname{div} \mathbf{w}_h) = (\mathbf{y}_h(\mathbf{u}) - \mathbf{y}_d, \mathbf{w}_h)\ \forall\, \mathbf{w}_h \in \mathbf{X}_h, \\ &(\lambda_h, \operatorname{div} \mathbf{z}_h) = 0\ \forall\, \lambda_h \in M_h. \end{aligned} \tag{4.10}$$

To prove this result, we notice that (4.9) is satisfied if and only if

$$(\boldsymbol{\Phi}_{\mathbf{u}}^h - \mathbf{z}_h, \pi_{\mathbf{u}}^h - q_h) = -T_h[B'(\mathbf{y}_{\mathbf{u}}^h)^* \boldsymbol{\Phi}_{\mathbf{u}}^h],$$

which is equivalent to

$$\begin{aligned} &a(\boldsymbol{\Phi}_{\mathbf{u}}^h - \mathbf{z}_h, \mathbf{w}_h) - (\pi_{\mathbf{u}}^h - q_h, \operatorname{div} \mathbf{w}_h) = (B'(\mathbf{y}_{\mathbf{u}}^h)^* \boldsymbol{\Phi}_{\mathbf{u}}^h, \mathbf{w}_h)\ \forall\, \mathbf{w}_h \in \mathbf{X}_h, \\ &(\lambda_h, \operatorname{div} \boldsymbol{\Phi}_{\mathbf{u}}^h - \operatorname{div} \mathbf{z}_h) = 0\ \forall\, \lambda_h \in M_h. \end{aligned} \tag{4.11}$$

Now using equation (4.10), we see that (4.11) is equivalent to (4.8). This completes the proof. ∎

We are going to prove error estimates for the discrete adjoint state. Set

$$\mathbf{V}_h = \Big\{ \boldsymbol{\Phi}_h \in X_h \mid (\lambda_h, \operatorname{div} \boldsymbol{\Phi}_h) = 0\ \forall\, \lambda_h \in M_h \Big\}.$$

LEMMA 4.13. *Let* $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ *be as in Theorem* 4.7. *There exists a constant* $C > 0$ *such that, for all* $\mathbf{u}$, $\hat{\mathbf{u}} \in B_{\rho_3}(\bar{\mathbf{u}})$ *and all* $0 < h < h_3$, *the solution* $(\boldsymbol{\Phi}_{\mathbf{u}}, \pi_{\mathbf{u}})$ *to* (3.8)

and the solutions $(\mathbf{\Phi}^h_{\mathbf{u}}, \pi^h_{\mathbf{u}})$ *and* $(\mathbf{\Phi}^h_{\hat{\mathbf{u}}}, \pi^h_{\hat{\mathbf{u}}})$ *to* (4.8) *obey the following estimates:*

$$\|\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}\|_{\mathbf{L}^2(\Omega)} \le Ch^2, \tag{4.12}$$

$$\|\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}\|_{\mathbf{H}^1_0(\Omega)} + \|\pi_{\mathbf{u}} - \pi^h_{\mathbf{u}}\|_{L^2_0(\Omega)} \le Ch, \tag{4.13}$$

$$\|\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\hat{\mathbf{u}}}\|_{\mathbf{H}^1_0(\Omega)} + \|\pi_{\mathbf{u}} - \pi^h_{\hat{\mathbf{u}}}\|_{L^2_0(\Omega)} \le C(h + \|\mathbf{u} - \hat{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}). \tag{4.14}$$

Moreover, if $\mathbf{u}_h \in B_{\rho_3}(\bar{\mathbf{u}})$ *and* $\mathbf{u}_h \rightharpoonup \mathbf{u}$ *weakly in* $L^2(\omega;\mathbb{R}^m)$*, then* $\mathbf{\Phi}^h_{\mathbf{u}} \to \mathbf{\Phi}_{\mathbf{u}}$ *strongly in* $C(\bar{\Omega};\mathbb{R}^d)$.

Proof. (i) We first show (4.13). From the proof of Lemma 4.12 it follows that $\mathcal{G}_{\mathbf{y_u}}$ is an automorphism in $\mathbf{H}^1_0(\Omega) \times L^2_0(\Omega)$, and that, for all $\mathbf{u} \in B_{\rho_3}(\bar{\mathbf{u}})$ and all $0 < h < h_3$, $\mathcal{G}_{\mathbf{y}^h_{\mathbf{u}}}$ is an automorphism in $\mathbf{H}^1_0(\Omega) \times L^2_0(\Omega)$ and

$$\|\mathcal{G}^{-1}_{\mathbf{y}^h_{\mathbf{u}},h}\|_{\mathcal{L}(\mathbf{H}^1_0(\Omega)\times L^2_0(\Omega))} \le 2\|\mathcal{G}^{-1}_{\bar{\mathbf{y}}}\|_{\mathcal{L}(\mathbf{H}^1_0(\Omega)\times L^2_0(\Omega))}.$$

Let us recall that $(\mathbf{\Phi}_{\mathbf{u}}, \pi_{\mathbf{u}})$ is the solution of the equation

$$\mathcal{G}_{\mathbf{y_u}}(\mathbf{\Phi}_{\mathbf{u}}, \pi_{\mathbf{u}}) = T(\mathbf{y_u} - \mathbf{y}_d),$$

and that $(\mathbf{\Phi}^h_{\mathbf{u}}, \pi^h_{\mathbf{u}})$ is the solution of

$$\mathcal{G}_{\mathbf{y}^h_{\mathbf{u}},h}(\mathbf{\Phi}^h_{\mathbf{u}}, \pi^h_{\mathbf{u}}) = T_h(\mathbf{y}^h_{\mathbf{u}} - \mathbf{y}_d).$$

Thus we have

$$\begin{aligned}
&\mathcal{G}_{\mathbf{y}^h_{\mathbf{u}},h}(\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}, \pi_{\mathbf{u}} - \pi^h_{\mathbf{u}}) \\
&= (\mathbf{\Phi}_{\mathbf{u}}, \pi_{\mathbf{u}}) + T_h(B'(\mathbf{y}^h_{\mathbf{u}})^*\mathbf{\Phi}_{\mathbf{u}}) - \mathcal{G}_{\mathbf{y}^h_{\mathbf{u}},h}(\mathbf{\Phi}^h_{\mathbf{u}}, \pi^h_{\mathbf{u}}) \\
&= T_h[B'(\mathbf{y}^h_{\mathbf{u}})^*\mathbf{\Phi}_{\mathbf{u}}] - T[B'(\mathbf{y_u})^*\mathbf{\Phi}_{\mathbf{u}}] + T(\mathbf{y_u} - \mathbf{y}_d) - T_h(\mathbf{y}^h_{\mathbf{u}} - \mathbf{y}_d) \\
&= (T - T_h)[\mathbf{y}^h_{\mathbf{u}} - B'(\mathbf{y}^h_{\mathbf{u}})^*\mathbf{\Phi}_{\mathbf{u}} - \mathbf{y}_d] \\
&\qquad + T[B'(\mathbf{y}^h_{\mathbf{u}})^*\mathbf{\Phi}_{\mathbf{u}} - B'(\mathbf{y_u})^*\mathbf{\Phi}_{\mathbf{u}}] + T[\mathbf{y_u} - \mathbf{y}^h_{\mathbf{u}}],
\end{aligned}$$

which yields

$$\begin{aligned}
&(\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}, \pi_{\mathbf{u}} - \pi^h_{\mathbf{u}}) \\
&= \Big(\mathcal{G}_{\mathbf{y}^h_{\mathbf{u}},h}\Big)^{-1}\Big((T - T_h)[\mathbf{y}^h_{\mathbf{u}} - B'(\mathbf{y}^h_{\mathbf{u}})^*\mathbf{\Phi}_{\mathbf{u}} - \mathbf{y}_d] \\
&\qquad + T[B'(\mathbf{y}^h_{\mathbf{u}})^*\mathbf{\Phi}_{\mathbf{u}} - B'(\mathbf{y_u})^*\mathbf{\Phi}_{\mathbf{u}}] + T[\mathbf{y_u} - \mathbf{y}^h_{\mathbf{u}}]\Big).
\end{aligned}$$

With estimate (4.5) and assumption (S2), we obtain

$$\|\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}\|_{\mathbf{H}^1_0(\Omega)} + \|\pi_{\mathbf{u}} - \pi^h_{\mathbf{u}}\|_{L^2_0(\Omega)} \le Ch.$$

(ii) To prove (4.12) we proceed as in [12, Chapter 2, Theorems 1.2 and 1.9]. The solution $(\mathbf{\Phi}_{\mathbf{u}}, \pi_{\mathbf{u}})$ to (3.8) and the solution $(\mathbf{\Phi}^h_{\mathbf{u}}, \pi^h_{\mathbf{u}})$ to (4.8) satisfy

$$\begin{aligned}
&a(\mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}, \mathbf{w}_h) + b(\mathbf{y_u}, \mathbf{w}_h, \mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}) + b(\mathbf{w}_h, \mathbf{y_u}, \mathbf{\Phi}_{\mathbf{u}} - \mathbf{\Phi}^h_{\mathbf{u}}) \\
&- (\pi_{\mathbf{u}} - \pi^h_{\mathbf{u}}, \operatorname{div} \mathbf{w}_h) = (\mathbf{y_u} - \mathbf{y}^h_{\mathbf{u}}, \mathbf{w}_h) + b(\mathbf{y_u} - \mathbf{y}^h_{\mathbf{u}}, \mathbf{w}_h, \mathbf{\Phi}^h_{\mathbf{u}}) \\
&+ b(\mathbf{w}_h, \mathbf{y_u} - \mathbf{y}^h_{\mathbf{u}}, \mathbf{\Phi}^h_{\mathbf{u}}) \ \forall\ \mathbf{w}_h \in \mathbf{X}_h, \\
&(\lambda_h, \operatorname{div} \mathbf{\Phi}_{\mathbf{u}} - \operatorname{div} \mathbf{\Phi}^h_{\mathbf{u}}) = 0 \ \forall\, \lambda_h \in M_h.
\end{aligned} \tag{4.15}$$

For all $\mathbf{g} \in \mathbf{L}^2(\Omega)$, let us consider the solution $(\mathbf{z_g}, q_\mathbf{g}) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ to

$$\begin{aligned} &a(\mathbf{z_g}, \mathbf{w}) + b(\mathbf{y_u}, \mathbf{z_g}, \mathbf{w}) + b(\mathbf{z_g}, \mathbf{y_u}, \mathbf{w}) - (q_\mathbf{g}, \operatorname{div} \mathbf{w}) = (\mathbf{g}, \mathbf{w}) \ \forall \mathbf{w} \in \mathbf{H}_0^1(\Omega), \\ &(\lambda, \operatorname{div} \mathbf{z_g}) = 0 \ \forall \lambda \in L_0^2(\Omega), \end{aligned} \tag{4.16}$$

and the solution $(\mathbf{z}_\mathbf{g}^h, q_\mathbf{g}^h) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ to

$$\begin{aligned} &a(\mathbf{z}_\mathbf{g}^h, \mathbf{w}_h) + b(\mathbf{y_u}, \mathbf{z}_\mathbf{g}^h, \mathbf{w}_h) + b(\mathbf{z}_\mathbf{g}^h, \mathbf{y_u}, \mathbf{w}_h) - (q_\mathbf{g}^h, \operatorname{div} \mathbf{w}_h) = (\mathbf{g}, \mathbf{w}_h) \ \forall \mathbf{w} \in \mathbf{X}_h, \\ &(\lambda, \operatorname{div} \mathbf{z}_\mathbf{g}^h) = 0 \ \forall \lambda \in M_h. \end{aligned}$$

Choosing $\mathbf{w}_h = \mathbf{z}_\mathbf{g}^h$ in (4.15) and $\mathbf{w} = \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h$ in (4.16) and combining the two identities, we obtain

$$\begin{aligned} &(\mathbf{g}, \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h) = a(\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h, \mathbf{z_g} - \mathbf{z}_\mathbf{g}^h) + b(\mathbf{y_u}, \mathbf{z_g} - \mathbf{z}_\mathbf{g}^h, \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h) \\ &+ b(\mathbf{z_g} - \mathbf{z}_\mathbf{g}^h, \mathbf{y_u}, \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h) + (\pi_\mathbf{u} - \pi_\mathbf{u}^h, \operatorname{div} \mathbf{z}_\mathbf{g}^h) - (q_\mathbf{g}, \operatorname{div} \mathbf{\Phi_u} - \operatorname{div} \mathbf{\Phi}_\mathbf{u}^h) \\ &+ (\mathbf{y_u} - \mathbf{y}_\mathbf{u}^h, \mathbf{z}_\mathbf{g}^h) + b(\mathbf{y_u} - \mathbf{y}_\mathbf{u}^h, \mathbf{z}_\mathbf{g}^h, \mathbf{\Phi}_\mathbf{u}^h) + b(\mathbf{z}_\mathbf{g}^h, \mathbf{y_u} - \mathbf{y}_\mathbf{u}^h, \mathbf{\Phi}_\mathbf{u}^h) \\ &= a(\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h, \mathbf{z_g} - \mathbf{z}_\mathbf{g}^h) - b(\mathbf{y_u}, \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h, \mathbf{z_g} - \mathbf{z}_\mathbf{g}^h) - b(\mathbf{z_g} - \mathbf{z}_\mathbf{g}^h, \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h, \mathbf{y_u}) \\ &+ (\mathbf{y_u} - \mathbf{y}_\mathbf{u}^h, \mathbf{z}_\mathbf{g}^h) - b(\mathbf{y_u} - \mathbf{y}_\mathbf{u}^h, \mathbf{\Phi}_\mathbf{u}^h, \mathbf{z}_\mathbf{g}^h) - b(\mathbf{z}_\mathbf{g}^h, \mathbf{\Phi}_\mathbf{u}^h, \mathbf{y_u} - \mathbf{y}_\mathbf{u}^h) \\ &+ (\pi_\mathbf{u} - \pi_\mathbf{u}^h, \operatorname{div} \mathbf{z}_\mathbf{g}^h - \operatorname{div} \mathbf{z_g}) - (q_\mathbf{g} - q_\mathbf{g}^h, \operatorname{div} \mathbf{\Phi_u} - \operatorname{div} \mathbf{\Phi}_\mathbf{u}^h). \end{aligned}$$

Thus we have

$$\begin{aligned} &\|\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h\|_{\mathbf{L}^2(\Omega)} = \sup_{\|\mathbf{g}\|_{\mathbf{L}^2(\Omega)}=1} (\mathbf{g}, \mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h) \\ &\le C \sup_{\|\mathbf{g}\|_{\mathbf{L}^2(\Omega)}=1} \Big\{ \|\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h\|_{\mathbf{H}_0^1(\Omega)} \|\mathbf{z_g} - \mathbf{z}_\mathbf{g}^h\|_{\mathbf{H}_0^1(\Omega)} \\ &\quad + \|\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h\|_{\mathbf{H}_0^1(\Omega)} \|\mathbf{z_g} - \mathbf{z}_\mathbf{g}^h\|_{\mathbf{L}^2(\Omega)} \|\mathbf{y_u}\|_{\mathbf{L}^\infty(\Omega)} \\ &\quad + \|\mathbf{y_u} - \mathbf{y}_\mathbf{u}^h\|_{\mathbf{L}^2(\Omega)} \|\mathbf{z}_\mathbf{g}^h\|_{\mathbf{L}^2(\Omega)} + \|\mathbf{y_u} - \mathbf{y}_\mathbf{u}^h\|_{\mathbf{L}^2(\Omega)} \|\mathbf{z}_\mathbf{g}^h\|_{\mathbf{L}^\infty(\Omega)} \|\mathbf{\Phi}_\mathbf{u}^h\|_{\mathbf{H}_0^1(\Omega)} \\ &\quad + \|\pi_\mathbf{u} - \pi_\mathbf{u}^h\|_{L_0^2(\Omega)} \|\mathbf{z_g} - \mathbf{z}_\mathbf{g}^h\|_{\mathbf{H}_0^1(\Omega)} + \|q_\mathbf{g} - q_\mathbf{g}^h\|_{L_0^2(\Omega)} \|\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h\|_{\mathbf{H}_0^1(\Omega)} \Big\}. \end{aligned} \tag{4.17}$$

To complete estimate (4.12), we are going to use (4.13) and a similar error estimate for $(\mathbf{z_g}, q_\mathbf{g})$:

$$\|\mathbf{z_g} - \mathbf{z}_\mathbf{g}^h\|_{\mathbf{H}_0^1(\Omega)} + \|q_\mathbf{g} - q_\mathbf{g}^h\|_{L_0^2(\Omega)} \le Ch(\|\mathbf{z_g}\|_{\mathbf{H}^2(\Omega)} + \|q_\mathbf{g}\|_{H^1(\Omega)}). \tag{4.18}$$

With (4.17), (4.13), (4.18), and (4.4), we obtain

$$\|\mathbf{\Phi_u} - \mathbf{\Phi}_\mathbf{u}^h\|_{\mathbf{L}^2(\Omega)} \le Ch^2.$$

The proof of (4.12) is complete. Estimate (4.14) and the last statement in the lemma can now be proved in the same way as we did it for the state. ∎

Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ be a nonsingular strict local minimum of (P) and $\{(\bar{\mathbf{u}}_h, \bar{\mathbf{y}}_h)\}_{h \le h_3}$ be a sequence of local minima of problems (P_h) converging to $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ in $\mathbf{L}^2(\omega; \mathbb{R}^m) \times \mathbf{H}_0^1(\Omega)$, with $\bar{\mathbf{u}}_h \in B_{\rho_3}(\bar{\mathbf{u}})$, where h_3 and ρ_3 are given by Lemma 4.12. Then every element $\bar{\mathbf{u}}_h$ from a sequence $\{\bar{\mathbf{u}}_h\}_{h \le h_3}$ is a local solution of the problem

$$(\hat{\mathrm{P}}_h) \begin{cases} \min J_h(\mathbf{u}) = F(\mathbf{u}, \mathbf{y}_\mathbf{u}^h), \\ \mathbf{u} \in U_{ad,h}, \end{cases}$$

where $(\mathbf{y}_{\mathbf{u}}^h, p_{\mathbf{u}}^h) = G_h(\mathbf{u})$, G_h being defined in Remark 4.9.

LEMMA 4.14. *Let $\bar{\mathbf{u}}_h$ be a solution to problem $(\hat{\mathrm{P}}_h)$, and let $(\bar{\mathbf{y}}_h, \bar{p}_h) \in \mathbf{X}_h \times M_h$ be the corresponding state and pressure. Then $\bar{\mathbf{u}}_h$ satisfies*

$$\int_\omega (\mathcal{C}^* \bar{\mathbf{\Phi}}_h + N\bar{\mathbf{u}}_h) \cdot (\mathbf{u}_h - \bar{\mathbf{u}}_h)\, dx \geq 0 \ \forall\, \mathbf{u}_h \in U_{ad,h},$$

where $(\bar{\mathbf{\Phi}}_h, \bar{\pi}_h) = (\mathbf{\Phi}^h_{\bar{\mathbf{u}}_h}, \pi^h_{\bar{\mathbf{u}}_h}) \in \mathbf{X}_h \times M_h$ is the discrete adjoint state associated with $\bar{\mathbf{u}}_h$, that is, the solution to the system (4.8) *where $\mathbf{u}$ is replaced by $\bar{\mathbf{u}}_h$.*

Proof. The lemma is a consequence of the following identity:

$$J_h'(\bar{\mathbf{u}}_h)(\mathbf{u}_h - \bar{\mathbf{u}}_h) = \int_\omega (\mathcal{C}^* \bar{\mathbf{\Phi}}_h + N\bar{\mathbf{u}}_h) \cdot (\mathbf{u}_h - \bar{\mathbf{u}}_h)\, dx. \qquad \square$$

Now we can establish uniform convergence for the controls.

LEMMA 4.15. *Let $\bar{\mathbf{u}}_h$ be as in Lemma* 4.14*; then* $\lim_{h\to 0} \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^\infty(\omega;\mathbb{R}^m)} = 0$.

Proof. Let us start with the case where $U_{ad,h} = U_{ad}^h$. Since the components of the elements of U_h are constant on every triangle, for all $T \in \mathcal{T}_h$ and $1 \leq i \leq m$, we have

$$\bar{u}_{i,h}|_T = \mathrm{Proj}_{[\alpha_i,\beta_i]} \left(-\frac{1}{N|T|} \int_T (\mathcal{C}^* \bar{\mathbf{\Phi}}_h)_i(x) dx \right).$$

For all $x \in T$, using (3.9), the integral mean value theorem, and the Lipschitz continuity of $\bar{\mathbf{\Phi}}$, we can write

$$\begin{aligned}
|\bar{u}_{i,h}(x) - \bar{u}_i(x)| &\leq \left| \frac{1}{N|T|} \int_T (\mathcal{C}^* \bar{\mathbf{\Phi}}_h)_i(s) ds - \frac{1}{N} (\mathcal{C}^* \bar{\mathbf{\Phi}})_i(x) \right| \\
&= \frac{1}{N} |(\mathcal{C}^* \bar{\mathbf{\Phi}}_h)_i(x_T) - (\mathcal{C}^* \bar{\mathbf{\Phi}})_i(x)| \\
&\leq \frac{1}{N} |(\mathcal{C}^* \bar{\mathbf{\Phi}}_h)_i(x_T) - (\mathcal{C}^* \bar{\mathbf{\Phi}})_i(x_T)| + \frac{1}{N} |(\mathcal{C}^* \bar{\mathbf{\Phi}})_i(x_T) - (\mathcal{C}^* \bar{\mathbf{\Phi}})_i(x)| \\
&\leq C \|\bar{\mathbf{\Phi}}_h - \bar{\mathbf{\Phi}}\|_{\mathbf{L}^\infty(\Omega)} + C|x_T - x| \leq C(\|\bar{\mathbf{\Phi}}_h - \bar{\mathbf{\Phi}}\|_{\mathbf{L}^\infty(\Omega)} + h)
\end{aligned}$$

for some $x_T \in T$. The uniform convergence of the adjoint states allows us to complete the proof in the case when $U_{ad,h} = U_{ad}^h$.

In the case when $U_{ad,h} = U_{ad}$ we have

$$\bar{u}_{i,h}(x) = \mathrm{Proj}_{[\alpha_i,\beta_i]} \left(-\frac{1}{N|T|} (\mathcal{C}^* \bar{\mathbf{\Phi}}_h)_i(x) \right).$$

The convergence of $\bar{\mathbf{u}}_h$ follows from Lemma 4.13. $\square$

4.4. Error estimates. Let $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ be a nonsingular local solution of (P) satisfying the sufficient second order optimality conditions (3.15) or, equivalently, (3.25). As a consequence of these conditions, we know that $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$ is a strict local minimum of (P). Let $\{(\bar{\mathbf{u}}_h, \bar{\mathbf{y}}_h)\}_h$ be a sequence of local solutions of problems (P_h) converging to $(\bar{\mathbf{u}}, \bar{\mathbf{y}})$; see Theorem 4.11 and Lemma 4.15. We assume that $h \leq h_3$ and $\bar{\mathbf{u}}_h \in B_{\rho_3}(\bar{\mathbf{u}})$, so that $\bar{\mathbf{u}}_h$ is a local minimum of $(\hat{\mathrm{P}}_h)$. The goal of this section is to estimate the order of convergence of this sequence.

LEMMA 4.16. *Let $\delta > 0$ be the constant defined in Corollary* 3.11*. There exists $0 < h_4 \leq h_3$ such that*

$$\frac{\delta}{2} \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|^2_{L^2(\omega;\mathbb{R}^m)} \leq (J'(\bar{\mathbf{u}}_h) - J'(\bar{\mathbf{u}}))(\bar{\mathbf{u}}_h - \bar{\mathbf{u}}) \ \forall\, 0 < h < h_4.$$

Proof. First, let us check that for $h > 0$ small enough, $\bar{\mathbf{u}}_h - \bar{\mathbf{u}}$ belongs to $C^\tau_{\bar{\mathbf{u}}}$. The sign condition (3.21)–(3.22) is trivial since $\bar{\mathbf{u}}_h \in U_{ad}$. We have to check condition (3.20). Let us set

$$\bar{\mathbf{d}}_h(x) = (\mathcal{C}^* \bar{\mathbf{\Phi}}_h)(x) + N\bar{\mathbf{u}}_h(x).$$

Take h_4 small enough to have

$$\|\bar{\mathbf{d}} - \bar{\mathbf{d}}_h\|_{L^\infty(\omega)} < \frac{\tau}{4}, \quad \text{and} \quad \|\bar{\mathbf{d}}(x_1) - \bar{\mathbf{d}}(x_2)\|_{\mathbb{R}^m} < \frac{\tau}{4} \quad \text{if} \quad \|x_1 - x_2\|_{\mathbb{R}^d} < h,$$

for all $0 < h \le h_4$. First consider the case where $U_{ad,h} = U_{ad}$. In that case, if $\bar{d}_i(\xi) > \tau$ (respectively, $\bar{d}_i(\xi) < -\tau$), we have $\bar{d}_{i,h}(\xi) > 3\tau/4$ (respectively, $\bar{d}_{i,h}(\xi) < -3\tau/4$), and $\bar{u}_i(\xi) = \alpha_i$ and $\bar{u}_{i,h}(\xi) = \alpha_i > -\infty$ (respectively, $\bar{u}_i(\xi) = \beta_i$ and $\bar{u}_{i,h}(\xi) = \beta_i < \infty$). Thus $\mathbf{u}_{i,h}(\xi) = \mathbf{u}_i(\xi)$ if $|\bar{d}_i(\xi)| > \tau$, and condition (3.20) is satisfied.

Now consider the case where $U_{ad,h} = U^h_{ad}$. For all $T \in \mathcal{T}_h$ and all $1 \le i \le m$ let us set

$$I_{i,T} = \int_T \bar{d}_{i,h}(x)dx.$$

Take $\xi \in \omega$ such that $\bar{d}_i(\xi) > \tau$. In this case $\bar{u}_i(\xi) = \alpha_i > -\infty$. Choose x in the same triangle T as ξ. Then

$$\bar{d}_{i,h}(x) = \bar{d}_{i,h}(x) - \bar{d}_i(x) + \bar{d}_i(x) - \bar{d}_i(\xi) + \bar{d}_i(\xi) > -\frac{\tau}{4} - \frac{\tau}{4} + \tau = \frac{\tau}{2}.$$

Therefore $I_{i,T} > 0$ and $\bar{u}_{i,h}|_T = \alpha_i$. In particular $\bar{u}_{i,h}(\xi) = \alpha_i$ and $\bar{u}_{i,h}(\xi) - \bar{u}_i(\xi) = 0$. Similarly if $\bar{d}_i(\xi) < -\tau$, we have $\bar{u}_{i,h}(\xi) = \beta_i < \infty$ and $\bar{u}_{i,h}(\xi) - \bar{u}_i(\xi) = 0$, and condition (3.20) is still satisfied in that case.

Thus second order sufficient conditions stated in Corollary 3.11 can be applied, and we have

$$J''(\bar{\mathbf{u}})(\bar{\mathbf{u}}_h - \bar{\mathbf{u}})^2 \ge \delta \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)}.$$

On the other hand, with the mean value theorem, we obtain

$$(J'(\bar{\mathbf{u}}_h) - J'(\bar{\mathbf{u}}))(\bar{\mathbf{u}}_h - \bar{\mathbf{u}}) = J''(\bar{\mathbf{u}} + \theta_h(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h))(\bar{\mathbf{u}}_h - \bar{\mathbf{u}})^2$$

for some $0 < \theta_h < 1$. Due to the uniform convergence properties stated for the control and the adjoint state and the explicit form of the second derivative of J, it is clear that we can choose h_4 small enough to have

$$J''(\bar{\mathbf{u}} + \theta_h(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h))(\bar{\mathbf{u}}_h - \bar{\mathbf{u}})^2 \ge \frac{\delta}{2} \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|^2_{L^2(\omega;\mathbb{R}^m)}$$

for all $0 < h \le h_4$. The proof is complete. □

LEMMA 4.17. *Assume that $U_{ad,h} = U^h_{ad}$. There exists $0 < h_5 \le h_4$ such that for every $0 < h \le h_5$ there exist $\mathbf{u}^*_h \in U_h$ and a constant $C > 0$ independent of h such that*

(1) $\mathbf{u}^*_h \in U_{ad,h}$,
(2) $J'(\bar{\mathbf{u}})\bar{\mathbf{u}} = J'(\bar{\mathbf{u}})\mathbf{u}^*_h$,
(3) $\|\bar{\mathbf{u}} - \mathbf{u}^*_h\|_{L^\infty(\omega;\mathbb{R}^m)} \le Ch$.

Proof. For every triangle $T \in \mathcal{T}_h$ and $1 \le i \le m$, define

$$I_{i,T} = \int_T \bar{d}_i(x)dx$$

and

$$u^*_{i,h}|_T = \begin{cases} \dfrac{1}{I_{i,T}} \displaystyle\int_T d_i(x)\bar{u}_i(x)dx & \text{if } I_{i,T} \neq 0, \\ \dfrac{1}{|T|} \displaystyle\int_T \bar{u}_i(x)dx & \text{if } I_{i,T} = 0. \end{cases}$$

Due to the Lipschitz continuity of $\bar{\mathbf{u}}$, there exists $0 < h_5 \le h_4$ such that, for $0 < h \le h_5$, each component $\bar{u}_i$ cannot achieve both values α and β in the same triangle. Hence, for each $T \in \mathcal{T}_h$, either $\bar{d}_i(x)$ is nonnegative for all $x \in T$ or $\bar{d}_i(x)$ is nonpositive for all $x \in T$. Therefore, $I_{i,T} = 0$ if and only if $\bar{d}_i(x) = 0$ for all $x \in T$. Moreover, if $I_{i,T} \neq 0$, then $\bar{d}_i(x)/I_{i,T} \ge 0$ for all $x \in T$. So applying the integral mean value theorem if $I_{i,T} = 0$ or the generalized mean value theorem if $I_{i,T} \neq 0$, we have $u^*_{i,h}|_T = \bar{u}_i(x_T)$ for some $x_T \in T$. As a first consequence, $\mathbf{u}^*_h \in U_{ad,h}$. Moreover, due to the Lipschitz continuity of $\bar{\mathbf{u}}$, we have that for $x \in \omega$, if we fix the triangle T such that $x \in T$,

$$|\bar{u}_i(x) - u^*_{i,h}(x)| = |\bar{u}_i(x) - \bar{u}_i(x^i_T)| \le C\|x - x^i_T\|_{\mathbb{R}^d} \le Ch,$$

and we have proved statement 3.

Since $I_{i,T} = 0$ if and only if $\bar{d}_i(x) = 0$ for all $x \in T$, we can claim that

$$I_{i,T}u^*_{i,h}|_T = \int_T \bar{d}_i(x)\bar{u}_i(x)dx$$

for all $T \in \mathcal{T}_h$ and all $1 \le i \le m$. A straightforward calculation yields statement 2:

$$J'(\bar{\mathbf{u}})\mathbf{u}^*_h = \int_\omega \bar{\mathbf{d}}(x) \cdot \bar{\mathbf{u}}^*_h(x)dx = \sum_{i=1}^m \sum_{T\in\mathcal{T}_h} \int_T \bar{d}_i(x)u^*_{i,h}(x)dx$$
$$= \sum_{i=1}^m \sum_{T\in\mathcal{T}_h} I_{i,T}u^*_{i,h}|_T = \sum_{i=1}^m \sum_{T\in\mathcal{T}_h} \int_T \bar{d}_i(x)\bar{u}_i(x)dx = J'(\bar{\mathbf{u}})\bar{\mathbf{u}}. \qquad \square$$

THEOREM 4.18. *There exists a constant $C > 0$ such that, for all $0 < h \le h_5$, we have*

$$\|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|_{L^2(\omega;\mathbb{R}^m)} \le Ch^2 \qquad \text{if } \ U_{ad,h} = U_{ad},$$

while

$$\|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|_{L^2(\omega;\mathbb{R}^m)} \le Ch \qquad \text{if } \ U_{ad,h} = U^h_{ad}.$$

Proof. (i) Let us start with the case where $U_{ad,h} = U^h_{ad}$. For $0 < h \le h_5$, we have

$$\begin{aligned} &\frac{\delta}{2}\|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|^2_{L^2(\omega;\mathbb{R}^m)} \le (J'(\bar{\mathbf{u}}) - J'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \\ &= (J'(\bar{\mathbf{u}}) - J'_h(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) + (J'_h(\bar{\mathbf{u}}_h) - J'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h). \end{aligned} \tag{4.19}$$

With (4.12) in Lemma 4.13, we can estimate the last term as follows:

$$
\begin{aligned}
&(J_h'(\bar{\mathbf{u}}_h) - J'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \\
&= \int_\omega (\mathcal{C}^*(\bar{\boldsymbol{\Phi}}_h - \boldsymbol{\Phi}_{\bar{\mathbf{u}}_h}) + N(\bar{\mathbf{u}}_h - \bar{\mathbf{u}}_h)) \cdot (\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) dx \\
&\le C\|\bar{\boldsymbol{\Phi}}_h - \boldsymbol{\Phi}_{\bar{\mathbf{u}}_h}\|_{\mathbf{L}^2(\Omega)} \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|_{L^2(\omega;\mathbb{R}^m)} \\
&\le Ch^2 \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|_{L^2(\omega;\mathbb{R}^m)}.
\end{aligned} \tag{4.20}
$$

Let us check what happens with the first term. From first order optimality conditions for problems (P) and (P$_h$) we have

$$
\begin{aligned}
J'(\bar{\mathbf{u}})(\bar{\mathbf{u}}_h - \bar{\mathbf{u}}) &\ge 0, \\
J_h'(\bar{\mathbf{u}}_h)(\mathbf{u}_h^* - \bar{\mathbf{u}}_h) = J_h'(\bar{\mathbf{u}}_h)(\mathbf{u}_h^* - \bar{\mathbf{u}}) &+ J_h'(\bar{\mathbf{u}}_h)(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \ge 0.
\end{aligned}
$$

Making the sum of these two expressions and using Lemma 4.17(2)–(3), we have

$$
\begin{aligned}
&J'(\bar{\mathbf{u}})(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) - J_h'(\bar{\mathbf{u}}_h)(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \le J_h'(\bar{\mathbf{u}}_h)(\mathbf{u}_h^* - \bar{\mathbf{u}}) \\
&= J_h'(\bar{\mathbf{u}}_h)(\mathbf{u}_h^* - \bar{\mathbf{u}}) - J'(\bar{\mathbf{u}})(\mathbf{u}_h^* - \bar{\mathbf{u}}) \\
&= \int_\omega (\mathcal{C}(\bar{\boldsymbol{\Phi}}_h - \bar{\boldsymbol{\Phi}}) + N(\bar{\mathbf{u}}_h - \bar{\mathbf{u}})) \cdot (\mathbf{u}_h^* - \bar{\mathbf{u}}) dx \\
&\le C(\|\bar{\boldsymbol{\Phi}}_h - \bar{\boldsymbol{\Phi}}\|_{\mathbf{L}^2(\Omega)} + \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}) \|\mathbf{u}_h^* - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)} \\
&\le Ch(\|\bar{\boldsymbol{\Phi}}_h - \boldsymbol{\Phi}_{\bar{\mathbf{u}}_h}\|_{\mathbf{L}^2(\Omega)} + \|\boldsymbol{\Phi}_{\bar{\mathbf{u}}_h} - \bar{\boldsymbol{\Phi}}\|_{\mathbf{L}^2(\Omega)} + \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}) \\
&\le Ch(h^2 + \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}).
\end{aligned} \tag{4.21}
$$

From (4.19), (4.20), and (4.21), we deduce that therefore there exists a constant $C > 0$, independent of h, such that

$$
\frac{\delta}{2} \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|^2_{L^2(\omega;\mathbb{R}^m)} \le Ch^3 + Ch\|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}.
$$

We conclude with Young's inequality.

(ii) Now let us consider the case where $U_{ad,h} = U_{ad}$. We rewrite the previous steps by introducing the simplifications corresponding to this case. For $0 < h \le h_5$, we have

$$
\begin{aligned}
\frac{\delta}{2} \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|^2_{L^2(\omega;\mathbb{R}^m)} &\le (J'(\bar{\mathbf{u}}) - J'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \\
&= (J'(\bar{\mathbf{u}}) - J_h'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) + (J_h'(\bar{\mathbf{u}}_h) - J'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h).
\end{aligned}
$$

Since $U_{ad,h} = U_{ad}$, from the first order optimality conditions satisfied by $\bar{\mathbf{u}}$ and $\bar{\mathbf{u}}_h$ we have

$$
(J'(\bar{\mathbf{u}}) - J_h'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \le 0.
$$

We have already seen that

$$
(J_h'(\bar{\mathbf{u}}_h) - J'(\bar{\mathbf{u}}_h))(\bar{\mathbf{u}} - \bar{\mathbf{u}}_h) \le Ch^2 \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|_{L^2(\omega;\mathbb{R}^m)}.
$$

Therefore there exists a constant $C > 0$ independent of h such that

$$
\frac{\delta}{2} \|\bar{\mathbf{u}} - \bar{\mathbf{u}}_h\|^2_{L^2(\omega;\mathbb{R}^m)} \le Ch^2 \|\bar{\mathbf{u}}_h - \bar{\mathbf{u}}\|_{L^2(\omega;\mathbb{R}^m)}.
$$

The proof is complete. □

From the previous theorem and Lemmas 4.10 and 4.13 we deduce

$$\|\bar{\mathbf{y}} - \bar{\mathbf{y}}_h\|_{\mathbf{H}_0^1(\Omega)} + \|\bar{p} - \bar{p}_h\|_{L_0^2(\Omega)} \leq Ch,$$
$$\|\bar{\mathbf{\Phi}} - \bar{\mathbf{\Phi}}_h\|_{\mathbf{H}_0^1(\Omega)} + \|\bar{\pi} - \bar{\pi}_h\|_{L_0^2(\Omega)} \leq Ch.$$

A SAMPLING METHOD AND APPROXIMATION RESULTS FOR IMPULSIVE SYSTEMS*

PETER R. WOLENSKI† AND STANISLAV ŽABIĆ†

Abstract. This paper studies an impulsive dynamical system that is in the form of a measure-driven differential inclusion. The employed solution concept depends upon a graph completion of the measure. The first main result shows that a subsequence of discrete-time trajectories *graph-converges* to a solution, and, under Lipschitz hypotheses, that every solution can be obtained in this manner. The second main result pursues a similar development with classical systems that approximate the given one.

Key words. impulsive systems, sampling, approximate solutions, optimal control, calculus of variations

1. Introduction.

This paper studies a *measure-driven* dynamical system of the form

$$\begin{cases} dx \in F\big(x(t)\big)\,dt + G\big(x(t)\big)\,\mu(dt), \\ x(0-) = x_0, \end{cases} \tag{1.1}$$

where $F(\cdot)$ and $G(\cdot)$ are multifunctions (set-valued maps) whose values, respectively, are subsets of $\mathbb{R}^n$ and $\mathcal{M}_{n\times m}$ (= the $n\times m$ matrices), and μ is a vector-valued measure with values in a closed convex cone $K \subseteq \mathbb{R}^m$. The system (1.1) is also referred to as an *impulsive* system since the measure may have atoms (i.e., *impulses*) which in effect may force the state trajectory $x(\cdot)$ to be discontinuous. Analogously to classical ODE theory, one can also consider the following integral inclusion:

$$\begin{cases} x(t) \in x_0 + \displaystyle\int_0^t F\big(x(\tau)\big)\,d\tau + \int_{[0,t)} G\big(x(\tau)\big)\,\mu(d\tau), \\ x(0-) = x_0. \end{cases} \tag{1.2}$$

One expects and certainly desires that the solution sets of (1.1) and (1.2) coincide; however, in both cases the precise notion of solution needs further explanation (see section 2 below). The mathematical formalisms (1.1) and (1.2) combine the following: (i) the system studied in [20, 21, 23] where the measure is positive and scalar-valued (that is, $m = 1$), and (ii) the system in [7] where the the set-valued maps are singletons (that is, (1.1) is an impulsive differential *equation*). The goal of the present paper is to prove closure and approximation results. More specifically, we develop an analogue of the Euler time-discretization method and prove results on absolute continuous approximations of μ. There are subtle modeling issues between the vector and scalar cases that we will discuss in more detail below. We first give a brief review of the relevant literature.

†Department of Mathematics, Louisiana State University, Baton Rouge, LA 70803-4918 (wolenski@math.lsu.edu, zabic@math.lsu.edu).

The early study of impulsive systems dates back to Rishel's paper [17], where the idea of handling impulses through time reparametrization was introduced. Warga [24] soon after extended this technique to a more general context. Another key insight was observed by Dal Maso and Rampazzo [7] (see also [3, 4, 10]), where the subtlety in defining the multiplication of a point-mass measure with a state-dependent term was observed as not well-defined unless a graph completion was also provided. Loosely speaking, a graph completion is a relation in graph space that extends the graph of the distribution function $u(\cdot)$ of μ to a connected subset by prescribing an arc to connect the right- and left-hand limits of $u(\cdot)$ at the points of discontinuity. This additional information is crucial since different graph completions can give rise to different solutions. The notion of a solution to a measure-driven differential *equation* (that is, $F(\cdot)$ and $G(\cdot)$ in (1.1) are singleton-valued) was defined in [7] as the solution to an auxiliary system that is reparameterized in time and depends on a given graph completion. The measure in [7] is vector-valued and is interpreted as the derivative of a control function of bounded variation. A natural extension to differential *inclusions* is considered in [21], where the main goals are to extend the robust solution concept to set-valued dynamics and to prove a closure property of the set of solutions. The measure here, however, is real-valued and positive, which essentially only uses the canonical completion. This will be discussed further in the next paragraph.

The idea of a reparameterized solution is further developed in a control setting by Bressan [2], Bressan and Rampazzo [3, 4], Motta and Rampazzo [14], Rampazzo and Sartori [16], and others. For the applications in mind, it is natural in these papers to use vector-valued measures since they appear as the derivative of a vector-valued control. We adopt that viewpoint as well. The major technical difference between a vector-valued versus a scalar-valued measure is the prominent feature of a graph completion in the former. In the [21] formulation, the measure is scalar-valued and so the graph completion is a straight-line scalar completion of the distribution of μ, and the behavior of the trajectory during a jump is driven by a differential inclusion involving only G during a time interval with length equal to the magnitude of the measure's atom. In [2, 4, 25] and in the present paper, μ is vector-valued and the choice of a graph completion is incorporated into the definition of solution. This means the behavior during a jump depends on the particular graph completion. The relationship between the two solution concepts is related but can be different if the underlying vector fields appearing as the columns of $G(\cdot)$ do not commute; see [3, 4]. These papers write $G(x)d\mu$ as $\sum_{i=1}^{m} g_i(x,u)\dot{u}^i$; again there are some subtle modeling issues as to whether the formalisms are equivalent to (1.1), which will be the topic of future work. If μ is vector valued, then the scalar-valued measure $\frac{d\mu}{d|\mu|}d|\mu|$ as developed in [21] can capture the same dynamics only when a straight-line completion is used. One can also incorporate the cone constraint into $G(\cdot)$ and obtain a solution set consisting of all solutions that exist for *some* graph completion; this is discussed further in the conclusion of the paper. Thus the solution set defined in [21] does not distinguish between solutions that arise from different graph completions, and thus are essentially only widely applicable in systems where the vector fields $\{g_i(\cdot)\}$ commute.

There is a vast and rapidly growing literature mostly in the engineering community of so-called hybrid systems. A consensus is perhaps forming as to what constitutes a hybrid system, but there is no universally accepted formulation. The key feature of all hybrid systems is that discrete and continuous variables interact over time; we refer the reader to the literature [12, 19, 9] and their many references. Although (1.1) has discrete features that may appear through the presence of atoms in the measure μ, the relationship between (1.1) and other formulations of hybrid systems found in

the engineering literature partially overlaps but is not exact.

We also mention related and independent work by Murray [15] who studied a proper extension of integral functionals from absolutely continuous arcs to ones of bounded variation. This approach can handle the above dynamics by encoding them through the technique of infinite penalization. The extension required the same type of graph completion of a vector-valued measure and the arcs are of bounded variation of the type we employ here.

We have proven in [25] that a related concept of solution, called a *direct* solution, can be formulated directly from the differential form (1.1) of the inclusion by matching the components of the decomposition of each measure into its absolutely continuous, continuous singular, and discrete parts (cf. [8, p. 102]). We show in [25] that it is equivalent to the other solution concepts. The advantage, in our view, of the direct solution concept is that it provides insight into formulating invariance concepts, developing a Hamilton–Jacobi theory, and proving stability results. These topics will be developed in future work.

The two major issues addressed in the present paper involve (1) time discretization of (1.1), and (2) absolutely continuous approximation to (1.1). We show in Theorem 3.1 that an analogue to the Euler one-step method can be developed to produce a sequence of sampled solutions that *graph-converge* to a solution of (1.1). The second part of this theorem shows that under additional Lipschitz assumptions, *every* solution of (1.1) is the limit of such a sequence. Time discretizations play a major role in classical optimal control theory in several ways. For example, sampling techniques are employed in proving invariance results (see [6]), deriving refined necessary conditions (see [13]), etc. For the same reasons that time-discretion has been a fruitful development in classical control systems, it seems desirable that such techniques are available for impulsive systems.

The second issue is the approximation of the measure μ by measures that are absolutely continuous with respect to Lebesgue measure. This is also natural and desirable, for it validates the interpretation that impulsive systems are the "completions" of classical ones. Theorem 4.1 has two parts analogous to the two parts of Theorem 3.1. The first part shows that if a sequence of absolutely continuous measures *graph-converge* to a given graph completion of μ, then any sequence $\{x(\cdot)\}$ of associated solutions contains a graph-convergent subsequence. The second part of the theorem shows that under additional Lipschitz assumptions, every solution of (1.1) is the limit of such a sequence. Further motivation and comparison of this result with the closure theorem in [20] is given in the conclusion.

Impulsive systems are introduced precisely in section 2, and the main result of [25] is reviewed to provide motivational background. Section 3 develops our sampling method, and section 4 relates solutions of (1.1) with solutions of approximate systems that have absolutely continuous measures. In section 5, we conclude the paper by comparing our limiting theorems with the main robustness result in [20]. The distinction will be more clear after we have precisely developed our results.

Throughout the paper, the following data with accompanying assumptions are given:

(H1) A closed convex cone $K \subseteq \mathbb{R}^m$.

(H2) A multifunction $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ with closed graph and convex values, and satisfying

$$f \in F(x) \implies |f| \leq c(1 + |x|) \quad \forall x \in \mathbb{R}^n$$

(where $c > 0$ is a given constant).

(H3) A multifunction $G : \mathbb{R}^n \rightrightarrows \mathcal{M}_{n\times m}$ (where $\mathcal{M}_{n\times m}$ denotes the $n \times m$ dimensional matrices with real entries) with closed graph and closed convex values, and satisfying

$$g \in G(x) \implies \|g\| \leq c(1 + |x|) \quad \forall x \in \mathbb{R}^n.$$

The set of vector-valued Borel measures defined on the interval $[0, T] \subset \mathbb{R}$ with values in K is denoted by $\mathcal{B}_K([0, T])$.

2. Impulsive systems and their trajectories. Suppose $\mu \in \mathcal{B}_K([0, T])$ is given. The impulsive system considered in this paper is described by the differential inclusion (1.1). Basic theory of differential inclusions without impulses is covered in [1, 22, 5, 6]. The trajectory $x(\cdot)$ is a function of bounded variation; however, as described in the introduction, further information is required to frame an unambiguous solution concept. Recall that the (right continuous) distribution function $u(\cdot) : [0, T] \to \mathbb{R}^m$ of μ is given by $u(t) = \mu([0, t])$. Following [4, 2], a graph completion of $u(\cdot)$ consists of a Lipschitz continuous map $(\phi_0, \phi) : [0, S] \to [0, T] \times \mathbb{R}^m$ so that $\phi_0(\cdot)$ is nondecreasing and mapping onto $[0, T]$, and for every $t \in [0, T]$, there exists an $s \in [0, S]$ with $\big(\phi_0(s), \phi(s)\big) = (t, u(t))$. The role of the graph completion is to pin down the behavior of the trajectory $x(\cdot)$ during the "jumps" of $u(\cdot)$ so that multiplication by $G(x)$ during this fast time movement is unambiguous. The function ϕ_0 is a reparameterized time variable, and in this paper we avoid additional technical issues by always choosing it as the "filled-in" inverse of

$$\eta(t) := t + |\mu|([0, t]); \tag{2.1}$$

that is,

$$\phi_0(s) = t \quad \Leftrightarrow \quad \eta(t-) \leq s \leq \eta(t+), \tag{2.2}$$

where $\eta(t-)$ and $\eta(t+)$, respectively, denote the left-hand limit $\lim_{t\nearrow t_0} \eta(t)$ and right-hand limit $\lim_{t\searrow t_0} \eta(t)$. These left- and right-hand limits are equal if and only if t is not an atom of μ. If 0 is an atom of μ, then $\eta(0-) = 0$ by convention. We let $\mathcal{I}$ be the at most countable index set of atoms $\mathcal{T} := \{t_i\}_{i\in\mathcal{I}}$, and $I_i := [s_i^-, s_i^+] := \phi_0^{-1}(t_i)$ the "fast" time consumed during the jump. Since ϕ_0 will always be specified as in (2.1) and (2.2), only the spatial component $\phi(\cdot)$ will be referred to as the graph completion, and it is uniquely determined at each $s \notin \cup_{i\in\mathcal{I}} I_i$, since then $t = \phi_0(s)$ is uniquely determined and $\phi(s) = u(t)$. We also require *cone adherence* of $\phi(\cdot)$, which means that

$$\dot{\phi}(s) \in K \tag{2.3}$$

hold for almost all $s \in [0, S]$.

Suppose we are now given $\mu \in \mathcal{B}_K([0, T])$. Consider a three-tuple

$$X_\mu := \big(x(\cdot), \phi(\cdot), \{y_i(\cdot)\}_{i\in\mathcal{I}}\big) \tag{2.4}$$

with the following constituents: $x(\cdot) : [0, T] \to \mathbb{R}^n$ is of bounded variation with its points of discontinuity contained in the set $\mathcal{T}$ of μ's atoms, $\phi(\cdot) : [0, S] \to \mathbb{R}^m$ is a graph completion of μ's distribution function $u(\cdot)$, and $\{y_i(\cdot)\}_{i\in\mathcal{I}}$ is a collection of Lipschitz functions, each defined on the nondegenerate interval $I_i := [s_i^-, s_i^+] := \phi_0^{-1}(t_i)$ and satisfying $y_i(s_i^\pm) = x(t_i\pm)$.

The following is a slight modification of a definition given in [4, 2].

DEFINITION 2.1. *Consider a three-tuple X_μ as in* (2.4)*, and let*

$$y(s) = \begin{cases} x(t) & \text{if } s \notin \cup_{i\in\mathcal{I}} I_i, \quad t = \phi_0(s), \\ y_i(s) & \text{if } s \in I_i. \end{cases} \tag{2.5}$$

Then X_μ is a reparameterized solution *of* (1.1) *provided $y(\cdot)$ is Lipschitz on $[0, S]$ and satisfies*

$$\begin{cases} \dot{y}(s) \in F\big(y(s)\big)\dot{\phi}_0(s) + G\big(y(s)\big)\dot{\phi}(s) & \text{a.e. } s \in [0, S], \\ y(0) = x_0. \end{cases} \tag{2.6}$$

One may observe that $y(\cdot)$ defined by (2.5) is a graph completion of the vector-valued function $x(\cdot)$.

We next introduce a solution concept with the same data structure as in (2.4), but which requires properties stated directly in the original time frame. Recall that an arc $x(\cdot)$ of bounded variation induces a measure dx that can be decomposed into absolutely continuous, continuous singular, and discrete (that is, purely atomic) parts, and so can be written as

$$dx = \dot{x}(t)\,dt + dx_\sigma + dx_D,$$

where dx_σ is a singular continuous measure and $dx_D := \sum_{i\in\mathcal{I}} \delta^x_{t_i}$ is the discrete part with $\delta^x_{t_i}$ denoting the point mass jump of the vector $x(t_i+) - x(t_i-)$. If 0 is an atom, then the initial point of the jump is denoted by $x(0-)$. Likewise, the measure $\mu \in \mathcal{B}_K([0,T])$ decomposes into $\mu = \dot{u}(t)\,dt + \mu_\sigma + \mu_D$, where $\mu_D = \sum_{i\in\mathcal{I}} \delta^u_{t_i}$.

DEFINITION 2.2. *The three-tuple X_μ in* (2.4) *is a* solution *of* (1.1) *provided*

(i) *for almost all $t \in [0,T]$,*

$$\begin{cases} \dot{x}(t) \in F\big(x(t)\big) + G\big(x(t)\big)\dot{u}(t), \\ x(0-) = x_0; \end{cases}$$

(ii) *there exists a bounded μ_σ-measurable selection $\gamma(t) \in G\big(x(t)\big)$ with*

$$dx_\sigma = \gamma(t)\,\mu_\sigma \quad \textit{(as measures on } [0,T]\textit{)};$$

(iii) *the set of atoms of dx is contained in $\mathcal{T} = \{t_i\}_{i\in\mathcal{I}}$, and for each $i \in \mathcal{I}$, $y_i(s_i^-) = x(t_i-)$, $y_i(s_i^+) = x(t_i+)$, and*

$$\dot{y}_i(s) \in G\big(y_i(s)\big)\dot{\phi}(s) \quad \text{a.e. } s \in I_i.$$

The fundamental role played by the graph completion in this definition surfaces in the differential inclusions stated in (iii), and in effect circumscribes the fast velocities that are available during that jump in t time. A simple concrete example is given in [2] where different graph completions give different reachable sets.

The following theorem is proven in [25]. Although this result is not required in the proofs that follow, we state it for completeness.

THEOREM 2.1. *Suppose $\mu \in \mathcal{B}_K([0,T])$ and X_μ is as in* (2.4)*. Then X_μ is a reparameterized solution of* (1.1) *if and only if X_μ is a solution of* (1.1)*.*

3. A sampling method. An Euler-type discretization procedure is introduced in this section that produces approximate discrete solutions (called *sampled trajectories*) when the measure μ and a graph completion are given. The limit of a subsequence of approximations will be shown to graph-converge in the Hausdorff metric to some solution X_μ of (1.1). In future work, we shall describe a sampling method that produces the measure and graph completion as well.

With X_μ as in (2.4), its graph is defined as the set

$$\operatorname{gr} X_\mu := \{(t, x(t)) : t \in [0,T]\} \cup \{(t_i, y_i(s)) : s \in I_i,\ i \in \mathcal{I}\}.$$

The idea is to discretize the ordinary trajectory $y(\cdot)$ that is defined in (2.5), where the "compactness of trajectories" is known to hold, and to project it down into t-space.

Let N be a positive integer, and let $h := \frac{S}{N}$ be the step-size parameter. Let $s_0 = 0 = t_0$, and for each $j = 1, \dots, N$, let $s_j = jh$, $t_j = \phi_0(s_j)$, and $\lambda_j = t_j - t_{j-1}$. Sampled points $\{x_j\}_{j=1}^N$ are defined and "velocity" data are selected as follows (the parameter N is suppressed in this notation):

$$\begin{array}{lll}
x_0 = x_0 & f_0 \in F(x_0) & g_0 \in G(x_0) \\
x_1 = x_0 + \lambda_1 f_0 + g_0\big(\phi(s_1) - \phi(s_0)\big) & & \\
 & f_1 \in F(x_1) & g_1 \in G(x_1) \\
\vdots & \vdots & \vdots \\
x_{j+1} = x_j + \lambda_j f_j + g_j\big(\phi(s_j) - \phi(s_{j-1})\big) & & \\
 & f_{j+1} \in F(x_{j+1}) & g_{j+1} \in G(x_{j+1}) \\
\vdots & \vdots & \vdots \\
x_N = x_{N-1} + \lambda_N f_{N-1} + g_{N-1}\big(\phi(s_N) - \phi(s_{N-1})\big) & &
\end{array}$$

We denote by Ω^N the graph of a sampled trajectory:

$$\Omega^N := \big\{(t_j, x_j) : j = 0, \dots, N\big\}. \tag{3.1}$$

Recall that the Hausdorff distance $\operatorname{dist}_{\mathcal{H}}(A_1, A_2)$ between two compact subsets A_1, A_2 of $\mathbb{R}^n$ is defined by

$$\operatorname{dist}_{\mathcal{H}}(A_1,\, A_2) = \min\big\{\delta \geq 0 : A_1 \subseteq A_2 + \delta\overline{\mathbb{B}} \text{ and } A_2 \subseteq A_1 + \delta\overline{\mathbb{B}}\big\},$$

and that any multifunction $M : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ with compact values is locally Lipschitz if for every bounded set $C \subset \mathbb{R}^n$ there exists a constant c so that

$$\operatorname{dist}_{\mathcal{H}}\big(M(x),\, M(y)\big) \leq c\|x - y\| \quad \forall\, x, y \in C.$$

The main result of this section follows.

THEOREM 3.1. *Suppose $\mu \in \mathcal{B}_K([0,T])$ and a graph completion $\phi(\cdot)$ are given.*

(a) *For every sequence $\{\Omega^N\}_N$ of graphs of sampled trajectories, there is a solution X_μ of (1.1) and a subsequence $\{\Omega^{N_k}\}_k$ of $\{\Omega^N\}_N$ such that*

$$\operatorname{dist}_{\mathcal{H}}\big(\Omega^{N_k},\, \operatorname{gr} X_\mu\big) \to 0 \quad \textit{as} \quad k \to \infty.$$

(b) *Assume F and G are locally Lipschitz. For every solution X_μ of* (1.1), *there exists a sequence $\{\Omega^N\}_N$ of graphs of sampled trajectories so that*

$$\operatorname{dist}_{\mathcal{H}}\big(\Omega^N, \operatorname{gr} X_\mu\big) \to 0 \quad \textit{as} \quad N \to \infty.$$

Proof. Suppose the sequences $\{f_j\}$, $\{g_j\}$, $\{x_j\}$ are constructed by the sampling method described above. We first show there exists a constant c_1 independent of N so that

$$\max_j \big\{\|x_j\|, \|f_j\|, \|g_j\|\big\} \le c_1 \tag{3.2}$$

for all j and $N \in \mathbb{N}$. Indeed, with r as in (2.3) (which is the Lipschitz constant of $\phi(\cdot)$) and c as in (H2) and (H3), we have

$$\begin{aligned} |x_{j+1}| &\le |x_j| + h|f_j| + \|g_j\| rh \\ &\le |x_j| + \big[c(1+|x_j|) + c(1+|x_j|r)\big]h \\ &= h\alpha + \big[1 + h\alpha\big]|x_j|, \end{aligned}$$

where $\alpha := c(1+r)$. It follows from the discrete Gronwall inequality that

$$|x_j| \le e^{\alpha S}\big(1 + |x_0|\big) - 1,$$

and that then (3.2) holds by (H2) and (H3) with $c_1 := c[e^{\alpha S}(1+|x_0|)]$.

Define the multifunction $M : [0,S] \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ by

$$M(s,y) = F(y)\dot{\phi}_0(s) + G(y)\dot{\phi}(s), \tag{3.3}$$

which is $\mathcal{L} \times \mathcal{B}$ measurable, has nonempty compact convex values, and has linear growth. Moreover, $M(s,\cdot)$ has closed graph for almost all $s \in [0,S]$. For each $N \in \mathbb{N}$, let $\tilde{\Omega}^N$ be the sampled trajectory in s-time:

$$\tilde{\Omega}^N := \big\{(s_j, x_j) : j = 0, \dots, N\big\}. \tag{3.4}$$

Also consider its related polygonal arc $y^N(\cdot)$ defined on $[0,S]$ given by

$$y^N(s) := x_j + \frac{s - s_j}{h}(x_{j+1} - x_j) \quad \text{for } s \in [s_j, s_{j+1}]. \tag{3.5}$$

Note for later use that

$$\operatorname{dist}_{\mathcal{H}}\big(\tilde{\Omega}^N, \operatorname{gr} y^N(\cdot)\big) \le \max\big\{h, c_1(1+r)h\big\}. \tag{3.6}$$

We claim there exist the sequences of

- positive numbers δ_N and r_N so that $\delta_N \to 0$ and $r_N \to 0$, and
- measurable sets $A_N \subseteq [0,S]$ so that $m(A_N) \to 0$,

where the limits are as $N \to \infty$, and that they satisfy

$$\inf\big\{\|\dot{y}^N(s) - v\| : v \in M\big(s, y^N(s) + \delta_N \overline{\mathbb{B}}\big)\big\} \;\le\; r_N \quad \text{a.e. } s \in A_N. \tag{3.7}$$

To see this, let $\delta_N = \frac{S}{N} c_1(1+r)$, where c_1 is as in (3.2). Note for each $j = 1, 2, \dots, N-1$ and $s \in [s_{j-1}, s_j]$ that

$$\begin{aligned} \big|y^N(s) - x_j\big| &\le \big|x_{j+1} - x_j\big| \\ &= \big|\lambda_{j+1} f_j + g_j\big(\phi(s_{j+1}) - \phi(s_j)\big)\big| \\ &\le h\big[|f_j| + \|g_j\| r\big] \\ &\le \delta_N. \end{aligned}$$

Next, for $s \in [0, S-h]$, define

$$\Phi_0^N(s) := \frac{1}{h}\int_s^{s+h} \dot\phi_0(s')ds' \quad \text{and} \quad \Phi^N(s) := \frac{1}{h}\int_s^{s+h} \dot\phi(s')ds'$$

and recall that $\Phi_0^N(s) \to \dot\phi_0(s)$ and $\Phi_0^N(s) \to \dot\phi(s)$ for almost all $s \in [0,S]$ as $N \to \infty$. By Egoroff's theorem, there exist measurable sets $A_N \subseteq [0,S]$ with $m(A_N) \to 0$ (and for notational simplicity, we may assume $[S-h, S] \subseteq A_N$) and satisfying

$$r_N := c_1 \max_{s\in[0,S]\setminus A_N} \left\{ \left|\Phi_0^N(s) - \dot\phi_0(s)\right|, \left|\Phi^N(s) - \dot\phi(s)\right| \right\} \to 0$$

as $N \to \infty$. Now let

$$v^N(s) := f_j\dot\phi_0(s) + g_j\dot\phi(s) \quad \text{for } s \in [s_j, s_{j+1}],$$

and note that $v^N(s) \in M(s, x_j)$ for almost all $s \in [s_j, s_{j+1}]$. Recall that $\dot y^N(s) = \Phi_0^N(s_j)f_j + g_j\Phi^N(s_j)$, and thus

$$\max_{s\in[0,S]\setminus A_N} \left|\dot y^N(s) - v^N(s)\right| \le \max_{\substack{j=1,\dots,N \\ s\in[s_j,s_{j+1}]\setminus A_N}} \left| \left(\Phi_0^N(s) - \dot\phi_0(s)\right)f_j + g_j\left(\Phi^N(s) - \dot\phi(s)\right)\right| \le r_N.$$

We have shown that (3.7) holds.

From the compactness of trajectories theorem [6, Theorem 4.1.11], there exists a trajectory $y(\cdot)$ of M and a subsequence (labeled $\{y^{N_k}(\cdot)\}_k$) of $\{y^N(\cdot)\}_N$ so that $y^{N_k}(\cdot) \to y(\cdot)$ uniformly on $[0,S]$. One sees easily that this means

$$\operatorname{dist}_{\mathcal H}\left(\operatorname{gr} y^{N_k}(\cdot), \operatorname{gr} y(\cdot)\right) \to 0 \tag{3.8}$$

as $k \to \infty$. We define the components of a solution X_μ to (1.1) as follows. Let $x(\cdot) : [0,T] \to \mathbb{R}^n$ be given by $x(t) = y\big(\eta(t)\big)$, and define the functions $y_i(\cdot)$ (for each $i \in \mathcal{I}$) as the restriction of $y(\cdot)$ to I_i.

Now recall Ω^N as in (3.1) and $\tilde\Omega^N$ as in (3.4), and observe the second coordinates are the same for each $j = 1, \dots, N$. Similarly, the second coordinates of $\operatorname{gr} X_\mu$ and $\operatorname{gr} y(\cdot) := \left\{\big(s, y(s)\big) : s \in [0,S]\right\}$ are the same for each $t \notin \mathcal{T}$, $t = \phi_0(s)$; and when $t \in \mathcal{T}$, the set of projections onto the second coordinate are the same. Thus the difference between the Hausdorff distances of Ω^N and $\operatorname{gr} X_\mu$ on the one hand and $\tilde\Omega^N$ and $\operatorname{gr} y(\cdot)$ on the other is affected by only the first coordinate. It follows that

$$\operatorname{dist}_{\mathcal H}\big(\Omega^N, \operatorname{gr} X_\mu\big) \le \operatorname{dist}_{\mathcal H}\big(\tilde\Omega^N, \operatorname{gr} y(\cdot)\big), \tag{3.9}$$

where the right-hand side is at most h larger than the left-hand side. By the triangle inequality, one has

$$\operatorname{dist}_{\mathcal H}\big(\tilde\Omega^N, \operatorname{gr} y(\cdot)\big) \le \operatorname{dist}_{\mathcal H}\big(\tilde\Omega^N, \operatorname{gr} y^N(\cdot)\big) + \operatorname{dist}_{\mathcal H}\big(\operatorname{gr} y^N(\cdot), \operatorname{gr} y(\cdot)\big). \tag{3.10}$$

Finally, passing to the subsequence $\{N_k\}$ and starting from (3.9), it follows from (3.10), (3.6), and (3.8) that

$$\operatorname{dist}_{\mathcal H}\big(\Omega^{N_k}, \operatorname{gr} X_\mu\big) \to 0,$$

which finishes the proof of part (a).

To prove part (b), assume now that F and G are locally Lipschitz, and X_μ is as in (2.4) and is a solution of (1.1). Let $y(\cdot)$ be defined as in (2.5), and so there exist measurable selections $f(\cdot)$ and $g(\cdot)$ of $F\big(y(\cdot)\big)$ and $G\big(y(\cdot)\big)$, respectively, so that

$$\dot{y}(s) = f(s)\dot{\phi}_0(s) + g(s)\dot{\phi}(s) \quad \text{a.e. } s \in [0, S].$$

In a manner similar to proving the discrete bound (3.2), one can show there exists a constant c_2 so that $|y(s)| \le c_2$. Observe that for $0 \le \bar{s} < \hat{s} \le S$, one has

$$\big|y(\hat{s}) - y(\bar{s})\big| \le \int_{\bar{s}}^{\hat{s}} |\dot{y}(s)|\, ds \le (1 + c_2)(1 + r)(\hat{s} - \bar{s}) =: c_3(\hat{s} - \bar{s}). \tag{3.11}$$

Let $L > 0$ be the Lipschitz constant for F and G on $c_2\overline{\mathbb{B}}$, and denote by $\mathrm{proj}_{F(y)}(f)$ the projection of f into $F(y)$ (which is unique since $F(y)$ is convex). If $|y_j| \le c_2$ $(j = 1, 2)$ and $f \in F(y_1)$, then $|f - \mathrm{proj}_{F(y_2)}(f)| \le L|y_1 - y_2|$. Similar considerations hold with F replaced by G.

We use the notation of the sampling method and will show there exists a sequence $\{\Omega^N\}$ that graph-converges to $\mathrm{gr}\, X_\mu$.

Let $f_0 = \frac{1}{h}\int_0^{s_1} \mathrm{proj}_{F(x_0)}\big(f(s)\big)\, ds$, let $g_0 = \frac{1}{h}\int_0^{s_1} \mathrm{proj}_{G(x_0)}\big(g(s)\big)\, ds$, and let x_1 be defined as in the sampling method. We observe

$$\begin{aligned} x_1 - y(s_1) \;=\; & \frac{\phi_0(s_1) - \phi_0(0)}{h} \int_0^{s_1} \big[\mathrm{proj}_{F(x_0)}\big(f(s)\big) - f(s)\big]\, ds \\ & + \int_0^{s_1} \big[\mathrm{proj}_{G(x_0)}\big(g(s)\big) - g(s)\big] \left(\frac{\phi(s_1) - \phi(0)}{h}\right) ds \\ & + \int_0^{s_1} \left(\frac{\phi_0(s_1) - \phi_0(0)}{h} - \dot{\phi}_0(s)\right) f(s)\, ds \\ & + \int_0^{s_1} g(s) \left(\frac{\phi(s_1) - \phi(0)}{h} - \dot{\phi}(s)\right) ds \\ =: \; & I + II + III + IV. \end{aligned}$$

Recall that $\phi_0(\cdot)$ is Lipschitz of rank 1, and so by the Lipschitz property of F, we have

$$|I| \le L \int_0^{s_1} \big|y(s) - x_0\big|\, ds \le Lc_3 \int_0^{s_1} s\, ds = \frac{Lc_3}{2} h^2,$$

where the second inequality follows from (3.11). In the same way, one can show $|II| \le \frac{Lc_3 r}{2} h^2$ since $\phi(\cdot)$ is Lipschitz of rank r. To estimate III and IV, we reuse earlier notation to redefine $\Phi^N(\cdot)$ on $[0, S]$ by setting

$$\Phi^N(s) := \max\left\{ \left| \frac{\phi_0(s_{j+1}) - \phi_0(s_j)}{h} - \dot{\phi}_0(s) \right|, \left| \frac{\phi(s_{j+1}) - \phi(s_j)}{h} - \dot{\phi}(s) \right| \right\}$$

whenever $s \in [s_j, s_{j+1}]$. Then it follows that both $|III|$ and $|IV|$ are bounded above by $c(1 + c_2)\int_0^{s_1} \Phi^N(s)\, ds$. Putting all this together, we have

$$|x_1 - y(s_1)| \le \frac{Lc_3(1 + r)}{2} h^2 + 2c(1 + c_2) \int_0^{s_1} \Phi^N(s)\, ds.$$

Inductively, one proceeds by setting $f_j = \frac{1}{h}\int_{s_j}^{s_{j+1}} f(s)\,ds$ and $g_j = \frac{1}{h}\int_{s_j}^{s_{j+1}} g(s)\,ds$, and letting x_{j+1} be as in the sampling method construction. The same argument used above can operate at each iteration, and inductively one has the following estimate:

$$|x_j - y(s_j)| \le \frac{Lc_3(1+r)}{2} jh^2 + 2c(1+c_2)\int_0^{s_j} \Phi^N(s)\,ds.$$

Since $\Phi^N(s)$ is bounded above and converges to 0 almost everywhere, it follows that $\tilde{\Omega}^N := \{(s_j, x_j) : j = 1, \dots, N\}$ satisfies $\operatorname{dist}_{\mathcal{H}}\big(\tilde{\Omega}^N, \operatorname{gr} y(\cdot)\big) \to 0$ as $N \to \infty$. The bound in (3.9) is still valid here, and the conclusion of (b) readily follows. □

4. Approximate controls. The original and perhaps most natural approach to defining solutions to the impulsive inclusion (1.1) is to consider limits of a sequence of solutions $x^N(\cdot)$ of an *approximate* control problem of the form

$$\dot{x}^N(t) \in F\big(x(t)\big)\dot{\phi}_0(t) + G\big(x(t)\big)\dot{u}^N(t), \tag{4.1}$$

where $d\mu^N = \dot{u}^N(\cdot)dt$ are absolutely continuous measures that approximate μ in some sense. See, for example, the discussion in [2]. We introduce in this section a concept of "graph convergence" of measures that is appropriate to carry out such an analysis. Graph convergence as defined below is perhaps considerably stronger than would be desirable, but we mention that even when the solutions of (4.1) are unique (which happens, for example, in the singleton case $F(x) = \{f(x)\}$ and $G(x) = \{g(x)\}$ with $f(\cdot)$ and $g(\cdot)$ smooth functions), the limit arc may not be unique if the measures converge in some weaker sense.

Suppose we are given the following: a measure $\mu \in \mathcal{B}_K([0,T])$, an associated graph completion $\phi(\cdot) : [0,S] \to \mathbb{R}^n$ that is Lipschitz of rank r, and a sequence $\{\mu^N\}$ of absolutely continuous measures belonging to $\mathcal{B}_K([0,T])$ whose associated distribution functions $u^N(t) := \mu^N\big([0,t]\big)$ are Lipschitz.

DEFINITION 4.1. *The sequence $\{\mu^N\}_N$ of absolutely continuous measures* graph-converges *to (μ, ϕ) provided*

(i) *there exist numbers $S^N > 0$ such that $S^N \to S$;*

(ii) *for each N, there exists a strictly increasing function $\phi_0^N(\cdot) : [0, S^N] \to [0,T]$ that is onto and Lipschitz of rank at most one, and such that*

$$\int_0^{\min\{S,S^N\}} \big|\dot{\phi}_0^N(s) - \dot{\phi}_0(s)\big|\,ds \to 0 \quad as \quad N \to \infty;$$

(iii) *for each N, the sequence of functions defined by $\phi^N(s) := \big(u^N \circ \phi_0^N\big)(s)$ is Lipschitz with $\limsup_{N\to\infty} \|\dot{\phi}^N(\cdot)\|_\infty \le r$ and satisfies*

$$\int_0^{\min\{S,S^N\}} \big|\dot{\phi}^N(s) - \dot{\phi}(s)\big|\,ds \to 0 \quad as \quad N \to \infty.$$

The main result in this section follows.

THEOREM 4.1. *Suppose the measure $\mu \in \mathcal{B}_K([0,T])$ and an associated graph completion $\phi(\cdot) : [0,S] \to \mathbb{R}^n$ are given.*

(a) *Suppose $\{\mu^N\}$ is a sequence of absolutely continuous measures that graph-converges to $\big(\mu, \phi(\cdot)\big)$, and $\{x^N(\cdot)\}$ is a sequence of absolutely continuous arcs satisfying*

$$\dot{x}^N(t) \in F\big(x^N(t)\big) + G\big(x^N(t)\big)\dot{u}^N(t). \tag{4.2}$$

Then there exists a solution X_μ *of* (1.1) *and a subsequence* $\{x^{N_k}(\cdot)\}$ *of* $\{x^N(\cdot)\}$ *such that*

$$\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} x^{N_k}(\cdot),\, \operatorname{gr} X_\mu\big) \to 0 \quad \textit{as} \quad k \to \infty.$$

(b) *Conversely, suppose* F *and* G *are locally Lipschitz multifunctions and* $X_\mu := \big(x(\cdot), \phi(\cdot), \{y_i(\cdot)\}_{i\in\mathcal{I}}\big)$ *is a solution of* (1.1). *Then there is a sequence* $\{\mu^N\}$ *of absolutely continuous measures that graph converge to* $\big(\mu, \phi(\cdot)\big)$, *and a sequence* $x^N(\cdot)$ *of solutions to* (4.2) *so that*

$$\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} x^{N}(\cdot),\, \operatorname{gr} X_\mu\big) \to 0 \quad \textit{as} \quad N \to \infty.$$

Proof. Suppose we are given the measures $d\mu^N = \dot{u}^N(t)dt$, the functions $\phi_0^N(\cdot)$ and $\phi^N(\cdot)$ satisfying Definition 4.1, and solutions $x^N(\cdot)$ of (4.2). Set $\bar{S}^N := \min\{S, S^N\}$. Let $y^N(s) = (x^N \circ \phi_0^N)(s)$, which for almost all $s \in [0, \bar{S}^N]$ satisfies

$$\begin{aligned}
\dot{y}^N(s) &= \dot{x}^N\big(\phi_0^N(s)\big)\dot{\phi}_0^N(s) \\
&\in F\big(y^N(s)\big)\dot{\phi}_0^N(s) + G\big(y^N(s)\big)\dot{u}^N\big(\phi_0^N(s)\big)\dot{\phi}_0^N(s) \\
&= F\big(y^N(s)\big)\dot{\phi}_0^N(s) + G\big(y^N(s)\big)\dot{\phi}^N(s),
\end{aligned}$$

where the last equality follows since $\dot{\phi}^N(s) = \dot{u}^N\big(\phi_0^N(s)\big)\dot{\phi}_0^N(s)$ almost everywhere. It follows that there exist measurable selections $f^N(s) \in F\big(y^N(s)\big)$ and $g^N(s) \in G\big(y^N(s)\big)$ so that

$$\dot{y}^N(s) = f^N(s)\dot{\phi}_0^N(s) + g^N(s)\dot{\phi}^N(s).$$

Recall that Definition 4.1 imposes a priori bounds on the Lipschitz rank of $\phi_0^N(\cdot)$ and $\phi^N(\cdot)$, and that $F(\cdot)$ and $G(\cdot)$ satisfy linear growth assumptions. A standard argument involving Gronwall's inequality implies there exists a constant c_4 independent of N that is an upper bound of both $\|f^N(\cdot)\|_\infty$ and $\|g^N(\cdot)\|_\infty$.

Let $M : [0, S] \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be defined as in (3.3), define $\dot{z}^N(\cdot) : [0, \bar{S}^N] \to \mathbb{R}^n$ by

$$\dot{z}^N(s) := f^N(s)\dot{\phi}_0(s) + g^N(s)\dot{\phi}(s),$$

and define $z^N(\cdot) : [0, \bar{S}^N] \to \mathbb{R}^n$ by $z^N(s) := x_0 + \int_0^s \dot{z}^N(s')\, ds'$. It is clear from the definitions that

$$\dot{z}^N(s) \in M\big(s, y^N(s)\big) \quad \text{a.e. } s \in [0, \bar{S}^N]. \tag{4.3}$$

Furthermore, it is readily seen that

$$\sup_{s\in[0,\bar{S}^N]} \big|z^N(s) - y^N(s)\big| \le c_4\big\{\|\dot{\phi}_0^N - \dot{\phi}_0\|_1 + \|\dot{\phi}^N - \dot{\phi}\|_1\big\},$$

which implies via the assumption of the graph convergence of the measures that $y^N - z^N$ approaches zero uniformly. In view of (4.3) and the compactness of trajectories theorem [6, Theorem 4.1.11], there exists $y(\cdot) : [0, S] \to \mathbb{R}^n$ that is a trajectory of M and to which a subsequence of $\{z^N(\cdot)\}$, and hence also of $\{y^N(\cdot)\}$, converges uniformly. That is, there exists a subsequence N_k for which

$$\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} y^{N_k}(\cdot),\, \operatorname{gr} y(\cdot)\big) \to 0 \quad \text{as } k \to \infty. \tag{4.4}$$

We now define X_μ as before; see the paragraph containing (3.8) in the previous section. Similar reasoning as employed there shows also that $\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} x^{N_k}(\cdot), \operatorname{gr} X_\mu\big)$ is bounded above by

$$\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} y^{N_k}(\cdot),\, \operatorname{gr} y(\cdot)\big) + \sup_{s\in[0,\bar{S}^{N_k}]} |\phi_0^{N_k}(s) - \phi_0(s)|,$$

which goes to zero as $k \to \infty$ by (4.4) and the assumption contained in Definition 4.1(ii). This finishes the proof of part (a).

We turn to part (b). Suppose F and G are now locally Lipschitz and X_μ is a solution to (1.1). For $N = 1, \dots,$ we proceed to construct the absolutely continuous measures μ^N and solutions $x^N(\cdot)$ of (4.2) that will converge in graph to X_μ. Fix $N > 0$ and set $h = \frac{S}{N}$, and for $j = 1, \dots, N$, set $s_j = jh$ and $t_j = \phi_0(s_j)$. We will first introduce a new partition $\{\bar{t}_j\}$ of $[0, T]$ consisting of N distinct points that resembles the partition $\{t_j\}$ but has repeated nodes "pulled apart" and indexed accordingly. To this end, let $\mathcal{J}_0^N$ be those indices j for which $t_{j-1} < t_j < t_{j+1}$ (to treat the endpoints, by convention, we take $t_{-1} < t_0$ and $t_{N+1} > t_N$; thus $t_0 \in \mathcal{J}_0^N$ if $t_0 < t_1$ and $t_N \in \mathcal{J}_0^N$ if $t_{N-1} < t_N$). We set $\bar{t}_j = t_j$ whenever $j \in \mathcal{J}_0^N$. Let $\mathcal{J}^N$ be those indices j for which $t_{j-1} < t_j = t_{j+1}$ (by convention, then, $t_0 \in \mathcal{J}^N$ if $t_0 = t_1$ and t_N cannot belong to $\mathcal{J}^N$). For these latter j, let $k_j \geq 1$ be such that $t_j = t_{j+1} = \cdots = t_{j+k_j} < t_{j+k_j+1}$, and

$$\lambda_j := \frac{1}{2} \min\big\{h^2, t_j - t_{j-1}, t_{j+k_j+1} - t_j\big\}$$

(if $0 \in \mathcal{J}^N$, then $\lambda_0 := \min\{h^2, \frac{t_{j+k_j+1}-t_j}{2}\}$). If $j \notin \mathcal{J}_0^N$, then $j = \bar{j} + k$, where there exists precisely one pair $(\bar{j}, k)$ with $\bar{j} \in \mathcal{J}^N$ and $0 \leq k \leq k_{\bar{j}}$. In this case $\bar{t}_j$ is defined by

$$\bar{t}_j := \begin{cases} t_j + \left[\frac{2k}{k_j} - 1\right] \lambda_j & \text{if } j \neq 0, \\ \frac{k}{k_0}\lambda_0 & \text{if } j = 0. \end{cases}$$

Thus a new partition $\{\bar{t}_j\}$ of $[0, T]$ has been constructed consisting of N distinct points, and which satisfy

$$|\bar{t}_j - t_j| \leq h^2 \quad \forall j. \tag{4.5}$$

Next, we define $\phi_0^N(\cdot) : [0, S] \to [0, T]$ by

$$\phi_0^N(s) = \bar{t}_j + \frac{s - s_j}{h}(\bar{t}_{j+1} - \bar{t}_j) \quad \text{whenever } s \in [s_j, s_{j+1}],$$

which is onto and Lipschitz of rank at most 1. We claim that $\dot{\phi}_0^N(\cdot)$ converges to $\dot{\phi}_0(\cdot)$ in $L^1[0, S]$. Indeed, let $\tilde{\phi}_0^N(\cdot) : [0, S] \to [0, T]$ be given by

$$\tilde{\phi}_0^N(s) = t_j + \frac{s - s_j}{h}(t_{j+1} - t_j) \quad \text{whenever } s \in [s_j, s_{j+1}].$$

The difference between the linear interpolations $\phi_0^N(\cdot)$ and $\tilde{\phi}_0^N(\cdot)$ is that $\phi_0^N(\cdot)$ maps s_j to $\bar{t}_j$, whereas $\tilde{\phi}_0^N(\cdot)$ maps s_j to t_j. For $s \in [s_j, s_{j+1}]$, we have

$$\big|\dot{\phi}_0^N(s) - \dot{\tilde{\phi}}_0^N(s)\big| = \frac{1}{h}|\bar{t}_{j+1} - \bar{t}_j - t_{j+1} + t_j| \leq 2h, \tag{4.6}$$

where the inequality is justified by (4.5). The Lebesgue differentiation theorem says that $\dot{\bar{\phi}}_0^N(s) \to \dot{\phi}_0(s)$ as $N \to \infty$ for almost all $s \in [0, S]$, and since these functions are bounded above by 1, the dominated convergence theorem implies that $\dot{\bar{\phi}}_0^N(\cdot) \to \dot{\phi}_0(\cdot)$ in $L^1[0, S]$. It follows from this and (4.6) that $\dot{\phi}_0^N(\cdot) \to \dot{\phi}_0(\cdot)$ in $L^1[0, S]$, as claimed.

Now define $u^N(\cdot) : [0, T] \to \mathbb{R}^n$ as the piecewise linear interpolation satisfying $u^N(\bar{t}_j) = \phi(s_j)$; that is,

$$u^N(t) = \phi(s_j) + \frac{t - \bar{t}_j}{\bar{t}_{j+1} - \bar{t}_j}\big(\phi(s_{j+1}) - \phi(s_j)\big) \quad \text{whenever } t \in [\bar{t}_j, \bar{t}_{j+1}].$$

Let $\phi^N(\cdot) := (u^N \circ \phi_0^N)(\cdot)$, and note $\phi^N(s_j) = \phi(s_j)$ for all j, and for $s \in [s_j, s_{j+1}]$ that

$$\dot{\phi}^N(s) = \dot{u}^N\big(\phi_0^N(s)\big)\dot{\phi}_0^N(s) = \frac{\phi(s_{j+1}) - \phi(s_j)}{\bar{t}_{j+1} - \bar{t}_j}\,\frac{\bar{t}_{j+1} - \bar{t}_j}{h} = \frac{\phi(s_{j+1}) - \phi(s_j)}{h}.$$

Since $\phi(\cdot)$ is Lipschitz of rank r, it follows that each of $\phi^N(\cdot)$ are also of rank at most r. Completely analogous to the proof above showing $\dot{\phi}_0^N(\cdot) \to \dot{\phi}_0(\cdot)$ in $L^1[0, S]$ as $N \to \infty$, one has that $\dot{\phi}^N(\cdot) \to \dot{\phi}(\cdot)$ in $L^1[0, S]$ as $N \to \infty$. Therefore, with μ^N the absolutely continuous measure satisfying $d\mu^N = \dot{u}^N(t)dt$, we have shown that μ^N graph-converges to $(\mu, \phi(\cdot))$ as $N \to \infty$ (where $S^N = S$ for all N in Definition 4.1).

We now turn to approximating a given solution X_μ by a solution of (4.2). By Theorem 3.1(b), there exists a sequence of sampled trajectories whose graphs converge to $\operatorname{gr} X_\mu$. Denote these graphs by

$$\Omega^N := \{(t_j, x_j) \mid j = 1, \dots, N\},$$

where $x_{j+1} = x_j + (t_{j+1} - t_j)f_j + (g_j)\big(\phi(s_{j+1}) - \phi(s_j)\big)$, $f_j \in F(x_j)$, and $g_j \in G(x_j)$, and they satisfy

$$\operatorname{dist}_{\mathcal{H}}\big(\Omega^N, \operatorname{gr} X_\mu\big) \to 0 \quad \text{as} \quad N \to \infty. \tag{4.7}$$

For simplicity of notation, the dependence of x_j, f_j, and g_j on N has been suppressed. A new sampled set of points $\{\bar{x}_j\}$ is defined by replacing the partition $\{t_j\}$ by $\{\bar{t}_j\}$ and "tracking" the given sampled data. This is done as follows. Let $\bar{f}_0 = f_0$ and $\bar{g}_0 = g_0$ and define

$$\bar{x}_1 = \bar{x}_0 + (\bar{t}_1 - \bar{t}_0)\bar{f}_0 + (\bar{g}_0)\big(\phi(s_1) - \phi(s_0)\big).$$

Having chosen the data at stage $j - i$, inductively let $\bar{f}_j \in F(\bar{x}_j)$ and $\bar{g}_j \in G(\bar{x}_j)$ be the projections of f_j and g_j onto $F(\bar{x}_j)$ and $G(\bar{x}_j)$, respectively. That is, $\bar{f}_j \in F(\bar{x}_j)$ and satisfies

$$|\bar{f}_j - f_j| = \inf_{f \in F(\bar{x}_j)} |f - f_j|,$$

and similarly for $\bar{g}_j$. Define the next node by

$$\bar{x}_{j+1} = \bar{x}_j + (\bar{t}_{j+1} - \bar{t}_j)\bar{f}_j + (\bar{g}_j)\big(\phi(s_{j+1}) - \phi(s_j)\big).$$

The linear growth assumptions on F and G guarantee that all of the sampled data remain in a bounded set, and let c_1 be as in (3.2) but such that it also bounds the newly sampled data. With L a Lipschitz constant for both F and G on $c_1\overline{\mathbb{B}}$, one has

$$|\bar{f}_j - f_j| \le L|\bar{x}_j - x_j| \quad \text{and} \quad \|\bar{g}_j - g_j\| \le L|\bar{x}_j - x_j|. \tag{4.8}$$

The estimate between the nodes x_j and $\bar{x}_j$ is calculated by

$$\begin{aligned}\left|\bar{x}_{j+1}-x_{j+1}\right| &\le |\bar{x}_j-x_j|+|t_{j+1}-t_j-\bar{t}_{j+1}+\bar{t}_j|\,|f_j|\\ &\quad+|\bar{t}_{j+1}-\bar{t}_j|\,|\bar{f}_j-f_j|+\|\bar{g}_j-g_j\|\,|\phi(s_{j+1})-\phi(s_j)|\\ &\le |\bar{x}_j-x_j|+2h^2c_1+hL|\bar{x}_j-x_j|+hLr|\bar{x}_j-x_j|\\ &= 2h^2c_1+(1+hL+hLr)|\bar{x}_j-x_j|,\end{aligned}$$

where the second inequality was deduced using (4.5), (4.8), and the fact that $\phi(\cdot)$ is Lipschitz of rank r. Gronwall's inequality implies

$$|\bar{x}_j-x_j|\le 2hc_1\frac{e^{LS(1+r)}-1}{L(1+r)}$$

for each $j=0,1,\dots,N$ and in particular implies that

$$\operatorname{dist}_{\mathcal{H}}(\Omega^N,\bar{\Omega}^N)\to 0 \quad \text{as } N\to\infty, \tag{4.9}$$

where $\bar{\Omega}^N$ is the newly sampled graph:

$$\bar{\Omega}^N:=\{(\bar{t}_j,\bar{x}_j)\mid j=1,\dots,N\}.$$

Next, let $\bar{x}^N(\cdot)$ be the piecewise linear arc interpolating the points in $\bar{\Omega}^N(\cdot)$, which specifically means

$$\bar{x}^N(t)=\bar{x}_j+(t-\bar{t}_j)\bar{f}_j+(t-\bar{t}_j)\bar{g}_j\frac{\phi(s_{j+1})-\phi(s_j)}{\bar{t}_{j+1}-\bar{t}_j} \quad \text{and}$$

$$\dot{\bar{x}}^N(t)=\bar{f}_j+\bar{g}_j\dot{u}^N(t)\in F(\bar{x}_j)+G(\bar{x}_j)\dot{u}^N(t) \quad \text{whenever } t\in(\bar{t}_j,\bar{t}_{j+1}). \tag{4.10}$$

Let $\Gamma^N(\cdot):[0,T]\times\mathbb{R}^n\rightrightarrows\mathbb{R}^n$ be given by $\Gamma^N(t,x):=F(x)+G(x)\dot{u}^N(t)$, which is the multifunction appearing in (4.2). It has convex compact values, is measurably Lipschitz (see [5]), and has linear growth in x. We will find a trajectory $x^N(\cdot)$ of Γ^N that is close to $\bar{x}^N(\cdot)$. Following the notation in [5], we have

$$\begin{aligned}\rho_\Gamma\big(\bar{x}^N(\cdot)\big) &:= \int_0^T \operatorname{dist}\Big(\dot{\bar{x}}^N(t),\Gamma^N\big(t,\bar{x}^N(t)\big)\Big)\,dt\\ &= \sum_{j=0}^{N-1}\int_{t_j}^{t_{j+1}} \operatorname{dist}\Big(\dot{\bar{x}}^N(t),\Gamma^N\big(t,\bar{x}^N(t)\big)\Big)\,dt\\ &\le \sum_{j=0}^{N-1}\int_{t_j}^{t_{j+1}} \operatorname{dist}_{\mathcal{H}}\Big(\Gamma^N\big(t,\bar{x}_j\big),\Gamma^N\big(t,\bar{x}^N(t)\big)\Big)\,dt\\ &\le L\sum_{j=0}^{N-1}\int_{t_j}^{t_{j+1}}\big(1+|\dot{u}^N(t)|\big)\big|\bar{x}^N(t)-\bar{x}_j\big|\,dt,\end{aligned} \tag{4.11}$$

where (4.10) was used in the first inequality, and the Lipschitz property of F and G in the second. For $t\in[\bar{t}_j,\bar{t}_{j+1}]$, one has

$$\begin{aligned}\big|\dot{\bar{x}}^N(t)-\bar{x}_j\big| &\le \frac{t-\bar{t}_j}{\bar{t}_{j+1}-\bar{t}_j}\big|\bar{x}_{j+1}-\bar{x}_j\big|\\ &\le \frac{t-\bar{t}_j}{\bar{t}_{j+1}-\bar{t}_j}\big[(\bar{t}_{j+1}-\bar{t}_j)|\bar{f}_j|+\|\bar{g}_j\|\,|\phi(s_{j+1})-\phi(s_j)|\big]\\ &\le c_1\left[1+\frac{rh}{\bar{t}_{j+1}-\bar{t}_j}\right](t-\bar{t}_j)\end{aligned}$$

and

$$|\dot{u}^N(t)| = \left| \frac{\phi(s_{j+1}) - \phi(s_j)}{\bar{t}_{j+1} - \bar{t}_j} \right| \leq \frac{rh}{\bar{t}_{j+1} - \bar{t}_j}.$$

We thus have

$$\begin{aligned}\int_{t_j}^{t_{j+1}} \big(1 + |\dot{u}^N(t)|\big) \big|\bar{x}^N(t) - \bar{x}_j\big|\, dt &\leq \left[1 + \frac{rh}{\bar{t}_{j+1} - \bar{t}_j}\right] c_1 \left[1 + \frac{rh}{\bar{t}_{j+1} - \bar{t}_j}\right] \int_{t_j}^{t_{j+1}} (t - \bar{t}_j)\, dt \\ &= c_1 \left[1 + \frac{rh}{\bar{t}_{j+1} - \bar{t}_j}\right]^2 \frac{(\bar{t}_{j+1} - \bar{t}_j)^2}{2} \\ &\leq c_6 h^2\end{aligned}$$

for some constant c_6. Combined with (4.11), this estimate yields that

$$\rho_\Gamma\big(\bar{x}^N(\cdot)\big) \leq LSc_6 h,$$

and so by Filippov's theorem (see [5, Theorem 3.1.6, p. 115]), for each N there exists a trajectory $x^N(\cdot)$ of Γ^N such that $x^N(0) = x_0$ and for which

$$\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} x^N(\cdot),\, \operatorname{gr} \bar{x}^N(\cdot)\big) \to 0 \tag{4.12}$$

as $N \to \infty$. Finally, we have by the triangular inequality

$$\begin{aligned}\operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} x^N(\cdot),\, \operatorname{gr} X_\mu\big) \leq{}& \operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} x^N(\cdot),\, \operatorname{gr} \bar{x}^N(\cdot)\big) + \operatorname{dist}_{\mathcal{H}}\big(\operatorname{gr} \bar{x}^N(\cdot),\, \bar{\Omega}^N\big) \\ &+ \operatorname{dist}_{\mathcal{H}}\big(\bar{\Omega}^N,\, \Omega^N\big) + \operatorname{dist}_{\mathcal{H}}\big(\Omega^N,\, \operatorname{gr} X_\mu\big),\end{aligned}$$

which approaches 0 as $N \to \infty$ by (4.12), (4.9), and (4.7). This finishes the proof. ∎

5. Conclusion. We developed a sampling method for impulsive systems that is analogous to the classical Euler one-step method of ODEs. These techniques will be employed in forthcoming work on invariance and Hamilton–Jacobi theory.

The second major result of the paper is concerned with approximation of the given measure by systems without impulses. We showed such approximation was possible if the measures graph-converged, which is a considerably stronger property than weak-$\star$ convergence of the measures. It is interesting to compare this result with the closure theorem in [21], which is the analogue of the compactness of trajectories theorem. It is shown in Theorem 5.1 of [21] that if a sequence of (positive, scalar-valued) measures $\{\mu^N\}_N$ converges weak-$\star$ to μ, then a subsequence of a given sequence of associated solutions to the inclusion involving μ^N converges to a solution of (1.1). The difference between this result and our Theorem 4.1 lies in the fact that the limiting arc in [21] would in general be a solution associated to *some* graph completion, whereas our goal in Theorem 4.1 was to tie the convergence to a particular graph completion.

CONVEX PROGRAMS FOR TEMPORAL VERIFICATION OF NONLINEAR DYNAMICAL SYSTEMS*

STEPHEN PRAJNA† AND ANDERS RANTZER‡

Abstract. A methodology for safety verification of continuous and hybrid systems using barrier certificates has been proposed recently. Conditions that must be satisfied by a barrier certificate can be formulated as a convex program, and the feasibility of the program implies system safety in the sense that there is no trajectory starting from a given set of initial states that reaches a given unsafe region. The dual of this problem, i.e., the reachability problem, concerns proving the existence of a trajectory starting from the initial set that reaches another given set. Using insights from the linear programming duality appearing in the discrete shortest path problem, we show in this paper that reachability of continuous systems can also be verified through convex programming. Several convex programs for verifying safety and reachability, as well as other temporal properties such as eventuality, avoidance, and their combinations, are formulated. Some examples are provided to illustrate the application of the proposed methods. Finally, we exploit the convexity of our methods to derive a converse theorem for safety verification using barrier certificates.

Key words. temporal verification, safety verification, reachability analysis, barrier certificate, density function, convex programming, duality

1. Introduction.

Consider a continuous-time dynamical system of the form

$$\dot{x}(t) = f(x(t)),$$

where $x(t)$ is the state of the system, taking its value in the set $\mathcal{X} \subseteq \mathbb{R}^n$. Also given are the set of possible initial states $\mathcal{X}_0 \subseteq \mathcal{X}$, the set of "bad" states $\mathcal{X}_u \subseteq \mathcal{X}$, and the set of "good" states $\mathcal{X}_r \subseteq \mathcal{X}$. In this paper, we will be concerned with methods for verifying or proving temporal properties of the system such as the following:

- *safety*: all trajectories of the system starting from $\mathcal{X}_0$ will never reach $\mathcal{X}_u$;
- *avoidance*: at least one trajectory of the system starting from $\mathcal{X}_0$ will never reach $\mathcal{X}_u$;
- *eventuality*: all trajectories of the system starting from $\mathcal{X}_0$ will reach $\mathcal{X}_r$ in finite time;
- *reachability*: at least one trajectory of the system starting from $\mathcal{X}_0$ will reach $\mathcal{X}_r$ in finite time.

They will be defined more precisely later in the paper. In addition, we will look at more complex temporal properties, which are the combinations of the above, and will also consider systems with uncertain time-varying disturbance inputs.

When the system under consideration is a discrete transition system, such as a finite automaton, the problem described above has been studied extensively in the

computer science literature, and has applications, e.g., in the verification of correctness of computer protocols, algorithms, and software. See [8, 10, 12, 18]. The methods that have been proposed fall into two mainstream approaches: *model checking* [8] and *deductive verification* (or *theorem proving*) [18]. Model checking performs an exhaustive exploration of all possible system behaviors in a fully automated way, but is applicable only to finite state systems. Deductive verification, on the other hand, verifies system properties through formal deduction based on a set of inference rules. It is applicable to infinite state systems, but has a drawback in the sense that guidance from users is often needed in the process.

Uncountable state space and continuous dynamics are introduced when we consider applications in control, since they usually involve physical plants whose dynamics is governed by differential equations. Here the need for temporal verification arises as the complexity of the system increases, especially in safety-critical applications such as air traffic management [29], automated highway systems [11], and life support systems [9]. For such systems, exact verification cannot be performed through simulation, due to the infinite number of possibilities taken by the continuous state and also the uncertainties of the system.

The success of model checking techniques in verification of discrete, finite state transition systems has prompted the development of analogous approaches for continuous and hybrid systems. These approaches (see, e.g., [1, 2, 3, 5, 7, 15, 16, 30, 31]) require explicit computation of the states reachable from the initial set, which, for example, is performed by propagating the set of states. Unfortunately, although they allow us to compute an exact or nearly exact approximation of reachable sets, it is very difficult to perform such a computation due to the uncountability of the state space, especially when the system is nonlinear and uncertain. Note also that most of the existing literature focuses on the verification of safety property, although some of their techniques can be used to verify other temporal properties stated at the beginning of this paper.

In a different vein, a deductive method for safety verification that does not require explicit computation of the reachable sets, but instead is based on functions of states termed barrier certificates, has been recently proposed in a work by the first author [21]. The idea here is to study properties of the system without the need to compute the flow explicitly. Our conditions for safety can be stated as follows. Suppose that the vector field $f(x)$ is continuous and that there exists a continuously differentiable function $B : \mathbb{R}^n \to \mathbb{R}$ such that the inequalities

$$B(x) \leq 0 \quad \forall x \in \mathcal{X}_0, \tag{1.1}$$

$$B(x) > 0 \quad \forall x \in \mathcal{X}_u, \tag{1.2}$$

$$\frac{\partial B}{\partial x}(x) f(x) \leq 0 \quad \forall x \in \mathcal{X} \tag{1.3}$$

are satisfied. Then the safety property is verified, namely, there is no trajectory $x(t)$ of the system $\dot{x} = f(x)$ such that $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_u$ for some $T \geq 0$, and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$. The function $B(x)$ here is called a *barrier certificate*. When $f(x)$ is polynomial and the sets $\mathcal{X}$, $\mathcal{X}_0$, $\mathcal{X}_u$ are semialgebraic, a polynomial barrier certificate $B(x)$ can be efficiently searched using sum of squares programming [22]—a convex optimization framework based on sum of squares decompositions of multivariate polynomials [20] and semidefinite programming [6]. Because of this, our method appears to be more scalable than many other methods. The method has also

been extended to handle hybrid, uncertain, and stochastic systems [21], and successful application to a NASA life support system, which is a nonlinear hybrid system with 6 discrete modes and 10 continuous state variables, has been reported [9]. To the best of our knowledge, all other verification methods that can handle nonlinear hybrid systems are practically limited to about 5 continuous state variables.

The above method is analogous to the Lyapunov method for stability analysis [14]. Contrary to stability analysis, however, no notion of equilibrium, stability, or convergence is required in temporal verification. For example, the system does not need to have an equilibrium, and also for the eventuality and reachability properties the system is not required to stay in $\mathcal{X}_r$ once the set is reached. Our method is also related to the viability theory [4], the smallest invariant set [13], and the invariant generation [26, 27, 28] approaches to safety verification. However, one of the distinctive features of our approach is that we use convex programming to verify properties of interest, which gives benefit in terms of *computation* and in terms of its inherent *duality structure*.

In the present paper, we use insights from the linear programming duality appearing in the discrete shortest path problem [19] and the concept of density function [23, 24] to formulate a convex program for proving reachability. In fact, not only safety and reachability, but also other temporal properties such as eventuality, avoidance, and their combinations can be verified through convex programming. Several convex programs for this will be formulated. Similar to before, when the description of the system is polynomial and the sets are semialgebraic, polynomial solutions to these programs can be searched using sum of squares programming. In addition to this, we will exploit strong duality to prove a converse theorem for safety verification using barrier certificates.

The outline of the paper is as follows. In section 2, we give an intuitive illustration of some main ideas by addressing the verification of a simple discrete transition system. The convex programs for verification of continuous-time systems are presented and proven in section 3. In section 4, some examples will be presented to illustrate the applications of the proposed method. A converse theorem for barrier certificates will be stated and proven in section 5, and we offer some conclusions in section 6.

2. Discrete example. Let us consider the verification of a simple discrete transition system, shown in Figure 2.1. The system has four states, labeled 1 through 4, and three transitions between states, represented by the directed edges in the graph. We assume that node 1 is the initial state and node 4 is the bad/unsafe state.

For verifying the safety property, conditions analogous to (1.1)–(1.3) that must be satisfied by a barrier certificate can be formulated. One way to find a barrier certificate which proves safety is by solving the linear program (LP)[1]

$$\max\ s^T B$$

$$\text{subject to } A^T B \leq 0,$$

where $B \triangleq \mathrm{col}(B_1, B_2, B_3, B_4) \in \mathbb{R}^4$ is the decision variable of the LP (i.e., the barrier

[1]Here we assume that there are only one initial state and one unsafe state. A generalization of this can be formulated by considering a bigger graph obtained by augmenting an extra "source" node and edges that connect it to all initial states, as well as an extra "sink" node and edges that connect all unsafe states to it.

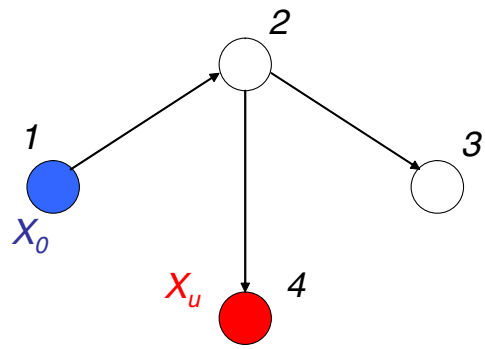

FIG. 2.1. *Verification of a simple discrete transition system. The nodes represent the states of the system, while the directed edges represent transitions between states. Node* 1 *is the initial state and node* 4 *is the unsafe state.*

certificate); A is the incidence matrix of the graph, in this case given by

$$A = \begin{bmatrix} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix}^T;$$

and s is a 4×1 column vector whose ith entry is equal to 1 if the ith node is the unsafe state, and equal to -1 if the ith node is the initial state. This formulation is similar to the continuous case. Analogous to (1.3), we ask that $B_j \leq B_i$ if there is a directed edge from node i to node j. The objective function of the LP is just the difference between the values of B at the unsafe state and at the initial state. If there is a feasible solution to the above LP such that the objective function is strictly positive, then the safety property can be inferred; i.e., we prove that there is no path going from node 1 to node 4.

The dual of the above LP is as follows:

$$\begin{aligned} &\min\ 0 \\ &\text{subject to } A\rho = s, \\ &\qquad \rho \geq 0, \end{aligned}$$

where $\rho \triangleq \text{col}(\rho_{12}, \rho_{23}, \rho_{24}) \in \mathbb{R}^3$ is the dual decision variables, whose entries correspond to the edges in the graph. The dual decision variable ρ_{ij} can be interpreted as the transportation density from node i to node j. The equality constraints basically state that conservation of flows holds at each node, namely, that the total flow into a node is equal to the total flow out. In addition, the first and third equality constraints indicate that there exist a unit source at node 1, i.e., the initial state, and a unit sink at node 4, i.e., the unsafe state. This duality interpretation has been studied extensively in the past; see, e.g., [19] and the references therein.

The existence of a feasible solution to the dual LP implies the existence of a path from the initial state to the unsafe state. This can be shown using the facts that the flows are conserved and that there are a unit source and a unit sink at the initial state and unsafe state, respectively. Hence, solving the dual LP can be used for verifying reachability. As a matter of fact, we obtain a linear programming formulation of the shortest path problem if we also add the objective function $\sum \rho_{ij}$ to the dual LP. In

this case, the nonzero entries corresponding to any optimal vertex solution to the LP will indicate a shortest path from the initial node to the unsafe node [19].

This duality argument can also be used to prove that the existence of a barrier certificate is both sufficient and necessary for safety. For this, suppose that there exists no barrier certificate for the system, which is equivalent to the maximum objective value of the primal LP being equal to zero. This objective value is attained by, e.g., $B_i = 0$ for all i. The linear programming duality [6] implies that there exists a feasible solution to the dual LP, from which we can further conclude the existence of a path from the initial state to the unsafe state, as explained in the previous paragraph. In the continuous case, a strong duality argument will also be used to prove a converse theorem for barrier certificates later in this paper.

For the above example, the optimal objective value of the primal LP is equal to zero, and hence the safety property does not hold. The unique feasible solution to the dual LP is given by $\rho_{12} = 1$, $\rho_{23} = 0$, $\rho_{24} = 1$, which shows the path from node 1 to node 4. If the direction of the edge from node 2 to node 4 were reversed, for example, the optimal objective value of the corresponding primal LP would be ∞, and there would be no feasible solution to the dual LP.

Other properties of this discrete transition system such as eventuality and avoidance can also be verified by solving some appropriate LPs. We will not state them here, but instead we will now proceed to discuss the corresponding convex programs for continuous systems.

3. Continuous systems. We denote the space of m-times continuously differentiable functions mapping $X \subseteq \mathbb{R}^n$ to $\mathbb{R}^p$ by $C^m(X, \mathbb{R}^p)$. When $p = 1$, we will simply write $C^m(X)$, and for continuous functions ($m = 0$), we will omit the superscript. The solution $x(t)$ of $\dot{x} = f(x)$ starting from $x(0) = x_0$, if unique, is denoted by $\phi_t(x_0)$. For a set Z, we define $\phi_t(Z) \triangleq \{\phi_t(x) : x \in Z\}$.

The divergence of a vector field $f \in C^1(X, \mathbb{R}^n)$ is denoted by $\nabla \cdot f(x)$. Finally, let $\mathrm{cl}(X)$ denote the closure of a set X, and let ∂X denote the boundary of X.

The following version of Liouville's theorem (from [23]) will be used in the proofs of the main theorems.

LEMMA 3.1. *Let $f \in C^1(D, \mathbb{R}^n)$, where $D \subseteq \mathbb{R}^n$ is open, and let $\rho \in C^1(D, \mathbb{R})$ be integrable, i.e., $\int_D \rho(x)dx$ is finite. Consider the system $\dot{x} = f(x)$. For a measurable set Z, assume that $\phi_\tau(Z)$ is a subset of D for all τ between 0 and T. Then*

$$\int_{\phi_T(Z)} \rho(x)dx - \int_Z \rho(z)dz = \int_0^T \int_{\phi_\tau(Z)} \left[\nabla \cdot (f\rho)\right](x)dxd\tau. \tag{3.1}$$

3.1. Safety and reachability verification. At this point, we are ready to state and prove the first pair of convex programs that verify safety and reachability for continuous systems. The first convex program was proposed in [21] but will be repeated here for completeness.

THEOREM 3.2. *Consider the system $\dot{x} = f(x)$ with $f \in C(\mathbb{R}^n, \mathbb{R}^n)$. Let the sets $\mathcal{X} \subseteq \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, and $\mathcal{X}_u \subseteq \mathcal{X}$ be given. Suppose that there exists a function $B \in C^1(\mathbb{R}^n)$ satisfying*

$$B(x) \leq 0 \quad \forall x \in \mathcal{X}_0, \tag{3.2}$$

$$B(x) > 0 \quad \forall x \in \mathcal{X}_u, \tag{3.3}$$

$$\frac{\partial B}{\partial x}(x) f(x) \leq 0 \quad \forall x \in \mathcal{X}. \tag{3.4}$$

Then the safety property holds; i.e., there exists no trajectory $x(t)$ of the system such that $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_u$ for some $T \geq 0$, and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.

Proof. Our proof is by contradiction. Assume that there exists a barrier certificate $B(x)$ satisfying conditions (3.2)–(3.4), while at the same time the system is not safe; i.e., there exist a time instance $T \geq 0$ and an initial condition $x_0 \in \mathcal{X}_0$ such that a trajectory $x(t)$ of the system starting at $x(0) = x_0$ satisfies $x(t) \in \mathcal{X}$ for all $t \in [0, T]$ and $x(T) \in \mathcal{X}_u$. Condition (3.4) implies that the derivative of $B(x(t))$ with respect to time is nonpositive on the time interval $[0, T]$. A direct consequence of this (which, for example, can be shown using the mean value theorem) is that $B(x(T))$ must be less than or equal to $B(x(0))$, which is contradictory to (3.2)–(3.3). Thus the initial hypothesis is not correct: the safety property must hold. ∎

We will next present a convex program for verifying reachability. It can be viewed as a continuous-time version of the dual LP in section 2. The decision variable $\rho(x)$ in this convex program is termed *density function* and has an interpretation as the stationary density of a substrate that is generated and consumed in various parts of the state space, and that is transported according to the vector field of the system. It has been previously used in an almost global stability criterion in [23].

THEOREM 3.3. *Consider the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$. Let the sets $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, and $\mathcal{X}_r \subseteq \mathcal{X}$ be given. Assume that the sets are bounded and that $\mathcal{X}_0$ has a nonempty interior. If there exists a function $\rho \in C^1(\mathbb{R}^n)$ satisfying*

$$\int_{\mathcal{X}_0} \rho(x)dx \geq 0, \tag{3.5}$$

$$\rho(x) < 0 \quad \forall x \in \mathrm{cl}(\partial\mathcal{X} \setminus \partial\mathcal{X}_r), \tag{3.6}$$

$$\nabla \cdot (\rho f)(x) > 0 \quad \forall x \in \mathrm{cl}(\mathcal{X} \setminus \mathcal{X}_r), \tag{3.7}$$

then the reachability property holds; i.e., there exists a trajectory $x(t)$ of the system such that $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_r$ for some $T \geq 0$, and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.

Proof. Let $X \subseteq \mathcal{X}_0$ be an open set on which $\rho(x) \geq 0$. We will first prove that there must be an initial condition $x_0 \in X$ whose flow $\phi_t(x_0)$ leaves $\mathcal{X} \setminus \mathcal{X}_r$ in finite time. In fact, the set of all initial conditions in X whose flows do not leave $\mathcal{X} \setminus \mathcal{X}_r$ in finite time is a set of measure zero. To show this, let Y be an open neighborhood of $\mathcal{X} \setminus \mathcal{X}_r$ such that $\nabla \cdot (\rho f)(x) > 0$ on $\mathrm{cl}(Y)$. Now define

$$Z = \bigcap_{i=1,2,\ldots} \{x_0 \in X : \phi_t(x_0) \in Y \quad \forall t \in [0, i]\}.$$

The set Z is an intersection of countable open sets and hence is measurable. It contains all initial conditions in X for which the trajectories stay in Y for all $t \geq 0$. That Z is a set of measure zero can be shown using Lemma 3.1 as follows. Since $\phi_t(Z) \subset Y$, Y is bounded, and $\rho(x)$ is continuous, the left-hand side of

$$\int_{\phi_t(Z)} \rho(x)dx - \int_Z \rho(x)dx = \int_0^t \int_{\phi_\tau(Z)} \left[\nabla \cdot (f\rho)\right](x)dxd\tau$$

is bounded for all $t \geq 0$. Therefore, for the above equation to hold, we must have $\int_{\phi_\tau(Z)} \left[\nabla \cdot (f\rho)\right](x)dx \to 0$ as $\tau \to \infty$, or, equivalently, the measure of $\phi_\tau(Z)$ converges to zero as $\tau \to \infty$. Suppose now that Z has nonzero measure. We have a contradiction since $\lim_{t\to\infty} \int_{\phi_t(Z)} \rho(x)dx = 0$, whereas $\lim_{t\to\infty} \int_0^t \int_{\phi_\tau(Z)} \left[\nabla \cdot (f\rho)\right](x)dxd\tau +$

$\int_Z \rho(x)dx$ is strictly positive, as implied by (3.5) and (3.7). Using this argument, we conclude that Z has measure zero. Since $\mathcal{X} \setminus \mathcal{X}_r \subset Y$, it follows immediately that the set of all initial conditions in X whose flows stay in $\mathcal{X} \setminus \mathcal{X}_r$ for all time is a set of measure zero.

Now take any $x_0 \in X$ whose flow leaves $\mathcal{X} \setminus \mathcal{X}_r$ in finite time; we will show that such a flow must enter $\mathcal{X}_r$ before leaving $\mathcal{X}$. Suppose to the contrary that the flow $\phi_t(x_0)$ leaves $\mathcal{X}$ without entering $\mathcal{X}_r$ first. Let $T > 0$ be the "first" time instant $\phi_t(x_0)$ leaves $\mathcal{X}$. By this we mean that either $\phi_t(x_0) \in \mathcal{X} \setminus \mathcal{X}_r$ for all $t \in [0, T)$ and $\phi_T(x_0) \notin \mathcal{X}$, or $\phi_t(x_0) \in \mathcal{X} \setminus \mathcal{X}_r$ for all $t \in [0, T]$ and $\phi_{T+\epsilon}(x_0) \notin \mathcal{X}$ for any $\epsilon > 0$. From conditions (3.6)–(3.7), it follows that for a sufficiently small neighborhood U of x_0 we have

$$\rho(x) \geq 0 \quad \forall x \in U,$$

$$\rho(x) < 0 \quad \forall x \in \phi_T(U),$$

$$\nabla \cdot (\rho f)(x) > 0 \quad \forall x \in \phi_t(U), t \in [0, T].$$

Apply Lemma 3.1 again to obtain a contradiction. According to the above, the left-hand side of

$$\int_{\phi_T(U)} \rho(x)dx - \int_U \rho(x)dx = \int_0^T \int_{\phi_\tau(U)} [\nabla \cdot (f\rho)](x)dxd\tau$$

is negative, while the right-hand side is positive. Thus there is a contradiction, and we conclude that for $x(0) = x_0$ there must exist $T \geq 0$ such that $x(T) \in \mathcal{X}_r$ and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$. □

Remark 3.4. Modulo the following modification on the assertion of Theorem 3.3, the conclusion will still hold even when the sets are not bounded. In particular, we need to add the condition that $\rho(x)$ is integrable on $\mathcal{X}$ (i.e., $\int_{\mathcal{X}} \rho(x)dx$ is finite) and replace (3.7) by

$$\nabla \cdot (\rho f)(x) \geq \epsilon \quad \forall x \in (\mathcal{X} \setminus \mathcal{X}_r)$$

for a positive number ϵ.

Notice that all the conditions presented in the above theorems (as well as in the theorems that will be presented later) form convex programming problems, as the sets of $B(x)$'s satisfying (3.2)–(3.4) or $\rho(x)$'s satisfying (3.5)–(3.7) are convex. This just follows from the definition of convexity. For example, if $B_1(x)$ and $B_2(x)$ satisfy (3.2)–(3.4), then for any $\alpha \in [0, 1]$, the function $\alpha B_1(x) + (1-\alpha)B_2(x)$ also satisfies the conditions. The convexity of the programs opens the possibility of computing $B(x)$ and $\rho(x)$ using convex optimization. For systems whose vector fields are polynomial and whose set descriptions are semialgebraic (i.e., described by polynomial equalities and inequalities), a computational method called sum of squares programming can be utilized if we use a polynomial parameterization for $B(x)$ or $\rho(x)$. The method is based on the sum of squares decomposition of multivariate polynomials [20] and semidefinite programming [6]. Software tools [22] are helpful for this purpose. See [21] for details.

When we set $\mathcal{X}_u = \mathcal{X}_r$, the convex programs in Theorems 3.2 and 3.3 form a pair of *weak alternatives*: at most one of them can be feasible. Nevertheless, strictly speaking it should be noted that these convex programs are not pairs of *Lagrange dual* problems [6] in the sense of convex optimization. We deliberately do not use Lagrange dual

problems to avoid computational problems when we postulate $B(x)$ or $\rho(x)$ as polynomials. For example, the Lagrange dual problem of the safety test in Theorem 3.2 will require $\nabla \cdot (\rho f)(x)$ to be zero on $\mathcal{X} \setminus (\mathcal{X}_0 \cup \mathcal{X}_u)$ (cf. section 5). Although useful for theoretical purposes, this will hinder the computation of $\rho(x)$ through polynomial parameterization and sum of squares programming. In this regard, some interesting future directions would be to see if a pair of Lagrange dual problems can be formulated so that both problems can be solved using sum of squares programming, or, more importantly, to see if the dual infeasibility certificate of one convex program can be interpreted directly as a feasible solution to the dual convex program.

3.2. Eventuality and avoidance verification. We will now present two other convex programs for verifying the eventuality and avoidance properties. Analogous to what we have in the previous subsection, when $\mathcal{X}_u = \mathcal{X}_r$ these programs form a pair of weak alternatives.

THEOREM 3.5. *Consider the system $\dot{x} = f(x)$ with $f \in C(\mathbb{R}^n, \mathbb{R}^n)$. Let $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, and $\mathcal{X}_r \subseteq \mathcal{X}$ be bounded sets. If there exists a function $B \in C^1(\mathbb{R}^n)$ satisfying*

$$B(x) \leq 0 \quad \forall x \in \mathcal{X}_0, \tag{3.8}$$

$$B(x) > 0 \quad \forall x \in \mathrm{cl}(\partial\mathcal{X} \setminus \partial\mathcal{X}_r), \tag{3.9}$$

$$\frac{\partial B}{\partial x}(x) f(x) < 0 \quad \forall x \in \mathrm{cl}(\mathcal{X} \setminus \mathcal{X}_r), \tag{3.10}$$

then the eventuality property holds; i.e., for all initial conditions $x_0 \in \mathcal{X}_0$, the trajectory $x(t)$ of the system starting at $x(0) = x_0$ satisfies $x(T) \in \mathcal{X}_r$ and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$ for some $T \geq 0$.

Proof. Consider any point $x_0 \in \mathcal{X}_0$, for which $B(x_0) \leq 0$, and let $x(t)$ be a trajectory of the system starting at $x(0) = x_0$. The trajectory $x(t)$ must leave $\mathcal{X} \setminus \mathcal{X}_r$ in finite time, since the derivative inequality (3.10) holds and $B(x)$ is bounded below on $\mathcal{X}$. Now, suppose that $x(t)$ leaves $\mathcal{X}$ without entering $\mathcal{X}_r$ first, and consider the "first" time instant $t = T$ at which it happens. Similar to the proof of Theorem 3.3, by this we mean that either $x(t) \in \mathcal{X} \setminus \mathcal{X}_r$ for all $t \in [0, T)$ and $x(T) \notin \mathcal{X}$, or $x(t) \in \mathcal{X} \setminus \mathcal{X}_r$ for all $t \in [0, T]$ and $x(T + \epsilon) \notin \mathcal{X}$ for any $\epsilon > 0$. From (3.10) and $B(x_0) \leq 0$, it follows that $B(x(T))$ is nonpositive, which is contradictory to (3.9). Thus we conclude that for any trajectory $x(t)$ starting at $x(0) = x_0$ there must exist $T \geq 0$ such that $x(T) \in \mathcal{X}_r$ and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$. Since x_0 is an arbitrary point in $\mathcal{X}_0$, the conclusion of the theorem follows. ∎

Remark 3.6. Similarly to before, with some modifications to the assertion of the theorem, the conclusion of Theorem 3.5 will still hold even when the sets are not bounded. In particular, we need to add the condition that $B(x)$ is bounded below on $\mathcal{X}$ and replace (3.10) by

$$\frac{\partial B}{\partial x}(x) f(x) \leq -\epsilon \quad \forall x \in (\mathcal{X} \setminus \mathcal{X}_r)$$

for a positive number ϵ.

THEOREM 3.7. *Consider the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$. Let $\mathcal{X} \subseteq \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, and $\mathcal{X}_u \subseteq \mathcal{X}$ be some given sets, with $\mathcal{X}_0$ having a nonempty interior. If*

there exist an open set $\tilde{\mathcal{X}}$ *and a function* $\rho \in C^1(\mathbb{R}^n)$ *such that* $\mathcal{X} \subseteq \tilde{\mathcal{X}}$ *and*

$$\int_{\mathcal{X}_0} \rho(x)dx \geq 0, \tag{3.11}$$

$$\rho(x) < 0 \quad \forall x \in \mathcal{X}_u, \tag{3.12}$$

$$\nabla \cdot (\rho f)(x) \geq 0 \quad \forall x \in \tilde{\mathcal{X}}, \tag{3.13}$$

then the avoidance property holds; i.e., for some initial condition $x_0 \in \mathcal{X}_0$*, there exists no* $T \geq 0$ *such that trajectory* $x(t)$ *of the system starting at* $x(0) = x_0$ *satisfies* $x(T) \in \mathcal{X}_u$ *and* $x(t) \in \mathcal{X}$ *for all* $t \in [0, T]$.

Proof. From (3.11), it follows that there exists an open set $X \subseteq \mathcal{X}_0$ on which $\rho(x) \geq 0$. Take any x_0 in X—we will show that the trajectory starting from this point will never reach $\mathcal{X}_u$. Suppose to the contrary that there exists a $T \geq 0$ such that $\phi_T(x_0) \in \mathcal{X}_u$ and $\phi_t(x_0) \in \mathcal{X}$ for $t \in [0, T]$. Then it follows from (3.12)–(3.13) that for a sufficiently small neighborhood Z of x_0 we have

$$\rho(x) \geq 0 \quad \forall x \in Z,$$

$$\rho(x) < 0 \quad \forall x \in \phi_T(Z),$$

$$\nabla \cdot (\rho f)(x) \geq 0 \quad \forall x \in \phi_t(Z), t \in [0, T].$$

Now apply Lemma 3.1 to obtain a contradiction. Use a bounded but sufficiently large $D \subset \mathbb{R}^n$ such that $\phi_t(Z) \subset D$ for all $t \in [0, T]$; then $\rho(x)$ is integrable on D. According to the above, the left-hand side of

$$\int_{\phi_T(Z)} \rho(x)dx - \int_Z \rho(x)dx = \int_0^T \int_{\phi_\tau(Z)} \left[\nabla \cdot (f\rho)\right](x)dxd\tau$$

is negative and the right-hand side is nonnegative. Hence there is a contradiction and the proof is complete. ∎

In applications where the system has stable equilibrium points, it is often convenient to exclude a neighborhood of the equilibria from the region where the divergence inequality (3.13) must be satisfied, since the inequality is otherwise impossible to satisfy without a singularity in $\rho(x)$. This does not make the conclusion of the theorem weaker, as long as the excluded set does not intersect $\mathcal{X}_u$ and is entirely surrounded by a region of positive $\rho(x)$.

Similarly, the Lie derivative inequality (3.10) is impossible to satisfy when the system has equilibrium points in $\mathcal{X} \setminus \mathcal{X}_r$. In this case, a neighborhood of the equilibria should also be excluded from the region where the inequality is to be satisfied. The conclusion of the theorem is still valid as long as the excluded set is entirely surrounded by a region of positive $B(x)$.

3.3. Some extensions. Whereas the convex programs for safety and reachability as well as eventuality and avoidance are related since they form pairs of weak alternatives, the safety property is also related to avoidance, and eventuality to reachability, via replacing the universal quantifier with an existential quantifier. As a consequence, reachability and avoidance verification can also be performed using the

barrier certificate $B(x)$. The conditions are similar to those in Theorems 3.5 and 3.2, respectively, but with conditions (3.8) and (3.2) replaced by

$$\int_{\mathcal{X}_0} B(x)dx \leq 0,$$

where we also ask that $\mathcal{X}_0$ has a nonempty interior. The proof is similar to the proofs of Theorems 3.5 and 3.2, noting that $B(x)$ will then be less than or equal to zero in some open set contained in $\mathcal{X}_0$.

A modification of the convex program involving $\rho(x)$ in Theorem 3.7 can also be used to verify the safety property. For this, we need to replace (3.11) by

$$\rho(x) \geq 0 \quad \forall x \in \tilde{\mathcal{X}}_0,$$

where $\tilde{\mathcal{X}}_0$ is an open set containing $\mathcal{X}_0$. Note that in this case $\mathcal{X}_0$ no longer needs to have a nonempty interior.

On the other hand, an analogous modification of Theorem 3.3 can only be used to verify the eventuality property in the *weak* sense: that *almost all* trajectories of the system starting from $\mathcal{X}_0$ will reach $\mathcal{X}_r$ in finite time. This is stated in the corollary below.

COROLLARY 3.8. *Consider the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$. Let the sets $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, and $\mathcal{X}_r \subseteq \mathcal{X}$ be given. Assume that the sets are bounded, and let $\tilde{\mathcal{X}}_0$ be an open set containing $\mathcal{X}_0$. If there exists a function $\rho \in C^1(\mathbb{R}^n)$ satisfying*

$$\rho(x) \geq 0 \quad \forall x \in \tilde{\mathcal{X}}_0, \tag{3.14}$$

$$\rho(x) < 0 \quad \forall x \in \mathrm{cl}(\partial\mathcal{X} \setminus \partial\mathcal{X}_r), \tag{3.15}$$

$$\nabla \cdot (\rho f)(x) > 0 \quad \forall x \in \mathrm{cl}(\mathcal{X} \setminus \mathcal{X}_r), \tag{3.16}$$

then the weak eventuality property holds; i.e., for almost all[2] *initial conditions $x_0 \in \mathcal{X}_0$, there exists $T \geq 0$ such that the trajectory $x(t)$ of the system starting at $x(0) = x_0$ satisfies $x(T) \in \mathcal{X}_r$ and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.*

Proof. Using an argument similar to the proof of Theorem 3.3, it can be shown that for almost all initial conditions $x_0 \in \tilde{\mathcal{X}}_0$, there exists $T \geq 0$ such that the trajectory $x(t)$ of the system starting at $x(0) = x_0$ satisfies $x(T) \in \mathcal{X}_r$ and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$. Since $\mathcal{X}_0 \subseteq \tilde{\mathcal{X}}_0$, the corollary follows. □

Example 3.9. To show that the weak eventuality property mentioned above cannot in general be strengthened to eventuality, consider the system $\dot{x} = x$, with $\mathcal{X} = (-5, 5) \subset \mathbb{R}$, $\mathcal{X}_0 = (-1, 1)$, $\mathcal{X}_r = (-5, -4) \cup (4, 5)$. The function $\rho(x) = 1$ satisfies all the conditions that guarantee weak eventuality; hence almost all trajectories starting from $\mathcal{X}_0$ will reach $\mathcal{X}_r$ in finite time. The only exception in this case is the trajectory $x(t) = 0$.

Let us now consider the verification of a system with disturbance input $\dot{x} = f(x, d)$, where $f \in C(\mathbb{R}^{n+m}, \mathbb{R}^n)$; the disturbance signal $d(t)$ is assumed to be piecewise continuous, bounded on any finite time interval, and take its value in a set $\mathcal{D} \subseteq \mathbb{R}^m$. Then solving the convex program in Theorem 3.2 with the Lie derivative inequality (3.4) replaced by

$$\frac{\partial B}{\partial x}(x) f(x, d) \leq 0 \quad \forall (x, d) \in \mathcal{X} \times \mathcal{D}$$

[2]This is in the sense that the set of initial conditions which do not satisfy the property is a set of measure zero.

will prove safety under all possible disturbances $d(t)$. Also, solving the convex program in Theorem 3.5 with the Lie derivative inequality (3.10) replaced by

$$\frac{\partial B}{\partial x}(x)f(x,d) \leq -\epsilon \quad \forall (x,d) \in (\mathcal{X} \setminus \mathcal{X}_r) \times \mathcal{D}$$

for some positive ϵ will prove eventuality under all possible disturbances $d(t)$. Similar adaptations can be applied to the convex programs that verify reachability and avoidance using $B(x)$.

At present, it is unclear how a similar worst-case analysis for systems with time-varying disturbance can be formulated using $\rho(x)$. However, as pointed out in [23], the density function $\rho(x)$ seems to have a better convexity property that is more beneficial for controller design. For a system $\dot{x} = f(x) + g(x)u(x)$, where $u(x)$ is the control input (assumed to be in a state feedback form), the inequalities (3.5)–(3.6) and

$$\nabla \cdot [\rho(f + ug)](x) > 0 \quad \forall x \in \mathrm{cl}(\mathcal{X} \setminus \mathcal{X}_r)$$

(and similarly for (3.11)–(3.13)) are certainly convex conditions on the pair $(\rho, \rho u)$. It is therefore natural to introduce $\psi = \rho u$ as a search variable and use convex optimization to find a feasible pair (ρ, ψ), then recover the control law as $u(x) = \psi(x)/\rho(x)$. Some results along this direction are available in [25].

While one may argue that the reachability and avoidance properties can be shown by running a numerical simulation of $\dot{x} = f(x)$ starting from a properly chosen $x_0 \in \mathcal{X}_0$, the merit of the convex programming tests presented before is twofold. First, a solution to the convex programs for reachability or avoidance will automatically indicate a set from which all points (or almost all points) can be chosen as the initial state. Second, the use of these convex programs allows us to also consider the verification of systems with disturbance (which obviously cannot be performed using simulation), or even the controller design problem, as we have seen above.

3.4. Other temporal properties. It is clear that the convex programs in the previous subsections can also be extended to prove combined temporal properties such as reachability–safety:

> there exists a trajectory $x(t)$ such that $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_r$ for some $T \geq 0$, and $x(t) \notin \mathcal{X}_u$, $x(t) \in \mathcal{X}$ for all $t \in [0, T]$;

and eventuality–safety[3] (or weak eventuality–safety):

> for all (or almost all) initial states $x_0 \in \mathcal{X}_0$, the trajectory $x(t)$ starting at $x(0) = x_0$ will satisfy $x(T) \in \mathcal{X}_r$ for some $T \geq 0$ and $x(t) \notin \mathcal{X}_u$, $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.

Note that for the above temporal specifications, the system can reach $\mathcal{X}_u$ *after* it reaches $\mathcal{X}_r$ first.

For instance, convex programs for verifying the eventuality–safety and weak eventuality–safety properties are stated in the following corollaries.

COROLLARY 3.10. *Consider the system $\dot{x} = f(x)$ with $f \in C(\mathbb{R}^n, \mathbb{R}^n)$ and let $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, $\mathcal{X}_u \subseteq \mathcal{X}$, $\mathcal{X}_r \subseteq \mathcal{X}$ be bounded. Suppose that there exists a function*

[3] In linear temporal logic (LTL), for example, this property corresponds to the "until" operator.

$B \in C^1(\mathbb{R}^n)$ satisfying

$$B(x) \le 0 \quad \forall x \in \mathcal{X}_0, \tag{3.17}$$

$$B(x) > 0 \quad \forall x \in \mathrm{cl}(\partial\mathcal{X} \setminus \partial\mathcal{X}_r) \cup \mathcal{X}_u, \tag{3.18}$$

$$\frac{\partial B}{\partial x}(x) f(x) < 0 \quad \forall x \in \mathrm{cl}(\mathcal{X} \setminus \mathcal{X}_r). \tag{3.19}$$

Then the eventuality–safety property holds; i.e., for all initial states $x_0 \in \mathcal{X}_0$, the trajectory $x(t)$ starting at $x(0) = x_0$ will satisfy $x(T) \in \mathcal{X}_r$ for some $T \ge 0$ and $x(t) \notin \mathcal{X}_u$, $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.

COROLLARY 3.11. *Consider the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$ and let $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, $\mathcal{X}_u \subseteq \mathcal{X}$, $\mathcal{X}_r \subseteq \mathcal{X}$ be bounded. If there exist an open set $\tilde{\mathcal{X}}_0$ containing $\mathcal{X}_0$ and a function $\rho \in C^1(\mathbb{R}^n)$ satisfying*

$$\rho(x) \ge 0 \quad \forall x \in \tilde{\mathcal{X}}_0, \tag{3.20}$$

$$\rho(x) < 0 \quad \forall x \in \mathrm{cl}(\partial\mathcal{X} \setminus \partial\mathcal{X}_r) \cup \mathcal{X}_u, \tag{3.21}$$

$$\nabla \cdot (\rho f)(x) > 0 \quad \forall x \in \mathrm{cl}(\mathcal{X} \setminus \mathcal{X}_r), \tag{3.22}$$

then the weak eventuality–safety property holds; i.e., for almost all initial states $x_0 \in \mathcal{X}_0$, the trajectory $x(t)$ starting at $x(0) = x_0$ will satisfy $x(T) \in \mathcal{X}_r$ for some $T \ge 0$ and $x(t) \notin \mathcal{X}_u$, $x(t) \in \mathcal{X}$ for all $t \in [0, T]$. In this case, the safety property holds also for trajectories that do not reach $\mathcal{X}_r$ in finite time.

4. Examples. We will now consider some examples to illustrate the application of the proposed methods. The MATLAB m-files for solving these examples can be found at http://www.cds.caltech.edu/∼prajna/files/PraR06.

4.1. Successive safety and reachability refinements. Consider the two-dimensional system

$$\dot{x}_1 = x_2,$$

$$\dot{x}_2 = -x_1 + \frac{1}{3}x_1^3 - x_2,$$

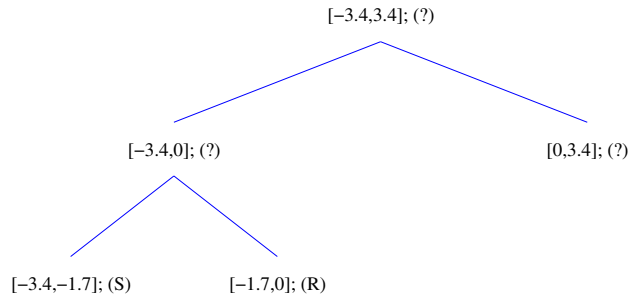
and let the set of states be $\mathcal{X} = [-3.5, 3.5] \times [-3.5, 3.5] \subset \mathbb{R}^2$. Furthermore, define

$$\mathcal{X}_0 = [-3.4, 3.4] \times [3.35, 3.45], \qquad \mathcal{X}_2 = [-3.5, 3.5] \times \{-3.5\},$$

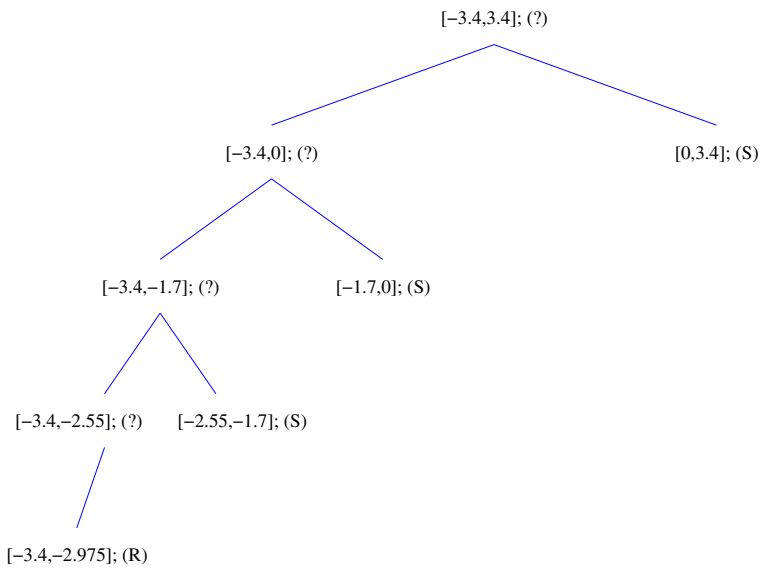
$$\mathcal{X}_1 = \{3.5\} \times [-3.5, 3.5], \qquad \mathcal{X}_3 = \{-3.5\} \times [-3.5, 3.5].$$

In this example, we will investigate the reachability of $\mathcal{X}_1$, $\mathcal{X}_2$, $\mathcal{X}_3$ from $\mathcal{X}_0$. Such facet-to-facet analysis is encountered when constructing a discrete abstraction of continuous or hybrid systems, or when analyzing a counterexample found during the verification of such an abstraction [1].

The convex programs in Theorems 3.2 and 3.3 will be used for our analysis. Since the vector field is polynomial and the sets are semialgebraic, we use polynomial parameterization for $B(x)$ and $\rho(x)$, and then utilize sum of squares programming to compute them. A degree bound equal to 8 is imposed on $B(x)$ and $\rho(x)$. Because of this, we might not be able to find a single $B(x)$ or $\rho(x)$ that proves safety or



(a) $\mathcal{X}_0 \to \mathcal{X}_1$



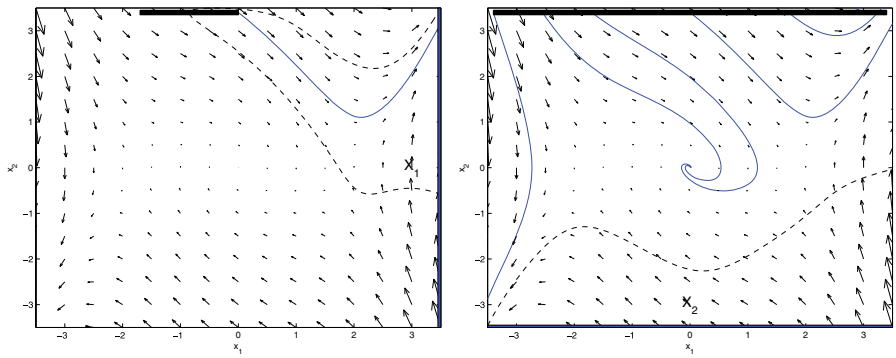
(b) $\mathcal{X}_0 \to \mathcal{X}_3$

FIG. 4.1. *Proving the reachability of $\mathcal{X}_1$ and $\mathcal{X}_3$ from $\mathcal{X}_0$ in the example of section* 4.1. *At each node we indicate the range of x_1 in $\mathcal{X}_0$ for which safety and reachability are tested. If neither is verified (denoted by ?), then the x_1-interval is divided into two and the tests are applied to the smaller sets. The annotation S (respectively, R) indicates that $B(x)$ (respectively, $\rho(x)$) is found. Breadth-first search starting from the leftmost branch is used. The verification of $\mathcal{X}_0 \nrightarrow \mathcal{X}_2$ terminates at the top node, since a barrier certificate $B(x)$ can be found directly.*

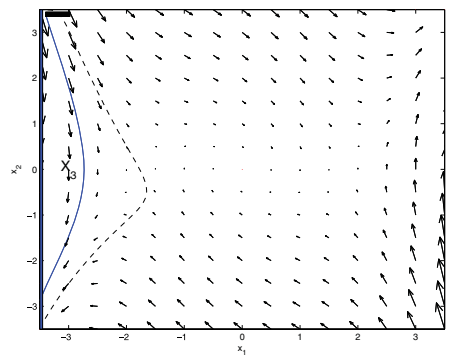
reachability for the whole $\mathcal{X}_0$. If neither $B(x)$ nor $\rho(x)$ can be found, we divide the interval of x_1 in $\mathcal{X}_0$ into two parts and apply the tests again to the smaller sets. A set is pruned if $B(x)$ is found, and this process is repeated until a $\rho(x)$ is found or the whole $\mathcal{X}_0$ is proven safe.

The result is as follows.

- We prove that the set $\mathcal{X}_1$ is reachable from $\mathcal{X}_0$. The verification progress is shown in Figure 4.1(a).



(a) $\mathcal{X}_0 \to \mathcal{X}_1$ (b) $\mathcal{X}_0 \nrightarrow \mathcal{X}_2$



(c) $\mathcal{X}_0 \to \mathcal{X}_3$

FIG. 4.2. *Possible transitions from $\mathcal{X}_0$ to $\mathcal{X}_1$, $\mathcal{X}_2$, and $\mathcal{X}_3$ in the example of section* 4.1. *In* (a) *and* (c), *dashed curves are the zero level sets of $\rho(x)$'s that certify reachability. In* (b), *the dashed curve is the zero level set of $B(x)$ that certifies safety; trajectories starting from $\mathcal{X}_0$ cannot cross this level set to reach $\mathcal{X}_2$. Thick solid lines at the top of the figures are the initial sets for which the certificates are computed. Some trajectories of the system are depicted by solid curves.*

- It can be proven directly that $\mathcal{X}_2$ is not reachable from $\mathcal{X}_0$.
- It is proven that the set $\mathcal{X}_3$ is reachable from $\mathcal{X}_0$. See Figure 4.1(b).

For proofs of the corresponding reachability and safety, see Figure 4.2.

Obviously, the above bisection algorithm is just a simple, straightforward approach to refine and prune the initial set, and other algorithms that are more efficient can be proposed in the future.

4.2. Van der Pol oscillator. Consider the van der Pol oscillator with disturbance input:

$$\dot{x}_1 = x_2,$$

$$\dot{x}_2 = x_2(1 - x_1^2) - x_1 + d,$$

where d is the disturbance input, taking its value in $\mathcal{D} = [-0.25, 0.25] \subset \mathbb{R}$. Let $\mathcal{X} = \{x \in \mathbb{R}^2 : 0.5 \le \|x\|_2 \le 5\}$. In addition, let

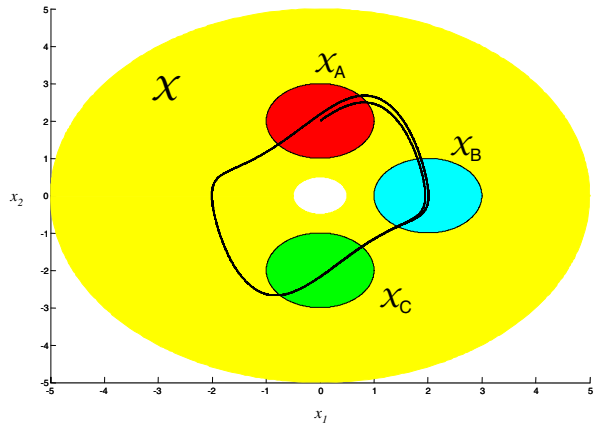


FIG. 4.3. *Verifying temporal properties of the van der Pol oscillator with disturbance. It is to be verified that under all possible disturbance input, if the system starts in $\mathcal{X}_A$, then both $\mathcal{X}_B$ and $\mathcal{X}_C$ are reached in finite time, but $\mathcal{X}_C$ will not be reached before the system reaches $\mathcal{X}_B$. The nominal trajectory of the system (i.e., for $d = 0$) starting at $x = (0, 2)$ is depicted by the solid curve.*

$$\mathcal{X}_A = \{x \in \mathbb{R}^2 : (x_1)^2 + (x_2 - 2)^2 \leq 1\},$$

$$\mathcal{X}_B = \{x \in \mathbb{R}^2 : (x_1 - 2)^2 + (x_2)^2 \leq 1\},$$

$$\mathcal{X}_C = \{x \in \mathbb{R}^2 : (x_1)^2 + (x_2 + 2)^2 \leq 1\}.$$

These sets are depicted in Figure 4.3, where a nominal trajectory of the system starting at $x = (0, 2)$ is also shown. Our objective in this example is to verify that under all possible piecewise continuous and bounded disturbances $d(t)$, if the system starts in $\mathcal{X}_A$, then both $\mathcal{X}_B$ and $\mathcal{X}_C$ are reached in finite time, but $\mathcal{X}_C$ will not be reached before the system reaches $\mathcal{X}_B$.

To verify this temporal specification, we will search for two barrier certificates $B_1(x)$ and $B_2(x)$ satisfying the following conditions:

$$\begin{cases} B_1(x) \leq 0 & \forall x \in \mathcal{X}_A, \\ B_1(x) > 0 & \forall x \in \partial\mathcal{X} \cup \mathcal{X}_C, \\ \frac{\partial B_1}{\partial x} f(x, d) \leq -\epsilon & \forall (x, d) \in (\mathcal{X} \setminus \mathcal{X}_B) \times \mathcal{D}, \end{cases}$$

$$\begin{cases} B_2(x) \leq 0 & \forall x \in \mathcal{X}_A, \\ B_2(x) > 0 & \forall x \in \partial\mathcal{X}, \\ \frac{\partial B_2}{\partial x} f(x, d) \leq -\epsilon & \forall x \in (\mathcal{X} \setminus \mathcal{X}_C) \times \mathcal{D} \end{cases}$$

for some positive ϵ. Using sum of squares programming, polynomials $B_1(x)$ and $B_2(x)$ of degree 10 can be found, and thus the temporal specification is verified.

5. A converse theorem. In this section, we will prove a converse theorem for safety verification using barrier certificates by exploiting the convexity of the problem formulation. The main result of the section can be stated as follows.

THEOREM 5.1. *Consider the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$. Let $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, $\mathcal{X}_u \subseteq \mathcal{X}$ be compact sets, and suppose that there exists a function $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x)f(x) < 0$ for all $x \in \mathcal{X}$. Then there exists a function $B \in C^1(\mathbb{R}^n)$ that satisfies*

$$B(x) \le 0 \quad \forall x \in \mathcal{X}_0, \tag{5.1}$$

$$B(x) > 0 \quad \forall x \in \mathcal{X}_u, \tag{5.2}$$

$$\frac{\partial B}{\partial x}(x)f(x) \le 0 \quad \forall x \in \mathcal{X} \tag{5.3}$$

if and only if the safety property holds, i.e., if there exists no trajectory $x(t)$ of the system such that $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_u$ for some $T \ge 0$, and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.

Notice that in the theorem we have used a seemingly strong assumption that there exists a function $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x)f(x) < 0$ for all $x \in \mathcal{X}$. Later in the section we will show that in many cases of interest the existence of such $\tilde{B}(x)$ is actually guaranteed.

Our proof of the converse statement in Theorem 5.1 consists of two parts, given in Lemmas 5.2 and 5.4 below. In the first lemma, we use the Hahn–Banach theorem to show that the nonexistence of a $B(x)$ satisfying the conditions in Theorem 5.1 implies the existence of measures ψ_0, ψ_u, ρ satisfying some appropriate conditions. Then in Lemma 5.4 we show that the existence of such ψ_0, ψ_u, ρ actually implies that there exists an unsafe trajectory of the system.

LEMMA 5.2. *Let $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$, and let $\mathcal{X} \subset \mathbb{R}^n$, $\mathcal{X}_0 \subseteq \mathcal{X}$, $\mathcal{X}_u \subseteq \mathcal{X}$ be compact sets. Suppose there exists a function $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x)f(x) < 0$ for all $x \in \mathcal{X}$. Then there exists no $B \in C^1(\mathbb{R}^n)$ satisfying (5.1)–(5.3) only if there are measures of bounded variation ψ_0, ψ_u, ρ (each defined on $\mathbb{R}^n$) such that ψ_0, ψ_u, ρ are nonnegative on $\mathbb{R}^n$ and equal to zero outside $\mathcal{X}_0$, $\mathcal{X}_u$, and $\mathcal{X}$, respectively; and*

$$\int_{\mathcal{X}_0} d\psi_0 = 1,$$

$$\int_{\mathcal{X}_u} d\psi_u = 1,$$

$$\nabla \cdot (\rho f) = \psi_0 - \psi_u,$$

where $\nabla \cdot (\rho f)$ is interpreted as a distributional derivative.

Proof. Let us consider the convex optimization problem

$$\begin{aligned} &\sup\ B_u - B_0 \\ &\text{subject to } B(x) - B_0 \le 0 \quad \forall x \in \mathcal{X}_0, \\ &\qquad B(x) - B_u \ge 0 \quad \forall x \in \mathcal{X}_u, \\ &\qquad \frac{\partial B}{\partial x}(x)f(x) \le 0 \quad \forall x \in \mathcal{X}, \end{aligned}$$

with the supremum denoted by γ, and taken over all $B_0 \in \mathbb{R}$, $B_u \in \mathbb{R}$, and $B \in C^1(\mathbb{R}^n)$. Since $B_0 = 0$, $B_u = 0$, and $B(x) = 0$ satisfy the constraint, γ must be greater

than or equal to zero. In addition, since the objective function and the constraints are all linear, the value of γ is either zero or ∞. There exists no $B \in C^1(\mathbb{R}^n)$ satisfying (5.1)–(5.3) if and only if the value of γ is equal to zero.

Now suppose that $\gamma = 0$. Let $\mathcal{K} = \mathbb{R} \times (C(\mathcal{X}))^3$, $\mathcal{B} = \mathbb{R}^2 \times C_0^1(\mathbb{R}^n)$, and define $\mathcal{K}_1$, $\mathcal{K}_2$ as follows:

$$\mathcal{K}_1 = \Bigg\{ (z, h_0, h_u, h) \in \mathcal{K} : h_0 = B_0 - B,\ h_u = B - B_u,\ h = -\frac{\partial B}{\partial x} f \text{ on } \mathcal{X};$$
$$z = B_u - B_0;\ \text{ and } (B_0, B_u, B) \in \mathcal{B} \Bigg\},$$

$$\mathcal{K}_2 = \{(z, h_0, h_u, h) \in \mathcal{K} : z \geq 0,\ h_0 \geq 0 \text{ on } \mathcal{X}_0,\ h_u \geq 0 \text{ on } \mathcal{X}_u,\ h \geq 0 \text{ on } \mathcal{X}\}.$$

Then both $\mathcal{K}_1$ and $\mathcal{K}_2$ are convex sets, and $\mathcal{K}_2$ has a nonempty interior in $\mathcal{K}$. Furthermore, since $\gamma = 0$, it follows that the first component in $\mathcal{K}_1$ is less than or equal to zero when the second, third, and fourth components are greater than or equal to zero, and therefore $\mathcal{K}_1 \cap \operatorname{int}(\mathcal{K}_2) = \emptyset$. Now, by the Hahn–Banach theorem [17], there exists a nonzero $k^* = (a, \tilde{\psi}_0, \tilde{\psi}_u, \tilde{\rho}) \in \mathcal{K}^* = \mathbb{R} \times (C(\mathcal{X})^*)^3$ such that

$$\sup_{k_1 \in \mathcal{K}_1} \langle k^*, k_1 \rangle \leq \inf_{k_2 \in \mathcal{K}_2} \langle k^*, k_2 \rangle, \tag{5.4}$$

where $C(\mathcal{X})^*$ in this case is the set of measures on $\mathcal{X}$ with bounded variation. The right-hand side of the inequality can be expanded as follows:

$$\inf_{k_2 \in \mathcal{K}_2} \langle k^*, k_2 \rangle = \inf_{(z, h_0, h_u, h) \in \mathcal{K}_2} az + \langle \tilde{\psi}_0, h_0 \rangle + \langle \tilde{\psi}_u, h_u \rangle + \langle \tilde{\rho}, h \rangle$$
$$= \begin{cases} 0 & \text{if } a \geq 0;\ \tilde{\psi}_0, \tilde{\psi}_u, \tilde{\rho} \geq 0; \text{ and} \\ & \quad \tilde{\psi}_0, \tilde{\psi}_u \text{ are zero outside } \mathcal{X}_0, \mathcal{X}_u, \text{ respectively;} \\ -\infty & \text{otherwise.} \end{cases}$$

Now denote the extension of $\tilde{\psi}_0$, $\tilde{\psi}_u$, $\tilde{\rho}$ to the whole $\mathbb{R}^n$ by ψ_0, ψ_u, ρ, which are obtained by letting them be equal to zero outside of $\mathcal{X}$. Then, for the left-hand side of (5.4), we have the following equality:

$$\sup_{k_1 \in \mathcal{K}_1} \langle k^*, k_1 \rangle = \sup_{(B_0, B_u, B) \in \mathcal{B}} a(B_u - B_0) + \langle \psi_0, B_0 - B \rangle$$
$$+ \langle \psi_u, B - B_u \rangle + \left\langle \rho, -\frac{\partial B}{\partial x} f \right\rangle$$
$$= \sup_{(B_0, B_u, B) \in \mathcal{B}} \left(-a + \int d\psi_0 \right) B_0 + \left(a - \int d\psi_u \right) B_u$$
$$+ \langle -\psi_0 + \psi_u + \nabla \cdot (\rho f), B \rangle$$
$$= \begin{cases} 0 & \text{if } \int_{\mathbb{R}^n} d\psi_0 = a, \int_{\mathbb{R}^n} d\psi_u = a, \text{ and} \\ & \quad -\psi_0 + \psi_u + \nabla \cdot (\rho f) = 0; \\ \infty & \text{otherwise,} \end{cases}$$

where $\nabla \cdot (\rho f)$ is interpreted as a distributional derivative. Thus, for the supremum to be less than or equal to the infimum, we must have a nonzero $(a, \psi_0, \psi_u, \rho)$, where ψ_0, ψ_u, ρ are measures of bounded variation on $\mathbb{R}^n$, such that $a \geq 0$; ψ_0, ψ_u, ρ are nonnegative; ψ_0, ψ_u, ρ are equal to zero outside $\mathcal{X}_0$, $\mathcal{X}_u$, and $\mathcal{X}$, respectively; and

$$\int_{\mathbb{R}^n} d\psi_0 = a,$$

$$\int_{\mathbb{R}^n} d\psi_u = a,$$

$$\nabla \cdot (\rho f) = \psi_0 - \psi_u.$$

We will next show that because of the assumption that there exists a $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x) f(x) < 0$ for all $x \in \mathcal{X}$, we must have $a > 0$. For this, let $\mathcal{L} = (C(\mathcal{X}))^3$, and define

$$\mathcal{L}_1 = \Bigg\{ (h_0, h_u, h) \in \mathcal{L} : h_0 = B_0 - B,\ h_u = B - B_u,\ h = -\frac{\partial B}{\partial x} f \text{ on } \mathcal{X};$$

$$\text{and } (B_0, B_u, B) \in \mathcal{B} \Bigg\},$$

$$\mathcal{L}_2 = \{ (h_0, h_u, h) \in \mathcal{L} : h_0 \geq 0 \text{ on } \mathcal{X}_0,\ h_u \geq 0 \text{ on } \mathcal{X}_u,\ h \geq 0 \text{ on } \mathcal{X} \}.$$

Note in particular that due to the above assumption and the compactness of $\mathcal{X}_0$, $\mathcal{X}_u$, $\mathcal{X}$, we have $\mathcal{L}_1 \cap \text{int}(\mathcal{L}_2) \neq \emptyset$. Now consider $k^* = (a, \tilde{\psi}_0, \tilde{\psi}_u, \tilde{\rho})$ that we have before. Suppose that $a = 0$ and substitute this to (5.4). Then we have a nonzero $(\tilde{\psi}_0, \tilde{\psi}_u, \tilde{\rho}) \in (C(\mathcal{X})^*)^3$, such that

$$\sup_{\ell_1 \in \mathcal{L}_1} \langle (\tilde{\psi}_0, \tilde{\psi}_u, \tilde{\rho}), \ell_1 \rangle \leq \inf_{\ell_2 \in \mathcal{L}_2} \langle (\tilde{\psi}_0, \tilde{\psi}_u, \tilde{\rho}), \ell_2 \rangle.$$

This implies that $\mathcal{L}_1 \cap \text{int}(\mathcal{L}_2) = \emptyset$, which is contradictory to the above. Thus a must be strictly positive. Without loss of generality, assume that k^* is scaled such that $a = 1$. This completes the proof of our lemma. ∎

Next, we will show that the existence of ψ_0, ψ_u, ρ in the conclusion of Lemma 5.2 implies that there exists an unsafe trajectory of the system. Since in this case we have a density function ρ which is in fact a measure, we need a version of the Liouville theorem which applies to measures.

LEMMA 5.3. *Let $f \in C^1(D, \mathbb{R}^n)$, where $D \subseteq \mathbb{R}^n$ is open. For a measurable set Z, assume that $\phi_t(Z)$ is a subset of D for all t between 0 and T. If ρ is a measure of bounded variation on D such that ρ has a compact support and the distributional derivative $\nabla \cdot (\rho f)$ is also a measure of bounded variation with compact support, then*

$$\int_{\phi_T(Z)} d\rho - \int_Z d\rho = \int_0^T \int_{\phi_t(Z)} d(\nabla \cdot (\rho f)) dt.$$

Proof. Choose $\rho_1, \rho_2, \ldots \in C_0^\infty(D)$ such that $\rho_k \to \rho$ in the (weak) topology of distributions. Then also $\nabla \cdot (\rho_k f) \to \nabla \cdot (\rho f)$ in the sense of distributions. In

particular

$$\lim_{k\to\infty}\int_X d|\rho_k-\rho|=0,$$

$$\lim_{k\to\infty}\int_X d|\nabla\cdot(\rho_k f)-\nabla\cdot(\rho f)|=0$$

for every $X\subset D$. The lemma (cf. Lemma 3.1) was proven for the case of smooth ρ in [23], i.e.,

$$\int_{\phi_T(Z)}\rho_k(x)dx-\int_Z\rho_k(x)dx=\int_0^T\int_{\phi_t(Z)}[\nabla\cdot(\rho_k f)(x)]dxdt.$$

So the desired equality is obtained in the limit as $k\to\infty$. □

LEMMA 5.4. *Consider the system $\dot{x}=f(x)$ with $f\in C^1(\mathbb{R}^n,\mathbb{R}^n)$, and let $\mathcal{X}\subset\mathbb{R}^n$, $\mathcal{X}_0\subseteq\mathcal{X}$, $\mathcal{X}_u\subseteq\mathcal{X}$ be compact sets. Suppose there exist measures of bounded variations ψ_0, ψ_u, ρ such that ψ_0,ψ_u,ρ are nonnegative on $\mathbb{R}^n$ and equal to zero outside $\mathcal{X}_0$, $\mathcal{X}_u$, and $\mathcal{X}$, respectively; and $\int_{\mathcal{X}_0}d\psi_0=1$, $\int_{\mathcal{X}_u}d\psi_u=1$, $\nabla\cdot(\rho f)=\psi_0-\psi_u$. Then there exists a $T\geq 0$ and a trajectory $x(t)$ of the system such that $x(0)\in\mathcal{X}_0$, $x(T)\in\mathcal{X}_u$, and $x(t)\in\mathcal{X}$ for all $t\in[0,T]$.*

Proof. Let $X_1,X_2,\ldots\subseteq\mathbb{R}^n$ be a sequence of open sets such that $\mathcal{X}_0\subseteq X_i$ for all i and $\lim_{i\to\infty}X_i=\mathcal{X}_0$. In addition, define the measurable sets

$$Z_i=\bigcup_{x_0\in X_i}\{x\in\mathbb{R}^n : x=\phi_t(x_0)\text{ for some }t\geq 0\}\text{ for }i=1,2,\ldots.$$

By the assertions of the lemma, both ρ and $\nabla\cdot(\rho f)$ are measures with bounded variation and compact support, so we can use Lemma 5.3 and $\nabla\cdot(\rho f)=\psi_0-\psi_u$ to obtain the relation

$$\int_{\phi_t(Z_i)}d\rho-\int_{Z_i}d\rho=\int_0^t\int_{\phi_\tau(Z_i)}d(\psi_0-\psi_u)d\tau$$

for all $t\geq 0$. Since $\rho\geq 0$ and $\phi_t(Z_i)\subseteq Z_i$ for all $t\geq 0$, the left-hand side of the above expression is less than or equal to zero. It follows from $\int_{\mathcal{X}_0}d\psi_0=1$ and $\psi_0\geq 0$ that $\mathcal{X}_u\cap Z_i\neq\emptyset$ for all $i=1,2,\ldots$, for otherwise the right-hand side of the expression can be made strictly greater than zero by taking some $t>0$, and we obtain a contradiction. Since the sets $\mathcal{X}_0$ and $\mathcal{X}_u$ are closed, we conclude that $\phi_T(x_0)\in\mathcal{X}_u$ for some $T\geq 0$ and $x_0\in\mathcal{X}_0$. For our purposes, let T be the first time instance such that $\phi_T(x_0)\in\mathcal{X}_u$.

The case in which $T=0$ is trivial since $\mathcal{X}_0\subseteq\mathcal{X}$. Consider now the case in which $T>0$. We will show that $\phi_t(x_0)\in\mathcal{X}$ for all $t\in[0,T]$ by a contradiction. Suppose to the contrary that there exists $\tilde{T}\in(0,T)$ such that $\phi_{\tilde{T}}(x_0)\notin\mathcal{X}$. Then, for a sufficiently small open neighborhood U of x_0, we have

$$\phi_{\tilde{T}}(U)\subset\mathbb{R}^n\setminus(\mathcal{X}),$$

$$\phi_t(U)\cap\mathcal{X}_u=\emptyset\quad\forall t\in[0,\tilde{T}].$$

Using Lemma 5.3 again we obtain

$$\int_{\phi_{\tilde{T}}(U)}d\rho-\int_U d\rho=\int_0^{\tilde{T}}\int_{\phi_\tau(U)}d(\psi_0-\psi_u)d\tau.$$

Since $\rho = 0$ on $\mathbb{R}^n \setminus (\mathcal{X})$, the first term on the left is equal to zero, and therefore the left-hand side is nonpositive, which leads to a contradiction since the right-hand side is strictly greater than zero. This lets us conclude that $\phi_t(x_0) \in \mathcal{X}$ for all $t \in [0, T]$, thus finishing the proof of the lemma. □

We are now ready to present the proof of the main theorem.

Proof of Theorem 5.1.

($\Rightarrow$): This has been proven in Theorem 3.2.

($\Leftarrow$): This follows from Lemmas 5.2 and 5.4. □

5.1. Some remarks. The result stated in Theorem 5.1 uses the assumption that the following Slater-like condition [6] is fulfilled: there exists a function $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x) f(x) < 0$ for all $x \in \mathcal{X}$. While in the discrete case strong duality holds (and hence so does the necessity of barrier certificates) without such an assumption, its proof depends on a special property of polyhedral convex sets, which does not carry over to the continuous case. Eliminating this condition in the continuous case will presumably require a different proof technique than the one presented in this paper. Nevertheless, there are cases in which the condition is automatically fulfilled—for instance, when the trajectories of the system starting from any $x_0 \in \mathcal{X}$ leave a neighborhood of $\mathcal{X}$ at least once, as shown in the following proposition.

PROPOSITION 5.5. *Consider the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$ and let $\mathcal{X} \subset \mathbb{R}^n$ be a compact set. Suppose there exist an open neighborhood $\tilde{\mathcal{X}}$ of $\mathcal{X}$ and a time instant $T > 0$ such that for all initial conditions $x_0 \in \mathcal{X}$, we have the flow $\phi_t(x_0)$ outside of $\mathrm{cl}(\tilde{\mathcal{X}})$ for some $t \in [0, T]$. Then there exists a function $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x) f(x) < 0$ for all $x \in \mathcal{X}$.*

Proof. Let $\mathcal{Y}$ be an open neighborhood of $\mathcal{X}$ such that its closure is contained in $\tilde{\mathcal{X}}$. In addition, let $\xi \in C^1(\mathbb{R}^n)$ be a nonnegative function such that $\xi(x) = 1$ for all $x \in \mathcal{Y}$ and $\xi(x) = 0$ for all $x \notin \tilde{\mathcal{X}}$; also let $\psi \in C^1(\mathbb{R}^n)$ be a function such that $\psi(x) > 0$ for all $x \in \mathcal{X}$ and $\psi(x) = 0$ for all $x \notin \mathcal{Y}$. Now consider the differential equation $\dot{x} = \xi(x) f(x)$. Denote the flow of $\dot{x} = \xi(x) f(x)$ starting at x_0 by $\tilde{\phi}_t(x_0)$. Modulo a time reparameterization, the flows $\tilde{\phi}_t(x_0)$ and $\phi_t(x_0)$ are identical up to some finite time. Next define

$$\tilde{B}(x_0) = \int_0^\infty \psi(\tilde{\phi}_t(x_0)) dt.$$

For all x_0 in a neighborhood of $\mathcal{X}$, the flow $\tilde{\phi}_t(x_0)$ is outside of $\mathcal{Y}$ for large t and thus by its construction $\psi(\tilde{\phi}_t(x_0))$ is equal to zero for large t and for all such x_0. It follows that $\tilde{B}(x)$ is well defined on a neighborhood of $\mathcal{X}$. The function $\tilde{B}(x)$ is continuously differentiable on $\mathcal{X}$ since both $\psi(x)$ and $\tilde{\phi}_t(x)$ are also continuously differentiable. Taking the total derivative of $\tilde{B}(x)$ with respect to time, we obtain

$$\frac{\partial \tilde{B}}{\partial x}(x) \xi(x) f(x) = -\psi(x),$$

which is strictly less than zero, on $\mathcal{X}$. Finally, recall that on $\mathcal{X}$ we have $\xi(x) = 1$. This completes the proof of the proposition. □

While the above Slater-like condition excludes the possibility of applying Theorem 5.1 when there is, e.g., an equilibrium point in $\mathcal{X}$, analysis can still be performed by excluding a neighborhood of the equilibrium point from $\mathcal{X}$ in the condition (3.4). If the excluded region is either backward or forward invariant, and does not intersect $\mathcal{X}_0$ and $\mathcal{X}_u$, then the safety criterion (5.1)–(5.3) will still apply in terms of the original sets.

Finally, note also that when *all* the connected components of $\mathbb{R}^n \setminus \mathcal{X}$ are either forward or backward invariant, an even stronger safety criterion can be obtained, as in the following proposition.

PROPOSITION 5.6. *Let the system $\dot{x} = f(x)$ with $f \in C^1(\mathbb{R}^n, \mathbb{R}^n)$ and the compact sets $\mathcal{X}_0 \subset \mathbb{R}^n$, $\mathcal{X}_u \subset \mathbb{R}^n$ be given, with $0 \notin \mathcal{X}_0 \cup \mathcal{X}_u$. Suppose that the origin is a globally asymptotically stable equilibrium of the system with a global strict Lyapunov function $V(x)$.*[4] *Let $\epsilon_1 = \min_{x \in \mathcal{X}_0 \cup \mathcal{X}_u} V(x)$ and $\epsilon_2 = \max_{x \in \mathcal{X}_0 \cup \mathcal{X}_u} V(x)$. Then there exists a function $B \in C^1(\mathbb{R}^n)$ satisfying*

$$B(x) \leq 0 \quad \forall x \in \mathcal{X}_0, \tag{5.5}$$

$$B(x) > 0 \quad \forall x \in \mathcal{X}_u, \tag{5.6}$$

$$\frac{\partial B}{\partial x}(x) f(x) \leq 0 \quad \forall x \in \{x \in \mathbb{R}^n : \epsilon_1 \leq V(x) \leq \epsilon_2\} \tag{5.7}$$

if and only if there exists no trajectory $x(t)$ of the system such that

$$x(0) \in \mathcal{X}_0, \tag{5.8}$$

$$x(T) \in \mathcal{X}_u \text{ for some } T \geq 0. \tag{5.9}$$

Proof. Define $\mathcal{X} = \{x \in \mathbb{R}^n : \epsilon_1 \leq V(x) \leq \epsilon_2\}$. In this case, the existence of a function $\tilde{B} \in C^1(\mathbb{R}^n)$ such that $\frac{\partial \tilde{B}}{\partial x}(x) f(x) < 0$ for all $x \in \mathcal{X}$ is guaranteed by Proposition 5.5, and even the Lyapunov function $V(x)$ can be used as $\tilde{B}(x)$. By Theorem 5.1, there exists a function $B \in C^1(\mathbb{R}^n)$ satisfying (5.5)–(5.7) if and only if there exists no trajectory $x(t)$ of the system such that $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_u$ for some $T \geq 0$, and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$.

Since the connected components of $\mathbb{R}^n \setminus \mathcal{X}$ are either forward or backward invariant, however, there can be no trajectory $x(t)$ of the system and time instants T_1, T_2, T_3 such that $T_1 < T_2 < T_3$, $x(T_1) \in \mathcal{X}$, $x(T_2) \in \mathbb{R}^n \setminus \mathcal{X}$, and $x(T_3) \in \mathcal{X}$. This combined with the fact that $\mathcal{X}_0, \mathcal{X}_u \subseteq \mathcal{X}$ implies that the set of trajectories satisfying $x(0) \in \mathcal{X}_0$, $x(T) \in \mathcal{X}_u$ for some $T \geq 0$ and $x(t) \in \mathcal{X}$ for all $t \in [0, T]$ is the same as the set of trajectories satisfying (5.8)–(5.9), and therefore the statement of the proposition follows. ∎

6. Conclusions. In the previous sections, we have used insights from the linear programming duality appearing in the shortest path problem and the concept of density function to formulate a convex program for reachability, which together with a convex program for safety verification using barrier certificates proposed in an earlier work form a pair of weak alternatives for safety and reachability verification. We have additionally shown that other temporal properties such as eventuality and avoidance can also be verified via convex programming and have presented convex programs to do so. This opens the possibility of performing the verification using convex optimization. In particular, sum of squares programming can be used for this purpose when the vector field of the system is polynomial and the sets are semialgebraic.

We have further commented on the use of this methodology for worst-case verification or controller synthesis. It was pointed out that the convex programs can be combined to verify properties such as reachability–safety and eventuality–safety. Some

[4] That is, $V \in C^1(\mathbb{R}^n)$ is radially unbounded, $V(x) > 0$ for all $x \neq 0$, and $\frac{\partial V}{\partial x}(x) f(x) < 0$ for all $x \neq 0$.

examples have been presented for illustration. At the end of the paper, a converse theorem in safety verification using barrier certificates was proven.

Even though the present tests are aimed for continuous systems, they are useful for constructing discrete abstractions of hybrid systems. In addition, we expect that all of them can also be extended to handle hybrid systems directly, using an approach similar to the one presented in [21].

LOCAL EXACT BOUNDARY CONTROLLABILITY FOR NONLINEAR WAVE EQUATIONS*

YI ZHOU† AND ZHEN LEI‡

Abstract. This paper deals with the local exact boundary controllability for dynamics governed by nonlinear wave equations, subject to Dirichlet, Neumann, or any other kind of boundary controls which result in well-posedness of the corresponding initial-boundary value problem. A constructive method is developed. The local exact boundary controllability for semilinear wave equations is constructed in the case of both three (odd) and two (even) space dimensions, and the boundary control is time optimal when the space dimension is three (odd). Especially, the local exact boundary controllability is established for quasi-linear wave equations in several space dimensions by using the constructive method.

Key words. local exact boundary controllability, semilinear wave equations, quasi-linear wave equations, time optimal

AMS subject classifications. 93B05, 35L05

1. Introduction.

The problems of controllability are clearly of significant practical interest. There is an extremely large number of publications on these topics. Some classical references are Lions [15] and Russell [17].

The aim of this paper is to study the local exact boundary controllability for semilinear and quasi-linear wave equations in several space dimensions. The problem can be described as follows: Let Ω_0 be a bounded open subset of $\mathbb{R}^n$ ($n = 1, 2, 3$ in the applications) with a smooth boundary Γ. The equations under consideration take the form

$$\Box u = F(t, x, u, u'), \quad 0 < t < T,\ x \in \Omega_0, \tag{1.1}$$

in the semilinear case, and the form

$$\Box u = G(t, x, u, u', u''), \quad 0 < t < T,\ x \in \Omega_0, \tag{1.2}$$

in the quasi-linear case, where $\Box = \partial_t^2 - \Delta$ is the wave operator, the Laplace Δ is taken with respect to the spatial variables $x = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n$, and F and G are smooth functions of their arguments, vanishing together with their first-order derivatives with respect to (u, u') or (u, u', u'') at $(u, u') = 0$ or $(u, u', u'') = 0$; namely,

the following holds in a neighborhood of $(u, u') = 0$ or $(u, u', u'') = 0$:

$$\begin{cases} F(t,x,u,u') = O\big(|u|^2 + |u'|^2\big), \\ G(t,x,u,u',u'') = O\big(|u|^2 + |u'|^2 + |u''|^2\big), \end{cases} \tag{1.3}$$

and $u' = (u_t, \nabla u)$, $u'' = (u_{tt}, \nabla u_t, \nabla^2 u)$ are the first-order and second-order space-time derivatives of $u(t,x)$. Without loss of generality, we shall assume that

$$G(t,x,u,u',u'') = g_{i\alpha}(t,x,u,u_t,\nabla u)\partial^2_{i\alpha} u + F(t,x,u,u'), \tag{1.4}$$

where $g_{i\alpha}$ are smooth functions with

$$g_{i\alpha}(t,x,0,0,0) = 0 \tag{1.5}$$

for all $1 \le i \le n$ and $0 \le \alpha \le n$. We point out here that in what follows, Latin indices $i, j, k, \dots$ range over $1, 2, \dots, n$, Greek indices $\alpha, \beta, \gamma, \dots$ over $0, 1, 2, \dots, n$, and summations over repeated indices are always well understood.

Consider the initial data

$$u(0,x) = f_0(x), \quad u_t(0,x) = f_1(x), \quad x \in \Omega_0, \tag{1.6}$$

and the final data

$$u(T,x) = g_0(x), \quad u_t(T,x) = g_1(x), \quad x \in \Omega_0, \tag{1.7}$$

with $f_0, g_0 \in H^{s+1}(\Omega_0)$ and $f_1, g_1 \in H^s(\Omega_0)$, $H^s(\Omega_0)$ being the standard Sobolev space of order s. We impose any one of the following boundary conditions for $0 \le t \le T$ and $x \in \partial\Omega_0$:

$$\begin{cases} u = h(t,x) & \text{of Dirichlet type,} \\ \frac{\partial u}{\partial n} = h(t,x) & \text{of Neumann type,} \\ \frac{\partial u}{\partial n} + bu = h(t,x) & \text{of the third type,} \\ \frac{\partial u}{\partial n} + \overline{b} u_t = h(t,x) & \text{of the dissipative type,} \end{cases} \tag{1.8}$$

where b and $\overline{b}$ are given positive constants.

Then the problem of exact boundary controllability for (1.1) or (1.2) is stated as follows: given $T > 0$, is it possible, for any initial data (f_0, f_1) and final data (g_0, g_1), to find an appropriate boundary control $h(t,x)$, such that the solution $u(t,x)$ of the semilinear system (1.1) with (1.6) and (1.8) (the quasi-linear system (1.2) with (1.6) and (1.8), respectively) satisfies the final state (1.7)?

This problem has received considerable attention in the literature, with numerous contributions over the past several decades, by using the so-called Hilbert uniqueness method introduced by Lions [14]. When $F = G \equiv 0$, the problem is by now well understood; for example, see [15, 17] and their references. In the case of linear wave equations with variable coefficients, there are also the works by Bardos, Lebeau, and Rauch [1], Cavalcanti [2], Tataru [18], and Yao [21]. For the semilinear case, there are plenty of results when $F = F(u)$ [8, 24, 25]. These works succeed in the framework of weak solutions such that the Hilbert uniqueness method can work. In the framework of classical solutions, Li [10] and Li et al. [12, 13] recently studied local exact boundary controllability for one-dimensional quasi-linear wave equations and hyperbolic systems with both one-sided and two-sided boundary controls. Yu [23] also

studied local exact boundary controllability for higher-order one-dimensional quasilinear hyperbolic equations. However, even in the weak sense, to our knowledge few results are known for the semilinear wave equations of the form (1.1) and the quasilinear wave equations of the form (1.2) in the multidimensional case. After completion of this work, we discovered that similar results were announced in Yao [22], a recently completed manuscript dealing with exact boundary controllability for quasi-linear wave equations under some geometrical conditions on the domain. His proof relies on the observability inequalities.

Our results are obtained in the framework of the classical solutions of wave equations. A constructive method is developed. We point out that the methods presented here are completely different from the recent work by Yao [22]. In the case of semilinear wave equations in three (odd) space dimensions, the local exact boundary controllability is established and the boundary control is time optimal. The proof relies on the so-called Huygens principle for the linear wave equation, which had been used by Russell [17] to treat the exact boundary controllability in the linear case. In the case of semilinear wave equations in two (even) space dimensions, we proved the fact that the energy is linearly dissipative when one adds a boundary condition of dissipative type by using Morawetz energy estimates. Then the desired local exact boundary controllability is established. We point out here that a similar idea and results have appeared in [17] in the linear case. The quasi-linear case is similar to the even space–dimensional semilinear case, but it is much more complicated and difficult. The proof relies on an exponentially dissipative energy estimate by using a shift technique, which reveals the underlying conservation law governing the system. In what follows, for convenience, the proofs will be illustrated in the cases of two and three space dimensions. However, the results presented here are also valid for general multidimensional cases.

Without loss of generality, we assume that

$$\Omega_0 \subset\subset \mathbb{B}_\rho, \tag{1.9}$$

where $\mathbb{B}_\rho$ is a ball of radius $\rho > 0$ centered at the origin. Define

$$R(T) = \Omega_0 \times (0, T).$$

The main result on the local exact boundary controllability for the three-dimensional semilinear wave equations can be stated as follows.

THEOREM 1.1. *Assume that $n = 3$ and F is a smooth function with respect to its arguments. Assume, furthermore, that* (1.3) *and* (1.9) *hold. Let $T > 2\rho$. Then, for any given initial data (f_0, f_1) and final data (g_0, g_1) with $f_0, g_0 \in H^{s+1}(\Omega_0)$, $f_1, g_1 \in H^s(\Omega_0)$, $s \geq 2$, there exist boundary controls h such that the mixed initial-boundary value problem* (1.1) *and* (1.6), (1.8) *admits a unique $\cap_{j=0}^{s+1} C^j\big([0,T]; H^{s+1-j}(\Omega_0)\big)$ solution $u = u(t,x)$ on the domain $R(T)$ satisfying the final condition* (1.7), *provided that*

$$\|(f_0, g_0)\|_{H^{s+1}(\Omega_0)} + \|(f_1, g_1)\|_{H^s(\Omega_0)} \leq \varepsilon_1, \tag{1.10}$$

where ε_1 is a sufficiently small positive constant.

REMARK 1.2. *The control time $T > 2\rho$ can be replaced by $T > \mathrm{diam}(\Omega_0)$ in Theorem* 1.1. *See also Remark* 2.2.

In the case of semilinear wave equations in two space dimensions, the boundary control is obtained for an appropriately large time.

THEOREM 1.3. *Assume that $n = 2$ and F is a smooth function with respect to its arguments. Assume, furthermore, that* (1.3) *and* (1.9) *hold. Then, for any given initial data (f_0, f_1) and final data (g_0, g_1) with $f_0, g_0 \in H^{s+1}(\Omega_0)$, $f_1, g_1 \in H^s(\Omega_0)$, $s \geq 2$, there exist boundary controls h such that the mixed initial-boundary value problem* (1.1) *and* (1.6), (1.8) *admit a unique $\cap_{j=0}^{s+1} C^j\big([0,T]; H^{s+1-j}(\Omega_0)\big)$ solution $u = u(t,x)$ on the domain $R(T)$ satisfying the final condition* (1.7), *provided that T is a big enough constant and*

$$\|(f_0, g_0)\|_{H^{s+1}(\Omega_0)} + \|(f_1, g_1)\|_{H^s(\Omega_0)} \leq \varepsilon_2, \tag{1.11}$$

where ε_2 is a sufficiently small positive constant.

REMARK 1.4. *There are results in the literature (see, e.g.,* [15, 7, 16]*) where the control time $T > \mathrm{diam}(\Omega_0)$ for a class of linear wave equations. Unfortunately, we cannot get this kind of sharp result for nonlinear wave equations.*

REMARK 1.5. *For semilinear wave equations in n space dimensions, the results in Theorems* 1.1 *and* 1.3 *are also valid if integer $s > \frac{n}{2}$. This amount of regularity is required for the classical local existence theorem of semilinear wave equations.*

Moreover, the local exact boundary controllability is also established for the quasi-linear wave equation in several space dimensions.

THEOREM 1.6. *Assume that $n = 2$ or 3 and G is a smooth function with respect to its arguments. Assume, furthermore, that* (1.9) *and* (1.4)–(1.5) *hold. Then, for any given initial data (f_0, f_1) and final data (g_0, g_1) with $f_0, g_0 \in H^{s+1}(\Omega_0)$, $f_1, g_1 \in H^s(\Omega_0)$, $s \geq 3$, there exist boundary controls h such that the mixed initial-boundary value problem* (1.2) *and* (1.6), (1.8) *admits a unique $\cap_{j=0}^{s+1} C^j\big([0,T]; H^{s+1-j}(\Omega_0)\big)$ solution $u = u(t,x)$ on the domain $R(T)$ satisfying the final condition* (1.7), *provided that T is a big enough constant and*

$$\|(f_0, g_0)\|_{H^{s+1}(\Omega_0)} + \|(f_1, g_1)\|_{H^s(\Omega_0)} \leq \varepsilon_3, \tag{1.12}$$

where ε_3 is a sufficiently small positive constant.

REMARK 1.7. *For quasi-linear wave equations in n space dimensions, the results in Theorem* 1.6 *are also valid if integer $s > \frac{n}{2} + 1$. This amount of regularity is required for the classical local existence theorem of quasi-linear wave equations.*

We point out here that the boundary control is not unique. By way of our construction, it does not matter what kind of boundary condition in (1.8) we use as long as the initial-boundary value problem is well-posed. However, the type of boundary condition may be relevant for other different approaches (especially when the control is assumed to be applied only on a part of the boundary, in which case the type of boundary control may lead to differences; for an example, see Lasiecka, Triggiani, and Zhang [9]). In what follows, we will concentrate on boundary controls of Dirichlet type.

The paper is organized as follows: Section 2 is devoted to establishing exact boundary controllability for linear wave equations. In the case of three space dimensions, one can utilize the so-called Huygens principle and then get time-optimal control. In the case of two space dimensions, one can construct the desired controllability by using Morawetz energy estimates, but one does not know how large the control time is. The results are then extended to the semilinear cases by the contraction mapping principle in section 3. The proofs of Theorems 1.1 and 1.3 can be found there. In section 4, the exponentially dissipative energy estimates of solutions for quasi-linear wave equations are established, and then the local exact boundary controllability is obtained for quasi-linear wave equations in both two and three space dimensions using a direct constructive method.

2. Exact boundary controllability for linear wave equations. In this section we investigate the controllability problem for the linear wave equation

$$\Box u = 0, \quad 0 \le t \le T,\ x \in \Omega_0, \tag{2.1}$$

with initial data (1.6) and final data (1.7), and boundary condition of Dirichlet type

$$u|_{\partial\Omega_0} = h, \quad 0 \le t \le T,\ x \in \partial\Omega_0. \tag{2.2}$$

We point out here that exact boundary controllability for linear wave equations has been studied by many authors and is now well known (see, e.g., [1, 16, 17, 15]). We study exact boundary controllability for linear wave equations in order to establish a basis for semilinear and quasi-linear wave equations.

Without loss of generality, we can assume that $\rho = 1$ and

$$\Omega_0 \subset\subset \mathbb{B}_1.$$

In fact, if $\rho \neq 1$, we can define $\widehat{u}(t,x) = u(\rho t, \rho x)$, $\widehat{f}_0(x) = f_0(\rho x)$, $\widehat{f}_1(x) = f_1(\rho x)$, $\widehat{g}_0(x) = g_0(\rho x)$, $\widehat{g}_1(x) = g_1(\rho x)$, and then consider the controllability problems for the $\widehat{u}$ system with initial data $\widehat{f}_0, \widehat{f}_1$ and final data $\widehat{g}_0, \widehat{g}_1$. Then we can always extend the functions f_0, g_0, f_1, g_1 to $\widetilde{f}_0, \widetilde{g}_0, \widetilde{f}_1, \widetilde{g}_1$ such that

$$\operatorname{supp}(\widetilde{f}_0, \widetilde{g}_0, \widetilde{f}_1, \widetilde{g}_1) \subset\subset \mathbb{B}_1 \tag{2.3}$$

and

$$\begin{cases} \|\widetilde{f}_0\|_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{g}_0\|_{H^{s+1}(\mathbb{B}_1)} \le C_s\big(\|f_0\|_{H^{s+1}(\Omega_0)} + \|g_0\|_{H^{s+1}(\Omega_0)}\big), \\ \|\widetilde{f}_1\|_{H^{s}(\mathbb{B}_1)} + \|\widetilde{g}_1\|_{H^{s}(\mathbb{B}_1)} \le C_s\big(\|f_1\|_{H^{s}(\Omega_0)} + \|g_1\|_{H^{s}(\Omega_0)}\big) \end{cases} \tag{2.4}$$

for some constants $C_s > 0$ and $s \ge 0$ (for example, see [4]). In what follows, we will use the same extension several times and always denote the extension operator by $\widetilde{\ }: f \longrightarrow \widetilde{f}$.

In three space dimensions, with the aid of the so-called Huygens principle, it is rather easy to construct the exact boundary control for the linear wave equation, and the control time is optimal in the sense of $T > \operatorname{diam}(\Omega_0)$. But in two space dimensions, the Huygens principle is invalid, the exact boundary controllability is not trivial, and we do not know how large the control time T is based on our methods. We begin with the easier case of three space dimensions.

2.1. Exact boundary controllability for linear wave equations in three space dimensions. First of all, we consider the Cauchy problem

$$\begin{cases} \Box v = 0, \quad 0 \le t \le T, \quad x \in \mathbb{R}^3; \\ v(0,x) = \widetilde{f}_0, \quad v_t(0,x) = \widetilde{f}_1, \quad x \in \mathbb{R}^3, \end{cases} \tag{2.5}$$

and the inverted Cauchy problem from some positive time T to 0,

$$\begin{cases} \Box w = 0, \quad 0 \le t \le T, \quad x \in \mathbb{R}^3; \\ w(T,x) = \widetilde{g}_0, \quad w_t(T,x) = \widetilde{g}_1, \quad x \in \mathbb{R}^3. \end{cases} \tag{2.6}$$

By the Huygens principle, we have that

$$\begin{cases} v(T,x) = v_t(T,x) = 0, \\ w(0,x) = w_t(0,x) = 0, \end{cases} \tag{2.7}$$

provided $T > 2$ and $x \in \mathbb{B}_1$.

Thus, if one defines

$$\mathcal{L}\big(\widetilde{f}_0, \widetilde{g}_0, \widetilde{f}_1, \widetilde{g}_1\big) = v + w, \quad 0 \le t \le T,\ x \in \Omega_0, \tag{2.8}$$

then it is obvious that $u = \mathcal{L}\big(\widetilde{f}_0, \widetilde{g}_0, \widetilde{f}_1, \widetilde{g}_1\big)$ solves (2.1) in $R(T)$ and verifies the initial and final data (1.6) and (1.7) for $x \in \Omega_0$. Consequently,

$$h = u|_{\partial\Omega_0} \tag{2.9}$$

is the boundary control we want. We point out here that a similar method was used by Russell [16, 17] in the seventies.

Summing up, we have the following lemma.

LEMMA 2.1. *Consider the linear wave equation* (2.1) *in three space dimensions. Then, for any given initial data* (f_0, f_1) *and final data* (g_0, g_1) *with* $f_0, g_0 \in H^{s+1}(\Omega_0)$, $f_1, g_1 \in H^s(\Omega_0)$, $s \ge 1$, *there exist boundary controls* h *such that the mixed initial-boundary value problem* (2.1), (2.2) *and* (1.6) *admits a unique* $\cap_{j=0}^{s+1} C^j\big([0,T]; H^{s+1-j}(\Omega_0)\big)$ *solution* $u = u(t,x)$ *on the domain* $R(T)$ *which arrives at the final condition* (1.7), *provided* $T > 2$. *Moreover, we have*

$$\sup_{0\le t\le T} \sum_{j=0}^{s+1} \|\partial_t^j u\|^2_{H^{s+1-j}(\Omega_0)} \le CT\Big(\|(\widetilde{f}_0, \widetilde{g}_0)\|^2_{H^{s+1}(\mathbb{B}_1)} + \|(\widetilde{f}_1, \widetilde{g}_1)\|^2_{H^s(\mathbb{B}_1)}\Big), \tag{2.10}$$

where C *is a positive constant independent of* T, u, *and the initial and final data.*

Proof. It remains to prove (2.10). By energy estimates, it is rather easy to see that

$$\sum_{j+k=0}^{s} \frac{d}{dt}\Big(\|\nabla^k \partial_t^{j+1} v\|^2_{L^2(\mathbb{R}^3)} + \|\nabla\nabla^k \partial_t^j v\|^2_{L^2(\mathbb{R}^3)}\Big) = 0,$$

which results in

$$\sum_{j=1}^{s+1} \|\partial_t^j v\|^2_{H^{s+1-j}(\mathbb{R}^3)} + \|\nabla v\|^2_{H^s(\mathbb{R}^3)} \le C\big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\big).$$

On the other hand, by using the identity

$$v(t,x) = \widetilde{f}_0 + \int_0^t v_s(s,x)ds,$$

we have

$$\|v\|^2_{L^2(\mathbb{R}^3)} \le 2\|\widetilde{f}_0\|^2_{L^2(\mathbb{R}^3)} + CT \sup_{0\le t\le T} \|v_t\|^2_{L^2(\mathbb{R}^3)} \le CT\Big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\Big).$$

Consequently, we have

$$\sum_{j=0}^{s+1} \|\partial_t^j v\|^2_{H^{s+1-j}(\mathbb{R}^3)} \le CT\Big(\|(\widetilde{f}_0, \widetilde{g}_0)\|^2_{H^{s+1}(\mathbb{B}_1)} + \|(\widetilde{f}_1, \widetilde{g}_1)\|^2_{H^s(\mathbb{B}_1)}\Big).$$

Obviously, the same result holds for w. Thus, (2.10) is proved. ∎

REMARK 2.2. *It is obvious that the result in Lemma* 2.1 *is also valid by replacing* $\mathbb{B}_1$ *by any open, connected set* $\Omega_1 \supset \Omega_0$*; then* $T > 2$ *can be replaced by* $T > \mathrm{diam}(\Omega_0)$ *by choosing* Ω_1 *such that the distance of* $\partial\Omega_1$ *and* $\partial\Omega_0$ *is small enough. Thus, the boundary controls for three-dimensional semilinear wave equations in section* 3 *are in fact time-optimal in the sense that* $T > \mathrm{diam}(\Omega_0)$*. In section* 3*, we will present the results in two- and three-dimensional cases in the uniform way since we do not pursue the time-optimal controls in the two-dimensional case.*

2.2. Exact boundary controllability for linear wave equations in two space dimensions. Now we shall construct the boundary controls for the linear wave equation (2.1) in two space dimensions. There are many well-known results on this subject, and time-optimal controllability especially has also been obtained for a class of hyperbolic equations (see, e.g., [7]). The result we present below is not time-optimal. However, our method has the flexibility to work in the quasi-linear case.

Compared to three space dimensions, the difficulty in two space dimensions lies in the invalidity of the Huygens principle. The proof relies first on the linearly dissipative energy estimates of solutions for a mixed initial-boundary value linear wave equation with a dissipative boundary condition, and then on a constructive method.

First of all, we focus our attention on the following initial-boundary value problem with a dissipative boundary condition:

$$\begin{cases} \Box\psi = 0, \quad 0 \le t \le T, \quad x \in \mathbf{B}_1, \\ \psi_t + \psi_r = 0, \quad 0 \le t \le T, \quad x \in \mathbf{S}^1, \\ \psi(0,x) = \widetilde{f}_0, \quad \psi_t(0,x) = \widetilde{f}_1, \quad x \in \mathbf{B}_1, \end{cases} \tag{2.11}$$

where ψ_r is the outer normal derivative of ψ on $\mathbf{S}^1$.

For system (2.11), we desire to establish the following lemma. See also [1], where similar results are obtained even for linear wave equations with variant coefficients. However, the methods we use below can be generalized to nonlinear cases.

LEMMA 2.3. *There exists a constant* $T_0 > 0$*, such that every solution* $\psi(t,x)$ *of system* (2.11) *satisfies*

$$\|\nabla\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)} + \|\psi_t(T,\cdot)\|^2_{L^2(\mathbb{B}_1)} \le \lambda_0\Big(\|\widetilde{f}_0\|^2_{H^1(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{L^2(\mathbb{B}_1)}\Big) \tag{2.12}$$

for $T > T_0$ *and some* $\lambda_0 \in (0,1)$*. Thus, we have*

$$\|\nabla\psi(T,\cdot)\|^2_{L^2(\Omega_0)} + \|\psi_t(T,\cdot)\|^2_{L^2(\Omega_0)} \le \lambda_0\Big(\|\widetilde{f}_0\|^2_{H^1(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{L^2(\mathbb{B}_1)}\Big) \tag{2.13}$$

for $T > T_0$ *and some* $\lambda_0 \in (0,1)$*.*

Proof. Let $\psi(t,x)$ be the solution of system (2.11). First of all, we claim that

$$\int_{\mathbb{B}_1} \psi_t(t,x)dx + \int_{\mathbb{S}^1} \psi(t,y)d\sigma_y = \int_{\mathbb{B}_1} \widetilde{f}_1 dx. \tag{2.14}$$

To carry out the details, let us integrate the linear wave equation with respect to x on the unit ball $\mathbb{B}_1$ to yield

$$\frac{d}{dt}\int_{\mathbb{B}_1} \psi_t dx - \int_{\mathbb{S}^1} \psi_r d\sigma_y = 0,$$

where we used the so-called Green's formula. By using the boundary condition in (2.11), we get

$$\frac{d}{dt}\Big(\int_{\mathbb{B}_1}\psi_t dx+\int_{\mathbb{S}^1}\psi d\sigma_y\Big)=0. \tag{2.15}$$

Noting (2.3), we have

$$\int_{\mathbb{S}^1}\widetilde{f}_0 d\sigma_y=0.$$

Then we have proved the claim (2.14).

Let us continue the proof of Lemma 2.3 under (2.14). By taking the L^2 inner product of the linear wave equation in system (2.11) with ψ_t, one obtains the following energy estimate:

$$\frac{1}{2}\frac{d}{dt}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)-\int_{\mathbb{S}^1}\psi_t\psi_r d\sigma_y=0.$$

With the aid of the boundary condition in (2.11), we have

$$\frac{1}{2}\frac{d}{dt}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)+\|\psi_t\|^2_{L^2(\mathbb{S}^1)}=0, \tag{2.16}$$

which implies that

$$\begin{aligned}&\|\nabla\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(T,\cdot)\|^2_{L^2(\mathbb{B}_1)}\\&\le\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\\&\le\|\nabla\psi(0,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(0,\cdot)\|^2_{L^2(\mathbb{B}_1)}\end{aligned} \tag{2.17}$$

for $0\le t\le T$.

Next we do the following energy estimate of Morawetz type. By taking the L^2 inner product of the linear wave equation in system (2.11) with $x\cdot\nabla\psi$, one gets

$$\begin{aligned}&\frac{d}{dt}\int_{\mathbb{B}_1}(x\cdot\nabla\psi)\psi_t dx-\int_{\mathbb{B}_1}x\cdot\nabla\frac{|\psi_t|^2}{2}dx\\&=\int_{\mathbb{B}_1}\nabla_k\big(\nabla_k\psi x\cdot\nabla\psi\big)-|\nabla\psi|^2-x\cdot\nabla\frac{|\nabla\psi|^2}{2}dx.\end{aligned} \tag{2.18}$$

Thus, by using Green's formula and integration by parts, one has

$$\begin{aligned}&\frac{d}{dt}\int_{\mathbb{B}_1}(x\cdot\nabla\psi)\psi_t dx+\frac{1}{2}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)\\&\le-\frac{1}{2}\int_{\mathbb{B}_1}\big(|\psi_t|^2-|\nabla\psi|^2\big)dx+\|\psi_t\|^2_{L^2(\mathbb{S}^1)}-\frac{1}{2}\|\Omega\psi\|^2_{L^2(\mathbb{S}^1)},\end{aligned} \tag{2.19}$$

where we used the boundary condition in system (2.11) and the following decomposition of spatial derivatives into radial and angular components:

$$\nabla=\frac{x}{r}\partial_r-\frac{x\wedge\Omega}{r^2}. \tag{2.20}$$

On the other hand, a straightforward calculation shows that

$$\begin{aligned}(2.21)\qquad &\int_{\mathbb{B}_1}\big(|\psi_t|^2-|\nabla\psi|^2\big)dx\\ &=\frac{d}{dt}\int_{\mathbb{B}^1}\psi\psi_t dx-\int_{\mathbb{B}_1}\psi\Delta\psi+|\nabla\psi|^2dx\\ &=\frac{d}{dt}\int_{\mathbb{B}_1}\psi\psi_t dx-\frac{1}{2}\int_{\mathbb{S}^1}\partial_r\psi^2 d\sigma_y\\ &=\frac{d}{dt}\Big(\int_{\mathbb{B}_1}\psi\psi_t dx+\frac{1}{2}\int_{\mathbb{S}^1}\psi^2 d\sigma_y\Big).\end{aligned}$$

Combining (2.19) and (2.21), and with the aid of (2.16), we arrive at

$$\begin{aligned}(2.22)\qquad &\frac{1}{2}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)+\frac{1}{2}\|\Omega\psi\|^2_{L^2(\mathbb{S}^1)}\\ &\le\|\psi_t\|^2_{L^2(\mathbb{S}^1)}-\frac{d}{dt}\Big[\int_{\mathbb{B}_1}\Big(\frac{1}{2}\psi+x\cdot\nabla\psi\Big)\psi_t dx+\frac{1}{4}\|\psi\|^2_{L^2(\mathbb{S}^1)}\Big]\\ &=-\frac{d}{dt}\Big[\int_{\mathbb{B}_1}\Big(\frac{1}{2}\psi+x\cdot\nabla\psi\Big)\psi_t dx+\frac{1}{4}\|\psi\|^2_{L^2(\mathbb{S}^1)}\\ &\qquad+\frac{1}{2}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)\Big].\end{aligned}$$

To estimate the right side of (2.22), we calculate

$$\begin{aligned}(2.23)\qquad &\Big|\int_{\mathbb{B}_1}\Big(\frac{1}{2}\psi+x\cdot\nabla\psi\Big)\psi_t dx\Big|\\ &\le\frac{1}{2}\int_{\mathbb{B}_1}\psi_t^2dx+\frac{1}{2}\int_{\mathbb{B}_1}\Big[\frac{1}{4}\psi^2+(x\cdot\nabla\psi)^2+\frac{1}{2}x\cdot\nabla\psi^2\Big]dx\\ &\le\frac{1}{2}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)\\ &\quad+\frac{1}{4}\|\psi\|^2_{L^2(\mathbb{S}^1)}-\frac{3}{8}\|\psi\|^2_{L^2(\mathbb{B}_1)}.\end{aligned}$$

Noting (2.17), and with the aid of (2.23), we integrate (2.22) with respect to t from 0 to T, which yields

$$\begin{aligned}(2.24)\qquad &\frac{T}{2}\Big(\|\nabla\psi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)\\ &\le\Big|\int_{\mathbb{B}_1}\Big(\frac{n-1}{2}\psi+x\cdot\nabla\psi\Big)\psi_t dx\Big|_{t=0}+\frac{1}{4}\|\psi(0,\cdot)\|^2_{L^2(\mathbb{S}^1)}\\ &\quad+\Big|\int_{\mathbb{B}_1}\Big(\frac{n-1}{2}\psi+x\cdot\nabla\psi\Big)\psi_t dx\Big|_{t=T}-\frac{1}{4}\|\psi(T,\cdot)\|^2_{L^2(\mathbb{S}^1)}\\ &\quad+\Big(\|\nabla\psi(0,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(0,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)\\ &\le 2\Big(\|\nabla\psi(0,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\|\psi_t(0,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big)+\frac{1}{2}\|\psi(0,\cdot)\|^2_{L^2(\mathbb{S}^1)}.\end{aligned}$$

In view of the so-called Poincaré inequality, we have

$$(2.25)\qquad \|\psi(0,\cdot)\|_{L^2(\mathbb{B}_1)}\le C\Big[\|\nabla\psi(0,\cdot)\|_{L^2(\mathbb{B}_1)}+\Big|\int_{\mathbb{S}^1}\psi(0,\cdot)dx\Big|\Big].$$

Thus, by (2.14), (2.25), and the trace theorem, it follows that

$$\begin{cases} \|\psi(0,\cdot)\|_{L^2(\mathbb{B}_1)} \le C\big(\|\nabla \widetilde{f}_0\|_{L^2(\mathbb{B}_1)} + \|\widetilde{f}_1\|_{L^2(\mathbb{B}_1)}\big), \\ \|\psi(0,\cdot)\|_{L^2(\mathbb{S}^1)} \le C\big(\|\nabla \widetilde{f}_0\|_{L^2(\mathbb{B}_1)} + \|\widetilde{f}_1\|_{L^2(\mathbb{B}_1)}\big). \end{cases} \tag{2.26}$$

Finally, combining (2.24) and (2.26), we arrive at

$$T\Big(\|\nabla\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)} + \|\psi_t(T,\cdot)\|^2_{L^2(\mathbb{B}_1)}\Big) \le C\Big(\|\widetilde{f}_0\|^2_{H^1(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{L^2(\mathbb{B}_1)}\Big).$$

We find that (2.12) is satisfied, provided $T_0 = 2C$ and $\lambda_0 = \frac{1}{2}$. Then the proof of Lemma 2.3 is complete. □

REMARK 2.4. *It is obvious that the conclusion in Lemma* 2.3 *is also valid for arbitrary time $T > 0$ if λ_0 is replaced by $\frac{C_0}{T}$ for some constant $C_0 > 0$.*

We also need the following improved regularity.

THEOREM 2.5. *Consider the initial-boundary value problem* (2.11). *Suppose that $f_0 \in H^{s+1}(\Omega_0)$, $f_1 \in H^s(\Omega_0)$, $s \ge 1$. Then there exists a positive constant T_1, such that if $T \ge T_1$, then*

$$\|\nabla\psi(T,\cdot)\|^2_{H^s(\Omega_0)} + \sum_{j=1}^{s+1} \|\partial_t^j \psi(T,\cdot)\|^2_{H^{s+1-j}(\Omega_0)} \le \lambda_1\big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\big) \tag{2.27}$$

holds for some $\lambda_1 \in (0,1)$.

Proof. This follows from Lemma 2.3 and the interior elliptic estimates. In fact, applying ∂_t^l, $1 \le l \le s$, to system (2.11) and then using Lemma 2.3, we deduce that

$$\begin{aligned} &\|\partial_t^{s+1}\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)} + \sum_{j=1}^{s} \|\partial_t^j\psi(T,\cdot)\|^2_{H^1(\mathbb{B}_1)} + \|\nabla\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)} \\ &\le C\lambda_0\big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\big). \end{aligned}$$

On the other hand, by regarding the wave equation as an elliptic equation

$$\Delta\psi = \psi_{tt}$$

and using the interior elliptic estimates, we have

$$\begin{cases} \|\partial_t^{s-1}\psi(T,\cdot)\|^2_{H^2(\mathbb{B}_{1-\frac{1}{s}d})} \le C\|\partial_t^{s+1}\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)} \\ \qquad + C\|\partial_t^{s-1}\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_1)}, \\ \|\partial_t^{s-2}\psi(T,\cdot)\|^2_{H^3(\mathbb{B}_{1-\frac{2}{s}d})} \le C\|\partial_t^{s}\psi(T,\cdot)\|^2_{H^1(\mathbb{B}_{1-\frac{1}{s}d})} \\ \qquad + C\|\partial_t^{s-2}\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_{1-\frac{1}{s}d})}, \\ \|\partial_t^{s-3}\psi(T,\cdot)\|^2_{H^4(\mathbb{B}_{1-\frac{3}{s}d})} \le C\|\partial_t^{s-1}\psi(T,\cdot)\|^2_{H^2(\mathbb{B}_{1-\frac{2}{s}d})} \\ \qquad + C\|\partial_t^{s-3}\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_{1-\frac{2}{s}d})}, \\ \quad \cdots\cdots, \\ \|\nabla\psi(T,\cdot)\|^2_{H^s(\Omega_0)} \le C\|\partial_t^2\psi(T,\cdot)\|^2_{H^{s-1}(\mathbb{B}_{1-\frac{s-1}{s}d})} \\ \qquad + C\|\nabla\psi(T,\cdot)\|^2_{L^2(\mathbb{B}_{1-\frac{s-1}{s}d})}, \end{cases} \tag{2.28}$$

where $d = \mathrm{dist}(\mathbb{S}^1, \partial\Omega_0)$, $\mathrm{dist}(\cdot,\cdot)$ being the standard distance function. Then (2.27) follows by selecting a small enough λ_0. □

REMARK 2.6. *It is obvious that the conclusion in Theorem* 2.5 *is also valid for arbitrary time $T > 0$ if λ_1 is replaced by $\frac{C_1}{T}$ for some constant $C_1 > 0$.*

At last, we construct the exact boundary control for the linear wave equation (2.1) in two space dimensions.

THEOREM 2.7. *Consider the linear wave equation* (2.1) *in two space dimensions. Then, for any given initial data (f_0, f_1) and final data (g_0, g_1) with $f_0, g_0 \in H^{s+1}(\Omega_0)$, $f_1, g_1 \in H^s(\Omega_0)$, $s \geq 1$, there exist a positive constant T_0 and a boundary control function h such that the mixed initial-boundary value problem* (2.1), (2.2) *and* (1.6) *admits a unique $\cap_{j=0}^{s+1} C^j\big([0,T]; H^{s+1-j}(\Omega_0)\big)$ solution $u = u(t,x)$ on the domain $R(T)$ which arrives at the final condition* (1.7), *provided $T > T_0$. Moreover, we have*

$$\sup_{0\leq t\leq T}\sum_{j=0}^{s+1}\|\partial_t^j u\|^2_{H^{s+1-j}(\Omega_0)} \leq C\big(\|(\widetilde{f}_0,\widetilde{g}_0)\|^2_{H^{s+1}(\mathbb{B}_1)} + \|(\widetilde{f}_1,\widetilde{g}_1)\|^2_{H^s(\mathbb{B}_1)}\big). \tag{2.29}$$

Proof. For $m \geq 1$, define

$$u^{(m)} = \sum_{k=1}^{m}(-1)^{k-1}\big(v^{(k)} + w^{(k)}\big), \tag{2.30}$$

where $v^{(1)}$ and $w^{(1)}$ are defined as the solutions of the following linear initial-boundary value problems:

$$\begin{cases} \Box v^{(1)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{B}_1, \\ v_t^{(1)} + v_r^{(1)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{S}^1, \\ v^{(1)}(0,x) = \widetilde{f}_0, \quad v_t^{(1)}(0,x) = \widetilde{f}_1, \quad x \in \mathbf{B}_1, \end{cases} \tag{2.31}$$

and

$$\begin{cases} \Box w^{(1)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{B}_1, \\ -w_t^{(1)} + w_r^{(1)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{S}^1, \\ w^{(1)}(T,x) = \widetilde{g}_0, \quad w_t^{(1)}(T,x) = \widetilde{g}_1, \quad x \in \mathbf{B}_1. \end{cases} \tag{2.32}$$

For $k \geq 2$, $v^{(k)}$ and $w^{(k)}$ are inductively defined as the solutions of the following linear initial-boundary value problems:

$$\begin{cases} \Box v^{(k)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{B}_1, \\ v_t^{(k)} + v_r^{(k)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{S}^1, \\ v^{(k)}(0,x) = [\chi w^{(k-1)}]\tilde{}\,(0,x), \quad v_t^{(k)}(0,x) = [\chi w_t^{(k-1)}]\tilde{}\,(0,x), \quad x \in \mathbf{B}_1, \end{cases} \tag{2.33}$$

and

$$\begin{cases} \Box w^{(k)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{B}_1, \\ -w_t^{(k)} + w_r^{(k)} = 0, \quad 0 \leq t \leq T, \quad x \in \mathbf{S}^1, \\ w^{(k)}(T,x) = [\chi v^{(k-1)}]\tilde{}\,(T,x), \quad w_t^{(k)}(T,x) = [\chi v_t^{(k-1)}]\tilde{}\,(T,x), \quad x \in \mathbf{B}_1, \end{cases} \tag{2.34}$$

where χ is the characteristic function defined as

$$\begin{cases} \chi \equiv 1, & x \in \Omega_0, \\ \chi \equiv 0, & x \in \mathbb{B}_1 \setminus \Omega_0, \end{cases}$$

and $[\cdot]^{\sim}$ represents the extension operator defined at the beginning of section 2.

First of all, we observe that

$$\Box u^{(m)} = 0, \quad 0 < t < T, \quad x \in \Omega_0, \tag{2.35}$$

and

$$\begin{cases} u^{(m)}(0,x) = f_0 + (-1)^{m-1} w^{(m)}(0,x), \\ u_t^{(m)}(0,x) = f_1 + (-1)^{m-1} w_t^{(m)}(0,x), \\ u^{(m)}(T,x) = g_0 + (-1)^{m-1} v^{(m)}(T,x), \\ u_t^{(m)}(T,x) = g_1 + (-1)^{m-1} v_t^{(m)}(T,x) \end{cases} \tag{2.36}$$

for $m \geq 1$.

To show that $u^{(m)}$ defined in (2.30) is convergent, together with

$$\begin{cases} \big(u_t^{(m)}(0,x), u_t^{(m)}(T,x)\big) \longrightarrow (f_1, g_1) \text{ in } H^s(\Omega_0), \\ \big(u^{(m)}(0,x), u^{(m)}(T,x)\big) \longrightarrow (f_0, g_0) \text{ in } H^{s+1}(\Omega_0), \end{cases} \tag{2.37}$$

as $m \longrightarrow \infty$, we need the following lemma.

LEMMA 2.8. *Let $v^{(k)}$ and $w^{(k)}$ be defined as the solutions of systems* (2.31)–(2.34); *$s \geq 1$ is an integer. Then the estimates*

$$\begin{aligned} &\sum_{j=0}^{s+1} \Big(\|\partial_t^j v^{(k)}(T,\cdot)\|_{H^{s+1-j}(\Omega_0)} + \|\partial_t^j w^{(k)}(0,\cdot)\|_{H^{s+1-j}(\Omega_0)} \Big) \\ &\leq \frac{1}{8} \sum_{j=0}^{s+1} \Big(\|\partial_t^j v^{(k-1)}(T,x)\|_{H^{s+1-j}(\Omega_0)} + \|\partial_t^j w^{(k-1)}(0,x)\|_{H^{s+1-j}(\Omega_0)} \\ &\qquad + \|\partial_t^j v^{(k-2)}(T,x)\|_{H^{s+1-j}(\Omega_0)} + \|\partial_t^j w^{(k-2)}(0,x)\|_{H^{s+1-j}(\Omega_0)} \Big) \end{aligned}$$

hold, provided that λ_1 is small enough and T is big enough.

Proof. Integrate (2.31) with respect to x on the unit ball $\mathbb{B}_1$ to yield

$$\frac{d}{dt}\Big[\int_{\mathbb{B}_1} \partial_t v^{(k)} dx + \int_{\mathbb{S}^1} v^{(k)} d\sigma_y \Big] = 0.$$

Then, by integrating the above equality with respect to t from 0 to T, we have

$$\begin{aligned} &\|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)} + \Big| \int_{\mathbb{S}^1} v^{(k)}(T,x) d\sigma_y \Big| \\ &\leq \|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)} + \Big| \int_{\mathbb{B}_1} \partial_t v^{(k)}(T,x) dx \Big| \\ &\quad + \Big| \int_{\mathbb{S}^1} v^{(k)}(0,x) d\sigma_y + \int_{\mathbb{B}_1} \partial_t v^{(k)}(0,x) dx \Big| \\ &\leq \|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)} + C\|\partial_t v^{(k)}(T,x)\|_{L^2(\mathbb{B}_1)} \\ &\quad + \Big| \int_{\mathbb{S}^1} [\chi w^{(k-1)}]^{\sim}(0,x) d\sigma_y + \int_{\mathbb{B}_1} [\chi \partial_t w^{(k-1)}]^{\sim}(0,x) dx \Big| \\ &= \|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)} + C\|\partial_t v^{(k)}(T,x)\|_{L^2(\mathbb{B}_1)} \end{aligned}$$

$$
\begin{aligned}
&+\Big|\int_{\mathbb{B}_1}[\chi\partial_t w^{(k-1)}]\tilde{}\,(0,x)dx\Big|\\
&\le C\Big(\|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)}+\|\partial_t v^{(k)}(T,x)\|_{L^2(\mathbb{B}_1)}+\ \|[\chi\partial_t w^{(k-1)}]\tilde{}\,(0,x)\|_{L^2(\mathbb{B}_1)}\Big)\\
&\le C\Big(\|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)}+\|\partial_t v^{(k)}(T,x)\|_{L^2(\mathbb{B}_1)}+\ \|\partial_t w^{(k-1)}(0,x)\|_{L^2(\mathbb{B}_1)}\Big).
\end{aligned}
$$

By (2.12), Remark 2.4, and (initial or final data in) (2.31)–(2.34), we arrive at

$$
\begin{aligned}
&\|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)}+\Big|\int_{\mathbb{S}^1}v^{(k)}(T,x)d\sigma_y\Big|\\
&\le\frac{C}{T}\Big(\|v^{(k)}(0,x)\|_{H^1(\mathbb{B}_1)}+\|\partial_t v^{(k)}(0,x)\|_{L^2(\mathbb{B}_1)}\\
&\qquad+\|w^{(k-1)}(T,x)\|_{H^1(\mathbb{B}_1)}+\|\partial_t w^{(k-1)}(T,x)\|_{L^2(\mathbb{B}_1)}\Big)\\
&=\frac{C}{T}\Big(\|[\chi w^{(k-1)}]\tilde{}\,(0,x)\|_{H^1(\mathbb{B}_1)}+\|[\chi\partial_t w^{(k-1)}]\tilde{}\,(0,x)\|_{L^2(\mathbb{B}_1)}\\
&\qquad+\|[\chi v^{(k-2)}]\tilde{}\,(T,x)\|_{H^1(\mathbb{B}_1)}+\|[\chi\partial_t v^{(k-2)}]\tilde{}\,(T,x)\|_{L^2(\mathbb{B}_1)}\Big)\\
&\le\frac{C}{T}\Big(\|w^{(k-1)}(0,x)\|_{H^1(\Omega_0)}+\|\partial_t w^{(k-1)}(0,x)\|_{L^2(\Omega_0)}\\
&\qquad+\|v^{(k-2)}(T,x)\|_{H^1(\Omega_0)}+\|\partial_t v^{(k-2)}(T,x)\|_{L^2(\Omega_0)}\Big).
\end{aligned}
\tag{2.38}
$$

The same results are also valid for $\|\nabla w^{(k)}(0,\cdot)\|_{L^2(\mathbb{B}_1)}+|\int_{\mathbb{S}^1}w^{(k)}(0,x)d\sigma_y|$. Thus, by Poincaré's inequality, we have

$$
\begin{aligned}
&\|v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)}+\|w^{(k)}(0,\cdot)\|_{L^2(\mathbb{B}_1)}\\
&\le C\Big(\|\nabla v^{(k)}(T,\cdot)\|_{L^2(\mathbb{B}_1)}+\Big|\int_{\mathbb{S}^1}v^{(k)}(T,x)d\sigma_y\Big|\Big)\\
&\quad+C\Big(\|\nabla w^{(k)}(0,\cdot)\|_{L^2(\mathbb{B}_1)}+\Big|\int_{\mathbb{S}^1}w^{(k)}(0,x)d\sigma_y\Big|\Big)\\
&\le\frac{C}{T}\Big(\|w^{(k-1)}(0,x)\|_{H^1(\Omega_0)}+\|\partial_t w^{(k-1)}(0,x)\|_{L^2(\Omega_0)}\\
&\qquad+\|v^{(k-2)}(T,x)\|_{H^1(\Omega_0)}+\|\partial_t v^{(k-2)}(T,x)\|_{L^2(\Omega_0)}\\
&\qquad+\|v^{(k-1)}(T,x)\|_{H^1(\Omega_0)}+\|\partial_t v^{(k-1)}(T,x)\|_{L^2(\Omega_0)}\\
&\qquad+\|w^{(k-2)}(0,x)\|_{H^1(\Omega_0)}+\|\partial_t w^{(k-2)}(0,x)\|_{L^2(\Omega_0)}\Big).
\end{aligned}
\tag{2.39}
$$

The combination of (2.39) and (2.27) gives

$$
\begin{aligned}
&\sum_{j=0}^{s+1}\Big(\|\partial_t^j v^{(k)}(T,\cdot)\|_{H^{s+1-j}(\Omega_0)}+\|\partial_t^j w^{(k)}(0,\cdot)\|_{H^{s+1-j}(\Omega_0)}\Big)\\
&\le\frac{1}{8}\sum_{j=0}^{s+1}\Big(\|\partial_t^j w^{(k-1)}(0,x)\|_{H^{s+1-j}(\Omega_0)}+\|\partial_t^j v^{(k-1)}(T,x)\|_{H^{s+1-j}(\Omega_0)}\\
&\qquad+\|\partial_t^j v^{(k-2)}(T,x)\|_{H^{s+1-j}(\Omega_0)}+\|\partial_t^j w^{(k-2)}(0,x)\|_{H^{s+1-j}(\Omega_0)}\Big),
\end{aligned}
$$

provided that λ_1 is small enough and T is big enough. □

Let us continue the proof of Theorem 2.7. By Lemma 2.8, we have

$$\begin{aligned}(2.40)\qquad &\sum_{j=0}^{s+1}\Big(\|\partial_t^j v^{(k)}(T,\cdot)\|^2_{H^{s+1-j}(\Omega_0)}+\|\partial_t^j w^{(k)}(0,\cdot)\|^2_{H^{s+1-j}(\Omega_0)}\Big)\\ &\le \frac{C}{2^k}\Big(\|(f_0,g_0)\|^2_{H^{s+1}(\Omega_0)}+\|(f_1,g_1)\|^2_{H^s(\Omega_0)}\Big)\end{aligned}$$

for any $k\ge 1$. Consequently, it follows that

$$(2.41)\qquad \begin{cases}\|\partial_t w^{(m)}(0,x)\|_{H^s(\Omega_0)}+\|\partial_t v^{(m)}(T,x)\|_{H^s(\Omega_0)}\longrightarrow 0,\\ \|w^{(m)}(0,x)\|_{H^{s+1}(\Omega_0)}+\|v^{(m)}(T,x)\|_{H^{s+1}(\Omega_0)}\longrightarrow 0\end{cases}$$

as $m\to+\infty$, which proves (2.37).

On the other hand, (2.41) is also valid with T being replaced by t for $0\le t\le T$ by an argument similar to that above. Thus, the series $\{u^{(m)}\}$ is convergent to a limit function $u(t,x)$. And, moreover, by (2.35), (2.40), and (2.37), the limit function $u(t,x)$ satisfies the linear wave equation (2.1), estimates (2.29), and verifies the initial data (1.6) and final data (1.7). Thus, if we let

$$(2.42)\qquad h(t,x)=u(t,x)|_{\partial\Omega_0},$$

then $h(t,x)$ is the desired boundary control. □

3. Local exact boundary control for semilinear wave equations. In this section we intend to construct the boundary controls for the semilinear wave equations (1.1). Applying the contraction mapping theorem, we can extend the results for the linear wave equations in section 2 to the semilinear case and prove Theorems 1.1 and 1.3.

Let $s\ge 2$. Define

$$\begin{aligned}\Sigma_\theta=\Big\{&v:[0,T]\times\Omega_0\to\mathbb{R}\big|v(0,x)=f_0,v_t(0,x)=f_1,\\ &(3.1)\qquad v(T,x)=g_0,v_t(T,x)=g_1,\mathcal{D}_\Sigma(v)\le\theta\Big\},\end{aligned}$$

where

$$(3.2)\qquad \mathcal{D}_\Sigma(v)=\sup_{0\le t\le T}\Big(\sum_{j=0}^{s+1}\|\partial_t^j v(t,\cdot)\|^2_{H^{s+1-j}(\Omega_0)}\Big)^{\frac12},$$

and $T>2$ in three space dimensions and $T>T_0$, with T_0 being determined in Theorem 2.7 in two space dimensions. We want to find a map

$$(3.3)\qquad \Pi_\Sigma: v\to u=\Pi_\Sigma v,$$

such that Π_Σ is a strict contraction from Σ_θ to itself, provided θ is small enough.

Let the operator Π_Σ be defined as follows. For $n=2$ or 3, given a function $v\in\Sigma_\theta$, let φ solve the Cauchy problem

$$(3.4)\qquad \begin{cases}\Box\varphi=F(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v}),\quad 0\le t\le T,\quad x\in\mathbb{B}_1,\\ \varphi(t,x)=0,\quad 0\le t\le T,\quad x\in\mathbb{S}^{n-1},\\ \varphi(0,x)=0,\quad \varphi_t(0,x)=0,\quad x\in\mathbb{B}_1.\end{cases}$$

Then, by using $\varphi(T,x)$ and $\varphi_t(T,x)$, we define ϕ via the following exact boundary controllability problem:

$$\begin{cases} \Box\phi = 0, \quad 0 \le t \le T, \quad x \in \Omega_0, \\ \phi(0,x) = f_0, \quad \phi_t(0,x) = f_1, \quad x \in \Omega_0, \\ \phi(T,x) = g_0 - \varphi(T,x), \quad \phi_t(T,x) = g_1 - \varphi_t(T,x), \quad x \in \Omega_0. \end{cases} \tag{3.5}$$

The theory set forth in section 2 ensures that ϕ is well-defined. At last, for $(t,x) \in [0,T] \times \Omega_0$, we define

$$\Pi_\Sigma v(t,x) = \varphi(t,x) + \phi(t,x). \tag{3.6}$$

We claim the following.

LEMMA 3.1. *Π_Σ is a strict contraction from Σ_θ to Σ_θ, provided that $\theta > 0$ is sufficiently small.*

To complete the proof of the above lemma, we need the following lemma.

LEMMA 3.2. *Suppose that $H = H(t,x,w)$ is a sufficiently smooth function of its arguments with $H(t,x,0) = 0$ and $\Omega_0 \subseteq \mathbb{R}^n$ is a bounded domain with smooth boundary. Then, for any given integer $s \ge 0$ and integer $m > 0$, if a smooth vector function $w = w(t,x) \in \mathbb{R}^m$ satisfies*

$$w(t,\cdot) \in H^s(\Omega_0) \quad \text{and} \quad \|w(t,\cdot)\|_{L^\infty(\Omega_0)} \le 1,$$

then the composite function $H(t,x,w) \in H^s(\Omega_0)$ and satisfies

$$\|H\big(t,\cdot,w(\cdot)\big)\|_{H^s(\Omega_0)} \le C(T)\|w(t,\cdot)\|_{H^s(\Omega_0)}$$

for $0 \le t \le T$.

The proof of Lemma 3.2 relies on the following proposition (see [20, Chapter 1, Proposition 3.9] or [11, Chapter 1, Theorem 4.3]).

PROPOSITION 3.3. *Suppose that $H_0 = H_0(w)$ is a sufficiently smooth function with $H_0(0) = 0$. Then, for any given integer $s \ge 0$ and integer $m > 0$, if a smooth vector function $w = w(x) \in \mathbb{R}^m$ satisfies*

$$w(\cdot) \in H^s(\mathbb{R}^n) \quad \text{and} \quad \|w\|_{L^\infty(\mathbb{R}^n)} \le 1,$$

then the composite function $H_0(w) \in H^s(\mathbb{R}^n)$ and satisfies

$$\|H_0\big(w(\cdot)\big)\|_{H^s(\mathbb{R}^n)} \le C\|w(\cdot)\|_{H^s(\mathbb{R}^n)},$$

where the constant $C > 0$ depends only on H_0.

Now we apply Proposition 3.3 to prove Lemma 3.2. First of all, we generalize Proposition 3.3 to the case when $H_0 = H_0\big(t,x,w(x)\big)$ with $H_0(t,x,0) = 0$ and $H_0(t,x,w) = 0$ for $|x| > 2\mathrm{diam}(\Omega_0)$. In fact, it is obvious that

$$\partial_t^\mu \nabla_x^{(l_0)} H_0(t,x,0) = 0,$$

where, in the context of the proof of Lemma 3.2, $(l_0),(l_1),\dots,(k_0),(k_1),\dots$ are used to represent multi-indices. Then, by the chain rule, the following holds:

$$\begin{aligned} &\|\nabla_x^{(l_0)}\big[H_0\big(t,\cdot,w(\cdot)\big)\big]\|_{L^2(\mathbb{R}^n)} \\ &\le C \sum_{(l_1)+(l_2)+\cdots+(l_m)\le(l_0)} \Big\{\|\nabla_x^{(l_1)} w_1(\cdot)\nabla_x^{(l_2)} w_2(\cdot)\cdots\nabla_x^{(l_m)} w_m(\cdot)\|_{L^2(\mathbb{R}^n)} \\ &\quad \times \sum_{|(k_0)|\le|(l_0)|,|(k_0)|+|(k_1)|\le|(l_0)|} \|\nabla_w^{(k_0)}[\nabla_x^{(k_1)} H_0]\big(t,\cdot,w(\cdot)\big)\|_{L^\infty(\mathbb{R}^n)}\Big\}. \end{aligned}$$

Since $H_0(t,x,w)$ is smooth enough, $\|w\|_{L^\infty(\mathbb{R}^n)} \le 1$, and $H(t,x,w) = 0$ for $|x| > 2\mathrm{diam}(\Omega_0)$, we have

$$\begin{aligned}&\|\nabla_x^{(l_0)}\big[H_0\big(t,\cdot,w(\cdot)\big)\big]\|_{L^2(\mathbb{R}^n)}\\ &\le C(T)\sum_{(l_1)+(l_2)+\cdots+(l_m)\le(l_0)}\|\nabla_x^{(l_1)}w_1(\cdot)\nabla_x^{(l_2)}w_2(\cdot)\cdots\nabla_x^{(l_m)}w_m(\cdot)\|_{L^2(\mathbb{R}^n)}.\end{aligned}$$

Then the desired generalization follows from the following lemma (see [20, Chapter 1, Lemma 3.10]).

LEMMA 3.4. *Let* $s = \sum_{i=1}^m |(l_i)|$, $|(l_i)| > 0$. *Then*

$$\begin{aligned}&\|\nabla_x^{(l_1)}w_1(\cdot)\nabla_x^{(l_2)}w_2(\cdot)\cdots\nabla_x^{(l_m)}w_m(\cdot)\|_{L^2(\mathbb{R}^n)}\\ &\le C\sum_{1\le k\le m}\frac{\|w_1(\cdot)\|_{L^\infty(\mathbb{R}^n)}\|w_2(\cdot)\|_{L^\infty(\mathbb{R}^n)}\cdots\|w_m(\cdot)\|_{L^\infty(\mathbb{R}^n)}}{\|w_k(\cdot)\|_{L^\infty(\mathbb{R}^n)}}\|w(\cdot)\|_{H^s(\mathbb{R}^n)}\end{aligned}$$

holds if the right-hand side is bounded.

Next, for any function $w \in \{w | w(\cdot) \in H^s(\Omega_0),\ \|w\|_{L^\infty(\Omega_0)} \le 1\}$, we can use the extension operator to get $\widetilde{w}$ (see (2.3) and (2.4)) such that

$$\|\widetilde{w}(\cdot)\|_{H^s(\mathbb{R}^n)} \le C_s\|w(\cdot)\|_{H^s(\Omega_0)},$$

where C_s is independent of w for $w \in \{w | w(\cdot) \in H^s(\Omega_0),\ \|w\|_{L^\infty(\Omega_0)} \le 1\}$. Thus, we have

$$\begin{aligned}&\|H_0\big(t,\cdot,w(\cdot)\big)\|_{H^s(\Omega_0)} \le \|H_0\big(t,\cdot,\widetilde{w}(\cdot)\big)\|_{H^s(\mathbb{R}^n)}\\ &\le C(T)\|\widetilde{w}(\cdot)\|_{H^s(\mathbb{R}^n)} \le C(T)C_s\|w(\cdot)\|_{H^s(\Omega_0)}.\end{aligned}$$

Note that the constants in the above inequalities are uniform for functions with bounded $H^s(\Omega_0)$ and $L^\infty(\Omega_0)$ norms. Consequently, they are also valid for $w = w(t,x)$, which satisfies the restrictions in Proposition 3.3. We complete the proof of Lemma 3.2.

Similarly, we also have the following lemma.

LEMMA 3.5. *Suppose that* $H = H(t,x,w)$ *is a sufficiently smooth function of its arguments with* $H(t,x,0) = 0$ *and* $\nabla_w H(t,x,0) = 0$, *and* $\Omega_0 \subseteq \mathbb{R}^n$ *is a bounded domain with smooth boundary. Then, for any given integer* $s \ge 0$ *and integer* $m > 0$, *if a smooth vector function* $w = w(t,x) \in \mathbb{R}^m$ *satisfies*

$$w(t,\cdot) \in H^s(\Omega_0) \quad \textit{and} \quad \|w(t,\cdot)\|_{L^\infty(\Omega_0)} \le 1,$$

then the composite function $H(t,x,w) \in H^s(\Omega_0)$ *and satisfies*

$$\|H\big(t,\cdot,w(\cdot)\big)\|_{H^s(\Omega_0)} \le C(T)\|w(t,\cdot)\|_{L^\infty(\Omega_0)}\|w(t,\cdot)\|_{H^s(\Omega_0)}$$

for $0 \le t \le T$.

LEMMA 3.6. *Suppose that* $H = H(t,x,w)$ *is a sufficiently smooth function of its arguments with* $H(t,x,0) = 0$ *and* $\nabla_w H(t,x,0) = 0$, *and* $\Omega_0 \subseteq \mathbb{R}^n$ *is a bounded domain with smooth boundary. Then, for any given integer* $s \ge 0$ *and integer* $m > 0$ *if two smooth vector functions* $w^1 = w^1(t,x) \in \mathbb{R}^m$, $w^2 = w^2(t,x) \in \mathbb{R}^m$ *satisfy*

$$(w^1, w^2)(t,\cdot) \in H^s(\Omega_0) \quad \textit{and} \quad \|(w^1, w^2)(t,\cdot)\|_{L^\infty(\Omega_0)} \le 1,$$

then we have

$$\begin{aligned}&\|H\big(t,\cdot,w^1(\cdot)\big)-H\big(t,\cdot,w^2(\cdot)\big)\|_{H^s(\Omega_0)}\\&\le C(T)\big(\|w^1(t,\cdot)\|_{L^\infty(\Omega_0)}+\|w^2(t,\cdot)\|_{L^\infty(\Omega_0)}\big)\|w^1(t,\cdot)-w^2(t,\cdot)\|_{H^s(\Omega_0)}\end{aligned}$$

for $0\le t\le T$.

Lemmas 3.5 and 3.6 can be proved by arguments similar to those of Lemma 3.2. We refer the reader to [11, Chapter 1, Corollary 4.3 and Theorem 4.6] for details.

Now let us begin to prove Lemma 3.1.

Proof. First of all, it is rather easy to see that

$$\begin{cases}u(0,x)=f_0, \quad u_t(0,x)=f_1,\\ u(T,x)=g_0, \quad u_t(T,x)=g_1\end{cases}\tag{3.7}$$

for $x\in\Omega_0$.

To confirm that $u=\Pi_\Sigma v\in\Sigma_\theta$, we need to go to estimate $\mathcal{D}_\Sigma(u)$. Applying ∂_t^j to (3.4), and then taking the L^2 inner product of the resulting equation with $\partial_t^{j+1}\varphi$ for $j=0,1,\dots,s$, respectively, and then adding them up, we have

$$\begin{aligned}&\frac12\frac{d}{dt}\Big(\|\partial_t^{s+1}\varphi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\sum_{j=1}^s\|\partial_t^j\varphi(t,\cdot)\|^2_{H^1(\mathbb{B}_1)}+\|\nabla\varphi(t,\cdot)\|^2_{L^2(\mathbb{B}_1}\Big)\\&\le C\sum_{j=0}^s\|\partial_t^{j+1}\varphi(t,\cdot)\|_{L^2(\mathbb{B}_1)}\sum_{j=0}^s\|\frac{d^j}{dt^j}F(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\|_{L^2(\mathbb{B}_1)}.\end{aligned}\tag{3.8}$$

Write $w=(\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})$. By (1.3),

$$\begin{cases}\partial_t^jF(t,x,0)=0, \quad \partial_t^j\nabla_wF(t,x,0)=0,\\ \sum_{j=2}^s\sum_{2\le|(k)|\le j}\|\partial_t^{j-|(k)|}\nabla_w^{(k)}F(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\|_{L^\infty(\mathbb{B}_1)}\le C(T)\end{cases}$$

holds, since F is smooth, where integer $j\ge0$ and (k) is a multi-index similar to that in the proof of Lemma 3.2. Thus, by (3.1), and looking at $\nabla_wF=0$, ∂_t^jF, and $\partial_t^j\nabla_wF$ as new functions appearing in Lemma 3.2 or Lemma 3.5, we have

$$\begin{aligned}&\sum_{j=0}^s\Big\|\frac{d^j}{dt^j}F(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\Big\|_{H^{s-j}(\mathbb{B}_1)}\le\|F(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\|_{H^s(\mathbb{B}_1)}\\&\quad+\Big(\|F_t(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\|_{H^{s-1}(\mathbb{B}_1)}+\|\nabla_wF(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})w_t\|_{H^{s-1}(\mathbb{B}_1)}\Big)\\&\quad+\sum_{j=2}^s\Big(\|\partial_t^jF(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\|_{H^{s-j}(\mathbb{B}_1)}+\|\partial_t^{j-1}\nabla_wF(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})w_t\|_{H^{s-j}(\mathbb{B}_1)}\\&\quad+\sum_{2\le|(k)|\le j}\|\partial_t^{j-|(k)|}\nabla_w^{(k)}F(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_t^{(k)}w\|_{H^{s-j}(\mathbb{B}_1)}\Big)\\&\le C(T)\theta^2.\end{aligned}\tag{3.9}$$

Consequently,

$$\|\partial_t^{s+1}\varphi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}+\sum_{j=1}^s\|\partial_t^j\varphi(t,\cdot)\|^2_{H^1(\mathbb{B}_1)}+\|\nabla\varphi(t,\cdot)\|^2_{L^2(\mathbb{B}_1)}\le C(T)\theta^4.\tag{3.10}$$

Invoking (3.9) and the elliptic estimates in (2.28), and by arguments similar to those in Theorem 2.5, we have

$$\sup_{0\le t\le T}\Big(\sum_{j=0}^{s+1}\|\partial_t^j\varphi(t,\cdot)\|^2_{H^{s+1-j}(\Omega_0)}\Big)^{\frac{1}{2}}\le\frac{1}{4}\theta, \tag{3.11}$$

provided that θ is sufficiently small.

It is obvious that the estimate (3.11) also holds for ϕ, provided ε_1 and ε_2 are small enough. Thus, we conclude that $\Pi_\Sigma v\in\Sigma_\theta$.

It remains to demonstrate that Π_Σ is a strict contraction. Given $v_i\in\Sigma_\theta$, $i=1,2$, let φ_i solve

$$\begin{cases}\Box\varphi_i=F(t,x,\widetilde{v}_i,\partial_t\widetilde{v}_i,\nabla\widetilde{v}_i), & 0<t<T,\quad x\in\mathbb{B}_1,\\ \varphi_i(t,x)=0, & 0\le t\le T,\quad x\in\mathbb{S}^{n-1},\\ \varphi_i(0,x)=0,\quad \partial_t\varphi_i(0,x)=0, & x\in\mathbb{B}_1.\end{cases} \tag{3.12}$$

Then, by using $\varphi_i(T,x)$ and $\partial_t\varphi(T,x)$, we define ϕ_i via the following exact boundary controllability problem:

$$\begin{cases}\Box\phi_i=0, & 0<t<T,\quad x\in\Omega_0,\\ \phi_i(0,x)=f_0,\quad \partial_t\phi_i(0,x)=f_1, & x\in\Omega_0,\\ \phi_i(T,x)=g_0-\varphi_i(T,x),\quad \partial_t\phi_i(T,x)=g_1-\partial_t\varphi_i(T,x), & x\in\Omega_0.\end{cases} \tag{3.13}$$

Of course ϕ_i may not be unique in general; we point out here that the ones we used here are constructed by Lemma 2.1 and Theorem 2.7. Let

$$u_i=\varphi_i+\phi_i.$$

We must show that

$$\mathcal{D}_\Sigma(u_1-u_2)\le\lambda\mathcal{D}_\Sigma(v_1-v_2) \tag{3.14}$$

for some positive constant $0<\lambda<1$.

To confirm (3.14), it is enough to show

$$\begin{cases}\mathcal{D}_\Sigma(\varphi_1-\varphi_2)\le\frac{\lambda}{2}\mathcal{D}_\Sigma(v_1-v_2),\\ \mathcal{D}_\Sigma(\phi_1-\phi_2)\le\frac{\lambda}{2}\mathcal{D}_\Sigma(v_1-v_2)\end{cases} \tag{3.15}$$

for some positive constant $0<\lambda<1$.

On one hand, note that

$$\begin{cases}\Box(\phi_1-\phi_2)=0, & 0<t<T,\quad x\in\Omega_0,\\ (\phi_1-\phi_2)(0,x)=0,\quad \partial_t(\phi_1-\phi_2)(0,x)=0, & x\in\Omega_0,\\ (\phi_1-\phi_2)(T,x)=(\varphi_i-\varphi_1)(T,x), & x\in\Omega_0,\\ \partial_t(\phi_1-\phi_2)(T,x)=\partial_t(\varphi_2-\varphi_1)(T,x), & x\in\Omega_0.\end{cases}$$

By Lemma 2.1 and Theorem 2.7, we have

$$\begin{aligned}\mathcal{D}_\Sigma(\phi_1-\phi_2)&\le C\Big(\|\partial_t(\varphi_2-\varphi_1)(T,\cdot)\|^2_{H^s(\Omega_0)}+\|(\varphi_2-\varphi_1)(T,\cdot)\|^2_{H^{s+1}(\Omega_0)}\Big)\\ &\le C\mathcal{D}_\Sigma(\varphi_1-\varphi_2).\end{aligned}$$

Thus, to confirm (3.15), it is enough to show that

$$\mathcal{D}_\Sigma(\varphi_1-\varphi_2)\le\frac{\lambda}{M}\mathcal{D}_\Sigma(v_1-v_2) \tag{3.16}$$

for an appropriately large constant M.

On the other hand, it is easy to see that

$$\begin{cases}\Box(\varphi_1-\varphi_2)=F(t,x,\widetilde{v}_1,\partial_t\widetilde{v}_1,\nabla\widetilde{v}_1)-F(t,x,\widetilde{v}_2,\partial_t\widetilde{v}_2,\nabla\widetilde{v}_2), & 0<t<T,\quad x\in\mathbb{B}_1,\\ (\varphi_1-\varphi_2)(t,x)=0, & 0\le t\le T,\quad x\in\mathbb{S}^{n-1},\\ (\varphi_1-\varphi_2)(0,x)=0,\quad \partial_t(\varphi_1-\varphi_2)(0,x)=0, & x\in\mathbb{B}_1.\end{cases}$$

By standard energy estimates, it is easy to verify (3.16) since (by Lemma 3.6 and arguments similar to those in (3.9))

$$\begin{aligned}&\sum_{j=0}^{s}\Big\|\frac{d^j}{dt^j}\Big(F(t,x,\widetilde{v_1},\partial_t\widetilde{v_1},\nabla\widetilde{v_1})-F(t,x,\widetilde{v_2},\partial_t\widetilde{v_2},\nabla\widetilde{v_2})\Big)\Big\|_{H^{s-j}(\mathbb{B}_1)}\\ &\le C(T)\theta\mathcal{D}_\Sigma(v_1-v_2).\end{aligned} \tag{3.17}$$

Hence, we complete the proof of Lemma 3.4. □

By the standard contraction mapping theorem, there exists a point $u\in\Sigma_\theta$, such that $u=\Pi_\Sigma u$. For $(t,x)\in[0,T]\times\partial\Omega_0$, let

$$h(t,x)=u(t,x);$$

then h is the desired control and the proofs of Theorems 1.1 and 1.3 are complete.

4. Local exact boundary controllability for quasi-linear wave equations. In this section, we study local exact boundary controllability for the quasi-linear wave equations (1.2). The argument is similar to the two-dimensional semilinear case in section 3, but much more complicated. The difficulty lies in the quasi-linearity, which leads to the invalidity of the equality (2.14). To overcome the difficulty, we introduce a shift variable below. This shift variable can only be used in the basic Morawetz energy estimates, not in the standard energy estimates or any higher-order energy estimates, because it will lead to the loss of derivatives. The proof relies on the careful estimates of both the original and shift variables.

For simplicity, we assume that $n=2$ or 3, and $F(t,x,u,u')\equiv0$ in (1.4). The following presentation can be easily generalized to the case that $F(t,x,u,u')$ is not identically zero by arguments similar to those in section 3.

Let $s\ge3$ be an integer. Define

$$\begin{aligned}\Lambda_\theta=\Big\{&v:[0,T]\times\Omega_0\to\mathbb{R}\big|v(0,x)=f_0,v_t(0,x)=f_1,\\ &v(T,x)=g_0,v_t(T,x)=g_1,\mathcal{D}_\Lambda(v)\le\theta\Big\},\end{aligned} \tag{4.1}$$

where

$$\mathcal{D}_\Lambda(v)=\sup_{0\le t\le T}\sum_{j=0}^{s+1}\Big(\|\partial_t^jv(t,\cdot)\|^2_{H^{s+1-j}(\Omega_0)}\Big)^{\frac12} \tag{4.2}$$

and with $T>0$ to be determined. We mention here that if $F(t,x,u,u')$ is not zero identically, the definitions for Λ_θ and $\mathcal{D}_\Lambda(v)$ are the same as in (4.1) and (4.2).

For any $v \in \Lambda_\theta$, let us define the series $\{\varphi^{(i)}\}$ and $\{\phi^{(i)}\}$ as follows. Let $\varphi^{(1)}$ be the solution of the linear initial-boundary value problem

$$\begin{cases} \Box\varphi^{(1)} = g_{i\alpha}(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_{i\alpha}^2\varphi^{(1)}, \quad 0 \le t \le T, \quad x \in \mathbb{B}_1, \\ \varphi_t^{(1)} + \varphi_r^{(1)} = 0, \quad 0 \le t \le T, \quad x \in \mathbb{S}^{n-1}, \\ \varphi^{(1)}(0,x) = \widetilde{f}_0, \quad \varphi_t^{(1)}(0,x) = \widetilde{f}_1, \quad x \in \mathbb{B}_1, \end{cases} \tag{4.3}$$

and let $\phi^{(1)}$ be the solution of the inverted initial-boundary value problem

$$\begin{cases} \Box\phi^{(1)} = g_{i\alpha}(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_{i\alpha}^2\phi^{(1)}, \quad 0 \le t \le T, \quad x \in \mathbb{B}_1, \\ \phi_t^{(1)} - \phi_r^{(1)} = 0, \quad 0 \le t \le T, \quad x \in \mathbb{S}^{n-1}, \\ \phi^{(1)}(T,x) = \widetilde{g}_0, \quad \phi_t^{(1)}(T,x) = \widetilde{g}_1, \quad x \in \mathbb{B}_1, \end{cases} \tag{4.4}$$

where we used the extension operator defined in (2.3) and (2.4). For $j \ge 2$, $\varphi^{(j)}$ is defined inductively as the solution of the linear initial-boundary value problem

$$\begin{cases} \Box\varphi^{(j)} = g_{i\alpha}(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_{i\alpha}^2\varphi^{(j)}, \quad 0 \le t \le T, \quad x \in \mathbb{B}_1, \\ \varphi_t^{(j)} + \varphi_r^{(j)} = 0, \quad 0 \le t \le T, \quad x \in \mathbb{S}^{n-1}, \\ \varphi^{(j)}(0,x) = [\chi\phi^{(j-1)}]\tilde{}\,(0,x), \quad \varphi_t^{(j)}(0,x) = [\chi\phi^{(j-1)}]\tilde{}\,(0,x), \quad x \in \mathbb{B}_1, \end{cases} \tag{4.5}$$

and $\phi^{(j)}$ is defined as the solution of the inverted initial-boundary value problem

$$\begin{cases} \Box\phi^{(j)} = g_{i\alpha}(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_{i\alpha}^2\phi^{(j)}, \quad 0 \le t \le T, \quad x \in \mathbb{B}_1, \\ \phi_t^{(j)} - \phi_r^{(j)} = 0, \quad 0 \le t \le T, \quad x \in \mathbb{S}^{n-1}, \\ \phi^{(j)}(T,x) = [\chi\varphi^{(j-1)}]\tilde{}\,(T,x), \quad \phi_t^{(j)}(T,x) = [\chi\varphi_t^{(j-1)}]\tilde{}\,(T,x), \quad x \in \mathbb{B}_1, \end{cases} \tag{4.6}$$

where χ is the characteristic function and $[\cdot]\tilde{}$ represents the extension operator defined in section 2.

Next, let us formally define a map $u = \Pi_\Lambda v$ by

$$\Pi_\Lambda v = \sum_{i=1}^{\infty}(-1)^{i-1}\big(\varphi^{(i)} + \phi^{(i)}\big). \tag{4.7}$$

We must show that the series is well-defined, and Π_Λ maps Λ_θ to itself and is a strict contraction with respect to the norm $\sup_{0\le t\le T}\sum_{j=0}^{s}(\|\partial_t^j v(t,\cdot)\|^2_{H^{s-j}(\Omega_0)})^{\frac{1}{2}}$, provided that ε_3 and θ are sufficiently small. Then, by the standard contraction mapping theorem, we can prove Theorem 1.6.

To verify this, we find that it is enough to prove the following theorem, and then all arguments are similar to those in sections 2 and 3.

THEOREM 4.1. *For $v \in \Lambda_\theta$, consider the following linear initial-boundary value problem:*

$$\begin{cases} \Box w = g_{i\alpha}(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_{i\alpha}^2 w, \quad 0 \le t \le T, x \in \mathbb{B}_1, \\ w_t + w_r = 0, \quad 0 \le t \le T, \quad x \in \mathbb{S}^{n-1}, \\ w(0,x) = \widetilde{f}_0, \quad w_t(0,x) = \widetilde{f}_1, \quad x \in \mathbb{B}_1. \end{cases} \tag{4.8}$$

Suppose that $f_0 \in H^{s+1}(\Omega_0)$, $f_1 \in H^s(\Omega_0)$, $s \ge 3$. Then there exists a positive constant T_1, such that if $T \ge T_1$, then

$$\|\nabla w(T,\cdot)\|^2_{H^s(\Omega_0)} + \sum_{j=1}^{s+1}\|\partial_t^j w(T,\cdot)\|^2_{H^{s+1-j}(\Omega_0)} \le \lambda_2\big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\big) \tag{4.9}$$

holds for some $\lambda_2 \in (0,1)$.

The well-posedness of classical solutions for linear system (4.8) can be established similarly by using semigroup methods as in Hughes, Kato, and Marsden [6] or energy methods based on differentiating the equation with respect to t as in Dafermos and Hrusa [3].

To complete the proof of the above theorem, we recall the following elliptic estimates involving the boundary condition of Neumann type [19].

LEMMA 4.2. *Suppose that* Ω_0 *is a bounded domain with smooth boundary* $\partial\Omega_0$ *and* $k = 0, 1, 2, \ldots$. *Given* $f \in H^k(\Omega_0)$, $g \in H^{k+\frac{1}{2}}(\partial\Omega_0)$, *and a solution* $h \in H^{k+2}(\Omega_0)$ *to the Neumann system*

$$\begin{cases} -\Delta h = f \quad on \quad \Omega_0, \\ \frac{\partial h}{\partial n} = g \quad on \quad \partial\Omega_0, \end{cases}$$

one has the estimate

$$\|h\|^2_{H^{k+2}(\Omega_0)} \le C_k\big(\|f\|^2_{H^k(\Omega_0)} + \|g\|^2_{H^{k+\frac{1}{2}}(\partial\Omega_0)} + \|h\|^2_{L^2(\Omega_0)}\big).$$

Next we return to prove Theorem 4.1.

Proof. The proof relies on the use of the underlying conservation law of the system, which is revealed by the shift technique presented below, and also on the energy estimates of Morawetz type. As the proof is rather long, we divide it into four steps.

Step 1. *A shift technique and estimates for* $\|\overline{w}\|_{L^2(\mathbb{B}_1)}$ *and* $\|\overline{w}\|_{L^2(\mathbb{S}^{n-1})}$. Let us integrate the linear wave equation in system (4.8) with respect to x on the unit ball $\mathbb{B}_1$ to yield

$$\frac{d}{dt}\int_{\mathbb{B}_1} w_t dx - \int_{\mathbb{S}^{n-1}} w_r d\sigma_y = \int_{\mathbb{B}_1} g_{i\alpha}\partial^2_{i\alpha} w dx.$$

Noting the dissipative boundary condition in system (4.8), we have

$$\frac{d}{dt}\Big[\int_{\mathbb{B}_1} w_t dx + \int_{\mathbb{S}^{n-1}} w d\sigma_y\Big] = \int_{\mathbb{B}_1} g_{i\alpha}\partial^2_{i\alpha} w dx.$$

Let

$$\mu_0 = \int_{\mathbb{B}_1} \widetilde{f}_1 dx + \int_{\mathbb{S}^{n-1}} \widetilde{f}_0 d\sigma_y = \int_{\mathbb{B}_1} \widetilde{f}_1 dx,$$

and then introduce a shift variable

$$\overline{w} = w - \frac{1}{|\mathbb{S}^{n-1}|}\Big[\mu_0 + \int_0^t \int_{\mathbb{B}_1} g_{i\alpha}\partial^2_{i\alpha} w dx d\tau\Big]. \tag{4.10}$$

We deduce that

$$\int_{\mathbb{B}_1} \overline{w}_t dx + \int_{\mathbb{S}^{n-1}} \overline{w} d\sigma_y = -\frac{|\mathbb{B}_1|}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1} g_{i\alpha}\partial^2_{i\alpha} w dx. \tag{4.11}$$

Moreover, a direct calculation shows that

$$\Big|\int_{\mathbb{B}_1} g_{i\alpha}\partial^2_{i\alpha} w dx\Big| \le C(T)\theta\big(\|\nabla w_t\|_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|_{L^2(\mathbb{B}_1)}\big). \tag{4.12}$$

Let us now go to estimate $\|\overline{w}\|_{L^2(\mathbb{B}_1)}$ and $\|\overline{w}\|_{L^2(\mathbb{S}^{n-1})}$. Combining (4.11) and (4.12), it is easy to get

$$\Big|\int_{\mathbb{B}_1}\overline{w}_t dx+\int_{\mathbb{S}^{n-1}}\overline{w}d\sigma_y\Big|\le C(T)\theta\big(\|\nabla w_t\|_{L^2(\mathbb{B}_1)}+\|\nabla^2 w\|_{L^2(\mathbb{B}_1)}\big). \tag{4.13}$$

Invoking the Poincaré inequality

$$\Big\|\overline{w}-\frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{S}^{n-1}}\overline{w}d\sigma_y\Big\|_{L^2(\mathbb{B}_1)}\le C\|\nabla\overline{w}\|_{L^2(\mathbb{B}_1)},$$

we can deduce from (4.13) that

$$\begin{aligned}&\|\overline{w}\|_{L^2(\mathbb{B}_1)}\\&\le C\|\nabla\overline{w}\|_{L^2(\mathbb{B}_1)}+C\Big|\int_{\mathbb{S}^{n-1}}\overline{w}d\sigma_y\Big|\\&\le C\big(\|\nabla\overline{w}\|_{L^2(\mathbb{B}_1)}+\|\overline{w}_t\|_{L^2(\mathbb{B}_1)}\big)\\&\quad+C(T)\theta\big(\|\nabla w_t\|_{L^2(\mathbb{B}_1)}+\|\nabla^2 w\|_{L^2(\mathbb{B}_1)}\big).\end{aligned} \tag{4.14}$$

Then, by the trace theorem, it follows that

$$\begin{aligned}&\|\overline{w}\|_{L^2(\mathbb{S}^{n-1})}\le C\|\overline{w}\|_{H^1(\mathbb{B}_1)}\\&\le C\big(\|\nabla\overline{w}\|_{L^2(\mathbb{B}_1)}+\|\overline{w}_t\|_{L^2(\mathbb{B}_1)}\big)\\&\quad+C(T)\theta\big(\|\nabla w_t\|_{L^2(\mathbb{B}_1)}+\|\nabla^2 w\|_{L^2(\mathbb{B}_1)}\big).\end{aligned} \tag{4.15}$$

Step 2. *Standard energy estimates.* The following energy estimates are standard. By taking the L^2 inner product of the linear wave equation in system (4.8) with w_t, and using Green's formula and integration by parts, we can compute as follows:

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\mathbb{B}_1}\big(|w_t|^2+|\nabla w|^2\big)dx-\int_{\mathbb{S}^{n-1}}w_t w_r dx\\&=\int_{\mathbb{B}_1}\Big(g_{i0}\partial_i\frac{|w_t|^2}{2}+\nabla_j(g_{ij}\nabla_i w w_t)\\&\qquad-\frac{d}{dx_j}g_{ij}\nabla_i w w_t-\frac{1}{2}g_{ij}\frac{d}{dt}(\nabla_i w\nabla_j w)\Big)dx\\&=-\frac{1}{2}\frac{d}{dt}\int_{\mathbb{B}_1}g_{ij}\nabla_i w\nabla_j w dx-\int_{\mathbb{B}_1}\Big(\frac{d}{dx_i}g_{i0}\frac{|w_t|^2}{2}+\frac{d}{dx_j}g_{ij}\nabla_i w w_t-\frac{1}{2}\frac{d}{dt}g_{ij}\nabla_i w\nabla_j w\Big)dx\\&\quad+\int_{\mathbb{S}^{n-1}}\Big(\frac{1}{2}g_{i0}x_i|w_t|^2+g_{ij}x_j\nabla_i w w_t\Big)d\sigma_y\\&\le-\frac{1}{2}\frac{d}{dt}\int_{\mathbb{B}_1}g_{ij}\nabla_i w\nabla_j w dx+\|\partial g_{i\alpha}\|_{L^\infty(\mathbb{B}_1)}\Big(\|w_t\|^2_{L^2(\mathbb{B}_1)}+\|\nabla w\|^2_{L^2(\mathbb{B}_1)}\Big)\\&\quad+\|g_{i\alpha}\|_{L^\infty(\mathbb{S}^{s-1})}\Big(\|w_t\|^2_{L^2(\mathbb{S}^{s-1})}+\|\Omega w\|^2_{L^2(\mathbb{S}^{s-1})}\Big).\end{aligned}$$

Keeping in mind (1.3), (1.5), and the boundary condition in (4.8), we deduce that

$$\begin{aligned}&\frac{d}{dt}\frac{1}{2}\Big[\|w_t\|^2_{L^2(\mathbb{B}_1)}+\|\nabla w\|^2_{L^2(\mathbb{B}_1)}+\int_{\mathbb{B}_1}g_{ij}\nabla_i w\nabla_j w dx\Big]+\|w_t\|^2_{L^2(\mathbb{S}^{n-1})}\\&\le C(T)\theta\big(\|w_t\|^2_{L^2(\mathbb{B}_1)}+\|\nabla w\|^2_{L^2(\mathbb{B}_1)}+\|w_t\|^2_{L^2(\mathbb{S}^{s-1})}+\|\Omega w\|^2_{L^2(\mathbb{S}^{s-1})}\big).\end{aligned} \tag{4.16}$$

Next, we do the higher-order energy estimates. The process is similar to the above. For $s \geq 3$ and $1 \leq k \leq s$, we apply the ∂_t^k derivative to the linear wave equation in system (4.8), and then take the L^2 inner product of the resulting equation with $\partial_t^{k+1} w$. Noting that $\partial_t^{k+1} w + \partial_t^k w_r = 0$ on the boundary, we finally arrive at

$$
\begin{aligned}
&\sum_{k=1}^{s}\Big\{\frac{1}{2}\frac{d}{dt}\Big(\|\partial_t^{k+1}w\|_{L^2(\mathbb{B}_1)}^2 + \|\nabla\partial_t^k w\|_{L^2(\mathbb{B}_1)}^2 \\
&\qquad + \int_{\mathbb{B}_1} g_{ij}\nabla_i\partial_t^k w\nabla_j\partial_t^k w dx\Big) + \|\partial_t^{k+1}w\|_{L^2(\mathbb{S}^{n-1})}^2\Big\} \\
&\leq C(T)\theta\sum_{k=0}^{s}\Big(\|\partial_t^{k+1}w\|_{L^2(\mathbb{S}^{s-1})}^2 + \|\Omega\partial_t^k w\|_{L^2(\mathbb{S}^{s-1})}^2\Big) \\
&\quad + C(T)\theta\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|_{H^k(\mathbb{B}_1)}^2 + C(T)\theta\|\nabla w\|_{H^s(\mathbb{B}_1)}^2.
\end{aligned}
\tag{4.17}
$$

Note that in the right-hand side of the above estimate $\|w\|_{H^{s+1}(\mathbb{B}_1)}^2$ doesn't appear.

By (4.8), we have

$$
\begin{cases}
\Delta(\partial_t^{s+1-k}w) = \partial_t^{s+3-k}w - \partial_t^{s+1-k}[g_{i\alpha}(t,x,\widetilde{v},\widetilde{v}_t,\nabla\widetilde{v})\partial_{i\alpha}^2 w], & x \in \mathbb{B}_1, \\
(\partial_t^{s+1-k}w)_r = -\partial_t^{s+2-k}w, & x \in \mathbb{S}^{n-1}.
\end{cases}
$$

Thus, proceeding from Lemma 4.2, we have

$$
\begin{aligned}
&\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|_{H^k(\mathbb{B}_1)}^2 = \|\partial_t^{s+1}w\|_{L^2(\mathbb{B}_1)}^2 \\
&\quad + \|\partial_t^s w\|_{H^1(\mathbb{B}_1)}^2 + \sum_{k=2}^{s}\|\partial_t^{s+1-k}w\|_{H^k(\mathbb{B}_1)}^2 \\
&\leq \|\partial_t^{s+1}w\|_{L^2(\mathbb{B}_1)}^2 + \|\partial_t^s w\|_{H^1(\mathbb{B}_1)}^2 + C\sum_{k=2}^{s}\Big(\|\partial_t^{s+1-k}w\|_{L^2(\mathbb{B}_1)}^2 \\
&\quad + \|\partial_t^{s+1-k}\big(w_{tt} - g_{i\alpha}\partial_{i\alpha}^2 w\big)\|_{H^{k-2}(\mathbb{B}_1)}^2 + \|\partial_t^{s+2-k}w\|_{H^{k-2+\frac{1}{2}}(\mathbb{S}^{n-1})}^2\Big).
\end{aligned}
$$

By the trace theorem, we obtain

$$
\begin{aligned}
&\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|_{H^k(\mathbb{B}_1)}^2 \\
&\leq \|\partial_t^{s+1}w\|_{L^2(\mathbb{B}_1)}^2 + \|\partial_t^s w\|_{H^1(\mathbb{B}_1)}^2 + C\sum_{k=2}^{s}\Big(\|\partial_t^{s+1-k}w\|_{L^2(\mathbb{B}_1)}^2 \\
&\quad + \|\partial_t^{s+3-k}w\|_{H^{k-2}(\mathbb{B}_1)}^2 + \|\partial_t^{s+1-k}\big(g_{i\alpha}\partial_{i\alpha}^2 w\big)\|_{H^{k-2}(\mathbb{B}_1)}^2 \\
&\quad + \|\partial_t^{s+2-k}w\|_{H^{k-1}(\mathbb{B}_1)}^2\Big) \\
&\leq C\|\partial_t^{s+1}w\|_{L^2(\mathbb{B}_1)}^2 + C\sum_{k=1}^{s}\|\partial_t^k w\|_{H^1(\mathbb{B}_1)}^2 \\
&\quad + C\sum_{k=0}^{s-1}\|\partial_t^{s+1-k}w\|_{H^k(\mathbb{B}_1)}^2 + C\|\partial_t^{s+1-k}\big(g_{i\alpha}\partial_{i\alpha}^2 w\big)\|_{H^{k-2}(\mathbb{B}_1)}^2.
\end{aligned}
$$

Thus, by (1.5), (4.1), and Lemma 3.5, we arrive at

$$\begin{aligned}
&\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}\\
&\le C\sum_{k=0}^{s-1}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}+C\|\partial_t^{s+1}w\|^2_{L^2(\mathbb{B}_1)}+C\sum_{k=1}^{s}\|\partial_t^{k}w\|^2_{H^1(\mathbb{B}_1)}\\
&\quad+C(T)\theta\Big(\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}+\|\nabla w\|^2_{H^s(\mathbb{B}_1)}\Big),
\end{aligned}$$

which leads to

$$\begin{aligned}
\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}&\le C\sum_{k=0}^{s-1}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}\\
&\quad+C\|\partial_t^{s+1}w\|^2_{L^2(\mathbb{B}_1)}+C\sum_{k=1}^{s}\|\partial_t^{k}w\|^2_{H^1(\mathbb{B}_1)}+\frac{1}{2}\|\nabla w\|^2_{H^s(\mathbb{B}_1)}
\end{aligned}$$

if we choose θ so small that $C(T)\theta<\frac{1}{2}$.

Repeating the above procedure for $s-1$ steps, we finally arrive at

$$\begin{aligned}
&\sum_{k=0}^{s}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}\\
&\le C\Big(\|\partial_t^{s+1}w\|^2_{L^2(\mathbb{B}_1)}+\sum_{k=1}^{s}\|\partial_t^{k}w\|^2_{H^1(\mathbb{B}_1)}+\|\nabla w\|^2_{H^s(\mathbb{B}_1)}\Big).
\end{aligned}\tag{4.18}$$

Similarly, by (4.14) and Lemma 4.2, we have

$$\begin{cases}
\|\nabla w\|^2_{H^1(\mathbb{B}_1)}\le C\Big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)}+\|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)}\\
\quad+\|w_t\|^2_{L^2(\mathbb{B}_1)}+\|w_{tt}\|^2_{L^2(\mathbb{B}_1)}+\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)}\Big),\\
\|\nabla w\|^2_{H^2(\mathbb{B}_1)}\le C\Big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)}+\|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)}\\
\quad+\|w_t\|^2_{L^2(\mathbb{B}_1)}+\|w_{tt}\|^2_{H^1(\mathbb{B}_1)}+\|\nabla w_t\|^2_{H^1(\mathbb{B}_1)}\Big),\\
\quad\cdots\cdots,\\
\|\nabla w\|^2_{H^s(\mathbb{B}_1)}\le C\Big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)}+\|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)}\\
\quad+\|w_t\|^2_{L^2(\mathbb{B}_1)}+\sum_{k=1}^{s}\|\partial_t^{s+1-k}w\|^2_{H^k(\mathbb{B}_1)}\Big),
\end{cases}\tag{4.19}$$

where the first estimate follows from the following calculation:

$$\begin{aligned}
&\|\nabla w\|^2_{H^1(\mathbb{B}_1)}=\|\nabla\overline{w}\|^2_{H^1(\mathbb{B}_1)}\le\|\overline{w}\|^2_{H^2(\mathbb{B}_1)}\\
&\le C\Big(\|\overline{w}\|^2_{L^2(\mathbb{B}_1)}+\|\overline{w}_r\|^2_{H^{\frac{1}{2}}(\mathbb{S}^{n-1})}+\|w_{tt}\|^2_{L^2(\mathbb{B}_1)}\Big)\\
&\quad+C(T)\theta\Big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)}+\|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\Big)\\
&=C\Big(\|\overline{w}\|^2_{L^2(\mathbb{B}_1)}+\|w_r\|^2_{H^{\frac{1}{2}}(\mathbb{S}^{n-1})}+\|w_{tt}\|^2_{L^2(\mathbb{B}_1)}\Big)\\
&\quad+C(T)\theta\Big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)}+\|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\Big)
\end{aligned}$$

$$\le C(T)\theta\|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)} + C\Big(\|w_{tt}\|^2_{L^2(\mathbb{B}_1)} + \|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{L^2(\mathbb{B}_1)}\Big),$$

which implies that

$$\|\nabla w\|^2_{H^1(\mathbb{B}_1)} + \|\overline{w}\|^2_{H^2(\mathbb{B}_1)} \le C\Big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|w_{tt}\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{H^1(\mathbb{B}_1)}\Big). \tag{4.20}$$

The second estimate in (4.19) can be obtained by similar argument:

$$\begin{aligned}
&\|\nabla w\|^2_{H^2(\mathbb{B}_1)} = \|\nabla\overline{w}\|^2_{H^2(\mathbb{B}_1)} \le \|\overline{w}\|^2_{H^3(\mathbb{B}_1)}\\
&\le C\Big(\|\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_r\|^2_{H^{\frac{3}{2}}(\mathbb{S}^{n-1})} + \|w_{tt}\|^2_{H^1(\mathbb{B}_1)}\Big)\\
&\quad + C(T)\theta\Big(\|\nabla w_t\|^2_{H^1(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{H^1(\mathbb{B}_1)}\Big)\\
&\le C\Big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{L^2(\mathbb{B}_1)}\\
&\qquad + \|w_{tt}\|^2_{H^1(\mathbb{B}_1)} + \|\nabla w_t\|^2_{H^1(\mathbb{B}_1)}\Big) + C(T)\theta\|\nabla w\|^2_{H^2(\mathbb{B}_1)},
\end{aligned}$$

which implies that

$$\|\nabla w\|^2_{H^2(\mathbb{B}_1)} + \|\overline{w}\|^2_{H^3(\mathbb{B}_1)} \le C\Big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|w_{tt}\|^2_{H^1(\mathbb{B}_1)} + \|w_t\|^2_{H^2(\mathbb{B}_1)}\Big),$$

and similar arguments yield the remaining estimates in (4.19).

Combining (4.18) and (4.19), we have

$$\begin{aligned}
&\|\nabla w\|^2_{H^s(\mathbb{B}_1)} + \sum_{k=0}^{s}\|\partial_t^{s+1-k} w\|^2_{H^k(\mathbb{B}_1)}\\
&\le C\Big(\|\partial_t^{s+1} w\|^2_{L^2(\mathbb{B}_1)} + \sum_{k=1}^{s}\|\partial_t^k w\|^2_{H^1(\mathbb{B}_1)}\\
&\qquad + \|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)}\Big).
\end{aligned} \tag{4.21}$$

By (4.10) and (4.12), it is easy to get

$$\begin{cases}
\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} \le C\big(\|\nabla w\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{L^2(\mathbb{B}_1)}\big)\\
\quad + C(T)\theta\big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big),\\
\|\nabla w\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{L^2(\mathbb{B}_1)} \le C\big(\|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)}\big)\\
\quad + C(T)\theta\big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big),\\
\|\overline{w}_t\|^2_{L^2(\mathbb{S}^{n-1})} \le \|w_t\|^2_{L^2(\mathbb{S}^{n-1})} + C(T)\theta\big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big),\\
\|w_t\|^2_{L^2(\mathbb{S}^{n-1})} \le \|\overline{w}_t\|^2_{L^2(\mathbb{S}^{n-1})} + C(T)\theta\big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big).
\end{cases} \tag{4.22}$$

Finally, by using (4.21) and (4.22), we can improve (4.17) as follows:

$$
\begin{aligned}
(4.23)\qquad &\sum_{k=1}^{s}\Big\{\frac{1}{2}\frac{d}{dt}\Big(\|\partial_t^{k+1}w\|^2_{L^2(\mathbb{B}_1)}+\|\nabla\partial_t^k w\|^2_{L^2(\mathbb{B}_1)}\\
&\quad+\int_{\mathbb{B}_1} g_{ij}\nabla_i\partial_t^k w\nabla_j\partial_t^k w dx\Big)+\|\partial_t^{k+1}w\|^2_{L^2(\mathbb{S}^{n-1})}\Big\}\\
&\le C(T)\theta\sum_{k=0}^{s}\Big(\|\partial_t^{k+1}w\|^2_{L^2(\mathbb{S}^{s-1})}+\|\Omega\partial_t^k w\|^2_{L^2(\mathbb{S}^{s-1})}\Big)\\
&\quad+C(T)\theta\Big(\|\partial_t^{s+1}w\|^2_{L^2(\mathbb{B}_1)}+\sum_{k=1}^{s}\|\partial_t^k w\|^2_{H^1(\mathbb{B}_1)}+\|\nabla w\|^2_{L^2(\mathbb{B}_1)}\Big).
\end{aligned}
$$

Step 3. *Morawetz's energy estimates.* First of all, we rewrite the linear wave equation in system (4.8) in terms of the shift variable $\overline{w}$ as follows:

$$
(4.24)\qquad \Box\overline{w}=g_{i\alpha}(t,x,v,v_t,\nabla v)\partial^2_{i\alpha}\overline{w}-\frac{1}{|\mathbb{S}^{n-1}|}\frac{d}{dt}\int_{\mathbb{B}_1} g_{i\alpha}\partial^2_{i\alpha}\overline{w}dx.
$$

Next, we do the energy estimates of Morawetz type. By taking the L^2 inner product of (4.24) with $x\cdot\nabla\overline{w}$, we deduce that

$$
\begin{aligned}
&\frac{d}{dt}\Big[\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}\ \overline{w}_t dx+\frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\Big]\\
&\quad-\int_{\mathbb{B}_1}\nabla_j(x\cdot\nabla\overline{w}\nabla_j\overline{w})dx+\int_{\mathbb{B}_1}|\nabla\overline{w}|^2dx\\
&=\frac{1}{2}\int_{\mathbb{B}_1} x\cdot\nabla\big(|\overline{w}_t|^2-|\nabla\overline{w}|^2\big)dx+\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}g_{i\alpha}\nabla_i\overline{w}_\alpha dx\\
&\quad+\frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}_t dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx.
\end{aligned}
$$

Keeping in mind the boundary condition in (4.8) and $g_{i\alpha}=g_{\alpha i}$, and using Green's formula and integration by parts, we compute

$$
\begin{aligned}
&\frac{d}{dt}\Big[\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}\ \overline{w}_t dx+\frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\Big]\\
&\quad-\int_{\mathbb{S}^{n-1}}|w_t|^2d\sigma_y+\frac{1}{2}\int_{\mathbb{B}_1}|\overline{w}_t|^2+|\nabla\overline{w}|^2dx\\
&=-\frac{n-1}{2}\int_{\mathbb{B}_1}\big(|\overline{w}_t|^2-|\nabla\overline{w}|^2\big)dx+\frac{1}{2}\int_{\mathbb{S}^{n-1}}\big(|\overline{w}_t|^2-|\nabla\overline{w}|^2\big)d\sigma_y\\
&\quad+\int_{\mathbb{S}^{n-1}} x\cdot\nabla\overline{w}g_{i\alpha}x_i\partial_\alpha\overline{w}d\sigma_y-\int_{\mathbb{B}_1}\Big(g_{i\alpha}\nabla_i\overline{w}\nabla_\alpha\overline{w}+x\cdot\nabla\overline{w}\frac{d}{dx_i}g_{i\alpha}\partial_\alpha\overline{w}\Big)dx\\
&\quad+\frac{1}{|\mathbb{S}^{n-1}|}\Big(\int_{\mathbb{S}^{n-1}}\overline{w}_t d\sigma_y-n\int_{\mathbb{B}_1}\overline{w}_t dx\Big)\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\\
&\quad+\frac{1}{2}\int_{\mathbb{B}_1}\Big(ng_{i\alpha}\nabla_i\overline{w}\nabla_\alpha\overline{w}+x\cdot\nabla g_{i\alpha}\nabla_i\overline{w}\nabla_\alpha\overline{w}\Big)dx-\frac{1}{2}\int_{\mathbb{S}^{n-1}} g_{i\alpha}\nabla_i\overline{w}\nabla_\alpha\overline{w}d\sigma_y\\
&\le-\frac{n-1}{2}\int_{\mathbb{B}_1}\big(|\overline{w}_t|^2-|\nabla\overline{w}|^2\big)dx-\frac{1}{2}\int_{\mathbb{S}^{n-1}}|\Omega w|^2d\sigma_y
\end{aligned}
$$

$$+ C(T)\theta\big(\|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{L^2(\mathbb{S}^{n-1})} + \|\Omega w\|^2_{L^2(\mathbb{S}^{n-1})}$$
$$+ \|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big),$$

where in the last inequality we used (2.20), (4.12), and (4.22). Consequently, we arrive at

$$\begin{aligned}(4.25)\qquad &\frac{d}{dt}\Big[\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}\ \overline{w}_t dx + \frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1} x\cdot\nabla\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\Big]\\ &\quad + \frac{2}{5}\big(\|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|\Omega w\|^2_{L^2(\mathbb{S}^{n-1})}\big)\\ &\le 2\|w_t\|^2_{L^2(\mathbb{S}^{n-1})} + C(T)\theta\big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big)\\ &\quad - \frac{n-1}{2}\int_{\mathbb{B}_1}\big(|\overline{w}_t|^2 - |\nabla\overline{w}|^2\big)dx.\end{aligned}$$

At this stage, it is clear that we should estimate the last term of the above inequality. A straightforward calculation shows that

$$\begin{aligned}&\int_{\mathbb{B}_1}\big(|\overline{w}_t|^2 - |\nabla\overline{w}|^2\big)dx\\ &= \frac{d}{dt}\int_{\mathbb{B}^1}\overline{w}\ \overline{w}_t dx - \int_{\mathbb{B}_1}\Big\{|\nabla\overline{w}|^2 + \overline{w}\big(\Delta\overline{w}\\ &\quad + g_{i\alpha}\nabla_i\partial_\alpha\overline{w} - \frac{1}{|\mathbb{S}^{n-1}|}\frac{d}{dt}\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\big)\Big\}dx\\ &= \frac{d}{dt}\Big[\int_{\mathbb{B}_1}\overline{w}\ \overline{w}_t dx + \frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1}\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\Big]\\ &\quad - \int_{\mathbb{S}^{n-1}}\overline{w}\big(\partial_r\overline{w} + g_{i\alpha}x_i\partial_\alpha\overline{w}\big)d\sigma_y + \int_{\mathbb{B}_1}\big(g_{i\alpha}\nabla_i\overline{w}\partial_\alpha\overline{w}\\ &\quad + \nabla_i g_{i\alpha}\overline{w}\partial_\alpha\overline{w}\big)dx - \frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1}\overline{w}_t dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx.\end{aligned}$$

By (4.12), (4.14), (4.15), and (4.22), we arrive at

$$\begin{aligned}(4.26)\qquad &\int_{\mathbb{B}_1}\Big(|\overline{w}_t|^2 - |\nabla\overline{w}|^2\Big)dx\\ &\le \frac{d}{dt}\Big[\int_{\mathbb{B}_1}\overline{w}\ \overline{w}_t dx + \frac{1}{|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1}\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx + \frac{1}{2}\int_{\mathbb{S}^1}\overline{w}^2 d\sigma_y\Big]\\ &\quad + C(T)\theta\Big(\|\overline{w}_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla\overline{w}\|^2_{L^2(\mathbb{B}_1)} + \|w_t\|^2_{L^2(\mathbb{S}^{s-1})}\\ &\quad + \|\Omega w\|^2_{L^2(\mathbb{S}^{s-1})} + \|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\Big).\end{aligned}$$

Combining (4.22), (4.25), and (4.26), we finally arrive at

$$\begin{aligned}(4.27)\qquad &\frac{d}{dt}\Big[\int_{\mathbb{B}_1}\Big(\frac{n-1}{2}\overline{w} + x\cdot\nabla\overline{w}\Big)\overline{w}_t dx + \frac{n-1}{4}\int_{\mathbb{S}^{n-1}}\overline{w}^2 d\sigma_y\\ &\qquad + \frac{n+1}{2|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1}\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\Big]\\ &\quad + \frac{1}{4}\big(\|w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla w\|^2_{L^2(\mathbb{B}_1)} + \|\Omega w\|^2_{L^2(\mathbb{S}^{n-1})}\big)\\ &\le 3\|w_t\|^2_{L^2(\mathbb{S}^{s-1})} + C(T)\theta\big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\big).\end{aligned}$$

Noting that at the boundary

$$\partial_t^{k+1} w + \partial_t^k w_r = 0$$

holds for $1 \le k \le s$, $s \ge 3$, a similar argument yields that

$$\begin{aligned}(4.28)\quad &\sum_{k=1}^{s}\Big\{\frac{d}{dt}\Big[\int_{\mathbb{B}_1}\Big(\frac{n-1}{2}\partial_t^k w + x\cdot\nabla\partial_t^k w\Big)\partial_t^{k+1} w dx + \frac{n-1}{4}\|\partial_t^k w\|^2_{L^2(\mathbb{S}^{n-1})}\Big]\\ &\qquad + \frac{1}{4}\Big(\|\partial_t^{k+1} w\|^2_{L^2(\mathbb{B}_1)} + \|\nabla\partial_t^k w\|^2_{L^2(\mathbb{B}_1)} + \|\Omega\partial_t^k w\|^2_{L^2(\mathbb{S}^{n-1})}\Big)\Big\}\\ &\le 3\sum_{k=0}^{s}\|\partial_t^{k+1} w\|^2_{L^2(\mathbb{S}^{s-1})}\end{aligned}$$

for $s \ge 3$ and $1 \le k \le s$. Note that for the higher-order Morawetz energy estimates, we cannot use the shift variable $\overline{w}$, which will be made clear in the next step. We also point out that in the above estimate we used the same techniques as in (4.23).

Step 4. *Dissipative energy estimates.* Define

$$\begin{aligned}(4.29)\qquad X_0 &= \int_{\mathbb{B}_1}\Big(\frac{n-1}{2}\overline{w} + x\cdot\nabla\overline{w}\Big)\overline{w}_t dx + \frac{n-1}{4}\|\overline{w}\|^2_{L^2(\mathbb{S}^{n-1})}\\ &\quad + \frac{n-1}{2|\mathbb{S}^{n-1}|}\int_{\mathbb{B}_1}\overline{w}dx\int_{\mathbb{B}_1} g_{i\alpha}\partial_{i\alpha}\overline{w}dx\end{aligned}$$

and

$$(4.30)\qquad X_k = \int_{\mathbb{B}_1}\Big(\frac{n-1}{2}\partial_t^k w + x\cdot\nabla\partial_t^k w\Big)\partial_t^{k+1} w dx + \frac{n-1}{4}\|\partial_t^k w\|^2_{L^2(\mathbb{S}^{n-1})}$$

for $1 \le k \le s$, $s \ge 3$. By (2.23), (4.15), (4.12), and (4.22), it is obvious that

$$(4.31)\qquad \begin{cases}\Big|\int_{\mathbb{B}_1}\big(\frac{n-1}{2}\partial_t^k w + x\cdot\nabla\partial_t^k w\big)\partial_t^{k+1} w dx\Big|\\ \quad \le \frac{1}{2}\Big(\|\partial_t^{k+1} w\|^2_{L^2(\mathbb{B}_1)} + \|\nabla\partial_t^k w\|^2_{L^2(\mathbb{B}_1)}\Big) + \frac{n-1}{4}\|\partial_t^k w\|^2_{L^2(\mathbb{S}^{n-1})},\\ \Big|X_0 - \frac{n-1}{4}\|\overline{w}\|^2_{L^2(\mathbb{S}^{n-1})}\Big| \le C\Big(\|w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla w\|^2_{L^2(\mathbb{B}_1)}\Big)\\ \quad + C(T)\theta\Big(\|\nabla w_t\|^2_{L^2(\mathbb{B}_1)} + \|\nabla^2 w\|^2_{L^2(\mathbb{B}_1)}\Big),\end{cases}$$

where $1 \le k \le s$.

Noting (4.21), we multiply inequalities (4.16) and (4.17) by MC and then add the resulting inequalities to (4.27) and (4.28) to yield

$$(4.32)\qquad \frac{d}{dt}(A_s + MCE_s) + \frac{B_s}{8} \le 0,$$

where M is a big enough positive constant, A_s and B_s are defined as

$$\begin{cases} A_s = \sum_{k=0}^{s}\Big(MC\int_{\mathbb{B}_1} g_{ij}\nabla_i\partial_t^k w\nabla_i\partial_t^k w dx + X_k\Big),\\ B_s = E_s + \sum_{k=0}^{s}(\|\Omega\partial_t^k w\|^2_{L^2(\mathbb{S}^{n-1})} + \|\partial_t^{k+1} w\|^2_{L^2(\mathbb{S}^{n-1})}),\end{cases}$$

and E_s is given by

$$E_s = \|\nabla w\|^2_{L^2(\mathbb{B}_1)} + \|\partial_t^{s+1} w\|^2_{L^2(\mathbb{B}_1)} + \sum_{k=1}^{s}\|\partial_t^k w\|^2_{H^1(\mathbb{B}_1)}.$$

By (4.29), (4.30), and (4.31), it is easy to see that

$$-CE_s \le A_s \le CB_s,$$

which implies that

$$E_s \le A_s + CME_s \le \frac{1}{\gamma} B_s \tag{4.33}$$

for some small positive constant γ. Thus, we get

$$\frac{d}{dt}(A_s + MCE_s) + \gamma(A_s + MCE_s) \le 0.$$

Noting (4.30) and (4.31), it is easy to get

$$A_s(0) \le C\Big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\Big).$$

By Gronwall's inequality, we have

$$E_s \le C\exp(-\gamma t)\Big(\|\widetilde{f}_0\|^2_{H^{s+1}(\mathbb{B}_1)} + \|\widetilde{f}_1\|^2_{H^s(\mathbb{B}_1)}\Big). \tag{4.34}$$

Finally, the estimate (4.9) follows (4.21), (4.22), (4.34), and the elliptic estimates in (2.28). □

In what follows, we will outline the steps to construct local exact boundary controllability for quasi-linear wave equations (1.2) with initial data (1.6) and final data (1.7), which are similar to those in sections 2 and 3.

Analogous to Lemma 2.8, we have the following.

LEMMA 4.3. *Let $\varphi^{(k)}$ and $\phi^{(k)}$ be defined as the solutions of systems* (4.3)–(4.6); *$s \ge 3$ is an integer. Then the estimates*

$$\begin{aligned}
&\sum_{j=0}^{s+1}\Big(\|\partial_t^j\varphi^{(k)}(T,\cdot)\|_{H^{s+1-j}(\Omega_0)} + \|\partial_t^j\phi^{(k)}(0,\cdot)\|_{H^{s+1-j}(\Omega_0)}\Big)\\
&\le \frac{1}{8}\sum_{j=0}^{s+1}\Big(\|\partial_t^j\varphi^{(k-1)}(T,x)\|_{H^{s+1-j}(\Omega_0)} + \|\partial_t^j\phi^{(k-1)}(0,x)\|_{H^{s+1-j}(\Omega_0)}\\
&\qquad + \|\partial_t^j\varphi^{(k-2)}(T,x)\|_{H^{s+1-j}(\Omega_0)} + \|\partial_t^j\phi^{(k-2)}(0,x)\|_{H^{s+1-j}(\Omega_0)}\Big)
\end{aligned}$$

hold, provided that θ is small enough and T is big enough.

By the above lemma, we can show that $u = \Pi_\Lambda v$ is well-defined and $u \in \Lambda_\theta$, similarly to Theorem 2.7.

Then, analogously to section 3, we can show that $\Pi_\Lambda : v \to u = \Pi_\Lambda v$ is a strict contraction from Λ_θ to itself. By the standard contraction mapping theorem, there exists a point $u \in \Lambda_\theta$, such that $u = \Pi_\Lambda u$. For $(t,x) \in [0,T] \times \partial\Omega_0$, let

$$h(t,x) = u(t,x);$$

then h is the desired control and the proof of Theorem 1.6 is complete.

ANTIANGIOGENIC THERAPY IN CANCER TREATMENT AS AN OPTIMAL CONTROL PROBLEM*

URSZULA LEDZEWICZ† AND HEINZ SCHÄTTLER‡

Abstract. Antiangiogenic therapy is a novel treatment approach in cancer therapy that aims at preventing a tumor from developing its own blood supply system that it needs for growth. In this paper a mathematical model for antiangiogenic treatments based on a biologically validated model by Hahnfeldt et al. is analyzed as an optimal control problem and a full solution of the problem is given. Geometric methods from optimal control theory are utilized to arrive at the solution.

Key words. optimal control, geometric methods, cancer treatment, antiangiogenic therapy

1. Introduction.

The most important limiting factor for the success of cancer chemotherapy treatments lies in both intrinsic and acquired drug resistance. Malignant cancer cell populations are highly heterogeneous—the number of genetic errors present within one cancer cell can lie in the thousands [16]—and fast duplications combined with genetic instabilities provide just one of several mechanisms which allow for quickly developing acquired resistance to anticancer drugs. In addition, intrinsic resistance (i.e., the specific drug's activation mechanism simply doesn't work) makes some cancer cells not susceptible to many cytotoxic agents. "... the truly surprising thing is that some malignancies can be cured even with current approaches" [8, p. 65]. Several mechanisms to circumvent the problem of drug resistance have been tried but so far without success, and currently no medical solution to the problem exists. In fact, it is acquired or intrinsic drug resistance which eventually makes most chemotherapy fail. At the same time, similar phenomena do not take place for the healthy proliferating cells. For example, regretfully, bone marrow does not develop drug resistance to the killing agent [10].

As of today, the search for therapy approaches that would avoid drug resistance still is of tantamount importance in medicine. Two such approaches that are currently being pursued in their experimental stages are immunotherapy and antiangiogenic treatments. While immunotherapy tries to coax the body's immune system to take action against the cancerous growth, tumor antiangiogenesis aims at depriving a tumor from developing the necessary blood cells and capillaries that it needs for further growth. Since the treatment does not target cancer cells but normal cells, no occurrence of drug resistance has been reported in lab studies. (These treatments, however, are only in the stage of experimental studies and initial clinical trials.) For

this reason tumor antiangiogenesis has been called a therapy resistant to resistance which provides a new hope in treatment of tumor-type cancers [10].

There exist several mathematical models for the evolution of tumor antiangiogenesis as a dynamical system, with the one formulated by Hahnfeldt et al. in [9] probably being the most prominent one. This model was biologically validated in lab experiments and became the basis for several modifications and simplifications [5, 6] undertaken in an effort to both better understand the dynamical properties of the underlying mechanisms and to make the mathematical model easier and more tractable for analysis. For example, a dynamical systems analysis of the model by Hahnfeldt et al. and of several modifications (with more general growth models for the growth of cancer cells and slightly different dynamics for the evolution related to endothelial cells) is given in the paper by d'Onofrio and Gandolfi [5]; Ergun, Camphausen, and Wein [6] consider an optimal control problem for the scheduling of antiangiogenic inhibitors both as monotherapy and in combination with radiotherapy. While these models are variations of the specific dynamics proposed by Hahnfeldt et al. in [9], in the papers by Agur et al. [1] and Forys, Keifetz, and Kogan [7] more generally dynamical properties of models for angiogenesis are investigated under minimal assumptions on the form of the growth functions describing the dynamics.

In this paper we consider the original mathematical model for tumor antiangiogenesis formulated and validated by Hahnfeldt et al. in [9] and analyze it as an optimal control problem. Using geometric methods of optimal control theory, for this model we compute how to schedule a given amount of angiogenic inhibitors to achieve the maximum reduction in tumor volume possible. The key feature of the solution is an optimal singular arc whose geometric analysis forms the core of the mathematical argument. Optimal controls then are concatenations of bang controls (constant controls that give either a full or no dose of inhibitors) and the optimal singular control (a specific smooth control that administers the inhibitors using a time-varying feedback schedule at less than a maximum rate). The most general structure of optimal controls possible is a concatenation of the form "**0asa0**," where **a** and **0** denote trajectories with *full*, respectively, *no* antiangiogenic therapy, and **s** stands for a segment along the *singular* arc. However, depending on the initial condition not all of these pieces are present. Our theoretical analysis reduces the structure of optimal controls to at most this structure but for some initial conditions still allows for a one-parameter family of extremals of this form. Then, given any initial condition, the optimal solution is easily computed numerically based on our analysis. The most typical and medically most relevant scenarios are optimal protocols that take the simple form "**a0**" when all inhibitors are administered at the beginning or "**as0**" when the dosage is adjusted as the singular arc is reached and then all available inhibitors are being used up along the singular arc. If the optimal policy along the singular arc comes close to a point where the singular control saturates at the upper value a, then optimal trajectories actually leave the singular arc prior to saturation (and this is consistent with the behavior of optimal controls near saturation points; see, for example, [17] or [2]) and are of the type "**asa0**." The full structure "**0asa0**" arises only for initial conditions that are not significant for the underlying problem.

A preliminary announcement of some partial results presented in this paper has been given without proofs in [14]. Here the analysis is completed, and proofs are included.

2. Medical background and mathematical model [9]. A growing tumor, after it reaches just a few millimeters in diameter, no longer can rely on blood vessels of the host for its supply of nutrients, but it needs to develop its own vessels and

capillaries for blood supply. In this process, called *angiogenesis*, there is a reciprocal signaling between endothelial cells and tumor cells. Tumor cells produce vascular endothelial growth factor (VEGF) to stimulate endothelial cell growth; endothelial cells in turn provide the lining for the newly forming blood vessels that supply nutrients to the tumor and thus sustain tumor growth. But endothelial cells also have receptors which make them sensitive to inhibitors of inducers of angiogenesis such as, for example, endostatin, and pharmacologic therapies typically target the growth factor VEGF trying to impede the development of new blood vessels and capillaries. Overall, angiogenesis can be viewed as a complex balance of stimulatory and inhibitory mechanisms regulated through microenvironmental factors.

In the model developed by Hahnfeldt et al. in [9] these effects are summarized in a two-dimensional dynamical system with the *primary tumor volume* p and the *carrying capacity of the vasculature* q as variables. The latter is defined as the "maximal tumor volume potentially sustainable by the network" [9] and is implicitly assumed proportional to the number of endothelial cells. Thus the set $\mathcal{D}_0 = \{(p,q) \in \mathbb{R}^2_+ : p = q\}$ corresponds to points where the vasculature is adequate to support the tumor, while $\mathcal{D}_- = \{(p,q) \in \mathcal{D} : p < q\}$ corresponds to growing tumors and $\mathcal{D}_+ = \{(p,q) \in \mathcal{D} : p > q\}$ to shrinking tumors. A growth function describes the size of the tumor dependent on the carrying capacity q and is chosen as Gompertzian in the original model. Other models are equally realistic and are considered, for instance, in [5] or [7], but here we stay with the original choice. Thus the rate of change in the primary tumor volume is modeled as

$$\dot{p} = -\xi p \ln\left(\frac{p}{q}\right), \tag{2.1}$$

where ξ denotes a tumor growth parameter. The overall dynamics for the carrying capacity is a balance between stimulation and inhibition, and its basic structure is of the form

$$\dot{q} = -\mu q + S(p,q) - I(p,q) - Guq, \tag{2.2}$$

where μq describes the loss of endothelial cells due to natural causes (death, etc.), I and S denote endogenous inhibition and stimulation terms, respectively, and Guq represents a loss due to additional outside inhibition. The variable u represents the control in the system and corresponds to the angiogenic dose rate, while G is a constant that represents the antiangiogenic killing parameter. Generally μ is small, often this term is negligible compared to the other factors, and thus in the literature often μ is set to 0 in this equation.

In [9] a spatial analysis of the underlying consumption-diffusion model was carried out that led to the following two principal conclusions:

1. The inhibitor will impact endothelial cells in a way that grows like the volume of cancer cells to the power $\frac{2}{3}$.

The exponent $\frac{2}{3}$ arises since inhibitors need to be released through the surface of the tumor. Thus in [9] the inhibitor term is taken in the form

$$I(p,q) = dp^{\frac{2}{3}}q, \tag{2.3}$$

with d a constant, the "death" rate. The second implication of the analysis in [9] is that:

2. the inhibitor term will tend to grow at a rate of $q^\alpha p^\beta$ faster than the stimulator term where $\alpha + \beta = \frac{2}{3}$.

However, the choice of α and β is not imperative in their analysis and in fact is one of the main sources for the various other models also considered in the literature [5, 6]. In their original work [9] Hahnfeldt et al. select $\alpha = 1$ and $\beta = -\frac{1}{3}$ resulting in the simple stimulation term

$$S(p, q) = bp, \tag{2.4}$$

with b a constant, the "birth" rate. However, other choices are possible, and, for example, choosing $\alpha = 0$ and $\beta = \frac{2}{3}$ results in the equally simple form $S(p, q) = bq$ chosen in [5]. In that paper the dynamics for both models is analyzed, and it is shown for the uncontrolled system that there exists a unique globally asymptotically stable equilibrium (which, of course, is not viable biologically). Adding a control term, this equilibrium can be shifted to lower values or, depending on the parameter values, even eliminated altogether. In the latter case all trajectories converge to the origin in infinite time. This, in principle, would be the desired situation.

The problem then becomes how to administer a given amount of inhibitors to achieve the "best possible" effect. In this paper we use the dynamics of the original model from [9] and formulate this aim as the following optimal control problem.

[HPFH]. For a free terminal time T, minimize the value $p(T)$ subject to the dynamics

$$\dot{p} = -\xi p \ln\left(\frac{p}{q}\right), \qquad p(0) = p_0, \tag{2.5}$$

$$\dot{q} = bp - (\mu + dp^{\frac{2}{3}})q - Guq, \qquad q(0) = q_0, \tag{2.6}$$

$$\dot{y} = u, \qquad y(0) = 0, \tag{2.7}$$

over all measurable functions $u : [0, T] \to [0, a]$ for which the corresponding trajectory satisfies $y(T) \le A$.

As is customary in optimal control formulations, we adjoin the constraint as a third variable. Later on, for all of our numerical illustrations we use the following parameter values which are taken from [9]: The variables p and q are volumes measured in mm^3; $\xi = \frac{0.192}{\ln 10} = 0.084$ per day (adjusted to the natural logarithm), $b = 5.85$ per day, $d = 0.00873$ per mm^2 per day, $G = 0.15$ kg per mg of dose per day, and for illustrative purposes we chose a small positive value for μ: $\mu = 0.02$ per day. But we want to emphasize already that *our mathematical analysis and conclusions are valid independently of the specific parameter values* and lead to robust implications about the structure of optimal controls for this model.

3. The dynamical systems for constant controls. For the analysis of the optimal control problem it is of benefit to fully understand the dynamic properties of the systems for a constant control $u \equiv v$, with v some value in the control set $[0, a]$. Our statements in this section are only minor extensions of the analysis given in the paper by d'Onofrio and Gandolfi [5], and we refer the reader to that paper for the proofs about our claims of stability properties of the equilibria. All statements are for the natural domain $\mathbb{R}^2_+ = \{(p, q) : p > 0, q > 0\}$ of the system. The following fact about the dynamical behavior of the system is an easy corollary of the results proven in [5].

PROPOSITION 3.1. *For any admissible control u and arbitrary positive initial conditions p_0 and q_0, the corresponding solution (p, q) exists for all times $t \ge 0$, and both p and q remain positive.*

Assuming $b > \mu$, the uncontrolled system ($u = 0$) has a unique globally asymptotically stable equilibrium point at $(\bar{p}, \bar{q})$ given by $\bar{p} = \bar{q} = (\frac{b-\mu}{d})^{\frac{3}{2}}$. This value naturally is far too high to be acceptable, and the medically relevant region is contained in the domain

$$\mathcal{D} = \{(p, q) : 0 < p \leq \bar{p},\ 0 < q \leq \bar{q}\}. \tag{3.1}$$

In order to exclude irrelevant discussions about the structure of optimal controls in regions where the model does not represent the underlying medical problem to begin with, we henceforth restrict our discussions to this square domain $\mathcal{D}$.

PROPOSITION 3.2. *$\mathcal{D}$ is positively invariant for the flow of the control system; i.e., if $(p_0, q_0) \in \mathcal{D}$, then for any admissible control u defined over the interval $[0, \infty)$ the solution $(p(\cdot), q(\cdot))$ to the corresponding dynamics with initial condition $(p(0), q(0)) = (p_0, q_0)$ exists for all times $t \geq 0$ and lies in $\mathcal{D}$, $(p(t), q(t)) \in \mathcal{D}$.*

Proof. The positive invariance of the region $\mathcal{P} = \{(p, q) : 0 < p,\ 0 < q\}$ for any admissible control u directly follows from Proposition 3.1. The dynamics is clearly pointing into $\mathcal{D}$ on the boundary segment $\{(p, q) \in \mathcal{D} : p = \bar{p},\ 0 < q < \bar{q}\}$, since for $p > q$ we always have $\dot{p} < 0$. For a constant control v, the isoclines for $\dot{q} = 0$ are given by

$$q = \Xi_v(p) = \frac{bp}{\mu + Gv + dp^{\frac{2}{3}}}. \tag{3.2}$$

The functions Ξ_v are strictly increasing, $\Xi_v(0) = 0$, and at $\bar{p}$ take the value

$$\Xi_v(\bar{p}) = \frac{b}{b + Gv}\bar{p}. \tag{3.3}$$

In particular, the smallest value is given for $v = a$ and $\Xi_0(\bar{p}) = \bar{p}$. It thus follows that on the boundary segment $\{(p, q) \in \mathcal{D} : 0 < p < \bar{p},\ q = \bar{q}\}$ we have $\dot{q} < 0$ for all controls. The point $(\bar{p}, \bar{q})$ is the equilibrium point for $u = 0$, and the dynamics points into $\mathcal{D}$ for $u = a$ at this point. Thus, regardless of the control value v, trajectories can never leave the region $\mathcal{D}$. □

By increasing the value v of the control, the equilibrium can be shifted towards the origin along the diagonal and finally be eliminated altogether. As a function of v the equilibrium is the unique fixed point of the equation $p = \Xi_v(p)$ in $\{p > 0\}$ and is given by

$$\bar{p}(v) = \bar{q}(v) = \left(\frac{b - \mu - Gv}{d}\right)^{\frac{3}{2}} \tag{3.4}$$

provided $b - \mu > Gv$, and this equilibrium $(\bar{p}(v), \bar{q}(v))$ still is globally asymptotically stable. As $b - \mu \leq Gv$, the system no longer has an equilibrium point, and now all trajectories converge to the origin as $t \to \infty$ [5]. Thus, theoretically eradication of the tumor was possible in this case under the unrealistic scenario of constant treatment with an unlimited supply of inhibitors. Since this is the most desirable situation, for our analysis of the optimal control problem we also **assume** that

$$(\mathbf{A}) \qquad \mathbf{Ga} > \mathbf{b} - \mu > \mathbf{0}. \tag{3.5}$$

Figure 3.1 shows the phase portraits of the uncontrolled system on the left and for $u \equiv a$ on the right. In our figures we prefer to have the tumor volume as the vertical

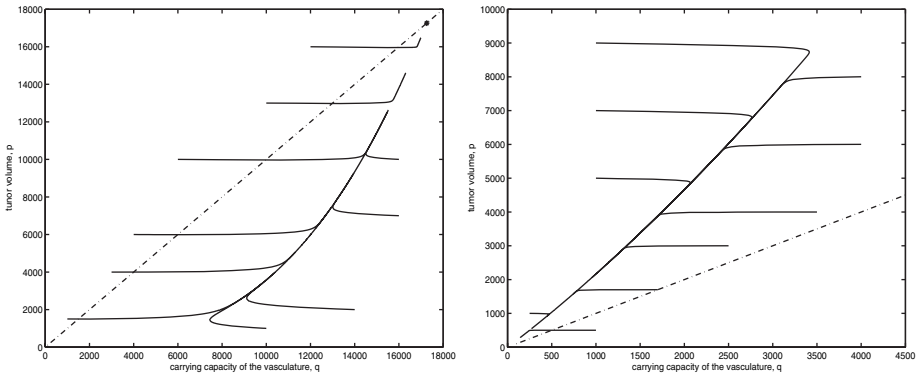

FIG. 3.1. *Phase portraits for* $u = 0$ *and* $u = a = 75$.

axis since this better visualizes the tumor reduction (respectively, increase). For comparison the diagonal is included in these figures as a dashed-dotted line. It is not difficult to extend all results of this paper to the case when the dynamics for $u \equiv a$ still has a positive equilibrium, but this will not be pursued here for reasons of space.

However, the domain $\mathcal{D}$ still contains initial conditions that give rise to degenerate cases that we want to exclude. Recall that $\mathcal{D}_+ = \{(p,q) \in \mathcal{D} : p > q\}$, $\mathcal{D}_0 = \{(p,q) \in \mathcal{D} : p = q\}$, and $\mathcal{D}_- = \{(p,q) \in \mathcal{D} : p < q\}$. Both of the trajectories for the constant controls $u = 0$ and $u = a$ cross the diagonal portion $\mathcal{D}_0$ transversally: For $u = 0$ trajectories cross from $\mathcal{D}_+$ into $\mathcal{D}_-$, while they cross in the opposite direction from $\mathcal{D}_-$ into $\mathcal{D}_+$ for $u = a$. Also, trajectories for $u = 0$ approach the stable equilibrium $(\bar{p}, \bar{q})$ from within the region $\mathcal{D}_-$, while trajectories for $u = a$ converge to the origin as $t \to \infty$ in the region $\mathcal{D}_+$. It follows from the dynamics for p, (2.5), that the p-value of trajectories is always decreasing in $\mathcal{D}_+$ and always increasing in $\mathcal{D}_-$. As a result, for some initial conditions (p_0, q_0, y_0), with $(p_0, q_0) \in \mathcal{D}_-$, it is possible that the (mathematically) optimal time T is $T = 0$. This situation arises when the amount of available inhibitors simply is not sufficient to reach a point in the region $\mathcal{D}_+$ that would have a lower p-value than p_0. In such a case it is not possible to decrease the tumor volume with the available amount of inhibitors. It is possible only to slow down the tumor's growth. Indeed, it is correct that the best way of doing this is to give the full dose $u = a$ until all inhibitors run out—this follows from the structure of optimal controls to be shown later—but this is not the mathematically "optimal" solution for problem [HPFH]. This one is simply to do nothing and take $T = 0$. Since this introduces a number of degeneracies into the analysis, we make the following definition.

DEFINITION 3.3. *We say an initial condition* $(p_0, q_0) \in \mathcal{D}_-$ *is* ill-posed *if for any admissible control it is not possible to reach a point* (p, q) *with* $p < p_0$. *In this case the optimal solution for the problem [HPFH] is given by* $T = 0$. *Otherwise* (p_0, q_0) *is* well-posed *and the optimal time* T *will be positive.*

It is clear that all initial conditions with $(p_0, q_0) \in \mathcal{D}_+ \cup \mathcal{D}_0$ are well-posed (since p decreases in $\mathcal{D}_+$ and trajectories with $u = a$ enter $\mathcal{D}_+$ from $\mathcal{D}_0$), and it is easily decided whether an initial condition $(p_0, q_0) \in \mathcal{D}_-$ is ill-posed. For our analysis of optimal controls, however, we *consider only well-posed initial conditions.*

4. The maximum principle and preliminary analysis of optimal controls. It follows from classical results that there exists an optimal solution to our

problem [4]. First-order necessary conditions for optimality of a control u are given by the *Pontryagin maximum principle* [18, 3, 4]: If u_* is an optimal control defined over an interval $[0,T]$ with corresponding trajectory $(p_*,q_*,y_*)^T$, then there exist a constant $\lambda_0 \geq 0$ and an absolutely continuous covector $\lambda : [0,T] \to (\mathbb{R}^3)^*$ (which we write as a row vector) such that (a) $(\lambda_0,\lambda(t)) \neq (0,0)$ for all $t \in [0,T]$, (b) the adjoint equations hold with transversality conditions

(4.1)
$$\dot{\lambda}_1 = \xi\lambda_1\left(\ln\left(\frac{p_*(t)}{q_*(t)}\right)+1\right)+\lambda_2\left(\frac{2}{3}d\frac{q_*(t)}{p_*^{\frac{1}{3}}(t)}-b\right), \quad \lambda_1(T)=\lambda_0,$$

(4.2)
$$\dot{\lambda}_2 = -\xi\lambda_1\frac{p_*(t)}{q_*(t)}+\lambda_2\left(\mu+dp_*^{\frac{2}{3}}(t)+Gu\right), \qquad \lambda_2(T)=0,$$

(4.3)
$$\dot{\lambda}_3 = 0, \qquad \lambda_3(T) = \begin{cases} 0 & \text{if } y(T)<A, \\ \text{free} & \text{if } y(T)=A, \end{cases}$$

and (c) the optimal control u_* minimizes the Hamiltonian H

$$H = -\lambda_1\xi p\ln\left(\frac{p}{q}\right)+\lambda_2\left(bp-\left(\mu+dp^{\frac{2}{3}}\right)q-Guq\right)+\lambda_3 u, \tag{4.4}$$

along $(\lambda(t),p_*(t),q_*(t))$ over the control set $[0,a]$ with the minimum value given by 0.

We call a pair $((p,q,y),u)$ consisting of an admissible control u with corresponding trajectory (p,q,y) an *extremal* (pair) if there exist multipliers (λ_0,λ) such that the conditions of the maximum principle are satisfied and the triple $((p,q,y),u,(\lambda_0,\lambda))$ is an extremal lift (to the cotangent bundle). Extremals with $\lambda_0 = 0$ are called *abnormal*, while those with a positive multiplier λ_0 are called *normal*. In this case it is possible to normalize $\lambda_0 = 1$. The following lemmas summarize some elementary properties of optimal controls and extremals for well-posed initial conditions.

LEMMA 4.1. *If u_* is an optimal control with corresponding trajectory $(p_*,q_*,y_*)^T$, then at the final time $p_*(T) = q_*(T)$ and $y_*(T) = A$; i.e., all available inhibitors have been used up.*

Proof. Since the p-dynamics is Gompertzian, (2.5), the cancer volume is growing for $p < q$ and is shrinking for $p > q$. This implies that optimal trajectories can terminate only at times where $p_*(T) = q_*(T)$. For, if $p_*(T) < q_*(T)$, then it would simply have been better to stop earlier since p was increasing over some interval $(T-\varepsilon,T]$. (Recall that we are assuming that the initial condition is well-posed so that the optimal final time T is positive.) On the other hand, if $p_*(T) > q_*(T)$, then we can always add another small interval $(T,T+\varepsilon]$ with the control $u = 0$ without violating any of the constraints and p will decrease along this interval if ε is small enough. Thus at the final time necessarily $p_*(T) = q_*(T)$. If now $y(T) < A$, then we can still add a small piece of a trajectory for $u = a$ over some interval $[0,\varepsilon]$. Since $\dot{q} < 0$ on the diagonal $\mathcal{D}_0$, the corresponding trajectory lies in $\mathcal{D}_+$, and thus the value of p is decreasing along this trajectory contradicting the optimality of T. ∎

LEMMA 4.2. *Extremals are normal. The multipliers λ_1 and λ_2 cannot vanish simultaneously; λ_2 has only simple zeros. The multiplier λ_3 is constant and nonnegative.*

Proof. The multipliers λ_1 and λ_2 satisfy the homogeneous linear system (4.1) and (4.2), and thus they vanish identically if they vanish at some time t. If $\lambda_0 = 0$, then

the nontriviality of $(\lambda_0, \lambda(t))$ implies that the multiplier λ_3, which is constant, is not zero. The condition $H \equiv 0$ on the Hamiltonian therefore gives $u \equiv 0$; i.e., the initial condition is ill-posed. Thus, without loss of generality we may assume that $\lambda_0 = 1$ and hence λ_1 and λ_2 cannot vanish simultaneously. In particular, whenever $\lambda_2(t) = 0$, then $\dot{\lambda}_2(t) \neq 0$, and thus λ_2 has only simple zeros.

For the final time T it follows from $p_*(T) = q_*(T)$, the transversality condition $\lambda_2(T) = 0$, and the condition $H(T) \equiv 0$ that $\lambda_3 u_*(T) = 0$. If $\lambda_3 < 0$, then the function $\Phi(t) = \lambda_3 - \lambda_2(t) G q_*(t)$ will be negative on some interval $(T - \varepsilon, T]$, and thus by the minimization condition (c) on the Hamiltonian the control must be given by $u_*(t) = a$ on this interval which is a contradiction. Hence $\lambda_3 \geq 0$. ∎

LEMMA 4.3. *If $\lambda_3 = 0$, then the corresponding optimal control is constant over the interval $[0, T]$ and given by the control $u \equiv a$.*

Proof. In this case the Hamiltonian function reduces to

$$H = -\lambda_1 \xi p \ln\left(\frac{p}{q}\right) + \lambda_2 \left(bp - \left(\mu + dp^{\frac{2}{3}}\right) q - Guq\right), \tag{4.5}$$

and thus the minimization condition (c) implies that

$$u_*(t) = \begin{cases} 0 & \text{if } \lambda_2(t) < 0, \\ a & \text{if } \lambda_2(t) > 0. \end{cases}$$

Since $\lambda_2(T) = 0$ and $\dot{\lambda}_2(T) = -\xi \lambda_1(T) \frac{p_*(t)}{q_*(t)} = -\xi < 0$, λ_2 is positive on some interval $(\tau, T]$, and here the control is given by $u_*(t) = a$. Since $p_*(T) = q_*(T)$, it follows that the trajectory entirely lies in $\mathcal{D}_-$ as long as the control is $u \equiv a$. But then λ_2 cannot have another zero τ since otherwise $H(\tau) = -\lambda_1(\tau) \xi p(\tau) \ln(\frac{p(\tau)}{q(\tau)}) \neq 0$. Thus the control must be constant $u \equiv a$. ∎

Except for this extremely degenerate case (the initial condition is such that with giving the full dose we reach the diagonal exactly when all inhibitors have been exhausted), we can, as we henceforth do, without loss of generality therefore assume that λ_3 is positive.

LEMMA 4.4. *If $\lambda_3 > 0$, then optimal controls end with an interval $(\tau, T]$ where $u_* \equiv 0$.*

The function

$$\Phi(t) = \lambda_3 - \lambda_2(t) G q_*(t), \tag{4.6}$$

which determines the structure of the optimal control u_* through the minimization property (c) on the Hamiltonian H, is called the *switching function* of the problem, and optimal controls satisfy

$$u_*(t) = \begin{cases} 0 & \text{if } \Phi(t) > 0, \\ a & \text{if } \Phi(t) < 0. \end{cases} \tag{4.7}$$

A priori the control is not determined by the minimum condition at times when $\Phi(t) = 0$. If $\Phi(\tau) = 0$, but $\dot{\Phi}(\tau) \neq 0$, then the control switches between $u = 0$ and $u = a$ depending on the sign of $\dot{\Phi}(\tau)$. On the other hand, if $\Phi(t)$ vanishes identically on an open interval, then the minimization property in itself gives no information about the control. However, in this case also all derivatives of $\Phi(t)$ must vanish, and this may and typically does determine the control. Controls of this kind are called *singular*, while we refer to the constant controls as *bang* controls. Optimal controls

then need to be synthesized from these candidates through an analysis of the switching function and its derivatives.

The computations of the derivatives of the switching function Φ can be expressed concisely within the framework of geometric optimal control theory, and we therefore now write the state as a 3-dimensional vector $z = (z_1, z_2, z_3)^T$, with $z_1 = p$, $z_2 = q$, and $z_3 = y$. In vector notation the dynamics takes the form

$$\dot{z} = f(z) + ug(z), \tag{4.8}$$

with

$$f(z) = \begin{pmatrix} -\xi p \ln\left(\frac{p}{q}\right) \\ bp - \left(\mu + dp^{\frac{2}{3}}\right) q \\ 0 \end{pmatrix} \tag{4.9}$$

and

$$g(z) = \begin{pmatrix} 0 \\ -Gq \\ 1 \end{pmatrix}. \tag{4.10}$$

The adjoint equation then simply becomes

$$\dot{\lambda}(t) = -\lambda(t) \left(Df(z(t)) + u_*(t) Dg(z(t))\right), \tag{4.11}$$

where Df and Dg denote the matrices of the partial derivatives of the vector fields which are evaluated along $z(t)$. The derivatives of the switching function can easily be computed using the following well known result that can be verified by an elementary direct calculation. Here $\langle \cdot, \cdot \rangle$ denotes the standard inner product on $\mathbb{R}^3$, i.e., for a covector $\lambda \in (\mathbb{R}^3)^*$ and a vector $z \in \mathbb{R}^3$, $\langle \lambda, z \rangle = \lambda z$.

PROPOSITION 4.5. *Let h be a continuously differentiable vector field, and define*

$$\Psi(t) = \langle \lambda(t), h(z(t)) \rangle. \tag{4.12}$$

Then the derivative of Ψ along a solution to the system equation (4.8) *for control u and a solution λ to the corresponding adjoint equation* (4.11) *is given by*

$$\dot{\Psi}(t) = \langle \lambda(t), [f + ug, h] z(t) \rangle, \tag{4.13}$$

where

$$[f, h](z) = Dh(z) f(z) - Df(z) h(z) \tag{4.14}$$

denotes the Lie bracket of the vector fields f and h.

5. Synthesis of optimal controlled trajectories. In this section we first give an overview of the structure of optimal controlled trajectories, but the proofs will be postponed to the remaining sections of the paper. We summarize the general structure of optimal controls and trajectories in the following theorem.

THEOREM 5.1. *Given $\tilde{z} = (\tilde{p}, \tilde{q}, 0)$, with $(\tilde{p}, \tilde{q}) \in \mathcal{D}$, optimal controls are* at most *concatenations of the form* **0asa0**, *with* **0** *denoting an arc along the constant control $u = 0$,* **a** *denoting an arc along the constant control $u = a$, and* **s** *denoting an arc along the singular curve $\mathcal{S}$.*

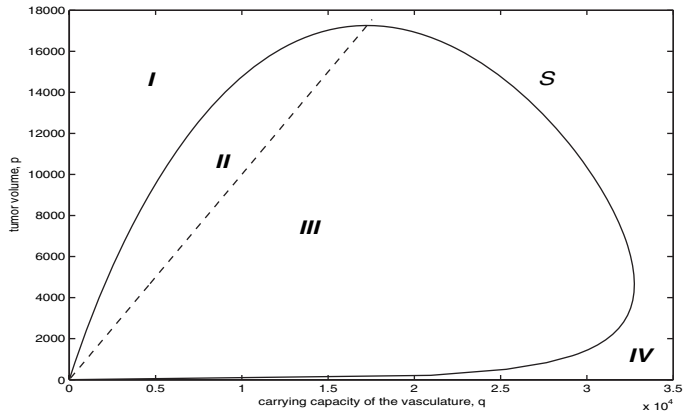

FIG. 5.1. *The regions* I, II, III, *and* IV.

This result limits the possible concatenations in the sense that it provides an upper bound. But for many initial conditions the concatenation structure is quite shorter (pieces are missing), and there exists a unique extremal of this type which is the optimal solution. However, there also are initial conditions for which there exists a one-parameter family of extremals of this type, and in these cases the optimal control needs to be computed numerically through minimizing a 1-dimensional function (see section 8). Once a simple maximal concatenation structure such as the one given in Theorem 5.1 has been determined, this is a straightforward argument.

Clearly, optimal trajectories lie in $\mathbb{R}^3$, and at every point the actions depend on the available amount of inhibitors. However, it is more illustrative to consider the projections of trajectories into the (p,q)-plane,[1] and it is convenient, and only a slight abuse of terminology, not to distinguish in our language between the trajectories in (p,q,y)-space and their projections onto the (p,q)-coordinates.

The anchor piece of the synthesis is an optimal singular arc. It will be shown in section 6 that singular trajectories can lie only on a looplike curve $\mathcal{S}$ in (p,q)-space where the vector fields f and the Lie bracket $[f,g]$ are linearly dependent and that there exists a unique arc Γ on $\mathcal{S}$ where the singular control is admissible, i.e., satisfies the control constraints $0 \le u \le a$. This curve $\mathcal{S}$ and the diagonal $\mathcal{D}_0 = \{(p,q) : p = q\}$ also form boundary curves between optimal bang-bang switchings in the order $a0$ and of the reverse order $0a$, and the concatenation structure of optimal controls is determined by the location of the initial condition relative to these curves. Denote by $\mathcal{S}_+$ the region outside of the singular loop $\mathcal{S}$ and by $\mathcal{S}_-$ the region inside this loop, and define the following regions (see Figure 5.1):

$$\mathrm{I} = \mathcal{D}_+ \cap \mathcal{S}_+, \quad \mathrm{II} = \mathcal{D}_+ \cap \mathcal{S}_-, \quad \mathrm{III} = \mathcal{D}_- \cap \mathcal{S}_-, \quad \mathrm{IV} = \mathcal{D}_- \cap \mathcal{S}_+.$$

In Figure 5.2 we indicate the structure of optimal controlled trajectories for a representative collection of initial conditions and have highlighted one example as a thick curve. (Pieces of trajectories corresponding to $u = a$ are shown as dashed curves, and pieces of $u = 0$ trajectories are shown as solid curves; pieces along the singular arc follow the curve $\mathcal{S}$.) The initial condition for the highlighted trajectory lies in region II, and the optimal control is of the form $as0$: The control initially is

[1] In our graphs we prefer to have q as the horizontal variable and p along the vertical axis. Visually this better corresponds to a decrease or increase in the primary cancer volume.

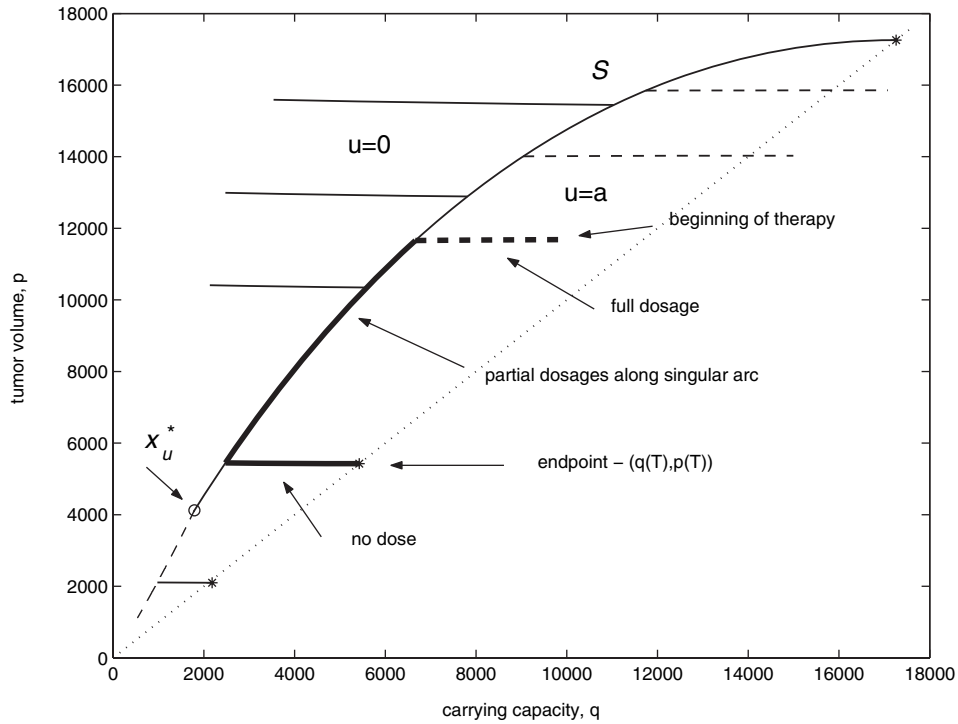

FIG. 5.2. *Synthesis of optimal controlled trajectories.*

given by $u = a$ until the singular arc Γ is reached; at this time the control switches to the singular control and follows the admissible singular arc Γ until all inhibitors have been exhausted; due to aftereffects the minimum value for the tumor volume then is reached when, after termination of therapy, the system crosses the diagonal along the trajectory for $u = 0$. This is the typical structure of optimal controlled trajectories for initial conditions in II, but it depends on two facts: The overall amount of inhibitors is large enough to reach the singular arc, but it is not so large that the singular control would saturate along the singular arc at a specific point x_u^* (computed in section 6.2). If there are not enough inhibitors to reach Γ, the optimal control is simple and is just of type $a0$, giving all inhibitors at maximum dosage from the beginning until they become exhausted. If the amount of inhibitors is large enough so that the singular control would saturate at the point x_u^* while following the singular arc, the structure of optimal controls is more complex, and in this case controls can be of type $a0$ or $asa0$. Typically, as the singular arc Γ is reached, now the control switches and follows the singular arc for some time period, but in this case optimal trajectories leave the singular arc before reaching x_u^*, and the remaining inhibitors are exhausted along a full dose segment with $u = a$. But for trajectories that meet the singular arc close to the saturation point x_u^* optimal controls do not switch to the singular control but simply follow $u = a$ until inhibitors are exhausted. The precise structure of optimal trajectories that come close to the saturation point is rather difficult but for a particular initial condition is easily resolved numerically.

For well-posed initial conditions in regions III and IV, optimal controlled trajectories will eventually enter region II along a trajectory for $u = a$ and then follow the pattern described above. The specific form depends on the amount of inhibitors

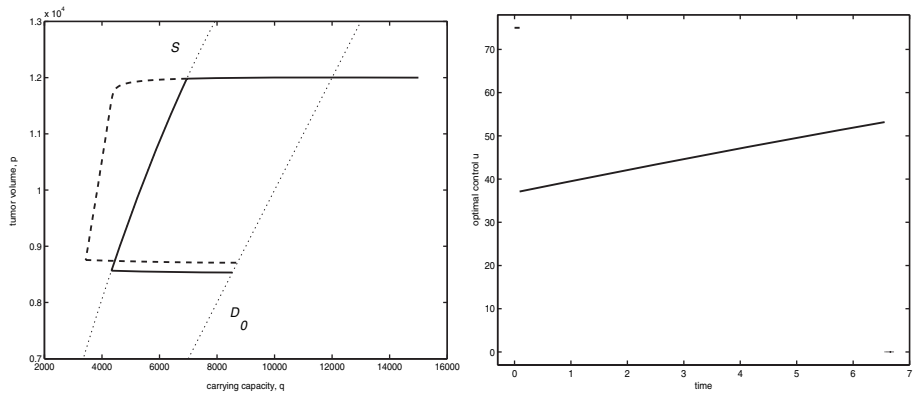

FIG. 5.3. *An optimal as*0 *trajectory with corresponding control.*

left over as the diagonal is crossed. For a typical initial condition, before crossing the diagonal $\mathcal{D}_0$, the control will simply be constant given by $u = a$ until region II is reached. Only for some initial conditions with a low p-value and a relatively high q-value can the control be $u = 0$ initially and then will switch to $u = a$. For some points in IV optimal controls could in principle have the full concatenation structure $0asa0$, but these are not of separate interest for the underlying problem. (Essentially, following $u = 0$ the trajectory enters the part of region III where the control switches to $u = a$ and then ends with the pattern described for region II.)

For initial conditions in region I the most typical structure of optimal controls is $0s0$. Since $p > q$, the tumor is shrinking already, but as the system reaches the singular arc, it is best to administer therapy according to the singular control until all inhibitors become exhausted. As above, if the trajectory comes close to the saturation point, this structure changes into $0sa0$, and if the initial condition actually already is close to this point, it may simply be $a0$ again.

A more precise description of all of these possibilities is given in section 8, where we prove these results. Also, the diagrams shown here are generated using the parameter values given in section 2 that are taken from [9], but the qualitative structure of the solutions described here is robust with respect to parameter changes. Only if the upper limit a on the dosage becomes too small will the singular arc disappear.

In Figure 5.3 we give one specific example of an optimal trajectory (on the left) and its corresponding control (on the right) of the type $as0$. The initial condition is given by $(\tilde{p}, \tilde{q}) = (12000, 15000)$ in region III. The optimal control takes the maximal value $u = a$ for the short interval from 0 to $t_1 = 0.0905$ when the trajectory reaches the singular arc. At this point the control switches to the time-varying singular control until all inhibitors are being exhausted at time $t_2 = 6.5579$. Then, due to aftereffects, the minimum value of the tumor volume is realized a short period later at the final time $T = 6.7221$ when the corresponding $u = 0$ trajectory reaches the diagonal. Note the extremely fast q-dynamics away from the singular arc. The optimal final value is given by $p_*(T) = 8533.4$. The optimal trajectory is shown as a solid curve in Figure 5.3, and the singular curve $\mathcal{S}$ and the diagonal $\mathcal{D}_0$ are shown as dotted curves. For comparison we also show the $a0$ trajectory that corresponds to the trajectory which applies all available inhibitors initially as a dashed curve. (Its initial segment agrees with the optimal trajectory and is not marked separately.) This strategy leads to a tumor reduction with value 8707.4 at time 4.1934.

6. Analysis of the singular arc. In this section we compute an explicit form for the singular control and the corresponding singular curve $\mathcal{S}$. We also show that there exists a unique connected arc of $\mathcal{S}$ where the singular control is admissible, i.e., satisfies the control constraints. Furthermore, the strengthened Legendre–Clebsch condition holds along $\mathcal{S}$, and thus the singular arc is locally optimal.

6.1. Computation of the singular control. Using Proposition 4.5 we get for the switching function $\Phi(t) = \langle \lambda(t), g(z(t)) \rangle$ that

$$\dot{\Phi}(t) = \langle \lambda(t), [f,g]z(t) \rangle \tag{6.1}$$

and

$$\ddot{\Phi}(t) = \langle \lambda(t), [f+ug,[f,g]]z(t) \rangle \,. \tag{6.2}$$

Direct calculations verify that

$$[f,g](z) = Gp \begin{pmatrix} \xi \\ -b \\ 0 \end{pmatrix} \tag{6.3}$$

and

$$[g,[f,g]](z) = -G^2 bp \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}. \tag{6.4}$$

If the switching function $\Phi(t) = \lambda_3 - \lambda_2(t) G q_*(t)$ vanishes at some time t, then $\lambda_2(t)$ is positive since $\lambda_3 > 0$, and thus we have

$$\langle \lambda(t), [g,[f,g]]z(t) \rangle = -\lambda_2(t) G^2 d p_*(t) < 0; \tag{6.5}$$

i.e., the so-called *strengthened Legendre–Clebsch condition* [11] is satisfied. Hence, and provided it is admissible, the singular control is of order 1, locally optimal, and given by

$$u_{\sin}(t) = -\frac{\langle \lambda(t), [f,[f,g]]z(t) \rangle}{\langle \lambda(t), [g,[f,g]]z(t) \rangle}. \tag{6.6}$$

Another direct computation verifies that

$$[f,[f,g]](z) = Gp \begin{pmatrix} \xi^2 + \xi b \frac{p}{q} \\ \xi b \ln\left(\frac{p}{q}\right) + \xi \left(\frac{2}{3} d \frac{q_*(t)}{\sqrt[3]{p_*(t)}} - b \right) - \left(\mu + d p_*^{\frac{2}{3}}(t) \right) b \\ 0 \end{pmatrix}. \tag{6.7}$$

The vector fields g, $[f,g]$, and $[g,[f,g]]$ are everywhere linearly independent, and thus $[f,[f,g]]$ can be expressed as a linear combination in this basis. In fact,

$$[f,[f,g]] = \left(\xi + b\frac{p}{q} \right) [f,g] - \psi [g,[f,g]], \tag{6.8}$$

with

$$\psi = \psi(p,q) = \frac{1}{G} \left(\xi \ln\left(\frac{p}{q}\right) + b\frac{p}{q} + \frac{2}{3}\xi \frac{d}{b} \frac{q}{p^{\frac{1}{3}}} - \left(\mu + d p^{\frac{2}{3}} \right) \right). \tag{6.9}$$

Along a singular arc we have that

$$\dot{\Phi}(t) = \langle \lambda(t), [f,g](z(t)) \rangle \equiv 0, \tag{6.10}$$

and therefore

$$\langle \lambda(t), [f,[f,g]](z(t)) \rangle = -\psi(z(t)) \langle \lambda(t), [g,[f,g]](z(t)) \rangle .$$

Since $\langle \lambda(t), [g,[f,g]](z(t)) \rangle \neq 0$, the singular control defined by (6.6) is simply given by the function ψ in feedback form, more precisely

$$u_{\sin}(t) = -\frac{\langle \lambda(t), [f,[f,g]]z(t) \rangle}{\langle \lambda(t), [g,[f,g]]z(t) \rangle} = \psi(p(t), q(t)). \tag{6.11}$$

Summarizing, we have so far the following.

PROPOSITION 6.1. *Let (z_*, u_*) be an extremal pair. If the control u_* is singular on an open interval (α, β), then u_* is of order 1, and the strengthened Legendre–Clebsch condition is satisfied. The singular control is given in feedback form as*

$$\begin{aligned} u_{\sin}(t) &= \psi(p_*(t), q_*(t)) \\ &= \frac{1}{G}\left(\xi \ln\left(\frac{p_*(t)}{q_*(t)} \right) + b\frac{p_*(t)}{q_*(t)} + \frac{2}{3}\xi \frac{d}{b} \frac{q_*(t)}{p_*^{\frac{1}{3}}(t)} - \left(\mu + d p_*^{\frac{2}{3}}(t) \right) \right). \end{aligned} \tag{6.12}$$

But note that the singular control is admissible only if this value lies in the interval $[0, a]$. Before addressing this issue, we first compute the singular curve itself.

6.2. Computation of the singular curve. For a trajectory to be an extremal, the singular curve also needs to satisfy the extra requirement that $H \equiv 0$ or, equivalently,

$$\langle \lambda(t), f(z(t)) \rangle \equiv 0. \tag{6.13}$$

Hence, along a singular arc, $\lambda(t)$ vanishes against the vector fields f, g, and $[f,g]$. Since $\lambda(t) \neq 0$, these vector fields must be linearly dependent. But g is always linearly independent of f and $[f,g]$, and thus the singular curve is precisely the locus where f and $[f,g]$ are linearly dependent. Both vector fields do not depend on y and have a y-coordinate equal to 0. With slight abuse of notation we can therefore also view them as vector fields on (p,q)-space and define the singular curve $\mathcal{S}$ as

$$\mathcal{S} = \{(p,q) : f(p,q) \wedge [f,g](p,q) = 0\}, \tag{6.14}$$

where

$$f(p,q) \wedge [f,g](p,q) = \begin{vmatrix} -\xi p \ln\left(\frac{p}{q}\right) & \xi \\ bp - \left(\mu + d p^{\frac{2}{3}}\right) q & -b \end{vmatrix}. \tag{6.15}$$

Thus the singular curve is given by the solutions of the equation

$$\mu + d p^{\frac{2}{3}} = b\frac{p}{q}\left(1 - \ln\left(\frac{p}{q} \right) \right). \tag{6.16}$$

The geometry of the singular curve becomes clear if we introduce a projective coordinate, i.e., make a blowup in the variables of the form

$$p = xq, \quad x > 0. \tag{6.17}$$

The quotient $\frac{q}{p}$ is proportional to the *endothelial density* which is used to replace the carrying capacity of the vasculature as a variable in some models like, for example, in [7]. As it turns out, the singular curve and its corresponding singular control can be expressed solely in terms of the variable x introduced here. This fact confirms mathematically the importance of this quantity. However, for the overall analysis, and in particular in view of a ready interpretation of the results, we preferred to keep the original variables p and q and use x only in the analysis of the singular arc. In these variables (6.16) simplifies to

$$\mu + dp^{\frac{2}{3}} = bx\,(1 - \ln x) \tag{6.18}$$

and can be rewritten in the form

$$p^2 + \varphi(x)^3 = 0, \tag{6.19}$$

with

$$\varphi(x) = \frac{bx(\ln x - 1) + \mu}{d}. \tag{6.20}$$

The function φ is strictly convex with a minimum at $x = 1$ and minimum value $\frac{\mu - b}{d}$. In particular, if $\mu \geq b$, then this equation has no positive solutions, and thus no admissible singular arc exists. The case $\mu < b$, which we assumed in (3.5), is the medically relevant case. For $\mu = 0$ the zeros of φ are given by $x_1^* = 0$ and $x_2^* = e$, and φ is negative on the interval $(0, e)$. In general, for $\mu > 0$, we have $\varphi(0) = \frac{\mu}{d} = \varphi(e)$, and thus now the zeros x_1^* and x_2^* satisfy $0 < x_1^* < 1 < x_2^* < e$. We thus have the following.

PROPOSITION 6.2. *The singular curve $\mathcal{S}$ entirely lies in the sector $\{(p, q) : x_1^* q < p < x_2^* q\}$, where x_1^* and x_2^* are the unique zeros of the equation $\varphi(x) = 0$ and satisfy $0 \leq x_1^* < 1 < x_2^* \leq e$. In the variables (p, x), with $x = \frac{p}{q}$, the singular curve can be parameterized in the form*

$$p^2 = \left(\frac{bx(1 - \ln x) - \mu}{d}\right)^3 \qquad \text{for} \quad x_1^* < x < x_2^*. \tag{6.21}$$

PROPOSITION 6.3. *Along the singular arc the singular control can be expressed solely as a function of x in the form*

$$\Psi(x) = \frac{1}{G}\left[\left(\frac{1}{3}\xi + bx\right)\ln x + \frac{2}{3}\xi\left(1 - \frac{\mu}{bx}\right)\right]. \tag{6.22}$$

There exists exactly one connected arc on the singular curve $\mathcal{S}$ along which the control is admissible, i.e., satisfies the bounds $0 \leq \Psi \leq a$. This arc is defined over an interval $[x_\ell^*, x_u^*]$, where x_ℓ^* and x_u^* are the unique solutions to the equations $\Psi(x_\ell^*) = 0$ and $\Psi(x_u^*) = a$, respectively, and these values satisfy $x_1^* < x_\ell^* < x_u^* < x_2^*$.

Figure 6.1 on the left gives a plot of the singular curve for the parameter values from [9] specified earlier and $\mu = 0.02$ and shows the admissible portion of the petallike

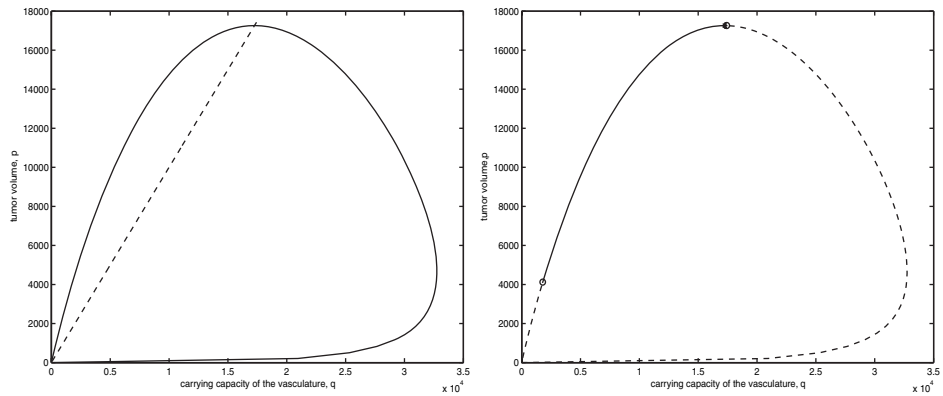

FIG. 6.1. *The singular curve and its admissible part.*

singular curve $\mathcal{S}$ for $a = 75$ marked as a solid curve on the right. The qualitative structure shown in Figure 6.1 is generally valid with the admissible portion shrinking for smaller values a.

Proof. In the variables p and x the singular control is given by

$$u_{\sin}(t) = \frac{1}{G}\left(\xi \ln x(t) + bx(t) + \frac{2}{3}\xi\frac{dp(t)^{\frac{2}{3}}}{bx(t)} - \left(\mu + dp(t)^{\frac{2}{3}}\right)\right). \tag{6.23}$$

But along the singular arc we have $p^{\frac{2}{3}} = -\varphi(x)$, and thus we obtain the singular control as a feedback function of x alone, $u_{\sin}(t) = \Psi(x(t))$, namely,

$$\begin{aligned}\Psi(x) &= \frac{1}{G}\left(\xi \ln x + bx + \frac{2}{3}\xi\frac{bx(1-\ln x)-\mu}{bx} - bx\,(1-\ln x)\right)\\ &= \frac{1}{G}\left[\left(\frac{1}{3}\xi + bx\right)\ln x + \frac{2}{3}\xi\left(1-\frac{\mu}{bx}\right)\right].\end{aligned}$$

Note that $\lim_{x\searrow 0}\Psi(x) = -\infty$ and $\lim_{x\to\infty}\Psi(x) = +\infty$. Now

$$\begin{aligned}\Psi'(x) &= \frac{1}{G}\left[b\,(\ln x + 1) + \frac{1}{3}\xi\left(\frac{1}{x} + 2\frac{\mu}{bx^2}\right)\right],\\ \Psi''(x) &= \frac{1}{Gx^3}\left(bx^2 - \frac{1}{3}\xi x - \frac{4}{3}\xi\frac{\mu}{b}\right),\end{aligned} \tag{6.24}$$

and the second derivative has a unique positive zero at

$$x_* = \frac{1}{6}\frac{\xi}{b}\left(1 + \sqrt{1 + 48\frac{\mu}{\xi}}\right).$$

It follows that Ψ is strictly concave for $0 < x < x_*$ and strictly convex for $x > x_*$. If the function Ψ has no stationary points, then Ψ is strictly increasing, and thus, as claimed, there exists a unique interval $[x_\ell^*, x_u^*]$ when Ψ takes values in $[0, a]$, and the limits are the unique solutions of the equations $\Psi(x) = 0$ and $\Psi(x) = a$, respectively. The same holds if Ψ has a unique stationary point at x_*. In the remaining case, it follows from the convexity properties that Ψ has a unique local maximum at $\tilde{x}_1 < x_*$ and a unique local minimum at $\tilde{x}_2 > x_*$. It suffices to show that Ψ is negative at

its local maximum. This, as before, implies that Ψ is strictly increasing when it is positive. Suppose now that $\Psi'(\tilde{x}) = 0$. Then

$$-b \ln \tilde{x} = b + \frac{1}{3}\xi \left(\frac{1}{\tilde{x}} + 2\frac{\mu}{b\tilde{x}^2} \right) > 0,$$

and thus

$$\begin{aligned} \Psi(\tilde{x}) &= \frac{1}{G}\left[\left(\frac{1}{3}\xi + b\tilde{x} \right) \left(-1 - \frac{1}{3}\frac{\xi}{b} \left(\frac{1}{\tilde{x}} + 2\frac{\mu}{b\tilde{x}^2} \right) \right) + \frac{2}{3}\xi \left(1 - \frac{\mu}{b\tilde{x}} \right) \right] \\ &= \frac{1}{G}\left[-b\tilde{x} - \frac{1}{9}\frac{\xi^2}{b} \left(\frac{1}{\tilde{x}} + 2\frac{\mu}{b\tilde{x}^2} \right) - \frac{4}{3}\frac{\xi\mu}{b\tilde{x}} \right] < 0. \end{aligned}$$

Hence Ψ is negative at any stationary point. □

7. Analysis of bang-bang junctions. Optimal controls are concatenations of the singular control with bang-bang structures, and in this section we analyze possible switchings among bang-bang pieces of an optimal trajectory. We start with a strictly local analysis of switchings that establishes the regions in (p, q)-space where switchings from $u = a$ to $u = 0$ or from $u = 0$ to $u = a$ are possible. We then proceed to analyze extremal bang-bang concatenation structures over the full interval. These results will then be used in section 8 to determine the overall concatenation structures of optimal controls.

The singular curve computed in section 6.2 also is a boundary curve between optimal switchings in the order $a0$ and of the reverse order $0a$. Recall that $\mathrm{I} = \mathcal{D}_+ \cap \mathcal{S}_+$, $\mathrm{II} = \mathcal{D}_+ \cap \mathcal{S}_-$, $\mathrm{III} = \mathcal{D}_- \cap \mathcal{S}_-$, and $\mathrm{IV} = \mathcal{D}_- \cap \mathcal{S}_+$.

PROPOSITION 7.1. *Along optimal trajectories there are no switchings from $u = a$ to $u = 0$ at points $(\tilde{p}, \tilde{q})$ in regions* I *and* III*, and there are no switchings from $u = 0$ to $u = a$ at points $(\tilde{p}, \tilde{q})$ in regions* II *and* IV.

Proof. It follows from (4.7) that the derivative of the switching function must be nonpositive at any time τ where the control switches from $u = 0$ to $u = a$ and nonnegative at every switching from $u = a$ to $u = 0$. Furthermore, since $H \equiv 0$ along extremal lifts, at any switching τ, the adjoint variable $\lambda(\tau)$ vanishes against both $f(z(\tau))$ and $g(z(\tau))$. Except for the points on the diagonal $\mathcal{D}_0 = \{(p, q) : p = q\}$, the vector fields f and g and the coordinate vector field $\frac{\partial}{\partial y} = (0, 0, 1)^T$ are linearly independent, and thus the Lie bracket $[f, g]$ can be written as a linear combination of these vector fields in the form

$$[f, g](z) = \alpha(z) f(z) + \beta(z) g(z) + \gamma(z) \frac{\partial}{\partial y};$$

i.e.,

$$Gp \begin{pmatrix} \xi \\ -b \\ 0 \end{pmatrix} = \alpha(z) \begin{pmatrix} -\xi p \ln\left(\frac{p}{q}\right) \\ bp - \left(\mu + dp^{\frac{2}{3}}\right) q \\ 0 \end{pmatrix} + \beta(z) \begin{pmatrix} 0 \\ -Gq \\ 1 \end{pmatrix} + \gamma(z) \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.$$

Thus we have

$$\alpha(z) = -\frac{G}{\ln\left(\frac{p}{q}\right)}, \quad \beta(z) = \frac{b\left(\frac{p}{q}\right)\left(\ln\left(\frac{p}{q}\right) - 1\right) + \left(\mu + dp^{\frac{2}{3}}\right)}{\ln\left(\frac{p}{q}\right)},$$

and

$$\gamma(z) = -\beta(z). \tag{7.1}$$

At a switching time τ,

$$\begin{aligned}\dot{\Phi}(\tau) &= \langle \lambda(\tau), [f,g](z(\tau))\rangle \\ &= \alpha(z)\,\langle \lambda(\tau), f(z(\tau))\rangle + \beta(z)\,\langle \lambda(\tau), g(z(\tau))\rangle - \beta(z)\lambda_3 \\ &= -\beta(z)\lambda_3,\end{aligned}$$

and by Lemma 4.3 we may assume that λ_3 is positive. Thus the sign of $\dot{\Phi}(\tau)$ is the opposite of the sign of β. The denominator of β is positive in $\mathcal{D}_+$ and negative in $\mathcal{D}_-$. The zero set of the numerator of β is exactly the locus where the vector fields f and $[f,g]$ are linearly dependent, i.e., the singular curve $\mathcal{S}$ (see (6.16)). We have labeled the regions so that the numerator is positive in $\mathcal{S}_+$ and negative in $\mathcal{S}_-$ (recall that $b > \mu$). Hence $\dot{\Phi}(\tau)$ is negative in regions I and III and positive in regions II and IV. This proves the proposition. □

We now proceed to the analysis of bang-bang controls over the full interval. The admissible portion of the singular arc does not meet $\mathcal{D}_-$, and in $\mathcal{D}_-$ optimal controls will be bang-bang. We therefore begin with this analysis and assume as given a well-posed initial condition $\tilde{z} = (\tilde{p}, \tilde{q}, \tilde{y})$, with $(\tilde{p}, \tilde{q}) \in \mathcal{D}_-$. We first establish that optimal trajectories that start in $\mathcal{D}_-$ will enter $\mathcal{D}_+$ but then cannot return to $\mathcal{D}_-$ any more.

PROPOSITION 7.2. *Suppose $(p_*(\cdot), q_*(\cdot))$ is an optimal trajectory defined over the interval $[0,T]$ with a well-posed initial condition $(\tilde{p}, \tilde{q}) \in \mathcal{D}_-$. Then there exists a time $\tau \in (0,T)$ so that the trajectory lies in $\mathcal{D}_-$ for $t \in [0,\tau)$, crosses into $\mathcal{D}_+$ at time τ, and remains in $\mathcal{D}_+$ for times $t \in (\tau, T)$. Over the interval $[0,\tau)$ the control either is constant given by $u \equiv a$ or is of the form $0a$. In the latter case the junction must lie in the set $\mathcal{N}_- = \{(p,q) \in \mathcal{D}_- : bp < (\mu + dp^{\frac{2}{3}})q\}$.*

Proof. Recall once more that we consider only initial conditions that are well-posed; i.e., the corresponding optimal trajectory does cross over into $\mathcal{D}_+$. Define τ as the (possibly) first time when the trajectory lies on the diagonal $\mathcal{D}_0$. We first show that τ cannot be a switching time. For, if this were the case, then, since $p(\tau) = q(\tau)$,

$$H(\tau) = \lambda_2(\tau)p(\tau)\left(b - \left(\mu + dp(\tau)^{\frac{2}{3}}\right)\right) = 0. \tag{7.2}$$

But on $\mathcal{D}_0$ we have $b > \mu + dp(\tau)^{\frac{2}{3}}$, and thus $\lambda_2(\tau) = 0$. Hence the switching function at time τ is positive: $\Phi(\tau) = \lambda_3 > 0$. But then the control must be $u = 0$ in a neighborhood of τ, and the trajectory crosses from $\mathcal{D}_+$ into $\mathcal{D}_-$, which is a contradiction.

Of the bang controls only $u = a$ steers the system from $\mathcal{D}_-$ into $\mathcal{D}_+$, and nothing more needs to be shown about the interval $[0,\tau)$ if the control is constant and given by $u = a$ on this interval. If not, there exists a maximal interval (α,β), with $0 < \alpha < \tau < \beta < T$, so that the switching function is negative for $t \in (\alpha,\beta)$ and has zeros at α and β: $\Phi(\alpha) = \Phi(\beta) = 0$. The function Φ has a minimum over the interval $[\alpha,\beta]$ at some time $\sigma \in (\alpha,\beta)$, and by (6.1) and (6.3) we have

$$\dot{\Phi}(\sigma) = Gp(\sigma)\,(\xi\lambda_1(\sigma) - b\lambda_2(\sigma)) = 0. \tag{7.3}$$

Hence $\lambda_1(\sigma)$ and $\lambda_2(\sigma)$ have the same sign. But λ_2 is positive along trajectories for $u = a$ since $\Phi(t) = \lambda_3 - \lambda_2(t)Gq(t) < 0$ and $\lambda_3 > 0$. Hence $\lambda_1(\sigma) > 0$. Since there is a

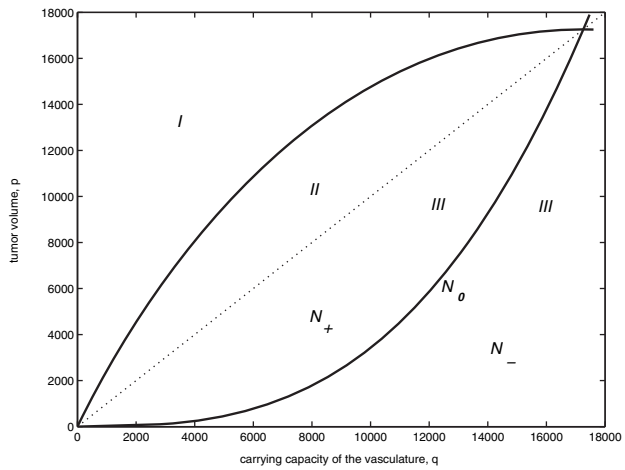

FIG. 7.1. *The curve* $\mathcal{N}_0$.

junction at time α, there also exists an interval $(\alpha - \varepsilon, \alpha)$ where the control is $u = 0$, and on this interval we have

$$H(t) = -\lambda_1(t)\xi p(t) \ln\left(\frac{p(t)}{q(t)}\right) + \lambda_2(t)\left(bp(t) - \left(\mu + dp(t)^{\frac{2}{3}}\right) q(t)\right) = 0, \tag{7.4}$$

while λ_2 is still positive for ε small. If we have

$$bp(\alpha) > (\mu + dp(\alpha)^{\frac{2}{3}})q(\alpha) \tag{7.5}$$

at the junction, then, by (7.4), λ_1 must be negative on this interval and also $\lambda_1(\alpha) < 0$. Hence there exists a last zero for λ_1 in the interval (α, σ), say, $\lambda_1(\rho) = 0$. At this zero the adjoint equation (4.2) reads

$$\dot{\lambda}_1(\rho) = \lambda_2(\rho)\left(\frac{2}{3} d \frac{q(\rho)}{\sqrt[3]{p(\rho)}} - b\right). \tag{7.6}$$

The curve $\mathcal{N}_0 = \{(p, q) : bp = (\mu + dp^{\frac{2}{3}})q\}$ is the $\dot{q}$-nullcline for $u = 0$, and since at the points on the $\dot{q}$-nullcline we have

$$f(z) = \begin{pmatrix} -\xi p \ln\left(\frac{p}{q}\right) \\ 0 \\ 0 \end{pmatrix} \tag{7.7}$$

with the first coordinate positive in $\mathcal{D}_-$, corresponding trajectories cross $\mathcal{N}_0$ from $\mathcal{N}_- = \{(p, q) : bp < (\mu + dp^{\frac{2}{3}})q\}$ into $\mathcal{N}_+ = \{(p, q) : bp > (\mu + dp^{\frac{2}{3}})q\}$ (Figure 7.1).

Because of the extra control term $-Gqa$ in the vector field g, this also holds for trajectories corresponding to the control $u = a$. Hence, if the junction at time α satisfies (7.5), then so does the arc forward in time; i.e., for all $t \in (\alpha, \sigma)$ we have

$$q(t) < \frac{bp(t)}{\mu + dp(t)^{\frac{2}{3}}}. \tag{7.8}$$

Hence

$$\frac{2}{3}d\frac{q(\rho)}{\sqrt[3]{p(\rho)}} - b < \frac{2}{3}d\frac{bp(\rho)^{\frac{2}{3}}}{\mu + dp(\rho)^{\frac{2}{3}}} - b = \frac{2}{3}b\frac{dp(\rho)^{\frac{2}{3}}}{\mu + dp(\rho)^{\frac{2}{3}}} - b < -\frac{1}{3}b < 0. \tag{7.9}$$

Since the multiplier λ_2 is positive along $u = a$, we therefore have $\dot{\lambda}_1(\rho) < 0$, which is a contradiction. Thus no $0a$-junction can lie in the interior of $\mathcal{N}_+$. The same reasoning also precludes that $0a$-junctions would lie on the $\dot{q}$-nullcline for $u = 0$, i.e., on $\mathcal{N}_0$. In this case it follows that $\lambda_1(\alpha) = 0$ and $\dot{\lambda}_1(\alpha) < 0$, and thus again there still exists a last zero of λ_1 in the interval (α, σ) where the same contradiction arises. Thus, any possible $0a$-junction in $\mathcal{D}_-$ must lie in $\mathcal{N}_-$.

We now show that if there is a junction at some time α, then the control must be constant $u = 0$ on the initial interval $[0, \alpha)$. Since trajectories for $u = 0$ cross $\mathcal{N}_0$ from $\mathcal{N}_-$ into $\mathcal{N}_+$, it follows that, as long as the control $u = 0$ is used for $t < \alpha$, the trajectory lies in $\mathcal{N}_-$. Since this trajectory also necessarily lies in $\mathcal{D}_-$ we have $p(t) < q(t)$. But then the identity

$$H(t) = -\lambda_1(t)\xi p(t)\ln\left(\frac{p(t)}{q(t)}\right) + \lambda_2(t)\left(bp(t) - \left(\mu + dp(t)^{\frac{2}{3}}\right)q(t)\right) = 0 \tag{7.10}$$

implies that neither λ_1 nor λ_2 can have any zeros (otherwise they would need to vanish simultaneously, contradicting Lemma 4.2). Hence λ_2 is positive, and λ_1 must be negative as long as the control is $u = 0$. This precludes any more switchings. For, if there is another switching $0 < \theta < \alpha$, then there also needs to be another zero for the derivative of the switching function in (θ, α), and at this derivative λ_1 and λ_2 must have the same sign.

Thus, if $(\tilde{p}, \tilde{q}) \in \mathcal{D}_-$ is a well-posed initial condition, then there exists a first time τ at which the trajectory crosses from $\mathcal{D}_-$ into $\mathcal{D}_+$ and the control over $[0, \tau)$ is either constant and given by $u \equiv a$ or it has exactly one switching from 0 to a with the junction in $\mathcal{N}_-$. It still remains to show that the trajectory cannot return from $\mathcal{D}_+$ into $\mathcal{D}_-$ for times $t > \tau$, i.e., that $(p(t), q(t))$ lies in $\mathcal{D}_+$ for $t \in (\tau, T)$. (It follows from Lemma 4.1 that the end point lies on $\mathcal{D}_0$.)

If the trajectory were to return to $\mathcal{D}_-$, then there would exist another time $\kappa > \beta$ where the trajectory again would cross $\mathcal{D}_0$ with control $u = 0$ in a neighborhood of κ. Now (7.10) implies that $\lambda_2(\kappa) = 0$, and thus the adjoint equation for λ_2 gives $\dot{\lambda}_2(\kappa) = -\xi\lambda_1(\kappa)$. Since λ_1 and λ_2 cannot vanish simultaneously, we have $\lambda_1(\kappa) \neq 0$, and λ_2 changes sign at τ. If $\lambda_1(\kappa) > 0$, then λ_2 is negative for $t > \tau$, t near τ. However, after crossing into $\mathcal{D}_-$, trajectories for $u = 0$ entirely lie in $\mathcal{D}_-$ and do not cross back into $\mathcal{D}_+$. Consequently it follows from (7.10) that λ_2 cannot have another zero along an $u = 0$ arc. (In $\mathcal{D}_-$ the expression $\lambda_1\xi p\ln(\frac{p}{q})$ can vanish only if $\lambda_1 = 0$, and this precludes λ_2 from having a zero.) But then the switching function $\Phi(t) = \lambda_3 - \lambda_2(t)Gq$ remains positive, and so there cannot be another switching in the control. But this structure clearly is not optimal since the value for p increases in $\mathcal{D}_-$, which is a contradiction. If $\lambda_1(\kappa) < 0$, we are back in the situation considered above: If all inhibitors have not been used up, there needs to exist another switching to $u = a$; but the entire forward orbit of the $u = 0$ trajectory lies in $\mathcal{N}_+$, and therefore this switching would lie in $\mathcal{N}_+$, violating the earlier statement. □

This proposition implies that, for well-posed initial conditions $(\tilde{p}, \tilde{q}, 0)$, with $(\tilde{p}, \tilde{q}) \in \mathcal{N}_+$, the optimal control is given in feedback form by $u \equiv a$ until the trajectory crosses over into $\mathcal{D}_+$ at time τ. The further structure of the optimal control depends on the

amount of inhibitors $y(\tau)$ that are still available at this time. If this amount is too small to reach the singular arc, then, since only junctions in the order $a0$ are optimal in region II $= \mathcal{D}_+ \cap \mathcal{S}_-$, the optimal control is simply given by $u = a$ until all inhibitors are exhausted and then follows $u = 0$ until the trajectory terminates on the diagonal $\mathcal{D}_0$. (If the control would switch prior to the time when all inhibitors are exhausted, by Proposition 7.1 it cannot switch back to the control $u = a$ in region II and thus would reach the diagonal with inhibitors still available, contradicting Lemma 4.1.) Hence, if enough inhibitors are available for the trajectory to reach the singular curve $\mathcal{S}$, then the trajectory will follow $u = a$ in region II.

We now consider the further structure of optimal controls for segments of the trajectory that lie in $\mathcal{D}_+$. We first show that segments corresponding to the control $u = 0$ can lie only at the beginning or at the end of the interval $[0, T]$.

PROPOSITION 7.3. *Let (α, β) be a maximal open interval where the optimal control is given by $u \equiv 0$ with corresponding trajectory (p_*, q_*) lying in $\mathcal{D}_+$. Then α and β cannot both be switching times. If α is a switching time, then $\beta = T$, the final time, and if β is a switching time, then $\alpha = 0$, the initial time.*

Proof. As before, on the interval (α, β), (7.10) holds, and on $\mathcal{D}_+$ we have $\xi p \ln(\frac{p}{q}) > 0$ and $bp - (\mu + dp^{\frac{2}{3}})q > 0$. As above, in this case neither λ_1 nor λ_2 can vanish, and therefore λ_1 and λ_2 have the same sign over (α, β). Since λ_2 is positive at switching times, it follows that both λ_1 and λ_2 are positive over $[\alpha, \beta]$ if at least one of the end points is a switching time. Along $u = 0$ the derivatives of the switching function are given by $\dot{\Phi}(t) = \langle \lambda(t), [f, g](z(t)) \rangle$ and $\ddot{\Phi}(t) = \langle \lambda(t), [f, [f, g]](z(t)) \rangle$. If there exists a time $\tau \in (\alpha, \beta)$ where $\dot{\Phi}(\tau) = 0$, then it follows from (6.3) and (6.8) that

$$\begin{aligned}
\ddot{\Phi}(\tau) &= \left(\xi + b\frac{p(\tau)}{q(\tau)}\right) \langle \lambda(\tau), [f, g](z(\tau)) \rangle - \psi(p(\tau), q(\tau)) \langle \lambda(\tau), [g, [f, g]](z(\tau)) \rangle \\
&= \left(\xi + b\frac{p(\tau)}{q(\tau)}\right) \dot{\Phi}(\tau) - \psi(p(\tau), q(\tau)) \langle \lambda(\tau), [g, [f, g]](z(\tau)) \rangle \\
&= \psi(p(\tau), q(\tau)) b G^2 p(\tau) \lambda_2(\tau) > 0. \qquad (7.11)
\end{aligned}$$

Here we use the fact that ψ is positive in $\mathcal{D}_+$.

Suppose α is a switching time. Then there exists an $\varepsilon > 0$ so that $\dot{\Phi}$ is positive in $(\alpha, \alpha + \varepsilon)$. (Since the control is $u = 0$, we have $\dot{\Phi}(\tau) \geq 0$, and even if $\dot{\Phi}(\alpha) = 0$, then this is implied by $\ddot{\Phi}(\alpha) > 0$.) Thus, if $\dot{\Phi}$ has zeros in (α, β), then there exists a smallest one; call it τ. But then $\dot{\Phi}(t) > 0$ on the interval (α, τ), and so Φ cannot have a local minimum at τ, contradicting $\ddot{\Phi}(\tau) > 0$. Hence Φ is strictly increasing over (α, β) as long as the control $u = 0$ is used, and there cannot be another zero at β. Similarly, if β is a switching time, then Φ is strictly decreasing over (α, β) as long as the control $u = 0$ is used, and again there cannot exist a previous zero at α. ∎

PROPOSITION 7.4. *Suppose (p_*, q_*) is an optimal trajectory corresponding to the constant control $u = a$ over some open interval (α, β) with switching times at α and β. Then $(p(\alpha), q(\alpha)) \notin$ II and $(p(\beta), q(\beta)) \in$ II. Furthermore, there exists a time $\tau \in (\alpha, \beta)$ where $\psi(p(t), q(t)) \geq a$.*

Proof. The statements about the junction points follow from Proposition 7.1. Along $u = a$ the switching function is negative over (α, β) and has a minimum at some time $\tau \in (\alpha, \beta)$ where $\dot{\Phi}(\tau) = 0$ and $\ddot{\Phi}(\tau) \geq 0$; the derivatives of the switching function are now given by $\dot{\Phi}(t) = \langle \lambda(t), [f, g](z(t)) \rangle$ and

$$\ddot{\Phi}(t) = \langle \lambda(t), [f + ag, [f, g]](z(t)) \rangle .$$

As above, it follows from (6.3) and (6.8) that

$$\begin{aligned}\ddot{\Phi}(\tau) &= \left(\xi + b\frac{p(\tau)}{q(\tau)}\right)\langle\lambda(\tau),[f,g](z(\tau))\rangle + \{a-\psi(p(\tau),q(\tau))\}\langle\lambda(\tau),[g,[f,g]](z(\tau))\rangle \\ &= \left(\xi + b\frac{p(\tau)}{q(\tau)}\right)\dot{\Phi}(\tau) + \{a-\psi(p(\tau),q(\tau))\}\langle\lambda(\tau),[g,[f,g]](z(\tau))\rangle \\ &= \{\psi(p(\tau),q(\tau))-a\}\,bG^2p(\tau)\lambda_2(\tau). \end{aligned} \tag{7.12}$$

Since $\Phi(\tau) = \lambda_3 - \lambda_2(\tau)Gaq(\tau) < 0$, we have $\lambda_2(\tau) > 0$, and thus we must have $\psi(p(\tau),q(\tau)) \geq a$. This proves the result. □

8. Synthesis of optimal controls. We now put together the results, consider concatenations between singular and bang arcs, and prove the results of section 5. We start with a strictly local analysis of singular junctions analogous to Proposition 7.1 for bang-bang junctions and show that all possible concatenations of bang controls with the singular arc are extremal. This classical result is included for the sake of completeness and is a direct consequence of the fact that the strengthened Legendre–Clebsch condition is satisfied. We then show that extremals which contain a saturating arc are not optimal and proceed to the analysis of the possible concatenations of bang and singular arcs.

PROPOSITION 8.1. *Let I be an open interval on which the optimal control u_* is singular and takes values in the interior of the control set. Then concatenations of both the forms* **bs** *and* **sb**, *where* **b** *stands for any of the two bang controls $u = 0$ or $u = a$, are extremal along I.*

Proof. Recall that, for any control u that is continuous from the left $(-)$ or right $(+)$, the second derivative of the switching function is given by

$$\ddot{\Phi}(t\pm) = \langle\lambda(t),[f,[f,g]](z(t))\rangle + u(t\pm)\langle\lambda(t),[g,[f,g]](z(t))\rangle,$$

and it vanishes identically on I along the singular control. Since the strengthened Legendre–Clebsch condition is satisfied, we have $\langle\lambda(t),[g,[f,g]](z(t))\rangle < 0$. By assumption the singular control takes values in the interior of the control set $[0,a]$, and thus $\langle\lambda(t),[f,[f,g]](z(t))\rangle > 0$. Hence, for $u = 0$ we get $\ddot{\Phi}(t) > 0$, and for $u = a$ we have $\ddot{\Phi}(t) < 0$. These signs are consistent with entry and exit from the singular arc for each control; i.e., for example, if $u = 0$ on an interval $(\tau-\varepsilon,\tau)$, then Φ is positive over this interval, consistent with the choice $u = 0$ as minimizing control. □

Thus, as long as the singular control has not saturated, it is possible to jump onto or off the singular arc with the constant controls $u = 0$ or $u = a$ at any point without violating the conditions of the maximum principle locally. Naturally, optimality over longer time intervals is not guaranteed and still needs to be analyzed. As an example, it follows from Proposition 7.3 that the singular arc can be left with the control $u = 0$ only when all inhibitors have been exhausted. On the other hand, trajectories for $u = a$ can (and sometimes must) leave the singular arc before all inhibitors have been exhausted. This follows from the result below. Recall that x_u^* is the point introduced in Proposition 6.3 where the singular control saturates at the upper control value a.

PROPOSITION 8.2. *At the saturation point x_u^* on the singular arc where the singular control saturates at the upper value $u = a$, it is not optimal to continue the control with $u = a$. Thus optimal trajectories need to leave the singular arc before saturation.*

This result may seem somewhat counterintuitive, but this is indeed the typical behavior at saturation in low dimensions (see, for example, [17] or [2]).

Proof. Consider the trajectory that follows the singular arc and at the saturation time τ continues with the control $u = a$. In general, we have

$$\ddot{\Phi}(t) = \left(\xi + b\frac{p(t)}{q(t)}\right)\dot{\Phi}(t) + (u(t) - \psi(p(t), q(t)))\,\langle\lambda(t), [g, [f, g]](z(t))\rangle\,.$$

Along the singular arc $\dot{\Phi}(\tau) = 0$ and at the saturation point we also have $\ddot{\Phi}(\tau) = 0$ for the control $u = a$ since $\psi = a$. Hence, along $u = a$ we get from the right that

$$\Phi^{(3)}(\tau+) = -\left(\frac{d}{dt}_{|t=\tau}\psi(p(t), q(t))\right)\langle\lambda(t), [g, [f, g]](z(t))\rangle \tag{8.1}$$

$$= \left(\frac{d}{dt}_{|t=\tau}\psi(p(t), q(t))\right) bG^2\lambda_2(\tau)p(\tau). \tag{8.2}$$

Recall that $\psi(p(t), q(t)) = \Psi(x(t))$, with $x = \frac{p}{q}$ and Ψ defined in (6.22) in Proposition 6.3. We thus have

$$\frac{d}{dt}_{|t=\tau}\psi(p(t), q(t)) = \Psi'(x_u^*)\dot{x}(\tau). \tag{8.3}$$

It follows from the proof of Proposition 6.3 that $\Psi'(x_u^*) > 0$, and in general we have

$$\dot{x} = \frac{\dot{p}q - p\dot{q}}{q^2} = -\xi x\ln x - bx^2 + (\mu + dp^{\frac{2}{3}})x + Gux.$$

Substituting $(\mu + dp^{\frac{2}{3}}) = bx(1 - \ln x)$ along the singular arc (cf. (6.18)), we get

$$\dot{x} = x\,(Gu - (\xi + bx)\ln x)\,.$$

But at the saturation point we also have

$$Gu(\tau) = Ga = \left(\frac{1}{3}\xi + bx(\tau)\right)\ln x(\tau) + \frac{2}{3}\xi\left(1 - \frac{\mu}{bx(\tau)}\right),$$

and thus

$$\dot{x}(\tau) = \frac{2}{3}\xi\left(x(\tau)\,(1 - \ln x(\tau)) - \frac{\mu}{b}\right) = \frac{2}{3}\frac{\xi}{b}dp(\tau)^{\frac{2}{3}} > 0.$$

Hence

$$\Phi^{(3)}(\tau+) > 0, \tag{8.4}$$

and Φ is positive for $t > \tau$, t near τ, contradicting the minimization property for $u = a$. □

Thus optimal trajectories cannot continue with the saturated control $u = a$ after the saturation point but instead must leave the singular arc prior to saturating. The analogous computation with $u = 0$ for $t > \tau$ shows that we can switch to $u = 0$ at saturation, but by Proposition 7.3 this is optimal only if all inhibitors have been exhausted. In general, if inhibitors are available to go beyond the saturation point, optimal trajectories must leave the singular arc before saturation occurs. When precisely this happens depends on the amount of inhibitors left. For example, it is

clear that if $\tilde{z} = (\tilde{p}, \tilde{q}, \tilde{y})$ is a point with $(\tilde{p}, \tilde{q}) \in \mathcal{S}$ before saturation for which $A - \tilde{y}$ is small, then it is not optimal to leave the singular arc simply because there are not enough inhibitors left so that the system could reach the region $\mathrm{II} = \mathcal{D}_+ \cap \mathcal{S}_-$, where a switching from $u = a$ to $u = 0$ again is optimal. In this case optimal trajectories follow the singular arc until inhibitors are exhausted. However, if enough inhibitors are available so that the singular arc would lose admissibility before they all are used up, then indeed by leaving the singular arc earlier trajectories can enter region II, and this will be the optimal strategy. But now the argument needs to become global. Since by now we have sufficiently reduced the possibilities in the structures of optimal controls and trajectories, we can reduce this problem to a 1-dimensional optimization problem that can easily be solved numerically. Based on our previous analysis of the structure of extremals, we now determine the optimal synthesis on $\mathcal{D}$. We not only establish the qualitative structure claimed in Theorem 5.1 but also show how to compute the optimal control for a given initial condition $\tilde{z} = (\tilde{p}, \tilde{q}, 0)$.

We will prove that, except for some initial conditions $(\tilde{p}, \tilde{q})$ in regions III and IV (which are less relevant for the underlying problem), our local analysis above only allows for at most a one-parameter family of extremals $\Gamma_\varepsilon(s) = (p_\varepsilon(s), q_\varepsilon(s), y_\varepsilon(s))$, $0 \le s \le T(\varepsilon)$, with the parameter ε ranging over a compact interval $I = [0, \theta]$. The corresponding value of the objective is given by $\upsilon(\varepsilon)$, $\upsilon(\varepsilon) = p_\varepsilon(T(\varepsilon))$, and it will be clear from the definition of the family Γ_ε that the value $\upsilon(\varepsilon)$ depends continuously on ε. Thus, for every initial condition there exists an optimal control that is determined by numerical minimization of $\upsilon(\varepsilon)$ over $[0, \theta]$. However, the structure of this one-parameter family of extremals depends on the location of $(\tilde{p}, \tilde{q})$, and we need to distinguish three cases.

Case 1. We start with an initial condition $(\tilde{p}, \tilde{q})$ in region I and will show that in this case optimal controls at most have the form **0sa0** (possibly with the initial **0s** sequence absent). Let ς_+ denote the reference trajectory that starts at $\tilde{z} = (\tilde{p}, \tilde{q}, 0)$, uses the control $u = 0$ until the singular arc is reached at some time τ (the existence of such a time is clear for initial conditions of this type), and then follows the singular arc for time σ until either all available inhibitors have been exhausted or the saturation point is reached. We now use the time ε along this trajectory as a parameter and construct the family Γ_ε over the compact parameter interval $[0, \theta]$, with $\theta = \tau + \sigma$ as follows: The trajectory $\Gamma_\varepsilon(\cdot)$ agrees with the reference trajectory ς_+ up to time ε and switches at time ε to the control $u = a$, which will then be followed until all remaining inhibitors have been exhausted, and then the control still is $u = 0$ until the trajectory terminates at time T as the diagonal is reached.

This family indeed contains all possible extremals starting at initial condition $\tilde{z}$: Initially the control can be only $u = 0$ or $u = a$. If the control is $u = a$, then it follows from the phase portrait for $u = a$ that this trajectory does not meet the admissible portion of the singular curve. Since any possible junction will lie in $\mathcal{D}_+$, it follows from Proposition 7.3 that the control can switch only to $u = 0$ as all inhibitors have been exhausted. At this point the optimal control then is still given by $u = 0$ until the diagonal $\mathcal{D}_0$ is reached at time $T(0)$ and the trajectory is terminated. This is the trajectory $\Gamma_0(\cdot)$ in our family. It actually follows from Proposition 7.1 that this trajectory would not be an extremal if the switching were to lie in region I, and in this case this trajectory could be excluded a priori. However, even if this is the case, for simplicity of argument we retain this curve anyway. Similarly, if initially the control is $u = 0$ on $[0, \varepsilon]$, with $\varepsilon \le \tau$, and then switches to $u = a$, the same reasoning applies, and the structure of the corresponding control is simply $0a0$. For $\varepsilon > \tau$, the trajectory $\Gamma_\varepsilon(\cdot)$ now follows the control $u = 0$ until time τ and then stays on the singular arc

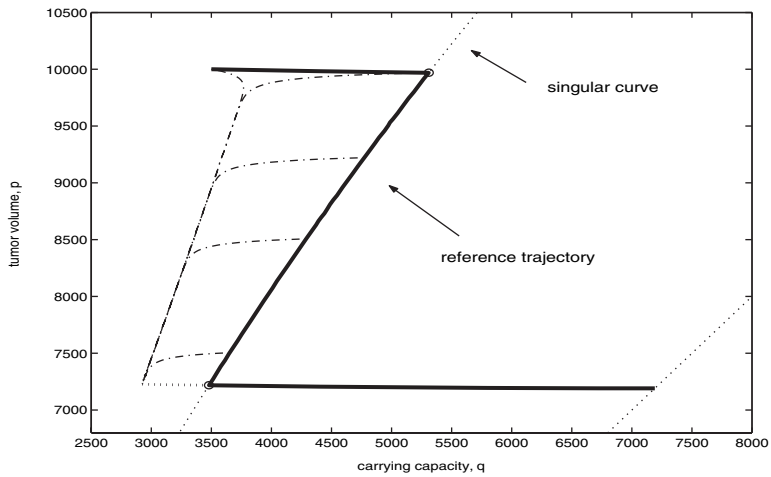

FIG. 8.1. *Parameterized extremals for an initial condition in region* I *without saturation.*

until time ε, at which time it leaves the singular arc to use $u = a$ until all inhibitors are being exhausted. The remaining time along the a trajectory is given by

$$\eta(\varepsilon) = \frac{1}{a}\left(A - \int_{\tau}^{\varepsilon} \psi(p_\varepsilon(s), q_\varepsilon(s))ds\right), \tag{8.5}$$

with $\eta(\tau + \theta) = 0$ if the inhibitors get exhausted along the singular arc. If the singular control saturates, we know that the trajectory $\Gamma_\theta(\cdot)$ is no longer optimal and therefore can terminate the construction of the one-parameter family of extremals with the trajectory that switches to $u = a$ at saturation. This simply provides us with a compact parameter interval, but in this case the minimum will be attained at a parameter $\varepsilon < \theta$. It follows from our local analysis given before that any possible extremal that could start at $\tilde{z}$ is part of this family $\Gamma_\varepsilon(\cdot)$. Essentially, trajectories cannot switch to $u = 0$ before all inhibitors have been exhausted, and thus once they switch to $u = a$ they need to use up all remaining inhibitors.

It is just a consequence of the continuous dependence of a solution to an ordinary differential equation on initial data and parameters that the end point $p_\varepsilon(T(\varepsilon))$ and thus the value $\upsilon(\varepsilon)$ depend continuously on ε. Hence, if $\hat{\varepsilon}$ is a parameter value where $\upsilon(\varepsilon)$ attains its minimum over $[0, \theta]$, then $\Gamma_{\hat{\varepsilon}}(\cdot)$ is the optimal trajectory starting at $\tilde{z}$ with a correspondingly defined optimal control.

The family $\Gamma_\varepsilon(s)$, $0 \le s \le T(\varepsilon)$, is illustrated in Figure 8.1 for the initial conditions $\tilde{p} = 10000$ and $\tilde{q} = 3500$. The reference trajectory is shown as a thick solid curve, and some sample trajectories of Γ_ε are shown as dashed-dotted curves. The heavily dotted curve is the curve of points when all inhibitors are being exhausted. Here the optimal control is of the type $0s0$ and given for $\varepsilon = \theta$; i.e., the optimal trajectory follows $u = 0$ until the singular curve $\mathcal{S}$ is reached, then follows the singular arc until all inhibitors have been exhausted, and finally uses $u = 0$ to reach the diagonal. This is always the case for initial conditions whose available inhibitors are too small to reach region II inside the loop $\mathcal{S}$ using the control $u = a$. This is the case for this example, and in fact the only extremal corresponding to this initial condition is the optimal trajectory Γ_θ. On the other hand, if initial conditions have an abundance of inhibitors so that the singular arc would saturate, then optimal trajectories exit the singular arc.

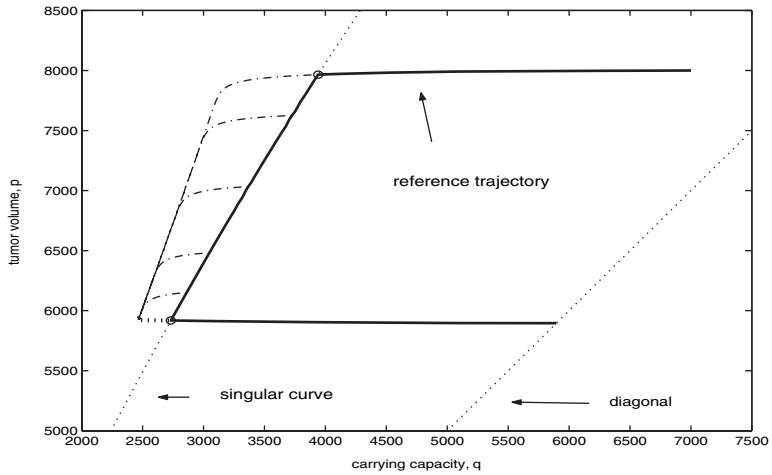

FIG. 8.2. *Parameterized extremals for an initial condition in region* II *without saturation.*

Case 2. Let $G = \text{II} \cup \mathcal{D}_0 \cup (\text{III} \cap \mathcal{N}_+)$, i.e., the region inside the loop $\mathcal{S}$, but "above" the curve $\mathcal{N}_0$, and consider a well-posed initial condition $\tilde{z} = (\tilde{p}, \tilde{q}, 0) \in G$. Then the optimal control is initially given by $u = a$. (If the control starts with $u = 0$, then the entire forward orbit lies in G, and in G switchings from 0 to a are not optimal (cf. Propositions 7.1 and 7.2)). If the a trajectory starting at $\tilde{z}$ does not intersect the admissible singular arc, the optimal control is simply $u = a$ until all inhibitors have been exhausted, and then $u = 0$ until the diagonal is reached. Nothing else needs to be done in this case. Otherwise let ς_- denote the reference trajectory that starts at $\tilde{z} = (\tilde{p}, \tilde{q}, 0)$, uses the control $u = a$ until the singular arc is reached at some time τ, and then, as above, follows the singular arc for time σ until either all available inhibitors have been exhausted or the saturation point is reached. Again we use the time along the singular arc of the reference trajectory as a parameter and construct the family Γ_ε over the compact parameter interval $[0, \theta]$, with $\theta = \sigma$ as follows: The trajectory $\Gamma_\varepsilon(\cdot)$ agrees with the reference trajectory ς_- along the initial segment for $u = a$ until the singular arc is reached at time τ and then $\Gamma_\varepsilon(\cdot)$ still follows the singular arc for time ε when it again switches to the control $u = a$. The end is as before: The control $u = a$ is used until all remaining inhibitors have been exhausted, at which time a final segment with $u = 0$ is added until the trajectory terminates at time T on the diagonal. Note that $\varepsilon = 0$ corresponds to the special case when the trajectory does not follow the singular arc but continues straight with $u = a$. As above, this family contains all possible extremals that start at $\tilde{z}$ but also may have some members that are not extremals (for example, the second arc with $u = 0$ may violate Proposition 7.4). The optimal trajectory is given by $\Gamma_{\hat{\varepsilon}}(\cdot)$, where $\hat{\varepsilon}$ is a minimizer of $\upsilon(\varepsilon)$ over $[0, \theta]$. In particular, in this case optimal controls at most have the form **asa0** with possibly some of the pieces absent.

Figure 8.2 shows an example of this family $\Gamma_\varepsilon(s)$, $0 \le s \le T(\varepsilon)$, for initial conditions $p_0 = 8000$ and $q_0 = 7000$. Like in Figure 8.1 the reference trajectory ς_- is shown as a thick solid curve, sample trajectories from the family are shown as dashed-dotted curves, and the heavily dotted curve of points is the curve when all inhibitors have been exhausted. As above, no saturation occurs, and it is optimal to follow the singular arc until all inhibitors have been exhausted (the trajectory corresponding to

the rightmost parameter value θ gives the minimum value). Also for this example this is in fact the only extremal.

This, however, is no longer true when there are still inhibitors available at the saturation point. An example of this scenario is given for the initial condition $p_0 = 5000$ and $q_0 = 2500$ in region III. In this case, however, the numerical differences between the values of the objectives are minute. In fact, no difference in the trajectories of the family is discernable, and the cost varies only between 3761.65 and 3761.98. It is clear that, although present mathematically, these differences are of no significance, and for all practical purposes one may simply continue the singular arc at saturation with $u = a$ without any noticeable loss.

It is furthermore clear that the case of initial conditions with $(\tilde{p}, \tilde{q})$ on the admissible portion of the singular arc can be analyzed in exactly the same way by setting $\tau = 0$. If the initial condition lies on the inadmissible portion, optimal controls are of the form $a0$ with all inhibitors being exhausted along $u = a$.

Case 3. The last case corresponds to initial conditions $(\tilde{p}, \tilde{q})$ in the region $F = (\mathrm{III} \cap \mathcal{N}_-) \cup (\mathcal{S} \cap \mathcal{D}_-) \cup \mathrm{IV}$, i.e., points that lie in $\mathcal{D}_-$ "below" $\mathcal{N}_0$. These initial conditions all have relatively very large q-values in contrast to small p-values. In these cases, in principle, the control can start with $u = 0$ and switch to $u = a$, while still in F. Once the control is $u = a$, the trajectory enters the region G and the construction of Case 2 applies. Thus, and if a large amount of inhibitors is available, here the full structure **0asa0** can arise. Since trajectories eventually enter the region G, and this leads to a repetition of the construction, we skip a precise description of what now would be a two-parameter family of extremals over a compact rectangle.

9. Conclusion. We presented a complete solution for a mathematical model for tumor antiangiogenesis for the problem of optimally scheduling a given number of inhibitors in order to minimize the primary tumor volume. Based on our theoretical analysis of the problem, for any specific initial condition the optimal solution can easily be computed numerically and as such provides a benchmark value to which other strategies should be compared. From a practical point of view, it is not realistic to employ the singular control. It is a feedback control, and the required information certainly is not available, although it could be predetermined offline from the initial condition. Naturally, strategies of the type $a0$ which give all available inhibitors in one session are the easiest to implement in practice. It follows from our analysis that for some initial conditions these are indeed the optimal ones. This is certainly the case for initial conditions for which a trajectories do not meet the admissible singular arc but also for initial conditions when this intersection point is close to the saturation point. Indeed, the dynamics for $u \equiv a$ very much has a differential algebraic structure with the q-dynamics fast and the p-dynamics slow. As a result, after a brief transient phase in steady state the system essentially follows the $\dot{q}$-nullcline. This nullcline is very close to the singular curve near the saturation point, and thus there the differences in the objective are almost unnoticeable. For initial conditions far away from this point the singular arc and the $\dot{q}$-nullcline are separated, and then the singular control is noticeably better. Of course, only knowing the optimal solution allows one to make such an analysis. However, this, and also comparisons with other models, will be pursued elsewhere.

Here we only conclude with the statement that it is shown in [12, 13] that the qualitative structure of optimal solutions as concatenations of the form $0asa0$ for the model by Hahnfeldt et al. [9] analyzed in this paper is exactly the same for the modified model considered by Ergun et al. [6] while optimal controls are bang-bang with at

most two switchings of the form $0a0$ for the modification considered by d'Onofrio and Gandolfi [5, 15].

Acknowledgments. We thank two anonymous referees for their careful reading of the paper and valuable suggestions regarding the exposition of the material. Thanks are especially due to a referee who clarified some of the underlying medical aspects and whose comments we incorporated into section 2.

BOUNDARY OBSERVATION AND EXACT CONTROL OF A QUASI-ELECTROSTATIC PIEZOELECTRIC SYSTEM IN MULTILAYERED MEDIA*

B. KAPITONOV†, B. MIARA‡, AND G. PERLA MENZALA§

Abstract. We study the evolution of a layered quasi-electrostatic piezoelectric system. Under suitable assumptions on the geometry of a region and the interfaces as well as a monotonicity condition on the coefficients, we prove a boundary observation inequality which together with the Hilbert uniqueness method introduced by Lions give us a solution of the exact controllability problem for the model under study.

Key words. distributed systems, boundary observation, transmission conditions, exact controllability

1. Introduction. Piezoelectricity is an electromechanical interaction. Piezoelectric materials have the property that an electric field creates stress and that a deformation creates polarization. These very special properties explain why such materials are of great use in industry: They are both actuators and sensors. The constitutive equations relate the stress tensor to the electric field and the polarization vector to the strain tensor (see [5] or [6]). In this work we consider the evolution problem of a piezoelectric structure whose three-dimensional (3-D) mechanical displacement vector field $u = u(x,t) = (u^1, u^2, u^3)$ and electric field E are acting on a bounded domain Ω of $\mathbb{R}^3$ with smooth boundary $\partial\Omega = S_0 \cup S_1$. The coupled system which models the phenomenon is

$$\begin{cases} u_{tt} - \operatorname{Div}\sigma = 0 \\ \operatorname{div}\mathcal{D} = 0 \end{cases} \qquad \text{in } \Omega \times (0, +\infty), \tag{1.1}$$

where

$$\sigma = C\,\mathcal{E}(u) - PE,$$
$$\mathcal{D} = P^t\,\mathcal{E}(u) + DE.$$

Here σ is the mechanical stress and $\mathcal{D}$ is the electric displacement. The linearized strain tensor $\mathcal{E}(u) = \left[\mathcal{E}_{k\ell}(u)\right]$ has components $\mathcal{E}_{k\ell}(u) = \frac{1}{2}\left(\frac{\partial u^\ell}{\partial x_k} + \frac{\partial u^k}{\partial x_\ell}\right)$, $1 \le \ell, k \le 3$.

We assume that the electric field E is such that $E = -\nabla q$, where q is the so-called electric potential. In (1.1), $C = (c_{ijk\ell})$ is the fourth order elasticity tensor, which is symmetric and positive, $P = (e_{kij})$ is a third order piezoelectric symmetric tensor, and $D = (d_{ij})$ is a second order symmetric and positive dielectric tensor. We assume that the material is piecewise homogeneous.

From now on, a summation convention with respect to repeated indices will be used. With the above considerations the quasi-electrostatic piezoelectric system (1.1) can be rewritten as $(1 \le i \le 3)$

$$\begin{cases} u^i_{tt} - \dfrac{\partial}{\partial x_j}\sigma_{ij}(u,q) = 0 \\ \dfrac{\partial}{\partial x_i} D_i(u,q) = 0 \end{cases} \qquad \text{in } \Omega \times (0,+\infty), \tag{1.2}$$

where $\sigma_{ij}(u,q) = c_{ijk\ell}\mathcal{E}_{k\ell}(u) + e_{kij}\,\frac{\partial q}{\partial x_k}$ and $D_i(u,q) = e_{ik\ell}\,\mathcal{E}_{k\ell}(u) - d_{ij}\,\frac{\partial q}{\partial x_j}$. We assume that the domain Ω with smooth boundary S has the form $\Omega = \mathcal{O}_0 \backslash \overline{\mathcal{O}}_1$, where $\mathcal{O}_0$ and $\mathcal{O}_1$ are open bounded domains with $\overline{\mathcal{O}}_1 \subset \mathcal{O}_0$, where $\overline{\mathcal{O}}_1$ denotes the closure of $\mathcal{O}_1$, $\partial\mathcal{O}_0 = S_0$, and $\partial\mathcal{O}_1 = S_1$. Thus $S = S_0 \cup S_1$. Let $n > 1$ be a given integer. For each m with $1 \le m \le n$ let B_m be an open subset with smooth boundary Γ_m and such that $\overline{\mathcal{O}}_1 \subset B_m \subset \mathcal{O}_0$, $\overline{B}_m \subset B_{m+1}$. We set $\Omega_0 = B_1 \backslash \overline{\mathcal{O}}_1$, $\Omega_m = B_{m+1} \backslash \overline{B}_m$ for $1 \le m \le n-1$ and $\Omega_n = \mathcal{O}_0 \backslash \overline{B}_n$.

We associate with system (1.2) the following given initial conditions,

$$u(x,0) = f_1(x), \quad u_t(x,0) = f_2(x), \tag{1.3}$$

and boundary conditions

$$\begin{cases} \sigma_{ij}(u,q)\eta_j = 0 \\ q = 0 \end{cases} \qquad \text{on } S_0 \times (0,+\infty), \tag{1.4}$$

$$\begin{cases} D_i(u,q)\eta_i = 0 \\ u = 0 \end{cases} \qquad \text{on } S_1 \times (0,+\infty), \tag{1.5}$$

where $\eta = \eta(x) = (\eta_1, \eta_2, \eta_3)$ is the unit normal vector pointing toward the exterior of Ω.

Our main purpose in this work will be to prove a special uniqueness theorem (boundary observation) for the transmission problem associated with (1.2)–(1.5). We will assume that the transmission conditions are the following:

$$\begin{cases} \sigma_{ij}\big(u^{(m-1)}, q^{(m-1)}\big)\eta_j = \sigma_{ij}\big(u^{(m)}, q^{(m)}\big)\eta_j, \\ D_i\big(u^{(m-1)}, q^{(m-1)}\big)\eta_i = D_i\big(u^{(m)}, q^{(m)}\big)\eta_i, \\ u^{(m-1)} = u^{(m)}, \quad q^{(m-1)} = q^{(m)}, \end{cases} \tag{1.6}$$

for any $(x,t) \in \Gamma_m \times (0,+\infty)$, $m = 1, 2, \ldots, n$, and all $i, j \in \{1,2,3\}$. Here $\eta = \eta(x)$ is the unit normal vector pointing toward the exterior of B_m.

In (1.6), $u^{(m)}$ and $q^{(m)}$ denote the restrictions of the corresponding functions on Ω_m, $1 \le m \le n$. Figures 1 and 2 illustrate simple such situations when $n = 0$ or $n = 2$.

FIG. 1. $n = 0$

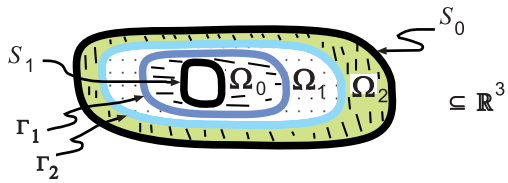

FIG. 2. $n = 2$

From now on we will assume that the coefficients $c_{ijk\ell}$, d_{ij}, and $e_{ik\ell}$ satisfy the symmetries

$$c_{ijk\ell} = c_{k\ell ij} = c_{jik\ell},$$
$$d_{ij} = d_{ji}, \quad e_{ik\ell} = e_{i\ell k}.$$

Also, the tensors $(c_{ijk\ell})$ and (d_{ij}) are elliptic in the sense that there exist $c_0 > 0$ and $d_0 > 0$ such that

$$c_{ijk\ell}\,\lambda_{k\ell}\,\lambda_{ij} \geq c_0 \sum_{i,j=1}^{3} (\lambda_{ij})^2, \quad d_{ij}\xi_j\xi_i \geq d_0|\xi|^2 \tag{1.7}$$

for any real symmetric matrix $[\lambda_{ij}]$ of order 3 and any vector $\xi = (\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3$.

In order to mention the main result of this paper we describe the assumptions on the coefficients for problem (1.2)–(1.6).

HYPOTHESIS I. *The coefficients $c_{ijk\ell} = c_{ijk\ell}(x)$ and $d_{ij} = d_{ij}(x)$ are piecewise constant functions on $\overline{\Omega}$, which lose continuity only on $\Gamma_1, \Gamma_2, \dots$ and Γ_n. All the coefficients e_{kij} are constant on $\overline{\Omega}$.*

We will obtain an estimate of the form

$$(T - T_0) \sum_{m=0}^{n} \int_{\Omega_m} \left\{ |u_t^{(m)}|^2 + c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)}) \mathcal{E}_{ij}(u^{(m)}) + d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \right\} dx \leq C \int_0^T \int_{S_0} |u_t|^2\, d\Gamma\, dt \tag{1.8}$$

for some $T_0 > 0$, $C > 0$, and any $T > T_0$. Here we use the notation $|u_t|^2 = \frac{\partial u}{\partial t} \cdot \frac{\partial u}{\partial t}$, where the dot $\cdot$ denotes the usual inner product in $\mathbb{R}^3$ and $\int_{S_0} |u_t|^2\, d\Gamma$ means the surface integral of $|u_t|^2$ over the surface S_0.

This is a so-called boundary observation inequality, which will be stated and proved in section 3 (see Theorem 3.3), provided that we assume geometric properties on the region Ω and the interfaces Γ_i. Such assumptions are basically of "star-shaped" type. In addition, to prove (1.8) we will assume monotonicity conditions on the coefficients of system (1.2).

The need for the above requirements was already noticed by Lions in [16] while treating transmission problems. Later on, Lagnese [13] also used those types of assumptions to prove controllability results for a large class of hyperbolic problems.

Results on controllability of physical systems are quite important, especially in the case of systems driven by coupled equations such as those found in thermoelasticity [14], magnetoelasticity [4], or for flexible multistructures [3], among many others.

In a simple case we may check that our monotonicity conditions are in fact optimal (see Hypothesis II, (e) and (f), in section 3): Suppose that the tensor (e_{kij}) vanishes in Ω. In this case the electric potential does not interact with the displacement vector, and u satisfies a wave-like equation that may be chosen to be a scalar wave equation with the corresponding boundary conditions. It follows from [13] that in this situation the above monotonicity assumptions are optimal. In the general case, that is, when the tensor (e_{kij}) does not vanish, the optimality would require further study.

Using (1.8) and the Hilbert uniqueness method (HUM) introduced by Lions [15], [16], we study the following exact controllability problem: Given, as in (1.3), an initial distribution $f = (f_1, f_2)$ and a desired terminal state $g = (g_1, g_2)$, with f and g belonging to appropriate function spaces, we want to find a vector-valued function $Q = Q(x,t)$ (the control function) in a suitable function space and a time $T > 0$ such that the solution u of (1.2), (1.3), (1.6) with boundary conditions

$$\begin{cases} \sigma_{ij}(u,q)\eta_j = Q^i(x,t) \\ q = 0 \end{cases} \qquad \text{on } S_0 \times (0,+\infty),$$

$$\begin{cases} D_i(u,q)\eta_i = 0 \\ u = 0 \end{cases} \qquad \text{on } S_1 \times (0,+\infty) \tag{1.9}$$

satisfies

$$u(x,T) = g_1(x), \qquad u_t(x,T) = g_2(x). \tag{1.10}$$

Several authors have considered the well-posedness of the initial-boundary value problem for quasi-electrostatic equations; see, for instance, [1], [2], [11], and [17] (and the references therein). The exact controllability problem for system (1.2) has been studied by Miara [18]. Boundary controllability in transmission problems for the wave equation was considered by Lions [16] and Nicaise [19], [20]. Uniform stabilization and exact control for the Maxwell system in multilayered media was studied by Kapitonov [7] (see also [21]). Boundary controllability in transmission problems for a class of second order hyperbolic systems has been studied by Lagnese [13]. Stabilization and exact boundary controllability for a system of electromagneto-elasticity was studied recently by Kapitonov and Perla Menzala [8], [10] and by Kapitonov and Raupp [9].

The sections of this paper are as follows. Solvability of (1.2)–(1.6) for the appropriate class of functions is shown in section 2. This is done via semigroup theory and with the help of known results for transmission problems for elliptic equations (see (2.1)–(2.2) below). Actually, for such a problem we could also give the variational form and the expression of the energy and conclude that the solution is a saddle point of this energy (hence, the Lax–Milgram theorem applies as well). In section 3 we prove the boundary observation result via the multiplier method "slightly" modified in order to take into account additional terms after spatial integration of the fundamental identity. In the last section, the exact controllability problem is solved using the boundary observability inequality and HUM.

2. Well-posedness. The well-posedness of the initial-boundary value problem with transmission conditions (1.2)–(1.6) is proved by standard semigroup methods. Thus, we just outline the proof of well-posedness. Let Ω be a bounded region of $\mathbb{R}^3$ with Lipschitz boundary as considered in section 1. Let us assume Hypothesis I on the coefficients and consider $F = [F_{k\ell}]$ to be a real symmetric matrix of order 3 such that $F_{k\ell} \in H^1(\Omega_m)$, $m = 0, 1, 2, \ldots, n$. In Ω we consider the elliptic problem

$$\frac{\partial}{\partial x_i}\left(d_{ij}\,\frac{\partial q}{\partial x_j}\right) = \frac{\partial}{\partial x_i}\big(e_{ik\ell}\,F_{k\ell}\big) \quad \text{in} \quad \Omega_m, \quad m = 0, 1, 2, \ldots, n, \tag{2.1}$$

with boundary conditions

$$\begin{cases} q = 0 \qquad \text{on} \qquad S_0, \\ d_{ij}\,\dfrac{\partial q}{\partial x_j}\,\eta_i = e_{ik\ell}\,F_{k\ell}\,\eta_i \quad \text{on} \quad S_1, \end{cases} \tag{2.2}$$

and transmission conditions on Γ_m, $m = 1, 2, \ldots, n$,

$$\begin{cases} q^{(m-1)} = q^{(m)}, \\ d_{ij}^{(m-1)}\,\dfrac{\partial q^{(m-1)}}{\partial x_j}\,\eta_i - d_{ij}^{(m)}\,\dfrac{\partial q^{(m)}}{\partial x_j}\,\eta_i \\ \qquad = e_{ik\ell}\,F_{k\ell}^{(m-1)}\,\eta_i - e_{ik\ell}\,F_{k\ell}^{(m)}\,\eta_i. \end{cases} \tag{2.3}$$

Using well-known elliptic results, we deduce that there exists a unique solution $q \in H^2(\Omega_m)$ of problem (2.1)–(2.3), which we will denote by $q = \beta(F)$. (Observe that the existence of a solution $q \in H^2(\Omega_m)$ of problem (2.1)–(2.3) depends on the regularity of the boundary and the boundary loading.) Additionally, the restriction of q to the subset Ω_m will be written as $q^{(m)} = \beta^{(m)}(F)$. Let X be the real Hilbert space of pairs (u, v) of three-component vector-valued functions u and v such that $v^{(m)} \in [L^2(\Omega_m)]^3$, $u^{(m)} \in [H^2(\Omega_m)]^3$, and $u = 0$ on S_1. Here $H^s(\Omega)$ denotes the Sobolev space of order s.

The inner product in X is given as follows:

$$\langle (u, v), (\tilde{u}, \tilde{v})\rangle_X = \sum_{m=0}^{n} \int_{\Omega_m} \Big\{ v \cdot \tilde{v} + c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(\tilde{u}) + d_{ij}\,\frac{\partial}{\partial x_j}\left(\beta(\mathcal{E}(u))\right)\frac{\partial}{\partial x_i}\left(\beta(\mathcal{E}(\tilde{u}))\right)\Big\} dx,$$

where $\mathcal{E}(u) = [\mathcal{E}_{k\ell}(u)]$. In X we define the unbounded operator $\mathcal{A}$ with domain $\mathcal{D}(\mathcal{A})$, which consists of all elements (u, v) belonging to X such that

$$v^{(m)} \in \left[H^1(\Omega_m)\right]^3, \quad v = 0 \quad \text{on } S_1,$$

$$\left[c_{ijk\ell}\,\mathcal{E}_{k\ell}(u) + e_{kij}\,\frac{\partial}{\partial x_k}\left(\beta(\mathcal{E}(u))\right)\right]\eta_j = 0 \quad \text{on } S_0,$$

and

$$\begin{cases} u^{(m)} = u^{(m-1)}, \\ \left[c_{ijk\ell}^{(m-1)}\,\mathcal{E}_{k\ell}(u^{(m-1)}) + e_{kij}\,\dfrac{\partial}{\partial x_k}\left(\beta^{(m-1)}(\mathcal{E}(u))\right)\right]\eta_j \\ \qquad = \left[c_{ijk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)}) + e_{kij}\,\dfrac{\partial}{\partial x_k}\left(\beta^{(m)}(\mathcal{E}(u))\right)\right]\eta_j \end{cases}$$

on Γ_m, $m = 1, 2, \ldots, n$. In $\mathcal{D}(\mathcal{A})$ the operator $\mathcal{A}$ is given by

$$\mathcal{A}(u,v) = \left(v, \frac{\partial}{\partial x_i} \left\{ c_{ijk\ell}\, \mathcal{E}_{k\ell}(u) + e_{kij}\, \frac{\partial}{\partial x_k} \left(\beta(\mathcal{E}(u)) \right) \right\} \right).$$

The skew-self-adjointness of $\mathcal{A}$ can be verified in the standard way. Consequently, the operator $\mathcal{A}$ generates a one-parameter group of unitary operators $\{U(t)\}_{t\in\mathbb{R}}$ on X, $U(t)$ is strongly continuous with respect to t, and $U(t)f$ is strongly differentiable with respect to t whenever $f = (f_1, f_2) \in \mathcal{D}(\mathcal{A})$. Furthermore, if $f = (f_1, f_2) \in X$, we consider $f^n = (f_1^n, f_2^n) \in \mathcal{D}(\mathcal{A})$ such that $||f - f^n||_X \to 0$ as $n \to +\infty$. Let $\Phi \in L^2(0,T;\mathcal{D}(\mathcal{A}^*))$ such that $\frac{d}{dt}\Phi \in L^2(0,T;X)$ and $\Phi(T) = 0$. For any such Φ we have that $U(t)f^n$ satisfies the identity

$$\int_0^T \left\{ \left\langle U(t)f^n, \frac{d}{dt}\Phi \right\rangle_X + \langle U(t)f^n, \mathcal{A}^*\Phi \rangle_X \right\} dt = -\langle f^n, \Phi(0) \rangle_X. \tag{2.4}$$

Passing to the limit in (2.4) as $n \to +\infty$, we obtain that

$$\int_0^T \left\{ \left\langle U(t)f, \frac{d}{dt}\Phi \right\rangle_X + \langle U(t)f, \mathcal{A}^*\Phi \rangle_X \right\} dt = -\langle f, \Phi(0) \rangle_X; \tag{2.5}$$

that is, $U(t)f$ is the weak solution of the abstract Cauchy problem

$$\frac{dV}{dt} = \mathcal{A}\, V, \quad V(0) = f$$

associated with (1.2)–(1.6).

3. Boundary observation. In this section we prove the boundary observation result (1.8). The proof is based on the theory of multipliers and is motivated by the invariance of system (1.2) relative to the one-parameter group of dilations in all variables. A good reference for the use of this technique is Komornik's book [12]. The multipliers have to be conveniently modified in such a way that we can handle the extra boundary terms appearing in the identities. Let $h = h(x)$ be an auxiliary scalar smooth function on $\overline{\Omega}$ (which we will choose later on). Consider the multipliers M_1 and M_2 (which is actually an operator) given by

$$M_1\, u^i = t\, \frac{\partial u^i}{\partial t} + \nabla h \cdot \nabla u^i + u^i, \quad i = 1, 2, 3,$$

and

$$M_2\, q = tq\, \frac{\partial}{\partial t} - \nabla h \cdot \nabla q.$$

We will use the standard notation

$$\nabla h \cdot \nabla = \sum_{j=1}^{3} \frac{\partial h}{\partial x_j}\, \frac{\partial}{\partial x_j}.$$

Let us multiply the first equation of (1.2) by $2M_1 u^i$ and apply the operator $2M_2 h$ to the second equation in (1.2). Here the derivatives of the components of the tensors

$C = (c_{ijk\ell})$, $D = (d_{ij})$, and $P^t = (e_{kij})$ have to be understood in the distributional sense. Adding and rearranging terms, we obtain

$$\begin{aligned} 0 &= 2M_1 u^i \left[u^i_{tt} - \frac{\partial}{\partial x_j} \left(c_{ijk\ell}\, \mathcal{E}_{k\ell}(u) + e_{kij}\, \frac{\partial q}{\partial x_k} \right) \right] \\ &\quad + 2M_2 q \left[\frac{\partial}{\partial x_i} \left\{ e_{ik\ell}\, \mathcal{E}_{k\ell}(u) - d_{ij}\, \frac{\partial q}{\partial x_j} \right\} \right] \\ &= \frac{\partial}{\partial t}\, F - \frac{\partial}{\partial x_j}\, G_j - J, \end{aligned} \tag{3.1}$$

where

$$\begin{aligned} F &= t \left[|u_t|^2 + c_{ijk\ell}\, \mathcal{E}_{k\ell}(u) \mathcal{E}_{ij}(u) + d_{ij}\, \frac{\partial q}{\partial x_j}\, \frac{\partial q}{\partial x_i} \right] \\ &\quad + 2u_t \cdot \big[(\nabla h \cdot \nabla) u + u \big], \end{aligned} \tag{3.2}$$

$$\begin{aligned} G_j &= 2\big[t\, u^i_t + \nabla h \cdot \nabla u^i + u^i \big] \left[c_{ijk\ell}\, \mathcal{E}_{k\ell}(u) + e_{kij}\, \frac{\partial q}{\partial x_k} \right] \\ &\quad + 2 \left(tq\, \frac{\partial}{\partial t} - \nabla h \cdot \nabla q \right) \left(d_{ij}\, \frac{\partial q}{\partial x_i} - e_{jk\ell}\, \mathcal{E}_{jk\ell}(u) \right) \\ &\quad + \frac{\partial h}{\partial x_j} \left[|u_t|^2 + d_{k\ell}\, \frac{\partial q}{\partial x_\ell}\, \frac{\partial q}{\partial x_k} - c_{pqk\ell}\, \mathcal{E}_{k\ell}(u) \mathcal{E}_{pq}(u) \right. \\ &\quad \left. - 2e_{ki\ell}\, \mathcal{E}_{i\ell}(u)\, \frac{\partial q}{\partial x_k} \right], \end{aligned} \tag{3.3}$$

$$\begin{aligned} J &= (\Delta h - 1) c_{ijk\ell}\, \mathcal{E}_{k\ell}(u) \mathcal{E}_{ij}(u) \\ &\quad - 2\, \frac{\partial^2 h}{\partial x_p \partial x_j}\, c_{ijk\ell}\, \mathcal{E}_{k\ell}(u)\, \frac{\partial u^i}{\partial x_p} + (3 - \Delta h) |u_t|^2 \\ &\quad + 2\, \frac{\partial^2 h}{\partial x_i \partial x_k}\, d_{ij}\, \frac{\partial q}{\partial x_j}\, \frac{\partial q}{\partial x_k} + (1 - \Delta h) d_{ij}\, \frac{\partial q}{\partial x_j}\, \frac{\partial q}{\partial x_i} \\ &\quad + 2(\Delta h - 1) e_{kij}\, \mathcal{E}_{ij}(u)\, \frac{\partial q}{\partial x_k} \\ &\quad - 2\, \frac{\partial^2 h}{\partial x_j \partial x_\ell}\, e_{kij}\, \frac{\partial u^i}{\partial x_\ell}\, \frac{\partial q}{\partial x_k} - 2\, \frac{\partial^2 h}{\partial x_i \partial x_j}\, e_{ik\ell}\, \mathcal{E}_{k\ell}(u)\, \frac{\partial q}{\partial x_j}. \end{aligned} \tag{3.4}$$

Observation. If we consider $h(x) = \frac{1}{2} |x - x_0|^2$ for some $x_0 \in \mathbb{R}^3$, then we can verify that $J \equiv 0$. In that case identity (3.1) represents a true conservation law. However, due to the terms appearing in G_j (see (3.4)), we would require a definite sign for $\frac{\partial h}{\partial \eta} \cdot$ That is why we will choose h as a "small" perturbation of $\frac{1}{2} |x - x_0|^2$.

Let $\{u, q\}$ be a smooth solution of (1.2)–(1.6). Integration over $\Omega_m \times (0, T)$ of

identity (3.1) and summation over m implies that

$$
\begin{aligned}
&T\sum_{m=0}^{n}\int_{\Omega_m}\left\{|u_t|^2+c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u)+d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_i}\right\}dx\\
&\quad+\left[2\sum_{m=0}^{n}\int_{\Omega_m}u_t\cdot\big\{(\nabla h\cdot\nabla)u+u\big\}dx\right]_{t=0}^{t=T}\\
&\quad=\sum_{m=1}^{n}\int_0^T\int_{\Gamma_m}\big(V_{m-1}-V_m\big)d\Gamma\,dt\\
&\quad+\int_0^T\int_{S_0}V_n\,d\Gamma\,dt+\int_0^T\int_{S_1}V_0\,d\Gamma\,dt\\
&\quad+\sum_{m=0}^{n}\int_0^T\int_{\Omega_m}J_m(x,t)dx\,dt,
\end{aligned}
\tag{3.5}
$$

where $J_m=J_m(u,q,h)$ denotes the restriction of J (given by (3.4)) to the region Ω_m and

$$
\begin{aligned}
V_m=\;&2\big[t\,u_t^{(m)}+(\nabla h\cdot\nabla)u^{(m)}+u^{(m)}\big]^i\left[c_{ijk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)})+e_{kij}\,\frac{\partial q^{(m)}}{\partial x_k}\right]\eta_j\\
&+\frac{\partial h}{\partial\eta}\left[|u_t^{(m)}|^2+d_{k\ell}^{(m)}\,\frac{\partial q^{(m)}}{\partial x_\ell}\,\frac{\partial q^{(m)}}{\partial x_k}-c_{pqk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{pq}(u^{(m)})\right.\\
&\left.-\,2e_{ki\ell}\,\mathcal{E}_{i\ell}(u^{(m)})\frac{\partial q^{(m)}}{\partial x_k}\right]\\
&+2tq^{(m)}\left[d_{ij}^{(m)}\,\frac{\partial^2 q^{(m)}}{\partial x_i\partial t}-e_{jk\ell}\,\mathcal{E}_{k\ell}(u_t^{(m)})\right]\eta_j\\
&-2\,\nabla h\cdot\nabla q^{(m)}\left[d_{ij}^{(m)}\,\frac{\partial q^{(m)}}{\partial x_i}-e_{jk\ell}\,\mathcal{E}_{k\ell}(u^{(m)})\right]\eta_j
\end{aligned}
\tag{3.6}
$$

$(0\le m\le n)$.

In (3.6), $\frac{\partial h}{\partial\eta}$ denotes the normal derivative of h at $x\in\Gamma_m$ (or S_0, S_1). The lemma that we prove below shows that the differences $V_{m-1}-V_m$ will have the "good" sign if we choose h conveniently and assume a monotonicity condition on the coefficients, as follows.

LEMMA 3.1. *Let $\{u,q\}$ be a smooth solution of problem* (1.2)–(1.6). *Then, the identity*

$$
\begin{aligned}
V_{m-1}-V_m=-\frac{\partial h}{\partial\eta}\Big[&\big(c_{ijk\ell}^{(m-1)}-c_{ijk\ell}^{(m)}\big)\mathcal{E}_{k\ell}(u^{(m-1)})\mathcal{E}_{ij}(u^{(m-1)})\\
&+c_{ijk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)}-u^{(m-1)})\mathcal{E}_{ij}(u^{(m)}-u^{(m-1)})\\
&+\left(d_{ij}^{(m)}-d_{ij}^{(m-1)}\right)\frac{\partial q^{(m)}}{\partial x_j}\,\frac{\partial q^{(m)}}{\partial x_i}\\
&+d_{ij}^{(m-1)}\left(\frac{\partial q^{(m-1)}}{\partial x_j}-\frac{\partial q^{(m)}}{\partial x_j}\right)\left(\frac{\partial q^{(m-1)}}{\partial x_i}-\frac{\partial q^{(m)}}{\partial x_i}\right)\Big]
\end{aligned}
\tag{3.7}
$$

holds on Γ_m for $m=1,2,\dots,n$.

Proof. We use interface conditions (1.6). In fact, direct calculations using (3.6) and the interface conditions imply that

$$
\begin{aligned}
V_{m-1} - V_m &= 2(\nabla h \cdot \nabla)(u^{i(m-1)} - u^{i(m)}) \left(c^{(m)}_{ijk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) + e_{kij}\, \frac{\partial q^{(m)}}{\partial x_k} \right) \eta_j \\
&\quad - \frac{\partial h}{\partial \eta} \left[c^{(m-1)}_{pqk\ell}\, \mathcal{E}_{k\ell}(u^{(m-1)}) \mathcal{E}_{pq}(u^{(m-1)}) - c^{(m)}_{pqk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) \mathcal{E}_{pq}(u^{(m)} \right] \\
&\quad + \frac{\partial h}{\partial \eta} \left[d^{(m-1)}_{k\ell}\, \frac{\partial q^{(m-1)}}{\partial x_\ell}\, \frac{\partial q^{(m-1)}}{\partial x_k} - d^{(m)}_{k\ell}\, \frac{\partial q^{(m)}}{\partial x_\ell}\, \frac{\partial q^{(m)}}{\partial x_k} \right] \\
&\quad - 2\, \frac{\partial h}{\partial \eta} \left[e_{ki\ell}\, \mathcal{E}_{i\ell}(u^{(m-1)}) \frac{\partial q^{(m-1)}}{\partial x_k} - e_{ki\ell}\, \mathcal{E}_{i\ell}(u^{(m)})\, \frac{\partial q^{(m)}}{\partial x_k} \right] \\
&\quad - 2 \left[d^{(m)}_{ij}\, \frac{\partial q^{(m)}}{\partial x_i} - e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) \right] \eta_j \left[\nabla h \cdot \nabla q^{(m-1)} - \nabla h \cdot \nabla q^{(m)} \right]. \qquad (3.8)
\end{aligned}
$$

We use the identity

$$
\begin{aligned}
(\nabla h \cdot \nabla)(u^{(m-1)} - u^{(m)}) &= \frac{\partial h}{\partial x_k} \left(\frac{\partial u^{(m-1)}}{\partial x_k} - \frac{\partial u^{(m)}}{\partial x_k} \right) \\
= \frac{\partial h}{\partial x_k}\, \eta_k \left(\frac{\partial u^{(m-1)}}{\partial \eta} - \frac{\partial u^{(m)}}{\partial \eta} \right) &= \frac{\partial h}{\partial \eta} \left(\frac{\partial u^{(m-1)}}{\partial \eta} - \frac{\partial u^{(m)}}{\partial \eta} \right)
\end{aligned}
$$

in order to obtain

$$
\begin{aligned}
&2(\nabla h \cdot \nabla)(u^{i(m-1)} - u^{i(m)}) \left(c^{(m)}_{ijk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) + e_{kij}\, \frac{\partial q^{(m)}}{\partial x_k} \right) \eta_j \\
&= 2\, \frac{\partial h}{\partial \eta} \left[\left(\frac{\partial u^{i(m-1)}}{\partial \eta} - \frac{\partial u^{i(m)}}{\partial \eta} \right) \eta_j \right] \left[c^{(m)}_{ijk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) + e_{kij}\, \frac{\partial q^{(m)}}{\partial x_k} \right] \\
&= 2\, \frac{\partial h}{\partial \eta} \left[\left(\frac{\partial u^{i(m-1)}}{\partial x_j} - \frac{\partial u^{i(m)}}{\partial x_j} \right) \right] \left[c^{(m)}_{ijk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) + e_{kij}\, \frac{\partial q^{(m)}}{\partial x_k} \right] \\
&= 2\, \frac{\partial h}{\partial \eta}\, c^{(m)}_{ijk\ell}\, \mathcal{E}_{k\ell}(u^{(m)})\, \mathcal{E}_{ij}(u^{(m-1)}) - 2\, \frac{\partial h}{\partial \eta}\, c^{(m)}_{ijk\ell}\, \mathcal{E}_{k\ell}(u^{(m)})\, \mathcal{E}_{ij}(u^{(m)}) \\
&\quad + 2\, \frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\, \frac{\partial q^{(m)}}{\partial x_k} - 2\, \frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m)})\, \frac{\partial q^{(m)}}{\partial x_k}. \qquad (3.9)
\end{aligned}
$$

In a similar way we get

$$
\begin{aligned}
&-2 \left[d^{(m)}_{ij}\, \frac{\partial q^{(m)}}{\partial x_i} - e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) \right] \eta_j \left[\left(\nabla h \cdot \nabla q^{(m-1)} \right) - \left(\nabla h \cdot \nabla q^{(m)} \right) \right] \\
&= -2 \left[\nabla h \cdot \eta \left(\frac{\partial q^{(m-1)}}{\partial \eta} - \frac{\partial q^{(m)}}{\partial \eta} \right) \right] \left[d^{(m)}_{ij}\, \frac{\partial q^{(m)}}{\partial x_i} - e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) \right] \eta_j \\
&= -2\, \frac{\partial h}{\partial \eta} \left[\left(d^{(m)}_{ij}\, \frac{\partial q^{(m)}}{\partial x_i} - e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) \right) \eta_j \left(\frac{\partial q^{(m-1)}}{\partial \eta} - \frac{\partial q^{(m)}}{\partial \eta} \right) \right] \\
&= 2\, \frac{\partial h}{\partial \eta} \left[d^{(m)}_{ij}\, \frac{\partial q^{(m)}}{\partial x_i} - e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)}) \right] \left[\frac{\partial q^{(m)}}{\partial x_j} - \frac{\partial q^{(m-1)}}{\partial x_j} \right]
\end{aligned}
$$

$$
\begin{aligned}
&= 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} - 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i} \\
&\quad + 2\,\frac{\partial h}{\partial \eta}\, e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)})\, \frac{\partial q^{(m-1)}}{\partial \eta} - 2\,\frac{\partial h}{\partial \eta}\, e_{jk\ell}\, \mathcal{E}_{k\ell}(u^{(m)})\, \frac{\partial q^{(m)}}{\partial x_j}. \qquad (3.10)
\end{aligned}
$$

From (3.8)–(3.10) we obtain the identity

$$
\begin{aligned}
V_{m-1} - V_m &= 2\,\frac{\partial h}{\partial \eta}\, c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)}) \mathcal{E}_{ij}(u^{(m-1)}) \\
&\quad - \frac{\partial h}{\partial \eta}\, c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)}) \mathcal{E}_{ij}(u^{(m)}) \\
&\quad - \frac{\partial h}{\partial \eta}\, c_{ijk\ell}^{(m-1)}\, \mathcal{E}_{k\ell}(u^{(m-1)}) \mathcal{E}_{ij}(u^{(m-1)}) \\
&\quad - 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_j} + \frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \\
&\quad + \frac{\partial h}{\partial \eta}\, d_{ij}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i} \\
&\quad + 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\, \frac{\partial q^{(m)}}{\partial x_k} - 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m)})\, \frac{\partial q^{(m)}}{\partial x_k} \\
&\quad + 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m)})\, \frac{\partial q^{(m-1)}}{\partial x_k} - 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\, \frac{\partial q^{(m-1)}}{\partial x_k}. \qquad (3.11)
\end{aligned}
$$

Using the interface conditions

$$
D_k\big(u^{(m-1)}, q^{(m-1)}\big)\eta_k = D_k\big(u^{(m)}, q^{(m)}\big)\eta_k,
$$

we obtain

$$
\begin{aligned}
&\big[e_{kij}\mathcal{E}_{ij}(u^{(m)}) - e_{ikj}\mathcal{E}_{ij}(u^{(m-1)})\big]\eta_k \\
&= \left(d_{k\ell}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_\ell} - d_{k\ell}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_\ell}\right)\eta_k. \qquad (3.12)
\end{aligned}
$$

Using (3.12), we deduce

$$
\begin{aligned}
&2\,\frac{\partial h}{\partial \eta}\ e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\, \frac{\partial q^{(m)}}{\partial x_k} - 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m)})\, \frac{\partial q^{(m)}}{\partial x_k} \\
&\quad + 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m)})\, \frac{\partial q^{(m-1)}}{\partial x_k} - 2\,\frac{\partial h}{\partial \eta}\, e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\, \frac{\partial q^{(m-1)}}{\partial x_k} \\
&= 2\,\frac{\partial h}{\partial \eta}\left[e_{kij}\, \mathcal{E}_{ij}(u^{(m)}) - e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\right]\left[\frac{\partial q^{(m-1)}}{\partial x_k} - \frac{\partial q^{(m)}}{\partial x_k}\right] \\
&= 2\,\frac{\partial h}{\partial \eta}\left[e_{kij}\, \mathcal{E}_{ij}(u^{(m)}) - e_{kij}\, \mathcal{E}_{ij}(u^{(m-1)})\right]\eta_k\left[\frac{\partial q^{(m-1)}}{\partial \eta} - \frac{\partial q^{(m)}}{\partial \eta}\right] \\
&= 2\,\frac{\partial h}{\partial \eta}\left[d_{k\ell}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_\ell} - d_{k\ell}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_\ell}\right]\eta_k\left[\frac{\partial q^{(m-1)}}{\partial \eta} - \frac{\partial q^{(m)}}{\partial \eta}\right] \\
&= -2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} + 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i} \\
&\quad - 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i} + 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i}. \qquad (3.13)
\end{aligned}
$$

From (3.9)–(3.13) it follows that

$$
\begin{aligned}
V_{m-1} - V_m = {} & 2\,\frac{\partial h}{\partial \eta}\, c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m-1)}) \\
& - \frac{\partial h}{\partial \eta}\, c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m)}) \\
& - \frac{\partial h}{\partial \eta}\, c_{ijk\ell}^{(m-1)}\, \mathcal{E}_{k\ell}(u^{(m-1)})\mathcal{E}_{ij}(u^{(m-1)}) \\
& + 2\,\frac{\partial h}{\partial \eta}\, d_{ij}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} - \frac{\partial h}{\partial \eta}\, d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \\
& - \frac{\partial h}{\partial \eta}\, d_{ij}^{(m-1)}\, \frac{\partial h^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i}.
\end{aligned}
\tag{3.14}
$$

The conclusion of Lemma 3.1 follows from (3.14), observing the validity of the identities

$$
\begin{aligned}
& c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\, \mathcal{E}_{ij}(u^{(m)}) + c_{ijk\ell}^{(m-1)}\, \mathcal{E}_{k\ell}(u^{(m-1)})\, \mathcal{E}_{ij}(u^{(m-1)}) \\
& \quad - 2\, c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\, \mathcal{E}_{ij}(u^{(m-1)}) \\
& \quad = \big(c_{ijk\ell}^{(m-1)} - c_{ijk\ell}^{(m)}\big)\mathcal{E}_{k\ell}(u^{(m-1)})\mathcal{E}_{ij}(u^{(m-1)}) \\
& \quad\quad + \, c_{ijk\ell}^{(m)} \Big[\mathcal{E}_{k\ell}(u^{(m)}) - \mathcal{E}_{k\ell}(u^{(m-1)})\Big] \Big[\mathcal{E}_{ij}(u^{(m)}) - \mathcal{E}_{ij}(u^{(m-1)})\Big]
\end{aligned}
$$

and

$$
\begin{aligned}
& d_{ij}^{(m)} \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_k} + d_{ij}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i} - 2\, d_{ij}^{(m-1)}\, \frac{\partial q^{(m-1)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \\
& \quad = \Big(d_{ij}^{(m)} - d_{ij}^{(m-1)}\Big)\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m-1)}}{\partial x_i} \\
& \quad\quad + d_{ij}^{(m-1)} \left(\frac{\partial q^{(m-1)}}{\partial x_j} - \frac{\partial q^{(m)}}{\partial x_j}\right) \left(\frac{\partial q^{(m-1)}}{\partial x_i} - \frac{\partial q^{(m)}}{\partial x_i}\right).
\end{aligned}
$$

Both identities together with (3.14) imply the conclusion of Lemma 3.1. □

Next, we would like to get a bound for the last term on the right-hand side of (3.5), as follows. Let us choose a convenient function $h(x)$: Let $\Phi(x)$ be the solution of the elliptic problem

$$
\begin{cases}
\Delta\, \Phi = 1 \quad \text{in} \quad \Omega, \\
\dfrac{\partial \Phi}{\partial \eta} = 2\, \dfrac{\mathrm{Vol}(\Omega)}{\mathrm{Area}(S_0)} \quad \text{on} \quad S_0, \\
\dfrac{\partial \Phi}{\partial \eta} = -\, \dfrac{\mathrm{Vol}(\Omega)}{\mathrm{Area}(S_0)} \quad \text{on} \quad S_1,
\end{cases}
\tag{3.15}
$$

where $\mathrm{Area}(S_j)$ means the surface area of S_j .

Clearly, problem (3.15) admits a solution $\Phi(x)$ (depending on the boundary regularity) such that $\Phi \in C^2(\Omega) \cap C^1(\overline{\Omega})$. Let $\delta > 0$ and $x_0 \in \mathbb{R}^3$ (to be chosen later) and define

$$
h(x) = \delta\, \Phi(x) + \frac{1}{2}\, |x - x_0|^2. \tag{3.16}
$$

Now, we will estimate the term $\sum_{m=0}^{n}\int_0^T\int_{\Omega_m} J_m\,dxdt$ in (3.5).

LEMMA 3.2. *Under the assumption of Lemma* 3.1, *Hypothesis* I, *and choosing* h *as in* (3.16), *we have that*

$$\sum_{m=0}^{n}\int_0^T\int_{\Omega_m} J_m\,dxdt \tag{3.17}$$
$$\leq \delta\,C\,T\sum_{m=0}^{n}\int_{\Omega_m}\left\{|u_t^{(m)}|^2+c_{ijk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m)})+d_{ij}^{(m)}\,\frac{\partial q^{(m)}}{\partial x_j}\,\frac{\partial q^{(m)}}{\partial x_i}\right\}dx$$

for any $\delta>0$ *and some positive constant* C *which depends only on* Φ *and the coefficients of system* (1.2).

Proof. The index m will be omitted to simplify notation. With our choice of $h(x)$, straightforward calculations show that J given by (3.4) while restricted to Ω can be written as

$$\begin{aligned}J=&-\delta\left[|u_t|^2+c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u)+d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_i}\right]\\&+2\delta\Bigg[c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u)-\frac{\partial^2\Phi}{\partial x_p\partial x_j}\,c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\,\frac{\partial u^i}{\partial x_p}\\&\quad+\frac{\partial^2\Phi}{\partial x_i\partial x_k}\,d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_k}+e_{kij}\,\mathcal{E}_{ij}(u)\,\frac{\partial q}{\partial x_k}\\&\quad-\frac{\partial^2\Phi}{\partial x_j\partial x_\ell}\,e_{kij}\,\frac{\partial u^i}{\partial x_\ell}\,\frac{\partial q}{\partial x_k}-\frac{\partial^2\Phi}{\partial x_i\partial x_j}\,e_{ik\ell}\,\mathcal{E}_{k\ell}(u)\,\frac{\partial q}{\partial x_j}\Bigg].\end{aligned} \tag{3.18}$$

Let us estimate each term on the right-hand side of (3.18).

Let us note $\psi=(\psi_1,\psi_2,\psi_3)$, where $\psi_i=\frac{\partial^2\Phi}{\partial x_i\partial x_j}\,\frac{\partial q}{\partial x_k}\cdot$ Thus, for any $\delta_1>0$ we have the inequality

$$2\delta\,\frac{\partial^2\Phi}{\partial x_i\partial x_j}\,d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_k}=2\delta\,D\nabla q\cdot\psi\leq\delta\,\delta_1\,D\nabla q\cdot\nabla q+\delta\,\delta_1^{-1}D\psi\cdot\psi, \tag{3.19}$$

where $D=(d_{ij})$. Letting

$$C(\Phi)=\max_{\substack{x\in\overline{\Omega}\\ i,j=1,2,3}}\left|\frac{\partial^2\Phi}{\partial x_i\partial x_j}\right|,$$

the use of Hypothesis I with (1.7) yields the inequality

$$|D\psi\cdot\psi|\leq 9||D||C^2(\Phi)d_0^{-1}\,D\nabla q\cdot\nabla q,$$

which together with (3.19) gives us the estimate

$$2\delta\,\frac{\partial^2\Phi}{\partial x_i\partial x_k}\,d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_k}\leq\delta\left[\delta_1+9d_0^{-1}\delta_1^{-1}||D||C^2(\Phi)\right]d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_i}. \tag{3.20}$$

Next, for any $\delta_2>0$ we have the inequality

$$2\delta\,e_{kij}\,\mathcal{E}_{ij}(u)\,\frac{\partial q}{\partial x_k}\leq 3\delta\,\delta_2||P||\mathcal{E}_{ij}^2(u)+9\delta\delta_2^{-1}||P||\,|\nabla q|^2,$$

where $P = (e_{kij})$. Again, we use Hypothesis I and (1.7) to obtain from the above inequality the estimate

(3.21)
$$2\delta\, e_{kij}\, \mathcal{E}_{ij}(u)\, \frac{\partial q}{\partial x_k} \leq 3\delta\delta_2 ||P|| c_0^{-1}\, c_{jk\ell}\, \mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u) + 9\delta\delta_2^{-1}||P||d_0^{-1} d_{ij}\, \frac{\partial q}{\partial x_j}\, \frac{\partial q}{\partial x_i}.$$

In a similar way we can deduce that for any $\delta_3 > 0$

$$\begin{aligned} -2\delta\, \frac{\partial^2 \Phi}{\partial x_i \partial x_j}\, e_{ik\ell}\, \mathcal{E}_{k\ell}(u)\, \frac{\partial q}{\partial x_j} &\leq 3\delta\delta_3 ||P|| c_0^{-1}\, c_{ijk\ell}\, \mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u) \\ &\quad + 81\, \delta\delta_3^{-1}||P||d_0^{-1}\, d_{ij}\, \frac{\partial q}{\partial x_j}\, \frac{\partial q}{\partial x_i}. \end{aligned} \tag{3.22}$$

Now, let us note $v_{ij} = \frac{\partial^2 \Phi}{\partial x_j \partial x_\ell}\, \frac{\partial u^i}{\partial x_\ell}\cdot$ Clearly, we have that $v_{ij}^2 \leq 9C^2(\Phi)\big(\frac{\partial u^k}{\partial x_\ell}\big)^2$. For any $\delta_4 > 0$, we have the estimate

$$\begin{aligned} &-2\delta\, \frac{\partial^2 \Phi}{\partial x_j \partial x_\ell}\, e_{kij}\, \frac{\partial u^i}{\partial x_\ell}\, \frac{\partial q}{\partial x_k} = -2\,\delta\, e_{kij}\, v_{ij}\, \frac{\partial q}{\partial x_k} \\ &\leq 3\,\delta\delta_4 ||P|| v_{ij}^2 + 9\delta\delta_4^{-1}||P||\, |\nabla q|^2 \\ &\leq 27\,\delta\delta_4 ||P|| C^2(\Phi) \sum_{i=1}^{3} |\nabla u^i|^2 + 9\,\delta\delta_4^{-1}||P||d_0^{-1}\, d_{ij}\, \frac{\partial q}{\partial x_j}\, \frac{\partial q}{\partial x_i}. \end{aligned} \tag{3.23}$$

Finally, we estimate the term $-2\delta\, \frac{\partial^2 \Phi}{\partial x_p \partial x_j}\, c_{ijk\ell}\, \mathcal{E}_{k\ell}(u)\, \frac{\partial u^i}{\partial x_p}$. Denoting by $\widetilde{C} = \max_{1\leq i,j,k,\ell\leq 3} |c_{ijk\ell}|$, and for any $\delta_5 > 0$, we have the inequalities

$$\begin{aligned} &-2\delta\, \frac{\partial^2 \Phi}{\partial x_p \partial x_j}\, c_{ijk\ell}\, \mathcal{E}_{k\ell}(u)\, \frac{\partial u^i}{\partial x_p} \leq 6\,\delta\,\tilde{c}|\mathcal{E}_{k\ell}(u)|c(\Phi) \sum_{j=1}^{3} \left|\frac{\partial u^i}{\partial x_j}\right| \\ &\leq 3\,\delta\delta_3^{-1}\,\tilde{c}c(\Phi)c_0^{-1}\, c_{ijk\ell}\, \mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u) + 9\,\delta\delta_5\tilde{c}\, c(\Phi)|\nabla u^i|^2, \end{aligned} \tag{3.24}$$

where we again used Hypothesis I. Integration of identity (3.18) on $\Omega_m \times (0,T)$, adding from $m = 0$ up to $m = n$, and estimates (3.19)–(3.24) give us the inequality

$$\begin{aligned} \sum_{m=0}^{n} \int_0^T \int_{\Omega_m} J_m\, dxdt &\leq \delta\, A \sum_{m=0}^{n} \int_0^T \int_{\Omega_m} c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m)}) dxdt \\ &\quad + \delta\, B \sum_{m=0}^{n} \int_0^T \int_{\Omega_m} d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i}\, dxdt \end{aligned} \tag{3.25}$$

for some positive constants A and B. According to our estimates (3.19)–(3.24) we can take

$$A = 1 + 3\tilde{c}(\Phi)\delta_5^{-1}c_0^{-1} + 3\tilde{c}\, c_0^{-1}(\delta_2 + \delta_3) + 9\alpha_0^{-1}\, \delta_5\tilde{c}\, c(\Phi) + 27\,\delta_4\alpha_0^{-1}\, \tilde{c}\, c^2(\Phi)$$

and

$$B = \delta_1 + 9\, d_0^{-1}\delta_1^{-1}||D||c^2(\Phi) + 9\, d_0^{-1}\delta_2^{-1}\tilde{c} + 81\, \tilde{c}\, d_0^{-1}\delta_3^{-1} + 9\, \tilde{c}\, d_0^{-1}\delta_4^{-1} - 1,$$

where $\alpha_0 > 0$ is chosen such that

$$\sum_{m=0}^{n} \int_{\Omega_m} c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m)}) dx \geq \alpha_0 \sum_{m=0}^{n} ||u^{(m)}||^2_{[H^1(\Omega_m)]^3} \tag{3.26}$$

for any $u^{(m)} \in [H^1(\Omega_m)]^3$ with $u^{(m-1)} = u^{(m)}$ on Γ_m, $m = 1, 2, \ldots, n$, and $u\big|_{S_1} = 0$. Choosing $\delta_1 > 1$, we conclude from (3.25) the existence of a positive constant C such that

$$\begin{aligned}
&\sum_{m=0}^{n} \int_0^T \int_{\Omega_m} J_m \, dxdt \\
&\quad \le \delta\, C \sum_{m=0}^{n} \int_0^T \int_{\Omega_m} \left\{ c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)})\, \mathcal{E}_{ij}(u^{(m)}) + d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \right\} dxdt \\
&\quad \le \delta\, C\, T \sum_{m=0}^{n} \int_{\Omega_m} \left\{ |u_t^{(m)}|^2 + c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)}) \mathcal{E}_{ij}(u^{(m)}) + d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \right\} dx
\end{aligned}$$

because we can easily verify that if $\{u, q\}$ is the solution of problem (1.2)–(1.6) as constructed in section 2, then the quantity

$$E(t) = \sum_{n=0}^{n} \int_\Omega \left\{ |u_t^{(m)}|^2 + c_{ijk\ell}^{(m)}\, \mathcal{E}_{k\ell}(u^{(m)}) \mathcal{E}_{ij}(u^{(m)}) + d_{ij}^{(m)}\, \frac{\partial q^{(m)}}{\partial x_j}\, \frac{\partial q^{(m)}}{\partial x_i} \right\} dx$$

is independent of t. This proves Lemma 3.2. □

HYPOTHESIS II. There exist $\delta_0 \ge 0$ and $x_0 \in \mathcal{O}_1$ ($\mathcal{O}_1$ is as in section 1) such that

(a) $\delta_0 C < 1$, where $C > 0$ is as in the conclusion of Lemma 3.2,

(b) $\delta_0 \frac{\partial \Phi}{\partial \eta} + (x - x_0) \cdot \eta \ge 0$ for any $x \in \Gamma_m$, $m = 1, 2, \ldots, n$,

(c) $(x - x_0) \cdot \eta \ge -2\delta_0 \frac{\mathrm{Vol}(\Omega)}{\mathrm{Area}(S_0)}$ for any $x \in S_0$,

(d) $(x - x_0) \cdot \eta \le \delta_0 \frac{\mathrm{Vol}(\Omega)}{\mathrm{Area}(S_1)}$ for any $x \in S_1$.

The coefficients of system (1.2) satisfy

(e) $\big(c_{ijk\ell}^{(m-1)} - c_{ijk\ell}^{(m)}\big)\lambda_{k\ell}\lambda_{ij} \ge 0$, $m = 1, 2, \ldots, n$, for any real symmetric matrix (λ_{ij}) of order 3,

(f) $\big(d_{ij}^{(m)} - d_{ij}^{(m-1)}\big)\xi_j\xi_i \ge 0$, $m = 1, 2, \ldots, n$, for any (real) vector $\xi = (\xi_1, \xi_2, \xi_3)$.

Remark. We note that above assumptions (a)–(d) in Hypothesis II are valid when $\delta_0 = 0$ for star-shaped surfaces $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$, S_0, S_1. Moreover, if $\Gamma_1, \ldots, \Gamma_n$ are strongly star-shaped with respect to a point x_0, then the above conditions hold with $\delta_0 > 0$ for a class of domains Ω which includes star-shaped domains. In this sense condition (b) could be considered as a relaxation of the star-shape condition that we usually find in piezoelectric problems.

From now on we fix $\delta_0 > 0$ and $x_0 \in \mathcal{O}_1$ satisfying Hypothesis II. Thus, we will work with the auxiliary function

$$h(x) = \delta_0\, \Phi(x) + \frac{1}{2}\, |x - x_0|^2.$$

The following inequality can be proved by standard arguments:

$$\begin{aligned}
&\left| 2 \sum_{m=0}^{n} \int_{\Omega_m} u_t^{(m)} \cdot \big[(\nabla h \cdot \nabla) u^{(m)} + u^{(m)} \big] dx \right| \\
&\qquad \le C_2 \sum_{m=0}^{n} \int_{\Omega_m} \left\{ |u_t^{(m)}|^2 + c_{ijk\ell}^{(m)}\, \mathcal{E}_{i\ell}(u^{(m)}) \mathcal{E}_{ij}(u^{(m)}) \right\} dx
\end{aligned} \tag{3.27}$$

for some positive constant C_2 which actually could be chosen to be $C_2 = \mathrm{Max}\ \{4, \alpha_0^{-1} \max\{1, C(\Omega)\}\}$, where $\alpha_0 > 0$ is as in (3.26) and

$$C(\Omega) = 2 \max_{x \in \overline{\Omega}} \left\{ \delta_0^2 |\nabla \Phi(x)|^2 + |x - x_0|^2 \right\}.$$

THEOREM 3.3. *Let $\{u,q\}$ be the unique solution of problem* (1.2)–(1.6) *obtained in section* 2. *Then, the inequality*

$$[(1-\delta_0 C)T - C_2]\sum_{m=0}^{n}\int_{\Omega_m}\Big\{|u_t^{(m)}|^2 + c_{ijk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m)}) + d_{ij}^{(m)}\,\frac{\partial q^{(m)}}{\partial x_j}\,\frac{\partial q^{(m)}}{\partial x_i}\Big\}dx \le \int_0^T\int_{S_0}\frac{\partial h}{\partial \eta}\,|u_t|^2\,d\Gamma\,dt$$

holds, where δ_0 is the fixed positive constant in the definition of $h(x)$, $C>0$, and C_2 is as in (3.27).

Proof. Using assumptions (b), (e), and (f) of Hypothesis II together with Lemma 3.1, we deduce that

$$V_{m-1} - V_m \le 0 \quad \text{on} \quad \Gamma_m \quad \text{for} \quad m = 1,2,\dots,n.$$

Thus, from (3.5), Lemma 3.2, and (3.27) we obtain that

$$[(1-\delta_0 C)T - C_2]\sum_{m=0}^{n}\int_{\Omega_m}\Big\{|u_t^{(m)}|^2 + c_{ijk\ell}^{(m)}\,\mathcal{E}_{k\ell}(u^{(m)})\mathcal{E}_{ij}(u^{(m)}) + d_{ij}^{(m)}\,\frac{\partial q^{(m)}}{\partial x_j}\,\frac{\partial q^{(m)}}{\partial x_i}\Big\}dx \le \int_0^T\int_{S_0} V_n\,d\Gamma\,dt + \int_0^T\int_{S_1} V_0\,d\Gamma\,dt. \tag{3.28}$$

Using the boundary conditions (1.4)–(1.5) and the expressions of V_m and V_0 in (3.6), we deduce that

$$V_n\Big|_{S_0} = \frac{\partial h}{\partial \eta}\,|u_t|^2 - \frac{\partial h}{\partial \eta}\left\{c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u) + d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_i}\right\},$$
$$V_0\Big|_{S_1} = \frac{\partial h}{\partial \eta}\left\{c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(u) + d_{ij}\,\frac{\partial q}{\partial x_j}\,\frac{\partial q}{\partial x_i}\right\}.$$

Substitution of the above expression into (3.28) proves the conclusion of Theorem 3.3. □

COROLLARY 3.4. *Under the assumptions of Theorem* 3.3, *let $(f_1,f_2)\in\mathcal{D}(\mathcal{A})$. Suppose that $\{u,q\}$ is the solution of problem* (1.2)–(1.6) *satisfying the condition*

$$u(x,t) = 0 \quad \textit{for any} \quad (x,t)\in S_0\times(0,T).$$

Then, $u(x,t)\equiv 0$, $q(x,t)\equiv 0$ $\forall\,(x,t)\in\Omega\times(0,T)$ for any $T>T_0=\frac{C_2}{1-\delta_0 C}$.

4. Exact controllability. As a consequence of Corollary 3.4 it follows that for $T>T_0=\frac{C_2}{1-\delta_0 C}$ the expression

$$||(f_1,f_2)||_{\mathcal{F}} = \left(\int_0^T\int_{S_0}|u_t|^2\,d\Gamma\,dt\right)^{1/2} \tag{4.1}$$

defines a norm on the set of initial data (f_1,f_2) (where $(u,u_t)=U(t)(f_1,f_2)$ and $\mathcal{F}$ denotes the Hilbert space obtained by completing $\mathcal{D}(\mathcal{A})$ with respect to the norm (4.1)). We also have

$$||(f_1,f_2)|| \le C||(f_1,f_2)||_{\mathcal{F}}.$$

Let us denote by $\mathcal{F}'$ the dual space of $\mathcal{F}$ with respect to X. In the cylinder $\Omega \times (0,T)$ we consider the mixed problem

$$\begin{cases} \dfrac{\partial^2 w_i}{\partial t^2} - \dfrac{\partial}{\partial x_j}\,\sigma_{ij}(w,\psi) = 0 \\ \dfrac{\partial}{\partial x_i}\,D_i(w,\psi) = 0 \end{cases} \qquad \text{in } \Omega_m \times (0,+\infty), \tag{4.2}$$

$m = 0, 1, 2, \ldots, n,$

$$w(x,0) = g_1(x), \quad w_t(x,0) = g_2(x) \quad \text{in} \quad \Omega_m, \tag{4.3}$$

$$\begin{cases} \sigma_{ij}(w,\psi)\eta_j = Q^i(x,t) \\ \psi = 0 \end{cases} \qquad \text{on } S_0 \times (0,+\infty), \tag{4.4}$$

$$\begin{cases} D_i(w,\psi)\eta_i = 0 \\ w = 0 \end{cases} \qquad \text{on } S_1 \times (0,+\infty),$$

$$\begin{cases} \sigma_{ij}\big(w^{(m-1)},\psi^{(m-1)}\big)\eta_j = \sigma_{ij}\big(w^{(m)},\psi^{(m)}\big)\eta_j, \\ D_i\big(w^{(m-1)},\psi^{(m-1)}\big)\eta_i = D_i\big(w^{(m)},\psi^{(m)}\big)\eta_i, \\ \quad w^{(m-1)} = w^{(m)}, \quad \psi^{(m-1)} = \psi^{(m)}, \\ \text{on} \quad \Gamma_m \times (0,T), \quad m = 1, 2, \ldots, n, \end{cases} \tag{4.5}$$

where $Q = Q(x,t) \in [L^2(S_0 \times (0,T))]^3$ and $g = (g_1, g_2) \in \mathcal{F}'$.

In order to give a definition of a solution of problem (4.2)–(4.5) we observe that, in the case when we have a smooth (vector) function w and scalar function ψ, the identity

$$\begin{aligned} \sum_{m=0}^{n} \int_{\Omega_m} \Big\{ & u_t \cdot w_t + c_{ijk\ell}\,\mathcal{E}_{k\ell}(u)\mathcal{E}_{ij}(w) \\ & + d_{ij}\,\frac{\partial}{\partial x_j}\,(\beta(\mathcal{E}(u)))\,\frac{\partial}{\partial x_i}\,(\beta(\mathcal{E}(w))\Big\} dx \Big|_{t=T} \\ = \sum_{m=0}^{n} \int_{\Omega_m} \Big\{ & f_2 \cdot g_2 + c_{ijk\ell}\,\mathcal{E}_{k\ell}(f_1)\mathcal{E}_{ij}(g_1) \\ & + d_{ij}\,\frac{\partial}{\partial x_j}\,(\beta(\mathcal{E}(f_1))\,\frac{\partial}{\partial x_i}\,(\beta(\mathcal{E}(g_1))\Big\} dx \\ & + \int_0^T \int_{S_0} u_t \cdot Q\, d\Gamma\, dt \end{aligned} \tag{4.6}$$

holds for all $f = (f_1, f_2) \in \mathcal{D}(\mathcal{A})$. Here, we note $(u, u_t) = U(t)f$. Given $\mathcal{E}(y)$ (or $\mathcal{E}(w)$), we note $\beta(\mathcal{E}(u))$ (or $\beta(\mathcal{E}(w))$), the solution of problem (2.1)–(2.3) as described in section 2.

We rewrite (4.2) in the form $\frac{d}{dt}(w, \tilde{w}) = \mathcal{A}(w, \tilde{w})$. By definition, $(w(t), \tilde{w}(t)) \in L^\infty(0,T;\mathcal{F}')$ is a solution of (4.2)–(4.5) if

$$\langle (w(t), \tilde{w}(t)), U(t)\varphi \rangle_X = \langle g, \varphi \rangle_X + \int_0^t \int_{S_0} Q \cdot v_t\, d\Gamma\, ds \tag{4.7}$$

for all $\varphi \in \mathcal{F}$ and $0 < t < T$. Let $(v, v_t) = U(t)\varphi$ and $\langle , \rangle$ be the duality $\mathcal{F}'\mathcal{F}$. In a similar way we define a solution of (4.2), (4.4), and (4.5) with zero data at $t = T$ as an element $(w(t), \tilde{w}(t)) \in L^\infty(0, T, \mathcal{F}')$ such that

$$\langle (w(t), \tilde{w}(t)), U(t)\varphi \rangle_X = -\int_t^T \int_{S_0} Q \cdot v_t \, d\Gamma \, ds \tag{4.8}$$

for all $\varphi \in \mathcal{F}$ and $0 < t < T$.

Let f be an arbitrary element of $\mathcal{F}$ and $(w(t), \tilde{w}(t))$ be a solution of (4.2), (4.4), (4.5) with zero data at $t = T > T_0 = \frac{C_2}{1-\delta_0 C}$ and boundary function $Q = -u_t$, where $(u, u_t) = U(t)f$. Let us define $Mf = (w(x, 0), \tilde{w}(x, 0))$. From (4.8) we deduce that

$$\langle Mf, \varphi \rangle = \int_0^T \int_{S_0} u_t \cdot v_t \, d\Gamma \, dt = \langle f, \varphi \rangle_{\mathcal{F}} \, . \tag{4.9}$$

From this it follows that M is an isomorphism from $\mathcal{F}$ onto $\mathcal{F}'$.

Finally, we consider problem (4.2)–(4.5) and suppose that the initial data $g = (g_1, g_2)$ belongs to $\mathcal{F}'$. We set

$$f = M^{-1}g, \quad (u, u_t) = U(t)f, \quad Q = -u_t \, .$$

Using identity (4.7) with $t = T > T_0$, we find that

$$\langle (w(T), \tilde{w}(T)), U(T)\varphi \rangle = \langle Mf, \varphi \rangle - \langle f, \varphi \rangle_{\mathcal{F}} = 0 \tag{4.10}$$

for any $\varphi \in \mathcal{F}$, due to (4.9). This means that $(w(T), \tilde{w}(T))$ "generates" the zero functional on $\mathcal{F}$. In conclusion, we have proved the following theorem.

THEOREM 4.1. *Let us assume Hypotheses* I *and* II. *If* $T > T_0 = \frac{C_2}{1-\delta_0 C}$, *then for any initial data* $f = (f_1, f_2) \in \mathcal{F}'$ *of problem* (1.2), (1.3), (1.6) *with boundary conditions*

$$\begin{cases} \sigma_{ij}(u, q)\eta_j = Q^i(x, t) \\ q = 0 \end{cases} \qquad \text{on } S_0 \times (0, +\infty), \tag{4.11}$$

$$\begin{cases} D_i(u, q)\eta_i = 0 \\ u = 0 \end{cases} \qquad \text{on } S_1 \times (0, +\infty), \tag{4.12}$$

we can find a vector-valued function $Q(x, t) \in \left[L^2(0, T; L^2(S_0))\right]^3$ *such that the corresponding solution of* (1.2), (1.3), (1.6), (4.11), (4.12) *satisfies*

$$u(x, T) = 0, \qquad u_t(x, T) = 0.$$

ON REGULARITY OF SOLUTIONS AND LAGRANGE MULTIPLIERS OF OPTIMAL CONTROL PROBLEMS FOR SEMILINEAR EQUATIONS WITH MIXED POINTWISE CONTROL-STATE CONSTRAINTS*

A. RÖSCH† AND F. TRÖLTZSCH‡

Abstract. A class of nonlinear elliptic and parabolic optimal control problems with mixed control-state constraints is considered. Extending a method known for the control of ordinary differential equations to the case of PDEs, the Yosida–Hewitt theorem is applied to show that the Lagrange multipliers are functions of certain L^p-spaces. By bootstrapping arguments, under natural assumptions, optimal controls are shown to be Lipschitz continuous in the elliptic case and Hölder continuous for parabolic problems.

Key words. optimal control, semilinear elliptic equation, semilinear parabolic equation, mixed control-state constraints, multiplier regularity, regularity of optimal controls, Yosida–Hewitt theorem

1. Introduction.

The solutions of optimal control problems with mixed control-state constraints exhibit better regularity properties than those with pure pointwise state constraints. This fact about the control of ordinary differential equations has been known for a long time. We refer the reader, for instance, to early contributions to linear programming problems related to control problems with constraints of bottleneck type in [22] or [11] and to the more recent exposition by Dmitruk [8]. A first extension to an optimal control problem for the heat equation was presented in [19].

More recently, associated results were shown for more general parabolic equations in Bergounioux and Tröltzsch [4] and Arada and Raymond [3], and for elliptic problems in Tröltzsch [21] and Rösch and Tröltzsch [17]. In all of these papers on the control of PDEs, it was shown that Lagrange multipliers exist in certain L^p-spaces. Different techniques were applied to prove these results. While [4], [17], and [21] used duality theorems, in [3] it was shown that multipliers in $(L^\infty)^*$ are more regular by exploiting the smoothing property of the state equation and using some compactification approach for parabolic equations.

Here, assuming a natural regularity condition, we show the regularity of Lagrange multipliers by the Yosida–Hewitt theorem [23], following an idea explained for ordinary differential equations by Dmitruk [8]. This approach is close to the one suggested by Arada and Raymond but still simplifies and unifies the proof, since compactification arguments are not needed. We also deal with the elliptic case that needs slightly different techniques than the parabolic problems discussed in [3].

Moreover, our paper differs from our former ones by deriving higher regularity of multipliers and optimal controls up to Lipschitz continuity. We extend ideas presented

by Rösch and Wachsmuth [18] for a simplified class of elliptic problems. This is the main contribution of this paper.

2. Elliptic optimal control problem and main assumptions. We consider first the following elliptic optimal control problem:

$$\min J(y,u) = \int_\Omega \varphi(x,y,u)\,dx + \int_\Gamma \psi(x,y)\,ds \tag{2.1}$$

subject to

$$\begin{aligned} A\,y + d(x,y) &= u \quad \text{in } \Omega, \\ \frac{\partial y}{\partial \nu_A} + b(x,y) &= 0 \quad \text{on } \Gamma \end{aligned} \tag{2.2}$$

and to

$$g_i(x,y(x),u(x)) \le 0 \quad \text{a.e. on } \Omega, \quad i = 1,\dots,k. \tag{2.3}$$

The inequalities (2.3) are our mixed control-state constraints, which are the main issue of this paper.

Our theory is based upon the following assumptions:

(A1) $\Omega \subset \mathbb{R}^N$, $N \in \mathbb{N}$, is a bounded domain with Lipschitz boundary in the sense of Nečas [13].

(A2) A is a uniformly elliptic differential operator of the form

$$Ay(x) = -\sum_{i,j=1}^N \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}y(x)\right) + c_0(x)y(x)$$

with coefficients $a_{ij} \in C^{0,1}(\bar\Omega)$, $i,j = 1,\dots,N$, that satisfy the condition of uniform ellipticity

$$\sum_{i,j=1}^N a_{ij}(x)\xi_i\xi_j \ge m_0|\xi|^2 \quad \forall x \in \bar\Omega,\ \forall \xi \in \mathbb{R}^N$$

with some $m_0 > 0$. Moreover, c_0 belongs to $L^\infty(\Omega)$ and satisfies $c_0 \ge 0$ a.e. on Ω and $c_0(x) > 0$ on a set of positive measure.

(A3) $\varphi = \varphi(x,y,u) : \Omega \times \mathbb{R}^2 \to \mathbb{R}$ and $g_i = g_i(x,y,u) : \Omega \times \mathbb{R}^2 \to \mathbb{R}$ are given functions enjoying the following properties:
For all fixed y, u, they are Lipschitz with respect to $x \in \Omega$. They are partially differentiable with respect to y and u for all fixed $x \in \bar\Omega$. The derivatives are uniformly Lipschitz on bounded sets, i.e.,
For all $M > 0$ there exists $L(M) > 0$ such that

$$\begin{aligned} &|\varphi(x,y_1,u_1) - \varphi(x,y_2,u_2)| + \left|\frac{\partial\varphi}{\partial y}(x,y_1,u_1) - \frac{\partial\varphi}{\partial y}(x,y_2,u_2)\right| \\ &+ \left|\frac{\partial\varphi}{\partial u}(x,y_1,u_1) - \frac{\partial\varphi}{\partial u}(x,y_2,u_2)\right| \\ &\qquad \le L(M)(|y_1 - y_2| + |u_1 - u_2|), \end{aligned} \tag{2.4}$$

$$\begin{aligned} &|g_i(x,y_1,u_1) - g_i(x,y_2,u_2)| + \left|\frac{\partial g_i}{\partial y}(x,y_1,u_1) - \frac{\partial g_i}{\partial y}(x,y_2,u_2)\right| \\ &+ \left|\frac{\partial g_i}{\partial u}(x,y_1,u_1) - \frac{\partial g_i}{\partial u}(x,y_2,u_2)\right| \\ &\qquad \le L(M)(|y_1 - y_2| + |u_1 - u_2|) \end{aligned} \tag{2.5}$$

hold for a.e. $x \in \Omega$, for all real y_j, u_j with $\max(|y_j|, |u_j|) \le M$, $j = 1, 2$, and for $i = 1, \dots, k$. Moreover, we require

$$|\varphi(x,0,0)| + \left|\frac{\partial \varphi}{\partial y}(x,0,0)\right| + \left|\frac{\partial \varphi}{\partial u}(x,0,0)\right| \le C \quad \text{a.e. on } \Omega,$$
$$|g_i(x,0,0)| + \left|\frac{\partial g_i}{\partial y}(x,0,0)\right| + \left|\frac{\partial g_i}{\partial u}(x,0,0)\right| \le C \quad \text{a.e. on } \Omega.$$

(A4) The functions $\psi = \psi(x,y) : \Gamma \times \mathbb{R} \to \mathbb{R}$, $d = d(x,y) : \Omega \times \mathbb{R} \to \mathbb{R}$, and $b = b(x,y) : \Gamma \times \mathbb{R} \to \mathbb{R}$ are measurable with respect to $x \in \Gamma$ or $x \in \Omega$, respectively, for all fixed $y \in \mathbb{R}$, and differentiable with respect to y for all x. For $y = 0$, they are bounded with respect to x; i.e.,

$$\|\psi(\cdot,0)\|_{L^\infty(\Omega)} + \left\|\frac{\partial \psi}{\partial y}(\cdot,0)\right\|_{L^\infty(\Omega)} + \|b(\cdot,0)\|_{L^\infty(\Gamma)} + \left\|\frac{\partial b}{\partial y}(\cdot,0)\right\|_{L^\infty(\Gamma)} + \|d(\cdot,0)\|_{L^\infty(\Omega)} + \left\|\frac{\partial d}{\partial y}(\cdot,0)\right\|_{L^\infty(\Omega)} \le C.$$

Moreover, they are uniformly Lipschitz on bounded sets; i.e., ψ, b, d, and their derivatives $\partial\psi/\partial y$, $\partial b/\partial y$, $\partial d/\partial y$ satisfy (2.4) or (2.5) with respect to y for almost all $x \in \Omega$ or $x \in \Gamma$, respectively.

(A5) It holds that

$$\frac{\partial d}{\partial y}(x,y) \ge 0 \qquad \forall y \in \mathbb{R}, \ \text{a.e. on } \Omega,$$
$$\frac{\partial b}{\partial y}(x,y) \ge 0 \qquad \forall y \in \mathbb{R}, \ \text{a.e. on } \Gamma.$$

We should mention that the Lipschitz continuity with respect to x of φ and g_i, $i = 1, \dots, k$, is needed only for the results of sections 5 and 6. To have Lagrange multipliers in L^p-spaces, measurability and boundedness with respect to x are sufficient.

3. L^1-regularity of Lagrange multipliers. We consider the controls in the space $U = L^\infty(\Omega)$ and the states y in $Y = H^1(\Omega) \cap C(\bar\Omega)$. Then, thanks to the assumptions (A1), (A2), and (A4), for all $u \in U$ a unique state $y_u \in Y$ exists that solves (2.2) in the weak sense. We refer the reader to Alibert and Raymond [2], who consider the nonlinear system (2.2) including distributed and boundary control and certain unbounded coefficients. Due to their more general setting, their assumptions differ slightly from ours. We also mention Casas [5], who presented a similar technique for the case of boundary control under assumptions that are analogous to ours. The boundedness of the solution y was proven in [2], [5] by the Stampacchia truncation method. For (2.2) and our assumptions, this method can be found in [21, Thm. 7.3].

The control-to-state mapping $G : u \mapsto y$ is continuously Fréchet differentiable from U to Y; cf. again the technique of [2], [5] that can be directly transferred to our problem.

We assume now once and for all that $\bar u \in U$ is a locally optimal control with associated state $\bar y = G(\bar u)$. Local optimality means that there is an $\varepsilon > 0$ such that

$$J(y,u) \ge J(\bar y, \bar u)$$

is satisfied for all (y,u) that satisfy (2.2)–(2.3) and $\|u - \bar u\|_{L^\infty(\Omega)} < \varepsilon$.

We do not discuss the existence of global solutions of the optimal control problem. If the constraints (2.3) include, in particular, $\alpha \le u \le \beta$ with $\alpha, \beta \in L^\infty(\Omega)$, the admissible set is nonempty, and suitable assumptions on the behavior of φ and g_i with respect to u are required, then the existence of a global solution can be shown. This is, however, not the issue of this paper.

We begin our analysis with the existence of Lagrange multipliers in $(L^\infty(\Omega))^*$, the dual space to $L^\infty(\Omega)$. The elements of $(L^\infty(\Omega))^*$ can be represented by finitely additive set functions on $\bar\Omega$ that are also called *finitely additive measures*. We shall use the latter terminology.

To derive necessary optimality conditions, we need a standard constraint qualification and assume the following *linearized Slater condition:*

(A6) There exist $\hat u \in L^\infty(\Omega)$ and $\sigma > 0$ such that

$$\begin{aligned} g_i(x,\bar y(x),\bar u(x)) + \frac{\partial g_i}{\partial y}(x,\bar y(x),\bar u(x))\hat y(x) & \\ + \frac{\partial g_i}{\partial u}(x,\bar y(x),\bar u(x))\hat u(x) &\le -\sigma \quad \text{a.e. in } \Omega, \end{aligned} \tag{3.1}$$

where $\hat y \in Y$ is the solution of the linearized equation

$$\begin{aligned} A\hat y + \frac{\partial d}{\partial y}(x,\bar y(x))\hat y &= \hat u \quad \text{in } \Omega \\ \frac{\partial \hat y}{\partial \nu_A} + \frac{\partial b}{\partial y}(x,\bar y(x))\hat y &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{3.2}$$

Remark 3.1. It holds that $\hat y = G'(\bar u)\hat u$.

Invoking this assumption, the following first-order necessary conditions of Karush–Kuhn–Tucker type can be shown.

THEOREM 3.2. *Suppose that $\bar u$ is locally optimal for* (2.1)–(2.3) *with associated state $\bar y = G(\bar u)$. If the assumptions* (A1)–(A6) *are satisfied, then there exist nonnegative finitely additive measures $\mu_i \in L^\infty(\Omega)^*$, $i = 1,\dots,k$, and an adjoint state $p \in W^{1,s}(\Omega)$ for all $1 \le s < \frac{N}{N-1}$, such that the conditions*

$$\int_\Omega \left(\frac{\partial \varphi}{\partial u}(x,\bar y,\bar u) + p\right) h\,dx + \int_\Omega \sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,\bar y,\bar u) h\,d\mu_i = 0 \quad \forall h \in L^\infty(\Omega), \tag{3.3}$$

$$\int_\Omega g_i(x,\bar y,\bar u)\,d\mu_i = 0, \quad i = 1,\dots,k, \tag{3.4}$$

and the adjoint equation

$$\begin{aligned} A^* p + \frac{\partial d}{\partial y}(x,\bar y)p &= \frac{\partial \varphi}{\partial y}(x,\bar y) + \sum_{i=1}^k \left(\frac{\partial g_i}{\partial y}(x,\bar y,\bar u)^*\mu_i\right)\Big|_\Omega, \\ \frac{\partial p}{\partial \nu_{A^*}} + \frac{\partial b}{\partial y}(x,\bar y)p &= \frac{\partial \psi}{\partial y}(x,\bar y) + \sum_{i=1}^k \left(\frac{\partial g_i}{\partial y}(x,\bar y,\bar u)^*\mu_i\right)\Big|_\Gamma \end{aligned} \tag{3.5}$$

are satisfied.

The proof of the theorem can be performed analogously to Alibert and Raymond [2] or Casas [5], where also the definition and the proof of existence and uniqueness of a weak solution of (3.5) are presented. Notice that the multiplication operators $y \mapsto$

$\frac{\partial g_i}{\partial y}(x,\bar y,\bar u)\,y$ are continuous from $C(\bar\Omega)$ to $L^\infty(\Omega)$. Therefore, the adjoint mappings $\mu_i \mapsto \frac{\partial g_i}{\partial y}(x,\bar y,\bar u)^*\,\mu_i$ are continuous from $L^\infty(\Omega)^*$ to $C(\bar\Omega)^*$ so that their images are regular Borel measures, and the restrictions of them to Ω and Γ are well defined.

As linear continuous functionals on $L^\infty(\Omega)$, the finitely additive measures μ_i must vanish on sets of Lebesgue measure zero. Thanks to Theorem 1.24 of Yosida and Hewitt [23], each $\mu \in L^\infty(\Omega)^*$ can be uniquely written in the form

$$\mu = \mu_c + \mu_p,$$

where μ_c is countably additive and μ_p is purely finitely additive. Moreover, if $\mu \ge 0$, then μ_c and μ_p are nonnegative, too [23, Thm. 1.23].

Let us briefly comment on the associated definitions. *Countable additivity* is equivalent to the following property: For every sequence $\{E_n\}_{n=1}^\infty$ of Lebesgue-measurable sets with $\bar\Omega \supset E_1 \supset E_2 \ldots \supset E_n \ldots$ and $\cap_{n=1}^\infty E_n = \emptyset$, it holds that

$$\lim_{n\to\infty} \mu_c(E_n) = 0. \tag{3.6}$$

Pure finite additivity is defined as follows [23, Def. 1.13]: A nonnegative finitely additive measure μ is said to be purely finitely additive if every countably additive measure λ with $0 \le \lambda \le \mu$ is identically zero. An arbitrary finitely additive measure is purely finitely additive if its nonnegative and its nonpositive parts are purely finitely additive.

Every nonnegative purely finitely additive measure μ_p can be characterized by the following behavior [23, Thm. 1.22]: If λ is nonnegative and countably additive, then there exists a decreasing sequence $\bar\Omega \supset E_1 \supset E_2 \ldots \supset E_n \ldots$ of Lebesgue-measurable sets such that $\lim_{n\to\infty} \lambda(E_n) = 0$ and $\mu_p(E_n) = \mu_p(\Omega)$ for all n. We refer the reader also to Ioffe and Tikhomirov [10, Chap. 8.3.3].

We shall apply this theorem with the Lebesgue measure λ. This means that $\lambda(E_n) = meas(E_n) \to 0$, $n \to \infty$, but

$$\int_{E_n} d\mu_p = \|\mu_p\|_{L^\infty(\Omega)^*} \quad \forall n. \tag{3.7}$$

Our next goal is to show that, under an additional constraint qualification, the singular (i.e., purely finitely additive) parts of all Lagrange multipliers vanish. In this case, we will have at least $\mu_i \in L^1(\Omega)$ for all $i \in \{1,\ldots,k\}$. This property is a consequence of the Radon–Nikodym theorem, since the measures vanish on sets of Lebesgue measure zero.

The following assumption is needed for this purpose.

(A7) Define, for $\delta > 0$, the δ-active sets

$$M_i^\delta := \{x \in \Omega :\ g_i(x,\bar y(x),\bar u(x)) \ge -\delta\}.$$

Assume that there exist $\delta > 0$ and $\tilde u \in L^\infty(\Omega)$ such that there holds

$$\frac{\partial g_i}{\partial u}(x,\bar y(x),\bar u(x))\tilde u(x) \ge 1 \quad \text{a.e. on } M_i^\delta \tag{3.8}$$

for all $i \in \{1,\ldots,k\}$.

We shall discuss the consequences of this assumption later. It is equivalent to a "uniformly positive linear independence condition"; cf. Dmitruk [8]. For some types

of constraints, this assumption is automatically satisfied. In other cases, the optimal solution must fulfill a separation condition.

THEOREM 3.3. *Suppose that $\bar{u} \in U$, $\bar{y} \in Y$, and $\mu_i \in L^\infty(\Omega)^*$, $\mu_i \geq 0$, $i \in \{1, \dots, k\}$, satisfy the first-order necessary optimality conditions of Theorem* 3.2*, and assume that* (A7) *is satisfied. Then the purely finitely additive parts of all μ_i are vanishing so that all μ_i, $i = 1, \dots, k$, can be represented by densities in $L^1(\Omega)$.*

Proof. The proof follows the one given by Dmitruk [8] for the case of ordinary differential equations. We mention first that

$$\int_{\Omega \setminus M_i^\delta} d\mu_i = 0$$

holds true for all $i \in \{1, \dots, k\}$. Otherwise the complementarity condition (3.4) cannot be satisfied, since $g_i < -\delta$ on $\Omega \setminus M_i^\delta$.

Consider, for arbitrary $j \in \{1, \dots, k\}$, the singular part $\mu_{p,j}$ of μ_j. Thanks to Theorem 1.22 of Yosida and Hewitt, there exists a decreasing sequence $\{E_n\}_{n=1}^\infty$ with the properties mentioned above such that

$$\int_{E_n} d\mu_{p,j} = \int_\Omega d\mu_{p,j} \quad \forall n. \tag{3.9}$$

Without limitation of generality, we can assume $E_n \subset M_j^\delta$. We define now

$$h_n = \chi_{E_n} \tilde{u},$$

where $\tilde{u}$ is taken from (3.8) and χ_{E_n} denotes the characteristic function of E_n. Inserting h_n into the gradient equation (3.3), we find that

$$\begin{aligned}
&- \int_\Omega \left(\frac{\partial \varphi}{\partial u}(x, \bar{y}, \bar{u}) + p \right) h_n \, dx = \int_\Omega \sum_{i=1}^k \frac{\partial g_i}{\partial u}(x, \bar{y}, \bar{u}) \, h_n \, d\mu_i \\
&= \sum_{i=1}^k \int_{M_i^\delta} \frac{\partial g_i}{\partial u}(x, \bar{y}, \bar{u}) \, \tilde{u} \, \chi_{E_n} \, d\mu_i \geq \int_{M_j^s} \frac{\partial g_i}{\partial u}(x, \bar{y}, \bar{u}) \, \tilde{u} \, \chi_{E_n} \, d\mu_j \\
&\geq \int_{M_j^\delta} \frac{\partial g_j}{\partial u}(x, \bar{y}, \bar{u}) \, \tilde{u} \, \chi_{E_n} \, d\mu_{p,j} \geq \int_{M_j^\delta} \chi_{E_n} \, d\mu_{p,j} \\
&= \int_{E_n} \chi_{E_n} \, d\mu_{p,j} = \int_\Omega \chi_{E_n} \, d\mu_{p,j} = \|\mu_{p,j}\|_{L^\infty(\Omega)^*}.
\end{aligned}$$

The last inequality was obtained by (3.8). In view of (3.6), the left-hand side tends to zero as $n \to \infty$. Therefore, $\|\mu_{p,j}\|_{L^\infty(\Omega)^*} = 0$. ∎

Remark 3.4. Thanks to the regularity $\mu_i \in L^1(\Omega)$, the adjoint equation admits the simpler form

$$\begin{aligned}
A^* p + \frac{\partial d}{\partial y}(x, \bar{y}) p &= \frac{\partial \varphi}{\partial y}(x, \bar{y}) + \sum_{i=1}^k \frac{\partial g_i}{\partial y}(x, \bar{y}, \bar{u}) \mu_i, \\
\frac{\partial p}{\partial \nu_{A^*}} + \frac{\partial b}{\partial y}(x, \bar{y}) p &= \frac{\partial \psi}{\partial y}(x, \bar{y}).
\end{aligned} \tag{3.10}$$

Moreover, the optimality condition (3.3) and the complementarity condition (3.4) read now

$$\frac{\partial \varphi}{\partial u}(x,\bar{y},\bar{u}) + p + \sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x,\bar{y},\bar{u})\mu_i = 0 \quad \text{a.e. in } \Omega, \tag{3.11}$$

$$\int_\Omega g_i(x,\bar{y},\bar{u})\mu_i(x)\,dx = 0 \quad \forall i \in \{1,\dots,k\}. \tag{3.12}$$

4. Some examples of constraints. Next, we discuss the regularity condition (3.8) for some examples that might be of interest in the applications.

Example 1 (control constraints). Consider the constraints

$$u_a(x) \le u(x) \le u_b(x) \quad \text{a.e. on } \Omega.$$

We define

$$g_1(x,y,u) = u - u_b(x),$$
$$g_2(x,y,u) = u_a(x) - u.$$

Assume $u_b(x) - u_a(x) \ge \alpha > 0$ a.e. on Ω, and take $\delta = \alpha/3$. Then $M_1(\delta) \cap M_2(\delta) = \emptyset$. Therefore, we can define

$$\tilde{u}(x) = \begin{cases} 1 & \text{on } M_1^\delta, \\ -1 & \text{on } M_2^\delta, \\ 0 & \text{else.} \end{cases}$$

Then

$$\begin{aligned} \frac{\partial g_1}{\partial u}\tilde{u} &= 1 \quad \text{on } M_1^\delta, \\ \frac{\partial g_2}{\partial u}\tilde{u} &= 1 \quad \text{on } M_2^\delta. \end{aligned}$$

In this case, the assumption (A7) is automatically satisfied. However, the existence of regular Lagrange multipliers can here be obtained in an easier and even better way, without assuming $u_b(x) - u_a(x) \ge \alpha > 0$, since

$$\mu_1(x) = \left(\frac{\partial \varphi}{\partial u}(x) + p(x)\right)^+,$$
$$\mu_2(x) = \left(\frac{\partial \varphi}{\partial u}(x) + p(x)\right)^-$$

are Lagrange multipliers; see [20, Thm. 2.29, (2.58), or sect. 6.1, (6.8)].

Example 2 (pure mixed control-state constraints of bottleneck type). Consider the constraint

$$y_a(x) \le \lambda u(x) + y(x) \le y_b(x)$$

with $\lambda \ne 0$ and assume again $y_b(x) - y_a(x) \ge \alpha > 0$ a.e. on Ω. We define $g_1(x,y,u) = \lambda u + y - y_b(x)$, $g_2(x,y,u) = -\lambda u - y + y_a(x)$, and

$$\tilde{u}(x) = \begin{cases} \frac{1}{\lambda} & \text{on } M_1^\delta, \\ -\frac{1}{\lambda} & \text{on } M_2^\delta, \\ 0 & \text{else.} \end{cases}$$

Again, condition (3.8) is automatically satisfied. Also here, the regularity of Lagrange multipliers can be obtained without assuming $y_b - y_a \geq \alpha$ by a transformation to a control constrained problem; cf. [12].

Example 3 (control constraints and unilateral mixed constraint). Let the following constraints be given:

$$\begin{array}{rcccl} u_a(x) & \leq & u(x) & \leq & u_b(x), \\ & & \lambda u(x) - y(x) & \leq & y_b(x), \end{array}$$

with $\lambda > 0$. We define

$$\begin{aligned} g_1(x,y,u) &= u - u_b(x), \\ g_2(x,y,u) &= u_a(x) - u, \\ g_3(x,y,u) &= \lambda u - y - y_b(x) \end{aligned}$$

and assume, for some $\delta > 0$, the separation condition $M_2^\delta \cap M_3^\delta = \emptyset$. Moreover, we assume again $u_b(x) - u_a(x) \geq \alpha > 0$. Then, if δ is sufficiently small, $M_1^\delta \cap M_2^\delta = \emptyset$ is automatically satisfied. We set

$$\tilde{u}(x) = \begin{cases} \max(1/\lambda, 1) & \text{on } M_1^\delta \cup M_3^\delta, \\ -1 & \text{on } M_2^\delta, \\ 0 & \text{else.} \end{cases}$$

Then (3.8) is satisfied. However, we had to assume a separation condition that depends on the unknown solution $(\bar{u}, \bar{y})$. If we have, for example, $u_a(x) \equiv 0$ and we know from maximum principle arguments that $u \geq 0 \Rightarrow y_u \geq 0$ a.e. on Ω, then obviously $y_b(x) \geq \beta > 0$ yields $y(x) + y_b(x) \geq \beta > 0$. In this case, $M_2^\delta \cap M_3^\delta = \emptyset$ is automatically satisfied; we have obtained a result of [17]. We should mention that Arada and Raymond [3] also introduced a separation condition of this type.

Example 4 (equidirected mixed constraints). Consider the general constraints (2.3) and assume that condition (5.2) below is satisfied. Here we can define

$$\tilde{u}(x) \equiv \frac{1}{m} \quad \forall x \in \Omega,$$

and (3.8) is automatically satisfied.

Example 5 (bilateral control and mixed control-state constraints). For the following constraints, a separation condition is needed again:

$$\begin{array}{rcccl} u_a & \leq & u & \leq & u_b, \\ y_a & \leq & u + y & \leq & y_b. \end{array}$$

We define g_1, g_2, g_3, and M_i^δ, $i = 1, 2, 3$, analogously to Example 3. Additionally, we introduce

$$g_4(x,y,u) = y_a(x) - u - y$$

and $M_4^\delta = \{x \in \Omega : y_a(x) - \bar{u}(x) - \bar{y}(x) \geq -\delta\}$. We require, for some $\delta > 0$,

$$(M_2^\delta \cup M_4^\delta) \cap (M_1^\delta \cup M_3^\delta) = \emptyset. \tag{4.1}$$

Then, by the same arguments as before, we see that (A7) is fulfilled. Again, we have to assume (4.1), an additional separation condition.

5. Higher regularity of local solutions. In this section we show how the regularity $\mu_i \in L^1(\Omega)$ can be improved by bootstrapping arguments to finally obtain Lipschitz regularity of $\bar{u}$. To this aim, we have to impose stronger conditions on φ and on the g_i:

(A8) The function φ possesses the second derivative $\partial^2\varphi/\partial u^2(x,y,u)$ on $\bar{\Omega}\times\mathbb{R}^2$. All functions g_i, $i=1,\dots,k$, are defined on $D\times\mathbb{R}^2$, where $D\subset\mathbb{R}^N$ is an open set containing $\bar{\Omega}$. They satisfy (A3) on this extended set.
Moreover, there is a constant $m>0$ such that the monotonicity properties

$$\frac{\partial^2\varphi}{\partial u^2}(x,y,u)\ge m \quad \forall x\in\bar{\Omega},\ \forall (y,u)\in\mathbb{R}^2, \tag{5.1}$$

$$\frac{\partial g_i}{\partial u}(x,y,u)\ge m \quad \forall x\in D,\ \forall (y,u)\in\mathbb{R}^2 \tag{5.2}$$

are satisfied.

Remark 5.1. The extension of the g_i from $\bar{\Omega}$ to a larger open set D is needed in the proof of the next theorem. We apply the Robinson implicit function theorem in an open covering of $\bar{\Omega}\times[-M,M]$. In our examples, the dependence of the g_i on x comes with that of the functions u_a, u_b or y_a, y_b defining the bounds. The extension of these functions to a neighborhood around $\bar{\Omega}$ should not cause difficulties.

We will also consider bilateral constraints of the form

$$\alpha_i(x)\le\gamma_i(x,y(x),u(x))\le\beta_i(x),\quad i=1,\dots,l, \tag{5.3}$$

where the γ_i, $i=1,\dots,l$, satisfy (A8) and $\alpha_i\le\beta_i$ are Lipschitz functions.

LEMMA 5.2. *Suppose that $g_1,\dots,g_k$ satisfy assumption* (A8). *Then there exist functions $\phi_i:\bar{\Omega}\times\mathbb{R}^2\to\mathbb{R}$ with the following properties: All $\phi_i(x,y)$ are Lipschitz with respect to x for all $y\in\mathbb{R}$,*

$$|\phi_i(x,y_1)-\phi_i(x,y_2)|\le L(M)|y_1-y_2| \tag{5.4}$$

is satisfied for all $x\in\bar{\Omega}$ and all $|y_j|\le M$, and there holds

$$g_i(x,y,u)\begin{cases} =0 & \Leftrightarrow \quad u=\phi_i(x,y),\\ <0 & \Leftrightarrow \quad u<\phi_i(x,y),\\ >0 & \Leftrightarrow \quad u>\phi_i(x,y).\end{cases} \tag{5.5}$$

Proof. Consider, for fixed i, the equation

$$g_i(x,y,u)=0. \tag{5.6}$$

By (5.2) we have $\lim_{u\to\pm\infty} g_i(x,y,u)=\pm\infty$, and hence, for each $(x,y)\in D\times\mathbb{R}$, (5.6) has a unique solution $u=\phi_i(x,y)$. To show the Lipschitz property of ϕ_i, we invoke the implicit function theorem of Robinson [16, Thm. 2.1]. It ensures that, for each pair $(x_0,y_0)\in D\times\mathbb{R}$ and each $\varepsilon>0$, there is an (open) neighborhood $N_\varepsilon(x_0,y_0)\subset D\times\mathbb{R}$ such that

$$|\phi_i(x,y)-\phi_i(\xi,\eta)|\le(\lambda+\varepsilon)|g_i(x,y,\phi_i(x,y))-g_i(\xi,\eta,\phi_i(x,y))| \tag{5.7}$$

holds for all (x,y) and (ξ,η) in $N_\varepsilon(x_0,y_0)$, where $\lambda=1/m$ with m defined by (5.2).

The collection of all neighborhoods $N_\varepsilon(x_0,y_0)$, $(x_0,y_0)\in D\times[-M,M]$, defines an open covering of the compact set $\bar{\Omega}\times[-M,M]$. Selecting a finite covering, an easy

application of the triangle inequality shows that (5.4) holds everywhere in $\bar{\Omega} \times \mathbb{R}$ with a suitable constant $L(M)$.

In view of the strong monotonicity of g with respect to u for all fixed (x, y), the reader may now readily verify the relations (5.5). □

LEMMA 5.3. *Assume that the optimality system* (3.10)–(3.12) *is fulfilled with Lagrange multipliers* $\mu_i \in L^1(\Omega)$. *If* (A8) *is satisfied, then the Lagrange multipliers* μ_i *satisfy a.e. on* Ω *the equation*

(5.8)
$$\sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x, \bar{y}(x), \bar{u}(x))\mu_i(x) = \max\left(0, -\left(\frac{\partial \varphi}{\partial u}\big(x, \bar{y}(x), \min_{i=1,\dots,k} \phi_i(x, \bar{y}(x))\big) + p(x)\right)\right).$$

Proof. We extend an idea introduced in [18] and consider two cases for $x \in \Omega$.

(i) $x \in M^+ = \{x \in \Omega : \sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x, \bar{y}(x), \bar{u}(x))\mu_i(x) > 0\}$.

Assumption (A8) ensures in particular that $\partial g_i/\partial u \geq 0$ so that, for each $x \in M^+$, at least one multiplier $\mu_i(x)$ must be positive. In view of the complementary slackness condition (3.12), a.e. in this set, at least one inequality constraint is active. Therefore, in view of (5.5), we have

$$\bar{u}(x) = \min_i \phi_i(x, \bar{y}(x)) \quad \text{a.e. on } M^+. \tag{5.9}$$

Moreover, from $\sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x, \bar{y}(x), \bar{u}(x))\mu_i(x) > 0$ and the gradient equation (3.11) we deduce

$$\frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \bar{u}(x)) + p(x) < 0 \qquad \text{a.e. on } M^+.$$

Inserting the expression (5.9) for $\bar{u}$ in this inequality, it follows that

$$0 < -\left(\frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \min_i \phi_i(x, \bar{y}(x))) + p(x)\right) \text{ a.e. on } M^+.$$

Therefore, again in view of (3.11), we obtain

$$\sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x, \bar{y}(x), \bar{u}(x))\mu_i(x) = \max\left(0, -\left(\frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \min_i \phi_i(x, \bar{y}(x))) + p(x)\right)\right),$$

since the left-hand side is positive.

(ii) $x \in \Omega \setminus M^+ = \{x \in \Omega : \sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x, \bar{y}(x), \bar{u}(x))\mu_i(x) = 0\}$.

Here, the gradient equation (3.11) shows

$$-\left(\frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \bar{u}(x)) + p(x)\right) = 0. \tag{5.10}$$

Moreover, we have

$$\bar{u}(x) \leq \min_i \phi_i(x, \bar{y}(x)).$$

From the monotonicity condition (5.1), it follows that

$$\frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \bar{u}(x)) \leq \frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \min_i \phi_i(x, \bar{y}(x))).$$

Together with (5.10), this implies

$$-\left(\frac{\partial\varphi}{\partial u}(x,\bar y(x),\min_i \phi_i(x,\bar y(x))) + p(x)\right) \le 0,$$

and hence

$$\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,\bar y(x),\bar u(x))\mu_i(x) = 0 = \max\left(0, -\left(\frac{\partial\varphi}{\partial u}(x,\bar y(x),\min_i \phi_i(x,\bar y(x))) + p(x)\right)\right)$$

holds also a.e. in $\Omega\setminus M^+$, too. □

THEOREM 5.4. *Suppose that $(\bar y,\bar u)\in H^1(\Omega)\cap C(\bar\Omega)\times L^\infty(\Omega)$ satisfy, together with $p\in W^{1,s}(\Omega)$, $1\le s<\frac{N}{N-1}$, and $\mu_1,\dots,\mu_k\in L^1(\Omega)$, the optimality conditions of Theorem 3.2. If the assumptions* (A3) *and* (A8) *are satisfied, then all multipliers μ_i, $i=1,\dots,k$, are bounded and measurable functions. If Γ is of class $C^{1,1}$, then $\bar u$ and $\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,\bar y,\bar u)\mu_i$ are Lipschitz functions on $\bar\Omega$.*

Proof. We show this result by a bootstrapping argument. At the beginning, we know that $\bar u\in L^\infty(\Omega)$ and $\bar y\in C(\bar\Omega)$.

Thanks to $p\in W^{1,s}(\Omega)$, by Sobolev embedding theorems there is a $\sigma>0$ such that $p\in L^{s_1}(\Omega)$ with $s_1=1+\sigma$ (see also our arguments at the end of the proof). From the gradient equation (3.11), we deduce

$$\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,\bar y,\bar u)\mu_i = -\frac{\partial\varphi}{\partial u}(x,\bar y,\bar u) - p \in L^{s_1}(\Omega). \tag{5.11}$$

Because of (5.2) and by the nonnegativity of the multipliers μ_i, this implies $\mu_i\in L^{s_1}(\Omega)$ for all $i\in\{1,\dots,k\}$ and hence

$$\sum_{i=1}^k \frac{\partial g_i}{\partial y}(x,\bar y,\bar u)\,\mu_i \in L^{s_1}(\Omega).$$

Inserting this into (3.10), the right-hand side is seen to belong to $L^{s_1}(\Omega)$. Therefore,

$$p\in W^{1,s_1}(\Omega)\hookrightarrow L^{s_2}(\Omega),\ \text{where } s_2=s_1+\sigma \text{ and } \sigma>0.$$

We explain below why the same σ can be taken. By (5.11), we find

$$\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,\bar y,\bar u)\mu_i \in L^{s_2}(\Omega).$$

Repeating this bootstrapping method, we get numbers s_i with $s_{i+1}\ge s_i+\sigma$. We can take the same $\sigma>0$ for all i for the following reason: If $p\in W^{1,s}(\Omega)$, then $p\in L^r(\Omega)$ for all r given by

$$\frac{1}{r}=\frac{1}{s}-\frac{1}{N}, \tag{5.12}$$

provided that $1<\frac{N}{s}$; cf. Adams [1]. Let us assume $1<\frac{N}{s}$. Then (5.12) implies

$$r-s=\frac{s^2}{N-s}>\frac{s^2}{N}>1/N$$

by $s \geq 1$, and we are justified to take $\sigma = 1/N$.

After finitely many steps, in any case we arrive at a situation, where $N/s_{i+1} < 1$ while $N/s_i > 1$ (notice that we have some freedom in the choice of σ to avoid the equality sign in both the equations).

In this case, it holds that $p \in W^{1,s_{i+1}}(\Omega) \hookrightarrow C(\bar{\Omega})$. This implies

$$\mu_i \in L^\infty(\Omega) \quad \forall i \in \{1, \dots, k\}.$$

Now we need the higher smoothness $C^{1,1}$ of Γ. Exploiting again (3.10), we obtain $p \in W^{2,s}(\Omega)$ for all $s < \infty$. This regularity result follows from Grisvard [9]. Therefore, p is continuously differentiable (Adams [1]) and hence Lipschitz.

Now, we invoke formula (5.8). Since $\bar{u}$ is bounded and measurable, $\bar{y}$ is also Lipschitz. The same holds true for the function

$$\min_{i \in \{1,\dots,k\}} \phi_i(x, \bar{y}(x)),$$

since all ϕ_i are Lipschitz. Thanks to this, the right-hand side of (5.8) is Lipschitz so that the left-hand side must have this property, too.

From the gradient equation (5.11), we now obtain

$$\frac{\partial \varphi}{\partial u}(\cdot, \bar{y}, \bar{u}) \in C^{0,1}(\bar{\Omega}). \tag{5.13}$$

Next we make use of the assumption (A8) and (5.1), i.e., $\frac{\partial^2 \varphi}{\partial u^2} \geq m > 0$. Invoking the implicit function theorem again, we arrive at the Lipschitz continuity of $\bar{u}$. □

Bilateral nonlinear mixed constraints. Finally, we consider the constraints (5.3), where we need an additional separation assumption to prove the Lipschitz continuity of $\bar{u}$. We assume the following.

(A9) The functions γ_i satisfy Assumption (A8) on the g_i. Moreover φ satisfies (A8), too, and there is a $\delta > 0$ such that the sets

$$M^\alpha_{i,\delta} := \{x : \gamma_i(x, \bar{u}(x), \bar{y}(x)) \leq \alpha_i(x) + \delta\},$$
$$M^\beta_{i,\delta} := \{x : \beta_i(x) - \delta \leq \gamma_i(x, \bar{u}(x), \bar{y}(x))\}$$

satisfy the condition

$$\bigcup_{i=1}^k M^\alpha_{i,\delta} \cap \bigcup_{i=1}^k M^\beta_{i,\delta} = \emptyset.$$

THEOREM 5.5. *Consider the optimal control problem* (2.1)–(2.3) *for constraints of the form* (5.3)*, i.e., for*

$$g_i = \begin{cases} \gamma_i - \beta_i, & i \in \{1, \dots, l\}, \\ \alpha_{i-l} - \gamma_{i-l}, & i \in \{l+1, \dots, 2l\}. \end{cases}$$

Suppose that $\bar{y} \in H^1(\Omega) \cap C(\bar{\Omega})$ *and* $\bar{u} \in L^\infty(\Omega)$ *satisfy together the first-order necessary optimality conditions. Assume that* (A9) *is satisfied and that* Γ *is of class* $C^{1,1}$*. Then the functions*

$$\sum_{i=1}^{l} \frac{\partial g_i}{\partial u}(x, \bar{y}, \bar{u})\mu_i, \qquad \sum_{i=l+1}^{2l} \frac{\partial g_i}{\partial u}(x, \bar{y}, \bar{u})\mu_i$$

and the optimal control $\bar u$ are Lipschitz.

Proof. Let us recall first that we have assumed $\partial\gamma_i/\partial u \ge m$ for all $i \in \{1,\dots,l\}$. Therefore, in view of the definition of the g_i, it holds that

$$\frac{\partial g_i}{\partial u} \ge m \ \text{ if } \ 1 \le i \le l, \qquad \frac{\partial g_i}{\partial u} \le -m \ \text{ if } \ l+1 \le i \le 2l.$$

Now we proceed similarly to the proof of Theorem 5.4 and distinguish four cases with respect to $x \in \Omega$:

$$\sum_{i=1}^{l} \frac{\partial g_i}{\partial u}\mu_i > 0,\ \sum_{i=1}^{l} \frac{\partial g_i}{\partial u}\mu_i = 0,\ \sum_{i=l+1}^{2l} \frac{\partial g_i}{\partial u}\mu_i < 0,\ \sum_{i=l+1}^{2l} \frac{\partial g_i}{\partial u}\mu_i = 0.$$

Here and in what follows we suppress the arguments $(x,\bar y,\bar u)$ in $\partial g_i/\partial u$ for convenience. The first two cases concern the upper bounds; hence they are of the type considered in Theorem 5.4. Let us therefore concentrate on the remaining two cases.

(i) $\sum_{i=l+1}^{2l}(\frac{\partial g_i}{\partial u}\mu_i)(x) < 0$. At least one of the multipliers μ_i, $i \in \{l+1,\dots,2l\}$, must be positive; thus one of the associated lower constraints is active. Hence, by the separation assumption (A9), no one of the upper constraints can be almost active. This implies that all multipliers μ_i with $i \in \{1,\dots,l\}$ must vanish a.e. on this set, i.e.,

$$\sum_{i=1}^{l} \left(\frac{\partial g_i}{\partial u}\mu_i\right)(x) = 0.$$

Invoking the gradient equation (3.3), we find

$$0 < -\sum_{i=l+1}^{2l} \left(\frac{\partial g_i}{\partial u}\mu_i\right)(x) = \frac{\partial \varphi}{\partial u}(x,\bar y(x),\bar u(x)) + p(x)$$

and hence

$$-\sum_{i=l+1}^{2l} \left(\frac{\partial g_i}{\partial u}\mu_i\right)(x) = \max\left(0, \frac{\partial \varphi}{\partial u}(x,\bar y(x),\bar u(x)) + p(x)\right).$$

Moreover, we have in this case that

$$\bar u(x) = \max_{i\in\{1,\dots,l\}} \phi_i^\alpha(x,\bar y(x))$$

with Lipschitz functions ϕ_i^α, which are associated to the lower bounds and defined by

$$g_i(x,y,u) = \alpha_i(x) \quad \Leftrightarrow \quad u = \phi_i^\alpha(x,y).$$

This follows by the arguments of Lemma 5.2. Consequently,

$$-\sum_{i=l+1}^{2l} \left(\frac{\partial g_i}{\partial u}\mu_i\right)(x) = \max\left(0, \frac{\partial \varphi}{\partial u}(x,\bar y(x), \max_{i\in\{1,\dots,l\}} \phi_i^\alpha(x,\bar y(x))) + p(x)\right)$$

holds on this set.

(ii) $\sum_{i=l+1}^{2l}(\frac{\partial g_i}{\partial u}\mu_i)(x) = 0$. The gradient equation implies then

$$\frac{\partial \varphi}{\partial u} + p = -\sum_{i=1}^{l}\left(\frac{\partial g_i}{\partial u}\mu_i\right)(x) \le 0$$

and

$$\bar{u}(x) \ge \max_{i\in\{1,\dots,l\}} \phi_i^\alpha(x, \bar{y}(x)).$$

In view of the monotonicity property (5.1), we obtain

$$\frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \max_{i\in\{1,\dots,l\}} \phi_i^\alpha(x, \bar{y}(x))) + p(x) \le \frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \bar{u}(x)) + p(x) \le 0.$$

Obviously, it therefore holds that

(5.14)
$$0 = -\sum_{i=l+1}^{2l}\left(\frac{\partial g_i}{\partial u}\mu_i\right)(x) = \max\left(0, \frac{\partial \varphi}{\partial u}(x, \bar{y}(x), \max_{i\in\{1,\dots,l\}} \phi_i^\alpha(x, \bar{y}(x))) + p(x)\right),$$

so that (5.14) is satisfied a.e. on Ω. Invoking the same bootstrapping arguments as in the proof of Theorem 5.4, we deduce the desired Lipschitz properties. ∎

6. The parabolic case. It is fairly obvious that the method of the preceding sections can be extended to problems with parabolic state equation. There are some differences in the regularity results of the equation, but the main ideas are analogous. Here, we briefly sketch the arguments to show Hölder regularity of the optimal control.

In [3], the L^1-regularity of Lagrange multipliers has already been investigated for parabolic equations. Therefore, we prove Hölder continuity on the assumption that the Lagrange multipliers belong to L^1. In [3], sufficient conditions can be found that ensure this property.

We consider the following parabolic counterpart to the elliptic optimal control problem (2.1)–(2.3):

$$\min J(y,u) := \int_\Omega \int_0^T \varphi(x,t,y,u)\,dxdt + \int_\Gamma \int_0^T \psi(x,t,y)\,dsdt \tag{6.1}$$

subject to

$$\begin{aligned} \frac{\partial y}{\partial t} + A\,y + d(x,t,y) &= u && \text{in } Q := \Omega\times(0,T),\\ \frac{\partial y}{\partial \nu_A} + b(x,t,y) &= 0 && \text{in } \Sigma := \Gamma\times(0,T),\\ y(\cdot,0) &= y_0(\cdot) && \text{in } \Omega \end{aligned} \tag{6.2}$$

and to

$$g_i(x,t,y(x,t),u(x,t)) \le 0 \quad \text{a.e. in } Q,\ i = 1,\dots,k. \tag{6.3}$$

We rely on the following general assumptions:

(A10) The given data have to satisfy direct extensions of (A1)–(A5) to the parabolic case that are obtained as follows: In (A1), we additionally assume that Γ is of class $C^{1,1}$. (A2) remains unchanged except that c_0 is now a function of $L^\infty(Q)$ not restricted in sign. In (A3)–(A5), the sets Ω and Γ are replaced by Q and Σ, respectively, and $\tilde{x} := (x,t)$ replaces x in these assumptions. Moreover, we assume that y_0 is Hölder continuous in Ω.

In particular, d, b are monotone nondecreasing with respect to y and $d(\cdot,\cdot,0)$, $b(\cdot,\cdot,0)$ belong to $L^\infty(Q)$ and $L^\infty(\Sigma)$, respectively.

Under these assumptions, for all $u \in L^r(Q)$ with $r > N/2+1$, the parabolic equation (6.2) has a unique solution $y \in W(0,T) \cap C(\bar{Q})$; cf. Casas [6] or Raymond and Zidani [15]. The space $W(0,T)$ is defined by

$$W(0,T) = \left\{ y \in L^2(0,T;H^1(\Omega)) : \frac{dy}{dt} \in L^2(0,T;H^1(\Omega)') \right\}.$$

For the remainder of this section, let $\bar{u} \in L^\infty(Q)$ be (locally) optimal for (6.1)–(6.3). We assume that nonnegative Lagrange multipliers $\mu_i \in L^1(Q)$ and an adjoint state p exist such that the following first-order necessary optimality conditions are satisfied:

$$\begin{aligned} -\frac{\partial p}{\partial t} + A^*p + \frac{\partial d}{\partial y}(x,t,\bar{y})\,p &= \frac{\partial \varphi}{\partial y}(x,t,\bar{y}) + \sum_{i=1}^k \frac{\partial g_i}{\partial y}(x,t,\bar{y},\bar{u})\,\mu_i && \text{in } Q, \\ \frac{\partial p}{\partial \nu_{A^*}} + \frac{\partial b}{\partial y}(x,t,\bar{y})\,p &= \frac{\partial \psi}{\partial y}(x,t,\bar{y}) && \text{in } \Sigma, \\ p(\cdot,T) &= 0 && \text{in } \Omega, \end{aligned} \tag{6.4}$$

$$\frac{\partial \varphi}{\partial u}(x,t,\bar{y},\bar{u}) + p + \sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,t,\bar{y},\bar{u})\,\mu_i = 0 \quad \text{a.e. in } Q, \tag{6.5}$$

$$\iint_Q g_i(x,t,\bar{y},\bar{u})\,\mu_i\,dxdt = 0 \quad \forall i \in \{1,\dots,k\}. \tag{6.6}$$

The adjoint state p is the weak solution of (6.4) and belongs to $L^{\tilde{r}}(0,T,W^{1,r}(\Omega))$ for all $\tilde{r} > 1$, $r > 1$ satisfying

$$\frac{N}{2} + \frac{1}{2} < \frac{N}{2r} + \frac{1}{\tilde{r}};$$

cf. [14, Thm. 4.3]. Now we are going to show Hölder continuity of $\bar{u}$. To this end, we additionally assume the following:

(A11) The function φ possesses the second-order derivative $\partial^2\varphi/\partial u^2(x,t,y,u)$ on $\bar{Q}\times\mathbb{R}^2$. All functions g_i, $i=1,\dots,k$, are defined on $D\times\mathbb{R}^2$, where $D \subset \mathbb{R}^{N+1}$ is an open set containing $\bar{Q}$. They satisfy (A3) on this extended set. There is a constant $m > 0$ such that the monotonicity properties

$$\frac{\partial^2 \varphi}{\partial u^2}(x,t,y,u) \ge m \quad \forall (x,t) \in \bar{Q},\ \forall (y,u) \in \mathbb{R}^2, \tag{6.7}$$

$$\frac{\partial g_i}{\partial u}(x,t,y,u) \ge m \quad \forall (x,t) \in D,\ \forall (y,u) \in \mathbb{R}^2 \tag{6.8}$$

are satisfied.

The assertions of the Lemmas 5.2 and 5.3 do not depend on the special structure of the underlying PDE. Obviously, they can be directly transferred to the parabolic case. Therefore, the following extension of (5.8) is satisfied a.e. in Q:

$$\begin{aligned} &\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,t,\bar{y}(x,t),\bar{u}(x,t))\mu_i(x,t) \\ &\qquad = \max\left(0, -\left(\frac{\partial \varphi}{\partial u}\big(x,t,\bar{y}(x,t), \min_{i=1,\dots,k} \phi_i(x,t,\bar{y}(x,t))\big) + p(x,t)\right)\right). \end{aligned} \tag{6.9}$$

The functions ϕ_i are constructed again by the Robinson implicit function theorem that ensures, in particular, an estimate of the type (5.7). Now, the functions g_i in this estimate are only locally Hölder continuous so that all $\phi_i(x,t,y)$ are locally Hölder continuous: There is a constant $\lambda \in (0,1)$ and, for all $M > 0$, a constant $H(M) > 0$ depending on M such that

$$|\phi_i(x_1,t_1,y_1) - \phi_i(x_2,t_2,y_2)| \le H(M)|(x_1,t_1,y_1) - (x_2,t_2,y_2)|^\lambda \tag{6.10}$$

holds for all $(x_i,t_i) \in \bar{Q}$ and for all $y_i \in [-M,M]$.

THEOREM 6.1. *Suppose that $(\bar{y},\bar{u}) \in W(0,T) \cap C(\bar{Q}) \times L^\infty(Q)$ satisfy, together with $p \in L^{\tilde{r}}(0,T,W^{1,r}(\Omega))$ for all $\tilde{r} > 1$, $r > 1$, and $\mu_1,\dots,\mu_k \in L^1(Q)$, the optimality conditions* (6.4)–(6.6). *If the assumptions* (A10) *and* (A11) *are satisfied, then all multipliers μ_i, $i = 1,\dots,k$, belong to $L^\infty(Q)$. Moreover, the optimal control $\bar{u}$ and the expression $\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,t,\bar{y},\bar{u})\mu_i$ are Hölder continuous on $\bar{Q}$.*

Proof. We proceed by bootstrapping arguments following the proof of Theorem 5.4. By our assumptions, we know $\bar{u} \in L^\infty(Q)$ and $\bar{y} \in C(\bar{Q})$.

Consider now the adjoint equation (6.4). Thanks to Theorem 4.2, (i), in [14], the right-hand sides of the adjoint equation in $L^s(Q)$ are transformed into solutions in $L^\alpha(Q)$ with $\alpha \ge s$, if

$$\frac{1}{s}\left(\frac{N}{2}+1\right) < \frac{1}{\alpha}\left(\frac{N}{2}+1\right) + 1,$$

and hence the right-hand sides from $L^s(Q)$ are transformed into $L^\alpha(Q)$ for all $\alpha \ge 1$ with

$$\alpha < \frac{s(N/2+1)}{N/2+1-s}$$

provided that $s < N/2+1$. For $s > N/2+1$, the transformation is from $L^s(Q)$ to $C(\bar{Q})$. The gain of smoothness $\alpha - s$ is

$$\alpha - s = \frac{s^2}{N/2+1-s} - \varepsilon,$$

where $\varepsilon > 0$ can be taken arbitrarily small. Therefore, by $s \ge 1$, at least the gain

$$\alpha - s \ge \frac{s^2}{N/2+1} \ge \frac{1}{N/2+1} =: \sigma$$

is obtained, and hence $p \in L^{s+\sigma}(Q)$.

We start a bootstrapping procedure at $s := 1$. From the gradient equation (6.5), we deduce

$$\sum_{i=1}^k \frac{\partial g_i}{\partial u}(x,t,\bar{y},\bar{u})\mu_i = -\frac{\partial \varphi}{\partial u}(x,t,\bar{y},\bar{u}) - p \ \in L^{s+\sigma}(Q). \tag{6.11}$$

Because of (6.8) and by the nonnegativity of the multipliers μ_i, this implies

$$\mu_i \in L^{s+\sigma}(Q) \quad \forall i \in \{1,\dots,k\}.$$

Inserting this into (6.4), the right-hand sides of the adjoint equation are seen to belong to $L^{s+\sigma}(Q)$. Therefore, we obtain by the same arguments as before

$$p \in L^{s+2\sigma}(Q).$$

By (6.11) and the boundedness of the functions $\partial g_i/\partial u(x,t,\bar{y},\bar{u})$, we find

$$\sum_{i=1}^{k} \frac{\partial g_i}{\partial u}(x,t,\bar{y},\bar{u})\mu_i \in L^{s+2\sigma}(Q).$$

Repeating this bootstrapping method, after finitely many steps, we arrive at the situation that $N/2+1 < 1+(j+1)\sigma$ while $N/2+1 > 1+j\sigma$. In this case, it holds that $p \in C(\bar{Q})$, and (6.11) implies

$$\mu_i \in L^\infty(Q) \quad \forall i \in \{1,\dots,k\}.$$

We know that p is bounded on $\bar{Q}$ and its terminal value is zero and hence Hölder continuous on $\bar{\Omega}$. Therefore, Theorem 4 in Di Benedetto [7] yields Hölder continuity of p. (For our case of variational boundary data, this theorem ensures Hölder continuity of the solution on $\bar{\Omega}\times[0,T-\varepsilon]$ for all $\varepsilon>0$. Moreover, it states Hölder continuity on $\bar{Q}$ if the prescribed terminal data are Hölder.)

Now, we invoke formula (6.9). Since $\bar{y}$ bounded and y_0 is Hölder continuous, $\bar{y}$ exhibits this property, too. The same holds true for the function

$$\min_{i\in\{1,\dots,k\}} \phi_i(x,t,\bar{y}(x,t)),$$

since, by (6.10), all ϕ_i are Hölder continuous. Thanks to this, the right-hand side of (6.9) is Hölder continuous so that the left-hand side has this property, too.

From the gradient equation (6.11), we now obtain

$$\frac{\partial \varphi}{\partial u}(\cdot,\bar{y},\bar{u}) \in C^{0,\kappa}(\bar{Q}) \tag{6.12}$$

with some $\kappa \in (0,1)$. Next we make use of the assumption (A11) and (6.7), i.e., $\frac{\partial^2 \varphi}{\partial u^2} \geq m > 0$. Invoking the implicit function theorem again, we deduce the Hölder continuity of $\bar{u}$. □

PATHWISE STOCHASTIC OPTIMAL CONTROL*

L. C. G. ROGERS†

Abstract. This paper approaches optimal control problems for discrete-time controlled Markov processes by representing the value of the problem in a dual Lagrangian form; the value is expressed as an infimum over a family of Lagrangian martingales of an expectation of a pathwise supremum of the objective adjusted by the Lagrangian martingale term. This representation opens up the possibility of numerical methods based on Monte Carlo simulation, which may be advantageous in high-dimensional problems or in problems with complicated constraints.

Key words. deterministic, stochastic, dynamic programming, pathwise optimization, dual

1. Introduction.

The title of this paper refers to this: we intend to show that the solution of a stochastic optimal control problem can be characterized in terms of a *pathwise* optimization. In simple terms, this means that we can repeatedly generate sample paths, solving a *deterministic* optimization for each sample path separately, to obtain an approximation to the solution of the problem.

This approach is in contrast to the more familiar method of trying to find the value function of the problem, and the associated optimal control; the more familiar approach requires consideration of all possible future evolutions of the process at each time that a control choice is to be made. This method is well developed and generally effective, but there are certainly problems (such as the optimal control of a diffusion in high dimensions) where the approach is impractical.

The approach we follow is foreshadowed by various papers in the control literature, where the relationship between deterministic and stochastic optimal control is explored. There is, for example, the paper of Davis and Burstein [4], where the theme of optimal control of a diffusion process is considered. The tools applied, notably the use of the stochastic flow of a "null" solution to the optimal control problem, are strongly specific to that particular context, but the form of the solution, involving a pathwise optimization of the original objective modified by a Lagrangian term, invites extension. Other interesting papers around this theme are those of Rockafellar and Wets [11] and Wets [13], and that of Back and Pliska [2], who present the maximization of some concave path functional over a family of adapted processes in terms of the maximization of the same functional modified by a linear (Lagrangian) functional over the larger family of *measurable* processes. The linear functional is of course the gradient of the objective at the optimum, in some suitable sense.

Contributions [11], [13], and [2] represent the Lagrangian form of the solution in quite abstract terms. In contrast, the approach to be followed in this paper derives simple and quite explicit representations which may be the basis for effective numerical techniques. This approach does not require any convexity assumptions on the objective, unlike [11], [13], [2], and the proofs are simple and completely elementary.

†Statistical Laboratory, University of Cambridge, Wilberforce Road, Cambridge CB3 0WB, UK (l.c.g.rogers@statslab.cam.ac.uk).

Although our first result has the appearance of the "Lagrangian form" of the problem studied in [11], [13], [2], the subsequent results do not.

The approach of this paper develops the recent result of Rogers [12], proved independently by Haugh and Kogan [6], on Monte Carlo pricing of American options.[1] This result states the following. Given an adapted process[2] $(Z_t)_{0\le t\le T}$, the value Y_0^* at time 0 of the optimal stopping problem satisfies

$$\begin{aligned} Y_0^* &\equiv \sup_{\tau\in\mathcal{T}} EZ_\tau \\ &= \inf_{M\in\mathcal{M}_0} E\left[\sup_{0\le t\le T}(Z_t - M_t)\right], \end{aligned} \tag{1}$$

where $\mathcal{T}$ is the family of stopping times, and $\mathcal{M}_0$ is the space of uniformly integrable martingales started at 0. The importance of this result is that it gives a way to find the value of an American option via Monte Carlo simulation; given the sample path of $Z - M$, we simply stop at the best place without considering what might be happening on any other path, and in particular without considering what the value function might be at any time. The numerical methods presented in [12] are crude but good enough to get upper and lower bounds in a number of interesting examples which were different by about 0.5%–2%. Andersen and Broadie [1] present a more systematic way to search out "good" martingales and achieve bounds that are generally better. Jamshidian [7] proposes a "multiplicative" version of the result of [12], [6].

Now the optimal stopping problem is a particularly simple class of optimal control problems; *could any variant of result* (1) *be used for more general stochastic control problems?* Passing to complete generality introduces a couple of major complications: the first is that the space of possible controls is no longer a two-point set but can be very large; and the second is that the choice of controls now affects the law of the process, and there is no canonical choice. However, the main message of this paper is that we *can* extend the dual methodology that worked so well for optimal stopping problems; we present a number of different forms of the main idea. We present results only in a discrete-time setting; there are doubtless continuous-time analogues, but we prefer to present the main ideas in the technically simplest form. Our main focus is on the development of Monte Carlo methodologies that use the main ideas of this paper to solve optimal control problems. Existing techniques for solving Hamilton–Jacobi–Bellman equations by PDE methods are reasonably satisfactory provided the problem is not too involved, but it does not take much imagination to come up with examples that are so complicated that only a simulation methodology could possibly work. The different forms of the main result that we derive suggest different techniques for approaching the problem of Monte Carlo approximation of the solution. There are also links to the "occupation measure" approach to optimal control of a Markov process (which Kurtz and Stockbridge [8] trace back to Manne [10]); this we discuss in an appendix.

2. The problem and its solution. We shall consider the optimal control of a discrete-time Markov process with a finite time horizon T. The Markov process X takes values in some measurable space $(\mathcal{X}, \mathcal{G})$, and the control process $\mathbf{a} \equiv$

[1] See Davis and Karatzas [5] for a weaker partial result.

[2] The process is also required to satisfy a mild integrability condition.

$(a_0, a_1, \ldots, a_{T-1})$ belongs to the class $\mathcal{A}$ of adapted processes with values in some measurable space $(A, \mathcal{B})$ of permitted controls. The objective is

$$E\left[\sum_{j=0}^{T-1} f_j(X_j, a_j) + F(X_T)\right], \tag{2}$$

which is to be maximized over $\mathbf{a} \in \mathcal{A}$. For simplicity, we shall assume that the functions f_j and F are *bounded* measurable to avoid having to worry over finiteness of objectives and other such inessential issues; this restriction is made solely for ease of exposition. We shall suppose that there is some reference measure m over $(\mathcal{X}, \mathcal{G})$ such that for each $a \in A$ the transition under control a has density $p(x, x'; a)$ with respect to m, and that there is some reference Markovian transition density $p^*(x, x')$. We write

$$\varphi(x, x'; a) = \frac{p(x, x'; a)}{p^*(x, x')}$$

for the controlled transition density with respect to the reference Markovian transition p^*. We write $V_j(x)$ for the value function of the problem starting from state x at time j:

$$V_j(x) = \sup_{\mathbf{a}\in\mathcal{A}} E\left[\sum_{r=j}^{T-1} f_r(X_r, a_r) + F(X_T) \,\middle|\, X_j = x\right]. \tag{3}$$

We may view the effect of control as being an alteration of the law of the underlying process X. If we do this, then by introducing the notation $(0 \le k \le t < T)$

$$\Lambda_{k,t}(\mathbf{a}) \equiv \prod_{r=k}^{t-1} \varphi(X_r, X_{r+1}; a_r), \quad \Lambda_t(\mathbf{a}) \equiv \Lambda_{0,t}(\mathbf{a}), \tag{4}$$

we may recast the optimization problem in the form

$$V_0(X_0) = \sup_{\mathbf{a}\in\mathcal{A}} E^*\left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) f_j(X_j, a_j) + \Lambda_T(\mathbf{a}) F(X_T)\right], \tag{5}$$

where the expectation is now taken with respect to the fixed reference probability P^*. We shall need the following notation (for (bounded) measurable $g, h_j : \mathcal{X} \mapsto \mathbb{R}$):

$$Pg(x, a) = E^*[\, g(X_1)\varphi(x, X_1; a) \mid X_0 = x], \quad (x \in \mathcal{X},\ a \in A), \tag{6}$$

$$(\mathcal{L}h)_j(x) = \sup_a\big[\, f_j(x, a) + Ph_{j+1}(x, a)\,\big], \quad (x \in \mathcal{X}, j = 0, \ldots, T-1). \tag{7}$$

The first notation is just the expectation of $g(X_1)$ if at time 0 we are in state x and use action a; the second defines the one-step Bellman operator.

The first result is the following.

THEOREM 1.

$$V_0(X_0) = \min_{(h_j)\in\mathcal{H}} E^*\left[\sup_{\mathbf{a}} \left\{ \sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\{f_j(X_j,a_j) + E_j^*(\eta_{j+1}) - \eta_{j+1}\} + \Lambda_T(\mathbf{a})F(X_T) \right\}\right] \tag{8}$$

$$= \min_{(h_j)\in\mathcal{H}} \left[h_0(X_0) + \sum_{j=0}^{T-1} E^* \sup_{\mathbf{a}} \Lambda_j(\mathbf{a}) \{ (\mathcal{L}h)_j(X_j) - h_j(X_j) \}^+ \right], \tag{9}$$

where the random variables η_j are defined in terms of the functions (h_j) via

$$\eta_{j+1} \equiv h_{j+1}(X_{j+1})\varphi(X_j, X_{j+1}; a_j), \tag{10}$$

and the set $\mathcal{H}$ is the set of sequences $(h_j)_{j=0}^T$ of (bounded) measurable functions from $\mathcal{X}$ to $\mathcal{X}$, satisfying the terminal condition

$$h_T = F.$$

Remarks. (i) To get from the form (5) to (8), we add a martingale-difference sequence $E_j^*(\eta_{j+1}) - \eta_{j+1}$ to the objective, then do a *pathwise* optimization over the controls, take expectations, and finally minimize over our choice of the martingale difference sequence. This is formally similar to what we did in (1); as there, the martingale-difference sequence can be interpreted as a Lagrangian process to account for the adapted constraint on the controls $\mathbf{a}$. Once we have included this term in the objective, we optimize pathwise, allowing ourselves to see the entire path and pick controls in an anticipative way. Notice that because of the form (10) of η_{j+1}, the conditional expectation appearing in (8) can as well be expressed as

$$E_j^*(\eta_{j+1}) = Ph_{j+1}(X_j, a_j). \tag{11}$$

(ii) As we shall see, the minimum is attained when we take $h_j = V_j$. This fact is of little practical value, however, since we cannot assume that we know V—it is, after all, the solution we seek! Nevertheless, the result allows us to obtain *upper* bounds on the value function.

(iii) The choice of reference measure must be expected to be critical in practice. We cannot expect a simulation method to work well if most of the paths simulated are quite unlike the paths of the optimally controlled process.

(iv) The form (8) is well suited to Monte Carlo, since it involves an expectation of a pathwise supremum. The second form (9) can be evaluated with no backward recursion. It can be reworked in the situation where

$$\psi(x) \equiv \int \sup_{a\in A} p(x,x';a)\, m(dx) < \infty \tag{12}$$

for all x. This allows us to define a new transition density

$$\bar{p}(x,x') = \frac{\sup_{a\in A} p(x,x';a)}{\psi(x)}$$

with a corresponding path probability $\bar{P}$. Writing $\Psi_j \equiv \prod_{i=0}^{j-1} \psi(X_i)$, the final form (9) becomes simply

$$\min_{(h_j)} \left[h_0(X_0) + \sum_{j=0}^{T-1} \bar{E}\Psi_j \{ (\mathcal{L}h)_j(X_j) - h_j(X_j) \}^+ \right]. \tag{13}$$

This is of interest because it expresses the solution in terms of a *fixed* measure, which we could call the *maximum-likelihood measure*, together with a reweighting factor which is independent of any choice of controls.

Proof. The problem is to find

$$V_0(X_0) = \sup_{\mathbf{a}\in\mathcal{A}} v_0(X_0; \mathbf{a}),$$

where of course we define

$$v_0(X_0; \mathbf{a}) \equiv E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) f_j(X_j, a_j) + \Lambda_T(\mathbf{a}) F(X_T) \right].$$

Now fixing $\mathbf{a} \in \mathcal{A}$, for any P^*-martingale M,

$$\begin{aligned} v_0(X_0; \mathbf{a}) &\equiv E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) f_j(X_j, a_j) + \Lambda_T(\mathbf{a}) F(X_T) \right] \\ &= E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) \{ f_j(X_j, a_j) + \Delta M_{j+1} \} + \Lambda_T(\mathbf{a}) F(X_T) \right], \end{aligned}$$

since for $\mathbf{a} \in \mathcal{A}$ the process $\Lambda(\mathbf{a})$ is adapted. We shall specialize the martingale slightly by expressing the martingale-differences as

$$\Delta M_{j+1} = E^*_j(\eta_{j+1}) - \eta_{j+1}, \quad \eta_{j+1} \equiv h_{j+1}(X_{j+1}) \varphi(X_j, X_{j+1}; a_j). \tag{14}$$

Notice that

$$\Lambda_j(\mathbf{a}) \eta_{j+1} = \Lambda_{j+1}(\mathbf{a}) h_{j+1}(X_{j+1}); \tag{15}$$

this fact is used in the following reworking. The first inequality comes by relaxing the constraint that $\mathbf{a} \in \mathcal{A}$:

$$\begin{aligned} V_0(X_0) &= \sup_{\mathbf{a}\in\mathcal{A}} v_0(X_0; \mathbf{a}) \\ &= \sup_{\mathbf{a}\in\mathcal{A}} E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) \{ f_j(X_j, a_j) + E^*_j(\eta_{j+1}) - \eta_{j+1} \} + \Lambda_T(\mathbf{a}) F(X_T) \right] \\ &= \sup_{\mathbf{a}\in\mathcal{A}} E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) \{ f_j(X_j, a_j) + P h_{j+1}(X_j, a_j) - \eta_{j+1} \} + \Lambda_T(\mathbf{a}) F(X_T) \right] \end{aligned}$$

$$\leq E^*\left[\sup_{\mathbf{a}}\left\{\sum_{j=0}^{T-1}\Lambda_j(\mathbf{a})\{f_j(X_j,a_j)+Ph_{j+1}(X_j,a_j)-\eta_{j+1}\}\right.\right.$$
$$\left.\left.+\Lambda_T(\mathbf{a})F(X_T)\right\}\right]$$
$$= E^*\left[\sup_{\mathbf{a}}\left\{\sum_{j=0}^{T-1}\left\{\Lambda_j(\mathbf{a})\{f_j(X_j,a_j)+Ph_{j+1}(X_j,a_j)\}-\Lambda_{j+1}(\mathbf{a})h_{j+1}(X_{j+1})\right\}\right.\right.$$
$$\left.\left.+\Lambda_T(\mathbf{a})F(X_T)\right\}\right]$$
$$= E^*\left[\sup_{\mathbf{a}}\left\{h_0(X_0)+\sum_{j=0}^{T-1}\Lambda_j(\mathbf{a})\{f_j(X_j,a_j)+Ph_{j+1}(X_j,a_j)-h_j(X_j)\}\right\}\right]$$
$$\leq E^*\left[h_0(X_0)+\sum_{j=0}^{T-1}\sup_{\mathbf{a}}\Lambda_j(\mathbf{a})\{f_j(X_j,a_j)+Ph_{j+1}(X_j,a_j)-h_j(X_j)\}\right]$$
$$= h_0(X_0)+\sum_{j=0}^{T-1}E^*\left[\sup_{\mathbf{a}}\Lambda_j(\mathbf{a})\{\,(\mathcal{L}h)_j(X_j)-h_j(X_j)\,\}\right]$$
$$\leq h_0(X_0)+\sum_{j=0}^{T-1}E^*\left[\sup_{\mathbf{a}}\Lambda_j(\mathbf{a})\{\,(\mathcal{L}h)_j(X_j)-h_j(X_j)\,\}^+\right].$$

Taking the infimum over the functions $(h_j)\in\mathcal{H}$, we get

$$V_0(X_0)\leq\inf_{(h_j)\in\mathcal{H}}E^*\left[\sup_{\mathbf{a}}\left\{\sum_{j=0}^{T-1}\Lambda_j(\mathbf{a})\{f_j(X_j,a_j)-\eta_{j+1}+E_j^*(\eta_{j+1})\}\right.\right.$$
$$\left.\left.+\Lambda_T(\mathbf{a})F(X_T)\right\}\right]$$
$$\leq\inf_{(h_j)\in\mathcal{H}}\left[h_0(X_0)+\sum_{j=0}^{T-1}E^*\left[\sup_{\mathbf{a}}\Lambda_j(\mathbf{a})\{\,(\mathcal{L}h)_j(X_j)-h_j(X_j)\,\}\right]\right]$$
$$\leq\inf_{(h_j)\in\mathcal{H}}\left[h_0(X_0)+\sum_{j=0}^{T-1}E^*\left[\sup_{\mathbf{a}}\Lambda_j(\mathbf{a})\{\,(\mathcal{L}h)_j(X_j)-h_j(X_j)\,\}^+\right]\right]. \tag{16}$$

In fact, there is equality throughout. To see this, we use the Bellman equation for the value function

$$V_j=(\mathcal{L}V)_j,$$

so if we take $h_j=V_j$, the sum in (16) vanishes and leaves only $h_0(X_0)=V_0(X_0)$. □

Remark. The proof also shows that

$$V_0(x_0) = \min_{(h_j)\in\mathcal{H}} \left[h_0(X_0) + \sum_{j=0}^{T-1} E^* \sup_{\mathbf{a}} \Lambda_j(\mathbf{a}) \{ (\mathcal{L}h)_j(X_j) - h_j(X_j) \} \right], \tag{17}$$

which is a fact that we will refer back to later.

Theorem 1 gives us a way to approach a stochastic optimal control problem by Monte Carlo methods, by simulating paths repeatedly and computing the expressions inside the expectations (8). However, it is important that this optimization, over the sequence $\mathbf{a}$, can be done efficiently; otherwise the method will be too slow. Fortunately, it turns out that the optimization required may be performed *recursively*, so we have a sequence of optimization problems over the choice of only one a_j at a time.

To explain this in more detail, let us focus on the form (8). We can rewrite the expression inside the expectation on the right-hand side as

$$\begin{aligned} &\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\{f_j(X_j,a_j) + Ph_{j+1}(X_j,a_j) - \eta_{j+1}\} + \Lambda_T(\mathbf{a})F(X_T) \\ &= \sum_{j=0}^{m-1} \Lambda_j(\mathbf{a})\{f_j(X_j,a_j) + Ph_{j+1}(X_j,a_j) - \eta_{j+1}\} + \Lambda_m(\mathbf{a})Z_m, \end{aligned}$$

where

$$Z_m \equiv \sum_{j=m}^{T-1} \Lambda_{m,j}(\mathbf{a})\{f_j(X_j,a_j) + Ph_{j+1}(X_j,a_j) - \eta_{j+1}\} + \Lambda_{m,T}(\mathbf{a})F(X_T)$$

contains all dependence on $a_m, \dots, a_{T-1}$. Recursively,

$$\begin{aligned} Z_m &= f_m(X_m,a_m) + Ph_{m+1}(X_m,a_m) - \eta_{m+1} + \Lambda_{m,m+1}(\mathbf{a})Z_{m+1} \\ &= f_m(X_m,a_m) + Ph_{m+1}(X_m,a_m) + \varphi(X_m,X_{m+1};a_m)\big[\, Z_{m+1} - h_{m+1}(X_{m+1})\,\big]. \end{aligned}$$

Assuming we already have the maximizing values of $a_{m+1}, \dots, a_{T-1}$, this is a maximization over a_m only!

3. Towards an algorithm. It is clear from the statement of Theorem 1 that the choice of the Lagrangian functions (h_j) is critical. The following little result offers a possible approach to finding good choices.

PROPOSITION 1. *Suppose that*

$$B \equiv \sup_{a,x,x'} \varphi(x,x';a) < \infty,$$

and suppose we are given a sequence $(V_j^{(0)})_{j=0}^T$ *of functions from* $\mathcal{X}$ *to* $\mathcal{X}$*, with* $V_T^{(0)} = F$*. Define recursively the functions* $(V_k^{(n)})_{k=0}^T$ *for* $n = 1, 2, \dots$ *by*

$$V_k^{(n+1)}(x) = E^* \left[\sup_{\mathbf{a}} \left\{ \sum_{j=k}^{T-1} \Lambda_{k,j}(\mathbf{a})\{f_j(X_j,a_j) - V_{j+1}^{(n)}(X_{j+1})\varphi(X_j,X_{j+1};a_j) + PV_{j+1}^{(n)}(X_j,a_j)\} + \Lambda_{k,T}(\mathbf{a})F(X_T) \right\} \,\middle|\, X_k = x \right] \tag{18}$$

for $x \in \mathcal{X}$, $k = 0, \ldots, T$. Defining

$$\Delta_k^{(n)} \equiv \sup_x |V_k^{(n)}(x) - V_k^{(n-1)}(x)|,$$

$k = 0, \ldots, T$, $n \geq 1$, we have

$$\Delta_k^{(n)} \leq (1+B) \sum_{r=k+1}^{T} \Delta_r^{(n-1)}. \tag{19}$$

Remarks. The impact of Proposition 1 lies in the fact that $V_T^{(n)} = F$ for all n, so $\Delta_T^{(n)} = 0$ for all n. Hence from (19) we conclude that (provided that the $\Delta_k^{(n-1)}$ are finite)

$$\Delta_k^{(n)} = 0 \quad \forall n \geq T - k.$$

Thus by applying the recursive construction of Proposition 1 we compute the true value function by going backwards step by step from the end. Now in one sense all we have done is re-express the familiar backward recursion of the Bellman equation in a more complicated form, but there is nevertheless something gained; if we are not able to compute the recursive recipe (18) exactly (as would be the case were we using Monte Carlo in a high-dimensional problem, for example), we can still use the *approximate* output of the nth stage to begin on the $(n+1)$th.

Proof. Clearly,

$$\begin{aligned} -V_{j+1}^{(n)}(X_{j+1})\varphi(X_j, X_{j+1}; a_j) &\leq -V_{j+1}^{(n-1)}(X_{j+1})\varphi(X_j, X_{j+1}; a_j) \\ &\quad + \Delta_{j+1}^{(n)}\varphi(X_j, X_{j+1}; a_j) \\ &\leq -V_{j+1}^{(n-1)}(X_{j+1})\varphi(X_j, X_{j+1}; a_j) + B\Delta_{j+1}^{(n)} \end{aligned}$$

and

$$PV_{j+1}^{(n)}(X_j, a_j) \leq PV_{j+1}^{(n-1)}(X_j, a_j) + \Delta_{j+1}^{(n)},$$

so using this in (18) gives us

$$\begin{aligned} V_k^{(n+1)}(x) &\equiv E^* \Bigg[\sup_{\mathbf{a}} \Bigg\{ \sum_{j=k}^{T-1} \Lambda_{k,j}(\mathbf{a}) \{ f_j(X_j, a_j) - V_{j+1}^{(n)}(X_{j+1})\varphi(X_j, X_{j+1}; a_j) \\ &\qquad + PV_{j+1}^{(n)}(X_j, a_j) \} + \Lambda_{k,T}(\mathbf{a}) F(X_T) \Bigg\} \,\Bigg|\, X_k = x \Bigg] \\ &\leq E^* \Bigg[\sup_{\mathbf{a}} \Bigg\{ \sum_{j=k}^{T-1} \Lambda_{k,j}(\mathbf{a}) \{ f_j(X_j, a_j) - V_{j+1}^{(n-1)}(X_{j+1})\varphi(X_j, X_{j+1}; a_j) \\ &\qquad + PV_{j+1}^{(n-1)}(X_j, a_j) \} + \Lambda_{k,T}(\mathbf{a}) F(X_T) \Bigg\} \,\Bigg|\, X_k = x \Bigg] \\ &\qquad + (1+B) \sum_{r=k+1}^{T} \Delta_r^{(n)} \\ &= V_k^{(n)}(x) + (1+B) \sum_{r=k+1}^{T} \Delta_r^{(n)}. \end{aligned}$$

Thus

$$V_k^{(n+1)}(x) - V_k^{(n)}(x) \le (1+B) \sum_{r=k+1}^{T} \Delta_r^{(n)},$$

and a similar bound on the other side establishes the result. □

Discussion. For the purposes of this discussion, we assume for ease of exposition that $f_j = f$ for all j, and that there exists a sequence of functions ψ_k such that the integral $P\psi_k(x,a)$ is known in closed form. The reason for this is to permit approximation of the value function as linear combinations of the ψ_k; this is similar to what Longstaff and Schwartz [9] do.

When might we use this approach? When the steps of the dynamic programming algorithm are numerically intensive as, for example, in a situation where $\mathcal{X}$ is very high dimensional and the required integrations are difficult to do, or when the pointwise optimization over $a \in A$ is hard, then the simulation-based approach of Theorem 1 may be of value. One advantage of this approach is that it seeks only the solution starting from a particular x_0, whereas the dynamic programming approach is calculating the solution from *all* starting points.

The first thing to do will be to simulate some paths of the process.

What law should we use for the initial simulation? Probably we should not use the reference Markovian law P^*, as the paths of X under P^* can't be expected to look very much like the paths of the optimally controlled process, and so we will get little relevant information about the objective if we just simulate from P^*. This problem becomes more acute the larger T is, so it may be worth simulating initially only out to some $T_1 < T$, and gradually increasing T_1 as the algorithm proceeds. Since the intermediate rewards f_j could all be zero (or very small), we should not forget to include a term $F(X_{T_1})$ in the objective, as we will ultimately be steering towards this. The *maximum likelihood measure* $\bar{P}$ is also not a very promising candidate, as the law does not depend in any way on f_j, F, but it suggests something we might try instead. Since the objective is

$$v_0(X_0;\mathbf{a}) \equiv E^*\left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) f(X_j,a_j) + \Lambda_T(\mathbf{a}) F(X_T)\right]$$

$$= E^*\left[\Lambda_T(\mathbf{a})\ \left\{\sum_{j=0}^{T-1} f(X_j,a_j) + F(X_T)\right\}\right]$$

$$\simeq \varepsilon^{-1} E^*\left[\Lambda_T(\mathbf{a}) \exp\left\{\varepsilon \sum_{j=0}^{T-1} f(X_j,a_j) + \varepsilon F(X_T)\right\} - 1\right]$$

$$= \varepsilon^{-1} E^*\left[\prod_{j=0}^{T-1} \varphi(X_j, X_{j+1}; a_j) e^{\varepsilon f(X_j,a_j)}\ .e^{\varepsilon F(X_T)} - 1\right],$$

this suggests we might modify the definition of $\bar{P}$ by defining

$$\psi(x) \equiv \int \sup_{a \in A} p(x, x'; a) e^{\varepsilon f(x,a)} \, m(dx),$$

$$\bar{p}(x, x') = \frac{\sup_{a \in A} p(x, x'; a) e^{\varepsilon f(x,a)}}{\psi(x)}.$$

The effect of this is to lead the process in directions where the running reward is higher. The choice of ε will need to be tuned a bit.

How do we move from one simulation to the next? We suppose that our current estimate $V_t^{(n)}$ of the value is expressed as a linear combination of the ψ_k:

$$V_t^{(n)} = \sum_k c_{t,k}^{(n)} \psi_k,$$

which allows us to write expressions for $PV_t^n(x, a)$. Once we have simulated sample paths $(X_0^{(i)}, X_1^{(i)}, \ldots, X_T^{(i)})$ for $i = 1, \ldots, N$, we perform the pathwise optimization in (8) and then have some estimate of the value at the points $X_t^{(i)}$ at time t. We now regress these values onto the functions ψ_k to get the next approximation to the value. The next simulation should follow according to what we now think is an approximation to the optimal path law, and one way to achieve this would be as follows. Suppose that at time t on the simulated path we have reached x; first choose $x' \in \{X_t^{(i)}, i = 1, \ldots, N\}$ at random, points "nearer" to x being chosen with higher probability, and jump to that point, $x' = X_t^{(q)}$, say. Then make the move to y at time $t + 1$ according to the density $p(x', \cdot; a_t^{(q)})$, where $a_t^{(q)}$ was the control optimally chosen at $X_t^{(q)}$.

4. Variants of the main result.

4.1. Least-squares characterization. The study [12] of Monte Carlo valuation of American options showed that the optimal policy was in some sense a "minimum-variance" policy, and there is an analogue in this setting too. Writing

$$Y(X; h) \equiv \sup_{\mathbf{a}} \left\{ \sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) \{ f_j(X_j, a_j) - \eta_{j+1} + E_j^*(\eta_{j+1}) \} + \Lambda_T(\mathbf{a}) F(X_T) \right\}$$

(where the η_j are as in (10)), Theorem 1 says that $V(X_0) = \inf_{(h_j)} E^*[\, Y(X; h)\,]$. Moreover, the infimum is attained by taking $h_j = V_j$, and in that case the proof of Theorem 1 shows that the random variable $Y(X; V)$ is almost surely constant. We therefore have the following alternative characterization of the optimal solution.

COROLLARY 1. *Assuming that V_0 is nonnegative,*[3] *the problem*

$$\inf_{(h_j) \in \mathcal{H}} E^*[\, Y(X; h)^2\,]$$

is solved by taking $h_j = V_j$.

[3]Nonnegativity is needed only because we use the reasoning $E^* Y(X; h)^2 = \operatorname{var}(Y(X; h)) + E^*(Y(X; h))^2 \geq E^*(Y(X; h))^2 \geq (\min E^* Y(X; h))^2$, and the final step is not true unless we have $E^* Y(X; h) \geq 0$ for all h.

4.2. Multiplicative form of the main result. As in the case of Jamshidian's version of the optimal stopping result, we have a multiplicative form of Theorem 1.

THEOREM 2.

$$V_0(X_0) \le \inf_{\eta>0} E^* \left[\sup_{\mathbf{a}} \left\{ \sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\, f_j(X_j, a_j)\, \frac{\eta_{j+1}}{E_j^*[\eta_{j+1}]} + \Lambda_T(\mathbf{a}) F(X_T) \right\} \right], \tag{20}$$

where the random variables η_j are positive. Provided

$$g_j^*(X_j, X_{j+1}, a_j) \equiv V_j(X_j) - V_{j+1}(X_{j+1})\varphi(X_j, X_{j+1}; a) > 0, \tag{21}$$

result (20) *can be strengthened into the statement*

$$V_0(X_0) = \min_{\eta>0} E^* \left[\sup_{\mathbf{a}} \left\{ \sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\, f_j(X_j, a_j)\, \frac{\eta_{j+1}}{E_j^*[\eta_{j+1}]} + \Lambda_T(\mathbf{a}) F(X_T) \right\} \right], \tag{22}$$

with the minimizing choice of η_{j+1} being $\eta_{j+1} = g_j^*(X_j, X_{j+1}, a_j)$.

Remark. Condition (21) could be weakened to nonnegativity; we simply need to change f_j to $f_j - j$ and apply the theorem to this modified problem (whose value is $T(T-1)/2$ less than the value of the original problem).

Proof. The proof follows similarly to the proof of Theorem 1. Fixing $\mathbf{a} \in \mathcal{A}$, and letting η be any strictly positive adapted process, we have

$$\begin{aligned} v_0(X_0; \mathbf{a}) &= E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a}) f_j(X_j, a_j) + \Lambda_T(\mathbf{a}) F(X_T) \right] \\ &= E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\, f_j(X_j, a_j)\, \frac{\eta_{j+1}}{E_j^*[\eta_{j+1}]} + \Lambda_T(\mathbf{a}) F(X_T) \right]. \end{aligned}$$

Just as before,

$$\begin{aligned} V_0(X_0) &= \sup_{\mathbf{a}\in\mathcal{A}} v_0(X_0; a) \\ &= \sup_{\mathbf{a}\in\mathcal{A}} E^* \left[\sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\, f_j(X_j, a_j)\, \frac{\eta_{j+1}}{E_j^*[\eta_{j+1}]} + \Lambda_T(\mathbf{a}) F(X_T) \right] \\ &\le E^* \left[\sup_{\mathbf{a}} \left\{ \sum_{j=0}^{T-1} \Lambda_j(\mathbf{a})\, f_j(X_j, a_j)\, \frac{\eta_{j+1}}{E_j^*[\eta_{j+1}]} + \Lambda_T(\mathbf{a}) F(X_T) \right\} \right]. \end{aligned}$$

Taking the infimum over all choices of η leads to the first statement, (20).

For the second statement, (22), we again use the Bellman equation; positivity of g_j^* allows us to conclude that

$$\frac{f_j(X_j, a_j)}{E_j^*[\eta_{j+1}]}\, \eta_{j+1} \le \eta_{j+1},$$

and once again the sum telescopes to $V_0(X_0)$. □

4.3. "Strong" form of the main result. In Theorems 1 and 2, the effect of the controls is to modify the measure; if we simulate paths according to the measure P^*, then the controls applied do not affect the path of X—they simply affect the value assigned to the path. It may sometimes be more helpful to be able to allow the controls to act on the path directly, for which we need to formulate the problem slightly differently.

We shall suppose that if some control sequence $(a_j)_{j=0}^{T-1}$ is chosen, and the initial value X_0 for the process is given, then the trajectory X is determined by the relations

$$X_{j+1} = \xi(j, X_j, a_j, \varepsilon_{j+1}), \qquad (j = 0, \dots, T-1), \tag{23}$$

where the ε_j are independent random variables with common distribution, which we could take to be uniform on $[0,1]$ if we wish. The function ξ expresses the Markovian evolution; from a theoretical point of view it may be a little unusual to specify a Markov process in this way, rather than through the transition kernel, but from the point of view of simulating the paths of the process, this is *exactly* the way we think of the controlled Markov process! The difference is exactly the difference between a strong solution of a stochastic differential equation, constructed over a given driving process, and a weak solution, constructed in law on some probability space (as in Theorems 1 and 2).

Given a sequence (h_j) of functions of the Markovian state variable, we define

$$Ph_{j+1}(x,a) = E\, h_{j+1}(\xi(j,x,a,\varepsilon_{j+1})).$$

Then we have the following result.

THEOREM 3.

$$V_0(X_0) = \min_{(h_j)\in\mathcal{H}} E\left[\sup_{\mathbf{a}} \left\{ \sum_{j=0}^{T-1} (f_j(X_j,a_j) - h_{j+1}(X_{j+1}) + Ph_{j+1}(X_j,a_j)) + F(X_T) \right\} \right], \tag{24}$$

where the X_j and a_j are related through (23). *The minimum is attained by taking $h_j = V_j$.*

Remarks. The Monte Carlo approach to evaluating the right-hand side of (24) would generate a sequence of ε values and then find the optimal controls. In effect, what this means is that we have to solve a deterministic optimization problem along each path, where the choice of control will now affect where the path goes, and doing this is arguably no easier than solving the Bellman equation for the original stochastic control problem. However, in situations where this deterministic control problem can be dealt with more simply, there may be value in this result.

Proof. This closely follows along the lines of the proof of Theorem 1; we leave this to the reader to check. □

4.4. Infinite horizon. So far we have been considering only finite-horizon problems, but it is at least as important to develop methods for infinite-horizon discounted problems, as these will generate time-independent strategies that are easier to interpret and implement. Throughout this section, we will assume that f is uniformly bounded, and that we aim to find the value function $V : \mathcal{X} \to \mathcal{X}$ solving

$$V(x) = \sup_a E^* \left[f(x,a) + \beta\varphi(x, X_1; a)V(X_1) \;\middle|\; X_0 = x \right]. \tag{25}$$

Under the assumptions that $0 < \beta < 1$ and that f is uniformly bounded, it is well known that the Bellman operator $\mathcal{L} : L^\infty(\mathcal{X}) \to L^\infty(\mathcal{X})$ defined by

$$\mathcal{L}g(x) \equiv \sup_{a \in \mathcal{A}} E^* \left[f(x,a) + \beta\varphi(x, X_1; a) g(X_1) \;\middle|\; X_0 = x \right] \tag{26}$$

is a monotone contraction whose unique fixed point is the value function V solving (25).

To see where the dual method leads in this infinite-horizon setting, we need to introduce for each $h \in L^\infty(\mathcal{X})$ the operator $\mathcal{L}_h : L^\infty(\mathcal{X}) \to L^\infty(\mathcal{X})$ defined by

$$\begin{aligned} \mathcal{L}_h g(x) \equiv E^* \Big[\sup_a \big\{ & f(x,a) + Ph(x,a) - h(X_1)\varphi(x, X_1; a) \\ & + \beta\varphi(x, X_1; a) g(X_1) \big\} \;\Big|\; X_0 = x \Big]. \end{aligned} \tag{27}$$

Just as for $\mathcal{L}$, the operator $\mathcal{L}_h$ is a monotone contraction with a unique fixed point, which we denote by g_h^*. The analogue of Theorem 1 for the infinite-horizon setting is the following.

THEOREM 4. *Assuming that f is uniformly bounded, the value function V is characterized as*

$$V = \inf_h \; g_h^* = \min_h \; g_h^*, \tag{28}$$

where the infimum is attained by taking $h = \beta V$.

Proof. Evidently, the supremum in the definition of $\mathcal{L}_h g$ will be reduced if we insist that a must be a function of only X_0 and not of X_1; therefore

$$\begin{aligned} \mathcal{L}_h g(x) &\geq \sup_a E^* \Big[f(x,a) + Ph(x,a) - h(X_1)\varphi(x, X_1; a) \\ &\qquad + \beta\varphi(x, X_1; a) g(X_1) \;\Big|\; X_0 = x \Big] \\ &= \sup_a E^* \Big[f(x,a) + \beta\varphi(x, X_1; a) g(X_1) \;\Big|\; X_0 = x \Big] \\ &\equiv \mathcal{L}g(x). \end{aligned}$$

Since $\mathcal{L}V = V$, we deduce immediately that whatever h is, we shall have $\mathcal{L}_h V \geq V$, and by induction we conclude that for all n,

$$\mathcal{L}_h^n V \geq V.$$

By the contraction mapping principle, $\mathcal{L}_h^n V \to g_h^*$ as $n \to \infty$, and so for any h we have $g_h^* \geq V$, and hence $V \leq \inf_h g_h^*$.

To conclude, we observe that taking $h = \beta V$ gives for any x, a,

$$f(x,a) + Ph(x,a) \leq \sup_{a'} \{ f(x,a') + Ph(x,a') \} = V(x).$$

Hence,

$$\mathcal{L}_h V(x) \equiv E^*\Bigg[\sup_a \big\{ f(x,a) - h(X_1)\varphi(x,X_1;a) + Ph(x,a) + \beta\varphi(x,X_1;a)V(X_1)\big\} \;\Big|\; X_0 = x \Bigg]$$

$$\leq V(x) + E^*\Bigg[\sup_a \big\{ -h(X_1)\varphi(x,X_1;a) + \beta\varphi(x,X_1;a)V(X_1)\big\} \;\Big|\; X_0 = x \Bigg]$$

$$= V(x).$$

By induction, $\mathcal{L}_h^n V \leq V$, and so taking the limit as $n \to \infty$ leads to the conclusion that $g_h^* \leq V$. □

As in the finite-horizon case, we can ask about possible recursive methods for generating a better approximation to the solution from an existing one. The following result, proved only under rather restrictive conditions, shows that something can be done.

PROPOSITION 2. *Suppose that f is uniformly bounded, that*

$$B \equiv \sup_{x,x',a} \varphi(x,x';a) < \infty,$$

and that β is so small that

$$\frac{\beta(1+B)}{1-\beta B} < 1.$$

Then the sequence $(g_n)_{n=0}^{\infty}$ generated by taking an arbitrary $g_0 \in L^\infty(\mathcal{X})$ and letting g_{n+1} be the unique fixed point of $\mathcal{L}_{\beta g_n}$ converges to the value function.

Proof. The relation linking g_{n+1} and g_n can be expressed as

$$g_{n+1}(x) = E^*\Bigg[\sup_a \big\{ f(x,a) - \beta g_n(X_1)(X_1)\varphi(x,X_1;a) + \beta P g_n(x,a) + \beta\varphi(x,X_1;a)g_{n+1}(X_1)\big\} \;\Big|\; X_0 = x \Bigg].$$

If we set $\Delta_n \equiv \sup_x |g_n(x) - g_{n-1}(x)|$, then this leads to

$$g_{n+1}(x) \leq E^*\Bigg[\sup_a \big\{ f(x,a) - \beta g_{n-1}(X_1)(X_1)\varphi(x,X_1;a) + \beta P g_{n-1}(x,a) + \beta(1+B)\Delta_n + \beta\varphi(x,X_1;a)g_{n+1}(X_1)\big\} \;\Big|\; X_0 = x \Bigg],$$

so if we set $\tilde{g}_{n+1} \equiv g_{n+1} + A$, we have

$$\tilde{g}_{n+1}(x) + A \le E^*\Bigg[\sup_a \big\{ f(x,a) - \beta g_{n-1}(X_1)(X_1)\varphi(x,X_1;a) + \beta P g_{n-1}(x,a) + \beta(1+B)\Delta_n + \beta\varphi(x,X_1;a)(\tilde{g}_{n+1}(X_1) + A)\big\} \;\Big|\; X_0 = x\Bigg]$$

$$\le E^*\Bigg[\sup_a \big\{ f(x,a) - \beta g_{n-1}(X_1)(X_1)\varphi(x,X_1;a) + \beta P g_{n-1}(x,a) + \beta(1+B)\Delta_n + \beta BA + \beta\varphi(x,X_1;a)\tilde{g}_{n+1}(X_1)\big\} \;\Big|\; X_0 = x\Bigg].$$

Taking

$$A \equiv \frac{\beta(1+B)\Delta_n}{1-\beta B}$$

gives us

$$\tilde{g}_{n+1}(x) \le E^*\Bigg[\sup_a \big\{ f(x,a) - \beta g_{n-1}(X_1)(X_1)\varphi(x,X_1;a) + \beta P g_{n-1}(x,a) + \beta\varphi(x,X_1;a)\tilde{g}_{n+1}(X_1)\big\} \;\Big|\; X_0 = x\Bigg],$$

from which we conclude that $\tilde{g}_{n+1} \equiv g_{n+1} - A \le g_n$. A similar argument for the lower bound gives

$$\Delta_{n+1} \le \frac{\beta(1+B)}{1-\beta B}\,\Delta_n,$$

and the result follows. □

Remarks. Proposition 2 shows how we may recursively construct approximations to the solution using this methodology, provided the discount factor β is small enough. The assumptions of Proposition 2 are unlikely to be satisfied in most applications, but at least the methodology can be tried; the conditions are sufficient but not necessary!

5. Conclusions. This paper has presented a novel strategy for solving stochastic optimal control problems by using duality ideas. This approach is completely general, but is particularly well suited to problems where the state space is so large that it is hard to determine where the value function should be closely approximated. The methodology involves modifying the objective by adding in appropriate martingale differences and then carrying out a *pathwise* optimization, an approach that is well suited to Monte Carlo evaluation. We have shown that under suitable regularity conditions, a recursive method for improving the martingale difference sequence converges to the true solution.

Choosing the martingale difference sequence well is of course key to the success of the method, but there remain important issues in performing the simulations and related calculations in an efficient manner. The whole study of numerical implementation has barely begun.

Appendix A. Links to the occupation measure approach. The approach of Theorem 1 is in some sense a dual approach, but how is it related to another dual approach, the occupation measure approach, as explained and studied in [10], [3], [8]? In this approach, the original optimization problem is re-expressed as

$$\sup_{(\mu_t),(\kappa_t)} \sum_{t=0}^{T} \int_{\mathcal{X}} \mu_t(dx) \int_A \kappa_t(x,da) f_t(x,a) \tag{A1}$$

subject to the constraints

$$\mu_0(dx) = \delta_{x_0}(dx), \tag{A2}$$

$$\mu_{t+1}(dx) = \int_{\mathcal{X}} \mu_t(dx') \int_A \kappa_t(x',da) p(x',x;a) m(dx), \quad (t = 0,\dots,T-1), \tag{A3}$$

where we write $f_T(x,a) \equiv F(x)$, and each of the measures μ_t is a probability measure, and κ_t is a Markov kernel from $\mathcal{X}$ into A for each t.

The interpretation of this is that μ_t is the law of the controlled process at time t under controls given by the Markov kernels κ_t; frequently, the Markov kernels will be degenerate, in the sense that $\kappa_t(x,da) = \delta_{\alpha(t,x)}(da)$ for all t,x, but this formulation allows randomized decision rules also.

Introducing Lagrangian multiplier functions $v_t : \mathcal{X} \to \mathbb{R}$ for each $t = 0,\dots,T$ changes the optimization problem into the Lagrangian form

$$\begin{aligned}
&\sup_{\mu_t,\kappa_t \geq 0} \Bigg[v_0(x_0) + \sum_{t=0}^{T-1} \int_{\mathcal{X}} \mu_t(dx) \Bigg\{ -v_t(x) + \int_A \kappa_t(x,da) f_t(x,a) \\
&\qquad + \int_A \kappa_t(x,da) P v_{t+1}(x,a) \Bigg\} + \int_{\mathcal{X}} \mu_T(dx) \int_A \kappa_T(x,da) \{F(x) - v_T(x)\} \Bigg] \\
&= \sup_{\mu_t,\kappa_t \geq 0} \Bigg[v_0(x_0) + \sum_{t=0}^{T-1} \int_{\mathcal{X}} \mu_t(dx) \int_A \kappa_t(x,da) \big\{ -v_t(x) + f_t(x,a) + P v_{t+1}(x,a) \big\} \\
&\qquad + \int_{\mathcal{X}} \mu_T(dx) \{F(x) - v_T(x)\} \Bigg].
\end{aligned}$$

We deduce the dual-feasibility conditions

$$v_t(x) \geq f_t(x,a) + P v_{t+1}(x,a) \quad (x \in \mathcal{X}, a \in A, t = 0,\dots,T-1), \tag{A4}$$

$$v_T(x) \geq F(x), \tag{A5}$$

and the dual problem is now to minimize $v_0(x_0)$ subject to (A4), (A5). These conditions are obviously equivalent to

$$v_t(x) \geq \sup_{a \in A} \big\{ f_t(x,a) + P v_{t+1}(x,a) \big\} \equiv (\mathcal{L}v)_t(x) \quad (x \in \mathcal{X}, t = 0,\dots,T-1), \tag{A6}$$

$$v_T(x) \geq F(x), \tag{A7}$$

which are solved by taking $v_T = F$, and $v_t = (\mathcal{L}v)_t$ for $0 \leq t < T$—the Bellman equations. The value of the dual problem is also evidently equal to the value of the

primal problem. However, it will often be the case that the operations involved in the Bellman equations (taking expectations; pointwise maximization) will be hard to do numerically, so casting the dual problem in Lagrangian form gives us

$$L(\{g_t\}) \equiv \inf_{(v_t)} \left\{ v_0(x_0) + \sum_{t=0}^{T-1} \int g_t(x)\{(\mathcal{L}v)_t(x) - v_t(x)\}\, m(dx) \right\}$$

for nonnegative multiplier functions (g_t). The dual form of this programming problem is

$$\sup_{g_t \geq 0} L(\{g_t\}) \leq V_0(x_0),$$

and (9) is the same expression, for a particular choice of the multipliers (g_t), attaining the value.

ANALYSIS OF THE SQP-METHOD FOR OPTIMAL CONTROL PROBLEMS GOVERNED BY THE NONSTATIONARY NAVIER–STOKES EQUATIONS BASED ON L^p-THEORY*

DANIEL WACHSMUTH†

Abstract. The aim of this article is to present a refined convergence theory of the SQP-method applied to optimal control problems for the nonstationary Navier–Stokes equations. We will employ a second-order sufficient optimality condition, which requires that the second derivative of the Lagrangian is positive definite on a subspace of inactive constraints. Therefore, we have to use the L^p-theory of optimal controls of the nonstationary Navier–Stokes equations rather than Hilbert space methods. Estimates of state and adjoint equations with respect to L^p-norms are provided. Finally, the local convergence of the SQP-method is confirmed by numerical tests.

Key words. optimal control, Navier–Stokes equations, control constraints, Lipschitz stability, SQP-method

1. Introduction.

We are considering the optimal control of the nonstationary Navier–Stokes equations. As a model problem we minimize the following quadratic objective functional J:

$$J(y,u) = \frac{\alpha_T}{2}\int_\Omega |y(x,T)-y_T(x)|^2dx + \frac{\alpha_Q}{2}\int_Q |y(x,t)-y_Q(x,t)|^2dxdt + \frac{\alpha_R}{2}\int_Q |\operatorname{curl} y(x,t)|^2dxdt + \frac{\gamma}{2}\int_Q |u(x,t)|^2dxdt \tag{1.1}$$

subject to the nonstationary Navier–Stokes equations

$$\begin{aligned} y_t - \nu\Delta y + (y\cdot\nabla)y + \nabla p &= u && \text{in } Q,\\ \operatorname{div} y &= 0 && \text{in } Q,\\ y(0) &= y_0 && \text{in } \Omega, \end{aligned} \tag{1.2}$$

and the control constraints $u \in U_{ad}$ with a set of admissible controls defined by

$$U_{ad} = \{u \in L^2(Q)^2 :\ u_{a,i}(x,t) \le u_i(x,t) \le u_{b,i}(x,t) \text{ a.e. on } Q,\ i=1,2\}.$$

Here, Ω is an open bounded subset of $\mathbb{R}^2$ with a C^3-boundary Γ such that Ω is locally on one side of Γ, and Q is defined by $Q = \Omega\times(0,T)$. Further, functions $y_T \in L^2(\Omega)^2$, $y_Q \in L^2(Q)^2$, and $y_0 \in H \subset L^2(\Omega)^2$ are given. The parameters γ and ν are positive real numbers. The bounds u_a, u_b are required to be in $L^2(Q)^2$ with $u_{a,i}(x,t) \le u_{b,i}(x,t)$ a.e. on Q, $i=1,2$.

Control of the nonstationary Navier–Stokes flow has been studied very intensively since the pioneering work [1]. Necessary as well as sufficient optimality conditions

were established; cf. [8, 9, 16, 17, 27]. The optimality system can be used to derive regularity properties of optimal controls. It was proved that under certain regularity assumptions a locally optimal control of the problem (1.1) is a continuous function in space and time; cf. [29].

The aim of this article is the presentation of a convergence theory of the SQP-method to solve the optimization problem (1.1). This method is widely applied to solve finite dimensional as well as function space optimization problems. If a stability result is available, one can prove local convergence of the SQP-method using the concept of strongly regular generalized equations [21]. The first convergence result in the context of optimal control of partial differential equations was given in [26]. A convergence proof for the SQP-method applied to constrained optimal control problems of the Navier–Stokes equations was given in [13]. However, the convergence was proved under a strong second-order sufficient optimality condition: the second derivative of the Lagrangian was required to be coercive for all control test functions.

We will prove quadratic convergence of the SQP-method in an L^∞-neighborhood of a reference control, which has to fulfill a second-order sufficient optimality condition. In contrast to the approaches in [13, 17], we require that the second derivative of the Lagrangian is positive definite only on a subspace associated with inactive constraints. Furthermore, we get convergence of the control iterates with respect to the L^∞-norm, whereas the convergence theory of [13, 17] gives convergence in weaker, say, L^q-norms, with $q < 7/2$.

The semismooth Newton method is another method to tackle nonlinear optimal control problems. It was applied to optimal control problems for nonstationary Navier–Stokes equations in [28]. Under the assumption of a strong sufficient optimality condition, locally superlinear convergence was proved. Applying the regularity results of our article, it is possible to prove convergence of that method under the weaker coercivity assumptions involving strongly active constraints.

The outline of the paper is as follows. In section 2, we will introduce some notation and state common results concerning solvability of the nonstationary Navier–Stokes system (1.2). Sections 3 and 4 contain a brief overview of optimality conditions including first-order necessary and second-order sufficient conditions. In section 5, the SQP-method is considered. The main result of the article—local convergence of SQP—is stated and proved in section 5.3. Numerical results confirming the convergence theory are presented in section 6. The required regularity results for the linearized Navier–Stokes equation and the adjoint equation can be found in sections 2.2 and 3.1. Throughout the article, we investigate the theory of optimal controls of the nonstationary Navier–Stokes equations in the L^p-space context.

2. Notation and preliminary results. Here, we will restrict ourselves to the two-dimensional case, $n = 2$. First, we introduce some notation and provide some results that we will need later on.

To begin with, we define the spaces of solenoidal functions

$$H_p := \{v \in L^p(\Omega)^2 : \operatorname{div} v = 0\}, \qquad V_p := \{v \in W_0^{1,p}(\Omega)^2 : \operatorname{div} v = 0\}.$$

Here, p denotes an arbitrary exponent $p \geq 2$. These spaces are Banach spaces with their norms denoted by $|\cdot|_p$ and $|\cdot|_{1,p}$, respectively. For $p = 2$, we get the frequently used solenoidal spaces $H := H_2$ and $V := V_2$, which are Hilbert spaces with scalar products $(\cdot,\cdot)_H$ and $(\cdot,\cdot)_V$, respectively. The dual of V with respect to the scalar product of H is denoted by V' with the duality pairing $\langle\cdot,\cdot\rangle_{V',V}$.

We shall work in the standard space of abstract functions from $[0,T]$ to a real Banach space X, $L^p(0,T;X)$, endowed with its natural norm,

$$\|y\|_{L^p(X)} := \|y\|_{L^p(0,T;X)} = \left(\int_0^T |y(t)|_X^p dt\right)^{1/p}, \quad 1 \le p < \infty,$$
$$\|y\|_{L^\infty(X)} := \operatorname*{vrai\,max}_{t\in(0,T)} |y(t)|_X.$$

In what follows, we will identify the spaces $L^p(0,T;L^p(\Omega)^2)$ and $L^p(Q)^2$ for $1 < p < \infty$, and denote their norm by $\|u\|_p := |u|_{L^p(Q)^2}$. We denote by $(\cdot,\cdot)_Q$ the usual $L^2(Q)^2$-scalar product to avoid ambiguity.

In all what follows, $\|\cdot\|$ stands for norms of abstract functions, while $|\cdot|$ denotes norms of "stationary" spaces such as H and V.

To deal with the time derivative in (1.2), we introduce the common spaces of functions y, whose time derivatives y_t exist as abstract functions

$$W^\alpha(0,T;V) := \{y \in L^2(0,T;V) :\ y_t \in L^\alpha(0,T;V')\}, \quad W(0,T) := W^2(0,T;V),$$

where $1 \le \alpha \le 2$. Endowed with the norm

$$\|y\|_{W^\alpha} := \|y\|_{W^\alpha(0,T;V)} = \|y\|_{L^2(V)} + \|y_t\|_{L^\alpha(V')},$$

these spaces are Banach spaces (respectively, Hilbert spaces) in the case of $W(0,T)$. Every function of $W(0,T)$ is, up to changes on sets of zero measure, equivalent to a function of $C([0,T],H)$, and the imbedding $W(0,T) \hookrightarrow C([0,T],H)$ is continuous; cf. [2, 20].

Furthermore, we introduce the following space of abstract functions in the L^p-context:

$$W_p^{2,1} := \{y \in L^p(0,T;W^{2,p}(\Omega)^2 \cap V_p) :\ y_t \in L^p(0,T;L^p(\Omega)^2)\},$$

which is continuously imbedded in $C([0,T], W_0^{2-2/p,\,p}(\Omega)^2)$ (see [19]). Here, $W_0^{2-2/p,\,p}(\Omega)^2$ denotes the space of solenoidal $W^{2-2/p,\,p}$-functions, where zero boundary values are prescribed if $p \ge 4/3$. We abbreviate $H^{2,1} = W_2^{2,1}$ for $p = 2$. Note that in this case we have $W_0^{2-2/2,\,2}(\Omega)^2 = V$.

We define the trilinear form $b : V \times V \times V \mapsto \mathbb{R}$ by

$$b(y,v,w) = ((y\cdot\nabla)v, w)_2 = \int_\Omega \sum_{i,j=1}^2 y_i \frac{\partial v_j}{\partial x_i}\, w_j\, dx.$$

To specify the problem setting, we introduce a linear operator $A : L^2(0,T;V) \mapsto L^2(0,T;V')$ by

$$\int_0^T \langle (Ay)(t),\, v(t)\rangle_{V',V} dt := \int_0^T (y(t), v(t))_V dt,$$

and a nonlinear operator B by

$$\int_0^T \big\langle \big(B(y)\big)(t),\, v(t)\big\rangle_{V',V} dt := \int_0^T b(y(t), y(t), v(t)) dt.$$

B is continuous, for instance, as an operator from $W(0,T)$ to $L^2(0,T;V')$. For convenience, we will use the notation

$$b_Q(y,v,w) = \int_0^T b(y(t), v(t), w(t)) dt.$$

2.1. The state equation. We begin with the investigation of weak solutions for the nonstationary Navier–Stokes equations (1.2) in the Hilbert space setting.

DEFINITION 2.1 (weak solution). *Let $f \in L^2(0,T;V')$ and $y_0 \in H$ be given. A function $y \in L^2(0,T;V)$ with $y_t \in L^2(0,T;V')$ is called a weak solution of* (1.2) *if*

$$\begin{aligned} y_t + \nu A y + B(y) &= f, \\ y(0) &= y_0. \end{aligned} \tag{2.1}$$

Results concerning the solvability of (2.1) are standard; cf. [24] for proofs and further details.

THEOREM 2.2 (existence and uniqueness of solutions). *For every $f \in L^2(0,T;V')$ and $y_0 \in H$,* (2.1) *has a unique solution $y \in W(0,T)$. Moreover, the mapping $(y_0, f) \mapsto y$ is locally Lipschitz continuous from $H \times L^2(0,T;V')$ to $W(0,T)$.*

For more regular data, one expects more regular solutions.

THEOREM 2.3 (regularity). *For the higher regularity of the weak solutions of* (2.1) *the following holds. Let $y_0 \in V$ and $f \in L^2(Q)^2$ be given. Then the weak solution of* (2.1) *fulfills $y \in H^{2,1}$. The solution mapping $(y_0, f) \mapsto y$ is locally Lipschitz continuous between $L^2(Q)^2 \times V$ and $H^{2,1}$.*

For the proof, we refer again to Temam [24]. However, the result was proved there under the additional assumption $f \in L^2(0,T;H)$. A closer inspection of the proof shows that $f \in L^2(Q)^2$ suffices to get $y \in L^2(0,T;H^2(\Omega)^2) \cap L^\infty(0,T;V)$ and $y_t \in L^2(Q)^2$. Then the regularity $y_t \in L^2(0,T;H)$ follows by density arguments.

Now, we want to specify the notation of a solution of (2.1) in the L^p-context.

DEFINITION 2.4 (strong solution in L^p). *Let $f \in L^p(Q)^2$ and $y_0 \in W_0^{2-2/p,\,p}(\Omega)^2$ be given. A function $y \in W_p^{2,1}$ is called a strong solution to the exponent $p > 2$ of* (1.2) *if there holds*

$$-\int_0^T (y, \phi')dt + \nu \int_0^T (\nabla y, \nabla \phi)dt + \int_0^T b(y,y,\phi) = \int_0^T (f,\phi)dt + (y_0, \phi(0)) \tag{2.2}$$

for all test functions $\phi \in L^q(0,T;V_q)$ with $\phi_t \in L^q(0,T;L^q(\Omega)^2)$ and $\phi(T) = 0$, where q is the dual exponent to p, $1/q + 1/p = 1$.

Here the space $W_0^{2-2/p,\,p}(\Omega)^2$ is the natural trace space. Every abstract function of $L^p(0,T;W^{2,p}(\Omega)^2)$ with a time derivative in $L^p(0,T;L^p(\Omega)^2)$ is—after changes on a zero measure set—continuous with values in this space [19]. Obviously, every strong L^p-solution is a weak solution. For existence of L^p-solutions we have the following theorem.

THEOREM 2.5 (L^p-solutions). *Let $f \in L^p(Q)^2$ and $y_0 \in W_0^{2-2/p,\,p}(\Omega)^2$ be given with $p \geq 2$. Then the weak solution y of* (2.1) *in the sense of Definition* 2.1 *is a strong solution and satisfies $y \in W_p^{2,1}$. There exists a constant $c > 0$ such that*

$$\|y\|_{W_p^{2,1}} \leq c\left\{|y_0|_{W^{2-2/p,\,p}} + \|f\|_p\right\}.$$

Moreover, the mapping $(f, y_0) \mapsto y$ is locally Lipschitz continuous, and hence the strong solution y is unique.

If $p = 2$, this result reduces to Theorem 2.3. For the non-Hilbert space case $p > 2$, existence and regularity was proved in [30]. Lipschitz continuity for this case is a conclusion of the estimates in the next section.

2.2. Linearized equation. In the course of the article, we will need a similar existence and regularity result for the linearized Navier–Stokes equations. Let a function $\bar{y} \in L^p(0,T;W^{2,p}(\Omega)^2) \cap L^\infty(0,T;W_0^{2-2/p,\,p}(\Omega)^2)$ be given. Then we are looking for solutions of the linearized system

$$\begin{aligned} y_t + \nu Ay + B'(\bar{y})y &= f, \\ y(0) &= y_0. \end{aligned} \tag{2.3}$$

We will show that this system admits a unique solution, which belongs to the space $W_p^{2,1}$ and depends continuously on the data.

To this end, we will rely on a regularity result for the nonstationary Stokes equations,

$$\begin{aligned} y_t + \nu Ay &= f, \\ y(0) &= y_0. \end{aligned} \tag{2.4}$$

Concerning L^p-solutions, the following result is due to Solonnikov [22] for the two- and three-dimensional cases; in [30] it was generalized to arbitrary spatial dimensions.

THEOREM 2.6. *Let $p > 1$, $p \neq 3/2$, $y_0 \in W_0^{2-2/p,\,p}(\Omega)^2$, $f \in L^p(Q)^2$. Then there exists a unique weak solution y of (2.4) satisfying $y \in W_p^{2,1}$. Furthermore, there exists a constant $c > 0$ such that the estimate*

$$\|y_t\|_p + \|y\|_{L^p(W^{2,p})} \leq c\left\{\|f\|_p + |y_0|_{W^{2-2/p,\,p}}\right\}$$

is satisfied.

Now, we can prove the regularity result for the linearized system. A similar result can be found in [23], where equations with the linear term $(\bar{y}\cdot\nabla)y$ instead of $B'(\bar{y})y = (\bar{y}\cdot\nabla)y + (y\cdot\nabla)\bar{y}$ are studied.

THEOREM 2.7. *Let $\bar{y} \in L^p(0,T;W^{2,p}(\Omega)^2) \cap L^\infty(0,T;W_0^{2-2/p,\,p}(\Omega)^2)$, $f \in L^p(Q)^2$, and $y_0 \in W_0^{2-2/p,\,p}(\Omega)^2$ be given with $2 \leq p < \infty$. Then the system (2.3) has a unique solution $y \in W_p^{2,1}$. Moreover, there is a constant $c > 0$ independent of f and y_0 such that the following estimate holds:*

$$\|y\|_{W_p^{2,1}} \leq c\left\{\|f\|_p + |y_0|_{W^{2-2/p,\,p}}\right\}. \tag{2.5}$$

Proof. Step 1. $p = 2$. The existence of a unique weak solution together with the estimate in the case $p = 2$ was proved in [17]. Let us write the system (2.3) in a slightly modified form,

$$\begin{aligned} y_t + \nu Ay &= f - B'(\bar{y})y, \\ y(0) &= y_0, \end{aligned} \tag{2.6}$$

to estimate y in terms of f, $B'(\bar{y})y$, and y_0. Here, we want to apply the regularity result of Theorem 2.6. To this end, we have to estimate the L^p-norm of the right-hand side of (2.6) for different values of p. The proof is then carried out using bootstrapping arguments.

Step 2. $2 < p < 4$. From the previous step, we know the existence of a unique weak solution $y \in W_2^{2,1}$ of (2.3). Let us investigate $B'(\bar{y})y = (y\cdot\nabla)\bar{y} + (\bar{y}\cdot\nabla)y$.

By assumption, we have $\bar{y} \in L^\infty(0,T;W_0^{2-2/p,\,p}(\Omega)^2)$. The space $W_0^{2-2/p,\,p}(\Omega)^2$ is continuously imbedded in $W^{1,q}(\Omega)^2$ for $q = \frac{2p}{4-p}$, $p < 4$; cf. [2, 25]. Furthermore,

the space V is continuously imbedded in $L^{q'}(\Omega)^2$ for $q' < \infty$. Applying Hölder's inequality with $\frac{1}{p} = \frac{1}{q} + \frac{1}{q'}$, we obtain

$$\|(y \cdot \nabla)\bar{y}\|_p \le c\|y\|_{L^\infty(L^{q'})}\|\bar{y}\|_{L^\infty(W^{1,q})} \le c\|y\|_{L^\infty(V)}\|\bar{y}\|_{L^\infty(W^{2-2/p,\,p})}. \tag{2.7}$$

The estimation of the second addend of $B'(\bar{y})y$ needs a bit more effort. Using the interpolation identity

$$[W^{2,2}(\Omega)^2, W^{1,2}(\Omega)^2]_\theta = W^{2-2/p,\,2}(\Omega)^2, \quad \theta = 1 - 2/p,$$

and the imbedding $W^{2-2/p,\,2}(\Omega)^2 \hookrightarrow W^{1,p}(\Omega)^2$, we find a.e. on $[0,T]$

$$|y(t)|^p_{W^{1,p}} \le c|y(t)|^p_{W^{2-2/p,\,2}} \le c|y(t)|^{p-2}_{W^{2,2}}|y(t)|^2_{W^{1,2}}.$$

Integrating with respect to the time variable yields

$$\|y\|^p_{L^p(W^{1,p})} \le c\|y\|^{p-2}_{L^{p-2}(W^{2,2})}\|y\|^2_{L^\infty(V)} \le c\|y\|^{p-2}_{L^2(W^{2,2})}\|y\|^2_{L^\infty(V)} \le c\|y\|^p_{W_2^{2,1}} \tag{2.8}$$

provided $p \le 4$. Also, we can derive

$$\|(\bar{y} \cdot \nabla)y\|_p \le c\|\bar{y}\|_\infty\|y\|_{L^p(W^{1,p})}. \tag{2.9}$$

Collecting (2.7)–(2.9), we find

$$\|B'(\bar{y})y\|_p \le c\|\bar{y}\|_{W_p^{2,1}}\|y\|_{W_2^{2,1}} \le c\|\bar{y}\|_{W_p^{2,1}}\left\{\|f\|_2 + |y_0|_V\right\}.$$

Now, we can utilize Theorem 2.6 to obtain the solution estimate

$$\begin{aligned}\|y\|_{W_p^{2,1}} &\le c\left\{\|f\|_p + |y_0|_{W^{2-2/p,\,p}} + \|B'(\bar{y})y\|_p\right\}\\ &\le c\left\{\|f\|_p + |y_0|_{W^{2-2/p,\,p}}\right\} + c\|\bar{y}\|_{W_p^{2,1}}\left\{\|f\|_2 + |y_0|_V\right\}\\ &\le c(1 + \|\bar{y}\|_{W_p^{2,1}})\left\{\|f\|_p + |y_0|_{W^{2-2/p,\,p}}\right\}.\end{aligned}$$

Thus, the (weak) solution y is of class $W_p^{2,1}$. Using density arguments, it is easy to verify that y is also a strong solution. Since every strong solution is a weak solution, and weak solutions are unique, it follows that y is the unique strong solution of the linearized system. This completes the proof for exponents $p \in (2,4)$.

Step 3. $4 \le p < \infty$. By Step 2, the solution y of (2.3) is in $W^{2,1}_{4-\varepsilon}$, $0 < \varepsilon \le 2$. It is—after changes on a set of zero measure—continuous with values in the space $W_0^{2-2/(4-\varepsilon),4-\varepsilon}(\Omega)^2$, which is itself continuously imbedded in $L^\infty(\Omega)^2$. Hence, the imbedding of $W^{2,1}_{4-\varepsilon}$ in $L^\infty(Q)^2$ is continuous.

Again, we have to estimate the L^p-norm of $B'(\bar{y})y$. We begin with its first addend, which can be treated as

$$\|(y \cdot \nabla)\bar{y}\|_p \le c\|y\|_\infty\|\nabla\bar{y}\|_p \le c\|y\|_{W^{2,1}_{4-\varepsilon}}\|\bar{y}\|_{W_p^{2,1}}. \tag{2.10}$$

To estimate the second addend of $B'(\bar{y})y$, we observe that for $\varepsilon = \frac{8}{p+2}$ the imbedding

$$W_0^{2-\frac{2}{4-\varepsilon},4-\varepsilon}(\Omega)^2 = W_0^{\frac{3}{2}-\frac{1}{p},\frac{4p}{p+2}}(\Omega)^2 \hookrightarrow W_0^{1,p}(\Omega)^2$$

is continuous. Consequently, we obtain for this choice of ε,

$$y \in W^{2,1}_{4-\varepsilon} \hookrightarrow L^\infty(0,T; W_0^{1,p}(\Omega)^2).$$

Hence, we arrive at

$$\|(\bar{y}\cdot\nabla)y\|_p \le c\|\bar{y}\|_\infty \|y\|_{L^\infty(W^{1,p})} \le c\|\bar{y}\|_{W_p^{2,1}} \|y\|_{W_{4-\varepsilon}^{2,1}}, \tag{2.11}$$

which allows us to conclude by Theorem 2.6,

$$\|y\|_{W_p^{2,1}} \le c(1+\|\bar{y}\|_{W_p^{2,1}})\left\{\|f\|_p + |y_0|_{W^{2-2/p,\,p}}\right\},$$

and the claim is proved for all p in $[2,\infty)$. □

Remark 2.8. The Lipschitz continuity of the solution mapping of the nonstationary Navier–Stokes equations can be proved using the previous lemma. Let data $f_i \in L^p(Q)^2$ and $y_{0,i} \in W_0^{2-2/p,\,p}(\Omega)^2$ be given, with $i = 1, 2$. Denote the associated strong solutions by y_i, $i = 1, 2$. Then the difference $d := y_1 - y_2$ satisfies

$$\begin{aligned} d_t + \nu A d + (y_1\cdot\nabla)d + (d\cdot\nabla)y_2 &= f_1 - f_2, \\ d(0) &= y_{0,1} - y_{0,2}. \end{aligned}$$

With analogous arguments as above, one can verify

$$\|y_1 - y_2\|_{W_p^{2,1}} \le c(1+\|y_1\|_{W_p^{2,1}} + \|y_2\|_{W_p^{2,1}})\left\{\|f_1 - f_2\|_p + |y_{0,1} - y_{0,2}|_{W^{2-2/p,\,p}}\right\},$$

which is the claimed Lipschitz continuity of the solution mapping associated with the nonlinear system.

3. First-order necessary optimality conditions. Now let us return to our optimal control problem. We briefly recall the necessary conditions for local optimality. For the proofs and further discussion see [1, 5, 9, 16, 27] and the references cited therein.

Definition 3.1 (locally optimal control). *A control $\bar{u} \in U_{ad}$ is said to be locally optimal in $L^2(Q)^2$ if there exists a constant $\rho > 0$ such that*

$$J(\bar{y},\bar{u}) \le J(y_\rho, u_\rho)$$

holds for all $u_\rho \in U_{ad}$ with $\|\bar{u} - u_\rho\|_2 \le \rho$. Here, $\bar{y}$ and y_ρ denote the states associated with $\bar{u}$ and u_ρ, respectively.

In the following, we denote by $B'(\bar{y})^*$ the adjoint of $B'(\bar{y})$, given by

$$[B'(\bar{y})^*\lambda]v = \int_Q b(\bar{y}, v, \lambda) + b(v, \bar{y}, \lambda)dt.$$

Theorem 3.2 (necessary condition). *Let $\bar{u}$ be a locally optimal control with associated state $\bar{y} = y(\bar{u})$. Then there exists a unique solution $\bar{\lambda} \in W^{4/3}(0,T;V)$ of the adjoint equation*

$$\begin{aligned} -\bar{\lambda}_t + \nu A\bar{\lambda} + B'(\bar{y})^*\bar{\lambda} &= \alpha_Q(\bar{y} - y_Q) + \alpha_R \vec{\operatorname{curl}}\operatorname{curl}\bar{y}, \\ \bar{\lambda}(T) &= \alpha_T(\bar{y}(T) - y_T). \end{aligned} \tag{3.1}$$

Moreover, the variational inequality

$$(\gamma\bar{u} + \bar{\lambda}, u - \bar{u})_{L^2(Q)^2} \ge 0 \quad \forall u \in U_{ad} \tag{3.2}$$

is satisfied.

Proofs can be found in [9, 10, 27]. The regularity of $\bar{\lambda}$ is proved in [17].

The variational inequality (3.2) can be reformulated equivalently in different ways. First, let us introduce the normal cone $N_{U_{ad}}(\bar u)$ of the set of admissible controls at a given control $\bar u$, which is defined by

$$N_{U_{ad}}(\bar u) = \begin{cases} \{ z \in L^2(Q)^2 : \ (z, u - \bar u)_2 \le 0 \ \forall u \in U_{ad} \} & \text{if } \bar u \in U_{ad}, \\ \emptyset & \text{otherwise.} \end{cases} \tag{3.3}$$

Then the variational inequality (3.2) can be written equivalently as the inclusion

$$\gamma \bar u + \bar\lambda + N_{U_{ad}}(\bar u) \ni 0. \tag{3.4}$$

This representation fits into the context of generalized equations (see, for instance, [13, 29]), and will be utilized in the course of the article.

Second, the variational inequality

$$(\gamma \bar u_i(x,t) + \bar\lambda_i(x,t)) \cdot (u - \bar u_i(x,t)) \ge 0 \quad \forall u \in [u_{a.i}(x,t), u_{b.i}(x,t)]$$

has to be fulfilled pointwise a.e. on Q for $i = 1, 2$. This is in turn equivalent to the projection representation of the optimal control

$$\bar u_i(x,t) = \mathrm{Proj}_{[u_{a,i}(x,t), u_{b,i}(x,t)]} \left(-\frac{1}{\gamma} \bar\lambda_i(x,t) \right) \qquad \text{a.e. on } Q,\ i = 1, 2. \tag{3.5}$$

With this formula, one can see that a locally optimal control inherits some regularity from the associated adjoint state. This form is also used in connection with Lipschitz stability of optimal controls, see section 5.2 below.

3.1. Adjoint equation. The adjoint state λ is the solution of a linearized adjoint equation backward in time. So it is natural to look for its dependence on the given data. The existence of L^p-solutions of the adjoint equation is the topic of the next theorem.

THEOREM 3.3. *Let $y_Q \in L^p(Q)^2$ and $y_T \in W_0^{2-2/p,\,p}(\Omega)^2$ be given with $p \ge 2$. If $\bar y \in L^p(0,T; W^{2,p}(\Omega)^2) \cap L^\infty(0,T; W_0^{2-2/p,\,p}(\Omega)^2)$, then the weak solution λ of (3.1) is a strong solution and satisfies $\lambda \in W_p^{2,1}$. Moreover, the adjoint λ depends continuously on the given data y_Q, y_T, $\bar y$.*

Proof. The result in the case $p = 2$ was proved in [17, Prop. 2.4] for the homogeneous final value $\lambda(T) = 0$. It can be extended to the inhomogeneous case using known results for the nonstationary Stokes system.

Let us sketch the proof for the case $p > 2$. For simplicity, we define $f := \alpha_Q(\bar y - y_Q) + \alpha_R \vec{\mathrm{curl}}\, \mathrm{curl}\, \bar y$ and $\lambda_T := \alpha_T(\bar y(T) - y_T)$. Under the assumptions of the theorem, we know that $f \in L^p(Q)^2$ and $\lambda_T \in W_0^{2-2/p,\,p}(\Omega)^2$. Now, we will investigate the system

$$\begin{aligned} -\lambda_t + \nu A\lambda + B'(\bar y)^* \lambda &= f, \\ \lambda(T) &= \lambda_T. \end{aligned} \tag{3.6}$$

Via the transformations $w(t) = \lambda(T - t)$, $\hat y(t) = \bar y(T - t)$, $g(t) = f(T - t)$, $w_0 = \lambda_T$, this system is carried over in the forward-in-time equation

$$\begin{aligned} w_t + \nu A w + B'(\hat y)^* w &= g, \\ w(0) &= w_0. \end{aligned} \tag{3.7}$$

Obviously, $\hat{y}, g, w_0$ inherits their regularity from $\bar{y}, f, \lambda_T$. Hence, the adjoint state λ has the same regularity as the auxiliary state w. The proof is finished if the next lemma is verified. ∎

LEMMA 3.4. *Let $\hat{y} \in L^p(0,T;W^{2,p}(\Omega)^2) \cap L^\infty(0,T;W_0^{2-2/p,\,p}(\Omega)^2)$, $g \in L^p(Q)^2$, and $w_0 \in W_0^{2-2/p,\,p}(\Omega)^2$ be given with $2 \le p < \infty$. Then the system (3.6) has a unique solution $w \in W_p^{2,1}$. Moreover, there is a constant $c > 0$ independent of g and w_0 such that the following estimate is true:*

$$\|w\|_{W_p^{2,1}} \le c\left\{\|g\|_p + |w_0|_{W^{2-2/p,\,p}}\right\}.$$

Proof. The proof is very similar to the proof of Theorem 2.7. Therefore, we will briefly repeat its steps. First, let us investigate the action of $B'(\hat{y})^* w$ on a test function $v \in W(0,T)$:

$$\begin{aligned}[B'(\hat{y})^* w]v &= b_Q(\hat{y}, v, w) + b_Q(v, \hat{y}, w) = -b_Q(\hat{y}, w, v) + b_Q(v, \hat{y}, w)\\ &= \sum_{i,j=1}^{2} \int_Q \left(-\hat{y}_i(x,t)\frac{\partial w_j(x,t)}{\partial x_i} v_j(x,t) + v_i(x,t)\frac{\partial \hat{y}_j(x,t)}{\partial x_i} w_j(x,t)\right) dxdt\\ &= \int_0^T [-(\hat{y}\cdot\nabla)w + (\nabla\hat{y})^T w]\cdot v\, dt.\end{aligned}$$

Here, we used the identity $b_Q(y,v,w) = -b_Q(y,w,v)$, which holds for functions $y, v, w \in L^2(0,T;V)$ [24]. Consequently, we are allowed to identify the functional $B(\hat{y})^* w$ with the function $-(\hat{y}\cdot\nabla)w + (\nabla\hat{y})^T w$. For $\hat{y}, w \in H^{2,1}$ we find $-(\hat{y}\cdot\nabla)w + (\nabla\hat{y})^T w \in L^2(Q)^2$.

Step 1. $p = 2$. The result for $p = 2$ was proved, for instance, in [17].

Step 2. $2 < p < 4$. With the help of (2.7)–(2.9), we conclude that

$$\|B'(\hat{y})^* w\|_p \le c\left(\|\hat{y}\|_\infty \|w\|_{W_2^{2,1}} + \|\hat{y}\|_{L^\infty(W^{2-2/p,\,p})}\|w\|_{L^\infty(V)}\right).$$

Then Theorem 2.6 gives us the boundedness of the solution w in $W_p^{2,1}$.

Step 3. $4 \le p < \infty$. Let $w \in W_{4-\varepsilon}^{2,1}$ be the strong solution of Step 2, $0 < \varepsilon < 2$. Analogously as in (2.10) and (2.11), we find

$$\|B'(\hat{y})^* w\|_p \le c\|\hat{y}\|_{W_p^{2,1}} \|w\|_{W_{4-\varepsilon}^{2,1}},$$

and the claim follows immediately. ∎

3.2. Lagrange functional. Let us introduce the Lagrange function

$$\mathcal{L} : W(0,T) \times L^2(Q)^2 \times W^{4/3}(0,T) \mapsto \mathbb{R}$$

for the optimal control problem as follows:

$$\mathcal{L}(y,u,\lambda) = J(u,y) - \left\{\langle y_t,\, \lambda\rangle_{L^2(V'),L^2(V)} + \nu(y,\lambda)_{L^2(V)} + b_Q(y,y,\lambda) - (u,\lambda)_Q\right\}.$$

This function is twice Fréchet-differentiable with respect to $(y,u) \in W(0,T)\times L^2(Q)^2$; cf. [27]. The reader can readily verify that the necessary conditions can be expressed equivalently by

$$\begin{gathered}\mathcal{L}_y(\bar{y},\bar{u},\bar{\lambda})\, h = 0 \quad \forall h \in W(0,T) \text{ with } h(0) = 0,\\ \mathcal{L}_u(\bar{y},\bar{u},\bar{\lambda})(u-\bar{u}) \ge 0 \quad \forall u \in U_{ad}.\end{gathered}$$

Here, $\mathcal{L}_y$, $\mathcal{L}_u$ denote the partial Fréchet-derivative of $\mathcal{L}$ with respect to y and u.

In what follows we denote the pair of state and control (y, u) by v for convenience. The second derivative of the Lagrangian $\mathcal{L}$ at $y \in W(0,T)$ with associated adjoint state λ in the directions $v_1 = (w_1, h_1)$, $v_2 = (w_2, h_2) \in W(0,T) \times L^2(Q)^2$ is given by

$$\mathcal{L}_{vv}(y,u,\lambda)[v_1,v_2] = \mathcal{L}_{yy}(y,u,\lambda)[w_1,w_2] + \mathcal{L}_{uu}(y,u,\lambda)[h_1,h_2] \tag{3.8}$$

with

$$\begin{aligned}\mathcal{L}_{yy}(y,u,\lambda)[w_1,w_2] = \alpha_T(w_1(T),w_2(T))_H + \alpha_Q(w_1,w_2)_Q + \alpha_R(\operatorname{curl} w_1, \operatorname{curl} w_2)_Q \\ - b_Q(w_1,w_2,\lambda) - b_Q(w_2,w_1,\lambda)\end{aligned}$$

and

$$\mathcal{L}_{uu}(y,u,\lambda)[h_1,h_2] = \gamma(h_1,h_2)_2.$$

It can be verified that it satisfies the estimate

$$|\mathcal{L}_{yy}(y,u,\lambda)[w_1,w_2]| \le c\left(1 + \|\lambda\|_{L^2(V)}\right)\|w_1\|_{W(0,T)}\|w_2\|_{W(0,T)} \tag{3.9}$$

for all $w_1, w_2 \in W(0,T)$. To shorten notation, we abbreviate $[v,v]$ by $[v]^2$, i.e.,

$$\mathcal{L}_{vv}(\bar v,\bar\lambda)[(w,h)]^2 := \mathcal{L}_{vv}(\bar v,\bar\lambda)[(w,h),(w,h)].$$

4. Second-order sufficient optimality condition. Let $\bar v := (\bar y, \bar u)$ be an admissible reference pair satisfying the first-order necessary optimality conditions.

Definition 4.1 (strongly active sets). *Let $\varepsilon > 0$ and $i \in \{1,2\}$ be given. Define sets $Q_{\varepsilon,i} \subseteq Q = \Omega \times [0,T]$ by*

$$Q_{\varepsilon,i} = \{(x,t) \in Q : |\gamma \bar u_i(x,t) + \bar\lambda_i(x,t)| > \varepsilon\}.$$

We assume further that the reference pair $\bar v = (\bar y, \bar u)$ satisfies the following coercivity assumption on $\mathcal{L}''(\bar v, \bar\lambda)$; in what follows, this is called the second-order sufficient condition:

(SSC)
There exist $\varepsilon > 0$ and $\delta > 0$ such that

$$\mathcal{L}_{vv}(\bar v,\bar\lambda)[(w,h)]^2 \ge \delta\,\|h\|_2^2$$

holds for all pairs $(w,h) \in W(0,T) \times L^2(Q)^2$ with

$$h = u - \bar u,\ u \in U_{ad},\ h_i = 0 \text{ on } Q_{\varepsilon,i} \text{ for } i = 1,2,$$

and $w \in W(0,T)$ being the weak solution of the linearized equation

$$\begin{aligned} w_t + Aw + B'(\bar y)w &= h, \\ w(0) &= 0. \end{aligned}$$

The sufficiency of (SSC) was proved in [27]: An admissible control that satisfies the first-order necessary conditions together with (SSC) is locally optimal in $L^\infty(Q)^2$. Observe that $\mathcal{L}''$ has to be positive definite only on the subspace of control variations that are zero on the set of strongly active constraints. We will show that for a control $\bar u$ satisfying (SSC), the SQP-method started in a neighborhood of $\bar u$ will indeed converge to that local solution.

5. SQP-method. In this section, we consider the SQP-method to compute a local optimum of the control problem (1.2). It is a well-known method, applied very often to optimal control problems of partial differential equations; see, e.g., [13, 26]. For the analysis of other local methods such as (quasi-) Newton and semismooth Newton methods in connection with nonstationary Navier–Stokes equations, we refer to [17, 28].

The SQP-method solves in every step a linear-quadratic optimal control problem (P^n). Given starting values y_n, u_n, λ_n, it computes the next iterates $y_{n+1}, u_{n+1}, \lambda_{n+1}$ as the minimizers of

$$J^n(y,u) = J(y_n,u_n) + \nabla J(y_n,u_n)(y-y_n,u-u_n) + \frac{1}{2}\mathcal{L}_{vv}(y_n,u_n,\lambda_n)[(y-y_n,u-u_n)]^2$$

subject to the linearized state equation

$$\begin{aligned} y_t + \nu Ay + B'(y_n)(y-y_n) &= u - B(y_n), \\ y(0) &= y_0, \end{aligned}$$

and the control constraint $u \in U_{ad}$. For convenience we write the functional as

$$\begin{aligned} J^n(y,u) = {} & \frac{\alpha_T}{2}\int_\Omega |y(x,T)-y_T(x)|^2 dx + \frac{\alpha_Q}{2}\int_Q |y(x,t)-y_Q(x,t)|^2 dxdt \\ & + \frac{\alpha_R}{2}\int_Q |\operatorname{curl} y(x,t)|^2 dxdt + \frac{\gamma}{2}\int_Q |u(x,t)|^2 dxdt - b_Q(y-y_n, y-y_n, \lambda_n). \end{aligned}$$

In what follows, we investigate local convergence of this method. Here, the sufficient condition (SSC) plays an essential role. As one expects, we get quadratic convergence as soon as the iterates lie in a neighborhood of a local solution.

5.1. Generalized Newton method. The SQP-method can be interpreted as a Newton method for a generalized equation of the form

$$0 \in F(x) + N(x), \tag{5.1}$$

where F is a $C^{1,1}$-mapping between two Banach spaces X and Z, while $N : X \mapsto 2^Z$ is a set-valued mapping with closed graph. One can write the Newton method formally as follows: Given iterate x_n, compute the next iterate x_{n+1} by solving

$$0 \in F(x_n) + F'(x_n)(x-x_n) + N(x).$$

Before we state an abstract result concerning the convergence of the generalized Newton method, we will introduce the notation of strong regularity in the sense of Robinson [21]. Let $\bar{x}$ be a solution of (5.1). The generalized equation is said to be *strongly regular* at the point $\bar{x}$ if there are open balls $B_X(\bar{x},\rho_x)$ and $B_Z(0,\rho_z)$ such that for all $z \in B_Z(0,\rho_z)$ the linearized and perturbed equation

$$z \in F(\bar{x}) + F'(\bar{x})(x-\bar{x}) + N(x)$$

admits a unique solution $x = x(z)$ in $B_X(\bar{x},\rho_x)$, and the mapping $z \mapsto x$ is Lipschitz continuous $B_Z(0,\rho_z)$ from to $B_X(\bar{x},\rho_x)$. The following theorem [3, 7] gives the mentioned convergence result.

THEOREM 5.1. *Let $\bar{x}$ be a solution of* (5.1) *and assume that* (5.1) *is strongly regular at $\bar{x}$. Then there exists an open ball $B_X(\bar{x},\rho_x')$ such that for every starting*

element $x_1 \in B_X(\bar{x}, \rho_x')$ the generalized Newton method generates a unique sequence $\{x_n\}_{n=1}^{\infty}$. The iterates x_n remain in $B_X(\bar{x}, \rho_x')$, and it holds that

$$\|x_{n+1} - \bar{x}\|_X \le c_N \|x_n - \bar{x}\|_X^2 \quad \forall n \in \mathbb{N}, \tag{5.2}$$

where c_N is independent of n.

5.2. Strong regularity: L^∞-stability of optimal controls. Let $(\bar{y}, \bar{u}, \bar{\lambda})$ satisfy the first-order necessary optimality conditions (see Theorem 3.2), together with the second-order sufficient optimality condition (SSC). The optimality system consisting of state equation (1.2), adjoint equation (3.1), and the inclusion (3.4) can be written in the condensed form

$$F(\bar{y}, \bar{u}, \bar{\lambda}) + \big(0, 0, 0, 0, N_{U_{ad}}(\bar{u})\big)^T \ni 0, \tag{5.3}$$

where the function F,

$$\begin{aligned} F : W_p^{2,1} \times L^\infty(Q)^2 \times W_p^{2,1} \to \\ L^p(Q)^2 \times W_0^{2-2/p,\,p}(\Omega)^2 \times L^p(Q)^2 \times W_0^{2-2/p,\,p}(\Omega)^2 \times L^\infty(Q)^2, \end{aligned} \tag{5.4}$$

is given by

$$F(y,u,\lambda) = \begin{pmatrix} y_t + \nu A y + B(y) \\ y(0) \\ -\lambda_t + \nu A \lambda + B'(y)^* \lambda \\ \lambda(T) \\ \gamma u + \lambda \end{pmatrix} - \begin{pmatrix} u \\ y_0 \\ \alpha_Q(y - y_Q) + \alpha_R \vec{\operatorname{curl}} \operatorname{curl} y \\ \alpha_T(y(T) - y_T) \\ 0 \end{pmatrix}. \tag{5.5}$$

Further, we have to redefine the normal cone $N_{U_{ad}}$ to be a subset of $L^\infty(Q)^2$,

$$N_{U_{ad}} = \begin{cases} \{ z \in L^\infty(Q)^2 : \, (z, u - \bar{u})_2 \le 0 \ \forall u \in U_{ad} \} & \text{if } \bar{u} \in U_{ad}, \\ \emptyset & \text{otherwise.} \end{cases}$$

We will apply Theorem 5.1 to the generalized equation (5.3). To do so, we have to show strong regularity of this equation at the reference triple $(\bar{y}, \bar{u}, \bar{\lambda})$. To this end, let us investigate the linearized and perturbed inclusion

$$z \in F(\bar{y}, \bar{u}, \bar{\lambda}) + F'(\bar{y}, \bar{u}, \bar{\lambda})(y - \bar{y}, u - \bar{u}, \lambda - \bar{\lambda}) + \big(0, 0, 0, 0, N_{U_{ad}}(\bar{u})\big)^T. \tag{5.6}$$

Here, the perturbation vector $z = (z_y, z_0, z_Q, z_T, z_u)$ is restricted to be in the space Z given by

$$Z := L^p(Q)^2 \times W_0^{2-2/p,\,p}(\Omega)^2 \times L^p(Q)^2 \times W_0^{2-2/p,\,p}(\Omega)^2 \times L^\infty(Q)^2. \tag{5.7}$$

We equip Z with the natural norm

$$\|z\|_Z = \|(z_y, z_0, z_Q, z_T, z_u)\|_Z := \|z_y\|_p + |z_0|_{W^{2-2/p,\,p}} + \|z_Q\|_p + |z_T|_{W^{2-2/p,\,p}} + \|z_u\|_\infty.$$

To prove strong regularity of (5.3), we have to consider the linearized and perturbed generalized equation (5.6). It represents a system that can be written in a more

convenient way. The addends coming from the Navier–Stokes nonlinearity can be equivalently transformed, due to its quadratic character, into

$$B(\bar y) + B'(\bar y)(y - \bar y) = B'(\bar y)y + B(\bar y) - B'(\bar y)\bar y = B'(\bar y)y - B(\bar y).$$

Then, (5.6) builds up the optimality system of the following perturbed linear-quadratic optimization problem, henceforth called (P_z): Find the minimizer of $J^{(z)}$ given by

$$\begin{aligned}(5.8)\quad J^{(z)}(y,u) = {}& \frac{\alpha_R}{2}\int_Q |\operatorname{curl} y|^2 + \frac{\gamma}{2}\int_Q |u|^2 \\ & + \frac{\alpha_T}{2}|y(T) - y_d|_H^2 + \frac{\alpha_Q}{2}\|y - y_Q\|_2^2 + \frac{\alpha_R}{2}\|\operatorname{curl} y\|_2^2 + \frac{\gamma}{2}\|u\|_2^2 \\ & + (z_Q, y)_Q + (z_T, y(T))_\Omega - (z_u, u)_Q - b_Q(y - \bar y, y - \bar y, \bar\lambda)\end{aligned}$$

subject to the linearized state equation

$$\begin{aligned}(5.9)\qquad y_t + \nu Ay + B'(\bar y)y &= u + B(\bar y) + z_y, \\ y(0) &= y_0 + z_0\end{aligned}$$

and the control constraint $u \in U_{ad}$. The adjoint equations associated with the perturbed problem (P_z) are given by

$$\begin{aligned}(5.10)\quad -\lambda_t + \nu A\lambda + B'(\bar y)^*\lambda &= -B'(y - \bar y)^*\bar\lambda + \alpha_Q(y - y_Q) + \alpha_R \vec{\operatorname{curl}}\operatorname{curl} y + z_Q, \\ \lambda(T) &= \alpha_T(y(T) - y_T) + z_T.\end{aligned}$$

The existence of a unique optimal control of the problem (P_z) cannot be guaranteed by the coercivity assumption (SSC). There, positivity of $\mathcal{L}_{vv}$ was assumed only for the subspace of directions, where the control $\bar u$ is not strong active. Hence, the optimization problem (P_z) is nonconvex in general. At this point, our method of proof differs from that of [13]: There a stronger coercivity assumption was used, which ensures the convexity of (P_z).

We will circumvent this difficulty in the following way: First, we show the existence of a unique solution if we substitute the control constraint by

$$(\widetilde{P_z})\qquad u \in \widetilde{U_{ad}} = \{v \in U_{ad} :\ v_i(x,t) = \bar u_i(x,t) \text{ iff } (x,t) \in Q_{\varepsilon,i}\}.$$

This solution also will be a solution to (P_z) provided the perturbations are small. In what follows, we will denote by $(\widetilde{P_z})$ the linear-quadratic optimization problem (P_z) with a changed set of admissible controls $\widetilde{U_{ad}}$. For the solvability of $(\widetilde{P_z})$, we have the following.

THEOREM 5.2. *Let (SSC) be satisfied for the reference solution $\bar v = (\bar y, \bar u)$ with adjoint state $\bar\lambda$. Moreover, assume that the data satisfy $y_0, y_T \in W_0^{2-2/p,\,p}(\Omega)^2$, $y_Q \in L^p(Q)^2$ with $2 < p < \infty$, and that the bounds u_a, u_b are in $L^\infty(Q)^2$.*

Then problem $(\widetilde{P_z})$ admits a unique solution (y_z, u_z, λ_z). Moreover, the solution mapping $z \to (y_z, u_z, \lambda_z)$ is Lipschitz continuous from Z to $W_p^{2,1} \times L^\infty(Q)^2 \times W_p^{2,1}$.

Proof. Let us denote the Lagrangian associated with (P_z) by $\mathcal{L}^{(z)}$. Then it holds for all y, u, λ that

$$(5.11)\qquad \mathcal{L}_{vv}^{(z)}(y,u,\lambda) = \mathcal{L}_{vv}(\bar y, \bar u, \bar\lambda).$$

Now take two controls $u_1, u_2 \in \widetilde{U_{ad}}$ with associated solutions y_1, y_2 of (5.9). Then the pair $(y_1 - y_2, u_1 - u_2)$ fits into the assumption of (SSC), and we find

$$\mathcal{L}_{vv}^{(z)}(y,u,\lambda)[(y_1-y_2,u_1-u_2)]^2 = \mathcal{L}_{vv}(\bar{y},\bar{u},\bar{\lambda})[(y_1-y_2,u_1-u_2)]^2 \geq \delta\|u_1-u_2\|_2^2.$$

Thus, the problem $(\widetilde{P_z})$ is convex on the space of admissible controls $\widetilde{U_{ad}}$, which yields the existence of a unique optimal control u_z with state y_z and adjoint λ_z.

Let be given two perturbation vectors $z_1,\ z_2 \in Z$. Denote by $u_i := u_{z_i}$ the optimal control of the associated problems $(\widetilde{P_z})$ together with states $y_i := y_{z_i}$ and adjoints $\lambda_i := \lambda_{z_i}$ for $i = 1, 2$.

Applying the convexity of the Lagrangian, the Lipschitz estimate

$$\|u_1-u_2\|_2 + \|y_1-y_2\|_{H^{2,1}} + \|\lambda_1-\lambda_2\|_{H^{2,1}} \leq c\|z_1-z_2\|_Z$$

can be proved following the lines of similar proofs in [13, 29]. It remains to show Lipschitz continuity of the solution mapping in stronger norms.

The space $H^{2,1}$ is continuously imbedded in $L^q(Q)^2$ for all $q < \infty$. Now, we get Lipschitz continuity of the mapping $z \mapsto u_z$ using the projection formula (3.5). Since the pointwise projection is Lipschitz continuous in L^p-spaces, we find

$$\begin{aligned}\|u_1-u_2\|_p &= \left\|\mathrm{Proj}_{\widetilde{U_{ad}}}\left(-\frac{1}{\gamma}\lambda_1\right) - \mathrm{Proj}_{\widetilde{U_{ad}}}\left(-\frac{1}{\gamma}\lambda_2\right)\right\|_p \\ &\leq \frac{1}{\gamma}\|\lambda_1-\lambda_2\|_p \leq c\|\lambda_1-\lambda_2\|_{H^{2,1}} \leq c\|z_1-z_2\|_Z.\end{aligned}$$

The states y_i are solutions of the linearized equation (5.9) with control u_i and perturbed data z_i. This equation is linearized around the state $\bar{y}$. The assumptions of the regularity result of [29] are fulfilled, which gives us $\bar{y} \in W_p^{2,1}$. Thus, we can apply Theorem 2.7 to obtain, for the difference $y_1 - y_2$,

$$\|y_1-y_2\|_{W_p^{2,1}} \leq c\left(\|u_1-u_2\|_p + \|z_1-z_2\|_Z\right) \leq c\|z_1-z_2\|_Z.$$

Finally, we give a Lipschitz estimate for the adjoint states. These are solutions of the adjoint system (5.10). Here, we make use of Theorem 3.3 to conclude

$$\|\lambda_1-\lambda_2\|_{W_p^{2,1}} \leq c\left(\|y_1-y_2\|_{W_p^{2,1}} + \|z_1-z_2\|_Z\right) \leq c\|z_1-z_2\|_Z.$$

After all, we proved the Lipschitz continuity of the solution mapping $z \to (y_z, u_z, \lambda_z)$ associated with the optimal control problem $(\widetilde{P_z})$. □

Note that by using Hilbert space methods it is not possible to derive such a result for the constrained optimal control problem of nonstationary Navier–Stokes equations. This is due to the following: Every regularity result for the nonstationary Navier–Stokes system in Hilbert spaces that gives solutions in $L^\infty(Q)^2$ or $C(\bar{Q})^2$ requires a certain regularity of *derivatives* of the control. But it is impossible to get Lipschitz estimates of the control with respect to $W^{1,p}$-norms, because such an estimation has to be based on the projection formula, which is not Lipschitz continuous between $W^{1,p}$-spaces. This means that one cannot get L^∞-Lipschitz estimates for the state and the adjoint and consequently for the control using Hilbert space theory.

Now, we study the behavior of u_z on the active set Q_ε. To this aim, we have to rely on the L^∞-stability result of the previous theorem.

COROLLARY 5.3. *Let the assumptions of Theorem* 5.2 *be fulfilled. Then there exist* $\rho_z > 0$ *such that for all* $z \in Z$ *with* $\|z\|_Z < \rho_z$ *the optimal control of* $(\widetilde{P_z})$, u_z, *is strongly active a.e. on* $Q_{\varepsilon,i}$; *i.e., it holds that*

$$|\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t)| > \frac{\varepsilon}{2},$$

and the signs of $(\gamma\bar{u}_i(x,t) + \bar{\lambda}_i(x,t))$ *and* $(\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t))$ *coincide a.e. on* $Q_{\varepsilon,i}$ *for* $i = 1, 2$.

Proof. By Theorem 5.2, the mapping $z \mapsto (y_z, u_z, \lambda_z)$ is Lipschitz continuous from Z to $W_p^{2,1} \times L^\infty(Q)^2 \times W_p^{2,1}$. By imbedding arguments, we find that $z \mapsto \gamma u_z + \lambda_z - z_u$ is Lipschitz as it maps Z to $L^\infty(Q)^2$.

Let $(x,t) \in Q_{\varepsilon,i}$ such that $\gamma\bar{u}_i(x,t) + \bar{\lambda}_i(x,t) > \varepsilon$. Using this, we derive

$$\begin{aligned}
\varepsilon &< \gamma\bar{u}_i(x,t) + \bar{\lambda}_i(x,t) \\
&= \gamma\bar{u}_i(x,t) + \bar{\lambda}_i(x,t) - (\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t)) \\
&\qquad + (\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t)) \\
&\le c\|z\|_Z + \gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t).
\end{aligned}$$

Therefore, the choice $\rho_z := c^{-1}\varepsilon/2$ yields $\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t) > \varepsilon/2$.

Analogously, if for $(x,t) \in Q_{\varepsilon,i}$ we have $\gamma\bar{u}_i(x,t) + \bar{\lambda}_i(x,t) < -\varepsilon$, then the same value of ρ_z gives $\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t) < -\varepsilon/2$. ∎

COROLLARY 5.4. *Let the assumptions of Theorem* 5.2 *be fulfilled. Then the control* u_z *associated with a perturbation* $z \in Z$ *with* $\|z\|_Z < \rho_z$, *where* ρ_z *is given by Corollary* 5.3, *fulfills the variational inequality*

$$(\gamma u_z + \lambda_z - z_u,\, u - u_z) \ge 0 \quad \forall u \in U_{ad}; \tag{5.12}$$

i.e., it satisfies the first-order necessary optimality condition of (P_z).

Proof. Let $u \in U_{ad}$ be given. We begin with

$$\begin{aligned}
\int_Q (\gamma u_{z,i} + \lambda_{z,i} - z_{u,i})(u_i - u_{z,i}) &= \int_{Q\setminus Q_{\varepsilon,i}} (\gamma u_{z,i} + \lambda_{z,i} - z_{u,i})(u_i - u_{z,i}) \\
&\quad + \int_{Q_{\varepsilon,i}} (\gamma u_{z,i} + \lambda_{z,i} - z_{u,i})(u_i - \bar{u}_i),
\end{aligned} \tag{5.13}$$

since $u_z \in \widetilde{U_{ad}}$ means $u_{z,i}(x,t) = \bar{u}_i(x,t)$ a.e. on $Q_{\varepsilon,i}$. The first integral is part of the first-order necessary optimality conditions of $(\widetilde{P_z})$. Therefore, it is nonnegative.

By Corollary 5.3, $(\gamma\bar{u}_i(x,t) + \bar{\lambda}_i(x,t))$ and $(\gamma u_{z,i}(x,t) + \lambda_{z,i}(x,t) - z_{u,i}(x,t))$ have the same sign a.e. on $Q_{\varepsilon,i}$. Furthermore, $\bar{u}_i(x,t)$ is active on this set, so that $u_i(x,t) - \bar{u}_i(x,t)$ always has the same sign regardless of the choice of $u_i(x,t)$. Since $\gamma\bar{u} + \bar{\lambda}$ satisfies $\int_{Q_{\varepsilon,i}} (\gamma\bar{u}_i + \bar{\lambda}_i)(u_i - \bar{u}_i) \ge 0$, the same is true for $\gamma u_z + \lambda_z - z_u$; i.e.,

$$\int_{Q_{\varepsilon,i}} (\gamma u_{z,i} + \lambda_{z,i} - z_{u,i})(u_i - \bar{u}_i) \ge 0$$

is satisfied. So, we proved that both integrals in (5.13) are nonnegative. Adding them, we derived the claim (5.12). ∎

So far, we showed that (y_z, u_z, λ_z) fulfills the optimality system of the perturbed problem (P_z), or equivalently, the linearized and perturbed generalized equation (5.6).

We have to ask whether it might be a local minimizer of (P_z). With the previous corollaries and the identity (5.11) we have all ingredients at hand to prove that (y_z, u_z, λ_z) satisfies a second-order sufficient optimality condition for the problem (P_z); i.e., it is indeed a locally optimal solution.

THEOREM 5.5. *Let the assumptions of Theorem* 5.2 *be fulfilled. Then, there are* $\rho_z, \rho_u > 0$ *such that the control* u_z *associated with a perturbation* $z \in Z$ *with* $\|z\|_Z < \rho_z$ *is a locally optimal solution of* (P_z)*, and it satisfies*

$$J^{(z)}(y_z, u_z) \le J^{(z)}(y, u)$$

for all $u \in U_{ad}$ *with* $\|u - u_z\|_\infty \le \rho_u$*. Here* y_z *and* y *are the solutions of* (5.9) *associated with the controls* u_z *and* u*.*

Proof. Let $u \in U_{ad}$ with $u_i = \bar{u}_i$ a.e. on $Q_{\varepsilon,i}$ be given. Denote by y the associated solution of (5.9). Set $h = u - u_z$ and $w = y - y_z$. This implies $h = 0$ a.e. on $Q_{\varepsilon,i}$. Therefore, h fits into the assumptions of (SSC). The triple $(\bar{y}, \bar{u}, \bar{\lambda})$ satisfies the second-order sufficient optimality condition (SSC), which means

$$\mathcal{L}^{(z)}_{vv}(y_z, u_z, \lambda_z)[(w,h)]^2 = \mathcal{L}_{vv}(\bar{y}, \bar{u}, \bar{\lambda})[(w,h)]^2 \ge \delta \|h\|_2^2. \tag{5.14}$$

Corollaries 5.3 and 5.4 and the coercivity relation (5.14) build up the second-order sufficient optimality condition connected with (P_z). Following the lines of [27], we conclude that u_z is locally optimal: There exists a constant $\rho_u > 0$ such that $J^{(z)}(y_z, u_z) \le J^{(z)}(y, u)$ holds for all $u \in U_{ad}$ with $\|u - u_z\|_\infty \le \rho_u$. ∎

COROLLARY 5.6. *Let the assumptions of Theorem* 5.2 *be fulfilled. Then the generalized equation* (5.3) *is strongly regular at* $(\bar{y}, \bar{u}, \bar{\lambda})$*.*

Proof. At first, the function F is a $C^{1,1}$-mapping in the setting (5.4), because all its components are linear with respect to the variables (y, u, λ) except the nonlinear term in the state equation. The mapping $y \mapsto B(y)$ is $C^{1,1}$ from $W_p^{2,1}$ to $L^p(Q)^2$.

Theorem 5.5 states that the perturbed linearized optimization problem (P_z) has a unique optimal solution in the ball $B_{L^\infty}(\bar{u}, \rho_u)$ for perturbations from $B_Z(0, \rho_z)$. By Theorem 5.2, the associated state y lies in the ball $B_{W_p^{2,1}}(\bar{y},\, c_y \rho_z)$, whereas the adjoint state λ_z is in $B_{W_p^{2,1}}(\bar{\lambda}, c_\lambda\, \rho_z)$. Here, c_y and c_λ are the Lipschitz constants given by Theorem 5.2. This altogether yields the unique solvability of the perturbed linearized generalized equation (5.6) in $B_{W_p^{2,1}}(\bar{y}, c_y\, \rho_z) \times B_{L^\infty}(\bar{u}, \rho_u) \times B_{W_p^{2,1}}(\bar{\lambda}, c_\lambda\, \rho_z)$ for perturbations from $B_Z(0, \rho_z)$. As already mentioned, the solution mapping $z \mapsto (y_z, u_z, \lambda_z)$ is Lipschitz. Therefore, all requirements for strong regularity are fulfilled. ∎

5.3. Local convergence of the SQP-type algorithm. With the help of the previous section, we are in the situation to apply the abstract convergence result of Theorem 5.1. However, we are not allowed to carry it over one-to-one. The SQP-method as stated in the beginning of section 5 requires us to find the *global* minimizer of the linear-quadratic subproblems (P^n). The analysis done so far guarantees only the existence of a *local* solution of those subproblems in the neighborhood of the reference control. Consequently, we have to modify the SQP-method to enforce the solutions of the subproblems to remain near the reference solution in the following way.

Given iterates y_n, u_n, λ_n, compute the next iterates $y_{n+1}, u_{n+1}, \lambda_{n+1}$ as the solution of (P^n) subject to the control constraint

$$u \in U_{ad}^\rho := U_{ad} \cap \{v \in L^\infty(Q)^2 :\ \|v - \bar{u}\|_\infty \le \rho\}. \tag{5.15}$$

See also [26], where those aspects are discussed in more detail.

Then Theorem 5.1 yields quadratic convergence in a neighborhood of the solution.

THEOREM 5.7. *Let the assumptions of Theorem* 5.2 *be satisfied. Then there is a constant* $\rho_s > 0$*, such that for every starting value* (y_1, u_1, λ_1) *with* $u_1 \in U_{ad}^{\rho_s}$ *the SQP-method with control constraint* (5.15) *generates a uniquely determined sequence* (y_n, u_n, λ_n) *with* $u_n \in U_{ad}^{\rho_s}$*, and it holds that*

$$\|y_{n+1} - \bar{y}\|_{W_p^{2,1}} + \|u_{n+1} - \bar{u}\|_\infty + \|\lambda_{n+1} - \bar{\lambda}\|_{W_p^{2,1}} \\ \leq c_s \left(\|y_n - \bar{y}\|_{W_p^{2,1}}^2 + \|u_n - \bar{u}\|_\infty^2 + \|\lambda_n - \bar{\lambda}\|_{W_p^{2,1}}^2 \right)$$

with a constant c_s *independently of* n*. Here,* y_n *and* λ_n *are the states and adjoints associated with the control* u_n*.*

The a priori unknown solution $\bar{u}$ appears in the definition of U_{ad}^{ρ}, which is necessary to establish the convergence theory. To overcome this difficulty, one has to use globalization techniques. For an application of a globalized SQP-method to compute optimal controls of nonstationary Navier–Stokes equations, we refer to [12]. However, in the numerical computations it was not necessary to enforce the method to stay in a neighborhood of the last iterate.

6. Numerical results. Here, we provide a computational example that confirms the convergence analysis of the SQP-method. The following control problem is given: We want to reduce the recirculation bubble after the backward-facing step. We try this by minimization of the objective functional

$$J(y,u) = \frac{1}{2} \int_{Q_c} |y(x,t) - y_Q(x,t)|^2 dxdt + \frac{\gamma}{2} \int_{Q_c} |u(x,t)|^2 dxdt$$

with $T = 1$ and $\gamma = 0.3$. The control has to satisfy $|u_i(x,t)| \leq 0.3$ a.e. on Q, $i = 1, 2$.

The computational domain Ω is the backward-facing step. Here, observation and control take place in the same part of the domain $Q_c = \Omega_c \times (0,T)$; cf. Figure 6.1.

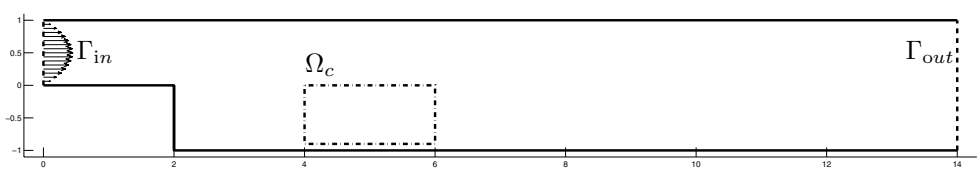

FIG. 6.1. *Flow configuration.*

As desired flow y_Q we chose the Stokes flow (see Figure 6.2), which is the solution of the stationary Stokes equation with the same boundary conditions as used for the nonstationary simulation.

At the inflow boundary Γ_{in} a parabolic velocity profile is prescribed, whereas at the boundary Γ_{out} we use the "do-nothing" boundary condition (cf. [11]): $\nu \frac{\partial y}{\partial n} - pn = 0$.

At the rest of the boundary we use homogeneous Dirichlet conditions. All computations were done with Reynolds number $Re = 400$, which yields a viscosity parameter $\nu = 1/400$. The initial velocity profile was chosen as the stationary limit of the uncontrolled Navier–Stokes equations; cf. Figure 6.3.

The continuous problem was discretized using Taylor–Hood finite elements with different mesh sizes. Further, we use a semi-implicit Euler scheme for time integration

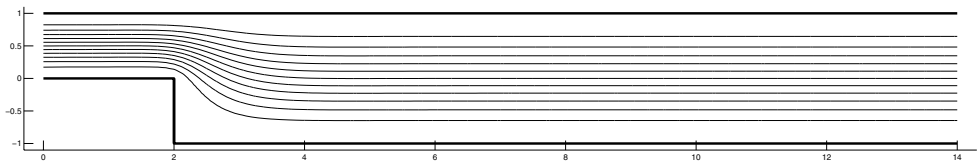

FIG. 6.2. *Desired profile is the Stokes flow.*

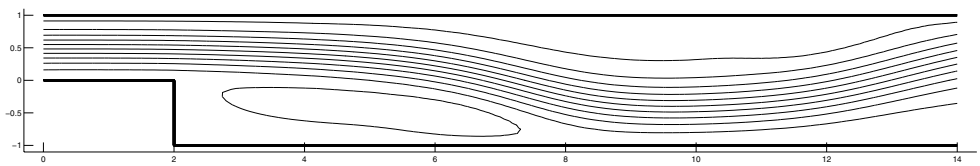

FIG. 6.3. *Initial flow profile* y_0.

with an equidistant time discretization with different step lengths. The computations are based on a finite element code of Hinze; see [16]. We computed solutions of the optimal control problem for different spatial and time discretizations. The discretization parameters can be found in Table 6.1.

TABLE 6.1. *Discretization parameters.*

	Triangles	Velocity nodes	Pressure nodes	Mesh size h	Time step τ
Coarse	416	905	245	0.5	0.01
	1664	3473	905	0.25	0.0025
Fine	6656	13601	3473	0.125	0.000625

On the finest discretization the number of unknown control variables is $1,388,800$, whereas the number of state and adjoint variables is each about 21 million. A further uniform refinement will result in an optimization problem that is very expensive to solve even on today's computers.

The arising discrete control problems are solved by the SQP-method without any globalization. The constrained SQP-subproblems (P^n) were solved by a primal-dual active-set method (see, for instance, [13, 18]) using the method of conjugate gradients (CGs) for the inner loop. Since those subproblems are linear-quadratic optimization problems, this active-set strategy can be interpreted as a semismooth Newton method [14] to solve the nonsmooth equation

$$u = \mathrm{Proj}_{U_{ad}}\left(-\frac{1}{\gamma}\lambda(u)\right);$$

cf. (3.5). Here, $\lambda(u)$ denotes the adjoint state for a given control u of the SQP-subproblem (P^n). This method is known to converge locally with a superlinear convergence rate [14] if the quadratic form $\mathcal{L}''$ is coercive. Under some strong assumptions it converges even globally [18]. Moreover, the SQP-method, as well as the semismooth Newton method, is known to exhibit a mesh-independence convergence; see [4, 15].

In all examples, the stopping criteria of the nested methods are balanced in the following way as proposed in [13].

The outer SQP-loop is terminated if two successive iterates are close enough:

$$\|y^n - y^{n-1}\|_\infty + \|u^n - u^{n-1}\|_\infty + \|\lambda^n - \lambda^{n-1}\|_\infty \le \varepsilon_{SQP}.$$

The primal-dual active-set method is stopped if either the active sets of two successive control iterates coincide or the error in the variational inequality given by

$$\phi(u) = \left\| u - \mathrm{Proj}_{U_{ad}}\left(-\frac{1}{\gamma}\lambda\right)\right\|_2$$

is reduced by a factor of 0.1. The innermost iteration procedure—the CG method—was stopped if the norm of the starting residual was reduced by a factor of 0.01. The initial guesses u^0 and y^0 for control and state were set to zero in all computations.

The convergence behavior of the method for the three different discretizations is listed in Table 6.2. We give an estimation of the convergence speed of the method with respect to the L^2- and L^∞-norms by

$$q_2^n = \frac{\|u^n - u^{n-1}\|_2}{\|u^{n-1} - u^{n-2}\|_2^2}, \quad q_\infty^n = \frac{\|u^n - u^{n-1}\|_\infty}{\|u^{n-1} - u^{n-2}\|_\infty^2}.$$

Now, let us have a look on the convergence history of the SQP-method for the three discretizations. It can be found in Table 6.2. The results for the two finest discretizations are close, such that one can see a mesh-independence behavior. The differences in the iterations on the coarse grid are due to the fact that the coarsest spatial grid was too coarse, and the accuracy of solving the state equation was too low. Mesh-independence results state that for discretizations that are sufficiently fine the iteration rates do not depend on the mesh; see, e.g., [4, 15].

TABLE 6.2. *Convergence history.*

Grid	Iteration	$\|u^n - u^{n-1}\|_\infty$	q_2^n	q_∞^n
Coarse	1	$3.00 \cdot 10^{-1}$		
	2	$1.92 \cdot 10^{-1}$	$5.87 \cdot 10^{-1}$	$2.14 \cdot 10^{0}$
	3	$2.24 \cdot 10^{-2}$	$3.73 \cdot 10^{0}$	$6.06 \cdot 10^{-1}$
	4	$1.24 \cdot 10^{-3}$	$1.32 \cdot 10^{1}$	$2.47 \cdot 10^{0}$
	5	$4.24 \cdot 10^{-5}$	$8.98 \cdot 10^{2}$	$2.76 \cdot 10^{1}$
	1	$3.00 \cdot 10^{-1}$		
	2	$1.97 \cdot 10^{-1}$	$6.24 \cdot 10^{-1}$	$2.19 \cdot 10^{0}$
	3	$3.71 \cdot 10^{-2}$	$4.70 \cdot 10^{0}$	$9.54 \cdot 10^{-1}$
	4	$1.49 \cdot 10^{-3}$	$4.74 \cdot 10^{0}$	$1.08 \cdot 10^{0}$
	5	$5.67 \cdot 10^{-5}$	$2.76 \cdot 10^{2}$	$2.49 \cdot 10^{1}$
Fine	1	$3.00 \cdot 10^{-1}$		
	2	$2.31 \cdot 10^{-1}$	$5.90 \cdot 10^{-1}$	$2.56 \cdot 10^{0}$
	3	$2.54 \cdot 10^{-2}$	$2.61 \cdot 10^{0}$	$4.76 \cdot 10^{-1}$
	4	$1.24 \cdot 10^{-3}$	$1.01 \cdot 10^{1}$	$1.91 \cdot 10^{0}$
	5	$5.89 \cdot 10^{-5}$	$2.12 \cdot 10^{2}$	$3.84 \cdot 10^{1}$

7. Conclusion. In this article, we investigated the SQP-method to solve optimal control problems with control constraints for the nonstationary Navier–Stokes equations. We were able to prove locally quadratic convergence of the SQP-method by using a sufficient condition, which is weaker than required in other articles. The control iterates will converge with respect to the L^∞-norm. The method of proof requires L^p-theory of the respective nonlinear and linearized state and adjoint equations, which were provided in the course of the article.

Acknowledgments. The author wishes to thank the two anonymous referees for their valuable comments leading to an improvement of the entire presentation.

ASYMPTOTIC PROPERTIES OF HYBRID DIFFUSION SYSTEMS*

C. ZHU† AND G. YIN‡

Abstract. In response to the increasing needs for control and optimization of hybrid systems, this work is concerned with such asymptotic properties as recurrence (also known as weak stochastic stability in the literature) and ergodicity of regime-switching diffusions. Using Liapunov functions, necessary and sufficient conditions for positive recurrence are developed. Then, ergodicity of positive recurrent regime-switching diffusions is obtained by constructing cycles using the associated discrete-time Markov chains.

Key words. switching diffusion, Liapunov function, weak stochastic stability, positive recurrence, ergodicity

1. Introduction.

1.1. Motivation. Owing to the increasing demands for modeling large-scale and complex systems, designing optimal control, and conducting optimization tasks, hybrid systems are lately receiving growing attention. A distinctive feature of these systems is the coexistence of continuous dynamics and discrete events. The collection of hybrid diffusion systems (also known as regime-switching diffusions) is such a class. Recent research efforts in such systems to capture random evolutions stem from emerging applications in financial engineering, wireless communications, manufacturing systems, and other related fields. For instance, there have been resurgent interests in using regime-switching diffusions to depict the financial market, where the switching or jump processes are used to describe stochastic volatility resulting from market modes, interest rates, as well as other economic factors. Regime-switching diffusions have also been used to enhance the versatility in risk management practice to better understand ruin probability in insurance and to carry out dividend optimization.

Since the underlying systems in applications are often in operation for a relatively long time, it is of foremost importance to understand the systems' asymptotic behavior. Considering average cost per unit time problems, we often wish to "replace" the time-dependent instantaneous measure by a steady state (or ergodic) measure. Thus we face the following questions. Do the systems possess ergodic property? Under what conditions do the systems have the desired ergodicity? In accordance with [22], a deterministic system $\dot{x} = g(t, x)$, which satisfies appropriate conditions, is Lagrange stable if the solutions are ultimately uniformly bounded. When stochastic systems are considered, almost sure boundedness excludes many systems. Thus, in lieu of such boundedness, one seeks stability in a certain weak sense [31]. One question of fundamental importance is, Under what conditions will the systems return to a prescribed

compact region in finite time? In this paper, we focus on asymptotic behaviors and address these issues. More specifically, we deal with such properties as recurrence, positive recurrence, and ergodicity. One of the main features of our approach is the use of appropriate Liapunov functions. We first develop Liapunov function–based general criteria for positive recurrence, followed by a further study on ergodicity in which we construct cycles using discrete-time Markov chains.

1.2. Formulation. Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, \mathbf{P})$ be a complete probability space with a filtration $\{\mathcal{F}_t\}_{t\geq 0}$ satisfying the usual condition (i.e., it is right continuous and $\mathcal{F}_0$ contains all $\mathbf{P}$-null sets). Let $x \in \mathbb{R}^r$, $\mathcal{M} = \{1, \ldots, m_0\}$, and $Q(x) = (q_{ij}(x))$ be an $m_0 \times m_0$ matrix depending on x and satisfying that for any $x \in \mathbb{R}^r$, $q_{ij}(x) \geq 0$ for $i \neq j$ and $\sum_{j=1}^{m_0} q_{ij}(x) = 0$. For each $i \in \mathcal{M}$, and for any twice continuously differentiable function $g(\cdot, i)$, define $\mathcal{L}$ by

$$\begin{aligned}\mathcal{L}g(x,i) &= \frac{1}{2}\sum_{j,k=1}^{r} a_{jk}(x,i)\frac{\partial^2 g(x,i)}{\partial x_j \partial x_k} + \sum_{j=1}^{r} b_j(x,i)\frac{\partial g(x,i)}{\partial x_j} + Q(x)g(x,\cdot)(i)\\ &= \frac{1}{2}\mathrm{tr}(a(x,i)\nabla^2 g(x,i)) + \big\langle b(x,i), \nabla g(x,i)\big\rangle + Q(x)g(x,\cdot)(i),\end{aligned} \tag{1.1}$$

where $\nabla g(\cdot, i)$ and $\nabla^2 g(\cdot, i)$ denote the gradient and Hessian of $g(\cdot, i)$, respectively, and

$$Q(x)g(x,\cdot)(i) = \sum_{j=1}^{m_0} q_{ij}(x)g(x,j) = \sum_{j\neq i, j\in\mathcal{M}} q_{ij}(x)(g(x,j) - g(x,i)), \quad i \in \mathcal{M}. \tag{1.2}$$

Consider a Markov process $Y(t) = (X(t), \gamma(t))$, whose associated operator is given by $\mathcal{L}$; see [28] for further references. Note that $Y(t)$ has two components, an r-dimensional diffusion component $X(t)$ and a jump component $\gamma(t)$ taking value in $\mathcal{M} = \{1, \ldots, m_0\}$.

The process $Y(t) = (X(t), \gamma(t))$ can be described by the following equations:

$$dX(t) = b(X(t), \gamma(t))dt + \sigma(X(t), \gamma(t))dw(t), \quad X(0) = x, \ \gamma(0) = \gamma, \tag{1.3}$$

and

$$\mathbf{P}\{\gamma(t+\Delta t) = j | \gamma(t) = i, X(s), \gamma(s), s \leq t\} = q_{ij}(X(t))\Delta t + o(\Delta t), \quad i \neq j, \tag{1.4}$$

where $w(t)$ is a d-dimensional standard Brownian motion, $b(\cdot,\cdot) : \mathbb{R}^r \times \mathcal{M} \mapsto \mathbb{R}^r$, and $\sigma(\cdot,\cdot) : \mathbb{R}^r \times \mathcal{M} \mapsto \mathbb{R}^{r\times d}$ satisfying $\sigma(x,i)\sigma'(x,i) = a(x,i)$ (where z' denotes the transpose of z for $z \in \mathbb{R}^{\iota_1 \times \iota_2}$ with $\iota_1, \ \iota_2 \geq 1$). We refer the reader to [28] for related stochastic differential equations involving Poisson measures describing the evolution of the jump processes. In this paper, our study will mainly be concerned with the use of the operator $\mathcal{L}$ given in (1.1). Throughout the paper, we assume that both $b(\cdot, i)$ and $\sigma(\cdot, i)$ satisfy the usual local Lipschitz condition and linear growth condition for each $i \in \mathcal{M}$ and that $Q(\cdot)$ is bounded and continuous. It is well known that under these conditions, the system (1.3)–(1.4) has a unique strong solution; see [12] or [28] for details. In what follows, denote the solution of (1.3)–(1.4) by $(X^{x,\gamma}(t), \gamma(t))$ if the emphasis on the initial data is needed. To study recurrence and ergodicity of the process $Y(t) = (X(t), \gamma(t))$, we further assume that the following condition (A) holds throughout the paper. For convenience, we also collect the boundedness and continuity of $Q(\cdot)$ in (A).

(A) The operator $\mathcal{L}$ satisfies the following conditions:

(i) For each $i \in \mathcal{M}$, $a(x,i) = (a_{jk}(x,i))$ is symmetric and satisfies

$$\kappa_1|\xi|^2 \le \langle a(x,i)\xi,\xi\rangle \le \kappa_1^{-1}|\xi|^2 \quad \text{for all } \xi \in \mathbb{R}^r, \tag{1.5}$$

with some constant $\kappa_1 \in (0,1]$ for all $x \in \mathbb{R}^r$.

(ii) For $i \ne j$, $q_{ij}(x) > 0$. The matrix-valued function $Q(\cdot)$ is bounded and continuous.

As mentioned earlier, the motivation of our study stems from recent interests in regime-switching diffusion processes that include a random process with a finite-state space in addition to the usual diffusion component. The finite-state process depicts a random environment that has right-continuous sample paths and that cannot be described by a diffusion. Consequently, both continuous dynamics (diffusions) and discrete events (jumps) coexist and yield hybrid dynamic systems, which provide a more realistic formulation for many applications.

Regime-switching diffusions lately have received much attention. For instance, optimal controls of switching diffusions were studied in [4] using a martingale problem formulation; jump-linear systems were considered in [13]; stability of semilinear stochastic differential equations with Markovian switching was considered in [2]; ergodic control problems of switching diffusions were studied in [9]; stability of stochastic differential equations with Markovian switching was treated in [23, 25, 33]; asymptotic expansions for solutions of integrodifferential equations for transition densities of singularly perturbed switching-diffusion processes were developed in [11]; and switching diffusions were used for stock liquidation models in [34]. For some recent applications of hybrid systems in communication networks, air traffic management, and control problems, etc., we refer the reader to [14, 15, 24, 26, 29] and references therein.

In [2, 23, 33, 34], $Q(x) = Q$, a constant matrix. In such cases, $\gamma(\cdot)$ is a continuous-time Markov chain. Moreover, it is assumed that the Markov chain $\gamma(\cdot)$ is independent of the Brownian motion. In our formulation, x-dependent $Q(x)$ is considered, and as a result, the transition rates of the discrete event $\gamma(\cdot)$ depend on the continuous dynamic $X(\cdot)$, as depicted in (1.4). Although the pair $(X(\cdot),\gamma(\cdot))$ is a Markov process, for x-dependent $Q(x)$, only for each fixed x, the discrete-event process $\gamma(\cdot)$ is a Markov chain. Such a formulation enables us to describe complex systems and their inherent uncertainty and randomness in the environment. However, it adds much difficulty to our analysis. Our formulation is motivated by the fact that in many applications, the discrete event and continuous dynamic are intertwined, and the independence assumption of the discrete-event process and the Brownian motion appears to be restrictive.

One of the important problems concerning switching models is their longtime behavior. Despite the growing interests in treating regime-switching systems (see the works mentioned in the previous paragraphs and references therein), the results regarding such issues as recurrence and positive recurrence (or weak stochastic stability as termed in [31]) are still scarce. Furthermore, these are not simple extensions of their diffusion counterparts. Due to the coupling and interactions, elliptic systems instead of a single elliptic equation must be treated. Moreover, even though the classical approaches such as Liapunov function methods and Dynkin's formula are still applicable for switching diffusions, the analysis is much more delicate than the diffusion counterparts. It requires careful handling of discrete-event component $\gamma(\cdot)$; see, for example, the proofs of Lemma 3.7, Lemma 3.8, and Theorem 3.12.

In addition to recurrence, many applications in control and optimization require minimizing an expected cost of a certain objective function. The computation is

difficult and complicated. Significant effort has been devoted to approximating such expected values by replacing the measures with stationary measures when the time horizon is long enough. To justify such a replacement, ergodicity is needed. For diffusion processes, much effort has been devoted to ergodicity; see, for example, [3, 20], among others. For regime-switching diffusions, asymptotic stability for the density of the so-called two-state diffusion process $(X(t), \gamma(t))$ was established in [25]; asymptotic stability in distribution for the process $(X(t), \gamma(t))$ was obtained in [33], where the jump component $\gamma(\cdot)$ is generated by some constant matrix Q and is independent of the Brownian motion. In this work, we will address ergodicity for $(X(t), \gamma(t))$ under different conditions than those in [25, 33]. Moreover, our work is applicable to more general settings. The discrete component $\gamma(\cdot)$ has an x-dependent generator $Q(x)$ and takes value in a finite-state space $\mathcal{M} = \{1, 2, \ldots, m_0\}$. Another highlight of this paper is that we obtain the explicit representation of the invariant measure of the process $(X(t), \gamma(t))$ by considering certain cylinder sets and by defining cycles appropriately. As a by-product, we demonstrate a strong law of large numbers type of theorem for positive recurrent regime-switching diffusions.

Compared with the existing work in the literature, the novelty and contribution of this paper are as follows. (a) By considering the x-dependent generator $Q(x)$, our model provides a more realistic formulation which allows the switching component to depend on the continuous states. This, in turn, allows for the coupling and correlation between $X(t)$ and $\gamma(t)$. (b) By appropriately defining cycles, we establish the ergodicity of the underlying process. (c) Moreover, explicit representation of the invariant measure for positive recurrent regime-switching diffusions is given.

The rest of the paper is arranged as follows. In section 2, in addition to introducing certain notation, we also provide definitions of regularity, recurrence, positive recurrence, and null recurrence. Section 3 focuses on positive recurrence. We present results of necessary and sufficient conditions for recurrence using Liapunov functions, along with two examples as applications of the general results. Section 4 develops ergodicity of switching-diffusion processes. Discussions and further remarks are made in section 5. An appendix containing the proofs of several technical lemmas is placed at the end of the paper to facilitate the reading.

2. Regularity, recurrence, positive recurrence, and null recurrence. This section is devoted to the definitions of regularity, recurrence, positive recurrence, and null recurrence. For simplicity, we introduce some notation as follows. For any $U = D \times J \subset \mathbb{R}^r \times \mathcal{M}$, where $D \subset \mathbb{R}^r$ and $J \subset \mathcal{M}$, denote

$$\begin{aligned} \tau_U &:= \inf\{t \geq 0 : (X(t), \gamma(t)) \notin U\}, \\ \sigma_U &:= \inf\{t \geq 0 : (X(t), \gamma(t)) \in U\}. \end{aligned} \tag{2.1}$$

In particular, if $U = D \times \mathcal{M}$ is a "cylinder," we set

$$\begin{aligned} \tau_D &:= \inf\{t \geq 0 : X(t) \notin D\}, \\ \sigma_D &:= \inf\{t \geq 0 : X(t) \in D\}. \end{aligned} \tag{2.2}$$

Definition 2.1 (regularity). *A Markov process $(X^{x,\gamma}(t), \gamma(t))$ is said to be* regular*, if for any $0 < T < \infty$,*

$$\mathbf{P}\left\{\sup_{0 \leq t \leq T} |X^{x,\gamma}(t)| = \infty\right\} = 0. \tag{2.3}$$

Remark 2.2. Let β_n be the first exit time of the process $(X^{x,\gamma}(t), \gamma(t))$ from the bounded set $\{\widetilde{x} : |\widetilde{x}| < n\} \times \mathcal{M}$, that is,

$$\beta_n = \inf\{t : |X^{x,\gamma}(t)| = n\}. \tag{2.4}$$

Then, the sequence $\{\beta_n\}$ is monotonically increasing and hence has a (finite or infinite) limit. It is not difficult to see that the process $(X^{x,\gamma}(t), \gamma(t))$ is regular if and only if

$$\beta_n \to \infty \text{ almost surely (a.s.) as } n \to \infty. \tag{2.5}$$

In what follows, we assume that the process $(X^{x,\gamma}(t), \gamma(t))$ is regular. Subsequently we will use (2.5) often.

DEFINITION 2.3. *Recurrence, positive recurrence, and null recurrence are defined as follows.*

(i) Recurrence. *For $U := D \times J$, where $J \subset \mathcal{M}$ and $D \subset \mathbb{R}^r$ is an open set with compact closure, let $\sigma_U^{x,\gamma} = \inf\{t : (X^{x,\gamma}(t), \gamma(t)) \in U\}$. A regular process $(X^{x,\gamma}(\cdot), \gamma(\cdot))$ is* recurrent *with respect to U if $\mathbf{P}\{\sigma_U^{x,\gamma} < \infty\} = 1$ for any $(x, \gamma) \in D^c \times \mathcal{M}$, where D^c denotes the complement of D.*

(ii) Positive recurrence and null recurrence. *A recurrent process with finite mean recurrence time for some set $U = D \times J$, where $J \subset \mathcal{M}$ and $D \subset \mathbb{R}^r$ is a bounded open set with compact closure, is said to be* positive recurrent *with respect to U; otherwise, the process is* null recurrent *with respect to U.*

3. Positive recurrence. This section takes up the positive recurrence issue. It entails the use of appropriate Liapunov functions. We begin this section with certain preparatory results, which indicate that the process $Y(t) = (X(t), \gamma(t))$ is recurrent (resp., positive recurrent) with respect to some "cylinder" $D \times \mathcal{M}$ if and only if it is recurrent (resp., positive recurrent) with respect to $D \times \{\ell\}$, where $D \subset \mathbb{R}^r$ is a nonempty open set with compact closure and $\ell \in \mathcal{M}$. We will also prove that the properties of recurrence and positive recurrence do not depend on the choice of the open set $D \subset \mathbb{R}^r$ or $\ell \in \mathcal{M}$. After the preparatory results, two subsections follow. The first presents Liapunov function–based criteria on positive recurrence. As applications of the general results, a subsection containing two examples is provided. Note that Example 3.16 is quite interesting because it shows that the combination of a transient diffusion and a positive recurrent diffusion is a positive recurrent switching diffusion.

3.1. Preparatory results. We first prove the following theorem, which asserts that under assumption (A), the process $Y(t) = (X(t), \gamma(t))$ will exit every bounded "cylinder" with a finite mean exit time.

THEOREM 3.1. *Let $D \subset \mathbb{R}^r$ be a nonempty open set with compact closure $\overline{D}$. Let $\tau_D := \inf\{t \geq 0 : X(t) \notin D\}$. Then*

$$\mathbf{E}_{x,i}\tau_D < \infty \quad \textit{for any} \quad (x, i) \in D \times \mathcal{M}. \tag{3.1}$$

Proof. First, note that from the uniform ellipticity condition (1.5), we have

$$\kappa_1 \leq a_{11}(x, i) \leq \kappa^{-1} \quad \text{for any} \quad (x, i) \in D \times \mathcal{M}. \tag{3.2}$$

For each $i \in \mathcal{M}$, consider $W(x, i) = k - (x_1 + \beta)^c$, where the constants k, c (with $c \geq 2$), and β are to be specified, and $x_1 = e_1'x$ is the first component of x, where $e_1 = (1, 0, \ldots, 0)'$. Direct computation leads to

$$\mathcal{L}W(x, i) = -c(x_1 + \beta)^{c-2}\left[b_1(x, i)(x_1 + \beta) + \frac{c-1}{2}a_{11}(x, i)\right].$$

Set

$$c = \frac{2}{\kappa_1}\left(\sup_{(x,i)\in\overline{D}\times\mathcal{M}} |b_1(x,i)(x_1+\beta)| + 1\right) + 1.$$

Then we have from (3.2) that

$$\frac{c-1}{2}a_{11}(x,i) + b_1(x,i)(x_1+\beta) \geq \frac{c-1}{2}\kappa_1 - \sup_{(x,i)\in\overline{D}\times\mathcal{M}} |b_1(x,i)(x_1+\beta)| \geq 1.$$

Meanwhile, since $x \in D \subset \overline{D}$ and $\overline{D}$ is compact, we can choose β such that $1 \leq x_1 + \beta \leq M$ for all $x \in D$, where M is some positive constant. Thus we have $(x_1+\beta)^{c-2} \geq 1^{c-2} = 1$. Finally, we choose k large enough so that $W(x,i) = k - (x_1+\beta)^c > 0$ for all $(x,i) \in D \times \mathcal{M}$. Therefore, $W(x,i), i \in \mathcal{M}$, are Liapunov functions satisfying

$$\mathcal{L}W(x,i) \leq -c \quad \text{for all} \quad (x,i) \in D \times \mathcal{M}. \tag{3.3}$$

Now let $\tau_D(t) := \min\{t, \tau_D\}$. Then we have from Dynkin's formula and (3.3) that

$$\begin{aligned}&\mathbf{E}_{x,i}W(X(\tau_D(t)),\gamma(\tau_D(t))) - W(x,i)\\ &\quad = \mathbf{E}_{x,i}\int_0^{\tau_D(t)} \mathcal{L}W(X(u),\gamma(u))du \leq -c\mathbf{E}_{x,i}\tau_D(t).\end{aligned}$$

Since the function $W(x,i)$ is nonnegative, we have

$$\mathbf{E}_{x,i}\tau_D(t) \leq \frac{1}{c}W(x,i). \tag{3.4}$$

Because

$$\mathbf{E}_{x,i}\tau_D(t) = \mathbf{E}_{x,i}\tau_D\chi_{[\tau_D\leq t]} + \mathbf{E}_{x,i}t\chi_{[\tau_D>t]},$$

we have from (3.4) that $t\mathbf{P}_{x,i}[\tau_D > t] \leq \frac{1}{c}W(x,i)$. Letting $t \to \infty$, we obtain $\mathbf{P}_{x,i}[\tau_D = \infty] = 0$ or $\mathbf{P}_{x,i}[\tau_D < \infty] = 1$. This yields that $\tau_D(t) \to \tau_D$ a.s. $\mathbf{P}_{x,i}$ as $t \to \infty$. Now applying Fatou's lemma, as $t \to \infty$, we obtain

$$\mathbf{E}_{x,i}\tau_D \leq \frac{1}{c}W(x,i) < \infty,$$

as desired. □

Remark 3.2. A closer examination of the proof shows that the conclusion of Theorem 3.1 remains valid if we replace the uniform ellipticity condition (1.5) by a weaker condition as follows: There exist some $\iota = 1, 2, \ldots, r$ and positive constant κ such that

$$a_{\iota\iota}(x,i) \geq \kappa \quad \text{for any} \quad (x,i) \in D \times \mathcal{M}. \tag{3.5}$$

To facilitate subsequent discussions, in what follows we present a twice continuously differentiable (with respect to the variable x) function $u(\cdot,\cdot) : \mathbb{R}^r \times \mathcal{M} \mapsto \mathbb{R}$ that is called $\mathcal{L}$-*harmonic* in a domain $U \subset \mathbb{R}^r \times \mathcal{M}$ if $\mathcal{L}u(x,i) = 0$ for all $(x,i) \in U$. Following the well-known arguments in [8, Vol. II, Chapter 13], we obtain the following two lemmas. (Note that Lemma 3.3 was also proved in [9, Lemma 4.3], and in [6] for the case when the operator $\mathcal{L}$ is in divergence form.)

LEMMA 3.3. *Let $U = D \times \mathcal{M} \subset \mathbb{R}^r \times \mathcal{M}$, where $D \subset \mathbb{R}^r$ is a nonempty open set. Assume that $\mathbf{P}_{x,i}\{\tau_U < \infty\} = 1$ for any $(x,i) \in D \times \mathcal{M}$ and that $f(\cdot,i) \in C^2(D) \cap C(\overline{D})$ for each $i \in \mathcal{M}$. Then*

$$\mathcal{L}f(x,i) = 0 \quad \text{for any} \quad (x,i) \in D \times \mathcal{M} \tag{3.6}$$

if and only if

$$f(x,i) = \mathbf{E}_{x,i} f(X(\tau_U), \gamma(\tau_U)) = \sum_{j=1}^{m_0} \int_{\partial D} \mathbf{P}_{x,i} \left\{ (X(\tau_U), \gamma(\tau_U)) \in (dy \times \{j\}) \right\} f(y,j).$$

Moreover, we further assume that ∂D is sufficiently smooth, $\overline{D}$ is compact, and $\varphi(\cdot,i)$ is an arbitrary continuous function on ∂D for any $i \in \mathcal{M}$. Then

$$f(x,i) = \mathbf{E}_{x,i} \varphi(X(\tau_U), \gamma(\tau_U)) \tag{3.7}$$

is the unique solution of the differential equation (3.6) *with boundary condition*

$$\lim_{x \to x_0} f(x,i) = \varphi(x_0,i) \quad \text{for any} \quad (x_0,i) \in \partial D \times \mathcal{M}. \tag{3.8}$$

LEMMA 3.4. *Let $U = D \times \mathcal{M} \subset \mathbb{R}^r \times \mathcal{M}$, where $D \subset \mathbb{R}^r$ is a nonempty open set with compact closure. Suppose $g(\cdot,i) \in C_b(\overline{D})$ and $f(\cdot,i) \in C^2(D)$ for each $i \in \mathcal{M}$. Then f solves the boundary value problem*

$$\begin{cases} \mathcal{L}f(x,i) = -g, & (x,i) \in D \times \mathcal{M}, \\ f(x,i) = 0, & (x,i) \in \partial D \times \mathcal{M} \end{cases}$$

if and only if

$$f(x,i) = \mathbf{E}_{x,i} \int_0^{\tau_U} g(X(t), \gamma(t)) dt \quad \text{for all} \quad (x,i) \in D \times \mathcal{M}.$$

Using Lemmas 3.3 and 3.4, we proceed to prove that if the process $Y(t) = (X(t), \gamma(t))$ is recurrent (resp., positive recurrent) with respect to some "cylinder" $D \times \mathcal{M} \subset \mathbb{R}^r \times \mathcal{M}$, then it is recurrent (resp., positive recurrent) with respect to any "cylinder" $E \times \mathcal{M} \subset \mathbb{R}^r \times \mathcal{M}$, where D is any nonempty domain in $\mathbb{R}^r$ with compact closure. These results are proved in the following two lemmas. To preserve the flow of presentation, the proofs are postponed to the appendix.

LEMMA 3.5. *Let $D \subset \mathbb{R}^r$ be a nonempty open set with compact closure. Suppose that*

$$\mathbf{P}_{x,i}\{\sigma_D < \infty\} = 1 \quad \text{for any} \quad (x,i) \in D^c \times \mathcal{M}. \tag{3.9}$$

Then for any nonempty open set $E \subset \mathbb{R}^r$, we have

$$\mathbf{P}_{x,i}\{\sigma_E < \infty\} = 1 \quad \text{for any} \quad (x,i) \in E^c \times \mathcal{M}.$$

LEMMA 3.6. *Let $D \subset \mathbb{R}^r$ be a nonempty open set with compact closure. Suppose that*

$$\mathbf{E}_{x,i} \sigma_D < \infty \quad \text{for any} \quad (x,i) \in D^c \times \mathcal{M}. \tag{3.10}$$

Then for any nonempty open set $E \subset \mathbb{R}^r$, we have

$$\mathbf{E}_{x,i}\sigma_E < \infty \quad \text{for any} \quad (x,i) \in E^c \times \mathcal{M}.$$

The following lemma shows that if the process $Y(t) = (X(t), \gamma(t))$ reaches the "cylinder" $D \times \mathcal{M}$ in finite time a.s. $\mathbf{P}_{x,i}$, then it will visit the set $D \times \{\ell\}$ in finite time a.s. $\mathbf{P}_{x,i}$ for any $\ell \in \mathcal{M}$. Its proof, together with the proof of Lemma 3.8, is also placed in the appendix.

LEMMA 3.7. *Let $D \subset \mathbb{R}^r$ be a nonempty open set with compact closure satisfying*

$$\mathbf{P}_{y,j}\{\sigma_D < \infty\} = 1 \quad \text{for any} \quad (y,j) \in D^c \times \mathcal{M}. \tag{3.11}$$

Then for any $(x,i) \in \mathbb{R}^r \times \mathcal{M}$,

$$\mathbf{P}_{x,i}\{\sigma_{D,\ell} < \infty\} = 1 \quad \text{for any} \quad \ell \in \mathcal{M}. \tag{3.12}$$

With Lemma 3.7, we can now prove that if the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent with respect to some "cylinder" $D \times \mathcal{M}$, then it is positive recurrent with respect to the set $D \times \{\ell\} \subset \mathbb{R}^r \times \mathcal{M}$.

LEMMA 3.8. *Let $D \subset \mathbb{R}^r$ be a nonempty open set with compact closure satisfying*

$$\mathbf{E}_{y,j}\sigma_D < \infty \quad \text{for any} \quad (y,j) \in D^c \times \mathcal{M}. \tag{3.13}$$

Then for any $(x,i) \in \mathbb{R}^r \times \mathcal{M}$,

$$\mathbf{E}_{x,i}\sigma_{D,\ell} < \infty \quad \text{for any} \quad \ell \in \mathcal{M}. \tag{3.14}$$

Remark 3.9. By virtue of Lemmas 3.5–3.8, under assumption (A), the process $Y(t) = (X(t), \gamma(t))$ is recurrent (resp., positive recurrent) with respect to some "cylinder" $D \times \mathcal{M}$ if and only if it is recurrent (resp., positive recurrent) with respect to the product set $D \times \{\ell\} \subset \mathbb{R}^r \times \mathcal{M}$ for any $\ell \in \mathcal{M}$. Also we have proved that the properties of recurrence and positive recurrence are independent of the choice of the set D. We summarize these into the following theorem.

THEOREM 3.10. *Suppose that* (A) *holds. Then the following assertions hold:*

(i) *The process $Y(t) = (X(t), \gamma(t))$ is recurrent (resp., positive recurrent) with respect to $D \times \mathcal{M}$ if and only if it is recurrent (resp., positive recurrent) with respect to $D \times \{\ell\}$, where $D \subset \mathbb{R}^r$ is a nonempty open set with compact closure and $\ell \in \mathcal{M}$.*

(ii) *If the process $Y(t) = (X(t), \gamma(t))$ is recurrent (resp., positive recurrent) with respect to some $U = D \times \mathcal{M}$, where $D \subset \mathbb{R}^r$ is a nonempty open set with compact closure, then it is recurrent (resp., positive recurrent) with respect to any $\widetilde{U} = \widetilde{D} \times \mathcal{M}$, where $\widetilde{D} \subset \mathbb{R}^r$ is any nonempty open set.*

Remark 3.11. In view of Theorem 3.10, we make the following remarks.

(i) A regular process $Y(t) = (X(t), \gamma(t))$ with the associated generator $\mathcal{L}$ satisfying (A) is said to be *recurrent* if it is recurrent with respect to some $U = D \times \{\ell\}$, where $D \subset \mathbb{R}^r$ is a nonempty bounded open set and $\ell \in \mathcal{M}$; otherwise it is said to be *transient*.

(ii) Henceforth, we call a recurrent process $Y(t) = (X(t), \gamma(t))$ *positive recurrent* if it is positive recurrent with respect to some bounded domain $U = D \times \{\ell\} \subset \mathbb{R}^r \times \mathcal{M}$; otherwise, we have a *null recurrent* process.

3.2. General criteria.

THEOREM 3.12. *A necessary and sufficient condition for positive recurrence with respect to a domain $U = D \times \{\ell\} \subset \mathbb{R}^r \times \mathcal{M}$ is that for each $i \in \mathcal{M}$, there exists a nonnegative function $V(\cdot, i) : D^c \mapsto \mathbb{R}$ such that $V(\cdot, i)$ is twice continuously differentiable and that*

$$\mathcal{L}V(x,i) = -1, \quad (x,i) \in D^c \times \mathcal{M}. \tag{3.15}$$

Let $u(x,i) = \mathbf{E}_{x,i}\sigma_D$. Then $u(x,i)$ is the smallest positive solution of

$$\begin{cases} \mathcal{L}u(x,i) = -1, & (x,i) \in D^c \times \mathcal{M}, \\ u(x,i) = 0, & (x,i) \in \partial D \times \mathcal{M}, \end{cases} \tag{3.16}$$

where ∂D denotes the boundary of D.

Proof. The proof is organized into three steps.

Step 1. Show that the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent if there exists a nonnegative function $V(\cdot, \cdot)$ satisfying the conditions of the theorem. Choose n_0 to be a positive integer sufficiently large so that $D \subset \{|x| < n_0\}$. Fix any $(x,i) \in D^c \times \mathcal{M}$. For any $t > 0$ and $n \in \mathbb{N}$ with $n > n_0$, we define

$$\sigma_D^{(n)}(t) = \min\{\sigma_D, t, \beta_n\},$$

where β_n is defined as in (2.4) and σ_D is the first entrance time to D. That is, $\sigma_D = \inf\{t : X(t) \in D\}$. Now Dynkin's formula and (3.15) imply that

$$\begin{aligned} &\mathbf{E}_{x,i} V\Big(X\Big(\sigma_D^{(n)}(t)\Big), \gamma\Big(\sigma_D^{(n)}(t)\Big)\Big) - V(x,i) \\ &\quad = \mathbf{E}_{x,i} \int_0^{\sigma_D^{(n)}(t)} \mathcal{L}V(X(s), \gamma(s))ds = -\mathbf{E}_{x,i}\sigma_D^{(n)}(t). \end{aligned}$$

Note that the function V is nonnegative; hence we have $\mathbf{E}_{x,i}\sigma_D^{(n)}(t) \le V(x,i)$. Meanwhile, since the process $Y(t) = (X(t), \gamma(t))$ is regular, it follows from (2.5) that $\sigma_D^{(n)}(t) \to \sigma_D(t)$ a.s. as $n \to \infty$, where $\sigma_D(t) = \min\{\sigma_D, t\}$. By virtue of Fatou's lemma, we obtain

$$\mathbf{E}_{x,i}\sigma_D(t) \le V(x,i). \tag{3.17}$$

Now the argument after (3.4) in the proof of Theorem 3.1 yields that $\mathbf{E}_{x,i}\sigma_D \le V(x,i) < \infty$. Then Lemma 3.8 implies that $\mathbf{E}_{x,i}\sigma_U = \mathbf{E}_{x,i}\sigma_{D,\ell} < \infty$. Since $(x,i) \in D^c \times \mathcal{M}$ is arbitrary, we conclude that $Y(t)$ is positive recurrent with respect to U.

Step 2. Show that $u(x,i) := \mathbf{E}_{x,i}\sigma_D$ is the smallest positive solution of (3.16). To this end, let n_0 be defined as before, that is, a positive integer sufficiently large so that $D \subset \{|x| < n_0\}$. For $n \ge n_0$, set $\sigma_D^{(n)} = \min\{\sigma_D, \beta_n\}$. Clearly, we have $\sigma_D^{(n)} \le \sigma_D^{(n+1)}$ for all $n \ge n_0$. Then the regularity of the process $Y(t)$ implies that $\sigma_D^{(n)} \nearrow \sigma_D$ a.s. as $n \to \infty$. Hence the monotone convergence theorem implies that as $n \to \infty$,

$$\mathbf{E}_{x,i}\sigma_D^{(n)} \nearrow \mathbf{E}_{x,i}\sigma_D. \tag{3.18}$$

Note that $\mathbf{E}_{x,i}\sigma_D < \infty$ from Step 1. Meanwhile, Lemma 3.4 implies that the function $u_n(x,i) = \mathbf{E}_{x,i}\sigma_D^{(n)}$ solves the boundary value problem

$$\mathcal{L}u_n(x,i) = -1, \quad u_n(x,i)|_{x \in \partial D} = 0, \quad u_n(x,i)|_{|x|=n} = 0, \quad i \in \mathcal{M}. \tag{3.19}$$

Thus the function $v_n(x,i) := u_{n+1}(x,i) - u_n(x,i)$ is $\mathcal{L}$-harmonic in the domain $(D^c \cap \{|x| < n\}) \times \mathcal{M}$. Since $\sigma_D^{(n)} \le \sigma_D^{(n+1)}$, it follows that $\mathbf{E}_{x,i}\sigma_D^{(n)} \le \mathbf{E}_{x,i}\sigma_D^{(n+1)}$, and hence $v_n(x,i) \ge 0$. Now (3.18) implies that

$$u(x,i) = u_{n_0}(x,i) + \sum_{k=n_0}^{\infty} v_k(x,i). \tag{3.20}$$

Using Harnack's inequality for $\mathcal{L}$-elliptic systems of equations (see [1, 7], and also [30] for general references on elliptic systems), it can be shown by a slight modification of the well-known arguments (see, for example, [10, pp. 21–22]) that the sum of a convergent series of positive $\mathcal{L}$-harmonic functions is also an $\mathcal{L}$-harmonic function. Hence we conclude that $u(x,i)$ is twice continuously differentiable and satisfies (3.16). To verify that $u(x,i)$ is the smallest positive solution of (3.16), let $w(x,i)$ be any positive solution of (3.16). Note that $u_n(x,i) = \mathbf{E}_{x,i}\sigma_D^{(n)}$ satisfies the boundary conditions

$$u_n(x,i)|_{x\in\partial D} = 0, \quad u_n(x,i)|_{|x|=n} = 0, \quad i \in \mathcal{M}.$$

Then the functions $u_n(x,i) - w(x,i), i \in \mathcal{M}$, are $\mathcal{L}$-harmonic and satisfy $u_n(x,i) - w(x,i) = 0$ for $(x,i) \in \partial D \times \mathcal{M}$ and $u_n(x,i) - w(x,i) < 0$ for $(x,i) \in \{|x| = n\} \times \mathcal{M}$. Hence it follows from the maximum principle for $\mathcal{L}$-elliptic system of equations [27, p. 192] that $u_n(x,i) \le w(x,i)$ in $(D^c \cap \{|x| < n\}) \times \mathcal{M}$ for all $n \ge n_0$. Letting $n \to \infty$, we obtain $u(x,i) \le w(x,i)$, as desired.

Step 3. Show that there exists a nonnegative function V satisfying the conditions of the theorem if the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent with respect to the domain $U = D \times \{\ell\}$. Then $\mathbf{E}_{x,i}\sigma_D < \infty$ for all $(x,i) \in D^c \times \mathcal{M}$, and consequently (3.20) and Harnack's inequality for the $\mathcal{L}$-elliptic system of equations [1, 7] imply that the bounded monotone increasing sequence $u_n(x,i)$ converges uniformly on every compact subset of $D^c \times \mathcal{M}$. Moreover, its limit $u(x,i)$ satisfies the equation $\mathcal{L}u(x,i) = -1$ for every $i \in \mathcal{M}$. Therefore the function $V(x,i) := u(x,i)$ satisfies (3.15). This completes the proof of the theorem. □

THEOREM 3.13. *A necessary and sufficient condition for positive recurrence with respect to a domain $U = D \times \{\ell\} \subset \mathbb{R}^r \times \mathcal{M}$ is that for each $i \in \mathcal{M}$, there exists a nonnegative function $V(\cdot,i) : D^c \mapsto \mathbb{R}$ such that $V(\cdot,i)$ is twice continuously differentiable and that for some $\alpha > 0$,*

$$\mathcal{L}V(x,i) \le -\alpha, \quad (x,i) \in D^c \times \mathcal{M}. \tag{3.21}$$

Proof. Necessity. This part follows immediately from the necessity of Theorem 3.12 with $\alpha = -1$.

Sufficiency. Suppose that there exists a nonnegative function V satisfying the conditions of the theorem. Define the stopping time $\sigma_D^{(n)}(t) = \min\{\sigma_D, t, \beta_n\}$ as in the proof of Theorem 3.12. Now Dynkin's formula and (3.21) imply that for any $(x,i) \in D^c \times \mathcal{M}$,

$$\begin{aligned}
&\mathbf{E}_{x,i}V\left(X\left(\sigma_D^{(n)}(t)\right), \gamma\left(\sigma_D^{(n)}(t)\right)\right) - V(x,i) \\
&\quad = \mathbf{E}_{x,i}\int_0^{\sigma_D^{(n)}(t)} \mathcal{L}V(X(s),\gamma(s))ds \le -\alpha\mathbf{E}_{x,i}\sigma_D^{(n)}(t).
\end{aligned}$$

Hence we have by the nonnegativity of the function V that $\mathbf{E}_{x,i}\sigma_D^{(n)}(t) \le \frac{1}{\alpha}V(x,i)$. Meanwhile, the regularity of the process $Y(t) = (X(t), \gamma(t))$ implies that $\sigma_D^{(n)}(t) \to$

$\sigma_D(t)$ a.s. as $n \to \infty$, where $\sigma_D(t) = \min\{\sigma_D, t\}$. Therefore Fatou's lemma leads to $\mathbf{E}_{x,i}\sigma_D(t) \le \frac{1}{\alpha}V(x,i)$. Moreover, from the proof of Theorem 3.12, $\sigma_D(t) \to \sigma_D$ a.s. as $t \to \infty$. Thus we obtain $\mathbf{E}_{x,i}\sigma_D \le \frac{1}{\alpha}V(x,i)$ by applying Fatou's lemma again. Then Lemma 3.8 implies that $\mathbf{E}_{x,i}\sigma_U = \mathbf{E}_{x,i}\sigma_{D,\ell} < \infty$. Since $(x,i) \in D^c \times \mathcal{M}$ is arbitrary, we conclude that $Y(t)$ is positive recurrent with respect to U. This completes the proof of the theorem. □

3.3. Examples. In this subsection, we provide two examples to illustrate Theorems 3.12 and 3.13.

Example 3.14. Suppose that for each $x \in \mathbb{R}^r$ and each $i \in \mathcal{M}$, there exist positive constants c and α such that for all x with $|x| \ge c$,

$$\left\langle b(x,i), \frac{x}{|x|} \right\rangle < -\alpha, \tag{3.22}$$

where $|x|$ denotes the norm of x. Then the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent.

First note that (1.5) implies that for all x with $|x| \ge \frac{r}{\alpha\kappa_1}$, we have

$$\operatorname{tr}(a(x,i)) = \sum_{j=1}^{r} \langle a(x,i)e_j, e_j \rangle \le \sum_{j=1}^{r} \kappa_1^{-1} \le \alpha|x|.$$

Then by Theorem 3.10, it is enough to prove that the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent with respect to the domain $U := \{|x| < \varrho\} \times \{\ell\}$ for some $\ell \in \mathcal{M}$, where $\varrho := \max\{c, \frac{r}{\alpha\kappa_1}\}$. To this end, consider the function

$$V(x,i) = \frac{1}{2}\langle x, x \rangle \quad \text{for each} \quad i \in \mathcal{M} \quad \text{and for all } |x| \ge \varrho.$$

Then for each $i \in \mathcal{M}$, $\nabla V(\cdot, i) = x$ and $\nabla^2 V(\cdot, i) = I$, where I is the $r \times r$ identity matrix. Thus by the definition of $\mathcal{L}$, we have for all $(x,i) \in \{|x| \ge \varrho\} \times \mathcal{M}$ that

$$\mathcal{L}V(x,i) = \frac{1}{2}\operatorname{tr}(a(x,i)) + \left\langle b(x,i), \frac{x}{|x|} \right\rangle |x| < \frac{1}{2}\alpha|x| - \alpha|x| = -\frac{1}{2}\alpha|x| \le -\frac{1}{2}\alpha\varrho.$$

Then the conclusion immediately follows from Theorem 3.13.

Remark 3.15. Suppose that the diffusion component $X(t)$ of the process $Y(t) = (X(t), \gamma(t))$ is one-dimensional and that there exist constants $c_0 > 0$ and $c_1 > 0$ such that for each $i \in \mathcal{M}$,

$$b(x,i) \begin{cases} < -c_1 & \text{for } x > c_0, \\ > c_1 & \text{for } x < -c_0. \end{cases} \tag{3.23}$$

Then the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent. In fact, the conclusion follows immediately if we observe that (3.23) satisfies (3.22). Alternatively, we can verify this directly by defining the Liapunov function $V(x,i) = |x|$ for each $i \in \mathcal{M}$.

Example 3.16. To illustrate the utility of Theorem 3.13, consider a real-valued process

$$dX(t) = b(X(t), \gamma(t))dt + \sigma(X(t), \gamma(t))dw(t), \tag{3.24}$$

where $\gamma(t)$ is a two-state random jump process, with x-dependent generator

$$Q(x) = \begin{pmatrix} -\frac{1}{3} - \frac{1}{4}\cos x & \frac{1}{3} + \frac{1}{4}\cos x \\ \frac{7}{3} + \frac{1}{2}\sin x & -\frac{7}{3} - \frac{1}{2}\sin x \end{pmatrix},$$

and

$$b(x,1) = -x, \quad \sigma(x,1) = 1, \quad b(x,2) = x, \quad \sigma(x,2) = 1.$$

Thus (3.24) can be regarded as the result of the following two diffusions:

$$dX(t) = -X(t)dt + dw(t), \tag{3.25}$$

$$dX(t) = X(t)dt + dw(t), \tag{3.26}$$

switching back and forth from one to the other according to the movement of $\gamma(t)$.

Note that (3.25) is positive recurrent while (3.26) is a transient diffusion process. But, the switching diffusion (3.24) is positive recurrent. We verify these as follows. Consider the Liapunov function $V(x,1) = |x|$. Let $\mathcal{L}_1$ be the operator associated with (3.25). Then we have for all $|x| \geq 1$, $\mathcal{L}_1 V(x,1) = -x \cdot \operatorname{sign} x = -|x| \leq -1 < 0$. Thus it follows from [16, Theorem 3.7.3] that (3.25) is positive recurrent. Recall that the real-valued diffusion process $dX(t) = b(X(t))dt + \sigma(X(t))dw(t)$ with $\sigma(x) \neq 0$ for all $x \in \mathbb{R}$ is recurrent if and only if $\int_0^x \exp\{-2\int_0^u \frac{b(z)}{\sigma^2(z)}dz\}du \to \pm\infty$ as $x \to \pm\infty$; see [16, p. 105]. Direct computation shows that (3.26) fails to satisfy this condition and hence is transient.

Next, we use Theorem 3.13 to demonstrate that the switching diffusion (3.24) is positive recurrent for appropriate Q. Consider Liapunov functions

$$V(x,1) = |x|, \quad V(x,2) = \frac{7}{3}|x|.$$

Then we have

$$\mathcal{L}V(x,1) = -x \cdot \operatorname{sign} x + \left(\frac{1}{3} + \frac{1}{4}\cos x\right)\left(\frac{7}{3} - 1\right)|x| \leq -\frac{2}{9}|x| \leq -\frac{2}{9},$$

$$\mathcal{L}V(x,2) = x \cdot \frac{7}{3}\operatorname{sign} x + \left(\frac{7}{3} + \frac{1}{2}\sin x\right)\left(1 - \frac{7}{3}\right)|x| \leq -\frac{1}{9}|x| \leq -\frac{1}{9}$$

for all $|x| \geq 1$. Then the switching diffusion (3.24) is positive recurrent by Theorem 3.13.

4. Ergodicity. In this section, we study the ergodic properties of the process $Y(t) = (X(t), \gamma(t))$ under the assumption that the process is positive recurrent with respect to some bounded domain $U = E \times \{\ell\}$, where $E \subset \mathbb{R}^r$ and $\ell \in \mathcal{M}$ are fixed throughout this section. We also assume that the boundary ∂E of E is sufficiently smooth. Let the operator $\mathcal{L}$ satisfy (A). Then it follows from Theorem 3.10 that the process is positive recurrent with respect to any nonempty open set.

Let $D \subset \mathbb{R}^r$ be a bounded ball with sufficiently smooth boundary ∂D such that $E \cup \partial E \subset D$. Let $\varsigma_0 = 0$ and define the stopping times $\varsigma_1, \varsigma_2, \ldots$ inductively as follows: ς_{2n+1} is the first time after ς_{2n} at which the process $Y(t) = (X(t), \gamma(t))$ reaches the set $\partial E \times \{\ell\}$, and ς_{2n+2} is the first time after ς_{2n+1} at which the path reaches the set $\partial D \times \{\ell\}$. Now we can divide an arbitrary sample path of the process $Y(t) = (X(t), \gamma(t))$ into cycles:

$$[\varsigma_0, \varsigma_2), [\varsigma_2, \varsigma_4), \ldots, [\varsigma_{2n}, \varsigma_{2n+2}), \ldots. \tag{4.1}$$

Figure 1 presents a demonstration of such cycles when the discrete component $\gamma(\cdot)$ has three states.

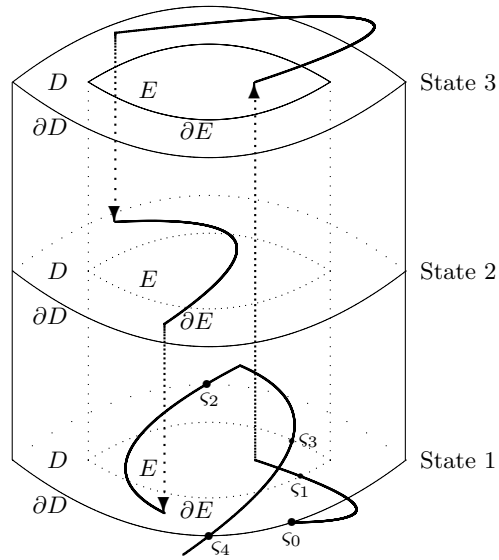

FIG. 1. *A sample path of the process* $Y(t) = (X(t), \gamma(t))$ *when* $m_0 = 3$.

The process $Y(t) = (X(t), \gamma(t))$ is positive recurrent with respect to $E \times \{\ell\}$ and hence positive recurrent with respect to $D \times \{\ell\}$ by Theorem 3.10. It follows that all the stopping times $\varsigma_0 < \varsigma_1 < \varsigma_2 < \varsigma_3 < \varsigma_4 < \cdots$ are finite a.s. Since the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent, we may assume without loss of generality that $Y(0) = (X(0), \gamma(0)) = (x, \ell) \in \partial D \times \{\ell\}$. It follows from the strong Markov property of the process $Y(t) = (X(t), \gamma(t))$ that the sequence $\{Y_n\}$ is a Markov chain on $\partial D \times \{\ell\}$, where $Y_n = Y(\varsigma_{2n}) = (X_n, \ell)$, $n = 0, 1, 2, \ldots$. Let $\widetilde{P}(x, A)$ denote the one-step transition probabilities of this Markov chain, that is,

$$\widetilde{P}(x, A) = \mathbf{P}\left(Y_1 \in (A \times \{\ell\}) \mid Y_0 = (x, \ell)\right),$$

for any $x \in \partial D$ and $A \in \mathcal{B}(\partial D)$, where $\mathcal{B}(\partial D)$ denotes the collection of Borel measurable sets on ∂D. Note that the process $Y(t) = (X(t), \gamma(t))$, starting from (x, ℓ), may jump many times before it reaches the set (A, ℓ); see [28] for more details. Denote by $\widetilde{P}^{(n)}(x, A)$ the n-step transition probability of the Markov chain for any $n \geq 1$. For any Borel measurable function $f : \mathbb{R}^r \mapsto \mathbb{R}$, set

$$\mathbf{E}_x f(X_1) := \mathbf{E}_{x,\ell} f(X_1) = \int_{\partial D} f(y) \widetilde{P}(x, dy). \tag{4.2}$$

Throughout this section, for simplicity we write $\mathbf{E}_x$ for $\mathbf{E}_{x,\ell}$. We will show that the process $Y(t) = (X(t), \gamma(t))$ possesses a unique stationary distribution. To this end, we need the following lemma.

LEMMA 4.1. *The Markov chain* $Y_i = (X_i, \ell)$ *has a unique stationary distribution* $m(\cdot)$ *such that*

$$\left|\widetilde{P}^{(n)}(x, A) - m(A)\right| < \lambda^n \quad \textit{for any} \quad A \in \mathcal{B}(\partial D), \tag{4.3}$$

for some constant $0 < \lambda < 1$.

Proof. Note that

$$\begin{aligned}\widetilde{P}(x,A) &= \mathbf{P}\left\{Y_1 \in (A\times\{\ell\})|Y_0=(x,\ell)\right\}\\ &= \int_{\partial E} \mathbf{P}_{x,\ell}\left\{(X(\varsigma_1),\gamma(\varsigma_1))\in(dy\times\{\ell\})\right\}\cdot \mathbf{P}_{y,\ell}\left\{(X(\varsigma_2),\gamma(\varsigma_2))\in(A\times\{\ell\})\right\}.\end{aligned}$$

Using the harmonic measure defined in and Lemmas 2.2 and 2.3 of [7], relating the kernel and surface area (similar to the solution for the diffusion process without switching in the form of double layer potential given in the first displayed equation in [16, p. 97]) and the harmonic measure, we can finish the proof of this lemma analogously to that of [16, Lemma 4.4.1]. The details are omitted here. □

Remark 4.2. Note that

$$(X^{s,X(s),\gamma(s)}(t),\gamma(t)) = (X^{0,X(0),\gamma(0)}(t+s),\gamma(t+s)), \tag{4.4}$$

where $(X^{0,X(0),\gamma(0)}(u),\gamma(u))$ denotes the sample path of the process $(X(\cdot),\gamma(\cdot))$ with initial point $(X(0),\gamma(0))$ at time $t=0$, and note the similar definition for $(X^{s,X(s),\gamma(s)}(t),\gamma(t))$. When no confusion arises, we simply write $(X(u),\gamma(u)) = (X^{0,X(0),\gamma(0)}(u),\gamma(u))$.

Let τ be an $\mathcal{F}_t$ stopping time with $\mathbf{E}_{x,i}\tau<\infty$ and let $f:\mathbb{R}^r\times\mathcal{M}\mapsto\mathbb{R}$ be a Borel measurable function. Then

$$\mathbf{E}_{x,i}\int_0^\tau f(X(s+t),\gamma(s+t))ds = \mathbf{E}_{x,i}\int_0^\tau \mathbf{E}_{X(s),\gamma(s)}f(X(s+t),\gamma(s+t))ds. \tag{4.5}$$

Now we can explicitly construct the stationary distribution of the process $Y(t)=(X(t),\gamma(t))$.

THEOREM 4.3. *The positive recurrent process $Y(t)=(X(t),\gamma(t))$ has a unique stationary distribution $\widehat{\nu}(\cdot,\cdot)=(\widehat{\nu}(\cdot,i):i\in\mathcal{M})$.*

Proof. Let $A\in\mathcal{B}(\mathbb{R}^r)$ and $i\in\mathcal{M}$. Denote by $\tau^{A\times\{i\}}$ the time spent by the path of $Y(t)=(X(t),\gamma(t))$ in the set $(A\times\{i\})$ during the first cycle (the cycles were defined in (4.1)). Set

$$\nu(A,i) := \int_{\partial D} m(dx)\mathbf{E}_x\tau^{A\times\{i\}}, \tag{4.6}$$

where $m(\cdot)$ is the stationary distribution of $Y_i=(X_i,\ell)$, whose existence is guaranteed by Lemma 4.1. It is easy to verify that $\nu(\cdot,\cdot)$ is a positive measure defined on $\mathcal{B}(\mathbb{R}^r)\times\mathcal{M}$. Thus for any bounded Borel measurable function $g(\cdot):\mathbb{R}^r\mapsto\mathbb{R}$, it follows from (4.2) and Fubini's theorem that

$$\int_{\partial D}\mathbf{E}_x g(X_1)m(dx) = \int_{\partial D} m(dx)\int_{\partial D} g(y)\widetilde{P}(x,dy) = \int_{\partial D} g(y)m(dy). \tag{4.7}$$

Now we claim that for any bounded and continuous function $f(\cdot,\cdot)$,

$$\sum_{j=1}^{m_0}\int_{\mathbb{R}^r} f(y,j)\nu(dy,j) = \int_{\partial D} m(dx)\mathbf{E}_x\int_0^{\varsigma_2} f(X(t),\gamma(t))dt \tag{4.8}$$

holds. In fact, if $f(y,j)=\chi_{[A\times\{i\}]}(y,j)$ for some $A\in\mathcal{B}(\mathbb{R}^r)$ and $i\in\mathcal{M}$, then from (4.6),

$$\begin{aligned}\sum_{j=1}^{m_0}\int_{\mathbb{R}^r}\chi_{[A\times\{i\}]}(y,j)\nu(dy,j) = \nu(A,i) &= \int_{\partial D} m(dx)\mathbf{E}_x\tau^{A\times\{i\}}\\ &= \int_{\partial D} m(dx)\mathbf{E}_x\int_0^{\varsigma_2}\chi_{[A\times\{i\}]}(X(t),\gamma(t))dt.\end{aligned}$$

Similarly, we obtain that (4.8) holds for f being a simple function:

$$f(y,j)=\sum_{p=1}^{n} c_p \chi_{U_p}(y,j), \text{ where } U_p \subset \mathbb{R}^r \times \mathcal{M}.$$

Finally, if f is a bounded and continuous function, (4.8) follows by approximating f by simple functions. It follows from (4.8), (4.4), and (4.5) that

$$\begin{aligned}
&\sum_{i=1}^{m_0} \int_{\mathbb{R}^r} \mathbf{E}_{x,i} f(X(t),\gamma(t))\nu(dx,i)\\
&\quad = \int_{\partial D} m(dx)\mathbf{E}_x \int_0^{\varsigma_2} \mathbf{E}_{X(s),\gamma(s)} f(X(t+s),\gamma(t+s))ds\\
&\quad = \int_{\partial D} m(dx)\mathbf{E}_x \int_0^{\varsigma_2} f(X(t+s),\gamma(t+s))ds\\
&\quad = \int_{\partial D} m(dx)\mathbf{E}_x \int_0^{\varsigma_2} f(X(u),\gamma(u))du\\
&\qquad + \int_{\partial D} m(dx)\mathbf{E}_x \int_{\varsigma_2}^{t+\varsigma_2} f(X(u),\gamma(u))du - \int_{\partial D} m(dx)\mathbf{E}_x \int_0^{t} f(X(u),\gamma(u))du.
\end{aligned}$$

Now applying (4.7) with $g(x)=\mathbf{E}_x \int_{\varsigma_2}^{\varsigma_2+t} f(X(u),\gamma(u))du$, we obtain

$$\begin{aligned}
&\int_{\partial D} m(dx)\mathbf{E}_x \int_{\varsigma_2}^{\varsigma_2+t} f(X(u),\gamma(u))du\\
&\qquad = \int_{\partial D} m(dx)\mathbf{E}_x \mathbf{E}_{X_1,\ell} \int_{\varsigma_2}^{\varsigma_2+t} f(X(u+\varsigma_2),\gamma(u+\varsigma_2))du\\
&\qquad = \int_{\partial D} m(dx)\mathbf{E}_x \int_0^{t} f(X(u),\gamma(u))du.
\end{aligned}$$

Note that in the above deduction, we used (4.4) again. Therefore, the above two equations and (4.8) yield that

$$\sum_{i=1}^{m_0} \int_{\mathbb{R}^r} \mathbf{E}_{x,i} f(X(t),\gamma(t))\nu(dx,i) = \sum_{i=1}^{m_0} \int_{\mathbb{R}^r} f(x,i)\nu(dx,i).$$

Thus, the normalized measure

$$\widehat{\nu}(A,i)=\frac{\nu(A,i)}{\sum_{j=1}^{m_0}\nu(\mathbb{R}^r,j)},\ i\in\mathcal{M}, \tag{4.9}$$

defines the desired stationary distribution. The theorem thus follows. □

THEOREM 4.4. *Denote by $\mu(\cdot,\cdot)$ the stationary density associated with the stationary distribution $\widehat{\nu}(\cdot,\cdot)$ constructed in Theorem* 4.3*, and let $f(\cdot,\cdot):\mathbb{R}^r\times\mathcal{M}\mapsto\mathbb{R}$ be a Borel measurable function such that*

$$\sum_{i=1}^{m_0}\int_{\mathbb{R}^r} |f(x,i)|\mu(x,i)dx<\infty. \tag{4.10}$$

Then

$$\mathbf{P}_{x,i}\left(\frac{1}{T}\int_0^T f(X(t),\gamma(t))dt \to \overline{f}\right)=1 \tag{4.11}$$

for any $(x,i)\in\mathbb{R}^r\times\mathcal{M}$, *where*

$$\overline{f}=\sum_{i=1}^{m_0}\int_{\mathbb{R}^r} f(x,i)\mu(x,i)dx. \tag{4.12}$$

Proof. We first prove (4.11) if the initial distribution is the stationary distribution of the Markov chain $Y_i=(X_i,\gamma_i)$, that is,

$$\mathbf{P}\{(X(0),\gamma(0))\in(A\times\{\ell\})\}=m(A) \tag{4.13}$$

for any $A\in\mathcal{B}(\partial D)$. Consider the sequence of random variables

$$\eta_n=\int_{\varsigma_{2n}}^{\varsigma_{2n+2}} f(X(t),\gamma(t))dt. \tag{4.14}$$

Then it follows from (4.13) that $\{\eta_n\}$ is a strictly stationary sequence. Also from (4.6) and (4.8), we have

$$\mathbf{E}\eta_n=\sum_{i=1}^{m_0}\int_{\mathbb{R}^r} f(x,i)\nu(dx,i) \tag{4.15}$$

for all $n=0,1,2,\ldots$. Meanwhile, (4.3) implies that the sequence η_n is metrically transitive. Let $\upsilon(T)$ denote the number of cycles completed up to time T. That is,

$$\upsilon(T):=\max\left\{n\in\mathbb{N}:\sum_{k=1}^{n}(\varsigma_{2k}-\varsigma_{2k-2})\le T\right\}.$$

Then we can decompose $\int_0^T f(X(t),\gamma(t))dt$ into

$$\int_0^T f(X(t),\gamma(t))dt=\sum_{n=0}^{\upsilon(T)}\eta_n+\int_{\varsigma_{2\upsilon(T)}}^{T} f(X(t),\gamma(t))dt, \tag{4.16}$$

with η_n as given in (4.14). We may assume without loss of generality that $f(x,i)\ge 0$; for the general case, we can write $f(x,i)$ as a difference of two nonnegative functions. Then it follows from (4.16) that

$$\sum_{n=0}^{\upsilon(T)}\eta_n\le\int_0^T f(X(t),\gamma(t))dt\le\sum_{n=0}^{\upsilon(T)+1}\eta_n.$$

Since the sequence $\{\eta_n\}$ is stationary and metrically transitive, the law of large numbers for such sequences implies that

$$\mathbf{P}\left\{\frac{1}{n}\sum_{k=0}^{n}\eta_k\overset{n\to\infty}{\longrightarrow}\sum_{i=1}^{m_0}\int_{\mathbb{R}^r} f(x,i)\nu(dx,i)\right\}=1. \tag{4.17}$$

In particular, if $f(x,i)\equiv 1$, then the above equation reduces to

$$\mathbf{P}\left\{\frac{\varsigma_{2n+2}}{n}\overset{n\to\infty}{\longrightarrow}\sum_{i=1}^{m_0}\nu(\mathbb{R}^r,i)\right\}=1. \tag{4.18}$$

Note that the positive recurrence of the process $Y(t) = (X(t), \gamma(t))$ implies that $\upsilon(T) \to \infty$ as $T \to \infty$. Clearly, $\upsilon(T)/(\upsilon(T)+1) \to 1$ a.s. as $T \to \infty$. Thus, it follows from (4.18) that as $T \to \infty$,

$$\frac{\varsigma_{2\upsilon(T)}}{\varsigma_{2\upsilon(T)+2}} = \frac{\frac{\varsigma_{2\upsilon(T)}}{\upsilon(T)}}{\frac{\varsigma_{2\upsilon(T)+2}}{\upsilon(T)+1}} \frac{\upsilon(T)}{\upsilon(T)+1} \to 1 \quad \text{a.s.} \tag{4.19}$$

Meanwhile, since $\varsigma_{2\upsilon(T)} \le T \le \varsigma_{2\upsilon(T)+2}$, we have

$$\frac{\varsigma_{2\upsilon(T)}}{\varsigma_{2\upsilon(T)+2}} \le \frac{\varsigma_{2\upsilon(T)}}{T} \le \frac{\varsigma_{2\upsilon(T)}}{\varsigma_{2\upsilon(T)}} = 1.$$

Therefore, we have from (4.19) that

$$\frac{\varsigma_{2\upsilon(T)}}{T} \to 1 \quad \text{a.s. as} \quad T \to \infty. \tag{4.20}$$

Moreover, (4.18) implies that

$$\frac{\upsilon(T)}{\varsigma_{2\upsilon(T)}} \to \frac{1}{\sum_{i=1}^{m_0} \nu(\mathbb{R}^r, i)} \quad \text{a.s. as} \quad T \to \infty. \tag{4.21}$$

Now using (4.17), (4.20), and (4.21), we obtain

$$\mathbf{P}\left\{ \frac{1}{T}\int_0^T f(X(t),\gamma(t))dt = \frac{\int_0^T f(X(t),\gamma(t))dt}{\upsilon(T)} \cdot \frac{\upsilon(T)}{\varsigma_{2\upsilon(T)}} \cdot \frac{\varsigma_{2\upsilon(T)}}{T} \right.$$
$$\left. \overset{T\to\infty}{\longrightarrow} \sum_{i=1}^{m_0} \int_{\mathbb{R}^r} f(x,i)\widehat{\nu}(dx,i) \right\} = 1.$$

Finally, we note that

$$\int_{\mathbb{R}^r} f(x,i)\widehat{\nu}(dx,i) = \int_{\mathbb{R}^r} f(x,i)\mu(x,i)dx$$

by the definition of $\mu(\cdot,\cdot)$. Thus, (4.11) holds. This proves (4.11) if the initial distribution is (4.13).

Now let $(x,i) \in \mathbb{R}^r \times \mathcal{M}$. Since the process $Y(t) = (X(t), \gamma(t))$ is positive recurrent with respect to the domain $D \times \{\ell\}$, we have

$$\begin{aligned}
&\mathbf{P}_{x,i}\left\{ \lim_{T\to\infty} \frac{1}{T}\int_0^T f(X(t),\gamma(t))dt = a \right\} \\
&\quad = \mathbf{P}_{x,i}\left\{ \lim_{T\to\infty} \frac{1}{T}\int_{\varsigma_2}^T f(X(t),\gamma(t))dt = a \right\} \\
&\quad = \int_{\partial D} \mathbf{P}_{x,i}\{(X(\varsigma_2),\gamma(\varsigma_2)) \in (dy,\ell)\} \cdot \mathbf{P}_{y,\ell}\left\{ \lim_{T\to\infty} \frac{1}{T}\int_0^T f(X(t),\gamma(t))dt = a \right\} \\
&\quad = \mathbf{P}_{y,\ell}\left\{ \lim_{T\to\infty} \frac{1}{T}\int_0^T f(X(t),\gamma(t))dt = a \right\}.
\end{aligned}$$

Therefore, (4.11) holds for all $(x,i) \in \mathbb{R}^r \times \mathcal{M}$. This completes the proof of the theorem. □

As a consequence of Theorem 4.4, we obtain the following corollary.

COROLLARY 4.5. *Let the assumptions of Theorem* 4.4 *be satisfied and let* $u(t,x,i)$ *be the solution of the Cauchy problem*

$$\begin{cases} \dfrac{\partial u(t,x,i)}{\partial t} &= \mathcal{L}u(x,i),\ i\in\mathcal{M},\\ u(0,x,i) &= f(x,i). \end{cases} \tag{4.22}$$

Then as $T\to\infty$,

$$\frac{1}{T}\int_0^T u(t,x,i)dt \to \sum_{i=1}^{m_0}\int_{\mathbb{R}^r} f(x,i)\mu(x,i)dx. \tag{4.23}$$

Proof. The generalized Itô's formula (see, for example, [5] or [28, Lemma 3, p. 104]) implies that $u(t,x,i)=\mathbf{E}_{x,i}f(X(t),\gamma(t))$. Thus we have

$$\frac{1}{T}\int_0^T u(t,x,i)dt = \mathbf{E}_{x,i}\left(\frac{1}{T}\int_0^T f(X(t),\gamma(t))dt\right). \tag{4.24}$$

Meanwhile (4.11) implies that

$$\frac{1}{T}\int_0^T f(X(t),\gamma(t))dt \overset{T\to\infty}{\longrightarrow} \sum_{i=1}^{m_0}\int_{\mathbb{R}^r} f(x,i)\mu(x,i)dx \text{ a.s.}$$

with respect to the probability $\mathbf{P}_{x,i}$. Then (4.23) follows from the dominated convergence theorem. □

5. Discussions and remarks.

5.1. Discussions. The recurrence and ergodicity obtained enable us to further study asymptotic properties of hybrid diffusion systems and to carry out control and optimization tasks. We outline several directions in what follows.

Easily verifiable conditions. In many applications, it is often more convenient to analyze weak stability through conditions on the coefficients of the corresponding stochastic differential equations. Assume for simplicity that $X(\cdot)$ is a real-valued process; assume also that condition (A) holds. Motivated by Examples 3.14 and 3.16, next we present easily verifiable conditions for positive recurrence when the coefficients of the switching diffusions (1.3)–(1.4) are linearizable in an x-neighborhood of ∞. Suppose that for each $i\in\mathcal{M}$, there exists $b_i\in\mathbb{R}$ such that

$$\frac{b(x,i)}{x} = b_i + o(1), \quad \text{and} \quad Q(x)\to\widetilde{Q}, \quad \text{as} \quad |x|\to\infty,$$

where $\widetilde{Q}=(\widetilde{q}_{ij})$ is the generator of a continuous-time ergodic Markov chain $\widetilde{\gamma}(t)$ whose stationary distribution is $\mu=(\mu_1,\mu_2,\ldots,\mu_m)\in\mathbb{R}^{1\times m}$. Then using Theorems 3.10 and 3.13, we can prove that the process is positive recurrent if $\sum_{i=1}^m \mu_i b_i<0$. The result can be strengthened if, in addition,

$$\frac{\sigma(x,i)}{x} = \sigma_i + o(1) \quad \text{as} \quad |x|\to\infty,$$

where $\sigma_i^2 > 0$. Then in this case, the process is positive recurrent if

$$\sum_{i=1}^{m} \mu_i \Big(b_i - \frac{\sigma_i^2}{2} \Big) < 0.$$

The details are omitted for brevity.

Path excursions. Applications of the positive recurrence criteria enable us to establish path excursions of the underlying processes. Suppose that $Y(t) = (X(t), \gamma(t))$ is positive recurrent. Suppose that the Liapunov functions $V(x,i)$ (with $i \in \mathcal{M}$) are given as in Theorem 3.13, as is the set D. Let D_0 be a bounded open set with a compact closure satisfying $D \subset D_0$, and τ be a random time such that $(X(\tau), \gamma(\tau)) \in D_0^c \times \mathcal{M}$, and $\tau_1 = \min\{t > \tau : (X(t), \gamma(t)) \in D_0 \times \mathcal{M}\}$. We can obtain

$$\begin{aligned} &\mathbf{P}\left(\sup_{\tau \le t \le \tau_1} V(X(t), \gamma(t)) \ge \kappa \right) \le \frac{\mathbf{E}V(X(\tau), \gamma(\tau))}{\kappa} \quad \text{for} \quad \kappa > 0, \\ &\mathbf{E}(\tau_1 - \tau) \le \frac{\mathbf{E}V(X(\tau), \gamma(\tau))}{\alpha}, \end{aligned}$$

where α is as given in Theorem 3.13.

Tightness. Under positive recurrence, we may obtain tightness (or boundedness in the sense of probability) of the underlying process. Suppose that $(X(t), \gamma(t))$ is positive recurrent. It is then possible to prove that for any compact set $\overline{D}$, the set $\cup_{x \in \overline{D}} \{(X(t), \gamma(t)) : t \ge 0,\ X(0) = x,\ \gamma(0) = \gamma\}$ is tight (or bounded in probability). For a study on the diffusion counterpart, we refer the reader to [19, p. 146].

Occupation measures. To illustrate the utility of Theorem 4.4, take $f(x,i) = \chi_{[B \times J]}(x,i)$, the indicator function of the set $B \times J$, where $B \subset \mathbb{R}^r$ and $J \subset \mathcal{M}$. Then Theorem 4.4 becomes a result regarding an occupation measure. In fact, we have

$$\frac{1}{T} \int_0^T \chi_{[B \times J]}(X(t), \gamma(t)) dt \to \sum_{i \in J} \int_B \mu(x,i) dx \quad \text{a.s. as} \quad T \to \infty.$$

Stochastic approximation. Consider a parameter optimization problem. We wish to find θ_*, a vector-valued parameter, so that the cost function

$$J(\theta) = \lim_{T \to \infty} E \frac{1}{T} \int_0^T \widehat{J}(\theta, Y(t)) dt$$

is minimized, where $Y(t)$ is a positive recurrent switching diffusion as considered in this paper and where, for each θ, $\widehat{J}(\theta, \cdot, \cdot)$ satisfies the conditions of Theorem 4.4. For simplicity, we assume that the gradient of $\widehat{J}(\cdot, x, i)$ with respect to θ is available for each x and each $i \in \mathcal{M}$. Then we consider a constant stepsize recursive algorithm

$$\theta_{n+1} = \theta_n - \varepsilon \frac{1}{T} \int_{nT}^{nT+T} \nabla \widehat{J}(\theta_n, Y(t)) dt,$$

or a decreasing stepsize algorithm

$$\theta_{n+1} = \theta_n - \varepsilon_n \frac{1}{T} \int_{nT}^{nT+T} \nabla \widehat{J}(\theta_n, Y(t)) dt,$$

where $\varepsilon > 0$, and $\varepsilon_n \to 0$ as $n \to \infty$ and $\sum_n \varepsilon_n = \infty$. Modifications and variants are possible. For example, we may include additional measurement noise, and the gradient of $\widehat{J}(\cdot)$ may be changed to its gradient estimates. The motivation for such algorithms stems from optimization of average cost per unit time problems arising from parameter estimations in switching systems of stochastic differential equations, manufacturing systems, and queueing networks; see related work in [21, Chapter 9] and [32]. The ergodicity of the switching diffusion is crucial in the study of the asymptotic behavior of the algorithms.

5.2. Further remarks. This work developed asymptotic properties of positive recurrent switching diffusions. Under general conditions, necessary and sufficient conditions for positive recurrence were developed. Then ergodicity was established for positive recurrent Markov processes with switching. Also provided were explicit representations of the invariant measures. For new results on related problems of stability for regime-switching diffusions, we refer the reader to our recent work [18].

A number of problems remains open. Obtaining large deviations type of bounds is a worthwhile undertaking, which will have an important impact on studying the associated control and optimization problems. Next, concerning null recurrent switching diffusions (see [16, 17]), can we obtain necessary and sufficient conditions? It appears that the desired criteria will be more difficult to obtain compared to a single diffusion process since one needs to solve systems of boundary value problems.

Appendix. Proofs of the lemmas.

Proof of Lemma 3.5. It suffices to prove the lemma for the case when $E \cup \partial E \subset D$ and ∂E is sufficiently smooth. Fix any $(x,i) \in E^c \times \mathcal{M}$. Let $G \subset \mathbb{R}^r$ be an open and bounded set with a sufficiently smooth boundary such that $D \cup \partial D \subset G$. Without loss of generality, we may further assume that $(x,i) \in G \times \mathcal{M}$. Define a sequence of stopping times by

$$\varsigma_1 := \inf\{t \geq 0 : X(t) \in \partial G\}, \tag{A.1}$$

and for $n = 1, 2, \ldots$,

$$\begin{aligned} \varsigma_{2n} &:= \inf\{t \geq \varsigma_{2n-1} : X(t) \in \partial D\}, \\ \varsigma_{2n+1} &:= \inf\{t \geq \varsigma_{2n} : X(t) \in \partial G\}. \end{aligned} \tag{A.2}$$

It follows from (3.9) and Theorem 3.1 that $\varsigma_n < \infty$ a.s. $\mathbf{P}_{x,i}$ for $n = 1, 2, \ldots$. Let $H := G - \overline{E}$ and define $u(x,i) := \mathbf{P}_{x,i}\{X(\tau_H) \in \partial E\}$. Note that $u(x,j)|_{x \in \partial E} = 1$ and $u(x,j)|_{x \in \partial G} = 0$ for all $j \in \mathcal{M}$. Therefore, it follows that

$$\begin{aligned} u(x,i) &= \sum_{j=1}^{m_0} \int_{\partial E} \mathbf{P}_{x,i}\{(X(\tau_H), \gamma(\tau_H)) \in (dy \times \{j\})\}\, u(y,j) \\ &\quad + \sum_{j=1}^{m_0} \int_{\partial G} \mathbf{P}_{x,i}\{(X(\tau_H), \gamma(\tau_H)) \in (dy \times \{j\})\}\, u(y,j) \\ &= \mathbf{E}_{x,i} u(X(\tau_H), \gamma(\tau_H)). \end{aligned}$$

Thus $u(x,i) \geq 0$ is $\mathcal{L}$-harmonic in $H \times \mathcal{M}$ by Lemma 3.3. Moreover, u is not identically zero since $u(x,i) = 1$ for $(x,i) \in \partial E \times \mathcal{M}$. Therefore the maximum principle for $\mathcal{L}$-harmonic functions [9] implies that

$$\inf_{(x,i) \in K \times \mathcal{M}} u(x,i) \geq \delta_1 > 0, \tag{A.3}$$

where K is some compact subset of H containing x and ∂D. Define

$$A_0 := \{X(t) \in \partial E \ \text{ for some } \ t \in [0, \varsigma_1)\}, \tag{A.4}$$

and for $n = 1, 2, \ldots$,

$$A_n := \{X(t) \in \partial E, \ \text{for some } t \in [\varsigma_{2n}, \varsigma_{2n+1})\}. \tag{A.5}$$

Note that the event A_0^c implies that $X(\tau_H) = X(\varsigma_1) \in \partial G$. Hence we have from (A.3) that

$$\mathbf{P}_{x,i}(A_0^c) \le \mathbf{P}_{x,i}(X(\tau_H) \in \partial G) = 1 - u(x,i) \le 1 - \delta_1.$$

Then it follows from the strong Markov property and (A.3) that

$$\mathbf{P}_{x,i}\left\{\bigcap_{k=0}^{n} A_k^c\right\} \le (1-\delta_1)^{n+1}. \tag{A.6}$$

Thus, we have

$$\begin{aligned}
\mathbf{P}_{x,i}\{\sigma_E = \infty\} &= \mathbf{P}_{x,i}\{X(t) \notin \partial E \text{ for any } t \ge 0\} \\
&\le \lim_{n\to\infty} \mathbf{P}_{x,i}\left\{\bigcap_{k=0}^{n} A_k^c\right\} \\
&\le \lim_{n\to\infty} (1-\delta_1)^{n+1} = 0.
\end{aligned}$$

Hence it follows that $\mathbf{P}_{x,i}\{\sigma_E < \infty\} = 1$ as desired. □

Proof of Lemma 3.6. As in Lemma 3.5, it is enough to prove the lemma for the case when $E \cup \partial E \subset D$ and ∂E is sufficiently smooth. Fix any $(x,i) \in E^c \times \mathcal{M}$. Let $G \subset \mathbb{R}^r$ be an open and bounded set with a sufficiently smooth boundary such that $D \cup \partial D \subset G$. As in the proof of Lemma 3.5, we may further assume that $(x,i) \in G \times \mathcal{M}$. Define stopping times $\varsigma_1, \varsigma_2, \ldots$ and events $A_0, A_1, A_2, \ldots$ as in (A.1), (A.2), (A.4), and (A.5) in the proof of Lemma 3.5. It follows from (3.10) and Lemma 3.5 that $\mathbf{P}_{x,i}\{\sigma_E < \infty\} = 1$. Note that if $\varsigma_{2n} < \sigma_E < \varsigma_{2n+1}$, then the event $\bigcap_{k=0}^{n-1} A_k^c$ happens a.s. Hence, it follows from (A.6) that

$$\mathbf{P}_{x,i}\{\varsigma_{2n} < \sigma_E < \varsigma_{2n+1}\} \le \mathbf{P}_{x,i}\left\{\bigcap_{k=0}^{n-1} A_k^c\right\} \le (1-\delta_1)^n.$$

Therefore, we have

$$\begin{aligned}
\mathbf{E}_{x,i}\tau_{E^c} &= \mathbf{E}_{x,i}\sigma_E \chi_{[0<\sigma_E<\varsigma_1]} + \sum_{n=1}^{\infty} \mathbf{E}_{x,i}\sigma_E \chi_{[\varsigma_{2n}<\sigma_E<\varsigma_{2n+1}]} \\
&\le \mathbf{P}_{x,i}[0 < \sigma_E < \varsigma_1]\mathbf{E}_{x,i}\varsigma_1 + \sum_{n=1}^{\infty} \mathbf{P}_{x,i}[\varsigma_{2n} < \sigma_E < \varsigma_{2n+1}]\mathbf{E}_{x,i}\varsigma_{2n+1} \\
&\le \sum_{n=0}^{\infty} (1-\delta_1)^n \mathbf{E}_{x,i}\varsigma_{2n+1}.
\end{aligned}$$

In what follows, denote by M_i $(i = 1, 2, 3)$ positive real numbers. Since $(x, i) \in G \times \mathcal{M}$, it follows from Theorem 3.1 that $\mathbf{E}_{x,i}\varsigma_1 = \mathbf{E}_{x,i}\tau_G \le M_1 < \infty$. Consequently, using σ_D and τ_G defined in (2.1),

$$\begin{aligned}\mathbf{E}_{x,i}\varsigma_3 &= \mathbf{E}_{x,i}\varsigma_1 + \mathbf{E}_{x,i}\mathbf{E}_{X(\varsigma_1),\gamma(\varsigma_1)}(\varsigma_3 - \varsigma_1)\\ &\le M_1 + \sup_{(y,j)\in\partial G\times\mathcal{M}} \mathbf{E}_{y,j}\sigma_D + \sup_{(z,k)\in\partial D\times\mathcal{M}} \mathbf{E}_{z,k}\tau_G\\ &\le M_1 + M_2 + M_3 \le 2M,\end{aligned}$$

where $M = \max\{M_1, M_2 + M_3\} < \infty$. Note that in the above deductions, we used (3.10) and Theorem 3.1. Likewise, in general, we have $\mathbf{E}_{x,i}\varsigma_{2n+1} \le (n+1)M$ for any $n = 1, 2, \ldots$ Therefore, it follows that

$$\mathbf{E}_{x,i}\sigma_E \le \sum_{n=0}^{\infty}(1-\delta_1)^n(n+1)M < \infty.$$

This completes the proof of the lemma. □

Proof of Lemma 3.7. Fix any $\ell \in \mathcal{M}$. It suffices to prove (3.12) when $(x, i) \in D \times (\mathcal{M} - \{\ell\})$ since the process $Y(t) = (X(t), \gamma(t))$, starting from $(y, j) \in D^c \times \mathcal{M}$, will reach $D \times \mathcal{M}$ in finite time a.s. $\mathbf{P}_{y,j}$ by (3.11). Choose $\varepsilon > 0$ sufficiently small such that $B \subset \overline{B} \subset B_1 \subset \overline{B_1} \subset D$, where

$$B = B(x, \varepsilon) = \{y \in \mathbb{R}^r : |y - x| < \varepsilon\} \quad \text{and} \quad B_1 = B(x, 2\varepsilon). \tag{A.7}$$

Redefine

$$\varsigma_1 := \inf\{t \ge 0 : X(t) \in \partial B\}, \tag{A.8}$$

and for $n = 1, 2, \ldots$,

$$\begin{aligned}\varsigma_{2n} &:= \inf\{t \ge \varsigma_{2n-1} : X(t) \in \partial B_1\},\\ \varsigma_{2n+1} &:= \inf\{t \ge \varsigma_{2n} : X(t) \in \partial B\}.\end{aligned} \tag{A.9}$$

Note that (3.11), Theorem 3.1, and Lemma 3.5 imply that $\varsigma_n < \infty$ a.s. $\mathbf{P}_{x,i}$. Set

$$u(x, i) := \mathbf{P}_{x,i}\left\{\sigma_{\overline{B}\times\{\ell\}} < \tau_{B_1}\right\}.$$

As in the proof of Lemma 3.5, we can verify that $u(x, i)$ is $\mathcal{L}$-harmonic in $B_1 \times \mathcal{M}$. Moreover, u is not identically zero, since $u(x, \ell)|_{x\in\partial B} = 1$. Therefore, the maximum principle [9] implies that

$$\inf_{(x,i)\in\overline{B}\times\mathcal{M}} u(x, i) \ge \delta_2 > 0. \tag{A.10}$$

Redefine

$$A_0 := \{\gamma(t) = \ell \text{ for some } t \in [0, \varsigma_2)\}, \tag{A.11}$$

and for $n = 1, 2, \ldots$,

$$A_n := \{\gamma(t) = \ell \text{ for some } t \in [\varsigma_{2n+1}, \varsigma_{2n+2})\}. \tag{A.12}$$

Using almost the same argument as in the proof of Lemma 3.5, we obtain that

$$\mathbf{P}_{x,i}(A_0^c) \le 1-\delta_2 \quad \text{and} \quad \mathbf{P}_{x,i}\left\{\bigcap_{k=0}^{n} A_k^c\right\} \le (1-\delta_2)^{n+1}. \tag{A.13}$$

Thus, we have

$$\begin{aligned}
&\mathbf{P}_{x,i}\left\{(X(t),\gamma(t)) \notin D\times\{\ell\} \text{ for any } t\ge 0\right\}\\
&\quad\le \mathbf{P}_{x,i}\left\{(X(t),\gamma(t)) \notin \overline{B_1}\times\{\ell\} \text{ for any } t\ge 0\right\}\\
&\quad\le \lim_{n\to\infty} \mathbf{P}_{x,i}\left\{\bigcap_{k=0}^{n} A_k^c\right\}\\
&\quad\le \lim_{n\to\infty} (1-\delta_2)^{n+1} = 0.
\end{aligned}$$

As a result, $\mathbf{P}_{x,i}\{\sigma_{D,\ell}=\infty\} = \mathbf{P}_{x,i}\left\{(X(t),\gamma(t)) \notin D\times\{\ell\} \text{ for any } t\ge 0\right\} = 0$, or $\mathbf{P}_{x,i}\{\sigma_{D,\ell}<\infty\}=1$. This completes the proof of the lemma. ∎

Proof of Lemma 3.8. Fix any $\ell\in\mathcal{M}$. As in Lemma 3.7, it is enough to prove (3.14) when $(x,i)\in D\times(\mathcal{M}-\{\ell\})$. Let the balls B and B_1, stopping times $\varsigma_1,\varsigma_2,\ldots$, and events $A_0,A_1,\ldots$ as in (A.7)–(A.9), (A.11), and (A.12) in the proof of Lemma 3.7. It follows from (3.13) and Lemma 3.7 that $\mathbf{P}_{x,i}\{\sigma_{D,\ell}<\infty\}=1$. Observe that if $\varsigma_{2n}\le\sigma_{D,\ell}<\varsigma_{2n+2}$, then the event $\bigcap_{k=0}^{n-1}A_k^c$ happens a.s. Hence we have from (A.13) that

$$\mathbf{P}_{x,i}\{\varsigma_{2n}\le\sigma_{D,\ell}<\varsigma_{2n+2}\} \le \mathbf{P}_{x,i}\left\{\bigcap_{k=0}^{n-1}A_k^c\right\} \le (1-\delta_2)^n.$$

It follows that

$$\begin{aligned}
\mathbf{E}_{x,i}\sigma_{D,\ell} &= \mathbf{E}_{x,i}\sigma_{D,\ell}\chi_{[0\le\sigma_{D,\ell}<\varsigma_2]} + \sum_{n=1}^{\infty}\mathbf{E}_{x,i}\sigma_{D,\ell}\chi_{[\varsigma_{2n}\le\sigma_{D,\ell}<\varsigma_{2n+2}]}\\
&\le \mathbf{P}_{x,i}[0\le\sigma_{D.\ell}<\varsigma_2]\mathbf{E}_{x,i}\varsigma_2 + \sum_{n=1}^{\infty}\mathbf{P}_{x,i}[\varsigma_{2n}\le\sigma_{D,\ell}<\varsigma_{2n+2}]\mathbf{E}_{x,i}\varsigma_{2n+2}\\
&\le \sum_{n=0}^{\infty}(1-\delta_2)^n\mathbf{E}_{x,i}\varsigma_{2n+2}.
\end{aligned}$$

Following almost the same argument as that for the proof of Lemma 3.6, we can show that $\mathbf{E}_{x,i}\varsigma_{2n}\le nM$ for some positive constant M. Consequently, $\mathbf{E}_{x,i}\sigma_{D,\ell}\le\sum_{n=0}^{\infty}(1-\delta_2)^n(n+1)M<\infty$. The proof of the lemma is thus completed. ∎

FINITE FUEL PROBLEM IN NONLINEAR SINGULAR STOCHASTIC CONTROL*

MONICA MOTTA† AND CATERINA SARTORI‡

Abstract. We investigate, via the dynamic programming approach, a finite fuel nonlinear singular stochastic control problem of Bolza type. We prove that the associated value function is continuous and that its continuous extension to the closure of the domain coincides with the value function of a nonsingular control problem, for which we prove the existence of an optimal control. Moreover, such a continuous extension is characterized as the unique viscosity solution of a quasi-variational inequality with suitable boundary conditions of mixed type.

Key words. singular stochastic control problems, degenerate parabolic HJB equations, viscosity solutions, representation formulas

1. Introduction.

We study a finite fuel stochastic control problem with finite horizon via the dynamic programming approach. For any initial condition $(\bar{t}, \bar{k}, \bar{x}) \in [0, T[\times[0, K] \times \mathbb{R}^n$ we consider the nonlinear stochastic differential equation

$$x_t = \bar{x} + \int_{\bar{t}}^{t} A(r, x_r)\, dr + \int_{\bar{t}}^{t} B(r, x_r) u_r\, dr + \int_{\bar{t}}^{t} D(r, x_r)\, d\mathcal{W}_r, \tag{1}$$

where the functions A, B, and D are deterministic, $\{\mathcal{W}_t\}$ is a Brownian motion, and $\{u_t\}$ is a control. All the processes are assumed to be defined on a probability space $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$. Given a closed convex cone $\mathcal{K} \subset \mathbb{R}^m$, the class of admissible controls, denoted by $\mathcal{C}(\bar{t}, \bar{k}, \bar{x})$, is given by the set of $\mathcal{K}$-valued, $\{\mathcal{G}_t\}$-predictable processes verifying the constraint

$$\int_{\bar{t}}^{T} |u_t|\, dt \le K - \bar{k}. \tag{2}$$

For any admissible control u we consider a cost of the form

$$\mathcal{J}(\bar{t}, \bar{k}, \bar{x}, u) = E_Q \left[\int_{\bar{t}}^{T} \left(l_0(r, x_r) + \langle l_1(r, x_r), u_r \rangle \right) dr + g(x_T) \right], \tag{3}$$

where l_0, l_1, and g are deterministic functions. The value function is defined as

$$\mathcal{V}(\bar{t}, \bar{k}, \bar{x}) = \inf_{u \in \mathcal{C}(\bar{t}, \bar{k}, \bar{x})} \mathcal{J}(\bar{t}, \bar{k}, \bar{x}, u). \tag{4}$$

In this paper we prove the continuity of the value function, and, via a dynamic programming principle, we show that the function V, which is the continuous extension of $\mathcal{V}$ to $[0,T]\times[0,K]\times\mathbb{R}^n$, is a viscosity solution of the following generalized Cauchy problem:

$$\max\left\{-\tfrac{\partial v}{\partial t}+\mathcal{F}(t,x,Dv,D^2v),-\tfrac{\partial v}{\partial k}+\mathcal{H}(t,x,Dv)\right\}=0 \quad \text{in }]0,T[\times]0,K[\times\mathbb{R}^n, \tag{5}$$

$$\max\left\{-\tfrac{\partial v}{\partial t}+\mathcal{F}(t,x,Dv,D^2v),-\tfrac{\partial v}{\partial k}+\mathcal{H}(t,x,Dv)\right\}\geq 0 \quad \text{on }]0,T[\times\{K\}\times\mathbb{R}^n, \tag{6}$$

$$v\leq g \ \text{ and } \ \max\left\{-\tfrac{\partial \mathrm{v}}{\partial \mathrm{t}}+\mathcal{F}(\mathrm{t},\mathrm{x},\mathrm{Dv},\mathrm{D}^2\mathrm{v}),-\tfrac{\partial \mathrm{v}}{\partial \mathrm{k}}+\mathcal{H}(\mathrm{t},\mathrm{x},\mathrm{Dv})\right\}\geq 0 \text{ if } \mathrm{v}<\mathrm{g} \quad \text{on } \{T\}\times]0,K]\times\mathbb{R}^n, \tag{7}$$

where Dv and D^2v denote the gradient and the matrix of the second derivatives of the function $v=v(t,k,x)$ with respect to the x variable,

$$\mathcal{F}(t,x,p,S)\doteq-\langle A(t,x),p\rangle-l_0(t,x)-\frac{1}{2}\mathrm{Tr}\{\tilde{D}(t,x)S\},$$

where $\tilde{D}(t,x)\doteq D(t,x)D(t,x)^T$, and

$$\mathcal{H}(t,x,p)\doteq\max_{w\in\mathcal{K},\ |w|=1}\{-\langle B(t,x)w,p\rangle-\langle l_1(t,x),w\rangle\}$$

for any $(t,x,p,S)\in\mathbb{R}_+\times\mathbb{R}^n\times\mathbb{R}^n\times\mathbf{M}(n,n)$, where $\mathbf{M}(n,n)$ denotes the set of $n\times n$ real matrices. A uniqueness theorem proven in [MS2] allows us to characterize V as the unique viscosity solution to the above boundary value problem. V is in fact the value function of a more regular problem for which we can also prove the existence of an optimal control.

This paper presents some new results on the dynamic programming approach of the theory of singular stochastic control problems as well as on its probabilistic aspects.

From the probabilistic point of view, we consider a singular control problem with a dynamic and a cost function in which the terms B and l_1 depend explicitly on the state variable x, an important difference with respect to previous works on singular stochastic controls (see, e.g., [HS1], [BC], [CMR], [SS], and the many references in [FS]). In order to deal with such general dynamics and cost, we introduce an extension of our problem by considering a new set of controls, called auxiliary controls, justified by the observation that optimal controls for the above problem may not exist and in fact quasi-optimal controls may be as close as desired to a control of impulsive type (see, e.g., [FS]), so that discontinuous trajectories should be allowed as solutions. It is known that a measure approach works if the terms B in the dynamics and l_1 in the cost do not depend on the state variable x. Such a special class of *state-independent* problems has been widely investigated in recent years and there are several results on the existence of (generalized) optimal controls, on the regularity, and on the characterization of $\mathcal{V}$ as the unique solution of a Cauchy problem for a suitable nonlinear PDE (see [HS1], [HS2], [SS], [CMR], and the references therein). If, instead, B and l_1 depend on the state variable x, a good definition of the solution to (1) requires a completely different approach in order to guarantee its robustness. In the deterministic context Bressan and Rampazzo [BR] introduced a definition of the generalized

solution to (1) based on a time change of the completion of the graphs (t, x_t) (see also [Be], [Se]). Only recently has such a definition been extended to the study of some stochastic control problems by Miller and Runggaldier [MiRu] in 1997, by Dorroh, Ferreyra, and Sundar [DFS] in 1999, and by Miller and Dufour [DM] in 2002. In particular, in [DM] the authors prove the existence of an auxiliary optimal control for a Mayer problem assuming (2). Using their stochastic framework we study the boundary value problem (5)–(7) associated to the minimization problem (1)–(4). In addition, we prove the existence of an optimal control, consistently improving their work since we avoid the convexity assumption, under which their main existence result was proven, but which does not hold in many cases.

This paper is a starting point in the program of extending to stochastic control problems, with nonlinear dynamics and nonlinear costs of the form considered here, several results obtained in singular or coercive linear control problems (that is, with B and l_1 not depending on x) concerning, in particular, the existence of optimal controls and the properties of the associated value functions. Besides the obvious goal of considering nonlinear versions of classical applications such as the finite fuel problem, introduced in [BC] to model an aircraft motion, the study of nonlinear problems is also motivated by some applications to economics for which we refer the interested reader to the recent works [A1], [A2].

From the PDE point of view, we are able to show that the value function is continuous and solves the quasi-variational inequality (5) which can be derived from the dynamic programming principle, either heuristically (as usually done in the literature on singular control), or from an equivalent formulation of the minimum problem that uses compact valued controls (as we do). Here a key tool is the concept of control rules together with the compactification method introduced by El Karoui, Ngoyen, and Jeanblanc-Picqué in [EKNP]. In fact we use an abstract version of the dynamic programming principle (DPP) introduced by Haussmann and Lepeltier [HL] and formulated in terms of control rules, in which, among other things, the terminal time is allowed to be an exit time or even a stopping time chosen by the controller, hard constraints (i.e., state constraints that must be met almost surely) as well as soft constraints (i.e., constraints that must be met in the mean) are considered, and very mild regularity of the data is required.

Thus, the notion of auxiliary controls allows us to reduce the minimization problem to an equivalent one where the controls take values in a compact set. The dynamic programming principle, given in terms of control rules, is the key point for proving that the value function $\mathcal{V}$ defined in (4) is continuous. Both of the concepts are essential in order to write a Hamilton–Jacobi equation like (5) which, a priori, is *not* the formal equation associated to the unbounded control problem, and to show that $\mathcal{V}$ solves (5)–(7) in the viscosity sense. Indeed, the formal equation associated to (1)–(4) involves a different Hamiltonian studied in section 6, which is obtained through a maximization over the unbounded control set $\mathcal{K}$.

A comment about the boundary conditions is in order since conditions (6) and (7) seem original in the setting of singular stochastic control problems. First of all, since we deal with problems of impulsive type, even when considering a finite horizon problem, the limit $\lim_{\bar{t}\to T^-} \mathcal{V}(\bar{t}, \bar{k}, \bar{x})$ does not coincide in general with the final cost $g(\bar{x})$ and, therefore, at time $\bar{t} = T$, we impose (7), which is an alternative between the quasi-variational inequality (5) and $v = g$. Such a generalized boundary condition was introduced in order to characterize continuous value functions of Dirichlet problems in [I], but it also perfectly fits our Cauchy problem. At the boundary $\bar{k} = K$,

instead, we introduce the supersolution condition (6) which replaces the Dirichlet condition $v(\bar{t}, K, \bar{x}) = J(\bar{t}, K, \bar{x}, 0)$, usually assumed in finite fuel control problems (see, e.g., [BJM], [FS]). It has the advantage that it does not require the computation of $J(\bar{t}, K, \bar{x}, 0)$. Supersolution type conditions have been considered first by [So] for problems with state constraints, and in fact by considering the fuel consumed at time t as a new variable, in view of (2) such a variable turns out to be constrained in $[0, K]$. Boundary value problems similar to (5)–(7) for first order Hamiltonians were already investigated by the authors in the context of impulsive deterministic control problems when either a constraint on the L^1 norm of the controls or a weak coercivity condition on the Lagrangian is imposed (see, e.g., [MoRa] and [MS1]). In such a context, it is worth mentioning that our approach leads to approximation schemes for the numerical evaluation of the value functions for first order Hamilton–Jacobi equations (see, e.g., [CF]), which for the second order case has not yet been done.

The paper is organized as follows. In section 2 we state the problem precisely and, following [DM], we introduce an auxiliary control problem whose value function V turns out to coincide with $\mathcal{V}$, but with the essential property that the auxiliary controls are *compact-valued*. In section 3 we introduce relaxed controls and control rules and prove, thanks to some technical results contained in the appendix, that there exists an auxiliary optimal control for our problem and that V is in fact the minimum value over relaxed controls. In section 4, using the DPP, we obtain the continuity of $\mathcal{V}$ (see Theorem 4.1). Section 5 is devoted to deducing the boundary value problem (5)–(7) and to showing that $\mathcal{V}$ is a viscosity solution to it. Then we apply a uniqueness theorem proven in [MS2] and prove in Theorem 5.3 that $\mathcal{V}$ is in fact the only solution to (5)–(7) in the class of the bounded functions which are continuous on $\partial(]0, T[\times]0, K[\times\mathbb{R}^n)$. Moreover, in section 6 we show that $\mathcal{V}$ also turns out to represent a solution of a generalized Cauchy problem for a second order semilinear degenerate parabolic PDE involving a noncoercive Hamiltonian defined via maximization over an unbounded set.

Notation. Throughout this paper we shall adopt the following notation. The symbol $|\cdot|$ denotes the norm of vectors and matrices and $\langle\cdot,\cdot\rangle$ denotes the scalar product for vectors. For any positive integer N and any $r > 0$, $B_N(r) = \{v \in \mathbb{R}^N : |v| < r\}$ and $\overline{B}_N(r) = \{v \in \mathbb{R}^N : |v| \le r\}$. $\mathbb{R}_+ = [0, +\infty[$. For arbitrary positive integers N, M, $\mathbf{M}(N, M)$ denotes the set of the $N \times M$ real matrices. $(^T)$ denotes the transposed operator. $\mathcal{C}_b^2(\mathbb{R}^N)$ is the set of the bounded real maps which are continuous on $\mathbb{R}^N$ with their first and second partial derivatives. Given a function $v : E \to \mathbb{R}$, $E \subset \mathbb{R}^N$, the upper and lower semicontinuous envelopes of v are defined by $v^*(x) \doteq \lim_{s\to 0^+} \sup\{v(y) : y \in E, |y - x| \le s\}$, $v_*(x) \doteq \lim_{s\to 0^+} \inf\{v(y) : y \in E, \quad |y - x| \le s\}$ for any $x \in \overline{E}$. Of course, v^* is upper semicontinuous and v_* is lower semicontinuous. Let $(\Omega, \mathcal{F}, P)$ be a probability space. We will use $E_P[\cdot]$ to denote the mathematical expectation on such a space. Given two random variables X, Y, the notation $X = Y$, $X \le Y$ means $P(X = Y) = 1$, $P(X \le Y) = 1$, respectively, $\delta_{\{w\}}$ denotes the Dirac measure at a fixed $w \in \mathcal{K}$, and T and K are fixed positive real numbers.

2. Statement of the problem. In this section we give the precise formulation of the nonlinear singular stochastic control problem described in the introduction, introduce the auxiliary control problem, and prove their equivalence.

2.1. The control problem. Throughout the paper we will use the following hypotheses.

(A0): There are some constants L_1, L_2 such that the deterministic functions $A : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^n$, $B : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbf{M}(n,m)$, and $D : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbf{M}(n,p)$ verify for all $t, s \in \mathbb{R}_+$ and $x, y \in \mathbb{R}^n$,

$$|A(t,x)| + |B(t,x)| + |D(t,x)| \le L_1(1+|x|),$$
$$|A(t,x) - A(s,y)| + |B(t,x) - B(s,y)| + |D(t,x) - D(s,y)| \le L_2(|t-s| + |x-y|).$$

(A1): There are some constants L, L_3 such that the functions $l_0 : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}$, $l_1 : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^m$, and $g : \mathbb{R}^n \to \mathbb{R}$ verify for all $t, s \in \mathbb{R}_+$ and $x, y \in \mathbb{R}^n$,

$$|l_0(t,x) - l_0(s,y)| + |l_1(t,x) - l_1(s,y)| \le L(|t-s| + |x-y|),$$
$$|g(x) - g(y)| \le L|x-y|,$$

and

$$|l_0(t,x)| + |l_1(t,x)| + |g(x)| \le L_3. \tag{8}$$

DEFINITION 2.1. *Given an initial condition* $(\bar t, \bar k, \bar x) \in [0,T[\times[0,K] \times \mathbb{R}^n$, *a* control *is a term*

$$c = (\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{u_t\}, \{\mathcal{W}_t\}, \{x_t\}),$$

where

- $(\Omega, \mathcal{G}, Q)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{G}_t\}$,
- $\{u_t\}$ *is a* $\mathcal{K}$*-valued process (*$\mathcal{K}$ *a closed, convex cone of* $\mathbb{R}^m$*) defined on* $[\bar t, T] \times \Omega$, *which is* $\{\mathcal{G}_t\}$*-predictable,*
- $\{\mathcal{W}_t\}$ *is a standard* p*-dimensional* $\{\mathcal{G}_t\}$*-Brownian motion,*
- $\{x_t\}$ *is an* $\mathbb{R}^n$*-valued process which is* $\{\mathcal{G}_t\}$*-progressively measurable, with continuous paths, such that*

$$x_t = \bar x + \int_{\bar t}^t A(r, x_r)\, dr + \int_{\bar t}^t B(r, x_r) u_r\, dr + \int_{\bar t}^t D(r, x_r)\, d\mathcal{W}_r \qquad \forall t \in [\bar t, T].$$

A control c *is* admissible *if*

$$\int_{\bar t}^T |u_t|\, dt \le K - \bar k. \tag{9}$$

The set of admissible controls *will be denoted by* $\mathcal{C}(\bar t, \bar k, \bar x)$.
For any admissible control c *we consider a cost of the form*

$$\mathcal{J}(\bar t, \bar k, \bar x, c) \doteq E_Q\left[\int_{\bar t}^T \left(l_0(r, x_r) + \langle l_1(r, x_r), u_r\rangle\right) dr + g(x_T)\right]. \tag{10}$$

The value function is defined for $(\bar t, \bar k, \bar x) \in [0,T[\times[0,K] \times \mathbb{R}^n$ *by*

$$\mathcal{V}(\bar t, \bar k, \bar x) \doteq \inf_{c \in \mathcal{C}(\bar t, \bar k, \bar x)} \mathcal{J}(\bar t, \bar k, \bar x, c). \tag{11}$$

Remark 2.1. If we replace the boundedness hypothesis (8) with

$$|l_0(t,x)| + |l_1(t,x)| + |g(x)| \le L_3(1+|x|) \qquad \forall t \in \mathbb{R}_+,\ x \in \mathbb{R}^n, \tag{12}$$

the main results of the paper remain true, except that, of course, the value function $\mathcal{V}$ is bounded no more but turns out to verify $|\mathcal{V}(t,k,x)| \le \bar C(1+|x|)$ for some $\bar C$ and for all $(t,k,x) \in [0,T[\times[0,K] \times \mathbb{R}^n$, as one can deduce from the proof of Theorem 4.1 (see also Corollary 4.2).

2.2. The auxiliary control problem. In this section, following [DM], we introduce an auxiliary control problem, equivalent to the original one, but with the key property that the controls take values in a compact set.

DEFINITION 2.2. *For any* $(\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ *an* auxiliary control *is a term*

$$\beta = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{w_s\}, \{(t_s, k_s, \xi_s)\}, \theta),$$

where the following **(B1)** *and* **(B2)** *are assumed.*

(B1) • $(\Omega, \mathcal{F}, P)$ *is a complete probability space, with a right continuous complete filtration* $\{\mathcal{F}_s\}$,
- $\{w_s\}$ *is a* $\overline{B}_m(1) \cap \mathcal{K}$*-valued control defined on* $[0, T+K] \times \Omega$ *which is* $\{\mathcal{F}_s\}$*-predictable,*
- θ *is an* $\{\mathcal{F}_s\}$*-stopping time such that* $\theta \le T + K$,

and

(B2) $\{(t_s, k_s, \xi_s)\}$ *is an* $\mathbb{R}^{2+n}$*-valued* $\{\mathcal{F}_s\}$*-progressively measurable process with continuous paths, such that, for* $0 \le s \le T + K$,

$$\begin{cases} t_s = \bar{t} + \int_0^s w_{0_\sigma}\, d\sigma, \\ k_s = \bar{k} + \int_0^s |w_\sigma|\, d\sigma, \\ \xi_s = \bar{x} + \int_0^s (A(t_\sigma, \xi_\sigma) w_{0_\sigma} + B(t_\sigma, \xi_\sigma) w_\sigma)\, d\sigma + \int_0^s D(t_\sigma, \xi_\sigma) \sqrt{w_{0_\sigma}}\, dW_\sigma, \end{cases}$$

where $\{W_s\}$ *is a standard p-dimensional* $\{\mathcal{F}_s\}$*-Brownian motion defined on* $[0, T+K] \times \Omega$ *and where we set* $w_{0_s}(\omega) \doteq 1 - |w_s(\omega)| \forall (s, \omega)$ *just for the sake of notation.*

The cost corresponding to an auxiliary control β *is of the form*

$$J(\bar{t}, \bar{k}, \bar{x}, \beta) \doteq E_P \left[\int_0^\theta (l_0(t_\sigma, \xi_\sigma) w_{0_\sigma} + \langle l_1(t_\sigma, \xi_\sigma), w_\sigma \rangle)\, d\sigma + g(\xi_\theta) + G(t_\theta, k_\theta) \right],$$

where $G(T, k) = 0$ *for all* $k \le K$ *and* $G(t, k) = +\infty$ *otherwise. We use* $\Gamma(\bar{t}, \bar{k}, \bar{x})$ *to denote the set of auxiliary controls, while*

$$\Gamma^a(\bar{t}, \bar{k}, \bar{x}) \doteq \left\{ \beta \in \Gamma(\bar{t}, \bar{k}, \bar{x}) : \quad J(\bar{t}, \bar{k}, \bar{x}, \beta) < +\infty \right\} \tag{13}$$

denotes the subset of admissible *auxiliary controls. We define for every* $(\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ *the* auxiliary *value function as*

$$V(\bar{t}, \bar{k}, \bar{x}) \doteq \inf_{\beta \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, \beta). \tag{14}$$

Remark 2.2. The definition of auxiliary controls given in [DM] is slightly different from Definition 2.2. More precisely, fixing an initial condition $(\bar{t}, \bar{k}, \bar{x})$, the natural extension of [DM], to our setting yields controls $\beta = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{w_s\}, \{(t_s, k_s, \xi_s)\}, \theta)$ with stopping times θ verifying the constraint

$$\theta \le (T - \bar{t}) + (K - \bar{k}), \tag{15}$$

with the cost functional defined by

$$\hat{J}(\bar{t}, \bar{k}, \bar{x}, \beta) = E_P \left[\int_0^\theta (l_0(t_\sigma, \xi_\sigma) w_{0_\sigma} + \langle l_1(t_\sigma, \xi_\sigma), w_\sigma \rangle)\, d\sigma + g(\xi_\theta) + \hat{G}(t_\theta) \right], \tag{16}$$

where $\hat{G}(T) = 0$ and $\hat{G}(t) = +\infty$ for all $t \neq T$. Moreover, a control β is admissible if $\hat{J}(\bar{t}, \bar{k}, \bar{x}, \beta) < +\infty$. In fact, we will show, in the proof of Theorem 2.3 below, that the two sets of admissible auxiliary controls coincide and therefore that the two definitions are equivalent. The reason we choose a different formulation of our problem is that Definition 2.2 is better suited to state a dynamic programming principle. It is well known, indeed, that if (t_s, k_s, ξ_s) is a process starting from $(\bar{t}, \bar{k}, \bar{x})$ at $s = 0$, in order to apply the dynamic programming technique, one needs to consider any state (t_s, k_s, ξ_s) for $s > 0$ as the initial condition, that is, to restate the problem with a random variable in place of a deterministic point as initial datum. Following [DM], therefore, one should deal with the hard constraint $\theta \leq (T - t_s) + (K - k_s)$ coming from condition (15).

The problems in Definitions 2.1 and 2.2 are equivalent in the following sense.

THEOREM 2.3. *Assume* **(A0)**, **(A1)**. *Then for any initial condition* $(\bar{t}, \bar{k}, \bar{x}) \in [0, T[\times[0, K] \times \mathbb{R}^n$ *one has*

(i) $\mathcal{C}(\bar{t}, \bar{k}, \bar{x}) \hookrightarrow \Gamma^a(\bar{t}, \bar{k}, \bar{x})$, *that is, for every control* $c \in \mathcal{C}(\bar{t}, \bar{k}, \bar{x})$ *there exists an admissible auxiliary control* $\beta \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})$ *such that* $J(\bar{t}, \bar{k}, \bar{x}, \beta) = \mathcal{J}(\bar{t}, \bar{k}, \bar{x}, c)$;

(ii) *for any admissible auxiliary control* $\beta \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})$ *there is a sequence of controls* $c^n \in \mathcal{C}(\bar{t}, \bar{k}, \bar{x})$ *such that* $\lim_n \mathcal{J}(\bar{t}, \bar{k}, \bar{x}, c^n) = J(\bar{t}, \bar{k}, \bar{x}, \beta)$;

(iii)

$$V(\bar{t}, \bar{k}, \bar{x}) = \mathcal{V}(\bar{t}, \bar{k}, \bar{x}). \tag{17}$$

Proof. Since the proof is based on that given in [DM], we begin by proving that the set $\Gamma^a(\bar{t}, \bar{k}, \bar{x})$ coincides with the set of admissible auxiliary controls introduced in [DM], that is, controls with stopping time θ verifying (15) and with a cost defined by (16), which must be bounded. To prove this claim, let us fix an admissible auxiliary control β in the sense considered in [DM]. First of all, let us notice that condition (15) in fact plays the role of the integral constraint (9) of Definition 2.1, in that it implies

$$\int_0^\theta |w_\sigma| \, d\sigma \leq K - \bar{k}.$$

Indeed, from $\hat{J}(\bar{t}, \bar{k}, \bar{x}, \beta) < +\infty$ it follows that $E_P[\hat{G}(t_\theta)] = 0$, that is, $t_\theta = T$. Moreover, since the stopping time θ verifies (15), one has

$$k_\theta = \bar{k} + \int_0^\theta |w_\sigma| \, d\sigma = \bar{k} + \theta - (t_\theta - \bar{t}) \leq \bar{k} + (K - \bar{k}) + (T - \bar{t}) - (T - \bar{t}) = K.$$

Thus $E_P[G(t_\theta, k_\theta)] = 0$, $\hat{J}(\bar{t}, \bar{k}, \bar{x}, \beta) = J(\bar{t}, \bar{k}, \bar{x}, \beta)$, and β turns out to belong to the set $\Gamma^a(\bar{t}, \bar{k}, \bar{x})$ defined in (13). On the contrary, given a control $\beta \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})$, from $J(\bar{t}, \bar{k}, \bar{x}, \beta) < +\infty$ it follows that $E_P[G(t_\theta, k_\theta)] = 0$, that is, $t_\theta = T$ and $k_\theta \leq K$. Hence $E_P[\hat{G}(t_\theta)] = 0$, $\hat{J}(\bar{t}, \bar{k}, \bar{x}, \beta) = J(\bar{t}, \bar{k}, \bar{x}, \beta)$, and in order to show that β is an admissible auxiliary control in the sense considered in [DM] it remains to prove that θ verifies condition (15). Since by definition

$$k_s + t_s = \bar{k} + \bar{t} + s \qquad s \geq 0,$$

one has that

$$\theta = (k_\theta - \bar{k}) + (t_\theta - \bar{t}) \leq (K - \bar{k}) + (T - \bar{t}),$$

which concludes the proof of the claim.

If the Lagrangian function $l = l_0 + \langle l_1, u\rangle$ is identically zero, statements (i) and (ii) have been proved by Dufour and Miller in Proposition 4.12, and in Proposition 4.8 and Theorem 4.15 of [DM], respectively. This yields the equality $V = \mathcal{V}$ in (iii) for a problem of Mayer type. The extension of these results to a Bolza problem is standard; therefore the proof is concluded. □

In the deterministic case, following the method of the graphs completion, the equivalence between an original singular control problem and a corresponding auxiliary control problem has been proven for several types of problems (see [MoRa], [MS1], and the references therein).

The following simple example taken from [MoRa] shows that at the points of the form $(T, \bar{k}, \bar{x})$, the value function V associated to the auxiliary control problem does not coincide in general with the terminal cost g.

Example 2.1 (see [MoRa]). Let us consider the deterministic control problem

$$x(t) = \bar{x} + \int_{\bar{t}}^{t} (c + u_1(r) + x(r)u_2(r))\, dr \quad \forall t \in [\bar{t}, T],$$

where $\bar{x} \in \mathbb{R}$, c is a positive constant, the control (u_1, u_2) defined on $[\bar{t}, T]$ assumes values on the closed cone

$$\mathcal{K} \doteq \{(w_1, w_2) \in \mathbb{R}^2 :\ w_1 \le 0,\ w_2 \ge 0\},$$

and it verifies the constraint

$$\int_{\bar{t}}^{T} |(u_1(r), u_2(r))|\, dr \le K - \bar{k},$$

where $0 \le \bar{k} \le K$. Let us minimize the following payoff in Mayer form:

$$\mathcal{J}(\bar{t}, \bar{k}, \bar{x}, u) = \arctan(x(T)).$$

For any $(\bar{t}, \bar{k}, \bar{x}) \in [0, T[\times[0, K] \times \mathbb{R}$, the maximum principle yields the existence of an optimal auxiliary control whose corresponding trajectory has a terminal position given by

$$\xi(T) = \begin{cases} \sinh(\operatorname{arcsinh}(\bar{x}) - (K - \bar{k})) + c(T - \bar{t}), & \bar{x} \le 0, \\ \sinh(\bar{x} - (K - \bar{k})) + c(T - \bar{t}), & 0 < \bar{x} < K - \bar{k}, \\ \bar{x} - (K - \bar{k}) + c(T - \bar{t}), & \bar{x} \ge K - \bar{k}, \end{cases} \tag{18}$$

so that $\mathcal{V}(\bar{t}, \bar{k}, \bar{x}) = V(\bar{t}, \bar{k}, \bar{x}) = \arctan(\xi(T))$. At the points $(T, \bar{k}, \bar{x}) \in \{T\} \times [0, K] \times \mathbb{R}^n$, V is given again by $\arctan(\xi(T))$ once we put $\bar{t} = T$ and obviously it does not coincide with $g(\bar{x}) = \arctan(\bar{x})$ unless $\bar{k} = K$.

This is a general result: V coincides with the continuous extension to $[0, T] \times [0, K] \times \mathbb{R}^n$ of the original value function $\mathcal{V}$ defined on the set $[0, T[\times[0, K] \times \mathbb{R}^n$ (see Corollary 4.2 in section 4) and in general it does not coincide with g at $\bar{t} = T$. For deterministic control problems, there are well known sufficient conditions under which $V(T, \bar{k}, \bar{x}) = g(\bar{x})\ \ \forall (T, \bar{k}, \bar{x}) \in \{T\} \times [0, K] \times \mathbb{R}^n$ (see [RS] and also Notes on [CIL, section 7]).

3. Relaxed controls and control rules. We devote this section to the definition of relaxed controls which are needed in order to introduce the concept of control rules and the compactification method, key tools to prove a dynamic programming principle. We follow here the presentation given by Haussman and Lepeltier in [HL], where an earlier work by El Karoui, Ngoyen, and Jeanblanc-Picqué [EKNP] is generalized to the case of unbounded data and controls and no fixed terminal time.

3.1. The martingale model. We introduce the equivalent formulation of the above auxiliary control problem as a martingale problem, where the ambiguous term represented by the Brownian motion, unknown in advance, is removed (see, e.g., Ikeda and Watanabe in[IW]). To this end, we introduce for all $\varphi \in \mathcal{C}_b^2(\mathbf{R}^{2+n})$, $(t,k,x) \in \mathbf{R}^{2+n}$, and $w \in \overline{B}_m(1) \cap \mathcal{K}$ the operator $\mathcal{L}$ defined by

$$\begin{aligned}&\mathcal{L}\varphi(t,k,x,w) \doteq \\ &\left[\tfrac{1}{2}\sum_{ij}\tilde{D}_{ij}(t,x)\tfrac{\partial^2\varphi}{\partial x_i \partial x_j}(t,k,x) + \sum_i A_i(t,x)\tfrac{\partial\varphi}{\partial x_i}(t,k,x) + \tfrac{\partial\varphi}{\partial t}(t,k,x)\right] w_0 \\ &\qquad + \sum_i \langle B_i(t,x), w\rangle \tfrac{\partial\varphi}{\partial x_i}(t,k,x) + \tfrac{\partial\varphi}{\partial k}(t,k,x)|w|,\end{aligned} \tag{19}$$

where $w_0 \doteq 1 - |w|$, $\tilde{D}_{ij}$ are the entries of $\tilde{D} = DD^T$, A_i are the components of A, and B_i are the rows of B. Notice that in this formulation the diffusion coefficient D disappears and is replaced by $\tilde{D}$, which, differently from D, is something intrinsic to a process ξ_s as defined in **(B2)**.

The following proposition establishes the correspondence between the martingale model and the control problem with the Brownian motion.

PROPOSITION 3.1 (see [HL, Proposition 3.1]). *Let us assume* **(A0)**, **(A1)**. *Let us fix* $(\bar{t},\bar{k},\bar{x}) \in [0,T]\times[0,K]\times\mathbb{R}^n$. *A control* $\beta = (\Omega,\mathcal{F},P,\{\mathcal{F}_s\},\{w_s\},\{(t_s,k_s,\xi_s)\},\theta)$ *such that*

(B3)
- $(\Omega,\mathcal{F},P)$ *is a probability space, with a filtration* $\{\mathcal{F}_s\}$,
- $\{w_s\}$ *is a* $\overline{B}_m(1)\cap\mathcal{K}$*-valued control, defined on* $[0,T+K]\times\Omega$, $\{\mathcal{F}_s\}$*-progressively measurable,*
- θ *is an* $\{\mathcal{F}_s\}$*-stopping time such that* $\theta \le T+K$

verifies **(B2)** *if and only if it verifies*

(B4)
- $\{(t_s,k_s,\xi_s)\}$ *is a* $\mathbb{R}^{2+n}$*-valued,* $\{\mathcal{F}_s\}$*-progressively measurable process for* $s \in [0,T+K]$, *with continuous paths, such that* $(t_s,k_s,\xi_s) = (\bar{t},\bar{k},\bar{x})$ *for* $s=0$, *for any* $\varphi \in \mathcal{C}_b^2(\mathbf{R}^{2+n})$, $\mathcal{M}_s(\varphi,\beta)$ *is a* $(P,\{\mathcal{F}_s\})$ *square integrable martingale for* $s \in [0,T+K]$, *where*

$$\mathcal{M}_s(\varphi,\beta) \doteq \varphi(t_s,k_s,\xi_s) - \int_0^s \mathcal{L}\varphi(t_\sigma,k_\sigma,\xi_\sigma,w_\sigma)\,d\sigma.$$

3.2. Relaxed controls. In a relaxed control, the $\overline{B}_m(1)\cap\mathcal{K}$-valued process $\{w_s\}$ is replaced by an $\mathbf{M}_1(\overline{B}_m(1)\cap\mathcal{K})$-valued process $\{\mu_s\}$, where $\mathbf{M}_1(\overline{B}_m(1)\cap\mathcal{K})$ is the space of probability measures on $\overline{B}_m(1)\cap\mathcal{K}$. We will extend any bounded measurable map $\psi : \overline{B}_m(1)\cap\mathcal{K} \to \mathbb{R}$ to $\mathbf{M}_1(\overline{B}_m(1)\cap\mathcal{K})$ by setting

$$\psi(\mu) = \int_{\overline{B}_m(1)\cap\mathcal{K}} \psi(w)\mu(dw).$$

DEFINITION 3.2. *Given* $(\bar{t},\bar{k},\bar{x}) \in [0,T]\times[0,K]\times\mathbb{R}^n$ *we say that* $\tilde{\alpha}$ *is a* relaxed control *and write* $\tilde{\alpha} \in \tilde{\Gamma}(\bar{t},\bar{k},\bar{x})$ *if*

$$\tilde{\alpha} = (\Omega,\mathcal{F},P,\{\mathcal{F}_s\},\{\mu_s\},\{(t_s,k_s,\xi_s)\},\theta),$$

where the following **(B3′)**, **(B4′)** *are assumed.*

(B3′)
- $(\Omega,\mathcal{F},P)$ *is a probability space with a filtration* $\{\mathcal{F}_s\}$,
- $\{\mu_s\}$ *is a* $\mathbf{M}_1(\overline{B}_m(1)\cap\mathcal{K})$*-valued process defined on* $[0,T+K]\times\Omega$ *which is* $\{\mathcal{F}_s\}$*-progressively measurable,*
- θ *is an* $\{\mathcal{F}_s\}$*-stopping time such that* $\theta \le T+K$,

(B4′) • *$\{(t_s, k_s, \xi_s)\}$ is an $\mathbb{R}^{2+n}$-valued $\{\mathcal{F}_s\}$-progressively measurable process for $s \in [0, T+K]$, with continuous paths, such that $(t_s, k_s, \xi_s) = (\bar{t}, \bar{k}, \bar{x})$ for $s = 0$, for any $\varphi \in \mathcal{C}_b^2(\mathbf{R}^{2+n})$, $\mathcal{M}_s(\varphi, \tilde{\alpha})$ is a $(P, \{\mathcal{F}_s\})$ square integrable martingale for $s \in [0, T+K]$, where*

$$M_s(\varphi, \tilde{\alpha}) \doteq \varphi(t_s, k_s, \xi_s) - \int_0^s \mathcal{L}\varphi(t_\sigma, k_\sigma, \xi_\sigma, \mu_\sigma)\, d\sigma.$$

For any $\tilde{\alpha} \in \tilde{\Gamma}(\bar{t}, \bar{k}, \bar{x})$ we define the cost

$$J(\bar{t}, \bar{k}, \bar{x}, \tilde{\alpha}) = E_P \left[\int_0^\theta \left(l_0(t_\sigma, \xi_\sigma)(1 - |\mu_\sigma|) + \langle l_1(t_\sigma, \xi_\sigma), \mu_\sigma \rangle \right) d\sigma + g(\xi_\theta) + G(t_\theta, k_\theta) \right]. \tag{20}$$

We use $\tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x})$ to denote the subset of admissible *relaxed controls, that is,*

$$\tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x}) \doteq \left\{ \tilde{\alpha} \in \tilde{\Gamma}(\bar{t}, \bar{k}, \bar{x}) : \quad J(\bar{t}, \bar{k}, \bar{\xi}, \tilde{\alpha}) < +\infty \right\}.$$

Remark 3.1. Following [HL], the processes that appear in Definition 3.2 are progressively measurable and the probability space is arbitrary. The processes that appear in the auxiliary controls of Definition 2.2, instead, are predictable processes and the probability space is complete and right continuous. Thus, it is not obvious a priori that the control problem in Definition 3.2 is the relaxed version of our auxiliary control problem. From Lemmatas A1–A3 in [DM], however, it follows that, given an initial condition $(\bar{t}, \bar{k}, \bar{x})$, for any control $\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{w_s\}, \{(t_s, k_s, \xi_s)\}, \theta)$ verifying **(B3)** and **(B2)** (or, equivalently, **(B3)** and **(B4)**, in view of Proposition 3.1), there exists a new control $\hat{\alpha} = (\hat{\Omega}, \hat{\mathcal{F}}, \hat{P}, \{\hat{\mathcal{F}}_s\}, \{\hat{w}_s\}, \{(\hat{t}_s, \hat{k}_s, \hat{\xi}_s)\}, \hat{\theta})$, where $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$ is a suitable modification of $(\Omega, \mathcal{F}, P)$, $\hat{\theta} = \theta$, the process $\{(\hat{t}_s, \hat{k}_s, \hat{\xi}_s)\}$ is indistinguishable from $\{(t_s, k_s, \xi_s)\}$, $\hat{\alpha}$ verifies **(B1)** and **(B2)**, and, moreover, $J(\bar{t}, \bar{k}, \bar{x}, \hat{\alpha}) = J(\bar{t}, \bar{k}, \bar{x}, \alpha)$. Therefore, if $J(\bar{t}, \bar{k}, \bar{x}, \alpha) < +\infty$, then $\hat{\alpha} \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})$.

The set $\Gamma^a(\bar{t}, \bar{k}, \bar{x})$ can be naturally embedded in $\tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x})$; therefore, the inequality

$$\inf_{\tilde{\alpha} \in \tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, \tilde{\alpha}) \leq \inf_{\alpha \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, \alpha)$$

is trivially verified. In fact, the converse inequality also holds true.

THEOREM 3.3. *Assume* **(A0)**, **(A1)**. *Then for any $(\bar{t}, \bar{k}, \bar{x}) \in [0, T] \times [0, K] \times \mathbb{R}^n$,*

$$V(\bar{t}, \bar{k}, \bar{x}) = \inf_{\alpha \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, \alpha) = \inf_{\tilde{\alpha} \in \tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, \tilde{\alpha}).$$

Moreover, the infimum over relaxed controls is attained and so is the infimum over auxiliary controls.

Remark 3.2. Dufour and Miller proved in [DM] the existence of an optimal control for the auxiliary problem in the case $l = l_0 + \langle l_1, u \rangle \equiv 0$ and while under the assumption that the set

$$\begin{aligned} &\tilde{M}(t, x) \doteq \big\{ (A(t, x)(1 - |w|) + B(t, x)w, (1 - |w|)D(t, x)D^T(t, x), |w|) : \\ &w \in \overline{B}_m(1) \cap \mathcal{K} \big\} \qquad \text{is convex} \quad \forall (t, x). \end{aligned} \tag{21}$$

It is important to observe that the presence of the terms depending on $|w|$ in (21) implies that such a condition does not hold in most cases. Let us point out that in

Theorem 3.3 the method of the graphs completion yields instead the existence of an optimal control for the auxiliary control problem just under assumptions **(A0)**, **(A1)**, without assumption (21).

Proof of Theorem 3.3. From [HL, Theorem 3.6] it follows straightforwardly that for any initial condition $(\bar t, \bar k, \bar x) \in [0,T]\times[0,K]\times\mathbb{R}^n$ there exists an optimal relaxed control

$$\tilde\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_s)\}, \theta) \in \tilde\Gamma^a(\bar t, \bar k, \bar x).$$

Let us set $\mu_{0_s}(\omega) = 1 - |\mu_s(\omega)|$ (pointwise) and let us define γ by

$$\begin{aligned}\gamma(s,\omega) &= \Big(A\mu_{0_s}(\omega) + B\mu_s(\omega), \mu_{0_s}(\omega)\tilde D, l_0\mu_{0_s}(\omega) + \langle l_1, \mu_s(\omega)\rangle, \mu_{0_s}(\omega)\Big)\,(t_s(\omega), \xi_s(\omega))\\ &= \textstyle\int_{\overline{B}_m(1)\cap\mathcal{K}} \Big(Aw_0 + Bw, w_0\tilde D, l_0 w_0 + \langle l_1, w\rangle, w_0\Big)\,(t_s(\omega), \xi_s(\omega))\,\mu_s(\omega, dw),\end{aligned}$$

where $w_0 = 1 - |w|$ for $w \in \overline{B}_m(1)\cap\mathcal{K}$. Since for every (t,x),

$$\begin{aligned}&\Big\{(A(t,x)w_0 + B(t,x)w, w_0\tilde D(t,x), z, w_0) :\\ &z \ge l_0(t,x)w_0 + \langle l_1(t,x), w\rangle, \quad (w_0, w) \in \mathbb{R}_+\times\mathcal{K},\ w_0 + |w| = 1\Big\},\\ &\subset \Big\{(A(t,x)w_0 + B(t,x)w, w_0\tilde D(t,x), z, w_0) :\\ &z \ge l_0(t,x)w_0 + \langle l_1(t,x), w\rangle, \quad (w_0, w) \in \mathbb{R}_+\times\mathcal{K},\ w_0 + |w| \le 1\Big\},\end{aligned}$$

where the last set is a compact, convex subset of $\mathbb{R}^n\times\mathbf{M}(n,n)\times\mathbb{R}^2$, arguing as in the proof of Theorem 3.6 in [HL] (see also Theorem A9 in [HL]) one can show that there exist

$$\begin{aligned}&\textit{two } \mathcal{F}_s\text{-progressively measurable processes } \{v_s\},\ \{(w_{0_s}, w_s)\},\\ &R_+ \text{ and } (\mathbb{R}_+\times\mathcal{K})\cap\{(w_0,w) :\ w_0 + |w| \le 1\}\text{-valued, respectively,}\end{aligned} \tag{22}$$

such that one has

$$\begin{aligned}\gamma(s,\omega) = &\Big(Aw_{0_s}(\omega) + Bw_s(\omega), w_{0_s}(\omega)\tilde D, l_0 w_{0_s}(\omega) + \langle l_1, w_s(\omega)\rangle, w_{0_s}(\omega)\Big)\,(t_s(\omega), \xi_s(\omega))\\ &+(0,0,v_s(\omega),0) \qquad\qquad \text{for almost all } (s,\omega).\end{aligned} \tag{23}$$

Let us define the *noncanonical control* α by

$$\alpha \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{(w_{0_s}, w_s)\}, \{(t_s, k_s, \xi_s)\}, \theta), \tag{24}$$

where $\{(w_{0_s}, w_s)\}$ is given in (22). In the rest of the proof, with a slight abuse of notation, let us use again the symbols J and $\mathcal{L}$ to denote the cost and the operator in (19) once the scalar process $\{w_{0_s}\}$ in their definitions is not subjected to the constraint $w_{0_s} = 1 - |w_s|$, but is an independent process with values in $[0,1]$. Then by (23) it follows that for any $\varphi \in \mathcal{C}_b^2(\mathbf{R}^{2+n})$, $\mathcal{L}\varphi(t_s, k_s, \xi_s, \mu_s) = \mathcal{L}\varphi(t_s, k_s, \xi_s, (w_{0_s}, w_s))$ except on a (s,ω) null set. Hence for all φ and all $s \in [0, T+K]$,

$$\mathcal{M}_s(\varphi, \tilde\alpha) = \mathcal{M}_s(\varphi, \alpha).$$

Moreover, since

$$\begin{aligned}l_0(t_s,\xi_s)\mu_{0_s} + \langle l_1(t_s,\xi_s), \mu_s\rangle &= l_0(t_s,\xi_s)w_{0_s} + \langle l_1(t_s,\xi_s), w_s\rangle + v_s\\ &\ge l_0(t_s,\xi_s)w_{0_s} + \langle l_1(t_s,\xi_s), w_s\rangle,\end{aligned}$$

and $J(\bar{t},\bar{k},\bar{x},\tilde{\alpha}) < +\infty$, then $J(\bar{t},\bar{k},\bar{x},\alpha) \le J(\bar{t},\bar{k},\bar{x},\tilde{\alpha}) < +\infty$. The noncanonical control α does not belong, however, to the set $\Gamma^a(\bar{t},\bar{k},\bar{x})$ since it does not verify **(B1)** and $w_{0_s} \neq 1 - |w_s|$. Therefore, in order to conclude the proof, it remains to prove the following.

Claim. There exists a control $\check{\alpha} = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{\check{w}_s\}, \{(\check{t}_s, \check{k}_s, \check{\xi}_s)\}, \check{\theta})$ verifying **(B3)** and **(B4)** and such that $J(\bar{t},\bar{k},\bar{x},\check{\alpha}) = J(\bar{t},\bar{k},\bar{x},\alpha)$.

In view of Remark 3.1, indeed, this is sufficient for the existence of a control $\hat{\alpha} \in \Gamma^a(\bar{t},\bar{k},\bar{x})$ such that $J(\bar{t},\bar{k},\bar{x},\hat{\alpha}) = J(\bar{t},\bar{k},\bar{x},\alpha)$ and $\hat{\alpha}$ is the required optimal auxiliary control. The claim will be proved in appendix (Remark 7.1 and Lemma 7.3). □

Remark 3.3. In general, the original control problem described in Definition 2.1 does not have an optimal control while, by Theorem 3.3, the auxiliary control problem does. Thanks to (ii) of Theorem 2.3, this yields a sequence of suboptimal controls $c^n \in \mathcal{C}(\bar{t},\bar{k},\bar{x})$ for the original problem for any $(\bar{t},\bar{k},\bar{x}) \in [0,T[\times[0,K] \times \mathbb{R}^n$.

3.3. Control rules. We are now going to recall very briefly the definition of control rules (for a detailed description, see [HL]). In order to introduce a canonical space for the problem, let us define the following spaces:

$$\mathcal{C}^{2+n} = \{f : [0, T+K] \to \mathbb{R}^{2+n},\ f \text{ continuous}\},$$

endowed with the topology of uniform convergence;

$$\mathcal{U} \doteq \{\nu : [0, T+K] \to \mathbf{M}_1(\overline{B}_m(1) \cap \mathcal{K}),\ \nu \text{ Borel measurable}\},$$

endowed with the stable topology;

$$\mathcal{Z} = \{\zeta : [0, T+K] \to \mathbb{R},\ \zeta = \chi_{s \ge \Delta},\ \Delta \in [0, +\infty]\}, \tag{25}$$

endowed with the topology of weak convergence of the corresponding (point) probability measures. We denote the map $\zeta \to \Delta$ by $\Delta(\cdot)$. Let $\tilde{\mathcal{C}}, \tilde{\mathcal{U}}, \tilde{\mathcal{Z}}$ denote their Borel σ-fields, let $\tilde{\mathcal{C}}_s, \tilde{\mathcal{U}}_s, \tilde{\mathcal{Z}}_s$ denote the σ-fields up to time s (e.g., $\tilde{\mathcal{Z}}_s = \sigma\{\zeta(s') :\ 0 \le s' \le s\}$), and let us introduce the canonical setting

$$\Omega = \mathcal{C}^{2+n} \times \mathcal{U} \times \mathcal{Z}, \qquad \mathcal{F} \doteq \tilde{\mathcal{C}} \times \tilde{\mathcal{U}} \times \tilde{\mathcal{Z}}, \qquad \mathcal{F}_s \doteq \tilde{\mathcal{C}}_s \times \tilde{\mathcal{U}}_s \times \tilde{\mathcal{Z}}_s. \tag{26}$$

Notice that Ω is metrizable and separable under the product topology.

DEFINITION 3.4. *Fix $(\bar{t},\bar{k},\bar{x}) \in [0,T] \times [0,K] \times \mathbf{R}^n$, and let Ω, $\mathcal{F}$ and $\{\mathcal{F}_s\}$ be defined by* (26). *We say that R is a* control rule *and we write that $R \in \mathcal{R}(\bar{t},\bar{k},\bar{x})$ if R is a probability measure on the canonical space $(\Omega,\mathcal{F})$, such that*

$$\tilde{\alpha} = (\Omega, \mathcal{F}, R, \{\mathcal{F}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_s)\}, \theta)$$

is a relaxed control (i.e., $\tilde{\alpha} \in \tilde{\Gamma}(\bar{t},\bar{k},\bar{x})$), where

$$(t_s, k_s, \xi_s)(\omega) = f_s, \quad \mu_s(\omega) = \nu_s, \quad \theta(\omega) = \Delta(\zeta)$$

for $\omega = (f, \nu, \zeta) \in \Omega$. Finally, we define the cost associated to R as $J(\bar{t},\bar{k},\bar{x},R) \doteq J(\bar{t},\bar{k},\bar{x},\tilde{\alpha})$, where $J(\bar{t},\bar{k},\bar{x},\tilde{\alpha})$ is given in (20). *The subset $\mathcal{R}^a(\bar{t},\bar{k},\bar{x})$ of the* admissible control rules *can be now defined as follows:*

$$\mathcal{R}^a(\bar{t},\bar{k},\bar{x}) \doteq \left\{R \in \mathcal{R}(\bar{t},\bar{k},\bar{x}) :\quad J(\bar{t},\bar{k},\bar{\xi},R) < +\infty\right\}.$$

Remark 3.4. For the sake of notation, in what follows a given element ω of the canonical space $\mathcal{C}^{2+n} \times \mathcal{U} \times \mathcal{Z}$ will be denoted by $\omega = ((t_\cdot, k_\cdot, \xi_\cdot), \mu_\cdot, \theta)$.

By definition, $\mathcal{R}(\bar{t}, \bar{k}, \bar{x}) \hookrightarrow \tilde{\Gamma}(\bar{t}, \bar{k}, \bar{x})$. In fact, the inverse embedding is also valid. In particular, one has the following proposition.

PROPOSITION 3.5. *Fix $(\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ and assume* **(A0)**, **(A1)**. *Then*

$$V(\bar{t}, \bar{k}, \bar{x}) = \inf_{\tilde{\alpha} \in \tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, \tilde{\alpha}) = \inf_{R \in \mathcal{R}^a(\bar{t}, \bar{k}, \bar{x})} J(\bar{t}, \bar{k}, \bar{x}, R). \tag{27}$$

Moreover, the infimum is attained in any one of $\mathcal{R}^a(\bar{t}, \bar{k}, \bar{x})$, $\tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x})$, and $\Gamma^a(\bar{t}, \bar{k}, \bar{x})$.

Proof. The first equality in (27) has been obtained in Theorem 3.3, while the second one follows from Theorem 3.13 in [HL]. The minimum for the auxiliary (and hence, for any other) control problem exists in view of Theorem 3.3. □

Let us conclude this subsection by recalling a dynamic programming principle established in [HL]. To this end, let us notice that the auxiliary control problem is in fact an *unconstrained* stopping time control problem. Indeed, from Definition 2.2 it follows that for all $(\bar{t}, \bar{k}, \bar{x})$ such that either $\bar{t} > T$ or $\bar{k} > K$, the set of admissible auxiliary controls $\Gamma^a(\bar{t}, \bar{k}, \bar{x})$ is empty. Hence the auxiliary value function V might be extended to the whole set $[0, +\infty[\times [0, +\infty[\times \mathbb{R}^n$ in a natural way by setting $V = +\infty$ outside $[0,T] \times [0,K] \times \mathbb{R}^n$.

PROPOSITION 3.6. *Assume* **(A0)**, **(A1)**. *For any $(\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$, one has*

$$V(\bar{t}, \bar{k}, \bar{x}) = \inf \left\{ E_R \left[\int_0^{\rho'} (l_0(t_\sigma, \xi_\sigma)(1 - |\mu_\sigma|) + \langle l_1(t_\sigma, \xi_\sigma), \mu_\sigma \rangle)\, d\sigma + V(t_{\rho'}, k_{\rho'}, \xi_{\rho'}) \right] \right\}, \tag{28}$$

where the infimum is taken over the set $\mathcal{R}^a(\bar{t}, \bar{k}, \bar{x})$ and $\rho' = \rho \wedge \theta$, ρ being any finite stopping time such that $0 \le \rho \le \theta$.

4. Continuity of the value function.

THEOREM 4.1. *Let* **(A0)**, **(A1)** *hold. Then the value function V is bounded and continuous. More precisely, there exists some $\bar{C} > 0$ such that V satisfies the following:*

$$|V(\bar{t}, \bar{k}, \bar{x})| \le \bar{C} \qquad \forall (\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n;$$

$$|V(\bar{t}_1, \bar{k}_1, \bar{x}_1) - V(\bar{t}_2, \bar{k}_2, \bar{x}_2)| \le \bar{C} \left[|\bar{x}_1 - \bar{x}_2| + (1 + |\bar{x}_1| \vee |\bar{x}_2|) \left(|\bar{t}_1 - \bar{t}_2|^{1/2} + |\bar{k}_1 - \bar{k}_2| \right) \right]$$

for all $(\bar{t}_1, \bar{k}_1, \bar{x}_1)$, $(\bar{t}_2, \bar{k}_2, \bar{x}_2) \in [0,T] \times [0,K] \times \mathbb{R}^n$.

Proof (*Boundedness*). It is very easy to see that for any initial condition $(\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ the set of admissible control rules is nonempty. Since the stopping time θ is bounded from above by $T + K$, the boundedness of V follows, therefore, straightforwardly from the boundedness of both the process $\{w_s\}$ and the data l_0, l_1, and g.

Lipschitz continuity in x. Fix $(\bar{t}, \bar{k}, \bar{x}_1), (\bar{t}, \bar{k}, \bar{x}_2) \in [0,T] \times [0,K] \times \mathbb{R}^n$ and assume that $V(\bar{t}, \bar{k}, \bar{x}_1) \ge V(\bar{t}, \bar{k}, \bar{x}_2)$. One has

$$0 \le V(\bar{t}, \bar{k}, \bar{x}_1) - V(\bar{t}, \bar{k}, \bar{x}_2) \le \sup_{P \in \mathcal{R}^a(\bar{t}, \bar{k}, \bar{x}_2)} \big(J(\bar{t}, \bar{k}, \bar{x}_1, Q) - J(\bar{t}, \bar{k}, \bar{x}_2, P) \big)$$

for every $Q \in \mathcal{R}^a(\bar{t}, \bar{k}, \bar{x}_1)$. Take $P \in \mathcal{R}^a(\bar{t}, \bar{k}, \bar{x}_2)$ arbitrary and let

$$(\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_{2_s})\}, \theta)$$

be the associated relaxed control. By the definition of control rules, there exists an extension $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\})$ of $(\Omega, \mathcal{F}, P, \{\mathcal{F}_s\})$, i.e., there exists another probability space $(\Omega', \mathcal{F}', \mathcal{F}'_s, P')$ such that $\tilde{\Omega} = \Omega \times \Omega'$, $\tilde{\mathcal{F}} = \mathcal{F} \times \mathcal{F}'$, $\tilde{\mathcal{F}}_s = \mathcal{F}_s \times \mathcal{F}'_s$, and $\tilde{P} = P \times P'$. We can extend the process $\{((t_\cdot, k_\cdot, \xi_\cdot), \mu_\cdot, \theta)\}$ to $\tilde{\Omega}$ by the following: for $\tilde{\omega} = (\omega, \omega') \in \tilde{\Omega}$,

$$(t_\cdot, k_\cdot, \xi_\cdot)(\tilde{\omega}) = (t_\cdot, k_\cdot, \xi_\cdot)(\omega), \quad \tilde{\mu}_\cdot(\tilde{\omega}) = \mu_\cdot(\omega), \quad \theta(\tilde{\omega}) = \theta(\omega).$$

On $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \tilde{\mathcal{F}}_s)$ there exists a standard p-dimensional Brownian motion $\{W_s\}$ such that for $s \in [0, T + K]$,

$$\begin{aligned}
t_s &= \bar{t} + \textstyle\int_0^s (1 - |\mu|_\sigma)\, d\sigma, \\
k_s &= \bar{k} + \textstyle\int_0^s |\mu_\sigma|\, d\sigma, \\
\xi_{2s} &= \bar{x}_2 + \textstyle\int_0^s \left(A(t_\sigma, \xi_{2\sigma})(1 - |\mu|_\sigma) + B(t_\sigma, \xi_{2\sigma})\mu_\sigma\right) d\sigma + \int_0^s D(t_\sigma, \xi_{2\sigma})\sqrt{1 - |\mu|_\sigma}\, dW_\sigma,
\end{aligned}$$

the control $\tilde{\beta} = (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_{2s})\}, \theta) \in \tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x}_2)$, where, by the definition of the set $\mathcal{Z}$ in (25), θ is the first time in which $\chi_{s \geq \theta}$ jumps from 0 to 1 and $J(\bar{t}, \bar{k}, \bar{x}_2, \tilde{\beta}) = J(\bar{t}, \bar{k}, \bar{x}_2, \tilde{P}) = J(\bar{t}, \bar{k}, \bar{x}_2, P)$.

Consider the equations with the initial condition $(\bar{t}, \bar{k}, \bar{x}_1)$, for $s \in [0, T + K]$,

$$\begin{aligned}
t_s &= \bar{t} + \textstyle\int_0^s (1 - |\mu|_\sigma)\, d\sigma, \\
k_s &= \bar{k} + \textstyle\int_0^s |\mu_\sigma|\, d\sigma, \\
\xi_{1s} &= \bar{x}_1 + \textstyle\int_0^s \left(A(t_\sigma, \xi_{1\sigma})(1 - |\mu|_\sigma) + B(t_\sigma, \xi_{1\sigma})\mu_\sigma\right) d\sigma + \int_0^s D(t_\sigma, \xi_{1\sigma})\sqrt{1 - |\mu|_\sigma}\, dW_\sigma
\end{aligned} \tag{29}$$

on the stochastic basis $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\})$. Under assumptions **(A0)**, **(A1)**, the strong solution to (29) exists and one can see that $\tilde{\alpha} = (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_{1s})\}, \theta) \in \tilde{\Gamma}^a(\bar{t}, \bar{k}, \bar{x}_1)$. Therefore, there exists a control rule $Q \in \mathcal{R}^a(\bar{t}, \bar{k}, \bar{x}_1)$ such that

$$J(\bar{t}, \bar{k}, \bar{x}_1, \tilde{\alpha}) = J(\bar{t}, \bar{k}, \bar{x}_1, Q).$$

We have

$$\begin{aligned}
&J(\bar{t}, \bar{k}, \bar{x}_1, Q) - J(\bar{t}, \bar{k}, \bar{x}_2, P) = J(\bar{t}, \bar{k}, \bar{x}_1, \tilde{\alpha}) - J(\bar{t}, \bar{k}, \bar{x}_2, \tilde{\beta}) \\
&\leq E_{\tilde{P}}\left[\int_0^\theta |l_0(t_\sigma, \xi_{1\sigma}) - l_0(t_\sigma, \xi_{2\sigma})|\, |1 - |\mu_\sigma||\, d\sigma + \int_0^\theta |l_1(t_\sigma, \xi_{1\sigma}) - l_1(t_\sigma, \xi_{2\sigma})||\mu_\sigma|\, d\sigma \right. \\
&\qquad \left. + |g(\xi_{1\theta}) - g(\xi_{2\theta})|\right] \leq L\, E_{\tilde{P}}\left[\int_0^\theta |\xi_{1\sigma} - \xi_{2\sigma}|\, d\sigma\right] + L\, E_{\tilde{P}}[|\xi_{1\theta} - \xi_{2\theta}|],
\end{aligned}$$

where we have used the Lipschitz continuity of l_0, l_1, and g and L is the same as in **(A1)**. Let us define $\hat{\xi}_{i_s} \doteq \xi_{i_{s \wedge \theta}}$ for all $s \geq 0$ and $i = 1, 2$. By the Burkholder–Gundy and Gronwall inequalities, we obtain that there exists a constant C, depending on the Lipschitz constant L_2 in **(A0)** and on $T + K$, such that, for all $0 \leq \sigma \leq T + K$,

$$E_{\tilde{P}}\left[\sup_{s \leq \sigma}(|\hat{\xi}_{1_s} - \hat{\xi}_{2s}|^2)\right] \leq C|\bar{x}_1 - \bar{x}_2|^2.$$

Since from the definitions of $\{\hat{\xi}_{1_s}\}$ and $\{\hat{\xi}_{2_s}\}$ it follows that

$$\begin{aligned}
E_{\tilde{P}}\left[\int_0^\theta |\xi_{1\sigma} - \xi_{2\sigma}|\, d\sigma\right] &\leq E_{\tilde{P}}\left[\int_0^{T+K} |\hat{\xi}_{1\sigma} - \hat{\xi}_{2\sigma}|\, d\sigma\right] \\
&\leq \left(\int_0^{T+K} E_{\tilde{P}}\left[\sup_{s \leq \sigma}(|\hat{\xi}_{1_s} - \hat{\xi}_{2s}|^2)\right] d\sigma\right)^{1/2},
\end{aligned} \tag{30}$$

in view of the arbitrariness of $P \in \mathcal{R}^a(\bar t, \bar k, \bar x_2)$, the previous estimates yield that

$$0 \le V(\bar t, \bar k, \bar x_1) - V(\bar t, \bar k, \bar x_2) \le \bar C |\bar x_1 - \bar x_2|$$

for a suitable constant $\bar C$, depending just on L, L_2, and $T + K$.

Hölder continuity in t. Fix $(\bar t_1, \bar k, \bar x)$, $(\bar t_2, \bar k, \bar x) \in [0, T] \times [0, K] \times \mathbb{R}^n$ and assume that $V(\bar t_1, \bar k, \bar x) \ge V(\bar t_2, \bar k, \bar x)$.

Case 1. $\bar t_1 < \bar t_2$. One has

$$0 \le V(\bar t_1, \bar k, \bar x) - V(\bar t_2, \bar k, \bar x) \le \sup_{P \in \mathcal{R}^a(\bar t_2, \bar k, \bar x)} \big(J(\bar t_1, \bar k, \bar x, Q) - J(\bar t_2, \bar k, \bar x, P) \big)$$

for every $Q \in \mathcal{R}^a(\bar t_1, \bar k, \bar x)$. Take $P \in \mathcal{R}^a(\bar t_2, \bar k, \bar x)$ arbitrary and let

$$(\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{\mu_s\}, \{(t_{2_s}, k_s, \xi_{2_s})\}, \theta_2)$$

be the associated relaxed control. Now, as in the previous step, there exist an extension $(\tilde\Omega, \tilde{\mathcal{F}}, \tilde P, \{\tilde{\mathcal{F}}_s\})$ of $(\Omega, \mathcal{F}, P, \{\mathcal{F}_s\})$ and a standard Brownian motion $\{W_s\}$ on $(\tilde\Omega, \tilde{\mathcal{F}}, \tilde P, \{\tilde{\mathcal{F}}_s\})$ such that, for $s \in [0, T + K]$,

$$\begin{aligned}
&t_{2s} = \bar t_2 + \textstyle\int_0^s (1 - |\mu_\sigma|)\, d\sigma,\\
&k_s = \bar k + \textstyle\int_0^s |\mu_\sigma|\, d\sigma,\\
&\xi_{2s} = \bar x + \textstyle\int_0^s \big(A(t_{2_\sigma}, \xi_{2_\sigma})(1 - |\mu_\sigma|) + B(t_{2_\sigma}, \xi_{2_\sigma})\mu_\sigma\big)\, d\sigma + \int_0^s D(t_{2_\sigma}, \xi_{2_\sigma})\sqrt{1 - |\mu_\sigma|}\, dW_\sigma,
\end{aligned}$$

the control $\tilde\beta = (\tilde\Omega, \tilde{\mathcal{F}}, \tilde P, \{\tilde{\mathcal{F}}_s\}, \{\mu_s\}, \{(t_{2_s}, k_s, \xi_{2_s})\}, \theta_2) \in \tilde\Gamma^a(\bar t_2, \bar k, \bar x)$, and $J(\bar t_2, \bar k, \bar x, \tilde\beta) = J(\bar t_2, \bar k, \bar x, P)$. Let us now consider the relaxed control that one obtains from the definition of $\tilde\beta$ when μ_s is replaced by $\mu_s \chi_{\{s \le \theta_2\}}$ for $s \ge 0$. It is easy to see that this control is admissible, that is, it belongs to $\tilde\Gamma^a(\bar t_2, \bar k, \bar x)$ and the corresponding cost coincides with $J(\bar t_2, \bar k, \bar x, P)$. With a small abuse of notation, from now on let us use $\tilde\beta$ to denote such control.

Let us introduce the stopping time $\theta_1 \doteq \theta_2 + (\bar t_2 - \bar t_1)$ and let $\{(t_{1_s}, k_s, \xi_{1_s})\}$ be the strong solution to

$$\begin{aligned}
&t_{1_s} = \bar t_1 + \textstyle\int_0^s (1 - |\mu_\sigma|)\, d\sigma,\\
&k_s = \bar k + \textstyle\int_0^s |\mu_\sigma|\, d\sigma,\\
&\xi_{1_s} = \bar x + \textstyle\int_0^s \big(A(t_{1_\sigma}, \xi_{1_\sigma})(1 - |\mu_\sigma|) + B(t_{1_\sigma}, \xi_{1_\sigma})\mu_\sigma\big)\, d\sigma + \int_0^s D(t_{1_\sigma}, \xi_{1_\sigma})\sqrt{1 - |\mu_\sigma|}\, dW_\sigma
\end{aligned}$$

on the stochastic basis $(\tilde\Omega, \tilde{\mathcal{F}}, \tilde P, \{\tilde{\mathcal{F}}_s\})$ for $s \in [0, T + K]$. As claimed in Remark 2.2, $\tilde\beta$ admissible implies that $\theta_2 \le (T - \bar t_2) + (K - \bar k)$, $t_{2_{\theta_2}} = T$, and $k_{\theta_2} \le K$. Hence one deduces that

$$\theta_1 \le (T - \bar t_2) + (K - \bar k) + (\bar t_2 - \bar t_1) = (T - \bar t_1) + (K - \bar k) \le T + K.$$

Moreover, since we identified μ_s with $\mu_s \chi_{\{s \le \theta_2\}}$ one has

$$t_{1_{\theta_1}} = t_{2_{\theta_2}} + (\theta_1 - \theta_2) - (\bar t_2 - \bar t_1), \qquad k_{\theta_1} = k_{\theta_2} \le K.$$

Therefore, $t_{1_{\theta_1}} = T$, $k_{\theta_1} \le K$, and the control $\tilde\alpha = (\tilde\Omega, \tilde{\mathcal{F}}, \tilde P, \{\tilde{\mathcal{F}}_s\}, \{\mu_s\}, \{(t_{1_s}, k_s, \xi_{1_s})\}, \theta_1)$ is in $\tilde\Gamma^a(\bar t_1, \bar k, \bar x)$. Thus there exists a control rule $Q \in \mathcal{R}^a(\bar t_1, \bar k, \bar x)$ such that

$J(\bar{t}_1, \bar{k}, \bar{x}, \tilde{\alpha}) = J(\bar{t}_1, \bar{k}, \bar{x}, Q)$. We have

$$\begin{aligned}
&J(\bar{t}_1, \bar{k}, \bar{x}, Q) - J(\bar{t}_2, \bar{k}, \bar{x}, P) = J(\bar{t}_1, \bar{k}, \bar{x}, \tilde{\alpha}) - J(\bar{t}_2, \bar{k}, \bar{x}, \tilde{\beta}) \\
&\le E_{\tilde{P}}\left[|g(\xi_{1_{\theta_1}}) - g(\xi_{2_{\theta_2}})|\right] + E_{\tilde{P}}\left[\int_0^{\theta_2} |l_0(t_{1_\sigma}, \xi_{1_\sigma}) - l_0(t_{2_\sigma}, \xi_{2_\sigma})|\ |1 - |\mu_\sigma||\, d\sigma\right] \\
&+E_{\tilde{P}}\left[\int_0^{\theta_2} |l_1(t_{1_\sigma}, \xi_{1_\sigma}) - l_1(t_{2_\sigma}, \xi_{2_\sigma})|\ |\mu_\sigma|\, d\sigma\right] \\
&+E_{\tilde{P}}\left[\int_{\theta_2}^{\theta_2 + (\bar{t}_2 - \bar{t}_1)} |l_0(t_{1_\sigma}, \xi_{1_\sigma})|\ |1 - |\mu_\sigma||\, d\sigma\right] \\
&\le L\left[E_{\tilde{P}}[|\xi_{1_{\theta_1}} - \xi_{2_{\theta_2}}|^2]\right]^{\frac{1}{2}} + LE_{\tilde{P}}\left[\int_0^{\theta_2} (|t_{1_\sigma} - t_{2_\sigma}| + |\xi_{1_\sigma} - \xi_{2_\sigma}|)\, d\sigma\right] + L_3(\bar{t}_2 - \bar{t}_1),
\end{aligned}$$

where the constants L and L_3 are the same as in **(A1)**. In order to conclude the proof, let us introduce for $s \ge 0$ the processes $\hat{\xi}_{i_s} \doteq \xi_{i_{s \wedge \theta_i}}$, for $i = 1, 2$. Since

$$t_{1_{\theta_2}} = t_{2_{\theta_2}} - (\bar{t}_2 - \bar{t}_1),$$

by standard calculations (see, e.g., [F]) one can prove that

$$E_{\tilde{P}}\left[\sup_{s \le \sigma} |\hat{\xi}_{2_s} - \hat{\xi}_{1_s}|^2\right] \le C^2(1 + |\bar{x}|)^2 |\bar{t}_2 - \bar{t}_1|,$$

for every $0 \le \sigma \le T + K$, with C a suitable constant depending on L_1, L_2 in **(A0)** and $T + K$. From the definitions of $\{\hat{\xi}_{2_s}\}$ and $\{\hat{\xi}_{1_s}\}$, this yields

$$E_{\tilde{P}}\left[\left|\xi_{2_{\theta_2}} - \xi_{1_{\theta_1}}\right|^2\right] = E_{\tilde{P}}\left[\left|\hat{\xi}_{2_{T+K}} - \hat{\xi}_{1_{T+K}}\right|^2\right] \le C^2(1 + |\bar{x}|)^2 |\bar{t}_2 - \bar{t}_1|.$$

Therefore, by (30) we obtain

$$J(\bar{t}_1, \bar{k}, \bar{x}, Q) - J(\bar{t}_2, \bar{k}, \bar{x}, P) \le \bar{C}\left[(1 + |\bar{x}|)|\bar{t}_1 - \bar{t}_2|^{\frac{1}{2}} + |\bar{t}_1 - \bar{t}_2|\right],$$

which, by the arbitrariness of P, yields

$$0 \le V(\bar{t}_2, \bar{k}, \bar{x}) - V(\bar{t}_1, \bar{k}, \bar{x}) \le \bar{C}(1 + |\bar{x}|)|\bar{t}_1 - \bar{t}_2|^{\frac{1}{2}}$$

for some constant $\bar{C}$ depending on the constants L, L_2, L_3, and $T + K$ in **(A0)**, **(A1)**.

Case 2. $\bar{t}_1 > \bar{t}_2$. Consider the dynamic programming principle (28) for $V(\bar{t}_2, \bar{k}, \bar{x})$,

$$\begin{aligned}
V(\bar{t}_2, \bar{k}, \bar{x}) = \inf_{R \in \mathcal{R}^a(\bar{t}_2, \bar{k}, \bar{x})} \Bigg\{ E_R\Bigg[\int_0^{r \wedge \theta} &(l_0(t_\sigma, \xi_\sigma)(1 - |\mu_\sigma|) \\
&+ \langle l_1(t_\sigma, \xi_\sigma), \mu_\sigma \rangle)\, d\sigma + V(t_{r \wedge \theta}, k_{r \wedge \theta}, \xi_{r \wedge \theta}) \Bigg] \Bigg\},
\end{aligned} \tag{31}$$

where we choose the (deterministic) time $r = \bar{t}_1 - \bar{t}_2$. It is easy to see that there exists an admissible control rule $P \in \mathcal{R}^a(\bar{t}_2, \bar{k}, \bar{x})$ associated to a relaxed control

$$(\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_s)\}, \theta)$$

and such that

$$P(\mu_s = \delta_{\{0\}} \quad 0 \le s \le \theta, \quad \theta = T - \bar{t}_2) = 1.$$

Then $P(\theta \geq r) = 1$; by the boundedness of l_0 one has

$$V(\bar{t}_2, \bar{k}, \bar{x}) \leq E_P \left[\int_0^r |l_0(t_\sigma, \xi_\sigma)| \, d\sigma + V(t_r, k_r, \xi_r) \right] \leq L_3 r + E_P[V(t_r, k_r, \xi_r)],$$

and by the Lipschitz continuity of the value function in x,

$$V(t_r, k_r, \xi_r) \leq V(t_r, k_r, \bar{x}) + C|\xi_r - \bar{x}|.$$

Hence

$$V(\bar{t}_2, \bar{k}, \bar{x}) - E_P[V(t_r, k_r, \bar{x})] \leq L_3 r + C E_P[|\xi_r - \bar{x}|] \leq L_3 r + C(E_P[|\xi_r - \bar{x}|^2])^{\frac{1}{2}}. \tag{32}$$

From the definition of control rules, we know that under P,

$$\begin{aligned} &t_r = \bar{t}_2 + r = \bar{t}_1, \\ &k_r = \bar{k}, \\ &\xi_r = \bar{x} + \textstyle\int_0^r A(t_\sigma, \xi_\sigma) \, d\sigma + M_r, \end{aligned} \tag{33}$$

where $\{M_r\}$ is a continuous square integrable martingale with

$$\langle M \rangle_r = \int_0^r \mathrm{Tr}\{\tilde{D}(t_\sigma, \xi_\sigma)\} \, d\sigma.$$

Therefore, by the Burkholder–Davis–Gundy inequality there exists a constant C, depending on L_1 in **(A0)**, such that

$$E_P[|\xi_r - \bar{x}|^2] \leq C^2(1 + |\bar{x}|)^2(r^2 + r). \tag{34}$$

Therefore, (32), (33), and (34) yield

$$0 \leq V(\bar{t}_2, \bar{k}, \bar{x}) - V(\bar{t}_1, \bar{k}, \bar{x}) \leq \bar{C}(1 + |\bar{x}|)|\bar{t}_2 - \bar{t}_1|^{\frac{1}{2}}$$

for some constant $\bar{C}$ depending on the constants introduced in **(A0)**, **(A1)**.

Lipschitz continuity in k. Fix $(\bar{t}, \bar{k}_1, \bar{x}), (\bar{t}, \bar{k}_2, \bar{x}) \in [0, T] \times [0, K] \times \mathbb{R}^n$, and assume that $V(\bar{t}, \bar{k}_1, \bar{x}) \geq V(\bar{t}, \bar{k}_2, \bar{x})$.

Case 1. $\bar{k}_1 < \bar{k}_2$. One has

$$0 \leq V(\bar{t}, \bar{k}_1, \bar{x}) - V(\bar{t}, \bar{k}_2, \bar{x}) \leq \sup_{P \in \mathcal{R}^a(\bar{t}, \bar{k}_2, \bar{x})} \big(J(\bar{t}, \bar{k}_1, \bar{x}, Q) - J(\bar{t}, \bar{k}_2, \bar{x}, P) \big)$$

for every $Q \in \mathcal{R}^a(\bar{t}, \bar{k}_1, \bar{x})$. As in the previous step, take $P \in \mathcal{R}^a(\bar{t}, \bar{k}_2, \bar{x})$ arbitrary and let $\{W_s\}$ be a standard Brownian motion on a suitable $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\})$ such that

$$\tilde{\beta} = (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\}, \{\mu_s\}, \{(t_s, k_{2_s}, \xi_s)\}, \theta_2) \in \tilde{\Gamma}^a(\bar{t}, \bar{k}_2, \bar{x})$$

is a relaxed control, where, for $s \in [0, T + K]$,

$$\begin{aligned} &t_s = \bar{t} + \textstyle\int_0^s (1 - |\mu_\sigma|) \, d\sigma, \\ &k_{2_s} = \bar{k}_2 + \textstyle\int_0^s |\mu_\sigma| \, d\sigma, \\ &\xi_s = \bar{x} + \textstyle\int_0^s \left(A(t_\sigma, \xi_\sigma)(1 - |\mu_\sigma|) + B(t_\sigma, \xi_\sigma)\mu_\sigma \right) d\sigma + \int_0^s D(t_\sigma, \xi_\sigma)\sqrt{1 - |\mu_\sigma|} \, dW_\sigma, \end{aligned}$$

and $J(\bar{t}, \bar{k}_2, \bar{x}, \tilde{\beta}) = J(\bar{t}, \bar{k}_2, \bar{x}, P)$. Moreover, setting for $s \geq 0$,

$$k_{1_s} \doteq \bar{k}_1 + \int_0^s |\mu_\sigma| \, d\sigma = k_{2_s} - (\bar{k}_2 - \bar{k}_1),$$

one easily sees that the control

$$\tilde{\alpha} = (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, \{\tilde{\mathcal{F}}_s\}, \{\mu_s\}, \{(t_s, k_{1_s}, \xi_s)\}, \theta_2)$$

is in $\tilde{\Gamma}^a(\bar{t}, \bar{k}_1, \bar{x})$. As before, there exists a control rule $Q \in \mathcal{R}^a(\bar{t}, \bar{k}_1, \bar{x})$ such that $J(\bar{t}, \bar{k}_1, \bar{x}, \tilde{\alpha}) = J(\bar{t}, \bar{k}_1, \bar{x}, Q)$. Since the cost functional J and the state process $\{\xi_s\}$ do not depend explicitly on the k variable, one has that

$$J(\bar{t}, \bar{k}_2, \bar{x}, P) = J(\bar{t}, \bar{k}_2, \bar{x}, \tilde{\beta}) = J(\bar{t}, \bar{k}_1, \bar{x}, \tilde{\alpha}) = J(\bar{t}, \bar{k}_1, \bar{x}, Q).$$

As a consequence, in this case,

$$V(\bar{t}, \bar{k}_1, \bar{x}) = V(\bar{t}, \bar{k}_2, \bar{x}).$$

Case 2. $\bar{k}_1 > \bar{k}_2$. Consider the dynamic programming principle (28) for $V(\bar{t}, \bar{k}_2, \bar{x})$,

$$V(\bar{t}, \bar{k}_2, \bar{x}) = \inf_{R \in \mathcal{R}^a(\bar{t}, \bar{k}_2, \bar{x})} \left\{ E_R \left[\int_0^{r \wedge \theta} (l_0(t_\sigma, \xi_\sigma)(1 - |\mu_\sigma|) + \langle l_1(t_\sigma, \xi_\sigma), \mu_\sigma \rangle) \, d\sigma + V(t_{r\wedge\theta}, k_{r\wedge\theta}, \xi_{r\wedge\theta}) \right] \right\},$$

where we choose the (deterministic) time $r = \bar{k}_1 - \bar{k}_2$. Let us fix an arbitrary $w \in \mathcal{K}$ with $|w| = 1$. Then there exists a control rule $P \in \mathcal{R}^a(\bar{t}, \bar{k}_2, \bar{x})$ associated to a relaxed control

$$\tilde{\beta} = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{\mu_s\}, \{(t_s, k_s, \xi_s)\}, \theta)$$

such that

$$P(\mu_s = \delta_{\{w\}} \quad 0 \le s \le \theta, \quad \theta = K - \bar{k}_2) = 1,$$

and $J(\bar{t}, \bar{k}_2, \bar{x}, \tilde{\beta}) = J(\bar{t}, \bar{k}_2, \bar{x}, P)$. Then, arguing as in the case "$\bar{t}_1 > \bar{t}_2$" of the proof of the continuity in t, we can deduce that an estimate analogous to (32) is still verified, that is

$$V(\bar{t}, \bar{k}_2, \bar{x}) - E_P[V(t_r, k_r, \bar{x})] \le L_3 r + C E_P[|\xi_r - \bar{x}|] \le L_3 r + C(E_P[|\xi_r - \bar{x}|^2])^{\frac{1}{2}}. \tag{35}$$

Now, under P we have

$$\begin{aligned} &t_r = \bar{t}, \\ &k_r = \bar{k}_2 + r = \bar{k}_1, \\ &\xi_r = \bar{x} + \textstyle\int_0^r B(t_\sigma, \xi_\sigma) \, d\sigma. \end{aligned} \tag{36}$$

Therefore, since $E_P[|B(t_s, \xi_s)|^2] \le E_P[[L_1(1 + |\xi_s|)]^2] \le C^2(1 + |\bar{x}|)^2$, we deduce that for $0 \le r \le \theta$,

$$E_P[|\xi_r - \bar{x}|^2] \le C^2(1 + |\bar{x}|)^2 r^2. \tag{37}$$

Then (35), (36), and (37) yield

$$0 \le V(\bar{t}, \bar{k}_2, \bar{x}) - V(\bar{t}, \bar{k}_1, \bar{x}) \le \bar{C}(1 + |\bar{x}|)|\bar{k}_2 - \bar{k}_1|.$$

The proof of Theorem 4.1 is thus concluded. □

By Theorem 2.3, as a straightforward consequence of Theorem 4.1 one has the following corollary.

COROLLARY 4.2. *Assume* **(A0)**, **(A1)**. *Then there exists a unique, bounded, continuous extension of the value function* $\mathcal{V} : [0,T[\times[0,K] \times \mathbb{R}^n \to \mathbb{R}$, *still denoted by* $\mathcal{V}$, *to the closed set* $[0,T] \times [0,K] \times \mathbb{R}^n$ *which coincides with the auxiliary value function* V. *Hence there exists some* $\bar{C} > 0$ *such that*

$$|\mathcal{V}(\bar{t},\bar{k},\bar{x})| \le \bar{C} \qquad \forall (\bar{t},\bar{k},\bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n,$$

$$|\mathcal{V}(\bar{t}_1,\bar{k}_1,\bar{x}_1) - \mathcal{V}(\bar{t}_2,\bar{k}_2,\bar{x}_2)| \le \bar{C}[|\bar{x}_1 - \bar{x}_2| + (1 + |\bar{x}_1| \vee |\bar{x}_2|)(|\bar{t}_1 - \bar{t}_2|^{1/2} + |\bar{k}_1 - \bar{k}_2|)]$$

for all $(\bar{t}_1,\bar{k}_1,\bar{x}_1)$, $(\bar{t}_2,\bar{k}_2,\bar{x}_2) \in [0,T] \times [0,K] \times \mathbb{R}^n$.

Therefore, from now on $\mathcal{V}$ will denote the extension of $\mathcal{V}$ to $[0,T] \times [0,K] \times \mathbb{R}^n$, which exists being equal to V.

5. Dynamic programming equation and boundary conditions. This section is devoted to showing that the value function $\mathcal{V}$ is a viscosity solution of (5)–(7). To this end, we will recall below the definition of viscosity sub- and supersolutions with generalized boundary conditions (see, e.g., [CIL]). A formal derivation of the boundary value problem described in the introduction is given in the following subsection.

5.1. Heuristic derivation of the quasi-variational inequality and of the boundary conditions. It is quite easy to deduce heuristically the boundary value problem (5)–(7) once we consider the value function V of the auxiliary optimization control problem defined in Definition 2.2 to which our original control problem, introduced in Definition 2.1, is equivalent. The auxiliary control problem is indeed formulated as an *unconstrained stopping time problem*, with bounded controls and discontinuous final cost given by

$$\tilde{G}(t,k,x) \doteq g(x) - G(t,k) \qquad \forall (t,k,x) \in \mathbb{R}^{2+n}.$$

Therefore, assuming V of class $C^{1,2}$, using Ito's formula and arguing as usual (see, e.g., [FS]), we can deduce from the dynamic programming principle (28) that V verifies the following equation:

$$\tilde{\mathcal{F}}\left(x, DV, \frac{\partial V}{\partial t}, \frac{\partial V}{\partial k}, D^2V\right) = 0 \qquad \text{in }]0,T[\times]0,K[\times\mathbb{R}^n,$$

where

$$\tilde{\mathcal{F}}(x,p_x,p_t,p_k,S) \doteq \max_{\{(w_0,w):\ w_0\ge 0,\ \ w\in\mathcal{K},\ w_0+|w|=1\}}\{-\tfrac{1}{2}w_0\mathrm{Tr}\{\tilde{D}(t,x)S\}$$
$$-\langle A(t,x)w_0 + B(t,x)w, p_x\rangle - l_0(t,x)w_0 - \langle l_1(t,x), w\rangle - p_t\, w_0 - p_k|w|\},$$

which is, in turn, equivalent to the quasi-variational inequality (5), as shown in [MS2].

More precisely, one can show that the value function of an optimal stopping time problem verifies

$$\max\left\{\tilde{\mathcal{F}}\left(x, DV, \frac{\partial V}{\partial t}, \frac{\partial V}{\partial k}, D^2V\right); V - \tilde{G}\right\} = 0 \qquad \text{in } \mathbb{R}^{2+n}, \tag{38}$$

due to the fact that the controller can decide to stop as soon as it is convenient (for the derivation of (38) in a viscosity framework we refer to [BP] and [BCD]). Since

$V(t,k,x) = +\infty$ outside $[0,T] \times [0,K] \times \mathbb{R}^n$ and the lower semicontinuous exit cost $\tilde{G}(t,k,x)$ is equal to $g(x)$ for $(t,x,k) \in \{T\} \times [0,K] \times \mathbb{R}^n$ and to $+\infty$ otherwise, by (38) it follows easily that (7) holds for every $(t,x,k) \in \{T\} \times [0,K] \times \mathbb{R}^n$ and that (6) holds for $(t,x,k) \in [0,T[\times[0,K] \times \mathbb{R}^n$.

We underline that, as far as we know, there is not in the literature a dynamic programming principle for the problem of Definition 2.1; hence, even assuming the value function $\mathcal{V}$ to be regular enough, there is no way to deduce the equation and the boundary conditions (5)–(7) directly for the original control problem.

5.2. Viscosity solution.

DEFINITION 5.1. *A locally bounded function v defined on $[0,T] \times [0,K] \times \mathbb{R}^n$ is a* viscosity subsolution *of* (5)–(7) *if for every point $\bar{z} = (\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ and for every map $\phi \in C_b^2([0,T] \times [0,K] \times \mathbb{R}^n)$ such that $v^* - \phi$ has a local maximum at $\bar{z}$ one has*

$$\max\left\{-\frac{\partial \phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})), -\frac{\partial \phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z}))\right\} \le 0$$

if $\bar{z} \in]0,T[\times]0,K[\times\mathbb{R}^n$, and

$$v^*(\bar{z}) \le g(\bar{x})$$

if $\bar{z} \in \{T\}\times]0,K] \times \mathbb{R}^n$.

A locally bounded function v defined on $[0,T] \times [0,K] \times \mathbb{R}^n$ is a viscosity supersolution *of* (5)–(7) *if for every point $\bar{z} = (\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ and for every map $\phi \in C_b^2([0,T] \times [0,K] \times \mathbb{R}^n)$ such that $v_* - \phi$ has a local minimum at $\bar{z}$ one has*

$$\max\left\{-\frac{\partial \phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})), -\frac{\partial \phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z}))\right\} \ge 0$$

if $\bar{z} \in]0,T[\times]0,K] \times \mathbb{R}^n$, and

$$\max\left\{-\frac{\partial \phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})), -\frac{\partial \phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z}))\right\} \ge 0 \quad \text{or} \quad v_*(\bar{z}) \ge g(\bar{x})$$

if $\bar{z} \in \{T\}\times]0,K] \times \mathbb{R}^n$.

A locally bounded function v defined on $[0,T] \times [0,K] \times \mathbb{R}^n$ is called a viscosity solution *of* (5)–(7) *if it is both a viscosity sub- and supersolution of* (5)–(7).

Example 5.1. Consider the control problem introduced in Example 2.1 and the following boundary value problem:

$$\max\left\{-\frac{\partial v}{\partial t} - cDv, -\frac{\partial v}{\partial k} + \mathcal{H}(x, Dv)\right\} = 0 \quad \text{in }]0,T[\times]0,K[\times\mathbb{R}, \tag{39}$$

$$\max\left\{-\frac{\partial v}{\partial t} - cDv, -\frac{\partial v}{\partial k} + \mathcal{H}(x, Dv)\right\} \ge 0 \quad \text{on }]0,T[\times\{K\} \times \mathbb{R}, \tag{40}$$

$$\begin{aligned} v(T,k,x) \le \arctan(x) \ \text{ and } \ & \max\left\{-\tfrac{\partial v}{\partial t} - cDv, -\tfrac{\partial v}{\partial k} + \mathcal{H}(x, Dv)\right\} \ge 0 \\ \text{if } \ v(T,k,x) < \arctan(x) \ & \text{ on } \{T\}\times]0,K] \times \mathbb{R}, \end{aligned} \tag{41}$$

where

$$\mathcal{H}(x,p) = \max_{(w_1,w_2) \in \mathcal{K},\, |(w_1,w_2)| = 1} \{-(w_1 + xw_2)p\}.$$

It is not difficult to prove that the value function $\mathcal{V}$ is a classical solution of (39, while we refer to [MoRa] to show that it satisfies (40)–(41) in the viscosity sense.

THEOREM 5.2. *Assume* **(A0)**, **(A1)**. *Then the value function* $\mathcal{V} : [0,T]\times[0,K]\times\mathbb{R}^n \to \mathbb{R}$ *solves the boundary value problem* (5)–(7) *in the viscosity sense.*

Proof. We postpone the proof of this theorem to the end of this section. □

THEOREM 5.3. *Assume* **(A0)**, **(A1)**. *Then the value function* $\mathcal{V} : [0,T]\times[0,K]\times\mathbb{R}^n \to \mathbb{R}$ *is the unique viscosity solution of* (5)–(7) *among the bounded functions defined on* $[0,T]\times[0,K]\times\mathbb{R}^n$ *which are continuous on* $\partial(]0,T[\times]0,K[\times\mathbb{R}^n)$.

Proof. This result follows straightforwardly from Corollary 6.1 of Theorem 3.1 in [MS2] in view of Theorem 5.2 and Corollary 4.2. □

Remark 5.1. When the boundedness assumption (8) in **(A1)** is weakened in the linear growth condition (12) introduced in Remark 2.1, in order to apply Corollary 6.1 in [MS2] we have to introduce the following stronger growth hypothesis on A, B, and $\tilde{D}$:

(A2) for any $\varepsilon > 0$ there is a constant $C_\varepsilon > 0$ for which

$$|A(t,x)| + |B(t,x)| \le C_\varepsilon + \varepsilon|x|, \quad |\tilde{D}(t,x)| \le C_\varepsilon + \varepsilon|x|^2 \quad \forall (t,x) \in [0,T]\times\mathbb{R}^n.$$

Then under hypotheses **(A0)**, **(A1)** with (8) replaced by (12) and **(A2)**, we obtain the uniqueness for the viscosity solution to (5)–(7) among the functions v which are continuous on $\partial(]0,T[\times]0,K]\times\mathbb{R}^n)$ and such that

$$\sup_{x\in\mathbb{R}^n} \frac{|v(t,k,x)|}{1+|x|} < +\infty \qquad \text{uniformly for } \ (t,k) \in [0,T]\times[0,K].$$

Proof of Theorem 5.2. Since $\mathcal{V} = V$, let us prove the theorem for V. Owing to Theorem 4.1, V is continuous, so that $V^* = V_* = V$. In what follows, for any $\bar{z} = (\bar{t},\bar{k},\bar{x}) \in [0,T]\times[0,K]\times\mathbb{R}^n$ and any $r' > 0$ let us set $\Theta_{r'} \doteq [0 \vee (\bar{t}-r'), T \wedge (\bar{t}+r')[\times[0 \vee (\bar{k}-r'), K \wedge (\bar{k}+r')[\times B_n(r')$.

Step 1. Let us start by showing that V is a viscosity subsolution of (5)–(7). Since at any point of the form $(T,\bar{k},\bar{x})$ (with $\bar{k} < K$ and $\bar{x} \in \mathbb{R}^n$) it is clear that there exists a control rule $P \in \mathcal{R}^a(T,\bar{k},\bar{x})$ such that

$$P(\theta = 0) = 1,$$

from the very definition of V it follows that $V(T,\bar{k},\bar{x}) \le g(\bar{x})$. Hence it remains to prove that V is a viscosity subsolution of (5). We argue by contradiction. If this fails to hold, then there is a point $\bar{z} = (\bar{t},\bar{k},\bar{x}) \in]0,T[\times]0,K[\times\mathbb{R}^n$, a test function $\phi \in C_b^2([0,T]\times[0,K]\times\mathbb{R}^n)$, and a constant $r_1 > 0$ such that $\bar{z}$ is a local maximum point for $V - \phi$, that is,

$$V(z) - \phi(z) \le V(\bar{z}) - \phi(\bar{z}) \quad \forall z = (t,k,x) \in \overline{\Theta}_{r_1},$$

and

$$\max\left\{ -\frac{\partial\phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})), -\frac{\partial\phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z}))\right\} > 0.$$

Here, either

$$-\frac{\partial\phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})) > 0 \tag{42}$$

or

$$-\frac{\partial \phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z})) > 0 \tag{43}$$

is verified. Since $\bar{t} < T$ and $\bar{k} < K$, in the definition of Θ_{r_1}, reducing r_1 if necessary, we can always assume that $\bar{t} + r_1 < T$ and $\bar{k} + r_1 < K$. If (42) is true, from the definition of $\mathcal{F}$, from the regularity hypotheses in **(A0)**, **(A1)** and from the fact that $\phi \in C^2$, it then follows that there exists some positive constant $r_2 \leq r_1$ such that

$$-\frac{\partial \phi}{\partial t}(t,k,x) - \langle A(t,x), D\phi(t,k,x)\rangle - l_0(t,x) - \frac{1}{2}\mathrm{Tr}\{\tilde{D}(t,x)D^2\phi(t,k,x)\} > 0$$

for all $z = (t,k,x) \in \overline{\Theta}_{r_2}$, and $\bar{t} + r_2 < T$, $\bar{k} + r_2 < K$. Take a control rule $P \in \mathcal{R}^a(\bar{t},\bar{k},\bar{x})$ such that

$$P\left(\mu_s = \delta_{\{0\}} \quad 0 \leq s \leq \theta, \quad \theta = T - \bar{t}\right) = 1.$$

It is easy to see that such a control rule exists; that, setting

$$\rho \doteq \inf\{s \in]0, T+K] : \ (t_s, k_s, \xi_s) \notin \Theta_{r_2}\},$$

by the continuity of the state process (t_s, k_s, ξ_s) one gets

$$P(T - \bar{t} > \rho) = 1, \qquad P(\rho > 0) = 1;$$

and that, for $0 \leq s < \rho$,

$$-\frac{\partial \phi}{\partial t}(t_s,k_s,\xi_s) - \langle A(t_s,\xi_s), D\phi(t_s,k_s,\xi_s)\rangle - \frac{1}{2}\mathrm{Tr}\{\tilde{D}(t_s,\xi_s)D^2\phi(t_s,k_s,\xi_s)\} - l_0(t_s,\xi_s) > 0.$$

Since $\mu_s = \delta_{\{0\}}$, this yields that

$$E_P\left[\int_0^\rho \left(-\mathcal{L}\phi(t_s,k_s,\xi_s,\mu_s) - l_0(t_s,\xi_s)(1-|\mu_s|) - \langle l_1(t_s,\xi_s),\mu_s\rangle\right) ds\right] > 0. \tag{44}$$

By the definition of control rule one has

$$\phi(t_\rho,k_\rho,\xi_\rho) = \phi(\bar{t},\bar{k},\bar{x}) + \int_0^\rho \mathcal{L}\phi(t_s,k_s,\xi_s,\mu_s)\, ds + \mathcal{M}_\rho\phi,$$

where $\mathcal{M}_\rho\phi$ is a continuous square-integrable martingale with respect to P. Hence,

$$E_P\left[\phi(t_\rho,k_\rho,\xi_\rho) - \phi(\bar{t},\bar{k},\bar{x})\right] = E_P\left[\int_0^\rho \mathcal{L}\phi(t_s,k_s,\xi_s,\mu_s)\, ds\right].$$

Since $(t_\rho,k_\rho,\xi_\rho) \in \overline{\Theta}_{r_2}$, one has

$$\begin{aligned} &E_P\left[V(t_\rho,k_\rho,\xi_\rho) - V(\bar{t},\bar{k},\bar{x})\right] \leq E_P\left[\phi(t_\rho,k_\rho,\xi_\rho) - \phi(\bar{t},\bar{k},\bar{x})\right] \\ &= E_P\left[\int_0^\rho \mathcal{L}\phi(t_s,k_s,\xi_s,\mu_s)\, ds\right] < -E_P\left[\int_0^\rho \left(l_0(t_s,\xi_s)(1-|\mu_s|) + \langle l_1(t_s,\xi_s),\mu_s\rangle\right) ds\right], \end{aligned}$$

where the last inequality follows from (44). This can be rewritten as

$$V(\bar{t},\bar{k},\bar{x}) > E_P\left[\int_0^\rho \left(l_0(t_s,\xi_s)(1-|\mu_s|) + \langle l_1(t_s,\xi_s),\mu_s\rangle\right) + V(t_\rho,k_\rho,\xi_\rho)\right],$$

in contradiction with the dynamic programming principle (28).

If (43) is true, reasoning as before one can deduce that there exist some positive constant $r_2 \le r_1$ and a vector $\bar{w} \in \mathcal{K}$ with $|\bar{w}| = 1$ such that

$$-\frac{\partial \phi}{\partial k}(t,k,x) - \langle B(t,x)\bar{w}, p\rangle - \langle l_1(t,x), \bar{w}\rangle > 0 \quad \forall z = (t,k,x) \in \overline{\Theta}_{r_2}.$$

Then, let us introduce a control rule $P \in \mathcal{R}^a(\bar{t},\bar{k},\bar{x})$ such that

$$P\left(\mu_s = \delta_{\{\bar{w}\}} \quad 0 \le s \le \theta, \quad \theta = K - \bar{k}\right) = 1.$$

From now on, the proof proceeds, with obvious changes, as in the previous case. The proof that $\mathcal{V}$ is a viscosity subsolution of (5)–(7) is therefore concluded.

Step 2. Let us assume by contradiction that V fails to be a viscosity supersolution of (5)–(7). Thus there is a point $\bar{z} = (\bar{t},\bar{k},\bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$, a test function $\phi \in C_b^2([0,T] \times [0,K] \times \mathbb{R}^n)$, and a constant $r_1 > 0$ such that $\bar{z}$ is a local minimum point for $V - \phi$, that is,

$$V(z) - \phi(z) \ge V(\bar{z}) - \phi(\bar{z}) \quad \forall z = (t,k,x) \in \overline{\Theta}_{r_1},$$

and either of the following cases hold.

Case 1. $(\bar{t},\bar{k},\bar{x})$ is such that $\bar{t} < T$, $\bar{k} \le K$, and

$$-\frac{\partial \phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})) < 0 \ \text{ and } \ -\frac{\partial \phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z})) < 0.$$

Case 2. $(\bar{t},\bar{k},\bar{x})$ is such that $\bar{t} = T$, $\bar{k} < K$, and

$$\max\left\{-\frac{\partial \phi}{\partial t}(\bar{z}) + \mathcal{F}(\bar{z}, D\phi(\bar{z}), D^2\phi(\bar{z})), -\frac{\partial \phi}{\partial k}(\bar{z}) + \mathcal{H}(\bar{z}, D\phi(\bar{z}))\right\} < 0 \ \text{ and } \ V(\bar{z}) < g(\bar{x}).$$

Let us first consider Case 1. Since $\bar{t} < T$, in the definition of Θ_{r_1}, reducing r_1 if necessary, we can always assume that $\bar{t} + r_1 < T$. From the regularity hypotheses in **(A0)**, **(A1)** and from the fact that $\phi \in C^2$, it follows that there exist some positive constants $r_2 \le r_1$ and $\varepsilon > 0$ such that

$$(45) \quad -\frac{\partial \phi}{\partial t}(z) + \mathcal{F}(z, D\phi(z), D^2\phi(z)) < -\varepsilon \ \text{ and } \ -\frac{\partial \phi}{\partial k}(z) + \mathcal{H}(z, D\phi(z)) < -\varepsilon$$

for all $z = (t,k,x) \in \overline{\Theta}_{r_2}$, and $\bar{t} + r_2 \le \bar{t} + r_1 < T$. Take an optimal control rule $P \in \mathcal{R}^a(\bar{t},\bar{k},\bar{x})$. Such a control rule exists in view of Proposition 3.5. Let us notice that at any point $(\bar{t},\bar{k},\bar{x})$ with $\bar{t} < T$, every control rule $Q \in \mathcal{R}^a(\bar{t},\bar{k},\bar{x})$ verifies

$$(46) \qquad Q\left(\theta \ge T - \bar{t} > 0\right) = 1.$$

Moreover (see Remark 2.2), in both cases, $\bar{k} < K$ and $\bar{k} = K$, one has

$$(47) \qquad Q\left(k_s \le K \quad 0 \le s \le \theta\right) = 1.$$

Equations (46) and (47) hold, in particular, for $Q = P$. Let us define the exit time

$$\rho \doteq \inf\{s \in]0, T+K] : \\ (t_s, k_s, \xi_s) \notin [0 \vee (\bar{t} - r_2), \bar{t} + r_2[\times [0 \vee (\bar{k} - r_2), \bar{k} + r_2[\times B_n(r_2)\}.$$

Observe that, if $\bar{k} < K$, then it is not restrictive to assume that $\bar{k} + r_2 < K$, so that ρ coincides with the first exit time from the set Θ_{r_2}. In case $\bar{k} = K$, instead, $\bar{k} + r_2 > K$ and ρ may be greater than the first exit time from Θ_{r_2}. However, taking into account (47), it is not difficult to see that in both cases $\bar{k} < K$ and $\bar{k} = K$, one has

$$(t_s, k_s, \xi_s) \in \overline{\Theta}_{r_2} \qquad 0 \le s \le \rho \wedge \theta.$$

Now, from the continuity of the process (t_s, k_s, ξ_s) it follows that

$$P(\rho > 0) = 1,$$

which together with (46) yields that the stopping time $\rho' \doteq \rho \wedge \theta$ verifies

$$P(\rho' > 0) = 1.$$

Therefore by (45) it follows that

$$E_P\left[\int_0^{\rho'} (\mathcal{L}\phi(t_s, k_s, \xi_s, \mu_s) + l_0(t_s, \xi_s)(1 - |\mu_s|) + \langle l_1(t_s, \xi_s), \mu_s\rangle)\, ds\right] \ge \varepsilon E_P[\rho'].$$

Applying Ito's formula, we have

$$E_P[\phi(t_{\rho'}, k_{\rho'}, \xi_{\rho'})] = \phi(\bar{t}, \bar{k}, \bar{x}) + E_P\left[\int_0^{\rho'} \mathcal{L}\phi(t_s, k_s, \xi_s, \mu_s)\, ds\right]$$

which yields

$$\begin{aligned} &E_P\left[\phi(t_{\rho'}, k_{\rho'}, \xi_{\rho'}) - \phi(\bar{t}, \bar{k}, \bar{x})\right] = E_P\left[\textstyle\int_0^{\rho'} \mathcal{L}\phi(t_s, k_s, \xi_s, \mu_s)\, ds\right] \\ &\ge E_P\left[\textstyle\int_0^{\rho'} (-l_0(t_s, \xi_s)(1 - |\mu_s|) - \langle l_1(t_s, \xi_s), \mu_s\rangle)\, ds\right] + \varepsilon E_P[\rho']. \end{aligned}$$

Since $(t_{\rho'}, k_{\rho'}, \xi_{\rho'}) \in \overline{\Theta}_{r_2}$ and $E_P[\rho'] > 0$, setting $\varepsilon' \doteq \varepsilon E_P[\rho']$, $\varepsilon' > 0$ one has

$$\begin{aligned} &E_P\left[V(t_{\rho'}, k_{\rho'}, \xi_{\rho'}) - V(\bar{t}, \bar{k}, \bar{x})\right] \ge E_P\left[\phi(t_{\rho'}, k_{\rho'}, \xi_{\rho'}) - \phi(\bar{t}, \bar{k}, \bar{x})\right] \\ &\ge E_P\left[\textstyle\int_0^{\rho'} (-l_0(t_s, \xi_s)(1 - |\mu_s|) - \langle l_1(t_s, \xi_s), \mu_s\rangle)\, ds\right] + \varepsilon', \end{aligned}$$

which, rewritten as

$$V(\bar{t}, \bar{k}, \bar{x}) \le E_P\left[\int_0^{\rho'} (l_0(t_s, \xi_s)(1 - |\mu_s|) + \langle l_1(t_s, \xi_s), \mu_s\rangle)\, ds + V(t_{\rho'}, k_{\rho'}, \xi_{\rho'})\right] - \varepsilon',$$

contradicts the dynamic programming principle (28).

Let $(T, \bar{k}, \bar{x})$ be some point satisfying the assumptions of Case 2. Since by definition $V(T, K, \bar{x}) = g(\bar{x}) \ \ \forall \bar{x} \in \mathbb{R}^n$, it must be that $\bar{k} < K$. Hence in the definition of Θ_{r_1}, reducing r_1 if necessary, we can always assume that $\bar{k} + r_1 < K$, $r_1 < T$ (while $(T + r_1) \wedge T = T$), and from the regularity hypotheses in **(A0)**, **(A1)** and from $\phi \in C^2$, it follows that there exist some positive constants $r_2 \le r_1$ and $\varepsilon > 0$ such that

$$-\frac{\partial \phi}{\partial t}(z) + \mathcal{F}(z, D\phi(z), D^2\phi(z)) < -\varepsilon, \quad -\frac{\partial \phi}{\partial k}(z) + \mathcal{H}(z, D\phi(z)) < -\varepsilon, \quad V(z) < g(x) - \varepsilon$$

for all $z = (t, k, x) \in \overline{\Theta}_{r_2}$, where now $\Theta_{r_2} = [T - r_2, T[\times[0 \vee (\bar{k} - r_2), \bar{k} + r_2[\times B_n(r_2)$. Let $P \in \mathcal{R}^a(T, \bar{k}, \bar{x})$ be an optimal control rule, which exists in view of Proposition 3.5. It is not difficult to see that every control rule $Q \in \mathcal{R}^a(T, \bar{k}, \bar{x})$ is such that

$$Q\,(t_s = T, \quad 0 \le s \le \theta) = 1, \tag{48}$$

and, if in addition $J(T, \bar{k}, \bar{x}, Q) < g(\bar{x})$, then ($\bar{k} < K$ and)

$$Q\,(\theta > 0) = 1. \tag{49}$$

Since $V(T, \bar{k}, \bar{x}) < g(\bar{x})$ by hypothesis, (48) and (49) hold, in particular, for $Q = P$. Let us define

$$\rho \doteq \inf\left\{s \in]0, T + K] : \ (t_s, k_s, \xi_s) \notin [T - r_2, T + r_2[\times[0 \vee (\bar{k} - r_2), \bar{k} + r_2[\times B_n(r_2)\right\}.$$

The exit time ρ may be greater than the first exit time from Θ_{r_2}, but from (48) it follows that

$$(t_s, k_s, \xi_s) \in \overline{\Theta}_{r_2}, \qquad 0 \le s \le \rho \wedge \theta.$$

Now the continuity of the process (t_s, k_s, ξ_s) implies that

$$P\,(\rho > 0) = 1.$$

Owing to (49), this yields that the stopping time $\rho' \doteq \rho \wedge \theta$ verifies

$$P\,(\rho' > 0) = 1.$$

From now on, the proof is analogous to the proof of Case 1, so we omit it. This proves that $\mathcal{V}$ is a viscosity supersolution of (5)–(7).

The proof that $\mathcal{V}$ is a viscosity solution of (5)–(7) is therefore concluded. □

6. Existence of solutions for generalized Cauchy problems with discontinuous Hamiltonians. The results of the previous sections allow us to prove the existence of a viscosity solution to a boundary value problem involving a second order semilinear Hamilton–Jacobi–Bellman equation such as

$$-\frac{\partial v}{\partial t} - \frac{1}{2}\mathrm{Tr}\{\tilde{D}(t,x)D^2 v\} + H\left(t, x, \frac{\partial v}{\partial k}, Dv\right) = 0 \qquad \text{on} \quad]0, T[\times]0, K[\times\mathbb{R}^n, \tag{50}$$

and mixed boundary conditions such as

$$-\frac{\partial v}{\partial t} - \frac{1}{2}\mathrm{Tr}\{\tilde{D}(t,x)D^2 v\} + H\left(t, x, \frac{\partial v}{\partial k}, Dv\right) \ge 0 \quad \text{on }]0, T[\times\{K\}\times\mathbb{R}^n, \tag{51}$$

$$v \le g \ \text{ and } \ -\tfrac{\partial v}{\partial t} - \tfrac{1}{2}\mathrm{Tr}\{\tilde{D}(t,x)D^2 v\} + H(t, x, \tfrac{\partial v}{\partial k}, Dv) \ge 0 \text{ if } v < g \text{ on } \{T\}\times]0, K]\times\mathbb{R}^n, \tag{52}$$

for a (possibly discontinuous) Hamiltonian of the form

$$H(t, x, p_k, p) \doteq \sup_{w\in\mathcal{K}}\{-\langle A(t,x) + B(t,x)w, p\rangle - l_0(t,x) - \langle l_1(t,x), w\rangle - p_k|w|\} \tag{53}$$

$\forall (t, x, p_k, p) \in [0,T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n$. We will refer to such a problem as a *generalized Cauchy problem with discontinuous Hamiltonian.*

We point out that the Hamiltonian H in (53), defined via a maximization over the unbounded control set $\mathcal{K}$, is the natural Hamiltonian related to the original minimization problem (4). In other words, at least formally, one expects that the value function $\mathcal{V}$ is a viscosity solution to the generalized Cauchy problem (50)–(52) rather than to (5)–(7). Such an observation motivates the study of such a boundary value problem (also in more general form, as in [MS2]), mainly dealing with existence and uniqueness of solutions.

Since H in (53) is in general discontinuous and equal to $+\infty$ in many points, we interpret solutions to (50)–(52) in the sense of the definition, due to Ishii [I], of discontinuous viscosity solutions for discontinuous Hamiltonians which we recall in the definition below.

DEFINITION 6.1. *A locally bounded function v defined on $[0,T[\times[0,K] \times \mathbb{R}^n$ is a* viscosity subsolution *of* (50)–(52) *if for every point $\bar{z} = (\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ and for every map $\phi \in C_b^2([0,T] \times [0,K] \times \mathbb{R}^n)$ such that $v^* - \phi$ has a local maximum at $\bar{z}$ one has*

$$-\frac{\partial \phi}{\partial t}(\bar{z}) - \mathrm{Tr}\{\tilde{D}(\bar{z}) D^2 \phi(\bar{z})\} + H_* \left(\bar{z}, \frac{\partial \phi}{\partial k}(\bar{z}), D\phi(\bar{z}) \right) \leq 0$$

if $\bar{z} \in]0,T[\times]0,K[\times\mathbb{R}^n$, and

$$v^*(\bar{z}) \leq g(\bar{x})$$

if $\bar{z} \in \{T\}\times]0,K] \times \mathbb{R}^n$.

A locally bounded function v defined on $[0,T[\times[0,K] \times \mathbb{R}^n$ is a viscosity supersolution *of* (50)–(52) *if for every point $\bar{z} = (\bar{t}, \bar{k}, \bar{x}) \in [0,T] \times [0,K] \times \mathbb{R}^n$ and for every map $\phi \in C_b^2([0,T] \times [0,K] \times \mathbb{R}^n)$ such that $v_* - \phi$ has a local minimum at $\bar{z}$ one has*

$$-\frac{\partial \phi}{\partial t}(\bar{z}) - \mathrm{Tr}\{\tilde{D}(\bar{z}) D^2 \phi(\bar{z})\} + H^* \left(\bar{z}, \frac{\partial \phi}{\partial k}(\bar{z}), D\phi(\bar{z}) \right) \geq 0$$

if $\bar{z} \in]0,T[\times]0,K] \times \mathbb{R}^n$, and

$$-\frac{\partial \phi}{\partial t}(\bar{z}) - \mathrm{Tr}\{\tilde{D}(\bar{z}) D^2 \phi(\bar{z})\} + H^* \left(\bar{z}, \frac{\partial \phi}{\partial k}(\bar{z}), D\phi(\bar{z}) \right) \geq 0 \quad \text{or} \quad v_*(\bar{z}) \geq g(\bar{x})$$

if $\bar{z} \in \{T\}\times]0,K] \times \mathbb{R}^n$.

A locally bounded function v defined on $[0,T[\times[0,K] \times \mathbb{R}^n$ is a called a viscosity solution *of* (50)–(52) *if it is both a viscosity sub- and supersolution of* (50)–(52).

We can show that $\mathcal{V}$ is a viscosity solution to the generalized Cauchy problem (50)–(52) since there exists a one-to-one correspondence among solutions to (50)–(52) and solutions to (5)–(7), as specified by the following theorem.

THEOREM 6.2 (see [MS2, Theorem 3.4]). *Assume* **(A0)**, **(A1)**. *Let* v *(resp., v)*: $[0,T] \times [0,K] \times \mathbb{R}^n \to \mathbb{R}$ *be a upper (resp., lower) semicontinuous locally bounded function. Then*

(a) v *is a viscosity subsolution to* (50)–(52) *if and only if it is a viscosity subsolution to* (5)–(7),

(b) *v is a viscosity supersolution to* (50)–(52) *if and only if it is a viscosity supersolution to* (5)–(7).

Therefore we can state the following existence (and uniqueness) theorem whose proof is a consequence of Theorems 6.2 and 5.3.

THEOREM 6.3. *Assume* **(A0)**, **(A1)**. *Then the value function* $\mathcal{V}$ *solves the boundary value problem* (50)–(52) *in the viscosity sense. Moreover, its continuous extension to* $[0,T]\times[0,K]\times\mathbb{R}^n$ *is the unique viscosity solution of* (50)–(52) *among the bounded functions defined on* $[0,T]\times[0,K]\times\mathbb{R}^n$ *which are continuous on* $\partial(]0,T[\times]0,K[\times\mathbb{R}^n)$.

7. Appendix. Before proving Lemma 7.3 on the claim stated in Theorem 3.3, we need to introduce some definitions and prove some technical results in Lemmas 7.1 and 7.2.

Let us consider the noncanonical control $\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{(w_{0_s}, w_s)\}, \{(t_s, k_s, \xi_s)\}, \theta)$ given by (24), whose existence is proved in Theorem 3.3. Let us understand that whenever the operators J and $\mathcal{L}$ have to be evaluated on such α, the constraint $w_{0_s} = 1 - |w_s|$ in their definition must be dropped. Let us notice that since we are only interested with the (random) time interval $0 \le s \le \theta$, with a small abuse of notation, we will denote still by α the control in which (w_{0_s}, w_s) is replaced by $(w_{0_s}, w_s)\chi_{\{s\le\theta\}} + (1,0)\chi_{\{s>\theta\}}$.

Remark 7.1. Given the control $\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{(w_{0_s}, w_s)\}, \{(t_s, k_s, \xi_s)\}, \theta)$, by (24), in Case 1 has

$$\int_0^\theta (w_{0_s} + |w_s|)\, ds = 0$$

(such an eventuality can happen only if $\bar{t} = T$), it is easy to check that any control $\check{\alpha}$, $\check{\alpha} = (\Omega, \{\mathcal{F}\}, P, \{\mathcal{F}_s\}, \check{w}_s, (\check{t}_s, \check{k}_s, \check{\xi}_s), \check{\theta}) \in \Gamma^a(\bar{t}, \bar{k}, \bar{x})$, such that

$$P\left(\check{\theta} = 0\right) = 1,$$

verifies the claim in Theorem 3.3 and $J(\bar{t}, \bar{k}, \bar{x}, \check{\alpha}) = J(\bar{t}, \bar{k}, \bar{x}, \alpha)$.

LEMMA 7.1. *Assume* **(A0)**, **(A1)**. *Let us consider the noncanonical control* $\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{(w_{0_s}, w_s)\}, \{(t_s, k_s, \xi_s)\}, \theta)$, *given by* (24). *Assume that* $\int_0^\theta (w_{0_s} + |w_s|)\, ds > 0$. *Let us define*

$$\Phi_s \doteq \int_0^s (w_{0_r} + |w_r|)\, dr,$$

for $0 \le s \le T + K$. *Let us denote by* $\{\Psi_\sigma\}$ *the right inverse of* Φ:

$$\Psi_\sigma \doteq \inf\{s \ge 0 :\ \Phi_s > \sigma\},$$

for $0 \le \sigma \le \Phi_{T+K}$. *Then* $\Phi_{T+K} > 0$ *and* $\{\Psi_\sigma\}$ *is a right continuous time change satisfying the following properties:*

(i) $\Psi_{\Phi_s} \ge s\ \forall s \ge 0$, $\Phi_{\Psi_\sigma} = \sigma\ \forall \sigma \ge 0$;

(ii) *let*

$$\check{\mathcal{F}}_\sigma \doteq \mathcal{F}_{\Psi_\sigma} \forall \sigma > 0; \tag{54}$$

then $\check{\mathcal{F}}_\sigma$ *is a filtration on the probability space* $(\Omega, \mathcal{F}, P)$;

(iii) Φ_θ *is a* $\check{\mathcal{F}}_\sigma$*-stopping time such that* $\Phi_\theta \le T + K$.

Proof. The proof follows from the definition of time change and right inverse and from Proposition 1.1, Chapter V, in [RY]. $\Phi_\theta \le T + K$ since $w_{0_s} + |w_s| \le 1$ for $s \ge 0$ by definition. □

LEMMA 7.2. *Assume* **(A0)**, **(A1)**. *Let us consider the noncanonical control* $\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{(w_{0_s}, w_s)\}, \{(t_s, k_s, \xi_s)\}, \theta)$, *given by* (24). *Assume that* $\int_0^\theta (w_{0_s} + |w_s|)\, ds > 0$. *On the probability space* $(\Omega, \mathcal{F}, P)$ *let us consider the filtration* $\check{\mathcal{F}}_\sigma$ *given by* (54). *Let us define the processes*

$$\check{t}_\sigma \doteq t_{\Psi_\sigma}, \quad \check{u}_\sigma \doteq \int_0^{\Psi_\sigma} w_r\, dr, \quad \check{k}_\sigma \doteq k_{\Psi_\sigma},$$

for $0 \le \sigma \le \Phi_{T+K}$. *Then there exists a* $\check{\mathcal{F}}_\sigma$*-progressively measurable process* $\{\check{w}_\sigma\}$, $\overline{B}_m(1) \cap \mathcal{K}$ *valued, such that, for* $0 \le \sigma \le \Phi_{T+K}$,

$$\begin{aligned} \check{t}_\sigma &= \bar{t} + \textstyle\int_0^\sigma (1 - |\check{w}_r|)\, dr \left(= \bar{t} + \int_0^{\Psi_\sigma} w_{0_r}\, dr \right), \\ \check{u}_\sigma &= \textstyle\int_0^\sigma \check{w}_r\, dr \left(= \int_0^{\Psi_\sigma} w_r\, dr \right), \\ \check{k}_\sigma &= \bar{k} + \textstyle\int_0^\sigma |\check{w}_r|\, dr \left(= \bar{k} + \int_0^{\Psi_\sigma} |w_r|\, dr \right). \end{aligned} \tag{55}$$

Proof. Let $\{u_s\}$ denote the (strong) solution to

$$u_s = \int_0^s w_r\, dr. \tag{56}$$

Since $\sigma = \Phi_s$ is the arclength parameter of both the processes (t_s, u_s) and (t_s, k_s), we know that $(\check{t}_\sigma, \check{u}_\sigma, \check{k}_\sigma)$ is absolutely continuous for $0 \le \sigma \le \Phi_{T+K}$. Consequently, from Proposition 3.13, Chapter I, in [JS], it follows that there exists a $\check{\mathcal{F}}_\sigma$-progressively measurable process $(\tilde{w}_{0_\sigma}, \tilde{w}_\sigma, z_\sigma)$, $\mathbb{R}_+ \times \mathcal{K} \times \mathbb{R}_+$-valued, such that, for $0 \le \sigma \le \Phi_{T+K}$,

$$\check{t}_\sigma = \bar{t} + \int_0^\sigma \tilde{w}_{0_r}\, dr, \quad \check{u}_\sigma = \int_0^\sigma \tilde{w}_r\, dr, \quad \check{k}_\sigma = \bar{k} + \int_0^\sigma z_r\, dr.$$

Moreover, by the properties of the arclength parameter for almost all $\omega \in \Omega$ there exists a set of measure zero $\mathcal{N}_\omega$ such that $\check{t}'_\sigma(\omega) + |\check{u}'_\sigma(\omega)| = 1$ and $\check{t}'_\sigma(\omega) + \check{k}'_\sigma(\omega) = 1$ for every $\sigma \notin \mathcal{N}_\omega$. This implies that $\tilde{w}_{0_\sigma}(\omega) + |\tilde{w}_\sigma(\omega)| = 1$ and $z_\sigma(\omega) = |\tilde{w}_\sigma(\omega)|$ for $\sigma \notin \mathcal{N}_\omega$. Let us define for every $\sigma \ge 0$ and for $i = 1, \dots, m$ the process

$$\check{w}^i_\sigma \doteq (-1 \vee \tilde{w}^i_\sigma) \wedge 1.$$

$\check{w}$ is $\check{\mathcal{F}}_\sigma$-progressively measurable, $\overline{B}_m(1) \cap \mathcal{K}$-valued. Moreover, $(\check{t}_\sigma, \check{u}_\sigma, \check{k}_\sigma)$ is indistinguishable from $(\bar{t} + \int_0^\sigma (1 - |\check{w}_r|)\, dr, \int_0^\sigma \check{w}_r\, dr, \bar{k} + \int_0^\sigma |\check{w}_r|\, dr)$. Indeed for almost all $\omega \in \Omega$ we have, for $0 \le \sigma \le \Phi_{T+K}$,

$$\check{t}_\sigma(\omega) = \bar{t} + \textstyle\int_{[0,\sigma]} \tilde{w}_{0_r}(\omega)\, dr = \bar{t} + \int_{[0,\sigma]\setminus\mathcal{N}_\omega} (1 - |\tilde{w}_r(\omega)|)\, dr = \bar{t} + \int_0^\sigma (1 - |\check{w}_r(\omega)|)\, dr,$$

$$\check{u}_\sigma(\omega) = \textstyle\int_{[0,\sigma]} \tilde{w}_r(\omega)\, dr = \int_{[0,\sigma]\setminus\mathcal{N}_\omega} \tilde{w}_r(\omega)\, dr = \int_0^\sigma \check{w}_r(\omega)\, dr,$$

$$\check{k}_\sigma(\omega) = \bar{k} + \textstyle\int_{[0,\sigma]} z_r(\omega)\, dr = \bar{k} + \int_{[0,\sigma]\setminus\mathcal{N}_\omega} z_r(\omega)\, dr = \bar{k} + \int_0^\sigma |\check{w}_r(\omega)|\, dr. \qquad \square$$

LEMMA 7.3. *Assume* **(A0)**, **(A1)**. *Let us consider the noncanonical control* $\alpha = (\Omega, \mathcal{F}, P, \{\mathcal{F}_s\}, \{(w_{0_s}, w_s)\}, \{(t_s, k_s, \xi_s)\}, \theta)$, *given by* (24). *Assume that* $\int_0^\theta (w_{0_s} + |w_s|)\, ds > 0$ *and* $J(\bar{t}, \bar{k}, \bar{x}, \alpha) < +\infty$. *Then the control*

$$\check{\alpha} \doteq (\Omega, \mathcal{F}, P, \check{\mathcal{F}}_\sigma, \{\check{w}_\sigma\}, \{(\check{t}_\sigma, \check{k}_\sigma, \check{\xi}_\sigma)\}, \check{\theta}),$$

where $\check\theta \doteq \Phi_\theta$, $\{\check w_\sigma\}$ *is the process whose existence is proved in* Lemma 7.2, $\{\check{\mathcal{F}}_\sigma\}$ *is given by* (54), $\{(\check t_\sigma, \check k_\sigma)\}$ *are given by* (55), $\check\xi_\sigma \doteq \xi_{\Psi_\sigma}$, *for* $0 \le \sigma \le \Phi_{T+K}$, *verifies* **(B3)**, **(B4)**, *and is such that*

$$J(\bar t, \bar k, \bar x, \check\alpha) = J(\bar t, \bar k, \bar x, \alpha).$$

Proof. We already proved that $\check\alpha$ verifies **(B3)** in Lemmas 7.1 and 7.2; therefore, in order to prove that condition **(B4)** holds, one has to show that for every $\varphi \in \mathcal{C}_b^2(\mathbb{R}^{2+n})$ $\check{\mathcal{M}}_\sigma(\varphi, \check\alpha)$ is a $(P, \{\check{\mathcal{F}}_\sigma\})$ square integrable martingale for $\sigma \in [0, \Phi_{T+K}]$, where

$$\check{\mathcal{M}}_\sigma(\varphi, \check\alpha) \doteq \varphi(\check t_\sigma, \check k_\sigma, \check\xi_\sigma) - \int_0^\sigma \mathcal{L}\varphi(\check t_r, \check k_r, \check\xi_r, \check w_r)\, dr.$$

To this end let us consider the square integrable martingale $\mathcal{M}_s(\varphi, \alpha)$ associated to the control α and let us notice that it is Ψ-continuous (that is, it is constant on each stochastic interval where $(w_{0_s}, w_s) = (0,0)$; see Definition 1.3 Chapter V, [RY]) and that by (56) and (55) one has

$$\begin{aligned} &dt_s = w_{0_s} d_s, \quad dt_{\Psi_\sigma} = d\check t_\sigma = (1 - |\check w_\sigma|) d\sigma, \\ &du_s = w_s ds, \quad du_{\psi_\sigma} = \check w_\sigma d\sigma, \\ &dk_s = |w_s| ds, \quad dk_{\Psi_\sigma} = d\check k_\sigma = |\check w_\sigma| d\sigma. \end{aligned}$$

By Proposition 1.4, Chapter V of [RY], for every process H which is $\mathcal{F}_s$-progressively measurable, if we denote by $\check H_\sigma \doteq H_{\psi_\sigma}$, since the process (t_s, u_s, k_s) is Ψ-continuous, one has that

$$\begin{aligned} &\textstyle\int_0^{\Psi_\sigma} H_s w_{0_s} ds = \int_0^{\Psi_\sigma} H_s\, dt_s = \int_0^\sigma \check H_\sigma d\check t_\sigma = \int_0^\sigma \check H_\sigma (1 - |\check w_\sigma|) d\sigma, \\ &\textstyle\int_0^{\Psi_\sigma} H_s w_s ds = \int_0^{\Psi_\sigma} H_s\, du_s = \int_0^\sigma \check H_\sigma d\check u_\sigma = \int_0^\sigma \check H_\sigma \check w_\sigma\, d\sigma, \\ &\textstyle\int_0^{\Psi_\sigma} H_s |w_s| ds = \int_0^{\Psi_\sigma} H_s\, dk_s = \int_0^\sigma \check H_\sigma d\check k_\sigma = \int_0^\sigma \check H_\sigma |\check w_\sigma| d\sigma. \end{aligned} \tag{57}$$

Therefore, for any $\varphi \in \mathcal{C}_b^2(\mathbb{R}^{2+n})$, by applying the first equation of (57) with $H_s = \frac{1}{2}\sum_{ij} \tilde D_{ij}(t_s, \xi_s)\, \frac{\partial^2 \varphi}{\partial x_i \partial x_j}(t_s, k_s, \xi_s) + \sum_i A_i(t_s, \xi_s) \frac{\partial \varphi}{\partial \xi_i}(t_s, k_s, \xi_s) + \frac{\partial \varphi}{\partial t}(t_s, k_s, \xi_s)$, the second one with $H_s = (B_1(t_s, \xi_s) \frac{\partial \varphi}{\partial x_1}(t_s, k_s, \xi_s), \dots, B_n(t_s, \xi_s) \frac{\partial \varphi}{\partial x_n}(t_s, k_s, \xi_s))^T$, the third one with $H_s = \frac{\partial \varphi}{\partial k}(t_s, k_s, \xi_s)$, by Proposition 1.5, Chapter V of [RY] one concludes that $\check{\mathcal{M}}_\sigma(\varphi, \check\alpha)$ is a martingale since it coincides with $\mathcal{M}_{\psi_\sigma}(\varphi, \alpha)$. Finally, it is also easy to see that $\check\alpha$ is admissible. Indeed since $J(\bar t, \bar k, \bar x, \alpha) < +\infty$, then $t_\theta = T$ and $k_\theta \le K$, which implies by Proposition 1.4, Chapter V of [RY] that

$$\check t_{\Phi_\theta} = \bar t + \int_0^{\Phi_\theta} (1 - |\check w_r|)\, dr = t_\theta = T \quad \text{and} \quad \check k_{\Phi_\theta} = \bar k + \int_0^{\Phi_\theta} |\check w_r|\, dr = k_\theta \le K$$

and

$$\begin{aligned} J(\bar t, \bar k, \bar k, \check\alpha) = E_P\Big[&\int_0^{\Phi_\theta} (l_0(\check t_\sigma, \check\xi_\sigma)(1 - |\check w_\sigma|) + \langle l_1(\check t_\sigma, \check\xi_\sigma), \check w_\sigma\rangle)\, d\sigma \\ &+ g(\check\xi_{\Phi_\theta}) + G(\check t_{\Phi_\theta}, \check k_{\Phi_\theta})\Big]. \end{aligned} \tag{58}$$

By the first and second equations in (57) with $H_s = l_0(t_s, \xi_s)$ and $H_s = l_1(t_s, \xi_s)$, respectively, and by the fact that, by Proposition 3.1, $\check\xi_{\Phi_\theta} = \xi_\theta$, one has $J(\bar t, \bar k, \bar k, \check\alpha) = J(\bar t, \bar k, \bar x, \alpha)$. ∎

ON THE UNIFORM CONTROLLABILITY OF THE BURGERS EQUATION*

O. GLASS† AND S. GUERRERO†

Abstract. In this paper, we deal with the viscous Burgers equation with a small dissipation coefficient ν. We prove the (global) exact controllability property to nonzero constant states, that is to say, the possibility of finding boundary values such that the solution of the associated Burgers equation is driven to a constant state. The main objective of this paper is to do so with control functions whose norms in an appropriate space are bounded independently of ν, which belongs to a suitably small interval. This result is obtained for a sufficiently large time.

Key words. controllability, Burgers equation, vanishing viscosity limit

DOI. 10.1137/060664677

1. Introduction.

1.1. Statement of the result and background. We are interested in the controllability of the Burgers equation in a bounded interval:

$$u_t + uu_x - \nu u_{xx} = 0 \text{ in } (0,T) \times (0,1), \tag{1}$$

where T is a positive real number. We complete this equation with the following: We give an initial condition,

$$u_{|t=0} = u_0 \text{ in } (0,1), \tag{2}$$

and controlled boundary values,

$$u_{|x=0} = v_1(t) \text{ in } (0,T), \quad u_{|x=1} = v_2(t) \text{ in } (0,T). \tag{3}$$

Here, v_1 and v_2 stand for control functions, which translates into the possibility of acting over the system through both endpoints of the boundary $x = 0$ and $x = 1$. Let $\bar{u}$ be a solution of (1) with Dirichlet boundary conditions (also called a trajectory). The *exact controllability to trajectories* holds if we can find controls v_1 and v_2 such that the associated solution coincides with $\bar{u}$ at time $t = T$. In this paper, we are interested in proving an exact controllability result uniformly with respect to the viscosity coefficient ν in a sufficiently small range.

Let us be more specific on the problem under review. We consider the system constituted by (1), (2), and (3). Let us fix the initial condition u_0 in some Banach space X and a constant $M \neq 0$; then, our goal is to find two controls v_1 and v_2 such that the associated solution u satisfies

$$u|_{t=T} = M \text{ in } (0,1). \tag{4}$$

Moreover, as we said above we are interested in finding controls whose norms in some Banach space Y are uniformly bounded with respect to ν, whenever ν is sufficiently

†Université Pierre et Marie Curie-Paris6, UMR 7598 Laboratoire Jacques-Louis Lions, Paris, F-75005, France (glass@ann.jussieu.fr, guerrero@ann.jussieu.fr).

small and T is sufficiently large. The main result of this paper is given in the following theorem, where we prove the previous results for $X = L^\infty(0,1)$ and $Y = L^\infty(0,T)$.

THEOREM 1. *There is a constant $\alpha_0 \geq 1$ such that for any $M \in \mathbb{R} \setminus \{0\}$ there exists $\nu_0 > 0$ such that for any $u_0 \in L^\infty([0,1])$, any time $T > \alpha_0/|M|$, and any $\nu \in (0,\nu_0)$ there exist controls v_1^ν and v_2^ν satisfying the following properties:*

- *$\|v_1^\nu\|_\infty$ and $\|v_2^\nu\|_\infty$ are uniformly bounded for $\nu \in (0,\nu_0)$; that is to say, there exists a constant $C(\alpha_0) > 0$ such that*

$$\|v_1^\nu\|_\infty + \|v_2^\nu\|_\infty \leq C(\|u_0\|_\infty + |M|).$$

- *The solution u of (1), (2), (3) associated with $v_1 = v_1^\nu$ and $v_2 = v_2^\nu$ satisfies (4).*

The controllability of the Burgers equation for fixed ν has been studied by several authors. In particular, two kinds of controllability properties have been studied:

- On the one hand, the *local exact controllability to trajectories*, which stands for the concept of exact controllability with the additional assumption that the initial state u_0 is close to the initial state of the targeted trajectory $\bar{u}_{|t=0}$; this has been established for the Burgers equation in [8]. It is also proved in [8] that the exact controllability does not hold when the control acts in a subinterval (a,b) of $(0,1)$, which is equivalent to control at one endpoint. In the more recent work [9], the authors prove that the global exact controllability for (1) does not hold even if the control is acting on both sides of the domain.
- On the other hand, in [4] the author establishes a global result between 0 and constant states; more precisely, the author proves that for $u_0 = 0$ and for any $T > 0$ one can drive the solution of (1) to any constant M satisfying that $|M|$ is sufficiently large with respect to T.

Here, as we are interested in the properties of uniform controllability as $\nu \to 0^+$, it seems natural to regard the inviscid framework ($\nu = 0$). In this case, and in the context of entropy solutions, the controllability of the equation

$$u_t + (u^2/2)_x = 0 \tag{5}$$

was studied in [12], where some conditions are given on the final state in order to ensure this property. More general convex scalar conservation laws

$$u_t + (f(u))_x = 0 \tag{6}$$

were considered in [1], for which the controllability problem is posed in the half line with a null initial condition. The set of attainable states is completely described.

We recall that for conservation laws such as (5), solutions generally develop singularities in finite time, regardless of the regularity of the initial condition. This leads to considering distributional solutions, but in this setting, uniqueness is lost. From both physical and mathematical standpoints, it is then natural to consider solutions that fulfill entropy conditions in order to extract the physically relevant solution. These conditions are the following: For any regular couple (η, q) defined on $\mathbb{R}$ and such that $\eta' f' = q'$ and η is convex, the following stands in the sense of measures:

$$\eta(u)_t + q(u)_x \leq 0.$$

We emphasize that entropy solutions are the ones which can be obtained by vanishing viscosity. One can summarize the situation by saying that the viscosity has

disappeared from the equation and is effective only for the selection of admissible discontinuities. Concerning the Cauchy problem, (1) was first approached by Hopf in [11], where an explicit formula is given and the limit as $\nu \to 0^+$ is considered. The convergence of vanishing viscosity approximations to the entropy solutions of a general scalar conservation law was studied in the celebrated work of Kružkov [13]. For a general reference to conservation laws, we refer to [6].

It is therefore very natural, when considering control problems for conservation laws, to consider the cost of the viscosity, that is, to determine if known controllability properties for the hyperbolic equation are still valid for the model with small viscosity, and how the size of the control evolves as the viscosity approaches 0. Note that some problems, such as the global approximate controllability of the Navier–Stokes equation with Navier slip boundary conditions [3], are obtained through controllability results for the inviscid equation (in this case, the Euler equation).

1.2. Some remarks. Let us make some remarks on the above theorem and state a corollary which concerns the system with $\nu = 1$.

Remark 1. In general, entropy solutions of (5) cannot reach a state M (starting, for instance, from $u_0 = 0$) in a time less than $1/|M|$. In particular, the state 0 cannot be reached unless one has $u_0 = 0$. This is easily seen by considering generalized backward characteristics (see [1]). Hence the time of control $O(1/M)$ is not surprising. Note that even in the case of a linear transport equation, the uniform controllability results [5, 10] consider a time of control of the form $C/|M|$, $C > 1$.

Remark 2. Following the proof of Theorem 1, one can check that Theorem 1 holds for the choices $\alpha_0 = 9$ (or in fact, as obtained numerically, approximately 6.3) and

$$\nu_0 = \nu_1 \min\{1, |M|/|\log(|M|)|\}, \tag{7}$$

where ν_1 is a small enough constant independent of M but depending on α_0.

Now we can present the following result as a consequence of Theorem 1.

COROLLARY 1. *Consider for $w^0 \in L^\infty(0,1)$ and $\tilde{T} > 0$ the following control problem:*

$$\begin{cases} w_t + ww_x - w_{xx} = 0 & \text{in } (0,\tilde{T}) \times (0,1), \\ w_{|x=0} = \tilde{v}_1(t), \quad w_{|x=1} = \tilde{v}_2(t) & \text{in } (0,\tilde{T}), \\ w_{|t=0} = w_0 & \text{in } (0,1). \end{cases} \tag{8}$$

Assume that $|M_0|$ is large enough in order that

$$|M_0|\nu_1 \geq |\log(|M_0|\nu_1)|,$$

where ν_1 is defined as in (7)*; then, for every $\tilde{T} > \alpha_0/|M_0|$ (where α_0 can be chosen as* 9*), there exist controls $\tilde{v}_1(t)$ and $\tilde{v}_2(t)$ in $L^\infty((0,T),\mathbb{R})$ such that the solution of* (8) *satisfies*

$$w_{|t=\tilde{T}} = M_0. \tag{9}$$

Note in particular that Corollary 1 implies that the result of [4] is valid for any $u_0 \in L^\infty(0,1)$. Let us also emphasize that the time we use to control the system depends only on the final state and is independent from the initial state.

Proof. This is a simple scaling argument. Indeed, let us set

$$\begin{cases} u(t,x) = \nu_1 w(\nu_1 t, x),\ v_1(t) = \nu_1 \tilde{v}_1(\nu_1 t),\ v_2(t) = \nu_1 \tilde{v}_2(\nu_1 t), \text{ and } u_0(x) = \nu_1 w_0(x), \\ t \in (0,T),\ x \in (0,1), \end{cases}$$

where we have denoted $T = \tilde{T}/\nu_1$. Then we have

$$\begin{cases} u_t + uu_x - \nu_1 u_{xx} = 0 & \text{in } (0,T)\times(0,1), \\ u_{|x=0} = v_1(t),\ u_{|x=1} = v_2(t) & \text{in } (0,T), \\ u_{|t=0} = w_0 & \text{in } (0,1). \end{cases} \tag{10}$$

Let us set $M := \nu_1 M_0$. From Theorem 1 and since $T > \alpha_0/|M|$ (thanks to the choice of $\tilde{T}$) and $\nu_1 \le \nu_1 \min\{1, |M|/|\log|M||\}$ (thanks to the choice of M_0), we know of the existence of v_1 and v_2 such that the solution of (10) satisfies $u|_{t=T} = M$ in $(0,1)$. Going back to w, this shows the existence of two controls $\tilde{v}_1$ and v_2 such that the associated solution of (8) satisfies $w|_{t=\tilde{T}} = M_0$ in $(0,1)$, as we wanted to prove. ∎

1.3. Structure of the paper. One of the main ingredients of the proof is the use of the *return method* by J. M. Coron, which consists of finding a particular trajectory of the system which moves far away from the initial state to get back to the final state afterward. In the present situation we steer the system toward a large constant state N, and then we get back to the constant state M.

Consequently, the proof of Theorem 1 is divided into two parts, which we summarize in the following propositions.

PROPOSITION 1. *There are some constants $\alpha_1 \ge 1$ and $\nu_1 > 0$ such that for any $u_0 \in L^\infty([0,1])$, for any $N \in \mathbb{R}$ with $|N|$ large enough (depending on $\|u_0\|_\infty$), and for any $\nu \in (0,\nu_1)$ there are controls w_1^ν and w_2^ν in $L^\infty(0,T_1)$, where $T_1 = \alpha_1/|N|$, satisfying the following properties:*

- *$\|w_1^\nu\|_\infty$ and $\|w_2^\nu\|_\infty$ are uniformly bounded for $\nu \in [0,\nu_1]$.*
- *The associated solution u satisfies $u_{|t=T_1} = N$ in $(0,1)$.*

PROPOSITION 2. *The conclusion of Theorem 1 is true when $M > 0$ and u_0 is a positive constant large enough with respect to M.*

The plan of the paper is the following. Proposition 1 is established in section 2. Section 3 is devoted to proving Proposition 2 and, finally, in section 4 we prove some technical results we need for the previous propositions.

2. Proof of Proposition 1. Due to the invariance of the solutions of (1) by the transformation $u(t,x) \leftrightarrow -u(t,1-x)$, we can assume that $N > 0$. Now the proof of Proposition 1 is divided into two parts. First, we prove that we can reach a state close to N in a time $O(1/N)$ (which is a kind of global approximate controllability, but where the target is a constant that depends on the initial state) and then we prove that we can steer the latter state exactly toward N in a time $O(1/N)$ (local exact controllability).

2.1. Reaching N approximately. In the following proposition we prove that, starting from an L^∞ initial condition, we can construct a solution of (1)–(2) which is close in the sense of the $W^{1,\infty}$ norm to some large constant.

PROPOSITION 3. *Given $u_0 \in L^\infty([0,1])$, one can find $N > 0$ large enough such that for any $\nu > 0$, one can find controls v_1 and v_2 such that the solution of* (1), (2), (3) *satisfies*

$$\|u(t,\cdot) - N\|_{L^\infty([0,1])} \le \left(\|u_0\|_\infty + \frac{N}{2}\right) \exp\left\{-\frac{3N^2}{16\nu}\left(t - \frac{8}{N}\right)\right\} \tag{11}$$

for any $t > 0$ *and*

$$\|u_x(t,\cdot)\|_{L^\infty([0,1])} \le C\frac{N^2}{\nu}\exp\left\{-\frac{3N^2}{16\nu}\left(t-\frac{8}{N}\right)\right\} \tag{12}$$

for any $t > (8/N)$ *and some* $C > 0$. *Moreover, the controls satisfy, independently from* ν,

$$\max(\|v_1\|_{L^\infty(0,T)}, \|v_2\|_{L^\infty(0,T)}) \le N. \tag{13}$$

Remark 3. All the above constants (such as 8 or 16) are not optimal (see the proof below) but are sufficient for our purpose (because N is arbitrarily large).

Proof of Proposition 3. The proof of this proposition relies on the comparison principle and on traveling waves for (1). Let us state precisely the comparison principle for the reader's convenience.

LEMMA 1 (comparison principle). *Consider* $\overline{u}_1$ *and* $\overline{u}_2$ *in* $L^\infty(\mathbb{R})$, *and the corresponding solutions* u_1 *and* u_2 *of the Burgers equation on the whole real line with initial conditions* $\overline{u}_1$ *and* $\overline{u}_2$, *respectively. Then, if*

$$\overline{u}_1 \le \overline{u}_2 \text{ in } \mathbb{R}, \tag{14}$$

we have

$$u_1(t,x) \le u_2(t,x) \text{ in } \mathbb{R}^+ \times \mathbb{R}. \tag{15}$$

Proof. A simple way to prove Lemma 1 (although it could be proven in a far more general setting) is to use Hopf's formula for solutions of the viscous Burgers equation [11]:

$$u_i(t,x) = \frac{\int_{-\infty}^{\infty} \frac{x-y}{t}\exp\left\{-\frac{1}{2\nu}\left(\frac{(x-y)^2}{2t} + \int_0^y \overline{u}_i(\eta)d\eta\right)\right\}dy}{\int_{-\infty}^{\infty}\exp\left\{-\frac{1}{2\nu}\left(\frac{(x-y)^2}{2t} + \int_0^y \overline{u}_i(\eta)d\eta\right)\right\}dy}, \quad i = 1,2. \tag{16}$$

We consider the function

$$\rho_i(x,y) := \exp\left\{-\frac{1}{2\nu}\left(\frac{(x-y)^2}{2t} + \int_0^y \overline{u}_i(\eta)d\eta\right)\right\},$$

and $d\mu_i$ the probability measure (depending on x) given by

$$d\mu_i := \frac{\rho_i(x,y)}{\int_{-\infty}^{\infty}\rho_i(x,\cdot)}dy.$$

Now we have

$$
\begin{aligned}
u_2(t,x) &= \int_{-\infty}^{+\infty} \frac{x-y}{t} d\mu_2 \\
&= \int_{-\infty}^{+\infty} \frac{x-y}{t} \exp\Big(-\frac{1}{2\nu} \int_0^y (\overline{u}_2(\eta) - \overline{u}_1(\eta)) d\eta \Big) d\mu_1 \cdot \frac{\int_{-\infty}^{+\infty} \rho_1(x,y)dy}{\int_{-\infty}^{+\infty} \rho_2(x,y)dy} \\
&\geq \int_{-\infty}^{+\infty} \frac{x-y}{t} d\mu_1 . \int_{-\infty}^{+\infty} \exp\Big(-\frac{1}{2\nu} \int_0^y (\overline{u}_2(\eta) - \overline{u}_1(\eta)) d\eta \Big) d\mu_1 \\
&\qquad \cdot \frac{\int_{-\infty}^{+\infty} \rho_1(x,y)dy}{\int_{-\infty}^{+\infty} \rho_2(x,y)dy} \\
&= \int_{-\infty}^{+\infty} \frac{x-y}{t} d\mu_1 = u_1(t,x).
\end{aligned}
$$

The inequality used above is Chebyshev's inequality: for μ a probability measure on $\mathbb{R}$ and two nondecreasing functions f and g, one has

$$\int_{\mathbb{R}} f g d\mu \geq \int_{\mathbb{R}} f d\mu \times \int_{\mathbb{R}} g d\mu.$$

(This follows easily by considering $\int\int (f(x)-f(y))(g(x)-g(y)) d\mu(x) d\mu(y)$.) □

Back to the proof of Proposition 3. We introduce traveling wave profiles for (1). These are solutions of the viscous Burgers equations on the whole real line, of the form

$$u(t,x) = U(x-ct) \quad t \in \mathbb{R}^+,\ x \in \mathbb{R},$$

with c a fixed real number, which will be chosen later on. Furthermore, u satisfies the following asymptotic properties:

$$u(t,x) \to U^- \text{ as } x \to -\infty, \quad u(t,x) \to U^+ \text{ as } x \to +\infty, \quad u_x(t,x) \to 0 \text{ as } x \to \pm\infty,$$

where U^- and U^+ are constant states. Straightforward computations show that these traveling waves are given by the following:

$$U^- \geq U^+, \tag{17}$$

$$c = \frac{U^- + U^+}{2}, \tag{18}$$

$$U(y) = \frac{U^- + U^+}{2} - \frac{U^- - U^+}{2} \tanh\Big(\frac{U^- - U^+}{2\nu} (y - y_0) \Big), \tag{19}$$

where of course y_0 is arbitrary (we will refer to y_0 as the center of the wave).

Now let us go back to the proof of Proposition 3. Given u_0, we choose $N > 2\|u_0\|_\infty$; later we will also take $N > L\|u_0\|_\infty$ for some $L \geq 2$, and in section 3 we will additionally require $N > |M|$.

We introduce the following:

- u as the solution of the Burgers equation on $\mathbb{R}$ with initial value

$$u(0,x) = \begin{cases} N \text{ for } x < 0, \\ u_0(x) \text{ for } 0 \le x \le 1, \\ 0 \text{ for } x > 1. \end{cases} \tag{20}$$

- $\check{u}$ as the traveling wave solution of the Burgers equation with $U^- = N$ and $U^+ = -2\|u_0\|_\infty$, initially centered at y_0, if $u_0 \not\equiv 0$. If $u_0 \equiv 0$, then we take, for instance, $U_+ := -N/4$.

The goal is to prove that the restriction of u to $[0,1]$ is a suitable solution for Proposition 3 (of course, v_1 and v_2 are defined as the traces of u at $x = 0$ and $x = 1$, respectively). Now if y_0 is such that

$$\check{u}(0,\cdot) \le u_0(\cdot) \text{ in } (0,1), \tag{21}$$

it follows from the comparison principle that

$$\check{u}(t,x) \le u(t,x) \le N \text{ in } \mathbb{R}^+ \times \mathbb{R}. \tag{22}$$

Let us make a choice of y_0 so that (21) is satisfied. Indeed, if we take, in the case $u_0 \not\equiv 0$,

$$y_0 = -\frac{2\nu}{N + 2\|u_0\|_\infty} \operatorname{arctanh}\left(\frac{N}{N + 2\|u_0\|_\infty}\right),$$

one can easily check that

$$\check{u}(0,x) \le -\|u_0\|_\infty \quad \forall x \in [0,1],$$

just taking into account that the maximum value of the function

$$x \in [0,1] \longmapsto -\tanh\left(\frac{U^- - U^+}{2\nu}(x - y_0)\right)$$

is reached at $x = 0$. The case $u_0 \equiv 0$ is similar.

Clearly, for N large enough, one has

$$y_0 \ge -1 \tag{23}$$

and

$$N - 2\|u_0\|_\infty \ge \frac{N}{2}. \tag{24}$$

Let us now prove that estimate (11) holds. We first recall the expression of $\check{u}$: for $t \in \mathbb{R}^+$ and $x \in \mathbb{R}$,

$$\check{u}(t,x) = \frac{N}{2} - \|u_0\|_\infty - \frac{N + 2\|u_0\|_\infty}{2} \tanh\left(\frac{N + 2\|u_0\|_\infty}{2\nu}\left(x - \frac{N - 2\|u_0\|_\infty}{2}t - y_0\right)\right). \tag{25}$$

From (23) and (24), we get for $t \in \mathbb{R}^+$ and $x \in [0,1]$,

$$\begin{aligned}
&\tanh\left(\frac{N+2\|u_0\|_\infty}{2\nu}\left(x-\frac{N-2\|u_0\|_\infty}{2}t-y_0\right)\right)\\
&\quad\le \tanh\left(\frac{N+2\|u_0\|_\infty}{2\nu}\left(-\frac{N}{4}t+2\right)\right)\\
&\quad\le \tanh\left(\frac{-3N^2}{16\nu}\left(t-\frac{8}{N}\right)\right).
\end{aligned}$$

On the other hand, from the definition of the function tanh, we readily deduce that

$$\tanh\left(\frac{-3N^2}{16\nu}\left(t-\frac{8}{N}\right)\right) \le -1+\exp\left\{\frac{-3N^2}{16\nu}\left(t-\frac{8}{N}\right)\right\}.$$

Going back to (25), we obtain

$$\check{u}(t,x)-N \ge -\left(\frac{N}{2}+\|u_0\|_\infty\right)\exp\left\{\frac{-3N^2}{16\nu}\left(t-\frac{8}{N}\right)\right\}.$$

Since $\check{u}(t,x)-N\le 0$ already holds (see (22)), we deduce (11).

In order to prove (12) we begin by giving an explicit representation of the spatial derivative of u in the following lemma.

LEMMA 2. *Let u be a solution of*

$$\begin{cases} u_t-\nu u_{xx}+uu_x=0, & (t,x)\in\mathbb{R}_+\times\mathbb{R},\\ u_{|t=0}=u_0, & x\in\mathbb{R}. \end{cases}$$

Then one has

$$\partial_x u(t,x)=\frac{\int_{-\infty}^{+\infty}\frac{y-x}{t}(u_0(y)-u(t,x))\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\right]\right\}dy}{2\nu\int_{-\infty}^{+\infty}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\right]\right\}dy}. \tag{26}$$

Proof. Let us define

$$f(t,x):=\int_{-\infty}^{+\infty}\frac{x-y}{t}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\right]\right\}dy$$

and

$$g(t,x):=\int_{-\infty}^{+\infty}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\right]\right\}dy.$$

From Hopf's formula (see (16)), we find

$$u(t,x)=\frac{f(t,x)}{g(t,x)},\quad (t,x)\in\mathbb{R}_+\times\mathbb{R}.$$

We notice that $\partial_x g=-\frac{1}{2\nu}f$ and

$$\partial_x f(t,x)=\frac{g}{t}-\frac{1}{2\nu t}\int_{-\infty}^{+\infty}\frac{(y-x)^2}{t}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\right]\right\}dy,$$

so that

$$\partial_x u(t,x) = \frac{1}{t} - \frac{1}{2\nu}\left[\frac{\int_{-\infty}^{+\infty} \frac{(y-x)^2}{t^2} \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy}{g} - \frac{f^2}{g^2}\right]. \tag{27}$$

Now let us consider the second term in the above right-hand side:

$$\begin{aligned} I &:= \int_{-\infty}^{+\infty} \frac{(y-x)^2}{t^2} \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy \\ &= \int_{-\infty}^{+\infty} \frac{y-x}{t}\left(\frac{y-x}{t} + u_0(y)\right) \exp\left\{-\frac{1}{2\nu}\left[\frac{(y-x)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy \\ &\quad - \int_{-\infty}^{+\infty} \frac{y-x}{t} u_0(y) \exp\left\{-\frac{1}{2\nu}\left[\frac{(y-x)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy \\ &= \frac{2\nu g}{t} - \int_{-\infty}^{+\infty} \frac{y-x}{t} u_0(y) \exp\left\{-\frac{1}{2\nu}\left[\frac{(y-x)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy. \end{aligned}$$

In the last identity we have used the fact that

$$\begin{aligned} &-2\nu \frac{d}{dy} \exp\left\{-\frac{1}{2\nu}\left[\frac{(y-x)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} \\ &\qquad = \left(\frac{y-x}{t} + u_0(y)\right) \exp\left\{-\frac{1}{2\nu}\left[\frac{(y-x)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} \end{aligned} \tag{28}$$

and we have integrated by parts. Injecting I into (27) yields

$$\partial_x u(t,x) = -\frac{1}{2\nu g}\Bigg[-\int_{-\infty}^{+\infty} \frac{y-x}{t} u_0(y) \exp\left\{-\frac{1}{2\nu}\left[\frac{(y-x)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy - u(t,x)f(t,x)\Bigg],$$

which yields (26). □

Back to the proof of (12). We consider $x \in [0,1]$ and use (26) to estimate $\partial_x u(t,x)$:

$$\begin{aligned} \partial_x u(t,x) &= \frac{1}{2\nu} \frac{\int_{-\infty}^{+\infty} \frac{y-x}{t}(u_0(y) - N) \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy}{\int_{-\infty}^{+\infty} \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy} \\ &\quad + \frac{1}{2\nu} \frac{\int_{-\infty}^{+\infty} \frac{y-x}{t}(N - u(t,x)) \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy}{\int_{-\infty}^{+\infty} \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t} + \int_0^y u_0(\eta)d\eta\right]\right\} dy}. \end{aligned}$$

Let us denote by A and B, respectively, the first and second term of the above right-hand side. Clearly,

$$B = -\frac{1}{2\nu}(N - u(t,x))u(t,x),$$

and this term is easily estimated using the L^∞ estimate on $N-u$. Concerning A, we first notice that, due to the initial condition of u (see (20)), one has

$$A = \frac{1}{2\nu}\frac{\int_0^{+\infty} \frac{y-x}{t}(u_0(y)-N)\exp\Big\{-\frac{1}{2\nu}\big[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\big]\Big\}dy}{\int_{-\infty}^{+\infty}\exp\Big\{-\frac{1}{2\nu}\big[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\big]\Big\}dy}.$$

Note that simple computations yield

$$\int_a^b \exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\alpha\, y\right]\right\}dy = 2\sqrt{\nu t}\exp\left\{\frac{\alpha(-2x+\alpha t)}{4\nu}\right\}\int_{\xi_-}^{\xi_+} e^{-t^2}dt \tag{29}$$

with

$$\xi_- := \frac{a-x+\alpha\, t}{2\sqrt{\nu t}} \quad \text{and} \quad \xi_+ := \frac{b-x+\alpha\, t}{2\sqrt{\nu t}},$$

and yield

$$\begin{aligned}
&\int_a^b y\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\alpha\, y\right]\right\}dy \\
&= 2\sqrt{\nu t}(x-\alpha t)\exp\left\{\frac{\alpha(-2x+\alpha t)}{4\nu}\right\}\int_{\xi_-}^{\xi_+} e^{-t^2}dt \qquad (30)\\
&-2\nu t\left\{\exp\left[-\frac{b^2-2bx+2b\alpha t+x^2}{4\nu t}\right]-\exp\left[-\frac{a^2-2ax+2a\alpha t+x^2}{4\nu t}\right]\right\}.
\end{aligned}$$

Also, we note that for $y>0$, one has

$$\int_y^{+\infty} e^{-s^2}ds \le \frac{e^{-y^2}}{2y}. \tag{31}$$

We estimate from below the denominator of A in the following way:

$$\begin{aligned}
\int_{-\infty}^{+\infty}\exp\Big\{-\frac{1}{2\nu}\Big[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\Big]\Big\}dy &\\
&\ge \int_{-\infty}^{0}\exp\Big\{-\frac{1}{2\nu}\Big[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\Big]\Big\}dy\\
&= \int_{-\infty}^{0}\exp\Big\{-\frac{1}{2\nu}\Big[\frac{(x-y)^2}{2t}+Ny\Big]\Big\}dy\\
&\ge \sqrt{\pi\nu t}\exp\left\{\frac{N}{2\nu}\left(\frac{Nt}{2}-x\right)\right\}.
\end{aligned}$$

The numerator is bounded by

$$\begin{aligned}
&\left|\int_0^{+\infty}\frac{y-x}{t}(u_0(y)-N)\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y u_0(\eta)d\eta\right]\right\}dy\right|\\
&\le \int_0^{+\infty}\frac{y+1}{t}(\|u_0\|_\infty+N)\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}-\|u_0\|_\infty y\right]\right\}dy\\
&\le 12\nu N\exp\left\{\frac{-x^2}{4\nu t}\right\},
\end{aligned}$$

where we used $N > \|u_0\|_\infty$ and $Nt - 1 > 1$ for the times under review.

Then (12) follows by taking $N \gg \|u_0\|_\infty$. Note that the estimate on the term A is better than the estimate on the term B, which comes directly from the L^∞ estimate.

Finally, estimate (13) comes directly from the maximum principle. □

Remark 4. Taking N large enough (as we may), it is easy to see that we can replace the properties (23)–(24) with the following ones:

$$y_0 \geq -\delta,$$

$$N - 2\|u_0\|_\infty \geq (1-\delta)N,$$

for some arbitrarily small parameter $\delta > 0$. Then following the above computations we obtain estimates of the form

$$\|u(t,\cdot) - N\|_{W^{1,\infty}([0,1])} \leq \frac{CN^2}{\nu} \exp\left\{-\frac{K}{\nu}\left(t - \frac{2(1+\delta)}{N(1-\delta)}\right)\right\}.$$

Hence the time of approximate controllability can be made close to $2/N$ for N large enough (as $\nu \to 0^+$). This is not surprising, since for the hyperbolic equation, the solution of the Riemann problem (5) with initial condition

$$u|_{t=0} = \begin{cases} N \text{ on } \mathbb{R}^-, \\ M \text{ on } \mathbb{R}^+, \end{cases}$$

with $N, M \in \mathbb{R}$, $N > M$, is given by a simple shock with speed $(N+M)/2$.

2.2. Reaching N exactly. Observe that from subsection 2.1, and after a time $t = \alpha_1/N$ has gone by (with, for instance, $\alpha_1 = 8$ or even $\alpha_1 > 2$, taking Remark 4 into account), we can assume that our new initial condition (which we also denote u_0) satisfies

$$\|u_0 - N\|_{W^{1,\infty}(0,1)} \leq e^{-CN/\nu} \tag{32}$$

for some $C > 0$, provided that $\nu \in (0, \nu_0)$.

Remark 5. As stated above, condition (32) trivially follows from Proposition 3, since ν_0 is small enough and N is large enough. In what follows we will prove that condition (32) suffices to reach N exactly with uniform bounds on the controls, which concludes the proof of Proposition 1. □

In what concerns the proof of Proposition 2, at this stage of the analysis, we will also have some initial state u_0 satisfying

$$\|u_0 - M\|_{W^{1,\infty}(0,1)} \leq e^{-CM/\nu},$$

provided that $\nu < \nu_0$, where ν_0 is small enough (see Proposition 5 below). As a consequence, arguing as in this subsection, we will be able to drive the solution exactly to M as well (with uniform bounds on the controls).

In this subsection we prove that we have a local exact (uniform in ν) controllability result for a time $T = O(1/N)$. Precisely, we establish the next proposition.

PROPOSITION 4. *Assume that* $u_0 \in W^{1,\infty}(0,1)$ *and there exists* $K_0 > 0$ *such that*

$$\|u_0 - N\|_{W^{1,\infty}(0,1)} \leq e^{-K_0 N/\nu}. \tag{33}$$

Then, one can find controls v_1 and v_2 such that the solution of (1), (2), (3) *satisfies, for* $T = \frac{\alpha_0 - 2}{N}$,

$$u|_{t=T} = N \quad \text{in } (0,1). \tag{34}$$

Moreover, the controls satisfy the following estimate, which is independent of $\nu \in (0, \nu_0)$:

$$\max(\|v_1\|_{W^{1,\infty}(0,T)}, \|v_2\|_{W^{1,\infty}(0,T)}) \leq 2N. \tag{35}$$

Proof. First, we set $y(t,x) = u(t,x) - N$ so that y fulfills

$$\begin{cases} y_t + yy_x - \nu y_{xx} + Ny_x = 0 & \text{in } (0,T) \times (0,1), \\ y|_{t=0} = y^0 := u^0 - N & \text{in } (0,1). \end{cases} \tag{36}$$

Now, our objective is to find boundary controls $y|_{x=0}(t) = v_1(t) - N$ and $y|_{x=1}(t) = v_2(t) - N$ such that

$$y|_{t=T} = 0 \quad \text{in } (0,1) \tag{37}$$

and

$$\|v_1(t) - N\|_{W^{1,\infty}(0,T)} + \|v_2(t) - N\|_{W^{1,\infty}(0,T)} \leq N. \tag{38}$$

We will prove this by means of a fixed point argument posed in a suitable Hilbert space Z.

2.2.1. Uniform null controllability of the linearized Burgers equation. In this subsection, we consider the following linearized Burgers equation:

$$\begin{cases} y_t - \nu y_{xx} + ((N + z(t,x)/2)y)_x = 0 & \text{in } (0,T) \times (0,1), \\ y|_{x=0} = \widetilde{v}_1, \quad y|_{x=1} = \widetilde{v}_2 & \text{in } (0,T), \\ y|_{t=0} = y^0 & \text{in } (0,1). \end{cases} \tag{39}$$

For this system, we prove the null controllability with controls bounded independently of ν. Specifically, we have the next lemma.

LEMMA 3. *Let z be in $L^1(0,T; W^{1,\infty}(0,1)) \cap L^\infty((0,T) \times (0,1))$ with*

$$\|z_x\|_{L^1_t L^\infty_x} + \|z\|_{L^\infty_t L^\infty_x} \leq \exp\left(-\frac{K_0 N}{5\nu}\right), \tag{40}$$

where K_0 is as introduced in Proposition 4, *and let us introduce the quantity*

$$D(T,N,z) := \frac{3e^{-2\|z_x\|_{L^1_t(L^\infty_x)}}}{4}\left(\frac{2T(N - \|z\|_\infty/2)}{3} - 1\right)^2 - 6\chi, \tag{41}$$

where χ is some positive constant defined in (84). *Assume that the initial condition $y^0 = u^0 - N$ satisfies* (33) *and that the final time T satisfies*

$$(N - \|z\|_\infty/2)2T/3 > 1. \tag{42}$$

Then, for any $\nu \in (0, \nu_0)$, there exist two controls $\widetilde{v}_1, \widetilde{v}_2 \in W^{1,\infty}(0,T)$ such that the associated solution to (39) *satisfies*

$$y|_{t=T} = 0 \quad \text{in } (0,1)$$

and

$$\|\widetilde{v}_1\|_{W^{1,\infty}(0,T)} + \|\widetilde{v}_2\|_{W^{1,\infty}(0,T)} \le e^{-K_0 N/(3\nu)} \left(e^{-D(T^*,N,z)/(\nu T^*)} + 1 \right), \tag{43}$$

where $T^* := \min\{T, 3/(N - \|z\|_\infty/2)\}$.

Remark 6. It will follow from Lemma 4 that one can take $6\chi = 4$ in (41). When we follow Remark 7 below (as found numerically), we see that one can estimate 6χ by 2.61.

Proof. First, choosing the controls $\widetilde{v}_1$ and $\widetilde{v}_2$ to be zero close to $t = 0$, and on account of the regularizing effect of the heat equation, one can always suppose that our initial condition y^0 belongs to $W^{2,\infty}(0,1)$, and thanks to (33), we can also assume that

$$\|y^0\|_{W^{2,\infty}(0,1)} \le e^{-K_0 N/(2\nu)}. \tag{44}$$

Now, we introduce a function $\widetilde{y}^0 \in W^{2,\infty}(-1,2)$ such that $\widetilde{y}^0 = y^0$ in $(0,1)$ and

$$\|\widetilde{y}^0\|_{W^{2,\infty}(-1,2)} \le C\|y^0\|_{W^{2,\infty}(0,1)} \tag{45}$$

for some $C > 0$. Let us first suppose that we can find two controls $\widetilde{v}_3$, $\widetilde{v}_4 \in L^2(0,T)$ satisfying

$$\begin{aligned} \|\widetilde{v}_3\|_{L^2(0,T^*)} + \|\widetilde{v}_4\|_{L^2(0,T^*)} &\le Ce^{-D(T^*,N,z)/(\nu T^*)}\|\widetilde{y}^0\|_{L^2(-1,2)} \\ &\le Ce^{-D(T^*,N,z)/(\nu T^*)}e^{-K_0 N/(2\nu)} \end{aligned} \tag{46}$$

for some $C > 0$, such that the solution $\widetilde{y} \in L^2((0,T)\times(-1,2))$ of

$$\begin{cases} \widetilde{y}_t - \nu\widetilde{y}_{xx} + ((N + z(t,x)/2)\widetilde{y})_x = 0 & \text{in } (0,T^*)\times(-1,2), \\ \widetilde{y}|_{x=-1} = \widetilde{v}_3, \quad \widetilde{y}|_{x=2} = \widetilde{v}_4 & \text{in } (0,T^*), \\ \widetilde{y}|_{t=0} = \widetilde{y}^0 & \text{in } (-1,2) \end{cases} \tag{47}$$

satisfies

$$\widetilde{y}|_{t=T^*} = 0 \quad \text{in } (-1,2).$$

Then, the function $y := \widetilde{y}|_{[0,1]}1_{(0,T^*)}$ fulfills system (39) with

$$\widetilde{v}_1(t) = \widetilde{y}|_{x=0}(t)1_{(0,T^*)} \quad \text{and} \quad \widetilde{v}_2(t) = \widetilde{y}|_{x=1}(t)1_{(0,T^*)} \tag{48}$$

and satisfies

$$y|_{t=T} = 0 \quad \text{in } (0,1)$$

(indeed, $y \equiv 0$ in (T^*,T)).

In order to prove estimate (43), it suffices to use classical localization arguments together with regularity estimates for the solution of (47). Precisely, for any $\delta > 0$, we can prove that there exists a positive constant $C > 0$ such that

$$\|\widetilde{y}\|_{W^{1,\infty}(0,T;H^1(-1+\delta,2-\delta))} \le (C/\nu)(\|\widetilde{y}^0\|_{W^{2,\infty}(-1,2)} + \|\widetilde{v}_3\|_{L^2(0,T^*)} + \|\widetilde{v}_4\|_{L^2(0,T^*)}).$$

In particular, this implies that $\widetilde{y}|_{x=0}$ and $\widetilde{y}|_{x=1}$ belong to $W^{1,\infty}(0,T^*)$, and thanks to (46), (33), and $\nu \in (0,\nu_0)$, they satisfy estimate (43).

Consequently, our task now will be to find $\widetilde{v}_3$ and $\widetilde{v}_4$ satisfying the above properties. We use the classical approach, consisting of obtaining a suitable observability inequality for the adjoint system of (47). For simplicity, we will suppose that we are working in the space interval $(0,1)$ instead of $(-1,2)$ (so, in particular, we will refer to system (39) instead of (47)). Thus, let us introduce the adjoint problem associated with (39):

$$\begin{cases} -\varphi_t - \nu\varphi_{xx} - (N + z(t,x)/2)\varphi_x = 0 & \text{in } (0,T^*)\times(0,1), \\ \varphi|_{x=0} = 0, \quad \varphi|_{x=1} = 0 & \text{in } (0,T^*), \\ \varphi|_{t=T^*} = \varphi^0 & \text{in } (0,1), \end{cases} \tag{49}$$

where $\varphi^0 \in H_0^1(0,1)$ is the initial condition.

We prove the following observability inequality for the solutions of (49):

$$\|\varphi|_{t=0}\|^2_{L^2(0,1)} \leq K(T^*,\nu)\int_0^{T^*} (|\varphi_x|_{x=0}|^2 + |\varphi_x|_{x=1}|^2)\,dt \tag{50}$$

for some positive constant $K(T^*,\nu)$. Then, it is not difficult to prove that the null controllability of system (39) holds with controls $\widetilde{v}_1$ and $\widetilde{v}_2$, whose L^2 norms are bounded by $K(T^*,\nu)/\nu$. We omit the proof of this fact for the sake of simplicity.

In order to prove estimate (50), we will follow the same ideas as in [5]. That is to say, we will combine a suitable Carleman inequality with a dissipation result for system (49).

Dissipation result. Let $t_0 \in (0,T^*)$. Then, following the steps of the proof in [7], one can prove

$$\begin{cases} \|\varphi|_{t=t_0}\|^2_{L^2(0,1)} \leq \exp\left\{ \dfrac{\|z_x\|_{L^1_t(L^\infty_x)}}{8} - \dfrac{((N-\|z\|_\infty/2)t^*-1)^2}{2\nu t^*} e^{-2\|z_x\|_{L^1_t(L^\infty_x)}} \right\} \\ \qquad\qquad \times \|\varphi|_{t=t_0+t^*}\|^2_{L^2(0,1)} \end{cases} \tag{51}$$

for any $t^* \in (0, T^* - t_0)$ such that

$$(N - \|z\|_\infty/2)t^* > 1. \tag{52}$$

Carleman inequality. Let $0 < \gamma < 1/3$ (one can take, for example, $\gamma := 1/6$). We will prove that, if (40) and (42) hold, then we have the following inequality:

$$\begin{aligned} &\int_0^1 \int_{2T^*/3}^{(2+3\gamma)T^*/3} |\varphi|^2\,dt\,dx \\ &\leqslant Ce^{6\chi/(\nu T^*)} \left(\frac{\nu^2 T^*}{N}\int_0^{T^*} |\varphi_x(t,0)|^2\,dt + \frac{1}{N}\int_0^1 |\varphi(0,x)|^2\,dx \right). \end{aligned} \tag{53}$$

The proofs of these results are postponed to the last section of the paper.

Now we are in position to establish our central observability inequality (50). We apply the dissipativity result (51) to φ (which is a solution of (49)) for each $t^* \in (2T^*/3, (2+3\gamma)T^*/3)$. This is possible by (42). We obtain

$$\int_0^1 \int_{2T^*/3}^{(2+3\gamma)T^*/3} |\varphi|^2\,dt\,dx \geq C(\nu,N,T^*,z)\int_0^1 |\varphi(0,x)|^2\,dx,$$

with

$$C(\nu, N, T^*, z) = \exp\left\{ -\frac{\|z_x\|_{L^1_t(L^\infty_x)}}{8} + 3e^{-2\|z_x\|_{L^1_t(L^\infty_x)}} \frac{(\frac{2T^*}{3}(N - \frac{\|z\|_\infty}{2}) - 1)^2}{4\nu T^*} \right\}.$$

Here, we have used the fact that

$$t^* \longmapsto \frac{((N - \|z\|_\infty/2)t^* - 1)^2}{4\nu t^*}$$

is an increasing function as long as (52) is satisfied.

Finally, we obtain the observability inequality (50) with

$$K(T^*, \nu) = C \exp\left(-\frac{D(T^*, N, z)}{\nu T^*} \right),$$

for some $C = C(T^*, N)$; recall that $D(T^*, N, z)$ was introduced in (41). In particular, estimate (46) holds.

This concludes the proof of Lemma 3. □

2.2.2. Fixed point argument. In this subsection, we end the proof of the null controllability of system (36) by performing a fixed point argument applied to the following application: With each $z \in W^{1,\infty}((0,T) \times (0,1))$ such that (41) holds, we associate a y solution of (39) given by Lemma 3. More precisely, let us first define the set of controls:

$$A(z) = \{(\widetilde{v}_1, \widetilde{v}_2) \in W^{1,\infty}(0,T)^2 : \tag{54}$$
$$y \text{ solution of (39) satisfies } y|_{t=T} = 0 \text{ and } \widetilde{v}_1,\ \widetilde{v}_2 \text{ satisfy (43)}\}.$$

Then, $\Lambda(z) = y$, where y fulfills system (39) for some controls $(\widetilde{v}_1, \widetilde{v}_2) \in A(z)$.

Let us recall Kakutani's fixed point theorem (see, for instance, [2]).

THEOREM 2. *Let Z be a Hilbert space and let $\Lambda : Z \mapsto Z$ be a set-valued mapping satisfying the following assumptions:*

1. *$\Lambda(z)$ is a nonempty closed convex set of Z for every $z \in Z$.*
2. *There exists a nonempty convex compact set $E \subset Z$ such that $\Lambda(E) \subset E$.*
3. *Λ is upper-hemicontinuous in Z; i.e., for each $\sigma \in Z'$ the single-valued mapping*

$$z \mapsto \sup_{y \in \Lambda(z)} \langle \sigma, y \rangle_{Z',Z} \tag{55}$$

is upper-semicontinuous.

Then Λ possesses a fixed point in the set E; i.e., there exists $z \in E$ such that $z \in \Lambda(z)$.

Let us check that Kakutani's theorem can be applied to Λ and to

$$Z = H^{3/4}(0,T; L^2(0,1)) \cap L^2(0,T; H^{7/4}(0,1)).$$

Observe that $Z \subset L^\infty(Q) \cap L^2(0,T; W^{1,\infty}(0,1))$.

Let us check the three assumptions of Theorem 2 separately:

• The fact that $\Lambda(z)$ is a nonempty closed convex set of Z for every $z \in Z$ is very easy to verify, so we leave it to the reader.

• Let us prove that Λ maps a compact set into itself. For this, we consider the Hilbert space

$$H = H^1(0,T;L^2(0,1)) \cap L^2(0,T;H^2(0,1)).$$

Then we introduce the space

$$E = \{w \in H : \|w\|_H \leq e^{-K_0 N/(5\nu)}\},$$

where K_0 is the constant in (33). Observe in particular that if $w \in E$, then $\|w\|_\infty \leq N$ as long as $\nu \in (0, \nu_0)$.

It is very easy to check that E is a compact set of Z. Moreover, since $E \subset L^2(0,T;W^{1,\infty}(0,1))$, one can prove that for each $z \in E$ the solution y of (39) belongs to H and there exists a constant $C > 0$ such that

$$\|y\|_H \leq C(\|\widetilde{v}_1\|_{W^{1,\infty}(0,T)} + \|\widetilde{v}_2\|_{W^{1,\infty}(0,T)} + \|y^0\|_{W^{1,p}(0,1)}). \tag{56}$$

Indeed, let us consider the following lifting of the boundary conditions:

$$V(t,x) = (1-x)\widetilde{v}_1(t) + x\widetilde{v}_2(t), \quad t \in (0,T),\ x \in (0,1).$$

By introducing $w := y - V$, our problem (39) is transformed into

$$\begin{cases} w_t - \nu w_{xx} + ((N + z(t,x)/2)w)_x = f(t,x) & \text{in } (0,T)\times(0,1), \\ w|_{x=0} = 0, \quad w|_{x=1} = 0 & \text{in } (0,T), \\ w|_{t=0} = y^0 - (1-x)\widetilde{v}_1(0) + x\widetilde{v}_2(0) & \text{in } (0,1), \end{cases} \tag{57}$$

where

$$f(t,x) = (1-x)\widetilde{v}_{1,t}(t) + x\widetilde{v}_{2,t}(t) + (N/2 + z(t,x))(-\widetilde{v}_1(t) + \widetilde{v}_2(t)) + z_x(t,x)V.$$

This is a linear parabolic equation with an $L^2_t(L^\infty_x)$ coefficient for the zero order term, an $L^\infty(Q)$ coefficient for the first order (in space) term, an $L^\infty(Q)$ right-hand side, and a $W^{1,\infty}(0,1)$ initial condition. In this situation, it is not difficult to prove that the solution of (57) belongs to H and (56) holds. (Observe that, thanks to (48), the initial data in (57) satisfies the required compatibility condition.)

Now, looking at the definition of D given in (41), we see that as long as $T > (\alpha_0 - 2)/N$ (for some $\alpha_0 < 9$), we have

$$D(T,N,z) \geq 0 \qquad \forall z \in E,\ \nu \in (0,\nu_0).$$

Then, from (56) and taking into account estimates (33) and (43), we obtain for some $C > 0$

$$\|y\|_H \leq C(e^{-K_0/\nu} + e^{-K_0/(3\nu)}) \leq e^{-K_0 N/(5\nu)}, \qquad \nu \in (0,\nu_0),$$

and so $y \in E$.

• It remains to check that Λ is upper-hemicontinuous. Thus, assume that $\sigma \in Z'$ and let a sequence $\{z_n\}$ be given, with $z_n \to z$ strongly in Z. We must prove that

$$\overline{\lim}_{n\to+\infty} \sup_{y\in\Lambda(z_n)} \langle \sigma, y\rangle_{Z',Z} \leq \sup_{y\in\Lambda(z)} \langle \sigma, y\rangle_{Z',Z}\ .$$

Let $\{z_{n'}\}$ be a subsequence of $\{z_n\}$ such that

$$\overline{\lim}_{n\to+\infty} \sup_{y\in\Lambda(z_n)} \langle \sigma, y\rangle_{Z',Z} = \lim_{n'\to+\infty} \sup_{y\in\Lambda(z_{n'})} \langle \sigma, y\rangle_{Z',Z} .$$

Since each $\Lambda(z_{n'})$ is a compact set of Z, for every n' we have

$$\sup_{y\in\Lambda(z_{n'})} \langle \sigma, y\rangle_{Z',Z} = \langle \sigma, y_{n'}\rangle_{Z',Z}$$

for some $y_{n'} \in \Lambda(z_{n'})$. On the other hand, since all the states $y_{n'}$ belong to the same compact set E, at least for a new subsequence (again indexed by n'), we must have $y_{n'} \to y$ strongly in Z. We will now prove that $y \in \Lambda(z)$. This will achieve the proof of the upper-hemicontinuity of Λ.

Indeed, it can be assumed that the controls $\widetilde{v}_{1,n'}$ and $\widetilde{v}_{2,n'}$ converge to some functions $\widetilde{v}_1$ and $\widetilde{v}_2$ weakly-$*$ in $W^{1,\infty}(0,T)$. Then y solves (39) and $y|_{t=T} = 0$. Moreover, since inequality (43) is independent of n, $\widetilde{v}_1$ and $\widetilde{v}_2$ also satisfy (43). Therefore, $(\widetilde{v}_1, \widetilde{v}_2) \in A(z)$. Consequently, it is immediate that y is the solution to (39) associated with the controls $\widetilde{v}_1$ and $\widetilde{v}_2$.

This shows that $y \in \Lambda(z)$ and, therefore, Λ is upper-hemicontinuous.

Consequently, Kakutani's theorem applies and this implies that there exists $y \in \Lambda(y)$; that is to say, we have found a function y solution of (36) such that (37) and (38) (thanks to (43)) are satisfied. The proof of Proposition 4 is finished. □

3. Proof of Proposition 2. Again relying on the invariance of the solutions of (1) by the transformation $u(t,x) \leftrightarrow -u(t,1-x)$, we can always assume that $M > 0$. Now Proposition 2 is proved approximately as Proposition 1, but here a (viscous) rarefaction wave is used in place of a traveling wave. More precisely, we start from N, which can be chosen larger than M. First, we reach M approximately and then reach M exactly by using the same argument as above.

3.1. Reaching M approximately. Let us prove the next proposition.

PROPOSITION 5. *One can find controls v_1 and v_2 such that the solution of* (1)–(3) *with initial condition $u_{|t=0} = N$ satisfies, for some constant $C > 0$ independent from M, N, and ν,*

$$\|u(t,\cdot) - M\|_{W^{1,\infty}([0,1])} \le CM\sqrt{\nu t} \exp\left\{-\frac{M^2}{4\nu}\left(t - \frac{2}{M}\right)\right\} \tag{58}$$

for any $t > \frac{2}{M}$ and, moreover, the controls satisfy, independently from ν,

$$\|v_1\|_{L^\infty(0,T)} + \|v_2\|_{L^\infty(0,T)} \le N. \tag{59}$$

Proof of Proposition 5. In this situation, the solution u is obtained by taking the restriction to $[0,T]\times[0,1]$ of the solution defined on the whole space domain $\mathbb{R}$ as the unique solution with initial condition:

$$u(0,x) := \hat{u}_0 = \begin{cases} M \text{ if } x \le 0, \\ N \text{ if } x > 0. \end{cases} \tag{60}$$

Then v_1 and v_2 are obtained by taking the traces of u along the lines $(0,T)\times\{0\}$ and $(0,T)\times\{1\}$. As before, (59) follows directly from the maximum principle, so we have only to check (58).

In a first step we consider only the L^∞ norm. The solution $u(t,x)$ has the following explicit form:

$$u(t,x) = \frac{\int_{-\infty}^{0} \frac{x-y}{t} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + My\Big)\Big\}dy + \int_{0}^{+\infty} \frac{x-y}{t} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + Ny\Big)\Big\}dy}{\int_{-\infty}^{0} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + My\Big)\Big\}dy + \int_{0}^{+\infty} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + Ny\Big)\Big\}dy}.$$

We note that

$$\int_{-\infty}^{0} \frac{x-y}{t} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + My\Big)\Big\}dy = 2\nu \exp\Big(-\frac{x^2}{4\nu t}\Big) + M\int_{-\infty}^{0} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + My\Big)\Big\}dy$$

(as seen by adding and subtracting M inside the integral). In the same way, we have

$$\int_{0}^{+\infty} \frac{x-y}{t} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + Ny\Big)\Big\}dy = -2\nu \exp\Big(-\frac{x^2}{4\nu t}\Big) + N\int_{0}^{+\infty} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + Ny\Big)\Big\}dy.$$

Hence we get that

$$u(t,x) - M = \frac{(N-M)\int_{0}^{+\infty} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + Ny\Big)\Big\}dy}{\int_{-\infty}^{0} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + My\Big)\Big\}dy + \int_{0}^{+\infty} \exp\Big\{ -\frac{1}{2\nu}\Big(\frac{(x-y)^2}{2t} + Ny\Big)\Big\}dy}.$$

Note that $\hat{u}_0$ is nondecreasing; hence $u(t,\cdot)$ is also nondecreasing (as seen from Lemma 1 and comparing the solutions corresponding to $\hat{u}_0$ and $\hat{u}_0(\cdot + h)$). Using the fact that $\hat{u}_0 \geq M$, we deduce, together with the maximum principle, that $u \geq M$. Consequently, it is sufficient to have an upper estimate for $u(t,1) - M$. Now from (29) we have

$$\int_{-\infty}^{0} \exp\left\{-\frac{1}{2\nu}\left(\frac{(1-y)^2}{2t} + My\right)\right\} dy = \sqrt{4\nu t} \exp\left(\frac{M(Mt-2)}{4\nu}\right) \int_{-\infty}^{\xi_M} e^{-s^2} ds,$$

$$\int_{0}^{+\infty} \exp\left\{-\frac{1}{2\nu}\left(\frac{(1-y)^2}{2t} + Ny\right)\right\} dy = \sqrt{4\nu t} \exp\left(\frac{N(Nt-2)}{4\nu}\right) \int_{\xi_N}^{+\infty} e^{-s^2} ds,$$

with

$$\xi_M := \frac{Mt-1}{2\sqrt{\nu t}} \text{ and } \xi_N := \frac{Nt-1}{2\sqrt{\nu t}}.$$

We deduce

$$u(t,1)-M \le \frac{(N-M)\int_0^{+\infty}\exp\Big\{-\frac{1}{2\nu}\Big(\frac{(1-y)^2}{2t}+Ny\Big)\Big\}dy}{\int_{-\infty}^{0}\exp\Big\{-\frac{1}{2\nu}\Big(\frac{(1-y)^2}{2t}+My\Big)\Big\}dy}$$

$$\le \frac{(N-M)\exp\big(\frac{M(Mt-2)}{4\nu}\big)\int_{-\infty}^{\xi_M} e^{-s^2}ds}{\exp\big(\frac{N(Nt-2)}{4\nu}\big)\int_{\xi_N}^{+\infty} e^{-s^2}ds}$$

$$\le \frac{(N-M)\exp\big(\frac{M(Mt-2)}{4\nu}\big)\int_{-\infty}^{\xi_M} e^{-s^2}ds}{\sqrt{\pi}/2}.$$

With (31), we get

$$u(t,1)-M \le \frac{2\sqrt{\nu t}}{\sqrt{\pi}}\frac{N-M}{Nt-1}\exp\left\{\frac{-1}{4\nu t}\right\}\exp\left\{-\frac{M^2}{4\nu}\left(t-\frac{2}{M}\right)\right\},$$

and the result in the L^∞ norm follows using $t>(2/M)$.

The L^∞ estimate on $\partial_x u$ is done approximately as in section 2.1 by using Lemma 2. We fix $x\in[0,1]$; we get

$$\partial_x u(t,x) = \frac{1}{2\nu}\frac{\int_{-\infty}^{+\infty}\frac{y-x}{t}(\hat{u}_0(y)-M)\exp\Big\{-\frac{1}{2\nu}\big[\frac{(x-y)^2}{2t}+\int_0^y\hat{u}_0(\eta)d\eta\big]\Big\}dy}{\int_{-\infty}^{+\infty}\exp\Big\{-\frac{1}{2\nu}\big[\frac{(x-y)^2}{2t}+\int_0^y\hat{u}_0(\eta)d\eta\big]\Big\}dy}$$

$$+\frac{1}{2\nu}\frac{\int_{-\infty}^{+\infty}\frac{y-x}{t}(M-u(t,x))\exp\Big\{-\frac{1}{2\nu}\big[\frac{(x-y)^2}{2t}+\int_0^y\hat{u}_0(\eta)d\eta\big]\Big\}dy}{\int_{-\infty}^{+\infty}\exp\Big\{-\frac{1}{2\nu}\big[\frac{(x-y)^2}{2t}+\int_0^y\hat{u}_0(\eta)d\eta\big]\Big\}dy}$$

$$=: A+B.$$

Using again the fact that $u(t,\cdot)$ is nondecreasing, we see that we have only to give an upper bound for $\partial_x u$. The second term B satisfies

$$B=\frac{1}{2\nu}(M-u(t,x))u(t,x)$$

and thus is clearly nonpositive, as follows from the maximum principle. Therefore, it remains to estimate the first term A. To this aim, we estimate the denominator from below as follows:

$$\int_{-\infty}^{+\infty}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y\hat{u}_0(\eta)d\eta\right]\right\}dy$$

$$\ge \int_{-\infty}^{0}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y\hat{u}_0(\eta)d\eta\right]\right\}dy$$

$$= \int_{-\infty}^{0}\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+My\right]\right\}dy$$

$$\ge \sqrt{\pi\nu t}\exp\left\{\frac{M}{2\nu}\left(\frac{Mt}{2}-x\right)\right\}.$$

For the numerator, thanks to (30), we have

$$\begin{aligned}
\mathcal{N} &:= \int_0^{+\infty} \frac{y-x}{t}(\hat{u}_0(y)-M)\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+\int_0^y \hat{u}_0(\eta)d\eta\right]\right\}dy \\
&\le \int_0^{+\infty} \frac{y}{t}(N-M)\exp\left\{-\frac{1}{2\nu}\left[\frac{(x-y)^2}{2t}+Ny\right]\right\}dy \\
&\le \frac{N-M}{t}\left[2\sqrt{\nu t}(x-Nt)\exp\left\{\frac{N(-2x+Nt)}{4\nu}\right\}\right. \\
&\qquad\qquad \left.\times\int_{\frac{-x+Nt}{2\sqrt{\nu t}}}^{+\infty} e^{-s^2}ds + 2\nu t\exp\left\{-\frac{x^2}{4\nu t}\right\}\right] \\
&= \frac{N-M}{t}\exp\left\{\frac{N(-2x+Nt)}{4\nu}\right\} \\
&\qquad\qquad \times\left[2\sqrt{\nu t}(x-Nt)\int_{\frac{-x+Nt}{2\sqrt{\nu t}}}^{+\infty} e^{-s^2}ds + 2\nu t\exp\left\{-\frac{(x-Nt)^2}{4\nu t}\right\}\right].
\end{aligned}$$

Simple integrations by parts prove that

$$-\int_y^{+\infty} e^{-s^2}ds + \frac{e^{-y^2}}{2y} \le \frac{e^{-y^2}}{4y^3}. \tag{61}$$

Plugging (61) with $y=\frac{-x+Nt}{2\sqrt{\nu t}}$ into the previous estimate of $\mathcal{N}$ and using $Nt \ge 1 \ge x$, we deduce

$$\mathcal{N} \le 4\frac{N-M}{(Nt-1)^2}\nu^2 t\exp\left\{\frac{-x^2}{4\nu t}\right\}.$$

Using $N > M$, we finally obtain

$$\mathcal{N} \le 4M\nu^2 t,$$

which yields the result.

3.2. Reaching M exactly. Reaching M exactly is done identically to reaching N exactly (see section 2.2). This is due to the fact that we did not use the size of N in subsection 2.2. This ends the proof of section 2 and hence of Theorem 1.

4. Technical results.

4.1. Proof of the dissipation result. In this first part, we will prove the estimate presented in (51):

$$\begin{aligned}
\|\varphi|_{t=t_0}\|_{L^2(0,1)} \le \exp\left\{\frac{\|z_x\|_{L^1_t(L^\infty_x)}}{8} - \frac{((N-\|z\|_\infty/2)t^*-1)^2}{4\nu t^*}e^{-2\|z_x\|_{L^1_t(L^\infty_x)}}\right\} \\
\times \|\varphi|_{t=t_0+t^*}\|_{L^2(0,1)},
\end{aligned} \tag{62}$$

for any $t_0 \in (0, T^*)$ and any $t^* \in (0, T^* - t_0)$ such that (52) is satisfied. Here, φ designs the solution of the system

$$\begin{cases} -\varphi_t - \nu\varphi_{xx} - (N + z(t,x)/2)\varphi_x = 0 & \text{in } (0,T^*)\times(0,1), \\ \varphi|_{x=0} = 0, \quad \varphi|_{x=1} = 0 & \text{in } (0,T^*), \\ \varphi|_{t=T^*} = \varphi^0 & \text{in } (0,1). \end{cases} \tag{63}$$

Let us first define a function $\Theta(t,x) = e^{\theta(t,x)}$, where $\theta \in L^\infty(0,T^*; W^{1,\infty}(0,1))$ is chosen as follows: We set $\theta(t,x) := r_0|\psi^{-1}(t,x)|$, with $r_0 > 0$ a constant which will be chosen later on, and where ψ is the backward flow associated with $N + z(t,x)/2$. More precisely, ψ is given by

$$\begin{cases} \dfrac{d\psi}{dt}(t,x) = N + \dfrac{z(t,\psi(t,x))}{2}, \\ \psi_{|t=t_0+t^*} = x. \end{cases}$$

Here, we have extended $z(t,\cdot)$ by $z(t,0)$ on the left of 0 and by $z(t,1)$ on the right of 1. In particular, Θ is defined for $x \in \mathbb{R}$ and satisfies

$$\Theta_t + (N + z(t,x)/2)\Theta_x = 0. \tag{64}$$

We regard the equation satisfied by $\Theta\,\varphi$ as the following (in fact, to be complete, we should regularize Θ and z, establish estimates for regularized Θ and z, and then pass to the limit):

$$-(\Theta\varphi)_t - \nu(\Theta\varphi)_{xx} - (N + z(t,x)/2)(\Theta\varphi)_x = -\nu\varphi\Theta_{xx} - 2\nu\varphi_x\Theta_x. \tag{65}$$

We multiply by $\Theta\varphi$ and integrate on $(0,1)$. After integration by parts we obtain

$$\begin{aligned} &-\frac{1}{2}\frac{d}{dt}\int_0^1 |e^\theta\varphi|^2\,dx + \frac{1}{4}\int_0^1 z_x|e^\theta\varphi|^2\,dx + \nu\int_0^1 |(e^\theta\varphi)_x|^2\,dx \\ &= \nu\int_0^1 |\Theta\theta_x\varphi|^2\,dx \le \nu\|\theta_x\|_\infty^2\int_0^1 |e^\theta\varphi|^2\,dx. \end{aligned} \tag{66}$$

After an application of Gronwall's lemma in the time interval $(t_0, t_0 + t^*)$, we find the following from (66):

$$\begin{aligned} &\int_0^1 |e^\theta\varphi|^2(t_0)\,dx \\ &\le \exp\left\{\frac{\|z_x\|_{L^1_t(L^\infty_x)}}{4} + 2\nu r_0^2 t^* \exp\left(2\|z_x\|_{L^1_t(L^\infty_x)}\right)\right\}\int_0^1 |e^\theta\varphi|^2(t_0+t^*)\,dx. \end{aligned} \tag{67}$$

Here, we have used the expression of θ together with the estimate

$$|\psi_x^{-1}(t,x)|^2 \le \exp\left\{2\int_0^{T^*} \|z_x(s)\|_\infty\,ds\right\}, \quad t \in (0,T),\ x \in (0,1).$$

Now, from the expression of $\psi^{-1}(t,x)$ we observe that

$$\psi^{-1}(t_0,x) \le 1 - (N - \|z\|_\infty/2)t^* \text{ for } x \in (0,1).$$

Then from (67) we find that

$$\int_0^1 |\varphi|^2(t_0)\,dx \leq C(r_0,t^*)\int_0^1 |\varphi|^2(t_0+t^*)\,dx, \tag{68}$$

with

$$C=\exp\left\{\frac{\|z_x\|_{L^1_t(L^\infty_x)}}{4}+\ 2\nu r_0^2 t^*\exp\left(2\|z_x\|_{L^1_t(L^\infty_x)}\right)+2r_0(1-(N-\|z\|_\infty/2)t^*)\right\}.$$

Finally, we choose

$$r_0=\frac{e^{-2\|z_x\|_{L^1_t(L^\infty_x)}}((N-\|z\|_\infty/2)t^*-1)}{2\nu t^*}$$

and we find the desired inequality (62) squared.

4.2. Proof of the Carleman inequality. In this, the last section of the paper, we will provide the proof of the Carleman inequality which was presented in (53). In order to prove this estimate, we follow the steps of the proof in [5].

Hence, let us first perform a change of variables in order to restrict ourselves to the case where $\nu=1$:

$$\begin{cases}\widetilde{t}=\nu t,\\ \widetilde{x}=x.\end{cases} \tag{69}$$

In the new variables, we have, with $\widetilde{\varphi}(\widetilde{t},\widetilde{x}):=\varphi(t,x)$ and $\widetilde{z}(\widetilde{t},\widetilde{x})=z(t,x)$,

$$\begin{cases}\widetilde{\varphi}_{\widetilde{t}}+\widetilde{\varphi}_{\widetilde{x}\widetilde{x}}+\nu^{-1}N\widetilde{\varphi}_{\widetilde{x}}=-\nu^{-1}(\widetilde{z}(\widetilde{t},\widetilde{x})/2)\widetilde{\varphi}_{\widetilde{x}}, & (\widetilde{t},\widetilde{x})\in(0,\nu T^*)\times(0,1),\\ \widetilde{\varphi}(\widetilde{t},0)=\widetilde{\varphi}(\widetilde{t},1)=0, & \widetilde{t}\in(0,\nu T^*),\\ \widetilde{\varphi}(\nu T^*,\widetilde{x})=\widetilde{\varphi}^0(\widetilde{x}), & \widetilde{x}\in(0,1).\end{cases} \tag{70}$$

Let

$$\widetilde{N}:=\frac{N}{\nu}, \tag{71}$$

$$\widetilde{T}:=\nu T^*. \tag{72}$$

Then, condition (42) implies

$$\widetilde{N}\widetilde{T}\geqslant(3/2). \tag{73}$$

Let us define a weight function, similar to the one introduced by Fursikov and Imanuvilov in [8],

$$\alpha(\widetilde{t},\widetilde{x}):=\frac{\beta(\widetilde{x})}{\widetilde{T}-\widetilde{t}}\quad(\widetilde{t},\widetilde{x})\in(0,\widetilde{T})\times(0,1), \tag{74}$$

where $0\leqslant\beta\in C^2([0,1])$ will be chosen below. We also introduce the function

$$\psi:=e^{-\alpha}\widetilde{\varphi},$$

which verifies

$$P_1\psi + P_2\psi = P_3\psi, \tag{75}$$

with

$$P_1\psi := \psi_{\widetilde{x}\widetilde{x}} + \alpha_{\widetilde{x}}^2\psi + \widetilde{N}\alpha_{\widetilde{x}}\psi + \alpha_{\widetilde{t}}\psi,$$

$$P_2\psi := \psi_{\widetilde{t}} + 2\alpha_{\widetilde{x}}\psi_{\widetilde{x}} + \widetilde{N}\psi_{\widetilde{x}},$$

$$P_3\psi := -\alpha_{\widetilde{x}\widetilde{x}}\psi - \nu^{-1}(\widetilde{z}(\widetilde{t},\widetilde{x})/2)(\alpha_{\widetilde{x}}\psi + \psi_{\widetilde{x}}).$$

We develop here the classical proof, consisting of taking the L^2 norm in identity (75), and then develop all the double products:

$$\|P_1\psi\|^2_{L^2(Q)} + \|P_2\psi\|^2_{L^2(Q)} + 2(P_1\psi, P_2\psi)_{L^2(Q)} = \|P_3\psi\|^2_{L^2(Q)}, \tag{76}$$

where Q stands for the open set $(0,\widetilde{T})\times(0,1)$.

Let us compute $2(P_1\psi, P_2\psi)_{L^2(Q)}$. Let us first compute the terms concerning $\psi_{\widetilde{x}\widetilde{x}}$. We have

$$(\psi_{\widetilde{x}\widetilde{x}}, \psi_{\widetilde{t}})_{L^2(Q)} = \frac{1}{2}\int_0^1 |\psi_{\widetilde{x}}(0,\widetilde{x})|^2\, d\widetilde{x}.$$

Moreover,

$$\begin{aligned} &2(\psi_{\widetilde{x}\widetilde{x}}, \alpha_{\widetilde{x}}\psi_{\widetilde{x}})_{L^2(Q)} \\ &\quad = \int_0^{\widetilde{T}} (\alpha_{\widetilde{x}}(\widetilde{t},1)|\psi_{\widetilde{x}}(\widetilde{t},1)|^2 - \alpha_{\widetilde{x}}(\widetilde{t},0)|\psi_{\widetilde{x}}(\widetilde{t},0)|^2)\, d\widetilde{t} - \iint_Q \alpha_{\widetilde{x}\widetilde{x}}|\psi_{\widetilde{x}}|^2\, d\widetilde{x}\, d\widetilde{t}. \end{aligned} \tag{77}$$

Finally,

$$\widetilde{N}(\psi_{\widetilde{x}\widetilde{x}}, \psi_{\widetilde{x}})_{L^2(Q)} = (\widetilde{N}/2)\int_0^{\widetilde{T}} (|\psi_{\widetilde{x}}(\widetilde{t},1)|^2 - |\psi_{\widetilde{x}}(\widetilde{t},0)|^2)\, d\widetilde{t}.$$

As far as the term $\alpha_{\widetilde{x}}^2\psi$ is concerned, we first have

$$(\alpha_{\widetilde{x}}^2\psi, \psi_{\widetilde{t}})_{L^2(Q)} = -\iint_Q \alpha_{\widetilde{x}}\alpha_{\widetilde{x}\widetilde{t}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t} - \frac{1}{2}\int_0^1 \alpha_{\widetilde{x}}^2(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\, d\widetilde{x}.$$

Next,

$$2(\alpha_{\widetilde{x}}^2\psi, \alpha_{\widetilde{x}}\psi_{\widetilde{x}})_{L^2(Q)} = -3\iint_Q \alpha_{\widetilde{x}\widetilde{x}}\alpha_{\widetilde{x}}^2|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.$$

Finally,

$$\widetilde{N}(\alpha_{\widetilde{x}}^2\psi, \psi_{\widetilde{x}})_{L^2(Q)} = -\widetilde{N}\iint_Q \alpha_{\widetilde{x}\widetilde{x}}\alpha_{\widetilde{x}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.$$

Let us next perform the terms concerning $\widetilde{N}\alpha_{\widetilde{x}}\psi$. First, we have

$$\widetilde{N}(\alpha_{\widetilde{x}}\psi, \psi_{\widetilde{t}})_{L^2(Q)} = -(\widetilde{N}/2)\iint_Q \alpha_{\widetilde{x}\widetilde{t}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t} - (\widetilde{N}/2)\int_0^1 \alpha_{\widetilde{x}}(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\, d\widetilde{x}.$$

Then, we find

$$2\widetilde{N}(\alpha_{\widetilde{x}}\psi, \alpha_{\widetilde{x}}\psi_{\widetilde{x}})_{L^2(Q)} = -2\widetilde{N}\iint_Q \alpha_{\widetilde{x}}\alpha_{\widetilde{x}\widetilde{x}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.$$

The last term provides

$$\widetilde{N}^2(\alpha_{\widetilde{x}}\psi, \psi_{\widetilde{x}})_{L^2(Q)} = -(\widetilde{N}^2/2)\iint_Q \alpha_{\widetilde{x}\widetilde{x}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.$$

Lastly, we deal with the computations of the term $\alpha_{\widetilde{t}}\psi$. First, we obtain

$$(\alpha_{\widetilde{t}}\psi, \psi_{\widetilde{t}})_{L^2(Q)} = -(1/2)\iint_Q \alpha_{\widetilde{t}\widetilde{t}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t} - (1/2)\int_0^1 \alpha_{\widetilde{t}}(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\, d\widetilde{x}.$$

Additionally, we find

$$(\alpha_{\widetilde{t}}\psi, 2\alpha_{\widetilde{x}}\psi_{\widetilde{x}})_{L^2(Q)} = -\iint_Q (\alpha_{\widetilde{t}}\alpha_{\widetilde{x}\widetilde{x}} + \alpha_{\widetilde{t}\widetilde{x}}\alpha_{\widetilde{x}})|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.$$

Finally,

$$(\alpha_{\widetilde{t}}\psi, \widetilde{N}\psi_{\widetilde{x}})_{L^2(Q)} = -(\widetilde{N}/2)\iint_Q \alpha_{\widetilde{t}\widetilde{x}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.$$

Putting all these computations together, we conclude that the double product term is

$$\begin{aligned}
2(P_1\psi, P_2\psi)_{L^2(Q)} &= \int_0^1 |\psi_{\widetilde{x}}(0,\widetilde{x})|^2\, d\widetilde{x} \\
&+ \int_0^{\widetilde{T}} ((2\alpha_{\widetilde{x}}(\widetilde{t},1) + \widetilde{N})|\psi_{\widetilde{x}}(\widetilde{t},1)|^2 - (2\alpha_{\widetilde{x}}(\widetilde{t},0) + \widetilde{N})|\psi_{\widetilde{x}}(\widetilde{t},0)|^2)\, d\widetilde{t} \\
&- 2\iint_Q \alpha_{\widetilde{x}\widetilde{x}}|\psi_{\widetilde{x}}|^2\, d\widetilde{x}\, d\widetilde{t} - 4\iint_Q \alpha_{\widetilde{x}}\alpha_{\widetilde{x}\widetilde{t}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t} \\
&- \int_0^1 \alpha_{\widetilde{x}}^2(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\, d\widetilde{x} - 2\iint_Q (3\alpha_{\widetilde{x}\widetilde{x}}\alpha_{\widetilde{x}}^2 + \widetilde{N}\alpha_{\widetilde{x}\widetilde{t}})|\psi|^2\, d\widetilde{x}\, d\widetilde{t} \\
&- \widetilde{N}\int_0^1 \alpha_{\widetilde{x}}(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\, d\widetilde{x} - \widetilde{N}\iint_Q (6\alpha_{\widetilde{x}}\alpha_{\widetilde{x}\widetilde{x}} + \widetilde{N}\alpha_{\widetilde{x}\widetilde{x}})|\psi|^2\, d\widetilde{x}\, d\widetilde{t} \\
&- \iint_Q \alpha_{\widetilde{t}\widetilde{t}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t} - \int_0^1 \alpha_{\widetilde{t}}(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\, d\widetilde{x} - 2\iint_Q \alpha_{\widetilde{t}}\alpha_{\widetilde{x}\widetilde{x}}|\psi|^2\, d\widetilde{x}\, d\widetilde{t}.
\end{aligned} \tag{78}$$

On the other hand, we have the following for the right-hand side term:

$$\|P_3\psi\|^2_{L^2(Q)} \le \iint_Q (2\alpha_{\widetilde{x}\widetilde{x}}^2|\psi|^2 + \nu^{-2}|\widetilde{z}(\widetilde{t},\widetilde{x})|^2(\alpha_{\widetilde{x}}^2|\psi|^2 + |\psi_{\widetilde{x}}|^2))\, d\widetilde{x}\, d\widetilde{t}. \tag{79}$$

Combining (78)–(79) with (76), we obtain

$$\begin{aligned}
&\int_0^{\widetilde{T}} (2\alpha_{\widetilde{x}}(\widetilde{t},1)+\widetilde{N})|\psi_{\widetilde{x}}(\widetilde{t},1)|^2\,d\widetilde{t} - 2\iint_Q \alpha_{\widetilde{x}\widetilde{x}}|\psi_{\widetilde{x}}|^2\,d\widetilde{x}\,d\widetilde{t} - 6\iint_Q \alpha_{\widetilde{x}\widetilde{x}}\alpha_{\widetilde{x}}^2|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&-2\iint_Q \alpha_{\widetilde{t}}\alpha_{\widetilde{x}\widetilde{x}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} - 6\widetilde{N}\iint_Q \alpha_{\widetilde{x}}\alpha_{\widetilde{x}\widetilde{x}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} - \widetilde{N}^2\iint_Q \alpha_{\widetilde{x}\widetilde{x}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad\leqslant \iint_Q (2\alpha_{\widetilde{x}\widetilde{x}}^2|\psi|^2+\nu^{-2}|\widetilde{z}(\widetilde{t},\widetilde{x})|^2(\alpha_{\widetilde{x}}^2|\psi|^2+|\psi_{\widetilde{x}}|^2))\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad+\int_0^{\widetilde{T}} (2\alpha_{\widetilde{x}}(\widetilde{t},0)+\widetilde{N})|\psi_{\widetilde{x}}(\widetilde{t},0)|^2\,d\widetilde{t} + 4\iint_Q \alpha_{\widetilde{x}}\alpha_{\widetilde{x}\widetilde{t}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad+2\widetilde{N}\iint_Q \alpha_{\widetilde{x}\widetilde{t}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} + \iint_Q \alpha_{\widetilde{t}\widetilde{t}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} + \int_0^1 \alpha_{\widetilde{x}}^2(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x}\\
&\qquad+\widetilde{N}\int_0^1 \alpha_{\widetilde{x}}(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x} + \int_0^1 \alpha_{\widetilde{t}}(0,\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x}.
\end{aligned}$$

From the definition of α (given in (74)), we find

$$\begin{aligned}
&\int_0^{\widetilde{T}} \left(2\frac{\beta'(1)}{\widetilde{T}-\widetilde{t}}+\widetilde{N}\right)|\psi_{\widetilde{x}}(\widetilde{t},1)|^2\,d\widetilde{t} - 2\iint_Q \frac{\beta''(\widetilde{x})}{\widetilde{T}-\widetilde{t}}|\psi_{\widetilde{x}}|^2\,d\widetilde{x}\,d\widetilde{t}\\
&-6\iint_Q \frac{\beta''(\widetilde{x})(\beta'(\widetilde{x}))^2}{(\widetilde{T}-\widetilde{t})^3}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} - 2\iint_Q \frac{\beta(\widetilde{x})\beta''(\widetilde{x})}{(\widetilde{T}-\widetilde{t})^3}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&-6\widetilde{N}\iint_Q \frac{\beta'(\widetilde{x})\beta''(\widetilde{x})}{(\widetilde{T}-\widetilde{t})^2}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} - \widetilde{N}^2\iint_Q \frac{\beta''(\widetilde{x})}{\widetilde{T}-\widetilde{t}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad\leqslant \frac{\|z\|_\infty^2}{\nu^2}\iint_Q |\psi_{\widetilde{x}}|^2\,d\widetilde{x}\,d\widetilde{t} + \iint_Q \frac{2(\beta''(\widetilde{x}))^2+\nu^{-2}\|z\|^2(\beta'(\widetilde{x}))^2}{(\widetilde{T}-\widetilde{t})^2}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad+\int_0^{\widetilde{T}} \left(2\frac{\beta'(0)}{\widetilde{T}-\widetilde{t}}+\widetilde{N}\right)|\psi_{\widetilde{x}}(\widetilde{t},0)|^2\,d\widetilde{t} + 4\iint_Q \frac{(\beta'(\widetilde{x}))^2}{(\widetilde{T}-\widetilde{t})^3}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad+2\iint_Q \left(\widetilde{N}\beta'(\widetilde{x})+\frac{\beta(\widetilde{x})}{\widetilde{T}-\widetilde{t}}\right)\frac{|\psi|^2}{(\widetilde{T}-\widetilde{t})^2}\,d\widetilde{x}\,d\widetilde{t} + \int_0^1 \frac{\beta'(\widetilde{x})^2}{\widetilde{T}^2}|\psi(0,\widetilde{x})|^2\,d\widetilde{x}\\
&\qquad+\frac{\widetilde{N}}{\widetilde{T}}\int_0^1 \beta'(\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x} + \frac{1}{\widetilde{T}^2}\int_0^1 \beta(\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x}.
\end{aligned} \tag{80}$$

Let us now define the function $\beta : [0,1] \mapsto \mathbb{R}$. We will take a function satisfying

$$\beta''(\widetilde{x}) = -\frac{1}{1-\delta}\frac{2(\beta'(\widetilde{x}))^2+\beta(\widetilde{x})}{3(\beta'(\widetilde{x}))^2+\beta(\widetilde{x})}, \quad \widetilde{x}\in[0,1], \tag{81}$$

together with the initial conditions

$$\beta(0) = \delta \text{ and } \beta'(0) = \lambda, \tag{82}$$

where $\lambda > 0$ and $\delta \in (0,1)$ are parameters to be determined.

Now we claim that for proper λ, the function β is well defined and satisfies

$$\beta > 0,\ \beta' > 0 \text{ and } \beta'' < 0 \text{ on } [0,1]. \tag{83}$$

Once such a function β is obtained, we consider χ a constant satisfying

$$\beta(1) < \chi. \tag{84}$$

In what follows, the smaller χ is, the better the estimates will be.

Remark 7. One can check, for instance with MATLAB, that, if $\delta > 0$ is small enough and if one fixes $\lambda := 0.807$, then the corresponding β is defined on $[0,1]$ and satisfies (84) with $\chi = 0.435$.

At the end of the paper, we will establish elementarily the following lemma.

LEMMA 4. *There are some values of $\lambda > 0$ and $\delta \in (0,1)$ such that the unique solution β of* (81)–(82) *is well defined in* $[0,1]$ *and satisfies*

$$\beta(1) < (2/3). \tag{85}$$

From now on, we suppose that we have such a β satisfying (81), (82), (83), and (84). We remark that the first term in the left-hand side of (80) is nonnegative, and we regroup the third and fourth terms of the left-hand side, together with the fourth and sixth terms of the right-hand side. We deduce

$$\begin{aligned}
&-2\iint_Q \frac{\beta''(\widetilde{x})}{\widetilde{T}-\widetilde{t}}|\psi_{\widetilde{x}}|^2\,d\widetilde{x}\,d\widetilde{t} - 6\delta\iint_Q \beta''(\widetilde{x})\frac{\beta(\widetilde{x})+3(\beta'(\widetilde{x}))^2}{(\widetilde{T}-\widetilde{t})^3}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&-6\widetilde{N}\iint_Q \frac{\beta'(\widetilde{x})\beta''(\widetilde{x})}{(\widetilde{T}-\widetilde{t})^2}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} - \widetilde{N}^2\iint_Q \frac{\beta''(\widetilde{x})}{\widetilde{T}-\widetilde{t}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\quad\leqslant \frac{\|z\|_\infty^2}{\nu^2}\iint_Q |\psi_{\widetilde{x}}|^2\,d\widetilde{x}\,d\widetilde{t} + \iint_Q \frac{2(\beta''(\widetilde{x}))^2+\nu^{-2}\|z\|^2(\beta'(\widetilde{x}))^2}{(\widetilde{T}-\widetilde{t})^2}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad+\int_0^{\widetilde{T}}\left(2\frac{\beta'(0)}{\widetilde{T}-\widetilde{t}}+\widetilde{N}\right)|\psi_{\widetilde{x}}(\widetilde{t},0)|^2\,d\widetilde{t} + 2\widetilde{N}\iint_Q \frac{\beta'(\widetilde{x})}{(\widetilde{T}-\widetilde{t})^2}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}\\
&\qquad+\frac{1}{\widetilde{T}}\int_0^1\left(\frac{\beta'(\widetilde{x})^2}{\widetilde{T}}+\widetilde{N}\beta'(\widetilde{x})\right)|\psi(0,\widetilde{x})|^2\,d\widetilde{x} + \frac{1}{\widetilde{T}^2}\int_0^1 \beta(\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x}.
\end{aligned} \tag{86}$$

Additionally, using (40), the definition of $\widetilde{T} = \nu T^*$ and the fact that $\beta''(\widetilde{x}) \leqslant -2/((1-\delta)3)$, we can absorb the first term in the right-hand side of (86) with

$$-2\iint_Q \frac{\beta''(\widetilde{x})}{\widetilde{T}-\widetilde{t}}|\psi_{\widetilde{x}}|^2\,d\widetilde{x}\,d\widetilde{t}$$

as long as ν is small enough. Furthermore, using $\beta \geq \delta$ and $-\beta'' \geq (2/3)$, the second term in the left-hand side of (86) can be estimated in the following way:

$$-6\delta\iint_Q \beta''(\widetilde{x})\frac{\beta(\widetilde{x})+3(\beta'(\widetilde{x}))^2}{(\widetilde{T}-\widetilde{t})^3}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} \geq \frac{4\delta^2}{\nu T^*}\iint_Q \frac{|\psi|^2}{(\widetilde{T}-\widetilde{t})^2}\,d\widetilde{x}\,d\widetilde{t}.$$

Then, thanks to (40) and taking $\nu \in (0,\nu_0)$, we have that

$$\frac{4\delta^2}{\nu T^*}\iint_Q \frac{|\psi|^2}{(\widetilde{T}-\widetilde{t})^2}\,d\widetilde{x}\,d\widetilde{t} \geqslant \iint_Q \frac{2(\beta''(\widetilde{x}))^2+\nu^{-2}\|z\|^2(\beta'(\widetilde{x}))^2+2\widetilde{N}\beta'(\widetilde{x})}{(\widetilde{T}-\widetilde{t})^2}|\psi|^2\,d\widetilde{x}\,d\widetilde{t}.$$

From (83) and (86), we have

$$-\widetilde{N}^2 \iint_Q \frac{\beta''(\widetilde{x})}{\widetilde{T}-\widetilde{t}}|\psi|^2\,d\widetilde{x}\,d\widetilde{t} \leqslant \int_0^{\widetilde{T}} (2\frac{\beta'(0)}{\widetilde{T}-\widetilde{t}}+\widetilde{N})|\psi_{\widetilde{x}}(\widetilde{t},0)|^2\,d\widetilde{t} + \frac{1}{\widetilde{T}}\int_0^1 \left(\frac{\beta'(\widetilde{x})^2}{\widetilde{T}}+\widetilde{N}\beta'(\widetilde{x})\right)|\psi(0,\widetilde{x})|^2\,d\widetilde{x} + \frac{1}{\widetilde{T}^2}\int_0^1 \beta(\widetilde{x})|\psi(0,\widetilde{x})|^2\,d\widetilde{x}. \tag{87}$$

Let us recall that $\psi := e^{-\alpha}\widetilde{\varphi}$. Then, from (73), (74), (83), and (87), we deduce that

$$\widetilde{N}\iint_Q \frac{1}{\widetilde{T}-\widetilde{t}}e^{-2\alpha}|\widetilde{\varphi}|^2\,d\widetilde{x}\,d\widetilde{t} \leqslant C\left(\int_0^{\widetilde{T}}|\widetilde{\varphi}_{\widetilde{x}}(\widetilde{t},0)|^2\,d\widetilde{t}+\frac{1}{\widetilde{T}}\int_0^1|\widetilde{\varphi}(0,\widetilde{x})|^2\,d\widetilde{x}\right). \tag{88}$$

In (88) and what follows, C will stand for generic positive constants independent of ν, N, T^*, and φ^0.

By (74) and (83), $e^{-2\alpha}$ reaches its minimum in the region $[2\widetilde{T}/3,(2+3\gamma)\widetilde{T}/3]\times[0,1]$ at $(\widetilde{t},\widetilde{x})=(2\widetilde{T}/3,1)$ (recall that $0<\gamma<(1/3)$ was introduced right before (53)). Hence

$$\begin{aligned}&\frac{\widetilde{N}}{\widetilde{T}}e^{-2\alpha(2\widetilde{T}/3,1)}\int_0^1\int_{2\widetilde{T}/3}^{(2+3\gamma)\widetilde{T}/3}|\widetilde{\varphi}|^2\,d\widetilde{t}\,d\widetilde{x}\\ &\leqslant C\left(\int_0^{\widetilde{T}}|\widetilde{\varphi}_{\widetilde{x}}(\widetilde{t},0)|^2\,d\widetilde{t}+\frac{1}{\widetilde{T}}\int_0^1|\widetilde{\varphi}(0,\widetilde{x})|^2\,d\widetilde{x}\right).\end{aligned} \tag{89}$$

From (74), we deduce, with (84) that

$$\exp\{-2\alpha(2\widetilde{T}/3,1)\}=\exp\{-6\beta(1)/\widetilde{T}\}>\exp\{-6\chi/\widetilde{T}\}. \tag{90}$$

Coming back to our original variables (see (69), (71), and (72)), we get from (89) and (90) the desired inequality (53).

Proof of Lemma 4. First, we introduce the unique maximal solution $\overline{\beta}$ of

$$\overline{\beta}''=-\frac{2\overline{\beta}'^2+\overline{\beta}}{3\overline{\beta}'^2+\overline{\beta}}, \tag{91}$$

with initial conditions

$$\overline{\beta}(0)=0 \text{ and } \overline{\beta}'(0)=1. \tag{92}$$

Clearly, for $a\in\mathbb{R}$ and $b\geq 0$, we have

$$\frac{2}{3}\leq\frac{2a^2+b}{3a^2+b}\leq 1. \tag{93}$$

Hence a solution of (91) can be locally extended as long as, for instance, $\overline{\beta}(x)\geq 0$. It straightforwardly follows that $\overline{\beta}$ is well defined on $[0,1]$ and, moreover, satisfies

$$\overline{\beta}'>0 \text{ on } [0,1), \text{ and hence } \overline{\beta}>0 \text{ on } (0,1].$$

Now it follows that

$$\overline{\beta}'<1-\frac{2x}{3} \text{ on } (0,1],$$

which yields

$$\overline{\beta}(1) < \frac{2}{3}.$$

Now, if we consider, instead of $\overline{\beta}$, the solution β_δ of (81)–(82) for $\lambda = 1$ and δ small enough, it follows easily (for instance, using Gronwall's lemma) that

$$\beta_\delta \longrightarrow \overline{\beta} \text{ uniformly on } [0,1], \text{ as } \delta \to 0^+.$$

Hence for δ small enough, $\beta := \beta_\delta$ satisfies (85).

A CURSE-OF-DIMENSIONALITY-FREE NUMERICAL METHOD FOR SOLUTION OF CERTAIN HJB PDES*

WILLIAM M. McENEANEY†

Abstract. In previous works of the author and others, max-plus methods have been explored for the solution of first-order, nonlinear Hamilton–Jacobi–Bellman partial differential equations (HJB PDEs) and corresponding nonlinear control problems. These methods exploit the max-plus linearity of the associated semigroups. In particular, although the problems are nonlinear, the semigroups are linear in the max-plus sense. These methods have been used successfully to compute solutions. Although they provide certain computational-speed advantages, they still generally suffer from the curse of dimensionality. Here we consider HJB PDEs in which the Hamiltonian takes the form of a (pointwise) maximum of linear/quadratic forms. The approach to the solution will be rather general, but in order to ground the work, we consider only constituent Hamiltonians corresponding to long-run average-cost-per-unit-time optimal control problems for the development. We obtain a numerical method not subject to the curse of dimensionality. The method is based on construction of the dual-space semigroup corresponding to the HJB PDE. This dual-space semigroup is constructed from the dual-space semigroups corresponding to the constituent linear/quadratic Hamiltonians. The dual-space semigroup is particularly useful due to its form as a max-plus integral operator with a kernel obtained from the originating semigroup. One considers repeated application of the dual-space semigroup to obtain the solution.

1. Introduction.

One approach to nonlinear control is through dynamic programming (DP). With DP, the solution of the control problem "reduces" to the solution of the corresponding partial differential equation (PDE). In the case of deterministic optimal control or deterministic games, where one player's feedback is prespecified, the PDE is a Hamilton–Jacobi–Bellman (HJB) PDE. If one can solve the HJB PDE, then this approach is ideal in that one obtains the optimal control for the given criterion as opposed to a control meeting only some weaker goal such as stability. The problem is that one must solve the HJB PDE! We should remark that such HJB PDEs also arise in robust/H_∞ nonlinear filtering and robust/H_∞ control under partial information.

Various approaches have been taken for solution of the HJB PDE. First, note that it is a fully nonlinear, first-order PDE. Consequently, the solutions are generally nonsmooth (with the exception of the linear/quadratic case, of course), and one must use the theory of viscosity solutions [3], [10], [11], [12], [20]. One approach to the solution is through generalized characteristics (cf. [36], [37], as well as [15], [23] for classical treatments). This approach can obtain the solution very quickly at a single point *if* the solution is smooth. However, the nonsmoothness introduces tremendous difficulties, which appear, to the author, to be difficult to handle in an automated

approach. In particular, the projections of the characteristics into the state space may cross and/or may not cover the entire state space (in analogy with shocks and rarefaction waves).

The most common methods by far fall into the class of grid-based methods (cf. [3], [4], [14], [20], [25] among many others). These require that one generate a grid over some bounded region of the state space. In this general class of methods, we include finite-difference methods, finite element methods, and those DP-based methods which map the continuum problem onto some discrete space. Although higher-order grid-based methods are being explored (cf. [6], [41], [16]), there are still hard lower limits to the computational growth as a function of the space dimension. In particular, suppose the region over which one constructs the grid is rectangular, say square, for simplicity. Further, suppose one uses 100 grid points per dimension. (Clearly 50 would be the minimum acceptable, and 100 could be a bit sparse.) If the state dimension is n, then one has 100^n grid points. Thus the computations grow exponentially in state-space dimension n. If the computations per grid point grew with a state-space dimension such as 2^n, then the computations would grow at a rate of $(200C)^n$ for some constant, C. For concreteness, we discuss only the steady-state PDE case here. If the state-space dimension is 3, it is feasible to solve these problems on current generation machinery. However, the computations will grow by more than 8×10^6 when going from a dimension 3 problem to a dimension 6 problem. Parallel algorithms can alleviate this problem to some extent (cf. [5]). However, there can be only rather limited improvement in the dimension of problems which can be handled by such techniques.

In recent years, an entirely new class of numerical methods for HJB PDEs has emerged [19], [34], [1], [22], [32], [31], [33], [30], [28]. These methods exploit the max-plus (or min-plus [9], [32]) linearity of the associated semigroup. They employ a max-plus basis function expansion of the solution, and the numerical methods obtain the coefficients in the basis expansion. We will refer to these methods as *max-plus basis methods.* Much of the previous work has concentrated on the (harder) steady-state HJB PDE class, where (for both max-plus basis and grid-based methods), one propagates forward in "time" to obtain the steady-state limit solution. With the max-plus basis methods, the number of basis functions required still typically grows exponentially with space dimension. For instance, one might use 25 basis functions per space dimension. Consequently, one still has the curse of dimensionality. With the max-plus basis methods, the "time-step" tends to be much larger than what can be used in grid-based methods (since it encapsulates the action of the semigroup propagation on each basis function), and so these methods can be quite fast on small problems. Even with a max-plus basis approach, the curse of dimensionality growth is so fast that one cannot expect to solve general problems of more than, say, dimension 5, on current machinery, and again, the computing machinery speed increases that are expected in the foreseeable future cannot do much to raise this.

Many researchers have noticed that the introduction of even a single, simple nonlinearity into an otherwise linear control problem of high dimensionality, say n, has disastrous computational repercussions. Specifically, one goes from solution of an n-dimensional Riccati equation to solution of a grid-based or max-plus basis method over a space of dimension n. While the Riccati equation may be "relatively" easily solved for large n, the max-plus and grid-based methods have no hope of obtaining solutions on general problems of dimension, say, $n \geq 6$. This has been a frustrating, counter-intuitive situation for decades.

This paper discusses an approach to certain nonlinear HJB PDEs which is not subject to the curse of dimensionality. Although this approach also utilizes the max-plus algebra, the method is largely unrelated to the max-plus basis approaches discussed above. In fact, for this new method, the computational growth in the state-space dimension is on the order of n^3. There is of course no "free lunch," and there is exponential computational growth in a certain measure of complexity of the Hamiltonian. Under this measure, the minimal complexity Hamiltonian is the linear/quadratic Hamiltonian—corresponding to a solution by a Riccati equation. If the Hamiltonian is given as a pointwise maximum or minimum of M linear/quadratic Hamiltonians, then one could say the *complexity* of the Hamiltonian is M. One could also apply this approach to a wider class of HJB PDEs with semiconvex Hamiltonians (by approximation of the Hamiltonian by a finite number of quadratic forms), but that is certainly beyond the scope of this paper.

The approach has been applied on some simple nonlinear problems. A steady-state HJB PDE comprised of 2 linear/quadratic components was solved in dimensions 2 and 3 in under 10 seconds on a standard PC, and in 20 seconds over $\mathbf{R}^4$. A few simple examples comprised of 3 linear/quadratic components were solved in 10–20 seconds over $\mathbf{R}^3$ and 10–45 seconds over $\mathbf{R}^4$. For these particular problems, the solution was obtained over the entire space (as opposed to a rectangular region) with the resulting errors in the *gradients* growing linearly in $|x|$. (See section 7 for more information on specific examples.) These speeds are of course unprecedented in standard general approaches to nonlinear PDEs. This code was not optimized, and there are many computational cost reduction methods that one could employ to further reduce computational growth. Further, the computational growth in going from $n = 4$ up to, say, $n = 6$ would be on the order of $6^3/4^3 \simeq 4$ as opposed to, say, more than 10^4 for a grid-based method.

We will be concerned here with HJB PDEs of the form $0 = \widetilde{H}(x, \operatorname{grad} V)$, where the Hamiltonians are given or approximated as

$$\widetilde{H}(x, \operatorname{grad} V) = \max_{m \in \{1,2,\ldots,M\}} \{H^m(x, \operatorname{grad} V)\}.$$

In order to make the problem tractable, we will concentrate on a single class of HJB PDEs: those for long-run average-cost-per-unit-time problems. However, the theory obviously can be expanded to a much larger class.

Since the development of the proposed method in the following sections takes quite a few pages, we briefly outline the main points here. First, recall that the solution of the above PDE is the eigenfunction of the corresponding semigroup, that is,

$$0 \otimes V = V = \widetilde{S}_\tau[V],$$

where $\oplus, \otimes$ denote max-plus addition and multiplication, and we note that $\widetilde{S}_\tau$ is max-plus linear (cf. [19], [27], [32]). The Legendre–Fenchel transform maps this into the dual-space eigenfunction problem

$$0 \otimes e = \widetilde{\mathcal{B}}_\tau \odot e,$$

where we use the $\odot$ notation to indicate $\widetilde{\mathcal{B}}_\tau \odot e \doteq \int^{\oplus}_{\mathbb{R}^n} \widetilde{\mathcal{B}}_\tau(x, y) \otimes e(y)\, dy$, where $\int^{\oplus}$ denotes max-plus integration (maximization). Then one approximates $\widetilde{\mathcal{B}}_\tau \simeq \bigoplus_{m \in \mathcal{M}} \mathcal{B}^m_\tau$, where $\mathcal{M} \doteq \{1, 2, \ldots, M\}$ and the $\mathcal{B}^m_\tau$ correspond to the H^m. The

max-plus power method [13], [24], [32] suggests that the solution is approximated by the form

$$e \simeq \lim_{N\to\infty} \left[\bigoplus_{m\in\mathcal{M}} \mathcal{B}_\tau^m\right]^N \odot 0 = \lim_{N\to\infty} \left[\bigoplus_{\{m_i\}_{i=1}^N} \mathcal{B}_\tau^{m_1} \otimes \mathcal{B}_\tau^{m_2} \otimes \cdots \mathcal{B}_\tau^{m_N}\right] \odot 0,$$

where the N superscript denotes the $\odot$ operation N times, and 0 represents the zero-function. Given linear/quadratic forms for each of the H^m, the $\mathcal{B}_\tau^m$ are obtained by Riccati equations. Let $e_N \doteq [\bigoplus_{m\in\mathcal{M}} \mathcal{B}_\tau^m]^N \odot 0$. Then $e_N \to e$. The convergence rate does not depend on the space dimension, but on the dynamics of the problem. There is no curse of dimensionality. The exponential growth is in $M = \#\mathcal{M}$. Given the solution of the Riccati equations for the H^m, the computation of each product, $\mathcal{B}_\tau^{m_1} \otimes \mathcal{B}_\tau^{m_2} \otimes \cdots \mathcal{B}_\tau^{m_N}$, is analytical, modulo $n \times n$ matrix inversions (and hence the n^3 computational growth rate).

In section 2, the class of control problems and HJB PDEs which we will use to demonstrate the theory will be given. We will also review the existing theory relevant to our problem there. In section 3 the relation between solution of the HJB PDEs and their corresponding semiconvex dual problems will be discussed. In section 4, a discrete-time approximation of the semigroup for the problem of interest will be introduced, and convergence of the solutions of the approximate problems to the original problem will be obtained. The algorithm itself will be developed in section 5. The basic algorithm is not subject to the curse of dimensionality. However, practical implementation requires some additional work; some initial remarks on this appear in section 6. The algorithm is applied to some simple examples in section 7. Finally, section 8 sketches some future directions.

2. Sample problem class and review of theory. There are certain conditions which must be satisfied for solutions to exist and the method to apply. In order that the assumptions are not completely abstract, we will work with a specific problem class: the infinite time-horizon H_∞ problem with fixed feedback. This class consists of long-term average-cost-per-unit-time problems. Moreover, it is a problem class in which there already exists a good deal of results, and so less analysis will be required for application of the new method.

As indicated above, we suppose the individual H^m are linear/quadratic Hamiltonians. Consequently, consider a finite set of linear systems

$$\dot{\xi}^m = A^m \xi^m + \sigma^m w, \quad \xi_0^m = x \in \mathbb{R}^n. \tag{1}$$

Let $w \in \mathcal{W} \doteq L_2^{loc}([0,\infty);\mathbb{R}^m)$, where we recall that $L_2^{loc}([0,\infty);\mathbb{R}^m) = \{w : [0,\infty) \to \mathbb{R}^m : \int_0^T |w_t|^2\,dt < \infty \text{ for all } T < \infty\}$. Let the cost functionals be

$$J^m(x,T;w) \doteq \int_0^T \frac{1}{2}\xi_t^m D^m \xi_t^m - \frac{\gamma^2}{2}|w_t|^2\,dt, \tag{2}$$

and let the value function (also known as the available storage in this context) be

$$V^m(x) = \sup_{w\in\mathcal{W}} \sup_{T<\infty} J^m(x,T;w) = \lim_{T\to\infty} \sup_{w\in\mathcal{W}} J^m(x,T;w). \tag{3}$$

We remark that a generalization of the second term in the integrand of the cost functional to $\frac{1}{2}w^T C^m w$ with C^m symmetric and positive definite is not needed since

this is equivalent to a change in σ^m in the dynamics (1). Obviously J^m and V^m require some assumptions in order to guarantee their existence. The assumptions will hold throughout the paper. Since these assumptions only appear together, we will refer to this entire set of assumptions as assumption block $(A.m)$, and these are as follows:

$(A.m)$ Assume that there exists $c_A \in (0,\infty)$ such that

$$x^T A^m x \le -c_A |x|^2 \qquad \forall\, x \in \mathbb{R}^n,\ m \in \mathcal{M}.$$

Assume that all D^m are positive definite and symmetric, and let c_D be such that

$$x^T D^m x \le c_D |x|^2 \qquad \forall\, x \in \mathbb{R}^n,\ m \in \mathcal{M}$$

(which is obviously equivalent to all eigenvalues of the D^m being no greater than c_D). Lastly, assume that $\gamma^2/c_\sigma^2 > c_D/c_A^2$, where $c_\sigma \ge \sigma^m$.

Note that these assumptions guarantee the existence of the V^m as locally bounded functions which are zero at the origin (cf. [35]). (These assumptions could be weakened by using the specific linear/quadratic structure, but that would distract from the goal of this paper.) The corresponding HJB PDEs are

$$\begin{aligned} (4)\qquad 0 &= -H^m(x, \operatorname{grad} V) \\ &= -\left\{ \frac{1}{2} x^T D^m x + (A^m x)^T \operatorname{grad} V + \max_{w \in \mathbb{R}^m} \left[(\sigma^m w)^T \operatorname{grad} V - \frac{\gamma^2}{2} |w|^2 \right] \right\} \\ &= -\left\{ \frac{1}{2} x^T D^m x + (A^m x)^T \operatorname{grad} V + \frac{1}{2} \operatorname{grad} V^T \Sigma^m \operatorname{grad} V \right\} \\ V(0) &= 0, \end{aligned}$$

where $\Sigma^m \doteq \frac{1}{\gamma^2} \sigma^m (\sigma^m)^T$. Let $\mathbb{R}^- \doteq \mathbb{R} \cup \{-\infty\}$. Recall that a function, $\phi : \mathbb{R}^n \to \mathbb{R}^-$ is semiconvex if given any $R \in (0,\infty)$ there exists $k_R \in \mathbb{R}$ such that $\phi(x) + \frac{k_R}{2}|x|^2$ is convex over $\overline{B}_R(0) = \{x \in \mathbb{R}^n : |x| \le R\}$. For a fixed choice of c_A, c_σ, $\gamma > 0$ satisfying the above assumptions, and for any $\delta \in (0, \gamma)$, we define

$$\mathcal{G}_\delta = \left\{ V : \mathbb{R}^n \to [0,\infty) \,\middle|\, V \text{ is semiconvex and } V(x) \le \frac{c_A(\gamma-\delta)^2}{c_\sigma^2} |x|^2 \ \forall x \in \mathbb{R}^n \right\}.$$

From [35] (undoubtedly among many others), each value function (3) is the unique viscosity solution of its corresponding HJB PDE (4) in the class $\mathcal{G}_\delta$ for sufficiently small $\delta > 0$.

From the structure of the running cost and dynamics, it is easy to see (cf. [42], [35]) that each V^m satisfies

$$(5)\quad V^m(x) = \sup_{T<\infty} \sup_{w \in \mathcal{W}} J^m(x,T;w) = \lim_{T\to\infty} \sup_{w\in\mathcal{W}} J^m(x,T;w) \doteq \lim_{T\to\infty} V^{m,f}(x,T),$$

and that each $V^{m,f}$ is the unique continuous viscosity solution of (cf. [3], [20])

$$(6)\qquad 0 = V_T - H^m(x, \operatorname{grad} V), \quad V(0,x) = 0.$$

It is easy to see that these solutions have the form $V^{m,f}(x,t) = \frac{1}{2} x^T P_t^{m,f} x$, where each $P^{m,f}$ satisfies the differential Riccati equation

$$(7)\qquad \dot{P}^{m,f} = (A^m)^T P^{m,f} + P^{m,f} A^m + D^m + P^{m,f} \Sigma^m P^{m,f}, \quad P_0^{m,f} = 0.$$

By (5) and (7), the V^m take the form $V(x) = \frac{1}{2}x^T P^m x$, where $P^m = \lim_{t\to\infty} P_t^{m,f}$. With this form and (4) (or (7)), we see that the P^m satisfy the algebraic Riccati equations

$$0 = (A^m)^T P^m + P^m A^m + D^m + P^m \Sigma^m P^m. \tag{8}$$

Combining this with the above, one has the following.

THEOREM 2.1. *Each value function* (3) *is the unique classical solution of its corresponding HJB PDE* (4) *in the class* $\mathcal{G}_\delta$ *for sufficiently small* $\delta > 0$. *Further,* $V^m(x) = \frac{1}{2}x^T P^m x$, *where* P^m *is the smallest symmetric, positive definite solution of* (8).

The duality between viscosity (and/or classical) solutions of the HJB PDEs and the corresponding value functions is certainly very important. However, the method we will use to obtain these value functions/HJB PDE solutions will be through the associated semigroups. These semigroups are equivalent to dynamic programming principles (DPPs). Consequently, for each m we define the semigroup

$$S_T^m[\phi] \doteq \sup_{w\in\mathcal{W}} \left[\int_0^T \frac{1}{2}(\xi_t^m)^T D^m \xi_t^m - \frac{\gamma^2}{2}|w_t|^2\,dt + \phi(\xi_T^m)\right], \tag{9}$$

where ξ^m satisfies (1). By [35], the domain of S_T^m includes $\mathcal{G}_\delta$ for all $\delta > 0$. The following result is similar to that in [32]; the only significant difference is that, in this case, $V^m(x) = \frac{1}{2}x^T P^m x$ is smooth.

THEOREM 2.2. *Fix any* $T > 0$. *Each value function,* V^m, *is the unique smooth solution of* $V = S_T^m[V]$ *in the class* $\mathcal{G}_\delta$ *for sufficiently small* $\delta > 0$. *Further, given any* $V \in \mathcal{G}_\delta$, $\lim_{T\to\infty} S_T^m[V](x) = V^m(x)$ *for all* $x \in \mathbb{R}^n$ *(uniformly on compact sets).*

Recall that the HJB PDE problem of interest is

$$0 = -\widetilde{H}(x, \operatorname{grad} V) \doteq -\max_{m\in\mathcal{M}} H^m(x, \operatorname{grad} V), \quad V(0) = 0. \tag{10}$$

The corresponding value function is

$$\widetilde{V}(x) = \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_\infty} \widetilde{J}(x, w, \mu) \doteq \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_\infty} \sup_{T<\infty} \int_0^T l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\,dt, \tag{11}$$

where $l^{\mu_t}(x) = \frac{1}{2}x^T D^{\mu_t} x$, $\mathcal{D}_\infty = \{\mu : [0,\infty) \to \mathcal{M} :\ \text{measurable}\}$, and ξ satisfies

$$\dot{\xi} = A^{\mu_t}\xi + \sigma^{\mu_t} w_t, \quad \xi_0 = x. \tag{12}$$

THEOREM 2.3. *Value function* $\widetilde{V}$ *is the unique viscosity solution of* (10) *in the class* $\mathcal{G}_\delta$ *for sufficiently small* $\delta > 0$.

Remark 2.4. The proof of Theorem 2.3 is nearly identical to the proofs of Theorems 2.5 and 2.6 from [35], with only trivial changes, and so is not included. In particular, rather than choosing any $w \in \mathcal{W}$, one chooses both any $w \in \mathcal{W}$ and any $\mu \in \mathcal{D}_\infty$.

Define the semigroup

$$\widetilde{S}_T[\phi] = \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_T} \left[\int_0^T l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\,dt + \phi(\xi_T)\right], \tag{13}$$

where $\mathcal{D}_T = \{\mu : [0,T) \to \mathcal{M} :\ \text{measurable}\}$. In analogy with Theorem 2.2, one has the following.

THEOREM 2.5. *Fix any $T > 0$. Value function $\widetilde{V}$ is the unique continuous solution of $V = \widetilde{S}_T[V]$ in the class $\mathcal{G}_\delta$ for sufficiently small $\delta > 0$. Further, given any $V \in \mathcal{G}_\delta$, $\lim_{T\to\infty} \widetilde{S}_T[V](x) = \widetilde{V}(x)$ for all $x \in \mathbb{R}^n$ (uniformly on compact sets).*

The proof is nearly identical to the proof of a similar result in [32] and so is not included. In particular, the only change is the addition of the supremum over $\mathcal{D}_T$—which makes no substantial change in the proof. More important, we also have the following.

THEOREM 2.6. *There exists $c_V > 0$ such that $\widetilde{V}(x) - \frac{1}{2}c_V|x|^2$ is strictly convex.*

Proof. Fix any $x, \nu \in \mathbb{R}^n$ with $|\nu| = 1$ and any $\delta > 0$. Let $\varepsilon > 0$. Given x, let $w^\varepsilon \in \mathcal{W}$, $\mu^\varepsilon \in \mathcal{D}_\infty$ be ε-optimal for $\widetilde{V}(x)$. Then

$$\begin{aligned}&\widetilde{V}(x-\delta\nu) - 2\widetilde{V}(x) + \widetilde{V}(x+\delta\nu)\\ &\quad\geq \widetilde{J}(x-\delta\nu, w^\varepsilon, \mu^\varepsilon) - 2\widetilde{J}(x, w^\varepsilon, \mu^\varepsilon) + \widetilde{J}(x+\delta\nu, w^\varepsilon, \mu^\varepsilon) - 2\varepsilon.\end{aligned} \tag{14}$$

Let $\xi^\delta, \xi^0, \xi^{-\delta}$ be solutions of dynamics (12), but with initial conditions $\xi_0^\delta = x + \delta\nu$, $\xi_0^0 = x$, and $\xi_0^{-\delta} = x - \delta\nu$, respectively, where the inputs are w^ε and μ^ε for all three processes. Then

$$\dot{\xi}^\delta - \dot{\xi}^0 = A^{\mu_t^\varepsilon}[\xi^\delta - \xi^0] \;\text{ and }\; \dot{\xi}^0 - \dot{\xi}^{-\delta} = A^{\mu_t^\varepsilon}[\xi^0 - \xi^{-\delta}]. \tag{15}$$

Letting $\Delta_t^+ \doteq \xi_t^\delta - \xi_t^0$, one also has $\xi_t^0 - \xi_t^{-\delta} = \Delta_t^+$, and by linearity one finds $\dot{\Delta}^+ = A^{\mu_t^\varepsilon}\Delta^+$. Also, using (14) and (11), we have

$$\widetilde{V}(x-\delta\nu) - 2\widetilde{V}(x) + \widetilde{V}(x+\delta\nu) \geq \int_0^\infty (\Delta^+)^T D^{\mu_t^\varepsilon}\Delta^+\,dt - 2\varepsilon. \tag{16}$$

Also, by the finiteness of $\mathcal{M}$, there exists $K < \infty$ such that

$$\frac{d}{dt}|\Delta^+|^2 = 2(\Delta^+)^T A^{\mu_t^\varepsilon}\Delta^+ \geq -K|\Delta^+|^2,$$

which implies

$$|\Delta^+|^2 \geq e^{-Kt}\delta^2 \qquad \forall\, t \geq 0. \tag{17}$$

Let $\lambda_D \doteq \min\{\lambda \in \mathbb{R} :\ \lambda \text{ is an eigenvalue of a } D^m\}$. By the positive definiteness of the D^m and finiteness of $\mathcal{M}$, $\lambda_D > 0$. Consequently, by (16), and then (17),

$$\widetilde{V}(x-\delta\nu) - 2\widetilde{V}(x) + \widetilde{V}(x+\delta\nu) \geq \int_0^\infty \lambda_D|\Delta^+|^2\,dt - 2\varepsilon \geq \frac{\lambda_D}{K}\delta^2 - 2\varepsilon. \tag{18}$$

Since $\varepsilon > 0$ and $|\nu| = 1$ were arbitrary, one obtains the result. ∎

3. Max-plus spaces and dual operators. Again, recall that a function $\phi : \mathbb{R}^n \to \mathbb{R}^-$ is semiconvex if, given any $R \in (0, \infty)$, there exists $\beta_R \in \mathbb{R}$ such that $\phi(x) + \frac{\beta_R}{2}|x|^2$ is convex over $\overline{B}_R(0) = \{x \in \mathbb{R}^n : |x| \leq R\}$. We will modify this definition by allowing the β_R to be $n \times n$, symmetric, and positive or negative definite matrices. We will denote the set of such matrices as $\mathcal{D}_n$. We say ϕ is uniformly semiconvex with (symmetric, definite matrix) constant $\beta \in \mathcal{D}_n$ if $\phi(x) + \frac{1}{2}x^T\beta x$ is convex over $\mathbb{R}^n$. Let $\mathcal{S}_\beta = \mathcal{S}_\beta(\mathbb{R}^n)$ be the set of functions mapping $\mathbb{R}^n$ into $\mathbb{R}^-$ which are uniformly semiconvex with (symmetric, definite matrix) constant β. (A negative definite semiconvexity constant corresponds to functions which are still convex after subtracting a convex quadratic.) Also note that $\mathcal{S}_\beta$ is a max-plus vector space (also

known as a moduloid) [19], [32], [2], [8], [26]. For instance, $\alpha_1 \otimes \phi_1 \oplus \alpha_2 \otimes \phi_2 \in \mathcal{S}_\beta$ for all $\alpha_1, \alpha_2 \in \mathbb{R}^-$ and all $\phi_1, \phi_2 \in \mathcal{S}_\beta$. Combining Theorems 2.1 and 2.6, we have the following.

THEOREM 3.1. *There exists $\overline{\beta} \in \mathcal{D}_n$ such that given any β such that $\beta - \overline{\beta} > 0$ (i.e., $\beta - \overline{\beta}$ positive definite), $\widetilde{V} \in \mathcal{S}_\beta$ and $V^m \in \mathcal{S}_\beta$ for all $m \in \mathcal{M}$. Further, one may take β negative definite (i.e., $\widetilde{V}, V^m$ are convex).*

We henceforth assume we have chosen β such that $\beta - \overline{\beta} > 0$.

Throughout the remainder, we will employ certain transform kernel functions, $\psi : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, which take the form

$$\psi(x, z) = \tfrac{1}{2}(x - z)^T C(x - z)$$

with nonsingular, symmetric C satisfying $C + \beta < 0$ (i.e., $C + \beta$ negative definite). The following semiconvex duality result [19], [31], [32] requires only a small modification of convex duality and Legendre–Fenchel transform results [38], [39].

THEOREM 3.2. *Let $\phi \in \mathcal{S}_\beta$. Let C and ψ be as above. Then, for all $x \in \mathbb{R}^n$,*

$$\phi(x) = \max_{z \in \mathbb{R}^n} [\psi(x, z) + a(z)] \tag{19}$$

$$= \int_{\mathbb{R}^n}^{\oplus} \psi(x, z) \otimes a(z)\, dz = \psi(x, \cdot) \odot a(\cdot), \tag{20}$$

where for all $z \in \mathbb{R}^n$,

$$a(z) = -\max_{x \in \mathbb{R}^n} [\psi(x, z) - \phi(x)] \tag{21}$$

$$= -\int_{\mathbb{R}^n}^{\oplus} \psi(x, z) \otimes [-\phi(x)]\, dx = -\left\{\psi(\cdot, z) \odot [-\phi(\cdot)]\right\}, \tag{22}$$

which, using the notation of [8],

$$= \left\{\psi(\cdot, z) \odot [\phi^-(\cdot)]\right\}^-. \tag{23}$$

We will refer to a as the *semiconvex dual* of ϕ (with respect to ψ).

Remark 3.3. We note that $\phi \in \mathcal{S}_\beta$ implies that ϕ is locally Lipschitz (cf. [18]). We also note that if $\phi \in \mathcal{S}_\beta$ and if there is any $x \in \mathbb{R}^n$ such that $\phi(x) = -\infty$, then $\phi \equiv -\infty$. Henceforth, we will ignore the special case of $\phi \equiv -\infty$ and assume that all functions are real-valued.

Semiconcavity is the obvious analogue of semiconvexity. In particular, a function, $\phi : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$, is uniformly semiconcave with constant $\beta \in \mathcal{D}_n$ if $\phi(x) - \frac{1}{2}x^T \beta x$ is concave over $\mathbb{R}^n$. Let $\mathcal{S}_\beta^-$ be the set of functions mapping $\mathbb{R}^n$ into $\mathbb{R} \cup \{+\infty\}$ which are uniformly semiconcave with constant β.

LEMMA 3.4. *Let $\phi \in \mathcal{S}_\beta$ (still with $C + \beta < 0$), and let a be the semiconvex dual of ϕ. Then $a \in \mathcal{S}_d^-$ for some $d \in \mathcal{D}_n$ such that $C + d < 0$.*

Proof. A proof only in the case $\phi \in C^2$ is provided; in the more general case, a mollification argument can be employed.

Noting that $\phi \in \mathcal{S}_\beta$ and $-C - \beta > 0$, there exists a unique minimizer,

$$\overline{x}(z) = \operatorname*{argmin}_{x \in \mathbb{R}} [\phi(x) - \psi(x, z)],$$

and one has

$$a(z) = \phi(\overline{x}(z)) - \psi(\overline{x}(z), z). \tag{24}$$

Fix any $z, \nu \in \mathbb{R}^n$ with $|\nu| = 1$. Define $a^s : \mathbb{R} \to \mathbb{R}$ and $\overline{x}^s : \mathbb{R} \to \mathbb{R}^n$ by

$$a^s(\delta) \doteq a(z + \delta\nu) \quad \text{and} \quad \overline{x}^s(\delta) = \overline{x}(z + \delta\nu). \tag{25}$$

We will obtain a lower bound on the second derivative of a^s, and this will prove the result. Differentiating a^s, one has

$$\begin{aligned}\left.\frac{da^s}{d\delta}\right|_{\delta=0} &= \frac{d}{d\delta}\left[\phi(\overline{x}(z+\delta\nu)) - \psi(\overline{x}(z+\delta\nu), z+\delta\nu)\right] \\ &= \operatorname{grad}_x \phi(\overline{x}(z)) \cdot \frac{d\overline{x}^s}{d\delta} - \operatorname{grad}_x \psi(\overline{x}(z), z) \cdot \frac{d\overline{x}^s}{d\delta} - \operatorname{grad}_z \psi(\overline{x}(z), z) \cdot \nu,\end{aligned}$$

which, using the fact that $\operatorname{grad}_x \phi(\overline{x}(z)) - \operatorname{grad}_x \psi(\overline{x}(z), z) = 0$,

$$= -\operatorname{grad}_z \psi(\overline{x}(z), z) \cdot \nu.$$

Differentiating again, one finds

$$\left.\frac{d^2a^s}{d\delta^2}\right|_{\delta=0} = -\sum_{i=1}^{n}\left\{\sum_{j=1}^{n}\psi_{z_i x_j}(\overline{x}(z), z)\frac{d\overline{x}_j^s}{d\delta}\nu_i + \sum_{k=1}^{n}\psi_{z_i z_k}(\overline{x}(z), z)\nu_k\nu_i\right\} \tag{26}$$

$$= -\nu^T C\nu + \nu^T C\left.\frac{d\overline{x}^s}{d\delta}\right|_{\delta=0}. \tag{27}$$

Now, differentiating both sides of $\operatorname{grad}_x \phi(\overline{x}(z+\delta\nu)) - \operatorname{grad}_x \psi(\overline{x}(z+\delta\nu), z+\delta\nu) = 0$ yields

$$\sum_{j=1}^{n}\phi_{x_i x_j}\frac{d\overline{x}_j^s}{d\delta} - \sum_{k=1}^{n}\psi_{x_i x_k}\frac{d\overline{x}_k^s}{d\delta} - \sum_{l=1}^{n}\psi_{x_i z_l}\nu_l = 0 \qquad \forall\, i,$$

which yields

$$\frac{d\overline{x}^s}{d\delta} = -\left[\phi_{xx}(\overline{x}(z), z) - C\right]^{-1} C\nu. \tag{28}$$

Substituting (28) into (27), one obtains

$$\frac{d^2a^s}{d\delta^2} = \nu^T\left\{-C + C\left[C - \phi_{xx}(\overline{x}(z), z)\right]^{-1} C\right\}\nu. \tag{29}$$

Now, $\phi \in \mathcal{S}_\beta$ implies $-\phi_{xx}(\overline{x}(z)) - \beta < 0$, which implies that there exists $k_0 > 0$ such that

$$\nu^T\left[-\beta - \phi_{xx}(\overline{x}(z))\right]\nu < -k_0|\nu|^2 \qquad \forall\, \nu.$$

Combining this with the fact that $C + \beta < 0$ implies that

$$\nu^T[C - \phi_{xx}(\overline{x}(z))]\nu < -k_0|\nu|^2 \qquad \forall\, \nu.$$

Now, $C - \phi_{xx}(\overline{x}(z))$ being symmetric, negative definite implies that $C - \phi_{xx}(\overline{x}(z)) = U\Lambda U^T$ for some diagonal Λ (with all diagonal entries negative, of course) and some

real, unitary U. Consequently, $[C-\phi_{xx}(\overline{x}(z))]^{-1} = U\Lambda^{-1}U^T < 0$, which is negative definite. Then, since $\zeta^T[C-\phi_{xx}(\overline{x}(z))]^{-1}\zeta < 0$ for all $\zeta \in \mathbb{R}^n$, $\zeta \neq 0$, one sees that

$$\nu^T C[C-\phi_{xx}(\overline{x}(z))]^{-1}C\nu < 0$$

for all $\nu \in \mathbb{R}^n$, $\nu \neq 0$, and so

$$C[C-\phi_{xx}(\overline{x}(z))]^{-1}C < 0. \tag{30}$$

Let $d \doteq -C+\frac{1}{2}C[C-\phi_{xx}(\overline{x}(z))]^{-1}C$. Then, by (30), $C+d = \frac{1}{2}C[C-\phi_{xx}(\overline{x}(z))]^{-1}C < 0$. (Note that if d is not definite, then by addition of εI for arbitrarily small ε, one can make d definite without violating the inequalities.) Further, by (29) and (30),

$$\left.\frac{d^2a^s}{d\delta^2}\right|_{\delta=0} = \nu^T\left[d+\frac{1}{2}C[C-\phi_{xx}(\overline{x}(z))]^{-1}C\right]\nu < \nu^T d\nu,$$

which yields the result. □

Remark 3.5. Fix any $\delta > 0$ such that $\widetilde{V} \in \mathcal{G}_\delta$, and let $K_\delta = 2\frac{c_A(\gamma-\delta)^2}{c_\sigma^2}$ so that $0 \leq \widetilde{V}(x) \leq \frac{K_\delta}{2}|x|^2$. Then, using Lemma 3.4 and the monotonicity of the dual operations, the semiconvex dual, $\widetilde{a}$, of $\widetilde{V}$ is in $\mathcal{S}_d^- \cap \mathcal{G}_\delta^-$ for some $d \in \mathcal{D}_n$ such that $C+d<0$, where $\mathcal{G}_\delta^-$ is the space of semiconcave functions satisfying

$$0 \leq \widetilde{a}(z) \leq \tfrac{1}{2}z^T Q_\delta^- z,$$

where $Q_\delta^- \doteq C(C-K_\delta I)^{-1}K_\delta(C-K_\delta I)^{-1}C - K_\delta^2(C-K_\delta I)^{-1}C(C-K_\delta I)^{-1}$, and where the last term on the right is the dual of $\frac{K_\delta}{2}|x|^2$. Further, by the monotonicity of the dual operations, any $a \in \mathcal{G}_\delta^-$ has dual $V \in \mathcal{G}_\delta$.

LEMMA 3.6. *Let $\phi \in \mathcal{S}_\beta$ with semiconvex dual a. Suppose $b \in \mathcal{S}_d^-$ with $C+d<0$ is such that $\phi = \psi(x,\cdot)\odot b(\cdot)$. Then $b=a$.*

Proof. Note that $-b \in \mathcal{S}_d$. Therefore, for all $y \in \mathbb{R}^n$, we have $-b(y) = \max_{\zeta\in\mathbb{R}^n}[\psi(y,\zeta)+\alpha(\zeta)]$, or equivalently,

$$b(y) = -\max_{\zeta\in\mathbb{R}^n}[\psi(y,\zeta)+\alpha(\zeta)], \tag{31}$$

where for all $\zeta \in \mathbb{R}^n$,

$$\alpha(\zeta) = -\max_{y\in\mathbb{R}^n}[\psi(y,\zeta)+b(y)],$$

which by assumption

$$= -\phi(\zeta). \tag{32}$$

Combining (31) and (32), and then using (21), one obtains

$$b(y) = -\max_{\zeta\in\mathbb{R}^n}[\psi(y,\zeta)-\phi(\zeta)] = a(y) \qquad \forall\, y \in \mathbb{R}^n. \qquad \square$$

We will hereafter refer to the uniqueness of the semiconvex dual in the sense of Lemma 3.6 simply as the uniqueness of the semiconvex dual. It will be critical to the method that the functions obtained by application of the semigroups to the $\psi(\cdot,z)$ be semiconvex with less concavity than the $\psi(\cdot,z)$ themselves. In other words, we will want, for instance, $\widetilde{S}_\tau[\psi(\cdot,z)] \in \mathcal{S}_{-(c+\varepsilon I)}$ for some $\varepsilon > 0$. This is the subject of the

next theorem. Also, in order to keep the theorem statement clean, we will first state some definitions. Define

$$\lambda_D \doteq \min\{\lambda \in \mathbb{R} : \lambda \text{ is an eigenvalue of } D^m,\ m \in \mathcal{M}\}.$$

Note that the finiteness of $\mathcal{M}$ and positive definiteness of the D^m imply that $\lambda_D > 0$. Let

$$I_C \doteq \left\{ C \in \mathcal{D}_n \;\middle|\; \min_{|\nu|=1} \min_{m\in\mathcal{M}} \nu^T \left[A^{m\,T} C + C A^m \right] \nu \geq -\lambda_D/4 \right\}.$$

THEOREM 3.7. *Let $C \in I_C$. Then there exists $\overline{\tau} > 0$ and $\eta > 0$ such that for all $\tau \in [0, \overline{\tau}]$,*

$$\widetilde{S}_\tau[\psi(\cdot, z)],\ S^m_\tau[\psi(\cdot, z)] \in \mathcal{S}_{-(C+\eta I\tau)}.$$

Remark 3.8. If we restrict our attention to $C = cI$ for some $c \in \mathbb{R}$, then $C \in I_C$ if one takes $|c| \leq \lambda_D/[8 \max_{m\in\mathcal{M}} |A^m|]$, $c \neq 0$, and so the theorem condition can be satisfied.

Proof. We prove the result only for $\widetilde{S}_\tau$. The proof for S^m_τ is nearly identical and slightly simpler.

The first portion of the proof is similar to the proof of Theorem 2.6. Again, fix any $x, \nu \in \mathbb{R}^n$ with $|\nu| = 1$ and any $\delta > 0$. Fix $\tau > 0$ (to be specified below), and let $\varepsilon > 0$. Let $w^\varepsilon, \mu^\varepsilon$ be ε-optimal for $\widetilde{S}_\tau[\psi(\cdot, z)](x)$. Specifically, suppose $\widehat{\mathcal{I}}^\psi(x, \tau, w^\varepsilon, \mu^\varepsilon) \geq \widetilde{S}_\tau[\psi(\cdot, z)](x) - \varepsilon$, where

$$\widehat{\mathcal{I}}^\psi(x, \tau, w, \mu) \doteq \int_0^\tau l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \psi(\xi_\tau, z) \tag{33}$$

and ξ_t satisfies (12). For simplicity of notation, let $\widehat{V}^{\tau,\psi} = \widetilde{S}_\tau[\psi(\cdot, z)]$. Then

$$\begin{aligned} &\widehat{V}^{\tau,\psi}(x - \delta\nu) - 2\widehat{V}^{\tau,\psi}(x) + \widehat{V}^{\tau,\psi}(x + \delta\nu) \\ &\quad \geq \widehat{\mathcal{I}}^\psi(x - \delta\nu, \tau, w^\varepsilon, \mu^\varepsilon) - 2\widehat{\mathcal{I}}^\psi(x, \tau, w^\varepsilon, \mu^\varepsilon) + \widehat{\mathcal{I}}^\psi(x + \delta\nu, \tau, w^\varepsilon, \mu^\varepsilon) - 2\varepsilon. \end{aligned} \tag{34}$$

Let $\xi^\delta, \xi^0, \xi^{-\delta}, \Delta^+$ be as given in the proof of Theorem 2.6. Note that

$$\psi(\xi^\delta_\tau, z) - 2\psi(\xi^0_\tau, z) + \psi(\xi^{-\delta}_\tau, z) = (\Delta^+_\tau)^T C \Delta^+_\tau. \tag{35}$$

Note also that as in the proof of Theorem 2.6,

$$\frac{1}{2}\left[\xi^\delta_t D^{\mu^\varepsilon_t} \xi^\delta_t - 2\xi^0_t D^{\mu^\varepsilon_t} \xi^0_t + \xi^{-\delta}_t D^{\mu^\varepsilon_t} \xi^{-\delta}_t \right] = (\Delta^+_t)^T D^{\mu^\varepsilon_t} \Delta^+_t. \tag{36}$$

Combining (33), (34), (35), and (36), one obtains

$$\begin{aligned} &\widehat{V}^{\tau,\psi}(x - \delta\nu) - 2\widehat{V}^{\tau,\psi}(x) + \widehat{V}^{\tau,\psi}(x + \delta\nu) \\ &\quad \geq \int_0^\tau (\Delta^+_t)^T D^{\mu^\varepsilon_t} \Delta^+_t\, dt + (\Delta^+_\tau)^T C \Delta^+_\tau - 2\varepsilon. \end{aligned} \tag{37}$$

Further, noting as before that $\dot{\Delta}^+ = A^{\mu^\varepsilon_t} \Delta^+$, one has

$$\Delta^+_t = \exp\left\{ \int_0^t A^{\mu^\varepsilon_r}\, dr \right\} \delta\nu \doteq \Lambda^\varepsilon_t \delta\nu. \tag{38}$$

Combining (37) and (38), one has

$$\widehat{V}^{\tau,\psi}(x-\delta\nu) - 2\widehat{V}^{\tau,\psi}(x) + \widehat{V}^{\tau,\psi}(x+\delta\nu)$$
$$\geq \delta^2\left\{\int_0^\tau \nu^T(\Lambda_t^\varepsilon)^T D^{\mu_t^\varepsilon}\Lambda_t^\varepsilon\nu\,dt + \nu^T(\Lambda_\tau^\varepsilon)^T C\Lambda_\tau^\varepsilon\nu\right\} - 2\varepsilon.$$

However, since $\lambda_D > 0$ and $\Lambda_0^\varepsilon = I$, there exists $\bar\tau > 0$ such that for all $\tau \in (0,\bar\tau)$,

$$\geq \delta^2\left[\frac{\lambda_D}{2}\tau + \nu^T C\nu\right] + \delta^2\left[\nu^T(\Lambda_\tau^\varepsilon)^T C\Lambda_\tau^\varepsilon\nu - \nu^T C\nu\right] - 2\varepsilon. \tag{39}$$

Now define $g_t^\nu \doteq \nu^T(\Lambda_t^\varepsilon)^T C\Lambda_t^\varepsilon\nu - \nu^T C\nu$. Noting that $\frac{d}{dt}[\Lambda_t^\varepsilon] = A^{\mu_t^\varepsilon}\Lambda_t^\varepsilon$, one obviously has

$$\frac{dg^\nu}{dt} = \nu^T\left[(\Lambda_t^\varepsilon)^T(A^{\mu_t^\varepsilon})^T C\Lambda_t^\varepsilon + (\Lambda_t^\varepsilon)^T C A^{\mu_t^\varepsilon}\Lambda_t^\varepsilon\right]\nu,$$

and consequently,

$$g_t^\nu = \int_0^t \nu^T\left[(\Lambda_r^\varepsilon)^T(A^{\mu_r^\varepsilon})^T C\Lambda_r^\varepsilon + (\Lambda_r^\varepsilon)^T C A^{\mu_r^\varepsilon}\Lambda_r^\varepsilon\right]\nu\,dr. \tag{40}$$

Also, define

$$\bar g_t^\nu \doteq \int_0^t \nu^T\left[(A^{\mu_r^\varepsilon})^T C + C A^{\mu_r^\varepsilon}\right]\nu\,dr.$$

Noting that Λ_t^ε is continuous, and that $\Lambda_0^\varepsilon = I$, one sees that there exist $\hat\delta > 0$ and $\hat\tau > 0$ such that for all $\tau \in (0,\hat\tau)$,

$$|g_t^\nu - \bar g_t^\nu| \leq \frac{\hat\delta}{2}t^2 \qquad \forall\, t \in (0,\hat\tau). \tag{41}$$

Let $\tilde\tau = \min\{\bar\tau, \hat\tau, \frac{\lambda_D}{4\hat\delta}\}$. By (39) and the definition of g^ν,

$$\widehat{V}^{\tau,\psi}(x-\delta\nu) - 2\widehat{V}^{\tau,\psi}(x) + \widehat{V}^{\tau,\psi}(x+\delta\nu) \geq \delta^2\nu^T C\nu + \delta^2\left[\frac{\lambda_D}{2}\tau + \bar g_\tau^\nu - |g_\tau^\nu - \bar g_\tau^\nu|\right] - 2\varepsilon,$$

which, by the definition of $\bar g^\nu$ and (41)

$$\geq \delta^2\nu^T C\nu + \delta^2\left[\frac{\lambda_D}{2}\tau + \int_0^\tau \nu^T\left[(A^{\mu_r^\varepsilon})^T C + C A^{\mu_r^\varepsilon}\right]\nu\,dr - \frac{\hat\delta}{2}\tau^2\right] - 2\varepsilon,$$

which, by the definition of $\tilde\tau$ and the assumption that $C \in \mathcal{I}_C$,

$$\geq \delta^2\nu^T C\nu + \delta^2\frac{\lambda_D\tau}{8} - 2\varepsilon \qquad \forall\,\tau \in (0,\tilde\tau).$$

Since this is true for all $\varepsilon > 0$, letting $\eta = \lambda_D/8$, one has

$$\widehat{V}^{\tau,\psi}(x-\delta\nu) - 2\widehat{V}^{\tau,\psi}(x) + \widehat{V}^{\tau,\psi}(x+\delta\nu) \geq \delta^2\nu^T[C + \eta I\tau]\nu \qquad \forall\,\tau \in (0,\tilde\tau). \qquad \square$$

COROLLARY 3.9. *We may choose $C \in \mathcal{D}_n$ such that $\widetilde{V}, V^m \in \mathcal{S}_{-C}$, and such that with $\psi, \overline{\tau}, \eta$ as in the statement of Theorem* 3.7,

$$\widetilde{S}_\tau[\psi(\cdot,z)], S_\tau^m[\psi(\cdot,z)] \in \mathcal{S}_{-(C+\eta I\tau)} \qquad \forall\,\tau \in [0,\overline{\tau}].$$

Henceforth, we suppose C chosen so that the results of Corollary 3.9 hold. We also suppose τ, η chosen according to the corollary as well.

Now for each $z \in \mathbb{R}^n$, $\widetilde{S}_\tau[\psi(\cdot, z)] \in \mathcal{S}_{-(C+\eta I\tau)}$. Therefore, by Theorem 3.2,

$$\widetilde{S}_\tau[\psi(\cdot,z)](x) = \int_{\mathbb{R}^n}^{\oplus} \psi(x,y) \otimes \widetilde{\mathcal{B}}_\tau(y,z)\, dy = \psi(x,\cdot) \odot \widetilde{\mathcal{B}}_\tau(\cdot,z), \tag{42}$$

where for all $y \in \mathbb{R}^n$,

$$\widetilde{\mathcal{B}}_\tau(y,z) = -\int_{\mathbb{R}^n}^{\oplus} \psi(x,y) \otimes \big\{-\widetilde{S}_\tau[\psi(\cdot,z)](x)\big\}\, dx = \big\{\psi(\cdot,y) \odot [\widetilde{S}_\tau[\psi(\cdot,z)](\cdot)]^-\big\}^-. \tag{43}$$

It is handy to define the max-plus linear operator with "kernel" $\widetilde{\mathcal{B}}_\tau$ (where we do not rigorously define the term kernel, as it will not be needed here) as $\widehat{\widetilde{\mathcal{B}}}_\tau[\alpha](z) \doteq \widetilde{\mathcal{B}}_\tau(z,\cdot) \odot \alpha(\cdot)$ for all $\alpha \in \mathcal{S}_{-C}$.

PROPOSITION 3.10. *Let $\phi \in \mathcal{S}_{-C}$ with the semiconvex dual denoted by a. Define $\phi^1 = \widetilde{S}_\tau[\phi]$. Then $\phi^1 \in \mathcal{S}_{-(C+\eta I\tau)}$, and*

$$\phi^1(x) = \psi(x,\cdot) \odot a^1(\cdot),$$

where

$$a^1(x) = \widetilde{\mathcal{B}}_\tau(x,\cdot) \odot a(\cdot).$$

Proof. The proof that $\phi^1 \in \mathcal{S}_{-(C+\eta I\tau)}$ is similar to the proof of Theorem 3.7. Consequently, we prove only the second assertion:

$$\begin{aligned}
\phi^1(x) &= \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_\infty} \left[\int_0^\tau l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \phi(\xi_\tau)\right] \\
&= \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_\infty} \max_{z\in\mathbb{R}^n} \left[\int_0^\tau l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \psi(\xi_\tau,z) + a(z)\right] \\
&= \max_{z\in\mathbb{R}^n} \Big\{\widetilde{S}_\tau[\psi(\cdot,z)](x) + a(z)\Big\},
\end{aligned}$$

which by (42),

$$\begin{aligned}
&= \max_{z\in\mathbb{R}^n} \max_{y\in\mathbb{R}^n} \Big\{\psi(x,y) + \widetilde{\mathcal{B}}_\tau(y,z) + a(z)\Big\} \\
&= \int_{y\in\mathbb{R}^n}^{\oplus} \int_{z\in\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(y,z) \otimes a(z)\, dz \otimes \psi(x,y)\, dy \\
&= \int_{y\in\mathbb{R}^n}^{\oplus} a^1(x) \otimes \psi(x,y)\, dy. \qquad \square
\end{aligned}$$

THEOREM 3.11. *Let $V \in \mathcal{S}_{-C}$, let a be its semiconvex dual (with respect to ψ), and suppose $\widetilde{\mathcal{B}}_\tau(z,\cdot) \odot a(\cdot) \in \mathcal{S}_d^-$ with $C + d < 0$. Then $V = \widetilde{S}_\tau[V]$ if and only if*

$$a(z) = \max_{y\in\mathbb{R}^n} \big[\widetilde{\mathcal{B}}_\tau(z,y) + a(y)\big],$$

which of course

$$= \int_{\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(z,y) \otimes a(y)\, dy = \widetilde{\mathcal{B}}_\tau(z,\cdot) \odot a(\cdot) = \widehat{\widetilde{\mathcal{B}}}_\tau[a](z) \qquad \forall\, z \in \mathbb{R}^n.$$

Proof. Since a is the semiconvex dual of V, for all $x \in \mathbb{R}^n$,

$$\begin{aligned}
\psi(x,\cdot) \odot a(\cdot) &= V(x) = \widetilde{S}_\tau[V](x) \\
&= \widetilde{S}_\tau \left[\max_{z\in\mathbb{R}^n} \{\psi(\cdot, z) + a(z)\} \right](x) \\
&= \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_\infty} \left[\int_0^\tau l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \max_{z\in\mathbb{R}^n} \{\psi(\xi_\tau, z) + a(z)\} \right] \\
&= \max_{z\in\mathbb{R}^n} \left[a(z) + \sup_{w\in\mathcal{W}} \sup_{\mu\in\mathcal{D}_\infty} \left\{ \int_0^\tau l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \psi(\xi_\tau, z) \right\} \right] \\
&= \max_{z\in\mathbb{R}^n} \left\{ a(z) + \widetilde{S}_\tau[\psi(\cdot, z)](x) \right\} \\
&= \int_{\mathbb{R}^n}^{\oplus} a(z) \otimes \widetilde{S}_\tau[\psi(\cdot, z)](x)\, dz,
\end{aligned}$$

which by (42)

$$\begin{aligned}
&= \int_{\mathbb{R}^n}^{\oplus} a(z) \otimes \int_{\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(y, z) \otimes \psi(x, y)\, dy\, dz \\
&= \int_{\mathbb{R}^n}^{\oplus} \int_{\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(y, z) \otimes a(z) \otimes \psi(x, y)\, dy\, dz \\
&= \int_{\mathbb{R}^n}^{\oplus} \left[\int_{\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(y, z) \otimes a(z)\, dz \right] \otimes \psi(x, y)\, dy \\
&= \left[\int_{\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(\cdot, z) \otimes a(z)\, dz \right] \odot \psi(x, \cdot),
\end{aligned}$$

where by Proposition 3.10, the first term is in $\mathcal{S}_{-(C+\eta I\tau)}$. Combining this with Lemma 3.6, one has

$$a(y) = \int_{\mathbb{R}^n}^{\oplus} \widetilde{\mathcal{B}}_\tau(\cdot, z) \otimes a(z)\, dz = \widetilde{\mathcal{B}}_\tau(y, \cdot) \odot a(\cdot) \qquad \forall\, y \in \mathbb{R}^n.$$

The reverse implication follows by supposing $a(\cdot) = \widetilde{\mathcal{B}}_\tau(y, \cdot) \odot a(\cdot)$ and reordering the above argument. □

COROLLARY 3.12. *Value function $\widetilde{V}$ is given by $\widetilde{V}(x) = \psi(x, \cdot) \odot \widetilde{a}(\cdot)$, where $\widetilde{a}$ is the unique solution of*

$$\widetilde{a}(y) = \widetilde{\mathcal{B}}_\tau(y, \cdot) \odot \widetilde{a}(\cdot) \qquad \forall\, y \in= \mathbb{R}^n,$$

or equivalently, $\widetilde{a} = \widehat{\widetilde{\mathcal{B}}}_\tau[\widetilde{a}]$.

Proof. Combining Theorems 2.5 and 3.11 yields the assertion that $\widetilde{V}$ has this representation. The uniqueness follows from the uniqueness assertion of Theorem 2.5 and Lemma 3.6. □

Similarly, for each $m \in \mathcal{M}$ and $z \in \mathbb{R}^n$, we have $S_\tau^m[\psi(\cdot, z)] \in \mathcal{S}_{-(C+\eta I\tau)}$ and

$$S_\tau^m[\psi(\cdot, z)](x) = \psi(x, \cdot) \odot \mathcal{B}_\tau^m(\cdot, z) \qquad \forall\, x \in \mathbb{R}^n,$$

where

$$\mathcal{B}_\tau^m(y, z) = \left\{ \psi(\cdot, y) \odot \left[S_\tau^m[\psi(\cdot, z)] \right]^-(\cdot) \right\}^- \qquad \forall\, y \in \mathbb{R}^n.$$

As before, it will be handy to define the max-plus linear operator with "kernel" $\mathcal{B}_\tau^m$ as $\widehat{\mathcal{B}}_\tau^m[a](z) \doteq \mathcal{B}_\tau^m(z, \cdot) \odot a(\cdot)$ for all $a \in \mathcal{S}_{-C}$. Further, one also obtains analogous results (by similar proofs). In particular, one has the following.

THEOREM 3.13. *Let $V \in \mathcal{S}_{-C}$, and let a be its semiconvex dual (with respect to ψ). Then $V = S_\tau^m[V]$ if and only if*

$$a(z) = \mathcal{B}_\tau^m(z,\cdot) \odot a(\cdot) \qquad \forall\, z \in \mathbb{R}^n.$$

COROLLARY 3.14. *Each value function V^m is given by $V^m(x) = \psi(x,\cdot) \odot a^m(\cdot)$, where each a^m is the unique solution of the problem $a^m(y) = \mathcal{B}_\tau^m(y,\cdot) \odot a^m(\cdot)$ for all $y \in \mathbb{R}^n$.*

4. Discrete-time approximation. The method developed here will not involve any discretization over space. Of course this is obvious since otherwise one could not avoid the curse of dimensionality. The discretization will be over time where approximate μ processes will be constant over the length of each time-step.

We define the operator $\bar{S}_\tau$ on $\mathcal{G}_\delta$ by

$$\begin{aligned}\bar{S}_\tau[\phi](x) &= \sup_{w\in\mathcal{W}} \max_{m\in\mathcal{M}} \left[\int_0^\tau l^m(\xi_t^m) - \frac{\gamma^2}{2}|w_t|^2\, dt + \phi(\xi_\tau^m)\right](x)\\ &= \max_{m\in\mathcal{M}} S_\tau^m[\phi](x),\end{aligned}$$

where ξ^m satisfies (1). Let

$$\overline{\mathcal{B}}_\tau(y,z) \doteq \max_{m\in\mathcal{M}} \mathcal{B}_\tau^m(y,z) = \bigoplus_{m\in\mathcal{M}} \mathcal{B}_\tau^m(y,z) \qquad \forall\, y,z \in \mathbb{R}^n.$$

The corresponding max-plus linear operator is

$$\widehat{\overline{\mathcal{B}}}_\tau = \bigoplus_{m\in\mathcal{M}} \widehat{\mathcal{B}}_\tau^m.$$

LEMMA 4.1. *For all $z \in \mathbb{R}^n$, we have $\bar{S}_\tau[\psi(\cdot,z)] \in \mathcal{S}_{-(C+\eta I\tau)}$. Further,*

$$\bar{S}_\tau[\psi(\cdot,z)](x) = \psi(x,\cdot) \odot \overline{\mathcal{B}}_\tau(\cdot,z) \qquad \forall\, x \in \mathbb{R}^n. \tag{44}$$

Proof. We provide the proof of the last statement as follows:

$$\begin{aligned}\bar{S}_\tau[\psi(\cdot,z)](x) &= \max_{m\in\mathcal{M}} S_\tau^m[\psi(\cdot,z)](x) = \max_{m\in\mathcal{M}} \psi(x,\cdot) \odot \mathcal{B}_\tau^m(\cdot,z)\\ &= \max_{m\in\mathcal{M}} \max_{y\in\mathbb{R}^n} [\psi(x,y) + \mathcal{B}_\tau^m(y,z)] = \max_{y\in\mathbb{R}^n}\Big[\psi(x,y) + \max_{m\in\mathcal{M}} \mathcal{B}_\tau^m(y,z)\Big]\\ &= \psi(x,\cdot) \odot \Big[\max_{m\in\mathcal{M}} \mathcal{B}_\tau^m(\cdot,z)\Big]. \qquad \square\end{aligned}$$

We remark that, parameterized by τ, the operators $\bar{S}_\tau$ do not necessarily form a semigroup, although they do form a sub-semigroup (i.e., $\bar{S}_{\tau_1+\tau_2}[\phi](x) \le \bar{S}_{\tau_1}\bar{S}_{\tau_2}[\phi](x)$ for all $x \in \mathbb{R}^n$ and all $\phi \in \mathcal{S}_{-C}$). In spite of this, one does have $S_\tau^m \le \bar{S}_\tau \le \widetilde{S}_\tau$ for all $m \in \mathcal{M}$.

With τ acting as a time-discretization step size, let

$$\begin{aligned}\mathcal{D}_\infty^\tau = \Big\{&\mu : [0,\infty) \to \mathcal{M} \mid \text{for each } n \in \mathbf{N}\cup\{0\}, \text{ there exists } m_n \in \mathcal{M}\\ &\text{such that } \mu(t) = m_n \ \forall\ t \in [n\tau,(n+1)\tau)\Big\},\end{aligned}$$

and for $T = \bar{n}\tau$ with $\bar{n} \in \mathbf{N}$ define $\mathcal{D}_T^\tau$ similarly but with domain $[0, T)$ rather than $[0, \infty)$. Let $\mathcal{M}^{\bar{n}}$ denote the outer product of $\mathcal{M}$, $\bar{n}$ times. Let $T = \bar{n}\tau$, and define

$$\bar{\bar{S}}_T^\tau[\phi](x) = \max_{\{m_k\}_{k=0}^{\bar{n}-1} \in \mathcal{M}^{\bar{n}}} \left\{ \prod_{k=0}^{\bar{n}-1} S_\tau^{m_k} \right\} [\phi](x) = (\bar{S}_\tau)^{\bar{n}}[\phi](0),$$

where the Π notation indicates operator composition, and the superscript in the last expression indicates repeated application of $\bar{S}_\tau$, $\bar{n}$ times.

We will approximate $\widetilde{V}$ by solving $V = \bar{S}_\tau[V]$ via its dual problem $a = \widehat{\bar{\mathcal{B}}}_\tau[a]$ for small τ. Consequently, we will need to show that there exists a solution to $V = \bar{S}_\tau[V]$, that the solution is unique, and that it can be found by solving the dual problem. We begin with existence.

THEOREM 4.2. *Let*

$$\overline{V}(x) \doteq \lim_{N \to \infty} \bar{\bar{S}}_{N\tau}^\tau[0](x) \tag{45}$$

for all $x \in \mathbb{R}^n$, where 0 here represents the zero-function. Then, $\overline{V}$ satisfies

$$V = \bar{S}_\tau[V], \qquad V(0) = 0. \tag{46}$$

Further, $0 \le V^m \le \overline{V} \le \widetilde{V}$ for all $m \in \mathcal{M}$, and consequently, $\overline{V} \in \mathcal{G}_\delta$.

Proof. Note that

$$\begin{aligned} V^m(x) &= \lim_{N \to \infty} S_{N\tau}^m[0](x) \le \limsup_{N \to \infty} \bar{\bar{S}}_{N\tau}^\tau[0] \\ &\le \lim_{N \to \infty} \widetilde{S}_{N\tau}[0](x) = \widetilde{V}(x) \qquad \forall\, x \in \mathbb{R}^n. \end{aligned} \tag{47}$$

Also,

$$\begin{aligned} \bar{\bar{S}}_{(N+1)\tau}^\tau[0](x) &= \bar{\bar{S}}_{N\tau}^\tau[\bar{S}_\tau[0](\cdot)](x) \\ &= \sup_{\hat{w} \in \mathcal{W}} \sup_{\hat{\mu} \in \mathcal{D}_{N\tau}} \int_0^{N\tau} l^{\hat{\mu}_t}(\xi_t) - \frac{\gamma^2}{2} |\hat{w}_t|^2 \, dt \\ &\quad + \sup_{w \in \mathcal{W}} \max_{m \in \mathcal{M}} \int_{N\tau}^{(N+1)\tau} l^m(\xi_t) - \frac{\gamma^2}{2} |w_t|^2 \, dt, \end{aligned} \tag{48}$$

which by taking $w \equiv 0$

$$\ge \sup_{\hat{w} \in \mathcal{W}} \sup_{\hat{\mu} \in \mathcal{D}_{N\tau}} \int_0^{N\tau} l^{\hat{\mu}_t}(\xi_t) - \frac{\gamma^2}{2} |\hat{w}_t|^2 \, dt = \bar{\bar{S}}_{N\tau}^\tau[0](x), \tag{49}$$

which implies that $\bar{\bar{S}}_{N\tau}^\tau[0](x)$ is a monotonically increasing function of N. Since it is also bounded from above (by (47)), one finds

$$V^m(x) \le \lim_{N \to \infty} \bar{\bar{S}}_{N\tau}^\tau[0](x) \le \widetilde{V}(x) \qquad \forall\, x \in \mathbb{R}^n, \tag{50}$$

which also justifies the use of the limit definition of $\overline{V}$ in the statement of the theorem. In particular, one has $0 \le V^m \le \overline{V} \le \widetilde{V}$, and so $\overline{V} \in \mathcal{G}_\delta$.

Fix any $x \in \mathbb{R}^n$, and suppose there exists $\delta > 0$ such that

$$\overline{V}(x) \le \bar{S}_\tau[\overline{V}](x) - \delta. \tag{51}$$

However, by the definition of $\overline{V}$, given any $y \in \mathbb{R}^n$, there exists $N_\delta < \infty$ such that for all $N \geq N_\delta$,

$$\overline{V}(y) \leq \bar{\bar{S}}^{\tau}_{N_\delta \tau}[0](y) + \delta/4. \tag{52}$$

Combining (51) and (52), one finds after a small bit of work that

$$\overline{V}(x) \leq \bar{S}_\tau \big[\bar{\bar{S}}^{\tau}_{N_\delta \tau}[0] + \delta/2\big](x) - \delta,$$

which, using the max-plus linearity of $\bar{S}_\tau$,

$$= \bar{\bar{S}}^{\tau}_{(N_\delta+1)\tau}[0](x) - \delta/2$$

for all $N \geq N_\delta$. Consequently, $\overline{V}(x) \leq \lim_{N\to\infty} \bar{\bar{S}}^{\tau}_{N\tau}[0](x) - \delta/2$, which is a contradiction. Therefore, $\overline{V}(x) \geq \bar{S}_\tau[\overline{V}](x)$ for all $x \in \mathbb{R}^n$. The reverse inequality follows in a similar way. Specifically, fix $x \in \mathbb{R}^n$ and suppose there exists $\delta > 0$ such that

$$\overline{V}(x) \geq \bar{S}_\tau[\overline{V}](x) + \delta. \tag{53}$$

By the monotonicity of $\bar{\bar{S}}^{\tau}_{N\tau}$ with respect to N, for any $N < \infty$,

$$\overline{V}(x) \geq \bar{\bar{S}}^{\tau}_{N\tau}[0](x) \qquad \forall\, x \in \mathbb{R}^n.$$

By the monotonicity of $\bar{S}_\tau$ with respect to its argument (i.e., $\phi_1(x) \leq \phi_2(x)$ for all x implying $\bar{S}_\tau[\phi_1](x) \leq \bar{S}_\tau[\phi_2](x)$ for all x), this implies

$$\bar{S}_\tau[\overline{V}] \geq \bar{\bar{S}}^{\tau}_{(N+1)\tau}[0] \qquad \forall\, x \in \mathbb{R}^n. \tag{54}$$

Combining (53) and (54) yields

$$\overline{V}(x) \geq \bar{\bar{S}}^{\tau}_{(N+1)\tau}[0](x) + \delta.$$

Letting $N \to \infty$ yields a contradiction, and so $\overline{V} \leq \bar{S}_\tau[\overline{V}]$. □

The following result is immediate.

THEOREM 4.3.

$$\overline{V}(x) = \sup_{\mu\in\mathcal{D}^{\tau}_{\infty}} \sup_{w\in\mathcal{W}} \sup_{T\in[0,\infty)} \left[\int_0^T l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt\right],$$

where ξ_t satisfies (12).

THEOREM 4.4. *$\overline{V}(x) - \frac{1}{2}c_V|x|^2$ is strictly convex.*

Proof. The proof is identical to the proof of Theorem 2.6 with the exception that μ^ε is chosen from $\mathcal{D}^{\tau}_{\infty}$ instead of $\mathcal{D}_\infty$. □

Remark 4.5. From the choice of β in section 3, this immediately implies that $\overline{V} \in \mathcal{S}_\beta$, and of course since $C + \beta < 0$, that $\overline{V} \in \mathcal{S}_{-C}$.

We now address the uniqueness issue. Similar techniques to those used for V^m and $\widetilde{V}$ will prove uniqueness for (46) within $\mathcal{G}_\delta$. A slightly weaker type of result under weaker assumptions will be obtained first; this result is similar in form to that of [40].

Suppose $\overline{V}' \neq \overline{V}$, $\overline{V}' \in \mathcal{G}_\delta$ satisfies (46). This implies that for all $x \in \mathbb{R}^n$ and all $N < \infty$

$$\begin{aligned}\overline{V}'(x) &= \bar{\bar{S}}^{\tau}_{N\tau}[\overline{V}'](x)\\ &= \sup_{w\in\mathcal{W}}\sup_{\mu\in\mathcal{D}^{\tau}_{\infty}}\left\{\int_0^{N\tau} l^{\mu_t}(\xi_t)-\frac{\gamma^2}{2}|w_t|^2\,dt+\overline{V}'(\xi_{N\tau})\right\},\end{aligned}$$

which, by taking $w^0\equiv 0$ (with corresponding trajectory denoted by ξ^0),

$$\geq \overline{V}'(\xi^0_{N\tau}). \tag{55}$$

However, by (12), one has $\dot{\xi}^0 = A^{\mu_t}\xi^0$, and so $|\xi^0_t|\leq e^{-c_A t}|x|$ for all $t\geq 0$, which implies that $|\xi^0_{N\tau}|\to 0$ as $N\to\infty$. Consequently

$$\lim_{N\to\infty}\overline{V}'(\xi^0_{N\tau})=0. \tag{56}$$

Combining (55) and (56), one has

$$\overline{V}'(x)\geq 0 \qquad \forall\, x\in\mathbb{R}^n. \tag{57}$$

Also, by (46)

$$\overline{V}'(x)=\lim_{N\to\infty}\bar{\bar{S}}^{\tau}_{N\tau}[\overline{V}'](x) \qquad \forall\, x\in\mathbb{R}^n.$$

By (57) and the monotonicity of $\bar{\bar{S}}^{\tau}_{N\tau}$ with respect to its argument, this is

$$\geq \lim_{N\to\infty}\bar{\bar{S}}^{\tau}_{N\tau}[0](x)=\overline{V}(x). \tag{58}$$

By (57) and (59), one has the uniqueness result analogous to [40], which is as follows.

THEOREM 4.6. *$\overline{V}$ is the unique minimal, nonnegative solution to* (46).

The stronger uniqueness statement (making use of the quadratic bound on $l^{\mu_t}(x)$) is as follows. As with $V^m,\widetilde{V}$, the proof is similar to that in [35]. However in this case, there is a small difference in the proof, and this difference requires another lemma. Due to this difference in the case of $\overline{V}$, we include a sketch of the proof (but with the new lemma in full) in Appendix A.

THEOREM 4.7. *$\overline{V}$ is the unique solution of* (46) *within the class $\mathcal{G}_\delta$ for sufficiently small $\delta>0$. Further, given any $V\in\mathcal{G}_\delta$, we have $\lim_{N\to\infty}\bar{\bar{S}}^{\tau}_{N\tau}[V](x)=\overline{V}(x)$ for all $x\in\mathbb{R}^n$ (uniformly on compact sets).*

Henceforth, we let $\delta>0$ be sufficiently small such that $V^m,\widetilde{V},\overline{V}\in\mathcal{G}_\delta$ for all $m\in\mathcal{M}$.

THEOREM 4.8. *Let $V\in\mathcal{S}_{-C}$, and let a be its semiconvex dual. Then, if $\overline{\mathcal{B}}_\tau(y,\cdot)\odot a(\cdot)\in\mathcal{S}^-_d$, $V=\bar{S}_\tau[V]$ if and only if $a(y)=\overline{\mathcal{B}}_\tau(y,\cdot)\odot a(\cdot)$ for all $y\in\mathbb{R}^n$.*

Proof. By the semiconvex duality,

$$\begin{aligned}\psi(x,\cdot)\odot a(\cdot) &= V(x)=\bar{S}_\tau[V](x)\\ &= \bar{S}_\tau\Big[\max_{z\in\mathbb{R}^n}\{\psi(\cdot,z)+a(z)\}\Big](x),\end{aligned} \tag{59}$$

which, as in the first part of the proof of Theorem 3.11,

$$=\int^{\oplus}_{\mathbb{R}^n} a(z)\otimes\bar{S}_\tau[\psi(\cdot,z)](x)\,dz,$$

which, by Lemma 4.1,

$$= \int_{\mathbb{R}^n}^{\oplus} a(z) \otimes \int_{\mathbb{R}^n}^{\oplus} \psi(x,y) \otimes \overline{\mathcal{B}}_\tau(y,z)\, dy\, dz,$$

which, as in the latter part of the proof of Theorem 3.11,

$$= \left[\int_{\mathbb{R}^n}^{\oplus} \overline{\mathcal{B}}_\tau(\cdot,z) \otimes a(z)\, dz \right] \odot \psi(x,\cdot). \tag{60}$$

By Lemmas 3.4 and 3.6, this implies

$$a(y) = \overline{\mathcal{B}}_\tau(y,\cdot) \odot a(\cdot) \qquad \forall\, y \in \mathbb{R}^n.$$

Alternatively, if $a(y) = \overline{\mathcal{B}}_\tau(y,\cdot) \odot a(\cdot)$ for all y, then

$$V(x) = \psi(x,\cdot) \odot a(\cdot) = \left[\int_{\mathbb{R}^n}^{\oplus} \overline{\mathcal{B}}_\tau(\cdot,z) \otimes a(z)\, dz \right] \odot \psi(x,\cdot) \qquad \forall\, x \in \mathbb{R}^n,$$

which by (59)–(60) yields $V = \bar{S}_\tau[V]$. □

COROLLARY 4.9. *Value function $\overline{V}$ given by* (45) *is in $\mathcal{S}_\beta \subset \mathcal{S}_{-C}$ and has representation $\overline{V}(x) = \psi(x,\cdot) \odot \overline{a}(\cdot)$, where $\overline{a}$ is the unique solution in $\mathcal{S}_d^- \cap \mathcal{G}_\delta^-$ of*

$$\overline{a}(y) = \overline{\mathcal{B}}_\tau(y,\cdot) \odot \overline{a}(\cdot) \qquad \forall\, y \in \mathbb{R}^n, \tag{61}$$

or equivalently, $\overline{a} = \widehat{\overline{\mathcal{B}}}_\tau[\overline{a}]$.

Proof. The fact that $\overline{V} \in \mathcal{S}_\beta$ follows from Theorem 4.4 and the choice of β. By Theorem 4.7, $\overline{V} \in \mathcal{G}_\delta$ and is the unique solution of (46) in $\mathcal{G}_\delta$.

By Theorem 4.8, its semiconvex dual, $\overline{a}$, satisfies (61), and by Lemma 3.4, $\overline{a} \in \mathcal{S}_d^-$ for some $d \in \mathcal{D}_n$ such that $C + d < 0$. Suppose there is $\hat{a} \in \mathcal{S}_d^- \cap \mathcal{G}_\delta^-$ for some $\hat{d} \in \mathcal{D}_n$ such that $C + \hat{d} < 0$, and that $\hat{a}$ satisfies (61). Then, by Theorem 4.8 and Remark 3.5, its dual, $\widehat{V}$, is in $\mathcal{G}_\delta$ and $\widehat{V} = \bar{S}_\tau[\widehat{V}]$, $\widehat{V}(0) = 0$. By Theorem 4.7 then, $\widehat{V} = \overline{V}$. By Lemma 3.6, this implies that $\hat{a} = \overline{a}$. □

The following result on propagation of the semiconvex dual will also come in handy.

PROPOSITION 4.10. *Let $\phi \in \mathcal{S}_\beta \subset \mathcal{S}_{-C}$ with the semiconvex dual denoted by a. Define $\phi^1 = \bar{S}_\tau[\phi]$. Then $\phi^1 \in \mathcal{S}_{-(C+\eta I\tau)}$, and*

$$\phi^1(x) = \psi(x,\cdot) \odot a^1(\cdot),$$

where

$$a^1(y) = \overline{\mathcal{B}}_\tau(y,\cdot) \odot a(\cdot) \qquad \forall\, y \in \mathbb{R}^n.$$

Proof. The proof is similar to the proof of Proposition 3.10, and consequently some details are not included. To begin, as in the proof of Proposition 3.10, we note that the proof that $\phi^1 \in \mathcal{S}_{-(C+\eta I\tau)}$ is nearly identical to the proof of Theorem 3.7. In particular, fix any $x, \nu \in \mathbb{R}^n$ with $|\nu| = 1$ and any $\delta > 0$. Let $\overline{m} \in \mathcal{M}$ be optimal, and w^ε be ε-optimal, for $\bar{S}_\tau[\phi](x)$. That is, suppose $\overline{\mathcal{I}}^\phi(x,\tau,w^\varepsilon,\overline{m}) \geq \bar{S}_\tau[\phi](x) - \varepsilon$, where

$$\overline{\mathcal{I}}^\phi(x,\tau,w,m) \doteq \int_0^\tau l^{\overline{m}}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\, dt + \phi(\xi_\tau)$$

and ξ satisfies (1). Then

$$\begin{aligned} &\bar{S}_\tau[\phi](x-\delta\nu) - 2\bar{S}_\tau[\phi](x) + \bar{S}_\tau[\phi](x+\delta\nu) \\ &\quad \geq \overline{\mathcal{I}}^\phi(x-\delta\nu,\tau,w^\varepsilon,\overline{m}) - 2\overline{\mathcal{I}}^\phi(x,\tau,w^\varepsilon,\overline{m}) + \overline{\mathcal{I}}^\phi(x+\delta\nu,\tau,w^\varepsilon,\overline{m}) - 2\varepsilon. \end{aligned}$$

Let $\xi^\delta, \xi^0, \xi^{-\delta}$ satisfy the dynamics of (1) with inputs w^ε and $\overline{m}$, and with initial conditions $\xi_0^\delta = x + \delta\nu$, $\xi_0^0 = x$, and $\xi_0^{-\delta} = x - \delta\nu$, respectively. Letting $\Delta_t^+ \doteq \xi_t^\delta - \xi_t^0$, one finds

$$\phi(\xi_\tau^\delta) - 2\phi(\xi_\tau^0) + \phi(\xi_\tau^{-\delta}) \geq (\Delta_\tau^+)^T C \Delta_\tau^+$$

because $\phi \in \mathcal{S}_{-C}$. One then continues as in the proof of Theorem 3.7, but with $D^{\overline{m}}$ and $A^{\overline{m}}$ replacing $D^{\mu_t^\varepsilon}$ and $A^{\mu_t^\varepsilon}$, respectively. In particular, one has $\Lambda_t^\varepsilon = \exp\{A^{\overline{m}} t\}$. More important, one may use the same values of η and τ which were fixed in section 3.

Now we turn to the second assertion of the proposition. This follows exactly as in the proof of Proposition 3.10 with two minor exceptions: First, the supremum over $\mu \in \mathcal{D}_\infty$ is replaced by a maximum over $m \in \mathcal{M}$. Second, the use of (42) is replaced by the invocation of (44). □

We now show that one may approximate $\widetilde{V}$, the solution of $V = \widetilde{S}_\tau[V]$, to as accurate a level as one desires by solving $V = \bar{S}_\tau[V]$ for sufficiently small τ. Recall that if $V = \bar{S}_\tau[V]$, then it satisfies $V = \bar{\bar{S}}_{N\tau}^\tau[V]$ for all $N > 0$ (while $\widetilde{V}$ satisfies $V = \widetilde{S}_{N\tau}[V]$), and so this is essentially equivalent to introducing a discrete-time $\overline{\mu} \in \mathcal{D}_{N\tau}^\tau$ approximation to the μ process in $\widetilde{S}_{N\tau}$. The result will follow easily from the following technical lemma. The lemma uses the particular structure of our example class of problems as given by assumption block $(A.m)$. As the proof of the lemma is technical and long, it is delayed to Appendix B.

LEMMA 4.11. *Given $\hat{\varepsilon} \in (0, 1]$, $\overline{T} < \infty$, there exist $T \in [\overline{T}/2, \overline{T}]$ and $\tau > 0$ such that*

$$\widetilde{S}_T[V^m](x) - \bar{\bar{S}}_T^\tau[V^m](x) \leq \hat{\varepsilon}(1 + |x|^2) \qquad \forall\, x \in \mathbb{R}^n,\ \forall m \in \mathcal{M}.$$

We now obtain the main approximation result.

THEOREM 4.12. *Given $\overline{\varepsilon} > 0$ and $R < \infty$, there exists $\tau > 0$ such that*

$$\widetilde{V}(x) - \overline{\varepsilon} \leq \overline{V}(x) \leq \widetilde{V}(x) \qquad \forall\, x \in \overline{B}_R(0).$$

Proof. From Theorem 4.2, we have

$$0 \leq V^m(x) \leq \overline{V}(x) \leq \widetilde{V}(x) \leq \frac{c_A(\gamma - \delta)^2}{c_\sigma^2}|x|^2 \qquad \forall\, x \in \mathbb{R}^n. \tag{62}$$

Also, with $T = N\tau$ for any positive integer N,

$$\bar{\bar{S}}_{N\tau}^\tau[\phi] \leq \widetilde{S}_T[\phi] \qquad \forall\, \phi \in \mathcal{G}_\delta. \tag{63}$$

Further, by Theorem 2.5, given $\varepsilon > 0$ and $R < \infty$, there exists $\widehat{T} < \infty$ such that for all $T > \widehat{T}$ and all $m \in \mathcal{M}$,

$$\widetilde{S}_T[\widetilde{V}](x) - \varepsilon/2 \leq \widetilde{S}_T[V^m](x) \qquad \forall\, x \in \overline{B}_R(0). \tag{64}$$

By (64) and Lemma 4.11, given $\overline{\varepsilon} > 0$ and $R < \infty$, there exists $T \in [0, \infty)$, $\tau \in [0, T]$, where $T = N\tau$ for some integer N such that for all $|x| \leq R$,

$$\begin{aligned} \widetilde{V}(x) - \overline{\varepsilon} &= \widetilde{S}_T[\widetilde{V}](x) - \overline{\varepsilon} \\ &\leq \widetilde{S}_T[V^m](x) - \overline{\varepsilon}/2 \\ &\leq \bar{\bar{S}}_T^\tau[V^m](x), \end{aligned}$$

where $\hat{\varepsilon}(1 + R^2) = \overline{\varepsilon}/2$, and which, by (62) and the monotonicity of $\bar{\bar{S}}_T^\tau[\cdot]$,

$$\leq \bar{\widetilde{S}}^{\tau}_{T}[\overline{V}](x),$$

which, by (63),

$$\leq \widetilde{S}_{T}[\overline{V}](x),$$

which, by the monotonicity of $\widetilde{S}_{T}[\cdot]$,

$$\leq \widetilde{S}_{T}[\widetilde{V}](x) = \widetilde{V}(x).$$

Noting (from Theorem 4.7) that $\overline{V} = \bar{\widetilde{S}}^{\tau}_{T}[\overline{V}]$ completes the proof. □

Remark 4.13. For this class of systems (defined by assumption block $(A.m)$), we expect this result could be sharpened to

$$\widetilde{V}(x) \leq -\hat{\varepsilon}(1+|x|^2) \leq \overline{V}(x) \leq \widetilde{V}(x) \qquad \forall\, x \in \mathbb{R}^n$$

by sharpening Theorem 2.5. However, this type of result might be valid only for limited classes of systems, and so we have not pursued it here.

5. The algorithm. We now begin discussion of the actual algorithm.

Let $C \in \mathcal{I}_C$ such that $C - c_V I < 0$, and initialize with $\overline{V}^0(x) \doteq \frac{c_V}{2}|x|^2$. From Theorem 4.2, $\overline{V} = \lim_{N\to\infty} \bar{\widetilde{S}}^{\tau}_{N\tau}[\overline{V}^0]$. Given $\overline{V}^k$, let

$$\overline{V}^{k+1} \doteq \bar{S}_{\tau}[\overline{V}^k]$$

so that $\overline{V}^k = \bar{\widetilde{S}}^{\tau}_{k\tau}[\overline{V}^0]$ for all $k \geq 1$.

Let $\overline{a}^k$ be the semiconvex dual of $\overline{V}^k$ for all k. Since $\overline{V}^0 = \frac{c_V}{2}|x|^2$, one easily finds the quadratic $\overline{a}^0(\cdot)$. Note also that by Proposition 4.10,

$$\overline{a}^{k+1} = \overline{\mathcal{B}}_{\tau}(x,\cdot) \odot \overline{a}^k(\cdot) = \widehat{\overline{\mathcal{B}}}_{\tau}[\overline{a}^k]$$

for all $n \geq 0$.

Recall that

$$\overline{\mathcal{B}}_{\tau}(x,\cdot) \odot \overline{a}^k(\cdot) = \int^{\oplus}_{\mathbb{R}^n} \overline{\mathcal{B}}_{\tau}(x,y) \otimes \overline{a}^k(y)\, dy = \int^{\oplus}_{\mathbb{R}^n} \bigoplus_{m\in\mathcal{M}} \mathcal{B}^m_{\tau}(x,y) \otimes \overline{a}^k(y)\, dy$$

$$= \bigoplus_{m\in\mathcal{M}} \int^{\oplus}_{\mathbb{R}^n} \mathcal{B}^m_{\tau}(x,y) \otimes \overline{a}^k(y)\, dy = \bigoplus_{m\in\mathcal{M}} \left[\mathcal{B}^m_{\tau}(x,\cdot) \odot \overline{a}^k(\cdot)\right]. \tag{65}$$

By (65),

$$\overline{a}^1(x) = \bigoplus_{m\in\mathcal{M}} \widehat{a}^1_m(x), \quad \text{where} \tag{66}$$

$$\widehat{a}^1_m(x) \doteq \mathcal{B}^m_{\tau}(x,\cdot) \odot \overline{a}^0(\cdot) \qquad \forall\, m.$$

By (65) and (66),

$$\overline{a}^2(x) = \bigoplus_{m_2\in\mathcal{M}} \int^{\oplus}_{\mathbb{R}^n} \mathcal{B}^{m_2}_{\tau}(x,y) \otimes \left[\bigoplus_{m_1\in\mathcal{M}} \widehat{a}^1_{m_1}(y)\right] dy$$

$$= \bigoplus_{\{m_1,m_2\}\in\mathcal{M}\times\mathcal{M}} \int^{\oplus}_{\mathbb{R}^n} \mathcal{B}^{m_2}_{\tau}(x,y) \otimes \widehat{a}^1_{m_1}(y)\, dy.$$

Consequently,

$$\overline{a}^2(x) = \bigoplus_{\{m_1,m_2\}\in\mathcal{M}^2} \widehat{a}^2_{\{m_1,m_2\}}(x), \quad \text{where}$$

$$\widehat{a}^2_{\{m_1,m_2\}}(x) \doteq \mathcal{B}^{m_2}_\tau(x,\cdot)\odot \widehat{a}^1_{m_1}(\cdot) \qquad \forall\, m_1, m_2 \tag{67}$$

and $\mathcal{M}^2$ represents the outer product $\mathcal{M}\times\mathcal{M}$. Proceeding with this, one finds that in general,

$$\overline{a}^k(x) = \bigoplus_{\{m_i\}_{i=1}^k\in\mathcal{M}^k} \widehat{a}^k_{\{m_i\}_{i=1}^k}(x), \quad \text{where} \tag{68}$$

$$\widehat{a}^k_{\{m_i\}_{i=1}^k}(x) \doteq \mathcal{B}^{m_k}_\tau(x,\cdot)\odot \widehat{a}^{k-1}_{\{m_i\}_{i=1}^{k-1}}(\cdot) \qquad \forall\, \{m_i\}_{i=1}^k \in \mathcal{M}^k.$$

Of course one can obtain $\overline{V}^k$ from its dual as

$$\begin{aligned}
\overline{V}^k(x) &= \max_{y\in\mathbb{R}^n}[\psi(x,y)+\overline{a}^k(y)] \\
&= \max_{y\in\mathbb{R}^n}\left[\psi(x,y)+\max_{\{m_i\}_{i=1}^k\in\mathcal{M}^k}\widehat{a}^k_{\{m_i\}_{i=1}^k}(y)\right] \\
&= \max_{\{m_i\}_{i=1}^k\in\mathcal{M}^k}\left\{\max_{y\in\mathbb{R}^n}[\psi(x,y)+\widehat{a}^k_{\{m_i\}_{i=1}^k}(y)]\right\} \\
&\doteq \max_{\{m_i\}_{i=1}^k\in\mathcal{M}^k}\widehat{V}^k_{\{m_i\}_{i=1}^k}(x), \qquad (69)
\end{aligned}$$

where

$$\widehat{V}^k_{\{m_i\}_{i=1}^k} = \max_{y\in\mathbb{R}^n}[\psi(x,y)+\widehat{a}^k_{\{m_i\}_{i=1}^k}(y)] = \int_{\mathbb{R}^n}^{\oplus}\psi(x,y)\otimes\widehat{a}^k_{\{m_i\}_{i=1}^k}(y)\,dy. \tag{70}$$

The algorithm will consist of the forward propagation of the $\widehat{a}^k_{\{m_i\}_{i=1}^k}$ (according to (68)) from $k=0$ to some termination step $k=N$, followed by construction of the value as $\widehat{V}^k_{\{m_i\}_{i=1}^k}$ (according to (70)).

It is important to note that the computation of each $\widehat{a}^k_{\{m_i\}_{i=1}^k}$ is analytical. We will indicate the actual analytical computations.

By the linear/quadratic nature of the m-indexed systems, we find that the $S^m_\tau[\psi(\cdot,z)]$ take the form

$$S^m_\tau[\psi(\cdot,z)](x) = \tfrac{1}{2}(x-\Lambda^m_\tau z)^T P^m_\tau (x-\Lambda^m_\tau) + \tfrac{1}{2} z^T R^m_\tau z,$$

where the time-dependent $n\times n$ matrices P^m_t, Λ^m_t, and R^m_t satisfy $P^m_0 = C$, $\Lambda^m_0 = I$, $R^m_0 = 0$:

$$\begin{aligned}
\dot{P}^m &= (A^m)^T P^m + P^m A^m + D^m + P^m \Sigma^m P^m, \\
\dot{\Lambda}^m &= \left[(P^m)^{-1} D^m - A^m\right]\Lambda^m, \\
\dot{R}^m &= (\Lambda^m)^T D^m \Lambda^m.
\end{aligned} \tag{71}$$

We note that each of the $P^m_\tau, \Lambda^m_\tau, R^m_\tau$ need only be computed once.

Next, one computes each quadratic function $\mathcal{B}^m_\tau(x,z)$ (one time only) as follows. One has

$$\mathcal{B}^m_\tau = -\max_{y\in\mathbb{R}^n}\left\{\psi(y,x) - S^m_\tau[\psi(\cdot,z)](y)\right\},$$

which, by the above,

(72)
$$= \min_{y\in\mathbb{R}^n} \left\{ \tfrac{1}{2}(y-x)^T C(y-x) + \tfrac{1}{2}(y-\Lambda_\tau^m z)^T P_\tau^m (y-\Lambda_\tau^m z) + \tfrac{1}{2} z^T R_\tau^m z \right\}.$$

Recall that by Theorem 3.7, this has a finite minimum ($P^m - (C + \eta I\tau)$ positive definite). Taking the minimum in (73), one has

$$\mathcal{B}_\tau^m(x,z) = \tfrac{1}{2}\left[x^T M_{1,1}^m x + x^T M_{1,2}^m z + z^T (M_{1,2}^m)^T x + z^T M_{2,2}^m z\right],$$

where, with shorthand notation $D_\tau \doteq (P_\tau^m - C)^{-1}$,

(73)
$$M_{1,1}^m = \left[C D_\tau^{-1} P_\tau^m D_\tau^{-1} C - (D_\tau^{-1} C + I)^T C (D_\tau^{-1} C + I)\right],$$
(74)
$$M_{1,2}^m = \left[(D_\tau^{-1} C + I)^T C D_\tau^{-1} P_\tau^m - C D_\tau^{-1} P_\tau^m (D_\tau^{-1} P_\tau^m - I)\right] \Lambda_\tau^m,$$
(75)
$$M_{2,2}^m = (\Lambda_\tau^m)^T \left[(D_\tau^{-1} P_\tau^m - I)^T P_\tau^m (D_\tau^{-1} P_\tau^m - I) - P_\tau^m D_\tau^{-1} C D_\tau^{-1} P_\tau^m\right] \Lambda_\tau^m + R_\tau^m.$$

Note that given the $P_\tau^m, \Lambda_\tau^m, R_\tau^m$, the $\mathcal{B}_\tau^m$ are quadratic functions with analytical expressions for their coefficients. Also note that all the matrices in the definition of $\mathcal{B}_\tau^m$ may be precomputed.

Now let us write the (quadratic) $\widehat{a}^k_{\{m_i\}_{i=1}^k}$ in the form

$$\widehat{a}^k_{\{m_i\}_{i=1}^k}(x) = \tfrac{1}{2}\left(x - \widehat{z}^k_{\{m_i\}_{i=1}^k}\right)^T \widehat{Q}^k_{\{m_i\}_{i=1}^k}\left(x - \widehat{z}^k_{\{m_i\}_{i=1}^k}\right) + \widehat{r}^k_{\{m_i\}_{i=1}^k}.$$

Then, for each m_{k+1},

$$\begin{aligned}
\widehat{a}^{k+1}_{\{m_i\}_{i=1}^{k+1}} &= \max_{z\in\mathbb{R}^n}\left\{\mathcal{B}_\tau^{m_{k+1}}(x,z) + \widehat{a}^k_{\{m_i\}_{i=1}^k}(z)\right\} \\
&= \max_{z\in\mathbb{R}^n}\Bigg\{ \tfrac{1}{2}\left[x^T M_{1,1}^m x + x^T M_{1,2}^m z + z^T (M_{1,2}^m)^T x + z^T M_{2,2}^m z\right] \\
&\quad + \tfrac{1}{2}\left(x - \widehat{z}^k_{\{m_i\}_{i=1}^k}\right)^T \widehat{Q}^k_{\{m_i\}_{i=1}^k}\left(x - \widehat{z}^k_{\{m_i\}_{i=1}^k}\right) + \widehat{r}^k_{\{m_i\}_{i=1}^k}\Bigg\} \\
&= \tfrac{1}{2}\left(x - \widehat{z}^{k+1}_{\{m_i\}_{i=1}^{k+1}}\right)^T \widehat{Q}^{k+1}_{\{m_i\}_{i=1}^{k+1}}\left(x - \widehat{z}^{k+1}_{\{m_i\}_{i=1}^{k+1}}\right) + \widehat{r}^{k+1}_{\{m_i\}_{i=1}^{k+1}}, \qquad (76)
\end{aligned}$$

where

(77)
$$\begin{aligned}
\widehat{Q}^{k+1}_{\{m_i\}_{i=1}^{k+1}} &= M_{1,1}^{m_{k+1}} - M_{1,2}^{m_{k+1}} \widehat{D}\left(M_{1,2}^{m_{k+1}}\right)^T, \\
\widehat{z}^{k+1}_{\{m_i\}_{i=1}^{k+1}} &= -\left(\widehat{Q}^{k+1}_{\{m_i\}_{i=1}^{k+1}}\right)^{-1} M_{1,2}^{m_{k+1}} \widehat{E}, \\
\widehat{r}^{k+1}_{\{m_i\}_{i=1}^{k+1}} &= \widehat{r}^k_{\{m_i\}_{i=1}^k} + \tfrac{1}{2}\widehat{E}^T M_{2,2}^m \widehat{z}^k_{\{m_i\}_{i=1}^k} - \tfrac{1}{2}\left(\widehat{z}^{k+1}_{\{m_i\}_{i=1}^{k+1}}\right)^T \widehat{Q}^{k+1}_{\{m_i\}_{i=1}^{k+1}} \widehat{z}^{k+1}_{\{m_i\}_{i=1}^{k+1}}, \\
\widehat{D} &= \left(M_{2,2}^{m_{k+1}} + \widehat{Q}^k_{\{m_i\}_{i=1}^k}\right)^{-1}, \\
\widehat{E} &= \widehat{D}\widehat{Q}^k_{\{m_i\}_{i=1}^k} \widehat{z}^k_{\{m_i\}_{i=1}^k}.
\end{aligned}$$

Thus we have the analytical expression for the propagation of each (quadratic) $\widehat{a}^k_{\{m_i\}_{i=1}^k}$ function. Specifically, we see that the propagation of each $\widehat{a}^k_{\{m_i\}_{i=1}^k}$ amounts to a set of matrix multiplications (and an inverse). Note that for the purely quadratic constituent Hamiltonians considered here (without terms that are linear or constant in

the state and gradient variables), one will have $\widehat{z}^k_{\{m_i\}_{i=1}^k} = 0$ and $\widehat{r}^k_{\{m_i\}_{i=1}^k} = 0$, and so computation of these terms is not necessary (unless one adds linear and/or constant terms).

At each step k, the semiconvex dual $\overline{a}^k$ of $\overline{V}^k$ is represented as the finite set of functions

$$\widehat{\mathcal{A}}_k \doteq \left\{ \widehat{a}^k_{\{m_i\}_{i=1}^k} \,|\, m_i \in \mathcal{M} \ \forall i \in \{1, 2, \ldots, k\} \right\},$$

where this is equivalently represented as the set of triples

$$\widehat{\mathcal{Q}}_k \doteq \left\{ \left(\widehat{Q}^k_{\{m_i\}_{i=1}^k}, \widehat{z}^k_{\{m_i\}_{i=1}^k}, \widehat{r}^k_{\{m_i\}_{i=1}^k} \right) | \, m_i \in \mathcal{M} \ \forall i \in \{1, 2, \ldots, k\} \right\}.$$

At any desired stopping time, one can recover a representation of $\overline{V}^k$ as

$$\widehat{\mathcal{V}}_k \doteq \left\{ \widehat{V}^k_{\{m_i\}_{i=1}^k} \,|\, m_i \in \mathcal{M} \ \forall i \in \{1, 2, \ldots, k\} \right\},$$

where these $\widehat{V}^k_{\{m_i\}_{i=1}^k}$ are also quadratics. In fact, recall

$$\begin{aligned}
\overline{V}^k(x) &= \max_{z \in \mathbb{R}^n} [\overline{a}^k(z) + \psi(x, z)] \\
&= \max_{\{m_i\}_{i=1}^k} \max_{z \in \mathbb{R}^n} \left[\tfrac{1}{2} (z - \widehat{z}^k_{\{m_i\}_{i=1}^k})^T \widehat{Q}^k_{\{m_i\}_{i=1}^k} (z - \widehat{z}^k_{\{m_i\}_{i=1}^k}) + \widehat{r}^k_{\{m_i\}_{i=1}^k} + \tfrac{c}{2} |x - z|^2 \right] \\
&\doteq \max_{\{m_i\}_{i=1}^k} \tfrac{1}{2} (x - \widehat{x}^k_{\{m_i\}_{i=1}^k})^T \widehat{P}^k_{\{m_i\}_{i=1}^k} (x - \widehat{x}^k_{\{m_i\}_{i=1}^k}) + \widehat{\rho}^k_{\{m_i\}_{i=1}^k} \\
&\doteq \bigoplus_{\{m_i\}_{i=1}^k} \widehat{V}^k_{\{m_i\}_{i=1}^k}(x),
\end{aligned}$$

where with $C \doteq cI$,

(78)

$$\begin{aligned}
\widehat{P}^k_{\{m_i\}_{i=1}^k} &= C\widehat{F}\widehat{Q}^k_{\{m_i\}_{i=1}^k}\widehat{F}C + (\widehat{F}C - I)^T C(\widehat{F}C - I), \\
\widehat{x}^k_{\{m_i\}_{i=1}^k} &= -\left(\widehat{P}^k_{\{m_i\}_{i=1}^k}\right)^{-1} \left[C\widehat{F}\widehat{Q}^k_{\{m_i\}_{i=1}^k}\widehat{G} + (\widehat{F}C - I)^T C\widehat{F}\widehat{Q}^k_{\{m_i\}_{i=1}^k} \right] \widehat{z}^k_{\{m_i\}_{i=1}^k}, \\
\widehat{\rho}^k_{\{m_i\}_{i=1}^k} &= \widehat{r}^k_{\{m_i\}_{i=1}^k} + \tfrac{1}{2} \left(\widehat{z}^k_{\{m_i\}_{i=1}^k}\right)^T \left[\widehat{G}^T \widehat{Q}^k_{\{m_i\}_{i=1}^k} \widehat{G} + \widehat{Q}^k_{\{m_i\}_{i=1}^k} \widehat{F}C\widehat{F}\widehat{Q}^k_{\{m_i\}_{i=1}^k} \right] \widehat{z}^k_{\{m_i\}_{i=1}^k}, \\
\widehat{F} &\doteq (\widehat{Q}^k_{\{m_i\}_{i=1}^k} + C)^{-1},
\end{aligned}$$

and

$$\widehat{G} \doteq (\widehat{F}\widehat{Q}^k_{\{m_i\}_{i=1}^k} - I).$$

Thus, $\overline{V}^k$ has the representation as the set of triples

$$\mathcal{P}_k \doteq \left\{ \left(\widehat{P}^k_{\{m_i\}_{i=1}^k}, \widehat{x}^k_{\{m_i\}_{i=1}^k}, \widehat{\rho}^k_{\{m_i\}_{i=1}^k} \right) | \, m_i \in \mathcal{M} \ \forall i \in \{1, 2, \ldots, k\} \right\}. \tag{79}$$

We note that the triples which comprise $\mathcal{P}_k$ are obtained from the triples

$$\left(\widehat{Q}^k_{\{m_i\}_{i=1}^k}, \widehat{z}^k_{\{m_i\}_{i=1}^k}, \widehat{r}^k_{\{m_i\}_{i=1}^k} \right)$$

by matrix multiplications and an inverse. The transference from triples

$$\left(\widehat{Q}^k_{\{m_i\}_{i=1}^k}, \widehat{z}^k_{\{m_i\}_{i=1}^k}, \widehat{r}^k_{\{m_i\}_{i=1}^k}\right)$$

to triples $(\widehat{P}^k_{\{m_i\}_{i=1}^k}, \widehat{x}^k_{\{m_i\}_{i=1}^k}, \widehat{\rho}^k_{\{m_i\}_{i=1}^k})$ need only be done once, which is at the termination of the algorithm propagation. Again, in the purely quadratic class of problems addressed here, and with the pure quadratic initialization, the $\widehat{x}^k_{\{m_i\}_{i=1}^k}$ and $\widehat{\rho}^k_{\{m_i\}_{i=1}^k}$ terms will be zero. We note that (79) is our approximate solution of the original control problem/HJB PDE.

The errors are due to our approximation of $\widetilde{V}$ by $\overline{V}$ (see Theorem 4.12 and Remark 4.13) and to the approximation of $\overline{V}$ by the prelimit $\overline{V}^N$ for stopping time $k = N$. Neither of these errors is related to the space dimension. The errors in $|\widetilde{V} - \overline{V}|$ are dependent on the step size τ. The errors in $|\overline{V}^N - \overline{V}| = |\bar{\bar{S}}^\tau_{N\tau}[0] - \overline{V}|$ are due to premature termination in the limit $\overline{V} = \lim_{N\to\infty} \bar{\bar{S}}^\tau_{N\tau}[0]$. The computation of each triple $(\widehat{P}^k_{\{m_i\}_{i=1}^k}, \widehat{x}^k_{\{m_i\}_{i=1}^k}, \widehat{\rho}^k_{\{m_i\}_{i=1}^k})$ grows as the cube of the space dimension (due to the matrix operations). Thus one avoids the curse of dimensionality. Of course if one then chooses to compute $\overline{V}^N(x)$ for all x on some grid over, say, a rectangular region in $\mathbb{R}^n$, then by definition one has exponential growth in this computation as the space dimension increases. We stress that one does not need to compute $\overline{V}^N \simeq \widetilde{V}$ at each such point.

However, the curse of dimensionality is replaced by another type of rapid computational cost growth. Here, we refer to this as the curse of complexity. If $\#\mathcal{M} = 1$, then all the computations of our algorithm (excepting the solution of the Riccati equation) are unnecessary, and we *informally* refer to this as complexity one. When there are $M = \#\mathcal{M}$ such quadratics in the Hamiltonian, $\widetilde{H}$, we say it has complexity M. Note that

$$\#\left\{\widehat{V}^k_{\{m_i\}_{i=1}^k} \,|\, m_i \in \mathcal{M}\ \forall i \in \{1, 2, \ldots, k\}\right\} \sim M^N.$$

For large N, this is indeed a large number. (We very briefly discuss means for reducing this in the next section.) Nevertheless, for small values of M, we obtain a very rapid solution of such nonlinear HJB PDEs, as will be indicated in the examples to follow. Further, the computational cost growth in space dimension n is limited to cubic growth. We emphasize that the existence of an algorithm avoiding the curse of dimensionality is significant regardless of the practical issues.

6. Practical issues. The bulk of this paper develops an algorithm which avoids the curse of dimensionality. However, the curse of complexity is also a formidable barrier. The purpose of the paper is to bring to light the existence of this class of algorithms. Considering the long development of finite element methods, it is clear that the development of highly efficient methods from this new class could be a further substantial achievement. (Nevertheless, some impressive computational times are indicated in the next section.) In this section, we briefly indicate some practical heuristics that have been helpful and outline the actual steps in an implementation of the basic algorithm.

6.1. Pruning. The number of quadratics in $\mathcal{Q}_k$ grows exponentially in k. However, in practice (for the cases we have tried) we have found that relatively few of these actually contribute to $\overline{V}^k$. Thus it would be very useful to prune the set.

Note that if

$$\widehat{a}^k_{\{\hat{m}_i\}_{i=1}^k}(x) \le \bigoplus_{\{m_i\}_{i=1}^k \neq \{\hat{m}_i\}_{i=1}^k} \widehat{a}^k_{\{m_i\}_{i=1}^k}(x) \qquad \forall\, x \in \mathbb{R}^n, \tag{80}$$

then

$$\int_{\mathbb{R}^n}^{\oplus} \overline{\mathcal{B}}_\tau(x,z) \otimes \overline{a}^k(z)\, dz \le \int_{\mathbb{R}^n}^{\oplus} \overline{\mathcal{B}}_\tau(x,z) \otimes \left[\bigoplus_{\{m_i\}_{i=1}^k \neq \{\hat{m}_i\}_{i=1}^k} \widehat{a}^k_{\{m_i\}_{i=1}^k}(z) \right] dz.$$

Consequently $\widehat{a}^k_{\{\hat{m}_i\}_{i=1}^k}$ will play no role whatsoever in the computation of $\overline{V}^k$. Further, it is easy to show that the progeny of $\widehat{a}^k_{\{\hat{m}_i\}_{i=1}^k}$ (i.e., those $\widehat{a}^{k+j}_{\{m_i\}_{i=1}^{k+j}}$ for which $\{m_i\}_{i=1}^k = \{\hat{m}_i\}_{i=1}^k$) never contribute either. Thus, one may prune such $\widehat{a}^k_{\{\hat{m}_i\}_{i=1}^k}$ without any loss of accuracy. This shrinks not only the current $\mathcal{Q}_k$, but also the growth of the future $\mathcal{Q}_{k+j}$.

In the examples to follow, we pruned $\widehat{a}^k_{\{\hat{m}_i\}_{i=1}^k}$ if there existed a single sequence $\{\tilde{m}_i\}_{i=1}^k$ such that $\widehat{a}^k_{\{\hat{m}_i\}_{i=1}^k}(x) \le \widehat{a}^k_{\{\tilde{m}_i\}_{i=1}^k}(x)$ for all x. This significantly reduced the growth in the size of $\mathcal{Q}_k$. However, it clearly failed to prune anywhere near the number of elements that could be pruned according to condition (80), and thus much greater computational reduction might be possible. This would require an ability to determine when a quadratic was dominated by the maximum of a set of other quadratic functions.

Also in the examples to follow, an additional heuristic pruning technique was applied for a number of iterations to delay hitting the curse of complexity growth rate. A function $\widehat{a}^k_{\{m_i\}_{i=1}^k}$ was pruned if it did not dominate at least one of the corners of the unit cube. Specifically, let $\mathcal{C} = \{x^j\}$ be the corners of the unit cube. The set of functions was pruned down to a subset of $L \le 2^n$ functions, $\{\widehat{a}^k_{\{\hat{m}_i^l\}_{i=1}^k} \,|\, l \le L\}$, such that $\overline{a}^k(x^j) = \max_{l \le L} \widehat{a}^k_{\{\hat{m}_i^l\}_{i=1}^k}(x^j)$ for all $x^j \in \mathcal{C}$. This introduces a component of the calculations which is subject to curse of dimensionality growth, but in the examples run so far it reduced the computations over what they were needed without the heuristic. (Also, the curse of dimensionality growth due to this heuristic is 2^n rather than on the order of 200^n, as in the discussion of other methods in section 1.)

6.2. Initialization. It is also easy to see that one may initialize with an arbitrary quadratic function less than an $\overline{a}^k(x)$ rather than with $\overline{a}^0 \equiv 0$. Significant savings were obtained by initializing with a set of $M = \#\mathcal{M}$ quadratics, $\{a^m(x)\}$ where the a^m were the convex duals of the V^m (which were each obtained by the solution of the corresponding Riccati equation). With $\overline{a}^0(z) \doteq \bigoplus_{m \in \mathcal{M}} a^m(z)$, one starts much closer to the final solution, and so the number of steps where one is encountering the curse of complexity is greatly reduced.

6.3. Pseudocode for the algorithm. In this short section, we briefly indicate the actual steps that one would code in an instantiation of the algorithm.

1. Choose a time-step size, τ, and number of steps, K. (We do not address error analysis and stopping-time criteria in this paper.)
2. For each $m \in \mathcal{M}$, compute P^m_τ from (71). Next, for each $m \in \mathcal{M}$, compute $M^m_{1,1}$, $M^m_{1,2}$, and $M^m_{2,2}$ from (73), (74), and (75), respectively. These are used in each iteration update below.

3. Initialize the iteration. One may initialize with $\overline{a}^0(x) \doteq 0$, which is $\widehat{\mathcal{Q}}_0 = \{\widehat{Q}_1^0\}$ with $\widehat{Q}_1^0 = 0$ (the $n \times n$ matrix of zeros). Note that in this pseudocode, we will index the $\widehat{Q}^k$ by a generic subscript rather than by the sequences $\{m_i\}_{i=1}^k$, as this is more convenient in software. Although this is a simple initialization, the computational time is hugely improved through the use of the initialization described in section 6.2. In this latter case, we first compute (approximately) the $P_\infty^m \doteq \lim_{t\to\infty} P_t^m$ from (71). The initialization is then $\widehat{\mathcal{Q}}_0 = \{\widehat{Q}_j^0\}_{j=1}^M$, where each $\widehat{Q}_j^0$ is obtained from the corresponding P_∞^j, by the dual operation, and in particular is given by

$$\widehat{Q}_j^0 = C(C - P_\infty^j)^{-1} P_\infty^j (C - P_\infty^j)^{-1} C - P_\infty^j (C - P_\infty^j)^{-1} C (C - P_\infty^j)^{-1} P_\infty^j.$$

4. Perform the basic iteration step. That is, given $\widehat{\mathcal{Q}}_k = \{\widehat{Q}_j^k\}_{j=1}^{J_k}$, compute $\widehat{\mathcal{Q}}_{k+1}$ as follows:
   (a) Start with $j = 1$ and $m = 1$. Let $\ell = 1$.
   (b) (iteration-subloop): Obtain $\widehat{Q}_\ell^{k+1}$ from update equation (78), that is,

$$\widehat{Q}_\ell^{k+1} = M_{1,1}^m - M_{1,2}^m \left(M_{2,2}^m + \widehat{Q}_j^k \right)^{-1} \left(M_{1,2}^m \right)^T.$$

   (c) Let $\ell = \ell + 1$. If $m < M$, set $m = m + 1$, and go to step 4(b). If $m = M$ and $j < J_k$, set $m = 1$, $j = j + 1$, and go to step 4(b). If $m = M$ and $j = J_k$, set $J_{K+1} = \ell - 1$; we are done with the iteration step.
5. Repeat step 4 K times.
6. Recover the solution approximation from the dual matrices. That is, given $\widehat{\mathcal{Q}}_K = \{\widehat{Q}_j^K\}_{j=1}^{J_K}$, compute $\mathcal{P}_k = \{\widehat{P}_j^k\}_{j=1}^{J_K}$ from (78). The solution approximation is the pointwise maximum $\overline{V}(x) = \max_{j \le J_K} \frac{1}{2} x^T \widehat{P}_j^K x$.

Remark 6.1. We emphasize that pruning techniques, such as those of section 6.1 are critical to rapid computational rates, but this is still an open area of research, and we leave instantiation of such to the intrepid researcher.

7. Examples. A number of examples have so far been tested. In these tests, the computational speeds were very great. This is due to the fact that $M = \#\mathcal{M}$ was small. The algorithm as described above was coded in MATLAB. This includes the very simple pruning technique and initialization discussed in the previous section. The quoted computational times were obtained with a standard 2001 PC. The times correspond to the times to compute $\mathcal{V}_N$ or, equivalently, $\mathcal{P}_N$. The plots below require one to compute the value function and/or gradients pointwise on planes in the state space. These plotting computations are not included in the quoted computational times.

We will briefly indicate the results of three similar examples with state-space dimensions of 2, 3, and 4. The number of constituent linear/quadratic Hamiltonians for each of them is 3. The structures of the dynamics are similar for each of them so as to focus on the change in dimension.

Example 1. The first case has constituent Hamiltonians with the A^m given by

$$A^1 = \begin{bmatrix} -1.0 & 0.5 \\ 0.1 & -1.0 \end{bmatrix}, \quad A^2 = (A^1)^T, \quad A^3 = \begin{bmatrix} -1.0 & 0.5 \\ 0.5 & -1.9 \end{bmatrix}.$$

The D^m and Σ^m are simply

$$D^1 = D^2 = D^3 = \begin{bmatrix} 1.5 & 0.2 \\ 0.2 & 1.5 \end{bmatrix}$$

and

$$\Sigma^1 = \Sigma^2 = \Sigma^3 = \begin{bmatrix} 0.27 & -0.01 \\ -0.01 & 0.27 \end{bmatrix}.$$

Figure 1 depicts the value function and first partial derivative (computed by a simple first-difference on the grid points) over the region $[-1, 1] \times [-1, 1]$. Note the discontinuity in the first partial along one of the diagonals. Figure 2 depicts the second partial and a backsubstitution error over the same region. The second partial also has a discontinuity along the same diagonal as the first. The error plot has been rotated for better viewing due to the high error along the discontinuity in the gradient. The backsubstitution error is computed by taking these approximate partials and substituting them back into the original HJB PDE. Consequently, the depicted errors contain components due to the approximate gradient dotted with the dynamics, and the term with the square in the gradient in the Hamiltonian. Perhaps it should be noted that the solutions of such problems *cannot* be obtained by patching together the quadratic functions corresponding to solutions of the corresponding algebraic Riccati equations. The computations required slightly less than 10 seconds.

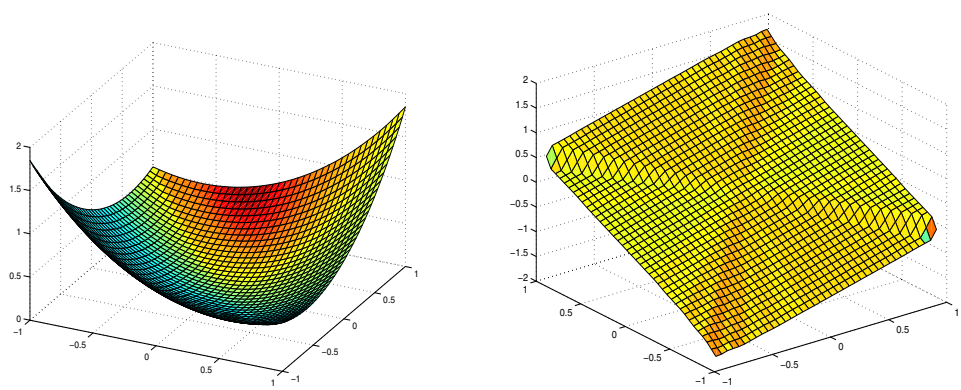

FIG. 1. *Value function and first partial (two-dimensional case).*

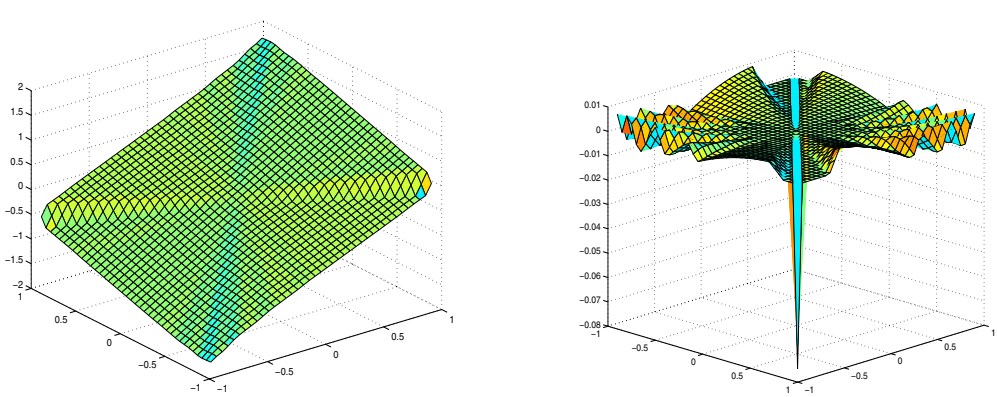

FIG. 2. *Second partial and backsubstitution error (two-dimensional case).*

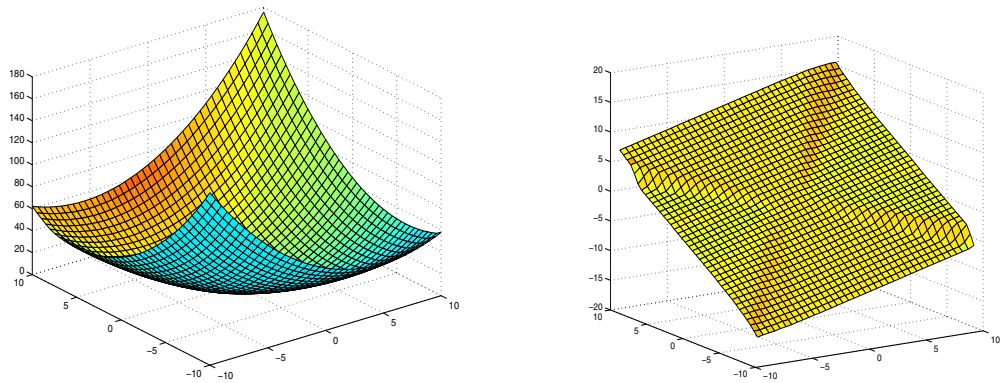

FIG. 3. *Value function and first partial (three-dimensional case).*

Example 2. We now consider a case where the A^m are given by

$$A^1 = \begin{bmatrix} -1.0 & 0.5 & 0.0 \\ 0.1 & -1.0 & 0.2 \\ 0.2 & 0.0 & -1.5 \end{bmatrix}, \quad A^2 = (A^1)^T, \quad A^3 = \begin{bmatrix} -1.0 & 0.5 & 0.0 \\ 0.1 & -1.0 & 0.2 \\ 0.2 & 0.0 & -1.5 \end{bmatrix},$$

the D^m are

$$D^1 = \begin{bmatrix} 1.5 & 0.2 & 0.1 \\ 0.2 & 1.5 & 0.0 \\ 0.1 & 0.0 & 1.5 \end{bmatrix}, \quad D^2 = \begin{bmatrix} 1.6 & 0.2 & 0.1 \\ 0.2 & 1.6 & 0.0 \\ 0.1 & 0.0 & 1.6 \end{bmatrix}, \quad D^3 = D^1,$$

and the Σ^m are

$$\Sigma^1 = \begin{bmatrix} 0.2 & -0.01 & 0.02 \\ -0.01 & 0.2 & 0.0 \\ 0.02 & 0.0 & 0.25 \end{bmatrix}, \quad \Sigma^2 = \begin{bmatrix} 0.16 & -0.005 & 0.015 \\ -0.005 & 0.16 & 0.0 \\ 0.015 & 0.0 & 0.2 \end{bmatrix}, \quad \Sigma^3 = \Sigma^1.$$

The results of this three-dimensional example appear in Figures 3–5. In this case, the results have been plotted over the region of the affine plane $x_3 = 3$ given by $x_1 \in [-10, 10]$ and $x_2 \in [-10, 10]$. The backsubstitution error has been scaled by dividing by $|x|^2 + 10^{-5}$. Note that the scaled backsubstitution errors (away from the discontinuity in the gradient) grow only slowly or are possibly bounded with increasing $|x|$. (Recall that the approximate solution is obtained over the whole space.) Since the gradient errors are multiplied by the nominal dynamics in one component of this term (as well as being squared in another), this indicates that the errors in the gradient itself likely grow only linearly (or nearly linearly) with increasing $|x|$. The computations required approximately 13 seconds.

Example 3. The four-dimensional example has constituent Hamiltonians with the A^m, D^m, and Σ^m given by

$$A^1 = \begin{bmatrix} -1.0 & 0.5 & 0.0 & 0.1 \\ 0.1 & -1.0 & 0.2 & 0.0 \\ 0.2 & 0.0 & -1.5 & 0.1 \\ 0.0 & -0.1 & 0.0 & -1.5 \end{bmatrix}, \quad A^2 = (A^1)^T,$$

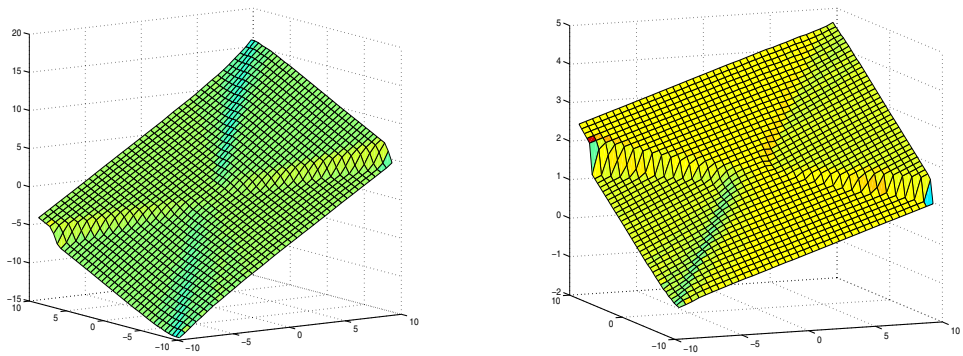

FIG. 4. *Second and third partials (three-dimensional case).*

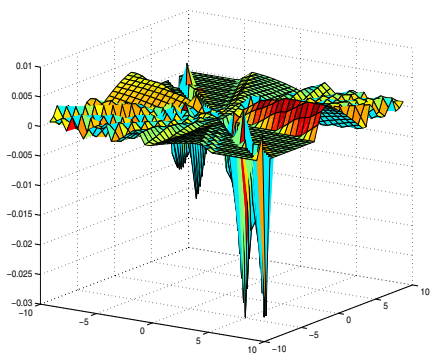

FIG. 5. *Scaled backsubstitution error (three-dimensional case).*

$$A^3 = \begin{bmatrix} -1.0 & 0.5 & 0.0 & 0.1 \\ 0.1 & -1.0 & 0.2 & 0.0 \\ 0.2 & 0.0 & -1.6 & -0.1 \\ 0.0 & -0.05 & 0.1 & -1.5 \end{bmatrix},$$

$$D^1 = D^2 = D^3 = \begin{bmatrix} 1.5 & 0.2 & 0.1 & 0.0 \\ 0.2 & 1.5 & 0.0 & 0.1 \\ 0.1 & 0.0 & 1.5 & 0.0 \\ 0.0 & 0.1 & 0.0 & 1.5 \end{bmatrix},$$

and

$$\Sigma^1 = \Sigma^2 = \Sigma^3 = \begin{bmatrix} 0.2 & -0.01 & 0.02 & 0.01 \\ -0.01 & 0.2 & 0.0 & 0.0 \\ 0.02 & 0.0 & 0.25 & 0.0 \\ 0.01 & 0.0 & 0.0 & 0.25 \end{bmatrix}.$$

The results for this example appear in Figures 6–8. In this case, the results have been plotted over the region of the affine plane $x_3 = 3$, $x_4 = -0.5$ given by $x_1 \in [-10, 10]$ and $x_2 \in [-10, 10]$. The backsubstitution error has again been scaled by dividing by $|x|^2 + 10^{-5}$. The computations required approximately 40 seconds. We remark that one cannot change dimension independent of dynamics (except in

the trivial case, where each component of the system has exactly the same dynamics of the other components with no interdependence), and so one cannot directly compare the computation times of these three examples. However, it is easy to see that the computation time increases are on the order of square to cubic in space dimension, rather than being subject to curse-of-dimensionality-type growth.

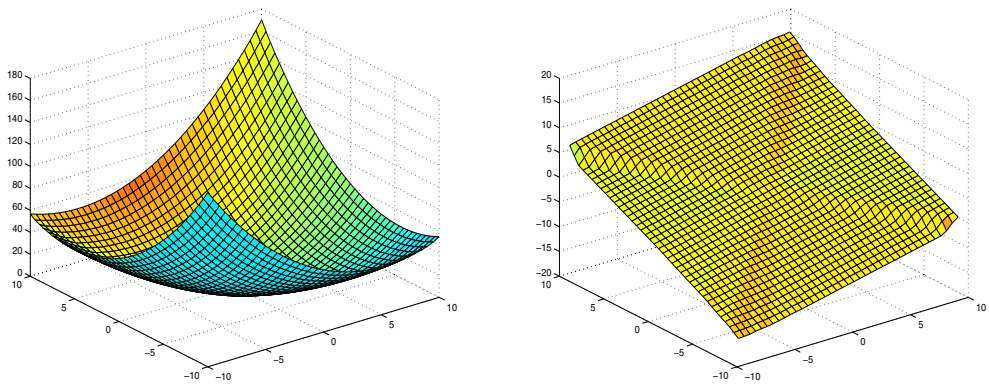

FIG. 6. *Value function and first partial (four-dimensional case).*

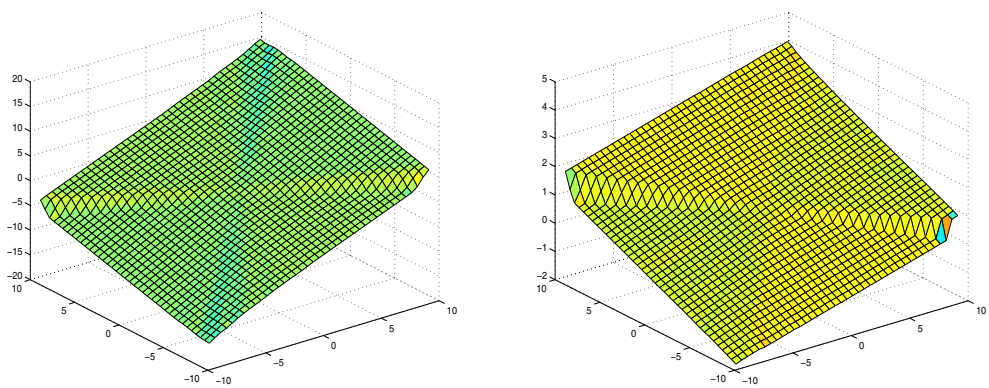

FIG. 7. *Second and third partials (four-dimensional case).*

8. Future directions.

Pruning. In order to make these methods more practical, algorithms need to be developed for determining when a quadratic function is dominated by the function, which is the pointwise maximum of a set of quadratic functions. This has the potential for greatly reducing the effects of the curse of complexity, and consequently greatly decreasing computational times.

Constant/linear terms. An instantiation of this class of methods was developed here for a very particular type of Hamiltonian, $\widetilde{H}(x,p) = \max_m\{H^m(x,p)\}$, where the H^m corresponded to a very specific type of linear/quadratic problem. One

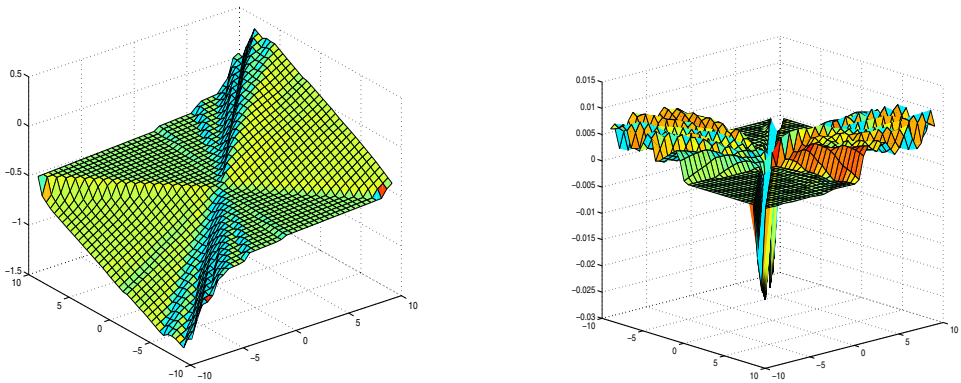

FIG. 8. *Fourth partial and scaled backsubstitution error (four-dimensional case).*

would like to generalize the H^m to, say,

$$H^m(x,p) = \tfrac{1}{2}x^T D^m x + \tfrac{1}{2}p^T \Sigma^m p + (A^m x)^T p + (l_1^m)^T x + (l_2^m)^T p + \alpha^m.$$

Clearly certain conditions on $\widetilde{H}(x,p) = \max_m\{H^m(x,p)\}$ would be necessary. It is not obvious that these conditions would need to apply to each of the constituent H^m individually. In the work here, the H^m corresponded to linear/quadratic problems with maximizing controllers/disturbances. It is not clear that the constituent linear/quadratic problems need to be constricted in this way either. For instance, could some or all of the H^m correspond to, say, game problems?

Convergence/error analysis. Only convergence of the approximation to the solution was obtained here. Estimates of error size and convergence rate need to be determined. For instance, it was hypothesized (and observed in the examples) that one obtains the solution over the whole state space with linear growth rate in the errors in the gradient. Is this true in any generality?

Nonergodic problem. The algorithm was developed for an infinite time-horizon problem, where the dynamics were stable to the origin. One expects the approach would also be applicable to discounted cost problems and exit problems. One would also expect that a similar theory could be developed for finite time-horizon problems such as robust filtering. Max-plus methods have also been discussed for problems corresponding to variational inequalities [30]. The analysis and algorithm necessary for a variational inequality would be of interest.

Other nonlinearities. This work concentrated only on the case of a nonlinearity due to taking the maximum of a set of Hamiltonians for linear/quadratic problems. An obvious question is how well this approach might work for other classes of nonlinearities. What classes of nonlinear HJB PDEs could be best approximated by maxima over reasonably small numbers of linear/quadratic HJB PDEs? Perhaps a single nonlinearity in only one variable (possibly appearing in multiple places) would be the most tractable?

Appendix A. Sketch of proof of Theorem 4.7. Fix $\delta > 0$ (used in the definition of $\mathcal{G}_\delta$). Suppose $\overline{V}' \in \mathcal{G}_\delta$ satisfies (46). Then,

$$\begin{aligned}\overline{V}'(x) &= \bar{\bar{S}}^\tau_{N\tau}[\overline{V}'](x)\\ &= \sup_{w\in\mathcal{W}}\sup_{\mu\in\mathcal{D}^\tau_\infty}\left\{\int_0^{N\tau} l^{\mu_t}(\xi_t) - \frac{\gamma^2}{2}|w_t|^2\,dt + \overline{V}'(\xi_{N\tau})\right\} \qquad \forall\, x\in\mathbb{R}^n,\end{aligned}$$

where ξ satisfies (12). Fix $x\in\mathbb{R}^n$, and let $\mu^\varepsilon \in \mathcal{D}^\tau_\infty$, $w^\varepsilon \in \mathcal{W}$ be ε-optimal , i.e.,

$$\overline{V}'(x) \le \int_0^{N\tau} l^{\mu^\varepsilon_t}(\xi^\varepsilon_t) - \frac{\gamma^2}{2}|w^\varepsilon_t|^2\,dt + \overline{V}'(\xi^\varepsilon_{N\tau}) + \varepsilon,$$

where ξ^ε satisfies (12) with inputs $\mu^\varepsilon, w^\varepsilon$.

Following the same steps as in [35], one obtains the same lemmas.

LEMMA A.1. *For any $N<\infty$, $\|w^\varepsilon\|^2_{L_2(0,N\tau)} \le \frac{\varepsilon}{\delta} + \frac{1}{\delta}\left[\frac{c_A\gamma^2}{c_\sigma^2}e^{-c_AN\tau} + \frac{c_D}{c_A}\right]|x|^2$.*

LEMMA A.2. *For any $N<\infty$,*

$$\int_0^{N\tau}|\xi^\varepsilon_t|^2\,dt \le \frac{\varepsilon}{\delta}\frac{c_\sigma^2}{c_A} + \frac{c_\sigma^2}{\delta}\left[\left(\frac{c_D}{c_A^2}+\frac{\gamma^2}{c_\sigma^2}\right)+\frac{1}{c_A}\right]|x|^2.$$

LEMMA A.3. *If $w^\varepsilon, \mu^\varepsilon$ are ε-optimal over $[0, N\tau)$, then they are also ε-optimal over $[0, n\tau)$ for all $n \le N$, i.e.,*

$$\int_0^{n\tau} l^{\mu^\varepsilon_t}(\xi^\varepsilon_t) - \frac{\gamma^2}{2}|w^\varepsilon_t|^2\,dt + \overline{V}'(\xi^\varepsilon_{n\tau}) \ge \overline{V}'(x) - \varepsilon.$$

The independence of the above bounds with respect to N is important. Specifically, since there is a finite bound on the energy (the bound on w^ε) coming into the trajectories, roughly speaking the ξ^ε "tend" toward the origin.

Now we need a lemma which will replace equation (20) in [35].

Lemma A.4. *For any $N<\infty$,*

$$\sum_{n=1}^N |\xi^\varepsilon_{n\tau}|^2 \le \frac{1}{1-e^{-c_A\tau}}\left[|x|^2 + \left(\frac{c_\sigma}{c_A^2}\right)\|w^\varepsilon\|^2_{L_2(0,N\tau)}\right].$$

Proof. Note that $\frac{d}{dt}|\xi^\varepsilon|^2 \le -c_A|\xi^\varepsilon| + \hat{d}|w^\varepsilon|^2$ with $\hat{d} = c_\sigma^2/c_A$. Solving this on intervals of the form $[n\tau,(n+1)\tau)$, one finds

$$\begin{aligned}|\xi^\varepsilon_\tau|^2 &\le |x|^2e^{-c_A\tau} + \hat{d}\|w^\varepsilon\|^2_{L_2(0,\tau)},\\ |\xi^\varepsilon_{2\tau}|^2 &\le |\xi^\varepsilon_\tau|^2e^{-c_A\tau} + \hat{d}\|w^\varepsilon\|^2_{L_2(\tau,2\tau)},\end{aligned}$$

and so on. Continuing this process, and combining the inequalities, yields

$$\sum_{n=1}^N |\xi^\varepsilon_{n\tau}|^2 \le \left(\sum_{n=1}^N e^{-nc_A\tau}\right)|x|^2 + \hat{d}\sum_{n=1}^N\left[\left(\sum_{j=0}^{N-n} e^{-jc_A\tau}\right)\|w^\varepsilon\|^2_{L_2((n-1)\tau,n\tau)}\right].$$

Using the standard geometric series limit yields the result. ∎

Combining Lemmas A.2 and A.4, one obtains a bound on $\sum_{n=1}^N |\xi^\varepsilon_{n\tau}|^2$ which is independent of N. Consequently, at least some of the $|\xi^\varepsilon_{n\tau}|$ can be guaranteed to

be arbitrarily small for large N. The remainder of the proof (of Theorem 4.7) then follows as in equations (24)–(28) in [35], but with $N\tau$ replacing T, and $n\tau$ replacing τ. This completes the sketch of the proof. □

Appendix B. Sketch of proof of Lemma 4.11. Fix $\delta > 0$ (used in the definition of $\mathcal{G}_\delta$). Fix $m \in \mathcal{M}$. Fix any $T < \infty$ and $x \in \mathbb{R}^n$. Let $\varepsilon = (\hat{\varepsilon}/2)(1 + |x|^2)$. Let $w^\varepsilon \in \mathcal{W}$, $\mu^\varepsilon \in \mathcal{D}_\infty$ be ε-optimal for $\widetilde{S}_T[V^m](x)$, i.e.,

$$\widetilde{S}_T[V^m](x) - \left[\int_0^T l^{\mu^\varepsilon_t}(\xi^\varepsilon{}_t) - \frac{\gamma^2}{2}|w^\varepsilon_t|^2\,dt + V^m(\xi^\varepsilon{}_T)\right] \le \varepsilon = \frac{\hat{\varepsilon}}{2}(1 + |x|^2), \tag{81}$$

where ξ^ε satisfies (12) with inputs w^ε, μ^ε.

We will let $\overline{\xi}^\varepsilon$ satisfy (12) with inputs w^ε and a $\overline{\mu}^\varepsilon \in \mathcal{D}^\tau_\infty$ (where τ has yet to be chosen). Solving (12), one has

$$\begin{aligned}
\xi^\varepsilon_t &= \exp\left[\int_0^t A^{\mu^\varepsilon_r}\,dr\right]x + \int_0^t \exp\left[\int_r^t A^{\mu^\varepsilon_\rho}\,d\rho\right]\sigma^{\mu^\varepsilon_r} w^\varepsilon_r\,dr,\\
\overline{\xi}^\varepsilon_t &= \exp\left[\int_0^t A^{\overline{\mu}^\varepsilon_r}\,dr\right]x + \int_0^t \exp\left[\int_r^t A^{\overline{\mu}^\varepsilon_\rho}\,d\rho\right]\sigma^{\overline{\mu}^\varepsilon_r} w^\varepsilon_r\,dr.
\end{aligned}$$

Consequently,

$$\begin{aligned}
|\xi^\varepsilon_t - \overline{\xi}^\varepsilon_t| \le{}& \left|\exp\left[\int_0^t A^{\mu^\varepsilon_r}\,dr\right] - \exp\left[\int_0^t A^{\overline{\mu}^\varepsilon_r}\,dr\right]\right| |x|\\
&+ \left\{\int_0^t \left|\exp\left[\int_r^t A^{\mu^\varepsilon_\rho}\,d\rho\right]\sigma^{\mu^\varepsilon_r} - \exp\left[\int_r^t A^{\overline{\mu}^\varepsilon_\rho}\,d\rho\right]\sigma^{\overline{\mu}^\varepsilon_r}\right|^2 dr\right\}^{1/2} \|w^\varepsilon\|_{L_2(0,t)}.
\end{aligned} \tag{82}$$

We now simply show that this can be made arbitrarily small by taking τ small. We will use the boundedness of $\|w^\varepsilon\|$ and $\|\xi^\varepsilon\|$ which are independent of t for this class of systems [35].

Consider the first term on the right in (82). Note that

$$\begin{aligned}
&\left|\exp\left[\int_0^t A^{\mu^\varepsilon_r}\,dr\right] - \exp\left[\int_0^t A^{\overline{\mu}^\varepsilon_r}\,dr\right]\right|\\
&\quad= \left|\exp\left[\int_0^t A^{\mu^\varepsilon_r}\,dr\right]\right| \left|1 - \exp\left[\int_0^t A^{\overline{\mu}^\varepsilon_r}\,dr - \int_0^t A^{\mu^\varepsilon_r}\,dr\right]\right|.
\end{aligned} \tag{83}$$

Fix $\tau > 0$. For any subset of $\mathbb{R}$, $\mathcal{I}$, let $\mathcal{L}(\mathcal{I})$ be the Lebesgue measure of $\mathcal{I}$. Let N be the largest integer such that $N\tau \le t$. Given $m \in \mathcal{M}$, let

$$\mathcal{I}^m = \{r \in [0, N\tau) \mid A^{\mu^\varepsilon_r} = A^m\} \quad \text{and} \quad \lambda^m = \mathcal{L}(\mathcal{I}^m).$$

Let $n_0 = 0$. For $1 \le k < M = \#\mathcal{M}$, let n_k be the largest integer such that $n_k\tau \le \lambda^k + n_{k-1}\tau$. For $m < M$, let

$$\overline{\mu}^\varepsilon_r = m \qquad \forall\, t \in [n_{m-1}\tau, n_m\tau).$$

Let $\overline{\mu}^\varepsilon{}_r = M$ for all $t \in [n_{M-1}\tau, t) = [n_{M-1}\tau, N\tau) \cup [N\tau, t)$. With this choice of $\overline{\mu}^\varepsilon$, one finds

$$\left|1 - \exp\left[\int_0^t A^{\overline{\mu}^\varepsilon_r}\,dr - \int_0^t A^{\mu^\varepsilon_r}\,dr\right]\right| < \beta^1_\tau, \tag{84}$$

where $\beta_\tau^1 \to 0$ as $\tau \to 0$ independent of t. We skip the details.

Let $y \in \mathbb{R}^n$. Define $F_t = \exp\bigl[\int_0^t A^{\mu_r^\varepsilon}\,dr\bigr]$. Then, using assumption block $(A.m)$,

$$\begin{aligned}\frac{d}{dt}\bigl[y^T F_t^T F_t y\bigr] &= y^T\left[F_t^T \dot F_t + \dot F_t^T F_t\right] y = 2y^T\left[F_t^T A^{\mu_t^\varepsilon} F_t\right] y \\ &= 2(F_t y)^T A^{\mu_t^\varepsilon}(F_t y) \le -2c_A|F_t y|^2 = -2c_A\bigl[y^T F_t^T F_t y\bigr].\end{aligned}$$

Solving this ordinary differential inequality, one finds $[y^T F_t^T F_t y] \le |y|^2 e^{-2c_A t}$. Since this is true for all $y \in \mathbb{R}^n$, we have

$$\left|\exp\left[\int_0^t A^{\mu_r^\varepsilon}\,dr\right]\right| \le e^{-c_A t} \qquad \forall\, t \ge 0. \tag{85}$$

By (83), (84), and (85),

$$\left|\exp\left[\int_0^t A^{\mu_r^\varepsilon}\,dr\right] - \exp\left[\int_0^t A^{\overline{\mu}_r^\varepsilon}\,dr\right]\right| \le \beta_\tau^1 e^{-c_A t} \qquad \forall\, t \ge 0. \tag{86}$$

We now turn to the second term on the right-hand side of (82). Note that

$$\begin{aligned}&\left\{\int_0^t \left|\exp\left[\int_r^t A^{\mu_\rho^\varepsilon}\,d\rho\right]\sigma^{\mu_r^\varepsilon} - \exp\left[\int_r^t A^{\overline{\mu}_\rho^\varepsilon}\,d\rho\right]\sigma^{\overline{\mu}_r^\varepsilon}\right|^2 dr\right\}^{1/2} \\ &\quad\le \left\{2\int_0^t \left|\exp\left[\int_r^t A^{\mu_\rho^\varepsilon}\,d\rho\right]\right|^2 \left|\sigma^{\mu_r^\varepsilon} - \sigma^{\overline{\mu}_r^\varepsilon}\right|^2 dr \right. \\ &\qquad \left. +2\int_0^t \left|\exp\left[\int_r^t A^{\mu_\rho^\varepsilon}\,d\rho\right] - \exp\left[\int_r^t A^{\overline{\mu}_\rho^\varepsilon}\,d\rho\right]\right|^2 \left|\sigma^{\overline{\mu}_r^\varepsilon}\right|^2 dr\right\}^{1/2},\end{aligned}$$

and proceeding as above,

$$\begin{aligned}&\le \left\{2\int_0^t e^{-2c_A(t-r)}\left|\sigma^{\mu_r^\varepsilon} - \sigma^{\overline{\mu}_r^\varepsilon}\right|^2 dr + 2\beta_\tau^1\int_0^t e^{-2c_A(t-r)}\left|\sigma^{\overline{\mu}_r^\varepsilon}\right|^2 dr\right\}^{1/2} \\ &\le \left\{2\left[\int_0^t e^{-4c_A(t-r)}\,dr\right]^{1/2}\left[\int_0^t \left|\sigma^{\mu_r^\varepsilon} - \sigma^{\overline{\mu}_r^\varepsilon}\right|^4 dr\right]^{1/2} + 2\beta_\tau^1 c_\sigma^2\int_0^t e^{-2c_A(t-r)}\,dr\right\}^{1/2}.\end{aligned}$$

Further, there exists β_τ^2 such that $[\int_0^t |\sigma^{\mu_r^\varepsilon} - \sigma^{\overline{\mu}_r^\varepsilon}|^4\,dr]^{1/2} \le \beta_\tau^2$, where $\beta_\tau^2 \to 0$ as $\tau \to 0$, and we skip the obvious, but technical, proof. Consequently,

$$\begin{aligned}&\left\{\int_0^t \left|\exp\left[\int_r^t A^{\mu_\rho^\varepsilon}\,d\rho\right]\sigma^{\mu_r^\varepsilon} - \exp\left[\int_r^t A^{\overline{\mu}_\rho^\varepsilon}\,d\rho\right]\sigma^{\overline{\mu}_r^\varepsilon}\right|^2 dr\right\}^{1/2} \\ &\qquad \le \left\{2\beta_\tau^2(4c_A)^{-1/2} + 2\beta_\tau^1 c_\sigma^2(2c_A)^{-1}\right\}^{1/2} \le \beta_\tau^3,\end{aligned} \tag{87}$$

where $\beta_\tau^3 \to 0$ as $\tau \to 0$ (independent of t).

Combining (82), (86), and (87), one has

$$|\xi_t^\varepsilon - \overline{\xi}_t^\varepsilon| \le \beta_\tau^1 e^{-c_A t}|x| + \beta_\tau^3\|w^\varepsilon\|_{L_2(0,t)}. \tag{88}$$

Now, by the system structure given by assumption block $(A.m)$ and by the fact that the V^m are in $\mathcal{G}_\delta$, one obtains the following lemmas exactly as in [35]. These are also analogous to their counterparts in Appendix A.

LEMMA B.1. *For any* $t < \infty$, $\|w^\varepsilon\|^2_{L_2(0,t)} \le \frac{\varepsilon}{\delta} + \frac{1}{\delta}\left[\frac{c_A\gamma^2}{c_\sigma^2}e^{-c_A N\tau} + \frac{c_D}{c_A}\right]|x|^2$.

LEMMA B.2. *For any* $t < \infty$,

$$\int_0^t |\xi_r^\varepsilon|^2\,dt \le \frac{\varepsilon}{\delta}\frac{c_\sigma^2}{c_A} + \frac{c_\sigma^2}{\delta}\left[\left(\frac{c_D}{c_A^2} + \frac{\gamma^2}{c_\sigma^2}\right) + \frac{1}{c_A}\right]|x|^2.$$

Let $c_1 \doteq \frac{\varepsilon}{\delta}$ and $c_2 \doteq \frac{1}{\delta}[\frac{c_A\gamma^2}{c_\sigma^2}e^{-c_A N\tau} + \frac{c_D}{c_A}]$. By Lemma B.1 and (88), for all $t < \infty$ one has

$$|\xi_t^\varepsilon - \overline{\xi}_t^\varepsilon| \le \beta_\tau^1 e^{-c_A t}|x| + \beta_\tau^3(c_1 + c_2|x|^2)^{1/2},$$

and by proper choice of β_τ^4,

$$\le \beta_\tau^4(1 + |x|), \tag{89}$$

where $\beta_\tau^4 \to 0$ as $\tau \to 0$ (independent of $t > 0$).

Now,

$$\begin{aligned}&\int_0^T l^{\mu_t^\varepsilon}(\xi_t^\varepsilon) - \frac{\gamma^2}{2}|w_t^\varepsilon|^2\,dt + V^m(\xi_T^\varepsilon) - \int_0^T l^{\overline{\mu}_t^\varepsilon}(\overline{\xi}_t^\varepsilon) - \frac{\gamma^2}{2}|w_t^\varepsilon|^2\,dt + V^m(\overline{\xi}_T^\varepsilon)\\ &= \int_0^T \xi_t^\varepsilon D^{\mu_t^\varepsilon}\xi_t^\varepsilon - \overline{\xi}_t^\varepsilon D^{\overline{\mu}_t^\varepsilon}\overline{\xi}_t^\varepsilon\,dt + (\xi_T^\varepsilon)^T P^m \xi_T^\varepsilon - (\overline{\xi}_T^\varepsilon)^T P^m \overline{\xi}_T^\varepsilon.\end{aligned} \tag{90}$$

Note that the integral term on the right-hand side in (90) is

$$\begin{aligned}&\int_0^T (\xi_t^\varepsilon)^T D^{\mu_t^\varepsilon}(\xi_t^\varepsilon - \overline{\xi}_t^\varepsilon) + (\xi_t^\varepsilon)^T\left(D^{\mu_t^\varepsilon} - D^{\overline{\mu}_t^\varepsilon}\right)\overline{\xi}_t^\varepsilon + (\xi_t^\varepsilon - \overline{\xi}_t^\varepsilon)^T D^{\overline{\mu}_t^\varepsilon}\overline{\xi}_t^\varepsilon\,dt\\ &\le \beta_\tau^4(1 + |x|)\int_0^T \left(|D^{\mu_t^\varepsilon}|\,|\xi_t^\varepsilon| + |D^{\overline{\mu}_t^\varepsilon}|\,|\overline{\xi}_t^\varepsilon|\right)dt + \beta_\tau^5\int_0^T |\xi_t^\varepsilon|\,|\overline{\xi}_t^\varepsilon|\,dt\end{aligned}$$

for appropriate $\beta_\tau^5 \to 0$ as $\tau \to 0$, which, after some work,

$$\le \beta_\tau^6(1 + |x|^2)(1 + \sqrt{T}) \tag{91}$$

for an appropriate choice of $\beta_\tau^6 \to 0$ as $\tau \to 0$ (independent of T).

Similarly, the last two terms on the right-hand side in (90) are

$$\begin{aligned}{\xi_T^\varepsilon}^T P^m \xi_T^\varepsilon - {\overline{\xi}_T^\varepsilon}^T P^m \overline{\xi}_T^\varepsilon &= (\xi_T^\varepsilon + \overline{\xi}_T^\varepsilon)^T P^m(\xi_T^\varepsilon - \overline{\xi}_T^\varepsilon)\\ &\le |P^m|\left[|\xi_T^\varepsilon - \overline{\xi}_T^\varepsilon|^2 + 2|\xi_T^\varepsilon|\,|\xi_T^\varepsilon - \overline{\xi}_T^\varepsilon|\right],\end{aligned}$$

which, by (89),

$$\le \beta_\tau^7(1 + |x|^2) + \beta_\tau^8|\xi_T^\varepsilon|(1 + |x|), \tag{92}$$

where $\beta_\tau^7, \beta_\tau^8 \to 0$ as $\tau \to 0$.

We also need the following lemma which is obtained in [35].

LEMMA B.3. *Given* $\overline{T} < \infty$, *there exist* $T \in [\overline{T}/2, \overline{T}]$ *and* ε*-optimal* $w^\varepsilon \in \mathcal{W}$, $\mu^\varepsilon \in \mathcal{D}_\infty$ *for* $\widetilde{S}_T[V^m]$ *such that*

$$|\xi_T^\varepsilon|^2 \le \frac{1}{\overline{T}}\left\{\frac{\varepsilon}{\delta}\frac{c_\sigma^2}{c_A} + \frac{c_\sigma^2}{\delta}\left[\left(\frac{c_D}{c_A^2} + \frac{\gamma^2}{c_\sigma^2}\right) + \frac{1}{c_A}\right]|x|^2\right\}.$$

Combining (92) and Lemma B.3, one finds that there exist $c_3, c_4 < \infty$ such that

$$\xi_T^{\varepsilon\,T} P^m \xi_T^\varepsilon - \overline{\xi}_T^{\varepsilon\,T} P^m \overline{\xi}_T^\varepsilon \le \beta_\tau^9 (1 + |x|^2), \tag{93}$$

where $\beta_\tau^9 \to 0$ as $\tau \to 0$ (independent of T).

Combining (90), (91), and (93),

$$\begin{aligned} &\int_0^T l^{\mu_t^\varepsilon}(\xi_t^\varepsilon) - \frac{\gamma^2}{2}|w_t^\varepsilon|^2\,dt + V^m(\xi_T^\varepsilon) - \int_0^T l^{\overline{\mu}_t^\varepsilon}(\overline{\xi}_t^\varepsilon) - \frac{\gamma^2}{2}|w_t^\varepsilon|^2\,dt + V^m(\overline{\xi}_T^\varepsilon) \\ &\qquad \le \beta_\tau^{10}(1 + |x|^2)(1 + \sqrt{T}), \end{aligned} \tag{94}$$

where $\beta_\tau^{10} \to 0$ as $\tau \to 0$ (independent of T).

Combining (81) and (94), one has

$$\widetilde{S}_T[V^m](x) - \int_0^T l^{\overline{\mu}_t^\varepsilon}(\overline{\xi}_t^\varepsilon) - \frac{\gamma^2}{2}|w_t^\varepsilon|^2\,dt + V^m(\overline{\xi}_T^\varepsilon) \le \frac{\varepsilon}{2}(1 + |x|^2) + \beta_\tau^{10}(1 + |x|^2)(1 + \sqrt{T}),$$

which, for τ sufficiently small (depending on T now),

$$\le \varepsilon(1 + |x|^2).$$

This completes the proof of Lemma 4.11. ∎

Acknowledgment. The author wishes to thank Prof. J. William Helton for helpful discussions, without which this direction may never have been explored.

FEEDBACK SOLUTIONS OF OPTIMAL CONTROL PROBLEMS WITH DAE CONSTRAINTS*

GALINA A. KURINA† AND ROSWITHA MÄRZ‡

Abstract. An optimal feedback control has been obtained for linear-quadratic optimal control problems with constraints described by differential-algebraic equations (DAEs). For that purpose, a new implicit Riccati equation (Riccati differential-algebraic system) is provided, and its solvability is investigated. It is shown that one can do without the strong consistency conditions as used in several previous papers. Furthermore, the solvability of the resulting closed loop system is considered and the relations between Riccati equations and Hamiltonian systems are elucidated.

Key words. linear-quadratic optimal control problems, feedback control, differential-algebraic equations, descriptor systems, Riccati equations, Hamiltonian systems

1. Introduction. Feedback solutions via Riccati differential equations are a known and proven tool for solving linear-quadratic optimal control problems given by the cost

$$J(u,x) := \frac{1}{2}\langle x(T), Vx(T)\rangle + \frac{1}{2}\int_0^T \left\langle \begin{bmatrix} x(t) \\ u(t) \end{bmatrix}, \begin{bmatrix} W(t) & S(t) \\ S(t)^* & R(t) \end{bmatrix} \begin{bmatrix} x(t) \\ u(t) \end{bmatrix} \right\rangle dt \tag{1.1}$$

and the side conditions

$$x'(t) = C(t)x(t) + D(t)u(t), \quad t \in [0,T], \tag{1.2}$$

$$x(0) = z_0. \tag{1.3}$$

The superscript * denotes the transpose.

Let all coefficients be continuous and certain standard conditions be fulfilled (cf. section 2). In the following, the argument t is dropped almost everywhere, and the given relations are meant pointwise for all $t \in [0,T]$.

The terminal value problem for the relevant Riccati matrix differential equation with the symmetric solution Y is (see, e.g., [20] for $S = 0$)

$$Y' = -YC - C^*Y + (S + YD)R^{-1}(S^* + D^*Y) - W, \tag{1.4}$$

$$Y(T) = V. \tag{1.5}$$

If the explicit ordinary differential equation (ODE) in (1.2) is replaced by a differential-algebraic equation (DAE)

$$Ex' = Cx + Du, \tag{1.6}$$

with E being a singular constant square matrix, the situation becomes much more complex, and several different generalizations of the Riccati-ansatz are possible. For this, quite a lot of references are available (in particular for the case of constant coefficients); however, we can mention here only part of them. We refer to [5], [18], and [14] for further sources.

In [5] it was first noted that the modification

$$E^*Y'E = -E^*YC - C^*YE + (S + E^*YD)R^{-1}(S^* + D^*YE) - W, \tag{1.7}$$

which is considered to be *obvious*, leads to unacceptable solvability conditions. Consequently, more specific Riccati approaches that skillfully make use of the inherent structures find favor with [5]. Starting from a singular value decomposition $UEV = \operatorname{diag}(\Sigma, 0)$ and certain rank conditions, lower dimensional Riccati equations of the form $\Sigma Y'\Sigma = \dots$ are introduced. From the point of view of DAE theory the rank conditions used in [5] imply that the related Hamilton–Lagrange system is a regular DAE with tractability index one (cf. [3]).

In [15], [16], [17] (in a more general Hilbert space setting, with $S = 0$) a different ansatz was followed with Riccati equations of the form

$$E^*Y' = -Y^*C - C^*Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W. \tag{1.8}$$

The solutions of the terminal value problem for (1.8) with the condition

$$E^*Y(T) = V \tag{1.9}$$

have the symmetry property $E^*Y = Y^*E$. Like (1.7), (1.8) also is primarily a matrix-DAE; however, (1.8) has much better solvability properties than (1.7). In [15], [16], a decoupling into characteristic components is not used for the ansatz of the Riccati equation itself, as was done in [5], but for proving the solvability of the Riccati terminal value problem (1.8), (1.9).

Kunkel and Mehrmann [14] consider the Riccati DAE

$$(E^*YE)' = -E^*YC - C^*YE + (S + E^*YD)R^{-1}(S^* + D^*YE) - W, \tag{1.10}$$

which generalizes (1.7) to allow for time-dependent coefficients E. However, this equation is as unsuitable as its time-invariant version (1.7), and the authors have to admit that, *unfortunately, this approach can be used only in very special cases since, for $E(t)$ singular, the solutions of* (1.10) *and the Euler–Lagrange equation are not related via $u = -R^{-1}(S + D^*YE)x$, as in the case of nonsingular $E(t)$*. The difficulties with (1.10) are illustrated in [14] by means of a small academic problem. Below we shall resume this special problem to show that things work well when using more appropriate Riccati DAE systems.

If, in (1.6), there is no constant matrix E in front of the derivative but a time-dependent matrix, it makes sense to change to a DAE with a *properly formulated leading term*, i.e., instead of (1.6), using

$$A(Bx)' = Cx + Du, \tag{1.11}$$

with well-matched A and B (cf. [4]). The corresponding initial condition is

$$A(0)B(0)x(0) = z_0 \tag{1.12}$$

with $z_0 \in \mathrm{im}(A(0)B(0))$. For arguments that state the leading term in this way we refer to [4], [22]. Notice that, in particular, such equations arise in circuit simulation via modified nodal analysis (see, e.g., [9], [11]).

Under the assumption that B is continuously differentiable, the terminal problem for the Riccati equation

$$\begin{aligned}(B^*A^*Y)' &= -Y^*(C - AB') - (C^* - B^{*\prime}A^*)Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W,\\ B(T)^*A(T)^*Y(T) &= V,\end{aligned} \tag{1.13}$$

with the symmetry property $B^*A^*Y = Y^*AB$, is proved to be relevant in [12] (in a more general Hilbert space setting).

The Riccati DAE

$$B^*(A^*Y)'B = -B^*Y^*C - C^*YB + (S + B^*Y^*D)R^{-1}(S^* + D^*YB) - W, \tag{1.14}$$

with B being just continuous, is investigated in [8]. This equation is, however, also a sort of generalization of (1.7) and adopts the bad solvability properties of (1.7). Under the condition that $\ker B^* = 0$, if there exists a solution Y of (1.14) that satisfies the terminal condition $B(T)^*A(T)^*Y(T)B(T) = V$, then this solution has the symmetry property $A^*Y = Y^*A$, and the ansatz $u = -R^{-1}(S^* + D^*YB)x$ actually leads to an optimal feedback control.

In this paper we work with the Riccati DAE

$$B^*(A^*YB^-)'B = -Y^*C - C^*Y + (S + Y^*D)R^{-1}(S^* + D^*Y) - W \tag{1.15}$$

and the terminal value condition

$$A(T)^*Y(T)B(T)^- = B(T)^{-*}VB(T)^-, \tag{1.16}$$

where B is assumed to be just continuous. Here, the solutions meet the symmetry condition $A^*YB^- = B^{-*}Y^*A$ (B^- is a special, generalized inverse).

While, e.g., in [5], [8] the Riccati-type DAEs are constructed to solve a linear boundary value problem serving as an extremal condition for the linear-quadratic optimal control problem, we justify the Riccati DAE (1.15) by a direct optimality proof (Theorem 2.5).

Notice that (1.11) is no longer necessarily square but may contain k equations, while $x(t)$ has m components.

In section 2 it is shown that, for the linear-quadratic optimal control problem (1.1), (1.11), (1.12), analogously to the classical case (1.1)–(1.5), optimal feedback controls can be established from the solutions of (1.15), (1.16). The main result in this respect is Theorem 2.5.

Section 3 investigates the solvability of the Riccati equation (1.15), generalizing the positive results from [16], [17]. The new solvability statements are provided in Theorem 3.4.

In section 4 we show that the solvability assumptions from Theorem 3.4 simultaneously imply the solvability of the closed loop initial value problems (IVPs).

In section 5 we work the same example as discussed in [14]. This example was used in [14] merely to demonstrate drawbacks with (1.10). In the present paper, we use this task to confirm the better solvability properties of the new Riccati equation (1.15).

Finally, section 6 elucidates the relation between solutions of the Riccati equation (1.15) and solutions of the corresponding implicit Hamiltonian system.

2. Optimal feedback control. We deal with the quadratic cost functional

$$\begin{aligned} J(u,x) :=& \frac{1}{2}\langle x(T), Vx(T)\rangle \\ &+\frac{1}{2}\int_0^T \{\langle x(t), W(t)x(t)\rangle + 2\langle x(t), S(t)u(t)\rangle + \langle u(t), R(t)u(t)\rangle\}dt \end{aligned} \tag{2.1}$$

to be minimized on pairs $(u,x) \in \mathcal{C}\times\mathcal{C}^1_B$ satisfying the IVP

$$A(t)(B(t)x(t))' = C(t)x(t) + D(t)u(t), \quad t\in[0,T], \tag{2.2}$$

$$A(0)B(0)x(0) = z_0. \tag{2.3}$$
