ON THE EXISTENCE OF CONJUGATE POINTS FOR A SECOND ORDER ORDINARY DIFFERENTIAL EQUATION*

ANGELO B. MINGARELLI†

Abstract. In this paper we show that a result of S. W. Hawking and R. Penrose [Proc. Roy. Soc. London Ser. A, 314 (1970), pp. 529–548] on the existence of conjugate points for a real second order linear differential equation is a consequence of a much earlier result of M. Yelchin [5]. Yelchin's original proof is clarified and corrected and his result is extended. As a result, we obtain extensions of the Hawking–Penrose theorem and Tipler's [J. Differential Equations, 30 (1978), pp. 165–174] a complementary result to said theorem.

Key words. conjugate points, disconjugacy

1. Introduction. In 1970 S. W. Hawking and R. Penrose ([3, p. 541], Hawking and Ellis [2, p. 98]) proved the following interesting result concerning the existence of conjugate points on $(-\infty, \infty)$ for

$$y'' + q(x)y = 0. \tag{1.1}$$

PROPOSITION 1 (Hawking and Penrose). *Let* q: $(-\infty, \infty) \to [0, \infty)$, q *continuous on* $(-\infty, \infty)$ *and* $q(t_1) > 0$ *for at least one point* $t_1 \in \mathbb{R}$. *Then* (1.1) *is not disconjugate on* $(-\infty, \infty)$.

We recall that (1.1) is said to be (Wintner) *disconjugate* on $(-\infty, \infty)$ provided every nontrivial solution has at most one zero on $(-\infty, \infty)$. It is nondisconjugate or, more simply, not disconjugate on $\mathbb{R}$ otherwise, i.e., there exists at least one nontrivial solution of (1.1) which has at least two zeros in $(-\infty, \infty)$.

The relevance of the study of conjugate points of (1.1) to general relativity has been pointed out in [4]. For example, the Jacobi equation

$$\frac{d^2 Z^\alpha}{dt^2} = R_{\alpha a \beta b} V^a Z^\beta V^b$$

which is defined along a timelike geodesic (see [2]) $\gamma(t)$ on which Z^α is a Jacobi field, t is the proper time along $\gamma(t)$, V^a is a unit tangent vector to $\gamma(t)$ and $R_{a\alpha\beta b}$ is the Riemann tensor, has a solution which vanishes at two points $t_1 < t_2$, $t_i \in I$, if and only if (for example, [4]) (1.1) has a solution $y \not\equiv 0$ vanishing at t_1 and t_2 where

$$q = \frac{1}{3}\left(R_{ab} V^a V^b + 2\sigma^2\right)$$

and R_{ab} is the Ricci tensor and σ^2 some nonnegative function. The existence of such conjugate points for (1.1) with q defined above is related to the incompleteness of timelike geodesics via the Avez–Hawking theorem (see [4] for further details).

*Received by the editors January 17, 1984, and in revised form October 10, 1984. This research was supported in part by the Natural Sciences and Engineering Research Council of Canada under grant UO 167.

† Department of Mathematics, University of Ottawa, Ottawa, Ontario, Canada K1N 9B4.

An elementary proof of Proposition 1 is given by F. J. Tipler [4, Thm. 1] who complements the Hawking–Penrose result with

PROPOSITION 2 (Tipler). *Let* q: $(-\infty,\infty)\to(-\infty,\infty)$, q *continuous on* $(-\infty,\infty)$ *and*

$$\int_{-\infty}^{\infty} q(s)\,ds>0, \tag{1.2}$$

(*where the integral is to be understood in the sense*

$$\liminf_{t_1\to-\infty}\left(\liminf_{t_2\to+\infty}\int_{t_1}^{t_2} q(s)\,ds\right)>0$$

whenever (1.2) *fails to converge*). *Then* (1.1) *is not disconjugate on* $(-\infty,\infty)$.

Tipler's results are reconsidered, in part, in a subsequent paper by C. D. Ahlbrandt, D. B. Hinton and R. T. Lewis [1] who present a *finite* interval analogue of Proposition 1 for the weighted equation

$$(y'(x)/r(x))'+q(x)y(x)=0, \qquad -\infty\leqq a<x<b\leqq\infty,$$

which, however, does not allow the case $r(x)=1$, [1, Thm. 3.3].

2. The aim of this paper is to show that, in fact, Propositions 1 and 2 above are consequences of a much earlier result of M. Yelchin [5, Thm. 1] which we call Yelchin's theorem and which we extend in Theorem 3.1. It is to be noted that Yelchin's proof of said theorem causes difficulties as there are many misprints, some of which appear to be errors on the author's part. However his proof can still be saved and the results duly extended to the case when q is merely required to be locally Lebesgue integrable on (a,b), (a finite or infinite interval).

Furthermore, we emphasize that Yelchin's results in [5] actually yield a *necessary and sufficient* condition for (1.1) to be nondisconjugate on (a,b). However, the stated condition is not wholly dependent upon q, as one may expect.

3. In the sequel all integrals are Lebesgue integrals and $AC_{\text{loc}}(a,b)$ stands for the class of all real-valued functions defined on (a,b) and locally absolutely continuous there. The interval (a,b) will be a finite or infinite interval, $-\infty\leqq a<x<b\leqq+\infty$. The (equivalence) class of all functions which are locally Lebesgue integrable on (a,b) will be denoted by $L_{\text{loc}}(a,b)$ and the Lebesgue measure of a measurable set $E\subset(a,b)$ by $\mu(E)$.

Next, let $\mathscr{A}$ denote the collection of all functions ψ: $(a,b)\to\mathbb{R}$ which satisfy (i) and (ii):

$$\text{(i)} \qquad \psi\in AC_{\text{loc}}(a,b), \tag{3.1}$$

$$\text{(ii)} \qquad \lim_{\substack{\beta\to b^-\\ \alpha\to a^+}}\left[\arctan\int_{x_0}^{x}\exp\left\{-2\int_{x_0}^{t}\psi(s)\,ds\right\}dt\right]_{x=\alpha}^{x=\beta}=\pi, \tag{3.2}$$

and $x_0\in(a,b)$ is a fixed (but otherwise arbitrary) point. The main result of this paper is

THEOREM 3.1a). *Let* $q\in L_{\text{loc}}(a,b)$. *Furthermore let* $\psi\in\mathscr{A}$ *satisfy*

$$\psi'(x)+\psi^2(x)+q(x)\geqq 0 \quad a.e.\ on\ (a,b) \tag{3.3}$$

with strict inequality holding on sets E^-, E^+ ($E^-\subset(a,x_0]$, $E^+\subset[x_0,b)$) *with* $\mu(E^{\pm})>0$. *Then* (1.1) *is not disconjugate on* (a,b).

THEOREM 3.1b). *Conversely, let* (1.1) *be nondisconjugate on* (a,b). *Then there exists a function* $\psi \in \mathscr{A}$ *which satisfies* (3.3) *a.e. on* (a,b).

As an immediate consequence we obtain Yelchin's theorems [5, Thms. 1, 2] which are stated there for *continuous* q.

COROLLARY 3.1. *Let* $q \in L_{\text{loc}}(-\infty,\infty)$, q: $(-\infty,\infty)\to[0,\infty)$ *and* $q(x)>0$ *on some measurable set* $E \subset (-\infty,\infty)$ *with* $\mu(E)>0$. *Then* (1.1) *is not disconjugate on* $(-\infty,\infty)$.

Remark 1. The above corollary contains the Hawking–Penrose results. For if q is continuous on $(-\infty,\infty)$, $q(x)\geqq 0$ and $q(t_1)>0$ for some point t_1, then $q(x)>0$ in some finite interval about t_1, by continuity. Such an interval has positive Lebesgue measure and hence Corollary 3.1 applies.

Remark 2. That the Hawking–Penrose result is a direct consequence of Yelchin's theorem is seen by choosing $\psi = 0$ in Theorem 3.1a) and applying a continuity argument to (3.3) in order to obtain strict inequality. (Note that (3.2) is trivially satisfied for this choice of ψ on $(-\infty,\infty)$).

COROLLARY 3.2. *Let* $q \in L_{\text{loc}}(-\infty,\infty)$, q: $(-\infty,\infty)\to(-\infty,\infty)$, *and that* q *satisfies* (3.4) *and* (3.5) *below* (*for some* $x_0 \in \mathbb{R}$)

$$\liminf_{x\to+\infty} \int_{x_0}^{x} q(s)\,ds > 0, \tag{3.4}$$

$$\liminf_{x\to-\infty} \int_{x}^{x_0} q(s)\,ds > 0. \tag{3.5}$$

Then (1.1) *is not disconjugate on* $(-\infty,\infty)$.

Remark 3. Note that Corollary 3.2 includes Proposition 2, cf. [4].

Remark 4. That Tipler's theorem (Proposition 2) is a direct consequence of Yelchin's theorem can be realized by choosing $\psi(x) = -\int_{x_0}^{x} q(s)\,ds$. This choice of ψ then satisfies all the hypotheses of Theorem 3.1a) and so Tipler's theorem follows (see the proof of Corollary 3.2 in §4 of this paper for details).

As a final application we give

PROPOSITION 3. *Let* $q \in L_{\text{loc}}(-\infty,\infty)$ *and assume that* $\int_{x_0}^{x_1} q(s)\,ds \neq 0$ *for some* x_0, x_1. *If*

$$-\infty < \liminf_{|x|\to+\infty} \int_{x_0}^{x}\int_{x_0}^{s} q(t)\,dt\,ds \leqq \liminf_{|x|\to+\infty} \int_{x_0}^{x}\int_{x_0}^{s} q(t)\,dt\,ds < +\infty. \tag{3.6}$$

then

$$y'' + \lambda q(t)\,y = 0 \tag{3.7}$$

is not disconjugate on $(-\infty,\infty)$ *for each real* $\lambda \neq 0$.

4. Proofs.

Proof of Theorem 3.1a). Let u be the solution of (1.1) satisfying the initial conditions $u(x_0)=1$, $u'(x_0)=\psi(x_0)$. Since $\psi \in \mathscr{A}$ the function

$$\Psi(x,\alpha) \equiv \psi'(x)+\psi^2(x)+\alpha\big(-q(x)-\psi'(x)-\psi^2(x)\big)$$

where $\alpha \in [0,1]$ is in $L_{\text{loc}}(a,b)$, as a function of x. Thus the initial value problem

$$u' = \Psi(x,\alpha)\,u, \tag{4.1}$$

$$u(x_0,\alpha)=1, \qquad u'(x_0,\alpha)=\psi(x_0), \tag{4.2}$$

where the prime always denotes differentiation with respect to x, admits a unique solution $u=u(x,\alpha)\in AC_{\text{loc}}(a,b)$ for which $u'(x,\alpha)\in AC_{\text{loc}}(a,b)$ and $u(x,\alpha)$ satisfies (4.1) a.e. for $a<x<b$. Note that for $\alpha=1$, (4.1) reduces to (1.1) while for $\alpha=0$, the solution $u(x,0)=\exp\{\int_{x_0}^{x}\psi(s)\,ds\}$.

We now use the Prüfer-type transformation in (4.1): $u=\rho\cos\phi$, $\phi(x_0)=0$. Let v be a linearly independent solution of (4.1) given by the solution of the differential equation $u'v-uv'=1$, $v(x_0)=0$. Then it is readily verified that ϕ, $\phi'\in AC_{\text{loc}}(a,b)$ and ϕ satisfies

$$\phi'=\rho^{-2},\quad \rho^2=u^2+v^2, \tag{4.3}$$

while ρ, $\rho'\in AC_{\text{loc}}(a,b)$ satisfies the equation

$$\rho''\rho^{-1}-\rho^{-4}=\Psi(x,\alpha) \tag{4.4}$$

a.e. on (a,b), (in contrast with [5, Eq. 8]). Now (4.3) implies that $\phi(\cdot,\alpha)$ is increasing for $x\in(a,b)$ with $\phi(x,\alpha)<0$ ($\phi(x,\alpha)>0$) for $a<x<x_0$ ($x_0<x<b$), for each α, $0\leqq\alpha\leqq 1$. Now $\phi(x,1)$ is the phase of (1.1) whereas $\phi(x,0)$ is the phase of (4.1)–(4.2) with $\alpha=0$. In fact $\phi(x,0)$ is given explicitly by

$$\phi(x,0)=\arctan\left\{\int_{x_0}^{x}\exp\left(-2\int_{x_0}^{t}\phi(s)\,ds\right)dt\right\}. \tag{4.5}$$

In the following, ρ_α will denote $\partial\rho/\partial\alpha$ while $'=\partial/\partial x$ as usual. Now because of the smoothess of Ψ as a function of α,u and v will enjoy the same property and thus ρ, as given in (4.3) is AC $[0,1]$, as a function of α for each x. So differentiating (4.4) with respect to α one finds, after a straightforward but lengthy calculation, that

$$\rho_\alpha''-\left(\rho''\rho^{-1}-4\rho^{-4}\right)\rho_\alpha=-\rho\left(q+\psi'+\psi^2\right), \tag{4.6}$$

i.e., ρ_α satisfies the second order linear differential equation (4.6) (in x) a.e. on (a,b).

Now a particular solution of (4.6) subject to the initial conditions $\rho_\alpha(x_0,\alpha)=\rho'_\alpha(x_0,\alpha)=0$ is given by

$$\rho_\alpha(x,\alpha)=-\rho(x,\alpha)\frac{\Phi(x,\alpha)}{2} \tag{4.7}$$

(since $\rho(x_0,\alpha)=1$, $\rho'(x_0,\alpha)=\psi(x_0)$) where

$$\Phi(x,\alpha)\equiv\int_{x_0}^{x}\rho^2(s,\alpha)\left[\psi'(s)+\psi^2(s)+q(s)\right]\sin 2\left[\phi(x,\alpha)-\phi(s,\alpha)\right]ds, \tag{4.8}$$

(in contrast with [5, Eqs. (11), (12)]). Note that (4.7) can be solved so as to yield information regarding $\rho(x,1)$ and $\rho(x,0)$ and so on $\phi'(x,1)$ and $\phi'(x,0)$ because of (4.3). Thus, integrating (4.7) with respect to α over $[0,1]$ for a fixed x, one easily finds

$$\left[\phi(x,1)-\phi(x,0)\right]'=\frac{\exp\left[\int_0^1\Phi(x,\alpha)\,d\alpha\right]-1}{\rho^2(x,0)}. \tag{4.9}$$

We now proceed with the proof. To this end assume the contrary, i.e., that (1.1) is disconjugate on (a,b). Then (3.3) and the Sturm comparison theorem imply that, for each value of α in $[0,1]$, there do not exist points $x_1(\alpha)$, $x_2(\alpha)$, $(a<x_1(\alpha)<x_0<x_2(\alpha)<b)$ which are zeros of $u(x,\alpha)$. Hence, by the definition of ϕ for each $x\in(a,b)$ and for each $\alpha\in[0,1]$, there holds

$$|\phi(x,\alpha)|<\frac{\pi}{2}. \tag{4.10}$$

Hence the increasing nature of ϕ and (4.10) now implies that $\sin 2[\phi(x,\alpha)-\phi(s,\alpha)]>0$ for each $x_0<s<x$. This, along with (3.3), implies that $\Phi(x,\alpha)\geqq 0$ for all $x\geqq x_0$ (with a similar argument holding if $x\leqq x_0$). Now for $x\in E^+$ such that $\mu(E^+\cap[x_0,x])>0$ (or $x\in E^-$), $\Phi(x,\alpha)>0$, as the inequality in (3.3) is strict for such x. Therefore, (4.9) implies that $\Phi(x,1)-\Phi(x,0)$ is nondecreasing for $x\in(a,b)$. Since $\mu(E^+)>0$, there exists a point $x^+\in E^+$ such that $\mu(E^+\setminus\{(x_0,x^+)\cap E^+\})>0$, and $\mu(E^+\cap(x,x^+))>0$ (by a simple measure-theoretic argument). If we now integrate (4.9) over $[x^+,x]$, where $x>x^+>x_0$, we obtain

$$\phi(x,1)>\phi(x,0)+\lambda^2 \tag{4.11}$$

where $\lambda^2\equiv\phi(x^+,1)-\phi(x^+,0)$, as the right side of (4.9) is positive on a set of positive Lebesgue measure lying to the right of x^+. We can now choose $x^-\in E^-$ similarly. Then for $x<x^-<x_0$,

$$\phi(x,1)<\phi(x,0)-\mu^2 \tag{4.12}$$

where $\mu^2=\phi(x^-,0)-\phi(x^-,1)$. Since ϕ is monotone we get

$$\lim_{x\to b^-}\phi(x,1)\geqq\lim_{x\to b^-}\phi(x,0)+\lambda^2 \tag{4.13}$$

and

$$\lim_{x\to a^+}\phi(x,1)\leqq\lim_{x\to a^+}\phi(x,0)-\mu^2. \tag{4.14}$$

Combining (4.13)–(4.14) we find (because of (3.2))

$$\lim_{x\to b^-}[\phi(x,1)]-\lim_{x\to a^+}[\phi(x,1)]\geqq\pi+\lambda^2+\mu^2.$$

However this contradicts (4.10) and this completes the proof.

Proof of Theorem 3.1b). This is identical to that corresponding to [5, Thm. 2] and so it is omitted.

Proof of Corollary 3.1. Let $\psi\equiv 0$ on $(-\infty,\infty)$. Then $\psi\in\mathscr{A}$ and clearly (3.3) is satisfied since $q(x)\geqq 0$ a.e. by hypothesis. For E bounded $\mu(E)>0$, there exists a point $x_0\in E$ such that $\mu((-\infty,x_0)\cap E)>0$ and $\mu(E\cap(x_0,\infty))>0$ (again by a straightforward measure-theoretic argument). Thus let $E^-\equiv(-\infty,x_0)\cap E$ and $E^+\equiv E\cap(x_0,\infty)$. Then $q(x)>0$ a.e. on $E^-\cup E^+$. (If E is unbounded and $\mu(E)>0$, there is a bounded subset F of E with $\mu(F)>0$. We can then apply the above argument to F.) Thus strict inequality in (3.3) holds on these sets and so Theorem 3.1a) implies that (1.1) is not disconjugate.

Proof of Corollary 3.2. Define ψ by $\psi(x)\equiv-\int_{x_0}^x q(s)\,ds$. Then $\psi\in AC_{\text{loc}}(-\infty,\infty)$ and (3.4) implies that $\psi(x)\leqq -c$ where $c>0$, provided $x\geqq x_1\geqq x_0$. Thus it is immediate that (3.3) is satisfied, since $\psi^2(x)>0$ on some interval about x_1. We now show that ψ satisfies (3.2). Note that

$$\exp\left\{-2\int_{x_0}^x\psi(s)\,ds\right\}=\exp(-2c_1)\exp\left(-2\int_{x_1}^x\psi(s)\,ds\right)$$

where $c_1=\int_{x_0}^{x_1}\psi(s)\,ds$. But $\psi(x)\leqq -c$, for $x\geqq x_1$ implies that

$$\exp\left\{-2\int_{x_0}^x\psi(s)\,ds\right\}\geqq\exp(-2c_1)\exp(2c(x-x_1)). \tag{4.15}$$

Hence

$$\lim_{x\to+\infty}\int_{x_1}^{x}\exp\left\{-2\int_{x_0}^{t}\psi(s)\,ds\right\}dt=+\infty \tag{4.16}$$

and so the same is true if x_1 is replaced by x_0. If $x\leqq x_0$, note that for $x\leqq x_2\leqq x_0$ (3.5) implies that $\int_x^{x_0} q(s)\,ds\geqq c_2>0$. Thus $\psi(x)\geqq c_2$ for all $x\leqq x_2$. As before we can easily derive that

$$\exp\left\{-2\int_{x_0}^{x}\psi(s)\,ds\right\}\geqq c_3\exp\left(2c_2(x_2-x)\right) \tag{4.17}$$

for all $x\leqq x_2$ where $c_3=\exp(-2\int_{x_0}^{x_2}\psi(s)\,ds)$. Now (4.17) implies that

$$\lim_{x\to-\infty}\int_{x_2}^{x}\exp\left(-2\int_{x_0}^{t}\psi(s)\,ds\right)dt=+\infty. \tag{4.18}$$

Combining (4.16) and (4.18) we obtain (3.2) as required. Thus $\psi\in\mathscr{A}$ and so Theorem 3.1a) implies that (1.1) is not disconjugate on $(-\infty,\infty)$.

Proof of Proposition 3. In order to show this we note that if q is such that for $\psi(x)\equiv\int_{x_0}^{x}-q(s)\,ds$, (3.2) holds, then (1.1) is not disconjugate on $(-\infty,\infty)$. Now $\psi(x_1)\neq 0$ by hypothesis and so (3.3) holds (with strict inequality around the point x_1). Again (3.1) is satisfied. Thus it suffices to show that

$$\lim_{x\to+\infty}\int_{x_0}^{x}\exp\left\{2\int_{x_0}^{x}\int_{x_0}^{t}q(s)\,ds\,dt\right\}dx=+\infty \tag{4.19}$$

with an analogous result for $x\to-\infty$. However (3.6) implies that

$$-M\leqq\int_{x_0}^{x}\int_{x_0}^{t}q(s)\,ds\,dt\leqq M \tag{4.20}$$

provided $|x|\geqq X_0$, where $M>0$. Applying the estimate (4.20) to the left side of (4.19) we indeed obtain (4.19). A similar result holds in the other case. Thus (3.6) implies that (1.1) is not disconjugate on $(-\infty,\infty)$. Now replacing q by λq as in (3.7) we still have $\int_{x_0}^{x_1}(\lambda q)(s)\,ds\neq 0$, provided $\lambda\neq 0$, and (3.6) clearly holds for each λ. Thus (3.7) is not disconjugate on $(-\infty,\infty)$ for each $\lambda\neq 0$ which is what we wished to show.

Note. Condition (3.6) excludes the case when q is of constant sign a.e. on $(-\infty,\infty)$ since, in the latter case, at least one of the quantities in (3.6) is infinite.

Hence (3.6) implies that q must be positive a.e. on a set of positive Lebesgue measure and negative a.e. on a (possibly different) set of positive Lebesgue measure.

GLOBAL SIMPLIFICATION OF A SINGULARLY PERTURBED ALMOST DIAGONAL SYSTEM*

HARRY GINGOLD† AND PO-FANG HSIEH‡

Abstract. Given a singularly perturbed differential system $\varepsilon^h Y' = [D(x,\varepsilon)+\varepsilon^\theta R(x,\varepsilon)]Y$, where D is a diagonal matrix, $x\in J=(a,b)$, $\varepsilon\in S_c=(0,c]$, and h and θ are positive numbers, this paper studies the conditions such that this system can be globally simplified by $Y=(I+P(x,\varepsilon))Z$ into $\varepsilon^h Z' = D(x,\varepsilon)Z$, valid in $J\times S_{c_1}$, $(0<c_1\leqq c)$. The method and results of Gingold [SIAM J. Math. Anal., 9 (1978), pp. 1076–1802] are used in this study. These results are also true for complex x and ε in certain domains. If $\theta=h$, the results hold also even when J contains turning points of the equations.

AMS-MOS subject classifications (1980). Primary 34E15; secondary 34E20

Key words. global simplification, singular perturbation, almost diagonal system, turning point

1. Introduction.

Consider an n-dimensional linear ordinary differential system

$$(E_1) \qquad \varepsilon^h Y' = \left[D(x,\varepsilon)+\varepsilon^\theta(x,\varepsilon)\right]Y, \qquad ' = \frac{d}{dx},$$

where x is a real or complex variable with $x\in J=(a,b)$, (J may be infinite), or $x\in G$, a simply connected domain in the complex plane, ε is a real or complex parameter with $\varepsilon\in S_c=(0,c]$ or $S_{\alpha c}=\{\varepsilon\,|\,|\arg\varepsilon|<\alpha,\ 0<|\varepsilon|<c\}$ and θ and h are positive numbers. Here $D(x,\varepsilon)$ and $R(x,\varepsilon)$ are n by n matrices and

$$(1.1) \qquad D(x,\varepsilon)=\operatorname{diag}\{d_1(x,\varepsilon),\cdots,d_n(x,\varepsilon)\}.$$

Let

$$(1.2) \qquad R(x,\varepsilon)=\left(r_{jk}(x,\varepsilon)\right), \qquad j,k=1,2,\cdots,n.$$

Without loss of generality, we can assume

$$(1.3) \qquad r_{jj}(x,\varepsilon)\equiv 0, \qquad j=1,2,\cdots,n.$$

Otherwise, r_{jj} can be combined in d_j.

DEFINITION. The system (E_1) is said to be a globally almost diagonal system (G.A.D.S.) in $\bar{J}$ [or in $\bar{G}$] if there exists an n by n matrix $P(x,\varepsilon)$ in the class of $C^1(\bar{J}\times S_{c_1})$, [or $C^1(\bar{G}\times S_{\alpha c_1})$], $(0<c_1\leqq c)$, such that for a suitable norm

$$(1.4) \qquad \lim\|P\|=0 \quad \text{as } \varepsilon\to 0 \text{ in } S_{c_1}\left[\text{or in } S_{\alpha c_1}\right],$$

uniformly for $x\in\bar{J}$ [or $x\in\bar{G}$] and the following relations hold:

$$(1.5) \qquad Y=(I+P(x,\varepsilon))Z \qquad (I\text{: identity matrix}),$$

$$(E_2) \qquad \varepsilon^h Z' = D(x,\varepsilon)Z.$$

‡ Department of Mathematics, Western Michigan University, Kalamazoo, Michigan 49008. The work of this author is partially supported by a Faculty Research Fellowship, Western Michigan University.

Namely, (E_1) has the fundamental matrix in the following form:

$$Y=(I+P(x,\varepsilon))\exp\left\{\varepsilon^{-h}\int^{x}D(t,\varepsilon)\,dt\right\}. \tag{1.6}$$

The existence of $P(x,\varepsilon)$ and validity of (1.4) on $\bar{J}$ [or on $\bar{G}$] justify the "globality" in contrast to "local" results obtained in a subset of J [or of G].

We shall investigate in this paper the sufficient conditions that (E_1) is a G.A.D.S. for both x in J and x in G.

It is important to identify a *final* stage of "asymptotic decomposition" of the given system (E_1) *as soon as possible*. By knowing this, we can avoid laborious linear transformations and laborious calculations of eigenvalues of n by n matrix functions. This is one of our aims in defining G.A.D.S.

2. Main theorems—real case. For $x,t\in\bar{J}$, $\varepsilon\in S_c$, let

$$D_{jk}(x,t,\varepsilon)=\mathrm{Re}\left\{\varepsilon^{-h}\int_{t}^{x}\left(d_j(s,\varepsilon)-d_k(s,\varepsilon)\right)ds\right\},\quad j,k=1,2,\cdots,n\quad(j\neq k). \tag{2.1}$$

The following assumption will be used.

Assumption 1. Assume that $d_j(x,\varepsilon)\in C(J\times S_c)$. For each pair (j,k), $(j\neq k;\ j,k=1,2,\cdots,n)$, there exist two fixed numbers m_{jk} and $\hat{m}_{jk}$ such that

$$\hat{m}_{jk}\leqq D_{jk}(x,t,\varepsilon)\leqq m_{jk} \tag{2.2}$$

for all $x,t\in\bar{J}$, $\varepsilon\in S_c$ or if $D_{jk}(x,t,\varepsilon)$ is unbounded, then for all $x,t\in J$, $\varepsilon\in S_c$, with either $x<t$ or $x>t$,

$$D_{jk}(x,t,\varepsilon)\leqq m_{jk}\quad\text{or}\quad\hat{m}_{jk}\leqq D_{jk}(x,t,\varepsilon). \tag{2.3}$$

For a suitable norm, let

$$r(\varepsilon)=\int_{a}^{b}\|R(t,\varepsilon)\|dt. \tag{2.4}$$

We have the following theorems for real x.

THEOREM 1. *Assume that*: (i) $D(x,\varepsilon)$ *and* $R(x,\varepsilon)$ *are in the class* $C(\bar{J}\times S_c)$, (ii) *Assumption* 1 *holds*, (iii) $\theta=h$, *and* (iv) $r(\varepsilon)=o(1)$ *as* $\varepsilon\to 0^{+}$. *Then*, (E_1) *is a* G.A.D.S., *where* $\|P(x,\varepsilon)\|=O(r(\varepsilon))$ *uniformly on* $\bar{J}$ *as* $\varepsilon\to 0^{+}$.

THEOREM 2. *Assume that*: (i) $D(x,\varepsilon)$ *and* $R(x,\varepsilon)$ *are in the class* $C^1(\bar{J}\times\bar{S}_c)$, (ii) *Assumption* 1 *holds*, (iii) $\theta>h/2$, (iv) *there is a fixed number* μ *such that*

$$\left|d_j(x,\varepsilon)-d_k(x,\varepsilon)\right|\geqq\mu>0,\qquad j,k=1,2,\cdots,n,\quad j\neq k \tag{2.5}$$

for all $x\in J$ *and* $\varepsilon\in S_c$. *Then* (E_1) *is a* G.A.D.S. *and* $\|P(x,\varepsilon)\|=O(\varepsilon^{\sigma})$ *uniformly on* $\bar{J}$ *as* $\varepsilon\to 0^{+}$, *where* $\sigma=\min\{\theta,2\theta-h\}$.

We shall prove Theorem 1 in §3 and use Theorem 1 to prove Theorem 2 in §7.

Combine the idea of G.A.D.S. with those theorems, we have the next theorem.

THEOREM 3. *Under the conditions of Theorem* 1 *or those of Theorem* 2, *the differential system* (E_1) *has the fundamental matrix with asymptotic expansion* (1.6) *uniformly on* $\bar{J}$.

Analogous theorems with complex x will be given as Theorem 4 and Theorem 5 in §8.

Theorem 1 and Theorem 4 include the case that (E_1) has certain types of turning points in J or in G. Extension of the method used in proving these theorems can be applied to the results of Wasow [15] and Lee [10]. Also extensions of the method and results presented in these theorems can be applied to improve those of Devinatz [2], Levinson [11], Harris and Lutz [6], and Hartman and Wintner [8]. These will be discussed in forthcoming papers.

The question of finding the "leading term" of the coefficient of (E_1) has been discussed by many over the years (see Hsieh [8]). The theorems in the paper indicate that $D(x,\varepsilon)$ is the leading term of the coefficients of (E_1) if $\theta > h/2$ and appropriate additional conditions are satisfied.

3. Proof of Theorem 1. From the equations (E_1), (1.5), (E_2) and $\theta = h$, we know that $P(x,\varepsilon)$ satisfies the following equation:

$$\varepsilon^h P' = D(x,\varepsilon)P - PD(x,\varepsilon) + \varepsilon^h R(x,\varepsilon)P + \varepsilon^h R(x,\varepsilon). \tag{3.1}$$

Let

$$E(x,t,\varepsilon) = \exp\left\{\varepsilon^{-h}\int_t^x D(s,\varepsilon)\,ds\right\} \tag{3.2}$$

and L be the integral operator

$$LP = \int^x E(x,t,\varepsilon)R(t,\varepsilon)P(t,\varepsilon)E^{-1}(x,t,\varepsilon)\,dt \tag{3.3}$$

with lower limits to be specified in the sequel. Then, by a well-known lemma (e.g. see Wasow [14, p. 169]), the solution P of (3.1) is given by

$$P(x,\varepsilon) = P_0 + LP, \qquad P_0 = LI. \tag{3.4}$$

Let

$$P = (p_{jk}), \quad RP = ((RP)_{jk}), \quad LP = ((LP)_{jk}), \qquad j,k = 1,2,\cdots,n. \tag{3.5}$$

Then

$$(LP)_{jk} = \int_{\beta_{jk}}^x (RP)_{jk} \exp\left\{\varepsilon^{-h}\int_t^x \left(d_j(s,\varepsilon) - d_k(s,\varepsilon)\right) ds\right\} dt, \tag{3.6}$$

where β_{jk} are chosen to be either a or b so that for t between β_{jk} and x, the exponential factor of the integrand remains bounded. Let

$$m = \max_{j,k}\left\{|m_{jk}|, |\hat{m}_{jk}|\right\} \tag{3.7}$$

and the norm is chosen that

$$|r_{jk}| \leqq \|R\| \quad \text{and} \quad \|R\| \leqq \left\|\left(|r_{jk}|\right)\right\|, \tag{3.8}$$

also, denote

$$|||P||| = \sup_J \|P\|. \tag{3.9}$$

Then, we have the estimate

$$(3.10)\qquad |(LP)_{jk}| \leqq \left| \int_{\beta_{jk}}^{x} (RP)_{jk}(\exp m)\, dt \right| \leqq e^m \sum_{l=1}^{n} \left| \int_{\beta_{jk}}^{x} |r_{jl}(t,\varepsilon)||p_{lk}(t,\varepsilon)|dt \right|$$

$$\leqq ne^m \left| \int_{\beta_{jk}}^{x} \|R\| \left(\max_{l,k} |p_{lk}| \right) dt \right| \leqq ne^m |||P||| \left| \int_{\beta_{jk}}^{x} \|R\| dt \right|.$$

Let

$$(3.11)\qquad K = ne^m.$$

We have

$$(3.12)\qquad \|LP\| \leqq K|||P||| \int_a^b \|R(t,\varepsilon)\| dt.$$

Similarly, we have

$$(3.13)\qquad \|LI\| \leqq K\|I\| \int_a^b \|R(t,\varepsilon)\| dt.$$

Thus, from (3.4), and (2.3) we have

$$(3.14)\qquad |||P||| \leqq K(\|I\| + |||P|||) r(\varepsilon).$$

By Theorem 1 (iv), if c_1 is chosen small enough, (3.4) defines a contraction mapping for $x \in \bar{J}$, $\varepsilon \in S_{c_1}$. Furthermore, we have

$$(3.15)\qquad |||P||| \leqq \frac{K\|I\| r(\varepsilon)}{1 - Kr(\varepsilon)}$$

and Theorem 1 is proved.

4. Fundamental lemmas. In order to prove Theorem 2, we need to establish the following fundamental lemmas.

LEMMA 1. *Let Z and P_{k0} be n by n matrices with $Z = (z_{jk})$, $j,k = 1,2,\cdots,n$ and P_{k0} is the matrix with one at its (k,k) entry and zero everywhere else. Then, Z commutes with P_{k0} if, and only if, that*

$$(4.1)\qquad z_{jk} = z_{kr} = 0 \quad \text{for } j, r \neq k.$$

LEMMA 2. *Assume that $D(x,\varepsilon)$ and $R(x,\varepsilon)$ satisfy* (1.1)–(1.3) *and* (i) *and* (iv) *of Theorem* 2. *Then*: (1) *the matrix $D(x,\varepsilon)+\eta R(x,\varepsilon)$ has distinct eigenvalues $\{\tilde{d}_1(x,\varepsilon,\eta), \tilde{d}_2(x,\varepsilon,\eta),\cdots,\tilde{d}_n(x,\varepsilon,\eta)\}$ for $x \in \bar{J}$, $\varepsilon \in S_c$, $|\eta| \leqq \eta_0$ with a suitable positive constant η_0*; (2) *the characteristic polynomial of $D(x,\varepsilon)+\eta R(x,\varepsilon)$ has the form*

$$(4.2)\qquad \tilde{p}_n(\lambda; x,\varepsilon,\eta) \equiv \det[D + \eta R - \lambda I] = p_n(\lambda; x,\varepsilon) + \eta^2 p_{n-2}(\lambda; x,\varepsilon,\eta),$$

where

$$(4.3)\qquad p_n(\lambda; x,\varepsilon) = \prod_{j=1}^{n} \left(d_j(x,\varepsilon) - \lambda \right),$$

$p_{n-2}(\lambda; x,\varepsilon,\eta)$ *is a polynomial in λ of degree $n-2$; and* (3) $\tilde{d}_j(x,\varepsilon,\eta)$ *satisfy the following relations*;

$$(4.4)\qquad \tilde{d}_j(x,\varepsilon,\eta) = d_j(x,\varepsilon) + O(\eta^2), \qquad j = 1,2,\cdots,n$$

for $x \in \bar{J}$, $\varepsilon \in \bar{S}_c$, $|\eta| \leqq \eta_1$.

LEMMA 3. *Given an n by n matrix* $D(x,\varepsilon)+\eta R(x,\varepsilon)$, *where D and R satisfy conditions* (1.3) *and* (i) *and* (iv) *of Theorem* 2, *and* η *is a complex number. Then, there is an n by n matrix* $Q(x,\varepsilon,\eta)$ *in the class of* $C^1(\bar{J}\times\bar{S}_c\times\{|\eta|\leqq\tilde{\eta}\})$ ($\tilde{\eta}$: *positive constant*) *satisfying*

$$\|Q(x,\varepsilon,\eta)\|\leqq K_1|\eta|, \qquad \|Q'(x,\varepsilon,\eta)\|\leqq K_2|\eta| \tag{4.5}$$

uniformly on $\bar{J}\times\bar{S}_c\times\{|\eta|\leqq\tilde{\eta}\}$ *for suitable positive constants* K_1 *and* K_2 *and*

$$(I+Q)^{-1}(D+\eta R)(I+Q)=\tilde{D}(x,\varepsilon,\eta) \tag{4.6}$$

where

$$\tilde{D}(x,\varepsilon,\eta)=\operatorname{diag}\{\tilde{d}_1(x,\varepsilon,\eta),\tilde{d}_2(x,\varepsilon,\eta),\cdots,\tilde{d}_n(x,\varepsilon,\eta)\}. \tag{4.7}$$

In order to show Lemma 1 subdivide Z according to P_{k0}, namely

$$Z=\begin{pmatrix} Z_{11} & Z_{12} & Z_{13} \\ Z_{21} & z_{kk} & Z_{23} \\ Z_{31} & Z_{32} & Z_{33} \end{pmatrix}, \tag{4.8}$$

where Z_{11} is $k-1$ by $k-1$, Z_{12} is $k-1$ by 1, Z_{13} is $k-1$ by $n-k$, Z_{21} is 1 by $k-1$, Z_{31} is $n-k$ by $k-1$ etc. Then, by equating $ZP_{k0}=P_{k0}Z$, we get that the entries of Z_{12}, Z_{21}, Z_{23}, and Z_{32} are all zero. Thus, Lemma 1 is proved.

5. Proof of Lemma 2. To show Lemma 2, first note that $D+\eta R$ is linear in η, and its eigenvalues are continuous functions of all of its variables (x,ε,η). For $\eta=0$, by (iv), the eigenvalues of D are distinct for $x\in J$ and $\varepsilon\in S_c$, there is a positive constant η_1 such that the eigenvalues $\{\tilde{d}_1(x,\varepsilon,\eta),\tilde{d}_2(x,\varepsilon,\eta),\cdots,\tilde{d}_n(x,\varepsilon,\eta)\}$ are distinct for $x\in J$, $\varepsilon\in S_c$, $|\eta|\leqq\eta_1$.

To show (4.2), by mathematical induction on n, note first that $r_{jj}\equiv 0$, by (1.3). For $n=2$,

$$\tilde{p}_2(\lambda;x,\varepsilon,\eta)=\begin{vmatrix} d_1-\lambda & \eta r_{12} \\ \eta r_{21} & d_2-\lambda \end{vmatrix}=(d_1-\lambda)(d_2-\lambda)-\eta^2 r_{12}r_{21}. \tag{5.1}$$

Thus (4.2) is true for $n=2$. Assume that (4.2) is true for $n=k$. Namely, when D and R are k by k matrices

$$\tilde{p}_k(\lambda;x,\varepsilon,\eta)=p_k(\lambda,x,\varepsilon)+\eta^2 p_{k-2}(\lambda;x,\varepsilon,\eta). \tag{5.2}$$

For $n=k+1$, expand $\tilde{p}_{k+1}(\lambda;x,\varepsilon,\eta)$ with respect to the last column. Then,

$$\begin{aligned}\tilde{p}_{k+1}(\lambda;x,\varepsilon,\eta)&=\det[D+\eta R-\lambda I] \\ &=(d_{k+1}-\lambda)\{p_k(\lambda;x,\lambda)+\eta^2 p_{k-2}(\lambda;x,\varepsilon,\eta)\} \\ &\quad+\eta\sum_{j=1}^{k} r_{j,k+1}\Delta_{j,k+1},\end{aligned} \tag{5.3}$$

where $\Delta_{j,k+1}$ are cofactors of $\eta r_{j,k+1}$. Since $\Delta_{j,k+1}$ is obtained by deleting the jth row and the last column from $\det[D+\eta R-\lambda I]$, it is a polynomial in λ of degree $k-1$ and has η as a common factor. Therefore

$$\eta^2(d_{k+1}-\lambda)p_{k-2}(\lambda;x,\varepsilon,\eta)+\eta\sum_{j=1}^{k} r_{j,k+1}\Delta_{j,k+1}=\eta^2 p_{k-1}(\lambda;x,\varepsilon,\eta), \tag{5.4}$$

where $p_{k-1}(\lambda; x, \varepsilon, \eta)$ is a polynomial in λ of degree $k-1$. Thus, (4.2) is true for all positive integers n.

To show (4.4), following the method given in Gingold [4], consider a new polynomial

$$q_n(\lambda; x, \varepsilon, \eta, \hat{\eta}) = p_n(\lambda; x, \varepsilon) + \hat{\eta} p_{n-2}(\lambda; x, \varepsilon, \eta), \tag{5.5}$$

where $\hat{\eta}$ is a complex number. We can assume, without loss of generality, that $q_n(\lambda; x, \varepsilon, \eta, \hat{\eta}) = 0$ has distinct roots for $x \in \bar{J}$, $\varepsilon \in \bar{S}_c$, $|\eta| \leqq \eta_1$, $|\hat{\eta}| \leqq \eta_2$, where η_2 is a small positive number. Regard these roots as functions of $\hat{\eta}$, and x, ε and η as their parameters. These roots satisfy the initial value problems

$$\frac{d\lambda}{d\hat{\eta}} = \frac{-p_{n-2}(\lambda; x, \varepsilon, \eta)}{\partial q_n / \partial \lambda}, \qquad \lambda(0) = d_j(x, \varepsilon), \qquad j = 1, 2, \cdots, n. \tag{5.6}$$

Then, these n distinct roots are holomorphic in $\hat{\eta}$ and expressible as

$$\lambda_j = d_j(x, \varepsilon) + O(\hat{\eta}), \qquad j = 1, 2, \cdots, n, \tag{5.7}$$

where $O(\hat{\eta})$ is uniform with respect to $x \in \bar{J}$, $\varepsilon \in \bar{S}_c$, $|\eta| \leqq \eta_0$. By letting $\hat{\eta} = \eta^2$, $\eta_0 = \min(\eta_1, \sqrt{\eta_2})$, $\lambda_j = \tilde{d}_j(x, \varepsilon, \eta)$, we have

$$\tilde{d}_j(x, \varepsilon, \eta) = d_j(x, \varepsilon) + O(\eta^2) \tag{4.4}$$

for $x \in J$, $\varepsilon \in S_c$, $|\eta| \leqq \eta_0$.

Thus Lemma 2 is proved.

6. Proof of Lemma 3. To prove Lemma 3, we will recreate the proofs of Gingold [3] carefully to obtain the desired estimates. As proved in Lemma 2, $D(x, \varepsilon) + \eta R(x, \varepsilon)$ has distinct eigenvalues $\{\tilde{d}_1(x, \varepsilon, \eta), \tilde{d}_2(x, \varepsilon, \eta), \cdots, \tilde{d}_n(x, \varepsilon, \eta)\}$ for $x \in J$, $\varepsilon \in S_c$, $|\eta| \leqq \eta_0$. Namely, there exists a fixed number $\hat{\mu}$, such that

$$\inf_{\substack{x \in J,\, \varepsilon \in S_c,\, |\eta| \leqq \eta_0 \\ 1 \leqq j,\, k \leqq n,\, j \neq k}} |\tilde{d}_j(x, \varepsilon, \eta) - \tilde{d}_k(x, \varepsilon, \eta)| \geqq \hat{\mu} > 0. \tag{6.1}$$

Let Γ_k, $k = 1, 2, \cdots, n$, be a set of rectifiable closed Jordan curves in the λ-plane such that Γ_k contains $\lambda = \tilde{d}_k(x, \varepsilon, \eta)$ in its interior and $\lambda = \tilde{d}_j(x, \varepsilon, \eta)$, $(j \neq k)$, in its exterior for all $x \in \bar{J}$, $\varepsilon \in \bar{S}_c$, $|\eta| \leqq \eta_0$. Consider the matrices $P_k(x, \varepsilon, \eta)$ given by

$$P_k(x, \varepsilon, \eta) = \frac{1}{2\pi i} \oint_{\Gamma_k} R_\lambda(x, \varepsilon, \eta)\, d\lambda, \qquad k = 1, 2, \cdots, n, \tag{6.2}$$

where

$$R_\lambda(x, \varepsilon, \eta) = [\lambda I - D - \eta R]^{-1} = R_{\lambda 0}(x, \varepsilon) \sum_{\nu=0}^{\infty} [\eta R_{\lambda 0} R]^\nu \tag{6.3}$$

with

$$R_{\lambda 0}(x, \varepsilon) = [\lambda I - D]^{-1} = \operatorname{diag}\left\{(\lambda - d_1(x, \varepsilon))^{-1}, \cdots, (\lambda - d_n(x, \varepsilon))^{-1}\right\}. \tag{6.4}$$

Then $P_k(x, \varepsilon, \eta)$ is a projection (e.g. see Riesz and Sz-Nagy [12, p. 419]) and in the class of $C^1(\bar{J} \times \bar{S}_c)$ and holomorphic in η for $\{|\eta| \leqq \eta_0\}$ for some positive η_0.

Similar to the differential equation introduced by Kato [9] and used by Coppel [1] and Gingold [3], consider the initial value problems

$$\frac{dW_k}{d\eta} = \left[\frac{dP_k}{d\eta} P_k - P_k \frac{dP_k}{d\eta}\right] W_k, \qquad W_k(x, \varepsilon, 0) = I, \quad k = 1, 2, \cdots, n, \tag{6.5}$$

and denote each of its unique n by n solution by $W_k(x,\varepsilon,\eta)$, $k=1,2,\cdots,n$. By the Cauchy's theorem, the following n by n matrix given by

$$P_{k0}=\frac{1}{2\pi i}\oint_{\Gamma_k} R_{\lambda 0}(x,\varepsilon)\,d\lambda \tag{6.6}$$

has entries all zero except the element at the (k,k) place which is one. Consequently,

$$W_k^{-1}(x,\varepsilon,0)P_{k0}W_k(x,\varepsilon,0)=P_{k0}. \tag{6.7}$$

As shown in Gingold [3], (6.7) implies

$$W_k^{-1}(x,\varepsilon,\eta)P_k(x,\varepsilon,\eta)W_k(x,\varepsilon,\eta)=P_{k0} \tag{6.8}$$

for all η, $|\eta|\leqq\eta_0$. Let

$$Z_k(x,\varepsilon,\eta)=W_k^{-1}(x,\varepsilon,\eta)(D+\eta R)W_k(x,\varepsilon,\eta) \tag{6.9}$$

and

$$Z_k(x,\varepsilon,\eta)=(z_{kij}),\qquad i,j=1,2,\cdots,n. \tag{6.10}$$

Note that $[\lambda I-D-\eta R]^{-1}$ and $D+\eta R$ are commutative, $P_k(x,\varepsilon,\eta)$ and $D+\eta R$ are commutative. By (6.8)

$$\begin{aligned} Z_k(x,\varepsilon,\eta)P_{k0} &= W_k^{-1}(x,\varepsilon,\eta)(D+\eta R)W_k(x,\varepsilon,\eta)P_{k0} \\ &= W_k^{-1}(x,\varepsilon,\eta)(D+\eta R)P_k(x,\varepsilon,\eta)W_k(x,\varepsilon,\eta) \\ &= W_k^{-1}(x,\varepsilon,\eta)P_k(x,\varepsilon,\eta)(D+\eta R)W_k(x,\varepsilon,\eta) \\ &= P_{k0}W_k^{-1}(x,\varepsilon,\eta)(D+\eta R)W_k(x,\varepsilon,\eta) \\ &= P_{k0}Z_k(x,\varepsilon,\eta). \end{aligned} \tag{6.11}$$

Namely, $Z_k(x,\varepsilon,\eta)$ and P_{k0} are commutative. By Lemma 1, we have

$$z_{kik}(x,\varepsilon,\eta)=z_{kkj}(x,\varepsilon,\eta)=0 \quad \text{for } i,j\neq k. \tag{6.12}$$

Also, note that the only nonzero element in $Z_k(x,\varepsilon,\eta)P_{k0}$ is z_{kkk} and P_k is the projection which takes the vector space on which $D+\eta R$ operates onto the subspace spanned by the eigenvector corresponding to $\tilde{d}_k(x,\varepsilon,\eta)$. Also, from (6.9), we have

$$(D+\eta R)W_k(x,\varepsilon,\eta)P_{k0}=W_k(x,\varepsilon,\eta)Z_k(x,\varepsilon,\eta)P_{k0}. \tag{6.13}$$

Therefore,

$$z_{kkk}(x,\varepsilon,\eta)=\tilde{d}_k(x,\varepsilon,\eta) \tag{6.14}$$

and $W_k(x,\varepsilon,\eta)P_{k0}$ has exactly one nonzero column which is the eigenvector of $D+\eta R$ corresponding to $\tilde{d}_k(x,\varepsilon,\eta)$.

Now, denote the coefficient of (6.5) by

$$\frac{dP_k}{d\eta}P_k-P_k\frac{dP_k}{d\eta}=N_k(x,\varepsilon,\eta) \tag{6.15}$$

which is in the class of $C^1(\bar{J}\times\bar{S}_c)$, holomorphic in η for $\{|\eta|\leqq\eta_0\}$. Thus, the solution of (6.5) can be written as

$$W_k(x,\varepsilon,\eta)=I+\int_0^{\eta}N_k(x,\varepsilon,\eta_1)\,d\eta_1 + \int_0^{\eta}N_k(x,\varepsilon,\eta_1)\int_0^{\eta_1}N_k(x,\varepsilon,\eta_2)\,d\eta_2 d\eta_1+\cdots \tag{6.16}$$

which converges uniformly for $|\eta|\leqq\tilde{\eta}_k$, for a certain positive constant $\tilde{\eta}_k$. Let

$$Q_k(x,\varepsilon,\eta)=W_k(x,\varepsilon,\eta)-I. \tag{6.17}$$

Then,

$$Q_k(x,\varepsilon,\eta)=\int_0^{\eta}N_k(x,\varepsilon,\eta_1)\,d\eta_1+\int_0^{\eta}N_k(x,\varepsilon,\eta_1)\int_0^{\eta_1}N_k(x,\varepsilon,\eta_2)\,d\eta_2 d\eta_1+\cdots. \tag{6.18}$$

Since N_k is in the class of $C^1(\bar{J}\times\bar{S}_c)$, and holomorphic in η for $\{|\eta|\leqq\tilde{\eta}_k\}$, there exists a positive constant g_k, independent of (x,ε,η), such that

$$\|N_k(x,\varepsilon,\eta)\|\leqq g_k \quad \text{for } (x,\varepsilon,\eta) \text{ in } \bar{J}\times\bar{S}_c\times\{|\eta|\leqq\tilde{\eta}_k\}. \tag{6.19}$$

Then,

$$\|Q_k(x,\varepsilon,\eta)\|\leqq g_k\left|\int_0^{\eta}d\eta_1\right|+g_k^2\left|\int_0^{\eta}\int_0^{\eta_1}d\eta_2 d\eta_1\right|+\cdots \tag{6.20}$$

$$\leqq e^{g_k|\eta|}-1\to 0 \quad \text{as } |\eta|\to 0.$$

Thus, we can put

$$Q_k(x,\varepsilon,\eta)=\eta G_k(x,\varepsilon,\eta), \tag{6.21}$$

where G_k is in the class of $C^1(\bar{J}\times\bar{S}_c)$ and holomorphic in η for $\{|\eta|\leqq\tilde{\eta}_k\}$.

Put

$$W(x,\varepsilon,\eta)=\sum_{k=1}^{n}W_k(x,\varepsilon,\eta)P_{k0}. \tag{6.22}$$

Then, by (6.9), (6.13) and (6.14), we have

$$\begin{aligned}(D+\eta R)W&=\sum_{k=1}^{n}(D+\eta R)W_k(x,\varepsilon,\eta)P_{k0}\\ &=\sum_{k=1}^{n}W_k(x,\varepsilon,\eta)Z_k(x,\varepsilon,\eta)P_{k0}\\ &=\sum_{k=1}^{n}W_k(x,\varepsilon,\eta)P_{k0}\tilde{D}(x,\varepsilon,\eta)\\ &=W(x,\varepsilon,\eta)\tilde{D}(x,\varepsilon,\eta),\end{aligned} \tag{6.23}$$

where $\tilde{D}$ is given in (4.7), namely

$$\tilde{D}(x,\varepsilon,\eta)=\operatorname{diag}\{\tilde{d}_1(x,\varepsilon,\eta),\cdots,\tilde{d}_n(x,\varepsilon,\eta)\}. \tag{4.7}$$

Put

$$W(x,\varepsilon,\eta)=I+Q(x,\varepsilon,\eta). \tag{6.24}$$

Then, since $\sum_{k=0}^{n} P_{k0} = I$, and by (6.22), we have

$$Q(x,\varepsilon,\eta) = \sum_{k=1}^{n} Q_k(x,\varepsilon,\eta) P_{k0} = \eta \sum_{k=1}^{n} G_k(x,\varepsilon,\eta) P_{k0}, \tag{6.25}$$

$$\begin{aligned} Q'(x,\varepsilon,\eta) &= \sum_{k=1}^{n} Q_k'(x,\varepsilon,\eta) P_{k0} \\ &= \eta \sum_{k=1}^{n} G_k'(x,\varepsilon,\eta) P_{k0}, \qquad \left(' = \frac{d}{dx}\right). \end{aligned} \tag{6.26}$$

Put

$$\tilde{\eta} = \min\{\tilde{\eta}_1, \tilde{\eta}_2, \cdots, \tilde{\eta}_n\}, \tag{6.27}$$

$$K_1 = \sup_{\bar{J}\times\bar{S}_c\times\{|\eta|\leqq\tilde{\eta}\}} \left\| \sum_{k=1}^{n} G_k(x,\varepsilon,\eta) P_{k0} \right\|, \tag{6.28}$$

and

$$K_2 = \sup_{\bar{J}\times\bar{S}_c\times\{|\eta|<\tilde{\eta}\}} \left\| \sum_{k=1}^{n} G_k'(x,\varepsilon,\eta) P_{k0} \right\|. \tag{6.29}$$

Thus, Lemma 3 is proved.

7. Proof of Theorem 2. First of all, since $D(x,\varepsilon)$ is diagonal, by Lemma 3 there exists an n by n matrix $Q(x,\varepsilon)$ in the class of $C^1(\bar{J}\times\bar{S}_c)$ such that

$$(I+Q)^{-1}(D+\varepsilon^{\theta}R)(I+Q) = \tilde{D}(x,\varepsilon), \tag{7.1}$$

where

$$\tilde{D}(x,\varepsilon) = \operatorname{diag}\{\tilde{d}_1(x,\varepsilon), \cdots, \tilde{d}_n(x,\varepsilon)\}. \tag{7.2}$$

Furthermore, we have

$$\|Q(x,\varepsilon)\| = O(\varepsilon^{\theta}), \qquad \|Q'(x,\varepsilon)\| = O(\varepsilon^{\theta}) \tag{7.3}$$

uniformly on $\bar{J}$ as $\varepsilon \to 0^+$.

Now, apply the transformation,

$$Y = (I+Q(x,\varepsilon))V, \tag{7.4}$$

which reduces (E_1) to

$$\begin{aligned} \varepsilon^h V' &= \left[\tilde{D}(x,\varepsilon) - \varepsilon^h (I+Q)^{-1} Q'\right] V \\ &= \left[\hat{D}(x,\varepsilon) + \varepsilon^h \hat{R}(x,\varepsilon)\right] V, \end{aligned} \tag{7.5}$$

where

$$\begin{aligned} \hat{D} &= \tilde{D} - \varepsilon^h \operatorname{diag}(I+Q)^{-1} Q', \\ \hat{R} &= -\left\{(I+Q)^{-1} Q' - \operatorname{diag}(I+Q)^{-1} Q'\right\}. \end{aligned} \tag{7.6}$$

Then, the system (7.5) satisfies the conditions of Theorem 1 with $r(\varepsilon)=O(\varepsilon^{\theta})$. Therefore, there exists an n by n matrix $\tilde{P}(x,\varepsilon)$ in the class of $C^1(\bar{J}\times\bar{S}_{c_2})$, $(0<c_2\leqq c)$, such that

$$Y=(I+Q)(I+\tilde{P})\exp\left\{\varepsilon^{-h}\int^{x}\hat{D}(t,\varepsilon)\,dt\right\}. \tag{7.7}$$

In order to show that (E_1) is a G.A.D.S. following an argument of Gingold [4], we intend to show that

$$\varepsilon^{-h}\int^{x}[\hat{D}(t,\varepsilon)-D(t,\varepsilon)]\,dt=O(\varepsilon^{\sigma}) \tag{7.8}$$

uniformly on $\bar{J}$ as $\varepsilon\to 0^{+}$. In fact, by Lemma 2

$$\tilde{p}_n(\lambda)=\operatorname{Det}(D+\varepsilon^{\theta}R-\lambda I)=p_n(\lambda)+\varepsilon^{2\theta}p_{n-2}(\lambda), \tag{7.9}$$

where

$$p_n(\lambda)=\prod_{j=1}^{n}\left(d_j(x,\varepsilon)-\lambda\right) \tag{7.10}$$

and $p_{n-2}(\lambda)$ is a polynomial of order $n-2$. Since, by (2.5), $p_n(\lambda)$ has distinct zeros d_j, $j=1,2,\cdots,n$, the zeros $\tilde{d}_j$ of $\tilde{p}_n(\lambda)$, as given in (7.2), are also distinct on $\bar{J}\times\bar{S}_{c_3}$ for some c_3 $(0<c_3\leqq c_2)$, and moreover, by suitable indexing of the zeros of $p_n(\lambda)$, we have

$$\tilde{d}_j(x,\varepsilon)=d_j(x,\varepsilon)+O(\varepsilon^{2\theta}),\qquad j=1,2,\cdots,n, \tag{7.11}$$

uniformly on $\bar{J}$ as $\varepsilon\to 0^{+}$. Thus,

$$\begin{aligned}\varepsilon^{-h}\int^{x}&[\hat{D}(t,\varepsilon)-D(t,\varepsilon)]\,dt\\ &=\varepsilon^{-h}\int^{x}[\tilde{D}(t,\varepsilon)-D(t,\varepsilon)]\,dt-\int^{x}\operatorname{diag}(I+Q(t,\varepsilon))^{-1}Q'(t,\varepsilon)\,dt\\ &=O(\varepsilon^{\sigma})\end{aligned} \tag{7.12}$$

uniformly on $\bar{J}$ as $\varepsilon\to 0^{+}$, as the first integral is of $O(\varepsilon^{2\theta-h})$, by (7.11), and the second integral is of $O(\varepsilon^{\theta})$, by (7.3). Let

$$P(x,\varepsilon)=(I+Q)(I+\tilde{P})\left(\exp\left\{\varepsilon^{-h}\int^{x}[\hat{D}(t,\varepsilon)-D(t,\varepsilon)]\,dt\right\}\right)-I, \tag{7.13}$$

thus Theorem 2 is proved.

8. Theorems for the complex variable case. For the case that x is a complex variable, the following assumption will be used.

Assumption 2. Assume that: (1) $D(x,\varepsilon)$ and $R(x,\varepsilon)$ are holomorphic on $\bar{G}\times\bar{S}_{\alpha c}$; (2) there are two fixed points a and b on the boundary of G such that for every $x\in G$, there exists a Jordan curve $\Gamma_x\in G$ connecting x to a and b, and the quantities $D_{jk}(x,t,\varepsilon)$ given by (2.1) are defined for $t\in\Gamma_x$; (3) for each pair j,k $(j\neq k;\ j,k=1,2,\cdots,n)$, there exist two numbers m_{jk} and $\hat{m}_{jk}$ such (2.2) holds for every $x\in G$ and $t\in\Gamma_x$, $\varepsilon\in S_{\alpha c}$, or if $D_{jk}(x,t,\varepsilon)$ is unbounded, then (2.3) holds for all $x\in G$, $t\in\Gamma_x$, $\varepsilon\in S_{\alpha c}$, with t on either side of x.

Let

$$\hat{r}(\varepsilon)=\sup_{\Gamma_x}\int_{\Gamma_x}\|R(t,\varepsilon)\|dt. \tag{8.1}$$

We have the following theorem.

THEOREM 4. *Assume that*: (i) *Assumption* 2 *holds*, (ii) $\theta = h$ *and* (iii) $\hat{r}(\varepsilon) = o(1)$ *as* $\varepsilon \to 0$ *in* $S_{\alpha c}$. *Then*, (E_1) *is a* G.A.D.S., *where* $\|P(x,\varepsilon)\| = O(\hat{r}(\varepsilon))$ *uniformly in* $\bar{G}$ *as* $\varepsilon \to 0$ *in* $S_{\alpha c_1}$, $(0 < c \leqq c_1)$.

THEOREM 5. *Assume that*: (i) *Assumption* 2 *holds*, (ii) $\theta > h/2$, (iii) *there exists a fixed number* μ *such that* (2.5) *holds for all* $x \in G$ *and* $\varepsilon \in S_{\alpha c}$. *Then*, (E_1) *is a* G.A.D.S. *and* $\|P(x,\varepsilon)\| = O(\varepsilon^{\sigma})$ *uniformly on* $\bar{G}$ *as* $\varepsilon \to 0$ *in* $S_{\alpha c_1}$, $(0 < c_1 \leqq c)$ *where* $\sigma = \min\{\theta, 2\theta - h\}$.

These theorems improve a special case of the result of Sibuya [13].

The proofs for Theorem 4 and Theorem 5 for a fixed path Γ_x are similar to those for Theorem 1 and Theorem 2, respectively. Then, employ a method similar to that in Gingold and Hsieh [5], there exist $P(x,\varepsilon)$ globally in G satisfying these theorems.

Remark. (1) Similar to discussions in Gingold and Hsieh [5], Assumption 2 is satisfied if the following condition is satisfied:

(K) There exist two points a and b on ∂G and positive constants α_1, α_2 and $\delta(\delta < \pi/2)$ such that every x in G can be connected with a and b by a smooth Jordan curve in G

$$\Gamma_x : s = s(\tau), \qquad 0 \leqq \tau \leqq 1 \tag{8.2}$$

satisfying:

$$s(0) = a, \quad s(1) = b, \quad s(\xi) = x \qquad (0 < \xi < 1) \tag{8.3}$$

$$0 < \alpha_1 \leqq \left| \frac{ds}{d\tau} \right| \leqq \alpha_2 \quad \text{for every } \Gamma_x, \tag{8.4}$$

$$-\frac{\pi}{2} + \delta \leqq \arg\left\{ \left[d_j(s(\tau),\varepsilon) - d_k(s(\tau),\varepsilon) \right] \frac{ds}{d\tau} \right\} - h \arg \varepsilon \leqq \frac{\pi}{2} - \delta \qquad (\mathrm{mod}\, 2\pi) \tag{8.5}$$

or

$$\frac{\pi}{2} + \delta \leqq \arg\left\{ \left[d_j(s(\tau),\varepsilon) - d_k(s(\tau),\varepsilon) \right] \frac{ds}{d\tau} \right\} - h \arg \varepsilon \leqq \frac{3\pi}{2} - \delta \qquad (\mathrm{mod}\, 2\pi) \tag{8.6}$$

for every Γ_x, $0 \leqq \tau \leqq 1$, $\varepsilon \in S_{\alpha c}$, $j \neq k, j, k = 1, 2, \cdots, n$.

(2) In particular, if G is a simply connected domain bounded by two conjugate circular arcs connecting the origin $x = 0$ and $x = b$, $(b > 0)$ such that their tangents at $x = 0$ are the straight lines $\arg x = \pm\gamma$, $(0 < \gamma < \pi/2)$, respectively, and if $\mathrm{Re}\{d_j(x,\varepsilon) - d_k(x,\varepsilon)\} \neq 0$ for $x \in G$, $\varepsilon \in S_{\alpha c}$, $j \neq k, j, k = 1, 2, \cdots, n$, then, for $x \in G$, $\mathrm{Im}\, x \neq 0$, Γ_x can be taken to be the circular arc passing through $s = 0$, $s = x$ and $s = b$, and for $\mathrm{Im}\, x = 0$, Γ_x is taken to be $\overline{Ob}$. Condition (K) is satisfied if γ and α are sufficiently small.

OSCILLATION RESULTS FOR SECOND ORDER DIFFERENTIAL SYSTEMS*

G. J. BUTLER† AND L. H. ERBE†

Abstract. Oscillation criteria are developed for the second order vector differential system (1) $y''+Q(t)y=0$ where $Q(t)$ is an $n\times n$ real continuous symmetric matrix. We show that $\lambda_1(t)=\lambda_1(\int_a^t Q(s)\,ds)\to+\infty$ as $t\to\infty$ along with either a condition on the trace of $\int_a^t Q(s)\,ds$, or a condition on the growth of $\lambda_1(t)/\lambda_n(t)$, imply oscillation of all solutions of (1). (Here $\lambda_1(\cdot)\geqq\cdots\geqq\lambda_n(\cdot)$ denote the (ordered) eigenvalues of the $n\times n$ matrix.). The results obtained generalize a theorem of Mingarelli.

1. Introduction.

Consider the second order vector differential equation

$$y''+Q(t)y=0,\qquad t\in[a,\infty) \tag{1.1}$$

where $Q(t)$ is a continuous real symmetric $n\times n$ matrix function. In partial answer to a conjecture in [6], it has been recently shown by Mingarelli [7] that the condition

$$\lim_{t\to\infty}\lambda_1\left(\int_a^t Q(s)\,ds\right)=+\infty, \tag{1.2}$$

where $\lambda_1(\cdot)$ denotes the maximum eigenvalue of the matrix, implies oscillation of (1.1) under the assumption that condition

$$\liminf_{t\to\infty}\frac{1}{t}\operatorname{tr}\left(\int_a^t Q(s)\,ds\right)>-\infty \tag{1.3}$$

holds, where $\operatorname{tr}(\cdot)$ represents the trace of the matrix. In this paper, we show that condition (1.2) implies oscillation of (1.1), even if (1.3) does not hold, provided a weaker condition than (1.3) holds (cf. §2). In addition, we show in §3 that condition (1.2) can also be weakened somewhat provided a certain relation holds between the largest and smallest eigenvalues of $\int_a^t Q(s)\,ds$ as $t\to\infty$.

Before proceeding with the statement of the results, we recall some pertinent definitions and notation which will be subsequently used. For any $n\times n$ matrix A, the *transpose* will be denoted by A^*; similarly y^* denotes the transpose of the column vector y. If t_0, $t_1\in[a,\infty)$, $t_0\neq t_1$ and if there exists a nontrivial solution $y(t)$ of (1.1) which vanishes at t_0 and t_1, then t_0 and t_1 are said to be (*mutually*) *conjugate* relative to (1.1). Equation (1.1) is said to be *disconjugate* on an interval $J\subset[a,\infty)$ if every nontrivial solution of (1.1) vanishes at most once in J and (1.1) is said to be *oscillatory* if for each $t_0>a$ there exists $t_1>t_0$ such that (1.1) is not disconjugate on $[t_0,t_1]$.

The matrix differential system associated to (1.1) is

$$Y''+Q(t)Y=0,\qquad t\in[a,\infty) \tag{1.4}$$

where Y is an $n\times n$ matrix and Q is as in (1.1). A solution of (1.4) is said to be *nontrivial* if $\det Y(t)\neq 0$ for at least one $t\in[a,\infty)$ and a nontrivial solution Y is said to be

*Received by the editors May 5, 1983, and in revised form April 5, 1984. This research was supported by the Natural Sciences and Engineering Research Council of Canada.

†Department of Mathematics, University of Alberta, Edmonton, Alberta, Canada.

prepared or *self-conjugate* in case

$$Y^*(t)Y'(t)-Y^{*\prime}(t)Y(t)\equiv 0, \qquad t\in[a,\infty). \tag{1.5}$$

(We note that for *any* solution Y of (1.4) the expression on the left side of (1.5) is constant.)

Equation (1.4) is said to be *oscillatory* in case the determinant of every nontrivial prepared solution vanishes on $[b,+\infty)$ for each $b>a$. This is equivalent to oscillation of equation (1.1) since any solution of (1.1) is of the form $y(t)\equiv Y(t)\alpha$ for some constant vector α and some nontrivial prepared solution $Y(t)$ of (1.4).

If A is a real symmetric $n\times n$ matrix, then its eigenvalues $\lambda_k(A)$, $1\leqq k\leqq n$ (which are all real) will be assumed to be ordered so that

$$\lambda_1(A)\geqq\lambda_2(A)\geqq\cdots\geqq\lambda_n(A), \tag{1.6}$$

$$\operatorname{tr}A=\sum_{k=1}^{n}\lambda_k(A). \tag{1.7}$$

We denote by $\mathcal{S}$ the linear space of all $n\times n$ real symmetric matrices. A linear functional $\phi\colon \mathcal{S}\to(-\infty,+\infty)$ is said to be *positive* if $\phi(A)\geqq 0$ for $A\in\mathcal{S}$ and $A\geqq 0$ (i.e. A symmetric positive semidefinite). Many of the recent results concerned with oscillation criteria for (1.1) and (1.4) have been based on the use of positive linear functionals. We refer to [6], [3], [4], [11], [5], [1], [10] and the references therein. The basic result obtained is that equation (1.1) (or (1.4)) is oscillatory on $[a,\infty)$ in case there exists a positive linear functional ϕ such that the scalar equation

$$u''+\phi(Q(t))u=0 \tag{1.8}$$

is oscillatory, where we assume that $\phi(I)=1$ (I=identity matrix) (cf. [3]). Hartman in [5] showed that many of the oscillation criteria can be generalized by replacing linear functionals by suitable *nonlinear* functionals.

We present in §4 a class of examples which serve to illustrate the results obtained in §§2 and 3. In particular, it is shown that there exist continuous matrix functions $Q(t)$ which are such that for *any* positive linear functional, equation (1.8) is nonoscillatory but by applying the results obtained here we may conclude that (1.1) (or (1.4)) is oscillatory. We also demonstrate that the results of §§2 and 3 are independent.

For completeness, we recall the following definitions (cf. [8]). For any subset E of the real line R, $\nu(E)$ denotes the Lebesgue measure of E. If $F(t)$ denotes a continuous real-valued function and if l, L satisfy $-\infty<l$, $L\leqq+\infty$, then we say $\operatorname{lim\,approx\,inf}_{t\to\infty}F(t)=l$ in case $\nu\{t\colon F(t)\leqq l_1\}<+\infty$ for all $l_1<l$ and $\nu\{t\colon F(t)\leqq l_2\}=+\infty$ for all $l_2>l$. Similarly, $\operatorname{lim\,approx\,sup}_{t\to\infty}F(t)=L$ in case $\nu\{t\colon F(t)\geqq L_1\}=+\infty$ for all $L_1<L$ and $\nu\{t\colon F(t)\geqq L_2\}<+\infty$ for all $L_2>L$. Finally, $\operatorname{lim\,approx}_{t\to\infty}F(t)=\lambda$ in case $\operatorname{lim\,approx\,sup}_{t\to\infty}F(t)=\operatorname{lim}_{t\to\infty}\operatorname{approx\,inf}F(t)=\lambda$. Clearly, $\operatorname{lim\,inf}_{t\to\infty}F(t)\leqq\operatorname{lim\,approx\,inf}_{t\to\infty}F(t)\leqq\operatorname{lim}_{t\to\infty}\operatorname{approx\,sup}F(t)\leqq\operatorname{lim}_{t\to\infty}\sup F(t)$.

2. We begin with the statement of the main result in this section.

THEOREM 2.1. *Let $g=g(t)$ be positive, absolutely continuous, and nondecreasing on $[a,+\infty)$ and assume*

$$\text{(i)}\quad \operatorname*{lim\,approx\,inf}_{t\to\infty}\frac{1}{g(t)}\operatorname{tr}\left(\int_a^t Q(s)\,ds\right)=l>-\infty,$$

$$\text{(ii)}\quad \operatorname*{lim\,approx\,inf}_{t\to\infty}\frac{1}{g(t)}\int_a^t\left(\lambda_1\left(\int_a^s Q(\sigma)\,d\sigma\right)\right)^2 ds=+\infty$$

and that

$$\lim_{t\to\infty} \lambda_1\Big(\int_a^t Q(s)\,ds\Big) = +\infty. \tag{1.2}$$

Then (1.1) *is oscillatory.*

The proof of Theorem 2.1 will be based on the following lemma which generalizes [7, Lemma 2.1].

LEMMA 2.2. *Let* $V(t)=V^*(t)$ *be a continuous* $n\times n$ *symmetric matrix function and suppose that*

$$\operatorname*{lim\,approx\,sup}_{t\to\infty} \frac{\operatorname{tr}\big(V(t)+\int_a^t V^2(s)\,ds\big)}{g(t)} = L < +\infty \tag{2.1}$$

where g *is positive, absolutely continuous, and nondecreasing on* $(a, +\infty)$. *Then it follows that*

$$\operatorname*{lim\,approx\,inf}_{t\to\infty} \frac{1}{g(t)} \int_a^t \lambda_1\big(V^2(s)\big)\,ds < +\infty. \tag{2.2}$$

Proof. Since $V(t)=V^*(t)$, it follows that $V^2(t)\geqq 0$ and so $F(t)\equiv\int_a^t V^2(s)\,ds$ satisfies $F(t_2)\geqq F(t_1)$, $a\leqq t_1<t_2<+\infty$ (i.e., $F(t_2)-F(t_1)$ is nonnegative definite). Therefore, since $(\lambda_1(V(t)))^2\leqq\lambda_1(V^2(t))\leqq\operatorname{tr}(V^2(t))\leqq n\lambda_1(V^2(t))$, it follows that if

$$\operatorname*{lim\,approx\,inf}_{t\to\infty} \frac{1}{g(t)} \int_a^t \lambda_1\big(V^2(s)\big)\,ds = +\infty$$

then

$$\operatorname*{lim\,approx\,inf}_{t\to\infty} \frac{1}{g(t)} \int_a^t \operatorname{tr}\big(V^2(s)\big)\,ds = \operatorname*{lim\,approx\,inf}_{t\to\infty} \frac{1}{g(t)} \operatorname{tr}\Big(\int_a^t V^2(s)\,ds\Big) = +\infty.$$

We define

$$H(t) \equiv \operatorname{tr}\Big(\int_a^t V^2(s)\,ds\Big) - Mg(t), \qquad t\geqq a$$

where $M>L$ is arbitrary. It follows then that

$$\operatorname*{lim\,approx\,inf}_{t\to\infty} \frac{H(t)}{g(t)} = +\infty$$

so that the inequality $H(t)>g(t)$ holds on a set E with $\nu(E)=+\infty$. Also, if we define the set E_1 by

$$E_1 \equiv \Big\{t:\ \frac{1}{g(t)}\big(\operatorname{tr} V(t)+H(t)\big)\geqq 0\Big\},$$

then by (2.1) we see that $\nu(E_1)<\infty$ since $M>L$ and so the complement of E_1 relative to $[a, +\infty)$, which we denote by $\tilde{E}_1$, satisfies $\nu(\tilde{E}_1)=+\infty$, and $H(t)<-\operatorname{tr} V(t)$ on $\tilde{E}_1$. Since $\nu(E\cap\tilde{E}_1)=+\infty$, we see that the inequality $g(t)<H(t)<-\operatorname{tr} V(t)$ holds on $E\cap\tilde{E}_1$. Thus, $g^2(t)\leqq H^2(t)\leqq(\operatorname{tr} V(t))^2\leqq n\operatorname{tr}(V^2(T))=n(H'(t)+Mg'(t))$ holds (a.e.) on $E\cap\tilde{E}_1$ and so we have

$$\frac{1}{n}\leqq\frac{H'(t)}{H^2(t)}+\frac{Mg'(t)}{H^2(t)}\leqq\frac{H'(t)}{H^2(t)}+\frac{Mg'(t)}{g^2(t)} \quad \text{on } E\cap\tilde{E}_1. \tag{2.3}$$

This is a contradiction since the integral of the right-hand side of (2.3) is less than $\int_{H(a)}^{\infty} u^{-2}\,du + \int_{g(a)}^{\infty} Mu^{-2}\,du$ which is finite, whereas the integral of the left-hand side is infinite since $\nu(E \cap \tilde{E_1}) = +\infty$. This proves the lemma.

Proof of Theorem 2.1. If (1.4) is not oscillatory, then there exists a nontrivial prepared solution $Y(t)$ of (1.4) with $\det Y(t) \neq 0$ on $[t_0, \infty)$ for some $t_0 \geqq a$. Let $V(t) = Y'(t)Y^{-1}(t)$, $t \geqq t_0$ so that $V^*(t) = V(t)$ and $V(t)$ satisfies the matrix Riccati equation

$$-V'(t) = Q(t) + V^2(t), \qquad t \geqq t_0. \tag{2.4}$$

Integrating (2.4) we obtain the equivalent integral equation

$$-V(t) + V(t_0) = \int_{t_0}^{t} Q(s)\,ds + \int_{t_0}^{t} V^2(s)\,ds \tag{2.5}$$

and hence

$$-V(t) + V(t_0) \geqq \int_{t_0}^{t} Q(s)\,ds. \tag{2.6}$$

Therefore, $\lambda_1(\int_{t_0}^{t} Q(s)\,ds) \leqq \lambda_1(-V(t)) + \lambda_1(V(t_0))$ by the subadditivity of λ_1 and (2.6). Since $\lambda_1(V^2(t)) \geqq (\lambda_1(-V(t))^2)$ we see that $\lim_{t\to\infty} \lambda_1(-V(t)) = \lim_{t\to\infty} \lambda_1(V^2(t)) = +\infty$. Now by condition (i) of the Theorem 2.1 and (2.5) it follows that

$$\begin{aligned} &\limapprox\sup_{t\to\infty} \left(\frac{1}{g(t)} \left(\operatorname{tr}\left(V(t) + \int_{t_0}^{t} V^2(s)\,ds \right) \right) \right) \\ &= \limapprox\sup_{t\to\infty} \left(\frac{1}{g(t)} \left(\operatorname{tr}\left(V(t_0) - \int_{t_0}^{t} Q(s)\,ds \right) \right) \right) = k - l < +\infty \end{aligned}$$

where $k = \lim_{t\to\infty} (\operatorname{tr} V(t_0)/g(t))$. Therefore, by Lemma 2.2 we have that

$$\limapprox\inf_{t\to\infty} \frac{1}{g(t)} \int_{t_0}^{t} \lambda_1(V^2(s))\,ds < +\infty.$$

Again, from (2.6) we have $\lambda_1(\int_{t_0}^{t} Q(s)\,ds) \leqq 2\lambda_1(-V(t))$ for all large t (since $\lambda_1(-V(t)) \to +\infty$) and therefore

$$\left(\lambda_1\left(\int_{t_0}^{t} Q(s)\,ds \right) \right)^2 \leqq 4\left(\lambda_1(-V(t))^2 \right) \leqq 4\lambda_1(V^2(t)) \tag{2.7}$$

for all large t. Thus, we obtain by integration

$$\frac{1}{g(t)} \int_{t_0}^{t} \left(\lambda_1\left(\int_{t_0}^{s} Q(r)\,dr \right) \right)^2 ds \leqq \frac{4}{g(t)} \int_{t_0}^{t} \lambda_1(V^2(s))\,ds \tag{2.8}$$

for all large r and hence taking lim approx inf of both sides as $t \to \infty$ we have a contradiction to condition (ii) of the hypotheses. This proves Theorem 2.1.

Remark. If $g(t) = t$ in Theorem 2.1, then condition (1.2) implies that

$$\lim_{t\to\infty} \frac{1}{t} \int_{a}^{t} \left(\lambda_1\left(\int_{a}^{s} Q(r)\,dr \right) \right)^2 ds = +\infty$$

so that Theorem 2.1 includes the results of Mingarelli [7] with "lim inf" replaced by "lim approx inf". In §4, we investigate further conditions (i) and (ii) by means of several examples.

Theorem 2.1 may also be generalized by considering the principal submatrices of $\int_a^t Q(s)\,ds$. We recall the notation (cf. [2]): For any $n\times n$ symmetric matrix A, the sequence of symmetric matrices $A_k\equiv(a_{ij})$, $i,j=1,\cdots,k$, for $k=1,2,\cdots,n$ satisfies $\lambda_{j+1}(A_{k+1})\leqq\lambda_j(A_k)\leqq\lambda_j(A_{k+1})$ where $\lambda_j(A_k)$ denotes the jth characteristic root of A_k (cf. [2, p. 113]). We may then state the next corollary.

COROLLARY 2.3. *Let $g=g(t)$ be positive, continuous, and nondecreasing in $[a,+\infty)$ and assume there exists k, $1\leqq k\leqq n$ such that*

$$(\mathrm{i})_k \quad \liminf_{t\to\infty}\operatorname{approx}\frac{1}{g(t)}\operatorname{tr}\left(\int_a^t Q_k(s)\,ds\right)>-\infty,$$

$$(\mathrm{ii})_k \quad \liminf_{t\to\infty}\operatorname{approx}\frac{1}{g(t)}\int_a^t\left(\lambda_1\left(\int_a^s Q_k(r)\,dr\right)\right)^2 ds=+\infty$$

and that

$$(1.2)_k \qquad \lim_{t\to\infty}\lambda_1\left(\int_a^t Q_k(s)\,ds\right)=+\infty.$$

Then equation (1.1) *is oscillatory.*

Proof. The proof proceeds as in Theorem 2.1 to obtain equation (2.5) from which we have

$$(2.9) \qquad -V_k(t)+V_k(t_0)=\int_{t_0}^t Q_k(s)\,ds+\int_{t_0}^t\left(V^2(s)\right)_k ds\geqq\int_{t_0}^t Q_k(s)\,ds,$$

and therefore $\lambda_1(-V_k(t))\to+\infty$ as $t\to\infty$ by $(1.2)_k$. A straightforward modification of the proof of Theorem 2.1 now yields a contradiction to condition (ii) and this proves Corollary 2.3.

3. In this section, we relax the condition (1.2) and replace hypotheses (i) and (ii) of Theorem 2.1 by a condition on the relative rates of growth of the largest and smallest eigenvalues of $\int_a^t Q(s)\,ds$ as $t\to\infty$. Abbreviate the notation for the eigenvalues of $\int_a^t Q(s)\,ds$ to $\lambda_1(t)\geqq\lambda_2(t)\geqq\cdots\geqq\lambda_n(t)$.

We shall require the following simple lemma.

LEMMA 3.1. *Let $p(t)$ be locally bounded, nonnegative and measurable on $[a,\infty)$ with $p(t)$ not zero a.e. Let $q(t)$ be nonnegative and locally integrable, such that*

$$p(t)\geqq q(t)\int_a^t p^2(s)\,ds \quad \textit{for almost all } t\geqq a.$$

Then for all sufficiently large $\bar a\geqq a$, we have $q\in L^2[\bar a,\infty)$.

Proof of Lemma 3.1. Let $P(t)=\int_a^t p^2(s)\,ds$. Then $P(t)$ is absolutely continuous, and by hypothesis, $P(t)>0$ for $t>a^*$, say. We have $P'(t)=P^2(t)\geqq q^2(t)P^2(t)$, and integrating $P'(s)/P^2(s)$ from $\bar a>a^*$ to t, we obtain

$$\frac{1}{P(\bar a)}-\frac{1}{P(t)}=\int_{\bar a}^t q^2(s)\,ds,$$

and so

$$\int_{\bar a}^{\infty} q^2(s)\,ds\leqq\frac{1}{P(\bar a)},$$

proving the lemma.

THEOREM 3.2. *Let one of the following set of hypotheses hold*:

(1) (a) $\operatorname{lim\,approx\,inf}\lambda_1(t)=\infty$ *and*

(b) $\operatorname{lim\,approx\,sup}_{t\to\infty}|\lambda_1(t)/\lambda_n(t)|>0$;

or

(2) (a) $\operatorname{lim\,approx\,sup}_{t\to\infty}\lambda_1(t)=\infty$ *and*

(b) $\operatorname{lim\,approx\,inf}_{t\to\infty}|\lambda_1(t)/\lambda_n(t)|>0$.

Then (1.1) *is oscillatory.*

Proof. Assume that (1) or (2) holds and suppose that (1.1) has a nonoscillatory solution $Y(t)$. Let $W(t)=-Y'(t)Y^{-1}(t)$ so that $W(t)$ satisfies

$$W(t)-\int_{t_0}^{t} W^2(s)\,ds=\int_a^t Q(s)\,ds+C, \qquad t\geqq t_0, \tag{3.1}$$

where $C=W(t_0)-\int_a^{t_0}Q(s)\,ds$.

It is known that for any continuous are symmetric matrix-valued function, a continuously varying orthonormal system may be selected [9]. It follows that we may choose a locally integrable vector $x(t)$ with $\|x(t)\|=1$ such that

$$x^*(t)\left(\int_a^t Q(s)\,ds\right)x(t)=\lambda_1(t). \tag{3.2}$$

Let the eigenvalues of $W(t)$ be $\mu_1(t)\geqq\cdots\geqq\mu_n(t)$. By the preceding remark, we may select a system of (orthonormal) locally integrable eigenvectors $e_i(t)$, such that

$$W(t)e_i(t)=\mu_i(t)e_i(t), \qquad e_i^*(t)e_j(t)=\delta_{ij}. \tag{3.3}$$

Define the functions $c_i(s,t)$, $i=1,\cdots,n$, $a\leqq s$, $t<\infty$, by

$$x(t)=\sum_{i=1}^{n} c_i(s,t)e_i(s). \tag{3.4}$$

The $c_i(s,t)$ are projections of $x(t)$ on to the orthonormal system $\{e_i(s)\}_{i=1}^n$, and are locally integrable with respect to both s and t.

We have

$$W(s)x(t)=\sum_{i=1}^{n}\mu_i(s)c_i(s,t)e_i(s). \tag{3.5}$$

Denote the left-hand side of (3.1) by $\Phi(t)$. From (3.1) to (3.5), we have

$$x^*(t)\Phi(t)x(t)=\sum_{i=1}^{n}\mu_i(t)c_i^2(t,t)-\int_{t_0}^{t}\left(\sum_{i=1}^{n}\mu_i^2(s)c_i^2(s,t)\right)ds. \tag{3.6}$$

At this point, in order to give a clearer presentation of the argument, we shall concentrate on the case $n=2$. Introduce angle-functions ϕ,θ by defining

$$\begin{aligned} e_1(s)&=\cos\phi(s)e_1(a)+\sin\phi(s)e_2(a),\\ e_2(s)&=-\sin\phi(s)e_1(a)+\cos\phi(s)e_2(a); \end{aligned} \tag{3.7}$$

$$c_1(a,t)=\cos\theta(t), \qquad c_2(a,t)=\sin\theta(t). \tag{3.8}$$

From (3.7) and (3.8), we find that

$$c_1(s,t)=\cos(\theta(t)-\phi(s)),\ c_2(s,t)=\sin(\theta(t)-\phi(s)).$$

If we put $\alpha(t)=\theta(t)-\phi(t)$, we may write (3.6) as

$$x^*(t)\Phi(t)x(t)=\mu_1(t)\cos^2\alpha(t)+\mu_2(t)\sin^2\alpha(t)$$

(3.9)

$$-\int_{t_0}^{t}\mu_1^2(s)\cos^2\{\alpha(t)+\phi(t)-\phi(s)\}\,ds-\int_{t_0}^{t}\mu_2^2(s)\sin^2\{\alpha(t)+\phi(t)-\phi(s)\}\,ds.$$

Now $x^*(t)\Phi(t)x(t)=\lambda_1(t)+x^*(t)Cx(t)$. Since C is constant and $\|x(t)\|=1$, we have

(3.10.1) $$\operatorname*{lim\,approx\,inf}_{t\to\infty} x^*(t)\Phi(t)x(t)=\infty$$

or

(3.10.2) $$\operatorname*{lim\,approx\,sup}_{t\to\infty} x^*(t)\Phi(t)x(t)=\infty$$

according as hypothesis (1a) or (2a) holds.

Our object is to demonstrate the incompatibility of (3.9) and (3.10.1) or (3.10.2). Parts b) of hypotheses (1) and (2) imply that there exists δ with $0<\delta<1$ such that

(3.11) $$\left|\frac{\lambda_1(t)}{\lambda_2(t)}\right|>\delta \quad \text{for all } t\in T_1$$

where $T_1\subset[a,\infty)$ satisfies

(3.12.1) $$\nu(T_1)=\infty \quad \text{(if (1) holds)},$$

(3.12.2) $$\nu(\tilde{T}_1)<\infty \quad \text{(if (2) holds)},$$

with $\tilde{T}_1=[a,\infty)-T_1$.

Let $\lambda(t)=\max(|\lambda_1(t)|,|\lambda_2(t)|)$. For $t\in T_1$, we have $\lambda(t)\leqq\lambda_1(t)/\delta$. For any $y\in R^n$ with $\|y\|\leqq\frac{1}{4}\delta$, we have

(3.13)
$$\begin{aligned}(x(t)+y)^*\Phi(t)(x(t)+y)&=x(*t)\Phi(t)x(t)+y^*\Phi(t)y+x^*(t)\Phi(t)y+y^*\Phi(t)x(t)\\&\geqq\lambda_1(t)-2\lambda(t)\|y\|-\lambda(t)\|y\|^2-\left(1+\frac{1}{4}\delta\right)^2\|C\|\\&\geqq\lambda_1(t)-\frac{1}{2}\lambda_1(t)-\frac{1}{16}\delta\lambda_1(t)-\left(1+\frac{1}{4}\delta\right)^2\|C\|,\quad \text{if } t\in T_1\\&\geqq\frac{1}{3}\lambda_1(t)-2\|C\|.\end{aligned}$$

Recall that $x(t)=\cos\theta(t)e_1(a)+\sin\theta(t)e_2(a)$. Simple trigonometry shows that we may choose $y=\hat{y}(t)$ with $\|\hat{y}(t)\|\leqq\frac{1}{4}\delta$, such that

$$x(t)+\hat{y}(t)=\cos\theta(t)e_1(a)+\sin\hat{\theta}(t)e_2(a)$$

where $\hat{\theta}(t)=\theta(t)+\delta/4$.

Now define $y(t)$ by

$$y(t)=\begin{cases}0 & \text{if } |\alpha(t)|\geqq\frac{\delta}{8}(\text{mod}\,\pi) \text{ and } \left|\alpha(t)-\frac{\pi}{2}\right|\geqq\frac{\delta}{8}(\text{mod}\,\pi),\\ y(t) & \text{otherwise,}\end{cases}$$

and let $\hat{x}(t)=x(t)+y(t)$. If $\hat{\alpha}(t)$ is defined by

$$\hat{x}(t)=\cos\hat{\theta}(t)e_1(a)+\sin\hat{\theta}(t)e_2(a), \qquad \hat{\alpha}(t)=\hat{\theta}(t)-\phi(t),$$

we obtain

$$|\hat{\alpha}(t)|\geqq\frac{\delta}{8}(\text{mod}\,\pi), \qquad \left|\hat{\alpha}(t)-\frac{\pi}{2}\right|\geqq\frac{\delta}{8}(\text{mod}\,\pi) \tag{3.14}$$

for all $t\geqq a$. Now (3.9) and (3.13) give

$$\begin{aligned}\hat{x}^*(t)\Phi(t)\hat{x}(t)&=\mu_1\cos^2\hat{\alpha}(t)+\mu_2(t)\sin^2\hat{\alpha}(t)\\ &\quad-\int_a^t\mu_2^2(s)\cos^2\{\hat{\alpha}(t)+\phi(t)-\phi(s)\}\,ds\\ &\quad-\int_a^t\mu_2^2(s)\sin^2\{\alpha(t)+\phi(t)-\phi(s)\}\,ds\\ &\geqq\frac{1}{3}\lambda_1(t)-2\|C\|, \qquad t\in T_1.\end{aligned} \tag{3.15}$$

Now parts (a) of the hypotheses of the theorem yield the existence of a subset T_2 of $[a,\infty)$ such that

$$\frac{1}{3}\lambda_1(t)-2\|C\|>0, \qquad t\in T_2 \tag{3.16}$$

and

$$\nu(\tilde{T}_2)<\infty \quad \text{(if (1) holds)}, \tag{3.17.1}$$

$$\nu(T_2)=\infty \quad \text{(if (2) holds)}, \tag{3.17.2}$$

($\tilde{T}_2=[a,\infty)-T_2$). Now (3.12), (3.14), (3.15), (3.16) and (3.17) show that there exists a subset T ($=T_1\cap T_2$) of $[a,\infty)$ with $\nu(T)=\infty$, such that

$$\begin{aligned}&\mu_1(t)\cos^2\hat{\alpha}(t)+\mu_2(t)\sin^2\hat{\alpha}(t)-\int_a^t\mu_1^2(s)\cos^2\{\hat{\alpha}(t)+\phi(t)-\phi(s)\}\,ds\\ &\qquad-\int_a^t\mu_2^2(s)\sin^2\{\hat{\alpha}(t)+\phi(t)-\phi(s)\}\,ds>0, \qquad t\in T,\end{aligned} \tag{3.18}$$

where $\alpha(t)$ is bounded away from 0 and $\pi/2$ (mod π). Let

$$U_1(t)=\mu_1(t)\cos^2\hat{\alpha}(t)-\int_a^t\mu_1^2(s)\cos^2\{\hat{\alpha}(t)+\phi(t)-\phi(s)\}\,ds \tag{3.19}$$

and let $S_1=\{t\colon U_1(t)>0\}$. By (3.14), there exist $\delta_1>0$ and a positive integer m such that

$$\cos^2(\hat{\alpha}(t)+\omega)\geqq\delta_1 \quad \text{for } t\geqq a, \qquad |\omega|\leqq\frac{1}{m} \quad (\text{mod}\,\pi). \tag{3.20}$$

For $i=1,2,\cdots,m$, define

$$A_i=\left\{t\geqq a:\ \frac{i-1}{m}\leqq\phi(t)<\frac{i}{m}(\mathrm{mod}\,\pi)\right\},$$

and let

$$\hat{\mu}_i(t)=\begin{cases}|\mu_1(t)| & t\in A_i,\\ 0, & \text{otherwise.}\end{cases}$$

If $t\in A_i$, we have by (3.20) that

$$U_1(t)\leqq\hat{\mu}_i(t)-\delta_1\int_a^t\hat{\mu}_i^2(s)\,ds. \tag{3.21}$$

By Lemma 3.1, either $\mu_i(t)=0$ a.e. or, if $q_i(t)$ is defined by

$$\hat{\mu}_i(t)=\hat{q}_i(t)\int_a^t\hat{\mu}_i^2(s)\,ds,$$

we have $\hat{q}_i\in L^2[\bar{a},\infty)$ for $\bar{a}$ sufficiently large. In the latter case, the set of t for which $\hat{q}_i(t)\geqq\delta_1$ has finite measure, and in either case, the set of t in A_i for which $U_1(t)>0$, has finite measure. Since $[a,\infty)=\bigcup_{i=1}^m A_i$, we have $\nu(S_1)<\infty$. Similar reasoning shows that if

$$U_2(t)=\mu_2(t)\sin^2\hat{\alpha}(t)-\int_a^t\mu_2^2(s)\sin^2\{\hat{\alpha}(t)+\phi(t)-\phi(s)\}\,ds$$

and $S_2=\{t:\ U_2(t)>0\}$, then $\nu(S_2)<\infty$. But this is in contradiction to (3.18), and now the theorem is proved for the case $n=2$.

In the general case $n>2$, the basic idea of proof is the same. We introduce the orthogonal matrix $U(s)$ whose rows are the eigenvectors $e_i(s)$ of $W(s)$ (see (3.3)). Denote the vector $(c_1(s,t),c_2(s,t),\cdots,c_n(s,t))^*$ by $c(s,t)$. Assuming, without loss of generality, that $U(a)$ is the identity matrix, (3.4) gives

$$c(s,t)=U^{-1}(s)c(a,t). \tag{3.22}$$

Now denote $U^{-1}(s)$ by $V(s)$, the components of $V(t)c(a,t)$ by $v_i(t)$ and the components of $(V(s)-V(t))c(a,t)$ by $w_i(s,t)$, $i=1,\cdots,n$. From (3.6), we may write $x^*(t)\Phi(t)x(t)$ as

$$\sum_{i=1}^n\mu_i(t)v_i^2(t)=\int_a^t\sum_{i=1}^n\mu_i^2(s)\big(v_i(t)+w_i(s,t)\big)^2ds. \tag{3.23}$$

By replacing $x(t)$ by an appropriate $\hat{x}(t)$ and obtaining the corresponding functions $\hat{v}_i(t)$, $\hat{w}_i(s,t)$, we have

$$\hat{x}^*(t)\Phi(t)\hat{x}(t)=\sum_{i=1}^n\mu_i(t)\hat{v}_i^2(t)-\int_a^t\sum_{i=1}^n\mu_i^2(s)\{\hat{v}_i(t)+\hat{w}_i(s,t)\}^2ds>0, \tag{3.24}$$

$$t\in T,$$

where $|v_i(t)|\geqq\delta_0>0$ on T, and T is a subset of $[a,\infty)$, of infinite measure, $\hat{w}_i(s,t)$ is the ith component of $(V(s)-V(t))\hat{c}(a,t)$, and $\|\hat{c}(a,t)\|=1$. Note that (3.24) is the analogue of (3.15) and (3.18). Since the $n\times n$ orthogonal matrices (identified with S^{n-1}) form a compact set, we may find a finite decomposition of S^{n-1}, $\{I_k\}_{k=1}^m$ say, such that $G,H\in I_k\Rightarrow\|G-H\|<\delta_0/2$, $k=1,\cdots,m$. Now define $A_k=\{t\geqq a:\ V(t)\in I_k\}$.

Then we shall have

$$\{\hat{v}_j(t)+\hat{w}_j(s,t)\}^2 \geqq \frac{\delta_0^2}{4} \tag{3.25}$$

whenever $s, t \in A_k$, $k=1,\cdots,m$, $j=1,\cdots,n$.

With (3.24), (3.25) and Lemma 3.1, we may complete the proof as in the case $n=2$.

4. We illustrate the results of §§2 and 3 with some examples.

1. Let $\delta > \eta > 0$ and let $\sigma=(\eta+\delta)/2-1$, $k=(\eta+\delta)/2$. Define $Q(t)$ to be

$$\begin{pmatrix} 0 & -kt^\sigma \\ -kt^\sigma & -q(t) \end{pmatrix}$$

where $q(t)=\delta t^{\delta-1}-\eta t^{\eta-1}$. Then $\int_1^t(\operatorname{tr} Q)\,ds = t^\eta - t^\delta \to -\infty$ as $t\to\infty$ and $\lambda_1(\int_1^t Q\,ds) = t^\eta \to \infty$ as $t\to\infty$. Let $g(t)=[\int_1^t(\lambda_1(\int_1^s Q\,d\sigma))^2 ds]^\gamma$ where $0<\gamma<1$. Then $g(t)\uparrow\infty$ as $t\to\infty$, and $g(t)\sim t^{(2\eta+1)\gamma}$. We have

$$\frac{\int_1^t(\operatorname{tr} Q)\,ds}{g(t)} \sim \frac{t^\eta - t^\delta}{t^{(2\eta+1)\gamma}} \geqq -t^{\delta-\gamma(2\eta+1)}$$

which is bounded below as $t\to\infty$ provided that $\delta(2\eta+1)\geqq\gamma$. Now

$$\frac{1}{g(t)}\int_1^t\left(\lambda\left(\int_1^s Q\,d\sigma\right)\right)^2 ds = \left[\int_1^t\left(\lambda_1\left(\int_1^s Q\,d\sigma\right)\right)^2 ds\right]^{1-\gamma} \to \infty$$

as $t\to\infty$. By Theorem 2.1, we shall have oscillation if $0<\eta<\delta<2\eta+1$ (choose $\gamma=\delta/2\eta+1$). If $\delta>1$, we have $1/t\int_1^t(\operatorname{tr} Q)\,ds\to-\infty$, so we cannot obtain oscillation by Mingarelli's result.

We recall that any positive functional $\phi(A)$ has the form

$$\phi(A)=\sum_{i,j=1}^n \alpha_{ij}a_{ij}$$

where $A=(a_{ij})$, and $\alpha=(\alpha_{ij})$ is nonnegative definite [11]. We have $\phi(Q(t))=-2kt^\sigma\alpha_{12}+\alpha_{22}(\eta t^{\eta-1}-\delta t^{\delta-1})\leqq 0$ for t sufficiently large, since $\alpha_{22}\geqq 0$ (with equality possible only if $\alpha_{12}=0$) and $\delta-1>\sigma>\eta-1$. Thus the 2nd order scalar equation $y''+\phi(Q(t))y=0$ is nonoscillatory for all positive functionals ϕ, and this class of tests for oscillation cannot be used.

2. To illustrate Theorem 3.2, we define the 3×3 matrix $Q(t)$ by specifying its integral from 0 to t. Let $\int_0^t Q(s)\,ds=$

$$\begin{pmatrix} t^{1/2}\cos^2 t - t^n\sin^2 t(1+\cos t) & \frac{1}{2}t^{1/2}\sin 2t\{1+t^{n-1}(1+\cos t)\} & 0 \\ \frac{1}{2}t^{1/2}\sin 2t\{1+t^{n-1}(1+\cos t)\} & t^{1/2}\sin^2 t - t^n\cos^2 t(1+\cos t) & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

where $n\geqq 1$.

A straightforward computation reveals that the eigenvalues of $\int_0^t Q(s)\,ds$ are $\lambda_1(t)=t^{1/2}$, $\lambda_2(t)=0$, $\lambda_3(t)=-t^n(1+\cos t)$. Let $t_m=(2m+1)\pi$ and $t=t_m+s$. Then it is easily verified that for t near t_m, $|\lambda_3(t)|\leqq c_1 s^2 m^n$, for some constant c_1. Since $|\lambda_1(t)|\geqq$

$c_2 m^{1/2}$, for some constant c_2, for t near t_m, we have $|\lambda_1(t)/\lambda_3(t)| \geqq 1$ if $|s| \leqq c_3 m^{1/4-n/2} (c_3 = (c_2/c_1)^{1/2})$. Thus $\{t\colon |\lambda_1(t)/\lambda_3(t)| \geqq 1\}$ has measure at least $c_4 \Sigma_{m=1}^{\infty} m^{1/4-n/2}$, for some constant $c_4 > 0$, i.e. has infinite measure if $n \leqq \frac{5}{2}$.

It follows that hypothesis (1) of Theorem 3.2 holds and equation (1.1) is oscillatory. It is easily verified that Theorem 2.1 cannot be used to verify oscillation in the case that $2 \leqq n \leqq \frac{5}{2}$.

COMPARISON THEOREMS FOR CERTAIN DIFFERENTIAL SYSTEMS OF ARBITRARY ORDER*

E. C. TOMASTIK†

Abstract. Comparison theorems are given for $(k,n-k)$-focal points of systems of the form $[rx^{(k)}]^{(n-k)}-(-1)^{n-k}px=0$, where r and p are $m\times m$ matrices. The system is not assumed to be selfadjoint, and for the "comparing" equation no sign assumptions are made on the elements of $r(t)$ and $p(t)$.

1. Introduction. In this paper are given comparison theorems for $(k,n-k)$-focal points of the two nth order differential systems

$$[r(t)x^{(k)}]^{(n-k)}-(-1)^{n-k}p(t)x=0 \tag{1}$$

and

$$[R(t)y^{(k)}]^{(n-k)}-(-1)^{n-k}P(t)y=0, \tag{2}$$

where $r(t)$, $p(t)$, $R(t)$ and $P(t)$ are all $m\times m$ matrices of continuous functions, r and $R\in C^{n-k}$, and $r^{-1}(t)$ and $R^{-1}(t)$ exist on the intervals under consideration. In addition, $R^{-1}(t)$ and $P(t)$ are assumed to satisfy a certain "positivity" condition with respect to a certain cone. However, no further conditions are given on the matrices $r(t)$ and $p(t)$. In particular, $r(t)$ and $p(t)$ may have oscillatory components. Since no assumptions are made concerning the symmetry of any of the matrices $r(t)$, $p(t)$, $R(t)$ and $P(t)$, and no assumptions are made on the integers k and n, the systems (1) and (2) may or may not be selfadjoint. But even in the case that both systems are selfadjoint, the results presented here are new.

Focal points play a critical role in variational theory when the systems (1) and (2) are selfadjoint, and certain comparison theorems have long been known in this case. For example, Morse [5] gave such comparison theorems for second order systems, and Reid [8, p. 356] gives such a comparison theorem for general selfadjoint systems of order $2n$. Roughly, these results in the selfadjoint case state that if the matrices $r(t)$ and $R(t)$ are positive definite and if the matrices $P(t)-p(t)$ and $R^{-1}(t)-r^{-1}(t)$ are both positive semidefinite everywhere and one of them is positive definite at one point, then the focal point of (1) lies to the right of the focal point of (2). (In the selfadjoint case the matrices $r(t)$, $R(t)$, $p(t)$ and $P(t)$ must all be symmetric.)

In the selfadjoint case, it is thus natural to define $P>p$ if $P(t)-p(t)$ is positive semidefinite everywhere and positive definite at at least one point. Thus we can say that if P is "larger" than p and if R^{-1} is "larger" then r^{-1}, then the focal point of (1) lies to the right of the focal point of (2), in agreement with the Sturm theory for scalar second order differential equations. Since in this paper none of the matrices $r(t)$, $p(t)$, $R(t)$ and $P(t)$ are assumed to be symmetric, the notion of positive definiteness cannot be used. A natural alternative definition of $P>p$ (or $p<P$) will mean that if $p=(p_{ij})$ and $P=(P_{ij})$, then $p_{ij}(t)\le P_{ij}(t)$, and for each row strict inequality occurs for one element at at least one point. This notion is of course independent of the notion of positive definite, even if p and P are symmetric. However, a selfadjoint example is given later to

* Received by the editors January 25, 1983, and in revised form February 3, 1984.
† Department of Mathematics, University of Connecticut, Storrs, Connecticut 06268.

show that if $p<P$ under this latter definition, the focal point of (1) may be the *left* of the focal point of (2), a very surprising situation. It will be shown in this paper that a sufficient condition to assure that the focal point of (1) lies to the right of that of (2) is to assume $\int_a^t |r_{ij}^{-1}(s)|\,ds \le \int_a^t |R_{ij}^{-1}(s)|\,ds$ and $|p_{ij}(t)| \le |P_{ij}(t)|$, and that the latter inequalities become strict inequalities for at least one element at at least one point in every row. The term r_{ij}^{-1} represents the element in the ith row and the jth column of the matrix r^{-1}. The integral condition on r^{-1} and R^{-1} is of course more general than just the condition $|r_{ij}^{-1}(t)| \le |R_{ij}^{-1}(t)|$, and is thus of some interest. It is interesting to note that in the classical results in the selfadjoint case, the assumption that $r(t)$ and $R(t)$ are at least positive semidefinite is essential. However, in this paper the matrices $r(t)$ and $R(t)$ need not be positive semidefinite even in the selfadjoint case.

Comparison theorems for focal points were given by the author [9] for $m=2$, $k=1$, but they required that $P_{ij}(t) \ge 0$ and $R_{ij}^{-1}(t) \ge 0$. These conditions are replaced with the much less restrictive conditions that $P(t)$ and $R^{-1}(t)$ be positive with respect to a certain cone. Thus the results presented here are new for the second order case also. Focal points were also studied by Keener and Travis [3] for second order systems with $r(t)$ and $R(t)$ the identity and without the assumption that $P(t)$ is symmetric. In the scalar case, comparison theorems of the "integral type" were first established by Nehari [6] for second order equations, by Travis [10] for selfadjoint equations of order $2n$, by Nehari [7], Gentry and Travis [2] and Keener and Travis [4] for a somewhat more general scalar equation than (1). Elias [1] also studied focal points of scalar equations.

Throughout this paper it is assumed that some partition $\{I,J\}$ of the integers $\{1,2,\cdots,m\}$ has been given, i.e., $I \cup J = \{1,2,\cdots,m\}$ with $I \cap J = \varnothing$, and that the set K is given by

$$K = \{(z_1,\cdots,z_m) : i \in I \Rightarrow z_i \ge 0,\ i \in J \Rightarrow z_i \le 0\}.$$

The interior of K, K^0, will be defined to be

$$K^0 = \{(z_1,\cdots,z_m) : i \in I \Rightarrow z_i > 0,\ i \in J \Rightarrow z_i < 0\}.$$

Also throughout this paper it is assumed that there is one point on $[a,b]$ at which no row of $P(t)$ is zero, and that $P(t)$ and $R^{-1}(t)$ satisfy the following positivity condition:

$$\text{For every } t \in [a,b], \quad P(t): K \to K \quad \text{and} \quad R^{-1}(t): K \to K.$$

If a matrix A satisfies the above positivity condition, then A shall be said to be "positive with respect to the cone K." If K is given by $K = \{(z_1,z_2) : z_1 \ge 0,\ z_2 \le 0,\}$ then two examples of such a matrix are

$$\begin{bmatrix} 2 & 0 \\ -1 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 2 & -2 \\ -1 & 1 \end{bmatrix}.$$

2. Focal points. A point $f(a) \in [a,b]$ is called a focal point of a relative to (1), provided there is a nontrivial solution $x(t)$ of (1) satisfying

$$(3) \quad x^{(i)}(a) = 0, \quad i = 0,1,\cdots,k-1, \qquad [rx^{(k)}]^{(i)}(f(a)) = 0, \quad i = 0,1,\cdots,n-k-1,$$

and there is no nontrivial solution $z(t)$ of (1) which satisfies

$$z^{(i)}(a) = 0, \quad i = 0,1,\cdots,k-1, \qquad [rz^{(k)}]^{(i)}(c) = 0, \quad i = 0,1,\cdots,n-k-1,$$

for $a < c < f(a)$. If (1) does not possess such a focal point on $(a,b]$, the equation will be said to be disfocal on $[a,b]$.

For any matrix $A(t)\in C^{n-k}[a,b]$ for which $A^{-1}(t)$ exists on $[a,b]$, define the differential operator D by

$$D(u)=(-1)^{n-k}\left[A(t)u^{(k)}(t)\right]^{(n-k)},$$

$$u^{(i)}(a)=0,\quad i=0,1,\cdots,k-1,\qquad [Au^{(k)}]^{(i)}(b)=0,\quad i=0,1,\cdots,n-k-1.$$

Then the Green's function $g(t,s,a,A^{-1})$ is given by $g=g(t,s,a,A^{-1})$, where

$$g=\frac{1}{(n-k-1)!(k-1)!}\int_a^t (t-\xi)^{k-1}(s-\xi)^{n-k-1}A^{-1}(\xi)\,d\xi,\qquad a\le t\le s\le b,$$

and

$$g=\frac{1}{(n-k-1)!(k-1)!}\int_a^s (t-\xi)^{k-1}(s-\xi)^{n-k-1}A^{-1}(\xi)\,d,\qquad a\le s\le t\le b.$$

Then $x(t)$ satisfies the differential equation (1) and boundary conditions (3) if and only if $x(t)$ satisfies

$$x(t)=\int_a^b g(t,s,a,r^{-1})p(s)x(s)\,ds.$$

It will be useful to state and prove some lemmas at this time.

Let $\delta_i=1$ if $i\in I$ and $\delta_i=-1$ if $i\in J$.

LEMMA 1. *If $A=(A_{ij})$ is positive with respect to the cone K, then $\delta_i\delta_j A_{ij}\ge 0$, $i,j=1,\cdots,n$.*

Proof. Let e_j denote the jth unit basis vector. Then $\delta_j e_j\in K$ and $A(\delta_j e_j)\in K$. But the transpose of $A\delta_j e_j$ is $(\delta_j A_{ij},\cdots,\delta_j A_{mj})$, and this implies $\delta_i\delta_j A_{ij}\ge 0$.

LEMMA 2. *If $A=(A_{ij})$ is positive with respect to the cone K and $v\in K$, then $\delta_i A_{ij}v_j\ge 0$.*

Proof. Since $\delta_j v_j\ge 0$ and, from Lemma 1, $\delta_i\delta_j A_{ij}\ge 0$, it follows that $0\le\delta_j v_j\delta_i\delta_j A_{ij}=\delta_j A_{ij}v_j$.

LEMMA 3. *If A and B are both positive with respect to the cone K, then so is AB.*

LEMMA 4. *If A is positive with respect to K, then $A:K^0\to K^0$ if and only if no row of A is zero.*

LEMMA 5. *If $h(t)$ is continuous on $[a,b]$, $h(t):[a,b]\to K$ and there exists $t_0\in[a,b]$ such that $h(t_0)\in K^0$, then $\int_a^b h(s)\,ds\in K^0$.*

The main theorem can now be given.

THEOREM 1. *Suppose that $y(t)$ is a solution of (2) satisfying the boundary condition (3) and that $y(t)\in K^0$ for $t\in(a,b)$. If $\int_a^t|r_{ij}^{-1}(s)|\,ds\le\int_a^t|R_{ij}^{-1}(s)|\,ds$ and $|p_{ij}(t)|\le|P_{ij}(t)|$ for all $i,j\in(1,\cdots,m)$ and for all $t\in[a,b]$, and if furthermore for any $i=1,\cdots,m$, there exists an integer $j=j(i)$, $1\le j\le m$, and $t_i\in[a,b]$ such that $|p_{ij}(t_i)|<|P_{ij}(t_i)|$, then (1) is disfocal on $[\alpha,\beta]$, $[\alpha,\beta]\subset[a,b]$.*

Proof. Suppose, contrary to the conclusion of Theorem 1, that $x(t)$ is a nontrivial solution of (1) satisfying the boundary conditions

$$x^{(i)}(\alpha)=0,\quad i=0,1,\cdots,k-1,\qquad [rx^{(k)}]^{(i)}(\beta)=0,\quad i=0,1,\cdots,n-k-1,$$

for some $\alpha,\beta\in[a,b)$. Then of course,

$$x(t)=\int_\alpha^\beta g(t,s,\alpha,r^{-1})p(s)x(s)\,ds.$$

Also,

$$y(t)=\int_a^b g(t,s,a,R^{-1})P(s)y(s)\,ds.$$

Obviously $y^{(i)}(a)=0$, $i=0,1,\cdots,k-1$. It will now be shown that if $y_i(t)$ is the ith component of $y(t)$, then $y_i^{(k)}(a)\neq 0$. Toward this end it is easy to see by calculation that

$$y^{(k)}(t)=\frac{1}{(n-k-1)!}R^{-1}(t)\int_t^b (s-t)^{n-k-1}P(s)y(s)\,ds$$

and

$$y^{(k)}(a)=\frac{1}{(n-k-1)!}R^{-1}(a)\int_a^b (s-a)^{n-k-1}P(s)y(s)\,ds.$$

By hypothesis, $y(s)\in K^0$ for $s\in(a,b)$ and $P(s)y(s)\in K$ for $s\in(a,b)$. Also by hypothesis there exists a $t_0\in(a,b)$ such that no row of $P(t_0)$ is zero, and by Lemma 4 $P(t_0)y(t_0)\in K^0$. An application of Lemma 5 then shows that $\int_a^b(s-a)^{n-k-1}P(s)y(s)\,ds\in K^0$. Of course no row of $R^{-1}(a)$ can be zero, and using Lemma 4 again,

$$y^{(k)}(a)=\frac{1}{(n-k-1)!}R^{-1}(a)\int_a^b (s-a)^{n-k-1}P(s)y(s)\,ds\in K^0.$$

This then implies that no component of $y^{(k)}(a)$ can be zero. This shows that for any i, $y_i(t)$ has a zero at $t=a$ of precisely order k. Since $y(t)\in K^0$ for $t\in(a,b)$, no component of $y(t)$ can be zero, for $t\in(a,b)$. Thus for $\alpha\in[a,b)$, $y_i(t)$ has a zero of order at most k. Of course $x_i(t)$ has a zero at $t=\alpha$ of at least order k. Thus the terms $|x_i(t)|/|y_i(t)|$ are continuous on $(a,b]$ and, most importantly, are bounded on $(\alpha,b]$, for any $\alpha\geq a$. Define

$$\|x_i\|=\begin{cases}\sup\{|x_i(t)|/|y_i(t)|:t\in[\alpha,b]\} & \text{if } \alpha\in(a,b),\\ \sup\{|x_i(t)|/|y_i(t)|:t\in(\alpha,b]\} & \text{if } \alpha=a.\end{cases}$$

Also define $\|x\|=\max\{\|x_i\|:i=1,\cdots,m\}$.

For any $t\in(\alpha,b]$ if $\alpha=a$, or for any $t\in[\alpha,b]$ if $\alpha\in(a,b)$,

$$\begin{aligned}|x_\mu(t)|&=\left|\sum_{i,j}\int_\alpha^\beta g_{\mu i}(t,s,\alpha,r^{-1})p_{ij}(s)x_j(s)\,ds\right|\\ &\leq\sum_{i,j}\int_\alpha^\beta |g_{\mu i}(t,s,\alpha,r^{-1})|\,|p_{ij}(s)|\,|y_j(s)|\,|x_j(s)|\,|y_j^{-1}(s)|\,ds\\ &\leq\sum_{i,j}\int_\alpha^\beta |g_{\mu i}(t,s,\alpha,r^{-1})|\,|p_{ij}(s)|\,|y_j(s)|\,ds\|x\|.\end{aligned}$$

It follows readily from a calculation that $\partial/\partial\alpha$ of the last term is

$$-\frac{1}{(n-k-1)!(k-1)!}\cdot\sum_{i,j}|r_{\mu i}(\alpha)|\int_\alpha^\beta (t-\alpha)^{k-1}(s-\alpha)^{n-k-1}|p_{ij}(s)|\,|y_j(s)|\,ds\|x\|\leq 0.$$

Thus

$$|x_\mu(t)| \leq \sum_{i,j} \int_a^b |g_{\mu i}(t,s,a,r^{-1})|\,|p_{ij}(s)|\,|y_j(s)|\,ds\|x\|.$$

If $A(t)=(a_{ij}(t))$ is a matrix, define the $m\times m$ matrix A_1 by $(|a_{ij}(t)|)$. Then using the definition of $g(t,s,a,r^{-1})$, it follows immediately that $|g_{\mu i}(t,s,a,r^{-1})| \leq g_{\mu i}(t,s,a,r_1^{-1})$. Also notice that if $F(t,s,\xi)=(t-\xi)^{k-1}(s-\xi)^{n-k-1}$, then

$$\begin{aligned}
&(n-k-1)!(k-1)!g_{\mu i}(t,s,a,r_1^{-1}) \\
&\quad = \int_a^\delta (t-\xi)^{k-1}(s-\xi)^{n-k-1}|r_{ij}^{-1}(\xi)|\,d\xi \\
&\quad = \int_a^\delta F(t,s,\xi)|r_{ij}^{-1}(\xi)|\,d\xi \\
&\quad = \int_a^\delta |r_{ij}^{-1}(\xi)|\,d\xi F(t,s,\delta) - \int_a^\delta \int_a^\xi |r_{ij}^{-1}(\eta)|\,d\eta \frac{\partial F(t,s,\xi)}{\partial \xi}\,d\xi \\
&\quad \leq \int_a^\delta |R_{ij}^{-1}(\xi)|\,d\xi F(t,s,\delta) - \int_a^\delta \int_a^\xi |R_{ij}^{-1}(\eta)|\,d\eta \frac{\partial F(t,s,\xi)}{\partial \xi}\,d\xi \\
&\quad = \int_a^\delta (t-\xi)^{k-1}(s-\xi)^{n-k-1}|R_{ij}^{-1}(\xi)|\,d\xi,
\end{aligned}$$

since $F(t,s,\delta)\geq 0$ and $\partial F(t,s,\xi)/\partial\xi \leq 0$ over the regions of integrations. These remarks then show that

$$|x_\mu(t)| \leq \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,R_1^{-1})|p_{ij}(s)|\,|y_j(s)|\,ds\|x\|. \tag{4}$$

But since $y_j(t)\neq 0$ on (a,b) for all j, and since by hypothesis $|p_{ij}(t_0)|<|P_{ij}(t_0)|$, and since at least one of the terms $R_{\mu i}^{-1}(t)$, $i=1,\cdots,m$, must not be zero for any $t\in[a,b]$, it can be seen that in the right-hand side of (4) the $|p_{ij}(s)|$ terms can be replaced with $|P_{ij}(s)|$ and obtain a strict inequality. That is,

$$|x_\mu(t)| < \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,R_1^{-1})|P_{ij}(s)|\,|y_j(s)|\,ds\|x\|.$$

Since $g(t,s,a,R^{-1})$ and P are both positive with respect to the cone K, their product is also. Then by Lemma 2, the right-hand side of the last term is just

$$\delta_\mu \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,R^{-1})P_{ij}(s)\,y_j(s)\,ds\|x\|,$$

where $\delta_i=1$ if $i\in I$ and $\delta_i=-1$ if $i\in J$. It then follows that

$$|x_\mu(t)|/|y_\mu(t)| = |x_\mu(t)|/\delta_\mu y_\mu(t),$$

and thus

$$\frac{|x_\mu(t)|}{|y_\mu(t)|} < \frac{1}{y_\mu(t)} \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,R^{-1})P_{ij}(s)\,y_j(s)\,ds\|x\|. \tag{5}$$

If $\alpha \in (a,b)$, then (5) holds for $t \in [\alpha,b)$. Now assume that $\alpha = a$. It will be shown that this strict inequality also holds at $t \to a+$. This will be done by showing that the inequality

$$(6) \qquad \frac{1}{\delta_\mu y_\mu(t)} \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,r_1^{-1}) |p_{ij}(s)| \, |y_j(s)| \, ds \|x\|$$

$$< \frac{1}{\delta_\mu y_\mu(t)} \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,R_1^{-1}) |P_{ij}(s)| \, |y_j(s)| \, ds \|x\|,$$

which has already been established for $t \in (a,b)$, can be extended as a strict inequality to $[\alpha,b]$. To do this, we simply use l'Hôpital's rule and find that the limit as $t \to a+$ of the left-hand side of (6) is at most

$$(7) \qquad \frac{1}{\delta_i y_i^{(k)}(a)} \sum_{i,j} \frac{1}{(n-k-1)!} |R_{\mu i}^{-1}(a)| \int_a^b (s-t)^{n-k-1} |p_{ij}(s)| \, |y_j(s)| \, ds \|x\|,$$

and the limit as $t \to a+$ of the right-hand side of (6) is

$$(8) \qquad \frac{1}{\delta_i y_i^{(k)}(a)} \sum_{i,j} \frac{1}{(n-k-1)!} |R_{\mu i}^{-1}(a)| \int_a^b (s-t)^{n-k-1} |P_{ij}(s)| \, |y_j(s)| \, ds \|x\|.$$

Just as before, we readily see that indeed (7) is strictly less than (8). Since the left-hand side of (5) is less than or equal to the left-hand side of (6), and since as we have seen before the right-hand side of (5) equals the right-hand side of (6), inequality (5) is true on $[\alpha,b]$ even if $\alpha = a$.

Since $y(t)$ satisfies (2),

$$y_\mu(t) = \sum_{i,j} \int_a^b g_{\mu i}(t,s,a,R^{-1}) P_{ij}(s) \, y_j(s) \, ds$$

and the right-hand side of (5) is just $\|x\|$. This implies that $\|x_\mu\| < \|x\|$, and this in turn implies that $\|x\| < \|x\|$. From this contradiction, we infer the truth of the theorem.

The following theorem is more general than Theorem 1. The proof is the same as Theorem 1 with only the most obvious changes.

THEOREM 2. *Suppose that $y(t)$ is a solution of* (2) *satisfying the boundary conditions*

$$\left[R y^{(k)} \right]^{(i)}(b) = 0, \qquad i = 0, \cdots, n-k-1,$$

and that $y(t) \in K^0$ for all $t \in (a,b)$ and $y^{(i)}(a) \in K$ for $i = 0,1,\cdots,k-1$. If $\int_a^t |r_{ij}^{-1}(s)| ds \le \int_a^t |R_{ij}^{-1}(s)| ds$ and $|p_{ij}(t)| \le |P_{ij}(t)|$ for all $i,j \in (1,\cdots,m)$ and for all $t \in [a,b]$, and if furthermore for any $i = 1,\cdots,m$, there exists an integer $j = j(i)$, $1 \le j \le m$, and $t_i \in [a,b]$ such that $|p_{ij}(t)| < |P_{ij}(t_i)|$, then (1) *is disfocal on $[\alpha,\beta] \subset [a,b]$.*

Theorems 1 and 2 require $y(t)$ not only to be a solution of (2) satisfying the boundary condition (3) but also to satisfy $y(t) \in K^0$ for all $t \in (a,b)$. Using the theory of μ_0-positive linear operators, it can readily be shown that such solutions do indeed exist for a large class of matrices $R(t)$ and $P(t)$. Such a condition is to assume that $P(t)$ satisfies the additional assumption that for $v \in K$ and $v \neq 0$, $P(t)v \in K^0$ for all $t \in [a,b.]$. Notice that this latter condition, among other things, restricts $P(t)$ never to be diagonal, whereas $P(t)$ could be diagonal before. Notice also that the first example given at the beginning does not satisfy this latter condition, but that the second example does. The following theorem can now be given.

THEOREM 3. *Suppose that $P(t)$ also satisfies the condition that for any $v\in K$, $v\neq 0$ and $t\in[a,b]$, then $P(t)v\in K^0$. Then if* (2) *has a focal point b, then* (2) *has a solution $y(t)$ that satisfies the boundary conditions* (3) *and $y(t)\in K^0$ for $t\in(a,b)$.*

Proof. To establish this theorem define the Banach space

$$B=\{u\in C([a,b]):u(a)=0\},$$

with $\text{norm}\|u\|_1=\sup\{|u(t)|:t\in[a,b]\}$. Also define the cone

$$\tilde{K}=\{u\in B:u(t)\in K \text{ for } t\in[a,b]\},$$

with interior $\tilde{K}^0=\{u\in B:u(t)\in K^0 \text{ for } t\in(a,b)\}$. It is apparent that the operator

$$T(u)=\int_a^b g(t,s,a,R^{-1})P(s)u(s)\,ds$$

maps $\tilde{K}$ into $\tilde{K}^0$, and therefore by arguments similar to that found in [2], T is μ_0-positive with respect to the cone $\tilde{K}$. From this, Theorem 3 follows in the same way as found in [2].

We can now state a comparison theorem for focal points of (1) and (2). Let $f_p(a)$ and $f_P(a)$ be the focal points of (1) and (2), respectively.

THEOREM 4. *Suppose that $P(t)$ satisfies the additional condition that for every $v\in K$, $v\neq 0$, $t\in[a,b]$, $P(t)v\in K^0$. If $\int_a^t|r_{ij}^{-1}(s)|ds\leq\int_a^t|R_{ij}^{-1}(s)|ds$ and if $|p_{ij}(t)|\leq|P_{ij}(t)|$ for $i,j\in(1,\cdots,m)$ and for all $t\in[a,f_p(a)]$, and if furthermore for any $i=1,\cdots,m$, there exists an integer $j=j(i)$, $1\leq j\leq m$, and $t_i\in[a,f_p(a)]$ such that $|p_{ij}(t_i)|<|P_{ij}(t_i)|$, then $f_p(a)>f_p(a)$.*

Proof. This theorem follows immediately from Theorems 1 and 3.

In all the theorems presented here, it has always been assumed that the absolute value of $p_{ij}(t)$ must be less than or equal to $|P_{ij}(t)|$, in order to assure that (1) oscillates slower than (2). This condition obviously says that $p_{ij}(t)$ cannot be too negative. The following example will demonstrate that the theorems presented here are not true if one just assumes that $p_{ij}(t)\leq|P_{ij}(t)|$. Let P be the identity matrix and let the symmetric matrix p be given by

$$p=\begin{bmatrix}1 & -1\\ -1 & 1\end{bmatrix}$$

and $n=2$, $k=1$. Of course $f_P(0)=\pi/2$. Notice that a solution of $x''+px=0$ is $x=(\sin\sqrt{2}\,t,\ -\sin\sqrt{2}\,t)/\sqrt{2}$, and it is easy to see that $f_p(0)=(\pi/2)\sqrt{2}<f_P(0)$. This example clearly shows that $p<P$ (in the sense that $p_{ij}(t)\leq P_{ij}(t)$) does not imply $f_P(a)<f_p(a)$, even in the selfadjoint case. This example also illustrates just how useful Theorem 1 can be. Change the roles of p and P, i.e., define p to be the identity matrix and P to be the other matrix. Notice that P is positive with respect to the cone $K=\{(z_1,z_2):z_1\geq 0,z_2\leq 0\}$ and that $y(t)=(\sin\sqrt{2}\,t,-\sin\sqrt{2}\,t)/\sqrt{2}$ is a solution of $y''+P(t)y=0$, $y(0)=0$, $y'(\pi/2\sqrt{2})=0$ and $y(t)\in K^0$ for $t\in(0,\pi/2\sqrt{2})$. Also $|p_{ij}(t)|\leq|P_{ij}(t)|$ and $|p_{12}|<|P_{12}|$. Thus Theorem 1 implies that $x''+p(t)x=0$ is disfocal on $[0,\pi/2\sqrt{2}]$, which it is, despite the fact that in some sense p is larger than P. By the way, it is interesting to notice that in these last examples that neither $p-P$ nor $P-p$ is positive semidefinite and that thus the classical theorems cannot apply.

ON THE STABILITY OF A DISTRIBUTED NETWORK*

JOSÉ M. FERREIRA†

Abstract. This paper is devoted to the study of the stability of a lossless transmission line network which is described by a one delay differential-difference equation of neutral type, involving three parameters. It is shown that for certain intervals of these parameters, asymptotic stability is available when the delay verifies a boundedness condition.

1. Introduction. This paper is devoted to the study of the asymptotic stability of the differential-difference equation of neutral type

$$\dot{x}(t)+k\dot{x}(t-r)+\alpha x(t)-\alpha k x(t-r)-h(x(t))-kh(x(t-r))=0, \tag{1.1}$$

where $r>0$, $k\neq 0$, $\alpha>0$ and $h\in C^1(\mathbb{R})$ is such that $h(0)=0$. According to [1], [6], this equation arises from a lossless transmission line network.

The exponential asymptotic stability of the zero solution of (1.1) is determined by the exponential asymptotic stability of the linearized problem, which in turn occurs if and only if for some $\varepsilon>0$, all roots of the characteristic equation

$$z(1+k\exp(-rz))+a-kb\exp(-rz)=0 \tag{1.2}$$

satisfy $\operatorname{Re} z\leqq -\varepsilon$, where $\gamma=h'(0)$, $a=\alpha-\gamma$ and $b=\alpha+\gamma$.

The case $\gamma<\alpha$ is considered in [1], [2], [6] (see also [3]). In [1], [2] in working on the characteristic equation, the exponential asymptotic stability of the linearized problem is shown for $\gamma<\alpha(1-|k|)/(1+|k|)$, as well as the existence of oscillations for certain choices of k and $\gamma\in]\alpha(1-|k|)/(1+|k|),\alpha[$. By use of Lyapunov functionals, Slemrod [6] shows the uniform asymptotic stability of (1.1) if $\sup_{x>0}(h(x)/x)<\alpha(1-|k|)/(1+|k|)$.

We will discuss here the case $\gamma\geqq\alpha$, that is when $0\leqq -a<b$. With respect to the parameter γ, the interval $[\alpha,+\infty[$ is given as a potential region of instability. This will be confirmed in §§2, 3. However imposing some bounds to the delay r, asymptotic stability is still available for some negative values of k. This is shown in §3.

Notice that when $k=0$, (1.2) has a solution with a nonnegative real part ($z=-a\geqq 0$), and as we will see this situation is maintained for $a/b\leqq k<0$. Therefore we cannot apply an argument of continuity of the spectra, as in [1], [2], in order to conclude asymptotic stability. We will prove that for k in some interval $]\beta,a/b[$, asymptotic stability occurs and disappears when $-1<k\leqq\beta$. This means that part of the spectrum of the linearized problem moves from the right-half complex plane to the left one and returns to the first after a certain value of k. This is a kind of situation which does not happen in the case $\gamma<\alpha$, where the whole spectrum is moving from the left-half complex plane to the right.

The linearized problem of (1.1) is exponentially asymptotically stable only if all solutions of the associated difference equation

$$x(t)+kx(t-r)=0 \tag{1.3}$$

exhibit an exponential decay [4]. In order to obtain this decay we will always assume $|k|<1$, since then all roots of

$$1+k\exp(-rz)=0 \tag{1.4}$$

satisfy $\operatorname{Re} z=(1/r)\log|k|<0$. As a preliminary result we have:

THEOREM 1.1. *The real part of all roots of* (1.2) *is less than* $c=(b-a)/2>0$. *For any* $0<\varepsilon<\delta(k,r)=-(1/r)\log|k|$, *the set of all roots of* (1.2), *such that* $\operatorname{Re} z\geqq-\varepsilon$, *is bounded.*

Proof. Assume that $z=u+iv$ is a root of (1.2). Since (1.2) can be written as

$$(z+a)+k(z-b)\exp(-rz)=0, \tag{1.5}$$

we have

$$\exp(ru)=\frac{|k||z-b|}{|z+a|}. \tag{1.6}$$

If $u\geqq c$ then $|z-b|\leqq|z+a|$, and consequently we obtain $u=\{\log(|k||z-b|/|z+a|)\}/r<0$, which is contradictory.

For the second part of the theorem, taking $M=1-|k|\exp(r\varepsilon)$ and z in the strip $-\varepsilon\leqq\operatorname{Re} z\leqq c$, we have $|1+k\exp(-rz)|\geqq M$. Thus if z is a root of (1.2) in the mentioned strip, we have $|z|\leqq(|a|+|b|)/M$. The statement then follows.

By analyticity, if all roots of (1.2) stay in the left-half complex plane, then by Theorem 1.1 they satisfy $\operatorname{Re} z\leqq-\varepsilon$ for some $0<\varepsilon<\delta(k,r)$. Therefore if we consider the rectangle $R_\nu=\{z:\ 0\leqq\operatorname{Re} z\leqq c,|\operatorname{Im} z|\leqq\nu\}$ for $\nu>0$, (1.2) has all roots satisfying $\operatorname{Re} z\leqq-\varepsilon$ for some $\varepsilon>0$ if and only if the function

$$f(z)=g(z)+k\exp(-rz),$$

where $g(z)=(z+a)/(z-b)$, has no roots in R_ν for every $\nu>0$.

Considering the boundary Γ_ν of R_ν, by the argument's principle, the existence and nonexistence of zeros with a nonnegative real part depends upon the variation of $f(z)$ when z proceeds along Γ_ν. In order to study this variation we develop a method introduced in [5], which consists in comparing the variation of $g(z)$ to the variation of $k\exp(-rz)$.

Making $z=u+iv$, we will write $g(z)$ as

$$g(u+iv)=G(u+iv)\exp(i\theta(u+iv)), \tag{1.7}$$

where

$$G(u+iv)=\frac{\left[(u+a)^2+v^2\right]^{1/2}}{\left[(u-b)^2+v^2\right]^{1/2}} \tag{1.8}$$

and

$$\theta(u+iv)=\arctan\left\{\frac{-(b+a)v}{\left[(u+a)(u-b)+v^2\right]}\right\}. \tag{1.9}$$

2. Oscillations. An oscillation for the linearized problem appears whenever $f(z)$ has a zero on the imaginary axis. Since $f(\bar z)=\overline{f(z)}$, it will be sufficient to study $f(z)$ for z along the nonnegative imaginary half-axis $\{z:\ z=iv, v\geqq0\}$. The same holds for $g(z)$, which study is stated in the following.

LEMMA 2.1. *For* $v \geqq 0$, $\theta(iv)$ *decreases in* $[0,(-ab)^{1/2}]$ *and increases in* $[(-ab)^{1/2}, +\infty)$; $\theta(0)=0$ *and* $-\pi/2<\theta(iv)<0$, $v\neq 0$. *On the other hand,* $G(iv)$ *increases in* $v\geqq 0$, $G(iv)<1$ *and* $\lim_{v\to+\infty} G(iv)=1$.

Proof. Make $u=0$ in (1.9) and (1.8). The sign of $(d/dv)\theta(iv)$ depends upon the sign of $ab+v^2$. In fact $\theta(iv)$ decreases as long as $ab+v^2\leqq 0$ and increases when $ab+v^2\geqq 0$.

As $g(0)>0$, then $\theta(0)=0$. Since $-\infty<\tan\theta(iv)<0$ for $v\neq 0$, we have $-\pi/2<\theta(iv)<0$. Moroever, $\lim_{v\to+\infty}\theta(iv)=0$.

On the other hand, as $b>-a$ then $G(iv)<1$ and $\lim_{v\to+\infty} G(iv)=1$. By derivation one easily sees that $G(iv)$ is increasing. □

Then, assuming $G(0)\leqq|k|$, let $v_0\geqq 0$ be such that $G(iv_0)=|k|$. In order to have $f(iv)=0$, it is necessary and sufficient that $v=v_0$ and that the origin be in the line segment of the complex plane

$$\langle g(iv), k\exp(-irv)\rangle = \{(1-\lambda)g(iv)+\lambda k\exp(-irv);\ 0\leqq\lambda\leqq 1\}.$$

The origin is aligned with $g(iv)$ and $k\exp(-irv)$ whenever

$$\arg g(iv)=\arg(k\exp(-irv))+n\pi \tag{2.1}$$

for some integer n. For $n=0$, $v=0$, we have always an initial alignment in the real axis.

If $k<0$, condition (2.1) becomes

$$\theta(iv)+rv=(n+1)\pi,$$

and since $-\pi/2<\theta(iv)\leqq 0$, we have that $n\geqq -1$. However, the alignments which have the origin in $\langle g(iv), k\exp(-irv)\rangle$ are given by (see Fig. 1)

$$\theta(iv)+rv=2n\pi \quad\text{and}\quad \frac{2n\pi}{r}\leqq v<\frac{(2n+1/2)\pi}{r}, \qquad n\geqq 0. \tag{2.2}$$

When $n\geqq 1$, as for $rv=2n\pi$, we have $\theta(iv)+rv<2n\pi$, and for $rv=(2n+1/2)\pi$, $\theta(iv)+rv>2n\pi$. By continuity we conclude that there is always an $\omega_n\in]2n\pi/r, (2n+1/2)\pi/r[$, which verifies (2.2). For $n=0$, if there exists an $\omega_0\in]0, \pi/2r[$ such that $\theta(i\omega_0)=-r\omega_0$, then we obtain another alignment, and $0\in\langle g(i\omega_0), k\exp(-ir\omega_0)\rangle$. This will happen if and only if $(d/dv)\theta(iv)|_{v=0}<-r$; that is, $r<(b+a)/(-ab)$.

If $k>0$, condition (2.1) can be written as

$$\theta(iv)+rv=n\pi,$$

where $n\geqq 0$. The alignments which have the origin in $\langle g(iv), k\exp(-irv)\rangle$ are given by $\theta(iv)+rv=(2n-1)\pi$ and $(2n-1)\pi/r<v<(2n-1/2)\pi/r$, $n\geqq 1$. As above, this condition is always verified for some ω_n in $](2n-1)\pi/r, (2n-1/2)\pi/r[$. Hence, $f(iv)=0$ if and only if $v=v_0=\omega_n$ for some $n\geqq 1$.

Notice that when $(d/dv)\theta(iv)<0$, we have $(d^2/dv^2)\theta(iv)\geqq 0$. This means that for $v\in[0,(-ab)]$, $\theta(iv)$ is a convex function. Therefore all the alignments mentioned above are unique in each considered interval.

The conditions obtained for the existence of oscillations are equivalent to those of Brayton in [1].

3. Stability for bounded delays. When we compare $g(z)$ with $k\exp(-rz)$, different conclusions may be obtained according to the signal of k. In the following we show that for $k<0$, asymptotic stability can be obtained.

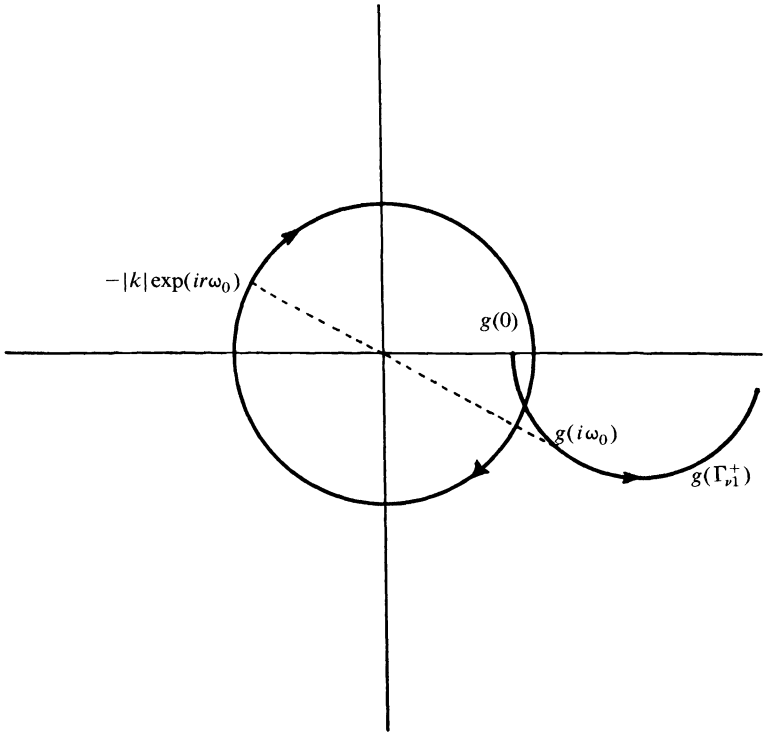

FIG. 1

When $-1<k<0$ we write $f(z)$ as

$$f(z)=g(z)-|k|\exp(-rz).$$

Therefore if $g(0)=|k|$ we have $f(0)=0$. We avoid this degenerate situation by assuming $g(0)\neq|k|$.

We have already seen that when $r<(b+a)/(-ab)$, there exists an $\omega_0\in]0, \pi/2r[$ such that $0\in\langle g(i\omega_0), -|k|\exp(-ir\omega_0)\rangle$. We will show:

THEOREM 3.1. *Let* $-1<k<a/b$ *and* $r<-(b+a)/(ab)$. *If* $|g(i\omega_0)|>|k|$, *then all zeros of* $f(z)$ *have negative real part. If* $|g(i\omega_0)|<|k|$, $f(z)$ *has two zeros with positive real part such that* $0<|\mathrm{Im}\, z|<\pi/r$. *If* $|g(i\omega_0)|=|k|$, *then* $f(\pm i\omega_0)=0$.

In order to prove this theorem we will consider the nonnegative imaginary part of the rectangle R_ν,

$$R_\nu^+=\{z: 0\leqq \mathrm{Re}\, z\leqq c, 0<\mathrm{Im}\, z\leqq \nu\},$$

which boundary we denote by Γ_ν^+. Decompose

$$\Gamma_\nu^+=\Gamma_{\nu 1}^+\cup\Gamma_{\nu 2}^+\cup\Gamma_{\nu 3}^+\cup\Gamma_{\nu 0},$$

where

$$\Gamma_{\nu 1}^+=\{iv: 0\leqq v\leqq \nu\},\qquad \Gamma_{\nu 2}^+=\{u+i\nu: 0\leqq u\leqq c\},$$

$$\Gamma_{\nu 3}^+=\{c+iv: 0\leqq v\leqq \nu\},\quad \Gamma_{\nu 0}=\{u: 0\leqq u\leqq c\}.$$

As we want to compare $g(z)$ with $-|k|\exp(-rz)$ when z proceeds along Γ_ν^+ clockwise from the origin, we first need to know the variation of $g(z)$ along Γ_ν^+. We recall that for $z=iv$ in $\Gamma_{\nu 1}^+$, $\theta(iv)$ is always decreasing if $ab+\nu^2\leqq 0$. *If* $ab+\nu^2>0$, $\theta(iv)$ decreases in $[0,(-\mathrm{ab})^{1/2}]$ and increases in $[(-ab)^{1/2},\nu]$. Moreover, $G(iv)$ is increasing and is less than one.

LEMMA 3.1. *For* $z=u+iv$ *along* $\Gamma_{\nu 2}^+$, $\theta(u+iv)$ *decreases. If* $(b+a)^2\leqq 4\nu^2$, *it is* $-\pi/2\leqq\theta(u+iv)<0$ *for* u *in* $[0,c]$; $\theta(u+iv)=-\pi/2$ *is satisfied only when* $(b+a)^2=4\nu^2$ *and* $u=c$. *If* $(b+a)^2>4\nu^2$, *there exists a* $u_0\in\,]0,c[$ *such that* $-\pi/2<\theta(u+iv)<0$ *in* $[0,u_0[$; $-\pi<\theta(u+iv)<-\pi/2$ *in* $]u_0,c]$ *and* $\theta(u_0+iv)=-\pi/2$. *Moreover,* $G(u+iv)<1$ *for* $u<c$ *and* $G(c+iv)=1$. *If* $\nu^2+ab\geqq 0$, $G(u+iv)$ *increases. If* $\nu^2+ab<0$, *there exists a* $u_1\in\,]0,c[$ *such that* $G(u+iv)$ *decreases in* $[0,u_1]$ *and increases in* $[u_1,c]$.

Proof. We have $\theta(u+iv)=\arctan\{-(b+a)\nu/[(u+a)(u-b)+\nu^2]\}$ and $(d/du)\theta(u+iv)<0$, except when $u=c$, where this derivative is zero. Then $\theta(u+iv)$ decreases. If $(b+a)^2<4\nu^2$, we have $p(u)=(u+a)(u-b)+\nu^2>0$ for every $u\geqq 0$, and then $-\pi/2<\theta(u+iv)<0$. For $(b+a)^2=4\nu^2$ the same holds except when $p(u)=0$, which happens only for $u=c$. Only in this case does $\theta(u+iv)=-\pi/2$. If $(b+a)^2>4\nu^2$, then $p(u)$ has only one positive root u_0 in $]0,c[$. We have $\theta(u_0+iv)=-\pi/2$, $\theta(u+iv)>-\pi/2$ for $0\leqq u<u_0$ and $\theta(u+iv)<-\pi/2$ for $u_0<u\leqq c$.

On the other hand, clearly $G(u+iv)\leqq 1$ and $G(u+iv)=1$ only if $u=c$. Moreover, as $(d/du)G(u+iv)^2=2(b+a)[\nu^2-(u+a)(u-b)]/[(u-b)^2+\nu^2]^2$, $G(u+iv)$ increases if $\nu^2+ab\geqq 0$. If $\nu^2+ab<0$, the polynomial $\nu^2-(u+a)(u-b)$ has only one positive real zero $u_1\in\,]0,c[$ and $G(u+iv)$ decreases in $[0,u_1]$ and increases in $[u_1,c]$. □

LEMMA 3.2. *For* $z=c+iv$ *moving along* $\Gamma_{\nu 3}^+$, *when* v *goes from* ν *to zero,* $\theta(c+iv)$ *decreases to* $\theta(c)=-\pi$. *If* $(b+a)>2\nu$, *it is* $-\pi\leqq\theta(c+iv)<-\pi/2$. *If* $(b+a)=2\nu$, *the same holds except for* $\theta(c+iv)=-\pi/2$. *If* $(b+a)<2\nu$, *there exists a* $v_1\in\,]0,\nu[$ *such that* $\theta(c+iv_1)=-\pi/2$, $\theta(c+iv)>-\pi/2$ *for* $v>v_1$ *and* $\theta(c+iv)<-\pi/2$ *for* $v<v_1$. *Furthermore,* $G(c+iv)=1$ *for every* $v\in[0,\nu]$.

Proof. When $z=c+iv$ we have $(d/dv)\theta(c+iv)>0$. Therefore when v goes from ν to zero, $\theta(c+iv)$ decreases. As $g(c)=-1$, it is $\theta(c)=-\pi$. One can easily see that $G(c+iv)=1$ for every v. The rest of the lemma follows as in Lemma 3.1. □

Let $g(0)=-a/b>|k|$ and recall the boundary Γ_ν of the rectangle R_ν. Taking ν sufficiently large, one can see by Lemmas 3.1 and 3.2 that $|g(z)|>|k|$ for every z in Γ_ν. Therefore as $|f(z)-g(z)|\leqq|k|$ for z in Γ_ν, we conclude by Rouché's theorem that f and g have the same number of zeros inside Γ_ν. Hence if $g(0)>|k|$, f has a unique zero, which is necessarily real, inside Γ_ν. This conclusion, which can also be reached in a more direct way, is the reason why in Theorem 3.1 we have to assume $g(0)=-a/b<|k|$.

Assume now $G(i\omega_0)>|k|$ and take $\nu=m\pi/r$, where m is a positive even integer arbitrarily large. Notice that then $v_0<\omega_0$.

For $z=u+iv$, the real and imaginary parts of $f(z)$ are

$$\begin{aligned}\mathrm{Re}f(u+iv)&=G(u+iv)\cos\theta(u+iv)-|k|\exp(-ru)\cos rv,\\ \mathrm{Im}f(u+iv)&=G(u+iv)\sin\theta(u+iv)+|k|\exp(-ru)\sin rv.\end{aligned}\tag{3.1}$$

(A) We will analyze here the variation of $f(z)$ for $z=iv$ along $\Gamma_{\nu 1}^+$.

(1) Let $v\in[0,\pi/2r]$. (i) for $v=0$ we have $\mathrm{Im}f(0)=0$ and $\mathrm{Re}f(0)=G(0)-|k|<0$. (ii) For $0<v\leqq v_0$, it is $-\pi/2<\theta(iv)<-rv\leqq 0$. Then $\cos\theta(iv)<\cos rv$ and $\mathrm{Re}f(iv)<(G(iv)-|k|)\cos rv\leqq 0$. (iii) When $v_0\leqq v\leqq\omega_0$, we have $-\pi/2<\theta(iv)\leqq -rv\leqq 0$ and $\sin\theta(iv)\leqq-\sin rv$. Thus, for $v<\omega_0$, $\mathrm{Im}f(iv)<(-G(iv)+|k|)\sin rv\leqq 0$. Moreover,

$\mathrm{Im} f(i\omega_0)=(-G(i\omega_0)+|k|)\sin r\omega_0<0$. (iv) If $\omega_0\leqq v\leqq \pi/2r$ then $\theta(iv)\geqq -rv$, which implies $\mathrm{Re} f(iv)>(G(iv)-|k|)\cos rv\geqq 0$ for $v>\omega_0$. Furthermore, $\mathrm{Re} f(i\omega_0)>0$.

(2) In each interval $[(2n+1/2)\pi/r,(2n+1)\pi/r]$, $n\geqq 0$, we have always $\mathrm{Re} f(iv)>0$.

(3) If $v\in[(2n+1)\pi/r,(2n+2)\pi/r]$, $n\geqq 0$ then $\mathrm{Im} f(iv)<0$.

(4) Now let $v\in[2n\pi/r,(2n+1/2)\pi/r]$ for $n\geqq 1$, and take the alignment ω_n in the interior of this interval. (i) For $2n\pi/r\leqq v\leqq\omega_n$ we have $\theta(iv)\leqq -rv+2n\pi$. Thus, as in (1) (iii), it is $\mathrm{Im} f(iv)<0$. (ii) When $\omega_n\leqq v\leqq(2n+1/2)\pi/r$ as in (1) (iv), we have $\mathrm{Re} f(iv)>0$.

Thus, for $z=iv$ moving along $\Gamma_{\nu 1}^{+}$, $f(z)$ starts in the left-half plane and passes into the right one at some v in $[v_0,\omega_0]$ with $\mathrm{Im} f(z)<0$. After that we have always either $\mathrm{Re} f(z)>0$ or $\mathrm{Im} f(z)<0$ (see Fig. 2 below).

(B) When $z=u+i\nu$ proceeds along $\Gamma_{\nu 2}^{+}$, we conclude by Lemma 3.1 that

$$\mathrm{Im} f(u+i\nu)=G(u+i\nu)\sin\theta(u+i\nu)<0.$$

(C) Now we will discuss the variation of $f(z)$ when $z=c+iv$ moves along $\Gamma_{\nu 3}^{+}$. By Lemma 3.2, for every $v\in[(2n+1)\pi/r,(2n+2)\pi/r]$, $n\geqq 0$, we have $\mathrm{Im} f(c+iv)=G(c+iv)\sin\theta(c+iv)+|k|\exp(-rc)\sin rv<0$. In each interval $[2n\pi/r,(2n+1)\pi/r]$, $n\geqq 0$, alignments exist for $g(c+iv)$, $-|k|\exp(-r(c+iv))$ and the origin such that $0\in\langle g(c+iv),\ -|k|\exp(-r(c+iv))\rangle$. In fact, as in §2, for each $n\geqq 0$, there exists a $\tau_n\in]2n\pi/r,(2n+1)\pi/r[$ such that $\theta(c+i\tau_n)+r\tau_n=2n\pi$. A final alignment exists along the negative real axis, when $n=0$, $v=0$—that is, for $z=c$.

(1) Let $\tau_n=(2n+1/2)\pi/r$. (i) Then $\theta(c+i\tau_n)=-\pi/2$, and consequently $\mathrm{Re} f(c+i\tau_n)=0$ and $\mathrm{Im} f(c+i\tau_n)=-1+|k|\exp(-rc)<0$. (ii) For $2n\pi/r\leqq v<(2n+1/2)\pi/r$ we have $\theta(c+iv)<\theta(c+i\tau_n)=-\pi/2$, and then $\mathrm{Re} f(c+iv)=\cos\theta(c+iv)-|k|\exp(-rc)\cos rv<0$. (iii) When $(2n+1/2)\pi/r<v\leqq(2n+1)\pi/r$ it is $\theta(c+iv)>-\pi/2$, and therefore $\mathrm{Re} f(c+iv)>0$.

(2) Now assume $\tau_n>(2n+1/2)\pi/r$. Then $\theta(c+i\tau_n)<-\pi/2$. (i) For $2n\pi/r\leqq v\leqq(2n+1/2)\pi/r$ we have $\theta(c+iv)<-\pi/2$, which implies $\mathrm{Re} f(c+iv)<0$. (ii) For $(2n+1/2)\pi/r\leqq v\leqq\tau_n$ we have $-\pi<\theta(c+iv)\leqq -rv+2n\pi\leqq -\pi/2$. Therefore $\cos\theta(c+iv)\leqq\cos(-rv+2n\pi)=\cos rv$ and $\mathrm{Re} f(c+iv)<(1-|k|\exp(-rc))\cos rv\leqq 0$ if $v<\tau_n$. On the other hand, $\mathrm{Re} f(c+i\tau_n)=(1-|k|\exp(-rc))\cos r\tau_n<0$. (iii) For $\tau_n\leqq v\leqq(2n+1)\pi/r$ and $\theta(c+iv)<-\pi/2$ we have $-\pi/2>\theta(c+iv)\geqq -rv+2n\pi>-\pi$, and then $\sin\theta(c+iv)\leqq-\sin rv$, which implies $\mathrm{Im} f(c+iv)<(-1+|k|\exp(-rc))\sin rv\leqq 0$ if $v>\tau_n$. On the other hand, $\mathrm{Im} f(c+i\tau_n)<0$. (iv) If $\tau_n\leqq v\leqq(2n+1)\pi/r$ and $\theta(c+iv)\geqq-\pi/2$, we have $\mathrm{Re} f(c+iv)>0$.

(3) Let $\tau_n<(2n+1/2)\pi/r$. Then $\theta(c+i\tau_n)>-\pi/2$. (i) For $2n\pi/r\leqq v\leqq\tau_n$ and $\theta(c+iv)\leqq-\pi/2$ we obtain $\mathrm{Re} f(c+iv)<0$. (ii) When $2n\pi/r\leqq v\leqq\tau_n$ and $\theta(c+iv)\geqq-\pi/2$, it is $-\pi/2\leqq\theta(c+iv)\leqq -rv+2n\pi\leqq 0$. Thus $\sin\theta(c+iv)\leqq-\sin rv$, and consequently $\mathrm{Im} f(c+iv)<(-1+|k|\exp(-rc))\sin rv\leqq 0$ if $v<\tau_n$. Clearly $\mathrm{Im} f(c+i\tau_n)<0$. (iii) When $\tau_n\leqq v\leqq(2n+1/2)\pi/r$, we have $0>\theta(c+iv)\geqq -rv+2n\pi\geqq-\pi/2$. Therefore $\mathrm{Re} f(c+iv)>0$. (iv) For $(2n+1/2)\pi/r\leqq v\leqq(2n+1)\pi/r$ it is $\theta(c+iv)>-\pi/2$, and then $\mathrm{Re} f(c+iv)>0$.

Recalling that $\theta(c)=-\pi$, for $z=c+iv$ moving along $\Gamma_{\nu 3}^{+}$, $f(z)$ goes back to the left-half plane, but whenever $f(z)$ crosses the imaginary axis it does with $\mathrm{Im} f(z)<0$.

(D) Finally when $z=u$ moves along $\Gamma_{\nu 0}$, we have $f(u)=(u+a)/(u-b)-|k|\exp(-ru)$, and since $r<-(b+a)/(ab)$ and $-a/b<|k|$, one can easily prove that $f(u)$ decreases when u increases in $[0,c]$. Therefore $f(z)$ has no zero on $\Gamma_{\nu 0}$, and when z moves along $\Gamma_{\nu 0}$ from c to zero, $f(z)$ moves along the negative real axis from $f(c)=-1-|k|\exp(-rc)$ to $f(0)=-a/b-|k|$.

Thus by the analysis made above, when z proceeds along Γ_ν^+ clockwise, $f(z)$ passes from the left- to the right-half complex plane and returns to the first. Whenever $f(z)$ crosses the imaginary axis we have $\mathrm{Im} f(z)<0$. This means that $f(\Gamma_\nu^+)$ never encircles the origin and that then $f(z)$ has no zeros in R_ν^+. Hence all zeros of $f(z)$ lie in the left-half plane.

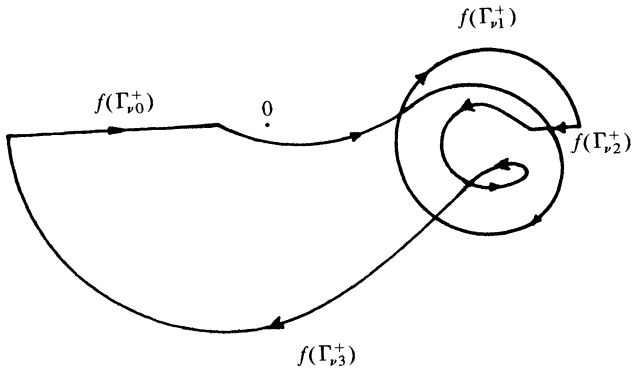

FIG. 2

Assume now $G(i\omega_0)<|k|$ and take $\nu=\pi/r$. It will be $v_0>\omega_0$, and we distinguish two cases: $v_0\leqq\pi/2r$ and $v_0>\pi/2r$. Using similar arguments to those in (A)(1), we have the following. (i) For $0\leqq v\leqq\omega_0$, $\mathrm{Re} f(iv)<0$. (ii) If $\omega_0\leqq v\leqq v_0\leqq\pi/2r$ then $\mathrm{Im} f(iv)>0$. (iii) When $v_0\leqq v\leqq\pi/2r$ it is $\mathrm{Re} f(iv)>0$. (iv) For $\omega_0\leqq v\leqq\pi/2r$ and $v_0>\pi/2r$ we have $\mathrm{Im} f(iv)>0$. (v) When $\pi/2r\leqq v\leqq\pi/r$ then $\mathrm{Re} f(iv)>0$.

Thus when $z=iv$ proceeds along $\Gamma_{\nu 1}$, $f(z)$ leaves the left-half plane and goes to the right one crossing the imaginary axis with $\mathrm{Im} f(z)>0$. For z running along $\Gamma_{\nu 2}^+$, as in (B), we have always $\mathrm{Im} f(z)<0$. When z moves along $\Gamma_{\nu 3}^+$, making $n=0$ in (C), we can see that $f(z)$ returns to the left-half plane crossing the imaginary axis with $\mathrm{Im} f(z)<0$. Finally, as before, for z along $\Gamma_{\nu 0}$, $f(z)$ runs over the negative real axis from $f(c)$ to $f(0)$. Hence $f(\Gamma_\nu^+)$ encircles the origin once, and consequently $f(z)$ has two zeros with positive real part such that $0<|\mathrm{Im} z|<\pi/r$. This achieves the proof of Theorem 3.1.

Notice that when $a=0$, Theorem 3.1 holds for every delay r. In fact, in this case, since we can make $\theta(0)=-\pi/2$, $\theta(iv)$ increases and the alignment ω_0 always exists.

In all other circumstances we are in a situation of instability. As a matter of fact, when $0<k<1$, it can be shown that $f(z)$ has always a real positive zero, and as we have seen, this situation is maintained when $-1<a/b<k<0$. When $-1<k<a/b<0$ and the alignment at some ω_0 in $]0,\pi/2r[$ does not exist, it can be seen that $f(z)$ has two zeros inside $\Gamma_{\pi/r}$.

When $0<\gamma<\alpha$ we have $0<a<b$. It is well known that for $|k|<a/b$, all roots of $f(z)$ lie in the left-half complex plane (see [6]). This can also be proved studying the variation of the function $g(z)$ and applying Rouché's theorem as before. When $0<a/b<k$, $f(z)$ has always a positive real zero, and for $k=a/b$ we have $f(0)=0$. For $-1<k<-a/b$, a statement similar to Theorem 3.1 holds, as was pointed out in [1].

In fact, using the same procedure, it can be shown that there exists always a unique $\omega_1\varepsilon]0,\pi/r[$ such that $f(\pm i\omega_1)=0$ if $|k|=|g(i\omega_1)|$. Therefore if $|k|<|g(i\omega_1)|$, all zeros of $f(z)$ have negative real part. Otherwise $f(z)=0$ for some z having $\mathrm{Re} z>0$ and $0<|\mathrm{Im} z|<\pi/r$.

SEMIGROUPS GENERATED BY A NEUTRAL FUNCTIONAL DIFFERENTIAL EQUATION*

OLOF J. STAFFANS†

Abstract. We discuss a number of semigroups generated by neutral functional differential equations of the form

$$\frac{d}{dt}(x(t)+\mu * x(t))+\nu * x(t)=f(t), \qquad t\geqq 0,$$
$$x(t)=\varphi(t), \qquad t\leqq 0.$$

They are of extended initial function type and of extended forcing function type, and they differ from each other by the amount of smoothness which is imposed on x and f above. The extended initial function type semigroups are adjoints of the extended forcing function type semigroups, and vice versa. The two types of semigroups are also equivalent in the sense that there is a one-to-one, bicontinuous mapping of the state space onto itself, which maps a semigroup of the initial function type onto a semigroup of the forcing function type. In particular, it suffices to study the asymptotic behavior of one of the two types of semigroups, because the results can easily be transferred to the other type of semigroups.

1. Introduction. We discuss a number of semigroups generated by functional differential equations of the form

$$\frac{d}{dt}(x(t)+\mu * x(t))+\nu * x(t)=f(t), \qquad t\geqq 0, \tag{1.1}$$

with initial condition

$$x(t)=\varphi(t), \qquad t\leqq 0. \tag{1.2}$$

The values of x, f and φ lie in $\mathbf{R}^n$, and μ and ν are n by n matrix valued measures on $[0,\infty)$. The measure μ is not allowed to have a point mass at zero. The convolution $\mu * x$ is defined a.e. by

$$\mu * x=\int_{[0,\infty)}[d\mu(s)]\,x(t-s), \qquad t\geqq 0.$$

Our semigroups act on certain "fading memory spaces" of functions of type L^p, or $W^{1,p}$, or $W^{-1,p}$, with $1<p<\infty$, defined on $\mathbf{R}^-=(-\infty,0]$ or $\mathbf{R}^+[0,\infty)$. More specifically, we let η be an "influence function", choose our initial function φ from either $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)$ or $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)$, and choose our forcing function from either $L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ or $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$. The semigroups which we construct are of two types; an extended initial function type, and an extended forcing function type. One gets an extended initial function type semigroup roughly by solving (1.1) with initial condition (1.2), taking a translate of the solution to be a new initial function, and taking a translate of the forcing function f to be the new forcing function. To get an extended forcing function type semigroup we, roughly speaking, solve (1.1) with zero initial condition, and let the new forcing function be a translate of the old forcing function f, plus a correction term which replaces the initial function term in the initial function type semigroup.

We show that the adjoint of a semigroup of extended initial function type is a semigroup of extended forcing function type, and vice versa. We also show that there is

*Received by the editors September 6, 1983, and in revised form March 16, 1984.
†Institute of Mathematics, Helsinki University of Technology, SF-02150 Espoo 15, Finland.

a continuous, one-to-one mapping of the state space onto itself, which maps a initial function type semigroup onto a forcing function type semigroup. In other words, the two types of semigroup are equivalent to each other. This means e.g. that it suffices to study the asymptotic behavior of one of the two types of semigroup, because the other type of semigroups behaves in exactly the same way.

This paper may be considered as a continuation of [33] where the same type of results are proved for a (nondifferentiated) functional equation. We expect the reader to be familiar with [33], and throughout use the same notations as in [33]. We also refer the reader to [33] for a short discussion of earlier comparable results.

In [33, §§5 and 6] we gave two examples on how the equivalence relation between the two types of semigroups could be used to find the generator of the extended forcing function semigroup, and to study the asymptotic behavior of the extended forcing function semigroup. The equivalence relationships which we state here can be used in the same way.

2. The initial function semigroups. In this work we shall for simplicity restrict ourselves to state spaces of type L^p, with $1<p<\infty$. Also, in [33] the limiting cases $p=1$ and $p=\infty$ were discussed. They could be included here, too, but the proofs are slightly simpler in the reflexive case $1<p<\infty$.

We let η be an influence function dominated by a dominating function ρ, and let $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)$ and $L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ be the standard L^p-spaces on $\mathbf{R}^-$ and $\mathbf{R}^+$ with weight η (cf. [33]). Our principal initial function space will be either $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)$ or $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)$, where

$$W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)=\{\varphi\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)|\varphi'\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\}.$$

Here the condition on the derivative φ' should be interpreted as requiring that φ has to be absolutely continuous. Our principal forcing function space will be either $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)$ or $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, a space of distributions which will be defined later. In addition to the principal spaces above, we shall also discuss certain initial and forcing function spaces of cross product type.

The measures μ and ν in (1.1) are throughout supposed to belong to $M(\mathbf{R}^+;\mathbf{R}^{n\times n};\rho)$, and μ is not allowed to have a point mass at zero.

To make a long story short, we define $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ to be the dual of the space $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$, where q is the conjugate index to p, and $\tilde{\eta}$ is the adjoint influence function to η, i.e. $\tilde{\eta}(t)=[\eta(-t)]^{-1}$, $t\in\mathbf{R}$. We postpone the precise definition of $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ to the next section. For the moment it suffices to know that an element of $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ can be identified with a distribution of the form $\delta z+f+g'$, where $(z,f,g)\in\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R};\eta)$, δ is the unit point mass at zero, and both f and g vanish on $\mathbf{R}^-$.

Under the general hypothesis, the equation (1.1) has a fundamental solution r, which vanishes on $\mathbf{R}^-$, belongs to $L^1(\mathbf{R}^+;\mathbf{R}^{n\times n};e^{-dt})$ and has a (distribution) derivative in $M(\mathbf{R}^+;\mathbf{R}^{n\times n};e^{-dt})$ for some sufficiently large number d. This function satisfies

$$r'+r'*\mu+r*\nu=r'+\mu*r'+\nu*r=\delta, \tag{2.1}$$

where δ is the unit point mass at zero, and the equation should be inerpreted as an equation in $M(\mathbf{R}^+;\mathbf{R}^{n\times n};e^{-dt})$. See [28, Thm. 5.2]. In particular, $r(0)=I$ (the identity matrix). In general r does not commute with μ and ν. However, by (2.1),

$$(\delta+\mu)*r'*(\delta+\mu)=(\delta+\mu)*(\delta-r*\nu)=(\delta-\nu*r)*(\delta+\mu),$$

so r satisfies

$$(\delta+\mu)*r*\nu=\nu*r*(\delta+\mu). \tag{2.2}$$

Equation (1.1) generates the following initial function type semigroup in $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^\eta;\eta)$.

THEOREM 2.1. *For each* $(\varphi,f)\in W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $x=x(\varphi,f)$ *be the solution of* (1.1) *with initial condition* (1.2), *and define* $T(t)(\varphi,f)=(x_t,f_t)$, $t\geqq 0$, *where* x_t *is the restriction to* $\mathbf{R}^-$ *of* $\tau_t x$, *and* f_t *is the restriction to* $\mathbf{R}^+$ *of* $\tau_t f$. *Then* T *is a strongly continuous semigroup in* $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

Here τ_t is the left-translation operator $\tau_t\varphi(s)=\varphi(s+t)$. In the sequel we shall use the subindex t with the same interpretation as in Theorem 1: Whenever a function, call it h, is given the subindex t, then we mean the restriction to either $\mathbf{R}^-$ or to $\mathbf{R}^+$ of $\tau_t h$.

Theorem 2.1 can be deduced from e.g. [30, §7] and [31, §7] (although it is not formulated there in exactly this form). In the situation above one can express the solution x of (1.1) with initial condition (1.2) e.g. in the form

$$x=\varphi+(r+r*\mu)\varphi(0)+r*(f+N(\varphi)+M(\varphi')), \tag{2.3}$$

where we have defined f, $M(\varphi')$ and $N(\varphi)$ to be zero on $(-\infty,0)$, φ and φ' to be zero on $\mathbf{R}^+$, and

$$\begin{aligned} M(\psi)(t)&=-\int_{(t,\infty)} d\mu(s)\psi(t-s), \qquad t\geqq 0,\\ N(\varphi)(t)&=-\int_{(t,\infty)} d\nu(s)\varphi(t-s), \qquad t\geqq 0. \end{aligned} \tag{2.4}$$

To verify that (2.3) is a solution of (1.1) one can simply differentiate (2.3), and use (2.1) and (2.2) above to get (1.1); by [28, §§4 and 7], the solution of (1.1) with initial condition (1.2) is unique under the assumption of Theorem 2.1.

In the sequel we shall throughout use the same convention as in (2.3), i.e. initial functions are always extended to $\mathbf{R}$ by zero on $\mathbf{R}^+$, and forcing functions are always extended to $\mathbf{R}$ by zero on $\mathbf{R}^-$.

Equation (1.1) with initial condition (1.2) generates initial function type semigroups also in other settings. If we relax the smoothness requirement on the initial function to $\varphi\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)$, then the forcing function space has to be changed, too, or some other modifications are necessary. One possible way, the one used in [28], is to rewrite (1.1) in the form

$$\begin{aligned} z'(t)+\nu*x(t)&=f(t), \qquad t\geqq 0,\\ x(t)+\mu*x(t)-z(t)&=g(t), \qquad t\geqq 0, \end{aligned} \tag{2.5}$$

and replace the initial condition by

$$x(t)=\varphi(t), \quad t<0, \qquad z(0)=\zeta. \tag{2.6}$$

Then one gets the following semigroup.

THEOREM 2.2. *For each* $(\varphi,\zeta,f,g)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $(x,z)=(x(\varphi,\zeta,f,g),\ z(\varphi,\zeta,f,g))$ *be the solution of* (2.5) *with initial condition* (2.6), *and define* $T(t)(\varphi,\zeta,f,g)=(x_t,z(t),f_t,g_t)$, $t\geqq 0$. *Then* T *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

Here, the solution (x,z) of (2.5) with initial condition (2.6) is given by

$$\begin{aligned} x &= \varphi + r\zeta + r*(f+N(\varphi)) + r'*(g+M(\varphi)), \\ z &= (r+\mu*r)\zeta + (r+\mu*r)*(f+N(\varphi)) - \nu*r*(g+M(\varphi)), \end{aligned} \tag{2.7}$$

where $M(\varphi)$ and $N(\varphi)$ are defined as in (2.4) (and initial and forcing functions are defined to be zero outside of their original domain).

Although it is true that x and z together determine the functions f and g in (2.5) uniquely, it is not true that x alone does so. This is a rather disturbing fact, because we only added the new variable z in order to make the problem "well posed", and it is not necessarily true that z has a natural physical interpretation. In other words there is a certain redundancy in the forcing function pair (f,g) in (2.5). One can remove this redundancy in many ways. One way is very obvious: If $g\equiv 0$, then the g-component of the semigroup remains zero, and by restricting the previous semigroup to the space $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times\{0\}$ we get the following semigroup.

THEOREM 2.3. *For each* $(\varphi,\zeta,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $(x,z)=(x(\varphi,\zeta,f),z(\varphi,\zeta,f))$ *be the solution of* (2.5) *with* $g\equiv 0$, *with initial condition* (2.6). *Define* $T(t)(\varphi,\zeta,f)=(x_t,z(t),f_t)$. *Then* T *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

Another equally obvious possibility is to take the f-component of the semigroup to be identically zero. This is roughly equivalent to replacing $f(t)$ in (1.1) by $df(t)/dt$.

Theorem 2.2 has the obvious disadvantage that the set of permitted forcing functions is much more restricted than the set of forcing functions in Theorem 2.2. Fortunately there is also another way of removing the redundancy in Theorem 2.2, which leaves the set of forcing functions intact. Interpreting (2.7) in the distribution sense, we can write x in the form

$$x=\varphi+r*N(\varphi)+r'*M(\varphi)+r*f, \tag{2.8}$$

where we have replaced $\delta z+f+g'$ in (2.7) by a distribution $f\in W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$. In Theorem 2.2 we have used a particular representation for $f\in W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, but the solution x depends only on the distribution f, and not on the particular representation. Therefore, we can interpret Theorem 2.2 in the following way.

THEOREM 2.4. *For each* $(\varphi,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *choose an arbitrary triple* $(\zeta,h,g)\in\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *representing* f, *in the sense that* $f=\delta\zeta+h+g'$, *and let* $(x,z)=(x(\varphi,\zeta,h,g),z(\varphi,\zeta,h,g))$ *be the solution of* (2.5) *with* f *replaced by* h, *and with initial condition* (2.6). *Define* $T(t)(\varphi,f)=(x_t,f_t)$, $t\geqq 0$, *where* $f_t=\delta z(t)+h_t+(g_t)'$. *Then* $T(t)$ *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

3. The adjoints of the rough initial function semigroups. We next want to compute the adjoints of the initial function semigroups found above. We begin with the adjoints of the "rough" semigroups in Theorems 2.2–2.4 (the adjoint of the semigroup in Theorem 2.1 will be discussed in §4).

In all the different cases considered above, the state space of the initial function type semigroups are reflexive. Therefore, the adjoint semigroups can simply be computed as the adjoints of the original semigroups (it is not necessary to restrict the dual space to the closure of the domain of the adjoint of the generator).

Let us first compute the adjoint of the semigroup in Theorem 2.2. The dual space of the state space can in this case be identified with $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times\mathbf{R}^n \times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$ through the duality mapping

$$\big\langle (f^*,g^*,\zeta^*,\varphi^*),(\varphi,\zeta,f,g)\big\rangle = \varphi^**\varphi(0)+\zeta^*\zeta+f^**f(0)+g^**g(0).$$

Here q is the conjugate index to p, and $\tilde{\eta}$ is the adjoint influence function to η, i.e. $\tilde{\eta}(t)=[\eta(-t)]^{-1}$, $t\in\mathbf{R}$. If we denote $T^*(f^*,g^*,\zeta^*,\varphi^*)(t)$ by $(\tilde{f},\tilde{g},\tilde{\zeta},\tilde{\varphi})$, then a straightforward computation, very similar to the corresponding one in [33], leads to the following equations for $\tilde{f},\tilde{g},\tilde{\zeta}$, and $\tilde{\varphi}$ (in particular, the adjoints of the operators M and N are computed in the same way as the adjoint of the operator G in [33]):

$$\begin{aligned}
\tilde{f} &= \tau_t\big[f^*+\zeta^*(r+\mu*r)+\varphi^**r\big],\\
\tilde{g} &= \tau_t\big[g^*-\zeta^*(\nu*r)+\varphi^**r'\big],\\
\tilde{\zeta} &= \zeta^*(r+\mu*r)(t)+\varphi^**r(t),\\
\tilde{\varphi} &= \tau_t\big[\varphi^*+N^*\big(\zeta^*(r+\mu*r)+\varphi^**r\big)\\
&\qquad +M^*\big(-\zeta^*(\nu*r)+\varphi^**r'\big)\big],
\end{aligned}$$

where M^* and N^* are defined analogously to M and N, namely

$$M^*g^*(s) = -\int_{(t,\infty)} g^*(t-s)\,d\mu(s), \qquad t\geqq 0,$$

$$N^*f^*(t) = -\int_{(t,\infty)} f^*(t-s)\,d\nu(s), \qquad t\geqq 0.$$

These equations can be interpreted in the following way. Define (x^*,z^*) by

$$\begin{aligned}
x^* &= f^*+\zeta^*(r+\mu*r)+\varphi^**r,\\
z^* &= g^*-\zeta^*(\nu*r)+\varphi^*+r'.
\end{aligned} \tag{3.1}$$

Then $x^*\in L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\cap W^{1,q}(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$, $z^*\in L^q(\mathbf{R},\mathbf{R}^n,\tilde{\eta})$, and $(x^*)'(t)=-\zeta^*(\nu*r)(t)+\varphi^**r'(t)=z^*(t)$ for almost all $t\geqq 0$. This means that (x^*,z^*) is the solution of the equations

$$\begin{aligned}
&(x^*)'(t)+\int_{(0,t]}(x^*)'(t-s)\,d\mu(s)+\int_{[0,t]}x^*(t-s)\,d\nu(s)=\varphi^*(t), && t\geqq 0,\\
&z^*(t)=(x^*)'(t), && t\geqq 0,
\end{aligned} \tag{3.2}$$

with initial conditions

$$x^*(t)=f^*(t),\quad z^*(t)=g^*(t),\quad t<0, \qquad x^*(0)=\zeta^*. \tag{3.3}$$

Moreover, $\tilde{f}=x_t^*$, $\tilde{g}=z_t^*$, $\tilde{\zeta}=x^*(t)$, and $\tilde{\varphi}=\varphi_t^*+N^*(x_t^*-f_t^*)+M^*(z_t^*+g_t^*)$. In other words, the adjoint semigroup can be described as follows.

THEOREM 3.1. *The state space of the adjoint semigroup T^* of the semigroup T in Theorem* 2.2 *is $L^q(\mathbf{R}^-,\mathbf{R}^n,\tilde{\eta})\times L^q(\mathbf{R}^-,\mathbf{R}^n,\tilde{\eta})\times\mathbf{R}^n\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$, and T^* is given by*

$$\begin{aligned}
&T^*(f^*,g^*,\zeta^*,\varphi^*)(t)\\
&\quad=\big(x_t^*,z_t^*,x^*(t),\varphi_t^*+N^*\big(x_t^*-f_t^*\big)+M^*\big(z_t^*-g_t^*\big)\big),
\end{aligned}$$

where $(x^*,z^*)=\big(x^*(f^*,g^*,\zeta^*,\varphi^*),z^*(f^*,g^*,\zeta^*,\varphi^*)\big)$ *is the solution of* (3.2) *with initial condition* (3.3), *and*

$$
\begin{aligned}
M^*\big(z_t^*-g_t^*\big)(s)&=-\int_{(s,s+t]}(x^*)'(t+s-v)\,d\mu(v), \qquad s\geqq 0,\\
N^*\big(x_t^*+f_t^*\big)(s)&=-\int_{(s,s+t]}x^*(t+s-v)\,d\nu(v), \qquad s\geqq 0.
\end{aligned}
\tag{3.4}
$$

The adjoint of the semigroup in Theorem 2.3 is obtained from the semigroup above, by simply deleting the g^*-component (it is possible to delete the g^*-component, because all the other components are independent of g^*; in particular, by (3.4), $M^*(z_t^*-g_t^*)$ depends only on $(x^*)'$, and not on g^*).

THEOREM 3.2. *The state space of the adjoint semigroup of the semigroup in Theorem* 2.3 *is* $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times\mathbf{R}^n\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$, *and it is obtained from the semigroup in Theorem* 3.1 *through a deletion of the* g^**-component.*

Before applying Theorem 3.1 to get the adjoint of the semigroup in Theorem 2.4, let us give a precise definition of $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$. As we already mentioned above, we define this space to be the dual space of $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$. More specifically, we imbed $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)$ into $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n$, identifying $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)$ with the subspace

$$\big\{\big(\varphi,\varphi',\varphi(0)\big)\big|\varphi\in W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\big\}$$

of $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n$. In the same way as imbed $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$ into $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times\mathbf{R}^n$. Every continuous linear functional on $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times\mathbf{R}^n$ can be represented by a triple $(z,f,g)\in\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ through the formula

$$\big\langle(z,f,g),(\varphi,\psi,\xi)\big\rangle=z\xi+f*\varphi(0)+g*\psi(0).$$

In particular, every continuous linear functional φ^* on $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$ can also be represented by a triple $(z,f,g)\in\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ through the formula

$$\big\langle\varphi^*,\varphi\big\rangle=z\varphi(0)+f*\varphi(0)+g*\varphi'(0). \tag{3.5}$$

Two functionals φ_1^* and φ_2^* induced by z_1,f_1,g_1 and z_2,f_2,g_2, respectively, are identical if and only if $z_2=z_1-h(0)$, $f_2=f_1-h'$ and $g_2=g_1+h$ for some function $h\in W^{1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$. In other words, the dual space of $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$ can be regarded as the quotient space of $\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ over its subspace

$$\big\{\big(-h(0),-h',h\big)\big|h\in W^{1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)\big\}.$$

(Of course, this subspace can also be identified with $W^{1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, but we shall not use that identification here; instead we interpret it to be the orthogonal complement to $W^{1,q}(\mathbf{R}^-,\mathbf{R}^n;\tilde{\eta})$ in $\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.) As we mentioned above, we shall denote this quotient space by $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

(The preceding notation is not completely standard. Frequently the notation $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ is used for the dual space of $W_0^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$, where $W_0^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})=\{\varphi\in W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\,|\,\varphi(0)=0\}$. One can get the latter space from the former by taking the quotient of $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ over the subspace of functionals in $W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ which are of the form (3.5) with $f\equiv g\equiv 0$.)

There is a simple distribution interpretation of (3.5) which we already used in the formulation of Theorem 2.4. Define $f(t)=g(t)=0$, $t<0$, and extend φ to a function in $W^{1,p}(\mathbf{R};\mathbf{R}^n;\eta)$ in an arbitrary way. Then $\langle\varphi^*,\varphi\rangle=(\delta z+f+g')*\varphi(0)$, where δ is the unit point mass at zero. This means that in the distribution sense, $\varphi^*=\delta z+f+g'$.

Let us go back to the adjoint of the semigroup in Theorem 2.4. To get this adjoint we have to restrict the semigroup in Theorem 3.1 to the dual space of $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, which is $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$. The latter space we have identified with the product of the subspace

$$\{(f^*,(f^*)',f^*(0))|f^*\in W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\}$$

of $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times\mathbf{R}^n$ and $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$. If we drop the g^*- and ζ^*-components of the semigroup in Theorem 3.1, replacing g^* by $(f^*)'$ and ζ^* by $f^*(0)$, then (3.2) and (3.3) become

$$(3.6)\quad (x^*)'(t)+\int_{(0,t]}(x^*)'(t-s)\,d\mu(s)+\int_{[0,t]}x^*(t-s)\,d\nu(s)=\varphi^*(t),\qquad t\geqq 0,$$

$$(3.7)\quad x^*(t)=f^*(t),\qquad t\leqq 0,$$

and we get the following semigroup in $W^{1,q}(\mathbf{R}^-,\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})$.

THEOREM 3.3. *The state space of the adjoint semigroup T^* of the semigroup T in Theorem* 2.4 *is $W^{1,q}(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$, and T^* is given by*

$$T^*(f^*,\varphi^*)(t)=\left(x_t^*,\varphi_t^*+N^*\left(x_t^*-f_t^*\right)+M^*\left(\left(x_t^*\right)'-\left(f_t^*\right)'\right)\right),$$

where $x^*=x^*(f^*,\varphi^*)$ is the solution of (3.6) *with initial condition* (3.7), *and the terms containing M^* and N^* are defined as in* (3.4).

We can rewrite (3.1)–(3.4) and (3.6), using the same type of notation as was used in §2, to get the following set of equations:

$$(3.8)\qquad \begin{aligned} x&=\varphi+(r+r*\mu)\xi+r*f,\\ y&=\psi-(r*\nu)\xi+r'*f,\end{aligned}$$

$$(3.9)\qquad \begin{aligned} &x'(t)+\int_{(0,t]}[d\mu(s)]x'(t-s)+\int_{[0,t]}[d\nu(s)]x(t-s)=f(t),\qquad t\geqq 0,\\ &y(t)=x'(t),\qquad t\geqq 0,\end{aligned}$$

$$(3.10)\qquad x(t)=\varphi(t),\ y(t)=\psi(t),\quad t<0,\qquad x(0)=\xi,$$

$$(3.11)\qquad \begin{aligned} M(y_t-\psi_t)&=-\int_{(s,s+t]}[d\mu(v)]x'(t+s-v),\qquad s\geqq 0,\\ N(x_t-\varphi_t)&=-\int_{(s,s+t]}[d\nu(v)]x(t+s-v),\qquad s\geqq 0,\end{aligned}$$

$$(3.12)\quad x'(t)+\int_{(0,t]}[d\mu(s)]x'(t-s)+\int_{[0,t]}[d\nu(x)](t-s)=f(t),\qquad t\geqq 0.$$

With the new notation the semigroup which we found in Theorems 3.1–3.3 can be described as follows.

THEOREM 3.4. *For each* $(\varphi,\psi,\xi,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $(x,y)=(x(\varphi,\psi,\xi,f),y(\varphi,\psi,\xi,f))$ *be the solution of* (3.9) *with initial condition* (3.10), *and define*

$$S(t)(\varphi,\psi,\xi,f)=(x_t,y_t,x(t),f_t+N(x_t-\varphi_t)+M(y_t+\psi_t)),$$

where $M(y_t-\psi_t)$ *and* $N(x_t-\varphi_t)$ *are defined as in* (3.11). *Then* S *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

THEOREM 3.5. *For each* $(\varphi,\xi,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *define* $S(t)(\varphi,\xi,f)$ *as above, ignoring the* ψ*-component. Then* S *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

THEOREM 3.6. *For each* $(\varphi,f)\in W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $x=x(\varphi,f)$ *be the solution of* (3.12) *with initial condition* (1.2), *and define*

$$S(t)(\varphi,f)=(x_t,f_t+N(x_t-\varphi_t)+M((x_t)'-(f_t)')),$$

where $M((x_t)'-(f_t)')$ *and* $N(x_t-\varphi_t)$ *are defined as in* (3.11). *Then* S *is a strongly continuous semigroup in* $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

4. The adjoint of the smooth initial function semigroup. We have still not computed the adjoint of the "smooth" initial function semigroup in Theorem 2.1. The dual space to the state space $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ is $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde\eta)\times W^{-1,q}(\mathbf{R}^+;\mathbf{R}^n;\tilde\eta)$, so we again have to work in a Sobolev space with negative index. Thinking of $W^{-1,q}(\mathbf{R}^+;\mathbf{R}^n;\tilde\eta)$ as a quotient of $\mathbf{R}^n\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde\eta)\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde\eta)$, whose dual space is $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;R^n;\eta)\times\mathbf{R}^n$, and looking at the semigroup presented in Theorem 3.6, one soon discovers that the initial function semigroup in Theorem 2.1 can be imbedded in a larger initial function semigroup, which acts on $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$. Basically, to get this semigroup one prescribes two initial functions in (1.1), i.e. one uses the initial function φ in the term $\nu * x$, but replaces φ' by a new initial function ψ in the term $\mu * x'$. The precise formulation resembles the formulation (3.9)–(3.10). We require (x,y) to satisfy

$$\begin{aligned} &y(t)+\mu * y(t)+\nu * x(t)=f(t), \qquad t\geqq 0,\\ &x'(t)=y(t), \qquad t\geqq 0, \end{aligned} \tag{4.1}$$

and use the initial condition (3.10). Here $(\varphi,\psi,\xi,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$. Using the fundamental solution r in (2.1), one finds that this set of equations has the unique solution

$$\begin{aligned} x&=\varphi+(r+r*\mu)\xi+r*(f+N(\varphi)+M(\psi)),\\ y&=\psi-(r*\nu)\xi+r'*(f+N(\varphi)+M(\psi)) \end{aligned} \tag{4.2}$$

(cf. (2.3) and (3.8)). Translating all functions to the left we get the following semigroup.

THEOREM 4.1. *For each* $(\varphi,\psi,\xi,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $(x,y)=(x(\varphi,\psi,\xi,f),y(\varphi,\psi,\xi,f))$ *be the solution of* (4.1) *with initial condition* (3.10). *Then* T *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

By taking $x\in W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)$, $y=x'$, $\xi=x(0)$, we get the semigroup in Theorem 2.1.

Now, just as in the preceding section, it is a straightforward task to compute the adjoint of the operator $T(t)$ in Theorem 4.1. If we denote $T^*(f^*,\xi^*,\varphi^*,\psi^*)(t)$ by $(\tilde{f},\tilde{\xi},\tilde{\varphi},\tilde{\psi})$, then one gets the following equations:

$$\begin{aligned}
\tilde{f}&=\tau_t[f^*+\xi^*r+\varphi^**r+\psi^**r')],\\
\tilde{\xi}&=\xi^*(r+r*\mu)+\varphi^**r+\varphi^**r*\mu-\psi^**r*\nu,\\
\tilde{\varphi}&=\tau_t[\varphi^*+N^*(\xi^*r+\varphi^**r+\psi^**r')],\\
\tilde{\psi}&=\tau_t[\psi^*+M^*(\xi^*r+\varphi^**r+\psi^**r')].
\end{aligned}$$

One can interpret these equations in the following way. Define

$$\begin{aligned}
x^*&=f^*+\xi^*r+\varphi^**r+\psi^**r',\\
y^*&=\xi^*(r+r*\mu)+\varphi^**(r+r*\mu)-\psi^**r*\nu.
\end{aligned}\tag{4.3}$$

Then $x^*\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)$, $y^*\in W^{1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, and (x^*,y^*) is the solution of the equation

$$\begin{aligned}
&(y^*)'(t)+\int_{[0,t]}x^*(t-s)\,d\nu(s)=\varphi^*(t),\qquad t\geqq 0,\\
&x^*(t)+\int_{(0,t]}x^*(t-s)\,d\mu(s)-y^*(t)=\psi^*(t),\qquad t\geqq 0,
\end{aligned}\tag{4.4}$$

with initial condition

$$x^*(t)=f^*,\quad t<0,\qquad y^*(0)=\xi^*.\tag{4.5}$$

Moreover, $\tilde{f}=x_t^*$, $\tilde{\xi}=y^*(t)$, $\tilde{\varphi}=\varphi_t^*-N^*(x_t^*-f_t^*)$, and $\tilde{\psi}=\psi_t^*+M^*(x_t^*-f_t^*)$. In other words, the adjoint of the semigroup in Theorem 4.1 can be described as follows.

THEOREM 4.2. *The state space of the adjoint semigroup T^* of the semigroup T in Theorem* 4.1 *is $L^q(\mathbf{R}^-;\mathbf{R}^n;\bar{\eta})\times\mathbf{R}^n\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})\times L^q(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$, and T^* is given by*

$$T^*(f^*,\xi^*,\varphi^*,\psi^*)=\big(x_t^*,y^*(t),\varphi_t^*+N^*(x^*{}_t-f^*{}_t),\psi^*{}_t+M^*\big(x_t^*-f_t^*\big)\big),$$

where $(x^*,y^*)=(x^*(f^*,\xi^*,\varphi^*,\psi^*),y^*(f^*,\xi^*,\varphi^*,\psi^*))$ is the solution of (4.4) *with initial condition* (4.5), *and the terms involving M^* and N^* are defined as in* (3.4) *(with $(x^*)'$ replaced by x^*).*

The definition of f^* in (4.3) can be interpreted in the distribution sense to mean

$$x^*=f^*+\varphi^**r,\tag{4.6}$$

where φ^* stands for the distribution $\xi^*\delta+\varphi^*+(\psi^*)'$ in (4.3). This distribution is uniquely determined as an element of the dual space $W^{-1,q}(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$ of $W^{1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$. In the same way we can interpret the definition of $T^*(t)$ in the distribution sense, and we find that the adjoint of the semigroup in Theorem 2.1 can be described as follows.

THEOREM 4.3. *The state space of the adjoint semigroup T^* of the semigroup T in Theorem* 2.1 *is $L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times W^{-1,q}(\mathbf{R}^+,\mathbf{R}^n;\tilde{\eta})$, and it is defined as follows. For each $(f^*,\varphi^*)\in L^q(\mathbf{R}^-;\mathbf{R}^n;\tilde{\eta})\times W^{-1,q}(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$, choose an arbitrary triple (ξ^*,γ^*,ψ^*) representing φ^* in the sense that $\varphi^*=\xi^*\delta+\gamma^*+(\psi^*)'$, let $(x^*,y^*)=(x^*(f^*,\xi^*,\gamma^*,\psi^*),y^*(f^*,\xi^*,\gamma^*,\psi^*))$ be the solution of* (4.4) *with φ^* replaced by γ^*, and with initial condition* (4.5). *Define $T^*(f^*,\varphi^*)=(x_t^*,\varphi_t^*)$, where $\varphi_t^*\in W^{-1,q}(\mathbf{R}^+;\mathbf{R}^n;\tilde{\eta})$ is the distribution $y^*(t)\delta+\gamma_t^*+N^*(x_t^*-f_t^*)+[\psi_t^*+M^*(x_t^*-f_t^*)]'$.*

Just like in §3, let us again change the notation and describe the last two semigroups in terms of equations directly related to (1.1). Equations (4.3), (4.4) and (4.6) become

$$\begin{aligned} x &= \varphi + r\zeta + r * f + r' * g, \\ z &= (r + \mu * r)\zeta + (r + \mu * r) * f - \nu * r * g, \end{aligned} \tag{4.7}$$

$$\begin{aligned} &z'(t) + \int_{[0,t]} [d\nu(s)]\, x(t-s) = f(t), \qquad t \geqq 0, \\ &x(t) + \int_{(0,t]} [d\mu(s)]\, x(t-s) - z(t) = g(t), \qquad t \geqq 0, \end{aligned} \tag{4.8}$$

$$x = \varphi + r * f, \tag{4.9}$$

and (4.5) becomes (2.6). Observe that apart from the initial function corrections to the forcing functions, formulas (4.7) and (4.9) agree with formulas (2.7) and (2.8).

With the new notation, the semigroups in Theorems 4.2 and 4.3 can be described as follows.

THEOREM 4.4. *For each* $(\varphi,\zeta,f,g) \in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta) \times \mathbf{R}^n \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta) \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *let* $(x,z) = (x(\varphi,\zeta,f,g),\ z(\varphi,\zeta,f,g))$ *be the solution of* (4.8) *with initial condition* (2.6), *and define* $S(t)(\varphi,\zeta,f,g) = (x_t, z(t), f_t + N(x_t - \varphi_t),\ g_t + M(x_t - \varphi_t))$, $t \geqq 0$. *Then* S *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta) \times \mathbf{R}^n \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta) \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

THEOREM 4.5. *For each* $(\varphi,f) \in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta) \times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *choose an arbitrary triple* $(\zeta,h,g) \in \mathbf{R}^n \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta) \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *representing* f *in the sense that* $f = \delta\zeta + h + g'$, *and let* $(x,z) = (x(\varphi,\zeta,h,g), z(\varphi,\zeta,h,g))$ *be the solution of* (4.8) *with* f *replaced by* h, *and with initial condition* (2.6). *Define* $S(t)(\varphi,f) = (x_t, f_t)$, $t \geqq 0$, *where* $f_t = \delta z(t) + h_t + N(x_t - \varphi_t) + [g_t + M(x_t - \varphi_t)]'$. *Then* S *is a strongly continuous semigroup in* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta) \times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$.

5. Initial and forcing function semigroups are equivalent. By now we have described a total of ten semigroups generated by (1.1) (plus five more adjoint semigroups). Five of them are of initial function type (the initial function does affect the values of the solution on $\mathbf{R}^+$), and five of them of forcing function type (the initial function does not affect the values of the solution on $\mathbf{R}^+$). Fortunately, one need not study all of them separately, because some of them are similar to each other. In particular, four of the initial function type semigroups are similar to four forcing function type semigroups. In the retarded case also the fifth pair of semigroups is similar. In all cases the similarity transformation is essentially the same, i.e. the operator which adds an initial function correction to the forcing function, as required by (1.1) in its different versions.

THEOREM 5.1. *For each* $(\varphi,f) \in W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta) \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *define* $D(\varphi,f) = (\varphi, f + N(\varphi) + M(\varphi'))$, *and let* T *and* S *be the semigroups in Theorems* 2.1 *and* 3.6. *Then* D *maps* $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta) \times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *one-to-one and continuously onto itself, its inverse is the operator which maps* (φ,f) *into* $(\varphi, f - N(\varphi) - M(\varphi'))$, *and* $S(t) = DT(t)D^{-1}$, $T(t) = D^{-1}S(t)D$ *for all* $t \geqq 0$.

THEOREM 5.2. *For each* $(\varphi,f) \in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta) \times W^{-1,p}(\mathbf{R}^+,\mathbf{R}^n;\eta)$, *define* $D(\varphi,f) + N(\varphi) + [M(\varphi)]')$ *and let* T *and* S *be the semigroups in Theorems* 2.4 *and* 4.5. *Then* D *maps* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta) \times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *one-to-one and continuously onto itself, its inverse is the operator which maps* (φ,f) *into* $(\varphi, f - N(\varphi) - [M(\varphi)]')$, *and* $S(t) = DT(t)D^{-1}$, $T(t) = D^{-1}S(t)D$ *for all* $t \geqq 0$.

THEOREM 5.3. *For each* $(\varphi,\zeta,f,g)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *define* $D(\varphi,\zeta,f,g)=(\varphi,\zeta,f+N(\varphi),g+M(\varphi))$, *and let* T *and* S *be the semigroups in Theorems* 2.2 *and* 4.4. *Then* D *maps* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *one-to-one and continuously onto itself, its inverse is the operator which maps* (φ,ζ,f,g) *into* $(\varphi,\zeta,f-N(\varphi),g-M(\varphi))$, *and* $S(t)=DT(t)D^{-1}$, $T(t)=D^{-1}S(t)D$ *for all* $t\geqq 0$.

THEOREM 5.4. *For each* $(\varphi,\psi,\xi,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *define* $D(\varphi,\psi,\xi,f)=(\varphi,\psi,\xi,f+N(\varphi)+M(\psi))$, *and let* T *and* S *be the semigroups in Theorems* 4.1 *and* 3.4. *Then* D *maps* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *one-to-one and continuously onto itself, its inverse is the operator which maps* (φ,ψ,ξ,f) *into* $(\varphi,\psi,\xi,f-N(\varphi)+M(\psi))$, *and* $S(t)=DT(t)D^{-1}$, $T(t)=D^{-1}S(t)D$ *for all* $t\geqq 0$.

THEOREM 5.5. *Suppose that the equation* (1.1) *is retarded, i.e. that* $\mu\equiv 0$. *For each* $(\varphi,\zeta,f)\in L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$, *define* $D(\varphi,\zeta,f)=(\varphi,\zeta,f+N(\varphi))$, *and let* T *and* S *be the semigroups in Theorems* 2.3 *and* 3.5. *Then* D *maps* $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times\mathbf{R}^n\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ *one-to-one and continuously onto itself, its inverse is the operator which maps* (φ,ζ,f) *into* $(\varphi,\zeta,f-N(\varphi))$, *and* $S(t)=DT(t)D^{-1}$, $T(t)=D^{-1}S(t)D$ *for all* $t\geqq 0$.

All these theorems are direct consequences of the previous constructions.

There is also another connection between some of the semigroups presented above, which should be pointed out. One can get the two semigroups in $W^{1,p}(\mathbf{R}^-;\mathbf{R}^n;\eta)\times L^p(\mathbf{R}^+;\mathbf{R}^n;\eta)$ (those in Theorem 5.1) by restricting the semigroups in $L^p(\mathbf{R}^-;\mathbf{R}^n;\eta)\times W^{-1,p}(\mathbf{R}^+;\mathbf{R}^n;\eta)$ (those in Theorem 5.2) to the domains of their generators. In [27] this relationship plays a key role.

STABILITY IN A REACTION-DIFFUSION MODEL OF MUTUALISM*

V. HUTSON†

Abstract. A reaction-diffusion model for the mutualistic interaction of two species is studied. A condition for the dominance of an equilibrium point in the bistable case is obtained, generalizing results for the well-known scalar case. It is also shown that the "hair trigger effect" operates when the corresponding kinetic system has a single globally asymptotically stable interior equilibrium point.

1. Introduction. Consider the pair of reaction-diffusion equations

$$u_{it}=u_i m_i(u)+\mu_i u_{ixx} \qquad (i=1,2) \tag{1.1}$$

with $u=(u_1,u_2)$, where the spatial region Ω is either $\mathbb{R}$, or a bounded open interval, a homogeneous Neumann condition being imposed on $\partial\Omega$. This system has been much studied recently, one of the most interesting applications being to biological problems with u interpreted as, say, population density. However, the mutualist case, that is when $\partial m_1/\partial u_2$, $\partial m_2/\partial u_1<0$, has been relatively neglected in the literature, and it is this case that is treated here, attention being concentrated on two of the most basic points of interest.

The first question concerns the dominance of an equilibrium point in the bistable case. To illustrate, take $\Omega=\mathbb{R}$. Recall that the scalar equation

$$u_t=um(u)+\mu u_{xx} \tag{1.2}$$

is said to be bistable when the corresponding kinetic equation $\dot{u}=um(u)$ has exactly three equilibrium points 0, $\tilde{u}$ and u^* with $0<\tilde{u}<u^*$, the points 0 and u^* being asymptotically stable and $\tilde{u}$ unstable. For (1.2), the dominance of one of the asymptotically stable equilibrium points over the other has been extensively discussed, see for example [1] and [4]. When u^* is dominant, if the initial value $u(x,0)$ is not too small on a sufficiently large (but finite) interval, then $u(x,t)\to u^*$ uniformly on compact sets as $t\to\infty$. For the two species mutualist case the phase plane may have the form shown in Fig. 1a, and by analogy this will be called the two species bistable case. We derive in §3 a condition for this case which will ensure that u^* is dominant.

Secondly, we consider in §4 the case when the kinetic system corresponding to (1.1) has a single globally asymptotically stable interior equilibrium point Q. If the origin is a source, it is shown in [5] that all solutions with initial values neither of whose components are identically zero are attracted to Q (the hair trigger effect). In §4 we extend this result to the case when the origin is a saddle point.

Our results have applications to the resolution of a paradox concerning the distribution of mutualistic systems in nature; for general biological background on mutualism see [2], [8], [9], [10], [11], [13] and [14]. If the kinetic model for mutualism is adopted, it is clear from Fig. 1a that the occurrence of obligate/obligate mutualisms[1] is

[1] The terminology of [2] is used: mutualism is an interaction between species that is beneficial to both; an obligate and a facultative mutualist cannot (respectively can) survive without its partner; on the other hand symbiosis is the living together of two organisms in close association.

relatively unlikely in an unstable environment. For if a natural disaster should sweep the population vector into the hatched region, the extinction of both species will follow. However, such mutualisms are common even in very variable temperate and arctic regions, see [8]. If the species may diffuse, the results of §3 show that the system is a great deal more resilient, for if some, perhaps quite limited region is left relatively unaffected, the species will return to their coexistence levels u^*. That is, the domain of attraction of Q is much larger for the reaction-diffusion system than for the kinetic system.

2. Preliminaries. We consider the problem of finding classical solutions of (1.1) given that the initial value $u(x,0)$ is bounded nonnegative and uniformly continuous on $\bar{\Omega}$, and that a homogeneous Neumann condition holds on $\partial\Omega$ when Ω is finite.

It will be assumed throughout that the following conditions are satisfied.

(C1) $\mu_1,\ \mu_2 > 0$.

(C2) $m_1,\ m_2 \in C^1(\mathbb{R}_2^+, \mathbb{R})$, and for all $u_1,\ u_2 \geqq 0$,

(i) $\partial m_1/\partial u_1,\ \partial m_2/\partial u_2 < 0$;

(ii) $\partial m_1/\partial u_2,\ \partial m_2/\partial u_1 > 0$.

(C3) There exist $\alpha_1,\ \alpha_2 \in \mathbb{R}$ such that

$$m_1(u_1,u_2) < 0 \qquad (u_1 \geqq \alpha_1, u_2 \geqq 0),$$
$$m_2(u_1,u_2) < 0 \qquad (u_1 \geqq 0, u_2 \geqq \alpha_2).$$

(C2)(i) implies that, because of intraspecific competition, the per capita rate of increase of each species decreases as its population increases, while (C2)(ii) is the mutualist assumption that an increase in the population of one species increases the per capita growth rate of the other. (C3) requires further that intraspecific competition causes the population density of each species to decrease if it is large enough no matter how numerous the other species may be; this appears essential if the equations are to reflect biological reality, and corresponds to a "finite world" assumption—for further discussion see [10], [11]. Of course a Lotka–Volterra system cannot satisfy both (C2) and (C3). Finally, for the equilibrium points of (1.1), assume that one of the following holds.

($C4_1$) There are in the interior of $\mathbb{R}_2^+$ exactly two equilibrium points $\tilde{u} = (a_1, a_2)$ and $u^* = (A_1, A_2)$ where $a_1 < A_1$, $a_2 < A_2$ (Fig. 1a).

($C4_2$) There is exactly one equilibrium point $u^* = (A_1, A_2)$ in the interior of $\mathbb{R}_2^+$ (Fig. 1b). When ($C4_1$) holds, apart from the configuration shown in Fig. 1a, there are other possibilities, for example that u_1 is facultative and u_2 is obligate, when the u_1 isocline cuts the positive u_1 axis at $(a,0)$ say, in which case $(0,0)$ will be a saddle point and $(a,0)$ will be asymptotically stable. When ($C4_2$) holds, apart from Fig. 1b, there are again other possibilities; for example u_2 may also be facultative, in which case the u_2 isocline will cut the positive u_2 axis.

For later reference some properties of the solutions of the kinetic equation are now quoted from [7].

PROPOSITION 2.1. *In case* ($C4_1$) *there is a one-dimensional stable manifold S through* $\tilde{u}$. *The point* u^* *is a global attractor for all population vectors whose initial values lie to the right of S, while if the initial values lie to the left of S* (*that is in the hatched region in Fig.* 1a), *at least one population tends to zero as* $t \to \infty$.

In case ($C4_2$), u^* *is globally asymptotically stable* (*with respect to all populations with* $u_1(0),\ u_2(0) > 0$).

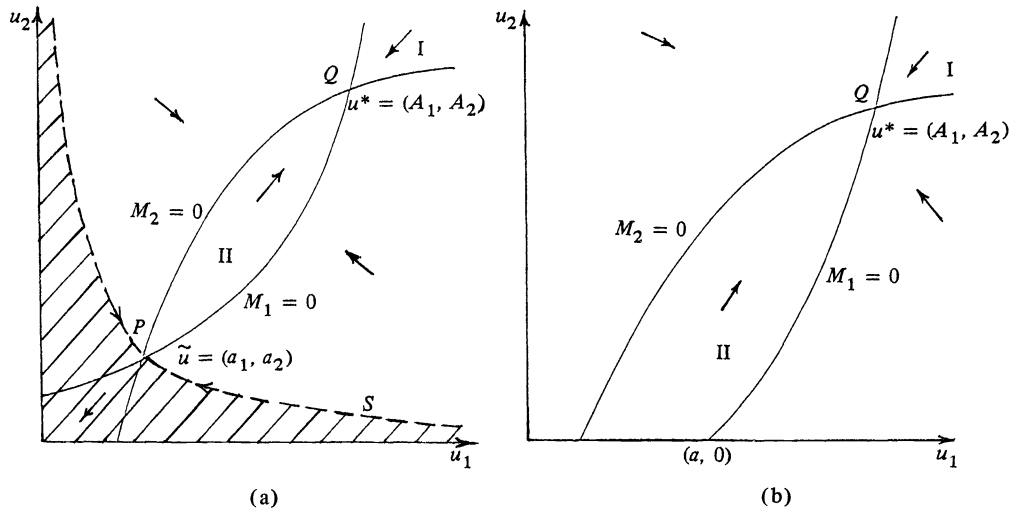

FIG. 1. *Possible configurations for the zero isoclines of cases* $(C4_1)$ *and* $(C4_2)$ *respectively, other possibilities being described in the text. In Fig.* 1a *both species are obligate, while in Fig.* 1b *the first species is obligate and the second facultative.*

Sub and supersolution techniques are particularly effective for mutualistic interactions. The basic mathematical apparatus is given in [5] and [6], and for later reference we outline the salient results specialised to (1.1). To fit the framework of [5], set $M_i(u)=u_i m_i$ and extend M_1 and M_2 to $\mathbb{R}_2$ by setting $M_1(u_1,u_2)=M_1(u_1,0)$, $M_2(u_1,u_2)=0$ for $u_1>0$ and $u_2<0$, $M_1(u_1,u_2)=M_2(u_1,u_2)=0$ for u_1, $u_2\leqq 0$, and $M_1(u_1,u_2)=0$, $M_2(u_1,u_2)=M_2(0,u_2)$ for $u_1<0$ and $u_2>0$. With $u=(u_1,u_2)$, $v=(v_1,v_2)$ the relation $u<v$ (respectively $u\leqq v$) means that $u_i<v_i$ (respectively $u_i\leqq v_i$) for $i=1,2$.

If $\Omega=\mathbb{R}$, a regular subsolution $\underline{u}$ is defined on an open set $X\subset\mathbb{R}\times\mathbb{R}$, and must satisfy

$$\underline{u}_{it}\leqq M_i(\underline{u})+\mu_i\underline{u}_{ixx} \qquad (i=1,2)$$

on X, with all derivatives appearing being continuous. Let $X=\Omega\times(0,\tau)$ for some $\tau>0$. $\underline{u}$ is said to be a subsolution if there is an $\varepsilon>0$ such that for every point $P\in\overline{X}$ there is a finite collection $\{\underline{u}^{(1)},\cdots,\underline{u}^{(\alpha)}\}$ of regular subsolutions in $B(P,\varepsilon)$, the ε-ball centre P, such that in $\overline{X}\cap B(P,\varepsilon)$,

$$\underline{u}(x,t)=\max_{1\leqq k\leqq\alpha}\underline{u}^{(k)}(x,t),$$

the max being taken componentwise. If Ω is bounded, it is required in addition that the outward normal derivative $\partial\underline{u}/\partial\nu\leqq 0$ on $\partial\Omega$. Supersolutions are defined analogously by reversing the inequalities and substituting "min" for "max". Of course every solution is a sub and supersolution.

PROPOSITION 2.2. *Under the stated conditions on* $u(x,0)$ *the following hold.*

(i) *Every solution of* (1.1) *is nonnegative and satisfies* $u(x,t)\leqq M$ *for some* M *and all* $t>0$. *Further, if* α *lies in a region* I (*Fig.* 1), *then* $u(x,t)\leqq\alpha$ *for large enough* t.

(ii) *A unique classical solution exists and is uniformly continuous in* $\overline{X}$.

(iii) *If neither of* $u_1(x,0)$, $u_2(x,0)$ *is identically zero, then* $u(x,t)>0$ *for all* $x\in\Omega$, $t>0$.

Proof. (i) The bound on u follows from [4, Thm. 5.1] when the properties of the kinetic system given by Proposition 2.1 are used. (ii) is a consequence of [4, Thm. 3.1] and [12, Thm. 14.4]. (iii) This follows from the strong maximum principle, see [12].

THEOREM 2.3. *Let $\underline{u}$ and $\bar{u}$ be bounded uniformly continuous sub and supersolutions in $\bar{X}$. If $\underline{u}(x,0) \leqq \bar{u}(x,0)$ then $\underline{u}(x,t) \leqq \bar{u}(x,t)$ in X.*

THEOREM 2.4. *Assume that u, $\bar{u}$ are bounded uniformly continuous stationary sub and supersolutions respectively with $\underline{u} \leqq \bar{u}$. Let u be the solution with $u(x,0) = \underline{u}(x)$. Then there is a stationary solution w with $\underline{u} \leqq w \leqq \bar{u}$ such that as $t \to \infty$, $u(x,t) \to w(x)$ uniformly on compact sets.*

Let $\Omega = \mathbb{R}$, and suppose that there is a neighborhood N of 0 such that $w(x+y) \geqq \underline{u}(x)$ for all $y \in N$. Then w is a constant.

3. Dominance for a two species bistable system. It will be assumed throughout this section that ($C4_1$) holds, a possible configuration of the isoclines being given in Fig. 1a. Theorem 3.1 shows that condition (D_Q) below yields an analogue of dominance for a one species problem.

Define $\mu = (\mu_1 \mu_2)^{1/2}$, and set

$$
\begin{aligned}
M(u) &= \mu \min\left[\mu_1^{-1} M_1(u,u), \mu_2^{-1} M_2(u,u)\right], \\
V(u) &= \int_0^u M(s)\, ds.
\end{aligned} \tag{3.1}
$$

$M(u)$ is negative for small and large $u > 0$, and it follows from the definition that if $\alpha > 0$ is a zero of M, then (α, α) lies in region II, whence a_1, $a_2 \leqq \alpha \leqq A_1$, A_2. Assume that the following holds (Fig. 2).

(D_Q) There exists a number $b > 0$ such that $V(u) < V(b)$ for $0 \leqq u < b$.

Note that a rescaling of u_1, u_2 in (1.1) may be advantageous in arranging for this condition to hold. The idea is roughly that as much as possible of the line $u_1 = u_2$ should lie in region II in Fig. 1a.

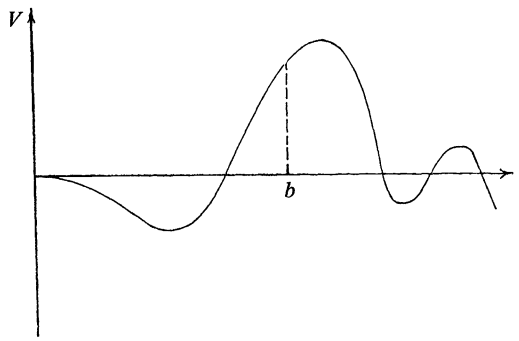

FIG. 2. *V when condition (D_Q) holds.*

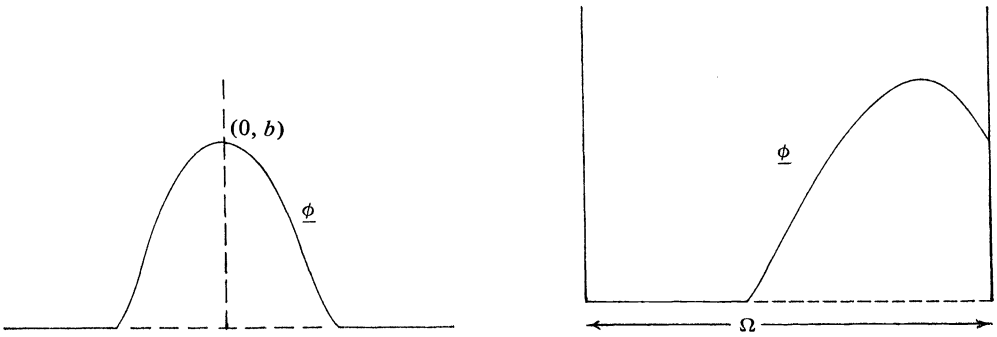
Assume that $0 \in \bar{\Omega}$, and let ϕ be the solution of the equation

$$\mu \phi'' + M(\phi) = 0, \tag{3.2}$$

with $\phi(0) = b$, $\phi'(0) = 0$. From the first integral

$$\mu \left[\phi'(x)\right]^2 = 2\left[V(b) - V(\phi(x))\right], \tag{3.3}$$

it is clear that if $\Omega=\mathbb{R}$, ϕ will eventually reach zero at points symmetrical with respect to 0. Define $\underline{\phi}(x)=\max[0,\phi(x)]$, see Fig. 3a. If Ω is finite, ϕ may first reach the boundary, where from (3.3) $\partial\phi/\partial\nu<0$ (Fig. 3b).



(a) (b)

FIG. 3. *Possibilities for $\underline{\phi}$ when $\Omega=\mathbb{R}$ and Ω is finite respectively.*

With $\underline{\Phi}=(\underline{\phi},\underline{\phi})$, we have the following result for the system (1.1).

THEOREM 3.1. *Suppose that $0\in\bar{\Omega}$, and assume that conditions* (C1)–(C3), ($C4_1$) *and* (D_Q) *hold. Let $u(x,t)$ be the solution of* (1.1) *with $u(x,0)\geqq\underline{\Phi}$ on Ω. Then $u\to u^*$ uniformly on compact sets as $t\to\infty$.*

Proof. Note first that $\underline{\Phi}$ is a subsolution of (1.2). For by (3.1) and (3.2),

$$\mu_i\underline{\phi}_{xx}+M_i(\underline{\phi},\underline{\phi})\geqq\mu_i\underline{\phi}_{xx}+\mu_i\mu^{-1}M(\underline{\phi})=0,$$

and $(0,0)$ is a subsolution. For $\Omega=\mathbb{R}$ the assertion follows as $\underline{\Phi}$ is the local maximum of regular subsolutions, and for Ω bounded also $\partial\underline{\Phi}/\partial\nu\leqq 0$ on $\partial\Omega$.

Choose any point $(\bar{u}_1,\bar{u}_2)$ in region I with $\bar{u}_i\geqq\sup_{x\in\Omega}u_i(x,0)$ for $i=1,2$. Let $\bar{u}$ be the (spatially independent) solution of (1.2) with $\bar{u}(0)=(\bar{u}_1,\bar{u}_2)$. Define $\underline{u}(x,t)$ to be the solution of (1.1) with $\underline{u}(x,0)=\underline{\Phi}$. Then by Theorem 2.3, for all $t>0$,

$$\underline{\Phi}(x)\leqq\underline{u}(x,t)\leqq u(x,t)\leqq\bar{u}(t).$$

Now from Proposition 2.1, $\lim_{t\to\infty}\bar{u}(t)=u^*$. Furthermore, $\underline{\Phi}$ and u^* are respectively stationary sub and supersolutions with $\underline{\Phi}\leqq u^*$. Hence from Theorem 2.4, there is a stationary solution w with $\underline{\Phi}\leqq w\leqq u^*$ such that $\underline{u}(x,t)\to w(x)$ uniformly on compact sets as $t\to\infty$. Therefore the proof will be complete if it can be shown that $w=u^*$.

Suppose first that $\Omega=\mathbb{R}$. Then $w(x)>\underline{\Phi}(x)$ for $x\in\Omega$. For if not there is an x_0 and an $i=1$ or 2 such that $w_i(x_0)=\underline{\phi}(x_0)$. But $\underline{\Phi}$ is a subsolution, $w(x)$ is a regular supersolution and $\underline{\Phi}\leqq w$. Hence from [5, Thm. 1], $w_i(x)=\underline{\phi}(x)$ for all x. This is impossible as $\underline{\phi}(x)$ has a discontinuous first derivative.

Now $\underline{\phi}$ has compact support. Hence if Ω_0 is any compact set containing the support of $\underline{\phi}$ in its interior, there exists $\delta=(\delta_1,\delta_2)>0$ such that $w(x)\geqq\underline{\Phi}(x)+\delta$ for $x\in\Omega_0$. It follows from uniform continuity that there is a neighborhood N of zero such that $w(x+y)>\underline{\Phi}(x)$ for all $y\in N$ and $x\in\mathbb{R}$. Therefore by Theorem 2.4, w is a constant.

Finally, if $\alpha>0$ is any zero of M, the point (α,α) lies in region II (Fig. 1a). But from the construction of $\underline{\phi}$, $\underline{\phi}(0)$ and so w_1 is greater than the smallest positive zero of

M. Therefore $w \neq \tilde{u}$, and so $w = u^*$. This completes the proof for $\Omega = \mathbb{R}$. It follows immediately that the only stationary solution w of (1.1) satisfying $\underline{\Phi} \leqq w \leqq u^*$ is u^* itself, a fact which will be used below.

When Ω is bounded, the result will be proved by first constructing an extension of w to $\mathbb{R}$. Consider then the stationary solution w of (1.1) on $\bar{\Omega}$ satisfying $\partial w/\partial \nu = 0$ on $\partial\Omega$. Let $\Omega = (\xi, \xi + \gamma)$ where $\xi \leqq 0 \leqq \xi + \gamma$. Define an extension of w to $\mathbb{R}$ by successively reflecting w in the lines $x = \xi$, $\xi - \gamma, \cdots$, and $x = \xi + \gamma$, $\xi + 2\gamma, \cdots$, and note that w then has period 2γ. Because $\partial w/\partial x = 0$ on $x = \xi$ and $x = \xi + \gamma$, w is a C^2-function which is a solution of (1.1) for all x. It is also clear from the evenness of $\underline{\phi}$ and the fact that it is decreasing for $x > 0$ that $w \geqq \underline{\Phi}$. This shows that w extended in this manner is a solution of (1.1) on $\mathbb{R}$ satisfying $\underline{\Phi} \leqq w \leqq u^*$, so by the final remark of the preceding paragraph, $w = u^*$. This completes the proof.

A similar mutualist system has been considered in [3] although from a different point of view. There Ω must be bounded, and a condition is imposed which requires among other things that μ_1 and μ_2 are sufficiently large relative to the length of Ω. Then u tends to a spatially independent solution for large t, so that the asymptotic behavior of u may be deduced from that of the solution of the analogous kinetic system. Under certain further restrictions it will be the case that if the space average of $u(x, 0)$ lies to the right of S, the solution will eventually return towards Q. The conditions in [3] and Theorem 3.1 are of course of quite a different nature, but from the point of view of biological applications the principal point of interest in Theorem 3.1 is that it shows that the restriction on the space average of $u(x, 0)$ and on μ_1, μ_2 can be removed if D_Q is imposed.

4. Global asymptotic stability. If there is exactly one interior equilibrium point for the kinetic equations, this point is globally asymptotically stable, and the aim now is to show that an analogous property also holds when there is diffusion. This extends a result in [5, §4] to the case where there is a saddle point at the origin.

THEOREM 4.1. *Assume that conditions* (C1)–(C3) *and* ($C4_2$) *hold. Let* $u(x, t)$ *be the solution of* (1.1) *with* $u(x, 0) \geqq 0$ *on* Ω, *and suppose that neither* $u_1(x, 0)$ *nor* $u_2(x, 0)$ *is identically zero. Then as* $t \to \infty$, $u \to u^*$ *uniformly on compact sets.*

Proof. By Proposition 2.2, $u(x, t) > 0$ for $t > 0$. Therefore, by shifting to a new time origin we may assume that $u(x, t) > 0$ in $\bar{\Omega}$ for $t \geqq 0$.

(i) Ω bounded. The proof is very simple. Let $\underline{u}(t)$ and $\bar{u}(t)$ be solutions of (2.1) with

$$\underline{u}_i(0) = \min_{x \in \bar{\Omega}} u_i(x, 0), \qquad \bar{u}_i(0) = \max_{x \in \bar{\Omega}} u_i(x, 0)$$

for $i = 1, 2$; by the remark above $\underline{u}(0) > 0$. Now $\underline{u}$, $\bar{u}$ are sub and supersolutions respectively, so by Theorem 2.3, $\underline{u}(t) \leqq u(x, t) \leqq \bar{u}(t)$ for $t > 0$. The result follows, for by Proposition 2.1, $\lim_{t \to \infty} \underline{u}(t) = \lim_{t \to \infty} \bar{u}(t) = u^*$.

(ii) $\Omega = \mathbb{R}$. A more elaborate proof is needed since it is not necessarily true that $\underline{u}(0) > 0$. If both species are facultative, then the origin lies in region II and is a source for the kinetic problem, so the argument of [5, §4] yields the result. However, if one species is obligate and one facultative, as is the case in Fig. 1, this argument does not work.

So far as the upper bound of u is concerned, of course it follows as in (i) above $u(x, t) \leqq \bar{u}(t)$, where $\lim_{t \to \infty} \bar{u}(t) = u^*$. We shall show that there is a function $z(x, t)$ which approaches u^* uniformly on compact sets as $t \to \infty$ such that $u(x, t) \geqq z(x, t)$ for large enough t, from which the assertion of the theorem follows.

From the assumption on $M_1(v_1,0)=v_1m_1(v_1,0)$ there exists an a_0 with $0<a_0<a$ and a $\gamma>0$ such that $M_1(v_1,0)\geqq\gamma^2\mu_1v_1$ for $0\leqq v_1\leqq a_0$. Since $u_1(x,0)>0$ for $x\in\Omega$, there is a δ with $0<\delta<a_0$ such that

$$\delta<\min_{-l_1\leqq x\leqq l_1}u_1(x,0),$$

where $l_1=\pi/2\gamma$. Set

$$v_1(x)=\begin{cases}\delta\cos\gamma x & (|x|\leqq\pi/2\gamma),\\ 0 & (|x|>\pi/2\gamma),\end{cases}$$

and let $v_1(x,t)$ be the solution of the one-dimensional problem

$$v_{1t}=M_1(v_1,0)+\mu_1v_{1xx}, \tag{4.1}$$

with $v_1(x,0)=v_1(x)$. Put $v(x,t)=(v_1(x,t),0)$ and note that v is a solution of (1.2).

LEMMA 4.2. *$v_1(x)$ is a stationary subsolution of* (4.1), *and the following hold.*

(i) $v_1(x)\leqq v_1(x,t)\leqq a$ $(t\geqq0)$.

(ii) $\partial v_1(x,t)/\partial t\geqq0$ *for* $x\in\Omega$ *and* $t>0$.

(iii) $v_1(x,t)\to$ *a uniformly on compact sets as* $t\to\infty$.

(iv) $u(x,t)\geqq v(x,t)$ *for* $t\geqq0$.

Proof. We have

$$M_1(v_1,0)+\mu_1v_{1xx}\geqq\gamma^2\mu_1v_1+\mu_1v_{1xx}=0,$$

and 0 is a solution. Hence v_1 is the local maximum of regular subsolutions, and is therefore a subsolution of (4.1). Also $a>v_1(x)$ is a supersolution, so (i), (ii) and (iii) follow from Theorems 4.1, 4.2, 4.8 respectively of [4]. Finally, $v(x,t)$ is a solution of (1.1), and since $u(x,0)\geqq v(x,0)$, Theorem 2.3 yields (iv). This concludes the proof of the lemma.

The lemma shows that on any compact set the lower bound of u_1 moves into region II for large t. Since $u_2>0$ it is plausible from the direction of the vector field that u is swept towards u^*. This is now proved by constructing another subsolution whose first component is based on the value of $v_1(x,t)$ for large t.

From the assumptions on $M_2(z_1,z_2)=z_2m_2(z_1,z_2)$ there are numbers $\varepsilon,b,\rho>0$ such that $M_2(a-\varepsilon,z_2)\geqq\rho^2\mu_2z_2$ for $0\leqq z_2\leqq b$. From (iii) of Lemma 4.2, there exists a t_0 such that $v_1(x,t_0)\geqq a-\varepsilon$ for $|x|\leqq\pi/2\rho$. Since $u_2(x,t_0)>0$ for $x\in\Omega$, there is a $\sigma>0$ such that

$$\sigma<\min_{-l_2\leqq x\leqq l_2}u_2(x,t_0),$$

where $l_2=\pi/2\rho$. Define $z(x)=(z_1(x),z_2(x))$ where

$$z_1(x)=v_1(x,t_0)\qquad(x\in\Omega),$$

$$z_2(x)=\begin{cases}\sigma\cos\rho x & (|x|\leqq\pi/2\rho),\\ 0 & (|x|>\pi/2\rho),\end{cases}$$

and let $z(x,t)$ be the solution of (2.1) with $z(x,t_0)=z(x)$. From the above construction and Lemma 4.2(iv), $u(x,t_0)\geqq z(x,t_0)\geqq v(x,t_0)$, and since $u(x,t)$, $z(x,t)$ and $v(x,t)$

are solutions of (1.2), from Theorem 2.3, $u(x,t) \geqq z(x,t) \geqq v(x,t)$ for $t \geqq t_0$. Now

$$\begin{aligned} M_1(z_1(x), z_2(x)) + \mu_1 z_{1xx}(x) &\geqq M_1(z_1(x), 0) + \mu_1 z_{1xx}(x) \\ &= M_1(v_1(x,t_0), 0) + \mu_1 \frac{\partial^2}{\partial x^2} v_1(x,t_0) \\ &= \frac{\partial v_1}{\partial t_0}(x,t_0) \\ &\geqq 0, \end{aligned}$$

by Lemma 4.2(ii). Also,

$$\begin{aligned} M_2(z_1(x), z_2(x)) + \mu_2 z_{2xx}(x) &\geqq M_2(a-\varepsilon, z_2(x)) + \mu_2 z_{2xx}(x) \\ &\geqq \rho^2 \mu_2 z_2(x) + \mu_2 z_{2xx}(x) = 0, \end{aligned}$$

and the left-hand side is zero when $z_2 = 0$. Thus $z(x)$ is the local maximum of regular subsolution, and so is a subsolution.

Now $z(x)$ is a subsolution, u^* is a supersolution and $z \leqq u^*$, so it follows from Theorem 2.4 that there is a stationary solution $w(x)$ with $z(x) \leqq w(x) \leqq u^*$ such that $z(x,t) \to w(x)$ uniformly on compact sets as $t \to \infty$. The final step is to show that $w = u^*$.

As noted above, $z_1(x,t) \geqq v_1(x,t)$, and since $v_1(x,t) \to a$ uniformly on compact sets, it follows that $w_1(x) \geqq a \geqq z_1(x)$. Also, since z_2 has compact support, by an argument used in proving Theorem 3.1, there is an $\alpha > 0$ such that $w_2(x) \geqq z_2(x) + \alpha$ on the support of z_2. There is therefore a neighborhood N of 0 such that $w(x+y) \geqq z(x)$ for $y \in N$. Therefore, by Theorem 2.4, w is a constant. However, the only constant solution satisfying $w \geqq z(x)$ is u^*, so $w = u^*$. This concludes the proof.

Acknowledgment. I would like to express my gratitude to Dr. R. Law of the University of York for discussions concerning this problem.

A PARABOLIC-HYPERBOLIC FREE BOUNDARY PROBLEM*

ANTONIO FASANO† AND MARIO PRIMICERIO†

Abstract. Change of phase problems with space-dependent melting temperature are considered. A weak formulation is given, pointing out that relevant differences occur with respect to the case of constant melting temperature. Next, analyzing the case in which weak solutions are suitably smooth, it is found that (i) mushy regions may appear even if volumetric heat sources are absent; (ii) a differential system is satisfied, consisting of parabolic equations and first order hyperbolic equations coupled through free boundaries; (iii) the interface conditions have the form of "unilateral constraints". Finally, a model problem is studied and the existence of a smooth solution is proved.

1. Introduction. In this paper we study a mathematical model for change of phase processes (e.g., freezing of lakes, thawing of glaciers, etc.) in which the melting temperature is space-dependent.

Among the main features of this model, we point out that "mushy" regions (see [1], [8], [11], [12], [13]) may appear even if volumetric heat sources are absent. Moreover, in such regions while temperature is locally constant (and equal to the melting temperature), heat conduction makes energy evolve with time.

This model could be the starting point of a classical theory for melting or solidification of alloys (see [2], [4], [14]). Actually, the results presented here show that the possible appearance of a mushy region during the solidification of an alloy is not necessarily related to the gap between the solidus and liquidus curves in the phase diagram. Indeed, when the concentration of the diluted component is not uniformly distributed and its diffusion is negligible, then an alloy in which the liquidus and solidus curves were supposed to be almost coincident would behave essentially as a medium with space-dependent melting temperature.

In §2 we will write the weak formulation of the problem in a general setting. In §3 we will sketch some properties of the classical solution in one space dimension. We will show that a differential system has to be satisfied, consisting of parabolic equations and first order hyperbolic equations coupled through free boundaries. Moroever, the interface conditions have the form of "unilateral constraints". In §4 a model problem will be considered, clearly exhibiting the spontaneous appearance of a mushy region. A well posedness theorem is stated and an outline of its proof is given. Details and a more comprehensive discussion of the model will appear in a forthcoming paper ([6]).

2. Weak formulation. Let x be a point in R^n and let t denote time, u temperature, k thermal conductivity, c heat capacity, r rate of heat supply per unit volume. Assume that the melting temperature u_m is a smooth function of x and that k, c, r, depend on the difference $w = u - u_m$ only, being bounded and smooth for $w \neq 0$. Moreover, $c, k \geqq a$ for some positive constant a.

The thermal energy E is defined as

$$E(x,t) = \int_0^{w(x,t)} c(y)\,dy + \Lambda \operatorname{sgn}^+ w(x,t), \tag{2.1}$$

*Received by the editors September 11, 1983, and in revised form June 25, 1984. This work was partially supported by the GNFM of the Italian CNR and by the University of Firenze.

†c/o Istituto Matematico "Ulisse Dini" viale Morgagni 67/a, I 50134 Firenze, Italy.

where Λ is the latent heat and

$$\operatorname{sgn}^+ z = \begin{cases} 0, & z<0, \\ [0,1], & z=0, \\ 1, & z>0. \end{cases}$$

Obviously, w can be found in terms of E as a single valued function $b(E)$, and

$$u(x,t)=u_m(x)+b(E(x,t)). \tag{2.2}$$

Moreover, we set

$$g(w)=\int_0^w k(y)\,dy, \tag{2.3}$$

$$B(E)=g(b(E)). \tag{2.4}$$

Given $T>0$ and a bounded domain $Q\subset R^n$ with smooth boundary ∂Q and outer normal n, let us define a weak solution of the change of phase problem with data $E_0(x)$, the initial energy, and $U(x,t)$, the boundary temperature. Here, we will assume that the subset of $\partial Q\times(0,T)$ where $U=u_m$ has zero measure.[1] We extend the functions

$$K(E)=k(b(E)), \qquad R(E)=r(b(E)), \qquad E\neq(0,\Lambda), \tag{2.5}$$

over the interval $(0,\Lambda)$ as linear interpolations.

We say that $E\in L^\infty(Q\times(0,T))$ is a weak solution if the following equation is satisfied for any $F\in C^\infty(\bar{Q}\times 0,T)$, vanishing for $t=T$ and on $\partial Q\times(0,T)$,

$$\int_0^T\int_Q [EF_t+B\operatorname{div}\operatorname{grad}F-K\operatorname{grad}u_m\cdot\operatorname{grad}F+RF]\,dx\,dt + \int_Q E_0(x)F(x,0)\,dx-\int_{\partial Q\times(0,T)} B_0\operatorname{grad}F\cdot n\,dS=0, \tag{2.6}$$

where $B_0=g(U-u_m)$.

3. Classical solutions. A solution $E(x,t)$ of the above mentioned problem is said to be a classical solution if it possesses some additional regularity properties which will be listed below for the case $n=1$, $Q=(0,1)$:

i) The function $u(x,t)$ given by (2.2) is continuous in the closure of $P=(0,1)\times(0,T)$.

ii) The sets

$$L=\{(x,t)\in P: u(x,t)>u_m\},$$
$$S=\{(x,t)\in P: u(x,t)<u_m\},$$
$$M=\mathring{N}, \qquad N=P\setminus(L\cup S),$$

are such that those parts of their boundaries which lie in P consist of N curves $x=s_i(t)$, $t\in I_i=(t_i',t_i'')\subset(0,T)$ such that $s_i\in C(\bar{I}_i)\cap C^1(I_i)$, $i=1,2,\cdots,N$.

iii) $u\in C^{2,1}(L\cup S)$ and u_x is continuous on each side of the curves $x=s_i(t)$.

iv) $E\in C^{1,1}(M)\cap C(\bar{M})$.

---

[1] When this condition is not fullfilled, the boundary data to be prescribed are the temperature or the energy, according to the thermal properties of the medium. This nontrivial point is discussed in [6], together with the analysis of the problem with Neumann data.

We will call L and S the liquid and the solid regions respectively, while M will be called the mushy region. In M it is $u(x,t)=u_m(x)$, and $E\in[0,\Lambda]$ (regions where $E=0$ or $E=\Lambda$ identically could be included in M as well).

It is immediately seen that the parabolic equation

$$cu_t=(ku_x)_x+r \tag{3.1}$$

holds in L and in S, and that the first order hyperbolic equation

$$E_t=\big(K(E)u'_m(x)\big)_x+R(E) \tag{3.2}$$

is satisfied in M. Moreover it is immediately found that the initial and boundary conditions are satisfied in a classical sense,

(3.3)

$$E(x,0)=E_0(x),\quad x\in(0,1),\qquad u(0,t)=U(0,t),\quad u(1,t)=U(1,t),\quad t\in(0,T).$$

To find the conditions satisfied on interfaces, multiply (3.1) and (3.2) by a test function F and use Green's theorem on each connected component of L, S and M. If we denote, for any function $f(x,t)$, $[f]_i=f(s_i(t)+,t)-f(s_i(t)-,t)$, we find by comparison with (2.6):

$$[E]_i\dot{s}_i+[Ku_x]_i=0,\qquad t\in I_i,\quad i=1,2,\cdots,N. \tag{3.4}$$

A careful analysis of condition (3.4) shows that the following local characteristic speed

$$v_0(x)=-hu'_m(x),\qquad h=\frac{dK}{dE},\quad E\in(0,\Lambda) \tag{3.5}$$

determines the form of the free boundary conditions. Namely:

(A) When $\dot{s}(t)>v_0(s(t))$ and $x=s(t)$ is a boundary between solid (for $x<s(t)$) and mush ($x>s(t)$), the free boundary condition is

$$E(s(t)+t,t)\big[\dot{s}(t)-v_0(s(t))\big]+K_S\big[u'_m(s(t))-u_x^s\big]=0, \tag{3.6}$$

where $K_S=K(0-)$ and $u_x^s=u_x(s(t)-,t)$.

(B) When $\dot{s}(t)\leqq v_0(s(t))$, the free boundary condition between solid and mush is

$$u_x^S=u'_m(s(t)), \tag{3.7}$$

and the condition

$$R(0-)+K_Su''_m(s(t))>0 \tag{3.8}$$

is needed.

Conditions (3.6), (3.7) can be summarized as

$$E(s(t)+,t)\big[\dot{s}(t)-v_0(s(t))\big]^++K_S\big[u'_m(s(t))-u_x^S\big]=0. \tag{3.9}$$

This unilateral form of the free boundary condition can be derived using the boundary point principle (see [6] for the details). Parallel results are found for an L-M interface, while on a L-S interface the usual Stefan condition is valid.

4. An example. In this section we produce a simple example in which, despite of the absence of volumetric heat sources, mushy regions appear as an effect of a variable melting temperature with nonvanishing second derivative. We note that in this definition of classical solution, possible effects of superheating are not taken into account.

Indeed our classical solution originates from a weak solution under suitable regularity requirements, and the definition of the "energy" function (2.1) is a constitutive law excluding nonequilibrium effects (see [6], [10], [11] and [13] for a discussion of this aspect).

We consider the slab $0<x<1$ assuming that no body sources are present ($r=0$), that the specific heat is constant throughout the slab (say, $c=1$) and that the conductivity has two constant values K_L and K_S in the liquid and in the solid, respectively. Therefore we define the function $K(E)$ as follows:

$$K(E)=\begin{cases} K_L, & E>\Lambda, \\ K_S+hE, & E\in(0,\Lambda), \quad h=\dfrac{K_L-K_S}{\Lambda}, \\ K_S, & E<0. \end{cases}$$

We will assume that the melting temperature is given by

$$u_m(x)=-1+x^2, \tag{4.1}$$

and that the initial and boundary conditions are

$$u(x,0)=-1+\frac{x^2}{2}, \qquad x\in(0,1), \tag{4.2}$$

$$u_x(0,t)=0, \qquad t>0, \tag{4.3}$$

$$u(1,t)=-\tfrac{1}{2} \qquad t>0. \tag{4.4}$$

We assume that this problem has a classical solution and we will derive some a priori information on the qualitative behaviour of the solution.

Our first result is aimed at characterizing the region S.

PROPOSITION 1. *There exists a function* $s(t)\geqq 0$, *such that* $S=\{(x,t)\colon s(t)<x<1, 0<t<T\}$. *Moreover,* $s(t)\not\equiv 0$ *in any neighborhood of* $t=0$.

The proof of this proposition is essentially based on the maximum principle. The next step will be to prove that a mushy region appears from the very beginning.

PROPOSITION 2. *There exists a function* $z(t)\geqq 0$, $z\not\equiv s$, *in any neighborhood of* $t=0$, $z(t)\leqq s(t)$, *such that* $u(x,t)=u_m(x)$ *in the set* $z(t)\leqq x\leqq s(t)$, $0<t<T$.

Proof. Suppose that there exist a $t_1>0$ and a region $R=\{y(t)<x<s(t), 0<t<t_1\}$ with $y(t)\geqq 0$, such that R is a component of $L\cap\{t<t_1\}$.

The maximum principle ensures that if $y(t)>0$, then the curve $x=y(t)$ is an interface between M and L. Following the discussion of the preceding section, it can be seen that the condition $u_m''>0$ implies $\dot{y}(t)<v_0(y(t))=-2hy(t)$, $t\in(0,t_1)$, thus contradicting $y(t)>0$, $y(0)=0$. Let us show that also assuming $y(t)$ identically equal to zero is contradictory. In such a case the pair (s,u) would be a solution of

$$\begin{aligned} &K_L u_{xx}-u_t=0, \quad 0<x<s(t), && 0<t<t_1, \\ &u_x(0,t)=0, && 0<t<t_1, \\ &u(s(t),t)=u_m(s(t)), && 0<t<t_1, \\ &u(x,t)>u_m(x), \quad 0<x<s(t), && 0<t<t_1. \end{aligned}$$

Using Green's theorem we find

$$\int_0^{s(t)} u(x,t)\,dx=\int_0^t K_L u_x(s(t')-,t')\,dt'+\int_0^t u(s(t'),t')\dot{s}(t')\,dt'. \tag{4.5}$$

The last integral is nothing but $\int_0^{s(t)} u_m(x)\,dx$, hence

$$0 \leqq \int_0^t K_L u_x^L dt' = -\Lambda s(t) + \int_0^t K_S u_x^s dt'$$

$$\leqq -\Lambda s(t) + \int_0^t K_S u'_m(s(t'))\,dt'.$$

This inequality is false, since $u'_m(s) = 2s$. The argument applies also in any interval $(t_a, t_b) \subset (0, T)$ in which $s(t) > 0$, $s(t_a) = 0$. Thus the only possibility is that the curve $x = s(t)$ is an interface between M and S.

By means of similar arguments it is possible to prove that the liquid region does not appear at $t = 0$. More precisely, we have

PROPOSITION 3. *There exists a time $t_0 > 0$ such that*

$$z(t) \equiv 0 \quad \text{in } (0, t_0).$$

Therefore, in this time interval $(0, t_0)$, we will have nothing but one free boundary separating regions M (for $x < s(t)$) and S (for $x > s(t)$).

Having concluded our a priori analysis, we can pass to the proof of our existence theorem. According to the results of §3, to find the interface between S and M together with the temperature in the region S we have to solve the following problem: find a $T > 0$, and $s(t) \in C[0, T] \cap C^1(0, T)$ and a $u(x,t) \in C^{2,1}(D_T) \cap C(\bar{D}_T)$ ($D_T \equiv \{(x,t)\colon s(t) < x < 1, 0 < t < T\}$) such that

$$\begin{aligned}
&K_S u_{xx} - u_t = 0 && \text{in } D_T,\\
&s(0) = 0,\\
&u(x,0) = -1 + \frac{x^2}{2}, && 0 < x < 1,\\
&u(1,t) = -\frac{1}{2}, && 0 < t < T,\\
&u(s(t),t) = -1 + s^2(t), && 0 < t < T,
\end{aligned} \tag{4.6}$$

and that

$$K_S\left[u_x(s(t),t) - 2s(t)\right] = E(s(t)-,t)\left[\dot{s}(t) - v_0(s(t))\right], \tag{4.7}$$

in the case $\dot{s}(t) < -2hs(t)$. In the case $\dot{s}(t) \geqq -2hs(t)$, instead of (4.7) the following condition has to be satisfied

$$u_x(s(t),t) = 2s(t). \tag{4.8}$$

If we disregard the condition $\dot{s} \geqq -2hs$, problem (4.6), (4.8) has a unique classical solution, such that $\lim_{t \to 0} \dot{s}(t) = +\infty$ and $s(t) \leqq 1 - (2)^{-1/2}$. This conclusion can be obtained using the results of [5]. Such solution is also a solution to the original problem if $h \geqq 0$ (the condition $\dot{s} \geqq -2hs$ is automatically satisfied). Otherwise a time $\bar{T} > 0$ exists such that $\dot{s}(\bar{T}) = -2hs(\bar{T})$, beyond which the solution has to be continued in a different way. The possibility of such a continuation will not be investigated here.

The determination of M requires first the solution of

$$E_t - 2hxE_x = 2(K_S + hE) \tag{4.9}$$

with the condition

$$E(s(t),t) = 0, \qquad 0 < t \quad \text{if } h > 0, \qquad 0 < t < \bar{T} \quad \text{if } h < 0 \tag{4.10}$$

and the constraint $E \in (0, \Lambda)$. This problem is easily solved and the curves $x = q_c(t)$ where $E = c$ are found to have positive and bounded slope for any value of c in $(0, \Lambda]$.

The L-M interface, $x = z(t)$, is expected to start from the point $(0, T_L)$, with $T_L = (2h)^{-1} \ln(1 + h\Lambda/K_S)$ for $h \neq 0$ and $T_L = \Lambda/(2K_S)$ for $h = 0$, and enter the region bounded by the curves $x = s(t)$ and $x = q_L(t)$.

On such an interface the energy balance condition is

$$K_L[u_x(z(t)-,t) - 2z(t)] = -[\Lambda - E(z(t)+,t)][\dot{z}(t) - v_0(z(t))], \qquad t > T_L. \tag{4.11}$$

As a matter of fact, it can be shown that the alternative condition $u_x(z(t)-,t) = 2z(t)$, valid when $\dot{z}(t) < v_0(z(t))$, never occurs

We have the following.

THEOREM. *The free boundary problem for the heat conduction equation in the liquid phase with free boundary conditions* (4.11), $z(T_L) = 0$ *and*

$$u(z(t),t) = -1 + z^2(t) \tag{4.12}$$

has one unique classical solution in some interval (T_L, T).

The proof of this theorem is complicated by the fact that the apparent latent heat in (4.11) vanishes for $t = T_L$. The main tool employed is to construct a sequence of monotone approximations by solving the following problems.

$$\begin{aligned}
&K_L u^{(i)}_{xx} - u^{(i)}_t = -2K_L \quad \text{in } D^{(i)}_c \equiv \{(x,t): 0 < x < z^{(i)}(t), T_L < t < T^{(i)}_c\}, \\
&z^{(i)}(T_L) = \frac{1}{i}, \\
&u^{(i)}(x, T_L) = 0, \qquad x \in \left(0, \frac{1}{i}\right), \\
&u^{(i)}_x(0,t) = 0, \qquad t \in (T_L, T^{(i)}_c), \\
&u^{(i)}(z^{(i)}(t),t) = 0, \qquad t \in (T_L, T^{(i)}_c), \\
&K_L u^{(i)}_x(z^{(i)}(t),t) = -L^*(z^{(i)}(t),t)[\dot{z}^{(i)}(t) + 2hz^{(i)}(t)], \qquad t \in (T_L, T^{(i)}_c).
\end{aligned} \tag{4.13}$$

In (4.13) the following symbols are used:

1) i is an integer not less than some i_0 such that $E(1/i_0, T_L)$ is defined and takes a value in $(0, \Lambda)$;

2) c is a constant in $(0, \Lambda)$ such that the level curve $x = q_c(t)$ hits $t = T_L$ on the left of $x = 1/i$;

3) $L^*(x,t) = \Lambda - E(x,t)$;

4) $T^{(i)}_c$ is the first instant (greater than T_L) such that the curve $x = z^{(i)}(t)$ hits either $x = q_c(t)$ or the boundary of the region where E is defined.

The convergence proof goes through the following steps.

First, one can prove as in [12] that for any $i > i_0$ there exists a constant $c_0(i)$ such that $T^{(i)}_c$ is uniformly estimated from below by some $T_0 > T_L$ for any $c \in (c_0, L)$. Hence the following definition makes sense

$$z(t) = \lim z^{(i)}(t), \qquad t \in (T_L, T_0).$$

Next, it can be shown that if the functions $q_\Lambda(t)$ and $z(t)$ do not coincide in any neighborhood of $t = T_L$, then $q_\Lambda(t) < z(t)$ in (T_L, T_0). The argument of the proof is based upon the construction of suitable barriers for $z^{(i)}$.

By means of a comparison technique it can then be proved that the convergence of the sequence $\{z^{(i)}\}$ is uniform in $[T_L, T_0]$ and that the limit function $z(t)$ is locally Lipschitz continuous. Moreover, let $\hat{u}(x,t)$ be the solution of the equation $K_L\hat{u}_{xx}-\hat{u}_t=-2K_L$ in the domain $0<x<z(t)$, $T_L<t<T_0$, subjected to the boundary conditions $\hat{u}_x(0,0)=0$, $\hat{u}(z(t),t)=0$. The maximum principle ensures that $\hat{u}(x,t)$ is the uniform limit of the sequence $\{u^{(i)}(x,t)\}$.

At this point it can be concluded that the pair (z,u), with $u=\hat{u}-1+x^2$, solves the free boundary problem in the liquid phase, i.e., that (4.11) is satisfied. To this end it is convenient to reformulate (4.11) in an integral form, using Green's identity, namely

$$\int_{T_L}^{t}\int_0^{z(t)} 2K_L\,dx\,dt' + A(z(t),t) + \int_{T_L}^{t} A_1(z(t),t)\,dt' - \int_0^{z(t)} \hat{u}(x,t)\,dx, \qquad t\in(T_L,T_0), \tag{4.14}$$

where

$$A(x,t) = -\int_0^x L^*(x',t)\,dx',$$

$$A_1(x,t) = -2hxL^*(x,t) + \int_0^x L_t^*(x',t)\,dx'.$$

In the present case (4.14) is seen to be equivalent to (4.11). Writing the corresponding equality for each of the pairs $(z^{(i)},u^{(i)})$ and passing to the limit shows the validity of (4.14).

As a consequence, the theorem will be proved if we can guarantee that the functions $q_\Lambda(t)$ and $z(t)$ are not identical in a right neighborhood of $t=T_L$. Assuming this is false, we immediately get a contradiction, since L^* and $\hat{u}_x$ vanish on $x=z(t)$, where $\hat{u}$ attains its minimum.

STANDING WAVE SOLUTIONS FOR A SYSTEM DERIVED FROM THE FITZHUGH–NAGUMO EQUATIONS FOR NERVE CONDUCTION*

GENE A. KLAASEN† AND ENZO MITIDIERI‡

Abstract. We focus our attention on the reaction-diffusion system $u_t = D_1\Delta u + f(u) - v$, $v_t = D_2\Delta v + \varepsilon(u - \gamma v)$ where $f(u) = u(1-u)(u-a)$, $0 < a < \frac{1}{2}$ and D_1, D_2, ε, γ are positive constants. The parameter γ is chosen large so that the associated dynamic equations ($D_1 = D_2 = 0$) have three constant solutions two of which are stable. The authors establish necessary and sufficient conditions that the Dirichlet problem for this system possesses two nontrivial time independent solutions.

1. Introduction.

We investigate the system

$$\begin{aligned} u_t &= D_1\Delta u + f(u) - v, \\ v_t &= D_2\Delta v + \varepsilon(u - \gamma v), \end{aligned} \tag{1.1}$$

where $\Delta \equiv \sum_{i=1}^{n} \partial^2/\partial x_i^2$, $n \geqq 1$, $t \geqq 0$, $(x_1, \cdots, x_n) \in \Omega \subseteq \mathbb{R}^n$, $f(u) = u(1-u)(u-a)$, $0 < a < \frac{1}{2}$, $D_1 > 0$, $D_2 > 0$, $\varepsilon > 0$, $\gamma > 0$. Equations (1.1) are an extension of the simpler FitzHugh–Nagumo [7], [13] equations, namely

$$\begin{aligned} u_t &= u_{xx} + f(u) - v, \\ v_t &= \varepsilon(u - \gamma v). \end{aligned} \tag{1.2}$$

The FitzHugh–Nagumo system serves as a prototype for nerve conduction and other chemical and biological systems. The interested reader is referred to [8], [15] for a review of results obtained to this date.

The space independent system (i.e., the dynamics of (1.1) and (1.2)) consists of the equations

$$\begin{aligned} u_t &= f(u) - v, \\ v_t &= \varepsilon(u - \gamma v). \end{aligned} \tag{1.3}$$

Of particular interest to us is the case of large γ for which (1.3) have three steady state solutions, two of which are stable and one unstable (see Fig. 1). This "bistability" phenomenon is present in a number of chemical and biological models [6], [13], [21].

Recently, Terman and Rinzel [18] have made a detailed mathematical and numerical study of the case γ large in a simplification of (1.2),

$$\begin{aligned} u_t &= u_{xx} + H(u - a) - u - v, \\ v_t &= \varepsilon(u - \gamma v), \end{aligned} \tag{1.4}$$

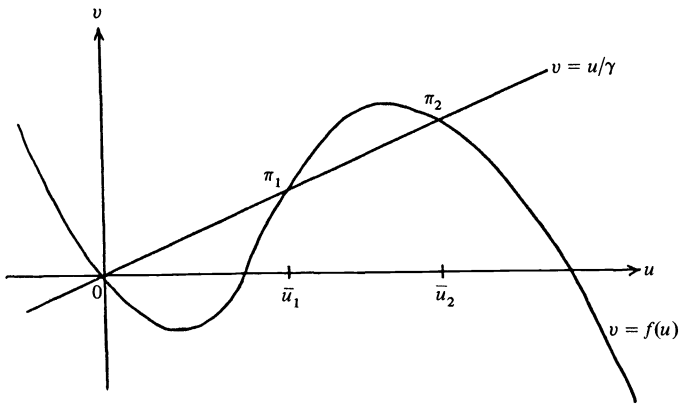

FIG. 1

where

$$H(u-a)=\begin{cases}1 & \text{if } u>a,\\ 0 & \text{if } u<a,\end{cases} \qquad -\infty<u<\infty.$$

For appropriate values of the parameters they find wave fronts, wave backs and pulse solutions of (1.4). One important result of their analysis is that $\varepsilon\gamma^2<1$ is a necessary and sufficient condition for the existence of a pulse solution.

In this paper we investigate the more complicated system (1.1). The addition of diffusion terms to the v equation reflects the possibility that more than one species may diffuse. For example, Tuckwell and Miura [19] have proposed a model for spreading cortical depression in the brain. In their system there are three steady state solutions and more than one species diffuses. Also, Koga and Kuramoto [10] examine a two diffusion modification of (1.4), namely

$$\begin{aligned} u_t &= D_1u_{xx}+H(u-a)-u-v,\\ v_t &= D_2v_{xx}+bu-cv, \qquad -\infty<x<\infty. \end{aligned} \tag{1.5}$$

They show that if the inhibiting diffusion D_2 is sufficiently large, (1.5) have 2 nonconstant steady state solutions, one of which is linearly stable. They also argue that such standing waves are likely in bistable excitable systems in which the inhibiting diffusion is large enough to halt the formation of a traveling wave.

Rothe and de Mottoni [16], [17] consider a system somewhat similar to (1.1) but with $D_2=\varepsilon=\gamma=1$ and a function f which satisfies $f(-u)=-f(u)$ and $f'(0)>0$. In contrast to our system, their model has a single constant solution which exhibits the diffusion driven instability property which Turing suggests as the dynamics of pattern formation. Moreover, since our f is not odd we cannot apply the Ljusternik–Schnirelmann theory as they do to obtain existence of steady state solutions.

Standing waves of (1.1) have been found when $n=1$. Ermentrout and Hastings [5] show when $\gamma>0$ is small that there are two standing waves. Klaasen and Troy [9] argue for $\gamma>0$ large and $\frac{1}{2}-a>0$ small, $n=1$ that system (1.1) has a standing wave solution and infinitely many periodic solutions.

Our main goal is to show the existence of standing wave solutions for system (1.1) when $n>1$. Our space domains are finite balls with sufficiently large radius, i.e., $B_R(0)=\{(x_1,\cdots,x_n)\,|\,\Sigma_{i=1}^n x_i^2\leqq R^2\}$, where $R>0$ is large.

In §2 we state our main results. In §3 we give the proofs of our theorems.

2. Statement of main results. We investigate (1.1) for the existence of steady state solutions on bounded domains Ω in $\mathbb{R}^N$ with zero boundary values. Such solutions $(u(x), v(x))$ solve the system

$$\begin{aligned} -D_1\Delta u &= f(u)-v, \\ -D_2\Delta v &= \varepsilon u-\varepsilon\gamma v, \end{aligned} \tag{2.1}$$

on Ω with $u=0$ and $v=0$ on $\partial\Omega$. By rescaling the equations using the transformations $x\to x/\sqrt{D_1}$, $\delta D_2=\varepsilon D_1$, we obtain the equivalent system

$$-\Delta u = f(u)-v \quad \text{on } \Omega, \qquad u=0, \quad v=0 \quad \text{on } \partial\Omega. \tag{2.2}$$

$$-\Delta v = \delta u-\delta\gamma v \tag{2.3}$$

We assume that $0<a<\frac{1}{2}$ and require $\gamma>4/(1-a)^2$. This latter condition guarantees that (2.2) have three constant solutions. The first of these, the so-called rest state, is given by $\pi_0=(0,0)$. The other two are denoted by $\pi_i=(\bar{u}_i,\bar{v}_i)$, $i=1,2$, where $0<\bar{u}_1<\bar{u}_2$ and $0<\bar{v}_1<\bar{v}_2$. By solving the equation $f(u)=u/\gamma$ it is easy to see (see Fig. 1) that

$$\bar{u}_i=\frac{1+a}{2}+\frac{(-1)^i}{2}\sqrt{(1+a)^2-4\left(a+\frac{1}{\gamma}\right)}, \qquad i=1,2.$$

If we assume $\partial\Omega$ is of class $C^{2+\alpha}$, where $\alpha\in(0,1)$, then, following [11], [16], [17], the system (2.2), (2.3) can be uncoupled since the boundary value problem

$$-\Delta v+\delta\gamma v=\delta u, \qquad v=0 \quad \text{on } \partial\Omega, \tag{2.4}$$

defines a transformation $v=B(u)$, where B can be viewed as a bounded invertible linear transformation from $C^{\alpha}(\bar{\Omega})$ into $C^{2+\alpha}(\bar{\Omega})$ or from $L^2(\Omega)$ into $H_0^1(\Omega)$ in the case of weak solutions. Substituting $v=B(u)$ into (2.2) we obtain an equivalent single operator equation

$$-\Delta u+B(u)=f(u) \quad \text{on } \Omega, \qquad u=0 \quad \text{on } \partial\Omega. \tag{2.5}$$

Finally if we define

$$h(u)=(u-a)(u-1),$$

then (2.5) becomes

$$-\Delta u+B(u)=-uh(u) \quad \text{on } \Omega, \qquad u=0 \quad \text{on } \partial\Omega. \tag{2.6}$$

Thus u, v is a solution for the Dirichlet problem (2.2), (2.3) if and only if $v=B(u)$ and u is a solution of (2.6).

The following lemma asserts that classical solutions of (2.6) are a priori bounded.

LEMMA 1. *Let $b_0>0$ be chosen so that $h(u)>1/\gamma$ whenever $|u|>b_0$. Then every C^2-solution u of* (2.6) *satisfies*

$$|u(x)|\leqq b_0, \qquad |Bu(x)|\leqq\frac{b_0}{\gamma} \quad \text{on } \Omega.$$

The variational approach to solving (2.6) is enhanced by the a priori bounds for classical solutions as established in Lemma 1. We use these bounds to modify h as follows. Let $g \in C'(\mathbb{R})$ be defined with the restrictions

$$\text{(2.7)} \quad \begin{aligned} &\text{(i)} \quad g(u)=h(u), && |u| \leqq b_0, \\ &\text{(ii)} \quad g(u)>\frac{1}{\gamma}, && |u|>b_0, \\ &\text{(iii)} \quad g \text{ and } g' \text{ are bounded on } \mathbb{R}. \end{aligned}$$

Then $-ug(u)$ is a modification of $f(u)$ and if $F(u)=\int_0^u f(s)\,ds$ then the function $\tilde{F}(u)=\int_0^u -sg(s)\,ds$ is a modification of F. Let the functional Φ be defined on $H_0^1(\Omega)$ by

$$\text{(2.8)} \qquad \Phi(u)=\frac{1}{2}\int_\Omega |\nabla u|^2 dx+\frac{1}{2}\int_\Omega uB(u)\,dx-\int_\Omega \tilde{F}(u)\,dx.$$

By standard critical point theory, see [10], critical points of Φ are weak solutions of the Dirichlet problem

$$\text{(2.9)} \qquad -\Delta u+B(u)=-ug(u) \quad \text{on } \Omega \qquad u=0 \quad \text{on } \partial\Omega.$$

Ambrosetti and Rabinowitz [2] and Ambrosetti [1] prove that if there are constants c_1, c_2 and p such that

$$|k(s)| \leqq c_1+c_2|s|^p$$

where

$$\text{(2.10)} \qquad \begin{aligned} &p>1 && \text{if } n=2, \quad \text{but} \\ &1 \leqq p<\frac{n+2}{n-2} && \text{if } n>2, \end{aligned}$$

then weak solutions of Dirichlet problems for $-\Delta u=k(u)$ on domains $\Omega \subset \mathbb{R}^n$ with $\partial\Omega \in C^{2+\alpha}$, $0<\alpha<1$, are of class $C^{2+\alpha}$. Our choice of g is such that there are constants c_1 and c_2 with $|sg(s)| \leqq c_1+c_2|s|$ and hence condition (2.10) follows for $k(u)=-ug(u)$. Because of the smoothing effect of B and (2.10), a standard "boot strap" argument (see [1] or [2]) can be applied to conclude that if

$$\text{(2.11)} \qquad \Omega \subset \mathbb{R}^n, \qquad \partial\Omega \in C^{2+\alpha} \quad \text{for some } 0<\alpha<1,$$

then weak solutions of (2.9) are classical solutions. But then Lemma 1 and (2.7) imply that these solutions are solutions of (2.6). Throughout the remainder of our discussion we will assume our domains Ω satisfy (2.11).

THEOREM 1. *Suppose* $0<a<\frac{1}{2}$, $\gamma>9/(2a^2-5a+2)$. *There exists an* $R_0>0$ *such that if* Ω *contains a ball of radius* R_0 *then the Dirichlet problem* (2.2), (2.3) *has a nontrivial solution pair* $u_1, v_1=B(u_1)$ *of class* $C^{2+\alpha}(\Omega)$ *which satisfies*

$$\inf_{H_0^1(\Omega)} \Phi(u)=\Phi(u_1)<0.$$

THEOREM 2. *If the hypotheses of Theorem* 1 *hold then a second nontrivial pair of solutions* $u_2, v_2=B(u_2)$ *of the Dirichlet problem* (2.2), (2.3) *exists of class* $C^{2+\alpha}(\Omega)$ *and satisfies*

$$\inf_{\sigma\in\Sigma} \max_{0\leqq t\leqq 1} \Phi(\sigma(t))=\Phi(u_2)>0,$$

where $\Sigma=\{\sigma \in C([0,1]; H_0^1(\Omega)) \mid \sigma(0)=0, \sigma(1)=u_1\}$.

The hypotheses of Theorem 1 and Theorem 2 are to a certain degree necessary as the following theorem indicates.

THEOREM 3. *The Dirichlet problem* (2.2), (2.3) *fails to have a weak nontrivial solution on* $\Omega = B_R(0)$ *if any one of the following hypotheses is assumed*:

(i) δ, γ *are fixed positive numbers and* $R > 0$ *is sufficiently small*;

(ii) $\delta\gamma^2 \geqq 1$, $\gamma < 4/(1-a)^2$ *and any* $R > 0$;

(iii) $\delta\gamma^2 < 1$, $2\sqrt{\delta} - \delta\gamma > (1-a)^2/4$ *and any* $R > 0$.

The hypothesis

$$\gamma > \frac{9}{2a^2 - 5a + 2} \tag{2.12}$$

present in Theorems 1 and 2 is quite natural. Firstly, since

$$\frac{9}{2a^2-5a+2} > \frac{4}{(1-a)^2},$$

condition (2.12) implies that the dynamics of (2.2) are bistable as mentioned earlier. Secondly, condition (2.12) is equivalent to the inequality

$$\int_0^{\bar{u}_2} \left(f(s) - \frac{s}{\gamma} \right) ds > 0, \tag{2.13}$$

where $\bar{u}_2$ is the first coordinate of the third constant solution $\pi_2 = (\bar{u}_2, \bar{v}_2)$ of (2.2). Inequality (2.13) is known to be a necessary condition for the existence of nontrivial solutions of Dirichlet problems associated with the single equation $-\Delta u = f(u) - u/\gamma$; see Berestycki and Lions [3].

In part (iii) of Theorem 3 the assumption that $\gamma < 4/(1-a)^2$ is implicit in the inequality $2\sqrt{\delta} - \delta\gamma > (1-a)^2/4$ since it is always true that $1/\gamma \geqq 2\sqrt{\delta} - \delta\gamma$. Hence a necessary condition for the existence of nontrivial solutions of the Dirichlet problem (2.2), (2.3) is that $\gamma > 4/(1-a)^2$.

3. Proofs. This section contains the proofs of Lemma 1 and Theorems 1, 2 and 3 of §2.

Proof of Lemma 1. This proof is essentially due to Lazer and McKenna [11]. Let u be a C^2-solution of (2.5) with Dirichlet boundary conditions. Let $\max_\Omega |u(x)| = b_1$. By applying the maximum principle to $-\Delta v = -\delta\gamma u + \delta u$ we see that $|Bu(x)| = |v(x)| \leqq b_1/\gamma$ on Ω. Suppose for contradiction that $b_1 > b_0$. If there exists $x_1 \in \Omega$ such that $u(x_1) = b_1$, then $\Delta u(x_1) \leqq 0$ and

$$u(x_1) < \gamma h(u(x_1))u(x_1) = \gamma\left[\Delta u(x_1) - B(u(x_1))\right] \leqq -\gamma B(u(x_1)) \leqq u(x_1),$$

which is impossible. Similarly there is no $x_2 \in \Omega$ such that $u(x_2) = -b_1$ and hence $b_1 > b_0$ is false and the lemma is proved.

Before proving Theorem 1 we introduce some notation and establish the validity of several useful lemmas.

On the Hilbert space $L^2(\Omega)$ the inner product is denoted by

$$(u, v) = \int_\Omega uv\, dx$$

and the norm is denoted by

$$\|u\|_2 = (u, u)^{1/2}.$$

If the Hilbert space is $H_0^1(\Omega)$, then the inner product will be

$$((u,v))=\int_\Omega(\nabla u\cdot\nabla v)\,dx$$

and the norm

$$\|u\|=((u,u))^{1/2}.$$

We seek nontrivial solutions of

$$-\Delta u+B(u)=-uh(u) \quad \text{on } \Omega, \qquad u=0 \quad \text{on } \partial\Omega. \tag{3.1}$$

Recalling the discussion following Lemma 1 of §2, we will assume $\Omega\subseteq R^n$ satisfies $\partial\Omega\in C^{2+\alpha}$, where $0<\alpha<1$, and obtain as a consequence that weak solutions u of (3.1) are of class $C^{2+\alpha}(\Omega)$ and $u,v=B(u)$ is a pair of classical solutions of (2.2), (2.3). Also weak solutions of (3.1) are critical points of the functional

$$\Phi(u)=\frac{1}{2}\int_\Omega|\nabla u|^2+\frac{1}{2}\int_\Omega uB(u)-\int_\Omega\tilde{F}(u), \tag{3.2}$$

where $\tilde{F}(u)=-\int_0^u sg(s)\,ds$.

LEMMA 2. *Let B be defined by* (2.4). *Then*

$$\|B\|\leqq\frac{1}{\gamma}, \quad \textit{where } \|B\|=\inf_{u\neq0}\frac{\|Bu\|_2}{\|u\|_2}.$$

Proof. If $u\in L^2(\Omega)$ and $v=B(u)$ then $(-\Delta v)v+\delta\gamma v^2=\delta uv$ and hence $\int_\Omega|\nabla v|^2+\delta\gamma\int_\Omega v^2=\delta\int uv\leqq\delta\|u\|_2\|v\|_2$. Consequently, $\delta\gamma\|Bu\|_2^2=\delta\gamma\int_\Omega v^2\leqq\delta\|u\|_2\|Bu\|_2$ and the lemma easily follows. □

Let $B_R=\{x\in\mathbb{R}^n\,|\,\|x\|<R\}$, $C_R=B_R-B_{R-1}$ and for any $\Omega\subseteq\mathbb{R}^n$ let $|\Omega|=\int_\Omega dx$.

LEMMA 3. *If $R>0$ is sufficiently large then there exists a $u\in H_0^1(B_R)$ such that $\Phi(u)<0$.*

Proof. For $R>0$ define $u_R\in H_0^1(B_R)$ by

$$u_R=\begin{cases}\bar{u}_2, & 0\leqq\|x\|\leqq R-1,\\ (R-\|x\|)\bar{u}_2, & R-1\leqq\|x\|\leqq R,\end{cases}$$

where $(\bar{u}_2,\bar{v}_2)$ is the third constant solution of (2.2). Then

$$\begin{aligned}\Phi(u_R)&=\frac{1}{2}\int_{B_R}|\nabla u_R|^2+\frac{1}{2}\int_{B_R}u_RB(u_R)-\int_{B_R}\tilde{F}(u_R)\\ &=\frac{1}{2}\int_{C_R}|\nabla u_R|^2+\frac{1}{2}\int_{B_R}u_RB(u_R)-\int_{B_{R-1}}\tilde{F}(\bar{u}_2)-\int_{C_R}\tilde{F}(u_R)\\ &\leqq\frac{\bar{u}_2^2}{2}|C_R|+\frac{1}{2\gamma}\int_{B_R}u_R^2-\tilde{F}(\bar{u}_2)|B_{R-1}|+c_1|C_R|,\end{aligned}$$

where c_1 is a positive constant independent of R. Recall that $|B_R|=k_nR^n$, where k_n is a constant depending only on the dimension n of the space. Thus there is a constant l_n such that $|C_R|\leqq l_nR^{n-1}$. Continuing the inequality we have that there exists a constant K_n such that

$$\Phi(u_R)\leqq K_nR^{n-1}+k_n\left(\frac{\bar{u}_2^2}{2\gamma}-\tilde{F}(\bar{u}_2)\right)R^n.$$

Since $a<\bar{u}_2<1<b_0$, $+\tilde{F}(\bar{u}_2)>\bar{u}_2^2/2$ if $\gamma>9/(2a^2-5a+2)$ and hence for R sufficiently large $\Phi(u_R)<0$. See (2.13).

Proof of Theorem 1. First we wish to argue that Φ, defined by (3.2), is bounded below on $H_0^1(\Omega)$. From (2.7) we have that $g(s)>1/\gamma$ for $|s|>b_0$ and hence there exists an $M>0$ such that $\tilde{F}(u)=\int_0^u sg(s)\,ds>-M$ for all $u\in\mathbb{R}$. Consequently $\int_\Omega \tilde{F}(u)\,dx>-M|\Omega|$ on $H_0^1(\Omega)$. If the second equation of (2.2) is multiplied by $v=B(u)$ and integrated we obtain $\int_\Omega|\nabla v|^2+\delta\gamma\int_\Omega|v|^2=\delta\int_\Omega uB(u)$ and hence $\int_\Omega uB(u)\geqq 0$ for all $u\in H_0^1(\Omega)$. Consequently $\Phi(u)\geqq -M|\Omega|$ on $H_0^1(\Omega)$.

Secondly, since $\int_\Omega\tilde{F}(u)\,dx>-M|\Omega|$, $\phi(u)\geqq\frac{1}{2}\|u\|^2-M|\Omega|$ on $H_0^1(\Omega)$ and hence $\Phi(u)\to\infty$ as $\|u\|\to\infty$.

Finally, by standard variational arguments Φ is weakly lower semicontinuous and consequently Φ attains a global minimum on $H_0^1(\Omega)$ at some critical point u_1 which is a weak solution of (3.1); see Vainberg [19] or Ambrosetti [1]. Lemma 3 implies that $\Phi(u_1)<0$ and u_1 is nontrivial. By the standard "bootstrap" arguments referred to earlier, $u_1\in C^{2+\alpha}(\Omega)$ and is a classical solution.

To prove Theorem 2 we use the following version of the mountain pass theorem of Ambrosetti and Rabinowitz [2]; see Mawhin [12].

THEOREM. *Let $\Phi\in C^1(E,\mathbb{R})$, where E is a Hilbert space and assume there exists $u_0\in E$, $u_1\in E$, $r>0$, $k>0$ satisfying the following conditions*:

(i) $\|u_0-u_1\|>r$;

(ii) $\Phi(u_0)<k$, $\phi(u_1)<k$;

(iii) $\Phi(u)\geqq k$ *for* $\|u-u_0\|=r$.

Let $\Sigma=\{\sigma\in C([0,1],E)\mid\sigma(0)=u_0,\ \sigma(1)=u_1\}$ *and define*

$$c=\inf_{\sigma\in\Sigma}\max_{u\in\sigma([0,1])}\Phi(u).$$

If Φ satisfies the Palais–Smale condition, then c is a critical value for Φ.

In the proof of Theorem 2, $E=H_0^1(\Omega)$, $u_0=0$; u_1 is described in Theorem 1. Since B is a compact operator the argument of Ambrosetti and Rabinowitz [2] or Ambrosetti [1] will show that the function Φ defined in (3.2) satisfies the Palais–Smale condition. The remainder of the hypotheses of the mountain pass theorem will be satisfied when we prove the following lemma.

LEMMA 4. *There exist $r>0$, $\rho>0$ such that $\Phi(u)>0$ for all $0<\|u\|\leqq r$ and $\phi(u)\geqq\rho$ for all $\|u\|=r$.*

Proof. Define $k(u)=ug(u)+au$ so that (2.9) becomes

$$-\Delta u+B(u)=-au+k(u). \tag{3.3}$$

Let $K(u)=\int_0^u k(s)\,ds$. Then from (2.6) and (2.7) we conclude that $k(u)=(1+a)u^2-u^3$ for $|u|\leqq b_0$ and since $|sg(s)|\leqq c_1+c_2|s|$ for $s\in\mathbb{R}$ we see that k satisfies (2.10). From this property Ambrosetti and Rabinowitz [2] show that $\int_\Omega K(u)\,dx=0(\|u\|^2)$ at $u=0$. Hence

$$\begin{aligned}\Phi(u)&=\frac{1}{2}\int_\Omega|\nabla u|^2+\int_\Omega B(u)u-\int_\Omega\tilde{F}(u)\\&\geqq\frac{1}{2}\int_\Omega|\nabla u|^2+\frac{a}{2}\int_\Omega u^2-\int_\Omega K(u)\\&\geqq\varepsilon\|u\|^2+O\big(\|u\|^2\big)\quad\text{for some fixed }\varepsilon>0\end{aligned}$$

and the lemma follows. □

In Theorem 3 we prove the nonexistence of nontrivial solutions to the boundary value problem

$$\begin{aligned} -\Delta u + B(u) &= f(u) && \text{on } B_0(R), \\ u &= 0 && \text{on } \partial B_0(R). \end{aligned} \tag{3.4}$$

Several lemmas are required to establish the validity of Theorem 3.

Consider the eigenvalue problem:

$$\begin{aligned} -\Delta u + Bu &= \mu u && \text{on } B_0(R), \\ u &= 0 && \text{on } \partial B_0(R). \end{aligned} \tag{3.5}$$

LEMMA 5. *If μ is an eigenvalue of* (3.5), *then $\mu = \lambda + \delta/(\lambda + \delta\gamma)$, where λ is an eigenvalue of*

$$\begin{aligned} -\Delta u &= \lambda u && \text{on } B_0(R), \\ u &= 0 && \text{on } \partial B_0(R). \end{aligned} \tag{3.6}$$

Proof. Suppose (μ, u) is an eigenvalue eigenfunction pair for equation (3.5) on $L^2(\Omega)$. Since $B = \delta(\delta\gamma - \Delta)^{-1}$ we operate on both sides of (3.5) by $(\delta\gamma - \Delta)$ to obtain

$$\begin{aligned} &\left((-\Delta)^{-2} + \delta\gamma(-\Delta) + \delta\right)u = (\mu\delta\gamma - \mu\Delta)u \quad \text{or} \\ &\left[(-\Delta)^2 + (\delta\gamma - \mu)(-\Delta) + (\delta - \mu\delta\gamma)\right]u = 0. \end{aligned} \tag{3.7}$$

By factoring the quadratic operator in $-\Delta$ we obtain

$$(-\Delta + a)(-\Delta + b)u = 0 \tag{3.8}$$

for appropriate complex numbers a and b. Both a and b must be real numbers for otherwise they are complex conjugates and both $(-\Delta + a)$ and $(-\Delta + b)$ are invertible. This would imply that $u = 0$ contradicting the fact that u is in eigenfunction. Hence a and b are both real and (3.8) implies that one is an eigenvalue of $-\Delta$ with eigenfunction u. If we suppose a is an eigenvalue then from (3.7) we conclude that $a^2 + \delta\gamma a + \delta - \mu\delta\gamma = 0$ and upon solving for μ we obtain the required relationship $\mu = a + \delta/(a + \delta\gamma)$.

LEMMA 6. *Let $\nu(\lambda) \equiv \lambda + \delta/(\lambda + \delta\gamma)$. Then on $(-\delta\gamma, \infty)$, $\nu(\lambda)$ has a unique positive minimum at $\lambda_0 = \sqrt{\delta} - \delta\gamma$ with $\nu(\lambda_0) = 2\sqrt{\delta} - \delta\gamma$. Moreover ν is increasing on $\left[\sqrt{\delta} - \delta\gamma, \infty\right)$ and $\lim_{\lambda \to \infty} \nu(\lambda) = \infty$. This lemma is obvious.*

LEMMA 7. *Let μ_1 be the first eigenvalue of* (3.5). *If the* BVP (3.1) *has a nontrivial solution, then $\mu_1 \leqq \frac{1}{4}(1-a)^2$.*

Proof. Let $u \in L^2(B_R(0))$ be a nontrivial solution of BVP (3.1), and let $C \equiv -\Delta + B$. Then by the Rayleigh–Ritz representation of the first eigenvalue of (3.5), see [4], we have $\mu_1 = \inf(Cv, v)/\|v\|_2^2$, where infimum is taken over all $v \in L^2(B_R(0))$, $v \neq 0$. Since $u \in L^2(B_R(0))$, we have

$$\begin{aligned} \mu_1 \|u\|_2^2 \leqq (Cu, u) = (f(u), u) &= \int_{B_R(0)} \left[-u^4 + (1+a)u^3 - au^2\right] \\ &= \int_{B_R(0)} u^2\left[-u^2 + (1+a)u - a\right] \leqq \int_{B_R(0)} u^2\left(\frac{1-a}{2}\right)^2 \\ &= \frac{(1-a)^2}{4}\|u\|_2^2 \end{aligned}$$

or $\mu_1 \leqq \frac{1}{4}(1-a)^2$.

Proof of Theorem 3. First we prove part (i).

Let $0<a<\frac{1}{2}$, δ, γ, be fixed. If $\lambda_1(R)$ is the first eigenvalue of (3.6), then $\lim_{R\downarrow 0}\lambda_1(R)=\infty$; see [4]. Hence, from Lemma 6, there exists $R_0>0$ such that if $0<R<R_0$ then $\nu(\lambda_1(R))>\frac{1}{4}(1-a)^2$ and $\lambda_1(R)>\lambda_0$. Hence the first eigenvalue $\mu_1(R)$ of (3.5) satisfies

$$\mu_1(R)=\lambda_n+\frac{\delta}{\lambda_n+\delta\gamma}=\nu(\lambda_n)\geqq\nu(\lambda_1(R))$$

and by Lemma 7 no nontrivial solution of (3.1) exists.

To prove part (ii), since $\delta\gamma^2\geqq 1$ and $1/\gamma>\frac{1}{4}(1-a)^2$, then in Lemma 6, $\lambda_0\leqq 0$ and hence $\mu(\lambda)$ is increasing on $[0,\infty)$. Thus

$$\frac{1}{\gamma}=\mu(0)<\mu(\lambda)$$

for all $\lambda>0$ and hence for some n, $\mu_1(R)=\mu(\lambda_n)>\mu(0)=1/\gamma>\frac{1}{4}(1-a)^2$ and by Lemma 7 no nontrivial solution of (3.1) exists.

Finally part (iii) follows by an argument similar to part (ii). For if u is a nontrivial solution of (3.1) for some $R>0$ then from Lemma 7 we have

$$\mu_1(R)\leqq\frac{1}{4}(1-a)^2<2\sqrt{\delta}-\delta\gamma=\min_{\lambda\geqq 0}\mu(\lambda)$$

which contradicts Lemma 5. Hence no nontrivial solution of (3.1) exists. □

REGULARIZATION FOR A CLASS OF NONLINEAR EVOLUTION EQUATIONS*

JAMES F. EPPERSON†

Abstract. We establish estimates of the regularization error for a class of nonlinear degenerate parabolic evolution equations, which includes the Stefan problem in enthalpy form.

1. Introduction. In this paper we consider the regularization of nonlinear parabolic equations in the form

$$u_t = \Delta f(u) + F, \tag{1}$$

where $f'(\xi) \geqq 0$, and equality holds for some $\xi \in \text{Range}(u)$. Our ultimate goal is to establish estimates for the error due to changing from f to f_ε, $f_\varepsilon'(\xi) \geqq \varepsilon > 0$ for all ξ.

Particular equations of the form (1) have been studied by many authors, including Friedman [8], Cannon and Hill [5], Brezis [3], Jerome [9] and Alexiades and Cannon [2], all of whom established existence and uniqueness in appropriate Sobolev spaces.

The question of regularization error for equations of the form (1) has been most closely tied to the Stefan problem. In [7] we established an $O(\varepsilon^{1/4})$ estimate for the L^2 error in temperature (corresponding to $f(u)$ in (1)), where ε is the regularizing parameter. This was extended in [6] to $O(\varepsilon^{1/2})$. Jerome and Rose [10] had earlier obtained a similar $O(\varepsilon^{1/2})$ result for a different regularization.

The importance of the regularization error lies in its effect on the error in numerical approximation. If the regularization f_ε is such that $f_\varepsilon'(\xi) \geqq \varepsilon > 0$, then typical numerical error estimates ([6], [10]) are proportional to positive powers of ε^{-1}. There thus exists an ε^* for which the approximation and regularization errors are balanced. The smaller the regularization error, then, the smaller the total error.

Our main result is Theorem 4.1, which characterizes the regularization error in both u and $f(u)$ for a fairly broad class of regularizations. This is followed by Theorem 4.2, which gives conditions under which the regularization error for the Stefan problem is $O(\varepsilon)$.

To fix notation, let $\Omega \subset \mathbb{R}^n$ be an open bounded domain with Lipschitz boundary $\partial\Omega = \Gamma$. For $T > 0$, $Q_T = \Omega \times (0, T]$ defines a space-time cylinder. The spaces $H^r(D)$ denote the usual Sobolev spaces of functions over D, with the standard norms $\|\cdot\|_{r,D}$ [1]. The notation $L^p(X)$ for $L^p(0, T; X)$ will be used for brevity, with the norm being written $\|\cdot\|_{L^p(X)}$. Finally, the letter C will be used to denote generic positive constants. Only where distinction is important will any attempt be made to distinguish between different constants.

2. The nondegenerate case. Consider the evolution problem

$$u_t = \Delta f(u) + F \quad \text{in } \Omega, \quad t > 0, \tag{2}$$

$$u = 0 \quad \text{on } \Gamma, \quad t > 0, \tag{3}$$

$$u(0) = u_0 \quad \text{on } \Omega, \quad t = 0, \tag{4}$$

*Received by the editors October 25, 1983, and in revised form May 10, 1984.

where we assume

(5) $f \in C(\mathbb{R})$ and is piecewise C^1,

(6) $f(0)=0, \qquad 0<\sigma \leqq f'(\xi) \leqq \kappa < \infty \quad$ all ξ.

We remark that the choice of homogeneous boundary data is not a restriction, since for smooth enough boundary data an appropriate translation of f and modification of F can always be done to achieve $u=0$ on Γ. We also take $F \in L^2(Q_T)$ and $u_0 \in H^1(\Omega)$, although the case $u_0 \in L^2(\Omega)$ will also be considered.

It follows from (5)–(6) that, for any $\xi, \eta \in \mathbb{R}^1$,

(7) $$(f(\xi)-f(\eta))\cdot(\xi-n) \geqq C\sigma(\xi-\eta)^2$$

and

(8) $$(f(\xi)-f(\eta))\cdot(\xi-\eta) \geqq C(f(\xi)-f(\eta))^2,$$

where C is independent of σ.

We begin by establishing certain a priori estimates for smooth solutions to (2)–(4). By "smooth" we mean a function in the space

$$V=\left\{ \varphi \in L^2(0,T;\, H^2(\Omega)\cap H_0^1(\Omega)) \,\middle|\, \varphi_t \in L^2(Q_T) \right\}.$$

LEMMA 2.1. *Let $\varphi \in V$ solve* (2)–(4) *a.e. in Q_T. Then*;

(i) $\|\varphi\|_{L^\infty(L^2)} \leqq CM_1$;

(ii) $\|\varphi\|_{L^2(H_0^1)} \leqq C\sigma^{-1/2}M_1$;

(iii) $\|f(\varphi)\|_{L^2(H_0^1)} \leqq CM_1$;

(iv) $\|(f(\varphi))_t\|_{L^2(L^2)}+\|f(\varphi)\|_{L^\infty(H_0^1)} \leqq CM_2$;

(v) $\|\varphi_t\|_{L^2(L^2)} \leqq C\sigma^{-1/2}M_2$;

(vi) $\|f(\varphi)\|_{L^2(H^2)} \leqq C\sigma^{-1/2}M_2$,

where

$$M_1=\|u_0\|_0+T^{1/2}\|F\|_{L^2(L^2)}, \qquad M_2=\|\nabla f(u_0)\|_0+\|F\|_{L^2(L^2)}.$$

The constants in (i)–(vi) *are all independent of σ.*

Proof. We use standard energy arguments. Multiply the equation by φ, integrate over space and time, and use the Poincaré inequality to get

(9) $$\|\varphi(t)\|_0^2+\sigma\int_0^t\|\varphi(\tau)\|_1^2 d\tau \leqq C\left(\|u_0\|_0^2+\int_0^t\int_\Omega|\varphi F|dx\,d\tau\right);$$

alternately, we can use (6) to obtain

(10) $$\|\varphi(t)\|_0^2+\int_0^t\|f(\varphi(\tau))\|_1^2 d\tau \leqq C\left(\|u_0\|_0^2+\int_0^t\int_\Omega|\varphi F|dx\,d\tau\right).$$

The last term on the right can be bounded by the Hölder inequality applied twice:

$$\begin{aligned}\int_0^t\int_\Omega|\varphi F|dx\,d\tau &\leqq \int_0^t\|\varphi(\tau)\|_0\|F(\tau)\|_0 d\tau\\ &\leqq \|\varphi\|_{L^\infty(L^2)}\int_0^t\|F(\tau)\|_0 d\tau\\ &\leqq t^{1/2}\|\varphi\|_{L^\infty(L^2)}\|F\|_{L^2(L^2)}.\end{aligned}$$

Results (i) and (ii) follow immediately from this last bound applied to (9); result (iii) follows when it is applied to (10).

If we now multiply (2) by $(f(\varphi))_t$ and again integrate twice, we get

$$\int_0^t\int_\Omega f'(\varphi)(\varphi_t)^2 dx\,d\tau+\int_0^t\int_\Omega \nabla(f(\varphi))_t\nabla f(\varphi)\,dx\,d\tau=\int_0^t\int_\Omega (f(\varphi))_t F\,dx\,d\tau,$$

which becomes

$$(11)\quad \int_0^t \|f(\varphi(\tau))_t\|_0^2\,d\tau+\|\nabla f(\varphi(t))\|_0^2\leqq C\left(\|\nabla f(u_0)\|_0^2+\int_0^t\int_\Omega |f(\varphi(\tau))_t F(\tau)|dx\,d\tau\right),$$

or, alternately

$$(12)\quad \sigma\int_0^t \|\varphi_t(\tau)\|_0^2\,d\tau+\|\nabla f(\varphi(t))\|_0^2\leqq C\left(\|\nabla f(u_0)\|_0^2+\int_0^t\int_\Omega |f(\varphi(\tau))_t F(\tau)|dx\,d\tau\right).$$

Part (iv) follows immediately from (11); part (v) then follows from (12) with (iv) used to bound the last integral on the right. Finally, part (vi) is established by multiplying (2) by $-\Delta f(\varphi)$ and bounding the φ_t term using (v).

THEOREM 2.2. *Suppose* $u_0\in H^1(\Omega)$ *and* $F\in L^2(Q_T)$. *Then there exists a unique* $u\in H^1(Q_T)$, *with* $f(u)\in L^2(H^2(\Omega))$, *solving* (2)–(4).

Proof. Existence and uniqueness were established in [5] for weak solutions in the sense that

$$(13)\qquad \int_0^T\int_\Omega \left[u\varphi_t+f(u)\Delta\varphi\right]dx\,dt+\int_\Omega u_0\varphi(0)\,dx+\int_0^T\int_\Omega F\varphi\,dx\,dt=0$$

for all $\varphi\in V$, $\varphi(T)=0$ a.e. in Ω. This analysis assumed homogeneous Neumann data and a specific choice of nonlinearity f, but can be easily generalized to our case. Further, the estimates of Lemma 2.1 imply the extended regularity $u\in H^1(Q_T)$, $f(u)\in L^2(0,T;H^2(\Omega))$, i.e., u is a strong solution in that (2) holds a.e. in Q_T.

THEOREM 2.3. *Suppose only that* $u_0\in L^2(\Omega)$ *and* $F\in L^2(Q_T)$. *Then there exists* u, *a unique weak solution* (*in the sense of* (13)) *to* (2)–(4), *such that* $u\in L^\infty(L^2(\Omega))$ *and* $f(u)\in L^2(H_0^1(\Omega))$.

Proof. The theorem follows from Theorem 2.2 and Lemma 2.1(iii) by taking a sequence $\{v_0^n\}$ in $H^1(\Omega)$ converging in $L^2(\Omega)$ to u_0.

3. The degenerate case. We now consider the problem (2)–(4), with hypothesis (6) changed to

$$(6')\qquad f(0)=0,\qquad 0\leqq f'(\xi)\leqq\kappa<\infty,\quad \text{all } \xi\in\mathbb{R}^1.$$

Because $\sigma=0$, many of the bounds from Lemma 2.1 no longer apply. Thus, the whole existence—uniqueness question becomes much more delicate. Direct proofs of existence of weak solutions are possible ([3], [8], for example), but we prefer here to establish existence as the limiting case, as $\sigma\to 0$, of (2)–(4), (6).

Consider the sequence of problems:

$$(14)\qquad u_t^{(n)}=\Delta\left(f(u^{(n)})+\sigma_n u^{(n)}\right)+F \quad \text{in } \Omega,\quad t>0,$$

$$(15)\qquad u^{(n)}=0 \quad \text{on } \Gamma,\quad t>0,$$

$$(16)\qquad u^{(n)}(0)=u_0 \quad \text{in } \Omega.$$

Each $u^{(n)}$ is the solution of a problem of the form (2)–(4), (6) and, if

$$\lim_{n\to\infty}\sigma_n=0,$$

then we can in fact construct the solution to the degenerate problem.

THEOREM 3.1. *Let* $F\in L^2(Q_T)$ *and* $u_0\in H^1(\Omega)$. *Then there exists a unique weak solution of* (2)–(4), (6′); *moreover*,

$$u\in L^\infty\big(0,T;\, L^2(\Omega)\big),$$
$$f(u)\in L^\infty\big(0,T;\, H_0^1(\Omega)\big),$$
$$f(u)_t\in L^2\big(0,T;\, L^2(Q_T)\big).$$

Proof. Consider the sequences $\{u^{(n)}\}$, $\{f_n(u^{(n)})\}$, defined by (14)–(16), where

$$f_n(\xi)=f(\xi)+\sigma_n\xi.$$

By Theorem 2.2, then, the sequences are well-defined and

$$\|u^{(n)}\|_{L^2(Q_T)}\leqq C,\qquad \big\|f_n(u^{(n)})\big\|_{H^1(Q_T)}\leqq C,$$

where C is independent of n for $\lim_{n\to\infty}\sigma_n=0$. Hence there exist subsequences such that

$$u^{(m)}\to\bar u \quad \text{weakly in } L^2(Q_T), \tag{17}$$

$$f_m(u^{(m)})\to\bar f \quad \text{strongly in } L^2(Q_T). \tag{18}$$

Clearly, if $\bar f=f(\bar u)$, then we have established existence, for the same analysis as in [5] will apply. Since f is continuous and monotone, it suffices to show that

$$\big(\bar u-v,\bar f-f(v)\big)\geqq 0,\quad \text{all } v\in L^2(Q_T). \tag{19}$$

So, we consider

$$\big(\bar u-v,\bar f-f(v)\big)=\big(\bar u-u^{(m)},\bar f-f(v)\big)+\big(u^{(m)}-v,\bar f-f_m(u^{(m)})\big)$$
$$+\big(u^{(m)}-v,f(u^{(m)})-f(v)\big)+\sigma_m\big(u^{(m)}-v,u^{(m)}\big).$$

In the limit, the first two terms go to zero by (17) and (18); the third term is positive since f is monotone; and the last goes to zero since σ_m does. Thus (19) holds, and so $\bar f=f(\bar u)$. Existence then follows.

For uniqueness, let $v\in L^2(Q_T)$ be a second solution. Then

$$\int_0^T\int_\Omega\big[(u-v)\varphi_t+\big(f(u)-f(v)\big)\Delta\varphi\big]\,dx\,dt=0$$

for all $\varphi\in V$. Factor out the $(u-v)$ to get

$$\int_0^T\int_\Omega(u-v)[\varphi_t+e\Delta\varphi]\,dx\,dt=0,\quad \text{where } e=\frac{f(u)-f(v)}{u-v}\geqq 0$$

and $e\in L^\infty(Q_T)$. Consider then the final value problem

$$\varphi_t^{(\varepsilon)}+(e+\varepsilon)\varphi^{(\varepsilon)}=\psi \quad \text{in } \Omega,\quad t<T,$$
$$\varphi^{(\varepsilon)}=0 \quad \text{on } \Gamma,\quad t<T,$$
$$\varphi^{(\varepsilon)}(T)=0, \quad \text{in } \Omega,$$

for $\psi\in C_0^\infty(Q_T)$, $\varepsilon>0$. By [11, pp. 179–180], this has a unique solution $\varphi^{(\varepsilon)}\in V$. Thus, for any $\psi\in C_0^\infty(Q_T)$,

$$\int_0^T\int_\Omega(u-v)\psi\,dx\,dt=\int_0^T\int_\Omega(u-v)\varepsilon\Delta\varphi^{(\varepsilon)}\,dx\,dt.$$

Again from [11, pp. 179–180], we have that

$$\|\varepsilon^{1/2}\Delta\varphi^{(\varepsilon)}\|_{L^2(L^2)} \leqq C$$

for C independent of ε. Hence, we have

$$\left|\int_0^T\int_\Omega (u-v)\psi\,dx\,dt\right| \leqq C\varepsilon^{1/2}\|u-v\|_{L^2(Q_T)}$$

for any $\psi \in C_0^\infty(Q_T)$, any $\varepsilon > 0$, which implies $u = v$ a.e. in Q_T.

As before, a solution for $u_0 \in L^2(\Omega)$ is possible.

THEOREM 3.2. *Let $F \in L^2(Q_T)$ and $u_0 \in L^2(\Omega)$. Then there exists a unique solution u to* (2)–(4), (6′); *moreover*

$$u \in L^\infty\big(L^2(\Omega)\big), \qquad f(u) \in L^2\big(H_0^1(\Omega)\big).$$

Proof. Again, take a sequence of $\{v_0^{(j)}\}$, $v_0^{(j)} \in H^1(\Omega)$, $v_0^{(j)} \to u_0$ in $L^2(\Omega)$.

4. Regularization. Consider the degenerate problem (2)–(4), (6′) and the associated regularization (14)–(16). What bounds, if any, can be placed on the errors $u - u^{(n)}$ and/or $f(u) - f_n(u^{(n)})$? In connection with numerical work for the Stefan problem, this question has been addressed before ([6], [7], [10]). The best estimates so far are ([6], [10]) $O(\varepsilon^{1/2})$ in $\|f(u) - f_\varepsilon(u^\varepsilon)\|_{L^2}$, where ε is the regularizing parameter ($f'(\xi) \geqq \varepsilon$). Here we generalize and improve upon some of these results.

For a given f satisfying (5) and (6′), define f_ε by

$$f_\varepsilon(\xi) = f(\xi) + e_\varepsilon(\xi),$$

where e_ε is continuous and such that

$$e_\varepsilon(0) = 0, \qquad f_\varepsilon'(\xi) \geqq \varepsilon \quad \text{for } \varepsilon < \varepsilon_0.$$

Let u^ε solve the corresponding problem (2)–(4). Then

THEOREM 5.1. *If $F \in L^2(Q_T)$ and $u_0 \in L^2(\Omega)$, then*

(i) $$\|u - u^\varepsilon\|_{L^2(L^2)} \leqq \varepsilon^{-1}\|e_\varepsilon(u)\|_{L^2(L^2)};$$

(ii) $$\|f(u) - f_\varepsilon(u^\varepsilon)\|_{L^2(L^2)} \leqq \big(1 + (\kappa/\varepsilon)^{1/2}\big)\|e_\varepsilon(u)\|_{L^2(L^2)}.$$

Proof. Let $E: H^{-1}(\Omega) \to H_0^1(\Omega)$ be the solution operator for the boundary value problem

$$-\Delta\varphi = \psi \quad \text{in } \Omega, \qquad \varphi = 0 \quad \text{on } \Gamma.$$

Then the PDE's can be written as

$$Eu_t^\varepsilon + f_\varepsilon(u^\varepsilon) = EF, \qquad u^\varepsilon(0) = u_0,$$
$$Eu_t + f(u) = EF, \qquad u(0) = u_0.$$

Subtract, multiply by $(u - u^\varepsilon)$, and integrate to get

$$\frac{1}{2}\|E^{1/2}(u - u^\varepsilon)\|_0^2(T) + \int_0^T\int_\Omega \big(u - u^\varepsilon, f(u) - f_\varepsilon(u^\varepsilon)\big)\,dx\,dt = 0,$$

hence

$$\int_0^T\int_\Omega \big(u - u^\varepsilon, f_\varepsilon(u) - f_\varepsilon(u^\varepsilon)\big)\,dx\,dt \leqq \int_0^T\int_\Omega e_\varepsilon(u)(u - u^\varepsilon)\,dx\,dt.$$

Thus, from (7), and the Schwarz inequality,

$$\varepsilon\|u-u^\varepsilon\|^2_{L^2(L^2)} \leqq \|e_\varepsilon(u)\|_{L^2(L^2)}\|u-u^\varepsilon\|_{L^2(L^2)},$$

which proves (i). Then, using (8),

$$\|f_\varepsilon(u)-f_\varepsilon(u^\varepsilon)\|^2_{L^2(L^2)} \leqq \kappa\|e_\varepsilon(u)\|_{L^2(L^2)}\|u-u^\varepsilon\|_{L^2(L^2)},$$

so

$$\|f_\varepsilon(u)-f_\varepsilon(u^\varepsilon)\|_{L^2(L^2)} \leqq \left(\frac{\kappa}{\varepsilon}\right)^{1/2}\|e(u)\|_{L^2(L^2)},$$

hence (ii) follows, using the triangle inequality.

The most obvious regularization is the global choice, $e_\varepsilon(u)=\varepsilon u$, for all u. In this case, Theorem 5.1 yields

$$\|f(u)-f_\varepsilon(u^\varepsilon)\|_{L^2(L^2)} = O(\varepsilon^{1/2})$$

for all ε, but only that $\|u-u^\varepsilon\|_{L^2(L^2)}$ is bounded.

On the other hand, for certain cases a regularization e_ε is possible which provides higher order convergence.

THEOREM 5.2. *Suppose that the following conditions hold for ε sufficiently small*:

(a) $\|e_\varepsilon(u)\|_{L^\infty(Q_T)} \leqq C\varepsilon$;

(b) $\mathrm{vol}(\mathrm{supp}\, e_\varepsilon(u)) \leqq C\varepsilon$.

Then, for ε sufficiently small:

(i) $\|u-u^\varepsilon\|_{L^2(L^2)} \leqq C\varepsilon^{1/2}$;

(ii) $\|f(u)-f_\varepsilon(u^\varepsilon)\|_{L^2(L^2)} \leqq C\varepsilon$.

Proof. Conditions (a) and (b) directly imply

$$\|e_\varepsilon(u)\|_{L^2(L^2)} \leqq C\varepsilon^{3/2},$$

from which both (i) and (ii) follow, using Theorem 5.1.

Consider, then, the Stefan problem in enthalpy form, in which case f has the general form

$$f(\xi)=\begin{cases}\xi+1, & 1\leqq\xi,\\ 0, & 0<\xi<1,\\ \xi, & \xi\leqq 0.\end{cases}$$

Define $e_\varepsilon(\xi)$ by

$$e_\varepsilon(\xi)=\begin{cases}0, & 1+\sqrt{\varepsilon}\leqq\xi,\\ \varepsilon-\sqrt{\varepsilon}(\xi-1), & 1\leqq\xi\leqq 1+\sqrt{\varepsilon},\\ \varepsilon\xi, & 0\leqq\xi\leqq 1,\\ 0, & \xi\leqq 0.\end{cases}$$

Clearly, Theorem 5.1 applies, with $\varepsilon_0=1$; moreover, condition (a) of Theorem 5.2 also holds.

Now suppose that the given problem also has a solution in the classical sense; for the Stefan problem this is the case under fairly mild and reasonable conditions on the data functions (see [4] and references therein). In this case, the degenerate region corresponds to the solid-liquid interface and hence has measure zero (it is an n-dimensional surface in $(n+1)$-space). Thus

$$\operatorname{vol}\{(x,t)|0 \leqq u(x,t) \leqq 1\} = 0.$$

But the degenerate region is very nearly the same as $\operatorname{supp} e_\varepsilon(u)$, and, in fact, as $\varepsilon \to 0$,

$$\operatorname{supp} e_\varepsilon(u) \to \{(x,t)|0 \leqq u \leqq 1\}.$$

Thus the hypothesis (b) of Theorem 5.2 becomes quite reasonable. This discussion then indicates that, for the classical Stefan problem, a regularization error that is $O(\varepsilon)$ is plausible although not yet rigorously established.

BIFURCATION IN DOUBLY-DIFFUSIVE SYSTEMS I. EQUILIBRIUM SOLUTIONS*

WAYNE NAGATA[†‡] AND JAMES W. THOMAS[†]

Abstract. The problem of the steady flow arising when a layer of fluid with a dissolved solute is heated from below is considered. The problem is placed in a functional analytic setting where bifurcation of convective solutions is proved and the stability of these bifurcating branches is studied.

Key words. doubly-diffusive systems, bifurcation, stability

1. Introduction. This paper studies steady convective flow that can arise when a layer of fluid with a dissolved solute is heated from below. The effect of a stabilizing solute gradient can be overcome by introducing a destabilizing temperature gradient, resulting in convective motions. Under some conditions these motions can correspond to steady cellular flow, as in the case of pure thermal (Bénard) convection. However, it is also possible for the convective motions to be periodic in time.

Double-diffusive convection was studied in 1965 by Veronis [19], who simplified a model describing two-dimensional cellular flow (rolls) into a system of coupled nonlinear ordinary differential equations. Numerical solutions of these equations showed both equilibrium and periodic solutions. Later, Huppert and Moore [7] numerically integrated the full partial differential equations describing rolls, and found equilibrium, periodic and aperiodic solutions. More recently, in 1981, Da Costa, Knobloch and Weiss [6] solved the system of ordinary differential equations of Veronis numerically and discovered further behavior-successive period doubling and apparently chaotic solutions.

The initial appearance of convective motion as the destabilizing temperature gradient is increased is suggested by a study of the linearized stability of the motionless conduction solution which is globally stable for small temperature gradients. If the thermal diffusivity of the fluid is greater than its solute diffusivity, we have the diagram shown in Fig. 1 for the linearized stability of the conduction solution in two-dimensional parameter space [7, p. 826]. The parameter r is proportional to the destabilizing temperature gradient and the parameter s is proportional to the stabilizing solute concentration gradient. In the region below the curve ACD, the spectrum of the linearization about the conduction solution lies in the negative complex half-plane, and hence the conduction solution is asymptotically stable with respect to small perturbations. In the region above the curve ACD, the linearization has part of its spectrum in the positive complex half-plane, and hence the conduction solution is unstable. From bifurcation theory, we expect to find nontrivial solutions corresponding to convective flows near the linearized stability boundary ACD: (i) on the open line segment AC, the linearization about the conduction solution has a zero eigenvalue; (ii) on the open line segment CD, the linearization about the conduction solution has two conjugate pure imaginary eigenvalues; (iii) at the point C, the linearization has a degenerate zero eigenvalue. Case (i) is associated with the appearance of steady convective motion, case

*Received by the editors May 10, 1983, and in revised form June 11, 1984.

(ii) is associated with the appearance of convective motion in which the flow reverses itself periodically in time, and case (iii) is associated with both types of convection interacting with each other. When the thermal diffusivity is less than or equal to the solute diffusivity, then the line CD in Fig. 1 is absent and the linearized stability boundary of the conduction solution consists of the line AB. In this case only steady convection can bifurcate from the conduction solutions.

The bifurcation of nontrivial equilibrium solutions corresponding to steady convection is similar to that which occurs in the Bénard problem which models a layer of fluid heated from below with no solute present. The existence and stability of bifurcating equilibrium solutions has been shown for the Bénard problem by several authors, for example [8], [9]. A review of bifurcations in fluid flow, including the Bénard problem, was given by Kirchgässner in [13].

In this paper we treat case (i). We first describe the mathematical model, which was also the basis of the numerical studies mentioned above. Then in §3 we formulate the problem in a function space setting and apply a theorem of Crandall and Rabinowitz [4] to prove the existence of bifurcating equilibrium solutions corresponding to two- and three-dimensional cellular convection. In §4 we compute the linearized stability of the bifurcating solutions. We find that the three-dimensional solutions can be stable under the same conditions which would make two-dimensional roll-like solutions unstable.

In later papers—Parts II (this issue, pp. 114–127) and III—we will treat case (ii), involving the bifurcation of periodic solutions, and case (iii), involving the interaction between bifurcating equilibrium and periodic solutions.

2. Formulation of the problem. In this section we describe how to obtain the system of partial differential equations which we will use and formulate the boundary conditions.

The double-diffusive convection equations. Consider an infinite horizontal layer of an incompressible fluid of uniform height h where the upper surface is maintained at a constant temperature T_1 and solute concentration S_1, while the lower surface is maintained at constant temperature T_0 and solute concentration S_0. We assume that $T_0 > T_1$ and $S_0 > S_1$. The equations governing the motion of the fluid are taken to be [19]

$$
\begin{aligned}
&\frac{\partial}{\partial t}\mathbf{U} + (\mathbf{U}\cdot\nabla)\mathbf{U} = -\frac{1}{\rho_0}(\nabla P + \rho g \mathbf{e}) + \nu\Delta\mathbf{U},\\
&\frac{\partial}{\partial t}T + (\mathbf{U}\cdot\nabla)T = \kappa_T \Delta T,\\
&\frac{\partial}{\partial t}S + (\mathbf{U}\cdot\nabla)S = \kappa_S \Delta S,\\
&\nabla\cdot\mathbf{U} = 0,
\end{aligned}
\tag{2.1}
$$

for $\mathbf{x} = (x, y, z)$ in $\mathbb{R}^2 \times (0, h)$ where

$\nabla = (\partial/\partial x, \partial/\partial y, \partial/\partial z)$ is the gradient operator, $\Delta = \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$ is the Laplacian operator,

$\mathbf{U} = (U, V, W)$ is the fluid velocity at $\mathbf{x}$,

T is the fluid temperature at $\mathbf{x}$,

S is the solute concentration at $\mathbf{x}$,

ρ is the fluid density at **x**,
ρ_0 is the fluid density at the lower surface $z=0$, assume to be constant,
P is the fluid pressure at **x**,
g is the acceleration due to gravity,
e is the unit vector $(0,0,1)$,
ν is the kinematic viscosity,
κ_T is the thermal diffusivity,
κ_S is the solute diffusivity.

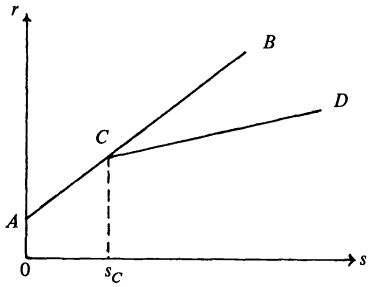

FIG. 1. *Linearized stability diagram for the conduction solution.*

We assume that the effects of the temperature and the solute appear only in the buoyancy force term $(\rho/\rho_0)g\mathbf{e}$, and that the fluid obeys an Oberbeck–Boussinesq equation of state

$$\rho=\rho_0[1-a(T-T_0)+b(S-S_0)], \tag{2.2}$$

where

$a=-\frac{1}{\rho}\frac{\partial\rho}{\partial T}$ is the thermal coefficient of volume expansion, assumed constant,

$b=\frac{1}{\rho}\frac{\partial\rho}{\partial S}$ is the solute coefficient of volume expansion, assumed constant.

We take ν, κ_T, κ_S to be constants, and we have the constant-gradient solution

$$\begin{aligned}
&\mathbf{U}^0=\mathbf{0},\\
&T^0=T_0-\left(\frac{T_0-T_1}{h}\right)z,\\
&S^0=S_0-\left(\frac{S_0-S_1}{h}\right)z,\\
&P^0=P_0-g\rho_0\left[z+\frac{a}{2}\left(\frac{T_0-T_1}{h}\right)z^2-\frac{b}{2}\left(\frac{S_0-S_1}{h}\right)z^2\right],
\end{aligned} \tag{2.3}$$

where P_0 is a constant. The solution (2.3) corresponds to pure conduction of heat and solute. We consider deviations from the conduction solution $\mathbf{u}=\mathbf{U}-\mathbf{U}^0$, $\theta=T-T^0$, $\zeta=S-S^0$, $p=P-P^0$. We also transform to dimensionless variables by making the

rescalings $\mathbf{x} \to h\mathbf{x}$, $t \to (h^2/\kappa_T)t$, $\mathbf{u} \to (\kappa_T/h)\mathbf{u}$, $\theta \to (T_0 - T_1)\theta$, $\zeta \to (S_0 - S_1)\zeta$, $p \to ((\rho_0 \nu \kappa_T)/h^2)p$. This leads to the dimensionless equations

$$
\begin{aligned}
&\frac{\partial}{\partial t}\mathbf{u} = \sigma(\Delta\mathbf{u} - \nabla p) + \sigma(r\theta - s\zeta)\mathbf{e} - (\mathbf{u}\cdot\nabla)\mathbf{u},\\
&\frac{\partial}{\partial t}\theta = \Delta\theta + w - (\mathbf{u}\cdot\nabla)\theta,\\
&\frac{\partial}{\partial t}\zeta = \tau\Delta\zeta + w - (\mathbf{u}\cdot\nabla)\zeta,\\
&\nabla\cdot\mathbf{u} = 0,
\end{aligned}
\tag{2.4}
$$

for $\mathbf{x} = (x, y, z)$ in the domain $\Omega_1 = \mathbb{R}^2 \times (0, 1)$, where $\mathbf{u} = (u, v, w)$ and

$$
r = \frac{ag(T_0 - T_1)h^3}{\kappa_T \nu}, \quad s = \frac{bg(S_0 - S_1)h^3}{\kappa_T \nu}, \quad \sigma = \frac{\nu}{\kappa_T}, \quad \tau = \frac{\kappa_S}{\kappa_T}.
$$

In the following sections we consider the system (2.4) with positive parameters r, s, σ and τ.

Boundary conditions. The upper and lower surfaces are maintained at constant temperatures and solute concentrations, so we must have

$$
\theta|_{z=0,1} = 0, \qquad \zeta|_{z=0,1} = 0 \tag{2.5}
$$

on the boundary of the domain. We assume that the fluid satisfies a stress-free condition on the boundary surfaces

$$
(\mathbf{u}\cdot\mathbf{N})|_{z=0,1} = 0, \qquad \left[\left(\nabla\mathbf{u} + (\nabla\mathbf{u})^T\right)\cdot\mathbf{N}\times\mathbf{N}\right]\Big|_{z=0,1} = 0,
$$

where $\mathbf{N}$ is the unit outward normal at a point on the boundary surface $(\nabla\mathbf{u})_{ij} = \partial u_i/\partial x_j$, and $(\cdot)^T$ denotes the matrix transpose. For the domain Ω_1 these conditions reduce to

$$
w|_{z=0,1} = 0, \quad \left.\frac{\partial u}{\partial z}\right|_{z=0,1} = 0, \quad \left.\frac{\partial v}{\partial z}\right|_{z=0,1} = 0. \tag{2.6}
$$

We note that the incompressibility condition $\nabla\cdot\mathbf{u} = 0$ and (2.6) together imply

$$
w|_{z=0,1} = \left.\frac{\partial^2 w}{\partial z^2}\right|_{z=0,1} = \left.\frac{\partial^4 w}{\partial z^4}\right|_{z=0,1} = \cdots = 0. \tag{2.7}
$$

Although these boundary conditions are difficult to approximate experimentally, they have the advantage that the eigenvalue problem for the linearization can be solved exactly.

Equations (2.4)–(2.6) comprise the problem which we study to find bifurcating nontrivial solutions. We observe that $\mathbf{u} = \mathbf{0}$, $\theta = 0$, $\zeta = 0$, $p =$ constant is always a solution of (2.4)–(2.6) for all positive values of the parameters r, s, σ and τ.

3. Bifurcation of equilibrium solutions. We begin this section by stating a theorem of Crandall and Rabinowitz which we will use to prove the existence of bifurcating equilibrium solutions of (2.4)–(2.6). We then examine the eigenvalue problem of the linearization to determine critical values of the parameters at which we expect to find bifurcations and set up the problem so that the critical (zero) eigenvalue is simple.

Finally, we define suitable function spaces and operators corresponding to the problem (2.4)–(2.6) and apply the bifurcation theorem.

The bifurcation theorem. Let us write (2.4)–(2.6) as a parameter-dependent evolution equation

$$\frac{du}{dt} = F(r,u) \tag{3.1}$$

in a suitable space of functions where s, σ and τ are considered fixed and the dependence of (3.1) on these parameters is suppressed. If $u=(\mathbf{u},\theta,\zeta)$, then $u\equiv 0$ is an equilibrium solution of (3.1) for all $r>0$. The following theorem gives conditions under which there exists a branch of nontrivial equilibrium solutions bifurcating from the trivial solution $u\equiv 0$; see [5, Lemma 1.1], proved in [4]. If L is a linear operator, we denote its null space by $N(L)$ and its range by $R(L)$.

THEOREM 1. *Let X and Y be real Banach spaces and let I be an open interval in $\mathbb{R}$. Suppose F: $I\times X\to Y$ is a C^{m+1} mapping with*

i) $F(r,0)=0$ *for all* $r\in I$,

ii) $\dim N(F_u(r_0,0)) = \operatorname{codim} R(F_u(r_0,0)) = 1$ *for some* $r_0\in I$,

iii) $F_{ru}(r_0,0)u_0 \notin R(F_u(r_0,0))$, *where* $N(F_u(r_0,0)) = \operatorname{span}\{u_0\}$.

Let Z be any complement of $\operatorname{span}\{u_0\}$ *in X. Then there exist an open interval I containing 0 and C^m functions r: $I\to\mathbb{R}$ and z: $I\to Z$ such that $r(0)=r_0$, $z(0)=0$ and if $u(\varepsilon)=\varepsilon u_0+\varepsilon z(\varepsilon)$, then $F(r(\varepsilon),u(\varepsilon))=0$ for all $\varepsilon\in I$. Moreover, the only nontrivial solutions of $F(r,u)=0$ near $(r_0,0)$ are of the form $(r(\varepsilon),u(\varepsilon))$ for some $\varepsilon\in I$.*

The eigenvalue problem for the linearization. To apply Theorem 1, we need to find function spaces X and Y such that zero is a simple eigenvalue of the Fréchet derivative $F_u(r_0,0)$. To this end, we first consider the eigenvalue problem for the linearization of (2.4)–(2.6):

$$\begin{aligned}
&\sigma(\Delta\mathbf{u}-\nabla p)+(r\sigma\theta-s\sigma\zeta)\mathbf{e}=\lambda\mathbf{u},\\
&\Delta\theta+w=\lambda\theta,\\
&\tau\Delta\zeta+w=\lambda\zeta,\\
&\nabla\cdot\mathbf{u}=0,\\
&\left.\frac{\partial u}{\partial z}\right|_{z=0,1} = \left.\frac{\partial v}{\partial z}\right|_{z=0,1} = w|_{z=0,1} = \theta|_{z=0,1} = \zeta|_{z=0,1} = 0.
\end{aligned} \tag{3.2}$$

As in the Bénard problem, we seek solutions corresponding to a regular pattern of convection cells. Since (2.4)–(2.6) and the domain Ω_1 are invariant under translations in the xy-plane, we can require that the fields $u=(u,\theta,\zeta)$ are doubly periodic in x and y:

$$u\left(x+\frac{2\pi}{\alpha},y,z\right) = u\left(x,y+\frac{2\pi}{\beta},z\right) = u(x,y,z) \quad \text{for all } \mathbf{x}\in\Omega_1, \tag{3.3}$$

for some nonnegative numbers α, β satisfying $\alpha^2+\beta^2\neq 0$. If we expand the fields in Fourier series

$$u(x,y,z) = \sum_{j,k=-\infty}^{\infty} u_{jk}(z)e^{i(j\alpha x+k\beta y)},\quad u_{-j,-k}(z)=\overline{u_{jk}(z)}, \tag{3.4}$$

and substitute (3.4) into (3.2), we obtain an infinite system of ordinary differential equations

$$
\begin{aligned}
&L_{jk}u_{jk} - ij\alpha p_{jk} = \sigma^{-1}\lambda u_{jk},\\
&L_{jk}v_{jk} - ik\beta p_{jk} = \sigma^{-1}\lambda v_{jk},\\
&L_{jk}w_{jk} - p^{*}_{jk} + r\theta_{jk} - s\zeta_{jk} = \sigma^{-1}\lambda w_{jk},\\
&L_{jk}\theta_{jk} + w_{jk} = \lambda\theta_{jk},\\
&\tau L_{jk}\zeta_{jk} + w_{jk} = \lambda\zeta_{jk},\\
&ij\alpha u_{jk} + ik\beta v_{jk} + w'_{jk} = 0,\\
&u'_{jk}\big|_{z=0,1} = v'_{jk}\big|_{z=0,1} = w_{jk}\big|_{z=0,1} = \theta_{jk}\big|_{z=0,1} = \zeta_{jk}\big|_{z=0,1} = 0
\end{aligned}
\tag{3.5}
$$

for each $(j,k)\in\mathbb{Z}\times\mathbb{Z}$, where $' = d/dz$, $L_{jk} = d^2/dz^2 - \omega_{jk}^2$ and $\omega_{jk}^2 = j^2\alpha^2 + k^2\beta^2$. These equations can be reduced to a single equation for $w_{jk}(z)$,

$$
\begin{aligned}
&\left[(\tau L_{jk}-\lambda)(L_{jk}-\lambda)(L_{jk}-\sigma^{-1}\lambda)L_{jk} + \omega_{jk}^2 r(\tau L_{jk}-\lambda) - \omega_{jk}^2 s(L_{jk}-\lambda)\right] w_{jk} = 0,\\
&w_{jk}\big|_{z=0,1} = w''_{jk}\big|_{z=0,1} = w^{(4)}_{jk}\big|_{z=0,1} = w^{(6)}_{jk}\big|_{z=0,1} = 0
\end{aligned}
\tag{3.6}
$$

for each $(j,k)\in\mathbb{Z}\times\mathbb{Z}$. Because of the boundary conditions, we can expand $w_{jk}(z)$ in a Fourier sine series

$$
w_{jk}(z) = \sum_{l=1}^{\infty} w_{jkl}\sin l\pi z \tag{3.7}
$$

for each $(j,k)\in\mathbb{Z}\times\mathbb{Z}$. Substituting (3.7) into (3.6), we obtain an algebraic equation for λ

(3.8)

$$
\lambda^3 + (\sigma+\tau+1)\gamma_{jkl}^2\lambda^2 + \left[(\sigma+\tau+\sigma\tau)\gamma_{jkl}^4 - \sigma\omega_{jk}^2\gamma_{jkl}^{-2}(r-s)\right]\lambda + \sigma\tau\gamma_{jkl}^6 + \sigma\omega_{jk}^2(s-\tau r) = 0
$$

for each $(j,k)\in\mathbb{Z}\times\mathbb{Z}$ and $l = 1,2,\cdots$, where $\gamma_{jkl}^2 = \omega_{jk}^2 + l^2\pi^2$. Thus the eigenvalues λ of the problem (3.2)–(3.3) are the roots of the cubic polynomials (3.8).

The location of the roots of (3.8) was studied by Baines and Gill [2], and a convenient summary is presented in [7, §2]. For certain values of r, s, σ and τ both zero and purely imaginary roots of (3.8) occur. For now we only need the fact that $\lambda = 0$ is a root of (3.8) if and only if

$$
r = \frac{s}{\tau} + \frac{\left(\omega_{jk}^2 + l^2\pi^2\right)^3}{\omega_{jk}^2} \tag{3.9}
$$

for each $(j,k)\in\mathbb{Z}\times\mathbb{Z}$. Furthermore, $\lambda = 0$ is a simple root of (3.8) provided $\tau \geqq 1$, or if $0 < \tau < 1$ and

$$
s \neq \frac{\tau^2(\sigma+1)\gamma_{jkl}^6}{\sigma(1-\tau)\omega_{jk}^2}. \tag{3.10}
$$

The case $\tau > 1$ corresponds to interchanging the roles of heat and solute to the case in which the temperature gradient is stabilizing and the solute gradient is destabilizing. This is the "fingering" regime. In the rest of this paper, we will restrict τ to $0 < \tau < 1$, the "diffusive" regime.

To determine the multiplicity of $\lambda = 0$ as an eigenvalue of (3.2)–(3.3), we note that for $\lambda = 0$ the boundary-value problem (3.6) reduces to

$$\left[L_{jk}^3 + \omega_{jk}^2\left(r - \frac{s}{\tau}\right)\right] w_{jk} = 0, \tag{3.11}$$
$$w_{jk}|_{z=0,1} = w_{jk}^{(2)}|_{z=0,1} = w_{jk}^{(4)}|_{z=0,1} = 0$$

for each $(j,k) \in \mathbb{Z} \times \mathbb{Z}$. Then (3.11) is equivalent to the integral equation

$$w_{jk}(z) = \mu_{jk} \int_0^1 K_{jk}(z,\hat{z}) w_{jk}(\hat{z})\, d\hat{z} \tag{3.11'}$$

for each (j,k) where $\mu_{jk} = \omega_{jk}^2(r - s/\tau)$, $K_{jk}(z,\hat{z})$ is the composition $K_{jk} = G_{jk} \circ G_{jk} \circ G_{jk}$, and $G_{jk}(z,\hat{z})$ is the Green's function for the regular Sturm–Liouville operator $(-L_{jk})$ defined by

$$(-L_{jk}) w_{jk} = \left(-\frac{d^2}{dz^2} + \omega_{jk}^2\right) w_{jk}, \qquad w_{jk}|_{z=0,1} = 0.$$

Since $(-L_{jk})$ has a positive spectrum, G_{jk} is an oscillating kernel [11, p. 538]. The composition K_{jk} of oscillating kernels is also an oscillating kernel, and one of the consequences of the theory of oscillating kernels is that the eigenvalues of the integral equation (3.11′) are simple and satisfy

$$0 < \mu_{jk1} < \mu_{jk2} < \cdots \to \infty$$

for each $(j,k) \in \mathbb{Z} \times \mathbb{Z}$ [10, Vol. I, pp. 251–255]. In fact, we have

$$\mu_{jkl} = \left(\omega_{jk}^2 + l^2\pi^2\right)^3, \qquad l = 1,2,\cdots \tag{3.12}$$

for each $(j,k) \in \mathbb{Z} \times \mathbb{Z}$. Hence, the smallest eigenvalue of (3.11) corresponds to $l = 1$. Now, $r = r(\omega_{jk}^2)$ given by (3.9) is a convex function of ω_{jk}^2 with a unique minimum when $l = 1$ at $\omega_{jk}^2 = \pi^2/2$, for which

$$r\left(\frac{\pi^2}{2}\right) = r_0 \equiv \frac{s}{\tau} + \frac{27\pi^4}{4}. \tag{3.13}$$

Thus $r = r_0$ is the smallest possible value for r which $\lambda = 0$ is an eigenvalue of (3.2)–(3.3). Moreover, this value of r corresponds to a one-dimensional subspace of nontrivial solutions of the integral equation (3.11) and hence of the system (3.5) for each (j,k) such that $\omega_{jk}^2 = \pi^2/2$ (see [9] or [17] for the application of oscillating kernel theory to the Bénard problem).

If we choose α and β such that

$$\alpha^2 + \beta^2 = \frac{\pi^2}{2}, \tag{3.14}$$

then the multiplicity of $\lambda = 0$ as an eigenvalue of (3.2)–(3.3) is equal to the number of grid points $(j,k) \in \mathbb{Z} \times \mathbb{Z}$ on the ellipse $x^2\alpha^2 + y^2\beta^2 = \pi^2/2$ in the xy-plane. This number is at least four if both α and β are nonzero, or two if either α or β vanishes. Thus, to ensure that $\lambda = 0$ is a simple eigenvalue of (3.2)–(3.3), we must further restrict the space of allowable solutions.

If we require that the solutions of (3.2)–(3.3) are covariant with respect to rotations in the xy-plane,

$$\mathbf{u}(g\mathbf{x}) = g\mathbf{u}(\mathbf{x}), \qquad (\theta,\zeta,p)(g\mathbf{x}) = (\theta,\zeta,p)(\mathbf{x}) \tag{3.15}$$

for all $x \in \Omega_1$ where g is a rotation of the form

$$g = \begin{bmatrix} \cos & -\sin\phi & 0 \\ \sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{bmatrix}, \qquad 0 \leqq \phi < 2\pi,$$

then the only possible ϕ for which there are nontrivial solutions of (3.2) also satisfying (3.3) are integer multiples of $\phi = 2\pi/k$, $k = 1,2,3,4$ or 6 [14]. We consider four cases which yield function spaces, with respect to which $\lambda = 0$ is a simple eigenvalue of (3.2)–(3.3) (consult [13] for details).

a) *Rolls.* We take $\alpha^2 = \pi^2/2$, $\beta^2 = 0$ in (3.3), and $\phi = \pi$ in (3.15). The flow is two-dimensional with $\mathbf{u}(\mathbf{x}) = (u(x,z), w(x,z))$. Rolls admit a Fourier series expansion of the form

$$u(x,z) = \sum_{j=0}^{\infty} \begin{bmatrix} u_j(z)\sin j\alpha x \\ w_j(z)\cos j\alpha x \\ \theta_j(z)\cos j\alpha x \\ \zeta_j(z)\cos j\alpha x \end{bmatrix} \tag{3.16}$$

and the eigenspace of roll-like solutions of (3.2)–(3.3) for $\lambda = 0$ when $r = r_0$ is the span of

$$u_0(x,z) = \begin{bmatrix} -\dfrac{2\alpha}{\pi}\sin\alpha x\cos\pi z \\ \cos\alpha x\sin\pi z \\ \dfrac{2}{3\pi^2}\cos\alpha x\sin\pi z \\ \dfrac{2}{3\pi^2\tau}\cos\alpha x\sin\pi z \end{bmatrix}. \tag{3.17}$$

b) *Rectangles.* We take $\alpha^2 + \beta^2 = \pi^2/2$, $\alpha, \beta > 0$, $\beta \neq \sqrt{m^2 - 1}\,\alpha$ for all $m \in \mathbb{N}$ in (3.3), and $\phi = \pi$ in (3.15). In addition, we require the invariance of $w(x,y,z)$ under the reflection $y \to -y$. Rectangles admit a Fourier series expansion of the form (cf. [17])

$$u(x,y,z) = \sum_{j,k=0}^{\infty} \begin{bmatrix} u_{jk}(z)\sin j\alpha x\cos k\beta y \\ v_{jk}(z)\cos j\alpha x\sin k\beta y \\ w_{jk}(z)\cos j\alpha x\cos k\beta y \\ \theta_{jk}(z)\cos j\alpha x\cos k\beta y \\ \zeta_{jk}(z)\cos j\alpha x\cos k\beta y \end{bmatrix}, \tag{3.18}$$

and the eigenspace of rectangular solutions of (3.2)–(3.3) for $\lambda=0$ when $r=r_0$ is the span of

$$u_0(x,y,z)=\begin{bmatrix} -\frac{2\alpha}{\pi}\sin\alpha x\cos\beta y\cos\pi z \\ -\frac{2\beta}{\pi}\cos\alpha x\sin\beta y\cos\pi z \\ \cos\alpha x\cos\beta y\sin\pi z \\ \frac{2}{3\pi^2}\cos\alpha x\cos\beta y\sin\pi z \\ \frac{2}{3\pi^2\tau}\cos\alpha x\cos\beta y\sin\pi z \end{bmatrix}, \tag{3.19}$$

c) *Squares.* We take $\alpha^2=\pi^2/4$, $\beta=\alpha$ in (3.3), and $\phi=\pi/2$ in (3.15). Then the Fourier series expansion and eigenfunction are as for rectangles, with $\beta=\alpha$.

d) *Hexagons.* Take $\alpha^2=\pi^2/8$, $\beta=\sqrt{3}\,\alpha$ in (3.3) and $\phi=2\pi/3$ in (3.15). In addition, $w(x,y,z)$ is required to be invariant under $y\to -y$. Hexagons admit a Fourier series expansion of the form (cf. [9])

$$\begin{aligned} \mathbf{u}(x,y,z)&=\frac{1}{3}\sum\left\{\mathbf{u}(j,z)e^{i\alpha(\hat{j}\cdot\hat{x})}+g^{-1}\mathbf{u}(\hat{j},z)e^{i\alpha(\hat{j}\cdot\hat{g}\hat{x})}+g\mathbf{u}(\hat{j},z)e^{i\alpha(\hat{j}\cdot\hat{g}^{-1}\hat{x})}\right\}, \\ \begin{bmatrix}\theta(x,y,z)\\ \zeta(x,y,z)\end{bmatrix}&=\frac{1}{3}\sum\begin{bmatrix}\theta(\hat{j},z)\\ \zeta(\hat{j},z)\end{bmatrix}\left\{e^{i\alpha(\hat{j}\cdot\hat{x})}+e^{i\alpha(\hat{j}\cdot\hat{g}\hat{x})}+e^{i\alpha(\hat{j}\cdot\hat{g}^{-1}\hat{x})}\right\}, \end{aligned} \tag{3.20}$$

where $\hat{j}=(j,\sqrt{3}\,k)$, the sums are over all j, k either both even or both odd, $\hat{x}=(x,y)$,

$$g=\left[\begin{array}{ccc} & \hat{g} & \begin{matrix}0\\ \\ 0\end{matrix} \\ \hline 0 & 0 & 1 \end{array}\right],$$

$\mathbf{u}(\hat{g}\hat{j},z)=g\mathbf{u}(\hat{j},z)$ and $(\theta,\zeta)(\hat{g}\hat{j},z)=(\theta,\zeta)(\hat{j},z)$ for all admissible $\hat{j}$, and the eigenspace of hexagonal eigenfunctions for $\lambda=0$ when $r=r_0$ is the span of

$$u_0(x,y,z)=\left\{\begin{bmatrix} \frac{i\pi}{4\alpha} \\ \frac{i\sqrt{3}\,\pi}{4\alpha} \\ 1 \\ \frac{2}{3\pi^2} \\ \frac{2}{3\pi^2\tau}\end{bmatrix}e^{i\alpha(x+\sqrt{3}y)}+\begin{bmatrix} \frac{i\pi}{4\alpha} \\ -\frac{i\sqrt{3}\,\pi}{4\alpha} \\ 1 \\ \frac{2}{3\pi^2} \\ \frac{2}{3\pi^2\tau}\end{bmatrix}e^{i\alpha(x-\sqrt{3}y)}+\begin{bmatrix} -\frac{i\pi}{2\alpha} \\ 0 \\ 1 \\ \frac{2}{3\pi^2} \\ \frac{2}{3\pi^2\tau}\end{bmatrix}e^{-i2\alpha x}+\text{c.c.}\right\}, \tag{3.21}$$

where c.c. denotes the complex conjugates of the preceding terms.

In each of the above cases a)–d), we say that a function *admits periodicity* Ω if it satisfies the symmetries corresponding to each of the cellular flows a)–d). Such functions are spatially periodic, with fundamental domain of spatial periodicity Ω. For rolls,

$$\Omega = \left\{ (x,z) : 0 < x < \frac{2\pi}{\alpha},\ 0 < z < 1 \right\};$$

for rectangles and squares,

$$\Omega = \left\{ (x,y,z) : 0 < x < \frac{2\pi}{\alpha},\ 0 < y < \frac{2\pi}{\beta},\ 0 < z < 1 \right\};$$

for hexagons, $\Omega = C \times (0,1)$, where C is the region in $\mathbb{R}^2$ enclosed by the six lines $y = \pm\pi/\sqrt{3}\,\alpha$, $y + \sqrt{3}\,x = \pm 2\pi/\sqrt{3}\,\alpha$, $y - \sqrt{3}\,x = \pm 2\pi/\sqrt{3}\,\alpha$ in Fig. 2.

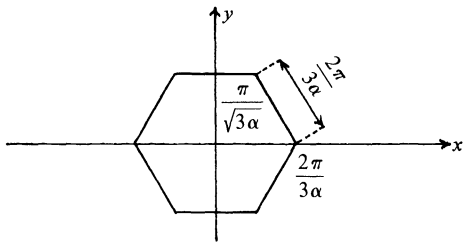

FIG. 2. *The region C.*

The adjoint problem. Integration by parts yields the adjoint eigenvalue problem to (3.2),

$$\begin{aligned}
&\sigma(\Delta \mathbf{u}^* - \nabla p^*) + (\theta^* + \zeta^*)\mathbf{e} = \bar{\lambda}\mathbf{u}^*, \\
&\Delta\theta^* + r\sigma w^* = \bar{\lambda}\theta^*, \\
&\tau\Delta\zeta^* - s\sigma w^* = \bar{\lambda}\zeta^*, \\
&\nabla \cdot \mathbf{u}^* = 0, \\
&\left.\frac{\partial u^*}{\partial z}\right|_{z=0,1} = \left.\frac{\partial v^*}{\partial z}\right|_{z=0,1} = w^*|_{z=0,1} = \theta^*|_{z=0,1} = \zeta^*|_{z=0,1} = 0.
\end{aligned} \tag{3.22}$$

We observe that $(\mathbf{u}_0, p_0, \theta_0, \zeta_0)$ solves (3.2) when $r = r_0$ and $\lambda = 0$ if and only if $(\mathbf{u}_0^*, p_0^*, \theta_0^*, \zeta_0^*) = N(\mathbf{u}_0, p_0, r_0\sigma\theta_0, -s\sigma\zeta_0)$, $N \neq 0$ solves (3.22) when $r = r_0$ and $\bar{\lambda} = 0$. Thus for each of the cellular flows a)–d) the adjoint problem (3.22) also has a one-dimensional null space.

Abstract formulation. Let $n = 2$ (for rolls), or 3 (for rectangles, squares or hexagons) and let $\Omega \in \mathbb{R}^n$ be the fundamental domain of spatial periodicity for functions admitting periodicity Ω. Also, let $\Omega_1 = \mathbb{R}^{n-1} \times (0,1)$, and define the following vector spaces of smooth functions from $\bar{\Omega}$ or Ω into $\mathbb{R}^m$

$$C^{\infty,\#}(\bar{\Omega}, \mathbb{R}^m) = \left\{ u \in C^\infty(\bar{\Omega}_1, \mathbb{R}^m) : u \text{ admits periodicity } \Omega \right\},$$

$$C_0^{\infty,\#}(\Omega, \mathbb{R}^m) = \left\{ u \in C^\infty(\Omega_1, \mathbb{R}^m) : u \text{ admits periodicity } \Omega,\ \operatorname{supp} u \subset \Omega_1 \right\},$$

for $m = 1, 2, \cdots$, and

$$\mathscr{J} = \left\{ \mathbf{u} \in C_0^{\infty,\#}(\Omega, \mathbb{R}^n) : \nabla \cdot \mathbf{u} = 0 \right\},$$

$$\mathscr{V} = \left\{ \mathbf{u} \in C^{\infty,\#}(\bar{\Omega}, \mathbb{R}^n) : \nabla \cdot \mathbf{u} = 0,\ (\mathbf{u} \cdot \mathbf{N})|_{z=0,1} = 0 \right\},$$

$$\mathscr{W} = \mathscr{V} \times C_0^{\infty,\#}(\Omega, \mathbb{R}^2),$$

where $\mathbf{N}$ is the unit outward normal vector on the boundary $z=0,1$. We define the Hilbert spaces

$H^0(\Omega,\mathbb{R}^m)=$ the completion of $C_0^{\infty,\#}(\Omega,\mathbb{R}^m)$ in the norm $\|\cdot\|_0$ associated with the inner product $(u,v)_0=\sum_{i=1}^m \int_\Omega u_i v_i dx$,

$H^k(\Omega,\mathbb{R}^m)=$ the completion of $C^{\infty,\#}(\bar{\Omega},\mathbb{R}^m)$ in the norm $\|\cdot\|_k$ associated with the inner product $(u,v)_k=\sum_{i=1}^m \sum_{|\nu|\le k} \int_\Omega D^\nu u_i D^\nu v_i dx$,

where $k=1,2,\cdots,\nu=(\nu_1,\cdots,\nu_n)$ is an n-tuple of nonnegative integers, D^ν is the partial derivative $\partial^{|\nu|}/\partial x_1^{\nu_1}\cdots\partial x_n^{\nu_n}$ of order $|\nu|=\nu_1+\cdots+\nu_n$,

$H_0^k(\Omega,\mathbb{R}^m)=$ the closure of $C_0^{\infty,\#}(\Omega,\mathbb{R}^m)$ in $H^k(\Omega,\mathbb{R}^m)$,

$J=$ the closure of $\mathscr{J}$ in $H^0(\Omega,\mathbb{R}^n)$,

$V=$ the closure of $\mathscr{V}$ in $H^1(\Omega,\mathbb{R}^n)$,

$W=$ the closure of $\mathscr{W}$ in $H^1(\Omega,\mathbb{R}^{n+2})$.

We note that $W=V\times H_0^1(\Omega,\mathbb{R})\times H_0^1(\Omega,\mathbb{R})$, and that $\mathscr{V}$ is dense in J. Finally we define the following Hilbert spaces

$$X=\left\{u=(\mathbf{u},\theta,\zeta)\in W\cap H^2(\Omega,\mathbb{R}^{n+2}):\ \left.\frac{\partial u}{\partial z}\right|_{z=0,1}=\left.\frac{\partial v}{\partial z}\right|_{z=0,1}=0\right\},$$

$$Y=J\times H^0(\Omega,\mathbb{R})\times H^0(\Omega,\mathbb{R})$$

where $\partial u/\partial z|_{z=0,1}=\gamma_{\mathbf{N}}(\nabla u)$ and $\gamma_{\mathbf{N}}$ is the trace operator extending $\gamma_{\mathbf{N}}\mathbf{u}=(\mathbf{u}\cdot\mathbf{N})|_{z=0,1}$ defined for smooth vector fields $\mathbf{u}$ [18].

We have the following properties [8]:

a) $H^0(\Omega,\mathbb{R}^n)=J\oplus J^\perp$, the topological direct sum of closed subspaces, where $J^\perp$ is the orthogonal complement of J in $H^0(\Omega,\mathbb{R}^n)$,

$$J^\perp=\{\nabla p: p\in H^1(\Omega,\mathbb{R})\}.$$

b) If Π denotes the orthogonal projection of $H^0(\Omega,\mathbb{R}^n)$ onto J, then Π is a bounded linear mapping from $H^k(\Omega,\mathbb{R}^n)$ into $H^k(\Omega,\mathbb{R}^n)\cap J$ for $k=0,1,2,\cdots$. We use Π to eliminate the pressure term in the equations, and formulate (2.6) as

$$\begin{aligned}\frac{d}{dt}\mathbf{u}&=\sigma\Pi[\Delta\mathbf{u}+(r\theta-s\zeta)\mathbf{e}]-\Pi(\mathbf{u}\cdot\nabla)\mathbf{u},\\ \frac{d}{dt}\theta&=\Delta\theta+w-\mathbf{u}\cdot\nabla\theta,\\ \frac{d}{dt}\zeta&=\tau\Delta\zeta+w-\mathbf{u}\cdot\nabla\zeta,\end{aligned}\tag{3.23}$$

for $(\mathbf{u},\theta,\zeta)\in X$. If we define

$$L(r)u=(\sigma\Pi[\Delta\mathbf{u}+(r\theta-s\zeta)\mathbf{e}],\ \Delta\theta+w,\ \tau\Delta\zeta+w)\tag{3.24}$$

for $u=(\mathbf{u},\theta,\zeta)\in X$ and $r>0$, then $L(r)$ is a bounded linear mapping from X into Y for all $r>0$. Define

$$M(u_1,u_2)=(-\Pi(\mathbf{u}_1\cdot\nabla)\mathbf{u}_2,\ -\mathbf{u}_1\cdot\nabla\theta_2,\ -\mathbf{u}_1\cdot\nabla\zeta_2)\tag{3.25}$$

for $u_i=(\mathbf{u}_i,\theta_i,\zeta_i)\in X$, $i=1,2$. Then M is a bounded bilinear mapping from $X\times X$ into Y [8].

We now let $F:(0,\infty)\times X\to Y$ be defined by

$$F(r,u)=L(r)u+M(u,u). \tag{3.26}$$

Then F is analytic, $F(r,0)=0$ for all $r\in(0,\infty)$, $F_u(r,0)=L(r)$ for all $r\in(0,\infty)$ and the null space $N(L(r_0))$ is a one-dimensional subspace of the space X of functions admitting periodicity Ω for each choice of Ω. To show that the range $R(L(r_0))$ has codimension one, we use the following lemma, which is proved in the appendix.

LEMMA 1. $R(L(r_0))=N(L(r_0)^*)^{\perp}$.

Since the adjoint problem has a one-dimensional null space $N(L(r_0)^*)$, we now have satisfied all the hypotheses of Theorem 1 except (iii). To verify this last hypothesis, it suffices to check that

$$\left(\Pi(\theta_0\mathbf{e}),u_0^*\right)_J\neq 0, \tag{3.27}$$

where $(\mathbf{u}_0,\theta_0,\zeta_0)$ spans $N(L(r_0))$ and $(\mathbf{u}_0^*,\theta_0^*,\zeta_0^*)=(\sigma^{-1}\mathbf{u}_0,\mathrm{r}_0\theta_0,-\mathrm{s}\zeta_0)$ spans $N(L(r_0)^*)$. Since $\mathbf{u}_0^*\in J$, and hence $\nabla\cdot\mathbf{u}_0^*=0$, (3.27) is equivalent to

$$\int_\Omega\theta_0 w_0\,dx\neq 0. \tag{3.28}$$

Since $w_0=-\Delta\theta_0$, θ_0 satisfies periodicity Ω, and $\theta_0|_{z=0,1}=0$, we have $\int_\Omega\theta_0 w_0\,dx=\int_\Omega|\nabla\theta_0|^2\,dx>0$, and hence (3.28) is satisfied for each cellular structure: rolls, rectangles, squares or hexagons.

Finally, we take $Z=N(L(r_0))^{\perp}$. Then Theorem 1 establishes the existence of a bifurcating curve $(r(\varepsilon),u(\varepsilon))$ of nontrivial equilibrium solutions near $(r_0,0)$. For each cellular structure, the bifurcation point corresponds to the same critical value r_0 given by (3.13).

4. Linearized stability of the bifurcating solutions. In this section we investigate the linearized stability of the bifurcating branch of nontrivial equilibrium solutions $(r(\varepsilon),u(\varepsilon))$, whose existence was proven in §3. This bifurcating solution is stable (resp. unstable) in the linearized sense if the small real eigenvalue $\tilde\lambda(\varepsilon)$ of the linearization $F_u(r(\varepsilon),u(\varepsilon))$ is negative (resp. positive) near $\varepsilon=0$. For Navier–Stokes type systems such as the one we use, Iooss [8] has shown that linearized stability implies the asymptotic stability of $u(\varepsilon)$ with respect to small initial perturbations.

We first summarize the linearized stability theory of Crandall and Rabinowitz [5] and then indicate how to use power series expansions to determine the sign of $\tilde\lambda(\varepsilon)$ near $\varepsilon=0$. We then present the results of our calculations.

Linearized stability. Before stating the main theorem on linearized stability, we first define the concept of a K-simple eigenvalue.

DEFINITION. Let X and Y be real Banach spaces, and let $L,K\in\mathcal{B}(X,Y)$. Then $\lambda\in\mathbb{R}$ is a *K-simple eigenvalue* of L if

i) $\dim N(L-\lambda K)=\operatorname{codim}R(L-\lambda K)=1$, and

ii) $Ku_0\notin R(L-\lambda K)$, where $N(L-\lambda K)=\operatorname{span}\{u_0\}$.

The following result shows that the simple zero eigenvalues of $F_u(r_0,0)$ in Theorem 1 are associated with a small eigenvalue $\tilde\lambda(\varepsilon)$ of the linearization $F_u(r(\varepsilon),u(\varepsilon))$ about the bifurcating branch. Let F, Z, u_0 be as in Theorem 1 and let $r(\varepsilon)$, $u(\varepsilon)=\varepsilon u_0+\varepsilon z(\varepsilon)$ be as supplied by the theorem.

LEMMA 2. [5, p. 165]. *Let $K\in\mathcal{B}(X,Y)$ and suppose zero is a K-simple eigenvalue of $F_u(r,0)$. Then there exist open intervals $\hat{\mathscr{I}},\hat{\mathscr{J}}$ with $r_0\in\hat{\mathscr{I}}$, $D\in\hat{\mathscr{J}}$ and smooth functions*

$$\lambda:\hat{\mathscr{I}}\to\mathbb{R},\quad\tilde\lambda:\hat{\mathscr{J}}\to\mathbb{R},\quad v:\hat{\mathscr{I}}\to X,\quad\tilde v:\hat{\mathscr{J}}\to X$$

such that

$$F_u(r,0)v(r)=\lambda(r)Kv(r) \quad \text{for } r\in\hat{\mathscr{I}},$$
$$F_u(r(\varepsilon),u(\varepsilon))\tilde{v}(\varepsilon)=\tilde{\lambda}(\varepsilon)K\tilde{v}(\varepsilon) \quad \text{for } \varepsilon\in\hat{\mathscr{I}}.$$

Moreover, $\lambda(r_0)=\tilde{\lambda}(0)=0$, $v(r_0)=\tilde{v}(0)=u_0$, $v(r)-u_0\in Z$, $\tilde{v}(\varepsilon)-u_0\in Z$.

The main result of [5] is Theorem 1.16.

THEOREM 2 [5, p. 165]. *Let the assumptions of Theorem* 1 *and Lemma* 2 *hold, and let* λ, $\tilde{\lambda}$ *be the functions supplied by Lemma* 2. *Then* $\lambda'(r_0)\neq 0$ *and*

$$\lim_{\substack{\varepsilon\to 0\\ \tilde{\lambda}(\varepsilon)\neq 0}}\left[-\frac{\varepsilon r'(\varepsilon)\lambda'(r_0)}{\tilde{\lambda}(\varepsilon)}\right]=1.$$

Moreover, there is a constant C *such that* $\|u'(\varepsilon)-\tilde{v}(\varepsilon)\|\leqq C\min\{|\varepsilon r'(\varepsilon)|, |\tilde{\lambda}(\varepsilon)|\}$ *near* $\varepsilon=0$.

In what follows we take K to be the continuous injection of X into Y, $Ku=u$. By Theorem 2, the sign of $\tilde{\lambda}(\varepsilon)$ near $\varepsilon=0$ is the same as the sign of $-\varepsilon r'(\varepsilon)\lambda'(r_0)$ near $\varepsilon=0$, provided $\tilde{\lambda}(\varepsilon)\neq 0$. To determine the sign of $-\varepsilon r'(\varepsilon)\lambda'(r_0)$, we use power series expansions.

Power series expansions. Since $F(r,u)$ is analytic in r and u, we can expand $r(\varepsilon)$ and $u(\varepsilon)$ in power series

$$\begin{aligned} r(\varepsilon)&=r_0+\varepsilon r_1+\varepsilon^2 r_2+\cdots,\\ u(\varepsilon)&=\varepsilon(u_0+\varepsilon u_1+\cdots). \end{aligned} \tag{4.1}$$

Substituting the power series (4.1) into $F(r(\varepsilon), u(\varepsilon))=0$, taking the inner product with u_0^* and collecting terms we obtain at order ε^2

$$r_1=-\frac{\big(M(u_0,u_0),u_0^*\big)}{\big(F_{ru}(r_0,0)u_0,u_0^*\big)}. \tag{4.2}$$

If $r_1=0$, then at order ε^3 we get

$$r_2=-\frac{\big(M(u_0,u_1)+M(u_1,u_0),u_0^*\big)}{\big(F_{ru}(r_0,0)u_0,u_0^*\big)}, \tag{4.3}$$

where $F_u(r_0,0)u_1=-M(u_0,u_0)$. If $r_2\neq 0$, then $\tilde{\lambda}(\varepsilon)\neq 0$ near $\varepsilon=0$ (expand $\tilde{\lambda}(\varepsilon)=\varepsilon\tilde{\lambda}_1+\varepsilon^2\tilde{\lambda}_2+\cdots$, $\tilde{v}(\varepsilon)=u_0+\varepsilon\tilde{v}_1+\cdots$ and substitute into $F_u(r(\varepsilon),u(\varepsilon))\tilde{v}(\varepsilon)=\tilde{\lambda}(\varepsilon)u(\varepsilon)$) and by Theorem 2, $\tilde{\lambda}(\varepsilon)$ has the same sign as $-r_2\lambda'(r_0)$ near $\varepsilon=0$.

Differentiating the equation $F_u(r,0)v(r)=\lambda(r)v(r)$ with respect to r, evaluating at $r=r_0$ and then taking the inner product with u_0^*, we obtain

$$\big(F_{ru}(r_0,0)u_0,u_0^*\big)=\lambda'(r_0)\big(u_0,u_0^*\big). \tag{4.4}$$

In §3 we determined that the left-hand side of (4.4) was strictly positive, and hence the sign of $\lambda'(r_0)$ is the same as the sign of (u_0,u_0^*) provided $(u_0,u_0^*)\neq 0$. For each cellular structure, simple computations show that

$$\begin{aligned} &\big(u_0,u_0^*\big)>0 \quad \text{if } 0<\tau<1 \text{ and } 0<s<s_C,\\ &\big(u_0,u_0^*\big)=0 \quad \text{if } 0<\tau<1 \text{ and } s=s_C,\\ &\big(u_0,u_0^*\big)<0 \quad \text{if } 0<\tau<1 \text{ and } s>s_C, \end{aligned} \tag{4.5}$$

where

$$s_C = \frac{27\pi^4}{4}\left(\frac{\tau^2}{1-\tau}\right)\left(1+\frac{1}{\sigma}\right)$$

(cf. (3.10)). If $0<\tau<1$ and $0<s<s_c$, then the zero eigenvalue of $F_u(r_0,0)$ crosses into the positive complex half-plane as r increases past r_0, and all the other eigenvalues of $F_u(r_0,0)$ are isolated points in the negative complex half-plane. Thus the bifurcating solution $u(\varepsilon)$ will be stable if $\varepsilon r'(\varepsilon)>0$ near $\varepsilon=0$, and unstable if $\varepsilon r'(\varepsilon)<0$ near $\varepsilon=0$. However, if $0<\tau<1$ and $s>s_c$, then the zero eigenvalue of $F_u(r_0,0)$ crosses into the negative complex half-plane and moreover, $F_u(r_0,0)$ has one positive real eigenvalue [7]. Thus $F_u(r(\varepsilon),u(\varepsilon))$ has a positive eigenvalue near $\varepsilon=0$ and the solution $u(\varepsilon)$ is unstable in this case, regardless of the sign of $\varepsilon r'(\varepsilon)$.

Results. Due to the dependence of the eigenfunctions u_0 on z for each cellular structure, $r_1=0$. Thus to determine the stability of the bifurcating solution $u(\varepsilon)$, we must solve $F_u(r_0,0)u_1=-M(u_0,u_0)$ and compute r_2 from (4.3). Then the sign of $\tilde{\lambda}(\varepsilon)$ near $\varepsilon=0$ is the same as the sign of $-r_2\lambda'(r_0)$ and hence for $0<\tau<1$ and $0<s<s_C$, the bifurcating solution $u(\varepsilon)$ is stable if $r_2>0$ and unstable if $r_2<0$.

a) For *rolls* we have

$$u_1=0, \qquad w_1=0,$$

$$\theta_1=-\frac{1}{12\pi^3}\sin 2\pi z, \qquad \zeta_1=-\frac{1}{12\pi^3\tau}\sin 2\pi z,$$

and r_2 has the same sign as $r_0-s/\tau^3=27\pi^4/4-((1-\tau^2)/\tau^3)s$. Thus $r_2>0$ if $0<\tau<1$ and $0<s<s_1\equiv(27\pi^4/4)(\tau^3/(1-\tau^2))$, while $r_2>0$ if $s>s_1$. We note that $s_1<s_C$ so that the branch of convecting rolls bifurcates subcritically as r increases past r_0 when $s_1<s<s_C$ (and when $s>s_C$). This result is well-known (see [10, Vol. II, p. 45] and the references therein) and moreover, the value s_1 is the same as the global nonlinear stability limit of the conduction solution $u=0$ when $r=r_0$, obtained by Joseph [10, Vol. II, pp. 42–46] using energy methods.

b) For *rectangles* we have

$$u_1=-\frac{\pi}{\alpha}w_{202}\sin 2\alpha x\cos 2\pi z,$$

$$v_1=-\frac{\pi}{\beta}w_{022}\sin 2\beta y\cos 2\pi z,$$

$$w_1=(w_{202}\cos 2\alpha x+w_{022}\cos 2\beta y)\sin 2\pi z,$$

$$\theta_1=\left\{-\frac{1}{24\pi^3}+\frac{1}{4(\pi^2+\alpha^2)}\left[w_{202}-\frac{1}{3\pi^3}\left(\frac{\pi^2}{2}-\alpha^2\right)\right]\cos 2\alpha x\right.$$

$$\left.+\frac{1}{4(\pi^2+\beta^2)}\left[w_{022}-\frac{1}{3\pi^3}\left(\frac{\pi^2}{2}-\beta^2\right)\right]\cos 2\beta y\right\}\sin 2\pi z,$$

$$\zeta_1=\left\{-\frac{1}{24\pi^3\tau}+\frac{1}{4\tau(\pi^2+\alpha^2)}\left[w_{202}-\frac{1}{3\pi^3\tau}\left(\frac{\pi^2}{2}-\alpha^2\right)\right]\cos 2\alpha x\right.$$

$$\left.+\frac{1}{4\tau(\tau^2+\beta^2)}\left[w_{022}-\frac{1}{3\pi^3\tau}\left(\frac{\pi^2}{2}-\beta^2\right)\right]\cos 2\beta y\right\}\sin 2\pi z,$$

where

$$w_{202} = -\frac{2\pi}{\sigma} f(\alpha)\left[1-\frac{2}{\pi^2}(\alpha^2-\beta^2)\right]\left[3+\frac{\sigma}{6\pi^2(\pi^2+\alpha^2)}\left(r_0-\frac{s}{\tau^2}\right)\right],$$

$$w_{022} = -\frac{2\pi}{\sigma} f(\beta)\left[1-\frac{2}{\pi^2}(\beta^2-\alpha^2)\right]\left[3+\frac{\sigma}{6\pi^2(\pi^2+\beta^2)}\left(r_0-\frac{s}{\tau^2}\right)\right],$$

$$f(\alpha) = 16\alpha^2(\pi^2+\alpha^2)\left[64(\pi^2+\alpha^2)^3 - 27\pi^4\alpha^2\right]^{-1}.$$

Then r_2 has the same sign as the expression

$$(4.6)\quad \frac{2\sigma}{9\pi^4}\left(r_0-\frac{s}{\tau^3}\right)\left\{4+\frac{\pi^2-2\alpha^2}{\pi^2+\alpha^2}\left[1-\frac{2}{\pi^2}(\alpha^2-\beta^2)\right]\right.$$

$$\left.+\frac{\pi^2-2\beta^2}{\pi^2+\beta^2}\left[1-\frac{2}{\pi^2}(\beta^2-\alpha^2)\right]\right\}$$

$$+\frac{2}{\sigma}\left\{f(\alpha)(\pi^2-2\alpha^2)\left[1-\frac{2}{\pi^2}(\alpha^2-\beta^2)\right]\left[3+\frac{\sigma}{6\pi^2(\pi^2+\alpha^2)}\left(r_0-\frac{s}{\tau^2}\right)\right]^2\right.$$

$$\left.+f(\beta)(\pi^2-2\beta^2)\left[1-\frac{2}{\pi^2}(\beta^2-\alpha^2)\right]\left[3+\frac{\sigma}{6\pi^2(\pi^2+\beta^2)}\left(r_0-\frac{s}{\tau^2}\right)\right]^2\right\}.$$

We observe that $\pi^2-2\alpha^2$, $\pi^2-2\beta^2$, $[1-(2/\pi^2)(\alpha^2-\beta^2)]$, $[1-(2/\pi^2)(\beta^2-\alpha^2)]$, $f(\alpha)$ and $f(\beta)$ are all strictly positive when $0<\alpha^2, \beta^2<\pi^2/2$.

c) For *squares*, $\alpha^2=\beta^2=\pi^2/4$ and the expression (4.6) simplifies to

$$(4.7)\quad \frac{16\sigma}{15\pi^4}\left(r_0-\frac{s}{\tau^3}\right)+\frac{40}{473\sigma}\left[3+\frac{2\sigma}{15\pi^4}\left(r_0-\frac{s}{\tau^2}\right)\right]^2.$$

d) For *hexagons* we have

$$u_1 = \frac{i\pi}{2\alpha}\left\{w_{112}\Phi_{11}^1 + w_{312}\Phi_{31}^1\right\}\cos 2\pi z,$$

$$v_1 = \frac{i\sqrt{3}\,\pi}{2\alpha}\left\{w_{112}\Phi_{11}^2 + w_{312}\Phi_{31}^2\right\}\cos 2\pi z,$$

$$w_1 = \left\{w_{112}\Phi_{11}^3 + w_{312}\Phi_{31}^3\right\}\cos 2\pi z,$$

$$\theta_1 = \left\{-\frac{2}{\pi^3}+\left[\frac{2}{9\pi^2}w_{112}-\frac{4}{9\pi^3}\right]\Phi_{11}^3+\left[\frac{2}{11\pi^2}w_{312}-\frac{4}{33\pi^3}\right]\Phi_{31}^3\right\}\cos 2\pi z,$$

$$\zeta_1 = \left\{-\frac{2}{\pi^3\tau^2}+\left[\frac{2}{9\pi^2\tau}w_{112}-\frac{4}{9\pi^3\tau^2}\right]\Phi_{11}^3+\left[\frac{2}{11\pi^2\tau}w_{312}-\frac{4}{33\pi^3\tau^2}\right]\Phi_{31}^3\right\}\cos 2\pi z,$$

where

$$-e^{i\alpha(-3x-\sqrt{3}y)}+e^{i\alpha(-3x+\sqrt{3}y)}+2e^{i2\sqrt{3}\alpha y},$$

$$\Phi_{31}^3 = e^{i\alpha(3x+\sqrt{3}y)}+e^{i\alpha(3x-\sqrt{3}y)}+e^{-i2\sqrt{3}\alpha y}+e^{i\alpha(-3x-\sqrt{3}y)}$$
$$+e^{i\alpha(-3x+\sqrt{3}y)}+e^{i2\sqrt{3}\alpha y}.$$

Then r_2 has the same sign as the expression

$$\frac{120\sigma}{11\pi^4}\left(r_0-\frac{s}{\tau^3}\right)+\frac{62208}{8125\sigma}+\frac{5936}{8125\pi^4}\left(r_0-\frac{s}{\tau^2}\right)+\frac{126848\sigma}{7239375\pi^8}\left(r_0-\frac{s}{\tau^2}\right)^2. \tag{4.8}$$

The linearized stability of the bifurcating three-dimensional cellular solutions—rectangles, squares and hexagons—all show similar dependence on the parameters s, σ and τ. If we substitute

$$r_0-\frac{s}{\tau^2} = -\frac{27\pi^4}{4\sigma}+\frac{1-\tau}{\tau^2}(s_C-s),$$
$$r_0-\frac{s}{\tau^3} = -\frac{27\pi^4(1+\sigma+\tau)}{4\sigma\tau}+\frac{1-\tau^2}{\tau^3}(s_C-s) \tag{4.9}$$

into the expressions (4.6), (4.7) and (4.8) we obtain

(4.10)

$$-\frac{3}{2}\left(\frac{1+\sigma+\tau}{\tau}\right)\left\{4+\frac{\pi^2-2\alpha^2}{\pi^2+\alpha^2}\left[1-\frac{2}{\pi^2}(\alpha^2-\beta^2)\right]+\frac{\pi^2-2\beta^2}{\pi^2+\beta^2}\left[1-\frac{2}{\pi^2}(\beta^2-\alpha^2)\right]\right\}$$
$$+\frac{2}{\sigma}\left\{f(\alpha)(\pi^2-2\alpha^2)\left[1-\frac{2}{\pi^2}(\alpha^2-\beta^2)\right]\left[\frac{15\pi^2+24\alpha^2}{8(\pi^2+\alpha^2)}\right]^2\right.$$
$$\left.+f(\beta)(\pi^2-2\beta^2)\left[1-\frac{2}{\pi^2}(\beta^2-\alpha^2)\right]\left[\frac{15\pi^2+24\beta^2}{8(\pi^2+\beta^2)}\right]^2\right\}+O(s_C-s)$$

for rectangles,

$$-\frac{36}{5}\left(\frac{1+\sigma+\tau}{\tau}\right)+\frac{84}{437\sigma}+O(s_C-s) \tag{4.11}$$

for squares, and

$$-\frac{810}{11}\left(\frac{1+\sigma+\tau}{\tau}\right)+\frac{314892}{89375\sigma}+O(s_C-s) \tag{4.12}$$

for hexagons. In each case the term $O(s_C-s)$ is of the form

$$O(s_C-s)=A(s_C-s)+B(s_C-s)^2, \qquad A,B>0 \tag{4.13}$$

so that, in particular, $\lim_{s\to s_C^-} O(s_C-s)=0$. From (4.6)–(4.8) we see that given any $\sigma>0$ and $0<\tau<1$ the coefficient r_2 is positive if s is near zero, but can be positive or negative as s increases up to s_C, depending on σ and τ. More explicitly, one sees from (4.10)–(4.13) that given $0<\tau<1$ one can choose σ sufficiently close to zero so that $r_2>0$ for all s, $0<s<s_C$; but given $\sigma>0$ one can choose τ sufficiently close to zero so that $r_2<0$ for all s, $s_1+\varepsilon_0<s<s_C$ where $0<\varepsilon_0<s_C-s_1$.

In Figs. 3–6 we have plotted the coefficient r_2 as a function of the size of the solute concentration gradient s for several values of σ and τ, comparing rolls, squares and hexagons. In Fig. 3, for $\sigma=7$ and $\tau=\frac{1}{80}$ (the appropriate values for salt dissolved in water) the cofficient r_2 is positive at $s=0$ and changes sign at a small positive value for s: for rolls r_2 changes sign at $s=0.00128$, while for squares and hexagons r_2 changes sign at slightly higher values $s=0.001311$ (squares), $s=0.001313$ (hexagons). As σ decreases towards 0, the differences become greater. In Fig. 4, for $\sigma=1$ and $\tau=0.1$ and more clearly in Fig. 5, for $\sigma=0.01$ and $\tau=0.1$ one can see that r_2 for squares and hexagons changes sign at higher values of s than does r_2 for rolls. For sufficiently small σ, as in Fig. 6, where $\sigma=0.001$ and $\tau=0.1$, the coefficients r_2 for squares and hexagons remain positive for all s, $0<s<s_C$. In contrast, r_2 for rolls is negative except for s very near $s=0$.

For most systems of physical interest, $0<\tau\ll 1$ and $\sigma\gtrsim 1$ so that the dependence of the coefficient r_2 on s for the three-dimensional cellular solutions is nearly the same as that for roll-like solutions, although r_2 is positive for a slightly larger range of s for the three-dimensional cellular solutions.

The sign of r_2 indicates the directions of bifurcation (supercritical if r_2 is positive, subcritical if r_2 is negative) and the stability of the equilibria on the branch of convective solutions, but only with respect to small perturbations having the same cellular structure. It is possible, for example, that solutions on a supercritical branch of hexagons are stable with respect to small perturbations having the same hexagonal structure, but are unstable with respect to other small perturbations. We discuss this possibility in the next section.

5. Comments on pattern selection. In a recent paper [20], Golubitsky, Swift and Knobloch investigate pattern selection between rolls, hexagons and two other cellular structures in a model of pure thermal (Bénard) convection with the same boundary conditions on the upper and lower surfaces. They treat bifurcation problems that are symmetric with respect to the group preserving doubly periodic functions on a hexagonal lattice. After reducing the problem at the bifurcation point to a six-dimensional phase space, all possible local bifurcation diagrams are found (given certain nondegeneracy conditions) involving rolls, hexagons, regular triangles and a "patchwork quilt"

of rectangles. Their results are applicable to the convection problem in this paper. In particular, the coefficients r_2 which we have computed for rolls and hexagons can be used to find the coefficients $l_3(0)$ and a of [20]. Provided a certain fifth order term $m_5(0)$ in the reduced bifurcation equations is nonzero, we have the following pattern selection results: (a) If $l_3(0)>0$ and $a<-1$, then rolls are stable in the sense of [20], i.e., near the bifurcation point rolls are stable with respect to small perturbations possessing the symmetries of the hexagonal lattice and midplane reflection; (b) if $l_3(0)<0$ and $a>-\frac{1}{3}$, then either hexagons of regular triangles are stable, depending on the sign of $m_5(0)$; (c) for all other values of $l_3(0)$ and a, solutions near the bifurcation point are unstable even though they may be on a supercritical branch.

The value of the coefficient $m_5(0)$ depends on the results of computations for the coefficient r_4 in (4.1). Although we have not computed r_4, both r_4 and $m_5(0)$ are most likely nontrivial functions of the parameters σ, τ and s, and $m_5(0)\neq 0$ for almost all parameter values $\sigma>0$, $0<\tau<1$, $0<s<s_C$.

In Fig. 7 we have plotted the coefficient a as a function of s, for $\sigma=0.01$ and $\tau=0.1$. We observe the following behavior: for $s=0$ and for s in a small right neighborhood of $s=0$, case (a) holds; and for all other values of s less than s_C, case (c) holds. Assuming that $m_5(0)\neq 0$, this implies that rolls are stable in the sense of [20] for $s=0$ and for s in the small right neighborhood of $s=0$, but for all other values of s less than s_C, neither rolls nor hexagons are stable, even though the branch of hexagons may bifurcate supercritically. For the other values of σ and τ corresponding to Figs. 3, 4 and 6 we observed similar behavior of the coefficients $l_3(0)$ and a as functions of s. In fact, it is easy to show that when $s=0$, and by continuity when s belongs to some right neighborhood of $s=0$, then $l_3(0)>0$ and $a<-1$. The case $s=0$ corresponds to pure thermal (Bénard) convection and this result agrees with that of [21]. We did not find any parameter values yielding case (b) in which stable hexagons are possible.

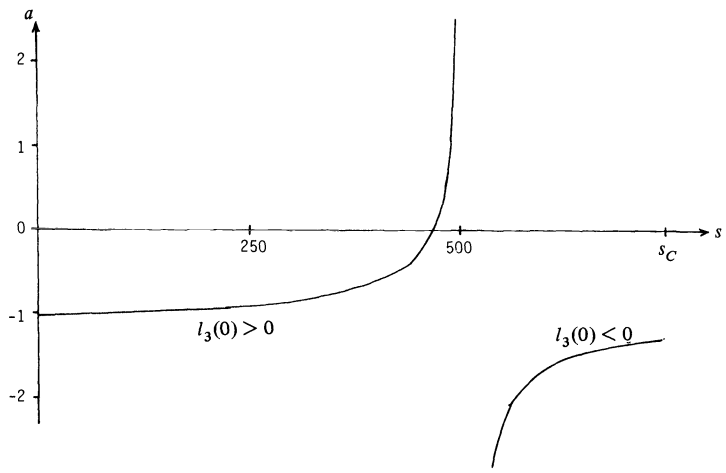

FIG. 7. *The hexagonal lattice coefficient a as a function of s when* $\sigma=0.01$, $\tau=0.1$ ($s_C=738$).

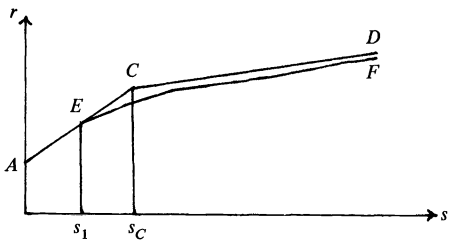
The pattern selection results do not apply to the squares and rectangles for which we have also computed values for r_2. A theory of pattern selection including more general cellular structures (for example, squares) with rolls and hexagons is not yet developed. However, in experiments performed on layers of fluid with finite extent, one usually sees either rolls or hexagons.

6. Conclusion. We have used a bifurcation theorem of Crandall and Rabinowitz to prove the existence of nontrivial equilibrium solutions of the doubly-diffusive convection equations. For fixed parameter values $\sigma > 0$ (Prandtl number), $0 < \tau < 1$ (ratio of solute diffusivity to thermal diffusivity) and $s \neq s_C$ (solute concentration gradient) there exist solutions corresponding to steady cellular convection for r (temperature gradient) in a neighborhood of the critical value r_0.

At the bifurcation point $u = 0$, $r = r_0$, four types of convective solutions (rolls, rectangles, squares and hexgaons) bifurcate supercritically when s is near 0. However, when s is near s_C rolls always bifurcate subcritically but three-dimensional cellular structures bifurcate supercritically if σ is sufficiently close to 0. Solutions on a subcritical branch near the bifurcation point are unstable, but solutions on a supercritical branch may only be stable with respect to a very restricted class of perturbations. Using the results of Golubitsky, Swift and Knobloch [20], we have found that near $s = 0$ rolls are stable with respect to a class of perturbations including both rolls and hexagons (assuming a nondegeneracy condition); but for the parameter values we explored, hexagons are unstable with respect to this class of perturbations even though the hexagon solutions may be on a supercritical branch.

Although we give only local existence and stability results, in a neighborhood of the bifurcation point $r = r_0$, $u = 0$, other methods applied to this problem have provided information on the global behavior of the bifurcating branches of equilibrium solutions. Using energy methods, Joseph studied the global stability of the conduction solution and for $0 < \tau < 1$ gives the following diagram [10, Vol. II, p. 46] (cf. Fig. 1). For (r,s) values above the curve AECD, the conduction solution is unstable (Fig. 8). For (r,s) values below the curve AEF, the conduction solution is globally stable. For (r,s) values between the two curves, the conduction solution is stable with respect to small perturbations, but other equilibrium solutions are possible. In fact, the two-dimensional roll-like solutions bifurcate subcritically ($r_2 < 0$, and hence $r(\varepsilon) < r_0$ near $\varepsilon = 0$) for values of (r,s) on the open line segment EC, and hence these solutions exist for (r,s) in a neighborhood below EC. Since they cannot exist for (r,s) below EF, it is plausible that the branch of solutions in ru-space for fixed s, $s_1 < s < s_C$, "turns back" and regains stability as is suggested by numerical calculations [7] and by the results of a perturbation analysis near $s = s_1$ [16]. The five-dimensional system of ordinary differential equations obtained by model truncation of the two-dimensional flow also has a branch of solutions corresponding to convection which bifurcates subcritically from the conduction solution and possesses a turning point [6]. Thus, it is reasonable to conjecture that this same behavior is repeated in the infinite-dimensional case.

The doubly-diffusive convection equations also admit periodic solutions, which have not been considered here. When $0 < \tau < 1$ and $s > s_C$, the bifurcating equilibrium



AECD: instability limit of conduction solution

AEF: stability limit of conduction solution

$r = r_0$ on AEC.

FIG. 8. *Stability and instability limits of the conduction solution.*

solutions near $r=r_0$, $u=0$ are unstable, but on the curve CD in Figs. 1 and 3, the linearization possesses two conjugate pure imaginary eigenvalues. We therefore expect a Hopf bifurcation of periodic solutions [7]. Furthermore, if $\sigma>0$, $0<\tau<1$, $s=s_C$ and $r=r_0$, then the linearization possesses a double zero eigenvalue, and in this case the bifurcation theorem used in this paper does not apply [15]. We will treat the Hopf bifurcation case and the double eigenvalue case in Parts II and III.

Appendix. In this appendix we regard $L(r)$ as a densely defined, unbounded operator in a Hilbert space H. By making use of the fact that $L(r)$ is a perturbation of a negative-definite, self-adjoint operator A, we can easily deduce some properties of $L(r)$ which will be useful in later work on the bifurcation of periodic solutions, as well as for proving Lemma 1.

The self-adjoint operator A. Let $\lambda>0$, $\mathbf{f}\in J$ and consider the Stokes problem: find $\mathbf{u}\in J$ with $\Delta u\in H^0(\Omega,\mathbb{R}^n)$ such that

$$\text{(A.1)}\qquad \begin{aligned} &-\Pi\Delta\mathbf{u}+\lambda\mathbf{u}=\mathbf{f},\\ &\left.\frac{\partial u}{\partial z}\right|_{z=0,1}=\left.\frac{\partial v}{\partial z}\right|_{z=0,1}=0,\\ &\mathbf{u}\text{ admits periodicity }\Omega. \end{aligned}$$

Then (A.1) is equivalent to a "variational" formulation of the problem [17]: find $\mathbf{u}\in V$ such that

$$\text{(A.2)}\qquad a(\mathbf{u},\mathbf{v})+\lambda(\mathbf{u},\mathbf{v})_0=(\mathbf{f},\mathbf{v})\quad\text{for all }\mathbf{v}\in V,$$

where $a(\mathbf{u},\mathbf{v})=\sum_{i=1}^n\sum_{j=1}^n\int_\Omega D_iu_jD_iv_j\,dx$ defines a bounded symmetric bilinear form on $V\times V$. By classical methods [1], [8] it can be shown that (A.1) has a unique solution $\mathbf{u}\in H^2(\Omega,\mathbb{R}^n)\cap V$, and that $\|\mathbf{u}\|_2\leqq C\|f\|_0$ for some constant C.

If we define the subspace

$$\mathscr{D}(-\Pi\Delta)=\left\{\mathbf{u}\in H^2(\Omega,\mathbb{R}^n)\cap V:\ \left.\frac{\partial u}{\partial z}\right|_{z=0,1}=\left.\frac{\partial v}{\partial z}\right|_{z=0,1}=0\right\},$$

then $-\Pi\Delta:\mathscr{D}(-\Pi\Delta)\to J$ is a densely defined, self-adjoint, closed operator in the Hilbert space J. For real $\lambda>0$, the left-hand side of (A.2) defines a coercive bilinear form on $V\times V$, which implies that any real $\lambda<0$ is in the resolvent set of the operator $(-\Pi\Delta)$. The resolvent operator takes values in V, and the injection of V into J is compact; thus, the resolvent operator $(-\Pi\Delta-\lambda I)^{-1}:J\to J$ is compact. By [12, Thm. II.6.29, p.187], we conclude that the spectrum of $(-\Pi\Delta)$ consists entirely of isolated eigenvalues of finite multiplicities, and that $(-\Pi\Delta-\lambda I)^{-1}$ is compact for every λ not an eigenvalue of $(-\Pi\Delta)$.

Similarly, if we consider the Dirichlet problem

$$\text{(A.3)}\qquad -\Delta\theta+\lambda\theta=f,\quad \theta|_{z=0,1}=0,\quad \theta\text{ admits periodicity }\Omega,$$

and define $\mathscr{D}(-\Delta)=H_0^2(\Omega,\mathbb{R})$, then $-\Delta:\mathscr{D}(-\Delta)\to H^0(\Omega,\mathbb{R})$ is a densely defined, self-adjoint closed operator in $H^0(\Omega,\mathbb{R})$, and every real $\lambda\leqq 0$ is in the resolvent set of $(-\Delta)$, with $(-\Delta-\lambda I)^{-1}$ compact.

Now let $Y=J\times H^0(\Omega,\mathbb{R})\times H^0(\Omega,\mathbb{R})$ and define the operator A by

$$\mathscr{D}(A)=\left\{u=(\mathbf{u},\theta,\zeta)\in H^2(\Omega,\mathbb{R}^{n+2})\cap W:\ \left.\frac{\partial u}{\partial z}\right|_{z=0,1}=\left.\frac{\partial v}{\partial z}\right|_{z=0,1}=0\right\},$$

$$Au=(\sigma\Pi\Delta\mathbf{u},\ \Delta\theta,\ \tau\Delta\zeta)\quad \text{for } u\in\mathscr{D}(A).$$

Then A is a densely defined, closed operator in Y whose spectrum consists entirely of isolated eigenvalues of finite multiplicities; each real $\lambda>0$ is in the resolvent set of A, and $(A-\lambda I)^{-1}: Y\to Y$ is compact for every λ not an eigenvalue of A. In addition, A is self-adjoint, and hence its spectrum $\Sigma(A)$ is a subset of the negative real line, and for every λ not an eigenvalue we have $\|(A-\lambda I)^{-1}\|=1/\operatorname{dist}(\lambda,\Sigma(A))$ [12, p. 272]. By substitution of the Fourier series of §3, it follows that the problem $Au=0$ admits only the trivial solution, and hence $\lambda=0$ is not an eigenvalue of A. Thus the resolvent set of A contains all real $\lambda\geqq 0$. We summarize the properties of A in the following proposition.

PROPOSITION A.1. *The spectrum of A consists entirely of isolated, real, negative eigenvalues of finite multiplicities. For every λ in the resolvent set of A, the resolvent operator $(A-\lambda I)^{-1}$ is compact, and for all real $\lambda>0$, we have the estimate*

$$\|(A-\lambda I)^{-1}\|\leqq\frac{1}{\lambda}. \tag{A.4}$$

The operator $L(r)$. Define the operator $B(r)$ for $r>0$ by

$$\mathscr{D}(B(r))=\mathscr{D}(A),$$

$$B(r)u=(\sigma\Pi[(r\theta-s\zeta)\mathbf{e}],w,w)\quad \text{for } u\in\mathscr{D}(B(r)).$$

Then $B(r)$ is a bounded linear operator in Y and, in particular, $B(r)$ is relatively bounded with respect to A [12, p. 190]: $\mathscr{D}(A)\subset\mathscr{D}(B(r))$ and there exist nonnegative constants a and b such that

$$\|B(r)u\|_0\leqq a\|u\|_0+b\|Au\|_0\quad \text{for all } u\in\mathscr{D}(A). \tag{A.5}$$

In our case we may take $a=\|B(r)\|$ and $b=0$.

Finally, we define $L(r)$ for $r>0$ by

$$\mathscr{D}(L(r))=\mathscr{D}(A),\qquad L(r)=A+B(r).$$

Then $L(r)$ is a densely defined, closed operator in Y. By (A.4), we can choose a real $\lambda>0$ sufficiently large so that

$$a\|(A-\lambda I)^{-1}\|+b<1,$$

where a, b are as in (A.5), and hence by Proposition A.1 and [12, Thm. IV.1.16, p. 196], $(L(r)-\lambda I)^{-1}$ is compact. Applying [12, Thm. III.6.29] again, we obtain the next proposition.

PROPOSITION A.2. *For each $r>0$, the spectrum of $L(r)$ consists entirely of isolated eigenvalues of finite multiplicities. Furthermore, $(L(r)-\lambda I)^{-1}$ is compact for every λ in the resolvent set of $L(r)$.*

Proof of Lemma 1. We can now use Proposition A.2 to prove Lemma 1 of §3. Let $f\in Y$ and consider the solvability of

$$L(r_0)u=f \tag{A.6}$$

for $u \in \mathscr{D}(L(r_0))$ $(=X)$. If λ is in the resolvent set of $L(r_0)$, then (A.6) is equivalent to the problem of finding $u \in Y$ such that

$$u+\lambda(L(r_0)-\lambda I)^{-1}u=(L(r_0)-\lambda I)^{-1}f. \tag{A.7}$$

By Proposition A.2, $(L(r_0)-\lambda I)^{-1}$ is compact for some real $\lambda \neq 0$, and hence by Riesz–Schauder theory a solution exists if and only if

$$\left((L(r_0)-\lambda I)^{-1}f, u^*\right)_0=0$$

for all u^* satisfying $u^*+\lambda[(L(r_0)-\lambda I)^{-1}]^*u^*=0$. But $\lambda \neq 0$ and hence this solvability condition is equivalent to the condition that

$$(f, u^*)_0=0$$

for all u^* satisfying $L(r_0)^*u^*=0$. Thus $R(L(r_0))=N(L(r_0)^*)^{\perp}$.

Acknowledgments. The authors thank the reviewers for many useful suggestions, and Professor Martin Golubitsky for bringing reference [20] to our attention and providing helpful comments.

BIFURCATION IN DOUBLY-DIFFUSIVE SYSTEMS II. TIME PERIODIC SOLUTIONS*

WAYNE NAGATA[†‡] AND JAMES W. THOMAS[†]

Abstract. We study a system of double-diffusive convection equations which describe a layer of fluid heated and salted from below. For suitable parameter values Hopf bifurcations of time periodic solutions occur in roll-like, square and hexagonal convection cell patterns. A version of the center manifold theorem suitable for partial differential equations is used to prove the existence of the bifurcating time periodic solutions, and the stability of these solutions is determined from the Poincaré normal form of the reduced equations on the center manifold.

Key words. doubly-diffusive systems, Hopf bifurcation, stability

1. Introduction. This is the second paper in a series of three concerning bifurcations which occur in double-diffusive convection equations. In the first paper [10] (this issue, pp. 91–113), which we will refer to as Part I, we investigated the existence and stability of bifurcating nontrivial equilibrium (steady) solutions. In the present paper we consider bifurcating time periodic solutions of the equations.

We refer to Part I for a description of the double-diffusive convection equations and the cellullar structures of rolls, rectangles, squares and hexagons. Proceeding as in §2 of Part I, we select one of the cellular structures, and then choose the parameters σ, τ and s so that

$$\begin{aligned} &\sigma>0, \qquad 0<\tau<1, \\ &s>\frac{27}{4}\pi^4\tau^2(1+\sigma^{-1})(1-\tau)^{-1}\equiv s_C. \end{aligned} \tag{1.1}$$

Then when

$$r=\left(\frac{\sigma+\tau}{\sigma+1}\right)s+\frac{27}{4}\pi^4(1+\tau)(1+\tau\sigma^{-1})\equiv r_H, \tag{1.2}$$

the linearization of the convection equations about the constant gradient solution possesses two simple eigenvalues $\lambda=\pm i\omega_0$, where

$$\omega_0^2=\frac{9}{4}\pi^4(\sigma+\tau+\sigma\tau)-\frac{1}{3}\sigma(r_H-s). \tag{1.3}$$

All the other eigenvalues of the linearization have negative real parts when $r=r_H$ [5]. We expect a Hopf bifurcation of time periodic solutions to occur at $r=r_H$ in the nonlinear convection equations.

The existence of Hopf bifurcations in *Navier–Stokes* type systems can be proven within a number of theoretical settings, for example [1], [3], [4], [6], [7], [8], [9]. These settings also provide means for computing the stability of the bifurcating solutions near the point of bifurcation. In this paper we use center manifold methods (see [3], [4], and [9]), which we feel are conceptually more natural.

In §2 we formulate the nonlinear convection equations as an abstract evolution equation in a Hilbert space, and prove the existence of bifurcating time periodic

solutions for each cellular structure. Then in §3 we compute for rolls, squares and hexagons the direction of bifurcation and the stability of the bifurcating solutions with respect to small perturbations having the same cellular structure. Our results for rolls agree with the results of formal computations performed previously by [5] and [2]. A simplified model corresponding to rolls with different dimensions was treated by [11].

2. Hopf bifurcations of time periodic solutions. In this section we express the double-diffusive convection equations as a one-parameter family of semilinear parabolic equations in a Hilbert space. The family satisfies hypotheses of a version of the center manifold theorem [4], and from this theorem follows the existence of Hopf bifurcations.

In §3 and the appendix of Part I we defined the Hilbert spaces X and Y and the operators A, $B(r)$ and M. We continue with the same notation. Since the unbounded, densely defined operator A is self-adjoint and negative definite, it follows that the fractional powers $(-A)^\alpha$ and the Banach spaces $X^\alpha = \mathscr{D}((-A)^\alpha)$ with norms $\|u\|_\alpha = \|(-A)^\alpha u\|_\gamma$ are well defined for $\alpha \geqq 0$ [4, p. 19]. If $\alpha = 0$, then $X^0 = Y$, and if $\alpha = 1$, then $X^1 = X = \mathscr{D}(A)$. Furthermore, if $0 \leqq \alpha < 1$, then $X \subset X^\alpha \subset Y$ with continuous imbeddings. Thus, the bounded linear operator $B(r)$ in Y defines an analytic mapping $(u,r) \mapsto B(r)u$ from $X^\alpha \times \mathbb{R}$ into Y, when $0 \leqq \alpha < 1$. The nonlinear operator M is a bounded bilinear operator from $X^\alpha \times X^\alpha$ into Y, when $\alpha > \frac{3}{4}$ [4, p. 79]. Thus,

$$f(u,r) = B(r)u + M(u,u) \tag{2.1}$$

defines an analytic operator $f\colon X^\alpha \times \mathbb{R} \to Y$. We observe that $f(0,r) = 0$ for all $r \in \mathbb{R}$, and $D_u f(0,r) = B(r)$.

We now write the double-diffusive convection equations in the abstract form

$$\frac{du}{dt} = Au + f(u,r) \tag{2.2}$$

for $u \in Y$, where $(-A)$ is a sectorial operator in Y and f is analytic when $\alpha > \frac{3}{4}$. Equation (2.2) generates a unique parametrized family of local semiflows in X^α for $\frac{3}{4} < \alpha < 1$ [4, p. 54], which is jointly analytic in the initial condition $u(0) \in X^\alpha$, the parameter $r \in \mathbb{R}$ and time $t > 0$ [4, p. 66].

When (1.1) and (1.2) are satisfied, the linearization $L(r_H) \equiv A + D_u f(0, r_H)$ at $r = r_H$ possesses two simple eigenvalues $\pm i\omega_0$ where ω_0 is given by (1.3), and all other eigenvalues of $L(r_H)$ have negative real parts as discussed above. Since the spectrum of $L(r)$ for $r \in \mathbb{R}$ is a closed subset of the complex plane consisting entirely of isolated eigenvalues which depend analytically on r, near $r = r_H$ the spectrum of $L(r)$ consists of

$$\{\alpha(r) \pm i\omega(r)\} \cup \Sigma',$$

where $\Sigma' \subset \{\operatorname{Re}\lambda < \beta < 0\}$, $\alpha(r_H) = 0$ and $\omega(r_H) = \omega_0$. By implicitly differentiating the dispersion relation for λ [Part I, (3.8)] with resepct to r, we obtain the nondegeneracy condtion

$$\alpha'(r_H) > 0, \tag{2.3}$$

i.e., the critical eigenvalues cross into the positive complex half plane with nonzero speed. It then follows from [4, p. 181] that (2.2) has a two-dimensional local invariant manifold S_r containing $0 \in X^\alpha$ for r near r_H. Local bifurcation and stability of solutions of (2.2) is determined by local bifurcation and stability of solutions for the flow in S_r.

Near the origin, the flow in S_r for r near r_H is described by

$$\begin{pmatrix} \dot{y}_1 \\ \dot{y}_2 \end{pmatrix} = \begin{bmatrix} \alpha(r) & \omega(r) \\ -\omega(r) & \alpha(r) \end{bmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} + \begin{pmatrix} \phi_1(y_1, y_2; r) \\ \phi_2(y_1, y_2; r) \end{pmatrix} \tag{2.4}$$

where $\alpha(r_H)=0$, $\alpha'(r_H)>0$, $\omega(r_H)=\omega_0>0$ and $\phi_{1,2}(y_1,y_2;r)=O(y_1^2+y_2^2)$ as $(y_1,y_2)\to(0,0)$. Under the additional assumption

(A) the origin is not a center for (2.4) when $r=r_H$, and this is true independent of terms of order $|y_1|^p+|y_2|^p$, for some $p\geqq 2$, Henry then concludes that (2.2) either has a supercritical or subcritical branch of time periodic solutions near $r=r_H$. More precisely, we have the following result.

THEOREM 1. *Let Ω be one of the following fundamental domains of spatial periodicity*:

i) (*Rolls*) $\Omega=C_1\times(0;1)\subset\mathbb{R}^2$, *where* $C_1=(0,2\sqrt{2})$,

ii) (*Rectangles*) $\Omega=C_2\times(0,1)\subset\mathbb{R}^3$, *where* $C_2=(0,2\pi/\alpha_1)\times(0,2\pi/\alpha_2)$ *and* $\alpha_1^2+\alpha_2^2=\pi^2/2$, $\alpha_1,\alpha_2>0$, $\alpha_2\neq\alpha_1\sqrt{m^2-1}$ *for all* $m\in N$,

iii) (*Squares*) $\Omega=C_3\times(0,1)\subset\mathbb{R}^3$, *where* $C_3=(0,4)\times(0,4)$,

iv) (*Hexagons*) $\Omega=C_4\times(0,1)\subset\mathbb{R}^3$, *where* C_4 *is the interior of a regular hexagon with sides of length* $4\sqrt{2}/3$.

Then for each fixed $\sigma\in(0,\infty)$, $\tau\in(0,1)$ *and* $s\in(s_c,\infty)$, (2.6) *can be reduced to the one-parameter family of equations* (2.4) *on local invariant manifolds* S_r *for* r *in some neighborhood of* r_H. *Moreover, if* (A) *is satisfied then one of the following two conclusions must hold* [4, *p.* 182]:

a. (*Supercritical Hopf bifurcation*) *The origin is asymptotically stable for* (2.2) *when* $r=r_H$, *and there is an* $\varepsilon_0>0$ *such that there is no periodic orbit of* (2.2) *in a neighborhood of the origin in* X^α *for* $r\in[r_H-\varepsilon_0,r_H]$, *but a unique family of orbitally asymptotically stable periodic orbits grows out of the origin for* $r\in(r_H,r_H+\varepsilon_0]$; *or*

b. (*Supercritical Hopf bifurcation*) *The origin is unstable for* (2.2) *when* $r=r_H$, *and there is an* $\varepsilon_0>0$ *such that for* $r\in[r_H-\varepsilon_0,r_H)$ *a unique family of unstable periodic orbits of* (2.2) *shrinks to the origin as* $r\to r_H-$, *but there is no periodic orbit of* (2.2) *in a neighborhood of the origin for* $r\in[r_H,r_H+\varepsilon_0]$.

In both cases the periods of the nontrivial periodic orbits approach $2\pi/\omega_0$ *as* $r\to r_H$.

In the next section we will show that there exist $\sigma\in(0,\infty)$, $\tau\in(0,1)$ and $s\in(s_c,\infty)$ such that assumption (A) is satisfied. In addition, we will be able to determine whether we have supercritical or subcritical Hopf bifurcations.

3. Stability of the bifurcating time periodic solutions. In this section we determine whether the bifurcating time periodic solutions described in the last section are orbitally asymptotically stable or are unstable. Following Hassard, Kazarinoff and Wan [3] we express the family of equation (2.4) in terms of the complex variable $z=y_1+iy_2$ as

$$\dot{z}=\lambda(r)z+g(z,\bar{z};r), \tag{3.1}$$

where $\bar{z}=y_1-iy_2$, $\lambda(r)=\alpha(r)+i\omega(r)$, $\lambda(r_H)=i\omega_0$, $\alpha'(r_H)>0$ and $g(z,\bar{z};r)=0(|z|^2)$ as $z\to 0$. By transforming (3.1) into the Poincaré normal form

$$\dot{\xi}=\lambda(r)\xi+c_1(r)\xi|\xi|^2+O\left(|\xi|\,|(\xi,r-r_H)|^4\right), \tag{3.2}$$

one can determine whether the Hopf bifurcation is supercritical or subcritical. If $\operatorname{Re}c_1(r_H)\neq 0$ then the origin is not a center for (3.2), and hence the origin is not a center for (3.1), when $r=r_H$. Furthermore, this is true independent of terms of order $|z|^4$

in (3.1). If we write

$$g(z,\bar{z};r)=\sum_{j+k=2}^{3} g_{jk}(r)\frac{z^j\bar{z}^k}{j!k!}+O\left(|z|^4\right) \tag{3.3}$$

for the term appearing in (3.1), then we can use the formula [3, p. 47]

$$c_1(r_H)=\frac{i}{2\omega_0}\left[g_{20}(r_H)g_{11}(r_H)-2|g_{11}(r_H)|^2-\frac{1}{3}|g_{02}(r_H)|^2\right]+\frac{1}{2}g_{21}(r_H). \tag{3.4}$$

The Hopf bifurcation is supercritical or subcritical according as $(\mathrm{Re}\,c_1(r_H))/\alpha'(r_H)$ is negative or positive, and the bifurcating periodic solutions for r near r_H are orbitally asymptotically stable with asymptotic phase or unstable according as $\mathrm{Re}\,c_1(r_H)$ is negative or positive. Thus to determine the stabilty of the bifurcating periodic orbits we must find the leading terms of the nonlinear part (3.3) of the equation on the center manifold (3.1).

To find $c_1(r_H)$, it suffices to reduce (2.2) to the center manifold at $r=r_H$. We follow the procedure of Hassard, Kazarinoff and Wan [3, Chap. 5], which we now outline. First, we rewrite (2.2) as

$$\frac{du}{dt}=L(r)u+M(u,u), \tag{3.5}$$

where $L(r)=A+D_uf(0,r)$. Next, we solve the eigenvalue problems

$$L(r_H)q=i\omega_0 q \tag{3.6}$$

and

$$L(r_h)^*q^*=-i\omega_0 q^*, \tag{3.7}$$

where the adjoint $L(r)^*$ of $L(r)$ is given explicitly in Part I.

We can then write X^α as the direct sum $X^\alpha=X_c\oplus X_s^\alpha$, where

$$X_c=\{zq+\bar{z}\bar{q}:\ z\in C\},\qquad X_s^\alpha=\{w\in X^\alpha:\ (w,q^*)=0\} \tag{3.8}$$

and $(\cdot,\cdot)$ is the restriction of the Y-inner product to X^α. Observe that this restriction is continuous with respect to the norm $\|\cdot\|_\alpha$ when $\alpha\geqq 0$, due to the continuity of the injection $X^\alpha\subset Y$. Thus for any $u\in X^\alpha$ we have

$$u=zq+\bar{z}\bar{q}+w \tag{3.9}$$

where $z=(u,q^*)$ and $w=u-(u,q^*)q-(u,\bar{q}^*)\bar{q}$ provided we have normalized $(q,q^*)=1$. Projecting (3.6) onto $\mathbb{C}\cong X_c^\alpha$ and X_s^α, we obtain

$$\frac{dz}{dt}=i\omega_0 z+(M(u,u),q^*) \tag{3.10}$$

and

$$\frac{dw}{dt}=L(r_H)w+H(z,\bar{z},w) \tag{3.11}$$

respectively, where u is given by (3.9) and

$$H(z,\bar{z},w)=M(u,u)=(M(u,u),q^*)q-(M(u,u),\bar{q}^*)\bar{q}. \tag{3.12}$$

The center manifold S_{r_H} can be expressed locally in terms of a function $w(z,\bar{z};r_H) \in X_s^\alpha$,

$$S_{r_H} = \{ zq + \bar{z}\bar{q} + w(z,\bar{z};r_H) : |z| < \delta \} \tag{3.13}$$

where $w(0,0;r_H)=0$ and $Dw(0,0;r_H)=0$. Since $f(u,r_H)$ is analytic in $u \in X^\alpha$, $w(z,\bar{z};r_H)$ can be approximated to arbitrarily high order p by a polynomial [4, p. 171]

$$w(z,\bar{z};r_H) = \sum_{j+k=2}^{p} \frac{z^j \bar{z}^k}{j!k!} w_{jk} + O(|z|^p). \tag{3.14}$$

Equation (3.1) with $r=r_H$ on the center manifold S_{r_H} is obtained by setting $u = zq + \bar{z}\bar{q} + w(z,\bar{z};r_H)$ in (3.10). Thus locally we have

$$g(z,z;r_H) = (M(zq+\bar{z}\bar{q}+w(z,z;r_H), zq+\bar{z}\bar{q}+w(z,z;r_H)), q^*). \tag{3.15}$$

To lowest order $u = zq + \bar{z}\bar{q} + O(|z|^2)$, and hence

$$M(u,u) = z^2 M(q,q) + 2z\bar{z}\,\mathrm{Re}\,M(q,\bar{q}) + \bar{z}^2 M(\bar{q},\bar{q}) + O(|z|^3). \tag{3.16}$$

Due to the boundary conditions, the eigenvalue problems (3.6) and (3.7) can be solved exactly for q and q^*, and then a calculation will show that $M(q,q)$, $\mathrm{Re}\,M(q,\bar{q})$ and $M(\bar{q},\bar{q})$ are all orthogonal to q^* (see the example for rolls later in this section). Hence

$$(M(u,u),q^*) = O(|z|^3), \tag{3.17}$$

$$g_{20}(r_H) = g_{11}(r_H) = g_{02}(r_H) = 0 \tag{3.18}$$

and

$$H(z,\bar{z},w(z,\bar{z};r_H)) = M(u,u) + O(|z|^3), \tag{3.19}$$

where $M(u,u)$ is given by (3.16). To determine the stability of the bifurcating solutions it follows from (3.5) and (3.18) that we only need to find $g_{21}(r_H)$. To do this we need the quadratic approximation to $w(z,\bar{z};r_H)$,

$$w(z,z;r_H) = \frac{1}{2} z^2 w_{20} + z\bar{z} w_{11} + \frac{1}{2} \bar{z}^2 w_{02} + O(|z|^3). \tag{3.20}$$

To find w_{20}, w_{11} and w_{02} we solve [3, p. 237]

$$\begin{aligned} (L(r_H) - 2i\omega_0) w_{20} &= -2M(q,q), \\ L(r_H) w_{11} &= -2\,\mathrm{Re}\,M(q,\bar{q}), \end{aligned} \tag{3.21}$$

and $w_{02} = \bar{w}_{20}$. Substituting (3.20) into (3.15) and collecting the coefficients in $\bar{z}^2 z$, we obtain

$$g_{21}(r_H) = (M(w_{20},\bar{q}) + M(\bar{q},w_{20}), q^*) + 2(M(w_{11},q) + M(q,w_{11}), q^*). \tag{3.22}$$

Since $\alpha'(r_H) > 0$ for $\sigma > 0$, $0 < \tau < 1$ and $s > s_c$, the Hopf bifurcation is supercritical or subcritical according to whether $\mathrm{Re}\,g_{21}(r_H)$ is negative or positive, and we have the following theorem.

THEOREM 2. *If* $\mathrm{Re}\,g_{21}(r_H) \neq 0$, *then assumption* (A) *of* §2 *is satisfied. Furthermore, if* $\mathrm{Re}\,g_{21}(r_H) < 0$ *then conclusion* (a) *of Theorem* 1 *holds, while if* $\mathrm{Re}\,g_{21}(r_H) > 0$ *then conclusion* (b) *holds.*

If $\mathrm{Re}\,g_{21}(r_H) = 0$ then higher order terms in (5.2) are required to see if (A) is satisfied.

We now illustrate the procedure of finding an explicit expression for $g_{21}(r_H)$ in the case of rolls. For $\Omega = C_1 \times (0,1)$ in $\mathbb{R}^2$ the components of an element $q \in Y$ have Fourier series expansions (see Part I)

$$
\begin{aligned}
q_1(x_1,x_3) &= \sum_{n_1=1}^{\infty} q_1(n_1,x_3)\sin n_1\alpha_1 x_1,\\
q_3(x_1,x_3) &= \sum_{n_1=0}^{\infty} q_3(n_1,x_3)\cos n_1\alpha_1 x_1,\\
q_4(x_1,x_3) &= \sum_{n_1=0}^{\infty} q_4(n_1,x_3)\cos n_1\alpha_1 x_1,\\
q_5(x_1,x_3) &= \sum_{n_1=0}^{\infty} q_5(n_1,x_3)\cos n_1\alpha_1 x_1,
\end{aligned}
\tag{3.23}
$$

where $\alpha_1 = \pi/\sqrt{2}$. Then the eigenvalue problems (3.6) and (3.7) become

(3.24)

$$
\begin{aligned}
&\sigma\Delta(n_1)q_1(n_1,x_3)+\sigma n_1\alpha_1 p(n_1,x_3) = i\omega_0 q_1(n_1,x_3),\\
&\sigma\Delta(n_1)q_3(n_1,x_3)-\sigma\frac{d}{dx_3}p(n_1,x_3)+\sigma r_H q_4(n_1,x_3)-\sigma s q_5(n_1,x_3) = i\omega_0 q_3(n_1,x_3),\\
&\Delta(n_1)q_4(n_1,x_3)+q_3(n_1,x_3) = i\omega_0 q_4(n_1,x_3),\\
&\tau\Delta(n_1)q_5(n_1,x_3)+q_3(n_1,x_3) = i\omega_0 q_5(n_1,x_3),\\
&n_1\alpha_1 q_1(n_1,x_3)+\frac{d}{dx_3}q_3(n_1,x_3) = 0 \quad \text{for } x_3 \in (0,1),\\
&\frac{d}{dx_3}q_1(n_1,x_3)\Big|_{x_3=0,1} = q_3(n_1,x_3)|_{x_3=0,1} = q_4(n_1,x_3)|_{x_3=0,1} = q_5(n_1,x_3)|_{x_3=0,1} = 0,
\end{aligned}
$$

and

(3.25)

$$
\begin{aligned}
&\sigma\Delta(n_1)q^*{}_1(n_1,x_3)+\sigma n_1\alpha_1 p^*(n_1,x_3) = -i\omega_0 q^*{}_1(n_1,x_3),\\
&\sigma\Delta(n_1)q^*{}_3(n_1,x_3)-\sigma\frac{d}{dx_3}p^*(n_1,x_3)+q^*{}_4(n_1,x_3)+q^*{}_5(n_1,x_3) = -i\omega_0 q^*{}_3(n_1,x_3),\\
&\Delta(n_1)q^*{}_4(n_1,x_3)+\sigma r_H q^*{}_3(n_1,x_3) = -i\omega_0 q^*{}_4(n_1,x_3),\\
&\tau\Delta(n_1)q^*{}_5(n_1,x_3)-\sigma s q^*{}_3(n_1,x_3) = -i\omega_0 q^*{}_5(n_1,x_3),\\
&n_1\alpha_1 q^*{}_1(n_1,x_3)+\frac{d}{dx_3}q^*{}_3(n_1,x_3) = 0 \quad \text{for } x_3 \in (0,1),\\
&\frac{d}{dx_3}q^*{}_1(n_1,x_3)\Big|_{x_3=0,1} = q^*{}_3(n_1,x_3)|_{x_3=0,1} = q^*{}_4(n_1,x_3)|_{x_3=0,1} = q^*{}_5(n_1,x_3)|_{x_3=0,1} = 0,
\end{aligned}
$$

for $n_1 = 0,1,2,\cdots$, where $\Delta(n_1) = (d/dx_3) - n_1^2\alpha_1^2$ and p, p^* are fluid pressures. The pressures can be eliminated, and the equations (3.24), (3.25) can be reduced to single equations for $q_3(n_1,x_3)$, $q^*{}_3(n_1,x_3)$ as in Part I. The boundary conditions allow the

Fourier series expansions

$$
\begin{aligned}
q_3(n_1,x_3) &= \sum_{n_3=1}^{\infty} q_3(n_1,n_3)\sin n_3\pi x_3,\\
q^*{}_3(n_1,x_3) &= \sum_{n_3=1}^{\infty} q^*{}_3(n_1,x_3)\sin n_3\pi x_3,
\end{aligned}
\tag{3.26}
$$

for $n_1 = 0, 1, 2, \cdots$. Equations (3.24), (3.25) have no nontrivial solutions unless $n_1 = n_3 = 1$ and we obtain the eigenfunctions in the case of rolls,

$$
q = \begin{pmatrix}
-\dfrac{2\alpha_1}{\pi}\sin\alpha_1 x_1\cos\pi x_3\\
\cos\alpha_1 x_1\sin\pi x_3\\
\left(\dfrac{3\pi^2}{2}+i\omega_0\right)^{-1}\cos\alpha_1 x_1\sin\pi x_3\\
\left(\dfrac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\cos\alpha_1 x_1\sin\pi x_3
\end{pmatrix},
\tag{3.27}
$$

$$
q^* = (\bar{N})^{-1}\begin{pmatrix}
-\dfrac{2\alpha_1}{\pi}\sin\alpha_1 x_1\cos\pi x_3\\
\cos\alpha_1 x_1\sin\pi x_3\\
\sigma r_H\left(\dfrac{3\pi^2}{2}-i\omega_0\right)^{-1}\cos\alpha_1 x_1\sin\pi x_3\\
-\sigma s\left(\dfrac{3\pi\tau}{2}-i\omega_0\right)^{-1}\cos\alpha_1 x_1\sin\pi x_3
\end{pmatrix}
\tag{3.28}
$$

where

$$
N = \frac{1}{2}\sqrt{2}\left[3+\sigma r_H\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-2}-\sigma s\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-2}\right]
\tag{3.29}
$$

is chosen so that

$$
(q,q^*) = \int_0^1\int_0^{\alpha_1/2\pi}(q_1\bar{q}^*{}_1+q_3\bar{q}^*{}_3+q_4\bar{q}^*{}_4+q_5\bar{q}^*{}_5)\,dx_1\,dx_3 = 1.
$$

We then compute

$$
(\nabla\cdot\underset{\sim}{q})\,q = \begin{pmatrix}
\alpha_1\sin 2\alpha_1 x_1\\
\dfrac{\pi}{2}\sin 2\pi x_3\\
\dfrac{\pi}{2}\left(\dfrac{3\pi^2}{2}+i\omega_0\right)^{-1}\sin 2\pi x_3\\
\dfrac{\pi}{2}\left(\dfrac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\sin 2\pi x_3
\end{pmatrix}
\tag{3.30}
$$

and

$$(\nabla\cdot\underset{\sim}{q})\bar{q}=\begin{pmatrix}\alpha_1\sin 2\alpha_1 x_1\\ \frac{\pi}{2}\sin 2\pi x_3\\ \frac{\pi}{2}\left(\frac{3\pi^2}{2}-i\omega_0\right)^{-1}\sin 2\pi x_3\\ \frac{\pi}{2}\left(\frac{3\pi^2\tau}{2}-i\omega_0\right)^{-1}\sin 2\pi x_3\end{pmatrix}. \tag{3.31}$$

Note that $(M(q,q),q)=(-\Pi_0(\nabla\cdot q)q,q)=(-(\nabla\cdot q)q,q)=0$, and similarly $(M(q,\bar{q}),q^*)=0$ since $\int_0^1\cos\pi x_3\,dx_3=0$ and $\int_0^1\sin\pi x_3\sin 2\pi x_3\,dx_3=0$. This verifies in the case of rolls the assertion following (3.16). For squares and hexagons, the assertion is true for similar reasons. We then solve (3.21) for w_{20} and w_{11} by finding their Fourier coefficients as we did for q and q^*, and obtain

$$w_2^0=\begin{pmatrix}0\\ 0\\ -(4\pi^2+2i\omega_0)^{-1}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\pi\sin 2\pi x_3\\ -(4\pi^2\tau+2i\omega_0)^{-1}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\pi\sin 2\pi x_3\end{pmatrix},$$

$$w_{11}=\begin{pmatrix}0\\ 0\\ -(4\pi^2)^{-1}\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\pi\sin 2\pi x_3\\ -(4\pi^2\tau)^{-1}\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\pi\sin 2\pi x_3\end{pmatrix}. \tag{3.32}$$

Finally from (3.22), (3.27), (3.28) and (3.32) we obtain the expression

(3.33)

$$\begin{aligned}g_{21}(r_H)=\frac{\sqrt{2}\pi}{2N}\Bigg\{&-\sigma r_H\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\Bigg[(4\pi^2+2i\omega_0)^{-1}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\\ &+2(4\pi^2)^{-1}\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\Bigg]\\ &+\sigma s\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\Bigg[(4\pi^2+2i\omega_0)^{-1}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\\ &+2(4\pi^2)^{-1}\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\Bigg]\Bigg\}.\end{aligned}$$

The computations to find $g_{21}(r_H)$ in the cases of squares and hexagons proceed similarly, but are somewhat longer. Here we state only the results: for squares we have

(3.34)

$$
\begin{aligned}
g_{21}(r_H) = \frac{2\pi^2}{N}\Bigg\langle & 3(A+2B) \\
& - \sigma r_H\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\Bigg\{4\left(4\pi^2+2i\omega_0\right)^{-1}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1} \\
& \qquad + 8(4\pi^2)^{-1}\,\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1} \\
& \qquad + \left(5\pi^2+2i\omega_0\right)^{-1}\left[\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-A\right] \\
& \qquad + 2(5\pi^2)^{-1}\left[\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-B\right]\Bigg\} \\
& + \sigma s\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\Bigg\{4\left(4\pi^2\tau+2i\omega_0\right)^{-1}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1} \\
& \qquad + 8(4\pi^2\tau)^{-1}\,\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1} \\
& \qquad + \left(5\pi^2\tau+2i\omega_0\right)^{-1}\left[\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}-A\right] \\
& \qquad + 2(5\pi^2\tau)-1\left[\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}-B\right]\Bigg\}\Bigg\rangle .
\end{aligned}
$$

where

$$
N = 3+\sigma r_H\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-2}-\sigma s\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-2},
$$

$$
\begin{aligned}
A = & \left[-\left(25\pi^2\sigma+10i\omega_0\right)+\sigma r_H\left(5\pi^2+2i\omega_0\right)^{-1}-\sigma s\left(5\pi^2\tau+2i\omega_0\right)^{-1}\right]^{-1} \\
& \cdot\left[3+\sigma r_H\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\left(5\pi^2+2i\omega_0\right)^{-1}\right. \\
& \qquad \left.-\sigma s\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\left(5\pi^2\tau+2i\omega_0\right)^{-1}\right],
\end{aligned}
$$

and

$$B=\left[-25\pi^2\sigma+\sigma r_H(5\pi^2)^{-1}-\sigma s(5\pi^2\tau)^{-1}\right]^{-1}$$
$$\cdot\left[3+\sigma r_H(5\pi^2)^{-1}\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-\sigma s(5\pi^2\tau)^{-1}\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\right],$$

while for hexagons

(3.35)

$$g_{21}(r_H)=\frac{\pi^2}{2N}\Bigg\langle 9A'+3A''+18B'+6B''$$
$$-\sigma r_H\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}\Bigg\{24(4\pi^2+2i\omega_0)^{-1}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}$$
$$+48(4\pi^2)^{-1}\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}$$
$$+3\left(\frac{9\pi^2}{2}+2i\omega_0\right)^{-1}\left[3\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-A'\right]$$
$$+6\left(\frac{9\pi^2}{2}\right)\left[3\,\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-B'\right]$$
$$+\left(\frac{11\pi^2}{2}+2i\omega_0\right)^{-1}\left[\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-A'\right]$$
$$+2\left(\frac{11\pi^2}{2}\right)^{-1}\left[\mathrm{Re}\left(\frac{3\pi^2}{2}+i\omega_0\right)^{-1}-B''\right]\Bigg\}$$
$$+\sigma s\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}\Bigg\{24(4\pi^2\tau+2i\omega_0)^{-1}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}$$
$$+48(4\pi^2\tau)^{-1}\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}$$
$$+3\left(\frac{9\pi^2\tau}{2}+2i\omega_0\right)^{-1}\left[3\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}-A'\right]$$
$$+6\left(\frac{9\pi^2\tau}{2}\right)^{-1}\left[3\,\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}-B'\right]$$
$$+\left(\frac{11\pi^2\tau}{2}+2i\omega_0\right)^{-1}\left[\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}-A''\right]$$
$$+2\left(\frac{11\pi^2\tau}{2}\right)^{-1}\left[\mathrm{Re}\left(\frac{3\pi^2\tau}{2}+i\omega_0\right)^{-1}-B''\right]\Bigg\}\Bigg\rangle$$

where

$$N = 3 + \sigma r\left(\frac{3\pi^2}{2} + i\omega_0\right)^{-2} - \sigma s\left(\frac{3\pi^2\tau}{2} + i\omega_0\right)^{-2},$$

$$A' = 3\left[-9\left(\frac{9\pi^2\sigma}{2} + 2i\omega_0\right) + \sigma r_H\left(\frac{9\pi^2}{2} + 2i\omega_0\right)^{-1} - \sigma s\left(\frac{9\pi^2\tau}{2} + 2i\omega_0\right)^{-1}\right]^{-1}$$
$$\cdot\left[3 + \sigma r_H\left(\frac{3\pi^2}{2} + i\omega_0\right)^{-1}\left(\frac{9\pi^2}{2} + 2i\omega_0\right)^{-1} - \sigma s\left(\frac{3\pi^2\tau}{2} + i\omega_0\right)^{-1}\left(\frac{9\pi^2\tau}{2} + 2i\omega_0\right)^{-1}\right],$$

$$A'' = \left[-\frac{11}{3}\left(\frac{11\pi^2\sigma}{2} + 2i\omega_0\right) + \sigma r_H\left(\frac{11\pi^2}{2} + 2i\omega_0\right)^{-1} - \sigma s\left(\frac{11\pi^2\tau}{2} + 2i\omega_0\right)^{-1}\right]^{-1}$$
$$\cdot\left[3 + \sigma r_H\left(\frac{3\pi^2}{2} + i\omega_0\right)^{-1}\left(\frac{11\pi^2}{2} + 2i\omega_0\right)^{-1} - \sigma s\left(\frac{3\pi^2\tau}{2} + i\omega_0\right)^{-1}\left(\frac{11\pi^2\tau}{2} + 2i\omega_0\right)^{-1}\right],$$

$$B' = 3\left[-9\left(\frac{9\pi^2\sigma}{2}\right) + \sigma r_H\left(\frac{9\pi^2}{2}\right)^{-1} - \sigma s\left(\frac{9\pi^2\tau}{2}\right)^{-1}\right]^{-1}$$
$$\cdot\left[3 + \sigma r_H\left(\frac{9\pi^2}{2}\right)^{-1}\mathrm{Re}\left(\frac{3\pi^2}{2} + i\omega_0\right)^{-1} - \sigma s\left(\frac{9\pi^2\tau}{2}\right)^{-1}\mathrm{Re}\left(\frac{3\pi^2\tau}{2} + i\omega_0\right)^{-1}\right],$$

$$B'' = \left[-\frac{11}{3}\left(\frac{11\pi^2\sigma}{2}\right) + \sigma r_H\left(\frac{11\pi^2}{2}\right)^{-1} - \sigma s\left(\frac{11\pi^2\tau}{2}\right)^{-1}\right]^{-1}$$
$$\cdot\left[3 + \sigma r_H\left(\frac{11\pi^2}{2}\right)^{-1}\mathrm{Re}\left(\frac{3\pi^2}{2} + i\omega_0\right)^{-1} - \sigma s\left(\frac{11\pi^2\tau}{2}\right)\mathrm{Re}\left(\frac{3\pi^2\tau}{2} + i\omega_0\right)^{-1}\right]^{-1}.$$

The dependence of $\mathrm{Re}\, g_{21}(r_H)$ on σ, τ and s does not appear to be obvious from (3.33), (3.34) or (3.35) so we evaluated $\mathrm{Re}\, g_{21}(r_H)$ numerically. For all four spatially periodic structures—rolls, rectangles, squares and hexagons—the locus of points in $\sigma\tau$ s-space where $\mathrm{Re}\, g_{21}(r_H) = 0$ appears to be a two-dimensional surface in the three-dimensional parameter space. If this is true, then for almost all admissible σ, τ and s, we have $\mathrm{Re}\, g_{21}(r_H) \neq 0$ and hence by Theorem 2 either supercritical or subcritical Hopf bifurcations exist.

In Figs. 1–5 we have plotted $\mathrm{Re}\, g_{21}(r_H)$ as a function of s, for several values of σ and τ. The values of σ and τ in Figs. 1–4 correspond to those in [5, Fig. 2], and the values of s at which $\mathrm{Re}\, g_{21}(r_H) = 0$ for rolls agree with [5]. In [2], Da Costa et al. give an analytic expression for $\mathrm{Re}\, g_{21}(r_H) = 0$, which also agrees with the results of [5]. The expression was obtained by considering a modal truncation of the full double-diffusive convection equations for rolls, which simplified the computation. However, the center manifold reduction used here provides justification for the validity of the truncation: enough modes were kept in [2] so as not to affect the normal form (3.2) in terms of order $\xi|\xi|^2$ or less.

We have also obtained results for squares and hexagons. In Figs. 1–4 the qualitative behavior of $\mathrm{Re}\, g_{21}(r_H)$ as a function of s for squares and hexagons is similar to the behavior for rolls: for s near s_C, $\mathrm{Re}\, g_{21}(r_H)$ is negative and increasing, and the graph crosses the s-axis as s is increased. The exact value of s at which $\mathrm{Re}\, g_{21}(r_H) = 0$ depends on the cellular structure considered. However, by varying σ and τ, one can observe

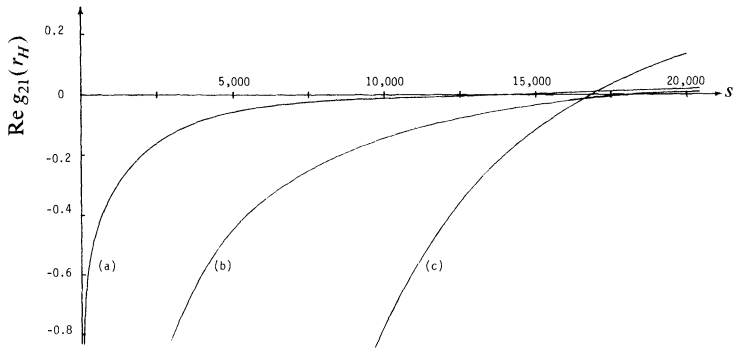

FIG. 1. Re $g_{21}(r_H)$ *as a function of* s *when* $\sigma = 1$, $\tau = 10^{-1/2}$ *for* (a) *rolls*, (b) *squares*, (c) *hexagons.*

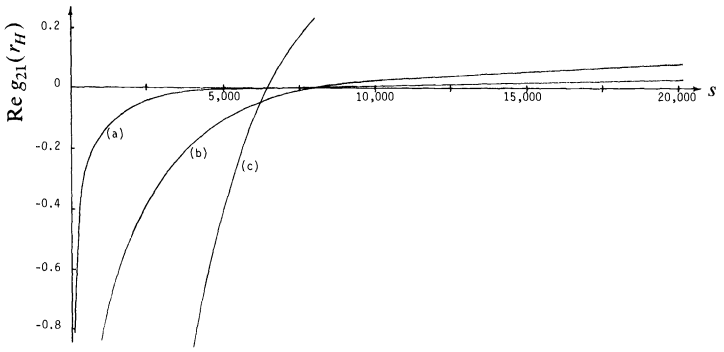

FIG. 2. Re $g_{21}(r_H)$ *as a function of* s *when* $\sigma = 1$, $\tau = 0.1$ *for* (a) *rolls*, (b) *squares*, (c) *hexagons.*

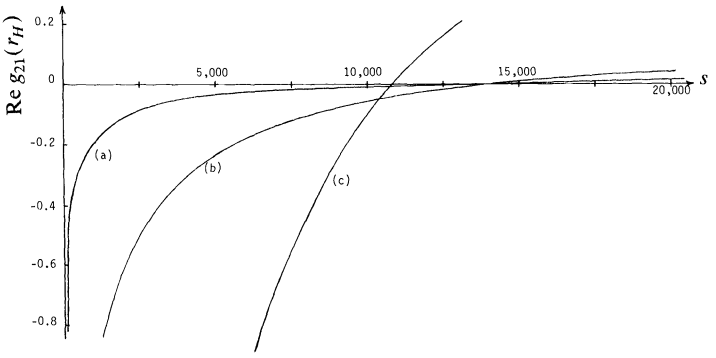

FIG. 3. Re $g_{21}(r_H)$ *as a function of* s *when* $\sigma = 10$, $\tau = 0.1$ *for* (a) *rolls*, (b) *squares*, (c) *hexagons.*

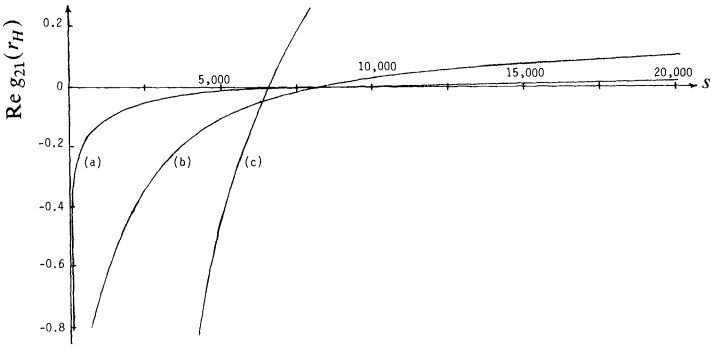

FIG. 4. Re $g_{21}(r_H)$ *as a function of* s *when* $\sigma = 7$, $\tau = 1/80$ *for* (a) *rolls*, (b) *squares*, (c) *hexagons.*

different behavior. For example, if the Prandtl number σ is decreased as in Fig. 5, where $\sigma = 0.001$ and $\tau = 0.1$, one sees that for s near s_C, $\mathrm{Re}\, g_{21}(r_H)$ is positive for squares and hexagons, but negative for rolls. Thus, branches of unstable time periodic square and hexagonal convection patterns bifurcate subcritically from the constant gradient solution at $r = r_H$, while branches of time periodic rolls bifurcate supercritically.

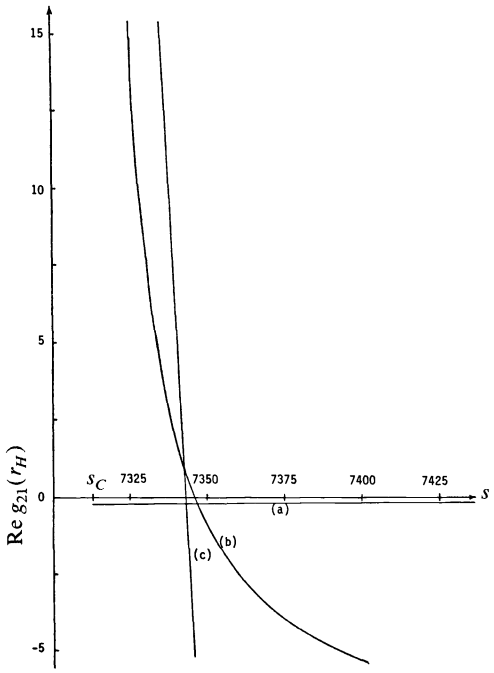

FIG. 5. $\mathrm{Re}\, g_{21}(r_H)$ *as a function of* s *when* $\sigma = 0.001$, $\tau = 0.1$ *for* (a) *rolls*, (b) *squares*, (c) *hexagons*.

It is possible that when $\mathrm{Re}\, g_{21}(r_H)$ is positive, the corresponding subcritical branch of unstable solutions may "turn back" at a limit point and the solutions on this branch beyond the limit point may be stable. This was conjectured by [5] for rolls, and the behavior of the modally truncated equations in [2] supports this conjecture. To verify this conjecture near parameter values where $\mathrm{Re}\, g_{21}(r_H) = 0$, one needs to compute the order $\xi|\xi|^4$ term in the normal form (3.2).

4. Conclusion. We have proved the existence of nontrivial time periodic solutions of double-diffusive convection equations, for suitable values of the parameters r, s, σ and τ. The solutions correspond to time periodic fluid flow in roll-like, rectangular, square and hexagonal convection cell patterns in the layer of fluid. The time periodic solutions bifurcate from the constant gradient solution either supercritically or subcritically, according to whether the sign of the coefficient $\mathrm{Re}\, g_{21}(r_H)$ is negative or positive. Solutions on a supercritical branch for r near r_H are orbitally asymptotically stable with respect to perturbations of the same cellular structure, while the solutions on a subcritical branch for r near r_H are unstable. As far as we know, a theory of pattern selection for Hopf bifurcation (which would determine whether solutions on a supercritical branch are also stable with respect to perturbations of a different cellular structure) is not yet available.

We have computed $\mathrm{Re}\, g_{21}(r_H)$ for rolls, squares and hexagons. For some parameter values, all three cellular structures exhibit similar functional dependence of $\mathrm{Re}\, g_{21}(r_H)$ on s, but as the Prandtl number σ is decreased, the behavior of $\mathrm{Re}\, g_{21}(r_H)$ for squares and hexagons is different than that for rolls.

THE GENERALIZED INVERSE OF AN UNBOUNDED LINEAR OPERATOR*

ROBERT NEFF BRYAN†

Abstract. Some necessary and some sufficient conditions are given for the existence of the Moore–Penrose generalized inverse of an unbounded linear operator between inner product spaces with an appropriately restricted domain. These results generalize a recent result of W. F. Langford.

1. Introduction. In this paper, we establish results similar to, but more general than, some of those given in a recent paper [1] by W. F. Langford regarding the existence of the Moore–Penrose generalized inverse of a certain unbounded linear operator between inner product spaces. Langford applied his results to a two-point ordinary differential boundary value problem to show that the associated operator has a generalized inverse, and, apparently, chose his assumptions on his operator so that his results would be applicable to the differential operator. Here, we show that his assumptions may be relaxed to some extent to obtain similar results, and we clarify the roles which certain of his assumptions play in the establishing of the results.

2. Notation and assumptions. We begin by listing our notation and stating our assumptions. Let X and Y denote real inner product spaces and l be a linear operator from X and Y. Let D be a subspace of X. We study the operator L which is l restricted to D. We denote the range of L by R, the kernel of l by k, and the kernel of L by K. The spaces of linear (not necessarily continuous) functionals on X and Y are denoted by X^* and Y^* respectively. The natural imbedding of X into X^* (and Y into Y^*) is denoted by J and maps $z \in X$ to $z^* \in X$ which satisfies $z^*(x) = \langle x, z \rangle$ for $x \in X$, where $\langle \cdot, \cdot \rangle$ is the inner product notation in X (and Y). We make extensive use of the following sets related to $S \subseteq X$:

$$S^{\perp} = \{ x \in X : \langle s, x \rangle = 0 \text{ for } s \in S \}$$

and

$$S^0 = \{ x^* \in X^* : x^*(s) = 0 \text{ for } s \in S \}.$$

The following lemma is interesting as it stands as well as useful in the sequel.

LEMMA 1. *Let X be an inner product space and S be a subspace of X. Then*

(1) *$J(S^{\perp}) = S^0$ implies $S^{\perp\perp} = S$;*

(2) *if $S^{\perp}$ is finite-dimensional and $S^{\perp\perp} = S$, then $J(S^{\perp}) = S^0$; and*

(3) *if $S^0 \subseteq J(X)$, then $J(S^{\perp}) = S^0$.*

Proof. (1) We need only show that $S^{\perp\perp} \subseteq S$. For some $t \in S^{\perp\perp} - S$ there is a functional $u \in X^*$ for which $u(t) = 1$ and $u(s) = 0$ for $s \in S$; hence, there exists $\bar{u} \in S^{\perp}$ for which $J(\bar{u}) = u$. This implies $\langle \bar{u}, t \rangle = 1$ which contradicts that $t \in S^{\perp\perp}$ and $u \in S^{\perp}$.

(2) Clearly, $J(S^{\perp}) \subseteq S^0$. We have, by hypothesis, $X = S \oplus S^{\perp}$. Let $u \in S^0$, and consider the restriction of u to $S^{\perp}$. Since $S^{\perp}$ is finite-dimensional, there is a $\bar{u} \in S^{\perp}$

*Received by the editors August 11, 1981, and in revised form March 19, 1984.

† Department of Mathematics, University of Western Ontario, London, Ontario, Canada N6A 589.

satisfying $u(x)=\langle \bar{u}, x\rangle$ for $x\in S^{\perp}$. Given an $x=x_1+x_2$, $x_1\in S$, $x_2\in S^{\perp}$, $u(x)=u(x_2)$ $=\langle \bar{u}, x_2\rangle=\langle \bar{u}, x\rangle$. Hence, $u=J(\bar{u})$ and $u\in J(S^{\perp})$. Thus, $J(S^{\perp})=S^0$.

(3) The proof is immediate.

3. Main results. First, we review some terminology. The equation $Lx=y$ has associated with it the set $S_y=\{x\in X:\ \|Lx-y\|\leqq\|Lz-y\|;\ z\in X\}$ of least squares solutions. The norm is given by the inner product on Y. The set S_y is convex. If there is a unique point x^+ in S_y satisfying $\|x^+\|\leqq\|x\|$ for all $x\in S_y$, then x^+ is called the best-least-squares solution (BLSS) of $Lx=y$. The operator L is said to have a (Moore–Penrose) generalized inverse, L^+, if $Lx=y$ has a BLSS for every y in Y, and, of course, $L^+y=x^+$.

In order to compare the results which follow with those of Langford in [1], the reader should keep in mind that in the setting of [1], the spaces k (and hence K) and $R^{\perp}$ are finite-dimensional. The assumptions regarding each of these spaces in this paper are included in each statement of a lemma or theorem which involves it, except Theorem 4 in which $R^{\perp}$ is assumed to be finite-dimensional.

Advantages of considering these slightly more general settings are that some proofs are simplified and the roles that the various assumptions play in the results are made explicit. This enables us to concentrate on the sets of sufficient conditions for the existence of L^+, each of which includes the completeness of K; they appear as the first statement in each of Theorems 1, 2, and 3 and in Theorem 4.

The finite-dimensional version of our first main result does not appear in [1], but is hinted at in the proof of Langford's Lemma 1 [1, p. 1085].

THEOREM 1. (1) *If $R^{\perp}$ and K are complete and $R^{\perp\perp}=R$, then L^+ exists*; (2) *if $R^{\perp}$ is complete and L^+ exists, then $R^{\perp\perp}=R$.*

Proof. (1) Since $R^{\perp}$ is complete, $Y=R^{\perp\perp}\oplus R^{\perp}=R\oplus R^{\perp}$. Hence, y, in Y, can be written as $y=y_1+y_2$, $y_1\in R$, $y_2\in R^{\perp}$. The projection theorem implies that $\|y-y_1\|<$ $\|y-z\|$ for all $z\in R-y_1$. Letting x_1 be a solution of $Lx=y_1$, we see that the inequality implies $\|Lx_1-y\|\leqq\|Lx-y\|$ for all $x\in D$. Since K is a complete subspace of X, we can apply the projection theorem again to obtain unique $m_0\in K$ satisfying $\|x_1-m_0\|\leqq\|x_1-m\|$ for all $m\in K$. Then $x^+=x_1-m_0$ is the BLSS of $Lx=y$. Thus, L^+ exists.

(2) Let $y\in Y$. There exists a unique $x^+=L^+u$ which satisfies $\|Lx^+-y\|\leqq\|Lx-y\|$ for all $x\in D$, so that there is a unique $\bar{y}=Lx^+\in R$ such that $\|\bar{y}-y\|\leqq\|z-y\|$ for all $z\in R$. Thus, by the alternate form of the projection theorem (see §6), $Y=R\oplus R^{\perp}$. But $Y=R^{\perp}\oplus R^{\perp\perp}$, so that $R^{\perp\perp}=R$.

The following theorem is a generalization of Langford's lemma [1, p. 1085], mentioned above. We note, in particular, that no assumptions are made here on the space k. The proof consists of applying Lemma 1 and Theorem 1.

THEOREM 2. (1) *If $R^{\perp}$ and K are complete and $J(R^{\perp})=R^0$, then L^+ exists.* (2) *If $R^{\perp}$ is finite-dimensional and L^+ exists, then $J(R^{\perp})=R^0$.*

The adjoint of l, denoted by l^*, is defined in the usual manner. If k, the kernel of l, is complete, then $R(l^*)$, the range of l^*, is the annihilator of k; i.e., $R(l^*)=k^0$. A proof of this is given in [1, Lemma 8, p. 1094], where only the completeness of k is used, not its finite-dimensionality.

We note that the following result does not depend on the dimensionality of any of the spaces involved.

LEMMA 2. (cf. [1, Lemma 2, p. 1086]). (1) $l^*(R^0)\subseteq D^0\cap k^0$; (2) *furthermore, if k is complete, then $D^0\cap k^0=l^*(R^0)$.*

Proof. (1) Let $u \in l^*(R^0)$, $v \in R^0$ so that $u = l^*v$. Then $u(x) = l^*v(x) = v(lx) = 0$ for $x \in D$, so $u \in D^0$. Clearly $u(x) = 0$ for $x \in k$, so $u \in k^0$.

(2) For $u \in D^0 \cap k^0$, $u \in R(l^*)$ so there is a $v \in Y^*$ for which $u = l^*$. Since $u \in D^0$, $l^*v(x) = 0$ for every $x \in D$. But $l^*(v) = v(lx)$ so $v(r) = 0$ for every $r \in R$; i.e., $v \in R^0$, so $u \in l^*(R^0)$. Thus, $D^0 \cap k^0 \subset l^*(R^0)$. Part (1) yields the equality,

Theorems 3 and 4, below, are generalizations of [1, Thm. 1]. The statements of those theorems indicate the interplay among the various assumptions made on k, K, and $R^\perp$ which are lost in [1, Thm. 1]. Together with Theorems 1 and 2, above, they provide several sets of necessary conditions and of sufficient conditions for the existence of L^+.

THEOREM 3. (1) *If $R^\perp$, k, and K are complete and $D^0 \cap k^0 \subseteq l^*[J(Y)]$, then L^+ exists.*

(2) *If L^+ exists, $R^\perp$ is finite-dimensional, and k is complete, then $D^0 \cap k^0 \subseteq l^*[J(Y)]$.*

Proof. (1) We have $D^0 \cap k^0 = l^*(R^0) \subseteq l^*[J(Y)]$ by Lemma 2, so that $R^0 \subseteq J(Y)$, since l^* is one-to-one. Thus, $R^0 = J(R^\perp)$, by Lemma 1, so L^+ exists, by Theorem 2.

(2) We use Lemma 2, Theorem 2, and the fact that $R^\perp \subseteq Y$, in turn, to establish that $D^0 \cap k^0 = l^*(R^0) = l^*[J(R^\perp)] \subset l^*[J(Y)]$.

The set $l^*[J(Y)]$, which is mentioned in Theorem 3, has an attractive characterization, which adds interest to that theorem. The characterization is given in the following remark.

Remark. If $u \in l^*[J(Y)]$, then there is a point $y \in Y$ for which $u(x) = \langle lx, y \rangle$ for $x \in X$, and conversely.

Using this result, we see, readily, the following lemma.

LEMMA 3. *If $D^0 \subseteq J(k) \oplus l^*[J(Y)]$, then $D^0 \cap k^0 \subseteq l^*[J(Y)]$.*

This gives us a sufficient condition on D for the existence of L^+; viz.,

COROLLARY (cf. [1, Corollary 1, p. 1086]). *If $R^\perp$, k, and K are complete and $D^0 \subseteq J(k) \oplus l^*[J(Y)]$, then L^+ exists.*

4. A result for L with special domain. In this section we choose a particular type of domain of L, essentially the same as that described in [1], and obtain a necessary and sufficient condition for the existence of L^+.

Let $\{f_1, f_2, \cdots, f_m\}$ be a linearly independent set in X^* and F be the subspace of X^* spanned by $f_1, \cdots, f_m$. Let $D = \{x \in X: f(x) = 0 \text{ for all } f \in F\}$. It is easily seen that D, given in this way, has finite codimension and that $D^0 = F$. This implies that $R^\perp$ is finite-dimensional and, hence, complete. Thus, for D as given here, we have, from Theorem 3, the following theorem.

THEOREM 4. *If k and K are complete, then L^* exists if and only if $F \cap k^0 \subseteq l^*[J(Y)]$.*

5. An example. We include an example to show that Theorem 1 applies in at least one case where Langford's Theorem 1 does not. Let $X_1 = \{a \in l^2: a_n = 0 \text{ for sufficiently large } n\}$ with l^2 inner product, $X = l^2 \oplus^\perp X_1$ with inner product $\langle s_1 + x_1, s_2 + x_2 \rangle = \langle s_1, s_2 \rangle + \langle x_1, x_2 \rangle$, and $Y = X_1$. Let T: $X_1 \to Y$ be defined by $T(a) = T[(a_1, a_2, \cdots)] = (a_1, 2a_2, 3a_3, \cdots)$. Then T is one-to-one but not continuous. Define l by $l(x) = l(s + a) = T(a)$, and let $D = \theta \oplus X_1$. Note that D has infinite codimension. Let L be l restricted to D. Then $R = Y = X_1$, $R^\perp = \{\theta\}$, which is complete, and $R^{\perp\perp} = R$; also, L is not continuous. The kernels, $k = K = l^2 \oplus \theta$, are infinite-dimensional but complete. Thus, L has a generalized inverse, by Theorem 1.

6. The projection theorem. We include two versions of the projection theorem which were applied in the proof of Theorem 1.

PROJECTION THEOREM. *Let V be an inner product space, M be a subspace of V and $v \in V - M$ and $m_0 \in M$. Then $\|v - m_0\| < \|v - m\|$ for all $m \in M - m_0$ if and only if $v - m_0 \in M^{\perp}$.*

PROJECTION THEOREM–ALTERNATE FORM. *Let V be an inner product space and M a subspace of V. Then for every $v \in V$ there exists a unique $m_0 \in M$ such that $\|v - m_0\| \leqq \|v - m\|$ for all $m \in M$ if and only if $V = M \oplus M^{\perp}$.*

LINEARIZATION STABILITY FOR AN INVERSE PROBLEM IN SEVERAL-DIMENSIONAL WAVE PROPAGATION*

W. W. SYMES†

Abstract. Inverse problems in wave propagation arise from the physical notion that the response of a mechanical continuum to a specified excitation should reflect the properties of the medium through which the excited waves travel, even though the waves are eventually measured at a remote location. We consider the formal linearization of a simple model inverse problem in several-dimensional wave propagation, in which the density distribution of a linear fluid is to be recovered from its remotely measured response to an incident plane-wave excitation, assuming the sound velocity distribution to be known and constant. We make reasonable choices for norms (error measures), and give simple examples establishing the ill-posed nature of the problem and indicating the mechanism of instability. We then show how the problem may be regularized (rendered well-posed) by the introduction of minimally stringent a priori constraints, motivated by a (crude) approximation to the singular value decomposition of the linearized problem.

AMS-MOS subject classification (1980). Primary 35R25

Key words. inverse, problem in wave propagation, linearization stability, regularization

Inverse problems in wave propagation arise from the physical notion that the response of a mechanical continuum to a specified excitation should reflect the properties of the medium through which the excited waves travel, even though the waves are eventually measured at a remote location. All measurement is contaminated by error, and the mathematical structures used to model wave propagation can be regarded only as approximate descriptions of actual physical processes. Therefore, the most important question about these problems (as for many other problems in applied mathematics) is: to what extent does error in data (remote measurement of wave fields) produce error in solution (estimates of mechanical parameters)? This question of *stability* or *condition* is also critical for the design of effective numerical algorithms.

In this paper, we address a very simple model inverse problem in several-dimensional wave propagation, by examining its formal linearization. We make (reasonable) explicit choices for norms (error measures) and give simple examples establishing the ill-posed nature of the linearized problem, and indicating the source of the difficulty. We then show how the problem may be rendered well-conditioned (*regularized*) by imposition of a priori constraints on the mechanical parameters. These constraints are essentially the least stringent possible, and amount to a crude approximation to the singular value decomposition of the linearized problem.

We expect these considerations to apply with some changes to more complex inverse problems of greater practical interest than the simple model problem considered here.

We consider an acoustic medium confined to a half-space $\{x \in \mathbb{R}^n: x_n \geqq 0\}$. We assume that the excess pressure u is small, and so is governed approximately by the linear acoustic wave equation

$$\left(\frac{1}{\rho c^2}\partial_t^2 - \nabla \cdot \frac{1}{\rho}\nabla\right) u = 0 \tag{1}$$

where ρ is the density and c the sound velocity; both depend on x. We assume that the fluid is initially quiescent, i.e., $u \equiv 0$ for $t \ll 0$, and that the boundary of the fluid is *fixed* (rigid) except at $t = 0$, when it is subject to an impulsive acceleration, uniformly over the entire boundary:

$$\partial_{x_n} u(\cdot, 0, t) = -\delta(t) \tag{2}$$

where we have written $x = (x', x_n)$, $x' \in \mathbb{R}^{n-1}$. A final simplifying assumption is that the velocity $c \equiv 1$, so that the rays of geometric acoustics are straight lines.

We take for the data of our problem the excess pressure measured at the boundary $x_n = 0$. Since the problem (1) is well posed, at least for smooth ρ, each distribution of density produces a (hopefully characteristic) response

$$\mathcal{T}(\rho) = u(\cdot, 0, \cdot).$$

The inverse problem thus amounts to the study of the functional equation

$$\mathcal{T}(\rho) = g. \tag{3}$$

Instead of considering (3) directly, we will examine its formal linearization

$$D\mathcal{T}(\rho^0) \cdot \rho^1 = g^1 \tag{4}$$

in which a perturbation ρ^1 about a reference density distribution ρ^0 is sought to produce a perturbation g^1 in the response.

We first give an example which shows that, for reasonable choices of norms (error measures) for ρ and g, one or both of $D\mathcal{T}$ and $D\mathcal{T}^{-1}$ are unbounded. This means that:

(i) Depending on choice of norm, either $\mathcal{T}$ is not differentiable, or its derivative is not boundedly invertible, or $D\mathcal{T}$ is not its derivative, or any sensible combination of these circumstances.

(ii) The equation (4) does not in general possess solutions.

Consequently, the only obvious computational option for (3), i.e. some version of Newton's method, is doomed to failure. Problem (3) and (4) must be modified by the introduction of a priori constraints, to restore continuous dependence of ρ^1 on g^1. By virtue of (ii), we cannot actually expect to solve (4), so we change it to a least-squares optimization problem with constraint, i.e. we seek to minimize

$$\left\| D\mathcal{T}(\rho^0) \cdot \rho^1 - g^1 \right\|^2, \qquad \rho^1 \in \mathfrak{R} \tag{5}$$

where $\mathfrak{R}$ is a *regularizing set* and the norm is an appropriate Hilbert space norm. If the optimization problem (5) is to have stable solutions, an inequality of the form

$$\|\rho^1\| \leqq C \left\| D\mathcal{T}(\rho^0) \cdot \rho^1 \right\|, \qquad \rho^1 \in \mathfrak{R} \tag{6}$$

must hold. The derivation of roughly such an inequality is the main goal of this paper.

The choice of $\mathfrak{R}$ is important. Unfortunate choices of $\mathfrak{R}$ may override some information present in the data. We want to choose $\mathfrak{R}$ to correspond roughly to the *small singular values* of $D\mathcal{T}$: that is, we want the condition $\rho^1 \in \mathfrak{R}$ to bound a priori the components of ρ^1 in the singular value decomposition corresponding to small singular values, but leave the other components unbounded. We identify a suitable $\mathfrak{R}$ below (though our choice is probably suboptimal, as we also discuss).

To complete the picture, and deduce similar results for the nonlinear problem (3), we need to establish that $\mathscr{T}$ is actually differentiable, and that $D\mathscr{T}$ is continuous. These goals can be accomplished by extending the arguments given in our previous paper [12], in which we established that $\mathscr{T}$ is Lipshitz-continuous when the domain (ρ) is metrized with an anisotropic Sobolev norm. The results of [12] are fundamental to those presented here, and we make the same choice of norm for the perturbations ρ^1 below.

To end this introduction, we note that essentially the same arguments yield similar results for *velocity-inversion*, a more practically motivated problem in which the sound velocity is to be determined from remote pressure measurements, provided that no caustics occur in the incident wavefront. This restriction is highly unnatural, but the presence of caustics introduces presently unresolved technical difficulties. On the other hand, many authors have discussed (formal aspects of) linearized inverse problems, most often linearized velocity inversion against a homogeneous or stratified background—see for instance [3] and references cited therein. Also, most current data-processing methods in seismic exploration for petroleum, nondestructive materials evaluation by ultrasonic probing, ocean acoustics, etc., are based in one way or another on the study of formal linearizations. Some authors have also written on iterative, formal algorithms for the solution of inverse problems of this type—see [8], [9], [10], [11]. For one-dimensional problems, a fair amount about the analytic structure of analogues of $\mathscr{T}$ is known—see [13], [15] and references cited there. In higher dimensions, very little of a nonformal nature seems to have been accomplished.

We introduce some convenient changes in notation: we write: $x \to (x,z)$, so that $x \in \mathbb{R}^{n-1}$, $z \in \mathbb{R}^+$. We use the notation $\|u\|_s$ for the norm of $u \in H^s(\Omega)$, suppressing the dependence on the domain Ω. We set

$$\partial_t = \frac{\partial}{\partial t}, \quad \partial_z = \frac{\partial}{\partial z}, \qquad D_k = \frac{\partial}{\partial x_k}, \quad k = 1, \cdots, n-1,$$

$$\nabla_x = (D_1, \cdots, D_{n-1}), \qquad \nabla = (\nabla_x, \partial_z),$$

$$\nabla^2 = \Delta = \sum_{j=1}^{n-1} \frac{\partial^2}{\partial x_j^2} + \frac{\partial^2}{\partial z^2} = \Delta_x + \frac{\partial^2}{\partial z^2}.$$

We shall also replace ρ by η^{-1} for convenience. Denote by u the solution of (1), i.e.

$$(1') \qquad \begin{aligned} &\left(\partial_t^2 - \Delta - \nabla \log \eta \cdot \nabla\right) u = 0, \\ &\partial_z u(\cdot, 0, t) = -\delta(t) \\ &u \equiv 0, \qquad t \ll 0. \end{aligned}$$

We suppose throughout that $\log \eta \in C^\infty(\mathbb{R}^n_+)$. It is then standard that u is smooth in the forward light cone $C_\infty = \{(x,z,t)\colon t > z > 0\}$, and on the boundary (wave front) $\{z = t\}$ undergoes a jump discontinuity determined by the transport equation of geometric optics. Consequently, inside the light cone u solves the characteristic initial/boundary value problem

$$(7) \qquad \begin{aligned} &\left(\partial_t^2 - \Delta - \nabla \log \eta \cdot \nabla\right) u \equiv 0, \\ &\partial_z u(\cdot, 0, \cdot) \equiv 0, \qquad t > 0, \\ &u(x, z, z^+) = \eta(x,0)^{1/2} \eta(x,z)^{-1/2} \end{aligned}$$

(see [5, pp. 42–46] or [4, Chap. VI, §4, pp. 633–655]).

Remark. The transport equation breaks down in the presence of caustics, which complicates the extension of the present reasoning to variable-velocity problems.

The characteristic geometry of the wave equation shows that $\{\eta(x,z)\colon z\leqq T\}$ determines $\{u(x,0,t)\colon t\leqq 2T\}$. For $\log\eta\in C^\infty(\mathbb{R}^{n-1}\times[0,T])$ or $C^\infty(\mathbb{R}^n_+)$ respectively, we define

$$\mathscr{T}_T(\eta) := u(\cdot,0,\cdot)\in C^\infty\big(\mathbb{R}^{n-1}\times[0,2T]\big),$$
$$\mathscr{T}_\infty(\eta) := u(\cdot,0,\cdot)\in C^\infty\big(\mathbb{R}^n_+\big).$$

When the value of T is implicit from context, we suppress the subscript, and write $\mathscr{T}_T=\mathscr{T}$.

We next formally linearize $\mathscr{T}$. Let $\eta=\eta^0+\varepsilon\eta^1$, $u=u^0+\varepsilon u^1+\cdots$, and substitute in (7). A short calculation yields the perturbational equations

$$\begin{aligned}&\big(\partial_t^2-\Delta-\nabla\log\eta^0\cdot\nabla\big)u^1=\nabla\frac{\eta^1}{\eta^0}\cdot\nabla u^0,\\ &\partial_z u^1(\cdot,0,\cdot)\equiv 0,\\ &\bar u^1=-\frac{1}{2}\eta_0^{1/2}\big(\eta^0\big)^{-3/2}\eta^1\end{aligned}\tag{8}$$

where we have used the useful notation $\bar u(x,z)=u(x,z,z^+)$. Thus

$$D\mathscr{T}\big(\eta^0\big)\cdot\eta^1=u^1(\cdot,0,\cdot).$$

To discuss the behavior of $D\mathscr{T}$, we must introduce norms for η^1 and g^1. For reasons discussed below, we choose the H^1-norm for η^1, and the Dirichlet norm for g^1.

We now sketch a pair of examples, based on the geometric optics construction, which show that $D\mathscr{T}(1)$ and $D\mathscr{T}(1)^{-1}$ are both unbounded. A very similar argument is given in [14, §3] for the time-like Cauchy problem, so we refer the reader to that paper for details of the estimates.

In fact these examples really concern the relation between initial and boundary values for solution of the wave equation, and express well-known facts. The first example (unboundedness of $D\mathscr{T}^{-1}$) shows (essentially) the ill-posedness of the time-like Cauchy problem. The second (unboundedness of $D\mathscr{T}$) shows that the boundary values are generally not as smooth as initial data. Perhaps by sharpening the second example, one could show that, in general, one loses exactly the half-derivative suggested by the trace theorem.

The first example also follows trivially from the existence of solutions with singularities along a single ray—see [17]. Presumably the second example could also be derived from a closer examination of the Gaussian beam construction, although the route pursued below (ordinary geometric optics) seems simpler. In both cases the pathology arises from energy propagating along grazing rays.

The simplest reference coefficient to consider is $\eta^0=1$, for which

$$u^0(x,z,t)=h(t-z)$$

where h is the Heaviside unit step function.

For u^1, obtain the equations for the so-called Born approximation:

$$\begin{aligned}&\big(\partial_t^2-\nabla^2\big)u^1=0, \qquad t>z,\\ &\partial_z u^1(x,0,t)=0, \qquad t>0,\\ &u^1(x,z,z^+)=-\tfrac{1}{2}\eta^1(x,z).\end{aligned}\tag{9}$$

For convenience, we temporarily allow η^1 and u^1 to be complex, with the understanding that only the real parts have significance.

Suppose χ is a smooth function of bounded support in $\mathbb{R}^2$ with unit L^2 norm, and set

$$\eta^1(x,z)=\frac{1}{i\omega}\chi(x,z)e^{i\omega(x+z)},$$

$$u_a^1(x,z,t)=\frac{-1}{2i\omega}\chi(x-z+t,z)e^{i\omega(x+t)} \quad \text{for } t>z.$$

In fact, u_a^1 is a horizontally moving monochromatic wave packet, and is an approximate solution of (9) in the sense that

$$(\partial_t^2-\nabla^2)u_a^1=O\left(\frac{1}{\omega}\right).$$

Also

$$u_a^1(x,z,z^+)=-\tfrac{1}{2}\eta^1(x,z).$$

If we reflect u_a^1 at the boundary i.e., replace $u_a^1(x,z,t)$ by $u_a^1(x,z,t)+u_a^1(x,-z,t)$, then u_a^1 differs from u^1, in the energy norm, by $O(1/\omega)$.

We distinguish two cases. First suppose that the support of χ is entirely contained in $\{z>0\}$. Then $u_a^1\equiv 0$, for $z=0$; it follows that there is some sequence of frequencies $\omega_n\to\infty$ for which

$$\int_0^T\int_{\mathbb{R}^{n-1}}dx\left\{\left|\partial_t u^1(x,0,t)\right|^2+\left|\nabla_x u^1(x,0,t)\right|^2\right\}\to 0$$

while

$$\int dz\int\left|\nabla\eta^1\right|^2\to 1.$$

That is, the boundary values of u^1 can become arbitrarily small in the mean-square sense, even when the derivatives of the coefficient η^1 remain large. Physically, the level surfaces of the oscillatory perturbation η^1 dip at 45°, and reflect the incident vertical rays horizontally. Since for large ω the field is essentially given by its geometric optics approximation u_a^1, the trace becomes small as $\omega\to\infty$.

For our second example, we assume that the support of χ does intersect $\{z=0\}$. We construct a family of η_ε^1, $u_{a,\varepsilon}^1$ depending on another parameter $\varepsilon>0$ as follows:

$$\eta_\varepsilon^1(x,z)=\frac{1}{i\omega}\chi\left(x,\frac{z}{\varepsilon}\right)e^{i\omega(x+z)},$$

$$u_{a,\varepsilon}^1(x,z,t)=\frac{-1}{2i\omega}\chi\left(x-z+t,\frac{z}{\varepsilon}\right)e^{i\omega(x+t)}.$$

Then

$$(\partial_t^2-\nabla^2)u_{a,\varepsilon}^1=O\left(\frac{1}{\omega\varepsilon^2}\right).$$

Also

$$\iint\left|\nabla\eta_\varepsilon^1\right|^2dx\,dz=O(\varepsilon)+O\left(\frac{1}{\omega^2\varepsilon}\right).$$

Now let $\omega \to \infty$, $\varepsilon \to 0$ in such a way that $\omega\varepsilon^2 \to \infty$. Then, as in [14], we can show that for some sequence of values of ω, ε,

$$\int \int_0^T \left|\partial_t u^1_{a,\varepsilon} - \partial_t u^1\right|^2_{(z=0)} dx\, dt \to 0.$$

However,

$$\int dx \int_0^T dt \left|\partial_t u^1_{a,\varepsilon}\right|^2_{(z=0)} = O(1)$$

whereas

$$\iint dx\, dz \left|\nabla \eta^1_\varepsilon\right|^2 \to 0.$$

This second example shows that $D\mathscr{T}$ itself is unbounded. As the inverse is also unbounded by the first part, no strengthening or weakening of topologies of the domain and range can render both bounded. We shall change the topology in the domain so as to make $D\mathscr{T}$ bounded, then ask for optimal regularization of $D\mathscr{T}^{-1}$.

Note that in both cases, the cause of unboundedness was rapid oscillation of η^1 in the x-("horizontal") directions. Therefore it seems reasonable that imposition of additional smoothness in horizontal directions might cure the difficulty, and this is indeed the case.

To state our main results, we shall make use of the spaces $\mathscr{H}_{(m,s)}$ [7, §2.5]. These are the completions of $C_0^\infty(\mathbb{R}^n)$ in the norms ($s \geqq 0$)

$$\|u\|^2_{(m,s)} = \sum_{j=0}^{m} \left\|\partial_z^j u\right\|^2_{(0,s+m-j)},$$

$$\|u\|_{(0,s)} = \left\|(1-\Delta_x)^{s/2} u\right\|_{L^2(\mathbb{R}^n)}.$$

The following facts are either easy to prove or are stated explicitly in [7, §2.5]:

(I) For any multiindex $\alpha = (\alpha', \alpha_z)$, $D^\alpha u \in \mathscr{H}_{(p,t)}$ if $u \in \mathscr{H}_{(m,s)}$ and $|\alpha| < m+s-(p+t)$, $\alpha_z \leqq m-p$.

(II) If $m+s > n/2$ and $m > \frac{1}{2}$, then $\mathscr{H}_{(m,s)} \subset L^\infty(\mathbb{R}^n) \cap C^0(\mathbb{R}^n)$ (continuous inclusion).

(III) $\|\ \|_{(1,s)}$ is equivalent to the graph norm of $(-\Delta_x)^{s/2}$, viewed as a densely defined operator on $H^1(\mathbb{R}^n)$.

THEOREM 1. *For $s > (n-1)/2$, there exists a constant $C > 0$ depending on s, T, n, $\|\log \eta^0(\cdot,0)\|_{H^{s+1}(\mathbb{R}^{n-1})}$, and $\|\log \eta^1\|_{\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1}\times[0,T])}$ so that for η^0, $\eta^1 \in C^\infty(\mathbb{R}^n_+)$, $\|D\mathscr{T}_T(\eta^0)\cdot\eta^1\|_1 \leqq C\|\eta^1\|_{(1,s+2)}$. Also for η^0, $\tilde{\eta}^0$, $\eta^1 \in C^\infty(\mathbb{R}^n_+)$,*

$$\left\|D\mathscr{T}_T(\eta^0)\cdot\eta^1 - D\mathscr{T}_T(\tilde{\eta}^0)\cdot\eta^1\right\|_1 \leqq C\left\|\log\eta^0 - \log\tilde{\eta}^0\right\|_{(1,s+2)}\left\|\eta^1\right\|_{(1,s+2)}.$$

In particular, $D\mathscr{T}_T$ extends to a Lipschitz-continuous map

$$\log\eta^0 \to D\mathscr{T}_T(\eta^0),$$

$$\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1}\times[0,T]) \to \mathscr{L}\left[\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1}\times[0,T]), H^1(\mathbb{R}^{n-1}\times[0,2T])\right].$$

Suppose $\gamma > 0$, and suppose $\Gamma \subset \mathbb{R}^n_+$ is a closed set for which $\Gamma \cap \{z = z_0\}$ is compact for every $z_0 \geqq 0$. We call such a Γ laterally compact. Define

$$\mathfrak{R}(\gamma, \Gamma) = \Big\{ f \in H^1(\mathbb{R}^n_+) : \operatorname{supp} f \subset \Gamma$$
$$\text{and for every } T > 0,\ \|f\|_{\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1} \times [0,T])} \leqq \gamma \|f\|_{H^1(\mathbb{R}^{n-1} \times [0,T])} \Big\}.$$

Remark. An inequality of the above form holds for every $f \in \mathscr{H}_{(1,s+2)}(\mathbb{R}^n_+)$ and every $T > 0$, but not necessarily with γ independent of T. Thus this inequality amounts to a strong form of the ban on horizontal oscillation mentioned above. If $f \in H^1(\mathbb{R}^n_+)$ and $\varphi \in C_0^\infty(\mathbb{R}^{n-1})$, then $f * \hat{\varphi}$ (convolution in the x-variables) obeys an inequality of this form. Also, results entirely analogous to those given here may be formulated for cylinder domains $\Omega \times \mathbb{R}_+$, rather than $\mathbb{R}^n_+ \simeq \mathbb{R}^{n-1} \times \mathbb{R}_+$, with Dirichlet or Neumann boundary conditions on $\partial\Omega \times \mathbb{R}_+$, or any other choice of boundary condition for which various integrations by points in the x-variables remain valid. In terms of the eigenfunctions of the $(n-1)$-dimensional Laplacian on such a (compact) Ω, an interesting class of subspaces of H^1 lying inside the regularizing sets $\mathfrak{R}$ are the H^1-functions of z with values in finite Fourier series in x, although these (linear) subspaces are clearly proper subsets of the conic regularizing sets $\mathfrak{R}$.

THEOREM 2. *Suppose T, $\gamma > 0$ and $\Gamma \subset \mathbb{R}^{n-1}$ is laterally compact. Then there exists a functional K: $\mathfrak{R}(\gamma, \Gamma) \to \mathbb{R}_+$ so that*

(i) *If $\{\eta^1_j\} \subset \mathfrak{R}(\gamma, \Gamma)$, $\eta^1_j \to 0$ weakly in $H^1(\mathbb{R}^n_+)$, then $K(\eta^1_j) \to 0$.*

(ii) *There exists $C > 0$ depending on $\|\log \eta^0\|_{(1,s+2)}$, s, n, and T, for which*

$$\|\eta^1\|^2_{H^1(\mathbb{R}^{n-1} \times [0,T])} \leqq C\Big(\big\| D\mathscr{T}_T(\eta^0) \cdot \eta^1 \big\|^2_{H^1(\mathbb{R}^{n-1} \times [0,2T])} + K(\eta^1) \Big).$$

Remark. The presence of the "compact" functional K on the r.h.s. of the above estimate means that we can only assert that a sufficiently small neighborhood of zero contains finitely many singular values of $D\mathscr{J}$. In particular we cannot rule out zero as a singular value (i.e. nonuniqueness), and therefore have not quite established continuity of the inverse. The best we can do in this direction is summarized in:

THEOREM 3. *Suppose that $\log \eta^0 \in \mathscr{H}_{(1,s+2)}(\mathbb{R}^n_+) \cap W^{1,\infty}(\mathbb{R}^n_+)$, and that $\gamma > 0$ and $\Gamma \subset \mathbb{R}^n_+$ is laterally compact. Then if $\eta^1 \in \mathfrak{R}(\gamma, \Gamma)$ satisfies*

$$D\mathscr{T}_\infty(\eta^0) \cdot \eta^1 = 0$$

it follows that $\eta^1 \equiv 0$.

THEOREM 4. *Suppose η^0, γ, Γ as above, and define*

$$\mathscr{A}: \mathfrak{R}(\gamma, \Gamma) \to H^1_{\mathrm{loc}}(\mathbb{R}^n_+) \oplus H^1(\mathbb{R}^{n-1})$$

by

$$\mathscr{A}\eta^1 = \big(D\mathscr{T}_\infty(\eta^0) \cdot \eta^1, \eta^1(\cdot, 0) \big).$$

Let $\mathscr{M}$ be a weakly closed subset of

$$\bigcup_{\gamma' > 0} \mathfrak{R}(\gamma', \Gamma)$$

and let $\mathscr{M}_\gamma = \mathscr{M} \cap \mathfrak{R}(\gamma, \Gamma)$, *given the topology of* $H^1_{\text{loc}}(\mathbb{R}^n_+)$. *Then*:

(i) *The restriction* $\mathscr{A}_\gamma$ *of* $\mathscr{A}$ *to* $\mathscr{M}_\gamma$ *has closed range.*

(ii) $\mathscr{A}_\gamma^{-1}$ *is continuous on* Range $\mathscr{A}_\gamma$.

Remarks. 1. It is commonplace in exploration seismology that seismic reflection data give much greater resolution of vertical rock structures than of horizontal variations, at least in the absence of substantial ray bending. As the present problem is a crude, straight-ray version of the seismic problem, the a priori constraint on horizontal derivatives of η^1, implied by $\eta^1 \in \mathfrak{R}$, seems quite natural.

2. Much sharper results are possible via propagation-of-singularities arguments—see [16] for such results for the (closely related) timelike Cauchy problem. In particular, the (regularized) dependence of η^1 on the data can be localized by ray-tracing. However, in that case the constants C depend on *higher* Sobolev norms of η^0 than appear in the above estimates for η^1; the dependence follows from results of Beals and Reed [2]. Such estimates force one to restrict the domain of $\mathscr{T}$ to a relatively compact subset to achieve continuity, whereas the inclusion $\mathscr{H}_{(1,s+2)} \subset H^1$ is not compact. Perhaps sharper propagation-of-regularity results would allow one to retain the local dependence property without such stringent regularization.

3. For layered media, i.e. η^0, η^1 independent of x, the inverse problem amounts to the much-studied impedance profile inversion problem, and the statement of Theorem 1 becomes (part of) the statement that $\mathscr{T}$ is a C^1-diffeomorphism $H^1[0,T] \to H^1[0,2T]$ in that case—see [15]. On the other hand, for topologies much weaker than H^1, $\mathscr{T}$ fails even to be continuous—see [6]—or $\mathscr{T}^{-1}$ fails to be continuous—see [1]. This accounts for our restriction to H^1 and related topologies. Also, rougher media may be approached via homogenization arguments.

4. Theorem 3 asserts uniqueness for the linearized inverse problem for the case $T = \infty$. For $n = 1$, a very similar argument yields uniqueness for $T < \infty$. We are prevented from making direct use of the one-dimensional pattern here by the lack of local uniqueness for the time-like Cauchy problem, and instead use a transform argument. The transform argument allows us to appeal to elliptic unique continuation results, but restricts us to the case $T = \infty$. Recently, Paul Sacks has used the full strength of the local part of the proof of Theorem 3, together with a very clever application of Hörmander's uniqueness theorem for the Cauchy problem, to extend Theorem 3 to the case $T < \infty$. Details may be found in [18].

5. The restriction of $\mathscr{A}$ in the statement of Theorem 4 is necessary because the sets $\mathfrak{R}(\gamma, \Gamma)$—or indeed their union over γ—are not weakly closed. An example of a function in the complement in $\mathscr{H}_{(1,s)}(\mathbb{R}^2_+)$ of $\cup_\gamma \mathfrak{R}(\gamma, \Gamma)$ is

$$\varphi(x) e^{-z} z^{s+1} \sin(xz^{-1})$$

with $\varphi \in C_0^\infty(\mathbb{R})$. Such functions may occur as the $\mathscr{H}_{(1,s)}$—weak limits of sequences in $\mathfrak{R}(\gamma, \Gamma)$. On the other hand, if we modify the definition of $\mathfrak{R}$ by requiring uniform integrability in x at infinity, rather than lateral compact support, then the class of uniformly x-bandlimited functions

$$\left\{ u \in \mathscr{H}_{(1,s+2)}(\mathbb{R}^n_+) : \hat{u}(z,\xi) = 0 \text{ for } |\xi| \geqq \Xi, z \geqq 0 \right\}$$

lies in the union of the modified $\mathfrak{R}(\gamma)$'s. Since Ξ is independent of γ in this regard and may be chosen as large as desired, perhaps the restriction is not particularly severe. For further discussion see [18], especially §5.

We shall need a number of the results of [12] concerning the relation between ρ^0 and u^0, as well as a technical lemma, which we now list:

(IV) ([12, Lemma 1]). Suppose $f \in \mathscr{S}(\mathbb{R}^n)$, $g_2 \in L^2(\mathbb{R}^n)$, $g_1 \in L^2(\mathbb{R}^n) \cap L^\infty(\mathbb{R}_z, L^2(\mathbb{R}_x^{n-1}))$, and $s > (n-1)/2$. Then for some $C = C(s,n) > 0$,

$$\left| \int_{\mathbb{R}} dz \int_{\mathbb{R}^{n-1}} dx f g_1 g_2 \right| \leqq C \|f\|_{(0,s)} \|g_2\|_{L^2(\mathbb{R}^n)} \sup_{z \in \mathbb{R}_z} \|g_1(\cdot, z)\|_{L^2(\mathbb{R}_x^{n-1})}. \tag{10}$$

Moreover, if f is independent of $x_1, \cdots, x_k$, then the same conclusion holds for $s \geqq \frac{1}{2}(n-k-1)$.

(V) An intermediate result in the proof of [12, Lemma 1] which we shall also need, is: suppose $f \in \mathscr{S}(\mathbb{R}^n)$, $g \in L^\infty(\mathbb{R}_z, L^1(\mathbb{R}_x^{n-1}))$. Then

$$\left| \int dz \int dx f g \right| \leqq C \int dz \|f(\cdot, z)\|_{H^s(\mathbb{R}_x^{n-1})} \|g(\cdot, z)\|_{L^1(\mathbb{R}_x^{n-1})} \tag{11}$$

with $C = C(s,n) > 0$.

Similarly,

$$\int dz \int dx f^2 |g| \leqq C \|f\|_{(0,s)}^2 \sup_z \|g(\cdot, z)\|_{L^1(\mathbb{R}^{n-1})}. \tag{12}$$

We also require the following Poincaré-style inequality:

(VI) Suppose that $s > (n-1)/2$, $\log a(\cdot, 0) \in H^{s+1}(\mathbb{R}^{n-1})$, $\log a \in \mathscr{H}_{(1,s+1)}(\mathbb{R}^{n-1} \times [0,T])$, $u(\cdot, 0) \in H^1(\mathbb{R}^{n-1})$, $u \in H^1(\mathbb{R}^{n-1} \times [0,T])$. Then for some constant $C > 0$ depending on $\|\log a(\cdot, 0)\|_s$, $\|\log a\|_{(1,s+1)}$, s, n, and T,

$$\|u\|_1^2 \leqq C \left\{ \|\nabla(au)\|_0^2 + \|u(\cdot, 0)\|_1^2 \right\}. \tag{13}$$

Proof of (13). First observe that $a_- \leqq a \leqq a_+$ with $a_\pm$ depending on $\|\log a(\cdot, 0)\|_S$, $\|\log a\|_{(1,s+1)}$, and T.

Next suppose $u(\cdot, 0) \equiv 0$. Then the simplest Poincaré inequality gives

$$\|au\|_1 \leqq C \|\nabla au\|_0. \tag{14}$$

Also

$$\|au(\cdot, z)\|_0 \leqq C \|au\|_1, \qquad 0 \leqq z \leqq T.$$

So

$$\begin{aligned} \|u\|_1^2 = \|u\|_0^2 + \|\nabla u\|_0^2 &\leqq a_-^{-1} \|au\|_0^2 + \|\nabla(a^{-1} \cdot au)\|_0^2 \\ &\leqq C \|au\|_0^2 + 2 \|(\nabla a^{-1}) au\|_0^2 + 2 a_-^{-1} \|\nabla au\|_0^2. \end{aligned} \tag{15}$$

But

$$\begin{aligned} \|(\nabla a^{-1}) au\|_0^2 &= \int_0^T dz \int dx (\nabla a^{-1})^2 |au|^2 \\ &\leqq \int_0^T dz \int dx |a^{-2} \nabla a|^2 \sup_z \|au(\cdot, z)\|_0^2 \leqq C \|au\|_1^2 \end{aligned}$$

which together with (15) gives

$$\|u\|_1^2 \leqq C \|au\|_1^2.$$

Combined with (14) this gives the result for the special case.

In general,

$$\begin{aligned}\|u\|_1 &\leqq \|u(\cdot,0)\|_1 + \|u-u(\cdot,0)\|_1 \\ &\leqq \|u(\cdot,0)\|_1 + C\|\nabla a(u-u(\cdot,0))\|_0 \\ &\leqq \|u(\cdot,0)\|_1 + C\{\|\nabla(au)\|_0 + \|\nabla(au(\cdot,0))\|_0\} \\ &\leqq \|u(\cdot,0)\|_1 + C\{\|\nabla au\|_0 + \|\nabla_x u(\cdot,0)\|_0 + \|u(\cdot,0)\|_0\}\end{aligned}$$

where in the last step we have used the estimate (12) with $f=\nabla a$ and $g=|u(\cdot,0)|^2$. Q.E.D.

(VII) The following estimates hold between u^0 and η^0 (each statement is followed by its reference in [12], of which it is (at most) a minor modification):

$$\int_0^{\min(T,t)} dz \int dx \eta^0\left(|\partial_t u^0|^2 + |\nabla u^0|^2\right)(x,z,t) := \|u^0(t)\|_E^2 \leqq \|\log \eta^0\|_1^2, \tag{16}$$

(Lemma 2),

$$\|D_j u^0(t)\|_E \leqq C\|\log \eta^0\|_{(1,s+1)} \qquad (j=1,\cdots,n-1), \tag{17}$$

(Lemma 3, Theorem 1),

$$\sup_{0\leqq z\leqq T}\int_z^{2T-z} dt \int dx\left(|\partial_t u^0|^2 + |\nabla u^0|^2\right)(x,z,t) \leqq CF\left(\|\log \eta^0\|_{(1,s+1)}, T\right), \tag{18}$$

(Theorem 1),

$$\|D_k D_j u^0(t)\|_E \leqq C\|\log \eta^0\|_{(1,s+2)} \qquad (k,j=1,\cdots,n-1), \tag{19}$$

(Lemma 5, Lemma 6),

$$\sup_{0\leqq z\leqq T}\int_z^{2T-z} dt \int dx\left\{|\partial_t D_k u^0|^2 + |\nabla D_k u^0|^2\right\}(x,z,t) \leqq CF\left(\|\log \eta^0\|_{(1,s+2)}, T\right), \tag{20}$$

(Lemma 6).

Here C denotes a constant depending on s, T, and n, and F is a smooth function of its arguments.

Proof of Theorem 1. We shall establish the first estimate. The second is proved by further arguments of the same sort, following the pattern of the proof of [15, Thm. 2.5]. Therefore we omit the proof of the second statement.

The main tool in the proof of *Theorem* 1 is the "sideways energy form"

$$Q(z) := \frac{1}{2}\int_z^{2T-z} dt \int dx\left\{|\partial_t u^1|^2 + |\nabla u^1|^2\right\}.$$

A short calculation yields

$$\begin{aligned}\frac{d}{dz}Q(z) = &-\int_z^{2T-z} dt \int dx\left\{\left(\partial_t^2 u^1 - \Delta u^1\right)\partial_z u^1 + 2\nabla_x u^1 \cdot \partial_z \nabla_x u^1\right\} \\ &-\frac{1}{2}\int dx\left[|\nabla \bar{u}^1|^2 + [\nabla \bar{\bar{u}}^1]^2\right](x,z)\end{aligned} \tag{21}$$

where $\bar{u}^1(x,z)=\bar{u}^1(x,z,z)$, as before, and $\bar{\bar{u}}(x,z) := u^1(x,z,2T-z)$.

Remark. The second term on the r.h.s. in (21) cannot be estimated in terms of Q alone, which reflects the nonhyperbolic nature of the timelike Cauchy problem.

Integrate (21) from z to T, make use of the boundary value problem (8) for u^1, and note that $Q(T)=0$ to obtain

$$
\begin{aligned}
Q(z) = -\int_z^T d\zeta \int_\zeta^{2T-\zeta} dt \int dx \Big\{ & \nabla \log \eta^0 \cdot \nabla u^1 \partial_z u^1 \\
& + \nabla \frac{\eta^1}{\eta^0} \cdot \nabla u^0 \partial_z u^1 + 2 \nabla_x u^1 \partial_z \nabla_x u^1 \Big\}(x,\zeta,t) \qquad (22) \\
& + \frac{1}{2} \int_z^T d\zeta \int dx \Big\{ |\nabla \bar{\bar{u}}^1|^2 + \frac{1}{4} \big| \nabla \big[\eta_0^{1/2} (\eta^0)^{-3/2} \eta^1 \big] \big|^2 \Big\}.
\end{aligned}
$$

Estimate the first term on the r.h.s. of (22) using (11): for $s > n/2 - 1$,

$$
\begin{aligned}
& \Big| \iiint \nabla \log \eta^0 \cdot \nabla \eta^1 \partial_z u^1 \Big| \\
& \quad \leqq C \int_z^T dz \| \nabla \log \eta^0(\cdot, z) \|_{H^s(\mathbb{R}^{n-1})} \| \nabla u^1 \partial_z u^1(\cdot, z, \cdot) \|_{L^1(\mathbb{R}^n)} \qquad (23) \\
& \quad \leqq C \int_z^T \sigma Q
\end{aligned}
$$

with

$$
\sigma(z) := \| \nabla \log \eta^0(\cdot, z) \|_{H^s(\mathbb{R}^{n-1})}.
$$

For the second term, use (10):

$$
\begin{aligned}
& \Big| \iiint \nabla \frac{\eta^1}{\eta^0} \cdot \nabla u^0 \partial_z u^1 \Big| \\
& \quad \leqq C \| \nabla \eta^1 \|_{(0,s)} \Big(\iiint |\partial_z u^1|^2 \Big)^{1/2} \sup_{z \leqq \zeta \leqq T} \| \nabla u^0(\cdot, \zeta, \cdot) \|_{L^2(\mathbb{R}^{n-1} \times [\zeta, 2T-\zeta])}.
\end{aligned}
$$

The first factor is bounded by $\|\eta^1\|_{(1,s+1)}$, the second by $(\int_z^T Q)^{1/2}$ and the third by $\|\eta^0\|_{(1,s+1)}$, according to (18). So we obtain

$$
\begin{aligned}
\Big| \iiint \nabla \frac{\eta^1}{\eta^0} \cdot \nabla u^0 \nabla_z u^1 \Big| & \leqq C \|\eta^1\|_{(1,s+1)} \Big(\int_z^T Q \Big)^{1/2} \\
& \leqq \frac{1}{2} C \Big(\|\eta^1\|_{(1,s+1)}^2 + \int_z^T Q \Big). \qquad (24)
\end{aligned}
$$

To estimate the third term, we require an energy estimate for the tangential derivatives $\nabla_x u^1$. Define $v_j = D_j u^1$, $j = 1, \cdots, n-1$. Then in $C_T := \{(x,z,t)\colon x \in \mathbb{R}^{n-1}, 0 \leqq z \leqq T, z \leqq t \leqq 2T - z\}$

$$
\begin{aligned}
& \big(\partial_t^2 - \nabla - \nabla \log \eta^0 \cdot \nabla \big) v_j = \nabla D_j \frac{\eta^1}{\eta^0} \cdot \nabla u^0 + \nabla \frac{\eta^1}{\eta^0} \cdot \nabla D_j u^0 + \nabla D_j \log \eta^0 \cdot \nabla u^1, \\
& \partial_z v_j(\cdot, 0, \cdot) = 0, \qquad (25) \\
& \bar{v}_j = -\frac{1}{2} D_j \big(\eta_0^{1/2} (\eta^0)^{-3/2} \eta^1 \big).
\end{aligned}
$$

Multiply the wave equation by $\eta^0 \partial_t v_j$ and integrate by parts over $\Omega \cap \{t \leqq \tau\}$ to obtain the energy identity

$$\iiint_{\Omega \cap \{t \leqq \tau\}} \eta^0 \left(\nabla D_j \frac{\eta^1}{\eta^0} \cdot \nabla u^0 + \nabla \frac{\eta^1}{\eta^0} \cdot \nabla D_j u^0 + \nabla D_j \log \eta^0 \cdot \nabla u^1 \right) \partial_t v_j$$

$$= -\frac{1}{2} \int_0^{\min(\tau, T)} dz \int dx \eta^0 |\nabla \bar{v}_j|^2 + \frac{1}{2} h(\tau - T) \int_{2T-\tau}^{T} dz \int dx \eta^0 |\nabla \bar{\bar{v}}_j|^2 \tag{26}$$

$$+ \frac{1}{2} \int_0^{\min(\tau, 2T-\tau)} dz \int dx \eta^0 \left\{ |\partial_t v_j|^2 + |\nabla v_j|^2 \right\}(x, z, \tau)$$

where h is the Heaviside function. Define $E_j(\tau)$ by the last term in (26). Estimate the first two terms on the l.h.s. of (26) by means of (11):

$$\left| \iiint_{\Omega \cap \{t \leqq \tau\}} \left(\nabla D_j \frac{\eta^1}{\eta^0} \cdot \nabla u^0 + \nabla \frac{\eta^1}{\eta^0} \cdot \nabla D_j u^0 \right) \partial_t v_j \right|$$

$$\leqq C \left\{ \|\eta^1\|_{(1, s+2)} \sup_{0 \leqq z \leqq T} \|\nabla u^0(\cdot, z, \cdot)\|_{L^2(\mathbb{R}^{n-1} \times [2T-z])} \right.$$

$$\left. + \|\eta^1\|_{(1, s+1)} \sup_{0 \leqq z \leqq T} \|\nabla D_j u^0(\cdot, z, \cdot)\|_{L^2(\mathbb{R}^{n-1} \times [z, 2T-z])} \right\} \left(\iiint_{\Omega \cap \{t \leqq T\}} |\partial_t v_j|^2 \right)^{1/2}.$$

The suprema in the above estimate are bounded in terms of $\|\eta^0\|_{(1, s+2)}$ according to (18) and (20). Also, the last factor is the integrated energy. Thus the left-hand side above is bounded by

$$\leqq C \left(\|\eta^1\|_{(1, s+2)}^2 \int_0^\tau E_j \right)^{1/2}$$

$$\leqq \frac{1}{2} C \left\{ \|\eta^1\|_{(1, s+2)}^2 + \int_0^\tau E_j \right\}. \tag{27}$$

Also,

$$\iiint_{\Omega \cap \{t \leqq \tau\}} |\nabla D_j \log \eta^0 \cdot \nabla u^1 \partial_t v_j|$$

$$\leqq C \sup_{0 \leqq z \leqq T} \|\nabla u^1(\cdot, z, \cdot)\|_{L^2(\mathbb{R}^{n-1} \times [z, 2T-z])} \times \left(\iiint_{\Omega \cap \{t \leqq \tau\}} |\partial_t v_j|^2 \right)^{1/2}.$$

Define $Q^* = \sup_{0 \leqq z \leqq T} Q(z)$. Then the above is

$$\leqq C \left(Q^* \int_0^\tau E_j \right)^{1/2}$$

$$\leqq \frac{1}{2} C \left(Q^* + \int_0^\tau E_j \right). \tag{28}$$

Combine (27), (28), and a slightly rearranged version of (26) to obtain

$$E_j(\tau) \leqq C \left\{ \|\eta^1\|_{(1, s+2)}^2 + Q^* + \int_0^\tau E_j \right\}$$

whence Gronwall's lemma implies

$$E_j(\tau) \leqq Ce^{C\tau}\left\{\|\eta^1\|^2_{(1,s+2)} + Q^*\right\}.$$

Now

$$\int_z^T d\zeta \int_\zeta^{2T-\zeta} dt \int dx \left|\nabla \cdot D_j u^2\right|^2 \leqq \int_0^{2T} E_j \leqq C\left(\|\eta^1\|^2_{(1,s+2)} + Q^*\right). \tag{29}$$

We also need an energy estimate for u^1. Multiply the wave equation in (8) by $\eta^0 \partial_t u^1$ and integrate by parts over $\Omega \cap \{t \leqq \tau\}$ to obtain

(30)

$$\begin{aligned}\iiint_{\Omega\cap\{t\leqq\tau\}} \left(\nabla \frac{\eta^1}{\eta^0}\cdot \nabla u^0\right)\partial_t u^1 = &-\frac{1}{2}\int_0^{\min(\tau,T)} dz \int dx\, \eta^0 |\nabla \bar{u}^1|^2 \\ &+ \frac{1}{2} h(\tau - T)\int_{2T-\tau}^T dz \int dx\, \eta^0 |\nabla \bar{\bar{u}}^1|^2 \\ &+ \frac{1}{2}\int_0^{\min(\tau,2T-\tau)} dz \int dx\, \eta^0 \left\{|\partial_t u^1|^2 + |\partial u^1|^2\right\}(x,z,\tau).\end{aligned}$$

Define E to be the last term above, and estimate the l.h.s. as before to obtain

$$E(\tau) \leqq C\left\{\|\eta^1\|^2_{(1,s+1)} + \int_0^\tau E\right\}$$

whence

$$E(\tau) \leqq Ce^{Ct}\|\eta^1\|^2_{(1,s+1)}. \tag{31}$$

Now estimate the third term in (22):

$$\begin{aligned}&\left|\int_z^T d\zeta \int_\zeta^{2T-\zeta} dz \int dx\left(\nabla_x u^1 \cdot \nabla_z \nabla_x u^1\right)\right| \\ &\leqq \left(\iiint |\nabla_x u^1|^2 \iiint |\partial_z \nabla_x u^1|^2\right)^{1/2} \\ &\leqq \left(\int_0^T E\right)^{1/2}\left(\sum_{j=1}^{n-1}\iiint \left|\left(\nabla \cdot D_j u^1\right)\right|^2\right)^{1/2} \\ &\leqq C\|\eta^1\|_{(1,s+1)}\left(\|\eta^1\|^2_{(1,s+2)} + Q^*\right)^{1/2}.\end{aligned} \tag{32}$$

To estimate the fourth term, note that (30) for $\tau = 2T$ reads

$$\begin{aligned}&\frac{1}{2}\int_0^T dz \int dx\, \eta^0 |\nabla \bar{\bar{u}}^1|^2 \\ &= \frac{1}{2}\int_0^T dz \int dx\, \eta^0 |\nabla \bar{u}^1|^2 + \iiint_\Omega \left(\nabla \frac{\eta^1}{\eta^0}\cdot \nabla u^0\right)\partial_t u^1 \\ &\leqq C\left\{\|\eta^1\|_1^2 + \|\eta^1\|_{(1,s+1)} \sup \|\nabla u^0(\cdot,z,\cdot)\|_{L^2(\mathbb{R}^{n-1}\times[z,2T-z])}\left(\iiint_\Omega |\partial_t u^1|^2\right)^{1/2}\right\} \\ &\leqq C\|\eta^1\|^2_{(1,s+1)}\end{aligned} \tag{33}$$

using bounds quoted above. Since η^0 is bounded below uniformly by a function of $\|\log\eta^0\|_{(1,s+1)}$, we have estimated the fourth term. In the process, we have estimated the fifth term also:

$$\int_0^T dz \int dx|\nabla\bar{u}^1|^2 \leqq C\|\eta^1\|_1^2. \tag{34}$$

Now, combining (22), (23), (24), (32), (33), and (34), we have

$$Q(z) \leqq C\left\{\|\eta^1\|_{(1,s+2)}^2 + \|\eta^1\|_{(1,s+1)}\left(\|\eta^1\|_{(1,s+2)}^2 + Q^*\right)^{1/2} + \int_z^T (\sigma+1)Q\right\}.$$

Now Gronwall's inequality implies

$$Q(z) \leqq C\|\eta^1\|_{(1,s+2)}\left(1+\left(\|\eta^1\|_{1,s+2}^2 + Q^*\right)^{1/2}\right), \qquad 0 \leqq z \leqq T.$$

Since we can replace $Q(z)$ by Q^* on the l.h.s., it follows immediately that Q is bounded by a function of $\|\eta^1\|_{1,s+2}$ and of course, of n, s, T and $\|\log\eta^0\|_{(1,s+2)}$, which finishes the proof of Theorem 1. For use in the proof of Theorem 3, note that inequality (i) together with (32) implies

$$E_j(\tau) \leqq C_1 e^{C_2 t}\|\eta^1\|_{(1,s+2)}^2. \tag{35}$$

Q.E.D.

For use in the proof of Theorem 2, we note another obvious consequence:

COROLLARY 1. (Same hypotheses as Theorem 1.) *For* $0 \leqq z \leqq T$,

$$\|\nabla_x u^1(\cdot, z, \cdot)\|_{L^2(\mathbb{R}^{n-1}\times[z,2T-z])} \leqq C\|\eta^1\|_{(1,s+2)}.$$

Proof. Integrating (35) from $\tau=0$ to $\tau=2T$, we see that $\nabla_x u^1$ has Dirichlet norm in C_T bounded by $C\|\eta^1\|_{(1,s+2)}$. By the transport equation its boundary value on $z=t$ is bounded by a similar quantity, so its L^2 norm, thus its H^1 norm, in C_T is also bounded by $C\|\eta^1\|_{(1,s+2)}$. Now the standard trace theorem implies the result. Q.E.D.

Proof of Theorem 2. The first step is to devise an identity similar to (22), involving an indefinite form: set

$$P(z) = \frac{1}{2}\int_z^{2T-z} dt \int dx\left\{\left(\partial_t u^1\right)^2 + \left(\partial_z u^1\right)^2 - \left|\nabla_x u^1\right|^2\right\}.$$

Then a short calculation yields

$$\begin{aligned}\partial_z P(z) = &-\frac{1}{2}\int dx\left\{\left[\left(\partial_z\bar{u}^1\right)^2 + \left(\partial_z\bar{\bar{u}}^1\right)^2\right] - \left[\left(\nabla_x\bar{u}^1\right)^2 + \left(\nabla_x\bar{\bar{u}}^1\right)^2\right]\right\} \\ &- \int_z^{2T-z} dt \int dx\left\{\nabla\log\eta^0\cdot\nabla u^1 + \nabla\left(\frac{\eta^1}{\eta^0}\right)\cdot\nabla u^0\right\}\partial_z u^1.\end{aligned} \tag{36}$$

Now

$$P(z) = Q(z) - 2\int_z^{2T-z} dt \int dx\left|\nabla_x u^1\right|^2.$$

Therefore, integration of (36) from $z=0$ to $z=T$ and some manipulation yields

$$
\begin{aligned}
&Q(z)+\frac{1}{2}\int_0^z d\zeta\int dx\left[|\nabla\bar{u}^1|^2+|\nabla\bar{\bar{u}}^1|^2\right]+\frac{1}{2}\|\eta^1(\cdot,0)\|_1^2\\
&\quad=Q(0)+2\int_z^{2T-z}dt\int dx|\nabla_x u^1|^2(x,z,t)-2\int_0^{2T}dt\int dx|\nabla_x u^1|^2(x,0,t)\\
&\quad\quad+\int_0^z d\zeta\int dx\left[|\nabla_x\bar{u}^1|^2+|\nabla_x\bar{\bar{u}}^1|^2\right]\\
&\quad\quad-\int_0^z dz\int_z^{2T-z}dt\int dx\left\{\nabla\log\eta^0\cdot\nabla\left(\frac{\eta^1}{\eta^0}\right)\cdot\nabla u^0\right\}\partial_z u^1+\frac{1}{2}\|\eta^1(\cdot,0)\|_1^2.
\end{aligned}
\tag{37}
$$

Recall that

$$
\bar{u}^1=-\frac{1}{2}\eta_0^{1/2}(\eta^0)^{-3/2}\eta^1.
$$

With $u\to\eta^1$ and $a\to\frac{1}{2}\eta_0^{1/2}(\eta^0)^{-3/2}$, the Poincaré inequality (13) implies the existence of a constant $C>0$, depending on η_0, η^0, and T, for which

$$
C\|\eta^1\|^2_{H^1(\mathbb{R}^{n-1}\times[0,z])}\leqq\frac{1}{2}\int_0^z d\zeta\int dx|\nabla\bar{u}^1|^2+\frac{1}{2}\|\eta^1(\cdot,0)\|_1^2.
\tag{38}
$$

Now (37) and (38) combine to yield for any $\alpha>0$,

$$
\begin{aligned}
&Q(z)+C_1\|\eta^1\|^2_{H^1(\mathbb{R}^{n-1}\times[0,z])}\\
&\quad\leqq Q(0)+2\|\nabla_x u^1(\cdot,z,\cdot)\|_0^2-2\|\nabla_x u^1(\cdot,0,\cdot)\|_0^2\\
&\quad\quad+\|\nabla_x\bar{u}^1\|^2_{L^2(\mathbb{R}^{n-1}\times[0,z])}+\|\nabla_x\bar{\bar{u}}^1\|^2_{L^2(\mathbb{R}^{n-1}\times[0,z])}\\
&\quad\quad+\int_0^z\left(\sigma+C_2\alpha^{-1}\right)Q+\alpha\left\|\nabla\frac{\eta^1}{\eta^0}\right\|^2_{\mathscr{H}_{(0,s)}(\mathbb{R}^{n-1}\times[0,z])}+\frac{1}{2}\|\eta^1(\cdot,0)\|_1^2.
\end{aligned}
\tag{39}
$$

Since

$$
\left\|\nabla\frac{\eta^1}{\eta^0}\right\|_{\mathscr{H}_{(0,s)}(\mathbb{R}^{n-1}\times[0,z])}\leqq C\|\eta^1\|_{\mathscr{H}_{(1,s+1)}(\mathbb{R}^{n-1}\times[0,z])}\leqq C\|\eta^1\|_{H^1(\mathbb{R}^{n-1}\times[0,z])}
$$

(the last inequality by virtue of $\eta^1\in\mathfrak{R}(\gamma,\Gamma)$), if we choose α small enough we can absorb the next-to-the-last term in (39) into the l.h.s., at the price of decreasing C_1 somewhat. Now Gronwall's inequality implies

$$
Q(z)+C_1\|\eta^1\|^2_{H^1(\mathbb{R}^{n-1}\times[0,z])}\leqq\left\{Q(0)+K(\eta^1)\right\}\exp\int_0^z\left(\sigma+C_2\alpha^{-1}\right)
$$

so ($Q(T)=0$)

$$
\|\eta^1\|_1^2\leqq C\left\{Q(0)+K(\eta^1)\right\}
$$

where we have defined

$$K(\eta^1) := -2\|\nabla_x u^1(\cdot,0,\cdot)\|^2 + \sup_{0\leqq z\leqq T}\Big\{\|\nabla_x \bar{u}^1\|^2_{L^2(\mathbb{R}^{n-1}\times[0,z])} + \|\nabla_x \bar{\bar{u}}^1\|^2_{L^2(\mathbb{R}^{n-1}\times[0,z])} + 2\|\nabla_x u^1(\cdot,z,\cdot)\|_{L^2(\mathbb{R}^{n-1}\times[z,2T-z])}\Big\} + \frac{1}{2}\|\eta^1(\cdot,0)\|_1^2.$$

It remains to verify the property claimed for K. Accordingly suppose $\{\eta_j^1\}\subset \mathfrak{R}(\gamma,\Gamma)$ with $\eta_j^1 \to 0$ weakly in $H^1(\mathbb{R}^{n-1}\times[0,T])$. Then $\{\eta_j^1\}$ is bounded in $\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1}\times[0,T])$ and so has a subsequence converging weakly in $\mathscr{H}_{(1,s+2)}$. Since the (weak) limit must be the same distribution as the (weak) limit in H^1, the limit is unique ($=0$); therefore the entire sequence tends weakly to zero in $\mathscr{H}_{(1,s+2)}$. Since $\{\eta_j^1\}$ share the same compact support, the supports of the u_j^1 are also contained in the same compact subset of C_T, and likewise for $\operatorname{supp}\nabla_x u^1(\cdot,z,\cdot)$ for each $z\in[0,T]$. Now the trace and embedding theorems for Sobolev classes (e.g. [7, Thms. 2.5.6 and 2.2.3]) imply that maps

$$\eta^1 \to \nabla_x \bar{u}^1,$$
$$\eta^1 \to \nabla_x \bar{\bar{u}}^1,$$
$$\eta^1 \to \eta^1(\cdot,0),$$
$$\eta^1 \to \nabla_x u^1(\cdot,z,\cdot)$$

from $\mathscr{H}_{(1,s+2)}(\Gamma) := \{f\in\mathscr{H}_{(1,s+2)}\mathbb{R}^{n-1}\times[0,T]\colon \operatorname{supp} f\subset\Gamma\}$ to $L^2(\mathbb{R}^{n-1}\times[0,z])$, $L^2(\mathbb{R}^{n-1}\times[0,z])$, $H^1(\mathbb{R}^{n-1})$, and $L^2(\mathbb{R}^{n-1}\times[z,2T-z])$ respectively, are *compact* for each $z\in[0,T]$. We conclude that

$$\|\nabla_x u_j^1(\cdot,0,\cdot)\|_{L^2(\mathbb{R}^{n-1}\times[0,2T])}\to 0, \qquad j\to\infty,$$

and for each z,

$$F_j(z) := \|\nabla_x \bar{u}_j^1\|^2_{L^2(\mathbb{R}^{n-1}\times[0,z])} + \|\nabla_x \bar{\bar{u}}_j^1\|^2_{L^2(\mathbb{R}^{n-1}\times[0,z])} + 2\|\nabla_x u_j^1(\cdot,z,\cdot)\|^2_{L^2(\mathbb{R}^{n-1}\times[z,2T-z])}\to 0, \qquad j\to\infty.$$

We claim that $\{F_j\}$ is uniformly Hölder-continuous with exponent one-half. In fact,

$$\partial_z F_j(z) = 2\int_z^{2T-z} dt\int dx\, \nabla_x u_j^i\cdot\nabla_x\partial_z u_j^i$$

so

$$|F_j(z_1)-F_j(z_2)|\leqq 2\|\nabla_x u_j^1\|\,\|\nabla_x\partial_z u_j^1\|$$

(where the norms are $L^2(C_T\cap\{z_1\leqq z\leqq z_2\})$). But $\|\nabla_x u_j^1\|_{H^1(C_T)}$ is bounded by $C\|\eta_j^1\|_{(1,s+2)}$; hence uniformly in j, as is $\|\nabla_x u_j^1(\cdot,z,\cdot)\|_{L^2(\mathbb{R}^{n-1}\times[z,2T-z])}$, $0\leqq z\leqq T$ (Corollary 1), and

$$\|\nabla_x u_j^1\|\leqq\sqrt{(z_2-z_2)}\sup_{z_1\leqq z\leqq z_2}\|\nabla_x u_j^1(\cdot,z,\cdot)\|_{L^2(\mathbb{R}^{n-1}\times[z,2T-z])}$$

so

$$|F_j(z_1)-F_j(z_2)| \leqq C|z_1-z_2|^{1/2}$$

with C independent of j.

Now let $\varepsilon>0$, and let $\{z_k\}_{k=0}^N$ be an ordered partition of $[0,T]$ with

$$\max(z_k-z_{k-1})<\varepsilon^2.$$

By the pointwise result derived earlier, for some $J\in\mathbb{N}$, $j\geqq J$ implies

$$F_j(z_k)<\varepsilon, \qquad k=0,\cdots,N.$$

On the other hand, if $z\in[z_k,z_{k+1})$,

$$|F_j(z)|\leqq|F_j(z_k)|+|F_j(z_k)-F_j(z)|\leqq(1+C)\varepsilon.$$

Since ε is arbitrary, we have established that $F_j\to 0$ uniformly in $[0,T]$. Since

$$K(\eta_j^1)=-2\|\nabla_x u^1(\cdot,0,\cdot)\|_0^2+\frac{1}{2}\|\eta^1(\cdot,0)\|_1+\|F_j\|_{CU^0[0,T]},$$

the theorem is proved. Q.E.D.

Proof of Theorem 3. We begin by establishing a local uniqueness result.

The hypotheses imply that, for any $T>0$, $Q(0)=0$. Now integrate (21) from 0 to z to obtain

$$\begin{aligned} &Q(z)+\frac{1}{2}\int_0^z d\zeta\int dx|\nabla\bar{u}^1|^2(x,\zeta)\\ &\leqq\int_0^z d\zeta\int_\zeta^{2T-\zeta}dt\int dx\left\{2|\nabla_x u^1\cdot\nabla_x\partial_z u^1|\right.\\ &\qquad\left.+|\nabla\log\eta^0\cdot\nabla u^1\partial_z u^1|+\left|\nabla\frac{\eta^1}{\eta^0}\cdot\nabla u^0\partial_z u^1\right|\right\}. \end{aligned}\tag{40}$$

From (35),

$$\iiint_\Omega|\nabla_x\partial_z u^1|^2\leqq C\|\eta^1\|_{(1,s+2)}^2.$$

(For the moment, $\|\eta^1\|_{(1,s+2)}=\|\eta^1\|_{\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1}\times[0,T])}$, etc.). Therefore, for any $\alpha>0$,

$$\begin{aligned} &\int_0^z d\zeta\int_\zeta^{2T-\zeta}dt\int dx|\nabla_x u^1\cdot\nabla_x\partial_z u^1|\\ &\leqq C\|\eta^1\|_{(1,s+2)}\left(\int_0^z d\zeta\int_\zeta^{2T-\zeta}dt\int dx|\nabla_x u^1|^2\right)^{1/2}\\ &\leqq C\left(\alpha\|\eta^1\|_{(1,s+2)}^2+\alpha^{-1}\int_0^z Q\right). \end{aligned}\tag{41}$$

The second term is estimated as in (23):

$$\int_0^z dz\int_\zeta^{2T-\zeta}dt\int dx|\nabla\log\eta^0\cdot\nabla u^1\cdot\partial_z u^1|\leqq C\int_0^z\sigma Q.\tag{42}$$

The third term is estimated as in (24):

$$\int_0^z d\zeta \int_\zeta^{2T-\zeta} dt \int dx \left| \nabla \frac{\eta^1}{\eta^0} \cdot \nabla u^0 \partial_z u^1 \right| \leqq C\left(\alpha \|\eta^1\|^2_{(1,s+2)} + \alpha^{-1} \int_0^z Q \right). \tag{43}$$

The upshot of (40), (41), (42), and (43) is

$$Q(z) + \frac{1}{2} \int_0^z d\zeta \int dx \left| \nabla \left[\eta_0^{1/2} (\eta^0)^{-3/2} \eta^1 \right] \right|^2 \leqq C\left\{ \alpha \|\eta^1\|^2_{(1,s+2)} + \int_0^z (\sigma + \alpha^{-1}) Q \right\}.$$

Consequently,

$$Q(z) + \frac{1}{2} \int_0^z d\zeta \int dx \left| \nabla \left[\eta_0^{1/2} (\eta^0)^{-3/2} \eta^1 \right] \right|^2 \leqq C\alpha \|\eta^1\|^2_{(1,s+2)} \exp\left[C \int_0^z (\sigma + \alpha^{-1}) \right].$$

Estimate the Dirichlet integral on the l.h.s. from below by means of the Poincaré inequality (13), as in the proof of the previous theorem, and replace $\|\eta^1\|_{(1,s+2)} = \|\eta^1\|_{\mathscr{H}_{(1,s+2)}(\mathbb{R}^{n-1}\times[0,T])}$ by $C_0\|\eta^1\|_1$, as we can since $\eta^1 \in \mathfrak{R}(\gamma, \mathbb{R}^n_+)$. The upshot is

$$C_1 \|\eta^1\|_1^2 \leqq e^{C_2 T/\alpha} \exp\left[C_2 \int_0^T \sigma \right] C_3 \alpha \|\eta^1\|_1^2. \tag{44}$$

If α is sufficiently small, and $T = 0(\alpha)$, then

$$e^{C_2 T/\alpha} \exp\left[C_2 \int_0^T \sigma \right] C_3 \alpha < C_1, \tag{45}$$

whence $\|\eta^1\|_1 = 0$ from (44), i.e.: $\eta^1 \equiv 0$ in $\mathbb{R}^{n-1} \times [0, T]$ for some (small) $T > 0$.

Now we shall show that, in fact, $u^1 \equiv 0$ in $\mathbb{R}^{n-1} \times [0, T] \times \mathbb{R}^+$. It will follow that the Cauchy data for u^1 vanish on $\{z = T\}$, so we can repeat the above argument to show that η^1 vanishes on a somewhat larger interval. The constants in (45) depend only on $\|\log \eta^0\|_{(1,s+2)}$, s, and n, and T, are smooth functions of T near $T = 0$. Therefore, the thickness δT of the slab $\{T \leqq z \leqq T + \delta T\}$ in which we conclude $\eta^1 \equiv 0$, provided $\eta^1 \equiv 0$ in $\{0 \leqq z \leqq T\}$, is bounded below independently of T. Thus for any $T > 0$, finitely many repetitions of this "continuation" procedure yield $\eta^1 \equiv 0$ on $\{0 \leqq z \leqq T\}$, and so we may conclude $\eta^1 \equiv 0$, which finishes the proof modulo proof of the claim.

Remark. For $n = 1$, this procedure yields uniqueness up to $z = T$ where Cauchy data for u^1 on $\{z = 0\}$ are required to vanish only on $\{0 \leqq t \leqq 2T\}$ (see [15, proof of Theorem 2.8]), because of local uniqueness in the time-like Cauchy problem for $n = 1$. Local uniqueness in the time-like Cauchy problem for the wave operator modulo lower-order terms no longer holds for $n > 1$, as a consequence of a theorem of Hörmander [7, Thm. 8.9.4]. Consequently we must require that the Cauchy data vanish globally in order to carry out the "continuation" step.

To show that $u^1 \equiv 0$ for $0 \leqq z \leqq T$, recall the estimates (31) and (35) for the energy of u^1 and $\nabla_x u^1$:

$$E(t) \leqq C_1 e^{C_2 t} \|\eta^1\|^2_{(1,s+1)},$$
$$E_j(t) \leqq C_3 e^{C_2 t} \|\eta^1\|^2_{(1,s+2)}, \qquad j = 1, \cdots, n.$$

Since $u^1 \equiv 0$ on $z = 0$, it actually follows that

$$\|u^1(\cdot,\cdot,t)\|^2_{H^1(\mathbb{R}^{n-1}\times[0,t])} + \|\partial_t u^1(\cdot,\cdot,t)\|^2_{L^2(\mathbb{R}^{n-1}\times[0,t])}$$
$$+ \|\nabla_x u^1(\cdot,\cdot,t)\|^2_{H^1(\mathbb{R}^{n-1}\times[0,t])} + \|\partial_t \nabla_x u^1(\cdot,\cdot,t)\|^2_{L^2(\mathbb{R}^{n-1}\times[0,t])}$$

grows exponentially in t. Note that the proof of the local result above actually shows that $u^1 \equiv 0$ in $\{0 \leqq z \leqq T,\ z \leqq t \leqq 2T - z\}$. Thus $u^1(\cdot,\cdot,t)$ is actually of class H^1 in the full cylinder $\mathbb{R}^{n-1}\times[0,T]$ for $0 \leqq t \leqq \infty$, as is $\nabla_x u^1$. Furthermore, the local H^1 norms in $\mathbb{R}^{n-1}\times[0,t]$ a fortiori grow at exponential rate C_2. Therefore the Laplace transform $\tilde{u}^1(x,z,s)$ exists for $s > C_2$, and satisfies

$$\tilde{u}^1(\cdot,\cdot,s) \in H^1(\mathbb{R}^{n-1}\times[0,t]), \tag{46a}$$

$$\nabla_x \tilde{u}^1(\cdot,\cdot,s) \in H^1(\mathbb{R}^{n-1}\times[0,t]), \tag{46b}$$

$$(s^2 - \nabla^2 - \nabla \log \eta^0 \cdot \nabla)\tilde{u}^1 \equiv 0, \quad \text{in } \mathbb{R}^{n-1}\times[0,t], \tag{46c}$$

$$\tilde{u}^1 = \partial_z \tilde{u}^1 \equiv 0 \quad \text{on } \{z = 0\}, \quad C_2 < s < \infty. \tag{46d}$$

Since we have assumed $\nabla \log \eta^0 \in L^\infty(\mathbb{R}^n_+)$, it follows from (46b) and (46c) that $\partial_z \tilde{u}^1 \in H^1(\mathbb{R}^{n-1}\times[0,T])$; hence $\tilde{u}^1 \in H^2(\mathbb{R}^{n-1}\times[0,t])$. Therefore, we can extend $\tilde{u}^1$ by zero to negative z with $\tilde{u}^1$ remaining in H^2_{loc}. We are now in position to apply [7, Thm. 8.9]. It is easy to check that any plane is strongly pseudoconvex with respect to the principal part $-\nabla^2$ of the operator on the l.h.s. of (46c). Therefore, $\tilde{u}^1$ vanishes in $0 \leqq z \leqq T$, and by uniqueness of the Laplace transform, so does u^1.

As noted above, this finishes the proof of Theorem 3. Q.E.D.

Proof of Theorem 4. The assertion of the theorem is equivalent to the following:

Suppose $\log \eta^0 \in \mathscr{H}_{(1,s+2)}(\mathbb{R}^n_+) \cap W^{1,\infty}_{\text{loc}}(\mathbb{R}^n_+)$, $\{\eta^1_j\} \subset \mathscr{M}_\gamma$, $\eta^1_j(\cdot,0) \to 0$ in $H^1(\mathbb{R}^{n-1})$, and $D\mathscr{T}_\infty(\eta^0)\cdot\eta^1_j \to 0$ in $H^1_{\text{loc}}(\mathbb{R}^n_+)$. Then $\eta^1_j \to 0$ in $H^1_{\text{loc}}(\mathbb{R}^n_+)$ (hence in $\mathscr{H}_{(1,s+2)_{\text{loc}}}(\mathbb{R}^n_+)$).

Since $\mathfrak{R}(\gamma,\Gamma) \subset H^1(\mathbb{R}^n_1)$, it does no harm to assume $\{\eta^1_j\}$ bounded in H^1, hence (passing to a subsequence) weakly convergent in H^1_{loc}. Since $\mathfrak{R}(\gamma,\Gamma) \subset \mathscr{H}_{(1,s+2)}(\mathbb{R}^n_+)$ also, we can as well assume $\{\eta^1_j\}$ bounded and weakly convergent in $\mathscr{H}_{(1,s+2),\text{loc}}$. Since $\mathscr{H}_{(1,s+2)}$ is stronger than H^1_{loc}, the weak limit is unique; denote by η^1_∞ the weak limit. Now Theorem 1 implies

$$D\mathscr{T}_T(\eta^0)\eta^1_\infty = w - \lim D\mathscr{T}_T(\eta^0)\eta^1_j = 0$$

for any $T > 0$, so $D\mathscr{T}_\infty(\eta^0)\eta^1_\infty = 0$. Also, the hypothesis on $\mathscr{M}$ implies that $\eta^1_\infty \in \mathscr{M}$; hence $\eta^1_\infty \in \mathfrak{R}(\gamma',\Gamma)$ for some $\gamma' > 0$. It follows immediately from Theorem 3 that $\eta^1_\infty = 0$. Since $\{\eta^1_j\} \to 0$ weakly in $H^1(\mathbb{R}^n_+)$, a fortiori $\{\eta^1_j\} \to 0$ weakly in $H^1(\mathbb{R}^{n-1}\times[0,T])$ for each $T > 0$. Also, since $\Gamma \cap (\mathbb{R}^{n-1}\times[0,T])$ is compact, and thus $\text{supp}(D\mathscr{T}_\infty(\eta^0)\cdot\eta^1_j) \cap (\mathbb{R}^{n-1}\times[0,T])$ is compact, uniformly in j, convergence to zero of $D\mathscr{T}_\infty(\eta^0)\cdot\eta^1_j$ in H^1_{loc} implies convergence to zero of $D\mathscr{T}_T(\eta^0)\cdot\eta^1_j$ in $H^1(\mathbb{R}^{n-1}\times[0,T])$. We conclude from Theorem 2 that $\eta^1_j \to 0$ strongly in $H^1(\mathbb{R}^{n-1}\times[0,T])$. Since T is arbitrary, the proof is complete. Q.E.D.

Remark. A number of Soviet mathematicians have derived uniqueness and continuous dependence results for inverse problems of hyperbolic partial differential equations, under the assumptions that the coefficients may be expressed as finite sums

$$\eta(x,z) = \sum a_i(z)\varphi_i(x)$$

the φ_i being some prescribed (smooth) functions of x. (See, for instance, V. G. Jahno, *Uniqueness theorem for an inverse problem for a hyperbolic partial differential equation*, Differential Equations, 13 (1977), pp. 544–551.) Note that the coefficients in this class belong to the regularizing set $\mathfrak{R}(\gamma, \Gamma)$ for suitable γ, Γ. Thus, these results seem to be related to those presented here.

Acknowledgments. I would like to thank Paul Sacks and Percy Deift for useful conversations leading to several corrections and revisions. I would also like to thank the referee for pointing out an error in an example.

A NONLINEAR INTEGRAL OPERATOR ARISING FROM A MODEL IN POPULATION GENETICS IV. CLINES*

ROGER LUI†

Abstract. We study the existence, uniqueness and stability properties of solutions to the integral equation $\phi = Q[\phi]$ with $\phi(-\infty)=1$, $\phi(\infty)=0$. Here $Q[u](x)=\int K(x-y)g(y,u(y))\,dy$ is defined on functions bounded between 0 and 1, K is a probability density function and $g(x,u)=[s(x)u^2+u]/[1+s(x)u^2+\sigma(x)(1-u)^2]$ according to a population genetics model. The hypotheses on g are based on the biological assumption that the homozygotes, that is individuals with genotypes AA or aa, are best fit to survive near opposite ends of the one-dimensional habitat.

1. Introduction. In the first section of [13] a population genetics model was formulated that describes the change in gene fractions over successive generations of a population living in a homogeneous one-dimensional habitat. The model took selection and migration into account and resulted in a recursion of the form

$$u_{n+1}=Q[u_n], \tag{1.1}$$

where $u_n(x)$ is the gene fraction of the population at location x in the nth generation. The operator

$$Q[u](x)=\int K(x-y)g(y,u(y))\,dy \tag{1.2}$$

is defined on the set of functions $\mathscr{C}=\{u: 0\leqq u\leqq 1,\ u \text{ piecewise continuous}\}$.

In the model, the selection process is described by a function $g:\mathbb{R}\times[0,1]\to[0,1]$, where

$$g(x,u)=\frac{s(x)u^2+u}{1+s(x)u^2+\sigma(x)(1-u)^2}. \tag{1.3}$$

Migration on the other hand is described by a probability density function K.

The formula (1.3) was arrived at under several severe restrictions, among which is the fact that fitnesses of the three genotypes AA, Aa and aa present in the population have to be in the ratio $1+s:1:1+\sigma$. In actual situations, the difference between these fitnesses is usually small.

Equation (1.1) has so far been studied only when $s\geqq\sigma$ are constants (g independent of x). The case $s>0>\sigma$ and $s\geqq\sigma>0$ are considered in the papers [10], [11] and [12], [13] respectively. The case $0>s\geqq\sigma$ is essentially the same as that of $s>0>\sigma$. It has also been mentioned in these papers that our model came as an improvement of a similar model proposed by R. A. Fisher in 1937 [6].

Fisher came up with the nonlinear diffusion equation $u_t=u_{xx}+f(u)$. This equation has received a lot of attention lately (see references in [13]). Our results in [10] through [13] agreed to a remarkable extent with those obtained for Fisher's equation. Not surprisingly, the results in this paper are in line with those in [4] and [18]. Judging from what is known, it is clear that the qualitative picture of the solutions is independent of the details of the modelling and therefore has much biological interest.

*Received by the editors January 17, 1984.
†Department of Mathematical Sciences, Worcester Polytechnic Institute, Worcester, Massachusetts 01609.

The purpose of this paper is to study (1.1) without assuming that s and σ are constants. We assume however that individuals of genotype AA are more fit to survive in the far left region of the habitat while the same is true for genotype aa in the far right. In terms of s and σ, we assume

(1.4) There exists $N>0$ such that $s(x)\geqq\sigma(x)$, $s(x)>0$ for $x\leqq -N$ and $s(x)\leqq\sigma(x)$, $\sigma(x)>0$ for $x\geqq N$.

We also assume that none of the homozygotes is lethal. That is to say,

$$1+s(x)>0, \qquad 1+\sigma(x)>0 \quad \text{in } \mathbb{R}. \tag{1.5}$$

This implies that $g(x,0)\equiv 0$, $g(x,1)\equiv 1$ and $\tilde{g}(x,0)\equiv 0$, $\tilde{g}(x,1)\equiv 1$. Here

$$\tilde{g}(x,u)\equiv 1-g(x,1-u)=\frac{\sigma(x)u^2+u}{1+\sigma(x)u^2+s(x)(1-u)^2}. \tag{1.6}$$

From (1.3)

$$g_x(x,u)=\frac{\left[s'u+(\sigma s'-s\sigma')u(1-u)-\sigma'(1-u)\right]u(1-u)}{\left[1+su^2+\sigma(1-u)^2\right]^2}.$$

According to (1.5), the denominator is always positive. If $\sigma'(x)>0$, $s'(x)<0$ and $0<u<1$, then $s'u[1+\sigma(1-u)]<0<\sigma'(1-u)[1+su]$ so that $g_x(x,u)<0$. Therefore we assume, in addition to (1.4) and (1.5),

$$\sigma'(x)\geqq 0, \qquad s'(x)\leqq 0 \quad \text{for } |x|\geqq N. \tag{1.7}$$

This will imply that $g_x(x,u)\leqq 0$ for $|x|\geqq N$.

Condition (1.7) is only enough to guarantee the existence of clines but not the uniqueness or stability. For these we need the more restrictive assumption

(1.8) $\sigma'(x)\geqq 0$, $s'(s)\leqq 0$ in $\mathbb{R}$ and there exists an interval $\mathscr{J}$ where $\sigma'(x)>0$, $s'(x)<0$.

In terms of g, (1.8) implies that, $g_x(x,u)\leqq 0$ and $g_x(x,u)<0$ in $\mathscr{J}\times(0,1)$.

Again from (1.3)

$$g_u(x,u)=\frac{-(s+2s\sigma+\sigma)u^2+(2s+2s\sigma)u+1+\sigma}{\left[1+su^2+\sigma(1-u)^2\right]^2}.$$

Let $N(u)=-(s+2s\sigma+\sigma)u^2+(2s+2s\sigma)u+1+\sigma$. Then $N(0)=1+\sigma>0$, $N(1)=1+s>0$ so that $N(u)>0$ in $[0,1]$ if $s+2s\sigma+\sigma\geqq 0$. When $s+2s\sigma+\sigma<0$, the minimum of N occurs at $u^*=s(1+\sigma)/(s+2s\sigma+\sigma)$. In order for $0\leqq u^*\leqq 1$, we must have $s\leqq 0$, $\sigma\leqq 0$. But then

$$N(u^*)=\frac{(1+\sigma)(1+s)[s+s\sigma+\sigma]}{s+2s\sigma+\sigma}>0,$$

since $s+s\sigma+\sigma\leqq s+2s\sigma+\sigma<0$. Thus $g_u(x,u)>0$ in $\mathbb{R}\times[0,1]$. Note that $g_u(x,0)=1/(1+\sigma)$ and $g_u(x,1)=1/(1+s)$.

To continue, consider

$$g(-N,u)=\frac{s(-N)u^2+u}{1+s(-N)u^2+\sigma(-N)(1-u)^2}.$$

From (1.4), $s(-N)$ is positive so that the numerator and denominator are both nonnegative. Since $s(-N)\geqq\sigma(-N)$, (1.7) implies that

$$(1.9)\quad g(x,u)\geqq g(-N,u)\geqq g_1(u)\equiv\frac{s(-N)u^2+u}{1+s(-N)u^2+s(-N)(1-u)^2}\quad\text{for } x\leqq -N.$$

Similarly, $\sigma(N)\geqq s(N)$ and (1.7) imply that

$$(1.10)\quad g(x,u)\leqq g(N,u)\leqq g_0(u)\equiv\frac{\sigma(N)u^2+u}{1+\sigma(N)u^2+\sigma(N)(1-u)^2}\quad\text{for } x\geqq N.$$

This last inequality is easy to verify if we look at $\tilde{g}(N,u)$.

We now summarize the hypotheses on K and g to be assumed throughout the entire paper except for condition (viii*) of (1.12). The hypotheses on K are identical to those assumed in [12]. We shall not assume g has the form (1.3) but only that it satisfies all the conditions listed in (1.12). Our discussion earlier made it clear what to assume of s and σ in order that (1.12) holds when g has the form (1.3).

(i) $K(x)\geqq 0$. If $B_1=\inf\{x:K(x)>0\}$, $B_2=\sup\{x:K(x)>0\}$, then $K(x)>0$ in (B_1,B_2). We allow $B_1=-\infty$, $B_2=+\infty$ so that K need not have compact support.

(ii) $K(x)$ is continuous in $\mathbb{R}$, except possibly at B_1 and B_2 where $\lim_{x\downarrow B_1}K(x)=p_1$, $\lim_{x\uparrow B_2}K(x)=p_2$.

(1.11) Also K may be written in the form

$$K(x)=K_a(x)-p_1\chi_{(-\infty,B_1]}-p_2\chi_{[B_2,\infty)},$$

where K_a is absolutely continuous and χ_S is the indicator function of the set S.

(iii) $\int K(x)\,dx=1$.

(iv) $\int e^{\mu x}K(x)\,dx$ is finite for all real μ.

(v) $\int_x^\infty K(y)\,dy\leqq \text{const}\,K(x)$ for large x, $\int_{-\infty}^x K(y)\,dy\leqq\text{const}\,K(x)$ for small x.

(vi) $g(x,u):\mathbb{R}\times[0,1]\to[0,1]$ has continuous derivative. g_x, g_u, g_{uu} are uniformly bounded.

(vii) $g(x,0)\equiv 0$, $g(x,1)\equiv 1$.

(viii) There exists $N>0$ such that $g_x(x,u)\leqq 0$ for $|x|\geqq N$; or

(viii*) $g_x(x,u)\leqq 0$ in $\mathbb{R}\times[0,1]$ and $g_x(x,u)<0$ in $\mathscr{J}\times(0,1)$ for some interval $\mathscr{J}$.

(ix) $g_u(x,u)\geqq 0$ in $\mathbb{R}\times[0,1]$ and $g_u\not\equiv 0$ in any rectangle.

(1.12) (x) $g_u(x,0)\in(0,1)$ uniformly for $x\geqq N$, $g_u(x,1)\in(0,1)$ uniformly for $x\leqq -N$.

(xi) There exist two functions g_+, g_- satisfying all the conditions in (1.13) such that $g(-N,u)\geqq g_-(u)$ and $g(N,u)\leqq g_+(u)$. Furthermore, $c_+^*(g_-)>0$ and $c_-^*(g_+)>0$.

At this point we must digress to explain the meaning of condition (xi). Consider first a function $g:[0,1]\to[0,1]$ satisfying the conditions:

(1.13)
(i) $g\in C^1[0,1]$.
(ii) $g(0)=0$, $g(1)=1$.
(iii) There exists a constant $\alpha\in(0,1)$ such that $g(u)<u$ in $(0,\alpha)$ and $g(u)>u$ in $(\alpha,1)$.
(iv) $g'(u)\geqq 0$ in $[0,1]$. If $\sigma_1=\inf\{u:g(u)>0\}$, $\sigma_2=\sup\{u:g(u)<1\}$, then $g'(u)>0$ in (σ_1,σ_2).
(v) $g'(0)<1$, $g'(1)<1$.
(vi) $g(u)\geqq g'(\alpha)(u-\alpha)+\alpha$ in $[0,\alpha]$ and $g(u)\leqq g'(\alpha)(u-\alpha)+\alpha$ in $[\alpha,1]$.
(vii) $g'(0)u\leqq g(u)\leqq g'(1)(u-1)+1$ in $[0,1]$.

Remark 1.1. Condition (vi) implies that $\max_{[0,1]}g(u)/u<g'(\alpha)$ and $\max_{[0,1]}((1-g(1-u))/u)<g'(\alpha)$. All the results in [12] are valid under conditions (1.11) and (1.13).

Let $\bar{Q}:\mathscr{C}\to\mathscr{C}$ be the nonlinear convolution operator $\bar{Q}[u]=K*g(u)$. Then associated with $\bar{Q}$ is a real number $c_+^*(g)$ such that the following holds.

THEOREM 1.1 (existence of travelling waves). *There exists a nonincreasing function* w, $w(-\infty)=1$, $w(\infty)=0$ *and* $w(x)=\bar{Q}[w](x+c_+^*(g))$.

THEOREM 1.2 (uniqueness). *Suppose* $u\in\mathscr{C}$ *satisfies* $u(-\infty)>\alpha$, $u(\infty)<\alpha$ *and* $u(x)=\bar{Q}[u](x+c)$. *Then* $c=c_+^*(g)$ *and* $u(x)=w(x-\tau)$ *for some constant* τ.

The above two theorems are [12, Thm. 5] and [2, Thm. 1.2] respectively. The function w is called a travelling wave solution of $\bar{Q}$ facing right. They are unique up to translation.

The number $c_+^*(g)$ is called the wave speed of $\bar{Q}$ in the positive direction [13], [21]. It should be pointed out that $c_+^*(g)$ is the asymptotic speed of propagation for certain class of initial data. For example, let $u_0\in\mathscr{C}$ be decreasing, $u_0(-\infty)>\alpha$, $u_0(\infty)<\alpha$ and $u_{n+1}=\bar{Q}[u_n]$ for all n. Then $\lim_{n\to\infty}(u_n^{-1}(\gamma)/n)=c_+^*(g)$ for every $0<\gamma<1$.

There are of course nondecreasing travelling waves facing left with wave speed $c_-^*(g)$ in the negative direction. The meaning of condition (xi) should now be clear.

Remark 1.2. If $u_n(x)=0$ for $x\geqq 0$, then $u_{n+1}(x)=0$ for $x\geqq B_2$. Thus the speed of propagation to the right, namely $c_+^*(g)$, cannot exceed B_2. We can show that $B_1<c_+^*(g)<B_2$ and $B_1<-c_-^*(g)<B_2$ so that condition (xi) implies $B_1<0<B_2$.

Remark 1.3. The wave speed depends monotonically on $\bar{Q}$. Given $\bar{Q}_1$ and $\bar{Q}_2$ with $\bar{Q}_1[u]\geqq\bar{Q}_2[u]$ for all $u\in\mathscr{C}$, then $c_+^*(\bar{Q}_1)\geqq c_+^*(\bar{Q}_2)$. For example, if $g_1(u)\geqq g_2(u)$ in $[0,1]$ and $\bar{Q}_1[u]=K*g_1(u)$, $\bar{Q}_2[u]=K*g_2(u)$, then $c_+^*(g_1)\geqq c_+^*(g_2)$. In fact, more is true. If $g_1(u)>g_2(u)$ in $(0,1)$ and $g_1'(0)>g_2'(0)$, $g_1'(1)<g_2'(1)$, then $c_+^*(g_1)>c_+^*(g_2)$ [2].

Remark 1.4. Let g_1, g_0 be defined as in (1.9) and (1.10). Then all the conditions in (1.13) are satisfied. It is easy to check that $\alpha=1/2$, $\sigma_1=0$, $\sigma_2=1$, $g_1'(0)=g_1'(1)=(1+s(-N))^{-1}$, $g_0'(0)=g_0'(1)=(1+\sigma(N))^{-1}$ and $g_i'(u)\leqq g_i'(1/2)$ in $[0,1]$. This last inequality obviously implies condition (vi) of (1.13). It may be proved by observing that $g_i'(u)$ is a rational function in u. The numerator has a maximum at $u=1/2$ and the denominator has a minimum also at $u=1/2$. The left-hand inequality in (vii) of (1.13) is straightforward. The right-hand inequality is equivalent to showing that $\tilde{g}_i(u)\equiv 1-g_i(1-u)\geqq g_i'(1)u$. But then $\tilde{g}_i=g_i$ and $g_i'(0)=g_i'(1)$ from (1.6), and so it is the same as the left-hand inequality.

Remark 1.5. If g is given by (1.3), we cannot take $g_-=g_1$ or $g_+=g_0$ in assumption (xi) of (1.12). In fact when K is even, $c_+^*(g_1)=c_-^*(g_0)=0$ [2]. However, if $s(-N)>\sigma(-N)$ in (1.4), we let $g_-(u)=(s(-N)u^2+u)/(1+s(-N)u^2+\sigma_1(1-u)^2)$ for some

$\max\{\sigma(-N),0\}<\sigma_1<s(-N)$. Then $g(-N,u)\geqq g_-(u)$ and if σ_1, is close enough to $s(-N)$, (1.13) will be satisfied by $c_+^*(g_-)>0$ (Remark 1.3). A similar arrangement can be made for g_0 when $s(N)<\sigma(N)$.

Finally a few words about references. As mentioned earlier, results in this paper parallel those obtained in [4] which considered the differential equation $u_t=u_{xx}+f(x,u)$. Almost identical results were obtained in [18] for the equation $u_t=u_{xx}+mu_x+f(x,u)$. The term mu_x came from assuming nonsymmetric migration. In [5], one of the homozygotes was assumed favored in the entire habitat, and the differential equation was allowed to have variable coefficients in some cases. This could happen in our model also if we do not assume the total population density $\mu(x)$ is a constant. Then K in (1.2) is replaced by

$$K(x,y)=\frac{K(x-y)\mu(y)}{\int K(x-y)\mu(y)\,dy},$$

see [21]. It is not clear if any of the techniques developed so far are applicable to this case.

The paper by Felsenstein [3] contains 152 references on the subject of variable selection and migration. Some of the fairly standard ones are [7], [14]–[17], [20]. We must also mention the work of Conley [1], who proved the existence of clines for the above differential equation with $f(x,u)=s(x)u(1-u)$, $s(\pm\infty)\neq 0$, using a topological argument. A radially symmetric problem with $x\in\mathbb{R}^2$ is also considered. The paper by Sawyer [19] contains more complete and recent information.

2. Statement of results.

THEOREM 2.1. *There exists a function* $\phi\in\mathscr{C}$ *such that* $\phi(-\infty)=1$, $\phi(\infty)=0$ *and* $\phi=Q[\phi]$.

Remark 2.1. If ϕ is nonincreasing, it is often referred to as a cline.

The rest of the results assume the stronger condition (viii*) of (1.12).

THEOREM 2.2. *There is at most one solution to the problem* $\phi\in\mathscr{C}$, $\phi(-\infty)=1$, $\phi(\infty)=0$ *and* $\phi=Q[\phi]$. *Furthermore, such a solution is decreasing in* $\mathbb{R}$.

In the next two theorems, u_n is defined recursively by (1.1) for a given u_0. ϕ is the unique monotone cline from Theorems 2.1 and 2.2.

From conditions (viii*) and (xi) of (1.12), we have $g(x,u)\geqq g_-(u)$ for $x\leqq -N$ and $g(x,u)\leqq g_+(u)$ for $x\geqq N$. Since $g_-(u)>u$ near 1 and $g_+(u)<u$ near 0, we can define the functions $a_1(x)=\inf\{u:g(x,u)>u\}$ for $x\leqq -N$ and $a_0(x)=\sup\{u:g(x,u)<u\}$ for $x\geqq N$. Also, $a_1(x)$ is nondecreasing in x and a_0 is nonincreasing in x. We let $a^-=\lim_{x\to\infty}a_0(x)$ and $a^+=\lim_{x\to-\infty}a_1(x)$. Clearly $a^+<1$ and $a^->0$.

THEOREM 2.3. *Suppose* u_0 *satisfies the condition* (i) $\phi(x-h_1)\leqq u_0(x)\leqq\phi(x-h_2)$ *for some* $h_1<0<h_2$ *or* (ii) $\liminf_{x\to-\infty}u_0(x)>a^+$, $\limsup_{x\to\infty}u_0(x)<a^-$, *then* $\lim_{n\to\infty}\|u_n-\phi\|_\infty=0$.

THEOREM 2.4. *There exist positive constants* δ, μ *and* C *such that if* $\|u_0-\phi\|_\infty\leqq\delta$, *then* $\|u_n-\phi\|_\infty\leqq Ce^{-\mu n}$ *for all* n. *Consequently, the uniform convergence in Theorem* 2.3 *may be replaced by exponential convergence.*

3. Proof of Theorem 2.1. We begin by proving left continuity of $c_+^*(g)$ with respect to g. It is a consequence of Theorem 1.2.

LEMMA 3.1. *Suppose* g_δ, $0<\delta<\delta_0$ *is a family of functions each of which satisfies the conditions in* (1.13) *with some* $\alpha_\delta\in(0,1)$. *Suppose further that* g_δ *increases uniformly to* g *as* $\delta\downarrow 0$. *Then* $\lim_{\delta\downarrow 0}c_+^*(g_\delta)=c_+^*(g)$.

Proof. By Remark 1.3, $c_\delta \equiv c_+^*(g_\delta)$ increases as δ decreases. Let $\lim_{\delta \downarrow 0} c_\delta = c_0 \leqq c_+^*(g)$. From Theorem 1.1, for each $\delta > 0$, there exists nonincreasing travelling waves w_δ such that $w_\delta(-\infty)=1$, $w_\delta(\infty)=0$ and

$$w_\delta(x)=\int K(x+c_\delta-y)g_\delta(w_\delta(y))\,dy.$$

Since w_δ is determined only up to translation, we may choose w_δ such that $w_\delta(0)=\gamma$ for some fixed $\gamma \in (\alpha,1)$. From (ii) of (1.11), $\|w_\delta'\|_\infty \leqq \|K_a'\|_1 + p_1 + p_2$. Arzela–Ascoli theorem implies that a subsequence, also denoted by w_δ, converges uniformly on compact sets to a nonincreasing function w^*. Furthermore, $w^*(0)=\gamma$ and $w^*(x)=\int K(x+c_0-y)g(w^*(y))\,dy$. Therefore $w^*(-\infty)=1$ and $w^*(\infty)=\alpha$ or 0. $w^*(\infty)$ cannot be α because $g(u)>u$ in $(\alpha,1)$ and such a solution connecting 1 and α exists if and only if $c_0 \geqq \rho_+^* > c_+^*(g)$. See [12, Prop. 3 and Lemma 2.2] for this fact and the definition of ρ_+^*. Thus $w^*(\infty)=0$ and by Theorem 1.2, $c_0 = c_+^*(g)$. Q.E.D.

LEMMA 3.2. *There exist two nonincreasing functions $\underline{u}$, $\bar{u}$ in $\mathscr{C}$ with the properties $\underline{u} \leqq \bar{u}$, $\underline{u} \leqq Q[\underline{u}]$ and $Q[\bar{u}] \leqq \bar{u}$.*

Proof. We first construct $\underline{u}$. From condition (xi) of (1.12), there exists g_- satisfying (1.13) with $c_+^*(g_-)>0$. Let $\delta_0>0$ be sufficiently small and for each $0<\delta<\delta_0$, construct $g_\delta \in C^1[0,1]$ such that $g_\delta = g_-$ on $[\delta,1]$, $g_\delta = 0$ on $[0,\delta/2]$ and on the interval $(\delta/2,\delta)$, $g_\delta'>0$ and g_δ increases uniformly to g_- as $\delta \downarrow 0$. It is clear that (1.13) is satisfied for each g_δ.

From Lemma 3.1, for sufficiently small $\delta>0$, $c_\delta \equiv c_+^*(g_\delta)>0$. Fix such a δ and let w_δ be the nonincreasing travelling wave of the operator $K * g_\delta(u)$, translated so that $w_\delta(-N)=\delta/2$. We have

$$\begin{aligned} w_\delta(x) &= \int K(x+c_\delta-y)g_\delta(w_\delta(y))\,dy = \int K(x-y)g_\delta(w_\delta(y+c_\delta))\,dy \\ &\leqq \int K(x-y)g_\delta(w_\delta(y))\,dy = \int_{-\infty}^{-N} K(x-y)g_\delta(w_\delta(y))\,dy \\ &\leqq \int_{-\infty}^{-N} K(x-y)g_-(w_\delta(y))\,dy. \end{aligned}$$

Let

$$\underline{u}(x)=\begin{cases} w_\delta(x) & \text{if } x \leqq -N, \\ 0 & \text{if } x > -N. \end{cases}$$

Then from (1.2) and (viii) of (1.12), we have

$$\begin{aligned} Q[\underline{u}](x) &= \int_{-\infty}^{-N} K(x-y)g(y,\underline{u}(y))\,dy \geqq \int_{-\infty}^{-N} K(x-y)g(-N,\underline{u}(y))\,dy \\ &\geqq \int_{-\infty}^{-N} K(x-y)g_-(\underline{u}(y))\,dy \geqq w_\delta(x). \end{aligned}$$

Therefore, $Q[\underline{u}](x) \geqq \underline{u}(x)$ for $x \leqq -N$. Since $Q[\underline{u}] \geqq 0$, the inequality holds for all x.

To construct $\bar{u}$, let $K_1(x)=K(-x)$, $\tilde{g}_+(u)=1-g_+(1-u)$ and $\tilde{Q}[u]=K_1 * \tilde{g}_+(u)$. The relation between this (dual) operator $\tilde{Q}$ and $\overline{Q}[u]=K * g_+(u)$ is given in [12, §2]. It is shown there that $\tilde{g}_+$ satisfies the set of hypotheses (1.13) and that the wave speed of $\tilde{Q}$ in the positive direction, hereby denoted by $\tilde{c}_+^*(\tilde{g}_+)$, is equal to the wave speed of $\overline{Q}$ in the negative direction, $c_-^*(g_+)$. This fact is a consequence of the symmetry between 0 and 1 in the graph of g_+.

As before, we construct $\tilde{g}_\delta$ increasing uniformly to $\tilde{g}_+$ as $\delta \downarrow 0$, $\tilde{g}_\delta(u)=0$ in $[0,\delta/2]$, $\tilde{g}_\delta=\tilde{g}_+$ in $[\delta,1]$ and each $\tilde{g}_\delta$ satisfies (1.13). Since $c^*_-(g_+)>0$, Lemma 3.1 and above implies that for sufficiently small $\delta>0$, $\tilde{c}_\delta \equiv \tilde{c}^*_+(\tilde{g}_\delta)$ is positive.

Now let $\tilde{w}_\delta$ be the nonincreasing travelling wave of the operator $K_1 * \tilde{g}_\delta(u)$ translated so that $\tilde{w}_\delta(-N)=\delta/2$. As before,

$$\begin{aligned}\tilde{w}_\delta(x) &= \int K_1(x-y)\tilde{g}_\delta(\tilde{w}_\delta(y+\tilde{c}_\delta))\,dy \\ &\leqq \int_{-\infty}^{-N} K(-x+y)\tilde{g}_\delta(\tilde{w}_\delta(y))\,dy \\ &= \int_N^\infty K(-x-y)\tilde{g}_\delta(\tilde{w}_\delta(-y))\,dy.\end{aligned}$$

Define $v(x)=1-\tilde{w}_\delta(-x)$. We have

$$\begin{aligned}v(x) &\geqq 1-\int_N^\infty K(x-y)\tilde{g}_\delta(\tilde{w}_\delta(-y))\,dy \\ &= 1-\int_N^\infty K(x-y)\tilde{g}_\delta(1-v(y))\,dy.\end{aligned}$$

Now let

$$\bar{u}(x)=\begin{cases}1 & \text{if } x\leqq N,\\ v(x) & \text{if } x\geqq N,\end{cases}$$

$\tilde{g}(x,u)=1-g(x,1-u)$. Then

$$\begin{aligned}Q[\bar{u}](x) &= 1-\int K(x-y)\tilde{g}(y,1-\bar{u}(y))\,dy \\ &= 1-\int_N^\infty K(x-y)\tilde{g}(y,1-\bar{u}(y))\,dy.\end{aligned}$$

From condition (xi) of (1.12), $\tilde{g}(x,u)\geqq \tilde{g}_+(u)$ for $x\geqq N$ so that

$$\begin{aligned}Q[\bar{u}](x) &\leqq 1-\int_N^\infty K(x-y)\tilde{g}_+(1-\bar{u}(y))\,dy \\ &\leqq 1-\int_N^\infty K(x-y)\tilde{g}_\delta(1-\bar{u}(y))\,dy \leqq v(x).\end{aligned}$$

Since $\bar{u}(x)=v(x)$ for $x\geqq N$ and $Q[\bar{u}]\leqq 1$, we have $Q[\bar{u}]\leqq \bar{u}$. It is also clear from the definitions of $\underline{u}$ and $\bar{u}$ that they are nonincreasing and $\underline{u}\leqq\bar{u}$. This completes the proof of Lemma 3.2.

To prove Theorem 2.1, we first observe that Q is order-preserving in the sense that $u\leqq v$ implies $Q[u]\leqq Q[v]$.

Let $\underline{u}_0=\underline{u}$, $\bar{u}_0=\bar{u}$ and define $\underline{u}_n$, $\bar{u}_n$ recursively as in (1.1). An inductive argument shows that $\underline{u}_0\leqq\underline{u}_n\leqq\underline{u}_{n+1}\leqq\bar{u}_{n+1}\leqq\bar{u}_n\leqq\bar{u}_0$ for all n. Therefore $\underline{u}_n$, $\bar{u}_n$ converge, as $n\to\infty$, to ϕ_1, ϕ_2 respectively. Since $\underline{u}\leqq\phi_1\leqq\phi_2\leqq\bar{u}$, we have $\phi_i(-\infty)=1$, $\phi_i(\infty)=0$ and $\phi_i=Q[\phi_i]$. The proof of Theorem 2.1 is complete if we take $\phi=\phi_1$ or ϕ_2.

Remark 3.1. It does not follow from the above construction that ϕ_i is nonincreasing in $\mathbb{R}$, even though $\underline{u}$, $\bar{u}$ are. This is true if we assume $g_x\leqq 0$. In this case there exists a cline.

Remark 3.2. The solution ϕ we have constructed in Theorem 2.1 lies between $\underline{u}$ and $\bar{u}$. Since $w_\delta(x)$, $\tilde{w}_\delta(x)$ converge to 1 exponentially as $x \to -\infty$ [12, Prop. 5], there exist $\mu > 0$, $C > 0$ such that $|\phi(x)| \leqq Ce^{-\mu x}$ as $x \to \infty$ and $|1-\phi(x)| \leqq Ce^{\mu x}$ as $x \to -\infty$.

Without further assumptions other than (viii) of (1.12), the solution ϕ is not unique. For example, let $h(x,u)$, defined on $\mathbb{R} \times [0,1]$, be sufficiently smooth and satisfy the conditions (i) $h(x,u)=0$ on $(-\infty, N] \times [\frac{1}{2}, 1]$ and $[-N, \infty) \times [0, \frac{1}{2}]$, (ii) $h(x,0)=h(x,1)=0$, (iii) $h_x(x,u) \leqq 0$ for $|x| \geqq N$ and (iv) $-\frac{1}{2} \leqq h(x,u) \leqq \frac{1}{2}$ in $\mathbb{R} \times [0,1]$. It is clear that such an h exists and if $\gamma \in (0,1)$, γh also satisfies conditions (i) to (iv).

Let $K(x)=K(-x)$, $g(x,u)=g_0(u)+\gamma h(x,u)$, where g_0 is given by (1.10). Choose γ so small that $g_0'(u)+\gamma h_u(x,u) > 0$ in $\mathbb{R} \times [0,1]$. This is possible since $\min_{[0,1]} g_0'(u) > 0$. For small γ, it is straightforward to verify that conditions (vi) to (x) of (1.12) are satisfied for g. However, according to Theorem 1.1 and Remark 1.5, there exists a nonincreasing function w, $w(-\infty)=1$, $w(0)=1/2$ and $w(\infty)=0$ such that $w(x)=\int K(x-y) g_0(w(y))\,dy$. From (i) above, it is easy to see that $w(x+\tau)=\int K(x-y) g(y, w(y+\tau))\,dy$ for $|\tau| \leqq N$. Therefore we have nonuniqueness.

4. Proof of Theorem 2.2. For the rest of the paper we assume condition (viii*) of (1.12). Proposition 4.2 is the basis for much of the results that follow. The following lemma is the heart of its proof.

LEMMA 4.1. *Let ϕ be nonincreasing, $\phi(-\infty)=1$, $\phi(\infty)=0$ and $\phi = Q[\phi]$. There exist two decreasing sequences $\{z_n\}$, $\{q_n\}$ such that if $v_n(x)=\phi(x-z_n)-q_n$, then $v_{n+1} \leqq Q[v_n]$ for all n.*

Remark 4.1. We shall see from the proof that there are no restrictions on z_0, q_0 except that $z_0 \leqq 0$ and $q_0 > 0$ be sufficiently small.

Proof. We begin by showing $\phi'(x) < 0$ in $\mathbb{R}$. From $g_x \leqq 0$ and our hypotheses, $\phi'(x) \leqq \int K(x-y) g_u(y, \phi(y)) \phi'(y)\,dy \leqq 0$. Let $\phi'(x_0)=0$. Then $g_u(y, \phi(y))\phi'(y)=0$ on the interval $[x_0-B_2, x_0-B_1]$, which, according to Remark 1.2, contains x_0. Since g_u does not vanish on any rectangle, $\phi'(x)=0$ on an open interval containing x_0. This means that the set S when $\phi'=0$ is open. From the continuity of ϕ', S is closed. Obviously ϕ is not a constant, S is empty and so $\phi'(x) < 0$ in $\mathbb{R}$.

Next we show that there exist constants q_0, δ, θ_1 all in the interval $(0,1)$ such that

$$g(x,u-q)-g(x,u) \geqq -\theta_1 q \quad \text{for } 0 \leqq q \leqq q_0, \tag{4.1}$$
$$u \in [1-\delta, 1] \text{ and } x \leqq -N \quad \text{or} \quad u \in [0, \delta] \text{ and } x \geqq N.$$

To begin, consider the function

$$\psi(x,u,q) = \begin{cases} \dfrac{g(x,u)-g(x,u-q)}{q} & \text{if } q > 0, \\ g_u(x,u) & \text{if } q = 0 \end{cases}$$

in the set $\mathscr{D} = \mathbb{R} \times [1-\delta, 1] \times [0, q_0]$, where we shall define $g(x,u)=0$ if $u < 0$. It is clear that ψ is uniformly continuous in $\mathscr{D}$. Also

$$\psi(x,1,q) = \frac{1-g(x,1-q)}{q} = g_u(x,\theta) \quad \text{where } 1-q \leqq \theta \leqq 1.$$

From (x) of (1.12) and the fact that g_u is uniformly continuous, there exists $\theta_1 \in (0,1)$ such that $\psi(x,1,q) < \theta_1 < 1$ for q sufficiently small and $x \leqq -N$. Since ψ is uniformly continuous in $\mathscr{D}$, $\psi(x,u,q) < \theta_1$ for u near 1. Therefore (4.1) holds when $x \leqq -N$ and $1-\delta \leqq u \leqq 1$.

Next consider $g(x,u-q)-g(x,u)$ for $0\leqq u\leqq\delta$ and $x\geqq N$. If $u-q\geqq 0$, then $g(x,u-q)-g(x,u)=-g_u(x,\theta)q$, where $u-q\leqq\theta\leqq u$. From (x) of (1.12) and uniformly continuity of g_u, we may assume (by increasing $\theta_1<1$ if necessary) that $g_u(x,\theta)<\theta_1<1$ for $x\geqq N$ and θ sufficiently small. Therefore (4.1) holds when $x\geqq N$ and u sufficiently small.

On the other hand, if $u-q<0$, then $g(x,u-q)-g(x,u)=-g(x,u)$. From the mean value theorem and the fact that g_{uu} is bounded, $\lim_{u\downarrow 0}(g(x,u)/u)=g_u(x,0)$ uniformly in $\mathbb{R}$. Therefore for $x\geqq N$ and u small $g(x,u)/u<\theta_1$ so that $g(x,u-q)-g(x,u)\geqq-\theta_1 u\geqq-\theta_1 q$. Altogether (4.1) is valid. It should be pointed out that (4.1) continues to hold with the same θ_1 and N if we decrease q_0 and δ.

To continue, let $M=\sup_{\mathbb{R}\times[0,1]}g_u(x,u)\geqq 1$ and choose $\varepsilon>0$, $\eta>0$ such that $\theta=\varepsilon M+\theta_1<1$,

$$\int_{\eta}^{\infty}K(x)\,dx\leqq\varepsilon,\qquad\int_{-\infty}^{-\eta}K(x)\,dx\leqq\varepsilon. \tag{4.2}$$

Define μ and q_n by $\theta=e^{-\mu}$ and $q_n=q_0e^{-\mu n}=q_0\theta^n$ for all n. Since $\phi'<0$ in $\mathbb{R}$, $\phi(-\infty)=1$, $\phi(\infty)=0$, we define $E_\gamma=\phi^{-1}(\gamma)$ for every $0<\gamma<1$.

Let $\Gamma=[E_{1-\delta}-2\eta,\ E_\delta+2\eta]$. We assume $\delta>0$ is sufficiently small so that $E_\delta\geqq N$, $E_{1-\delta}\leqq -N$. There exists $\theta_2>0$ such that

$$\phi(\xi_1)-\phi(\xi_2)\leqq-\theta_2(\xi_1-\xi_2)\quad\text{if }\xi_1>\xi_2\text{ are in }\Gamma. \tag{4.3}$$

Finally, let $z_0\leqq 0$ be arbitrary and define z_n recursively by

$$z_{n+1}=\frac{(\theta-M)q_0e^{-\mu n}}{\theta_2}+z_n. \tag{4.4}$$

Clearly z_n's are nonpositive and decreasing and converge to the limit

$$x_1=\frac{(\theta-M)q_0}{\theta_2}\left(\frac{1}{1-e^{-\mu}}\right)+z_0.$$

We may assume that q_0 is sufficiently small so that $(M-\theta)q_0\theta_2^{-1}\leqq\eta$.

Having defined all the constants, we proceed to prove the inequality $v_{n+1}\leqq Q[v_n]$, where $v_n(x)=\phi(x-z_n)-q_n$. This is equivalent to showing

$$\begin{aligned}&\phi(x-z_{n+1})-\phi(x-z_n)\\&\quad-\int K(x-y)\left[g(y,\phi(y-z_n)-q_n)-g(y-z_n,\phi(y-z_n))\right]dy\leqq q_{n+1}.\end{aligned} \tag{4.5}$$

Let

$$\Gamma_n=[E_{1-\delta}+z_n,\ E_\delta+z_n],\qquad\Gamma_n'=[E_{1-\delta}+z_n-\eta,\ E_\delta+z_n+\eta]$$

and

$$h_n(x)=g(x,\phi(x-z_n)-q_n)-g(x-z_n,\phi(x-z_n)).$$

Then

$$\begin{aligned}\int K(x-y)h_n(y)\,dy&=\int_{\Gamma_n}K(x-y)h_n(y)\,dy+\int_{y\geqq E_\delta+z_n}K(x-y)h_n(y)\,dy\\&\quad+\int_{y\leqq E_{1-\delta}+z_n}K(x-y)h_n(y)\,dy,\\&\equiv I_1+I_2+I_3.\end{aligned}$$

Consider first the case $x \notin \Gamma_n'$. Since $z_n \leqq 0$,

$$I_1 \geqq \int_{\Gamma_n} K(x-y)\left[g(y,\phi(y-z_n)-q_n)-g(y,\phi(y-z_n))\right] dy$$

$$= \int_{\Gamma_n} K(x-y)\, g_u(y,\theta)(-q_n)\, dy \geqq -Mq_n \int_{\Gamma_n} K(x-y)\, dy \geqq -Mq_n\varepsilon.$$

The last inequality follows from (4.2).

If $y \geqq E_\delta + z_n$, then $y - z_n \geqq E_\delta \geqq N$ and $\phi(y-z_n) \leqq \delta$. From (4.1),

$$h_n(y) \geqq g(y-z_n, \phi(y-z_n)-q_n) - g(y-z_n, \phi(y-z_n)) \geqq -\theta_1 q_n.$$

Therefore, $I_2 \geqq -\theta_1 q_n \int_{y \geqq E_\delta + z_n} K(x-y)\, dy$. Similarly, if $y \leqq E_{1-\delta} + z_n$, then $y - z_n \leqq E_{1-\delta} \leqq -N$ and $\phi(y-z_n) \geqq 1-\delta$. Again from (4.1), $h_n(y) \geqq g(y, \phi(y-z_n)-q_n) - g(y, \phi(y-z_n)) \geqq -\theta_1 q_n$ so that $I_3 \geqq -\theta_1 q_n \int_{y \leqq E_{1-\delta}+z_n} K(x-y)\, dy$.

Combining all three inequalities, we have, when $x \notin \Gamma_n'$,

$$\int K(x-y) h_n(y)\, dy \geqq -Mq_n\varepsilon - \theta_1 q_n = -\theta q_n = -q_{n+1}.$$

Since $z_{n+1} \leqq z_n$ and ϕ is nonincreasing, the difference between the first two terms in (4.5) is nonpositive. Therefore (4.5) is established when $x \notin \Gamma_n'$.

If $x \in \Gamma_n'$, then $E_{1-\delta} - \eta \leqq x - z_n \leqq E_\delta + \eta$ and

$$h_n(y) \geqq g(y, \phi(y-z_n)-q_n) - g(y, \phi(y-z_n)) = g_u(y,\theta)(-q_n) \geqq -Mq_n.$$

Therefore $\int K(x-y) h_n(y)\, dy \geqq -Mq_n$. From (4.4), $z_n - z_{n+1} \leqq (M-\theta) q_0 \theta_2^{-1} \leqq \eta$ and hence $x - z_n \leqq x - z_{n+1} \leqq E_\delta + 2\eta$. From (4.3) and (4.4), $\phi(x-z_{n+1}) - \phi(x-z_n) \leqq -\theta_2(z_n - z_{n+1}) = (\theta - M) q_0 e^{-\mu n} = (\theta - M) q_n$. Hence (4.5) is valid if $x \in \Gamma_n'$. This completes the proof of Lemma 4.1.

PROPOSITION 4.2. *Let u_0 satisfy the conditions*

$$\liminf_{x \to -\infty} u_0(x) > a^+ \quad \text{and} \quad \limsup_{x \to \infty} u_0(x) < a^-.$$

Let ϕ be a nonincreasing function satisfying $\phi(-\infty) = 1$, $\phi(\infty) = 0$ and $\phi = Q[\phi]$. Then there exist constants x_1, x_2, q_0', μ, the last two positive, such that

$$\phi(x - x_1) - q_0' e^{-\mu n} \leqq u_n(x) \leqq \phi(x - x_2) + q_0' e^{-\mu n} \quad \text{for all } n.$$

Proof. We only prove the left-hand inequality. The right-hand inequality is the same but requires a result like Lemma 4.1 with $v_{n+1} \geqq Q[v_n]$. We begin by showing that $u_n(-\infty)$ increases to 1 as $n \to \infty$.

Since $a_1(x)$ decreases to a^+ as $x \to -\infty$ (see §2), there exist $\varepsilon > 0$, $N_\varepsilon > N$ such that

$$a^+ \leqq a_1(x) \leqq a_1(-N_\varepsilon) < a^+ + \varepsilon \leqq u_0(x)$$

and

$$g(x, u_0(x)) \geqq g(-N_\varepsilon, u_0(x)) \geqq g(-N_\varepsilon, a^+ + \varepsilon) \quad \text{for } x \leqq -N_\varepsilon.$$

From Fatou's lemma,

$$\liminf_{x \to -\infty} u_1(x) \geqq \int K(y) \liminf_{x \to -\infty} g(x-y, u_0(x-y))\, dy \geqq g(-N_\varepsilon, a^+ + \varepsilon).$$

Now suppose $\liminf_{x \to -\infty} u_n(x) \geqq g^n(-N_\varepsilon, a^+ + \varepsilon)$. Then for any $\delta > 0$, $u_n(x) \geqq q^n(-N_\varepsilon, a^+ + \varepsilon) - \delta$ and $g(x, u_n(x)) \geqq g(-N_\varepsilon, u_n(x)) \geqq g(-N_\varepsilon, g^n(-N_\varepsilon, a^+ + \varepsilon) - \delta)$ for x

near $-\infty$. Hence $\liminf_{x\to-\infty} u_{n+1}(x) \geqq \int K(y) \liminf_{x\to-\infty} g(x-y, u_n(x-y))\,dy \geqq g(-N_\varepsilon, g^n(-N_\varepsilon, a^+ + \varepsilon) - \delta)$. Since $\delta > 0$ is arbitrary, we have

$$\liminf_{x\to-\infty} u_n(x) \geqq g^n(-N_\varepsilon, a^+ + \varepsilon) \quad \text{for all } n. \tag{4.6}$$

From the definition of $a_1(x)$, we have $g(-N_\varepsilon, u) > u$ for $a_1(-N_\varepsilon) < u < 1$. This implies that $g^n(-N_\varepsilon, a^+ + \varepsilon)$ increases to 1 as $n \to \infty$. Therefore, let $q_0 > 0$ be as defined in Lemma 4.1. There exist, by (4.6) positive integers k and N_0 such that $u_k(x) \geqq 1 - q_0$ for $x \leqq -N_0$. Hence $v_0(x) = \phi(x - z_0) - q_0 \leqq 1 - q_0 \leqq u_k(x)$ for $x \leqq -N_0$. From Remark 4.1, $z_0 \leqq 0$ is arbitrary and we now choose it sufficiently negative so that $\phi(-N_0 - z_0) - q_0 \leqq 0$. Therefore, $v_0(x) \leqq u_k(x)$ for all x.

Since $v_{n+1} \leqq Q[v_n]$ and Q is order-preserving, an inductive argument shows that $v_n \leqq u_{k+n}$ for all $n \geqq 0$. Explicitly,

$$\phi(x - z_n) - q_0 e^{-\mu n} \leqq u_{k+n}(x) \quad \text{for } n \geqq 0.$$

Since z_n is decreasing, we may replace z_n by its limit x_1 in the above inequality. Doing so and writing n for $k+n$, we have

$$\phi(x - x_1) - q_0' e^{-\mu n} \leqq u_n(x) \quad \text{for } n \geqq k, \text{ where } q_0' = q_0 e^{\mu k}.$$

The first k terms are then taken care of by increasing q_0' until $1 - q_0' e^{-\mu k} \leqq 0$. This completes the proof of Proposition 4.2.

Remark 4.2. The condition $\limsup_{x\to\infty} u_0(x) < a^-$ is needed to prove the right-hand inequality.

LEMMA 4.3. *Let ϕ satisfy $\phi = Q[\phi]$ and let $u_0(x) = \phi(x - h)$. Then u_n, defined recursively by* (1.1), *is nonincreasing (nondecreasing) in n if $h > 0$ ($h < 0$).*

Proof. We only prove the case $h > 0$. Proceeding by induction,

$$u_1(x) = \int K(x-y) g(y, \phi(y-h))\,dy = \int K(x-h-y) g(y+h, \phi(y))\,dy$$

$$\leqq \int K(x-h-y) g(y, \phi(y))\,dy = u_0(x).$$

Assume that $u_n \leqq u_{n-1}$. Then since Q is order-preserving, we have $u_{n+1} = Q[u_n] \leqq Q[u_{n-1}] = u_n$. Therefore $u_{n+1} \leqq u_n$ for all n and the lemma is proved.

To show uniqueness of clines, we first recall from Remark 3.1 that $g_x \leqq 0$ implies the existence of at least one cline ϕ. Suppose u is another solution of $u = Q[u]$ with $u(-\infty) > a^+$, $u(\infty) < a^-$. Proposition 4.2 with $u_0 = u$ implies that $\phi(x - x_1) - q_0' e^{-\mu n} \leqq u(x) \leqq \phi(x - x_2) + q_0' e^{-\mu n}$ for all n. Letting $n \to \infty$, we have $\phi(x - x_1) \leqq u(x) \leqq \phi(x - x_2)$. Since ϕ is nonincreasing, we may assume that $x_1 < 0$ and $x_2 > 0$.

Let $\underline{u}_0(x) = \phi(x - x_1)$, $\bar{u}_0(x) = \phi(x - x_2)$ and define $\underline{u}_n$, $\bar{u}_n$ recursively by $\underline{u}_{n+1} = Q[\underline{u}_n]$, $\bar{u}_{n+1} = Q[\bar{u}_n]$. Clearly, $\underline{u}_n \leqq u \leqq \bar{u}_n$ and $\underline{u}_n \leqq \phi \leqq \bar{u}_n$ for all n. From Lemma 4.3, $\underline{u}_n$ increases to a nonincreasing function $\underline{u}$ with the properties $\underline{u} \leqq u$, $\underline{u} \leqq \phi$, $\underline{u}(-\infty) = 1$, $\underline{u}(\infty) = 0$ and $\underline{u} = Q[\underline{u}]$. Similarly, $\bar{u}_n$ decreases to a nonincreasing function $\bar{u}$ with the properties $u \leqq \bar{u}$, $\phi \leqq \bar{u}$, $\bar{u}(-\infty) = 1$, $\bar{u}(\infty) = 0$ and $\bar{u} = Q[\bar{u}]$. In order to show that $u = \phi$, it suffices to show that $\underline{u} = \bar{u}$. This follows from Remark 3.2 and the next lemma.

LEMMA 4.4. *Let ϕ_1, ϕ_2 be two nonincreasing solutions of $\phi = Q[\phi]$, $\phi_1 \leqq \phi_2$ which both converge to* 1 *and* 0 *exponentially as $x \to \mp\infty$. Then $\phi_1 \equiv \phi_2$.*

Before we can prove Lemma 4.4, we must establish two lemmas.

From Proposition 4.2, $\phi_2(x+h)\leqq\phi_1(x)$ for some $h>0$. Let h be the infimum of such h. We assume that $h>0$ and derive from it a contradiction. Note that from (viii*) of (1.12), the function $\int K(x-y)[g(y+h,\phi(y+h))-g(y,\phi(y+h))]\,dy$ is not identically zero if $h\neq 0$. Therefore translation of ϕ_i is not a solution of $\phi=Q[\phi]$.

Let $u_\varepsilon(x)=\phi_2(x+h-\varepsilon)$ for $0\leqq\varepsilon\leqq h/2$. According to the definition of h, we have $u_\varepsilon(x)>\phi(x)$ on some interval for sufficiently small $\varepsilon>0$. Write

$$u_\varepsilon(x)=\int K(x-y)g(y,u_\varepsilon(y))\,dy+n_\varepsilon(x),$$

where $n_\varepsilon(x)=\int K(x-y)[g(y+h-\varepsilon,u_\varepsilon(y))-g(y,u_\varepsilon(y))]\,dy$ is nonpositive but not identically zero. Let $\psi_\varepsilon(x)=u_\varepsilon(x)-\phi_1(x)$. Then

$$\psi_\varepsilon(x)=\int K(x-y)h_\varepsilon(y)\psi_\varepsilon(y)\,dy+n_\varepsilon(x), \tag{4.7}$$

where we set

$$h_\varepsilon(x)=\frac{g(x,u_\varepsilon(x))-g(x,\phi_1(x))}{u_\varepsilon(x)-\phi_1(x)}\geqq 0.$$

We shall employ the following notation: $\mathscr{H}=L^2(\mathbb{R})$ with inner product $(\cdot,\cdot)$, $\psi^+=\max\{\psi,0\}$, $K_\varepsilon:\mathscr{H}\to\mathscr{H}$ is the linear operator

$$K_\varepsilon\psi(x)=\int K(x-y)h_\varepsilon(y)\psi(y)\,dy.$$

From Young's inequality, K_ε is bounded. Observe that $\psi_\varepsilon^+\not\equiv 0$ for every $\varepsilon>0$ sufficiently small but $\psi_0^+\equiv 0$. Finally for an operator $A:\mathscr{H}\to\mathscr{H}$, the symbols $\sigma(A)$, $r(A)$, A^* and $\|A\|$ will denote respectively the spectrum of A, spectral radius of A, adjoint of A and operator norm of A.

We state two lemmas and defer their proofs until after we have proved Lemma 4.4.

LEMMA 4.5. *For $\varepsilon>0$ sufficiently small* (i) *K_ε is a positive operator in the sense that $\psi\geqq 0$ implies that $K_\varepsilon\psi\geqq 0$;* (ii) *K_ε is quasi-compact, i.e., there exist operators V_ε and C_ε such that $\|C_\varepsilon\|<1$, V_ε is compact and $K_\varepsilon=C_\varepsilon+V_\varepsilon$,* (iii) $\lim_{\varepsilon\downarrow 0}\|K_\varepsilon-K_0\|=0$.

LEMMA 4.6. $r(K_0)<1$.

Proof of Lemma 4.4. From (4.7), $\psi_\varepsilon\leqq K_\varepsilon\psi_\varepsilon$ so that $\psi_\varepsilon^+\leqq[K_\varepsilon\psi_\varepsilon]^+\leqq K_\varepsilon\psi_\varepsilon^+$. Since the operator K_ε is order-preserving, an inductive argument shows that $K_\varepsilon^n\psi_\varepsilon^+\geqq\psi_\varepsilon^+\geqq 0$ for all n. From our hypotheses, $\psi_\varepsilon\in\mathscr{H}$. Therefore $\|K_\varepsilon^n\psi^+\|_2\geqq\|\psi_\varepsilon^+\|_2$ which implies that $\|K_\varepsilon^n\|^{1/n}\geqq 1$ for all n. Now if we fix n and let $\varepsilon\downarrow 0$, we have from Lemma 4.5, $\|K_0^n\|^{1/n}\geqq 1$. Hence $\lim_{n\to\infty}\|K_0^n\|^{1/n}=r(K_0)\geqq 1$ which contradicts Lemma 4.6. Therefore $h=0$ and $\phi_1\equiv\phi_2$. The proof of Lemma 4.4 is complete.

Proof of Lemma 4.5. K_ε is positive because $K_\varepsilon(x)\geqq 0$ and $h_\varepsilon(x)\geqq 0$ in $\mathbb{R}$. To show that K_ε is quasi-compact, recall from the definition of h_ε that $h_\varepsilon(x)=g_u(x,\theta_\varepsilon)$, where θ_ε is between u_ε and ϕ_1. From hypothesis (x) of (1.12), there exist $\delta>0$, $\theta_1\in(0,1)$ such that $g_u(x,u)\leqq\theta_1<1$ for $u\in[0,\delta]$, $x\geqq N$ or $u\in[1-\delta,1]$, $x\leqq -N$. Since $u_\varepsilon(-\infty)=\phi_1(-\infty)=1$, $u_\varepsilon(\infty)=\phi_1(\infty)=0$. We can choose $a_\varepsilon>N$ such that $|h_\varepsilon(x)|\leqq\theta_1<1$, when $x\in[-a_\varepsilon,a_\varepsilon]^c$.

Define C_ε, $V_\varepsilon:\mathscr{H}\to\mathscr{H}$ by

$$C_\varepsilon\psi(x)=\int K(x-y)\chi_{[-a_\varepsilon,a_\varepsilon]^c}(y)h_\varepsilon(y)\psi(y)\,dy$$

and

$$V_\varepsilon\psi(x)=\int K(x-y)\chi_{[-a_\varepsilon,a_\varepsilon]}(y)h_\varepsilon(y)\psi(y)\,dy.$$

Then $K_\varepsilon=C_\varepsilon+V_\varepsilon$ and V_ε is compact because $\int\int K^2(x-y)\chi^2_{[-a_\varepsilon,a_\varepsilon]}(y)h^2_\varepsilon(y)\,dy\,d\dot{x}$ is finite. For C_ε, we have $\|C_\varepsilon\psi\|_2=\|K*[\chi_{[-a_\varepsilon,a_\varepsilon]^c}h_\varepsilon\psi]\|_2\leqq\theta_1\|K\|_1\|\psi\|_2$. Therefore $\|C_\varepsilon\|\leqq\theta_1<1$ and K_ε is quasi-compact.

Finally it is elementary to show that h_ε converges to h_0 pointwise as $\varepsilon\downarrow 0$ and $\|(K_\varepsilon-K)\psi\|_2=\|K*[h_\varepsilon-h_0]\psi\|_2\leqq\|K\|_2\|[h_\varepsilon-h_0]\psi\|_1\leqq\|K\|_2\|h_\varepsilon-h_0\|_2\|\psi\|_2$. From the fact that $h_\varepsilon(x)=g_u(x,\theta_\varepsilon)$, where θ_ε is between u_ε and ϕ_1, we have

$$|h_\varepsilon(x)-h_0(x)|=|g_{uu}(x,\xi)||\theta_\varepsilon-\theta_0|\leqq\text{const.}\,|\theta_\varepsilon-\theta_0|.$$

But then ϕ_1, ϕ_2 converge to 1 and 0 exponentially as $x\to\mp\infty$. Thus $|\theta_\varepsilon-\theta|$ is dominated by a square integrable function independently of ε. From the dominated convergence theorem, $\lim_{\varepsilon\downarrow 0}\|h_\varepsilon-h_0\|_2=0$. This establishes (iii) and completes the proof of Lemma 4.5.

Proof of Lemma 4.6. From (4.7), we have

$$\psi_0(x)=K_0\psi_0(x)+n_0(x), \tag{4.8}$$

where ψ_0 and n_0 are both nonpositive and not identically zero.

From Lemma 4.5, $K_0^*=C_0^*+V_0^*$. As is well known, $\|C_0^*\|=\|C_0\|$ and V_0^* is compact if and only if V_0 is compact. Therefore K_0^* is also quasi-compact. In fact, K_0^* is the operator $K_0^*\psi(x)=h_0(x)\int K(y-x)\psi(y)\,dy$. Therefore K_0^* is a positive operator.

According to [9, Thm. 4], since K_0^* is a positive operator $r(K_0^*)\in\sigma(K_0^*)$. If $r(K_0^*)<1$, then $r(K_0)=r(K_0^*)<1$ and the lemma is proved. We cannot have $r(K_0^*)\geqq 1$. For if so, $r(K_0^*)\notin\sigma(C_\varepsilon)$ since $\|C_\varepsilon\|<1$. However, K_ε is a perturbation of C_ε by a compact operator. Weyl's lemma says that perturbation by a compact operator can only change the spectrum of an operator by eigenvalues, [8]. Therefore, $r(K_0^*)$ is an eigenvalue of K_0^* and clearly has the largest modulus among the eigenvalues of K_0^*. By [9, Thm. 5, Cor. 1] applied to $r(K_0^*)$, there exists a nonnegative eigenfunction e_0 corresponding to $r(K_0^*)$. That is to say, $r(K_0^*)e_0(x)=h_0(x)\int K(y-x)e_0(y)\,dy\geqq 0$. Using the same idea we used to show $\phi'<0$ at the beginning of the proof of Lemma 4.1, we see that $e_0(x)>0$ in $\mathbb{R}$.

From (4.8), we have $(\psi_0,e_0)=(K_0\psi_0,e_0)+(n_0,e_0)<(K_0\psi_0,e_0)=(\psi_0,K_0^*e_0)=r(K_0^*)(\psi_0,e_0)$. Since $\psi_0\leqq 0$, we have $r(K_0^*)<1$ which is a contradiction to our assumption. Lemma 4.6 is therefore established and so is Theorem 2.2.

5. Proof of Theorem 2.3. The argument given after Lemma 4.3 actually provides a proof for part (i) of Theorem 2.3. Letting $\underline{u}_0(x)=\phi(x-h_1)$ and $\bar{u}_0(x)=\phi(x-h_2)$, we have $\underline{u}_n\leqq u_n\leqq\bar{u}_n$ for all n, and $\underline{u}_n$, $\bar{u}_n$ converge monotonically to the (unique) cline ϕ. With all the properties $\underline{u}_n$, $\bar{u}_n$ and ϕ have, it is an elementary exercise to show that the convergence is uniform in $\mathbb{R}$.

To prove part (ii) of Theorem 2.3, we first observe that $\|u_n'\|_\infty\leqq\|K_a\|_1+p_1+p_2$ so that $\{u_n\}$ is an equicontinuous sequence of functions. By the Arzela–Ascoli theorem, a subsequence $\{u_{n_k}\}$ will converge uniformly on compact subsets of $\mathbb{R}$ to some continuous function U. From Proposition 4.2, $\phi(x-x_1)\leqq U(x)\leqq\phi(x-x_2)$. We may assume that $x_1<0$ and $x_2>0$. Apply part (i) of Theorem 2.3 with U as the initial data. Then

$U_n \equiv Q^n[U]$ converges uniformly to ϕ as $n \to \infty$. The convergence of u_{n_k} to U is also uniform in $\mathbb{R}$, since u_n, ϕ are uniformly close to 1 and 0 near $\mp\infty$ respectively.

We now state a lemma and use it to prove part (ii) of Theorem 2.3. The proof of the lemma will be given at the end of this section.

LEMMA 5.1. *Given* $\varepsilon > 0$, *there exists* $\delta' > 0$ *such that if* $\|v_0 - \phi\|_\infty \leqq \delta'$, *then* $\|v_n - \phi\|_\infty \leqq \varepsilon$ *for all* n.

Let $M = \sup_{\mathbb{R}\times[0,1]} g_u(x,u)$. We have $\|Q^n[u] - Q^n[v]\|_\infty \leqq M^n \|u - v\|_\infty$ for all n and $u, v \in \mathscr{C}$. For any $\varepsilon > 0$, let δ' be chosen as in Lemma 5.1 and let k_1, k_2 be positive integers such that

$$\|U_k - \phi\|_\infty \leqq \frac{\delta'}{2} \quad \text{if } k \geqq k_1, \qquad \|u_{n_k} - U\|_\infty \leqq \frac{\delta'}{2M^{k_1}} \quad \text{if } k \geqq k_2.$$

Then

$$\left\|Q^{k_1}[u_{n_k}] - Q^{k_1}[U]\right\|_\infty \leqq M^{k_1}\|u_{n_k} - U\|_\infty \leqq \frac{\delta'}{2} \quad \text{if } k \geqq k_2.$$

Furthermore,

$$\begin{aligned}\left\|u_{n_k+k_1} - \phi\right\|_\infty &\leqq \left\|Q^{k_1}[u_{n_k}] - Q^{k_1}[U]\right\|_\infty + \left\|Q^{k_1}[U] - \phi\right\|_\infty \\ &\leqq \delta' \quad \text{if } k \geqq k_2.\end{aligned}$$

Now set $k = k_2$ and $v_0 = u_{n_k+k_1}$. From Lemma 5.1, we have $\limsup_{n\to\infty}\|u_n - \phi\| \leqq \varepsilon$. Since $\varepsilon > 0$ is arbitrary, Theorem 2.3 is proved.

Proof of Lemma 5.1. We have to look carefully into the proofs of Proposition 4.2 and Lemma 4.1. Recall from Remark 4.1 that the only requirements on z_0 and q_0 for Lemma 4.1 to hold are $z_0 \leqq 0$ and that $q_0 > 0$ be sufficiently small. Also, in the proof of the left-hand inequality in Proposition 4.2, k, z_0, q_0 have to satisfy the condition $\phi(x - z_0) - q_0 \leqq u_k(x)$ in $\mathbb{R}$. From our hypothesis, $\phi(x) - \delta' \leqq v_0(x)$ in $\mathbb{R}$. Therefore, we set $z_0 = 0$ and $\delta' = q_0 = q_0'$ small enough to obtain the inequality $\phi(x - z_n) - q_0 e^{-\mu n} \leqq v_n(x)$ for all n. Again from the proof of Lemma 4.1, $\lim_{n\to\infty} z_n = x_1 = (\theta - M)q_0\theta_2^{-1}(1 - e^{-\mu})^{-1}$. Now (4.1) is valid with the same θ_1, δ, N if we decrease $q_0 > 0$. Consequently, θ, M, θ_2, μ above are independent of δ' $(= q_0)$ if δ' is sufficiently small. Hence let δ' be so small that $|x_1| \leqq \varepsilon/2\|\phi'\|_\infty$ and $q_0 \leqq \varepsilon/2$. Then

$$\phi(x) - q_0 e^{-\mu n} = \phi(x - x_1) - q_0 e^{-\mu n} + \phi(x) - \phi(x - x_1) \leqq u_n(x) + \frac{\varepsilon}{2}.$$

This implies that $\phi(x) - \varepsilon \leqq u_n(x)$ for all n which is half of Lemma 5.1. The other half may be proved similarly.

6. Proof of Theorem 2.4. Let $T: \mathscr{H} \to \mathscr{H}$ be the bounded linear operator

$$T\psi(x) = \int K(x - y) g_u(y, \phi(y))\psi(y)\, dy.$$

It is easy to see that T is positive and quasi-compact. Furthermore, the proof of Lemma 4.6 can be used to show that $r(T) < 1$. In place of (4.8), we use

$$\phi'(x) = \int K(x - y) g_u(y, \phi(y))\phi'(y)\, dy + \int K(x - y) g_y(y, \phi(y))\, dy,$$

where the last term is nonpositive and not identically zero.

Choose $\lambda \in (r(T),1)$ and $\eta \in \mathscr{H}$ such that $\eta(x)>0$ in $\mathbb{R}$. Then $\lambda w - Tw = \eta$ has a unique solution $w \in \mathscr{H}$. Since $(\lambda - T)^{-1} = \sum_{j=0}^{\infty} T^j/\lambda^{j+1}$, we see that $w \geqq 0$. In fact $\eta > 0$ implies that $w(x)>0$ in $\mathbb{R}$. By adjusting η, we may assume that $\|w\|_\infty = 1$ and that w is sufficiently regular.

Consider the following inequality:

$$\int K(x-y) g_u(y,\phi(y))\,dy \leqq \int_{|y|\geqq N_1} K(x-y) g_u(y,\phi(y))\,dy + \text{const.} \int_{|y|\leqq N_1} K(x-y)\,dy.$$

From condition (xi) of (1.12), $g_u(x,\phi(x)) < \theta_1 < 1$ if $|x| \geqq N_1$ for some large N_1. Therefore, $\int K(x-y) g_u(y,\phi(y))\,dy \leqq \theta_1 < 1$ if $|x| \geqq N_2$. We extend g to $\mathbb{R}\times\mathbb{R}$ so that $g_u(x,u) \geqq 0$ and $M = \frac{1}{2}\sup_{\mathbb{R}\times\mathbb{R}} g_{uu}(x,u)$ is finite.

Choose $\mu > 0$ such that $\lambda < e^{-\mu} < 1$. On the interval $|x| \leqq N_2$, let $w(x) \geqq m > 0$. Define $m_1 = \sup_{\mathbb{R}} \int K(x-y) g_u(y,\phi(y))\,dy$, $\gamma = (e^{-\mu} - \lambda)m/(m_1 - \theta_1)$, $\beta = \gamma(e^{-\mu} - \theta_1)/M(1+\gamma)^2$ and $z_n(x) = \beta(w(x)+\gamma)e^{-\mu n}$ for all n.

We claim that $N[z_n] \leqq z_{n+1}$ for all n where

$$N[z](x) = \int K(x-y)[g(y,\phi(y)+z(y)) - g(y,\phi(y))]\,dy.$$

Write

$$N[z](x) = \int K(x-y) g_u(y,\phi(y)) z(y)\,dy + \int K(x-y) h(y,z(y)) z(y)\,dy,$$

where

$$h(x,z) = \frac{g(x,\phi(x)+z) - g(x,\phi(x))}{z} - g_u(x,\phi(x)).$$

By the mean value theorem, $|h(x,z)z| \leqq M|z|^2$.

To begin we have $Tz_n(x) = \beta e^{-\mu n}[\lambda w(x) - \eta(x) + \gamma \int K(x-y) g_u(y,\phi(y))\,dy]$ and $N_1[z_n](x) = \int K(x-y) h(y,z_n(y)) z_n(y)\,dy$ satisfies the inequality

$$|N_1[z_n](x)| \leqq M \int K(x-y)|z_n(y)|^2\,dy \leqq M\beta^2 e^{-\mu n}(1+\gamma)^2.$$

Hence $N[z_n](x) \leqq \beta e^{-\mu n}[\lambda w(x) + \gamma \int K(x-y) g_u(y,\phi(y))\,dy + \beta M(1+\gamma)^2]$.

If $|x| \geqq N_2$, the term inside the square bracket is bounded above by $e^{-\mu} w(x) + \gamma\theta_1 + \beta M(1+\gamma)^2$ which by the definition of β is equal to $(w(x)+\gamma)e^{-\mu}$. Therefore, $N[z_n](x) \leqq z_{n+1}(x)$ if $|x| \geqq N_2$. On the other hand if $|x| \leqq N_2$, we have

$$\begin{aligned}(\lambda - e^{-\mu}) w(x) + \gamma \int K(x-y) g_u(y,\phi(y))\,dy + \beta M(1+\gamma)^2 - \gamma e^{-\mu} \\ \leqq (\lambda - e^{-\mu}) m + \gamma(m_1 - e^{-\mu}) + \beta M(1+\gamma)^2 \\ = (\lambda - e^{-\mu}) m + \gamma(m_1 - \theta_1) = 0,\end{aligned}$$

and so the term inside the square bracket is bounded above by $e^{-\mu}(w(x)+\gamma)$. Therefore, $N[z_n](x) \leqq z_{n+1}(x)$ if $|x| \leqq N_2$ and our claim is proved.

Finally let $\delta=\beta\gamma$ in the statement of Theorem 2.4 and $v_n=u_n-\phi$ for all n. If $v_0\leqq\delta$, then $v_0\leqq z_0$ since $w>0$. Proceeding inductively, suppose $v_n\leqq z_n$, then

$$v_{n+1}(x)=u_{n+1}(x)-\phi(x)=\int K(x-y)\left[g(y,\phi(y)+v_n(y))-g(y,\phi(y))\right]dy$$

$$\leqq\int K(x-y)\left[g(y,\phi(y)+z_n(y))-g(y,\phi(y))\right]dy$$

$$=N[z_n](x)\leqq z_{n+1}(x).$$

Hence, $u_n(x)-\phi(x)\leqq Ce^{-\mu n}$ for all n where $C=\beta(1+\gamma)$. This proves half of Theorem 2.4.

To show the other half, we first observe that the proof of $N[z_n]\leqq z_{n,+1}$ also shows that $N[-z_n]\geqq -z_{n+1}$ for all n. This part involves no more than changing the sign of some of the terms in the proof of $N[z_n]\leqq z_{n+1}$.

Now suppose $v_0\geqq-\delta\geqq-z_0$. Proceeding inductively as before, assuming that $v_n\geqq-z_n$, we have

$$u_{n+1}(x)-\phi(x)=\int K(x-y)\left[g(y,\phi(y)+v_n(y))-g(y,\phi(y))\right]dy$$

$$\geqq\int K(x-y)\left[g(y,\phi(y)-z_n(y))-g(y,\phi(y))\right]dy$$

$$=N[-z_n](x)\geqq-z_{n+1}(x).$$

Therefore, $\phi(x)-u_n(x)\leqq Ce^{-\mu n}$ for all n. The proof of Theorem 2.4 is now complete.

Note added in proof. Since this paper was accepted, Dr. Odo Diekmann in Amsterdam has informed the author that some of the results in this paper overlap with his paper, *Clines in a discrete time model in population genetics*, Proc. Conference on Models of Biological Growth and Spread, W. Jäger, ed., Lecture Notes in Biomathematics, 38, Springer-Verlag, New York, 1981.

STABILITY OF A SURFACE DETERMINED FROM MEASURES OF POTENTIAL*

CARLO DOMENICO PAGANI†

Abstract. Let G be a bounded domain in R^3 whose boundary Γ is connected. Let $V_G\sigma$ be the Newtonian potential produced by a mass of density σ distributed over G. We assume a model distribution for σ and consider the problem of finding G from the knowledge of the potential (a) on Γ, (b) on Γ_a, a large spherical surface surrounding G. These problems are unstable and we investigate what kind of supplementary information on the solutions is needed in order to restore stability. We prove that, in case (a), solutions whose H^s norm ($s>3$) (Sobolev norm) is bounded by a given constant constitute a Hölder-stable class; in case (b), a class of Hölder-stable solutions consists of real analytic functions whose derivatives are suitably bounded.

Introduction. Let G be a bounded domain in R^3 whose boundary Γ is connected. Let $V_G\sigma$ be the Newtonian (electrostatic) potential produced by a mass (charge) of density σ distributed over G,

$$V_G\sigma(x)=\int_G \sigma(y)|x-y|^{-1}dy. \tag{0.1}$$

The classical inverse problems for the potential are of two kinds: a) we are given G; find σ by measuring the potential outside of G. b) we assume a model distribution for σ: $\sigma=\tilde{\sigma}$ say; then find G by measuring the potential.

Both problems have been considered by several authors. A common feature to these problems is that they are ill posed in the sense of Hadamard. The most striking aspect of ill-posedness is their instability, namely the impossibility of efficiently determining the solution from the measured data. This aspect of the problem has been analyzed, in the case a), in [7], [12], [3]. Here we wish to consider problem b). Our aim is to find classes of stable solutions. Let us pose precisely the problem. Let G_0 be a reference bounded domain in R^3 whose boundary Γ_0 is connected and smooth: although it is not necessary, we shall assume through this paper that G_0 is a ball, centered at the origin, with radius r_0. Let z: $\Gamma_0\to R$ be a function belonging to the set

$$\mathscr{A}\equiv\{z\in C^2(\Gamma_0);\ |z|\leqq z^*\} \tag{0.2}$$

where z^* is a given constant, $z^*<r_0$. Let us consider the map

$$\begin{aligned}&\Phi_z\colon \Gamma_0\to R^3,\\ &\Gamma_0\ni\omega\to\Phi_z(\omega)=\omega+z(\omega)n_\omega\end{aligned} \tag{0.3}$$

(n_ω is the outward unit normal to Γ_0 at ω) and define Γ_z as the image of Γ_0 given by Φ_z: $\Gamma_z=\Phi_z\Gamma_0$; G_z is the bounded domain whose boundary is Γ_z. We assume that Φ_z induces a diffeomorphism of class C^2 between Γ_z and Γ_0. Finally, let Γ_a be a surface of a large ball, centered at the origin, with radius $r_0+a(a>z^*)$. Let $\tilde{\sigma}$ be a positive smooth function (typically, $\tilde{\sigma}$ is a constant) and consider the potential $V_{G_z}\tilde{\sigma}$, that we shall denote simply by $V_z\tilde{\sigma}$. Let us define $U_z\sigma$ by writing

$$V_z\sigma=V_0\sigma+U_z\sigma. \tag{0.4}$$

*Received by the editors April 19, 1984.
† Department of Mathematics, Politechnic of Milano, 20133 Milano, Italy.

We define now two operators: $A: \mathscr{A} \subset L^2(\Gamma_0) \to L^2(\Gamma_0)$ and $B: \mathscr{A} \subset L^2(\Gamma_0) \to L^2(\Gamma_0)$ as follows (the physical meaning of these definitions is explained below)

$$A[z] \equiv U_z \tilde{\sigma} \circ \Phi_z, \tag{0.5}$$

$$B[z] \equiv U_z \tilde{\sigma} \circ \Phi_a \tag{0.6}$$

(here $\circ$ means composition). Consequently we shall pose two problems:

Problem I (resp. II). Find z: $A[z]=v$ (resp. $B[z]=v$), where v is a given function defined on Γ_0.

We expect that both problems are ill posed, for the image of A is contained in the Sobolev space $H^{3/2}(\Gamma_0)$ and the image of B is a subset of $C^\infty(\Gamma_0)$. Then the maps: $z \to A[z]$ and $z \to B[z]$ are smoothing, so that the inverse maps will not be continuous in L^2-norm. Thus an approximate knowledge of the potential v does not permit one to recover z. We shall investigate which kind of supplementary information on the solutions is needed in order to stabilize the problems. We shall prove, for Problem I, that a subset of $\mathscr{A}$ consisting of those functions z whose H^s-norm ($s > 3$) is bounded by a given constant, is a class of Hölder type stability, i.e., the inverse of the restriction of A to this subset is a Hölder continuous operator. The precise statement is our Theorem 2.7. A similar result is proved for Problem II: a class of Hölder-stable solutions consists now of real analytic functions z whose derivatives are suitably bounded (see Theorem 2.8).

Inverse problems for potentials arise in many fields of applied sciences; in particular Problem II is classical in geophysics: it is the problem of finding the position and the shape of a body G_z of known density $\tilde{\sigma}$ from the measure of the potential generated by this body on the surface Γ_a surrounding G_z. For that problem one can find uniqueness results in [6] (with $\tilde{\sigma}=1$) and in [9] (and several other papers of the same author) (with $\tilde{\sigma}>0$). Results about stability are given in [9] and in [1]. In this last paper, M. M. Lavrent'ev states that solutions of class C^1 with the first derivatives bounded by a given constant are stable: however, the stability is very poor, being of logarithmic type. Our result is in some sense complementary to that one: for we exhibit a stronger stability (namely of Hölder type) for a restricted class of solutions (analytic functions). Problem I, in case the right member of the equation $A[z]v$ is a constant and z is negative (i.e., the unknown surface Γ_z is contained in the ball G_0) has a plain physical interpretation; see Schaeffer [11], who studied the problem (in [11] $\tilde{\sigma}$ is 1 and Γ_0 any C^∞ surface) and proved the existence of a C^∞ solution. Here, for any right member, we prove a stability estimate (hence uniqueness). Existence results for a similar problem are proved also in [13].

The stability of the maps A and B is studied via a lemma (Lemma 2.1) which rests on the knowledge of the spectrum of some linear approximations of A and B. §1 is devoted to the study of these linear approximations; it is written in a self-consistent form, independent on the remaining part of the paper. We study there the classical inverse problem for the single layer potential: to determine the density of a single layer supported by a given surface Γ_z from the knowledge of the potential created by this layer (on Γ_z or on Γ_a).

Section 2 is devoted to our main problems I and II. First (§2.1) we prove the basic lemma which gives us a criterion for Hölder stability of a nonlinear map. Then (§2.2) we prepare the problems I and II in such a way to apply this criterion; in §2.3 the main results (Theorems 2.7 and 2.8) are stated and proved, by taking account of the results of §1.

Remark about the notation. We shall use through this paper the Sobolev spaces $H^s(\Gamma)$ (for the definition and main properties of such spaces see, e.g., [2, Chap. 7]); we will use the notation

$$\|u\|_s \quad \text{for } \|u\|_{H^s(\Gamma_0)}.$$

1. The single layer potential. Let us consider a fixed surface Γ_z, ($z \in \mathscr{A}$) and the single layer potential generated by a density distributed over Γ_z; in the region $\Gamma_0 \times (-z^*, z^*)$ let us use the coordinates (ω, t) to denote points $y = \omega + tn_\omega$, $\omega \in \Gamma_0$, $t \in (-z^*, z^*)$; let $j(\omega, t)$ be the jacobian of the transformation $y \to (\omega, t)$. Now by using surface coordinates on Γ_0, let us consider the potential written in the form (the reasons for this form will appear clear in §2):

$$W_z\rho(x) \equiv \int_{\Gamma_0} \frac{\rho(\omega)\, j(\omega, z(\omega))\, d\omega}{|x - (\omega + z(\omega)n_\omega)|}. \tag{1.1}$$

We shall consider two circumstances: i) the potential is measured on Γ_z; ii) the potential is measured on Γ_a. Consequently we pose

$$M_z[\rho] \equiv W_z\rho \circ \Phi_z, \tag{1.2}$$

$$N_z[\rho] \equiv W_z\rho \circ \Phi_a \tag{1.3}$$

and formulate two problems:

Problem i (resp. ii). Find ρ: $M_z[\rho] = u$ (resp. $N_z[\rho] = u$), where u is a given function defined on Γ_0.[1]

1.1. Problem i): existence, uniqueness and instability. A classical solution to problem i) is given by the following theorem.

THEOREM 1.1. *For every $u \in H^1(\Gamma_0)$ there exists a unique $\rho \in L^2(\Gamma_0)$ satisfying the equation*

$$M_z[\rho] = u. \tag{1.4}$$

Moreover the estimate

$$\|\rho\|_0 \leqq c(z)\|u\|_1, \tag{1.5}$$

holds where $c(z)$ denotes a constant depending only on the surface Γ_z.

Proof. First we prove the assertion in case Γ_z is a spherical surface, Γ_0 say; next we prove for any z the a priori estimate

$$\|\rho\|_0 \leqq c(z)\|M_z[\rho]\|_1. \tag{1.6}$$

Hence the assertion of the theorem follows from standard principles of functional analysis. The first step proves via a spherical harmonics expansion (for a standard reference on spherical harmonics see, e.g., [5]). If we expand ρ:

$$\rho(\omega) = \sum \alpha_{hj} r_0^n S_{nj}(\theta, \varphi)$$

(θ, φ are the geographical coordinates of a point $\omega \in \Gamma_0$; in the sum n goes from 0 to $+\infty$ and j from 1 to $2n+1$), we get

$$M_0[\rho](\omega) = 4\pi \sum r_0^{n+1}(2n+1)^{-1}\alpha_{nj} S_{nj}(\theta, \varphi).$$

[1] If $\tilde{u}(y)$ is the potential measured on Γ_z, we pose $u(\omega) = \tilde{u}(\omega + z(\omega)n_\omega)$; analogously for Problem ii.

Now, if β_{nj} are the coefficients of the expansion of u, (1.4) (with $z=0$) is uniquely solved by choosing

$$\alpha_{nj}=\frac{1}{4\pi r_0}(2n+1)\beta_{nj}.$$

Then we get

$$\|\rho\|_0=\left(\sum r_0^{2n+2}\alpha_{nj}^2\right)^{1/2}=\frac{1}{4\pi}\left(\sum r_0^{2n}(2n+1)^2\beta_{nj}^2\right)^{1/2}\leqq c\|u\|_1.$$

To prove the second step we can use a representation formula for ρ; we know in fact that, if W is the potential due to a single layer of charge of density σ on a surface Γ, then W is continuous across Γ and the normal derivative suffers a jump of magnitude $4\pi\rho$. Now, let w_+ be the solution of the boundary problem

$$\Delta w_+=0 \quad \text{in } G_z,$$
$$w_+=M_z[\rho]\circ\Phi_z^{-1} \quad \text{on } \Gamma_z$$

and w_- be the solution of the corresponding exterior problem. Then $W_z\rho=w_+$ on G_z and w_- on the complement of G_z. Therefore ρ equals the difference in the normal derivatives

$$\rho=\frac{\partial w_+}{\partial n}\circ\Phi_z-\frac{\partial w_-}{\partial n}\circ\Phi_z$$

(at least within a geometric factor), where n is the outward unit normal to Γ_z.

Now, let $z\in C^{2+s}(\Gamma_0)(s\geqq 0)$. Then, we know (cf. e.g. [2, Chap. 2]) that if $M_z[\rho]\in H^{s+1}(\Gamma_0)$ (so the boundary datum in the previous Dirichlet problem belongs to $H^{s+1}(\Gamma_z)$), then $w_+\in H^{s+3/2}(G_z)$ and its normal derivative belongs to $H^s(\Gamma_z)$; analogous statements hold for w_-. Finally we have

$$\|\rho\|_s\leqq c_s(z)\|M_z[\rho]\|_{s+1}. \tag{1.6'}$$

For the sake of completeness notice also that the converse inequality is true: *if* $z\in C^{2+s}(\Gamma_0)$ $(s\geqq 0)$ *operator* M_z *acts continuously from* $H^s(\Gamma_0)$ *to* $H^{s+1}(\Gamma_0)$ *and the estimate holds*:

$$\|M_z[\rho]\|_{s+1}\leqq c_s(z)\|\rho\|_s. \tag{1.7}$$

This assertion is immediately deducible from the results of [4, §5]. Estimate (1.5) shows a dependence of the density ρ on the gradient of the potential. But an error in the measure of the potential prevents us from having any information on its derivatives, hence on the solution. That is what we called instability.

1.2. Problem i): stabilization. As is known in the theory of ill-posed problems, supplementary information on the solutions can help to restore stability. Such information is usually supplied in the form of a priori bounds on the solutions themselves.

LEMMA 1.2. *Let* $z\in C^{(2-\alpha)/(1-\alpha)}(\Gamma_0)$ $(0<\alpha<1)$. *Then every function* $\rho\in H^{\alpha/(1-\alpha)}(\Gamma_0)$ *satisfies the inequality*

$$\|\rho\|_0\leqq c_\alpha(z)\|M_z[\rho]\|_0^{\alpha}\|\rho\|_{\alpha/(1-\alpha)}^{1-\alpha}. \tag{1.8}$$

Let us define the convex set

$$H_\alpha(E)\equiv\left\{\rho\in L^2(\Gamma_0):\ \|\rho\|_{\alpha/(1-\alpha)}\leqq E\right\}, \tag{1.9}$$

where E is a given positive constant. Then we immediately deduce the following theorem.

THEOREM 1.3. *Let* $z \in C^{(2-\alpha)/(1-\alpha)}(\Gamma_0)$; *every pair of solutions* ρ_1, ρ_2, *to problem* i) *corresponding to data* u_1, u_2 *and belonging to the set* $H_\alpha(E)$ *satisfies the inequality*

$$\|\rho_1 - \rho_2\|_0 \leqq c_\alpha(z) E^{1-\alpha} \|u_1 - u_2\|_0^\alpha. \tag{1.10}$$

Expression (1.10) is a stability estimate. It shows that the restriction of the map M_z to the (non-linear) set $H_\alpha(E)$ has a continuous inverse in $L^2(\Gamma_0)$ and the continuity of the inverse map is Hölderian (with exponent α). In such cases we speak of *Hölder stability*.

Proof of Lemma 1.2. The proof follows from: i) the "a priori" estimate (1.6); ii) inequality (1.7), that we shall use with $s = \alpha/(1-\alpha)$; iii) the estimate

$$\|\psi\|_1 \leqq c_\alpha \|\psi\|_{1/(1-\alpha)}^{1-\alpha} \|\psi\|_0^\alpha \tag{1.11}$$

valid for every function $\psi \in H^{1/(1-\alpha)}(\Gamma_0)$; this estimate is easy to prove by using spherical harmonic expansion and the Hölder inequality. Combining i), iii), and ii), one then gets

$$\begin{aligned} \|\rho\|_0 &\leqq c(z) \|M_z[\rho]\|_1 \\ &\leqq c_\alpha(z) \|M_z[\rho]\|_{1/(1-\alpha)}^{1-\alpha} \|M_z[\rho]\|_0^\alpha \\ &\leqq c_\alpha(z) \|\rho\|_{\alpha/(1-\alpha)}^{1-\alpha} \|M_z[\rho]\|_0^\alpha. \end{aligned}$$

The lemma is proved.

1.3. Problem ii): existence, uniqueness and instability. Let Γ be a spherical surface of radius r; let us define a class of real analytic functions on Γ. Let u be a $L^2(\Gamma)$ function whose coefficients, when expanded in spherical harmonics, are β_{nj}. For reals $s \geqq 0$, $\gamma \geqq 1$ consider the linear space spanned by such functions u that

$$\sum (1+n^2)^s \gamma^{2n} r^{2n+2} \beta_{nj}^2 < +\infty. \tag{1.12}$$

Notice that, by writing $\gamma^{2n} = \sum_{0k}^{\infty} (2n \log \gamma)^k / k!$, we get

$$\text{series (1.12)} \leqq \sum_0^\infty {}_k \frac{2^k (\log \gamma)^k}{k!} \|u\|_{H^{k/2+s}(\Gamma)}^2. \tag{1.13}$$

Definition. We call $\mathscr{U}_\gamma^s(\Gamma)$ the Banach space consisting of those functions $u \in L^2(\Gamma)$ satisfying (1.12) and whose norm is given by the square root of the expression appearing in (1.12). Notice that, if $\gamma = 1$, this space can be identified with $H^s(\Gamma)$. In particular we will use the following values for γ: $\gamma_+ = (r_0 + a)/(r_0 + \sup z)$, $\gamma_- = (r_0 + a)/(r_0 + \inf z)$. We will use the notation:

$$|u; \gamma|_s \quad \text{for } \|u\|_{\mathscr{U}_\gamma^s(\Gamma_0)}.$$

Remark. For every $\rho \in H^s(\Gamma_0)$, $s \geqq 0$, *if* $z \in C^{2+s}(\Gamma_0)$, *then* $N_z[\rho] \in \mathscr{U}_{\gamma_+}^{s+1}(\Gamma_0)$ *and*

$$|N_z[\rho]; \gamma_+|_{s+1} \leqq c_s(z) \|\rho\|_s. \tag{1.14}$$

This assertion can be easily checked for spheres (i.e., $z = \text{constant}$); for general surfaces, consider the restrictions of the potential $W_z \rho$ to Γ_0 (φ say) and to Γ_a (ψ say, obviously related to $N_z[\rho]$ via the map Φ_a). From [4, §5] we deduce that $\varphi \in H^{s+1}(\Gamma_0)$ and $\|\varphi\|_{s+1} \leqq c_s(z) \|\rho\|_s$; then we check that $\|\psi\|_{\mathscr{U}_{\gamma_+}^{s+1}(\Gamma_a)} = \|\varphi\|_{s+1}$ and finally that

$$|N_z[\rho]; \gamma_+|_{s+1} = \frac{1}{\gamma_+} \|\psi\|_{\mathscr{U}_{\gamma_+}^{s+1}(\Gamma_a)}.$$

Now, if we take $u \in \mathscr{U}^1_{\gamma_-}(\Gamma_0)$, i.e. $u(\omega)=\sum \alpha_{nj} r_0^n S_{nj}(\theta,\varphi)$ with $\sum(1+n^2)\alpha_{nj}^2 \gamma_-^{2n} r_0^{2n+2} < +\infty$, then the function U:

$$U(x)=\sum \alpha_{nj}\left(\frac{r_0+a}{|x|}\right)^n r_0^n S_{nj}(\theta,\varphi)$$

is harmonic for $|x|>r_0+\inf z$, $U\circ\Phi_a(\omega)=u(\omega)$, and

$$U\circ\Phi_{\inf z}(\omega)=\sum \alpha_{nj}\gamma_-^n r_0^n S_{nj}(\theta,\varphi)$$

belongs to $H^1(\Gamma_0)$. Thus $U\circ\Phi_z$ also belongs to $H^1(\Gamma_0)$ and there exists a unique density $\rho\in L^2(\Gamma_0)$ (Theorem 1.1) which creates a potential whose restriction to Γ_z is $U\circ\Phi_z$; this single layer potential coincides with $U(x)$ in the region exterior to Γ_z. Thus we have proved the following

THEOREM 1.4. *For every $u\in\mathscr{U}^1_{\gamma_-}(\Gamma_0)$, there exists a unique $\rho\in L^2(\Gamma_0)$ satisfying the equation*

$$N_z[\rho]=u. \tag{1.15}$$

Moreover the estimate holds

$$\|\rho\|_0 \leqq c(z)\,|u;\gamma_-|_1. \tag{1.16}$$

Inequality (1.16) *shows that problem* ii), *as was expected, is much more unstable than Problem* i); *nevertheless, it can be stabilized in the same class $H_\alpha(E)$ as before, as we now show by an example.*

1.4. Problem ii): stabilization.

ASSERTION. *Every pair of solutions ρ_1, ρ_2 (corresponding to data u_1, u_2) of the equation $N_0[\rho]=u$ belonging to the set $H_{1/2}(E)$ satisfy the inequality*

$$\|\rho_1-\rho_2\|_0 \leqq 2E\left\{q\left(\|u_1-u_2\|_0^2/4E^2\right)\right\}^{1/2}. \tag{1.17}$$

Here $0\leqq t\to q(t)$ is a certain concave function, increasing from $q(0)=0$ to $q(+\infty)=+\infty$ and exhibiting the following behavior near the origin.

$$q(t)\approx\left(2\log\left(\frac{r_0}{r_0+a}\right)/\log t\right)^2 \quad \text{as } t\approx 0+. \tag{1.18}$$

Inequality (1.17) shows that the restriction of the map N_0 to $H_{1/2}(E)$ does have a continuous inverse in $L^2(\Gamma_0)$, but the continuity of the inverse operator is now very poor, namely of logarithmic type.

Proof of the assertion. The proof follows, via spherical harmonic expansion, from the application of Jensen's inequality for convex functions. Let $0<\lambda\to p(\lambda)$ be the function given by

$$p(\lambda)=\frac{r_0^2}{4}\lambda^2\gamma^{-2/\sqrt{\lambda}} \qquad (\gamma_-=\gamma_+=\gamma). \tag{1.19}$$

One can easily verify that p is convex; notice also that $p(\lambda)$ and $p(\lambda)/\lambda$ are positive increasing.

The following chain of inequalities holds:

$$p\left(\frac{\|\rho\|_0^2}{\|\rho\|_1^2}\right)=p\left(\frac{\Sigma r_0^{2n+2}\alpha_{nj}^2}{\Sigma r_0^{2n+2}(n(n+1)+1)\alpha_{nj}^2}\right)$$

(α_{nj} are the coefficients of the expansion of ρ in spherical harmonics)

$$\leqq\frac{\frac{1}{4}\Sigma r_0^2 r^{-2\sqrt{n(n+1)+1}} r_0^{2n+2}\alpha_{nj}^2}{\Sigma r_0^{2n+2}(n(n+1)+1)\alpha_{nj}^2}$$

(Jensen's inequality)

$$\leqq\frac{\|N_0[\rho]\|_0^2}{\|\rho\|_1^2}.$$

Thus (1.17) follows by taking $q=p^{-1}$.

On the other hand, we are looking for classes of Hölder stable solutions. Then, let us define the convex set

$$K_\alpha(E)\equiv\left\{\rho\in C^\infty(\Gamma_0):\ |N_z[\rho];\gamma_1|_{1/(1-\alpha)}\leqq E\right\} \tag{1.20}$$

where $\gamma_1=\gamma_-^{1/1-\alpha}$. Notice that, because $\gamma_1>\gamma_-\geqq\gamma_+$, form $N_z[\rho]$ belong to some $\mathscr{U}_{\gamma_1}^{s+1}(\Gamma_0)$ one requires that ρ and z belong to some class of analytic functions; e.g., if z is constant, ρ must belong to $\mathscr{U}_{\gamma_1/\gamma_+}^{s}(\Gamma_0)$.

THEOREM 1.5. *Every pair of solutions ρ_1, ρ_2 to problem* ii) *corresponding to data u_1, u_2 and belonging to the set $K_\alpha(E)$ satisfy the inequality*

$$\|\rho_1-\rho_2\|_0\leqq c_\alpha(z)E^{1-\alpha}\|u_1-u_2\|_0^\alpha. \tag{1.21}$$

Proof of the theorem. The proof follows, analogously to the proof of Lemma 1.2, from inequality (1.16) and from the following:

$$|\psi;\gamma_-|_1\leqq c_\alpha|\psi;\gamma_1|_{1/(1-\alpha)}^{1-\alpha}\|\psi\|_0^\alpha. \tag{1.22}$$

This one proves by using spherical harmonics and Hölder's inequality. Combining (1.16) and (1.22), one gets

$$\begin{aligned}\|\rho\|_0&\leqq c(z)|N_z[\rho];\gamma_-|_1\\&\leqq c_\alpha(z)|N_z[\rho];\gamma_1|_{1/(1-\alpha)}^{1-\alpha}\|N_z[\rho]\|_0^\alpha,\end{aligned}$$

from which (1.21) immediately follows.

2. The nonlinear Problems I and II.

2.1. A criterion for Hölder stability.

Assumptions. a) X, Y are Banach spaces, x_1 is an element of X; for every $x_2\in X$ belonging to some neighborhood of x_1 we write $x_2=x_1+h$.

b) Let C: $X\to Y$ be a map continuously differentiable in a neighborhood of x_1 and such that

$$\|C[x_1+h]-C[x_1]-C'(x_1)[h]\|_Y\leqq c(x_1)\|h\|_Y^{1+\varepsilon} \tag{2.1}$$

for some $\varepsilon > 0$. c) The linear map $C'(x_1)$: $X \to Y$ is not invertible; but there exists a linear operator S: $X \to X$ such that, if we define the set

$$\mathscr{H}(E) \equiv \{ x \in X; \|S[x]\|_X \leqq E \}, \tag{2.2}$$

the estimate

$$\|h\|_X \leqq c(x_1, E, \gamma) \|C'(x_1)[h]\|_Y^{\gamma} \tag{2.3}$$

is valid for some γ: $0 < \gamma < 1$ and every $x_2 \in X$ with $h = x_2 - x_1 \in \mathscr{H}(E)$.

LEMMA 2.1. *Assuming that* a), b), c) *hold, the following assertion is valid: if*

$$(1+\varepsilon)\gamma > 1, \tag{2.4}$$

then there exist numbers $R = R(x_1, E, \gamma)$ *and* $c = c(x_1, E, \gamma)$ *such that the estimate*

$$\|h\|_X \leqq c \|C[x_1 + h] - C[x_1]\|_Y^{\gamma} \tag{2.5}$$

holds for every $h \in \mathscr{H}(E)$ *with* $\|h\|_X \leqq R$.

As a consequence, if x_1, x_2 are solutions to the equation $C[x] = f$ with $f = f_1$, f_2 respectively (and all the previous hypotheses hold), we get, by linearizing around x_1, the stability estimate

$$\|x_2 - x_1\|_X \leqq c(x_1, E, \gamma) \|f_2 - f_1\|_Y^{\gamma}. \tag{2.6}$$

We emphasize that the determination of the stability class $\mathscr{H}(E)$ depends only on the linear approximation C' of C, provided that this class is of Hölder type (with suitable Hölder exponent). A counterexample to the lemma is given in [8]; it shows that, if hypothesis (2.4) is not satisfied, then a bound (on the solutions) which is sufficient to stabilize the linear problem is completely inadequate to stabilize the nonlinear operator.

Proof of Lemma 2.1. Let us consider the identity

$$C'(x_1)[h] = C[x_1 + h] - C[x_1] - (C[x_1 + h] - C[x_1] - C'(x_1)[h]).$$

Now we apply first inequality (2.3), then the triangular inequality, finally (2.1); we get:

$$\|h\|_X \leqq c(x_1, E, \gamma) \{ \|C[x_1 + h] - C[x_1]\|_Y + \|C[x_1 + h] - C[x_1] - C'(x_1)[h]\|_Y \}^{\gamma}$$

$$\leqq c(x_1, E, \gamma) \{ \|C[x_1 + h] - C[x_1]\|_Y^{\gamma} + \|h\|_X^{\gamma(1+\varepsilon)} \}.$$

Because of (2.4) the last term at the right of the previous inequality is dominated by the terms at the left when $\|h\|_X \to 0$. That proves the lemma.

2.2. Linear approximations of *A* and *B*. Let us recall the definition of the potential $U_z\tilde{\sigma}$, given in (0.4), and write it by using surface coordinates

$$U_z\tilde{\sigma}(x) = \int_{\Gamma_0} d\omega \int_0^{z(\omega)} \frac{\tilde{\sigma}(\omega + tn_\omega) j(\omega, t)\, dt}{|x - (\omega + tn_\omega)|}. \tag{2.7}$$

We recall that the given function $\tilde{\sigma}$ is smooth (C^∞ say) and strictly positive, so that the product $\tilde{\sigma}(\omega + tn_\omega) j(\omega, t)$ is also smooth and there exist positive constants c_1, c_2 such

that

$$c_1 \leqq |\tilde{\sigma}(\omega + tn_\omega)\, j(\omega, t)| \leqq c_2. \tag{2.8}$$

In what follows $\tilde{\sigma}$ is considered as fixed and perfectly known and we will ignore the dependence of the relevant quantities of $\tilde{\sigma}$. As we said in the introduction, the map A, defined in (0.5), with domain in $\mathscr{A}$, has values in $H^{3/2}(\Gamma_0)$; while the map B, defined in (0.6), has values in $C^\infty(\Gamma_0)$. The next two lemmas describe a linear approximation of A and B.

LEMMA 2.2. *The map* A: $\mathscr{A} \subset L^2(\Gamma_0) \to L^2(\Gamma_0)$ *is differentiable at the origin; its Fréchet derivative,* $A'(0)$ *say, is given by*

$$A'(0)[\rho] = M_0[\tilde{\rho}\rho] \tag{2.9}$$

(*here is* $\tilde{\rho}(\omega) = \tilde{\sigma}(\omega)$, *see Lemma* 2.3). *Moreover the estimates hold*:

$$\|A[z]\|_0 \leqq c(z^*)\|z\|_0 \tag{2.10}$$

for every $z \in \mathscr{A}$, *and*

$$\|A[\rho] - M_0[\tilde{\rho}\rho]\|_0 \leqq c\|\rho\|_0^{1+\varepsilon} \tag{2.11}$$

for every ε: $0 < \varepsilon < \frac{1}{3}$. *The constant appearing in* (2.11) *depends on* z^* *and on the* $W^{1,\infty}(\Gamma_0)$ *norm of* ρ.

LEMMA 2.3. *The map* B: $\mathscr{A} \subset L^2(\Gamma_0) \to L^2(\Gamma_0)$ *is continuously Fréchet differentiable at any point* $\bar{z} \in \mathscr{A}$; *its Fréchet derivative,* $B'(\bar{z})$ *say, is given by*

$$B'(\bar{z})[\rho] = N_{\bar{z}}[\tilde{\rho}\rho], \tag{2.12}$$

where $\tilde{\rho}(\omega) = \tilde{\sigma}(\omega + \bar{z}(\omega)n_\omega)$; *the estimates*

$$\|B[z]\|_0 \leqq c(z^*)\|z\|_0, \tag{2.13}$$

$$\|B[\bar{z}+\rho] - B[\bar{z}] - N_{\bar{z}}[\tilde{\rho}\rho]\|_0 \leqq c\|\rho\|_0^{1+\varepsilon} \tag{2.14}$$

hold for every ε: $0 < \varepsilon < \frac{1}{3}$. *The constant appearing in* (2.14) *depends on* $z^*, \bar{z}$, *and on the* $W^{1,\infty}(\Gamma_0)$ *norm of* ρ.

Remark. For the operator A we can prove a more complete result, as we did for B: *The map* A *is continuously Fréchet differentiable at any point* $\bar{z} \in \mathscr{A}$; *we have*

$$A'(\bar{z})[\rho] = M_z[\tilde{\rho}\rho] + g_{\bar{z}}\rho \tag{2.9'}$$

where $g_{\bar{z}}$: $\Gamma_0 \to R$ *is the function so defined*

$$g_{\bar{z}}(\omega) = -\int_{R_{\bar{z}}} \frac{\langle \omega + \bar{z}(\omega)n_\omega - y, n_\omega \rangle \tilde{\sigma}(y)\, dy}{|\omega + \bar{z}(\omega)n_\omega - y|^3} \tag{2.15}$$

and $R_{\bar{z}}$ *is the symmetric difference between* G_0 *and* $G_{\bar{z}}$. *Moreover it holds an estimate quite analogous to* (2.11).

The proof of this assertion is rather lengthy; we refrain from writing it out, and observe that in the next section we will use only the partial result stated in Lemma 2.2.

The next three lemmas are technical and will be useful in the proofs of Lemma 2.2 and 2.3.

LEMMA 2.4. *Let* $\omega, \omega' \in \Gamma_0$, t, t', t_1, t_2, δ *reals*, $0 \leqq \delta \leqq 2$, $|t|, |t_1|, |t_2| < z^*$. *The following inequalities hold*:

$$|\omega - \omega' + tn_\omega - t'n_{\omega'}| \geqq c|\omega - \omega'|, \tag{2.16}$$

$$|\omega - \omega' + tn_\omega - t'n_{\omega'}| \geqq c|t - t'|, \tag{2.17}$$

$$|\omega - \omega' + tn_\omega - t'n_{\omega'}|^2 \geqq c|\omega - \omega'|^\delta |t - t'|^{2-\delta} \tag{2.18}$$

$$|\omega - \omega' + t'n_{\omega'} - t_1 n_\omega|^{-1} - |\omega - \omega' + t'n_{\omega'} - t_2 n_\omega|^{-1} \leqq c|t_1 - t_2|^{\delta - 1} |\omega - \omega'|^{-\delta} \tag{2.19}$$

for some positive constants c, *possibly depending on* z^*.

LEMMA 2.5. *For every real valued functions* $\rho, \sigma \in L^2(\Gamma_0)$ *and a real number* $\delta < 2$ *one gets*

$$\int_{\Gamma_0} d\omega' \left(\int_{\Gamma_0} \frac{\rho(\omega)^2 d\omega}{|\omega - \omega'|^\delta} \right)^2 \leqq c \int_{\Gamma_0} \rho(\omega)^4 d\omega, \tag{2.20}$$

$$\int_{\Gamma_0} \sigma(\omega')^2 d\omega' \left(\int_{\Gamma_0} \frac{\rho(\omega) d\omega}{|\omega - \omega'|^\delta} \right)^2 \leqq c \left(\int_{\Gamma_0} \sigma(\omega)^4 d\omega \right)^{1/2} \left(\int_{\Gamma_0} \rho(\omega)^4 d\omega \right)^{1/2}. \tag{2.20'}$$

LEMMA 2.6. *For every real valued function* $\rho \in C^1(\Gamma_0)$ *and positive* $\delta \leqq 3$ *one gets*

$$\int_{\Gamma_0} |\rho(\omega)|^{2\delta} d\omega \leqq c\big(\|\rho\|_{W^{1,\infty}(\Gamma_0)}\big) \left(\int_{\Gamma_0} \rho(\omega)^2 d\omega \right)^{2\delta/3}. \tag{2.21}$$

Proof of Lemma 2.3. First we prove (2.13). We have

$$|B[z](\omega')| = \left| \int_{\Gamma_0} d\omega \int_0^{z(\omega)} \frac{\tilde{\sigma}(\omega + tn_\omega) j(\omega, t)\, dt}{|\omega' + an_{\omega'} - (\omega + tn_\omega)|} \right|$$

$$\leqq c(z^*) \int_{\Gamma_0} \frac{|z(\omega)|\, d\omega}{|\omega - \omega'|}.$$

Here we have used (2.8) and (2.16). Then (2.13) follows from known properties of the single layer potential.

To justify (2.12) and prove (2.14) it is sufficient, because of the definition of B, to estimate the difference

$$U_{\bar{z}+\rho}\tilde{\sigma}(x) - U_{\bar{z}}\tilde{\sigma}(x) - W_{\bar{z}}\rho\tilde{\rho}(x). \tag{2.22}$$

We write it as follows:

$$\int_{\Gamma_0} d\omega \int_{\bar{z}(\omega)}^{\bar{z}(\omega)+\rho(\omega)} dt \left[\frac{\tilde{\sigma}(\omega + tn_\omega) j(\omega, t)}{|x - (\omega + tn_\omega)|} - \frac{\tilde{\rho}(\omega) j(\omega, \bar{z}(\omega))}{|x - (\omega + \bar{z}(\omega) n_\omega)|} \right]$$

$$= \int_{\Gamma_0} d\omega \int_{\bar{z}(\omega)}^{\bar{z}(\omega)+\rho(\omega)} dt \frac{\tilde{\sigma}(\omega + tn_\omega) j(\omega, t) - \tilde{\rho}(\omega) j(\omega, \bar{z}(\omega))}{|x - (\omega + tn_\omega)|}$$

$$+ \int_{\Gamma_0} d\omega \int_{\bar{z}(\omega)}^{\bar{z}(\omega)+\rho(\omega)} dt \tilde{\rho}(\omega) j(\omega, \bar{z}(\omega)) \Big[|x - (\omega + tn_\omega)|^{-1} - |x - (\omega + \bar{z}(\omega) n_\omega)|^{-1} \Big].$$

In the last equality the integrand of the first integral is estimated by $|t-\bar{z}(\omega)||\omega-\omega'|^{-1}$, having put $x=\omega'+an_{\omega'}$, $\omega'\in\Gamma_0$; we took account of (2.16) and the smoothness of $\tilde{\sigma}$ and j. The integrand of the second integral is estimated by $|t-\bar{z}(\omega)|^{\delta-1}|\omega-\omega'|^{-\delta}$, $(0<\delta<2)$, thanks to (2.19). Then we get

$$
\begin{aligned}
&|\text{expression (2.22)}| \\
&\leqq c(z^*)\left[\int_{\Gamma_0} d\omega \int_{\bar{z}(\omega)}^{\bar{z}(\omega)+\rho(\omega)} dt \frac{|t-\bar{z}(\omega)|}{|\omega-\omega'|}+\int_{\Gamma_0} d\omega \int_{\bar{z}(\omega)}^{\bar{z}(\omega)+\rho(\omega)} dt \frac{|t-\bar{z}(\omega)|^{\delta-1}}{|\omega-\omega'|^{\delta}}\right] \\
&\leqq c(z^*)\left[\int_{\Gamma_0} \frac{\rho(\omega)^2 d\omega}{|\omega-\omega'|}+\int_{\Gamma_0} \frac{|\rho(\omega)|^{\delta} d\omega}{|\omega-\omega'|^{\delta}}\right].
\end{aligned}
$$

Now the $L^2(\Gamma_0)$ norm of the first integral (in the last inequality) is plainly estimated by $\|\rho^2\|_0$, while the $L^2(\Gamma_0)$ norm of the second integral, thanks to Lemma (2.5), is estimated by $\||\rho|^{\delta}\|_0$. So we got, for $0<\delta<2$,

$$
\|B[\bar{z}+\rho]-B[\bar{z}]-N_{\bar{z}}[\tilde{\rho}\rho]\|_0 \leqq c(z^*)\left\||\rho|^{\delta}\right\|_0.
$$

Now (2.14) follows from Lemma 2.6. Lemma 2.3 is proved.

Proof of Lemma 2.2. Inequality (2.10) is proved in a quite analogous manner as (2.13). To justify (2.9) and prove (2.11) we have to estimate the difference $A[\rho]-M_0[\tilde{\rho}\rho]$, that we write as follows:

$$
\left[U_\rho\tilde{\sigma}\circ\Phi_\rho-U_\rho\tilde{\sigma}\circ\Phi_0\right]+\left[\left(U_\rho\tilde{\sigma}-W_0\tilde{\rho}\rho\right)\circ\Phi_0\right].
$$

The expression in the second bracket handles exactly as we did before in the proof of Lemma 2.3; then its $L^2(\Gamma_0)$ norm is estimated by $\|\rho\|_0^{1+\varepsilon}$ with $\varepsilon<\frac{1}{3}$. The expression in the first bracket is

$$
\int_{\Gamma_0} d\omega \int_0^{\rho(\omega)} dtj(\omega,t)\tilde{\sigma}(\omega+tn_\omega)\left[|\omega'+\rho(\omega')n_{\omega'}-(\omega+tn_\omega)|^{-1}-|\omega'-(\omega+tn_\omega)|^{-1}\right].
$$

The integrand is estimated by $|\rho(\omega')|^{\delta-1}|\omega-\omega'|^{-\delta}$, thanks to (2.19). Then all the expression is estimated by

$$
|\rho(\omega')|^{\delta-1}\int_{\Gamma_0}\frac{|\rho(\omega)|\,d\omega}{|\omega-\omega'|^{\delta}}
$$

and its $L^2(\Gamma_0)$ norm by $\||\rho|^{\delta}\|_0$, because of (2.20′). Then (2.11) follows by applying Lemma 2.6. Lemma 2.2 is proved.

Proof of Lemma 2.4. Inequalities (2.16) and (2.17) are almost trivial; (2.18) is a simple consequence of the first two; (2.19) is derived from (2.18) by observing that

$$
\frac{d}{dt}|\omega'+t'n_{\omega'}-(\omega+tn_\omega)|^{-1}\leqq|\omega'+t'n_{\omega'}-(\omega+tn_\omega)|^{-2}
$$

and applying the fundamental theorem of calculus.

Proof of Lemma 2.5. From the Schwarz inequality, by taking $\delta-1<\alpha<1$, we have

$$
\text{(2.23)}\qquad \left(\int_{\Gamma_0}\frac{\rho(\omega)^2 d\omega}{|\omega-\omega'|^{\delta}}\right)^2\leqq\int_{\Gamma_0}\frac{d\omega}{|\omega-\omega'|^{2(\delta-\alpha)}}\int_{\Gamma_0}\frac{\rho(\omega)^4 d\omega}{|\omega-\omega'|^{2\alpha}}=c\int_{\Gamma_0}\frac{\rho(\omega)^4 d\omega}{|\omega-\omega'|^{2\alpha}}.
$$

Then

$$\int_{\Gamma_0} d\omega' \left(\int_{\Gamma_0} \frac{\rho(\omega)\, d\omega}{|\omega - \omega'|^{\delta}} \right)^2 \leqq c \int_{\Gamma_0} \rho(\omega)^4 d\omega \int_{\Gamma_0} \frac{d\omega'}{|\omega - \omega'|^{2\alpha}} = c \int_{\Gamma_0} \rho(\omega)^4 d\omega.$$

To prove (2.20′) we proceed analogously, by first applying the Schwarz inequality

$$\int_{\Gamma_0} \sigma(\omega')^2 d\omega' \left(\int_{\Gamma_0} \frac{\rho(\omega)\, d\omega}{|\omega - \omega'|^{\delta}} \right)^2 \leqq \left(\int_{\Gamma_0} \sigma(\omega')^4 d\omega' \right)^{1/2} \left(\int_{\Gamma_0} d\omega' \left(\int_{\Gamma_0} \frac{\rho(\omega)\, d\omega}{|\omega - \omega'|^{\delta}} \right)^4 \right)^{1/2};$$

then, by applying repeatedly (2.23), we get

$$\int_{\Gamma_0} d\omega' \left(\int_{\Gamma_0} \frac{\rho(\omega)\, d\omega}{|\omega - \omega'|^{\delta}} \right)^4 \leqq \int_{\Gamma_0} \rho(\omega)^4 d\omega.$$

Lemma 2.5 is proved.

Proof of Lemma 2.6. In the Sobolev inequality

$$\left(\int_{\Gamma_0} |u(\omega)|^p d\omega \right)^{1/p} \leqq c \int_{\Gamma_0} \left(|u(\omega)| + |Du(\omega)| \right) d\omega,$$

which holds with $p \leqq 2$, take $u = |\rho|^3$; then choose $p = 2\delta/3$; so we get

$$\int_{\Gamma_0} |\rho(\omega)|^{2\delta} d\omega \leqq c \left(\max|\rho| + 3 \max|D\rho| \right)^{2\delta/3} \left(\int_{\Gamma_0} \rho(\omega)^2 d\omega \right)^{2\delta/3}.$$

Lemma 2.6 is proved.

2.3. Stability results for Problems I and II. Now we are in the position to draw some conclusions about the stability of the solutions of Problems I and II, for the results of §1 give us information about the Hölder stability of the linear operators A' and B'. That is true for $B'(z)$, which substantially coincides with N_z, while $A'(z)$, as we noted in the remark after Lemma 2.3, differs from M_z by the perturbation term g_z; so the linearized equation $A'(z)[\rho] = f$ is an integral equation of the second kind. This equation presents problems of instability analogous to those exhibited by the first kind equation: $M_z[\rho] = f$ discussed in §1; for the term g_z is actually small, and it can vanish (if $z \equiv 0$, then, as we saw, $g_z \equiv 0$). Now, using the results of §1 directly, we will take, for Problem I, $\bar{z} = 0$; thus we will get a stability result for solutions of Problem I which are close to the origin.

THEOREM 2.7. *Let $v \in L^2(\Gamma_0)$ be a given function and $z \in \mathscr{A}$ a solution of the equation $A[z] = v$ belonging to the set $H_\alpha(E)$ with $\alpha > \frac{3}{4}$. Then there exist numbers $R = R(\alpha, E)$ and $c = c(\alpha)$ such that the estimate*

$$\|z\|_0 \leqq c E^{1-\alpha} \|v\|_0^{\alpha} \tag{2.24}$$

is valid for every z with $\|z\|_0 \leqq R$.

Proof. We have only to verify that the hypotheses of Lemma 2.1 are fulfilled. We apply Lemma 2.1 by taking $X = Y = L^2(\Gamma_0)$ and $x_1 = 0$. Inequality (2.1) is satisfied with $\varepsilon < \frac{1}{3}$ (cf. inequality (2.11)). The stability class $\mathscr{K}(E)$ is the set $H_\alpha(E)$ defined in (1.9) and inequality (2.3) is satisfied with $\gamma = \alpha$ (cf. inequality (1.10)); notice that the dependence of the constant appearing in (2.3) on E is explicit in (1.10). Then the hypothesis

$(1+\varepsilon)\gamma > 1$ can be satisfied with $\alpha > \frac{3}{4}$; so (2.24) follows. Notice that the dependence of the constants on $\|z\|_{W^{1,\infty}(\Gamma_0)}$ (coming from (2.11)) has disappeared, because the stability constraint: $\|z\|_{\alpha/1-\alpha} \leqq E$ with $\alpha > \frac{3}{4}$ also bounds the $W^{1,\infty}$ norm of z by the same constant E. A more complete stability result can be proved for Problem II.

THEOREM 2.8. *Let $v_1, v_2 \in L^2(\Gamma_0)$ be given functions and $z_1, z_2 \in \mathscr{A}$ be the corresponding solutions of the equation $B[z]=v$. If $z_2 - z_1 \in K_\alpha(E)$ with $\alpha > \frac{3}{4}$ then there exist numbers $R = R(\alpha, E, z_1)$ and $c = c(\alpha, z_1)$ such that the estimate*

$$\|z_2 - z_1\|_0 \leqq cE^{1-\alpha}\|v_2 - v_1\|_0^{\alpha} \tag{2.25}$$

is valid for $\|z_2 - z_1\|_0 \leqq R$.

The proof follows from Lemma 2.1 in a way analogous to the previous theorem.

ABSOLUTELY CONTINUOUS SPECTRA OF SECOND ORDER DIFFERENTIAL OPERATORS WITH SHORT AND LONG RANGE POTENTIALS*

D. B. HINTON† AND J. K. SHAW‡

Abstract. For ordinary second order differential operators with one or two singular endpoints, the problem is considered of determining when a continuous spectrum is absolutely continuous or is of class $C^{(1)}$. Operators are considered which have a smooth part plus perturbation terms. The perturbation terms considered are short and long range type potentials and also potentials of a highly oscillatory character. The absolutely continuous spectrum found is either a ray $[\lambda_0, \infty)$ or a whole line $(-\infty, \infty)$. For a certain class of equations, the spectrum is also found to be bounded below. The theory developed is applied to the energy operator of the hydrogen atom.

1. Introduction. As is well known, singular boundary value problems often have continuous spectra. It is of interest in applications to know if this spectrum is absolutely continuous. We consider here a class of such problems for second order ordinary differential equations in both the half line and whole line cases. One version of the problem may be described as follows. Let

$$L(y) = w^{-1}\{-(py')' + qy\} = \lambda y, \qquad a \leqq x < \infty, \tag{1.1}$$

$$\sin\alpha\, y(a) + \cos\alpha\,(py')(a) = 0 \tag{1.2}$$

be an eigenvalue problem such that L is in the limit point case at infinity. Let $\psi(x,\lambda)$ be the solution of (1.1) defined by $\psi(a,\lambda) = \cos\alpha$, $(p\psi')(a,\lambda) = -\sin\alpha$. Then there is a nondecreasing function ρ on $(-\infty, \infty)$ such that the equations

$$g(\lambda) = \int_a^\infty f(x) w(x) \psi(x,\lambda)\, dx,$$

$$f(x) = \int_{-\infty}^\infty g(\lambda)\psi(x,\lambda)\, d\rho(\lambda),$$

define a linear isometry between the Hilbert spaces

$$\mathscr{L}_w^2(a,\infty) = \left\{ f \,\middle|\, \int_a^\infty w|f|^2\, dx < \infty \right\},$$

$$\mathscr{L}^2(-\infty,\infty) = \left\{ g \,\middle|\, \int_{-\infty}^\infty |g|^2\, d\rho < \infty \right\}.$$

We refer the reader to [7. Chap. 9]. The above isometry is a unitary transformation which takes the self-adjoint operator T associated with (1.1)–(1.2) to the self-adjoint transformation in $\mathscr{L}_\rho^2(-\infty,\infty)$ which is multiplication by the independent variable λ. We may then characterize the spectrum of T, $\sigma(T)$, as the points of increase of ρ. Further the eigenvalues of T, $D\sigma(T)$, are the jumps of ρ, and the essential spectrum of T, $E\sigma(T)$, is the set of limit points of $\sigma(T)$. We define the continuous spectrum $C\sigma(T)$

as $E\sigma(T)\backslash D\sigma(T)$. The problem we consider is to find conditions on the coefficients of (1.1) so that if $[a,b]\subset C\sigma(T)$, then $[a,b]$ is an absolutely continuous spectrum, i.e., ρ is absolutely continuous on $[a,b]$. Our conditions will in fact imply ρ is of class $C^{(1)}$.

In order to consider equations like (1.1), we define below a generalization of the equation,

$$y''+\left[\lambda+v_1(x)+v_2(x)+v_3(z)\right]y=0, \qquad a\leqq x<\infty, \tag{1.3}$$

which will include (1.1) after a change of independent and dependent variables. In (1.3) regard v_1 as absolutely continuous with $\int_a^\infty |v_1'|<\infty$, v_2 as having a small integral, and v_3 as being small in the sense of $\int_a^\infty |v_3|<\infty$. Such v_1, v_3 are called long and short range potentials, respectively. An example of the type of equation we wish to consider is,

$$y''+\left[\lambda+(x+1)^{-1}+x\sin x^4+e^{-x}x^{-1/2}\right]y=0, \qquad 0\leqq x<\infty.$$

This work is motivated by recent work of S. Itatsu and H. Kaneta [10], as well as by classical work of E. C. Titchmarsh [16, pp. 116–128]. In [16], the case $v_1=v_2\equiv 0$ is considered as well as certain equations in which a change of variable is made. The change of independent variable is nonreal and places restrictions on the coefficients. In particular, perturbation terms are not allowed. We are able to avoid many of these restrictions by making the change of independent variable real. This however, may make the terms v_1, v_2, and v_3 λ-dependent. In [10], (1.3) is considered with $v_2\equiv 0$, and the authors use the method of singular integral equations to obtain asymptotics for (1.3). We find it more advantageous to develop the theory along the lines of Titchmarsh.

A different approach to showing continuous spectrum is absolutely continuous has been taken by J. Weidmann [18] and J. Walter [17]. They approximate the singular problem by a sequence of regular problems and apply estimates on the number of eigenvalues lying in a given interval. It does not appear that this method can be used to show additional smoothness properties of ρ, e.g., to show ρ is of class $C^{(1)}$. In [18], (1.3) is considered with $\int_a^\infty |dv_1|<\infty$, $\int_a^\infty |v_3|<\infty$, and $v_2\equiv 0$. In [17], (1.1) is considered with $p=w\equiv 1$ and q sufficiently smooth.

Also related to the resutls here are those of M. Ben-Artzi and A. Devinatz [2] and M. Ben-Artzi [3], [4]. In [2], [3], [4], the operator $-\Delta+V$ is considered on R^n where V is spherically symmetric. In addition to the question of absolute continuity of the spectrum, the existence and completeness of wave operators is discussed. The ordinary differential operators considered are defined on $(0,\infty)$, with both endpoints being singular. In [2], [3] an operator of type (1.3) is considered. The singularity at infinity has $v_2=0$, but allows a v_1 term more general than that considered here. The singularity at zero has more stringent growth conditions than that required by Theorem 4.2 below. In [4], similar questions are discussed for (1.1) with $p=w=1$ and q sufficiently smooth.

Additional criteria for the continuous spectrum to be absolutely continuous may be found in P. A. Rejto [13], [15], and P. A. Rejto and K. Sinha [14]. These operators are of type (1.1) with $p=w=1$, but with two singular endpoints. In [13], [15] operators are considered on $(0,\infty)$, and in [14] they are considered on $(-\infty,\infty)$. The method in these papers is to apply an abstract criterion for absolute continuity based on the resolvent operator. In [2], [3], [4] the criterion is similar but based on the Green's function. The method employed here uses a numerical component of the Green's function—the Titchmarsh–Weyl coefficient whose singular structure yields the various components of the spectrum (cf. [6]).

For two singular endpoint problems we follow the method of [10] which treats each singular endpoint separately. This allows greater flexibility in placing constraints on the coefficients. This permits, for example, a generalization of [13, Thm. 2.1] along the lines of §6 where the singularity at zero is transformed to infinity.

A problem related to this paper is showing the absence of eigenvalues embedded in the continuous spectrum. Some sharp bounds for cutoff of eigenvalues may be found in the paper of F. V. Atkinson and W. N. Everitt [1].

In §2 below we define a generalization of (1.3) and show how it relates to transformed equations. In §3 we develop the necessary asymptotics for solutions. In §4, the Titchmarsh–Weyl m-coefficient is employed to obtain absolute continuity of the continuous spectrum. In §5, the theory of §4 is applied to analyze the two-singular endpoint problem, and a connection is made with recent work of R. Carmona [5]. In §6, the theory is applied to the hydrogen atom.

By the norm of a vector we mean the Euclidean norm; by the norm of a matrix we mean the corresponding operator norm. Standard notation is used for the components of vectors and matrices. For $w(x)>0$ and Lebesgue measurable, $\mathscr{L}_w^p(I)$ denotes the Banach space of all equivalence classes of complex-valued functions f satisfying $\int_I w|f|^p < \infty$.

2. A general equation. The equation considered is

$$y''+\left[a(\lambda)^2+v_1(x,\lambda)+v_2(x,\lambda)+v_3(x,\lambda)\right]y=0, \qquad a\leqq x<\infty, \tag{2.1}$$

where the conditions on a, v_1, v_2, and v_3 are given below. To motivate the form of (2.1) considered, we return to (1.1) with a singular point at b, $b\leqq\infty$, i.e.

$$-(py')'+qy=\lambda wy, \qquad a\leqq x<b. \tag{2.2}$$

Suppose in (2.2) we make the Kummer–Liouville change of variables,

$$y(x)=h(x)z(t), \quad h=(pw)^{-1/4}, \quad t=f(x)=\int_a^x\left(\frac{w}{p}\right)^{1/2},$$

where p,w are positive and sufficiently smooth and $\int_a^b (w/p)^{1/2}=\infty$. Then (2.2) becomes

$$-\ddot{z}(t)+Q(t)z(t)=\lambda z(t), \qquad 0\leqq t<\infty, \tag{2.3}$$

with $Q(t)=[q/w-h(ph')'/f'](x)$. For appropriate p,q, and w, (2.3) is of type (2.1). Using the Titchmarsh–Weyl m-coefficient below to analyze the spectrum of (2.2), we need only know the asymptotics of (2.3).

Suppose now in (2.2), $q=-n-r$ where $n(x)>0$ is a smooth part of q and r is a perturbation part. If we make the change of variables

$$y(x)=h(x)z(t), \quad h=(pn)^{-1/4}, \quad t=f(x)=\int_a^x\left(\frac{n}{p}\right)^{1/2}$$

where $\int_a^\infty (n/p)^{1/2}=\infty$, then (2.2) becomes

$$-\ddot{z}(t)-[1+Q(t)]z(t)=0, \qquad 0\leqq t<\infty, \tag{2.4}$$

with $Q(t)=[r/n+h(ph')'/f'+\lambda w/n](x)$; hence the λ-dependence is changed to a v term in (2.1), and $a(\lambda)$ is constant. The case $n(x)<0$ above is not considered since it typically leads to an empty continuous spectrum.

Let $C_+ = \{\lambda | \operatorname{Im}\lambda \geqq 0\}$ and $C_0 = \{\lambda \in C_+ | \operatorname{Re}\lambda \geqq 0\}$. Our assumptions for (2.1) are:

(A_1) For $i=1,2,3$, $v_i(x,\lambda) = v_{i1}(x) + \lambda v_{i2}(x)$ where each v_{ij} is real and locally Lebesgue integrable. Further

a) For $j=1,2$, $v_{1j}(x) \to 0$ as $x \to \infty$, v_{1j} is absolutely continuous with $v'_{1j} \in \mathscr{L}(a,\infty)$; $v_{12}(x) \geqq 0$.

b) For $j=1,2$, $\int_a^\infty v_{2j}$ exists (conditionally), $V_{2j}(x) = \int_x^\infty v_{2j}$ is in $\mathscr{L}(a,\infty)$; $W_{sj}(x) = \int_x^\infty |v'_{1s} V_{2j}|$ is in $\mathscr{L}(a,\infty)$ for $s,j=1,2$.

(c) For $j=1,2$, $v_{3j} \in \mathscr{L}(a,\infty)$.

(A_2) $a(\lambda)$ is continuous on C_+, analytic on the interior of C_+, and $a(C_+) \subset C_0$. There is a number $\lambda_0 \in C_+$ such that if U is a closed subset of C_+ not containing λ_0, then $a(U)$ is bounded away from zero.

Note that if U is as in (A_2), then $|a(\lambda)|^2 \geqq \varepsilon > 0$ on U for some $\varepsilon > 0$. Now if U is compact or $v_{12}(x) \equiv 0$ we may, by redefining v_3 if necessary, assume $|v_1(x,\lambda)| \leqq \varepsilon/2$ for $a \leqq x < \infty$, $\lambda \in U$. Without loss of generality we will always make this assumption for U in (A_2) compact or $v_{12}(x) \equiv 0$.

3. Asymptotic theory of (2.1). We suppose in this section that (A_1)–(A_2) hold and U is a closed subset of C_+ not containing λ_0, and that either U is compact or $v_{12}(x) \equiv 0$. Hence

$$K = K(x,\lambda) = \left[a(\lambda)^2 + v_1(x,\lambda)\right]^{1/2} \tag{3.1}$$

is a well-defined element of C_0 and satisfies for some $\varepsilon > 0$

$$|K(x,\lambda)| \geqq \left(\frac{\varepsilon}{2}\right)^{1/2}, \qquad \lambda \in U, \quad a \leqq x < \infty. \tag{3.2}$$

Write (2.1) in system form as

$$\begin{pmatrix} y \\ y' \end{pmatrix}' = \left\{ \begin{pmatrix} 0 & 1 \\ -K^2 & 0 \end{pmatrix} - (v_2 + v_3) \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \right\} \begin{pmatrix} y \\ y' \end{pmatrix}. \tag{3.3}$$

First we transform (3.3) as in [10]. Set

$$S = \begin{pmatrix} 1 & 1 \\ iK & -iK \end{pmatrix}, \qquad \psi = S^{-1} \begin{pmatrix} y \\ y' \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 & 1/iK \\ 1 & -1/iK \end{pmatrix} \begin{pmatrix} y \\ y' \end{pmatrix};$$

hence (3.3) becomes

$$\psi' = \left\{ iK \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} - \left(\frac{v_2 + v_3}{2iK}\right) \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} - \frac{K'}{2K} \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix} \right\} \psi. \tag{3.4}$$

Define

$$N = \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}, \qquad R = \left(\frac{-v_3}{2iK}\right) N - \frac{K'}{2K} \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix},$$

$$E = E(x,\lambda) = \begin{pmatrix} \exp\left(\int_a^x iK\right) & 0 \\ 0 & \exp\left(\int_a^x -iK\right) \end{pmatrix},$$

$$W = W(x,\lambda) = \int_x^\infty \frac{v_2}{2iK}.$$

Then by the variation of constants formula, (3.4) can be written as

$$\psi(x,\lambda)=E(x,\lambda)\Big\{\psi(a)+\int_a^x E^{-1}[W'N+R]\psi\Big\}. \tag{3.5}$$

Integrating the term $\int_a^x E^{-1}W'N\psi$ in (3.5) by parts and using $\psi'=[E'E^{-1}+W'N+R]\psi$, we obtain after simplifying that

$$\begin{aligned}&[I-W(x,\lambda)N]\psi(x,\lambda)\\ &\quad=E(x,\lambda)\Big\{[I-W(a,\lambda)N]\psi(a,\lambda)\\ &\qquad+\int_a^x E^{-1}[R+E'E^{-1}WN-WNE'E^{-1}]\psi\Big\}.\end{aligned} \tag{3.6}$$

Equation (3.6) simplifies to

$$\begin{aligned}&[I-W(x,\lambda)N]\psi(x,\lambda)\\ &\quad=E(x,\lambda)\Big\{[I-W(a,\lambda)N]\psi(a,\lambda)+\int_a^x E^{-1}R_1\psi\Big\}\end{aligned} \tag{3.7}$$

where

$$R_1=R_1(x,\lambda)=R(x,\lambda)+2iK(x,\lambda)W(x,\lambda)\begin{pmatrix}0&1\\1&0\end{pmatrix}. \tag{3.8}$$

The definition of W and an integration by parts yields that

$$W(x,\lambda)=\frac{V_2(x,\lambda)}{2iK(x,\lambda)}-\int_x^\infty (V_2v_1'/4iK^3) \tag{3.9}$$

where $V_2(x,\lambda)=\int_x^\infty v_2$. Thus by (A_1)–(A_2) we have for each compact set F in C_+ a constant M_F such that for all $\lambda\in U\cap F$,

$$\int_a^\infty \|R_1(x,\lambda)\|\,dx\leqq M_F,\qquad |W(x,\lambda)|\leqq M_F. \tag{3.10}$$

In case $v_{2j}(x)\equiv 0$ for $j=1,2,3$, (3.10) holds for $F=C_+$. Set

$$\begin{pmatrix}c_1\\c_2\end{pmatrix}=[I-W(a,\lambda)N]\psi(a,\lambda),\qquad \psi_1(x,\lambda)=\Big[\exp\Big(\int_a^x iK\Big)\Big]\psi(x,\lambda). \tag{3.11}$$

Then (3.7) becomes

$$\begin{aligned}&[I-W(x,\lambda)N]\psi_1(x,\lambda)\\ &\quad=\begin{pmatrix}\exp\Big(2i\int_a^x K\Big)&0\\0&1\end{pmatrix}\begin{pmatrix}c_1\\c_2\end{pmatrix}\\ &\qquad+\int_a^x\begin{pmatrix}\exp\Big(2i\int_s^x K\Big)&0\\0&1\end{pmatrix}R_1(s,\lambda)\psi_1(x,\lambda)\,ds.\end{aligned} \tag{3.12}$$

Note that by (3.10), for $\lambda\in U\cap F$.

$$\big\|[I-W(x,\lambda)N]^{-1}\big\|=\|[I+W(x,\lambda)N]\|\leqq 1+M_F\|N\|. \tag{3.13}$$

LEMMA 3.1. *Suppose* (A_1)–(A_2) *hold,* U *is as above,* $F \subset C_+$ *is compact and* (3.11) *holds. Then for* $\lambda \in U \cap F$ *and* $a \leqq x < \infty$,

$$\|\psi_1(x,\lambda)\| \leqq \gamma \left\| \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} \right\| e^{\gamma M_F} \tag{3.14}$$

where $\gamma = 1 + M_F \|N\|$.

Proof. Recall $\operatorname{Im} K(x,\lambda) \geqq 0$. Thus by (3.12) and (3.13),

$$\|\psi_1(x,\lambda)\| \leqq \gamma \left[\left\| \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} \right\| + \int_a^x \|R_1(x,\lambda)\| \|\psi_1(s,\lambda)\| \, ds \right].$$

Equation (3.14) now follows by an application of Gronwall's inequality.

Lemma 3.1 yields asymptotic behavior of ψ_1 as $x \to \infty$ and hence of y, y'. First we rewrite (3.12) as

(3.15)

$$[I - W(x,\lambda)N]\psi_1(x,\lambda) = \begin{pmatrix} 0 \\ A(\lambda) \end{pmatrix} - \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \int_x^\infty R_1\psi_1 + \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \left\{ \left[\exp\left(2i \int_a^x K \right) \right] \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} + \int_a^x \left[\exp\left(2i \int_s^x K \right) \right] R_1\psi_1 \right\}$$

where

$$\begin{pmatrix} 0 \\ A(\lambda) \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \left\{ \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} + \int_a^\infty R_1\psi_1 \right\}. \tag{3.16}$$

LEMMA 3.2. *Suppose* (A_1)–(A_2) *hold,* U *is as above, and* $y(\cdot,\lambda)$ *is a solution of* (2.1) *with* $y(0,\lambda)$ *and* $y'(0,\lambda)$ *independent of* λ. *Then* $A(\lambda) = A_y(\lambda)$ *defined by* (3.16) *is continuous in* λ *for* λ *in* U *and analytic on the interior of* U.

Proof. The method of successive approximations for existence of solutions shows $y(x,\lambda)$ is jointly continuous in x and λ and entire in λ for fixed x. Since K is analytic in λ for λ in the interior of U and continuous in λ for λ in U, the functions $R_1(x,\lambda)$ and $\psi_1(x,\lambda)$ have the same properties for fixed x; further they are jointly continuous in x and λ. Hence by the bounds (3.10) and (3.14), $A(\lambda)$ is the limit of a sequence of functions which are (i) continuous on U, (ii) analytic on interior U, and (iii) uniformly bounded on compact sets. By Vitali's theorem, $A(\lambda)$ is analytic on interior U. Further, (A_1) implies that $\int_n^\infty \|R_1(s,\lambda)\| ds \to 0$ as $n \to \infty$, uniformly for λ in compact sets. Thus $A(\lambda)$ is continuous on U.

Fix now $\lambda \in U$. If $a(\lambda)$ is in the interior of C_0 or $a(\lambda)$ is on the positive imaginary axis, then $K(x,\lambda) \to a(\lambda)$ as $x \to \infty$. Then $\exp \int_a^x iK \to 0$ as $x \to \infty$, and we have the following asymptotic behavior. (Note that $W(x,\lambda) \to 0$ as $x \to \infty$.) As $x \to \infty$,

$$\begin{aligned} \psi_1(x,\lambda) &= \begin{pmatrix} 0 \\ A(\lambda) \end{pmatrix} + o(1), \\ \begin{pmatrix} y \\ y' \end{pmatrix}(x,\lambda) &= \left[\exp\left(- \int_a^x iK \right) \right] A(\lambda) \begin{pmatrix} 1 + o(1) \\ -iK + o(1) \end{pmatrix}. \end{aligned} \tag{3.17}$$

If $a(\lambda)$ is in the positive real axis, then

$$K = \left(a(\lambda)^2 + v_1 \right)^{1/2} = a(\lambda)\left(1 + v_1 / a(\lambda)^2 \right)^{1/2}$$

from which we conclude that

$$\int_a^\infty \operatorname{Im} K(x,\lambda)\,dx=\infty \Leftrightarrow \int_a^\infty \operatorname{Im} v_1(x,\lambda)\,dx=\infty.$$

If $\int_a^\infty \operatorname{Im} v_1=\infty$, then (3.17) holds. If $\int_a^\infty \operatorname{Im} v_1<\infty$, then from (3.15) we conclude that as $x\to\infty$,

$$\psi_1(x,\lambda)=\begin{pmatrix}0\\ A(\lambda)\end{pmatrix}+\exp\left(2i\int_a^x K\right)\begin{pmatrix}B(\lambda)\\ 0\end{pmatrix}+o(1), \tag{3.18}$$

$$\begin{pmatrix}y\\ y'\end{pmatrix}(x,\lambda)=\exp\left(-\int_a^x iK\right)A(\lambda)\begin{pmatrix}1+o(1)\\ -iK+o(1)\end{pmatrix}$$

$$+\exp\left(\int_a^x iK\right)B(\lambda)\begin{pmatrix}1+o(1)\\ iK+i(1)\end{pmatrix},$$

where

$$\begin{pmatrix}B(\lambda)\\ 0\end{pmatrix}=\begin{pmatrix}1&0\\ 0&0\end{pmatrix}\left\{\begin{pmatrix}c_1\\ c_2\end{pmatrix}+\int_0^\infty \exp\left(-2i\int_a^s K\right)R_1\psi_1\right\}.$$

If now in (3.18), $y(x,\lambda)$ is real and $K(x,\lambda)$ is real, then from $\operatorname{Im} y(x,\lambda)\equiv 0$ we conclude that $B(\lambda)=\overline{A(\lambda)}$.

4. Application to half-line problems. Consider first equation (1.1) with the boundary condition (1.2). Define a fundamental set of solutions θ_α, ϕ_α of (1.1) by the initial values

$$\begin{pmatrix}\theta_\alpha & \phi_\alpha\\ p\theta_\alpha' & p\phi_\alpha'\end{pmatrix}(a,\lambda)=\begin{pmatrix}\sin\alpha & -\cos\alpha\\ \cos\alpha & \sin\alpha\end{pmatrix}. \tag{4.1}$$

If L is in the limit point case at infinity, then the limit, for $\operatorname{Im}\lambda\neq 0$,

$$\lim_{x\to\infty} -\frac{\theta_\alpha(x,\lambda)}{\phi_\alpha(x,\lambda)}=m_\alpha(\lambda) \tag{4.2}$$

exists and is analytic on $\operatorname{Im}\lambda\neq 0$. Further the self-adjoint operator T determined by (1.1)–(1.2) has spectral function ρ_α related to m_α by

$$\rho_\alpha(t)-\rho_\alpha(s)=\lim_{\varepsilon\downarrow 0}\frac{1}{\pi}\int_s^t \operatorname{Im} m_\alpha(u+i\varepsilon)\,du \tag{4.3}$$

at points of continuity s,t of ρ_α. (cf. [7, Chap. 9]).

Detailed relations between the singular structure of m_α and the spectrum have been established by J. Chandhuri and W. N. Everitt [6]. In particular we note that the isolated eigenvalues coincide with the poles of m_α.

In this section we solve the half-line problem for (1.3) and then show how the Kummer–Liouville transformation, together with the asymptotic theory of §3 solves a wider class of problems. For (1.3), we take in (A_1)–(A_2) for some real λ_0 that

$$a(\lambda)=\sqrt{\lambda-\lambda_0}, \qquad v_{12}=v_{22}=v_{32}\equiv 0. \tag{4.4}$$

The set U used in §3 may be taken to be any closed subset of C_+ not containing λ_0. Let A_ϕ, A_θ be the functions defined by (3.16) for ϕ_α, θ_α respectively. Then A_ϕ, A_θ are continuous on $C_+\backslash\{\lambda_0\}$ and analytic on the interior of this set. Further for λ real, $\lambda<\lambda_0$, iK and hence A_ϕ, A_θ are real. Thus by reflection, A_ϕ, A_θ have analytic continuations into $\{\lambda\colon \mathrm{Re}\lambda<\lambda_0\}$.

For real λ, $\lambda>\lambda_0$, write

$$A_\phi = a_\phi + ib_\phi, \qquad A_\theta = a_\theta + ib_\theta, \tag{4.5}$$

where a_ϕ, b_ϕ, a_θ, b_θ are real. From the asymptotic formula (3.18) we have as $x\to\infty$, $\lambda>\lambda_0$,

$$\begin{aligned}\phi_\alpha(x,\lambda) &= 2a_\phi(\lambda)\cos\int_a^x K + 2b_\phi(\lambda)\sin\int_a^x K + o(1),\\ \phi'_\alpha(x,\lambda) &= 2K(x,\lambda)\Big[-a_\phi(\lambda)\sin\int_a^x K + 2b_\phi(\lambda)\cos\int_a^x K\Big] + o(1),\end{aligned} \tag{4.6}$$

with similar formulas for θ_α, θ'_α. From the Wronskian,

$$1\equiv\begin{vmatrix}\theta_\alpha & \phi_\alpha\\ \theta'_\alpha & \phi'_\alpha\end{vmatrix}(x,\lambda) = 4K(x,\lambda)\big[a_\theta(\lambda)b_\phi(\lambda)-a_\phi(\lambda)b_\theta(\lambda)\big]+o(1),$$

we conclude that for $\lambda>\lambda_0$,

$$a_\theta(\lambda)b_\phi(\lambda)-a_\phi(\lambda)b_\theta(\lambda) = \frac{1}{4(\lambda-\lambda_0)^{1/2}}. \tag{4.7}$$

This shows that $A_\phi(\lambda)$, $A_\theta(\lambda)$ do not vanish for real $\lambda>\lambda_0$ and hence also for λ sufficiently near this set. For $\mathrm{Im}\lambda>0$ such that $A_\phi(\lambda)\neq 0$, we have from the asymptotic formula (3.18) and (4.2) that

$$m_\alpha(\lambda) = -\lim_{x\to\infty}\frac{\exp(-i\int_a^x K)\big[A_\theta(\lambda)+o(1)\big]}{\exp(-i\int_a^x K)\big[A_\phi(\lambda)+o(1)\big]} = -\frac{A_\theta(\lambda)}{A_\phi(\lambda)}. \tag{4.8}$$

Recall that A_θ, A_ϕ are analytic on $\mathrm{Im}\lambda>0$ and $\mathrm{Re}\lambda<\lambda_0$ and that they are continuous on $C_+\backslash\{\lambda_0\}$. From (4.5), (4.7), and (4.8), we have that for $\mu>\lambda_0$,

$$\begin{aligned}\lim_{\varepsilon\downarrow 0+}\mathrm{Im}\,m_\alpha(\mu+i\varepsilon) &= -\mathrm{Im}\,\frac{A_\theta(\mu)}{A_\phi(\mu)}\\ &= -\frac{-a_\theta b_\phi + a_\phi b_\theta}{a_\phi^2+b_\phi^2}(\mu)\\ &= \frac{1}{4(\mu-\lambda_0)^{1/2}\big[a_\phi^2(\mu)+b_\phi^2(\mu)\big]}.\end{aligned} \tag{4.9}$$

Since $A_\phi(\mu)\neq 0$, and the limit in (4.9) is uniform on compact subintervals of (λ_0,∞), we have from (4.3) that for $\mu>\lambda_0$, ρ_α is class $C^{(1)}$ with

$$\rho'_\alpha(\mu) = \frac{1}{4(\mu-\lambda_0)^{1/2}\big[a_\phi^2(\mu)+b_\phi^2(\mu)\big]}.$$

On the other hand A_θ, A_ϕ are real for $\mu<\lambda_0$. Thus $m_\alpha(\lambda)$ is meromorphic on $\mathrm{Re}\lambda<\lambda_0$, and on a compact subinterval of $(-\infty,\lambda_0)$, ρ_α is a step function with a finite number of jumps.

THEOREM 4.1. *Assume in* (1.3) *that* v_1, v_2, v_3 *are locally Lebesgue integrable and* (i) $v_1(x)\to-\lambda_0$ *as* $x\to\infty$. (ii) $V_2(x)=\int_x^\infty v_2$ *exists, and* (iii) v_1', v_3, V_2, *and* W_0 *are in* $\mathscr{L}(a,\infty)$ *where* $W_0(x)=\int_x^\infty |v_1'V_2|$. *Let* $0\leqq\alpha<\pi$ *and* T_α *in* $\mathscr{L}^2(a,\infty)$ *be defined by*

$$T_\alpha(y)=-(y''+[v_1+v_2+v_3]y)$$

with domain T_α *being all* $y\in\mathscr{L}^2(a,\infty)$ *such that* y,y' *are locally absolutely continuous,* $T_\alpha(y)\in\mathscr{L}^2(a,\infty)$, *and* y *satisfies the boundary condition* $\sin\alpha\, y(a)+\cos\alpha\, y'(a)=0$. *Then* T_α *is self-adjoint, on* (λ_0,∞) *its spectral function* ρ_α *is* $C^{(1)}$ *with* $\rho_\alpha'(\mu)>0$, *on each compact subinterval of* $(-\infty,\lambda_0)$, *the spectrum of* T_α *is either empty or consists of a finite number of eigenvalues, and the spectrum of* T_α *is bounded below.*

Proof. The asymptotic form of solutions (4.6) shows that for $\lambda>\lambda_0$, (1.3) has no solutions in $\mathscr{L}^2(a,\infty)$. Thus T_α is of limit point type at infinity, and the theory of self-adjoint extensions of symmetric operators shows T_α is self-adjoint. The only part of Theorem 4.1 not proved above is that the spectrum is bounded below. We now prove that under the above assumptions, a solution y of (1.3), with $y(a\lambda)$ and $y'(a,\lambda)$ independent of λ, satisfies

$$\lim_{\lambda\to-\infty} A_y(\lambda)=y(a)/2 \tag{4.10}$$

where $A(\lambda)=A_y(\lambda)$ is given by (3.16). First we show that (4.10) implies the spectrum of T_α is bounded below. Since m_α is meromorphic on $\mathrm{Re}\lambda<\lambda_0$, the conclusion follows by showing m_α has a limit as $\lambda\to-\infty$. For $\alpha\neq\pi/2$, (4.10) implies $m_\alpha(\lambda)\to -\theta_\alpha(a,\lambda)/\phi_\alpha(a,\lambda)=\tan\alpha$ as $\lambda\to-\infty$. For $\alpha=\pi/2$, $\phi_\alpha(a,\lambda)=0$ and $\theta_\alpha(a,\lambda)=1$ so that (4.10) implies $m_\alpha(\lambda)^{-1}\to0$ as $\lambda\to-\infty$.

Thus the zeros of $m_\alpha(\lambda)$ are bounded below; hence the poles of $m_\alpha(\lambda)$ are bounded below since $m_\alpha(\lambda)$ is real on $(-\infty,\lambda_0)$. Further, $\mathrm{Im}\, m_\alpha(\lambda)>0$ for $\mathrm{Im}\lambda>0$, and we have by orientation preserving properties of analytic functions that $m_\alpha(\lambda)\to -\infty$ as $\lambda\to-\infty$.

To establish (4.10) we first note that in this case the bounds (3.10) hold for $F=C_+$, $U=\{\lambda\in C_+\,|\,\mathrm{Re}\lambda\leqq\lambda_0-1\}$. This is because of the way λ enters the various terms of $R_1(x,\lambda)$.

From (3.11) and (3.16)

$$A_y(\lambda)=\left[\frac{1}{2}+W(a,\lambda)\right]y(a)-\frac{1}{2}\frac{y'(a)}{iK(a,\lambda)}+\int_a^\infty (R_1\psi_1)_2. \tag{4.11}$$

The definition of K and (3.9) show that for each x,

$$\lim_{\lambda\to-\infty} W(x,\lambda)=0.$$

The definition of R shows $\int_a^\infty \|R(x,\lambda)\|dx\to0$ as $\lambda\to-\infty$. Since ψ_1 is uniformly bounded on $a\leqq x<\infty$, $\lambda\leqq\lambda_0-1$, we conclude that

$$\int_a^\infty \|R(x,\lambda)\psi_1(x,\lambda)\|\,dx\to0 \quad \text{as } \lambda\to\infty.$$

Thus to complete the proof of (4.10), we have from (4.11) and (3.8) that it is sufficient to prove as $\lambda\to-\infty$,

$$\int_a^\infty \left\{2iKW\begin{pmatrix}0&1\\1&0\end{pmatrix}\psi_1\right\}_2=\int_a^\infty 2iKW(\psi_1)_1\to0. \tag{4.12}$$

Since $iK(x,\lambda)=i(\lambda-\lambda_0+v_1(x))^{1/2}$, we have from the equation (3.15) that $(\psi_1(x,\lambda))_1\to 0$ as $\lambda\to-\infty$. Now from (3.9), we see that there is a constant k such that for $a\leqq x<\infty$, $-\infty<\lambda\leqq\lambda_0-1$,

$$|K(x,\lambda)W(x,\lambda)|\leqq k\left[|V_2(x)|+W_0(x)\right]. \tag{4.13}$$

Since $(\psi_1(x,\lambda))_1$ is uniformly bounded for $a\leqq x<\infty$, $-\infty<\lambda\leqq\lambda_0-1$, and for fixed x tends to zero as $\lambda\to-\infty$, application of (4.13) and the Lebesgue dominated convergence theorem yields (4.12).

An example of an equation of type (2.2) to which Theorem 4.1 applies is

$$-y''+\left[\frac{c}{x^2(\ln x)}+r(x)\right]y=\lambda x^{-2}y,\qquad e\leqq x<\infty, \tag{4.14}$$

where x is a constant and $\int_e^\infty x|r(x)|dx<\infty$. The transformed equation (2.3) is ($t=\ln x, h(x)=x^{1/2}, y(x)=h(x)z(t)$),

$$-\ddot{z}(t)+\left[\frac{c}{t}+x^2r(x)+\frac{1}{4}\right]z(t)=\lambda z(t),\qquad 1\leqq t<\infty,$$

which satisfies the conditions of Theorem 4.1. A calculation shows that the change of variable is a unitary map from $\mathscr{L}^2_w(e,\infty)$ onto $\mathscr{L}^2(1,\infty)$. Thus the spectral function ρ of a self-adjoint operator associated with (4.14) satisfies $\rho'(\mu)>0$ on $(\frac{1}{4},\infty)$.

Examples given by M. S. P. Eastham and H. Kalf [8, p. 89] show that v terms in (1.3) cannot be much larger without possibly introducing an eigenvalue in the continuous spectrum. As shown in [8], the equation, on $1\leqq x<\infty$,

$$y''(x)+\left[1-4x^{-1}\sin 2x+x^{-2}(2\cos^2 x+4\cos^4 x)\right]y=0$$

has a solution $y(x)=O(x^{-1})$. Thus $\lambda=1$ is an eigenvalue in the continuous spectrum $[0,\infty)$ for an appropriate boundary condition imposed at $x=1$.

As a second application of the asymptotic theory of §3, we allow the potential to go to infinity.

THEOREM 4.2. *Suppose p,n,r, and w are real locally Lebesgue integrable functions on $[a,b)$ with p,n, and w positive. Suppose p and n are of class $C^{(2)}[a,\infty)$, $\int_a^b (n/p)^{1/2}=\infty$, and $\int_a^b wh^2=\infty$ where $h=(pn)^{-1/4}$. Set $t=f(x)=\int_a^x (n/p)^{1/2}$ and suppose*

$$\left[\frac{h(ph')'}{f'}+\frac{r}{n}\right](x)=v_{11}(t)+v_{21}(t)+v_{31}(t),$$
$$\left(\frac{w}{n}\right)(x)=v_{12}(t)+v_{22}(t)+v_{32}(t)$$

where the $v_{ij}(t)$ satisfy the hypothesis (A_1). *Define an operator T_α in $\mathscr{L}^2_w(a,b)$ by $T_\alpha(y)=w^{-1}[-(py')'-(n+r)y]$ where the domain of T_α is the set of all y in $\mathscr{L}^2_w(a,b)$ such that y,y' are locally absolutely continuous, $T_\alpha(y)\in\mathscr{L}^2_w(a,b)$, and y satisfies the boundary condition $\sin\alpha\, y(a)+\cos\alpha\,(py')(a)=0$. Then T_α is self-adjoint and its spectral function ρ_α is of class $C^{(1)}(-\infty,\infty)$ with $\rho'_\alpha(\mu)>0$ for all real μ.*

Proof. As in (2.2), make the transformation

$$y(x)=h(x)z(t),\quad h=(pn)^{-1/4},\quad t=f(x)=\int_a^x (n/p)^{1/2}, \tag{4.15}$$

so that z satisfies

$$\ddot{z}(t)+[1+Q(t)]z(t)=0 \tag{4.16}$$

with, using the above notation,

$$Q(t)=[v_{11}(t)+v_{21}(t)+v_{31}(t)]+\lambda[v_{12}(t)+v_{22}(t)+v_{32}(t)].$$

With $a(\lambda)=1$, the theory of §3 is applicable. Since

$$\int_0^\infty v_{12}(t)\,dt=\int_a^b (w/n)(n/p)^{1/2}\,dx-\int_0^\infty [v_{22}(t)+v_{32}(t)]\,dt=\infty,$$

we obtain from (3.17) and (3.18) that for a solution $z(t,\lambda)$ of (4.16), as $t\to\infty$,

$$\begin{aligned}
&\operatorname{Im}\lambda>0\colon z(t,\lambda)=\exp\Big(-\int_0^t iK\Big)[A_z(\lambda)+o(1)],\\
&\operatorname{Im}\lambda=0\colon z(t,\lambda)=\exp\Big(-\int_0^t iK\Big)[A_z(\lambda)+o(1)],\\
&\qquad+\exp\Big(\int_0^t iK\Big)[\overline{A_z(\lambda)}+o(1)].
\end{aligned}\tag{4.17}$$

As in the proof of Theorem 4.1, it follows that $A_z(\lambda)\neq 0$ for λ real. Since the Wronskian of two solutions of (4.16) is constant, it follows from the asymptotic form of $z,\dot z$ for $\operatorname{Im}\lambda=0$ that $A_{z_1}(\lambda)/A_{z_2}(\lambda)$ is not real for linearly independent solutions z_1, z_2 of (4.16). After some calculations it follows that for some $\delta>0$, $0\leqq t<\infty$,

$$|z_1(t,\lambda)|^2+|z_2(t,\lambda)|^2\geqq\delta.$$

If y_1 and y_2 are the corresponding solutions of (2.2),

$$\int_a^b w\left[|y_1|^2+|y_2|^2\right]\geqq\delta\int_a^b w(pn)^{-1/2}=\infty.$$

Thus (2.2) is of limit point type at b; hence T_α as defined above is self-adjoint.

Consider the solutions θ_α, ϕ_α of (2.2) defined by the initial conditions

$$\begin{pmatrix}\theta_\alpha & \phi_\alpha\\ \theta_\alpha' & \phi_\alpha'\end{pmatrix}(a,\lambda)=\begin{pmatrix}\sin\alpha & -\cos\alpha\\ \cos\alpha & \sin\alpha\end{pmatrix}$$

and let z_θ, z_ϕ be the corresponding solutions of (4.16). Now for $\operatorname{Im}\lambda>0$ in (4.17),

$$m_\alpha(\lambda)=-\lim_{x\to b}\frac{\theta_\alpha(x,\lambda)}{\phi_\alpha(x,\lambda)}=-\lim_{t\to\infty}\frac{z_\theta(t,\lambda)}{z_\phi(t,\lambda)}=\frac{-A_{z_\theta}(\lambda)}{A_{z\phi}(\lambda)}.\tag{4.18}$$

Since A_{z_θ}, A_{z_ϕ} are continuous on C_+ and do not vanish for λ real, it follows as in (4.9) that $\operatorname{Im} m_\alpha(\mu+i\varepsilon)$ has a positive limit as $\varepsilon\downarrow 0$. This completes the proof.

The proof shows that the condition $\int_a^b w(pn)^{-1/2}=\infty$ is required to prevent the equation (2.2) from being of limit circle type at b. In this case the essential spectrum would be empty. It is also required to produce the asymptotic behavior (4.17) for $\operatorname{Im}\lambda>0$ which in turn implies (4.18).

An example of an equation which satisfies the hypothesis of Theorem 4.2 is:

$$y''+[\lambda+x^2+ax^\alpha\sin x^\beta+bxf(x)]y=0,\qquad 1\leqq x<\infty,$$

with $\beta>\alpha+2$, $\int_1^\infty|f|<\infty$, a and b constants.

5. Application to whole-line problems. We consider here only the equation

$$y''+[\lambda+v_1(x)+v_2(x)+v_3(x)]y=0, \qquad -\infty<x<\infty, \tag{5.1}$$

where the v_i satisfy the conditions of Theorems 4.1 at each of $\pm\infty$. The methods employed here will apply to other classes of equations. Following [10], let

$$v_{\pm}=\lim_{x\to\pm\infty} -v_1(x).$$

Since (5.1) is in the limit point case at $\pm\infty$, a self-adjoint operator T is defined in $\mathscr{L}^2(-\infty,\infty)$ by

$$T(y)=-(y''+[v_1(x)+v_2(x)+v_3(x)]y)$$

where the domain of T consists of all $y\in\mathscr{L}^2(-\infty,\infty)$ with y,y' locally absolutely continuous and $T(y)\in\mathscr{L}^2(-\infty,\infty)$. We define a basis θ,ϕ of (5.1) by the initial values

$$\begin{pmatrix}\theta & \phi\\ \theta' & \phi'\end{pmatrix}(0,\lambda)=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}.$$

The Titchmarsh–Weyl m-coefficients $m_{\pm}$ are defined on $\operatorname{Im}\lambda>0$ by

$$m_{\pm}(\lambda)=-\lim_{x\to\pm\infty}\frac{\theta(x,\lambda)}{\phi(x,\lambda)}.$$

Then for $\operatorname{Im}\lambda>0$, $\operatorname{Im}m_+(\lambda)>0$ and $\operatorname{Im}m_-(\lambda)<0$ (cf. [9]). The spectral function ρ of T is a 2×2 matrix and depends on the choice of basis [7, Chap. 9]. However, any two such ρ's are similar [9]. For the basis above, we have at points of continuity t,s,

$$\rho(t)-\rho(s)=\lim_{\varepsilon\downarrow0}\frac{1}{\pi}\int_s^t \operatorname{Im}M(u+i\varepsilon)\,du \tag{5.2}$$

where M is given by

$$M=\begin{pmatrix}1/(m_--m_+) & (m_++m_-)/2(m_--m_+)\\ (m_++m_-)/2(m_--m_+) & m_+m_-/(m_--m_+)\end{pmatrix} \tag{5.3}$$

$$=\begin{pmatrix}m_{11} & m_{12}\\ m_{21} & m_{22}\end{pmatrix}.$$

Suppose we write for $\operatorname{Im}\lambda>0$, with a,b,c,d real,

$$m_+(\lambda)=a(\lambda)+ib(\lambda), \qquad m_-(\lambda)=c(\lambda)+id(\lambda).$$

Then a straightforward calculation yields

$$\begin{aligned}
&\operatorname{Im}m_{11}=\frac{b-d}{D}, \qquad D=(c-a)^2+(b-d)^2,\\
&\operatorname{Im}m_{12}=\operatorname{Im}m_{21}=\frac{bc-ad}{D},\\
&\operatorname{Im}m_{22}=\frac{bc^2-a^2d+bd^2-b^2d}{D},\\
&\det\operatorname{Im}M=\frac{-bd}{D}.
\end{aligned} \tag{5.4}$$

Now apply Theorem 4.1 to T. Note that to apply Theorem 4.1 to (5.1) on $(-\infty,0]$, the change of variable $t=f(x)=-x$ is made. This results in $m_-(\lambda)\to\infty$ as $\lambda\to-\infty$. Assume $v_-<v_+$ (the other cases are similar). From the equations (5.4) we can now draw the following conclusions. Note that a,b (c,d) have a continuous extension to the real axis except at poles of $m_+(m_-)$ (by the proof of Theorem (4.1)). Further, (4.9) implies $b(\lambda)>0$ on (v_+,∞) and $d(\lambda)<0$ on (v_-,∞). The argument below follows that of [10] in cases (1) and (2).

1. $v_+<\mu<\infty$. Then ρ is of class $C^{(1)}(v_+,\infty)$; further $\rho'_{11}(\mu)>0$, $\rho'_{22}(\mu)>0$ since $b(\mu)>0$, $d(\mu)<0$. Also rank $\rho'(\mu)=2$.

2. $v_-<\mu<v_+$. If μ is not a pole of m_+, then

$$\operatorname{Im}M(\mu)=\begin{pmatrix}-d/D & -ad/D\\ -ad/D & -a^2d/D\end{pmatrix}(\mu).$$

If μ is a pole of m_+, then as $\lambda\to\mu$

$$M(\lambda)\to\begin{pmatrix}0 & -1/2\\ -1/2 & m_-(\mu)\end{pmatrix},\qquad \operatorname{Im}M(\mu)\to\begin{pmatrix}0 & 0\\ 0 & -d(\mu)\end{pmatrix}.$$

Thus $\rho\in C^{(1)}(v_-,v_+)$, $\operatorname{rank}\rho'(\mu)=1$ on (v_-,v_+). Also $\rho'_{11}(\mu)>0$ except at a pole of m_+ in which case $\rho'_{11}(\mu)=0$, $\rho'_{22}(\mu)>0$; $\rho'_{22}(\mu)>0$ except at zeros of m_+.

3. $\mu<v_-$. m_+ and $m_-$are meromorphic on $\operatorname{Re}\lambda<v_-$. Thus $\operatorname{Im}M=0$ except at poles of M. These poles occur either where $a(\mu)=c(\mu)$ or where m_+ and m_- have a simultaneous pole. The poles of M, which are the eigenvalues of T, are bounded below since $m_+(\lambda)\to-\infty$, $m_-(\mu)\to\infty$ as $\lambda\to-\infty$. Thus v_- is the only possible accumulation point of these poles.

Finally we show at a pole μ_0 of M, $\mu_0<v_-$, the residue of M at μ_0 is of rank one. This means the eigenspace is of dimension one. If μ_0 is a pole of both m_+ and m_-, with residues σ_+ and σ_- respectively, then a calculation using (5.3) shows that the residue of M is

$$\lim_{\varepsilon\to0} i\varepsilon M(\mu_0+i\varepsilon)=\begin{pmatrix}0 & 0\\ 0 & \sigma_+\sigma_-/(\sigma_--\sigma_+)\end{pmatrix}.$$

If $m_-(\mu_0)=m_+(\mu_0)$ and $m_\pm$ are analytic at μ_0, then

$$m_\pm(\lambda)=a_0^\pm+a_1^\pm(\lambda-\mu_0)+\cdots$$

where all the $a_i^\pm$ are real. Further, $a_1^+>0$ since $\operatorname{Im}m_+(\lambda)>0$ on $\operatorname{Im}\lambda>$; similarly $a_1^-<0$. A calculation using (5.3) again gives the residue of M at μ_0 as

$$\begin{pmatrix}(a_1^+-a_1^-)^{-1} & (a_0^++a_0^-)/2(a_1^+-a_1^-)\\ (a_0^++a_0^-)/2(a_1^+-a_1^-) & a_0^+a_0^-/(a_1^+-a_1^-)\end{pmatrix}.$$

In both cases the residue has rank one.

The above calculations show a connection with recent work of R. Carmona [5]. Return to (5.3) and suppose on an interval I, one of m_+,m_-, say m_+, has $\operatorname{Im}m_+(\lambda)$ continuous on

$$I_\varepsilon=\{\lambda\,|\,\operatorname{Re}\lambda\in I,0<\operatorname{Im}\lambda\leqq\varepsilon\}$$

with a continuous extension to the closure of the above set. Further suppose on $\bar{I}_\varepsilon$, $\operatorname{Im} m_+(\lambda) > 0$. Hence on I_ε, $\operatorname{Im} m_+(\lambda)$ is bounded above and below by positive numbers. An examination of the formulas (5.4) shows that there is a constant k so that

$$|\operatorname{Im} m_{ij}(\lambda)| \leqq k$$

for $\lambda \in I_\varepsilon$, $i,j = 1,2$. This means that ρ_{ij} is absolutely continuous on I and has Lipschitz constant k. Thus the behavior of the potential at the other singular point cannot prevent the spectrum from being absolutely continuous on I. This phenomenon has been reported by R. Carmona [5] for a class of random polynomials which are of class $\mathscr{L}^p$, $p = 1$, at one singular endpoint.

6. The hydrogen atom. In this section we consider the energy operator of the hydrogen atom and show how the results of §§4 and 5 apply. The equation is [11, Chap. 10].

$$y'' + \left[\lambda + \frac{a}{x} - \frac{b}{x^2}\right] y = 0, \qquad 0 < x < \infty, \tag{6.1}$$

where $a > 0$ and $b = l(l+1) \geqq 0$. We split $0 < x < \infty$ at $x = 1$ and use any basis to define m_+ and m_-. First consider (6.1) on $1 \leqq x < \infty$. Then a/x is a v_1 type term of Theorem 4.1 and $-b/x^2$ is a v_3 type term. Thus m_+ behaves as follows. (i) On $0 < \lambda < \infty$, $\lim \operatorname{Im} m_+(\lambda + i\varepsilon)$ exists as $\varepsilon \downarrow 0$ and defines a continuous and positive function. (ii) On $\operatorname{Re}\lambda < 0$, m_+ is meromorphic and its poles are bounded below. If we appeal to the connection between oscillation theory and spectral theory [12, p. 163], we conclude that m_+ has an infinite number of poles on $(-\infty, 0)$ (thus they converge to 0) because (6.1) is oscillatory at infinity for $\lambda = 0$. The oscillation test $\int_1^x (as^{-1} - bs^{-2})\,dx \to \infty$ as $x \to \infty$ shows (6.1) is oscillatory at infinity for $\lambda = 0$ (cf. [12, p. 208]).

To consider m_-, we transform the singular point at $x = 0$. Let

$$y(x) = x^{1/2} z(t), \quad t = -\ln x, \quad 0 < x \leqq 1.$$

Then $x = 0$ is transformed to $t = \infty$, and a calculation shows that z satisfies the equation,

$$\ddot{z}(t) + \left[-\left(b + \frac{1}{4}\right) + ae^{-t} + \lambda e^{-2t}\right] z(t) = 0, \qquad 0 \leqq t < \infty. \tag{6.2}$$

By the Sturm comparison theorem (6.2) is nonoscillatory at infinity for every λ. Thus (6.1) is nonoscillatory at 0 for every λ. This means (cf. [12, p. 163]) any eigenvalue problem associated with (6.1) on $0 < x \leqq 1$ has as spectrum a sequence of eigenvalues increasing to infinity. Thus m_- is meromorphic on the complex plane with poles a sequence on the real axis increasing to infinity.

Thus by the argument of §5, we have for the spectral matrix of (6.1):

(i) On $(0, \infty)$: $\rho \in C^{(1)}(0, \infty)$; $\operatorname{rank} \rho'(\mu) = 1$; $\rho'_{11}(\mu) > 0$ except at a pole of m_- where $\rho'_{11} = 0$, $\rho'_{22} > 0$; $\rho'_{22}(\mu) > 0$ except at a zero of m_-.

(ii) On $(-\infty, 0)$: The sequence of (6.1) is purely discrete with spectrum bounded below. The eigenvalues cluster at 0. This latter point follows from considering a graph of $\operatorname{Re} m_+$, $\operatorname{Re} m_-$ on $(-\infty, 0)$. m_+ (which has negative residues) has a sequence of poles clustering at 0. m_- (which has positive residues) has a finite number of poles on $(-\infty, 0)$. The two graphs have a finitely number of intersections with cluster point zero. Alternatively, oscillation theory may be applied as in [12].

By the theory of §4 we could add perturbation terms to (6.1), such as $x \sin x^4$, without changing the basic conclusions above.

Acknowledgments. The authors gratefully acknowledge helpful discussions concerning this work with Professor S. G. Halvorsen of the University of Trondheim, Norway.

ASYMPTOTIC BEHAVIOR OF PERIODIC STRAIN STATES*

KENNETH B. HOWELL†

Abstract. The asymptotic behavior of the general periodic strain elastic state is discussed. The components of the elastic state are initially assumed to be bounded by an arbitrary polynomial. It is then shown that many of the components—for the case of plane strain, all of the components—can be approximated by second degree polynomials whose coefficients can be readily computed from data generally available in such problems. The error in using the approximation at different points in the elastic body is on the order of the reciprocal of any polynomial of the distance to the boundary of the body.

Consequences of these results are then discussed with regard to Saint-Venant's principle, the periodicity of solutions to periodic boundary value problems, the uniqueness of the solutions to periodic and "slightly periodic" boundary value problems, and various formulations of the theorem of work and energy.

1. Introduction. When dealing with problems involving infinite domains, one must have some concern about the asymptotic behavior of the functions "near infinity". Often, for example, it is desired—and assumed—that one or more of the functions and their derivatives rapidly and uniformly approach well defined (and computable) limits "at infinity". Muskhelishvili [6] and Gurtin and Sternberg [1] have shown the extent to which this type of asymptotic behavior can be expected in classical elastostatic problems on domains exterior to some compact set. (See also Knops and Payne [5, Chap. 6] for a discussion of similar problems on the whole- and half-space.) Unfortunately, it is not always clear that the asymptotic behavior one would desire or expect can be guaranteed on more complex domains. Indeed, in many cases just determining what behavior should be desired or expected is a significant problem in itself. The problem is often complicated by the fact that the asymptotic behavior may be strongly dependent on the direction along which "infinity" is approached. One class of problems in which this difficulty arises is the class of periodic and slightly periodic boundary value problems in elasticity. In this paper we shall examine the behavior of periodic strain states at great distances from the boundary of the elastic body. It shall be discovered—in Lemma 6.1 and Theorem 7.1—that certain (in some cases, all) components of the elastic state rapidly approach fixed values as the components are measured at increasing distances from the boundary of the domain. This "asymptotic state" is easily computed from the values of the displacement and traction on a portion of the boundary. In spite of the rather strong bounds which will be derived, the bounds initially assumed are quite weak—namely that the components of the elastic state are bounded by some arbitrary polynomial. After the derivation of these results, the implications of this asymptotic behavior will be discussed (in §§8 and 9) with regard to such issues as Saint-Venant's principle, the periodicity of solutions to periodic boundary value problems, and the uniqueness of solutions to slightly periodic boundary value problems. In addition, extensions of the theorem of work and energy will be discussed.

This is the second of two papers dealing with directionally dependent asymptotic behavior of biharmonic functions. In the first (Howell [4]) bounds were derived on the derivatives of the general biharmonic function based on bounds assumed for the original function. The major results of this first paper will be used extensively here, and are summarized here in §3.

2. Preliminaries: Elasticity. Whenever convenient, the points in k-dimensional Euclidean space will be identified with the vectors in $\mathbb{R}^k$ in the standard manner—i.e., through the agency of a suitably chosen Cartesian coordinate system. The induced orthonormal frame of vectors will be denoted by $\{\mathbf{e}^1, \mathbf{e}^2, \cdots, \mathbf{e}^k\}$. As usual, if $\mathbf{v}$ and $\mathbf{T}$ are, respectively, a vector and a (second rank) tensor, then v_i will denote $\mathbf{v}\cdot\mathbf{e}^i$ and T_{ij} will denote $\mathbf{e}^i\cdot\mathbf{T}\mathbf{e}^j$.

The (elastic) body will be denoted by $\mathscr{B}$ and its closure by $\mathrm{cl}\,\mathscr{B}$. It occupies an open connected subset of k-dimensional Euclidean space such that, if $\mathscr{D}$ is any ball of finite radius, then $\partial(\mathscr{B}\cap\mathscr{D})$ consists of a finite union of smooth $(k-1)$-dimensional manifolds with boundaries. In this paper, it will be assumed that the ambient space is either two- or three-dimensional and (within this range) k, the dimension of the space, will be arbitrary unless otherwise noted. The terms "volume" and "area" are to be interpreted accordingly. In particular, if $k=2$ then "volume" actually refers to area and "surface area" actually refers to arc length.

The outward pointing unit normal vector field on the boundary of $\mathscr{B}$ (or any subbody of $\mathscr{B}$ under discussion) will be denoted by $\mathbf{n}$.

The displacement, strain, and stress fields of an elastic state will be denoted by $\mathbf{u}$, $\mathbf{E}$, and $\mathbf{S}$, respectively, and are related throughout $\mathscr{B}$ by

$$\begin{aligned}\mathbf{E} &= \operatorname{sym}\nabla\mathbf{u},\\ \mathbf{S} &= \mathbf{C}[\mathbf{E}],\\ \operatorname{div}\mathbf{S}+\mathbf{b} &= \mathbf{0}\end{aligned}$$

where $\mathbf{C}$ is the elasticity tensor field on $\mathscr{B}$ and $\mathbf{b}$ denotes the body forces. If $\mathbf{n}$ is defined, $\mathbf{s}$ will denote the corresponding surface traction field, $\mathbf{Sn}$. Unless otherwise noted, the standard continuity and differentiability conditions assumed in classical treatments will be assumed here. The reader is reminded that $\mathbf{S}$ is a symmetric tensor field, that $\mathbf{C}[\mathbf{W}]$ vanishes whenever $\mathbf{W}$ is a skew tensor, and that if $\mathbf{E}$ vanishes in some region, then $\mathbf{u}$ is a rigid displacement in that region (i.e., $\nabla\mathbf{u}$ is a fixed skew tensor).

In this paper it shall always be assumed that the media composing $\mathscr{B}$ is homogeneous and isotropic. Thus, there will be two constants, μ and λ (the Lamé moduli) such that for any strain field, $\mathbf{E}$,

$$\mathbf{S}=\mathbf{C}[\mathbf{E}]=2\mu\mathbf{E}+\lambda(\operatorname{tr}\mathbf{E})\mathbf{Id}$$

where $\mathbf{Id}$ denotes the identity tensor. The corresponding displacement satisfies Navier's equation:

$$\mu\nabla\mathbf{u}+(\mu+\lambda)\nabla\operatorname{div}\mathbf{u}+\mathbf{b}=\mathbf{0}.$$

In addition, it is to be understood that $\mu(\lambda+2\mu)\neq 0$. Under these assumptions, it is well-known that, if $\mathbf{b}$ is both curl-free and divergence-free, then $\mathbf{u}$, $\mathbf{E}$, and $\mathbf{S}$ are biharmonic and infinitely differentiable on $\mathscr{B}$.

At times, additional assumptions will be made on the elasticity field, $\mathbf{C}$. One common assumption will be that $\mathbf{C}$ is positive definite. This means there exists a positive constant, c, such that given any symmetric tensor, $\mathbf{E}$, then

$$\mathbf{E}\cdot\mathbf{C}[\mathbf{E}]>c|\mathbf{E}|^2.$$

If $\mathscr{B}$ is two-dimensional, then $\mathbf{C}$ is positive definite if both $\mu>0$ and $\lambda+2\mu>0$. For three-dimensional bodies positive definiteness is equivalent to the Lamé moduli satisfying $\mu>0$ and $3\lambda+2\mu>0$. Occasionally, the slightly weaker assumption that $\mathbf{C}$ is strongly elliptic will be made. In this case the Lamé moduli satisfy $\mu(\lambda+2\mu)>0$, regardless of the dimension of the space.

For a given (mixed) boundary value problem, the Lamé moduli, μ and λ and the body force field, $\mathbf{b}$, are specified and the boundary of $\mathscr{B}$ is partitioned into two subsurfaces, $\mathscr{S}_1$ and $\mathscr{S}_2$, each of which is the domain of a predetermined vector field, $\hat{\mathbf{u}}$ and $\hat{\mathbf{s}}$, respectively. A solution to the boundary value problem consists of an elastic state, $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ satisfying

$$\mathbf{u} = \hat{\mathbf{u}} \quad \text{on } \mathscr{S}_1,$$
$$\mathbf{s} = \hat{\mathbf{s}} \quad \text{on } \mathscr{S}_2.$$

If $\mathscr{S}_1$ consists of the entire boundary of $\mathscr{B}$, the problem is referred to as a (surface) displacement problem, while if $\mathscr{S}_2$ equals the boundary of $\mathscr{B}$ (up to a set of surface measure zero), then the problem is termed a (surface) traction problem. If the body is unbounded, one also usually desires that the elastic state at the point $\mathbf{x}$ behaves "reasonably" as $|\mathbf{x}|$ approaches infinity along one or more paths in $\mathscr{B}$. Precisely what is meant by "reasonable" and the extent to which "reasonable behavior" can be expected, depends on the particular problem at hand and is the main object of much of the study presented in this paper.

Given any mixed boundary value problem, there exists the corresponding null boundary value problem in which $\hat{\mathbf{u}}$, $\hat{\mathbf{s}}$, and $\mathbf{b}$ all vanish on their respective domains (μ, λ, $\mathscr{S}_1$, and $\mathscr{S}_2$ are as in the original problem). An obvious, but important, fact is that the difference between two solutions to the same mixed boundary value problem is a solution to the corresponding null boundary value problem.

Other types of boundary value problems can be described. In this paper the term "boundary value problem" implies that μ, λ, and $\mathbf{b}$ are prescribed and that if $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ is the difference between any two solutions to the problem then $\mathbf{u} \cdot \mathbf{s}$ vanishes almost everywhere on the boundary of $\mathscr{B}$. It is trivial to verify that this includes the mixed boundary value problems described above. For this more general class of boundary value problems, the corresponding null boundary value problem is defined in the obvious manner.

The uniqueness of the solutions to various boundary value problems is discussed in the following two theorems. They will be used and refined later on in this paper.

THEOREM 2.1. *Let $\mathscr{B}$ be an unbounded body with positive definite elasticity field. Suppose that $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ is the difference between two solutions to the same general boundary value problem on $\mathscr{B}$ and that*

$$\int_{\mathscr{B} \cap \partial \mathscr{D}_R} |\mathbf{u}|^2 da = O(R) \quad \text{as } R \to \infty$$

where $\mathscr{D}_R$ is the ball of radius R about the origin. Then $\mathbf{E}$ and $\mathbf{S}$ vanish on $\mathscr{B}$ and $\mathbf{u}$ is a rigid displacement.

THEOREM 2.2. *Let $\mathscr{B}$ be a two-dimensional unbounded body whose Lamé moduli satisfy*

$$\mu(2\mu + \lambda)(\mu + \lambda) \neq 0$$

and for which there exists a fixed vector, $\mathbf{v}^0$, such that

$$\mathbf{v}^0 \cdot \mathbf{n} > 0$$

almost everywhere (in the surface measure) on $\partial \mathscr{B}$. If $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ is the difference between two solutions to the same traction problem on $\mathscr{B}$ such that

$$\int_{\mathscr{B} \cap \partial \mathscr{D}_R} |\nabla \mathbf{u}||\mathbf{S}| \, da = o(1) \quad \text{as } R \to \infty$$

where $\mathscr{D}_R$ is the ball of radius R about the origin, and

$$|\mathbf{S}(\mathbf{x})| = o(1) \quad \text{as } |\mathbf{x}| \to \infty,$$

then **E** *and* **S** *vanish on* $\mathscr{B}$ *and* **u** *is a rigid displacement.*

The above two theorems, in somewhat more general form, appear in Howell [2] (Theorems 2.1 and 5.2, respectively). In the same paper is a theorem very similar to Theorem 2.1 dealing with the displacement problem on bodies with a strongly elliptic elasticity (Theorem 4.1). It is not difficult, in fact, to show that all the results in the present paper involving a "general boundary value problem" on a body with "positive definite elasticity" will hold equally well for a "displacement problem" on a body with "strongly elliptic elasticity". This will be left to the interested reader.

3. Preliminaries: Asymptotic behavior of biharmonic functions. We are specifically concerned with the behavior of elastic states "near infinity". Since the components of the states which will be discussed are biharmonic, it is appropriate to quickly review the notation and major results reported in Howell [4] concerning the behavior of biharmonic functions "near infinity".

Let $\mathbf{x}$ be a fixed point in space, $\mathbf{v}$ a unit vector, and θ a scalar satisfying $0 < \theta < \pi/2$. The corresponding cone, $\mathscr{K} = \mathscr{K}(\mathbf{x}, \mathbf{v}, \theta)$, is the region in space given by

$$\mathscr{K} = \{\mathbf{y} : (\mathbf{y} - \mathbf{x}) \cdot \mathbf{v} < |\mathbf{y} - \mathbf{x}| \cos\theta\}.$$

This corresponds, of course, to the standard notion of a solid cone with vertex at $\mathbf{x}$, axis in the direction of $\mathbf{v}$, and whose sides make an angle of θ with the axis.

If, instead, one has a set of points in space, Σ, and a unit vector field on Σ, $\mathbf{v}(\mathbf{x})$, and a single fixed θ with $0 < \theta < \pi/2$, then the corresponding cone, $\mathscr{K} = \mathscr{K}(\Sigma, \mathbf{v}, \theta)$, is given by

$$\mathscr{K}(\Sigma, \mathbf{v}, \theta) = \bigcup_{\mathbf{x} \in \Sigma} \mathscr{K}(\mathbf{x}, \mathbf{v}(\mathbf{x}), \theta).$$

Finally, if n is a nonnegative integer, the nth subcone, $\mathscr{K}_n$, of $\mathscr{K}(\Sigma, \mathbf{v}, \theta)$ is defined by

$$\mathscr{K}_n = \mathscr{K}(\Sigma, \mathbf{v}, 2^{-n}\theta).$$

It may be noted that $\mathscr{K}_0 = \mathscr{K}$.

THEOREM 3.1. *Let Σ be a set of points in space, $\mathbf{v}$ a unit vector field on Σ, θ a constant with $0 < \theta \leqq \pi/2$, and $\mathscr{K} = \mathscr{K}(\Sigma, \mathbf{v}, \theta)$, and assume that*

$$\Sigma \subseteq \mathrm{cl}\mathscr{K}.$$

Let f be a positive-valued, locally integrable, nonincreasing function on $[0, \infty)$; let $\mathbf{m}$ be some fixed unit vector, and let ζ, ν, and c be real constants with c positive and $-1 < \nu$. Finally, let $\rho(\mathbf{x})$ denote the minimum distance from $\mathbf{x}$ to the closure of Σ.

i. *If $-1 < \nu \leqq 0$ and ϕ is a biharmonic function on $\mathscr{K}$ satisfying*

$$|\phi(\mathbf{x})| \leqq c(1 + |\mathbf{m} \cdot \mathbf{x}|)^{\nu} [\rho(\mathbf{x})]^{\zeta} f(\rho(\mathbf{x}))$$

for all $\mathbf{x}$ in $\mathscr{K}$, then

$$|\nabla\phi(\mathbf{x})| \leqq Bc(1 + |\mathbf{m} \cdot \mathbf{x}|)^{\nu} [\rho(\mathbf{x})]^{\zeta - 1} f\left(\frac{1}{2}\alpha\rho(\mathbf{x})\right)$$

for all $\mathbf{x}$ *in* $\mathscr{K}_1$, *where*

$$\alpha = \sin\left(\frac{1}{2}\theta\right), \qquad B = \frac{9}{2}\left[\frac{2}{\alpha}\right]^{|\zeta|+1} C_\nu$$

and C_ν *is a constant depending on* ν *only.*

ii. *If* $0 < \nu$ *and* ϕ *and* ψ *are biharmonic functions on* $\mathscr{K}$ *satisfying*

$$|\phi(\mathbf{x})| \leqq c(1+|\mathbf{m}\cdot\mathbf{x}|)^\nu [\rho(\mathbf{x})]^\zeta f(\rho(\mathbf{x})),$$
$$|\psi(\mathbf{x})| \leqq c\{[\rho(\mathbf{x})]^{\zeta+\nu} + (1+|\mathbf{m}\cdot\mathbf{x}|)^\nu [\rho(\mathbf{x})]^\zeta\} f(\rho(\mathbf{x}))$$

for all $\mathbf{x}$ *in* $\mathscr{K}$, *then*

$$|\nabla\phi(\mathbf{x})| \leqq Bc\{[\rho(\mathbf{x})]^{\zeta+\nu-1} + (1+|\mathbf{m}\cdot\mathbf{x}|)^\nu [\rho(\mathbf{x})]^{\zeta-1}\} f\left(\frac{1}{2}\alpha\rho(\mathbf{x})\right),$$
$$|\nabla\psi(\mathbf{x})| \leqq Mc\{[\rho(\mathbf{x})]^{\zeta+\nu-1} + (1+|\mathbf{m}\cdot\mathbf{x}|)^\nu [\rho(\mathbf{x})]^{\zeta-1}\} f\left(\frac{1}{2}\alpha\rho(\mathbf{x})\right)$$

for all $\mathbf{x}$ *in* $\mathscr{K}_1$, *where*

$$\alpha = \sin\left(\frac{1}{2}\theta\right),$$
$$B = \frac{9}{2^{\nu+1}}\left[\frac{2}{\alpha}\right]^{|\zeta|+\nu+1} C_\nu,$$
$$M = \frac{9[2^{|\zeta|+\nu} C_0 + 2^{|\zeta|} C_\nu]}{2^{|\zeta|+\nu+1}}$$

and C_0 *and* C_ν *are constants depending only on* ν.

4. Preliminaries: Periodicity. Let $\mathbf{p}$ be a fixed nonzero vector. A scalar-, vector-, or tensor-valued function, ϕ, with domain Ω is said to be periodic (with period $\mathbf{p}$) if both of the following hold:

1. $\mathbf{x}$ is in Ω if and only if $\mathbf{x}+\mathbf{p}$ is in Ω.
2. $\phi(\mathbf{x}+\mathbf{p}) = \phi(\mathbf{x})$ for every $\mathbf{x}$ in Ω.

For convenience, the following conventions will be implicit for the remainder of this paper:

1. The Cartesian coordinant system mentioned in the first paragraph of §2 is chosen so that

$$\mathbf{p} = p\mathbf{e}^1$$

where $p = |\mathbf{p}|$.

2. Unless otherwise stated, all periodic functions have the same period, $\mathbf{p}$.

A periodic boundary value problem is a boundary value problem in which the prescribed data ($\mathbf{b}$ and the boundary data) is given by periodic functions. An elastic state, $(\mathbf{u}, \mathbf{E}, \mathbf{S})$, on $\mathscr{B}$ may have periodic displacement, periodic strain, or periodic stress. Clearly, if the displacement is periodic so is the strain, and if the strain is periodic so is the stress. Likewise, if $\mathbf{C}$ (when restricted to the symmetric tensors) is invertible, then periodic stress implies periodic strain. Periodic strain, however, does not necessarily imply periodic displacement. A trivial example would be an elastic state in which $\mathbf{u}$ is a rigid displacement and $\mathbf{E}$ vanishes everywhere. Less trivial examples will be found in the next section. Perhaps even more disconcerting is an example of a solution to a periodic boundary value problem in which the strain is not periodic. Such an example may be found in Howell [3, §3].

A somewhat more general class of problems is the class of *slightly* periodic boundary value problems. A problem is said to be "slightly periodic" if its corresponding null boundary value problem—but not necessarily the original problem—is a periodic boundary value problem. An obvious example of a slightly periodic problem would be any traction problem on a half-space.

For many slightly periodic problems it will be convenient to define corresponding "period sections". Let $\mathbf{x}$ be any point in space and let $\mathscr{L}_{\mathbf{x}}^0$ be any plane through $\mathbf{x}$ which is not parallel to $\mathbf{p}$—that is, $(\mathbf{y}-\mathbf{x})\cdot\mathbf{p}$ is nonzero for every $\mathbf{y}\neq\mathbf{x}$ in $\mathscr{L}_{\mathbf{x}}^0$. $\mathscr{L}_{\mathbf{x}}$ will denote the intersection of $\mathscr{L}_{\mathbf{x}}^0$ with $\mathscr{B}$, while $\mathscr{P}_{\mathbf{x}}$ and $\mathscr{P}$ will both denote the set

$$\mathscr{P}=\{\mathbf{y}\in\mathscr{B}:\text{ for some } 0<\alpha<1,\ \mathbf{y}-\alpha\mathbf{p}\in\mathscr{L}_{\mathbf{x}}^0\}$$

$\mathscr{P}$ will also be referred to as a period section. It should be obvious that the boundary of $\mathscr{P}$ is the disjoint union of $\partial\mathscr{P}\cap\partial\mathscr{B}$ with the two parallel "faces" of $\mathscr{P}$, $\mathscr{L}_{\mathbf{x}}$ and $\mathscr{L}_{\mathbf{x}+\mathbf{p}}$. It should also be clear that if $\mathbf{n}$ is the outward normal vector field to $\mathscr{P}$ on $\partial\mathscr{P}$ and $\mathbf{y}$ is a point on $\mathscr{L}_{\mathbf{x}}$, then $\mathbf{n}(\mathbf{y})=-\mathbf{n}(\mathbf{y}+\mathbf{p})$.

Proofs of the following two theorems may be found in Howell [3, Lemma 4.1 and Thm. 3.1, respectively]. The first discusses the extent to which the displacement corresponding to a periodic strain state may, itself, fail to be periodic. The second theorem deals with the uniqueness of solutions to certain slightly periodic boundary value problems.

THEOREM 4.1. *Let* $(\mathbf{u},\mathbf{E},\mathbf{S})$ *be an elastic state on* $\mathscr{B}$ *with periodic strain,* $\mathbf{E}$. *Then, there is a fixed skew tensor,* $\overline{\mathbf{W}}$, *a constant,* κ, *and a fixed vector,* $\bar{\mathbf{u}}$, *such that*

$$\mathbf{p}\cdot\bar{\mathbf{u}}=0$$

and, for each $\mathbf{x}$ *in* $\mathscr{B}$,

$$\mathbf{u}(\mathbf{x}+\mathbf{p})-\mathbf{u}(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}.$$

Furthermore, if $\mathbf{w}$ *is the rigid displacement given by*

$$\mathbf{w}(\mathbf{x})=p^{-2}[(\mathbf{p}\otimes\bar{\mathbf{u}})-(\bar{\mathbf{u}}\otimes\mathbf{p})]\mathbf{x}$$

and $\tilde{\mathbf{u}}$ *given by*

$$\tilde{\mathbf{u}}(\mathbf{x})=\mathbf{u}(\mathbf{x})+\mathbf{w}(\mathbf{x}),$$

then, for every $\mathbf{x}$ *in* $\mathscr{B}$,

$$\tilde{\mathbf{u}}(\mathbf{x}+\mathbf{p})-\tilde{\mathbf{u}}(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}.$$

THEOREM 4.2. *Assume that the elasticity tensor is positive definite. Let* $(\mathbf{u},\mathbf{E},\mathbf{S})$ *be the difference between two solutions to the same general boundary value problem on* $\mathscr{B}$ *and assume that* $\mathbf{u}$ *is periodic. If, letting* $\mathscr{D}_R$ *be the circular cylinder of radius* R *about the* X_1*-axis,*

$$\int_{\mathscr{P}\cap\partial\mathscr{D}_R}|\mathbf{u}|^2\,da=O(R)\quad\text{as } R\to\infty, \tag{4.1}$$

then $\mathbf{E}$ *and* $\mathbf{S}$ *vanish on* $\mathscr{B}$ *and* $\mathbf{u}$ *is a rigid displacement.*

Henceforth, whenever $(\mathbf{u},\mathbf{E},\mathbf{S})$ is a periodic strain state, $\overline{\mathbf{W}}$, κ, and $\bar{\mathbf{u}}$ will denote, respectively, the skew tensor, constant, and vector whose existence is guaranteed by Theorem 4.1. In addition, if $\mathscr{B}$ is two-dimensional, then ω will denote the constant such that

$$\overline{\mathbf{W}}=\begin{pmatrix}0 & \omega\\ -\omega & 0\end{pmatrix}$$

while if $\mathscr{B}$ is three-dimensional, then ω_1, ω_2, and ω_3 will denote the constants such that

$$\overline{\mathbf{W}} = \begin{pmatrix} 0 & \omega_1 & \omega_2 \\ -\omega_1 & 0 & \omega_3 \\ -\omega_2 & -\omega_3 & 0 \end{pmatrix}.$$

It should be observed that the proof of Theorem 4.2, above, required a rather straightforward modification of the proof of Theorem 2.1. A similar modification can easily be made in the proof of Theorem 5.2 from Howell [2]. The resulting theorem (for two-dimensional problems) is given below. The details of the proof are left to the reader.

THEOREM 4.3. *Let $\mathscr{B}$ be a two-dimensional unbounded body whose Lamé moduli satisfy*

$$\mu(2\mu+\lambda)(\mu+\lambda) \neq 0$$

and for which there exists a fixed vector, $\mathbf{v}^0$, such that

$$\mathbf{v}^0 \cdot \mathbf{n} > 0$$

almost everywhere (in the surface measure) on $\partial\mathscr{B}$. Let $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ be the difference between two solutions to the same slightly periodic traction problem on $\mathscr{B}$ such that

$$\int_{\mathscr{P}\cap\partial\mathscr{D}_R} |\nabla\mathbf{u}||\mathbf{S}|\, da = o(1) \quad \text{as } R \to \infty \tag{4.2}$$

where $\mathscr{D}_R$ is the cylinder of radius R about the X_1-axis, and

$$|\mathbf{S}(\mathbf{x})| = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}. \tag{4.3}$$

If the stress field, $\mathbf{S}$, is periodic and the corresponding skew tensor, $\overline{\mathbf{W}}$, is the zero tensor, then $\mathbf{E}$ and $\mathbf{S}$ vanish on $\mathscr{B}$ and $\mathbf{u}$ is a rigid displacement.

For virtually every case of interest, Lemma 5.3 from Howell [3] can be employed to show that in Theorem 4.3, above, the assumption that $\overline{\mathbf{W}}$ vanish is unnecessary. In §6 of this paper, however, the asymptotic behavior of periodic strain states shall be studied in great detail. As a corollary of this study and Theorem 3.1, it shall be seen that, in many cases, uniqueness theorems comparable to the above two can be proven without assuming a periodic strain and with conditions (4.1), (4.2), and (4.3) replaced by much weaker assumptions.

5. Three important periodic strain states. Three special examples of periodic strain states will now be presented. To distinguish these states from the others, they shall be termed "base periodic strain states." While of some interest as counterexamples demonstrating the limitations of Theorems 4.2 and 4.3, the main reason for introducing these states—especially the first state below—will be their intimate relationship with the asymptotic behavior "near infinity" of other elastic states.

The base periodic strain state associated with two-dimensional periodic strain states. If $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ is a two-dimensional periodic strain state with

$$\mathbf{u}(\mathbf{x}+\mathbf{p}) - \mathbf{u}(\mathbf{x}) = \overline{\mathbf{W}}\mathbf{x} + \kappa\mathbf{p} + \bar{\mathbf{u}},$$

then the associated base periodic strain state $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is given by:

$$\mathbf{u}^*(x,y)=\frac{\omega}{2p}\begin{pmatrix}2xy\\-x^2\end{pmatrix}+\kappa\begin{pmatrix}x\\0\end{pmatrix}-\frac{\lambda}{2(2\mu+\lambda)p}\begin{pmatrix}0\\\omega y^2+2p\kappa y\end{pmatrix}+\left[\frac{\omega}{2}+\frac{\bar{u}_2}{p}\right]\begin{pmatrix}-y\\x\end{pmatrix},$$

$$\mathbf{E}^*=\operatorname{sym}\nabla\mathbf{u}^*,$$

$$\mathbf{S}^*=2\mu\mathbf{E}^*+\lambda(\operatorname{tr}\mathbf{E}^*)\,\mathbf{Id}=\frac{4\mu(\mu+\lambda)}{(2\mu+\lambda)p}\begin{pmatrix}\omega y+\kappa p & 0\\0 & 0\end{pmatrix}.$$

The following are easily verified:

1) $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ is a periodic strain state corresponding to zero body force (i.e. $\operatorname{div}\mathbf{S}^*=\mathbf{0}$).

2) $\mathbf{u}^*(\mathbf{x}+\mathbf{p})-\mathbf{u}^*(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}=\mathbf{u}(\mathbf{x}+\mathbf{p})-\mathbf{u}(\mathbf{x})$.

3) $[\nabla\mathbf{u}^*(\mathbf{x})]\mathbf{p}=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}+\frac{1}{2}\omega\mathbf{p}$.

4) The surface traction, $\mathbf{s}^*=\mathbf{S}^*\mathbf{n}$, vanishes on any line parallel to the X_1-axis. Hence, $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ is a nontrivial solution to the null traction problem on any two-dimensional body whose boundary is parallel to the X_1-axis.

The base periodic strain state associated with three-dimensional periodic strain states. If $(\mathbf{u},\mathbf{E},\mathbf{S})$ is a three-dimensional periodic strain state with

$$\mathbf{u}(\mathbf{x}+\mathbf{p})-\mathbf{u}(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}},$$

then the associated base periodic strain state $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ is given by:

$$2p\mathbf{u}^*(x,y,z)=\begin{pmatrix}0\\-\omega_1\\-\omega_2\end{pmatrix}x^2+\begin{pmatrix}2\omega_1\\0\\-2\omega_3\end{pmatrix}xy+\begin{pmatrix}2\omega_2\\2\omega_3\\0\end{pmatrix}xz$$

$$+\frac{\lambda}{2(\mu+\lambda)}\left\{-2\kappa p\begin{pmatrix}0\\y\\z\end{pmatrix}+\begin{pmatrix}0\\-\omega_1\\\omega_2\end{pmatrix}y^2-\begin{pmatrix}0\\2\omega_2\\2\omega_1\end{pmatrix}yz+\begin{pmatrix}0\\\omega_1\\-\omega_2\end{pmatrix}z^2\right\}$$

$$+\begin{pmatrix}2\kappa p\\p\omega_1\\p\omega_2\end{pmatrix}x+\begin{pmatrix}-2\omega_3yz-p\omega_1y-p\omega_2z\\0\\0\end{pmatrix}-2p^{-1}[(\mathbf{p}\otimes\bar{\mathbf{u}})-(\bar{\mathbf{u}}\otimes\mathbf{p})]\mathbf{x},$$

$$\mathbf{E}^*=\operatorname{sym}\nabla\mathbf{u}^*,$$

$$\mathbf{S}^*(x,y,z)=2\mu\mathbf{E}^*+\lambda(\operatorname{tr}\mathbf{E}^*)\,\mathbf{Id}$$

$$=\begin{pmatrix}\frac{\mu(2\mu+3\lambda)}{(\mu+\lambda)p}[\omega_1y+\omega_2z+\kappa p] & 0 & \frac{-\omega_3y}{p}\\0 & 0 & 0\\\frac{-\omega_3y}{p} & 0 & 0\end{pmatrix}.$$

The following are easily verified:

1) $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ is a periodic strain state corresponding to zero body force (i.e., $\operatorname{div}\mathbf{S}^*=\mathbf{0}$).

2) $\mathbf{u}^*(\mathbf{x}+\mathbf{p})-\mathbf{u}^*(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}=\mathbf{u}(\mathbf{x}+\mathbf{p})-\mathbf{u}(\mathbf{x})$.

3) $[\nabla\mathbf{u}^*(\mathbf{x})]\mathbf{p}=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}+\frac{1}{2}\omega_1p\mathbf{e}_2+\frac{1}{2}\omega_2p\mathbf{e}_3$.

4) $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ is a nontrivial solution to the null traction problem on any body whose boundary is parallel to the X_1-X_3 plane.

5) If $\omega_3=0$, $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ is a nontrivial solution to the null traction problem on any body whose boundary consists of straight lines parallel to the X_1-axis.

The alternate base periodic strain state associated with three-dimensional periodic strain states. If $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ is a three-dimensional periodic strain state with

$$\mathbf{u}(\mathbf{x}+\mathbf{p})-\mathbf{u}(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}},$$

then the alternate associated base periodic strain state, $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is given by

$$\begin{aligned}\mathbf{u}^*(x,y,z)=&\frac{\omega_1}{2p}\begin{pmatrix}2xy\\-x^2\\0\end{pmatrix}+\frac{\omega_2}{2p}\begin{pmatrix}2xz\\0\\-x^2\end{pmatrix}\\&+\frac{\omega_3}{p}\begin{pmatrix}0\\xz\\-xy\end{pmatrix}+\kappa\begin{pmatrix}x\\0\\0\end{pmatrix}-\frac{\lambda}{2p(2\mu+\lambda)}\begin{pmatrix}0\\\omega_1 y^2\\\omega_2 z^2\end{pmatrix}\\&-\frac{\lambda\kappa}{2(\mu+\lambda)}\begin{pmatrix}0\\y\\z\end{pmatrix}+\left[\frac{\omega_1}{2}+\frac{\bar{u}_2}{p}\right]\begin{pmatrix}-y\\x\\0\end{pmatrix}+\left[\frac{\omega_2}{2}+\frac{\bar{u}_3}{p}\right]\begin{pmatrix}-z\\0\\x\end{pmatrix},\end{aligned}$$

$$\mathbf{E}^*=\operatorname{sym}\nabla\mathbf{u}^*,$$

$$\mathbf{S}^*=2\mu\mathbf{E}^*+\lambda(\operatorname{tr}\mathbf{E}^*)\,\mathbf{Id}$$

$$=p^{-1}\begin{pmatrix}4\mu\dfrac{\mu+\lambda}{2\mu+\lambda}[\omega_1 y+\omega_2 z]+\mu\dfrac{2\mu+3\lambda}{\mu+\lambda}\kappa & \mu\omega_3 zp & -\mu\omega_3 y\\ \mu\omega_3 z & \dfrac{2\mu\lambda}{2\mu+\lambda}\omega_2 z & 0\\ -\mu\omega_3 y & 0 & \dfrac{2\mu\lambda}{2\mu+\lambda}\omega_1 y\end{pmatrix}.$$

The following are easily verified:

1) $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is a periodic strain state corresponding to zero body force (i.e., $\operatorname{div}\mathbf{S}^*=\mathbf{0}$).
2) $\mathbf{u}^*(\mathbf{x}+\mathbf{p})-\mathbf{u}^*(\mathbf{x})=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}=\mathbf{u}(\mathbf{x}+\mathbf{p})-\mathbf{u}(\mathbf{x})$.
3) $[\nabla\mathbf{u}^*(\mathbf{x})]\mathbf{p}=\overline{\mathbf{W}}\mathbf{x}+\kappa\mathbf{p}+\bar{\mathbf{u}}+\frac{1}{2}\omega_1 p\mathbf{e}_2+\frac{1}{2}\omega_2 p\mathbf{e}_3$.
4) If $\omega_2=\omega_3=0$, $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is a nontrivial solution to the null traction problem on any body whose boundary is parallel to the X_1-X_3 plane.
5) If $\omega_1=\omega_2=0$, $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is a nontrivial solution to the null traction problem on any body whose boundary is a right circular cylinder centered on the X_1-axis.
6) If $\omega_1=\omega_2=\omega_3=0$, $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is a nontrivial solution to the null traction problem on any body whose boundary consists of straight lines parallel to the X_1-axis.

6. The major lemma.

LEMMA 6.1. *Suppose* $\mathscr{K}=\mathscr{K}(\Sigma, \mathbf{v}, \theta)$ *is a nontrivial cone* $(\theta\neq 0)$ *satisfying the following conditions*:

i. Σ *is a nontrivial closed subset of* $\partial\mathscr{K}$;

ii. *for each real* η *and each nonnegative integer,* m, $\mathbf{x}+\eta\mathbf{e}^1$ *is contained in* $\mathscr{K}_m=\mathscr{K}(\Sigma, \mathbf{v}, 2^{-m}\theta)$ *whenever* $\mathbf{x}$ *is a point in* $\mathscr{K}_1$.

Let $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *be a periodic strain state on* $\mathscr{K}$ *(with period* $\mathbf{p}$*) corresponding to a body force with vanishing curl and divergence, and suppose that for some fixed* $\beta \geqq 2$*, either*

$$\mathbf{u}(\mathbf{x}) = O\left(|\mathbf{x}|^{\beta}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{K} \tag{6.1}$$

or

$$\mathbf{E}(\mathbf{x}) = O\left(|\mathbf{x}|^{\beta-1}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{K}_1. \tag{6.2}$$

Then, given any integer, $n \geqq 2$,

$$[\nabla \mathbf{u}(\mathbf{x})]\mathbf{p} - [\overline{\mathbf{W}}\mathbf{x} + \kappa \mathbf{p} + \bar{\mathbf{u}} + \mathbf{h}] = O(\rho^{\beta-n}) \quad \text{as } \rho \to \infty \quad \text{on } \mathscr{K}_n$$

where $\rho = \rho(\mathbf{x})$ *denotes the distance from* $\mathbf{x}$ *to* Σ *and*

$$\mathbf{h} = \begin{cases} \frac{1}{2} p \omega \mathbf{e}^2 & \text{if } \mathbf{E} \text{ is a plane strain,} \\ \frac{1}{2} p \omega_1 \mathbf{e}^2 + \frac{1}{2} p \omega_2 \mathbf{e}^3 & \text{otherwise.} \end{cases}$$

Proof. It should be noted that (6.1) and (6.2) both imply

$$\mathbf{E}(\mathbf{x}) = O(\rho^{\beta-1}) \quad \text{as } \rho \to \infty \quad \text{on } \mathscr{K}_1. \tag{6.3}$$

To see this, first observe that if (6.1) holds, then there must exist some nonincreasing, locally integrable function, $f(\rho)$, such that

$$|\mathbf{u}(\mathbf{x})| \leqq \left[\rho^{\beta} + \left(1 + |x_1|\right)^{\beta}\right] f(\rho)$$

for each $\mathbf{x}$ in $\mathscr{K}$. But, since $\mathbf{E}$ is the symmetric gradient of $\mathbf{u}$, Theorem 3.1 (with $\nu = 0$ and $\zeta = \beta$) can be employed to show that

$$|\mathbf{E}(\mathbf{x})| \leqq M\left[\rho^{\beta-1} + \left(1 + |x_1|\right)^{\beta} \rho^{-1}\right] f\left(\frac{1}{2}\alpha\rho\right)$$

for each $\mathbf{x}$ in $\mathscr{K}_1$ (M and α are constants from Theorem 3.1). Thus, by the geometry of the period sections,

$$\mathbf{E}(\mathbf{x}) = O(\rho^{\beta-1}) \quad \text{as } \rho \to \infty \quad \text{on } \mathscr{K}_1 \cap \mathscr{P} \tag{6.4}$$

where $\mathscr{P}$ is any period section. In a much more obvious manner, (6.4) also follows from (6.2). (6.3) now follows immediately since $\mathbf{E}$ is periodic on $\mathscr{K}_1$.

Now, let $(\tilde{\mathbf{u}}, \tilde{\mathbf{E}}, \tilde{\mathbf{S}})$ be the elastic state defined by

$$\tilde{\mathbf{u}} = \mathbf{u} - \mathbf{u}^*$$

where $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ is any of the corresponding base periodic strain states associated with $(\mathbf{u}, \mathbf{E}, \mathbf{S})$. Clearly, $(\tilde{\mathbf{u}}, \tilde{\mathbf{E}}, \tilde{\mathbf{S}})$ is a periodic displacement state on $\mathscr{K}_1$ which also satisfies (6.3), that is

$$\tilde{\mathbf{E}}(\mathbf{x}) = O(\rho^{\beta-1}) \quad \text{as } \rho \to \infty \quad \text{on } \mathscr{K}_1. \tag{6.5}$$

Employing Theorem 3.1 again (this time with $\nu = 0$ and $\zeta = \beta - 1$), it can be seen that (6.5) implies

$$\nabla \tilde{\mathbf{E}}(\mathbf{x}) = O(\rho^{\beta-2}) \quad \text{as } \rho \to \infty \quad \text{on } \mathscr{K}_2.$$

But it is easily checked that

$$\tilde{u}_{i,jk} = \tilde{E}_{ij,k} - \tilde{E}_{ik,j} + \tilde{E}_{jk,i}$$

and, thus,

$$\nabla\nabla\tilde{\mathbf{u}}(\mathbf{x}) = O(\rho^{\beta-2}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_2.$$

By this, the periodicity of $\tilde{\mathbf{u}}$, condition ii., and basic calculus:

$$\begin{aligned}[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} &= [\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} - [\tilde{\mathbf{u}}(\mathbf{x}+\mathbf{p}) - \tilde{\mathbf{u}}(\mathbf{x})] \\ &= \int_{\sigma=0}^{p} [\nabla\tilde{\mathbf{u}}(\mathbf{x}) - \nabla\tilde{\mathbf{u}}(\mathbf{x}+\sigma\mathbf{e}^1)]\mathbf{e}^1\, d\sigma \\ &= -\int_{\sigma=0}^{p}\int_{\tau=0}^{\sigma} [\nabla\tilde{\mathbf{u}}_{,1}(\mathbf{x}+\tau\mathbf{e}^1)]\mathbf{e}^1\, d\tau\, d\sigma \\ &= O(\rho^{\beta-2}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_2,\end{aligned}$$

which, of course, is equivalent to

$$\tilde{\mathbf{u}}_{,1}(\mathbf{x}) = O(\rho^{\beta-2}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_2 \tag{6.6}$$

since $\mathbf{p} = p\mathbf{e}^1$.

Theorem 3.1 can now be applied to $\mathbf{u}_{,1}$ using the bounds indicated by (6.6). The result is that

$$\nabla\tilde{\mathbf{u}}_{,1}(\mathbf{x}) = O(\rho^{\beta-3}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_3.$$

The above integration is still valid but now yields

$$\begin{aligned}[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} &= -\int_{\sigma=0}^{p}\int_{\tau=0}^{\sigma} [\nabla\tilde{\mathbf{u}}_{,1}(\mathbf{x}+\tau\mathbf{e}^1)]\mathbf{e}^1\, d\tau\, d\sigma \\ &= O(\rho^{\beta-3}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_3.\end{aligned}$$

Thus,

$$[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} = O(\rho^{\beta-2}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_2 \tag{6.7}$$

implies

$$[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} = O(\rho^{\beta-3}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_3. \tag{6.8}$$

Repeating the arguments which led from (6.7) to (6.8), one quickly discovers that (6.8) implies

$$[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} = O(\rho^{\beta-4}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_4$$

which, in turn, leads to

$$[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} = O(\rho^{\beta-5}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_5$$

and so forth. Taking the inductive leap, one obtains

$$[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} = O(\rho^{\beta-n}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_n$$

for every integer, $n \geqq 2$. This essentially completes the proof since by the definition of $\tilde{\mathbf{u}}$

$$[\nabla\tilde{\mathbf{u}}(\mathbf{x})]\mathbf{p} = [\nabla\mathbf{u}(\mathbf{x})]\mathbf{p} - [\nabla\mathbf{u}^*(\mathbf{x})]\mathbf{p}$$

and, as was observed in §5,

$$[\nabla\mathbf{u}^*(\mathbf{x})]\mathbf{p} = \overline{\mathbf{W}}\mathbf{x} + \kappa\mathbf{p} + \bar{\mathbf{u}} + \mathbf{h}$$

for any of the base periodic strain states associated with $(\mathbf{u}, \mathbf{E}, \mathbf{S})$. □

It should be observed that, often, $\mathscr{K}=\mathscr{K}_1=\mathscr{K}_2$, etc. In these cases, the above results are quite strong. Examples of such situations would be problems involving half-spaces and bodies exterior to cylinders (more generally, periodic fractional spaces and periodic exterior bodies, see Howell [4, §7]).

In the next section Lemma 6.1 will prove extremely useful in establishing completely the asymptotic behavior of periodic plane strain states. A somewhat simpler application of Lemma 6.1 can be found in the next corollary.

COROLLARY 6.2. *Let $\mathscr{K}$ be as in Lemma* 6.1 *and let f denote a locally integrable, nonincreasing function on $[0,\infty)$ such that*

$$f(\rho)=o(1) \quad \text{as } \rho\to\infty.$$

Suppose that $(\mathbf{u},\mathbf{E},\mathbf{S})$ *is a periodic strain state on a body containing $\mathscr{K}$ and suppose that either*

$$|\mathbf{u}(\mathbf{x})|\leqq\left[\rho+(1+|x_1|)\right]f(\rho) \tag{6.9}$$

for every $\mathbf{x}$ *in $\mathscr{K}$ or that*

$$|\mathbf{S}(\mathbf{x})|\leqq f(\rho) \tag{6.10}$$

for every $\mathbf{x}$ *in $\mathscr{K}_1$. Then* $|\overline{\mathbf{W}}|=\kappa=0$.

Proof. Using the invertibility of the relationship between the strain and the stress, and arguments similar to those used in the proof of Lemma 6.1, it can be shown that either (6.9) or (6.10) implies that

$$\nabla\nabla\mathbf{u}(\mathbf{x})=O(\rho^{-1}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_3$$

and

$$E_{11}(\mathbf{x})=o(1) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_2.$$

It then follows that

$$\begin{aligned}\overline{\mathbf{W}}&=\nabla\mathbf{u}(\mathbf{x}+\mathbf{p})-\nabla\mathbf{u}(\mathbf{x})\\&=\int_{\sigma=0}^{p}\nabla\mathbf{u}_{,1}(\mathbf{x}+\sigma\mathbf{e}^1)\,d\sigma=O(\rho^{-1}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_3\end{aligned}$$

which is possible only if $\overline{\mathbf{W}}$ is the zero tensor.

Now, since $\overline{\mathbf{W}}$ is the zero tensor, Lemma 6.1 implies that

$$[\nabla\mathbf{u}(\mathbf{x})]\mathbf{p}-[\kappa\mathbf{p}+\mathbf{u}]=O(\rho^{-2}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_4.$$

Here, we have also used the fact that $\mathbf{h}$ vanishes if $\overline{\mathbf{W}}$ vanishes and the fact that by either (6.9) or (6.10), $\beta=2$. Taking the first component, rearranging slightly, and recalling that $E_{11}=u_{1,1}$ gives

$$\kappa p=pE_{11}(\mathbf{x})+O(\rho^{-2}) \quad \text{as } \rho\to\infty \quad \text{on } \mathscr{K}_4$$

which, since $E_{11}(\mathbf{x})$ also vanishes as $\rho\to\infty$, forces κ to be zero. □

7. Asymptotic behavior of periodic plane strain states. In this section and the next, attention will be restricted to plane strain states on bodies containing the upper half-plane, $\{\mathbf{x}=(x,y):y>0\}$. For convenience, the notation (x,y) rather than (x_1,x_2) will be adopted for the components of $\mathbf{x}$. It should be clear that the upper half-plane can be viewed as the cone $\mathscr{K}=\mathscr{K}(\Sigma_0,\mathbf{e}^2,\theta)$, where Σ_0 is the X_1-axis and θ is arbitrary. Thus, the results from the previous section can be applied. Let us also, at this time, take

note of the following two observations:

1. $\rho(\mathbf{x})$, the distance between Σ_0 and $\mathbf{x}=(x,y)$, is given by $|y|$.
2. For any nonnegative integer, n, $\mathscr{K}_n=\mathscr{K}$.

It will be shown that at great distances from the boundary, any periodic plane strain state, $(\mathbf{u},\mathbf{E},\mathbf{S})$, can be closely approximated once four constants corresponding to the state have been determined. Not surprisingly, two of these constants are ω and κ. The other two constants are the components of the "negative mean surface traction," $\bar{\mathbf{s}}$, defined by

$$\bar{\mathbf{s}}=\lim_{y\to-\infty}\frac{-1}{p}\int_{\mathscr{S}_y}\mathbf{S}\mathbf{n}\,da \tag{7.1}$$

where, for any period section, $\mathscr{P}$,

$$\mathscr{S}_y=\partial\big(\mathscr{B}\cap\{(x,\hat{y}):\hat{y}\geqq y\}\big)\cap\mathrm{cl}\,\mathscr{P}.$$

It will be seen that the negative mean surface traction does always exist.

Let $(\mathbf{u},\mathbf{E},\mathbf{S})$ be a periodic strain state with corresponding negative mean surface traction $\bar{\mathbf{s}}=(\bar{s}_1,\bar{s}_2)$ and corresponding base periodic strain state $(\mathbf{u}^*,\mathbf{E}^*,\mathbf{S}^*)$ (as defined in §5 for plane strains). The "asymptotic state", $(\mathbf{u}^0,\mathbf{E}^0,\mathbf{S}^0)$, corresponding to $(\mathbf{u},\mathbf{E},\mathbf{S})$ is given by the following formulas:

$$\begin{aligned}\mathbf{u}^0(x,y)&=\mathbf{u}^*(x,y)+\frac{\lambda}{\mu(2\mu+\lambda)}\begin{pmatrix}[2\mu+\lambda]\bar{s}_1y\\ \mu\bar{s}_2y\end{pmatrix}\\&=\frac{\omega}{2p}\begin{pmatrix}2xy\\ -x^2\end{pmatrix}+\frac{\lambda}{2p(2\mu+\lambda)}\begin{pmatrix}0\\ \omega y^2+2p\kappa y\end{pmatrix}\\&\quad+\kappa\begin{pmatrix}x\\0\end{pmatrix}+\left[\frac{\omega}{2}+\frac{\bar{u}_2}{p}\right]\begin{pmatrix}-y\\ x\end{pmatrix}+\frac{1}{\mu(2\mu+\lambda)}\begin{pmatrix}[2\mu+\lambda]\bar{s}_1y\\ \mu\bar{s}_2y\end{pmatrix},\end{aligned} \tag{7.2}$$

$$\mathbf{E}^0=\operatorname{sym}\nabla\mathbf{u}^0=\mathbf{E}^*+\frac{1}{2\mu(2\mu+\lambda)}\begin{pmatrix}0&(2\mu+\lambda)\bar{s}_1\\ (2\mu+\lambda)\bar{s}_1&2\mu\bar{s}_2\end{pmatrix}, \tag{7.3}$$

$$\mathbf{S}^0(x,y)=2\mu\mathbf{E}^0+\lambda(\operatorname{tr}\mathbf{E}^0)\,\mathbf{Id}=\begin{pmatrix}A[\omega y+\kappa p]+B\bar{s}_2&\bar{s}_1\\ \bar{s}_1&\bar{s}_2\end{pmatrix}, \tag{7.4}$$

where

$$A=\frac{4\mu(\mu+\lambda)}{p(2\mu+\lambda)},\qquad B=\frac{\lambda}{2\mu+\lambda}.$$

It is easily verified that $(\mathbf{u}^0,\mathbf{E}^0,\mathbf{S}^0)$ is a periodic strain state corresponding to zero body force (i.e. $\operatorname{div}\mathbf{S}^0=\mathbf{0}$) and that $\mathbf{u}-\mathbf{u}^0$ is a periodic displacement. The next theorem establishes much more, namely that $(\mathbf{u}^0,\mathbf{E}^0,\mathbf{S}^0)$ closely approximates $(\mathbf{u},\mathbf{E},\mathbf{S})$ at great distances from the boundary of the elastic body.

THEOREM 7.1. *Suppose that $\mathscr{B}$ is a two-dimensional elastic body containing the upper half plane, $\{(x,y):y>0\}$, and that $(\mathbf{u},\mathbf{E},\mathbf{S})$ is a periodic strain state on $\mathscr{B}$ corresponding to zero body force. Assume, also, that for some arbitrary real β and some period section, $\mathscr{P}$, either*

$$\mathbf{u}(\mathbf{x})=O\big(|\mathbf{x}|^{\beta}\big)\quad \text{as } |\mathbf{x}|\to\infty\quad \text{on } \mathscr{P}$$

or

$$\mathbf{E}(\mathbf{x}) = O\left(|\mathbf{x}|^{\beta}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}.$$

Then the negative mean surface traction, $\bar{\mathbf{s}}$, *exists. Moreover, there is a fixed vector,* $\mathbf{v}^0$, *such that, for any positive* γ,

$$\mathbf{u}(x,y) - \mathbf{u}^0(x,y) - \mathbf{v}^0 = 0(y^{-\gamma}) \quad \text{as } y \to \infty, \tag{7.5}$$

$$\mathbf{E}(x,y) - \mathbf{E}^0(x,y) = O(y^{-\gamma}) \quad \text{as } y \to \infty, \tag{7.6}$$

$$\mathbf{S}(x,y) - \mathbf{S}^0(x,y) = O(y^{-\gamma}) \quad \text{as } y \to \infty, \tag{7.7}$$

where $(\mathbf{u}^0, \mathbf{E}^0, \mathbf{S}^0)$ *is the asymptotic state corresponding to* $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *given by formulas* (7.2), (7.3), *and* (7.4).

Proof. Let $(\mathbf{u}^*, \mathbf{E}^*, \mathbf{S}^*)$ be the base periodic strain state corresponding to $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ and let $(\tilde{\mathbf{u}}, \tilde{\mathbf{E}}, \tilde{\mathbf{S}})$ be the elastic state on defined by

$$\tilde{\mathbf{u}}(\mathbf{x}) = \mathbf{u}(\mathbf{x}) - \mathbf{u}^*(\mathbf{x}).$$

It is easily checked that $(\tilde{\mathbf{u}}, \tilde{\mathbf{E}}, \tilde{\mathbf{S}})$ is a periodic displacement state on $\mathscr{B}$ corresponding to zero body force and, by Lemma 6.1,

$$[\nabla \tilde{\mathbf{u}}(x,y)]\mathbf{p} = O(y^{-\gamma-1}) \quad \text{as } y \to \infty$$

for all positive γ. By Theorem 3.1, then,

$$\tilde{u}_{i,jk}(x,y) = O(y^{-\gamma-2}) \quad \text{as } y \to \infty \tag{7.8}$$

for all possible i, j, and k except $i=j=2$. However, since the body force is zero, the two-dimensional Navier equation can be written

$$\tilde{u}_{1,11} + \tilde{u}_{1,22} + \frac{\mu+\lambda}{\mu}(\tilde{u}_{1,11} + \tilde{u}_{2,12}) = 0,$$

$$\tilde{u}_{2,11} + \tilde{u}_{2,22} + \frac{\mu+\lambda}{\mu}(\tilde{u}_{1,12} + \tilde{u}_{2,22}) = 0$$

which can be solved for $\tilde{u}_{1,22}$ and $\tilde{u}_{2,22}$ in terms of the other second derivatives of $\tilde{\mathbf{u}}$. But, it is for these other second derivatives that (7.8) holds. Thus,

$$\nabla\nabla\tilde{\mathbf{u}}(x,y) = O(y^{-\gamma-2}) \quad \text{as } y \to \infty \tag{7.9}$$

for any positive γ.

Now, choose any pair of points (x,y) and $(\bar{x},\bar{y})$ with $|x-\bar{x}| \leqq p$ and $0 < y \leqq \bar{y}$. Integrating $\nabla\nabla\tilde{\mathbf{u}}$ along a straight line path between (x,y) and $(\bar{x},\bar{y})$ leads to

$$\nabla\tilde{\mathbf{u}}(x,y) - \nabla\tilde{\mathbf{u}}(\bar{x},\bar{y}) = O(y^{-\gamma-1}) \quad \text{as } y \to \infty$$

for any positive γ. Straightforward "Cauchy sequence" arguments shows that this implies the existence of a fixed tensor, $\hat{\mathbf{T}}$, such that

$$\nabla\tilde{\mathbf{u}}(x,y) - \hat{\mathbf{T}} = O(y^{-\gamma-1}) \quad \text{as } y \to \infty.$$

Using either the periodicity of $\tilde{\mathbf{u}}$ or the asymptotic behavior of $\nabla\nabla\mathbf{u}(x,y)$ as $y \to \infty$, it is easily seen that $\hat{\mathbf{T}}$ is independent of the choice of x.

Using $\nabla \mathbf{u}(x,y)-\hat{\mathbf{T}}$ instead of $\nabla \nabla \mathbf{u}(x,y)$, the above succession of integration and "Cauchy sequence" arguments proves that there is a fixed vector, $\mathbf{v}^0$, such that

$$\tilde{\mathbf{u}}(\mathbf{x})-\hat{\mathbf{T}}\mathbf{x}-\mathbf{v}^0=O(y^{-\gamma}) \quad \text{as } y\to\infty \tag{7.10}$$

where $\mathbf{x}=(x,y)$ and γ is any positive real constant.

Letting $(\hat{\mathbf{u}},\hat{\mathbf{E}},\hat{\mathbf{S}})$ be the elastic state given by

$$\begin{aligned}\hat{\mathbf{u}}(\mathbf{x})&=\hat{\mathbf{T}}\mathbf{x},\\ \hat{\mathbf{E}}&=\operatorname{sym}\nabla\hat{\mathbf{u}},\\ \hat{\mathbf{S}}&=2\mu\hat{\mathbf{E}}+\lambda(\operatorname{tr}\hat{\mathbf{E}})\,\mathbf{Id}\end{aligned}$$

and recalling the definition of $\tilde{\mathbf{u}}$, it becomes clear that (7.10) is equivalent to

$$\mathbf{u}(\mathbf{x})-\mathbf{u}^*(\mathbf{x})-\hat{\mathbf{u}}(\mathbf{x})-\mathbf{v}^0=O(y^{-\gamma}) \quad \text{as } y\to\infty \tag{7.11}$$

which by Theorem 3.1, implies

$$\mathbf{E}(\mathbf{x})-\mathbf{E}^*(\mathbf{x})-\hat{\mathbf{E}}=O(y^{-\gamma}) \quad \text{as } y\to\infty \tag{7.12}$$

and

$$\mathbf{S}(\mathbf{x})-\mathbf{S}^*(\mathbf{x})-\hat{\mathbf{S}}=O(y^{-\gamma}) \quad \text{as } y\to\infty \tag{7.13}$$

where $\mathbf{x}=(x,y)$ and γ is any positive real constant. Comparing the last three expressions with (7.5) through (7.7), along with (7.2) through (7.4), leads to the realization that the theorem will be proven once $\bar{\mathbf{s}}$ has been shown to exist and once it has been shown that

$$\hat{\mathbf{T}}\mathbf{x}=\frac{1}{\mu(2\mu+\lambda)}\begin{pmatrix}[2\mu+\lambda]\bar{s}_1 y\\ \mu\bar{s}_2 y\end{pmatrix} \tag{7.14}$$

for each $\mathbf{x}=(x,y)$. It should be observed that (7.14) certainly holds if both $\hat{T}_{i1}=0$ and $\hat{S}_{i2}=\bar{s}_i$ for $i=1$ and 2.

First, consider the fixed tensor $\hat{\mathbf{T}}$. By the periodicity of $\tilde{\mathbf{u}}$ and (7.10)

$$\hat{\mathbf{T}}\mathbf{p}=[\tilde{\mathbf{u}}(\mathbf{x})-\hat{\mathbf{T}}\mathbf{x}]-[\tilde{\mathbf{u}}(\mathbf{x}+\mathbf{p})-\hat{\mathbf{T}}\mathbf{x}-\hat{\mathbf{T}}\mathbf{p}]=O(y^{-\gamma}) \quad \text{as } y\to\infty$$

for each $\mathbf{x}=(x,y)$ and $\gamma>0$. Thus,

$$\hat{T}_{11}=\hat{T}_{21}=0.$$

Next, fix $\mathbf{z}$ and $y>0$ arbitrarily, and let

$$\begin{aligned}\mathscr{P}&=\mathscr{P}_{\mathbf{z}},\\ \mathscr{C}_y&=\{(x,\bar{y}):|\bar{y}|<y\},\\ \ell_y&=\{(x,\bar{y}):\bar{y}=y\}.\end{aligned}$$

It then follows that

$$\begin{aligned}\mathbf{0}&=\int_{\mathscr{P}\cap\mathscr{C}_y}\operatorname{div}\mathbf{S}\,dv=\int_{\partial(\mathscr{P}\cap\mathscr{C}_y)}\mathbf{S}\mathbf{n}\,da\\ &=\int_{\mathscr{P}\cap\ell_y}\mathbf{S}\mathbf{e}^2\,da+\int_{\mathscr{S}_{-y}}\mathbf{S}\mathbf{n}\,da+\int_{\mathscr{L}_{\mathbf{z}}\cap\mathscr{C}_y}\mathbf{S}\mathbf{n}\,da+\int_{\mathscr{L}_{\mathbf{z}+\mathbf{p}}\cap\mathscr{C}_y}\mathbf{S}\mathbf{n}\,da,\end{aligned} \tag{7.15}$$

where $\mathscr{L}_{\mathbf{z}}$ and $\mathscr{L}_{\mathbf{z}+\mathbf{p}}$ are the left and right faces of $\mathscr{P}$ and $\mathscr{S}_{-y}$ is as defined by (6.1). **S**, however, is periodic and, for each **x** in $\mathscr{L}_{\mathbf{z}}$, $\mathbf{n}(\mathbf{x})=-\mathbf{n}(\mathbf{x}+\mathbf{p})$. Hence, the last two integrals in (7.15) cancel each other. What remains can be written:

$$\frac{-1}{p}\int_{\mathscr{S}_{-y}}\mathbf{Sn}\,da=\frac{1}{p}\int_{\mathscr{P}\cap\ell_y}\mathbf{Se}^2\,da. \tag{7.16}$$

The limit, as y approaches infinity, of the right-hand side of (7.16), can easily be computed using (7.13) and the definitions of **S*** and $\hat{\mathbf{S}}$. The result is

$$\lim_{y\to\infty}\frac{-1}{p}\int_{\mathscr{S}_{-y}}\mathbf{Sn}\,da=\hat{\mathbf{S}}\mathbf{e}^2 \tag{7.17}$$

proving, in a single step, that $\bar{\mathbf{s}}$ exists and that

$$\hat{S}_{i2}=\bar{s}_i$$

for $i=1$ and 2. □

By the above, it makes sense to discuss the vector $\mathbf{Se}^2$ "at $y=+\infty$". Likewise, if $\mathscr{B}$ contains a lower half plane (i.e., a set of the form $\{(x,y):y<y^0\}$ for some y^0), then $\mathbf{Se}^2$ "at $y=-\infty$" is also a well-defined fixed vector. These two tractions, however, may not be equal. Indeed, if $\mathscr{B}$ does contain a lower half plane, then (7.15) leads to

$$\frac{-1}{p}\int_{\partial\mathscr{B}\cap\partial\mathscr{P}}\mathbf{s}\,da-\mathbf{Se}^2|_{y=-\infty}=\bar{\mathbf{s}}=\mathbf{Se}^2|_{y=+\infty}$$

from which the following observations may be made:

1. If $\mathscr{B}$ is contained in a single half plane, then $\mathbf{Se}^2|_{y=+\infty}$ is determined entirely by **s** on $\partial\mathscr{B}$ through the formula

$$\mathbf{Se}^2|_{y=+\infty}=\frac{-1}{p}\int_{\partial\mathscr{B}\cap\partial\mathscr{P}}\mathbf{s}\,da.$$

2. If $\mathscr{B}$ contains both upper and lower half planes, then $\mathbf{Se}^2|_{y=+\infty}$ equals $\mathbf{Se}^2|_{y=-\infty}$ if and only if

$$\int_{\partial\mathscr{B}\cap\partial\mathscr{P}}\mathbf{s}\,da=\mathbf{0}.$$

8. Consequences. It would be unnatural not to discuss the implications of Theorem 7.1 with regard to questions concerning the finiteness of the total energy, the uniqueness of solutions, Saint-Venant's principle, etc. We shall not be unnatural. To simplify the discussion it will be assumed in this section that any body, $\mathscr{B}$, satisfies all of the following in addition to being homogeneous and isotropic.

1. $\mathscr{B}$ is two-dimensional.
2. The characteristic function for $\mathscr{B}$ is periodic (with period **p**).
3. $\partial\mathscr{B}\cap\partial\mathscr{P}$ is a bounded set in space.

The first theorem is simply the observation that Theorem 7.1 can be viewed as a sort of Saint-Venant's principle. Details of the proof will be left to the reader.

THEOREM 8.1 (Saint-Venant's principle). *Let* $(\mathbf{u}^1, \mathbf{E}^1, \mathbf{S}^1)$ *and* $(\mathbf{u}^2, \mathbf{E}^2, \mathbf{S}^2)$ *be two periodic strain solutions to two, possibly different, periodic boundary value problems on* $\mathscr{B}$ *both involving the same body force. Assume that one of the following holds*:

i. $\mathbf{u}^1(\mathbf{x}) - \mathbf{u}^2(\mathbf{x}) = o(|\mathbf{x}|)$ *as* $|\mathbf{x}| \to \infty$ *on* $\mathscr{P}$;

ii. $\mathbf{S}^1(\mathbf{x}) - \mathbf{S}^2(\mathbf{x}) = o(1)$ *as* $|\mathbf{x}| \to \infty$ *on* $\mathscr{P}$;

iii. $\mathscr{S}_1^i$, *the surface on which* $\mathbf{u}^i$ *is prescribed, is nontrivial for both* $i = 1$ *and* $i = 2$, *and either*

$$\mathbf{S}^1\mathbf{e}^1 - \mathbf{S}^2\mathbf{e}^1 = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}$$

or

$$\mathbf{S}^1\mathbf{e}^2 - \mathbf{S}^2\mathbf{e}^2 = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P};$$

iv. $\mathscr{B}$ *is contained in a single half plane and both of the following hold*:

$$\int_{\partial\mathscr{B}\cap\partial\mathscr{P}} \mathbf{S}^1\mathbf{n}\, da = \int_{\partial\mathscr{B}\cap\partial\mathscr{P}} \mathbf{S}^2\mathbf{n}\, da,$$

$$S_{11}^1(\mathbf{x}) - S_{11}^2(\mathbf{x}) = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}.$$

Then, for some fixed vector, $\mathbf{v}^0$, *and any positive constant,* γ,

$$\mathbf{u}^1(\mathbf{x}) - \mathbf{u}^2(\mathbf{x}) - \mathbf{v}^0 = o\left(|\mathbf{x}|^{-\gamma}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P},$$

$$\mathbf{E}^1(\mathbf{x}) - \mathbf{E}^2(\mathbf{x}) = o\left(|\mathbf{x}|^{-\gamma}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P},$$

$$\mathbf{S}^1(\mathbf{x}) - \mathbf{S}^2(\mathbf{x}) = o\left(|\mathbf{x}|^{-\gamma}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}.$$

The next theorem is the extension of the well-known theorem of work and energy which states that if $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ is an elastic state corresponding to a body force $\mathbf{b}$ on a *bounded* body, Ω, then

$$\int_\Omega \mathbf{E}\cdot\mathbf{S}\, dv = \int_{\partial\Omega} \mathbf{u}\cdot\mathbf{s}\, da + \int_\Omega \mathbf{u}\cdot\mathbf{b}\, dv.$$

The main difficulty in extending the classical theorem of work and energy to elastic states on unbounded bodies lies in the difficulty of assuring the convergence of the resulting improper integrals without making undesirably strong assumptions on the behavior of the state "near infinity". Fortunately, Theorem 7.1 insures that periodic strain states on $\mathscr{B}$ do approach their values "at infinity" quite rapidly. Thus, in this case, extending the theorem of work and energy is a very simple exercise and will be left to the reader.

THEOREM 8.2 (work and energy). *Let* $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *be a periodic strain state corresponding to zero body force on* $\mathscr{B}$ *which satisfies either*

$$\mathbf{u}(\mathbf{x}) = o(|\mathbf{x}|) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}$$

or

$$\mathbf{S}(\mathbf{x}) = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}.$$

Then the total work expended in the deformation of any period section, $\mathscr{P}$, *is finite and is given by*

$$\int_{\mathscr{P}} \mathbf{E}\cdot\mathbf{S}\, dv = \int_{\partial\mathscr{P}\cap\partial\mathscr{B}} \mathbf{u}\cdot\mathbf{s}\, da.$$

If, however, $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *is a periodic strain corresponding to zero body force on* $\mathscr{B}$ *which satisfies either*

$$\mathbf{u}(\mathbf{x}) = o\left(|\mathbf{x}|^2\right) \quad as\ |\mathbf{x}| \to \infty \quad on\ \mathscr{P}$$

or

$$\mathbf{S}(\mathbf{x}) = o\left(|\mathbf{x}|\right) \quad as\ |\mathbf{x}| \to \infty \quad on\ \mathscr{P},$$

then

$$\lim_{y \to \infty} \frac{1}{\mathscr{V}_y} \int_{\mathscr{P}_y^+} \mathbf{E} \cdot \mathbf{S}\, dv$$

exists and equals

$$\frac{4\mu(\mu+\lambda)}{2\mu+\lambda}\left[\frac{\omega}{p} y + \kappa\right]^2 + \frac{1}{\mu}(\bar{s}_1)^2 + \frac{1}{2\mu+\lambda}(\bar{s}_2)^2,$$

where

$$\mathscr{P}_y^+ = \mathscr{P} \cap \{(x, \bar{y}) : 0 < \bar{y} < y\}$$

and

$$\mathscr{V}_y = \text{the area of } \mathscr{P}_y^+$$

and ω, κ, $\bar{s}_1$, *and* $\bar{s}_2$ *are the constants from the definition of* $(\mathbf{u}^0, \mathbf{E}^0, \mathbf{S}^0)$ *in Theorem* 7.1.

Later (in §9), a theorem of work and energy will be presented in which the body force is not assumed to be zero.

The reader may have already recognized that the bodies being considered here are the two-dimensional analogues of the periodic exterior bodies discussed in [4]. Indeed, the restriction that periodic exterior bodies be three-dimensional could have been dropped without affecting any of the theorems (Theorems 8.1 through 8.5 in [4]). The advantage of waiting until now to discuss these theorems with two-dimensional problems lies, of course, in the fact that, with Theorem 7.1, these same theorems can be simplified and strengthened. The resulting improvements are summarized in the two theorems below. The proofs will not be given. To simplify the statements of the theorems, the difference operator, δ, will be used where, for any suitable function, ϕ,

$$\delta\phi(\mathbf{x}) = \delta^1\phi(\mathbf{x}) = \phi(\mathbf{x}+\mathbf{p}) - \phi(\mathbf{x}),$$
$$\delta^{n+1}\phi = \delta\delta^n\phi.$$

The reader is reminded, once again, that in all theorems in this section, $\mathscr{B}$ is two-dimensional.

THEOREM 8.3 (periodicity of solutions). *Let* $\mathscr{B}$ *have positive definite elasticity and let* $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *be a solution to a periodic boundary value problem on* $\mathscr{B}$. *Assume that there are real constants,* C *and* β, *such that, for some nonnegative integer,* n, *either*

$$|\delta^n \mathbf{u}(x,y)| \leqq C\left(1 + |y|^\beta\right)\left(1 + |x|^{1/2}\right)$$

for every (x,y) *in* $\mathscr{B}$, *or*

$$|\delta^n \nabla \mathbf{E}(x,y)| \leqq C\left(1 + |y|^\beta\right)\left(1 + |x|^{1/2}\right)$$

for every (x,y) *in* $\mathscr{B}$. *Then* $\mathbf{E}$ *and* $\mathbf{S}$ *are periodic provided any one of the following hold*:

1. $\mathbf{u}(\mathbf{x}) = o(|\mathbf{x}|^2)$ *as* $|\mathbf{x}| \to \infty$ *on* $\mathscr{P}$;
2. $\mathbf{S}(\mathbf{x}) = o(|\mathbf{x}|)$ *as* $|\mathbf{x}| \to \infty$ *on* $\mathscr{P}$;
3. $\mathscr{S}_1$, *the surface on which* $\mathbf{u}$ *is prescribed, is nontrivial and either*

$$\mathbf{Se}^1 = o(|\mathbf{x}|) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}$$

or

$$\mathbf{Se}^2 = o(|\mathbf{x}|) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P};$$

4. $\mathscr{B}$ *is contained in a single half plane, the traction is prescribed on almost all of* $\partial\mathscr{B}$, *and*

$$S_{11}(\mathbf{x}) = o(|\mathbf{x}|) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P};$$

5. *for each* $\mathbf{x}$ *in* $\mathscr{B}$

$$\delta\mathbf{S}(\mathbf{x} + k\mathbf{p}) = o(1) \quad \text{as } k \to \infty \quad \text{on } \mathbb{N};$$

6. *for each* $\mathbf{x}$ *in* $\mathscr{B}$

$$\delta\nabla\mathbf{S}(\mathbf{x} + k\mathbf{p}) = o(1) \quad \text{as } k \to \infty \quad \text{on } \mathbb{N}$$

and there are two points on $\partial\mathscr{B}$ *at which* $\mathbf{s}$ *is prescribed such that the normals to* $\partial\mathscr{B}$ *at these two points span* $\mathbb{R}^2$;

7. *for some nonnegative integer,* m, *and each* $\mathbf{x}$ *in* $\mathscr{B}$

$$\nabla^m\mathbf{u}(\mathbf{x} + k\mathbf{p}) = o(1) \quad \text{as } k \to \infty \quad \text{on } \mathbb{N}$$

and the projection of $\mathscr{S}_1$ *onto the* X_2*-axis has nontrivial interior.*

THEOREM 8.4 (uniqueness of solutions to slightly periodic problems). *Let* $\mathscr{B}$ *have positive definite elasticity and let* $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *be the difference between two solutions to the same slightly periodic boundary value problem on* $\mathscr{B}$. *Assume that there are real constants,* C *and* β, *such that, for some nonnegative integer,* n, *either*

$$|\delta^n\mathbf{u}(x,y)| \leqq C\left(1 + |y|^\beta\right)\left(1 + |x|^{1/2}\right)$$

for every (x,y) *in* $\mathscr{B}$, *or*

$$|\delta^n\nabla\mathbf{E}(x,y)| \leqq C\left(1 + |y|^\beta\right)\left(1 + |x|^{1/2}\right)$$

for every (x,y) *in* $\mathscr{B}$. *If any one of the following conditions holds, then* $\mathbf{E}$ *and* $\mathbf{S}$ *vanish throughout* $\mathscr{B}$ *and* $\mathbf{u}$ *is a rigid displacement*:

1. $\mathbf{u}(\mathbf{x}) = o(|\mathbf{x}|)$ *as* $|\mathbf{x}| \to \infty$ *on* $\mathscr{P}$;
2. $\mathbf{S}(\mathbf{x}) = o(1)$ *as* $|\mathbf{x}| \to \infty$ *on* $\mathscr{P}$;
3. $\mathscr{S}_1$, *the surface on which* $\mathbf{u}$ *is prescribed, is nontrivial and either*

$$\mathbf{Se}^1 = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}$$

or

$$\mathbf{Se}^2 = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P};$$

4. $\mathscr{B}$ *is contained in a single half plane, the traction is prescribed on almost all of* $\partial\mathscr{B}$, *and*

$$S_{11}(\mathbf{x}) = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P};$$

5. *for each* $\mathbf{x}$ *in* $\mathscr{B}$

$$\mathbf{S}(\mathbf{x}+k\mathbf{p})=o(1) \quad \text{as } k\to\infty \quad \text{on } \mathbb{N};$$

6. *for each* $\mathbf{x}$ *in* $\mathscr{B}$

$$\nabla\mathbf{S}(\mathbf{x}+k\mathbf{p})=o(1) \quad \text{as } k\to\infty \quad \text{on } \mathbb{N};$$

and there are two points on $\partial\mathscr{B}$ *at which* $\mathbf{s}$ *is prescribed such that the normals to* $\partial\mathscr{B}$ *at these two points span* $\mathbb{R}^2$;

7. *for some nonnegative integer,* m, *and each* $\mathbf{x}$ *in* $\mathscr{B}$

$$\nabla^m\mathbf{u}(\mathbf{x}+k\mathbf{p})=o(1) \quad \text{as } k\to\infty \quad \text{on } \mathscr{B}$$

and the projection of $\mathscr{S}_1$ *onto the* X_2*-axis has nontrivial interior.*

It should be noted that conditions 5, 6, and 7 in the above two theorems were discussed in the corresponding theorems in [4]. If one of these three conditions is the condition which holds, then Theorem 7.1 need not be used in proving the claimed periodicity or uniqueness.

The final theorems of this section involve the traction problem. The restrictions on the Lamé moduli will be greatly weakened, while an additional condition (along with those assumed at the beginning of this section) will be imposed on the geometry of $\mathscr{B}$. That condition is

4. There is a fixed vector, $\mathbf{m}^0$, such that

$$\mathbf{m}^0\cdot\mathbf{n}>0$$

almost everywhere on the boundary of $\mathscr{B}$.

The term "quasi-half plane" will be used (with some apologies) to denote a body which satisfies Condition 4 as well as the conditions already assumed at the beginning of this section. The only restriction on the Lamé moduli is that

$$\mu(2\mu+\lambda)(\mu+\lambda)\neq 0.$$

The first result in this final sequence of theorems is the obvious improvement of Theorem 4.3 using Theorem 7.1. The proof is straightforward and will be omitted.

THEOREM 8.5 (uniqueness of periodic strain solutions). *Let* $\mathscr{B}$ *be a quasi-half plane and let* $(\mathbf{u},\mathbf{E},\mathbf{S})$ *be the difference between two solutions to the same traction problem on* $\mathscr{B}$. *Suppose that* $\mathbf{E}$ *is periodic and, for some* $\beta>0$, *satisfies*

$$\mathbf{E}(\mathbf{x})=O\big(|\mathbf{x}|^{\beta}\big) \quad \text{as } |\mathbf{x}|\to\infty \quad \text{on } \mathscr{P}.$$

If either

$$\mathbf{u}(\mathbf{x})=o(|\mathbf{x}|) \quad \text{as } |\mathbf{x}|\to\infty \quad \text{on } \mathscr{P}$$

or

$$S_{11}(\mathbf{x})=o(1) \quad \text{as } |\mathbf{x}|\to\infty \quad \text{on } \mathscr{P}$$

then $\mathbf{E}$ *and* $\mathbf{S}$ *vanish throughout* $\mathscr{B}$ *and* $\mathbf{u}$ *is a rigid displacement.*

In [4] it was shown that combining a general uniqueness theorem with a corresponding uniqueness theorem for periodic strain states and successive applications of Theorem 4.2 led to the assertion that certain periodic boundary value problems had only periodic strain solutions (see Theorems 8.1 and 8.3 of [4]). Likewise, an intelligent combination of Theorems 2.2 and 8.5, above, along with several applications of Theorem 3.1 will prove the following theorem. The proof however, will be omitted since it is both tedious and similar in spirit to those in [4].

THEOREM 8.6 (periodicity of solutions). *Let $\mathscr{B}$ be a quasi-half plane and let* $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *be a solution to a periodic traction problem on $\mathscr{B}$. Suppose that for some $\beta > 0$,*

$$\nabla \mathbf{u}(\mathbf{x}+\mathbf{p}) - \nabla \mathbf{u}(\mathbf{x}) = O\left(|y|^{\beta}\right) \quad \text{as } |y| \to \infty$$

and

$$\frac{\mathbf{S}(\mathbf{x}+\mathbf{p}) - \mathbf{S}(\mathbf{x})}{1+|y|^{\beta}} = o(1) \quad \text{as } |x| \to \infty$$

where $(x,y) = \mathbf{x}$. Then $\mathbf{E}$ *and* $\mathbf{S}$ *are periodic.*

Finally, consider an arbitrary, not necessarily periodic, traction problem on a quasi-half plane. By the definition of quasi-half plane the corresponding null traction problem is periodic. Thus, Theorem 8.6 can be applied using the difference between any two solutions. Once the difference is found to be periodic, Theorem 8.5 can be invoked to prove that, in fact, the difference is a trivial elastic state. This analysis is summarized in the following theorem.

THEOREM 8.7 (uniqueness in the general traction problem). *Let $\mathscr{B}$ be a quasi-half plane, and let* $(\mathbf{u}, \mathbf{E}, \mathbf{S})$ *be the difference between two solutions to the same traction problem on $\mathscr{B}$. Suppose that for some $\beta > 0$,*

$$\mathbf{E}(\mathbf{x}) = O\left(|\mathbf{x}|^{\beta}\right) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P},$$

$$\nabla \mathbf{u}(\mathbf{x}+\mathbf{p}) - \nabla \mathbf{u}(\mathbf{x}) = O\left(|y|^{\beta}\right) \quad \text{as } |y| \to \infty$$

and

$$\frac{\mathbf{S}(\mathbf{x}+\mathbf{p}) - \mathbf{S}(\mathbf{x})}{1+|y|^{\beta}} = o(1) \quad \text{as } |x| \to \infty$$

where $(x,y) = \mathbf{x}$. If either

$$\mathbf{u}(\mathbf{x}) = o(|\mathbf{x}|) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}$$

or

$$S_{11}(\mathbf{x}) = o(1) \quad \text{as } |\mathbf{x}| \to \infty \quad \text{on } \mathscr{P}$$

or

$$S_{11}(\mathbf{x}) = o(1) \quad \text{as } |x| \to \infty,$$

then $\mathbf{E}$ *and* $\mathbf{S}$ *vanish throughout $\mathscr{B}$ and* $\mathbf{u}$ *is a rigid displacement.*

9. Nonvanishing body forces. Although the major lemma, Lemma 6.1, was derived without regard to the presence or absence of a nontrivial body force field, $\mathbf{b}$, the vanishing of $\mathbf{b}$ was an assumption in Theorem 7.1. If, instead, one assumes in Theorem 7.1 that the body force field, $\mathbf{b}$, is curl-free and divergence-free and satisfies

$$\mathbf{b}(x,y) = O(y^{-\alpha}) \quad \text{as } y \to \infty$$

for some real constant, α, then (7.9) in the proof of Theorem 7.1 becomes

$$\nabla \nabla \mathbf{u}(x,y) = O(y^{-\alpha}) \quad \text{as } y \to \infty.$$

If, in addition

$$\lim_{y\to\infty}\int_{\mathscr{P}\cap\mathscr{C}_y}\mathbf{b}\,da=0$$

where

$$\mathscr{C}_y=\{(x,\bar{y}):\bar{y}<y\},$$

then slight modifications in (7.15) and (7.16) still imply (7.17). With these changes, Theorem 7.1 becomes

THEOREM 9.1. *Suppose that $\mathscr{B}$ is a two-dimensional elastic body containing the upper half plane, $\{(x,y):y>0\}$, and that $(\mathbf{u},\mathbf{E},\mathbf{S})$ is a periodic strain state on $\mathscr{B}$ corresponding to a body force, $\mathbf{b}$, satisfying both*

$$\lim_{y\to\infty}\int_{\mathscr{P}\cap\mathscr{C}_y}\mathbf{b}\,da=0$$

and, for some $\alpha>0$,

$$\mathbf{b}(x,y)=O(y^{-\alpha})\quad \text{as } y\to\infty.$$

Assume, also, that for some arbitrary real β and some period section $\mathscr{P}$, either

$$\mathbf{u}(\mathbf{x})=O(|\mathbf{x}|^{\beta})\quad \text{as } |\mathbf{x}|\to\infty\quad \text{on } \mathscr{P}$$

or

$$\mathbf{E}(\mathbf{x})=O(|\mathbf{x}|^{\beta})\quad \text{as } |\mathbf{x}|\to\infty\quad \text{on } \mathscr{P}.$$

If $\alpha>1$, then the negative mean surface traction, $\bar{\mathbf{s}}$, exists and

$$\mathbf{E}(x,y)-\mathbf{E}^0(x,y)=O(y^{1-\alpha})\quad \text{as } y\to\infty,$$
$$\mathbf{S}(x,y)-\mathbf{S}^0(x,y)=O(y^{1-\alpha})\quad \text{as } y\to\infty$$

where $(\mathbf{u}^0,\mathbf{E}^0,\mathbf{S}^0)$ is the elastic state defined in §7. Moreover, if $\alpha>2$, then there is a fixed vector, $\mathbf{v}^0$, such that

$$\mathbf{u}(x,y)-\mathbf{u}^0(x,y)-\mathbf{v}^0=O(y^{2-\alpha})\quad \text{as } y\to\infty.$$

From this can be derived the following theorem of work and energy (compare with Theorem 8.2). $\mathscr{B}$ is as described in §8.

THEOREM 9.2 (work and energy). *Let $(\mathbf{u},\mathbf{E},\mathbf{S})$ be a periodic strain state on $\mathscr{B}$ corresponding to a curl free and divergence free body force, $\mathbf{b}$. Assume that*

$$\lim_{y\to\infty}\int_{\mathscr{P}\cap\mathscr{C}_y}\mathbf{b}\,dv=0$$

and that, for some $\alpha>2$,

$$\mathbf{b}(\mathbf{x})=O(|\mathbf{x}|^{-\alpha})\quad \text{as } |\mathbf{x}|\to\infty\quad \text{on } \mathscr{P}$$

and that either

$$\mathbf{u}(\mathbf{x})=o(|\mathbf{x}|)\quad \text{as } |\mathbf{x}|\to\infty\quad \text{on } \mathscr{P}$$

or

$$\mathbf{S}(\mathbf{x}) = o(1) \quad as\ |\mathbf{x}| \to \infty \quad on\ \mathscr{P}.$$

Then the total work expended in the deformation of any period section, $\mathscr{P}$, is finite and is given by

$$\int_{\mathscr{P}} \mathbf{E} \cdot \mathbf{S}\, dv = \int_{\partial\mathscr{B} \cap \partial\mathscr{P}} \mathbf{u} \cdot \mathbf{s}\, da + \int_{\mathscr{P}} \mathbf{u} \cdot \mathbf{b}\, dv.$$

In a similar fashion, versions of Saint-Venant's principle (Theorem 8.1) involving nonvanishing body forces can be derived as direct consequences of Theorem 9.1. These will be left to the interested reader.

10. Asymptotic behavior of periodic nonplanar strain states. There does not exist a theorem analogous to Theorem 7.1 for nonplanar strain states. This can be seen by taking the two base periodic states from §4 associated with an arbitrary three-dimensional periodic strain state in which $\omega_1 = \omega_2 = 0$. Letting $\mathscr{B}$ be the upper half space, $\{(x,y,z) : z > 0\}$, it is clear that the negative mean strain, $\bar{\mathbf{s}}$, associated with each base state is $\mathbf{0}$. Thus, provided a theorem analogous to 7.2 did hold for such states, the two base states should approach the same "asymptotic state" as z approaches infinity. Clearly, however, they do not.

QUASI INNER PRODUCTS OF ANALYTIC FUNCTIONS WITH APPLICATIONS TO SPECIAL FUNCTIONS*

L. R. BRAGG†

Abstract. Let $f(z)=\sum_{n=0}^{\infty}a_n z^n$, $g(z)=\sum_{n=0}^{\infty}b_n z^n$ be analytic functions in a disk D. For $z\in D$, define the quasi inner product of f and g by

$$f(z)\circ g(z)=\frac{1}{2\pi}\cdot\int_0^{2\pi} f(ze^{i\theta})g(ze^{-i\theta})\,d\theta=\sum_{n=0}^{\infty}a_n b_n z^{2n}.$$

In this paper, (i) we treat the analytic and algebraic properties of $\circ$ and (ii) apply this composition to special functions. Included are treatments of the hypergeometric functions, generating functions, and the Lerch transcendent function. Certain generalizations of the composition $\circ$ are also considered.

Key words. analytic function, quasi inner products, diagonal of product series, special functions, generating functions, representations

1. Introduction. Let x,y,z denote complex variables and let $f(z)$, $g(z)$ be a pair of functions of z that are analytic in a disk D of radius R with center 0. Suppose that $f(z)=\sum_{n=0}^{\infty}a_n z^n$ and $g(z)=\sum_{n=0}^{\infty}b_n z^n$. Then if x, $y\in D$, we define the compositions $f(x)\circ g(y)$ of f and g by the relation

$$f(x)\circ g(y)=\frac{1}{2\pi}\cdot\int_0^{2\pi} f(xe^{i\theta})g(ye^{-i\theta})\,d\theta=\sum_{n=0}^{\infty}a_n b_n x^n y^n. \tag{1.1}$$

The last member of this is simply the sum of the main diagonal terms in the product of the series for $f(x)$ and $g(y)$. The integral in (1.1) defines a convolution of two functions and is a modified version of a contour integral employed by M. L. J. Hautus and D. A. Klarner in their treatment of the diagonal terms of a double power series whose coefficients are defined by a linear recurrence relation [8]. In addition, J. Hadamard made use of an integral analogous to (1.1) to determine the singularities of the function defined by the series $\sum_{n=0}^{\infty}a_n b_n z^n$ (Hadamard's multiplication theorem) [13]. If the a_n and b_n are real, then the right member of (1.1) assigns a real value to each fixed pair of reals x, $y\in D$ and has the form of an inner product. Similar inner products appear in H^2 space theory [5], [9], [12]. In our discussions, we permit x and y to vary in D in (1.1) and refer to the composition in (1.1) as a *quasi inner product* which we abbreviate by qip.

Our interest in qip (1.1) (and a number of its generalizations) is motivated by (i) its utility in developing integral representations and related results for special functions and (ii) its applicability to transmutations (see [1], [3]) and the representation of solutions of partial differential equations. Qip's can be used as function builders and (1.1) permits the introduction of multipliers. Thus, if $g(y)$ is analytic in a region which includes $|y|=1$, then by selecting $y=1$ in (11.) we have the formula

$$\sum_{n=0}^{\infty}a_n b_n x^n=\frac{1}{2\pi}\cdot\int_0^{2\pi} f(xe^{i\theta})g(e^{-i\theta})\,d\theta \tag{1.2}$$

*Received by the editors February 3, 1983, and in revised form March 14, 1984.

in which the coefficients a_n in the expansion of $f(x)$ are multiplied by the b_n's (see [6]). As an example of (i) suppose we select $f(x)=g(z)=e^{z/2}$. Then (1.1) immediately yields the familiar result:

$$\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{z\cos\theta}\,d\theta = e^{z/2}\circ e^{z/2} = \sum_{n=0}^{\infty}\frac{z^{2n}}{2^{2n}(n!)^2} = I_0(z),$$

a modified Bessel function of index 0. By making other suitable choices for $f(z)$, $g(z)$ in (1.1) as special functions or generators of special functions, one can easily obtain numerous integration results that would, at best, be more tedious using standard methods. With modifications in the right member of (1.1), one can also construct superdiagonal sums (i.e. $\Sigma_{n=0}^{\infty}a_nb_{n+j}x^ny^{n+j}j\geqq 1$) or subdiagonal sums ($\Sigma_{n=0}^{\infty}a_{n+j}b_nx^{n+j}y^n, j\geqq 1$) from the product $f(x)\cdot g(y)$. For instance, if we replace $f(x)$ in (1.1) by $x^jf(x), j$ a positive integer, it is easy to verify that

$$\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{ji\theta}f(xe^{i\theta})g(ye^{-i\theta})\,d\theta = \sum_{n=0}^{\infty}a_nb_{n+j}x^ny^{n+j}. \tag{1.3}$$

Again, taking $f(z)=g(z)=e^{z/2}$ in this, it follows that

$$I_j(z)=\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{ji\theta}e^{z\cos\theta}\,d\theta=\frac{1}{2\pi}\cdot\int_0^{2\pi}(\cos j\theta)\,e^{z\cos\theta}\,d\theta.$$

One can construct other qip's such as

$$f(z)\,{}_p\circ_q\, g(y)=\frac{1}{2\pi}\cdot\int_0^{2\pi} f(xe^{pi\theta})g(ye^{-qi\theta})\,d\theta \tag{1.4}$$

with p,q positive integers and, for simplicity, $(p,q)=1$. This will select out sums of terms from $f(x)\cdot g(y)$ along rays other than the usual diagonals. Modifications similar to (1.3) can also be developed for this qip. The qip's (1.1) and (1.4) bring together notions from both analytic functions and Fourier analysis.

In this paper, we will treat the basic properties of these qip's and certain of their applications to special functions while deferring their uses in p.d.e's. Section 2 will be concerned with the analytic properties of qip's (1.1.) and (1.4). By making use of relations such as (1.3) for superdiagonal and subdiagonal sums, we construct a partial sum integral that approximates the product $f(x)\cdot g(y)$. Not surprising, the kernel function in this approximation is the same as the one in the Fourier series case and leads to analogous convergence results. We also note the algebraic and differentiation properties of these quasi inner products. Finally, in §§3–5, we apply these qip's to obtain a variety of representations and results for special functions. Many of these appear to be new while, in other cases, the method leads to simplifications over standard treatments. In §3, we apply these techniques to the hypergeometric functions ${}_pF_q$. We apply (1.1) and (1.4) in §4 to a number of generating functions of special polynomials and functions. In §5, we note some results for the Lerch transcendent function. Finally, we consider some examples that involve extensions of the ideas behind the compositions $\circ$ and ${}_p\circ_q$.

2. Analytic properties of (1.1) and (1.4). If $f(x)$, $g(y)$ are analytic for x, $y\in D$, then it readily follows that $f(x)\circ g(y)$ is analytic in x and y. For, there exists $\rho>0$ with $\max(|x|,|y|)<\rho<R$ and $M>0$, $N>0$ such that $|a_n|<M/\rho^n$, $|b_n|<N/\rho^n$. Hence

$$\left|\frac{1}{2\pi}\cdot\int_0^{2\pi} f(xe^{i\theta})g(ye^{-i\theta})\,d\theta\right|\leqq\sum_{n=0}^{\infty}|a_n||b_n||xy|^n\leqq\sum_{n=0}^{\infty}MN\frac{|xy|^n}{\rho^{2n}}$$

and this last series converges by the ratio test. Thus, $f(x) \circ g(y)$ is well defined for x, $y \in D$.

If at least one of the two functions appearing in the qip (1.1) is entire, say $g(z)$, then one can prove the following result.

THEOREM 2.1. *Let $f(x)$ be analytic in x with*

$$\limsup_{n \to \infty} |a_n|^{1/n} = \frac{1}{R}, \qquad 0 < R < \infty,$$

and let $g(y)$ be entire in y. Then for $|x| < R$, $f(x) \circ g(y)$ is entire in xy.

In the proof of Theorem 2.1, the restriction imposed on x is necessitated by requiring the integral in (1.1) to be well defined. However, the right member of (1.1) is well defined for all xy. In practice, one can select $x \in D$, $x \neq 0$, and then choose y so that xy takes on the value one wishes to use.

In addition to these results, there are a variety of algebraic and other analytic properties associated with the qip (1.1). The following can be easily verified by the reader.

THEOREM 2.2. *Let $f(z)$, $g(z)$, and $h(z)$ be analytic for $z \in D$. Then for $x, y, z \in D$, we have*

(i) $f(x) \circ g(y) = g(y) \circ f(x)$;

(ii) $f(x) \circ [g(y) + h(y)] = f(x) \circ g(y) + f(x) \circ h(y)$;

(iii) *if $f(z)$ and $g(z)$ have no powers of z in common in their expansions, then* $f(z) \circ g(z) = 0$;

(iv) *for n a nonnegative integer.*

$$z^n \frac{d^n}{dz^n}(f(z) \circ g(z)) = \sum_{j=0}^{n} \binom{n}{j} \left[\left(z^{n-j} f^{(n-j)}(z) \right) \circ \left(z^j g^{(j)}(z) \right) \right].$$

The last of these can be checked by induction. On the other hand, we have, in general,

$$f(z) \circ [g(z) \circ h(z)] \neq [f(z) \circ g(z)] \circ h(z) \tag{2.1}$$

(for example, select $f(z) = g(z) = z$ and $h(z) = z^2$). Thus, relative to the composition $\circ$, the set of functions analytic in D have divisors of 0 and are nonassociative. Further, if $g(z) = z$, then $1 \circ g(z) = 0$ so that 1 does not serve as a multiplicative identity relative to the $\circ$ composition. In using the qip (1.1) to construct "advanced" functions from elementary ones, the failure of associativity usually presents no serious problems. One computes, say, $f(z) \circ g(z)$ and then replaces z^2 in this by a new variable before making further applications of the $\circ$ composition.

In (1.3), we obtained an integral formula for the sums of terms of $f(x) \cdot g(y)$ taken from the superdiagonals. Similarly, if we replace $g(y)$ in (1.1) by $y^j \cdot g(y)$, one can verify that

$$\frac{1}{2\pi} \cdot \int_0^{2\pi} e^{-ji\theta} f(xe^{i\theta}) g(ye^{-i\theta}) \, d\theta = \sum_{n=0}^{\infty} a_{n+j} b_n x^{n+j} y^n, \qquad j \geqq 1. \tag{2.2}$$

The right member of this yields a sum of terms from $f(x) \cdot g(y)$ taken over a subdiagonal.

Finally, suppose we sum the left members of (1.3) and (2.2) on j from $-N$ to N by using (2.2) for j negative and (1.3) for j nonnegative. We get

(2.3)

$$\frac{1}{2\pi}\cdot\int_0^{2\pi} f(xe^{i\theta})g(ye^{-i\theta})\left(\sum_{j=-N}^{N} e^{ji\theta}\right)d\theta=\frac{1}{2\pi}\int_0^{2\pi} f(xe^{i\theta})g(ye^{-i\theta})\left\{\frac{\sin(N+\frac{1}{2})\theta}{\sin\frac{1}{2}\theta}\right\}d\theta.$$

Since $f(xe^{i\theta})$ and $g(ye^{-i\theta})$ are analytic and periodic in θ of period 2π for fixed x and y, it follows, from the Dirichlet convergence criterion for Fourier series ([4], [13]), that

$$\lim_{N\to\infty}\frac{1}{2\pi}\cdot\int_0^{2\pi} f(xe^{i\theta})g(ye^{-i\theta})\frac{\sin(N+\frac{1}{2})\theta}{\sin\frac{1}{2}\theta}\,d\theta=f(x)\cdot g(y). \tag{2.4}$$

Alternatively, one could assume that the sum of the diagonal, superdiagonal, and subdiagonal terms of $f(x)\cdot g(y)$ converges to $f(x)\cdot g(y)$. From this, we could then infer the limit relation (2.4).

We observe that if $f(z)$ is analytic in a disk D of radius $R>1$, then

$$\frac{1}{2\pi}\cdot\int_0^{2\pi}|f(e^{i\theta})|^2\,d\theta=\sum_{n=0}^{\infty}a_n^2,\qquad a_n \text{ real}. \tag{2.5}$$

If, for example, we make the choice

$$f(z)=\frac{1}{a-bz}=\sum_{n=0}^{\infty}\frac{b^n z^n}{a^{n+1}},\qquad a>b>o,$$

then (2.5) leads to the integral evaluation

$$\int_0^{2\pi}[a^2+b^2-2ab\cos\theta]^{-1}\,d\theta=\frac{2\pi}{a^2-b^2}.$$

Hence, if $c>d>0$, we get

$$\int_0^{2\pi}(c-d\cos\theta)^{-1}\,d\theta=\frac{2\pi}{(c^2-d^2)^{1/2}}. \tag{2.6}$$

For the qip (1.4), it is easy to show that

$$f(x)\,{}_p\circ_q\, g(y)=\sum_{n=0}^{\infty}a_{nq}b_{np}x^{nq}y^{np} \tag{2.7}$$

and the right member of this is analytic if $x, y\in D$. The properties (ii)–(iv) of Theorem 2.2 as well as the nonassociativity (2.1) are applicable to the qip ${}_p\circ_q$. We note that the commutative law fails for this qip but we do have the relation

$$f(x)\,{}_p\circ_q\, g(y)=g(y)\,{}_q\circ_p\, f(x).$$

One also obtains somewhat more general results than ones such as (1.3) or (2.6) for (1.1). In fact, a straightforward calculation shows that

$$\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{ki\theta}f(xe^{pi\theta})g(ye^{-qi\theta})\,d\theta=\sum_{\substack{m,n\geqq 0\\ mq-np=k}}a_n b_m x^n y^m,\qquad k\geqq 1. \tag{2.8}$$

Suppose that m_0, n_0 are the least nonnegative integer values of m,n such that $mq-np=k$. Then we take $m=lp+m_0$, $n=lq+n_0$, $l=0,1,2,\cdots$ for this Diophantine equation. The relation (2.8) becomes

$$\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{ki\theta}f(xe^{pi\theta})g(ye^{-qi\theta})\,d\theta=\sum_{l=0}^{\infty}a_{lq+n_0}b_{lp+m_0}x^{lq+n_0}y^{lp+m_0}. \tag{2.9}$$

If we desire a formula analogous to (1.3), select $m_0=j$ and $n_0=0$ in (2.9); then k is required to have the value $q\cdot m_0$ in the left member of (2.9).

3. The hypergeometric functions. Let α and β denote a pair of vectors with $\alpha=(\alpha_1,\cdots,\alpha_{p_1})$, $\beta=(\beta_1,\cdots,\beta_{q_1})$ where the α_i and β_j are real, $q_1+1\geqq p_1$, and $\beta_j>0$ for $j=1,\cdots,q_1$. Let $(\alpha)_n=\prod_{i=1}^{p_1}(\alpha_i)_n$ where $(\alpha_i)_n=\alpha_i(\alpha_i+1)\cdots(\alpha_i+n-1)$. Then we can express the generalized hypergeometric function ${}_{p_1}F_{q_1}(\alpha_1,\cdots,\alpha_{p_1};\beta_1,\cdots,\beta_{q_1};z)$ in the form

$${}_{p_1}F_{q_1}(\alpha;\beta;z)=\sum_{n=0}^{\infty}\frac{(\alpha)_n}{(\beta)_n}\frac{z^n}{n!}. \tag{3.1}$$

Next, suppose γ and δ are a second pair of vectors analogous to α and β having p_2 and q_2 components, respectively, with $q_2+1\geqq p_2$. Denote the concatenated vector $(\alpha_1,\cdots,\alpha_{p_1},\gamma_1,\cdots,\gamma_{p_2})$ of length p_1+p_2 by $\alpha\oplus\gamma$. It follows from (3.1) and (1.1) that if $|x|<1$, $|y|<1$, then

$$\begin{aligned}{}_{p_1+p_2}F_{q_1+q_2+1}(\alpha\oplus\gamma;\beta\oplus\delta\oplus 1;xy)&\\ ={}_{p_1}F_{q_1}(\alpha;\beta;x)\circ{}_{p_2}F_{q_2}(\gamma;\delta;y)&\\ =\frac{1}{2\pi}\cdot\int_0^{2\pi}{}_{p_1}F_{q_1}(\alpha;\beta;xe^{i\theta})\,{}_{p_2}F_{q_2}(\gamma;\delta;ye^{-i\theta})\,d\theta.&\end{aligned} \tag{3.2}$$

In the following, we develop integrals and related results for some special cases of (3.2). To avoid lengthy details, we will not reduce all integrands obtained in real form. In the last example, we will make use of the qip ${}_1\circ{}_2$. For our purposes, we require the following:

$$\begin{aligned}&\text{(a)}\quad {}_0F_0(-;-;z)=e^z,\\ &\text{(b)}\quad {}_1F_0(\alpha;-;z)=(1-z)^{-\alpha}=\sum_{n=0}^{\infty}\frac{(\alpha)_n}{n!}z^n,\\ &\text{(c)}\quad {}_1F_1(1;c;z)=\sum_{n=0}^{\infty}\frac{z^n}{(c)_n},\qquad c>0.\end{aligned} \tag{3.3}$$

I. *The standard Bessel functions.* In the introduction, we indicated how to use (1.3). To obtain analogous but slightly more general forms for the J_ν's, ν a nonnegative integer, suppose we select $j=\nu$, $f(x)=e^{\lambda^2 x}(\lambda>0)$, and $g(x)=e^{-x}$ in (1.3). Then that formula yields

$$\begin{aligned}\frac{1}{2\pi}\cdot\int_0^{2\pi}e^{\nu i\theta}e^{\lambda^2 xe^{i\theta}}e^{-xe^{-i\theta}}\,d\theta&=\frac{1}{2\pi}\cdot\int_0^{2\pi}e^{(\lambda^2-1)x\cos\theta}\cos\left[(\nu\theta+(\lambda^2+1)x\sin\theta)\right]d\theta\\ &=(-1)^\nu\lambda^{-\nu}J_\nu(2\lambda x)\end{aligned}$$

or

$$J_\nu(2\lambda x)=\frac{(-1)^\nu\lambda^\nu}{2\pi}\int_0^{2\pi} e^{(\lambda^2-1)x\cos\theta}\cos\left[\nu\theta+(\lambda^2+1)x\sin\theta\right]d\theta. \tag{3.4}$$

It is useful to compare the above derivation of the integral for $J_\nu(2\lambda x)$ with the standard one starting with the generating function for the Bessel functions.

II. *A* ${}_2F_1$ *function.* Suppose we select $f(z)=(1-z)^{-\alpha}$, $g(z)=(1-z)^{-\beta}$, $\alpha>0$, $\beta>0$. Then for $|z|<1$, we have, by (3.3b)

$$f(z)\circ g(z)=\frac{1}{2\pi}\cdot\int_0^{2\pi}(1-ze^{i\theta})^{-\alpha}(1-ze^{-i\theta})^{-\beta}d\theta \tag{3.5}$$

$$={}_2F_1(\alpha,\beta;1;z^2).$$

The integral in this can be expressed in the form

$$\frac{1}{2\pi}\cdot\int_0^{2\pi}\frac{\cos(\beta-\alpha)\phi}{[1-2z\cos\theta+z^2]^{(\alpha+\beta)/2}}d\theta,$$

with

$$\phi=\tan^{-1}\left(\frac{z\sin\theta}{1-z\cos\theta}\right)\quad\text{if } z \text{ is real.}$$

III. *A definite integral involving ultraspherical polynomials.* Let $\alpha=\beta$ in (3.5). Then, for $|z|<1$,

$$(1-ze^{i\theta})^{-\alpha}(1-ze^{-i\theta})^{-\alpha}=(1-2z\cos\theta+z^2)^{-\alpha},$$

this last being a generating function for the ultraspherical polynomials $P_n^\alpha(\cos\theta)$ [10]. Hence

$$f(z)\circ g(z)=\frac{1}{2\pi}\cdot\int_0^{2\pi}(1-2z\cos\theta+z^2)^{-\alpha}d\theta$$

$$=\frac{1}{2\pi}\cdot\int_0^{2\pi}\left(\sum_{n=0}^{\infty}P_n^\alpha(\cos\theta)z^n\right)d\theta \tag{3.6}$$

$$=\sum_{n=0}^{\infty}z^n\left(\frac{1}{2\pi}\cdot\int_0^{2\pi}P_n^\alpha(\cos\theta)\,d\theta\right).$$

But from (3.5) with $\beta=\alpha$, we have

$$f(z)\circ g(z)={}_2F_1(\alpha,\alpha;1;z^2)=\sum_{n=0}^{\infty}\frac{[(\alpha)_n]^2}{(n!)^2}z^{2n}. \tag{3.7}$$

Comparing the right member of (3.6) with the right member of (3.7), we obtain the familiar integral evaluation ([10])

$$\frac{1}{2\pi}\cdot\int_0^{2\pi}P_n^\alpha(\cos\theta)\,d\theta=\begin{cases}0, & n \text{ odd},\\ \left(\dfrac{(\alpha)_m}{m!}\right)^2, & n=2m.\end{cases} \tag{3.8}$$

The choice $\alpha=\frac{1}{2}$ in (3.8) gives the result for Legendre polynomials. We note the economy in obtaining (3.8) using $\circ$ as compared with standard techniques.

IV. *A* ${}_1F_1$ *type transformation.* From (3.3b, c), the reader can verify that

$$ {}_1F_1(1;c;x)\circ {}_1F_0(\alpha;-;y)={}_1F_1(\alpha;c;xy). \tag{3.9}$$

Now ${}_1F_1(1;c;x)$ is entire and ${}_1F_0(\alpha;-;y)$ is analytic with $R=1$. Theorem 2.1 shows that ${}_1F_1(\alpha;c;xy)$ is entire in xy if $|y|<1$.

V. *A* ${}_p\circ_q$ *example.* If we select $f(x)=e^x$ and $g(y)=(1-y)^{-\alpha}$, then it follows by (2.7) that

$$\begin{aligned} f(x)\,{}_1\circ_2\, g(y) &= \sum_{n=0}^{\infty} \frac{1}{(2n)!}\,\frac{(\alpha)_n}{n!}x^{2n}y^n \\ &= {}_1F_2\left(\alpha;\frac{1}{2},1;\frac{x^2y}{4}\right) \\ &= \frac{1}{2\pi}\cdot\int_0^{2\pi} e^{xe^{i\theta}}\left(1-ye^{-2i\theta}\right)^{-\alpha}d\theta. \end{aligned}$$

4. Generating functions. Quasi inner products, when used in conjunction with generating functions, are convenient for developing results for special functions. This is particularly true when the generating function is of exponential type and the Euler relations can be called upon to express integrals in a real form. In the following, we apply (1.1) and (1.4) to various generating functions to derive integral representations for certain infinite sums of products of special polynomials. We include cases that involve the Hermite, the generalized Hermite, and the ultraspherical polynomials. One example is given, without detailed development, that involves products of two different types of polynomials. Since these generating functions contain both variables and parameters, it will be necessary to distinguish which variable or parameter multiplies $e^{i\theta}$ or $e^{-i\theta}$ (respectively, $e^{pi\theta}$ or $e^{-qi\theta}$) in the choices for f and g in (1.1) (or 1.4). We do this by underscoring the designated variable or parameter.

A. *Hermite polynomials.* The Hermite polynomials are generated by means of the relation

$$f(x,t)=e^{2xt-t^2}=\sum_{n=0}^{\infty}\frac{H_n(x)t^n}{n!}. \tag{4.1}$$

If we take $g(x,t)=f(x,t)$, then

$$\begin{aligned} f(x,\underline{t})\circ f(x,\underline{t}) &= \sum_{n=0}^{\infty}\frac{[H_n(x)]^2}{(n!)^2}t^{2n} \\ &= \frac{1}{2\pi}\cdot\int_0^{2\pi}\exp(2txe^{i\theta}-t^2e^{2i\theta})\exp(2xte^{-i\theta}-t^2e^{-2i\theta})\,d\theta \\ &= \frac{1}{2\pi}\cdot\int_0^{2\pi}\exp(4tx\cos\theta-2t^2\cos 2\theta)\,d\theta. \end{aligned} \tag{4.2}$$

Similarly, the quasi inner product $f(x,\underline{t})\circ f(y,\underline{t})$ leads to the relationship

$$\begin{aligned} &\sum_{n=0}^{\infty}\frac{H_n(x)H_n(y)}{(n!)^2}t^{2n} \\ &\quad=\frac{1}{2\pi}\cdot\int_0^{2\pi}\exp(2t(x+y)\cos\theta-2t^2\cos 2\theta)\cos[2t(x-y)\sin\theta]\,d\theta. \end{aligned} \tag{4.3}$$

We note that (4.3) reduces to (4.2) when $y=x$.

B. *The generalized Hermite polynomials.* The generalized Hermite polynomials $g_n^p(x)$ are generated by the relation

$$f(x,t)=\exp(pxt-t^p)=\sum_{n=0}^{\infty}\frac{1}{n!}g_n^p(x)t^n \tag{4.4}$$

(see [7], also [2]). Using a calculation as in A above, we get

$$\begin{aligned} f(x,\underline{t})\circ f(x,\underline{t}) &= \frac{1}{2\pi}\cdot\int_0^{2\pi}\exp(2pxt\cos\theta-2t^p\cos p\theta)\,d\theta \\ &= \sum_{n=0}^{\infty}\frac{\{g_n^p(x)\}^2}{(n!)^2}t^{2n}. \end{aligned} \tag{4.5}$$

One can similarly obtain a formula analogous to (4.3).

C. *Ultraspherical polynomials.* We refered to these earlier and have, in fact

$$f(x,t)=(1-2xt+t^2)^{-\lambda}=\sum_{n=0}^{\infty}P_n^{\lambda}(x)t^n \tag{4.6}$$

with $|t|<1$ and $\lambda>0$. Forming $f(x,\underline{t})\circ f(x,\underline{t})$, we get

$$\sum_{n=0}^{\infty}\left[P_n^{\lambda}(x)\right]^2t^{2n}=\frac{1}{2\pi}\cdot\int_0^{2\pi}\left[1+4x^2t^2-4xt(1+t^2)\cos\theta+2t^2\cos 2\theta\right]^{-\lambda}d\theta. \tag{4.7}$$

D. *Hermite polynomials using* ${}_1\circ_2$. Suppose we again select $f(x,t)$ as in A above. Then

$$\begin{aligned} f(x,\underline{t})\,{}_1\circ_2 f(x,\underline{t}) &= \sum_{n=0}^{\infty}\frac{H_n(x)H_{2n}(x)}{n!(2n)!}t^{3n} \\ &= \frac{1}{2\pi}\cdot\int_0^{2\pi}\exp(2xt\cos\theta+(2xt-t^2)\cos 2\theta-t^2\cos 4\theta) \\ &\qquad\cdot\cos\left[2xt\sin\theta-(t^2+2xt)\sin 2\theta-t^2\sin 4\theta\right]d\theta. \end{aligned} \tag{4.8}$$

Finally, it should be observed that one can use qip's to compose generating functions for different types of polynomials to construct examples involving mixed products. For example, if we select $f(x,t)$ as in A above and select

$$g(x,t)=e^{xt}\cosh(t\sqrt{x^2-1})=\sum_{n=0}^{\infty}\frac{T_n(x)}{n!}t^n$$

in which $T_n(x)$ denotes a Chebyshev polynomial of degree n (see [10]), then $f(x,\underline{t})\circ g(x,\underline{t})$ leads to the relation

$$\sum_{n=0}^{\infty}\frac{H_n(x)T_n(x)}{n!n!}t^{2n}=\frac{1}{2\pi}\cdot\int_0^{2\pi}\exp(3xt\cos\theta-t^2\cos 2\theta)\,h(x,t,\theta)\,d\theta$$

with

$$h(x,t,\theta)=\cos\alpha\cos\beta\cosh\gamma+\sin\alpha\sin\beta\sinh\gamma,$$

where

$$\alpha = xt\sin\theta - t^2\sin 2\theta,$$
$$\beta = t\sqrt{x^2-1}\,\sin\theta,$$
$$\gamma = t\sqrt{x^2-1}\,\cos\theta.$$

5. Some further relations. In the following, we first apply (1.1) and (1.4) to obtain transformations on the Lerch transcendent function. We then consider certain generalizations of integrals of the type involved in (1.1) and (1.4) that involve three functions. This will lead to some results on Bessel functions and some integral evaluations for Fourier coefficients.

A. *The Lerch transcendent function.* This function is defined by the series

$$\Phi(z,s,\alpha) = \sum_{n=0}^{\infty} (\alpha+n)^{-s} z^n, \qquad |z|<1. \tag{5.1}$$

For our purposes, we assume that $s>1$ and $\alpha \geqq 1$. Then the series in (5.1) converges when $|z|=1$. It follows that if $|x|\leqq 1$, $|y|\leqq 1$, then

$$\Phi(x,s_1,\alpha)\circ\Phi(y,s_2,\alpha) = \Phi(xy,s_1+s_2,\alpha) \qquad \text{for } s_1, s_2>1. \tag{5.2}$$

For the choice $\alpha=1$ and $s_1=s_2=s$, this becomes

$$\frac{1}{2\pi}\cdot\int_0^{2\pi} \Phi(e^{i\theta},s,1)\Phi(e^{-i\theta},s,1)\,d\theta = \zeta(2s), \tag{5.3}$$

where $\zeta(-)$ denotes the Riemann zeta function. For $\lambda\geqq 1$ and $(p,q)=1$, we also have

$$\Phi(x,s_1,\lambda q)_p{}^{\circ}{}_q\,\Phi(y,s_2,\lambda p) = \sum_{n=0}^{\infty}\left\{\frac{1}{(nq+\lambda q)^{s_1}}\frac{1}{(np+\lambda p)^{s_2}}\right\}x^{nq}y^{np}$$
$$= \frac{1}{q^{s_1}p^{s_2}}\sum_{n=0}^{\infty}\left\{\frac{1}{(n+\lambda)^{(s_1+s_2)}}\right\}(x^qy^p)^n$$

or

$$\Phi(x,s_1,\lambda q)_p{}^{\circ}{}_q\,\Phi(y,s_2,\lambda p) = \frac{1}{q^{s_1}p^{s_2}}\Phi(x^qy^p,s_1+s_2,\lambda). \tag{5.4}$$

B. *Some generalizations.* Let $f(z)$, $g(z)$, and $h(z)$ be analytic in D and consider the integral

$$I = \frac{1}{2\pi}\cdot\int_0^{2\pi}\left[f(xe^{pi\theta})g(ye^{\pm qi\theta})h(ze^{-ri\theta})\right]d\theta \tag{5.5}$$

where f and g have expansions as in the introduction and $h(z)=\sum_{n=0}^{\infty}c_nz^n$. Then, by replacing f, g, and h in I by their expansions, we obtain

$$I = \sum_{j,k,l=0}^{\infty} a_jb_kc_lx^jy^kz^l\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{i(pj\pm qk-rl)\theta}\,d\theta. \tag{5.6}$$

The integrals in this sum vanish unless the summation indices satisfy the following Diophantine equation:

$$pj\pm qk-rl=0, \qquad j,k,l\geqq 0. \tag{5.7}$$

If one is able to solve for, say, the values of l in terms of the set of values for j and k, then the triple sum in (5.6) reduces to a double sum. If a partial summation can be carried out on this resulting double sum, then we can use (5.6) along with (5.5) to obtain further integral relations or evaluations for sums of special functions.

To avoid the complications of solving a general linear Diophantine equation, such as (5.7), in this paper we consider some specific choices for p,q,r. Suppose we first select $p=q=r=1$ and use the minus sign preceding the q in (5.7). Then we get $j=k+l$ so that (5.6) becomes

$$I=\sum_{k,l=0}^{\infty} a_{k+l}b_k c_l x^{k+l}y^k z^l. \tag{5.8}$$

As an interesting special case of (5.8), suppose we choose $f(z)=g(z)=h(z)=e^z$. Then the double sum I, with $x=y=z$, becomes

$$I=\sum_{k=0}^{\infty}\left(\sum_{l=0}^{\infty}\frac{1}{l!(l+k)!}z^{2l+k}\right)\frac{z^k}{k!}=\sum_{k=0}^{\infty}\frac{z^k}{k!}I_k(2z). \tag{5.9}$$

By reducing the integral in (5.5) to real form in θ using this choice of functions, we finally get

$$\sum_{k=0}^{\infty}\frac{z^k I_k(2z)}{k!}=\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{3z\cos\theta}\cos(z\sin\theta)\,d\theta. \tag{5.10}$$

One can also use this method with $p=q=r=1$ and a plus sign in front of the q in (5.7) to deduce

$$\sum_{l=0}^{\infty}\frac{(-1)^l t^l}{l!}J_l(2x)=\frac{1}{2\pi}\cdot\int_0^{2\pi} e^{-t\cos\theta}\cos[(2x+t)\sin\theta]\,d\theta. \tag{5.11}$$

As a final example, suppose we select $f(x)=e^x$, $g(y)=h(y)=(1-y)^{-\lambda}$ and $p=q=r=1$ with a plus sign preceding the q in (5.7). The sum in (5.6) reduces to

$$\begin{aligned} I&=\sum_{j,k=0}^{\infty}\frac{1}{j!}\frac{(\lambda)_k}{k!}\frac{(\lambda)_{j+k}}{(k+j)!}x^j y^{2k+j} \qquad \text{(by (4.5b))}\\ &=\sum_{j=0}^{\infty}\frac{(xy)^j}{j!}\frac{(\lambda)_j}{(1)_j}\left(\sum_{k=0}^{\infty}\frac{(\lambda)_k(\lambda+j)_k}{k!(1+j)_k}y^{2k}\right) \qquad (5.12)\\ &=\frac{1}{\Gamma(\lambda)}\sum_{j=0}^{\infty}\frac{\Gamma(\lambda+j)(xy)^j}{(j!)^2}\,{}_2F_1(\lambda,\lambda+j;1+j;y^2), \end{aligned}$$

where $\Gamma(-)$ denotes the usual gamma function. Further, since $g(ye^{i\theta})h(ye^{-i\theta})=(1-2y\cos\theta+y^2)^{-\lambda}$, the corresponding integral (5.5) with integrand in real form in θ becomes

$$I=\frac{1}{2\pi}\cdot\int_0^{2\pi}\frac{e^{x\cos\theta}\cos(x\sin\theta)}{(1-2y\cos\theta+y^2)^{\lambda}}\,d\theta. \tag{5.13}$$

Now, select $\lambda = 1$. Then $\Gamma(\lambda + j) = j!$ and ${}_2F_1(\lambda, \lambda + j; 1 + j; y^2) = 1/(1 - y^2)$. The equality of (5.12) and (5.13) leads to the relation

$$\frac{1}{2\pi} \cdot \int_0^{2\pi} \frac{e^{x\cos\theta} \cos(x \sin\theta)(1 - y^2)}{(1 - 2y\cos\theta + y^2)} \, d\theta = e^{xy}. \tag{5.14}$$

The expansion of both sides of this in powers of y and a comparison of their corresponding coefficients yields the following integral evaluations:

$$\begin{aligned} &\frac{1}{2\pi} \cdot \int_0^{2\pi} e^{x\cos\theta} \cos(x \sin\theta) \, d\theta = 1, \\ &\frac{1}{2\pi} \cdot \int_0^{2\pi} e^{x\cos\theta} \cos(x \sin\theta) \cos n\theta \, d\theta = \frac{x^n}{n!}, \qquad n \geqq 1. \end{aligned} \tag{5.15}$$

UNIVALENCE CONSTRAINTS ON THE SCHWARZ–CHRISTOFFEL PARAMETERS*

JOHN A. PFALTZGRAFF†

Dedicated to Professor A. W. Goodman on the occasion of his seventieth birthday.

Abstract. The Area Theorem and coefficient inequalities for univalent functions are used to derive inequality constraints on the accessory parameters in the Schwarz–Christoffel formula for the conformal mapping of the unit disk onto the interior or onto the exterior of a polygon. The constraints restrict the choice of prevertices and are necessary for the univalence of the mapping. The conditions are explicit, easy to compute and are applicable to the numerical computation of the Schwarz–Christoffel map. The relative effectiveness of the constraints is illustrated by elementary examples.

Key words. accessory parameters, area theorem, conformal map, exterior mapping, prevertices, univalent, Schwarz–Christoffel formula

1. Introduction. In general it is very difficult to determine $z_k = e^{i\theta_k}$ $(k=1,\cdots,N)$, the *prevertices* (accessory parameters), in the Schwarz–Christoffel formula,

$$f(z) = C\int_0^z \prod_{k=1}^{N} (\zeta - z_k)^{-\beta_k} d\zeta + f(0), \tag{1.1}$$

$$\theta_1 < \theta_2 < \cdots < \theta_N < \theta_1 + 2\pi, \quad -1 \leqq \beta_k \leqq 3, \quad \sum_{k=1}^{N} \beta_k = 2, \tag{1.2}$$

for the conformal map of the unit disk $E = \{z: |z|<1\}$ onto the interior of a polygon P with interior angles $\pi(1-\beta_k)$ at the vertices $w_k = f(z_k)$, $k=1,\cdots,N$. When $-1 \leqq \beta_k < 1$ the vertex w_k is finite and $\pi\beta_k$ measures the turning of the tangent at w_k as the boundary of P is traversed in a counterclockwise direction. Vertices at ∞ correspond to the β_k with $1 \leqq \beta_k \leqq 3$ and the usual interpretation of interior and exterior angle at such a vertex [2, Thm. 5.12 e], [6, p. 83].

It is well known that formula (1.1) forces the image of the unit circle, $f(|z|=1)$, to be a polygonal path with vertices $w_k = f(z_k)$ and the specified exterior angles $\pi\beta_k$ at each vertex. The main difficulty in applying (1.1) is the choosing of C and the prevertices so that f will be univalent in E and P will have the correct side lengths (see [6, pp. 83–84]).

In this note we use results from univalent function theory to derive inequality constraints on the prevertices that are necessary for f in (1.1) to be univalent in E. We also give analogous conditions for the Schwarz–Christoffel mapping of E onto the exterior of a polygon. The accessory parameter problem is the most difficult and time consuming task in the numerical computation of the Schwarz–Christoffel transformation [6]. Although our results are extremely elementary, they provide explicit, computable constraints on the choice of accessory parameters.

2. The interior mapping. Since $z_k\bar{z}_k=1$ in (1.1) we may rewrite that formula as

$$f(z)=C\int_0^z \prod_{k=1}^{N}(1-\zeta\bar{z}_k)^{-\beta_k}\,d\zeta+f(0) \tag{2.1}$$

with a new constant C. Our necessary conditions for univalence of f involve the weighted power sums

$$s_n=\sum_{k=1}^{N}\beta_k\bar{z}_k^{n+1}, \qquad n=0,1,\cdots, \tag{2.2}$$

that appear as the Taylor coefficients in

$$\frac{f''(z)}{f'(z)}=\sum_{k=1}^{N}\frac{\beta_k\bar{z}_k}{1-z\bar{z}_k}=\sum_{n=0}^{\infty}s_nz^n, \qquad z\in E. \tag{2.3}$$

Note that (2.3) is independent of $f(0)$ and the scale factor $C=f'(0)$. Indeed, if $f(z)$ is univalent in E then

$$F(z)=\frac{f(z)-f(0)}{C}=z+\sum_{n=2}^{\infty}a_nz^n, \qquad z\in E, \tag{2.4}$$

belongs to the class S of normalized univalent functions and

$$\frac{F''(z)}{F'(z)}=\frac{f''(z)}{f'(z)}=\sum_{n=0}^{\infty}s_nz^n, \qquad z\in E. \tag{2.5}$$

THEOREM 1. *Let $z_k=e^{i\theta_k}$ and $\beta_k(k=1,\cdots,N)$ be given subject to conditions* (1.2). *If the function $f(z)$ defined by* (2.1) *is univalent in E then*

$$|s_0|=\left|\sum_{k=1}^{N}\beta_kz_k\right|\leqq 4, \tag{2.6}$$

$$|s_1+s_0^2|=\left|\sum_{k=1}^{N}\beta_kz_k^2+\left(\sum_{k=1}^{N}\beta_kz_k\right)^2\right|\leqq 18 \tag{2.7}$$

and

$$\left|s_1-\frac{1}{2}s_0^2\right|=\left|\sum_{k=1}^{N}\beta_kz_k^2-\frac{1}{2}\left(\sum_{k=1}^{N}\beta_kz_k\right)^2\right|\leqq 6. \tag{2.8}$$

Proof. Using the series expansion (2.4) in (2.5) we have

$$\sum_{n=0}^{\infty}(n+1)(n+2)a_{n+2}z^n=\left(1+\sum_{n=1}^{\infty}(n+1)a_{n+1}z^n\right)\sum_{n=0}^{\infty}s_nz^n$$

and the system

$$(n+1)(n+2)a_{n+2}=s_n+\sum_{k=1}^{n}(k+1)a_{k+1}s_{n-k}, \qquad n=0,1,\cdots, \tag{2.9}$$

which can be solved recursively to express a_n in terms of the s_k $(k\leqq n-2)$. The first two formulas are

$$2a_2=s_0, \qquad 6a_3=s_1+s_0^2. \tag{2.10}$$

If f is univalent in E then F belongs to S and therefore

$$|a_2| \leqq 2, \quad |a_3| \leqq 3, \quad |a_3 - a_2^2| \leqq 1, \tag{2.11}$$

[5, p. 213], [1, p. 94], which with (2.10) give (2.6), (2.7), and (2.8) respectively.

Clearly one can continue the foregoing method of proof with (2.9) and the sharp coefficient bounds $|a_n| \leqq n$ [7] to extend (2.6)–(2.8) to an infinite sequence of conditions on the s_n necessary for f to be univalent. Our second example below shows that (2.8) is more sensitive to nonunivalence of f than either (2.6) or (2.7). Note that $|a_3 - a_2^2| \leqq 1$ is simply the inequality $|b_1| \leqq 1$, obtained by applying the area theorem, $\sum_{n=1}^{\infty} n|b_n|^2 \leqq 1$ [5, p. 210] to

$$\frac{1}{F(z)} = \frac{1}{z} + b_0 + b_1 z + \cdots. \tag{2.12}$$

Thus it may be more fruitful to use the series expansion (2.4) in (2.12) to obtain the system

$$-b_n = a_{n+2} + \sum_{k=1}^{n-1} b_k a_{n+1-k}, \qquad n = 0, 1, \cdots, \tag{2.13}$$

solve (2.9) and (2.13) recursively to express b_n $(n = 1, \cdots, m)$ in terms of the s_k, and then apply the area theorem inequalities $\sum_{n=1}^{m} n|b_n|^2 \leqq 1$, $m = 1, 2, \cdots$.

Example 1. Let $f(z)$ be defined by (2.1) with $N = 4$, $(\beta_1, \beta_2, \beta_3, \beta_4) = (-\frac{3}{4}, -\frac{3}{4}, \frac{3}{4}, \frac{11}{4})$, $z_1 = (-5 + i\sqrt{11})/6, z_2 = \bar{z}_1, z_3 = -i, z_4 = 1$. Then f is not univalent since

$$\left| \sum_{k=1}^{4} \beta_k z_k \right| = \left| 4 - i\frac{3}{4} \right| > 4,$$

violating condition (2.6).

Example 2. Let $f(z)$ be defined by (2.1) with $N = 4$, β_k $(k = 1, 2, 3, 4)$ the same as in Example 1, $z_1 = (-47 + i\sqrt{1391})/60$, $z_2 = \bar{z}_1$, $z_3 = -i$, $z_4 = 1$. Then easy calculations show that both (2.6) and (2.7) are satisfied (3.9960... for (2.6) and 17.521... for (2.7)), but (2.8) is violated (6.470... is the value of (2.8)).

Remarks. Condition (2.6) is the unit disk version of E. Johnston's condition (3) (with $z_0 = i$) in [3] for the Schwarz–Christoffel mapping of the upper half-plane onto a polygon. We are able to construct nonunivalent examples with only four vertices (rather than six as in [3]) because we permit vertices at ∞ with exterior angles as large as 3π. Our formulation for the unit disk eliminates the need to translate results about the class S from E to the upper half-plane [3, Lemma, p. 702]. Furthermore the weighted power sums s_n are easy to compute, and they have a nice geometrical interpretation as moments of a distribution of weights β_k $(-1 \leqq \beta_k \leqq 3)$, on the unit circle.

3. The exterior mapping. If $g(z)$ is analytic in $0 < |z| < 1$ with a simple pole at 0, and if g maps E conformally onto the exterior of a bounded polygon P then g is given by the Schwarz–Christoffel formula

$$g(z) = C \int_a^z \prod_{k=1}^{N} (1 - \zeta \bar{z}_k)^{-\beta_k} \zeta^{-2} \, d\zeta + C_1, \tag{3.1}$$

$z_k = e^{i\theta_k}$, $\theta_1 < \theta_2 < \cdots < \theta_N < \theta_1 + 2\pi$ and

$$-1 \leqq \beta_k < 1, \quad \sum_{k=1}^{N} \beta_k = -2, \quad \sum_{k=1}^{N} \beta_k \bar{z}_k = 0, \tag{3.2}$$

[4, p. 331], [2, pp. 413–414]. The points $w_k = g(z_k)$, $k = 1, \cdots, N$, are the vertices of P, and since g reverses the boundary orientation, $\pi\beta_k$ measures the turning of the tangent at w_k as the boundary of P is traversed in a *clockwise* direction. The condition $\sum_{k=1}^{N} \beta_k \bar{z}_k = 0$ insures that $g'(z)$ has zero residue at the origin and hence that $g(z)$ is single valued. Indeed, if this condition holds then $g(z)$ has the Laurent expansion

$$g(z) = C\left(-\frac{1}{z} + \sum_{n=0}^{\infty} b_n z^n\right), \qquad 0 < |z| < 1, \tag{3.3}$$

and

$$z^2 g'(z) = C \prod_{k=1}^{N} (1 - z\bar{z}_k)^{-\beta_k} = C\left(1 + \sum_{n=1}^{\infty} n b_n z^{n+1}\right),$$

with

$$\operatorname{Res}(g'(z); 0) = C \sum_{k=1}^{N} \beta_k \bar{z}_k = 0.$$

The weighted power sums s_n defined by (2.2) now appear as the Taylor coefficients in

$$\begin{aligned} \frac{(z^2 g'(z))'}{z^2 g'(z)} &= \sum_{k=1}^{N} \frac{\beta_k \bar{z}_k}{1 - z\bar{z}_k} = \sum_{n=1}^{\infty} s_n z^n \\ &= \left(\sum_{n=1}^{\infty} n(n+1) b_n z^n\right) \Big/ \left(1 + \sum_{n=1}^{\infty} n b_n z^{n+1}\right), \qquad z \in E. \end{aligned} \tag{3.4}$$

THEOREM 2. *Let $z_k = e^{i\theta_k}$ and β_k $(k = 1, \cdots, N)$ be given satisfying conditions* (3.2). *If the function $g(z)$ defined by* (3.1) *is univalent in E then*

$$|s_1| = \left| \sum_{k=1}^{N} \beta_k z_k^2 \right| \leqq 2. \tag{3.5}$$

Proof. Using the series expansions in (3.4) we have $2b_1 = s_1$ and

$$n(n+1) b_n = s_n + \sum_{k=1}^{n-2} k b_k s_{n-1-k}, \qquad n = 2, 3, \cdots. \tag{3.6}$$

If g is univalent in E then by the area theorem $\sum_{n=1}^{\infty} n|b_n|^2 \leqq 1$. In particular $|b_1| \leqq 1$ which yields (3.5).

Again it is clear that additional univalence constraints on the s_n can be obtained by solving (3.6) recursively for b_n in terms of the s_k and then applying the area theorem. The process is simpler for the exterior mapping than for the interior mapping where there are two systems, (2.9) and (2.13), to solve.

Example 3. Let $g(z)$ be defined by (3.1) with $N=5$, $(\beta_1,\beta_2,\beta_3,\beta_4,\beta_5)=(-\frac{9}{10},-\frac{1}{2},-\frac{1}{2},-\frac{9}{10},\frac{4}{5})$, $z_1=\bar{z}_4=(4+i\sqrt{65})/9$, $z_2=\bar{z}_3=i$, $z_5=1$. Then the β_k and z_k satisfy conditions (3.2), but g is not univalent since

$$b_1=\frac{1}{2}\sum_{k=1}^{5}\beta_k z_k^2=1+\frac{4}{9}>1.$$

CRITICAL VALUES AND REPRESENTATION OF FUNCTIONS BY MEANS OF COMPOSITIONS*

Y. YOMDIN†

Abstract. The structure of the set of critical values of a composition of differentiable mappings is studied. On this base some explicit examples of differentiable functions, not representable by compositions of certain types, are given.

The question of a representability of functions of a given class by means of compositions of functions, belonging to some other given classes, has been studied in many publications (see e.g. [1], [2], [3], [4]). The known results on a nonrepresentability are mostly based on considerations of a "massiveness" of corresponding subsets in a suitable functional space. Therefore, showing the existence of nonrepresentable functions, they do not give explicit examples.

In this paper we consider some special question of the above type, which roughly can be formulated as follows: what functions of a given smoothness and a given number of variables can be represented in a form $f=g\circ h$, where g depends on a smaller number of variables than f (and, possibly, has a lower smoothness), while the smoothness of h is higher than the smoothness of f.

We find an upper bound for the entropy dimension of the set of critical values of the function, represented in such a form. Using this bound we give the necessary condition for the representability, and some examples of nonrepresentable functions.

The result of Theorem 1 below can be considered as a generalization to the case of composed mappings of the sharp estimates for the entropy dimension of critical values of differentiable mappings, obtained in [6].

Let f: $U\to R^m$ be a continuously differentiable mapping of an open domain $U\subset R^n$. For $\gamma\geqq 0$ define the set of "γ-near-critical" points of f, $\Sigma(f,\gamma)$, by $\Sigma(f,\gamma)=\{x\in U/\|df(x)\|\leqq\gamma\}$, and let $\Delta(f,\gamma)=f(\Sigma(f,\gamma))$ be the corresponding set of "γ-near-critical" values of f. The set of critical points $\Sigma(f,0)$ we denote by $\Sigma(f)$ and the set of critical values $\Delta(f,0)$ by $\Delta(f)$.

For a compact domain $D\subset R^n$ let $C^k(D,m)$ denote the space of mappings f: $D\to R^m$, which can be extended to a k times continuously differentiable mapping of some open neighborhood of D. For $f\in C^k(D,m)$ let

$$M_i(f)=\max_{y\in D}\|d^i f(y)\|,\qquad i=0,\cdots,k.$$

(The Euclidean spaces R^q and the spaces of their linear and multilinear mappings are considered with the usual Euclidean norms.)

We recall the definition of the entropy dimension: for a bounded subset $A\subset R^m$ and $\varepsilon>0$ let $M(\varepsilon,A)$ be the minimal number of balls of radius ε, covering A. Then the entropy dimension $\dim_e A$ is defined by

$$\dim_e A=\inf\left\{\beta\geqq 0/\exists K,\forall\varepsilon,1\geqq\varepsilon>0,M(\varepsilon,A)\leqq K\left(\frac{1}{\varepsilon}\right)^{\beta}\right\}.$$

(See e.g. [3], [6] for some properties of $M(\varepsilon,A)$ and of the entropy dimension.)

* Received by the editors November 29, 1983, and in revised form August 13, 1984.
† Department of Mathematics, Ben-Gurion University of the Negev, Beer-Sheva 84120, Israel.

Now let $B^\alpha \subset R^{n_\alpha}$ be closed balls of radii ρ_α, respectively, $\alpha = 1, \cdots, s+1$, and let f: $B^1 \to B^{s+1}$ be given as a composition $f = f^s \circ f^{s-1} \circ \cdots \circ f^1$, where f^α: $B^\alpha \to B^{\alpha+1}$, $f^\alpha \in C^{k_\alpha}(B^\alpha, n_{\alpha+1})$, $k_\alpha \geqq 2$, $\alpha = 1, \cdots, s$.

Below we assume that the dimensions n_α do not increase: $n_1 \geqq n_2 \geqq \cdots \geqq n_s \geqq n_{s+1}$. (The problem of a factorization through lower-dimensional spaces has an essentially different nature.) Without loss of generality we can also assume that $k_1 > k_2 > \cdots > k_s$. Indeed, one can easily prove that if $k_2 \geqq k_1$ and $n_1 \geqq n_2 \geqq n_3$, then all the mappings f: $B^1 \to B^3$, belonging to $C^{k_1}(B^1, n_3)$, and only these mappings, are representable as $f = f^2 \circ f^1$, f^α: $B^\alpha \to B^{\alpha+1}$, $f^\alpha \in C^{k_\alpha}(B^\alpha, n_{\alpha+1})$, $\alpha = 1, 2$.

Let f be represented as a superposition of s mappings as above. We call $S = (n_1, k_1, n_2, k_2, \cdots, n_s, k_s)$ the diagram of the representation and say that f is representable with the diagram S.

For a given diagram S define $\sigma(S)$ as

$$\frac{n_1 - n_2}{k_1 - 1} + \frac{n_2 - n_3}{k_2 - 1} + \cdots + \frac{n_{s-1} - n_s}{k_{s-1} - 1} + \frac{n_s}{k_s - 1}.$$

THEOREM 1. *If f is representable with the diagram S, then*

$$\dim_e \Delta(f) \leqq \sigma(S).$$

Proof. Fix some $\varepsilon > 0$, $\varepsilon \leqq 1$. Below we denote by K_j some constants, depending only on the set of data $Q = \{\rho_\alpha, n_\alpha, k_\alpha, M_i(f^\alpha), \alpha = 1, \cdots, s+1, i = 0, \cdots, k_\alpha\}$, but not on ε.

For each $\alpha = 1, \cdots, s$ let $r_\alpha = \varepsilon^{1/(k_\alpha - 1)}$. Consider in each $B^\alpha \subset R^{n_\alpha}$ the points with the coordinates of the form $mr_\alpha/\sqrt{n_\alpha}$, $m \in Z$, and denote these poins by x_β^α, $1 \leqq \beta \leqq d_\alpha$. The balls B_β^α of the radius r_α, centered at x_β^α, cover B^α.

Let P_β^α be the Taylor polynomial of order k_α of the mapping f^α at the point x_β^α.

For any s-tuple $(\beta_1, \cdots, \beta_s)$, $1 \leqq \beta_\alpha \leqq d_\alpha$, denote by $P_{\beta_1, \cdots, \beta_s}$ the polynomial mapping

$$P_{\beta_s}^s \circ P_{s-1}^{s-1} \circ \cdots \circ P_{\beta_1}^1 \colon R^{n_1} \to R^{n_{s+1}}.$$

We also denote by $D_{\beta_1, \cdots, \beta_s}$ the set

$$\left\{ x \in B_{\beta_1}^1 / f^\alpha \circ f^{\alpha-1} \circ \cdots \circ f^1(x) \in B_{\beta_{\alpha+1}}^{\alpha+1}, \alpha = 1, \cdots, s-1 \right\}.$$

LEMMA 2. *For any s-tuple $(\beta_1, \cdots, \beta_s)$ and for any $x \in D_{\beta_1, \cdots, \beta_s}$,*
(i) $\|f(x) - P_{\beta_1, \cdots, \beta_s}(x)\| \leqq K_1 \varepsilon$,
(ii) $\|df(x) - dP_{\beta_1, \cdots, \beta_s}(x)\| \leqq K_1 \varepsilon$.

Proof. By induction on α. Denote $f^\alpha \circ f^{\alpha-1} \circ \cdots \circ f^1$ by F^α, and $P_{\beta_\alpha}^\alpha \circ \cdots \circ P_{\beta_1}^1$ by Q^α and assume that (i) and (ii) are satisfied for $F^{\alpha-1}$, $Q^{\alpha-1}$ with the constant K_1^α.

By the choice of r_α and by the Taylor formula we have for any $y \in B_{\beta_\alpha}^\alpha$:

$$\left\| f^\alpha(y) - P_{\beta_\alpha}^\alpha(y) \right\| \leqq K_2 r_\alpha^k = K_2 \varepsilon^{k_\alpha/(k_\alpha - 1)} \leqq K_2 \varepsilon,$$

$$\left\| df^\alpha(y) - dP_{\beta_\alpha}^\alpha \right\| \leqq K_3 r_\alpha^{k_\alpha - 1} = K_3 \varepsilon.$$

Now denote $F^{\alpha-1}(x)$ by y_1, $Q^{\alpha-1}(x)$ by y_2. Since $x \in D_{\beta_1, \cdots, \beta_s}$, $y_1 \in B_{\beta_\alpha}^\alpha$. We have:

$$\begin{aligned} \|F^\alpha(x) - Q^\alpha(x)\| &= \left\| f^\alpha(y_1) - P_{\beta_\alpha}^\alpha(y_2) \right\| \\ &\leqq \left\| f^\alpha(y_1) - P_{\beta_\alpha}^\alpha(y_1) \right\| + \left\| P_{\beta_\alpha}^\alpha(y_1) - P_{\beta_\alpha}^\alpha(y_2) \right\| \\ &\leqq K_2 \varepsilon + M_1\left(P_{\beta_\alpha}^\alpha\right) \|y_1 - y_2\| \leqq K_2 \varepsilon + K_4 K_1^{\alpha - 1} \varepsilon = K_5 \varepsilon. \end{aligned}$$

In a similar way, for the first derivatives we have:

$$\begin{aligned}\|dF^{\alpha}(x)-dQ^{\alpha}(x)\| &= \|df^{\alpha}(y_1)\circ dF^{\alpha-1}(x)-dP^{\alpha}_{\beta_\alpha}(y_2)\circ dQ^{\alpha-1}(x)\| \\ &\leqq \|df^{\alpha}(y_1)-dP^{\alpha}_{\beta_\alpha}(y_1)\|\|dF^{\alpha-1}(x)\| \\ &\quad + \|dP^{\alpha}_{\beta_\alpha}(y_1)\|\|dF^{\alpha-1}(x)-dQ^{\alpha-1}(x)\| \\ &\quad + \|dP^{\alpha}_{\beta_\alpha}(y_1)-dP^{\alpha}_{\beta_\alpha}(y_2)\|\|dQ^{\alpha-1}(x)\| \\ &\leqq K_3\varepsilon K_6 + K_7K_1^{\alpha-1}\varepsilon + M_2\left(P^{\alpha}_{\beta_\alpha}\right)K_1^{\alpha-1}\varepsilon K_8 = K_9\varepsilon.\end{aligned}$$

Denoting $\max(K_5, K_9)$ by K_1^{α}, we obtain the required inequalities, with $K_1 = K_1^s$.

For any s-tuple $(\beta_1,\cdots,\beta_s)$ let $\Sigma_{\beta_1,\cdots,\beta_s} = \Sigma(f)\cap D_{\beta_1,\cdots,\beta_s} \subset B^1$ and let $\Delta_{\beta_1,\cdots,\beta_s} = f(\Sigma_{\beta_1,\cdots,\beta_s})$.

LEMMA 3. *For any $(\beta_1,\cdots,\beta_s)$, $\Delta_{\beta_1,\cdots,\beta_s}$ can be covered by K_{10} balls of radius ε.*

Proof. By Lemma 2 ii, $\Sigma_{\beta_1,\cdots,\beta_s} \subset \tilde{\Sigma}(P_{\beta_1,\cdots,\beta_s}, K_1\varepsilon)$. By i, $\Delta_{\beta_1,\cdots,\beta_s}$ is thus contained in a $K_1\varepsilon$-neighborhood of $\Delta(P_{\beta_1,\cdots,\beta_s}, K_1\varepsilon)$. Now by [6, Cor. 2.14], this last set, being the set of near critical values of the polynomial mapping $P_{\beta_1,\cdots,\beta_s}$ on the ball B^1 of radius ρ_1, can be covered by N balls of radius $\rho_1 K_1\varepsilon$, where $N = N(n_1, n_{s+1}, k_1\cdot k_2\cdots k_s)$ depends only on the dimensions n_α and on the degrees of differentiability k_α. Hence $\Delta_{\beta_1,\cdots,\beta_s}$ can be covered by the same number of balls of radius $(\rho_1+1)K_1\varepsilon$, or by $N[\sqrt{n_{s+1}}(2\rho_1+2)K_1]^{n_{s+1}} = K_{10}$ balls of radius ε.

Of course, all the sets $\Delta_{\beta_1,\cdots,\beta_s}$, $1 \leqq \beta_\alpha \leqq d_\alpha$, cover $\Delta(f)$. But in fact many of these sets are empty. So to prove Theorem 1 it remains to estimate the number of nonempty $\Delta_{\beta_1,\cdots,\beta_s}$, which, in turn, does not exceed the number of nonempty $D_{\beta_1,\cdots,\beta_s}$.

LEMMA 4. *Let $\beta_1,\cdots,\beta_{\alpha-1}$ be fixed, $\alpha = 1,\cdots,s$. Then the number of the indices β_α, for which $D_{\beta_1,\cdots,\beta_{\alpha-1},\beta_\alpha,\beta_{\alpha+1},\cdots,\beta_s}$ is not empty for some $\beta_{\alpha+1},\cdots,\beta_s$, does not exceed $K_{11}(1/\varepsilon)^{-n_\alpha/(k_{\alpha-1}-1)+n_\alpha/(k_\alpha-1)}$ (where $k_0 \overset{\text{def}}{=} \infty$).*

Proof. By definition, $D_{\beta_1,\cdots,\beta_s} = \{x \in B^1_{\beta_1}/F^{\alpha-1}(x) \in B^{\alpha}_{\beta_\alpha}, \alpha = 1,\cdots,s\}$. Hence $F^{\alpha-1}(D_{\beta_1,\cdots,\beta_s}) \subset B^{\alpha}_{\beta_\alpha} \cap f^{\alpha-1}(B^{\alpha-1}_{\beta_{\alpha-1}})$. Now $B^{\alpha-1}_{\beta_{\alpha-1}}$ is a ball of radius $r_{\alpha-1}$, and therefore $f^{\alpha-1}(B^{\alpha-1}_{\beta_{\alpha-1}})$ is contained in some ball B in R^{n_α} of radius $M_1(f^{\alpha-1})r_{\alpha-1} \leqq K_{12}r_{\alpha-1}$. But clearly B has nonempty intersection with not more than

$$\left(2\sqrt{n_\alpha}K_{12}r_{\alpha-1}/r_\alpha\right)^{n_\alpha} = K_{11}\left(\frac{1}{\varepsilon}\right)^{n_\alpha/(k_\alpha-1)-n_\alpha/(k_{\alpha-1}-1)}$$

balls B^{α}_{β}.

Thus the number of nonempty $D_{\beta_1,\cdots,\beta_s}$ is bounded by

$$K_{11}^s\left(\frac{1}{\varepsilon}\right)^{n_1/(k_1-1)-n_2/(k_1-1)+n_2/(k_2-1)-\cdots-n_s/(k_{s-1}-1)+n_s/(k_s-1)} = K_{13}\left(\frac{1}{\varepsilon}\right)^{\sigma(S)}.$$

Since by Lemma 3 each $\Delta_{\beta_1,\cdots,\beta_s}$ can be covered by K_{10} balls of radius ε, we have $M(\varepsilon, \Delta(f)) \leqq K_{10}K_{13}(1/\varepsilon)^{\sigma(S)}$. Theorem 1 is proved.

Theorem 1 can be applied to the representability question in the following way: clearly, any mapping f, representable with the diagram $S = (n_1, k_1, \cdots, n_s, k_s)$, $n_1 \geqq n_2 \geqq \cdots \geqq n_s$, $k_1 > k_2 > \cdots > k_s$, is at least k_s-smooth. On the other hand, any k_1-smooth mapping is representable with the diagram S by the remark above. Hence, the question is nontrivial for mappings f: $B^1 \to B^{s+1}$ of smoothness q, $k_1 > q > k_s$.

Now we use the sharp estimate of the entropy dimension of the set of critical values, obtained in [6]. By [6, Thm. 5.6], for any $f \in C^q(B^1, n_{s+1})$, $\dim_e \Delta(f) \leqq n_1/q$, and for any $\eta < n_1/q$ there are mappings $f \in C^q(B^1, n_{s+1})$ with $\dim_e \Delta(f) > \eta$. Thus we have the following:

COROLLARY 5. *Let S be a given diagram and let $k_1 > q > k_s$. If $n_1/q > \sigma(S)$, then there are mappings $f \in C^q(B^1, n_{s+1})$, not representable with the diagram S.*

As a criterion of existence of nonrepresentable mappings, Corollary 5 is weaker than the result of Vitushkin, Kolmogorov and Tikhomirov [3], [4]. Indeed, by [3, Thm. XXVII], there are mappings in $C^q(B_1, n_{s+1})$, nonrepresentable with the diagram S, if $n_1/q > \max_\alpha(n_\alpha/k_\alpha)$. But easy computations show that always $\delta(S) \geqq \max_\alpha(n_\alpha/k_\alpha)$, and usually the strict inequality holds.

The reason is that the entropy dimension of critical values of a composition can be greater than that of each of the composed mappings, while the functional dimension of the class of representable mappings (considered in [3], [4]), is equal to the maximal functional dimension of classes, participating in the representation.

But this functional dimension, as an invariant of the whole class, does not allow to find explicit examples of nonrepresentable functions. On the contrary, the entropy dimension of critical values is the invariant of individual mappings, and the mappings with the "big" set of critical values can be built explicitly. Hence in any situation, covered by Corollary 5, we can find explicit examples of nonrepresentable mappings. In particular, let $B \subset R^n$ be the closed unit ball and let $h_n \in C^{n-1}(B, 1)$ be the Whitney function (see [5]) with $\Delta(f) = [0, 1]$. Since $\dim_e [0, 1] = 1$, we obtain

COROLLARY 6. *h_n cannot be represented with the diagram $S = (n, k_1, n_2, k_2)$, if*

$$\frac{n - n_2}{k_1 - 1} + \frac{n_2}{k_2 - 1} < 1.$$

In particular, $h_{10}(x_1, \cdots, x_{10})$ cannot be written as $h_{10}(x_1, \cdots, x_{10}) = \psi(y_1, \cdots, y_5)$, $y_i = \psi_i(x_1, \cdots, x_{10})$, $i = 1, \cdots, 5$, with $\psi \in C^7$ and $\psi_i \in C^{32}$.

There is some similarity in the properties of functions representable by means of compositions of smooth functions and maximum functions of smooth families (compare [7]), although the last class contains nondifferentiable functions.

It is interesting whether direct connections between these two classes can be found.

POLYNOMIAL ANALOGUES OF PROLATE SPHEROIDAL WAVE FUNCTIONS AND UNCERTAINTY*

MARCI PERLSTADT†

Abstract. Slepian, Landau, and Pollak used prolate spheroidal wave functions to demonstrate how nearly "time" and "bandlimited" a square-integrable function can be. In this note we show how their results extend easily to cover orthogonal polynomial expansions. In particular, we study how close a square-integrable function can come to being a polynomial of degree $\leqq L$ and simultaneously to vanishing off some set $\mathscr{A}$.

1. Introduction. Let $f \in L^2(\mathbb{R})$ with Fourier transform $\hat{f}$. We say that f is time-limited to the set $\mathscr{A} \subset \mathbb{R}$ if $\chi_{\mathscr{A}} \cdot f = f$ and that f is bandlimited to the set $\mathscr{B} \subset \mathbb{R}$ if $\chi_{\mathscr{B}} \cdot \hat{f} = \hat{f}$ (here $\chi_{\mathscr{A}}$, $\chi_{\mathscr{B}}$ are the respective characteristic functions of the sets $\mathscr{A}$, $\mathscr{B}$). It is well known that f cannot be simultaneously time and bandlimited and the extend to which f can be "approximately" time and bandlimited has been the subject of many inquiries.

In a remarkable series of papers ([1], [2], [3]) Slepian, Landau, and Pollak demonstrated the key role of the prolate spheroidal wave functions in understanding this problem. The prolate spheroidal wave functions were shown to be the eigenfunctions of the operator that timelimits, then bandlimits, and then again timelimits a function. This interpretation of the prolate spheroidal wave functions led to a very exact picture of the trade-off involved in the time and bandlimiting of functions, including a generalization of the Heisenberg uncertainty principle.

In a recent series of papers ([4], [5], [6], [7]) the notion of "time" and "bandlimiting" was explored for more general "Fourier-type" situations, in particular for expansions in terms of orthogonal polynomials. The operator that "time", then "band", and then "time limits" a function was studied and, for some special cases, an efficient means of determining the eigenfunctions of this operator was given (analogous to the method employed in [1]). The purpose of this note is to take the eigenfunctions generated in this new situation and show that they too enable us to draw an accurate picture of the extent to which functions can be "time" and bandlimited". One should note that the techniques employed in [2] generalize readily to this new situation and thus the real work has already been done. We further remark that many of the properties we will be discussing were shown in [8] for the case of expansions in Legendre polynomials.

2. Background. Let f be a square integrable function with Fourier transform $\hat{f}$. Let A be the operator that timelimits f and let B be the operator that bandlimits f, i.e.

$$Af = f \cdot \chi_{\mathscr{A}}, \qquad B\hat{f} = \hat{f} \cdot \chi_{\mathscr{B}}.$$

Let F and F^{-1} denote the operations of Fourier transform and inverse Fourier transform:

$$F(f) = \hat{f}, \qquad F^{-1}(\hat{f}) = f.$$

The (self-adjoint) operator that time-band-timelimits a function is given by

$$AF^{-1}BFA = E^*E, \quad \text{where } E = BFA.$$

*Received by the editors September 15, 1983, and in revised form April 5, 1984. This work was supported in part by the National Science Foundation under grant MCS-8302526.

†Department of Mathematics, Drexel University, Philadelphia, Pennsylvania 19104.

The operator E^*E is a finite convolution integral operator. For the case when $\mathscr{A}=[-T,T]$ and $\mathscr{B}=[-W,W]$,

$$E^*Ef(x)=\int_{\mathscr{A}} \frac{\sin W(x-y)}{x-y} f(y)\,dy, \qquad x\in\mathscr{A}$$

and the eigenfunctions of E^*E are the prolate spheroidal wave functions [1].

Extensions of this work to more general "Fourier-type" situations were discussed in [4], [5], [6], [7]. In particular we will consider complete orthogonal families of polynomials $\{p_i(x)|i=0,1,2,\cdots\}$ with continuous nonnegative weight functions $w(x)$ on set $\mathscr{C}$. Thus for f square integrable (with respect to $w(x)$, $\mathscr{C}$) we can write

$$f(x)=\sum_{i=0}^{\infty} \hat{f}(i)p_i(x), \qquad \hat{f}(i)=\langle f(x),p_i(x)\rangle_{w(x),\mathscr{C}}$$

where the $p_i(x)$'s are suitably normalized and

$$\langle g,h\rangle_{w(x),\mathscr{C}}=\int_{\mathscr{C}} g(x)h(x)w(x)\,dx.$$

Our analogues of time and bandlimiting will be given as follows:

$$Af=f\cdot\chi_{\mathscr{A}}$$

$$B\hat{f}(i)=\begin{cases}\hat{f}(i), & i=0,1,\cdots,L,\\ 0, & i>L\end{cases}$$

where $\mathscr{A}\subset\mathscr{C}$ has positive measure strictly less than the measure of $\mathscr{C}$, i.e.

$$0<\int_{\mathscr{A}} w(x)\,dx<\int_{\mathscr{C}} w(x)\,dx. \tag{2.0}$$

Thus

$$E^*Ef(x)=\int_{\mathscr{A}} K_L(x,y)f(y)w(y)\,dy, \qquad x\in\mathscr{A}$$

where

$$K_L(x,y)=\sum_{i=0}^{L} p_i(x)p_i(y).$$

We note that in addition to the time-band-timelimiting operator E^*E, one can equally well study the band-time-bandlimiting operator EE^*. This operator is given by the $(L+1)\times(L+1)$ matrix G with entries

$$G_{ij}=\langle p_i(x),p_j(x)\rangle_{w(x),\mathscr{A}}=\int_{\mathscr{A}} p_i(x)p_j(x)w(x)\,dx, \qquad 0\leqq i\leqq j\leqq L.$$

The duality between the operators E^*E and EE^* is given in Lemma 2.1 below and will be exploited shortly.

LEMMA 2.1. *If f is an eigenfunction of $E^*E=AF^{-1}BFA$ with eigenvalue $\lambda\neq 0$, then BFf is an eigenvector of $EE^*=BFAF^{-1}B$ with eigenvalue λ. Similarly if $\hat{f}$ is an eigenvector of EE^* with eigenvalue $\lambda\neq 0$, then $AF^{-1}\hat{f}$ is an eigenfunction of E^*E with eigenvalue λ.*

For a proof of Lemma 2.1, see [4].

We also remark that by taking $\mathscr{A} \subset \mathscr{C}$ as in (2.0), we are assured of the existence of a complete orthogonal family of polynomials on $\mathscr{A}$ with respect to $w(x)$. The completeness of polynomials for $L^2_{w(x),\mathscr{A}}$ follows immediately from their completeness in $L^2_{w(x),\mathscr{C}}$. The linear independence of $\{1, x, x^2, \cdots\}$ in $\mathscr{A}$ follows readily since $\mathscr{A}$ has positive measure and any polynomial $p(x)$ has only a finite number of zeros.

3. The eigenfunctions of E^*E: polynomial analogues of the prolate spheroidal wave functions. It follows from Lemma 2.1 that for any expansion in terms of a complete orthogonal polynomial family and set $\mathscr{A} \subset \mathscr{C}$ ($\mathscr{A}$ as in (2.0)) the eigenfunctions of E^*E can be obtained by determining the eigenvectors of matrix G. In particular if $\mathbf{c} = (c_0, c_1, \cdots, c_L)$ is an eigenvector of G with eigenvalue $\lambda \neq 0$, then setting $\phi(x) = \sum_{i=0}^{L} c_i p_i(x)$, we have $A\phi(x) = \phi^{\mathscr{A}}(x)$ is an eigenfunction of E^*E (we will use $f^{\mathscr{A}}(x)$ to indicate Af). Note that $\phi(x)$ is "bandlimited" ($\phi(x)$ is a polynomial of degree $\leqq L$) and that $\phi^{\mathscr{A}}(x)$ is "timelimited". The $\phi(x)$'s are our polynomial analogues of the prolate spheroidal wave functions. Many of the properties of the $\phi(x)$'s listed below (such as their double orthogonality on $\mathscr{A}$ and $\mathscr{C}$, Lemma 3.1), are readily seen to be analogous to the properties of the prolate spheroidal wave functions (see [1]).

From Lemma 2.1 it follows that E^*E has at most $(L+1)$ linearly independent eigenfunctions corresponding to nonzero eigenvalues. If we denote these eigenfunctions (before chopping to $\mathscr{A}$) by $\phi_0(x), \phi_1(x), \cdots, \phi_k(x)$ with corresponding eigenvalues $\lambda_0 \geqq \lambda_1 \geqq \cdots \geqq \lambda_k$, then we note that in fact $k = L$. This follows since every function f, square integrable with respect to $\langle \cdot, \cdot \rangle_{w(x),\mathscr{A}}$, can be rewritten as

$$f^{\mathscr{A}}(x) = \sum_{i=0}^{k} a_i \phi_i^{\mathscr{A}}(x) + h^{\mathscr{A}}(x), \quad \text{where}$$

$$E^*Eh^{\mathscr{A}}(x) = 0 \quad \text{and} \quad \langle h^{\mathscr{A}}(x), \phi_i(x) \rangle_{w(x),\mathscr{A}} = 0, \qquad i = 0, 1, \cdots, k.$$

Thus for all $x \in \mathscr{A}$ we have

$$E^*Eh^{\mathscr{A}}(x) = \int_{\mathscr{A}} h(y) K_L(x,y) w(y)\, dy = \sum_{i=0}^{L} p_i(x) \langle h(y), p_i(y) \rangle_{w(x),\mathscr{A}} = 0.$$

and conclude that $\langle h(y), p_i(y) \rangle_{w(x),\mathscr{A}} = 0$. Therefore for any polynomial $q(x)$ of degree $\leqq L$, $\langle h(x), q(x) \rangle_{w(x),\mathscr{A}} = 0$. Since there is a complete orthogonal family of polynomials $q_i(x)$ ($i = 0, 1, 2, \cdots$, degree $q_i(x) = i$) with respect to $\langle \cdot, \cdot \rangle_{w(x),\mathscr{A}}$, we have that for $i = 0, 1, \cdots, L$, $q_i(x)$ can be written as a sum of the $\phi_j(x)$'s, $j = 0, 1, \cdots, k$. Thus $k = L$ and we see that $\{q_i(x) | i = L+1, L+2, \cdots\}$ form a basis for $H = \{h(x) | E^*Eh(x) = 0\}$.

The lemmas below summarize a number of properties of the ϕ_i's that will be used in the next section.

LEMMA 3.1. *Let $\{p_i(x)\}$ be a complete orthogonal family of polynomials ($i = 0, 1, 2, \cdots$ degree $p_i(x) = i$) with respect to the nonnegative continuous weight function $w(x)$ on $\mathscr{C}$. Let $\mathscr{A} \subset \mathscr{C}$ be as in* (2.0). *Then the operator E^*E has $L+1$ linearly independent eigenfunctions $\phi_0(x), \phi_1(x), \cdots, \phi_L(x)$ corresponding to the nonzero eigenvalues $1 > \lambda_0 \geqq \lambda_1 \geqq \cdots \geqq \lambda_L > 0$. Without loss of generality the ϕ_i's can be normalized so that*

(a) $\int_{\mathscr{A}} K_L(x,y) \phi_i(y) w(y)\, dy = \lambda_i \phi_i(x)$ *for all* $x \in \mathscr{C}$.

(b) $\langle \phi_i(x), \phi_j(x) \rangle_{w(x),\mathscr{C}} = \delta_{ij}$.

(c) $\langle \phi_i(x), \phi_j(x) \rangle_{w(x),\mathscr{A}} = \lambda_i \delta_{ij}$.

(d) *The* ϕ_i's *comprise a complete orthonormal set for the space of bandlimited functions.*

(e) *The* $\phi_i^{\mathscr{A}}$'s *together with the polynomials* $q_{L+1}, q_{L+2}, \cdots$ *where* $\{q_i(x)\}$ *is the orthogonal polynomial family for* $\langle \cdot, \cdot \rangle_{w(x),\mathscr{A}}$ *form a complete orthogonal set for the space of square integrable timelimited functions.*

Proof. (a) Corresponding to each ϕ_i is an eigenvector $\mathbf{c} = (c_0, \cdots, c_L)$ of EE^*:

$$BFAF^{-1}B\mathbf{c} = \lambda_i \mathbf{c}.$$

Applying F^{-1} on both sides of the above yields (a).

(b) *and* (c) That the ϕ_i's can be chosen orthogonal on $\mathscr{A}$ follows since E^*E is self-adjoint. From (a) and the fact that

$$\int_{\mathscr{C}} K_L(x,y) K_L(x,z) w(x)\, dx = K_L(y,z),$$

we have that

$$\begin{aligned}\langle \phi_i, \phi_j \rangle_{w(x),\mathscr{C}} &= \frac{1}{\lambda_i \lambda_j} \int_{\mathscr{C}} \left(\int_{\mathscr{A}} \phi_i(y) K_L(x,y) w(y)\, dy \right) \\ &\quad \cdot \left(\int_{\mathscr{A}} \phi_j(z) K_L(x,z) w(z)\, dz \right) w(x)\, dx \\ &= \frac{1}{\lambda_i \lambda_j} \int_{\mathscr{A}} \int_{\mathscr{A}} \phi_i(y) \phi_j(z) w(y) w(z) \left[\int_{\mathscr{C}} K_L(x,y) K_L(x,z) w(x)\, dx \right] dy\, dz \\ &= \frac{1}{\lambda_i} \int_{\mathscr{A}} \phi_i(y) \phi_j(y) w(y)\, dy = \frac{1}{\lambda_i} \langle \phi_i, \phi_j \rangle_{w(x),\mathscr{A}}.\end{aligned}$$

Thus orthogonality on $\mathscr{A}$ implies orthogonality on $\mathscr{C}$ and without loss of generality the ϕ_i's can be chosen to be orthonormal on $\mathscr{C}$ and (b) and (c) hold. Furthermore taking $i = j$ in the above shows $0 < \lambda_i \leqq 1$. That $\lambda_i < 1$ follows from Lemma 3.2 below.

(d) *and* (e) are clear from the earlier discussion in this section.

We will also be interested in looking at our operators on the set $\sim\mathscr{A}$ where $\sim\mathscr{A}$ is the complement of $\mathscr{A}$ in $\mathscr{C}$ ($\sim\mathscr{A} = \mathscr{C} - \mathscr{A}$). Using the notation

$$\sim A f(x) = f(x) \cdot \chi_{\sim\mathscr{A}}(x) = f^{\sim\mathscr{A}}(x),$$

we see that

LEMMA 3.2. (a) $\langle \sim A\phi_i, \sim A\phi_i \rangle_{w(x),\mathscr{C}} = 1 - \lambda_i$.

(b) $[\sim AF^{-1}BF \sim A]\phi_i(x) = (1 - \lambda_i)\phi_i(x)$.

Proof. (a) is immediate.

(b) follows since $F^{-1}BF\phi_i = \phi_i$ and thus $F^{-1}BF(A + \sim A)\phi_i = \phi_i$. Therefore, $F^{-1}BFA\phi_i + F^{-1}BF \sim A\phi_i = \lambda_i \phi_i + (1 - \lambda_i)\phi_i$.

We will also need:

LEMMA 3.3. *For* $h(x)$ *such that* $E^*Eh(x) = 0$ $(x \in \mathscr{A})$ *we have in fact* $F^{-1}BFAh(x) = 0$ *for all* $x \in \mathscr{C}$.

Proof.

$$F^{-1}BFAh(x) = \sum_{i=0}^{L} p_i(x) \int_{\mathscr{A}} h(y) p_i(y) w(y)\, dy = 0$$

for all $x \in \mathscr{C}$ since

$$\int_{\mathscr{A}} h(y)\, p_i(y)\, w(y)\, dy = 0 \quad \text{for } i = 0, 1, \cdots, L.$$

4. The uncertainty principle. The Heisenberg uncertainty principle measures how closely a function f and its Fourier transform ($\hat{f} = \int_{-\infty}^{\infty} f(s) e^{-i\delta s}\, ds$) can be simultaneously concentrated about a point. In particular, if

$$\mathscr{T}^2 = \frac{\int (x - x_0)^2 |f(x)|^2\, dx}{\int |f(x)|^2\, dx} \quad \text{and} \quad \Omega^2 = \frac{\int (\delta - \delta_0)^2 |\hat{f}(\delta)|^2\, d\delta}{\int |\hat{f}(\delta)|^2\, d\delta},$$

then for any x_0, δ_0 we have $\Omega\mathscr{T} \geqq \frac{1}{2}$ and thus Ω and $\mathscr{T}$ cannot both be small [9].

In many situations, however, one is more interested in the extent to which a function can be concentrated on some subset of the real line (e.g. an interval). Thus in [2] Landau and Pollak studied the quantities

$$\alpha^2 = \frac{\|Af\|_2^2}{\|f\|_2^2} \quad \text{and} \quad \beta^2 = \frac{\|B\hat{f}\|_2^2}{\|\hat{f}\|_2^2}.$$

Using the fact that the prolate spheroidal wave functions are the eigenfunctions of E^*E, they were able to determine all possible values of (α, β) for f square integrable. Thus, for example, to determine how nearly "timelimited" a "bandlimited" function can be, simply maximize α for $\beta = 1$.

What we will do here is to consider the quantities α and β for the case of orthogonal polynomial expansions. The theorem below will follow from minor modifications of the arguments given in [2].

THEOREM 4.1. *Let* $\{p_i(x)\}$, $i = 0, 1, 2, \cdots$, *be a complete orthogonal polynomial family* (*degree* $p_i(x) = i$) *with respect to the inner product* $\langle f, g \rangle_{w(x), \mathscr{C}}$ *where* $w(x)$ *is nonnegative and continuous. Let* $\mathscr{A} \subset \mathscr{C}$ *be as in* (2.0). *Then there is a square integrable function*

$$f(x) = \sum_{i=0}^{\infty} \hat{f}(i)\, p_i(x)$$

such that

$$\alpha^2 = \frac{\|Af\|_2^2}{\|f\|_2^2} \quad \textit{and} \quad \beta^2 = \frac{\|B\hat{f}\|_2^2}{\|\hat{f}\|_2^2} = \frac{\sum_{i=0}^{L} \hat{f}^2(i)}{\sum_{i=0}^{\infty} \hat{f}^2(i)}$$

if and only if

(a) *for* $\beta^2 = 1$, $\lambda_L \leqq \alpha^2 \leqq \lambda_0$,

(b) *for* $\alpha^2 = 1$, $0 \leqq \beta^2 \leqq \lambda_0$,

(c) *for* $\alpha^2 = 0$, $0 \leqq \beta^2 \leqq 1 - \lambda_L$,

(d) *for* $\beta^2 = 0$, $0 \leqq \alpha^2 \leqq 1$,

(e) *for* $\lambda_L \leqq \alpha^2 \leqq \lambda_0$, $0 \leqq \beta^2 \leqq 1$,

(f) *for* $\lambda_0 \leqq \alpha^2 \leqq 1$, $\cos^{-1}\alpha + \cos^{-1}\beta \geqq \cos^{-1}\sqrt{\lambda_0}$ $(\beta \geqq 0)$,

(g) *for* $0 \leqq \alpha^2 \leqq \lambda_L$, $\cos^{-1}(1-\alpha) + \cos^{-1}\beta \geqq \cos^{-1}\sqrt{1-\lambda_L}$ $(\beta \geqq 0)$.

Before proving Theorem 4.1 several comments are in order. If we look at all possible pairs (α, β) in the square $0 \leqq \alpha^2 \leqq 1$, $0 \leqq \beta^2 \leqq 1$, then (a)–(d) tell us the attainable boundary values, indicated by the darkened lines in Fig. 1 and (e) is handled by the

shaded area

The areas marked by

follow readily from (f) and (g). Thus it is only in the two upper corners that the picture becomes complicated. The similarity of this result with the result for the standard Fourier transform in [2] is readily apparent. The only real change here is the upper left-hand corner.

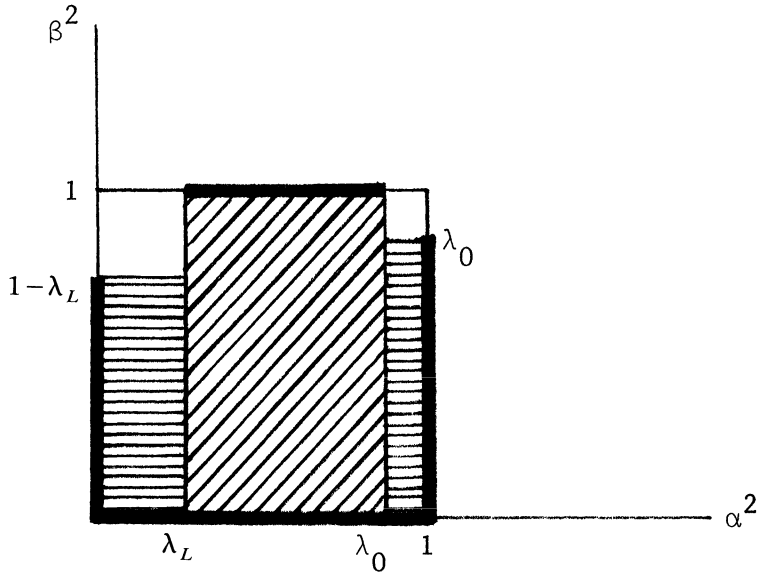

FIG. 1

Some information about the geometry of the space $\mathscr{W}+\mathscr{T}$ where $\mathscr{W}=\{\text{bandlimited functions}\}$ and $\mathscr{T}=\{\text{timelimited functions}\}$ will be needed for the proof of Theorem 4.1. These results were obtained for the standard Fourier transform in [2] and the proofs there apply readily to our more general situation and will not be repeated here. A brief outline of the results will be given below.

Define the angle θ between two functions f and g ($\|f\|, \|g\| > 0$) as

$$\theta(f,g) = \cos^{-1} \frac{\langle f,g \rangle}{\|f\| \, \|g\|}.$$

Note that for $f \in \mathscr{W}$ and $g \in \mathscr{T}$, $\theta(f,g) > 0$ since $\mathscr{W} \cap \mathscr{T}$ contains only $f = 0$. Landau and Pollak show that there is a least angle between $\mathscr{W}$ and $\mathscr{T}$;

THEOREM 4.2. *There exists a least angle between $\mathscr{W}$ and $\mathscr{T}$. This angle equals* $\cos^{-1}\sqrt{\lambda_0}$ *and is assumed by* $\phi_0 \in \mathscr{W}$ *and* $D\phi_0 \in \mathscr{T}$, i.e.,

$$\min_{\substack{f \in \mathscr{W} \\ g \in \mathscr{T}}} \phi(f,g) = \cos^{-1}\sqrt{\lambda_0}.$$

Landau and Pollak also give the following lemma which extends directly to the situation we are studying:

LEMMA 4.3. *$\mathscr{W}+\mathscr{T}$ is closed.*

Proof of Theorem 4.1. (a) $\beta=1$: Thus f is "bandlimited," $f(x)=\sum_{i=0}^{L} c_i\phi_i(x)$ and without loss of generality $\|f\|=\|\hat{f}\|=1$. Thus

$$Af=\sum_{i=0}^{L} c_i\phi_i(x), \qquad \alpha^2=\sum_{i=0}^{L} c_i^2\lambda_i \quad \text{where} \quad \sum_{i=0}^{L} c_i^2=1.$$

Clearly α^2 is maximized for $c_0=1$ ($f=\phi_0$) and minimized for $c_L=1$ ($f=\phi_L$). Thus $\alpha^2\leqq\lambda_0$ and $\lambda_L\leqq\alpha^2$. To see that we can obtain all values of α^2 between λ_0 and λ_L, consider $g=a\phi_0+b\phi_L$ where $a^2+b^2=1$. For g we have $\beta^2=1$ and $\alpha^2=a^2\lambda_0+b^2\lambda_L$. Thus as a, b range from 0 to 1 all values of α^2 between λ_0 and λ_L are attained.

(b) $\alpha=1$. Thus f is "timelimited". If $f=\phi_0^{\mathscr{A}}$ then $\alpha^2=1$ and since $FBF^{-1}A\,\phi_0^{\mathscr{A}}=\lambda_0\phi_0$, $\beta^2=\lambda_0$. If $f=h^{\mathscr{A}}(x)$ ($E^*Eh(x)=0$) then $\alpha^2=1$, $\beta^2=0$. That all values of β^2 between 0 and λ_0 are attained can be seen by taking $g(x)=a\phi_0^{\mathscr{A}}(x)+bh^{\mathscr{A}}(x)$ with $0\leqq a,\ b\leqq 1$. Thus $\alpha^2=1$ and $F^{-1}BFAg(x)=a\lambda_0\phi_0(x)$ which gives $\beta^2=a^2\lambda_0^2/(a^2\lambda_0+b^2\mu)$ where $\mu=\|h^{\mathscr{A}}(x)\|_2^2$. This produces all intermediate values.

That β^2 cannot be greater than λ_0 follows from Theorem 4.2 (see also the proof of part (f)).

(c) $\alpha=0$. This is the opposite of $\alpha=1$ in that we now have $f^{\sim\mathscr{A}}(x)=f(x)$. Taking $f(x)=\sum_{i=0}^{L} c_i\phi_i^{\sim\mathscr{A}}(x)+h_2^{\sim\mathscr{A}}(x)$ where $h_2^{\sim\mathscr{A}}(x)$ satisfies $\sim AF^{-1}BF\sim Ah_2^{\sim\mathscr{A}}(x)=0$, we have $F^{-1}BF\sim Af(x)=\sum_{i=0}^{L} c_i(1-\lambda_i)\phi_i(x)$ and reasoning analogous to that in (b) yields $0\leqq\beta^2\leqq 1-\lambda_L$.

(d) $\beta=0$. Choose $h_1^{\mathscr{A}}(x)$ so that $E^*Eh_1^{\mathscr{A}}(x)=0$ and let $h_2^{\sim\mathscr{A}}(x)$ be as in part (c). Thus for $h_1^{\mathscr{A}}(x)$, $\beta=0$ and $\alpha=1$ and for $h_2^{\sim\mathscr{A}}(x)$, $\beta=0$ and $\alpha=0$. That all values of α between 0 and 1 can be attained is seen by taking $g(x)=a_1h_1^{\mathscr{A}}(x)+a_2h_2^{\sim\mathscr{A}}(x)$ where $0<a_1,\ a_2<1$.

(e) $\lambda_L\leqq\alpha^2\leqq\lambda_0$. Fix some α, $\lambda_L\leqq\alpha^2\leqq\lambda_0$. Thus we can find f and g such that:

$$\|f\|=1, \quad \|f^{\mathscr{A}}\|=\alpha, \quad \beta=0, \quad f=a_1h_1^{\mathscr{A}}+a_2h_2^{\sim\mathscr{A}} \quad \text{(see (d))}$$

and

$$\|g\|=1, \quad \|g^{\mathscr{A}}\|=\alpha, \quad \beta=1, \quad g=b_1\phi_0+b_2\phi_L \quad \text{(see (a))}.$$

Since $\langle f,g\rangle_{w(x),\mathscr{C}}=\langle f,g\rangle_{w(x),\mathscr{A}}=0$, letting $t(x)=c_1f(x)+c_2g(x)$, $c_1^2+c_2^2=1$, we can attain all values of β between 0 and 1.

(f) $\lambda_0\leqq\alpha^2\leqq 1$. We begin by showing that if $\|f\|=1$ and $\|Df\|=\alpha$, then $\beta\leqq\cos(\cos^{-1}\sqrt{\lambda_0}-\cos^{-1}\alpha)$ with equality attained for

$$f=p\phi_0+qD\phi_0 \quad \text{with } p=\sqrt{\frac{1-\alpha^2}{1-\lambda_0}} \quad \text{and} \quad q=\frac{\alpha}{\sqrt{\lambda_0}}-\sqrt{\frac{1-\alpha^2}{1-\lambda_0}}\,.$$

This result follows exactly from the argument in [2] and we will just briefly outline the steps here. Since $\mathscr{W}+\mathscr{T}$ is closed for any f with $\|f\|=1$ and $\|f^{\mathscr{A}}\|=\alpha$, we can find g orthogonal to $f^{\mathscr{A}}$ and $f^{\mathscr{B}}=F^{-1}BFf$ such that

$$f=\lambda f^{\mathscr{A}}+\mu f^{\mathscr{B}}+g. \tag{4.4}$$

By taking inner products of (4.4) with $f, f^{\mathscr{A}}, f^{\mathscr{B}}$, and g and eliminating (g,f), λ, and μ from the resulting equations, we get (for $\alpha\beta \neq 0$):

$$\beta^2 - 2\langle f^{\mathscr{A}}, f^{\mathscr{B}}\rangle = -\alpha^2 + 1 - \frac{\langle f^{\mathscr{A}}, f^{\mathscr{B}}\rangle^2}{\alpha^2\beta^2} - \|g\|^2\left(1 - \frac{\langle f^{\mathscr{A}}, f^{\mathscr{B}}\rangle^2}{\alpha^2\beta^2}\right).$$

Setting

$$\cos\theta = \frac{\langle f^{\mathscr{A}}, f^{\mathscr{B}}\rangle}{\|f^{\mathscr{A}}\|\|f^{\mathscr{B}}\|},$$

one obtains

$$(\beta - \alpha\cos\theta)^2 \leqq (1-\alpha^2)\sin^2\theta$$

with equality if and only if $g = 0$. Therefore

$$\beta \leqq \cos(\theta - \cos^{-1}\alpha)$$

and since by Theorem 4.2, $\theta \geqq \cos^{-1}\sqrt{\lambda_0}$,

$$\cos^{-1}\alpha + \cos^{-1}\beta \geqq \cos^{-1}\sqrt{\lambda_0}. \tag{4.5}$$

Equality in (4.5) is attained by

$$f(x) = p\phi_0(x) + q\phi_0^{\mathscr{A}}(x) \tag{4.6}$$

with

$$p = \sqrt{\frac{1-\alpha^2}{1-\lambda_0}} \quad \text{and} \quad q = \frac{\alpha}{\sqrt{\lambda_0}} - \sqrt{\frac{1-\alpha^2}{1-\lambda_0}}.$$

To see that in fact $0 \leqq \beta \leqq \cos(\cos^{-1}\sqrt{\lambda_0} - \cos^{-1}\alpha)$ simply consider

$$cf(x) + d\frac{g(x)}{\|g(x)\|}$$

where $g(x)$ is as in the proof of (d) ($g(x) = a_1 h_1^{\mathscr{A}}(x) + a_2 h_2^{\sim\mathscr{A}}(x)$) and $f(x)$ is as in 4.6 and $c^2 + d^2 = 1$.

(g) $0 \leqq \alpha^2 \leqq \lambda_L$: Consider all $f \in \mathscr{L}^2$ with $\|f\| = 1$, $\|f^{\mathscr{A}}\| = \alpha$. We first determine the maximum β. This is really equivalent to part (f) with $\alpha' = \|f^{\sim\mathscr{A}}\| = 1 - \alpha$ and $\beta' = \beta$. Thus

$$0 \leqq \beta' = \beta \leqq \cos\left(\cos^{-1}\sqrt{1-\lambda_L} - \cos^{-1}(\alpha')\right)$$

completing the proof.

We note that when $\beta = 1$, $\alpha^2 \leqq \lambda_0$ and $\alpha^2 = \lambda_0$ for $f(x) = \phi_0(x)$. Thus $\phi_0(x)$ is the polynomial of degree $\leqq L$ that has the greatest proportion of its norm in $\mathscr{A}$. Similarly $\phi_L(x)$ represents the polynomial of degree $\leqq L$ that has the least proportion of its norm in $\mathscr{C}$. For some graphs of these functions for the case of the Legendre polynomials ($w(x) = 1$, $\mathscr{C} = [-1, 1]$) see [8].

5. Conclusion. Recall that the values λ_0 and λ_L needed in Theorem 4.1 are respectively the largest and smallest eigenvalues of the matrix G of §2. Thus if L is not too large (and the entries of G are available) the work involved in the computation of λ_0 and λ_L is not excessive. In certain special cases (notably the classical orthogonal polynomials where $\mathscr{C}=(\delta,\varepsilon)$ and $\mathscr{A}=(\delta',\varepsilon)$, $\delta<\delta'$), there is a relatively simple means of obtaining the eigenvectors ([4], [5]).

It should also be noted that while the prolate spheroidal wave functions depend only on the product $c=WT$, the eigenfunctions in the polynomial case depend on both L and $\mathscr{A}$. Thus in [2], the authors are able to write a Heisenberg-like bound:

$$WT \geqq \phi(\alpha,\beta), \quad \text{where } \mathscr{A}=[-W,W], \quad \mathscr{B}=[-T,T]$$

for some explicit function ϕ. In the polynomial case we have been unable to do this.

SYMMETRY AND STABILITY IN TAYLOR-COUETTE FLOW*

MARTIN GOLUBITSKY† AND IAN STEWART‡

Abstract. We study the flow of a fluid between concentric rotating cylinders (the Taylor problem) by exploiting the symmetries of the system. The Navier–Stokes equations, linearized about Couette flow, possess two zero and four purely imaginary eigenvalues at a suitable value of the speed of rotation of the outer cylinder. There is thus a reduced bifurcation equation on a six-dimensional space which can be shown to commute with an action of the symmetry group $O(2)\times SO(2)$. We use the group structure to analyze this bifurcation equation in the simplest (nondegenerate) case and to compute the stabilities of solutions. In particular, when the outer cylinder is counterrotated we can obtain transitions which seem to agree with recent experiments of Andereck, Liu, and Swinney [1984]. It is also possible to obtain the "main sequence" in this model. This sequence is normally observed in experiments when the outer cylinder is held fixed.

Introduction. The flow of a fluid between concentric rotating cylinders, or *Taylor–Couette flow*, is known to exhibit a variety of types of behavior, the most celebrated being *Taylor vortices* (Taylor [1923]). The problem has been studied by a large number of authors: a recent survey is that of DiPrima and Swinney [1981]. The experimental apparatus has circular symmetry, and the standard mathematical idealization (periodic boundary conditions at the ends of the cylinder) introduces a further symmetry. As a result the Navier–Stokes equations for this problem are covariant with respect to the action of a symmetry group $O(2)\times SO(2)$. It has become clear that the symmetries inherent in bifurcating systems have a strong influence on their behavior. In this paper we study a series of bifurcations that occur in Taylor–Couette flow placing emphasis on the role of symmetry. (Schecter [1976] and Chossat and Iooss [1984] have also studied the problem from this viewpoint, and we discuss the relations between our work and theirs below.)

DiPrima and Grannick [1971] have found that when the outer cylinder is rotated in a direction opposite to that of the inner cylinder, the Navier–Stokes equations, linearized about Couette flow, possess six eigenvalues on the imaginary axis. It follows that aspects of the dynamics can be reduced (either by Lyapunov–Schmidt or center manifold reduction) to a vector field on $\mathbf{R}^6$; furthermore, this vector field commutes with an action of $O(2)\times SO(2)$. Moreover, as we explain in §7, recent experimental results due to Andereck, Liu, and Swinney [1984] seem to confirm the existence of the six-dimensional kernel.

We point out in particular that the six-dimensional kernel is a codimension one phenomenon, and hence it is not surprising that it should be possible to find it by varying only one parameter. Indeed, this degeneracy should occur relatively often in various circumstances, and so deserves detailed analysis.

We study the general class of bifurcation problems on $\mathbf{R}^6$ having this $O(2)\times SO(2)$ symmetry. We derive the general form possible for the vector field, and by classifying

the possible ways to break symmetry, obtain equations for the bifurcating branches (subject to certain nondegeneracy conditions). We also obtain the (linearized orbital) stabilities of these branches.

By introducing an additional parameter α we split the kernel $\mathbf{R}^6$ into two subspaces $\mathbf{R}^2$ and $\mathbf{R}^4$ corresponding to a steady-state and a periodic bifurcation respectively. Depending on the sign of α, one or other of these bifurcations occurs first.

By inspecting the symmetries of the physically observed solutions we may tentatively identify them with various branches: in particular the flows known as Taylor vortices, wavy vortices, twisted vortices, helices (or spirals) seem to correspond naturally to solution branches; and there is also a branch described by DiPrima and Grannick [1971] as the "nonaxisymmetric simple mode".

The experimental results of Andereck, Liu, and Swinney may be summarized as follows. In the weakly counterrotating case (that is, when the speed of the outer cylinder Ω_0 is slightly less than the critical speed Ω_0^* where the six-dimensional kernel appears) the following transition sequence is observed as Ω_i, the speed of the inner cylinder, is increased.

$$\text{Couette flow} \to \text{Taylor vortices} \to \text{wavy vortices} \to \cdots$$

where the final state obtained when the wavy vortices lose stability seems not to be one representable in the six-dimensional kernel. In the strongly counterrotating case (that is, when Ω_0 is slightly greater than Ω_0^*) the observed transition sequence is:

$$\text{Couette flow} \to \text{spiral cells} \to \text{wavy spiral cells}.$$

We shall show in §7 that it is possible to make a nondegenerate choice of vector fields on $\mathbf{R}^6$ having $O(2)\times SO(2)$ symmetry which produces the same transition sequences in the following sense. It is possible to determine constraints on the Taylor expansion of this vector field, given only by inequalities on coefficients in this Taylor expansion, so that the solutions corresponding to these states are (orbitally) asymptotically stable and lose stability in a way that should produce the desired transitions. Moreover, when these inequalities are satisfied, no other solutions are asymptotically stable.

We also show in §7 that it is possible to choose these constraints differently, so that the "main sequence" of transitions occurs, namely,

$$\text{Couette flow} \to \text{Taylor vortices} \to \text{wavy vortices}$$
$$\to \cdot\,\text{modulated wavy vortices} \to \cdots.$$

This transition sequence is usually observed when the outer cylinder is held stationary ($\Omega_0 = 0$). What we show is that it is possible for the "wavy vortex solutions" to lose stability to a torus bifurcation, where two Floquet exponents cross the imaginary axis. This tertiary bifurcation has never been demonstrated theoretically hitherto. At this point, however, we cannot prove that the branch of "modulated wavy vortices" is asymptotically stable, though we hope that the results of Scheurle and Marsden [1984] will provide the techniques required to carry out this computation. We do show, moreover, that no other solutions are asymptotically stable when these constraints hold. In particular, stable spiral cells should not occur in this experimental situation.

The paper is organized as follows. In §1 we describe some of the flows observed in the Taylor experiment and review the evidence for the existence of a six-dimensional kernel. In §2 we discuss the symmetries that act on the six-dimensional kernel, and in §3 we discuss the symmetries of the observed flows. In §4 (and the Appendix) we

discuss the reduction procedure and derive the exact form of the reduced mapping (or vector field) on the six-dimensional kernel prescribed by those symmetries. We classify the (conjugacy classes) of isotropy subgroups (which describe the type of symmetry-breaking that occurs at bifurcations). The heart of the paper is §5, where we analyze the branching equations and the stability of branches. In §6 we use these to obtain a list of the sixteen inequalities that must be imposed to ensure (what we mean by) nondegeneracy. Finally, in §7, we compare the six-dimensional model with experimental observations in both the counterrotating case and the case when the outer cylinder is held fixed.

1. The Taylor problem. By the term "Taylor problem" we mean the study of both the possible states of fluid flow between two rotating concentric cylinders, and the transitions between these states. The Taylor problem provides a beautiful example of a bifurcation problem with symmetry. In this paper we discuss how these symmetries affect the structure of the bifurcating solutions.

We denote the angular velocities of the inner and outer cylinders by Ω_i and Ω_0 respectively. To specify a direction, we assume that $\Omega_i \geqq 0$. In the standard experiments the outer cylinder is held fixed ($\Omega_0 = 0$) and the inner cylinder is speeded up in stages from $\Omega_i = 0$, at each stage allowing the flow to settle into a stable pattern; see Taylor [1923], Gollub and Swinney [1975]. Experiments have been performed in both the *corotating* case ($\Omega_0 > 0$), see Andereck, Dickman and Swinney [1983], and the *counter-rotating* case ($\Omega_0 < 0$), see Andereck, Liu, and Swinney [1984]. (These papers cite the earlier experimental work.) The experiments begin by rotating the outer cylinder at constant speed, and allowing the flow to stabilize; then the inner cylinder is speeded up as before. The experiments reveal a large number of fluid states, only some of which are understood on theoretical grounds. There can exist multiple steady states whose exploration requires different experimental procedures; see for example Coles [1965], Benjamin [1978a, b], Benjamin and Mullin [1982]. In our discussion we shall assume a fixed (but unspecified) value of Ω_0, and treat Ω_i (or the corresponding Reynolds number) as a bifurcation parameter. Our main concern will be with the series of bifurcations that occurs as Ω_i is increased steadily. We mention this because many numerical computations fix the ratio Ω_0/Ω_i, and hence do not correspond directly to the usual experimental procedure—a fact that, in the presence of multiple states, raises some problems of interpretation.

In the standard experiments, with $\Omega_0 = 0$, the first transition is from Couette (laminar) flow to (Taylor) *vortices*. Both flows are time-independent. This transition was first described, in terms of a steady state bifurcation, by Davey [1962]. He showed that as Ω_i is increased, the Navier–Stokes equations linearized about Couette flow have a double zero eigenvalue at the first bifurcation. At this eigenvalue Couette flow loses stability, and a branch of vortex solutions bifurcates. Davey's observations have been reproduced by several authors in different contexts, cf. the survey by DiPrima and Swinney [1981, §6.3]. Note that the appearance of a double zero eigenvalue might be surprising were it not for the existence of symmetries (which can couple eigenvalues together and force a degeneracy).

Again, in the standard experiments with $\Omega_0 = 0$, a second transition is observed, in which vortices lose stability to a time-periodic state known as *wavy vortices*. Presumably this transition takes place by way of a Hopf type bifurcation in which several eigenvalues (governing the stability of vortices) cross the imaginary axis as Ω_i is increased. However, this presumption has never been established directly. What has been shown (in Davey, DiPrima, and Stuart [1968]) is that along the Couette branch of solutions

several eigenvalues of the linearized Navier–Stokes equations cross the imaginary axis as Ω_i is increased. In particular the next set of eigenvalues to cross the imaginary axis is a complex conjugate pair of purely imaginary eigenvalues, each of multiplicity two. Again, it would be surprising to see four eigenvalues crossing the imaginary axis simultaneously were it not for the symmetry. We note in passing (and amplify these remarks below) that the $O(2)$ symmetry which couples these four eigenvalues together forces the occurrence of two branches of time-periodic solutions bifurcating from the (unstable) main Couette branch: see Schecter [1976], and Golubitsky and Stewart [1985]. However, neither of these solutions can correspond to wavy vortex states, since their symmetries do not match those of wavy vortices. In fact, one of them has the symmetries of spiral cells (helices).

There are three additional facts which suggest that there might be a *relatively* simple local explanation for many of the observed states in the Taylor problem, at least in the counterrotating case $\Omega_0 < 0$. First, as observed in DiPrima and Grannick [1971], and Krueger, Gross, and DiPrima [1966], there is a critical speed of counterrotation $\Omega_0^* < 0$ such that, as Ω_i is increased, Couette flow loses linearized stability by having six eigenvalues cross the imaginary axis. These six eigenvalues are obtained by amalgamating the double zero eigenvalues and the complex conjugate pair of purely imaginary eigenvalues of multiplicity two, described above. Further, when Ω_0 is slightly less than Ω_0^*, the first bifurcation from Couette flow occurs when four eigenvalues (a complex conjugate pair each of multiplicity two) cross the imaginary axis; and there is a double zero eigenvalue at a higher value of Ω_i.

Second, in experiments in which Ω_0 is sufficiently negative, the primary bifurcation is not to the time-independent Taylor vortices, but to time-dependent spiral cells, see Andereck, Liu, and Swinney [1984].

Third, it is possible to produce a solution from the interaction of the four-dimensional center manifold (associated with the purely imaginary eigenvalues) and the two-dimensional center manifold (associated with the double zero eigenvalues) that has the same symmetry as wavy vortices. This suggests that it might be possible to prove the existence of a Hopf-type bifurcation from vortices to wavy vortices as a *secondary* bifurcation. This was observed by DiPrima and Sijbrand [1982] and again by Chossat and Iooss [1984].

Given these three facts, it would appear reasonable to study the Taylor problem in terms of perturbations of the degenerate case $\Omega_0 = \Omega_0^*$, using either a center manifold or a Lyapunov–Schmidt reduction from the Navier–Stokes equations. We call this degeneracy the *six-dimensional kernel* since the linearized equation has a kernel of dimension six and the reduced problem may therefore be posed on $\mathbf{R}^6$. The hope raised by the above facts is that one might be able to find a six-dimensional model which explains the observed prechaotic states and transitions in the counterrotating Taylor problem.

Let us consider the reduction in more detail. Rigorously, one can use the center manifold theorem to reduce the (infinite-dimensional) dynamics of the Navier–Stokes equations, near $\Omega_0 = \Omega_0^*$ and near Couette flow, to the study of some vector field g on a six-dimensional center manifold. Alternatively, one can focus only on time-independent and time-periodic solutions and use a reduction of the Lyapunov–Schmidt type to show the existence of a smooth (i.e. $\mathbf{C}^\infty$) mapping h: $\mathbf{R}^6 \to \mathbf{R}^6$ whose zeros are in one-to-one correspondence with the small-amplitude time-periodic (and time-independent) solutions of the Navier–Stokes equations. In either case, to study the dynamics $\dot{x} = g(x)$ on $\mathbf{R}^6$ or to solve $h(x) = 0$ in $\mathbf{R}^6$ would be a highly nontrivial task—were it not for the symmetries in the Taylor problem. Both reduction procedures can be performed so as to respect these symmetries. Therefore, g and h will commute with an action of

the symmetry group $O(2)\times S^1$ as we explain below. This places considerable restrictions on the form that g and h may take. When, as here, we are studying only steady and periodic states, it is sufficient to use the simpler Lyapunov–Schmidt reduction. This is our approach. For a complete study of the dynamics, the same restrictions on the form of g will be true *provided* a smooth center manifold exists. (It is plausible that the symmetry might imply this, but we have not attempted to address this issue here.)

In this paper we give an explicit representation for all smooth mappings that commute with this action of $O(2)\times S^1$. We use the symmetries to show how to solve the equation $h=0$ (in the Lyapunov–Schmidt interpretation), and to determine (in most instances) the signs of the eigenvalues of the 6×6 Jacobian matrix $dh\,|_{h=0}$. In particular we compute these eigenvalues for the solutions corresponding to wavy vortices.

In this respect our results resemble those of a recent paper of Chossat and Iooss [1984]. However, instead of working on the six-dimensional kernel, Chossat and Iooss track the bifurcations step by step using the symmetry in the primary bifurcation to analyze the possible types of symmetry-breaking at secondary bifurcations, in terms of the linearized eigenfunctions. The types of solution that they find can all be expressed as combinations of the six linearized eigenfunctions that make up the six-dimensional kernel; but no reduction to $\mathbf{R}^6$ is used explicitly. Thus, although the various pieces of the bifurcation diagram are studied, their overall arrangement (and consistency) is not.

In our approach group theory is used to provide a coherent framework that organizes the analysis and in particular the computation of stabilities, leading to more detailed results. In particular we confirm, in our setting, a conjecture made by Chossat and Iooss [1984] about *tertiary* bifurcation to modulated wavy vortices. We show that (with suitable parameter values) the branch of wavy vortices loses stability by a torus bifurcation. In experiments this transition is observed, the new state being called *modulated wavy vortices*. See Rand [1982], Gorman, Swinney, and Rand [1981], Shaw et al. [1982].

The analysis of the simplest (nondegenerate) $O(2)\times S^1$-symmetric bifurcation problems on the six-dimensional kernel leads to a picture that includes branches corresponding to a variety of the observed flows: Couette, vortices, wavy vortices, twisted vortices, spiral cells, modulated wavy vortices, wavy spirals and an unstable flow found numerically by DiPrima and Grannick [1971] which they call the "non-axisymmetric simple mode." By "correspond" we mean that the solutions we find on the six-dimensional kernel appear to have the same symmetries as the experimentally determined states. As we indicated in the introduction, it is further possible to choose parameters in the model to mimic the observed transition sequences when the outer cylinder is held fixed, and also in the counterrotating case.

DiPrima, Eagles, and Sijbrand [1984] are currently making numerical calculations of certain of the Taylor coefficients of the vector field g obtained by a center manifold reduction. These or similar numerical results should make it possible to determine to what extent the six-dimensional model reflects the expected transitions in the Taylor problem, at least in the counterrotating case.

2. Symmetries on the six-dimensional kernel. Symmetries are introduced in the Taylor problem in three distinct ways:

(1) by the experimental apparatus,

(2) by the mathematical idealization,

(3) by the mathematical analysis.

Since each of these ways introduces a circle group of symmetries the result may seem confusing at first. However, these symmetries do affect the mathematically determined

solutions and, moreover, seem to be present in the experimentally determined states.

The symmetries arising through the apparatus would appear to be the most natural. All formulations of the Taylor problem are invariant under rotation in the azimuthal plane, a plane perpendicular to the cylindrical axis. Rotation through θ in this plane moves one fluid state to another. We denote these symmetries by $SO(2)$.

Next we discuss the symmetries introduced by the mathematical idealization. In the experiments, when vortex flow is observed these vortices tend to have square cross-sections; that is, the height of each vortex is approximately equal to the distance between the cylinders. As a result, in an apparatus whose cylinder length is long compared with the distance between the cylinders, many vortices form at the initial bifurcation. Moreover, the vortex flow appears to be invariant under translation along the cylindrical axis by two band-widths, at least away from the ends of the cylinder. (In the cross-sectional regions vortex flow alternates between clockwise and counterclockwise.)

Thus in the mathematical idealization we assume that the cylinders have infinite length and look only for periodic solutions of period equal to two band-widths. As a result, the Navier–Stokes equations are invariant under both translations along the cylindrical axis and reflection of the cylinder through the azimuthal plane. Periodicity implies that translation by two band-widths acts as the identity. Thus the effective action of this group is by the (compact) group $O(2)$.

Finally, we consider a circle group of symmetries which is introduced into this problem by the technique we use to analyze the bifurcation structure. We use a Lyapunov–Schmidt reduction to determine time-periodic solutions of the Navier–Stokes equations which lie near Couette flow and the parameter values yielding the six-dimensional kernel. The circle group S^1, acting by change of phase on periodic functions, introduces symmetries into this problem. The addition of these S^1 symmetries by the Lyapunov–Schmidt procedure, to the symmetries mentioned above, is described in Sattinger [1983] and Golubitsky and Stewart [1985].

We summarize our discussion here as follows. The full group of symmetries of the Taylor problem on the six-dimensional kernel is:

$$O(2)\times SO(2)\times S^1 \tag{2.1}$$

where $O(2)$ acts by translation and flipping along the cylindrical axis, $SO(2)$ acts by rotation of the azimuthal plane and S^1 acts by change of phase of periodic solutions. For simplicity of notation we assume that the period of the cylindrical translations is 2π and that the period of patterns around the cylinder (in the azimuthal plane) is also 2π. In particular, rotation of the cylinder by half a period is $\pi \in SO(2)$. Moreover, we assume that solutions are 2π-periodic in time.

These assumptions do not affect the group-theoretic formulation of the problem, or its analysis; but they must be correctly interpreted in connection with the observed flows. Since the situation is potentially confusing, a few clarifying remarks may be in order. There is no problem in arranging period 2π for translations: we merely scale the distance along the axis. For periodic solutions in the azimuthal direction a little more caution is required. For example, it is commonly observed in experiments that wavy vortex solutions may appear with wave numbers 3 or 4 (say); that is, with 3 or 4 complete periods relative to a single turn of the cylinder. Provided only *one* such mode is present, we may scale the azimuthal angle to "factor out" this additional periodicity. The angle 2π then represents one period ($2\pi/3$ or $2\pi/4$ on the physical cylinder). In group-theoretic terms, an action of $SO(2)$ for which $\theta \in SO(2)$ produces a rotation by

$k\theta$, k an integer, can be viewed as the standard ($k=1$) action of $SO(2)/Z_k$ and this group may be *identified* with $SO(2)$.

On the six-dimensional kernel, only one such periodic mode occurs, and this procedure may be followed. If two modes with different wave numbers occur, it would be necessary to make $SO(2)$ act by $k\theta$ and $l\theta$ (where k, l are the respective wavenumbers) on the corresponding spaces of eigenfunctions and to carry out the analysis for the appropriate action of $O(2)\times SO(2)\times S^1$. See Chossat [1985].

3. Observed solutions and their symmetries. In the experiments a number of prechaotic states are observed. In this section we discuss the symmetries of each of the following states: Couette flow, Taylor vortices, wavy vortices, spiral cells, and twisted vortices.

Both the *Couette* and *vortex* flows are time-independent. As noted above, vortex flow produces bands along which the flow is in the azimuthal plane. See Fig. 3.1(a).

When $\Omega_0 \leqq 0$, vortex flow loses stability, and a time periodic state called *wavy vortices* appears. See Fig. 3.1(b). This periodic flow has the special form of rotating waves. More precisely, the solution $u(t)$ is a rotating wave if $u(t+\theta)=R_\theta u(t)$ where R_θ denotes rotation by angle θ in the azimuthal plane. We shall see in §4 that *all* periodic solutions obtained from the six-dimensional kernel must be rotating waves.

When $\Omega_0=\Omega$, wavy vortex solutions lose stability, and a new quasi-periodic solution with two independent frequencies appears. This new state is called *modulated wavy vortices*. It is interesting to observe, at this point, how the modulated wavy vortex solution might be detected by our proposed method using a Lyapunov–Schmidt reduction. The idea is to compute the Floquet exponents along the wavy vortex branch of solutions and show that certain of these exponents cross the imaginary axis. Then apply the Sacker–Neimark torus bifurcation theorem to conclude the existence of quasiperiodic solutions. We show in §7 that this scenario is possible. A similar remark holds for identifying wavy spiral states when $\Omega_0<0$.

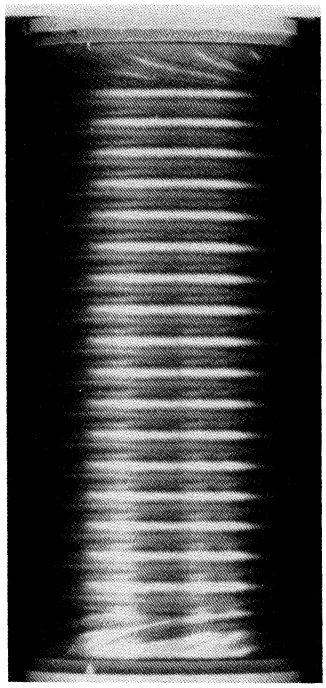
We note that the actual transition to chaos cannot be explained by our analysis. Nevertheless, chaotic behavior may be present in our model and this point deserves further investigation.

We also note here that in the corotating and counterrotating Taylor problems solutions with different planforms are observed. For example, in the corotating case Andereck, Dickman and Swinney [1983] have observed *twisted vortices*. See Fig. 3.1 (c). In the strongly counterrotating case, Couette flow loses stability to a helicoidal pattern called *spiral cells*, which are time-periodic rotating waves. See Fig. 3.1(d).

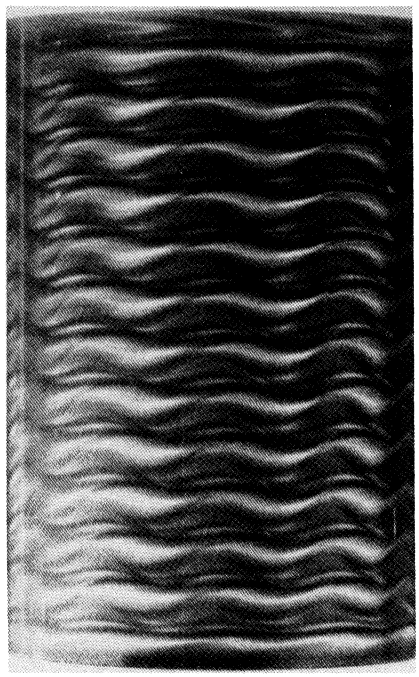
We can distinguish each of the states described above by their *isotropy subgroups*; that is, by the subgroup of (2.1) which leaves the given state invariant. In Table 3.1 we list the isotropy subgroups for each fluid state described above.

We now discuss the entries in Table 3.1. The steady-state solutions are invariant under change of phase (S^1); the periodic solutions are all rotating waves and are invariant under Δ since a change of phase may be compensated for by rotating the cylinder. Couette flow is invariant under all symmetries. Taylor vortices are invariant under all rotations ($SO(2)$) and the flip along the cylindrical axis κ. We denote by $Z_2(\kappa)$ the two-element group generated by κ.

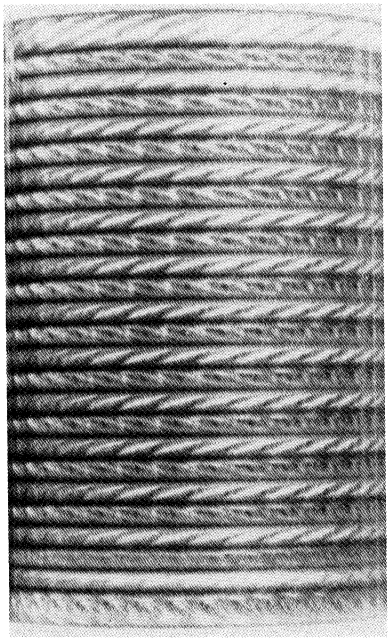
Isotropy subgroups for the periodic solutions are obtained as follows. The helical state, spiral cells, is invariant under $\widetilde{SO(2)}$ since a translation along the cylinder axis may be compensated for by a rotation of the cylinder. Next observe that wavy vortices are invariant under the group element obtained by composing the flip (κ) with rotation



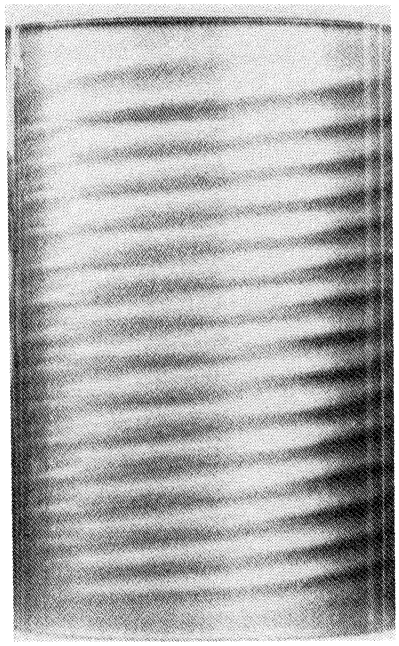
(a) *Taylor vortices* ($R_o = 1164$, $R_i = 1161$).



(b) *Modulated wavy vortices* ($R_o = -100$, $R_i = 350$). *In a still photograph wavy vortices and modulated wavy vortices have a similar appearance.*



(c) *Twisted vortices* ($R_o = 721$, $R_i = 1{,}040$).



(d) *Spiral cells* ($R_o = -295$, $R_i = 237$).

FIG. 3.1. *Observed flows in the Taylor experiment. Reynolds numbers for the inner* (R_i) *and outer* (R_o) *cylinders. Photographs kindly supplied by Harry Swinney and Randy Tagg. Similar photographs will appear in Andereck, Liu and Swinney* [1985].

TABLE 3.1
Isotropy subgroups of observed fluid states.

State	Isotropy subgroup
Couette flow	$O(2)\times SO(2)\times S^1$
Taylor vortices	$Z_2(\kappa)\times SO(2)\times S^1$
Wavy vortices	$Z_2(\kappa,\pi)\times\Delta$
Twisted vortices	$Z_2(\kappa)\times\Delta$
Spiral cells	$\widetilde{SO}(2)\times\Delta$

$\Delta=\{(\theta,-\theta)\in SO(2)\times S^1\}$
$\kappa\in O(2)$ is the flip $z\to -z$ along the cylindrical axis
$\pi\in SO(2)$ is rotation of the azimuthal plane by one-half period
$\widetilde{SO}(2)=\{(\psi,-\psi)\in O(2)\times SO(2)\}$

of the cylinder by half a period $\pi\in SO(2)$. Finally, twisted vortices are invariant under the flip κ.

It is worth noting that the first three bifurcations in the standard Taylor problem ($\Omega_0=0$) break symmetry in a simple way. Couette flow to Taylor vortices breaks the translational symmetries; Taylor vortices to wavy vortices breaks the rotational symmetries ($SO(2)$); and wavy vortices to modulated wavy vortices breaks the rotating wave symmetries (Δ).

4. Group theory and the six-dimensional kernel. In this section, we answer four questions:

(1) What is the exact form of the six-dimensional kernel?

(2) What is the action of the symmetries of the Taylor problem on this kernel?

(3) What is the form of the reduced mapping h, obtained by the Lyapunov–Schmidt procedure?

(4) What are the possible isotropy subgroups of points in the six-dimensional kernel?

We answer the first question by referring to DiPrima and Sijbrand [1982]. Let $\eta=R_i/R_o$ be the ratio of the radii of the inner and outer cylinders. We quote:

> Thus, for example, for $\eta=0.95$ and $\Omega_0/\Omega_i=-0.73976$, Couette flow is simultaneously unstable to an axisymmetric disturbance with wave numbers $(\lambda,m)=(3.482,0)$ and a nonaxisymmetric disturbance with wavenumbers $(\lambda,m)=(3.482,1)$. We also note that...there are 6 critical modes with axial (Z) and azimuthal (Θ) dependence as follows:

$$\cos\lambda Z,\ \sin\lambda Z,\ e^{\pm i\Theta}\cos(\lambda Z),\ e^{\pm i\Theta}\sin(\lambda Z). \tag{4.1}$$

The action of the translations in $O(2)$ on the eigenfunctions in (4.1) is generated by translations of the axial (angle) Z and the flip (κ) which acts by $Z\to -Z$. Rotations in the azimuthal plane act by translations in Θ. (We have omitted the radial dependence of the eigenfunctions here as the group $O(2)\times SO(2)$ acts trivially in the radial direction.) Observe that the resulting action of $O(2)\times SO(2)$ on the six-dimensional space generated by the eigenfunctions in (4.1) leads to the following equivalent action. We identify the six-dimensional kernel with

$$V=\mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C}) \tag{4.2}$$

and let elements of $O(2)$ act on $\mathbf{R}^2$ in the standard way and elements of $SO(2)$ act by

multiplication on $\mathbf{C}$. That is

$$(\theta,\psi)(v,w\otimes z)=\big(R_\theta v,(R_\theta w)\otimes(e^{i\psi}z)\big)$$

where R_θ is the usual rotation of $\mathbf{R}^2$ through the angle θ. Similarly, the flip κ acts by $(Kv,Kw\otimes z)$, where K is the matrix $\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$. The action of the phase shifts S^1 in V turns out to be identical with the action of $SO(2)$ on V. This fact can be verified by direct computation. First observe that the $\mathbf{R}^2$ summand in V is spanned by $\{\cos(\lambda Z),\sin(\lambda Z)\}$, a steady-state kernel. As such, S^1 acts trivially on $\mathbf{R}^2$. Next, observe that S^1 commutes with $O(2)\times SO(2)$ and hence the actions of S^1 and $O(2)\times SO(2)$ on $\mathbf{R}^2\otimes\mathbf{C}$ commute. Since the only matrices acting on $\mathbf{R}^2\otimes\mathbf{C}$ commuting with $O(2)\times SO(2)$ are scalar multiples of matrices in $SO(2)$ (see Golubitsky and Stewart [1985, Lemma 3.2]), it follows that the elements of S^1 act in a fashion identical to elements of $SO(2)$. Without loss of generality, we may identify the actions of $SO(2)$ and S^1.

One consequence of this identification is that the subgroup $\Delta=\{(\psi,-\psi)\in SO(2)\times S^1\}$ is in the isotropy subgroup of every element in V. Thus, we have proved:

LEMMA 4.1. *Every periodic solution found in the six-dimensional kernel is a rotating wave.*

A second consequence of the identification of the actions of $SO(2)$ and S^1 is the simple form that the reduction bifurcation equation $h\colon V\to V$, obtained via a Lyapunov–Schmidt reduction, must take. (The function h depends on a number of extra parameters, Ω_0 for example. We suppress this dependence here.) Let the purely imaginary eigenvalues of the linearized Navier–Stokes equations be $\pm\omega i$. For simplicity, use a scaling argument to assume $\omega=1$. Then the idea behind the Lyapunov–Schmidt reduction is to look for small amplitude periodic solutions of period near 2π. One does this by rescaling time in the original equation by a perturbed period parameter τ and looking for precisely 2π-periodic solutions to the scaled equations. What results, after appropriate applications of the implicit function theorem, is a reduction equation

$$h(v,\tau)=0$$

where $h\colon V\times\mathbf{R}\to V$ is smooth and commutes with $O(2)\times SO(2)\times S^1$. We claim that we may assume that the dependence of h on τ is particularly simple. In fact,

$$h(v,\tau)=g(v)-(1+\tau)J \tag{4.3}$$

where J is the matrix form of the action by $\pi/2\in S^1$ on V.

To verify this claim, suppose for the moment that there exists a smooth center manifold. Let $g(v)$ be the reduction vector field on that center manifold. It was proved in Golubitsky and Stewart [1985] that if the Lyapunov–Schmidt reduction is applied to g, introducing τ, then the resulting function h has exactly the form (4.3). This fact relies on having the spatial symmetries $SO(2)$ identified with the temporal symmetries S^1.

If we perform the Lyapunov–Schmidt reduction directly from the Navier–Stokes equations, then the reduced function has the same form as (4.3), at least to first order in τ. In any case, the form (4.3) is used later only to solve certain equations for τ explicitly. If higher order terms are present, then these equations may be solved implicitly, which is sufficient for our purposes. Therefore we lose nothing by working with h in the form (4.3). Moreover, we note that g commutes with the action of $O(2)\times SO(2)\times S^1$ on V and may be identified with the mapping on V obtained by a center manifold reduction, at least up to any finite order in its Taylor expansion.

For the remainder of this section we describe precisely the form that mappings g which commute with $O(2)\times SO(2)\times S^1$ must have. Note that a third consequence of identifying the actions of $SO(2)$ and S^1 is that at this stage we may ignore one of them. Henceforth, we assume that

$$\Gamma = O(2)\times S^1 \tag{4.4}$$

is our group of symmetries and turn attention to the action of Γ on V.

At this point we choose coordinates on V. First write $V = V_1 \oplus V_2$ where $V_1 = \mathbf{R}^2 \cong \mathbf{C}$ and $V_2 = \mathbf{R}^2 \otimes \mathbf{C} \cong M(2,\mathbf{R})$, the space of 2×2 matrices with real entries. Thus elements of V have the form

$$(z,A) \tag{4.5}$$

where

$$z = x + iy \in \mathbf{C} \quad \text{and} \quad A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M(2,\mathbf{R}).$$

In these coordinates the group action of $\Gamma = O(2)\times S^1$ on (z,A) is defined as follows:

$$(\theta,\psi)(z,A) = \left(e^{i\theta}z, R_\theta A R_\psi\right) \tag{4.6}$$

where

$$R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$$

is the rotation matrix. See Golubitsky and Stewart [1985, §3] for more detail.

We now answer the third question by describing in detail the invariant functions and the equivariant mappings corresponding to this group action. (Recall that Φ: $V \to V$ is equivariant if $\Phi(\gamma v) = \gamma\Phi(v)$ for all $\gamma \in \Gamma$, $v \in V$.) Proofs are found in the Appendix.

PROPOSITION 4.2. *Let ϕ: $V \to R$ be a smooth function defined in a neighborhood of the origin which is invariant with respect to the action of Γ in* (4.6). *Then there exists a smooth function h: $\mathbf{R}^5 \to \mathbf{R}$ defined near* 0 *such that*

$$\phi(v) = h(\beta, N, \delta^2, \gamma, \sigma)$$

where

$$\begin{aligned} &\beta \equiv z\bar{z} = x^2 + y^2, \\ &N = a^2 + b^2 + c^2 + d^2, \\ &\delta = \det A, \\ &\gamma = \operatorname{Re}(z^2\bar{\zeta}), \\ &\sigma = i\delta \operatorname{Im}(z^2\bar{\zeta}) \end{aligned} \tag{4.7}$$

and

$$\zeta = a^2 + b^2 - c^2 - d^2 + 2i(ac + bd).$$

THEOREM 4.3. *Let Φ: $V \to V$ be a smooth Γ-equivariant mapping defined near* 0. *Then there exist Γ-invariant functions*

$$p, q, r, s, P^1, P^2, Q^1, Q^2, Q^3, Q^4, R^1, R^2, R^3, R^4, M^3, M^4$$

such that

$$\Phi(z,A)=\left(pz+qi\delta z+r\bar{z}\zeta+si\delta\bar{z}\zeta,\ \sum_{j=1}^{4}\left(S^jK_j+T^jL_j\right)\right), \tag{4.8}$$

where

$$K_1=\begin{pmatrix}a & b\\ c & d\end{pmatrix},\quad K_2=\begin{pmatrix}-b & a\\ -d & c\end{pmatrix},\quad K_3=\begin{pmatrix}a & b\\ -c & -d\end{pmatrix},\quad K_4=\begin{pmatrix}-b & a\\ d & -c\end{pmatrix},$$
$$L_1=\begin{pmatrix}-c & -d\\ a & b\end{pmatrix},\quad L_2=\begin{pmatrix}d & -c\\ -b & a\end{pmatrix},\quad L_3=\begin{pmatrix}c & d\\ a & b\end{pmatrix},\quad L_4=\begin{pmatrix}-d & c\\ -b & a\end{pmatrix}, \tag{4.9}$$

and

&T^4=-Q^4\,\mathrm{Im}(\bar{z}^2)+R^4\delta\,\mathrm{Re}(\bar{\zeta})+M^4\delta\,\mathrm{Re}(\bar{z}^2).
\end{aligned} \tag{4.10}$$

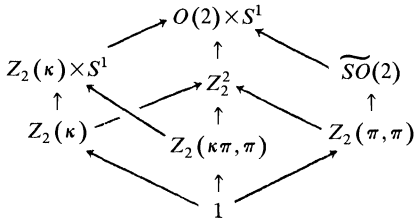
We shall exploit the form of ϕ in (4.8) to solve explicitly the reduced bifurcation equation $g=0$. In order to understand what types of solutions one may find in $g=0$ we answer the fourth question of this section. By determining, up to conjugacy, the set of all isotropy subgroups of elements in V, we determine the symmetries that possible solutions to the Navier–Stokes equations found by reducing to V may have.

The lattice (of conjugacy classes) of isotropy subgroups for Γ acting on V is given in Table 4.1. Containment of one conjugacy class in another is indicated by arrows. In Table 4.2 we list these isotropy subgroups along with the states in the Taylor problem which have those symmetries. We use the notation Z_2 to indicate a two-element group and $Z_2(\alpha)$ to indicate the two-element group generated by $\alpha\in\Gamma$.

We emphasize that the containments in Table 4.1 are of conjugacy classes. For example, $Z(\kappa\pi,\pi)$ is not contained in $Z_2(\kappa)\times S^1$. However, $Z_2(\kappa\pi,\pi)$ is conjugate to $Z_2(\kappa,\pi)$ which is contained in $Z_2(\kappa)\times S^1$.

TABLE 4.1

Lattice of conjugacy classes of isotropy subgroups of Γ *acting on* V.



Note: Z_2^2 is generated by κ, $(\kappa\pi,\pi)$, (π,π).

TABLE 4.2

The symmetries associated with observed fluid states.

Isotropy subgroup	Solution type
$O(2)\times S^1$	Couette flow
$Z_2(\kappa)\times S^1$	Taylor vortices
$\widetilde{SO}(2)$	spiral cells
$Z_2(\kappa\pi,\pi)$	wavy vortices
$Z_2(\kappa)$	twisted vortices

We derive the lattice pictured in Table 4.1 by first considering orbit representatives. Begin by considering the action of $O(2)\times S^1$ on $\mathbf{R}^2\otimes\mathbf{C}\cong M(2,\mathbf{R})$. Let A be a 2×2 matrix. As shown in Golubitsky and Stewart [1985, §7], we can choose an element of $O(2)\times S^1$ so that A is conjugated to the diagonal matrix $\left(\begin{smallmatrix} a & 0 \\ 0 & d \end{smallmatrix}\right)$ where $a\geqq d\geqq 0$. It is then easy to show that there are four types of orbits as shown in Table 4.3.

TABLE 4.3

Orbit representatives of $O(2)\times S^1$ acting on $M(2,\mathbf{R})$.

Orbit representative	Isotropy subgroup
0	$O(2)\times S^1$
$\left(\begin{smallmatrix} a & 0 \\ 0 & 0 \end{smallmatrix}\right)$, $a>0$	Z_2^2
$\left(\begin{smallmatrix} a & 0 \\ 0 & a \end{smallmatrix}\right)$, $a>0$	$\widetilde{SO}(2)$
$\left(\begin{smallmatrix} a & 0 \\ 0 & d \end{smallmatrix}\right)$, $a>d>0$	$Z_2(\pi,\pi)$

Having put the matrices in $M(2,\mathbf{R})$ into normal form, we now use the isotropy subgroups of these matrices to conjugate the elements $z\in\mathbf{C}\cong\mathbf{R}^2$. In this way we obtain representatives for all the orbits of $O(2)\times S^1$ acting on $\mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})$. These results are summarized in Table 4.4.

TABLE 4.4

Orbit representatives of $O(2)\times S^1$ acting on $\mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})$.

Orbit representative (z,A)	Isotropy subgroup
$(0,0)$	$O(2)\times S^1$
$(x,0)$, $x>0$	$Z_2(\kappa)\times S^1$
$\left(0,\left(\begin{smallmatrix} a & 0 \\ 0 & 0 \end{smallmatrix}\right)\right)$, $a>0$	Z_2^2
$\left(x,\left(\begin{smallmatrix} a & 0 \\ 0 & 0 \end{smallmatrix}\right)\right)$, $x>0$, $a>0$	$Z_2^2(\kappa)$
$\left(iy,\left(\begin{smallmatrix} a & 0 \\ 0 & 0 \end{smallmatrix}\right)\right)$, $y>0$, $a>0$	$Z_2^2(\kappa\pi,\pi)$
$\left(x+iy,\left(\begin{smallmatrix} a & 0 \\ 0 & 0 \end{smallmatrix}\right)\right)$, $x>0$, $y>0$, $a>0$	1
$\left(0,\left(\begin{smallmatrix} a & 0 \\ 0 & a \end{smallmatrix}\right)\right)$, $a>0$	$\widetilde{SO}(2)$
$\left(x,\left(\begin{smallmatrix} a & 0 \\ 0 & a \end{smallmatrix}\right)\right)$, $x>0$, $a>0$	1
$\left(0,\left(\begin{smallmatrix} a & 0 \\ 0 & d \end{smallmatrix}\right)\right)$, $a>d>0$	$Z_2(\pi,\pi)$
$\left(x+iy,\left(\begin{smallmatrix} a & 0 \\ 0 & d \end{smallmatrix}\right)\right)$, $\lvert x+iy\rvert\neq 0$, $x\geqq 0$, $a>d>0$	1

TABLE 4.5

Fixed-point subspaces of $O(2)\times S^1$ acting on V.

Isotropy subgroup	Fixed-point subspace	Dimension
$O(2)\times S^1$	0	0
$Z_2(\kappa)\times S^1$	$(x,0)$	1
Z_2^2	$\left(0,\begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}\right)$	2
$\widetilde{SO}(2)$	$\left(0,\begin{pmatrix} a & b \\ -b & a \end{pmatrix}\right)$	2
$Z_2(\kappa)$	$\left(x,\begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}\right)$	3
$Z_2(\kappa\pi,\pi)$	$\left(iy,\begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}\right)$	3
$Z_2(\pi,\pi)$	$\left(0,\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right)$	4
1	$\left(x+iy,\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right)$	6

In the last table of this section we present the fixed-point subspaces of the various isotropy subgroups. More precisely, let $\Sigma\subset\Gamma$ be a subgroup. Define

$$V^{\Sigma}=\{v\in V \mid \sigma v=v \text{ for all } \sigma\in\Sigma\}. \tag{4.11}$$

Observe that if Φ: $V\to V$ commutes with Γ, then Φ maps V^{Σ} to itself (see Golubitsky and Stewart [1985, (1.6)]).

5. Branching and stability. Let $h(z,A,\lambda,\tau)$ be the mapping on the six-dimensional kernel obtained via the Lyapunov–Schmidt reduction. Note that h depends explicitly on the bifurcation parameter λ and the perturbed period τ. In addition, we know that h commutes with the symmetries in the Taylor problem. We shall use the consequences of this fact to explain how to compute both the solutions to $h=0$ and the eigenvalues of the 6×6 Jacobian matrix dh along branches of solutions to $h=0$. One consequence of the $O(2)\times SO(2)\times S^1$ symmetries is that the eigenvalues of dh determine the orbital asymptotic stability of solutions.

Let us be more precise. Recall the form of h in (4.3) with its simple τ-dependence, namely

$$h(z,A,\lambda,\tau)=g(z,A,\lambda)-(1+\tau)\left(0,\begin{pmatrix} -b & a \\ -d & c \end{pmatrix}\right) \tag{5.1}$$

where $A=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. In deriving this form we note that if the Navier–Stokes equations admit a smooth center manifold then h will have exactly the form (5.1), where g is the reduced vector field on that center manifold. We proved in Golubitsky and Stewart [1985, Thm. 8.2] that the eigenvalues of dh determine the orbital asymptotic stability of solutions to the vector field g on the center manifold. Moreover the center manifold reduction implies that the stabilities of solutions to the vector field g are the same as the stabilities of the corresponding solutions to the Navier–Stokes equations.

If there should not exist a smooth center manifold (which we doubt) then we are computing the correct stabilities for g, accurate to any finite order, by using the eigenvalues of $(dh)\,|_{h=0}$.

We now describe how to compute the eigenvalues of dh. Recall that (4.8) restricts the form of g in (5.1) to:

$$g(z,A,\lambda)=\left(pz+qi\delta z+r\bar{z}\zeta+si\delta\bar{z}\zeta,\ \sum_{j=1}^{4}S^jK_j+T^jL_j\right) \tag{5.2}$$

where p,q,r,s and the coefficients $P^1,\cdots,M^4$ appearing in (4.11) are invariant functions, hence functions of the five variables $\beta,N,\delta^2,\gamma,\sigma$ defined in (4.7) and λ. Moreover, since h is obtained via the Lyapunov–Schmidt reduction, the linear terms must vanish. Hence

$$p(0)=0,\quad P^1(0)=0,\quad P^2(0)=1. \tag{5.3}$$

Equivariance shows that to solve the equations $h=0$ we need only evaluate h on typical orbit representatives. The resulting equations are listed in Table 5.1. See Table 4.4 for the list of orbit representatives and their isotropy subgroups.

Remarks. (i) The equations involving τ serve only to determine the perturbed period of the associated periodic solution. Note that (5.1) allows us to eliminate τ by solving these equations explicitly (or implicitly if there does not exist a smooth center manifold, see §4 above).

(ii) Observe that τ is indeterminate on the $Z_2(\kappa)\times S^1$ branch, which is to be expected since the bifurcation is to a "steady state."

(iii) Observe that the theoretical basis of our explicit calculations is given by (4.10): fixed-point subspaces V^Σ are mapped to themselves by equivariant mappings. Therefore we may restrict h to V^Σ and seek solutions to $h\,|\,V^\Sigma=0$, considering each isotropy subgroup Σ in turn.

Table 5.1 also lists the coefficients that determine the signs of the (real parts of the) eigenvalues of dh. We consider the branching equations briefly first, and then describe in more detail the eigenvalue calculations.

By writing (4.9) in coordinates we obtain

$$h\left(x,y,\begin{pmatrix}a & b\\ c & d\end{pmatrix}\right)=\left(X,Y,\begin{pmatrix}A & B\\ C & D\end{pmatrix}\right), \tag{5.4}$$

where

$$\begin{aligned}
&\text{(a)}\ X=px-q\delta y+rx\,\mathrm{Re}(\zeta)+ry\,\mathrm{Im}(\zeta)+s\delta y\,\mathrm{Re}(\zeta)-s\delta x\,\mathrm{Im}(\zeta),\\
&\text{(b)}\ Y=py+q\delta x-ry\,\mathrm{Re}(\zeta)-rx\,\mathrm{Im}(\zeta)+s\delta x\,\mathrm{Re}(\zeta)+s\delta y\,\mathrm{Im}(\zeta),\\
&\text{(c)}\ A=(S^1+S^3)a+(-S^2-S^4)b+(-T^1+T^3)c+(T^2-T^4)d,\\
&\text{(d)}\ B=(S^2+S^4)a+(S^1+S^3)b+(-T^2+T^4)c+(-T^1+T^3)d,\\
&\text{(e)}\ C=(T^1+T^3)a+(-T^2-T^4)b+(S^1-S^3)c+(-S^2+S^4)d,\\
&\text{(f)}\ D=(T^2+T^4)a+(T^1+T^3)b+(S^2-S^4)c+(S^1-S^3)d.
\end{aligned} \tag{5.5}$$

The branching equations always take the form $X=Y=A=B=C=D=0$, evaluated on the appropriate orbit representative. The entries in the table follow readily. However, a few comments should be made regarding the last four entries of "unknown" type.

TABLE 5.1

Branching equations and eigenvalues for solutions with given symmetry.

Solution type; Isotropy; orbit	Branching equations (to be evaluated at orbit representative shown)	Signs of eigenvalues	Multiplicity

unknown $Z_2(\pi,\pi)$ $\left(0,\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}\right)$	$R^2+(a^2+d^2)R^4=0$ plus others at: $(0,a^2+d^2,a^2d^2,0,0,\lambda)$	not computed	

TABLE 5.1 (continued)

unknown 1 $\left(x,\begin{pmatrix} a & 0 \\ 0 & a \end{pmatrix}\right)$	$q=0$ plus others at: $(x^2, 2a^2, a^4, 0, 0, \lambda)$	not computed	
unknown 1 $\left(x+iy,\begin{pmatrix} a & 0 \\ 0 & 0 \end{pmatrix}\right)$	$r=0$ plus others at: $(x^2+y^2, a^2, 0, (x^2-y^2)a^2, 0, \lambda)$	not computed	
unknown 1 $\left(x+iy,\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}\right)$	$X=Y=A=B=C=D=0$ at: $(x^2+y^2, a^2+d^2, a^2d^2,$ $(x^2-y^2)(a^2-d^2), 2xyad(a^2-d^2), \lambda)$	not computed	

Notes: [1] The equations must be evaluated at $(\beta, N, \delta^2, \gamma, \sigma, \lambda)$ where these in turn are evaluated on an orbit representative to yield the form stated.

[2] The remaining eigenvalues are those of the specified 2×2 matrix. Its determinant and trace are shown to lowest order (omitting positive factors) to determine their signs.

When the isotropy group is $Z_2(\pi,\pi)$ we take two of the equations, namely $A=0=D$, which reduce to:

$$(S^1+S^3)a+(T^2-T^4)d=0,$$

$$(T^2+T^4)a+(S^1-S^3)d=0.$$

Now observe that S^1+S^3 and T^2+T^4 have a factor d. Divide this out and subtract. The result has a factor (a^2-d^2), and the entry in the table follows. We do not require the remaining equations, because an appeal to nondegeneracy (§6) now rules out this case.

For the next two cases, the equations $X=Y=0$ lead, among other things, to the listed equation, which is also ruled out by nondegeneracy. The final case is extremely complicated and it remains possible that such a branch might occur: see §7 for further discussion.

The computation of the eigenvalues, particularly those along the $Z_2(\kappa)$ and $Z_2(\kappa\pi,\pi)$ branches, is the most difficult part of this section. This computation is facilitated by the use of several results in Golubitsky and Stewart [1985, §8b]. The first is that along a solution branch (v_0,λ_0,τ_0) with isotropy subgroup Σ, the derivative $(dh)_{v_0,\lambda_0,\tau_0}$ commutes with Σ. This implies (Lemma 8.4 of that paper) that $(dh)_{v_0,\lambda_0,\tau_0}$ leaves invariant the subspaces W_j of V formed by adding together all subspaces of V on which Σ acts by a fixed irreducible representation. We use the W_j to put dh into block diagonal form.

The second fact is that $(dh)_{v,\lambda,\tau}$ vanishes on all vectors tangent to the orbit of v under the action of $O(2)\times S^1$. These null-vectors are given by:

$$\text{(5.6)}\qquad \text{(a)}\quad (z,A)\to\frac{d}{d\theta}(z,AR_\theta)\Big|_{\theta=0}=\left(0,A\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\right),$$

$$\text{(b)}\quad (z,A)\to\frac{d}{d\psi}\left(e^{i\psi}z,R_\psi A\right)\Big|_{\psi=0}=\left(iz,\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}A\right).$$

We now outline the explicit computation of the eigenvalues listed in Table 5.1.

(a) $Z_2 \times S^1$ (*Taylor vortices*). Decompose $V = \mathbf{R}^2 \oplus (\mathbf{R}^2 \otimes \mathbf{C})$ into irreducibles for $Z_2 \times S^1$. We get $V = W_0 \oplus W_1 \oplus W_2 \oplus W_3$ where

$$W_0 = \{(x,0)\}, \qquad W_2 = \left\{\left(0, \begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}\right)\right\},$$

$$W_1 = \{(iy,0)\}, \qquad W_3 = \left\{\left(0, \begin{pmatrix} 0 & 0 \\ c & d \end{pmatrix}\right)\right\}.$$

The actions are given by

	W_0	W_1	W_2	W_3
$\kappa \in O(2)$	1	-1	1	-1
$\psi \in SO(2)$	1	1	$\mathbf{R}_\psi$	$\mathbf{R}_\psi$

which are distinct irreducible actions. Therefore, dh leaves each W_j invariant. Let $\Phi_j = dh \mid W_j$, so that dh has the block form:

	x	y	a b	c d
x	Φ_0	0	0	0
y	0	Φ_1	0	0
a b	0	0	Φ_2	0
c d	0	0	0	Φ_3

We evaluate the Φ_j at the orbit representative $(x,0)$, with the following results.

$\Phi_0 = X_x = p + p_x x = p_x x$ since $p = 0$ on this branch by Table 5.1. Now $x > 0$ so we can divide it out.

$$\Phi_1 = Y_y = p + p_y y = 0,$$

$$\Phi_2 = \begin{bmatrix} A_a & A_b \\ B_a & B_b \end{bmatrix} = \begin{bmatrix} S^1 + S^3 & -S^2 - S^4 \\ S^2 + S^4 & S^1 + S^3 \end{bmatrix} = \begin{bmatrix} P^1 + x^2 Q^3 & -(P^2 - 1 - \tau + x^2 Q^4) \\ P^2 - 1 - \tau + x^2 Q^4 & P^1 + x^2 Q^3 \end{bmatrix}.$$

Since a matrix $\left(\begin{smallmatrix} \alpha & -\beta \\ \beta & \alpha \end{smallmatrix}\right)$ has eigenvalues $a \pm i\beta$, the entry in the table follows. Similarly

$$\Phi_3 = \begin{bmatrix} C_c & C_d \\ D_c & D_d \end{bmatrix} = \begin{bmatrix} S^1 - S^3 & -S^2 + S^4 \\ S^2 - S^4 & S^1 - S^3 \end{bmatrix} = \begin{bmatrix} P^1 - x^2 Q^3 & -(P^2 - 1 - \tau - x^2 Q^4) \\ P^2 - 1 - \tau - x^2 Q^4 & P^1 - x^2 Q^3 \end{bmatrix}.$$

The entries for vortices in Table 5.1 follow. Note that Φ_2 and Φ_3 have to be scalar multiples $\left(\begin{smallmatrix} \alpha & -\beta \\ \beta & \alpha \end{smallmatrix}\right)$ of rotations since dh commutes with S^1; direct calculation confirms this.

(b) Z_2^2 (*unknown*). We use the same decomposition $V = W_0 \oplus W_1 \oplus W_2 \oplus W_3$ as in (a). The actions are:

	W_0	W_1	W_2	W_3
κ	1	-1	1	-1
(π,π)	-1	-1	1	1

So the irreducible components on these spaces are distinct. Therefore dh leaves each W_j invariant: set $\Phi_j = dh \mid W_j$. We have

$$\Phi_0 = p + ra^2, \qquad \Phi_1 = p - ra^2.$$

Now dh has one eigenvalue 0 on each of W_2 and W_3, so the remaining eigenvalues are $\operatorname{Tr}\Phi_2$, $\operatorname{Tr}\Phi_3$. Use (5.4) here. These are computed as follows.

$$\operatorname{Tr}\Phi_2 = A_a + B_b = (S^1 + S^3) + (S_a^1 + S_a^3)a + (S^1 + S^3) + (S_b^2 + S_b^4)a$$

since $b = c = d = 0$ on the orbit. The branching equations show that $S^1 + S^3 = 0$, so the sign is given by $S_a^1 + S_a^3 + S_b^2 + S_b^4$. Now on the orbit we have $z = 0$, $\delta = 0$, $\zeta = a^2$, $\delta_a = 0$, $\delta_b = 0$. So by (4.11) we compute this as $P_a^1 + P_b^2$. But $N_b = 0$ on the orbit, so this becomes $P_N^1 \cdot 2a$. Dividing by $2a > 0$ gives the table entry. (From now on, we omit such details from the calculation.)

Similarly,

$$\operatorname{Tr}\Phi_3 = C_c + D_d = S^1 - S^2 + (T_c^1 + T_c^3)a + (S^1 - S^3) + (T_d^2 + T_d^4)a.$$

But $S^1 + S^3 = 0$ on this branch, so this is

$$4S^1 + a(T_c^1 + T_c^3 + T_d^2 + T_d^4) = a^2R^2 + a^4R^4.$$

(c) $\widetilde{SO}(2)$ (*spiral cells*). Let

$$W_0 = \mathbf{C}, \quad W_1 = \left\{\begin{pmatrix} a & b \\ -b & a \end{pmatrix}\right\}, \quad W_2 = \left\{\begin{pmatrix} a & b \\ b & -a \end{pmatrix}\right\}.$$

These are irreducible under $\widetilde{SO}(2)$; and $(\theta, -\theta) \in \widetilde{SO}(2)$ acts on W_0 as $e^{i\theta}$, on W_1 as the identity, and on W_2 as $e^{2i\theta}$ (see Golubitsky and Stewart [1985, (10.5)]). Hence the W_j are invariant under dh. Let $\Phi_j = dh \mid W_j$ as usual. We compute

$$\Phi_0 = \begin{bmatrix} p & -qa^2 \\ qa^2 & p \end{bmatrix},$$

which has the form $\left(\begin{smallmatrix} \alpha & -\beta \\ \beta & \alpha \end{smallmatrix}\right)$ required to commute with $\widetilde{SO}(2)$. Now Φ_1 has one zero eigenvalue on W_1, so the other is

$$\operatorname{Tr}\Phi_1 = A_a + A_d + B_b - B_c$$

by Golubitsky and Stewart [1985, (10.11)]. We compute this on the orbit $(0, \left(\begin{smallmatrix} a & 0 \\ 0 & a \end{smallmatrix}\right))$. The result is

$$\operatorname{Tr}\Phi_1 = 2a(S_a^1 + S_a^3 + T_a^2 - T_a^4 + S_d^1 + S_d^4 + T_d^2 - T_d^4).$$

In deriving this, note that $S^1 + S^3 + T^3 - T^4 = 0$ by the branching equations. Also, the b- and c-derivatives of the invariants are equal, so the b- and c-derivative terms cancel. The a- and d-derivatives of β, N, δ, γ, σ are equal, whereas $\zeta_a = 2a = -\zeta_d$. Hence the only terms that remain, on dividing out positive factors, are

$$2P_N^1 + R^2 + a^2(P_{\delta^2}^1 + 2R_N^2) + a^4R_{\delta^2}^2.$$

The matrix of Φ_2 can be computed as

$$\begin{bmatrix} A_a - A_d & A_b + A_c \\ B_a - B_d & B_b + B_c \end{bmatrix}$$

and must be of the form $\begin{pmatrix} \alpha & -\beta \\ \beta & \alpha \end{pmatrix}$ by Golubitsky and Stewart [1985, §10]. Much as above, we find that

$$A_a - A_d = -2a^2(R^2 + 2a^2R^4),$$
$$A_b + A_c = -2a^2(R^1 + 2a^2R^4),$$

as required for the entry in the table.

(d) $Z_2(\kappa\pi, \pi)$ (*wavy vortices*). We decompose $V = W_0 \oplus W_1$ where

$$W_0 = \langle y, a, b \rangle = +1 \text{ eigenspace},$$
$$W_1 = \langle x, c, d \rangle = -1 \text{ eigenspace},$$

and take a basis in the order

$$y, a, b; x, c, d.$$

Let $\Phi_j = dh \mid W_j$. The null-vectors for the two zero eigenvalues of dh may be found from (5.4) and are

$$\begin{bmatrix} 0 \\ 0 \\ -a \\ 0 \\ 0 \\ 0 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 \\ 0 \\ 0 \\ -y \\ a \\ 0 \end{bmatrix}$$

with respect to this basis, when evaluated on the orbit. So column b of dh is zero and columns x, c are linearly dependent. Direct calculation yields $C_x = D_x = 0$, whence by linear dependence $C_c = D_c = 0$. So dh is of the form

$$\begin{array}{c} \\ y \\ a \\ b \\ \hline x \\ c \\ d \end{array} \begin{array}{c} \begin{array}{cccccc} y & a & b & x & c & d \end{array} \\ \left[\begin{array}{cccccc} * & * & 0 & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & * & * & * \\ 0 & 0 & 0 & 0 & 0 & * \\ 0 & 0 & 0 & 0 & 0 & * \end{array}\right] \end{array}.$$

The eigenvalues of Φ_2 are therefore

$$0,$$
$$X_x = 2ra^2,$$
$$D_d = a^2R^2 + 2y^2Q^3 + ay^2Q_d^4 + a^4R^4 - a^2y^2M^4,$$

and those of Φ_1 are given by

$$\begin{bmatrix} Y_y & Y_a \\ A_y & A_a \end{bmatrix}.$$

Now

$$
\begin{aligned}
Y_y &= p + p_y y - ra^2 - r_y y a^2 = p_y y - r_y a^2 y, \\
Y_a &= p_a y - \left(a^2 r_a + 2ar\right) y, \\
A_y &= \left(S_y^1 + S_y^3\right) a, \\
A_a &= \left(S_a^1 + S_a^3\right) a \quad \text{since } S^1 + S^3 = 0.
\end{aligned}
$$

To evaluate the y- and a-derivatives, note that on the orbit,

$$
\begin{aligned}
&N_y = 0, \quad \beta_y = 2y, \quad (\delta^2)_y = 0, \quad \gamma_y = -2ya^2, \quad \sigma_y = 0, \\
&N_a = 2a, \quad \beta_a = 0, \quad (\delta^2)_a = 0, \quad \gamma_a = -2ay^2, \quad \sigma_a = 0.
\end{aligned}
$$

The y-derivatives introduce a factor y, the a-derivatives a factor a. So the matrix is of the form

$$
\begin{bmatrix} e_{11} y^2 & e_{12} ay \\ e_{21} ay & e_{22} a^2 \end{bmatrix}
$$

for certain functions e_{ij}. We therefore evaluate the e_{ij} to lowest order. The result is

$$
\begin{aligned}
\begin{bmatrix} e_{11} y^2 & e_{12} ay \\ e_{21} ay & e_{22} a^2 \end{bmatrix} &= \begin{bmatrix} p_y y & p_a y - 2ary \\ \left(S_y^1 + S_y^3\right) a & \left(S_a^1 + S_a^3\right) a \end{bmatrix} \\
&= \begin{bmatrix} 2p_\beta y^2 & 2\left(p_N - r\right) ay \\ 2\left(P_\beta^1 - Q^3\right) ay & 2P_N^1 a^2 \end{bmatrix}.
\end{aligned}
$$

The determinant and trace of Φ_1 therefore have the signs indicated in the table.

(e) $Z_2(\kappa)$ (*twisted vortices*). This is similar to (d). The decomposition into invariant subspaces is now $V = W_0 \oplus W_1$ where

$$
\begin{aligned}
W_0 &= \langle x, a, b \rangle = +1 \text{ eigenspace for } \kappa, \\
W_1 &= \langle y, c, d \rangle = -1 \text{ eigenspace for } \kappa.
\end{aligned}
$$

We take a basis for V in the order

$$
x, a, b; y, c, d.
$$

Then dh has block form, and we let $dh \mid W_j = \Phi_j$.

There are two zero eigenvalues of dh given by (5.4). In the basis above the associated eigenvectors are

$$
\begin{bmatrix} x \\ a \\ b \\ y \\ c \\ d \end{bmatrix} \to \begin{bmatrix} 0 \\ b \\ -a \\ 0 \\ d \\ -c \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} -y \\ -c \\ -d \\ x \\ a \\ b \end{bmatrix}.
$$

Evaluation on the orbit representative $(x, \left(\begin{smallmatrix} a & 0 \\ 0 & 0 \end{smallmatrix}\right))$ yields the eigenvectors

$$\begin{bmatrix} 0 \\ 0 \\ -a \\ 0 \\ 0 \\ 0 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 \\ 0 \\ 0 \\ x \\ a \\ 0 \end{bmatrix}.$$

Therefore column b of dh is zero and columns y and c are linearly dependent. Putting the zeros in column b, we get

$$d\phi = \begin{array}{c} \\ x \\ a \\ b \\ y \\ c \\ d \end{array} \left[\begin{array}{ccc|ccc} x & a & b & y & c & d \\ * & * & 0 & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & \multicolumn{3}{c}{\multirow{3}{*}{Φ_1}} \\ 0 & 0 & 0 & & & \\ 0 & 0 & 0 & & & \end{array}\right].$$

Direct calculation, evaluating at $y=b=c=d=0$, yields $C_y=0$, $D_y=0$, whence by linear dependence of columns y and c we also have $C_c=D_c=0$. So

$$\Phi_1 = \left[\begin{array}{cc|c} Y_y & Y_c & Y_d \\ \hline 0 & 0 & C_d \\ 0 & 0 & D_d \end{array}\right].$$

This is triangular, so its eigenvalues are

$$0,$$
$$Y_y = p - a^2 r = -2ra^2,$$
$$D_d = a^2R^2 - 2x^2Q^3 - ax^2Q_d^4 + a^4R^4 + a^2x^2M^4,$$

using the branching equations.

Since column b of Φ_0 is zero, the eigenvalues of Φ_0 are 0, together with those of

$$\begin{bmatrix} X_x & X_a \\ A_x & A_a \end{bmatrix}.$$

Now

$$X_x = p_x x + r_x x a^2,$$
$$X_a = p_a x + \left(a^2 r_a + 2ar\right)x,$$
$$A_x = \left(S_x^1 + S_x^3\right)a,$$
$$A_a = \left(S_a^1 + S_a^3\right)a.$$

Again the matrix is of the form

$$\begin{bmatrix} f_{11}y^2 & f_{12}ay \\ f_{21}ay & f_{22}a^2 \end{bmatrix}$$

and we may retain only the lowest order terms in the f_{ij}. The result is

$$\begin{bmatrix} 2p_\beta x^2 & 2(p_N+r)ax \\ 2(P^1_\beta - Q^3)ax & 2P^1_N a^2 \end{bmatrix}$$

so the determinant and trace have the indicated signs.

Notice the "duality" between wavy and twisted vortices. This completes the verification of Table 5.1.

6. Nondegeneracy conditions. We now proceed to a detailed analysis of the solutions to the branching equations, and the signs of the real parts of the eigenvalues along branches, which determine (orbital asymptotic) stability. The main qualitative features of the bifurcation diagrams, and their associated stabilities, depend upon the signs of a number of coefficients. We therefore impose appropriate *nondegeneracy conditions*: these coefficients should be nonzero.

Recall from §1 that in order to obtain the six-dimensional kernel we had to fix the speed of counterrotation of the outer cylinder at some critical value Ω_0^*. At this speed we found a two-dimensional eigenspace associated with zero eigenvalues, $\mathbf{R}^2$, coalescing with a four-dimensional space associated with a pair of complex conjugate purely imaginary eigenvalues, $\mathbf{R}^2 \otimes \mathbf{C}$. Thus, in order to model the effects of counterrotation in the Taylor experiment, we must introduce a perturbation parameter α which will split apart the bifurcations corresponding to $\mathbf{R}^2$ (vortices) and $\mathbf{R}^2 \otimes \mathbf{C}$ (spiral cells and Z_2^2).

We choose to do this by replacing P^1 in (5.2) by $\alpha + P^1$. If $\alpha < 0$, then the bifurcation to vortices occurs second (in the bifurcation parameter $\lambda = \Omega_i$); if $\alpha > 0$, it occurs first. Thus, we may think of α as $\Omega_0 - \Omega_0^*$. See Fig. 6.1.

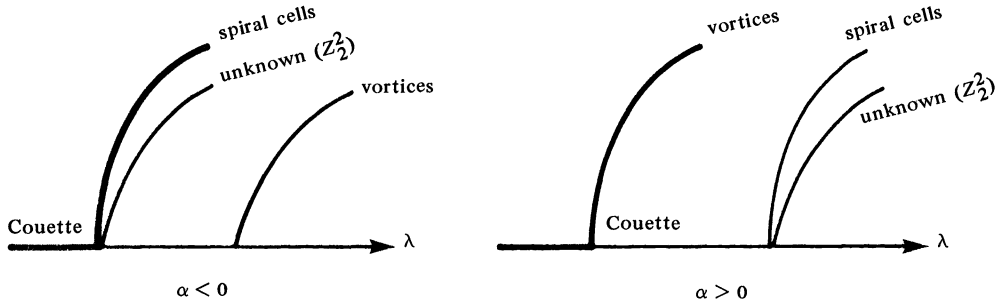

FIG. 6.1. *Schematic rendition of the effect of the perturbation α. The directions of the branches are chosen arbitrarily and secondary branches have been suppressed.*

The nondegeneracy conditions we impose on h are stated when $\alpha = 0$ and when $z = 0, A = 0$.

In Table 6.1 we list sixteen nondegeneracy conditions; a Γ-equivariant bifurcation

TABLE 6.1
Nondegeneracy conditions for h.

(a)	p_β	(h)	R^2
(b)	p_λ	(i)	$2P^1_N + R^2$
(c_1)	$(P^1_\beta + Q^3)p_\lambda - P^1_\lambda p_\beta$	(j)	$2(p_N P^1_\lambda - P^1_{Np\lambda}) - p_\lambda R^2$
(c_2)	$(P^1_\beta - Q^3)p_\lambda - P^1_\lambda p_\beta$	(k)	$P^1_N p_\beta - (P^1_\beta + Q^3)(p_N + r)$
(d)	P^1_N	(l)	$P^1_N p_\beta - (P^1_\beta - Q^3)(p_N - r)$
(e)	P^1_λ	(m)	r
(f)	$P^1_\lambda(p_N + r) - p_\lambda P^1_N$	(n)	Q^3
(g)	$P^1_\lambda(p_N - r) - p_\lambda P^1_N$	(o)	q

problem h is called *nondegenerate* if these sixteen expressions are nonzero for h. In Table 6.2 we list the lower order terms for each solution branch of $h=0$ and each eigenvalue of dh along these branches. For nondegenerate h these lower order terms determine the direction of branching (super or subcritical) and the (orbital) asymptotic stability of each solution. In Table 6.1 we use the convention that all quantities are to be evaluated at the origin. So, for example, P_N^1 means $P_N^1(0,0,0,0,0,0)$. The terms (a)–(n) in Table 6.2 refer to the corresponding expressions in Table 6.1.

TABLE 6.2

Branching equations and eigenvalues to lowest order for nondegenerate problems.

	Branching equations	Sign of real part of eigenvalues	Multiplicity
Couette flow $(O(2)\times S^1)$ $(0,0)$	None	$(b)\lambda$ $\alpha+(e)\lambda$	2 4
Taylor vortices $Z_2(\kappa)\times S^1$ $(x,0)$	$\lambda=-\dfrac{(a)}{(b)}x^2$	0 (a) $\alpha+\dfrac{(c_1)}{(b)}x^2$ $\alpha+\dfrac{(c_2)}{(b)}x^2$	1 1 2 2
unknown Z_2^2 $\left(0,\begin{pmatrix} a & 0\\ 0 & 0\end{pmatrix}\right)$	$\lambda=\dfrac{-1}{(e)}[\alpha+(d)a^2]$	0 $-\dfrac{(b)}{(e)}\alpha+\dfrac{(f)}{(e)}a^2$ $-\dfrac{(b)}{(e)}\alpha+\dfrac{(g)}{(e)}a^2$ (d) (h)	2 1 1 1 1
spiral cells $\widetilde{SO}(2)$ $\left(0,\begin{pmatrix} a & 0\\ 0 & a\end{pmatrix}\right)$	$\lambda=-\dfrac{1}{(e)}[\alpha+(i)a^2]$	0 $-\dfrac{(b)}{(e)}\alpha+\dfrac{(j)}{(e)}a^2$ (i) $-(h)$	1 2 1 2
wavy vortices $Z_2(\kappa\pi,\pi)$ $\left(iy,\begin{pmatrix} a & 0\\ 0 & 0\end{pmatrix}\right)$	$-\dfrac{(c_2)}{(b)}y^2+\dfrac{(g)}{(b)}a^2=\alpha$ $\lambda=\dfrac{(a)}{(c_2)}\alpha+\dfrac{(l)}{(c_2)}a^2$	0 (m) $2(n)y^2+(h)a^2$ $\det\begin{bmatrix} Y_y & Y_a\\ A_y & A_a\end{bmatrix}=(l)$ $\operatorname{tr}\begin{bmatrix} Y_y & Y_a\\ A_y & A_a\end{bmatrix}=(a)y^2+(d)a^2$	2 1 1 2

TABLE 6.2 (continued)

twisted vortices $Z_2(\kappa)$ $\left(x,\begin{pmatrix} a & 0 \\ 0 & 0 \end{pmatrix}\right)$	$-\frac{(c_1)}{(b)}x^2+\frac{(f)}{(b)}a^2=\alpha$ $\lambda=\frac{(a)}{(c_1)}\alpha+\frac{(k)}{(c_1)}a^2$	0 $-(m)$ $2(n)x^2+(h)a^2$ $\det\begin{bmatrix} X_x & X_a \\ A_x & A_a \end{bmatrix}=(k)$ $\operatorname{tr}\begin{bmatrix} X_x & X_a \\ A_x & A_a \end{bmatrix}=(a)x^2+(d)a^2$	2 1 1 2
$Z_2(\pi,\pi)$	No solutions by (h)		
1	No solutions by (m), (o) except perhaps on the orbit	$\left(x+iy,\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}\right)$	

*The terms (a)–(o) are defined in Table 6.1 and required, by assumption of nondegeneracy, to be nonzero.

In our analysis of the bifurcation diagrams and the asymptotic stability of the associated solutions, we use only the equivariant form of the bifurcation equations and the implicit function theorem. Moreover, in each appeal to the implicit function theorem we find a neighborhood of the origin in (z,A,λ,α)-space on which its consequences are valid. Since we use the implicit function theorem only finitely many times, all of our conclusions hold simultaneously in some fixed neighborhood of $(0,0,0,0)$ in (z,A,λ,α)-space. This neighborhood does depend, however, on the particular values that enter into the nondegeneracy conditions.

The computation of the entries in Table 6.2 may be completed in a routine fashion using the entries in Table 5.1. We give the flavor of these computations by presenting the results for wavy vortices.

The branching equations for $Z_2(\kappa\pi,\pi)$ are

$$p(y^2,a,0^2,-a^2y^2,0,\lambda)-a^2r(y^2,a^2,0,-a^2y^2,0,\lambda)=0,$$
$$\alpha+P(y^2,a^2,0,a^2y^2,0,\lambda)+y^2Q^3(y^2,a^2,0,-a^2y^2,0,\lambda)=0.$$

See Table 5.1. (The third branching equation in that table is used only to eliminate τ.) Expanding to lowest order, we have

$$0=p_\beta(0)y^2+(p_N(0)-r(0))a^2+p_\lambda(0)\lambda+\cdots,$$

$$0=\alpha+P_\beta(0)y^2+P_N(0)a^2+P_\lambda(0)\lambda-Q^3(0)y^2+\cdots.$$

Using the implicit function theorem, we can solve for λ and y^2 as a function of a^2 if

$$p_\beta(0)P^1_\lambda(0)-p_\lambda(0)\left(P^1_\beta(0)-Q^3(0)\right)\neq 0.$$

This is condition (c_2) of Table 6.1. We then obtain

$$\lambda = \frac{p_\beta(0)}{(c_2)}\alpha + \frac{P_N^1(0)p_\beta(0) - \big(P_\beta^1(0) - Q^3(0)\big)\big(p_N(0) - r(0)\big)}{(c_2)}a^2 + \cdots,$$

$$y^2 = -\frac{p_\lambda(0)}{(c_2)}\alpha - \frac{p_\lambda(0)p_N^1(0) - P_\lambda^1(0)\big(p_N^1(0) - r(0)\big)}{(c_2)}a^2 + \cdots.$$

Using the entries in Table 6.1 along with some rearrangement of terms, we obtain the entry in Table 6.2.

7. Comparison with experiment. In this section we discuss how the above model bifurcation problem(s) on the six-dimensional kernel compare with experimental observations in the two main settings.

(1) Experiments by Andereck, Liu, and Swinney [1984] in the counterrotating case, including parameter values near a point at which the six-dimensional kernel appears to occur.
(2) The standard "main sequence" of bifurcations in the case where the outer cylinder is held fixed:

Couette flow → Taylor vortices → wavy vortices → modulated wavy vortices → ···

We will show below that it is possible to make choices for the signs of the coefficients that appear in Table 6.1 as nondegeneracy conditions, so that the resulting bifurcation sequences are in qualitative agreement with the experimentally observed bifurcation sequences. In the counterrotating case we have direct (numerical) evidence for the existence of the six-dimensional kernel through the work of DiPrima and Grannick [1971]; no evidence for this six-dimensional kernel currently exists when the outer cylinder is held fixed. We hasten to add, however, that the existence of the six-dimensional kernel is, because of symmetry, only a codimension one phenomenon; it should occur frequently in various forms of Taylor–Couette flow. We also note that, unfortunately, there are many different choices for the signs of the nondegeneracy conditions in Table 6.1 (over 10,000), so many different bifurcation sequences are possible besides the ones we consider here. However, the possibilities are not totally arbitrary, as we see below.

7.1. The counterrotating case. In a private communication, D. Andereck gave us the (qualitative) form of the experimental results for counterrotating Taylor–Couette flow, which have since appeared in Andereck, Liu, and Swinney [1984]. We present these results in Fig. 7.1. There are three features that deserve mention here.

(i) There is a critical speed of counterrotation Ω_0^* at which the primary bifurcation from Couette flow changes from Taylor vortices to spiral cells. This corresponds to the critical speed of counterrotation found numerically by DiPrima and Grannick [1971]. However, they presumably performed the calculations for values of the dimensions of the apparatus which differ from those used by Andereck, Liu and Swinney [1984].

(ii) In the weakly counterrotating case $\Omega_0 < \Omega_2^*$—this corresponds to the case

($\alpha > 0$) where our perturbation parameter α is positive—the observed bifurcation sequence is:

Couette → vortices → wavy vortices

See Fig. 7.2.

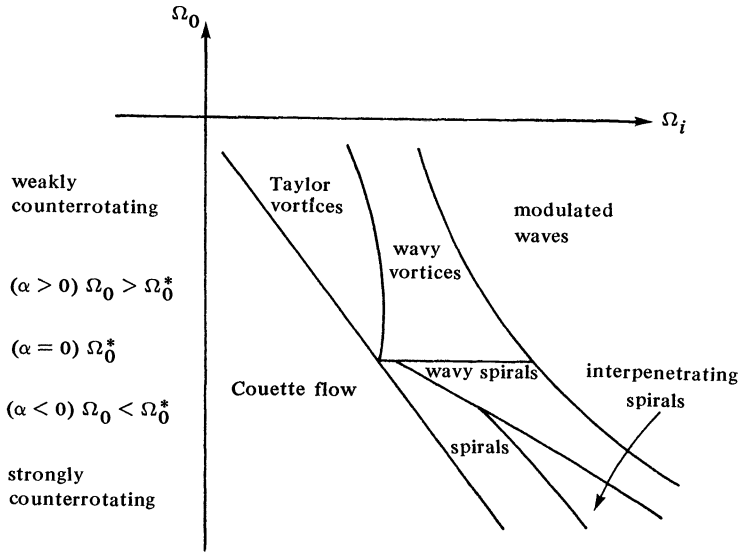

FIG. 7.1. *Qualitative version of the experimental results of Andereck, Liu, and Swinney* [1984] *showing observed transitions between stable states in the counterrotating Taylor–Couette system.*

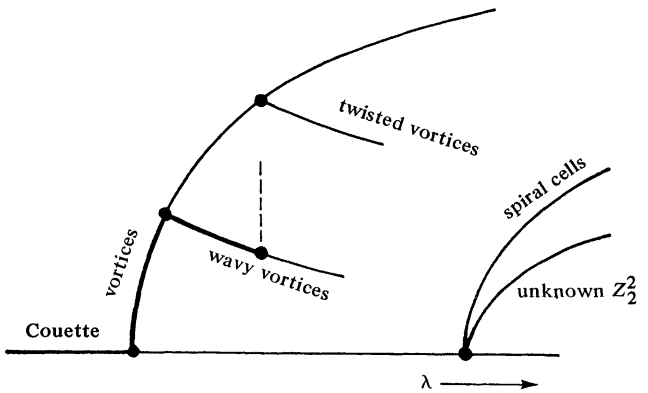

FIG. 7.2. *Schematic bifurcation diagram when* $\alpha > 0$ *corresponding to the observations of Andereck, Liu, and Swinney* [1984]. (*Secondary branches may or may not join other branches, depending on the values of the coefficients.*)

If the speed of the inner cylinder is increased further, then the wavy vortices lose stability to another state which does not appear to correspond to any state in our model.

(iii) In the strongly counterrotating case where Ω_0 is slightly greater than Ω_0^*—this corresponds to our $\alpha < 0$—the observed transition sequence is:

Couette → spiral cells → wavy spiral cells

See Fig. 7.3.

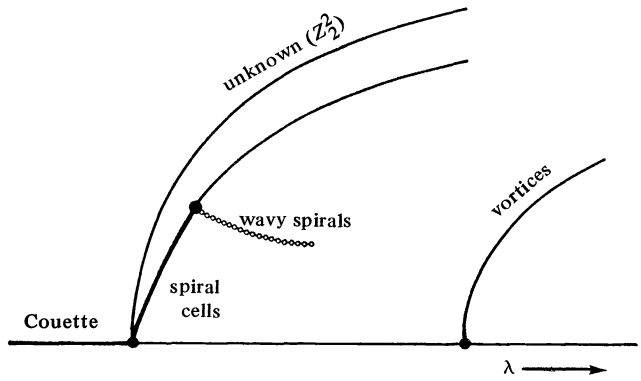

FIG. 7.3. *Schematic bifurcation diagram when* $\alpha < 0$ *corresponding to the observations of Andereck* [1984].

In order to reproduce qualitatively the experimental results, we demand the following:

(7.1)
(a) Couette flow is stable for $\lambda \ll 0$.
(b) Vortices bifurcate supercritically and stably when $\alpha > 0$.
(c) There is a secondary bifurcation from vortices to wavy vortices when $\alpha > 0$.
(d) Wavy vortices are supercritical and stable at the initial bifurcation from vortices.
(e) Spiral cells bifurcate supercritically and stably when $\alpha < 0$.
(f) Spiral cells lose stability to a Hopf bifurcation.

We claim that it is possible to choose signs for the nondegeneracy conditions in Table 6.1 so that each of the conditions in (7.1) is satisfied. Moreover, we claim that when these nondegeneracy conditions are satisfied, it follows that:

(7.2) Any bifurcation from vortices to Taylor vortices occurs after the bifurcation from vortices to wavy vortices.

The assumptions in (7.1) correspond, in order, to the following nondegeneracy conditions (cf. Table 6.1):

(7.3)
(a) $(e) < 0, (b) < 0$.
(b) $(a) > 0$.
(c) $(c_2) > 0$.
(d) $(l) > 0; (m) > 0, (n) > 0$.
(e) $(i) > 0, (h) < 0$.
(f) $(j) > 0$.

It is a simple matter to check that the conditions (7.3) are precisely the conditions needed to satisfy (7.1). The only point which requires comment is asymptotic stability of the wavy vortex branch. Observe that at the bifurcation from vortices to wavy vortices, $a = 0$ and $y \neq 0$. It follows from Table 6.2 that the wavy vortices are stable if

$$(m) > 0, \quad (n) > 0, \quad (l) > 0, \quad \text{and } (a) > 0.$$

However, $(l) > 0$ when the branch of wavy vortices is supercritical, and $(a) > 0$ has already been assumed in (7.3b). Observe that the branch of wavy vortices can lose

stability if either

$$(d)<0 \quad \text{or} \quad (h)<0. \tag{7.4}$$

If $(d)<0$ then this branch will lose stability to a torus bifurcation. However,

$$(d)=((i)-(h))/2, \tag{7.5}$$

and the assumption that spiral cells are stable implies that $(i)>0$, $(h)<0$ (cf. (7.3e)) so this possibility cannot occur. Nevertheless, $(h)<0$ is satisfied, and wavy vortices may lose stability by a single real eigenvalue passing through zero. This observation verifies (7.2a). It is possible that a new solution branch with isotropy subgroup 1 will appear at this bifurcation, but we have neither confirmed nor eliminated this possibility. See Table 5.1.

Finally, we verify (7.2b). The wavy vortex branch begins at $\lambda_w(a)/(c_2)$, while a branch of twisted vortices would begin at $\lambda_t=(a)/(c_2)$. We compute $\operatorname{sgn}(\lambda_t-\lambda_w)$. Now

$$\operatorname{sgn}(\lambda_t-\lambda_w)=\operatorname{sgn}\left(\frac{1}{(c_1)}-\frac{1}{(c_2)}\right), \tag{7.6}$$

since $(a)>0$ by (7.3b). However,

$$(c_2)-(c_1)=-2Q^3p_\lambda=-2(n)(b)>0$$

using (7.3a, d). Hence (7.6) implies that $\lambda_t>\lambda_w$ as claimed in (7.2b). Observe that it is possible, under different circumstances, for twisted vortices to bifurcate supercritically and stably from vortices. Such a transition has been observed in the corotating case. See Andereck, Dickman and Swinney [1983].

7.2. The main sequence. Here we verify that the main sequence of bifurcations can also occur in the six-dimensional model. This sequence of bifurcations is observed in experiments when the outer cylinder is held fixed. For this sequence to hold, we need Couette flow to lose stability first to vortices. This happens in our model when $\alpha>0$, and we concentrate on this case.

To obtain the main sequence, we need (7.1a, b, c, d) to hold. Of course, this is possible precisely when the nondegeneracy conditions (7.3a, b, c, d) hold. If we wish to show in this model that, in addition, the wavy vortex solutions lose stability to a torus bifurcation, then two complex conjugate eigenvalues must cross the imaginary axis along the branch of wavy vortices. This can happen only if $(d)<0$. Note that if $(d)<0$ then (7.5) implies that (7.3e) is not valid, and that spiral cells cannot be asymptotically stable.

As we saw above, wavy vortices can lose stability by a real eigenvalue crossing through 0. However, this eventuality cannot occur if $(h)>0$, which is possible, since we have assumed nothing about (i). Thus, assuming

$$(d)<0, \qquad (h)>0$$

leads to the main sequence. (See Fig. 7.4.) Other choices for the main sequence are possible.

We conclude that both the main sequence and certain regimes in the experiments of Andereck, Liu, and Swinney [1984] appear to be qualitatively consistent with our six-dimensional model, for suitable values of the coefficients. (Note that aside from the states discussed above, no other stable states occur except perhaps with isotropy group

1, as mentioned.) Since the coefficients can in principle be computed by Lyapunov–Schmidt reduction from the Navier–Stokes equations, further numerical work should be able to provide a more stringent test. It would also be of interest to determine, in terms of the physical parameters in the problem, the location of the codimension one set of values at which the six-dimensional kernel occurs.

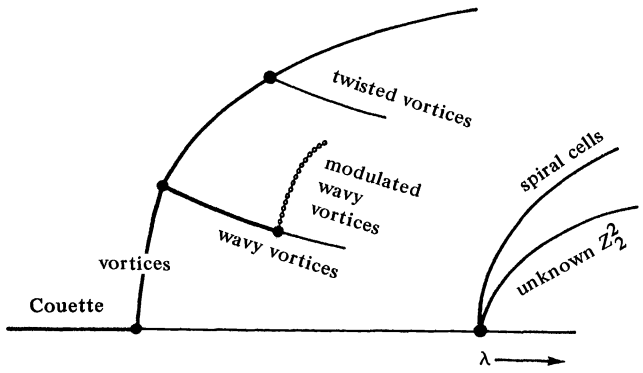

FIG. 7.4. *Schematic bifurcation diagram corresponding to (one occurrence of) the main sequence.*

Appendix. Equivariant mappings on the six-dimensional kernel. Let $V=\mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})$ be the six-dimensional kernel described in §4. Recall that $\Gamma=O(2)\times S^1$ acts on V by

$$(\theta,\psi)(v,w\otimes z)=\big(R_\theta v,(R_\theta w)\otimes(e^{i\psi}Z)\big).$$

For computational purposes we choose coordinates by identifying the first $\mathbf{R}^2$ with $\mathbf{C}$, and $\mathbf{R}^2\otimes\mathbf{C}$ with 2×2 matrices as described in §4, so that an element of V is written (z,a) where

$$z\in\mathbf{C},\quad A=\begin{pmatrix}a & b\\ c & d\end{pmatrix},\quad a,b,c,d\in\mathbf{R}.$$

Recall that a (smooth) function $\phi\colon V\to\mathbf{R}$ is *invariant* under Γ if

$$\phi(\gamma v)=\phi(v),\qquad \gamma\in\Gamma,\quad v\in V,$$

and a (smooth) mapping $\Phi\colon V\to V$ is *equivariant* if it commutes with Γ, that is

$$\Phi(\gamma v)=\gamma\Phi(v),\qquad \gamma\in\Gamma,\quad v\in V.$$

The aim of this appendix is to describe completely these invariant functions and equivariant mappings, as promised in §4 above. The main result, which will yield Theorem 4.3 when appropriate terms are collected together, is:

PROPOSITION A.1. (a) *Every invariant function on V is of the form*

$$\phi(v)=h(\beta,N,\delta^2,\gamma,\sigma) \tag{A.1}$$

for a smooth function $h\colon\mathbf{R}^5\to\mathbf{R}$, where

$$\begin{aligned}\beta&=z\bar z=x^2+y^2,\\ N&=a^2+b^2+c^2+d^2,\\ \delta^2&=(ad-bc)^2,\\ \gamma&=\mathrm{Re}(z^2\bar\zeta),\\ \sigma&=\delta\,\mathrm{Im}(z^2\bar\zeta)\end{aligned} \tag{A.2}$$

and

$$\zeta = (a^2+b^2-c^2-d^2)+2i(ac+bd). \tag{A.3}$$

(b) *Every equivariant mapping $V \to V$ is of the form*

$$\begin{aligned}\Phi(z,A) = \big(& pz + qi\delta z + r\bar{z}\zeta + si\delta\bar{z}\zeta, \\ & P^1 \operatorname{Re}(H_1) + P^2 \operatorname{Re}(H_2) \\ & + Q^1 \operatorname{Im}(z^2\bar{\zeta}) \operatorname{Im}(H_1) + Q^2 \operatorname{Im}(z^2\bar{\zeta}) \operatorname{Im}(H_2) \\ & + Q^3 \operatorname{Re}(\bar{z}^2 H_3) + Q^4 \operatorname{Re}(\bar{z}^2 H_4) \\ & + R^1\delta \operatorname{Im}(H_1) + R^2\delta \operatorname{Im}(H_2) + R^3\delta \operatorname{Im}(\bar{\zeta}H_3) + R^4\delta \operatorname{Im}(\bar{\zeta}H_4) \\ & + M^3\delta \operatorname{Im}(\bar{z}^2 H_3) + M^4\delta \operatorname{Im}(\bar{z}^2 H_4)\big),\end{aligned} \tag{A.4}$$

where

$$H_1 = \begin{pmatrix} a-ic & b-id \\ c+ia & d+ib \end{pmatrix}, \qquad H_3 = \begin{pmatrix} a+ic & b+id \\ -c+ia & -d+ib \end{pmatrix},$$
$$H_2 = \begin{pmatrix} -b+id & a-ic \\ -d-ib & c+ia \end{pmatrix}, \qquad H_4 = \begin{pmatrix} -b-id & a+ic \\ d-ib & -c+ia \end{pmatrix},$$

and

$$p, q, r, s, P^1, P^2, Q^1, Q^2, Q^3, Q^4, R^1, R^2, R^3, R^4, M^3, M^4$$

are invariant functions.

In more abstract language, Proposition A.1 says that the ring of invariant functions is *generated* by $\beta, N, \delta^2, \gamma, \sigma$; and that the module of equivariant mappings is generated over the invariants by the twelve mappings in (A.4), whose coefficients are $p, q, r, s, P^1, \cdots, M^4$. By standard results of Schwarz [1975] and Poénaru [1976] we may assume ϕ and Φ are polynomials when proving Proposition A.1.

The computation comes in two stages. First we compute the (polynomial) S^1-invariants and -equivariants; then we use this information and the $O(2)$-action to obtain the $O(2)\times S^1$-invariants and -equivariants. Since S^1 acts trivially on $z \in \mathbf{R}^2$, we need consider only the action on $A \in \mathbf{R}^2 \otimes \mathbf{C}$. We take complex coordinates

$$z_1 = a+ib, \qquad z_2 = c+id.$$

Then we may identify $\mathbf{R}^2 \otimes \mathbf{C}$ with $\mathbf{C} \oplus \mathbf{C}$, where S^1 acts diagonally:

$$\theta(z_1, z_2) = (e^{i\theta}z_1, e^{i\theta}z_2).$$

LEMMA A.2. *The real S^1-invariants on $\mathbf{C}\oplus\mathbf{C}$ are generated by $z_1\bar{z}_1$, $z_2\bar{z}_2$, $\operatorname{Re} z_1\bar{z}_2$, $\operatorname{Im} z_1\bar{z}_2$. The S^1-equivariants are generated over the invariants by $(z_1, 0)$, $(0, z_1)$, $(z_2, 0)$, $(0, z_2)$, $(i\bar{z}_1, 0)$, $(0, i\bar{z}_1)$, $(i\bar{z}_2, 0)$, $(0, i\bar{z}_2)$.*

Proof. These results (which generalize easily to S^1 acting on $\mathbf{C}^n$) are no doubt well-known, but for completeness we sketch a proof. The idea is first to find the complex invariants and equivariants and then to read off the real ones.

Consider a $\mathbf{C}$-valued polynomial function

$$p(z_1, \bar{z}_1, z_2, \bar{z}_2) = \sum A_{\alpha\beta\gamma\delta} z_1^{\alpha} \bar{z}_1^{\beta} z_2^{\gamma} \bar{z}_2^{\delta}.$$

Since $\overline{e^{i\theta}z} = e^{-i\theta}\bar{z}$, we can use S^1-invariance to exclude all terms other than those for which

$$\alpha - \beta + \gamma - \delta = 0.$$

So p is a polynomial in $z_1\bar{z}_1$, $z_2\bar{z}_2$, $\bar{z}_1 z_2$, and $z_1\bar{z}_2$. If p is to be real in a, b, c, d, then we have $p = \bar{p}$, so $A_{\alpha\beta\gamma\delta} = \bar{A}_{\beta\alpha\delta\gamma}$. This leads to the real invariant generators stated.

For the equivariants, we consider a pair of functions p_1, p_2 of the above form. Equivariance excludes all terms other than those for which

$$\alpha - \beta + \gamma - \delta = 1.$$

This yields equivariant generators which are *complex* scalar multiples of $(z_1, 0)$, $(z_2, 0)$, $(0, z_1)$, $(0, z_2)$. Taking real and imaginary parts, we obtain the stated real equivariant generators.

In $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ coordinates, we have the invariant generators

$$\begin{aligned} &z_1\bar{z}_1 = a^2 + b^2, \\ &z_2\bar{z}_2 = c^2 + d^2, \\ &\mathrm{Re}(z_1\bar{z}_2) = ac + bd, \\ &\mathrm{Im}(z_1\bar{z}_2) = bc - ad = -\delta, \end{aligned} \tag{A.5}$$

and the equivariant generators $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \to$

$$E_1 = \begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}, \quad E_2 = \begin{pmatrix} 0 & 0 \\ a & b \end{pmatrix}, \quad E_3 = \begin{pmatrix} 0 & 0 \\ c & d \end{pmatrix}, \quad E_4 = \begin{pmatrix} c & d \\ 0 & 0 \end{pmatrix}, \tag{A.6}$$

$$E_5 = \begin{pmatrix} -b & a \\ 0 & 0 \end{pmatrix}, \quad E_6 = \begin{pmatrix} 0 & 0 \\ -b & a \end{pmatrix} \quad E_7 = \begin{pmatrix} 0 & 0 \\ -d & c \end{pmatrix}, \quad E_8 = \begin{pmatrix} -d & c \\ 0 & 0 \end{pmatrix}.$$

Note that there is a relation

$$(a^2 + b^2)(c^2 + d^2) = (ac + bd)^2 + (ad - bc)^2.$$

We are now ready for the:

Proof of Proposition A.1 (a). The calculations are easier if we use complex notation. Let

$$\zeta = (a^2 + b^2 - c^2 - d^2) + 2i(ac + bd).$$

Then every real-valued function of the four invariant generators can be written in terms of $N = a^2 + b^2 + c^2 + d^2$, ζ, $\bar{\zeta}$, and δ. Note that N and δ^2 are $O(2)$-invariant. See Golubitsky and Stewart [1985, §9].

Since S^1 acts trivially on $z \in \mathbf{R}^2$, we can write the S^1-invariants on $\mathbf{R}^2 \oplus (\mathbf{R}^2 \otimes \mathbf{C})$ in the form

$$\phi(z, \bar{z}, N, \zeta, \bar{\zeta}, \delta).$$

Under the $O(2)$-action these transform as follows:

	z	$\bar{z}$	ζ	$\bar{\zeta}$	δ	N
κ	$\bar{z}$	z	$\bar{\zeta}$	ζ	$-\delta$	N
θ	$e^{i\theta}z$	$e^{-i\theta}\bar{z}$	$e^{2i\theta}\zeta$	$e^{-2i\theta}\bar{\zeta}$	δ	N

(The expressions ζ and $\bar{\zeta}$ are introduced because of this pleasant transformation behavior.)

Since $z\bar{z}$, $\zeta\bar{\zeta}$, N, and δ^2 are $O(2)$-invariant, we can write the general $O(2)\times S^1$-invariant in the form

$$\begin{aligned}\phi &= az^\alpha\zeta^\beta + bz^\alpha\bar{\zeta}^\beta + c\bar{z}^\alpha\zeta^\beta + d\bar{z}^\alpha\bar{\zeta}^\beta + \delta\left(ez^\alpha\zeta^\beta + fz^\alpha\bar{\zeta}^\beta + g\bar{z}^\alpha\zeta^\beta + h\bar{z}^\alpha\bar{\zeta}^\beta\right)\\ &\equiv \phi_0 + \delta\phi_1\end{aligned} \tag{A.7}$$

where $a,b,\cdots,h\in\mathbf{C}[z\bar{z},N,\delta^2]$. (Note: $\zeta\bar{\zeta}=N-4\delta^2$ so no $\zeta\bar{\zeta}$ terms are required.) Reality of ϕ implies that

$$\bar{a}=d,\quad \bar{b}=c,\quad \bar{e}=h,\quad \bar{f}=g,$$

while κ-invariance leads to

$$a=b,\quad c=d,\quad e=-h,\quad f=-g.$$

Hence a,b,c,d are real and e,f,g,h are purely imaginary.

Finally we apply $SO(2)$-invariance. Since δ is $SO(2)$-invariant and is independent of $z,\bar{z},\zeta,\bar{\zeta}$, we must have ϕ_0 and ϕ_1 separately $SO(2)$-invariant. This excludes all terms other than

$$a\left(z^\alpha\zeta^\beta+\bar{z}^\alpha\bar{\zeta}^\beta\right) \quad \text{when } \alpha+2\beta=0, \tag{A.8}$$

$$b\left(z^\alpha\bar{\zeta}^\beta+\bar{z}^\alpha\zeta^\beta\right) \quad \text{when } \alpha-2\beta=0, \tag{A.9}$$

$$\delta e\left(z^\alpha\zeta^\beta-\bar{z}^\alpha\bar{\zeta}^\beta\right) \quad \text{when } \alpha+2\beta=0, \tag{A.10}$$

$$\delta f\left(z^\alpha\bar{\zeta}^\beta-\bar{z}^\alpha\zeta^\beta\right) \quad \text{when } \alpha-2\beta=0, \tag{A.11}$$

Now (A.8) and (A.10) imply $\alpha=\beta=0$, giving nothing new. The others yield $\alpha=2\beta$.

We claim that only $\alpha=2$, $\beta=1$ yield new generators. For example

$$\left(z^{\alpha+2}\bar{\zeta}^{\beta+1}+\bar{z}^{\alpha+2}\zeta^{\beta+1}\right)=\left(z^\alpha\bar{\zeta}^\beta+\bar{z}^\alpha\zeta^\beta\right)\left(z^2\bar{\zeta}+\bar{z}^2\zeta\right)-\left(z\bar{z}\right)^2\left(\zeta\bar{\zeta}\right)\left(z^{\alpha-2}\bar{\zeta}^{\beta-1}+\bar{z}^{\alpha-2}\zeta^{\beta-1}\right).$$

Since b is real and f purely imaginary, we obtain generators

$$\mathrm{Re}\left(\bar{z}^2\bar{\zeta}\right),\ i\delta\,\mathrm{Im}\left(z^2\bar{\zeta}\right)$$

in addition to $z\bar{z}$, N, δ^2. This proves part (a) of Proposition A.1.

Proof of Proposition A.1 (b). Write the general equivariant in the form

$$\Phi(z,A)=\left(\Phi_0(z,A),\Phi_1(z,A)\right)$$

where

$$\Phi_0\colon \mathbf{R}^2\oplus\left(\mathbf{R}^2\otimes\mathbf{C}\right)\to\mathbf{R}^2,$$
$$\Phi_1\colon \mathbf{R}^2\oplus\left(\mathbf{R}^2\otimes\mathbf{C}\right)\to\mathbf{R}^2\otimes\mathbf{C}.$$

We begin with Φ_0. Since the S^1-action on $\mathbf{R}^2$ is *trivial*, the S^1-equivariance condition implies that Φ_0 is S^1-invariant and hence can be written in the form (A.7) above.

However, this time there is no reality condition since we seek mappings into $\mathbf{R}^2$, not $\mathbf{R}$. The κ-equivariance again implies a,b,c,d are real, and e,f,g,h are purely imaginary. Replacing the latter by ie, if, ig, ih, we may assume all coefficients $a-h$ are real, and replace δ by $i\delta$. Write $\Phi_0=\phi_0+i\delta\phi_1$: again we can treat ϕ_0 and ϕ_1 separately.

Now $SO(2)$-equivariance excludes all terms other than

$$z^\alpha\zeta^\beta,\ i\delta z^\alpha\zeta^\beta;\quad \alpha+2\beta=1, \tag{A.12}$$

$$z^\alpha\bar{\zeta}^\beta,\ i\delta z^\alpha\bar{\zeta}^\beta;\quad \alpha-2\beta=1, \tag{A.13}$$

(A.14) $$\bar{z}^{\alpha}\zeta^{\beta},\ i\delta\bar{\zeta}^{\alpha}\zeta^{\beta};\quad -\alpha+2\beta=1,$$

(A.15) $$\bar{z}^{\alpha}\bar{\zeta}^{\beta},\ i\delta\bar{z}^{\alpha}\bar{\zeta}^{\beta};\quad -\alpha-2\beta=1.$$

In (A.12) we have $\alpha=1$, $\beta=0$, yielding z and $i\delta z$. In (A.13) we have $\alpha=2\beta+1$. As before, we may use the invariance of $z\bar{z}$ and $\zeta\bar{\zeta}$ to reduce the size of α and β:

$$\begin{aligned} z^{2\beta+1}\bar{\zeta}^{\beta} &= z^{2\beta-1}\left(z^2\bar{\zeta}\right)\bar{\zeta}^{\beta-1} \\ &= \left(z^2\bar{\zeta}+\bar{z}^2\zeta\right)z^{2\beta-1}\bar{\zeta}^{\beta-1}-\left(z\bar{z}\right)^2\left(\zeta\bar{\zeta}\right)z^{2\beta-3}\bar{\zeta}^{\beta-2}. \end{aligned}$$

Thus we can reduce β by 1 and α by 2. The process stops when $\beta=1$, $\alpha=2$. But now

$$z^3\bar{\zeta}=zz^2\bar{\zeta}=\left(z^2\bar{\zeta}+\bar{z}^2\zeta\right)z-\left(z\bar{z}\right)\bar{z}\zeta.$$

Thus we get new generators $\bar{z}\zeta$, $i\delta\bar{z}\zeta$. In (A.14) we can similarly assume $\beta\leqq 2$. But $\beta=2$ gives

$$\bar{z}^3\zeta^2=\left(\bar{z}^2\zeta+z^2\bar{\zeta}\right)\bar{z}\zeta-\left(z\bar{z}\right)\left(\zeta\bar{\zeta}\right)z$$

so no new generator arises; and $\beta=1$ gives $\bar{z}\zeta$ which is already included. Finally (A.15) is not possible.

Thus we have found four generators $(z,0)(i\delta z,0)$, $(\bar{z}\zeta,0)$, $(i\delta\bar{z}\zeta,0)$ corresponding to mappings of $\mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})$ into $\mathbf{R}^2$.

Now we look at

$$\Phi_1\colon \mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})\to\mathbf{R}^2\otimes\mathbf{C}.$$

Again complex notation is more convenient. Define (in a notation consistent with the statement of Proposition A.1) the complex matrices

(A.16)
$$\begin{aligned} H_1&=(E_1+E_3)+i(E_2-E_4),\\ H_2&=(E_5+E_7)+i(E_6-E_8),\\ H_3&=(E_1-E_3)+i(E_2+E_4),\\ H_4&=(E_5-E_7)+i(E_6+E_8). \end{aligned}$$

Then the S^1-equivariants on $\mathbf{R}^2\otimes\mathbf{C}$ are generated over $\mathbf{C}$ by H_k, $\overline{H}_k$ $(k=1,\cdots,4)$ and over $\mathbf{R}$ by the real and imaginary parts of H_k $(k=1,\cdots,4)$. Since S^1 acts trivially on $z\in\mathbf{R}^2$ we can think of the S^1-equivariants mapping $\mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})\to\mathbf{R}^2$ as S^1-equivariants mapping $\mathbf{R}^2\otimes\mathbf{C}\to\mathbf{R}^2$ parametrized by z and $\bar{z}$. Thus they are linear combinations of H_k, $\overline{H}_k$, $(k=1,\cdots,4)$ with coefficients in $\mathbf{C}[N,\delta,\zeta,\bar{\zeta};z,\bar{z}]$.

We write the equivariance condition $\phi(\gamma v)=\gamma\Phi(v)$ in the form

(A.17) $$\Phi(v)=\gamma^{-1}\Phi(\gamma v).$$

Suppose

$$\Phi(v)=\rho(v)H(v)$$

where $\rho\colon \mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})\to\mathbf{R}$, $H\colon \mathbf{R}^2\oplus(\mathbf{R}^2\otimes\mathbf{C})\to\mathbf{R}^2\otimes\mathbf{C}$. Then (A.17) is equivalent to

(A.18) $$\rho(v)H(v)=\gamma^{-1}\rho(\gamma v)H(\gamma v)=\rho(\gamma v)\gamma^{-1}H(\gamma v).$$

We compute this action on H_k $(k=1,\cdots,4)$ when $\gamma\in O(2)$. Using (A.16) and noting that

$$\kappa(z,A)=\left(\bar{z},\begin{pmatrix}1&0\\0&-1\end{pmatrix}A\right),$$

$$\psi(z,A)=\left(e^{i\psi}z,R_\psi A\right)$$

where

$$R_\psi=\begin{pmatrix}\cos\psi&-\sin\psi\\\sin\psi&\cos\psi\end{pmatrix},$$

we find

(A.19)

$H(v)$	$\kappa^{-1}H(\kappa v)$	$\psi^{-1}H(\psi v)$
H_1	$\overline{H}_1$	H_1
H_2	$\overline{H}_2$	H_2
H_3	$\overline{H}_3$	$e^{2i\psi}H_3$
H_4	$\overline{H}_4$	$e^{2i\psi}H_4$

We can write the general S^1-equivariant Φ_1: $\mathbf{R}^2\oplus(\mathbf{R}\otimes\mathbf{C})\to\mathbf{R}^2\otimes\mathbf{C}$ in the form

(A.20) $$\Phi_1=\mathrm{Re}\left\{\sum_{k=1}^{4}(\rho_k+\delta\sigma_k)H_k\right\}$$

where the ρ_k, σ_k are polynomials over $\mathbf{C}$ of the form

$$\rho_k=\rho_k(N,\delta^2,\zeta,\bar{\zeta};z,\bar{z}),\qquad \sigma_k=\sigma_k(N,\delta^2,\zeta,\bar{\zeta};z,\bar{z}).$$

Since $z\bar{z}$ and $\zeta\bar{\zeta}$ are $O(2)$-invariant, we can write the ρ_k and σ_k as

(A.21) $$az^\alpha\zeta^\beta+bz^\alpha\bar{\zeta}^\beta+c\bar{z}^\alpha\zeta^\beta+d\bar{z}^\alpha\bar{\zeta}^\beta$$

with $a,b,c,d,\in\mathbf{C}[N,\delta^2]$.

We now apply κ- and ψ-equivariance in the form (A.17), writing

$$\tilde{\rho}=\rho(\kappa z,\kappa A),\qquad \hat{\rho}=\rho(\psi z,\psi A).$$

Now κ-equivariance (using (A.18) and (A.19)) implies that

(A.22) $$\tilde{\rho}_k=\bar{\rho}_k,$$

(A.23) $$\tilde{\sigma}_k=-\bar{\sigma}_k$$

and ψ-equivariance implies

(A.24)
(A.25) $$\hat{\rho}_k=\begin{cases}\rho_k & (k=1,2),\\ e^{-2i\psi}\rho_k & (k=3,4),\end{cases}$$

(A.26)
(A.27) $$\hat{\sigma}_k=\begin{cases}\sigma_k & (k=1,2),\\ e^{-2i\psi}\sigma_k & (k=3,4).\end{cases}$$

Now write the ρ_k and σ_k in the form (A.20) (we suppress unnecessary fine points of notation in the interests of clarity). From (A.22) we get

$$\text{(A.28)} \qquad (\text{for } \rho_k)\ a=\bar{a},\quad b=\bar{b},\quad c=\bar{c},\quad d=\bar{d},$$

and from (A.23)

$$\text{(A.29)} \qquad (\text{for } \sigma_k)\ a=-\bar{a},\quad b=-\bar{b},\quad c=-\bar{c},\quad d=-\bar{d}.$$

That is, the coefficients are real for ρ_k and purely imaginary for σ_k. We therefore replace σ_k by $i\sigma_k$, so that ρ_k and σ_k are real: now (A.20) takes the form

$$\text{(A.30)} \qquad \Phi=\operatorname{Re}\left\{\sum_{k=1}^{4}(\rho_k+i\delta\sigma_k)H_k\right\}.$$

The ψ-action multiplies z, ζ, and H_k by complex constants $e^{i\psi}$, $e^{2i\psi}$, $e^{2i\psi}$ respectively. Hence we may consider each of the eight terms in (A.30) separately. From (A.26) and (A.27) we obtain the following conditions on the exponents α, β, required for ψ-equivariance:

	Real part of:	$k=1,2$	$k=3,4$
(A.31)	$z^\alpha\zeta^\beta H_k$	$\alpha+2\beta=0$	$\alpha+2\beta=-2$
(A.32)	$z^\alpha\bar{\zeta}^\beta H_k$	$\alpha-2\beta=0$	$\alpha-2\beta=-2$
(A.33)	$\bar{z}^\alpha\zeta^\beta H_k$	$-\alpha+2\beta=0$	$-\alpha+2\beta=-2$
(A.34)	$\bar{z}^\alpha\bar{\zeta}^\beta H_k$	$-\alpha-2\beta=0$	$-\alpha-2\beta=-2$
(A.35)	$i\delta z^\alpha\zeta^\beta H_k$	$\alpha+2\beta=0$	$\alpha+2\beta=-2$
(A.36)	$i\delta z^\alpha\bar{\zeta}^\beta H_k$	$\alpha-2\beta=0$	$\alpha-2\beta=-2$
(A.37)	$i\delta\bar{z}^\alpha\zeta^\beta H_k$	$-\alpha+2\beta=0$	$-\alpha+2\beta=-2$
(A.38)	$i\delta\bar{z}^\alpha\bar{\zeta}^\beta H_k$	$-\alpha-2\beta=0$	$-\alpha-2\beta=-2$

We deal with these terms case by case, first for $k=1,2$; then for $k=3,4$. So let $k=1,2$.

(A.31) implies $\alpha=\beta=0$, leading to the generators

$$\text{(A.39)} \qquad \operatorname{Re}(H_k),\qquad k=1,2.$$

(A.32) requires $\alpha=2\beta$, so we get

$$\text{(A.40)} \qquad z^{2\beta}\bar{\zeta}^\beta H_k+\bar{z}^{2\beta}\zeta^\beta\overline{H}_k.$$

Similarly (A.33) requires $\alpha=2\beta$, and the result is

$$\text{(A.41)} \qquad \bar{z}^{2\beta}\zeta^\beta H_k+z^{2\beta}\bar{\zeta}^\beta\overline{H}_k.$$

Forming the sum and difference of (A.40) and (A.41) we may replace them by

$$x_\beta=(z^{2\beta}\bar{\zeta}^\beta+\bar{z}^{2\beta}\zeta^\beta)(H_k+\overline{H}_k),$$

$$y_\beta=(z^{2\beta}\bar{\zeta}^\beta-\bar{z}^{2\beta}\zeta^\beta)(H_k-\overline{H}_k).$$

We observe the following identities:

$$x_{\beta+1}=2\operatorname{Re}(z^2\bar{\zeta})x_\beta-(z^2\bar{z}^2\zeta\bar{\zeta})x_{\beta-1},$$

$$y_{\beta+1}=2\operatorname{Re}(z^2\bar{\zeta})y_\beta-(z^2\bar{z}^2\zeta\bar{\zeta})y_{\beta-1},$$

which have invariant functions as coefficients. Since

$$x_0 = 2\,\mathrm{Re}(H_k), \quad y_0 = 0, \quad x_1 = 2\,\mathrm{Re}(z^2\bar{\zeta})\mathrm{Re}(H_k),$$

and these may be obtained from the generators (A.39), an inductive argument shows that only y_1 need be retained in a list of generators. So we obtain the new generators

$$\mathrm{Im}(z^2\bar{\zeta})\mathrm{Im}(H_k), \qquad k = 1,2. \tag{A.42}$$

For (A.34) we have $\alpha = \beta = 0$ and nothing new results.

For (A.35) we have $\alpha = \beta = 0$, leading to new generators $\mathrm{Re}(i\delta H_k)$, or equivalently

$$\delta\,\mathrm{Im}(H_k), \quad k = 1,2. \tag{A.43}$$

From (A.36) and (A.37) we get $\alpha = 2\beta$, yielding

$$i\delta z^{2\beta}\bar{\zeta}^{\beta}H_k - i\delta\bar{z}^{2\beta}\zeta^{\beta}\overline{H}_k,$$
$$i\delta\bar{z}^{2\beta}\zeta^{\beta}H_k - i\delta z^{2\beta}\bar{\zeta}^{\beta}\overline{H}_k.$$

Forming the sum and difference, we replace these by

$$v_\beta = i\delta\left(z^{2\beta}\bar{\zeta}^{\beta} + \bar{z}^{2\beta}\zeta^{\beta}\right)\left(H_k - \overline{H}_k\right),$$
$$w_\beta = i\delta\left(z^{2\beta}\bar{\zeta}^{\beta} - \bar{z}^{2\beta}\zeta^{\beta}\right)\left(H_k + \overline{H}_k\right).$$

We note the identities

$$v_{\beta+1} = 2\,\mathrm{Re}\left(z^2\bar{\zeta}\right)v_\beta - \left(z^2\bar{z}^2\zeta\bar{\zeta}\right)v_{\beta-1},$$
$$w_{\beta+1} = 2\,\mathrm{Re}\left(z^2\bar{\zeta}\right)w_\beta - \left(z^2\bar{z}^2\zeta\bar{\zeta}\right)w_{\beta-1},$$
$$v_1 = \mathrm{Re}\left(z^2\bar{\zeta}\right)\delta\,\mathrm{Im}(H_k),$$
$$w_1 = \delta\,\mathrm{Im}\left(z^2\bar{\zeta}\right)\mathrm{Re}(H_k).$$

It follows by induction that no new generators arise here.

Finally (A.38) leads to $\alpha = \beta = 0$, and no new generators. This completes the analysis for $k = 1,2$.

Next, we let $k = 3,4$. The calculations follow a similar pattern.

(A.31) is impossible.

(A.32) and (A.33) lead to

$$t_\beta = z^{2\beta-2}\bar{\zeta}^{\beta}H_k + \bar{z}^{2\beta-2}\zeta^{\beta}\overline{H}_k, \qquad \beta \geqq 1,$$
$$u_\beta = \bar{z}^{2\beta+2}\zeta^{\beta}H_k + z^{2\beta+2}\bar{\zeta}^{\beta}H_k, \qquad \beta \geqq 0.$$

Now

$$t_{\beta+1} = 2\,\mathrm{Re}\left(z^2\bar{\zeta}\right)t_\beta - \left(z^2\bar{z}^2\zeta\bar{\zeta}\right)t_{\beta-1}, \qquad (\beta \geqq 2),$$
$$t_2 = 2\,\mathrm{Re}\left(z^2\bar{\zeta}\right)t_1 - \left(\zeta\bar{\zeta}\right)u_0,$$
$$u_{\beta+1} = 2\,\mathrm{Re}\left(z^2\bar{\zeta}\right)u_\beta - \left(z^2\bar{z}^2\zeta\bar{\zeta}\right)u_{\beta-1}, \qquad (\beta \geqq 1),$$
$$u_1 = 2\,\mathrm{Re}\left(z^2\bar{\zeta}\right)u_0 - \left(z^2\bar{z}^2\right)x_1.$$

Hence inductively the only new generators are t_1 and u_0; that is,

$$\begin{aligned} &\bar{\zeta}H_k+\zeta\overline{H}_k, \qquad k=3,4,\\ &\bar{z}^2H_k+z^2\overline{H}_k, \qquad k=3,4. \end{aligned} \tag{A.44}$$

However, we observe that the identities

$$\begin{aligned} N\,\mathrm{Re}(H_1)-2\delta\,\mathrm{Im}(H_2)&=\mathrm{Re}(\bar{z}H_3),\\ 2\delta\,\mathrm{Im}(H_1)+N\,\mathrm{Re}(H_2)&=\mathrm{Re}(\bar{z}H_4) \end{aligned}$$

are valid. Thus the generators $\bar{z}^2H_k+z^2\overline{H}_k$ $(k=3,4)$ are redundant and can be omitted.

From (A.34) we have either $\alpha=0$, $\beta=1$ or $\alpha=2$, $\beta=0$. These lead to t_1 and u_0 again.

For convenience we now consider (A.38), for which $\alpha=2$, $\beta=0$ or $\alpha=0$, $\beta=1$. These lead to new generators

$$\begin{aligned} &\delta\,\mathrm{Im}(\bar{\zeta}H_k), \qquad k=3,4,\\ &\delta\,\mathrm{Im}(\bar{z}^2H_k), \qquad k=3,4. \end{aligned} \tag{A.45}$$

Finally we take (A.36) and (A.37), yielding $\alpha=2\beta-2$ $(\beta\geqq 1)$ and $\alpha=2\beta+2$ respectively. So we have terms

$$\begin{aligned} r_\beta&=i\delta z^{2\beta-2}\bar{\zeta}^\beta H_k-i\delta\bar{z}^{2\beta-2}\zeta^\beta\overline{H}_k \qquad (\beta\geqq 1),\\ s_\beta&=i\delta\bar{z}^{2\beta-2}\zeta^\beta H_k-i\delta z^{2\beta-2}\bar{\zeta}^\beta\overline{H}_k \qquad (\beta\geqq 0). \end{aligned}$$

As usual, we find that

$$\begin{aligned} r_{\beta+1}&=2\,\mathrm{Re}(z^2\bar{\zeta})r_\beta-(z^2\bar{z}^2\zeta\bar{\zeta})r_{\beta-1} \qquad (\beta\geqq 2),\\ r_2&=2\,\mathrm{Re}(z^2\bar{\zeta})\delta\,\mathrm{Im}(\bar{\zeta}H_k)-(\zeta\bar{\zeta})\delta\,\mathrm{Im}(\bar{z}^2H_k),\\ s_{\beta+1}&=2\,\mathrm{Re}(z^2\bar{\zeta})s_\beta-(z^2\bar{z}^2\zeta\bar{\zeta})s_{\beta-1},\\ s_1&=2\,\mathrm{Re}(z^2\bar{\zeta})s_0-(z^2\bar{z}^2)\delta\,\mathrm{Im}(\bar{\zeta}H_k),\\ s_0&=\delta\,\mathrm{Im}(\bar{z}^2H_k). \end{aligned}$$

Taking (A.45) into account, we find no new generators.

This completes the analysis. We have found twelve generators (A.39), (A.42), (A.43), (A.44), (A.45). Proposition A.1(b) now follows.

Note that the invariants (A.2) for $O(2)\times S^1$ do not form a polynomial ring: there is a relation

$$\delta^2\gamma^2-\sigma^2=(z\bar{z})^2(\zeta\bar{\zeta})=\beta^2(N-4\delta^2).$$

Further, the equivariants do not form a free module, although the relations have degree 9 or more. For example

$$[\sigma][\delta\,\mathrm{Im}(H_1)]=[\delta^2][\mathrm{Im}(z^2\bar{\zeta})\mathrm{Im}(H_1)].$$

(There are other relations too). In consequence, the singularity theory of $O(2)\times S^1$ on the six-dimensional kernel would be extremely complicated to compute.

Finally, we turn to the statement of Theorem 4.3. We obtain the form stated there for the equivariants from that used in Proposition A.1, by defining

$$K_j = \mathrm{Re}(H_j), \quad L_j = \mathrm{Im}(H_j), \quad j = 1,2,3,4,$$

and collecting terms according to the matrices K_j, L_j that occur.

Acknowledgments. We are grateful to Bill Langford for suggesting that group theory might be useful in the analysis of the six-dimensional kernel. We thank Mike Gorman for helping to interpret the experimental evidence and David Andereck for sharing his unpublished observations. John Guckenheimer pointed out some redundancies in our original list of generators for the module of equivariant mappings, thus simplifying a number of calculations.

This work was carried out while the second author held a visiting position in the Mathematics Department, University of Houston.

BIFURCATIONS IN DOUBLY-DIFFUSIVE SYSTEMS III. INTERACTION OF EQUILIBRIUM AND TIME PERIODIC SOLUTIONS*

WAYNE NAGATA† AND JAMES W. THOMAS‡

Abstract. The bifurcations associated with a double zero eigenvalue which occur in equations describing double-diffusive convection in a layer of fluid are studied. Two-dimensional roll-like, and three-dimensional rectangular, square and hexagonal convection cell patterns are considered. The equations are reduced to a center manifold and further reduced to a normal form so that the complete unfolding of the codimension two bifurcation can be determined. In addition to primary pitchfork and Hopf bifurcations, saddle connections exist for roll-like, square and hexagonal convective solutions. For certain parameter values, secondary Hopf bifurcations and semistable periodic orbits exist for square and hexagonal convective solutions.

Key words. double-diffusive convection, codimension two bifurcation

1. Introduction. This is the final paper in a series of three concerning bifurcations in double-diffusive convective equations. The equations model an idealized infinite horizontal layer of fluid that is heated and salted from below. For more background we refer to the first paper of this series [8], which we will call Part I, and the references therein. In Part I we treated the bifurcation of equilibrium solutions corresponding to steady convective cells, and in the second paper of the series [9], which we will call Part II, we treated the Hopf bifurcation of time periodic solutions corresponding to oscillating (overstable) convection cells. In the present paper we consider the interactions between equilibrium and time periodic solutions and show the existence of further bifurcations such as saddle connections and secondary Hopf bifurcations, in some cases (see Figs. 3.4 and 3.6).

We restrict the convection equations to classes of functions corresponding to prescribed cellular convection patterns. The linearization of the restricted equations can then have a nilpotent double zero eigenvalue, and the associated codimension two bifurcation is analyzed using center manifold and normal form reductions to obtain our results. However, our stability results are incomplete since we consider only local asymptotic stability within a prescribed class of convection cell pattterns. For example, our results may show that hexagon pattern solutions are locally asymptotically stable with respect to hexagon pattern disturbances, but more generally they may well be unstable with respect to roll-like disturbances. By considering instead a wider class of solutions, namely those which are doubly periodic with respect to a hexagonal lattice, one can treat rolls, hexagons, triangles and a class of rectangles simultaneously to obtain pattern selection results. Motivated by the Rayleigh–Bénard problem modelling an infinite horizontal layer of fluid heated from below (no salt), Golubitsky, Swift and Knobloch [15] developed a theory of pattern selection in the hexagonal lattice. Bifurcations of equilibrium solutions associated with a six-dimensional semisimple eigenspace were treated. The third-order coefficients computed in Part I were sufficient (assuming a generically satisfied condition involving fifth-order coefficients) to determine some pattern selection results in the hexagonal lattice for steady convection. To treat pattern

selection in the hexagonal lattice in the context of the present paper, one must analyze the dynamic bifurcations associated with a twelve-dimensional nilpotent eigenspace. This is a substantial project and we do not attempt it here. Should such a project be completed, however, the third-order normal form coefficients computed in this paper would be expected to be incorporated into the hexagonal lattice normal form to give specific pattern selection results as in Part I.

In any case, results for the hexagonal lattice do not include square and most rectangular convection cell patterns. Sattinger [16] includes a discussion of square and rectangular lattices, but so far there are no results comparing the stability of solutions in one lattice with respect to disturbances in another. Furthermore, we do not consider stability of solutions with respect to more general disturbances, for example spatially periodic disturbances with different wave numbers. For the stability of rolls in the Rayleigh–Bénard problem with respect to a wide variety of disturbances, see Busse [13]. Finally, we do not consider the effects of sidewalls in a finite layer of fluid. These are perhaps the most important effects (and most difficult to treat mathematically) which must be considered in any complete treatment of pattern selection. For some results on rolls, in the Raleigh–Bénard problem, see Daniels [14].

The plan of this paper is as follows: First, in this section we review the parametrized system of partial differential equations modelling double-diffusive convection, and the symmetry conditions corresponding to cellular convection patterns. We then consider the eigenvalue problem for the linearization, linearized about the constant gradient solution. For certain critical parameter values, the linearization has a double zero eigenvalue when restricted to functions satisfying the symmetry conditions. We then reformulate the problem in terms of operators in Hilbert spaces. The operators and spaces are equivalent to those used in Parts I and II, but instead are formulated in terms of Fourier series. In §2 we apply a version of the center manifold theorem due to Henry [5] to reduce the parametrized partial differential equations to a two-parameter family of ordinary differential equations on two-dimensional invariant manifolds. All of the dynamics in the original family of partial differential equations for parameter values near the critical ones are retained by the family of reduced ordinary differential equations. We then further reduce the equations to a normal form, from which the complete local bifurcation and stability behavior of solutions to the equations can be deduced. In §3 we present the results of our computations to find the normal form coefficients. These coefficients determine the unfolding of the degenerate vector field in the neighborhood of critical parameter values. Two-dimensional roll-like solutions can exhibit only one case of the unfolding, but we find that three-dimensional cellular solutions (rectangular, square or hexagonal) can exhibit further cases depending on the values of auxiliary parameters.

We recall from Parts I and II that the deviation $u=(u_1,u_2,u_3,u_4,u_5)$ from the constant gradient solution satisfies the system of coupled partial differential equations

$$
\begin{aligned}
&\frac{\partial}{\partial t}\mathbf{u}=\sigma(\Delta\mathbf{u}-\nabla p)+(r\sigma u_4-s\sigma u_5)\mathbf{e}_3-(\mathbf{u}\cdot\nabla)\mathbf{u},\\
&\frac{\partial}{\partial t}u_4=\Delta u_4+u_3-(\mathbf{u}\cdot\nabla)u_4,\\
&\frac{\partial}{\partial t}u_5=\tau\Delta u_5+u_3-(\mathbf{u}\cdot\nabla)u_5,\\
&\operatorname{div}\mathbf{u}=0,
\end{aligned}
\tag{1.1}
$$

for $\mathbf{x}=(x_1,x_2,x_3)$ in $\mathbb{R}^2\times(0,1)$, where $\mathbf{e}_3$ is the unit vector $(0,0,1)$, $\mathbf{u}=(u_1,u_2,u_3)$ is the nondimensionalized fluid velocity, u_4 is the nondimensionalized fluid temperature deviation from the constant gradient solution and u_5 is the nondimensionalized solute concentration deviation from the constant gradient solution. The parameters r, s, σ and τ are all positive, with $0<\tau<1$. We take free-surface boundary conditions for $\mathbf{u}$ and Dirichlet boundary conditions for u_4 and u_5 at the boundary surfaces $x_3=0$ and $x_3=1$:

$$\left.\frac{\partial u_1}{\partial x_3}\right|_{x_3=0,1}=\left.\frac{\partial u_2}{\partial x_3}\right|_{x_3=0,1}=u_3|_{x_3=0,1}=u_4|_{x_3=0,1}=u_5|_{x_3=0,1}=0. \tag{1.2}$$

We require that solutions of (1.1)–(1.2) are periodic with fundamental domain of spatial periodicity Ω, where Ω corresponds to roll-like, rectangular, square or hexagonal convection cells, as described below. Then we can express the functions u_k, $k=1,\cdots,5$ and p as Fourier series (cf. Part I)

$$w(\mathbf{x})=\sum_{\mathbf{j}\in\mathbb{Z}^n}\hat{w}(\mathbf{j})e^{i(j_1\alpha_1x_1+\cdots+j_3\alpha_3x_3)},\qquad \bar{\hat{w}}(\mathbf{j})=\hat{w}(-\mathbf{j}), \tag{1.3}$$

where $\mathbf{j}=(j_1,j_2,j_3)$, $w=u_k$, $k=1,\cdots,5$ or p, $n=2$ or 3, $\alpha_1^2+\alpha_2^2=\pi^2/2$ and $\alpha_3=\pi$. The Fourier coefficients u_k, p are required to satisfy symmetry conditions

$$\begin{aligned}
&\hat{u}_1(\mathbf{j}) \text{ is odd in } j_1, \quad \text{even in } j_2, \quad \text{even in } j_3,\\
&\hat{u}_2(\mathbf{j}) \text{ is even in } j_1, \quad \text{odd in } j_2, \quad \text{even in } j_3,\\
&\hat{u}_3(\mathbf{j}) \text{ is even in } j_1, \quad \text{even in } j_2, \quad \text{odd in } j_3,\\
&\hat{w}(\mathbf{j}) \text{ is even in } j_1, \quad \text{even in } j_2, \quad \text{odd in } j_3,
\end{aligned} \tag{1.4}$$

where $\hat{w}=\hat{u}_4$, $\hat{u}_5$ or $\hat{p}$, and

$$\hat{\mathbf{u}}(g\mathbf{j})=g\hat{\mathbf{u}}(\mathbf{j}),\qquad \hat{w}(g\mathbf{j})=\hat{w}(\mathbf{j}), \tag{1.5}$$

where $\hat{w}=\hat{u}_4$, $\hat{u}_5$ or $\hat{p}$, and g is a 3×3 matrix of the form

$$g=\begin{bmatrix}\cos\phi & -\sin\phi & 0\\ \sin\phi & \cos\phi & 0\\ 0 & 0 & 1\end{bmatrix}$$

representing rotations by the angle ϕ about the x_3 axis.

We define the following classes of functions corresponding to the cellular convection patterns (cf. Part I):

(a) *Rolls.* $\alpha_1=\pi/2^{1/2}$, $\alpha_2=0$ in (1.3). For rolls only, we modify the definitions of $\mathbf{x}$, $\mathbf{u}$ and $\mathbf{j}$ to $\mathbf{x}=(x_1,x_3)$, $\mathbf{u}=(u_1,u_3)$ and $\mathbf{j}=(j_1,j_3)$. The sum in (1.3) is over $\mathbf{j}\in\mathbb{Z}^2$ for rolls ($n=2$). $\phi=\pi$ in (1.5) and $\Omega=(0,2\pi/\alpha_1)\times(0,1)$.

(b) *Rectangles.* $\alpha_1^2+\alpha_2^2=\pi^2/2$, $\alpha_1,\alpha_2>0$, $\alpha_2\neq\alpha_1[m^2-1]^{1/2}$ for any positive integer m in (1.3). $\phi=\pi$ in (1.5) and $\Omega=(0,2\pi/\alpha_1)\times(0,2\pi/\alpha_2)\times(0,1)$.

(c) *Squares.* $\alpha_1=\alpha_2=\pi/2$ in (1.3). $\phi=\pi/2$ in (1.5) and $\Omega=(0,2\pi/\alpha_1)\times(0,2\pi/\alpha_1)\times(0,1)$.

(d) *Hexagons.* $\alpha_1=2^{1/2}\pi/4$, $\alpha_2=6^{1/2}\pi/4$ in (1.3). $\phi=2\pi/3$ in (1.5) and $\Omega=H\times(0,1)$, where H is the open hexagonal region in $\mathbb{R}^2$ enclosed by the six lines $x_2=\pm\pi/3^{1/2}\alpha_1$, $x_2+3^{1/2}x_1=\pm2\pi/3^{1/2}\alpha_1$, $x_2-3^{1/2}x_1=\pm2\pi/3^{1/2}\alpha_1$.

We observe that by (1.4) we have

$$\hat{u}_k(\mathbf{0})=0,\quad k=1,\cdots,5,\qquad \hat{p}(\mathbf{0})=0 \tag{1.6}$$

and furthermore, all the $\hat{u}_k(\mathbf{j})$, $\hat{p}(\mathbf{j})$ are pure imaginary. Thus, if desired we can write the Fourier series (1.3) as (cf. Part I)

$$u_k(\mathbf{x}) = \sum_{j_1,j_2=-\infty}^{\infty} \left[\hat{u}_k(j_1,j_2,0) + \sum_{j_3=1}^{\infty} 2\hat{u}_k(\mathbf{j}) \cos j_3 \pi x_3 \right] e^{i(j_1\alpha_1 x_1 + j_2\alpha_2 x_2)}$$

for $k=1,2$ and

$$(\mathbf{x}) = \sum_{j_1,j_2=-\infty}^{\infty} \left[\sum_{j_3=1}^{\infty} 2i\hat{w}(\mathbf{j}) \sin j_3 \pi x_3 \right] e^{i(j_1\alpha_1 x_1 + j_2\alpha_2 x_2)}$$

where $w=u_3$, u_4, u_5 or p. For rolls there are slight modifications ($\alpha_2=0$, $\mathbf{u}=(u_1,u_3)$ sum only over j_1,j_3).

If we substitute the Fourier series (1.3) with the Fourier coefficients satisfying the symmetries corresponding to one of the cellular convection patterns (a)–(d) into the eigenvalue problem for the linearization

$$\begin{aligned} &\sigma(\Delta\mathbf{u} - \nabla p) + (r\sigma u_4 - s\sigma u_5)\mathbf{e}_3 = \lambda\mathbf{u}, \\ &\Delta u_4 + u_3 = \lambda u_4, \\ &\tau\Delta u_5 + u_3 = \lambda u_5, \\ &\operatorname{div}\mathbf{u} = 0, \end{aligned} \tag{1.7}$$

with the boundary conditions (1.2), we find that the critical eigenvalues λ belong to the lowest mode and are given by the roots of the cubic equation

$$\begin{aligned} \lambda^3 + (3\pi^2/2)(1+\sigma+\tau)\lambda^2 + \left[(9\pi^4/4)(\sigma+\tau+\sigma\tau) - (1/3)\sigma(r-s)\right]\lambda \\ + (27\pi^6/8)\sigma\tau + (\pi^2/2)\sigma(s-\tau r) = 0 \end{aligned} \tag{1.8}$$

with the same multiplicities. Higher modes correspond to eigenvalues whose real parts are negative when (1.8) has solutions λ with real part near 0. For $\sigma>0$, $0<\tau<1$ and for the critical parameter values

$$\begin{aligned} r = r_0 &\equiv (27\pi^4/4)\sigma^{-1}(1-\tau)^{-1}(\sigma+\tau), \\ s = s_0 &\equiv (27\pi^4/4)\tau^2(1-\tau)^{-1}(1+\sigma^{-1}) \end{aligned} \tag{1.9}$$

the equation (1.8) has a double root $\lambda=0$ and the remaining root is real and negative (cf. Part I).

Thus for $\sigma>0$, $0<\tau<1$ and for each Ω corresponding to roll-like, rectangular, square or hexagonal convection cells, the eigenvalue problem (1.7) for u_k, $k=1,\cdots,5$ and p satisfying (1.3)–(1.5) has a double zero eigenvalue when (1.9) holds. All other eigenvalues have negative real parts for these critical parameter values.

We now reformulate the eigenvalue problem (1.7) in terms of an abstract differential operator in a space of functions. Let $n=2$ (for rolls) or $n=3$ (for rectangles, squares or hexagons) and define the spaces of functions corresponding to one of the cellular convection patterns (a)–(d)

$$\dot{H}^{\beta}_{\#}(\Omega) = \left\{ w : w(\mathbf{x}) \text{ has the form (1.3)}, \sum_{\mathbf{j}\in\mathbb{Z}^n} |\mathbf{j}|^{2\beta} |\hat{w}(\mathbf{j})|^2 < \infty, \hat{w}(\mathbf{j}) \text{ satisfy (1.4) and (1.5)} \right\}$$

and

$$\dot{\mathbf{H}}^{\beta}_{\#}(\Omega)=\Big\{\mathbf{u}: u_k(\mathbf{x}) \text{ have the form (1.3)}, k=1,\cdots,3,$$

$$\sum_{\mathbf{j}\in\mathbb{Z}^n}|\mathbf{j}|^{2\beta}|\hat{\mathbf{u}}(\mathbf{j})|^2<\infty, \hat{\mathbf{u}}(\mathbf{j}) \text{ satisfy (1.4) and (1.5)}\Big\}$$

where $\beta\in\mathbb{R}$, and the numbers α_1, α_2, α_3 in (1.3) and the matrix g in (1.5) are appropriate to rolls, rectangles, squares or hexagons. The function spaces $\dot{H}^{\beta}_{\#}(\Omega)$ and $\dot{\mathbf{H}}^{\beta}_{\#}(\Omega)$ are closed subspaces of the Hilbert spaces $\dot{H}^{\beta}_{p}(Q)$ and $\dot{\mathbb{H}}^{\beta}_{p}(Q)$ defined in [12] with $Q=(0,2\pi/\alpha_1)\times(0,2\pi/\alpha_3)$ for rolls or $Q=(0,2\pi/\alpha_1)\times(0,2\pi/\alpha_2)\times(0,2\pi/\alpha_3)$ for rectangles, squares, or hexagons; hence the statements made in [12, pp. 7–11] regarding $\dot{H}^{\beta}_{p}(Q)$, $\dot{\mathbb{H}}^{\beta}_{p}(Q)$ and the Stokes operator A carry over with minor modifications to our present case.

In particular, $\dot{H}^{\beta}_{\#}(\Omega)$ is a Hilbert space with norm

$$\|w\|_{\beta}=\left[\sum_{\mathbf{j}\in\mathbb{Z}^n}|\mathbf{j}|^{2\beta}|\hat{w}(\mathbf{j})|^2\right]^{1/2}$$

and $\dot{\mathbf{H}}^{\beta}_{\#}(\Omega)$ is a Hilbert space with the product structure of $[\dot{H}^{\beta}_{\#}(\Omega)]^n$. The closed subspace

$$J=\{\mathbf{u}\in\dot{\mathbf{H}}^{0}_{\#}(\Omega):\operatorname{div}\mathbf{u}=0\}$$

of $\dot{H}^{0}_{\#}(\Omega)$ has the orthogonal complement

$$G=\{\mathbf{u}\in\dot{\mathbf{H}}^{0}_{\#}(\Omega):\mathbf{u}=\nabla p \text{ for some } p\in\dot{H}^{1}_{\#}(\Omega)\}.$$

Let $X=J\times\dot{H}^{0}_{\#}(\Omega)\times\dot{H}^{0}_{\#}(\Omega)$ with the norm induced by the product structure of $[\dot{H}^{0}_{\#}(\Omega)]^{n+2}$. By solving the boundary-value problem

$$\begin{aligned}&\sigma(\Delta\mathbf{u}-\nabla p)=\mathbf{f},\\&\Delta u_4=f_4,\\&\tau\Delta u_5=f_5,\\&\operatorname{div}\mathbf{u}=0\end{aligned}\tag{1.10}$$

with boundary values (1.2) explicitly for the Fourier coefficients of $u=(\mathbf{u},u_4,u_5)$ when $\sigma>0$, $0<\tau<1$ and $f=(\mathbf{f},f_4,f_5)\in X$ as in [12], it follows that $p=0$ and that the operator defined by

$$\begin{aligned}&D(A)=X\cap\left[\dot{H}^{2}_{\#}(\Omega)\right]^{n+2},\\&Au=(\sigma\Delta\mathbf{u},\Delta u_4,\tau\Delta u_5)\quad \text{for } u\in D(A)\end{aligned}\tag{1.11}$$

is a closed, densely defined selfadjoint operator in X with compact inverse $A^{-1}:X\to X$. The norm

$$|u|_1=\|Au\|_X$$

on $D(A)$ is equivalent to the norm induced by the product structure of $[\dot{H}^2_{\#}(\Omega)]^{n+2}$. The operator $-A$ is sectorial (cf. [5, p. 19]), and hence we can define the powers $(-A)^\alpha$ for all real $\alpha \geqq 0$ and the Hilbert spaces

$$X^\alpha = D\big((-A)^\alpha\big)$$

with norms

$$|u|_\alpha = \|(-A)^\alpha u\|_X.$$

We have $D(A) = X^1 \subset X^\alpha \subset X^0 = X$ for $0 \leqq \alpha \leqq 1$, the inclusions being continuous. In terms of the spaces $\dot{H}^\beta_{\#}(\Omega)$ we have

$$X^\alpha = \left\{ u = (\mathbf{u}, u_4, u_5) \in \dot{\mathbf{H}}^{2\alpha}_{\#}(\Omega) \times \dot{H}^{2\alpha}_{\#}(\Omega) \times \dot{H}^{2\alpha}_{\#}(\Omega) : \operatorname{div} \mathbf{u} = 0 \right\}$$

and the norm $|u|_\alpha$ is equivalent to the norm by the product structure of $[\dot{H}^{2\alpha}_{\#}(\Omega)]^{n+2}$.

Let Π denote the orthogonal projection of $\dot{\mathbf{H}}^0_{\#}(\Omega)$ onto J, and let

$$\Pi_0 = \Pi \times I \times I : J \times \dot{H}^0_{\#}(\Omega) \times \dot{H}^0_{\#}(\Omega) \to X,$$

where I is the identity mapping on $\dot{H}^0_{\#}(\Omega)$. Then Π_0 is a continuous linear mapping, and for $\sigma > 0$, the operator

$$B(r,s)u = \Pi_0\big((r\sigma u_4 - s\sigma u_5)\mathbf{e}_3, u_3, u_3\big) \tag{1.12}$$

is a continuous linear mapping in u, from X^α into X, for each fixed pair $(r,s) \in \mathbb{R}^2$. Furthermore, $B(r,s)$ depends analytically on (r,s).

We let

$$L(r,s)u = Au + B(r,s)u, \qquad u \in D(L(r,s)) = D(A). \tag{1.13}$$

Since A has a compact inverse, the argument in the Appendix of Part I can be used to show that the spectrum of $L(r,s)$ consists entirely of isolated eigenvalues of finite multiplicities. The eigenvalue problem (1.7) can now be written as

$$L(r,s)u = \lambda u, \qquad u \in D(L(r,s)). \tag{1.14}$$

The eigenvalues of (1.14) corresponding to the lowest mode are given by (1.8). Thus $L(r_0, s_0)$ has a double zero eigenvalue, and the rest of the spectrum of $L(r_0, s_0)$ consists of isolated eigenvalues with negative real parts. Note that the space X corresponds to a particular choice of cellular convection—rolls, rectangles, squares or hexagons.

Finally, we express the nonlinear double-diffusive convection equations in abstract form. From the argument given in [5, pp. 79–81] and from the continuity of Π_0, it follows that the operator M: $X^\alpha \times X^\alpha \to X$, defined by

$$M(u,v) = -\Pi_0\big((\mathbf{u}\cdot\nabla)\mathbf{v}, (\mathbf{u}\cdot\nabla)v_4, (\mathbf{u}\cdot\nabla)v_5\big) \tag{1.15}$$

is a continuous bilinear mapping for $3/4 < \alpha < 1$. Thus

$$f(u,r,s) = B(r,s)u + M(u,u) \tag{1.16}$$

is analytic mapping f: $X^\alpha \times \mathbb{R}^2 \to X$. We write the double-diffusive convection equations (1.1), with the boundary conditions (1.2) and one of the cellular convection patterns (a)–(d) as

$$\frac{du}{dt} = Au + f(u,r,s) \tag{1.17}$$

where $-A$ is sectorial and f is analytic. Furthermore, the linear part of the right-hand side of (1.17) is

$$Au + D_u f(0,r,s)u = L(r,s)u, \tag{1.18}$$

where $D_u f$ is the partial derivative of f with respect to u.

We note that (1.17) generates a unique parametrized family of local semiflows near the origin in X^α, $\frac{3}{4} < \alpha < 1$, which are the solutions of (1.17) with initial conditions $u(0) = u_0 \in X^\alpha$ [5, p. 54]. This family of semiflows is jointly analytic in (t, u_0, r, s) for $t > 0$ on its domain of existence [5, p. 66].

2. Center manifold reduction. The study of bifurcation and stability in differential equations can often be greatly simplified by the use of the center manifold theorem. This theorem allows one to reduce the dimension of the state space while preserving the local behavior of solutions of a differential equation. As an example, consider the ordinary differential equation

$$\frac{du}{dt} = Lu + g(u), \qquad u \in \mathbb{R}^m, \tag{2.1}$$

where L is an $m \times m$ matrix, g: $\mathbb{R}^m \to \mathbb{R}^m$ is a smooth nonlinear mapping with $g(0) = 0$ and $g'(0) = 0$. Then the origin $u = 0$ is an equivalent solution of (2.1), and to study the stability of the origin we determine the spectrum of L, $\Sigma(L)$. Suppose that the origin is a degenerate equilibrium of (2.1), i.e. $\Sigma(L)$ contains eigenvalues with zero real part. For example, if $\Sigma(L)$ consists of m_c eigenvalues with zero real part and m_s eigenvalues with negative real part, $m_c + m_s = m$, then the phase space $\mathbb{R}^m$ splits into a direct sum of L-invariant subspaces Y_c (the center eigenspace) and Y_s (the stable eigenspace)

$$\mathbb{R}^m = Y_c \oplus Y_s$$

where $\dim Y_c = m_c$ and $\dim Y_s = m_s$, and thus every $u \in \mathbb{R}^m$ can be uniquely expressed as

$$u = u_c + u_s, \quad \text{for some } u_c \in Y_c, \quad u_s \in Y_s.$$

Furthermore, the restrictions $L \mid_{Y_c}$ and $L \mid_{Y_s}$ have spectra consisting of the eigenvalues of L with zero real parts, and the eigenvalues of L with negative real parts, respectively. Provided g is smooth enough, the center manifold theorem then states that there is a (not necessarily unique) local invariant manifold W_c—a submanifold of $\mathbb{R}^m$ defined in some neighborhood of the origin, consisting of solution curves of (2.1)—tangent to Y_c at the origin

$$W_c = \{ u = u_c + u_s \in \mathbb{R}^m : u_s = h(u_c), |u_c| < \delta \}$$

where h is a smooth function from a neighborhood of the origin in Y_c into Y_s, with $h(0) = 0$ and $h'(0) = 0$. W_c is called a center manifold.

The asymptotic behavior of solutions of (2.1) near the origin is determined by the m_c-dimensional equation in Y_c

$$\frac{du_c}{dt} = L_c u_c + P_c g(u_c + h(u_c)), \tag{2.2}$$

where $L_c = L \mid_{Y_c}$ and P_c is the projection of $\mathbb{R}^m$ onto Y_c, along Y_s. More precisely, if the origin is stable (asymptotically stable, unstable) for (2.2), then the origin is stable (asymptotically stable, unstable) for (2.1) [1, p. 4]. Thus, center manifold theory allows one to study the stability of an equivalent solution by locally reducing the differential equation to one of lower dimension.

To study bifurcations near the origin in a k-parameter family of differential equations

$$\frac{du}{dt} = L(\mu)u + g(u,\mu), \qquad u \in \mathbb{R}^m, \quad u \in \mathbb{R}^k, \tag{2.3}$$

where $L(\mu)$ is an $m \times m$ matrix depending smoothly on μ, $L(0)$ has m_c eigenvalues with zero real part and m_s eigenvalues with negative real part, $m_c + m_s = m$, $g(0,\mu) = 0$ and $D_u g(0,\mu) = 0$, we apply the center manifold to the $(m+k)$-dimensional system

$$\frac{du}{dt} = L(\mu)u + g(u,\mu), \qquad \frac{d\mu}{dt} = 0 \tag{2.4}$$

for $(u,\mu) \in \mathbb{R}^{m+k}$. $\mathbb{R}^m$ splits into a direct sum of $L(0)$-invariant subspaces $\mathbb{R}^m = X_c \oplus X_s$, where $\mathrm{Re}\,\Sigma(L(0) \mid_{X_c}) = 0$, $\mathrm{Re}\,\Sigma(L(0) \mid_{X_s}) < 0$; and $\mathbb{R}^{m+k}$ splits into a direct sum $\mathbb{R}^{m+k} = Y_c \oplus Y_s$, where $Y_c = X_c \times \mathbb{R}^k$, $Y_s = X_s$. The center manifold theorem applied to (2.4) gives the existence of a center manifold defined by a smooth function $h(u_c,\mu)$ mapping a neighborhood of the origin in $X_c \times \mathbb{R}^k$ into X_s. Bifurcation and stability of solutions of (2.3) near the origin, for μ near 0, is determined by the reduced system

$$\frac{du_c}{dt} = P_c L(\mu)u_c + P_c g(u_c + h(u_c,\mu),\mu) \tag{2.5}$$

for $u_c \in X_c$, $\mu \in \mathbb{R}^k$ [1, p. 12], [6, pp. 471–473]. Thus local bifurcations in (2.3) can be studied by means of a reduced system (2.5). Moreover, in many applications it suffices to determine only the first few terms in the Taylor series expansion of the right-hand side of (2.5) in order to obtain the complete unfolding of (2.3) near $\mu = 0$.

In this section we apply a suitable version of the center manifold theorem to reduce the (r,s)-parametrized family of abstract differential equations (1.17) to a two-parameter family of ordinary differential equations in a two-dimensional phase space, the dimension two of the phase space being determined by the multiplicity two of the zero eigenvalue of the linearization (1.14). We explicitly describe X_c, P_c and the first few terms in the Taylor series expansion of a center manifold function h when the state space X of (1.17) corresponds to rolls, rectangles, squares or hexagons.

We apply the following theorems due to Henry [5, Thm. 6.2.1 and Cor. 6.2.2, pp. 168–171]:

THEOREM 1. *Consider the abstract differential equation*

$$\frac{du}{dt} = Au + f(u), \tag{2.6}$$

where $-A$ is a sectorial operator in a Banach space Y, $0 \leqq \alpha < 1$, U is a neighborhood of the origin in Y^α, and f: $U \to Y$ is C^1 with $f(0) = 0$ and f' Lipschitz continuous in U. Assume $L = A + f'(0)$ has $\mathrm{Re}\,\Sigma(L) \leqq 0$ with $\Sigma(L) \cap \{\mathrm{Re}\,\lambda = 0\}$ a spectral set. Let $Y = Y_c + Y_s$ be the decomposition into L-invariant subspaces with $\mathrm{Re}\,\Sigma(L \mid_{Y_c}) = 0$ and $\mathrm{Re}\,\Sigma(L \mid_{Y_s}) < 0$.

Then there exists a C^1 local invariant manifold (a center manifold)

$$W_c = \{ u = u_c + u_s : u_s = h(u_c), u_c \in Y_c, \|u_c\|_Y < \delta \}$$

tangent to Y_c at the origin. The flow in W_c is represented by the ordinary differential equation

$$\frac{du_c}{dt} = l_c u_c + P_c g(u_c + h(u_c)), \tag{2.7}$$

where $g(u) = f(u) - f'(0)u$, $L_c = L|_{Y_c}$ and P_c is the projection of Y onto Y_c along Y_s. If the origin is asymptotically stable for (2.7), *then the origin is asymptotically stable in Y^α for* (2.6); *if the origin is unstable for* (2.7), *then the origin is unstable in Y^α for* (2.6).

If the nonlinear part f in Theorem 1 is smooth enough, the center manifold W_c is smooth and we can approximate $h(u_c)$ by the first finitely many terms in the Taylor series for $h(u_c)$ [5, Thm. 6.2.3, p. 171]:

THEOREM 2. *Assume the hypotheses of Theorem* 1, *and assume that g: $U \to Y$ is C^p, where $g(u) = f(u) + f'(0)u$. If there is a C^1 function ϕ with Lipschitzian derivative from a neighborhood of the origin in Y_c into Y_s^α, with range in $D(L|_{Y_s})$, such that*

$$\phi'(u_c)\left[L_c u_c + P_c g(u_c + \phi(u_c))\right] - L_s \phi(u_c) - P_s g(u_c + \phi(u_c)) = O\left(\|u_c\|^p\right) \tag{2.8}$$

as $u_c \to 0$ in Y_c, where $L_c = L|_{Y_c}$, $L_s = |_{Y_s}$, P_c is the projection of Y onto Y_c along Y_s, $P_s = I - P_c$, then

$$|h(u_c) - \phi(u_c)|_\alpha = O\left(\|u_c\|^p\right) \tag{2.9}$$

as $u_c \to 0$ in Y_c, where $h(u_c)$ defines the center manifold of Theorem 1. *If g is C^p near the origin, there is a unique polynomial function ϕ of order p satisfying the conditions above.*

We apply Theorems 1 and 2 to the system

$$\frac{du}{dt} = Au + f(u,r,s), \quad \frac{dr}{dt} = 0, \quad \frac{ds}{dt} = 0, \tag{2.10}$$

in the Hilbert space $Y = X \times \mathbb{R}^2$, where X is the space defined in §1, $-A$ is the sectorial operator defined by (1.11) and f is the operator defined by (1.16).

By the remarks in §1,

$$L_0 = L(r_0, s_0) = A + D_u f(0, r_0, s_0) \tag{2.11}$$

has $\mathrm{Re}\,\Sigma(L_0) \leqq 0$ with $\Sigma(L_0) \cap \{\mathrm{Re}\,\lambda = 0\} = \{0\}$. Suppose we find a Jordan basis for the zero eigenspace satisfying

$$\begin{aligned} &L_0 q_1 = 0, && L^*_0 q^*_1 = q^*_2, \\ &L_0 q_2 = q_1, && L^*_0 q^*_2 = 0, \\ &(q_j, q^*_k) = \delta_{jk}, && j,k = 1,2, \end{aligned} \tag{2.12}$$

where $(\ ,\ )$ is the inner product in X and L^*_0 is the adjoint of L_0 (see Part I). Then the operator P_c: $X \to \mathrm{span}\{q_1, q_2\}$ defined by

$$P_c u = (u, q^*_1) + (u, q^*_2) q_2 \tag{2.13}$$

is a projection onto the double zero eigenspace $\mathrm{span}\{q_1, q_2\}$, with

$$P_c L_0 u = L_0 P_c u \quad \text{for all } u \in D(L_0). \tag{2.14}$$

Thus L_0 leaves the subspaces

$$R(P_c)=\operatorname{span}\{q_1,q_2\}, \qquad N(P_c)=\{q^*_1,q^*_2\}^{\perp}$$

invariant, with

$$X=R(P_c)\oplus N(P_c) \tag{2.15}$$

and

$$\Sigma\left(L_0|_{R(P_c)}\right)=\{0\}, \qquad \operatorname{Re}\Sigma\left(L_0|_{N(P_c)}\right)<0. \tag{2.16}$$

Define

$$X_c=R(P_c), \qquad X_s=N(P_c). \tag{2.17}$$

Then by (2.15) and (2.16), X_c is the generalized eigenspace for the double zero eigenvalue of L_0 and X_s is a complementary subspace. By Theorem 1 applied to (2.10), we obtain the existence of a local center manifold

$$W_c=\left\{\left(u_c,r',s'\right)+h\left(u_c,r',s'\right)\colon \|u_c\|_X<\delta,\ |r'|<\delta,\ |s'|<\delta\right\},$$

where $r'=r-r_0$, $s'=s-s_0$ and h is a C^1 mapping from a neighborhood of the origin in $X_c\times\mathbb{R}^2$ into $X_s^\alpha=X_sX^\alpha$, $3/4<\alpha<1$, with $h(0,0,0)=0$, $h'(0,0,0)=0$. Actually, h is C^p for any integer $p>0$ (although h is not necessarily analytic) since f in (2.10) is analytic. The flow in W_c is represented by

$$\frac{du_c}{dt}=P_cL(r,s)u_c+P_cg\left(u_c+h\left(u_c,r',s'\right)\right), \tag{2.18}$$

where $g(u)=f(u,r,s)-D_uf(0,r,s)u=M(u,u)$. Bifurcation and asymptotic behavior of solutions near $u=0$, with r near r_0 and s near s_0 in the abstract differential equation (1.17) can now be studied by means of the oridinary differential equation (2.18).

We get explicit expressions for q_1, q_2, q^*_1 and q^*_2 in (2.12) by substituting the appropriate Fourier expansions into (2.12) and solving for the Fourier coefficients. For rolls, we obtain

$$q_1=\begin{bmatrix} -\left(2^{1/2}/N\right)\sin\alpha_1x_1\cos\pi x_3 \\ (1/N)\cos\alpha_1x_1\sin\pi x_3 \\ \left(2/3\pi^{2N}\right)\cos\alpha_1x_1\sin\pi x_3 \\ \left(2/3\pi^2N\tau\right)\cos\alpha_1x_1\sin\pi x_3 \end{bmatrix}, \quad q_2=\begin{bmatrix} -2^{1/2}C\sin\alpha_1x_1\cos\pi x_3 \\ C\cos\alpha_1x_1\sin\pi x_3 \\ Q_{2,4}\cos\alpha_1x_1\sin\pi x_3 \\ Q_{2,5}\cos\alpha_1x_1\sin\pi x_3 \end{bmatrix}, \tag{2.19a}$$

$$q^*_1=\begin{bmatrix} 0 \\ 0 \\ -\left(4\sigma r_0/9\pi^4\right)\cos\alpha_1x_1\sin\pi x_3 \\ \left(4\sigma s_0/9\pi^4\tau^2\right)\cos\alpha_1x_1\sin\pi x_3 \end{bmatrix}, \quad q^*_2=\begin{bmatrix} -2^{1/2}\sin\alpha_1x_1\cos\pi x_3 \\ \cos\alpha_1x_1\sin\pi x_3 \\ \left(2\sigma r_0/3\pi^2\right)\cos\alpha_1x_1\sin\pi x_3 \\ -\left(2\sigma s_0/3\pi^2\tau\right)\cos\alpha_1x_1\sin\pi x_3 \end{bmatrix},$$

where $N=2^{1/2}(1+\sigma+\tau)/\pi^2\tau$, $C=2(1+\sigma+\tau+\sigma\tau+\tau^2)/3\pi^2(1+\sigma+\tau)N\tau$, $Q_{2,4}=(2C/3\pi^2)-(4/9\pi^4N)$ and $Q_{2,5}=(2C/3\pi^2)-(4/9\pi^4N\tau)$. For rectangles and squares, we have

(2.19b)
$$q_1=\begin{bmatrix}(2i\alpha_1/\pi N)\Phi_1\\(2i\alpha_2/\pi N)\Phi_2\\(1/N)\Phi_3\\(2/3\pi^2N)\Phi_3\\(2/3\pi^2N\tau)\Phi_3\end{bmatrix},\qquad q_2=\begin{bmatrix}(2i\alpha_1C/\pi)\Phi_1\\(2i\alpha_2C/\pi)\Phi_2\\C\Phi_3\\Q_{2,4}\Phi_3\\Q_{2,5}\Phi_3\end{bmatrix},$$

$$q^*{}_1=\begin{bmatrix}0\\0\\0\\-(4\sigma r_0/9\pi^4)\Phi_3\\(4\sigma s_0/9\pi^4\tau^2)\Phi_3\end{bmatrix},\qquad q^*{}_2=\begin{bmatrix}(2i\alpha_1/\pi)\Phi_1\\(2i\alpha_2/\pi)\Phi_2\\\Phi_3\\(2\sigma r_0/3\pi^2)\Phi_3\\-(2\sigma s_0/3\pi^2\tau)\Phi_3\end{bmatrix},$$

where C, $Q_{2,4}$ and $Q_{2,5}$ are the same expressions as those for rolls, $N=16(1+\sigma+\tau)/\alpha_1\alpha_2\tau$,

$$\begin{aligned}\Phi_1&=[\omega_{1,1}-\omega_{-1,1}-\omega_{-1,-1}+\omega_{1,-1}]\cos\pi x_3,\\\Phi_2&=[\omega_{1,1}+\omega_{-1,1}+\omega_{-1,-1}+\omega_{1,-1}]\cos\pi x_3,\\\Phi_3&=[\omega_{1,1}+\omega_{-1,1}+\omega_{-1,-1}+\omega_{1,-1}]\cos\pi x_3,\\\omega_{j_1,j_2}&=e^{i(j_1\alpha_1x_1+j_2\alpha_2x_2)}.\end{aligned}$$

For hexagons we obtain the same expressions as (2.19b), except with $N=24(1+\sigma+\tau)/\alpha_1\alpha_2\tau$,

$$\begin{aligned}\Phi_1&=[\omega_{1,1}-2\omega_{-2,0}+\omega_{1,-1}-\omega_{-1,-1}+2\omega_{2,0}-\omega_{-1,1}]\cos\pi x_3,\\\Phi_2&=[\omega_{1,1}-\omega_{-1,-1}-\omega_{-1,-1}+\omega_{-1,1}]\cos\pi x_3,\\\Phi_3&=[\omega_{1,1}+\omega_{-2,0}+\omega_{-1,-1}+\omega_{-1,-1}+\omega_{2,0}+\omega_{-1,1}]\sin\pi x_3.\end{aligned}$$

If we write

(2.20)
$$u_c=y_1q_1+y_2q_2,$$

where $y_k=(u_c,q^*{}_k)\in\mathbb{R}$, $k=1,2$, we can obtain an explicit representation for $P_cL(r,s)u_c$ in (2.18) by substituting the expressions (2.19a, b) into (2.13) and computing

(2.21)
$$P_cL(r,s)=y_2q_1+(\mu_1y_1+\mu_2y_2)q_2,$$

where u_c is given by (2.20), and

$$\text{(2.22a)}\qquad \begin{aligned}\mu_1 &= \frac{\sigma\tau}{3(1+\sigma+\tau)}\left(r'-\frac{s'}{\tau}\right),\\ \mu_2 &= \frac{2\sigma\tau}{9\pi^2(1+\sigma+\tau)}\left[\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{1+\sigma+\tau}\left(r'-\frac{s'}{\tau}\right)-\tau\left(r'-\frac{s'}{\tau^2}\right)\right]\end{aligned}$$

for rolls, rectangles, squares and hexagons. One notes that μ_1, μ_2 are independent linear functions of r', s', and that (2.22a) is invertible for $\sigma>0$ and $0<\tau<1$. The inverse transformation is

$$\text{(2.22b)}\qquad \begin{aligned}r' &= -\frac{3(1+\sigma+\tau)}{\sigma(1+\sigma-\mathrm{t}-\tau^2)}\left[(\sigma+\tau)\mu_1-(3\pi^2/2\tau)(1+\sigma+\tau)\mu_2\right],\\ s' &= -\frac{3(1+\sigma+\tau)}{\sigma(1+\sigma-\sigma\tau-\tau^2)}\left[(1+\sigma)\mu_1-(3\pi^2/2)(1+\sigma+\tau)\mu_2\right].\end{aligned}$$

Thus, we can write equation (2.18) as an ordinary differential equation

$$\text{(2.23)}\qquad \frac{d}{dt}\begin{bmatrix}y_1\\ y_2\end{bmatrix}=\begin{bmatrix}0 & 1\\ \mu_1 & \mu_2\end{bmatrix}\begin{bmatrix}y_1\\ y_2\end{bmatrix}+\begin{bmatrix}g_1(y,\mu)\\ g_2(y,\mu)\end{bmatrix},$$

where $g_k(y,\mu)=(M(u_c+h(u_c,r',s'),u_c+h(u_c,r',s')),q^*_k)$ for $k=1, 2$, $y=(y_1,y_2)$, $\mu=(\mu_1,\mu_2)$, $u_c=y_1q_1+y_2q_2$ as in (2.20), and r', s' are given (2.22b).

Next, we apply Theorem 2 to obtain a polynomial approximation to a center manifold. Let

$$\text{(2.24)}\qquad \phi(y,\mu)=\frac{1}{2}y_1^2\phi_{11}+y_1y_2\phi_{12}+\frac{1}{2}y_2^2\phi_{22},\qquad \phi_{jk}\in X_x^\alpha,$$

where $u_c=y_1q_1+y_2q_2$ and $\mu=(\mu_1,\mu_2)$. By substituting the expressions (2.20) and (2.24) into (2.8), and equating coefficients of powers of y_k, we obtain the equations

$$\text{(2.25)}\qquad \begin{aligned}L_s\phi_{11}\omega_{1,-1} &= -2P_sM(q_1,q_1),\\ L_s\phi_{12} &= -P_s[M(q_1,q_2)+M(q_2,q_1)]+\phi_{11},\\ L_s\phi_{22} &= -2P_sM(q_2,q_2)+2\phi_{12}.\end{aligned}$$

When the solutions ϕ_{jk} of (2.25) are substituted into (2.24), then by Theorem 2 we have the approximation

$$\text{(2.26)}\qquad h(y,\mu)=\phi(y,\mu)+O(|y||\mu|)+O\left(|(y,\mu)|^3\right)$$

as $(y,\mu)\to O$ in $\mathbb{R}^4$, where $h(y,\mu)=h(u_c,r',s')$, using (2.20) and (2.22b).

We can solve (2.25) uniquely and obtain explicit expressions for ϕ_{11}, ϕ_{12} and ϕ_{22} by substituting the expressions (2.19) for q_k into the right-hand sides of (2.25) and solving for the Fourier coefficients of the ϕ_{jk}. It turns out that $P_sM(q_j,q_k)=M(q_j,q_k)$, $j, k=1$, 2, due to the multiplication and orthogonality properties of trigonometric polynomials.

For example, for rolls

$$M(q_1,q_1)=-\frac{1}{2}\Pi_0\begin{bmatrix}(2\alpha_1/N^2)\sin 2\alpha_1 x_1\\(\pi/N^2)\sin 2\pi x_3\\(2/3\pi N^2)\sin 2\pi x_3\\(2/3\pi N^2\tau)\sin 2\pi x_3\end{bmatrix} \tag{2.27}$$

belongs to $\{q^*_1,q^*_2\}^\perp = R(P_s)$. Similar results are obtained for the other $M(q_j,q_k)$, and for the other cellular structures. An explicit expression for ϕ_{22} is not actually needed to determine the unfoldings; solving for ϕ_{11} and ϕ_{12}, we obtain, in the case of rolls,

(2.28a)
$$\phi_{11}=\begin{bmatrix}0\\0\\-(1/6\pi^3N^2)\sin 2\pi x_3\\-(1/6\pi^3N^2\tau^2)\sin 2\pi x_3\end{bmatrix},\quad \phi_{12}=\begin{bmatrix}0\\0\\\left(\dfrac{-C}{6\pi^3N}+\dfrac{7}{72\pi^5N^2}\right)\sin 2\pi x_3\\\left(\dfrac{-C}{6\pi^3N\tau^2}+\dfrac{7}{72\pi^5N^2\tau^3}\right)\sin 2\pi x_3\end{bmatrix}.$$

For rectangles and squares we obtain

$$\phi_{11}=\begin{bmatrix}2\hat\phi_{11,1}(2,0,2)\Theta_{1,1}\\2i\hat\phi_{11,3}(2,0,2)\Theta_{1,3}\\2i\hat\phi_{11,4}(2,0,2)\Theta_{1,3}\end{bmatrix}+\begin{bmatrix}0\\2\hat\phi_{11,2}(0,2,2)\Theta_{2,2}\\2i\hat\phi_{11,3}(0,2,2)\Theta_{2,3}\\2i\hat\phi_{11,4}(0,2,2)\Theta_{2,3}\\2i\hat\phi_{11,5}(0,2,2)\Theta_{2,3}\end{bmatrix} \tag{2.28b}$$

$$+\begin{bmatrix}0\\0\\0\\-(4/3\pi^3N^2)\sin 2\pi x_3\\-(4/3\pi^3N^2\tau^2)\sin 2\pi x_3\end{bmatrix},$$

$$\hat{\phi}_{12,4}(3,1,2)=2\hat{\phi}_{12,3}(3,1,2)/11\pi^2-4\hat{\phi}_{11,3}(3,1,2)/121\pi^4$$
$$+2iC/33\pi^3N-35i/2{,}178\pi^5N^2,$$
$$\hat{\phi}_{12,5}(3,1,2)=2\hat{\phi}_{12,3}(3,1,2)/11\pi^2\tau-4\hat{\phi}_{11,3}(3,1,2)/121\pi^4\tau^2$$
$$+2iC/33\pi^3N\tau^2-35i/2{,}178\pi^5N^2\tau^3.$$

If we substitute (2.20), (2.24) and (2.26) into equation (2.23), we obtain

$$\frac{dy_1}{dt}=y_2+a_1y_1^3+b_1y_1^2y_2+c_1y_1y_2^2+d_1y_2^3+\rho_1(y,\mu), \tag{2.29}$$
$$\frac{dy_2}{dt}=\mu_1y_1+\mu_2y_2+a_2y_1^3+b^2y_1^2y_2+c_2y_1y_2^2+d_2y_2^3+\rho_2(y,\mu).$$

where $\rho_k(y,\mu)=0(|y||\mu|^2+|y|^2|\mu|)+0(|(y,\mu)|^4)$, and

$$a_k=\frac{1}{2}(M(q_1,\phi_{11})+M(\phi_{11},q_1),q^*{}_k), \tag{2.30}$$
$$b_k=(M(q_1,\phi_{12})+M(\phi_{12},q_1)q^*{}_k)+\frac{1}{2}(M(q_2,\phi_{11})+M(\phi_{11},q_2),q^*{}_k),$$
$$c_k=(M(q_2,\phi_{12})+M(\phi_{12},q_2),q^*{}_k)+\frac{1}{2}(M(q_1,\phi_{22})+M(\phi_{22},q_1),q^*{}_k),$$
$$d_k=\frac{1}{2}(M(q_2,\phi_{22})+M(\phi_{22},q_2),q^*{}_k),$$

for $k=1, 2$. We have used the fact that $M(q_j,q_k)\in\{q_1,q_2\}^{\perp}$, $j, k=1, 2$ so that the quadratic terms in y vanish. In fact, since the functions in X^{α} and equation (1.17) are covariant with respect to the $\mathbb{Z}_2$ symmetry represented by (1.4), the reduced equations (2.29) are odd with respect to y. Thus, no even-order terms in y occur in (2.29) [4, p. 256] and we have in fact

$$\rho_k(y,\mu)=0\big(|y||\mu|^2+|y|^3|\mu|+|y|^5\big),\qquad k=1,2.$$

In the following section we determine the unfolding of the degenerate vector field represented by the right-hand side of (2.29) about $\mu=0$, and hence determine the unfolding of the parametrized family of abstract differential equations (1.17) about $(r,s)=(r_0,s_0)$ for almost all $\sigma>0$ and $0<\tau<1$.

3. Normal form coefficients and results. The flow of a nonlinear ordinary differential equation near a degenerate equilibrium point can be analyzed, after a center manifold reduction, by means of a nonlinear change of coordinates which simplifies the expression of the vector field. A normal form is a "simplest" expression resulting from a smooth nonlinear change of coordinates. More precisely, for certain differential equations the first finitely many terms in the Taylor series expansion of the vector field are sufficient to determine the asymptotic behavior of solutions near a degenerate equilibrium. In such cases, the normal form theorem ([11], see also [6, p. 459]) is used to find the minimum number of terms essential to describe the local flow. One can then construct coordinate transformations which transform the original vector field into a normal form, modulo higher-order terms. This procedure can be modified for use with parametrized systems such as (2.29) to determine the unfolding of a degenerate vector field [6, pp. 473–474].

In this section we present the results of our computations of the normal form coefficients which determine the unfolding of (2.29). The values of these coefficients completely determine all the local bifurcations which occur in (2.29) for μ near 0, as well as the stability of each of the bifurcating solutions. In this way we obtain complete information about local bifurcation and stability in the abstract equations (1.17) for (r,s) near (r_0,s_0), for almost all values of $\sigma>0$ and $0<\tau<1$.

For equation (2.29), terms of order three in y are sufficient to determine the flow for (y,μ) near $(0,0)$, and a suitable normal form is

$$\frac{dy_1}{dt}=y_2, \qquad \frac{dy_2}{dt}=\mu_1 y_1+\mu_2 y_2+a_2' y_1^3+b_2' y_1^2 y_2, \tag{3.1}$$

if $a_2'\neq 0$ and $b_2'\neq 0$ [6, p. 474]. Since two parameters μ_1 and μ_2 are necessary and sufficient to determine all the local bifurcations in (3.1), this is called a codimension two bifurcation. By a suitable smooth change of coordinates preserving the symmetry $y\to -y$, we can transform (2.29) into

$$\frac{dy_1}{dt}=y_2+\rho_1(y,\mu), \qquad \frac{dy_2}{dt}=\mu_1 y_1+\mu_2 y_2+a_2' y_1^3+b_2' y_1^2 y_2+\rho_2(y,\mu), \tag{3.2}$$

where $\rho_k(y,\mu)=O(|y||\mu|^2+|y|^3|\mu|+|y|^3)$ for $k=1, 2$, and the normal form coefficients are

$$a_2'=a_2, \qquad b_2'=3a_1+b_2 \tag{3.3}$$

[6, p. 466], [1, p. 81]. The values of a_2' and b_2' completely determine the qualitative behaviors of all the local flows of (3.2), and hence of (2.29) for μ near 0.

We compute the values of the normal form coefficients by substituting expressions (2.19), (2.28) and (2.30) into (3.3). For rolls, we obtain

$$a_2'=\frac{9}{2^{1/2}8N^3}\left[\frac{1+\sigma+\tau}{\tau}\right], \qquad b_2'=-\frac{21}{2^{1/2}16\pi^2N^3}\left[\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\tau^2}\right]. \tag{3.4a}$$

For rectangles, we obtain

$$\begin{aligned} a_2'=\frac{8\pi^2}{\alpha_1\alpha_2 N_3}\Bigg\{&\frac{1+\sigma+\tau}{\tau}\left[4+\sum_{k=1}^{2}\frac{(\pi^2-2\alpha_k^2)\delta_k^2}{\pi^2(\pi^2+\alpha_k^2)}\right]\\ &-\frac{1}{\sigma}\left[\sum_{k=1}^{2}\frac{3\alpha_k^2(\pi^2-2\alpha_k^2)(5\pi^2+8\alpha_k^2)^2\delta_k^2}{\pi^2(\pi^2+\alpha_k^2)\gamma^6}\right]\Bigg\}, \end{aligned}$$

$$\begin{aligned} b_2'=\frac{8}{\alpha_1\alpha_2 N^3}\Bigg\{&-\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\tau^2}\left[7+\sum_{k=1}^{2}\frac{(7\pi^4-10\pi^2\alpha_k^2-8\alpha_k^4)\delta_k^2}{4\pi^2(\pi^2+\alpha_k^2)}\right]\\ &-\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\sigma\tau(1+\sigma+\tau)}\left[\sum_{k=1}^{2}\frac{7\alpha_k^2(\pi^2-2\alpha_k^2)(5\pi^2+8\alpha_k^2)^2\delta_k^2}{\pi^2(\pi^2+\alpha_k^2)\gamma_k^6}\right]\\ &-\frac{1+\sigma+\tau}{\sigma\tau}\left[\sum_{k=1}^{2}\frac{36\alpha_k^2(\pi^2-2\alpha_k^2)(5\pi^2+8\alpha_k^2)\delta_k^2}{(\pi^2+\alpha_k^2)\gamma_k^6}\right]\\ &+\frac{1}{\sigma^2}\left[\sum_{k=1}^{2}\frac{9\alpha_k^2(\pi^2-2\alpha_k^2)(5\pi^2+8\alpha_k^2)^2\delta_k^2}{(\pi^2+\alpha_k^2)^2\gamma_k^6}\right]\Bigg\}. \end{aligned} \tag{3.4b}$$

Note that the quantitites in square brackets are positive. For squares, the expressions (3.4b) simplify to

$$a_2' = \frac{32}{N^3}\left\{\frac{36}{5}\left[\frac{1+\sigma+\tau}{\tau}\right] - \frac{882}{2{,}365}\left[\frac{1}{\sigma}\right]\right\},$$

$$\text{(3.4c)}\quad b_2' = \frac{32}{\pi^2 N^3}\left\{-\frac{207}{25}\left[\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\tau^2}\right] - \frac{2{,}352}{2{,}365}\left[\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\sigma\tau(1+\sigma+\tau)}\right] - \frac{18{,}816}{11{,}875}\left[\frac{1+\sigma+\tau}{\sigma\tau}\right] + \frac{441}{2{,}365}\left[\frac{1}{\sigma^2}\right]\right\}.$$

For hexagons, we obtain

$$a_2' = \frac{48}{3^{1/2}N^3}\left\{\frac{810}{11}\left[\frac{1+\sigma+\tau}{\tau}\right] - \frac{314{,}892}{89{,}375}\left[\frac{1}{\sigma}\right]\right\},$$

$$\text{(3.4d)}\quad b_2' = \frac{48}{3^{1/2}\pi^2 N^3}\left\{-\frac{226}{33}\left[\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\tau^2}\right] - \frac{242{,}928}{89{,}375}\left[\frac{1+\sigma+\tau+\sigma\tau+\tau^2}{\sigma\tau(1+\sigma+\tau)}\right] - \frac{1{,}092{,}828}{983{,}125}\left[\frac{1+\sigma+\tau}{\sigma\tau}\right] + \frac{471{,}269{,}040}{726{,}171{,}875}\left[\frac{1}{\sigma^2}\right]\right\}.$$

The bifurcation structure of (3.2) is now a straightforward application of the theory already developed for (3.1). The unfolding of (3.2) is completely determined by the signs of the coefficients a_2' and b_2'. The following cases are possible [1, Chap. 4], [3, Chap. 7]:

Case 1a. $a_2' > 0$, $b_2' < 0$: See Fig. 3.1 for bifurcation set and associated phase portraits.

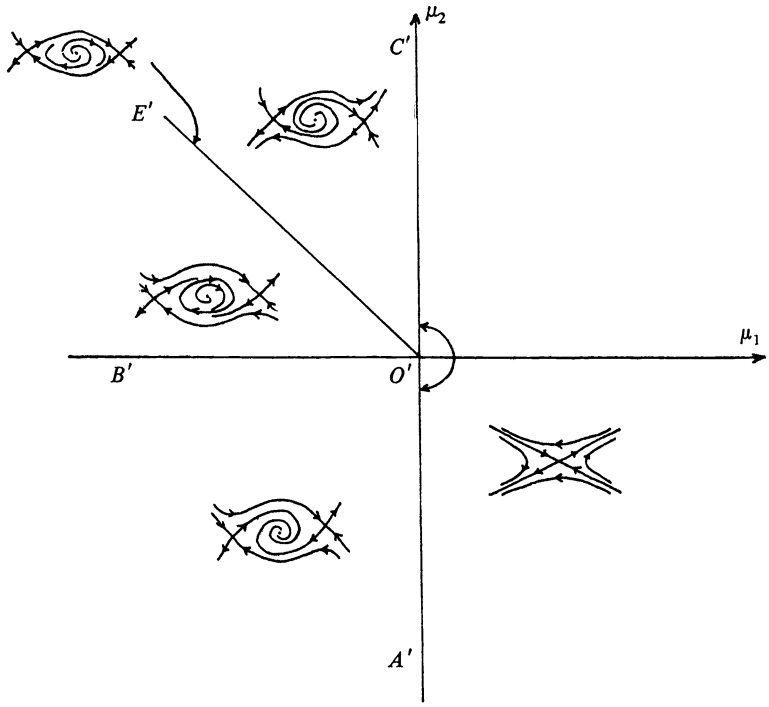

FIG. 3.1. *Bifurcation set and corresponding phase portraits for Case* 1a *unfolding* ($a_2' > 0$, $b_2' < 0$).

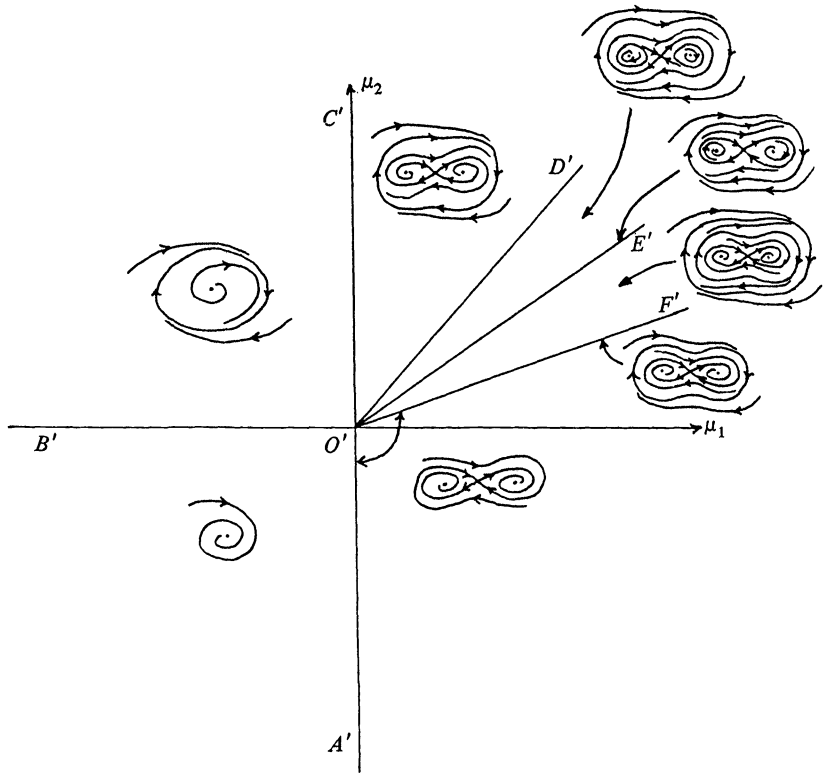

FIG. 3.2. *Bifurcation set and corresponding phase portraits for Case* 2a *unfolding* ($a_2' < 0$, $b_2' < 0$).

Case 1b. $a_2' > 0$, $b_2' > 0$: Bifurcation set and associated phase portraits for this case are obtained from Fig. 3.1 by the transformations $\mu_2 \to -\mu_2$, $y_2 \to -y_2$ and $t \to -t$.

Case 2a. $a_2' < 0$, $b_2' < 0$: See Fig. 3.2 for bifurcation and set associated phase portraits.

Case 2b. $a_2' < 0$, $b_2' > 0$: Bifurcation and associated phase portraits for this case are obtained from Fig. 3.2 by the transformations $\mu_2 \to -\mu_2$, $y_2 \to -y_2$ and $t \to -t$.

The lines $A'O'C'$ and $O'B'$ in (μ_1, μ_2)-parameter space shown in Figs. 3.1–3.2, correspond to the lines AOC and OB in (s, r)-parameter space shown in Figs. 3.3 and 3.5. The corresponding bifurcations—pitchfork and Hopf, respectively—are local ones branching from the trivial (constant gradient) solution $u = 0$ of (1.17) when $s \neq s_0$. They are treated in Parts I and II.

However, we have further local bifurcations. The line $O'D'$ in Fig. 3.2 corresponds to Hopf bifurcations from two equilibrium points symmetrically located about the origin in phase space. The curves $O'E'$ and $O'F'$ in Figs. 3.1 and 3.2 are tangent to straight lines at the origin in parameter space, and correspond to saddle connections and coalescence of xperiodic orbits. For more details consult [1] or [3].

It is clear from (3.4a) that for rolls, only Case 1a unfoldings occur for all $\sigma > 0$ and $0 < \tau < 1$. However, different cases of unfoldings can occur for rectangles, squares and hexagons. For example, from (3.4c, d) it follows that Case 1b unfoldings occur for squares and hexagons when $\sigma \ll 1$ and and $\tau = 17\sigma \ll 1$, and Case 2a occurs when $\sigma \ll 1$ and $\tau = 25\sigma \ll 1$. Cases 1b and 2a can also occur for rectangles. From (3.4b, c, d) one can see that Case 2b unfoldings occur for rectangles, squares and hexagons provided σ

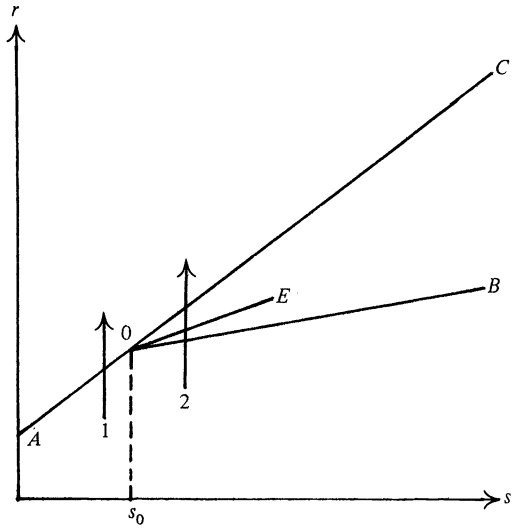

FIG. 3.3. *Case* 1a *bifurcation set in* (s,r) *parameter space.*

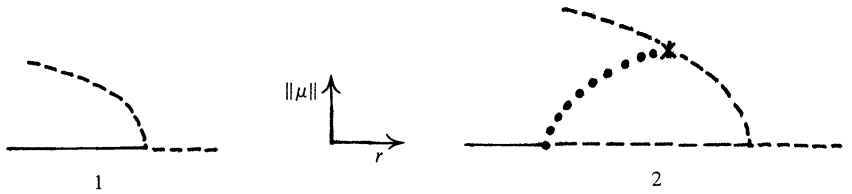

FIG. 3.4. *Bifurcation diagrams corresponding to parameter paths* 1 *and* 2 *in Fig.* 3.3. *Solid lines represent stable equilibrium solutions, broken lines represent unstable equilibrium solutions, solid circles represent stable periodic solutions, open circles represent unstable periodic solutions and asterisks represent saddle connections.*

is sufficiently small compared to τ, and the Case 1a unfoldings occur when σ is sufficiently large compared to τ.

The bifurcation sets in terms of the original parameters r and s of the double-diffusive convection equations can be found by means of (2.22a, b). The slopes of the tangent lines to the curves $O'D'$, $O'E'$ and $O'F'$ in Figs. 3.1–3.2 depend on the numerical values of a_2' and b_2', but their relative positions with respect to each other and to the lines $A'O'C'$ and $O'B'$ are unchanged. Thus, the corresponding tangent lines to the curves OD, OE and OF in (s,r) parameter space maintain their relative positions with respect to each other and to the lines AOC and OB. For example, in Case 1a we have the bifurcation set illustrated in Fig. 3.3, valid for r near r_0 and s near s_0. Following parameter path 1 in Fig. 3.3 (s fixed near s_0, $s<s_0$, r increasing) gives a subcritical pitchfork bifurcation, and following parameter path 2 in Fig. 3.3 gives the more complicated bifurcation diagram illustrated in Fig. 3.4. In case 2b, parameter paths 3 and 4 in Fig. 3.5 correspond to the bifurcation diagrams of Fig. 3.6. It is possible that the unstable subcritical branches of equilibrium solutions in Figs. 3.4 and 3.6 may "turn back" and regain stability as they have been shown to do in the case of rolls for s near $s_1=27\pi^4\tau^3/4(1-\tau^2)$ [10]. However, we do not address this question here.

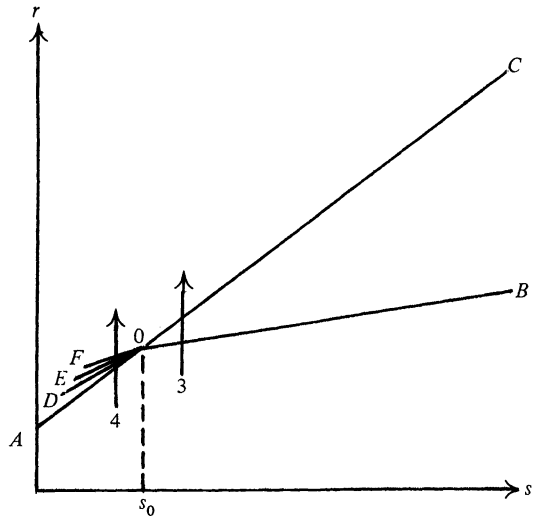

FIG. 3.5. *Case* 2b *bifurcation set in* (s,r) *parameter space.*

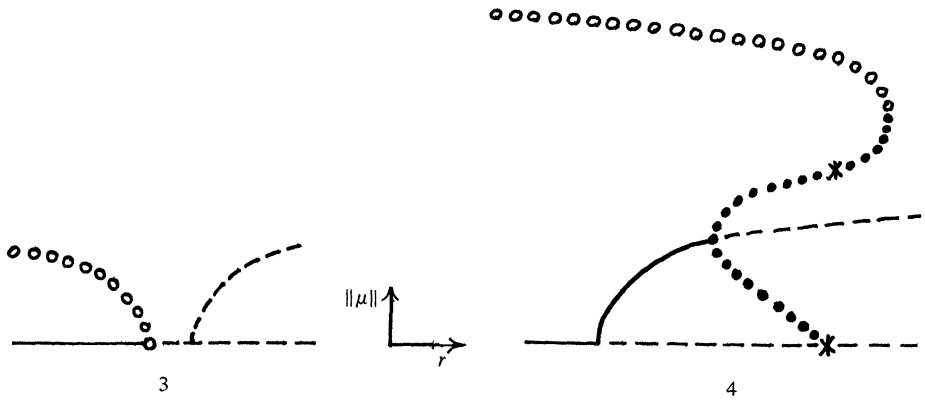

FIG. 3.6. *Bifurcation diagrams corresponding to parameter paths* 3 *and* 4 *in Fig.* 3.5. (*See Fig.* 3.4 *legend*).

"Physically reasonable" parameter values are σ near 1 or greater, and $\tau \ll 1$. These correspond to Case 1a unfoldings for all four types of cellular convection patterns considered. However, the possibility exists, at least mathematically, that rectangles, squares and hexagons can have a different unfolding than the one that rolls must have. This is implied by our previous results in Part I and II.

For parameter values σ and τ such that $a_2'=0$ or $b_2'=0$, the normal form (3.1) is inadequate to determine the unfolding of (1.17) about (r_0,s_0), but such values constitute a set of measure zero in the space of parameter values $\sigma>0$, $0<\tau<1$.

4. Conclusion. We have studied bifurcations which occur in a system of equations describing double-diffusive convection in a layer of fluid. The partial differential equations were expressed as a single abstract evolution equation in an infinite-dimensional Hilbert space corresponding to two-dimensional roll-like convection cells, or three-dimensional convection cells with rectangular, square, or hexagonal plan-forms. At the critical parameter values r_0 and s_0 for which the linear part of the equation has a

double zero eigenvalue, the infinite-dimensional equation was reduced to a finite dimensional one by means of center manifold theorem. The resulting equation was then further reduced to a normal form, from which one obtains a complete description of the local bifurcations which occur in the double-diffusive convection equations, for almost all $\sigma < 0$ and $0 < \tau < 1$. The bifurcations take place in a phase space that corresponds to a single type of cellular convection pattern. We have found that the three-dimensional convection patterns can have different bifurcations from those associated with two-dimensional roll-like convection.

Our result for rolls agrees with that of [7], who applied perturbation methods to a system of ordinary differential equations obtained from the partial differential equations by modal truncation. In addition, our result was obtained via center manifold and normal form reductions, and so no other bifurcation behavior occurs locally. One cannot conclude this from the perturbation methods alone. Numerical studies of the same ordinary differential equations show that the bifurcation results obtained locally actually extend to parameter values some distance away from the critical ones which give the double zero eigenvalue [2]. A related problem of thermally driven convection in a rotating fluid layer was treated by [4]. Center manifold and normal form reductions were applied to a similar system of ordinary differential equations resulting from modal truncation. The normal form used was the same as (3.1), and the same case of unfoldings were present. All three papers [7], [2] and [4] treated only two-dimensional roll-like convection, and in all three papers a system of partial differential equations was first reduced to a system of ordinary differential equations by means of a modal truncation.

SECONDARY BIFURCATIONS OF A THIN ROD UNDER AXIAL COMPRESSION*

ERNESTO BUZANO†

Abstract. We study the post-buckling behavior of a prismatic rod with rectangular cross-section, under axial compression. We employ the nonlinear rod theory stated in [2]. Let δ be the difference between the sides of the cross-section. When $\delta \neq 0$ there are two distinct eigenvalues which coalesce when $\delta = 0$ and the cross-section becomes a square. By employing equivariant singularity theory [4], we unfold the bifurcation problem corresponding to $\delta = 0$ and study also the case $\delta \neq 0$. We obtain bifurcation diagrams with second bifurcations when $\delta \neq 0$.

Introduction. A fruitful way of studying secondary bifurcation problems is that of forcing two eigenvalues to coincide by varying some parameter of the problem and then unfolding the multiple eigenvalue so obtained. This technique, due to Bauer, Keller and Reiss [11], has been coupled with singularity theory by Schaeffer and Golubitsky in [9], where they give an explanation of the phenomenon of mode-jumping observed experimentally in the post-buckling behavior of a rectangular plate under compression. Other applications are given in [3] and [10].

Here we apply this procedure to the study of secondary bifurcations of a prismatic rod with rectangular cross-section. Let δ be the difference between the sides of the cross-section. When $\delta \neq 0$ there are two distinct eigenvalues which coalesce when $\delta = 0$ and the cross-section becomes a square. In this last case we can apply the results obtained in [2], where the bifurcation problem has been reduced to finite dimension. The problem obtained in this way has topological codimension 1 in the module of the mappings which commute with the symmetries of the rectangle. Therefore it is possible to unfold it and study also the case $\delta \neq 0$. The bifurcation diagrams we obtain are given at the end of the paper. They show that secondary bifurcations occur when $\delta \neq 0$.

The classical rod model, based on linear constitutive equations (see for example [6] or [7]), has infinite codimension in our context. We reduce our problem to finite codimension by employing the nonlinear rod theory stated in [2].

Evidence for secondary bifurcations of a prismatic rod has also been obtained by Kovari in [5], by using elliptic functions and numerical computations. However these bifurcations do not coincide with ours because they concern the case $\delta = 0$ where we do not obtain secondary bifurcations.

1. Geometry of the deformation. In [2, Chap. 1] a simple nonlinear director theory has been employed to understand the effects of the symmetry of the cross-sections on the post-buckling behavior of a thin rod under axial compression. This theory is a special case of a more general situation studied in [1], but it relies upon a weaker transverse isotropy condition in order to distinguish between rods with polygonal and circular cross-section. Here we recall briefly such a theory in the case of a rectangular cross-section. The reader should refer to [2, Chap. 1] for the details.

We denote by $\mathscr{C}$ the *axis* of the rod, that is the line of centroids of the cross-sections. We assume that $\mathscr{C}$ is of length 1 and parametrize $\mathscr{C}$ by arc-length $s \in [0,1]$. Throughout the paper we set $J = [0,1]$ and denote by a dash the derivative with respect

* Received by the editors July 19, 1984, and in final revised form November 16, 1984.
† Dipartimento di Matematica, Università di Torino, Via Carlo Alberto 10, 10123 Torino, Italy.

to $s \in J$. Let us consider a right-handed orthonormal reference frame $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ fixed in space. We assume that the rod is naturally straight with the end $s=0$ at the origin and its axis $\mathscr{C}$ along the direction $\mathbf{e}_3$. We take such a configuration as a *reference configuration*. We describe the *deformed configuration* by three vector functions $\mathbf{r}$, $\mathbf{a}_1$, $\mathbf{a}_2$ of the variable $s \in J$, such that $\mathbf{r}(s)$ is the *position vector* joining the origin $t=0$ and the centroid $t=s$, and $\mathbf{a}_1(s)$, $\mathbf{a}_2(s)$ are two orthonormal vectors fixed flat to the cross-section Σ through the centroid s. Define

$$\mathbf{a}_3(s) = \mathbf{a}_1(s) \times \mathbf{a}_2(s),$$

and assume that the rod can suffer neither extension nor shear; that is that (Kirchhoff hypotheses)

$$\mathbf{r}'(s) = \mathbf{a}_3(s). \tag{1}$$

Let $\mathbf{u}(s)$ be the unique vector satisfying

$$\mathbf{a}_j'(s) = \mathbf{u}(s) \times \mathbf{a}_j(s), \qquad j = 1, 2, 3.$$

Let

$$\mathbf{r}(s) = \sum_{i=1}^{3} x_i(s)\mathbf{e}_i$$

and

$$\mathbf{u}(s) = \sum_{i=1}^{3} u_i(s)\mathbf{a}_i(s).$$

In our theory u_j are the *strains*. From (1) we have

$$x_3'(s) = \left[1 - \left(x_1'^2(s) + x_2'^2(s)\right)\right]^{1/2}. \tag{2}$$

Let θ, ψ, ϕ be the (English) Euler angles describing the rotation of $\{\mathbf{a}_i(s)\}$ with respect to $\{\mathbf{e}_i\}$ (see [7, Article 253]), and let

$$\alpha = \frac{\pi}{2} - (\psi + \phi);$$

then it is easy to compute u_j in terms of x_1', x_2' and α, obtain (see [2, §1.1]):

$$\begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} = \begin{bmatrix} \cos\alpha & -\sin\alpha & 0 \\ \sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} x_1'' - \dfrac{x_1' x_3''}{1 + x_3'} \\ x_2'' - \dfrac{x_2' x_3''}{1 + x_3'} \\ -\alpha' + \dfrac{x_1'' x_2' - x_1' x_2''}{1 + x_3'} \end{bmatrix}. \tag{3}$$

Actually it is easy to realize that $\{\mathbf{a}_i(s)\}$ can be obtained from $\{\mathbf{e}_i\}$ by rotation $-\alpha$ around the $\mathbf{e}_3$-axis (torsion) followed by rotation around an axis in the $(\mathbf{e}_1, \mathbf{e}_2)$-plane and taking $\mathbf{e}_3$ onto $\mathbf{a}_3(s)$ (flexure). This makes it clearer that the state of the strain may be described purely in terms of x_1, x_2 and α.

2. Deformation energy. Following the usual director approach (see [1] and [2]), we assume that the *deformation energy* is given by

$$\int_0^1 \mathcal{W}(\mathbf{u}(s))\,ds, \tag{4}$$

where $\mathcal{W}$ is a smooth function such that $\mathcal{W}(0)=0$ and satisfying suitable symmetry hypotheses, which we describe below. We assumed that $\mathcal{W}$ does not depend explicitly on s; this means that the cross-sections do not depend on s, that is that the rod is *prismatic*. As we said above, $\mathcal{W}$ satisfies also suitable symmetry conditions which reflect the geometry of the cross-section. More precisely, the usual Kirchhoff transverse isotropy conditions state that if the principal moments of inertia of the cross-section are equal, then $\mathcal{W}$ is invariant with respect to the action of $\mathbb{O}(2)\oplus\mathbb{Z}_2\subset\mathbb{O}(3)$ on (u_1,u_2,u_3), defined by

$$(\gamma,\varepsilon)\cdot\mathbf{u}=\begin{bmatrix}\gamma_{11} & \gamma_{12} & 0\\ \gamma_{21} & \gamma_{22} & 0\\ 0 & 0 & \varepsilon\end{bmatrix}\cdot\begin{bmatrix}u_1\\ u_2\\ u_3\end{bmatrix},$$

where $\gamma=[\gamma_{jk}]$ is an orthogonal matrix and $\varepsilon=\pm 1$. The invariance of $\mathcal{W}$ with respect to the second summand, i.e. to $\mathbb{Z}_2$, represents indifference with respect to left-handed and right-handed twist. As regards the first summand, i.e. $\mathbb{O}(2)$, we already pointed out in [2, §1.2], that this hypothesis does not take completely into account the geometry of the cross-section Σ. For example, if Σ is a regular n-gon, its group of symmetries is $\mathbb{D}_n$ rather than $\mathbb{O}(2)$; thus it is more natural to *assume that $\mathcal{W}$ is invariant only under the action of $\Gamma_\Sigma\oplus\mathbb{Z}_2\subset\mathbb{O}(3)$, where Γ_Σ is the subgroup of $\mathbb{O}(2)$ which leaves invariant the cross-section Σ*. As we already said, if Σ is a regular n-gon we have $\Gamma_\Sigma=\mathbb{D}_n$; while if Σ is a rectangle, then $\Gamma_\Sigma=\mathbb{Z}_2\oplus\mathbb{Z}_2$.

Let us assume that the cross-section Σ is a rectangle with sides $2b_1$ and $2b_2$ as in Fig. 1. Define by $\delta=b_2-b_1$ the *aspect* of the cross-section. When $\delta=0$, Σ becomes a

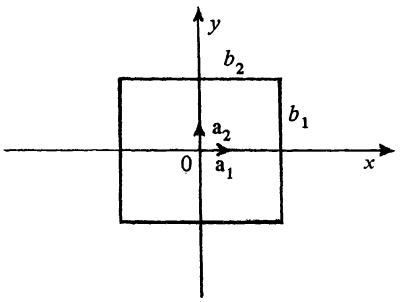

FIG. 1

square. On the ground of what we said above, *we assume that $\mathcal{W}$ is a smooth function of* $\mathbf{u}$ *and* δ, *invariant with respect to the action of $\mathbb{Z}_2\oplus\mathbb{Z}_2\oplus\mathbb{Z}_2$ when $\delta\neq 0$ and with respect to the action of $\mathbb{D}_4\oplus\mathbb{Z}_2$ when $\delta=0$*. Hence $\mathcal{W}$ is an invariant of the reflections $u_j\to -u_j$, $j=1,2,3$; thus, in a similar way as in [2, Prop. 1.13] one can prove that $\mathcal{W}$ depends on u_j^2 only. Therefore there exists a smooth function K such that

$$\mathcal{W}(\mathbf{u},\delta)=K\left(u_1^2,u_2^2,u_3^2,\delta\right). \tag{5}$$

Of course when $\delta=0$, that is the cross-section Σ is a square, K must also be an invariant of the rotation $\pi/2$ in the plane $u_3=0$; therefore by [2, Prop. 1.13] (with $n=4$) there exists a smooth function H such that

$$K(u_1^2,u_2^2,u_3^2,0)=H(\tau_1,\tau_2,\tau_3), \tag{6}$$

where $\tau_1=u_1^2+u_2^2$, $\tau_2=u_1^4-6u_1^2u_2^2+u_2^4$, $\tau_3=u_3^2$. In the following we shall write:

$$K(u^2,\delta)=K(u_1^2,u_2^2,u_3^2,\delta), \qquad H(\tau)=H(\tau_1,\tau_2,\tau_3).$$

Naturally if we expand K up to first order, we must obtain the classical quadratic energy of a rod (see [6, §18]):

$$K(u^2,\delta)=\frac{E_0}{2}\big(I_1(\delta)u_1^2+I_2(\delta)u_2^2\big)+\frac{C(\delta)}{2}u_3^2+\text{h.o.t.}, \tag{7}$$

where E_0 is the Young modulus, $I_1(\delta)$ and $I_2(\delta)$ are the principal moments of inertia of the cross-section and $C(\delta)$ is the torsional rigidity. It is possible to verify by a direct computation (a bit long for $C(\delta)$) that I_1, I_2 and C depend smoothly on δ, that is consistent with our assumptions on K. Moreover the following is true:

$$I_1(\delta)<I_2(\delta) \quad \text{if and only if} \quad \delta<0. \tag{8}$$

3. The variational problem. We can now give the *energy functional* f to be (locally) minimised by the rod. We hold fixed the end $s=0$ and apply a *terminal load force* P along the axis of the rod at the end $s=1$. Thus the *total energy* of the rod is the deformation energy minus the work done by P in moving along its line of action. The end $s=1$ moves ($x_3(0)=0$):

$$1-x_3(1)=\int_0^1\big(1-x_3'(s)\big)\,ds.$$

Thus from (4) and (5) we have

$$f(x_1,x_2,\alpha,P,\delta)=\int_0^1\big\{K(u^2(s),\delta)-P\big(1-x_3'(s)\big)\big\}\,ds. \tag{9}$$

We consider the rod clamped at both ends; that is satisfying the following set of boundary conditions:

$$x_1(0)=x_1(1)=x_2(0)=x_2(1)=0, \tag{10}$$

$$x_1'(0)=x_1'(1)=x_2'(0)=x_2'(1)=0, \tag{11}$$

$$\alpha(0)=\alpha(1)=0. \tag{12}$$

Conditions (11) and (12) mean that the ends $s=0$ and $s=1$ cannot rotate. In particular it is possible to prove that boundary conditions (10) to (12) correspond to have (see [2, §1.2])

$$\mathbf{a}_1(0)=\mathbf{a}_1(1)=\mathbf{e}_2, \quad \mathbf{a}_2(0)=\mathbf{a}_2(1)=-\mathbf{e}_1, \quad \mathbf{a}_3(0)=\mathbf{a}_3(1)=\mathbf{e}_3,$$

which fix the position of the rod in the unstressed state.

In order to state our variational problem, define the following Banach space

$$X=C_0^2(J)\times C_0^2(J)\times C_0^1(J),$$

where $C_0^k(J)=\{g:J\to\mathbb{R}\mid g$ is continuous with its derivatives $g^{(j)}$ for $0\leqq j\leqq k$ and $g^{(j)}(0)=g^{(j)}(1)=0$, for $0\leqq 2j\leqq k\}$. Moreover $C_0^k(J)$ is equipped with the maximum norm $|g_k|=\sup\{|g^{(j)}(s)|:s\in J$ and $0\leqq j\leqq k\}$ and X with the product-norm $\|x\|_X$. We denote by $x=(x_1,x_2,\alpha)$ the elements of X. Let

$$\Omega=\left\{(x,P,\delta)\in X\times\mathbb{R}\times\mathbb{R}\mid\sup_{s\in J}\left(x_1'^2(s)+x_2'^2(s)<1\right)\right\}.$$

It is easy to see that Ω is open and that by (2) and (3) we have $f\in C^\infty(\Omega,\mathbb{R})$.

The equilibria of the rod are given by the critical points with respect to $x\in X$ of the energy functional $f:\Omega\to\mathbb{R}$. In particular we are interested in (statically) *stable equilibria*, which correspond to (strict) *minima* of f. Let

$$P_j(\delta)=4\pi^2E_0I_j(\delta)=E_0I_j(\delta)\inf_{\phi\in C_0^2(J)}\frac{\int_0^1\phi''^2\,ds}{\int_0^1\phi'^2\,ds},\qquad j=1,2. \tag{13}$$

PROPOSITION 1. *For each $P\in\mathbb{R}$ and $\delta\in\mathbb{R}$, the unstressed configuration $(x_1,x_2,\alpha)=(0,0,0)$ is a critical point of the energy functional f. For $P<\inf\{P_1(\delta),P_2(\delta)\}$ the unstressed configuration $(0,0,0)$ corresponds to a strict (local) minimum of the energy functional f and hence to a stable equilibrium. Finally the second derivative $D_x^2f(0,P,\delta)$ is a degenerate quadratic form for $P=P_j(\delta)$, $j=1,2$.*

Proof. From (9), (5), (7), (3) and (2) one can compute easily the second derivative at $(0,P,\delta)$:

$$D_x^2f(0,P,\delta)[x,x]=\int_0^1\left\{E_0\left(I_1(\delta)x_1''^2+I_2(\delta)x_2''^2\right)+C(\delta)\alpha'^2-P\left(x_1'^2+x_2'^2\right)\right\}ds$$

and the result follows immediately. □

From Proposition 1 it follows immediately that $(0,P_j(\delta),\delta)$, $j=1,2$ are possible bifurcation points for f. On the other hand we have $P_1(0)=P_2(0)$, consequently it makes sense to state the following *perturbed variational bifurcation problem*: *find the number of (stable) critical points of f for (x,P,δ) near $(0,P_0,0)$, where $P_0=P_1(0)=P_2(0)$.*

4. Bifurcation analysis. In order to solve the problem stated above, we first reduce it to finite dimension, then we employ singularity theory. By applying Magnus' splitting lemma (see [2, Thm. 2.1] and [8]), we reduce the functional f to a function $\tilde f$ on a finite dimensional space in the same way as we did in [2]. Here we outline the reduction steps, referring to [2, Chap. 2] for the details. Let $I_0=I_1(0)=I_2(0)$; then $P=P_0$ $(=P_1(0)=P_2(0))$ is the first eigenvalue of the boundary-value problem

$$\begin{aligned}&E_0I_0\phi^{(4)}-P\phi''=0,\\&\phi(0)=\phi(0)=0,\\&\phi'(0)=\phi'(0)=0.\end{aligned}$$

The relevant eigenfunction is $\phi_0(s)=1-\cos 2\pi s$. Let

$$V=\left\{(\eta_1\phi_0(s),\eta_2\phi_0(s),0)\in X\mid\eta_1,\eta_2\in\mathbb{R}\right\}.$$

Define the Banach space

$$Y=C^0(J)\times C^0(J)\times C^0(J),$$

where $C^0(J)=\{g: J\to\mathbb{R} \mid g \text{ is continuous}\}$ and the continuous linear mapping $\omega: Y\to X^*$ (where X^* is the dual space to X) by

$$\langle y,x\rangle=\sum_{j=1}^{2}\int_0^1 y_j x_j''\,ds+\int_0^1 y_3\alpha'\,ds,$$

where $x=(x_1,x_2,\alpha)\in X$ and $y=(y_1,y_2,y_3)\in Y$ and $\langle\cdot,\cdot\rangle$ is the duality between X^* and X. Define $F:\Omega\to Y$ by

$$F(x,P,\delta)=\Bigg(\sum_{j=1}^{3}\left(K_{,u_j}u_{j,x_1''}-\int_0^1 K_{,u_j}u_{j,x_1'}\,dt\right)+P\int_0^1\left(1-x_3'\right)_{,x_1'}dt,$$

$$\sum_{j=1}^{3}\left(K_{,u_j}u_{j,x_2''}-\int_0^1 K_{,u_j}u_{j,x_2'}\,dt\right)+P\int_0^1\left(1-x_3'\right)_{,x_2'}dt,$$

$$\sum_{j=1}^{3}\left(K_{,u_j}u_{j,\alpha'}-\int_0^1 K_{,u_j}u_{j,\alpha}\,dt\right)\Bigg),$$

where a subscript following a comma indicates partial differentiation. We have $F\in C^\infty(\Omega, Y)$. Moreover, by an integration by parts one verifies that

$$D_x f(x,P,\delta)[\hat{x}]=\langle F(x,P,\delta),\,\hat{x}\rangle.$$

Let

$$T=D_x F(0,P_0,0).$$

Following the same steps as in [2, §2.3], we obtain that:

1) There exist decompositions $X=V\oplus Z$ and $Y=W\oplus Q$ such that $V=T^{-1}W$ and $T_{|Z}: Z\to Q$ is an isomorphism.

2) There exists a neighborhood U of $(0,P_0,0)\in X\times\mathbb{R}\times\mathbb{R}$ such that:

a) There exists a smooth mapping $h: U'\to Z$, with $U'=U\cap(V\times\mathbb{R}\times\mathbb{R})$, which is the unique solution $z=h(v,P,\delta)$ of the equation

$$P_Q F(v\oplus z,P,\delta)=0,$$

where P_Q is the orthogonal projection onto Q.

b) If we let $\eta=(\eta_1,\eta_2)\in\mathbb{R}^2$, $v=(\eta_1\phi_0,\eta_2\phi_0,0)\in V$, $\lambda=P-P_0$ and $\tilde{f}(\eta,\lambda,\delta)=f(v\oplus h(v,P,\delta),\,P,\delta)$, then

$$(\eta,\lambda,\delta)\to(v\oplus h(v,P,\delta),\,P,\delta)$$

defines a one-to-one and onto correspondence between the critial points of $\tilde{f}(\eta,\lambda,\delta)$ in U' and those of f in U. Moreover this correpondence preserves the minima.

3) $\tilde{f}(\eta,\lambda,\delta)$ is an invariant of the action of $\mathbb{Z}_2\oplus\mathbb{Z}_2$ on $\mathbb{R}^2$ generated by the symmetries $(\eta_1,\eta_2)\to(-\eta_1,\eta_2)$ and $(\eta_1,\eta_2)\to(\eta_1,-\eta_2)$.

In this way we reduce our problem to finding the number of (stable) critical points of $\tilde{f}$ for fixed λ and for (η,λ,δ) near $(0,0,0)$. This is equivalent to solving the following perturbed bifurcation problem:

$$G(\eta,\lambda,\delta)=0, \tag{14}$$

where $G = D_\eta \tilde{f}$, λ is the bifurcation parameter and δ is the perturbation parameter. Of course the minima of $\tilde{f}$, i.e., the (statically) stable equilibria, correspond to *positive* eigenvalues of the Jacobian matrix $D_\eta G$. Finally we have that the invariance of $\tilde{f}$ forces G to be $\mathbb{Z}_2 \oplus \mathbb{Z}_2$-equivariant i.e.:

$$G_1(-\eta_1, \eta_2, \lambda, \delta) = -G_1(\eta_1, \eta_2, \lambda, \delta),$$
$$G_2(-\eta_1, \eta_2, \lambda, \delta) = G_2(\eta_1, \eta_2, \lambda, \delta),$$

and

$$G_1(\eta_1, -\eta_2, \lambda, \delta) = G_1(\eta_1, \eta_2, \lambda, \delta),$$
$$G_2(\eta_1, -\eta_2, \lambda, \delta) = -G_2(\eta_1, \eta_2, \lambda, \delta),$$

where $G_j = \partial \tilde{f} / \partial \eta_j$, $j = 1, 2$.

In order to study the bifurcation problem (14), we employ, in the case of the symmetry group being $\mathbb{Z}_2 \oplus \mathbb{Z}_2$, the theory formulated in [4]. Recall briefly that two bifurcation problems G and $\hat{G}$ are $\mathbb{Z}_2 \oplus \mathbb{Z}_2$-equivalent if (see again [4, §§1 and 4])

$$\hat{G}(\eta, \lambda) = T(\eta, \lambda) G(E(\eta, \lambda), L(\lambda))$$

for some smooth family of invertible matrices T and a smooth diffeomorphism $(\eta, \lambda) \to (E(\eta, \lambda), L(\lambda))$ such that $(\partial L / \partial \lambda)(0) > 0$. Moreover we require that T and E be $\mathbb{Z}_2 \oplus \mathbb{Z}_2$-equivariant. It is easy to see that such an equivalence preserves the number of solutions for fixed λ, which is the information we are looking for.

Coming back to our problem, we have that in [2, Thm. 5.13] we have proven that if the function H in (6) is such that $(\partial H / \partial \tau_2)(0) \neq 0$ and the rod is prismatic, then $G(\eta, \lambda, 0)$ is $\mathbb{D}_4$-equivalent, hence $\mathbb{Z}_2 \oplus \mathbb{Z}_2$-equivalent, to

$$(A\eta_1^2 + \eta_2^2) - \lambda \begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix} + \varepsilon \begin{bmatrix} \eta_1^3 - 3\eta_1\eta_2^2 \\ \eta_2^3 - 3\eta_1^2\eta_2 \end{bmatrix} = 0, \tag{15}$$

where $A > 1$ and $\varepsilon = [\operatorname{sgn}(\partial H / \partial \tau_2)(0)]1$. Moreover the above equivalence preserves the signature of the real part of the eigenvalues of $D_\eta G$, that is the stability assignments of the solutions. This essentially solves our problem for $\delta = 0$.

It is worthwhile to remark that if H does not depend on τ_2 (and so in particular $(\partial H / \partial \tau_2)(0) = 0$) then one can prove that $g(\eta, \lambda, 0)$ has infinite $\mathbb{Z}_2 \oplus \mathbb{Z}_2$-codimension and our analysis fails. This is the main reason to consider nonlinear constitutive equations in our model.

Now we study $G(\eta, \lambda, \delta) = 0$ for δ near 0. Rewrite (15) as

$$\begin{bmatrix} (A+\varepsilon)\eta_1^3 + (A-3\varepsilon)\eta_1\eta_2^2 - \lambda\eta_1 \\ (A-3\varepsilon)\eta_1^2\eta_2 + (A+\varepsilon)\eta_2^3 - \lambda\eta_2 \end{bmatrix} = 0, \tag{16}$$

then multiply (16) by the matrix

$$\begin{bmatrix} \sqrt{A+\varepsilon} & 0 \\ 0 & \sqrt{A+\varepsilon} \end{bmatrix}$$

and divide η_j by $\sqrt{A+\varepsilon}$. We obtain that (16) is $\mathbb{Z}_2 \oplus \mathbb{Z}_2$-equivalent to

$$\begin{bmatrix} \eta_1^3 + \mu\eta_1\eta_2^2 - \lambda\eta_1 \\ \nu\eta_1^2\eta_2 + \eta_2^3 - \lambda\eta_2 \end{bmatrix} = 0, \tag{17}$$

with

$$\mu=\nu=\frac{A-3\varepsilon}{A+\varepsilon}. \tag{18}$$

Now (17) is a *double cusp bifurcation problem* and has been studied in [4, §4] and in [9, §6]. If it satisfies the nondegeneracy conditions

$$\mu\neq 1, \quad \nu\neq 1, \quad \mu\nu\neq 1, \tag{19}$$

it has universal unfolding

$$\begin{bmatrix} \eta_1^3+\tilde{\mu}\eta_1\eta_2^2-\lambda\eta_1 \\ \tilde{\nu}\eta_1^2\eta_2+\eta_2^3-(\lambda+a)\eta_2 \end{bmatrix}=0, \tag{20}$$

with $\tilde{\mu}$ and $\tilde{\nu}$ near μ and ν and a near 0. The Universal Unfolding Theorem (see [4, Thm. 1.8]) says that $G(\eta,\lambda,\delta)$ factors through (20), that is that there exists a smooth mapping $\delta\to(\tilde{\mu}(\delta),\tilde{\nu}(\delta),a(\delta))$ such that for each δ near 0, G and (20) are $\mathbb{Z}_2\oplus\mathbb{Z}_2$-equivalent. Now the nondegeneracy conditions (19) split the (μ,ν)-plane into 7 regions such that for fixed a all the bifurcation diagrams inside each region are topologically equivalent (see [9, §6]). Now if $(\tilde{\mu}(\delta),\ \tilde{\nu}(\delta))$ belongs to one of these regions for $\delta=0$, it will stay there also for each small $\delta\neq 0$. It follows that for a given δ our problem is associated to one of the regions according to the value of $\tilde{\mu}(0)$ and $\tilde{\nu}(0)$. Finally in each region there are three different diagrams according as $a(\delta)\lesseqgtr 0$ (see [9, §6]). Now for

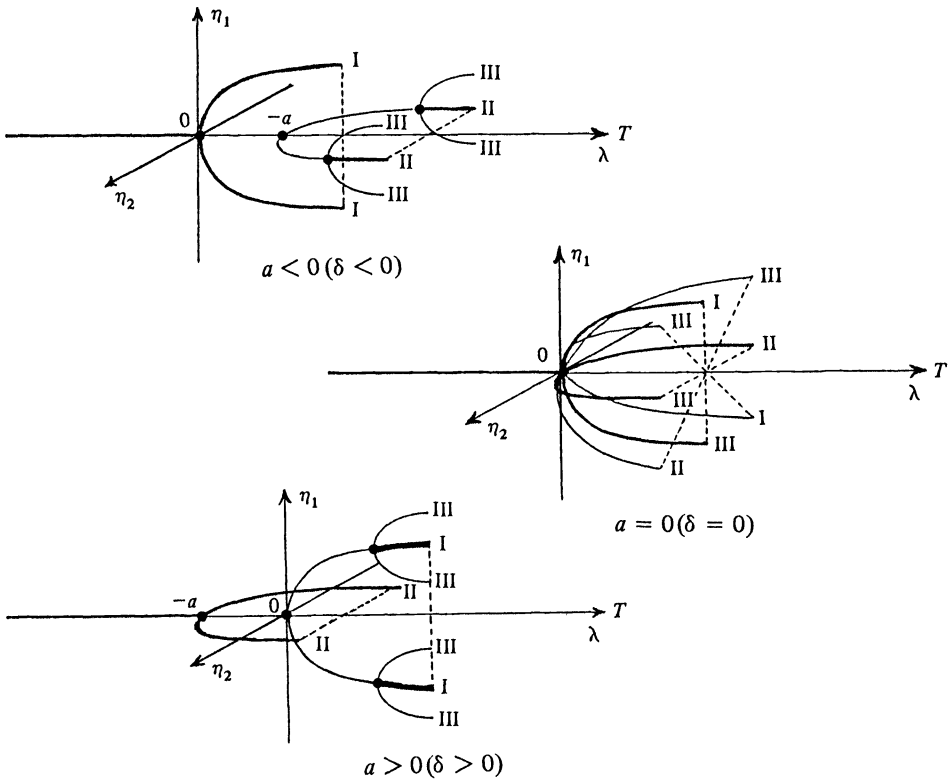

FIG. 2

our problem we have $\tilde{\mu}(0)=\tilde{\nu}(0)=(A-3\varepsilon)/(A+\varepsilon)$, thus there are only two possibilities: $(A-3\varepsilon)/(A+\varepsilon)\lesseqgtr 1$, corresponding to $\varepsilon=\pm 1$. So we have inspected all the possible cases and we are able to give the bifurcation diagrams. However, first we prefer to make some observations:

1) The bifurcation diagrams relate only to the number of solutions for fixed λ, their stability and their buckling features, as explained below.

2) As we did in [2, §§3.4 and 5.3], we can classify the solutions in three types, besides the trivial ones, according to their symmetry group and the kind of buckling the rod undergoes; see Table 1.

TABLE 1

Solution type	Symmetry group	Buckling
T	$\mathbb{Z}_2\oplus\mathbb{Z}_2$	trivial equilibrium
I	$\mathbb{Z}_2$ (reflection through η_2-axis)	in the plane $x_2=0$
II	$\mathbb{Z}_2$ (reflection through η_1-axis)	in the plane $x_1=0$
III	$\{1\}$	spatial

2) Table 1 allows us to relate the sign of a to the sign of δ. In fact $-a$ is the bifurcation point of solutions of type II and this is negative if and only if the rod buckles first in the plane $x_1=0$. Now by Proposition 1 this happens if and only if $P_2(\delta)<P_1(\delta)$, that is if and only if $\delta>0$, by (8) and (13).

5. Bifurcation diagrams. In the diagrams in Figs. 2 and 3 we draw stable equilibria (i.e. minima) in heavy black.

EXACT BOUNDARY CONDITIONS AT AN ARTIFICIAL BOUNDARY FOR PARTIAL DIFFERENTIAL EQUATIONS IN CYLINDERS*

THOMAS HAGSTROM† AND H. B. KELLER‡

Abstract. The numerical solution of partial differential equations in unbounded domains requires a finite computational domain. Often one obtains a finite domain by introducing an artificial boundary and imposing boundary conditions there. This paper derives exact boundary conditions at an artificial boundary for partial differential equations in cylinders. An abstract theory is developed to analyze the general linear problem. Solvability requirements and estimates of the solution of the resulting finite problem are obtained by use of the notions of exponential and ordinary dichotomies. Useful representations of the boundary conditions are derived using separation of variables for problems with constant tails. The constant tail results are extended to problems whose coefficients obtain limits at infinity by use of an abstract perturbation theory. The perturbation theory approach is also applied to a class of nonlinear problems. General asymptotic formulas for the boundary conditions are derived and displayed in detail.

Key words. artificial boundary conditions, asymptotic expansions for PDE's

1. Introduction. Many of the boundary value problems arising in applied mathematics are given on unbounded domains. Examples include the problems of fluid flow and wave propagation in channels or past bodies. The numerical solution of these problems, however, requires a finite domain. In this paper, we develop a theory for the exact reduction of a boundary value problem for a partial differential equation on an unbounded cylindrical domain to a problem on a bounded domain. That is, an "artifical" boundary is introduced and the proper boundary condition to be imposed there is derived. In other works, [8] and [9], we use our theory to solve nonlinear problems of both elliptic and parabolic type.

For ordinary differential equations, exact reduction theories have been developed by many authors: de Hoog and Weiss [5], Keller and Lentini [11], Jepson and Keller [10] and Markowich [12]. Few works on artificial boundary conditions for partial differential equations, on the other hand, have discussed exact conditions. An exception is the paper of Gustafsson and Kreiss [6], where the form of the proper conditions for a general hyperbolic problem is derived. They go on to find representations of the exact conditions in various simple cases for problems of both hyperbolic and elliptic type.

We illustrate the derivation of exact conditions with the following example:

$$
\begin{aligned}
&\text{a)} \quad \nabla^2 u + a(x,\mathbf{y})u = f(x,\mathbf{y}), \quad (x,\mathbf{y}) \in [0,\infty)\times\Omega, \quad \Omega \subset R^{n-1},\\
&\text{b)} \quad c(x,\mathbf{y})\frac{\partial u}{\partial \nu}(x,\mathbf{y}) + d(x,\mathbf{y})u(x,\mathbf{y}) = \gamma_\Omega(x,\mathbf{y}), \qquad \mathbf{y} \in \partial\Omega,\\
&\text{c)} \quad \alpha(\mathbf{y})\frac{\partial u}{\partial x}(0,\mathbf{y}) + b(\mathbf{y})u(0,\mathbf{y}) = \gamma_0(\mathbf{y}), \qquad \mathbf{y} \in \Omega,\\
&\text{d)} \quad \lim_{x\to\infty} u(x,\mathbf{y}) = 0,\\
&\text{e)} \quad c(x,\mathbf{y}) = c_\infty(\mathbf{y}), \quad d(x,\mathbf{y}) = d_\infty(\mathbf{y}), \quad a(x,\mathbf{y}) = a_\infty(\mathbf{y}), \quad x \geqq x_0,\\
&\qquad f(x,\mathbf{y}) = \gamma_\Omega(x,\mathbf{y}) = 0, \qquad x \geqq x_0.
\end{aligned} \tag{1.1}
$$

‡Applied Mathematics, California Institute of Technology, Pasadena, California 91125.

(We say that (1.1) has a constant tail, due to condition (1.1e).) We choose some point $x=\tau \geqq x_0$ as the location of the artificial boundary. In the "tail", $x \geqq \tau$, we have:

$$
\begin{aligned}
&\text{a)} \quad \nabla^2 u + a_\infty(\mathbf{y})u = 0, \qquad (x,\mathbf{y}) \in [\tau,\infty)\times\Omega; \\
&\text{b)} \quad c_\infty(\mathbf{y})\frac{\partial u}{\partial \nu}(x,\mathbf{y}) + d_\infty(\mathbf{y})u(x,\mathbf{y}) = 0, \qquad \mathbf{y}\in\partial\Omega; \\
&\text{c)} \quad \lim_{x\to\infty} u(x,\mathbf{y}) = 0.
\end{aligned} \tag{1.2}
$$

Problem (1.2) can be easily analyzed by separation of variables. Consider the following eigenvalue problem:

$$
\begin{aligned}
&\text{a)} \quad \nabla_{\mathbf{y}}^2 Y_n(\mathbf{y}) + a_\infty(\mathbf{y})Y_n(\mathbf{y}) = \omega_n Y_n(\mathbf{y}), \qquad \mathbf{y}\in\Omega, \\
&\text{b)} \quad c_\infty(\mathbf{y})\frac{\partial}{\partial \nu}Y_n(\mathbf{y}) + d_\infty(\mathbf{y})Y_n(\mathbf{y}) = 0, \qquad \mathbf{y}\in\partial\Omega; \\
&\text{c)} \quad \int_\Omega d\mathbf{y}\, Y_n^2(\mathbf{y}) = 1.
\end{aligned} \tag{1.3}
$$

Given certain assumptions on the boundary condition, (1.3b), the set of eigenfunctions, $\{Y_n\}$, is complete in that subspace of $L_2(\Omega)$ consisting of functions satisfying it. (See Berezanskii [3].) For simplicity, we further assume that the ω_n are distinct and that $\omega_n = 0$ is not an eigenvalue. We rewrite the $\{\omega_n\}$ in the following way:

$$
\begin{aligned}
&\omega_n = \alpha_n^2 > 0, \qquad n = 1,\cdots,m, \\
&\omega_n = -\lambda_n^2 < 0, \qquad n = m+1,\ m+2,\cdots.
\end{aligned} \tag{1.4}
$$

Expanding u in terms of the Y_n's,

$$
u(x,\mathbf{y}) = \sum_{n=1}^{\infty} c_n(x)Y_n(\mathbf{y}) \tag{1.5}
$$

problem (1.2) becomes:

$$
\begin{aligned}
&\text{a)} \quad c_n'' = \begin{cases} -\alpha_n^2 c_n, & n = 1,\cdots,m, \\ \lambda_n^2 c_n, & n = m+1,\ m+2,\cdots, \end{cases} \qquad x\in[\tau,\infty); \\
&\text{b)} \quad \lim_{x\to\infty} c_n(x) = 0, \qquad n = 1,2,\cdots.
\end{aligned} \tag{1.6}
$$

As (1.6a) can be trivially solved, we see that (1.6b) is satisfied if and only if:

$$
\begin{aligned}
&\text{a)} \quad c_n(\tau) = c_n'(\tau) = 0, \qquad n = 1,\cdots,m; \\
&\text{b)} \quad c_n'(\tau) = -\lambda_n c_n(\tau), \qquad n = m+1,\ m+2,\cdots.
\end{aligned} \tag{1.7}
$$

This allows us to replace (1.1) by an equivalent finite domain problem:

$$
\begin{aligned}
&\text{a)} \quad \nabla^2 u + a(x,\mathbf{y})u = f(x,\mathbf{y}), \quad (x,\mathbf{y})\in[0,\tau]\times\Omega; \\
&\text{b)} \quad c(x,\mathbf{y})\frac{\partial u}{\partial \nu}(x,\mathbf{y}) + d(x,\mathbf{y})u(x,\mathbf{y}) = \gamma_\Omega(x,\mathbf{y}), \quad \mathbf{y}\in\partial\Omega; \\
&\text{c)} \quad \alpha(\mathbf{y})\frac{\partial u}{\partial x}(0,\mathbf{y}) + b(\mathbf{y})u(0,\mathbf{y}) = \gamma_0(\mathbf{y}), \quad \mathbf{y}\in\Omega; \\
&\text{d)} \quad \int_\Omega d\mathbf{y}\, u(\tau,\mathbf{y})Y_n(\mathbf{y}) = \int_\Omega d\mathbf{y}\frac{\partial u}{\partial x}(\tau,\mathbf{y})Y_n(\mathbf{y}) = 0, \quad n = 1,\cdots,m; \\
&\qquad \int_\Omega d\mathbf{y}\frac{\partial u}{\partial x}(\tau,\mathbf{y})Y_n(\mathbf{y}) = -\lambda_n\int_\Omega d\mathbf{y}\, u(\tau,\mathbf{y})Y_n(\mathbf{y}), \quad n = m+1,\ m+2,\cdots.
\end{aligned} \tag{1.8}
$$

That is, (1.1) has a solution if and only if (1.8) does and the solutions agree on a finite domain.

In §2 of this work we derive boundary conditions for the reduction of a general partial differential equation in a semi-infinite cylindrical domain to a finite one. These turn out to be the requirement that the appropriate data at the artificial boundary lie in a certain affine set. We find it convenient to rewrite the problem as an ordinary differential equation in a Banach space, making transparent the connection between our reduction and the reduction theorems for the case of ordinary differential equations. In §3 we introduce the notion of a dichotomy for our abstract equation and use it to develop error estimates and solvability requirements for the finite problem.

We first consider the problem of representing the boundary conditions in §4. Here separation of variables is used to analyze constant tail problems such as the one presented above. The exact representation we obtain is equivalent to (1.8d) in that case.

We develop a perturbation theory to analyze nonconstant tail problems in §5. Assuming the limiting problem at infinity can be solved by separation of variables, a perturbation expansion of the exact boundary condition can be calculated. We carry out this expansion for the Helmholtz equation exterior to a body, recovering the conditions of Bayliss, Gunzburger and Turkel [2]. Finally, in §6, nonlinear problems are considered. We use the perturbation theory of the preceding section to prove, under certain conditions, the existence of an exact nonlinear boundary condition and to calculate an expansion which approximates it.

We note that many authors have derived boundary conditions for specific problems. We do not, in general, attempt to examine the connection between their conditions and ours. For more discussion of these connections as well as for a more extensive bibliography, the reader is referred to Hagstrom [7].

2. Basic linear reduction theorem. We consider abstract boundary value problems of the form:

$$
\begin{aligned}
&\text{a)} \quad \frac{du}{dx} = A(x)u + f(x), \quad 0 < x < \infty; \\
(2.1)\quad &\text{b)} \quad B_0 u(0) = \gamma_0, \\
&\text{c)} \quad \lim_{x \to \infty} B_\infty u(x) = 0.
\end{aligned}
$$

In addition we may impose:

$$
\text{d)} \quad \| u(x) \| \text{ bounded as } x \to \infty.
$$

For some Banach space, $\mathscr{B}$, we seek $u(x) \in \mathscr{B}$ for $x \in [0, \infty]$. We suppose that $A(x)$, B_0 and B_∞ are linear operators with domain in $\mathscr{B}$, to which we also constrain the range of $A(x)$. Finally, $f(x) \in \mathscr{B}$.

Problems of form (1.1) can be obtained from general partial differential equation problems in cylindrical domains. Specifically we consider

$$
(2.2) \qquad \left(\sum_{j=1}^{n} P_j\left(\mathbf{y}, \mathbf{x}, \frac{\partial}{\partial \mathbf{y}}\right) \frac{\partial^j}{\partial x^j} \right) \omega = g(x, \mathbf{y});
$$

on the cylindrical domain

$$
(x, \mathbf{y}) \in [0, \infty) \times \Omega, \qquad \Omega \subset \mathbf{R}^n.
$$

Homogeneous boundary conditions are imposed on $\partial\Omega$ involving ω and its normal derivatives;

$$\sum_{j=0}^{m} B_{\Omega,hj}(\mathbf{y})\frac{\partial^j \omega}{\partial \nu^j}(x,\mathbf{y})=0, \qquad \mathbf{y}\in\partial\Omega. \tag{2.3}$$

We further suppose that, subject to these boundary conditions,

$$P_n^{-1}\left(x,\mathbf{y},\frac{\partial}{\partial \mathbf{y}}\right)$$

exists for all x. Now (2.2) can be rewritten in the form of (2.1a) by introducing

$$u=\begin{pmatrix} \dfrac{\partial^{n-1}\omega}{\partial x^{n-1}} \\ \dfrac{\partial^{n-2}\omega}{\partial x^{n-2}} \\ \vdots \\ \omega \end{pmatrix}. \tag{2.4}$$

The space, $\mathscr{B}$, is some space of n-tuples of functions on Ω which satisfy the homogeneous boundary conditions, (2.3). It is necessary to eliminate inhomogeneous conditions on $\partial\Omega$ in order to reduce the problem to the abstract form. This can be accomplished by subtracting a function that satisfies the inhomogeneous condition. We note that the functions $B_{\Omega,j}$ affect P_n^{-1} and, ultimately, $A(x)$.

Returning to (2.1) we choose some finite point, $x=\tau$, and attempt to reduce the infinite problem on $[0,\infty)$ to a finite one on $[0,\tau]$. We define $\mathbf{A}(\tau;\mathrm{f})$, the admissible set of Cauchy data at $x=\tau$, as the set leading to solutions, u, in the tail, $x\in[\tau,\infty)$. More precisely we have:

DEFINITION 2.5. The set $\mathbf{A}(\tau;f)\subset\mathscr{B}$, the admissible set at $x=\tau$, is the set of all $u_0\in\mathscr{B}$ such that there exists $u(x)\in\mathscr{B}$, $x\in[\tau,\infty)$, satisfying:

$$\begin{aligned} &\text{a)} \quad \frac{du}{dx}=A(x)u+f(x), \qquad \tau<x<\infty, \\ &\text{b)} \quad u(\tau)=u_0; \end{aligned} \tag{2.5}$$

as well as (2.1c, d) as appropriate.

It is now possible to write down an exact reduction of (2.1) to a problem on a finite domain. We state the reduction as a theorem whose proof follows immediately from the definition of $\mathbf{A}(\tau;f)$.

THEOREM 2.6. *Problem* (2.1) *has a solution if and only if the following problem has a solution*:

$$\begin{aligned} &\text{a)} \quad \frac{d\omega}{dx}=A(x)\omega+f(x), \qquad x\in[0,\tau]; \\ &\text{b)} \quad B_0\omega(0)=\gamma_0; \\ &\text{c)} \quad \omega(\tau)\in\mathbf{A}(\tau;f). \end{aligned} \tag{2.6}$$

Furthermore, whenever (2.1) has a solution $u(x)$, (2.6) has a solution which is identical to u on $[0,\tau]$.

Proof. Suppose (2.6) has a solution. Then, by the definition of $\mathbf{A}(\tau;f)$, there exists $u^+(x)$, $x\in[\tau,\infty)$, satisfying (2.1a) and (2.1c, d) as appropriate as well as $\omega(\tau)=u^+(\tau)$. Define

$$u(x)=\begin{cases}\omega(x), & x\in[0,\tau],\\ u^+(x), & x\in[\tau,\infty).\end{cases}$$

Then, u is a solution of (2.1). Now, suppose that (2.1) has a solution. The restriction of u to $[\tau,\infty)$ satisfies (2.5) and (2.1c, d) and, hence, by the definition of $\mathbf{A}(\tau;f)$, $u(\tau)\in\mathbf{A}(\tau;f)$. This implies that the restriction of u to $[0,\tau]$ satisfies (2.6), completing the proof.

The set $\mathbf{A}(\tau;f)$ is an affine subset of $\mathscr{B}$. A convenient representation of $\mathbf{A}$ can be found in terms of its underlying linear subspace and some particular element of $\mathscr{B}$. We consider the homogeneous problem in the tail associated with (2.1):

$$\text{(2.7)}\quad \begin{aligned}&\text{a)}\quad \frac{dv}{dx}=A(x)v, \qquad x\in[\tau,\infty);\\ &\text{b)}\quad \lim_{x\to\infty} B_\infty v(x)=0,\end{aligned}$$

and, if (2.1d) is imposed,

$$\text{c)}\quad \|v(x)\| \text{ bounded as } x\to\infty.$$

We define $\mathscr{A}(\tau)$, the admissible space at $x=\tau$, as the set of all Cauchy data leading to solutions of (2.7). That is:

DEFINITION 2.8. The set $\mathscr{A}(\tau)\subset\mathscr{B}$, the admissible space at $x=\infty$, is the set of all $v_0\in\mathscr{B}$ such that (2.7) has a solution satisfying:

$$\text{(2.8)}\qquad v(\tau)=v_0.$$

We note that $\mathscr{A}(\tau)$ is independent of the inhomogeneous term in (2.1). We further require a particular solution, $u_p(x)$, which satisfies:

$$\text{(2.9)}\quad \begin{aligned}&\text{a)}\quad \frac{du_p}{dx}=A(x)u_p+f(x), \qquad x\in[\tau,\infty);\\ &\text{b)}\quad \lim_{x\to\infty} B_\infty u_p(x)=0;\end{aligned}$$

and, if (2.1d) is imposed

$$\text{c)}\quad \|u_p(x)\| \text{ bounded as } x\to\infty.$$

We note that if $\mathbf{A}(\tau;f)$ is nonempty, at least one such $u_p(x)$ must exist. It is now possible to prove:

THEOREM 2.10. *Let $u_0\in\mathscr{B}$. Then $u_0\in\mathbf{A}(\tau;f)$ if and only if, for any particular solution $u_p(x)$*

$$\text{(2.10)}\qquad u_0-u_p(\tau)\in\mathscr{A}(\tau).$$

Proof. The proof is an immediate consequence of the definitions of $\mathbf{A}(\tau;f)$, $\mathscr{A}(\tau)$ and $u_p(x)$ combined with the linearity of (2.1).

If we assume that there exists a projection operator, $Q(\tau)$, into $\mathscr{A}(\tau)$, we can rewrite (2.10):

$$(I-Q(\tau))(u_0-u_p(\tau))=0.$$

In particular, the boundary condition, (2.6c), can be replaced by:

$$(2.6c') \qquad (I-Q(\tau))\omega(\tau)=(I-Q(\tau))u_p(\tau).$$

We emphasize that $u_p(x)$ can be any particular solution.

Finally, we write down a corollary of Theorem 2.6 which concerns the uniqueness of solutions.

COROLLARY. *Suppose that for all* $v_0\in\mathscr{A}(\tau)$ *solutions to the Cauchy problem defined by* (2.7a) *and* (2.8) *are unique. Then* (2.6) *has a unique solution if and only if* (2.1) *does.*

Proof. Assuming uniqueness of solutions to (2.1) immediately yields uniqueness for (2.6). In the other direction, note that the assumption above guarantees the uniqueness of $u_+(x)$ which, combined with the uniqueness of the finite interval solution, implies the uniqueness of u.

3. Solvability of the finite problem. In this section we assume that solutions to the homogeneous Cauchy problems:

$$(3.1) \quad \text{a)} \quad \frac{dv}{dx}=A(x)v, \quad x_0\leqq x\leqq x_1 \text{ if } x_1>x_0; \quad x_1\leqq x\leqq x_0 \text{ if } x_0>x_1;$$
$$\text{b)} \quad v(x_0)=v_0;$$

are unique for all x_0, $x_1\in[0,\infty)$. We define a solution operator $S(x_1,x_0;A)$ in the following way:

DEFINITION 3.2. Let $v_0\in\mathscr{B}$. If there exists a solution, $v(x)$ to problem (3.1) then

$$(3.2) \qquad S(x_1,x_0;A)v_0=v(x_1).$$

Otherwise, v_0 is said to be outside the domain of $S(x_1,x_0;A)$.

The linearity of the differential equation implies the linearity of s. The stated uniqueness of solutions implies the consistency of the definition. Note that it is certainly necessary to restrict the domain of S for ill-posed Cauchy problems such as those which arise in the study of elliptic equations. Whenever S exists, however, it does have the familiar semi-group properties:

$$(3.3) \quad \text{a)} \quad S(x_1,x^*;A)S(x^*,x_0;A)=S(x_1,x_0;A),$$
$$\text{b)} \quad S(x_0,x_0;A)=I.$$

The notion of dichotomies is very useful in what follows. First we present definitions of exponential and ordinary dichotomies. These are adapted from Daletskiy and Krein [4], with some modifications required by the poosible nonexistence of solutions.

DEFINITION 3.4. We say that the problem

$$(3.4) \qquad \frac{dv}{dx}=A(x)v, \qquad x\in[0,\infty);$$

has an exponential dichotomy if, for any $x^* \in [0, \infty)$, the space $\mathscr{B}$ can be decomposed into a direct sum of subspaces $\mathscr{B}_-(x^*)$ and $\mathscr{B}_+(x^*)$ such that:

(3.5)
a) If $v \in \mathscr{B}_-(x^*)$ then, for some N_- and $\alpha_- > 0$
i) $S(x, x^*; A)\, v$ exists for any $x \geqq x^*$;
ii) $\| S(x, x^*; A) v \| \leqq N_- e^{-\alpha_-(x - x^*)} \| v \|$.

(3.6)
b) If $v \in \mathscr{B}_+(x^*)$ then, for some N_+ and $\alpha_+ > 0$
i) $S(x, x^*; A) v$ exists for any $x \leqq x^*$;
ii) $\| S(x, x^*; A) v \| \leqq N_+ e^{-\alpha_+(x^* - x)} \| v \|$.

(3.7)
c) There exists $\gamma > 0$, independent of x^*, such that

$$\inf_{\substack{u_\pm \in \mathscr{B}_\pm(x^*) \\ \|u_\pm\| = 1}} \| u_+ + u_- \| \geqq \gamma.$$

(This infimum is typically called the angular distance between $\mathscr{B}_+(x^*)$ and $\mathscr{B}_-(x^*)$.)

An ordinary dichotomy is defined as above except that $\alpha_\pm = 0$ is allowed. No "continuity" of the spaces as functions of x^* has so far been required. In general, we impose a sort of continuity in the form of the following "no-mixing" condition.

DEFINITION 3.8. The dichotomy (3.5–3.7) satisfies the no-mixing condition if whenever

(3.8)
a) $Q(x)$ is the projection operator into $\mathscr{B}_-(x)$,
b) $S(x_1, x_0; A)\, v$ exists

then

c) $Q(x_1) S(x_1, x_0; A) v = S(x_1, x_0; A) Q(x_0) v$.

Assuming that the homogeneous problem has a dichotomy in the tail and that $\mathscr{B}_-(x)$ coincides with the admissible space, $\mathscr{A}(x)$, it is possible to write down an integral expression for a particular solution, $u_p(x)$ which is valid whenever $\|f(x)\|$ is integrable;

$$u_p(x) = \int_\tau^x S(x, p; A) Q(p) f(p)\, dp - \int_x^\infty S(x, p; A)(I - Q(p)) f(p)\, dp. \tag{3.9}$$

(The validity of (2.9a) follows from the direct differentiation of (3.9) while (2.9b) is insured by the identity of $\mathscr{B}_-(x)$ and $\mathscr{A}(x)$ combined with the absolute convergence of the integrals.) Note that it is always the case that $\mathscr{B}_-(x) = \mathscr{A}(x)$ if there is an exponential dichotomy. Then, only boundedness of $\|f\|$ need be assumed.

Formula (3.9) is extremely useful in the development of a perturbation theory. For now, we simply use it to write down a new expression for the boundary condition, (2.6c):

$$(I - Q(\tau))\, \omega(\tau) = -\int_\tau^\infty S(\tau, p)(I - Q(p)) f(p)\, dp. \tag{3.10}$$

Extending the dichotomy to the entire interval, we now can prove an existence theorem for the finite boundary value problem (2.6).

THEOREM 3.11. *Suppose that solutions to all Cauchy problems* (3.1) *are unique for* x_0, $x_1 \in [0,\tau]$ *and that* (3.1a) *has a nonmixing ordinary dichotomy on* $[0,\tau]$ *with projector* $Q(x)$ *into* $\mathscr{B}_-(x)$. *Also assume that* $\mathscr{B}_-(\tau)=\mathscr{A}(\tau)$. *Then* (2.6) *has a solution for arbitrary* $f(x)$, $u_p(\tau)$ *and* γ_0 *in the range of* B_0 *if and only if the operator*

$$\Phi\omega = \begin{Bmatrix} (I-Q(0))\omega \\ B_0\omega \end{Bmatrix} \tag{3.11}$$

has an inverse with domain containing all pairs of the form:

$$\begin{pmatrix} 0 \\ \gamma \end{pmatrix}, \quad \gamma \in \text{Range}\,(B_0). \tag{3.12}$$

The solution is unique and bounded in terms of the inhomogeneous data if and only if this (*restricted*) *inverse is.*

Proof. We use the ordinary dichotomy defined by $Q(x)$ to solve certain initial value problems. Let

$$\omega_+(x) = S(x,\tau;A)(I-Q(\tau))u_p(\tau) + \int_\tau^x S(x,p;A)(I-Q(p))f(p)\,dp. \tag{3.13}$$

This exists for all x on $[0,\tau]$ by the definition of Q. If we seek solutions to (2.6) in the form

$$\omega(x) = \omega_+(x) + \omega_-(x) \tag{3.14}$$

then ω is a solution if and only if ω_- solves

$$\begin{aligned} &\text{a)} \quad \frac{d\omega_-}{dx} = A(x)\omega_- + Q(x)f(x); \\ &\text{b)} \quad B_0\omega_-(0) = \gamma_0 - B_0\omega_+(0); \\ &\text{c)} \quad (I-Q(\tau))\omega_-(\tau) = 0. \end{aligned} \tag{3.15}$$

We write $\omega_-(x)$ in the form:

$$\omega_-(x) = S(x,0;A)\omega_-(0) + \int_0^x S(x,p;A)Q(p)f(p)\,dp. \tag{3.16}$$

The integral term again exists by the definition of Q so that this representation is valid for any solution of (3.15a). By (3.15c) and (3.8c) we have:

$$0 = (I-Q(\tau))\omega_-(\tau) = S(\tau,0;A)(I-Q(0))\omega_-(0);$$

which, by the uniqueness of solutions to the Cauchy problem, implies

$$(I-Q(0))\omega_-(0) = 0.$$

Hence, we can find a solution to (3.15) if and only if we can simultaneously solve:

$$\begin{aligned} &(I-Q(0))\omega_-(0) = 0; \\ &B_0\omega_-(0) = \gamma_0 - B_0\omega_+(0); \end{aligned}$$

which in component form yields (3.11), completing the proof.

Estimates of the solution in terms of the inhomogeneous data are now obtained from the explicit representation in terms of ω_+ and ω_-. Assume that

$$
\begin{aligned}
&\text{a)} \quad \|S(x,p;A)Q(p)\| \leqq K_-(x,p), \qquad 0 \leqq p \leqq x \leqq \tau;\\
&\text{b)} \quad \|S(x,p;A)(I-Q(p))\| \leqq K_+(x,p), \qquad 0 \leqq x \leqq p \leqq \tau;\\
&\text{c)} \quad \left\|\Phi^{-1}\begin{pmatrix}0\\ \gamma\end{pmatrix}\right\| \leqq K_\phi \|\gamma\|, \qquad \gamma \in \text{Range}(B_0);\\
&\text{d)} \quad \|B_0\| \leqq K_0.
\end{aligned} \tag{3.17}
$$

Then we have, directly estimating (3.13) and (3.16) and using the fact that $Q(0)\omega_-(0) = \omega_-(0)$,

$$
\begin{aligned}
\|\omega(x)\| \leqq K_-(x,0)\|\gamma_0\| &+ \max_{x\in[0,\tau]} \|f(x)\| \int_0^x K_-(x,p)\,dp\\
&+ \max_{x\in[0,\tau]} \|f(x)\| \left(\int_x^\tau K_+(x,p)\,dp + K_-(x,0)K_\phi K_0 \int_0^\tau K_+(0,p)\,dp \right)\\
&+ \|u_p(\tau)\| \left(K_+(x,\tau) + K_-(x,0)K_\phi K_0 K_+(0,\tau) \right).
\end{aligned} \tag{3.18}
$$

Equation (3.18) allows us to estimate the errors caused by approximations to $Q(\tau)$ and $u_p(\tau)$. Suppose we solve the following finite problem instead of (2.6):

$$
\begin{aligned}
&\text{a)} \quad \frac{d\omega_a}{dx} = A(x)\omega_a + f(x), \qquad 0 \leqq x \leqq \tau,\\
&\text{b)} \quad B_0\omega_a(0) = \gamma_0;\\
&\text{c)} \quad (I-Q^*(\tau))\omega_a(\tau) = (I-Q^*(\tau))u_p^*(\tau);
\end{aligned} \tag{3.19}
$$

where $Q^*(\tau)$ and $u_p^*(\tau)$ differ from $Q(\tau)$ and $u_p(\tau)$. We define the error, $e(x)$, by

$$e(x) \equiv \omega(x) - \omega_a(x)$$

and find that it satisfies:

$$
\begin{aligned}
&\text{a)} \quad \frac{de}{dx} = A(x)e, \qquad 0 \leqq x \leqq \tau,\\
&\text{b)} \quad B_0 e(0) = 0,\\
&\text{c)} \quad (I-Q(\tau))e(\tau) = (I-Q(\tau))\left(u_p(\tau) - u_p^*(\tau)\right)\\
&\qquad\qquad + \left(Q(\tau)-Q^*(\tau)\right)\left(u_p^*(\tau) - \omega_a(\tau)\right)\\
&\qquad\qquad \equiv \Delta(t).
\end{aligned} \tag{3.20}
$$

Note that $\Delta(\tau)$, by construction, is in the range of $I-Q(\tau)$. (We assume, of course, that $\omega_a(x)$ exists.) Therefore we have:

$$(I-Q(\tau))\Delta(\tau) = \Delta(\tau).$$

We now plug into (3.18) to obtain:

$$\|e(x)\| \leqq \left(K_+(x,\tau) + K_-(x,0)K_\phi K_0 K_+(0,\tau)\right)\|\Delta(\tau)\|. \tag{3.21}$$

Further specializing to the case of an exponential dichotomy this becomes:

$$\|e(x)\| \leqq \left(N_+ e^{\alpha_+(x-\tau)} + N_- e^{-\alpha_- x} K_\phi K_0 N_+ e^{-\alpha_+ \tau}\right) \|\Delta(\tau)\|. \tag{3.22}$$

That is, the large part of the error decays exponentially off the artificial boundary.

4. Problems with constant tails. In this section we restrict ourselves to problems which are autonomous in x for x sufficiently large. That is, we assume there exists τ such that:

$$A(x) \equiv A_\infty, \qquad x \geqq \tau. \tag{4.1}$$

We also require that the constant coefficient problem in the tail be separable. That is, we require that a complete spectral representation be associated with A_∞:

Assumption 4.2. There exists a countable set of pairs, (λ_n, u_n), with λ_n a complex number, $u_n \in \mathscr{B}$ and 0 not an accumulation point of $\{\lambda_n\}$ and there exist adjoint pairs, (λ_n^*, v_n), with $v_n \in \text{Dual}(\mathscr{B})$, satisfying

$$\begin{aligned} &\text{i)} \quad A_\infty u_n = \lambda_n u_n; \\ &\text{ii)} \quad A_\infty^* v_n = \lambda_n^* v_n; \\ &\text{iii)} \quad (v_m, u_n) = \delta_{mn}. \end{aligned} \tag{4.2}$$

Furthermore, any function $u \in \mathscr{B}$ can be uniquely written in the form:

$$u = \sum_{n=1}^{\infty} c_n u_n, \qquad c_n = (v_n, u). \tag{4.3}$$

Using the eigenfunction expansions defined above, it is easy to write down conditions for the existence of dichotomies for the constant problem as well as representations of the various operators discussed in the preceding sections. In particular we have the following theorem, whose proof follows immediately from the (formal) solution of the Cauchy problem in terms of the eigenfunction expansions. (For the details of these see Hagstrom [7].)

THEOREM 4.4. a) *If all eigenvalues, λ_n, of A_∞ are bounded away from the imaginary axis, then the homogeneous problem associated with A_∞ has an exponential dichotomy with spaces*

$$\begin{aligned} \mathscr{B}_+ &\equiv \text{span}\{u_i : \text{Re}\lambda_i > 0\}; \\ \mathscr{B}_- &\equiv \text{span}\{u_i : \text{Re}\lambda_i < 0\}. \end{aligned} \tag{4.4}$$

The exponents, $\alpha_\pm$, are given by:

$$\begin{aligned} \alpha_+ &= \underset{\text{Re}\lambda_i > 0}{\text{g.l.b.}} |\text{Re}\lambda_i|; \\ \alpha_- &= \underset{\text{Re}\lambda_i < 0}{\text{g.l.b.}} |\text{Re}\lambda_i|. \end{aligned} \tag{4.5}$$

b) *Let $\mathscr{B}_\pm$ be defined as above and let $\mathscr{B}_0$ be given by*:

$$\mathscr{B}_0 \equiv \text{span}\{u_i : \text{Re}\lambda_i = 0\}. \tag{4.6}$$

Let $\mathscr{B}_0^+ \oplus \mathscr{B}_0^-$ be any direct sum decomposition of $\mathscr{B}_0$. Then an ordinary dichotomy is induced by the spaces $\mathscr{B}_+ \oplus \mathscr{B}_0^+$ and $\mathscr{B}_- \oplus \mathscr{B}_0^-$.

We note that by the conclusions of part (b), there can be many ordinary dichotomies associated with a problem whose operator has eigenvalues with zero real part. Which of these is the right one to use for the boundary condition depends on the boundary operator at infinity, B_∞. Representations of the solution operator, S, are also easy to obtain.

The theorem above can be applied to the example of §1, problem (1.1). Rewriting the problem in first order form according to transformation (2.4), the operator A_∞ is given by:

$$A_\infty = \begin{pmatrix} 0 & -\nabla_y^2 - a_\infty \\ 1 & 0 \end{pmatrix}.$$

Its eigenvalues are given by $\pm\lambda_n$ and $\pm i\alpha_n$, defined by the reduced eigenvalue problem (1.3) through equation (1.4). If (1.3) had no positive eigenvalues, the problem in the tail would have an exponential dichotomy. In the case of an ordinary dichotomy, the boundary condition (1.7a) corresponds to the choice:

$$\mathcal{B}_0^+ \equiv \mathcal{B}_0, \qquad \mathcal{B}_0^- \equiv \varnothing .$$

If, instead of (1.1d), some other condition was imposed (for example a radiation condition) this choice would change. We note that using the integral representation of the boundary condition, (3.10), the condition that the inhomogeneous term vanish in the tail can be replaced by an integrability assumption. The boundary condition, (1.7), is then replaced by:

$$\frac{1}{2}\begin{pmatrix} 1 & \lambda_n \\ \frac{1}{\lambda_n} & 1 \end{pmatrix}\begin{pmatrix} c_n'(\tau) \\ c_n(\tau) \end{pmatrix} = -\frac{1}{2}\int_\tau^\infty ds e^{-\lambda_n(s-\tau)}\begin{pmatrix} 1 & \lambda_n \\ \frac{1}{\lambda_n} & 1 \end{pmatrix}\begin{pmatrix} f_n(s) \\ 0 \end{pmatrix}$$

which implies

$$c_n'(\tau) = -\lambda_n c_n(\tau) - \int_\tau^\infty ds e^{-\lambda_n(s-\tau)} f_n(s), \qquad n = m+1,\ m+2, \cdots . \tag{4.7}$$

For the imaginary eigenvalues we have:

$$\begin{pmatrix} c_n'(\tau) \\ c_n(\tau) \end{pmatrix} = -\frac{1}{2}\int_\tau^\infty ds \left\{ e^{-i\alpha_n(s-\tau)}\begin{pmatrix} 1 & i\alpha_n \\ \frac{1}{i\alpha_n} & 1 \end{pmatrix} + e^{i\alpha_n(s-\tau)}\begin{pmatrix} 1 & -i\alpha_n \\ \frac{1}{i\alpha_n} & 1 \end{pmatrix}\right\}\begin{pmatrix} f_n(s) \\ 0 \end{pmatrix}$$

which implies

$$\begin{aligned} c_n'(\tau) &= -\int_\tau^\infty \cos[\alpha_n(s-\tau)] f_n(s)\, ds; \\ c_n(\tau) &= \frac{1}{\alpha_n}\int_\tau^\infty \sin[\alpha_n(s-\tau)] f_n(s)\, ds. \end{aligned} \tag{4.8}$$

For a general partial differential equation with a constant tail, the eigenvalue problem of its operator, A_∞, can be reduced to an eigenvalue problem for a partial differential operator. In particular, it's eigenvalues, λ, correspond to solutions of:

$$\left[\sum_{j=0}^{n} P_j\left(y, \frac{\partial}{\partial y}\right)\lambda^j\right] Y(y) = 0, \tag{4.9}$$

coupled with the appropriate boundary conditions. This is the eigenvalue problem associated with the Laplace transform in x of the equation in the tail. We note that in practice it is the reduced eigenvalue problem, (4.9), which we suggest be solved to obtain the boundary conditions. The reduction to first order form is made in an effort to simplify the theory. The use of (4.9) to derive boundary conditions was first suggested by Gustafsson and Kreiss [6].

The completeness of the eigenfunctions of A_∞ depends on the completeness of the eigenfunctions of (4.9). This property does not hold in general and is difficult to check. For a class of elliptic and parabolic problems, Agmon and Nirenberg [1, Thm. 5.8] establish the completeness of the eigenfunctions and generalized eigenfunctions of (4.9) whose eigenvalues have negative real part in the class of solutions which are absolutely integrable along with their first $n-1$ x derivatives. In this case, the solution of (4.9) is guaranteed to yield a representation of the admissible space.

5. Perturbation theory and asymptotic boundary conditions. In the preceding section we found useful representations of the projection operator, $Q(\tau)$, of the admissible space and of the particular solution, $u_p(x)$ for equations of the form (2.1) with constant tails. In the present section we relax this assumption and replace it with:

$$\lim_{x\to\infty} A(x)=A_\infty. \tag{5.1}$$

Equivalently we write:

$$A(x)=A_\infty+B(x), \qquad \lim_{x\to\infty}\|B(x)\|=0. \tag{5.2}$$

Assuming A_∞ has a dichotomy, it is possible to make an asymptotic analysis of the perturbed problem defined by $A(x)$. In particular, we obtain representations of the projector, $Q(\tau)$, into the admissible space. Consider the homogeneous problem in the tail:

$$\begin{aligned} &\text{a)} && \frac{dv}{dx}=A_\infty v+B(x)v,\ x\geqq\tau;\\ &\text{b)} && \lim_{x\to\infty} B_\infty v(x)=0;\\ &\text{c)} && \|u(x)\| \text{ bounded as } x\to\infty. \end{aligned} \tag{5.3}$$

Treating $B(x)v$ as an inhomogeneous term, we have, by (3.10), that $v(x)$ must satisfy:

$$(I-Q_\infty(\tau))v(\tau)=-\int_\tau^\infty S(\tau,p;A_\infty)(I-Q_\infty(p))B(p)v(p)\,dp. \tag{5.4}$$

Also, from (3.10), we have a representation of v which must be valid if v exists;

$$\begin{aligned} v(x)=S(x,\tau;A_\infty)Q_\infty(\tau)v(\tau)+\int_\tau^x S(x,p;A_\infty)Q_\infty(p)B(p)v(p)\,dp\\ -\int_x^\infty S(x,p;A_\infty)(I-Q_\infty(p))B(p)v(p)\,dp. \end{aligned} \tag{5.5}$$

Let any $\xi_0\in\mathscr{A}_\infty(\tau)$ be given and replace $Q_\infty(\tau)v(\tau)$ in (5.5) by ξ_0. If the following condition holds:

$$\begin{aligned} \sup_{x\geqq\tau}\Big\|\Big[\int_\tau^x S(x,p;A_\infty)Q_\infty(p)B(p)\,dp\\ -\int_x^\infty S(x,p;A_\infty)(I-Q_\infty(p))B(p)\,dp\Big]\Big\|=K<1; \end{aligned} \tag{5.6}$$

then the contraction mapping theorem can be used to establish the existence of a unique bounded solution to equation (5.5), $v(x;\xi_0)$. Furthermore, we clearly have that:

$$\begin{aligned} &Q_\infty v(\tau;\xi_0)=\xi_0;\\ &(I-Q_\infty(\tau))v(\tau;\xi_0)=-\int_\tau^\infty S(\tau,p;A_\infty)(I-Q_\infty(p))B(p)v(p;\xi_0)\,dp. \end{aligned} \tag{5.7}$$

Hence, whenever (5.6) is valid, we can find, for any $\xi_0\in\mathscr{A}_\infty(\tau)$, a unique element, $v(\tau;\xi_0)$, of $\mathscr{A}(\tau)$. A projector into $\mathscr{A}(\tau)$ is given implicitly by (5.7):

$$Q(\tau)\xi=Q_\infty(\tau)\xi-\int_\tau^\infty dpS(\tau,p;A_\infty)(I-Q_\infty(p))B(p)v(p;Q_\infty(\tau)\xi). \tag{5.8}$$

These conditions lead us to the following theorem:

THEOREM 5.9. *We suppose that either the unperturbed problem has an ordinary dichotomy and* $\|B(x)\|$ *is integrable or that the unperturbed problem has an exponential dichotomy. Then, for* τ *sufficiently large, a unique solution,* $v(x;\xi_0)$, *exists for any* $\xi_0\in\mathscr{A}_\infty(\tau)$ *and* (5.8) *is valid.*

Proof. It is only necessary to satisfy (5.6). In the first case we have:

$$K\leqq(N_+ + N_-)\int_\tau^\infty \|B(x)\|\,dx;$$

while in the second we have:

$$K\leqq\left(\frac{N_+}{\alpha_+}+\frac{N_-}{\alpha_-}\right)\max_{x\geqq\tau}\|B(x)\|.$$

For both cases, the assumptions on B allow us to make the right-hand sides arbitrarily small by choosing τ sufficiently large, completing the proof.

The contraction mapping solution of (5.5) leads to a natural iterative procedure for the approximation of $v(x;\xi_0)$ and, ultimately, of the operator Q. We let:

$$\begin{aligned} &v^{(0)}(x;\xi_0)=S(x,\tau;A_\infty)\xi_0;\\ &v^{(n+1)}(x;\xi_0)=v^{(0)}(x;\xi_0)+\int_\tau^x dpS(x,p;A_\infty)Q_\infty(p)B(p)v^{(n)}(p;\xi_0)\\ &\qquad\qquad -\int_x^\infty dpS(x,p;A_\infty)(I-Q_\infty(p))B(p)v^{(n)}(p;\xi_0). \end{aligned} \tag{5.9}$$

Then, by the contraction estimates:

$$\|v^{(n)}(x;\xi_0)-v(x;\xi_0)\|\leqq\frac{K^{n+1}}{1-K}\|v^{(0)}(x;\xi_0)\|. \tag{5.10}$$

We define our nth approximation to $A(\tau)$, $Q^{(n)}(\tau)$, by:

(5.11)

$$Q^{(n)}(\tau)\xi=Q_\infty(\tau)\xi-\int_\tau^\infty dpS(\tau,p;A_\infty)(I-Q_\infty(p))B(p)v^{(n-1)}(p;Q_\infty(\tau)\xi).$$

The error due to this approximation is estimated by:

$$\|Q(\tau)\xi-Q^{(n)}(\tau)\xi\|\leqq\frac{K^{n+1}}{1-K}\|v^{(0)}(x;Q_\infty(\tau)\xi)\|. \tag{5.12}$$

(Note: in all cases the norm of a $\mathscr{B}$-valued function of x is taken to be the maximum in x of its $\mathscr{B}$ norms.)

We now apply these results to the case when the constant tail problem has an exponential dichotomy and A_∞ has a complete spectrum. We assume that $B(x)$ has an expansion of the form:

$$B(x)=\frac{1}{x}B^{(1)}+\frac{1}{x^2}B^{(2)}+\cdots. \tag{5.13}$$

(The expansions could easily be carried out for more general forms.) Plugging into the formulas above we have:

(5.14)

$$V^{(1)}(x;\xi)=\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n<0}} c_n e^{\lambda_n(x-\tau)}+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n<0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}}\int_\tau^x dp e^{\lambda_n(x-p)}B_{nm}(p)c_m e^{\lambda_m(p-\tau)}$$

$$-\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n>0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}}\int_x^\infty dp e^{\lambda_n(x-p)}B_{nm}l(p)c_m e^{\lambda_m(p-\tau)};$$

where

$$c_n=(v_n,\xi),\qquad B_{nm}(x)=(v_n,B(x)u_m). \tag{5.15}$$

Using (5.13) and approximating the integrals using integration by parts yields to within an $O(1/\tau^2)$ error:

(5.16)

$$v^{(1)}(x;\xi)=\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n<0}} u_n c_n e^{\lambda_n(x-\tau)}+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n<n}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0\\ \lambda_m\neq\lambda_n}} u_n\frac{B^{(1)}_{nm}}{\lambda_m-\lambda_n}c_m\left(\frac{e^{\lambda_m(x-\tau)}}{x}-\frac{e^{\lambda_n(x-\tau)}}{\tau}\right)$$

$$+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n<0}} u_n B^{(1)}_{nm}c_n e^{\lambda_n(x-\tau)}\log\left(\frac{x}{\tau}\right)+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n>0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}} u_n\frac{B^{(1)}_{nm}}{\lambda_m-\lambda_n}c_m\frac{e^{\lambda_m(x-\tau)}}{x}.$$

Putting this expression into (5.11) and approximating the integrals in a similar fashion yields:

$$Q(\tau)\xi=\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n<0}} c_n u_n+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n>0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}} u_n\left(B^{(1)}_{nm}+\frac{1}{\tau}B^{(2)}_{nm}\right)c_m\frac{1}{(\lambda_m-\lambda_n)\tau}$$

$$+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n>0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}} u_n B^{(1)}_{nm}c_m\frac{1}{(\lambda_m-\lambda_n)^2\tau^2}$$

$$-\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n>0}}\sum_{\substack{j\\ \mathrm{Re}\,\lambda_j<0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}} u_n B^{(1)}_{nj}B^{(1)}_{jm}c_m\frac{1}{\tau^2(\lambda_m-\lambda_n)(\lambda_j-\lambda_n)} \tag{5.17}$$

$$+\sum_{\substack{n\\ \mathrm{Re}\,\lambda_n>0}}\sum_{\substack{j\\ \mathrm{Re}\,\lambda_j>0}}\sum_{\substack{m\\ \mathrm{Re}\,\lambda_m<0}} u_n B^{(1)}_{nj}B^{(1)}_{jm}c_m\frac{1}{\tau^2(\lambda_m-\lambda_j)(\lambda_m-\lambda_n)}+O\left(\frac{1}{\tau^3}\right);$$

$$c_n=(v_n,\xi).$$

The generality of the expansion given above makes its automatic computation a real possibility. Note that the expansion is equivalent to the one obtained by Jepson and Keller [10] for ordinary differential equations.

Formula (5.17) can be applied to the Laplacian example, (1.1), where the potential $a(\mathbf{y})$ is replaced by:

$$a(x,\mathbf{y}) = a_0(\mathbf{y}) + \frac{1}{x}a_1(\mathbf{y}) + \frac{1}{x^2}a_2(\mathbf{y}) + \cdots. \tag{5.18}$$

Then, the matrix elements $B_{nm}^{(i)}$ are given by:

$$B_{nm}^{(i)} = \frac{1}{2\lambda_n}\int_{\Omega} d\mathbf{y}\, Y_n(\mathbf{y}) Y_m(\mathbf{y}) a_i(\mathbf{y}). \tag{5.19}$$

Expansions of a particular solution can be derived in a similar manner. Let $u_\infty(x)$ be any particular solution of the unperturbed problem. Then, a solution of the integral equation:

$$\begin{aligned} u(x) = u_\infty(x) &+ \int_\tau^x 4k\, S(x,p) Q_\infty(p) B(p) u(p)\, dp \\ &- \int_x^\infty S(x,p)(I - Q_\infty(p)) B(p) u(p)\, dp \end{aligned} \tag{5.20}$$

is a particular solution of the perturbed problem. Given the inequality (5.6), a unique bounded solution of (5.20) exists by the contraction mapping theorem. It can be approximated by an iterative process analogous to the one described by (5.9). Perturbations of the inhomogeneous term could also be included.

Finally, we note that (5.17) is valid for some problems which do not satisfy (5.6). An important example is afforded by the exterior Helmholtz problem in two dimensions. The equation in the tail is:

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} + k^2 u = 0, \qquad r \in [\tau, \infty), \quad \theta \in [0, 2\pi) \tag{5.21}$$

together with boundary conditions

$$\begin{aligned} &\text{a)} \quad u \text{ periodic in } \theta; \\ &\text{b)} \quad \lim_{r\to\infty} r^{1/2}\left(\frac{\partial u}{\partial r} - iku\right) = 0. \end{aligned} \tag{5.22}$$

Rewritten in first order form these become:

$$\begin{aligned} &\text{a)} \quad \frac{\partial}{\partial r}\begin{pmatrix}\omega\\ u\end{pmatrix} + \begin{pmatrix} 0 & k^2 \\ -1 & 0\end{pmatrix}\begin{pmatrix}\omega\\ u\end{pmatrix} + \frac{1}{r}\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}\begin{pmatrix}\omega\\ u\end{pmatrix} \\ &\qquad\qquad + \frac{1}{r^2}\begin{pmatrix} 0 & \dfrac{\partial^2}{\partial\theta^2} \\ 0 & 0\end{pmatrix}\begin{pmatrix}\omega\\ u\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix}; \\ &\text{b)} \quad \begin{pmatrix}\omega\\ u\end{pmatrix} \text{ periodic in } \theta; \\ &\text{c)} \quad \lim_{r\to\infty} r^{1/2}(\omega - iku) = 0. \end{aligned} \tag{5.23}$$

There are two obstacles to the application of the preceding theory to problem (5.23). The first is that the perturbation

$$\frac{1}{r^2}\begin{pmatrix} 0 & \dfrac{\partial^2}{\partial\theta^2} \\ 0 & 0 \end{pmatrix}$$

is apparently unbounded. The second is that the perturbation

$$\frac{1}{r}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

is nonintegrable while the limiting equation,

$$\frac{\partial}{\partial r}\begin{pmatrix} \omega \\ u \end{pmatrix}+\begin{pmatrix} 0 & k^2 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} \omega \\ u \end{pmatrix}=\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{5.24}$$

has an ordinary rather than an exponential dicohotomy. Nonetheless, it is possible to apply formula (5.17), or any higher order approximation to the boundary condition, to this problem. (It is necessary, of course, to identify the imaginary eigenvalue ik with eigenvalues with negative real part and $-ik$ with eigenvalues with positive real part when applying the formulas.) The resulting boundary condition is:

(5.25)

$$\begin{aligned}(I-Q(\tau))\begin{pmatrix} \omega(\tau) \\ u(\tau) \end{pmatrix} &= \frac{1}{2}\begin{pmatrix} 1 & -ik \\ -\dfrac{1}{ik} & 1 \end{pmatrix}\begin{pmatrix} \omega(\tau) \\ u(\tau) \end{pmatrix} \\ &\quad -\frac{1}{2ik\tau}\left(\frac{1}{2}+\frac{1}{2ik\tau}\frac{\partial^2}{\partial\theta^2}\right)\begin{pmatrix} -\dfrac{1}{2} & \dfrac{-ik}{2} \\ \dfrac{1}{2ik} & \dfrac{1}{2} \end{pmatrix}\begin{pmatrix} \omega(\tau) \\ u(\tau) \end{pmatrix} \\ &\quad +\frac{1}{4k^2\tau^2}\cdot\frac{1}{2}\begin{pmatrix} -\dfrac{1}{2} & \dfrac{-ik}{2} \\ \dfrac{1}{2ik} & \dfrac{1}{2} \end{pmatrix}\begin{pmatrix} \omega(\tau) \\ u(\tau) \end{pmatrix} \\ &\quad +\frac{1}{4k^2\tau^2}\cdot\frac{1}{4}\begin{pmatrix} -\dfrac{1}{2} & \dfrac{-ik}{2} \\ \dfrac{1}{2ik} & \dfrac{1}{2} \end{pmatrix}\begin{pmatrix} \omega(\tau) \\ u(\tau) \end{pmatrix} \\ &\quad -\frac{1}{4k^2\tau^2}\cdot\frac{1}{4}\begin{pmatrix} -\dfrac{1}{2} & \dfrac{-ik}{2} \\ \dfrac{1}{2ik} & \dfrac{1}{2} \end{pmatrix}\begin{pmatrix} \omega(\tau) \\ u(\tau) \end{pmatrix}+O\left(\frac{1}{\tau^3}\right)=\begin{pmatrix} 0 \\ 0 \end{pmatrix},\end{aligned}$$

which can be written:

$$\frac{\partial u}{\partial r}(\tau,\theta)=iku(\tau,\theta)-\frac{1}{2\tau}u(\tau,\theta)-\frac{1}{2ik\tau^2}\frac{\partial^2 u}{\partial\theta^2}(\tau,\theta)-\frac{1}{8ik\tau^2}u(\tau,\theta). \tag{5.26}$$

The validity of (5.26) can be established by other means. See, for example, Bayliss, Gunzburger and Turkel [2]. We note that the error depends on higher θ derivatives of u.

6. Nonlinear problems. In this final section we apply the perturbation theory to nonlinear problems. We restrict ourselves to abstract problems of the form:

$$\begin{aligned} &\text{a)} \quad \frac{du}{dx} = F(u), \qquad x \geqq \tau; \\ (6.1)\quad &\text{b)} \quad \lim_{x\to\infty} u(x) = u_\infty; \\ &\text{c)} \quad F(u_\infty) = 0; \end{aligned}$$

where $u(x)$ is an element of some Banach space, $\mathscr{B}$, and F is a nonlinear operator with domain and range in $\mathscr{B}$. Letting $v = u - u_\infty$, we rewrite (6.1):

$$\begin{aligned} &\text{a)} \quad \frac{dv}{dx} = F_u(u_\infty)v + R(v), \qquad x \geqq \tau; \\ (6.2)\quad &\text{b)} \quad \lim_{x\to\infty} v(x) = 0; \\ &\text{c)} \quad R(v) \equiv F(u_\infty + v) - F_u(u_\infty)v. \end{aligned}$$

One approach to the solution of (6.1) or (6.2) would be Newton's method. Then, the theory of the preceding sections could be applied at each stage of the iteration. We, however, choose to work directly with (6.2), deriving exact boundary conditions which can be approximated by the methods of §5.

We generalize the notion of an admissible set (Definition 2.5) to be applicable to (6.2). Note that it is no longer an affine subset of $\mathscr{B}$. Central to our analysis is the behavior of solutions to the linearized problem in the tail:

$$\frac{d\omega}{dx} = F_u(u_\infty)\omega, \qquad x \geqq \tau. \tag{6.3}$$

Treating the nonlinearity, $R(v)$, as an inhomogeneous term leads to the following equations for v, which are analogous to (5.4) and (5.5);

$$(I - Q_\infty(\tau))v(\tau) = -\int_\tau^\infty S(\tau, p; F_u(u_\infty))(I - Q_\infty(p))R(v(p))\,dp; \tag{6.4}$$

$$\begin{aligned} v(x) = {} & S(x,\tau; F_u(u_\infty))Q_\infty(\tau)v(\tau) + \int_\tau^x S(x,p; F_u(u_\infty))Q_\infty(p)R(v(p))\,dp \\ & - \int_x^\infty S(x,p; F_u(u_\infty))(I - Q_\infty(p))R(v(p))\,dp. \end{aligned} \tag{6.5}$$

Here, Q_∞ projects into the admissible space of the linearized problem (6.3). As in the linear case, the condition that (6.4) and (6.5) be simultaneously solvable is viewed as a condition for the admissibility of $v(\tau)$.

Following the derivation for the linear problem, we let $\xi_0 \in \mathscr{A}_\infty(\tau)$ be given and use a contraction argument to establish the existence of a solution to the integral equation, (6.5), with $Q_\infty(\tau)v(\tau)$ replaced by ξ_0. Due to the nonlinearity, some additional assumptions are needed:

Assumption 6.6. a) There exists $\delta > 0$ such that if u_1, $u_2 \in \mathscr{B}$ and $\|u_i\| \leqq \delta$, $i = 1, 2$, then

$$\begin{aligned} \sup_{x\geqq\tau} \Big\| & \int_\tau^x S(x,p; F_u(u_\infty))Q_\infty(p)(R(u_1) - R(u_2))\,dp \\ & - \int_x^\infty S(x,p; F_u(u_\infty))(I - Q_\infty(p))(R(u_1) - R(u_2))\,dp \Big\| \\ & \leqq K\|u_1 - u_2\|, \qquad K < 1. \end{aligned}$$

b) There exists $\delta_1 > 0$ such that if $u \in \mathscr{B}$ and $\|u\| < \delta$, then

$$\sup_{x \geqq \tau} \left\| \int_\tau^x S(x,p;F_u(u_\infty))Q_\infty(p)R(u)\,du - \int_x^\infty S(x,p;F_u(u_\infty))(I-Q_\infty(p))R(u)\,dp \right\| \leqq \delta - \delta_1.$$

c)

$$\sup_{x \geqq \tau} \|S(x,\tau;F_u(u_\infty))\xi_0\| < \delta_1.$$

Given these, a solution to (6.5) is guaranteed by the contraction mapping theorem. Denoting this solution by $v(x;\xi_0)$, an exact boundary condition, valid for small boundary data, can be written down from (6.4):

(6.6)

$$(I-Q_\infty(\tau))v(\tau) = -\int_\tau^\infty S(\tau,p;F_u(u_\infty))(I-Q_\infty(p))R(v(p;Q_\infty(\tau)v(\tau)))\,dp.$$

An approximation to (6.6) can be obtained from an iterative approximation to the solution of (6.5):

(6.7)

a) $v^{(0)}(x;\xi_0) = S(x,\tau;F_u(u_\infty))\xi_0,$

b) $v^{(n+1)}(x;\xi_0) = v^{(0)}(x;\xi_0) + \int_\tau^x S(x,p;F_u(u_\infty))Q_\infty(p)R(v^{(n)}(p;\xi_0))\,dp - \int_x^\infty S(x,p;F_u(u_\infty))(I-Q_\infty(p))R(v^{(n)}(p;\xi_0))\,dp.$

The nth approximation to the boundary condition is, then, given by:

(6.8)

$$(I-Q_\infty(\tau))v(\tau) = -\int_\tau^\infty dpS(\tau,p;F_u(u_\infty))(I-Q_\infty(p))R(v^{(n)}(p;Q_\infty(\tau)v(\tau))).$$

Error estimates follow as in the linear case and will be proportional to $K^{n+1}\|v^{(0)}\|$ which, in turn, we expect to be proportional to $\|v(\tau)\|^{n+2}$. Note that R will often be given as an expansion:

$$R(v) \sim \frac{1}{2}F_{uu}(u_\infty)vv + \frac{1}{6}F_{uuu}(u_\infty)vvv + \cdots. \tag{6.9}$$

We take as many terms in this expansion when evaluating the integrals as is consistent with the number of terms in (6.7) we intend to retain.

Assume now that the linearized operator, $F_u(u_\infty)$, has a complete spectrum. Then, in order to satisfy part (a) of assumption (6.6), it is necessary to assume that there is an exponential dichotomy. From (6.9) we derive the following representation of $R(v)$ in terms of the eigenfunctions of $F_u(u_\infty)$:

(6.10)

a) $v = \sum_{n=1}^\infty c_n u_n,\ c_n = (v_n, u);$

b) $R(v) = \sum_{n=1}^\infty \gamma_n(v)u_n,\ \gamma_n(v) \sim \sum \alpha_{ij}^{(n)} c_i c_j + \sum_{i,j,k} \beta_{ijk}^{(n)} c_i c_j c_k + \cdots;$

c) $\alpha_{ij}^{(n)} = \left(v_n, \frac{1}{2}F_{uu}u_i u_j\right),\ \beta_{ijk}^{(n)} = \left(v_n, \frac{1}{6}F_{uuu}u_i u_j u_k\right), \cdots.$

The function $v^{(1)}(x;\xi)$ is given by:

(6.11)

$$
\begin{aligned}
v^{(1)}(x;\xi) = & \sum_{\substack{n \\ \mathrm{Re}\lambda_n<0}} u_n c_n e^{\lambda_n(x-\tau)} \\
& + \sum_{\substack{n \\ \mathrm{Re}\lambda_n<0}} \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0 \\ \lambda_i+\lambda_j\neq\lambda_n}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j<0}} u_n \alpha_{ij}^n \frac{c_i c_j}{(\lambda_i+\lambda_j-\lambda_n)} \left(e^{(\lambda_i+\lambda_j)(x-\tau)} - e^{\lambda_n(x-\tau)}\right) \\
& + \sum_{\substack{n \\ \mathrm{Re}\lambda_n<0}} \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0 \\ \lambda_i+\lambda_j=\lambda_n}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j<0}} u_n \alpha_{ij}^n c_i c_j e^{\lambda_n(x-\tau)}(x-\tau) \\
& + \sum_{\substack{n \\ \mathrm{Re}\lambda_n>0}} \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j<0}} u_n \alpha_{ij}^n c_i c_j \frac{1}{\lambda_i+\lambda_j-\lambda_n} e^{(\lambda_i+\lambda_j)(x-\tau)} + O\left(\|\xi\|^3\right); \\
c_n = & (v_n, \xi).
\end{aligned}
$$

This yields the following approximation to the boundary condition, which we write in terms of the expansion coefficients. Here, n is such that $\mathrm{Re}\lambda_n > 0$.

(6.12)

$$
\begin{aligned}
c_n = & \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j<0}} \alpha_{ij}^n \frac{c_i c_j}{\lambda_i+\lambda_j-\lambda_n} + \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j<0}} \sum_{\substack{k \\ \mathrm{Re}\lambda_k<0}} \beta_{ijk}^n c_i c_j c_k \frac{1}{\lambda_i+\lambda_j+\lambda_k-\lambda_n} \\
& - \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j<0}} \sum_{\substack{k \\ \mathrm{Re}\lambda_k<0}} \sum_{\substack{l \\ \mathrm{Re}\lambda_l<0}} \left\{\alpha_{ij}^n \alpha_{kl}^j + \alpha_{ji}^n \alpha_{kl}^j\right\} c_i c_k c_l \frac{1}{(\lambda_k+\lambda_l+\lambda_i-\lambda_n)(\lambda_i+\lambda_j-\lambda_n)} \\
& + \sum_{\substack{i \\ \mathrm{Re}\lambda_i<0}} \sum_{\substack{j \\ \mathrm{Re}\lambda_j>0}} \sum_{\substack{k \\ \mathrm{Re}\lambda_k<0}} \sum_{\substack{l \\ \mathrm{Re}\lambda_l<0}} \left\{\alpha_{ij}^n \alpha_{kl}^j + \alpha_{ji}^n \alpha_{kl}^j\right\} c_i c_k c_l \frac{1}{(\lambda_k+\lambda_l+\lambda_i-\lambda_n)(\lambda_k+\lambda_l-\lambda_j)}.
\end{aligned}
$$

This general formula can be applied, for example, to nonlinear elliptic problems of the form:

$$
\begin{aligned}
&\text{a)} \quad \nabla^2 u = f(u, \mathbf{y}), \qquad (x, \mathbf{y}) \in [\tau, \infty) \times \Omega; \\
&\text{b)} \quad B_\Omega u = 0, \qquad \mathbf{y} \in \partial\Omega; \\
&\text{c)} \quad \lim_{x\to\infty} u(x, \mathbf{y}) = u_\infty(\mathbf{y});
\end{aligned} \tag{6.13}
$$

where $u_\infty(\mathbf{y})$ satisfies;

$$
\begin{aligned}
&\text{a)} \quad \nabla_{\mathbf{y}}^2 u_\infty = f(u_\infty, \mathbf{y}), \qquad \mathbf{y} \in \Omega; \\
&\text{b)} \quad B_\Omega u_\infty = 0, \qquad \mathbf{y} \in \partial\Omega.
\end{aligned} \tag{6.14}
$$

The linearized equation in the tail is given by:

$$
\nabla^2 v - f_u(u_\infty, \mathbf{y}) v = 0; \tag{6.15}
$$

which is of the form analyzed in §3. The condition that (6.15) have an exponential dichotomy is that all eigenvalues, α_n, of the problem

$$(6.16)\quad \begin{aligned} &\text{a)} \quad \nabla_{\mathbf{y}}^2 Y_n - f_u(u_\infty, \mathbf{y}) Y_n = \alpha_n Y_n, \qquad \mathbf{y} \in \Omega; \\ &\text{b)} \quad B_\Omega Y_n = 0, \qquad \mathbf{y} \in \partial\Omega; \end{aligned}$$

be negative. Then, the following boundary condition can be derived from (6.12):

$$(6.17)\quad c_n' = -\lambda_n c_n - \sum_{i=1}^{\infty}\sum_{j=1}^{\infty} \alpha_{ij}^n \frac{c_i c_j}{\lambda_i+\lambda_j+\lambda_n} - \sum_{i=1}^{\infty}\sum_{j=1}^{\infty}\sum_{k=1}^{\infty} \beta_{ijk}^n \frac{c_i c_j c_k}{\lambda_i+\lambda_j+\lambda_k+\lambda_n}$$
$$+ \sum_{i=1}^{\infty}\sum_{j=1}^{\infty}\sum_{k=1}^{\infty}\sum_{l=1}^{\infty} \alpha_{ij}^n \alpha_{kl}^j \frac{c_i c_k c_l}{\lambda_k+\lambda_l+\lambda_i+\lambda_n}\left(\frac{1}{\lambda_k+\lambda_l+\lambda_j} - \frac{1}{\lambda_i+\lambda_n+\lambda_j}\right);$$
$$n = 1, 2, 3, \cdots.$$

Here we have:

$$(6.18)\quad \begin{aligned} c_i &= \int_\Omega d\mathbf{y}\, Y_i(\mathbf{y}) V(\tau, \mathbf{y}); \\ \lambda_i &= \sqrt{-\alpha_i}\,; \\ \alpha_{ij}^n &= \int_\Omega d\mathbf{y}\, \frac{1}{2} f_{uu}(u_\infty, \mathbf{y}) Y_i(\mathbf{y}) Y_j(\mathbf{y}) Y_n(\mathbf{y}); \\ \beta_{ijk}^n &= \int_\Omega d\mathbf{y}\, \frac{1}{6} f_{uuu}(u_\infty, \mathbf{y}) Y_i(\mathbf{y}) Y_j(\mathbf{y}) Y_k(\mathbf{y}) Y_n(\mathbf{y}). \end{aligned}$$

The quadratic approximation to this condition is used in a numerical computation by the authors in [8].

CHEMICAL SURFACE REACTIONS AND NONLINEAR STABILITY BY THE METHOD OF ENERGY*

CAROL L. McTAGGART† AND BRIAN STRAUGHAN‡

Abstract. By means of energy stability theory, the nonlinear stability of a two-component reactive fluid, composed of the dimer A_2 and the monomer A, confined between two infinite parallel plates and subject to the surface catalyzed reaction ($A_2 \rightleftharpoons 2A$), is analysed. The stability boundary is calculated in the cases (a) when the catalytic plate is conducting, in which case the linear and nonlinear energy parameter boundaries coincide and (b) when the plate is insulating, for which a global stability criterion is found.

1. Introduction. The convective instability which results when a chemically inert fluid in a gravitational field is heated from below has long been recognized as a problem of crucial importance in many fields of fluid mechanics. More recently, however, the effects caused by finer details such as chemical reactions or phase changes have been shown to play an important role on convection in specific applications, see e.g., Bdzil and Frisch [2], [3], Loper and Roberts [8]. The purpose of this work is to provide a *nonlinear* stability analysis for the conduction-diffusion Bénard problem in which the upper surface is stress free while the lower surface experiences a catalyzed chemical reaction.

Throughout we confine attention to the effects which the heterogeneous surface catalyzed reaction $A_2 \rightleftharpoons 2A$ may have on the hydrodynamic stability of the fluid mixture containing the dimer A_2 and monomer A, where we suppose the fluid is only slightly removed from chemical equilibrium and contained in the layer between the surfaces $z=0$ and $z=d$, the lower surface being catalytic. Bdzil and Frisch [2], [3] draw attention to the application of such problems to the dissociation of oxygen, hydrogen or nitrogen near a hot surface such as occurs in the vicinity of the gas-solid interface of a space vehicle upon re-entry into the earth's atmosphere. We would, however, anticipate future applications of our results in laboratory controlled experiments.

The model we adopt is that of Bdzil and Frisch [2], [3] who restrict attention to linearized instability analyses. The situation is described by a Newtonian fluid model, to which a Boussinesq approximation has been applied, in which the basic fields are those of velocity $\mathbf{v}$, pressure p, temperature T and degree of dissociation α ($=$ fraction of pure monomers present). The novelty of the problem is best described in terms of the heat flux $\mathbf{q}$ and mass flux $\mathbf{J}$ (local flux of α) in terms of which the conditions to be satisfied at the catalyzed boundary ($z=0$) are

$$\mathbf{J}\cdot\mathbf{k}=R, \quad \text{with either (A) } T=T_0, \quad \text{or (B) } \mathbf{q}\cdot\mathbf{k}=0, \tag{1.1}$$

where T_0 is a prescribed temperature, $\mathbf{k}$ is the vector $(0,0,1)$ and R is the rate at which the monomer is formed by the surface reaction. The reaction rate is, in fact, taken to be

linear in α, i.e.,

$$R = -\sigma(\alpha - \alpha^e), \tag{1.2}$$

where α^e is the equilibrium value of α on the surface.

The solutions to the model in the steady state ($\mathbf{v}^s \equiv \mathbf{0}$) are given by [2, (9)] and for α, T are (the pressure p^s is also easily calculated but not given here as it is not required)

$$\alpha^s(z) = \alpha_d + \gamma(d-z), \qquad T^s(z) = T_d + \beta(d-z), \tag{1.3}$$

where α_d, T_d are the prescribed values of α and T on $z=d$, and γ, β are constants which for positive constants K_1, K_2 (given in [2]) may be written as

$$\gamma = -\sigma K_1(\alpha_d - \alpha^e), \tag{1.4}$$

$$\beta = \begin{cases} (T_0 - T_d)/d & \text{if (1.1) (A) is adopted,} \\ \sigma K_2(\alpha_d - \alpha^e) & \text{when (1.1) (B) holds.} \end{cases} \tag{1.5}$$

Our object is to investigate the nonlinear stability of $(\mathbf{v}^s, T^s, \alpha^s, p^s)$ and to this end we must determine the governing equations for an arbitrary perturbation $(\mathbf{u}, \theta, \phi, p)$ to this solution. This calculation is routine and so omitted; however, after nondimensionalization the required equations are seen to be (from the governing equations in [2])

$$\begin{aligned} &u_{i,t} + u_j u_{i,j} = -p_{,i} + \Delta u_i + (R\theta + S\phi)k_i, \qquad \begin{cases} \mathrm{Pr}(\theta_{,t} + u_i\theta_{,i}) = \Delta\theta + H_1 R w, \\ \mathrm{Sc}(\phi_{,t} + u_i\phi_{,i}) = \Delta\phi + H_2 S w, \end{cases} \\ &u_{i,i} = 0, \end{aligned} \tag{1.6}$$

which are to be solved in the layer $\mathbb{R}^2 \times (0,1)$.

In (1.6) $\mathbf{u} = (u,v,w)$, Pr, Sc are the Prandtl and Schmidt numbers, $H_1 = \operatorname{sgn}\beta$, $H_2 = \operatorname{sgn}\gamma$ and R^2, S^2 are the Rayleigh and dissociation Rayleigh numbers, respectively.

Finally, the complete boundary conditions which the solution to (1.6) must satisfy are:

$$\begin{aligned} &\mathbf{u} = \mathbf{0}, \quad z=0, \qquad \frac{\partial u}{\partial z} = \frac{\partial v}{\partial z} = w = 0, \quad z=1, \\ &\theta = \phi = 0, \quad z=1, \\ &\frac{\partial \phi}{\partial z} = r\phi, \quad z=0, \qquad \text{either (A) } \theta = 0, \ z=0, \\ &\qquad\qquad\qquad\qquad\quad \text{or} \quad \text{(B) } \frac{\partial \theta}{\partial z} = -s\phi, \ z=0, \end{aligned} \tag{1.7}$$

where r, s are positive nondimensional surface reaction numbers. In accordance with the observed cellular structure of Bénard instabilities in the presence of a free surface, we shall restrict attention to perturbations $(\mathbf{u}, \theta, \phi, p)$ which are periodic in x and y. A typical period cell in the nondimensional layer will be denoted by Ω and that part of the surface $z=0$ which forms part of the boundary of Ω will be denoted by Γ.

It is convenient to refer to the two situations (A) and (B) above, which correspond to prescribed temperature or thermal insulation, as cases (A) and (B).

2. Nonlinear energy stability for case (A). Mathematically, case (A) and case (B) are very different. In this section we examine case (A) when the applied temperature gradient is destabilizing, i.e., $H_1 = 1$, and when $\alpha_d < \alpha^e$, i.e., $H_2 = 1$. Under these conditions system (1.6) together with the appropriate boundary conditions (1.7) possesses the

desirable property that the linear operator associated with the linear time independent equations is symmetric with respect to the usual inner product on the Hilbert space $(L^2(\Omega))^5$. To verify this $\mathscr{L}$ denote the linear operator defined by the right-hand side of (1.6) and let $D(\mathscr{L})$ be the subset of $(L^2(\Omega))^5$ consisting of C^2 functions whose first three components are solenoidal and which satisfy the boundary conditions of case (A). Then if $(\mathbf{u}^\alpha, \theta^\alpha, \phi^\alpha) = a^\alpha$, $\alpha = 1,2$, are any two elements in $D(\mathscr{L})$, and we denote by $\langle \cdot, \cdot \rangle$ and $D(\cdot, \cdot)$ the inner product on $(L^2(\Omega))^5$ and the Dirichlet integral, a routine calculation shows that

$$\begin{aligned}\langle \mathscr{L}a^1, a^2 \rangle &= -D(\mathbf{u}^1, \mathbf{u}^2) - D(\theta^1, \theta^2) - D(\phi^1, \phi^2) \\ &\quad - r\int_\Gamma \phi^1\phi^2\, dA + R\int_\Omega \left[\theta^1 w^2 + w^1\theta^2\right] dx + S\int_\Omega \left[\phi^1 w^2 + w^1\phi^2\right] dx \\ &= \langle a^1, \mathscr{L}a^2 \rangle,\end{aligned}$$

and the truth of our claim is established.

To determine the nonlinear stability limit we introduce an energy

$$E(t) = \frac{1}{2}\|u\|^2 + \frac{1}{2}\mathrm{Pr}\|\theta\|^2 + \frac{1}{2}\mathrm{Sc}\|\phi\|^2, \tag{2.1}$$

$\|\cdot\|$ denoting the $L^2(\Omega)$ norm, and from (1.6), (1.7) case (A) we may then derive

$$\dot{E} = -\mathscr{D} + I \leqq -\mathscr{D}\left(1 - \max\frac{I}{\mathscr{D}}\right), \tag{2.2}$$

where the maximum is taken over the set of admissible solutions and where

$$\mathscr{D} = D(\mathbf{u}) + D(\theta) + D(\phi), \tag{2.3}$$

$$I = 2R\langle \theta, w \rangle + 2S\langle \phi, w \rangle - r\int_\Gamma \phi^2\, dA. \tag{2.4}$$

Here and for the remainder of the paper $D(\cdot)$ denotes the Dirichlet integral and $\langle \cdot, \cdot \rangle$ is the inner product on $L^2(\Omega)$. Since $\theta = \phi = 0$ on $z = 1$, Poincaré's inequality ensures the existence of a constant $\xi^2 > 0$ such the $\mathscr{D} \geqq \xi^2 E$, and so if

$$\max\frac{I}{D} < 1, \tag{2.5}$$

then (2.2) yields

$$\dot{E} \leqq -\xi^2 E\left(1 - \max\frac{I}{\mathscr{D}}\right),$$

from which it follows that $E \to 0$, $t \to \infty$, and the steady solution of (1.3) is nonlinearly stable. In [5] it is shown that for a symmetric system (2.5) is equivalent to finding the critical values of R and S of the time independent linearized system of equations from which (2.5) arose. In the present context this means we must determine the lowest eigenvalues R, S of the system (1.6), with the nonlinear terms and all time derivative terms set equal to zero, which meet the boundary conditions (1.7) case (A).

This is a convenient point to observe that if the *linearized* system of equations corresponding to (1.6) is studied then the symmetry of $\mathscr{L}$ ensures that the eigenvalues λ_n of linear theory arising from a time dependence like $e^{-\lambda t}$ are all real and so the results for linear stability coincide with those for nonlinear stability. The connection between

the linear and nonlinear results follows from the work of Galdi and Straughan [5]. The importance of this fact is that subcritical instabilities cannot occur and so instability may occur only by stationary convection.

The $\max(I/\mathscr{D})$ problem of determining the criteria for *nonlinear stability* of solution (1.3) then reduces to solving the linear eigenvalue problem

$$\begin{aligned} &\Delta u_i+(R\theta+S\phi)k_i=p_{,i}, \quad \Delta\phi+Sw=0, \\ &\Delta\theta+Rw=0, \end{aligned} \tag{2.6}$$

in Ω, with $\mathbf{u}$ solenoidal, and

$$\begin{aligned} &\mathbf{u}=0, \quad z=0, \qquad \frac{\partial u}{\partial z}=\frac{\partial v}{\partial z}=w=0, \quad z=1, \\ &\theta=\phi=0, \quad z=1, \quad \frac{\partial\phi}{\partial z}=r\phi, \quad \theta=0, \quad z=0. \end{aligned} \tag{2.7}$$

Even this system does not seem solvable analytically because of complications caused by the $z=0$ boundary conditions, although we could solve it numerically. However, the case of constant temperature is of interest and was solved in the linear case by Bdzil and Frisch [2] *when both boundaries are either stress free or fixed.* We are able to present an analytical treatment in the isothermal case and this is given next.

For the isothermal problem (2.6), (2.7) hold with $R\equiv\theta=0$. Due to linearity and the assumed periodicity of the solution a representation in the form $\mathbf{u}(\mathbf{x})=e^{i(kx+my)}\mathbf{u}(z)$ is possible, with a similar form for ϕ,p. Let $u_3(z)=W(z)$, $D=d/dz$ and $a^2=k^2+m^2$, then (2.6), (2.7) reduce to

$$(D^2-a^2)^3W=-a^2S^2W, \qquad z\in(0,1), \tag{2.8}$$

$$\begin{aligned} &W=DW=(D^2-a^2)^2(D-r)W=0, \quad z=0, \\ &W=D^2W=(D^2-a^2)^2W=0, \qquad z=1. \end{aligned} \tag{2.9}$$

Bdzil and Frisch [2] determine the first eigenvalue S_c^2 of (2.8), but with (2.9) replaced by conditions appropriate to both boundaries being simultaneously free *or* fixed. Their procedure depends on a variational principle and approximate values of S_c^2 are given for the limiting cases $r\to 0$, $r\to\infty$. For comparison with our results we include their values below.

TABLE 1

Values for S_c in isothermal case; after Bdzil and Frisch [2].

	$r\to\infty$		$r\to 0$	
Boundary conditions	a_c	S_c^2	a_c	S_c^2
2 free surfaces	2.2	658	2.0	546
2 rigid surfaces	3.2	1700	2.5	1066

In the above a_c denotes the critical value of the wavenumber, a, at the onset of instability.

For the physically relevant problem (2.8), (2.9) we find it unnecessary to resort to a variational principle: instead we employ an apparently less known technique of Chandrasekhar [4] appropriate to the rigid-free surface problem.

The idea is to shift the fluid domain to $-\frac{1}{2}<z<\frac{1}{2}$ and suppose $(2.9)_1$ holds on $z=-\frac{1}{2}$, but temporarily replace the conditions on the upper plane $z=\frac{1}{2}$ by

$$W=DW=(D^2-a^2)^2(D+r)W=0. \tag{2.10}$$

It follows from the evenness of the operator $(D^2-a^2)^3$ and the boundary conditions which now have to be satisfied at $z=\pm\frac{1}{2}$, that the solutions to (2.8) fall into two noncombining groups of even and odd functions.

The general solution to (2.8) may be expressed as a superposition of solutions of the form $W=e^{\pm qz}$, where q^2 is a root of the equation

$$(q^2-a^2)^3=-S^2a^2. \tag{2.11}$$

By letting $S^2=\tau^3a^4$ the six roots of (2.8) are $\pm iq_0$, $\pm q$, $\pm q^*$, where * denotes complex conjugate and where

$$\begin{aligned}
&q_0=a(\tau-1)^{1/2},\\
&\mathrm{re}(q)=q_1=a\left[\frac{1}{2}(1+\tau+\tau^2)^{1/2}+\frac{1}{2}\left(1+\frac{1}{2}\tau\right)\right]^{1/2},\\
&\mathrm{im}(q)=q_2=a\left[\frac{1}{2}(1+\tau+\tau^2)^{1/2}-\frac{1}{2}\left(1+\frac{1}{2}\tau\right)\right]^{1/2}.
\end{aligned}$$

It will be seen later that it is sufficient to consider only the odd solutions. Then,

$$W=A_0\sin q_0z+A\sinh qz+A^*\sinh q^*z,$$

for constants A_0, A. Boundary conditions $(2.9)_1$, (2.10) then determine three simultaneous linear equations for A_0, A, A^* and the solution of these requires the following determinant to vanish:

$$\begin{vmatrix}
1 & 1 & 1\\
q_0\cot\frac{1}{2}q_0 & q\coth\frac{1}{2}q & q^*\coth\frac{1}{2}q^*\\
q_0\cot\frac{1}{2}q_0+r & \frac{1}{2}(i\sqrt{3}-1)\left(q\coth\frac{1}{2}q+r\right) & -\frac{1}{2}(i\sqrt{3}+1)\left(q^*\coth\frac{1}{2}q^*+r\right)
\end{vmatrix}. \tag{2.12}$$

This condition reduces to

$$\begin{aligned}
&\sqrt{3}\left(q_0\cot\frac{1}{2}q_0+r\right)(q_1\sin q_2-q_2\sinh q_1)(\cosh q_1-\cos q_2)\\
&\quad=(q_1\sinh q_1+q_2\sin q_2)^2-rq_0\cot\frac{1}{2}q_0(\cosh q_1-\cos q_2)^2\\
&\quad\quad+(q_2\sinh q_1-q_1\sin q_2)^2\\
&\quad\quad-(\cosh q_1-\cos q_2)(q_1\sinh q_1+q_2\sin q_2)\left(q_0\cot\frac{1}{2}q_0-r\right).
\end{aligned} \tag{2.13}$$

When the dimensionless reaction rate r (the ratio of the rate of reaction to the rate of diffusion) is large ($r \to \infty$), (2.13) reduces to

$$q_0 \cot \frac{1}{2} q_0 = \frac{(q_1 + q_2\sqrt{3})\sinh q_1 - (q_1\sqrt{3} - q_2)\sin q_2}{\cosh q_1 - \cos q_2}, \tag{2.14}$$

consistent with that obtained by Chandrasekhar [4, p. 41], for the standard rigid-free Bénard problem.

Equation (2.13) is a transcendental equation relating a and τ which we solve numerically. The idea is to determine τ for a given a; the corresponding characteristic value of S^2 then follows. The critical S^2 which governs the nonlinear stability boundary corresponds to the minimum.

The even solutions obtained by taking

$$W = A_0 \cos q_0 z + A \cosh qz + A^* \cosh q^* z,$$

also lead to a characteristic equation for S^2. However, returning to the original problem with

$$W = D^2 W = (D^2 - a^2)^2 W = 0,$$

on the upper surface, it should be noted that the odd solutions satisfy these boundary conditions on $z = 0$. Thus we consider only the odd solutions in the layer between $z = \pm \frac{1}{2}$ and recover the solution to the original problem on a layer of half the depth. The eigenvalue, S^2, to the original problem is the $\frac{1}{16}$th the value obtained from the problem under consideration.

The final results for the case of a lower catalytic rigid boundary and a free upper boundary are given in Table 2.

TABLE 2

r	a_c	S_c^2
10^{10}	2.682	1100.65
100	2.668	1084.64
50	2.653	1070.46
10	2.564	996.50
5	2.492	949.64
2.5	2.412	904.77
0.8	2.304	853.30
0.6	2.285	845.19
0.4	2.264	836.46
0.2	2.241	827.01
0.0	2.215	816.74

Our numerical results are consistent with Chandrasekhar [4] in that when $r \to \infty$ we recover the result of [4], viz. $S_c^2 = 1100.65$.

Notes. 1. It is worth observing that the above method may be employed in the free-free boundary problem considered by Bdzil and Frisch [2].

2. Although the analysis presented here has been restricted to an isothermal system we may, for the nonisothermal case, in the limit $r \to \infty$, deduce the stability boundary easily. In this case (2.6), (2.7) yield

$$(D^2 - a^2)^3 W = -a^2(R^2 + S^2)W,$$

subject to the boundary conditions

$$W = DW = (D^2 - a^2)^2 W = 0, \quad \text{on } z = 0,$$
$$W = D^2 W = (D^2 - a^2)^2 W = 0, \quad \text{on } z = 1.$$

Stability follows in this case provided

$$R^2 + S^2 \leqq 1100.65$$

this result being in agreement with those of Joseph [6], [7].

3. Nonlinear energy stability for case (B). In this section we return to the nonisothermal problem with a thermally insulated lower catalytic plate, the upper surface being stress free. Thus we are investigating the stability of a solution to (1.6) subject to boundary conditions (1.7) case (B). For clarity we rewrite the boundary conditions appropriate to case (B) here,

$$\mathbf{u} = \mathbf{0}, \quad \frac{\partial \phi}{\partial z} = r\phi, \quad \frac{\partial \theta}{\partial z} = -s\phi, \quad z = 0, \tag{3.1}$$

$$\frac{\partial u}{\partial z} = \frac{\partial v}{\partial z} = w = \theta = \phi = 0, \qquad z = 1 \tag{3.2}$$

with $\mathbf{u}, \phi, \theta, p$ still periodic in x, y as stated in the paragraph following (1.7).

We are interested in the case where $H_1 = -1$ and so from (1.4) and (1.5), $H_2 = +1$. Case (B) is mathematically very different from case (A) partly because $H_1 = -1$ and partly due to the boundary conditions on $\partial\theta/\partial z$ at $z = 0$. Both conditions lead to loss of symmetry of the linear time independent operator in (1.6) and so we are no longer able to infer nonlinear stability from an investigation of the equations appropriate to linear stationary convection. Nevertheless, we commence with the energy functional (2.1) and derive the energy equation as

$$\dot{E} = -D(\mathbf{u}) - D(\theta) - D(\phi) + 2S\langle \phi, w \rangle - r\int_\Gamma \phi^2 \, dA + s\int_\Gamma \phi\theta \, dA. \tag{3.3}$$

Because of the integrals over Γ the analysis analogous to that leading from (2.2) to (2.7) yields a complicated Euler–Lagrange system which we would only be able to solve by means of numerical eigenvalue techniques. We have, therefore, developed an alternative technique which avoids heavy numerical work and allows us to use the results of §2 to obtain the nonlinear stability estimates appropriate to this section.

Basically, the idea is to first estimate the integrals over Γ by means of the Cauchy–Schwarz, Poincaré and trace inequalities (see e.g., Bandle [1, p. 101]). As we wish to obtain *quantitative* stability results, however, we need specific values for the constants in these inequalities and so proceed directly as follows. Since $\phi = 0$ on $z = 1$, for x, y fixed we have

$$\phi(x,y,0) = -\int_0^1 \frac{\partial \phi}{\partial z}(x,y,z)\, dz \leqq \left(\int_0^1 \left[\frac{\partial \phi}{\partial z}(x,y,z) \right]^2 dz \right)^{1/2},$$

by Cauchy–Schwarz. Hence, squaring and integrating over Γ,

$$\int_\Gamma \phi^2 \, dA \leqq D(\phi). \tag{3.4}$$

Obviously, the same inequality holds for θ.

Next, the Cauchy–Schwarz and arithmetic-geometric mean inequalities together with (3.4) allow us to show

$$s\int_\Gamma \theta\phi\, dA \leqq \frac{1}{2}s\gamma D(\theta)+\frac{1}{2}s\gamma^{-1}D(\phi), \tag{3.5}$$

where $\gamma=1$. Inequality (3.5) is employed in (3.3) together with the θ-version of (3.4) to yield,

$$\dot{E}\leqq -D(\mathbf{u})+2S\langle\phi,w\rangle-\left(1-\frac{1}{2}s\right)[D(\phi)+D(\theta)]-r\int_\Gamma\phi^2\,dA. \tag{3.6}$$

To use (3.6) we must require

$$s<2. \tag{3.7}$$

Denote by η the number $1-\frac{1}{2}s$ (>0). Then by an argument similar to that used in §2 we obtain from (3.6),

$$\dot{E}\leqq -\mathscr{D}\left(1-\frac{S}{\Lambda}\right)-\eta D(\theta), \tag{3.8}$$

where

$$1|\Lambda=\max\frac{I}{\mathscr{D}}, \tag{3.9}$$

with $I=2\langle\phi,w\rangle$, $\mathscr{D}=D(\mathbf{u})+\eta D(\phi)+A$,[1] and where the maximum is over the set of admissible solutions $\mathbf{u},\phi$. If $S<\Lambda$ then since $\mathscr{D}$ and $D(\theta)$ both satisfy Poincaré's inequality we may derive an inequality of the form $\dot{E}\leqq-\mu E$, $\mu>0$, from which nonlinear stability follows.

The nonlinear stability problem is, therefore, reduced to solving the maximum problem (3.9). We are led naturally to the Euler–Lagrange equations[2]

$$\Delta\mathbf{u}+S_E\phi\mathbf{k}-\nabla p=0,\qquad S_E w+\eta\Delta\phi=0, \tag{3.10}$$

to be solved subject to boundary conditions (3.1), (3.2). In (3.10) S_E is an eigenvalue which arises from the introduction of a Lagrange multiplier. It is easy to show that $S_E=\Lambda$ and so $S<S_E$ is a sufficient condition to guarantee the decay of not necessarily infinitesimal disturbances. The functions u,v,p,ϕ are next eliminated from (3.10) and then due to linearity and the periodicity of w we may write $w=W(z)\cdot\exp[i(kx+my)]$ to obtain,

$$(D^2-a^2)^3W=-\eta^{-1}S_E^2a^2W,\qquad z\in(0,1), \tag{3.11}$$

the solution to which must satisfy,

$$\begin{aligned} &W=D^2W=(D^2-a^2)^2W=0, && z=1,\\ &W=DW=(D^2-a^2)^2(D-q)W=0, && z=0. \end{aligned} \tag{3.12}$$

---

[1] $A=r\int_\Gamma\phi^2\,dA$.

[2] With $q=r/\eta$; cf. [9].

Of course, (3.11) and (3.12) may be identified with (2.8) and (2.9) and so we may use the results in Table 2 to deduce nonlinear stability in case (B), provided also the restriction (3.7) is satisfied. To illustrate, we give two examples. The equilibrium solution (1.3) is nonlinearly stable provided

$$r\to 0, \quad s<2, \quad S^2<816.74\left(1-\frac{1}{2}s\right), \tag{3.13}$$

or

$$r=0.6\left(1-\frac{1}{2}s\right), \quad s<2, \quad S^2<845.19\left(1-\frac{1}{2}s\right). \tag{3.14}$$

It might be observed that our stability criterion places no restriction on the size of the Rayleigh number. This is due to the fact that $H_1=-1$; in the absence of reaction this corresponds to heating the layer from above and a similar conclusion is possible there, see Joseph [7].

In the limiting case $r\to 0$, $s\to 0$ both the linear and energy stability boundaries are easily obtained and serve a very useful purpose. Assuming stationary convection the linear equations which arise from (1.6) yield

$$(D^2-a^2)^3W=-a^2(S^2-R^2)W,$$

with the boundary conditions

$$\begin{aligned} w=D^2W=(D^2-a^2)^2W=0, &\qquad \text{on } z=1,\\ W=DW=D(D^2-a^2)^2W=0, &\qquad \text{on } z=0. \end{aligned}$$

Again the results of Table 2 apply and so the instability boundary is given by

$$S^2-R^2=816.74.$$

From (3.13) there is nonlinear energy stabilty provided

$$S^2<816.74.$$

Therefore, there is the possibility of oscillatory convection (subcritical bifurcation) for S^2 in the region

$$816.74<S^2<816.74+R^2.$$

ON THE SPECTRAL PROPERTIES OF A CLASS OF ELLIPTIC FUNCTIONAL DIFFERENTIAL OPERATORS ARISING IN FEEDBACK CONTROL THEORY FOR DIFFUSION PROCESSES*

A. VAN HARTEN†

Abstract. In this paper Dirichlet boundary value problems are considered for certain operators of the form $L+\Pi$, where L is a 2nd order, elliptic, formally self-adjoint *PDO* and Π is a feedback operator with finite-dimensional range.

The results concern mainly the resolvent $(L+\Pi-\lambda)^{-1}$, the analyticity of the semigroup generated by $L+\Pi$, the location of the spectrum $\sigma(L+\Pi)$ and the completeness of the eigenspaces and the eigenprojections associated to $\sigma(L+\Pi)$.

As a consequence of the completeness of the eigenprojections it is possible to derive quite a number of interesting formulas of the "resolution of the identity" type.

1. Introduction. In this paper we shall consider problems of Dirichlet type on a bounded domain $D\subset\mathbb{R}^d$ for a class of operators of the form $L+\Pi$. Here L will be a linear, uniformly elliptic, formally selfadjoint, 2nd order partial differential operator with time-independent real coefficients

$$L=\sum_{i=1}^{d}\sum_{j=1}^{d}\frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}\right)+a_0. \tag{1.1}$$

For the sake of simplicity we shall usually assume that the domain D has a smooth boundary ∂D and that the coefficients of L are elements of $C^\infty(\overline{D})$.

Of course $\overline{D}$ denotes the closure of D in $\mathbb{R}^d$.

The matrix $A=(a_{ij})$ is strictly positive definite, uniformly on $\overline{D}$ and symmetric. The structure of Π will be as follows:

$$\Pi=\sum_{i=1}^{p}c_iP_i,\qquad p<\infty. \tag{1.2}$$

The c_i's will be real functions only dependent of the space-coordinates $x\in\overline{D}$. They will be chosen as elements of some Banach space Y of real functions on $\overline{D}$.

The P_i's will be time-independent real continuous linear functionals on some Banach space X of real functions on $\overline{D}$, i.e. the P_i's are elements of $X'=$ the dual space of X.

Therefore the operator Π can be interpreted as an element of $\mathscr{L}(X\to Y)=$ the space of continuous linear operators from X into Y. Due to the requirement $p<\infty$ the operator Π has a finite-dimensional range, i.e. is degenerate (see Kato (1966)). A striking difference between the operator Π and the differential operator L is that Π possesses a nonlocal character. This explains that $L+\Pi$ is referred to as a functional differential operator in the title of this paper.

*Received by the editors July 2, 1980, and in final revised form September 12, 1984.
†Rijksuniversiteit Utrecht, Mathematisch Institut, 3508 TA Utrecht, the Netherlands.

The problems we shall look at can now be formulated as follows:

$$\frac{\partial v}{\partial t} = (L+\Pi)v, \tag{1.3}$$

$v=0$ on ∂D, boundary conditions of Dirichlet type;

$v(\cdot,0)=\Psi$, initial conditions,

$$(L+\Pi-\lambda)u=g, \tag{1.4}$$

$u=0$ on ∂D, boundary conditions of Dirichlet type.

Note that (1.3) constitutes a set of equations for the evolution in time of the function v, whereas (1.4) is a stationary problem for the function u.

In (1.4) λ has to be considered as a spectral parameter and the function g is some inhomogeneous term.

The emphasis in this paper will be on the spectral analysis associated to (1.4).

1.1. On the relation to feedback control problems. The topics considered in this paper have their origin in the study of controlled heat-diffusion processes. The control applied to such a process will be instantaneous and of an automatic feedback type. The heating/cooling of this feedback mechanism will flow directly into the domain (i.e. not through the boundary). If we further suppose that no convection of heat will take place and that the temperature is given on the boundary ∂D, then a homogeneous version of a mathematical model which describes the evolution in time of the temperature is given by (1.3). In (1.3) the effect of diffusion of heat and direct exchange with the surroundings is incorporated in L. The effect of the feedback control is described by the operator Π. In this context the functions c_i ar called the "control inputs" and the P_i's are called "observers". The operator Π will sometimes be referred to as the feedback control operator.

Very simple illustrations of what we have in mind may serve. The following examples have $p=1$, $\Pi=c_1P_1$.

(i) $c_1\in H^s(D)$ for some $s\geqq 0$, $P_1\in L_2(D)'$ f.e. the observer P_1 observes the average over D: $P_1w=\int_D w(x)\,dx$ for $w\in L_2(D)$;

(ii) $c_1\in C^\alpha(\overline{D})$ for some $\alpha\geqq 0$, $P_1\in C(D)'$ f.e. the observer P_1 observes the value in a point $y\in\overline{D}$: $P_1w=w(y)$ for $w\in C(\overline{D})$.

Here the following notation is used:

$L_2(D)$ = space of equivalence classes of square integrable functions on D;

$H^s(D)$ = Sobolev space of order S on D; (see Adams (1975); Lions and Magenes (1971));

$C^\alpha(\overline{D})$ = Hölder space of order α on $\overline{D}$ (see Adams, (1975); Ladyzhenskaya and Ural'tseva (1968)).

Other examples are explored in van Harten, Schumacher (1980). For further information on this type of control problems we refer to Curtain and Pritchard (1978). For a related class of problems in which the control enters in the b.c. we refer to Triggiani (1980) and references given there.

1.2. Description of the contents. The results of this paper can be divided into two groups. The first group of results concerns the solvability theory for the problem (1.4), the properties of the resolvent $(L+\Pi-\lambda)^{-1}$ and the solution of (1.3) in terms of the analytic semigroup generated by $L+\Pi$. These results are found in the §§3 and 4 and they can be considered as basic material for the second group of results. The results on the analytic semigroup generated by $L+\Pi$ are a generalization of an analogous result

for bounded Π, see Curtain and Pritchard (1978, Thm. 2.31) and also of Kato (1966, pp. 498–499). The second group contains results on the location of the spectrum associated to (1.4) and on the completeness of the eigenspaces and eigenprojections associated to this spectrum. The completeness results given here are certainly nontrivial since in general $L+\Pi$ is not formally self-adjoint in any sense. The results on completeness of eigenprojections are generalizations of Kato (1966, Thms. 4.15 and 4.16, Chap. V, §4.5). From these results we can deduce very interesting "resolution of the identity" formula's in $L_2(D)$ and certain other Hilbert spaces. These "resolutions of the identity" look promising with respect to applications, also applications outside the control context. The second group of results can be found in the Theorems 5, 6, 7 and 8.

Let us conclude the introduction with a few remarks. Our first remark concerns the spaces X and Y mentioned in the description of the operator Π.

It is important to notice that for a given problem it is always possible to choose the spaces X and Y in several ways. It is then of course logical to take Y as "small" as possible and X as "large" as possible in order to get a most significant theory. In any way building a theory for these problems (1.3)–(1.4) will depend strongly on what one takes for X and Y. The choices which we allow for X and Y will be specified further on.

Secondly, though from a physical point of view it is natural to look at L and Π as operators on real functions, it will sometimes be profitable to extend L and Π to complex functions. Notationally we shall not distinguish between real operators and function spaces and their obvious complex extensions.

2. The uncontrolled problem. The main purpose of this section is to introduce some notations and concepts, which will be used further on. First this will be done for the solution(s), their regularity properties, the spectrum and the eigenprojections associated with the problem:

$$(L-\lambda)u=g, \tag{2.1}$$

$$u=0 \quad \text{on } \partial D \quad (BC). \tag{2.2}$$

In §2.2 we introduce some notation concerning fractional powers of $-L+\lambda_0$, $\lambda_0 \in \mathbb{R}$ sufficiently large.

2.1. Solutions of (2.1), (2.2); spectrum and eigenprojections. It is well known that for $\lambda=\lambda_0$, with λ_0 real and sufficiently large >0 the resolvent $(L-\lambda_0)^{-1}$ is a compact, selfadjoint operator from $L_2(D)$ into $L_2(D)$ (see Trèves (1975)). Consequently the spectrum $\sigma(L)$ associated to (2.1)–(2.2) on $L_2(D)$ consists of a denumerable infinite set of isolated eigenvalues on the real axis bounded at the positive side and extending towards $-\infty$ without accumulation points (see Dunford and Schwartz (1963)). Each eigenvalue has a finite algebraic multiplicity and the number of linearly independent eigenfunctions corresponding with an eigenvalue equals its algebraic multiplicity. Further the eigenfunctions can be chosen in such a way that they form an orthonormal, complete basic system in $L_2(D)$.

For the sequence of eigenvalues and corresponding linearly independent orthonormal eigenfunctions we shall use the notation:

$$\mu_n, \phi_n \quad \text{with } n \in N. \tag{2.1.1}$$

The numbering is such that

$$k>n \quad \Rightarrow \quad \mu_k \leqq \mu_n \text{ and } \langle \phi_k, \phi_n \rangle_{L_2(D)} = \delta_{n,k}. \tag{2.1.2}$$

In this numbering each eigenvalue is repeated according to its algebraic multiplicity.

For the system $\{\phi_n; n\in\mathbb{N}\}$ we have the "resolution of the identity" formula inherent to the completeness of this system in $L_2(D)$:

$$I=\sum_{n=1}^{\infty}\phi_n\langle\phi_n|\cdot\rangle_{L_2(D)}. \tag{2.1.3}$$

For $\lambda\in\sigma(L)$ we shall denote by $E(\lambda)$: $L_2(D)\to L_2(D)$ the orthogonal projection on the eigenspace corresponding to λ. If $\lambda\in\sigma(L)$ we define $J(\lambda)=\{n\in\mathbb{N}\,|\,\mu_n=\lambda\}$. Hence

$$E(\lambda)=\sum_{n\in J(\lambda)}\phi_n\langle\phi_n|\cdot\rangle_{L_2(D)}. \tag{2.1.4}$$

To conclude this subsection we mention some rather elementary facts on the growth of the eigenvalues for $n\to\infty$.

Using Minakshisundaram and Pleyel (1949) or Garabedian (1964) we see that for n sufficiently large the eigenvalues satisfy

$$R_1 n^{\nu}\leqq|\mu_n|\leqq R_2 n^{\nu},\qquad n\geqq n_0. \tag{2.1.5}$$

Here R_1, R_2 are real constants >0 and $\nu=2/d$ with d the dimension of D.

The problem (2.1)–(2.2) possesses a unique solution for all $g\in L_2(D)$ if and only if $\lambda\notin\sigma(L)$. This solution will be denoted by

$$u=(L-\lambda)^{-1}g.$$

In the case $\lambda\in\sigma(L)$ the problem (2.1)–(2.2) possesses a solution if and only if $g\in L_2(D)$ satisfies $E(\lambda)g=0$. Under this condition the solution space of (2.1)–(2.2) is given by

$$\begin{aligned}&u\in(L-\lambda)^{-1}g\Leftrightarrow\\&u=(L-\lambda)_*^{-1}g-u_1\quad\text{with}\\&(L-\lambda)_*^{-1}=\sum_{n\notin J(\lambda)}\phi_n(\mu_n-\lambda)^{-1}\langle\phi_n,g\rangle_{L_2(D)},\\&u_1\in\operatorname{span}\{\phi_n|n\in J(\lambda)\}.\end{aligned} \tag{2.1.6}$$

The operator $(L-\lambda)_*^{-1}$ will be called the restricted resolvent at $\lambda\in\sigma(L)$. Once a solution of (2.1)–(2.2) exists, it possesses the following regularity properties:

$$\begin{aligned}&g\in H^s(D)\Rightarrow u\in H^{s+2}(D),\quad s\geqq 0,\quad s\notin\mathbb{N}-\tfrac{1}{2},\\&g\in C^{\alpha}(\overline{D})\Rightarrow u\in C^{\alpha+2}(\overline{D}),\quad \alpha>0,\quad \alpha\notin\mathbb{N}.\end{aligned} \tag{2.1.7}$$

Moreover the operators $(L-\lambda)^{-1}$, $\lambda\notin\sigma(L)$ and $(L-\lambda)_*^{-1}$, $\lambda\in\sigma(L)$ are bounded in each sense suggested by (2.1.7). For these results we refer to: Lions and Magenes (1972, Part I) and Ladyzhenskaya and Ural'tseva (1968).

Note that as a consequence of (2.1.7) all eigenfunctions are elements of $C^{\infty}(\overline{D})$.

2.2. Fractional powers of $-L+\lambda_0$, $\lambda_0\in\mathbb{R}$ sufficiently large. In this section we shall suppose that $\lambda_0\in\mathbb{R}$ satisfies

$$\lambda_0\geqq\max_{\overline{D}}a_0+1\underset{\text{def}}{=}\mu_0. \tag{2.2.1}$$

Let us introduce the simplified notation A for the operator induced by $-L+\lambda_0$ with Dirichlet boundary conditions on either $L_2(D)$ or $C(\overline{D})$. Using variational techniques and the maximum principle for 2nd order elliptic P.D.E., it is easy to check that the

resolvent $(s+A)^{-1}$ with $s\in\mathbb{R}$, $s>0$ satisfies the following estimates:

$$\|\|\|(s+A)^{-1}\|\|\|_{L_2(D)}\leqq(1+s)^{-1}, \tag{2.2.2}$$

$$\|\|\|(s+A)^{-1}\|\|\|_{C(\overline{D})}\leqq(1+s)^{-1}. \tag{2.2.3}$$

Here we use the notation $\|\|\|\ \|\|\|_X$ for the usual norm on the space of bounded operators from the Banach space X into itself.

The operator A defined on $L_2(D)$ is closed, its domain is dense is $L_2(D)$ and because of (2.3.2) this operator is of positive type (see Krasnoselskii (1976, p. 279)).

Of course it is not true that the operator A defined on $C(\overline{D})$ has a domain dense in $C(\overline{D})$. This is remedied by restricting the operator to

$$C_0(\overline{D})=\{f\in C(\overline{D})\,|\,f=0 \text{ on } \partial D\}.$$

On $C_0(\overline{D})$ the operator A is also closed, densely defined and of positive type.

These facts induce that on $L_2(D)$ or $C_0(\overline{D})$ fractional powers of A are well defined; see Krasnoselskii (1976, pp. 280–288).

It will be very useful to introduce some Hilbert and Banach spaces connected to these fractional powers of A. For $\alpha\geqq 0$ we define:

$$HD(\alpha)=\text{range of } A^{-\alpha} \text{ on } L_2(D)=\text{domain of } A^{\alpha} \text{ w.r.t. } L_2(D), \tag{2.2.4}$$
$$\|u\|_{HD(\alpha)}=\|A^{\alpha}u\|_{L_2(D)},\quad \langle u,v\rangle_{HD(\alpha)}=\langle A^{\alpha}u,A^{\alpha}v\rangle_{L_2(D)},$$

$$C_0D(\alpha)=\text{range of } A^{-\alpha} \text{ on } C_0(\overline{D})=\text{domain of } A^{\alpha} \text{ w.r.t. } C_0(\overline{D}), \tag{2.2.5}$$
$$\|u\|_{C_0D(\alpha)}=\|A^{\alpha}u\|_{C(\overline{D})},$$

$$CD(\alpha)=\{u\in HD(\alpha)\,|\,A^{\alpha}f\in C(\overline{D})\}, \tag{2.2.6}$$
$$\|u\|_{CD(\alpha)}=\|A^{\alpha}u\|_{C(\overline{D})}.$$

It is not difficult to check that different choices of λ_0 lead to equivalent spaces and norms, see also van Harten (1979).

Note that for $\alpha_1>\alpha_2$ we have $HD(\alpha_1)\subset_{\text{dense}} HD(\alpha_2)$, $C_0D(\alpha_1)\subset_{\text{dense}} C_0D(\alpha_2)$, see Krasnoselskii (1976, pp. 286). It is also true that $\alpha_1>\alpha_2\Rightarrow CD(\alpha_1)\subset CD(\alpha_2)$, but in this case the inclusion is not necessarily dense (see Appendix, Proposition A.4).

The spaces $HD(\alpha)$, $CD(\alpha)$ and $C_0D(\alpha)$ will play a dominant role in the theory to be developed further on.

A very natural and important question about the spaces and norms introduced in (2.2.4)–(2.2.6) is how they are related to the Sobolev and Hölder spaces, $H^s(D)$ and $C^s(\overline{D})$, $s>0$. It is possible to show, that

$$HD(\alpha)\cong\{u\in H^{2\alpha}(D)\,|\,L^k u=0 \text{ on } \partial D,\ k \text{ integer},\ 0\leqq 2k<2\alpha-\tfrac{1}{2}\}, \tag{2.2.7}$$
if $2\alpha+\frac{3}{2}\in\mathbb{N}$;

$$C_0D(\alpha)\subset\{u\in C^{2\beta}(\overline{D})\,|\,L^k u=0 \text{ on } \partial\partial,\ k \text{ integer},\ 0\leqq k\leqq\beta\}, \text{ if } 0\leqq\beta<\alpha; \tag{2.2.8}$$
$$C_0D(\alpha)\supset\{u\in C^{2\beta}(\overline{D})\,|\,L^k u=0 \text{ on } \partial\partial,\ k \text{ integer},\ 0\leqq k\leqq\alpha\}, \text{ if } \beta>\alpha;$$

$$A^{-\beta}CD(\alpha)\supset C_0D(\alpha+\beta-\varepsilon),\ \alpha\geqq 0,\ \beta>0,\ 0\leqq\varepsilon<\alpha+\beta \tag{2.2.9}$$
or equivalently,
$$CD(\alpha)\subset C_0D(\alpha-\varepsilon),\qquad 0<\varepsilon<\alpha,$$
$$CD(\alpha)\supset C_0D(\alpha).$$

All these inclusions are accompanied by continuous injections.

The relation between $HD(\alpha)$ and Sobolev spaces as given in (2.2.7) is well known (see for example Lions and Magenes (1972, Part I, Remark 2.3, p. 10)).

To this author's knowledge the contents of (2.2.8)–(2.2.9) though not difficult to prove, are not available in the literature. The proofs of the statements (2.2.8) and (2.2.9) can be found in an Appendix.

Let us now look at the problem (2.1)–(2.2) with g in the space $HD(\alpha)$, $CD(\alpha)$ or $C_0D(\alpha)$. The list given in (2.1.7) for the regularity of a solution can be extended as follows:

$$
\begin{aligned}
&g\in HD(\alpha)\Rightarrow u\in HD(\alpha+1), && \alpha\geqq 0,\\
&g\in CD(\alpha)\Rightarrow u\in CD(\alpha+1), && \alpha\geqq 0,\\
&g\in C_0D(\alpha)\Rightarrow u\in C_0D(\alpha+1), && \alpha\geqq 0.
\end{aligned}
\tag{2.2.10}
$$

This is easily seen by rewriting (2.1)–(2.2) as $Au=(\lambda_0-\lambda)u-g$.

We conclude this section with a remark on the eigenfunctions $\{\phi_n\colon n\in\mathbb{N}\}$ introduced in §2.1.It is straightforward to check, that $\{\phi_n/\|\phi_n\|_{HD(\alpha)}; n\in\mathbb{N}\}$ defines an orthonormal sequence in $HD(\alpha)$. Using the selfadjointness of A^{-1} on $HD(\alpha)$, we see that this orthonormal sequence of functions is also complete in $HD(\alpha)$. As a consequence analogues of (2.1.3) and (2.1.4) can be given in $HD(\alpha)$.

3. The controlled problem: application of the Weinstein–Aronszajn theory. For future reference we shall now present some well-known basic material on the solvability of the problem:

$$(L+\Pi-\lambda)u=g, \tag{3.1}$$

$$u=0 \quad \text{on } \partial D, \quad \text{boundary condition of Dirichlet type.} \tag{3.2}$$

This theory is essentially due to Weinstein and Aronszajn and it is built in an essential way on the degeneracy, i.e. finite-dimensional range property, of the operator $\Pi=\sum_{i=1}^{p}c_iP_i$ with $c_i\in Y$ and $P_i\in X'$.

For the Banach spaces X, Y we allow the following choices:

$$
\begin{aligned}
&\text{a.}\quad X=H^{s+2}(D),\ Y=H^{s}(D), && s\geqq 0,\ s\notin -\tfrac{1}{2}+N,\\
&\text{b.}\quad X=C^{\alpha+2}(\overline{D}),\ Y=C^{\alpha}(\overline{D}), && \alpha\geqq 0,\ \alpha\notin\mathbb{N} \quad \text{or}\\
&\text{c.}\quad X=HD(\alpha+1),\ Y=HD(\alpha), && \alpha\geqq 0 \quad \text{or}\\
&\text{d.}\quad X=CD(\alpha+1),\ Y=CD(\alpha), && \alpha\geqq 0 \quad \text{or}\\
&\text{e.}\quad X=C_0D(\alpha+1),\ Y=C_0D(\alpha), && \alpha\geqq 0.
\end{aligned}
\tag{3.3}
$$

In our consideration we shall always take

$$g\in Y. \tag{3.4}$$

Next we shall look for a solution u of (3.1)—(3.2) in the space X. Note, that L is a closed operator on Y with domain X and that because of (2.1.7), (2.2.10) Π is relatively bounded w.r.t L. As a consequence the theory as given in Kato (1966, Chap. IV, §6) can be applied and it leads to the following results.

First we consider case (i), where $\lambda\notin\sigma(L)$. Let c denote the p-vector of control inputs, i.e. $c\in Y^P$. Analogously we define p as the p-vector of observers i.e. $P\in\{X'\}^P$.

Let $\Omega(\lambda)$ be the $p\times p$ matrix with the following matrix elements:

$$[\Omega(\lambda)]_{i,j}=P_i(L-\lambda)^{-1}c_j+\delta_{ij}. \tag{3.5}$$

In case (i) the problem (3.1), (3.2) is uniquely solvable if and only if the matrix $\Omega(\lambda)$ is nonsingular.

The solution is then given by

$$(3.6)\quad u=(L+\Pi-\lambda)^{-1}g=(L-\lambda)^{-1}g-\left\langle (L-\lambda)^{-1}c, \Omega(\lambda)^{-1}P(L-\lambda)^{-1}g\right\rangle,$$

where $\langle\ ,\ \rangle$ denotes the obvious pairing between X^P and $\mathbb{C}^P$. The resolvent $(L+\Pi-\lambda)^{-1}$ is an element of $\mathscr{L}(Y\to X)$.

If for $\lambda\notin\sigma(L)$ it holds true that the matrix $\Omega(\lambda)$ is singular then λ is a point of the spectrum associated to to (3.1), (3.2). The homogeneous problem then possesses nontrivial solutions which are given by

$$(3.7)\qquad u=\left\langle (L-\lambda)^{-1}c,\xi\right\rangle \text{ with } \xi\in\text{null space of } \Omega(\lambda).$$

Let us now consider case (ii), where $\lambda\in\sigma(L)$. We introduce the notation $J(\lambda)=\{k+i\,|\,1\leqq i\leqq m\}$ with m the algebraic multiplicity of the eigenvalue $\lambda\in\sigma(L)$, and we define terms as follows. Let $\phi\in X^m$ be the vector of eigenfunctions $\phi_{k+1},\cdots,\phi_{k+m}$. By ϕ' we shall denote the element of $\{Y'\}^m$ with components

$$\langle\phi_{k+1},\cdot\rangle_{L_2(D)},\cdots,\langle\phi_{k+m},\cdot\rangle_{L_2(D)}.$$

Let us introduce the following matrices

$$\begin{aligned}
&[\Omega_*(\lambda)]_{i,j}=P_i(L-\lambda)_*^{-1}c_j+\delta_{ij}, && \text{a } p\times p \text{ matrix},\\
&[P\phi^T]_{i,j}=P_i\phi_{k+j}, && \text{a } p\times p \text{ matrix},\\
&[\phi' c^T]_{i,j}=\langle\phi_{k+i},c_j\rangle_{L_2(D)}, && \text{a } m\times p \text{ matrix}.
\end{aligned}$$

Further we need the following $(p+m)\times(p+m)$ matrix:

$$(3.8)\qquad \hat{\Omega}(\lambda)=\begin{pmatrix}\Omega_*(\lambda) & P\phi^T\\ \phi' c^T & 0\end{pmatrix}.$$

It is easy to see that in case (ii) the problem (3.1.2) is uniquely solvable if and only if the matrix $\hat{\Omega}(\lambda)$ is nonsingular. The solution is then given by

(3.9)

$$u\underset{\text{def}}{=}(L+\Pi-\lambda)_*^{-1}g=(L-\lambda)^{-1}g+\left\langle\begin{pmatrix}(L-\lambda)_*^{-1}c\\ \phi\end{pmatrix},\quad \hat{\Omega}(\lambda)^{-1}\begin{pmatrix}P(L-\lambda)_*^{-1}\\ \phi'\end{pmatrix}g\right\rangle.$$

In these circumstances $(L+\Pi-\lambda)^{-1}$ is again an operator $\in\mathscr{L}(Y\to X)$. If for $\lambda\in\sigma(L)$ it holds true that the matrix $\hat{\Omega}(\lambda)$ is singular then λ is a point of the spectrum associated with (3.1–2).

The homogeneous problem then possesses nontrivial solutions given by

$$(3.10)\qquad u=\left\langle\begin{pmatrix}(L-\lambda)_*^{-1}c\\ \phi\end{pmatrix},\quad \begin{pmatrix}\xi\\ \zeta\end{pmatrix}\right\rangle \text{ with } \begin{pmatrix}\xi\\ \zeta\end{pmatrix}\in\text{null space of } \hat{\Omega}(\lambda).$$

Hence, let $\sigma(L+\Pi)$ be the spectrum associated with the controlled operator. Then a Fredholm alternative is valid: $\lambda\in\sigma(L+\Pi)\Leftrightarrow$ the problem (3.1)–(3.2) possesses non-trivial solutions in the space X. Moreover,

(3.11) $\lambda\in(L+\Pi)\Leftrightarrow$ (i) $\lambda\notin\sigma(L)$ and the matrix $\Omega(\lambda)$ (see (3.7)) is singular or
(ii) $\lambda\in\sigma(L)$ and the matrix $\dot{\Omega}(\lambda)$ (see (3.10)) is singular.

If $\lambda\notin\sigma(L+\Pi)$ then the resolvent of (3.1)–(3.2) $(L+\Pi-\lambda)^{-1}$ is a compact operator from Y into Y, because of the compact imbedding of x into y. Hence for the spectrum $\sigma(L+\Pi)$ there are two possibilities.

1. The normal case: $\sigma(L+\Pi)$ consists of a denumerable sequence of eigenvalues of finite algebraic multiplicity without accumulation points,

2. the super-singular case: $\sigma(L+\Pi)=\mathbb{C}$.

In §7 an example will be given where the spectrum associated to (3.1)–(3.2) is super-singular.

It is also possible to describe $\sigma(L+\Pi)$ in terms of the following meromorphic function:

(3.12) $$\omega(\lambda)=\det\Omega(\lambda) \quad \text{with } \Omega(\lambda) \text{ as in (3.5)}.$$

It appears that $\omega(\lambda)$ is the so-called Weinstein–Aronszajn determinant of the operator $L+\Pi$ with Dirichlet b.c. (see Kato (1966, Chap. IV, §6)). The following results are a direct consequence of the theory given there.

Let $i(\lambda_0;\omega)$ denote the Laurent index of the meromorphic function $\omega(\lambda)$ for $\lambda\to\lambda_0$, i.e. if $\omega\not\equiv 0$ then $i(\lambda_0;\omega)$ is the number $i\in\mathbb{Z}$ such that $\omega(\lambda).(\lambda-\lambda_0)^{-i}$ has a finite limit $\neq 0$ for $\lambda\to\lambda_0$; if $\omega\equiv 0$ then $i(\lambda_0;\omega)=\infty$ for all $\lambda_0\in\mathbb{C}$. Let $m(\lambda_0;L)$ denote the multiplicity of λ_0 with respect to $\sigma(L)$, i.e. if $\lambda_0\notin\sigma(L)$ then $m(\lambda_0;L)=0$; if $\lambda_0\in\sigma(L)$ then $m(\lambda_0;L)=\sum J(\lambda_0)$ with $J(\lambda_0)$ as defined in (2.1.4). Now the following characterization is valid:

(3.13) $$\lambda_0\in\sigma(L+\Pi)\Leftrightarrow i(\lambda_0;\omega)+m(\lambda_0;L)>0.$$

If $\sigma(L+\Pi)\neq\mathbb{C}$ then for each $\lambda_0\in\sigma(L+\Pi)$ its algebraic multiplicity is given by $i(\lambda_0;\omega)+m(\lambda_0,\omega)$. This result shows clearly that each point of $\sigma(L+\Pi)$ is either in $\sigma(L)$ or is a zero of the function $\omega(\lambda)$.

The solvability theory and the propertries of the spectrum will frequently be used in the sequel.

4. Exponential stability of the null-solution of the time-dependent controlled problem. It is well known that in the uncontrolled case the operator L with Dirichlet boundary conditions generates an analytic semigroup on each of the spaces $HD(\alpha)$, $C_0D(\alpha)$, $\alpha\geqq 0$ (see Dunford and Schwartz (1963) and Stewart (1974), (1980), respectively). Furthermore the stability of the null-solution can be characterized in terms of $\nu=\sup_{\lambda\in\sigma(L)}\mathrm{Re}\lambda$. Analogous results hold in the case of the controlled system, see Theorem 4.1. If the control operator Π is a bounded operator from $HD(\beta)$ into $HD(\alpha)$ as in case a from Theorem 4.1 or from $C_0D(\beta)$ into $C_0D(\alpha)$ with $0\leqq\alpha\leqq\beta<\alpha+1$ this is a direct consequence of a perturbation result for analytic semigroups see Kato (1966, pp. 497–498)). This result is applicable here, because Π is an A (see §2.3) bounded operator with A-bound equal to zero, as one can easily verify using interpolation inequalities.

However, in the Banach space case we can improve on this result. We shall show that $L+\Pi$ generates an analytic semigroup on $C_0D(\alpha)$ even if $\Pi=\sum_{i=1}^{p}c_iP_i$ is a bounded map from $C_0D(\beta)$ into $CD(\alpha)$ with $0\leqq\alpha\leqq\beta<\alpha+1$. In comparison with the previous result where range $\Pi\subset C_0D(\alpha)$ we can now allow for a more general class of control functions c_i: $i=1,\cdots,p$. For example, if $\alpha=0$ it is no longer necessary that $c_i=0$ on the boundary ∂D. It will be clear that Π is no longer relatively bounded w.r.t. A in this situation. This improved result is formulated in Theorem 4.1(b). The proof of that result is such that "mutatis mutandis" it also covers case (a).

THEOREM 4.1. *Let* Π *be* $\in\mathscr{L}(X\to Y)$ *with*

$$\begin{aligned}&\text{a.}\quad X=HD(\beta),\quad Y=HD(\alpha),\quad 0\leqq\alpha\leqq\beta<\alpha+1\quad \textit{or}\\ &\text{b.}\quad X=C_0D(\beta),\quad Y=CD(\alpha),\quad 0\leqq\alpha\leqq\beta<\alpha+1.\end{aligned}\tag{4.1}$$

Then $L+\Pi$ *with Dirichlet boundary conditions generates an analytic semigroup on the space* Y_0 *with*

$$\begin{aligned}&\text{a.}\quad Y_0=HD(\alpha),\\ &\text{b.}\quad Y_0=C_0D(\alpha).\end{aligned}\tag{4.2}$$

The solution of (1.3): $v(\cdot,t)=e^{(L+\Pi)t}\Psi$ *satisfies the usual estimate for* $t\to\infty$

$$\|v(\cdot,t)\|_{Y_0}\leqq K(\varepsilon)e^{(\mu+\varepsilon)t}\|\Psi\|_{Y_0}\quad\forall\Psi\in Y_0\tag{4.3}$$

with $\mu=\sup_{\lambda\in\sigma(L+\Pi)}\operatorname{Re}\lambda$, $\varepsilon>0$ *arbitrarily small. If* $\mu<0$ *this implies exponential stability of the null solution of* (1.1)–(1.3) *with respect to initial perturbations in* Y_0.

Proof of Theorem 4.1. We consider case (b). We shall first show that $\exists\sigma_0>0$ such that $\forall\lambda$ with $\operatorname{Re}\lambda\geqq\sigma_0$:

$$\left\|\left|(L+\Pi-\lambda)^{-1}\right|\right\|_{Y_0}\leqq K(1+|\lambda|)^{-1}.\tag{4.4}$$

In order to derive (4.4) we make some preparations.

Step 1. $\exists\sigma_0\geqq 0\ \exists K>0\ \forall\lambda$ with $\operatorname{Re}\lambda\geqq\sigma_0\ \forall f\in C(\bar{D})$:

$$\|(L-\lambda)^{-1}f\|\leqq\frac{K}{1+|\lambda|}\|f\|\tag{4.5}$$

with $\|\cdot\|=\|\cdot\|_{C(\bar{D})}$.For $f\in C_0(\bar{D})$ this estimate is a consequence of the fact that L generates a semigroup on $C_0(\bar{D})$ (see Krasnoselskii (1976, pp. 270)). The estimate for $f\in C(\bar{D})$ follows by approximation with a sequence $\{f_n;n\in\mathbb{N}\}$ in $C_0(\bar{D})$ such that $|f_n|\leqq|f|$ and measure $\{x\in\bar{D}\,|\,f_n(x)\neq f(x)\}\to 0$ for $n\to\infty$. Since

$$|(L-\lambda)^{-1}f(x)|\leqq\|(L-\lambda)^{-1}f_n\|+\left|\int_D G_\lambda(x,\xi)(f-f_n)(\xi)\,d\xi\right|$$

with G_λ the Green kernel of $(L-\lambda)^{-1}$, it is then a consequence of the integrability of the singularity of the Green kernel.

Step 2. $\exists\sigma_0\geqq 0\exists C>0\exists\varepsilon>0\ \forall\lambda$ with $\operatorname{Re}\lambda\geqq\sigma_0$:

$$|P_i(L-\lambda)^{-1}c_j|\leqq C(1+|\lambda|)^{-\varepsilon}\|c_j\|_Y,\qquad 1\leqq i,j<p.\tag{4.6}$$

In order to prove this estimate, we rewrite $P_i(L-\lambda)^{-1}c_j$ as $P_iA^{-\beta}\cdot A^{\delta}(L-\lambda)^{-1}e_j$ with A as in §2.3, $\delta=\beta-\alpha<1$ and $e_j=A^{\alpha}c_j\in C(\bar{D})$. Using (2.2.9) and (2.2.10), it is not difficult to see that $(L-\lambda)^{-1}e_j$ is an element $C_0D(\gamma)$ with $\delta<\gamma<1$. Now we can estimate

$$\begin{aligned}\left|P_i(L-\lambda)^{-1}c_j\right| &\leqq \left\|P_iA^{-\beta}\right\|'\left\|A^{\delta}(L-\lambda)^{-1}e_j\right\| \\ &\leqq k\left\|P_iA^{-\beta}\right\|'\left\|A^{\gamma}(L-\lambda)^{-1}e_j\right\|^{\delta/\gamma}\left\|(L-\lambda)^{-1}e_j\right\|^{1-\delta/\gamma}\end{aligned}$$

with $\|\cdot\|'=\|\cdot\|_{C_0(\bar{D})'}$.

The second inequality is a consequence of Krasnoselskii (1976, Thm. 14.2, pp. 290).

Next we notice, that $\|A^{\gamma}(L-\lambda)^{-1}e_j\|=\|A^{-\tilde{\gamma}}A(A+\tilde{\lambda})^{-1}\tilde{e}_j\|$ with $\tilde{\gamma}=(1-\gamma)/2$, $\tilde{\lambda}=\lambda-\lambda_0$ and $\tilde{e}_j=A^{-\tilde{\gamma}}e_j$. It is now easy to check that $\|A(A+\tilde{\lambda})^{-1}\tilde{e}_j\|\leqq(K+1)\|\tilde{e}_j\|$ if $\lambda_0\geqq\sigma_0$ with σ_0 as in (4.5).

Consequently $\|A^{\gamma}(L-\lambda)^{-1}e_j\|$ is bounded independently of λ for $\mathrm{Re}\lambda\geqq\sigma_0$.

Hence, (4.5) implies (4.6) with $\varepsilon=1-\delta/\gamma$.

Step 3. A trivial consequence of (4.6) is that $\exists\sigma_0>0$ such that $\forall\lambda$ with $\mathrm{Re}\lambda\geqq\sigma_0$, $\Omega(\lambda)$ as defined in §3, (3.5) is nonsingular.

Next using (3.6) and the results from the previous steps we find that $\forall\lambda$ with $\mathrm{Re}\lambda\geqq\sigma_0$ the resolvent $(L+\Pi-\lambda)^{-1}$ is well defined on Y and satisfies the estimate (4.4).

$$\left\|\left|(L+\Pi-\lambda)^{-1}\right|\right\|_Y\leqq K(1+|\lambda|)^{-1}. \tag{4.7}$$

Using (2.2.9), (2.2.10) it is easily verified that $(L+\Pi-\lambda)^{-1}$ maps $Y_0\subset Y$ into Y_0. Then (4.4) is the restriction of (4.7) to Y_0.

In order to complete the proof that $L+\Pi$ generates an analytic subgroup on Y_0 we shall now use the famous characterisation for generators of analytic semigroups as given in Krasnoselskii (1976, Thm. 13.2, pp. 270). Besides (4.4) this characterisation requires that $L+\Pi-\lambda_0$ is densely defined on Y_0. In order to show this it is sufficient to restrict ourselves to the case $\alpha=0$, for the domain $V(\alpha,\Pi)=\{u\in CD(\alpha+1)\,|\,(L_0-\sigma+\Pi)u\in C_0D(\alpha)\}=A^{-\alpha}V(0,\tilde{\Pi})$ with $\tilde{\Pi}=A^{\alpha}\Pi A^{-\alpha}$. Now take $u_0\in C_0(\bar{D})\cap C^{\infty}(\bar{D})$; then $f_0=(L+\Pi-\lambda_0)u_0$ can be approximated by a smooth function with compact support $\tilde{f}_0$ in the sense of $\|\ \|_{L^q(D)}$ with q arbitrarily large. Now take q so large that because of Sobolev's imbedding theorems $C^{\tilde{\beta}}(\bar{D})$ is compactly imbedded in $W^{2,q}(D)$ with $\tilde{\beta}>\beta$ (see Adams (1975)). Using (3.6) and Agmon, Douglis, Nirenberg's a priori estimates we find that for $\tilde{u}_0=(L+\Pi-\lambda_0)^{-1}\tilde{f}_0$ it holds that $\|u_0-\tilde{u}_0\|_{W^{2,q}(\bar{D})}\leqq C\|f-\tilde{f}_0\|_{L^q(D)}$. The conclusion is that indeed $V(0,\Pi)$ is a dense subset of Y_0.

Using that $(L+\Pi-\lambda)^{-1}$ and $e^{(L+\Pi)t}$, $t>0$ are compact operators on Y the contents of (4.3) are a direct consequence of Hale (1971, Lemmas 22.1 and 22.2). □

The compactness of the resolvent $(L+\Pi-\lambda)^{-1}$ on Y_0 for λ with $\mathrm{Re}\lambda\geqq\sigma_0$ in combination with the compactness of $e^{(L+\Pi)t}$ on Y_0 for $t>0$ and Hale (1971, Lemma 22.1) has another nice implication for the location of the spectrum $\sigma(L+\Pi)$. Namely: if (4.1a) or (4.1b) is satisfied then we are in case 1° mentioned in Theorem 3.1 and moreover $\forall\mu\in\mathbb{R}$

$$\mathbb{X}(\mu)=\{\lambda\in\sigma(L+\Pi)\,|\,\mathrm{Re}\lambda\geqq\mu\}<\infty. \tag{4.8}$$

Equation (4.8) implies that the spectrum $\sigma(L+\Pi)$ can be given as a sequence $\{\lambda_n;n\in\mathbb{N}\}$ such that $n>m\Rightarrow\mathrm{Re}\lambda_n\leqq\mathrm{Re}\lambda_m$ and $\mathrm{Re}\lambda_n\downarrow-\infty$ for $n\uparrow\infty$.

Hence, certainly in this situation the super-singular case cannot occur (see also Kato) (1966, pp. 250(b)).

In §5 more detailed information on the location of $\sigma(L+\Pi)$ will be derived.

5. Some remarks on the location of the spectrum. Again we restrict ourselves to cases where Π falls into one of the classes of (3.3). Let us start with a few simple consequences of the Weinstein–Aronszajn theory described in §3.

LEMMA 5.1. *If* $\lambda_0 \in \sigma(L)$ *satisfies* $m(\lambda_0; L) > q = \dim \operatorname{ran} \Pi$ *then* $\lambda_0 \in \sigma(L+\Pi)$.

Proof of Lemma 5.1. If $\dim \operatorname{ran} \Pi = q$ then $\Pi = \sum_{i=1}^{q} \hat{c}_i \hat{P}_i$ with linearly independent $\hat{c}_i$, $i=1,\cdots,q$ and $\hat{P}_i$, $i=1,\cdots,q$. It is now easy to verify that the last m columns of the matrix $\hat{\Omega}(\lambda_0)$ given in (3.5) are linearly dependent. Hence (3.11)(ii) yields $\lambda_0 \in \sigma(L+\Pi)$. □

LEMMA 5.2. *Suppose* $\lambda \notin \sigma(L)$. *If one of the following conditions holds*

$$\text{(5.1)} \qquad \text{a.} \quad \sum_{i=1}^{p} \left| P_i (L-\lambda)^{-1} c_j \right| < 1 \quad \text{for } j=1,\cdots,p \quad \text{or}$$

$$\text{b.} \quad \sum_{j=1}^{p} \left| P_i (L-\lambda)^{-1} c_j \right| < 1 \quad \text{for } i=1,\cdots,p,$$

then $\lambda \notin \sigma(L+\Pi)$.

Proof. It follows from Gershgorin's theorem (see Wilkinson (1965)) that 0 cannot be an eigenvalues of the matrix $\Omega(\lambda)$ given in (3.6). This implies $\lambda \notin \sigma(L+\Pi)$ because of (3.11)(i). □

The latter lemma appears to be very useful in the derivation of the following theorem.

THEOREM 5.1. *In the case where* Π *lies in the class specified in* (4.1a) *i.e.* $P_i \in HD(\beta)'$, $c_i \in HD(\alpha)$, $i=1,\cdots,p$; $0 \leqq \alpha \leqq \beta < \alpha+1$ *the following estimate holds true for the location of* $\sigma(L+\Pi)$:

$$\text{(5.2)} \qquad \sigma(L+\Pi) \subset \left\{ \lambda \mid d(\lambda) \leqq N |\lambda - \mu_0|^{\gamma} \right\} \cup \left\{ \lambda \mid d(\lambda) \leqq N^{\delta} \right\}$$

with $\gamma = \beta - \alpha$, $\delta = (1-\gamma)^{-1}$, $\mu_0 = \max_{\bar{D}} a_0 + 1$ *and*

$$N = 2p \max_{\substack{1 \leqq i \leqq p \\ 1 \leqq j \leqq p}} \|c_j\|_{HD(\alpha)} \|P_i A^{-\gamma}\|_{HD(\alpha)'},$$

$$d(\lambda) = \text{distance}\,(\lambda, \sigma(L)).$$

Proof of Theorem 5.1. We start with the following observation:

$$\text{(5.3)} \qquad P_i (L-\lambda)^{-1} c_j = \sum_{n \geqq 1} (\mu_n - \lambda)^{-1} (\mu_0 - \mu_n)^{\gamma} P_i A^{-\gamma} \hat{\phi}_n \langle \hat{\phi}_n, c_j \rangle_{HD(\alpha)}$$

with $\hat{\phi}_n = \phi_n / \|\phi_n\|_{HD(\alpha)}$, $n \in \mathbb{N}$.

Since $P_i A^{-\gamma} \in HD(\alpha)'$ there exists an element $W_i \in HD(\alpha)$ with $\|W_i\|_{HD(\alpha)} = \|P_i A^{-\gamma}\|_{HD(\alpha)'}$ such that $P_i A^{-\gamma} = \langle W_i, \cdot \rangle_{HD(\alpha)}$. As a consequence we can deduce from (5.3) the following estimate:

$$\text{(5.4)} \qquad \left| P_i (L-\lambda)^{-1} c_j \right| \leqq \max_{\mu \in \sigma(L)} \frac{|\mu_0 - \mu|^{\gamma}}{|\mu - \lambda|} \sum_{n \geqq 1} \left| \langle W_i, \hat{\phi}_n \rangle_{HD(\alpha)} \right| \left| \langle \hat{\phi}_n, c_j \rangle_{HD(\alpha)} \right|.$$

An application of Schwarz' inequality leads to

$$(5.5)\qquad \sum_{n\geqq 1}\left|\langle W_i,\hat{\phi}_n\rangle_{HD(\alpha)}\right|\left|\langle\hat{\phi}_n,c_j\rangle_{HD(\alpha)}\right|$$

$$\leqq\left\{\sum_{n\geqq 1}\left|\langle W_i,\hat{\phi}_n\rangle_{HD(\alpha)}\right|^2\right\}^{1/2},\qquad\left\{\sum_{n\geqq 1}\left|\langle\hat{\phi}_n,c_j\rangle_{HD(\alpha)}\right|^2\right\}^{1/2}$$

$$=\|W_i\|_{HD(\alpha)}\|c_j\|_{HD(\alpha)}=\|P_iA^{-\gamma}\|_{HD(\alpha)}\|c_j\|_{HD(\alpha)}\leqq\frac{N}{2p}.$$

Further it is clear that for each $\mu\in\sigma(L)$:

$$(5.6)\qquad \frac{|\mu_0-\mu|^\gamma}{|\mu-\lambda|}\leqq\frac{|\mu_0-\lambda|^\gamma+|\mu-\lambda|^\gamma}{|\mu-\lambda|}\leqq\frac{|\mu_0-\lambda|^\gamma}{d(\lambda)}+d(\lambda)^{\gamma-1}.$$

From (5.4)–(5.6) we deduce that for $j=1,\cdots,p$:

$$(5.7)\qquad \sum_{i=1}^{p}\left|P_i(L-\lambda)^{-1}c_j\right|\leqq\frac{N}{2}\left\{\frac{|\mu_0-\lambda|^\gamma}{d(\lambda)}+d(\lambda)^{\gamma-1}\right\}.$$

If $N|\mu_0-\lambda|^\gamma/d(\lambda)<1$ and $Nd(\lambda)^{\gamma-1}<1$ we can conclude from Lemma 5.2 that $\lambda\notin\sigma(L+\Pi)$ i.e. $\sigma(L+\Pi)\subset\{\lambda|N|\mu_0-\lambda|^\gamma/d(\lambda)\geqq 1$ or $Nd(\lambda)^{\gamma-1}\geqq 1\}$ which are exactly the contents of (5.2). □

In some important cases it is possible to improve Theorem 5.1.

THEOREM 5.2. *Suppose* Π *lies in the class specified in* (4.1a) *with* $\beta=\alpha$, (*i.e.* $\gamma=0$ *in* (5.2)). *Then there exists a sequence* $\{\rho_n;n\in\mathbb{N}\}$ *with* $\rho_n\downarrow 0$ *for* $n\uparrow\infty$ *such that*

$$(5.8)\qquad \sigma(L+\Pi)\subset\bigcup_{n=1}^{\infty}\{\lambda\,|\,|\lambda-\mu_n|\leqq\rho_n\}.$$

Explicit expressions for the ρ_n*'s are given in* (5.13).

Proof of Theorem 5.2. Define:

$$(5.9)\qquad N_{ij}(\lambda)=\sum_{\substack{n\in\mathbb{N}\\ \mu_n-\mu_1\leqq\frac{1}{2}(\mathrm{Re}\,\lambda-\mu_1)}}\left|P_i\hat{\phi}_n\right|\left|\langle\hat{\phi}_n,c_j\rangle_{HD(\alpha)}\right|,\qquad N_{ij}=N_{ij}(\mu_1),$$

$$N(\lambda)=2p\max_{\substack{1\leqq i\leqq p\\ 1\leqq j\leqq p}}N_{ij}(\lambda),\qquad N=N(\mu_1).$$

It is not difficult to verify that N as defined here has the same interpretation as the N of Theorem 5.1. It will further be clear that $0\leqq N_{ij}(\lambda)\leqq N_{ij}$, $0\leqq N(\lambda)\leqq N$ and $\mathrm{Re}\,\lambda\downarrow-\infty$ implies $N_{ij}(\lambda)\downarrow 0$, $N(\lambda)\downarrow 0$. Now we have

$$(5.10)\qquad \left|P_i(L-\lambda)^{-1}c_j\right|\leqq\left(\sum_1+\sum_2\right)|\lambda-\mu_n|^{-1}\left|P_i\hat{\phi}_n\right|\left|\langle\hat{\phi}_n,c_j\rangle_{HD(\alpha)}\right|$$

where

Σ_1 runs over $n\in\mathbb{N}$ such that $\mu_n-\mu_1\leqq\frac{1}{2}(\mathrm{Re}\,\lambda-\mu_1)$,

Σ_2 runs over $n\in\mathbb{N}$ such that $\mu_n-\mu_1>\frac{1}{2}(\mathrm{Re}\,\lambda-\mu_1)$.

In Σ_1 we use that $|\lambda-\mu_n|^{-1}\leqq d(\lambda)^{-1}$ and in Σ_2 we use that $|\lambda-\mu_n|^{-1}=|\lambda-\mu_1|^{-1}\cdot|1-(\mu_n-\mu_1)(\lambda-\mu_1)^{-1}|^{-1}\leqq 2|\lambda-\mu_1|^{-1}$. This leads to

$$\left|P_i(L-\lambda)^{-1}c_j\right|\leqq d(\lambda)^{-1}N_{ij}(\lambda)+2|\lambda-\mu_1|^{-1}\left(N_{ij}(\mu_1)\right).$$

So for all $j=1,\cdots,p$

$$\sum_{i=1}^{p}\left|P_i(L-\lambda)^{-1}c_j\right|\leqq\frac{1}{2}d(\lambda)^{-1}N(\lambda)+|\lambda-\mu_1|^{-1}N. \tag{5.11}$$

Using Lemma 5.2 we find from (5.11) that certainly $\lambda\notin\sigma(L+\Pi)$ if

$$d(\lambda)>\frac{3}{2}N(\lambda)\quad\text{and}\quad|\lambda-\mu_1|>\frac{3}{2}N. \tag{5.12}$$

Let us next give a sufficient condition in order to ensure $d(\lambda)>\frac{3}{2}N(\lambda)$. Define $\mu(\lambda)$ as the largest $\mu\in\sigma(L)$ such that $d(\lambda)=|\mu-\lambda|$. It is clear that $\mu(\lambda)=\mu\in\sigma(L)\Leftrightarrow\nu_-(\mu)\leqq\operatorname{Re}\lambda<\nu_+(\mu)$. Here $\nu_+(\mu)=\infty$ if $\mu=\mu_1$ and $\nu_+(\mu)=\frac{1}{2}(\mu+\mu_+)$ else with μ_+ the right-hand neighbour of μ in $\sigma(L)$. Further $\nu_-(\mu)=\frac{1}{2}(\mu+\mu_-)$ with μ_- the left-hand neighbour of μ in $\sigma(L)$. If $\mu(\lambda)=\mu$ then $|\lambda-\mu|>\frac{3}{2}N(\nu_+(\mu))$ is such a sufficient condition.

It is not difficult to verify that (5.12) is certainly satisfied if $\forall n\in\mathbb{N}$

$$|\lambda-\mu_n|>\rho_n=\frac{3}{2}N(\nu_+(\mu_n)), \tag{5.13}$$

and this proves the theorem. □

Some additional remarks to Theorem 5.2 can be made concerning the decay of the ρ_n's for $n\uparrow\infty$.

COROLLARY *to Theorem* 5.2.

a. *If for either* (i): *each c_i consists of a finite linear combination of eigenfunctions ϕ_n or* (ii): *each P_i is of the form $\langle W_i,\cdot\rangle_{L_2(D)}$ where W_i consists of a finite linear combination of eigenfunctions ϕ_n then only finitely many ρ_n's are >0.*

b. *If for $i=1,\cdots,p$: $P_i\in HD(\beta)'$ and $c_i\in HD(\beta+\gamma)$ with $\beta\geqq 0$ and $\gamma>0$ then $\forall n\in\mathbb{N}$:*

$$\rho_n\leqq 3\cdot 2^{\gamma}\cdot p\max_{\substack{1\leqq i\leqq p\\ 1\leqq j\leqq p}}\|P_i\|_{HD(\beta)'}\|A^{\gamma}c_j\|_{HD(\beta)}(\mu_0-\mu_{n+})^{-\gamma} \tag{5.14}$$

i.e. $\rho_n=O(n^{-2\gamma/d})$ for $n\to\infty$.

c. *If for $i=1,\cdots,p$: $P_i=\langle W_i,\cdot\rangle_{HD(\alpha)}$ with $W_i\in HD(\alpha+\gamma)$ and $c_i\in HD(\alpha)$, $\alpha\geqq 0$, $\gamma\geqq 0$ then $\forall n\in\mathbb{N}$.*

$$\rho_n\leqq 3\cdot 2^{\gamma}\cdot p\max_{\substack{1\leqq i\leqq p\\ 1\leqq j\leqq p}}\|A^{\gamma}W_i\|_{HD(\alpha)}\|c_j\|_{HD(\alpha)}(\mu_0-\mu_{n_+})^{-\gamma} \tag{5.15}$$

i.e. $\rho_n=O(n^{-2\gamma/d})$ for $n\to\infty$.

Note that parts b and c can be seen as dual statements.

For part a of the corollary we use (5.13) and the fact that under the given conditions the functions $N_{ij}(\lambda)$ given in (5.9) vanish if $\mathrm{Re}\lambda$ becomes too negative. For part b of the corollary we use (5.13) and the estimate

$$N_{ij}(\lambda) = \sum_{\substack{n\in\mathbb{N} \\ \mu_n-\mu_i\leqq\frac{1}{2}(\mathrm{Re}\lambda-\mu_1)}} (\mu_0-\mu_n)^{-\gamma}|P_i\hat{\phi}_n|\left|\left\langle \hat{\phi}_n, A^{\gamma}c_j\right\rangle_{HD(\beta)}\right|,$$

$$\leqq\left(\frac{1}{2}\right)^{-\gamma}(\mu_0-\mathrm{Re}\lambda)^{-\gamma}\sum_{n\in\mathbb{N}}|P_i\hat{\phi}_n|\left|\left\langle \hat{\phi}_n, A^{\gamma}c_j\right\rangle_{HD(\beta)}\right|.$$

The last statement of the corollary is a consequence of the asymptotics of the eigenvalues. Part c is proven completely analogous to part b.

6. On the occurrence of the super-singular case: $\sigma(L+\Pi)=\mathbb{C}$. First we shall give an example which demonstrates that cases where $\sigma(L+\Pi)=\mathbb{C}$ really can occur.

In this example we take L as in (1.4) and

$$\Pi = c\delta_y L \tag{6.1}$$

with

y some point on ∂D, $\delta_y w = w(y)$,

c some function $\in C^{\infty}(\overline{D})$ with the property,

$c(y) = -1$.

Note that this example falls in the context of §3, for (3.3a) is applicable for any $s > d/2$, $s \notin -\frac{1}{2}+\mathbb{N}$ with d the dimension of the space or (3.3b) is applicable for any $\alpha > 0$, $\alpha \in \mathbb{N}$. Let us now calculate the Weinstein–Aronszajn determinant

$$\omega(\lambda) = 1+\delta_y L(L-\lambda)^{-1}c = 1+\delta_y\left\{1+\lambda(L-\lambda)^{-1}\right\}c \tag{6.2}$$

$$= 1+\delta_y c = 0,$$

for all $\lambda \notin \sigma(L)$! Here we used that $\delta_y(L-\lambda)^{-1}=0$ because of the Dirichlet b.c. and $y \in \partial D$. Consequently $\omega \equiv 0$ on $\mathbb{C}$ and Theorem 5.1 yields $\sigma(L+\Pi)=\mathbb{C}$.

We observe that in this example the operator L is not densely defined on the space Y. Hence it is not very surprising, that perturbations of L can destroy its nice spectral properties. Nevertheless, even in this situation though apparently cases with $\sigma(L+\Pi)=\mathbb{C}$ can occur, one intuitively gets the feeling that the occurrence of these super-singular cases is very rare. This feeling will be given a mathematical base in Theorem 7.1. First we introduce some concepts. From now on we suppose that X, Y are spaces of real or complex functions as indicated in (3.3).

The set of admissible feedback controls is defined to be

$$RC = \{\Pi \in \mathscr{L}(X \to Y) \mid \Pi \text{ real and } \dim \mathrm{ran}\,\Pi \leqq p\}. \tag{6.3}$$

RC is a closed subset of $\mathscr{L}(X \to Y)$, which we endow with the norm inherited from $\mathscr{L}(X \to Y)$. Note that RC is not a linear space. It is true that $\Pi \in RC \Rightarrow \alpha\Pi \in RC$ for each $\alpha \in \mathbb{R}$, but $\Pi_1 \in RC$ and $\Pi_2 \in RC$ does not necessarily imply $\Pi_1+\Pi_2 \in RC$!

Each element of RC is of the form $\sum_{i=1}^{p} c_i P_i$ with some real $(c,P) \in Y^p \times (X')^p$. However quite a number of different (c,P)'s in $Y^p \times (X')^p$ correspond to the same $\Pi \in RC$. This induces an equivalence relation on $Y^p \times (X')^p$ as follows $(c,P) \sim (\hat{c},\hat{P}) \Leftrightarrow \sum_{i=1}^{p} c_i P_i = \sum_{i=1}^{p} \hat{c}_i \hat{P}_i$.

So RC can be identified with $\{Y^p \times (X')^p\}/\sim$. The following statement, which relates the topology of RC to the topology of $Y^p \times (X')^p$, can easily be verified. Let $\Pi \in RC$ be given with $\dim \operatorname{ran} \Pi = q \leqq p$, $\Pi = \sum_{i=1}^{p} c_i P_i$ with $c_i = 0$, $P_i = 0$ for $i > q$. Then $\exists M > 0\ \exists \varepsilon_0 > 0\ \forall \varepsilon \in (0, \varepsilon_0)\ \forall \Pi^{(1)} \in RG$:

$$\|\Pi - \Pi^{(1)}\|_{RC} \leqq \varepsilon \Rightarrow \exists (c^{(1)}, P^{(1)}) \in Y^p \times (X')^p, \tag{6.4}$$

such that $\|(c, P) - (c^{(1)}, P^{(1)})\|_{Y^p \times (X')^p} \leqq M\varepsilon^{1/2}$ and $\Pi^{(1)} = \sum_{i=1}^{p} c_i^{(1)} P_i^{(1)}$.

Let us further introduce RC_0, RC_s the subsets of RC consisting of nonsingular, singular controls

$$\begin{aligned} &\Pi \in RC_0 \Rightarrow \sigma(L + \Pi) \neq \mathbb{C}, \\ &\Pi \in RC_s \Rightarrow \sigma(L + \Pi) = \mathbb{C}. \end{aligned} \tag{6.5}$$

THEOREM 6.1.

a. *The property of nonsingularity of the feedback control is generic*: RC_0 *is an open and dense subset of* RC.

b. *Singular feedback controls have a neglectable probability of occurrence in the following sense*: *for each finite dimensional linear subspace* H *of* RC *the Lebesgue measure in* H *of* $H \cap RC_s$ *equals* 0.

Proof of Theorem 6.1. In order to express the dependence of the Weinstein–Aronszajn determinant on Π we introduce the notation $\omega(\lambda; \Pi)$. Using (6.4) it is easily checked that for each fixed $\lambda \notin \sigma(L)$ the map $\omega(\lambda; \cdot)$ from RC into $\mathbb{C}$ is continuous.

(i) We shall show that RC_0 is open in RC. $\Pi \in RC_0$ implies $\omega(\lambda; \Pi) \neq 0$ for some $\lambda \notin \sigma(L)$, see Theorem 5.1. Consequently the following formula holds true:

$$RC_0 = \bigcup_{\lambda \notin \sigma(L)} \omega(\lambda; \cdot)^{-1}\{\mathbb{C} \setminus \{0\}\}.$$

$\mathbb{C} \setminus \{0\}$ is open and $\omega(\lambda; \cdot)^{-1}\{\mathbb{C} \setminus \{0\}\}$ is open in RC. RC_0 is the union of open sets and hence it is open itself.

(ii) Let us next demonstrate that RC_0 is dense in RC. Take $\Pi \in RC_0$. For fixed $\lambda \notin \sigma(L)$ we have that $\omega(\lambda; (1 - \varepsilon)\Pi)$ is a nonconstant polynomial in ε. So for $\varepsilon \neq 0$ and ε arbitrarily small we see that $(1 - \varepsilon)\Pi \in RC_0$.

(iii) Our last step is to show that for each finite dimensional linear subspace H of RC we have meas $(H \cap RC_s) = 0$. Let $\Pi_1, \cdots, \Pi_m$ be a base of H. For each fixed $\lambda \notin \sigma(L)$ the function $\omega(\lambda; \sum_{i=1}^{m} \xi_i \Pi_i)$ defines a polynomial in $\xi_1, \cdots, \xi_m$ which equals 1 for $\xi = 0 \in \mathbb{R}^m$. This implies that the set $\{\xi \in \mathbb{R}^m \mid \omega(\lambda; \sum_{i=1}^{m} \xi_i \Pi_i) = 0\}$ has measure $= 0$ in $\mathbb{R}^m$. In other words $Z(\lambda; H) = \{\Pi \in H \mid \omega(\lambda; \Pi) = 0\}$ has measure $= 0$ in H. So certainly $RC_s \cap H = \bigcap_{\lambda \notin \sigma(L)} Z(\lambda; H)$ has measure zero in H. □

7. On the completeness of generalized eigenspaces and their eigenprojections. Let us assume that Π is of one of the types indicated in (3.3) and that $\sigma(L + \Pi) \neq \mathbb{C}$. The resolvent $(L + \Pi - \lambda)^{-1}$ is then a compact operator on Y for $\lambda \notin \sigma(L + \Pi)$.

Hence to each $\lambda \in \sigma(L + \Pi)$ there corresponds a generalized eigenspace $N(\lambda)$ with a dimension equal to the algebraic multiplicity of λ and a projection operator $P(\lambda)$ into $N(\lambda)$. Here $N(\lambda)$ and $P(\lambda)$ with $\lambda \in \sigma(L + \Pi)$ are given by:

$$N(\lambda) = \text{null space of } (L + \Pi - \lambda)^s, \tag{7.1}$$

$$P(\lambda) = \frac{1}{2\pi i} \int_{\Gamma(\lambda)} (L + \Pi - \lambda)^{-1} d\zeta, \tag{7.2}$$

see Kato (1966, Chap. III).

In (7.1) s is a sufficiently large number $\in \mathbb{N}$. The smallest number $s \in \mathbb{N}$ such that (7.1) is true will be denoted by $s(\lambda)$. In (7.2) $\Gamma(\lambda)$ is a smooth contour which encircles the eigenvalue λ in such a way that $\sigma(L+\Pi)\backslash\{\lambda\}$ lies outside $\Gamma(\lambda)$.

In Lemma 7.1 we shall give somewhat more explicit expressions for the forms of $N(\lambda)$ and $P(\lambda)$, $\lambda \in \sigma(L+\Pi)$.

Further, in Theorems 7.1 and 7.2 we shall prove that under certain conditions the system of eigenprojections is complete i.e.

$$I = \sum_{\lambda \in \sigma(L+\Pi)} P(\lambda).$$

Let us now first introduce some further notation. For $\lambda \in \sigma(L+\Pi)$ we define $q(\lambda) \in \mathbb{Z}$ and $p \times p$ matrices $Q_r(\lambda)$ with $r \in \mathbb{Z}$, $r \geqq q(\lambda)$ by

$$\Omega(\zeta)^{-1} = \sum_{r \geqq q(\lambda)} (\zeta - \lambda)^r Q_r(\lambda). \tag{7.3}$$

Here (7.3) expresses the Laurent expansion for $\zeta \to \lambda$ of the matrix function $\Omega(\zeta)^{-1}$ with Ω as defined in (3.5). $q(\lambda)$ is such that $Q_{q(\lambda)}(\lambda) \neq 0$, so $q(\lambda)$ is the Laurent index of Ω^{-1} at the point λ.

From the Weinstein–Aronszajn theory it follows, that if $\lambda \in \sigma(L+\Pi)\backslash\sigma(L)$ then $q(\lambda) < 0$.

In Lemma 7.1 the notation $\langle\ ,\ \rangle$ will be used analogous to (3.6) and (3.9).

LEMMA 7.1.

a. *If* $\lambda \in \sigma(L+\Pi)\backslash\sigma(L)$ *then*

(i) $N(\lambda)$ *has a basis* $\{\chi_i^\lambda : 1 \leqq i \leqq \dim N(\lambda)\}$ *with each* χ_i^λ *a linear combination of the functions* $(L-\lambda)^{-k} c_j$, $1 \leqq k \leqq s(\lambda)$, $1 \leqq j \leqq p$;

(ii) *the eigenprojection* $P(\lambda)$ *has the form*

$$P(\lambda) = \sum_{\substack{r \geqq q(\lambda) \\ k \geqq 1,\ m \geqq 1 \\ k+m+r=1}} \left\langle (L-\lambda)^{-k} c, Q_r(\lambda) P (L-\lambda)^{-m} . \right\rangle. \tag{7.4}$$

b. *If* $\lambda \in \sigma(L+\Pi) \cap \sigma(L)$ *then*

(i) $N(\lambda)$ *has a basis* $\{\chi_i^\lambda; 1 \leqq i \leqq \dim N(\lambda)\}$ *with each* χ_i^λ *a linear combination of the functions* $(L-\lambda)_*^{-k} c_j$, ϕ_n, $1 \leqq k \leqq s(\lambda)$, $1 \leqq j \leqq p$, $n \in J(\lambda)$;

(ii) *the eigenprojection* $P(\lambda)$ *has the form*

$$\begin{aligned} P(\lambda) = E(\lambda) &- \sum_{\substack{r \geqq q(\lambda) \\ k \geqq 1 \\ k+r=1}} \left\langle (L-\lambda)_*^{-k} c, Q_r(\lambda) P E(\lambda) . \right\rangle \\ &- \sum_{\substack{r \geqq q(\lambda) \\ m \geqq 1 \\ m+r=1}} \left\langle E(\lambda) c, Q_r(\lambda) P (L-\lambda)_*^{-m} . \right\rangle \\ &+ \sum_{\substack{r \geqq q(\lambda) \\ k \geqq 1,\ m \geqq 1 \\ k+m+r=1}} \left\langle (L-\lambda)_*^{-k} c, Q_r(\lambda) P (L-\lambda)_*^{-m} . \right\rangle. \end{aligned} \tag{7.5}$$

Proof of Lemma 7.1.

(i) Let us first prove a(i) and b(i). Let us denote by $(L+\Pi-\lambda)^{-1} g$ with $\lambda \in \sigma(L+\Pi)$ the space of solutions u of (3.1)–(3.2). In case a $(L+\Pi-\lambda)^{-1} g$ is given by the right-hand side of (3.6) with $\Omega(\lambda)^{-1} P (L-\lambda)^{-1} g$ interpreted as the set of solutions of

$\Omega(\lambda)\xi = P(L-\lambda)^{-1}g$. In case b $(L+\Pi-\lambda)^{-1}g$ is given by the right-hand side of (3.9) where $\hat{\Omega}(\lambda)^{-1}\binom{P(L-\lambda)^{-1}_*}{\phi'}g$ is interpreted in the obvious way. Of course for $V \subset Y$ we mean by $(L+\Pi-\lambda)^{-1}V$ the union of the $(L+\Pi-\lambda)^{-1}$ with $g \in V$.

Now we have the formula

$$N(\lambda) = (L+\Pi-\lambda)^{-s(\lambda)}\{0\}. \tag{7.6}$$

Repeated application of the adapted forms of (3.6)–(3.9) to (7.6) shows immediately that a(i) and b(i) hold.

(ii) Let us now prove a(ii) and b(ii). From the definition in (7.2) we derive using the expression (3.6) for $(L+\Pi-\zeta)^{-1}$

(7.7)

$$P(\lambda) = -\frac{1}{2\pi i}\oint_{\Gamma(\lambda)}(L-\zeta)^{-1}\,d\zeta + \frac{1}{2\pi i}\oint_{\Gamma(\lambda)}\left\langle (L-\zeta)^{-1}c, \Omega(\zeta)^{-1}(L-\zeta)^{-1}\cdot\right\rangle d\zeta.$$

For $\Gamma(\lambda)$ we choose a contour $|\lambda-\zeta| = \delta$ with $\delta > 0$ so small that $\{\sigma(L+\Pi)\cup\sigma(L)\}\cap\{\zeta \,|\, |\lambda-\zeta| \leqq \delta\} = \{\lambda\}$.

Next we plug the Laurent expansion of $\Omega(\zeta)^{-1}$ given in (8.3) and the Laurent expansion of $(L-\zeta)^{-1}$ for $\zeta \to \lambda$ to be given here below in (7.8) into (7.7):

$$\begin{aligned}(L-\zeta)^{-1} &= \sum_{k=0}^{\infty}(L-\lambda)^{-k-1}(\zeta-\lambda)^k \quad \text{in case a,}\\ -(\zeta-\lambda)^{-1}E(\lambda) &+ \sum_{k=0}^{\infty}(L-\lambda)_*^{-k-1}(\zeta-\lambda)^k \quad \text{in case b.}\end{aligned} \tag{7.8}$$

The convergence of the sums in (7.8) is in $L(HD(\alpha) \to HD(\alpha))$. An application of the Cauchy residue theorem then gives (7.4) in case a and (7.5) in case b. □

Let us now suppose that Π satisfies the same assumption as in (4.1a), namely for $i = 1, \cdots, p$: $c_i \in HD(\alpha)$, $P_i \in HD(\beta)$, $0 \leqq \alpha \leqq \beta < \alpha + 1$.

The spectrum $\sigma(L+\Pi)$ can then be given as a sequence $\{\lambda_n; n \in \mathbb{N}\}$ such that $n > m \Rightarrow \lambda_m$, $\mathrm{Re}\lambda_n \leqq \mathrm{Re}\lambda_m$ and $\mathrm{Re}\lambda_n \downarrow -\infty$ for $n \uparrow \infty$.

Let us denote for a finite subset $F \subset \mathbb{N}$ by $N(\lambda_n; n \in F)$ the finite-dimensional linear subspace of $HD(\alpha)$ spanned by the $N(\lambda_n)$'s with $n \in F$.

Then since A is selfadjoint, $A^{-1}\Pi$ is compact and A^{-m} is of Hilbert type, it is a well-known result (see Dunford and Schwartz (1962, p. 2374) or Gohberg and Krein (1969, pp. 276–277)) that the generalized eigenspaces are complete in the following sense

$$\begin{aligned}&\forall u \in HD(\alpha)\ \exists\{u_k; k \in \mathbb{N}\} \text{ with } u_k \in N(\lambda_n; 1 \leqq n \leqq k)\\ &\text{such that } \lim_{k\to\infty}\|u-u_k\|_{HD(\alpha)} = 0.\end{aligned} \tag{7.9}$$

This result shows that each element of $HD(\alpha)$ can be approximated with linear combinations of generalized eigenfunctions.

Next we shall prove that the eigenprojections $P(\lambda)$ with $\lambda \in \sigma(L+\Pi)$ are "conditionally complete" in certain cases.

This means that elements of $HD(\alpha)$ can be expanded in terms of generalized eigenfunctions. In order to prove this, we have to make rather strong assumptions. In the first place:

$$\text{for } 1 \leqq i \leqq p\text{: } P_i \in HD(\alpha)', \qquad c_i \in HD(\alpha) \quad \text{with } \alpha \geqq 0, \tag{7.10}$$

i.e. Π falls in the class of (4.1a) with $\alpha=\beta$. For our other assumptions we have to introduce some notation. Let $\{\hat{\phi}_n; n\in\mathbb{N}\}$ be the sequence of eigenfunctions of the uncontrolled problem normalized in $HD(\alpha)$ i.e. $\hat{\phi}_n=\phi_n/\|\phi_n\|_{HD(\alpha)}$, ϕ_n as in (2.1.1), (2.1.2).

For $n\in\mathbb{N}$ we define the following numbers:

$$C^{(n+1)}=\sqrt{p}\max_{j=i,\cdots,p}\left\{\sum_{\substack{k\in\mathbb{N}\\ \mu_k-\mu_1\leqq\frac{1}{2}(\mu_n-\mu_1)}}\left|\left\langle c_j,\hat{\phi}_k\right\rangle_{HD(\alpha)}\right|^2\right\}^{1/2},$$

$$Q^{(n+1)}=p\max_{i=1,\cdots,p}\left\{\sum_{\substack{k\in\mathbb{N}\\ \mu_k-\mu_1\leqq\frac{1}{2}(\mu_n-\mu_1)}}\left|P_i\hat{\phi}_k\right|^2\right\}^{1/2}, \tag{7.11}$$

$$r(n)=4C^{(n)}Q^{(n)},$$

$$h(n)=\frac{r(n-1)}{\mu_{n-1}-\mu_n},\qquad g(n)=\frac{(\mu_n-\mu_{n+1})(\mu_1-\mu_n)}{\left(C^{(n)}+Q^{(n)}\right)^2}.$$

Here we use the convention: $a.0^{-1}=\infty$ for $a>0$ and $0.0^{-1}=1$. Note that $r(n)\downarrow 0$ for $n\uparrow\infty$ and, that $r(n)\geqq\rho_n$ with ρ_n as in Theorem 5.2 and (5.13), if $\mu_n<\mu_{n-1}$. Consequently we have $\sigma(L+\Pi)\subset\bigcup_{n\in\mathbb{N}}\{\lambda\,|\,|\mu_n-\lambda|\leqq r(n)\}$. This fact will play an important role further on. In order to show the conditional completeness of the eigenprojections, we now assume that there exists a strictly increasing subsequence of $\mathbb{N}$, which we denote by $\{s(n); n\in\mathbb{N}\}$, with the following properties:

$$\lim_{n\to\infty}h(s(n))=0, \tag{7.12}$$

$$\lim_{n\to\infty}g(s(n)-1)=\infty. \tag{7.13}$$

These conditions are rather frequently satisfied. Roughly speaking they require that the expansion coefficients of the c_i's and P_j's w.r.t. the basis of eigenfunctions corresponding to L decay sufficiently fast compared with the length of certain gaps in the spectrum of L towards $+\infty$. For example, in the case of the Laplace operator: $L=\Delta$ on a block: $D=\{x\,|\,|x_i-a_i|<L_i, i=1,\cdots,d\}$ in d dimensions, these assumptions are fulfilled, because the difference between two different consecutive eigenvalues $\mu_{n-1}-\mu_n$ is larger than π^2L^{-2} with $L=\min_{i=1,\cdots,d}L_i$, and: $\mu_1-\mu_n\uparrow\infty$ for $n\uparrow\infty$, $C^{(n)}$, $Q^{(n)}\downarrow 0$ for $n\uparrow\infty$. From the general theory for the asymptotics of the eigenvalues given in (2.1.5) it follows that:

$$\exists K>0\ \forall M>0\ \exists n\geqq M \text{ such that}$$
$$\text{(i) } \mu_1-\mu_n\leqq Kn^{2/d} \text{ and (ii) } \mu_{n-1}-\mu_n\geqq Kn^{(2-d)/d}$$

with d the dimension of the domain D. The second part of this statement has to hold, because its denial: $\forall K>0\ \exists M>0$ such that $\forall n\geqq M$: $\mu_{n-1}-\mu_n\leqq Kn^{(2-d)/d}$, implies: $\mu_1-\mu_n=o(n^{2/d})$ for $n\to\infty$, which contradicts (2.1.5). For a suitable choice of K the first part holds for every n. An immediate consequence of this statement is that

$$\exists K>0\ \forall M>0\ \exists n\geqq M:$$
$$\text{(i) } h(n)\leqq K^{-1}r(n-1)\cdot n^{(d-2)/d} \text{ and (ii) } g(n-1)\geqq K^2n^{(4-d)/d}\cdot R\left(C^{(n)}+Q^{(n)}\right)^{-2}.$$

The conclusion is that (7.12) is automatically satisfied if $d=1,2$ and that (7.13) is automatically satisfied if $d=1,2,3,4$. In order to ensure that (7.12)–(7.13) are satisfied in situations where the dimension of the domain is not as specified above, it is sufficient to require more regularity for the c_i's and P_j's:

$$c_i \in HD(\alpha+\gamma),$$
$$P_i = \langle W_i, \cdot \rangle_{HD(\alpha)} \text{ with } W_i \in HD(\alpha+\gamma).$$

It will be clear that both $C^{(n)}$ and $Q^{(n)}$ behave then as $o((\mu_1-\mu_n)^{-\gamma})$ for $n\to\infty$. Therefore, (7.12) is fulfilled if $\gamma \geqq \max(0, \frac{1}{4}(d-2))$ and in order to fulfill (7.13) we must have $\gamma \geqq \max(0, \frac{1}{4}(d-4))$. Thus we have demonstrated that (7.11)–(7.13) are not very restrictive.

Finally we introduce the notation for $S \subset \mathbf{C}$

$$P(\lambda;\lambda\in S) = \sum_{\lambda\in S\cap\sigma(L+\Pi)} P(\lambda), \tag{7.14}$$
$$P(\lambda;\lambda\in\varnothing)=0.$$

We shall prove the following result.

THEOREM 7.1. *Suppose that the conditions* (7.10) *and* (7.13) *are satisfied. Then the eigenprojections are conditionally complete in the following sense*:

$$I = \sum_{n=1}^{\infty} P(\lambda;\lambda\in S_n) \tag{7.15}$$

where by definition: $S_1=\{\lambda \mid \mathrm{Re}\lambda > \mu_{s(n-1)}+r(1)\}$ *and for* $n>1$ $S_n=\{\lambda \mid \mu_{s(n)}+r(n)< \mathrm{Re}\lambda < \mu_{s(n-1)}+r(n-1)\}$. *The convergence of the sum in* (7.15) *is strongly in* $HD(\alpha)$.

Proof of Theorem 7.1. The scheme of this proof is identical to the proof of Kato (1966, Thm. 4.5, Chap. V, §4.5, pp. 293–295). We already know that

$$I = \sum_{n=1}^{\infty} E(\lambda;\lambda\in S_n) \tag{7.16}$$

where $E(\lambda;\lambda\in S_n)=\sum_{\lambda\in S_n\cap\sigma(L)}E(\lambda)$ with $E(\lambda)$ as in (2.1.4). The convergence of the sum in (7.16) is strongly in $HD(\alpha)$. We shall now show that

$$R_N = \sum_{n=1}^{N} P(\lambda;\lambda\in S_n) - \sum_{n=1}^{N} E(\lambda;\lambda\in S_n) \to 0 \quad \text{for } N\to\infty \tag{7.17}$$

in $\mathscr{L}(HD(\alpha)\to HD(\alpha))$. It is then clear that (7.15) holds true. We have the following formula

$$R_N = -\frac{1}{2\pi i}\oint_{\gamma_N} \{(L+\Pi-\xi)^{-1}-(L-\xi)^{-1}\}\,d\zeta, \tag{7.18}$$

see, Kato (1966, p. 294, 4.19). Here γ_N is the contour consisting of

(i) half the circle $\{\zeta \mid |\xi-\nu_N|=R, \mathrm{Re}\,\xi \geqq \nu_N\}$,

(ii) the vertical interval $\{\xi \mid \mathrm{Re}\,\xi=\nu_N, |\mathrm{Im}\,\xi| \geqq R\}$, with $\nu_N=\frac{1}{2}(\mu_{s(N)}+\mu_{s(N)-1})$ and R sufficiently large. Of course, (7.18) holds since $\{\sigma(L+\Pi)\cup\sigma(L)\}\cap\bigcup_{n=1}^{N}S_n$ lies inside the contour γ_N, if R is sufficiently large (Theorem 5.2!)

Using the form of $(L+\Pi+\xi)^{-1}$ given in (3.6), we get

$$R_N=\frac{1}{2\pi i}\oint_{\gamma_n}\left\langle\left\{(L-\xi)^{-1}c,\Omega(\xi)^{-1}P(L-\xi)^{-1}\right\}\right\rangle d\xi. \tag{7.19}$$

Since on the half circle $\{\xi\,|\,|\xi-\nu_N|=R,\operatorname{Re}\xi\geqq\nu_N\}$ $|||(L-\xi)^{-1}|||_{HD(\alpha)}=O(1/R)$ for $R\uparrow\infty$, we can reduce (7.19) to

$$R_N=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\left\langle(L-\nu_N-i\xi)^{-1}c,\Omega(\nu_N+i\xi)^{-1}P(L-\nu_N-i\xi)^{-1}\right\rangle d\xi. \tag{7.20}$$

Thus we obtain the following estimate

$$|||R_n|||_{HD(\alpha)}\leqq\frac{w_0}{\pi}\int_0^{\infty}\left\|(L-\nu_N-\xi)^{-1}c\right\|_{\{HD(\alpha)\}^p}\left\|P(L-\nu_N-i\xi)^{-1}\right\|_{\{HD(\alpha)'\}^p}d\xi \tag{7.21}$$

with

$$w_0=\max_{\xi\notin\bigcup_{n\in\mathbb{N}}\{\lambda\,|\,|\mu_n-\lambda|\leqq r(n)\}}\left|\left|\left|\Omega(\zeta)^{-1}\right|\right|\right|_{\mathbb{C}^p}.$$

Let us first show that $w_0<\infty$. Analogous to the proof of Theorem 5.2 one can show that $\zeta\in\bigcup_{n\in\mathbb{N}}\{\lambda\,|\,|\mu_n-\lambda|\leqq r(n)\}$ implies for $j=1,\cdots,p$:

$$\begin{aligned}\sum_{i=1}^{p}\left|P_i(L-\zeta)^{-1}c_j\right|&\leqq\frac{1}{d(\zeta)}\sum_{i=1}^{p}\sum_{\substack{n\\ \mu_n-\nu_1\leqq\frac{1}{2}(\operatorname{Re}\zeta-\mu_1)}}|P_i\hat{\phi}_n|\cdot\left|\left\langle\hat{\phi}_n,c_j\right\rangle_{HD(\alpha)}\right|\\&\quad+\frac{2}{|\xi-\mu_1|}\cdot\sum_{i=1}^{p}\sum_{\substack{n\in\mathbb{N}\\ \mu_n-\mu_1>\frac{1}{2}(\operatorname{Re}\xi-\mu_1)}}|P_i\cdot\hat{\phi}_n|\cdot\left|\left\langle\hat{\phi}_n,c_j\right\rangle_{HD(\alpha)}\right|\\&\leqq r(n)^{-1}\cdot\frac{1}{4}r(n)+2\cdot r(1)^{-1}\cdot\frac{1}{4}r(1)=\frac{3}{4}.\end{aligned}$$

So in the matrix norm $\|Z\|_a=\max_{j=1,\cdots,p}\sum_{i=1}^{p}|Z_{ij}|$ it is true that $\|I-\Omega(\zeta)\|_a\leqq\frac{3}{4}$. Consequently $\Omega(\zeta)$ is invertible and $\|\Omega(\zeta)^{-1}\|_a\leqq 4$. Since there is a constant $M>0$, such that $|||\cdot|||_{C^p}\leqq M\|\cdot\|_a$ it is clear that $w_0<\infty$.

In order to get further estimates from (7.21), we use the following trick. We decompose

$$c=E_1^Nc+E_2^Nc,\qquad P=PE_1^N+PE_2^N \tag{7.22}$$

with

$$\begin{aligned}E_1^N&=\sum_{\substack{k\in\mathbb{N}\\ \mu_k-\mu_1\leqq\frac{1}{2}d(N)}}\hat{\phi}_k\left\langle\hat{\phi}_k,\cdot\right\rangle_{HD(\alpha)},\\E_2^N&=\sum_{\substack{k\in\mathbb{N}\\ \mu_k-\mu_1>\frac{1}{2}d(N)}}\hat{\phi}_k\left\langle\hat{\phi}_k,\cdot\right\rangle_{HD(\alpha)},\\d(N)&=\mu_{s(N)-1}-\mu_1.\end{aligned}$$

It is easy to verify that for $\zeta \in (0, \infty)$:

$$
\begin{aligned}
&\left\|(L-\nu_N-i\zeta)^{-1}E_1^N c\right\|_{HD(\alpha)^p} \leqq \left\{\frac{1}{4}i_0(N)^2+\zeta^2\right\}^{-1/2} C_1^N,\\
&\left\|(L-\nu_N-i\zeta)^{-1}E_2^N c\right\|_{HD(\alpha)^p} \leqq \left\{\frac{1}{4}d(N)^2+\zeta^2\right\}^{-1/2} C_2,\\
&\left\|PE_1^N(L-\nu_N-i\zeta)^{-1}\right\|_{\{HD(\alpha)'\}^p} \leqq \left\{\frac{1}{4}i_0(N)^2+\zeta^2\right\}^{-1/2} Q_1^N,\\
&\left\|PE_2^N(L-\nu_N-i\zeta)^{-1}\right\|_{\{HD(\alpha)'\}^p} \leqq \left\{\frac{1}{4}d(N)^2+\zeta^2\right\}^{-1/2} Q_2,
\end{aligned}
\tag{7.23}
$$

with $i_0(N)=\mu_{s(N)-1}-\mu_{s(N)}$.

$$
\begin{aligned}
C_1^N &= \sqrt{p}\max_{j=1,\cdots,p}\left\{\sum_{\substack{k\in\mathbb{N}\\ \mu_k-\mu_1\leqq\frac{1}{2}d(N)}}\left|\left\langle\phi_k, c_j\right\rangle_{HD(\alpha)}\right|^2\right\}^{1/2} = C^{(s(N)-1)},\\
C_2 &= \sqrt{p}\max_{j=1,\cdots,p}\|c_j\|_{HD(\alpha)},\\
Q_1^N &= \sqrt{p}\max_{i=1,\cdots,p}\left\{\sum_{\substack{k\in\mathbb{N}\\ \mu_k-\mu_1\leqq\frac{1}{2}d(N)}}\left|P_i\hat{\phi}_k\right|^2\right\}^{1/2} = Q^{(s(N)-1)},\\
Q_2 &= \sqrt{p}\max_{i=1,\cdots,p}\|P_i\|_{HD(\alpha)'}.
\end{aligned}
$$

Using (7.22)–(7.23), we obtain from (7.21)

(7.24)

$$
\begin{aligned}
\|\!|R_N|\!\|_{HD(\alpha)} &\leqq \frac{w_0}{\pi}\left\{C_1^N Q_1^N\int_0^\infty\left[\frac{1}{4}i_0(N)^2+\zeta^2\right]^{-1}d\zeta\right.\\
&\quad +\left(C_1^N Q_2+C_2 Q_1^N\right)\int_0^\infty\left[\frac{1}{4}i_0(N)^2+\zeta^2\right]^{-1/2}\left[\frac{1}{4}d(N)^2+\zeta^2\right]^{-1/2}d\zeta\\
&\quad \left.+C_2 Q_2\int_0^\infty\left[\frac{1}{4}d(N)^2+\zeta^2\right]^{-1}d\zeta\right\}\\
&\leqq w_0\left\{\frac{C_1^N Q_1^N}{i_0(N)}+\frac{C_1^N Q_2+C_2 Q_1^N}{\sqrt{i_0(N)d(N)}}+\frac{C_2 Q_2}{d(N)}\right\}\\
&\leqq w_0\left\{\frac{1}{4}h(s(N))+g(s(N)-1)^{-1/2}(C_2+Q_2)+\frac{C_2 Q_2}{d(N)}\right\}.
\end{aligned}
$$

Using (7.13) it is clear that $\lim_{N\to\infty}\|\!|R_N|\!\|_{HD(\alpha)}=0$ and this proves the theorem. □

In the following theorem it is shown that at least in certain cases the eigenprojections are not only conditionally complete (i.e. complete for a prescribed way of summation) but even unconditionally complete.

THEOREM 7.2. *Suppose that*:

(i) *only a finite number of eigenvalues* $\lambda \in \sigma(L)$ *have multiplicities* >1;

(ii) *the feedback operator* Π *satifies* (7.10) *and instead of* (7.13) *the following stronger condition holds*:

$$\sum_{n=1}^{\infty} \left| \frac{C^{(n)}}{i(n)} \right|^2 < \infty, \quad \sum_{n=1}^{\infty} \left| \frac{Q^{(n)}}{i(n)} \right|^2 < \infty, \quad \lim_{n \to \infty} \left| \frac{r(n)}{i(n)} \right| = 0 \tag{7.25}$$

with $C^{(n)}$, $Q^{(n)}$, $r(n)$ *as in* (7.11) *and* $i(n)$ = *the distance of* μ_n *to* $\sigma(L) \setminus \{\mu_n\}$;

(iii) *the dimension of the domain D satisfies* $d \leqq 3$.

Then the eigenprojections are unconditionally complete, i.e.

$$I = \sum_{\lambda \in \sigma(L+\Pi)} P(\lambda) \tag{7.26}$$

without any restriction on the numbering in the summation.

Proof of Theorem 7.2. We shall show that there is a constant $M>0$ such that for each subset $\Lambda \subset \sigma(L+\Pi)$

$$\left\| \sum_{\lambda \in \Lambda} P(\lambda) \right\|_{HD(\alpha)} \leqq M. \tag{7.27}$$

Let us first demonstrate that (7.27) implies (7.26). Let $\{\Lambda_n : n \in \mathbb{N}\}$ be a sequence of subsets of $\sigma(L+\Pi)$ such that each Λ_n is finite, $m>n \Rightarrow \Lambda_m \supset \Lambda_n$ and $\sigma(L+\Pi) = \bigcup_{n \in \mathbb{N}} \Lambda_n$.

Take $\varepsilon>0$ arbitrarily small and pick $u \in HD(\alpha)$. Using Theorem 7.1, we can choose $N(\varepsilon)>0$ such that

$$\left\| \left\{ I - \sum_{n=1}^{N(\varepsilon)} P(\lambda; \lambda \in S_n) \right\} u \right\|_{HD(\alpha)} \leqq \varepsilon.$$

Take $M_0(\varepsilon)$ such that $\Lambda_{M_0(\varepsilon)} \supset \bigcup_{n=1}^{N(\varepsilon)} S_n \cap \sigma(L+\Pi)$. Then we have for $m \geqq M_0(\varepsilon)$:

$$I - \sum_{\lambda \in \Lambda_m} P(\lambda) = \left(\sum_{\lambda \in \sigma(L+\Pi) \setminus \Lambda_m} P(\lambda) \right) \left(I - \sum_{n=1}^{N(\varepsilon)} P(\lambda; \lambda \in S_n) \right).$$

So $\| \{ I - \Sigma_{\lambda \in \Lambda_m} P(\lambda) \} u \|_{HD(\alpha)} \leqq M\varepsilon$, i.e. $I = \lim_{n \to \infty} \Sigma_{\lambda \in \Lambda_n} P(\lambda)$ strongly in $HD(\alpha)$. In other words (7.27) implies (7.26).

In order to prove (7.27), our reasoning proceeds as follows. Define $\sigma_1(L)$ as the subset of $\sigma(L)$ consisting of all eigenvalues μ_n which have a multiplicity 1 and for which $r(n)/i(n) < \frac{1}{2}$, $h(n) < \frac{1}{2}$ with $h(n)$ as defined in (7.12). Note that because of the conditions (i) and (ii) the set $\sigma(L) \setminus \sigma_1(L)$ contains only a finite number of eigenvalues. An important remark is that for each $\mu_n \in \sigma_1(L)$ there is exactly one eigenvalue $\lambda_n \in \sigma(L+\Pi)$ for which $|\lambda_n - \mu_n| < \frac{1}{2} i(n)$ and the algebraic multiplicity of this eigenvalue λ_n is equal to 1.

We observe namely that as a consequence of Theorem 5.2 for each $\delta \in [0,1]$ the curve $\Gamma_n = \{\lambda \,|\, |\lambda - \mu_n| = \frac{1}{2} i(n)\}$ separates the spectrum $\sigma(L+\delta\Pi)$ into two parts. From the theory given in Kato (1966, Chap. IV, §3.5, pp. 213–214) it follows that the part of $\sigma(L+\delta\Pi)$ inside Γ_n consists for all $\delta \in [0,1]$ of exactly one point $\lambda_n(\delta)$ which has multiplicity 1 and varies continuously with δ. This implies the remark given above.

Let us now for $\mu_n \in \sigma_1(L)$ consider the difference between the one-dimensional projections $P(\lambda_n)$ and $E(\mu_n)$. We have:

(7.28)

$$
\begin{aligned}
P(\lambda_n)-E(\mu_n) &= -\frac{1}{2\pi i}\oint_{\Gamma_n}\left[(L+\Pi-\zeta)^{-1}-(L-\zeta)^{-1}\right]d\zeta \\
&= \frac{1}{2\pi i}\oint_{\Gamma_n}(L+\Pi-\zeta)^{-1}\Pi(L-\zeta)^{-1}d\zeta \\
&= \frac{1}{2\pi i}\oint_{\Gamma_n}(L-\zeta)^{-1}\Pi(L-\zeta)^{-1}d\zeta \\
&\quad -\frac{1}{2\pi i}\oint_{\Gamma_n}\left\langle (L-\zeta)^{-1}c, \Omega(\zeta)^{-1}P(L-\zeta)^{-1}\Pi(L-\zeta)\cdot\right\rangle d\zeta \\
&= -E(\mu_N)\Pi(L-\mu_n)_*^{-1}-(L-\mu_n)_*^{-1}\Pi E(\mu_n) \\
&\quad -\frac{1}{2\pi i}\oint_{\Gamma_n}\left\langle (L-\zeta)^{-1}c, \Omega(\zeta)^{-1}P(L-\zeta)^{-1}\Pi(L-\zeta)^{-1}\cdot\right\rangle d\zeta.
\end{aligned}
$$

The first and second equalities in (7.28) are obvious. For the third equality in (7.28) we used (3.6). For the final equality in (7.28) we used (7.8), case b and Cauchy's residue theorem. Using analogous tricks as in (7.21)–(7.23) we derive the following norm estimate for $P(\lambda_n)-E(\mu_n)$ from (7.28):

(7.29)
$$
\begin{aligned}
&|||P(\lambda_n)-E(\mu_n)|||_{HD(\alpha)} \\
&\leqq 2\hat{c}(n)\left(\frac{Q^{(n)}}{i(n)}+\frac{Q_2}{d_0(n)}\right)+2\hat{P}^{(n)}\left(\frac{C^{(n)}}{i(n)}+\frac{C_2}{d_0(n)}\right) \\
&\quad +4w_0\|P\|_{\{HD(\alpha)'\}^p}i(n)\left(\frac{C^{(n)}}{i(n)}+\frac{C_2}{d_0(n)}\right)^2\left(\frac{Q^{(n)}}{i(n)}+\frac{Q_2}{d_0(n)}\right)
\end{aligned}
$$

with

$$
\begin{aligned}
\hat{c}^{(n)} &= \sqrt{p}\max_{i=1,\cdots,p}|\langle c_i, \hat{\phi}_n\rangle_{HD(\alpha)}|, \\
\hat{P}^{(n)} &= \sqrt{p}\max_{i=1,\cdots,p}|P_i\hat{\phi}_n|, \\
d_0(n) &= \begin{cases} \mu_1-\mu_{n-1}+\frac{1}{2}i(n) & \text{for } n\geqq 2, \\ \infty & \text{for } n=1. \end{cases}
\end{aligned}
$$

Note that because of (2.1.5) and condition (iii) we have $\Sigma_{n=1}^{\infty} d_0(n)^{-2}<\infty$. If we call the right-hand side in the estimate (7.29) rhs(n) then rhs(n) makes sense for all $n\in\mathbb{N}$ and it is not difficult to verify that $\Sigma_{n=1}^{\infty}\text{rhs}(n)<\infty$. Now define $\sigma_1(L+\Pi)=\sigma(L+\Pi)\cap\{\cup_{\mu_n\in\sigma_1(L)}\{\lambda\,|\,|\lambda-\mu_n|<\frac{1}{2}i(n)\}\}$. It is clear that $\sigma(L+\Pi)\backslash\sigma_1(L+\Pi)$ is finite. For a

subset $\Lambda \subset \sigma(L+\Pi)$ we now decompose:

$$(7.30)\qquad \sum_{\lambda\in\Lambda} P(\lambda) = \sum_{\lambda\in\sigma_1(L+\Pi)\cap\Lambda} P(\lambda) + \sum_{\substack{n\\ \lambda_n\in\sigma_1(L+\Pi)\cap\Lambda}} \big(P(\lambda_n)-E(\mu_n)\big) + \sum_{\substack{n\\ \lambda_n\in\sigma_1(L+\Pi)\cap\Lambda}} E(\mu_n).$$

From (7.30) we deduce

$$(7.31)\qquad \Big|\!\Big|\!\Big| \sum_{\lambda\in\Lambda} P(\lambda) \Big|\!\Big|\!\Big| \leqq \sum_{\lambda\in\sigma(L+\Pi)\setminus\sigma_1(L+\Pi)} |||P(\lambda)||| + \sum_{\substack{n\\ \lambda_n\in\sigma_1(L+\Pi)}} |||P(\lambda_n)-E(\mu_n)||| + \Big|\!\Big|\!\Big| \sum_{\substack{n\\ \lambda_n\in\sigma_1(L+\Pi)\cap\Lambda}} E(\mu_n) \Big|\!\Big|\!\Big|$$

$$\leqq \sum_{\lambda\in\sigma(L+\Pi)\setminus\sigma_1(L+\Pi)} |||P(\lambda)||| + \sum_{n=1}^{\infty} \mathrm{rhs}(n) + 1.$$

Here $|||\ |||$ is a shorthand notation for $|||\ |||_{HD(\alpha)}$.

In the second inequality of (7.31) we used the orthogonality of the projections $E(\mu_n)$ in the sense of $\langle\ ,\ \rangle_{HD(\alpha)}$.

Herewith (7.27) has been verified and the proof is complete. □

Note that in the one-dimensional case with $L = d^2/dx^2 - q$ the condition (7.25) is always satisfied.

This follows from the estimate $|\mu_n + n^2\pi^2/1^2| \leqq \max_{x\in D}|q(x)|$, $1 =$ length of the interval D, which holds for n sufficiently large.

Theorem 7.1 can be seen as a generalization of a theorem given in Schwartz (1954) or Kramer (1957) for the special case that their perturbing operator (i.e. Π here) has a finite-dimensional range. The advantage of the theorem given here is that it is also useful in certain nontrivial cases with $d>1$ whereas the conditions for the theorems given in the above mentioned references are such that these cases are automatically excluded.

For example, consider the case of the Laplace operator on a 2-dimensional rectangular domain $\{(x,y)\,|\,0\leqq x\leqq L, 0\leqq y\leqq \sqrt{p}\cdot L\}$ with $p\in\mathbb{R}\setminus\mathbb{Q}$. For each $a\in\mathbb{R}$ there is at most one pair n,m such that $n^2+pm^2=a$. The conclusion is, that all eigenvalues $\pi^2L^{-2}\{n^2+pm^2\}$ are simple; thus condition (i) in Theorem 7.2 is satisfied. In order to satisfy (7.25) in this example it is sufficient that the coefficients $P_i\hat{\phi}_k$ and $\langle c_j, \hat{\phi}_k\rangle_{HD(\alpha)}$ decrease sufficiently fast for $k\uparrow\infty$ compared with $i(k)$.

8. Some remarkable "resolution of the identity" formulae. Using the results on completeness of eigenprojections as given in §7 it is possible to deduce some remarkable formulae of the "resolution of the identity" type. We shall formulate these formulae without any reference to the control context where they come from. This is done in order to emphasize the general character of these formulae, which makes them interesting also outside the control context.

THEOREM 8.1. *Let L be a linear, uniformly elliptic, formally selfadjoint, 2nd order partial differential operator with coefficients $\in C^\infty(\bar{D})$, $D\subset\mathbb{R}^d$ a bounded domain with a smooth boundary. Let $\sigma(L)$ be the spectrum associated to the Dirichlet problem for L. Suppose that each eigenvalue $\in\sigma(L)$ is simple and number these eigenvalues as $\{\mu_n;\mu\in\mathbb{N}\}$ in such a way that $m>n\Rightarrow\mu_m<\mu_n$.*

Let ϕ and Ψ be two functions $\in HD(\gamma)$ with $\gamma \geqq \max(0, \frac{1}{4}(d-2))$. Suppose that ϕ and Ψ are such that the meromorphic function $\omega(\lambda)=1+\langle \Psi,(L-\lambda)^{-1}\phi\rangle_{L_2(D)}$ has (i) *poles of order* 1 *in all points $\mu_n \in \sigma(L)$* (ii) *only simple zeros.*

Then it is possible to number the zeros of $\omega(\lambda)$ as $\{\mu_n; n\in\mathbb{N}\}$ in such a way that for $n\uparrow\infty$: $\mathrm{Im}(\lambda_n)\downarrow -\infty$, $\mathrm{Re}(\lambda_n)\to 0$. Further we have the following resolutions of the identity in $L_2(D)$:

$$I=\sum_{n\in\mathbb{N}}{}' \left[\frac{d\omega}{d\lambda}(\lambda_n)\right]^{-1}\cdot(L-\lambda_n)^{-1}\phi\cdot\left\langle\left(L-\bar{\lambda}_n\right)^{-1}\Psi,\cdot\right\rangle_{L_2(D)}, \tag{8.1}$$

$$I=\sum_{n\in\mathbb{N}}{}' \left[\frac{dw}{d\lambda}(\lambda_n)\right]^{-1}\cdot(L-\lambda_n)^{-1}\Psi\cdot\left\langle\left(L-\bar{\lambda}_n\right)^{-1}\phi,\cdot\right\rangle_{L_2(D)}. \tag{8.2}$$

Here $\sum'_{n\in\mathbb{N}}$ means that the summation has to be done in a special order: $\sum'_{n\in\mathbb{N}}=\sum_{m=1}^{\infty}(\sum_{k(m)}^{k(m+1)-1}\cdot)$ with $k(1)=1$, $m_1>m_2\Rightarrow k(m_1)>k(m_2)$. The convergence in (8.1)–(8.2) *is meant in the following sense:*

$$\sum_{m=1}^{N}\left(\sum_{kk(m)}^{k(m+1)-1}\cdot\right)\to I \text{ for } N\to\infty \text{ strongly in } L_2(D).$$

In the special case $d=1$ and $L=(d^2/dx^2)-q$ one can replace in (8.1) *and* (8.2) *$\sum'_{n\in\mathbb{N}}$ by the normal summation $\sum_{n\in\mathbb{N}}$.*

The sequences of functions $\{(L-\lambda_n)^{-1}\phi; n\in\mathbb{N}\}$ and $\{(L-\bar{\lambda}_n)^{-1}\Psi; n\in\mathbb{N}\}$ which appear in (8.1) *and* (8.2) *satisfy a biorthogonality condition in $L_2(D)$:*

$$\left\langle\left(L-\bar{\lambda}_k\right)^{-1}\Psi,(L-\lambda_m)^{-1}\phi\right\rangle_{L_2(D)}=0 \quad \text{if } k\neq m. \tag{8.3}$$

Proof of Theorem 8.1. Consider the operator $L+\Pi_1$ with

$$\Pi_1=\phi\langle\Psi,\cdot\rangle_{L_2(D)}. \tag{8.4}$$

Now the theory developed in the preceding sections is applicable to the Dirichlet problem for $L+\Pi$ with $X=Y=L_2(D)$. Note that $\omega(\lambda)$ is the Weinstein–Aronszajn determinant corresponding to $L+\Pi_1$, see §3.

It is now clear that $\sigma(L+\Pi_1)$ coincides with the set of zero's of $\omega(\lambda)$ and that each eigenvalue of $L+\Pi_1$ with Dirichlet b.c. has an algebraic multiplicity $=1$.

As a consequence of Theorem 5.2 they can be numbered in the way of Theorem 8.1.

Using Lemma 7.1a we find that the projection on the one-dimensional eigenspace $N(\lambda_n)$, $\lambda_n\in\sigma(L+\Pi_1)$ is given by:

$$\begin{aligned}P(\lambda_n)&=\left[\frac{d\omega}{d\lambda}(\lambda_n)\right]^{-1}\cdot(L-\lambda_n)^{-1}\phi\cdot\left\langle\Psi,(L-\lambda_n)^{-1}\cdot\right\rangle_{L_2(D)}\\&=\left[\frac{d\omega}{d\lambda}(\lambda_n)\right]^{-1}\cdot(L-\lambda_n)^{-1}\phi\left\langle\left(L-\bar{\lambda}_n\right)^{-1}\Psi,\cdot\right\rangle_{L_2(D)}.\end{aligned} \tag{8.5}$$

The resolution of the identity formula given in (8.1) is now found by applying Theorem 7.2. Note that the condition (7.13) is satisfied since ϕ, $\Psi\in HD(\gamma)$ with $\gamma\geqq\max(0,\frac{1}{4}(d-2))$.

By repeating the arguments above for $L+\Pi_2$ with

$$\Pi_2=\Psi\langle\phi,\cdot\rangle_{L_2(D)} \tag{8.6}$$

the contents of (8.2) are found.

The remark in Theorem 8.1 that in (8.1) $\Sigma'_{n\in\mathbb{N}}$ can be replaced by $\Sigma_{n\in\mathbb{N}}$ in the special case $d=1$, $L=d^2/dx^2q$ follows from Theorem 8.3, especially the remark just below the proof of that theorem.

The biorthogonality relation given in (8.3) follows directly from the following property of the projection $P(\lambda_n)$: $P(\lambda_n)N(\lambda_m)=\{0\}$ for $n\neq m$. Consequently $P(\lambda_n)(L-\lambda_m)^{-1}\phi=0$ for $n\neq m$ and since $[d\omega/d\lambda(\lambda_n)]^{-1}(L-\lambda_n)^{-1}\phi\neq 0$ we have to have (8.3). □

Note that one way to look at Theorem 8.1 is that the theorem, given the operator L, constructs for almost arbitrary ϕ and Ψ biorthogonal sequences of the structure $\{(L-\lambda_n)^{-1}\phi, (L-\bar{\lambda}_n)^{-1}\Psi; n\in\mathbb{N}\}$ which have a completeness property. The possibility of such a construction for almost arbitrary ϕ and Ψ is not at all trivial!

Further we note that the idea of the proof of Theorem 8.1 can be used in many other situations to find interesting resolutions of the identity.

We shall give two other examples.

THEOREM 8.2. *Let L and $\sigma(L)$ satisfy the same conditions as in Theorem* 8.1. *Now suppose that two functions ϕ and $\Psi\in HD(\gamma)$ with $\gamma\geqq\max(0,\frac{1}{4}(d-2))$ are given with the property that $\forall n\in\mathbb{N}$:*

$$\hat{\phi}_n,\hat{\Psi}_n=0 \tag{8.7}$$

with $\hat{\phi}_n=\langle\phi,\phi_n\rangle_{L_2(D)}$, $\hat{\Psi}_n=\langle\Psi,\phi_n\rangle_{L_2(D)}$, ϕ_n as in (2.1), (2.2).

Then the following resolution of the identity holds true in $L_2(D)$:

$$I=\sum_{n\in\mathbb{N}}{}'\big(\phi_n-\alpha_n\hat{\Psi}_n(L-\mu_n)_*^{-1}\phi\big)\big\langle\phi_n-\beta_n\hat{\phi}_n(L-\mu_n)_*^{-1}\Psi,\cdot\big\rangle_{L_2(D)} \tag{8.8}$$

with

$$\alpha_n=\begin{cases}0 & \text{if } \hat{\phi}_n\neq 0,\\ 1 & \text{if } \hat{\phi}_n=0,\end{cases}\qquad \beta_n=\begin{cases}0 & \text{if } \hat{\Psi}_n\neq 0,\\ 1 & \text{if } \hat{\Psi}_n=0.\end{cases}$$

The sequence $\{\phi_n-\alpha_n\hat{\Psi}_n(L-\mu_n)_*^{-1}\phi; n\in\mathbb{N}\}$ are biorthonormal in $L_2(D)$. In the special case $d=1$, $L=d^2/dx^2-q$ we can replace $\Sigma'_{n\in\mathbb{N}}$ by the normal summation $\Sigma_{n\in\mathbb{N}}$.

Proof of Theorem 8.2. In this case we have $\omega(\lambda)=1+\langle\Psi,(L-\lambda)^{-1}\phi\rangle\equiv 1$ on $\mathbb{C}$. For the operator $L+\Pi$ with $\Pi=\phi\langle\Psi,\ \rangle_{L_2(D)}$ we find from the Weinstein–Aronzajn theory that $\sigma(L+\Pi)=\sigma(L)$ and that $\mu_n\in\sigma(L+\Pi)$ has an algebraic multiplicity $=1$. For the eigenprojection on the 1-dimensional eigenspace corresponding to $\mu_n\in\sigma(L+\Pi)$ we find using Lemma 8.1b:

$$\begin{aligned}P(\mu_n)&=E(\mu_n)-(L-\mu_n)_*^{-1}\big\langle E(\mu_n)\Psi,\cdot\big\rangle_{L_2(D)}\\&\quad-E(\mu_n)\phi\big\langle(L-\mu_n)_*^{-1}\Psi,\cdot\big\rangle_{L_2(D)}\\&=E(\mu_n)-(L-\mu_n)_*^{-1}\big\langle E(\mu_n)\Psi,\cdot\big\rangle_{L_2(D)}\quad\text{if }\hat{\phi}_n=0,\\&\quad E(\mu_n)-E(\mu_n)\phi\big\langle(L-\mu_n)_*^{-1}\psi,\cdot\big\rangle_{L_2(D)}\quad\text{if }\hat{\Psi}_n=0\\&=\big(\phi_n-\hat{\Psi}_n(L-\mu_n)_*^{-1}\phi\big)\langle\phi_n,\cdot\rangle_{L_2(D)}\quad\text{if }\hat{\phi}_n=0\\&\quad\phi_n\big\langle\phi_n-\hat{\phi}_n(L-\mu_n)_*^{-1}\Psi,\cdot\big\rangle_{L_2(D)}\quad\text{if }\hat{\Psi}_n=0\\&=\big(\phi_n-\alpha_n\hat{\Psi}_n(L-\mu_n)_*^{-1}\phi\big)\big\langle\phi_n-\beta_n\hat{\Phi}_n(L-\mu_n)^{-1}\Psi,\cdot\big\rangle_{L_2(D)}.\end{aligned} \tag{8.9}$$

Using Theorem 7.2, we then find (8.8). The biorthogonality of the sequences of functions associated to (8.8) follows from the projection properties of the $P(\mu_n)$'s, namely:

$$P(\mu_n)\big(\phi_m - \alpha_m \hat{\Psi}_m (L-\mu_m)_*^{-1}\phi\big) = \begin{cases} 0 & \text{if } m \neq n \\ \phi_n - \alpha_n \Psi_n (L-\mu_n)_*^{-1} & \text{if } m = n. \end{cases}$$

The last statement of Theorem 8.2 is derived analogous to the analogous statement in Theorem 8.1. □

THEOREM 8.3. *Let L and $\sigma(L)$ be as in Theorem* 8.1. *Here we shall suppose that the dimension of D satisfies $d \leqq 3$. Now let ϕ be a function $\in HD(\alpha+2\gamma)$ with $\alpha > \frac{d}{4}$, $\gamma \geqq \min(0, \frac{1}{4}(d-2))$ and let y be a point $\in D$. Suppose that ϕ and y are such that the meromorphic function $\omega(\lambda) = 1 + [(L-\lambda)^{-1}\phi](y)$ has* (i) *poles of order* 1 *in all points of $\sigma(L)$ and* (ii) *only simple zero's. Then it is possible to number the zeros of $\omega(\lambda)$ as $\{\lambda_n, n \in \mathbb{N}\}$ in such a way that for $n \uparrow \infty \Rightarrow \operatorname{Im}\lambda_n \downarrow 0$, $\operatorname{Re}\lambda_n \to 0$.*

The following resolution of the identity formula is valid for $HD(\alpha+\gamma)$:

$$I = \sum_{n\in\mathbb{N}}{}' \left[\frac{d\omega}{d\lambda}(\lambda_n)\right]^{-1} (L-\lambda_n)^{-1}\phi \left\langle G(y,\cdot,\bar{\lambda}_n), \cdot \right\rangle_{L_2(D)} \tag{8.10}$$

with $G(x,\xi;\lambda)$ the Green's kernel of the Dirichlet problem for $L-\lambda$. The sequences of functions $\{(L-\lambda_n)^{-1}\phi; n \in \mathbb{N}\}$ and $\{G(y,\cdot;\bar{\lambda}_n); n \in \mathbb{N}\}$ are biorthogonal in $L_2(D)$.

In the special case $d=1$, $L=(d^2/dx^2)-q$ we can replace $\Sigma'_{n\in\mathbb{N}}$ in (8.10) *by the normal summation $\Sigma_{n\in\mathbb{N}}$.*

Proof of Theorem 8.3. Because of Sobolev's theorem (see Adams (1975)) and the imbeddings given in (2.2.7) we see that for $\alpha > d/4$ the functional δ_y which maps u to $u(y)$ is a well-defined element of $HD(\alpha)'$. $\omega(\lambda)$ is now the Weinstein–Aronszajn determinant corresponding to $L+\Pi$ with $\Pi = \phi\delta_y$. Here we consider Π as an element of $\mathscr{L}(X \to Y)$ with $X = Y = HD(\alpha+\gamma)$.

From here on the proof continues completely analogous to the proof of Theorem 8.1. We now find

$$P(\lambda_n) = \left[\frac{d\omega}{d\lambda}(\lambda_n)\right]^{-1} \cdot (L-\lambda_n)^{-1}\phi \cdot \delta_y (L-\lambda_n)^{-1}. \tag{8.11}$$

Since we required that $d \leqq 3$ the singularity of the Green's kernel $G(\chi,\zeta;\lambda_n)$ is quadratically integrable and we can rewrite

$$\delta_y (L-\lambda_n)^{-1} = \left\langle G(y,\cdot;\bar{\lambda}_n), \cdot \right\rangle_{L_2(D)}. \tag{8.12}$$

Next we apply Theorem 7.1. The condition (7.12)–(7.13) is satisfied since the $C^{(n)}$ corresponding to ϕ and the $Q^{(n)}$ corresponding to δ_y are both $O((\mu_1-\mu_n)^{-\gamma})$.

Thus we are led to (8.10). Further details of the proof are left to the reader. □

9. On the possibility of generalizations. Many generalizations of the results developed in the preceding sections can probably be given. Let us discuss a few of them. It is rather obvious that most of the results can be generalized to feed-back control problems for 2nd order elliptic operators L as in 1.4, but with b.c. of Neumann-type, such that the operator becomes formally selfadjoint. Generalizations to feed-back control of higher order elliptic formally selfadjoint operators subject to Dirichlet or other b.c. that make the operator selfadjoint are certainly also possible. Generalizations of our results to some cases with L as in (1.4) and Dirichlet or other formally selfadjoint b.c. but with a domain D with corners can also be given. Here one should be reminded that

$(L-\lambda)^{-1}$ with $\lambda \notin \sigma(L)$ operates from $L_2(D)$ to $H^2(D)$, but in general even for $f \notin C^\infty(\overline{D})$ the regularity at the corners in the boundary of $(L-\lambda)^{-1}f$ is not better than $H^2(D)$.

Appendix. In this appendix $\subset$ will always be meant in the following sense: "can be considered as a subset, where the canonical injection is bounded". Let us start with some simple observations: $n \in \mathbb{N} \Rightarrow$

$$\text{(A.1)} \qquad CD(n) \supset \left\{u \in C^{2n}(\overline{D}) \,\middle|\, A^k u = 0 \text{ on } \partial D, 0 \leqq k < n\right\},$$
$$C_0 D(n) \supset \left\{u \in C^{2n}(\overline{D}) \,\middle|\, A^k u = 0 \text{ on } \partial D, 0 \leqq k \leqq n\right\}.$$

However the following proposition is less trivial.

PROPOSITION A.1. *For* $\alpha > 0$ *and* $0 \leqq \beta < \alpha$

$$\text{(A.2)} \qquad C_0 D(\alpha) \subset \left\{u \in C^{2\beta}(\overline{D}) \,\middle|\, A^k u = 0 \text{ on } \partial D, 0 \leqq k \leqq \beta\right\}.$$

Proof of Proposition A.1. Using (repeatedly) the relation $C_0 D(\alpha+1) = A^{-1} C_0 D(\alpha)$ and the properties of A^{-1} (see (2.1.7) and (2.2.10)) we see that it is sufficient to show (A.2) for $0 < \alpha < 1$.

For $\alpha = 1$ it is possible to prove (A.2) from the properties of the Green's kernel of A^{-1} (see Ladyzhenskaya and Ural'tseva (1968)) analogous to their calculations on the pp. 110–120.

Further details are left to the reader.

In the case $0 < \alpha < 1$ the following lemma will be useful.

LEMMA A.1. *Let* $\beta \in (0,1)$ *be given. Then*:

a. $\forall \varepsilon \in (0, 1-\beta)\ \exists K(\varepsilon) > 0\ \forall u \in C_0 D(1)$:

$$\text{(A.3)} \qquad \|u\|_{C^{2\beta}(\overline{D})} \leqq K(\varepsilon) \|Au\|^{\beta+\varepsilon}_{C(\overline{D})} \|u\|^{1-\beta-\varepsilon}_{C(\overline{D})}.$$

b. $\forall \varepsilon \in (0, 1-\beta)\ \exists \hat{K}(\varepsilon) > 0\ \forall t \geqq 0\ \forall f \in C_0(\overline{D})$:

$$\text{(A.4)} \qquad \left\|(A+t)^{-2} f\right\|_{C^{2\beta}(\overline{D})} \leqq \hat{K}(\varepsilon)(1+t)^{-2+\beta+\varepsilon} \|f\|_{C(\overline{D})}.$$

Proof of Lemma A.1.

a. We have already shown that $C_0 D(1) \subset C^{2\beta}(\overline{D})$. Because of an "interpolation" argument for $C^{2\beta}(\overline{D})$ in between $C^{2\delta}(\overline{D})$, $\beta < \delta < 1$, and $C(\overline{D})$, (see Miranda (1970)) the following estimate is valid:

$$\|u\|_{C^{2\beta}(\overline{D})} \leqq K_1 \|u\|^{\beta/\delta}_{C^{2\delta}(\overline{D})} \|u\|^{1-\beta/\delta}_{C(\overline{D})}.$$

Using the continuity of the injection associated to $C_0 D(1) \subset C^{2\beta}(\overline{D})$ we find

$$\|u\|_{C^{2\beta}(\overline{D})} \leqq K_2 \|Au\|^{\beta/\delta}_{C(\overline{D})} \|u\|^{1-\beta/\delta}_{C(\overline{D})}.$$

By putting $\beta/\delta = \beta + \varepsilon$ (A.3) is obtained.

b. Since $(A+t)^{-2} f \in C_0 D(1)$ we can use (A.3). This yields

$$\left\|(A+t)^{-2} f\right\|_{C^{2\beta}(\overline{D})} \leqq K \left\|A(A+t)^{-2} f\right\|^{\beta+\varepsilon}_{C(\overline{D})} \left\|(A+t)^{-2} f\right\|^{1-\beta-\varepsilon}_{C(\overline{D})}$$
$$\leqq \hat{K}(1+t)^{-(\beta+\varepsilon)} (1+t)^{-2(1-\beta-\varepsilon)} \|f\|_{C(\overline{D})}.$$

For the latter inequality we have used the formula $A(A+t)^{-2} = (A+t)^{-1} - t(A+t)^{-2}$ and (2.2.3). □

Now we shall show that for $0<\alpha<1$ and $0\leqq\beta<\alpha$ there is a constant $M>0$ such that $\forall f\in C_0(\bar{D})$

$$\|A^{-\alpha}f\|_{C^{2\beta}(\bar{D})}\leqq M\|f\|_{C(\bar{D})}. \tag{A.5}$$

By definition (see Krasnoselskii (1976, p. 281)) we have

$$A^{-\alpha}f=C(\alpha)\int_0^\infty t^{1-\alpha}(A+t)^{-2}f\,dt.$$

Because of (A.4) the integrand satisfies

$$\left\|t^{1-\alpha}(A+t)^{-2}f\right\|_{C^{2\beta}(\bar{D})}\leqq\hat{K}(\varepsilon)t^{-1-(\alpha-\beta-\varepsilon)}$$

where $\varepsilon>0$ is still a free parameter. By choosing $\varepsilon=\frac{1}{2}(\alpha-\beta)$ we see that the integral makes sense in $C^{2\beta}(\bar{D})$ and that (A.5) holds true.

From (A.5) we can conclude $C_0D(\alpha)\subset C^{2\beta}(\bar{D})\cap C_0(\bar{D})$ and this completes the proof of (A.2). □

Our following step will be to prove the next proposition.

PROPOSITION A.2. *For $\alpha>0$ and $\beta>\alpha$:*

$$C_0D(\alpha)\supset\left\{u\in C^{2\beta}(\bar{D})\,\middle|\,A^k u=0 \text{ on } \partial D, 0\leqq k\leqq\alpha\right\}. \tag{A.6}$$

Proof. It is again sufficient to show (A.6) for $0<\alpha\leqq1$. For $\alpha=1$ it is clear that (A.6) is contained in (A.1).

For $0<\alpha<1$ the following lemma will be useful.

LEMMA A.2. *Let $\gamma\in(0,1)$ be given. There exists a constant $K(\gamma)>0$ such that $\forall t\geqq0$ $\forall f\in C^{2\gamma}(\bar{D})$:*

$$\left\|A(A+t)^{-1}f\right\|_{C(\bar{D})}\leqq K(\gamma)(1+t)^{-\gamma}\|f\|_{C^{2\gamma}(\bar{D})}. \tag{A.7}$$

Proof of Lemma A.2. Let us introduce the notation $u=A(A+t)^{-1}f$. We shall decompose u in the following way:

$$\begin{aligned} &u=(f-\tilde{f})+(\tilde{f}-\tilde{w})+(\tilde{w}-w),\\ &w=t(A+t)^{-1}f,\qquad \tilde{w}=t(A+t)^{-1}\tilde{f}. \end{aligned} \tag{A.8}$$

The function $\tilde{f}$ will be an approximation of f which we construct from f by a "smoothing" process:

$$\tilde{f}(x)=\int_{\mathbb{R}^n}f^{\text{ext}}(y)\phi^\varepsilon(x-y)\,dy.$$

Here f^{ext} is an extension of f from $\bar{D}$ to the whole of $\mathbb{R}^n$ such that

$$\|f^{\text{ext}}\|_{C^{2\gamma}(\mathbb{R}^n)}\leqq2\|f\|_{C^{2\gamma}(\bar{D})}.$$

Further: $\phi^\varepsilon(x)=\phi(\varepsilon x)/\varepsilon^n$ with ϕ a spherical symmetric, positive, ∞-differentiable function which satisfies:

$$\begin{aligned} &\phi(x)=0\quad\text{for } \|x\|\geqq1,\\ &\int_{\mathbb{R}^n}\phi(x)\,dx=1. \end{aligned}$$

The parameter ε is taken equal to $(1+t)^{-1/2}$.

We shall now estimate the norms of the three terms in the decomposition (A.6):

(i) It is not difficult to verify that

$$\|f-\tilde{f}\|_{C(\bar{D})} \leqq K_1 \varepsilon^{2\gamma} \|f\|_{C^{2\gamma}(\bar{D})}.$$

(ii) Using (2.3.3) we find that

$$\|w-\tilde{w}\|_{C(\bar{D})} \leqq t(1+t)^{-1} \|f-\tilde{f}\|_{C(\bar{D})} \leqq K_1 \varepsilon^{2\gamma} \|f\|_{C^{2\gamma}(\bar{D})}.$$

(iii) Since $\tilde{f}-\tilde{w} = A(A+t)^{-1}\tilde{f}$ we obtain by applying (2.3.3)

$$\|\tilde{f}-\tilde{w}\|_{C(\bar{D})} \leqq (1+t)^{-1} \|A\tilde{f}\|_{C(\bar{D})}.$$

It is easy to see that

$$\|A\tilde{f}\|_{C(\bar{D})} \leqq K_2 \varepsilon^{2\gamma-2} \|f\|_{C^{2\gamma}(\bar{D})}.$$

By applying the triangle inequality to (A.8) and next substituting the estimates given in (i), (ii), (iii) the desired result (A.7) is found. □

Let us continue the proof of (A.6). Of course we can now continue ourselves to the situation $0 < \alpha < \beta < 1$. For $u \in C_0 D(1)$ we have

$$A^{\alpha} u = C(\alpha) \int_0^{\infty} t^{\alpha} (A+t)^{-1} \cdot A(A+t)^{-1} u \, dt$$

and

$$\|A^{\alpha} u\|_{C(\bar{D})} \leqq C(\alpha) \int_0^{\infty} t^{\alpha} (1+t)^{-1} \|A(A+t)^{-1} u\|_{C(\bar{D})} dt.$$

Because of (A.2) the function $u \in C_0 D(1)$ is certainly an element of $C^{2\beta}(\bar{D})$ and Lemma A.2 can be used to estimate $\|A(A+t)^{-1}u\|_{C(\bar{D})}$. In this way we obtain

$$\|A^{\alpha} u\|_{C(\bar{D})} \leqq K \int_0^{\infty} t^{\alpha} (1+t)^{-(\beta+1)} dt \cdot \|u\|_{C^{2\beta}(\bar{D})}. \tag{A.9}$$

The estimate in (A.9) is not only valid for $u \in C_0 D(1)$, but for all $u \in C^{2\beta}(\bar{D}) \cap C_0(\bar{D})$. This follows from the fact that $C_0 D(1)$ is dense in $C^{2\beta}(\bar{D}) \cap C_0(\bar{D})$ (see A.1!). Herewith the proof is complete. □

It is obvious that (2.2.8) is implied by Propositions A.1 and A.2. We shall continue this appendix by proving (2.2.9).

PROPOSITION A.3. *For* $\alpha > 0$ *and* $0 \leqq \beta < \alpha$:

$$CD(\alpha) \subset C_0 D(\beta). \tag{A.10}$$

Proof of Proposition A.3. It is again sufficient to show that (A.10) holds true for $0 < \alpha \leqq 1$. An argument analogous to the one given in the proof of Proposition A.1 gives the result

$$CD(1) \subset C^{2\beta}(\bar{D}) \cap C_0(\bar{D}) \quad \text{for } 0 \leqq \beta < 1.$$

Because of Proposition A.2 this implies

$$CD(1) \subset C_0 D(\beta) \quad \text{for } 0 \leqq \beta < 1.$$

Hence if we put $\alpha = 1-\delta$, $\beta = \alpha - \varepsilon$, $0 < \varepsilon \leqq 1-\delta$ then it is also true that

$$CD(\alpha) = A^{\delta} CD(1) \subset A^{\delta} C_0 D(1-\varepsilon) = C_0 D(1-\varepsilon-\delta) = C_0 D(\beta). \qquad \square$$

Let us conclude this appendix with the following result.

PROPOSITION A.4. *For $\alpha > 0$, $\alpha \notin N$ and β such that $\alpha \leqq \beta \leqq [\alpha]+1$ it holds true that*

$$CD(\beta) \text{ is dense in } CD(\alpha). \tag{A.11}$$

Proof. Let u be an element of $CD(\alpha)$. Then there exists a sequence $\{f_n; n \in \mathbb{N}\}$ in $C^{\infty}(\overline{D})$ such that $f_n \to A^{\alpha} u$ for $n \to \infty$ in $C(\overline{D})$. Using regularity theory and (A.2), (A.3), we see that $A^{-\alpha} f_n \in \{w \in C^{\infty}(\overline{D}) \mid A^k w = 0 \text{ on } \partial D, 0 \leqq k \leqq [\alpha]\}$. Consequently $A^{-\alpha} f_n \in CD([\alpha]+1)$ and $A^{-\alpha} f_n \to u$ for $n \to \infty$ in $CD(\alpha)$. This implies (A.11). $\square$

ON THE CONSTRUCTION OF SERIES SOLUTIONS TO THE FIRST BIHARMONIC BOUNDARY VALUE PROBLEM ON A RECTANGLE*

CHARLES V. COFFMAN†

Abstract. This paper is concerned with the problem of finding a biharmonic function u on a rectangle Ω which vanishes on $\partial\Omega$ and has a preassigned normal derivative there. The solution u is developed in a series; however the family of functions that enters into this series development is not orthogonal and thus the determination of the coefficients requires the solution of an infinite system of linear equations. In implementation of this method of course the coefficients are obtained by solving a truncation of the original infinite system. The bulk of the paper is devoted to the estimation of the error that results from this truncation.

AMS(MOS) subject classifications. Primary 35J40, 31A30, 65N99

Key words. clamped rectangular plate, series solution

1. Introduction. The difficulty in solving the first biharmonic boundary value problem on a rectangle Ω may be said to reside in the particular case

$$\Delta^2 u = 0 \quad \text{in } \Omega, \tag{1.1}$$

$$u = 0, \quad \frac{\partial u}{\partial \nu} = g \quad \text{on } \partial\Omega, \tag{1.2}$$

(ν denotes the interior normal). That is, the first boundary value problem with general data can be decomposed into problems solvable by separation of variables and a problem of the form (1.1), (1.2).

In this paper we discuss the representation of solutions to (1.1), (1.2) as infinite series involving trigonometric and hyperbolic functions. To determine the coefficients in this expansion, one must solve an infinite system of linear equations. The main purpose of this paper is to obtain a priori estimates for the error that results from truncation of this infinite system.

The methods employed here have a long history in the literature of both pure and applied mathematics. Two principal ideas are involved: first, the reduction of the general problem to the particular problem (1.1), (1.2); and second, the choice of the appropriate set of functions in which to expand the solution to the latter problem.

Except for a difference in choice of coordinates, the procedure described below, as it is applied to the problem of the clamped plate in §7, is precisely the same as that presented by Timoshenko in [13] (see also [12]). The basic ideas involved trace back to the beginning of the century (for references see [12]). The reduction to (1.1), (1.2) is accomplished by solving the problem of the simply supported plate, or by finding some other solution w to (7.1) that vanishes on $\partial\Omega$ and then solving (1.1), (1.2), with $g = \partial w/\partial \nu$, for the biharmonic function which when added to w gives the solution for the clamped plate. This procedure is easily seen to be equivalent to the method of Zaremba [1], [2], [4], [6], or the closely related method of the "nonharmonic residue" of Rafal'son [11] (see also [10]).

*Received by the editors March 29, 1983, and in final revised form October 19, 1984. This research was supported by the National Science Foundation under grant MCS 80-02851.

† Department of Mathematics, Carnegie-Mellon University, Pittsburgh, Pennsylvania 15213.

The expansion used below (formula (3.10)) can be traced back at least to Lauricella [8] (however the procedure given there for determination of the coefficients is in error). Prior to [2] no theoretical justification had been given for this representation and of course neither had convergence estimates been given. The justification that is given in [2] reduces to the demonstration that the angle θ, with respect to the inner product (3.7), between the spaces generated respectively by the functions (3.1), $j=0,1$, $n=1,2,\cdots$, and (3.2), $j=0,1$, $n=1,2,\cdots$ is positive. The a priori estimates there are in terms of $\cos\theta$; these are based on results of [1] where the procedure in [2] was already outlined. As indicated in [2] these estimates are primarily of theoretical interest and are too pessimistic to be of practical value. Here we obtain a priori estimates on the error involved in the truncation of the infinite system that must be solved and which, while they also may be excessively pessimistic in some cases, are nevertheless of practical value. Specifically, we show that under rather mild assumptions on the smoothness of the solution the error in a given coefficient is $O(N^{-\sigma})$ for any σ with $0<\sigma<3$, where N is the number of equations in the truncated system.

2. Preliminaries. We shall assume that the boundary data g in (1.1), (1.2) is sufficiently smooth that the solution u will have its Laplacian in $L^2(\Omega)$. Accordingly, we define $B_0(\Omega)$ to be the Hilbert space that consists of real-valued functions u that are continuous on $\bar{\Omega}$, biharmonic on Ω, vanish on $\partial\Omega$ and have Laplacian in $L^2(\Omega)$; the inner product on $B_0(G)$ is

$$\langle u,v\rangle=\int\int_{\Omega}\Delta u\Delta v\,dx\,dy. \tag{2.1}$$

Let $G(x,y;\xi,\eta)$ denote the harmonic Green's function for Ω. Then a function u defined on Ω belongs to $B_0(\Omega)$ if and only if

$$u(x,y)=\int\int_{\Omega}G(x,y;\xi,\eta)f(\xi,\eta)\,d\xi\,d\eta, \tag{2.2}$$

where f is harmonic and square-integrable on Ω; in this case of course

$$-\Delta u=f.$$

Since the L^2-harmonic functions form a closed subspace of $L^2(\Omega)$ the completeness of $B_0(\Omega)$ follows from the representation (2.2).

The second boundary condition in (1.2) is assumed to hold in the following weak sense

$$\int\int_{\Omega}\varphi\Delta u\,dx\,dy=-\int_{\partial\Omega}\varphi g\,ds, \tag{2.3}$$

for every φ that is harmonic on some neighborhood of $\bar{\Omega}$.

We specify Ω to be of the form

$$\Omega=\{(x,y):0<x<a,0<y<b\}. \tag{2.4}$$

We then express g in terms of sine series as follows

$$\begin{aligned} g(x,\eta)&=\sum_{n=1}^{\infty}\alpha_n(\eta)\sin\frac{n\pi x}{a}, \qquad \eta=0,b,\\ g(\xi,y)&=\sum_{n=1}^{\infty}\beta_n(\xi)\sin\frac{n\pi y}{b}, \qquad \xi=0,a, \end{aligned} \tag{2.5}$$

where

$$\alpha_n(\eta)=\frac{2}{a}\int_0^a g(x,\eta)\sin\frac{n\pi x}{a}\,dx,$$
$$\beta_n(\xi)=\frac{2}{b}\int_0^b g(\xi,y)\sin\frac{n\pi y}{b}\,dy. \tag{2.6}$$

We shall say that

$$g\in H^k(\partial\Omega)$$

if and only if

$$\sum_{n=1}^{\infty} n^{2k}\left(\alpha_n^2(0)+\alpha_n^2(b)+\beta_n^2(0)+\beta_n^2(a)\right)<\infty. \tag{2.7}$$

By expanding a function $u\in B_0(\Omega)$ in a double sine series on Ω and computing $\partial u/\partial\nu$ therefrom, one easily sees that:

(*) *A necessary condition for* (1.1), (1.2) *to admit a solution* $u\in B_0(\Omega)$ *is that* $g\in H^{1/2}(\partial\Omega)$.

The converse is also true.

PROPOSITION 2.1. *The problem* (1.1), (1.2) *has a solution* $u\in B_0(\Omega)$ *if and only if* $g\in H^{1/2}(\partial\Omega)$.

The proof is deferred to the appendix.

It readily follows from assertion (*) and the weak formulation (2.3) of (1.2) that, for a given g, the problem (1.1), (1.2), has at most one solution in $B_0(\Omega)$.

3. Series representation of the solution. We define the functions $\{\varphi_n^j\}$, $\{\psi_n^j\}$, $j=0,1$ as follows

$$\varphi_n^j(x,y)=\frac{c_n^j}{\sqrt{2n\pi}}\sin\frac{n\pi x}{a}\left[(b-y)\sinh\frac{n\pi y}{a}+(-1)^j y\sinh\frac{n\pi}{a}(b-y)\right], \tag{3.1}$$

$$\psi_n^j(x,y)=\frac{d_n^j}{\sqrt{2n\pi}}\sin\frac{n\pi y}{b}\left[(a-x)\sinh\frac{n\pi x}{b}+(-1)^j x\sinh\frac{n\pi}{b}(a-x)\right], \tag{3.2}$$

where

$$c_n^j=\left(\left(\sinh\frac{n\pi b}{a}+(-1)^j\frac{n\pi ub}{a}\right)\left(\cosh\frac{n\pi b}{a}+(-1)^j\right)\right)^{-1/2}, \tag{3.3}$$

$$d_n^j=\left(\left(\sinh\frac{n\pi a}{b}+(-1)^j\frac{n\pi a}{b}\right)\left(\cosh\frac{n\pi a}{b}+(-1)^j\right)\right)^{-1/2}. \tag{3.4}$$

We then have

$$\Delta\varphi_n^j(x,y)=-\sqrt{2n\pi}\,\frac{c_n^j}{a}\sin\frac{n\pi x}{a}\left[\cosh\frac{n\pi y}{a}+(-1)^j\cosh\frac{n\pi}{a}(b-y)\right], \tag{3.5}$$

$$\Delta\psi_n^j(x,y)=-\sqrt{2n\pi}\,\frac{d_n^j}{b}\sin\frac{n\pi y}{b}\left[\cosh\frac{n\pi x}{b}+(-1)^j\cosh\frac{n\pi}{b}(a-x)\right], \tag{3.6}$$

and

$$\int_0^b \int_0^a \left|\Delta\varphi_n^j(x,y)\right|^2 dx\,dy = \int_0^b \int_0^a \left|\Delta\psi_n^j(x,y)\right|^2 dx\,dy = 1,$$

for $j=0,1, n=1,2,\cdots$.

It is clear that the sets $\{\varphi_n^j: j=0,1; n=1,2,\cdots\}$ and $\{\psi_n^j: j=0,1; n=1,2,\cdots\}$ are orthonormal with respect to the inner product

$$\langle u,v\rangle = \int_0^b \int_0^a \Delta u \Delta v\,dx\,dy. \tag{3.7}$$

Two terms φ_n^j and ψ_m^i will have nonzero inner product only if their parities with respect to the lines $x=a/2$ and $y=b/2$ are the same; this necessary condition for φ_n^j and ψ_m^i to have nonzero inner product can be written

$$(-1)^{n+i} = (-1)^{m+j} = -1. \tag{3.8}$$

(*) *If* (3.8) *holds, then*

(3.9)

$$\langle \varphi_n^j, \psi_m^i\rangle = \frac{8a^2b^2(mn)^{3/2}}{\pi(m^2a^2+n^2b^2)^2} c_n^j d_m^i \left[1+(-1)^{m+1}\cosh\frac{n\pi b}{a}\right]\left[1+(-1)^{n+1}\cosh\frac{m\pi a}{b}\right];$$

otherwise

$$\langle \varphi_n^j, \psi_m^i\rangle = 0.$$

Suppose now that u is the solution to (1.1), (1.2), then by Green's formula, (3.5) and (2.5)

$$\begin{aligned}\langle \varphi_n^j, u\rangle &= -\int_0^a \left(\Delta\varphi_n^j(x,b)g(x,b) + \Delta\varphi_n^j(x,0)g(x,0)\right)dx \\ &= \sqrt{\frac{n\pi}{2}}\, c_n^j\left(\cosh\frac{n\pi b}{a} + (-1)^j\right)\left(\alpha_n(b) + (-1)^j\alpha_n(0)\right),\end{aligned}$$

and similarly

$$\langle \psi_n^j, u\rangle = \sqrt{\frac{n\pi}{2}}\, d_n^j\left(\cosh\frac{n\pi a}{b} + (-1)^j\right)\left(\beta_n(a) + (-1)^j\beta_n(0)\right).$$

We put

$$\begin{aligned}\bar{\alpha}_{n,j} &= \sqrt{\frac{n\pi}{2}}\, c_n^j\left(\cosh\frac{n\pi b}{a} + (-1)^j\right)\left(\alpha_n(b) + (-1)^j\alpha_n(0)\right), \\ \bar{\beta}_{n,j} &= \sqrt{\frac{n\pi}{2}}\, d_n^j\left(\cosh\frac{n\pi a}{b} + (-1)^j\right)\left(\beta_n(a) + (-1)^j\beta_n(0)\right),\end{aligned}$$

and note that, in view of (3.3), (3.4),

$$\begin{aligned}\lim_{n\to\infty} c_n^j \cosh\frac{n\pi b}{a} &= 1, \\ \lim_{n\to\infty} d_n^j \cosh\frac{n\pi a}{b} &= 1,\end{aligned}$$

$j=0,1$, so that $g\in H^k(\partial\Omega)$ if and only if

$$\sum_{n=1}^{\infty} n^{2k-1}\bar{\alpha}_{n,j}^2, \quad \sum_{n=1}^{\infty} n^{2k-1}\bar{\beta}_{n,j}^2<\infty, \qquad j=0,1.$$

We seek to represent the solution u to (1.1), (1.2) in the form

$$u(x,y)=\sum_{j=0}^{1}\sum_{n=1}^{\infty}\left(A_n^j\varphi_n^j(x,y)+B_n^j\psi_n^j(x,y)\right), \tag{3.10}$$

where

$$\sum_{j=0}^{1}\sum_{n=1}^{\infty}\left(\left|A_n^j\right|^2+\left|B_n^j\right|^2\right)<\infty. \tag{3.11}$$

When u is so represented, the coefficients must satisfy the infinite system of linear equations

$$\begin{aligned} &A_{2n-1+i}^j+\sum_{k=1}^{\infty} B_{2k-1+j}^i\left\langle \varphi_{2n-1+i}^j,\psi_{2k-1+j}^i\right\rangle=\bar{\alpha}_{2n-1+i,j},\\ &B_{2n-1+j}^i+\sum_{k=1}^{\infty} A_{2k-1+i}^j\left\langle \psi_{2n-1+j}^i,\varphi_{2k-1+i}^j\right\rangle=\bar{\beta}_{2n-1+j,i},\\ &i,j=0,1, \qquad n=1,2,\cdots. \end{aligned} \tag{3.12}$$

The above computations yield immediately the following.

THEOREM 3.1. *Let u_N denote the projection of u onto*

$$\operatorname{sp}\{\varphi_n^i,\psi_n^i: i=0,1; n=1,2,\cdots,2N\}$$

with respect to the inner product (3.7). *Then*

$$u_N(x,y)=\sum_{j=0}^{1}\sum_{n=1}^{2N}\left(\bar{A}_n^j\varphi_n^j(x,y)+\bar{B}_n^j\psi_n^j(x,y)\right) \tag{3.13}$$

where $\{\bar{A}_n^j,\bar{B}_n^j\}$ satisfy

$$\begin{aligned} &\bar{A}_{2n-1+i}^j+\sum_{k=1}^{N}\bar{B}_{2k-1+j}^i\left\langle \varphi_{2n-1+i}^j,\psi_{2k-1+j}^i\right\rangle=\bar{\alpha}_{2n-1+i,j},\\ &\bar{B}_{2n-1+j}^i+\sum_{k=1}^{N}\bar{A}_{2k-1+i}^j\left\langle \psi_{2n-1+j}^i,\varphi_{2n-1}^j\right\rangle=\bar{\beta}_{2n-1+j,i},\\ &i,j=0,1, \qquad n=1,2,\cdots,N. \end{aligned} \tag{3.14}$$

Proof. If u_N is given by (3.13) and (3.14) holds, then

$$\left\langle u-u_N,\varphi_n^j\right\rangle=\left\langle u-u_N,\psi_n^j\right\rangle=0,$$

for $j=0,1, n=1,2,\cdots,2N$.

4. Row and column estimates. In this section we will derive row and column decay estimates for the inverse of the matrix that appears on the left in (3.12). These will be used in the following sections to estimate the error that results from truncation of

(3.12). The system (3.12) is of the form

$$\begin{aligned} A+\Gamma B&=\alpha,\\ \Gamma^*A+B&=\beta; \end{aligned} \tag{4.1}$$

moreover, it decomposes into four subsystems (corresponding to the four choices of the pair (i,j)) all of the form (4.1). If the matrices $I-\Gamma^*\Gamma$, $I-\Gamma\Gamma^*$ are invertible, then the solution to (4.1) is

$$\begin{aligned} A&=(I-\Gamma\Gamma^*)^{-1}(\alpha-\Gamma\beta),\\ B&=(I-\Gamma^*\Gamma)^{-1}(\beta-\Gamma^*\alpha). \end{aligned}$$

In what follows, we shall assume (4.1) to denote one of the subsystems of (3.12), as indicated above. It then follows from the results of [2], (see Appendix), that

$$\|\Gamma\|<1 \tag{4.2}$$

where, here and throughout, $\|\Gamma\|$ denotes the norm of Γ as an operator on l^2. It follows that the series

$$\Gamma\Gamma^*+(\Gamma\Gamma^*)^2+\cdots+(\Gamma\Gamma^*)^n+\cdots,\quad \Gamma^*\Gamma+(\Gamma^*\Gamma)^2+\cdots+(\Gamma^*\Gamma)^n+\cdots, \tag{4.3}$$

are convergent with respect to the norm $\|\cdots\|$. Here we will be concerned with the convergence of these series with respect to norms of the form

$$\|\Gamma\|_\delta=\sup_{m,n}|\gamma_{mn}|\max\{m^{\delta-1/2}n^{3/2-\delta},m^{3/2-\delta}n^{\delta-1/2}\}, \tag{4.4}$$

where $0<\delta\leqq\frac{1}{2}$.

LEMMA 4.1. *Let* $0\leqq\delta\leqq\frac{1}{2}$, *let* $\Gamma=\{\gamma_{mn}\}$ *satisfy*

$$\overline{\lim_{m\to\infty}}\, m^{(3/2)-\delta}\sum_{n=1}^{\infty}|\gamma_{mn}|n^{\delta-3/2}<\rho \tag{4.5}$$

and let the matrix $\Lambda=\{\lambda_{mn}\}$ *satisfy the column decay inequalities*

$$|\lambda_{mn}|\leqq c_0 m^{\delta-3/2}n^{1/2-\delta},\qquad m,n=1,2,\cdots. \tag{4.6}$$

Then the product $\Lambda'=\Gamma\Lambda$ *satisfies the column decay inequalities*

$$|\lambda'_{mn}|\leqq\left(\max\{C\|\Lambda\|,\rho c_0\}\right)m^{\delta-3/2}n^{1/2-\delta}, \tag{4.7}$$

where C *is a constant that depends only on* Γ.

Proof. Choose N so that

$$m^{3/2-\delta}\sum_{k=1}^{\infty}|\gamma_{mk}|k^{\delta-3/2}<\rho \tag{4.8}$$

for $m\geqq N$. Upon combining (4.6) and (4.8) we then have

$$|\lambda'_{mn}|=\left|\sum_{k=1}^{\infty}\gamma_{mk}\lambda_{kn}\right|\leqq\rho c_0 m^{\delta-3/2}n^{1/2-\delta}, \tag{4.9}$$

for $m \geqq N$. For $m \leqq N$,

$$|\lambda'_{mn}| \leqq \left(\sum_{k=1}^{\infty} |\gamma_{mk}|^2 \right)^{1/2} \left(\sum_{k=1}^{\infty} |\lambda_{kn}|^2 \right)^{1/2} \tag{4.10}$$

$$\leqq (N^{3/2-\delta}\|\Gamma\|)\|\Lambda\| m^{\delta-3/2} n^{1/2-\delta}.$$

The inequality (4.7) thus holds with $C = N^{(3/2)-\delta}\|\Gamma\|$.

LEMMA 4.2. *For $i,j = 0,1$, $0 \leqq \delta \leqq \frac{1}{2}$, we have*

$$\lim_{m\to\infty} \left[m^{3/2-\delta} \sum_{k=1}^{\infty} \left| \left\langle \varphi^j_{2m-1+i}, \psi^i_{2k-1+j} \right\rangle \right| k^{\delta-3/2} \right] = \frac{4}{\pi} \left(\frac{a}{b} \right)^{1-\delta} \int_0^{\infty} \frac{s^{\delta}\, ds}{(1+s^2)^2},$$

$$\lim_{m\to\infty} \left[m^{3/2-\delta} \sum_{k=1}^{\infty} \left| \left\langle \psi^j_{2n-1+i}, \varphi^i_{2k-1+j} \right\rangle \right| k^{\delta-3/2} \right] = \frac{4}{\pi} \left(\frac{b}{a} \right)^{1-\delta} \int_0^{\infty} \frac{s^{\delta}\, ds}{(1+s^2)^2}.$$

Proof. Let i,j be fixed and put

$$s(k,m) = (2k-1+j)b/(2m-1+i)a,$$

and

$$\Delta_k x(k,m) = s(k+1,m) - s(k,m) = 2b/(2m-1+i)a.$$

Then it follows from (3.3), (3.4) and (3.9) that

$$m^{3/2-\delta} \sum_{k=1}^{\infty} \left| \left\langle \varphi^j_{2m-1+i}, \psi^i_{2k-1+j} \right\rangle \right| k^{\delta-3/2}$$

$$= \frac{4}{\pi} \left(\frac{b}{a} \right)^{\delta} (1+f(m)) \sum_{k=1}^{\infty} \frac{[s(k,m)]^{\delta}(1+g(k))\Delta_k s(k,m)}{\left(1+(s(k,m))^2\right)^2},$$

where

$$\lim_{m\to\infty} f(m) = \lim_{k\to\infty} g(k) = 0.$$

The first of the asserted formulas follows readily; the proof of the second is exactly the same.

LEMMA 4.3. *Let (i,j) be fixed $(i,j = 0,1)$ and let $\Gamma = \{\gamma_{mk}\}$ where*

$$\gamma_{mk} = \left\langle \varphi^j_{2m-1+i}, \psi^i_{2k-1+j} \right\rangle. \tag{4.11}$$

Let $0 \leqq \delta \leqq \frac{1}{2}$ and let

$$\|\Gamma\|, \frac{4}{\pi} \int_0^{\infty} \frac{s^{\delta}\, ds}{(1+s^2)^2} < \kappa. \tag{4.12}$$

Then there exists a constant C', depending only on Γ, κ, δ, such that

$$\|(\Gamma\Gamma^*)^n\|_\delta, \|(\Gamma^*\Gamma)^n\|_\delta \leqq C'\kappa^{2n}, \qquad n=1,2,\cdots. \tag{4.13}$$

Proof. Suppose that the inequality (4.13) holds for 1 through n and suppose moreover that

$$C'\left(\frac{a}{b}\right)^{1-\delta}, C'\left(\frac{b}{a}\right)^{1-\delta} \geqq \kappa^{-1}C, \tag{4.14}$$

where C is the constant in Lemma 4.1. It follows then from (4.11), the definition (4.4) and Lemmas 4.1 and 4.2 that $\Gamma^*(\Gamma\Gamma^*)^n = \{\lambda'_{mk}\}$ satisfies the column decay inequalities

$$|\lambda'_{mk}| \leqq C'\left(\frac{b}{a}\right)^{1-\delta} \kappa^{2n+1} m^{\delta-3/2} k^{1/2-\delta}. \tag{4.15}$$

We multiply again on the left, this time by Γ, and repeat the same argument; taking into account the symmetry of the matrix there results

$$\|(\Gamma\Gamma^*)^{n+1}\|_\delta \leqq C'\kappa^{2n+2}.$$

Thus if C' is suitably chosen, the first inequality in (4.13) follows by induction; the proof of the second is exactly the same.

LEMMA 4.4. *Let* $0<\delta\leqq\frac{1}{2}$. *Then*

$$\frac{4}{\pi}\int_0^\infty \frac{s^\delta\, ds}{(1+s^2)^2} < 1. \tag{4.16}$$

Proof. We have

$$\frac{4}{\pi}\int_0^\infty \frac{ds}{(1+s^2)^2} = 1, \qquad \frac{4}{\pi}\int_0^\infty \frac{s\, ds}{(1+s^2)^2} = \frac{2}{\pi},$$

and

$$\frac{4}{\pi}\int_0^\infty \frac{s^\delta\, ds}{(1+s^2)^2} \leqq \left(\frac{4}{\pi}\int_0^\infty \frac{s\, ds}{(1+s^2)^2}\right)^\delta \left(\frac{4}{\pi}\int_0^\infty \frac{ds}{(1+s^2)^2}\right)^{1-\delta}.$$

Combining Lemma 4.3 and 4.4 and using (4.2), we obtain the following.

PROPOSITION 4.1. *Let* $\Gamma=\{\gamma_{mk}\}$ *where* (4.11) *holds and* (i,j) $(i,j=0,1)$ *is fixed. Then the series* (4.3) *are convergent in the norm* (4.4) *for* $0<\delta\leqq\frac{1}{2}$.

The above discussion leads readily to the following.

THEOREM 4.1. *The solution to* (3.12) *is given by a system of the form*

$$\begin{aligned} A^j_{2n-1+i} &= \bar\alpha_{2n-1+i} + \sum_{k=1}^\infty \left(\lambda_{2n-1+i,2k-1+i}\bar\alpha_{2k-1+i} + \mu_{2n-1+i,2k-1+j}\bar\beta_{2k-1+j}\right), \\ B^i_{2n-1+j} &= \bar\beta_{2n-1+j} + \sum_{k=1}^\infty \left(\mu^*_{2n-1+j,2k-1+i}\bar\alpha_{2k-1+i} + \lambda^*_{2n-1+j,2k-1+j}\bar\beta_{2k-1+j}\right), \\ &\qquad\qquad i,j=0,1, \quad n=1,2,\cdots, \end{aligned} \tag{4.17}$$

and for $0<\delta\leqq\frac{1}{2}$,

$$\sup_{m,n}\left\{\left(|\lambda_{mn}|+|\mu_{mn}|+|\lambda^*_{mn}|+|\mu^*_{mn}|\right)\max\left(m^{\delta-1/2}n^{3/2-\delta}, m^{3/2-\delta}n^{\delta-1/2}\right)\right\} < \infty.$$

Remark. It is easily seen that if the infinite matrix $\Lambda = \{\lambda_{mn}\}$ has

$$\|\Lambda\|_\delta < \infty$$

for $0 < \delta \leqq \frac{1}{2}$ then

$$\sup_n \sum_{m=1}^{\infty} |m^\sigma \lambda_{mn} n^{-\sigma}|, \ \sup_m \sum_{n=1}^{\infty} |m^\sigma \lambda_{mn} n^{-\sigma}| < \infty$$

for $0 \leqq \sigma < \frac{1}{2}$. It follows then from Young's inequality that the matrix Λ induces an operator that is continuous with respect to the sequence space norm

$$|a| = \left(\sum_{n=1}^{\infty} n^{2\sigma} a_n^2 \right)^{1/2}$$

for $0 \leqq \sigma < \frac{1}{2}$. It follows therefore from Theorem 4.1 (cf. §3) that if $g \in H^k(\partial\Omega)$, $\frac{1}{2} \leqq k < 1$, then

$$\sum_{j=0}^{1} \sum_{n=1}^{\infty} n^{2k-1} \left(|A_n^j|^2 + |B_n^j|^2 \right) < \infty.$$

5. Truncation estimates. It is not difficult to see that the methods of the preceding section could be applied to obtain row and column decay estimates, uniform with respect to N, for the inverses of the matrices that appear in the truncated systems (3.14). Stronger results can be obtained by observing that, in view of (3.8) and (3.9), if $\gamma_{mk}^{(i,j)} = \gamma_{mk}$ is given by (4.11) and $\Gamma^{(i,j)} = \{\gamma_{mk}^{(i,j)}\}$ then the matrices $(-1)^{i+j}\Gamma^{(i,j)}$ have nonnegative entries. Thus, for example, for any of the matrices Γ, if Γ_N is a truncation of Γ then $\Gamma\Gamma^*$, $\Gamma_N\Gamma_N^*$ have nonnegative entries and the entries of $I + (\Gamma_N\Gamma_N^*) + \cdots + (\Gamma_N\Gamma_N^*)^n + \cdots$ do not exceed the corresponding entries of $I + (\Gamma\Gamma^*) + \cdots + (\Gamma\Gamma^*)^n + \cdots$. We conclude the following.

PROPOSITION 5.1. *Inversion of the finite system* (3.14) *yields a finite system of the form* (4.17) *with corresponding coefficients* $\lambda_{mn}(N)$, $\mu_{mn}(N)$, $\mu_{mn}^*(N)$, $\lambda_{mn}^*(N)$, $m, n = 1, \cdots, 2N$. *Moreover, if* $N' > N$ *then*

$$0 \leqq \lambda_{mn}(N) \leqq \lambda_{mn}(N') \leqq \lambda_{mn}, \ 0 \leqq \lambda_{mn}^*(N) \leqq \lambda_{mn}^*(N) \leqq \lambda_{mn}^*(N') \leqq \lambda_{mn}^*,$$
$$|\mu_{mn}(N)| \leqq |\mu_{mn}(N')| \leqq |\mu_{mn}|, \ |\mu_{mn}^*(N)| \leqq |\mu_{mn}^*(N')| \leqq |\mu_{mn}^*|.$$

Finally,

$$\sup_{m,n \leqq 2N} \left\{ |\lambda_{mn}(N)| + |\mu_{mn}(N)| + |\lambda_{mn}^*(N)| + |\mu_{mn}^*(N)| \right\} \times \max(m^{\delta - 1/2} n^{3/2 - \delta}, m^{3/2 - \delta} n^{\delta - 1/2}) \leqq C \tag{5.1}$$

for $0 < \delta \leqq \frac{1}{2}$, *where* $C = C(\delta)$ *is independent of* N.

Remark. Regarding the rate of convergence, it can be shown that

$$|\lambda_{mn}(N) - \lambda_{mn}|, \ |\mu_{mn}(N) - \lambda_{mn}|, \ |\mu_{mn}^*(N) - \mu_{mn}^*|, \ |\lambda_{mn}^*(N) - \lambda_{mn}^*| < C m^{1/2 - \delta} n^{1/2 - \delta} N^{2\delta - 2}, \qquad 1 \leqq m, n \leqq 2N, \tag{5.2}$$

for $0 \leqq \delta \leqq \frac{1}{2}$, where again C depends on δ but not on N.

In the absence of a better estimate than (5.2) for the rate of convergence of the inverses of the truncated matrices, in order to get better than $O(N^{-2})$ convergence of the solutions to (3.14) we must assume an a priori hypothesis concerning the decay of the coefficients A_n^j, B_n^j themselves. In the final sections we show when such an hypothesis can be verified.

In what follows, as in §3, $\bar{A}_n^j = \bar{A}_n^j(N)$, $\bar{B}_n^j = \bar{B}^j(N)$, $i,j=0,1$; $n=1,\cdots,2N$, denote the components of the solution to (3.14).

THEOREM 5.1. *Suppose that for some nonnegative number* σ, *the solution to* (3.12) *satisfies*

$$\sum_{i=0}^{1}\sum_{n=1}^{\infty} n^{2\sigma}\left(\left|A_n^i\right|^2+\left|B_n^i\right|^2\right)<\infty. \tag{5.3}$$

Then for $0<\delta\leqq\frac{1}{2}$,

$$\left|\bar{A}_n^i(N)-A_n^i\right|,\ \left|\bar{B}_n^i(N)-B_n^i\right|\leqq Cn^{1/2-\delta}N^{-1-\sigma+\delta}, \tag{5.4}$$

where $C=C(\delta)$.

Proof. Put

$$a_n^i(N)=\bar{A}_n^i(N)-A_n^i,\qquad b_n^i(N)=\bar{B}_n^i(N)-B_n^i.$$

The a_n^i, b_n^i satisfy the linear system with the same matrix that appears in (3.14) and the right-hand terms

$$\sum_{k=N+1}^{\infty} B_{2k-1+j}^i\left\langle\varphi_{2n-1+i}^j,\psi_{2k-1+j}^i\right\rangle=f_{2n-1+i}^j(N)$$

and

$$\sum_{k=N+1}^{\infty} A_{2k-1+i}^j\left\langle\psi_{2n-1+j}^i,\varphi_{2k-1+i}^j\right\rangle=h_{2n-1+j}^i(N),\qquad i,j=0,1,\quad n=1,\cdots,N.$$

From (3.9) and (5.3) we have, for example,

$$\begin{aligned}\left|f_n^j(N)\right|&\leqq Cn^{3/2}\sum_{k=N+1}^{\infty}k^{-5/2}B_{2k-1+j}^i,\\&\leqq Cn^{3/2}\left(\sum_{k=N+1}^{\infty}k^{-5-2\sigma}\right)^{1/2}\left(\sum_{k=1}^{\infty}k^{2\sigma}\left|B_{2k-1+j}^i\right|^2\right)^{1/2}\\&\leqq Cn^{3/2}N^{-2-\sigma},\end{aligned}$$

(here $(-1)^{n+i}=-1$). Similarly

$$\left|h_n^i(N)\right|\leqq Cn^{3/2}N^{-2-\sigma}.$$

We then apply Proposition 5.1, specifically inequality (5.1), to obtain (5.4).

6. Smooth solutions. We now show that if

$$g\in H^k(\partial\Omega),\qquad k\geqq\tfrac{3}{2}, \tag{6.1}$$

and if the solution u to (1.1), (1.2) belongs to $H^4(\Omega)$ or at least

$$\frac{\partial^2}{\partial y^2}\Delta u \in L^2(\Omega), \tag{6.2}$$

then the coefficients in the expansion (3.10) satisfy (5.3) with $\sigma = 2$.

Indeed if (6.2) holds, then by i) of Proposition A.1 in the Appendix we have

$$\frac{\partial^2}{\partial y^2}\Delta u = \sum_{i=0}^{1}\sum_{n=1}^{\infty}\left(A_n^i \Delta\varphi_n^i + B_n^i \Delta\psi_n^i\right)$$

where

$$\sum_{i=0}^{1}\sum_{n=1}^{\infty}\left(\left|A_n^i\right|^2 + \left|B_n^i\right|^2\right) < \infty.$$

Thus

$$u = v + w, \tag{6.3}$$

where

$$v = \frac{1}{\pi^2}\sum_{i=0}^{1}\sum_{n=1}^{\infty} n^{-2}\left(a^2 A_n^i \varphi_n^i - b^2 B_n^i \psi_n^i\right) \tag{6.4}$$

and

$$\Delta w = C_1 + C_2 x + C_3 y + C_4 xy. \tag{6.5}$$

To complete the proof of our assertion, we show that, given (6.1), we must have

$$C_1 = C_2 = C_3 = C_4 = 0. \tag{6.6}$$

LEMMA 6.1. *Suppose that u has the expansion* (3.10) *and* (5.3) *holds for some* σ *on the range*

$$0 \leqq \sigma < \tfrac{3}{2}. \tag{6.7}$$

Then

$$\frac{\partial u}{\partial \nu} \in H^{\sigma+1/2}(\partial\Omega). \tag{6.8}$$

LEMMA 6.2. *Suppose that*

$$w \in B_0(\Omega)$$

and (6.5) *holds. Then*

$$\frac{\partial w}{\partial \nu} \in H^k(\partial\Omega),$$

for $k \geqq \frac{3}{2}$ *implies* (6.6).

Proof of Lemma 6.1. From (3.9) it follows that the matrices $\Gamma = \{\gamma_{mn}\}$, Γ as in Lemma 4.3, satisfy

$$\sup_m m^\sigma \sum_{n=1}^{\infty} |\gamma_{mn}| n^{-\sigma}, \quad \sup_n n^{-\sigma} \sum_{m=1}^{\infty} |\gamma_{mn}| m^\sigma \leqq C$$

for $0 \leqq \sigma < \frac{3}{2}$. It then follows from (5.3) and Young's inequality that

$$\sum_{i=0}^{1} \sum_{n=1}^{\infty} n^{2\sigma}\left(|\overline{\alpha}_{n,i}|^2 + |\overline{\beta}_{n,i}|^2\right) < \infty,$$

provided (6.7) holds. Thus (cf. §3) if (6.7) holds then (5.3) implies (6.8).

Proof of Lemma 6.2. If we decompose u as

$$u = \sum_{i=0}^{1} \sum_{j=0}^{1} u^{(i,j)}, \tag{6.9}$$

where

$$u^{(i,j)}(x,y) = \tfrac{1}{4}\big[u(x,y) + (-1)^i u(a-x,y) + (-1)^j u(x,b-y) + (-1)^{i+j} u(a-x,b-y)\big], \tag{6.10}$$

then it is clear that the smoothness properties (6.1) ($g = \partial u/\partial \nu$) and (6.2) are invariant under $u \mapsto u^{(i,j)}$, $i,j = 0,1$. Let $w^{(i,j)} \in B_0(\Omega)$ be determined by

$$\Delta w^{(i,j)}(x,y) = \left(\frac{2}{a}x - 1\right)^i \left(\frac{2}{b}y - 1\right)^j.$$

Then

$$w^{(i,j)}(x,y) = \sum_{n=1}^{\infty} \tilde{A}^j_{2n-1+i} \varphi^j_{2n-1+i} + \sum_{n=1}^{\infty} \tilde{B}^i_{2n-1+j} \psi^i_{2n-1+j}, \tag{6.11}$$

where

$$\tilde{A}^j_n = (-1)^{n+j} \frac{a}{c^j_n\big[(-1)^j \cosh(n\pi b/a) + 1\big]} \left(\frac{2}{\pi n}\right)^{3/2}, \tag{6.12}$$

$$\tilde{B}^j_n = (-1)^{n+j} \frac{b}{d^j_n\big[(-1)^j \cosh(n\pi a/b) + 1\big]} \left(\frac{2}{\pi n}\right)^{3/2}, \tag{6.13}$$

cf. (3.5), (3.6). We find the coefficients α_n, β_n in the expansion (2.5) of $g = (\partial w^{(i,j)}/\partial \nu)$ as follows. The coefficients $\overline{A}^j_n$, $\overline{B}^j_n$ in (6.11) satisfy equations (3.12) with the $\overline{\alpha}_{n,j}$, $\overline{\beta}_{n,j}$ on the right defined in terms of the α_n, β_n as indicated in §3. A check of the signs in (3.9) and (6.12), (6.13) shows that in all of the resulting equations (3.12) the first term on the left and the summation always agree in sign. Thus, for example

$$|\tilde{A}^j_{2n-1+i}| \leqq \left|\tilde{A}^j_{2n-1+i} + \sum_{k=1}^{\infty} \tilde{B}_{2k-1+j} \left\langle \varphi^j_{2n-1+i}, \psi^i_{2k-1+j} \right\rangle\right|.$$

It readily follows from (6.12), (6.13), that

$$\frac{\partial w^{(i,j)}}{\partial \nu} \notin H^k(\partial\Omega)$$

for $k \geqq \frac{3}{2}$.

To complete the proof, we consider one of the $u^{(i,j)}$ given by (6.10). If we make the decomposition (6.3), as indicated above, of $u^{(i,j)}$, then the second term w is of the form $Cw^{(i,j)}$; however $(\partial u^{(i,j)}/\partial \nu) \in H^k(\partial\Omega)$, for some $k \geqq \frac{3}{2}$; by (6.4) and Lemma 6.1, the first term v has $(\partial v/\partial \nu) \in H^2(\partial\Omega)$ and thus we must have $C=0$.

We summarize the above observations in the following.

PROPOSITION 6.1. *Let* (6.1) *hold and suppose that the solution u to* (1.1), (1.2) *satisfies* (6.2). *Then the coefficients in the expansion* (3.10) *of u satisfy* (5.3) *with*

$$\sigma = 2.$$

7. The clamped plate. The problem of the clamped plate is

$$\Delta^2 u = f \quad \text{in } \Omega, \tag{7.1}$$

$$u = \frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega. \tag{7.2}$$

The formula of Zaremba, in its usual formulation, (cf. e.g. [1], a more general formulation is given in [4]) expresses the Green's function Γ for (7.1), (7.2) as

$$\Gamma = \Gamma_1 - \Gamma_2, \tag{7.3}$$

where Γ_1 is the Green's function for the differential equation (7.1) and boundary conditions

$$u = \Delta u = 0 \quad \text{on } \partial\Omega; \tag{7.4}$$

(in the case of a rectangle, or more generally a polygon, conditions (7.4) are the boundary conditions of the simply supported plate) and Γ_2 is the reproducing kernel of the space $B_0(\Omega)$. Thus the solution u to (7.1), (7.2) decomposes as

$$u = u_1 - u_2 \tag{7.5}$$

where u_1 is obtained by solving (7.1), (7.4) and u_2 can be computed using Γ_2 when the latter is known. Alternatively, u_2 can be found by solving (1.1), (12) with

$$g = \frac{\partial u_1}{\partial \nu}.$$

Note that the representation of u_1 as a double sine series can be written immediately once a similar representation for f is obtained.

It is easily seen that if

$$f \in L^2(\Omega), \tag{7.6}$$

then the solution u_1 to (7.1), (7.4) belongs to $H^4(\Omega)$. Moreover, an argument similar to that indicated for the proof of assertion (*) in §2 shows that (7.6) implies

$$\frac{\partial u_1}{\partial \nu} \in H^{5/2}(\partial\Omega). \tag{7.7}$$

Finally, in the case of a rectangle Ω the solution to (7.1), (7.2) is known to belong to $H^4(\Omega)$ when (7.6) holds [7]. We conclude that $u_2 \in H^4(\Omega)$ and thus in view of (7.7) u_2 satisfies the hypothesis of Proposition 6.1. If u_2 is to be found by the method described above, then the truncation estimates (5.4) hold with $\sigma = 2$.

8. Example. We consider now the special case of the problem (7.1), (7.2) in which Ω is the square of side π and

$$f \equiv 1 \quad \text{in } \Omega.$$

This computation has been performed repeatedly before, [5], [12], [13]. We are primarily interested here in demonstrating how the coefficients of the truncated reduced problem vary with N.

Following Hencky [5] (see also [9]), we write the solution u as

$$u = w - v$$

where

$$w(x,y) = \tfrac{1}{8}xy(\pi - x)(\pi - y) \tag{8.1}$$

and v is biharmonic on Ω with

$$v = 0, \qquad \frac{\partial v}{\partial \nu} = \frac{\partial w}{\partial \nu} \quad \text{on } \partial\Omega.$$

Because of the symmetries involved we see that v can be represented (with the notation of §3 and with $a = b = \pi$) in the form

$$v(x,y) = \sum_{k=1}^{\infty} A_{2k+1}\left(\varphi^0_{2k+1}(x,y) + \psi^0_{2k+1}(x,y)\right).$$

The equations that determine the A_n are

$$A_n = \sqrt{\frac{1+\cosh n\pi}{n\pi + \sinh n\pi}}\left[\frac{\sqrt{2\pi}}{n^{5/2}} - \frac{8n^{3/2}}{\pi}\sum \frac{m^{3/2}}{(m^2+n^2)^2}\sqrt{\frac{1+\cosh m\pi}{m\pi + \sinh m\pi}}\, A_m\right], \tag{8.2}$$

$n = 1, 3, 5, \cdots$; the summation on the right in (8.2) is over the positive odd integers.

The form in which (8.2) has been written lends itself to an obvious iterative procedure (a minor variant of Gauss–Seidel) for solution of the truncated systems. Because the matrix need not be stored, this can even be carried out on a programmable calculator such as e.g. the Texas Instrument TI-59. The number of computations can be reduced by making the change of variable

$$\bar{A}_n = \sqrt{\frac{1+\cosh n\pi}{n\pi + \sinh n\pi}}\, A_n$$

in (8.2).

Using the TI-59 the truncated systems involving the first 8, 15, 20, 25 equations were solved (it would be possible, but because of the time involved not practical, to handle up to 50 equations). These systems were solved consecutively and, for example, the first solution (of the 8×8) was augmented with 7 zeros and used as the initial point for the iterative solution of the 15×15 system. The values obtained for the A_n are

shown in Table 1.

Appendix. Here we shall fill in briefly the theoretical details on which the preceding development was based.

Let $H(\Omega)$ denote the subspace of $L^2(\Omega)$ that consists of harmonic functions and let $H_1(\Omega)$ and $H_2(\Omega)$ denote respectively the subspaces of $H(\Omega)$ that are spanned by the sets

$$S_1 = \{\Delta\varphi_n^i(x,y): i=0,1; n=1,2,\cdots\},$$

and

$$S_2 = \{\Delta\psi_n^i(x,y): i=0,; n=1,2,\cdots\};$$

cf. (3.5), (3.6).

PROPOSITION A.1. *The following are equivalent*:

i) $H(\Omega)$ *admits the direct sum representation*

$$H(\Omega) = H_1(\Omega) + H_2(\Omega);$$

ii) *every* $u \in B_0(\Omega)$ *is uniquely representable in the form* (3.10) *where* (3.11) *holds*;

iii) *for each pair* (i,j) *the matrix* $\Gamma = \{\langle \varphi_{2m-j}^i, \psi_{2h-1+i}^{1-j} \rangle\}$ *satisfies*

$$\|\Gamma\| < 1.$$

Proof. Recall that the sets S_1 and S_2 are orthonormal in $L^2(\Omega)$. The equivalence of i) and ii) is immediate from the representation (2.2). To see the equivalence of i) and iii), one notes that the matrices Γ can be used to represent the restriction to $H_1(\Omega)$ of the orthogonal projection onto $H_2(\Omega)$ with respect to the orthonormal bases S_1 and S_2.

Remark. Assertion i) in Proposition A.1 is proved in [2].

PROPOSITION A.2. *The following are equivalent*:

i) *every* $u \in B_0(\Omega)$ *is uniquely representable in the form* (3.10) *where* (3.11) *holds*;

ii) *if* $u \in B_0(\Omega)$ *then there exists a* $v \in B_0$ *such that*

$$\frac{\partial v}{\partial \nu} = \frac{\partial u}{\partial \nu} \quad \text{on } \{(x,y): 0<x<a, y=0 \text{ or } y=b\},$$

and

$$\frac{\partial v}{\partial \nu} = 0 \quad \text{on } \{(x,y): 0<y<b, x=0 \text{ or } x=a\};$$

iii) *the problem* (1.1), (1.2) *has a solution* $u \in B_0(\Omega)$ *if and only if*

$$g \in H^{1/2}(\partial\Omega). \tag{A.1}$$

Proof. We have already noted ((*) §2) the necessity of (A.1). To see that i) implies ii), let i) be assumed; then if $u \in B_0(\Omega)$ has the representation (3.10),

$$u \mapsto \sum_{j=0}^{1} \sum_{n=1}^{\infty} A_n^j \psi_n^j$$

is a bounded projection in $B_0(\Omega)$, call it P. Using Green's theorem, one easily sees that for $u \in B_0(\Omega)$, $v = P^* u$ satisfies the conditions of ii); (P^* denotes the adjoint of P). Conversely, if ii) holds, then it follows from the necessity of (A.1) and the closed graph theorem that $u \mapsto v$ is a bounded projection. The converse implication follows readily, cf. [4]. The implication iii) implies ii) is immediate. Conversely, suppose data (2.5), satisfying (2.6), are given. For simplicity assume $\beta_n(0) = \beta_n(a) = 0$, $n = 1, 2, \cdots$. One can then obviously find w of the form

$$w = \sum_{i=0}^{1} \sum_{n=1}^{\infty} A_n^i \varphi_n^i, \qquad \sum_{i=0}^{1} \sum_{n=1}^{\infty} A_n^2 < \infty,$$

such that

$$\frac{\partial w}{\partial \nu} = g \quad \text{on } \{(x,y): 0<x<a, y=0 \text{ or } y=b\},$$

the assumption ii) then implies the existence of a $u \in B_0(\Omega)$ whose normal derivative coincides with the given data.

Remark. As we noted in [4], the assertion ii) of Proposition A.2 follows readily from the existence theorem for the first biharmonic boundary value problem on a rectangle that is stated in [2]; the proof of that theorem was given in [3].

We shall now sketch an elementary proof of assertion ii) of Proposition A.2.

LEMMA A.1. *Let* $v(x,y)$ *be of class* C^∞ *on a neighborhood of*

$$s = \{(x,y): 0 \leqq x, y, x^2 + y^2 < \varepsilon^2\}$$

and such that

i) $$v(0,y)=0, \quad 0\leqq y\leqq \varepsilon, \quad v(x,0)=0, \quad 0\leqq x\leqq \varepsilon,$$

and

ii) $$v(x,y)=0, \qquad x^2+y^2\geqq \tfrac{1}{2}\varepsilon^2.$$

Let

$$w(x,y)=\tan^{-1}\frac{y}{x}v(x,y), \qquad x,y\in s.$$

Then

$$\iint_s |\Delta w(x,y)|^2\,dx\,dy\leqq C\iint_s |\Delta v(x,y)|^2\,dx\,dy,$$

where C is an absolute constant.

Proof. We have

$$\text{(A.2)} \qquad \iint_s |\Delta v|^2\,dx\,dy\Gamma\int_0^{\pi/2}\int_0^{\varepsilon}\left[\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial v}{\partial r}+\frac{1}{r^2}\frac{\partial^2 v}{\partial\theta^2}\right]^2 r\,dr\,d\theta.$$

Since v is of class C^∞ on a neighborhood of $(0,0)$, it follows from i) that

$$\lim_{r\to 0}\frac{1}{r}\frac{\partial^2 v}{\partial\theta\,\partial r}\frac{\partial v}{\partial\theta}=0.$$

Using this and integrating by parts, we get

$$\text{(A.3)} \quad \int_0^{\pi/2}\int_0^{\varepsilon}\left(\frac{\partial}{\partial r}r\frac{\partial v}{\partial r}\right)\frac{1}{r^2}\frac{\partial^2 y}{\partial\theta^2}\,dr\,d\theta$$
$$=\int_0^{\pi/2}\int_0^{\varepsilon}\left[\frac{1}{r}\left(\frac{\partial^2 v}{\partial r\,d\theta}\right)^2-\frac{2}{r^2}\frac{\partial v}{\partial\theta}\frac{\partial^2 v}{\partial\theta\,\partial r}\right]dr\,d\theta.$$

We have

$$\text{(A.4)} \quad \int_0^{\pi/2}\int_0^{\varepsilon}\frac{2}{r^2}\frac{\partial v}{\partial\theta}\frac{\partial^2 v}{\partial\theta\,\partial r}\,dr\,d\theta\leqq\int_0^{\pi/2}\int_0^{\varepsilon}\left[\frac{1}{r}\left(\frac{\partial^2 v}{\partial r\,\partial\theta}\right)^2+\frac{1}{r^3}\left(\frac{\partial v}{\partial\theta}\right)^2\right]dr\,d\theta$$
$$\leqq\int_0^{\pi/2}\int_0^{\varepsilon}\left[\frac{1}{r}\left(\frac{\partial^2 v}{\partial r\,d\theta}\right)^2+\frac{1}{16r^3}\left(\frac{\partial^2 v}{\partial\theta^2}\right)^2\right]dr\,d\theta;$$

the last step follows by noting that $\int_0^{\pi/2}(\partial v/\partial\theta)\,d\theta=0$ for any r and expanding $\partial^2 v/\partial\theta^2$ in a Fourier series. From (A.3) and (A.4) we have

$$\text{(A.5)} \qquad -\frac{1}{8}\int_0^{\pi/2}\int_0^{\varepsilon}\frac{1}{r^3}\left(\frac{\partial^2 v}{\partial\theta^2}\right)^2 dr\,d\theta\leqq 2\int_0^{\pi/2}\int_0^{\varepsilon}\left(\frac{\partial}{\partial r}r\frac{\partial v}{\partial\theta}\right)\frac{1}{r^2}\frac{\partial^2 v}{\partial\theta^2}\,dr\,d\theta.$$

Upon expanding the right-hand side of (A.2) and using (A.5) we get

$$\text{(A.6)} \qquad \int_0^{\pi/2}\int_0^{\varepsilon}\frac{1}{r^3}\left(\frac{\partial^2 v}{\partial\theta^2}\right)^2 dr\,d\theta\leqq 2\int_0^{\pi/2}\int_0^{\varepsilon}|\Delta v|^2 r\,dr\,d\theta.$$

Now

$$\Delta w = \Delta(\theta v) = \theta \Delta v + \frac{2}{r^2}\frac{\partial v}{\partial \theta},$$

so that the asserted inequality follows from (A.6) and the inequality

$$\int_0^{\pi/2}\int_0^{\varepsilon} \frac{1}{r^3}\left(\frac{\partial v}{\partial \theta}\right)^2 dr\,d\theta \leqq \frac{1}{16}\int_0^{\pi/2}\int_0^{\varepsilon} \frac{1}{r^3}\left(\frac{\partial^2 v}{\partial \theta^2}\right) dr\,d\theta.$$

Let $X(\Omega)$ denote the set of functions of the form

$$u(x,y) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} a_{mn} \sin\frac{m\pi x}{a}\sin\frac{n\pi y}{b} \tag{A.7}$$

and let

$$\|u\|^2 = \frac{\pi^2}{4ab}\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}(a^2n^2+b^2m^2)^2 a_{mn}^2 < \infty,$$

(note that $\|u\|^2 = \int\int_{\Omega} |\Delta u|^2\,dx\,dy$). With the norm $\|\cdots\|$, $X(\Omega)$ is a Hilbert space and $B_0(\Omega)$ is a subspace. The orthogonal complement of $B_0(\Omega)$ in $X(\Omega)$ is the space $X_0(\Omega)$ of the clamped plate (i.e., the completion in $X(\Omega)$ of $C_0^{\infty}(\Omega)$)

$$X(\Omega) = B_0(\Omega) \oplus X_0(\Omega),$$

and $u \in X_0(\Omega)$ implies

$$u = \frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega.$$

Let Q denote the orthogonal projection of $X(\Omega)$ onto $B_0(\Omega)$. Then if $w \in X(\Omega)$ and $\partial w/\partial \nu = g$ on $\partial\Omega$ then $u = Qw$ is the unique solution to (1.1), (1.2). We claim that it is possible to construct an operator A on $X(\Omega)$ such that if $u = Aw$ then $\partial w/\partial \nu$ and $\partial u/\partial \nu$ agree on the horizontal segments of $\partial\Omega$ while $\partial u/\partial \nu = 0$ on the vertical segments. The operator P^* described above is then obtained as the restriction to $B_0(\Omega)$.

Let $w \in X(\Omega)$ and be the sum of a finite series of the form (A.7). Using a partition of the identity, we can write

$$w = u + v$$

where u satisfies the hypothesis of Lemma A.1 and

$$\|u\|,\ \|v\| \leqq C\|w\|,$$

where C depends only on the partition. From Lemma A.1 it follows that

$$w_1 = \left(1 - \frac{2}{\pi}\tan^{-1}\frac{y}{x}\right) w \in X_0(\Omega)$$

and

$$\|w_1\| \leqq C'\|w\|.$$

Note that

$$\frac{\partial w_1}{\partial \nu} = 0$$

on the left-hand vertical segment of $\partial\Omega$ while $\partial w_1/\partial\nu$ nd $\partial u/\partial\nu$ agree on the lower horizontal segment. The construction of the specified operator A can now be carried out using appropriate partitions of identity and the above construction at the corners. We thus can prove the following.

PROPOSITION A.3. *There exists a bounded projection P^* on $B_0(\Omega)$ such that for any $u \in B_0(\Omega)$ if $v = P^*u$ then $\partial v/\partial\nu$ and $\partial u/\partial\nu$ agree on the horizontal segments of $\partial\Omega$ while*

$$\frac{\partial v}{\partial \nu} = 0$$

on the vertical segments. Thus each of the equivalent assertions of Propositions A.1 *and* A.2 *is valid.*

ABSTRACT NONLINEAR VOLTERRA EQUATIONS WITH POSITIVE KERNELS*

NORIMICHI HIRANO†

Abstract. The existence of the solutions of the equation

$$u(t)+\int_0^t a(t-s)Au(s)\,ds \ni f(t), \qquad 0 \leqq t \leqq T,$$

in a Hilbert space, is proved, where $A : H \to H$ is a pseudo-monotone operator and $f \in L^2(0, T;\ H)$.

1. Introduction. In this paper we consider the existence of solutions to the abstract Volterra integral equation

$$u(t)+\int_0^t a(t-s)Au(s)\,ds \ni f(t), \qquad 0 \leqq t \leqq T, \tag{1.1}$$

in a Hilbert space H, where A is a nonlinear (possibly multivalued) operator from H into itself, $a(t)$ is a real function on $[0, T]$, f is a function from $[0, T]$ into H. General existence results for (1.1) were obtained by Barbu [1], Crandall and Nohel [5], and Gripenberg [6]. Recently Kiffe and Stecher [7], [8] obtained existence results for (1.1) in case A is maximal monotone without assuming any continuity condition on A or differentiability conditions on f. In the present paper, we also consider the problem (1.1) without assuming any continuity on A or differentiability condition on f. Our purpose in this paper is to establish existence results for the problem (1.1) under the assumption that A is a pseudo-monotone operator on H. It is known that a broad class of (multivalued) operators satisfy the pseudo-monotonicity. To prove our results we make use of an existence result for pseudo-monotone operators [3].

In §2, we give notation, definitions, and the statements of our results. In §3, the proofs of the results are given. We give examples in §4.

2. Statement of results. Throughout this paper H will denote a real Hilbert space with the norm denoted $|\cdot|$ and the inner product $(\cdot, \cdot)$. We will denote by $L^2(0, T;\ H)$ the space of all H-valued function $u : [0, T] \to H$ such that $\int_0^T |u(t)|^2\,dt < +\infty$ and by $L^\infty(0, T;\ H)$ the space of H-valued function such that $\operatorname{ess\,sup}_{t \in [0, T]} |f(t)| < \infty$. The norm and inner product of $L^2(0, T;\ H)$ will be denoted by $\|\cdot\|$ and $\langle \cdot, \cdot \rangle$. Strong and weak convergence in $L^2(0, T;\ H)$ is denoted by "$\to$" and "$\rightharpoonup$" respectively. Let A be a nonlinear (multivalued) operator from H into itself. We shall denote by $D(A)$ the domain of A, i.e., $D(A) = \{x \in H;\ Ax \neq \emptyset\}$. For each $z \in H$, A_z denotes the operator defined by $A_z x = A(x+z)$, for $x \in D(A)$. The multivalued mapping $A : H \to H$ is said to be pseudo-monotone on H [3], if A satisfies the following conditions:

(1) $D(A) = H$.

(2) For any sequence $\{u_n\}$ and $\{w_n\}$ in H such that u_n converges weakly to u, $w_n \in Au_n$ for each $n \geqq 1$, and $\limsup_{n \to \infty} (w_n, u_n - u) \leqq 0$, and for any $v \in H$, there exists $w \in Au$ such that

$$(w, u-v) \leqq \liminf_{n \to \infty} (w_n, u_n - v). \tag{2.1}$$

*Received by the editors August 18, 1983, and in revised form January 25, 1984.

† Department of Mathematics, Yokohama National University, 156, Tokiwadai, Hodogaya, Yokohama, Japan.

The mapping $A: H \to H$ is said to be finitely continuous if Ax is closed convex subset of H for each $x \in H$ and for each finite set G of H, A is upper semicontinuous mapping from the closed convex hull of G into 2^H, with respect to the weak topology of H. The mapping A is said to be monotone if

$$(x_1 - x_2, y_1 - y_2) \geqq 0$$

for $x_i \in H$, $y_i \in Ax_i$ $(i = 1, 2)$. A monotone mapping A is said to be maximal monotone if the range of $I + \lambda A$ is H for all $\lambda > 0$. It is known that a maximal monotone operator with $D(A) = H$ is finitely continuous and pseudo-monotone (cf. [3]). A mapping $A: H \to H$ is said to be completely continuous if it is continuous from the weak topology of H to the strong topology of H. For each $a \in L^1(0, T)$, L_a denotes a linear continuous operator from $L^2(0, T)$ into itself defined by

$$(L_a f)(t) = \int_0^t a(t-s) f(s)\, ds \quad \text{for } 0 \leqq t \leqq T$$

for each $f \in L^2(0, T)$. Then the adjoint operator L_a^* is given by

$$(L_a^* f)(t) = \int_t^T a(s-t) f(s)\, ds \quad \text{for } 0 \leqq t \leqq T.$$

We now state the assumptions for the kernel function $a(t)$.

(2.2) $a(t) \in L^1(0, T)$ is of positive type on $[0, T]$, i.e., for each $f \in L^2(0, T)$,

$$\int_0^t f(\tau) \int_0^\tau a(\tau - s) f(s)\, ds\, d\tau \geqq 0 \quad \text{for } 0 \leqq t \leqq T.$$

(2.3) L_a^* is injective, i.e., $L_a^* f = 0$ means $f = 0$.

Sufficient conditions for $a(t)$ to satisfy (2.2) are given in [10] and [11]. It is easy to see that $a(t)$ satisfies (2.3) if $a(0) \neq 0$, $a \in C(0, T)$ and $a' \in L^1(0, T)$. It is also easy to see that the sum of a function of positive type $b(t)$ and a positive constant c, $a(t) = b(t) + c$ satisfies (2.3).

Let $A: H \to H$ be a multivalued operator with $D(A) = H$. Denote by $\tilde{A}$ the operator defined by

$$\tilde{A}u = \{ w \in L^2(0, T;\ H) : w(t) \in Au(t) \text{ a.e. on } [0, T] \},$$

for each $u \in L^2(0, T;\ H)$. It is well known that if A is a maximal monotone operator on H, then $\tilde{A}$ is a maximal monotone operator on $L^2(0, T;\ H)$. We now state basic assumptions for the nonlinear operator A on H.

(2.4) There exist constants c_1, c_2 such that

$$|y| \leqq c_1 + c_2 |x| \quad \text{for all } y \in Ax,\ x \in H,$$

(2.5) $$\liminf_{y \in Ax,\ |x| \to \infty} (x, y)/|x| > -\infty.$$

Remark. The condition (2.5) guarantees that for each $\varepsilon > 0$, $\varepsilon I + A$ is coercive, i.e., $\lim_{y \in \varepsilon x + Ax,\ |x| \to \infty} \langle x, y \rangle / |x| = +\infty$. We note that if A is monotone, then A satisfies (2.5).

We next state assumptions for the nonlinear operator A on $L^2(0,T;\ H)$ corresponding to (2.4) and (2.5).

$(2.4)'$ There exist constants c_1', c_2' such that

$$\|v\| \leqq c_1' + c_2' \|u\| \quad \text{for all } v \in Au,\ u \in L^2(0,T;\ H),$$

$(2.5)'$ $$\liminf_{v \in Au,\ \|u\| \to \infty} (v,u)/\|u\| > -\infty.$$

Remark. If a maximal monotone operator $A : H \to H$ with $D(A) = H$ satisfies (2.4), then we can see that $D(\tilde{A}) = L^2(0,T;\ H)$. It is obvious that if an operator $A : H \to H$ satisfies (2.4), then $\tilde{A}$ satisfies $(2.4)'$. It is also easy to see that $\tilde{A}$ satisfies $(2.5)'$ whenever A satisfies (2.4) and (2.5).

THEOREM 1. *Let A be a finitely continuous pseudo-monotone operator on $L^2(0,T;\ H)$ and satisfy $(2.4)'$, $(2.5)'$. Suppose that $a(t)$ satisfies (2.2) and $c_2' \|a\|_{L^1(0,T)} < 1$. Then for each $f \in L^2(0,T;\ H)$, the equation*

$$u(t) + \int_0^t a(t-s)(Au)(s)\, ds \ni f(t), \qquad 0 \leqq t \leqq T, \tag{2.6}$$

has a solution on $[0,T]$.

Remark. It is known that the sum of monotone operator and completely continuous operator, $A = B + C$ is pseudo-monotone. Then Theorem 1 is applicable to the existence problems of local solutions of equations of the form

$$\frac{du}{dt} + A(t)u(t) + \int_0^T k(t,s) Bu(s)\, ds \ni 0, \qquad u(0) = u_0, \tag{2.7}$$

where $A(t) : H \to H$ is a maximal monotone operator for each $0 \leqq t \leqq T$, $B : H \to H$ is completely continuous operator, $u_0 \in H$ and $k(t,s) \in L^2([0,T] \times [0,T])$. In fact, by integrating the above differential equation, the problem (2.7) arrives at the problem (2.6).

COROLLARY 1. *Let $A : H \to H$ be a multivalued operator satisfying (2.4) and (2.5). Suppose that for each $t \in [0,T]$, $\tilde{A}$ is finitely cotinuous and pseudo-monotone on $L^2(0,t;\ H)$. Then for each $f \in L^2(0,T;\ H)$, (1.1) has a solution on $[0,T]$.*

COROLLARY 1′ (Kiffe and Stecher [7]). *Let $A : H \to H$ be a maximal monotone operator with $D(A) = H$ and satisfy (2.4). Let $a(t)$ satisfy (2.2). Then for each $f \in L^2(0,T;\ H)$, (1.1) has a solution on $[0,T]$.*

Remark. Corollary 1 is a reformulation of Theorem 1 in case where A is an operator on H and we can obtain Kiffe and Stecher's result (Corollary 1′) from Corollary 1. But we can see that Theorem 1 (or Corollary 1) is not very effective for operators on H because, except for monotone operators, operators on H rarely satisfy the assumption that $\tilde{A}$ is pseudo-monotone on $L^2(0,t;\ H)$. Thus it is desirable to establish an existence result under the assumption that $A : H \to H$ is pseudo-monotone on H. We next state our main result.

THEOREM 2. *Let $A : H \to H$ be a finitely continuous pseudo-monotone operator on H satisfying (2.4), (2.5). Suppose that $a(t) \in L^2(0,T)$ satisfies (2.2) and (2.3). Then for each $f \in L^2(0,T;\ H)$, (1.1) has a solution on $[0,T]$.*

COROLLARY 2. *Let $A : H \to H$ be a maximal monotone operator with $D(A) = H$ and $B : H \to H$ be a completely continuous operator with $D(B) = H$. Suppose that $A + B$ satisfy (2.4) and (2.5) with A replaced by $A + B$. Let $a(t) \in L^2(0,T)$ satisfy (2.2) and (2.3).*

Then for each $f \in L^2(0,T;H)$, *the equation*

$$u(t)+\int_0^t a(t-s)(Au(s)+Bu(s))\,ds \ni f(t), \qquad 0 \leqq t \leqq T, \tag{2.8}$$

has a solution on $[0,T]$.

3. Proofs. We first give fundamental lemmas. The following lemma is a direct consequence of the definition of pseudo-monotonicity.

LEMMA 1. *Let* F *be a real Hilbert space and* A *be a pseudo-monotone operator on* F. *Let* $\{u_n\}$ *and* $\{w_n\}$ *be sequences such that* u_n *converges weakly to* u, $w_n \in Au_n$ *for each* $n \geqq 1$ *and* $\liminf_{n\to\infty}(w_n, u_n-u) \leqq 0$. *Then* $\liminf_{n\to\infty}(w_n, u_n-u)=0$.

Proof. Choose a subsequence $\{u_{n_i}\}$ of $\{u_n\}$ such that

$$\lim_{i\to\infty}(w_{n_i}, u_{n_i}-u)=\liminf_{n\to\infty}(w_n, u_n-u).$$

Then from the definition of pseudo-monotonicity, there exists $w \in Au$ such that

$$0=(w,u-u) \leqq \lim_{i\to\infty}(w_{n_i}, u_{n_i}-u).$$

Thus we obtain that $\liminf_{n\to\infty}(w_n, u_n-u)=0$.

LEMMA 2. *Let* F *be a real Hilbert space and* A *be a finitely continuous pseudo-monotone operator on* F. *Let* $\{u_n\}$ *and* $\{w_n\}$ *be sequences such that* u_n *converges weakly to* u, $w_n \in Au_n$ *for each* $n \geqq 1$ *and* $\limsup_{n\to\infty}(w_n, u_n-u) \leqq 0$. *Suppose that* w_n *converges weakly to* w. *Then* $w \in Au$.

Proof. By Lemma 1, we have that $\lim_{n\to\infty}(w_n, u_n-u)=0$. Then for each $v \in F$,

$$\liminf_{n\to\infty}(w_n, u_n-v)=\liminf_{n\to\infty}(w_n, u-v)=\lim_{n\to\infty}(w_n, u-v)=(w, u-v), \tag{3.1}$$

while, for each $v \in F$, there exists $w_v \in Au$ such that

$$(w_v, u-v) \leqq \liminf_{n\to\infty}(w_n, u_n-v). \tag{3.2}$$

Combining (3.1) with (3.2), we obtain that for any $v \in F$, there exists $w_v \in Au$ such that

$$(w_v, u-v) \leqq (w, u-v). \tag{3.3}$$

Suppose that $w \notin Au$. Then since Au is a closed convex set of F, there exists $z \in F$ such that

$$\langle w, z\rangle < \inf\{\langle y, z\rangle : y \in Au\}.$$

Put $v=u-z$ in (3.3). Then we obtain

$$\langle w_v, z\rangle \leqq \langle w, z\rangle < \langle w_v, z\rangle.$$

This is a contradiction. Thus we obtain that $w \in Au$.

LEMMA 2′. *Let* F *and* A *be as in Lemma* 2. *Let* $\{u_n\}$ *and* $\{w_n\}$ *be sequences such that* u_n *converges weakly to* u, $w_n \in Au_n$ *for each* $n \geqq 1$ *and* $\limsup_{n\to\infty}(w_n, u_n-u) \leqq 0$. *Suppose that* $\{w_n\}$ *is bounded in* F. *Then* $\bigcap_k \overline{\mathrm{co}}\{w_n : n \geqq k\} \subset Au$.

Proof. Let W be the set of all weak subsequential limits of $\{w_n\}$. Then by Lemma 2, $W \subset Au$. Since Au is closed and convex, $\overline{\mathrm{co}}\, W \subset Au$. Then since $\overline{\mathrm{co}}\, W = \bigcap_k \overline{\mathrm{co}}\{w_n : n \geqq k\}$ (cf. Bruck [4, Lemma 1.2]), the consequence follows.

LEMMA 3. *Let F and A be as in Lemma 2. Let L be a linear continuous and injective operator from F into itself and f be an element of F. Then the mapping L^*A_fL is a pseudo-monotone operator on F. Moreover if A maps bounded sets of F into bounded sets, then L^*A_fL is finitely continuous.*

Proof. Let $\{u_n\}$ and $\{w_n\}$ be sequences such that u_n converges weakly to u, $w_n \in L^*A_fLu_n$ for each $n \geqq 1$, and

$$\limsup_{n\to\infty}(w_n, u_n - u) \leqq 0.$$

Let $\{v_n\}$ be a sequence such that $v_n \in A(Lu_n + f)$ and $w_n = L^*v_n$, for each $n \geqq 1$. Then we have that for each $n \geqq 1$,

$$\liminf_{n\to\infty}(w_n, u_n - u) = \liminf_{n\to\infty}(v_n, Lu_n + f - (Lu + f)).$$

Then since A is pseudo-monotone and $Lu_n + f$ converges weakly to $Lu + f$, for given $z \in F$, there exists $v \in A(Lu + f)$ such that

$$\begin{aligned}(L^*v, u - z) &= (v, Lu + f - (Lz + f)) \\ &\leqq \liminf_{n\to\infty}(v_n, Lu_n + f - (Lz + f)) \\ &= \liminf_{n\to\infty}(v_n, Lu_n - Lz) \\ &= \liminf_{n\to\infty}(L^*v_n, u_n - z).\end{aligned}$$

Then since $L^*v \in L^*A(Lu + f)$, L^*A_fL is pseudo-monotone.

Suppose that A maps bounded sets of F into bounded sets. Then to see that L^*A_fL is finitely continuous, it is sufficient to show that L^*A_fL is demiclosed, i.e., the graph of L^*A_fL is strongly-weakly closed in $F \times F$, because $(L^*A_fL)G$ is relatively weakly compact for each compact subset G of F (cf. Browder [1, Proposition 2.6] or [2]). Let $\{u_n\}$ and $\{w_n\}$ be sequences in F such that $\{u_n\}$ is contained in the closed convex hull of a finite subset G of F, u_n converges strongly to u, $w_n \in L^*A_fLu_n$ and w_n converges weakly to w. Then since L^*A_fL is pseudo-monotone on F and $\limsup_{n\to\infty}\langle w_n, u_n - u\rangle \leqq 0$, we obtain, by Lemma 2, that $w \in L^*A_fLu$. This completes the proof.

LEMMA 4. *Let $A : L^2(0, T; H) \to L^2(0, T; H)$ be a multivalued operator with $D(A) = L^2(0, T; H)$. Let $a(t) \in L^1(0, T)$ and $f \in L^2(0, T; H)$. Then the equation*

$$u + L_aAu \ni f \tag{3.4}$$

has a solution u on $[0, T]$ if and only if the following equation has a solution v on $[0, T]$;

$$v + A(L_av + f) \ni 0. \tag{3.5}$$

Proof. Let u be a solution of (3.4). Put $z = u - f$. Then (3.4) is equal to

$$z + L_aA(z + f) \ni 0. \tag{3.6}$$

Then there exists $v \in L_a^{-1}z$ which satisfies (3.5). It is also easy to see the "if" part.

Proof of Theorem 1. For simplicity we write L instead of L_a. Let $f\in L^2(0,T;\ H)$. For each $n\geqq 1$, we set $L_n=(L+1/n)I$. Then since L is positive,

$$\langle L_n u,u\rangle=\langle L_n^* u,u\rangle\geqq\frac{1}{n}\|u\|^2 \quad \text{for } u\in L^2(0,T;\ H). \tag{3.7}$$

We first claim that for each $n\geqq 1$,

$$v+A(L_n v+f)\ni 0 \tag{3.8}$$

has a solution $v\in L^2(0,T;\ H)$. Since L_n^* is bijective by (3.7), $v\in L^2(0,T;\ H)$ is a solution of (3.8) if and only if v is a solution of

$$L_n^* v+L_n^* A(L_n v+f)\ni 0. \tag{3.9}$$

Then we show that (3.9) has a solution. For each $n\geqq 1$, $L_n^* A_f L_n$ is finitely continuous and pseudo-monotone by Lemma 3. Then $(1/n)I+L_n^* A_f L_n$ is also finitely continuous and pseudo-monotone for each $n\geqq 1$. From (2.4)′ we have that for each $u\in L^2(0,T;\ H)$ and $w\in A(L_n u+f)$,

$$\begin{aligned}\left\langle \frac{1}{n}u+L_n^* w,u\right\rangle&=\frac{1}{n}\|u\|^2+\langle w,L_n u\rangle\\ &=\frac{1}{n}\|u\|^2+\langle w,L_n u+f\rangle-\langle w,f\rangle \qquad (3.10)\\ &\geqq\frac{1}{n}\|u\|^2+\langle w,L_n u+f\rangle-\|f\|\left(c_1'+c_2'\left(\|a\|_{L^1(0,T)}\|u\|+\frac{1}{n}\|u\|+\|f\|\right)\right).\end{aligned}$$

Then by (2.5)′, (3.10) implies that for each $n\geqq 1$,

$$\lim_{\substack{z\in L_n^* A_f L_n u\\ \|u\|\to\infty}}\left\langle \frac{1}{n}u+z,u\right\rangle/\|u\|=\infty,$$

i.e., $(1/n)I+L_n^* A\mathscr{L}_n$ is coercive. By (2.4)′, $(1/n)I+L_n^* A_f L_n$ is bounded for each $n\geqq 1$. On the other hand, (3.7) implies that $L_n^*-(1/n)I$ is positive for each $n\geqq 1$. Then by [3, Thm. 7.8], we obtain that the sum of $(L_n^*-(1/n)I)$ and $((1/n)I+L_n^* A_f L_n)$ is surjective. Therefore (3.9) has a solution. Let $\{u_n\}\subset L^2(0,T;\ H)$ be a sequence such that $u_n+A(L_n u_n+f)\ni 0$, for each $n\geqq 1$. Let $\{w_n\}$ be a sequence such that $w_n\in A(L_n u_n+f)$ and $u_n+w_n=0$, for each $n\geqq 1$. Then by (2.4)′, we have that

$$\|u_n\|\leqq c_1'+c_2'\|L_n u_n+f\|\leqq c_1'+c_2'\left(\|a\|_{L^1(0,T)}\|u_n\|+\frac{1}{n}\|u_n\|+\|f\|\right). \tag{3.11}$$

Since $c_2'\|a\|_{L^1(0,T)}<1$, (3.11) implies that there exists $M>0$ such that

$$\|u_n\|\leqq M \quad \text{for all } n\geqq 1.$$

Then we can assume without any loss of generality that $u_n\rightharpoonup u$ and $w_n\rightharpoonup w$. Since $u_n+w_n=0$, we have that

$$\langle u_n,L_n u_n-Lu\rangle+\langle w_n,L_n u_n-Lu\rangle=0. \tag{3.12}$$

Since $\lim_{n\to\infty} L_n u = Lu$ and weak-$\lim_{n\to\infty} L_n u_n = $ weak-$\lim_{n\to\infty} Lu_n + (1/n)u_n = Lu$, it follows that

$$\begin{aligned}(3.13)\quad &\liminf_{n\to\infty} \langle u_n, L_n u_n - Lu\rangle \\ &= \liminf_{n\to\infty} \langle u_n - u, L_n u_n - L_n u\rangle + \lim_{n\to\infty} \langle u, L_n u_n - L_n u\rangle + \lim_{n\to\infty} \langle u_n, L_n u - Lu\rangle \\ &\geqq 0.\end{aligned}$$

Then combining (3.12) with (3.13), we have that

$$\limsup_{n\to\infty} \langle w_n, L_n u_n - Lu\rangle \leqq 0.$$

Then by Lemma 2, we obtain that $w \in A(Lu+f)$, and this implies $u + A(Lu+f) \ni 0$. Then by Lemma 4, (2.6) has a solution on $[0,T]$.

Proof of Corollary 1. We first note that from the condition (2.4), we have that for each $t \in [0,T]$,

$$\|y\|_{L^2(0,t;H)} \leqq \sqrt{T}\, c_1 + c_2 \|x\|_{L^2(0,t;H)},$$

for all $x \in L^2(0,t;\ H)$ and $y \in \tilde{A}x$. This implies that for each $t \in [0,T]$, (2.4)′ holds with $c_1' = \sqrt{T}\, c_1$ and $c_2' = c_2$. Then we choose $T' \in [0,T]$ such that $c_2 \|a\|_{L^1(0,T')} < 1$. Then by Theorem 1, there exists a solution u of (1.1) on $[0,T']$, i.e., there exists $w : [0,T'] \to H$ such that $w(t) \in Au(t)$ a.e. on $[0,T']$ and

$$u(t) + \int_0^t a(t-s) w(s)\, ds = f(t), \qquad 0 \leqq t \leqq T'.$$

By using the continuation argument employed in the proof of [1, Thm. 1], we show that $u(t)$ can be continued on $[0,T]$. Consider the equation

$$(3.14)\quad v(t) + \int_0^t a(t-s) Av(s)\, ds \ni f(t+T) - \int_0^T a(T+t-s) w(s)\, ds, \qquad 0 \leqq t \leqq T'',$$

where $T'' = \min(T', T-T')$. Let $f_1(t)$ denote the right side of (3.14). Then again by Theorem 1, there exists a solution v of (3.14). We define a function $\tilde{u} : [0, T'+T''] \ H$ by

$$\tilde{u}(t) = \begin{cases} u(t) & \text{on } [0,T'], \\ v(t-T') & \text{on } (T', T'+T'']. \end{cases}$$

Then $\tilde{u}$ is a solution of (1.1) on $[0, T+T'']$. By repeating this continuation, we obtain a solution u of (1.1) on $[0,T]$.

To prove Theorem 2, we need some lemmas and propositions. The continuation argument employed in Corollary 1 is available under the assumption of Theorem 2. Therefore in the following propositions, we assume that $c_2 \|a\|_{L^1(0,T)} < 1$ for $a(t) \in L^1(0,T)$ and A satisfying (2.4).

PROPOSITION 1. *Let $A : H \to H$ be an operator satisfying* (2.4) *and* (2.5). *Let $a(t) \in L^2(0,T)$ satisfy* (2.2) *and* (2.3). *Suppose that*

$$(3.15)\quad \begin{aligned}&\text{for each } f \in L^2(0,T;\ H),\ L_a^* \tilde{A}_f L_a \text{ is finitely continuous} \\ &\text{and pseudo-monotone on } L^2(0,T;\ H).\end{aligned}$$

Then for each $f \in L^2(0,T;\ H)$, (1.1) *has a solution on* $[0,T]$.

Proof. Let $f\in L^2(0,T;\ H)$. As in the proof of Theorem 1, we write L instead of L_a. From (2.4), (2.5) and (3.15), it follows that $((1/n)I+L^*\tilde{A}_fL)$ is finitely continuous, pseudo-monotone, coercive and bounded. Then since L^* is positive, by [3, Thm. 7.8], we obtain that for each $n\geqq 1$, there exists a solution u_n of the equation

$$L^*u_n+\frac{1}{n}u_n+L^*\tilde{A}_fLu_n\ni 0. \tag{3.16}$$

Since L^* is injective by (2.3), (3.16) implies

$$u_n+\frac{1}{n}L^{*-1}u_n+\tilde{A}_fLu_n\ni 0. \tag{3.17}$$

Multiplying (3.17) by u_n gives

$$\begin{aligned}\|u_n\|^2 &\leqq \|u_n\|\left(\sqrt{T}\,c_1+c_2\left(\|Lu_n+f\|\right)\right)\\ &\leqq \|u_n\|\left(\sqrt{T}\,c_1+c_2\|a\|_{L^1(0,T)}\|u_n\|+c_2\|f\|\right).\end{aligned} \tag{3.18}$$

Then it follows from (3.18) that there exists $M>0$ such that

$$\|u_n\|\leqq M \quad \text{for all } n\geqq 1. \tag{3.19}$$

Let $\{w_n\}$ be a sequence such that $w_n\in L^*\tilde{A}_fLu_n$ and $L^*u_n+(1/n)u_n+w_n=0$. Then by (3.19) and (2.4), we may assume that $u_n\to u$ and $w_n\to w$ in $L^2(0,T;\ H)$. Then since $(1/n)u_n\to 0$ and

$$\begin{aligned}\liminf_{n\to\infty}\left\langle L^*u_n,u_n-u\right\rangle &= \liminf_{n\to\infty}\left\langle L^*u_n-L^*u,u_n-u\right\rangle+\lim_{n\to\infty}\left\langle L^*u,u_n-u\right\rangle\\ &\geqq 0,\end{aligned}$$

multiplying (3.16) by u_n-u gives

$$\limsup_{n\to\infty}\left\langle w_n,u_n-u\right\rangle\leqq 0.$$

Then by Lemma 2, $w\in L^*\tilde{A}_fLu$ and therefore we obtain that $L^*u+L^*\tilde{A}(Lu+f)\ni 0$. Since L^* is injective, we have that $u+\tilde{A}(Lu+f)\ni 0$. Then by Lemma 4, (1.1) has a solution on $[0,T]$.

Theorem 2 follows from Proposition 1 and the following proposition.

PROPOSITION 2. *Let $A:H\to H$ be a finitely continuous pseudo-monotone operator on H. Let $a(t)\in L^2(0,T)$ satisfy* (2.2) *and* (2.3). *Then for each $f\in L^2(0,T;\ H)$, the operator $L^*\tilde{A}_fL$ is finitely continuous and pseudo-monotone on $L^2(0,T;\ H)$.*

For the sake of simplicity of the proof, we prove the case $f=0$ in Proposition 2. To prove Proposition 2, we need some lemmas. In the followings, we suppose that A and $a(t)$ satisfy the assumption of Proposition 2. We write L instead of L_a.

LEMMA 5. *Let $\{u_n\}$, $\{w_n\}\subset L^2(0,T;\ H)$ be sequences such that $u_n\to u$ in $L^2(0,T;\ H)$, $w_n\in\tilde{A}Lu_n$ for each $n\geqq 1$ and $\limsup_{n\to\infty}\langle w_n,Lu_n-Lu\rangle\leqq 0$. Then $\lim_{n\to\infty}\langle w_n,Lu_n-Lu\rangle=0$.*

Proof. We first observe that for each $t\in[0,T]$, $(Lu_n)(t)$ converges weakly to $(Lu)(t)$ in H. For each $z\in H$, $a(t)z\in L^2(0,T;\ H)$. Then since $u_n\to u$ in $L^2(0,T;\ H)$, we obtain that for each $t\in[0,T]$ and $z\in H$,

$$\begin{aligned}\lim_{n\to\infty}(z,(Lu_n)(t)-(Lu)(t))&=\lim_{n\to\infty}\left(z,\int_0^t a(t-s)(u_n(s)-u(s))\,ds\right)\\&=\lim_{n\to\infty}\int_0^t(a(t-s)z,\ u_n(s)-u(s))\,ds\\&=0.\end{aligned}$$

From the above observation and Lemma 1, we obtain that $\liminf_{n\to\infty}(w_n(t),(Lu_n)(t)-(Lu)(t))\geqq 0$ a.e. on $[0,T]$. We also have that there exists $M>0$ such that $|(Lu_n)(t)|\leqq M$ for all $n\geqq 1$ and $t\in[0,T]$. Then by the condition (2.4), we obtain that there exists $K>0$ such that $|(w_n(t),(Lu_n)(t)-(Lu)(t))|\leqq K$ for all $n\geqq 1$ and $t\in[0,T]$. The by Fatou's lemma, it follows that

$$\begin{aligned}0&\leqq\int_0^T\liminf_{n\to\infty}(w_n(t),(Lu_n)(t)-(Lu)(t))\,dt\\&\leqq\liminf_{n\to\infty}\langle w_n,Lu_n-Lu\rangle\\&\leqq\limsup_{n\to\infty}\langle w_n,Lu_n-Lu\rangle\\&\leqq 0,\end{aligned}$$

and this completes the proof.

LEMMA 6. *Let* $\{u_n\}$, $\{w_n\}\subset L^2(0,T;\ H)$ *be sequences such that* $u_n\to u$ *in* $L^2(0,T;\ H)$, $w_n\in\tilde{A}Lu_n$ *for all* $n\geqq 1$ *and* $\limsup_{n\to\infty}\langle w_n,Lu_n-Lu\rangle\leqq 0$. *Then for given* $\varepsilon>0$, *there exists* $n_0\geqq 1$ *such that* (*for all* $n\geqq n_0$),

$$(w_n(t),(Lu_n)(t)-Lu(t))>-\varepsilon,$$

for all $t\in[0,T]$.

Proof. Suppose that there exist $\varepsilon>0$, a sequence $\{t_i\}$ and a subsequence $\{u_{n_i}\}$ of $\{u_n\}$ such that

$$\lim_{i\to\infty}(w_{n_i}(t_i),(Lu_{n_i})(t_i)-(Lu)(t_i))\leqq-\varepsilon. \tag{3.20}$$

We may suppose without any loss of generality that $t_i\to t_0$. Then since $a(t)\in L^2(0,T)$ and $u_n\to u$ in $L^2(0,T;\ H)$, it is easy to see that $(Lu_{n_i})(t_i)$ converges weakly to $(Lu)(t_0)$ in H and $(Lu)(t_i)$ converges strongly to $(Lu)(t_0)$ in H. Then (3.20) implies

$$\lim_{i\to\infty}(w_{n_i}(t_i),(Lu_{n_i})(t_i)-(Lu)(t_0))\leqq-\varepsilon.$$

On the other hand, by Lemma 1, we have that

$$\liminf_{i\to\infty}(w_{n_i}(t_i),(Lu_{n_i})(t_i)-(Lu)(t_0))=0.$$

This is a contradiction.

LEMMA 7. *Let* $\{u_n\}$, $\{w_n\}$ *be sequences such that* $u_n\to u$ *in* $L^2(0,T;\ H)$, $w_n\in\tilde{A}Lu_n$ *for each* $n\geqq 1$ *and* $\limsup_{n\to\infty}\langle w_n,Lu_n-Lu\rangle\leqq 0$. *Then there exists a subsequence* $\{u_{n_i}\}$ *of* $\{u_n\}$ *such that*

$$\limsup_{i\to\infty}(w_{n_i}(t),(Lu_{n_i})(t)-(Lu)(t))\leqq 0\quad a.e.\ on\ [0,T]. \tag{3.21}$$

Proof. From Fatou's lemma, we have that

$$0 = \lim_{n\to\infty} \langle w_n, Lu_n - Lu\rangle \tag{3.22}$$
$$\leqq \int_0^T \limsup_{n\to\infty} (w_n(t), (Lu_n)(t) - (Lu)(t))\, dt$$
$$\leqq \lim_{k\to\infty} \int_0^T \sup_{n\geqq k} (w_n(t), (Lu_n)(t) - (Lu)(t))\, dt.$$

By Lemma 1, we have that

$$\liminf_{n\to\infty} (w_n(t), (Lu_n)(t) - (Lu)(t)) \geqq 0 \quad \text{a.e. on } [0,T]. \tag{3.23}$$

Then it is sufficient to prove that there exists a subsequence $\{u_{n_i}\}$ of $\{u_n\}$ such that

$$\lim_{j\to\infty} \int_0^T \sup_{i\geqq j} \left(w_{n_i}(t), (Lu_{n_i})(t) - (Lu)(t)\right) dt = 0. \tag{3.24}$$

In fact, if $\{u_{n_i}\}$ satisfies (3.24), we have, by (3.22), that

$$\int_0^T \limsup_{i\to\infty} \left(w_{n_i}(t), (Lu_{n_i})(t) - (Lu)(t)\right) dt = 0. \tag{3.25}$$

Then from (3.23) and (3.25), (3.21) follows. For each $n \geqq 1$ and $i \geqq 1$, we put

$$P_n(i) = \{t \in [0,T] : (w_n(t), (Lu_n)(t) - (Lu)(t)) \geqq 1/i\}.$$

We claim that there exists a subsequence $\{u_{n_i}\}$ of $\{u_n\}$ such that $m(P_{n_i}(i)) \leqq 1/2^i$ for all $i \geqq 1$, where m is the usual measure on $[0,T]$. Fix $i \geqq 1$ and choose $\varepsilon > 0$ such that $\varepsilon T + \varepsilon < (i2^i)^{-1}$. From Lemmas 5 and 6, we can choose n_i such that

$$\langle w_{n_i}, Lu_{n_i} - Lu\rangle < \varepsilon$$

and

$$\left(w_{n_i}(t), (Lu_{n_i})(t) - (Lu)(t)\right) \geqq -\varepsilon \quad \text{a.e. on } [0,T].$$

Then since

$$\varepsilon > \langle w_{n_i}, Lu_{n_i} - Lu\rangle$$
$$= \int_{P_{n_i}(i)} \left(w_{n_i}(t), (Lu_{n_i})(t) - (Lu)(t)\right) dt$$
$$+ \int_{[0,T]\setminus P_{n_i}(i)} \left(w_{n_i}(t), (Lu_{n_i})(t) - (Lu)(t)\right) dt$$
$$\geqq i^{-1} m\left(P_{n_i}(i)\right) - \varepsilon\left(T - m\left(P_{n_i}(i)\right)\right).$$

Then we obtain that $m(P_{n_i}(i)) < 2^{-i}$. Now we show that

$$\lim_{j\to\infty} \int_0^T \sup_{i\geqq j} \left(w_{n_i}(t), (Lu_{n_i})(t) - (Lu)(t)\right) dt = 0. \tag{3.26}$$

Since $\{u_n\}$ is bounded in $L^2(0,T;\ H)$, $a(t)\in L^2(0,T)$ and A satisfies (2.4), there exists $M>0$ such that $|(Lu_n)(t)|\leqq M$ and $|w_n(t)|\leqq M$ for all $n\geqq 1$ and $t\in[0,T]$. Then for given $\varepsilon>0$, we choose $i_0\geqq 1$ so large that $Ti_0^{-1}+2M^2(\Sigma_{i\geqq i_0}2^{-i})<\varepsilon$. Then we have

$$\begin{aligned}
&\int_0^T \sup_{i\geqq i_0}\left(w_{n_i}(t),\left(Lu_{n_i}\right)(t)-(Lu)(t)\right)dt\\
&\quad=\int_{\bigcup_{i\geqq i_0}P_{n_i}(i)} \sup_{i\geqq i_0}\left(w_{n_i}(t),\left(Lu_{n_i}\right)(t)-(Lu)(t)\right)dt\\
&\qquad+\int_{[0,T]\setminus\bigcup_{i\geqq i_0}P_{n_i}(i)} \sup_{i\geqq i_0}\left(w_{n_i}(t),\left(Lu_{n_i}\right)(t)-(Lu)(t)\right)dt\\
&\quad\leqq 2M^2\left(\sum_{i\geqq i_0}2^{-i}\right)+Ti_0^{-1}<\varepsilon.
\end{aligned}$$

Therefore we obtain (3.26). This completes the proof.

LEMMA 8. *Let* $\{u_n\}$, $\{w_n\}\subset L^2(0,T;\ H)$ *be sequences such that* $u_n\to u$ *in* $L^2(0,T;\ H)$, $w_n\in\tilde{A}Lu_n$ *for each* $n\geqq 1$ *and*

$$\limsup_{n\to\infty}\left(w_n(t),\left(Lu_n\right)(t)-(Lu)(t)\right)\leqq 0\quad a.e.\ on\ [0,T].$$

Suppose that $w_n\to w$ *in* $L^2(0,T;\ H)$. *Then* $w\in\tilde{A}Lu$.

Proof. It is easy to see that for each $t\in[0,T]$, $\{w_n(t)\}$ is bounded in H, because $(Lu_n)(t)$ is bounded in H and A satisfies (2.4), while, from the assumption, it is obvious that $w\in\overline{\mathrm{co}}\{w_n:n\geqq k\}$ for each $k\geqq 1$. Then we have that there exists a sequence $\{h_k\}$ such that $h_k\in\mathrm{co}\{w_n:n\geqq k\}$ and $h_k\to w$ in $L^2(0,T;\ H)$. Then we may assume without any loss of generality that $h_k(t)\to w(t)$ a.e. on $[0,T]$. Then since $h_k(t)\in\mathrm{co}\{w_n(t):n\geqq k\}$, we have that $w(t)\in\bigcap_k\mathrm{co}\{w_n(t):n\geqq k\}$ a.e. on $[0,T]$. Then by Lemma 2′, we obtain that $w(t)\in A(Lu)(t)$ a.e on $[0,T]$, i.e., $w\in\tilde{A}Lu$.

Remark. It is easy to verify that Lemmas 5, 6, 7, and 8 hold with $\tilde{A}$ replaced by $\tilde{A}_f$ ($f\in L^2(0,T;\ H)$.)

Proof of Proposition 2. For the sake of simplicity of the proof, we suppose that $f=0$. We prove that $L^*\tilde{A}L$ is pseudo-monotone on $L^2(0,T;\ H)$. Let $\{u_n\}$, $\{w_n\}\subset L^2(0,T;\ H)$ be sequences such that $u_n\to u$ in $L^2(0,T;\ H)$, $w_n\in\tilde{A}Lu_n$ for each $n\geqq 1$ and $\limsup_{n\to\infty}\langle w_n,Lu_n-Lu\rangle\leqq 0$. Let $v\in L^2(0,T;\ H)$. We show that there exists $w\in\tilde{A}Lu$ such that $\langle w,Lu-Lv\rangle\leqq\liminf_{n\to\infty}\langle w_n,Lu_n-Lv\rangle$. By Lemma 5, we have that $\lim_{n\to\infty}\langle w_n,Lu_n-Lu\rangle=0$. Hence we choose a subsequence $\{u_{n_i}\}$ of $\{u_n\}$ such that $w_{n_i}\to w$ in $L^2(0,T;\ H)$ and $\lim_{i\to\infty}\langle w_{n_i},Lu_{n_i}-Lv\rangle=\liminf_{n\to\infty}\langle w_n,Lu_n-Lv\rangle$. Then we have that

$$\begin{aligned}
\liminf_{n\to\infty}\langle w_n,Lu_n-Lv\rangle&=\lim_{i\to\infty}\langle w_{n_i},Lu_{n_i}-Lv\rangle\\
&=\lim_{i\to\infty}\langle w_{n_i},Lu_{n_i}-Lu\rangle+\lim_{i\to\infty}\langle w_{n_i},Lu-Lv\rangle\\
&=\lim_{i\to\infty}\langle w_{n_i},Lu-Lv\rangle\\
&=\langle w,Lu-Lv\rangle.
\end{aligned}$$

On the other hand, by Lemma 7, we may assume that

$$\limsup_{i\to\infty}\left\langle w_{n_i}(t),\,(Lu_{n_i})(t)-(Lu)(t)\right\rangle \leqq 0 \quad \text{a.e. on } [0,T].$$

Then by Lemma 8, it follows that $w\in\tilde{A}Lu$. Therefore $L^*\tilde{A}L$ is pseudo-monotone on $L^2(0,T;\ H)$. We can prove that $L^*\tilde{A}L$ is finitely continuous by the parallel argument as in the proof of Lemma 3. Then we omit the proof.

4. Examples.

Example 1. Let H be a real Hilbert space and let $A:H\to H$ be an operator defined by

$$Ax=\begin{cases}|\langle x_0,x\rangle|x/|x| & \text{if } x\neq 0,\\ \{x\in H:|x|\leqq 1.\} & \text{if } x=0,\end{cases}$$

where $x_0\in H$. Then it is easy to see that A is finitely continuous and pseudo-monotone on H. Let $a(t)$ be an element of $L^2(0,T)$ such that $a(0)>0$, a and a' are nonnegative convex on $[0,\infty)$. Then $a(t)$ satisfies (2.2) and (2.3) on each interval $[0,T](T>0)$. Moreover by Theorem 2, (1.1) has a solution on $[0,T]$ for every $f\in L^2(0,T;\ H)$.

Example 2. Let H be a real Hilbert space and $A:H\to H$ be a multivalued compact operator (i.e., A is upper semicontinuous and maps bounded sets to compact sets). Suppose that Au is convex for each $u\in H$. Then A is finitely continuous and pseudo-monotone on H. Suppose that A satisfies (2.4) and (2.5). Let $a(t)$ be as in example 1. Then for each $f\in L^2(0,T;\ H)$, (1.1) has a solution on $[0,T]$.

Acknowledgments. The author wishes to express his hearty thanks to Professor W. Takahashi, Professor J. A. Nohel and referees for many suggestions and advice regarding this paper.

EIGENVALUES OF DIFFERENTIABLE POSITIVE DEFINITE KERNELS*

CHUNG-WEI HA†

Abstract. The main object of this note is to answer in the affirmative a conjecture in [4] that for an integral operator generated by a p times continuously differentiable positive definite kernel, the eigenvalues are $o(1/n^{p+1})$.

AMS(MOS) subject classifications. Primary 45B05, 45M05; secondary 47B10

Key words. L^2-kernel, singular value, eigenvalue, trace class operator

1. Introduction. A function $K(x,t)\in L^2[0,1]^2$ is known as an L^2-kernel. It defines a compact operator on $L^2[0,1]$ by

$$Kf(x)=\int_0^1 K(x,t)f(t)\,dt.$$

The adjoint K^* of K is generated by the kernel $\overline{K(t,x)}$ so that the operator K or its kernel $K(x,t)$ is Hermitian if $K(x,t)=\overline{K(t,x)}$ for almost all $0\leqq x,\ t\leqq 1$. Suppose that $K(x,t)$ is Hermitian and positive definite, that is,

$$\int_0^1\int_0^1 K(x,t)\overline{f(x)}f(t)\,dx\,dt\geqq 0$$

for all $f\in L^2[0,1]$. Then the spectrum of K consists of a sequence of positive eigenvalues $\{\lambda_n(K)\}$ which converges to 0. These eigenvalues are arranged in decreasing order and repeated according to their multiplicities. Assume also that $K(x,t)$ is continuous on $[0,1]^2$. If $\{\phi_n\}$ is the corresponding orthonormal sequence of eigenfunctions of K, then the well-known Mercer's theorem says that $K(x,t)$ has the eigenfunction expansion

$$K(x,t)=\sum_{n=1}^{\infty}\lambda_n(K)\phi_n(x)\overline{\phi_n(t)}, \tag{1}$$

where the series converges absolutely and uniformly on $[0,1]$. A kernel of this type generates an operator of trace class; the trace of K is given by

$$\sum_{n=1}^{\infty}\lambda_n(K)=\int_0^1 K(t,t)\,dt<\infty.$$

Consequently

$$\lambda_n(K)=o\left(\frac{1}{n}\right) \tag{2}$$

*Received by the editors January 17, 1984.
†Department of Mathematics, National Tsing Hua University, Hsin Chu, Taiwan, Republic of China.

as $n \to \infty$. Recently Reade [4] showed that if it is also assumed that $K(x,t) \in C^1[0,1]^2$, then (2) can be improved to $\lambda_n(K) = o(1/n^2)$ as $n \to \infty$. It is also suggested in [4] that if $p \geqq 1$ is an integer and if $K(x,t) \in C^p[0,1]^2$ is positive definite Hermitian, then

$$\lambda_n(K) = o\left(\frac{1}{n^{p+1}}\right)$$

as $n \to \infty$. The main object of this note is to prove this conjecture.

2. Singular values. Suppose that T is an integral operator not necessarily Hermitian. Then T^*T is positive definite Hermitian and so has a sequence of positive eigenvalues which converges to 0. The positive square roots of these eigenvalues, arranged in decreasing order and denoted by $\{s_n(T)\}$, are called singular values of T (see [3, Chap. 2]). It can be proved that T and T^* have the same singular values (see [3, p. 28]). If T is positive definite Hermitian, then the eigenvalues and the singular values of T coincide. The singular values of T have the characterization that

$$s_n(T) = \inf\{\|T|_H\|: H \text{ is a vector subspace, } \operatorname{codim} H \leqq n-1\},$$

where $T|_H$ denotes the restriction of T on H (see e.g. [1]). The infimum is attained when H is the vector subspace formed by $f \in L^2[0,1]$ which are orthogonal to the first $n-1$ eigenfunctions $\phi_1, \cdots, \phi_{n-1}$ of T^*T. Consequently, if $r \geqq 1$ is an integer and if H is a vector subspace of codimension $\leqq r$, then

$$s_{n+r}(T) \leqq s_n(T|_H). \tag{3}$$

Moreover, if K is positive definite Hermitian, then we can write $T^*KT = (K^{1/2}T)^*(K^{1/2}T)$, where $K^{1/2}$ denotes the positive square root of K, and so

$$\lambda_{m+n-1}(T^*KT) = s_{m+n-1}(T^*KT) \leqq s_m(K)s_n^2(T) = \lambda_m(K)\lambda_n(T^*T). \tag{4}$$

To prove the main results, we also need to compute the singular values of the operator

$$Jf(x) = \int_x^1 f(t)\,dt.$$

The numbers $s_n^2(J)$, which are eigenvalues of the operator J^*J, must satisfy

$$\phi_n(x) = \frac{1}{s_n^2(J)} \int_0^x \left\{ \int_t^1 \phi_n(s)\,ds \right\} dt,$$

that is,

$$\phi_n'' + \frac{1}{s_n^2(J)}\phi_n = 0, \qquad \phi_n(0) = \phi_n'(1) = 0.$$

A simple calculation shows (see [3, p. 120]) that

$$\lambda_n(J^*J) = s_n^2(J) = \frac{4}{\pi^2(2n-1)^2}. \tag{5}$$

3. The results. Suppose that the kernel $K(x,t)$ is positive definite Hermitian. If the symmetric derivative

$$K_{rr}(x,t) = \frac{\partial^{2r}}{\partial x^r \partial t^r} K(x,t) \tag{6}$$

exists and is continuous on $[0,1]^2$, then $K_{rr}(x,t)\in C[0,1]^2$ is also positive definite Hermitian, and so by Mercer's theorem, $K_{rr}(x,t)$ generates an integral operator of trace class. Indeed, it is shown in [2] that the eigenfunctions ϕ_n of K are in $C^r[0,1]$ and the eigenfunction expansion (1) can be differentiated term by term so that

$$K_{rr}(x,t)=\sum_{n=1}^{\infty}\lambda_n(K)\phi_n^{(r)}(x)\overline{\phi_n^{(r)}(t)}.$$

The series converges absolutely and uniformly on $[0,1]$.

THEOREM 1. *If $K(x,t)$ is positive definite Hermitian and if the symmetric derivative* (6) *exists and is continuous on* $[0,1]^2$, *then*

$$\sum_{n=1}^{\infty} n^{2r}\lambda_n(K)<\infty. \tag{7}$$

Consequently,

$$\lim_{n\to\infty} n^{2r+1}\lambda_n(K)=0. \tag{8}$$

Proof. The proof is suggested by a method of Krein (see [3, p. 121]). Let H_1 be the vector subspace formed by $f\in L^2[0,1]$ which are orthogonal to the constant function $e(t)\equiv 1$ and the function $K(t,0)$; then H_1 is of codimension $\leqq 2$. If $f\in H_1$, then

$$\int_0^1 f(t)\,dt=0 \quad\text{and}\quad \int_0^1 K(0,t)f(t)\,dt=0, \tag{9}$$

and so we have the expression

$$\begin{aligned} Kf(x)&=\int_0^1 K(x,t)f(t)\,dt \\ &=\int_0^x\left\{\int_0^1 K_{11}(y,s)\left(\int_s^1 f(t)\,dt\right)ds\right\}dy \\ &=J^*K_{11}Jf(x). \end{aligned} \tag{10}$$

We also have an expression symmetric to (10). Let G be the vector subspace formed by $g\in L^2[0,1]$ which are orthogonal to the functions $e(t)$ and $K(t,1)$. Then for $g\in G$

$$\int_0^1 g(t)\,dt=0 \quad\text{and}\quad \int_0^1 K(1,t)g(t)\,dt=0,$$

and so

$$\begin{aligned} Kg(x)&=\int_0^1 K(x,t)g(t)\,dt \\ &=\int_x^1\left\{\int_0^1 K_{11}(y,s)\left(\int_0^s g(t)\,dt\right)ds\right\}dy \\ &=JK_{11}J^*g(x). \end{aligned} \tag{11}$$

For $r=2$, let H_2 be the vector subspace formed by $f\in H_1$ which are orthogonal to the functions $J^*e(t)$ and $J^*K_{11}(t,1)$, then H_2 is codimension $\leqq 4$. If $f\in H_2$, then in addition to (9), f also satisfies

$$\int_0^1 Jf(t)\,dt=0 \quad \text{and} \quad \int_0^1 K_{11}(1,t)Jf(t)\,dt=0.$$

Now (9) holds, and by applying (11) to the function $Jf(t)$ with the kernel $K_{11}(x,t)$ in place of $K(x,t)$,

$$K_{11}Jf(x)=JK_{22}J^*Jf(x).$$

Substituting into (10), we have

$$Kf(x)=J^*JK_{22}J^*Jf(x).$$

If $r\geqq 3$, we can keep on applying (10) and (11) by turns. Let T_0 be the identity operator and for $1\leqq j\leqq r$, let

$$T_j=\underbrace{A\cdots J^*J}_{j \text{ factors}}$$

where $A=J$ if j is odd and $A=J^*$ if j is even; the operator T_j is the product of j factors which are either J or J^* appearing alternately. Let H_r be the vector subspace formed by $f\in L^2[0,1]$ which are orthogonal to the $2r$ functions

$$T_j^*e(t) \quad \text{and} \quad T_j^*K_{jj}(t,a)$$

for $j=0,1,\cdots,r-1$, where $a=0$ if j is even, $a=1$ if j is odd and $K_{00}(x,t)=K(x,t)$. Then H_r is of codimension $\leqq 2r$ and for $f\in H_r$,

$$Kf(x)=T_r^*K_{rr}T_rf(x).$$

Since $T_r^*T_r=(J^*J)^r$ and is positive definite Hermitian, $\lambda_n(T_r^*T_r)=\{\lambda_n(J^*J)\}^r$. By (3), (4) and (5) for $n\geqq 2r+1$

$$\begin{aligned}(12)\qquad \lambda_{2n}(K)&\leqq\lambda_{2n-1}(K)\leqq\lambda_{2n-2r-1}(T_r^*K_{rr}T_r)\\ &\leqq\lambda_{n-2r}(T_r^*T_r)\lambda_n(K_{rr})=\{\lambda_{n-2r}(J^*J)\}^r\lambda_n(K_{rr})\\ &\leqq\frac{4^r}{\pi^{2r}(2n-4r-1)^{2r}}\lambda_n(K_{rr}).\end{aligned}$$

As noted above, the operator K_{rr} is of trace class and so (7) is proved. (8) follows immediately from (7) (see [3, p. 122]).

THEOREM 2. *If $K(x,t)\in C^p[0,1]^2$ is positive definite Hermitian, then*

$$(13)\qquad \lambda_n(K)=o\left(\frac{1}{n^{p+1}}\right)$$

as $n\to\infty$.

Proof. If p is even, then (8) gives (13). If p is odd, then set $r=(p-1)/2$. Since $K_{rr}(x,t)\in C^1[0,1]^2$ is positive definite Hermitian, Reade's result [4] implies that

$$\lim_{n\to\infty} n^2\lambda_n(K_{rr})=0.$$

Relation (13) now follows from (12).

POSITIVE DEFINITE C^p KERNELS*

J. B. READE†

Abstract. It was shown in [SIAM J. Math. Anal. 15 (1984), pp. 137–142] that the eigenvalues (λ_n) of any positive definite C^p kernel are $o(1/n^{p+1})$ as $n\to\infty$. More recently, Ha has proved [SIAM J. Math. Anal., 17 (1986), pp. 415–419] that, for p even, a stronger result holds, namely, that $\Sigma_1^\infty n^p\lambda_n<\infty$. It is the purpose of this note to show by counterexample that Ha's result is not true for p odd.

1. Introduction. Any p times continuously differentiable kernel $K(x,t)$ on $|x|\leqq 1$, $|t|\leqq 1$ gives rise to a compact operator

$$Tf(x)=\int_{-1}^{1} K(x,t)f(t)\,dt$$

on $L^2[-1,1]$. If $K(t,x)=\overline{K(x,t)}$, then T is also symmetric and so has an orthonormal sequence (ϕ_n) of eigenfunctions whose eigenvalues (λ_n) form a real sequence convergent to zero. Also $K(x,t)$ has the expansion

$$K(x,t)=\sum_1^\infty \lambda_n\phi_n(x)\overline{\phi_n(t)}$$

mean square convergent over $|x|\leqq 1$, $|t|\leqq 1$. If, further, $K(x,t)$ is positive definite, i.e.,

$$\int_{-1}^{1}\int_{-1}^{1} K(x,t)f(x)\overline{f(t)}dx\,dt\geqq 0$$

for all $f\in L^2[-1,1]$, then $\lambda_n\geqq 0$ for all n, and, if we assume

$$\lambda_1\geqq\lambda_2\geqq\cdots\geqq\lambda_n\geqq\cdots,$$

then we have $n^{p+1}\lambda_n\to 0$ as $n\to\infty$ if p odd, and $\Sigma_1^\infty n^p\lambda_n<\infty$ if p even. (See [1] (this issue, pp. 415–419), [2].)

We shall show both these results are best possible in the sense that, given any real decreasing sequence (λ_n) such that $n^{p+1}\lambda_n\to 0$ as $n\to\infty$ in case p odd, $\Sigma_1^\infty n^p\lambda_n<\infty$ in case p even, there exist positive definite C^p kernels whose eigenvalues are (λ_n). The divergence of the series $\Sigma_1^\infty 1/n\log n$ shows that any positive definite C^p kernel with eigenvalues $\lambda_n=1/n^{p+1}\log n$, where p is odd, cannot satisfy $\Sigma_1^\infty n^p\lambda_n<\infty$.

2. Trigonometric series.

LEMMA 1. *The trigonometric series $\Sigma_1^\infty n^{-1}\sin nt$ has uniformly bounded partial sums over all real t.*

Proof. The maximum value of $|\Sigma_1^N n^{-1}\sin nt|$ occurs at $t=\pi/N+1$ and is $\Sigma_1^N n^{-1}\sin n\pi/N+1$ which converges to $\int_0^\pi t^{-1}\sin t\,dt$ as $N\to\infty$. Q.E.D.

LEMMA 2. *If p is odd, and if (λ_n) is any decreasing real sequence such that $n^{p+1}\lambda_n\to 0$ as $n\to\infty$, then*

$$f(t)=\sum_1^\infty \lambda_n\cos nt$$

is C^p.

* Received by the editors April 3, 1984.
† Mathematics Department, Manchester University, Manchester, M13 9PL, England.

Proof. The series obtained by formally differentiating term by term p times is $\pm\sum_1^\infty n^p\lambda_n \sin nt$ which is uniformly convergent over all real t by Dirichlet's test (see [3, p. 50]) since $n^{p+1}\lambda_n$ decreases and converges to zero and $\sum_1^\infty n^{-1}\sin nt$ has uniformly bounded partial sums. Q.E.D.

LEMMA 3. *If p is even, and if (λ_n) is any real sequence such that $\sum_1^\infty n^p\lambda_n < \infty$, then*

$$f(t)=\sum_1^\infty \lambda_n \cos nt$$

is C^p.

Proof. p formal differentiations give $\pm\sum_1^\infty n^p\lambda_n \cos nt$ which is uniformly convergent by the Weierstrass M-test (see [3, p. 49]). Q.E.D.

3. The counterexamples. The sequence $(\cos \pi nt)_{n\geq 1}$ is orthonormal in $L^2[-1,1]$ and so, for any sequence (λ_n) such that $\sum_1^\infty \lambda_n^2 < \infty$, the kernel

$$K(x,t)=\sum_1^\infty \lambda_n \cos \pi nx \cos \pi nt = \frac{1}{2}\sum_1^\infty \lambda_n(\cos \pi n(x+t)+\cos \pi n(x-t))$$

is compact symmetric having eigenvalues (λ_n). $K(x,t)$ is C^p if, for p odd, λ_n decreases and $n^{p+1}\lambda_n \to 0$, or if, for p even, $\sum_1^\infty n^p\lambda_n < \infty$, by Lemmas 2 and 3.

UNIFORM ASYMPTOTIC SOLUTIONS OF A CLASS OF SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS HAVING A TURNING POINT AND A REGULAR SINGULARITY, WITH AN APPLICATION TO LEGENDRE FUNCTIONS*

W. G. C. BOYD† AND T. M. DUNSTER†

Abstract. The asymptotic behaviour, as a parameter $u \to \infty$, of solutions of second-order linear differential equations with a turning point and a regular (double pole) singularity is considered. It is shown that the solutions can be approximated by expressions involving Bessel functions in a region which includes both the turning point and the singularity. Explicit error bounds for the difference between the approximations and the exact solutions are established. The theory is applied to find uniform asymptotic expansions for Legendre functions.

1. Introduction. In this paper we examine the asymptotic behaviour for large positive u of solutions of differential equations of the form

$$\frac{d^2w}{dx^2} = \{u^2 f(\alpha,x) + g(\alpha,x)\}w. \tag{1.1}$$

The equation is assumed to have a regular singularity at $x=0$ and, except when $\alpha=0$, a simple turning point at $x=x_t$. The real parameter α, which we define more precisely in a moment, is a measure of the severity of the singularity at $x=0$; we assume that it ranges in the interval $0 \leqq \alpha < \alpha_0$, where α_0 is a given constant which may be infinite. The position x_t of the turning point is assumed to be a continuous real function of α which tends to zero as $\alpha \to 0$. It is supposed that $g(\alpha,x)$ is small in absolute value compared with $u^2 f(\alpha,x)$ except near the turning point. We find asymptotic expansions and rigorous error bounds which are *uniformly* valid as α varies in an interval which includes $\alpha=0$. We consider separately the cases when the independent variable x takes real or complex values.

In the real-variable case, we shall suppose that the equation (1.1) is given in the x-interval (x_1,x_2) which includes 0, x_t; the endpoints x_1, x_2 may be infinite. Both $x^2 f(\alpha,x)$ and $x^2 g(\alpha,x)$ will be assumed to be infinitely differentiable functions of x and continuous functions of α and x simultaneously. (If one requires only asymptotic approximations to solutions of (1.1) instead of asymptotic expansions—i.e. requires only a finite number of terms—then the restriction to infinite differentiability can be relaxed.) The limits of $x^2 f(\alpha,x)$ and $x^2 g(\alpha,x)$ as $x \to 0$ will be assumed to be $\alpha^2/4$ and $-\frac{1}{4}$ respectively: if necessary, the parameter u is redefined to ensure that the condition on $g(\alpha,x)$ is met. We shall assume that for each nonzero value of α, $f(\alpha,x)$ has a simple zero at $x=x_t$ and elsewhere is nonzero. In the case $\alpha=0$, we shall assume that $f(0,x) \neq 0$ for $x \neq 0$ and that as $x \to 0$ the limit of $xf(0,x)$ is nonzero.

In the complex-variable case, we shall suppose that the equation (1.1) is given in a domain D of the complex z-plane which contains $z=0$ and $z=x_t$, and may be unbounded. Both $f(\alpha,z)$, $g(\alpha,z)$ will be assumed to be holomorphic functions of z and continuous functions of α and z simultaneously except when $z=0$. We shall assume that for each value of α the only singularities of $f(\alpha,z)$ and $g(\alpha,z)$ are at $z=0$: the

*Received by the editors May 24, 1983 and in final revised form August 9, 1984.
†School of Mathematics, University of Bristol, Bristol, England BS8 1TW.

Laurent series expansions of f and g about $z=0$ will be assumed to have leading terms $\alpha^2/4z^2$ and $-1/4z^2$ respectively. For each nonzero value of α, we shall assume that the function $f(\alpha,z)$ has a simple zero at the point on the real axis $z=x_t$ and elsewhere is nonzero. In the case $\alpha=0$, we shall assume that the function $f(0,z)$ is nonzero and has a simple pole at $z=0$.

In a review of unsolved problems in asymptotics, Olver (1975c, p. 117) suggests that uniform asymptotic expansions of solutions of (1.1) may be found in terms of Bessel functions of order $u\alpha$. We indeed find this to be the case. Expansions of this kind have been established previously by Olver (1958), (1974, Chap. 12) and Thorne (1957). Olver treats the case when α is small ($O(u^{-1})$). His 1974 results include explicit bounds for the error terms in the expansions. Thorne treats the case when α is not small. He does not obtain explicit error bounds. Our treatment differs in two major ways from those of Olver (1958) and Thorne (1957a). First, the expansions will be shown to be uniformly valid in an interval including $\alpha=0$ (so unifying the results of Olver and Thorne). Secondly, we obtain explicit error bounds, as Olver (1974) did for the case α small. The advantage of the first of these extensions is that the expansions can be used with confidence when α is either small or moderate (cf. Olver (1975a, pp. 138, 139)). The advantage of the second, other than the obvious computational consideration, is that the conditions under which the expansions may be regarded as asymptotic to exact solutions can readily be established a posteriori (cf. Olver (1975a, p. 139) and Olver (1980)).

We refer also to the work of Baldwin (1979). At first sight the problem he tackled may seem to be a special case of ours. This is not so: for example, in our notation the limit as $x\to 0$ of $xf(0,x)$ is zero for his problem. Nevertheless his work has some connections with ours.

We tackle the problem using the standard approach in problems of this sort: the comparison equation method. We transform the original equation into one of the form

$$\frac{d^2W}{d\zeta^2}=\left\{u^2\left(\frac{\alpha^2}{4\zeta^2}-\frac{1}{4\zeta}\right)+\frac{\psi(\alpha,\zeta)}{\zeta}-\frac{1}{4\zeta^2}\right\}W, \tag{1.2}$$

an equation which has the appropriate singular behaviour near $\zeta=0$ and a turning point at $\zeta=\alpha^2$. This choice of comparison equation is the same as that of Olver (1974, Chap. 12), but differs from that of Thorne (1957a). (Thorne's equation (2.4) may however be readily transformed to the above form.) With our choice of comparison equation, the transformation $z\to\zeta$ of the independent variable is analytic throughout D, whereas Thorne's is not at $z=0$.

The plan of the paper is as follows. In §2, we describe the formal series solutions for the real variable case and in §3 develop error bounds for them; §4 applies the results to the Legendre functions of real variable. In §5 we discuss the formal series and the corresponding error bounds for the complex variable case; §6 applies the result to the Legendre functions of complex argument.

2. Formal series solutions: the real-variable case. To transform the original equation (1.1) to the form (1.2) we define a new independent variable ζ and a new dependent variable W by

$$f(\alpha,x)\left(\frac{dx}{d\zeta}\right)^2=\frac{\alpha^2}{4\zeta^2}-\frac{1}{4\zeta}, \qquad \left(\frac{d\zeta}{dx}\right)^{1/2}w(x)=W(\zeta). \tag{2.1}$$

Without loss of generality we assume that $x_t > 0$ when $\alpha \neq 0$. We then specifically define ζ by

$$\text{(2.2a)} \qquad \int_{\alpha^2}^{\zeta} \frac{(\xi-\alpha^2)^{1/2}}{2\xi}\,d\xi = \int_{x_t}^{x} \{-f(\alpha,t)\}^{1/2}\,dt \qquad (x > x_t \text{ or } \zeta > \alpha^2),$$

$$\text{(2.2b)} \qquad \int_{\alpha^2}^{\zeta} \frac{(-\xi+\alpha^2)^{1/2}}{2\xi}\,d\xi = \int_{x_t}^{x} \frac{\{t^2 f(\alpha,t)\}^{1/2}}{t}\,dt \qquad (x < x_t \text{ or } \zeta < \alpha^2).$$

Each of the square roots in (2.2a, b) is taken to be positive or zero. When $\zeta < 0$ and $x < 0$, the integrals in (2.2b) are defined by their Cauchy principal values (for $\alpha \neq 0$). This latter convention introduces ambiguities into the transformation (2.2b) which we must resolve. Consider the left-hand side of (2.2b) when $\alpha \neq 0$: in any neighbourhood of $\zeta = 0$ there are pairs of values of ζ (one positive and the other negative) for which the integrals are equal; an analogous remark applies to the right-hand side of (2.2b). To remove the resulting ambiguities from the transformation $x \to \zeta$ we impose the restriction that the sign of ζ must be the same as that of the corresponding x.

We remark that the integrals on the left-hand sides (2.2a, b) are expressible in terms of elementary functions. They are respectively

$$\text{(2.3)} \qquad (\zeta-\alpha^2)^{1/2} - \alpha \tan^{-1}\frac{(\zeta-\alpha^2)^{1/2}}{\alpha}, \qquad \zeta > \alpha^2$$

and

$$(-\zeta+\alpha^2)^{1/2} - \frac{1}{2}\alpha \ln \frac{\alpha+(-\zeta+\alpha^2)^{1/2}}{|\alpha-(-\zeta+\alpha^2)^{1/2}|}, \qquad \zeta < \alpha^2.$$

The function $\zeta(x)$ defined by (2.2a, b) is monotonically increasing and infinitely differentiable in the interval $x_1 < x < x_2$. These results can be readily established by considering separately the intervals $(x_1, 0)$, $(0, x_t)$, (x_t, x_2) and neighbourhoods of the points $x = 0$, $x = x_t$. We denote the endpoints $\zeta(x_1)$ and $\zeta(x_2)$ by ζ_1, ζ_2 respectively.

The effect of the transformations (2.1) is to yield the new differential equation

$$\text{(2.4)} \qquad \frac{d^2W}{d\zeta^2} = \left\{u^2\left(\frac{\alpha^2}{4\zeta^2} - \frac{1}{4\zeta}\right) + \frac{\psi(\alpha,\zeta)}{\zeta} - \frac{1}{4\zeta^2}\right\} W,$$

where, with $'$ representing differentiation with respect to ζ,

$$\text{(2.5)} \qquad \frac{\psi(\alpha,\zeta)}{\zeta} = x'^{1/2}\frac{d^2}{d\zeta^2}(x'^{-1/2}) + g x'^2 + \frac{1}{4\zeta^2}.$$

A straightforward calculation yields the result

$$\text{(2.6)} \quad \psi(\alpha,\zeta) = \frac{1}{16}(\zeta-\alpha^2)^{-2}(\zeta+4\alpha^2) + \frac{1}{64}\zeta^{-1}(\zeta-\alpha^2)f^{-3}(5\dot{f}^2 - 4f\ddot{f} - 16gf^2),$$

where $\cdot$ represents differentiation with respect to x. Since $x(\zeta)$ and $x^2 g(x)$ are infinitely differentiable and $x'(\zeta) > 0$, it follows from (2.5) that $\psi(\alpha,\zeta)$ is an infinitely differentiable function of ζ for $\zeta_1 < \zeta < \zeta_2$, except possibly at $\zeta = 0$ where the third and fourth terms on the right-hand side of (2.5) have singularities of $O(\zeta^{-2})$. Consideration of the Maclaurin series of $x^2 g(\alpha, x)$ about $x = 0$ however, shows that as $\zeta \to 0$, the third and fourth terms together are $O(\zeta^{-1})$ and so the Maclaurin series of $\psi(\alpha,\zeta)$ about $\zeta = 0$ exists to all orders; in particular $\psi(\alpha,\zeta)$ is infinitely differentiable at $\zeta = 0$.

There is a further property of $\psi(\alpha,\zeta)$ that we shall require: continuity as a function of α, ζ simultaneously. This result is needed to ensure that the asymptotic expansions we find are *uniformly* valid near $\zeta=0$, $\alpha=0$. For convenience we introduce the notation

$$f(\alpha,x)=\frac{x_t(\alpha)-x}{4x^2}p(\alpha,x).$$

We may then, following Olver (1975a, p. 142), prove the following result.

LEMMA 1. *Assume that*

(i) $p(\alpha,x)$, $\partial p(\alpha,x)/\partial x$, $\partial^2 p(\alpha,x)/\partial x^2$ *and* $g(\alpha,x)$ *are continuous functions of* α *and* x *in the region* $0\leqq\alpha<\alpha_0$, $x_1<x<x_2$;

(ii) $p(\alpha,x)$ *is positive throughout the same region*;

(iii) $|\partial^3 p(\alpha,x)/\partial x^3|$ *is bounded in a neighbourhood of the point* $\alpha=x=0$;

(iv) $x_t(\alpha)$ *is a continuous function of* α *when* $0\leqq\alpha<\alpha_0$, *which takes positive values when* $\alpha>0$ *and tends to zero as* $\alpha\to 0$.

Then the function $\psi(\alpha,\zeta)$ *defined by* (2.5) *is continuous in the corresponding region of the* (α,ζ)*-plane.*

There is a corresponding result for complex x, which is fairly easy to prove. The real-variable proof is rather more difficult, but largely follows that given by Olver (1975a, p. 142). It is outlined in Appendix A.

If the term $\psi(\alpha,\zeta)/\zeta$ is neglected in (2.4) the resulting equation has solutions of the form $\zeta^{1/2}\mathscr{C}_{u\alpha}(u\zeta^{1/2})$ when $\zeta>0$, where $\mathscr{C}$ denotes the Bessel functions J, Y, or any combination of them; when $\zeta<0$, solutions are $|\zeta|^{1/2}\mathscr{L}_{u\alpha}(u|\zeta|^{1/2})$, where $\mathscr{L}$ denotes the modified Bessel functions I, K, or any combination of them. The solutions corresponding to J, Y and to I, K each constitute linearly independent pairs. For the purposes of our error analysis we shall need to select solutions which satisfy the more demanding restriction that they constitute numerically satisfactory pairs (Olver (1974, p. 154)). The solutions corresponding to J, Y and to I, K do each constitute numerically satisfactory pairs in $\zeta>0$ and $\zeta<0$ respectively. When ζ is complex, neither pair is satisfactory.

When account is taken of the term $\psi(\alpha,\zeta)/\zeta$ in (2.4), the functions we have just discussed are only the first terms in asymptotic expansions of solutions of (2.4): we seek expansions of the form

$$\zeta^{1/2}\mathscr{C}_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{\infty}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{\zeta}{u}\mathscr{C}'_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{\infty}\frac{B_s(\alpha,\zeta)}{u^{2s}}\qquad(\zeta>0),\tag{2.7}$$

where $\mathscr{C}$ denotes J, Y or any combination of these. Formal substitution of this series into (2.4) yields

$$\zeta^{1/2}\mathscr{C}_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{\infty}\frac{C_s}{u^{2s}}+u\zeta\mathscr{C}'_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{\infty}\frac{D_s}{u^{2s}}=0,$$

where

$$C_s=\zeta^{-1}A'_s+A''_s-\zeta^{-1}\psi A_s-\frac{1}{2}\zeta^{-1}B_s-B'_s-\alpha^2\zeta^{-1}B'_s,$$

$$D_s=\zeta^{-1}A'_s+\zeta^{-1}B'_{s-1}+B''_{s-1}-\zeta^{-1}\psi B_{s-1}.$$

In these and subsequent expressions, quantities with negative indices are to be understood to be identically zero. The differential equation can then be formally satisfied provided $C_s=0$, $D_s=0$ for $s=0,1,2,\cdots$. Thus we require

$$|\zeta-\alpha^2|^{1/2}\left(|\zeta-\alpha^2|^{1/2}B_s\right)'=\zeta A_s''+A_s'-\psi A_s, \tag{2.8a}$$

$$A_s'=-\left(\zeta B_{s-1}'\right)'+\psi B_{s-1}. \tag{2.8b}$$

These relations can be satisfied by

$$B_s(\alpha,\zeta)=|\zeta-\alpha^2|^{-1/2}\int_{\alpha^2}^{\zeta}|\xi-\alpha^2|^{-1/2}\big(\xi A_s''(\alpha,\xi)+A_s'(\alpha,\xi) -\psi(\alpha,\xi)A_s(\alpha,\xi)\big)\,d\xi, \tag{2.9a}$$

$$A_s(\alpha,\zeta)=-\zeta B_{s-1}'(\alpha,\zeta)+\int_{\alpha^2}^{\zeta}\psi(\alpha,\xi)B_{s-1}(\alpha,\xi)\,d\xi+\lambda_s. \tag{2.9b}$$

In (2.9b), λ_s is an arbitrary constant of integration; the corresponding constant in (2.9a) has been set equal to zero to ensure that $B_s(\zeta)$ is differentiable at $\zeta=\alpha^2$. Without loss of generality, we take $\lambda_0=1$, so that $A_0(\alpha,\zeta)\equiv 1$. Relations (2.9a, b) then successively determine $B_0,A_1,B_1,A_2,\cdots$. The remaining arbitrary constants $\lambda_1,\lambda_2,\cdots$ may be assigned values by reference to the specific properties of that solution whose asymptotic expansion is being found. It follows immediately from (2.9a, b) that $A_s(\alpha,\zeta)$, $B_s(\alpha,\zeta)$ are infinitely differentiable functions of ζ in the interval $0\leqq\zeta<\zeta_2$ for each value of α (cf. Olver (1974, p. 410)).

When $\zeta<0$, we seek formal series solutions of the form

$$|\zeta|^{1/2}\mathscr{L}_{u\alpha}\left(u|\zeta|^{1/2}\right)\sum_{s=0}^{\infty}\frac{A_s(\zeta)}{u^{2s}}+\frac{|\zeta|}{u}\mathscr{L}_{u\alpha}\left(u|\zeta|^{1/2}\right)\sum_{s=0}^{\infty}\frac{B_s(\zeta)}{u^{2s}} \tag{2.10}$$

where $\mathscr{L}$ denotes I, K or any combination of these. One finds that the coefficients $A_s(\zeta)$, $B_s(\zeta)$ in (2.10) satisfy the same differential equations (2.8a, b) as do the coefficients in the formal series solution (2.7): we define $A_s(\zeta)$, $B_s(\zeta)$ for $\zeta<0$ by analytic continuation from $\zeta<0$, so that (2.9a, b) are valid in $\zeta<0$ too. (Thus $A_s(\zeta)$, $B_s(\zeta)$ are infinitely differentiable in $\zeta_1<\zeta<\zeta_2$.)

3. Error bounds (real variables). To verify that the series (2.7), (2.10) are uniformly valid asymptotic expansions of an exact solution $W(u,\alpha,\zeta)$ of (2.4) we terminate the series after a finite number of terms and then find an upper bound for the error. Thus when $\zeta>0$, we write

$$W(u,\alpha,\zeta)=\zeta^{1/2}\mathscr{C}_{u\alpha}\left(u\zeta^{1/2}\right)\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{\zeta}{u}\mathscr{C}'_{u\alpha}\left(u\zeta^{1/2}\right)\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}}+\varepsilon_{2n+1}(u,\alpha,\zeta), \tag{3.1}$$

where $\mathscr{C}$ denotes J, Y or a combination of them. The standard method of obtaining a bound for ε_{2n+1} is first to find a differential equation for ε_{2n+1}; then this differential equation is re-expressed as a Volterra integral equation, a bound for the solution of which may be found by the method of successive approximations (Olver (1974, p. 141)).

The differential equation for ε_{2n+1} is readily found to be

$$(3.2)\quad \varepsilon''_{2n+1}+\left\{-u^2\left(\frac{\alpha^2}{4\zeta^2}-\frac{1}{4\zeta}\right)+\frac{1}{4\zeta^2}\right\}\varepsilon_{2n+1}$$
$$=-\frac{1}{u^{2n}}\left|\zeta-\alpha^2\right|^{1/2}\left\{\left|\zeta-\alpha^2\right|^{1/2}B_n(\alpha,\zeta)\right\}'\zeta^{-1/2}\mathscr{C}_{u\alpha}(u\zeta^{1/2})+\frac{\psi}{\zeta}\varepsilon_{2n+1},$$

where the primes denote ζ-derivatives. Given some arbitrary value $\tilde{\zeta}$ $(0\leqq\tilde{\zeta}\leqq\zeta_2)$, consider that solution of (3.2) for which $\varepsilon_{2n+1}(u,\alpha,\tilde{\zeta})=\varepsilon'_{2n+1}(u,\alpha,\tilde{\zeta})=0$: except possibly when $\tilde{\zeta}=0$ or ∞, it satisfies the integral equation

$$(3.3)\quad \varepsilon_{2n+1}(u,\alpha,\zeta)=\int_{\tilde{\zeta}}^{\zeta}K(\zeta,\xi)\left[-\frac{1}{u^{2n}}\left\{\left|\xi-\alpha^2\right|^{1/2}B_n(\alpha,\xi)\right\}'\xi^{1/2}\mathscr{C}_{u\alpha}(u\xi^{1/2})\right.$$
$$\left.+\left|\xi-\alpha^2\right|^{-1/2}\psi(\alpha,\xi)\varepsilon_{2n+1}(u,\alpha,\xi)\right]d\xi$$

where

$$K(\zeta,\xi)=\pi\left|\xi-\alpha^2\right|^{1/2}\left\{\zeta^{1/2}Y_{u\alpha}(u\zeta^{1/2})\xi^{-1/2}J_{u\alpha}(u\xi^{1/2})\right.$$
$$\left.-\zeta^{1/2}J_{u\alpha}(u\zeta^{1/2})\xi^{-1/2}Y_{u\alpha}(u\xi^{1/2})\right\}.$$

Bounds for ε_{2n+1} and ε'_{2n+1} can now be found by using a standard theorem given by Olver (1974, p. 219).

To use this theorem, we introduce a modulus function $M_\nu(x)$, a phase function $\theta_\nu(x)$, and a weight function $E_\nu(x)$ which are related by

$$E_\nu(x)J_\nu(x)=M_\nu(x)\cos\theta_\nu(x),\qquad E_\nu^{-1}(x)Y_\nu(x)=M_\nu(x)\sin\theta_\nu(x).$$

Following Olver (1974, p. 437) we define $E_\nu(x)$ as follows. Let $x=X_\nu$ be the smallest positive root of the equation

$$(3.4)\qquad J_\nu(x)=-Y_\nu(x).$$

Then define

$$E_\nu(x)=\begin{cases}\left(-Y_\nu(x)/J_\nu(x)\right)^{1/2}, & 0<x\leqq X_\nu,\\ 1, & x\geqq X_\nu.\end{cases}$$

As Olver shows, $E_\nu(x)$ is a monotonically nonincreasing function of x. One finds

$$M_\nu(x)=\begin{cases}\left(-2J_\nu(x)Y_\nu(x)\right)^{1/2}, & 0<x\leqq X_\nu,\\ \left(J_\nu^2(x)+Y_\nu^2(x)\right)^{1/2}, & x\geqq X_\nu,\end{cases}$$

$$\theta_\nu(x)=\begin{cases}-\pi/4, & 0<x\leqq X_\nu,\\ \tan^{-1}\left(Y_\nu(x)/J_\nu(x)\right), & x\geqq X_\nu.\end{cases}$$

The branch of the inverse tangent is chosen so that $\theta_\nu(x)$ is continuous. We also introduce modulus and phase functions for $J_\nu'(x)$, $Y_\nu'(x)$ as follows. Define

$$E_\nu(x)J_\nu'(x)=N_\nu(x)\cos\omega_\nu(x), \qquad E_\nu^{-1}(x)Y_\nu'(x)=N_\nu(x)\sin\omega_\nu(x),$$

where $E_\nu(x)$ is unchanged. Thus

$$N_\nu(x)=\begin{cases}\left(\dfrac{Y_\nu^2(x)J_\nu'^2(x)+J_\nu^2(x)Y_\nu'^2(x)}{-J_\nu(x)Y_\nu(x)}\right)^{1/2}, & 0<x\leqq X_\nu,\\ \left(J_\nu'^2(x)+Y_\nu'^2(x)\right)^{1/2}, & x\geqq X_\nu,\end{cases}$$

$$\omega_\nu(x)=\begin{cases}\tan^{-1}\left(-\dfrac{J_\nu(x)Y_\nu'(x)}{Y_\nu(x)J_\nu'(x)}\right), & 0<x\leqq X_\nu,\\ \tan^{-1}\left(\dfrac{Y_\nu'(x)}{J_\nu'(x)}\right), & x\geqq X_\nu.\end{cases}$$

The branches of the inverse tangents are chosen so that $\omega_\nu(x)$ is continuous, and $\omega_\nu(x)\to-\pi/4$ as $x\to0$ ($\nu>0$) or $\omega_\nu(x)\to-\pi/2$ as $x\to0$ ($\nu=0$).

Before stating the theorem on error bounds, we introduce the following constants:

$$\begin{aligned}\kappa^+&=\sup\left\{\pi|x^2-\nu^2|^{1/2}M_\nu^2(x)\right\},\\ \mu_1^+&=\sup\left\{\pi|x^2-\nu^2|^{1/2}E_\nu(x)M_\nu(x)|J_\nu(x)|\right\},\\ \mu_2^+&=\sup\left\{\pi|x^2-\nu^2|^{1/2}E_\nu^{-1}(x)M_\nu(x)|Y_\nu(x)|\right\},\end{aligned}\tag{3.5}$$

each supremum being evaluated over $x>0$ and $\nu\geq0$. In Appendix B we show that κ^+ exists and is finite. The proofs for μ_1^+ and μ_2^+ are similar. Numerical calculations indicate that $\kappa^+=2.08\cdots$ with the supremum being achieved as $x,\nu\to\infty$ such that $x\sim\nu-(1.33\cdots)^{1/3}\nu^{1/3}$ (see part (d) of Lemma 2, Appendix B), and that $\mu_1^+=\mu_2^+=2$ with the supremum being achieved as $x\to\infty$ for fixed ν.

THEOREM 1. *With the conditions described in* §§1 *and* 2, *equation* (2.4) *has, for each pair of values of* u *and* α *and each nonnegative integer* n, *solutions* $W_{2n+1,1}(u,\alpha,\zeta)$, $W_{2n+1,2}(u,\alpha,\zeta)$ *which are infinitely differentiable in* $0<\zeta<\zeta_2$ *and satisfy*

$$W_{2n+1,1}(u,\alpha,\zeta)=\zeta^{1/2}J_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{\zeta}{u}J_{u\alpha}'(u\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}}+\varepsilon_{2n+1,1}(u,\alpha,\zeta),\tag{3.6}$$

$$W_{2n+1,2}(u,\alpha,\zeta)=\zeta^{1/2}Y_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{\zeta}{u}Y_{u\alpha}'(u\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}}+\varepsilon_{2n+1,2}(u,\alpha,\zeta),\tag{3.7}$$

where

(3.8)

$$\frac{|\varepsilon_{2n+1,1}(u,\alpha,\zeta)|}{\zeta^{1/2}M_{u\alpha}(u\zeta^{1/2})}, \qquad \frac{|\partial\varepsilon_{2n+1,1}(u,\alpha,\zeta)/\partial\zeta|}{(1/2)uN_{u\alpha}(u\zeta^{1/2})+(1/2)\zeta^{-1/2}M_{u\alpha}(u\zeta^{1/2})}$$

$$\leqq \frac{1}{u^{2n+1}}\mu_1^+ E_{u\alpha}^{-1}(u\zeta^{1/2})\mathscr{V}_{0,\zeta}\left\{|\xi-\alpha^2|^{1/2}B_n(\xi)\right\}\exp\left(\frac{\kappa^+}{u}\mathscr{V}_{0,\zeta}\left\{|\xi-\alpha^2|^{1/2}B_0(\xi)\right\}\right),$$

(3.9)

$$\frac{|\varepsilon_{2n+1,2}(u,\alpha,\zeta)|}{\zeta^{1/2}M_{u\alpha}(u\zeta^{1/2})}, \qquad \frac{|\partial\varepsilon_{2n+1,2}(u,\alpha,\zeta)/\partial\zeta|}{(1/2)uN_{u\alpha}(u\zeta^{1/2})+(1/2)\zeta^{-1/2}M_{u\alpha}(u\zeta^{1/2})}$$

$$\leqq \frac{1}{u^{2n+1}}\mu_2^+ E_{u\alpha}(u\zeta^{1/2})\mathscr{V}_{\zeta_2,\zeta}\left\{|\xi-\alpha^2|^{1/2}B_n(\xi)\right\}\exp\left(\frac{\kappa^+}{u}\mathscr{V}_{\zeta_2,\zeta}\left\{|\xi-\alpha^2|^{1/2}B_0(\xi)\right\}\right).$$

Here and subsequently, we use the symbol $\mathscr{V}$ to denote the variational operator, a formal definition of which may be found in Olver (1974, p. 27).

These results are proved following the standard method referenced below equation (3.3). An essential feature of the proofs is the observation that

$$E_{u\alpha}(u\zeta^{1/2}) \leqq E_{u\alpha}(u\xi^{1/2}) \quad \text{for } 0<\xi<\zeta. \tag{3.10}$$

In the notation of (3.3), choose $\tilde{\zeta}=0$, $\mathscr{C}\equiv J$ to arrive at (3.6), (3.8) and $\tilde{\zeta}=\zeta_2$, $\mathscr{C}\equiv Y$ to arrive at (3.7), (3.9). When $\zeta_2=\infty$, (3.9) is meaningful provided the variations of $(\zeta-\alpha^2)^{1/2}B_s(\zeta)$ converge at infinity. A sufficient condition for this is that as $\zeta\to\infty$, the ζ-derivatives $\psi^{(s)}(\alpha,\zeta)$ are $O(\zeta^{-1/2-s-\sigma})$ where σ is some positive constant (cf. Olver (1974, p. 445, exercise 4.2)). If the variations fail to converge, $\tilde{\zeta}$ has to be chosen to be finite, $\tilde{\zeta}_0$ say, and the results of the theorem then apply to the interval $0<\zeta<\tilde{\zeta}_0$.

The bounds (3.8), (3.9) can be used to deduce the asymptotic nature of the expansions (2.7). Consider (3.8). In the first place, we see at once that

$$\varepsilon_{2n+1,1}(u,\alpha,\zeta)=\zeta^{1/2}J_{u\alpha}(u\zeta^{1/2})O(\zeta) \quad \text{as } \zeta\to 0 \tag{3.11}$$

from which we deduce that the exact solution $W_{2n+1,1}(u,\alpha,\zeta)$ is recessive as $\zeta\to 0$. To within a multiplicative constant, therefore, $W_{2n+1,1}(u,\alpha,\zeta)$ is uniquely defined. Now consider the asymptotic nature of the approximation as $u\to\infty$. Since the variations, $\mathscr{V}_{0,\zeta}$, that occur in (3.8) are bounded for each α, we deduce

$$\varepsilon_{2n+1,1}(u,\alpha,\zeta)=\zeta^{1/2}E_{u\alpha}^{-1}(u\zeta^{1/2})M_{u\alpha}(u\zeta^{1/2})O(u^{-2n-1}) \quad \text{as } u\to\infty$$

uniformly in the ζ-interval $(0,\zeta_2)$, provided $\zeta_2<\infty$, and the α-interval $[0,\alpha_0']$, where α_0' is any constant satisfying $0<\alpha_0'<\alpha_0$. (The uniformity is a consequence of Lemma 1.) This result can be used to show that (2.7), with $\mathscr{C}=J$, is a uniformly valid compound asymptotic expansion of $W_{2n+1,1}(u,\alpha,\zeta)$. To do so, express

$$E_\nu^{-1}(x)M_\nu(x)=a_\nu(x)J_\nu(x)+b_\nu(x)xJ_\nu'(x),$$

where

$$a_\nu(x)=\begin{cases}2^{1/2}, & 0<x\leqq X_\nu,\\ -\frac{1}{2}\pi x Y_\nu'(x)M_\nu(x), & x>X_\nu,\end{cases}$$

and

$$b_\nu(x)=\begin{cases}0, & 0<x\leqq X_\nu,\\ \frac{1}{2}\pi Y_\nu(x)M_\nu(x), & x>X_\nu.\end{cases}$$

It then suffices to observe that $a_\nu(x)$ and $b_\nu(x)$ are uniformly bounded for $\nu\geqq 0$, $x>0$. (This can be demonstrated from considerations analogous to those discussed in the proof of Lemma 2 in Appendix B.)

The other solution, $W_{2n+1,2}(u,\alpha,\zeta)$, is dominant as $\zeta\to 0$: it must be identified by reference to its properties elsewhere (e.g. as $\zeta\to\zeta_2$). Proceeding as above, one can show that (2.7), with $\mathscr{C}=Y$, is a compound asymptotic expansion of $W_{2n+1,2}(u,\alpha,\zeta)$, uniformly valid as $u\to\infty$ in the ζ-interval $(0,\zeta_2)$ and the α-interval $[0,\alpha_0']$.

There are two further remarks to be made about (3.6), (3.7). The first is that there are solutions $W_1(u,\alpha,\zeta)$ and $W_2(u,\alpha,\zeta)$ which are independent of n and have the infinite series (2.7), with $\mathscr{C}=J$, Y respectively, as their compound asymptotic expansions. (This can be shown by the method of Olver (1974, Chap. 10, §6).) The second is that when $\zeta_2=\infty$, the expansions will be *uniformly* valid in the ζ-interval $(0,\infty)$ provided the variations of $(\zeta-\alpha^2)^{1/2}B_s(\zeta)$ converge at infinity; sufficient conditions for this to be true have been already noted.

When $\zeta<0$ the observation that $I_{u\alpha}(u|\zeta|^{1/2})$ and $K_{u\alpha}(u|\zeta|^{1/2})$ are respectively monotonically increasing and decreasing functions of $|\zeta|$ for fixed u, α leads to the following result.

THEOREM 2. *With the conditions described in* §§1 *and* 2, *equation* (2.4) *has, for each pair of values of* u *and* α *and each nonnegative integer* n, *solutions* $W_{2n+1,3}(u,\alpha,\zeta)$, $W_{2n+1,4}(u,\alpha,\zeta)$ *which are infinitely differentiable in* $\zeta_1<\zeta<0$ *and satisfy*

$$W_{2n+1,3}(u,\alpha,\zeta)=|\zeta|^{1/2}I_{u\alpha}\big(u|\zeta|^{1/2}\big)\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{|\zeta|}{u}I'_{u\alpha}\big(u|\zeta|^{1/2}\big)\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}}+\varepsilon_{2n+1,3}(u,\alpha,\zeta), \tag{3.12}$$

$$W_{2n+1,4}(u,\alpha,\zeta)=|\zeta|^{1/2}K_{u\alpha}\big(u|\zeta|^{1/2}\big)\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{|\zeta|}{u}K'_{u\alpha}\big(u|\zeta|^{1/2}\big)\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}}+\varepsilon_{2n+1,4}(u,\alpha,\zeta), \tag{3.13}$$

where

$$\frac{|\varepsilon_{2n+1,3}(u,\alpha,\zeta)|}{|\zeta|^{1/2}I_{u\alpha}\big(u|\zeta|^{1/2}\big)},\quad \frac{|\partial\varepsilon_{2n+1,3}(u,\alpha,\zeta)/\partial\zeta|}{(1/2)(1+u\alpha)|\zeta|^{-1/2}I_{u\alpha}\big(u|\zeta|^{1/2}\big)+uK^{-1}_{u\alpha}\big(u|\zeta|^{1/2}\big)K_{u\alpha+1}\big(u|\zeta|^{1/2}\big)I_{u\alpha}\big(u|\zeta|^{1/2}\big)} \tag{3.14}$$

$$\leqq\frac{1}{u^{2n+1}}\kappa^{-}\mathscr{V}_{0,\zeta}\big\{|\xi-\alpha^2|^{1/2}B_n(\xi)\big\}\exp\Big(\frac{\kappa^{-}}{u}\mathscr{V}_{0,\zeta}\big\{|\xi-\alpha^2|^{1/2}B_0(\xi)\big\}\Big),$$

$$\frac{|\varepsilon_{2n+1,4}(u,\alpha,\zeta)|}{|\zeta|^{1/2}K_{u\alpha}\big(u|\zeta|^{1/2}\big)},\quad \frac{|\partial\varepsilon_{2n+1,4}(u,\alpha,\zeta)/\partial\zeta|}{(1/2)(1+u\alpha)|\zeta|^{-1/2}K_{u\alpha}\big(u|\zeta|^{1/2}\big)+uK_{u\alpha+1}\big(u|\zeta|^{1/2}\big)} \tag{3.15}$$

$$\leqq\frac{1}{u^{2n+1}}\kappa^{-}\mathscr{V}_{\zeta_1,\zeta}\big\{|\xi-\alpha^2|^{1/2}B_n(\xi)\big\}\exp\Big(\frac{\kappa^{-}}{u}\mathscr{V}_{\zeta_1,\zeta}\big\{|\xi-\alpha^2|^{1/2}B_0(\xi)\big\}\Big).$$

Here,

$$\kappa^- = \sup\left\{2(x^2+\nu^2)^{1/2} I_\nu(x) K_\nu(x)\right\}, \tag{3.16}$$

the supremum being evaluated over $x>0$ and $\nu \geqq 0$. The existence of the supremum is discussed in Appendix B. Numerical calculations indicate $\kappa^- = 1.0667\cdots$, the supremum being achieved when $x = 1.07501\cdots$, $\nu = 0$.

The bounds (3.14), (3.15) can be used to deduce the asymptotic nature of the expansions (2.10); the discussion is similar to that which follows Theorem 1. Thus the solutions $W_{2n+1,3}(u,\alpha,\zeta)$ and $W_{2n+1,4}(u,\alpha,\zeta)$ are respectively recessive and dominant at $\zeta = 0$. With $\mathscr{L} = I$, K, (2.10) is a uniformly valid compound asymptotic expansion as $u \to \infty$ of $W_{2n+1,3}(u,\alpha,\zeta)$ and $W_{2n+1,4}(u,\alpha,\zeta)$ respectively. There are solutions $W_3(u,\alpha,\zeta)$, $W_4(u,\alpha,\zeta)$ independent of n for which (2.10), with $\mathscr{L} = I$, K, respectively, is a compound asymptotic expansion. When $\zeta_1 = -\infty$, the theorem will be meaningful and the expansions will be uniformly valid in the ζ-interval $(-\infty, 0)$ if as $\zeta \to -\infty$, the ζ-derivatives $\psi^{(s)}(\alpha,\zeta)$ are $O(|\zeta|^{-1/2-s-\sigma})$ for some positive constant σ.

4. Legendre functions of large order and degree: real variables. We shall illustrate the results of the previous two sections by constructing asymptotic expansions for $\nu \to \infty$ of solutions for the associated Legendre equation which are uniformly valid for $x \geqq 0$, $0 \leqq \mu/(\nu+\frac{1}{2}) \leqq 1-\delta$ for arbitrarily small $\delta > 0$. (See Olver 1975c, p. 125).) Corresponding results for negative values of ν, μ, or x may be obtained by using the appropriate connection formulae. Our choice of solutions is $P_\nu^{-\mu}(x)$, $Q_\nu^\mu(x)$ in $x>1$ and the Ferrers functions $\mathrm{P}_\nu^{-\mu}(x)$, $\mathrm{Q}_\nu^\mu(x)$ in $x<1$; our notation is that of Olver (1974, Chap. 5, definitions (12.04), (13.14), (15.01), (15.02)) respectively.

The functions $(x^2-1)^{1/2}P_\nu^{-\mu}(x)$, $(x^2-1)^{1/2}Q_\nu^\mu(x)$, $(1-x^2)^{1/2}\mathrm{P}_\nu^{-\mu}(x)$, $(1-x^2)^{1/2}\mathrm{Q}_\nu^\mu(x)$ each satisfy

$$\frac{d^2w}{dx^2} = \left\{\frac{\mu^2-1}{(1-x^2)^2} - \frac{\nu(\nu+1)}{1-x^2}\right\} w. \tag{4.1}$$

To within multiplicative constants, these solutions may be identified by their properties that $\mathrm{P}_\nu^{-\mu}(x)$, $P_\nu^{-\mu}(x)$ are recessive at $x=1$ for $\mu \geqq 0$ and $Q_\nu^\mu(x)$, $\mathrm{Q}_\nu^\mu(x)$ are recessive at $x=\infty$ for $\nu \geqq -\frac{1}{2}$. In terms of our previous notation, we define

$$u = \nu + \frac{1}{2}, \quad \alpha = \frac{\mu}{(\nu+1/2)}, \quad f(x) = \frac{\alpha^2}{(1-x^2)^2} - \frac{1}{1-x^2}, \quad g(x) = \frac{-1}{(1-x^2)^2} + \frac{1}{4(1-x^2)}.$$

The singular point is at $x=1$ and the turning point at $x_t = (1-\alpha^2)^{1/2}$. In order that the turning point be real, it is necessary for us to demand $\alpha < 1$: this is the reason for our requiring $\mu < \nu + \frac{1}{2}$.

The x-ζ transformations (2.2a, b) are, for this problem,

$$\int_{\alpha^2}^{\zeta} \frac{(\xi-\alpha^2)^{1/2}}{2\xi}\,d\xi = -\int_{(1-\alpha^2)^{1/2}}^{x} \frac{(1-\alpha^2-t^2)^{1/2}}{1-t^2}\,dt \tag{4.2a}$$

$$\left(\zeta > \alpha^2 \text{ or } x < (1-\alpha^2)^{1/2}\right),$$

$$\int_{\alpha^2}^{\zeta} \frac{(\alpha^2-\xi)^{1/2}}{2\xi}\,d\xi = -\int_{(1-\alpha^2)^{1/2}}^{x} \frac{(t^2-1+\alpha^2)^{1/2}}{1-t^2}\,dt \tag{4.2b}$$

$$\left(\zeta < \alpha^2 \text{ or } x > (1-\alpha^2)^{1/2}\right),$$

the latter integrals being understood to be the Cauchy principal values in $\zeta<0$ or $x>1$ (for $\alpha\neq 0$). The integrals on the right-hand side of (4.2a, b) may be evaluated. For example (4.2b) is

$$\ln\frac{x+(x^2-1+\alpha^2)^{1/2}}{(1-\alpha^2)^{1/2}}+\frac{\alpha}{2}\ln\frac{|1-x|}{1+x}\,\frac{x+1-\alpha^2-\alpha(x^2-1+\alpha^2)^{1/2}}{x-1+\alpha^2+\alpha(x^2-1+\alpha^2)^{1/2}} \tag{4.3}$$

(see, for example, Gradshteyn and Ryzhik (1980, p. 81)). With the new dependent variable W defined by

$$w=\left(\frac{\zeta-\alpha^2}{1-\alpha^2-x^2}\right)^{1/4}\left(\frac{1-x^2}{2\zeta}\right)^{1/2}W$$

one finds that the differential equation (4.1) transforms to

$$\frac{d^2W}{d\zeta^2}=\left\{u^2\left(\frac{\alpha^2}{4\zeta^2}-\frac{1}{4\zeta}\right)-\frac{1}{4\zeta^2}+\frac{\psi(\alpha,\zeta)}{\zeta}\right\}W, \tag{4.4}$$

where

(4.5)

$$\psi(\alpha,\zeta)=\frac{1}{16}(\zeta-\alpha^2)^{-2}\left[\zeta+4\alpha^2+\frac{1-x^2}{\zeta}\left(\frac{\zeta-\alpha^2}{1-\alpha^2-x^2}\right)^3\{(-4\alpha^2+1)x^2+(\alpha^4-1)\}\right].$$

Before proceeding to establish the asymptotic nature of the solutions of (4.4), it is convenient at this stage to describe the nature of the x-ζ transformation near $x=1$ and $x=\infty$. As $x\to 1$, one finds that $\zeta\to 0$ such that

$$1-x=\frac{e^2}{2(1+\alpha)^{1+1/\alpha}(1-\alpha)^{1-1/\alpha}}\zeta+O(\zeta^2). \tag{4.6}$$

We remark that this result is uniformly valid for all values of α (see proof of Lemma 1 in Appendix A); when $\alpha=0$ the limiting form of (4.6), $1-x\sim\frac{1}{2}\zeta$, applies. As $x\to\infty$, one finds $\zeta\to-\infty$ such that

$$x=\frac{1}{2}(1+\alpha)^{1/2+\alpha/2}(1-\alpha)^{1/2-\alpha/2}\exp|\zeta|^{1/2}\left\{1+O\left(|\zeta|^{-1/2}\right)\right\}. \tag{4.7}$$

These results follow readily from (2.3) and (4.3).

We shall now find uniform asymptotic expansions for $\mathrm{P}_\nu^{-\mu}(x)$ in $0\leqq x<1$ and for $P_\nu^{-\mu}(x)$ in $x>1$. Both solutions are recessive as $x\to 1$. In particular

$$\mathrm{P}_\nu^{-\mu}(x)=\frac{(1-x)^{\mu/2}}{2^{\mu/2}\Gamma(\mu+1)}(1+o(1))\quad\text{as } x\to 1 \tag{4.8}$$

(Olver (1974, p. 186)). It follows from (3.11) that for each nonnegative integer n,

$$\mathrm{P}_\nu^{-\mu}(x)=c_{2n+1,1}\left(\frac{\zeta-\alpha^2}{1-\alpha^2-x^2}\right)^{1/4}\zeta^{-1/2}W_{2n+1,1}(u,\alpha,\zeta). \tag{4.9}$$

for some constant $c_{2n+1,1}$. The coefficient $c_{2n+1,1}$ can be evaluated by comparing (4.8) with the behaviour of $W_{2n+1,1}(u,\alpha,\zeta)$ as $\zeta\to 0$. The behaviour of $J_{u\alpha}(u\zeta^{1/2})$ near $\zeta=0$ implies that

$$(4.10)\quad W_{2n+1,1}(u,\alpha,\zeta)=\frac{u^{u\alpha}}{2^{u\alpha}\Gamma(1+u\alpha)}\zeta^{1/2+u\alpha/2}\cdot\left(1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}\right)\quad\text{as }\zeta\to 0,$$

where $A_s(\alpha,\zeta)$, $B_s(\alpha,\zeta)$ are defined by (2.9a, b). We shall not attempt to define the arbitrary constants λ_s which appear in (2.9b) at this stage but, following Thorne (1957b), determine them recursively (see (6.8)). It follows from (4.6), (4.8)–(4.10) that

$$(4.11)\quad c_{2n+1,1}=e^{\mu}\left(\nu+\frac{1}{2}+\mu\right)^{-\nu/2-1/4-\mu/2}\left(\nu+\frac{1}{2}-\mu\right)^{\nu/2+1/4-\mu/2}\cdot\left(1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}\right)^{-1}.$$

We subsequently derive another expression for $c_{2n+1,1}$ (equation (6.10)).

A powerful check on the validity of (4.9) is provided by evaluating left- and right-hand sides at $x=0$. The left-hand side yields (Olver (1974, p. 187))

$$(4.12)\quad \mathrm{P}_{\nu}^{-\mu}(0)=2^{-\mu}\pi^{-1/2}\cos\left(\tfrac{1}{2}\pi\nu-\tfrac{1}{2}\pi\mu\right)\Gamma\left(\tfrac{1}{2}\nu+\tfrac{1}{2}-\tfrac{1}{2}\mu\right)/\Gamma\left(\tfrac{1}{2}\nu+1+\tfrac{1}{2}\mu\right).$$

By using the Liouville–Green expansion of $J_{\mu}((\nu+\frac{1}{2})\zeta^{1/2})$ for large argument and order, one can show that to leading order the right-hand side of (4.9) yields, for $n=0$,

$$(4.13)\quad c_{1,1}(1-\alpha^2)^{-1/4}\left(\frac{2}{\pi(\nu+1/2)}\right)^{1/2}\cos\left(\tfrac{1}{2}\pi\nu-\tfrac{1}{2}\pi\mu\right).$$

When Stirling's formula is used in (4.12), it is found that to leading order, (4.12) and (4.13) are indeed the same. This provides independent verification of the correctness of the asymptotic theory.

In the interval $x>1$, one can show in a similar manner that, at least pointwise,

$$(4.14)\quad P_{\nu}^{-\mu}(x)=c_{2n+1,3}\left(\frac{\zeta-\alpha^2}{1-\alpha^2-x^2}\right)^{1/4}|\zeta|^{-1/2}W_{2n+1,3}(u,\alpha,\zeta),$$

where $c_{2n+1,3}=c_{2n+1,1}$. Actually, it can be shown that (4.14) is *uniformly* valid in $x>1$: it follows from (4.5)–(4.7) that $\psi^{(s)}(\alpha,\zeta)=O(|\zeta|^{-s-1})$ as $\zeta\to-\infty$, and as we remarked in §3, this guarantees uniform validity.

Next, we find a uniform asymptotic expansion for the function $Q_{\nu}^{\mu}(x)$ in $x>1$. Its distinguishing property is that it is recessive as $x\to\infty$. In applying Theorem 2 to the function $Q_{\nu}^{\mu}(x)$ we first observe that since $\psi^{(s)}(\alpha,\zeta)=O(|\zeta|^{-s-1})$ as $\zeta\to-\infty$, the theorem is meaningful for $\zeta_1=-\infty$, and the expansions are uniformly valid in $\zeta<0$. Since $I_{u\alpha}(u|\zeta|^{1/2})$, $K_{u\alpha}(u|\zeta|^{1/2})$ are respectively dominant and recessive as $\zeta\to-\infty$, we deduce that

$$(4.15)\quad Q_{\nu}^{\mu}(x)=c_{2n+1,4}\left(\frac{\zeta-\alpha^2}{1-\alpha^2-x^2}\right)^{1/4}|\zeta|^{-1/2}W_{2n+1,4}(u,\alpha,\zeta),\qquad x>1$$

for some constant $c_{2n+1,4}$. We evaluate $c_{2n+1,4}$ by considering the behaviour of left- and right-hand sides of (4.15) as $x\to 1$. For the left-hand side we have (Olver (1974, Chap. 5, (12.21) and (13.14)))

$$Q_\nu^\mu(x)=e^{\mu\pi i}2^{\mu/2-1}\Gamma(\mu)(x-1)^{-\mu/2}(1+o(1)) \quad \text{as } x\to 1. \tag{4.16}$$

The behaviour of $K_{u\alpha}(u|\zeta|^{1/2})$ near $\zeta=0$ implies that on the right-hand side,

(4.17)

$$W_{2n+1,4}(u,\alpha,\zeta)=\frac{2^{u\alpha-1}\Gamma(u\alpha)}{u^{u\alpha}}|\zeta|^{1/2-u\alpha/2}$$
$$\cdot\left(1-\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}+\delta_{2n+1,4}+o(1)\right) \quad \text{as } \zeta\to 0,$$

for $\alpha>0$, where $\delta_{2n+1,4}$ is a constant bounded by

$$|\delta_{2n+1,4}|\leqq\frac{1}{u^{2n+1}}\kappa^-\mathscr{V}_{0,-\infty}\left\{|\xi-\alpha^2|^{1/2}B_n(\xi)\right\}\exp\left(\frac{\kappa^-}{u}\mathscr{V}_{0,-\infty}\left\{|\xi-\alpha^2|^{1/2}B_0(\xi)\right\}\right).$$

It follows from (4.6), (4.15)–(4.17) that

$$c_{2n+1,4}=e^{-\mu+\mu\pi i}\left(\nu+\frac{1}{2}+\mu\right)^{\nu/2+1/4+\mu/2}\left(\nu+\frac{1}{2}-\mu\right)^{-\nu/2-1/4+\mu/2} \tag{4.18}$$
$$\cdot\left(1-\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}+\delta_{2n+1,4}\right)^{-1}.$$

A continuity argument shows that (4.18) is appropriate for $\alpha=0$ also. We subsequently derive another expression for $c_{2n+1,4}$ (equation (6.11)).

It remains to find a uniform asymptotic expansion for $\mathrm{Q}_\nu^{-\mu}(x)$ in $0\leqq x<1$. (The result is simpler than that for $\mathrm{Q}_\nu^\mu(x)$.) One could arrive at a result following the method described by Olver (1974, Chap. 12) in dealing with the corresponding problem when μ is not large: effectively this means taking $\zeta_2=\zeta(0)$ in (3.9). As Olver remarks, this method has disadvantages, and we shall leave the derivation of the result to the complex variable theory of §6 (see (6.12)).

Our results for the Legendre functions, here and in §6, are more general than those given by Olver (1974, Chap. 12) or Thorne (1957b). They may be regarded as complementary to the results of Olver (1975b), which are uniformly valid in the interval $-1<x<1$.

5. Expansions for complex argument. The definition of the x-ζ transformation given in (2.2a, b) is no longer appropriate when x is supposed to be a complex variable. Now we replace x by z and define

$$\int_{\alpha^2}^{\zeta}\frac{(\xi-\alpha^2)^{1/2}}{2\xi}d\xi=\int_{x_t}^{z}\frac{(t^2f(t))^{1/2}}{t}dt \tag{5.1}$$

where account has to be taken of the branches resulting both from the square roots and the logarithmic singularities. It is easy to see that the branches can be chosen so that $\zeta(z)$ is analytic at both $z=0$ and $z=x_t$; subject to this requirement, the actual choice of branches is unimportant. The dependent variable is transformed as in the real case:

$$\left(\frac{d\zeta}{dz}\right)^{1/2}w(z)=W(\zeta). \tag{5.2}$$

With the transformations (5.1), (5.2) we arrive at (2.4) again, i.e.

$$\frac{d^2W}{d\zeta^2} = \left\{ u^2\left(\frac{\alpha^2}{4\zeta^2} - \frac{1}{4\zeta} \right) + \frac{\psi(\alpha,\zeta)}{\zeta} - \frac{1}{4\zeta^2} \right\} W. \tag{5.3}$$

We continue to assume the parameters satisfy $\alpha \geqq 0$, $u > 0$, but now suppose ζ is a complex variable and that (5.3) holds in some complex domain Δ which includes $\zeta = 0$ and $\zeta = \alpha^2$ and in which $\psi(\alpha,\zeta)$ is holomorphic.

If the term $\psi(\alpha,\zeta)/\zeta$ is neglected in (5.3) the resulting equation has solutions of the form $\zeta^{1/2}\mathscr{C}_{u\alpha}(u\zeta^{1/2})$ where $\mathscr{C}$ denotes one of the Bessel functions J, $H^{(1)}$, $H^{(2)}$, or any combination of them. We shall seek formal series solutions of (5.3) of the form

$$\zeta^{1/2}\mathscr{C}_{u\alpha}(u\zeta^{1/2}) \sum_{s=0}^{\infty} \frac{A_s(\alpha,\zeta)}{u^{2s}} + \frac{\zeta}{u}\mathscr{C}'_{u\alpha}(u\zeta^{1/2}) \sum_{s=0}^{\infty} \frac{B_s(\alpha,\zeta)}{u^{2s}}, \tag{5.4}$$

where the coefficients $A_s(\alpha,\zeta)$, $B_s(\alpha,\zeta)$ are the analytic continuations of those defined by (2.9a, b). The square root $\zeta^{1/2}$ which occurs in (5.4) will be defined by

$$\chi_0 < \arg\zeta^{1/2} < \chi_0 + \pi \tag{5.5}$$

for some χ_0 ($-\pi \leqq \chi_0 \leqq 0$). The choice of χ_0 is determined by the particular problem under consideration: a common choice is $\chi_0 = 0$. Let $\boldsymbol{\Delta}$ denote the intersection of Δ and the ζ-plane cut along $\arg\zeta = 2\chi_0$: we shall seek solutions of the form (5.4) in the domain $\boldsymbol{\Delta}$.

It is convenient for our purposes to introduce the notation $\mathscr{C}^{(j)}$, where $\mathscr{C}^{(j)}$ denotes $2J$, $H^{(1)}$, $H^{(2)}$ for $j = 0, 1, 2$ respectively. Subsequently, we shall suppose j is enumerated modulo 3. See also Baldwin (1979).

In order that we may construct auxiliary functions with the appropriate asymptotic properties we have to take account of the asymptotic behaviour of the functions $\mathscr{C}_\nu^{(j)}(z)$ in the complex z-plane. It might therefore seem natural to define weight functions $E_\nu^{(j)}(z)$ by

$$\left| \exp\left(-i\int_\nu^z \frac{(t^2-\nu^2)^{1/2}}{t}\, dt \right) \right|. \tag{5.6}$$

However this choice proves inappropriate when ν and z are both small and would not give us the *uniformly* valid result we seek. Instead we define weight functions which are close to (5.6) when ν or $|z|$ is large but otherwise differ significantly.

To this end, we first note that (Olver (1974, p. 438))

$$X_\nu = \nu - c\left(\frac{1}{2}\nu\right)^{1/3} + O(\nu^{-1/3}) \quad \text{as } \nu \to \infty,$$

where c denotes the negative root of the equation $\mathrm{Ai}(x) = \mathrm{Bi}(x)$ of smallest absolute value. Let us define $\hat{\nu}$ to be real (nonnegative) solution of

$$\nu = \hat{\nu} - c\left(\frac{1}{2}\hat{\nu}\right)^{1/3}.$$

Then $\hat{X}_\nu$, the smallest zero of $J_{\hat{\nu}}(x) + Y_{\hat{\nu}}(x)$ (cf. (3.4)), is such that

$$\hat{X}_\nu = \nu + O(\nu^{-1/3}) \quad \text{as } \nu \to \infty$$

and $\hat{X}_\nu \geqq X_0 > 0$ (Olver (1974, p. 438, footnote)). Now define a function $\Phi_\nu^{(j)}(z)$ by

$$\Phi_\nu^{(j)}(z) = \int_{\hat{X}_\nu}^{z} \frac{\left(t^2 - \hat{X}_\nu^2\right)^{1/2}}{t}\, dt. \tag{5.7}$$

The function $\Phi_\nu^{(j)}(z)$ has branch points at $z = 0, \pm\hat{X}_\nu$. In respect of the branch point at $z = 0$, we can either introduce a branch cut or allow $\arg z$ to take a range of values greater than 2π: we shall do both as appropriate. In respect of the branch points at $z = \pm\hat{X}_\nu$, we introduce cuts along $\operatorname{Im}\Phi_\nu^{(j)}(z) = 0$. There are thus three possible cuts emanating from each of $\pm\hat{X}_\nu$, distinguishable by the angles they make with the real axis at $\pm\hat{X}_\nu$. We define $\Phi_\nu^{(j)}(z)$ to have that cut which makes the angle $-2\pi j/3$ with the positive real axis at $\hat{X}_\nu$, and to have the corresponding cut emanating from $z = -\hat{X}_\nu$ which is obtained by reflection about the imaginary z-axis.

The branch cuts we have introduced divide the z-plane into three regions which we denote by $\mathscr{S}_\nu^{(j)}$, $j = 0, 1, 2$ (see figure 1); $j = 0$ corresponds to the eye-shaped region around the origin, while $j = 1, 2$ respectively correspond to those regions outside the eye-shaped region for which $\operatorname{Im} z > 0$ and $\operatorname{Im} z < 0$. The function $\mathscr{C}_\nu^{(j)}(z)$ is recessive in $\mathscr{S}_\nu^{(j)}$ and dominant in $\mathscr{S}_\nu^{(j-1)} \cup \mathscr{S}_\nu^{(j+1)}$; with this in mind the branch of $(t^2 - \hat{X}_\nu^2)^{1/2}$ in (5.6) is defined to be that for which $\operatorname{Im}\Phi_\nu^{(j)}(z) > 0$ in $\mathscr{S}_\nu^{(j)}$ (see (5.8)).

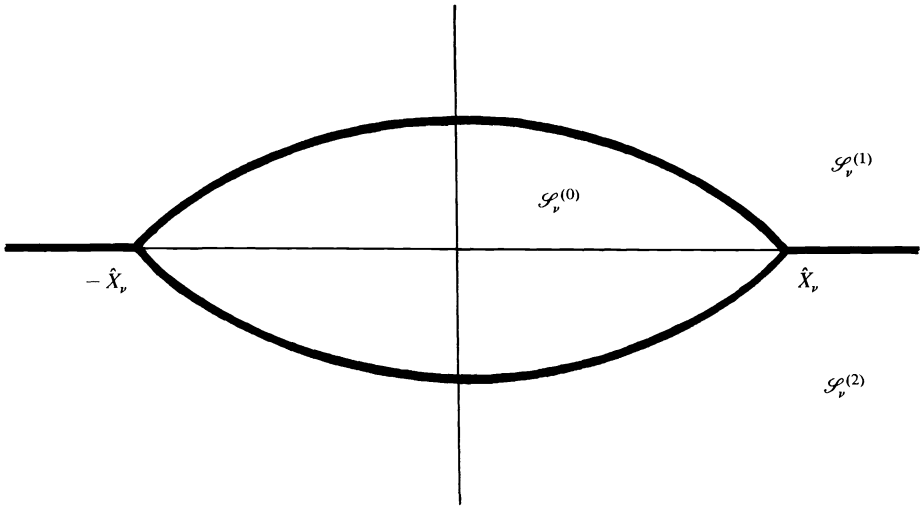

FIG. 1. *The complex z-plane. The regions $\mathscr{S}_\nu^{(j)}$ are defined to be the domains indicated, together with their boundaries.*

We define weight functions $E_\nu^{(j)}(z)$ separately in each of the three regions $\mathscr{S}_\nu^{(0)}$, $\mathscr{S}_\nu^{(1)}, \mathscr{S}_\nu^{(2)}$. In $\mathscr{S}_\nu^{(1)}$ and $\mathscr{S}_\nu^{(2)}$ we define $E_\nu^{(j)}(z)$ by

$$E_\nu^{(j)}(z) = \left|\exp\left(-i\Phi_\nu^{(j)}(z)\right)\right|, \tag{5.8}$$

where the branch of $(t^2 - \hat{X}_\nu^2)^{1/2}$ is chosen so that $E_\nu^{(j)}(z) \geqq 1$ in $\mathscr{S}_\nu^{(j)}$ and $E_\nu^{(j)}(z) \leqq 1$ in $\mathscr{S}_\nu^{(j-1)} \cup \mathscr{S}_\nu^{(j+1)}$ (cf. Olver (1974, p. 415)). In $\mathscr{S}_\nu^{(0)}$, we first define subdomains $\mathscr{D}_\nu^{(j)}(z)$ as follows. Given any point $z \in \mathscr{S}_\nu^{(0)}$, we define $\mathscr{D}_\nu^{(0)}(z)$ to be the set of points satisfying the two conditions

$$\operatorname{Im}\Phi_\nu^{(0)}(t) < \operatorname{Im}\Phi_\nu^{(0)}(z), \tag{5.9a}$$

$$-\pi < \arg t < \pi, \tag{5.9b}$$

and $\mathscr{D}_\nu^{(1)}(z)=\mathscr{D}_\nu^{(2)}(z)=\mathscr{S}_\nu^{(0)}-\mathscr{D}_\nu^{(0)}(z)$. We remark that $\Phi_\nu^{(0)}=-\Phi_\nu^{(1)}=-\Phi_\nu^{(2)}$ in $\mathscr{S}_\nu^{(0)}$. Then we define

$$e_\nu^{(j)}E_\nu^{(j)}(z)^{-1}=\sup_{\mathscr{D}_\nu^{(j)}(z)}\left\{\left|z^2-\nu^2\right|^{1/4}\left|\mathscr{C}_\nu^{(j)}(z)\right|\right\}\qquad(j=0,1,2),\tag{5.10}$$

where the constants $e_\nu^{(j)}$ are normalizing factors which are chosen to ensure the continuity of $E_\nu^{(j)}(z)$. Thus

$$e_\nu^{(j)}=\sup_{\mathscr{D}_\nu^{(j)}(\hat{X}_\nu)}\left\{\left|z^2-\nu^2\right|^{1/4}\left|\mathscr{C}_\nu^{(j)}(z)\right|\right\}\qquad(j=0,1,2).$$

(Note that since $\overline{H_\nu^{(1)}(\bar{z})}=H_\nu^{(2)}(z)$, where $\bar{\ }$ denotes complex conjugate, $e_\nu^{(1)}=e_\nu^{(2)}$.) We observe that $E_\nu^{(j)}(z)$ are continuous functions of both ν and z.

Consider further the definitions of $E_\nu^{(j)}(z)$ in $\mathscr{S}_\nu^{(0)}$. By virtue of the maximum modulus theorem we deduce that $|J_\nu(z)|$ achieves its maximum either on that part of the boundary corresponding to (5.9a) or to (5.9b). Since $|J_\nu(t)|$ is a monotonically increasing function of $|t|$ near the origin, it follows that for sufficiently small z, the maximum occurs on that part of the boundary corresponding to (5.9a). It is thus easy to deduce that $e_\nu^{(0)}E_\nu^{(0)}(z)^{-1}\sim 2|z^2-\nu^2|^{1/4}|J_\nu(z)|$ as $z\to 0$. Likewise one can show that as $z\to 0$, $e_\nu^{(1,2)}E_\nu^{(1,2)}(z)^{-1}\sim|z^2-\nu^2|^{1/4}|H_\nu^{(1)}(z)|$ or $|z^2-\nu^2|^{1/4}|H_\nu^{(2)}(z)|$.

Next we define modulus and phase functions

$$\begin{aligned}E_\nu^{(j+1)}(z)\left|\mathscr{C}_\nu^{(j+1)}(z)\right|&=M_\nu^{(j)}(z)\sin\theta_\nu^{(j)}(z),\\ E_\nu^{(j-1)}(z)\left|\mathscr{C}_\nu^{(j-1)}(z)\right|&=M_\nu^{(j)}(z)\cos\theta_\nu^{(j)}(z),\end{aligned}\tag{5.11}$$

where $M_\nu^{(j)}(z)$ is real and positive, and $\theta_\nu^{(j)}(z)$ is real. Thus

$$\begin{aligned}M_\nu^{(j)}(z)&=\left\{E_\nu^{(j+1)}(z)^2\left|\mathscr{C}_\nu^{(j+1)}(z)\right|^2+E_\nu^{(j-1)}(z)^2\left|\mathscr{C}_\nu^{(j-1)}(z)\right|^2\right\}^{1/2},\\ \theta_\nu^{(j)}(z)&=\tan^{-1}\left\{E_\nu^{(j+1)}(z)\left|\mathscr{C}_\nu^{(j+1)}(z)\right|/\left(E_\nu^{(j-1)}(z)\left|\mathscr{C}_\nu^{(j-1)}(z)\right|\right)\right\},\end{aligned}$$

where $\tan^{-1}$ takes its principal value. We remark that as $|\Phi_\nu^{(j)}(z)|\to\infty$, $\theta_\nu^{(j)}(z)\to\pi/4$ except near the boundary of $\mathscr{S}_\nu^{(j-1)}\cup\mathscr{S}_\nu^{(j+1)}$.

Likewise, we define modulus and phase functions for $\mathscr{C}_\nu^{(j)\prime}(z)$ by

$$E_\nu^{(j+1)}(z)\left|\mathscr{C}_\nu^{(j)\prime}(z)\right|=N_\nu^{(j)}(z)\sin\omega_\nu^{(j)}(z),\ E_\nu^{(j-1)}(z)\left|\mathscr{C}_\nu^{(j)\prime}(z)\right|=N_\nu^{(j)}(z)\cos\omega_\nu^{(j)}(z)\tag{5.12}$$

where $N_\nu^{(j)}(z)$ is real and positive, and $\omega_\nu^{(j)}$ is real.

It is convenient, at this stage, to introduce the constant κ which we shall require in Theorem 3. We define $\kappa=\kappa_0\kappa_1$ where

$$\begin{aligned}\kappa_0&=\sup\left\{\tfrac{1}{2}\pi\left|z^2-\nu^2\right|^{1/2}\sum_{j=0}^{2}E_\nu^{(j)}(z)^2\left|\mathscr{C}_\nu^{(j)}(z)\right|^2\right\},\\ \kappa_1&=\sup\left\{E_\nu^{(0)}(z)^{-1}E_\nu^{(1)}(z)^{-1}\right\},\end{aligned}\tag{5.13}$$

the suprema being taken over all $\nu\geqq 0$ and all $|z|>0$. The existence of κ_0 is a consequence of Lemma 3 given in Appendix B and the existence of κ_1 may be shown in a similar manner.

Now consider the functions $\mathscr{C}_{u\alpha}^{(j)}(u\zeta^{1/2})$ where the branch of $\zeta^{1/2}$ is defined in (5.5). Then under the transformation $z=u\zeta^{1/2}$, we define regions $S_\alpha^{(j)}$ in the ζ-plane corresponding to the regions $\mathscr{S}_{u\alpha}^{(j)}$ in the z-plane. These are illustrated in Fig. 2a for the case $-\frac{1}{2}\pi<\chi_0<0$.

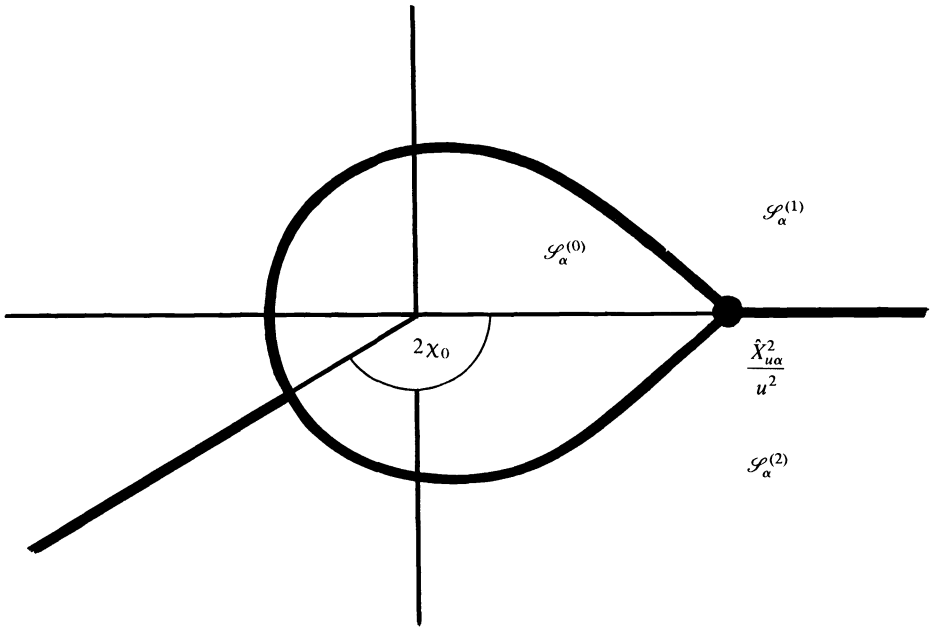

FIG. 2a. *The complex ζ-plane.*

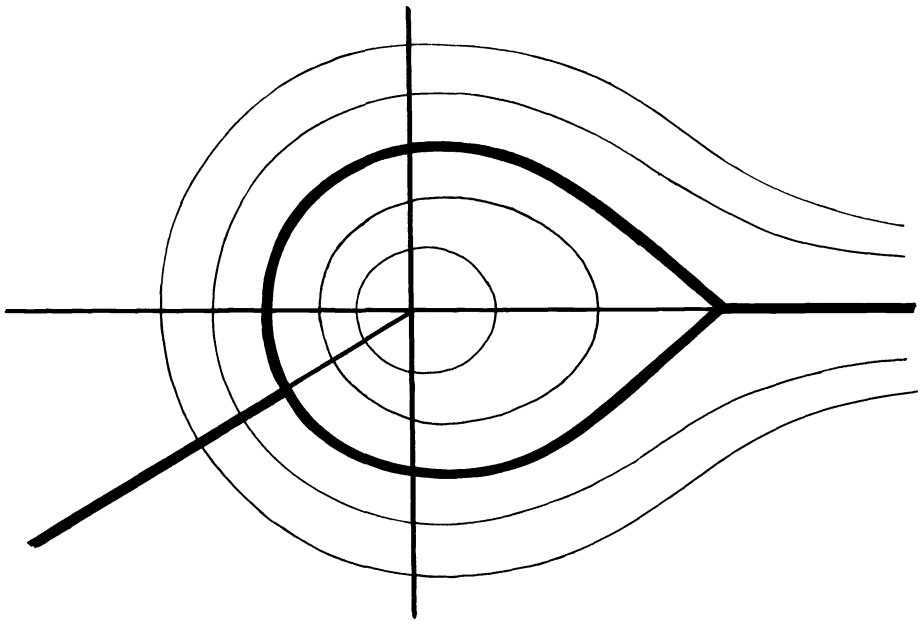

FIG. 2b. *The curves* $\operatorname{Im}\Phi_{u\alpha}^{(j)}(u\zeta^{1/2})=$ *constant.*

In order that we may state our theorem on error bounds we introduce reference points $\tilde{\zeta}^{(j)}$, $j=0,1,2$: $\tilde{\zeta}^{(0)}=0$, and $\tilde{\zeta}^{(1)}$, $\tilde{\zeta}^{(2)}$ are points (perhaps at infinity) in $S_\alpha^{(1)}$, $S_\alpha^{(2)}$ respectively, which we choose to suit our purposes. Given these $\tilde{\zeta}^{(j)}$, we define the domains $\Delta^{(j)}$, $j=0,1,2$, to be the set of points in Δ which can be linked to $\tilde{\zeta}^{(j)}$ by a path $\mathscr{P}^{(j)}$ which consists of a finite chain of arcs in R_2 having the property that as ξ passes along $\mathscr{P}^{(j)}$ from $\tilde{\zeta}^{(j)}$ to ζ,

$$\operatorname{Im}\Phi_{u\alpha}^{(j)}(u\xi^{1/2}) \geqq \operatorname{Im}\Phi_{u\alpha}^{(j)}(u\zeta^{1/2}). \tag{5.14}$$

This condition is satisfied if $\operatorname{Im}\Phi_{u\alpha}^{(j)}(u\xi^{1/2})$ is nonincreasing as ξ passes along $\mathscr{P}^{(j)}$ from $\tilde{\zeta}^{(j)}$ to ζ: this condition is useful in applications of the theory, and any such path is said to be progressive. The curves $\operatorname{Im}\Phi_{u\alpha}^{(j)}(u\xi^{1/2})=$ constant are illustrated in Fig. 2b.

THEOREM 3. *With the conditions described in* §1 *and the present section, equation* (5.3) *has, for each pair of values of* u *and* α *and each nonnegative integer* n, *solutions* $W_{2n+1}^{(j)}(u,\alpha,\zeta)$, $j=0,1,2$, *which are holomorphic in* Δ *and satisfy*

$$W_{2n+1}^{(j)}(u,\alpha,\zeta)=\zeta^{1/2}\mathscr{C}_{u\alpha}^{(j)}(u\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{\zeta}{u}\mathscr{C}_{u\alpha}^{(j)\prime}(u\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}} + \varepsilon_{2n+1}^{(j)}(u,\alpha,\zeta), \tag{5.15}$$

where

$$\frac{|\varepsilon_{2n+1}^{(j)}(u,\alpha,\zeta)|}{\zeta^{1/2}M_{u\alpha}^{(j\pm1)}(u\zeta^{1/2})},\quad \frac{|\partial\varepsilon_{2n+1}^{(j)}(u,\alpha,\zeta)/\partial\zeta|}{(1/2)uN_{u\alpha}^{(j\pm1)}(u\zeta^{1/2})+(1/2)\zeta^{-1/2}M_{u\alpha}^{(j\pm1)}(u\zeta^{1/2})} \tag{5.16}$$

$$\leqq \frac{1}{u^{2n+1}}\kappa E_{u\alpha}^{(j)}(u\zeta^{1/2})^{-1}\mathscr{V}_{\mathscr{P}^{(j)}}\left\{(\xi-\alpha^2)^{1/2}B_n(\xi)\right\}\exp\left(\frac{\kappa}{u}\mathscr{V}_{\mathscr{P}^{(j)}}\left\{(\xi-\alpha^2)^{1/2}B_0(\xi)\right\}\right),$$

when $\zeta\in\Delta^{(j)}$. *In* (5.16), *the suffix on* M *and* N *is* $j+1$ *when* $\zeta\in S_\alpha^{(j-1)}\cup S_\alpha^{(j)}$ *and* $j-1$ *when* $\zeta\in S_\alpha^{(j)}\cup S_\alpha^{(j+1)}$.

This theorem is proved in a similar manner to Theorems 1, 2. The bounds (5.16) can be sharpened somewhat by a more complicated choice of constants than the single constant defined by (5.13), but we shall not pursue this.

The bounds (5.16) can be used to deduce the asymptotic nature of the expansions (5.4); the discussion is similar to those which follow Theorems 1, 2. Thus the solution $W_{2n+1}^{(j)}(u,\alpha,\zeta)$ is recessive at $\zeta=0$ for $j=0$ and is dominant there for $j=1,2$. One can show that (5.4) is a uniformly valid compound asymptotic expansion of $W_{2n+1}^{(j)}(u,\alpha,\zeta)$. To do so, write

$$\begin{aligned} E_\nu^{(j)}(z)^{-1}M_\nu^{(j-1)}(z)&=a_\nu^{(j,-)}(z)\mathscr{C}_\nu^{(j)}(z)+b_\nu^{(j,-)}(z)z\mathscr{C}_\nu^{(j)\prime}(z),\\ E_\nu^{(j)}(z)^{-1}M_\nu^{(j+1)}(z)&=a_\nu^{(j,+)}(z)\mathscr{C}_\nu^{(j)}(z)+b_\nu^{(j,+)}(z)z\mathscr{C}_\nu^{(j)\prime}(z), \end{aligned} \tag{5.17}$$

where

$$\begin{aligned} a_\nu^{(j,-)}(z)&=E_\nu^{(j)}(z)^{-1}M_\nu^{(j-1)}(z)z\mathscr{C}_\nu^{(j+1)\prime}(z),\\ b_\nu^{(j,-)}(z)&=E_\nu^{(j)}(z)^{-1}M_\nu^{(j-1)}(z)\mathscr{C}_\nu^{(j+1)}(z),\\ a_\nu^{(j,+)}(z)&=E_\nu^{(j)}(z)^{-1}M_\nu^{(j+1)}(z)z\mathscr{C}_\nu^{(j-1)\prime}(z),\\ b_\nu^{(j,+)}(z)&=E_\nu^{(j)}(z)^{-1}M_\nu^{(j+1)}(z)\mathscr{C}_\nu^{(j-1)}(z), \end{aligned} \tag{5.18}$$

except when $j=0$: then (5.18) apply except in $\mathscr{S}_\nu^{(0)}$ where

$$a_\nu^{(0,\pm)}(z)=E_\nu^{(0)}(z)^{-1}M_\nu^{(\pm 1)}(z)/2J_\nu(z), \qquad b_\nu^{(0,\pm)}=0. \tag{5.19}$$

It then suffices to observe that for each j, $|a_\nu^{(j,-)}(z)|$ and $|b_\nu^{(j,-)}(z)|$ are uniformly bounded for $\nu\geqq 0$ in $\mathscr{S}_\nu^{(j)}\cup\mathscr{S}_\nu^{(j+1)}$, and $|a_\nu^{(j,+)}(z)|$ and $|b_\nu^{(j,-)}(z)|$ are uniformly bounded for $\nu\geqq 0$ in $\mathscr{S}_\nu^{(j-1)}\cup\mathscr{S}_\nu^{(j)}$. These results can be established by considerations similar to those motivating the proof of Lemma 3 in Appendix B.

Finally, we remark that when the domain Δ is unbounded, Theorem 3 will yield meaningful results for large ζ whenever the variations of the function $(\zeta-\alpha^2)^{1/2}B_s(\zeta)$ converge at infinity.

6. Legendre functions of large degree and order: complex variables. We use the results of §5 to construct asymptotic expansions as $\nu\to\infty$ of solutions of Legendre's equation which are uniformly valid for $0\leqq\mu/(\nu+\frac{1}{2})\leqq 1-\delta$ $(\delta>0)$ in the complex z-plane. We shall assume $\operatorname{Re} z\geqq 0$. The connection formulae for Legendre functions can be used as in §4 to derive corresponding results for other values of ν, μ, z. The pair of solutions we consider here is $P_\nu^{-\mu}(z)$ and $Q_\nu^\mu(z)$.

We proceed in a similar fashion as we did in §4: $u,\alpha,\psi(\alpha,\zeta)$ are defined as in §4, and in place of (4.2a, b) we define

$$\int_{\alpha^2}^{\zeta}\frac{(\xi-\alpha^2)^{1/2}}{2\xi}d\xi=-\int_{(1-\alpha^2)^{1/2}}^{z}\frac{(1-\alpha^2-t^2)^{1/2}}{1-t^2}dt \tag{6.1}$$

(cf. (5.1)). The functions $P_\nu^{-\mu}(z)$ and $Q_\nu^\mu(z)$ are each expressible in the form

$$\left(\frac{\zeta-\alpha^2}{1-\alpha^2-z^2}\right)^{1/4}\zeta^{-1/2}W(\zeta),$$

where $W(\zeta)$ satisfies (5.3). The domain Δ associated with (5.3) is illustrated in Fig. 3a.

A knowledge of the general configuration of the curves $\operatorname{Im}\Phi_{u\alpha}^{(j)}(u\zeta^{1/2})=\text{constant}$ in the ζ-plane is essential in applying the theory of §5. The curves, and those corresponding to them in the z-plane are shown in Figs. 3a, b (under the assumption that u is sufficiently large). In arriving at these configurations it is helpful to note that $\hat{X}_{u\alpha}/u\alpha=1+O(u^{-4/3})$ as $u\to\infty$.

It is conventional to take the branch cut associated with the Legendre functions to run along the real z-axis from $z=1$ to $z=-\infty$. With this convention, the corresponding cut in the ζ-plane is from $\zeta=0$ along the positive real axis. In the notation of §5, $\chi_0=0$ and Δ is the intersection of Δ and the ζ-plane cut along $\arg\zeta=0$.

The recessive behaviour of $P_\nu^{-\mu}(z)$ as $z\to 1$ implies that

$$P_\nu^{-\mu}(z)=c_{2n+1}^{(0)}\left(\frac{\zeta-\alpha^2}{1-\alpha^2-z^2}\right)^{1/4}\zeta^{-1/2}W_{2n+1}^{(0)}(u,\alpha,\zeta) \tag{6.2}$$

for some constant $c_{2n+1}^{(0)}$. The procedure which led to (4.11) now yields

$$c_{2n+1}^{(0)}=\frac{1}{2}e^{-\mu\pi i/2}c_{2n+1,1}. \tag{6.3}$$

It may readily be seen that the path $\mathscr{P}^{(0)}$ can be chosen to be progressive for all points in Δ (so that $\Delta^{(0)}=\Delta$). The uniform asymptotic nature of (6.2) is thus established.

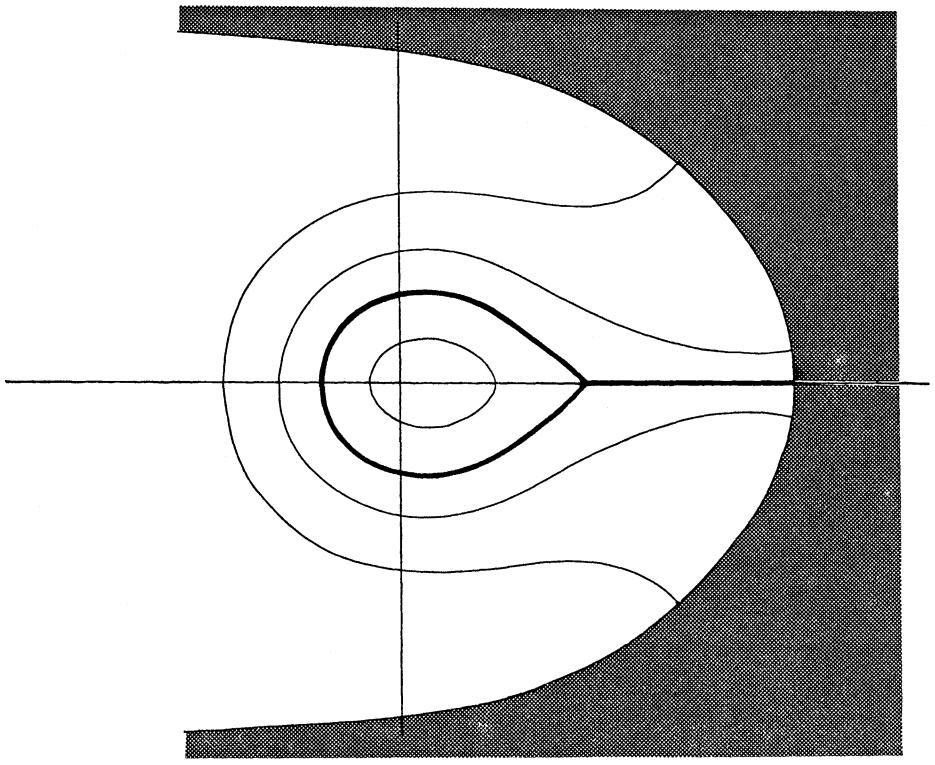

FIG. 3a. *The domain* Δ *in the complex* ζ*-plane, with curves* $\operatorname{Im} \Phi_{u\alpha}^{(j)}(u\zeta^{1/2}) = \text{constant}$.

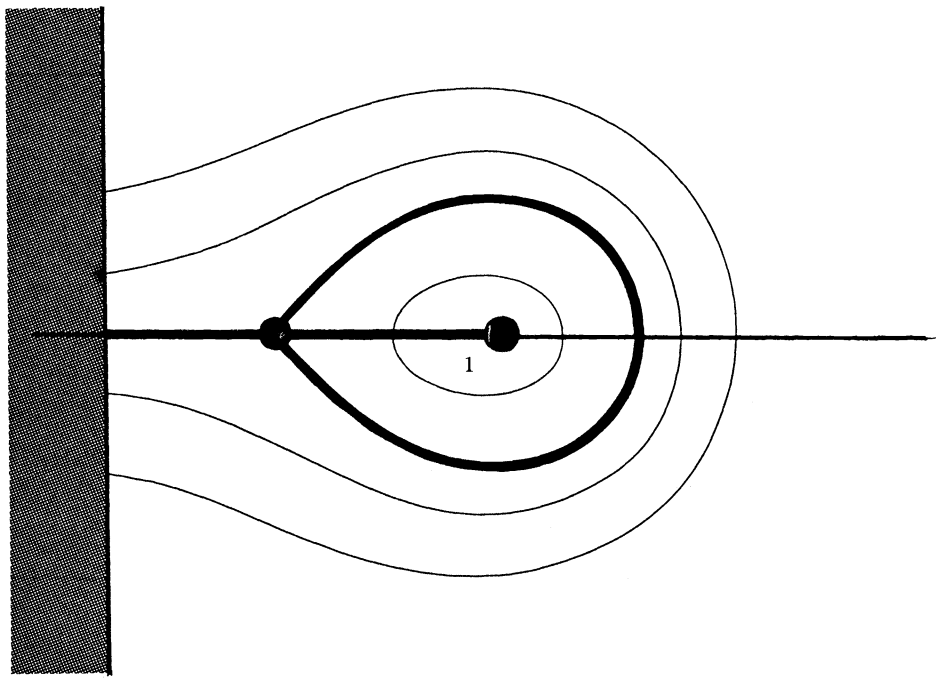

FIG. 3b. *The complex z-plane* ($\operatorname{Re} z > 0$) *with curves corresponding to* $\operatorname{Im} \Phi_{u\alpha}^{(j)}(u\zeta^{1/2}) = \text{constant}$ *in the* ζ*-plane.*

One can likewise show, by taking account of the recessive behaviour of $Q_\nu^\mu(z)$ as $z \to \infty$, that

$$Q_\nu^\mu(z) = c_{2n+1}^{(1)} \left(\frac{\zeta - \alpha^2}{1 - \alpha^2 - z^2} \right)^{1/4} \zeta^{-1/2} W_{2n+1}^{(1)}(u, \alpha, \zeta) \tag{6.4}$$

for some constant $c_{2n+1}^{(1)}$. One finds (cf. (4.18)) that

$$c_{2n+1}^{(1)} = \frac{1}{2} \pi i e^{\mu \pi i/2} c_{2n+1,4}. \tag{6.5}$$

In arriving at (6.4) the endpoint of integration is taken to be $\zeta_1 = -\infty$. It may readily be seen that the path $\mathscr{P}^{(1)}$ can be chosen to be progressive for all points in Δ (so that $\Delta^{(1)} = \Delta$). This establishes the uniform asymptotic nature of (6.4).

The results (6.2) and (6.4) can be used to determine a relation between the coefficients $c_{2n+1,1}$, $c_{2n+1,4}$, and thence the as yet undefined constants λ_s of (2.9b). If in the relation

$$i\pi \frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)} \mathrm{P}_\nu^{-\mu}(x) = -e^{-\mu\pi i/2} Q_\nu^\mu(x+i0) + e^{-3\mu\pi i/2} Q_\nu^\mu(x-i0), \qquad -1 < x < 1,$$

(which may be derived from the formulae of Olver (1974, Chap. (15.02), (15.03))), one substitutes the results (4.9) and (6.4), (6.5), one finds that for each n,

$$\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)} c_{2n+1,1} = e^{-\mu\pi i} c_{2n+1,4}. \tag{6.6}$$

When the formulae (4.11) for $c_{2n+1,1}$ and (4.19) for $c_{2n+1,4}$ are substituted into (6.6), the result is

$$\begin{aligned} &\left(1 + \alpha \sum_{s=0}^{n-1} \frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}} + \sum_{s=1}^{n} \frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}} \right) \\ &\quad \cdot \left(1 - \alpha \sum_{s=0}^{n-1} \frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}} + \sum_{s=1}^{n} \frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}} + \delta_{2n+1,4} \right)^{-1} \\ &\quad = e^{2\mu} \left(\nu + \frac{1}{2} + \mu \right)^{-\nu-1/2-\mu} \left(\nu + \frac{1}{2} - \mu \right)^{\nu+1/2-\mu} \frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}. \end{aligned} \tag{6.7}$$

An asymptotic expansion of the right-hand side in descending powers of $(\nu + \frac{1}{2})$ may be found by application of Stirling's formula; however one chooses the arbitrary constants λ_s of (2.9b), the coefficients of the corresponding power of $(\nu + \frac{1}{2})$ on the left-hand side must agree. To determine the constants λ_5, we note that the expression

$$\begin{aligned} &\left(1 + \alpha \sum_{s=0}^{n-1} \frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}} + \sum_{s=1}^{n} \frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}} \right) \\ &\quad \cdot \left(1 - \alpha \sum_{s=0}^{n-1} \frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}} + \sum_{s=1}^{n} \frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}} \right) \end{aligned}$$

is a polynomial in powers of $(\nu+\frac{1}{2})^{-2}$. We may therefore choose $\lambda_1,\lambda_2,\cdots,\lambda_n$ in turn so that the coefficients $(\nu+\frac{1}{2})^{-2},(\nu+\frac{1}{2})^{-4},\cdots(\nu+\frac{1}{2})^{-2n}$ vanish: thus

$$(6.8)\quad \left(1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}\right)\cdot\left(1-\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}+\delta_{2n+1,4}\right)=1+\delta_{2n+1},$$

where δ_{2n+1} is $O(u^{-2n-1})$ and may be expressed explicitly in terms of $\delta_{2n+1,4}$, $A_1,\cdots,A_n,B_1,\cdots,B_{n-1}$. Furthermore (6.7), (6.8) together imply

$$(6.9)\quad \left(1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}\right)(1+\delta_{2n+1})^{-1/2}$$

$$=\left(1-\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{(\nu+1/2)^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{(\nu+1/2)^{2s}}+\delta_{2n+1,4}\right)^{-1}(1+\delta_{2n+1})^{1/2}$$

$$=e^{\mu}\left(\nu+\frac{1}{2}+\mu\right)^{-\nu/2-1/4-1/2}\left(\nu+\frac{1}{2}-\mu\right)^{\nu/2+1/4-\mu/2}\left\{\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}\right\}^{1/2}.$$

One immediately deduces from (6.9) that for our choice of λ_s, (4.11) becomes

$$(6.10)\qquad c_{2n+1,1}=\left\{\frac{\Gamma(\nu-\mu+1)}{\Gamma(\nu+\mu+1)}\right\}^{1/2}(1+\delta_{2n+1})^{-1/2}$$

and (4.19) becomes

$$(6.11)\qquad c_{2n+1,4}=\left\{\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}\right\}^{1/2}e^{\mu\pi i}(1+\delta_{2n+1})^{-1/2}.$$

Finally, we return to the problem left unsolved at the end of §4: finding a uniform asymptotic expansion for $Q_\nu^{-\mu}(x)$ in $0\leqq x<1$. Given the relation

$$Q_\nu^{-\mu}(x)=\frac{\Gamma(\nu-\mu+1)}{2\Gamma(\nu+\mu+1)}\left(e^{-\mu\pi i/2}Q_\nu^{\mu}(x+i0)+e^{-3\mu\pi i/2}Q_\nu^{\mu}(x-i0)\right)$$

[Olver (1974, Chap. 5, (13.15), (15.02))], one deduces from (6.4) that

(6.12)

$$Q_\nu^{-\mu}(x)=-\frac{1}{2}\pi c_{2n+1,1}\left(\frac{\zeta-\alpha^2}{1-\alpha^2-x^2}\right)^{1/4}\cdot\left[Y_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{u^{2s}}+\frac{\zeta^{1/2}}{u}Y'_{u\alpha}(u\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{u^{2s}}+\operatorname{Im}\left\{(\zeta+i0)^{-1/2}\varepsilon_{2n+1}^{(1)}(u,\alpha,\zeta+i0)\right\}\right],$$

and the constants λ_s are again defined implicitly by (6.8).

Appendix A. Proof of Lemma 1 (continuity of ψ). The proof is similar to that given by Olver (1975a, pp. 142–150) and to avoid undue repetition we shall simply refer to "Olver" without further specification in this appendix.

First, when the variable x is complex, the use of Cauchy's formula enables the result to be proved without difficulty (Olver, p. 142).

In the real-variable case, the proof is again relatively straightforward when $\alpha>0$ and also when $\alpha=0$, $\zeta\neq 0$. One may follow closely Olver's analysis (Olver, p. 144).

The difficult part of the proof is to establish continuity of $\psi(\alpha,\zeta)$ at the critical point $\alpha=\zeta=0$ in the real-variable case. The difficulty is essentially due to the coalescence of two critical points in the (α,ζ)-plane. In Olver's problem, these are turning points at $\zeta=\pm\alpha$. He establishes continuity by considering a deleted neighbourhood of the origin $0\leqq|\zeta|\leqq\delta$, $0\leqq\alpha\leqq\delta$, finding Taylor expansions of $x(\zeta)$ and its derivatives about each turning point, uniformly valid in α, and then appealing to his formula (2.10) for ψ. Because of the symmetry of his problem, the two proofs are effectively identical. In our problem, we proceed in a similar fashion, arriving at uniformly valid Taylor expansions of $x(\zeta)$ and its derivatives about the turning point $\zeta=\alpha^2$ and about the pole $\zeta=0$ in a deleted neighbourhood of the origin, $0\leqq|\zeta|\leqq\delta$, $0\leqq\alpha\leqq\delta^{1/2}$. More precisely we find Taylor expansions about $\zeta=\alpha^2$ for $\zeta\geqq\frac{1}{2}\alpha^2$ and about $\zeta=0$ for $\zeta\leqq\frac{1}{2}\alpha^2$. Because our problem is not symmetric with respect to the two critical points, each of the two cases has to be considered separately.

Consider first $\zeta\geqq\frac{1}{2}\alpha^2$. One finds that the proof of continuity of ψ proceeds in a very similar manner to that of Olver (pp. 145–149). This is perhaps as one would expect since in both his and our problems one is calculating Taylor expansions about a turning point.

It remains to consider $\zeta\leqq\frac{1}{2}\alpha^2$. Here there are significant differences between our analysis and Olver's. Our starting point is (2.2a) which, in terms of the function $p(\alpha,x)$ introduced in (2.6), may be written

$$\int_{\alpha^2}^{\zeta}\frac{(\alpha^2-\xi)^{1/2}}{2\xi}\,d\xi=\int_{a^2}^{x}\frac{(a^2-t)^{1/2}}{2t}\,p^{1/2}(t)\,dt, \tag{A.1}$$

where for convenience we have written $x_t=a^2$. We shall first find Taylor expansions about $\zeta=0$ in $0\leqq\zeta\leqq\frac{1}{2}\alpha^2$ and to this end we rewrite (A.1) in the form

$$\int_{\varepsilon}^{\zeta}\frac{(\alpha^2-\xi)^{1/2}}{2\xi}\,d\xi-\int_{\varepsilon/p(0)}^{x}\frac{(a^2-t)^{1/2}}{2t}\,p^{1/2}(t)\,dt = \int_{\varepsilon}^{\alpha^2}\frac{(\alpha^2-\xi)^{1/2}}{2\xi}\,d\xi-\int_{\varepsilon/p(0)}^{a^2}\frac{(a^2-t)^{1/2}}{2t}\,p^{1/2}(t)\,dt, \tag{A.2}$$

where ε is arbitrarily chosen to satisfy $0<\varepsilon<\zeta$.

The integrals on the left-hand side of (A.2) may be evaluated to yield $\frac{1}{2}\alpha\ln(\zeta/\varepsilon)+O(\zeta)$ as $\zeta\to 0$ and $-\frac{1}{2}\alpha\ln(p(0)x/\varepsilon)+O(x)$ as $x\to 0$ respectively. Since $x\to 0$ as $\zeta\to 0$, we therefore deduce that the left-hand side of (A.2) is $-\frac{1}{2}\alpha\ln(p(0)x/\zeta)$ together with a term which tends to zero as $\varepsilon\to 0$. As $\zeta\to 0$, $\varepsilon\to 0$ and the right-hand side tends to

$$\alpha\int_0^1\frac{(1-v)^{1/2}}{2v}\left\{1-\frac{p^{1/2}(a^2v)}{p^{1/2}(0)}\right\}dv.$$

We thus deduce that the ratio x/ζ is bounded as $\zeta \to 0$. The limit is actually the leading coefficient in the Taylor expansion of $x(\zeta)$. It is relatively straightforward to calculate the higher terms in the series: one finds

$$x = X_1\zeta + X_2\zeta^2 + X_3\zeta^3 + \eta, \tag{A.3}$$

where

$$X_1 = \frac{1}{p(0)} \exp \int_0^1 \frac{(1-v)^{1/2}}{v} \left\{ \frac{p^{1/2}(a^2 v)}{p^{1/2}(0)} - 1 \right\} dv,$$

$$X_2 = -\frac{1}{2\alpha^2} X_1 + \left(\frac{1}{2a^2} - \frac{1}{2} \frac{\dot{p}(0)}{p(0)} \right) X_1^2,$$

$$X_3 = \frac{1}{16\alpha^4} X_1 + \left(-\frac{1}{2} \frac{1}{a^2\alpha^2} + \frac{1}{2} \frac{p(0)}{\alpha^2 p(0)} \right) X_1^2,$$

$$+ \left(\frac{7}{16} \frac{1}{a^4} - \frac{5}{8} \frac{\dot{p}(0)}{a^2 p(0)} + \frac{7}{16} \frac{\dot{p}^2(0)}{p^2(0)} - \frac{1}{8} \frac{\ddot{p}(0)}{p(0)} \right) X_1^3.$$

In our subsequent analysis, it is necessary that these coefficients be continuous functions of α at $\alpha = 0$. To show this, we have to establish the relation between α and a. Since $x^2 f(\alpha, x) \to \alpha^2/4$ as $x \to 0$, it follows from (2.6) that

$$\alpha = a p^{1/2}(0).$$

One then readily finds that as $a \to 0$,

$$X_1 = \frac{1}{p(0)} + \frac{1}{3} \frac{\dot{p}(0)}{p^2(0)} a^2 + \left(\frac{1}{45} \frac{\dot{p}^2(0)}{p^3(0)} + \frac{1}{15} \frac{\ddot{p}(0)}{p^2(0)} \right) a^4 + O(a^6),$$

$$X_2 = -\frac{1}{3} \frac{\dot{p}(0)}{p^3(0)} + \left(-\frac{4}{15} \frac{\dot{p}^2(0)}{p^2(0)} + \frac{1}{30} \frac{\ddot{p}(0)}{p^3(0)} \right) a^2 + O(a^4), \tag{A.4}$$

$$X_3 = \frac{11}{45} \frac{\dot{p}^2(0)}{p^5(0)} - \frac{1}{10} \frac{\ddot{p}(0)}{p^4(0)} + O(a^2),$$

whence continuity follows.

We show next that $\eta = O(\zeta^4)$ in (A.3) uniformly in α. By arranging the integrals in (A.2) and taking the limit $\varepsilon \to 0$, one finds

$$I = \lim_{\varepsilon \to 0} \left\{ \int_\varepsilon^\zeta \frac{(\alpha^2 - \xi)^{1/2}}{2\xi} d\xi - J_\varepsilon \right\} - \alpha \int_0^1 \frac{(1-v)^{1/2}}{2v} \left\{ 1 - \frac{p^{1/2}(a^2 v)}{p^{1/2}(0)} \right\} dv, \tag{A.5}$$

where

$$I = \int_{X_1\zeta + X_2\zeta^2 + X_3\zeta^3}^{X_1\zeta + X_2\zeta^2 + X_3\zeta^3 + \eta} \frac{(a^2 - t)^{1/2}}{2t} p^{1/2}(t)\, dt$$

and

$$J_\varepsilon = \int_{\varepsilon/p(0)}^{X_1\zeta + X_2\zeta^2 + X_3\zeta^3} \frac{(a^2-t)^{1/2}}{2t} p^{1/2}(t)\, dt.$$

We shall show that the right-hand side of (A.5) is bounded above by $\alpha O(\zeta^3)$ and that the left-hand side is bounded below by $\alpha A|\eta/\zeta|$ for some constant A: we thus deduce $\eta = O(\zeta^4)$ uniformly.

To arrive at the first of these results, we closely follow the corresponding steps in Olver's calculation (pp. 146–147). In the integral J_ε we take a new integration variable y defined by

$$t = X_1 y + X_2 y^2 + X_3 y^3.$$

The factors in the integrand of J_ε have now to be expressed in terms of y; in particular, we find

$$a^2 - t = (\alpha^2 - y)\{Y_0 + Y_1 y + Y_2 y^2 + Y_3 y^3\} + Y_3 y^4,$$

where

$$\alpha^2 Y_0 = a^2,\ \alpha^2 Y_s = Y_{s-1} - X_s \quad \text{for } s = 1,2,3.$$

It may readily be verified that as $a \to 0$,

$$Y_0 = \frac{1}{p(0)},$$

$$Y_1 = -\frac{1}{3}\frac{\dot{p}(0)}{p^3(0)} + \left(-\frac{1}{45}\frac{\dot{p}^2(0)}{p^4(0)} - \frac{1}{15}\frac{\ddot{p}(0)}{p^3(0)}\right)a^2 + O(a^4),$$

$$Y_2 = \frac{11}{45}\frac{\dot{p}^2(0)}{p^5(0)} - \frac{1}{10}\frac{\ddot{p}(0)}{p^4(0)} + O(a^2),$$

$$Y_3 = O(1).$$

This last result enables us to claim that

$$a^2 - t = (\alpha^2 - y)\{Y_0 + Y_1 y + Y_2 y^2 + O(y^3)\}$$

uniformly for $0 < y \leqq \frac{1}{2}\alpha^2$. When all the other factors in the integrand of J_ε are expressed in powers of y we find

$$J_\varepsilon = \int_{\varepsilon_1}^{\zeta} \frac{(\alpha^2 - y)^{1/2}}{2y}\{1 + O(y^3)\}\, dy,$$

where the order term is uniformly valid in α, and ε_1 is the appropriate solution of the equation

$$\varepsilon/p(0) = X_1\varepsilon_1 + X_2\varepsilon_1^2 + X_3\varepsilon_1^3.$$

We thus deduce that the right-hand side of (A.5) is

$$\int_0^{\zeta}(\alpha^2-\xi)^{1/2}O(\xi^2)\,d\xi+\lim_{\varepsilon\to 0}\int_{\varepsilon}^{\varepsilon_1}\frac{(\alpha^2-\xi)^{1/2}}{2\xi}d\xi-\alpha\int_0^1\frac{(1-v)^{1/2}}{2v}\left\{1-\frac{p^{1/2}(a^2v)}{p^{1/2}(0)}\right\}dv,$$

and since it is easily seen that the last two terms cancel, we find that the right-hand side of (A.5) is uniformly bounded by $\alpha O(\zeta^3)$ in $0<\zeta\leqq\frac{1}{2}\alpha^2$.

Consider now the left-hand side of (A.5). By using the mean value theorem for integrals one can readily show that

$$|I|>\alpha A|\ln(1+\chi)|$$

for some constant A, uniformly in α, where

$$\chi=\eta/(X_1\zeta+X_2\zeta^2+X_3\zeta^3).$$

We showed in the previous paragraph that $I=\alpha O(\zeta^3)$ in $0<\zeta\leqq\frac{1}{2}\alpha^2$, and so it follows that in this domain

$$|\ln(1+\chi)|=O(\zeta^3)\quad\text{uniformly in }\alpha.$$

In particular we deduce that in any given neighbourhood of the origin in the (α,ζ)-plane, for $0<\zeta\leqq\frac{1}{2}\alpha^2$, the function $|\ln(1+\chi)|$ is uniformly bounded. By considering the graph of $|\ln(1+\chi)|$, we may therefore claim the existence of a constant B such that

$$|\ln(1+\chi)|>B|\chi|$$

throughout the region in question. We thus deduce that $\eta=O(\zeta^4)$ uniformly in α for $0<\zeta\leqq\frac{1}{2}\alpha^2$.

Similar arguments obtain in $\zeta<0$: one thus deduces that $\eta=O(\zeta^4)$ uniformly for $\zeta\leqq\frac{1}{2}\alpha^2$. The uniform validity of differential forms of (A.3), namely

$$\begin{aligned}x'&=X_1+2X_2\zeta+3X_3\zeta^2+O(\zeta^3),\\ x''&=2X_2+6X_3\zeta+O(\zeta^2),\\ x'''&=6X_3+O(\zeta),\end{aligned}$$

may be demonstrated, with calculations similar to those of Olver (pp. 148–149).

The continuity of ψ at the origin follows from (2.5) and the above results.

Appendix B. Existence of suprema. We shall discuss a number of results left unproved earlier. The first group of such results concern the existence of the suprema (3.5), (3.16). It suffices to consider only one of these, κ^+, in detail: the other proofs are similar. The existence of κ^+ is a consequence of the following lemma.

LEMMA 2. *Let $f(x,\nu)=\pi|x^2-\nu^2|^{1/2}M_\nu^2(x)$. Then $f(x,\nu)$ is uniformly bounded in the first quadrant of the $x\nu$-plane.*

Proof. Since $f(x,\nu)$ is continuous for $x>0$, $\nu\geqq 0$, it suffices to show

(a) $f(x,\nu)$ is uniformly bounded for $x>0$ when $\nu=0$.

(b) $\lim_{x\to 0}f(x,\nu)$ exists and is uniformly bounded for $\nu>0$.

(c) $f(x,\nu)$ is uniformly bounded as $x^2+\nu^2\to 0$ for $0<\phi<\frac{1}{2}\pi$.

(d) $f(x,\nu)$ is uniformly bounded as $x^2+\nu^2\to\infty$ for $0<\phi<\frac{1}{2}\pi$.

Here $\phi=\tan^{-1}\nu/x$.

In the following, we use several properties of $J_\nu(x)$, $Y_\nu(x)$ which can be established, for example, by perusing Olver (1974).

Condition (a).

$$f(x,0)=\begin{cases}-2\pi xJ_0(x)Y_0(x), & x\leqq X_0,\\ \pi x\big(J_0^2(x)+Y_0^2(x)\big), & x\geqq X_0.\end{cases}$$

It follows from the asymptotic behaviour of $J_0(x)$ and $Y_0(x)$ that $f(x,0)\to 0$ as $x\to 0$ and $\to 2$ as $x\to\infty$. Therefore, since $J_0(x)$ and $Y_0(x)$ are continuous for $x>0$, it follows that $f(x,0)$ is uniformly bounded for $x>0$.

Condition (b). This follows immediately from the result

$$\lim_{x\to 0} f(x,\nu)=2, \qquad \nu>0.$$

Condition (c). Define $\delta=(x^2+\nu^2)^{1/2}$. Then for $\delta<X_0$,

$$f(x,\nu)=-2\pi|x^2-\nu^2|^{1/2}J_\nu(x)Y_\nu(x).$$

We consider separately the cases $x\leqq\nu$, $x\geqq\nu$.

First, when $x\leqq\nu$ we may write

$$f(x,\nu)=-2\pi\left(1-\frac{x^2}{\nu^2}\right)^{1/2}\frac{\nu}{\sin\nu\pi}\big[\cos(\nu\pi)J_\nu^2(x)-J_\nu(x)J_{-\nu}(x)\big].$$

Now

$$J_\nu^2(x)=x^{2\nu}(1+O(\delta)), \qquad J_\nu(x)J_{-\nu}(x)=1+O(\delta^2) \quad \text{as } \delta\to 0,$$

these results being uniformly valid in x and ν, and so since $x^{2\nu}$ is uniformly bounded for $\nu>0$ and $x<1$, we deduce that $f(x,\nu)$ is uniformly bounded as $\delta\to 0$ for $x\leqq\nu$.

Next consider $x\geqq\nu$. Then we may write

$$f(x,\nu)=-2\pi\left(1-\frac{\nu^2}{x^2}\right)^{1/2}\big\{x^{1/2}J_\nu(x)\big\}\big\{x^{1/2}Y_\nu(x)\big\}.$$

It is easy to see that $x^{1/2}J_\nu(x)$ and $x^{1/2}Y_\nu(x)$ are uniformly bounded for sufficiently small x, ν. Hence $f(x,\nu)$ is uniformly bounded as $\delta\to 0$ for $x\geqq\nu$.

Actually, one can show that $f(x,\nu)\to 0$ as $\delta\to 0$ for $0\leqq\phi<\frac{1}{2}\pi$, though the limit is not uniform; as $\phi\to\frac{1}{2}\pi$ for fixed δ, $f(x,\nu)\to 2$.

Condition (d). Let us write

$$G(R,\phi)=f(x,\nu) \quad \text{when } x=R\cos\phi, \quad \nu=R\sin\phi.$$

Then

$$\text{(B.1)}\quad G(R,\phi)=\begin{cases}-2\pi R|\cos^2\phi-\sin^2\phi|^{1/2}J_{R\sin\phi}(R\cos\phi)Y_{R\sin\phi}(R\cos\phi), & \phi\geqq\phi_R,\\ \pi R|\cos^2\phi-\sin^2\phi|^{1/2}\big(J_{R\sin\phi}^2(R\cos\phi)+Y_{R\sin\phi}^2(R\cos\phi)\big), & \phi\leqq\phi_R,\end{cases}$$

where ϕ_R is the value of ϕ for which $J_{R\sin\phi}(R\cos\phi)=-Y_{R\sin\phi}(R\cos\phi)$. We wish to bound $G(R,\phi)$ as $R\to\infty$. We have the results, uniformly valid in ϕ as $R\to\infty$,

$$\text{(B.2)}\quad \begin{aligned} J_{R\sin\phi}(R\cos\phi)&\sim R^{-1/3}\left(\frac{4\zeta}{\cos^2\phi-\sin^2\phi}\right)^{1/4}\mathrm{Ai}\big(R^{2/3}\zeta\big),\\ Y_{R\sin\phi}(R\cos\phi)&\sim -R^{-1/3}\left(\frac{4\zeta}{\cos^2\phi-\sin^2\phi}\right)^{1/4}\mathrm{Bi}\big(R^{2/3}\zeta\big),\end{aligned}$$

where

$$\frac{2}{3}\zeta^{3/2} = -\int_{\sin\phi}^{\cos\phi} \frac{(\sin^2\phi - t^2)^{1/2}}{t}\,dt \qquad \left(\phi \geqq \frac{1}{4}\pi \text{ or } \zeta > 0\right),$$

$$\frac{2}{3}(-\zeta)^{3/2} = \int_{\sin\phi}^{\cos\phi} \frac{(t^2 - \sin^2\phi)^{1/2}}{t}\,dt \qquad \left(\phi \leqq \frac{1}{4}\pi \text{ or } \zeta < 0\right).$$

Let c be the negative root of the equation $\mathrm{Ai}(x) = \mathrm{Bi}(x)$ of smallest absolute value (Olver (1974, p. 395); $c = -0.366\cdots$). Effectively then, from (B.1), (B.2), $G(R,\phi)$ will be uniformly bounded as $R \to \infty$ in $0 < \phi < \frac{1}{2}\pi$ provided one can bound the following function of y:

$$4\pi|y|^{1/2}\mathrm{Ai}(y)\mathrm{Bi}(y), \qquad y \geqq c,$$
$$2\pi|y|^{1/2}[\mathrm{Ai}^2(y) + \mathrm{Bi}^2(y)], \qquad y \leqq c.$$

This is considered by Olver (1974, p. 397): the maximum occurs when $y = 1.33\cdots$ and the value of the maximum is $2.08\cdots$.

Each of conditions (a)–(d) is thus satisfied.

Next we prove the existence of κ_0, the supremum defined in (5.13). We first define, for each of $j = 0, 1, 2$,

$$f_\nu^{(j)}(z) = \frac{1}{2}\pi|z^2 - \nu^2|^{1/2} E_\nu^{(j)}(z)^2 \left|\mathscr{C}_\nu^{(j)}(z)\right|^2, \qquad z \neq 0,$$
$$f_\nu^{(j)}(0) = \frac{1}{2}\pi e_\nu^{(j)2}.$$

The existence of κ_0 is a consequence of the following lemma.

LEMMA 3. *Each of $f_\nu^{(0)}(z), f_\nu^{(1)}(z), f_\nu^{(2)}(z)$ is uniformly bounded for all $\nu \geqq 0$ and all z.*

Proof. One readily sees that $f_\nu^{(j)}(z)$ is a continuous function of ν and z for all $\nu \geqq 0$ and all z. The result will follow provided we can show that $f_\nu^{(j)}(z)$, as a function of z, is bounded throughout the z-plane including the point at infinity, and that the bound is uniform in ν.

To establish this, consider separately $z \in \mathscr{S}_\nu^{(0)}$ and $\mathscr{S}_\nu^{(1)} \cup \mathscr{S}_\nu^{(2)}$. When $z \in \mathscr{S}_\nu^{(0)}$, the definitions of $E_\nu^{(j)}(z)$ at once imply that $f_\nu^{(j)}(z) \leqq \frac{1}{2}\pi e_\nu^{(j)2}$, and consideration of the asymptotic behaviour of $\mathscr{C}_\nu^{(j)}(z)$ for large order and argument shows that $e_\nu^{(j)}$ remains bounded as $\nu \to \infty$. When $z \in \mathscr{S}_\nu^{(1)}$ or $\mathscr{S}_\nu^{(2)}$ we appeal to the inequality

$$|z^2 - \nu^2|^{1/4}\left|\mathscr{C}_\nu^{(j)}(z)\right| \leqq A\left|\exp\left(i\int_\nu^z \frac{(t^2 - \nu^2)^{1/2}}{t}\,dt\right)\right|, \tag{B.3}$$

where A is some constant independent of ν and z. Here the branch of $(t^2 - \nu^2)^{1/2}$ is defined in a similar manner as that in (5.8). The inequality (B.3) can readily be demonstrated to hold for $|\arg z| \leqq \frac{1}{2}\pi$ by using results analogous to (B.2); for $\frac{1}{2}\pi < |\arg z| \leqq \pi$ we appeal to the continuation formulae for $\mathscr{C}_\nu^{(j)}(z)$ and the result

$$\mathrm{Im}\int_{-\nu}^{\nu} \frac{(t^2 - \nu^2)^{1/2}}{t}\,dt = 0.$$

Then $f_\nu^{(j)}(z)$ will be uniformly bounded in $\mathscr{S}_\nu^{(1)}$ and $\mathscr{S}_\nu^{(2)}$ provided we can show that

$$\int_\nu^z \frac{(t^2-\nu^2)^{1/2}}{t}\,dt - \int_{\hat{X}_\nu}^z \frac{(t^2-\hat{X}_\nu^2)^{1/2}}{t}\,dt \tag{B.4}$$

is uniformly bounded for all $\nu \geqq 0$ and all $z \in \mathscr{S}_\nu^{(1)} \cup \mathscr{S}_\nu^{(2)}$. One can show, by considering separately the cases $|z/\nu|$ bounded and $|z/\nu|$ large, that (B.4) is uniformly bounded throughout $\mathscr{S}_\nu^{(1)} \cup \mathscr{S}_\nu^{(2)}$ and furthermore that the bound is $O(\nu^{-1/3})$ as $\nu \to \infty$. (Recall that $\hat{X}_\nu = \nu(1 + O(\nu^{-4/3}))$.)

The lemma follows.

Acknowledgments. We are grateful to Professor F. W. J. Olver for a number of valuable comments. This work was carried out while TMD was supported by an S.E.R.C. research studentship.

ASYMPTOTIC BEHAVIOR OF THE INVARIANT DENSITY OF A DIFFUSION MARKOV PROCESS WITH SMALL DIFFUSION*

SHUENN-JYI SHEU†

Abstract. Let $X(t)$ be the n-dimensional diffusion process governed by the following equation: $dx(t)=b(x(t))\,dt+\sqrt{\varepsilon}\,dw(t)$. Assume $b(x)=\nabla I(x)+l(x)$, $\nabla I\cdot l=0$. Then under some growth conditions on I and l, we show $x(\cdot)$ has unique invariant measure with density $p^\varepsilon(x)$. And we establish the following asymptotic behavior for p^ε: $p^\varepsilon(x)=\varepsilon^{-n/2}\exp(-2I(x)/\varepsilon)(R_0(x)+O(\varepsilon))$.

Introduction. Let $x(\cdot)$ be an n-dimensional diffusion satisfying the following equation:

$$dx(t)=b(x(t))\,dt+\sqrt{\varepsilon}\,dw(t). \tag{1}$$

We will write $x^\varepsilon(\cdot)$ to indicate the dependence of $x(\cdot)$ on ε. Suppose for each $\varepsilon>0$, the diffusion process $x(\cdot)$ has invariant measure with density $p^\varepsilon(x)$. We will be interested in establishing the following limiting behavior of $p^\varepsilon(x)$:

$$\lim_{\varepsilon\to 0}\varepsilon\log p^\varepsilon(x)=-v(x), \tag{2}$$

$$p^\varepsilon(x)=\varepsilon^{-n/2}e^{-v(x)/\varepsilon}\big(T_0(x)+T_1(x)+\cdots+\varepsilon^n T_n(x)+O(\varepsilon^{n+1})\big). \tag{3}$$

A formal argument indicates that the function $v(\cdot)$ is given by the following expression:

$$v(x)=\inf_{\substack{\phi(0)=x\\ \phi(\infty)=0}}\frac{1}{2}\int_0^\infty|\dot\phi(t)+b(\phi(t))|\,dk, \tag{4}$$

where $\dot\phi(t)$ is the derivative of $\phi(t)$ at t. And T_0, T_1, $\cdots$ can be obtained by solving a family of first order partial differential equations.

This paper shows that if the function $v(x)$ given by (4) is smooth and satisfies some growth conditions, then it is possible to establish the results like (2) and a weaker result of (3), i.e.

$$\begin{aligned}&p_\varepsilon(x)=\varepsilon^{-n/2}e^{-v(x)/\varepsilon}R_\varepsilon(x),\\ &\lim R_\varepsilon(x)=R_0(x).\end{aligned} \tag{5}$$

A recent result of M. Day shows that there is a nice relation between the limiting behavior of p^ε and of the exit distribution of $x^\varepsilon(\cdot)$ from a domain (cf. [3]). A result like (5) will be useful in this respect.

† Institute of Mathematics, Academia Sinica, Nankang, Taipei, Taiwan, Republic of China.

The plan of this paper is as follows. The assumptions are stated in §1. Under these assumptions, we give an estimation for $p^\varepsilon(\cdot)$. Section 2 shows a Ventsel–Friedlin type result (2). The basic idea is to use the relation between p^ε and the transition density. Section 3 proves the result (5). This result depends on the smoothness of the function $v(\cdot)$. However, this is a local property in the sense that if we know that (2) and the smoothness of $v(\cdot)$ on a certain region containing 0 and x, then it is possible that (5) holds.

Notation. x,y,z denote vectors in $\mathbb{R}^n$. $x\cdot y$ is the usual inner product and $|x|=(x\cdot x)^{1/2}$. For a smooth real valued function f on $\mathbb{R}^n$ $D^\alpha f(x)=(\partial^{|\alpha|}f/\partial^{\alpha_1}\cdots\partial^{\alpha_n})(x)$ for $\alpha=(\alpha_1,\cdots,\alpha_n)$, where $\alpha_i\geqq 0$ are integers.

1. Assumptions and initial results. We make the following assumptions through this paper.

Assumption (A). Assume $b(x)=-\nabla I(x)+l(x)$ where $\nabla I(x)$ is the gradient of the real valued function $I(x)$. Moreover,

(a) $\nabla I(x)\cdot l(x)=0$, $\forall x\in\mathbb{R}^n$.

(b) $I(\cdot)$, $b(\cdot)\in C^\infty$ and

$$\sup_x |D^\alpha I(x)|\leqq C_\alpha \quad \forall|\alpha|\geqq 2,$$

$$\sup_x |D^\alpha b_i(x)|\leqq C_\alpha \quad \forall|\alpha|\geqq 1,\ b(x)=(b_1(x),\cdots,b_n(x)).$$

(c) $\inf\{|\nabla I(x)|;\ |x|\geqq R\}=\delta(R)\geqq K_1 R$ if R is small, and $I(x)\to\infty$ as $|x|\to\infty$, $I(0)=0$,

(d) $b(0)=0$, $[\partial b_i(0)/\partial x_j]$ has eigenvalues with only negative real part.

LEMMA 1.1.

$$2I(x)=\inf_{\substack{\phi(0)=x\\ \phi(\infty)=0}}\frac{1}{2}\int_0^\infty |\phi(t)+b(\phi(t))|^2\,dt. \tag{1.1}$$

Proof. Since $v(x)=2I(x)$ satisfies $1/2|\nabla v(x)|^2+b(x)\cdot\nabla v(x)=0$, we realize that this is the Hamilton–Jacobi equation satisfied by the value function defined by the right-hand side of (1.1). We expect (1.1) to hold by some "verification theorem" (cf. [7]). However, it can be proved as follows.

Let $\phi^0(t)$ be the solution of

$$\frac{d\phi^0}{dt}(t)=-(b+2\nabla I)(\phi^0(t)),\qquad \phi^0(0)=x. \tag{1.2}$$

Then

$$\begin{aligned}\frac{dI(\phi^0(t))}{dt}&=-\nabla I\cdot(b+2\nabla I)(\phi^0(t))\\ &=-|\nabla I(\phi^0(t))|^2\\ &=-\frac{1}{4}|\phi^0(t)+b(\phi^0(t))|^2.\end{aligned}$$

This implies

$$I(\phi^0(T))-I(x)=-\frac{1}{4}\int_0^T |\dot{\phi}^0(t)+b(\phi^0(t))|^2\,dt,$$
$$\phi^0(T)\to 0 \quad \text{as } T\to\infty.$$

Therefore

$$I(x)=\frac{1}{4}\int_0^\infty |\dot{\phi}^0(t)+b(\phi^0(t))|^2\,dt.$$

On the other hand, for any curve $\phi(t)$,

$$\begin{aligned}|\dot{\phi}(t)+b(\phi(t))|^2&=|\dot{\phi}(t)-\nabla I(\phi(t))+l(\phi(t))|^2\\&=|\dot{\phi}(t)|^2-2\dot{\phi}(t)\cdot\nabla I(\phi(t))\\&\quad+2\dot{\phi}(t)\cdot l(\phi(t))+|\nabla I(\phi(t))|^2+|l(\phi(t))|^2\\&\geqq -4\dot{\phi}(t)\cdot\nabla I(\tau(t))\\&=-4\frac{d}{dt}I(\phi(t)).\end{aligned}$$

Therefore

$$I(x)\leqq\frac{1}{4}\int_0^\infty |\dot{\phi}(t)+b(\phi(t))|^2\,dt \quad \text{if } \phi(\infty)=0.$$

Thus we complete the proof.

Remark. For general $b(\cdot)$, without assuming (A), if the function $v(\cdot)$ defined by the right-hand side of (1.1) is smooth, then $v(\cdot)$ satisfies

$$\frac{1}{2}|\nabla v(x)|^2+b(x)\cdot V(x)=0. \tag{1.3}$$

From this we have $b(x)=-\nabla I(x)+l(x)$, where $v(x)=2I(x)$, and $\nabla I(x)\cdot l(x)=0$.

LEMMA 1.2. *Under assumption* (A), *there is a unique invariant density* $p^\varepsilon(\cdot)$ *for* $x^\varepsilon(\cdot)$. *Moreover, we have*

$$\int \exp\left(\frac{2m}{\varepsilon}I(y)\right)p^\varepsilon(y)\,dy\leqq C_m, \qquad 0<m<1 \tag{1.4}$$

for some $C_m>0$ *which is independent of* ε.

Proof. Let $f(x)=\exp((2m/\varepsilon)I(x))$ and

$$dx(t)=b(x(t))\,dt+\sqrt{\varepsilon}\,dw(t),$$
$$x(0)=x,$$
$$Lf=\frac{\varepsilon}{2}\Delta f+b\cdot\nabla f=\left(m\Delta I-\frac{2m(1-m)}{\varepsilon}|\nabla I|^2\right)f.$$

It is easy to see by our assumption that $I(x) \leqq c|x|^2$ for some $c > 0$. Then,

$$Lf(y) \leqq \begin{cases} C^{(m)} & \text{if } |y| \leqq K_m\sqrt{\varepsilon}, \\ -\alpha f(y) & \text{if } |y| \geqq K_m\sqrt{\varepsilon}. \end{cases}$$

α can be chosen as large as we want by choosing K_m such that

$$m \sup_x |\Delta I(x)| - 2m(1-m)K_1^2 K_m^2 < -\alpha.$$

Thus $f(\cdot)$ can serve as a Lyapunov function. Then $x^\varepsilon(\cdot)$ has a unique invariant density $p^\varepsilon(\cdot)$. (See [10].)

Let $\tau_R = \inf\{t: |x(t)| = R\}$. By a simple calculation

$$d(f(x(t))\exp(\alpha t)) = Lf(x(t) + \alpha f(x(t)))\exp(\alpha t)\,dt + dM(t),$$

where $M(t)$ is a martingale. Then

$$\begin{aligned} &E_x[f(x(t \wedge \tau_R))\exp(\alpha t \wedge \tau_R)] - f(x) \\ &\quad = E_x\left[\int_0^{\tau_R \wedge t} (Lf(x(s)) + \alpha f(x(s)))\exp(\alpha s)\,ds\right] \\ &\quad \leqq c\int_0^t \exp(\alpha s)\,ds \\ &\quad \leqq c_m \exp(\alpha t). \end{aligned}$$

Letting $R \to \infty$, we get

$$E_x[f(x(t))] \leqq c_m + f(x)\exp(-\alpha t).$$

We prove (1.4) by letting $t \to \infty$.

2. Ventsel–Friedlin type result. The main result of this section is the following theorem.

THEOREM 2.1.

$$\lim_{\varepsilon \to 0} \varepsilon \log p^\varepsilon(x) = -2I(x).$$

We will prove the following results:

$$\overline{\lim}\, \varepsilon \log p^\varepsilon(x) \leqq -2I(x), \tag{2.1}$$

$$\underline{\lim}\, \varepsilon \log p^\varepsilon(x) \geqq -2I(x). \tag{2.2}$$

For (2.1), we have the following estimation.

LEMMA 2.2. *There is a* $c_m > 0$ *such that*

$$\exp\left(\frac{2m}{\varepsilon} I(y)\right) p^\varepsilon(y) \leqq c_m \varepsilon^{-n/2}, \qquad 0 < m < 1.$$

Proof. We write $p^\varepsilon(t,x,y)$ and $q^\varepsilon(t,x,y)$ for the transition density of diffusion processes $x(t)$ and $y(t)$ respectively, where

$$\begin{aligned} dx(t) &= b(x(t))\,dt + \sqrt{\varepsilon}\,dw(t), \\ dy(t) &= (2\nabla I(y(t)) + b(y(t)))\,dt + \sqrt{\varepsilon}\,dw(t). \end{aligned}$$

Also, let $\pi^\varepsilon(t,x,y)=\exp((-2/\varepsilon)I(y))p^\varepsilon(t,x,y)\exp(\frac{2}{\varepsilon}I(y))$. We will obtain the following estimate:

$$p^\varepsilon(t,x,y)\leqq c_t\varepsilon^{-n/2}, \tag{2.3}$$

$$q^\varepsilon(t,x,y)\leqq c_t\varepsilon^{-n/2}, \tag{2.4}$$

$$\pi^\varepsilon(t,x,y)\leqq c_t\varepsilon^{-n/2}. \tag{2.5}$$

Assuming these, then

$$\begin{aligned} p^\varepsilon(y)&=\int p^\varepsilon(x)p^\varepsilon(t,x,y)\,dx \\ &=\int p^\varepsilon(x)\exp\left(\frac{2m}{\varepsilon}I(x)\right)\exp\left(-\frac{2m}{\varepsilon}I(x)\right)p^\varepsilon(t,x,y)\,dx. \end{aligned}$$

Together with the following inequality,

$$\begin{aligned} &\exp\left(-\frac{2m}{\varepsilon}I(x)\right)p^\varepsilon(t,x,y)\exp\left(\frac{2m}{\varepsilon}I(y)\right) \\ &\qquad=\pi^\varepsilon(t,x,y)^m p^\varepsilon(t,x,y)^{1-m}\leqq c_t\varepsilon^{-n/2}, \end{aligned}$$

we get, by using Lemma 1.2,

$$p^\varepsilon(y)\exp\left(\frac{2m}{\varepsilon}I(y)\right)\leqq c_t\varepsilon^{-n/2}\int p^\varepsilon(x)\exp\left(\frac{2m}{\varepsilon}I(x)\right)dx\leqq c_m\varepsilon^{-n/2}.$$

It remains to show (2.3), (2.4), (2.5). The proof of (2.3) and (2.4) are the same, it depends only on the estimation of the drift of the diffusion. We only consider $p^\varepsilon(t,x,y)$. It is easy to see that $p^\varepsilon(t,x,y)=\varepsilon^{-n/2}\tilde{p}^\varepsilon(t,x/\varepsilon,y/\varepsilon)$ where $\tilde{p}^\varepsilon(t,x,y)$ is the transition density of the diffusion $z(\cdot)$,

$$\begin{aligned} dz(t)&=\tilde{b}(z(t))\,dt+dw(t), \\ \tilde{b}(z)&=\frac{1}{\sqrt{\varepsilon}}b(\sqrt{\varepsilon}\,z). \end{aligned}$$

By a theorem [11, Cor. 3.37] $\tilde{p}^\varepsilon(t,x,y)\leqq c_t$. Therefore we get (2.3).

Now consider $\pi^\varepsilon(t,x,y)$. By a simple calculation, we get

$$\begin{aligned} \frac{d\pi^\varepsilon}{dt}&=\frac{\varepsilon}{2}\Delta_x\pi^\varepsilon+(2\nabla I+b)\cdot\nabla_x\pi^\varepsilon+\Delta I\cdot\pi^\varepsilon, \\ \frac{d\pi^\varepsilon}{dt}&=\frac{\varepsilon}{2}\Delta_y\pi^\varepsilon-(2\nabla I+b)\cdot\nabla_y\pi^\varepsilon-(\Delta I+\operatorname{div}b)\pi^\varepsilon, \end{aligned}$$

where ∇_x, Δ_x (resp. ∇_y, Δ_y) mean gradient and Laplacian with respect to the variable x (resp. y). From this

$$\pi^\varepsilon(t,x,y)=E_x\left[\exp\left(\int_0^t\Delta I(y(s))\,ds\right)\ y(t)=y\right]q^\varepsilon(t,x,y)$$

where $dy(t)=(2\nabla I(y(t))+b(y(t)))dt+\sqrt{\varepsilon}\,dw(t)$. Hence, by using (2.4), we obtain (2.5).

We now prove (2.2). We need a lemma from [12].

LEMMA 2.3. *Let*

$$I(T,x,y)=\inf_{\substack{\phi(0)=x\\ \phi(T)=y}}\frac{1}{2}\int_0^T|b(\phi(t))+\dot{\phi}(t)|^2\,dt.$$

Then $\lim_{\varepsilon\to 0}\varepsilon\log p^\varepsilon(T,y,x)\geqq -I(T,x,y)$ *uniformly for* x, y *on compact sets.*

Proof. See [12], or we can prove this by mimicing the arguments in [4].

LEMMA 2.4.

$$\lim_{\varepsilon\to 0}\varepsilon\log p^\varepsilon(x)\geqq -\sup_{|y|\leqq 1}I(T,x,y)\quad\forall T>0.$$

Proof. By Lemma 1.2,

$$\int_{|y|\geqq 1}p^\varepsilon(y)\,dy\to 0\quad\text{as }\varepsilon\to 0.$$

On the other hand,

$$\begin{aligned}p^\varepsilon(x)&=\int p^\varepsilon(y)p^\varepsilon(T,y,x)\,dy\\ &\geqq\int_{|y|\leqq 1}p^\varepsilon(y)p^\varepsilon(T,y,x)\,dy\\ &\geqq c(\varepsilon)\inf_{|y|\leqq 1}p^\varepsilon(T,y,x)\end{aligned}$$

where $c(\varepsilon)=\int_{|y|\leqq 1}p^\varepsilon(y)\,dy\to 1$ as $\varepsilon\to 0$. We obtain Lemma 2.4 easily by the above inequality and Lemma 2.3.

LEMMA 2.5.

$$\begin{aligned}&\lim_{T\to\infty}I(T,x,y)=v(x)=2I(x),\\ &v(x)=\inf_{\substack{\phi(0)=x\\ \phi(\infty)=0}}\frac{1}{2}\int_0^\infty|\dot{\phi}(t)+b(\phi(t))|^2\,dt.\end{aligned}$$

Proof. $v(x)=2I(x)$ was proved in Lemma 1.1. We prove the first equality as follows.

We fix x, y. Let $\phi(\cdot)$ be a curve such that $\phi(0)=x$, $\phi(T)=y$. For any $0<t<T$, following the proof of Lemma 1.1, we have

$$\begin{aligned}&\frac{1}{2}\int_0^T|\dot{\phi}(s)+b(\phi(s))|^2\,ds\geqq 2(I(\phi(t))-I(y)),\\ &\frac{1}{2}\int_0^T|\dot{\phi}(s)+b(\phi(s))|^2\,ds\geqq 2(I(x)-I(\phi(t))).\end{aligned}$$

From these we show that if there is $0<t<T$ such that $|\phi(t)|$ is large, then $\frac{1}{2}\int_0^T|\dot{\phi}(s)+b(\phi(s))|^2\,ds$ is large since $I(z)\to\infty$ as $|z|\to\infty$. And if there is $0<t<T$ such that $|\phi(t)|$ is small, then

$$\frac{1}{2}\int_0^T|\dot{\phi}(s)+b(\phi(s))|^2\,ds\geqq 2(I(x)-I(\phi(t)))\simeq 2I(x).$$

On the other hand, following an argument in [5, Lemma 3.1, p. 334], we can establish the following property:

$$\frac{1}{2}\int_0^T |\dot{\phi}+b(\phi(s))|^2 ds \to \infty \quad \text{as } T\to\infty$$

if $\delta \leqq |\phi(s)| \leqq R$, $\forall 0 \leqq s \leqq T$, where δ, R are fixed positive numbers.

By combining above results, it is easy to show

$$\varliminf_{T\to\infty} I(T,x,y) \geqq 2I(x) \quad \text{uniformly on compact sets.}$$

By using $\phi^0(\cdot)$ defined in (1.2), we can also show

$$\varlimsup_{T\to\infty} I(T,x,y) \leqq 2I(x) \quad \text{uniformly on compact sets.}$$

This completes the proof of Lemma 2.5.

3. Further results. Now consider the function R^ε defined by

$$p^\varepsilon(x) = \varepsilon^{-n/2} e^{-2I(x)/\varepsilon} R^\varepsilon(x). \tag{3.1}$$

We have the following refined result of Theorem 2.1.

THEOREM 3.1.

$$R^\varepsilon(x) \to R_0(x) \quad \textit{as } \varepsilon\to 0$$

where R_0 is the solution of the following equation:

$$-(b+2\nabla I)\cdot\nabla R_0 - (\operatorname{div} b + \Delta I) R_0 = 0, \qquad R_0(0) = c, \tag{3.2}$$

with

$$c\int \exp(-x^* A x)\, dx = 1, \qquad A = \left[\frac{\partial^2 I}{\partial x_i \partial x_j}(0)\right].$$

We compare the functions R^ε and R_0 before we give the proof of this theorem. It is not difficult to see that R^ε satisfies the following equation

$$\frac{1}{2}\varepsilon\Delta R^\varepsilon - (b+2\nabla I)\cdot\nabla R^\varepsilon - (\operatorname{div} b + \Delta I) R^\varepsilon = 0. \tag{3.3}$$

Formally, by letting $\varepsilon\to 0$ in (3.3), we get the equation (3.2) satisfied by R_0. On the other hand we have the following result which will give the condition $R_0(0)=c$.

LEMMA 3.2.

$$R^\varepsilon(\sqrt{\varepsilon}\, x) \to c \quad \textit{as } \varepsilon\to 0 \textit{ uniformly for } x \textit{ in compact sets.}$$

Proof. Let $\tilde{R}^\varepsilon(x) = R^\varepsilon(\sqrt{\varepsilon}\, x)$. Then

$$\tilde{p}(x) = \exp\bigl(-2/\varepsilon I(\sqrt{\varepsilon}\, x)\bigr)\tilde{R}^\varepsilon(x) \tag{3.4}$$

$\tilde{p}^\varepsilon$ is the invariant density for the diffusion process $y(\cdot)$

$$dy(t) = \tilde{b}^\varepsilon(y(t))\, dt + dw(t),$$

where $\tilde{b}^\varepsilon(y)=(1/\sqrt{\varepsilon})b(\sqrt{\varepsilon}y)$. Also $\tilde{p}^\varepsilon$ satisfies the following equation

$$\frac{1}{2}\Delta\tilde{p}^\varepsilon-\tilde{b}^\varepsilon\cdot\nabla\tilde{p}^\varepsilon-\operatorname{div}\tilde{b}^\varepsilon\tilde{p}^\varepsilon=0.$$

First $\tilde{p}^\varepsilon(x)\leqq c$ with c independent of ε and x by using

$$\tilde{p}^\varepsilon(x)=\int\tilde{p}^\varepsilon(y)\tilde{p}^\varepsilon(t,y,x)\,dy$$

and the fact that $\tilde{p}^\varepsilon(t,y,x)\leqq c_t$ with c_t independent of ε, x, y. Since $\tilde{b}^\varepsilon$ with all their derivatives are bounded, independent of ε, on bounded set, we can show (see [9, Theorem 6.2]) $\{\tilde{p}^\varepsilon\}$ is a compact subset of $C(\mathbb{R}^n)$ the family of all continuous real valued functions on $\mathbb{R}^n$. Also, the limit points of $\{\tilde{p}^\varepsilon\}$ are solutions of the following equation

$$\frac{1}{2}\Delta p-B\cdot\Delta p-\operatorname{div}Bp=0,$$

where $B(y)=By$ with $B=[\partial b_i/\partial x_j](0)$. On the other hand, the family of probability measures $\{\tilde{P}^\varepsilon\}$ with densities $\{\tilde{p}^\varepsilon\}$ is tight by appealing to Lemma 1.2. From these facts, $\tilde{p}$ is the only limit point of $\{\tilde{p}^\varepsilon\}$, where $\tilde{p}$ is the invariant density of

$$dy(t)=B(y(t))\,dt+dw(t)$$

and is given by

$$\tilde{p}(y)=c\exp\left(-\frac{y*Dy}{2}\right),$$

D is the only positive definite matrix satisfying $\frac{1}{2}|Dy|^2+By\cdot Dy=0$ for all $y\in R^n$.

It is not difficult to see that $D=2A$ by using the property $b(y)\cdot\nabla I(y)+|\nabla I(y)|^2=0$. Then we can get $\tilde{R}^\varepsilon(x)\to c$ by (3.4) and $\tilde{p}^\varepsilon(y)\to p(y)$ as $\varepsilon\to 0$. This completes the proof.

Proof of Theorem 3.1. Let $z(\cdot)$ be the diffusion satisfying

$$dz(t)=-(b+2\nabla I)(z(t))\,dt+\sqrt{\varepsilon}\,dw_t$$

and $\tau=\inf\{t;I(z(t))=\varepsilon R \text{ or } R\}$, where R is a fixed positive number. Then, by (3.3), we have

$$R^\varepsilon(x)=E_x\left[R^\varepsilon(z(\tau))\exp\left(-\int_0^T(\operatorname{div}b+\Delta I)(z(s))\,ds\right)\right].$$

Since $(\operatorname{div}b+\Delta I)(0)=0$, $|(\operatorname{div}b+\Delta I)(z)|\leqq c|z|$ for all z. We need the following properties:

(i) Fix R_1, $\delta_1>0$; then there is $c>0$ such that $R^\varepsilon(z)\leqq ce^{-\delta_1/\varepsilon}$ if $|z|\leqq R_1$.

(ii) There is a $\delta>0$ such that $P\{I(z(\tau))=R\}<e^{-\delta/\varepsilon}$.

(iii) $\forall p>1$, $\exists C_p>0$ with C_p independent of $\varepsilon>0$ such that

$$E_x\left[\exp\left(p\int_0^\tau|z(s)|ds\right)\right]\leqq C_p.$$

Since

$$R^\varepsilon(x)=E_x\left[R^\varepsilon(z(\tau))\exp\left(-\int_0^\tau(\operatorname{div}b+\Delta I)(z(s))\,ds\right);\ I(z(\tau))=R\right]$$
$$+E_x\left[R^\varepsilon(z(\tau))\exp\left(-\int_0^\tau(\operatorname{div}b+\Delta I)(z(s))\,ds\right);\ I(z(\tau))=\varepsilon R\right].$$

The first term on the right tends to zero because of the properties (i), (ii), (iii). On the other hand, when z is small $I(z)\simeq c_0|z|^2$ for some $c_0>0$. Therefore $R^\varepsilon(z(\tau))\to c$ as $\varepsilon\to 0$ if $I(z(\tau))=\varepsilon R$ (see Lemma 3.2). Property (iii) implies

$$\exp\left(-\int_0^\tau(\operatorname{div}b+\Delta I)(z(s))\,ds\right)\to\exp\left(-\int_0^\infty(\operatorname{div}b+\Delta I)(z_0(s))\,ds\right)$$

in L^p for any $p>1$, where $z_0(s)$ is the solution of

$$\frac{dz_0(t)}{dt}=-(b+2\nabla I)(z_0(t)).$$

Hence

$$R^\varepsilon(x)\to c\exp\left(-\int_0^\infty(\operatorname{div}b+\Delta I)(z_0(s))\,ds\right)=R_0(x).$$

It remains to show (i), (ii), (ii). (i) follows from Lemma 2.2. (ii) is a weaker result in [2]. As for (iii), we have the following lemma.

LEMMA 3.3. $E_x[\exp(p\int_0^\tau|z(s)|ds)]\leqq\exp(cpI(x)^{1/2})$ *for some* $c>0$.

Proof. Since $g(x)=E_x[\exp(p\int_0^\tau|z(s)|ds)]$ satisfies

$$Ag(x)=\frac{\varepsilon}{2}\Delta g(x)-(b+2\nabla I)\cdot\nabla g(x)+p|x|g(x)=0,$$
$$g(x)=1\quad\text{on } I(x)=\varepsilon R \text{ or } R.$$

We will choose a function $f(x)$ such that

$$\begin{aligned}&Af(x)\leqq 0\quad\text{on } \{x;\varepsilon R\leqq I(x)\leqq R\},\\ &f(x)\geqq 1\quad\text{on } I(x)=\varepsilon R \text{ or } R.\end{aligned}\tag{3.5}$$

Assuming such function $f(x)$, then, by Ito's formula

$$\begin{aligned}&d\left(f(z(\tau))\exp\left(p\int_0^t|z(s)|\,ds\right)\right)\\ &\quad=Af(z(\tau))\exp\left(p\int_0^T|z(s)|\,ds\right)dt+dM(t),\end{aligned}\tag{3.6}$$

$M(t)$ is a martingale. Equation (3.5) gives

$$E_x\left[f(z(\tau))\exp\left(p\int_0^\tau|z(s)|\,ds\right)\right]\leqq f(x)$$

by taking expectation in (3.6). Therefore

$$E_x\left[\exp\left(p\int_0^\tau|z(s)|\,ds\right)\right]\leqq f(x),$$

which gives a bound for $E_x[\exp(p\int_0^\tau|z(s)|ds)]$.

We will try $f(x)=\exp(cpI(x)^{1/2})$. A calculation gives

$$Af(x)=\left[\frac{\varepsilon}{2}\left(cp\frac{\Delta I}{I^{1/2}}(x)-cp\frac{1}{2}\frac{|\Delta I|^2}{I^{3/2}}(x)+c^2p^2\frac{|\nabla I|^2}{I}(x)\right)-cp\frac{|\nabla I|^2}{I^{1/2}}(x)+p|x|\right]f(x).$$

By assumption, on $\{x;\varepsilon R\leqq I(x)\leqq R\}$, the first term on the right is $O(\sqrt{\varepsilon})$ and

$$-cp\frac{|\nabla I|^2}{I^{1/2}}(x)+p|x|\leqq(-cp\alpha+p)|x|\leqq(-cp\alpha+p)k\sqrt{\varepsilon}$$

for some $\alpha>0$, $k>0$, where we use $I(x)>0$ if $|x|\neq 0$ and $I(x)\simeq c_0|x|^2$ if $|x|$ is small. If we choose c to be large enough, we have (3.5), then the result of the lemma.

Acknowledgment. The author would like to thank Professor W. H. Fleming for suggesting the problem and for many useful discussions.

ELECTROSTATICS AND THE ZEROS OF THE CLASSICAL POLYNOMIALS*

P. J. FORRESTER† AND J. B. ROGERS‡

Abstract. New interpretations of the zeros of the classical polynomials as the equilibrium positions of two-dimensional electrostatic problems are given. The electrostatic problems solved include determining the equilibrium position on the circle of $n2^M$ particles of unit charge and 2^M particles of charge $+q$, given that between every two $+q$ charges there are n unit charges.

AMS(MOS) subject classifications. Primary 82, 33

Key words. orthogonal polynomials, crystal lattices, Coulomb system

1. Introduction. Almost one hundred years ago Stieltjes gave a two-dimensional electrostatics interpretation to the zeros of the classical polynomials ([4], [5], [6]; see Szegö [7, Chap. 6]). Motivated by the desire to obtain exact information about the ground state of two-component systems interacting via the logarithmic potential, we extend Stieltjes' results. These new results supplement exact results recently obtained for the nonzero temperature statistical mechanics of such a system [1], [2].

As an illustration of our extensions, consider the unit circle in the complex plane. At the point $z=1$ fix a particle of charge $+q$ and at $z=-1$ fix a particle of charge $+p$. We show that the equilibrium position of $2N$ unit charges on the circle, symmetrically distributed about the real axis, can be written in terms of the zeros of the Jacobi polynomials. By utilizing an elementary partial fractions identity ((4.9) below), we find that the solution to more general equilibrium problems can be written down from the knowledge of the above problem. The more general problem is the determination of the equilibrium position on the circle of $n2^M$ particles of unit charge and 2^M particles of charge $+q$, given that between every two $+q$ charges there are n unit charges. We thus provide the exact structure of a local minimum of the Hamiltonian for a two-component system.

Properties of the ground states can be described in detail, as the zeros of the Jacobi polynomials have been extensively studied [7]. Conversely, many intuitively obvious properties of the electrostatic problem can be formulated as theorems regarding the zeros of the Jacobi polynomials, thus providing electrostatic interpretations to those theorems.

2. Two impurities on the circle. Consider a system of $2N$ particles of charge $+1$, labelled $\theta_1, \theta_2, \cdots, \theta_{2N}$, confined to a circle of radius R interacting via the potential

$$V(\theta_j,\theta_k) = -q_k \log R|e^{i\theta_j}-e^{i\theta_k}|. \tag{2.1}$$

At $\theta=0$ fix a particle of charge $+q$ and at $\theta=\pi$ fix a particle of charge $+p$. The uniform neutralizing background necessary to obtain thermodynamic stability is not

† Department of Theoretical Physics, Research School of Physical Sciences, The Australian National University, Canberra, Australia 2601.

‡ Department of Mathematics, University of Melbourne, Parkville, Victoria, Australia 3052.

relevant when calculating the ground state equilibrium positions, since it only contributes a constant to the Hamiltonian. Thus ignoring constant terms, we may take for the Hamiltonian

$$H_0 = -q\sum_{k=1}^{2N}\log|1-e^{i\theta_k}| - p\sum_{k=1}^{2N}\log|1+e^{i\theta_k}| - \sum_{1\leq k<j\leq N}\log|e^{i\theta_k}-e^{i\theta_j}|. \tag{2.2}$$

Note that the radius has been scaled out of the Hamiltonian. We seek the minimum of H_0 subject to the requirement

$$0<\theta_j<\pi, \quad j=1,2,\cdots,N \quad \text{and} \quad \pi<\theta_j<2\pi, \quad j=N+1,\cdots,2N. \tag{2.3}$$

Such a minimum exists and is unique [7, p. 140]. By symmetry $\theta_j=-\theta_{2N+1-j}$, $j=1,2,\cdots,N$. The location of the minimum is given by the following result.

THEOREM 2.1. *The minimum of the function H_0 subject to the constraint* (2.3) *occurs at the zeros of the Jacobi polynomial $P_N^{(q-1/2,p-1/2)}(\cos\theta)$, $0<\theta<2\pi$.*

Proof. Using the identity

$$|e^{i\theta_j}-e^{i\theta_k}| = i^{-1}(e^{i\theta_j}-e^{i\theta_k})\exp\left(-\frac{i}{2}(\theta_j+\theta_k)\right), \qquad \theta_j\geq\theta_k, \tag{2.4}$$

we see that the condition for a minimum is the set of nonlinear equations

$$0=\frac{\partial H}{\partial\theta_k} = -i\Bigg(qe^{i\theta_k}/(e^{i\theta_k}-1)+pe^{i\theta_k}/(e^{i\theta_k}+1) - (2N-1+p+q)/2+\sum_{j=1}^{2N}{}'\, e^{i\theta_k}/(e^{i\theta_k}-e^{i\theta_j})\Bigg), \qquad 1\leq k\leq 2N, \tag{2.5}$$

where the prime on the sum indicates that the $j=k$ term is to be omitted. Following Stieltjes, consider the polynomial

$$f(x)=\prod_{l=1}^{2N}(x-e^{i\theta_l}), \tag{2.6}$$

which has its zeros at the minimum of H_0. A short calculation then shows

$$\frac{f''(e^{i\theta_k})}{f'(e^{i\theta_k})} = 2\sum_{j=1}^{N}{}'\,\frac{1}{(e^{i\theta_k}-e^{i\theta_j})}. \tag{2.7}$$

Thus we can write the ground state condition (2.5) as

(2.8)

$$0=e^{i\theta_k}(e^{2i\theta_k}-1)f''(e^{i\theta_k}) + \left(2qe^{i\theta_k}(e^{i\theta_k}+1)+2pe^{i\theta_k}(e^{i\theta_k}-1)-(2N-1+p+q)(e^{2i\theta_k}-1)\right)f'(e^{i\theta_k}), \qquad 1\leq k\leq 2N.$$

The $(2N+1)$th order polynomial

$$x(x^2-1)f''(x)+\left(2qx(x+1)+2px(x-1)-(2N-1+p+q)(x^2-1)\right)f'(x) \tag{2.9}$$

therefore has zeros at $x=e^{i\theta_k}$, $k=1,2,\cdots,2N$, and so is proportional to $(x-A)f(x)$ where A is a constant. By equating like powers of x^{2N+1} we find the proportionality constant to be $2N(p+q)$, so

$$(2.10)\quad x(x^2-1)f''(x)+\big(2qx(x+1)+2px(x-1)-(2N-1+p+q)(x^2-1)\big)f'(x) \\ -2N(p+q)(x-A)f(x)=0.$$

It follows from the uniqueness of a minimum of H_0 that there is one and only one value of A such that (2.6) satisfies (2.10) with the θ_k constrained by (2.3). When $N=1$ it is a simple exercise to derive

$$(2.11)\qquad A=(p-q)/(p+q).$$

We now verify that the choice (2.11) gives the required polynomial solution of (2.10) for general N. By making standard transformations applicable to second-order differential equations [7, p. 16] and then changing variables $x=e^{i\theta}$, we write (2.10) with A given by (2.11) in the form

$$(2.12)\quad u''+\big(q(1-q)/(4\sin^2\theta/2)+p(1-p)/(4\cos^2\theta/2)+(2N+p+q)^2/4\big)u=0,$$

where

$$(2.13)\qquad u(\theta)=(\sin^q\theta/2)(\cos^p\theta/2)e^{-iN\theta}f(e^{i\theta}).$$

However (2.12) is also a transformed version of the differential equation of the Jacobi polynomials [7, p. 67] and is satisfied by

$$(2.14)\qquad u(\theta)=(\sin^q\theta/2)(\cos^p\theta/2)\,P_N^{(q-1/2,p-1/2)}(\cos\theta).$$

Hence we have

$$(2.15)\qquad f(e^{i\theta})=e^{iN\theta}P_N^{(q-1/2,p-1/2)}(\cos\theta),$$

which is the desired polynomial solution of (2.10) satisfying the constraint (2.3).

Theorem 2.1 is to be compared to Stieltjes' interpretation [7, p. 140].

THEOREM 2.2 (Stieltjes). *The minimum of the function*

$$(2.16)\qquad T=-\sum_{k=1}^{N}\big(\log(1+x_k)^P+\log(1-x_k)^Q\big)-\sum_{1\le k<j\le N}\log|x_k-x_j|,$$

$P, Q>0$, $-1<x_k<1$, *occurs at the zeros of the Jacobi polynomial* $P_N^{(2Q-1,2P-1)}(x)$.

The expression T is the Hamiltonian for N unit charges confined to the interval $[-1,1]$ by a particle of charge P fixed at $x=1$, and a particle of charge Q fixed at $x=-1$, interacting via the logarithmic potential. Thus comparing Theorems 2.1 and 2.2, we see that the equilibrium positions are closely related. Consider the unit circle in the complex plane. At $z=1$ fix a particle of charge $q=2Q-\frac{1}{2}$, and at $z=-1$ a particle of charge $p=2P-\frac{1}{2}$ ($p,q\ge 0$). If the equilibrium positions of the $2N$ charges as given by Theorem 2.1 are projected orthogonally onto the real axis, then we locate the equilibrium positions of Stieltjes' problem, Theorem 2.2.

As an example of a theorem regarding the zeros of the Jacobi polynomials which is intuitively obvious when viewed from the electrostatic interpretation, consider the following result [7, p. 121].

THEOREM 2.3 (Markoff, Stieltjes). *Let* $\{x_\nu = x_\nu(\alpha,\beta)\}$ *denote the zeros of the Jacobi polynomial* $P_N^{(\alpha,\beta)}(x)$. *Then*

$$\text{(i)} \quad \frac{\partial x_\nu}{\partial \alpha} < 0, \qquad \text{(ii)} \quad \frac{\partial x_\nu}{\partial \beta} > 0.$$

From Stieltjes' interpretation of the zeros of $P_N^{(\alpha,\beta)}$, this is equivalent to saying that (i) when the charge at $x=1$ is increased, the N unit charges are repelled towards the fixed charge at $x=-1$; (ii) when the charge at $x=-1$ is increased, the N unit charges are repelled towards the fixed charge at $x=1$. Thus Theorem 2.3 is intuitively obvious.

Reconsider Theorem 2.1. The positions of the unit charges around an impurity (the $+q$ charge at $\theta=0$, say) in the large N limit are of particular interest. We have the following theorem [7, p. 193].

THEOREM 2.4. *Let* $x_{1N} > x_{2N} > \cdots$ *be the zeros of* $P_N^{(\alpha,\beta)}(x)$ *in* $[-1,+1]$ *in decreasing order* (α,β *real but otherwise arbitrary*). *If we write* $x_{\nu N} = \cos\theta_{\nu N}$, $0 < \theta_{\nu N} < \pi$, *then for fixed* ν,

$$\lim_{N\to\infty} N\theta_{\nu N} = j_{\nu,\alpha},$$

where $j_{\nu,\alpha}$ *denotes the* ν*th positive zero of* $J_\alpha(z)$, J_α *denoting the Bessel function of order* α.

Regarding the $N\to\infty$ limit as the thermodynamic limit, with particle density π/N, we have from Theorems 2.1 and 2.4 the following result.

THEOREM 2.5. *Consider the real line with a particle of charge* $+q$ *fixed at the origin, and particles of unit charge at unit density immersed in a uniform neutralizing background. In the thermodynamic limit the ground state positions of the unit charges are given by*

$$\pm j_{\nu,q-1/2}/\pi, \qquad \nu = 1,2,\cdots.$$

3. A single impurity on the line. In §2 it was shown how an equilibrium problem on the circle gave rise to the Jacobi polynomials. In this section we consider an analogous physical problem, in which the equilibrium position of the charges are given in terms of the Laguerre polynomials.

Consider $2N$ particles of unit charge free to move on the real line with a particle of charge $+q$ fixed at the origin. The system is made electrically neutral by imposing a background charge density of profile

$$\sigma(y) = \begin{cases} -(c/\pi)(1-y^2/L^2)^{1/2}, & |y|<L, \\ 0, & |y|\geqq L, \end{cases} \tag{3.1}$$

$c = 2(2N+q)/L$.

To compute the Hamiltonian for the system we require the integral [3, p. 44]

$$\frac{1}{\pi}\int_{-L}^{L} dy(1-y^2/L^2)^{1/2}\log|x-y| = x^2/2L + K, \tag{3.2}$$

where K is independent of x. This gives us the contribution to the Hamiltonian of the particle-background interaction. Thus if we ignore constant terms, the Hamiltonian is given by

$$H_1=\left(\frac{c}{2L}\right)\sum_{j=1}^{2N}x_j^2-q\sum_{k=1}^{2N}\log|x_k|-\sum_{1\leqq j<k\leqq 2N}\log|x_j-x_k|, \tag{3.3}$$

where we have labelled the $2N$ unit charges $x_1, x_2, \cdots, x_{2N}$.

We seek the minimum of H_1 subject to the condition that N particles are on either side of the impurity at the origin; that is,

$$x_k<0, \quad k=1,2,\cdots,N \quad \text{and} \quad x_k>0, \quad k=N+1,\cdots,2N. \tag{3.4}$$

It is a simple exercise to prove that such a minimum exists and is unique [7, p. 140]. By symmetry we must have

$$-x_k=x_{N+k}, \qquad k=1,2,\cdots,N. \tag{3.5}$$

The location of the minimum is given by the following result.

THEOREM 3.1. *The minimum of the function H_1 subject to the constraint* (3.5) *occurs when the x_k are the zeros of the Laguerre polynomial*

$$L_N^{(q-1/2)}(cx^2/L). \tag{3.6}$$

Proof. The condition for a minimum is the set of nonlinear equations

$$0=\frac{\partial H_1}{\partial x_k}=(c/L)x_k-\sum_{j=1}^{2N}{}'\frac{1}{x_k-x_j}-\frac{q}{x_k}, \qquad k=1,\cdots,2N. \tag{3.7}$$

Consider the polynomial

$$g(x)=\prod_{l=1}^{2N}(x-x_l) \tag{3.8}$$

which has its zeros at the minimum of H_1. Then we can write (3.7) as

$$0=x_kg''(x_k)+\left(-(2c/L)x_k^2+2q\right)g'(x_k), \qquad k=1,\cdots,2N. \tag{3.9}$$

Thus we have a $(2N+1)$th order polynomial which has the $2N$ zeros of $g(x)$. Hence

$$xg''(x)+\left(-(2c/L)x^2+2q\right)g'(x)+a(x-b)g(x)=0. \tag{3.10}$$

By equating like coefficients of x^{2N}, we find $a=4Nc/L$. Furthermore the symmetry condition (3.5) requires g to be even. Using this condition in (3.10) gives $b=0$.

Replacing x by $(Lx/c)^{1/2}$ the differential equation assumes the form

$$xu''+\left(-x+(q+1/2)\right)u'+Nu=0, \tag{3.11}$$

$$u(x)=g\left((Lx/c)^{1/2}\right). \tag{3.12}$$

We recognize (3.11) as the differential equation satisfied by the Laguerre polynomial [7, p. 100] so that

$$u(x)=L_N^{(q-1/2)}(x). \tag{3.13}$$

If we substitute (3.13) in (3.12), Theorem 3.1 follows immediately.

As $L\to\infty$ and y remains finite, $\sigma(y)\to -c/\pi$. Therefore in the thermodynamic limit if we choose $c=\pi$ (and thus $L=2(2N+q)/\pi^2$), the background around the origin tends to a constant unit density. From Theorem 2.4 we know the equilibrium position of unit charges immersed in a neutralizing background at unit density around a $+q$ impurity on the line. Hence from the equivalence of the two physical problems in the thermodynamic limit, we can deduce the well-known theorem relating the zeros of the Laguerre polynomials to the zeros of the Bessel functions [7, p. 193].

THEOREM 3.2. *Let $y_{1N}<y_{2N}<\cdots$ be the zeros of $L_N^{(q-1/2)}(y)$ in increasing order. Then*

$$\lim_{N\to\infty} Ny_{lN}=\frac{1}{4}\left(j_{l,q-1/2}\right)^2.$$

4. Crystal lattices on the circle. In this section crystal lattice structures are given for the equilibrium positions on the circle of two-component systems. By a crystal lattice we mean a lattice which has a cell repeated periodically. We have the following result.

THEOREM 4.1. *Suppose there are $n2^M$ particles of unit charge and 2^M particles of charge $+q$ on the circle with one of the $+q$ charges fixed at $\theta=0$. Require that between every two $+q$ charges there are n unit charges. Then the equilibrium position of the $n2^M$ particles of unit charge are given by the zeros of*

$$P_{n/2}^{((q-1)/2,-1/2)}(\cos 2^M\theta), \qquad 0<\theta<2\pi \tag{4.1}$$

if n is even, and the zeros of

$$P_{(n-1)/2}^{((q-1)/2,1/2)}(\cos 2^M\theta), \qquad 0<\theta<2\pi \tag{4.2}$$

if n is odd. The equilibrium position of the (2^M-1) particles of charge $+q$ occurs at

$$\theta=\frac{2\pi k}{2^M}, \qquad k=1,2,\cdots,(2^M-1). \tag{4.3}$$

Proof. Label the coordinates of the particles of charge $+q$ $\phi_0=0$, $\phi_1,\cdots,\phi_{2^M-1}$ and the particles of unit charge θ_1, $\theta_2,\cdots,\theta_{n2^M}$. Then the Hamiltonian for the system is

$$\begin{aligned} H_2=&-q^2\sum_{0\le j<k\le 2^M-1}\log|e^{i\phi_j}-e^{i\phi_k}| \\ &-q\sum_{0\le j\le 2^M-1}\ \sum_{1\le k\le n2^M}\log|e^{i\phi_j}-e^{i\phi_k}|-\sum_{1\le j<k\le 2^M}|\log e^{i\theta_j}-e^{i\theta_k}|. \end{aligned} \tag{4.4}$$

Again it is easy to show the existence and uniqueness of the required minimum [7, p. 140]. To prove the theorem we must show that the equations for a minimum, obtained by taking partial derivatives of H_2, are satisfied when the angles are given by

(4.1), (4.2) and (4.3). Explicitly we must show

$$0 = q \sum_{j=0}^{2^M-1} \left(e^{i(\theta_{k'}+2\pi l')/2^M} / e^{i(\theta_{k'}+2\pi l')/2^M} e^{2\pi i j/2^M} \right) \tag{4.5}$$

$$+ \sum_{k=1}^{n} \sum_{l=0}^{2^M-1}{}' e^{i(\theta_{k'}+2\pi l')/2^M} / \left(e^{i(\theta_{k'}+2\pi l')/2^M} - e^{i(\theta_k+2\pi i l)/2^M} \right)$$

$$- \left[(n+q)2^M - 1 \right]/2, \qquad 1 \leqq k' \leqq n, \quad 0 \leqq l' \leqq 2^M - 1,$$

and

$$0 = q \sum_{k=1}^{n} \sum_{l=0}^{2^M-1} e^{2\pi i k'/2^M} / \left(e^{(2\pi i k'/2^M)} - e^{i(\theta_k+2\pi l)/2^M} \right) \tag{4.6}$$

$$+ q^2 \sum_{\substack{k=0 \\ k \neq k'}}^{2^M-1} e^{2\pi i k'/2^M} / \left(e^{2\pi i k'/2^M} - e^{2\pi i k/2^M} \right)$$

$$- \left(q^2(2^M-1) + qn2^M \right)/2, \qquad 0 \leqq k' \leqq 2^M - 1,$$

where here the θ_k are the zeros of

$$P_{n/2}^{((q-1)/2,-1/2)}(\cos\theta), \qquad 0 < \theta < 2\pi, \tag{4.7}$$

if n is even, and the zeros of

$$P_{(n-1)/2}^{((q-1)/2,1/2)}(\cos\theta), \qquad 0 < \theta < 2\pi, \tag{4.8}$$

if n is odd.

We will reduce (4.5) to the solution of the impurity problem, Theorem 2.1. Consider the identity

$$\frac{e^{i\theta}}{e^{i\theta} - e^{i\phi}} = \frac{1}{2} \left(\frac{e^{i\theta/2}}{e^{i\theta/2} - e^{i\phi/2}} + \frac{e^{i\theta/2}}{e^{i\theta/2} - e^{i(\phi+2\pi)/2}} \right). \tag{4.9}$$

Applying (4.9) iteratively M times we have the identity

$$e^{i\theta} / \left(e^{i\theta} - e^{i\phi} \right) = \left(\frac{1}{2^M} \right) \sum_{j=0}^{2^M-1} \frac{e^{i\theta/2^M}}{\left(e^{i\theta/2^M} - e^{i(\phi+2\pi j)/2^M} \right)}. \tag{4.10}$$

Substitution of (4.10) in the first sum of (4.5) with $\theta = \theta_{k'} + 2\pi i l'$ and $\phi = 0$, and the second sum of (4.5) with $\theta = \theta_{k'} + 2\pi i l'$ and $\phi = \theta_k + 2\pi i l$ $(k \neq k')$ reduces (4.5) to

$$0 = \frac{q e^{i\theta_{k'}}}{(e^{i\theta_{k'}} - 1)} - \frac{\left((n+q)2^M - 1 \right)}{2^{M+1}} \tag{4.11}$$

$$+ \sum_{k=1}^{n} \frac{e^{i\theta_{k'}}}{\left(e^{i\theta_{k'}} - e^{i\theta_k} \right)} + 2^{-M} \sum_{l=0}^{2^M-1}{}' \frac{e^{2\pi i l'/2^M}}{\left(e^{2\pi i l'/2^M} - e^{2\pi i l/2^M} \right)}.$$

However, it is a simple exercise in summing series to prove that the last sum equals $(2^M-1)/2$, so we reclaim (2.5) (with $p=0$ and $n=2N$ if n is even, $p=1$ and $n-1=2N$ if n is odd), which we know from Theorem 2.1 is satisfied by the choices (4.7) and (4.8).

To prove (2.6), note that the second sum is equal to $(2^M-1)/2$ and that the first sum can be reduced using the identity (4.10) with $\theta=2\pi k'$ and $\phi=\theta_k+2\pi l$. Thus we are required to show

$$0=-n/2+\sum_{k=1}^{n}1/(1-e^{i\theta_k}). \tag{4.12}$$

This follows immediately from the fact that the θ_k are situated symmetrically about the real axis, and from the identity

$$1/(1-e^{i\theta_k})+1/(1-e^{-i\theta_k})=1. \tag{4.13}$$

If we regard the $N\to\infty$ limit as the thermodynamic limit with particle density of the $+q$ species $\pi/2^{M-1}$, we have from Theorem 4.1 the following result.

THEOREM 4.2. *Consider the real line with n particles of unit charge arranged between every pair of particles of charge $+q$. Suppose the particles of charge $+q$ are at unit density and all the charges are immersed in a neutralizing uniform background. Then in the thermodynamic limit the ground state for the system is a crystal lattice with cells of unit length. When n is even, a cell is specified by a $+q$ charge at $x=0$, with the n unit charges at the zeros of $P_{n/2}^{((q-1)/2,\,-1/2)}(\cos 2\pi x)$, $0<x<1$, while when n is odd a cell is specified by a $+q$ charge at $x=0$, with the n unit charges at the zeros of $P_{(n-1)/2}^{((q-1)/2,\,1/2)}(\cos 2\pi x)$, $0<x<1$.*

ON THE ORDER OF MAGNITUDE OF FOURIER COEFFICIENTS*

J. B. READE†

Abstract. The main result is that the Fourier coefficients of any continuous function are $o(1/n)$ if a monotonicity condition is assumed. The proof is achieved by showing the coefficients are always $o(1/n)$ in a certain weaker sense, and then proving a Tauberian theorem giving $o(1/n)$ in the ordinary sense under the extra assumption of monotonicity.

1. Let $f(t)\in L^1[-1,1]$ have Fourier cosine coefficients

$$a_n=\int_{-1}^{1} f(t)\cos n\pi t\,dt.$$

The Riemann–Lebesgue lemma says that $a_n\to 0$ as $n\to\infty$. The convergence can be arbitrarily slow, since, for any sequence (k_n) such that $|k_n|\to\infty$ as $n\to\infty$, we have

$$k_n a_n=\int_{-1}^{1} f(t)k_n\cos n\pi t\,dt=T_n f,$$

where T_n is a linear functional on $L^1[-1,1]$ having norm

$$\|T_n\|=\max_{|t|\leqq 1}|k_n\cos n\pi t|=|k_n|,$$

so $k_n a_n\to 0$ for every $f\in L^1[-1,1]$ would contradict the uniform boundedness principle. The same is true for $f(t)\in C[-1,1]$ for similar reasons.

It turns out, however, that one can make positive assertions about the order of magnitude of Fourier cosine coefficients if one interprets, e.g., $na_n\to 0$ in a weaker sense. Specifically, we shall show firstly that, if $f(t)\in L^2[-1,1]$, then $n^{1/2}a_n\to 0$ in the sense of Cesaro, i.e.,

$$\frac{a_1+2^{1/2}a_2+\cdots+n^{1/2}a_n}{n}\to 0,$$

and secondly that, if $f(t)\in C[-1,1]$, then $na_n\to 0$ in the double Cesaro sense, i.e., if

$$u_n=\frac{a_1+2a_2+\cdots+na_n}{n},$$

$$v_n=\frac{u_1+u_2+\cdots+u_n}{n},$$

then $v_n\to 0$. It is possible to deduce, e.g., that, if $a_n\geqq a_{n+1}\geqq 0$ for all $n\geqq 0$, then convergence is in the ordinary sense in both cases.

We also prove similar results for Fourier sine coefficients

$$b_n=\int_{-1}^{1} f(t)\sin n\pi t\,dt,$$

though in some cases the proofs are different.

*Received by the editors December 12, 1983, and in revised form June 15, 1984.

2. The result concerning $f(t)\in L^2[-1,1]$ depends on the Riesz–Fischer theorem and two lemmas about Cesaro convergence.

LEMMA 1. *For any convergent series* $\Sigma_1^\infty a_n$, *we have* $na_n\to 0$ *in the sense of Cesaro.*

Proof. Let $s_n=a_1+a_2+\cdots+a_n\to s$. Then

$$\frac{a_1+2a_2+\cdots+na_n}{n}=\frac{s_1+2(s_2-s_1)+\cdots+n(s_n-s_{n-1})}{n}$$

$$=s_n-\frac{s_1+s_2+\cdots+s_{n-1}}{n}$$

$$\to s-s=0. \qquad \text{Q.E.D.}$$

LEMMA 2. *If* $a_n\geqq 0$ *and* $a_n\to 0$ *in the sense of Cesaro, then also* $a_n^{1/2}\to 0$ *in the sense of Cesaro.*

Proof. We have

$$\frac{a_1^{1/2}+\cdots+a_n^{1/2}}{n}\leqq\frac{\left(n(a_1+\cdots+a_n)\right)^{1/2}}{n},$$

by Cauchy's inequality,

$$=\left[\frac{a_1+\cdots+a_n}{n}\right]^{1/2}\to 0. \qquad \text{Q.E.D.}$$

THEOREM 1. *If* $f(t)\in L^2[-1,1]$ *has Fourier cosine coefficients*

$$a_n=\int_{-1}^{1} f(t)\cos n\pi t\,dt,$$

then $n^{1/2}a_n\to 0$ *in the sense of Cesaro.*

Proof. By the Riesz–Fischer theorem, we have $\Sigma_1^\infty a_n^2<\infty$. Therefore, by Lemma 1, $na_n^2\to 0$ in the sense of Cesaro, and therefore, by Lemma 2, $n^{1/2}a_n\to 0$ in the sense of Cesaro. Q.E.D.

3. The result concerning $f(t)\in C[-1,1]$ depends on Fejer's theorem and a further lemma about Cesaro convergence.

LEMMA 3. *If* $\Sigma_1^\infty a_n$ *is convergent in the sense of Cesaro, then* $na_n\to 0$ *in the double Cesaro sense.*

Proof. Let

$$s_n=a_1+a_2+\cdots+a_n,$$

$$\sigma_n=\frac{s_1+s_2+\cdots+s_n}{n},$$

and suppose $\sigma_n\to\sigma$.

If

$$u_n=\frac{a_1+2a_2+\cdots+na_n}{n},$$

$$v_n=\frac{u_1+u_2+\cdots+u_n}{n},$$

then

$$u_n=\frac{s_1+2(s_2-s_1)+\cdots+n(s_n-s_{n-1})}{n}$$
$$=\frac{ns_n-s_1-s_2-\cdots-s_{n-1}}{n}$$
$$=s_n-\frac{n-1}{n}\sigma_{n-1}$$
$$=s_n-t_n,$$

where

$$t_n=\frac{n-1}{n}\sigma_{n-1}\to\sigma,$$

and hence

$$v_n=\sigma_n-\frac{t_1+t_2+\cdots+t_n}{n}$$
$$\to\sigma-\sigma=0. \qquad \text{Q.E.D.}$$

The counterexample $\Sigma_1^\infty(-1)^n$ shows that we cannot deduce $na_n\to 0$ in the single Cesaro sense under the same hypotheses.

THEOREM 2. *If $f(t)\in C[-1,1]$ has Fourier cosine coefficients*

$$a_n=\int_{-1}^{1}f(t)\cos n\pi t\,dt,$$

then $na_n\to 0$ in the double Cesaro sense.

Proof. By Fejer's theorem, $\Sigma_0^\infty a_n$ is convergent in the Cesaro sense (to $f(0)$). Hence the result follows from Lemma 3. Q.E.D.

Observe that we have only assumed $f(t)$ is continuous at $t=0$.

A uniform boundedness principle argument shows there exist $f(t)\in C[-1,1]$ for which na_n does not $\to 0$ in the single Cesaro sense. We need the following lemma.

LEMMA 4. *The variation of*

$$\frac{\sin\pi t+\sin 2\pi t+\cdots+\sin n\pi t}{n}=\frac{1}{2n}\left[\cot\tfrac{1}{2}\pi t-\frac{\cos(n+1/2)\pi t}{\sin(\pi t/2)}\right]$$

over $|t|\leqq 1$ tends to infinity as $n\to\infty$.

Proof. The graph of

$$\cot\tfrac{1}{2}\pi t-\frac{\cos(n+1/2)\pi t}{\sin(\pi t/2)}$$

lies between the graphs of $\cot\frac{1}{4}\pi t$ and $-\tan\frac{1}{4}\pi t$ over $0\leqq t\leqq 1$, touching each alternately at

$$t=\frac{1}{n+1/2},\frac{2}{n+1/2},\cdots,\frac{n}{n+1/2}.$$

Therefore

$$\operatorname*{var}_{0\leqq t\leqq 1}\left[\cot \tfrac{1}{2}\pi t-\frac{\cos(n+1/2)\pi t}{\sin(\pi t/2)}\right]$$

$$>2\left[\cot\left(\tfrac{1}{4}\frac{\pi}{n+1/2}\right)+\tan\left(\tfrac{1}{4}\frac{2\pi}{n+1/2}\right)+\cdots+\cot\left(\tfrac{1}{4}\frac{n\pi}{n+1/2}\right)\right]$$

if n odd,

$$>2\left(n+\tfrac{1}{2}\right)\left(1+\tfrac{1}{3}+\cdots+\tfrac{1}{n}\right)$$

using the inequality $\tan \tfrac{1}{4}\pi x<x$ for $0<x<1$,

$$\sim n\log n$$

as $n\to\infty$. Similarly for n even. Q.E.D.

COROLLARY. *If*

$$\phi_n(t)=\frac{d}{dt}\,\frac{\sin\pi t+\sin 2\pi t+\cdots+\sin n\pi t}{n},$$

then

$$\int_{-1}^{1}|\phi_n(t)|dt\to\infty$$

as $n\to\infty$.

Proof. Clearly,

$$\int_{-1}^{1}|\phi_n(t)|dt=\operatorname*{var}_{|t|\leqq 1}\frac{\sin\pi t+\sin 2\pi t+\cdots+\sin n\pi t}{n}.$$ Q.E.D.

Now suppose (for contradiction) that $na_n\to 0$ in the single Cesaro sense for every $f(t)\in C[-1,1]$. Then

$$\frac{a_1+2a_2+\cdots+na_n}{n}=\int_{-1}^{1}f(t)\,\frac{\cos\pi t+2\cos 2\pi t+\cdots+n\cos n\pi t}{n}\,dt$$

$$=\frac{1}{\pi}\int_{-1}^{1}f(t)\phi_n(t)\,dt$$

$$=T_nf,$$

where T_n is a linear functional on $C[-1,1]$ having

$$\|T_n\|=\frac{1}{\pi}\int_{-1}^{1}|\phi_n(t)|dt$$

which tends to infinity as $n\to\infty$, so $T_nf\to 0$ as $n\to\infty$ for every $f\in C[-1,1]$ contradicts the uniform boundedness principle.

4. We now show how ordinary convergence can be proved under the extra assumption that $a_n\geqq a_{n+1}\geqq 0$ for all n.

LEMMA 5. *If* $a_n \geqq a_{n+1} \geqq 0$ *and* $n^{1/2}a_n \to 0$ *in the sense of Cesaro, then* $n^{1/2}a_n \to 0$ *in the ordinary sense.*

Proof. Given any $\varepsilon > 0$, we have, for all large enough n,

$$\begin{aligned}\varepsilon &> \frac{a_1 + 2^{1/2}a_2 + \cdots + n^{1/2}a_n}{n} \\ &\geqq \frac{1 + 2^{1/2} + \cdots + n^{1/2}}{n} a_n \\ &> \frac{a_n}{n}\int_0^n t^{1/2}\,dt \\ &= \tfrac{2}{3}n^{1/2}a_n. \end{aligned}$$

Q.E.D.

LEMMA 6. *If* $a_n \geqq a_{n+1} \geqq 0$ *and* $na_n \to 0$ *in the double Cesaro sense, then* $na_n \to 0$ *in the ordinary sense.*

Proof. We have

$$u_n = \frac{a_1 + 2a_2 + \cdots + na_n}{n} \geqq \tfrac{1}{2}(n+1)a_n \geqq \tfrac{1}{2}na_n,$$

$$v_n = \frac{u_1 + u_2 + \cdots + u_n}{n} \geqq \frac{a_1 + 2a_2 + \cdots + na_n}{2n} = \tfrac{1}{2}u_n \geqq \tfrac{1}{4}na_n,$$

which gives the result. Q.E.D.

5. We now turn our attention to Fourier sine coefficients

$$b_n = \int_{-1}^{1} f(t)\sin n\pi t\,dt.$$

Theorem 1 goes through verbatim for sine coefficients. Theorem 2 also goes through, but a different proof is required since Fejer's theorem does not hold for sine coefficients. (Consider, e.g.,

$$f(t) = \sum_2^\infty \frac{\sin n\pi t}{n \log n}.)$$

LEMMA 7. *If* B *is a Banach space and* (T_n) *is a sequence of linear functionals on* B *such that* $\|T_n\|$ *is bounded over* n *and* $T_n f \to 0$ *as* $n \to \infty$ *for every* f *in some fundamental set in* B, *then* $T_n f \to 0$ *as* $n \to \infty$ *for every* f *in* B.

(We say a subset of B is *fundamental* if linear combinations of elements of the subset are dense in B.)

Proof. Let $f \in B$ and $\varepsilon > 0$ be given. Then we can choose a linear combination g of elements in the fundamental set such that $\|f - g\| < \varepsilon$. Now $T_n g \to 0$ as $n \to \infty$, so we can choose N such that $|T_n g| < \varepsilon$ for all $n > N$. Therefore

$$|T_n f| \leqq \|T_n\|\|f - g\| + |T_n g| < (M+1)\varepsilon$$

for all $n > N$, where $M = \sup_n \|T_n\|$. Q.E.D.

LEMMA 8. *The variation of*

$$\psi_n(t)=\frac{\sin^2(n\pi t/2)}{\sin^2(\pi t/2)}$$

over $|t|\leqq 1$ *is* $O(n^2)$ *as* $n\to\infty$.

Proof. The graph of $\psi_n(t)$ over $0\leqq t\leqq 1$ lies between the graph of $\operatorname{cosec}^2\frac{1}{2}\pi t$ and the horizontal axis, touching each alternately at

$$t=\frac{1}{n},\frac{2}{n},\cdots,1.$$

Hence, clearly,

$$\operatorname*{var}_{0\leqq t\leqq 1}\psi_n(t)<n^2+2\left(\operatorname{cosec}^2\left(\tfrac{1}{2}\frac{2\pi}{n}\right)+\operatorname{cosec}^2\left(\tfrac{1}{2}\frac{4\pi}{n}\right)+\cdots+\operatorname{cosec}^2\left(\tfrac{1}{2}\pi\right)\right)$$

if n is even,

$$<n^2+2n^2\left(\frac{1}{2^2}+\frac{1}{4^2}+\cdots+\frac{1}{n^2}\right),$$

using the inequality $\sin\frac{1}{2}\pi x>x$ for $0<x<1$,

$$<\left(1+\frac{\pi^2}{12}\right)n^2.$$

Similarly if n is odd. Q.E.D.

THEOREM 2′. *If* $f(t)\in C[-1,1]$ *has Fourier sine coefficients*

$$b_n=\int_{-1}^{1}f(t)\sin n\pi t\,dt,$$

then $nb_n\to 0$ *in the double Cesaro sense.*

Proof. If we write

$$u_n=\frac{b_1+2b_2+\cdots+nb_n}{n},$$

$$v_n=\frac{u_1+u_2+\cdots+u_n}{n},$$

and $T_nf=v_n$, then $T_nf\to 0$ as $n\to\infty$ for every f in the fundamental set

$$\tfrac{1}{2},\cos\pi t,\cos 2\pi t,\cdots,\sin\pi t,\sin 2\pi t,\cdots$$

in the Banach space $C[-1,1]$, and

$$\|T_n\|=\frac{1}{2\pi n^2}\operatorname*{var}_{|t|\leqq 1}\psi_{n+1}(t)$$

is bounded over n. Q.E.D.

If instead we take $T_nf=u_n$, we have

$$\|T_n\|=\frac{1}{2\pi n}\operatorname*{var}_{|t|\leqq 1}\frac{\sin(n+1/2)\pi t}{\sin(\pi t/2)}$$

which tends to infinity as $n \to \infty$ since

$$n \log n = O\left[\operatorname*{var}_{|t| \leqq 1} \frac{\sin(n+1/2)\pi t}{\sin(\pi t/2)} \right]$$

by a similar argument to that used in the proof of Lemma 4. So it follows by the uniform boundedness principle that there exist $f \in C[-1,1]$ for which nb_n does not $\to 0$ in the single Cesaro sense.

6. If $f(t) \in AC[-1,1]$ is absolutely continuous over the interval $[-1,1]$, then $f(t)$ has a derivative $f'(t) \in L^1[-1,1]$ and the fundamental theorem of calculus holds. If also $f(1)=f(-1)$, then we have

$$\begin{aligned} a_n' &= \int_{-1}^{1} f'(t) \cos n\pi t \, dt \\ &= f(t) \cos n\pi t \Big|_{-1}^{1} + n\pi \int_{-1}^{1} f(t) \sin n\pi t \, dt \\ &= n\pi b_n, \\ b_n' &= \int_{-1}^{1} f'(t) \sin n\pi t \, dt \\ &= f(t) \sin n\pi t \Big|_{-1}^{1} - n\pi \int_{-1}^{1} f(t) \cos n\pi t \, dt \\ &= -n\pi a_n. \end{aligned}$$

Hence, always assuming $f(1)=f(-1)$, we have $na_n \to 0$ and $nb_n \to 0$ in general (see [1, p. 24]), $n^{3/2}a_n \to 0$ and $n^{3/2}b_n \to 0$ in the sense of Cesaro if $f'(t) \in L^2[-1,1]$, and $n^2 a_n \to 0$, $n^2 b_n \to 0$ in the double Cesaro sense if $f(t) \in C^1[-1,1]$. It follows, as in §4, that the second two pairs of results hold for convergence in the ordinary sense if the Fourier coefficients are real, positive and decreasing. Observe that the condition $f(1)=f(-1)$ is not needed for the results concerning cosine coefficients since the proof of $b_n' = -n\pi a_n$ does not require this condition.

The second two results for monotonic cosine coefficients can be obtained as corollaries of theorems about the order of magnitude of the eigenvalues of certain integral equations. In fact, if real, even $f(t) \in L^1[-1,1]$ is extended to $[-2,2]$ by requiring it to be periodic with period 2, then

$$T\phi(x) = \int_{-1}^{1} f(x-t)\phi(t) \, dt$$

defines a compact symmetric operator T on the Hilbert space $L^1[-1,1]$ whose eigenvalues are $(a_n)_{n \geqq 0}$ (multiplicity one for $n=0$, two for $n \geqq 1$). H. Weyl has shown (see [4]) that for an operator

$$T\phi(x) = \int_{a}^{b} K(x,t)\phi(t) \, dt$$

with a general symmetric C^1 kernel $K(x,t)$ defined on the square $[a,b]^2$, the eigenvalues (λ_n) satisfy $n^{3/2}\lambda_n \to 0$ when arranged in descending order of modulus. It can be shown that this result still holds when $K(x,t)$ is assumed to be absolutely continuous in

each variable for each fixed value of the other variable and the partial derivatives are in $L^2[a,b]^2$ (see [3]). It can also be shown that, if the eigenvalues are positive and $K(x,t) \in C^1[a,b]^2$, then $n^2\lambda_n \to 0$ (see [2]).

Similar results hold with correspondingly higher powers of n for functions $f(t)$ with higher order derivatives.

GENERALIZATION OF ZEMANIAN SPACES OF GENERALIZED FUNCTIONS WHICH HAVE ORTHONORMAL SERIES EXPANSIONS*

STEVAN PILIPOVIĆ†

Abstract. We define the space of generalized functions $\exp_p \mathscr{A}'$, $p \in N$. If $f \in \exp_p \mathscr{A}'$, then f can be uniquely expanded into a series of the form

$$(*) \qquad f = \sum_{n=0}^{\infty} a_n \psi_n,$$

where $\{\psi_n\}_{n=0}^{\infty}$ is an orthonormal base of the corresponding space $L^2(I)$, I is an interval in R, $\{b_n\}_{n=0}^{\infty}$ is a sequence of complex numbers, such that for some $k \in N$,

$$(**) \qquad b_n = O\left(\left(\underbrace{\exp \exp \cdots \exp}_{p} \tilde{\lambda}_n\right)^k\right), \qquad n = 0, 1, \cdots;$$

$\{\lambda_n\}_{n=0}^{\infty}$ is a sequence of eigenvalues of a corresponding operator $\mathscr{R}$ ($\mathscr{R}\psi_n = \lambda_n \psi_n$), and $\tilde{\lambda}_n = |\lambda_n|$ if $\lambda_n \neq 0$ and $\tilde{\lambda}_n = 1$ if $\lambda_n = 0$.

The series in (*) converges in the sense of weak topology in $\exp_p \mathscr{A}'$. Conversely, if a sequence $\{b_n\}_{n=0}^{\infty}$ satisfies (**) for some $k \in N$, a unique element in $\exp_p \mathscr{A}'$ is defined by the series in (*).

We give representation theorems for elements from $\exp_p \mathscr{A}'$, $p = 1, 2, \cdots$, which show that spaces $\exp \mathscr{A}$; $\exp_2 \mathscr{A}', \cdots$ are natural generalizations of the space $\mathscr{A}'$ from [8].

1. Introduction and notation. In his book [8], Zemanian presented remarkable methods for constructing spaces of generalized functions which correspond to integral transformations and differential operators.

In this paper we shall generalize results from [8, Chap. 9], so we shall use notations from this monograph.

Let I be an open interval of the real line R, and let $L^2(I)$ be the space of square integrable functions with the usual norm. We denote by $\mathscr{R}$ a linear differential self-adjoint operator of the form

$$\mathscr{R} = \theta_0 D^{n_1} \theta_1 D^{n_2} \cdots D^{n_\nu} \theta_\nu$$

such that

$$\mathscr{R} = \bar{\theta}_\nu (-D)^{n_\nu} \cdots (-D)^{n_2} \bar{\theta}_1 (-D)^{n_1} \bar{\theta}_0,$$

where $D = d/dx$, $\{\eta_k\}_{k=1}^{\nu}$ are nonnegative integers, $\{\theta_k\}_{k=0}^{\nu}$ are smooth functions on I without zeros, and $\bar{\theta}_k$ are complex conjugates of θ_k, $k = 0, 1, \cdots, \nu$. We suppose that there exist a sequence of real numbers $\{\lambda_n\}_{n=0}^{\infty}$ and a sequence of smooth functions $\{\psi_n\}_{n=0}^{\infty}$ such that $\mathscr{R}\psi_n = \lambda_n \psi_n$. Furthermore we suppose that the sequence $\{|\lambda_n|\}_{n=0}^{\infty}$ monotonically tends to infinity and that $\{\psi_n\}$ forms an orthonormal base of $L^2(I)$.

† University of Novi Sad, Institute of Mathematics, Novi Sad, Yugoslavia.

If $\{\alpha_n\}_{n=0}^{\infty}$ is a sequence of complex numbers different from zero, we denote by $S(\alpha_n)$ and $S^x(\alpha_n)$ the sequence spaces defined in the following way (see [2]):

$$\{a_n\}_{n=0}^{\infty} \in S(\alpha_n) \text{ iff for every } k \in N_0,\ \sum_{n=0}^{\infty} |a_n|^2 |\alpha_n|^{2k} < \infty,$$

$$\{b_n\}_{n=0}^{\infty} \in S^x(\alpha_n) \text{ iff for some } k \in N_0,\ \sum_{n=0}^{\infty} |b_n|^2 |\alpha_n|^{-2k} < \infty$$

($N_0 = N \cup \{0\}$).

Zemanian proved in [8, Chap. 9] that there exists a bijection between the space of generalized functions $\mathscr{A}'$ whose elements may be uniquely expanded into a series and the space $S^x(\tilde{\lambda}_n)$ where $\tilde{\lambda}_n = |\lambda_n|$ if $\lambda_n \neq 0$ and $\tilde{\lambda}_n = 1$ if $\lambda_n = 0$, $n = 0, 1, \cdots$.

In this paper we shall investigate the space of generalized functions $\exp\mathscr{A}'$ which contains $\mathscr{A}'$ as a proper subspace. The elements of the space $\exp\mathscr{A}'$ have unique orthonormal expansions of the form

$$\exp\mathscr{A}' \ni f = \sum_{n=0}^{\infty} b_n \psi_n, \qquad b_n = \langle f, \bar{\psi}_n \rangle, \qquad n \in N_0,$$

where this series converges weakly in $\exp\mathscr{A}'$. We shall show that there exists a bijection between the spaces $\exp\mathscr{A}'$ and $S^x(\exp\tilde{\lambda}_n)$:

$$\exp\mathscr{A}' \ni f = \sum_{n=0}^{\infty} b_n \psi_n \leftrightarrow \{b_n\} \in S^x(\exp\tilde{\lambda}_n).$$

We shall give the representation theorem for the element of the space $\exp\mathscr{A}'$ Moreover, we shall investigate further generalizations of the spaces $\exp\mathscr{A}'$, spaces $\exp\exp\mathscr{A}'$, $\exp\exp\exp\mathscr{A}', \cdots$, for which we shall give representation theorems.

We shall briefly show in §5, Remark 2 that, similar to [8, 9.7], our theory can be applied in solving a class of differential equations of infinite order.

If we use the approach from the paper [6], we can construct the most general space of generalized functions whose elements have orthonormal expansion of the form $f = \sum_{n=0}^{\infty} b_n \psi_n$ without any condition on the coefficients b_n, $n \in N_0$.

In this paper our intention is to more precisely characterize generalized functions which have unique orthonormal expansions; for that purpose the spaces $\exp_p\mathscr{A}'$ are more convenient.

We notice that the generalizations of the spaces $\mathscr{A}'$ given in this paper can be done for the spaces $\tilde{\mathscr{A}}'$ from [7] without difficulty.

2. Spaces $\exp\mathscr{A}$ and $\exp\mathscr{A}'$. We denote by $\exp\mathscr{A}$ the subspace of $L^2(I)$ defined in the following way:

$$\phi \overset{2}{=} \sum_{n=0}^{\infty} a_n \psi_n \in \exp\mathscr{A} \quad \text{iff } \{a_n\} \in S(\exp\tilde{\lambda}_n)$$

($\overset{2}{=}$ means equality in the L^2 sense. If there is no possibility for misinterpretation, we shall put $=$ instead of $\overset{2}{=}$).

In the space $\exp\mathscr{A}$ we introduce the sequence of norms

$$\gamma_k(\phi) := \sqrt{\sum_{n=0}^{\infty} |a_n|^2 (\exp\tilde{\lambda}_n)^{2k}}, \qquad k \in N_0.$$

This sequence of norms defines the usual topology in $S(\exp\tilde{\lambda}_n)$ [2]. Thus the spaces $\exp\mathscr{A}$ and $S(\exp\tilde{\lambda}_n)$ are isomorphic.

If we denote by $(\exp\mathscr{A})_k$ the subspace of $L^2(I)$ such that

$$\phi \in (\exp\mathscr{A})_k \quad \text{iff} \quad \gamma_k(\phi) < \infty,$$

it is easy to show that $(\exp\mathscr{A})_k$, $k \in N_0$, are Banach spaces. The sequence of norms $\{\gamma_k\}_{k=0}^{\infty}$ is pairwise, compatible [1, p. 13] and monotone ($\gamma_p(\phi) \leqq \gamma_{p+1}(\phi)$, $p \in N_0$). Since $\exp\mathscr{A}$ is a dense subspace of $(\exp\mathscr{A})_k$ according to the norm γ_k, from [1, p. 36] we have

$$\exp\mathscr{A}' = \bigcup_{k=0}^{\infty} (\exp\mathscr{A})_k'. \tag{1}$$

PROPOSITION 1. (i) *The space* $\exp\mathscr{A}$ *is a dense subspace of* $\mathscr{A}$ and $\mathscr{E}(I)$. *Moreover, the inclusion mappings of* $\exp\mathscr{A}$ *into* $\mathscr{A}$ *or* $\mathscr{E}(I)$ *are continuous.* ($\mathscr{E}(I)$ *is the space* $C^{\infty}(I)$ *with the usual topology.*)

(ii) *The space* $\exp\mathscr{A}$ *is nuclear if for some* $k \in N_0$, $\sum_{n=0}^{\infty} (\exp\tilde{\lambda}_n)^{-2k} < \infty$.

(iii) *If* $\phi \in \exp\mathscr{A}$, $\phi = \sum_{n=0}^{\infty} a_n \psi_n$ *then for any* $k \in N_0$, $\mathscr{R}^k\phi = \sum_{n=0}^{\infty} \lambda_n^k a_n \psi_n \in \exp\mathscr{A}$, *where the series converges in the sense of convergence in* $\exp\mathscr{A}$.

Proof. (i) If $\phi = \sum_{n=0}^{\infty} a_n\psi_n \in \mathscr{A}$, then $\{\sum_{n=0}^{\nu} a_n\psi_n\}$ is a sequence from $\exp\mathscr{A}$ which in the sense of convergence in $\mathscr{A}$ converges to ϕ. If

$$\phi_p = \sum_{n=0}^{\infty} a_{n,p}\psi_n, \qquad p \in N,$$

is a sequence from $\mathscr{A}$ and $\phi = \sum_{n=0}^{\infty} a_n\psi_n \in \mathscr{A}$, then $\phi_p \to \phi$ in $\mathscr{A}$ iff for every $k \in N_0$, $\sum_{n=0}^{\infty} |a_{n,p} - a_n|^2 \tilde{\lambda}_n^{2k} \to 0$. So it is clear that the inclusion mapping (i): $\exp\mathscr{A} \to \mathscr{A}$ is continuous. Since $\mathscr{A}$ is a dense subspace of $\mathscr{E}(I)$ and the inclusion mapping i: $\mathscr{A} \to \mathscr{E}(I)$ is continuous ([8, Lem. 9.3.4]), it follows that $\exp\mathscr{A}$ is a dense subspace of $\mathscr{E}(I)$ and the inclusion mapping i: $\exp\mathscr{A} \to \mathscr{E}(I)$ is continuous.

(ii) This follows from [3] because the space $S(\exp\tilde{\lambda}_n)$ is equal to the space $\lambda(\exp\tilde{\lambda}_n) = \{\{x_n\}_{n=0}^{\infty};\ \sum_{n=0}^{\infty} |x_n| (\exp\tilde{\lambda}_n)^k < \infty$ for every $k \in N_0\}$ iff for some $k \in N_0$, $\sum_{n=0}^{\infty} (\exp\tilde{\lambda}_n)^{-k} < \infty$ holds ([5]).

(iii) Since this assertion holds for elements from $\mathscr{A}$, it is easy to prove that this holds for elements from $\exp\mathscr{A}$.

THEOREM 2. (i) *If* $\phi \in \exp\mathscr{A}$, *then for every* $k \in N_0$,

$$\theta_k(\phi) := \sum_{n=0}^{\infty} \frac{k^n}{n!} \|\mathscr{R}^n\phi\|_2 < \infty.$$

(ii) *The sequences of norms* $\{\theta_k\}$ *and* $\{\gamma_k\}$ *in* $\exp\mathscr{A}$ *are equivalent.*

Proof. (i) Let $\phi = \sum_{n=0}^{\infty} a_n\psi_n \in \exp\mathscr{A}$. Since

$$\|\mathscr{R}^k\phi\|_2 = \sqrt{\sum_{p=0}^{\infty} |a_p|^2 \lambda_p^{2k}},$$

we have (with $m>k$ and some $C>0$)

$$\theta_k(\phi)=\sum_{n=0}^{\infty}\frac{k^n}{n!}\sqrt{\sum_{p=0}^{\infty}|a_p|^2\lambda_p^{2n}}=\sum_{n=0}^{\infty}\sqrt{\sum_{p=0}^{\infty}\frac{k^{2n}}{n!^2}|a_p|^2\lambda_p^{2n}}$$

$$\leqq C\sqrt{\sum_{n=0}^{\infty}\sum_{p=0}^{\infty}\left(\frac{m^n}{n!}|a_p|\tilde{\lambda}_p^n\right)^2}=C\sqrt{\sum_{p=0}^{\infty}|a_p|^2\sum_{n=0}^{\infty}\left(\frac{m^n}{n!}\tilde{\lambda}_p^n\right)^2}$$

$$\leqq C\sqrt{\sum_{p=0}^{\infty}|a_p|^2\left(\sum_{n=0}^{\infty}\frac{m^n}{n!}\tilde{\lambda}_p^n\right)}=C\sqrt{\sum_{p=0}^{\infty}|a_p|^2(\exp\tilde{\lambda}_p m)}$$

$$\leqq C\gamma_m(\phi)<\infty.$$

(ii) In (i) we proved that $\theta_k(\phi)\leqq C\gamma_m(\phi)$, so we have to prove that for a given $k\in N_0$ there exist $C>0$ and $m\in N_0$ such that

$$\gamma_k(\phi)\leqq C\theta_m(\phi).$$

Since finitely many λ_n may be equal to zero, we have (with $m>r>k$ and suitable $C_{11}C_{21}C$)

$$\gamma_k(\phi)=\sqrt{\sum_{n=0}^{\infty}|a_n|^2(\exp\tilde{\lambda}_n k)^2}\leqq C_1\sqrt{\sum_{n=0}^{\infty}|a_n|^2\left(\sum_{p=0}^{\infty}\frac{(|\lambda_n|k)^p}{p!}\right)^2}$$

$$\leqq C_2\sqrt{\sum_{n=0}^{\infty}|a_n|^2\sum_{p=0}^{\infty}\frac{|\lambda_n|^{2p}r^{2p}}{p!^2}}=C_2\sqrt{\sum_{p=0}^{\infty}\frac{r^{2p}}{p!^2}\sum_{n=0}^{\infty}|a_n|^2|\lambda_n|^{2p}}$$

$$\leqq C\sup_p\left\{\frac{m^p}{p!}\sqrt{\sum_{n=0}^{\infty}|a_n|^2|\lambda_n|^{2p}}\right\}\leqq C\sum_{p=0}^{\infty}\frac{m^p}{p!}\sqrt{\sum_{n=0}^{\infty}|a_n|^2|\lambda_n|^{2p}}=C\theta_m(\phi).$$

So the proof is complete.

If we denote by $\widetilde{(\exp\mathscr{A})}_k$, $k\in N_0$, a subspace of $\mathscr{A}$ such that $\phi\in(\exp\mathscr{A})_k$ iff $\theta_k(\phi)<\infty$, by the standard arguments one can prove:

PROPOSITION 3. *The space* $\widetilde{(\exp\mathscr{A})}_k$, $k\in N_0$, *is a Banach space.*

The sequence of norms $\{\theta_k\}$ monotonically increases and any two norms from this sequence are consistent.

If $\phi\overset{2}{=}\sum_{n=0}^{\infty}a_n\psi_n$ is an arbitrary element from $(\exp\mathscr{A})_k$, then the sequence $\{\sum_{n=0}^{\nu}a_n\psi_n\}_{\nu=0}^{\infty}$ from $\exp\mathscr{A}$ converges to ϕ in the sense of convergence in $\widetilde{(\exp\mathscr{A})}_k$.

So $\widetilde{(\exp\mathscr{A})}_k$ is a completion of $\exp\mathscr{A}$ according to the norm θ_k, and we have:

PROPOSITION 4. $\exp\mathscr{A}'=\bigcup_{k=0}^{\infty}\widetilde{(\exp\mathscr{A})}_k'$.

3. Representation theorems. [8, Thms. 9.5.1 and 9.6.1] directly imply:

THEOREM 5. (i) *If* $f\in\exp\mathscr{A}'$, *then there exists a sequence of complex numbers* $\{b_n\}_{n=0}^{\infty}$ *such that*

$$f=\sum_{n=0}^{\infty}b_n\psi_n,\qquad b_n=\langle f,\bar{\psi}_n\rangle,\qquad n\in N_0,\tag{2}$$

where the series converges weakly in $\exp\mathscr{A}'$.

(ii) *The series on the right side of* (2) *converges in* $\exp\mathscr{A}'$ *iff there exists* $r\in N_0$ *such that* $\sum_{n=0}^{\infty}|b_n|^2\exp(-2r\tilde{\lambda}_n)<\infty$ (*that is*, $\{b_n\}\in S^x(\exp\tilde{\lambda}_n)$).

We shall prove:

THEOREM 6. *If* $f\in\exp\mathscr{A}'$, *there exists a sequence* $\{f_n\}_{n=0}^{\infty}$ *from* $L^2(I)$ *and* $k\in N_0$ *such that*

$$f=\sum_{n=0}^{\infty}\frac{k^n}{n!}\mathscr{R}^n f_n \tag{3}$$

and

$$\sup_{n\in N_o}\|f_n\|_2<\infty. \tag{4}$$

Conversely, if a sequence $\{f_n\}$ *from* $L^2(I)$ *satisfies* (4), *with the series on the right side of* (3) *a unique element from* $\exp\mathscr{A}'$ *is defined.*

Proof. For the proof we shall use an idea from [9] (see also [4]). If $f\in\exp\mathscr{A}'$, then from Proposition 4 it follows that f may be extended from $\exp\mathscr{A}$ onto $(\widetilde{\exp\mathscr{A}})_k$ for some $k\in N_0$, to become an element of $(\widetilde{\exp\mathscr{A}})'_k$. We denote this element from $(\widetilde{\exp\mathscr{A}})'_k$ again by f. So we shall give a representation of any element from $(\widetilde{\exp\mathscr{A}})'_k$, $k\in N_0$.

We denote by Γ the subspace of the Tikhonov product $\Pi_{p=0}^{\infty}L^2(I)$ defined in the following way:

$$\{f_n\}_{n=0}^{\infty}\in\Gamma \quad\text{iff}\quad \|\{f_n\}\|_\Gamma:=\sum_{n=0}^{\infty}\|f_n\|_2<\infty.$$

The mapping α from $(\widetilde{\exp\mathscr{A}})_k$ to Γ is defined by

$$\alpha(\phi)=\left\{\frac{k^n}{n!}\mathscr{R}^n\phi\right\}_{n=0}^{\infty}$$

is an isometry of $(\widetilde{\exp\mathscr{A}})_k$ and of $((\widetilde{\exp\mathscr{A}})_k)\subset\Gamma$. We define a continuous linear functional $\tilde{f}$ on $\alpha((\widetilde{\exp\mathscr{A}})_k)$ by

$$\langle\tilde{f},\psi\rangle=\langle f,\alpha^{-1}(\psi)\rangle\psi\in\alpha\left(\left(\widetilde{\exp\mathscr{A}}\right)_k\right).$$

From the Hahn–Banach theorem it follows that $\tilde{f}$ may be extended onto Γ continuously and linearly. We denote this extension by F. It is known that if $F\in\Gamma'$, then there exists a sequence of functions $\{f_n\}$ from $L^2(I)$ such that

$$\langle F,\{\psi_n\}\rangle=\sum_{n=0}^{\infty}\int_I f_n(x)\psi_n(x)\,dx,\ \{\psi_n\}\in\Gamma,\quad\text{and}\quad\sup_{n\in N_0}\|f_n\|_2<\infty.$$

This means that if $\phi\in\exp\mathscr{A}$, then in the sense of weak convergence in $\exp\mathscr{A}'$, we have

$$\begin{aligned}\langle f,\phi\rangle&=\sum_{n=0}^{\infty}\int_I f_n(x)\frac{k^n}{n!}\mathscr{R}^k\phi(x)\,dx=\sum_{n=0}^{\infty}\frac{k^n}{n!}\langle f_n,\mathscr{R}^k\phi\rangle\\&=\sum_{n=0}^{\infty}\left\langle\frac{k^n}{n!}\mathscr{R}^k f_n,\phi\right\rangle=\left\langle\sum_{n=0}^{\infty}\frac{k^n\mathscr{R}^k f_n}{n!},\phi\right\rangle.\end{aligned} \tag{5}$$

It follows that f is of the form (3) such that (4) holds.

4. Spaces $\exp_p \mathscr{A}$ and $\exp_p \mathscr{A}'$ ($p \geq 2$). If $\phi \in \exp\mathscr{A}$ then the series $\sum_{n=0}^{\infty}(k^n/n!)\mathscr{R}^k\phi$ converges in $L^2(I)$. This follows from Theorem 2 (i). Let us denote by

$$E_1^k = (\exp\mathscr{R})^k = \exp k\mathscr{R}, \qquad k \in N_0,$$

the linear differential operator from $\exp\mathscr{A}$ to $L^2(I)$ defined by

$$\phi \mapsto (\exp k\mathscr{R})\phi := \sum_{n=0}^{\infty} \frac{k^n}{n!}\mathscr{R}^n\phi, \qquad \phi \in \exp\mathscr{A}.$$

We have

PROPOSITION 7. *The operator E_1^k, $k \in N_0$, is the continuous operator of the space $\exp\mathscr{A}$ into the same space.*

Proof. If $\phi = \sum_{n=0}^{\infty} a_n\psi_n \in \exp\mathscr{A}$ and $E_1^k\phi = \sum_{n=0}^{\infty} c_n\psi_n \in L^2(I)$, we have

$$c_p = \left\langle \sum_{n=0}^{\infty} \frac{k^n}{n!}\mathscr{R}^n\phi, \bar{\psi}_p \right\rangle = \sum_{n=0}^{\infty} \frac{k^n}{n!}\lambda_p^n\langle\phi, \bar{\psi}_p\rangle = a_p \exp(k\lambda_p), \qquad p \in N_0. \tag{6}$$

From (6) it easily follows that $E_1^k\phi \in \exp\mathscr{A}$ and that the mapping E_1^k: $\exp\mathscr{A} \mapsto \exp\mathscr{A}$ is continuous.

We denote by $\exp\exp\mathscr{A}$ the subspace of $\exp\mathscr{A}$ defined in the following way

$$\phi = \sum_{n=0}^{\infty} a_n\psi_n \in \exp\exp\mathscr{A}$$

iff for every $k \in N_0$,

$${}_2\gamma_k(\phi) := \sqrt{\sum_{n=0}^{\infty} |a_n|^2 (\exp\exp\tilde{\lambda}_n)^{2k}} < \infty \quad (\text{that is, } \{a_n\} \in S(\exp\exp\tilde{\lambda}_n)).$$

If $\phi = \sum_{n=0}^{\infty} a_n\psi_n \in \exp\mathscr{A}$, then $\{\sum_{n=0}^{\nu} a_n\psi_n\}_{\nu=0}^{\infty}$ is a sequence from $\exp\exp\mathscr{A}$ which converges to ϕ in $\exp\mathscr{A}$. This implies that $\exp\exp\mathscr{A}$ may be continuously embedded into $\exp\mathscr{A}$ and $\mathscr{E}(I)$ as a dense subspace.

The sequence of norms $\{{}_2\gamma_k\}_{k=0}^{\infty}$ is equivalent with the following sequence of norms on $\exp\exp\mathscr{A}$:

$${}_2\theta_k(\phi) := \sum_{n=0}^{\infty} \frac{k^n}{n!} \sum_{m=0}^{\infty} \frac{n^m}{m!} \|\mathscr{R}^m\phi\|_2.$$

This may be proved similarly as in Theorem 2.

We may construct in the same way the spaces $\exp\exp\exp\exp\mathscr{A}$, $\exp\exp\exp\mathscr{A}, \cdots$, defined respectively by the norms $\{{}_3\gamma_k\}$, $\{{}_4\gamma_k\}, \cdots$, where

$${}_p\gamma_k(\phi) := \sqrt{\sum_{n=0}^{\infty} |a_n|^2 \Big(\underbrace{\exp\exp\cdots\exp}_{p}\tilde{\lambda}_n\Big)^{2k}}, \qquad k \in N_0, \qquad p = 3, 4, \cdots,$$

is a norm on

$$\Big(\underbrace{\exp\cdots\exp}_{p}\mathscr{A}\Big).$$

Let us denote the latter space $\exp_p\mathscr{A}$. The operator

$$E_p^k=\Big(\underbrace{\exp\exp\cdots\exp}_{p}\mathscr{R}\Big)^k,\qquad k\in N_0,\ p\geqq 2,$$

on $\exp_p\mathscr{A}$, $p\geqq 2$, defined by

$$E_p^k\phi=\sum_{m_1=0}^{\infty}\frac{k^{m_1}}{m_1!}\sum_{m_2=0}^{\infty}\frac{m_1^{m_2}}{m_2!}\cdots\sum_{m_p=0}^{\infty}\frac{m_{p-1}^{m_p}}{m_p!}\mathscr{R}^{m_p}\phi,\qquad \phi\in\exp_p\mathscr{A},$$

continuously maps $\exp_p\mathscr{A}$ into $\exp_p\mathscr{A}$.

Similarly as for the space $\exp\mathscr{A}$ one can prove:

THEOREM 8. (i) *The space* $\exp_p\mathscr{A}$, $p\geqq 2$, *may be continuously embedded into the spaces* $\exp_{p-1}\mathscr{A},\cdots,\exp\mathscr{A},\mathscr{E}(I)$.

(ii) *The sequence of norms* $\{{}_p\gamma_k\}_{k=0}^{\infty}$ *on* $\exp\mathscr{A}$, $p\geqq 2$, *is equivalent to the sequence of norms*

$${}_p\theta_k(\phi):=\sum_{m_1=0}^{\infty}\frac{k^{m_1}}{m_1!}\sum_{m_2=0}^{\infty}\frac{m_1^{m_2}}{m_2!}\cdots\sum_{m_p=0}^{\infty}\frac{m_{p-1}^{m_p}}{m_p!}\|\mathscr{R}^{m_p}\phi\|_2,\qquad k\in N_0,\qquad p\geqq 2.$$

This means that $\mathscr{E}'(I),\mathscr{A}',\cdots,\exp_{p-1}\mathscr{A}'$ *are subspaces of* $\exp_p\mathscr{A}'$.

Now, we shall give the generalizations of Theorems 5 and 6.

THEOREM 9. (i) *If* $f\in\exp_p\mathscr{A}'$, *then there exists a sequence of complex numbers* $\{b_n\}$ *such that*

$$f=\sum_{n=0}^{\infty}b_n\psi_n,\qquad b_n=\langle f,\bar{\psi}_n\rangle,\qquad n\in N_0,\tag{7}$$

where the series converges weakly in $\exp_p\mathscr{A}$.

(ii) *The series on the right side of* (7) *converges in* $\exp_p\mathscr{A}'$ *iff there exists an* $r\in N_0$ *such that*

$$\sum_{n=0}^{\infty}|b_n|^2\exp\Big(-2r\Big(\underbrace{\exp\cdots\exp}_{p-1}\lambda_n\Big)\Big)<\infty\ \Big(\{b_n\}\in S^x\Big(\underbrace{\exp\cdots\exp}_{p}\tilde{\lambda}_n\Big)\Big).$$

THEOREM 10. *If* $f\in\exp_p\mathscr{A}$, *there exist a sequence* $\{f_{(m_1,\cdots,m_p)}\}$, $(m_1,\cdots,m_p)\in N_0^p$ *from* $L^2(I)$ *and a* $k\in N_0$ *such that*

$$f=\sum_{m_1=0}^{\infty}\frac{k^{m_1}}{m_1!}\sum_{m_2=0}^{\infty}\frac{m_1^{m_2}}{m_2!}\cdots\sum_{m_p=0}^{\infty}\frac{m_{p-1}^{m_p}}{m_p!}\mathscr{R}^{m_p}f_{(m_1,\cdots,m_p)}\tag{8}$$

and

$$\sup\Big\{\big\|f_{(m_1,\cdots,m_p)}\big\|_2;\ (m_1,m_2,\cdots,m_p)\in N_0^p\Big\}<\infty.\tag{9}$$

Conversely, if a sequence $\{f_{(m_1,\cdots,m_p)}\}$ *from* $L^2(I)$ *satisfies* (9), *a unique element from* $\exp_p\mathscr{A}'$ *is defined by the series on the right of* (8).

5. Remarks.

Remark 1. It is clear that if $\{\mu_n\}_{n=0}^{\infty}$ is a sequence of complex numbers such that

$$\mu_n = O\left(\left(\underbrace{\exp\cdots\exp}_{p}\tilde{\lambda}_n\right)^k\right) \quad \text{for some } k\in N,$$

then by

$$\sum_{n=0}^{\infty} a_n\psi_n \mapsto \sum_{n=0}^{\infty} a_n\mu_n\psi_n, \tag{10}$$

a linear continuous operator of multiplier type from $\mathscr{A}'$ into $\exp_p\mathscr{A}'$ or from $\exp_m\mathscr{A}'$ into $\exp_{m+p}\mathscr{A}'$ is defined. (We suppose in (10) that the series converges in the weak sense of the corresponding spaces of generalized functions.)

Remark 2. In the preceding section we defined differential operators of infinite orders E_p^k, $p\in N$, $k\in N$. As in [8, 9.7], one can easily show that the differential equation of the form

$$\left(P_0(\mathscr{R})+P_1(E_1)+\cdots+P_p(E_p)\right)f=g,$$

where $g\in\exp_p\mathscr{A}'$ and $P_0, P_1,\cdots,P_p$ are arbitrary polynomials, has a solution in the space $\exp_p\mathscr{A}'$.

ANALYTICITY SPACES OF SELF-ADJOINT OPERATORS SUBJECTED TO PERTURBATIONS WITH APPLICATIONS TO HANKEL INVARIANT DISTRIBUTION SPACES*

S. J. L. VAN EIJNDHOVEN† AND J. DE GRAAF†

Abstract. A new theory of generalized functions has been developed by one of the authors (de Graaf). In this theory the analyticity domain of each positive self-adjoint unbounded operator $\mathscr{A}$ in a Hilbert space X is regarded as a test space denoted by $\mathscr{S}_{X,\mathscr{A}}$. In the first part of this paper, we consider perturbations $\mathscr{P}$ on $\mathscr{A}$ for which there exists a Hilbert space Y such that $\mathscr{A}+\mathscr{P}$ is a positive self-adjoint operator in Y. In particular, we investigate for which perturbations $\mathscr{P}$ and for which $\nu>0$, $\mathscr{S}_{X,\mathscr{A}^\nu}\subset\mathscr{S}_{Y,(\mathscr{A}+\mathscr{P})^\nu}$. The second part is devoted to applications. We construct Hankel invariant distribution spaces. The corresponding test spaces are described in terms of the $\mathscr{S}_\alpha^\beta$-spaces introduced by Gel'fand and Shilov. It turns out that the modified Laguerre polynomials establish an uncountable number of bases for the space of even entire functions in $\mathscr{S}_\mu^\mu$ ($\frac{1}{2}\leqq\mu\leqq 1$). For an even entire function φ we give necessary and sufficient conditions on the coefficients in the Fourier expansion with respect to each basis such that $\varphi\in\mathscr{S}_\mu^\mu$.

Introduction. Let X be a separable infinitely dimensional Hilbert space and let $\mathscr{L}$ be a linear operator in X. Then $\mathfrak{D}^\omega(\mathscr{L})$, the analyticity domain of $\mathscr{L}$, consists of all vectors $v\in\bigcap_{n=1}^\infty\mathfrak{D}(\mathscr{L}^n)$ satisfying

$$\exists_{a>0}\exists_{b>0}\forall_{n\in\mathbf{N}}:\|\mathscr{L}^n v\|\leqq n!a^n b.$$

For a positive self-adjoint operator $\mathscr{A}$ in X, Nelson [13] proved that $\mathscr{D}^\omega(\mathscr{A})$ can also be described as

$$\mathfrak{D}^\omega(\mathscr{A})=\bigcup_{t>0}e^{-t\mathscr{A}}(X)=\{e^{-t\mathscr{A}}w\mid w\in X,\ t>0\}.$$

Instead of $\mathfrak{D}^\omega(\mathscr{A})$ we use the notation $\mathscr{S}_{X,\mathscr{A}}$ introduced by de Graaf. The spaces of type $\mathscr{S}_{X,\mathscr{A}}$ are called analyticity spaces. They are nonstrict inductive limits of Hilbert spaces. Together with their strong duals $\mathscr{T}_{X,\mathscr{A}}$ they establish the functional analytic description of the distribution theory in [7].

For each positive constant ν the operator $\mathscr{A}^\nu$ is well defined, positive and self-adjoint in X. So it makes sense to write $\mathscr{S}_{X,\mathscr{A}^\nu}$. The question arises for which perturbations $\mathscr{P}$ on $\mathscr{A}$ there can be found a Hilbert space Y such that $\mathscr{A}+\mathscr{P}$ is a positive self-adjoint operator in Y and $\mathscr{S}_{X,\mathscr{A}^\nu}\subset\mathscr{S}_{Y,(\mathscr{A}+\mathscr{P})^\nu}$. In the paper [1] the case $\nu=1$ has been considered. Also some results concerning analytic dominancy can be found there.

In the second part of this paper we study a class of Hankel invariant test and distribution spaces, and also their relations to the $\mathscr{S}_\alpha^\beta$-spaces of Gel'fand and Shilov [9]. With our papers [2] and [4] we have started this study. There we have shown that the space of even functions in $\mathscr{S}_{1/2}^{1/2}$ remains invariant under the modified Hankel transforms $\mathbf{H}_\alpha$, $\alpha>-1$, defined by

$$(\mathbf{H}_\alpha f)(x)=\int_0^\infty(xy)^{-\alpha}J_\alpha(xy)f(y)y^{2\alpha+1}dy.$$

Moreover, for each $\alpha>-1$ the space of even functions in $\mathscr{S}_{1/2}^{1/2}$ equals the analyticity space $\mathscr{S}_{X_\alpha,\mathscr{A}_\alpha}$ where $X_\alpha=\mathfrak{L}_2((0,\infty),x^{2\alpha+1}dx)$ and $\mathscr{A}_\alpha=-d^2/dx^2+x^2-(2\alpha+1)xd/dx$.

*Received by the editors December 6, 1983.

† Department of Mathematics and Computing Science, Eindhoven University of Technology, Eindhoven, the Netherlands.

The operator $\mathscr{A}_\alpha$ has an orthonormal basis of eigenvectors $(\mathbf{L}_n^{(\alpha)})_{n=0}^\infty$ with eigenvalues $4n+2\alpha+2$. So for each even $f\in\mathscr{S}_{1/2}^{1/2}$ there exists an l_2-sequence $(\omega_n)_{n=0}^\infty$ and $t>0$ such that $f=\sum_{n=0}^\infty \exp(-(4n+2\alpha+2)t)\omega_n\mathbf{L}_n^{(\alpha)}$. Here we prove similar results for the spaces $\mathscr{S}_{X_\alpha,(\mathscr{A}_\alpha)^\nu}$ with $\nu\geqq\frac{1}{2}$ and $\alpha>-1$. It will follow that for all $\alpha,\beta>-1$ and all $\nu\geqq\frac{1}{2}$

$$\mathscr{S}_{X_\alpha,(\mathscr{A}_\alpha)^\nu}=\mathscr{S}_{X_\beta,(\mathscr{A}_\beta)^\nu}.$$

For $\nu\in[\frac{1}{2},1]$ the analyticity space $\mathscr{S}_{X_{-1/2},(\mathscr{A}_{-1/2})^\nu}$ contains just the even functions in $\mathscr{S}_{1/2\nu}^{1/2\nu}$.

1. General theory. Let $\mathscr{A}$ be a positive self-adjoint operator in a Hilbert space X and let $\nu>0$. It makes sense to write $\mathscr{A}^\nu$ and the operator $\mathscr{A}^\nu$ is positive and self-adjoint in X. So the space $\mathscr{S}_{X,\mathscr{A}^\nu}$ is well defined. Its elements are characterized by

LEMMA 1.1. *For each $f\in\mathscr{D}(\mathscr{A}^\infty)\subset X$ the following statements are equivalent:*

(i) $\exists_{a>0}\exists_{b>0}\forall_{k\in\mathbf{N}}:\|\mathscr{A}^k f\|\leqq(k!)^{1/\nu}a^k b$.

(ii) $f\in\mathscr{S}_{X,\mathscr{A}^\nu}$.

Proof. (i)$\Rightarrow$(ii). Let $N\in\mathbf{N}$ and let $\tau>0$. Consider the following estimation

$$(*)\qquad \sum_{k=0}^N \frac{\tau^k}{k!}\|\mathscr{A}^{\nu k}f\|\leqq\sum_{k=0}^N\frac{\tau^k}{k!}\|\mathscr{A}^{-1+\nu k-[\nu k]}\|\|\mathscr{A}^{[\nu k]+1}f\|$$

$$\leqq b_1\sum_{k=0}^N\frac{\tau^k}{k!}(([\nu k]+1)!)^\nu a^k$$

where $b_1=b\sup_{k\in\mathbf{N}\cup\{0\}}(\|\mathscr{A}^{-1+\nu k-[\nu k]}\|)$. The following inequalities are valid:

$$([\nu k]+1)!\leqq([\nu k]+1)([\nu k]+1)^{[\nu k]}\leqq e([\nu k]+1)(\nu k)^{\nu k}.$$

So $([\nu k]+1)!\leqq(e([\nu k]+1))^{1/\nu}(\nu e)^k k!$, and for $\tau<(\nu e a)^{-1}$ the series $(*)$ converges. It implies that $f\in\exp(-\tau\mathscr{A}^\nu)(X)$.

(ii)$\Rightarrow$(i). Suppose $g\in\mathscr{S}_{X,\mathscr{A}^\nu}$. Then there exists $s>0$ and $w\in X$ such that $g=\exp(-s\mathscr{A}^\nu)w$. Let $k\in\mathbf{N}$. Then we estimate as follows

$$\|\mathscr{A}^k f\|\leqq\|\mathscr{A}^k\exp(-s\mathscr{A}^\nu)\|\|w\|=\|w\|\left(\frac{k}{\nu s}\right)^{k/\nu}e^{-k/\nu}$$

$$\leqq\|w\|(1/\nu s)^{k/\nu}\cdot(k!)^{1/\nu}.$$

With $a=(\nu s)^{-1/\nu}$ and $b=\|w\|$ the implication (ii)$\Rightarrow$(i) has been proved. □

Let $\mathscr{L}$ be an unbounded linear operator in X. Then the operators $\mathscr{L}^2,\mathscr{L}^3,\cdots$ are well defined. As a corollary of the previous theorem we get the following.

COROLLARY 1.2. *Let $n\in\mathbf{N}$ and let $f\in\mathscr{D}^\omega(\mathscr{L})$. The following statements are equivalent.*

(i) $\exists_{a>0}\exists_{b>0}\forall_{k\in\mathbf{N}}:\|\mathscr{L}^k f\|\leqq(k!)^{1/n}a^k b$.

(ii) $f\in\mathscr{D}^\omega(\mathscr{L}^n)$.

As mentioned in the introduction we investigate perturbations $\mathscr{P}$ on $\mathscr{A}$ such that $\mathscr{D}^\omega((\mathscr{A}+\mathscr{P})^\nu)\supset\mathscr{S}_{X,\mathscr{A}^\nu}$. For $\nu=1$ the following result has been proved in [1]. Here we consider general $\nu>0$.

THEOREM 1.3. *Let $\mathscr{P}$ be a linear operator in X with $\mathfrak{D}(\mathscr{P}) \supset \mathscr{S}_{X,\mathscr{A}^\nu}$. Suppose the following conditions are satisfied.*

(i) *There exists a Hilbert space Y such that $\exp(-t\mathscr{A}^\nu)$ maps X into Y for all $t>0$.*

(ii) *In addition, $\mathscr{A}+\mathscr{P}$ defined on $\mathscr{S}_{X,\mathscr{A}^\nu}$ is positive and essentially self-adjoint in Y.*

(iii) *There exists an everywhere defined, monotone nonincreasing function φ on $(0,1)$ such that*

$$\forall_{r:0<r<1}: \|\exp(r\mathscr{A}^\nu)\mathscr{P}\mathscr{A}^{-1}\exp(-r\mathscr{A}^\nu)\|_X \leqq \varphi(r).$$

Then $\mathscr{S}_{X,\mathscr{A}^\nu} \subset \mathscr{S}_{Y,(\mathscr{A}+\mathscr{P})^\nu}$.

Proof. We note first that $\mathscr{S}_{X,\mathscr{A}^\nu} = \bigcup_{0<t<1} \exp(-t\mathscr{A}^\nu)(X)$. So let $0<t<1$, and let $0<\tau<t$. Put $s = t-\tau$. We want to estimate the norm of the operator $\exp(\tau\mathscr{A}^\nu)\cdot(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)$ for each $k\in\mathbf{N}$. Therefore we factor as follows

$$\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)$$

$$= \prod_{j=0}^{k-1}\left\{\exp\left(\left(\tau+\frac{j}{k}s\right)\mathscr{A}^\nu\right)(\mathscr{I}+\mathscr{P}\mathscr{A}^{-1})\exp\left(-\left(\tau+\frac{j}{k}s\right)\mathscr{A}^\nu\right)\mathscr{A}\exp\left(-\frac{s}{k}\mathscr{A}^\nu\right)\right\}.$$

This factoring yields the estimate

$$\left\|\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)\right\|$$

$$\leqq \left\|\mathscr{A}\exp\left(-\frac{s}{k}\mathscr{A}^\nu\right)\right\|^k \prod_{j=0}^{k-1}\left\|\exp\left(\left(\tau+\frac{j}{k}s\right)\mathscr{A}^\nu\right)(\mathscr{I}+\mathscr{P}\mathscr{A}^{-1})\exp\left(-\left(\tau+\frac{j}{k}s\right)\mathscr{A}^\nu\right)\right\|$$

$$\leqq (k!)^{1/\nu}\left(\frac{1}{\nu s}\right)^{k/\nu}\prod_{j=0}^{k-1}\left(1+\varphi\left(\tau+\frac{j}{k}s\right)\right).$$

Since $\varphi(\tau+js/k)\leqq\varphi(\tau)$ for all $j=0,1,\cdots,k-1$, we get

$$\prod_{j=0}^{k-1}\left(1+\varphi\left(\tau+\frac{j}{k}s\right)\right)\leqq(1+\varphi(\tau))^k.$$

Thus we have proved that

$$\forall_{t>0}\forall_{\tau,0<\tau<t}\exists_{a>0}\forall_{k\in\mathbf{N}\cup\{0\}}: \left\|\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)\right\|\leqq(k!)^{1/\nu}a^k.$$

Let $t>0$ and let $w\in X$. Set $f=\exp(-t\mathscr{A}^\nu)w$. Then for $0<\tau<t$ fixed there exists $a>0$ such that

$$\|(\mathscr{A}+\mathscr{P})^k f\|_Y \leqq \|\exp(-\tau\mathscr{A}^\nu)\|_{X\to Y}\|\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k f\|_X$$

$$\leqq \|\exp(-\tau\mathscr{A}^\nu)\|_{X\to Y}\|w\|_X a^k(k!)^{1/\nu}.$$

From Lemma 1.1 it follows that $f\in\mathscr{S}_{Y,(\mathscr{A}+\mathscr{P})^\nu}$. □

Remark. Suppose there exists $k\in\mathbf{N}$ such that the operator $\mathscr{A}^{-k}$ maps X continuously into Y. Then Condition (iii) of Theorem 1.3 is fulfilled because

$$\|\exp(-t\mathscr{A}^\nu)\|_{X\to Y}\leqq\|\mathscr{A}^{-k}\|_{X\to Y}\|\mathscr{A}^k\exp(-t\mathscr{A}^\nu)\|_X.$$

COROLLARY 1.4. *Let $\mathscr{P}$ be an operator in X and let $n\in\mathbf{N}$ with $\mathfrak{D}(\mathscr{P})\supset\mathscr{S}_{X,\mathscr{A}^n}$. Suppose there exists an everywhere defined monotone nonincreasing function φ on $(0,1)$ such that*

$$\forall_{0<r<1}:\left\|\exp(r\mathscr{A}^n)\mathscr{P}\mathscr{A}^{-1}\exp(-r\mathscr{A}^n)\right\|\leqq\varphi(r).$$

Then $\mathscr{S}_{X,\mathscr{A}^n}\subset\mathfrak{D}^\omega((\mathscr{A}+\mathscr{P})^n)$.

Proof. As in the proof of the previous theorem: $\forall_{t>0}\forall_{\tau,0<\tau<t}\exists_{a>0}\forall_{k\in\mathbf{N}}$:

$$\left\|\exp(\tau\mathscr{A}^n)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^n)\right\|\leqq(k!)^{1/n}a^k.$$

So for $f=\exp(-t\mathscr{A}^n)w$, $t>0$, $w\in X$, we get

$$\left\|(\mathscr{A}+\mathscr{P})^k f\right\|_X\leqq\left\|\exp(\tau\mathscr{A}^n)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^n)\right\|\|w\|\leqq(k!)^{1/n}a^k\|w\|.\qquad\square$$

Remark. If $\mathscr{P}$ satisfies the conditions in Corollary 1.4, then $\mathscr{A}^n$ analytically dominates $(\mathscr{A}+\mathscr{P})^n$. (For the terminology, see [6].)

In order to prove the converse statement of Theorem 1.3, i.e.,

$$\mathscr{S}_{Y,(\mathscr{A}+\mathscr{P})^\nu}\subset\mathscr{S}_{X,\mathscr{A}^\nu}$$

we have to interchange the roles of $\mathscr{A}$ and $\mathscr{A}+\mathscr{P}$. Put differently, if we write $\mathscr{B}=\mathscr{A}+\mathscr{P}$ and hence $\mathscr{A}=\mathscr{B}-\mathscr{P}$, then we have to check whether the pair $\mathscr{B}$, $\mathscr{P}$ satisfies the conditions required in Theorem 1.3.

2. Hankel invariant distribution spaces. In our papers [2], [4] on Hankel invariant distribution spaces the following results have been proved.

Let $\mathscr{A}_\gamma$ denote the differential operator $-d^2/dx^2+x^2-(2\gamma+1)/x\,d/dx$ and let X_γ denote the Hilbert space $\mathfrak{L}_2((0,\infty),x^{2\gamma+1}dx)$ where we take $\gamma>-1$. Then for every $\alpha,\beta>-1$ we have shown that

$$\mathscr{S}_{X_\alpha,\mathscr{A}_\alpha}=\mathscr{S}_{X_\beta,\mathscr{A}_\beta}.$$

Moreover, $f\in\mathscr{S}_{X_\gamma,\mathscr{A}_\gamma}$ if and only if f is extendible to an even function in $\mathscr{S}^{1/2}_{1/2}$. Also, it has been proved that the space $\mathscr{S}_{X_\gamma,\mathscr{A}_\gamma}$ remains invariant under the modified Hankel transform $\mathbf{H}_\gamma$ defined by

$$(\mathbf{H}_\gamma f)(x)=\int_0^\infty f(y)(xy)^{-\gamma}J_\gamma(xy)\,y^{2\gamma+1}dy.$$

Here J_γ denotes the Bessel function of the first kind and of order γ. The Hankel transform $\mathbf{H}_\gamma$ extends to a unitary operator on X_γ and $\mathbf{H}_\gamma\mathscr{A}_\gamma=\mathscr{A}_\gamma\mathbf{H}_\gamma$. It follows that for all $\alpha,\beta>-1$, $\mathbf{H}_\alpha$ maps the space $\mathscr{S}_{X_\beta,\mathscr{A}_\beta}$ onto itself. By duality, each $\mathbf{H}_\alpha$ leaves invariant each space of generalized functions $\mathscr{T}_{X_\beta,\mathscr{A}_\beta}$ corresponding to $\mathscr{S}_{X_\beta,\mathscr{A}_\beta}$. The functions $\mathbf{L}_n^{(\gamma)}$ defined by

$$\mathbf{L}_n^{(\gamma)}(x)=\left(\frac{2\Gamma(n+1)}{\Gamma(n+\gamma+1)}\right)^{1/2}e^{-x^2/2}\mathscr{L}_n^{(\gamma)}(x^2),\qquad n\in\mathbf{N}\cup\{0\},\quad x>0$$

establish an orthonormal basis in X_γ and they are the eigenfunctions of the self-adjoint operator $\mathscr{A}_\gamma$ with respective eigenvalues $4n+2\gamma+2$. Here $\mathscr{L}_n^{(\gamma)}$ denotes the nth generalized Laguerre polynomial of order γ. We note that $\mathbf{H}_\gamma\mathbf{L}_n^{(\gamma)}=(-1)^n\mathbf{L}_n^{(\gamma)}$. We recall that for each $\alpha,\beta>-1$ the functions $f\in\mathscr{S}_{X_\alpha,\mathscr{A}_\alpha}$ can be written as $f=\sum_{n=0}^\infty\omega_n\mathbf{L}_n^{(\beta)}$ where $\omega_n=O(e^{-nt})$ for some $t>0$.

With the aid of the theory presented in the first part of this paper we extend the mentioned results and prove that

$$\mathcal{S}_{X_\alpha\{\mathcal{A}_\alpha\}^\nu}=\mathcal{S}_{X_\beta\{\mathcal{A}_\beta\}^\nu}$$

for all $\nu\geqq\frac{1}{2}$ and all $\alpha,\beta>-1$. In addition, we show that for each $\nu\in[\frac{1}{2},1]$ and all $\alpha>-1$ the space $\mathcal{S}_{X_\alpha\{\mathcal{A}_\alpha\}^\nu}$ contains just the even functions of the Gel'fand–Shilov space $\mathcal{S}^{1/2\nu}_{1/2\nu}$. So each even function $f\in\mathcal{S}^{1/2\nu}_{1/2\nu}$ admits Fourier expansions $f=\sum_{n=0}^{\infty}\rho_n^{(\alpha)}\mathbf{L}_n^{(\alpha)}$ with $\rho_n^{(\alpha)}=O(\exp(-n^\nu t))$.

Let $\alpha,\beta>-1$. Then $\mathcal{A}_\alpha$ can be written as

$$\mathcal{A}_\alpha=\mathcal{A}_\beta+2(\alpha-\beta)\mathcal{R}$$

where we put $\mathcal{R}=(1/x)d/dx$. Obviously, $\mathcal{A}_\alpha$ can be obtained from $\mathcal{A}_\beta$ by means of the "perturbation" $2(\alpha-\beta)\mathcal{R}$, and $\mathcal{A}_\beta$ from $\mathcal{A}_\alpha$ by means of $2(\beta-\alpha)\mathcal{R}$. In order to show that $\mathcal{R}$ and hence $c\mathcal{R}$, $c\in\mathbf{C}$, is a perturbation in the sense of Theorem 1.3 we compute the matrix of $\mathcal{R}$ with respect to the orthonormal basis $(\mathbf{L}_n^{(\gamma)})_{n=0}^{\infty}$. To this end, we mention that

$$\mathcal{R}\mathbf{L}_n^{(\gamma)}=-\mathbf{L}_n^{(\gamma+1)}-2\mathbf{L}_{n-1}^{(\gamma+1)}$$

where the relation $d\mathcal{L}_n^{(\gamma)}/dx=-\mathcal{L}_{n-1}^{(\gamma+1)}$ is used.

Now $\mathcal{L}_k^{(\gamma+1)}=\sum_{j=0}^{k}\mathcal{L}_j^{(\gamma)}$ and hence

$$\mathcal{R}\mathbf{L}_n^{(\gamma)}=-\left(\frac{2\Gamma(n+1)}{\Gamma(n+\gamma+1)}\right)^{1/2}\left[\left(\frac{\Gamma(n+\gamma+1)}{\Gamma(n+1)}\right)^{1/2}\mathbf{L}_n^{(\gamma)}+2\sum_{m=0}^{n-1}\left(\frac{\Gamma(m+\gamma+1)}{2\Gamma(m+1)}\right)^{1/2}\mathbf{L}_m^{(\gamma)}\right].$$

Thus we obtain the matrix of $\mathcal{R}$ with respect to the basis $(\mathbf{L}_n^{(\gamma)})_{n=0}^{\infty}$

$$\left(\mathcal{R}\mathbf{L}_k^{(\gamma)},\mathbf{L}_l^{(\gamma)}\right)_\gamma=\begin{cases}-1 & \text{if } l=k,\quad k\in\mathbf{N},\\ 0 & \text{if } l>k,\quad k\in\mathbf{N}\cup\{0\},\\ -2\left(\dfrac{\Gamma(k+1)}{\Gamma(k+\gamma+1)}\dfrac{\Gamma(l+\gamma+1)}{\Gamma(l+1)}\right)^{1/2} & \text{if } 0\leqq l<k,\quad k\in\mathbf{N}.\end{cases}$$

The inequality (cf. [11])

$$n^{1-s}\leqq\frac{\Gamma(n+1)}{\Gamma(n+s)}\leqq(n+1)^{1-s},\qquad 0\leqq s\leqq 1,\quad n\in\mathbf{N}$$

yields

$$\left|\left(\mathcal{R}\mathbf{L}_k^{(\gamma)},\mathbf{L}_l^{(\gamma)}\right)\right|\leqq\begin{cases}2 & \text{if } \gamma\geqq 0,\ 0\leqq l<k,\ k\in\mathbf{N}\cup\{0\},\\ 2k^{-\gamma/2} & \text{if } -1<\gamma<0,\ 0\leqq l<k,\ k\in\mathbf{N}\cup\{0\}.\end{cases}$$

For each $\nu\geqq\frac{1}{2}$, the operator $\exp(r(\mathcal{A}_\gamma)^\nu)\mathcal{R}(\mathcal{A}_\gamma)^{-1}\exp(-r(\mathcal{A}_\gamma)^\nu)$ has to satisfy Condition (iii) of Theorem (1.3). We define the weighted shift operators $\mathcal{W}_{\gamma,\nu}^{(n)}(r)$, $n\in\mathbf{N}\cup\{0\}$,

$$\left(\mathcal{W}_{\gamma,\nu}^{(n)}(r)\mathbf{L}_k^{(\gamma)},\mathbf{L}_l^{(\gamma)}\right)_\gamma=\begin{cases}0 & \text{if } k\neq l+n,\\ \left(\mathcal{R}\mathbf{L}_{l+n}^{(\gamma)},\mathbf{L}_l^{(\gamma)}\right)\dfrac{\exp\left(-r\left(4(l+n)+2\gamma+2\right)\right)^\nu-(4l+2\gamma+2)^\nu}{4(l+n)+2\gamma+2}\end{cases}$$

with norms

(*)

$$\left\|\mathscr{W}_{\gamma,\nu}^{(n)}(r)\right\|_{X_\gamma}=\sup_{l\in\mathbf{N}\cup\{0\}}\left|\left(\mathscr{R}\mathbf{L}_{l+n}^{(\gamma)},\mathbf{L}_l^{(\gamma)}\right)\right|\frac{\exp\left(-r\left(4(l+n)+2\gamma+2\right)\right)^\nu-\left(4l+2\gamma+2\right)^\nu}{4(l+n)+2\gamma+2}.$$

So $\|\mathscr{W}_{\gamma,\nu}^{(0)}(r)\|\leqq 1/(2\gamma+2)$. Now let $n\in\mathbf{N}$. The inequality

$$\left(4(l+n)+2\gamma+2\right)^\nu-\left(4l+2\gamma+2\right)^\nu\geqq(l+n)^{1/2}-l^{1/2}$$

is valid for all $l\in\mathbf{N}\cup\{0\}$ and all $\nu\geqq\frac{1}{2}$. In addition, the matrix elements $|(\mathscr{R}\mathbf{L}_{l+n}^{(\gamma)},\mathbf{L}_l^{(\gamma)})|$ are smaller than $2(l+n)^{-\gamma/2}$ for $-1<\gamma<0$ and smaller than 2 for $\gamma\geqq 0$. If $-1<\gamma\leqq 0$ we therefore get

$$\begin{aligned}\left\|\mathscr{W}_{\gamma,\nu}^{(n)}(r)\right\|&\leqq\sup_{l\in\mathbf{N}\cup\{0\}}\frac{2(l+n)^{-\gamma/2}}{4(l+n)+2\gamma+2}\exp\left(-r\left((l+n)^{1/2}-l^{1/2}\right)\right)\\&\leqq\sup_{l\in\mathbf{N}\cup\{0\}}\left(\frac{1}{2}(l+n)^{-1/2\gamma-1}\exp\left(-\frac{1}{2}rn(l+n)^{-1/2}\right)\right)\\&\leqq\frac{1}{2}\left(1+\frac{1}{2}\gamma\right)^{2+\gamma}\left(\frac{1}{r}\right)^{2+\gamma}\left(\frac{1}{n}\right)^{2+\gamma}\exp(2+\gamma)=:d_1\left(\frac{1}{r}\right)^{2+\gamma}\left(\frac{1}{n}\right)^{2+\gamma}.\end{aligned}$$

Since

$$\exp\left(r\left(\mathscr{A}_\gamma\right)^\nu\right)\mathscr{R}\left(\mathscr{A}_\gamma\right)^{-1}\exp\left(-r\left(\mathscr{A}_\gamma\right)^\nu\right)=\sum_{n=0}^{\infty}\mathscr{W}_{\gamma,\nu}^{(n)}(r)$$

we can use the following straightforward estimate for all $r>0$

$$\begin{aligned}\left\|\exp\left(r\left(\mathscr{A}_\gamma\right)^\nu\right)\mathscr{R}\left(\mathscr{A}_\gamma\right)^{-1}\exp\left(-r\left(\mathscr{A}_\gamma\right)^\nu\right)\right\|&\leqq\sum_{n=0}^{\infty}\left\|\mathscr{W}_{\gamma,\nu}^{(n)}(r)\right\|\\&\leqq\frac{1}{2\gamma+2}+d_1\left(\frac{1}{r}\right)^{2+\gamma}\sum_{n=1}^{\infty}\left(\frac{1}{n}\right)^{2+\gamma}\\&\leqq d_\gamma\left(\frac{1}{r}\right)^{2+\gamma}+\frac{1}{2\gamma+2}\end{aligned}$$

where $d_\gamma=d_1\sum_{n=1}^{\infty}(1/n)^{2+\gamma}$. Summarized we have

LEMMA 2.1. *Let $\gamma>-1$. Then there exist constants $d_\gamma>0$ and $p_\gamma>0$ such that*

$$\forall_{r>0}:\left\|\exp\left(r\left(\mathscr{A}_\gamma\right)^\nu\right)\mathscr{R}\mathscr{A}_\gamma^{-1}\exp\left(-r\left(\mathscr{A}_\gamma\right)^\nu\right)\right\|\leqq d_\gamma\left(\frac{1}{r}\right)^{p_\gamma}+\frac{1}{2\gamma+2}.$$

Proof. For $-1<\gamma\leqq 0$ the assertion has already been proved. For $\gamma>0$ it follows from the matrix expressions for $\mathscr{R}$ that

$$\left\|\exp r\left(\mathscr{A}_\gamma\right)^\nu\mathscr{R}\mathscr{A}_\gamma^{-1}\exp\left(-r\left(\mathscr{A}_\gamma\right)^\nu\right)\right\|\leqq d_0\left(\frac{1}{\gamma}\right)^{p_0}+\frac{1}{2\gamma+2}.$$

□

In addition, we show that given $r>0$, $\gamma,\delta>-1$, the operator $\exp(-r(\mathscr{A}_\gamma)^\nu)$ maps X_γ into X_δ. In [2, p. 17], the following result has been proved

$$\forall_{s\in\mathbf{N}}\exists_{l\in\mathbf{N}}:\left\|\mathscr{Q}^{2s}(\mathscr{A}_\gamma)^{-l}\right\|_\gamma<\infty.$$

Here $\mathscr{Q}$ denotes the multiplication operator in X_γ given by

$$(\mathscr{Q}f)(x)=xf(x).$$

Now let $\delta>-1$ and let $f\in X_\gamma$. Put $s:=[\max\{0,(\delta-\gamma)/2\}]+1$. Then there exists $l_0\in\mathbf{N}$ such that $\|\mathscr{Q}^{2s}\mathscr{A}_\gamma^{-l}\|_\gamma<\infty$ for all $l\geqq l_0$. So we derive

$$(*)\qquad \int_1^\infty\left|\left((\mathscr{A}_\gamma)^{-l}f\right)(x)\right|^2x^{2\delta+1}dx=\int_1^\infty x^{2(\delta-\gamma)}\left|\left((\mathscr{A}_\gamma)^{-l}f\right)(x)\right|^2x^{2\gamma+1}dx$$

$$\leqq\int_1^\infty x^{4s}\left|\left((\mathscr{A}_\gamma)^{-l}f\right)(x)\right|^2x^{2\gamma+1}dx$$

$$\leqq\left\|\mathscr{Q}^{2s}(\mathscr{A}_\gamma)^{-l}\right\|_\gamma^2\|f\|_\gamma^2.$$

Following [12, p. 248], there exists $l_1\in\mathbf{N}$ and $d>0$ such that

$$\max_{x\in[0,1]}\left|\mathbf{L}_k^{(\gamma)}(x)\right|\leqq d(k+1)^{l_1}.$$

For $l>l_1$ it yields

$$(**)\qquad \int_0^1\left|\left((\mathscr{A}_\gamma)^{-2}f\right)(x)\right|^2x^{2\delta+1}dx$$

$$\leqq\left(\max_{x\in[0,1]}\left|\left((\mathscr{A}_\gamma)^{-l}f\right)(x)\right|\right)^2\int_0^1x^{2\delta+1}dx$$

$$\leqq\frac{1}{2\delta+2}\left(\sum_{k=0}^\infty(f,\mathbf{L}_k^{(\gamma)})_\gamma\left(\frac{1}{4k+2\gamma+2}\right)^l\max_{x\in[0,1]}\left|\mathbf{L}_k^{(\gamma)}(x)\right|\right)^2$$

$$\leqq\frac{1}{2\delta+2}\left(d^2\sum_{k=0}^\infty\frac{(k+1)^{2l_1}}{(4k+2\gamma+2)^{2l}}\right)\|f\|_\gamma^2.$$

From $(*)$ and $(**)$ we get

$$\forall_{\gamma>-1}\forall_{\delta>-1}\exists_{l\in\mathbf{N}}\exists_{c>0}\forall_{f\in X_\gamma}:$$

$$\left\|(\mathscr{A}_\gamma)^{-l}f\right\|_\delta^2=\int_0^\infty\left|\left((\mathscr{A}_\gamma)^{-l}f\right)(x)\right|^2x^{2\delta+1}dx\leqq c\|f\|_\gamma^2$$

i.e. $(\mathscr{A}_\gamma)^{-l}$ is a continuous linear operator from X_γ into X_δ.

LEMMA 2.2. *Let* $\gamma>-1$. *Then for every* $r>0$, $\nu>0$ *and* $\delta>-1$ *the operator* $\exp(-r(\mathscr{A}_\gamma)^\nu)$ *is a continuous linear operator from* X_γ *into* X_δ.

Proof. Let $r>0$, $\nu>0$ and let $\delta>-1$. Then there exists $l\in\mathbf{N}$ such that $(\mathscr{A}_\gamma)^{-l}$ is a continuous linear mapping from X_γ into X_δ. Hence $\exp(-r(A_\gamma)^\nu)=(\mathscr{A}_\gamma)^{-l}\{(\mathscr{A}_\gamma)^l\exp(-r(\mathscr{A}_\gamma)^\nu)\}$ is also a continuous linear mapping from X_γ into X_δ. □

Lemmas 2.1 and 2.2 yield the following important result.

THEOREM 2.3. *Let $\alpha, \beta > -1$. Then for every $\nu \geqq \frac{1}{2}$*

$$\mathcal{S}_{X_\alpha,(\mathcal{A}_\alpha)^\nu} = \mathcal{S}_{X_\beta,(\mathcal{A}_\beta)^\nu}.$$

Proof. Let $\nu \geqq \frac{1}{2}$. We have shown that:
$-\exp(-t(\mathcal{A}_\alpha)^\nu)$, $t>0$, maps X_α continuously into X_β.
$-\mathcal{D}(\mathcal{R}) \supset \mathcal{S}_{S_\alpha,(\mathcal{A}_\alpha)^\nu}$, and $\mathcal{A}_\beta = \mathcal{A}_\alpha + 2(\alpha-\beta)\mathcal{R}$ is positive and self-adjoint in X_β.
$-$There exist constants $d_\alpha, p_\alpha > 0$ such that for all $r>0$

$$\left\| \exp\left(r(\mathcal{A}_\alpha)^\nu\right) \mathcal{R}(\mathcal{A}_\alpha)^{-1} \exp\left(-r(\mathcal{A}_\alpha)^\nu\right) \right\|_\alpha \leqq d_\alpha \left(\frac{1}{r}\right)^{p_\alpha} + \frac{1}{2\alpha+2}.$$

So by Theorem 1.3, $S_{X_\alpha,(\mathcal{A}_\alpha)^\nu} \subset \mathcal{S}_{X_\beta,(\mathcal{A}_\beta)^\nu}$. Interchanging α and β we get the wanted result. □

Let $\alpha > -1$. Since $\mathbf{H}_\alpha \mathcal{A}_\alpha = \mathcal{A}_\alpha \mathbf{H}_\alpha$, also $\mathbf{H}_\alpha (\mathcal{A}_\alpha)^\nu = (\mathcal{A}_\alpha)^\nu \mathbf{H}_\alpha$. So the Hankel transform $\mathbf{H}_\alpha$ is a continuous bijection on the space $\mathcal{S}_{X_\alpha,(\mathcal{A}_\alpha)^\nu}$, $\nu \geqq \frac{1}{2}$, and hence on the spaces $\mathcal{S}_{X_\beta,(\mathcal{A}_\beta)^\nu}$, $\nu \geqq \frac{1}{2}$, $\beta > -1$. By duality each transform $\mathbf{H}_\alpha$ leaves invariant the spaces of generalized functions $\mathcal{T}_{X_\beta,(\mathcal{A}_\beta)^\nu}$. For $\alpha = -\frac{1}{2}$ we get $X_{-1/2} = \mathfrak{L}_2((0,\infty))$ and $\mathcal{A}_{-1/2} = -(d^2/dx^2) + x^2$. The functions $\mathbf{L}_k^{(-1/2)}$ are the even Hermite functions. With the aid of the papers [8] and [10] the following characterization of the spaces $\mathcal{S}_{X_{-1/2},(\mathcal{A}_{-1/2})^\nu}$, $\nu \in [\frac{1}{2}, 1]$, can be obtained,

$$f \in \mathcal{S}_{X_{-1/2},(\mathcal{A}_{-1/2})^\nu} : \Leftrightarrow f \text{ is extendible to an even function in the space } \mathcal{S}_{1/2\nu}^{1/2\nu}.$$

The spaces $\mathcal{S}_p^q$, $p+q \geqq 1$, $p,q \geqq 0$, are introduced by Gel'fand and Shilov in [9]. In this connection we note that in our paper [5] we have proved that the spaces $\mathcal{S}_{1/k+1}^{k/k+1}$ are analyticity spaces; explicitly

$$\mathcal{S}_{1/k+1}^{k/k+1} = \mathcal{S}_{\mathfrak{L}_2(\mathbf{R}),\mathcal{B}_k} \quad \text{with } \mathcal{B}_k = \left(-\frac{d^2}{dx^2} + x^{2k} \right)^{(k+1)/2k}.$$

Relevant for the present paper are the spaces $\mathcal{S}_\mu^\mu$, $\frac{1}{2} \leqq \mu \leqq 1$. We have

$\varphi \in \mathcal{S}_\mu^\mu$, $\frac{1}{2} \leqq \mu \leqq 1$ if and only if φ is an entire function satisfying $\exists_{A,B,C>0} : |\varphi(x+iy)| \leqq C \exp(-A|x|^{1/\mu} + B|y|^{1/1-\mu})$

and

$\varphi \in \mathcal{S}_1^1$ if and only if φ is analytic on a strip about the real axis say of width $r>0$ and satisfying $\exists_{A,C>0} : \sup_{|y|<r} |\varphi(x+iy)| \leqq C \exp(-A|x|)$.

Now Theorem 2.3 leads to the following important results.

COROLLARY 2.4. *Let $\alpha > -1$ and let $\nu \in [\frac{1}{2}, 1]$. Then $f \in \mathcal{S}_{X_\alpha,(\mathcal{A}_\alpha)^\nu}$ if and only if f is extendible to an even function in the space $\mathcal{S}_{1/2\nu}^{1/2\nu}$.*

COROLLARY 2.5. *Let $f \in \mathcal{S}_{1/2\nu}^{1/2\nu}$ be even, with $\nu \in [\frac{1}{2}, 1]$. Then for each $\gamma > -1$, there exists an l_2-sequence $(\omega_n^{(\gamma)})_{n=0}^\infty$ and $t>0$ such that $f = \sum_{n=0}^\infty \exp(-n^\nu t)\omega_n^{(\gamma)} \mathbf{L}_n^{(\gamma)}$ where the series converges pointwise.*

Appendix. The set of so-called entire vectors for a positive self-adjoint operator $\mathscr{A}$ in a Hilbert space X is equal to

$$\mathfrak{D}^\infty(e^{\mathscr{A}}) = \bigcap_{t>0} e^{-t\mathscr{A}}(X).$$

In [3], van Eijndhoven has used the Fréchet space $\mathfrak{D}^\infty(e^{\mathscr{A}})$ as the test space in a theory of generalized functions which is a kind of reverse of the theory in [7]. The space $\mathfrak{D}^\infty(e^{\mathscr{A}})$ is denoted by $\tau(X,\mathscr{A})$ and it may be called the entireness space. To our opinion the well-known theory of tempered distributions is considerably generalized in [3]. (Put $\mathscr{A}=\log(-d^2/dx^2+x^2+1)$. Then $\tau(\mathfrak{L}_2(\mathbf{R}), \mathscr{A})$ is the space $\mathscr{S}(\mathbf{R})$ of functions of rapid decrease.)

Similar to Theorem 1.3 we prove

THEOREM A.1. *Let $\mathscr{P}$ be a linear operator in X with $\mathfrak{D}(\mathscr{P})\supset \exp(-\sigma\mathscr{A}^\nu)(X)$ for some $\sigma>0$ sufficiently large. Suppose the following conditions are satisfied.*

(i) *There exists a Hilbert space Y such that $\exp(-t\mathscr{A}^\nu)$ maps X into Y for all $t>0$.*

(ii) *Also, $\mathscr{A}+\mathscr{P}$ defined on $\exp(-\sigma\mathscr{A}^\nu)(X)$ is a positive essentially self-adjoint operator in Y.*

(iii) *There exist positive constants $r_0\geqq 1$, $d>0$ and $0\leqq q<1/\nu$ such that for all $r>r_0$*

$$\|\exp(r\mathscr{A}^\nu)\mathscr{P}\mathscr{A}^{-1}\exp(-r\mathscr{A}^\nu)\|_X < dr^q.$$

Then $\tau(X,\mathscr{A}^\nu)\subset\tau(Y,(\mathscr{A}+\mathscr{P})^\nu)$.

Proof. Since $\tau(X,\mathscr{A}^\nu)=\bigcap_{t>r_0}\exp(-t\mathscr{A}^\nu)(X)$, we consider $t>r_0$ only. Let $0<\tau<1$ with $s=t-\tau>1$. The factoring used in Theorem 1.3 yields the following estimate

$$\|\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)\| \leqq k!\left(\frac{1}{\nu s}\right)^{k/\nu}\prod_{j=0}^{k-1}(1+d(\tau+js/k)^q).$$

Put $b_\tau=1+d\tau^q$. Then

$$\prod_{j=0}^{k-1}(1+d(\tau+js/k)^q)\leqq b_\tau\prod_{j=1}^{k-1}(1+d)\left(\frac{k+js}{k}\right)^q\leqq b_\tau(1+d)^k 2^{qk}s^{qk}.$$

Set $a=(1+d)2^q(\frac{1}{\nu})^{1/\nu}$. Then

$$\|\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)\|_X\leqq(k!)^{1/\nu}\left(\frac{1}{s}\right)^{(-q+1/\nu)k}a^k b_\tau.$$

For $f\in\exp(-t\mathscr{A}^\nu)(X)$ it yields

$$\begin{aligned}\|(\mathscr{A}+\mathscr{P})^k f\|_Y &\leqq \|\exp(-\tau A^\nu)\|_{X\to Y}\|\exp(\tau\mathscr{A}^\nu)(\mathscr{A}+\mathscr{P})^k\exp(-t\mathscr{A}^\nu)\|_X\|\exp(t\mathscr{A}^\nu)f\| \\ &\leqq (k!)^{1/\nu}\left(a\cdot\left(\frac{1}{s}\right)^{1/\nu-q}\right)^k b_\tau\|\exp(-\tau\mathscr{A}^\nu)\|_{X\to Y}\|\exp(t\mathscr{A}^\nu)f\|_X.\end{aligned}$$

Thus we find that $f\in\exp(-r(\mathscr{A}+\mathscr{P})^\nu)(Y)$ for all $r<(1/\nu ae)s^{-q+1/\nu}$. Now put $r(t)=(1/(\nu ae+1))s^{-q+1/\nu}$ with $s=t+1/t-1$ for instance. Then we get

$$\begin{aligned}\tau(X,\mathscr{A}^\nu) &= \bigcap_{t>r_0}(\exp(-t\mathscr{A}^\nu)(X))\subset\bigcap_{t>r_0}\left(\exp(-r(t)(\mathscr{A}+\mathscr{P})^\nu)(Y)\right) \\ &= \bigcap_{r>0}\left(\exp(-r(\mathscr{A}+\mathscr{P})^\nu)(Y)\right)\Big) = \tau(Y,(\mathscr{A}+\mathscr{P})^\nu).\end{aligned}$$

□

It is not hard to see that the spaces $\tau(X_\alpha, (\mathscr{A}_\alpha)^\nu)$, $\alpha > -1$, are Hankel invariant, and hence their strong duals $\sigma(X_\alpha, (\mathscr{A}_\alpha)^\nu)$. The previous theorem and the Lemmas 2.1 and 2.2 lead to the following classification.

THEOREM A.2. *Let* $\alpha, \beta > -1$ *and let* $\nu \geqq \frac{1}{2}$. *Then*

$$\tau\left(X_\alpha, (\mathscr{A}_\alpha)^\nu\right) = \tau\left(X_\beta, (\mathscr{A}_\beta)^\nu\right).$$

By [2] *and* [8] *we obtain the following characterizations*

$f \in \tau(X_{-1/2}, \mathscr{A}_{-1/2})$ *iff* f *is extendible to an even entire function for which* $\forall_{0<a<1} \exists_{C>0} \forall_{x+iy \in C}: |f(x+iy)| \leqq C \exp(-\frac{1}{2}ax^2 + \frac{1}{2a}y^2)$

and

$f \in \tau(X_{-1/2}, (\mathscr{A}_{-1/2})^{1/2})$ *iff* f *is extendible to an even entire function for which* $\forall_{r>0}: \sup_{|y|<r, -\infty<x<\infty} e^{r|x|} |f(x+iy)| < \infty$.

Finally, Theorem A.2 gives the characterization in classical analytic terms of the elements in each $\tau(X_\alpha, \mathscr{A}_\alpha)$, respectively $\tau(X_\alpha, (\mathscr{A}_\alpha)^{1/2})$, $\alpha > -1$.

LIMIT CYCLES IN THE JOSEPHSON EQUATION*

JAN A. SANDERS† AND RICHARD CUSHMAN‡

Abstract. Using techniques from bifurcation theory, we find the bifurcation diagram and corresponding phase portraits on TS^1 of the Josephson equation: $\dot{\phi}=y$, $\dot{y}=-\sin\phi+\varepsilon(a-(1+\gamma\cos\phi)y)$.

AMS(MOS) subject classifications. Primary 58F21; secondary 34C05

Key words. Josephson equation, averaging method, Picard–Fuchs equation, limit cycle, saddle connection, homoclinic loop

1. Introduction. Mathematically, a single point contact Josephson junction is described by the nonlinear second order differential equation

$$\beta\frac{d^2\phi}{d\tau^2}+(1+\gamma\cos\phi)\frac{d\phi}{d\tau}+\sin\phi=\alpha, \qquad \phi\in S^1 \quad \alpha,\beta,\gamma\in\mathbb{R} \tag{1.1}$$

which we call the Josephson equation. In many applications [14], [19] point contact Josephson junctions are used as precision voltage sources. Here the voltage of a solution of (1.1) is the time average of $d\phi/d\tau$. Unfortunately the output voltage of a Josephson junction is very small. In order to physically detect it one first drives the Josephson junction with a high frequency sine wave of low amplitude and then one measures the voltage of a phased locked solution. Mathematically, one is looking at the time average of $d\phi/d\tau$ on a periodic solution which lies on an invariant torus of the driven equation. Because the amplitude of the driving is small, one expects that the invariant tori come from limit cycles of the Josephson equation. Therefore one needs to know the entire phase portrait of (1.1).

We shall study (1.1) when β is large and α is small. More specifically, let $\varepsilon=\beta^{-1/2}$ be a small positive parameter. Then set $\alpha=\varepsilon a$ and $\tau=\varepsilon t$. With $\dot{}=d/dt$ we write (1.1) as

$$X_{a,\gamma}: \quad \begin{aligned}\dot{\phi}&=y,\\ \dot{y}&=-\sin\phi+\varepsilon[a-(1+\gamma\cos\phi)y].\end{aligned} \tag{1.2}$$

Holding ε fixed, $X_{a,\gamma}$ is a two-parameter family of vectorfields on the cylinder TS^1, which we will study by the averaging method.

We now derive the averaged equation. When $\varepsilon=0$ (1.2) is the Hamiltonian vectorfield X_H describing the mathematical pendulum where the Hamiltonian function is

$$H(\phi,y)=\frac{1}{2}y^2-\cos\phi. \tag{1.3}$$

Instead of the variables (ϕ,y) we will use the variables (ϕ,h), where h is defined as

$$h=\frac{1}{2}y^2-\cos\phi.$$

Differentiating (1.3) with respect to ϕ and using (1.2) gives

$$\frac{dh}{d\phi}=\varepsilon[a-(1+\gamma\cos\phi)y(\phi,h)] \tag{1.4}$$

where $y(\phi,h)=\pm(\sqrt{2}(h+\cos\phi))^{1/2}$. Averaging (1.4) over a compact connected component Γ_h of the level set $H^{-1}(h)$ (which is a periodic solution of X_h except when $h=1$) leads to the averaged equation

$$\frac{\overline{dh}}{d\phi}=\varepsilon\left[a\int_{\Gamma_h}d\phi-\int_{\Gamma_h}y\,d\phi-\gamma\int_{\Gamma_h}y\cos\phi\,d\phi\right]. \tag{1.5}$$

Nondegenerate zeros of the right-hand side of (1.5) correspond to limit cycles of $X_{a,\gamma}$.

In earlier publications [3], [17], the averaged equation was studied by expressing the integrals

$$\mathscr{A}(h)=\int_{\Gamma_h}d\phi,\quad \mathscr{B}(h)=\int_{\Gamma_h}y\,d\phi,\quad \mathscr{C}(h)=\int_{\Gamma_h}y\cos\phi\,d\phi, \tag{1.6}$$

in terms of the complete elliptic integrals E and K. Because of the complicated implicit relationship between the elliptic modulus parameter k and the energy parameter h, this special function approach led to meager incomplete results. The technique we use to study the averaged equation is to find the Picard–Fuchs equation satisfied by $\mathscr{A}$, $\mathscr{B}$ and $\mathscr{C}$ and then to analyze the solutions of the resulting Riccati equations. This is the approach used in the study of codimension two bifurcations of planar vectorfields [4]–[9], [11]–[13] and is quite widely applicable. For instance, for all perturbations of the mathematical pendulum by a vectorfield on TS^1 whose components are polynomical in y, $\cos\phi$, and $\sin\phi$, there is a systematic way of finding the Picard–Fuchs equation for the integrals appearing in the averaged equation. However for the analysis of the resulting Riccati equations there are no known general techniques. Here we must proceed on a case by case basis, although one can obtain upper estimates on the number of solutions in terms of the degree of the polynomial [18].

We return to studying the zeros of the averaged equation (1.5). First, we remark that there are *three* distinct families of closed cycles Γ_h on TS^1 (see Fig. 1):

i. Γ_h^0, when $-1<h<1$. The level set $H^{-1}(h)$ is smooth, connected, compact, and contractible to a point.

ii. Γ_h^+, when $h>1$ and $y>0$. Γ_h^+ is the component of the level set $H^{-1}(h)$ given by the graph of the function $y=\sqrt{2(h+\cos\phi)}$; Γ_h^+ is not contractible to a point (it winds around the cylinder).

iii. Γ_h^-, when $h>1$ and $y<0$. Γ_h^- is as in (ii), except that $y=-\sqrt{2(h+\cos\phi)}$.

From here on we use the superscripts 0 and $\pm$ on $\mathscr{A}$, $\mathscr{B}$ and $\mathscr{C}$ to denote which Γ_h-family is being used. For a fixed value of the parameter a, those values of γ which give rise to zeros of $\overline{dh}/d\phi$ in (1.5) are exactly the values of the function

$$\eta(h)=a\frac{\mathscr{A}(h)}{\mathscr{C}(h)}-\xi(h), \tag{1.7}$$

where

$$\xi(h)=\frac{\mathscr{B}(h)}{\mathscr{C}(h)}. \tag{1.8}$$

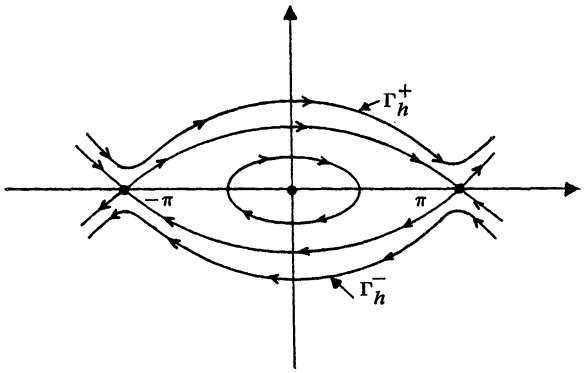

FIG. 1. *Level sets of H on* TS^1.

The main result of this paper is the following.

THEOREM. *For* $h \in (-1,1)$, $\eta^0 = -\xi^0$ *is a strictly monotonic decreasing function with range* $(-3,-1)$; *moreover* η^0 *does not depend on the parameter a.*

Let $a^{\pm} = \pm 16/3\pi$. *For each* $a < a^+$, η^+ *is a strictly monotonic decreasing function of h on* $(1,\infty)$ *with range* $(-\infty, 3\pi a/4 - 3)$; *while for each* $a > a^+$, *when* $h > 1$, η^+ *has a unique maximum* $\tilde{\eta}^+(a)$ *and has range* $(-\infty, \tilde{\eta}^+(a))$. *For each* $a > a^-$, η^- *is strictly monotonic decreasing function on* $(1,\infty)$ *with range* $(-\infty, 3\pi a/4 - 3)$; *while for each* $a < a^-$, *when* $h > 1$, η^- *has a unique maximum* $\tilde{\eta}^-(a)$ *and has range* $(-\infty, \tilde{\eta}^-(a))$.

Figure 2 gives the a-γ plane bifurcation diagram for $X_{a,\gamma}$, while Fig. 3 depicts the phase portraits of $X_{a,\gamma}$, along two curves in the a-γ plane. In §2 we will show that Figs. 2 and 3 follow from the above theorem. In §3 and §4 we give somewhat technical proofs of the key properties of the functions ξ and η, which culminate in the proof of the theorem.

FIG. 3 (*cont.*) *Phase portraits of* $X_{a,\gamma}$.

2. Phase portraits. Consider Figs. 2 and 3. Following the dotted line in Fig. 2 from the right to the left we go through numbered regions and curves with Roman numerals corresponding with phase portraits in Fig 2. We shall now see why the phase portraits follow from our knowledge of η. Before beginning our discussion we would like to warn the ambitious reader who tries to fill in the details omitted in our severely condensed arguments that the Poincaré–Bendixson theorem [10] does not help in finding the α and ω limit sets of orbits of $X_{a,\gamma}$ because TS^1 is not a compact and hence the orbits may run off to infinity. Also one should note that the divergence criterion holds only on simply connected regions.

The sections correspond to the number of the region in Figs. 2 and 3. Note that Fig. 3 is symmetric about the γ axis since (1.1) is the same when (a, ϕ) is replaced by $(-a, -\phi)$. Also the phase portraits are the same when a is replaced by $-a$. Thus we suppose $a \geqq 0$.

1. First we show that there is a $y_0 > 0$ such that $\mathcal{D} = \{(\phi, y) \in TS^1 \,|\, |y| \leqq y_0\}$ is an attracting domain for $X_{a,\gamma}$. From the averaging theorem it follows that an integral curve on $X_{a,\gamma}$ starting at p lies within an ε tube of an integral curve of X_H starting at p for all $t \in [0, C\varepsilon^{-1}]$. Choose y_0 so large that every integral curve of X_H which starts outside $\mathcal{D}$ has a period less than $\frac{1}{2}C\varepsilon^{-1}$. Therefore any vertical line $l = \{(\phi, y) \in TS^1 \,|\, \phi = \phi_0\}$ is a global cross-section for $X_{a,\gamma}$ outside $\mathcal{D}$. Again, using the averaging theorem, it follows that outside $\mathcal{D}$ the change in H along an integral curve of $X_{a,\gamma}$ between successive crossings of l is equal to $\overline{dh/d\phi}$ plus terms of order ε^2. Since (a, γ) lies in region 1,

$$\eta^{0,+}(h) > \gamma \tag{2.1}$$

for all $h > -1$. From (4.1), the definition of η (1.7) and the fact that $C^{0,+}(h) > 0$ (3.4 & 3.29), it follows that $\overline{dh/d\phi} < 0$. Therefore, on each integral curve of $X_{a,\gamma}$ starting outside $\mathcal{D}$, H is strictly decreasing. Consequently, $\mathcal{D}$ is a compact attracting domain for $X_{a,\gamma}$.

The original system (1.2) has stationary points given by

$$\sin\phi = \varepsilon a, \qquad y = 0.$$

Thus ϕ is approximately 0 or π. In what follows we shall denote the two equilibrium points by $(0, 0)$ and $(\pi, 0)$ to keep the notation simple. The linearization of (1.2) at these stationary points is approximately

$$\begin{pmatrix} 0 & 1 \\ \mp 1 & -\varepsilon(1 \pm \gamma) \end{pmatrix} \tag{2.2}$$

where the + corresponds with $(0,0)$ and the $-$ with $(\pi,0)$. The point $(\pi,0)$ is a saddle point. At $(0,0)$ the trace of (2.2) is $-\varepsilon(1+\gamma)$. Thus for $\gamma>-1$ the point $(0,0)$ is attracting.

We now finish the discussion of the phase portrait of $X_{a,\gamma}$. Since (2.1) holds, $X_{a,\gamma}$ has no limit cycles or saddle connections in $\mathscr{D}$. Therefore by the Poincaré–Bendixson theorem, the ω-limit set of every integral curve of $X_{a,\gamma}$ in $\mathscr{D}$ is an equilibrium point. Since $X_{a,\gamma}$ has no saddle connections, the ω-limit of the unstable manifold of $(\pi,0)$ is $(0,0)$. Therefore $(0,0)$ is a global attractor for $X_{a,\gamma}$ except for the stable manifold of $(\pi,0)$ whose α-limit set runs off to infinity.

2. On I: $\gamma=\eta^+(a)$, we witness a saddle node type bifurcation of a stable and unstable winding limit cycle. In region 2, the unstable winding limit cycle divides the attraction domains of the stable winding limit cycle and the two stationary points.

3. On II: $\gamma=3(\pi a/4-1)$, $\gamma>1$, the unstable winding limit cycle forms a noncontractible homoclinic saddle connection. This can also be deduced from the vanishing of the Melnikov function for those readers who prefer to use techniques other than averaging. If, after crossing II, the ω-limit set of both branches of the unstable manifold again would be the point $(0,0)$, then there is no way for the α-limit set of the stable manifold to exist. Therefore, since the Melnikov function changes sign at the bifurcation, the ω-limit set consists of the point $(0,0)$ and the attracting winding limit cycle. The domains of attraction are separated by the stable manifold of the saddle point. The existence of contractible limit cycles is ruled out by the fact that the range of η^0 is $[-3,-1]$ and, for $|\gamma|<1$, by the negativity of the divergence of $X_{a,\gamma}$.

4. Crossing III: $\gamma=-1$, a Hopf bifurcation takes place. This gives rise to the existence of a stable contractible limit cycle for $\gamma\in[-3,-1]$, the range of η^0. The Hopf limit cycle takes over the role of the point attractor as described in part 3. The part of the unstable manifold that is approaching the contractible limit cycle is characterized by the fact that it intersects the line segment $y=0$, $\pi<\phi<2\pi$, i.e. it intersects the ϕ-axis going from the positive ($y>0$) half to the negative half of the cylinder. Due to the growth of the contractible limit cycle, as reflected in the monotonicity of η^0, this intersection takes place closer and closer to the saddle point, until, at IV: $\gamma=-3$, a homoclinic (contractible) saddle connection is formed. The existence of this homoclinic connection follows from a continuity argument relating the behavior of the unstable manifold for $\gamma>-3$ to that for $-3-3\pi a/4<\gamma<-3$ (see the next section).

5. For $\gamma<-3$, the only attractor is the winding limit cycle. The point $(0,0)$ stays unstable. There is one orbit going out of $(0,0)$ to the saddle point. Both branches of the unstable manifold of the saddle point are attracted to the winding limit cycle. The only other possibilities would be:

i. The unstable manifold forms a noncontractible homoclinic saddle connection. This is ruled out by the Melnikov function.

ii. It forms a contractible homoclinic connection (as for $\gamma=-3$). If we average the original equation along this connection, we find that $\overline{dh}/d\phi$ is strictly positive. This is a contradiction. A branch of unstable manifold of the saddle point cannot cross the line segment S: $y=0$ from $(0,0)$ to $(\pi,0)$, since if it did this would imply the existence of a stable contractible limit cycle (because the point $(0,0)$ is unstable). Therefore this branch has to cross $y=0$ between $(-\pi,0)$ and $(0,0)$. Thereafter it approaches the winding limit cycle. Since the branch of the unstable manifold with initial negative velocity crosses the line segment S when $\gamma>-3$, it follows by continuity that for γ near -3 this branch of the unstable manifold goes into the saddle point and thus forms a contractible homoclinic connection.

6. At V: $\gamma = -3 - 3\pi a/4$, γ is in the range of η^-. One branch of the unstable manifold of the saddle point forms a noncontractible homoclinic saddle connection, which, for smaller γ, splits off as a stable winding limit cycle. The unstable manifold now has both winding limit cycles as its ω-limit set, while the stable manifold has $(0,0)$ as its α-limit set. This concludes our discussion of the phase portraits along the dotted line in Fig. 3.

Along the dashed line in Fig. 3, the main difference is that the stable limit cycle is not born from a saddle node type bifurcation, but from a noncontractible homoclinic saddle connection, as in the transition from 5 to 6. Since the techniques needed to analyze all other phase portraits and their bifurcations are essentially the same as we have used thus far, we shall not give any more details.

3. Properties of the function ξ. In this section we show that the function ξ has the following properties:

i. For $h \in (-1,1)$, $\eta^0 = -\xi^0$; for $h \in (1,\infty)$, $\xi^- = \xi^+$.

ii. $\xi = \xi^{0,\pm}$ satisfies the Riccati equation

$$2(1-h^2)\frac{d\xi}{dh} = 3 + 2h\xi - \xi^2,$$

with boundary values

$$\xi^0(-1) = 1, \quad \xi^{0,\pm}(1) = 3, \quad \lim_{h\to\infty} \xi^{\pm}(h) = \infty.$$

iii. For $h \in (-1,1)$, ξ^0 is strictly monotonic increasing.

iv. For $h \in (1,\infty)$, $3h < \xi^{\pm}(h) \leqq 4h$ and $\xi^{\pm}$ is strictly monotonic increasing.

In each numbered section below we prove the corresponding property of ξ.

3i. For $h \in (-1,1)$ observe that Γ_h^0 is contractible to the point $(0,0) \in TS^1$. Therefore

$$\mathscr{A}^0 = \int_{\Gamma_h^0} d\phi = 0, \tag{3.1}$$

which implies that $\eta^0 = a\mathscr{A}^0/\mathscr{C}^0 - \xi^0 = -\xi^0$, provided that $\mathscr{C}^0$ is finite and nonzero. But

$$\mathscr{C}^0(h) = \int_{\Gamma_h^0} y\cos\phi\, d\phi = 2\sqrt{2}\int_{\phi_-}^{\phi_+} (h+\cos\phi)^{1/2}\cos\phi\, d\phi \tag{3.2}$$

(where $h + \cos\phi_{\pm} = 0$ and y is given in (1.3)), which implies that $\mathscr{C}^0(h)$ is finite for $h \in (-1,1)$. Differentiating (1.3) with respect to ϕ gives

$$\frac{dy}{d\phi} = -\frac{\sin\phi}{y} \tag{3.3}$$

and integrating (3.2) by parts yields

$$\mathscr{C}^0(h) = -\int_{\Gamma_h^0} \frac{dy}{d\phi}\sin\phi\, d\phi = \int_{\Gamma_h^0} \frac{\sin^2\phi}{y}\, d\phi = \sqrt{2}\int_{\phi_-}^{\phi_+} \frac{\sin^2\phi}{(h+\cos\phi)^{1/2}}\, d\phi. \tag{3.4}$$

From (3.4) it follows that $\mathscr{C}^0(h)>0$ for $h\in(-1,1)$. This proves that $\eta=-\xi^0$, and also we have shown that ξ^0 is continuous. To show that $\xi^-=\xi^+$, we demonstrate that

$$\mathscr{B}^+=\mathscr{B}^-, \qquad \mathscr{C}^+=\mathscr{C}^-. \tag{3.5}$$

This follows from the fact that y is positive on Γ_h^+, while it is negative on Γ_h^-. Because Γ^+ and Γ^- have opposite orientations, $\mathscr{B}$ and $\mathscr{C}$ are invariant under the $\pm$-change. For future reference, we note that the last argument also shows that

$$\mathscr{A}^+=-\mathscr{A}^-. \tag{3.6}$$

3ii. We begin by deriving the Riccati equation satisfied by $\xi=\xi^{0,\pm}$. In what follows all integrals are taken over the closed cycle $\Gamma_h^{0,\pm}$. Differentiating $\mathscr{B}=\mathscr{B}^{0,\pm}$ and $\mathscr{C}=\mathscr{C}^{0,\pm}$ with respect to h gives

$$\frac{d\mathscr{B}}{dh}=\int\frac{dy}{dh}d\phi=\int\frac{1}{y}d\phi \tag{3.7}$$

and

$$\frac{d\mathscr{C}}{dh}=\int\frac{dy}{dh}\cos\phi\,d\phi=\int\frac{1}{y}\cos\phi\,d\phi \tag{3.8}$$

(since differentiating (1.3) with respect to h yields $dy/dh=1/y$). Integrating $\mathscr{C}$ by parts and using (3.3) gives

$$\begin{aligned}\mathscr{C}&=\int y\cos\phi\,d\phi=-\int\frac{dy}{d\phi}\sin\phi\,d\phi=\int\frac{\sin^2\phi}{y}d\phi\\&=\int\frac{1}{y}\left[1-\left(\frac{1}{2}y^2-h\right)^2\right]d\phi\\&=\int\left[\frac{1}{y}-\frac{1}{4}y^3+hy-\frac{h^2}{y}\right]d\phi\\&=\int\left[\frac{1}{y}-\frac{1}{2}y(h+\cos\phi)+hy-\frac{h^2}{y}\right]d\phi\\&=(1-h^2)\frac{d\mathscr{B}}{dh}+\frac{1}{2}h\mathscr{B}-\frac{1}{2}\mathscr{C},\end{aligned} \tag{3.9}$$

which implies

$$(1-h^2)\frac{d\mathscr{B}}{dh}=-\frac{1}{2}h\mathscr{B}+\frac{3}{2}\mathscr{C}. \tag{3.10}$$

Similarly

$$\frac{d\mathscr{C}}{dh}=\int\frac{\cos\phi}{y}d\phi=\int\frac{1}{y}\left(\frac{1}{2}y^2-h\right)d\phi=\frac{1}{2}\mathscr{B}-h\frac{d\mathscr{B}}{dh},$$

which implies

$$(1-h^2)\frac{d\mathscr{C}}{dh}=\frac{1}{2}\mathscr{B}-\frac{3}{2}h\mathscr{C}. \tag{3.11}$$

Therefore the Picard–Fuchs equation for $\mathscr{B}$ and $\mathscr{C}$ is

$$2(1-h^2)\frac{d}{dh}\begin{pmatrix}\mathscr{B}\\ \mathscr{C}\end{pmatrix}=\begin{pmatrix}-h & 3\\ 1 & -3h\end{pmatrix}\begin{pmatrix}\mathscr{B}\\ \mathscr{C}\end{pmatrix}. \tag{3.12}$$

Since $\xi=\mathscr{B}/\mathscr{C}$, the Riccati equation satisfied by $\xi=\xi^{0,\pm}$ is

$$2(1-h^2)\frac{d\xi}{dh}=2(1-h^2)\frac{1}{\mathscr{C}}\frac{d\mathscr{B}}{dh}-\frac{\mathscr{B}}{\mathscr{C}}2(1-h^2)\frac{1}{\mathscr{C}}\frac{d\mathscr{B}}{dh}=3+2h\xi-\xi^2. \tag{3.13}$$

Next we compute the values of $\xi^{0,\pm}$ at $h=\pm 1$. We begin with the value of ξ^0 at $h=1$. As $h\uparrow 1$, the smooth closed path Γ_h^0 converges to the nonsmooth, but closed, path

$$\Gamma_1^0:\frac{1}{2}y^2=1+\cos\phi=2\cos^2\frac{\phi}{2},\qquad \phi\in[-\pi,\pi].$$

Therefore $\mathscr{B}^0$ converges to

$$\mathscr{B}^0(1)=\int_{\Gamma_1^0}y\,d\phi=4\int_{-\pi}^{\pi}\left|\cos\frac{\phi}{2}\right|d\phi=16, \tag{3.14}$$

while $\mathscr{C}^0$ converges to

$$\mathscr{C}^0(1)=\int_{\Gamma_1^0}\frac{\sin^2\phi}{y}d\phi=4\int_{-\pi}^{\pi}\sin^2\frac{\phi}{2}\left|\cos\frac{\phi}{2}\right|d\phi=\frac{16}{3}. \tag{3.15}$$

Therefore

$$\xi^0(1)=3. \tag{3.16}$$

As $h\downarrow -1$, Γ_h^0 shrinks to the point $(0,0)$. Let D_h^0 be the disk bounded by Γ_h^0. Then $\Gamma_h^0=\partial D_h^0$. Hence by Stokes' theorem

$$\xi^0(-1)=\lim_{h\to -1}\frac{\int_{\Gamma_h^0}y\,d\phi}{\int_{\Gamma_h^0}y\cos\phi\,d\phi}=\frac{\lim_{h\to -1}\int_{D_h^0}dy\,d\phi}{\lim_{h\to -1}\int_{D_h^0}\cos\phi\,dy\,d\phi}=1. \tag{3.17}$$

To compute $\xi^{\pm}$ at $h=1$, we note that the limit of $\Gamma_h^{\pm}$ at $h=1$ is given by

$$\Gamma_1^+:\frac{1}{2}y^2=1+\cos\phi=2\cos^2\frac{\phi}{2},\qquad \phi\in[-\pi,\pi],\quad y\geqq 0,$$

$$\Gamma_1^-:\frac{1}{2}y^2=1+\cos\phi=2\cos^2\frac{\phi}{2},\qquad \phi\in[-\pi,\pi],\quad y\leqq 0$$

(we may write $\Gamma_1^0=\Gamma_1^+\cup\Gamma_1^-$). Thus

$$\mathscr{B}^{\pm}(1)=8,\qquad \mathscr{C}^{\pm}(1)=\frac{8}{3} \tag{3.18}$$

and consequently

$$\xi^{\pm}(1)=3. \tag{3.19}$$

Then ξ is continuous at $h=1$, if we extend ξ^0 with either ξ^+ or ξ^-. Finally to show that $\lim_{h\to\infty}\xi^+(h)=\infty$, we need estimates for $\mathscr{B}^+$ and $\mathscr{C}^+$. When $h>1$ we obtain

$$\mathscr{C}^+(h)=\int_{\Gamma_h^+}\frac{\sin^2\phi}{y}d\phi=\frac{1}{\sqrt{2}}\int_{-\pi}^{\pi}\frac{\sin^2\phi}{(h+\cos\phi)^{1/2}}d\phi<\sqrt{2}\,\pi\frac{1}{\sqrt{h-1}} \tag{3.20}$$

and

$$\mathscr{B}^+(h)=\int_{\Gamma_h^+} y\,d\phi=\sqrt{2}\int_{-\pi}^{\pi}(h+\cos\phi)^{1/2}d\phi>2\pi\sqrt{2}\sqrt{h-1}\,. \tag{3.21}$$

Therefore when $h>1$

$$\xi^+(h)=\frac{\mathscr{B}^+(h)}{\mathscr{C}^+(h)}>\frac{2\pi\sqrt{2}\sqrt{h-1}}{\pi\sqrt{2}}\sqrt{h-1}=2(h-1) \tag{3.22}$$

which implies that $\lim_{h\to\infty}\xi^+(h)=\infty$.

3iii. To show that $\xi=\xi^0$ is strictly monotonic increasing we give an argument analogous to that used in Cushman and Sanders [9]. First observe that the connected components of

$$3+2h\xi-\xi^2=0 \tag{3.23}$$

are strictly monotonic functions of h, because differentiating (3.23) with respect to h and putting $d\xi/dh=0$ gives $\xi=0$. But this is ruled out by (3.23).

We now use this observation to show that the range of ξ^0 on $[-1,1]$ is $[1,3]$. From (3.13) it follows that on $(-1,1)$

$$\text{when } 0<\xi<1 \text{ then } \frac{d\xi}{dh}>0 \tag{3.24a}$$

while

$$\text{when } \xi>3 \text{ then } \frac{d\xi}{dh}<0. \tag{3.24b}$$

We now argue by contradiction. Suppose that for some $h_0\in(-1,1)$ we have $\xi(h_0)>3$. Since $\xi(-1)=1$, $\xi(1)=3$ and ξ is continuous, there is an $h_1\in(-1,h_0)$ such that $\xi(h_1)=3$. Since (3.13) implies that ξ is continuously differentiable on $(-1,1)$, there is an $h_2\in(h_1,h_0)$ such that $\xi(h_2)>0$ and $(d\xi/dh)(h_2)>0$. But this contradicts (3.24b). Therefore $\xi(h)\leqq 3$ for $h\in(-1,1)$. By an analogous argument one proves that $\xi(h)\geqq 1$ for $h\in(-1,1)$. Thus we have $1\leqq\xi(h)\leqq 3$ for all $h\in[-1,1]$.

Next we show that the derivative of ξ on $(-1,1)$ does not vanish. Suppose the contrary, that is, suppose that for some $h_0\in(-1,1)$, $(d\xi/dh)(h_0)=0$. Then differentiating (3.13) with respect to h and evaluating at h_0 gives

$$(1-h_0^2)\frac{d^2\xi}{dh^2}(h_0)=\xi(h_0). \tag{3.25}$$

Since the range of ξ on $[-1,1]$ is $[1,3]$, $(d^2\xi/dh^2)(h_0)>0$. In other words, we have shown that any extremum of ξ on $(-1,1)$ is a nondegenerate minimum. Because $\xi(-1)=1<\xi(h_0)$, ξ must have a maximum between -1 and h_0. But every extremum is a minimum on $(-1,1)$; so we have a contradiction. Consequently the derivative of ξ does not vanish on $(-1,1)$. Since $\xi(-1)=1$ and $\xi(1)=3$, $d\xi/dh>0$ on $(-1,1)$, that is, ξ is strictly monotonic increasing on $(-1,1)$.

3iv. Applying the change of variables

$$x=\frac{1}{\xi^+},\qquad t=\frac{1}{h} \tag{3.26}$$

to (3.13) gives

$$2t(1-t^2)\frac{dx}{dt} = t - 2x - 3tx^2. \tag{3.27}$$

We know that $\xi^+(1)=3$ and $\lim_{h\to\infty}\xi^+(h)=\infty$, so

$$x(0)=0 \quad \text{and} \quad x(1)=\frac{1}{3}.$$

First we prove that $x(t)\leqq t/3$ for $t\in[0,1]$. Let $y=x-t/3$, then $y(0)=y(1)=0$. From (3.27) it follows that

$$2t(1-t^2)\frac{dy}{dt} = -3ty^2 - 2y(1+t^2) - \frac{t}{3}(1-t^2). \tag{3.28}$$

Suppose that $y(\tau)>0$ for some $\tau\in(0,1)$. Then there is a $\tau_0\in(0,\tau)$ with $(dy/d\tau)(\tau_0)>0$ and $y(\tau_0)>0$; but this is in contradiction with the differential equation (3.28). Thus $y(t)\leqq 0$ for all $t\in[0,1]$, that is,

$$x(t)\leqq \frac{t}{3}. \tag{3.29}$$

Consequently by (3.24)

$$\xi^+(h)\geqq 3h \quad \text{for all } h\in[1,\infty). \tag{3.30}$$

Now suppose that $y(\tau)=0$ for some $\tau\in(0,1)$. Then from (3.28) we conclude that $(dy/dt)(\tau)<0$. But this contradicts the fact that $y(t)\leqq 0$ for all $t\in[0,1]$. Therefore

$$\xi^+(h)>3h \quad \text{for all } h\in(1,\infty). \tag{3.31}$$

The following argument shows that ξ^+ is strictly monotonic increasing on $(1,\infty)$. Since the zero isocline $3+2h-\xi^2=0$ of the Riccati equation (3.13) is strictly monotonic increasing for $h\in(1,\infty)$, ξ^+ can intersect this isocline at most once. From (3.25) it follows that ξ^+ has a nondegenerate (global) maximum at this intersection. This contradicts (3.31). Therefore $d\xi^+/dh>0$ on $(1,\infty)$. Consequently ξ^+ is strictly monotonic increasing on $(1,\infty)$.

Next we show that $\xi^+(h)\leqq 4h$ on $[1,\infty)$. Toward this end, let $y=x-t/4$; then $y(0)=0$, $y(1)=\frac{1}{12}$ and (3.27) becomes

$$2t(1-t^2)\frac{dy}{dt} = -3ty^2 - \left(2+\frac{3}{2}t^2\right)y + \frac{5}{16}t^3. \tag{3.32}$$

Suppose that for some $\tau\in(0,1)$, $y(\tau)<0$. Then there is a $\tau_0<(0,\tau)$ with $(dy/dt)(\tau_0)<0$ and $y(\tau_0)<0$. But, by (3.29)

$$y(t)=x(t)-\frac{t}{4}\leqq \frac{t}{3}-\frac{t}{4}=\frac{t}{12},$$

which implies

$$2t(1-t^2)\frac{dy}{dt} \geqq \frac{7}{24}t^3 - \left(2+\frac{3}{2}t^2\right)y. \tag{3.33}$$

Therefore $(dy/dt)(\tau_0)>0$, which is a contradiction. Thus $y(t)\geqq 0$ for all $t\in[0,1]$ or equivalently

$$x(t)\geqq \frac{t}{4}, \tag{3.34}$$

that is,

$$\xi^+(h) \leqq 4h \quad \text{for all } h \in [1, \infty). \tag{3.35}$$

Combining (3.31) and (3.35), we find that

$$3h < \xi^+(h) \leqq 4h \quad \text{for all } h \in (1, \infty). \tag{3.36}$$

This completes the proof of the properties of the function ξ.

4. Properties of the function η. Throughout this section we assume that $h > 1$. We will show that the function $\eta = \eta^{\pm}$, where

$$\eta = a\frac{\mathscr{A}}{\mathscr{C}} - \xi \tag{4.1}$$

has the following properties:

(4.2)
i. $\eta^{\pm}(1) = \pm 3\pi a/4 - 3$.
ii. $\eta = \eta^{\pm}$ satisfies the Riccati equation

$$2(h^2-1)\frac{d\eta}{dh} = 3 - h\xi - 3h\eta + \xi\eta \tag{4.3}$$

where $\xi = \xi^{\pm}$.

iii. Let

$$\zeta(h) = \frac{h\xi - 3}{\xi - 3h}; \tag{4.4}$$

then $\zeta(1) = 1$. In addition, the zero isocline $\eta^{\pm} = \xi$ of (4.3), is continuous and strictly monotonic increasing.

iv. If $\eta^{\pm}(1) > 1$, that is, if

$$a > \frac{16}{3\pi}, \quad \eta = \eta^+ \quad \text{or} \quad a < -\frac{16}{3\pi}, \quad \eta = \eta^-,$$

then $\eta^{\pm}$ has a unique maximum $\tilde{\eta}^{\pm}(a)$ when $h > 1$; moreover $\lim_{a \to \pm 16/3\pi} \tilde{\eta}^{\pm}(a) = 1$. If $\eta^{\pm}(1) < 1$, then $\eta^{\pm}$ is strictly monotonic decreasing on $(1, \infty)$.

As before, in each numbered section we prove the corresponding property of η.

4i. Since $\mathscr{C}^+ = \mathscr{C}^-$, $\xi^+ = \xi^-$ and $\mathscr{A}^+ = -\mathscr{A}^-$ with $\mathscr{C}^+(1) = \frac{8}{3}$ (3.18), $\xi^+(1) = 3$ (3.19), and $\mathscr{A}^+(h) = 2\pi$ we get

$$\eta^+(1) = \frac{3\pi}{4}a - 3 \quad \text{and} \quad \eta^-(1) = -\frac{3\pi}{4}a - 3. \tag{4.5}$$

4ii. Let $\eta = \eta^{\pm}$. Then differentiating (4.1) with respect to h using (3.11), (3.13) and some regrouping gives

$$2(h^2-1)\frac{d\eta}{dh} = 3 - h\xi - 3h\eta + \xi\eta. \tag{4.6}$$

Here the fact that $\mathscr{A}^{\pm}$ is constant on $(1, \infty)$ has been used.

4iii. The zero isocline of (4.3) is the locus of zeros of the right-hand side of (4.6) which is given by $\eta = \eta^{\pm} = \zeta$ where

$$\zeta(h) = \frac{h\xi - 3}{\xi - 3h}. \tag{4.7}$$

Since $\xi > 3h$ when $h > 1$ (3.31), we see that ζ is continuous on $(1, \infty)$. To show that ζ is strictly monotonic increasing on $(1, \infty)$, we differentiate (4.7) with respect to h and obtain

$$\frac{d\zeta}{dh} = -\frac{1}{2(\xi - 3h)^2}(9 - 6h\xi + \xi^2). \tag{4.8}$$

Put $\theta(h) = 9 - 6h\xi + \xi^2$. Since $\xi(1) = 3$, $\theta(1) = 0$; moreover, since $3h < \xi(h) \leqq 4h$ for $h \in [1, \infty)$,

$$\theta(h) \leqq 9 - 2h^2 \quad \text{on } [1, \infty). \tag{4.9}$$

Therefore $\theta(h) < 0$ for $h > \frac{3}{2}\sqrt{2}$. To show that $d\zeta/dh > 0$ it suffices to show that $\theta < 0$ for all $h > 1$. Toward this end we differentiate θ with respect to h. Repeatedly using $\xi^2 = \theta + 6h\xi - 9$ we obtain

$$(h^2 - 1)\frac{d\theta}{dh} = (h + \xi)\theta + 6(h^2 - 1)\xi, \tag{4.10}$$

which may be rewritten as

$$\frac{d\theta}{dh} = 6\xi + \frac{h + \xi}{h^2 - 1}\theta. \tag{4.11}$$

Suppose that there is an $h_0 > 1$ such that $\theta(h_0) \geqq 0$. Since $\theta(h) < 0$ for all $h > \frac{3}{2}\sqrt{2}$, there is an $h_1 \geqq h_0$ such that $\theta(h_1) = 0$. Take h_1 to be the largest value of h such that $\theta(h_1) = 0$. Then $\theta(h) < 0$ for all $h > h_1$. It follows from (4.11) and (3.31) that

$$\frac{d\theta}{dh}(h_1) \geqq 6\xi(h_1) > 18h_1. \tag{4.12}$$

Thus there is an $h_2 > h_1$, for which $\theta(h_2) = 0$; but this contradicts the maximality of h_1. Therefore $\theta(h) < 0$ for $1 < h < \infty$, which implies that ζ is strictly monotonic increasing on $(1, \infty)$.

To compute $\lim_{h \to 1^+} \zeta(h)$, we first have to show that

$$\lim_{h \to 1^+} \xi'(h) = \infty. \tag{4.13}$$

The following argument shows that either $\lim \xi' < \infty$ or $\lim \xi' = \infty$ as $h \to 1^+$. Suppose not, then

$$\liminf \xi' < \limsup \xi' \tag{4.14a}$$

and

$$-\infty < \liminf \xi' < \infty. \tag{4.14b}$$

Since ξ is monotonic increasing on $(1, \infty)$, we may replace (4.14b) with

$$0 \leqq \liminf \xi' < \infty. \tag{4.15}$$

From (4.14a) there is a sequence $\{h_n\}$, $h_n \to 1^+$ such that ξ' has a local minimum at h_n, that is, $\xi''(h_n) = 0$. Differentiating the Riccati equation (3.13) gives

$$2(1 - h^2)\xi'' = 2(3h - \xi)\xi' + 2\xi \tag{4.16a}$$

which evaluated at h_n gives

$$0=2(3h_n-\xi(h_n))\xi'(h_n)+2\xi(h_n). \tag{4.16b}$$

Taking the lim inf as $h_n\to 1^+$ of both sides of (4.16a) gives

$$0=\liminf_{h_n\to 1^+}\xi'\lim_{h_n\to 1^+}(3h_n-\xi(h_n))+\lim_{h_n\to 1^+}\xi(h_n) \tag{4.17}$$

since ξ is continuous, the first term in (4.17) vanishes because $\xi(1)=3$ and (4.15), while the second term equals 3. Thus (4.17) is false. Consequently either $\lim_{h\to 1^+}\xi'<\infty$ or $\lim_{h\to 1^+}\xi'=\infty$. Now suppose that $\lim_{h\to 1^+}\xi'<\infty$. Then the Riccati equation (3.13) gives the asymptotic relation

$$\xi''\sim\frac{1}{(1+h)(1-h)}\xi\sim\frac{3}{2(1-h)}\quad\text{as } h\to 1^+$$

which integrated shows that $\xi'\to\infty$ as $h\to 1^+$. This contradicts the hypothesis. Therefore (4.13) holds.

Using l'Hôpital's rule and (4.12), we compute $\zeta(1)$ as follows:

$$\zeta(1)=\lim_{h\to 1^+}\frac{h\xi-3}{\xi-3h}=\lim_{h\to 1^+}\frac{\xi(h)+h\xi'(h)}{\xi'(h)-3}=1. \tag{4.18}$$

4iv. Let $\eta=\eta^+$. From (4.3) it follows that $d\eta/dh>0$ above the graph of ζ, while $d\eta/dh<0$ below. Thus when $\eta(1)<1$, η is strictly monotonic decreasing for $h>1$. In addition the range of η is $(-\infty,\eta(1))$, as we shall prove below (see (4.21)).

When $\eta(1)>1$ and $h>1$, η is strictly monotonic increasing as long as its graph does not intersect the graph of ζ. But this can happen at most once, because η is strictly monotonic decreasing after such an intersection and ζ is strictly monotonic increasing when $h>1$.

To show that the graphs of η and ζ intersect when $h>1$, we show that $\lim_{h\to\infty}\eta(h)=-\infty$, whatever the initial condition $\eta(1)$. First we find the asymptotic behavior of $\mathscr{C}^+$:

$$\begin{aligned}\mathscr{C}^+(h)&=\int_{\Gamma_h^+}\frac{\sin^2\phi}{y}d\phi=\frac{1}{\sqrt{2h}}\int_{-\pi}^{\pi}\sin^2\phi\left(1+h^{-1}\cos\phi\right)^{-1/2}d\phi\\&=\frac{1}{2h}\left[\int_{-\pi}^{\pi}\left(\sin^2\phi+O\left(\frac{1}{h}\right)\right)d\phi\right]=\frac{\pi}{\sqrt{2h}}+O\left(\frac{1}{h^{3/2}}\right).\end{aligned} \tag{4.19}$$

From the definition of $\eta=\eta^{\pm}$ (1.7) we obtain

$$\eta^{\pm}(h)=\frac{a\mathscr{A}^{\pm}}{\mathscr{C}^{\pm}}-\xi^{\pm}=\frac{2\pi a}{\mathscr{C}^{\pm}(h)}-\xi^{\pm}(h)=\pm\frac{2\pi a}{\left(\pi/\sqrt{2h}+O(1/h^{3/2})\right)}-\xi^{\pm}(h). \tag{4.20}$$

Since $3h<\xi(h)\leqq 4h$ it follows that

$$\lim_{h\to\infty}\eta^{\pm}(h)=-\infty. \tag{4.21}$$

This implies that the range of η is $(-\infty,\eta(1))$ if $\eta(1)<1$ and $(-\infty,\tilde{\eta}(a))$ if $\eta(1)>1$, where $\tilde{\eta}(a)$ is the maximum value of η.

Because the range of $\eta^{\pm}$ is $(-\infty, 1]$ when $a = \pm 16/3\pi$, by continuity it follows that the maximum value of η^{+}, respectively η^{-}, for $a > 16/3\pi$, respectively, $a < -16/3\pi$, lies in the range $(1, \infty)$. Thus

$$\lim_{a \to (16/3\pi)^{+}} \tilde{\eta}^{+}(a) = \lim_{a \to -(16/3\pi)^{-}} \tilde{\eta}^{-}(a) = 1.$$

This completes the proof of the properties of η. Thus we have proved the main theorem stated in §1.

5. Appendix: Asymptotic expansions for ξ and η when h is slightly greater than 1. The maximum value of η as a function of a has to be computed numerically. This proved difficult to do for a near $16\pi/3$. In this appendix we give asymptotic approximations for η to explain this difficulty and to provide an alternative proof that

$$\lim_{a \to (16\pi/3)^{+}} \tilde{\eta}^{+}(a) = 1.$$

Consider the Riccati equation (3ii)

$$2(1-h^2)\frac{d\xi}{dh} = 3 + 2h\xi - \xi^2. \tag{5.1}$$

Since $\xi(1) = 3$, taking the limit as $h \to 1^{+}$ of both sides of (5.1) gives

$$\lim_{h \to 1^{+}} (1-h)\frac{d\xi}{dh} = 0. \tag{5.2}$$

Now we deduce an asymptotic relation for ξ as $h \to 1^{+}$. Differentiating (5.1) with respect to h gives

$$(1-h)(1+h)\frac{d^2\xi}{dh^2} = \xi + (3h - \xi)\frac{d\xi}{dh}. \tag{5.3}$$

Because $\xi(1) = 3$ and (5.2), from (5.3) we obtain the asymptotic relation

$$\frac{d^2\xi}{dh^2} \sim \frac{-3}{2(h-1)} \quad \text{as } h \to 1^{+}. \tag{5.4}$$

Integrating (5.4) twice gives

$$\xi(h) \sim 3 - \frac{3}{2}(h-1)\log(h-1), \qquad h \to 1^{+} \tag{5.5}$$

as desired.

Next we deduce an asymptotic relation for $\eta \to 1^{+}$. Substituting (5.5) into the Riccati equation (4.3),

$$2(h^2-1)\frac{d\eta}{dh} = 3 - h\xi - 3h\eta + \xi\eta, \tag{5.6}$$

gives

$$2(h-1)(h+1)\frac{d\eta}{dh} \sim -3(h-1) - 3\eta(1)(h-1) + \frac{3}{2}(h - \eta(1))(h-1)\log(h-1).$$

that is,

$$\frac{d\eta}{dh} \sim -3(1+\eta(1)) + \frac{3}{2}(1-\eta(1))\log(h-1) \text{ as } h \to 1^{+}. \tag{5.7}$$

Integrating (5.7) gives the asymptotic relation

$$(5.8)\quad \eta(h)\sim\eta(1)-\frac{3}{8}(3+\eta(1))(h-1)+\frac{3}{8}(1-\eta(1))(h-1)\log(h-1)\quad \text{as } h\to 1^+$$

as desired. To compute an asymptotic relation for the critical point $h=h^*$ of η, we equate the right-hand side of (5.7) to zero. Thus

$$(5.9)\qquad h^*-1=\exp\left[\frac{2(1+\eta(1))}{1-\eta(1)}\right].$$

Now $\eta(1)=3\pi a/4-3$. Putting $a=(16/3\pi)(1+\varepsilon/4)$ gives $\eta(1)=1+\varepsilon$, which substituted into (5.9) yields

$$(5.10)\qquad h^*-1=e^{-2}e^{-4/\varepsilon}.$$

Substituting (5.10) into (5.8) gives the asymptotic relation

$$(5.11)\qquad \eta_{\max}=\eta(h^*)\sim\eta(1)-\frac{3}{8}(4+\varepsilon)e^{-2}e^{-4/\varepsilon}+\frac{3}{8}\left(\frac{4}{\varepsilon}+2\right)e^{-2}e^{-4/\varepsilon}$$

$$=\eta(1)+\frac{3}{8}\varepsilon e^{-2}e^{-4/\varepsilon}\quad \text{as } \varepsilon\to 0^+.$$

Therefore the difference between the maximum value of η for a slightly greater than $16/3\pi$ and the boundary value $\eta(1)$ is exponentially small. This explains the difficulty in computing the maximum of η near the critical value $a=16/3\pi$.

Acknowledgments. We would like to thank Prof. M. van Veldhuizen of the Free University in Amsterdam for doing the numerical calculations which resulted in Fig. 2. We would also like to thank the referee for the proof of (4.13) and helpful comments which greatly improved the organization and exposition of this paper.

BREAKDOWN OF STABILITY IN SINGULARLY PERTURBED AUTONOMOUS SYSTEMS I. ORBIT EQUATIONS*

K. NIPP†

Abstract. In singular perturbation analysis two stages can generally be distinguished: First, by some method a sequence of formal approximations is constructed which are supposed to form together an asymptotic approximation to the solution of the singular perturbation problem. Second, it should be proved that the sequence provides a correct approximation in a rigorous mathematical sense.

For this second stage analytical results providing error estimates are needed. A classical one is due to A. N. Tikhonov (see e.g. [10]). We quote this theorem, and state and prove results for the trajectories of a singularly perturbed autonomous system that are extensions of the Tikhonov Theorem in the neighborhood of a point where a certain stability assumption ceases to be valid.

1. Introduction.

Consider the autonomous system

$$\begin{aligned} \dot{x} &= f(x,y)+\varepsilon f^1(x,y,\varepsilon), \\ \varepsilon\dot{y} &= g(x,y)+\varepsilon g^1(x,y,\varepsilon), \end{aligned} \tag{1}$$

together with the initial conditions

$$x(0,\varepsilon)=x^0(\varepsilon), \qquad y(0,\varepsilon)=y^0(\varepsilon) \tag{2}$$

where x and y are m- and n-vectors, respectively, and ε is a small nonnegative parameter. We assume that f, f^1 and g, g^1 are sufficiently smooth with respect to all variables in the domain considered as are x^0, y^0 for $\varepsilon\in[0,\varepsilon_0]$, with $\varepsilon_0<1$.

The corresponding reduced problem is obtained by putting $\varepsilon=0$ and by dropping the initial data on y:

$$\begin{aligned} \dot{x} &= f(x,y), \qquad x(0)=x^0(0), \\ 0 &= g(x,y). \end{aligned} \tag{3}$$

We make the following assumption:

(4) There is a continuously differentiable vector function $\phi(x)$ defined in some domain $D\subset\mathbb{R}^m$ containing $x^0(\varepsilon)$ for $\varepsilon\in[0,\varepsilon_0]$ and a positive constant b such that $g(x,\phi(x))=0$ for $x\in D$ and all the eigenvalues of the Jacobian matrix $g_y(x,\phi(x))$ have real parts smaller than $-b$ for $x\in D$.

The set $(x,\phi(x))$ is called a reduced manifold of the system (1). The property (4) implies stability of this reduced manifold in the sense of Theorem 1 below.

Moreover, we suppose that the problem (3) has a continuously differentiable solution $(X(t), Y(t))$ for $t\in[0,t_1]$, lying in the stable reduced manifold (i.e. $\dot{X}(t)=f(X(t),\phi(X(t)))$, $X(0)=x^0(0)$; $Y(t)=\phi(X(t))$). Then the following theorem due to A. N. Tikhonov holds.

*Received by editors May 31, 1983, and in revised form August 6, 1984.

†Applied Mathematics, ETH-Zentrum, CH-8092 Zürich, Switzerland. This work was carried out while the author was at the Department of Mathematical Sciences, Rensselaer Polytechnic Institute, Troy, New York, 12181. This work was supported by a grant from the Schweizerischer Nationalfonds.

THEOREM 1. *If* $|y^0(\varepsilon)-Y(0)|$ *is sufficiently small, then for* ε *small enough the solution* $(x(t,\varepsilon), y(t,\varepsilon))$ *of* (1), (2) *exists and is unique for* $t\in[0,t_1]$ *and satisfies*

$$|x(t,\varepsilon)-X(t)|=O(\varepsilon) \quad \textit{uniformly for } t\in[0,t_1]$$

and

$$|y(t,\varepsilon)-Y(t)|=O(\varepsilon) \quad \textit{uniformly for } t\in[\tau,t_1],\ \textit{any } \tau\in(0,t_1).$$

The above formulation is analogous to the one given in [2] or [5] with sharper estimates than in [10]. Of course, a similar result holds in the nonautonomous case.

In this paper we are interested in situations where the stability property (4) ceases to be valid. One of the implications of this condition is that the reduced manifold $y=\phi(x)$ is locally unique. This excludes bifurcation of the reduced manifold. In [3] and [4] Lebovitz and Schaar considered the two kinds of bifurcations sketched in Fig. 1, with the components of the reduced manifold being locally linear or quadratic, respectively, in the essential variables and having the indicated stability properties. At the origin, which is the point of bifurcation, exactly one single eigenvalue of the Jacobian is supposed to vanish.

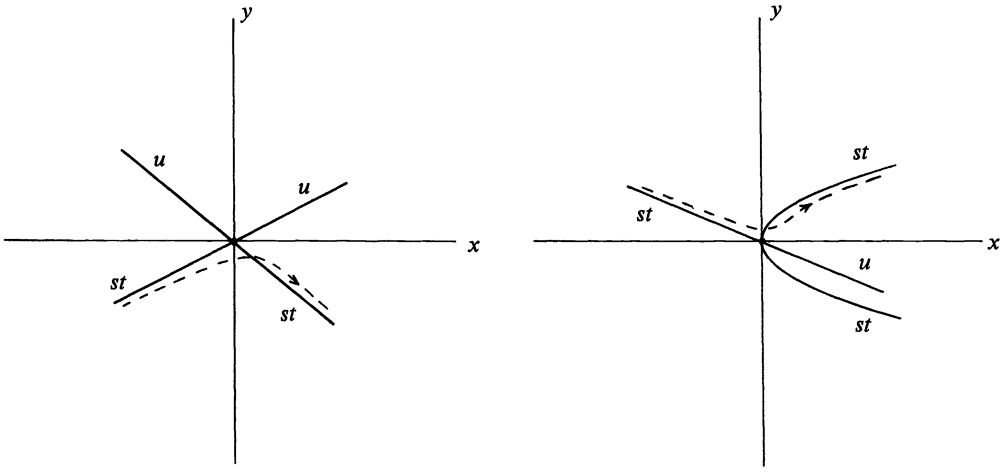

FIG. 1

Another bifurcation case is the so-called jump point situation sketched in Fig. 2, arising frequently in the context of relaxation oscillations. In both figures, the dashed lines represent a possible trajectory of the system (1). In the case of Fig. 2, typically, the trajectory follows the stable branch of the reduced manifold until it reaches a vicinity of the bifurcation point where it drops off.

There are several papers in the Russian literature dealing with this situation (see e.g. [8], [9]). It is also treated in the book by Mishchenko and Rozov [5] in the context of relaxation oscillations. These authors, however, consider only reduced manifolds which are locally quadratic in the essential variables. Moreover, they are primarily interested in working out the forms of the approximations to the IVP (1), (2) to the highest possible order rather than in giving a rigorous proof of their validity. There are error estimates provided in [9], [5] for the higher dimensional case which do seem not to be optimal, however.

In this paper our goal is to obtain sharp estimates for the domain of validity as well as for the error of an approximation given by the solution of the reduced system (3) in the neighborhood of a point where the stability property (4) is weakened. Therefore, the results stated below are extensions of Theorem 1.

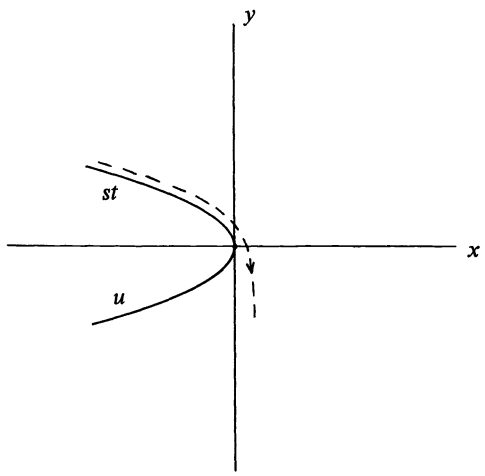

FIG. 2

It may be worthwhile to discuss some conceptual points. Rather than treat some specific problem we propose to derive certain general local results that permit to establish local estimates which, if taken together with Tikhonov's Theorem as well as some trivial estimates from regular perturbation theory, allow to provide global estimates for various bifurcation situations. In particular, the two kinds of bifurcations sketched in Figs. 1 and 2 turn out to be special cases with the reduced manifold being locally linear or quadratic.

We will first give a precise formulation of the problem. There are two cases which are treated separately. In the first one the reduced trajectory encounters a point where stability breaks down (as e.g. in Fig. 1 or Fig. 2 for $x<0$). The second case is characterized by the fact that the reduced trajectory departs from this point, a situation which arises in bifurcations of the type sketched in Fig. 1 ($x>0$). In this first paper we state and prove the results for the *orbits*. The transfer of the estimates to the *solutions* is postponed to Part II also to appear in this journal. There we will as well give an application of our results and of the concept mentioned above.

A two-dimensional version of the first of our results was given in [7]. As far as the construction of suitable local approximations is concerned the reader is referred to [6].

2. Formulation of the problem for the case "$s<0$". In this section we give a detailed formulation of the problem for the first case mentioned at the end of the previous section. This is in a sense the easier and more natural situation since the initial conditions for the local problem are provided by Theorem 1. We take the point, where the stability assumption (4) ceases to hold, to be the origin in $\mathbb{R}^{m+n}$. And we suppose that $f(0,0)\neq 0$ so that the origin is not a critical point of the full system (1). Without loss of generality we may assume that

H1. $$f_1(0,0)>0,\ f_k(0,0)=0 \qquad (k=2,3,\cdots,m).$$

Hence, there exist a domain U containing the origin and a positive constant ρ such that $f_1(x,y)>\rho$ for $(x,y)\in U$. And we may introduce $s=x_1$ as the independent variable. By dividing the rest of the equations of (1) by the first one we obtain, for ε small enough, the following orbit equations

$$\begin{aligned}\frac{d\bar{x}}{ds}&=F(s,\bar{x},y)+\varepsilon F^1(s,\bar{x},y,\varepsilon),\\ \varepsilon\frac{dy}{ds}&=G(s,\bar{x},y)+\varepsilon G^1(s,\bar{x},y,\varepsilon),\end{aligned}\tag{5}$$

where $\bar{x}$ represents the last $m-1$ components of x; $F:=\bar{f}/f_1$, $G:=g/f_1$, F^1 and G^1 are defined for $(x,y)\in U$, and $F(0,0,0)=0$, $G(0,0,0)=0$. The initial conditions are

$$\bar{x}(s^0,\varepsilon)=\bar{x}^0(\varepsilon),\qquad y(s^0,\varepsilon)=y^0(\varepsilon)\tag{6}$$

where we suppose that $s^0(\varepsilon)=S^0+O(\varepsilon)$ with $S^0<0$ independent of ε.

We assume that the Jacobian matrix $g_y(0,0)$ has zero as a simple eigenvalue and all the other eigenvalues have negative real parts. Hence the same is true for G_y. By appropriate choice of basis in $\mathbb{R}^n$, we may suppose that

H2. $$G_y(0,0,0)=\begin{pmatrix}0 & 0 & \cdots & 0\\ 0 & & & \\ \vdots & & \bar{A} & \\ 0 & & & \end{pmatrix}$$

where all the eigenvalues of the $(n-1)\times(n-1)$ matrix $\bar{A}$ have negative real parts. Moreover, let $\bar{y}:=(y_2,\cdots,y_n)$. Then

$$\bar{G}(x,y_1,\bar{y})=\bar{A}\bar{y}+Bx+\bar{c}y_1^2+\hat{G}(x,y_1,\bar{y})\tag{7}$$

where the remainder term $\hat{G}$ is quadratic in (x,y) and cubic in y_1. Without loss of generality we may assume that $\bar{c}=0$. (This can always be achieved by a simple transformation of variables (cf. [4])).

H2 implies that there exists a unique solution $\bar{w}(s,\bar{x},y_1)$ of $\bar{G}(s,\bar{x},y_1,\bar{y})=0$ in a neighborhood of the origin, having continuous partial derivatives there and satisfying $\bar{w}(0,0,0)=0$. For the remaining equation

$$G_1(s,\bar{x},y_1,\bar{w}(s,\bar{x},y_1))=0\tag{8}$$

we require:

H3. There exists a function $\phi_1(s,\bar{x})$, which is defined and continuous for $s\in J:=[s^0,0]$, $\bar{x}$ in some neighborhood $\bar{\Omega}$ of $\bar{x}=0$, has continuous partial derivatives with respect to $\bar{x}$ there, and is C^1 in $[s^0,0)\times\bar{\Omega}$, satisfying

$$\begin{aligned}&G_1(s,\bar{x},\phi_1(s,\bar{x}),\bar{w}(s,\bar{x},\phi_1(s,\bar{x})))=0,\qquad (s,\bar{x})\in J\times\bar{\Omega},\\ &\phi_1(0,0)=0\end{aligned}\tag{9}$$

and

$$\phi_1(s,\bar{x})=a_1(-s)^{\alpha}+p(s,\bar{x}),\qquad (s,\bar{x})\in J\times\bar{\Omega},\tag{10}$$

$$\phi_{1,s}(s,\bar{x})=a_{11}(-s)^{\alpha-1}+p_1(s,\bar{x}),\qquad (s,\bar{x})\in[s^0,0)\times\bar{\Omega},\tag{11}$$

where $\alpha>0$ and a_1, $a_{11}\neq 0$, $p(0,0)=0$, $p(s,0)=o((-s)^{\alpha})$ and $p_1(s,0)=o((-s)^{\alpha-1})$ as $s\to 0^-$.

H3′. If $\alpha \geqq 1$ we suppose that $\phi_1(s,\bar{x}) \in C^1(J \times \bar{\Omega})$.

Remark 1. In the case $\alpha \geqq 1$ (H3′) (11) follows from (10), but not in the case $\alpha < 1$ since in general order relations may not be differentiated. An assumption implying (10), (11) and easy to verify would be: There exists a function $\hat{\phi}(\hat{s},\bar{x}) \in C^1(\Omega_1 \times \bar{\Omega})$ (Ω_1 an appropriate interval containing 0) with $\hat{\phi}(0,0)=0$, $\hat{\phi}_{\hat{s}}(0,0) \neq 0$ and $\phi_1(s,\bar{x}) = \hat{\phi}((-s)^{\alpha},\bar{x})$, $(s,\bar{x}) \in J \times \bar{\Omega}$. This is a natural condition for jump points.

Let now $\bar{\phi}(s,\bar{x}) := \bar{w}(s,\bar{x},\phi_1(s,\bar{x}))$ and $\phi(s,\bar{x}) := (\phi_1,\bar{\phi})$, and consider the initial value problem

$$\frac{d\bar{x}}{ds} = F(s,\bar{x},\phi(s,\bar{x})), \qquad \bar{x}(0)=0. \tag{12}$$

We suppose the following.

H4. The solution $\bar{X}(s)$ of (12) exists for $s \in J$ and there is $c_0 > 0$ such that

$$|\bar{x}^0(\varepsilon) - \bar{X}(s^0)| < c_0\varepsilon, \qquad |y^0(\varepsilon) - Y(s^0)| < c_0\varepsilon,$$

where $Y(s) := \phi(s,\bar{X}(s))$.

Remark 2. H4 is naturally satisfied (by means of Theorem 1) if we assume having a global problem (i.e. system (1) together with some initial conditions) which is of Tikhonov type away from the origin, or more precisely whose reduced trajectory is stable as long as it is in a finite distance from the origin and, moreover, is zero there. Thus, without loss of generality, we may assume that the initial conditions (6) are "small enough", i.e. such that they lie in the appropriate neighborhood of the origin considered here. In the following this will also be referred to by the expression "for $|s^0|$ small enough". In particular we assume $|s^0| < 1$.

We now state the essential stability condition which, together with H2, replaces assumption (4) for the Tikhonov case and which is much more general than the corresponding ones given in [3], [4], [5].

H5. There are positive constants k and q such that

$$G_{1,y_1}(s,\bar{X}(s),Y(s)) \leqq -k(-s)^q, \qquad s \in J.$$

Remark 3. In order to verify this assumption the asymptotic relations for $(\bar{X}(s), Y(s))$ given in the next section may be used. The estimates (27)–(29) might, however, be sharper in a given application. We will also derive relations between q and α stated in two lemmas in the next section.

3. Preliminaries. In this section we provide all estimates needed for proving the subsequent results.

Let the functions $u(s,\varepsilon)$ and $v(s,\varepsilon)$ be defined by means of

$$\bar{x}(s,\varepsilon) = \bar{X}(s) + u(s,\varepsilon), \qquad y(s,\varepsilon) = Y(s) + v(s,\varepsilon). \tag{13}$$

They satisfy the differential equations

$$\begin{aligned}
&\frac{du}{ds} = F_{\bar{x}}(s)u + F_y(s)v + R(s,u,v,\varepsilon),\\
&\varepsilon\frac{dv_1}{ds} = G_{1,\bar{x}}(s)u + G_{1,y_1}(s)v_1 + G_{1,\bar{y}}(s)\bar{v} + S_1(s,u,v,\varepsilon) - \varepsilon Y_1'(s),\\
&\varepsilon\frac{d\bar{v}}{ds} = \bar{G}_{\bar{x}}(s)u + \bar{G}_{y_1}(s)v_1 + \bar{G}_{\bar{y}}(s)\bar{v} + \bar{S}(s,u,v,\varepsilon) - \varepsilon\bar{Y}'(s),
\end{aligned} \tag{14}$$

where $F_{\bar{x}}(s) := F_{\bar{x}}(s,\bar{X}(s),Y(s))$ and similarly for the other coefficient functions.

For some choice of the positive constants $K>1$, $\theta_1 \geqq |s^0|$ and θ the remainder terms R, S_1 and $\bar{S}$ in (14) satisfy the following estimate

$$|R(s,u,v,\varepsilon)| \leqq K\left(\varepsilon + |u|^2 + |v|^2\right) \quad \left(\text{and similarly for } S_1 \text{ and } \bar{S}\right) \tag{15}$$

if $-\theta_1 \leqq s \leqq 0$, $|u|+|v|<\theta$, and $\varepsilon \in (0,\varepsilon_0)$. The common constant K is supposed to be so large that these and later estimates hold simultaneously. We will see below that it is possible to slightly improve the estimates of S_1 and $\bar{S}$.

As initial conditions to the system (14) we have

$$u(s^0,\varepsilon) = \bar{x}^0(\varepsilon) - \bar{X}(s^0), \qquad v(s^0,\varepsilon) = y^0(\varepsilon) - Y(s^0). \tag{16}$$

Let $U(s,\sigma)$, $V_1(s,\sigma,\varepsilon)$, $\bar{V}(s,\sigma,\varepsilon)$ be the fundamental matrix solutions of

$$\frac{dU}{ds} = F_{\bar{x}}(s)U, \quad \frac{dV_1}{ds} = \varepsilon^{-1}G_{1,y_1}(s)V_1, \quad \frac{d\bar{V}}{ds} = \varepsilon^{-1}\bar{G}_{\bar{y}}(s)\bar{V}, \tag{17}$$

reducing to the unit matrices of dimensions $m-1$, 1, $n-1$, respectively, when $s=\sigma$.

The initial value problem (14), (16) is equivalent to the following system of integral equations (for convenience we are dropping the ε in $u(s,\varepsilon)$ etc.):

$$\begin{aligned}
u(s) &= U(s,s^0)u(s^0) + \int_{s^0}^{s} U(s,\sigma)\left[F_y(\sigma)v(\sigma) + R(\sigma,u,v,\varepsilon)\right]d\sigma,\\
v_1(s) &= V_1(s,s^0,\varepsilon)v_1(s^0)\\
&\quad + \varepsilon^{-1}\int_{s^0}^{s} V_1(s,\sigma,\varepsilon)\left[G_{1,\bar{x}}(\sigma)u(\sigma) + G_{1,\bar{y}}(\sigma)\bar{v}(\sigma)\right.\\
&\qquad \left. + S_1(\sigma,u,v,\varepsilon) - \varepsilon Y_1'(\sigma)\right]d\sigma,\\
\bar{v}(s) &= \bar{V}(s,s^0,\varepsilon)\bar{v}(s^0)\\
&\quad + \varepsilon^{-1}\int_{s^0}^{s} \bar{V}(s,\sigma,\varepsilon)\left[\bar{G}_{\bar{x}}(\sigma)u(\sigma) + \bar{G}_{y_1}(\sigma)v_1(\sigma)\right.\\
&\qquad \left. + \bar{S}(\sigma,u,v,\varepsilon) - \varepsilon\bar{Y}'(\sigma)\right]d\sigma.
\end{aligned} \tag{18}$$

We have to provide estimates for all the terms appearing on the right-hand side of (18).

Since all eigenvalues of the matrix $\bar{G}_{\bar{y}}(0)=\bar{A}$ have negative real parts there exists $\mu \in (0,1)$ for $|s^0|$ small enough such that $\bar{G}_{\bar{y}}(s)$ has eigenvalues with real parts smaller than -2μ for $s \in J$. Hence, by a lemma due to Flatto and Levinson [1] we have

$$|\bar{V}(s,\sigma,\varepsilon)| \leqq Ke^{-\mu(s-\sigma)/\varepsilon} \quad \text{for } s^0 \leqq \sigma \leqq s \leqq 0. \tag{19}$$

Using H5 and integrating (17) yields an estimate for V_1:

$$V_1(s,\sigma,\varepsilon) \leqq e^{\hat{k}[(-s)^{\hat{q}} - (-\sigma)^{\hat{q}}]/\varepsilon} \quad \text{for } s^0 \leqq \sigma \leqq s \leqq 0, \tag{20}$$

where $\hat{q} := q+1$, $\hat{k} := k/\hat{q}$.

The fundamental matrix solution $U(s,\sigma)$ satisfies

$$|U(s,\sigma)| \leqq K \quad \text{for } s^0 \leqq \sigma \leqq s \leqq 0. \tag{21}$$

Moreover, we have

$$|F_y(s)| \leqq K, \quad |\bar{G}_{\bar{x}}(s)| \leqq K, \quad |G_{1,\bar{x}}(s)| \leqq K \quad \text{for } s \in J. \tag{22}$$

Remark 4. For $\alpha \geqq 1$, when $\phi(x)$ has continuous partial derivatives, $G_1(x,\phi(x))=0$ for $x \in J \times \bar{\Omega}$ implies $G_{1,x}(x,\phi(x))+G_{1,y}(x,\phi(x))\phi_x(x)=0$, and this together with $G_{1,y}(0,0)=0$ yields $G_{1,x}(0,0)=0$. $G_{1,\bar{x}}(0,0)=0$ is also true for $\alpha<1$ if $G_1(s,\bar{x},y)$ has no linear terms in $\bar{x}$. Hence, in these two cases we will be able to derive a better estimate for $G_{1,\bar{x}}(s)$ than the one given in (22).

Since $G_{1,\bar{y}}(x,y)$ and $\bar{G}_{y_1}(x,y)$ vanish at the origin (see H2) we will also have better estimates for $G_{1,\bar{y}}(s)$ and $\bar{G}_{y_1}(s)$. In order to find these estimates we need the asymptotic behavior of $\bar{X}(s)$ and $\bar{Y}(s)$ as $s \to 0^-$.

In the domain corresponding to the one introduced in (15) F satisfies the estimate

$$|F(s,\bar{x},y_1,\bar{y})| \leqq K\big((-s)+|\bar{x}|+|y_1|+|\bar{y}|\big). \tag{23}$$

From H2 we know that

$$\begin{aligned} G_1(x,y_1,\bar{y}) &= \sum_{i=1}^{m} c_i x_i + a y_1^2 + \hat{G}_1(x,y_1,\bar{y}), \\ \bar{G}(x,y_1,\bar{y}) &= \bar{A}\bar{y} + Bx + \hat{G}(x,y_1,\bar{y}), \end{aligned} \tag{24}$$

where the Taylor formulae of $\hat{G}_1$ and $\hat{G}$ begin with quadratic terms in (x,y) and with a cubic term in y_1. Hence

$$\bar{\phi}(s,\bar{x}) = \bar{w}(s,\bar{x},\phi_1(s,\bar{x})) = \bar{a}s + \tilde{B}\bar{x} + \tilde{G}(s,\bar{x},\phi_1(s,\bar{x})) \tag{25}$$

where the remainder term again is at least quadratic in $(s,\bar{x},\phi_1)$ and cubic in ϕ_1. This together with (10) provides the following estimate

$$|\bar{\phi}(s,\bar{x})| \leqq K\big((-s)^{\tilde{\alpha}}+|\bar{x}|\big) \quad \text{where } \tilde{\alpha} := \min(3\alpha,1). \tag{26}$$

Using (23) and (26) in (12) we find for $\bar{X}(s)$ that for some $\bar{K}>0$

$$|\bar{X}(s)| \leqq \bar{K}\int_s^0 \big((-\sigma)^{\hat{\alpha}}+|\bar{X}(\sigma)|\big)\,d\sigma = \frac{\bar{K}}{\hat{\alpha}+1}(-s)^{\hat{\alpha}+1} + \bar{K}\int_s^0 |\bar{X}(\sigma)|\,d\sigma$$

where $\hat{\alpha} := \min(\alpha,1)$.

Applying the generalized Gronwall lemma we obtain

$$|\bar{X}(s)| \leqq \hat{K}(-s)^{\hat{\alpha}+1}, \qquad s \in J, \tag{27}$$

for some $\hat{K}>0$. From (27) and (10) we get[1]

$$|Y_1(s)| \leqq K_1(-s)^{\alpha_1}, \qquad s \in J, \tag{28}$$

$\alpha_1 := \min(\alpha,2)$, and from (26) and (27)[2]

$$|\bar{Y}(s)| \leqq \tilde{K}(-s)^{\tilde{\alpha}}, \qquad s \in J. \tag{29}$$

---

[1] There is a more precise assertion for $\alpha<1$:

$$Y_1(s) = a_1(-s)^{\alpha} + o\big((-s)^{\alpha}\big), \qquad s \to 0^-.$$

[2] Using (25) directly and footnote 1 we find for $\alpha<1$ that

$$\bar{Y}(s) = \bar{a}s + O\big((-s)^{\tilde{\tilde{\alpha}}}\big), \qquad s \to 0^-,$$

where $\tilde{\tilde{\alpha}} := \min(1+\alpha, 3\alpha)$.

Finally, using (24) this allows us to state

$$\begin{aligned} &|G_{1,\bar{x}}(s)| \leqq C(-s)^{\gamma}, \\ &|G_{1,\bar{y}}(s)| \leqq C(-s)^{\nu}, \qquad s \in J, \\ &|\bar{G}_{y_1}(s)| \leqq C(-s)^{\bar{\alpha}}, \end{aligned} \tag{30}$$

where $\gamma \in \{0, \hat{\alpha}\}$, $\nu = \hat{\alpha}$, $\bar{\alpha} = \min(2\alpha, 1)$ and C some positive constant depending on K.

Remark 5. Usually $\gamma = 0$ as we have seen in (22); however, $\gamma = \hat{\alpha}$ for the two cases indicated in Remark 4.

From (24) we conclude that

$$|\bar{S}(s,u,v,\varepsilon)| \leqq \bar{K}\left(\varepsilon + |u|^2 + |\bar{v}|^2 + (-s)^{\hat{\alpha}}|v_1|^2 + |v_1|^3\right). \tag{31}$$

An analogous estimate holds for S_1 if $G_1(x,y)$ has no quadratic term in y_1. (Of course, all these estimates can be improved if the vector functions F and G are of special form.) Here, we take into account only one such special case corresponding to bifurcation situations similar to the one considered in [4], where $\alpha < 1$ and $G_1(x,y)$ has no linear term in x. Since then, substituting in the first expression of (24) the above estimates for $\bar{X}$, Y_1, $\bar{Y}$, we obtain

$$0 = aa_1(-s)^{2\alpha} + o\left((-s)^{2\alpha}\right), \qquad s \to 0^-,$$

and this implies $a = 0$. Thus

$$|S_1(s,u,v,\varepsilon)| \leqq C_1\left(\varepsilon + |u|^2 + |\bar{v}|^2 + (-s)^{\beta}|v_1|^2 + |v_1|^3\right)$$

where we define

$$\beta := \begin{cases} \alpha & \text{if } \alpha < 1 \text{ and } G_1 \text{ has no linear term in } x, \\ 0 & \text{otherwise.} \end{cases} \tag{32}$$

In order to save writing we will drop the term $|v_1|^3$ of (31) and (32) in what follows, since it can easily be verified that it is always less or equal than the preceding $|v_1|^2$-term in the case of Theorem 2 (cf. (52) and (57)) and also in the case of Theorem 3 (cf. (76)).

The estimates for $|Y_1'(s)|$ and $|\bar{Y}'(s)|$ are still missing. In the case $\alpha \geqq 1$ (H3′) both quantities are bounded. In the case $\alpha < 1$ the first estimate follows from (11) and (27):

$$|Y_1'(s)| \leqq C(-s)^{\beta_1}, \qquad s \in [s^0, 0), \tag{33}$$

where $\beta_1 := \min(\alpha - 1, 0)$. From

$$\bar{Y}'(s) = \frac{d}{ds}\bar{\phi}\left(s, \bar{X}(s)\right) = \frac{d}{ds}\bar{w}\left(s, \bar{X}(s), Y_1(s)\right) = \bar{w}_s(s) + \bar{w}_{\bar{x}}(s)F(s) + \bar{w}_{y_1}(s)Y_1'(s)$$

together with (25) and (33), we conclude

$$|\bar{Y}'(s)| \leqq \bar{C}(-s)^{\bar{\beta}}, \qquad s \in [s^0, 0), \tag{34}$$

where $\bar{\beta} := \min(3\alpha - 1, 0)$.

Now, applying all these estimates to (18) we obtain

(35)

$$|u(s)| \leqq Kc_0\varepsilon + K^2 \int_{s_0}^{s} \Big[|v(\sigma)| + \varepsilon + |u(\sigma)|^2 + |v(\sigma)|^2 \Big] d\sigma,$$

$$|v_1(s)| \leqq c_0\varepsilon + \varepsilon^{-1} \int_{s_0}^{s} e^{\hat{k}[(-s)^{\hat{q}} - (-\sigma)^{\hat{q}}]/\varepsilon} \Big[C(-\sigma)^{\gamma} |u(\sigma)| + C(-\sigma)^{\nu} |\bar{v}(\sigma)| + C_1\Big(\varepsilon + |u(\sigma)|^2 + |\bar{v}(\sigma)|^2 + (-\sigma)^{\beta} |v_1(\sigma)|^2\Big) + C(-\sigma)^{\beta_1}\varepsilon \Big] d\sigma,$$

$$|\bar{v}(s)| \leqq Kc_0\varepsilon + \varepsilon^{-1} K \int_{s_0}^{s} e^{-\mu(s-\sigma)/\varepsilon} \Big[K|u(\sigma)| + C(-\sigma)^{\bar{\alpha}} |v_1(\sigma)| + \bar{K}\Big(\varepsilon + |u(\sigma)|^2 + |\bar{v}(\sigma)|^2 + (-\sigma)^{\hat{\alpha}} |v_1(\sigma)|^2\Big) + \bar{C}(-\sigma)^{\bar{\beta}}\varepsilon \Big] d\sigma.$$

In the subsequent proofs we will also need the following two auxiliary results which are obtained by simple integration:

(36) $$\int_{s_0}^{s} e^{-\mu(s-\sigma)/\varepsilon} d\sigma < \frac{\varepsilon}{\mu},$$

(37) $$\int_{s_0}^{s} e^{\hat{k}[(-s)^{\hat{q}} - (-\sigma)^{\hat{q}}]/\varepsilon} k(-\sigma)^q d\sigma < \varepsilon, \qquad s \in J.$$

Moreover, we are now able to state two lemmas which provide relations between q and α that will prove useful in formulating our results.

LEMMA 1. *q satisfies*

(38) $$q \geqq \hat{\alpha}$$

and if $\beta = \alpha$ (cf. (32))

(39) $$q \geqq 2\alpha.$$

Proof. $G_1(x, y_1, \bar{y})$ is a smooth function with respect to all variables and satisfies $G_1(0,0,0) = 0$, $G_{1,y_1}(0,0,0) = 0$ and $G_{1,\bar{y}}(0,0,0) = 0$ (cf. H2). Hence, G_1 has the following expansion in the neighborhood of the origin

(40) $$G_1(x, y_1, \bar{y}) = L_0(x) + ay_1^2 + L_1(x, \bar{y})\, y_1 + Q_0(x, \bar{y}) + by_1^3 + \hat{G}_1(x, y_1, \bar{y})$$

where L indicates linear terms, Q quadratic terms and the terms in the remainder are at least cubic. This implies

(41) $$G_{1,y_1}(x, y_1, \bar{y}) = 2ay_1 + L_1(x, \bar{y}) + 3by_1^2 + \hat{G}_{1,y_1}(x, y_1, \bar{y})$$

where the terms in the remainder are at least quadratic. The functions $\bar{X}(s)$, $Y_1(s)$ and $\bar{Y}(s)$ satisfy

(42) $$G_1\big(s, \bar{X}(s), Y_1(s), \bar{Y}(s)\big) = 0 \quad \text{for } s \in J.$$

Moreover, H5 implies that there are positive constants k and q such that

(43) $$\big|G_{1,y_1}\big(s, \bar{X}(s), Y_1(s), \bar{Y}(s)\big)\big| \geqq k(-s)^q \quad \text{for } s \in J.$$

Hence, inserting the functions $\bar{X}(s)$, $Y(s)$ in (41) and making use of their asymptotic behavior given in (27), (28) and (29), respectively, we derive that

$$k(-s)^q \leqq k_1(-s)^{\alpha_1} + k_2(-s)^{\tilde{\alpha}}, \qquad s \in J \tag{44}$$

for some positive constants k_1, k_2. And this implies that $q \geqq \min(\alpha_1, \tilde{\alpha})$ which proves (38).

In the case $\beta = \alpha$ we have $\alpha < 1$ and $L_0 \equiv 0$, $a = 0$ in (40). Hence

$$G_1(x, y_1, \bar{y}) = L_1(x, \bar{y})\, y_1 + Q_0(x, \bar{y}) + b y_1^3 + \hat{G}_1(x, y_1, \bar{y}) \tag{45}$$

and

$$G_{1,y_1}(x, y_1, \bar{y}) = L_1(x, \bar{y}) + 3b y_1^2 + \hat{G}_{1,y_1}(x, y_1, \bar{y}). \tag{46}$$

And by the same argument as before we obtain that $q \geqq \min(2\alpha, \tilde{\alpha})$. This implies $q \geqq \bar{\alpha}$ and proves (39) for $\alpha \leqq \frac{1}{2}$.

Assume now that $\alpha > \frac{1}{2}$ and $q < 2\alpha$. Thus, we have $1 \leqq q < 2\alpha < 1 + \alpha < 3\alpha$. Inserting $\bar{X}(s)$, $Y_1(s)$ and $\bar{Y}(s)$ in (46) we find that all terms not in L_1 and all terms in L_1 with $\bar{X}_l(s)$ are $O((-s)^{2\alpha})$. The remaining terms in L_1 are the terms $c_0 s$ and $c_i \bar{Y}_i(s)$, $i = 1, \cdots, n-1$, with the asymptotic behavior $\bar{Y}_i(s) = \bar{a}_i s + O((-s)^{2\alpha})$ as $s \to 0^-$. Thus, (43) can only be satisfied if

$$c_0 + \sum_{i=1}^{n-1} c_i \bar{a}_i \neq 0.$$

Consider now $(45)_s$, i.e. $\bar{X}(s)$, $Y_1(s)$, $\bar{Y}(s)$ inserted in (45). Here, we have the terms $c_0 s Y_1(s)$ and $c_i \bar{Y}_i(s) Y_1(s)$; and all the other terms are $O((-s)^\rho)$, $\rho = \min(2, 3\alpha)$. Hence, (42) admits the representation

$$0 = a_1 c_0 (-s)^{1+\alpha} + a_1 \sum_{i=1}^{n-1} c_i \bar{a}_i (-s)^{1+\alpha} + o\big((-s)^{1+\alpha}\big), \qquad s \to 0^-,$$

implying $c_0 + \Sigma c_i \bar{a}_i = 0$ and leading to a contradiction. □

LEMMA 2. *If $\alpha = q$, then $\alpha \geqq \frac{1}{2}$.*[3]

Proof. We use the same arguments as in the proof of Lemma 1. If $q = \alpha < \frac{1}{2}$, the term $2aY_1(s)$, $a \neq 0$, is the only one in $(41)_s$ that can satisfy (43); all other terms are $O((-s)^{2\alpha})$. And, (42) admits

$$0 = a_1 a (-s)^{2\alpha} + o\big((-s)^{2\alpha}\big), \qquad s \to 0^-.$$

This, however, implies $a = 0$ and, hence, leads to a contradiction. □

4. The main results in the case "$s < 0$". In this section we state the results for the trajectories in the phase-space for the case "$s < 0$". The proofs are given in §5.

Theorem 2 below provides an existence result for the solution $(\bar{x}(s, \varepsilon), y(s, \varepsilon))$ of the initial value problem (5), (6) as well as an estimate for the domain of validity and the error of the approximation $(\bar{X}(s), Y(s))$ which is the solution of the reduced initial value problem (12).

[3] There is strong evidence that $\alpha + q \geqq 1$ also holds in general, under the hypotheses H1–H5.

THEOREM 2. *Suppose the hypotheses* H1–H5 *hold, and let* $\hat{\alpha} := \min(\alpha, 1)$, $\bar{\alpha} := \min(2\alpha, 1)$, $q_1 := 1 - \hat{\alpha} + q$. *If* q *satisfies*

$$q < \min(1 + \gamma, \bar{\alpha} + \nu) \tag{47}$$

where $\gamma \geqq 0$ ($\geqq 1$, *if* $\alpha \geqq 1$) *and* $\nu \geqq \hat{\alpha}$ *are defined by* (30); *then, if* $|s^0|$ *is taken sufficiently small, the following result holds*:

There exist positive constants c *and* $\varepsilon_1 \leqq \varepsilon_0$ *such that the solution* $(\bar{x}(s,\varepsilon), y(s,\varepsilon))$ *of the initial value problem* (5), (6) *exists at least for* $s \in J^* := [s^0, -c\varepsilon^{q^*}]$, *where* $q^* := 1/(q_1 + q - \beta)$, $\beta \in \{0, \alpha\}$ *defined in* (32), *and*

$$|\bar{x}(s,\varepsilon) - \bar{X}(s)| < \begin{cases} c\varepsilon \log(-s)^{-1}, & q_1 = 1, \\ c\varepsilon(-s)^{1-q_1}, & q_1 > 1, \end{cases}$$

$$|y_1(s,\varepsilon) - Y_1(s)| < c\varepsilon(-s)^{-q_1},$$

$$|\bar{y}(s,\varepsilon) - \bar{Y}(s)| < \begin{cases} c\varepsilon \log(-s)^{-1}, & q_1 = 1, \\ c\varepsilon(-s)^{\bar{\alpha}-q_1}, & q_1 > 1 \end{cases}$$

for $s \in J^*$, $\varepsilon \in (0, \varepsilon_1)$.

Remark 6. Since $q \geqq \hat{\alpha}$ (cf. Lemma 1), we always have $q_1 \geqq 1$. There are exactly two cases where $q_1 = 1$: (i) $q = \alpha < 1$ and (ii) $\alpha \geqq 1$, $q = 1$. Note, that we have $q_1 = q$ for $\alpha \geqq 1$, and that always $q^* < 1/q_1 \leqq 1$ (cf. Lemma 1). The restriction (47) on q depends on the lowest order terms of $G_{1,\bar{x}}(s)$ and $G_{1,\bar{y}}(s)$, or in other words is due to the coupling of the y_1-equation to the rest of the system (5). With the assumptions made in this paper we have seen that $\gamma = 0$ or $\gamma = \hat{\alpha}$ and $\nu = \hat{\alpha}$ (see (30) and Remark 5). However, if $G_1(x,y)$ is of special form such that the coupling is weaker, both quantities may be greater than $\hat{\alpha}$ (compare formulas (27)–(30)).

For applications it is often useful to have the estimates of Theorem 2 in a more transparent form with respect to the dependence on ε. We state this slightly weaker result as Theorem 2′. It is obtained from Theorem 2 essentially by considering the right end-point of J^* as being variable, i.e. by varying q^* below its maximum.

THEOREM 2′. *Suppose the same assumptions are satisfied as in Theorem* 2, *and let* $\hat{\alpha} := \min(\alpha, 1)$, $\bar{\alpha} := \min(2\alpha, 1)$, $q_1 := 1 - \hat{\alpha} + q$ *and* $|s^0|$ *be sufficiently small. Then there exist positive constants* c *and* $\varepsilon_1 \leqq \varepsilon_0$ *such that the solution* $(\bar{x}(s,\varepsilon), y(s,\varepsilon))$ *of* (5), (6) *exists at least for* $s \in J^* := [s^0, -c\varepsilon^{\delta_0/q_1}]$, *where* $\delta_0 := q_1/(q_1 + q - \beta)$, $\beta \in \{0, \alpha\}$ *defined by* (32). *Moreover, for every* $\delta \in (0, \delta_0]$ *we have*

$$|\bar{x}(s,\varepsilon) - \bar{X}(s)| < \begin{cases} c\varepsilon \log \varepsilon^{-1}, & q_1 = 1, \\ c\varepsilon^{1-\delta+\delta/q_1}, & q_1 > 1, \end{cases}$$

$$|y_1(s,\varepsilon) - Y_1(s)| < c\varepsilon^{1-\delta},$$

$$|\bar{y}(s,\varepsilon) - \bar{Y}(s)| < \begin{cases} c\varepsilon \log \varepsilon^{-1}, & q_1 = 1, \\ c\varepsilon^{1-\delta+\bar{\alpha}\delta/q_1}, & q_1 > 1 \end{cases}$$

for $s \in [s^0, -c\varepsilon^{\delta/q_1}]$, $\varepsilon \in (0, \varepsilon_1)$.

Remark 7. Note that, the smaller the s-interval in which the approximation $(\bar{X}(s), Y(s))$ is considered the better the error estimates. Only in the case $q_1 = 1$ the estimates for the $\bar{x}$- and $\bar{y}$-components are independent of δ.

5. Proofs. In this section we give the proofs of the theorems stated in §4.

Proof of Theorem 2. (a) We first consider the case $\alpha<1$. Define

$$
\begin{aligned}
&s^*(\varepsilon):=-k^*\varepsilon^{q^*},\\
&r(s,\varepsilon):=\begin{cases}k_0\varepsilon\log(-s)^{-1}, & q_1=1,\\ k_0\varepsilon(-s)^{1-q_1}, & q_1>1,\end{cases}\\
&r_1(s,\varepsilon):=k_1\varepsilon(-s)^{-q_1},\\
&\bar r(s,\varepsilon):=\begin{cases}\bar k_0\varepsilon\log(-s)^{-1}, & q_1=1,\\ \bar k_0\varepsilon(-s)^{\bar\alpha-q_1}, & q_1>1,\end{cases}
\end{aligned}
\tag{48}
$$

where all the constants involved are supposed to be positive, $q_1\geqq 1$, $q^*q_1<1$, and will be specified more precisely later. These functions are defined and continuous for $\varepsilon\in[0,\varepsilon_0]$ and $s\in[s^0,0)$. Moreover, the positive functions r, r_1, $\bar r$ increase as s increases.

Now, consider the set $\mathfrak{d}\subset\mathbb{R}^{m+n}$ defined by

$$
\mathfrak{d}:=\{|u|<r\}\times\{|v_1|<r_1\}\times\{|\bar v|<\bar r\}\times\{s\in J^*\}
\tag{49}
$$

where $J^*:=[s^0,s^*]$. For ε small enough, $\mathfrak{d}$ lies in the domain considered.

With respect to $\mathfrak{d}$ the solution $(u(s,\varepsilon),\ v(s,\varepsilon))$ of the initial value problem (14), (16) is assumed to exist on $[s^0,m_+)$, where m_+ may depend on ε.

For ε and $|s^0|$ sufficiently small we can always achieve that

$$
r(s)\leqq\bar r(s)<r_1(s)<1\quad\text{for } s\in J^*.
\tag{50}
$$

Thus, from the estimates given in (35) and also using (36), (37) we derive the following estimates for the solution of (14), (16):

$$
\begin{aligned}
&|u(s)|\leqq M\Big[\varepsilon+\int_{s^0}^{s}r_1(\sigma)\,d\sigma\Big],\\
&|v_1(s)|\leqq M\big[\varepsilon(-s)^{-q}+(-\tau)^{\gamma-q}r(\tau)+(-\tau)^{\nu-q}\bar r(\tau)\\
&\qquad\qquad+\bar r^2(s)(-s)^{-q}+(-s)^{\beta-q}r_1^2(s)+(-\tau)^{\beta_1-q}\varepsilon\big],\\
&|\bar v(s)|\leqq M\big[\varepsilon+r(s)+(-\tau)^{\bar\alpha}r_1(\tau)+\bar r^2(s)+(-s)^{\hat\alpha}r_1^2(s)+(-\tau)^{\bar\beta}\varepsilon\big],
\end{aligned}
\tag{51}
$$

for $s\in[s^0,m_+)$, where M is a positive constant depending on all constants appearing in (35) and on θ_1 introduced in (15), and τ stands for s or s^0, respectively, depending on whether the exponent of the corresponding expression is negative or nonnegative (e.g. $(-\tau)^{\bar\alpha}r_1(\tau)=k_1\varepsilon(-\tau)^{\bar\alpha-q_1}\to k_1\varepsilon(-s)^{\bar\alpha-q_1}$ if $q_1>\bar\alpha$). Since $\alpha<1$, we have $\hat\alpha=\alpha$ and $\beta_1=\alpha-1<0$, $\bar\beta=\min(3\alpha-1,0)$ and $\gamma\geqq 0$, $\nu\geqq\alpha$. We may write (51) more explicitly (for simplicity we write down only the case $q_1>1$):

$$
\begin{aligned}
&|u(s)|\leqq M\Big[\varepsilon+k_1\varepsilon\int_{s^0}^{s}(-\sigma)^{-q_1}d\sigma\Big],\\
&|v_1(s)|\leqq M\big[\varepsilon(-s)^{-q}+k_0\varepsilon(-\tau)^{1-q_1+\gamma-q}+\bar k_0\varepsilon(-\tau)^{\bar\alpha-q_1+\nu-q}\\
&\qquad\qquad+\bar k_0^2\varepsilon^2(-s)^{2\bar\alpha-2q_1-q}+k_1^2\varepsilon^2(-s)^{\beta-2q_1-q}+\varepsilon(-s)^{\alpha-1-q}\big],\\
&|\bar v(s)|\leqq M\big[\varepsilon+k_0\varepsilon(-s)^{1-q_1}+k_1\varepsilon(-s)^{\bar\alpha-q_1}\\
&\qquad\qquad+k_1^2\varepsilon^2(-s)^{\alpha-2q_1}+\bar k_0^2\varepsilon^2(-s)^{2\bar\alpha-2q_1}+\varepsilon(-\tau)^{\bar\beta}\big],\qquad\text{for } s\in[s^0,m_+).
\end{aligned}
\tag{52}
$$

We now choose $q_1 := 1-\alpha+q$. (By Lemma 1 we know that $q_1 \geqq 1$.) We want to show that

$$
\begin{aligned}
&|u(s)| \leqq \frac{r}{2} \\
&|v_1(s)| \leqq \frac{r_1}{2} \qquad \text{for } s \in [s^0, m_+). \\
&|\bar{v}(s)| \leqq \frac{\bar{r}}{2}
\end{aligned} \tag{53}
$$

We only have to consider the case $\tau = s$ since for $\tau = s^0$ the right-hand sides of (52) are always smaller (for the same choice of constants) than in the case $\tau = s$.

Let us consider the case $q_1 > 1$ first. It can easily be seen, by taking into account the assertions of Lemma 1 and Lemma 2, that if q satisfies

$$q < 1+\gamma \quad \text{and} \quad q < \bar{\alpha}+\nu \tag{54}$$

then, for $|s^0|$ and ε sufficiently small, (53) holds under the following conditions concerning the constants involved:

$$M\left(1+\frac{k_1}{q_1-1}\right) \leqq \frac{k_0}{2}, \quad M(6) \leqq \frac{k_1}{2}, \quad M(4+k_0+k_1) \leqq \frac{\bar{k}_0}{2} \tag{55}$$

and

$$k^* := k_1^2, \qquad q^* := \frac{1}{q_1+q-\beta}. \tag{56}$$

It is obvious that (55) can be satisfied by choosing $k_1 (\geq 1)$ first (so that the second inequality holds), k_0 second and then $\bar{k}_0$ large enough.

In the case $q_1 = 1$, where $\alpha = q$ and $\bar{\alpha} = 1$ (by means of Lemma 2), and $\beta = 0$ (cf. (39), Lemma 1), the situation is exactly the same only with k_1 having a factor 1 instead of $1/(q_1-1)$ in the first inequality of (55). (54) is automatically satisfied. Having shown (53), the proof of Theorem 2, as far as the case $\alpha < 1$ is concerned, is completed by applying the Global Existence Theorem for ode's; and by choosing c as the maximum of k_0, k_1, $\bar{k}_0$ and k^*, and ε_1 sufficiently small.

(b) The case $\alpha \geqq 1$ is formally completely analogous and we therefore only point out the differences in the formulas. We have $\hat{\alpha} = 1$, $\beta_1 = 0$, $\bar{\beta} = 0$, $\beta = 0$ and $\gamma \geqq 1$, $\nu \geqq 1$, $\bar{\alpha} = 1$. Thus, for $q_1 > 1$, we obtain instead of (52)

$$
\begin{aligned}
&|u(s)| \leqq M\left[\varepsilon + k_1\varepsilon \int_{s^0}^{s} (-\sigma)^{-q_1} d\sigma\right], \\
&|v_1(s)| \leqq M\left[\varepsilon(-s)^{-q} + k_0\varepsilon(-\tau)^{1-q_1+\gamma-q}\right. \\
&\qquad\qquad \left. + \bar{k}_0\varepsilon(-\tau)^{1-q_1+\nu-q} + k_1^2\varepsilon^2(-s)^{-2q_1-q}\right], \\
&|\bar{v}(s)| \leqq M\left[\varepsilon + k_0\varepsilon(-s)^{1-q_1} + k_1\varepsilon(-s)^{1-q_1} + k_1^2\varepsilon^2(-s)^{1-2q_1} + \bar{k}_0^2\varepsilon^2(-s)^{2-2q_1}\right],
\end{aligned} \tag{57}
$$

for $s \in [s^0, m_+)$, where M again is a common constant.

We choose $q_1 := q$ ($\geqq 1$, by Lemma 1); and we find, first for $q_1 > 1$, that if

$$q < 1+\gamma \quad \text{and} \quad q < 1+\nu \tag{58}$$

then, for $|s^0|$ and ε sufficiently small, the estimate (53) holds under the following conditions:

$$M\left(1+\frac{k_1}{q_1-1}\right) \leqq \frac{k_0}{2}, \quad M(4) \leqq \frac{k_1}{2}, \quad M(3+k_0+k_1) \leqq \frac{\bar{k}_0}{2} \tag{59}$$

and

$$k^* := k_1^2, \qquad q^* := \frac{1}{q_1+q}. \tag{60}$$

The inequalities (59) can again be satisfied by choosing k_1 ($\geqq 1$) first such that the second inequality holds and then taking k_0, $\bar{k}_0$ large enough.

In the case $q_1 = 1$, where (58) holds anyway, again the only difference lies in the factor 1 of k_1 in the first inequality of (59).

The proof is completed in the same way as in part (a). □

Proof of Theorem 2'. Since the functions $r(s,\varepsilon)$, $r_1(s,\varepsilon)$ and $\bar{r}(s,\varepsilon)$, defined in (48), are increasing functions of s, Theorem 2 implies that

$$\begin{aligned}
&|\bar{x}(s,\varepsilon) - \bar{X}(s)| < \begin{cases} k_0 q^* \varepsilon \log \varepsilon^{-1}, & q_1 = 1, \\ k_0 k^{*-(q_1-1)} \varepsilon^{1-(q_1-1)q^*}, & q_1 > 1, \end{cases} \\
&|y_1(s,\varepsilon) - Y_1(s)| < k_1 k^{*-q_1} \varepsilon^{1-q_1 q^*}, \\
&|\bar{y}(s,\varepsilon) - \bar{Y}(s)| < \begin{cases} \bar{k}_0 q^* \varepsilon \log \varepsilon^{-1}, & q_1 = 1, \\ \bar{k}_0 k^{*-(q_1-\bar{\alpha})} \varepsilon^{1-(q_1-\bar{\alpha})q^*}, & q_1 > 1, \end{cases}
\end{aligned} \tag{61}$$

for $s \in [s^0, -k^* \varepsilon^{q^*}]$, $\varepsilon \in (0, \varepsilon_1)$, where we have replaced the common constant c by the original constants. Now, let $\delta \in (0, \delta_0]$, where $\delta_0 := q_1/(q_1+q-\beta)$. Then, (61) also holds for $q^* = \delta/q_1$. Thus, $\delta = \delta_0$ gives the maximal q^* defined in Theorem 2, $\delta < \delta_0$ means considering a smaller s-interval on which we have better estimates, however, due to Theorem 2. If we take only q^* variable (by varying δ) but k^* fixed in $s^*(\varepsilon) = -k^* \varepsilon^{q^*}$, then we can take the same constants c and ε_1 as in Theorem 2, since $q^* < 1$, $k^* \geqq 1$, and they are independent of δ. □

6. The case "$s > 0$". In this section we will deal with the case where the flow along a stable branch of the reduced manifold of (1) leads away from the point at which the stability assumption (4) is violated. This situation is encountered in bifurcation diagrams of the type sketched in Fig. 1. Another possible situation is given in Fig. 3.

In our formulation of the problem with H1 supposed to hold this second case will occur for $s > 0$ in the orbit equations (5). We again want to provide a maximal domain of validity (with sharpest possible error estimates) of an approximation given by a reduced trajectory. And again we have to consider only a small neighborhood of that unstable point where Theorem 1 is not yet applicable ("not yet" instead of "no more" as in the case "$s < 0$").

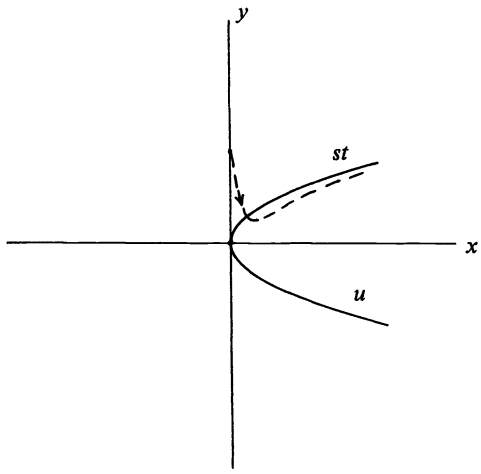

FIG. 3

The reason why this case is different from the one considered in the previous sections and in fact more involved is that the initial conditions to the orbit equations (5) can no longer be assumed, by means of Theorem 1, to satisfy a condition H4 with an estimate ε. And since we want to give a general result for this case we do not know the estimates in the transition interval[4] which depend on the global problem at hand. Hence, we know neither the starting point $s=s^*(\varepsilon)>0$ for the approximation nor the approximate size of possible initial conditions. The following questions, however, seem to be appropriate: What is the smallest possible $s^*(\varepsilon)$, and what estimates for the initial conditions are required in order that the reduced trajectory considered approximates the corresponding trajectory of the full system on the interval $[s^*(\varepsilon),s^1]$ for some $s^1\in(0,1)$, independent of ε? And what is the sharpest possible estimate that can be achieved in a given situation? Theorem 3 below will give an answer to these questions.

Let us become more precise now. Besides assumption H1 we again suppose that H2 is satisfied. Let us denote the yet unknown initial conditions to the system (5) by

$$\bar{x}(s^*,\varepsilon)=\bar{x}^0(\varepsilon),\qquad y(s^*,\varepsilon)=y^0(\varepsilon) \tag{62}$$

where $s^*(\varepsilon)>0$ for $\varepsilon\in(0,\varepsilon_0)$ and $s^*\to 0$ as $\varepsilon\to 0$.

The appropriate s-interval in H3 is now $\hat{J}:=[0,s^1]$ for some $0<s^1<1$, independent of ε; and in the formulas (10), (11) $(-s)$ has to be replaced by s. Let us denote the so adjusted hypothesis by $\hat{\text{H}}3$, and let us assume that the hypotheses $\hat{\text{H}}3'$ and $\hat{\text{H}}5$ which have to be altered in the analogous way hold, too. The assumption H4 has to be changed into the following.

$\hat{\text{H}}4$. The solution $(\bar{X}(s), Y(s))$ of (12), where $Y(s):=\phi(s,\bar{X}(s))$, exists for $s\in\hat{J}$.

Under these hypotheses H1, H2, $\hat{\text{H}}3$–$\hat{\text{H}}5$ estimates for the solution corresponding to (62) of the system (14) can be derived completely analogous to those given in §3. We

[4] That is, the ε-dependent interval containing the unstable point (and overlapping with the interval J^* of Theorem 2) where the solution of the IVP (5), (6) cannot be approximated by a solution of the reduced system $(5)_{\varepsilon=0}$ (cf. [6] and Part II of this paper).

only state the final assertion which corresponds to (35):

$$|u(s)| \leqq K|u(s^*)| + K^2 \int_{s^*}^{s} \left[|v(\sigma)| + \varepsilon + |u(\sigma)|^2 + |v(\sigma)|^2 \right] d\sigma,$$

$$\begin{aligned} |v_1(s)| &\leqq e^{-\hat{k}(s^{\hat{q}} - s^{*\hat{q}})/\varepsilon} |v_1(s^*)| \\ &\quad + \varepsilon^{-1} \int_{s^*}^{s} e^{-\hat{k}(s^{\hat{q}} - \sigma^{\hat{q}})/\varepsilon} \Big[C\sigma^{\gamma} |u(\sigma)| + C\sigma^{\nu} |\bar{v}(\sigma)| \\ &\quad + C_1 \left(\varepsilon + |u(\sigma)|^2 + |\bar{v}(\sigma)|^2 + \sigma^{\beta} |v_1(\sigma)|^2 \right) + C\sigma^{\beta_1} \varepsilon \Big] d\sigma, \end{aligned} \tag{63}$$

$$\begin{aligned} |\bar{v}(s)| &\leqq K e^{-\mu(s-s^*)/\varepsilon} |\bar{v}(s^*)| \\ &\quad + \varepsilon^{-1} K \int_{s^*}^{s} e^{-\mu(s-\sigma)/\varepsilon} \Big[K|u(\sigma)| + C\sigma^{\bar{\alpha}} |v_1(\sigma)| \\ &\quad + \bar{K} \left(\varepsilon + |u(\sigma)|^2 + |\bar{v}(\sigma)|^2 + \sigma^{\hat{\alpha}} |v_1(\sigma)|^2 \right) + \bar{C}\sigma^{\bar{\beta}} \varepsilon \Big] d\sigma \end{aligned}$$

for $s \in [s^*, s^1]$, with μ and $\hat{q}$, $\hat{k}$ defined in (19) and (20), respectively. And again estimates analogous to (36) and (37) hold:

$$\int_{s^*}^{s} e^{-\mu(s-\sigma)/\varepsilon} d\sigma < \frac{\varepsilon}{\mu}, \tag{64}$$

$$\int_{s^*}^{s} e^{-\hat{k}(s^{\hat{q}} - \sigma^{\hat{q}})/\varepsilon} k\sigma^{q} d\sigma < \varepsilon, \qquad s \in [s^*, s^1]. \tag{65}$$

The estimate (65) can also be replaced by one which is sometimes better for our purposes:

$$\int_{s^*}^{s} e^{-\hat{k}(s^{\hat{q}} - \sigma^{\hat{q}})/\varepsilon} d\sigma \leqq \int_{s^*}^{s} e^{-\psi(s)(s-\sigma)/\varepsilon} d\sigma < \frac{\varepsilon}{\psi(s)} \tag{66}$$

where $\psi(s) := \hat{k} s^q$.

We will also need the following estimate

$$\int_{s^*}^{s} e^{-\hat{\psi}(s-\sigma)/\varepsilon} \sigma^{\rho} d\sigma < \frac{\varepsilon}{\hat{\psi}} s^{\rho} + \hat{\rho} \frac{\varepsilon^2}{\hat{\psi}^2} s^{*\rho - 1}, \qquad s \in [s^*, s^1] \tag{67}$$

where $\rho \in \mathbb{R}$, $\hat{\psi} = \psi(s)$ or $\hat{\psi} = \mu$, respectively, and

$$\hat{\rho} = \begin{cases} 0, & \rho \geqq 0, \\ -\rho, & \rho < 0. \end{cases}$$

The two lemmas of §3 hold true, of course, also in the case "$s > 0$". In order to be able to prove Theorem 3 we need one more estimate which we state as

LEMMA 3. *For every $\rho \geqq 0$ we have*

$$e^{-\hat{k}(s^{\hat{q}} - \sigma^{\hat{q}})/\varepsilon} \leqq \left(\frac{\sigma}{s} \right)^{\rho}$$

if $(\rho\varepsilon/k)^{1/\hat{q}} \leqq \sigma \leqq s$.

Proof. The function $h(\tau) := e^{-\hat{k}\tau^{\hat{q}}/\varepsilon\tau^{\rho}}$ is decreasing for $\tau > (\rho\varepsilon/k)^{1/\hat{q}}$. □

Remark 8. Lemma 3 holds, of course, also for the special choice $\hat{k} = \mu$ and $\hat{q} = 1$ with $k = \mu$.

We now state the main result for the case "$s > 0$". It again provides an existence statement for a solution $(\bar{x}(s,\varepsilon),\ y(s,\varepsilon))$ of the orbit equations (5) but now to the initial conditions (62), as well as a maximal domain of validity with sharpest possible error estimates for the approximation $(\bar{X}(s),\ Y(s))$ which is the solution of the reduced initial value problem (12). Theorem 3, in contrast to Theorem 2, contains two free parameters due to the fact that the size of the initial values is unknown.

THEOREM 3. *Suppose the hypotheses* H1, H2, Ĥ3–Ĥ5 *hold, and let* $\hat{\alpha} := \min(\alpha, 1)$, $\bar{\alpha} := \min(2\alpha, 1)$ *and let* $\beta \in \{0, \alpha\}$ *be defined by* (32). *Moreover, assume that* q_1 *and* $\bar{\omega}$ *are in* $[0,1)$ *and such that*

$$\beta \leqq \bar{\omega} \leqq q_1 \leqq \min(\bar{\alpha}, 2q)$$

and let

$$q^* := \frac{1}{1+2q-\hat{\alpha}-\beta}, \qquad \delta := (q_1+q-\beta)q^*. \tag{68}$$

If q satisfies

$$q \leqq q_1+\gamma \quad \text{and} \quad q \leqq \bar{\omega}+\nu \tag{69}$$

(*for* $\bar{\omega} = \bar{\alpha}$ *the equality sign does not apply in the second inequality*) *where* $\gamma \geqq 0$ ($\geqq 1$, *if* $\alpha \geqq 1$) *and* $\nu \geqq \hat{\alpha}$ *are defined by* (30), *then the following result holds*:

There exist positive constants c, $\hat{s}^1 \leqq s^1$ *and* $\varepsilon_1 \leqq \varepsilon_0$ *such that the solution* $(\bar{x}(s,\varepsilon),\ y(s,\varepsilon))$ *of the initial value problem* (5), (62) *exists for* $s \in \hat{J}^* := [s^*(\varepsilon), \hat{s}^1]$, *where* $s^*(\varepsilon) := c\varepsilon^{q^*}$, *provided the initial values at* $s = s^*$ *satisfy*

$$\begin{aligned} &|\bar{x}^0(\varepsilon) - \bar{X}(s^*)| = O(\varepsilon^{\delta}), \\ &|y_1^0(\varepsilon) - Y_1(s^*)| = o(\varepsilon^{\delta_1}), \qquad \delta_1 := (q-\beta)q^*, \\ &|\bar{y}^0(\varepsilon) - \bar{Y}(s^*)| = o(\varepsilon^{\bar{\delta}}), \qquad \bar{\delta} := (\bar{\omega}+q-\beta)q^*, \end{aligned} \tag{70}$$

where the little o can be replaced by capital O in the y_1*-component if* $q_1 = 0$ *and in the* $\bar{y}$*-component if* $\bar{\omega} = q_1$.

Moreover, $(\bar{x}(s,\varepsilon),\ y(s,\varepsilon))$ *possesses the following estimates*

$$\begin{aligned} &|\bar{x}(s,\varepsilon) - \bar{X}(s)| < c\varepsilon^{\delta}, \\ &|y_1(s,\varepsilon) - Y_1(s)| < c\varepsilon^{\delta} s^{-q_1}, \\ &|\bar{y}(s,\varepsilon) - \bar{Y}(s)| < c\varepsilon^{\delta} s^{\bar{\omega}-q_1}, \end{aligned} \tag{71}$$

for $s \in \hat{J}^*$ *and* $\varepsilon \in (0, \varepsilon_1)$, $(\bar{X}(s),\ Y(s))$ *being the solution of the reduced initial value problem* (12).

Remark 9. Note that $0 < \delta < 1$, and that $\delta_1 \leqq \bar{\delta} \leqq \delta$, and in particular $\delta_1 < \delta$, except if $q_1 = 0$ (which is usually excluded by (69)). This allows to have less rigid requirements for the initial value $y_1^0(\varepsilon)$ (or also for $\bar{y}^0(\varepsilon)$ if $\bar{\omega}$ is chosen in an appropriate way),

which is an important fact since these initial values are, in general, provided by weaker estimates in the transition interval. Applying Theorem 3, one has to choose the two parameters q_1 and $\bar{\omega}$ such that the given initial values satisfy (70) and the q, ν, γ at hand satisfy (69). q_1 is, of course, taken as large as possible since this increases δ and yields optimal estimates (71) (or the other way around: taking the optimal δ by means of (70) gives a possible q_1 defined by (68), if (69) as well as $q_1<1$ and $\leqq \min(\bar{\alpha}, 2q)$[5] is satisfied). Note also that q^*, and hence the interval of validity $\hat{J}^*$ of the approximation $(\bar{X}(s), Y(s))$, is independent of q_1, $\bar{\omega}$ and δ. Moreover, $q^*=1/2q$ and $\delta=(q_1+q)/2q$ for $\alpha \geqq 1$.

There again exists the slightly weaker version of Theorem 3 with the estimates (71) not depending on s but only on ε. We are not going to state this Theorem 3′ here, since it can be derived from Theorem 3 in a way completely analogous to how Theorem 2′ has been obtained from Theorem 2.

7. Proof of Theorem 3. The proof is analogous to the one for Theorem 2. We define

$$
\begin{aligned}
&s^*(\varepsilon) := k^*\varepsilon^{q^*},\\
&r(\varepsilon) := k_0\varepsilon^{\delta}, \quad r_1(s,\varepsilon) := k_1\varepsilon^{\delta}s^{-q_1}, \quad \bar{r}(s,\varepsilon) := \bar{k}_0\varepsilon^{\delta}s^{\bar{\omega}-q_1}
\end{aligned} \tag{72}
$$

where $k^*(\geqq 1)$, k_0, k_1, $\bar{k}_0$ are positive constants, and $0 \leqq q_1 < 1$, $0 \leqq \bar{\omega} \leqq q_1$, $0<\delta<1$ and $q_1 q^* < \delta$. All these quantities will be specified more precisely later. The positive functions r, r_1, $\bar{r}$ are defined and continuous for $\varepsilon \in (0, \varepsilon_0)$ and $s \in (0, s^1]$ and decrease as s increases (if they are not constant).

Furthermore, we suppose that the initial values (62) to the system (5) obey the estimates

$$
\begin{aligned}
&|\bar{x}(s^*,\varepsilon) - \bar{X}(s^*)| \leqq c_0\varepsilon^{\lambda},\\
&|y_1(s^*,\varepsilon) - Y_1(s^*)| \leqq c_1\varepsilon^{\lambda_1},\\
&|\bar{y}(s^*,\varepsilon) - \bar{Y}(s^*)| \leqq \bar{c}_0\varepsilon^{\bar{\lambda}},
\end{aligned} \tag{73}
$$

where c_0, c_1, $\bar{c}_0$ are positive quantities and λ, λ_1, $\bar{\lambda}$ are positive constants $\leqq 1$.

Now, consider the set $\mathfrak{d} \subset \mathbb{R}^{m+n}$ defined by

$$
\mathfrak{d} := \{|u|<r\} \times \{|v_1|<r_1\} \times \{|\bar{v}|<\bar{r}\} \times \{s \in \hat{J}^*\} \tag{74}
$$

where $\hat{J}^* := [s^*(\varepsilon), \hat{s}^1]$, $\hat{s}^1$ independent of ε and $0<\hat{s}^1 \leqq s^1$. For ε and $\hat{s}^1$ small enough, $\mathfrak{d}$ lies in the domain considered.

With respect to $\mathfrak{d}$ the solution $(u(s,\varepsilon), v(s,\varepsilon))$ of the initial value problem (14), (73) is assumed to exist on $[s^*, m_+)$.

For ε and $\hat{s}^1$ small enough we can always achieve that

$$
r \leqq \bar{r}(s) \leqq r_1(s) < 1 \quad \text{for } s \in \hat{J}^*. \tag{75}
$$

[5] Since $2q \geqq \hat{\alpha} + q$ (cf. Lemma 1), there is strong evidence that always $2q \geqq 1$ (cf. footnote 3) and therefore $q_1 \leqq 2q$ is automatically satisfied.

(a) We consider first the case $\alpha<1$. Thus, from (63) and also using (64)–(67) we derive the following estimates for the solution $(u(s,\varepsilon), v(s,\varepsilon))$:

$$
\begin{aligned}
|u(s)| &\leqq M\left[c_0\varepsilon^{\lambda}+k_1\varepsilon^{\delta}\int_{s^*}^{s}\sigma^{-q_1}\,d\sigma\right],\\
|v_1(s)| &\leqq M\Big[e^{-\hat{k}(s^{\hat{q}}-s^{*\hat{q}})/\varepsilon}c_1\varepsilon^{\lambda_1}+\varepsilon s^{-q}+k_0\varepsilon^{\delta}s^{\gamma-q}\\
&\qquad +\bar{k}_0\varepsilon^{\delta}\left(s^{\nu+\bar{\omega}-q_1-q}+\varepsilon\hat{h}(\nu+\bar{\omega}-q_1)s^{*\nu+\bar{\omega}-q_1-1}s^{-2q}\right)\\
&\qquad +k_1^2\varepsilon^{2\delta}\left(s^{\beta-2q_1-q}+\varepsilon\hat{h}(\beta-2q_1)s^{*\beta-2q_1-1}s^{-2q}\right)\\
&\qquad +\varepsilon\left(s^{\alpha-1-q}+\varepsilon s^{*\alpha-2}s^{-2q}\right)\Big],\\
|\bar{v}(s)| &\leqq M\Big[e^{-\mu(s-s^*)/\varepsilon}\bar{c}_0\varepsilon^{\bar{\lambda}}+\varepsilon+k_0\varepsilon^{\delta}+k_1\varepsilon^{\delta}s^{\bar{\alpha}-q_1}\\
&\qquad +k_1^2\varepsilon^{2\delta}\left(s^{\alpha-2q_1}+\varepsilon\hat{h}(\alpha-2q_1)s^{*\alpha-2q_1-1}\right)\\
&\qquad +\bar{k}_0^2\varepsilon^{2\delta}\left(s^{2\bar{\omega}-2q_1}+\varepsilon\hat{h}(\bar{\omega}-q_1)s^{*2\bar{\omega}-2q_1-1}\right)+\varepsilon\left(s^{\bar{\beta}}+\varepsilon\hat{h}(\bar{\beta})s^{*\bar{\beta}-1}\right)\Big]
\end{aligned}
\tag{76}
$$

for $s\in[s^*,m_+)$, where M is a positive constant depending on all constants appearing in (63), and on s^1 (but not on $\hat{s}^1$),

$$
\hat{h}(z):=\begin{cases}0, & z\geqq 0,\\ -z, & z<0.\end{cases}
$$

We want to show that

$$
\begin{aligned}
|u(s)| &\leqq \frac{r}{2},\\
|v_1(s)| &\leqq \frac{r_1}{2} \qquad \text{for } s\in[s^*,m_+).\\
|\bar{v}(s)| &\leqq \frac{\bar{r}}{2}
\end{aligned}
\tag{77}
$$

For that, we have to get rid of the two exponential terms in (76). This can be done by applying Lemma 3 for $\sigma=s^*$, $\rho=q_1$ and $\rho=q_1-\bar{\omega}$, respectively, and yields the following two estimates

$$
\begin{aligned}
e^{-\hat{k}(s^{\hat{q}}-s^{*\hat{q}})/\varepsilon}c_1\varepsilon^{\lambda_1} &\leqq c_1k^{*q_1}\varepsilon^{\lambda_1+q_1q^*}s^{-q_1},\\
e^{-\mu(s-s^*)/\varepsilon}\bar{c}_0\varepsilon^{\bar{\lambda}} &\leqq \bar{c}_0k^{*(q_1-\bar{\omega})}\varepsilon^{\bar{\lambda}+(q_1-\bar{\omega})q^*}s^{\bar{\omega}-q_1},
\end{aligned}
\tag{78}
$$

provided

$$
q^*\leqq\frac{1}{1+q} \quad\text{and}\quad k^*\geqq\max\left(\left(\frac{q_1}{k}\right)^{1/(1+q)},\ \frac{q_1-\bar{\omega}}{\mu}\right)
\tag{79}
$$

holds.

It can easily be seen, by taking into account the assertions of Lemma 1, that if

$$
q_1\leqq\min(\bar{\alpha},2q), \qquad q\leqq q_1+\gamma \quad\text{and}\quad q\leqq\bar{\omega}+\nu
\tag{80}
$$

then, for $\hat{s}^1$ and ε sufficiently small, (77) holds under the following conditions concerning the constants involved

$$
\begin{aligned}
&M(c_0+1)\leqq\frac{k_0}{2},\\
&M\big(1+c_1+k_0+\bar{k}_0+6\big)\leqq\frac{k_1}{2},\\
&M(1+\bar{c}_0+k_0+8)\leqq\frac{\bar{k}_0}{2},
\end{aligned}
\tag{81}
$$

and

$$
\begin{aligned}
&q^*:=\frac{1}{1+2q-\alpha-\beta},\qquad \delta:=(q_1+q-\beta)q^*\\
&\beta\leqq\bar{\omega}<\bar{\alpha},\\
&\lambda\geqq\delta,\quad \lambda_1\geqq(q-\beta)q^*,\quad \bar{\lambda}\geqq(\bar{\omega}+q-\beta)q^*
\end{aligned}
\tag{82}
$$

as well as

$$
\begin{aligned}
&k^*:=\max\left(1,k_1^{2/(q_1+q-\beta)},\ k_1^2,\ \bar{k}_0^2,\ \left(\frac{q_1}{k}\right)^{1/(1+q)},\ \frac{q_1-\bar{\omega}}{\mu}\right)\\
&c_1\leqq k^{*-q_1},\ \bar{c}_0\leqq k^{*\bar{\omega}-q_1}\quad\text{(only if } q_1>0 \text{ or } \bar{\omega}<q_1\text{, respectively)}.
\end{aligned}
\tag{83}
$$

It is obvious that (81) can be satisfied by choosing k_0 first (such that the first inequality holds), $\bar{k}_0$ second and finally k_1 large enough.

We have excluded $\bar{\omega}=\bar{\alpha}$ in (82). In this case everything holds true, too, if $q<\bar{\alpha}+\nu$. We only get slightly different inequalities (81), namely $\bar{k}_0$ in the second inequality has to be replaced by 1 and k_1 has to be added to the expression in parentheses of the third inequality. And the only effect is that k_1, instead of $\bar{k}_0$, has to be chosen second after k_0, in order to satisfy the three inequalities.

Having shown (77) the proof of Theorem 3, as far as the case $\alpha<1$ is concerned, is completed by applying the Global Existence Theorem for ode's; and by taking ε_1 sufficiently small and choosing c as the maximum of k_0, k_1, $\bar{k}_0$ and k^*.

(b) The case $\alpha\geqq 1$ is formally completely analogous to the case $\alpha<1$. Since $\beta=\bar{\beta}=\beta_1=0$ the last term in the right-hand side of the v_1-component of (76) as well as the last term in the right-hand side of the $\bar{v}$-component can be dropped. Moreover, α and $\bar{\alpha}$ have to be replaced by 1 (hence $\bar{\omega}=\bar{\alpha}$ is not possible), and we know that $\gamma\geqq 1$ and $\nu\geqq 1$ in this case. The rest is identical to part (a). □

Acknowledgment. The author wishes to thank Professor R. E. O'Malley, Jr. for the invitation to visit the Mathematical Sciences Department of Rensselaer Polytechnic Institute, Troy, New York, and for providing such a good working atmosphere during this year.

SAUTS DES SOLUTIONS DES ÉQUATIONS $\varepsilon\ddot{x}=f(t,x,\dot{x})$*

FRANCINE DIENER†

Abstract. One of the main difficulties in the study of the equations $\varepsilon\ddot{x}=f(t,x,\dot{x})$ for small ε is created by the existence of parts of solutions, called "jumps" for which the velocity is large. We give here precise definitions of such jumps, their extremities, and their thickness, and we show that, for most equations of the type considered, it is easy to compute, up to an infinitesimal, the position of jumps, extremities and thickness for each solution. Our methods use both nonstandard analysis and a geometrical approach consisting of, among other things, observing solutions in some convenient planes, (plans d'observabilité) of the phase space.

Nous proposons ci-dessous l'étude des sauts des solutions des équations différentielles du type

$$\text{(I)} \qquad \varepsilon\ddot{x}=f(t,x,\dot{x}), \qquad \varepsilon \text{ infinitesimal,}^{1} \text{ positif,}$$

c'est-à-dire l'étude des portions de solutions parcourues à vitesse grande (*). On appelle souvent ces sauts des "couches" limites, libres, ou intérieures. On sait que la présence de sauts est liée à la petitesse de ε et qu'elle constitue l'une des principales difficultés dans l'étude du comportement des solutions de ces équations.

Nous montrons que, pour une classe étendue d'équations de ce type, on peut, moyennant un choix convenable d'échelle de vitesse, décrire simultanément les sauts de *toutes* les solutions d'une équation donnée, calculer leur équation à un infinitésimal près, et déterminer pour chacun d'eux son extrémité en fonction de son origine, ainsi que le temps nécessaire pour le parcourir.

Les équations du type envisagé ont intéressé, au cours des trente dernières années, de nombreux auteurs qui se sont principalement attachés à prouver l'existence d'*une* solution d'un problème aux limites (et plus rarement d"un problème de conditions initiales) qui présente certains types de sauts à des instants prescrits. Des techniques plus ou moins élaborées de développements asymptotiques, faisant intervenir un changement d'échelle du temps t (là où nous utilisons un changement d'échelle de vitesse), permettent de traiter un tel problème aux limites dans les cas semi-linéaires (f ne dépend pas de $\dot{x}$) et quasi-linéaires (f est linéaire en $\dot{x}$) [24], [19], [9]. Dans les cas où f n'est pas linéaire en $\dot{x}$, les études sont beaucoup plus rares [23]. Les résultats les plus importants obtenus à ce jour sont dus à Howes [12], [11], qui à l'aide de méthodes d'inéquations différentielles, retrouve facilement et étend les résultats de ses prédécesseurs dans le cas où f est un polynôme en $\dot{x}$ de degré 0, 1, ou 2. Quelques articles proposent également d'astucieuses généralisarions à certains cas où f est "superquadratique" en $\dot{x}$ [14].

Au premier chapitre nous donnons des définitions précises des objets étudiés (sauts, leur origine, leur extrémité, leur épaisseur), définitions absentes des études précédentes et qui apparaissent très naturellement ici grâce au point de vue non

[1] Nous adoptons dans cet article le point de vue non standard qui, comme cela a été souvent développé [20], [16], présente bien des avantages dans ce contexte. Pour guider un lecteur qui ignorerait ces nouvelles "règles du jeu", nous proposons en annexe un index terminologique (auquel renvoie le symbole (*) placé après le mot concerné) comprenant les principaux résultats non standard dont nous avons besoin et, entre crochets, les équivalents anglosaxons [Robinson/Nelson] lorsque ceux-ci existent.

standard adopté. Nous précisons également la classe d'équations étudiée. On verra qu'elle est très générale et contient, en particulier, les cas usuels, semi-linéaires, quasi-linéaires, et quadratiques. Nous présentons au second chapitre la méthode employée sur un exemple simple. Enfin, nous indiquons au troisième chapitre les principaux résultats obtenus et donnons leur démonstration.

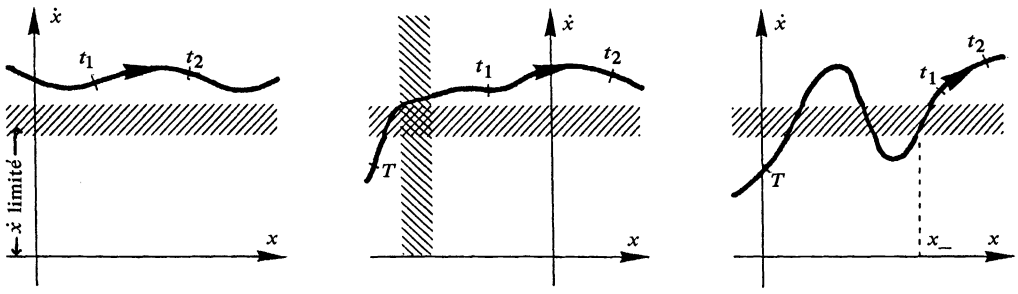
1. Quelques définitions.

Sauts d'une fonction. Soit $x: I \to \mathbb{R}$ une fonction interne (*) de classe C^1. On dit que $x(t)$ présente un *saut* sur l'intervalle $[t_1, t_2] \subset I$ si, sur cet intervalle, la vitesse $\dot{x}(t)$ est grande et si $x(t_1) \not\approx x(t_2)$ (*), avec $x(t_1)$ et $x(t_2)$ limités (*). On notera que l'intervalle $[t_1, t_2]$ est nécessairement petit (*), et que, comme la variation de x sur cet intervalle est supposée appréciable (*), les sauts apparaissent sur le graphe $(t, x(t))$ de la fonction comme des portions de ce graphe d'ombre (*) verticale, d'où leur nom. Une fonction qui présente un saut sur l'intervalle $[t_1, t_2]$ n'est pas S-continue (*) sur cet intervalle.

Comme, par continuité, $\dot{x}(t)$ ne peut changer de signe sans devenir limitée, tout saut est soit croissant, soit décroissant. Sauf mention contraire, on se bornera désormais au cas des sauts croissants, celui des sauts décroissants s'en déduisant immédiatement.

Pour t_0 réel standard (*), on dit que la fonction x présente un saut à l'instant t_0 s'il existe un intervalle $[t_1, t_2] \subset I$ contenu dans le halo de t_0 (*) sur lequel x présente un saut. On notera que $\dot{x}$ n'est pas nécessairement grand, ni même défini au point t_0.

Origine et extrémité d'un saut. Si $x(t)$ est une fonction présentant un saut sur l'intervalle $[t_1, t_2]$, on peut, dans certains cas, définir l'origine de ce saut; on peut, biensûr, procéder de manière analogue pour définir l'extrémité d'un saut. Trois cas sont à envisager (Fig. 1):



Saut sans origine *Saut d'origine $-\infty$* *Saut d'origine x_-*

FIG. 1

1) Ou bien, pour tout $t \in I$, si $t \leqq t_1$, alors $\dot{x}(t)$ est grand. On dit que *le saut sur* $[t_1, t_2]$ *est sans origine sur* I.

2) Ou bien il existe $T \in I$, $T < t_1$, tel que $\dot{x}(T)$ est limité, mais pour tout $t \in [T, t_1]$, si $x(t)$ est limité alors $\dot{x}(t)$ est grand. On dit que *le saut sur* $[t_1, t_2]$ *a son origine en* $x = -\infty$ (ou $+\infty$ dans le cas d'une fonction décroissante). On notera que ceci ne signifie pas que x tend vers $-\infty$, mais seulement que x "n'arrête pas de sauter" avant d'atteindre (à reculons) des réels grands négatifs.

3) Ou bien il existe $T \in I$, $T < t_1$, tel que $x(T)$ et $\dot{x}(T)$ sont limités, et $\dot{x}(t)$ est positif pour tout $t \in [T, t_2]$; x est donc croissante sur cet intervalle. Dans ce cas on souhaite définir l'*origine du saut sur* $[t_1, t_2]$ comme *le standard* (x_-) *tel que, pour tout* $t \in [T, t_1]$, *si* $x(t) \gg x_-$ (*), *alors* $\dot{x}(t)$ *est grand, et au contraire, si* $x(t) \ll x_-$, *alors il*

existe $\tau \in [t, t_1]$ *tel que* $\dot{x}(\tau)$ *est limité.* Notons que, comme les notions de "grand" et "limité" sont externes, il serait illusoire d'espérer pouvoir remplacer les "doubles chevrons" $\gg$ ou $\ll$ par de simples inégalités (internes) $>$ ou $<$.

Pour établir l'existence de x_-, on procède de la manière suivante: considérons tout d'abord la coupure externe (C_-, C_+) de $\mathbb{R}$ définie par $C_- = \{\xi \in \mathbb{R}$, tels qu'il existe $\tau \in [T, t_1]$, avec $\dot{x}(\tau)$ limité et $x(\tau) \geqq \xi\}$ et $C_+ = \mathbb{R} \setminus C_-$.

Remarquons que $x(T) \in C_-$, $x(t_1) \in C_+$, et $x(T)$ ainsi que $x(t_1)$ sont limités. On pose alors $S_- = {}^S C_- =$ standardisé $(*)$ de C_-, c'est à dire l'unique sous-ensemble standard de $\mathbb{R}$ ayant les mêmes éléments standards que C_-; de façon analogue, on pose $S_+ = {}^S C_+$. A présent, comme tout élément de C_+ domine tout élément de C_-, c'est en particulier vrai pour tout élément standard: ceci montre que tout élément standard de S_+ domine tout élément standard de S_-, d'où, par transfert, S_+ domine S_-. On démontre de même que (S_+, S_-) est une partition de $\mathbb{R}$. Comme ${}^0x(T) - 1 \in S_-$, $S_- \neq \varnothing$; et comme ${}^0x(t_1) + 1 \in S_+$, $S_+ \neq \varnothing$; (S_-, S_+) constitute donc une coupure standard de $\mathbb{R}$: elle détermine un unique standard x_-.

Vérifions que le standard x_- a bien la propriété souhaitée. Soit $t \in [T, t_1]$ tel que $x(t) \ll x_-$. Comme x est croissante, on a par ailleurs que $x(T) \leqq x(t) \leqq x(t_1)$; $x(t)$ est donc limité; soit $x_0 = {}^0x(t)$. Par hypothèse $x_0 < x_-$; donc $(x_0 + x_-)/2 \in S_-$, et comme il est standard, $(x_0 + x_-)/2 \in C_-$. Il existe donc $\tau \in [T, t_1]$ tel que $\dot{x}(\tau)$ est limité et $(x_0 + x_-)/2 \leqq x(\tau)$. A présent $x(t) \simeq x_0 \ll (x_0 + x_-)/2 \leqq x(\tau)$. D'où $x(t) < x(\tau)$; comme x est croissante, ceci montre que $\tau \in [t, t_1]$. On montre tout aussi facilement que pour $t \in [T, t_1]$, so $x(t) \gg x_-$ alors $\dot{x}(t)$ est grand. CQFD

Notons que d'après le principe de Fehrele $(*)$, non seulement les $x(t) \gg x_-$ sont tels que $\dot{x}(t)$ est grand, mais il existe $t_- \in [T, t_1]$ tel que $x(t_-) \simeq x_-$, et que $\dot{x}(t)$ est grand pour tout $t \geqq t_-$ (inférieur à t_2). On ne peut espérer un résultat analogue pour les $x(t) \ll x_-$, comme le montre l'exemple de la Fig. 2.

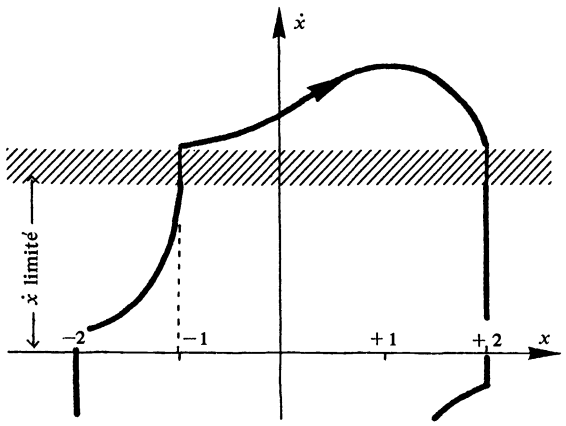


FIG. 2. *La solution périodique de l'équation de Van der Pol* $\varepsilon\ddot{x} + (x^2 - 1)\dot{x} + x = 0$ *présente un saut d'origine* -1 *et d'extrémité* 2. *La vitesse est limitée tant que* $x(t) \ll -1$ *et grande dès que* $x(t) \simeq -1$.

Si l'on considère cette fois le problème de l'extrémité d'un saut, on sera amené à distinguer comme ci-dessus, parmi les sauts (croissants), ceux qui n'ont pas d'extrémité, ceux qui ont $+\infty$ pour extrémité, et ceux qui ont une extrémité x_+ ayant la propriété analogue de celle déterminant l'origine x_- du saut. Lorsqu'un saut de x possède à la fois une origine et une extrémite non infinie, on dira qu'il est *borné*. A l'inverse, si l'une ou l'autre est infinie, ou n'existe pas, on dira qu'il est *non borné*.

Epaisseur d'un saut. Outre l'origine et l'extrémité, une autre notion est utile pour la caractérisation d'un saut: c'est son "épaisseur", qui indique, grosso modo, le temps nécessaire pour accomplir le saut. Voici la définition que nous adopterons [3], généralisant celle de [16].

Nous supposerons systématiquement que la fonction $x: I \to \mathbb{R}$ considérée est monotone et qu'elle présente un saut à l'instant t_0 ayant au moins une extrémité finie. Nous supposerons en outre que ce saut est croissant: on déduit facilement la définition correspondante dans le cas d'un saut décroissant.

Considérons tout d'abord le cas d'un saut borné, d'origine x_- et d'extrémité x_+. On appelle *épaisseur du saut* l'ensemble

$$\mathscr{E} = \{ t \in I, \text{ tels que } x_- \ll x(t) \ll x_+ \}.$$

On vérifie facilement qu'il s'agit d'un ensemble strictement externe (*), et plus précisement d'une galaxie (*) contenue dans le halo de t_0 (voir exemples ci-dessous). Il apparait donc qu'une bonne connaissance des galaxies de $\mathbb{R}$ (voir l'annexe à ce sujet) sera utile pour étudier les épaisseurs de sauts.

Considérons à présent le cas d'un saut non borné, et supposons qu'il n'a pas d'origine ou qu'il a $-\infty$ pour origine. Soit x_+ son extrémité. L'épaisseur du saut sera alors l'ensemble

$$\mathscr{E} = \{ t \in I, \text{ tels que } x(t) \ll x_+ \}.$$

C'est également une galaxie, mais elle n'est pas nécessairement petite; elle contient tout un segment initial de I.

Cas des solutions des équations (I). Soit f une fonction interne, définie sur $\mathbb{R}^3$ et suffisamment régulière pour que l'équation différentielle

$$\text{(I)} \qquad \varepsilon \ddot{x} = f(t, x, \dot{x})$$

possède la propriété d'existence locale et d'unicité des solutions pour $\varepsilon > 0$. De n'imposer à f que le fait d'être interne permet de considérer non seulement les cas où f est standard, mais aussi les cas où $f = F(t, x, \dot{x}, \varepsilon)$, et plus généralement les cas où $f(t, x, \dot{x}) = F(t, x, \dot{x}, a)$, où F est standard et a est un paramètre pouvant prendre des valeurs non standard.

Considérons le champ lent-rapide (*) associé à l'équation (I) dans l'espace des phases $(t, x, \dot{x} = v)$:

$$\text{(II)} \qquad \begin{aligned} \dot{t} &= 1, \\ \dot{x} &= v, \\ \varepsilon \dot{v} &= f(t, x, v). \end{aligned}$$

La trajectoire $(t, x(t), v(t))$ de (II) correspondant à une solution $x(t)$ de l'équation (I) qui présente un saut sur l'intervalle $[t_1, t_2]$ reste entièrement contenue, pendant ce laps de temps, dans l'une des parties H^+ ou H^- de $\mathbb{R}^3$ où v est grand (H^+ si le saut est croissant, H^- s'il est décroissant). Elle reste également proche, durant ce laps de temps, du plan vertical d'équation $t = t_0$, où $t_0 = {}^0t_1$. Notons que les parties H^+, H^-, et le complémentaire de $H^+ \cup H^-$ noté G, sont strictement externes. Lorsqu'une trajectoire de (II), correspondant à une solution présentant un saut est de coordonnées limitées en un instant T antérieur au saut, il découle de ce qui précède que le saut possède une

origine x_-. Nous dirons que "*la trajectoire sort de la région G* (des vitesses limitées) *avec une abscisse* x_-". De même, si le saut a une extrémité x_+, nous dirons que "*la trajectoire rentre dans G avec une abscisse* x_+"

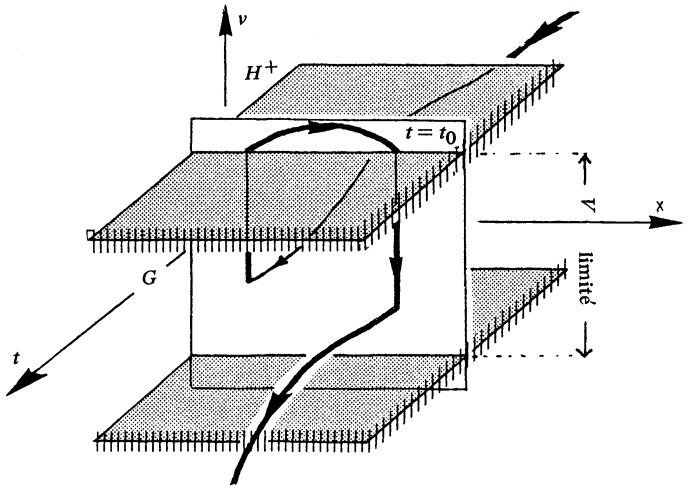

FIG. 3. *Trajectoire du champ* (II) *associé à une solution de* (I) *présentant un saut croissant à l'instant* t_0.

Voici quelques exemples de sauts de solutions et leur épaisseur:

1°) La solution $x(t)=th(t/\varepsilon)$ de l'équation $\varepsilon\ddot{x}=-2x\dot{x}$ présente en $t_0=0$ un saut d'origine $x_-=-1$ et d'extrémité $x_+=1$. Son épaisseur est l'ensemble des réels pouvant s'écrire $t=\varepsilon s$, où s est limité, ensemble qu'on appelle la $\varepsilon-$galaxie de 0(*).

2°) La solution $x(t)=\sqrt{\varepsilon}/(t+\sqrt{\varepsilon})$, $t>-\sqrt{\varepsilon}$, de l'équation $\varepsilon\ddot{x}=2x^3$ présente un saut non borné pour $t_0=0$, d'extrémité $x_+=0$. Son épaisseur est la réunion de $]-\sqrt{\varepsilon}, 0]$ et de la moitié positive de la galaxie des réels pouvant s'écrire $t=\sqrt{\varepsilon}\,s$, où s est limité, encore appelée $\sqrt{\varepsilon}$ −galaxie de 0.

Dans ces deux exemples, comme dans bon nombre d'exemples classiques, les épaisseurs sont réunion d'une partie interne (éventuellement vide) et d'une galaxie très simple (la ε on $\sqrt{\varepsilon}$ −galaxie par example) dite galaxie linéaire (*). Cela se traduit en pratique par le fait qu'il est possible "d'étaler" ces sauts au moyen d'une homothétie. Ainsi les changements de temps $s=t/\varepsilon$ et $s=t/\sqrt{\varepsilon}$ transforment respectivement les examples précédents en $th(s)$ et $1/(s+1)$, fonctions qui ne présentent plus de saut. Cette propriété, que possèdent beaucoup de sauts, de pouvoir s'étaler au moyen d'un changement de temps linéaire $s=(t-t_1)/\varphi(\varepsilon)$, est en fait, à la base de plusieurs méthodes d'étude des sauts, en particulier la méthode des "développements asymptotiques recollés". Cependant, il existe également de nombreuses équations (I) dont les solutions présentent des sauts n'ayant pas cette propriété. En termes d'épaisseur, cela se traduit par le fait que $\mathscr{E}$ s'exprime à l'aide de galaxies non linéaires (*). C'est l'existence de sauts d'épaisseur non linéaire qui conduit à dépasser l'idée un peu trop naïve de caractériser l'épaisseur par un *nombre* ou "ordre de grandeur" (ε ou $\sqrt{\varepsilon}$ par exemple), et de lui substituer un *ensemble* $\mathscr{E}$ strictement externe. Voici un exemple de saut d'épaisseur non linéaire.

3°) La solution $x(t)=-\varepsilon\log(t+e^{-1/\varepsilon})$, $t>-e^{-1/\varepsilon}$, de l'équation $\varepsilon\ddot{x}=\dot{x}^2$ présente un saut non borné en $t=0$, d'extrémité $x_+=0$. Un calcul simple montre que son épaisseur est la réunion de $]-e^{-1/\varepsilon}, 0]$ et de la galaxie des réels pouvant s'ecrire

$t=e^{-1/\varepsilon s}$, avec $s>0$ limité, qu'on appelle la (moitié positive de la) ε–micro-galaxie (*). On notera que cette galaxie contient par exemples les deux nombres $e^{-1/\varepsilon}$ et $e^{-1/2\varepsilon}$ qui ne sont pas du "même ordre de grandeur" puisque leur rapport n'est pas appréciable.

Type de croissance de f en ẋ. Voici à présent quelques définitions concernant le comportement de la fonction f lorsque $\dot{x}$ est grand, qui vont nous permettre de préciser quelle classe d'équations (I) nous nous proposons d'étudier. Nous nous bornerons au cas des vitesses positives, celui des vitesses négatives s'en déduisant aisément.

Soit $F(v)$ une fonction interne de classe $S^0(*)$, continûment dérivable, définie pour tout v positif grand, non décroissante, positive et non petite. Comme F est interne, il existe nécessairement v_0 standard tel que F soit définie et possède encore les propriétés ci-dessus pour tout $v\in[v_0, +\infty[$. On dira que F est le *type de croissance de f par rapport à v pour les v positifs*, s'il existe deux fonctions internes $a(t,x)$ et $r(t,x,v)$ continues et de classe S^0 telles que, pour tout t et x limités, on ait

$$f(t,x,v)=a(t,x)F(v)+r(t,x,v)$$

et

$$r(t,x,v)/F(v)\simeq 0$$

pour tout v positif grand. On appellera la fonction $a(t,x)$ la *mantisse* de f (pour les v positifs). On remarquera que si F et $\bar{F}$ sont deux types de croissance de f, il existe un réel positif R tel que pour tout v grand, $F(v)/\bar{F}(v)\simeq R$. En particulier, si F et $\bar{F}$ sont standard, elles diffèrent par une constante multiplicative pour tout v grand, donc, par le principe de Cauchy (*), pour tout $v\geqq v_0$, avec v_0 standard. Par contre le choix de F est parfaitement arbitraire sur $[0, v_0[$, v_0 standard.

On notera également que si l'on se restreint aux fonctions f et F standard, il est équivalent de supposer que f possède la fonction F comme type de croissance par rapport à v ou que, pour tout t et x limités, $f(t,x,\cdot)$ est un "0" de F et que la limite, quand v tend vers $+\infty$, de f/F existe.

Voici quelques exemples de fonctions avec ou sans type de croissance:

1°) Les cas classiques où f est quasi-linéaire ($f=a(t,x)$), semi-linéaire ($f=a(t,x)v+b(t,x)$), et quadratique ($f=a(t,x)v^2+b(t,x)v+c(t,x)$) ont pour type de croissance respectivement $F(v)=1$, $F(v)=v$, et $F(v)=v^2$, et pour mantisse les fonctions $a(t,x)$.

2°) Plus généralement, si f est un polynôme de degré n en v, ou une somme de "monômes" du type $a(t,x)v^\nu$ où ν est réel positif, le type de croissance de f par rapport à v est v^n, ou v^{ν_0}, où ν_0 est l'exposant le plus grand de v, et la mantisse est le "coefficient" de v^{ν_0}.

3°) Dans l'exemple suivant (étudié par Howes [13])

$$\varepsilon\ddot{x}=(x-t^2)^{2q+1}(1+\dot{x}^2)^{3/2},$$

le type de croissance est $F(v)=v^3$ et la mantisse $(x-t^2)^{2q+1}$.

4°) Dans l'exemple suivant (étudié par Levinson [15])

$$\varepsilon\ddot{x}=4\dot{x}/(3-\dot{x}^4)-x,$$

le type de croissance est $F(v)=1$ (-1 dans le cas des vitesses négatives) et la mantisse est $-x$ (on trouvera une étude nonstandard de cet exemple dans [22]).

5°) Dans les exemples précédents, les types de croissance sont toujours des puissances de v. On peut cependant fort bien envisager d'autres types de croissance. Ainsi, par exemple:

$$\varepsilon\ddot{x}=a(t,x)\dot{x}\log\dot{x} \quad \text{ou} \quad \varepsilon\ddot{x}=a(t,x)th\,\dot{x}\cdots.$$

6°) On construit facilement des exemples d'équations (I) pour lesquelles f n'a pas de type de croissance par rapport à $\dot{x}$ (indépendent de t et x), comme par exemple $\varepsilon\ddot{x}=\sin t\dot{x}$ ou $\varepsilon\ddot{x}=e^{x\dot{x}}$. Cependant, il ne semble pas que de telles équations aient fait l'objet d'études jusqu'ici (l'auteur serait intéressée de connaître une telle étude, pour autant qu'elle existe, ou à défaut une application qui la motiverait).

Les résultats principaux de cet article concernent les équations (I) pour lesquelles f a un type de croissance par rapport à $\dot{x}$. Il convient en outre de supposer que ce type de croissance ne croit pas "trop" vite, et plus précisément, que

$$\text{(III)} \qquad \int_{v_0}^{+\infty}\frac{v\,dv}{F(v)}=+\infty.$$

Cette condition est équivalente, dans le cas des fonctions puissance, au fait que le type de croissance F est au plus quadratique ($\nu_0\leqq 2$). On notera cependant qu'il existe des fonctions "sur-quadratiques", par exemple $F(v)=v^2\log v$, qui la vérifient également. Nous posons cette hypothèse car lorsque le type de croissance de f est plus grand (par exemple $F(v)=v^3$), aucune solution de l'équation ne présente plus de saut, à l'exception éventuellement de ce qu'il est convenu d'appeler des sauts singuliers, c'est à dire des sauts tels que la trajectoire de (II) associée, soit contenue dans le halo de la surface d'équation $f(t,x,v)=0$ (la démonstration de ce fait, ainsi que l'étude des sauts singuliers fait l'objet d'une étude séparée [7]).

2. Un exemple. Dans ce chapitre nous présentons sur un exemple simple la plupart des résultats qui seront démontrés dans le cas général au chapitre suivant. Nous avons choisi pour cela la famille d'équations

$$\text{(IV)} \qquad \varepsilon\ddot{x}=x\dot{x}^{[s]}, \qquad 0<s\leqq 2$$

où $\dot{x}^{[s]}$ est défini par $\dot{x}^{[s]}=|\dot{x}|^{s-1}\dot{x}$.

Outre sa grande simplicité, cette famille présente l'avantage suivant: les portions de solutions ne contenant pas de saut étant toutes presque-constantes (*), les seules portions non triviales des solutions sont des sauts, qui précisément nous intéressent ici.

L'équation correspondant à $s=1$ (qui est intégrable explicitement) est souvent utilisée pour illustrer des sauts de solutions, en particulier dans le cadre des problèmes aux limites [19], [12], [16]. Comme le point de vue adopté ici permet de traiter sans plus de difficulté les cas où $0<s\leqq 2$, nous nous plaçons d'emblée dans ce cadre un peu plus général; ceci nous permet en outre de mettre en évidence, dans un cas particulier, le lien qui existe entre le type de croissance de l'équation, ici $F(v)=v^{[s]}$, et les propriétés des sauts.

Comportement des solutions à vitesse limitée. Ce n'est pas notre propos ici d'étudier les propriétés des solutions lorsque leur vitesse est limitée; cependant, il sera plus facile de comprendre le rôle joué par les sauts si l'on connait le comportement global des solutions et donc, en particulier, leur comportement à vitesse limitée.

Considérons le champ lent-rapide associé à (IV).

$$\text{(V)} \qquad \begin{aligned} &\dot{t}=1,\\ &\dot{x}=v,\\ &\varepsilon\dot{v}=xv^{[s]}, \qquad 0<s\leqq 2. \end{aligned}$$

Bien que ce champ de vecteurs ne vérifie pas, aux points $v=0$, la condition de Lipschitz envlorsque $s<1$, on notera cependant que, par un tel point (distinct de $(t,0,0)$), il passe une unique trajectoire, qui est le graphe d'une solution de l'équation

$$\frac{dx}{dv}=\frac{\varepsilon v}{xv^{[s]}}$$

qui vérifie, elle, la condition de Lipschitz en x. On a donc unicité des solutions de ce champ.

Du fait que ε est supposé petit, il est facile de décrire, à un infinitésimal près, le comportement des trajectoires du champ dans la région G de l'espace où v est limité (Fig. 4). Par les raisonnements usuels de champs lents-rapides (voir par exemple [16]), on montre que, le long d'une trajectoire, aucune variation appréciable de x n'est possible tant que v (et x) sont limités.

Notons également que le comportement des trajectoires du champ (V) est le même quelque soit $s\in]0,2]$.

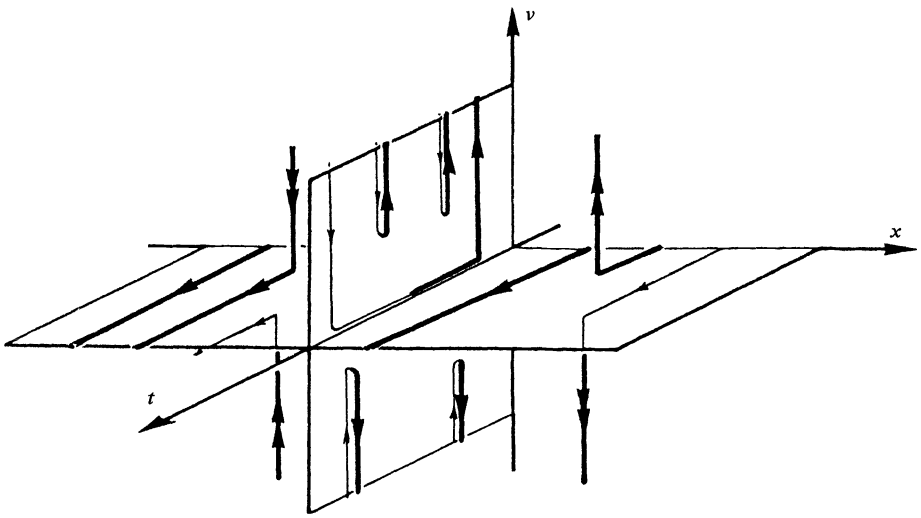

FIG. 4. *Les trajectoires du champ associé à l'équation* $\varepsilon\ddot{x}=x\dot{x}^{[s]}$ *dans l'espace des phases sont presque verticales tant qu'elles restent hors des halos des plans d'équation* $v=0$ *et* $x=0$. *Dans le halo du premier, elles sont proches de droites "horizontales", x constant, et dans le halo du second, elles sont proches de "demi-droites verticales", t constant, ou de "U".*

Comportement des solutions à vitesse grande. En dehors de la région G, c'est à dire dans l'une des régions H^+ ou H^- des points d'ordonnée v grande, positive ou négatives respectivement, la troisième composante du champ (V) cesse d'être grande par rapport aux autres; les trajectoires n'ont plus le comportement caricatural, typique des champs

lents-rapides, évoqué ci-dessus. Une étude particulière est nécessaire. Il n'est pas facile de la mener dans l'espace des phase: les portions de trajectoires sont "trop éloignée". Afin de les "rapprocher", on utilise un macroscope (*), qui est, ici, un changement d'échelle (*) de vitesse. Ce macroscope devra évidement être d'autant plus puissant que la vitesse sur les trajectoires considérées est grande. Cette vitesse dépend, comme on l'imagine, du type de croissance de l'équation et donc, ici, de s. On verra au paragraphe suivant qu'il convient de choisir, lorsque $F(v)=v^{[s]}$, le macroscope suivant:

$$\text{(VI)} \qquad v=\begin{cases}(((2-s)/\varepsilon)V)^{[1/(2-s)]} & \text{si } s\neq 2,\\ \sigma\exp(\sigma V/\varepsilon) & \text{si } s=2,\end{cases}$$

où σ vaut $+1$ ou -1 selon que V est positif ou négatif. A la nouvelle échelle, le champ (V) s'écrit

$$\begin{aligned}&\dot t=1,\\ &\dot x=v,\\ &\dot V=xv \quad \text{où } v \text{ est donné par (VI).}\end{aligned}$$

Nous nous proposons de décrire, à un infinitésimal près, les portions de trajectoires de ce champ, contenues dans le région H_ε^+, image de H^+ par le macroscope, et celles contenues dans la région H_ε^-, image de H^-. Notons que H_ε^+ et H_ε^- contiennent, en particulier, tous les points qui, à cette échelle, ont une ordonnée V non petite, positive ou négative, respectivement.

On ne change pas les trajectoires, pour $V\neq 0$, en multipliant le champ précédent par la fonction nulle part nulle $1/v$ (où $v=v(V)$ est défini par (VI)). cette constatation élémentaire révèle le point de vue "trajectorien" (voir par example [10]) adopté ici, qui fait l'originalité de notre méthode. Il consiste à envisager les trajectoires plutôt comme des objets géométriques de $\mathbb{R}^3$ que comme des graphes de fonctions solutions. De ce fait, le paramétrage étant indifferent, on peut le changer de façon que les sauts, initialement parcourus à vitesse grande, le soit alors à vitesse limitee. La quantité $1/v$ est petite sur H^+ et H^-. Le champ $\mathscr{C}$ ainsi obtenu est donc équivalent, sur $H_\varepsilon^+\cup H_\varepsilon^-$, à un champ $\mathscr{C}_0$ standard et intégrable

$$\mathscr{C}\ \begin{cases}t'=1/v,\\ x'=1,\\ V'=x,\end{cases}\quad\simeq\quad \mathscr{C}_0\ \begin{cases}t'=0,\\ x'=1,\\ V'=x.\end{cases}$$

Les trajectoires de $\mathscr{C}_0$ (Fig. 5) sont des paraboles d'équation

$$t=t_0,\quad V=x^2/2+V_0,\quad t_0,V_0\in\mathbb{R}.$$

On notera que $\mathscr{C}_0$ est indépendant de s. En d'autres termes, si le macroscope dépend, lui, de s, ce que l'on "voit" sous le macroscope, au contraire, est identique, à un petit près, pour toutes les valeurs de s considérées.

Sauts des solutions des équations (IV). Ceci va permettre d'étudier les sauts des solutions des équations (IV). Soit $x(t)$ une solution de (IV) présentant un saut sur $[t_1,t_2]$. La trajectoire correspondante dans l'espace des phase reste contenue dans H (si le saut est croissant) ou H^- (sinon); sous le macroscope, cette trajectoire est le graphe

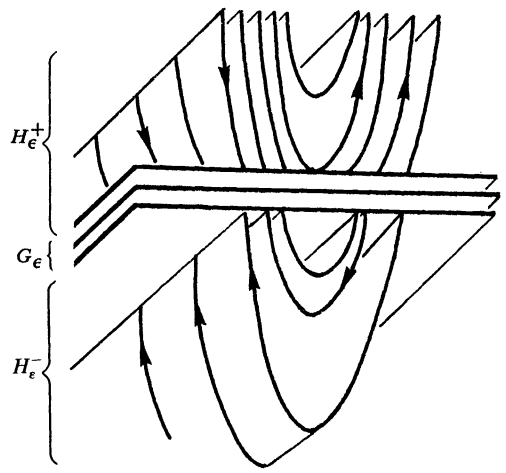

FIG. 5. *Vues sous le macroscope* (VI), *les trajectoires du champ associé à l'équation* $\varepsilon\ddot{x} = x\dot{x}^{[s]}$ *restent proches des paraboles d'équation* $V = x^2/2 + C_0$ *dans les deux halos* H_ε^+ *et* H_ε^-. *Leur ombre est indépendante de* $s \in]0, 2]$.

d'une fonction $(t(x), V(x))$, car $x' = 1$, qui, si $V(x(t_1))$ est limité, vérifie pour tout s, les presque-équations (*)

$$t(x) \simeq t_0 \quad \text{et} \quad V(x) \simeq x^2/2 + V_0$$

où $t_0 = {}^0t_1$ et la constante V_0 est telle que la parabole $V = x^2/2 + V_0$ passe par le point de coordonnées ${}^0(x(t_1), V(x(t_1)))$.

En revenant à l'échelle initiale, tout saut croissant d'une équation (IV) vérifie donc, pour $t \in [t_1, t_2]$, la presque-équation

ou

$$\begin{aligned} &(\varepsilon/(2-s))\dot{x}(t)^{[2-s]} \simeq x^2(t)/2 + V_0, && \text{si } s \neq 2, \\ &\varepsilon \log \dot{x}(t) \simeq x^2(t)/2 + V_0, && \text{si } s = 2, \end{aligned}$$

appelée *équation des sauts*, où V_0 est une constante qui dépend du saut considéré.

On peut également préciser les origines et extrémités des sauts. Pour cela, il convient de s'assurer que les courbes qui sont les ombres des trajectoires dans G (Fig. 4) et celles qui sont les ombres des trajectoires hors de G vues sous le macroscope (Fig. 5), se recollent bien les unes aux autres de la manière qu'on imagine. Plus précisément, il s'agit de vérifier qu'une trajectoire qui atteint des vitesses grandes en longeant (*) une verticale $t = t_0$ et $x = x_-$ vérifiera l'équation des sauts ci-dessus avec $V_0 = -x_-^2/2$, c'est à dire tel que $V(x_-) = 0$; et de même, que celle qui reprend des vitesses limitées en longeant une verticale $t = t_0$, $x = x_+$, la vérifiera pour $V_0 = -x_+^2/2$, c'est à dire que $V(x_+) = 0$. Ces propriétés de recollement sont, comme nous le verrons au chapitre 3, des conséquences du lemme de l'ombre courte (*).

On en déduit facilement les deux résultats suivants:

1°) Tout saut décroissant d'origine ou d'extrémité finie est également d'extrémité ou d'origine finie respectivement, et ces abscisses x_- et x_+ sont reliées par le relation *sortie-entrée* $x_-^2/2 = x_+^2/2$, c'est à dire

$$x_+ = -x_-.$$

2°) Aucun saut croissant n'est borné. Il est soit d'origine $-\infty$ et d'extrémité $x_- \leqq 0$, soit d'origine $x_+ \geqq 0$ et d'extrémité $+\infty$.

On peut également déduire de l'étude précédente l'épaisseur des sauts. Contrairement à l'équation des sauts ou à la relation sortie-entrée, l'épaisseur, elle, dépend de s. Calculons à titre d'exemple cette épaisseur $\mathscr{E}$ dans le cas $s=1$, pour un saut borné (donc décroissant) d'origine x_- et d'extrémité x_+. Par définition, lorsque t est élément de $\mathscr{E}$, $\dot{x}(t)$ est grande et donc $x(t)$ vérifie l'équation des sauts

$$\varepsilon\dot{x}(t) \simeq \left(x^2(t) - x_-^2\right)/2$$

On en déduit, en vertu de la définition de $\mathscr{E}$, que t est un élément de $\mathscr{E}$ si et seulement si $\varepsilon\dot{x}(t) \not\simeq 0$ (c'est à dire qu'au cours du saut, la vitesse est d'ordre $1/\varepsilon$). Comme

$$t = t_1 + \int_{x(t_1)}^{x(t)} \frac{dx}{\dot{x}(t)} = t_1 + \varepsilon \int_{x(t_1)}^{x(t)} \frac{dx}{\varepsilon\dot{x}(t)},$$

t appartient à $\mathscr{E}$ si et seulement si $t = t_1 + \tau$ avec τ/ε limité. En d'autres termes, $\mathscr{E}$ est la ε – galaxie de t_1.

Dans le cas d'un saut non borné dont l'une des extrémités est finie, un raisonnement semblable conduit, toujours pour $s=1$, à la conclusion que $\mathscr{E}$ est la réunion de la galaxie précédente et de la demi-droite $]-\infty, t_1]$, ou $[t_1, +\infty[$. Notons que l'épaisseur d'un saut borné (respectivement non borné) d'extrémité finie est identique pour tous les sauts d'une même équation. On verra au chapitre suivant que cette propriété est générale et que seul le type de croissance de l'équation détermine l'épaisseur des sauts.

Problèmes aux limites. Lutz et Sari ont indiqué [17] comment tirer profit des méthodes non standard pour l'étude de problèmes aux limites concernant certaines équations (I). Nous nous proposons d'examiner, à propos de l'exemple des équations (IV), ce que peut apporter une bonne connaissance des sauts des solutions pour la résolution d'un problème aux limites.

Considérons le problème aux limites suivant associé à (IV):

$$\text{(VII)} \qquad \begin{aligned} &\varepsilon\ddot{x} = x\dot{x}^{[s]}, \quad 1 \leqq s \leqq 2, \\ &x(-1) = a, \quad x(+1) = b. \end{aligned}$$

Traduit en termes de trajectoires de l'espace des phases, ce problème consiste à trouver une trajectoire du champ associé qui joint un point de la verticale d'équation $t=-1$, $x=a$, à un point de la verticale d'équation $t=+1$, $x=b$. La détermination du comportement selon les valeurs de a et b d'une solution de (VII), si elle existe, découle facilement des quelques observations suivantes.

1°) Les solutions de (IV) sont toutes, à l'exception des solutions constantes $x=x_0$, soit croissantes, soit décroissantes (i.e. les deux demi-espaces $v>0$ et $v<0$ sont invariants pour le champ (V) associé à (IV)).

2°) Aucune variation appréciable de x n'est possible à vitesse limitée, pour x limité.

3°) A l'exception des solutions dont les trajectoires associées ont pour ombre, sous le macroscope, une parabole d'équation $V = x^2/2$ ($V_0 = 0$), aucune solution de (IV) ne peut présenter plus d'un saut, les premières présentant, quant à elles, au plus deux sauts.

La Fig. 6 indique, selon les valeurs de a et de b ces comportements nécessaires. En procèdant comme dans [16], on établit l'existence de solutions du problème aux limites

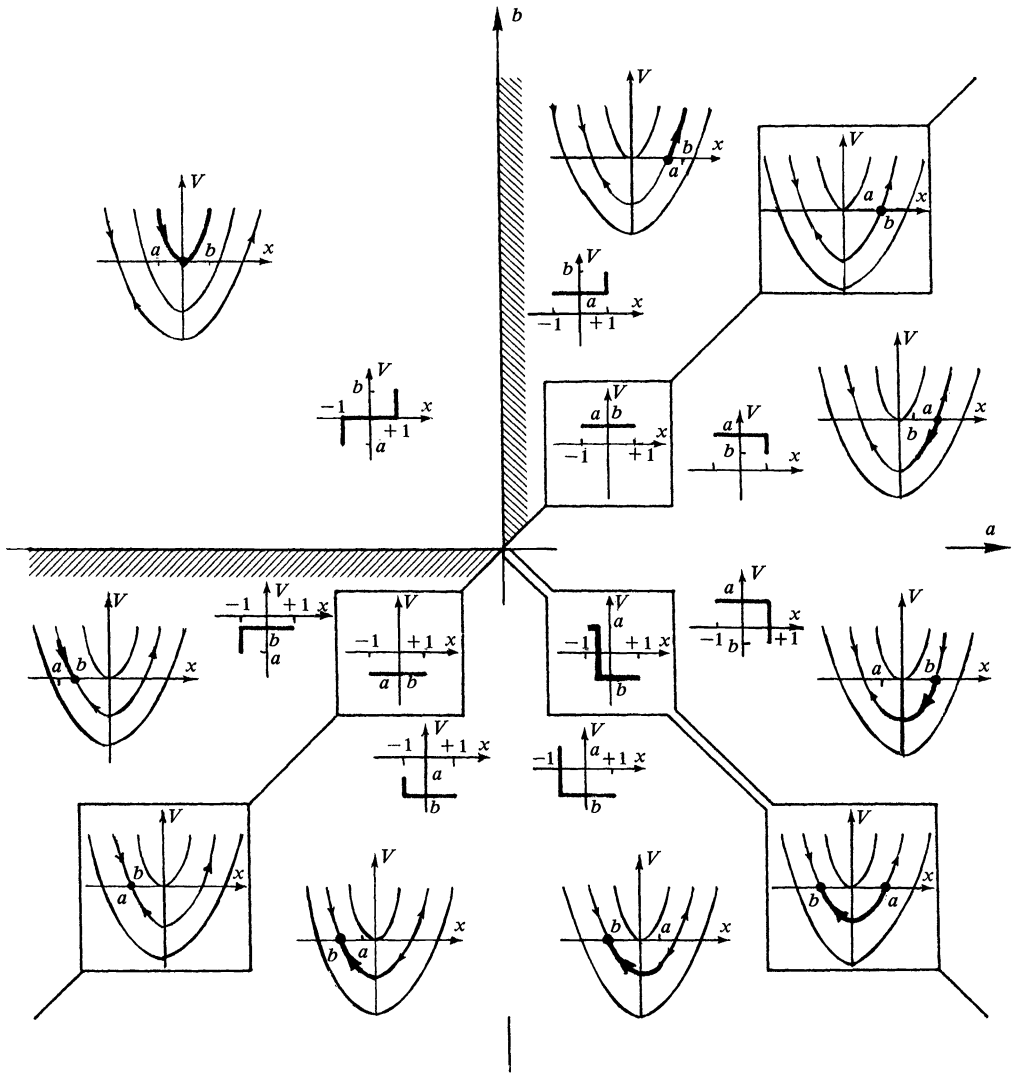

FIG. 6. *Solutions du problème aux limites* $\varepsilon\ddot{x} = x\dot{x}^{[s]}$, $x(-1) = a$, $s(+1) = b$, *selon les valeurs de a et b. Au centre, les graphes* $(t, x(t))$ *de ces solutions; à l'extérieur, les trajectoires associées* $(x, V(x))$, *vues sous le macroscope* (VI). *Du point de vu des sauts, on peut grouper ces solutions en cinq régions*:

Région 1: $a \simeq b$. *Pas de saut.*

Région 2: ${}^0b \leqq 0$, $b < -a$, $b \not\simeq \pm a$. *Un saut à l'instant* -1, *d'origine a et d'extrémité b, et d'équation* $V(t) \simeq x^2(t)/2 - b^2/2$.

Région 3: ${}^0a \geqq 0$, $b > -a$, $b \not\simeq \pm a$. *Un saut à l'instant* $+1$, *d'origine a et d'extrémité b, et d'équation* $V(t) \simeq x^2(t)/2 - a^2/2$.

Région 4: $a \simeq b$, $a > 0$. *Un saut à un instant* $t_0 \in [-1, +1]$ *d'origine a et d'extrémité b, et d'équation* $V(t) \simeq x^2(t)/2 - a^2/2$. *Si* $a = b$, $t_0 = 0$.

Région 5: ${}^0a > 0$, ${}^0b < 0$. *Un saut à l'instant* $t = -1$ *d'origine a et d'extrémité* 0 *et un saut à l'instant* $t = +1$ *d'origine* 0 *et d'extrémité b, tout deux d'équation* $V(t) \simeq x^2(t)/2$.

(VII) présentant chacun de ces comportements, comme un conséquence du théorème de la valeur intermédiaire (shooting) et du lemme de l'ombre courte. Les résultats obtenus ainsi sont connus lorsque $s = 1$. Ce qui est remarquable est qu'ils restent valables pour les autres valeurs de $s \in]0, 2]$.

Ajoutons un commentaire concernant les solutions du problème (VII) présentant une "couche libre" (région 4 de la Fig. 6). On ne trouve pas dans les études antérieures de solutions de (VII) présentant un saut "intérieur" à l'instant $t_0 \neq 0$. Toutefois, pour des raisons de continuité, on peut trouver de telles solutions en choisissant des conditions limités a et b, non toutes deux standard, mais telles que $a \simeq -b$. En termes classiques, l'équivalent de telles conditions aux limites serait obtenu en considérant a et b comme des fonctions $a(\varepsilon)$ et $b(\varepsilon)$ de ε. Il serait d'ailleurs intéressant de calculer une estimation de l'instant de saut t_0 en fonctions de a et de b (et de ε).

3. Equation des sauts. Les solutions d'une équation de type (I) se composent, en général, à la fois de portions parcourues à vitesse limitée, et de portions parcourues à vitesse grande. Leur étude comporte donc deux parties distinctes: l'une concernant les portions lentes, l'autre concernant les sauts. La première est généralement bien connue, car on dispose dans ce cas de l'équation réduite:

$$f(t,x,\dot{x})=0.$$

En effet, si la vitesse est limitée, les solutions sont "bien approchées" (à des sauts de vitesse près) par les solutions de cette équation du premier ordre, comme on peut le voir en examinant les trajectoires associées dans l'espace des phases. En d'autres termes, si la vitesse est limitée, "on peut négliger ε".

Par contre, il n'en est plus ainsi lorsque la vitesse est grande, et le problème se pose de trouver l'analogue, dans ce cas, de l'équation réduite, c'est à dire de trouver une équation, si possible facile à calculer à partir de (I), dont les solutions seraient de "bonnes approximations" des sauts. L'existence d'une telle équation fait l'objet du premier théorème, que nous nous bornons à énoncer dans le cas des sauts croissants.

THEOREME 1 (équation des sauts). *Soit $f(t,x,v)$ une fonction ayant pour type de croissance en v la fonction $F:[v_0,+\infty[\to\mathbb{R}^+$ vérifiant la condition* (III), *et pour mantisse la fonction $a(t,x)$. Soit $x(t)$ une solution croissante limitée de l'équation $\varepsilon\ddot{x}=f(t,x,\dot{x})$ présentant un saut sur l'intervalle $[t_1,t_2]$. Il existe un changement d'échelle de vitesse*

$$v=h(V/\varepsilon)$$

tel que, pour tout $t\in[t_1,t_2]$, $x(t)$ satisfait à

(i)

$$(V(x(t))=:)\,\varepsilon h^{-1}(\dot{x}(t))\simeq V_1+\int_{x(t_1)}^{x(t)}a(t_1,s)\,ds$$

où $V_1=\varepsilon h^{-1}(\dot{x}(t_1))$.

La fonction h est le difféomorphisme de classe S_0 de $[0,+\infty[$ sur $[v_0,+\infty[$ défini par

(ii) $h'=F(h)/h$ *et* $h(0)=v_0$.

Preuve. Il convient tout d'abord de s'assurer que la fonction h définie par (ii) satisfait bien aux propriétés indiquées: h est de classe S_0, car F est de classe S_0 et que $h(0)=v_0$ est limité; par hypothèse F est strictement positive, donc h est strictement croissante, et h est non bornée, car l'ordonnée d'une asymptote horizontale serait un zéro de F. Elle est prolongeable sur tout $[0,+\infty[$ en vertu du lemme suivant:

LEMME. *Soit $F:[v_0,+\infty[\to\mathbb{R}_*^+$ une fonction de classe C^1 et soit h la solution de l'équation différentielle $h'=F(h)/h$ telle que $h(0)=v_0$. Alors h est prolongeable jusqu'à $+\infty$ si et seulement si F vérifie la condition* (III).

Preuve du lemme. Notons $[0,y_0[$ l'intervalle maximal d'existence de la solution h considérée. De l'égalité $1=hh'/F(h)$, on déduit que

$$y=\int_0^y \frac{h(s)h'(s)}{F(h(s))}ds$$

pour tout $y\in[0,y_0[$, ou encore, en posant $u=h(s)$,

$$y=\int_{v_0}^{h(y)} \frac{u}{F(u)}du.$$

Or y_0 est fini si et seulement si $h(y)$ tend vers l'infini quant y tend vers y_0, d'où le lemme.

La fonction h a donc bien les propriétés annoncées. Il reste à montrer que les sauts vérifient la presque-équation(i). Pour cela, on considère le champ (II) associé à l'équation dans l'espace des phases. Le macroscope $h=v(V/\varepsilon)$ transforme ce champ en

$$\begin{aligned}
&\dot{t}=1,\\
&\dot{x}=h(V/\varepsilon),\\
&\dot{V}=f(t,x,h(V/\varepsilon))/h'(V/\varepsilon).
\end{aligned}$$

Soit $x(t)$ un saut sur l'intervalle $[t_1,t_2]$ et $(t,x(t),V(t))$ la trajectoire correspondante, vue sous le macroscope. Au cours du saut, t reste équivalent à t_1 et, comme $\dot{x}=v=h(V/\varepsilon)$ ne peut s'annuler, la trajectoire est le graphe d'une fonction $x\mapsto(t(x),V(x))$ vérifiant $t(x)\simeq t_1$ et

$$V(x)\simeq V(x(t_1))+\int_{x(t_1)}^{x} \frac{f(t_1,s,h)(V(s)/\varepsilon)}{h(V(s)/\varepsilon)h'(V(s)/\varepsilon)}ds.$$

Comme, au cours du saut, la vitesse $v=h(V/\varepsilon)$ est grande, comme h vérifie l'équation (ii), et comme, par hypothèse sur f on a

$$f(t,x,v)/F(v)\simeq a(t,x)$$

pour tout v grand, on en déduit que

$$V(x)\simeq V(x(t_1))+\int_{x(t_1)}^{x} a(t_1,s)\,ds$$

d'où (i). CQFD.

Commentaires. 1) Ce théorème assure l'existence d'une fonction h qui ne dépend que du type de croissance de f par rapport à $\dot{x}$: elle porte le nom *d'ajustement*. La connaissance de h permet, en effet, de "règler" le macroscope afin de "ramener dans son champ de vision" les sauts qui initialement, dans l'espace des phases, sont trop éloignés pour pouvoir être observés. On a, par exemple, si $F(v)=1$ (cas quasi linéaire) et si on choisit $v_0=1$, $h(y)=(2y+1)^{1/2}$. Si $F(v)=v$ (cas semi linéaire) et si on choisit $v_0=1$, $h(y)=y+1$. Si $F(v)=v^2$ (cas quadratique) et si on choisit $v_0=1$, on a $h(y)=\exp y$. Enfin, si $F(v)=v^2\log v$ et si on choisit $v_0=e$, on a $h(y)=\exp(\exp y)$. On voit sur ces exemples que le choix de v_0 est largement arbitraire, et donc aussi celui de h. De plus, pour les deux premiers examples, il semblerait à priori plus naturel de choisir le macroscope $v=h(V/\varepsilon)$ tel que h soit la solution de "l'équation d'ajustment" $h'=F(h)/h$ vérifiant $h(0)=0$, c'est à dire les macoscope $v=(V/\varepsilon)^{1/2}$ et $v=V/\varepsilon$ respectivement. Cependant, un tel choix de $h(0)$ conduirait à un "ajustement" identiquement nul

pour le troisième exemple, de la même façon que le choix $h(0)=1$ conduirait à un ajustement constant et égal à 1 pour le dernier exemple, ce qui ne peut évidemment pas convenir.

2) Géométriquement, ce théorème indique l'existence d'un changement d'échelle permettant de "voir" simultanément dans le plan $(t=t_0, x, V)$ les ombres de tous les sauts à l'instant t_0 de l'équation considérée. On désigne ces plans du nom de *plans d'observabilité des sauts* [3]. On notera que dans un tel plan d'observabilité les sauts croissants ($V>0$) et les sauts décroissants ($V<0$) n'obéissent pas nécessairement aux même règles. Cependant, si pour tous t et x (limités), la fonction $f(t,x,v)$ est impaire par rapport à v (pour $|v|\geqq v_0$, v_0 standard), comme dans l'exemple de chapitre 2, les ombres des sauts dans leur plan d"observabilité sont des courbes qui se déduisent l'une de l'autre par translation verticale. Si pour tout t et x la fonction $f(t,x,v)$ est paire par rapport à v (pour $|v|\geqq v_0$, v_0 standard), les ombres des sauts dans leur plan d'observabilité pour $V>0$ se déduisent de celles pour $V<0$ par symétrie par rapport à l'axe $V=0$ (Fig. 7). On notera également que, lorsque, l'équation considérée est autonôme, les ombres des sauts dans le plan d'observabilité $t=t_0$ sont indépendantes de t_0. Enfin, les ombres des sauts sont des graphes de fonctions V de x croissantes ou décroissantes selon que $a(t_0,x)$ est positive ou négative, et les extréma de ces fonctions sont situés sur les droites $x=x_0$, où x_0 est un zéro de $a(t_0,x)$. Il en résulte que, si pour une solution $x(t)$, $\dot{x}(t)$ est extrémal au cours d'un saut, alors $x(t)$ est à cet instant t_1 dans le halo d'un zéro de $a({}^0t_1,x)$: on a ${}^0(a(t_1,x(t_1)))=0$.

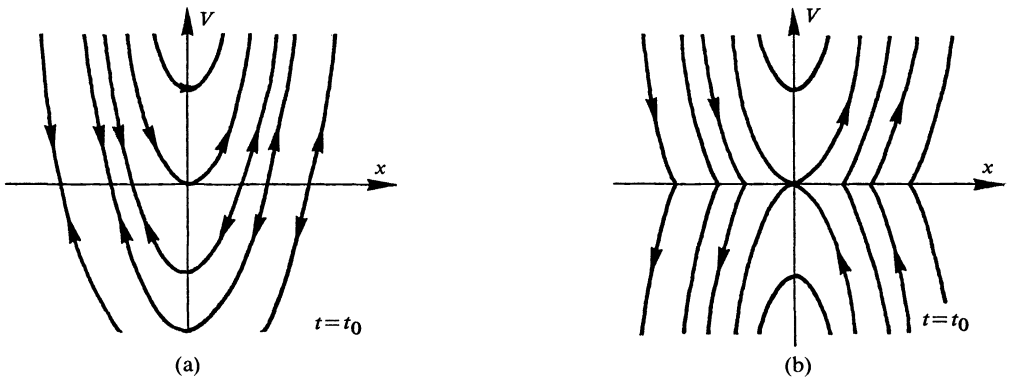

FIG. 7. a) *Trajectoires de l'équation* $\varepsilon\ddot{x}=x\dot{x}^{[2]}$ *dans le plan d'observabilité* $t=t_0$. b) *Trajectoires de l'équation* $\varepsilon\ddot{x}=x\dot{x}^2$ *dans le plan d'observabilité* $t=t_0$.

3) On connait depuis fort longtemps un analogue du plan d'observabilité pour l'étude globale des solutions (et donc en particulier celle des sauts) dans le cas particulier des équations quasi linéaires et autonômes, qu'on appelle encore équations de Lienard:

$$\varepsilon\ddot{x}=a(x)\dot{x}+b(x).$$

On étudie en effet d'ordinaire les solutions de ces équations non dans leur plan de phases $(x, v=\dot{x})$ mais dans leur "plan de Liénard" (x,u) obtenu en posant $u=\varepsilon\dot{x}-A(x)$ où $A(x)=\int_0^x a(s)ds$. A cette échelle, le champ associé est le champ lent-rapide

$$\varepsilon\dot{x}=u+A(x), \qquad \dot{u}=b(x)$$

dont les trajectoires ont des ombres constituées de segments de demi-droites horizontales et de portions de la courbe $u=-{}^0A(x)$. On vérifie facilement que les sauts de

l'équation initiale correspondent précisément aux portions presque-horizontales des trajectories de ce champ. En fait le plan de Liénard (x,u), et le plan d'observabilité $(x, V=\varepsilon v)$ jouent des rôles tout à fait semblables dans l'étude des sauts (ils se correspondent par le difféomorphisme presque-standard $u=V-A(x)$). Cependant, le premier n'existe que pour des équations quasi linéaires, alors que le second peut être utilisé pour toute équation (I) qui vérifie les hypothèses du Théorème 1.

4) L'équation des sauts (i) renseigne également sur "l'ordre de grandeur de la vitesse" au cours des sauts: on constate qu'il existe deux types de sauts: ceux qui, dans leur plan d'observabilité sont d'ordonnée limitée en un point et qui le restent alors en tout point (cas où V_1 est limité), et ceux qui sont d'ordonnée V grande quelque soit x (cas où V_1 est grand). On a donc le résultat suivant:

COROLLAIRE. *Soit f vérifiant les hypothèses du théorème* 1. *Si $x(t)$ est une solution de l'équation $\varepsilon\ddot{x}=f(t,x,\dot{x})$ ayant, à un instant t au moins, à la fois une position et une vitesse limitées, alors la vitesse au cours du saut de x reste nécessairement contenue dans la galaxie des réels pouvant s'écrire $h(\theta/\varepsilon)$, avec θ limité.*

On notera que cette galaxie, qui indique l'ordre de grandeur des vitesses au cours des sauts, ne dépend que du type de croissance de f, et non de la solution ou du saut particulier considéré.

Le théorème 1 indique le comportement des solutions *pendant* les sauts. Nous allons préciser maintenant leur comportement aux "extrémités des sauts". Pour cela, nous supposerons que les sauts considérés ont au moins une extrémité finie et donc, en vertu du corollaire précédent, l'ordonnée $V=h(\dot{x}(t)/\varepsilon)$ reste limitée sur la trajectoire correspondante. Nous désignerons par $A(x)$ la quantité

$$\text{(VIII)} \qquad A(x)={}^0V_1+\int_{0_{x_1}}^{x} {}^0a({}^0t_1,s)\,ds, \quad \text{où } x_1=x(t_1) \text{ et } V_1=h^{-1}(\dot{x}(t_1)).$$

Pour chaque couple (x_1, V_1), A est une fonction standard, continue, définie pour tout x. Le théorème 1 affirme qu'au cours des sauts, les ombres des solutions, dans leur plan d'observabilité, sont contenues dans l'une des courbes d'équation $V=A(x)$. Dans le théorème 2 ci-dessous, nous nous proposons de montrer à présent que si un saut a pour origine x_- (ou pour extrémité x_+), son ombre est contenue dans celle de ces courbes qui passe par le point $(x,V)=(x_-,0)$ (ou $(x,V)=(x_+,0)$). Réciproquement, nous établissons que, si son ombre passe par un tel point, sous de bonnes hypothèses, le saut a x_- pour origine (ou x_+ pour extrémité).

Pour simplifier, le théorème 2 est énoncé dans le cas d'un saut croissant. L'énoncé pour un saut décroissant s'en déduit facilement.

THEOREME 2. *Soit $f(t,x,v)$ une fonction ayant pour type de croissance par rapport à v une fonction F vérifiant la condition* (III), *et $a(t,x)$ pour mantisse. Soit $x(t)$ une solution maximale de l'équation $\varepsilon\ddot{x}=f(t,x,\dot{x})$ présentant un saut croissant sur l'intervalle $[t_1,t_2]$.*

1) *Si ce saut a x_- pour origine, alors $A(x_-)=0$; s'il a x_+ pour extrémité, alors $A(x_+)=0$.*

2) *Réciproquement, s'il existe $x_-<{}^0x_1$ tel que $A(x_-)=0$, si de plus $A(x)\neq 0$ pour tout $x\in]x_-, {}^0x_1]$ et si $a(t_1,x_-)\neq 0$, alors x_- est l'origine du saut.*

De même, s'il existe $x_+>{}^0x_1$ tel que $A(x_+)=0$, si de plus $A(x)\neq 0$ pour tout $x\in[{}^0x_1, x_+[$ et si $a(t_1,x_+)\neq 0$, alors x_+ est l'extrémité du saut.

Preuve. Voici la démonstration du théorème relative à l'origine du saut; on en déduit facilement la démonstration correspondante pour l'extrémité.

On utilise le macroscope $v=h(V/\varepsilon)$ introduit au théorème 1. Sous ce macroscope, le champ associé à l'équation $\varepsilon\ddot{x}=f(t,x,\dot{x})$ dans l'espace des phases devient

$$\begin{aligned}\dot{t}&=1,\\ \dot{x}&=h(V/\varepsilon),\\ \dot{V}&=f(t,x,h(V/\varepsilon))/h'(V/\varepsilon).\end{aligned}$$

Désignons par H_ε^+ et H_ε^- les images par le macroscope des halos H^+ et H^-, des points de l'espace des phases d'ordonnée v grande, positive et négative, respectivement.

Dans H_ε^- et H_ε^+, du fait que $h(V/\varepsilon)$ $(=v)$ est non nul, le champ a les mêmes trajectoires que le champ $\mathscr{C}$, obtenu en multipliant ses composantes par $1/h(V/\varepsilon)$, ce qui revient à effectuer un changement (non standard) de paramétrage de ses trajectoires. Or, en vertu de la définition de h et des hypothèses sur f, ce champ $\mathscr{C}$ est proche, en tout point de $H_\varepsilon^- \cup H_\varepsilon^+$, d'un champ standard $\mathscr{C}_0$:

$$\mathscr{C}\ \begin{cases}t'=1/h(V/\varepsilon),\\ x'=1,\\ V'=f(t,x,h(V/\varepsilon))/h(V/\varepsilon)h'(V/\varepsilon),\end{cases}\quad\simeq\quad \mathscr{C}_0\ \begin{cases}t'=0,\\ x'=1,\\ V'={}^0a({}^0t_1,x).\end{cases}$$

Soit $x: I\to\mathbb{R}$ une solution (maximale) qui présente un saut croissant sur $[t_1,t_2]\subset I$, à l'instant $t_0={}^0t_1$, d'origine x_-. Par définition de l'origine, $\dot{x}(t)$ est grand dés que $x(t)\gg x_-$ (et que $x(t)\leqq x(t_2)$). Dans l'espace des phases, la portion de trajectoire correspondant à cette solution est donc contenue dans H^+, pourvu que $x_-\ll x(t)\leqq x(t_2)$. Vu sous le macroscope, cette portion de trajectoire est une trajectoire de $\mathscr{C}$; puisque $x'=1$, elle s'écrit donc $\gamma(x)=(t(x),x,V(x))$ avec $\gamma(x)\in H_\varepsilon^+$ pour $x_-\ll x\leqq x(t_2)$. Soit $\gamma_0(x)$ la trajectoire de $\mathscr{C}_0$ issue du point ${}^0\gamma(x_1)$. En intégrant ${}_0$, on constate que $\gamma_0(x)=(t_0,x,A(x))$. Et comme $\mathscr{C}$ et $\mathscr{C}_0$ sont proches sur H_ε^+, on a évidement $\gamma(x)\simeq\gamma_0(x)$, et en particulier $V(x)\simeq A(x)$, pour tout x tel que $x_-\ll x\leqq x(t_2)$, l'intervalle $[x_-,x(t_2)]$ étant limité. Comme pour ces valeurs de x, $V(x)\geqq 0$, il en sera de même de $A(x)$ et donc, par continuité de A, on aura $a(x_-)\geqq 0$. Nous allons montrer que $A(x_-)$ ne peut être strictement positif. En effet, comme A est une fonction standard et continue, il existerait sinon un voisinage standard de x_- sur lequel $A(x)>0$. Soit $[b,c]$ un tel voisinage de x_- avec $c\leqq x(t_2)$ (Fig. 8a). Comme $x_-\ll c\leqq x(t_2)$, on a, d'après ce qui précède, $\gamma(c)\simeq\gamma_0(c)$. Par ailleurs, comme $A(x)>0$ pour tout $x\in[b,c]$, $\gamma_0(x)$ $(=(t_0,x,A(x)))$ reste contenue dans la galaxie G^+ des points d'ordonnée V non petite et positive, tant que $x\in[b,c]$. Comme G^+ est une galaxie contenue dans H^+ (où $\mathscr{C}\simeq\mathscr{C}_0$) et contenant le halo de tous ses points, on en déduit, en vertu du lemme de l'ombre courte (*), que $\gamma(x)$ est défini pour tout $x\in[b,c]$ et qu'elle reste proche de $\gamma_0(x)$ sur tout cet intervalle; en particulier $V(x)\gg 0$ pour $x\in[b,c]$. On en déduit que pour tout t tel que $x(t)\in[b,c]$, $\dot{x}(t)$ est grand, ce qui contredit le fait que x_- est l'origine du saut.

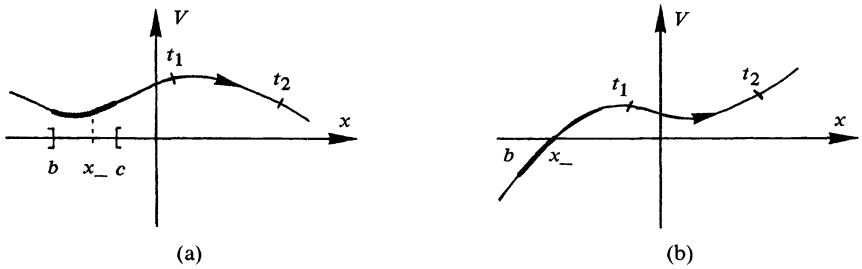

Fig. 8

Montrons la réciproque: Soit $x: I \to \mathbb{R}$ une solution maximale ayant un saut sur l'intervalle $[t_1, t_2]$. Soit $\gamma(x) = (t, x, V(x))$ la trajectoire correspondante du champ $\mathscr{C}$, et $\gamma_0 = (t_0, x, A(x))$ son ombre, trajectoire du champ $\mathscr{C}_0$. Supposons que A s'annule en $x_- < x_1$ $(= x(t_1))$ et qu'elle soit strictement positive pour tout $x \in]x_-, {}^0x_1]$. Comme A est standard et continue, $A(x) \gg 0$ pour $x_- \ll x \leqq {}^0x_1$ et donc aussi $V(x)$. Il en résulte que, pour ces valeurs de x, γ (et γ_0) restent dans H_ε^+ et donc $\dot{x}(t)$ est grande.

D'autre part, comme par hypothèse ${}^0(a(t_1, x_-)) \neq 0$, la fonction standard A a une dérivée non nulle au point standard x_-. Il existe donc un standard $b < x_-$ tel que $A(x) \ll 0$ pour $b \leqq x \ll x_-$. Si, par l'absurde, il existait un voisinage standard $\mathscr{V}_0$ de x_- sur lequel $\dot{x}(t)$ est grande et positive, on aurait, en vertu du théorème 1, $V(x) \simeq A(x)$ pour tout $x \in \mathscr{V}_0$ et donc $V(x) < 0$ pour $x \in]b, x_-[\cap \mathscr{V}_0$ tel que $x \neq x_-$, ce qui est absurde. CQFD

COROLLAIRE (fonction sortie-entrée). *Soit f vérifiant les hypothèses du théorème 2. Si $x(t)$ est une solution de l'équation $\varepsilon\ddot{x} = f(t, x, \dot{x})$ qui présente à l'instant t_0 un saut borné, alors l'origine x_- et l'extrémité x_+ du saut sont liées par la relation:*

$$\int_{x_-}^{x_+} {}^0a(t_0, s)\, ds = 0.$$

Commentaires. 1) La seconde partie du théorème 2 a été établie sous l'hypothèse que le zéro de $A(x)$ considéré n'est pas également un zéro de sa dérivée ${}^0a(t_0, x)$. En termes géométriques, cela signifie que dans le plan d'observabilité le courbe d'équation $V = A(x)$ qui contient l'ombre du saut entre $x(t_1)$ et $x(t_2)$ et qui rencontre l'axe $V = 0$ au point d'abscisse x_- (ou x_+) n'est pas tangente à cet axe en ce point. Ce n'est évidemment pas une condition nécessaire pour que x_- soit l'origine du saut, comme le montre l'exemple du chapitre 2 qui présente un saut d'origine $x = 0$, bien que 0 soit un zéro de $a(t_0, x) \eqsim x$ (Fig. 5). Généralement, lorsqu'une courbe $V = A(x)$ dans un plan d'observabilité est tangente à l'axe $V = 0$ en un point d'abscisse x_-, elle contient à la fois l'ombre de sauts d'origine x_- et l'ombre de sauts pour lesquels x_- n'est pas l'origine, soit que cette origine soit strictement inférieure, soit qu'ils soient sans origine (Fig. 9).

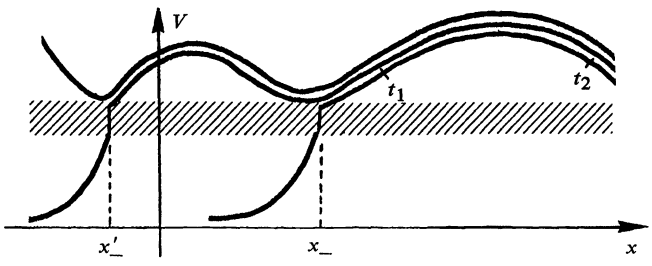

FIG. 9. *Sauts avec "rebond" ou sans "rebond" en x_-.*

2) Lorsque la mantisse $a(t, x)$ est identiquement nulle pour $t = t_0$, ou plus généralement lorsque la fonction $x \mapsto a(t_0, x)$ a des zéros non isolés, les renseignements sur les sauts de l'équation à l'instant t_0 fournis par le théorème 1 sont inutilisables, et le théorème 2 ne s'applique plus. En effet, l'équation possède alors des sauts dont l'ombre, dans leur plan d'observabilité, a pour équation $V = 0$. Il est impossible de déterminer, à cette échelle, l'origine ou l'extrémité de tels sauts; la fonction sortie-entrée n'existe pas

en général (x_+ dépend à la fois de x_- et de la solution considérée), (Fig. 10). Il apparait que le plan d'observabilité n'est pas la "bonne échelle" pour l'étude de ces sauts (voir à ce sujet [7]).

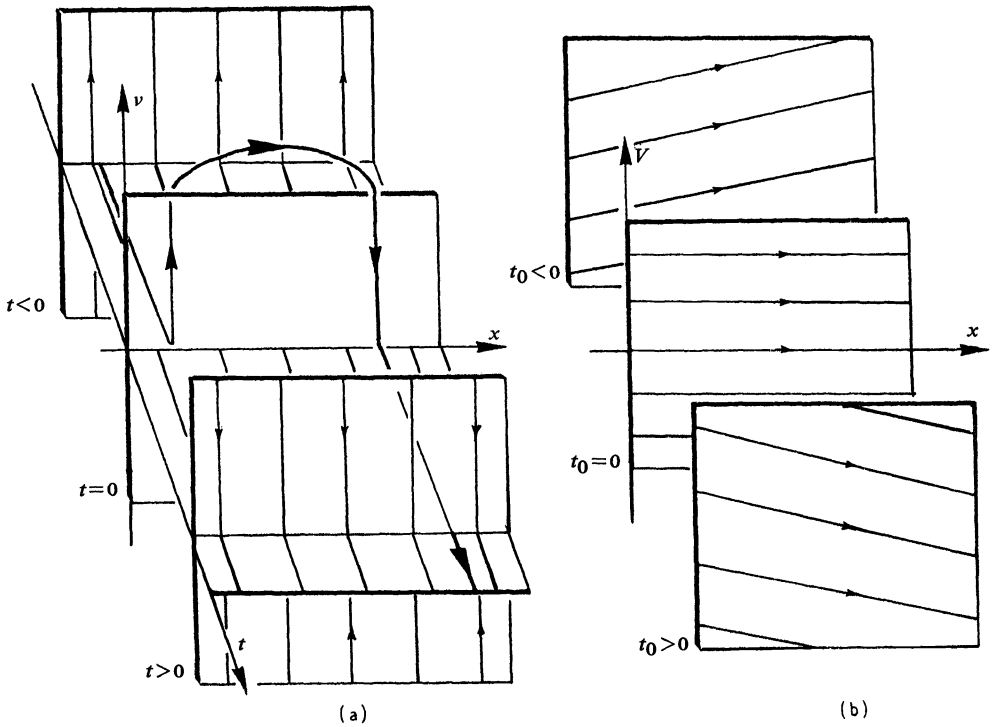

FIG. 10. *Trajectoires du champ associé à l'équation* $\varepsilon\ddot{x} = -t\dot{x}$, *(a) dans l'espace des phases (b) dans des plans d'observabilité (l'équation des sauts est* $V(x) \simeq -t_0 x$*). On observe qu'il ne peut y avoir de saut borné qu'à l'instant* $t_0 = 0$*. L'équation d'un saut borné est alors* $V(x) \simeq 0$*. On ne peut donc pas calculer de fonction sortie-entrée. De fait, en intégrant l'équation, on a* $x(t) = \int_{x(0)}^{x} (C_1 \exp(-t^2/2) + C_2)\, dt$*; on constate que pour tout couple* (x_-, x_+) *de réels standard, il existe une solution présentant un saut à l'instant* $t_0 = 0$ *d'origine* x_- *et d'extrémité* x_+.

4. Epaisseur des sauts. Nous allons voir à présent que les résultats des théorèmes 1 et 2 permettent généralement de calculer l'épaisseur des sauts en fonction de l'ajustement h. Une nouvelle fois, nous nous bornerons au cas des sauts croissants.

Soit h un ajustement (défini au théorème 1) associé à une équation (I), c'est à dire un difféomorphisme de classe S^0 de $[0, +\infty[$ sur $[v_0, +\infty[$ vérifiant l'équation $hh' = F(h)$. Soit $h_\varepsilon : \mathbb{R} \to \mathbb{R}$ l'homéomorphisme croissant défini par

$$h_\varepsilon(y) = \begin{cases} 1/h(1/\varepsilon y) & \text{pour } y > 0, \\ 0 & \text{pour } y = 0, \\ -1/h(-1/\varepsilon y) & \text{pour } y < 0. \end{cases}$$

Soit enfin G_h l'image par h_ε de la galaxie principale $G(*)$. L'ensemble G_h a les propriétés suivantes:

C'est une galaxie: en effet, G_h est par définition une prégalaxie $(*)$; elle est strictement externe car h_ε est continue et prend à la fois des valeurs limitées et des valeurs grandes.

Cette galaxie est convexe (h est continue et non bornée), et est symétrique par rapport à 0 (h est impaire).

Elle est contenue dans le halo de zéro: ceci découle du fait que l'ajustement $h(y)$ est grand pour toute valeur grande de y. En effet, h est de classe S^0 et ${}^0h$ est solution de l'équation standard $h' = {}^0F(h)/h$. Comme h et ${}^0h$ sont proches pour tout y limité, ils sont encore proches pour tout $y \leqq Y$ pour un Y grand (principe de Fehrele). Donc $h(y)$ est grand pour tout y grand inférieur à Y; par monotonie de h, cela reste donc vrai pour les y supérieurs à Y également.

C'est un sous-groupe (externe) de $\mathbb{R}$: En effet, comme G_h est convexe et symétrique par rapport à 0, il suffit de vérifier que pour tout $t>0$, si $t \in G_h$ alors $2t \in G_h$. Notons tout d'abord que h^2 est une fonction convexe, puisque

$$(h^2)'' = (2hh')' = (2F(h))' = 2F'(h)h'$$

et donc $(h^2)''$ est positive car F et h sont croissantes. Comme $t>0$, il existe y limité tel que $t = 1/h(1/\varepsilon y)$. Comme G_h est convexe et contient 0, pour montrer que $2t \in G_h$, il suffit de montre que $2t$ est majoré par un élément de G_h, c'est à dire qu'il existe Y limité tel que

$$(2t =) \quad 2/h(1/\varepsilon y) \leqq 1/h(1/\varepsilon Y)$$

ou encore, tel que

$$4h^2(1/\varepsilon Y) \leqq h^2(1/\varepsilon y).$$

Mais comme h^2 est convexe, on a, pour tout z,

$$h^2(z) \leqq \big(h^2(2z) + h^2(0)\big)/2$$

ou encore, en réappliquant deux fois cette inégalité,

$$h^2(z) \leqq \big(h^2(8z) + 7h^2(0)\big)/8.$$

Comme $h^2(0) = v_0^2$ est limité et que $h^2(8z)$ est grand des que z est grand, on en déduit que pour tout z grand,

$$8h^2(z) \leqq 2h^2(8z).$$

Il suffit donc de poser $Y = 8y$.

Voici quelques exemples de galaxies G_h:

Si $h(y) = y$, G_h est la ε-galaxie de 0. Plus généralement, si $h(y) = y^r$, G_h est la ε^r-galaxie de 0; c'est donc une galaxie linéaire. Par contre, si $h(y) = \exp(y)$, G_h est la ε–micro-galaxie; c'est donc une galaxie non linéaire.

Comme les deux précédents, le théorème 3 sera énoncé dans le cas d'un saut croissant:

THEOREME 3 (épaisseur des sauts). *Soit $f(t,x,v)$ une fonction ayant un type de croissance F par rapport à v vérifiant la condition* (III). *Soient h un ajustement correspondant, et G_h la galaxie associée. Soient $x(t)$ un saut borné de l'équation $\varepsilon\ddot{x} = f(t,x,\dot{x})$ d'épaisseur noté $\mathscr{E}$, et t_1 un élément de $\mathscr{E}$. Supposons que*

(i) *la fonction $A(x)$ définie par* (VIII) *ne s'annule en ancun point strictement compris entre les extrémités du saut,*

(ii) *la fonction $H(V) =: h(V/\varepsilon)/h(1/\varepsilon)$ soit de classe S^1 en $V = 0$.*

Alors $\mathscr{E}=t_1+G_h$ (*= image de* G_h *par la translation* $t\mapsto t+t_1$).

Preuve. Comme $\dot{x}(t)=v$, et qu'au cours d'un saut, $v(t)$ peut s'exprimer comme fonction de $x(t)$, on a

$$t=t_1+\int_{x(t_1)}^{x(t)}\frac{ds}{v(s)}=t_1+\int_{x(t_1)}^{x(t)}\frac{ds}{h(V(s)/\varepsilon)} \quad \text{car } v=h(V/\varepsilon).$$

Posons

$$e(x)=\int_{x_1}^{x}\frac{ds}{h(V(s)/\varepsilon)}, \quad \text{où } x_1=x(t_1).$$

Soient x_- et x_+ les extrémités du saut, et notons

$$E=\{\, x \mid x_- \ll x \ll x_+ \,\} \quad \text{et} \quad \mathscr{E}_0=e(E).$$

On a $\mathscr{E}=t_1+\mathscr{E}_0$, et le théorème affirme que $\mathscr{E}_0=G_h$.

Notons tout d'abord que $\mathscr{E}_0$ et G_h sont des convexes contenant 0, et donc, pour que t soit un élément d'un tel ensemble, il suffit qu'il existe t' dans cet ensemble tel que $t'/t\geqq 1$.

1) Montrons tout d'abord que $\mathscr{E}_0\subset G_h$: Par définition des extrémités x_+ et x_-, $v(x)$ est grand pour tout $x\in E$ donc, en vertu du théorème 1, $V(x)\simeq A(x)$ pour $x\in E$. Du fait de l'hypothèse (i), $A(x)\neq 0$ pour tout $x\in E$ et, en fait, $A(x)\gg 0$ puisque le saut est supposé croissant et que A est standard et continue. Donc $V(x)\gg 0$ pour tout $x\in E$. On en déduit que, pour tout $x\in E$, $1/h(V(x)/\varepsilon)$ est un élément de G_h. A présent, pour tout $x_0\in E$, on a par le théorème de la moyenne, que $e(x_0)=(x_0-x_1)/h(V(x)/\varepsilon)$ pour un $x\in E$. Comme $1/h(V(x)/\varepsilon)\in G_h$, que G_h est un groupe, et que (x_0-x_1) est limité, on a $e(x_0)\in G_h$. D'où l'inclusion recherchée.

2) Montrons que réciproquement $G_h\subset\mathscr{E}_0$: Pour cela, nous allons montrer que pour tout $T\in G_h$, $T>0$, il existe $t\in\mathscr{E}_0$ tel que $t>T$, c'est à dire qu'il existe $x\in E$ tel que $e(x)>T$. On procèderait de manière analogue pour $T<0$.

Envisageons d'abord le cas où G_h est une galaxie linéaire, c'est à dire qu'il existe α tel que $G_h=\alpha\mathbb{G}$, où $\mathbb{G}$ est la galaxie principale. De par la définition de G_h, on peut choisir $\alpha=1/h(1/\varepsilon)$. Il convient donc de prouver, sous cette hypothèse, que pour tout y limité, il existe $x\in E$ tel que $h(1/\varepsilon)\cdot e(x)>y$, ou encore, tel que

$$\int_{x_1}^{x}\frac{ds}{H(V(s))}>y.$$

Or la fonction $H(V)$ est limitée pour V limité, et non petite pour $V\gg 0$. Comme par hypothèse cette fonction dérivable est de classe S^1 en $V=0$, il existe un intervalle standard $[0, V_0]$ sur lequel H reste proche d'une fonction standard H_0, dérivable en $V=0$, et nulle en ce point car $H(0)\simeq 0$. Son inverse $1/H_0$ est donc d'intégrale divergente en $V=0$. Ceci va nous permettre de conclure. En effet, comme H (et donc H_0) est non petite pour $V\gg 0$, $1/H(V(x))\simeq 1/H_0(V(x))$, pour tout $x\in E$. Or l'ensemble des x pour lesquels l'équivalence ci-dessus est vérifiée est un halo qui contient la galaxie E. Par le principe de Fehrele, il contient également des $x\notin E$. Il existe donc $x_0\simeq x_+$ tel que cette équivalence soit satisfaite pour tout $x\in[x_1, x_0]$. Mais comme x_+ est l'extrémité du saut, on a $V(x_+)\simeq 0$ (théorème 2). Donc, pour tout $x\leqq x_0$, l'intégrale $\int_{x_1}^{x}(ds/H(V(s)))$ est équivalente à l'intégrale $\int_{x_1}^{x}(ds/H_0(V(s)))$ qui est grande dès que $x\simeq x_+$. En effet, si $x\simeq x_+$, $V(x)\simeq 0$ (théorème 2). Par continuité, pour tout y limité, il

existe donc $x \ll x_+$ tel que

$$\int_{x_1}^{x} \frac{ds}{H(V(s))} > y$$

ce qui achève la démonstration dans le cas où G_h est linéaire.

Considérons à présent le cas où G_h est une galaxie non linéaire. La non linéarité de G_h peut s'exprimer par la propriété suivante [1]:

"Pour tout $T \in G_h$, il existe $T' \in G_h$ tel que T'/T est grand". Comme la quantité $1/h(V(x)/\varepsilon)$ est une fonction croissante de x pour x assez proche de x_+, et comme elle appartient à G_h tant que $x \ll x_+$ et qu'elle quitte G_h dès que $x \simeq x_+$ (car $V(x) \simeq 0$, d'après le théorème 2), pour tout $T' \in G_h$ il existe une valeur $x_0 \ll x_+$ telle que $1/h(V(x)/\varepsilon) > T'$ pour tout $x \in [x_0, x_+]$. Soit x_0' tel que $x_0 \ll x_0' \ll x_+$. On a

$$e(x_0') = \int_{x_1}^{x_0'} \frac{ds}{h(V(s)/\varepsilon)} > \int_{x_0}^{x_0'} \frac{ds}{h(V(s)/\varepsilon)} > \int_{x_0}^{x_0'} T' ds > T. \qquad \text{CQFD}$$

Remarque. On notera que dans le cas où G_h est non linéaire, l'hypothèse (ii) du théorème n'intervient pas dans la démonstration. Il semble qu'elle soit toujours satisfaite dans ce cas.

Commentaires. 1) Ce théorème montre en particulier que, sous les hypothèses (i) et (ii), tout saut borné d'une équation (I) peut être "étalé" sur la galaxie principale par le changement de temps $\tau \mapsto t = t_1 + 1/h(1/\varepsilon\tau)$. Dans le cas quasi linéaire ($h(y) = y$), par exemple, on retrouve le changement de variable adopté habituellement: $t - t_1 = \varepsilon\tau$. Du théorème, il découle également que les épaisseurs de sauts bornés sont les images par des translations, de sous groupes convexes de $\mathbb{R}$ (si $t \in \mathscr{E}$, $2(t - t_1) + t_1 \in \mathscr{E}$) et qu'il s'agit de galaxies linéaires si et seulement si G_h est linéaire. On comprend à présent pourquoi il n'est pas toujours possible "d'étaler" les sauts par des changements de temps du type $t - t_1 = 1(\varepsilon)\tau$: ce n'est possible que lorsque G_h est linéaire. En particulier pour les équations dont le type de croissance $F(v)$ est une fonction puissance $x \mapsto x^s$, la linéarité de G_h équivaut à la condition $s < 2$ (h croit "nettement moins vite" que la fonction exponentielle). Dans le cas général, il serait utile de diposer d'un critère simple sur le type de croissance F de l'équation qui équivaille à la linéarité de G_h (et donc à la linéarité de l'épaisseur des sauts). Il semble que le critère suivant devrait convenir:

$$G_h \text{ est linéaire} \Leftrightarrow \int_{v_0}^{+\infty} \frac{F(v)}{v^3} dv < \infty,$$

ce qui est, par définition de h, équivalent à

$$G_h \text{ est linéaire} \Leftrightarrow \int_0^{+\infty} \left(\frac{h'(y)}{h(y)} \right)^2 dy < \infty.$$

2) Précisons le sens des hypothèses (i) et (ii) du théorème: La première porte sur les sauts. Elle signifie géométriquement que, dans le plan d'observabilité, l'ombre du saut ne rencontre pas l'axe $V = 0$ en des points d'abscisse strictement comprise entre les extrémités' x_- et x_+, et donc, en quelque sorte, qu'il s'agit d'un saut sans "rebond" Lorsqu'un saut ne vérifie pas cette hypothèse, on déduira facilement du théorème que son épaisseur $\mathscr{E}$ est alors la réunion d'un intervalle petit $I = [t_1, t_2]$ et des deux galaxies

$t_1+G_h^-$ et $t_2+G_h^+$, avec $G_h^{\pm}=G_h\cap\mathbb{R}^{\pm}$, le saut parcourant les divers rebonds pout $t\in[t_1,t_2]$.

La seconde hypothèse porte sur l'équation. Elle signifie que la fonction H (que l'on peut calculer dès que l'on connait F, et donc h) est équivalente sur un voisinage standard de 0 à une fonction standard H_0 dérivable au point $V=0$. Elle est vérifiée, par exemple, lorsque h est l'identité (cas quasi linéaire), car $H(V)=H=V_0(V)$. Elle est aussi vérifiée lorsque h est une exponentielle (cas quadratique) car $H(V)=e^{(V-1)/\varepsilon}$ est infinitésimale pour tout $V\ll 1$, donc $H_0(V)=0$, pour $V\ll 1$. Par contre elle est en défaut lorsque $h(v)=\sqrt{v}$ (cas semi-linéaire) car $H(V)=\sqrt{V}=H_0(V)$ n'est pas dérivable en 0. Plus généralement, si le type de croissance est une fonction puissance $F(v)=v^s$, l'hypothèse (ii) est équivalente à la condition $s\geqq 1$. Il est probable qu'une condition équivalente à (ii) serait:

$$\int_{v_1}^{+\infty}\frac{F(v)}{v^2}dv=+\infty$$

ou encore, en fonction de h:

$$\int_{v_1}^{+\infty}\frac{(h'(y))^2}{h(y)}dy=+\infty.$$

On peut, cependant, se poser la question de savoir quelle est l'épaisseur des sauts lorsque la condition (ii) n'est pas remplie, par exemple pour des équations ayant un type de croissance $F(v)=v^s$ avec $s<1$. L'inclusion $\mathscr{E}\subset t_1+G_h$ reste valable dans tous les cas, mais il arrive que cette inclusion soit stricte. Plus précisément, on peut montrer par un affinement de la preuve précédente, que les conclusions du théorème subsistent pourvu que l'ombre du saut dans son plan d'observabilité soit tangente à l'axe $V=0$ en ses extrémités (voir [3]). Dans le cas contraire, l'épaisseur n'est plus la translaté d'une galaxie sous-groupe, mais c'est une galaxie obtenue à partir d'un intervalle auquel on retire un halo de l'extrémité concernée. Ce halo est le translaté d'un halo sous-groupe; il peut également être exprimé en fonction de h ([3]).

3) Pour simplifier, le théorème précédent a été énoncé dans le cas des sauts ayant à la fois une origine *et* une extrémité finies. En fait, par une adaptation évidente de la preuve qui a été donnée, on établirait un résultat englobant le cas des sauts non bornés, ayant une origine *ou* une extrémité finie. En effet, s'il s'agit par exemple d'un saut d'extrémité finie, alors, sous les hypothèses du théorème, on a montré que

$$\{t\in\mathscr{E},\ t\geqq t_2\}=t_2+G_h^+\quad\text{où } G_h^+=G_h\cap\mathbb{R}^+.$$

De même que, s'il s'agit d'un saut d'origine finie, alors

$$\{t\in\mathscr{E},\ t\leqq t_1\}=t_1+G_h^-\quad\text{où } G_h^-=G_h\cap\mathbb{R}^-.$$

Les épaisseurs de sauts non bornés sont donc la réunion d'un segment (interne) et de l'image par une translation de la partie positive ou de la partie négative de G_h.

Annexe non standard. Des adjectifs tels que petit, grand, appréciable, n'étaient pas d'usage courant en mathématiques jusqu'à l'apparition récente des mathématiques non standard. Pourtant le non mathématicien, physicien ou chimiste par exemple, qui propose à notre sagacité des équations du type (I) n'hésite pas à parler de "petit" paramètre pour désigner ε. Pour lui, en effet, cette petitesse ne fait pas mystère: il s'agit

par exemple d'un paramètre de l'ordre de 10^{-1} ou 10^{-2} alors que les autres paramètres intervenant dans l'équation sont de l'ordre de 10 ou 100. A défaut d'un formalisme adapté, on traduisait généralement la "petitesse" de ε par l'introduction d'une variable ε tendant vers 0 ce qui, en rendant variable une quantité qui ne l'était pas à priori, ne contribuait pas à simplifier le problème. C'est à Reeb [20] que l'on doit l'idée d'introduire l'Analyse Non Standard dans ces questions de perturbations singulières. Ce fut le point de départ de nombre d'études d'équations de type (I), ou plus généralement, de champs lents-rapides. Aux principes originaux de l'analyse non standard, tels qu'on pourra les trouver exposés dans [21] ou [18], se sont ainsi ajoutés petit à petit divers objets ou qualificatifs liés au contexte particulier des équations différentielles, et certains raisonnements omniprésents qui portent aujourd'hui des noms particuliers. C'est l'abondance de ce vocabulaire inhabituel qui me pousse à proposer l'index ci-dessous. Le lecteur n'aura pas manqué de remarquer qu'une part importante des termes utilisés peuvent être interprétés dans un premier temps dans un sens intuitif (celui du physicien, par exemple). C'est un des mérites de l'analyse non standard que de rendre possible cet usage rigoureux de notions jusqu'ici heuristiques. Pour une véritable initiation aux méthodes non standard, nous renvoyons le lecteur à [16] ou [6].

Nous utilisons couramment les symboles suivants:

$\simeq$, $\not\simeq$, $\gg$, $\ll$: voir "équivalent".
${}^0(\,)$: voir "standard".
${}^S(\,)$: voir "standardisé".
$\mathrm{hal}(a)$, $\varepsilon-\mathrm{hal}(a)$: voir "halo".
$\mathbb{G}$, $\varepsilon-\mathrm{gal}(a)$: voir "galaxie".

ajustement: voir théorème 1 et ses commentaires.

appréciable: Se dit d'un réel qui n'est ni petit ni grand (voir ces mots). Un vecteur de $\mathbb{R}^n$ est dit appréciable si ses coordonnées le sont.

Cauchy (principe de): voir "principes de permanence".

changement d'échelle: Difféomorphisme dont la dérivée est grande ou petite. Les plus simples sont les *loupes*, c'est-à-dire les homotéthies (ou affinités) de rapport grand, tels que $x \mapsto x/\varepsilon$. On distingue parmi les changements d'échelle les *microscopes*, qui "grossissent", c'est à dire par lesquels l'image d'une région petite peut être une région appréciable, et les *macroscopes*, qui "rappetissent", c'est à dire par lesquels l'image d'une région grande peut être une région limitée. Ainsi le difféomorphisms $x \mapsto x^{[\varepsilon]} = |x|^{\varepsilon-1}x$ est un macroscope pour $|x| \gg 1$ et un microscope pour $|x| \ll 1$.

classe S^0, S^1 (fonction de): Lorsqu'une fonction interne est non standard, elle peut ou non être proche d'une fonction standard. Si elle est dérivable, la question se pose également pour sa dérivée, etc... Ainsi la fonction $x \mapsto \varepsilon x$ est proche de la fonction nulle, mais la fonction $x \mapsto e^{x/\varepsilon}$ n'est proche d'aucune fonction standard si $x > 0$. Une fonction interne est dite *S-continue* au point x si, pour tout y,

$$y \simeq x \Rightarrow f(y) \simeq f(x).$$

Une fonction interne est de classe S^0 sur une partie E si elle prend des valeurs presque-standard (voir ce mot) aux points presque-standard de E et si elle est S-continue en ces points. Une fonction interne est de classe S^1 sur une partie E si elle est de classe S^0 sur E et si pour tout a presque standard de E, et pour tout x et y équivalents (voir ce mot) à a, le rapport

$$\frac{f(x)-f(y)}{x-y}$$

est presque standard. On montre [6] que toute fonction de classe S^0 est proche d'une unique fonction standard continue, et toute fonction de classe S^1 est proche d'une unique fonction standard de classe C^1. On définit de manière analogue les fonctions de classe S^n [6].

épaisseur (d'un saut): voir chapitre 1.

équivalent: Deux nombres réels sont dits équivalents s'ils diffèrent l'un de l'autre par un infinitésimal (voir ce mot). Ainsi, si ε est petit, 1 et $1+\varepsilon$ sont équivalents. On note $\simeq$ pour "équivalent" et $\not\simeq$ pour "non équivalent" ($2 \not\simeq 3$). La notation $a \ll b$ signifie $a<b$ et $a \not\simeq b$. On dit que a est *nettement inférieur à* b. De même pour $a \gg b$. Deux fonctions f et g sont dites équivalentes sur E si pour tout $x \in E$, $f(x)$ est équivalent à $g(x)$. Si f est interne, l'ensemble des x pour lesquels $f(x) \simeq g(x)$ est un préhalo (voir "halo"). [infinitely close]

externe: Le mathématicien non standard travaille avec deux sortes d'ensembles: les premiers sont les ensembles usuels de la théorie des ensembles de Zermelo–Fraenkel (par exemple): on les appelle *internes*. Ce sont par exemple $\mathbb{N}$, $\mathbb{R}$, ou $[-\omega, +\alpha]$. Les seconds sont ceux qu'on définit en faisant usage de l'adjectif "standard" (ou de ses dérivés "petit", "grand", "limité", $\simeq$, $\ll$) et qu'on appelle *externes*, ou *strictement externes* quand il est établi que le fait de les supposer internes conduirait à une contradiction. Ainsi l'ensemble des réels standard, ou l'ensemble des infinitésimaux sont des ensembles strictement externes (ils sont majorés et n'ont pas de borne supérieure). Une fonction est dite interne si son graphe est un ensemble interne. Ainsi $x \mapsto \varepsilon x$ est interne, mais la fonction qui à x associe la valeur 0 si x est petit, et la valeur 1 sinon est externe.

Extrémité (d'un saut): voir chapitre 1.

Fehrele (principe de): voir "principes de permanence".

galaxie: On appelle *galaxie principale*, et on note $\mathbb{G}$, l'ensemble (strictement externe) des réels limités (voir ce mot). Une *prégalaxie* est l'image réciproque de $\mathbb{G}$ par une fonction f interne. Elle peut être interne (par exemple si $f(x)=1$), ou strictement externe (par exemple si $f(x)=x/\varepsilon$). Dans ce dernier cas, la prégalaxie est appelée une galaxie [2], [8]. Si a est un réel standard, on appelle *ε-galaxie de a*, et on note $\varepsilon-\mathrm{gal}(a)$, l'image réciproque de $\mathbb{G}$ par $f(x)=(x-a)/\varepsilon$, et *ε-microgalaxie de a*, l'image réciproque de $\mathbb{G}$ par $f(x)=1/(\varepsilon \log|x-a|)$. Le complémentaire, dans un interne, d'une galaxie, est un halo (voir également ce mot).

grand: Un réel est dit grand s'il est plus grand que tout entier standard. L'existence d'entiers (et donc de réels) grands est une conséquence du principe d'idéalisation (voir ce mot). [infinite/unlimited]

halo: On appelle halo de 0, noté hal(0), l'ensemble strictement externe des infinitésimaux (voir ce mot). Un *préhalo* est l'image réciproque de hal(0) par une fonction interne f. Il peut être interne (si par exemple f est constante), ou strictement externe (si par exemple $f(x)=x/\varepsilon$). Dans ce dernier cas, le préhalo est appelé un halo [2], [8]. Si a est un réel, on appelle $\varepsilon-$halo de a, et on note $\varepsilon-\mathrm{hal}(a)$, l'image réciproque de hal(0) par $f(x)=(x-a)/\varepsilon$, et ε-microhalo de a, la préimage de hal(0) par $f(x)=1/(\varepsilon \log|x-a|)$. Si A est une partie d'un espace métrique, le halo de A, noté hal(A), est l'ensemble des points à distance petite de A. [monad]

idéalisation: C'est l'un des trois principes fondamentaux de l'analyse non standard I.S.T. [18], [6]. Il s'énonce ainsi: Pour toute formule interne B, contenant au moins deux variables libres x et y, on a:

$$(\forall z,\ z \text{ standard et fini} \Rightarrow \exists x, \forall y \in z,\ B(x,y)) \Leftrightarrow (\exists x_0, \forall y,\ y \text{ standard} \Rightarrow B(x_0,y))$$

On déduit de ce principe l'existence d'entiers grands, et donc de réels petits non nuls.

infinitésimal: Synonyme de "réel petit"' (voir ce mot).

interne: voir "externe".

lemme de l'ombre courte: Soient X et X_0 deux champs de vecteurs localement lipschitziens, définis sur un ouvert de $\mathbb{R}^n$, le premier interne, le second standard. Soit H le (pré)halo où $X \simeq X_0$. Soit I un intervalle compact standard, t_0 un point standard de I, et u_0 une trajectoire de X_0, définie sur I. Soit u une trajectoire de X telle que $u(t_0) \simeq u_0(t_0)$. S'il existe une galaxie G limitée, contenant $u_0(I)$, contenue dans H, et si G contient le halo de tous ses points, alors $u(t)$ est prolongeable à tout I, et on a, pour tout $t \in I$, $u(t) \simeq u_0(t)$ [3].

lemme de Robinson: voir "principes de permanence".

limité: Un réel est dit limité s'il n'est pas grand. Tout réel limité x est équivalent à un unique réel standard, qu'on appelle sa partie standard, et qu'on note ${}^0x$. [finite/limited]

linéaire (galaxie ou halo): Une galaxie (voir ce mot) est dite linéaire si elle est l'image réciproque de $\mathbb{G}$ par une application affine. Ainsi les ε-galaxies d'un point sont linéaires, mais les ε-microgalaxies ne le sont pas. On définit de même les halos linéaires [2], [8].

longer: Une courbe $t \mapsto x(t)$ dans $\mathbb{R}^2$ ou $\mathbb{R}^3$ longe une courbe ou une surface si son image reste à distance petite de cette courbe ou surface.

loupe: voir "changement d'échelle".

macroscope: voir "changement d'échelle".

microscope: voir "changement d'échelle".

ombre courte: voir "lemme de 1".

ombre: L'ombre d'une partie interne A de $\mathbb{R}^n$, notée $[A]$, est le standardisé (voir ce mot) du halo de A. Si la partie A est limitée, son ombre est l'unique ensemble standard compact proche (voir ce mot) de A. Si une fonction est de classe S^0, l'ombre de son graphe est le graphe d'une fonction standard continue. [standard part]

partie standard: voir "limité" et "standard".

petit: Un réel est dit petit si sa valeur absolue est plus petite que tout réel standard strictement positif. [infinitesimal]

plan de Liénard: voir [3] et chapitre 3, commentaire du théorème 1.

plan d'observabilité: voir chapitre 3, commentaire du théorème 1.

prégalaxie: voir "galaxie".

préhalo: voir "halo".

presque-: Dans des expressions telles que "presque-verticale", "presque-horizontale", cet adverbe prend le sens de "à un infinitésimal près". Une presque équation est une relation $R(x)$ obtenue en exprimant que deux termes internes $f(x)$ et $g(x)$ sont équivalents: $f(x) \simeq g(x)$.

principes de permanence: Le plus connu est le *lemme de Robinson* [21]: "Soit (u_n) une suite interne de réels. Si $u_n \simeq 0$ pour tout n limité, alors il existe un N grand tel que $u_n \simeq 0$ pour tout $n \leqq N$". Deux autres principes de permanence sont très utiles: Le *principe de Cauchy*, "aucun ensemble strictement externe n'est interne", n'est rien d'autre que la définition des ensembles strictement externes, et le *principe de Fehrele*, "aucun halo n'est une galaxie", est une généralisation du lemme de Robinson [8], [6].

proche: Deux parties de $\mathbb{R}^n$ sont dites proches si tout point de l'une est équivalent à au moins un point de l'autre. [infinitely close (for sets)]

Robinson (lemme de): voir "principes de permanence".

S-continue: voir "classe S^0"

saut: voir chapitre 1.

standard: C'est un prédicat indéfini (comme $\in$ en théorie des ensembles), dont l'usage (et le sens) est gouverné par trois axiomes: idéalisation, standardisation, et transfert. Tout ensemble est soit standard, soit non standard. Les ensembles $\mathbb{R}$, $\mathbb{Q}$, $\mathbb{C}$, $[0,1]$, ϕ $(=0)$, $\{\phi\}$ $(=1), \cdots, \sin x$, $e^x, \cdots$, sont standard; un infinitésimal ε $(\neq 0)$, la fonction $x \mapsto \varepsilon x$, l'intervalle $[\omega, \omega+1]$ pour ω grand sont non standard. La *partie standard* d'un réel x, notée ${}^0x$, est l'unique standard (s'il existe, voir "limité") qui est équivalent à x. La partie standard d'une fonction f est l'unique fonction standard, notée ${}^0f$, si elle existe, telle que $f(x) \simeq {}^0f(x)$ pour tout x presque standard.

standardisation: C'est l'un des trois principes fondamentaux de l'analyse non standard (voir idéalisation et transfert). Il peut s'énoncer ainsi: "Pour tout ensemble E (interne ou non), il existe un unique ensemble standard, noté ${}^SE$, ayant précisement les mêmes éléments standard que E". Cet ensemble est appelé le *standardisé* de E. L'existence de la partie standard d'un réel limité et de l'ombre d'une partie découle de ce principe.

strictement externe: voir "externe".

transfert: C'est l'un des trois principes fondamentaux de l'analyse non standard. Il s'énonce ainsi: Pour toute formule standard $F(x,t)$, on a, pour t standard:

$$\forall x\ (x \text{ standard} \Rightarrow F(x,t)) \Leftrightarrow \forall x (F(x,t)).$$

ASYMPTOTIC ANALYSIS OF SINGULAR SINGULARLY PERTURBED BOUNDARY VALUE PROBLEMS*

CHRISTIAN SCHMEISER† AND RICHARD WEISS†

Abstract. Singularly perturbed systems ordinary differential equations for which the reduced system has a manifold of solutions are called singular singularly perturbed. Boundary value problems for a general class of such systems are examined. Conditions are derived which ensure the existence of a locally unique solution, which can be approximated by an asymptotic expansion. The main tool for our analysis is the theory of boundary value problems on long intervals.

AMS(MOS) subject classifications. Primary 34B15, 34E15

Key words. ordinary differential equations, boundary value problems, singular perturbations, asymptotic expansions

1. Introduction.

We consider boundary value problems of the form

$$\varepsilon y' = f(y,t,\varepsilon) \qquad 0 \leqq t \leqq 1, \tag{1.1}$$

$$b(y(0),y(1)) = 0, \tag{1.2}$$

where y is an n-vector, ε is small and positive, and f and b are nonlinear mappings.

The asymptotic analysis of (1.1), (1.2) starts with an investigation of the reduced system

$$0 = f(y,t,0). \tag{1.3}$$

If there is a locally unique solution $y = Y(t)$ to (1.3) and the matrix $f_y(Y(t),t,0)$ has just strictly stable and strictly unstable eigenvalues, then (1.1), (1.2) is called a regular singular-perturbation problem. Problems of this type are quite well understood. Combining the results of Vasileva and Butuzov (1973) and Esipova (1975) yields a complete asymptotic analysis, even if equations for "slow" components are added to (1.1).

We want to treat the case of the existence of a solution manifold $y = \phi(\alpha,t)$ of (1.3), with α being an n_0-dimensional parameter. We wish to consider problems satisfying an additional assumption:

The matrix $f_y(\phi(\alpha,t),t,0)$ has an n_0-dimensional null space with the real parts of the remaining $n - n_0$ eigenvalues being bounded away from zero.

This assumption rules out the existence of turning points, highly oscillatory solutions and boundary layer variables different from $\tau = t/\varepsilon$ and $\sigma = (1-t)/\varepsilon$. Note that regular singularly perturbed systems of the form

$$\varepsilon y' = g(y,z,t,\varepsilon), \qquad z' = h(y,z,t,\varepsilon)$$

obviously fit into our theory if the equations for z are multiplied by ε.

Singular singularly perturbed problems have received a significant amount of attention recently. General nonlinear initial value problems satisfying the above assumptions have been treated by O'Malley and Flaherty (1980) and Vasileva and Butuzov (1978). In the work by Vasileva and Butuzov also boundary value problems of a special structure are analysed. To the knowledge of the authors no complete classification of problems violating the above assumptions on the eigenstructure of f_y $(\phi(\alpha,t),t,0)$ is available. One of the possible effects in this case is the occurrence of multiple layers. This has been demonstrated on a linear problem by O'Malley (1979).

The asymptotic analysis of (1.1), (1.2) proceeds in two steps: The construction of a formal approximation of the solution and the proof of validity of this approximation.

The first step is contained in §2, where the method of matched asymptotic expansions is used to construct a sequence of formal approximations. The problem defining the first term in the sequence, i.e. the leading term in the asymptotic expansion, is nonlinear in general if (1.1), (1.2) is nonlinear. A key assumption in this paper is the existence of an isolated solution of this problem. It is then shown that this assumption implies the existence and uniqueness of terms of arbitrary order in the asymptotic expansion, since the linear operator in the equations defining these terms is the linearization of the nonlinear problem defining the leading term.

In the proof of the validity of the asymptotic expansion in §4 the contraction principle is used. Thus it is necessary to obtain stability estimates for the linearization of (1.1), (1.2) at the formal approximation, i.e. we have to obtain estimates for the solutions of linear singular singularly perturbed problems, where the coefficients contain boundary layer terms. For the analysis of these problems the theory of boundary value problems on infinite and "long" intervals is used extensively. It is one of the key points of this paper to stress the applicability of this theory to singularly perturbed problems. Some results of this theory are collected in §3. In the proofs given in the Appendix the methods of de Hoog and Weiss (1980) and Markowich (1982, 1983) are used.

The solution of the problem defining the leading term in the expansion is demonstrated on an example from semiconductor theory in §5. The singular perturbation approach to semiconductor problems was originated by Vasileva, Kardosysoev and Stelmakh (1976). Recently the great importance of semiconductor device simulation caused intensive work on the subject. References to some papers using singular perturbation theory are given in §5.

Another nonlinear example can be found in Schmeiser (1985) where a problem modelling large deflections of a thin beam, suggested by Flaherty and O'Malley (1981), is analyzed in the framework of the theory of this paper.

For a class of singular singularly perturbed boundary value problems considered in Vasileva and Butuzov (1978), contraction mapping techniques are employed to establish the validity of the formal asymptotic expansion. The structure of this class is simple enough to a priorily guarantee the existence and uniqueness of an isolated solution to the problem defining the leading term of the expansion and to allow the reduction of the analysis of the linearized problem to that of a scalar second order equation whose coefficients have boundary layers. The stability results employed for this equation have been previously developed in Vasileva (1972).

2. Asymptotic expansion. We consider problems of the form (1.1), (1.2) which satisfy

Hypothesis H1. Denoting the n_0-dimensional solution manifold of the reduced equation by $\phi(\alpha,t)$, the matrix $\phi_\alpha(\alpha,t)$ has constant rank n_0. The Jacobian

$f_y(\phi(\alpha,t),t,0)$ has n_- strictly stable and n_+ strictly unstable eigenvalues with $n_-+n_+ +n_0=n$, for $0\leqq t\leqq 1$.

Differentiation of

$$f(\phi(\alpha,t),t,0)=0$$

with respect to α implies

$$\bar{f}_y\phi_\alpha(\alpha,t)=0, \tag{2.1}$$

where from now on the bar above partial derivatives of f indicates the argument $(\phi(\alpha,t),t,0)$. Thus $\bar{f}_y$ has an n_0-dimensional null space spanned by the columns of $\phi_\alpha(\alpha,t)$. By adding n_++n_- columns which span the stable and unstable subspaces of $\bar{f}_y$ we obtain a transformation matrix $E(\alpha,t)=(E_\pm(\alpha,t),\phi_\alpha(\alpha,t))$ which block-diagonalizes $\bar{f}_y$:

$$E^{-1}\bar{f}_yE=\Lambda=\begin{pmatrix}\Lambda_- & & \\ & \Lambda_+ & \\ & & 0\end{pmatrix}.$$

Denoting the last n_0 rows of $E^{-1}(\alpha,t)$ by $H(\alpha,t)$ it follows that

$$H(\alpha,t)\phi_\alpha(\alpha,t)=I_{n_0} \tag{2.2}$$

and

$$H(\alpha,t)\bar{f}_y=0, \tag{2.3}$$

where I_r is the $r\times r$ identity matrix.

For solutions $y(t,\varepsilon)$ of (1.1),(1.2) we use the ansatz

$$y(t,\varepsilon)\sim\sum_{i=0}^{\infty}(\bar{y}_i(t)+L_iy(\tau)+R_iy(\sigma))\varepsilon^i, \tag{2.4}$$

where $\tau=t/\varepsilon$, $\sigma=(1-t)/\varepsilon$ and

$$\lim_{\tau\to\infty}L_iy(\tau)=0,\qquad \lim_{\sigma\to\infty}R_iy(\sigma)=0,\qquad i=0,1,\cdots. \tag{2.5}$$

2.1. The construction of the leading term. Substituting (2.4) into (1.1) and setting $\varepsilon=0$ yields

$$\bar{y}_0(t)=\phi(\alpha,t). \tag{2.6}$$

Differential equations determing the as yet unknown parameter α as a function of t are obtained from the relations we get by collecting the terms of order ε in (1.1), i.e.

$$\bar{y}_0'=\bar{f}_y\bar{y}_1+\bar{f}_\varepsilon. \tag{2.7}$$

Using (2.6), (2.7) reads

$$\phi_\alpha\alpha'+\phi_t=\bar{f}_y\bar{y}_1+\bar{f}_\varepsilon. \tag{2.8}$$

Multiplying (2.8) by $H(\alpha,t)$ and using (2.2) and (2.3) yields the relations for α,

$$\alpha'=H\big(\bar{f}_\varepsilon-\phi_t\big),\quad 0\leqq t\leqq 1. \tag{2.9}$$

Note that in practice (2.9) is usually obtained from (2.8) without the explicit use of H by eliminating $\bar{y}_1$ from n_0 equations in (2.8).

The equations for the layer corrections are

$$\frac{dL_0y}{d\tau}=f(\phi(\alpha(0),0)+L_0y,0,0),\quad 0\leqq\tau<\infty,\quad L_0y(\infty)=0, \tag{2.10}$$

and

$$\frac{dR_0y}{d\sigma}=-f(\phi(\alpha(1),1)+R_0y,1,0),\quad 0\leqq\sigma<\infty,\quad R_0y(\infty)=0. \tag{2.11}$$

Equating coefficients of order zero in (1.2) yields

$$b(\phi(\alpha(0),0)+L_0y(0),\phi(\alpha(1),1)+R_0y(0))=0. \tag{2.12}$$

We can now state our second fundamental assumption.

Hypothesis H2. The boundary value problem (2.9)–(2.12) has an isolated solution.

Because of the boundary conditions at infinity in (2.10), (2.11) stable manifolds naturally enter our discussion. There is an extensive literature on the subject of invariant manifolds. Some basic results, which can be found in Kelley (1967), imply the existence of an n_--dimensional stable manifold for (2.10) and an n_+-dimensional stable manifold for (2.11). The boundary conditions at infinity require L_0y and R_0y to be trajectories on these manifolds. Then Lemma 3 in Kelley (1967) implies the estimates

$$\begin{aligned}\|L_0y(\tau)\|&\leqq\text{const}\,e^{-\kappa\tau},\\ \|R_0y(\sigma)\|&\leqq\text{const}\,e^{-\kappa\sigma}\end{aligned} \tag{2.13}$$

with a positive constant κ. Subsequently $\|\cdot\|$ will denote a vector norm or the induced matrix norm.

In general, trying to solve problem (2.9)–(2.12) is quite unpleasant. The differential equations on finite and infinite intervals have to be solved simultaneously because there is a coupling by boundary conditions. In applications, however, some knowledge about the structure of the stable manifolds of (2.10) and (2.11) often enables us to obtain from (2.12) n_0 "reduced" boundary conditions for (2.9) alone which do not contain $L_0y(0)$ and $R_0y(0)$. This is the case in all of the above mentioned applications, where the problems on the interval $[0,1]$ and the problems on the infinite interval $[0,\infty)$ can be solved consecutively.

Hypothesis H2 implies that the linearized system

$$w'=\left[H_\alpha\langle\cdot,\tilde f_\varepsilon-\phi_t\rangle+H\left(\bar f_{y\varepsilon}\phi_\alpha-\phi_{\alpha t}\right)\right]w, \tag{2.14a}$$

$$\frac{du}{d\tau}=f_y(\phi(\alpha(0),0)+L_0y,0,0)(u+\phi_\alpha(\alpha(0),0)w(0)), \tag{2.14b}$$

$$\frac{dv}{d\sigma}=-f_y(\phi(\alpha(1),1)+R_0y,1,0)(v+\phi_\alpha(\alpha(1),1)w(1)), \tag{2.14c}$$

$$b_0(\phi_\alpha(\alpha(0),0)w(0)+u(0))+b_1(\phi_\alpha(\alpha(1),1)w(1)+v(0))=0, \tag{2.14d}$$

$$u(\infty)=0,\qquad v(\infty)=0 \tag{2.15}$$

has only the trivial solution. In (2.14d) b_0 and b_1 are the partial derivatives of b with respect to the first and second argument respectively at $(\phi(\alpha(0),0)+L_0y(0),\ \phi(\alpha(1),1)+R_0y(0))$. For bilinear forms B we use the notation $B\langle\cdot,\cdot\rangle$.

2.2. The construction of higher order terms. (2.8) is a linear equation for the smooth part $\bar y_1$ of the first order term. The coefficient matrix $\bar f_y$ is singular. By (2.9) we have chosen the inhomogeneity $\phi_\alpha\alpha'+\phi_t-\bar f_\varepsilon$ in a way that a solution to (2.8) exists. The

general solution of (2.8) can be written in the form

$$\bar{y}_1(t)=\phi_\alpha(\alpha,t)\beta_1(t)+\bar{y}_{1p}(t),$$

where $\bar{y}_{1p}(t)$ is a particular solution and β_1 is an n_0-dimensional parameter. To determine $\beta_1(t)$ we equate coefficients of ε^2 in (1.1) and obtain

$$\phi_\alpha\beta_1'+\phi_\alpha'\beta_1+\bar{y}_{1p}'=\bar{f}_y\bar{y}_2+\frac{1}{2}\bar{f}_{yy}\langle\bar{y}_1,\bar{y}_1\rangle+\bar{f}_{y\varepsilon}\bar{y}_1+\frac{1}{2}\bar{f}_{\varepsilon\varepsilon}. \tag{2.16}$$

Analogously to the determination of α, multiplying (2.16) by H yields

$$\beta_1'=H\left[\frac{1}{2}\bar{f}_{yy}\langle\bar{y}_1,\bar{y}_1\rangle+\bar{f}_{y\varepsilon}\bar{y}_1-\phi_\alpha'\beta_1\right]+H\left[\frac{1}{2}\bar{f}_{\varepsilon\varepsilon}-\bar{y}_{1p}'\right]. \tag{2.17}$$

Vasileva and Butuzov (1978, p. 68) show that (2.17) is a linear equation for β_1. Since we require the coefficient matrix explicitly, we will reproduce their argument. In (2.17) we write

$$\frac{1}{2}H\bar{f}_{yy}\langle\bar{y}_1,\bar{y}_1\rangle=\frac{1}{2}H\bar{f}_{yy}\langle\phi_\alpha\beta_1,\phi_\alpha\beta_1\rangle+H\bar{f}_{yy}\langle\phi_\alpha\beta_1,\bar{y}_{1p}\rangle+\frac{1}{2}\bar{f}_{yy}\langle\bar{y}_{1p},\bar{y}_{1p}\rangle, \tag{2.18}$$

which follows from the fact that $\bar{f}_{yy}$ is a symmetric bilinear form. Differentiating (2.3) with respect to α yields

$$H_\alpha\langle\cdot,\bar{f}_y\cdot\rangle+H\bar{f}_{yy}\langle\phi_\alpha\cdot,\cdot\rangle=0. \tag{2.19}$$

Multiplying (2.19) with ϕ_α gives

$$H_\alpha\langle\cdot,\bar{f}_y\phi_\alpha\cdot\rangle+H\bar{f}_{yy}\langle\phi_\alpha\cdot,\phi_\alpha\cdot\rangle=0.$$

Due to (2.1) ($\bar{f}_y\phi_\alpha=0$) the first term on the right-hand side of (2.18) disappears and (2.17) can be written in the form

$$\beta_1'=H\left[\bar{f}_{yy}\langle\phi_\alpha\cdot,\bar{y}_{1p}\rangle+\bar{f}_{y\varepsilon}\phi_\alpha-\phi_\alpha'\right]\beta_1+\bar{G}_1, \tag{2.20}$$

where $\bar{G}_1$ depends on α and t only. Next we will show that the coefficient matrix S in (2.20) is equal to that in (2.14a). Obviously

$$S=H\left[\bar{f}_{yy}\langle\phi_\alpha\cdot,\bar{y}_{1p}\rangle-\phi_{\alpha\alpha}\langle\alpha',\cdot\rangle\right]+H\left[\bar{f}_{y\varepsilon}\phi_\alpha-\phi_{\alpha t}\right]. \tag{2.21}$$

Differentiation of (2.2) with respect to α gives

$$H_\alpha\langle\cdot,\phi_\alpha\cdot\rangle+H\phi_{\alpha\alpha}\langle\cdot,\cdot\rangle=0. \tag{2.22}$$

It follows from (2.19), (2.21) and (2.22) that

$$S=H_\alpha\langle\cdot,\phi_\alpha\alpha'-\bar{f}_y\bar{y}_{1p}\rangle+H\left[\bar{f}_{y\varepsilon}\phi_\alpha-\phi_{\alpha t}\right].$$

Using the fact that $\bar{y}_{1p}$ is a particular solution of (2.8) it is now obvious that the coefficient matrices in (2.14a) and (2.20) are the same.

Suppose we have constructed $\bar{y}_0,\cdots,\bar{y}_{n-1}$, $n\geqq 2$. Then we determine $\bar{y}_n$ from an equation of the form

$$\bar{f}_y\bar{y}_n=F_n(\bar{y}_0,\cdots,\bar{y}_{n-1}), \tag{2.23}$$

where the inhomogeneity satisfies the solvability condition $HF_n=0$. Thus the general solution of (2.23) can be written as

$$\bar{y}_n=\phi_\alpha\beta_n+\bar{y}_{np}.$$

Equating coefficients of ε^{n+1} in (1.1) gives

$$\phi_\alpha \beta_n' + \phi_\alpha' \beta_n = \bar{f}_y \bar{y}_{n+1} + \bar{f}_{yy}\langle \bar{y}_1, \bar{y}_n \rangle + \bar{f}_{y\varepsilon} \bar{y}_n + \tilde{G}_n,$$

with $\tilde{G}_n$ depending only on $\bar{y}_0, \cdots, \bar{y}_{n-1}$. Multiplying by H and repeating the argument we used for proving the linearity of the equations for β_1 we get

$$\beta_n' = H\left[\bar{f}_{yy}\langle \bar{y}_{1p}, \phi_\alpha \rangle + \bar{f}_{y\varepsilon}\phi_\alpha - \phi_\alpha'\right]\beta_n + \bar{G}_n, \tag{2.24}$$

which has the same coefficient matrix as (2.20). $\bar{G}_n$, like $\tilde{G}_n$, depends only on $\bar{y}_0, \cdots, \bar{y}_{n-1}$. Suppose we have constructed $\bar{y}_0, \cdots, \bar{y}_{n-1}$; $L_0 y, \cdots, L_{n-1} y$; $R_0 y, \cdots, R_{n-1} y$, where the layer corrections $L_i y$, $R_i y$ satisfy exponential estimates of the type (2.13). Then $L_n y$ and $R_n y$ satisfy

$$\frac{dL_n y}{d\tau} = f_y\big(\phi(\alpha(0),0) + L_0 y, 0, 0\big)\big(L_n y + \phi_\alpha(\alpha(0),0)\beta_n(0)\big) + L_n G, \tag{2.25a}$$

$$\frac{dR_n y}{d\sigma} = -f_y\big(\phi(\alpha(1),1) + R_0 y, 1, 0\big)\big(R_n y + \phi_\alpha(\alpha(1),1)\beta_n(1)\big) + R_n G, \tag{2.25b}$$

$$L_n y(\infty) = 0, \qquad R_n y(\infty) = 0, \tag{2.25c}$$

where $L_n G$ and $R_n G$ depend on the terms in the expansion up to order $n-1$. Besides, $L_n G$ and $R_n G$ satisfy exponential estimates of the type (2.13). (2.25a) and (2.25b) differ from (2.14b), (2.14c) only in the terms $L_n G$ and $R_n G$. Equating coefficients of ε^n in (1.2) yields the boundary conditions

$$b_0\big(\phi_\alpha(\alpha(0),0)\beta_n(0) + L_n y(0)\big) + b_1\big(\phi_\alpha(\alpha(1),1)\beta_n(1) + R_n y(0)\big) = c_n, \tag{2.26}$$

where c_n depends on the same terms as $L_n G$ and $R_n G$. These boundary conditions differ from (2.14d) only in the right-hand side c_n. The unique solvability of the problem (2.24) ((2.20) for $n=1$), (2.25) and (2.26) follows from the fact that (2.14), (2.15) has only the trivial solution. $L_n y$ and $R_n y$ are exponentially decaying functions, which is a consequence of Lemma 3.2 in the next section. Thus, the terms in the formal asymptotic expansion (2.4) can be constructed consecutively up to arbitrary order.

3. BVP's on infinite and "long" intervals. In this section we investigate linear problems of the type

$$y' = A(t)y + g(t), \quad t \geqq 0, \quad y \in R^n, \tag{3.1a}$$

$$y(\infty) = 0, \qquad \text{i.e. } \lim_{t\to\infty} y(t) = 0, \tag{3.1b}$$

$$By(0) = \beta. \tag{3.1c}$$

Also we shall derive results on the well-posedness of problems obtained from (3.1) by cutting the infinite interval at a large T and replacing (3.1b) by an appropriate boundary condition at T.

The proofs of the results we state will be given in the Appendix and follow along the lines of de Hoog and Weiss (1980) and Markowich (1982, 1983). In these papers instead of (3.1b) the weaker condition $y \in C[0,\infty]$, i.e. $\lim_{t\to\infty} y(t)$ exists and is finite, is used. However, in the singular perturbation context, (3.1b) is relevant (cf. condition (2.5)). Thus the results are slightly different, but the methods of proof are similar.

3.1. Problems with constant coefficients. We consider the problem

$$y' = My + g(t), \qquad t \geqq 0, \tag{3.2a}$$

$$y(\infty) = 0, \tag{3.2b}$$

$$By(0) = \beta, \tag{3.2c}$$

where the matrix M has a splitting

$$E^{-1}ME = \Lambda = \begin{pmatrix} \Lambda_- & & \\ & \Lambda_+ & \\ & & 0 \end{pmatrix},$$

with the eigenvalues of the n_--dimensional square matrix Λ_- having negative real parts, the eigenvalues of the n_+-dimensional matrix Λ_+ having positive real parts and the zero matrix having dimension $n_0 = n - n_- - n_+$. We denote the column decomposition of E corresponding to the diagonal blocks of Λ by $E = (E_-, E_+, E_0)$ and the row decomposition of E^{-1} by $(E^{-1})^T = ((E_-^{-1})^T, (E_+^{-1})^T, (E_0^{-1})^T)$.

To satisfy (3.2b), we pose the following restrictions on $g(t)$:

$$g \in C[0,\infty], \quad g(\infty) = 0 \quad \text{and} \quad \|E_0^{-1} g(t)\| = O(t^{-1-\nu}), \quad \nu > 0. \tag{3.3}$$

Regarding the unique solvability of (3.2), we have

THEOREM 3.1. *The boundary value problem* (3.2) *has a unique solution for all* $\beta \in R^{n_-}$ *and for all* $g(t)$ *satisfying* (3.3), *iff the matrix* B *has* n_- *rows and* BE_- *is regular.*

LEMMA 3.1. *Let the assumptions of Theorem* 3.1 *and*

$$\|g(t)\| = O(e^{-\kappa t}), \qquad \kappa > 0, \tag{3.4}$$

be valid. Then the solution $y(t)$ *of* (3.2) *satisfies*

$$\|y(t)\| = O(e^{-\kappa t}), \qquad \kappa > 0. \tag{3.5}$$

(*Henceforth in exponential estimates of the type* (3.4), (3.5) κ *will denote a generic constant.*)

Next we consider a problem on the finite interval $[0, T]$:

$$x_T' = Mx_T + g(t), \qquad 0 \leqq t \leqq T, \tag{3.6a}$$

$$\begin{pmatrix} E_+^{-1} \\ E_0^{-1} \end{pmatrix} x_T(T) = \gamma, \tag{3.6b}$$

$$Bx_T(0) = \beta. \tag{3.6c}$$

THEOREM 3.2. *Let the assumptions of Theorem* 3.1 *be valid. Then* (3.6) *has a unique solution* $x_T(t)$ *for all* $T > 0$ *and for all* $g \in C[0,T]$, $\beta \in R^{n_-}$ *and* $\gamma \in R^{n_+ + n_0}$. x_T *satisfies the estimate*

$$\|x_T\|_{[0,T]} \leqq \text{const}\big(T\|g\|_{[0,T]} + \|\beta\| + \|\gamma\|\big), \tag{3.7}$$

where the norm $\|\cdot\|_{[t_1,t_2]}$ *on the space* $C[t_1,t_2]$ *is defined by*

$$\|f\|_{[t_1,t_2]} := \sup_{s \in [t_1,t_2]} \|f(s)\|.$$

3.2. Problems with variable coefficients. We consider problem (3.1) with

$$A(t)=M+F(t), \quad \text{where } \|F(t)\|=O(e^{-\kappa t}). \tag{3.8}$$

In the Appendix we will show that the general solution of the homogeneous problem (3.1a), (3.1b), with $A(t)$ defined by (3.8), is of the form $y(t)=\Phi_-(t)\eta_-$ with $\eta_-\in R^{n_-}$, where the $n\times n_-$-matrix $\Phi_-(t)$ is defined in the Appendix. We then have

THEOREM 3.3. *The boundary value problem* (3.1) *with* $A(t)$ *given by* (3.8) *has a unique solution for all* $\beta\in R^{n_-}$ *and for all* $g(t)$ *satisfying* (3.3), *iff* B *has* n_- *rows and* $B\Phi_-(0)$ *is regular.*

The analogue to Lemma 3.1 is

LEMMA 3.2. *Let the assumptions of Theorem* 3.3 *and* (3.4) *be valid. Then the solution* $y(t)$ *of* (3.1) *satisfies* (3.5).

Again we consider the "finite" problem

$$x_T'=A(t)x_T+g(t), \qquad 0\leqq t\leqq T, \tag{3.9a}$$

$$\begin{pmatrix} E_+^{-1} \\ E_0^{-1} \end{pmatrix} x_T(T)=\gamma, \tag{3.9b}$$

$$Bx_T(0)=\beta. \tag{3.9c}$$

THEOREM 3.4. *Let the assumptions of Theorem* 3.3 *be valid. Then* (3.9) *has a unique solution* $x_T(t)$ *for* T *big enough and for all* $g\in C[0,T]$, $\beta\in R^{n_-}$ *and* $\gamma\in R^{n_++n_0}$. x_T *satisfies the estimate* $\|x_T\|_{[0,T]}\leqq \text{const}(T\|g\|_{[0,T]}+\|\beta\|+\|\gamma\|)$.

THEOREM 3.5. *There exists a fundamental solution* $\psi_T(t)$ *of* (3.9a) *which satisfies*

$$\|\psi_T(t)-X_T(t)\|=O(e^{-\kappa t}), \tag{3.10}$$

where

$$X_T(t)=E\begin{pmatrix} e^{\Lambda_- t} & & \\ & e^{\Lambda_+(t-T)} & \\ & & I \end{pmatrix}$$

is a fundamental solution of (3.6a).

4. Existence and uniqueness result. Let $Y_i(t,\varepsilon)$ denote the ith partial sum in (2.1), i.e.

$$Y_i(t,\varepsilon)=\sum_{j=0}^{i}\left(\bar y_j(t)+L_j y\left(\frac{t}{\varepsilon}\right)+R_j y\left(\frac{1-t}{\varepsilon}\right)\right)\varepsilon^j.$$

Let the space $C^1[0,1]$ be equipped with the norm $\|\cdot\|_*$ defined by

$$\|y\|_*=\|y\|_{[0,1]}+\varepsilon\|y'\|_{[0,1]}.$$

Then $(C^1[0,1], \|\cdot\|_*)$ is a Banach space. Balls in this space will be denoted by

$$B_\delta(y_0)=\{\, y\in C^1[0,1] \mid \|y-y_0\|_*\leqq\delta\,\}.$$

We now prove the main result of this paper.

THEOREM 4.1. *Let* f *and* b *in* (1.1), (1.2) *be infinitely differentiable and let hypotheses* H1, H2 *be valid. Then there are constants* c, $\varepsilon_0>0$ *such that for* $0<\varepsilon\leqq\varepsilon_0$ *a solution* $y(t,\varepsilon)$ *to* (1.1), (1.2) *exists which is unique in the ball* $B_{c\varepsilon}(Y_1)$ *and satisfies*

$$\|y-Y_i\|_*=O(\varepsilon^{i+1}), \qquad i\geqq 0.$$

Proof. Common methods for proving results like Theorem 4.1 are based on the fixed point theorem for contraction mappings in Banach spaces (cf., e.g. Eckhaus (1979) for general results in perturbation theory and Vasileva and Butuzov (1973), (1978) for applications in singular perturbations). We shall apply a theorem due to Van Harten (1978) stated by Eckhaus (1979, p. 237 f). Using his notation, (1.1), (1.2) is written as

$$L_\varepsilon y = 0. \tag{4.1}$$

In our case L_ε is an operator from the Banach space $(C^1[0,1], \|\cdot\|_*)$ to $(C[0,1]\times R^n, \|\cdot\|_{**})$, where we define the norm $\|\cdot\|_{**}$ as the sum of the supremum norm on $C[0,1]$ and the maximum norm on R^n. Our method of constructing the formal approximation Y_i yields

$$L_\varepsilon Y_i = \rho_i, \tag{4.2}$$

where $\|\rho_i\|_{**} = O(\varepsilon^{i+1})$. Subtracting (4.2) from (4.1) yields the following problem for the remainder term $R_i = y - Y_i$:

$$\hat{L}_\varepsilon R_i := L_\varepsilon(R_i + Y_i) - L_\varepsilon Y_i = -\rho_i. \tag{4.3}$$

Denoting the linearization of L_ε at Y_i by A_ε, we obtain that decomposition

$$\hat{L}_\varepsilon = A_\varepsilon + P_\varepsilon.$$

The above mentioned theorem requires us

a) to obtain an estimate

$$\|A_\varepsilon^{-1}\|_* \leqq \lambda(\varepsilon),$$

b) to prove a Lipschitz condition for P_ε of the form

$$\|P_\varepsilon v_1 - P_\varepsilon v_2\|_{**} \leqq \mu(\varepsilon,\delta)\|v_1 - v_2\|_*$$

for v_1, $v_2 \in B_\delta(0)$, where $\lim_{\delta\to 0}\mu(\varepsilon,\delta) = 0$. Then we have to determine $\bar{\delta} = \bar{\delta}(\varepsilon)$, such that

$$\lambda(\varepsilon)\mu(\varepsilon,\delta) \leqq 1-\gamma, \qquad \gamma \in (0,1)$$

for all $\delta \leqq \bar{\delta}$. If

$$\|\rho_i\|_{**} < \frac{\gamma\bar{\delta}}{\lambda(\varepsilon)}$$

then there is a solution R_i of (4.3) which is unique in the ball $B_{\bar{\delta}}(0)$ and satisfies

$$\|R_i\|_* \leqq \frac{1}{\gamma}\lambda(\varepsilon)\|\rho_i\|_{**}.$$

We will show that in our case

$$\mu(\varepsilon,\delta) = c_1\delta, \tag{4.4}$$

$$\lambda(\varepsilon) = \frac{c_2}{\varepsilon}. \tag{4.5}$$

Thus, we obtain $\bar{\delta} = \varepsilon(1-\gamma)/c_1c_2$ and the following condition for ρ_i

$$\|\rho_i\|_{**} < \frac{\varepsilon^2\gamma(1-\gamma)}{c_1c_2^2}.$$

This certainly holds for $i \geqq 2$ and ε small enough. We then have a solution R_i of (4.3), which is unique in $B_{c\varepsilon}(0)$ with $c = (1-\gamma)/c_1 c_2$ and satisfies

$$\|R_i\|_* \leqq \frac{c_2}{\gamma\varepsilon}\|\rho_i\|_{**} = O(\varepsilon^i).$$

By the argument

$$\|R_{i-1}\|_* \leqq \|R_i\|_* + \|Y_i - Y_{i-1}\|_* = O(\varepsilon^i)$$

the results of Theorem 4.1 are established. It remains to show (4.4) and (4.5): Using a formula for $P_\varepsilon v_1 - P_\varepsilon v_2$ (Eckhaus (1979, p. 239)) (4.4) follows immediately.

To establish (4.5), we have to analyze the linearization of (1.1), (1.2), which reads

$$\begin{aligned} &\varepsilon\hat{y}' = f_y(Y_i, t, \varepsilon)\hat{y} + g(t), \\ &\hat{b}_0(Y_i(0), Y_i(1))\hat{y}(0) + \hat{b}_1(Y_i(0), Y_i(1))\hat{y}(1) = \beta \end{aligned} \tag{4.6}$$

or

$$\begin{aligned} &\varepsilon\hat{y}' = f_y(\phi(t) + \varepsilon\bar{y}_1 + L_0 y + R_0 y, t, \varepsilon)\hat{y} + \omega(\varepsilon^2 + \varepsilon e^{-\kappa\tau} + \varepsilon e^{-\kappa\sigma})\hat{y} + g(t), \\ &b_0\hat{y}(0) + b_1\hat{y}(1) = \omega(\varepsilon)(\hat{y}(0), \hat{y}(1)) + \beta, \end{aligned} \tag{4.7}$$

where $\phi(t)$ stands for $\phi(\alpha(t), t)$, b_0 and b_1 are like in §2 and ω is used generically to denote linear operators satisfying $\|\omega(r(\varepsilon, t))\| = O(r(\varepsilon, t))$. As in Vasileva and Butuzov (1973) we introduce a partition of the interval $[0,1]$ into three parts $[0, t_0]$, $[t_0, t_1]$ and $[t_1, 1]$, where

$$t_0 = -\frac{2}{\kappa}\varepsilon\ln\varepsilon, \qquad t_1 = 1 + \frac{2}{\kappa}\varepsilon\ln\varepsilon,$$

and κ is taken from the estimate (2.13). We define

$$\tau_0 = \frac{t_0}{\varepsilon}, \qquad \sigma_1 = \frac{1 - t_1}{\varepsilon}.$$

With (2.13) we obtain

$$\|L_0 y(\tau)\| = O(\varepsilon^2), \quad \tau \geqq \tau_0, \qquad \|R_0 y(\sigma)\| = O(\varepsilon^2), \qquad \sigma \geqq \sigma_1.$$

Introducing the independent variables τ and σ on the short intervals $[0, t_0]$ and $[t_1, 1]$, we obtain a problem equivalent to (4.7),

$$\text{(4.8a)} \quad \frac{d\hat{y}_1}{d\tau} = f_y(\phi(0) + L_0 y, 0, 0)\hat{y}_1 + \omega(\varepsilon\ln\varepsilon)\hat{y}_1 + g(\varepsilon\tau), \qquad 0 \leqq \tau \leqq \tau_0,$$

$$\text{(4.8b)} \quad \frac{d\hat{y}_2}{d\sigma} = -f_y(\phi(1) + R_0 y, 1, 0)\hat{y}_2 + \omega(\varepsilon\ln\varepsilon)\hat{y}_2 + g(1 - \varepsilon\sigma), \qquad 0 \leqq \sigma \leqq \sigma_1,$$

$$\text{(4.8c)} \quad \varepsilon\hat{y}_3' = f_y(\phi(t) + \varepsilon\bar{y}_1, t, \varepsilon)\hat{y}_3 + \omega(\varepsilon^2)\hat{y}_3) + g(t), \qquad t_0 \leqq t \leqq t_1,$$

$$\text{(4.8d)} \quad b_0\hat{y}_1(0) + b_1\hat{y}_2(0) = \omega(\varepsilon)(\hat{y}_1(0), \hat{y}_2(0) + \beta,$$

$$\text{(4.8e)} \quad \hat{y}_1(\tau_0) = \hat{y}_3(t_0), \qquad \hat{y}_2(\sigma_1) = \hat{y}_3(t_1).$$

The transformation

$$\hat{y}_3 = E\xi, \qquad \text{where } \xi = \begin{pmatrix} \xi_\pm \\ \xi_0 \end{pmatrix},$$

changes (4.8c) to

$$\varepsilon\xi' = \left(E^{-1}f_y(\phi(t)+\varepsilon\bar{y}_1,t,\varepsilon)E-\varepsilon E^{-1}E'\right)\xi+\omega(\varepsilon^2)\xi+E^{-1}g(t). \tag{4.9}$$

From

$$f_y(\phi(t)+\varepsilon\bar{y}_1,t,\varepsilon)=\bar{f}_y+\varepsilon\left(\bar{f}_{yy}\langle\cdot,\bar{y}_1\rangle+\bar{f}_{y\varepsilon}\right)+\omega(\varepsilon^2).$$

It follows on using (2.19) and (2.1) that (4.9) can be written as

$$\varepsilon\xi'_{\pm}=\Lambda_{\pm}\xi_{\pm}+\omega(\varepsilon)\xi+E_{\pm}^{-1}g(t), \tag{4.10a}$$

$$\xi'_0=\left(H\bar{f}_{yy}\langle\phi_\alpha\cdot,\bar{y}_{1p}\rangle+H\bar{f}_{y\varepsilon}\phi_\alpha-H\phi'_\alpha\right)\xi_0 \tag{4.10b}$$

$$+H\left[\bar{f}_{yy}\langle E_{\pm}\cdot,\bar{y}_1\rangle+\bar{f}_{y\varepsilon}E_{\pm}-E'_{\pm}\right]\xi_{\pm}+\omega(\varepsilon)\xi+\frac{1}{\varepsilon}Hg(t).$$

With the decoupling transformation

$$\xi_0=\tilde{\xi}_0+\varepsilon H\left[\bar{f}_{yy}\langle E_{\pm}\cdot,\bar{y}_1\rangle+\bar{f}_{y\varepsilon}E_{\pm}-E'_{\pm}\right]\Lambda_{\pm}^{-1}\xi_{\pm},\qquad \tilde{\xi}=\begin{pmatrix}\xi_{\pm}\\ \tilde{\xi}_0\end{pmatrix}$$

(4.10b) becomes

$$\tilde{\xi}'_0=\left(H\bar{f}_{yy}\langle\phi_\alpha\cdot,\bar{y}_{1p}\rangle+H\bar{f}_{y\varepsilon}\phi_\alpha-H\phi'_\alpha\right)\tilde{\xi}_0+\omega(\varepsilon)\tilde{\xi}+\omega\left(\frac{1}{\varepsilon}\right)g(t). \tag{4.11}$$

Introducing the transformation

$$\begin{aligned}\hat{y}_1&=\mu+\phi_\alpha(0)\tilde{\xi}_0(t_0),\\ \hat{y}_2&=\nu+\phi_\alpha(1)\tilde{\xi}_0(t_1),\end{aligned} \tag{4.12}$$

up to $O(\varepsilon\ln\varepsilon)$ terms, (4.8) takes the form

$$\tilde{\xi}'_0=\left[H_\alpha\langle\cdot,\bar{f}_\varepsilon-\phi_t\rangle+H\left(\bar{f}_{y\varepsilon}-\phi_{\alpha t}\right)\right]\tilde{\xi}_0+k_1(t),\qquad t_0\leqq t\leqq t_1, \tag{4.13a}$$

$$\frac{d\mu}{d\tau}=f_y(\phi(0)+L_0y,0,0)(\mu+\phi_\alpha(0)\tilde{\xi}_0(t_0))+k_2(\tau),\qquad 0\leqq\tau\leqq\tau_0, \tag{4.13b}$$

$$\frac{d\nu}{d\sigma}=-f_y(\phi(1)+R_0y,1,0)(\nu+\phi_\alpha(1)\tilde{\xi}_0(t_1))+k_3(\sigma),\qquad 0\leqq\sigma\leqq\sigma_1, \tag{4.13c}$$

$$b_0(\mu(0)+\phi_\alpha(0)\tilde{\xi}_0(t_0))+b_1(\nu(0)+\phi_\alpha(1)\tilde{\xi}_0(t_1))=\beta_1, \tag{4.13d}$$

$$\varepsilon\xi'_{\pm}=\Lambda_{\pm}\xi_{\pm}+k_4(t),\qquad t_0\leqq t\leqq t_1 \tag{4.14a}$$

$$\begin{aligned}&\mu(\tau_0)+\phi_\alpha(0)\tilde{\xi}_0(t_0)=E(t_0)\tilde{\xi}(t_0)+\beta_2,\ \nu(\sigma_1)+\phi_\alpha(1)\tilde{\xi}_0(t_1)\\ &\qquad=E(t_1)\tilde{\xi}(t_1)+\beta_3.\end{aligned} \tag{4.14b}$$

where we now employ arbitrary inhomogeneities k_i and β_j. The equality of the coefficient matrices in (4.11) and (4.13a) has been proven in §2. Thus, the homogeneous equations (4.13) correspond to (2.14), and the solvability of (2.14), (2.15) will now be employed to conclude unique solvability of (4.13), (4.14). The general solutions of the

differential equations in (4.13), (4.14) have the form

$$
\begin{aligned}
&\mu(\tau)=M(\tau)\eta+P(\tau)\tilde{\xi}_0(t_0)+\mu_p(\tau),\\
&\nu(\sigma)=N(\sigma)\delta+Q(\sigma)\tilde{\xi}_0(t_1)+\nu_p(\sigma),\\
&\xi_{\pm}(t)=G_{\pm}(t)\gamma_{\pm}+\xi_{\pm p}(t),\\
&\tilde{\xi}_0(t)=G_0(t)\gamma_0+\tilde{\xi}_{0p}(t).
\end{aligned}
\tag{4.15}
$$

From Theorem 3.5 we obtain for $M(\tau)$ and $N(\sigma)$,

$$
\left\| M(\tau)-E(0)\begin{pmatrix} \exp(\Lambda_-(0)\tau) & \\ & \exp(\Lambda_+(0)(\tau-\tau_0)) \end{pmatrix}_I \right\| = O(e^{-\kappa\tau}),
\tag{4.16a}
$$

$$
\left\| N(\sigma)-E(1)\begin{pmatrix} \exp(-\Lambda_-(1)(\sigma-\sigma_1)) & \\ & \exp(-\Lambda_+(1)\sigma) \end{pmatrix}_I \right\| = O(e^{-\kappa\sigma}),
\tag{4.16b}
$$

and it follows from the proof of Theorem 3.4 that

$$
\begin{aligned}
&\|\mu_p\|_{[0,\tau_0]}\leqq \text{const}\,\tau_0\|k_2\|_{[0,\tau_0]}=\text{const}\ln\frac{1}{\varepsilon}\|k_2\|_{[0,\tau_0]},\\
&\|\nu_p\|_{[0,\sigma_1]}\leqq \text{const}\,\sigma_1\|k_3\|_{[0,\sigma_1]}=\text{const}\ln\frac{1}{\varepsilon}\|k_3\|_{[0,\sigma_i]}.
\end{aligned}
$$

Due to (2.1), $f_y(\phi(0)+L_0y,0,0)\phi_\alpha(0)$ and $f_y(\phi(1)+R_0y,1,0)\phi_\alpha(1)$ decay exponentially. Lemma 3.2 therefore implies

$$
\|P(\tau)\|=O(e^{-\kappa\tau}),\qquad \|Q(\sigma)\|=O(e^{-\kappa\sigma}).
\tag{4.17}
$$

Standard results yield

$$
G_{\pm}(t)=\begin{pmatrix} \exp\left(\Lambda_-(t_0)\dfrac{t-t_0}{\varepsilon}\right) & \\ & \exp\left(\Lambda_+(t_1)\dfrac{t-t_1}{\varepsilon}\right) \end{pmatrix}+O(\varepsilon),
\tag{4.18a}
$$

$$
\|\xi_{\pm p}\|_{[t_0,t_1]}\leqq \text{const}\,\|k_4\|_{[t_0,t_1]}
\tag{4.18b}
$$

and

$$
\|\tilde{\xi}_{0p}\|_{[t_0,t_1]}\leqq \text{const}\|k_1\|_{[t_0,t_1]}.
$$

Substituting the representation (4.15) into the boundary conditions (4.13d) and (4.14b), we obtain

$$
\begin{aligned}
&b_0[M(0)\eta+P(0)G_0(t_0)\gamma_0+\phi_\alpha(0)G_0(t_0)\gamma_0]\\
&\quad+b_1[N(0)\delta+Q(0)G_0(t_1)\gamma_0+\phi_\alpha(1)G_0(t_1)\gamma_0]=\bar{\beta}_1,\\
&M(\tau_0)\eta+P(\tau_0)G_0(t_0)\gamma_0+\phi_\alpha(0)G_0(t_0)\gamma_0-E_{\pm}(t_0)G_{\pm}(t_0)\gamma_{\pm}-\phi_\alpha(t_0)G_0(t_0)\gamma_0=\bar{\beta}_2,\\
&N(\sigma_1)\delta+Q(\sigma_1)G_0(t_1)\gamma_0+\phi_\alpha(1)G_0(t_1)\gamma_0-E_{\pm}(t_1)G_{\pm}(t_1)\gamma_{\pm}-\phi_\alpha(t_1)G_0(t_1)\gamma_0=\bar{\beta}_3,
\end{aligned}
$$

where the $\bar{\beta}_j$ contain the contributions of the β_j and the particular solutions. Denoting the coefficient matrix of this linear system by $C(\varepsilon)$, the estimates (4.16)–(4.18) imply that $C(\varepsilon)=C(0)+\omega(\varepsilon\ln\varepsilon)$, where

$$C(0)=\left[\begin{array}{c|c|cc|c} b_0M(0) & b_1N(0) & 0 & & S \\ 0\ E_+(0)\ E_0(0) & 0 & -E_-(0) & 0 & 0 \\ 0 & E_-(1)\,0\,E_0(1) & 0 & -E_+(1) & 0 \end{array}\right] \tag{4.19}$$

and

$$S=b_0\left[P(0)+\phi_\alpha(0)\right]G_0(0)+b_1\left[Q(0)+\phi_\alpha(1)\right]G_0(1).$$

Here the ordering of the unknowns is η, δ, $\gamma_\pm$, γ_0, with the partitions $\eta^T=(\eta_-^T,\eta_+^T,\eta_0^T)$, $\delta^T=(\delta_-^T,\delta_+^T,\delta_0^T)$, $\gamma_\pm^T=(\gamma_-^T,\gamma_+^T)$. Permutation of the columns in (4.19), corresponding to the ordering η, δ_+, γ_0, $-\gamma_-$, η_+, η_0, δ_-, $-\gamma_+$, δ_0 yields the matrix

$$\begin{pmatrix} \bar{C} & X_1 & X_2 \\ 0 & E(0) & 0 \\ 0 & 0 & E(1) \end{pmatrix} \tag{4.20}$$

where $\bar{C}$, X_1, X_2 are square matrices. It follows on employing Theorem 3.3 that the unique solvability of (2.14), (2.15) is equivalent to C being nonsingular, which implies that the matrix (4.20) is nonsingular. Thus, $C(\varepsilon)$ is nonsingular as well and has a bounded inverse for ε small enough. This and the estimates on the particular solutions imply that (4.13), (4.14) is uniquely solvable for small ε and that

$$\begin{aligned}&\|\tilde{\xi}\|_{[t_0,t_1]},\ \|\mu\|_{[0,\tau_0]},\ \|\nu\|_{[0,\sigma_1]}\\ &\qquad\leqq \text{const}\left(\sum_{i=1}^{3}\|\beta_i\|+\|k_1\|_{[t_0,t_1]}+\|k_4\|_{[t_0,t_1]}+\ln\frac{1}{\varepsilon}\left(\|k_2\|_{[0,\tau_0]}+\|k_3\|_{[0,\sigma_1]}\right)\right).\end{aligned}$$

This allows the application of a contraction mapping argument to obtain unique solvability of (4.8), which is equivalent to (4.6). We thus have unique solvability of (4.6) for ε small enough, with the estimate

$$\|\hat{y}\|_{[0,1]}\leqq\text{const}\left(\|\beta\|+\varepsilon^{-1}\|g\|_{[0,1]}\right).$$

The differential equation in (4.6) can be used to obtain an estimate on $\varepsilon\|\hat{y}'\|_{[0,1]}$ which finally yields

$$\|\hat{y}\|_*\leqq\text{const}\left(\|\beta\|+\varepsilon^{-1}\|g\|_{[0,1]}\right)\leqq\text{const}\,\varepsilon^{-1}\|(\beta,g)\|_{**}.$$

This establishes (4.5) and completes the proof of the theorem.

5. Example. We consider the fundamental semiconductor device equations for the case of a symmetric $p-n$ junction with piecewise constant doping. The singular perturbation approach for this problem was originated by Vasileva, Kardosysoev and Stelmakh (1976). We assume that recombination-generation effects are negligible and that the total current is kept at a prescribed value J. For the scaling which leads to the formulation as a singular perturbation problem, see also Markowich et al. (1982). The

governing equations are

$$\begin{aligned} \varepsilon\psi' &= E, \\ \varepsilon E' &= n-p-1, \\ \varepsilon n' &= nE+\frac{\varepsilon J}{2}, \\ \varepsilon p' &= -pE-\frac{\varepsilon J}{2}. \end{aligned} \tag{5.1}$$

$$\begin{aligned} &\psi(0)=0, \\ &n(0)=p(0), \\ &p(1)=\frac{1}{2}\left(-1+\sqrt{1+4\delta^4}\right)=p_1, \\ &n(1)=p_1+1. \end{aligned} \tag{5.2}$$

The variables ψ, E, n and p are scaled and proportional to the potential, the electric field, the electron density and the hole density in the device. ε and δ result from the scaling. ε is equal to the Debye length, and is small when the doping is large. Thus (5.1) is singularly perturbed in this situation.

In Vasileva and Stelmakh (1977) and Vasileva and Butuzov (1978) (5.1), (5.2) is considered with $\delta=0$. Smith (1980) treats the case of a symmetric $p-n$ junction where the doping and the given electron and hole current densities are not constant. In all these papers results are proven which are more or less equivalent to the one we will obtain below by an application of the general result Theorem 4.1.

The reduced equations

$$0=\bar{E}, \quad 0=\bar{n}-\bar{p}-1, \quad 0=\bar{n}\bar{E}, \quad 0=-\bar{p}\bar{E} \tag{5.3}$$

have the solution

$$\bar{\psi}=\alpha_1, \quad \bar{E}=0, \quad \bar{n}=\alpha_2+1, \quad \bar{p}=\alpha_2. \tag{5.4}$$

The Jacobian of the right-hand side of (5.1) at the solution of (5.3) is

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 0 & \alpha_2+1 & 0 & 0 \\ 0 & -\alpha_2 & 0 & 0 \end{pmatrix}$$

with the eigenvalues $\lambda_{1,2}=0$ and $\lambda_{3,4}=\pm\sqrt{2\alpha_2+1}$. Obviously, the matrix has rank 2. Thus hypothesis H1 is fulfilled with the assumption $\alpha_2 \geqq 0$ which is natural because $\bar{p}=\alpha_2$ denotes a density. As in chapter 2 we find differential equations for α_1 and α_2:

$$\begin{aligned} &\text{a)} \quad \alpha_1' = -\frac{J}{2\alpha_2+1}, \\ &\text{b)} \quad \alpha_2' = -\frac{J}{2(2\alpha_2+1)}. \end{aligned} \tag{5.5}$$

The equations for the left layer terms are

$$\begin{aligned}
&\text{a)} && \frac{dL\psi}{d\tau} = LE,\\
&\text{b)} && \frac{dLE}{d\tau} = Ln - Lp,\\
&\text{c)} && \frac{dLn}{d\tau} = (\alpha_2(0)+1+Ln)\,LE,\\
&\text{d)} && \frac{dLp}{d\tau} = -(\alpha_2(0)+Lp)\,LE.
\end{aligned} \tag{5.6}$$

The zeroth order right layer terms disappear. This is due to the fact that the last condition in (5.2) is consistent with (5.3), and will be proved by showing that there is a unique solution of (5.5), (5.6) satisfying the boundary conditions

$$\begin{aligned}
&\text{a)} && \alpha_1(0)+L\psi(0)=0,\\
&\text{b)} && Ln(0)+1=Lp(0),\\
&\text{c)} && \alpha_2(1)=p_1,\\
&\text{d)} && L\psi(\infty)=LE(\infty)=Lp(\infty)=Ln(\infty)=0.
\end{aligned} \tag{5.7}$$

Introducing $L\psi$ as a new independent variable in (5.6c), (5.6d) and solving the resulting linear equations yields with (5.7d)

$$\begin{aligned}
Ln &= (\alpha_2(0)+1)(e^{L\psi}-1),\\
Lp &= \alpha_2(0)(e^{-L\psi}-1).
\end{aligned} \tag{5.8}$$

Now we substitute (5.8) in (5.6b) and solve this equation again with $L\psi$ as independent variable. We obtain

$$LE = -\sqrt{2}\left[(\alpha_2(0)+1)e^{L\psi}+\alpha_2(0)e^{-L\psi}-L\psi-2\alpha_2(0)-1\right]^{1/2}\operatorname{sgn} L\psi, \tag{5.9}$$

where the sign of LE is determined by the condition that the remaining equation for $L\psi$ has to have decaying solutions. (5.8), (5.9) represent the stable manifold of (5.6). Using (5.8) in (5.7b–c) gives

$$\begin{aligned}
&(\alpha_2(0)+1)e^{-\alpha_1(0)} = \alpha_2(0)e^{\alpha_1(0)},\\
&\alpha_2(1)=p_1.
\end{aligned} \tag{5.10}$$

The solution of (5.5), (5.10) is

$$\begin{aligned}
\alpha_1(t) &= \sqrt{1+4\delta^4+2J(1-t)} - \sqrt{1+4\delta^4+2J} + \ln\frac{1+\sqrt{1+4\delta^4+2J}}{\sqrt{4\delta^4+2J}},\\
\alpha_2(t) &= \frac{1}{2}\left(-1+\sqrt{1+4\delta^4+2J(1-t)}\right).
\end{aligned} \tag{5.11}$$

(5.7a) and (5.11) yield an initial value for $L\psi$:

$$L\psi(0) = -\ln\frac{1+\sqrt{1+4\delta^4+2J}}{\sqrt{4\delta^4+2J}}.$$

The proof of the isolatedness of this solution, i.e. the invertibility of the linearization of (5.5)–(5.7), is now outlined. We denote the linearization of the equation (a, b) by $(a, b)_1$ and proceed as follows: The terminal value problem $(5.5b)_1$, $(5.7c)_1$ has a unique solution. The equations $(5.6c, d)_1$ can be integrated similarly to (5.6c, d), and jointly with $(5.7a, b)_1$ lead to an initial condition for $(5.5a)_1$. It remains to determine a decaying solution of $(5.6a, b)_1$ with an initial value defined by $(5.7a)_1$. Writing $(5.6a, b)_1$ as a scalar second order equation, we can use the results of Fife (1974) on such problems to conclude existence and uniqueness of the desired solution.

Thus Hypothesis H2 has been verified and the validity of the formal approximation follows from Theorem 4.1.

Appendix: Proofs of the Results in §3.

Proof of Theorem 3.1. The general solution of (3.2a) is

$$y(t) = Y(t)\eta + y_p(t),$$

where $Y(t) = Ee^{\Lambda t}$ and

$$y_p(t) = H^\delta g(t) = E \begin{pmatrix} \int_\delta^t e^{\Lambda_-(t-s)} E_-^{-1} g(s)\, ds \\ \int_\infty^t e^{\Lambda_+(t-s)} E_+^{-1} g(s)\, ds \\ \int_\infty^t E_0^{-1} g(s)\, ds \end{pmatrix} \quad \text{with } \delta \geqq 0.$$

LEMMA A.1. *$H^\delta g(\infty) = 0$ holds for $g(t)$ satisfying* (3.3).

Proof.

a) $$\left\| \int_\delta^t e^{\Lambda_-(t-s)} E_-^{-1} g(s) \right\| \leqq \text{const} \int_\delta^t e^{-\kappa(t-s)} \| g(s) \|\, ds$$

$$= \text{const} \left(\int_\delta^{(t+\delta)/2} + \int_{(t+\delta)/2}^t \right) e^{-\kappa(t-s)} \| g(s) \|\, ds$$

$$\leqq \text{const} \left((e^{-\kappa(t-\delta)/2} - e^{-\kappa(t-\delta)}) \| g \|_{[\delta, (t+\delta)/2]} + \| g \|_{[(t+\delta)/2, t]} \right)$$

$$\to 0 \text{ for } t \to \infty$$

b) $$\left\| \int_\infty^t e^{\Lambda_+(t-s)} E_+^{-1} g(s)\, ds \right\| \leqq \text{const} \| g \|_{[t, \infty]} \int_t^\infty e^{\kappa(t-s)}\, ds$$

$$\leqq \text{const} \| g \|_{[t, \infty]} \to 0 \text{ for } t \to \infty$$

c) $$\left\| \int_\infty^t E_0^{-1} g(s)\, ds \right\| \leqq \text{const} \int_\infty^t s^{-1-\nu}\, ds = \text{const}\, t^{-\nu} \to 0 \text{ for } t \to \infty.$$

In $Y(t)$ the components corresponding to zero eigenvalues and eigenvalues with positive real parts do not satisfy (3.2b). Therefore, the general solution of (3.2a),(3.2b) is

$$y(t) = E_- e^{\Lambda_- t} \eta_- + H^\delta g(t). \tag{A.1}$$

Substituting (A.1) into (3.2c) shows the validity of Theorem 3.1.

Proof of Lemma 3.1. The proof is similar to that of Lemma A.1 and therefore omitted.

Proof of Theorem 3.2. The general solution of (3.6a) reads

$$x_T(t) = X_T(t)\eta + H_T^\delta g(t), \tag{A.2}$$

where

$$X_T(t) = E \begin{pmatrix} e^{\Lambda_- t} & & \\ & e^{\Lambda_+(t-T)} & \\ & & I \end{pmatrix}$$

and

$$H_T^\delta g(t) = E \begin{pmatrix} \int_\delta^t e^{\Lambda_-(t-s)} E_-^{-1} g(s)\, ds \\ \int_T^t e^{\Lambda_+(t-s)} E_+^{-1} g(s)\, ds \\ \int_T^t E_0^{-1} g(s)\, ds \end{pmatrix}.$$

Similarly to the proof of Lemma A.1 we derive the estimate

$$\| H_T^\delta g \|_{[0,T]} \leqq \text{const} \| g \|_{[0,T]} \text{ for all } g \in C[0,T]. \tag{A.3}$$

Applying the boundary conditions (3.6b), (3.6c) to (A.2) yields

$$BX_T(0)\eta + BH_T^\delta g(0) = \beta,$$
$$\begin{pmatrix} E_+^{-1} \\ E_0^{-1} \end{pmatrix} X_T(T)\eta + \begin{pmatrix} E_+^{-1} \\ E_0^{-1} \end{pmatrix} H_T^\delta g(T) = \gamma.$$

The coefficient matrix in these equations for η is

$$\begin{pmatrix} BE_- & BE_+ e^{-\Lambda_+ T} & BE_0 \\ 0 & I_{n_+} & 0 \\ 0 & 0 & I_{n_0} \end{pmatrix}.$$

Obviously, this matrix is regular since BE_- is regular, and has a bounded inverse for all $T > 0$. This fact together with (A.3) yields unique solvability and the estimate (3.7).

Proof of Theorem 3.3. For solutions of (3.1a), (3.1b)

$$y(t) = E_- e^{\Lambda_- t}\eta_- + H^\delta F y(t) + H^\delta g(t)$$

must hold, which can be written as

$$(I - H^\delta F)\, y(t) = E_- e^{\Lambda_- t}\eta_- + H^\delta g(t), \tag{A.4}$$

where $I - H^\delta F$ is considered as an operator from the space $A_\delta = \{ f \in C[\delta, \infty] \mid f(\infty) = 0 \}$ to itself.

Lemma A.2. $\| H^\delta F f(t) \| \leqq \text{const}\, e^{-\kappa t} \| f \|_{[\delta,\infty]}$, $t \geqq \delta$, *holds for all* $f \in A_\delta$ (*with the constants independent of* δ).

Proof. The proof is similar to that of Lemma A.1 and is therefore omitted.

It follows from Lemma A.2 that

$$\| H^\delta F \|_{[\delta,\infty]} \leqq \text{const}\, e^{-\kappa\delta}.$$

Hence

$$\|H^{\delta_1}F\|_{[\delta_1,\infty]}\leqq\frac{1}{2} \tag{A.5}$$

for some δ_1 big enough. Thus, the operator $I-H^{\delta_1}F$ on A_{δ_1} is invertible and (A.4) yields

$$y(t)=\Phi_-(t)\eta+\tilde{H}g(t),\ t\geqq\delta_1, \tag{A.6}$$

where $\Phi_-(t)=(I-H^{\delta_1}F)^{-1}E_-e^{\Lambda_- t}$ and $\tilde{H}g(t)=(I-H^{\delta_1}F)^{-1}H^{\delta_1}g(t)$. As solutions of (3.1a) Φ_- and $\tilde{H}g$ can be extended to $[0,\infty)$. Applying the boundary conditions (3.1c) to (A.6) confirms the results of Theorem 3.3.

Proof of Lemma 3.2. The result immediately follows from Lemma 3.1, if we can prove

LEMMA A.3. $\|((I-H^{\delta_1}F)^{-1}-I)f(t)\|\leqq\text{const}\,e^{-\kappa t}$ *holds for all* $f\in A_{\delta_1}$.

Proof. We use the identity $(I-H^{\delta_1}F)^{-1}=\sum_{i=0}^{\infty}(H^{\delta_1}F)^i$. It follows from Lemma A.2 and from (A.5) that

$$\|(H^{\delta_1}F)^i f(t)\|\leqq\text{const}\,e^{-\kappa t}2^{1-i}\|f\|_{[\delta_1,\infty]}\text{ for } i\geqq 1.$$

Thus

$$\|((I-H^{\delta_1}F)^{-1}-I)f(t)\|\leqq\sum_{i=1}^{\infty}\text{const}\,e^{-\kappa t}2^{1-i}\|f\|_{[\delta_1,\infty]}=\text{const}\,e^{-\kappa t}.$$

Proof of Theorem 3.4. Solutions of (3.9a) satsify

$$x_T(t)=X_T(t)\eta+H_T^{\delta}Fx_T(t)+H_T^{\delta}g(t),$$

which implies

$$(I-H_T^{\delta}F)x_T(t)=X_T(t)\eta+H_T^{\delta}g(t),$$

where we consider $I-H_T^{\delta}F$ as an operator from $C[\delta,T]$ to itself. An analogous result to Lemma A.2 is

LEMMA A.4. *For* $f\in C[\delta,T]$ *the estimate*

$$\|H_T^{\delta}Ff(t)\|\leqq\text{const}\,e^{-\kappa t}\|f\|_{[\delta,T]},\qquad t\geqq\delta$$

holds (*with the constants independent of* δ *and* T).

Proof. Again the proof is similar to that of Lemma A.1 and is therefore omitted. Lemma A.4 yields

$$\|H_T^{\delta_2}F\|_{[\delta_2,T]}\leqq\frac{1}{2}$$

for δ_2 big enough and all $T\geqq\delta_2$. Thus, $(I-H_T^{\delta_2}F)$ is invertible and we have

$$x_T(t)=\psi_T(t)\eta+\tilde{H}_Tg(t),\qquad \delta_2\leqq t\leqq T, \tag{A.7}$$

where $\psi_T(t)=(I-H_T^{\delta_2}F)^{-1}X_T(t)$ and $\tilde{H}_Tg(t)=(I-H_T^{\delta_2}F)^{-1}H_T^{\delta_2}g(t)$. ψ_T and $\tilde{H}_Tg$ are defined on $[0,T]$ by continuation. An argument as in the proof of Lemma A.3 yields the estimate

$$\|\psi_T(t)-X_T(t)\|\leqq\text{const}\,e^{-\kappa t}. \tag{A.8}$$

Let ψ_T^- be defined by $\psi_T^-(t)=(I-H_T^{\delta_2}F)^{-1}E_-e^{\Lambda_- t}$ for $t\in[\delta_2,T]$, and by continuation for $t\in[0,\delta_2]$. We will now prove that

$$\lim_{T\to\infty}\|\psi_T^- - \Phi_-\|_{[0,T]}=0. \tag{A.9}$$

We define $Z=\psi_T^- - \Phi_-$ and substitute $\bar{\delta}=\max\{\delta_1,\delta_2\}$ for δ in the definitions of H^δ and H_T^δ. The definitions of ψ_T^- and Φ_- imply that Z is defined on $[0,\bar{\delta}]$ by continuation as a solution of $Z'=A(t)Z$. Thus, it suffices to show that

$$\lim_{T\to\infty}\|Z\|_{[\bar{\delta},T]}=0. \tag{A.10}$$

The definitions of ψ_T^- and Φ_- on $[\bar{\delta},T]$ yield

$$Z=H_T^{\bar{\delta}}F\psi_T^- - H^{\bar{\delta}}F\Phi_- = H_T^{\bar{\delta}}FZ + H_T^{\bar{\delta}}F\phi_- - H^{\bar{\delta}}F\phi_-.$$

Thus

$$Z=\left(I-H_T^{\bar{\delta}}F\right)^{-1}\left(H_T^{\bar{\delta}}F\Phi_- - H^{\bar{\delta}}F\Phi_-\right).$$

This implies (A.10), since obviously

$$\lim_{T\to\infty}\left\|H_T^{\bar{\delta}}F\Phi_- - H^{\bar{\delta}}F\Phi_-\right\|_{[\bar{\delta},T]}=0.$$

Now we apply the boundary conditions (3.9b), (3.9c) to (A.7) and obtain equations for η with the coefficient matrix

$$C(T)=\begin{pmatrix} B\psi_T(0) \\ E_+^{-1}\psi_T(T) \\ E_0^{-1}\psi_T(T)\end{pmatrix}.$$

The relations (A.8) and (A.9) imply that

$$\lim_{T\to\infty}C(T)=\begin{pmatrix} B\Phi_-(0) & D \\ 0 & I_{n_+ + n_0}\end{pmatrix}, \tag{A.11}$$

where D is some rectangular matrix. The matrix $B\Phi_-(0)$ is regular which implies regularity of $C(T)$ and boundedness of $\|C^{-1}(T)\|$ for T big enough. An argument similar to the proof of Lemma A.3 and (A.3) yields the estimate

$$\|\tilde{H}_T g\|_{[0,T]}\leqq \text{const}\, T\|g\|_{[0,T]}.$$

This completes the proof of Theorem 3.4.

Proof of Theorem 3.5. It follows from the proof of Theorem 3.4 that $\psi_T(t)$ in (A.7) is a fundamental solution of (3.9a). The inequality (3.10) has been shown during the proof of Theorem 3.4.

SECOND ORDER NONLINEAR SINGULAR PERTURBATION PROBLEMS WITH BOUNDARY CONDITIONS OF MIXED TYPE*

JENS LORENZ† AND RICHARD SANDERS‡

Abstract. We study nonlinear turning point problems that admit boundary and/or interior layers at positions that are not determined a priori. Our study differs from previous investigations in that for positive "viscosity" first order derivative terms are allowed in the boundary operator. Under certain conditions, shown in a sense to be sharp, we characterize the viscous limit of such problems and prove that they are identical to those limit solutions obtained from the pure Dirichlet problem.

Key words. singular perturbations, turning points, bifurcation, viscosity method, mixed boundary conditions

1. Introduction.

In this paper we study boundary value problems of the form:

$$T_\varepsilon u \equiv -\varepsilon u'' + f(u)' + b(x,u) = 0, \qquad 0 \leqq x \leqq 1, \tag{1.1a}$$

$$R_\varepsilon u \equiv \begin{pmatrix} u(0) - \alpha\varepsilon u'(0) \\ u(1) + \beta\varepsilon u'(1) \end{pmatrix} = \begin{pmatrix} \gamma_0 \\ \gamma_1 \end{pmatrix}, \tag{1.1b}$$

where $\varepsilon > 0$ is destined to vanish. For simplicity we assume that $f \in C^2(\mathbb{R})$ and $b \in C^1([0,1]\times\mathbb{R})$ though weaker smoothness assumptions would be sufficient for most of our results. Throughout we define $' = d/dx$ and $f(u)' = a(u)u'$. We also allow $a(u)$ to vanish at arbitrarily many u values, i.e. turning points. If (1.1b) is of Dirichlet type, that is $\alpha = \beta = 0$, and if

$$b_u(x,u) \geqq \mu > 0 \quad \text{for all } (x,u) \in [0,1]\times\mathbb{R} \tag{1.2}$$

then the following basic problem has been solved: For $\varepsilon > 0$, (1.1) has a unique solution u_ε and for ε tending to zero, these functions u_ε tend boundedly a.e. to a limit function u. The limit function u has bounded variation and is characterized by a variational inequality. See [12], [13]; also see [1] for time dependent problems in many space dimensions and see [6], [9] for a treatment of examples.

When α and β are nonzero, the study of the limit behavior of solutions to (1.1) becomes more involved. The difficulty is essentially due to the fact that u_ε' may be of order $1/\varepsilon$ at either boundary; thus the influence of the additional terms in (1.1b) cannot be neglected as ε tends to zero. We shall consider (1.1) under condition (1.2) and also assume that

$$\alpha \geqq 0, \qquad \beta \geqq 0. \tag{1.3a}$$

The main results of this paper are now summarized:

(i) Suppose that α and β satisfy (1.3a) as well as

$$-1/\beta \leqq a(u) \leqq 1/\alpha, \tag{1.3b}$$

for all u in an a priori interval $[m,M]$. The interval $[m,M]$ is determined by the maximum principle developed in §2. Then, (1.1) has a unique solution, u_ε, for all $\varepsilon>0$ and u_ε tends boundedly a.e. to a limit solution of bounded variation. Furthermore, this limit u is independent of α and β and is in fact the same function (a.e.) as the one coming from the Dirichlet problem (i.e. the limit of solutions to (1.1) with $\alpha=\beta=0$).

(ii) If (1.3b) is relaxed, that is if either $\max a(u)>1/\alpha$ or $\min a(u)<-1/\beta$, then (1.1) may have multiple solutions even when $\varepsilon>0$. Two solutions of (1.1) are presented in §3 via a bifurcation argument.

The final paragraphs of this section are devoted to a heuristic argument demonstrating the necessity of (1.3b) for uniqueness. First consider the following specific example:

$$-\varepsilon u''+\left(\tfrac{1}{2}u^2\right)'+u=0, \quad u(0)-\alpha\varepsilon u'(0)=2, \quad u(1)=-2. \tag{1.4}$$

Note that the functions

$$u_0(x)=-x+\text{const.}$$

are outer solutions, i.e. they solve the reduced differential equation. (The singular outer solutions $u\equiv 0$ does not play a role in our argument.) There are (at least) two candidates of global outer solutions, namely the discontinuous function

$$\bar{u}_0(x)=\begin{cases} -x+2, & 0\leqq x<\frac{1}{2}, \\ -x-1, & \frac{1}{2}<x\leqq 1 \end{cases} \tag{1.5}$$

and the continuous function $\hat{u}_0(x)=-x-1$, $0<x\leqq 1$. $\bar{u}_0$ satisfies the boundary conditions up to order ε. In the stretched variable $s=(x-x_0)/\varepsilon$ one obtains the inner differential equation

$$-U''+\left(\tfrac{1}{2}U^2\right)'=0, \qquad '=\frac{d}{ds} \tag{1.6}$$

when neglecting terms of order ε. In order to match the inner solution with an outer solution u_0 at an interior discontinuity, say at x_0, we require that

$$\bar{U}(-\infty)=u_0(x_0-0), \qquad \bar{U}(+\infty)=u_0(x_0+0) \tag{1.7}$$

and when u_0 violates the boundary condition at $x=0$ by 0(1), we require that

$$U(0)-\alpha U'(0)=\gamma_0, \qquad U(+\infty)=u_0(0).$$

Integration of (1.6) yields

$$U'(s)=\tfrac{1}{2}\left(U^2(s)-c_0^2\right).$$

Hence with $c_0=\frac{3}{2}$ the matching condition (1.7) is fulfilled for the specific outer solution $\bar{u}_0$ given in (1.5) which satisfies the boundary conditions up to order ε. Therefore $\bar{u}_0$ is a candidate limit solution for all values of α. (It follows from the results proved below that $\bar{u}_0$ is the *only* limit solution for $0\leqq\alpha\leqq\frac{1}{2}$.) When can we fulfill the matching condition at $x=0$ with $\hat{u}_0(x)=-x-1$? The condition $U(+\infty)=\hat{u}_0(0)$ yields

$$U'(s)=\tfrac{1}{2}\left(U^2(s)-1\right).$$

Therefore, if α is a value for which the equation

$$U(0)-\frac{\alpha}{2}\left(U^2(0)-1\right)=2$$

has a solution $U(0)$ in $(-1,1)$, the matching condition can be satisfied. Thus for large values of α other candidates of limit solutions are obtained.

If we generalize the considerations of this specific example slightly, we see that limit solutions different from the Dirichlet limit can possibly occur if α or β are so large that the functions

$$U\to U-\alpha f(u) \quad \text{or } U\to U+\beta f(U)$$

are not monotonically increasing in the range of U-values of interest. But condition (1.3b) exactly requires monotonicity of the above functions.

As we would like to mention, David Brown, California Institute of Technology, found multiple solutions numerically of the type presented here while this paper was written. He used his code described in [10]. We also like to mention that Howes [5] has considered singularly perturbed problems with non-Dirichlet boundary conditions (1.1b) using the method of upper and lower solutions. His assumptions do not allow for turning points, however.

2. Existence and uniqueness for positive ε. In this section we show the problem (1.1) has a solution given that (1.2) and (1.3a) are satisfied. In addition, we show that this solution is unique given (1.3b). We begin with the maximum principle.

LEMMA 2.1. *Assume* (1.2) *and* (1.3a), *and let* u_ε *denote a solution of* (1.1). *Then*

$$m\leqq u_\varepsilon(x)\leqq M, \tag{2.1}$$

where

$$m=\min\left(\gamma_0,\gamma_1,\min\{c(x)\colon 0\leqq x\leqq 1\}\right),$$

$$M=\max\left(\gamma_0,\gamma_1,\max\{c(x)\colon 0\leqq x\leqq 1\}\right).$$

Above, $c(x)$ *is determined by* $b(x,c(x))=0$. *The function* $c(x)$ *is bounded since* $b(x,0)$ *is bounded and* $b_u(x,u)\geqq\mu>0$.

Proof. Let $d=\max\{u_\varepsilon(x)\colon 0\leqq x\leqq 1\}$, and let $y\in[0,1]$ be such that $u_\varepsilon(y)=d$. If $y=0$ we have $u_\varepsilon'(0)\leqq 0$ and (1.1b) implies that $u_\varepsilon(0)\leqq\gamma_0$. If $0<y<1$, the differential equation (1.1a) shows that $b(y,u_\varepsilon(y))\leqq 0=b(y,c(y))$. Thus using (1.2), we have $d=u_\varepsilon(y)\leqq c(y)$. The other estimates follow in a similar manner.

Existence of a solution of (1.1) follows directly from a generalization of the classical Nagumo theorem (see [7], [14]) which has been observed in [4]. Obviously we can apply [4, Thm. 1] using the constant upper and lower functions identically to M and m, respectively, and obtain:

LEMMA 2.2. *Under the conditions* (1.2) *and* (1.3a), *the differential equation* (1.1a) *with boundary conditions* (1.1b) *has a solution* $u_\varepsilon(x)$ *for any* $\varepsilon>0$ *satisfying the estimate* (2.1).

As remarked earlier, conditions (1.2) and (1.3a) are not sufficient to guarantee uniqueness of solutions to (1.1). However, if (1.3b) is also imposed, a solution of (1.1) is unique. We use L^1 techniques to show this. The L^1 techniques used below motivate the characterization of the limit solution presented in §4. Another uniqueness proof is given in an appendix. The second proof, which uses adjoints and an inverse monotonicity

argument, yields additional information; in particular, it shows that solutions u_ε constitute a smooth branch w.r.t. ε. This justifies continuation techniques with ε as a parameter in numerical computations.

THEOREM 2.3. *Suppose conditions* (1.2), (1.3a) *and* (1.3b) *are satisfied. Then the problem* (1.1) *has a unique solution for any* $\varepsilon > 0$. (*When* $\alpha = 0$ *or* $\beta = 0$ *the corresponding estimate in condition* (1.3b) *is considered satisfied.*)

Proof. The method of proof is standard. Define the sign function $\operatorname{sgn}(s)$ by

$$\operatorname{sgn}(s) = \begin{cases} -1 & s < 0, \\ 0, & s = 0, \\ 1, & s > 0, \end{cases}$$

and denote by $\operatorname{sgn}_\delta(s)$, $\delta > 0$, a smooth nondecreasing function with $\operatorname{sgn}_\delta(s) = \operatorname{sgn}(s)$ when $|s| \geqq \delta$ and $s = 0$, and $(d/ds)\operatorname{sgn}_\delta(s) \leqq 2/\delta$ when $|s| \leqq \delta$. For fixed $\varepsilon > 0$ suppose u and v are two solutions of (1.1) and define $w = u - v$. Applying integration by parts to

$$\int_0^1 \operatorname{sgn}_\delta(w)(T_\varepsilon u - T_\varepsilon v)\, dx = 0,$$

one obtains

$$\begin{aligned} &\operatorname{sgn}_\delta(w)\left(-\varepsilon w' + f(u) - f(v)\right)\Big|_0^1 \\ &\quad - \int_0^1 \operatorname{sgn}_\delta(w)'\left(f(u) - f(v)\right) dx \\ &\quad + \int_0^1 \operatorname{sgn}_\delta(w)\left(b(x,u) - b(x,v)\right) dx \leqq 0. \end{aligned} \tag{2.2}$$

Sending δ to zero and using Lebesgue's dominated convergence theorem, we find that the third term above approaches

$$\int_0^1 |b(x,u) - b(x,v)|\, dx.$$

The second term can be shown to approach zero using Lebesgue's theorem again. With the boundary conditions (1.1b) and condition (1.3b) we find that the first term above approaches a nonnegative value. Therefore, we have that any two solutions of (1.1) must satisfy

$$\mu \int_0^1 |u - v|\, dx \leqq \int_0^1 |b(x,u) - b(x,v)|\, dx \leqq 0,$$

and are necessarily the same.

We later need L^1 continuity with respect to the boundary conditions:

LEMMA 2.4. *Suppose* u_1 *and* u_2 *are two solutions of* (1.1a); u_1 (*resp.* u_2) *satisfying the boundary conditions* (1.1b) *where* α, β *are replaced by* α_1, β_1 (*resp.* α_2, β_2). *Further suppose that* $\alpha_1 > 0$, $\beta_1 > 0$ *satisfy* (1.3b). *We then have for* $\alpha_2 > 0$, $\beta_2 > 0$

$$\int_0^1 |u_1 - u_2|\, dx \leqq \text{const.} \left(\left| \frac{1}{\alpha_1} - \frac{1}{\alpha_2} \right| + \left| \frac{1}{\beta_1} - \frac{1}{\beta_2} \right| \right)$$

where the constant above does not depend on $\varepsilon > 0$, α_1, α_2, β_1, β_2.

Proof. Sending δ to zero in (2.2) and using the boundary conditions, one obtains

$$\operatorname{sgn}(w(1))\left\{\frac{u_1(1)-\gamma_1}{\beta_1}-\frac{u_2(1)-\gamma_1}{\beta_2}+f(u_1(1))-f(u_2(1))\right\}$$

$$-\operatorname{sgn}(w(0))\left\{\frac{\gamma_0-u_1(0)}{\alpha_1}-\frac{\gamma_0-u_2(0)}{\alpha_2}+f(u_1(0))-f(u_2(0))\right\}+\mu\int_0^1|u_1-u_2|\,dx\leqq 0$$

with $w=u_1-u_2$. Now use monotonicity of the functions

$$u\to\frac{u}{\beta_1}+f(u),\qquad U\to\frac{u}{\alpha_1}-f(u)$$

in the a priori domain to obtain the result.

3. Rigorous proof of nonuniqueness for (1.3b) violated. If (1.3b) is violated, we show that bifurcation can—and under special assumptions will—occur for problems where (1.2), (1.3a) holds. We actually construct a problem with a nonsingular $u_\varepsilon(x)$ at which *sufficient* conditions for bifurcation are satisfied. First note that a *necessary* condition for bifurcation at $u_\varepsilon(x)$ is the following: The linear problem

$$\begin{aligned}&(T_\varepsilon' u_\varepsilon)v\equiv-\varepsilon v''-\big(a(u_\varepsilon(x))v\big)'+b_u(x,u_\varepsilon(x))v=0,\\&R_\varepsilon v=0\end{aligned}\tag{3.1}$$

has a nontrivial solution v. The following lemma is crucial:

LEMMA 3.1. *Given $\alpha>0$, $\beta\geqq 0$ and $p_0>1/\alpha$. There is $\varepsilon_0>0$ and a smooth function $p(x)$ with $-1/\beta\leqq p(x)\leqq p_0$ such that the eigenvalue problem*

$$L_\varepsilon v\equiv-\varepsilon v''+\big(p(x)v\big)'=\sigma v,\qquad R_\varepsilon v=0\tag{3.2}$$

has a smallest eigenvalue $\sigma_1=\sigma_1(\varepsilon)$ which is less than 0 for $0<\varepsilon\leqq\varepsilon_0$.

Proof. (i) First assume that $p(x)$ in (3.2) is an arbitrary C^1-function. As is well-known, multiplication of the equation $L_\varepsilon v=\sigma v$ by

$$\exp\left(-\frac{1}{\varepsilon}\int_0^x p(s)\,ds\right)$$

transforms the eigenvalue problem (3.2) into a symmetric problem to which the classical Sturm–Liouville theory applies. Thus all eigenvalues of (3.2) are real, and there is a smallest eigenvalue σ_1. To decide upon the sign of σ_1, it suffices to study the homogeneous equation $L_\varepsilon v=0$, which has the general solution

$$v(x)=c_1\phi_1(x)+c_2\phi_2(x)$$

with

$$\phi_1(x)=\exp(r(x)/\varepsilon),\qquad r(x)=\int_0^x p(s)\,ds,$$

$$\phi_2(x)=\phi_1(x)\int_0^x\exp(-r(y)/\varepsilon)\,dy.$$

If we take $c_1=1$, $c_2=(1/\varepsilon)(1/\alpha-p(0))$ we obtain the function

$$\bar v(x)=\phi_1(x)\left\{1+\frac{1}{\varepsilon}\left(\frac{1}{\alpha}-p(0)\right)\int_0^x\exp(-r(y)/\varepsilon)\,dy\right\}\tag{3.3}$$

which satisfies $L_\varepsilon \bar{v}=0$, $R_\varepsilon^{(0)}\bar{v}=0$, $\bar{v}(0)>0$. Here $R_\varepsilon^{(0)}$ denotes the first component of the boundary operator R_ε. With $R_\varepsilon^{(1)}$ we will denote the second component.

(ii) We claim now that the smallest eigenvalue σ_1 of (3.2) is negative if $\bar{v}(1)<0$. To show this, assume that $\bar{v}(1)<0$ and first assume $\sigma_1>0$. If $\sigma_1>0$ then the pair $(L_\varepsilon, R_\varepsilon)$ must be inverse monotone, i.e. for any $w\in C^2[0,1]$ the implication

$$L_\varepsilon w\geqq 0,\ R_\varepsilon^{(0)}w\geqq 0,\ R_\varepsilon^{(1)}w\geqq 0\Rightarrow w\geqq 0 \tag{3.4}$$

holds. (See e.g. [15, Chap. 1, Thm. 17].) But since $L_\varepsilon\bar{v}=0$, $R_\varepsilon^{(0)}\bar{v}=0$ we find that $v\geqq 0$ if $R_\varepsilon^{(1)}v\geqq 0$ and $\bar{v}\leqq 0$ if $R_\varepsilon^{(1)}v\leqq 0$, a contradiction to $\bar{v}(0)\bar{v}(1)<0$. We also arrive at a contradiction if $\bar{v}(1)<0$, $\sigma_1=0$. If $\sigma_1=0$, then $\bar{v}$ is an eigenfunction to σ_1, but the eigenfunction to the smallest eigenvalue is known to be of one sign. (See e.g. [15, Chap. 1, Thm. 16].)

(iii) To conclude the proof of the lemma, note that we allow for $1/\alpha-p(0)<0$ in (3.3). Thus for appropriate $p(x)$ we obtain $\bar{v}(1)<0$ for $0<\varepsilon\leqq\varepsilon_0$ (e.g., take a function $p(x)$ with $p(0)=p_0$, $-1/\beta\leqq p(x)\leqq p_0$, $\int_0^1 \mathrm{p(x)\,dx}<0$).

Assume now $\alpha>0$, $\beta\geqq 0$, $p_0>1/\alpha$ are given and $p(x)$ and $\varepsilon_0>0$ are determined according to Lemma 3.1. We fix $\varepsilon\in(0,\varepsilon_0]$; thus the eigenvalue problem (3.2) has a smallest eigenvalue $\sigma_1<0$. Now take

$$f(u)=\frac{u^2}{2},\qquad a(u)=u,$$

and set $u_\varepsilon(x):=p(x)$,

$$\begin{aligned} B(x)&:=-\varepsilon u_\varepsilon''(x)+f(u_\varepsilon(x))'-\sigma_1 u_\varepsilon(x),\\ b(x,u)&:=-\sigma_1 u-B(x),\\ \gamma&:=R_\varepsilon u_\varepsilon. \end{aligned}$$

By construction the problem

$$\begin{aligned} T_\varepsilon&\equiv -\varepsilon u''+f(u)'+b(x,u)=0,\\ R_\varepsilon u&=\gamma \end{aligned}$$

has $p(x)=u_\varepsilon(x)$ as a solution, and the linearization at $u_\varepsilon(x)$ is

$$\left(T_\varepsilon' u_\varepsilon\right)v=-\varepsilon v''-\left(a(u_\varepsilon(x))v\right)'-\sigma_1 v=-\varepsilon v''+\left(p(x)v\right)'-\sigma_1 v.$$

Thus by construction the eigenvalue problem

$$\left(T_\varepsilon' u_\varepsilon\right)v=\sigma v,\qquad R_\varepsilon v=0 \tag{3.5}$$

has $\sigma=0$ as smallest eigenvalue. Therefore u_ε is a potential bifurcation point if we introduce a parameter λ in the boundary value problem. To make this precise, we use the following theorem from bifurcation theory (see e.g. [16] and see [2], [8] for earlier versions).

THEOREM 3.2. *Let X, Y be real Banach spaces and let*

$$A:\mathbb{R}\times X\to Y$$

denote a twice continuously differentiable operator. Assume $\bar{z}=(\bar{\lambda},\bar{u})\in\mathbb{R}\times X$ *is a point with* $A(\bar{z})=0$ *at which the following conditions hold*:

(i) $\ker(A'(\bar{z}))=\operatorname{span}\{\eta,\xi\}$ *with linear independent* $\eta,\ \xi\in\mathbb{R}\times X$.

(ii) *There is a continuous linear functional* $\psi\colon Y\to\mathbb{R}$ *with* $\operatorname{range}(A'(\bar{z}))=\ker(\psi)$.

(iii) *For the numbers*

$$\bar{a}=\psi\big(A''(\bar{z})\eta\cdot\eta\big),\quad \bar{b}=\psi\big(A''(\bar{z})\eta\cdot\xi\big),\quad \bar{c}=\psi\big(A''(\bar{z})\xi\cdot\xi\big)$$

the hyperbolicity condition $\bar{a}\bar{c}<\bar{b}^2$ *holds.*

Then the solution set of

$$A(z)=0$$

in a neighborhood of $\bar{z}=(\bar{\lambda},\bar{u})$ *consists of exactly two branches which intersect in* $\bar{z}$. *Especially, given any* $\delta>0$ *there is* λ *with*

$$|\lambda-\bar{\lambda}|<\delta$$

for which the equation

$$A(\lambda,\cdot)=0$$

has at least two solutions.

We now claim

LEMMA 3.3. *The abstract Theorem* 3.2 *can be applied if we take* $X=C^2[0,1]$, $Y=C[0,1]\times\mathbb{R}^2$,

$$A(\lambda,u)=\big(T_\varepsilon u+\lambda(u-u_\varepsilon),R_\varepsilon u-\gamma\big)$$

and $(\bar{\lambda},\bar{u})=(0,u_\varepsilon)$, *where* T_ε, R_ε, u_ε, γ *are constructed as above. Especially, for any* $\delta>0$ *there is* λ *with* $|\lambda|<\delta$ *such that the boundary value problem*

$$-\varepsilon u''+\left(\frac{u^2}{2}\right)'+b(x,u)+\lambda(u-u_\varepsilon)=0,\qquad R_\varepsilon u=\gamma$$

has at least two solutions.

Proof. To check conditions (i), (ii), (iii) of Theorem 3.2 first note:

$$\begin{aligned}
&A_\lambda(\lambda,u)\alpha=\big(\alpha(u-u_\varepsilon),0\big),\\
&A_u(\lambda,u)v=\big(\big(T_\varepsilon'u\big)v+\lambda v,R_\varepsilon v\big),\\
&A_{\lambda\lambda}(\lambda,u)\equiv 0,\\
&A_{\lambda u}(\lambda,u)\alpha\cdot v=A_{u\lambda}(\lambda,u)v\cdot\alpha=(\alpha v,0),\\
&A_{uu}(\lambda,u)v\cdot w=\big(\big(T_\varepsilon''u\big)v\cdot w,0\big),
\end{aligned}$$

for $\lambda,\ \alpha\in\mathbb{R}$, $u,v,w\in C^2[0,1]$. By $r(x)$ and $l(x)$ we denote right and left eigenfunctions of (3.5) to $\sigma=0$, i.e.

$$\begin{aligned}
&\big(T_\varepsilon'u_\varepsilon\big)r=0,\qquad R_\varepsilon r=0,\\
&\big(T_\varepsilon'u_\varepsilon\big)^*l=0,\qquad R_\varepsilon^*l=0.
\end{aligned}$$

One can assume

$$r(x)>0,\quad l(x)>0\quad\text{for } 0<x<1$$

since by construction $\sigma=0$ is the smallest eigenvalue of (3.3).

Determination of $\ker A'(0,u_\varepsilon)=:N$: Since $A'(0,u_\varepsilon)(\alpha,v)=((T_\varepsilon'u_\varepsilon)v,R_\varepsilon v)$ it follows that

$$\eta=(0,r), \qquad \xi=(1,0)$$

constitute a basis of N.

Determination of range $(A'(0,u_\varepsilon)):=R$: Let $(c,\beta)\in C\times\mathbb{R}^2$. If $(c,\beta)\in R$ there is $v\in C^2$ with

$$\left(T_\varepsilon'u_\varepsilon\right)v=c, \qquad R_\varepsilon v=\beta.$$

Now choose for $\beta\in\mathbb{R}^2$ a function $w_\beta(x)\in C^2$ with

$$R_\varepsilon w_\beta=\beta$$

such that $\beta\to w_\beta$ is linear. Then

$$R_\varepsilon(v-w_\beta)=0$$

and therefore

$$\begin{aligned}0&=\int_0^1\left\{\left(T_\varepsilon'u_\varepsilon\right)^*l\right\}(v-w_\beta)\,dx\\&=\int_0^1 l\left\{\left(T_\varepsilon'u_\varepsilon\right)(v-w_\beta)\right\}dx=\int_0^1\left\{lc-l\left(T_\varepsilon'u_\varepsilon\right)w_\beta\right\}dx:=\psi(c,\beta).\end{aligned}$$

With the linear functional ψ: $Y\to\mathbb{R}$ defined by the last equation we have shown $R\subset\ker\psi$. But since $\dim N=2$ it follows from Fredholm index theory that $\operatorname{codim}R=1$, and thus $R=\ker\psi$. The hyperbolicity condition: In general holds

$$\begin{aligned}A''(\lambda,u)(\alpha_1,v_1)\cdot(\alpha_2,v_2)=&A_{\lambda\lambda}(\lambda,u)\alpha_1\cdot\alpha_2+A_{\lambda u}(\lambda,u)\alpha_1\cdot v_2\\&+A_{u\lambda}(\lambda,u)v_1\cdot\alpha_2+A_{uu}(\lambda,u)v_1\cdot v_2.\end{aligned}$$

This specializes to

$$\begin{aligned}\bar B&:=A''(0,u_\varepsilon)(0,r)\cdot(1,0)=A_{u\lambda}(0,u_\varepsilon)r\cdot 1=(r,0),\\\bar C&:=A''(0,u_\varepsilon)(1,0)\cdot(1,0)=0.\end{aligned}$$

Therefore

$$\bar b=\psi(\bar B)=\int_0^1 l(x)r(x)\,dx>0$$

and $\bar c=\psi(\bar C)=0$, and thus $\bar a\bar c<\bar b^2$.

Remark. Our construction shows that the condition (1.3b) which guarantees uniqueness in Theorem 2.3, cannot be relaxed, in general. Note that $p_0>1/\alpha$ was arbitrary, and a similar construction can be made if $-1/\beta\leqq a(u)$ is relaxed.

4. The characterization of $\lim_\varepsilon u_\varepsilon$. The question of convergence of u_ε as ε tends to zero is addressed in this section. We show below, given the conditions (1.2), (1.3a) and (1.3b), that as ε tends to zero the solutions to (1.1) converge in L^1 to a limit function. This limit function is characterized by a well-known integral inequality, the so-called entropy inequality as developed by Kruzkov [11], in the study of scalar conservation laws. As will be seen, the Kruzkov theory plays a key role in our analysis. We begin with a simple estimate.

LEMMA 4.1. *Given* (1.2) *and* (1.3a), *we have that any solution of* (1.1) *must satisfy*

$$\int_0^1 \left| \frac{du_\varepsilon}{dx} \right| dx \leqq \text{const.},$$

where the constant above does not depend on $\varepsilon > 0$.

Proof. Differentiating (1.1a) and following the notation of Theorem 2.3, we find that

$$0 = \int_0^1 \operatorname{sgn}_\delta(u_\varepsilon') \cdot \left(-\varepsilon u_\varepsilon''' + f(u_\varepsilon)'' + b(x,u_\varepsilon)' \right) dx.$$

Integrating by parts and using the differential equation (1.1a) in the boundary terms obtained from the integration by parts, we have

$$0 = -\operatorname{sgn}_\delta(u_\varepsilon') b(x,u_\varepsilon)\Big|_0^1 + \int_0^1 \left(\frac{d}{dx} \operatorname{sgn}_\delta(u_\varepsilon') \right) \cdot \left(\varepsilon u_\varepsilon'' - f(u_\varepsilon)' \right) dx$$

$$+ \int_0^1 \operatorname{sgn}_\delta(u_\varepsilon') \cdot \left(b_x(x,u_\varepsilon) + b_u(x,u_\varepsilon) u_\varepsilon' \right) dx.$$

As in Theorem 2.3, sending δ to zero gives us that

$$\int_0^1 b_u(x,u_\varepsilon) |u_\varepsilon'| \, dx \leqq |b(1,u_\varepsilon(1))| + |b(0,u_\varepsilon(0))| + \int_0^1 |b_x(x,u_\varepsilon)| \, dx,$$

from which hypothesis (1.2) and the maximum principle, Lemma 2.1, make the final result obvious.

The importance of the estimate obtained above is the following. As is well-known, any sequence of functions having uniformly bounded variation is sequentially compact in the L^1 topology; see e.g. [3, Chap. IV, 8.20]. Lemma 4.1 tells us that $\{u_\varepsilon\}_{\varepsilon > 0}$ has variation which is bounded uniformly for $\varepsilon > 0$. We therefore have a function, say u, along with a sequence ε tending to zero, such that $u_\varepsilon \to u$ in L^1. What remains to be shown is that u is the unique limit point of u_ε with ε tending to zero.

For the moment, we shall assume a strict version of condition (1.3b). We assume that α and β in the boundary conditions (1.1b) satisfy

$$-1/\beta < a(u) < 1/\alpha, \tag{4.1}$$

for all u in the a priori domain $[m,M]$. It will be seen by virtue of the continuity estimate, Lemma 2.4, that (4.1) is an adequate assumption to prove the main result stated in the introduction. This point is discussed further in the proof of Theorem 4.6.

With condition (4.1) in place over (1.3b), we now have a lemma concerning the behavior of u_ε at $x = 0$ and at $x = 1$.

LEMMA 4.2. *Given* (1.2), (1.3a) *and* (4.1), *and assume that* u_ε *tends in* L^1 *to a function* u *of bounded variation for some sequence* ε_n *tending to zero. We then have, for the same sequence* ε_n, *that*

(i) $\lim u_\varepsilon(0)$ *and* $\lim u_\varepsilon(1)$ *exist, and*

(ii)

$$\lim \varepsilon u_\varepsilon'(0) = \lim f(u_\varepsilon(0)) - f(\gamma u(0)),$$
$$\lim \varepsilon u_\varepsilon'(1) = \lim f(u_\varepsilon(1)) - f(\gamma u(1)).$$

$\gamma u(0)$ *and* $\gamma u(1)$ *denote the boundary traces of the BV function* u.

Proof. To prove (i) at $x=1$ we may assume that $\beta>0$ in (1.1b); otherwise there is nothing to prove. Define ρ to be a smooth nondecreasing function with $\rho(0)=0$ and $\rho(1)=1$. Multiplying (1.1a) with ρ and integrating by parts, we find that

$$\varepsilon u_\varepsilon'(1)-f(u_\varepsilon(1))=\int_0^1 \left(\rho'\left(\varepsilon u_\varepsilon'-f(u_\varepsilon)\right)+\rho b(x,u_\varepsilon)\right)dx. \tag{4.2}$$

(1.1b) gives us that $\varepsilon u_\varepsilon'(1)=(\gamma_1-u_\varepsilon(1))/\beta$. Therefore, (4.2) may be written as

$$u_\varepsilon(1)+\beta f(u_\varepsilon(1))=\gamma_1-\beta\int_0^1 \left(\rho'\left(\varepsilon u_\varepsilon'-f(u_\varepsilon)\right)+\rho b(x,u_\varepsilon)\right)dx.$$

Condition (4.1) implies that the left-hand side of this identity is a strictly increasing function. The right-hand side has a limit by virtue of the hypotheses of the lemma. So we have $\lim u_\varepsilon(1)$ exists and similarly $\lim u_\varepsilon(0)$ exists.

To prove (ii), we return to (4.2). Sending ε to zero, we find that

$$\lim \varepsilon u_\varepsilon'(1)=\lim f(u_\varepsilon(1))+\int_0^1 \left(-\rho' f(u)+\rho b(x,u)\right)dx,$$

where $u=\lim u_\varepsilon$ in L^1. Since u has bounded variation, a simple exercise would show that

$$\lim_{\delta\to 0} 1/\delta\int_{1-\delta}^1 f(u)\,dx=f\Big(\lim_{x\uparrow 1} u(x)\Big)\equiv f(\gamma u(1)).$$

Setting

$$\rho(x)=\begin{cases}1+(x-1)/\delta, & 1-\delta\leqq x\leqq 1,\\ 0, & x\leqq 1-\delta,\end{cases}$$

we have

$$\begin{aligned}\lim \varepsilon u_\varepsilon'(1)&=\lim f(u_\varepsilon(1))+\lim_{\delta\to 0}\left[-1/\delta\int_{1-\delta}^1 f(u)\,dx+O(\delta)\right]\\ &=\lim f(u_\varepsilon(1))-f(\gamma u(1)),\end{aligned}$$

which completes the proof of the lemma.

Next we obtain an integral inequality that every limit function of u_ε, with ε tending to zero, satisfies. This inequality is frequently referred to as an entropy inequality in the literature. A significant implication of the entropy inequality derived below is that only one BV function can satisfy it; see Proposition 4.5. This fact combined with the result of Lemma 4.1 implies that u_ε converges to a limit u independent of any particular sequence of ε-values tending to zero. The entropy inequality therefore characterizes the limit function of u_ε.

LEMMA 4.3. *Given* (1.2), (1.3a) *and* (4.1), *we have that any* L^1 *limit of* u_ε, *say* u, *must satisfy*

$$\begin{aligned}-\int_0^1 \operatorname{sgn}(u-k)\big((f(u)-f(k))\phi_x-b(x,u)\phi\big)\,dx&\\ \leqq \operatorname{sgn}(u(1)-k)\big(f(k)-f(\gamma u(1))\big)\phi(1)&\\ -\operatorname{sgn}(u(0)-k)\big(f(k)-f(\gamma u(0))\big)\phi(0),&\end{aligned}$$

where k *is any real number and* ϕ *is any smooth nonnegative function. Above,* $u(0)=\lim u_\varepsilon(0)$, $u(1)=\lim u_\varepsilon(1)$ *and they are in general not equal to* $\gamma u(0)$, $\gamma u(1)$.

Proof. Multiply the identity

$$-\varepsilon u_\varepsilon'' + \{f(u_\varepsilon) - f(k)\}' + b(x, u_\varepsilon) = 0$$

by $\operatorname{sgn}_\delta(u_\varepsilon - k)\phi$, integrate from zero to one using integration by parts, and send δ to zero. Then obtain

$$\begin{aligned} &-\int_0^1 \operatorname{sgn}(u_\varepsilon - k)\big((f(u_\varepsilon) - f(k))\phi_x - b(x, u_\varepsilon)\phi\big)\,dx \\ &\quad \leqq -\operatorname{sgn}(u_\varepsilon - k)(f(u_\varepsilon) - f(k))\phi\big|_0^1 + \operatorname{sgn}(u_\varepsilon - k)\varepsilon u_\varepsilon'\phi\big|_0^1 \\ &\qquad -\varepsilon\int_0^1 \operatorname{sgn}(u_\varepsilon - k)u_\varepsilon'\phi_x\,dx. \end{aligned}$$

The last term on the right-hand side above goes to zero with ε. For k different from $u(0)$ and $u(1)$, the second result of Lemma 4.2 inserted into the $\varepsilon u_\varepsilon'$-term above would complete the proof. Taking limits with k approaching $u(0)$ or $u(1)$ from above and below will establish the entropy inequality also in the exceptional cases; that is, those cases in which the discontinuity of the sign function must be taken into account.

The limit function u coming from (1.1) with mixed boundary conditions also satisfies the entropy inequality satisfied by limit solutions of the pure Dirichlet problem (i.e. $u_\varepsilon(0) = \gamma_0$ and $u_\varepsilon(1) = \gamma_1$). This fact is fundamental in proving the main result of this section. With this in mind, we state:

LEMMA 4.4. *With the same assumptions of Lemma* 4.3, *we have that u satisfies*

(4.3)

$$\begin{aligned} &-\int_0^1 \operatorname{sgn}(u - k)\big((f(u) - f(k))\phi_x - b(x, u)\phi\big)\,dx \\ &\quad \leqq \operatorname{sgn}(\gamma_1 - k)(f(k) - f(\gamma u(1)))\phi(1) - \operatorname{sgn}(\gamma_0 - k)(f(k) - f(\gamma u(0)))\phi(0), \end{aligned}$$

for all real numbers k and any smooth nonnegative ϕ.

Proof. The proof of the lemma is immediate once that

$$\operatorname{sgn}(u(1) - k)(f(k) - f(\gamma u(1))) \leqq \operatorname{sgn}(\gamma_1 - k)(f(k) - f(\gamma u(1))) \tag{4.4}$$

and a similar inequality at 0 is shown. To prove (4.4), first note that (4.4) is nontrivial only if $\beta > 0$ and $\gamma_1 \leqq k \leqq u(1)$ or $u(1) \leqq k \leqq \gamma_1$. For definiteness let

$$\gamma_1 \leqq k \leqq u(1). \tag{4.5}$$

Using (ii) from Lemma 4.2 and the boundary condition (1.1b), we have that

$$u(1) + \beta f(u(1)) = \gamma_1 + \beta f(\gamma u(1)).$$

Since the function $v \to v + \beta f(v)$ increases, we find with (4.5) that

$$\begin{aligned} k + \beta f(k) &\leqq u(1) + \beta f(u(1)) \\ &= \gamma_1 + \beta f(\gamma u(1)) \leqq k + \beta f(\gamma u(1)); \end{aligned}$$

thus $f(k) \leqq f(\gamma u(1))$. This shows (4.4).

We next prove that only one L^1 limit function of u_ε can satisfy the entropy inequality of Lemma 4.4. This result is not new; see [1], [12] for example; however, for completeness we shall sketch the proof.

PROPOSITION 4.5. *Suppose u_1 and u_2 are two BV functions that satisfy the entropy inequality of Lemma* 4.4. *Further let $b_u \geqq 0$. Then*

$$\int_0^1 |b(x,u_1)-b(x,u_2)|\,dx=0.$$

Proof. Take a nonnegative test function ϕ with $\phi(y)=\phi(-y)$ for all y. Let $u=u_1(x)$ and set $k=u_2(x')$ and $\phi=\phi(x-x')$ in (4.3). Integrate the result with respect to the variable x'. Reversing the roles of u_1 and u_2, x and x', and adding the two inequalities together yields

(4.6)

$$\int_0^1\int_0^1 \operatorname{sgn}(u_1(x)-u_2(x'))\{b(x,u_1(x))-b(x',u_2(x'))\}\phi(x-x')\,dx'\,dx$$

$$\leqq \sum_{i=0,1}\eta_i\int_0^1 (f(u_2)-f(\gamma u_1(i)))\operatorname{sgn}(\gamma_i-u_2)\phi(i-x')\,dx'$$

$$+\sum_{i=0,1}\eta_i\int_0^1 (f(u_1)-f(\gamma u_2(i)))\operatorname{sgn}(\gamma_i-u_1)\phi(x-i)\,dx.$$

Here we used the notation $\eta_i=(-1)^{i+1}$. Now, letting $\phi(x)$ approach the delta function, we have that the above double integral tends to

$$\int_0^1 |b(x,u_1)-b(x,u_2)|\,dx.$$

The right-hand side of (4.6) can be treated as follows. Consider, e.g., the first term for $i=1$ and find

$$\int_0^1 [f(u_2)-f(\gamma u_1(1))]\operatorname{sgn}(\gamma_1-u_2)\phi(1-x)\,dx$$

$$\leqq\int_0^1 [f(u_2)-f(\gamma_1)]\operatorname{sgn}(\gamma_1-u_2)\phi(1-x)\,dx$$

$$+\int_0^1 |f(\gamma_1)-f(\gamma u_1(1))|\phi(1-x)\,dx.$$

For $\phi(x)\to\delta(x)$ the right-hand side of this inequality approaches

$$\frac{1}{2}[f(\gamma u_2(1))-f(\gamma_1)]\operatorname{sgn}(\gamma_1-\gamma u_2(1))+\frac{1}{2}|f(\gamma_1)-f(\gamma u_1(1))|.$$

The other terms on the right-hand side of (4.6) can be treated similarly and one finds the estimate

$$\int_0^1 |b(x,u_1)-b(x,u_2)|\,dx$$

$$\leqq\frac{1}{2}\sum_{i=0,1}\eta_i\{[f(\gamma u_2(i))-f(\gamma_i)]\operatorname{sgn}(\gamma_i-\gamma u_2(i))$$

$$+[f(\gamma u_1(i))-f(\gamma_i)]\operatorname{sgn}(\gamma_i-\gamma u_1(i))$$

$$+\eta_i|f(\gamma_i)-f(\gamma u_2(i))|+\eta_i|f(\gamma_i)-f(\gamma u_1(i))|\}.$$

It thus remains to be shown for $u=u_1$ and $u=u_2$:

$$\eta_i \operatorname{sgn}(\gamma_i-\gamma u(i))[f(\gamma u(i))-f(\gamma_i)] \leqq 0.$$

But this inequality follows from (4.3) if one takes there $k=\gamma_i$ and chooses ϕ as in the proof of Lemma 4.4.

We finally are ready to state and prove the main result of this section.

THEOREM 4.6. *Suppose u_ε is a sequence of solutions to* (1.1) *with ε tending to zero. Further suppose that the differential equation satisfies conditions* (1.2), (1.3a) *and* (1.3b). *Then, u_ε tends boundedly a.e. to a limit function and this limit function is characterized by the entropy inequality* (4.3). *Furthermore, the limit function is independent of α and β and is in fact the same a.e. as the limit function coming from the Dirichlet problem.*

Proof. First, the combined results of this section prove the theorem in the case when the strict condition (4.1) is in place over (1.3b). That is, we have shown that every sequence of u_ε, ε tending to zero, has a convergent subsequence to a unique limit function which is independent of α or β. What remains to be shown is that the theorem remains valid when (4.1) is weakened to (1.3b). To show this, we consider a second family of solutions, $u_{\delta,\varepsilon}$, to a modified problem:

$$\begin{aligned} &T_\varepsilon u_{\delta,\varepsilon}=0,\\ &u_{\delta,\varepsilon}(0)-\alpha(1-\delta)\varepsilon u'_{\delta,\varepsilon}(0)=\gamma_0,\\ &u_{\delta,\varepsilon}(1)+\beta(1-\delta)\varepsilon u'_{\delta,\varepsilon}(1)=\gamma_1, \end{aligned}$$

where we may assume that $\alpha>0$ and $\beta>0$. If the boundary conditions above satisfy (1.3b) with $\delta=0$, then they satisfy (4.1) with $0<\delta<1$. So we have

$$\|u_\varepsilon-u\|_1 \leqq \|u_\varepsilon-u_{\delta,\varepsilon}\|_1+\|u_{\delta,\varepsilon}-u\|_1$$

where u is the limit of solutions to the Dirichlet problem.

Now, let η be an arbitrary positive number. The continuity estimate of Lemma 2.4 allows us to fix $\delta>0$ sufficiently small such that

$$\|u_\varepsilon-u_{\delta,\varepsilon}\|_1<\eta/2$$

for all $\varepsilon>0$. Since $u_{\delta,\varepsilon}$ satisfies (4.1), we may choose ε sufficiently small such that

$$\|u_{\delta,\varepsilon}-u\|_1<\eta/2,$$

thus completing the proof of the theorem.

5. Appendix: Alternate proof of uniqueness using inverse-monotonicity. Given the problem (1.1) with (1.2), (1.3a, b) is satisfied. The linearization of T_ε at any function $u(x)\in C^2$ reads

$$(T'_\varepsilon u)v=-\varepsilon v''+(a(u(x))v)'+b_u(x,u(x))v.$$

Thus we study linear operators

$$L_\varepsilon v=-\varepsilon v''+(p(x)v)'+q(x)v. \tag{5.1}$$

The following lemma is the key of the uniqueness argument:

LEMMA 5.1. *Let L_ε be given by* (5.1) *and assume $q(x)>0$ in* $[0,1]$ *as well as*

$$-\frac{1}{\beta}\leqq p(x)\leqq\frac{1}{\alpha} \quad \text{in } [0,1]$$

where $\alpha \geqq 0$, $\beta \geqq 0$ *determine* R_ε *as in* (1.1b). *Then* $(L_\varepsilon, R_\varepsilon)$ *is inverse-monotone, i.e.* (3.4) *holds. Especially, the homogeneous equation* $L_\varepsilon v = 0$, $R_\varepsilon v = 0$ *has only the trivial solution.*

Proof. Let $L_\varepsilon^* u = -\varepsilon u'' - p(x)u' + q(x)u$. Using the notation

$$(c_1, c_2)_2 = \int_0^1 c_1(x) c_2(x)\, dx$$

we have for all $u, v \in C^2$:

$$(L_\varepsilon v, u)_2 = (v, L_\varepsilon^* u)_2 + B(u, v)$$

with $B(u,v) = \{-\varepsilon(v'u - vu') + pvu\}\,|_0^1$. If $R_\varepsilon v = 0$ one has for all $u \in C^2$:

$$B(u,v) = \varepsilon v'(0)\{(1 - \alpha p(0))u(0) - \alpha\varepsilon u'(0)\}$$
$$-\varepsilon v'(1)\{(1 + \beta p(1))u(1) + \beta\varepsilon u'(1)\}.$$

Thus we define the adjoint boundary operator

$$R_\varepsilon^* u = \begin{pmatrix} (1 - \alpha p(0))u(0) - \alpha\varepsilon u'(0) \\ (1 + \beta p(1))u(1) + \beta\varepsilon u'(1) \end{pmatrix}.$$

Thus $R_\varepsilon v = R_\varepsilon^* u = 0$ implies

$$(L_\varepsilon v, u)_2 = (v, L_\varepsilon^* u)_2.$$

Since $q(x) > 0$, $1 - \alpha p(0) \geqq 0$, $1 + \beta p(1) \geqq 0$ we have

$$L_\varepsilon^* \bar{e} > 0, \qquad R_\varepsilon^* \bar{e} \geqq 0$$

with $\bar{e}(x) \equiv 1$; thus $\bar{e}(x)$ is a majorizing function for $(L_\varepsilon^*, R_\varepsilon^*)$. Then it is known that $(L_\varepsilon^*, R_\varepsilon^*)$ has a nonnegative Green's function (e.g. [15]) and the assertion follows. The following theorem is an immediate consequence of Lemma 5.1.

THEOREM 5.2. *For the problem* (1.1) *assume*

$$b_u(x,u) \geqq \mu > 0, \qquad \alpha \geqq 0, \quad \beta \geqq 0$$

and let

$$-\frac{1}{\beta} \leqq a(u) \leqq \frac{1}{\alpha} \quad \text{for } m \leqq u \leqq M$$

where $[m, M]$ *denotes the a priori domain.*

(i) *If* $u(x)$, $v(x) \in C^2$ *satisfy*

$$m \leqq u(x), \qquad v(x) \leqq M,$$

then

$$T_\varepsilon u \leqq T_\varepsilon v, \qquad R_\varepsilon u \leqq R_\varepsilon v$$

implies $u \leqq v$. *Especially,* (1.1) *is uniquely solvable.*

(ii) *At any* $u(x) \in C^2$ *with* $m \leqq u(x) \leqq M$, *the linear problem*

$$(T_\varepsilon' u)v = 0, \qquad R_\varepsilon v = 0$$

only has the trivial solution. As a consequence, if $u_\varepsilon(x)$ *denotes the solution of* (1.1), *the mapping* $\varepsilon \to u_\varepsilon$ *is continuous from* $(0, \infty)$ *into* C^2.

Proof. We only have to show (i). For $0 \leqq s \leqq 1$ let

$$z_s(x) = v(x) + s[u(x) - v(x)].$$

If we set

$$p(x) = \int_0^1 a(z_s(x))\, ds,$$
$$q(x) = \int_0^1 b_u(x, z_s(x))\, ds$$

and define L_ε by (5.1) then

$$T_\varepsilon u - T_\varepsilon v = L_\varepsilon(u - v).$$

The assertion now follows directly from Lemma 5.1.

A PRIORI BOUNDS AND EXISTENCE OF POSITIVE SOLUTIONS FOR SINGULAR NONLINEAR BOUNDARY VALUE PROBLEMS*

D. R. DUNNINGER† AND J. C. KURTZ†

Abstract. We consider singular nonlinear problems of the form $-(1/p)(pu')'=f(u)$ on $(0,1)$ with Dirichlet or mixed boundary conditions. The existence of a positive solution is obtained by first deriving a priori bounds in an appropriate weighted Sobolev norm, which in turn imply L^∞ a priori bounds. We then apply known results concerning fixed points of mappings of a cone.

1. Introduction. In this paper we seek the existence of solutions to singular problems of the form

$$Lu \equiv -\frac{1}{p}(pu')' = f(u) \quad \text{on } (0,1)$$

with $u(1)=0$ and boundary conditions at $t=0$ which will be determined by the behaviour of $p(t)$ near $t=0$. We will always assume at least that $p \in C[0,1] \cap C^1(0,1]$, $p(0)=0$ and $p(t)>0$ on $(0,1]$.

Linearly independent solutions of $Lu=0$ are $u_1(t)\equiv 1$ and $u_2(t)=\int_t^1 (ds/p(s))$. Thus, if p satisfies $\int_0^1 (ds/p(s))<\infty$, then u_1, u_2 are bounded and we may consider the Dirichlet problem

$$\begin{aligned} &Lu=f(u) \quad \text{on } (0,1),\\ &u(0)=u(1)=0. \end{aligned} \tag{1.1}$$

On the other hand, if $\int_0^1 (ds/p(s))=\infty$, then u_2 becomes unbounded near $t=0$, and the Dirichlet problem is inappropriate. In this case we take as our model the Dirichlet problem in $R^n (n \geqq 3)$

$$\begin{aligned} &-\Delta u = f(u), \qquad |x|<1,\\ &u=0 \quad \text{on } |x|=1. \end{aligned}$$

The equation for radial solutions $u=u(r)$, $r=|x|$, is then

$$\begin{aligned} &-r^{1-n}(r^{n-1}u')' = f(u), \qquad r \in (0,1),\\ &u(1)=0 \end{aligned}$$

and one seeks solutions satisfying $u'(0)=0$ so that the solution $u=u(|x|)$ is C^2 at the origin. Thus we are led to consider the problem

$$\begin{aligned} &Lu=f(u) \quad \text{on } (0,1),\\ &u(1)=0, \qquad \lim_{t\to 0^+} p(t)u'(t)=0. \end{aligned} \tag{1.2}$$

This weaker form of the boundary condition at $t=0$ seems more natural in the weak formulation of the problem, and will eventually lead to $u'(0)=0$.

*Received by the editors August 25, 1983, and in revised form October 15, 1984.

In the sequel it will become clear that problem (1.2) is also appropriate in the case $\int_0^1 (dt/p(t)) < \infty$. Thus we will consider (1.2) in both cases.

We shall denote the problems (1.1) and (1.2) collectively by

$$\begin{aligned} &Lu = f(u) \quad \text{on } (0,1), \\ &u \in \mathscr{B}, \end{aligned} \tag{1.3}$$

where $u \in \mathscr{B}$ means that u satisfies the appropriate boundary conditions depending on the behaviour of p near $t=0$.

For regular boundary value problems, fairly general conditions on the function f which ensure the existence of a solution have recently been given in [3], [4]. This approach is being pursued by the authors in a separate paper [1] for the singular problem.

In the present paper we consider a much different class of nonlinearities, and prove the existence of a positive solution by first deriving a priori bounds for any positive solution. Our approach is generally along the lines of [2] and [11]. Existence alone can be obtained under weaker hypotheses (see [2, Thm. 2.3]).

Sections 2 and 3 contain definitions and a number of technical results, which will be needed later, concerning the operator L and the various spaces involved. In §4 we obtain a priori L^∞-bounds for positive solutions of (1.3). Finally, in §5 we use the a priori bounds to obtain the existence of a positive solution by a fixed point argument.

2. Definitions and imbedding theorems. For $i=1,2$, we define the spaces $(X_i, \|\cdot\|_X)$ by

$$X_i = \{ u \mid u \in C[0,1],\ pu' \in C[0,1],\ Lu \in C[0,1],\ u \in \mathscr{B}_i \}$$

where

$$\begin{aligned} \mathscr{B}_1 &= \Big\{ u \Big| u(1) = \lim_{t \to 0^+} p(t)u'(t) = 0 \Big\}, \\ \mathscr{B}_2 &= \{ u \mid u(0) = u(1) = 0 \}, \end{aligned}$$

and

$$\|u\|_X = |u|_0 + |pu'|_0 + |Lu|_0,$$

where as usual

$$|u|_0 = \max_{0 \leqq t \leqq 1} |u(t)|.$$

Correspondingly, we define $(Y_i, \|\cdot\|_Y)$ by

$$\begin{aligned} Y_1 &= \{ u \mid u \in AC_{\text{loc}}(0,1],\ u(1) = 0,\ \|u\|_Y < \infty \}, \\ Y_2 &= \{ u \mid u \in AC_{\text{loc}}(0,1],\ u \in \mathscr{B}_2,\ \|u\|_Y < \infty \}, \end{aligned}$$

where

$$\|u\|_Y = \left(\int_0^1 u'(t)^2 p(t)\, dt \right)^{1/2}.$$

We denote by L_p^q the space of all measurable functions u for which

$$\|u\|_{L_p^q}=\left(\int_0^1|u(t)|^q p(t)\,dt\right)^{1/q}<\infty$$

and by $W_p^{1,2}$ the space of functions $u\in AC_{\text{loc}}(0,1]$ for which $u,u'\in L_p^2$ with

$$\|u\|_{W_p^{1,2}}=\left\{\|u\|_{L_p^2}^2+\|u'\|_{L_p^2}^2\right\}^{1/2}.$$

Remark 2.1. If we assume the condition

$$\int_0^1\frac{1}{p(s)}\int_0^t p(t)\,dt\,ds<\infty, \tag{P1}$$

then $\|u\|_Y$ is equivalent to $\|u\|_{W_p^{1,2}}$. In fact, for $u\in Y_i$ we have

$$|u(t)|\leqq\left(\int_t^1 u'(\tau)^2 p(\tau)\,d\tau\right)^{1/2}\left(\int_t^1\frac{d\tau}{p(\tau)}\right)^{1/2}, \tag{2.1}$$

and thus

$$\int_0^1 u(t)^2 p(t)\,dt\leqq\|u\|_Y^2\int_0^1\frac{1}{p(\tau)}\int_0^\tau p(t)\,dt\,d\tau.$$

We now state and prove a number of imbedding theorems.

LEMMA 2.1. *If* (P1) *holds, the imbedding* $i: X_1\to C[0,1]$ *is compact.*

Proof. For $u\in X_1$ we have

$$|p(t)u'(t)|\leqq\int_0^t|Lu|p(\tau)\,d\tau\leqq\|u\|_X\int_0^t p(\tau)\,d\tau \tag{2.2}$$

from which it follows that

$$|u(t_2)-u(t_1)|\leqq\|u\|_X\int_{t_1}^{t_2}\frac{1}{p(t)}\int_0^t p(\tau)\,d\tau\,dt$$

and

$$|u(t)|\leqq\|u\|_X\int_0^1\frac{1}{p(t)}\int_0^t p(\tau)\,d\tau\,dt.$$

The result now follows from the Arzela–Ascoli theorem.

LEMMA 2.2. *If* p *satisfies*

$$\int_0^1\frac{dt}{p(t)}<\infty \tag{P2}$$

the imbedding $i: X_2\to C[0,1]$ *is compact.*

Proof. If $u\in X_2$ we have

$$|u(t_2)-u(t_1)|\leqq\|u\|_X\int_{t_1}^{t_2}\frac{dt}{p(t)}$$

and

$$|u(t)|\leqq\|u\|_X\int_0^1\frac{dt}{p(t)}$$

and the result follows again from the Arzela–Ascoli theorem.

LEMMA 2.3. *If* (P1) ((P2)) *holds, then the imbedding* $i: X_1 \to Y_1$ ($i: X_2 \to Y_2$) *is continuous.*

Proof. In the first case we have from (2.2)

$$\int_0^1 u'(t)^2 p(t)\,dt \leqq \|u\|_X^2 \int_0^1 \frac{1}{p(t)} \left(\int_0^t p(\tau)\,d\tau \right)^2 dt$$

$$\leqq C\|u\|_X^2 \int_0^1 \frac{1}{p(t)} \int_0^t p(\tau)\,d\tau\,dt$$

while in the second case we have

$$\int_0^1 u'(t)^2 p(t)\,dt = \int_0^1 \frac{1}{p(t)} \left(p(t)u'(t) \right)^2 dt \leqq \|u\|_X^2 \int_0^1 \frac{dt}{p(t)}.$$

LEMMA 2.4. *If* (P2) *holds, the imbedding* $i: Y_2 \to C[0,1]$ *is compact.*

Proof. For $u \in Y_2$ we have from (2.1)

$$|u(t)| \leqq \|u\|_Y \left(\int_0^1 \frac{dt}{p(t)} \right)^{1/2}.$$

Since

$$|u(t_2) - u(t_1)| \leqq \|u\|_Y \left(\int_{t_1}^{t_2} \frac{dt}{p(t)} \right)^{1/2}$$

the result follows once more from the Arzela–Ascoli theorem.

In order to prove a corresponding imbedding theorem for Y_1 we must impose more restrictions on $p(t)$, namely

(P3) $$\lim_{t \to 0^+} \frac{tp'(t)}{p(t)} = \alpha > 0,$$

(P4) $$C_1 \left(1 + |\log t| \right)^{-1} \leqq \frac{t^\alpha}{p(t)} \leqq C_2 \left(1 + |\log t| \right).$$

Remark 2.2. It follows from (P3) that

$$\lim_{t \to 0^+} \frac{1}{p(t)} \int_0^t p(\tau)\,d\tau = \lim_{t \to 0^+} \frac{p(t)}{p'(t)} = 0$$

so that (P1) also holds. In addition, it follows easily from (P4) that (P2) holds for $0 < \alpha < 1$, whereas if $\alpha \geqq 1$,

$$\int_0^1 \frac{ds}{p(s)} = \infty.$$

We now define

$$\sigma + 1 = \sup \left\{ q \,\middle|\, \int_0^1 \left(\int_t^1 \frac{d\tau}{p(\tau)} \right)^{q/2} p(t)\,dt < \infty \right\}.$$

LEMMA 2.5. *Let* (P3), (P4) *hold. Then*

$$\sigma + 1 = \begin{cases} +\infty & \text{if } 0 < \alpha \leqq 1, \\ \dfrac{2(\alpha+1)}{\alpha - 1} & \text{if } \alpha > 1. \end{cases}$$

Proof. For $0<\alpha<1$, (P2) holds, and therefore $\sigma+1=\infty$.

For $\alpha=1$,

$$\int_t^1 \frac{d\tau}{p(t)} \leqq C_2 \int_t^1 \frac{(1-\log\tau)}{\tau} d\tau \leqq C(1-\log t)^2$$

and therefore,

$$\int_0^1 \left(\int_t^1 \frac{d\tau}{p(\tau)} \right)^{q/2} p(t)\, dt \leqq C \int_0^1 t(1-\log t)^{1+q} dt < \infty$$

for every q, which implies $\sigma+1=+\infty$.

For $\alpha>1$,

$$\int_t^1 \frac{d\tau}{p(\tau)} \leqq C_2 \int_t^1 \tau^{-\alpha}(1-\log\tau)\, d\tau \leqq C t^{1-\alpha}(1-\log t)$$

and therefore,

$$\int_0^1 \left(\int_t^1 \frac{d\tau}{p(t)} \right)^{q/2} p(t)\, dt \leqq C \int_0^1 t^{\alpha+(1-\alpha)q/2}(1-\log t)^{1+(q/2)} dt.$$

The last integral, however, is finite if $\alpha+(1-\alpha)q/2>-1$, i.e., $q<2(\alpha+1)/(\alpha-1)$. Thus $\sigma+1 \geqq 2(\alpha+1)/(\alpha-1)$. Similarly we can show that $\sigma+1 \leqq 2(\alpha+1)/(\alpha-1)$ which completes the proof.

LEMMA 2.6. *If* (P3), (P4) *hold, then the imbedding* $i: Y_1 \to L_p^q$ *is compact for* $2 \leqq q < \sigma+1$.

Proof. Using (2.1) we obtain

$$\int_0^\varepsilon |u(t)|^q p(t)\, dt \leqq \|u\|_Y^q \int_0^\varepsilon p(t) \left(\int_t^1 \frac{d\tau}{p(\tau)} \right)^{q/2} dt = o(1)\|u\|_Y^q \quad \text{as } \varepsilon \to 0^+. \tag{2.3}$$

Assuming $\|u_n\|_Y \leqq C$, it follows from Remark 2.1 that $\|u_n\|_{W_p^{1,2}}$ is also uniformly bounded. Since for every $\varepsilon>0$, $W_p^{1,2} \subseteq W^{1,2}([\varepsilon,1])$, the usual Sobolev space, it follows that there exists a subsequence, which we again call $\{u_n\}$, and a function $u \in Y_1$ such that $u_n \to u$ uniformly on compact subsets of $(0,1]$. From (2.3) we can easily infer that $\|u_n-u\|_Y \to 0$, which completes the proof.

LEMMA 2.7. *Let* (P3) *hold and, in addition, assume*

$$C_1(1+|\log t|)^{-1} \leqq \frac{t^\alpha}{p(t)} \leqq C_2, \tag{P4}'$$

$$p'(t)>0 \quad \text{on } (0,1). \tag{P5}$$

Then, if $\alpha>1$, *the imbedding* $i: Y_1 \to L_p^{\sigma+1}$ *is continuous.*

Proof. For $u \in Y_1$, set $v=|u|^{2\alpha/(\alpha-1)}$. Then

$$\begin{aligned} |v(t)| &\leqq \frac{1}{p(t)} \int_t^1 |v'(\tau)|\, p(\tau)\, d\tau, \\ |v(t)|^{1+(1/\alpha)} &\leqq C \int_t^1 |v(\tau)|^{1/\alpha} |v'(\tau)|\, d\tau, \end{aligned} \tag{2.4}$$

and therefore,

$$\int_0^1 |v(t)|^{1+(1/\alpha)} p(t)\,dt \leqq C\int_0^1 p(t)\int_t^1 |v(\tau)|^{1/\alpha}|v'(\tau)|\,d\tau\,dt$$

$$\leqq C\sup_{\tau>0}\left\{|v(\tau)|^{1/\alpha}\frac{1}{p(\tau)}\int_0^\tau p(t)\,dt\right\}\int_0^1 |v'(\tau)|p(\tau)\,d\tau.$$

Using (2.4) and (P4)′ we obtain

$$\int_0^1 |v(t)|^{1+(1/\alpha)} p(t)\,dt \leqq C\left(\int_0^1 |v'(\tau)|p(\tau)\,d\tau\right)^{1+(1/\alpha)} \sup_{\tau>0}\left\{p(\tau)^{-1-(1/\alpha)}\int_0^\tau p(t)\,dt\right\}$$

$$\leqq C\left(\int_0^1 |v'(\tau)|p(\tau)\,d\tau\right)^{1+(1/\alpha)}.$$

Now

$$|v'(t)| \leqq \frac{2\alpha}{\alpha-1}|u(t)|^{(\alpha+1)/(\alpha-1)}|u'(t)|.$$

Thus

$$\left(\int_0^1 |u(t)|^{\sigma+1} p(t)\,dt\right)^{\alpha/(\alpha+1)} \leqq C\int_0^1 |u(t)|^{(\alpha+1)/(\alpha-1)}|u'(t)|p(t)\,dt$$

$$\leqq C\left(\int_0^1 u'(t)^2 p(t)\,dt\right)^{1/2}\left(\int_0^1 |u(t)|^{\sigma+1} p(t)\,dt\right)^{1/2}$$

and finally

$$\left(\int_0^1 |u(t)|^{\sigma+1} p(t)\,dt\right)^{1/(\sigma+1)} \leqq C\left(\int_0^1 u'(t)^2 p(t)\,dt\right)^{1/2}.$$

3. Further preliminary results. In this section we examine some properties of the operator L and the solutions of problem (1.3).

For $i=1,2$, let L_i be the operator given by $L_i \equiv L: X_i \to C[0,1]$. Then we have the following:

LEMMA 3.1. *If* (P1) ((P2)) *holds, then* L_1 (L_2) *is bounded, one-to-one, onto, and has an inverse* G_1 (G_2) *which is compact as an operator on* $C[0,1]$. *Moreover,*

$$G_i h(t) = \int_0^1 g_i(t,s)h(s)p(s)\,ds, \qquad h \in C[0,1],$$

where

$$g_1(t,s) = \begin{cases} \displaystyle\int_s^1 \frac{d\tau}{p(\tau)}, & t \leqq s, \\ \displaystyle\int_t^1 \frac{d\tau}{p(\tau)}, & t \geqq s, \end{cases}$$

$$g_2(t,s) = \begin{cases} \displaystyle\left(\int_0^1 \frac{d\tau}{p(\tau)}\right)^{-1}\int_s^1 \frac{d\tau}{p(\tau)}\int_0^t \frac{d\tau}{p(\tau)}, & t \leqq s, \\ \displaystyle\left(\int_0^1 \frac{d\tau}{p(\tau)}\right)^{-1}\int_t^1 \frac{d\tau}{p(\tau)}\int_0^s \frac{d\tau}{p(\tau)}, & t \geqq s. \end{cases}$$

Proof. Since $|L_i u|_0 \leqq \|u\|_X$, it follows that each L_i is bounded and one-to-one. By a direct computation we find that $G_i: C[0,1] \to X_i$ and $G_i = L_i^{-1}$. The compactness of the G_i follows from the closed graph theorem and Lemmas 2.1 and 2.2.

LEMMA 3.2. *Let* $f \in C(\mathbb{R})$. (i) *If* $u \in X_1$ *is a positive solution of* (1.2), *then* $u'(t) < 0$ *on* $(0,1]$. (ii) *If* $u \in X_2$ *is a positive solution of* (1.1), *then* $u'(t) > 0$ *on* $[0, t_0)$ *and* $u'(t) < 0$ *on* $(t_0, 1]$ *for some* $t_0 \in (0,1)$.

Proof. The proofs follow along the lines of [7, Lemma 4.1].

LEMMA 3.3. *Let* (P3), (P4) *hold. Suppose* $f \in C(\mathbb{R})$ *and* $f(t) = O(t^k)$ *for some* $k \in [1, \sigma)$. *If* $u \in Y_1$ *is a weak solution of* (1.2), *then in fact* $u \in C^2[0,1]$ *and* $u'(0) = 0$.

Proof. We recall first that $u \in Y_i$ is a weak solution of (1.3) if

$$\int_0^1 u'(t) w'(t) p(t)\, dt = \int_0^1 f(u(t)) w(t) p(t)\, dt \tag{3.1}$$

holds for all $w \in Y_i$. In view of Lemma 2.4, Lemma 2.6 and the estimate $|f(u)| \leqq C_1 + C_2 |u|^k$ it follows in standard fashion that the right-hand side of (3.1) is well defined.

Next we note that in fact $u \in C^2(0,1]$ and satisfies (1.2), cf. [9, Lemma 1, p. 209].

We now show that $u \in L^\infty$. If $\alpha < 1$, then by Remark 2.2, $\int_0^1 (ds/p(s)) < \infty$ and the result follows from (2.1).

Now suppose $\alpha \geqq 1$. Integrating (1.2) twice gives

$$u(t) = \int_t^1 \frac{1}{p(\tau)} \int_0^\tau f(u(s)) p(s)\, ds\, d\tau. \tag{3.2}$$

Since $|f(u)| \leqq C_1 + C_2 |u|^k$, (3.2) yields

$$|u(t)| \leqq C_1 + C_2 \int_t^1 \frac{1}{p(\tau)} \int_0^\tau |u(s)|^k p(s)\, ds\, d\tau. \tag{3.3}$$

We now iterate (3.3), beginning with the initial estimate

$$u(t) = O\left(t^{(1-\alpha)/2} (1 - \log t)^{1/2}\right)$$

which follows from (2.1) and (P4). If at the ith stage we have

$$u(t) = O\left(t^{\lambda_i} (1 - \log t)^{\beta_i}\right),$$

where $\lambda_i \geqq 1 - \alpha/2$ and $\beta_i > 0$, then (3.3) yields (for $\alpha > 1$):

$$|u(t)| \leqq C_1 + C_2 \int_t^1 \tau^{1 + k\lambda_i} (1 - \log \tau)^{k\beta_i + 2} d\tau$$

$$= \begin{cases} O(1), & 1 + k\lambda_i > -1, \\ O\left(t^{2 + k\lambda_i} (1 - \log t)^{k\beta_i + 2}\right), & 1 + k\lambda_i < -1, \\ O\left((1 - \log t)^{k\beta_i + 3}\right), & 1 + k\lambda_i = -1. \end{cases}$$

Thus $\lambda_i \geqq (1 - \alpha)/2$ and $1 + k\lambda_i < -1$ imply $\lambda_{i+1} = k\lambda_i + 2$. Moreover, it is readily seen that $\lambda_{i+1} > \lambda_i$. If $1 + k\lambda_i < -1$ for all i, then λ_i converges to some λ and $\lambda = k\lambda + 2$. But this means

$$\lambda = \frac{2}{1-k} < \frac{2}{1-\sigma} = \frac{1-\alpha}{2},$$

which is impossible. If at some stage $1+k\lambda_i=-1$, then one more iteration gives $u\in L^\infty$. Thus after finitely many iterations $1+k\lambda_i\geqq -1$, and we have $u\in L^\infty$. The case $\alpha=1$ is similar.

For the second part of the lemma we observe first that

$$u(0)=\int_0^1 \frac{1}{p(\tau)}\int_0^\tau f(u(s))p(s)\,ds\,d\tau.$$

Hence

$$\left|\frac{u(t)-u(0)}{t}\right|\leqq \frac{C}{t}\int_0^t \frac{1}{p(\tau)}\int_0^\tau p(s)\,ds\,d\tau,$$

which by Remark 2.2 implies $u'(0)=0$. Next we see that

$$\frac{u'(t)}{t}=-\frac{1}{tp(t)}\int_0^t f(u(s))p(s)\,ds,$$

which by l'Hôpital's rule and (P3) gives

$$u''(0)=-\lim_{t\to 0^+}\frac{f(u(t))p(t)}{p(t)+tp'(t)}=-\frac{f(u(0))}{\alpha+1}.$$

On the other hand, we have from the equation

$$\lim_{t\to 0^+}u''(t)=\lim_{t\to 0^+}\left\{-f(u(t))-\left(\frac{tp'(t)}{p(t)}\right)\left(\frac{u'(t)}{t}\right)\right\}=-\frac{f(u(0))}{\alpha+1}=u''(0),$$

and therefore $u\in C^2[0,1]$.

Finally, we shall need a result concerning eigenvalues and eigenfucntions of (1.3).

First we recall that if for a complex number λ there is a nontrivial $v\in Y_i$ such that

$$a_i(v,w)\equiv\int_0^1 v'(t)w'(t)p(t)\,dt=\lambda\int_0^1 v(t)w(t)p(t)\,dt$$

holds for all $w\in Y_i$, then we call λ an eigenvalue of L and we call v a generalized eigenfunction (corresponding to λ).

Under the assumption (P1), it follows from Remark 2.1 that the bilinear from $a_i(v,w)$ is positive definite. Moreover, assuming (P2)–(P4), it follows from Lemmas 2.4 and 2.6 that the imbedding $i: Y_i\to L_p^2$ is compact. Thus by a standard result [10], there exists a sequence of eigenvalues and generalized eigenfunctions of L.

In addition, we have the well-known result:

LEMMA 3.4. *Assume* (P2)–(P4). *Let* λ_1 *be the first eigenvalue of L with corresponding generalized eigenfunction* $v_1\in Y_i$. *Then* $\lambda_1>0$ *and*

$$\lambda_1=\min_{\substack{u\in Y_i\\ u\neq 0}}\frac{\int_0^1 u'(t)^2p(t)\,dt}{\int_0^1 u(t)^2p(t)\,dt}.$$

Moreover, v_1 *may be chosen to be positive in* $(0,1)$.

Remark 3.1. It follows from Lemmas 3.2–3.4 that

(i) For problem (1.2) the eigenfunction v_1 is positive and strictly decreasing.

(ii) For problem (1.1) the eigenfunction v_1 is positive and strictly increasing on $[0,t_0]$, strictly decreasing on $[t_0,1]$, for some $t_0\in(0,1)$.

It follows also from (1.1) (1.2) that $v_1\in X_1$ ($v_1\in X_2$).

4. A priori bounds. We consider first problem (1.1).

THEOREM 4.1. *Suppose*

$$\int_0^1 \frac{dt}{p(t)} < \infty \tag{P2}$$

holds and f satisfies

$$f \in C(\mathbb{R}^+), \tag{F1}$$

$$\liminf_{t\to\infty} \frac{f(t)}{t} > \lambda_1. \tag{F2}$$

Then any positive solution $u \in X_2$ of (1.1) *satisfies $|u|_0 \leqq C$, where C is independent of u.*

Here and in all that follows, C will denote a constant, different on different appearances, which is independent of u.

Proof. Multiplying (1.1) by pv_1 and integrating by parts gives

$$\int_0^1 u'v_1' p\,dt = \int_0^1 f(u)v_1 p\,dt. \tag{4.1}$$

Similarly, multiplying $Lv_1 = \lambda_1 v_1$ by pu and integrating by parts yields

$$\int_0^1 u'v_1' p\,dt = \lambda_1 \int_0^1 uv_1 p\,dt$$

which, taken together with (4.1) gives

$$\lambda_1 \int_0^1 uv_1 p\,dt = \int_0^1 f(u)v_1 p\,dt. \tag{4.2}$$

It follows from (F2) that there exist $s_0 > 0$, $\lambda > \lambda_1$ such that $f(s) \geqq \lambda s$ whenever $s \geqq s_0$. Thus (4.2) yields

$$\lambda \int_0^1 uv_1 p\,dt \leqq \int_0^1 f(u)v_1 p\,dt + C = \lambda_1 \int_0^1 uv_1 p\,dt + C$$

so that

$$\int_0^1 uv_1 p\,dt \leqq \frac{C}{\lambda - \lambda_1}, \qquad \int_0^1 f(u)v_1 p\,dt \leqq \frac{C\lambda_1}{\lambda - \lambda_1},$$

and finally also

$$\int_0^1 |f(u)|v_1 p\,dt \leqq C. \tag{4.3}$$

By Remark 3.1 and Lemma 3.2 we have for $0 \leqq t \leqq \varepsilon$, ε sufficiently small,

$$C \geqq \int_0^1 uv_1 p\,d\tau \geqq \int_\varepsilon^{2\varepsilon} uv_1 p\,d\tau \geqq u(t)\varepsilon v_1(\varepsilon) \min_{\varepsilon \leqq \tau \leqq 2\varepsilon} p(\tau)$$

so that $u(t) \leqq C$ for $0 \leqq t \leqq \varepsilon$. Similarly, $u(t) \leqq C$ for $1 - \varepsilon \leqq t \leqq 1$. It follows easily from (4.3) that

$$\int_0^1 |f(u)|p\,dt \leqq C.$$

Next, since $u = G_1 f(u)$ by Lemma 3.1,

$$p(t)u'(t) = \left(\int_0^1 \frac{d\tau}{p(\tau)}\right)^{-1} \left\{ \int_t^1 \left(\int_s^1 \frac{d\tau}{p(\tau)} \right) f(u(s)) p(s)\, ds \right.$$
$$\left. - \int_0^t \left(\int_0^s \frac{d\tau}{p(\tau)} \right) f(u(s)) p(s)\, ds \right\}$$

which in view of (P2) yields

$$|p(t)u'(t)| \leqq \int_0^1 |f(u(s))|\, p(s)\, ds \leqq C.$$

Thus

$$|u(t)| = \left| - \int_t^1 \frac{1}{p(\tau)} (p(\tau)u'(\tau))\, d\tau \right|$$
$$\leqq \left(\int_0^1 |f(u(\tau))|\, p(\tau)\, d\tau \right) \left(\int_0^1 \frac{d\tau}{p(\tau)} \right) \leqq C$$

and the theorem is proved.

Next we turn our attention to problem (1.2).

THEOREM 4.2. *Suppose*

(P3) $$\lim_{t \to 0^+} \frac{tp'(t)}{p(t)} = \alpha > 0,$$

(P4)′ $$C_1 (1 + |\log t|)^{-1} \leqq \frac{t^\alpha}{p(t)} \leqq C_2,$$

(P5) $$p'(t) > 0 \quad \text{on } (0,1),$$

hold and f satisfies (F1), (F2) *and*

(F3) $$\lim_{t \to \infty} t^{-\sigma} f(t) = 0 \qquad (\alpha > 1),$$
$$f(t) = O(t^r) \quad \text{for some } r \in (0, \infty), \text{ as } t \to \infty, \ (0 < \alpha \leqq 1),$$

(F4) $$\overline{\lim_{t \to \infty}} \frac{tf(t) - \theta F(t)}{t^2 f(t)^{2/(\alpha+1)}} \leqq 0,$$
$$\text{for some } \theta \in [0, \sigma + 1) \text{ if } \alpha > 1, \text{ where } F(t) = \int_0^t f(s)\, ds.$$

Then any positive solution $u \in X_1$ of (1.2) *satisfies* $|u|_0 \leqq C$.

Remark 4.1. Consider the typical case $p(t) = t^{n-1}$ $(n \geqq 3)$, where $\alpha = n-1$, $\sigma = (n+2)/(n-2)$. Since (F4) is satisfied in the case where $t^{-\theta} F(t)$ is decreasing for large t, it follows easily that (F1)–(F4) are satisfied for $f(u) = u^k$, $1 < k < (n+2)/(n-2)$.

Proof of Theorem 4.2. The proof is very similar to the proof of [2, Thm. 1.1]. We include the details for the sake of completeness.

As in the proof of Theorem 4.1 we have

(4.4) $$\int_0^1 |f(u)|\, p\, dt \leqq C.$$

Multiplying (1.2) by p and integrating gives

$$p(t)u'(t) = -\int_t^1 f(u(\tau))p(\tau)\,d\tau$$

and thus

$$|u'(t)| \leqq \frac{1}{p(1-\varepsilon)}\int_0^1 |f(u)|p\,d\tau \leqq C_\varepsilon$$

for $1-\varepsilon \leqq t \leqq 1$.

We now consider the case $\alpha > 1$ and obtain a "Pohozaev" type identity. Multiplying (1.2) by u' and integrating we get

$$\frac{1}{2}\{u'(1)^2 - u'(t)^2\}p(t) + p(t)\int_t^1 \frac{p'(\tau)}{p(\tau)}u'(\tau)^2 d\tau,$$

which implies

$$\begin{aligned}\int_0^1 F(u(t))p(t)\,dt &= \frac{1}{2}u'(t)^2\int_0^1 p(t)\,dt - \frac{1}{2}\int_0^1 u'(t)^2 p(t)\,dt \\ &\quad + \int_0^1 p(t)\int_t^1 \frac{p'(\tau)}{p(\tau)}u'(\tau)^2 d\tau\,dt \\ &= \frac{1}{2}u'(1)^2 P(1) + \int_0^1 \left\{\frac{P(t)p'(t)}{p^2(t)} - \frac{1}{2}\right\}u'(t)^2 p(t)\,dt\end{aligned}$$

where

$$P(t) = \int_0^t p(\tau)\,d\tau.$$

It follows from (P3) and l'Hôpital's rule that

$$\lim_{t\to 0^+}\frac{P(t)p'(t)}{p^2(t)} - \frac{1}{2} = \frac{1}{\sigma+1}.$$

Thus we may choose $\eta \in (\theta, \sigma+1)$ so that

$$\frac{P(t)p'(t)}{p^2(t)} - \frac{1}{2} \leqq \frac{1}{\eta} \quad \text{on } (0,\varepsilon),$$

and

$$\int_0^1 F(u)\,p\,dt \leqq C_\varepsilon + \frac{1}{\eta}\int_0^1 (u')^2 p\,dt \leqq C_\varepsilon + \frac{1}{\eta}\int_0^1 uf(u)\,p\,dt. \tag{4.5}$$

Using (F4) we have for every $\varepsilon > 0$ the existence of a $t_\varepsilon > 0$ such that

$$tf(t) \leqq \theta F(t) + \varepsilon t^2 |f(t)|^{2/(\alpha+1)} \quad \text{for } t \geqq t_\varepsilon.$$

This together with (4.5) gives

$$\begin{aligned}\int_0^1 f(u)up\,dt &\leqq \theta\int_0^1 F(u)\,p\,dt + \varepsilon\int_0^1 u^2 |f(u)|^{2/(\alpha+1)} p\,dt + C_\varepsilon \\ &\leqq \frac{\theta}{\eta}\int_0^1 f(u)up\,dt + \varepsilon\int_0^1 u^2 |f(u)|^{2/(\alpha+1)} p\,dt + C_\varepsilon.\end{aligned} \tag{4.6}$$

But, by (4.4) and Lemma 2.7, we have

$$\int_0^1 u^2 |f(u)|^{2/(\alpha+1)} p\,dt \leqq \left(\int_0^1 |f(u)|p\,dt\right)^{2/(\alpha+1)} \left(\int_0^1 |u|^{\sigma+1} p\,dt\right)^{(\alpha-1)/(\alpha+1)}$$
$$\leqq C\int_0^1 (u')^2 p\,dt = C\int_0^1 f(u)up\,dt.$$

Combining this with (4.6) gives

$$\int_0^1 f(u)up\,dt \leqq \frac{\theta}{\eta}\int_0^1 f(u)up\,dt + C\varepsilon\int_0^1 f(u)up\,dt + C_\varepsilon$$

and thus

$$\left(1-\frac{\theta}{\eta}-C\varepsilon\right)\int_0^1 f(u)up\,dt \leqq C_\varepsilon.$$

Choosing $\varepsilon > 0$ sufficiently small gives

$$\int_0^1 f(u)up\,dt = \int_0^1 (u')^2 p\,dt \leqq C.$$

Next we observe that for $r > 1$

$$r\int_0^1 (u')^2 u^{r-1} p\,dt = \frac{4r}{(r+1)^2}\int_0^1 \left|(u^{(r+1)/2})'\right|^2 p\,dt = \int_0^1 f(u)u^r p\,dt. \tag{4.7}$$

According to (F3) we have

$$f(u)u^r \leqq \varepsilon u^{\sigma+r} + C_\varepsilon. \tag{4.8}$$

Setting $q = (\sigma+1)((r-1)/2)$ we obtain from (4.7), (4.8) and Lemma 2.7

$$\left(\int_0^1 u^q p\,dt\right)^{2/(\sigma+1)} = \left(\int_0^1 (u^{(r+1)/2})^{\sigma+1} p\,dt\right)^{2/(\sigma+1)}$$
$$\leqq C\int_0^1 \left|(u^{(r+1)/2})'\right|^2 p\,dt = C\int_0^1 f(u)u^r p\,dt$$
$$\leqq C\varepsilon\int_0^1 u^{r+1}u^{\sigma-1} p\,dt + C_\varepsilon$$
$$\leqq C\varepsilon\left(\int_0^1 u^q p\,dt\right)^{2/(\sigma+1)} \left(\int_0^1 u^{\sigma+1} p\,dt\right)^{(\sigma-1)/(\sigma+1)} + C_\varepsilon$$
$$\leqq C\varepsilon\left(\int_0^1 u^q p\,dt\right)^{2/(\sigma+1)} \left(\int_0^1 (u')^2 p\,dt\right)^{(\sigma-1)/2} + C_\varepsilon$$
$$\leqq C\varepsilon\left(\int_0^1 u^q p\,dt\right)^{2/(\sigma+1)} + C_\varepsilon.$$

It follows that

$$\left(\int_0^1 u^q p\,dt\right)^{1/q} \leqq C \tag{4.9}$$

for $q=(\sigma+1)((r+1)/2)$, for all $r>1$; i.e. for all $q>\sigma+1$. Hence (4.9) is valid for all $q\geqq 1$. Finally, we have from (3.1) and (4.9)

$$\begin{aligned}|u(t)| &\leqq \int_0^1 \frac{1}{p(t)} \int_0^t |f(u(s))|p(s)\,ds\,dt \\ &= \int_0^1 |f(u(s))| \left(\int_s^1 \frac{dt}{p(t)} \right) p(s)\,ds \\ &\leqq \left(\int_0^1 |f(u(s))|^{r/(r-2)} p(s)\,ds \right)^{1-(2/r)} \left(\int_0^1 p(s) \left(\int_s^1 \frac{dt}{p(t)} \right)^{r/2} \right)^{2/r}.\end{aligned}$$

Taking $2<r<\sigma+1$ gives

$$|u(t)| \leqq C_1 \left(\int_0^1 u^{r\sigma/(r-2)} p\,ds \right)^{1-(2/r)} + C_2 \leqq C.$$

According to Lemma 2.5, $\sigma=+\infty$ when $\alpha=1$. Thus in view of (F3) and Lemma 2.6 it follows as above that $|u|_0 \leqq C$.

For the case $0<\alpha<1$, according to (F3), we may choose $\gamma\in(0,1)$ so that

$$\lim_{t\to\infty} \frac{tf(t)}{t^2 f(t)^\gamma} = 0.$$

Then for every $\varepsilon>0$ there exists a $t_\varepsilon>0$ such that

$$tf(t) \leqq \varepsilon t^2 f(t)^\gamma \quad \text{for } t\geqq t_\varepsilon.$$

Thus

$$\begin{aligned}\int_0^1 (u')^2 p\,dt = \int_0^1 f(u) up\,dt &\leqq \varepsilon \int_0^1 u^2 |f(u)|^\gamma p\,dt + C_\varepsilon \\ &\leqq \varepsilon \left(\int_0^1 |f(u)|p\,dt \right)^\gamma \left(\int_0^1 u^{2/(1-\gamma)} p\,dt \right)^{1-\gamma} + C_\varepsilon \\ &\leqq C\varepsilon \int_0^1 (u')^2 p\,dt + C_\varepsilon\end{aligned}$$

by (4.4) and Lemma 2.6, and again

$$\int_0^1 (u')^2 p\,dt \leqq C.$$

Using (3.1) again we have

$$|u(t)| \leqq \left(\int_0^1 \frac{dt}{p(t)} \right) \int_0^1 |f(u)|p\,dt \leqq C$$

in view of (4.4) and Remark 2.2. Thus the theorem is proved.

Remark 4.2. If in Theorem 4.2 we replace conditions (F3) and (F4) (in the case $\alpha>1$) by

$$(\text{F3})' \qquad \lim_{t\to\infty} t^{-l} f(t) = 0, \qquad 1<l<\sigma,$$

$$(\text{F4})' \qquad \overline{\lim_{t\to\infty}} \frac{tf(t)-\theta F(t)}{t^2 f(t)^{2/(\beta+1)}}, \qquad \theta\in[0,l+1),$$

where $\beta=(l+3)/(l-1)$, then condition (P4)′ may be replaced by the weaker (P4). The proof is essentially unchanged if we replace σ by l, α by β, and use Lemma 2.6 in place of Lemma 2.7.

5. Existence of a positive solution. We first observe that, by Lemma 3.1 and the classical maximum principle, finding a positive solution of (1.3) is equivalent to finding a nonzero solution $u\in K=\{u\mid u\in C[0,1],\ u\geqq 0\}$ of the equation

$$u=\Phi_i(u)\equiv G_i f(u). \tag{5.1}$$

Our tool in this regard is

PROPOSITION 5.1 (see [2]). *Let K be a cone in a Banach space B and $\Phi: K\to K$ a compact map with $\Phi(0)=0$. Assume that there exist numbers $0<r<R$ and a vector $v\in K-\{0\}$ such that* (i) $x\neq t\Phi(x)$ *for* $0\leqq t\leqq 1$ *and* $\|x\|=r$ *and* (ii) $x\neq\Phi(x)+tv$ *for* $t\geqq 0$ *and* $\|x\|=R$. *If* $U=\{x\in K\mid r<\|x\|<R\}$ *and* $B_\rho=\{x\in K\mid\|x\|<\rho\}$, *then Φ has a fixed point in U.*

Remark 5.1. (i) is satisfied if there exists a bounded linear map $A: B\to B$ such that $A(K)\subseteq K$, A has spectral radius less than 1, and $\Phi(x)\leqq A(x)$ for $x\in K$ and $\|x\|=r$. In addition, (ii) may be replaced by (ii)′ there exists a compact map $F:\bar{B}_R\times[0,\infty)\to K$ such that $F(x,0)=\Phi(x)$ for $\|x\|=R$, $F(x,t)\neq x$ for $\|x\|=R$ and $0\leqq t<\infty$, and $F(x,t)=x$ has no solution $x\in\bar{B}_R$ for $t\geqq t_0$.

THEOREM 5.1. *Let $f:\mathbb{R}^+\to\mathbb{R}^+$ be locally Lipschitzian and suppose the hypotheses of either Theorem* 4.1 *or Theorem* 4.2 *are satisfied. Assume in addition that*

$$\overline{\lim_{t\to 0^+}}\frac{f(t)}{t}<\lambda_1,\qquad f(0)=0. \tag{F5}$$

Then there exists at least one positive solution $u\in X_i$ of (1.3).

Proof. We seek a fixed point $u\in K$ of (5.1). By (F5) we may choose $r>0$, $\alpha<\lambda_1$ so that $f(t)\leqq\alpha t$ for $0\leqq t\leqq r$. Then $\Phi_i(u)\leqq\alpha G_i(u)$ for $|u|_0\leqq r$, and $\|\alpha G_i\|\leqq\alpha/\lambda_1<1$ so that (i) is satisfied. Next we set

$$F_i(u,t)=G_i(f(u)+t).$$

It can be shown using the techniques of the proof of Theorem 4.1 that $F_i(u,t)=u$ has no positive solutions for $t\geqq t_0$. It follows then as in §4 that the a priori bounds for positive solutions hold uniformly in t. Thus there exists $R>r$ such that $F(u,t)=u$ has no solution for $|u|_0\geqq R$. It follows from Proposition 5.1 that Φ has a fixed point $u\in U$.

A FREE BOUNDARY PROBLEM ARISING FROM THE LEACHING OF SALINE SOILS*

PETER KNABNER†

Abstract. A multidimensional parabolic free boundary problem of the implicit type arises in models in the soil sciences. Existence, uniqueness and asymptotic behaviour of weak and classical solutions are considered.

AMS(MOS) subject classifications. Primary 35R35; secondary 35K20, 35K55, 35K60, 35K65

Key words. free boundary problems, parabolic boundary problems, nonlinear parabolic systems, parabolic systems, parabolic systems of degenerate type

1. Introduction. Approximately one-third of the developed agricultural lands in the arid and semi-arid regions of the world exhibit harmful salinity accumulation. This leads to considerably reduced crop yields (compare e.g. [4]). Reclamation of saline soils is done by leaching, the process whereby soil solution of high salt concentration is displaced by less concentrated solution until the accumulated solid salt is removed. A comprehensive exposition concerning saline soils may be found in [3]. In this paper we develop and investigate a model that describes the leaching process with special regard to the dynamics of the amount of the solid salt. One-dimensional and other simplified versions of this model appear in [9], [6], [7]: [9] compares numerical computations against experimental data, while in [6], [7] existence and uniqueness are investigated. Mathematically our multidimensional model generalizes most of the previous results in [6], [7]. Especially we have a stronger notion of solution, while we require weaker assumptions on the smoothness of the data.

2. The problem. Soil is a porous system, consisting of the solid soil matrix, the soil solution, i.e. water with dissolved substances, and the soil atmosphere, which both fill the pore space. We start with the macroscopic mass balance law for a solute, which is derived from the microscopic law by averaging over the water filled part of a "Representative Elementary Volume (REV)" (compare [1, pp. 513–520]):

$$\frac{\partial(\theta C+S)}{\partial t}=-\operatorname{div}[\mathbf{J}_1+\mathbf{J}_2+\mathbf{J}_3]+\tilde{F}, \tag{2.1}$$

where: θ is the volumetric water content, i.e. the ratio of the volume of water to the total volume of an REV, C is the concentration of the dissolved salt and S is the concentration of solids absorbed on soil surfaces or located in dead-end pore space.

$\mathbf{J}_1$ denotes the convective flux density of the solute, thus

$$\mathbf{J}_1=C\mathbf{V}, \tag{2.2}$$

where $\mathbf{V}$ is the flow rate of the soil solution. $\mathbf{J}_2$ is the dispersive flux density, due to variations of the flow velocity at the microscopic scale, and $\mathbf{J}_3$ is the flux density as a

*Received by the editors March 6, 1984. This work was supported by CNR, Italy.
† Mathematisches Institut, Universität Augsburg, 8900 Augsburg, West Germany.

result of molecular diffusion, and finally $\tilde{F}$ is the volumetric rate of supply or loss. All quantities are to be understood as averages, C over the water-filled part of an REV, while $\mathbf{V}$, S, and $\tilde{F}$ are over the total volume.

We assume

$$\mathbf{J}_2 = -\theta \mathbf{D}_1 \operatorname{grad} C, \tag{2.3}$$

$$\mathbf{J}_3 = -\theta \mathbf{D}_2 \operatorname{grad} C \quad \text{(Fick's law)}, \tag{2.4}$$

$$S = K_1 C + K_2 \quad \text{(Lapidus/Amundson, compare [2])}. \tag{2.5}$$

$\mathbf{D}_i$ are symmetric matrices, $\mathbf{D}_1$ may depend on $\mathbf{V}$ (compare [1, pp. 232–239]), K_i are functions with $K_1 \geqq 0$, both only dependent of x.

Furthermore, assuming the incompressibility of water, we can use the macroscopic balance equation for the water volume

$$\frac{\partial \theta}{\partial t} = -\operatorname{div} \mathbf{V} \tag{2.6}$$

to simplify (2.1) to:

$$AC_t - \frac{\partial}{\partial x_i}\left(D_{ij}\frac{\partial C}{\partial x_j}\right) + V_i \frac{\partial C}{\partial x_i} = \tilde{F}, \tag{2.7}$$

denoting $A := \theta + K_1$, $\mathbf{D} := \theta(\mathbf{D}_1 + \mathbf{D}_2)$ and applying Einstein's summation convention.

Let N denote the average concentration of the solid salt. Then, under assumptions described in [9], we have, as long as $N(\mathbf{x}, t) > 0$:

$$N_t = -\gamma(C^* - C). \tag{2.8}$$

C^* is the saturation concentration and γ is a known function, e.g. of the form $\tilde{\gamma}\theta$ for a constant $\tilde{\gamma} > 0$. The dissolution of N serves as a source for C, such that

$$\tilde{F} = -N_t + F. \tag{2.9}$$

For the completion of our description we need initial conditions for C and N and boundary conditions for C. The boundary conditions are assumed to be

$$D_{ij}\frac{\partial C}{\partial x_j} n_i = \beta(C - C_*) \tag{2.10}$$

with given functions β and C_*, while $\mathbf{n}$ denotes the outward normal vector. This form includes the cases (i) $\beta = V_i n_i$ and (ii) $\beta = 0$. At the portion of the boundary where we have (i), water with a salt concentration C_* flows in or out and (2.10) expresses the continuity of the mass flux density in the normal direction. In case (ii) we have either impermeability of that part of the boundary for the water and solute flux or the situation of (i) but with $C = C_*$, i.e. continuity of the concentration across the boundary. Neglecting the influence of the solute on the water flow, we can regard θ and $\mathbf{V}$ as known functions of space and time. Due to the interface between the regions $N > 0$ and

$N \equiv 0$ there is a discontinuity, since in general N_t will not vanish there. Thus a classical description has to deal with this free boundary:

Let Ω be a domain in $\mathbb{R}^n$, $n \in \mathbb{N}$, $S := \partial\Omega$, $T > 0$, $Q_{T_1T_2} := \Omega \times (T_1, T_2)$, $Q_T := Q_{0T}$, $S_T := S \times [0, T]$. Let A, D_{ij}, V_i, F, γ, C^* be given functions on $\overline{Q}_T$, C_0, N_0 are given on $\overline{\Omega}$ and β, C_* are given on S_T respectively, $i,j = 1, \cdots, n$. We will use for the elliptic part of the differential operator

$$LC := \frac{\partial}{\partial x_i}\left(D_{ij}\frac{\partial C}{\partial x_j}\right) - V_i\frac{\partial C}{\partial x_i},$$

and, $\mathbf{n}$ being the outward normal, for the outward conormal

$$\frac{\partial C}{\partial \nu} := D_{ij}\frac{\partial C}{\partial x_j}n_i.$$

For function spaces we adopt the notion of [8]; thus we use $\|\cdot\|_{q,Q_T}$ for the norm in $L_q(Q_T)$, $\|\cdot\|^{(2l)}_{q,Q_T}$ for the norm in $W_q^{2l,l}(Q_T)$ and $|\cdot|^{(l)}_{Q_T}$ for the norm in $H^{l,l/2}(\overline{Q}_T)$. In accordance with this the maximum norm is denoted by $|\cdot|^{(0)}_{Q_T}$.

DEFINITION 2.1. A triple (C, N, Φ) is called a *classical solution* in Q_T, if:

(2.11) $N \in C(\overline{Q}_T)$, $N \geqq 0$ on $\overline{Q}_T$.
Let $\Omega_{0,T} := \{x \in \overline{\Omega} \mid \text{there exists } t \in [0,T] : N(x,t) = 0\}$;
then $\Phi \in C(\Omega_{0,T})$, $\Phi(x) \in [0,T]$ for $x \in \Omega_{0,T}$.

(2.12) $N(x,t) > 0 \Leftrightarrow \Phi(x) > t$ for $x \in \Omega_{0,T}$, $t \in [0,T]$.

(2.13) Let $Q_+ := \{(x,t) \in Q_T \mid N(x,t) > 0\}$, $Q_- := Q_T \setminus \overline{Q}_+$;
then $C \in C^{2,1}(Q_+) \cap C^{2,1}(Q_-) \cap C(\overline{Q}_T)$,
$\dfrac{\partial C}{\partial x_i} \in C(\overline{Q}_T)$, $\quad i = 1, \cdots, n$, $N_t \in C(Q_+)$.

(2.14) $AC_t - LC + N_t = F$ in Q_+,
$AC_t - LC = F$ in Q_-.

(2.15) $C(x,0) = C_0(x)$, $\quad x \in \overline{\Omega}$,
$\dfrac{\partial C}{\partial \nu} = \beta(C - C_*)$ on S_T.

(2.16) $N_t = -\gamma(C^* - C)$ in Q_+.

(2.17) $N(x,0) = N_0(x)$, $\quad x \in \overline{\Omega}$.

The free boundary $\Phi(x) = t$ separates the regions $N > 0$ and $N \equiv 0$. The free boundary conditions are contained in (2.11), (2.13), assuming the continuity of N, C and $\partial C/\partial x_i$ across the interface; in particular we have $N(x, \Phi(x)) = 0$. To preserve this condition, we must have the restricted domain of definition for Φ. As we are mainly interested in the existence of classical solutions, we consider only smooth data. In the whole paper

we use

Assumption 2.2.

(2.18) $A(x,t)>0$ for all $(x,t)\in\overline{Q}_T$.

(2.19) $(D_{ij}(x,t))_{i,j}$ is symmetric and positive definite for all $(x,t)\in\overline{Q}_T$.

(2.20) $A,\ D_{ij},\ \partial D_{ij}/\partial x_i,\ V_i,\ \gamma,\ C^*,\ F\in H^{\alpha,\alpha/2}(\overline{Q}_T)$ for some $\alpha\in(0,1)$, $i,j=1,\cdots,n$.

$A(\cdot,0)$ is continuously differentiable in a neighborhood of S.

(2.21) $C_0\in W_q^{2-2/q}(\Omega)$ for some $q>(n+2)/2$, $q\geqq 2$, $q\neq n+2$.
C_0 is continuously differentiable in a neighborhood of S.
$N_0\in H^{\alpha}(\overline{\Omega})$.

(2.22) $C_*\in W_q^{1-1/q,(1-1/q)/2}(S_T)$.
$\beta,\ D_{ij}n_i\in H^{1-1/q+\varepsilon,(1-1/q+\varepsilon)/2}(\overline{S}_T)$ for some $\varepsilon>0$, $j=1,\cdots,n$.

(2.23) If $q>3$: $\partial C_0(x)/\partial\nu=\beta(x,0)(C_0(x)-C_*(x,0))$ for $x\in S$.

(2.24) $S\in H^{2+\alpha}$.

3. Existence of weak solutions. The differential equation in (2.14) can be written as

$$AC_t-LC+H(N)N_t=F, \tag{3.1}$$

where

$$H(s):=\begin{cases}1, & s>0,\\ 0, & s\leqq 0,\end{cases}\quad s\in\mathbb{R}. \tag{3.2}$$

Motivated by this, we develop the following notion:

DEFINITION 3.1. A pair $(C,\tilde{N})$ is called a *weak solution* in Q_T, if

$$C\in W_2^{1,1}(Q_T)\cap C(\overline{Q}_T),\ \tilde{N}\in C(\overline{Q}_T),\ C(x,0)=C_0(x) \text{ in } \overline{\Omega} \tag{3.3}$$

$$\begin{aligned}&\int_{Q_T}AC_t\phi\,dx\,dt+\int_{Q_T}D_{ij}\frac{\partial C}{\partial x_j}\frac{\partial\phi}{\partial x_i}dx\,dt\\ &\quad-\int_{S_T}\beta(C-C_*)\phi\,dx\,dt+\int_{Q_T}V_i\frac{\partial C}{\partial x_i}\phi\,dx\,dt\\ &\quad-\int_{Q_T}\hat{H}(\tilde{N})\phi_t\,dx\,dt-\int_{\Omega}\hat{H}(N_0(x))\phi(x,0)\,dx=\int_{Q_T}F\phi\,dx\,dt\end{aligned} \tag{3.4}$$

for all $\phi\in W_2^{1,1}(Q_T)$ such that $\phi(\cdot,T)=0$ a.e. in Ω, whereby $\hat{H}(s):=\max(s,0)$, $s\in\mathbb{R}$;

$$\tilde{N}(x,t)=N_0(x)-\int_0^t(\gamma(C^*-C))(x,\tau)\,d\tau \quad \text{in } \overline{Q}_T. \tag{3.5}$$

We first show the existence of a weak solution and later examine the relation between classical and weak solutions.

We use the following smoothing of H:

$$H_\varepsilon(s) := \begin{cases} 0, & s \leqq -\varepsilon/2, \\ s/\varepsilon + 1/2, & |s| < \varepsilon/2, \\ 1, & s \geqq \varepsilon/2 \end{cases} \tag{3.6}$$

and consider the following regularized problem:

DEFINITION 3.2. Let $\varepsilon > 0$. A pair $(C_\varepsilon, N_\varepsilon)$ is called a solution of (P_ε), if it classically fulfills

$$AC_{\varepsilon_t} - LC_\varepsilon + H_\varepsilon(N_\varepsilon) N_{\varepsilon_t} = F \quad \text{in } Q_T, \tag{3.7}$$

the identity (3.5), and the initial and boundary conditions (2.15).

LEMMA 3.3. (P_ε) *possesses a solution* $(C_\varepsilon, N_\varepsilon)$, $C_\varepsilon \in W_q^{2,1}(Q_T)$. *A constant* K *independent of* ε *exists such that*

$$\|C_\varepsilon\|^{(2)}_{q, Q_T} \leqq K. \tag{3.8}$$

Proof. Define the operator $\mathcal{F} = \mathcal{F}_\varepsilon$:

$$(\mathcal{F}(N))(x,t) := N_0(x) - \int_0^t (\gamma(C^* - C))(x,\tau)\, d\tau,$$

C being the classical solution $C_\varepsilon^{(N)}$ of

$$AC_t - LC - H_\varepsilon(N)\gamma(C^* - C) = F \quad \text{in } Q_T \tag{3.9}$$

with initial and boundary conditions (2.15).

Let $\delta := \min(\alpha, 2-(n+2)/q)/2$. We will prove the existence of a fixed point N_ε of $\mathcal{F}$ in $X := H^{\delta, \delta/2}(\overline{Q}_T)$. Obviously $(C_\varepsilon^{(N_\varepsilon)}, N_\varepsilon)$ is the desired solution. The proof will be accomplished by Schauder's theorem.

(i) $\mathcal{F}$ is well defined from X into X.

Let $N \in X$. $C_\varepsilon^{(N)}$ exists uniquely (e.g. [5, p. 147, Cor. 2]) and is in $W_q^{2,1}(Q_T)$ (compare [8, IV, §9], and [10, Thm. 17]); therefore $C_\varepsilon^{(N)}$ is also in $H^{\tilde{\alpha}, \tilde{\alpha}/2}(\overline{Q}_T)$, with $\tilde{\alpha} := 2-(n+2)/q$ [8, II, Lemma 3.3]. A fortiori we have $\mathcal{F}(N) \in X$.

In the following K denotes constants independent of N and ε:

ii) For some K the closed ball $B_K(0)$ is mapped by $\mathcal{F}$ into itself.

Let $N \in X$; then we have (compare [10, Thm. 17], [8, IV, §9])

$$\begin{aligned} \|C_\varepsilon^{(N)}\|^{(2)}_{q, Q_T} &\leqq K\left(1 + \|F + H_\varepsilon(N)\gamma(C^* - C_\varepsilon^{(N)})\|_{q, Q_T}\right) \\ &\leqq K\left(1 + \|C_\varepsilon^{(N)}\|_{q, Q_T}\right). \end{aligned}$$

We can conclude from the maximum principle (e.g. [8, Chap. I, Thm. 2.3])

$$|C_\varepsilon^{(N)}|^{(0)}_{Q_T} \leqq K,$$

and thus we get

$$\|C_\varepsilon^{(N)}\|^{(2)}_{q, Q_T} \leqq K \tag{3.10}$$

and especially ([8, Chap. II, Lemma 3.3])

$$|C_\varepsilon^{(N)}|_{Q_T}^{(2\delta)} \leqq K. \tag{3.11}$$

This also means that X is mapped into a ball $B_K(0)$.

iii) $\mathscr{F}$ is continuous.

Let $N_{1,2} \in X$; then $w := C_\varepsilon^{(N_1)} - C_\varepsilon^{(N_2)}$ fulfills

$$\begin{aligned} &Aw_t - Lw + H_\varepsilon(N_1)\gamma w = \gamma\big(C^* - C_\varepsilon^{(N_2)}\big)\big(H_\varepsilon(N_1) - H_\varepsilon(N_2)\big) := f \quad \text{in } Q_T, \\ &w(x,0) = 0, \qquad x \in \overline{\Omega}, \\ &\frac{\partial w}{\partial \nu} = \beta w \quad \text{on } S_T. \end{aligned}$$

Now applying [5, Thm. 4′, p. 213] we get:

$$|C_\varepsilon^{(N_1)} - C_\varepsilon^{(N_2)}|_{Q_T}^{(\delta)} \leqq K|f|_{Q_T}^{(0)} \leqq K/\varepsilon |N_1 - N_2|_{Q_T}^{(0)}$$

using e.g. (3.11). Therefore:

$$|\mathscr{F}(N_1) - \mathscr{F}(N_2)|_{Q_T}^{(\delta)} \leqq K/\varepsilon |N_1 - N_2|_{Q_T}^{(0)}.$$

To finish the proof, we have to establish:

iv) $\mathscr{F}[B_K(0)]$ is precompact, K according to ii).

This is true because of (3.11) and the compactness of the imbedding $H^{2\delta,\delta}(\overline{Q}_T) \to X$.

Finally due to (3.10) we also have (3.8). □

THEOREM 3.4. *There exists a weak solution* $(C, \tilde{N})$ *such that*

$$C \in W_q^{2,1}(Q_T).$$

Proof. The solutions of (P_ε) satisfy (3.5) and an integral relation $(3.4)_\varepsilon$, which equals (3.4) after substituting $\hat{H}$ by

$$\hat{H}_\varepsilon(s) := \int_0^s H_\varepsilon(\xi)\, d\xi. \tag{3.12}$$

Using (3.8), we see, by passing to a subsequence if necessary, that:

$$\begin{aligned} &C_\varepsilon \to C \quad \text{weakly in } W_q^{2,1}(Q_T) \qquad (3.13) \\ &C_\varepsilon \to C \quad \text{strongly in } H^{\tilde{\alpha},\tilde{\alpha}/2}(\overline{Q}_T) \qquad (3.14) \end{aligned} \quad \text{for } \varepsilon \to 0$$

with $\tilde{\alpha} \in (0, 2-(n+2)/q)$.

From (3.14) we conclude

$$N_\varepsilon \to \tilde{N} \quad \text{strongly in } C(\overline{Q}_T), \tag{3.15}$$

and $\tilde{N}$ fulfills (3.5). (3.3) is satisfied, too.

To finish the proof, we have to establish the convergence of $(3.4)_\varepsilon$ to (3.4), where due to (3.13) it suffices to show:

$$\gamma \int_{Q_T} \big(\hat{H}_\varepsilon(N_\varepsilon) - \hat{H}(\tilde{N})\big)\phi_t\, dx\, dt \to 0 \tag{3.16}$$

for $\varepsilon \to 0$ and all test functions ϕ.

We have:

$$(\hat{H}_\varepsilon(N_\varepsilon)-\hat{H}_\varepsilon(\tilde{N}))(x,t)=H_\varepsilon(\xi(x,t))(N_\varepsilon(x,t)-\tilde{N}(x,t))$$

for some $\xi(x,t)\in\langle N_\varepsilon(x,t),\ \tilde{N}(x,t)\rangle$, and therefore from (3.15)

$$|\hat{H}_\varepsilon(N_\varepsilon)-\hat{H}_\varepsilon(\tilde{N})|^{(0)}_{Q_T}\to 0 \quad \text{for } \varepsilon\to 0. \tag{3.17}$$

Furthermore $\|\hat{H}_\varepsilon-\hat{H}\|_{L^\infty}\to 0$ for $\varepsilon\to 0$ such that

$$|\hat{H}_\varepsilon(\tilde{N})-\hat{H}(\tilde{N})|^{(0)}_{Q_T}\to 0 \quad \text{for } \varepsilon\to 0. \tag{3.18}$$

(3.17), (3.18) imply (3.16). □

As a first regularity result let us mention:

THEOREM 3.5. *Let $(C,\tilde{N})$ be a weak solution such that $C\in W_p^{2,1}(Q_T)$ for some $p>1$.*

Let Q be a cylinder with smooth boundary, $\overline{Q}\subset Q_1$ or $\overline{Q}\subset Q_2$ with

$$Q_i:=\left\{(x,t)\in Q_T \mid (-1)^{i+1}\tilde{N}(x,t)>0\right\},\ i=1,2.$$

Then $C\in H^{2+\alpha,1+\alpha/2}(\overline{Q})$ and $(C,\tilde{N})$ fulfills classically

$$AC_t-LC+\tilde{N}_t=F \quad \text{in } Q_1, \tag{3.19}$$

$$QC_t-LC=F \quad \text{in } Q_2. \tag{3.20}$$

Proof. For definiteness we regard $\overline{Q}\subset Q_1$; the other case is strictly similar. Choose an analogous open cylinder $\tilde{Q}$ such that $\overline{Q}\subset\tilde{Q}\subset Q_1$. Let ϕ be an infinitely differentiable function in $\tilde{Q}$ with compact support. If we extend ϕ outside of $\tilde{Q}$ by 0, we obtain an admissible test function for (3.4) such that after partial integration we get

$$\int_{\tilde{Q}}(AC_t-LC+\tilde{N}_t-F)\phi\,dx\,dt=0$$

because $\hat{H}(\tilde{N})=\tilde{N}$ in $\tilde{Q}$. Therefore we have a generalized solution of (3.19) in $W_p^{2,1}(\tilde{Q})$, which by means of (3.5), possesses the desired regularity (compare [8, III, Thm. 12.2]). □

4. Uniqueness of weak and classical solutions. In this section we will use additionally the following:

Assumption 4.1.

1) $$A_t,\ \frac{\partial V_i}{\partial x_i}\in L^2(Q_T),\quad i=1,\cdots,n.$$

2) $$V_i n_i\in H^{1/2+\varepsilon,(1/2+\varepsilon)/2}(\overline{S}_T) \quad \text{for some } \varepsilon>0.$$

We start with the investigation of the following auxiliary problem for given f and h:

$$\left((A\phi)_t+\frac{\partial}{\partial x_i}\left(D_{ij}\frac{\partial\phi}{\partial x_j}\right)+\frac{\partial}{\partial x_i}(V_i\phi)\right)(x,t)$$
$$+\gamma(x,t)\int_t^T(h\phi_t)(x,\tau)\,d\tau=f(x,t) \quad \text{in } Q_T, \tag{4.1}$$

$$\phi(x,T)=0 \quad \text{in } \Omega, \tag{4.2}$$

$$\frac{\partial\phi}{\partial\nu}=(\beta-V_i n_i)\phi \quad \text{on } S_T. \tag{4.3}$$

LEMMA 4.2. *Let* $f \in L^2(Q_T)$, $h \in L^\infty(Q_T)$; *then there exists a generalized solution* ϕ *of* (4.1)–(4.3) *in* $W_2^{2,1}(Q_T)$.

Proof. Let $N \in \mathbb{N}$ and $\bar{T} := T/N$, $Q_k := Q_{T-k\bar{T},T-(k-1)\bar{T}}$ for $k = 1, \cdots, N$. For some $N \in \mathbb{N}$ we prove the existence of solutions $\phi_k \in W_2^{2,1}(Q_k)$ of

$$(4.4)\qquad \left((A\phi_k)_t + \frac{\partial}{\partial x_i}\left(D_{ij}\frac{\partial \phi_k}{\partial x_j}\right) + \frac{\partial}{\partial x_i}(V_i\phi_k)\right)(x,t) + \gamma(x,t)\int_t^{T-(k-1)\bar{T}} (h\phi_{k_t})(x,\tau)\,d\tau = f(x,t) - \gamma(x,t)\sum_{l=1}^{k-1}\int_{T-l\bar{T}}^{T-(l-1)\bar{T}} (h\phi_{l_t})(x,\tau)\,d\tau \quad \text{in } Q_k$$

with $\Sigma_{l=1}^{0} := 0$,

$$(4.5)\qquad \phi_k(x, T-(k-1)\bar{T}) = \phi_{k-1}(x, T-(k-1)\bar{T}) \quad \text{in } \Omega$$

with $\phi_{-1} := 0$, and of (4.3).

Let $\phi(x,t) := \phi_i(x,t)$ for $(x,t) \in Q_i$; we then get a function in $W_2^{2,1}(Q_T)$ because of (4.5), which is a solution of (4.1)–(4.3).

Now consider $1 \leqq k \leqq n$ and assume that the existence of a solution ϕ_l for $1 \leqq l < k$ is proven. For $k = 1$ this assumption is void. Define an operator $\mathcal{F}$ on $W_2^{2,1}(Q_k)$ by $\mathcal{F}z := u$, u being the solution in $W_2^{2,1}(Q_k)$ of (4.5), (4.3) and a differential equation similar to (4.4), but with

$$(4.6)\qquad \gamma(x,t)g^{(z)}(x,t), \quad g^{(z)}(x,t) := \int_t^{T-(k-1)\bar{T}} (hz_t)(x,\tau)\,d\tau,$$

as the integral term on the left-hand side.

In particular the right-hand side and $\gamma g^{(z)}$ are in $L^2(Q_i)$, and

$$\phi_{k-1}(\cdot, T-(k-1)\bar{T}) \in W_2^1(\Omega)$$

(e.g. [8, Chap. II, Lemma 3.4]); this operator is well defined (compare again [8, Chap. IV, §9], [10, Thm. 17]) and there exists a constant C independent of $\bar{T}$ and k such that for $z_1, z_2 \in W_2^{2,1}(Q_k)$:

$$(4.7)\qquad \|\mathcal{F}(z_1) - \mathcal{F}(z_2)\|_{2,Q_k}^{(2)} \leqq C\|g^{(z_1-z_2)}\|_{2,Q_k}.$$

An easy calculation shows for $z \in W_2^{2,1}(Q_k)$:

$$(4.8)\qquad \|g^{(z)}\|_{2,Q_k} \leqq |h|_{Q_T}^{(0)}\bar{T}\|z_t\|_{2,Q_k}.$$

Therefore it suffices to take N so large such that e.g.

$$(4.9)\qquad C|h|_{Q_T}^{(0)}\bar{T} \leqq \tfrac{1}{2}.$$

Then $\mathcal{F}$ is a contraction on $W_2^{2,1}(Q_k)$ and therefore Banach's fixed point theorem guarantees the unique existence of a solution ϕ_k in $W_2^{2,1}(Q_k)$ of (4.3)–(4.5). Thus we get a solution for all Q_k, which proves the assertion. □

Now we can show

LEMMA 4.3. *There exists at most a weak solution in* Q_T.

Proof. Let $(C,\tilde{N})$ be a weak solution and take test functions $\phi\in W_2^{2,1}(Q_T)$ such that $\phi(\cdot,T)=0$ a.e. in Ω. By partial integration we get:

$$
\begin{aligned}
(4.10)\quad & -\int_{Q_T} C(A\phi)_t\,dx\,dt-\int_\Omega (A\phi)(x,0)C_0(x)\,dx \\
& -\int_{Q_T} C\frac{\partial}{\partial x_i}\left(D_{ij}\frac{\partial\phi}{\partial x_j}\right)dx\,dt+\int_{S_T} CD_{ij}\frac{\partial\phi}{\partial x_j}n_i\,dx\,dt \\
& -\int_{S_T}\beta(C-C_*)\phi\,dx\,dt-\int_{Q_T} C\frac{\partial}{\partial x_i}(V_i\phi)\,dx\,dt \\
& +\int_{S_T} CV_in_i\phi\,dx\,dt-\int_{Q_T}\hat{H}(\tilde{N})\phi_t\,dx\,dt-\int_\Omega \hat{H}(N_0(x))\phi(x,0)\,dx \\
& =\int_{Q_T} F\phi\,dx\,dt.
\end{aligned}
$$

Now we consider two weak solutions $(C_i,\tilde{N}_i)$, $i=1,2$ and set $C:=C_1-C_2$, $\tilde{N}:=\tilde{N}_1-\tilde{N}_2$.

At first we show that

$$
(4.11)\qquad \hat{H}(\tilde{N}_1)-\hat{H}(\tilde{N}_2)=h(\tilde{N}_1-\tilde{N}_2)\quad\text{for some } h=h(\tilde{N}_1,\tilde{N}_2)\in L^\infty(Q_T).
$$

In fact, taking $Q_1:=\{(x,t)\in Q_T\mid(\tilde{N}_1-\tilde{N}_2)(x,t)\neq 0\}$ and $Q_2:=Q_T\backslash Q_1$, we can define h in the open set Q_1 as

$$
h(x,t):=\frac{(\hat{H}(\tilde{N}_1)-\hat{H}(\tilde{N}_2))(x,t)}{(\tilde{N}_1-\tilde{N}_2)(x,t)}.
$$

Thus h is a continuous function with values in $[0,1]$, which is easily checked. In Q_2 the definition is at our disposal, say $h(x,t):=0$. Therefore

$$
(4.12)\qquad (\hat{H}(\tilde{N}_1)-\hat{H}(\tilde{N}_2))(x,t)=h(x,t)\int_0^t(\gamma C)(x,\tau)\,d\tau
$$

and by partial integration:

$$
\begin{aligned}
(4.13)\quad & \int_{Q_T} h(x,t)\int_0^t(\gamma C)(x,\tau)\,d\tau\phi_t(x,t)\,dx\,dt \\
& =\int_{Q_T}(\gamma C)(x,t)\int_t^T(h\phi_t)(x,\tau)\,d\tau\,dx\,dt
\end{aligned}
$$

for all considered test functions ϕ. Let us apply (4.10) to C_1 and C_2 and subtract the two relations. By means of (4.12) and (4.13) we get:

$$
\begin{aligned}
(4.14)\quad & -\int_{Q_T} C(x,t)\left\{\left((A\phi)_t+\frac{\partial}{\partial x_i}\left(D_{ij}\frac{\partial\phi}{\partial x_j}\right)+\frac{\partial}{\partial x_i}(V_i\phi)\right)(x,t)\right. \\
& \qquad\left.+\gamma(x,t)\int_t^T(h\phi_t)(x,\tau)\,d\tau\right\}dx\,dt \\
& +\int_{S_T} C(x,t)\left(\frac{\partial\phi}{\partial\nu}-(\beta-V_in_i)\phi\right)(x,t)\,dx\,dt=0
\end{aligned}
$$

for all $\phi\in W_2^{2,1}(Q_T)$ such that $\phi(\cdot,T)=0$ a.e. in Ω.

Let $f \in L^2(Q_T)$ and take ϕ as a generalized solution of (4.1)–(4.3) with this f as right-hand side and $h = h(\tilde{N}_1, \tilde{N}_2)$. ϕ exists according to Lemma 4.2 and is an admissible test function. (4.14) implies

$$\int_{Q_T} C(x,t) f(x,t)\, dx\, dt = 0, \tag{4.15}$$

and thus $C = 0$, i.e. $C_1 = C_2$.

Because of (3.5) we also have $\tilde{N}_1 = \tilde{N}_2$, which proves our assertion. □

Remark 4.4. 1) We have actually proven that a solution $(C, \tilde{N})$, say $C, \tilde{N} \in C(\overline{Q}_T)$, of (4.10) and (3.5) is unique.

2) The additional assumption 4.1 should be as weak as possible so as not to be in conflict with the general situation of partially unsaturated soil.

THEOREM 4.5. *Let* (C_i, N_i, Φ_i) *be classical solutions,*

$$Q_+^i := \{ (x,t) \in Q_T \mid N_i(x,t) > 0 \}, \qquad Q_-^i := Q_T \backslash \overline{Q_+^i}, \qquad i = 1,2.$$

We assume:

$$\gamma(C^* - C_i) \geqq 0 \text{ on } Q_T, \ i = 1,2. \tag{4.16}$$

$$\text{The divergence theorem is valid in } Q_+^i \text{ and } Q_-^i, \qquad i = 1,2. \tag{4.17}$$

Then we have $(C_1, N_1, \Phi_1) = (C_2, N_2, \Phi_2)$.

Proof. Let (C, N, Φ) be a classical solution fulfilling (4.16), (4.17). Set

$$\tilde{N}(x,t) := N_0(x) - \int_0^t (\gamma(C^* - C))(x,\tau)\, d\tau. \tag{4.18}$$

Because of (4.16) we have

$$\tilde{N}(x,t) \leqq 0 \quad \text{for all } (x,t) \in Q_-. \tag{4.19}$$

In fact, (4.19) is implied by

$$\tilde{N}(x,t) > 0 \Rightarrow N(x,t) > 0 \quad \text{for } (x,t) \in Q_T. \tag{4.20}$$

To prove (4.20), suppose that $N(x,t) = 0$ for some $(x,t) \in Q_T$, for which $\tilde{N}(x,t) > 0$. Then $t \geqq \Phi(x)$ and therefore

$$0 < \tilde{N}(x,t) \leqq \tilde{N}(x, \Phi(x)). \tag{4.21}$$

On the other hand we can conclude

$$\tilde{N}(\xi,\tau) = N(\xi,\tau) \quad \text{for all } (\xi,\tau) \in \overline{Q}_+, \tag{4.22}$$

and thus

$$\tilde{N}(x, \Phi(x)) = N(x, \Phi(x)) = 0. \tag{4.23}$$

This is a contradiction to (4.21).

Now let $\phi \in C^{2,1}(\overline{Q}_T)$. We start with

$$\int_{Q_+} F\phi\, dx\, dt = \int_{Q_+} (AC_t - LC + N_t)\phi\, dx\, dt \tag{4.24}$$

and integrate by parts. Doing the same in Q_-, we can add these expressions and see that all integrals over the boundary $\Phi(x)=t$ cancel because of the continuity of N, C and $\partial C/\partial x_i$ in $\overline{Q}_T$. By means of (4.19) and (4.22) we can substitute for the integrals involving N

$$(4.25)\qquad -\int_{Q_T}\hat{H}(\tilde{N})\phi_t\,dx\,dt+\int_\Omega(\hat{H}(\tilde{N})\phi)(x,T)\,dx-\int_\Omega\hat{H}(N_0(x))\phi(x,0)\,dx.$$

The relation we now have achieved is also valid for all $\phi\in W_2^{2,1}(Q_T)$, as we see by passing to the limit. In this way we have verified (4.10) for $(C,\tilde{N})$. Therefore we see from Remark 4.4 that

$$(4.26)\qquad C_1=C_2,\qquad \tilde{N}_1=\tilde{N}_2,$$

$\tilde{N}_i$ being defined as in (4.18). It remains to prove $\Phi_1=\Phi_2$ and its consequence $N_1=N_2$.

Let $\Omega^i_{0,T}$ be the domains of Φ_i. At first we show:

$$(4.27)\qquad \Omega^1_{0,T}=\Omega^2_{0,T}=:\Omega_{0,T}.$$

Assume there exists $x\in\Omega^1_{0,T}$, such that $x\notin\Omega^2_{0,T}$. As

$$(4.28)\qquad \xi\notin\Omega_{0,T}\Rightarrow(\xi,\tau)\in\overline{Q}_+\quad\text{for all }\tau\in[0,T]$$

we have by (4.22)

$$(4.29)\qquad \tilde{N}_2(x,t)>0\quad\text{for all }t\in[0,T].$$

On the other hand by (4.23) $\tilde{N}_1(x,\Phi_1(x))=0$, which contradicts (4.26), (4.29).

Now let $x\in\Omega\cap\Omega_{0,T}$ and $\Phi_1(x)<\Phi_2(x)$. Then $N_2(x,\Phi_1(x))>0$, again leading to a contradiction by (4.22), (4.23). This proves $\Phi_1=\Phi_2$. $N_1=N_2$ follows along the same lines. □

Remark 4.6. As in the physical situation $\gamma>0$ and C^* is the saturation concentration, (4.16) is not restrictive (compare Theorem 5.5).

5. Existence of classical solutions. To obtain a classical solution from the weak solution constructed in Theorem 3.4, we must study the nature of the set $\tilde{N}=0$. This will be accomplished by deriving a lower bound for C^*-C. Since we cannot apply the strong maximum principle directly, we reconsider the solutions of the smoothed problem (P_ε). Throughout the section we will use

Assumption 5.1.

$$(5.1)\qquad \gamma(x,t)>0\quad\text{for all }(x,t)\in\overline{Q}_T.$$

$$(5.2)\qquad C^*\in H^{2+\alpha,1+\alpha/2}(\overline{Q}_T),$$
$$\hat{F}:=F-AC_t^*+LC^*\leqq 0\quad\text{in }\overline{Q}_T.$$

$$(5.3)\qquad \frac{\partial C^*}{\partial\nu}\geqq 0\quad\text{on }S_T.$$

$$(5.4)\qquad C_0(x)\leqq C^*(x,0)\quad\text{for all }x\in\overline{\Omega}.$$

(5.5) $$\beta \leqq 0 \qquad \text{on } S_T.$$

(5.6) $$C_* \leqq C^* \qquad \text{on } S_T.$$

(5.7) i) There exists $\bar{x} \in \Omega$ such that $C_0(\bar{x}) < C^*(\bar{x}, 0)$ or there exists a sequence $(x_n, t_n) \in S_T$, $t_n \to 0$, satisfying one of the following conditions:

ii) $\beta(x_n, t_n) < 0, \qquad C_*(x_n, t_n) < C^*(x_n, t_n),$

iii) $$\frac{\partial C^*}{\partial \nu}(x_n, t_n) > 0.$$

(5.8) $$N_0 \geqq 0 \quad \text{in } \bar{\Omega}.$$

Having in mind the discussion of the physical meaning in §2, we see that this leaching situation is covered by these assumptions. In particular, (5.7ii) is fulfilled, if at some portion of the boundary (the soil-atmosphere interphase) water, with a concentration beneath the saturation concentration, filters through.

As comparison function we regard the classical solution of

(5.9) $$Aw_t - Lw + \gamma w = -\hat{F} \quad \text{in } \bar{Q}_T,$$

(5.10) $$w(x,0) = C^*(x,0) - C_0(x), \qquad x \in \bar{\Omega},$$

(5.11) $$\frac{\partial w}{\partial \nu} = \beta\big(w - [C^* - C_*]\big) + \frac{\partial C^*}{\partial \nu} \quad \text{on } S_T.$$

w exists uniquely (e.g. [5, p. 147, Cor. 2]).

LEMMA 5.2. *$w(x,t) > 0$ for all $(x,t) \in \bar{\Omega} \times (0,T]$.*

Proof. Let us first show: $w \geqq 0$ in $\bar{Q}_T$. Suppose not; then w has a negative minimum in $(\bar{x}, \bar{t}) \in \bar{Q}_T$. Because of (5.1), (5.2) the strong minimum principle is applicable (e.g. [5, p. 34, Thm. 1]) and thus $(\bar{x}, \bar{t}) \in \Omega \times (0, T]$ contradicts (5.4).

The same is true for $\bar{t} = 0$. For $\bar{x} \in S$ we have, by a lemma of Viborny–Friedman ([5, p. 49, Thm. 14]), $(\partial w/\partial \nu)(\bar{x}, \bar{t}) < 0$ and thus using (5.3), (5.5), (5.6):

(5.12) $$w(\bar{x}, \bar{t}) > (C^* - C_*)(\bar{x}, \bar{t}) \geqq 0.$$

This is also a contradiction, i.e. $w \geqq 0$ in $\bar{Q}_T$.

If $w(\bar{x}, \bar{t}) = 0$ for some $(\bar{x}, \bar{t}) \in \bar{\Omega} \times (0, T]$, then w attains its minimum in $(\bar{x}, \bar{t})$. In the case $(\bar{x}, \bar{t}) \in \Omega \times (0, T]$ we get $w = 0$ in $\bar{Q}_{\bar{t}}$ by the strong minimum principle and thus a contradiction to (5.7). Finally, $\bar{x} \in S$ is impossible due to (5.12). □

LEMMA 5.3. *Let $(C_\varepsilon, N_\varepsilon)$ be a solution of* (P_ε). *Then*

$$C^* - C_\varepsilon \geqq w \quad \text{in } \bar{Q}_T.$$

Proof. Set $u_\varepsilon := C^* - C_\varepsilon$. Then u_ε solves

(5.13) $$Au_{\varepsilon_t} - Lu_\varepsilon + H_\varepsilon(N_\varepsilon)\gamma u_\varepsilon = -\hat{F} \quad \text{in } \bar{Q}_T$$

and (5.10), (5.11). Therefore $z := u_\varepsilon - w$ fulfills

(5.14) $$Az_t - Lz + \gamma H_\varepsilon(N_\varepsilon) z = \gamma\big(1 - H_\varepsilon(N_\varepsilon)\big) w \quad \text{in } \bar{Q}_T,$$

(5.15) $$z(x,0) = 0, \qquad x \in \bar{\Omega},$$

(5.16) $$\frac{\partial z}{\partial \nu} = \beta z \quad \text{in } S_T.$$

We want to show $z \geqq 0$ in $\bar{Q}_T$.

Since $\gamma H_\varepsilon(N_\varepsilon) \geqq 0$ and $\gamma(1-H_\varepsilon(N_\varepsilon))w \geqq 0$ due to Lemma 5.2, again we can apply the strong minimum principle to show this in the same way as in Lemma 5.2. □

We now conclude

THEOREM 5.4. *There exists a weak solution* $(C, \tilde{N})$, $C \in W_q^{2,1}(Q_T)$, *such that*

$$C(x,t) < C^*(x,t) \text{ for all } (x,t) \in \bar{\Omega} \times (0,T]. \tag{5.17}$$

$$\tilde{N}(x,\cdot) \text{ is strictly decreasing in } [0,T] \text{ for all } x \in \bar{\Omega}. \tag{5.18}$$

$$\begin{aligned} &\text{There is a } \psi \in C(\bar{\Omega}),\ 0 \leqq \psi(x) \leqq T \text{ for all } x \in \bar{\Omega} \text{ such that } \psi(x) > 0 \Leftrightarrow \\ &N_0(x) > 0 \text{ and for all } t \in [0, \psi(x)) : \tilde{N}(x,t) > 0, \text{ for all } t \in (\psi(x), T] : \\ &\tilde{N}(x,t) < 0,\ \psi(x) < T \Rightarrow \tilde{N}(x, \psi(x)) = 0. \end{aligned} \tag{5.19}$$

Proof. We consider the weak solution $(C, \tilde{N})$ constructed in Theorem 3.4. Let $\delta > 0$. Lemmas 5.2, 5.3 imply for some $K(\delta) > 0$

$$C^* - C_\varepsilon \geqq K(\delta) \quad \text{in } \bar{\Omega} \times [\delta, T],$$

and thus by (3.14) we have the validity of (5.17).

Furthermore, because of (5.1), we have for some $\underline{\gamma} > 0$:

$$N_{\varepsilon_i} \leqq -\underline{\gamma} K(\delta) \quad \text{in } \bar{\Omega} \times [\delta, T]$$

and therefore again by (3.14):

$$\tilde{N}_t \leqq -\underline{\gamma} K(\delta) \quad \text{in } \bar{\Omega} \times [\delta, T]. \tag{5.20}$$

In particular, this means (5.18). Now define

$$\psi(x) := \begin{cases} 0, & \tilde{N}(x,t) \leqq 0 \quad \text{for all } t \in [0,T], \\ \sup\{\, t \in [0,T] \mid \tilde{N}(x,t) > 0 \,\} & \text{otherwise.} \end{cases} \tag{5.21}$$

The properties in (5.19) are verified immediately. In particular, continuity is proved by checking upper and lower semicontinuity, which follows from the other assertions in (5.19). □

Collecting the results we get:

THEOREM 5.5. *Let* $q > n+2$. *There exists a classical solution* (C, N, Φ) *such that*

$$C \in W_q^{2,1}(Q_T) \text{ and } C \text{ fulfills } (5.17).$$

If $N_0 \in C^1(\bar{\Omega}_1)$ *and* γ *and* C^* *are continuously differentiable with respect to* x *in* $\bar{\Omega}_1 \times [0,T]$, *then*

$$\Phi \in C^1(\bar{\Omega}_1), \tag{5.22}$$

setting $\Omega_1 := \{ x \in \Omega_{0,T} \cap \Omega \mid 0 < \Phi(x) < T \}$.

Proof. We consider the weak solution $(C, \tilde{N})$ of Theorem 5.4. Defining $N(x,t) := (\tilde{N}(x,t))_+$ in $\bar{Q}_T$, we see

$$\begin{aligned} Q_+ &= \{\, (x,t) \in Q_T \mid \tilde{N}(x,t) > 0 \,\}, \\ Q_- &= \{\, (x,t) \in Q_T \mid \tilde{N}(x,t) < 0 \,\}. \end{aligned} \tag{5.23}$$

Therefore Theorem 3.5 assures (2.14), while (2.16), (2.17) are clear by the definition of N. Having in mind (3.14), we notice that (2.13) and (2.15) are satisfied.

We define $\Phi := \psi|_{\Omega_{0,T}}$, ψ according to Theorem 5.4. Then from (5.19) we conclude

$$\tilde{N}(x,\Phi(x))=0 \quad \text{for all } x\in\Omega_{0,T}, \tag{5.24}$$

and thus (2.11) and (2.12).

Finally (5.22) is a consequence of (5.24) and the implicit function theorem, the continuity of $\tilde{N}_x$ and $\tilde{N}_t$ in $\bar{\Omega}_1\times[0,T]$ and $\tilde{N}_t(x,\Phi(x))<0$ for $x\in\bar{\Omega}_1$. □

6. Asymptotic behavior. It is not yet clear whether N vanishes for large times, i.e. $\Phi(x)$ exists for each $x\in\bar{\Omega}$. We will give a sufficient condition for this situation. First, we regard all functions as given for all $T>0$ and the assumptions 2.2 and 5.1, which are also in force, are to be understood in this sense. Furthermore we use the following assumption in the sense of [5, p. 157] and with $Q := \bigcup_{T>0} Q_T$.

Assumption 6.1.

(6.1) $A(x,t)\geqq a$ for some $a>0$ and all $(x,t)\in\bar{Q}$,
$\gamma(x,t)\geqq \underline{\gamma}$ for some $\underline{\gamma}>0$ and all $(x,t)\in\bar{Q}$.

(6.2) $D_{ij}\xi_i\xi_j \geqq d|\xi|^2$ for some $d>0$ and all $(x,t)\in\bar{Q}$, $\xi\in\mathbb{R}^n$.

(6.3) The following functions converge as $t\to\infty$ uniformly in $\bar{Q}$ to a function in $H^\alpha(\bar{\Omega})$:

$$A,\ D_{ij},\ \sum_{i=1}^{n}\frac{\partial D_{ij}}{\partial x_i},\ V_i,\ \gamma,\ F,\ C_t^*,\ \frac{\partial C^*}{\partial x_i},\ \frac{\partial^2 C^*}{\partial x_i\partial x_j}, \qquad i,j=1,\cdots,n.$$

(6.4) $S=S_1\dot{\cup}S_2$, S_1 closed, and
$\beta(x,t)\leqq -b$ for some $b>0$ and all $x\in S_1$, $t>0$,
$\beta(x,t)\geqq -b$ for all $x\in S_2$, $t>0$.
$C^*(x,t)=C_*(x,t)$ for all $x\in\partial S_1$, $t>0$.

(6.5) $\beta(x,t)\to\beta(x)$, $C_*(x,t)\to C_*(x)$, $C^*(x,t)\to C^*(x)$ as $t\to\infty$ uniformly in S_1.

(6.6) There is an $\bar{x}\in S_1$ such that $C_*(\bar{x})<C^*(\bar{x})$.
In (5.7ii) the x_n are in S_1.

Again S_1 has to be understood as part of the soil-atmosphere interface and $-\beta$ as the flow velocity into the interior. With regard to the comparison function w it is necessary to change the boundary condition in its definition. To this end we extend β outside of S_1, such that the resulting function k has the properties

$$\begin{aligned} &k\in C(S_T),\ k_{|S_1\times[0,T]}=\beta \text{ for all } T>0,\\ &k(x,t)\leqq -b \text{ for all } (x,t)\in\bar{Q},\\ &k(x,t)\to k(x) \text{ as } t\to\infty \text{ uniformly in } S. \end{aligned} \tag{6.7}$$

Instead of (5.11) we now use as boundary condition for w

$$(6.8)\qquad \begin{aligned} &\frac{\partial w}{\partial \nu}=\beta\big(w-[C^*-C_*]\big)+\frac{\partial C^*}{\partial \nu} \quad \text{on } S_1\times[0,T],\\ &\frac{\partial w}{\partial \nu}=kw+\frac{\partial C^*}{\partial \nu} \quad \text{on } S_2\times[0,T]. \end{aligned}$$

The existence of a unique classical solution in Q_T for every $T>0$ is guaranteed. In the same manner as in §5 we prove the following lemmas.

LEMMA 6.2. *$w(x,t)>0$ for all $(x,t)\in\bar{\Omega}\times(0,T]$ for every $T>0$.*

LEMMA 6.3. *Let $(C_\varepsilon,N_\varepsilon)$ be a solution of (P_ε). Then $C^*-C_\varepsilon\geqq w$ in $\bar{Q}_T$ for every $T>0$.*

The conditions we have imposed are sufficient to insure the lower bound for w globally:

LEMMA 6.4. *For each $\delta>0$ there is a constant $K(\delta)>0$ such that $w(x,t)\geqq K(\delta)$ for all $x\in\bar{\Omega}$, $t\in[\delta,T]$ for every $T>\delta$.*

Proof. Assumption 6.1 assures that

$$(6.9)\qquad w(x,t)\to z(y),\qquad (x,t)\in\bar{Q} \quad \text{as } x\to y,\quad t\to\infty,$$

uniformly in $\bar{Q}$ ([5, p. 167, Thm. 5]), z being the solution of an elliptic problem with the limits of the coefficients and right-hand side as the corresponding terms. Applying the minimum principle and the lemma of Hopf (e.g. [5, p. 55, Thm. 21]) we can show using (6.6) and $\beta(\bar{x})<0$:

$$(6.10)\qquad z(x)>0 \quad \text{for all } x\in\bar{\Omega}.$$

From this, (6.9) and Lemma 6.2 the assertion follows. □

Before we can use this result together with Lemma 6.3, we have to assure that we can speak of $(C_\varepsilon,N_\varepsilon)$ in $\bar{Q}$ in a unique way:

LEMMA 6.5. *Let $T>0$. There exists at most a solution $(C_\varepsilon,N_\varepsilon)$ of (P_ε).*

Proof. Let $\varepsilon>0$ be fixed and (C_i,N_i), $i=1,2$, be solutions of (P_ε). $C:=C_1-C_2$ fulfills

$$(6.11)\qquad \begin{aligned} &(AC_t-LC+H_\varepsilon(N_1)\gamma C)(x,t)\\ &\qquad=\big(\gamma(C^*-C_2)B\big)(x,t)\int_0^t(\gamma C)(x,\tau)\,d\tau \quad \text{for } (x,t)\in Q_T, \end{aligned}$$

$$(6.12)\qquad C(x,0)=0,\qquad x\in\bar{\Omega},$$

$$(6.13)\qquad \frac{\partial C}{\partial \nu}=\beta C \quad \text{on } S_T,$$

whereby $B\in L^\infty(Q_T)$ such that in Q_T:

$$H_\varepsilon(N_1(x,t))-H_\varepsilon(N_2(x,t))=B(x,t)\int_0^t(\gamma C)(x,\tau)\,d\tau.$$

Now it is easy to show, with the aid of the usual L^∞-estimate (e.g. [8, Chap. I, Thm. 2.3]) applied to C and C_2 that for some $\bar{T}\in(0,T]$ the only possibility is $C\equiv 0$ in $\bar{Q}_{\bar{T}}$. In $Q_{\bar{T},2\bar{T}}$ we can repeat the argument and thus finally get $C\equiv 0$ in $\bar{Q}_T$, i.e. the uniqueness of the solution. □

THEOREM 6.6. *Let $q>n+2$. There exist (C,N,Φ) in $\bar{Q}$ and $\hat{T}>0$ such that (C,N,Φ) is a classical solution in Q_T for all $T>\hat{T}$ with the property $\Omega_{0,T}=\bar{\Omega}$, i.e. there is some $\hat{T}>0$ such that $N(x,t)=0$ for all $x\in\bar{\Omega}$, $t\geqq\hat{T}$.*

Proof. Because of Lemma 6.5 there are $(C_\varepsilon, N_\varepsilon)$ in $\overline{Q}$ such that their restrictions to Q_T are the solutions of (P_ε) in Q_T for every $T>0$. We can find a subsequence, denoted in the same way, such that

$$C(x,t)=\lim_{\varepsilon\to 0} C_\varepsilon(x,t), \qquad \tilde{N}(x,t)=\lim_{\varepsilon\to 0} N_\varepsilon(x,t) \quad \text{in } \overline{Q}$$

and in $\overline{Q}_T$ $(C,\tilde{N})$ is the weak solution constructed in Theorem 3.4.

As in the proof of Theorem 5.4, we can derive by using Lemmas 6.3, 6.4:

$$\tilde{N}_t \leqq -\underline{\gamma} K(\delta) \quad \text{in } \overline{\Omega}\times[\delta,T] \quad \text{for every } T>\delta. \tag{6.14}$$

Therefore there is a $\hat{T}>0$ such that

$$\tilde{N}(x,t)<0 \quad \text{for all } x\in\overline{\Omega}, \quad t\geqq\hat{T}. \tag{6.15}$$

Thus the solution constructed by Theorem 5.4 and 5.5 fulfills the assertion. □

Acknowledgments. This paper originated in part during the author's stay at the Istituto Matematico, University of Florence. The author would like to express his deep appreciation to Professors A. Fasano and M. Primicerio for their hospitality and their advice. Furthermore the author is indebted to Miss I. Kögel (University of Bayreuth) for introducing him to the field of soil science.

A RELATION BETWEEN SEMI-INVERSE AND SAINT-VENANT SOLUTIONS FOR PRISMS*

DAVID KINDERLEHRER†

Abstract. It is shown that in an infinite prism the linearization at a natural state of a family of Ericksen's semi-inverse solutions is a combination of elementary St.-Venant solutions, namely, extension bending and torsion. Moreover, the span of these St. Venant solutions is precisely the linear manifold of solutions having locally uniformly bounded strain energy. This implies that any solution of a linearized problem in a finite prism continuable to a solution in the infinite prism in a manner that its energy on any portion of fixed length remains bounded, is an elementary St.-Venant solution.

Key words. nonlinear elliptic systems, asymptotic properties, finite elasticity, St.-Venant's principle

1. Introduction.

Consider an infinite prism

$$\mathbb{P}=\Omega\times\mathbb{R}\subset\mathbb{R}^3$$

where $\Omega\subset\mathbb{R}^2$ is a region with boundary Γ composed of a material with strain energy density $W(F)$, a real valued function of 3×3 matrices F with $\det F>0$. The body is in equilibrium in the configuration

$$y=y(x)\colon \mathbb{P}\to\mathbb{R}^3$$

provided

$$\delta\int_{\mathbb{P}} W(\nabla y)\,dx=0, \tag{1.1}$$

where this is taken in an appropriate sense. Here we mean that $y(x)$ is a smooth function satisfying the system of equations

$$\begin{aligned} &-\operatorname{div} S(\nabla y)=0 \quad \text{in } \mathbb{P},\\ &S(\nabla y)\nu=0 \quad \text{on } \partial\mathbb{P}=\Gamma\times\mathbb{R} \end{aligned} \tag{1.2}$$

where $S(F)=W'(F)=(\partial W/\partial F_j^i)$ is the Piola stress and ν is the outward directed normal of Γ.

Inasmuch as $\mathbb{P}$ is infinite and no boundary conditions prevail as $|x_3|\to+\infty$, one scarcely expects this problem to have a unique solution or even a finite dimensional manifold of them. The distinguished class discussed here are the semi-inverse solutions introduced by J. Ericksen [1], [2] and our intention is to illustrate their connections with the St.-Venant solutions familiar in the linear theory of elasticity. The St.-Venant solutions may be characterized in terms of energy, the subject of §2. They are also linearizations of semi-inverse solutions, which we show in §3. Existence of semi-inverse solutions and their properties will be considered elsewhere [5]. The St.-Venant flexure solutions arise only indirectly in the present context. They are disucssed in §4.

*Received by the editors July 30, 1984.
†School of Mathematics, University of Minnesota, Minneapolis, Minnesota 55455.

There are many ways of describing St. Venant solutions, some of which are in terms of energy (Sternberg and Knowles [11], Maisonneauve [9], Ericksen [3].) The one given here, although it may properly be interpreted as a technical device rather than a physical statement, is not a minimum principle but an extensibility property of the solution. This permits several ways of distinguishing St.-Venant and semi-inverse solutions; we may as well indulge ourselves in one of them whose origin is in the work of Ericksen [3], [4].

According to our theorem, the only solutions of the linearized problem of (1.2) in $\mathbb{P}$ with locally uniformly bounded strain energy are the St.-Venant solutions of extension, bending, and torsion. Incidentally they are also the ones with uniformly bounded strain, owing to the modern theory of elliptic systems. It follows that they are the only solutions in finite prisms which admit extensions to infinite ones retaining these properties. This renders them especially appropriate in a formulation of St.-Venant's principle and is one version of the set $S(\infty)$ defined in [4]. Moreover they are the linearizations of a family of finite deformations of the infinite prism $\mathbb{P}$.

Another interpretation is related more generally to nonlinear problems. In a suitable functional framework, the St.-Venant solutions are eigenfunctions with eigenvalue $\mu=0$ of a linearized problem. The existence of a family of solutions of the system (1.2) emanating from the eigenspace is strongly indicated under these circumstances. Semi-inverse solutions are on such family, a particular one, it is possible to show, whose (nonlinear) strain energy is uniformly bounded.

A different perspective is taken by Muncaster [8], [9] in his interesting work.

I take this opportunity to thank Professor Ericksen for introducing me to this question and for many stimulating discussions. I also thank Professor Muncaster for his generous remarks.

We introduce a few notions and state our results. Let $W(F)$ be a smooth function defined on 3×3 matrices $F=(F_j^i)$ with $\det F>0$ satisfying the condition of frame indifference

$$W(QF)=W(F) \quad \text{for } Q^TQ=\mathbb{1}, \quad \det Q=1,$$

and set

$$S(F)=W'(F)=\left(\partial W/\partial F_j^i\right)$$

its Piola–Kirchoff stress which satisfies, therefore,

$$S(QF)=QS(F) \quad \text{for } Q^TQ=\mathbb{1}, \quad \det Q=1. \tag{1.3}$$

We assume that the material is isotropic,[1]

$$S(\mathbb{1})=0,$$

and

$$S'[X]=\lim_{t\to 0}\frac{1}{t}S(\mathbb{1}+tX)=X+X^T+(a-1)\operatorname{tr}X\mathbb{1} \tag{1.4}$$

---

[1] St.-Venant solutions for linear isotropic materials are very familiar, thus our restriction here. Less well known is that they may be defined for any (homogeneous, let us say) material satisfying

$$S'[\varepsilon]\cdot\varepsilon\geqq\alpha_0|\varepsilon|^2, \quad \varepsilon=\varepsilon^T, \quad \alpha_0>0,$$

a fact known to St.-Venant. The conclusions of this work hold also in the anisotropic case. Additional discussion of this may be found in [5].

where $a > \frac{1}{3}$. Given a function $v = (v^1, v^2, v^3)$, we set

$$\varepsilon(v) = \tfrac{1}{2}(\nabla v + \nabla v^T) \quad \text{and} \quad \sigma(v) = S'[\nabla v] = S'[\varepsilon(v)].$$

The restriction on a ensures that there is an $\alpha > 0$ such that

$$\sigma(v) \cdot \varepsilon(v) \geqq \alpha |\varepsilon(v)|^2 \quad \text{for any } v \tag{1.5}$$

or simply that

$$S'[X] \cdot X = S'[X] \cdot \frac{1}{2}(X + X^T) \geqq \frac{\alpha}{4}(X + X^T)^2, \quad \text{for any matrix } X.$$

In this note, by a semi-inverse deformation we understand a smooth mapping

$$y: \overline{\mathbb{P}} \to \mathbb{R}^3$$

satisfying the condition of axial indifference

$$y(x', x_3 + t) = Q(t)(y(x) + p(t)), \qquad -\infty < t < \infty, \tag{1.6i}$$

for some rotation $Q(t), \det Q(t) = 1$, and vector valued function $p(t)$, which vary smoothly with t. We also impose the condition

$$\det \nabla y > 0 \quad \text{in } \mathbb{P} \tag{1.6ii}$$

Alternative formulations of (1.6) are suggested in the work of Ericksen and Muncaster. The first of these below is the one we shall use most frequently. The mapping $y(x)$ is a semi-inverse; deformation provided (1.6ii) is satisfied and there are a Λ, $\Lambda + \Lambda^T = 0$, a $\xi \in \mathbb{R}^3$, and a vector field

$$u: \overline{\Omega} \to \mathbb{R}^3$$

such that

$$\begin{aligned} &y(x) = R(x_3)(u(x') + p(x_3)), \qquad x \in \overline{\mathbb{P}}, \\ &R(x_3) = e^{x_3 \Lambda} \quad \text{and} \quad \frac{dp}{dx_3} + \Lambda p = \xi, \quad x_3 \in \mathbb{R}. \end{aligned} \tag{1.7}$$

or provided the Cauchy–Green strain

$$C = \nabla y^T \nabla y \quad \text{is a function of } x' \in \Omega. \tag{1.8}$$

Some clarification of this is given in [1], [5], but we point out that it is elementary. A semi-inverse solution is a semi-inverse deformation satisfying the field equations (1.2).

The four "elementary" St.-Venant solutions, corresponding to extension, bending with moments parallel to the x_1 and x_2 axes, and torsion, are denoted by v_0, v_1, v_2 and v_3 and are described in the appendix for the reader's convenience.

THEOREM 1. *Suppose that v, subject to the condition*

$$\int_{I_l} \int_{\Omega} |\varepsilon(v)|^2 dx \leqq M < \infty \tag{1.9}$$

where I_l is any interval of the x_3-axis of fixed length $2l > 0$, is a solution of the linear system

$$\begin{aligned} &-\operatorname{div} \sigma(v) = 0 \quad &&\text{in } \mathbb{P}, \\ &\sigma(v)\nu = 0 \quad &&\text{on } \partial\mathbb{P}. \end{aligned} \tag{1.10}$$

Then

$$v=\sum_0^3 \lambda_i v_i+\gamma$$

where γ *is an affine rigid motion and* $\lambda_i\in\mathbb{R}$, $i=0,1,2,3$. *Thus* v *is a linear combination of "elementary" St.-Venant solutions plus an affine rigid motion.*

Consider a family of semi-inverse solutions passing through $y=x$, which we abbreviate by writing "a family of semi-inverse solutions" and by which we intend a curve of semi-inverse solutions

$$\begin{aligned} &y=y(x,t), \qquad |t| \text{ small},\\ &y(x,0)=x,\\ &y(x,t)=R(x,t)(u(x',t)+p(x_3,t)),\\ &R(x_3,t)=e^{x_3 t\Lambda} \quad \text{for a fixed } \Lambda,\ \Lambda+\Lambda^T=0, \end{aligned} \tag{1.11}$$

and

$$\xi(t)=(1+t\lambda_0)e_3+t(\mu_1 e_1+\mu_2 e_2).$$

It should be clear that we have chosen R and ξ as the first order terms in t of an arbitrary smooth curve.

THEOREM 2. *Assume that* $y(x,t)$ *is a family of semi-inverse solutions, that is,* $y(x,t)$ *satisfies* (1.11) *and* (1.2). *Then*

$$\left.\frac{dy}{dt}\right|_{t=0}=\sum_0^3 \lambda_i v_i+\gamma \quad \text{in } \mathbb{P}$$

where the v_i *are the "elementary" St.-Venant solutions and* γ *is an affine rigid motion.*

The number of parameters available to a family of semi-inverse solutions are six, three from Λ and three from $\xi'(0)$. It is not difficult to check that different values of μ_1, μ_2 correspond to the slightly altered family

$$\tilde{y}(x,t)=R(x_3)Q(t)(u(x')+p(t))$$

for an appropriate family $Q(t)$,

$$Q(t)^T Q(t)=\mathbb{1}, \quad \det Q(t)=1, \quad Q(0)=\mathbb{1},$$

which leads to the conclusion that μ_1, μ_2 only determine a rigid motion and not a St.-Venant solution.

2. An energy characterization of St.-Venant solutions. This section is devoted to the proof of Theorem 1. We begin with an elementary lemma. For a displacement ζ, set

$$\sigma^3(\zeta)=\sigma(\zeta)e_3.$$

LEMMA 2.1. *Suppose that* $v=(v^1,v^2,v^3)$ *satisfies* (1.9) *and* (1.10). *Then for any affine rigid motion*

$$\int_{\Omega\times\{b\}} \sigma^3(v)\gamma\, dx' = \text{const.} \tag{2.1}$$

$$\int_{\Omega\times\{b\}} \sigma^3\left(\frac{\partial v}{\partial x_3}\right)\gamma\, dx' = 0, \tag{2.2}$$

for all $b\in\mathbb{R}$.

Proof. In view of (1.10) and the divergence theorem, for any interval $I=(a,b)$,

$$0=\int_{\Omega\times I}\operatorname{div}\sigma(v)\gamma\,dx=\int_{\Omega\times\{b\}}\sigma^3(v)\gamma\,dx'=\int_{\Omega\times\{a\}}\sigma^3(v)\gamma\,dx',$$

verifying (2.1). Writing

$$\int_{\Omega\times\{b\}}\sigma^3(v)\gamma\,dx'=\int_{\Omega}\sigma^3(v(x',b))\gamma(x',b)\,dx',$$

it follows that

$$0=\frac{\partial}{\partial b}\int_{\Omega\times\{b\}}\sigma^3(v)\gamma\,dx' \tag{2.3}$$

$$=\int_{\Omega\times\{b\}}\sigma^3\left(\frac{\partial v}{\partial x_3}\right)\gamma\,dx'+\int_{\Omega\times\{b\}}\sigma^3(v)\frac{\partial}{\partial x_3}\gamma\,dx'.$$

We want to prove that the second integral in (2.3) vanishes, which will require (1.9). With $\gamma(x)=c+\omega x$, $\omega+\omega^T=0$,

$$\frac{\partial}{\partial x_3}\gamma^i=\omega_{i3},\qquad \frac{\partial}{\partial x_3}\gamma=(\omega_{13},\omega_{23},0),$$

so

$$\int_{\Omega\times\{b\}}\sigma^3(v)\frac{\partial}{\partial x_3}\gamma\,dx'=\sum_{\mu<3}\int_{\Omega\times\{b\}}\sigma_{\mu3}(v)\omega_{\mu3}\,dx'$$

choose

$$\gamma^\mu=\omega_{\mu3}x_3,\qquad \gamma^3=\sum\omega_{3\mu}x_\mu=-\sum\omega_{\mu3}x_\mu.$$

Substituting this on (2.1),

$$b\int_{\Omega\times\{b\}}\sum_\mu\sigma_{\mu3}\omega_{\mu3}\,dx'-\int_{\Omega\times\{b\}}\sigma_{33}\sum\omega_{\mu3}x_\mu\,dx'$$

$$=a\int_{\Omega\times\{a\}}\sigma_{\mu3}\omega_{\mu3}\,dx'-\int_{\Omega\times\{a\}}\sigma_{33}\sum\omega_{\mu3}x_\mu\,dx'.$$

Again by (2.1),

$$\int_{\Omega\times\{a\}}\sigma_{\mu3}\omega_{\mu3}\,dx'=\int_{\Omega\times\{b\}}\sigma_{\mu3}\,dx'$$

so

$$(b-a)\int_{\Omega\times\{a\}}\sum\sigma_{\mu3}\omega_{\mu3}\,dx'=\int_{\Omega\times\{b\}}\sigma_{33}\sum\omega_{\mu3}x_\mu\,d\mu'-\int_{\Omega\times\{a\}}\sigma_{33}\sum\omega_{\mu3}x_\mu\,dx'.$$

Integrating this expression in x_3 over an interval of length l and then applying (1.9), we have

$$l(b-a)\int_{\Omega\times\{a\}}\sum\sigma_{\mu3}\omega_{\mu3}\,dx'=\int_{\Omega\times(b,b+l)}\sigma_{33}\sum\omega_{\mu3}x_\mu\,dx-\int_{\Omega\times(a,a+l)}\sigma_{33}\sum\omega_{\mu3}x_\mu\,dx$$

$$\leqq CM|\omega|.$$

Above we have also used the algebraic fact that

$$|\sigma(v)|^2 \leqq \text{const.}|\varepsilon(v)|^2.$$

Finally choosing

$$\omega_{\mu 3} = \operatorname{sgn} \int_{\Omega\times\{a\}} \sigma_{\mu 3}\, dx',$$

$$\sum \left| \int_{\Omega\times\{a\}} \sigma_{\mu 3}\, dx' \right| \leqq \frac{CM}{l(b-a)} \quad \text{for all } a<b.$$

Letting $b\to\infty$ gives that

$$\int_{\Omega\times\{a\}} \sigma_{\mu 3}\, dx' = 0, \qquad \mu = 1,2, \quad -\infty < a < \infty.$$

Recalling (2.3), the lemma is established. Q.E.D.

Before completing the proof of the theorem we wish to remark about the use of Korn's inequality. If u is a solution of

$$\begin{aligned} &-\operatorname{div}\sigma(u) = 0 \quad \text{in } \mathbb{P}, \\ &\sigma(u)\nu = 0 \quad \text{on } \partial\mathbb{P}. \end{aligned} \tag{2.4}$$

The well-known technique of difference quotients (Nirenberg [10]) yields that for any $l>0$ and interval $I_l(a)=\{|a-x_3|<l\}$,

$$\int_{\Omega\times I_l(a)} |\nabla^2 u|^2\, dx \leqq C \int_{\Omega\times I_{2l}(a)} \left(|\nabla u|^2 + |u|^2\right) dx, \qquad -\infty < a < \infty, \tag{2.5}$$

$$\leqq C \int_{\Omega\times I_{2l}(a)} \left(|\varepsilon(u)|^2 + |u|^2\right) dx$$

where C depends on l.

Let γ be an affine rigid motion chosen so that $\int_{\Omega\times I_{2l}(a)} \nabla(u-\gamma)\, dx$ is symmetric, so $u-\gamma$ also satisfies (2.4) and $\nabla^2 u = \nabla^2(u-\gamma)$. In addition, by Kron's inequality

$$\int_{\Omega\times I_{2l}(a)} |u-\gamma|^2\, dx \leqq C_k \int_{\Omega\times I_{2l}(a)} |\varepsilon(u-\gamma)|^2\, dx$$

$$= C_k \int_{\Omega\times I_{2l}(a)} |\varepsilon(u)|^2\, dx,$$

C_k = Korn's constant for $\Omega\times I_{2l}(a)$. Combining this with (2.5), we conclude that a solution u of the system (2.4) satisfies

$$\int_{\Omega\times I_l(a)} |\nabla^2 u|^2\, dx \leqq C_0 \int_{\Omega\times I_{2l}(a)} |\varepsilon(u)|^2\, dx \tag{2.6}$$

where C_0 depends on l but not a or u. In particular, if v satisfies (1.9), (1.10) then

$$\int_{\Omega\times I_l(a)} |\nabla^2 v|^2\,dx \leqq 2C_0M, \qquad -\infty < a < \infty. \tag{2.7}$$

LEMMA 2.2. *If v satisfies* (1.9) *and* (1.10), *then*

$$\frac{\partial}{\partial x_3}\varepsilon(v) = \varepsilon\left(\frac{\partial}{\partial x_3}v\right) = 0 \quad \text{in } \mathbb{P}.$$

It is well known that the only solutions of (1.10) whose strain is independent of the axial coordinate comprise the subspace spanned by $\{v_0, v_1, v_2, v_3\}$ and the affine rigid motions. Thus the lemma gives the theorem. For the reader's convenience, a brief description of this is given in the appendix.

Proof. Obviously

$$-\operatorname{div}\sigma(v_{x_3}) = 0 \quad \text{in } \mathbb{P},$$
$$\sigma(v_{x_3})\nu = 0 \quad \text{on } \partial\mathbb{P}.$$

One standard way to proceed is to multiply the above by ηv_{x_3} and integrate over $\mathbb{P}$ where, for $a < b$ and $l > 0$,

$$\eta = \eta(x_3) = \begin{cases} 1, & a \leqq x \leqq b, \\ 0, & x < a-2 \text{ or } x > b+l, \end{cases}$$

$\eta' = 1/l$ in $(a-l, a)$ and $\eta' = -1/l$ in $(b, b+l)$. Thus

$$\begin{aligned} 0 &= -\int_{\mathbb{P}} \operatorname{div}\sigma(v_{x_3})\eta v_{x_3}\,dx \\ &= \int_{\mathbb{P}} \sigma(v_{x_3})\cdot\nabla(\eta v_{x_3})\,dx \\ &= \int_{\mathbb{P}} \eta\sigma(v_{x_3})\cdot\varepsilon(v_{x_3})\,dx + \int_{\mathbb{P}} \sigma(v_{x_3})\cdot\nabla\eta\otimes v_{x_3}\,dx \\ &= \int_{\mathbb{P}} \eta\sigma(v_{x_3})\cdot\varepsilon(v_{x_3})\,dx + \int_{\mathbb{P}} \sigma(v_{x_3})\cdot\eta' e_3\otimes v_{x_3}\,dx. \end{aligned}$$

Since $\sigma\cdot\varepsilon \geqq \alpha|\varepsilon|^2$,

$$\begin{aligned} \alpha\int_{\Omega\times(a,b)} |\varepsilon(v_{x_3})|^2\,dx &\leqq -\int_{\mathbb{P}} \sigma(v_{x_3})\cdot\eta' e_3\otimes v_{x_3}\,dx \\ &= \frac{1}{l}\int_{\Omega\times(b,b+l)} \sigma(v_{x_3})\cdot v_{x_3}\,dx - \frac{1}{l}\int_{\Omega\times(a-l,a)} \sigma(v_{x_3})\cdot v_{x_3}\,dx. \end{aligned}$$

Thus for some $C > 0$,

$$\int_{\Omega\times(a,b)} |\varepsilon(v_{x_3})|^2\,dx \leqq C\left\{\int_{\Omega\times(b,b+l)} \sigma^3(v_{x_3})v_{x_3}\,dx - \int_{\Omega\times(a-l,a)} \sigma^3(v_{x_3})v_{x_3}\,dx\right\}.$$

According to Lemma 2.1, for any affine rigid motions γ, β the right-hand side is unaltered if v_{x_3} is replaced by $v_{x_3}-\gamma$ or $v_{x_3}-\beta$. Consequently, using (2.7),

$$\begin{aligned}\int_{\Omega\times(a,b)} |\varepsilon(v_{x_3})|^2\,dx &\leqq C\Big\{\int_{\Omega\times(b,b+l)} \sigma^3(v_{x_3})(v_{x_3}-\gamma)\,dx \\ &\qquad -\int_{\Omega\times(a-l,a)} \sigma^3(v_{x_3})(v_{x_3}-\beta)\,dx\Big\} \\ &\leqq C\Big\{\|\nabla^2 v\|_{L^2(\Omega\times I_l(b))}\|v_{x_3}-\gamma\|_{L^2(\Omega\times I_l(b))} \\ &\qquad +\|\nabla^2 v\|_{L^2(\Omega\times I_l(a))}\|v_{x_3}-\beta\|_{L^2(\Omega\times I_l(a))}\Big\} \\ &\leqq CC_0M^{1/2}\Big(\|v_{x_3}-\gamma\|_{L^2(\Omega\times I_d l(b))}+\|v_{x_3}-\beta\|_{L^2(\Omega\times I_l(a))}\Big).\end{aligned}$$

Choosing γ and β appropriately, by Korn's inequality we conclude that

$$\begin{aligned}(2.8)\quad \int_{\Omega\times(a,b)} |\varepsilon(v_{x_3})|^2\,dx &\leqq 2CC_0M^{1/2}\Big\{\|\varepsilon(v_{x_3})\|_{L^2(\Omega\times I_l(b))}+\|\varepsilon(v_{x_3})\|_{L^2(\Omega\times I_l(a))}\Big\} \\ &\leqq 4CC_0M\end{aligned}$$

so that $\varepsilon(v_{x_3})\in L^2(\mathbb{P})$. Again, with l fixed, choose sequences $a_k\to-\infty$ and $b_k\to+\infty$ such that

$$\|\varepsilon(v_{x_3})\|_{L^2(\Omega\times I_l(b_k))}+\|\varepsilon(v_{x_3})\|_{L^2(\Omega\times I_l(a_k))}\to 0.$$

From (2.8) we conclude that

$$\int_{\mathbb{P}} |\varepsilon(v_{x_3})|^2\,dx=0$$

so $\varepsilon(v_{x_3})=0$ in $\mathbb{P}$. Q.E.D.

3. Semi-inverse solutions. A brief presentation of the field equations for a semi-inverse solution is our starting point. Assume that

$$(3.1)\qquad y(x)=R(x_3)(u(x')+p(x_3)),\qquad x\in\mathbb{P}$$

is a semi-inverse deformation. Temporarily writing $e=e_3$,

$$\begin{aligned}\nabla y(x) &= R(x_3)\Big(\nabla u+\frac{dp}{dx_3}\otimes e\Big)+R(x_3)\Lambda(u+p)\otimes e \\ &= R(x_3)(\nabla u+\Lambda u\otimes e+\xi\otimes e) \\ &\equiv R(x_3)U(x')\end{aligned}$$

and

$$S(\nabla y)=RS(U).$$

It follows that if y is a semi-inverse solution, then u is a solution of

$$(3.2)\qquad \begin{aligned}&\operatorname{div} S(U)+\Lambda S^3(U)=0 \quad \text{in } \Omega,\\ &S(U)\nu=0 \quad \text{on } \Gamma,\\ &U=\nabla u+\Lambda u\otimes e+\xi\otimes e,\end{aligned}$$

where $S^3(F)=S^3(F)e_3$ denotes the third column of $S(F)$. No ambiguity in (3.2) concerning the symbol "div" is possible since U depends only on x'.

Restricting our attention to deformations $y(x,t)$ satisfying (1.11), which entails imposition of initial conditions at $t=0$, we are able to write a full set of field equations for u and p. So we have for $|t|$ small

$$\begin{aligned} &U=U'(x',t)=\nabla u+t\Lambda u\otimes e+\xi(t),\\ &U(x',0)=\mathbb{1} \end{aligned} \tag{3.3}$$

satisfies

$$\begin{aligned} &\operatorname{div} S(U)+t\Lambda S^3(U)=0 \quad &&\text{in } \Omega,\\ &S(U)\nu=0 &&\text{on } \Gamma \end{aligned} \tag{3.4}$$

and

$$\begin{aligned} &\frac{dp}{dx_3}+t\Lambda p=\xi(t), \qquad -\infty<x_3<\infty,\\ &p(x_3,0)=x_3e,\\ &p(0,t)=0. \end{aligned} \tag{3.5}$$

Observe that

$$\left.\frac{dy}{dt}\right|_{t=0}=\left(\frac{du}{dt}+\frac{dp}{dt}\right)\Big|_{t=0}+x_3\Lambda x. \tag{3.6}$$

An incomplete version of Theorem 2 may be easily derived. Since

$$W(\nabla y)=W(RU)=W(U)$$

and U is a function of x', for small $|t|$ there is a constant $C(t)$, varying smoothly with t, such that

$$\int_{\Omega\times I_l(a)} W(\nabla y)\,dx=C(t)l, \qquad -\infty<a<\infty.$$

Thus

$$\int_{\Omega\times I_l(a)} S(\nabla y)\left[\nabla\frac{dy}{dt}\right]dx=\frac{d}{dt}\int_{\Omega\times I_l(a)} W(\nabla y)\,dx=c'(t)l,$$

also independent of $a\in\mathbb{R}$. By Taylor's theorem, with

$$\begin{aligned} v&=\left.\frac{dy}{dt}\right|_{t=0},\\ S(\nabla y)&=S(\mathbb{1})+t\nabla v+O(t^2))\\ &=S(\mathbb{1})+tS'(\mathbb{1})[\nabla v]+O(t^2)\\ &=t\sigma(v)+O(t^2) \end{aligned}$$

since $S(\mathbb{1})=0$. Consequently v is a solution of (1.10) satisfying

$$\int_{\Omega\times I_l(a)} \sigma(v)\cdot\varepsilon(v)\,dx=c_1l \qquad -\infty<a<\infty,$$

which implies (1.9). By Theorem 1 we conclude that

$$\left.\frac{dy}{dt}\right|_{t=0} = v = \sum_0^3 \mu_i v_i + \gamma \quad \text{in } \mathbb{P},$$

which in some qualitative way is the content of Theorem 2. However, it does not identify the coefficients μ_i with the matrix Λ and λ_0, so we turn instead to the explicit linearization of the equations (3.4), (3.5). This will also illustrate that the complete four-parameter family of St.-Venant solutions may be realized as linearizations of semi-inverse ones, provided, of course, the latter exist.

The linearization will give a system of equations for

$$\zeta = \left.\frac{du}{dt}\right|_{t=0}.$$

Indeed, since $U = \mathbb{1}$ at $t=0$,

$$\frac{dU}{dt} = \nabla\zeta + \Lambda u_0 \otimes e + \xi'(0) \otimes e,$$

$$u_0(x') = \begin{pmatrix} x_1 \\ x_2 \\ 0 \end{pmatrix},$$

we obtain

$$\operatorname{div} S'\left[\frac{dU}{dt}\right] + \Lambda S^3(\mathbb{1}) = 0 \quad \text{in } \Omega,$$

$$S'\left[\frac{dU}{dt}\right]\nu = 0 \quad \text{on } \Gamma$$

where $S' = S'(\mathbb{1})$. Now $S(\mathbb{1}) = 0$ gives

$$\begin{aligned} -\operatorname{div}\sigma(\zeta) &= \operatorname{div} S'[\Lambda u_0 \otimes e + \xi'(0) \otimes e] = f \quad \text{in } \Omega, \\ \sigma(\zeta)\nu &= -S'[\Lambda u_0 \otimes e + \xi'(0) \otimes e] = g \quad \text{on } \Gamma. \end{aligned} \tag{3.7}$$

With $'$ denoting the first two components, it may be convenient to note that (3.7) may be rewritten

$$\begin{aligned} -\Delta\zeta' - a\nabla \operatorname{div}\zeta' &= f' \quad \text{in } \Omega, \\ \sigma(\zeta')\nu &= g' \quad \text{on } \Gamma \end{aligned} \tag{3.8$_1$}$$

and

$$\begin{aligned} -\Delta\zeta^3 &= f_3 \quad \text{in } \Omega, \\ \frac{\partial\zeta^3}{\partial\nu} &= g_3 \quad \text{on } \Gamma. \end{aligned} \tag{3.8$_2$}$$

In addition

$$q(x_3) = \left.\frac{dp}{dt}\right|_{t=0}$$

is the solution of

$$\frac{dq}{dx_3} = \xi'(0) - x_3\Lambda e, \qquad q(0) = 0. \tag{3.9}$$

The systems (3.7), (3.9) are linear in λ_0 and the elements of Λ so it suffices to consider four separate cases corresponding to one $\lambda_i = 1$ with the rest set to zero. This may seem presumptuous, but we reserve to the end discussion of the bogus parameters μ_1, μ_2 which occur in $\xi'(0)$.

Set

$$\Lambda = \begin{pmatrix} 0 & -\lambda_3 & \lambda_2 \\ \lambda_3 & 0 & -\lambda_1 \\ -\lambda_2 & \lambda_1 & 0 \end{pmatrix}.$$

and suppose $\mu_1 = \mu_2 = 0$.

Case 0. (extension) $\lambda_0 = 1$, $\lambda_i = 0$, $i = 1,2,3$. Here the system (3.7) is

$$\begin{aligned} &-\operatorname{div}\sigma(\zeta) = 0 \quad \text{in } \Omega, \\ &\sigma(\zeta)\nu = -S'[e \otimes e]\nu = (1-a)\nu \quad \text{on } \Gamma \end{aligned}$$

and, clearly

$$q(x_3) = x_3 e.$$

So $\zeta = (1-a)/2a u_0(x') = -c_p u_0(x')$, where

$$c_p = \frac{1}{2a}(a-1) \tag{3.10}$$

denotes the Poisson ratio. Thus

$$\left.\frac{dy_0}{dt}\right|_{t=0} = v_0 = (-c_p x_1, -c_p x_2, x_3).$$

We turn now to torsion

Case 3. (torsion) $\lambda_3 = 1$, $\lambda_i = 0$, $i = 0,1,2$. In terms of (3.8), the system is

$$\begin{aligned} &-\Delta\zeta' - a\nabla \operatorname{div}\zeta' = 0 && \text{in } \Omega, \\ &\sigma(\zeta')\nu = 0 && \text{on } \Gamma, \\ &-\Delta\zeta^3 = 0 && \text{in } \Omega, \\ &\frac{\partial\zeta^3}{\partial\nu} = x_2\nu_1 - x_1\nu_2 && \text{on } \Gamma. \end{aligned}$$

Hence $\zeta' = 0$ and $\zeta^3 = \varphi$, the St.-Venant warping function. Moreover, $q \equiv 0$. Hence

$$\left.\frac{dy_3}{dt}\right|_{t=0} = v_3 = (-x_2x_3, x_1x_3, \varphi(x')), \qquad x \in \mathbb{P}.$$

Case 1. (e_1-bending) $\lambda_1 = 1$, $\lambda_i = 0$, $i = 0,2,3$. In this case

$$\Lambda u_0 = x_2 e$$

for which it is easily checked that

$$\begin{aligned} &-\Delta\zeta' - a\nabla \operatorname{div}\zeta' = \operatorname{div}(a-1)x_2\mathbb{1} = \begin{pmatrix} 0 \\ a-1 \end{pmatrix} && \text{in } \Omega, \\ &\sigma(\zeta')\nu = -(a-1)x_2\nu && \text{on } \Gamma \end{aligned}$$

and

$$\Delta\zeta^3=0 \quad \text{in } \Omega,$$
$$\frac{\partial\zeta^3}{\partial\nu}=0 \quad \text{on } \Gamma.$$

A solution is given by

$$\zeta(x')=\left(-c_p x_1 x_2, -\frac{1}{2}c_p\left(x_2^2-x_1^2\right),0\right).$$

For the auxiliary function q we find that

$$q(x_3)=+\frac{1}{2}x_3^2 e_2.$$

Combining these in (3.6) gives that

$$\frac{dy_1}{dt}\bigg|_{t=0}=v_1=\left(-c_p x_1 x_2, -\frac{c_p}{2}\left(x_2^2-x_1^2\right)-\frac{1}{2}x_3^2, x_2 x_3\right) \quad \text{on } \mathbb{P} \tag{3.11}$$

with c_p given by (3.10).

Finally, assume that all $\lambda_i=0$, $i=1,2,3$, and μ_i are given. For ζ this leads to the equations

$$-\operatorname{div}\sigma(\zeta)=0,$$
$$\sigma(\zeta)\nu=-\mu\cdot\nu e$$

so $\zeta=(0,0,-\mu\cdot x')$ while

$$\frac{dq}{dx_3}=\mu_i e_i, \qquad q(0)=0$$

implies $q(x_3)=x_3\mu_i e_i$. Thus

$$\frac{dy}{dt}\bigg|_{t=0}=\gamma x=\begin{pmatrix}0 & 0 & \mu_1\\ 0 & 0 & \mu_2\\ -\mu_1 & -\mu_2 & 0\end{pmatrix}x,$$

a rigid motion.

4. St.-Venant's flexure solution. The St.-Venant flexure solutions, which do not satisfy the energy restriction (1.9), are not easily accomodated in the present framework. In this way our discussion is more restrictive than Muncaster's [8], [9]. The flexure solution, however, is not especially satisfactory, even in the linear theory [2], [3]. We show here that they may be interpreted, rather casually, as displacements close to the linearized solutions of semi-inverse ones. Additional comments follow.

First consider the semi-inverse e_1-bending solution, corresponding to case 1 of §3, whose form is

$$\eta(x)=R(x_3)\left(u(x')+p(x_3)\right) \quad \text{in } \mathbb{P}$$

for

$$R(x_3)=e^{\delta x_3 M_1}, \quad M_1=\begin{pmatrix}0 & 0 & 0\\ 0 & 0 & -1\\ 0 & 1 & 0\end{pmatrix}, \quad \delta \text{ small},$$

and suppose there exists a family of solutions of the field equations (1.2) of the type

$$y(x,t)=Q(t)\eta(x,t), \qquad |t| \text{ small}$$

with $\eta(x,0)=\eta(x)$ as above and

$$Q(t)=e^{tx_3H}, \qquad H=\begin{pmatrix}0 & -1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 0\end{pmatrix}.$$

Calculation of $dy/dt|_{t=0}$ and approximation of the linearized equations at $\eta(x,0)$ by those at $y=x$, (1.10), leads to the credible approximation of $dy/dt|_{t=0}$ by the St.-Venant flexure solution.

Another interpretation is in terms of second derivatives. Suppose now that

$$y=y(x,\mu,\lambda)=R(x_3)(u(x')+p(x_3)) \quad \text{in } \mathbb{P}$$

is a two parameter family of semi-inverse solutions with

$$\Lambda=\begin{pmatrix}0 & -\lambda & 0\\ \lambda & 0 & -\mu\\ 0 & \mu & 0\end{pmatrix}.$$

Assuming that

$$\frac{\partial^2 y}{\partial\mu\,\partial\lambda}\bigg|_{\mu=\lambda=0}$$

may be written as flexure + error, the error contributes no resultant force on the planes $x_3=\text{const}$. Actually this is wrong by a numerical coefficient. Moreover, the term "flexure" here means just that portion of the St.-Venant solution involving the classical flexure functions.

The suggested conclusion, which in view of the brevity of this discussion, the reader may be reluctant to embrace, is that St.-Venant flexure is sufficiently close to the semi-inverse family that it does not determine, by itself, an especially interesting family of solutions of the finite equations. Geometrically, analogues of large twisting and bending may be achieved by seeking solutions

$$y(x)=e^{x_3\Lambda}(u(x')-b+p(x_3))$$

subject to the conditions $p(0)=0$ and

$$\int_\Omega u(x')\,dx=0,$$

as discussed in Ericksen [2].

5. Some remarks. From Theorem 1, the kernel of a certain linear operator defined on the unbounded domain $\mathbb{P}$ is identified. For example, the Banach space may be chosen to be

$V=$ functions which are locally in $C^{2,\alpha}(\overline{\mathbb{P}})$ with $\|\varepsilon(v)\|_{C^{0,\alpha}(\overline{\mathbb{P}})}+\|\nabla^2 v\|_{C^{0,\alpha}(\overline{\mathbb{P}})}<\infty$,

$Y=C^{0,\alpha}(\mathbb{P})\times C^{1,\alpha}(\partial\mathbb{P})$

with the operator

$$L: V \to Y, \qquad Lv = (-\operatorname{div}\sigma(v), \sigma(v)\nu).$$

It would be useful to know the index of L, especially for the study of small deformations superimposed on large. This is also connected to the notion of stability of solutions.

Given a family of semi-inverse solutions of the form

$$y = y(x) = y(x, \Lambda, \lambda_0) = R(x_3)(u(x') + p(x_3)), \qquad x \in \mathbb{P},$$
$$R(x_3) = e^{x_3 \Lambda}$$

depending on four parameters $\lambda_0, \cdots, \lambda_3$, let us say, the displacements $\partial y/\partial \lambda_i$, $i = 0, 1, 2, 3$, are good candidates for St.-Venant solutions associated to the solution $y(x)$. From the standpoint of energy, these linearizations do not seem to have any apparent interpretation, such as that given by Theorem 1. The argument at the beginning of §3 relies on the vanishing of the stress tensor at $\mathbb{1}$. The linearized strain, however, E, given by

$$2E = \left(\nabla \frac{\partial y}{\partial \lambda_i}\right)^T F + F^T \left(\nabla \frac{\partial y}{\partial \lambda_i}\right), \qquad F = \nabla y,$$
$$= \frac{\partial}{\partial \lambda_i} U^T U$$

is independent of x_3. Is every solution of the linearized equations at $y = y(x)$ with this property such a "St.-Venant" solution?

Appendix. St.-Venant solutions. For the reader's convenience we take up here the description of displacements $v(x)$ with

$$\frac{\partial}{\partial x_3} \varepsilon(v) = 0 \quad \text{in } \mathbb{P} \tag{A.1}$$

which implies that

$$\frac{\partial v}{\partial x_3} = \Lambda x + c, \quad \Lambda + \Lambda^T = 0, \quad c \in \mathbb{R}^3. \tag{A.2}$$

As the expression above is linear in the parameters occurring in Λ and c, it suffices to consider separate cases and to then superimpose their solutions. We consider here the case of torsion, where

$$\Lambda = H = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad c = 0.$$

Solutions $u = (u^1, u^2)$ to the two-dimensional system

$$-\operatorname{div}\sigma(u) = 0 \quad \text{in } \Omega,$$
$$\sigma(u)\nu = 0 \quad \text{on } \Gamma$$

are unique to within a affine rigid motion. Our choice of St.-Venant solution will reflect this property.

From (A.2),

$$\frac{\partial v^1}{\partial x_3} = -x_2, \quad \frac{\partial v^2}{\partial x_3} = x_1, \quad \frac{\partial v^3}{\partial x_3} = 0$$

whence

$$\begin{aligned} v^1 &= -x_2 x_3 + \varphi^1(x^1), \\ v^2 &= x_1 x_3 + \varphi^2(x') \quad \text{in } \mathbb{P}, \\ v^3 &= \varphi^3(x'). \end{aligned}$$

Substituting this in the equations (1.10) gives

$$\begin{aligned} &\operatorname{div} \sigma(v) = \Delta\varphi + a\nabla \operatorname{div}\varphi = 0 \quad \text{in } \mathbb{P}, \\ &\sigma(v)\nu = 0 \quad \text{on } \partial\mathbb{P} \end{aligned}$$

so, with $\varphi' = (\varphi^1, \varphi^2)$,

$$\begin{aligned} &\Delta\varphi' + a\nabla \operatorname{div}\varphi' = 0 \quad \text{in } \Omega, \\ &\sigma(\varphi')\nu = 0 \quad \text{on } \Gamma \end{aligned}$$

and

$$\begin{aligned} &\Delta\varphi^3 = 0 \quad \text{in } \Omega, \\ &\frac{\partial \varphi^3}{\partial \nu} + (-x_2\nu_1 + x_1\nu_2) = 0 \quad \text{on } \Gamma. \end{aligned}$$

Thus φ' is a two-dimensional rigid motion we may set equal to zero and

$$\varphi^3 = \varphi$$

the St.-Venant warping function. Thus

$$v = (-x_2 x_3, x_1 x_3, \varphi(x')), \qquad x \in \mathbb{P}.$$

The bending and extension solutions may be determined in the same way. We do not pursue this here since they are described, from a different viewpont, in §3.

Of course, Love [6] is an ideal source of information about St.-Venant solutions.

ON THE BEHAVIOR OF THE SOLUTIONS TO THE LAMM EQUATION OF THE ULTRACENTRIFUGE II*

ATSUSHI YOSHIKAWA†

Abstract. In the ultracentrifugal analysis of a two-component solute-solvent system, the concentration $c(r,t)$ of the solute is described by the Lamm equation $\partial c/\partial t = r^{-1}\partial(r\{D_0\partial c/\partial r - r\omega^2 s_0 c/(1+kc)\})/\partial r$, $0<r_a<r<r_b$, $t>0$, with the nonlinear boundary conditions $D_0\partial c/\partial r - r\omega^2 s_0 c/(1+kc)=0$ at $r=r_a$ and $r=r_b$, and the initial data $c=c_0(r)$ when $t=0$. Here D_0, s_0, k, ω are positive constants independent of c. In the present paper, it is shown that for any smooth nonnegative initial data $c_0(r)$, compatible with the boundary conditions, the solution $c(r,t)$ converges to the equilibrium solution as $t\to+\infty$. The rate of convergence is also given. These improve some of the results obtained in [SIAM J. Math. Anal., 15 (1984), pp. 686–711] under more stringent assumptions on $c_0(r)$.

Introduction. Consider the following Lamm equation of the ultracentrifugal analysis:

$$\frac{\partial c}{\partial t} = r^{-1}\frac{\partial}{\partial r}\left\{r\left(D_0\frac{\partial c}{\partial r} - r\omega^2 sc\right)\right\}, \tag{0.1}$$

$0<r_a<r<r_b$, $t>0$, with the (nonlinear) boundary conditions

$$D_0\frac{\partial c}{\partial r} - r\omega^2 sc = 0 \tag{0.2}$$

at $r=r_a$ and $r=r_b$, and the initial data

$$c = c_0(r) \quad \text{when } t=0. \tag{0.3}$$

Here $c(r,t)$ stands for the concentration of the solute in a two-component system (see Fujita [1]). D_0 is the diffusion coefficient and ω the frequency of the rotor. We assume that D_0 and ω are positive constants independent of c. s is the sedimentation coefficient, which is given by

$$s = s(c) = \frac{s_0}{1+kc} \tag{0.4}$$

with positive constants s_0 and k.

From the physical point of view, it is natural to require that the initial concentration $c_0(r)$ satisfy

$$c_0(r) \geqq 0 \tag{0.5}$$

and

$$\int_{r_a}^{r_b} c_0(r)\,r\,dr > 0. \tag{0.6}$$

* Received by the editors May 12, 1983, and in revised form September 15, 1984.

† Department of Mathematics, Faculty of Science, Hokkaido University, Sapporo 060, Japan. Present address, Department of Applied Science, Faculty of Engineering, Kyushu University, Hakozaki, Fukuoka 812, Japan.

Some of the basic properties of the solution $c(r,t)$ of the Lamm equation (0.1)–(0.6) have been established in [2]. In particular, the existence and uniqueness of the solution to the Lamm equation have been verified [2, Thm. 1]. The property of the equilibrium solution $c_E(r)$ has also been discussed [2, Thm. 2]. Namely, $c_E(r)$ satisfies the equation

$$D_0\frac{\partial c_E}{\partial r}-r\omega^2 s(c_E)c_E=0 \tag{0.7}$$

in $r_a<r<r_b$ with

$$\int_{r_a}^{r_b} c_E(r)r\,dr=m_0. \tag{0.8}$$

However, the convergence of $c(r,t)$ to $c_E(r)$ as $t\to\infty$ has been shown only under the requirement that either $c_0(r)$ be nondecreasing in r or $c_0(r)$ satisfy

$$\left|D_0\frac{\partial c_0(r)}{\partial r}-r\omega^2 s(c_0(r))c_0(r)\right|\leqq\frac{D_0^2}{s_0\omega^2 r_b^3 k}$$

[2, Thm. 3].

In the present paper, we remove these restrictions on $c_0(r)$ and prove the following:

THEOREM 0.1. *Let $c_0(r)$ be a smooth function, compatible with the boundary conditions* (0.2), *and satisfying* (0.5) *and* (0.6). *Let $c(r,t)$ be the corresponding classical solution to the problem, and $c_E(r)$ be the equilibrium solution with the same mass as $c_0(r)$. Then there is a positive constant C independent of t, r such that for each $t>0$,*

$$|c(\cdot,t)-c_E|_\infty\leqq C\exp(-\lambda_E t). \tag{0.9}$$

In the above statement, $|\ |_\infty$ stands for the norm of the Banach space $L^\infty(r_a,r_b)$. λ_E is the smallest positive eigenvalue of the linearization $\hat{L}_E$ at $c=c_E$. That is, $\hat{L}_E$ is the self-adjoint extension in the Hilbert space $L^2(r_a,r_b;q(r)r\,dr)$ of the operator L_E:

$$L_E u=-r^{-1}\frac{\partial}{\partial r}\left(r\left\{D_0\frac{\partial}{\partial r}u-rs_0\omega^2 s_1'(c_E(r))u\right\}\right)$$

for $u\in C^2(r_a,r_b)$ with

$$D_0\frac{\partial}{\partial r}u-rs_0\omega^2 s_1'(c_E(r))u=0$$

at $r=r_a$ and $r=r_b$. Here we have employed $s_1(c)=c/(1+kc)$ and $s_1'(c)=1/(1+kc)^2$.

$$q(r)=\exp\left\{-D_0^{-1}s_0\omega^2\int_{r_a}^{r}s_1'(c_E(r'))r'\,dr'\right\}.$$

For the benefit of the readers, we include a few words about how $L_E u$ is derived. Suppose a solution c of (0.1)–(0.2) is written in the form $c=c_E+u$. Then from (0.1) and (0.2), we get

$$\frac{\partial u}{\partial t}-r^{-1}\frac{\partial}{\partial r}\left(r\left\{D_0\frac{\partial}{\partial r}u-rs_0\omega^2 s_1'(c_E(r))u\right\}\right)=\frac{1}{r}\frac{\partial}{\partial r}R(r;u,c_E),$$

$t>0$, $r_1<r<r_b$, and

$$D_0\frac{\partial}{\partial r}u-rs_0\omega^2 s_1'(c_E(r))u=R(r;u,c_E)$$

at $r=r_a$ and $r=r_b$. Here

$$R(r;u,c_E)=-\frac{r\omega^2 s_0 k u^2}{(1+kc_E)(1+kc_E+ku)}$$

and is considered to be of second order in u because of the fact that $c_E>0$, $c_E+u\geqq 0$ [2, Thm. 1]. Thus to obtain the part of order 1 in u, we put $R=0$ and get the operator L_E.

The proof of Theorem 0.1 is given in the next section. It depends on a better choice of the Lyapunov functional. Our technique relies on smoothness of the solution $c(r,t)$. In the meantime, Professor Barbu has shown me that the above problem (0.1)–(0.4) falls in the category of problems to which the monotone operator theory (in $L^2(r_a,r_b;r\,dr)$) is applicable. The initial concentration may then merely be in $L^2(r_a,r_b;r\,dr)$. Since such generalized possibly multivalued solutions are out of the scope of the techniques employed in the present note, we do not know if Theorem 0.1 still prevails under such a weak requirement on the initial concentration. However, it is certainly the case once the solution achieves regularity at some instant.

1. Proof of Theorem 0.1. Let $c(r,t)$ be the smooth classical solution of the problem (0.1)–(0.4) with the initial data satisfying (0.5) and (0.6). The smoothness and compatibility requirements of the initial concentration $c_0(r)$, on the other hand, are to guarantee the existence of such a smooth solution.

Let

$$J(c(r,t))=D_0\frac{\partial c}{\partial r}-rs_0\omega^2 s_1(c) \tag{1.1}$$

for $c=c(r,t)$. Recall that $s_1(c)=c/(1+kc)$. To control the behavior of $c(r,t)$ as $t\to+\infty$, we employ the following Lyapunov functional:

$$E(c(\cdot,t))=\int_{r_a}^{r_b} J(c(r,t))^N r\,dr, \tag{1.2}$$

with N a positive even integer large enough.

We can then show:

PROPOSITION 1.1. *Given nonnegative smooth compatible initial data $c_0(r)$, there are an even positive integer N_0 and a positive number q such that for any even integer $N\geqq N_0$, we have*

$$E(c(\cdot,t))\leqq e^{-qt}E(c_0), \qquad t>0.$$

Once this proposition is admitted, it is fairly immediate that the ω-limit set $\omega_p(c_0)$ of $c_0(r)$ in $L^p(r_a,r_b;r\,dr)$, $1\leqq p<\infty$, or in $C^0(r_a,r_b)$ (i.e., $p=\infty$), consists of the unique point $c_E(r)$, the equilibrium solution with the mass $m_0=\int_{r_a}^{r_b}c_0(r)r\,dr$. In fact, there is a sequence $t_1<t_2<\cdots<t_n<\cdots\to+\infty$ such that $J(c(r,t_i))$ converges to 0 almost everywhere in (r_a,r_b). Then the proof of [2, Thm. 3] is applicable to derive (0.9).

Proof of Proposition 1.1. Because of our regularity assumptions, $u(r,t)=J(c(r,t))$ satisfies the following equation:

$$\frac{\partial u}{\partial t}=D_0\frac{\partial^2 u}{\partial r^2}+A\frac{\partial}{\partial r}u-Bu, \tag{1.3}$$

$r_a<r<r_b$, $t>0$, with the boundary condition

$$u=0 \quad \text{at } r=r_a \text{ and } r=r_b, \tag{1.4}$$

and the initial data

$$u=J(c_0(r)) \quad \text{when } t=0. \tag{1.5}$$

Here

$$A=A(r,c)=\frac{D_0}{r}-s_0\omega^2 s_1'(c)r,$$

$$B=B(r,c)=s_0\omega^2 s_1'(c)+\frac{D_0}{r^2},$$

with $s_1'(c)=1/(1+kc(r,t))^2$ (see [2, §3]). Since

$$B\geqq\frac{D_0}{r_a^2}>0, \tag{1.6}$$

we have

$$|u(r,t)|\leqq\sup_r J(c_0(r))=M_0$$

in view of the maximum principle. Since $s_1(c)\leqq 1/k$, we have

$$\left|\frac{\partial c(r,t)}{\partial r}\right|\leqq D_0^{-1}M_0+r_b s_0\omega^{k-1}=M_1 \tag{1.7}$$

for all $t>0$ and $r_a<r<r_b$. Now using (1.3) and (1.4), we get by a routine computation

$$\frac{d}{dt}E(c(\cdot,t))=-N(N-1)D_0\int_{r_a}^{r_b}u^{N-2}u_r^2 r\,dr-\int_{r_a}^{r_b}(rA)_r u^N dr-N\int_{r_a}^{r_b}Bu^N r\,dr. \tag{1.8}$$

By (1.7),

$$(rA_r)=A+rA_r=\frac{D_0}{r}-3s_0\omega^2 r s_1'(c)-s_0\omega^2 r^2 s_1''(c)c_r \tag{1.9}$$

$$\geqq\frac{D_0}{r_b}-3s_0\omega^2 r_b-2ks_0\omega^2 r_b^2 M_1=M_2.$$

Therefore, from (1.6), (1.8) and (1.9) we get

$$\frac{d}{dt}E(c(\cdot,t))\leqq -qE(c(\cdot,t)) \tag{1.10}$$

if $N\geqq N_0>-M_2 r_a^2/(D_0 r_b)$, and thus

$$q=N\frac{D_0}{r_a^2}+\frac{M_2}{r_b}>0.$$

Proposition 1.1 is now immediate from (1.10) and (1.5).

Observe that the exponent q in Proposition 1.1 depends on N and also on $c_0(r)$. On the other hand, we know that

$$\lim_{p\to\infty}\left\{\int_{r_a}^{r_b}|v(r)|^p r\,dr\right\}^{1/p}=|v|_\infty$$

for any bounded measurable function $v=v(r)$ on the interval (r_a, r_b). From this fact, we immediately get the following:

COROLLARY 1.2. *Under the assumptions of Proposition* 1.1 *we have*

$$|J(c(\cdot,t))|_\infty \leqq e^{-Qt}|J(c_0(\cdot))|_\infty, \qquad t>0,$$

with $Q \geqq D_0/r_a^2$.

It is also immediate that $|J(c(\cdot,t))|_\infty$ is a decreasing function of t. This shows that $|J(c(\cdot,t))|_\infty$ would be the right choice as the Lyapunov functional, although the functional $E(c(\cdot,t))$ of (1.2) and Proposition 1.1 already provide enough information for our present purpose.

R-SEPARATION FOR HEAT AND SCHRÖDINGER EQUATIONS I *

GREGORY JOHN REID†

Abstract. We classify all R-separable coordinate systems for the equation

$$(*) \qquad \Delta_m \Psi + 2\varepsilon \partial_t \Psi = E\Psi, \qquad \Delta_m = \sum_{u=1}^{m} \partial_{y^u y^u},$$

which for $\varepsilon = \frac{i}{2}$ and $\varepsilon = -\frac{1}{2}$, $E=0$ yields standardised versions of the Schrödinger and Heat equations respectively. The classification problem is solved by utilising the fact that (*) is a symmetry-reduced version of the Helmholtz equation on $m+2$ dimensional Minkowski space for which there is a well developed theory of separation. In all cases the separated solutions are eigenfunctions of a commuting set of operators which are at most quadratic in the operators which generate the motions of the symmetry group of (*). A detailed treatment is provided of the physically interesting case $m=3$.

1. Introduction. In this article a complete treatment of the variable separation problem is given for the equation

$$(*) \qquad \Delta_m \Psi + 2\varepsilon \partial_t \Psi = E\Psi \qquad \left(\Delta_m = \sum_{u=1}^{m} \partial_{y^u y^u}\right),$$

in the real variables y^u and t. When $\varepsilon = i/2$ this equation is a standardised version of the "constant potential Schrödinger equation" which will be referred to as the "Schrödinger equation". If $\varepsilon = -\frac{1}{2}$ and $E=0$ then (*) is a standardised version of the Heat or diffusion equation.

The coordinate system

$$(1.1) \qquad \begin{aligned} &y^u = y^u(\mathbf{x}), \qquad u = 1,2,\cdots,m, \\ &t = t(\mathbf{x}), \qquad \mathbf{x} = (x^1,\cdots,x^{m+1}), \end{aligned}$$

is *R-separable* if there are complex analytic functions Ψ, Ψ_j and R, such that (*) admits a solution of form

$$(1.2) \qquad \Psi(\mathbf{x},\mathbf{c}) = e^{R(\mathbf{x})} \prod_{j=1}^{m+1} \Psi_j(x^j,\mathbf{c}),$$

where $\mathbf{c} = (c_1,\cdots,c_{m+1})$ are the $m+1$ separation constants. It is the main task of this article to classify these systems. At first it might seem that any solution of (*) is R-separable but the independence of R from the constants c_j severely limits the possible R-separable solutions. Pure separation corresponds to $R=0$ and trivial R-separation to

$$(1.3) \qquad R = \sum_{i=1}^{m+1} R_i(x^i).$$

In the time independent case (i.e. $\partial_t \Psi = 0$), equation (*) reduces to the Helmholtz equation if $E \neq 0$ and to the Laplace equation when $E=0$ on real Euclidean space $\mathbb{R}^m$.

* Received by the editors January 30, 1984, and in revised form May 15, 1984.

† Mathematics Department, University of Waikato, Hamilton, New Zealand. Present address, Mathematics Department, South Dakota State University, Brookings, South Dakota 57007-1297.

A classification of the R-separable systems for these equations in three spatial dimensions ($m=3$) was first provided by Böcher (1894). Eisenhart (1934) gave a rigorous derivation of the systems obtained by Böcher. Eisenhart (1934) also characterized variable separation in a geometric manner that could be systematically applied to the variable separation problem on any Riemannian space.

Separable solutions $\Phi=\Pi_1^m\Phi_i(x^i)$ of the time independent form of (*) $\Delta_m\Phi=K\Phi$, also provide separable solutions $\Psi=e^{\lambda t}\Phi$ of the time-dependent form of (*) if $K+2\varepsilon\lambda=E$. However there are many R-separable systems for (*) where the time dependence is not so trivial. Only recently has a systematic investigation of such systems been undertaken. Kalnins and Miller (1974) classified all R-separable systems for the potential-free Schrödinger equation in one spatial dimension (i.e. (*) with $\varepsilon=i/2$ and $m=1$). Subsequently Boyer, Kalnins and Miller (1975a) classified all R-separable systems for the Schrödinger equation in two spatial dimensions. These and earlier investigators showed that the separability of these equations was intimately related to their respective point symmetry groups. More specifically they showed that the R-separated solutions were eigenfunctions of a set of mutually commuting sets of linear and/or quadratic combinations of the partial differential operators that generate the motions of the group. In Boyer, Kalnins and Miller (1975a, b) these group theoretical characterisations are used to give efficient and well-motivated derivations of addition theorems both old and new for the various special functions that appeared as eigensolutions of the separated problems. In his book *Symmetry and Separation of Variables*, Miller (1977) collects the results of the above papers and also characterises group theoretically variable separation for many of the common partial differential equations of mathematical physics.

The present paper is an extension of Kalnins and Miller's work to m dimensions. Kalnins and Miller (1982a) have already constructed all separable systems for $\Delta_m\Psi=E\Psi$ (i.e. (*)with $\varepsilon=0$). It is out of their construction that we will be able to build all R-separable systems for the time dependent case.

The *symmetry group* (Bluman and Cole (1974), Boyer (1974)) of (*) will prove to be of great use in our study. This is the group of coordinate transformations which leaves the form of (*) invariant. If two R-separable systems are related by the action of this group then we will not distinguish between them. We will often work with the *Lie* algebra corresponding to this group. The infinitesimal generators

$$L=\alpha^i(\mathbf{Y})\partial_{Y^i}+b(\mathbf{Y}) \tag{1.4}$$

for this algebra are found by solving the relation

$$[Q,L]=M(\mathbf{Y})Q, \tag{1.5}$$

where $Q=\Delta_m+2\varepsilon\partial_t-E$ and $\mathbf{Y}=(y^1,\cdots,y^m,t)$. Here [,] is the commutator bracket and we have used the Einstein summation convention which will always be assumed unless indicated otherwise. These generators can also be interpreted as symmetry operators in the sense that they map solutions to solutions: if Φ is a solution of (*) then so too is $L\Phi$.

Another illustration of the importance of the symmetry group is in the case of *ignorable variables*. A variable is *ignorable* if it is possible to choose (via the freedom (1.8a) defined below) an R-separable coordinate system such that this variable does not appear explicitly in (*). Greek indices will be used to denote such variables. Nonignorable coordinates will be referred to as being *essential variables*. Ignorables correspond to elements of the Lie algebra and systems containing N of them correspond to N

dimensional abelian subalgebras. The determination of these subalgebras under the adjoint action of the Lie algebra will be of great use in the solution of our problem.

In all cases the R-separated solutions Ψ will be characterised as eigenfunctions of a commuting set of $m+1$ partial differential operators quadratic in the elements of the Lie algebra. We will thus be able to extend the group theoretical characterisation found in lower dimensions by Kalnins and Miller (1974), Shapovalov and Sukhomlin (1974) to the time dependent Heat and Schrödinger equations of any spatial dimension.

The partial differential operators corresponding to ignorables are first order so the eigenfunction condition implies that

$$L_\alpha \Psi = l_\alpha \Psi, \tag{1.6}$$

in which case the x^α dependence in Ψ is simply

$$\Psi_\alpha = e^{l_\alpha x^\alpha}. \tag{1.7}$$

The remainder of the operators are second order.

To simplify this study we will say that two R-separable coordinate systems $\{\mathbf{x}\}$ and $\{\bar{\mathbf{x}}\}$ are *equivalent* if

$$\bar{x}^a = f^a(x^a), \tag{1.8a}$$

$$\bar{x}^\alpha = c^\alpha_\beta x^\beta + \sum_a g_a(x^a), \qquad \det(c^\alpha_\beta) \neq 0. \tag{1.8b}$$

or

(1.8c) they are related by the action of the symmetry group.

Here the c^α_β are real constants and the x^a are essential variables. Benenti (1980) has given a rigorous definition of *equivalence* for the Hamilton–Jacobi equation. By his definition two separable coordinate systems for this equation are equivalent if their separated complete integrals are the same (see §2 for the definition of separation for the Hamilton–Jacobi equation). He shows that by using this definition the only possible types of equivalence transformations are (1.8a) and (1.8b). These two equivalences extend naturally to our case since both of these transformations preserve the R-separability of (∗). We add (1.8c) because equivalence under the group removes the distinction between many different coordinate transformations leading to the same functional form of (∗).

In the early stages of this work a program (see Reid (1984)) was written in the symbolic language MACSYMA capable of producing all the time-consuming details of separation for flat spaces. Although a general theory was finally set up dispensing with the need for this program, it proved extremely useful in checking the results.

The structure of this article is as follows. In §2 we transform (∗) to the Helmholtz equation in Minkowski space, and exploit the fact that both this equation and the even simpler Hamilton–Jacobi equation separate in the same coordinate systems. Section 2 is also introductory in nature as it outlines much of the basic material needed for our study. In §3 we determine the possible sets of commuting Killing vectors (or abelian sub algebras) characterising separable systems for the Hamilton–Jacobi equation. Using these abelian subalgebras a simple form is then found for the metric. As a result the Riemann curvature conditions are solved in §4 and the metric completely determined. The technical work of finding the coordinate transformations is also carried out in §4. This work is summarised in graphical form in §5. In §6 we determine the operators for (∗) and in §7 the R-separable solutions. The results for physically interesting cases $m = 1, 2$, and 3 are tabulated in Appendix A.

2. Passage to the Hamilton–Jacobi equation in Minkowski space. The problem of finding all R-separable systems for (∗) is shown to be equivalent to that of finding all separable systems for the Helmholtz equation (2.1) defined on Minkowski space with symmetry (2.2). The conditions for separability of (2.1) are best derived from its classical counterpart, the Hamilton–Jacobi equation (2.15). We show that the symmetry algebras of (∗) and (2.15) are isomorphic to the Schrödinger algebra when $E=0$ and to the Galilean algebra when $E\neq 0$. The central result is the following theorem.

THEOREM 2.1. *There is a mapping between R-separable coordinate systems of* (∗) *and separable coordinate systems for the Helmholtz equation on* $n(=m+2)$ *dimensional Minkowski space.*

$$\square_n \bar{\Psi} = E\bar{\Psi}, \qquad n=m+2, \tag{2.1}$$

whose solutions $\bar{\Psi}$ *are eigenfunctions of the symmetry operator*

$$\partial_{\bar{x}^n} = \tfrac{1}{2}\left(\partial_{\bar{y}^{n-1}} + \partial_{\bar{y}^n}\right) \tag{2.2}$$

with associated eigenvalue ε (*i.e.* $\partial_{\bar{x}^n}\bar{\Psi} = \varepsilon\bar{\Psi}$). *Here the D'Alembertian operator on Minkowski space with the coordinates* $\bar{y}^i$, $i=1,2,\cdots,n$, *is defined by*

$$\square_n = \partial_{\bar{y}^1\bar{y}^1} + \cdots + \partial_{\bar{y}^{n-1}\bar{y}^{n-1}} - \partial_{\bar{y}^n\bar{y}^n}. \tag{2.3}$$

Proof. We first construct the mapping from (∗) to (2.1). Suppose

$$\begin{aligned} &y^j = y^j(x^1,\cdots,x^{n-1}), \qquad j=1,2,\cdots,n-2,\\ &t = t(x^1,\cdots,x^{n-1}), \end{aligned} \tag{2.4}$$

is an R-separable system for (∗); then there are functions Ψ, Ψ_j and R such that

$$\Psi = e^R \prod_{j=1}^{n-1} \Psi_j(x^j). \tag{2.5}$$

Consider the coordinate system $\bar{x}^i$

$$\begin{aligned} &\bar{y}^j = y^j(\bar{x}^1,\cdots,\bar{x}^{n-1}), \qquad j=1,2,\cdots,n-2,\\ &\bar{y}^{n-1} - \bar{y}^n = 2t(\bar{x}^1,\cdots,\bar{x}^{n-1}),\\ &\bar{y}^{n-1} + \bar{y}^n = \bar{x}^n - R/\varepsilon. \end{aligned} \tag{2.6}$$

This is a system in Minkowski space with ignorable $\bar{x}^n$, corresponding to the symmetry operator (2.2) whose eigenvalue we shall specify as ε. Let

$$\bar{\Psi} = e^{\varepsilon\bar{x}^n} \prod_{j=1}^{n-1} \Psi_j(\bar{x}^j) = e^{[\varepsilon(\bar{y}^{n-1}+\bar{y}^n)+R]} \prod_{j=1}^{n-1} \Psi_j(\bar{x}^j). \tag{2.7}$$

As Ψ satisfies (∗), $\bar{\Psi}$ is easily shown to satisfy (2.1). In other words (2.6) is a separable coordinate system for the Helmholtz equation (2.1). We now show that the mapping from (2.4) to (2.6) is onto by constructing its inverse. If $\{\bar{\mathbf{x}}\}$ is a separable system for (2.1) with symmetry operator (2.2), then

$$\begin{aligned} &\bar{y}^j = \bar{y}^j(\bar{x}^1,\cdots,\bar{x}^{n-1}), \qquad j=1,2,\cdots,n-2,\\ &\bar{y}^{n-1} - \bar{y}_n = 2t(\bar{x}^1,\cdots,\bar{x}^{n-1}),\\ &\bar{y}^{n-1} + \bar{y}^n = \bar{x}^n + f(\bar{x}^1,\cdots,\bar{x}^{n-1}) \end{aligned} \tag{2.8}$$

which if we let

$$f = -R/\varepsilon \tag{2.9}$$

is the image of (2.4), and the theorem is proved. Q.E.D.

In fact (2.1) separates in the same coordinate systems for each nonzero value of E. Care must be taken when $E=0$. When this occurs, (2.1) is the wave equation which in general separates in additional coordinate systems as is shown in Kalnins and Miller (1982b). However if we define

$$\tilde{\Psi} = e^{-Et/2\varepsilon}\Psi \tag{2.10}$$

then by substitution:

$\tilde{\Psi}$ is an R-separable solution for $(*)$ with $E=0$ iff Ψ is an R-separable solution for $(*)$.

The presence of the symmetry (2.2) has eliminated these additional systems. This means that a classification for nonzero E will also yield all possible systems when $E=0$. Again care must be taken as the symmetry group of the wave equation is larger: it admits additional conformal symmetries. In essence, some of the systems which are inequivalent for $(*)$ when $E\neq 0$ become equivalent under the action of the extra symmetries when $E=0$. We will return to this point later. All that we need to know at the moment is that everything can be obtained from the nonzero case.

One of the advantages of transforming our problem to the Helmholtz equation (2.1) is that to such an equation we can naturally associate a Riemannian geometry. Here (2.1) corresponds to the metric

$$ds^2 = (dy^1)^2 + \cdots + (dy^{n-1})^2 - (dy^n)^2 \tag{2.11}$$

which is the metric of a general n-dimensional Minkowski space $E(n,1)$. The classification of coordinates can now be framed as the classification of the metrics $ds^2 = g_{ij}dx^i dx^j$ arising from the fundamental metric (2.11) using the results of Riemannian geometry. Since the space is Minkowski, these results imply that all the components of the Riemann curvature tensor are identically zero, i.e.

$$R_{ijkl} \equiv 0, \qquad 1 \leqq i,j,k,l \leqq n. \tag{2.12}$$

For the definition of this tensor the reader is directed to Eisenhart (1949). Continuing our discussion in general let V_n be a (local) pseudo-Riemannian manifold specified by its metric

$$ds^2 = g_{ij}dx^i dx^j, \qquad g = \det(g_{ij}) \neq 0. \tag{2.13}$$

The Helmholtz equation for V_n is expressed in local coordinates by

$$\frac{1}{g^{1/2}}\,\partial_i\left(g^{1/2}g^{ij}\partial_j\Psi\right) = E\Psi \tag{2.14}$$

where E is a nonzero constant. Closely associated with the Helmholtz equation is the Hamilton–Jacobi equation

$$H(p_i) = g^{ij}p_i p_j = E, \quad p_i = \frac{\partial W}{\partial x^i}, \tag{2.15}$$

where W is the Hamilton–Jacobi function or complete integral of (2.15). This equation is said to be separable if there are functions W_i such that

$$W(\mathbf{x},\boldsymbol{\lambda})=\sum_{i=1}^{n} W_i(x^i,\boldsymbol{\lambda}), \tag{2.16}$$

where

$$\boldsymbol{\lambda}=(\lambda_1,\cdots,\lambda_n) \tag{2.17}$$

are the n constants of the motion necessary for a complete integral. (N.B. W is a complete integral if $\det(\partial W_i/\partial\lambda_j)\neq 0$). One of these constants can always be taken as E. Both (2.14) and (2.15) are coordinate independent and the passage between them is analogous to that between Classical and Quantum mechanics. A close relationship also exists in the case of variable separation. Every separable system for the Helmholtz equation also separates the Hamilton–Jacobi equation. This was demonstrated for orthogonal coordinates by Robertson (1927), and can be verified for nonorthogonal coordinate systems by using the results of Kalnins and Miller (1983). Robertson (1927) also supplied the extra condition (called the Robertson condition) for the converse of his result, i.e. for Hamilton–Jacobi separation to imply Helmholtz separation. The generalisation of the Robertson condition to nonorthogonal coordinates can be obtained from the work of Kalnins and Miller (1983).

The above results imply that every separable coordinate system of (2.1) is a separable system for the Hamilton–Jacobi equation

$$H=P_1^2+\cdots+P_{n-1}^2-P_n^2=E, \qquad P_i=\frac{\partial W}{\partial y^i} \tag{2.18}$$

with Minkowski space metric (2.11) and symmetry operator (2.2). The generalised Robertson condition depends on the metric components and is especially complicated in metrics with many nonorthogonal terms. In our case this condition can be shown to be always satisfied after the metric has been reduced to a simple form in §3. That is, the Hamilton–Jacobi equation and (2.1) separate in exactly the same coordinate systems. This result can also be proved by making the following observation which avoids introducing the technical details of the generalised Robertson condition. The separability of (2.1) in all separable systems for the Hamilton–Jacobi equation (2.18) is ultimately demonstrated in §7 by obtaining the corresponding separation equations for (*). In summary our problem has been reduced to the much easier one of finding all separable systems for the Hamilton–Jacobi equation (2.18).

Working with the Hamilton–Jacobi equation is more convenient since its form (2.15) is not as complicated as that of the Helmholtz equation (2.1) and is more closely related to the metric (2.13) (it is just the inverse). Using his definition of *equivalence*, Benenti (1980) was able to give the conditions for separability of the Hamilton–Jacobi equation (2.18). He showed that each of his classes contained a *canonical* separable system $\{x^a,x^r,x^\alpha\}$ with contravariant metric

$$(g^{ij})=\begin{pmatrix} \delta^{ab}g^{aa} & 0 & 0 \\ 0 & 0 & g^{r\alpha} \\ 0 & g^{r\alpha} & g^{\alpha\beta} \end{pmatrix}\begin{matrix} n_1 \\ n_2 \\ n_3 \end{matrix}. \tag{2.19}$$

Here $n_3 \geqq n_2$ and the integers a, r, α vary in the ranges $1 \leqq a,\ b \leqq n_1;\ n_1+1 \leqq r \leqq n_1+n_2;$ $n_1+n_2+1 \leqq \alpha,\ \beta \leqq n_1+n_2+n_3=n$. The nonzero components of the contravariant metric (2.19) are

$$g^{aa}=\frac{\psi^{a1}}{\psi},\quad g^{r\alpha}=B_r^{r\alpha}(x^r)\frac{\psi^{r1}}{\psi},\quad g^{\alpha\beta}=\sum_b A_b^{\alpha\beta}(x^b)\frac{\psi^{b1}}{\psi}, \tag{2.20}$$

where ψ and ψ^{i1} are the determinant and $i1$ cofactors of the $(n_1+n_2)\times(n_1+n_2)$ Stäckel matrix $(\psi_{ij}(x^i))$. Furthermore, $\partial_\alpha g^{ij}=0$ for each *ignorable* variable x^α. The variables x^a and x^r are referred to as *Stäckel* and *first order* variables respectively. Together these variables form the class of essential variables that was mentioned in the Introduction. The form of (2.19) implies that the first order variables are of null-type, and the signature of Minkowski space which is $n-1$ thus limits the number of these variables (n_2) to 1. A discussion of null variables is given in Eisenhart (1949).

Since our problem will be solved using the Hamilton–Jacobi equation (2.18), we first find the Killing vectors corresponding to the first order symmetries of (2.1) and (*) when $E \neq 0$. To find these Killing vectors, we solve the analogue of (1.5):

$$\{H, \mu\}_P = 0 \tag{2.21}$$

where $\{\ ,\ \}_P$ is the Poisson bracket and $\mu = a^j(\mathbf{y})P_j$. When $E \neq 0$ the Hamilton–Jacobi equation (2.18) admits a Lie algebra of Killing vectors which is the Lie algebra of Minkowski space $e(n,1)$. All the coordinate systems we are considering possess the symmetry (2.2) and so by the abelian subalgebra condition all symmetries of (2.1) must commute with (2.2). The Killing vector counterpart of this relation is

$$\{\hat{\varepsilon}, \mu\}_P = 0, \qquad \hat{\varepsilon} = \tfrac{1}{2}(P_{n-1}+P_n) \tag{2.22}$$

where $\hat{\varepsilon}$ is the Killing vector corresponding to (2.2). This extra condition confines us to a subalgebra of $e(n,1)$—the Galilean algebra g_m of dimension $\frac{1}{2}m(m+1)+2$ and basis

$$\hat{\varepsilon},\ P_u,\ M_{uv}=y^uP_v-y^vP_u,\quad B_u=y^u\hat{\varepsilon}-tP_u,\quad K_{-2}=P_t. \tag{2.23}$$

Here $u, v \in U=\{1,\cdots,n-2\}$. In general the indices u and v will be taken from the set U. Since the above Killing vectors form a basis, any Killing vector has the form

$$\lambda_\alpha = \rho_\alpha^u P_u + m_\alpha^{uv}M_{uv} + \beta_\alpha^u B_u + \kappa_\alpha K_{-2}, \tag{2.24}$$

where the ρ_α^u, m_α^{uv}, β_α^u and κ_α are all real constants. The commutation relations for g_m may be derived from Table 2.1. The symmetry algebra for the Helmholtz equation (2.1) ($E \neq 0$) is again g_m with the identifications

$$\begin{gathered}\hat{\varepsilon} \to \tfrac{1}{2}(\partial_{n-1}+\partial_n),\quad P_u \to \partial_u,\quad M_{uv} \to y^u\partial_v - y^v\partial_u,\\ B_u \to y^u\hat{\varepsilon} - t\partial_u,\qquad K_{-2} \to \partial_t.\end{gathered} \tag{2.25}$$

By solving (1.5) for (*) we find that g_m is also the symmetry algebra for (*) except that the operator $\hat{\varepsilon}$ is replaced by its eigenvalue ε.

If $E=0$ the symmetries of (2.1) are of the form a^jP_j+f where $\{H,a^jP_j+f\}_P=M(\mathbf{Y})H$ and then there are two extra symmetries.[1] When expressed as conformal Killing vectors, these are:

$$K_2=-t^2P_t-t\sum_u y^uP_u+\frac{1}{2}\hat{\varepsilon}\sum_u(y^u)^2, \qquad D=\sum_u y^uP_u+2tP_t, \tag{2.26}$$

and as operators for (*)

$$K_2=-t^2\partial_t-t\sum_u y^u\partial_u-\frac{1}{2}mt+\frac{1}{2}\varepsilon\sum_u(y^u)^2, \qquad D=\sum_u y^u\partial_u+2t\partial_t+\frac{1}{2}m. \tag{2.27}$$

These satisfy the commutation relations

$$\begin{aligned}&[D,P_u]=-P_u,\quad [D,M_{uv}]=0,\quad [D,B_u]=B_u,\quad [D,K_{\pm 2}]=\pm 2k_{\pm 2},\\ &[K_2,P_u]=-B_u,\quad [K_2,M_{uv}]=0,\quad [K_2,B_u]=0,\quad [K_2,K_{-2}]=D.\end{aligned} \tag{2.28}$$

This enlarged algebra is the Schrödinger algebra s_m of dimension $\frac{1}{2}m(m+3)+4$.

Geometrically the P_u and M_{uv} are generators of space translations and rotations under which (*) is clearly invariant. Less obvious are the transformations corresponding to the B_u's. These are the Galilean or velocity boosts and illustrate the fact that (*) retains its form in uniformly moving frames of reference. When $E=0$ we have the additional conformal Killing vectors D and K_2. D is the generator of the dilatation symmetry $\Psi(\mathbf{y},t)\to\Psi(\alpha\mathbf{y},\alpha^2t)$. The action of K_2 is rather complicated and it does not have a simple geometrical interpretation.

One of the applications of these symmetry algebras will be to determine the abelian subalgebras corresponding to sets of ignorable variables. Again the action of the group helps us choose simple representatives for these subalgebras. The group acts on the algebra g_m via its *adjoint action*. In general, for two members of a Lie algebra L_1 and L_2, the adjoint action of L_1 on L_2 is given by

$$e^{aL_1}L_2e^{-aL_1}=e^{a\,\mathrm{Ad}\,L_1}L_2 \tag{2.29}$$

where $\mathrm{Ad}\,L_1(L_2)\equiv[L_1,L_2]$. A proof of this result is given by Hausner and Schwartz (1968). The adjoint actions for the Galilean algebra are summarised in Table 2.1. In Table 2.1, each entry represents $e^{a\,\mathrm{Ad}\,L_1}(L_2)$, e.g. $e^{a\,\mathrm{Ad}\,P_u}(B_w)=B_w+a\delta_{uw}\varepsilon/2$. If the adjoint has no effect, i.e. $e^{a\,\mathrm{Ad}\,L_1}(L_2)=L_2$, then there is no entry. From (2.29) the commutation relations are simply the coefficients of a in the table. For example $[M_{uv},P_w]=\delta_{vw}P_u-\delta_{uw}P_v$ where δ_{jk} is the Kronecker delta.

The operators P_u, B_u, ε generate the $(2m+1)$-dimensional Weyl algebra w_m and the M_{uv}'s generate the $\frac{1}{2}m(m-1)$-dimensional orthogonal algebra $o(m)$. If we define

---

[1] The referee has commented that if we consider E-dependent operators, then

$$K_2=-t^2\left(\partial_t-\frac{E}{2\varepsilon}\right)-t\sum_u y^u\partial_u-\frac{1}{2}mt+\frac{1}{2}\varepsilon\sum_u(y^u)^2,$$

$$D=2t\left(\partial_t-\frac{E}{2\varepsilon}\right)+\sum_u y^u\partial_u+\frac{1}{2}m+2\varepsilon Et,$$

are conformal symmetries of (*) even when $E\neq 0$. This reflects the fact that solutions for $E\neq 0$ can be mapped to those for $E=0$ by the E-dependent relation (2.10).

the operators

$$A_1 = D, \quad A_2 = K_2 + K_{-2}, \quad A_3 = K_{-2} - K_2, \tag{2.30}$$

these satisfy the commutation relations

$$[A_1, A_2] = -2A_3, \quad [A_3, A_1] = 2A_2, \quad [A_2, A_3] = 2A_1 \tag{2.31}$$

and form a basis for the Lie algebra $sl(2,\mathbb{R})$. It follows that the structure of s_m is

$$s_m = (sl(2,\mathbb{R}) \oplus o(m)) \oplus w_m. \tag{2.32}$$

where $\oplus$ represents the direct sum and $\oplus$ the indirect sum. Similarly the Galilean algebra has structure

$$g_m = (t_1 \oplus o(m)) \oplus w_m \tag{2.33}$$

where t_1 is the one-dimensional algebra of time translations. Using standard results from Lie theory, these operators can be exponentiated to obtain the Schrödinger and Galilean groups. These groups act on the space of locally analytic functions of the real variables y^j, t and map solutions of (*) into solutions. Expressions for the actions of these groups appear in Miller (1977).

TABLE 2.1

Adjoint actions for the Galilean algebra.

L_1 \ L_2	P_w	M_{wz}	B_w	K_{-2}
P_u		$M_{wz} + a(\delta_{uw}P_z - \delta_{uz}P_w)$	$B_w + \frac{a\delta_{uw}\varepsilon}{2}$	
M_{uv}	$P_w + a(\delta_{vw}P_u - \delta_{uw}P_v) + a^2 \ldots$ †	$M_{wz} + a(\delta_{vw}M_{uz} - \delta_{vz}M_{uw} + \delta_{uz}M_{vw} - \delta_{uw}M_{vz}) + a^2 \ldots$ †	$B_w + a(\delta_{vw}B_u - \delta_{uw}B_v) + a^2 \ldots$ †	
B_u	$P_w - \frac{a\delta_{uw}\varepsilon}{2}$	$M_{wz} + a(\delta_{uw}B_z - \delta_{uz}B_w)$		$K_{-2} + aP_u - \frac{a^2\varepsilon}{4}$
K_{-2}			$B_w - aP_w$	

†The adjoint action of M_{uv} on the P_w's is $e^{a\,\mathrm{Ad}\,M_{uv}}(\rho_u P_u + \rho_v P_v) = \rho'_u P_u + \rho'_v P_v$ where ρ'_u and ρ'_v are determined by

$$\begin{pmatrix} \rho'_u \\ \rho'_v \end{pmatrix} = \begin{pmatrix} \cos(a) & \sin(a) \\ -\sin(a) & \cos(a) \end{pmatrix} \begin{pmatrix} \rho_u \\ \rho_v \end{pmatrix}$$

It acts on the B_u's in exactly the same manner. $(u, v, w, z \in U = \{1, \cdots, n-2\})$.

3. Reducing the Hamilton–Jacobi equation. In this section we find simple forms for both the metric and the Killing vectors, summarising these results in the following theorem.

THEOREM 3.1. *All Hamilton–Jacobi separable coordinate systems for* (2.18) *with Killing vector* $\hat{\varepsilon}$, *are equivalent to a coordinate system associated with the Hamilton–Jacobian equation*

$$g^{11}p_1^2 + \cdots + g^{(n-2)(n-2)}p_{n-2}^2 + g^{nn}p_n^2 + 2p_{n-1}p_n = E. \tag{3.1}$$

Moreover if one variable is first order, and there are r ignorables $x^{\alpha(1)},\cdots,x^{\alpha(r)}$ in addition to x^n, the corresponding Killing vectors are

$$
\begin{aligned}
&\lambda_n=\frac{1}{2}(P_{n-1}+P_n)=\hat{\varepsilon},\\
&\lambda_{\alpha(1)}=M_{12},\cdots,\lambda_{\alpha(p)}=M_{2p-1,2p},\\
&\lambda_{\alpha(p+1)}=P_{2p+1},\cdots,\lambda_{\alpha(q)}=P_{p+q},\\
&\lambda_{\alpha(q+1)}=B_{p+q+1}-\rho^{p+q+1}P_{p+q+1},\cdots,\lambda_{\alpha(r)}=B_{p+r}-\rho^{p+r}P_{p+r}.
\end{aligned}
\tag{3.2}
$$

If there are no first order variables then all the Killing vectors except for one[2] will be those in (3.2).

Proof. Let x^a be a Stäckel variable while x^r is first order. From (2.8)

$$g_{ni}=\frac{\partial t}{\partial x^i} \tag{3.3}$$

so that

$$\frac{\partial t}{\partial x^a}=0,\qquad \frac{\partial t}{\partial x^\alpha}=g_{n\alpha}(x^r), \tag{3.4}$$

since inversion of (2.19) shows that for Stäckel variables $g_{ai}=\delta^{ai}(g^{aa})^{-1}$. The equations in (3.4) can be integrated to give

$$t=h(x^r)+\sum_\alpha g_{n\alpha}(x^r)x^\alpha. \tag{3.5}$$

Now from (3.5) and (2.8)

$$\lambda_\alpha=y^u_\alpha P_u+g_{n\alpha}(P_{n-1}-P_n)+\tfrac{1}{2}f,_\alpha(P_{n-1}+P_n),\quad \alpha\neq n, \tag{3.6}$$

so (2.24) implies

$$g_{n\alpha}=\kappa_\alpha. \tag{3.7}$$

We know from §2 that $n_2\leqq 1$. If $n_2=0$ then;

$$t=\kappa_\alpha x^\alpha\to x^{n-1} \tag{3.8}$$

under a general linear motion amongst the ignorables. Consider $n_2=1$. If for some β, $\kappa_\beta\neq 0$, we can use a general linear motion and then the freedom (1.8b) to transform t to x^{n-2}, i.e.,

$$t\to h(x^{n-1})+x^{n-2}\to x^{n-2}. \tag{3.9}$$

Thus from (3.7), the metric g_{ij} has form:

$$ds^2=\sum_{a=1}^{n_1} g_{aa}(dx^a)^2+\sum_{k,l} g_{kl}dx^k dx^l+2dx^{n-2}dx^n \qquad (n_1+1\leqq k,l\leqq n-1). \tag{3.10a}$$

---

[2] This Killing vector can only be calculated from the coordinate transformations (4.30). It has form $K_{-2}+\beta^u B_u$, but its knowledge was not needed to produce the reduced form of the contravariant metric (3.1). It may be regarded as a special subcase when the first order variable has become ignorable.

The variable x^{n-1} is first order, thus $g^{(n-1)(n-1)}=0$ and by taking the inverse of (3.10a), (g^{ij}) has form

(3.10b)
$$\begin{pmatrix} * & & & & & & & & \\ & \ddots & & & & & & & \\ & & * & & & & & & \\ & & & * & * & \cdots & * & 0 & * & * \\ & & & * & & & \cdot & 0 & * & \cdot \\ & & & \cdot & & & \cdot & \cdot & \cdot & \cdot \\ & & & * & \cdot & \cdots & * & \cdot & \cdot & * \\ & & & 0 & \cdot & & \cdot & 0 & 0 & 1 \\ & & & * & * & \cdots & * & 0 & 0 & * \\ & & & * & \cdot & \cdots & * & 1 & * & * \end{pmatrix}$$

The vectors

(3.11)
$$\begin{aligned} \mathbf{X}^{n-1} &= (0,0,\cdots,0,0,1,0), \\ \mathbf{X}^{n-2} &= (0,0,\cdots,0,1,0,0) \end{aligned}$$

are orthogonal and null with respect to (g^{ij}), which is impossible in Minkowski space (see Eisenhart (1949)). Thus

(3.12)
$$\kappa_\alpha = 0, \quad \text{for } \textit{each } \alpha.$$

It is now possible to use the freedom (1.8a) to change variables so that

(3.13)
$$h(x^{n-1}) \to x^{n-1}.$$

We see that whether x^{n-1} is first order or ignorable the coordinate transformations are

(3.14)
$$\begin{aligned} y^u &= y^u(x^1,\cdots,x^{n-1}), \\ y^{n-1} - y^n &= 2x^{n-1} = 2t, \\ y^{n-1} + y^n &= x^n + f(x^1,\cdots,x^{n-1}). \end{aligned}$$

This is progress as the time coordinate t has been identified as just x^{n-1}.

From (2.24) and (3.14)

(3.15)
$$\lambda_\alpha = \rho_\alpha^u P_u + m_\alpha^{uv} M_{uv} + \beta_\alpha^u B_u, \qquad \alpha \neq n-1.$$

To solve the orbit problem, i.e., to establish the possible commuting sets of Killing vectors, we refer the reader to Reid (1984). The essential element of that argument is to notice that when we set time to be a constant, i.e., $x^{n-1} = \textit{constant} = c$, in the coordinate transformations (3.14), then we have a separable system for $\Delta_m \Psi = E\Psi$, parameterised by c. The results for the orbit analysis for this equation are known (see Kalnins and Miller (1982a)), and are used in Reid (1984) to determine some of the unknown constants in (3.15). Further simplification of the orbits is achieved through the use of the adjoint actions given in Table 2.1. After some work the Killing vectors are shown to have the form given in (3.2). Solving the characteristic equations resulting from (3.2) shows that the metric can be written as

(3.16)
$$ds^2 = \sum_u g_{uu}(dx^u)^2 + g_{(n-1)(n-1)}(dx^{n-1})^2 + 2\,dx^{n-1}\,dx^n.$$

Inversion of (3.16) gives the Hamilton–Jacobi equation in the form (3.1)—all the conditions of Theorem 3.1 have now been satisfied.

By finding the symmetries and using the restrictive signature of Minkowski space we have reduced the nonorthogonal part of the Hamilton–Jacobi equation to one off-diagonal element.

4. Metric and coordinates. In the previous section we established a simple form (3.1) for the contravariant metric and this will enable us to use the curvature conditions (2.12) to determine this form exactly. We will also find the coordinate transformations.

THEOREM 4.1. *The Hamilton–Jacobi equation can be written*

$$\sum_{q\in Q}\frac{1}{\sigma_q}\sum_{b\in B_q}\bar{g}^{bb}p_b^2+2p_{n-1}p_n+\sum_{q\in Q}\frac{V_q}{\sigma_q}p_n^2=E, \tag{4.1}$$

where

$$Q=\{q_i\colon q_1<q_2<\cdots<q_l\} \tag{4.2}$$

is some subset of $U=\{1,\cdots,m\}$ *and the sets*

$$B_{q_i}=\{q_i,q_i+1,\cdots,q_{i+1}-1\},\qquad 1\leqq i\leqq l, \tag{4.3}$$

form a partition of U. *Here* σ_q *is a function of* x^{n-1} *alone, and if* $b\in B_q$

$$\bar{g}^{bb}=\bar{g}^{bb}(x^c),\qquad V_q=V_q(x^c) \tag{4.4}$$

where $c\in B_q$.

As an illustration of the notation used in Theorem 4.1 see (5.14). There $U=Q=\{1,2\}$, $B_1=\{1\}$ and $B_2=\{2\}$. In (5.17) $Q=\{1\}$, $B_1=\{1,2\}$ and $\sigma_1=|(x^3)^2+1|^{1/2}$. To prove the Theorem, we will make use of the following equivalent condition for the Stäckel matrix found by Eisenhart (1934).

LEMMA 4.1. *The nonsingular* $Q\times Q$ *matrix* (ψ_{ij}) *is a Stäckel matrix if and only if*

$$\begin{aligned}\partial_{jk}\log\left(\frac{\psi}{\psi^{i1}}\right)&=\partial_j\log\left(\frac{\psi}{\psi^{i1}}\right)\partial_k\log\left(\frac{\psi}{\psi^{i1}}\right)-\partial_j\log\left(\frac{\psi}{\psi^{i1}}\right)\partial_k\log\left(\frac{\psi}{\psi^{j1}}\right)\\&\quad-\partial_k\log\left(\frac{\psi}{\psi^{i1}}\right)\partial_j\log\left(\frac{\psi}{\psi^{k1}}\right),\qquad 1\leqq j<k\leqq Q.\end{aligned} \tag{4.5}$$

We now prove Theorem 4.1.

Proof of Theorem 4.1. For notational convenience we need only assume $n_2=1$ since the functional form for $n_2=0$ is just a special case. Consider the matrix

$$(\Phi_{ij})=\begin{pmatrix}\psi_{ab} & 0\\ A_{\beta a} & I_{MM}\end{pmatrix} \tag{4.6}$$

where

$$A_{\beta a}=-A_a^{\beta\beta},\qquad \beta=n_1+1,\cdots,n-2 \tag{4.7}$$

is an $M\times N$ matrix ($N=n_1+1, M=n-2-n_1$) and I_{MM} is the $M\times M$ identity matrix. This matrix has the properties

$$g^{aa}=\frac{\Phi^{a1}}{\Phi},\quad g^{\beta\beta}=\frac{\Phi^{\beta 1}}{\Phi},\quad g^{(n-1)n}=1=\frac{\Phi^{(n-1)1}}{\Phi}. \tag{4.8}$$

These will enable us to make extensive use of Lemma 4.1. It follows immediately from (3.1) and Lemma 4.1 that

$$\partial_{v(n-1)}\log g_{uu}=\partial_v\log g_{uu}\partial_{n-1}\log g_{uu}-\partial_v\log g_{uu}\partial_{n-1}\log g_{vv}. \tag{4.9}$$

It is easily shown that

$$R_{vuu(n-1)}=\frac{1}{2}g_{uu}\partial_{v(n-1)}\log(g_{uu}) + \frac{g_{uu}}{4}\left[\partial_v\log(g_{uu})\partial_{n-1}\log g_{uu}-\partial_v\log(g_{uu})\partial_{n-1}\log(g_{vv})\right]=0. \tag{4.10}$$

Substitution of (4.9) into $[\cdot]$ in (4.10) gives

$$\partial_{v(n-1)}\log(g_{uu})=0. \tag{4.11}$$

This implies

$$g_{uu}=\sigma_u(x^{n-1})\bar{g}_{uu} \tag{4.12}$$

where $\bar{g}_{uu}$ does not depend on x^{n-1}. From (4.9) and (4.11)

$$\partial_v\log(g_{uu})\,\partial_{n-1}\log(\sigma_u/\sigma_v)=0. \tag{4.13}$$

We can define an equivalence relation $\sim$ on U by $u\sim v$ if σ_u is proportional to σ_v, and by rescaling coordinates there is no loss in assuming that $\sigma_u=\sigma_v$ on each equivalence class. By reordering the indices, the sets of the partition can be taken to be the B_q's of Theorem 4.1. Furthermore, (4.13) implies that the $\bar{g}_{bb}$'s are only functions of those x^c's in their class, i.e. they satisfy property (4.4) in Theorem 4.1. Defining

$$V_q=\sum_{b\in B_q}\bar{g}^{bb}A_b^{nn}, \tag{4.14}$$

the Hamilton–Jacobi equation takes the form (4.1) given in Theorem 4.1. Q.E.D.

THEOREM 4.2. *The spaces with metrics*

$$d\bar{s}_q^2=\sum_{b\in B_q}\bar{g}_{bb}(dx^b)^2 \tag{4.15}$$

are separable, flat and positive definite. Also we have

$$\partial_{x^cx^d}V_q=0,\quad c\neq d,\quad c,\,d\in B_q. \tag{4.16}$$

Proof. We first show that the metrics (4.15) are differentially flat, separable and positive definite. The flatness conditions $R_{ijkl}=0$ with $i,j,k,l\in B_q$, are equivalent to $\bar{R}_{ijkl}=0$, i.e., those for the metrics in (4.15). It follows that the spaces associated with these metrics are flat. Since the metrics in (4.15) are orthogonal, the separability conditions (4.5) for $i,j,k\in B_q$ can be applied to show that these metrics are also separable. To show that the metrics in (4.15) are positive definite, we first compute the eigenvalues of (4.1). These are

$$\xi_u=g^{uu},\qquad \xi_\pm=\tfrac{1}{2}\left[g^{nn}\pm\sqrt{(g^{nn})^2+4}\right]. \tag{4.17}$$

Regardless of the value of g^{nn} the eigenvalues ξ_+ and ξ_- are positive and negative

respectively. The remaining eigenvalues ξ_u must be positive since the space is Minkowski with signature $n-1$. It now follows from (4.1) that

$$\sigma_q > 0 \quad \text{and} \quad \bar{g}_{uu} > 0, \tag{4.18}$$

redefining σ_q and $\bar{g}_{uu}$ to be their negatives if necessary. This shows that the metrics (4.15) are positive definite.

To prove condition (4.16) of the theorem we notice that since V_q is given by (4.14), the extension of Lemma 4.1 (see (4.8)) can be used to obtain

$$\partial_{cd}V_q + \partial_c V_q \partial_d \log(g_{cc}) + \partial_d V_q \partial_c \log(g_{dd}) = 0. \tag{4.19}$$

Alternatively this result can be obtained by considering the Hamilton–Jacobi equation (artificially created for our purpose) $\Sigma_{b\in B_q}\bar{g}^{bb}p_b^2 + \Sigma_q V_q p_{n-1}^2$. As this equation is separable the results of Lemma 4.1 can be applied: equation (4.19) is derived from (4.5) with $j=c$, $k=d$ and $i=n-1$. Combining this result with the curvature conditions $R_{c(n-1)(n-1)d}=0$, which are equivalent to

$$-\tfrac{1}{2}\partial_{cd}V_q + \partial_c V_q \partial_d \log(g_{cc})/4 + \partial_d V_q \partial_c \log(g_{dd})/4 = 0, \tag{4.20}$$

we obtain condition (4.16). Q.E.D.

We now go on to determine the exact form of the unknown functions $\bar{g}_{bb}$, σ_q, V_q, and hence obtain the classification we are seeking. First since the spaces defined by the metrics (4.15) are positive definite, we can use the results of Kalnins and Miller (1982a), in which they completely classified such spaces; this determines the $\bar{g}_{uu}$'s. By transforming to standard cartesian coordinates on each $\mathbb{R}^{n_q}$, the σ_q and V_q are determined. In transforming back to general separable coordinates, however, the separability is not necessarily preserved, so we find the compatibility conditions to ensure this preservation.

Since the spaces defined by the metrics are flat and positive definite we can choose standard coordinates z^b:

$$z^b = z^b(x^c), \qquad b, c \in B_q, \tag{4.21}$$

and

$$d\bar{s}_q^2 = \sum_{b\in B_q} (dz^b)^2. \tag{4.22}$$

Working in terms of these coordinates (4.19) implies that

$$\partial_{z^c z^d}V_q = 0, \quad c, d \in B_q, \quad c \neq d. \tag{4.23}$$

$R_{(n-1)cc(n-1)}=0$ is equivalent to

$$\frac{1}{2}\sigma_q'' - \frac{(\sigma_q')^2}{4\sigma_q} - \frac{1}{2}\sum_{t\in Q}\frac{V_{t,cc}}{\sigma_t} = 0 \tag{4.24}$$

where the prime denotes differentiation with respect to x^{n-1}. Together with (4.23) this last equation implies that

$$V_q = \sum_{b\in B_q}\left(\frac{\xi_q}{4}(z^b)^2 + \gamma_b z^b\right) + \delta \tag{4.25}$$

and

$$2\sigma_q\sigma_q''-(\sigma_q')^2=\zeta_q,\quad \sigma_q>0,\quad \zeta_q,\delta\in\mathbb{R}. \tag{4.26}$$

Making a transformation of form $x^n\to x^n+g(x^{n-1})$, we can take $\delta=0$ in (4.25). When $\zeta_q\neq 0$ it is possible to translate z^b so that $\gamma_b\to 0$. To solve (4.26), differentiate it to obtain $\sigma'''=0$ and substitute the resulting quadratic into the original equation (4.26). Application of the coordinate freedoms (1.8) leads to the five possibilities $\mathrm{I}\to\mathrm{IV}\pm$ in Table 4.1. The constants ζ_q, γ_b, v_q and w_q are all real.

TABLE 4.1

Possibilities for $\sigma(x^{n-1})$.

Type	σ_q	ζ_q	γ_q
I	1	0	arbitrary
II	$(x^{n-1}+v_q)^2$	0	arbitrary
III	$(x^{n-1}+v_q)$	-1	0
IV$\pm$	$\left\lvert(x^{n-1}+v_q)^2\pm w_q^2\right\rvert$	$\pm 4w_q^2$, $w_q\neq 0$	0

A knowledge of the lower dimensional cases, and a little guesswork leads to the transformations for $n=3(m=1)$. They are

$$\begin{aligned} &y^1=z^1\sigma^{1/2}+\frac{1}{2}\gamma\int\int\sigma^{-3/2},\\ &y^2+y^3=x^3-\sigma'(z^1)^2/4-\frac{1}{2}\gamma z^1\sigma^{1/2}\int\sigma^{-3/2}-\frac{\gamma^2}{8}\int\left(\int\sigma^{-3/2}\right)^2,\\ &y^2-y^3=2x^2, \end{aligned} \tag{4.27}$$

where

$$\int f(y)=\int_{y=y_0}^{x^2} f(y)\,dy. \tag{4.28}$$

We now show that this one-dimensional case forms the building block for all others. Define

$$F_{uq}(z^u,x^{n-1})=z^u\sigma_q^{1/2}+\frac{1}{2}\gamma_u\iint\sigma_q^{-3/2}, \tag{4.29}$$

and

$$G_{uq}(z^u,x^{n-1})=\sigma_q'(z^u)^2/4+\frac{1}{2}\gamma_u z^u\sigma_q^{1/2}\int\sigma_q^{-3/2}+\frac{\gamma_u^2}{8}\int\left(\int\sigma_q^{-3/2}\right)^2, \tag{4.30}$$

then the coordinate transformations are

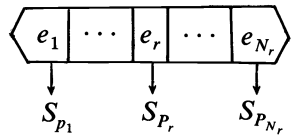
$$\begin{aligned} &y^u=F_{uq},\\ &y^{n-1}+y^n=x^n-\sum_{q\in Q}\sum_{b\in b_q}G_{bq},\\ &y^{n-1}-y^n=2x^{n-1}. \end{aligned} \tag{4.31}$$

These results can be checked by computing the metric using (4.31) and then taking its inverse to obtain the Hamilton–Jacobi equation (4.1). In the above transformations we will say that the γ_u term is *attached* to the z^u coordinate.

To obtain the coordinate transformations in terms of the x^i we simply substitute the expressions given for the z^b in (4.21). Not all the systems thus obtained will be separable. Naturally they will be separable when $\gamma_u=0$ for all u and $\zeta_q=0$, or for all values of these parameters when the coordinates are cartesian. Given a certain separable system (4.21) the problem is to work out the form of V_q (or equivalently the values of the parameters γ_u and ζ_q) to ensure separation in the variables x^i.

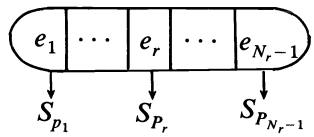
To tackle this problem it is necessary to know just what the possible systems (4.21) are. We give a brief summary of the solution provided by Kalnins and Miller (1982a). They show that it is possible to decompose $\mathbb{R}^n$ into a direct sum of subspaces $\mathbb{R}^{n_r}$ in such a way that the separable coordinates on each of these are of either "elliptic" or "parabolic" type with graphical representations

(4.32A)



or

(4.32B)



respectively. We will say that $\mathbb{R}^n$ *splits* into the subspaces $\mathbb{R}^{n_r}$. Cartesian coordinates on $\mathbb{R}^{n_r}$ for case A are given by

$$z^i=({}_{N_r}w_j)({}_{p_j}s_{q_j}),\qquad 1\leqq i\leqq n_r,\quad 1\leqq j\leqq N_r \tag{4.33A}$$

and for case B

$$\begin{aligned} &z^1=({}_{N_r}w_1),\\ &z^i=({}_{N_r}w_j)({}_{p_j}s_{q_j}),\qquad 2\leqq i\leqq n_r,\quad 2\leqq j\leqq N_r. \end{aligned} \tag{4.33B}$$

Here the ${}_{p_j}s_{q_j}$, $1\leqq q_j\leqq p_j=1$ are coordinates on the p_j-dimensional sphere S_{p_j} and therefore satisfy

$$\sum_{q_j=1}^{p_j+1} {}_{p_j}s_{q_j}^2=1. \tag{4.34}$$

In (4.32) the sphere S_{p_j} is said to be *attached* to e_j or equivalently to the coordinate ${}_{N_r}w_j$. When $p_j=0$, S_{p_j} is the "zero dimensional" or "trivial" sphere. Equivalently there is no sphere attached to ${}_{N_r}w_j$.

For elliptic-type coordinates A

$${}_{N_r}w_j^2=c_r^2\frac{\prod_{l=1}^{N_r}(x_r^l-e_j^r)}{\prod_{l\neq j}(e_l^r-e_j^r)},\qquad j=1,\cdots,N_r, \tag{4.35A}$$

where

$$e_1^r<x_r^1<\cdots<e_{N_r}^r<x_r^{N_r},\qquad c_r,\ e_j^r\in\mathbb{R}.$$

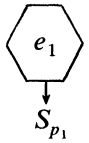
For parabolic coordinates B

$$
\begin{aligned}
{}_{N_r}w_1 &= \frac{c_r}{2}\left(\sum_{l=1}^{N_r} x_r^l + \sum_{l=1}^{N_r-1} e_l^r\right), \\
{}_{N_r}w_j^2 &= -c_r^2 \frac{\prod_{l=1}^{N_r}\left(x_r^l - e_{j-1}^r\right)}{\prod_{l\neq j-1}\left(e_l^r - e_{j-1}^r\right)}, \qquad j=2,\cdots,N_r,
\end{aligned}
\tag{4.35B}
$$

where

$$x_r^1 < e_1^r < \cdots < e_{N_r-1}^r < x_r^{N_r}, \qquad c_r,\ e_j^r \in \mathbb{R}.$$

If the case $N_r=1$ is treated in the same way as $N_r>1$, it is possible to have the elliptic and parabolic systems

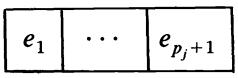


and

corresponding to the metrics $ds^2=(dx^1)^2/(x^1-e_1)$ and $ds^2=(dx^1)^2$ respectively. Both of these systems are equivalent via the scaling transformation (1.8a). This explains why the parabolic case does not appear when $N_r=1$. This will help clarify some of the exceptional behaviour that we will later encounter for $N_r=1$.

The classification also depends on the possible separable systems on the spheres S_{p_j}. The structure of these systems is independent of the V_q and σ_q terms. Separable systems on S_{p_j} can be built from irreducible blocks, each having graphical representation

(4.36)

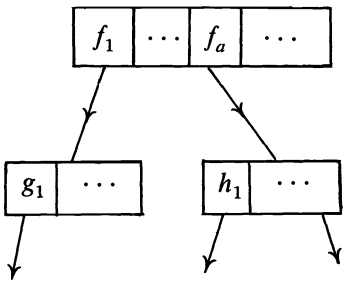


The coordinate transformations for this block are

$$
{}_p s_i^2 = c^2 \frac{\prod_{j=1}^{p}\left(x^j - e_i\right)}{\prod_{j\neq i}\left(e_j - e_i\right)}, \qquad 1 \leqq i \leqq p+1
\tag{4.37}
$$

where $e_1 < x^1 < \cdots < x^p < e_{p+1}$. A general graph for S_{p_j} has form

(4.38)



The coordinates for (4.38) can be built in multiplicative-iterative fashion from those of (4.37). This process is best understood by consulting Kalnins and Miller (1982a) and the examples provided in Tables 2 and 5 of the Appendix.

Applying these results to our case, decomposing the space corresponding to $d\bar{s}_q^2$, corresponds to partitioning B_q into subsets E_r in just the same way that we partitioned

U into the subsets B_q (i.e. the set E_r is labelled by its minimum value r). For example in (5.17), $E_1=\{1\}$, $E_2=\{2\}$, and in (5.22) $E_1=\{1,2\}$. Using this partition,

$$d\bar{s}_q^2=\sum_{r\in\mathscr{R}\cap B_q} d\bar{s}_r^2 \tag{4.39}$$

where $d\bar{s}_r^2$ is the infinitesimal distance

$$d\bar{s}_r^2=\sum_{b\in E_r}\bar{g}_{bb}(d\bar{x}^b)^2. \tag{4.40}$$

Here $\mathscr{R}$ is the set of all the (minimum) indices r (e.g. in both (5.14) and (5.17) $\mathscr{R}=\{1,2\}$). For simplicity on each irreducible block E_r of form (4.32a) or (4.32b) the coordinates x^r, $x^{r+1},\cdots,x^{r+n_r-1}$ are relabelled as x^1, $x^2,\cdots,x^{n_r}$. V_r for each of these blocks is defined as in (4.14) but with b restriced to E_r. Confining ourselves to one of these blocks E_r we systematically determine V_r.

Suppose that $\zeta_q\neq 0$ (i.e. σ_q is of types III or IV$\pm$) on E_r. Here

$$V_r=\sum_{i=1}^{n_r}\frac{\zeta_q}{4}(z^i)^2 \tag{4.41}$$

and from (4.33) and (4.34).

$$V_r=\frac{\zeta_q}{4}\sum_{j=1}^{N_r}{}_{N_r}w_j^2. \tag{4.42}$$

Substituting for the ${}_{N_r}w_j$ from (4.35) and expanding in partial fractions in terms of the e_j's, we find after some time that for the elliptic case A

$$V_r=\frac{\zeta_q c_r^2}{4}\left[\sum_{i=1}^{N_r}x^i-\sum_{i=1}^{N_r}e_i\right], \tag{4.43A}$$

and for the parabolic case B

$$V_r=\frac{\zeta_q c_r^2}{16}\left[2\sum_{i=1}^{N_r}(x^i)^2-\left(\sum_{i=1}^{N_r}x^i\right)^2+6\sum_{i=1}^{N_r}x^i\sum_{t=1}^{N_r-1}e_t-\left(\sum_{t=1}^{N_r-1}e_t\right)^2-2\sum_{t=1}^{N_r-1}e_t^2\right]. \tag{4.43B}$$

However only the V_r of (4.43A) satisfies (4.16). This means that if $\zeta_q\neq 0$ only elliptical-type coordinates are separable.

Now consider $\zeta_q=0$ and suppose that at least one of the γ_i's (γ_k say) is nonzero. In this case σ_q is of type I or II and

$$V_r=\sum_1^{n_r}\gamma_i z^i=\sum_{j=1}^{N_r}{}_{N_r}w_j\sum_{q_j=1}^{p_j+1}\gamma^i_{q_j p_j}s_{q_j}. \tag{4.44}$$

Let x^i be any of the separable coordinates on the sphere S_{p_1}. From (4.16)

$$\partial_{x^1x^i}V_r\left(x^1,x^2=e_2,\cdots,x^{N_r}=e_{N_r}\right)=0=\partial_{x^1}({}_{N_r}w_1)\,\partial_{x^i}\left(\sum_{q_1=1}^{p_1+1}\gamma^1_{q_1 p_1}s_{q_1}\right) \tag{4.45}$$

since ${}_{N_r}w_k(x^k=e_k)=0$. Now $\partial_{x^l}({}_{N_r}w_1)\neq 0$ so that

$$\partial_{x^l}\left(\sum_{q_1=1}^{p_1+1}\gamma^1_{q_1 p_1}{}_{p_1}s_{q_1}\right)=0. \tag{4.46}$$

i.e. $\sum_{q_1=1}^{p_1+1}\gamma^1_{q_1 p_1}{}_{p_1}s_{q_1}=A$, a constant. Such a relation cannot exist among the ${}_{p_1}s_{q_1}$'s unless $p_1=0$. No sphere can be attached to the coordinate ${}_{N_r}w_1$. This is demonstrated as follows. As the $\gamma^1_{q_1}$'s are real, rotations can be used to pass to an equivalent set of separable coordinates ${}_{p_1}\tilde{s}_{q_1}$, for the sphere S_{p_1} such that

$$\sum_{q_1=1}^{p_1+1}\gamma^1_{q_1 p_1}{}_{p_1}s_{q_1}\to\left[\sum_{q_1}\left(\gamma^1_{q_1}\right)^2\right]^{1/2}_{p_1}\tilde{s}_1. \tag{4.47}$$

Since $\sum_{q_1}(\gamma^1_{q_1})^2\neq 0$ equation (4.46) now implies

$$\partial_{x^l}({}_{p_1}\tilde{s}_1)=0, \quad \text{for } \textit{all } l. \tag{4.48}$$

This is only possible if $p_1=0$, i.e, no sphere is attached to the ${}_{N_r}w_1$ coordinate.

Still assuming $\zeta_q=0$ and $\gamma_k\neq 0$, consider the elliptic case. Let $N_r=1$. No spheres are attached to ${}_1w_1$ by the argument above and so $z^1={}_1w_1=x^1$. Condition (4.16) is satisfied and the system is separable. Let $N_r\geqq 2$. Using the above argument and the symmetry of the elliptic coordinate transformations (4.35A) shows that no spheres (beside the trivial ones) can be attached to any of the ${}_{N_r}w_j$ coordinates. Let x^1 and x^2 be any two of the elliptic-type coordinates in (4.35A). Equation (4.16) yields

$$\partial_{x^1x^2}V_r=0=\sum_i\frac{\gamma_i\,{}_{N_r}w_i}{4(x^1-e_i)(x^2-e_i)}. \tag{4.49}$$

Multiplying this last expression by $(x^2-e_2)^{1/2}$ and setting $x_i=e_i$ for $i\geqq 2$, we find that $\gamma_2=0$. This result is easily generalised to show that $\gamma_i=0$, for all i: contradicting our initial assumption that one of the γ_i's was nonzero. Under these conditions, it follows that the elliptic block E_r leads to separability only if $V_r=0$.

In the parabolic case using the same methods we find that only γ_1 can be nonzero and then

$$V_r=\gamma_1\,{}_{N_r}w_1=\frac{1}{2}\gamma_1 c_r\left(x^1+\cdots+x^{N_r}+e_1+\cdots+e_{N_r-1}\right). \tag{4.50}$$

i.e. parabolic coordinates are separable in this case.

Finally if $\gamma_1=0=\zeta_q$ (i.e. σ_q is of type I or II), then both elliptic or parabolic type blocks are possible.

We have determined all Euclidean coordinate systems that can combine with a given V_q to form a separable system for (4.1). Thus using the results of §2 the R-separation problem for (*) has been solved. This procedure is systematised in graphical form in the next section.

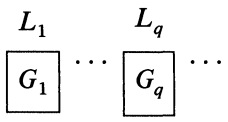
5. Graphical representation of coordinates. We develop a graphical calculus to represent the R-separable coordinate systems for (*), illustrating this procedure in detail for $m=1,2,3$—the cases of physical interest.

From (4.28) and (4.30) the coordinate transformations for (*) are given by

$$y^u=z^u\sigma_q^{1/2}+\frac{1}{2}\gamma_u\iint\sigma_q^{-3/2}, \qquad u\in B_q, \quad q\in Q, \tag{5.1}$$
$$t=x^{n-1},$$

and these can be given the graphical representation

(5.2)



Here G_q is a separable system on $\mathbb{R}^{n(B_q)}$ and the box indicates that there is just one function σ_q on G_q, while the Latin number L_q(I, II, III or IV$\pm$) specifies its type. G_q is one of Kalnins and Miller's graphs and will in general have form

$$G_q^1 \cdots G_q^r \cdots \tag{5.3}$$

where each G_q^r is one of the elliptic or parabolic types given in (4.32A) and (4.32B).

At the end of the last section we found the compatibility conditions for a $\sigma_q - G_q^r$ combination to be separable. To summarise these results we start with a given separable Euclidean system G_q^r and then give the compatible σ functions.

If G_q^r is of elliptic-type, then L_q could take any of its values I $\to$ IV$\pm$. However the cases $\zeta_q = 0$, $\gamma_u \neq 0$ where x^u is one of the coordinates on G_q^r can only occur if G_q^r has form $\langle\!\overline{e}\!\rangle$. If the block G_q^r is of parabolic-type, it is only compatible with the σ-types I and II since it was shown in §4 that $\zeta_q \neq 0$ did not satisfy (4.16). In the allowed cases I and II, the γ_u term *attaches* itself to the coordinate ${}_{N_r}w_1$ of (4.35B).

These results are now generalised to a block of form

(5.4)

If all the G_q^r's are of elliptic-type, then L_q can take any of its values, I $\to$ IV$\pm$. The parameters γ_u on G_q can only be nonzero if the blocks G_q^r to which they are attached have form $\langle\!\overline{e}\!\rangle$.

If at least one G_q^r is of parabolic-type, then L_q is restricted to types I or II. The exceptional case $N = 1$ can be given our uniform general treatment if we regard it as being equivalent to the two systems $\bigcirc$ and $\langle\!\overline{e}\!\rangle$ as discussed in §4. A γ_u term can be attached to $\bigcirc$ (no spheres can be attached to this graph). Spheres can be attached to $\langle\!\overline{e}\!\rangle$ and this is compatible with $\zeta_q \neq 0$ but not with $\zeta_q = 0$ and $\gamma_u \neq 0$.

The parameters w_q and v_q can be normalised, since by making the separability preserving transformations

$$x^{n-1} \to ax^{n-1} + b, \tag{5.5}$$

we can take one v_q to be zero and one w_q to be 1. Further normalisations are possible when $E = 0$ because of the extra conformal symmetries K_2 and D. For instance, consider the case when one of the L_q's is I in (5.2). The coordinates on this block are

$$y^b = z^b + \gamma_b (x^{m+1})^2/4, \qquad b \in B_q. \tag{5.6}$$

The dilatation D acts on the coordinates as

$$y^b \to cy^b, \quad t \to c^2 t, \quad c \in \mathbb{R}. \tag{5.7}$$

If this action is combined with the *equivalence* transformations

$$z^b \to cz^b, \qquad x^{m+1} \to c^2 x^{m+1}, \tag{5.8}$$

and $c=\gamma_b^{-1/3}$ then γ_b can be normalised to 1 or 0. If L_q is II on a block, then the same normalisation is possible by similar methods. There are more equivalences possible under the conformal symmetries, but the discussion of these will be postponed until the operators have been determined in §6. It is not possible to simultaneously normalise all the γ_b's. There is a different coordinate system for each vlaue of γ_b. Thus in general, there is an infinite number of R-separable coordinate systems for (*) and the numbering of these systems in the Appendix is for tidiness only.

The following procedure emerges for the construction of all R-separable systems for (*).

A. Construct the graphs representing all separable systems on $\mathbb{R}^m$.

B. For each of these construct all possible boxings.

C. From the discussion above determine all possible σ's compatible with the boxings.

We now go through this procedure for $m=1$.

A. There is only one possible separable system on $\mathbb{R}^1$

(5.9) 

corresponding to the choice of coordinate

(5.10) $$z^1=x^1.$$

B. There is only one possible boxing:

(5.11)  .

C. The resulting types with their coordinate transformations are listed in Table 1 of the Appendix.

We have displayed possible normalisations of the parameters v_q, w_q in brackets alongside L_q, but have not substituted their values in the coordinate transformations since the unnormalised forms will be needed for the $m=2$ and $m=3$ classifications.

For $m=2$ the separable systems resulting from step A are listed in Table 2 of the Appendix. There are three classes of boxings arising from step B.

(5.12a) 
where G is the elliptic, parabolic or polar system of Table 2 in the Appendix,

(5.12b) 
and

(5.12c) 
where G_c is $\langle\overline{0}\rangle$. The only new systems are those of type (5.12a) as it will be shown that the remaining systems can be derived from the $m=1$ case. The unsplit class a types are

listed in Table 3 of the Appendix. The class b systems are mixtures of the $m=1$ systems

$$\overset{L_1}{\boxed{G_c}} \quad \text{and} \quad \overset{L_2}{\boxed{G_c}} \tag{5.13}$$

where $\sigma_1 \neq \sigma_2$, and these are listed in Table 4 of the Appendix. $\mathbb{R}^2$ has *split* into $\mathbb{R} \oplus \mathbb{R}$ and so these coordinate systems are referred to as *splitting types*. For example, the system 5: II, III ($v_2=0$) in Table 4 has coordinate transformations

$$\begin{aligned} y^1 &= (x^3+v_1)x^1 + \gamma_1/4(x^3+v_1), \\ y^2 &= |x^3|^{1/2}x^2, \\ t &= x^3 \end{aligned} \tag{5.14}$$

that are easily derived from systems II and III in Table 1. The remaining systems of class c are simply combinations of the $m=1$ systems

$$\overset{L_1}{\boxed{G_c}} \quad \text{and} \quad \overset{L_1}{\boxed{G_c}} \tag{5.15}$$

where $\sigma_1=\sigma_2$, that is class b with $L_1=L_2$. They are listed in Table 4 of the Appendix. For example the coordinate transformations for IV$+(v_1=0, w_1^2=1)$ can be derived from those of the system

$$\overset{IV+(v_1=0,\, w_1^2=1)}{\boxed{\langle 0 \rangle}} \tag{5.16}$$

given in Table 1. They are

$$\begin{aligned} y^1 &= \left|(x^3)^2+1\right|^{1/2}x^1, \\ y^2 &= \left|(x^3)^2+1\right|^{1/2}x^2, \\ t &= x^3. \end{aligned} \tag{5.17}$$

Miller (1977) has also classified the R-separable systems for $m=2$ and developed many of their properties but misses splitting types such as (5.14) and (5.17). In general, his classification only includes those mixing types of class b for which one of the coordinates is $y^1=x^1$. These omissions are rectified in Kalnins and Miller (1979).

For general m the R-separable systems have form

$$\overset{L_1}{\boxed{G}}, \tag{5.18}$$

where G is of parabolic or elliptic-type, or they will be a mixture of systems like (5.2). In this case (*) is equivalent to the equations

$$(\Delta_q + 2\varepsilon\partial_t)\Psi_q = T_q\Psi_q, \qquad \Psi = \prod_{q\in Q}\Psi_q, \tag{5.19}$$

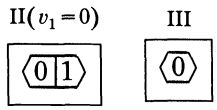
where

$$\Psi_q = \Psi_q(x^b), \qquad b \in B_q. \tag{5.20}$$

All such mixtures can be classified from the lower dimensional equations given in (5.19).

The classification for $m=3$ for the unsplit types given in Table 5 of the Appendix has not appeared before. These systems can of course be derived from our general procedure but we list them for easy access. The splitting types for $m=3$ can be derived from the tables for $m=1$ and $m=2$ given in the Appendix. For example consider

(5.21)



for which the coordinates are

$$\begin{aligned} y^1 &= cx^4 \cosh(x^1)\cos(x^2), \\ y^2 &= cx^4 \sinh(x^1)\sin(x^2), \\ y^3 &= |x^4 + v_3|^{1/2} x^3, \\ t &= x^4, \end{aligned} \tag{5.22}$$

and these can be obtained from the tables for $m=1$ and $m=2$.

6. Operators. Each R-separable system for $(*)$ is characterised as a commuting set of second order differential operators that are in the enveloping algebra of $(*)$. These operators are derived from those representing separable systems on $\mathbb{R}^m$. In this way we will establish the connection between separation of variables for $(*)$ and the symmetry group of $(*)$.

We will first derive the operators for (2.1) from the Killing tensors λ_i for the Hamilton–Jacobi equation (4.1) associated with (2.1). The Killing tensors characterising separable systems for (4.1) are of second order, and the work of Thomas (1946) implies that they are in the enveloping algebra of $e(n,1)$. In other words if the Killing vectors μ_j are a basis for $e(n,1)$ then there are real constants a^{jk} such that

$$\lambda_i = \sum_{j,k} a^{jk} \{\mu_j, \mu_k\}, \qquad 1 \leqq i,j,k \leqq n. \tag{6.1}$$

Recall that $\{\cdot,\cdot\}$ is the symmetric bracket which is defined by

$$\{\mu_j, \mu_k\} = \frac{\mu_j \mu_k + \mu_k \mu_j}{2}. \tag{6.2}$$

By a simple generalisation of the work of Kalnins and Miller (1977) the corresponding operators $\tilde{\lambda}_i$ for (2.1) can be obtained by the identification $\mu_j \to \tilde{\mu}_j$ defined in (2.25) so that

$$\tilde{\lambda}_i = \sum_{j,k} a^{jk} \{\tilde{\mu}_j, \tilde{\mu}_k\}. \tag{6.3}$$

These will also be operators for $(*)$ with the identification $\hat{\varepsilon} \to \varepsilon$ since

$$\tilde{\lambda}_i = \overline{\Psi} = l_i \overline{\Psi} \quad \text{iff} \quad \tilde{\lambda}_i \Psi = l_i \Psi \tag{6.4}$$

where $\overline{\Psi}$ and Ψ are defined in (2.7).

The work of Shapovalov (1979), and Kalnins and Miller (1981) provides the machinery to determine the Killing tensors. They are

$$\lambda_i = \sum_{a=1}^{n-2} \frac{\Phi^{ai}}{\Phi} p_a^2 + 2\frac{\Phi^{(n-1)i}}{\Phi} p_{n-1}p_n + \sum_{a=1}^{n-2} \frac{\Phi^{ai}}{\Phi} A_a^{nn} p_n^2, \qquad i=1,2,\cdots,n-1, \tag{6.5}$$

where (Φ_{ij}) is the Stäckel matrix defined in (4.6). We first find this matrix in terms of the Stäckel matrices for the embedded separable Euclidean systems $d\bar{s}_q^2$. These are the $n(B_q)\times n(B_q)$ dimensional matrices, $(\Phi_q)_{ij}$, such that

$$\bar{g}^{bb} = \frac{\Phi_q^{b1}}{\Phi_q}, \qquad \Phi_q = \det\left((\Phi_q)_{ij}\right). \tag{6.6}$$

The matrix (Φ_{ij}) can be taken as

$$\begin{pmatrix} 0 & \boxed{\Phi_1} & \cdots & 0 & \cdots & 0 \\ \vdots & & \ddots & & & \\ & & 0 & \boxed{\Phi_q} & \cdots & \\ 0 & & & \vdots & \ddots & \\ 1 & \frac{-1}{\sigma_1} & 0 & \cdots & \frac{-1}{\sigma_q} \quad 0 & \cdots \end{pmatrix} \tag{6.7}$$

since this matrix satisfies

$$g^{bb} = \frac{\Phi^{b1}}{\Phi} = \frac{1}{\sigma_q}\frac{\Phi_q^{b1}}{\Phi_q}, \quad \text{for } b \in B_q \tag{6.8}$$

By substituting for (Φ_{ij}) from (6.7) into (6.5), the Killing tensors are

$$\begin{aligned} &\lambda_v = \sum_{b\in B_q} \frac{\Phi_q^{bv}}{\Phi_q} p_b^2 + U_v p_n^2, \\ &v = 1,2,\cdots,m, \\ &\lambda_{m+1} = E, \end{aligned} \tag{6.9}$$

where

$$U_v = \sum_{b\in B_q} \frac{\Phi_q^{bv}}{\Phi_q} A_b^{nn}. \tag{6.10}$$

In (6.9) the terms $\Sigma_{b\in B_q}(\Phi_q^{bv}/\Phi_q)p_b^2$ can be recognised as having the same form as that for the constants of the motion for the separable system $d\bar{s}_q^2$. This fact will guide us in what follows.

The constant of the motion λ_v may also be written

$$\lambda_v = \mathbf{p}^t \Lambda_v \mathbf{p} \tag{6.11}$$

where

$$\mathbf{p}=\begin{pmatrix} p_1 \\ \vdots \\ p_n \end{pmatrix},$$

and

$$\Lambda_v=\begin{pmatrix} 0 & & & & & & \\ & \ddots & & & & 0 & \cdots \\ & & & & \Lambda_v^E & & \\ & & & \iddots & & \ddots & \\ & & 0 & & & & \\ \cdots & & & & & & U_v \end{pmatrix}. \tag{6.12}$$

Here Λ_v^E is a diagonal matrix whose elements as determined by (6.9) are $(\Lambda_v^E)_{bc}=\delta^{bc}\Phi_q^{bv}/\Phi_q$. It is what will be called the matrix form of the Euclidean constants of the motion arising on $d\bar{s}_q^2$. We express λ_v in terms of the y^i coordinates by using the transformation matrix J:

$$J_{ab}=\frac{\partial y^b}{\partial x^a}. \tag{6.13}$$

In the y^i coordinates

$$\lambda_v=\mathbf{P}^t J^t \Lambda_v J \mathbf{P} \tag{6.14}$$

where

$$\mathbf{P}=\begin{pmatrix} P_1 \\ \vdots \\ P_n \end{pmatrix}, \qquad P_i=\partial_{y^i} W. \tag{6.15}$$

and t denotes matrix transposition. Using (6.13) J is given by

$$\begin{pmatrix} \sigma_1^{1/2}J_1 & & \cdots & & & \mathbf{c}_1 & \mathbf{c}_1 \\ & \ddots & & & 0 & \vdots & \vdots \\ & & \sigma_q^{1/2}J_q & & & \mathbf{c}_q & \mathbf{c}_q \\ & 0 & & \ddots & & \vdots & \vdots \\ B_1 & \cdots & B_q & \cdots & & X & Y \\ 0 & \cdots & 0 & \cdots & & \tfrac{1}{2} & \tfrac{1}{2} \end{pmatrix} \tag{6.16}$$

where from (4.30)

$$(\mathbf{c}_q)_a=-\frac{1}{2}\partial_{x^a}\sum_{b\in B_q} G_{bq} \quad \text{and} \quad (J_q)_{ab}=\partial z^b/\partial x^a. \tag{6.17}$$

As our final result is independent of the quantities B_q, X and Y we need not calculate

them. Finally

$$\lambda_v=\sigma_q\mathbf{P}_q^t\tilde{\Lambda}_v^E\mathbf{P}_q-\mathbf{P}_q^t\varepsilon\left[\sigma_q'\sigma_q^{1/2}\tilde{\Lambda}_v^E\mathbf{z}_q+\sigma_q^{1/2}\left(\int\sigma_q^{-3/2}\right)\tilde{\Lambda}_v^E\boldsymbol{\gamma}_q\right]+F_v\varepsilon^2. \tag{6.18}$$

In this equation

$$F_v=4\mathbf{c}_q^t\tilde{\Lambda}_v^E\mathbf{c}_q+U_v,\qquad \tilde{\Lambda}_v^E=J^t\Lambda_u^EJ \tag{6.19a}$$

and $\boldsymbol{\gamma}_v$, $\mathbf{P}_q$ and $\mathbf{z}_q$ are $n(B_q)\times 1$ vectors:

$$(\boldsymbol{\gamma}_q)_b=\gamma_b,\quad(\mathbf{P}_q)_b=P_b,\quad(\mathbf{z}_q)_b=z^b,\quad b\in B_q. \tag{6.19b}$$

From (6.19a) $\tilde{\Lambda}_v^E$ is just Λ_v^E in the z^b coordinates. Equation (6.18) implies that the constants of the motion for $v\in B_q$ do not depend on the structure of (*) on any of the other blocks. This is natural since (*) is equivalent to the set of lower dimensional equations given in (5.19). The problem of finding the operators for a general system has now reduced to the determination of the constants of the motion on one of the blocks

$$\begin{matrix}L_q\\ \boxed{G_q}\end{matrix}. \tag{6.20}$$

Kalnins and Miller (1982a) give specific formulae for the Euclidean constants of the motion $\tilde{\Lambda}_{\lesssim}^E$. On each irreducible block they find that

$$P_b^2,\ M_{ab}^2 \text{ and } \{M_{qb},P_b\},\qquad a,\ b\in B_q, \tag{6.21}$$

are a basis so that

$$\tilde{\Lambda}_v^E=\sum_b A^bP_b^2+\sum_b B^b\{M_{qb},P_b\}+\sum_{a<b}C^{ab}M_{ab}^2,\qquad A^b,\ B^b,\ C^{ab}\in\mathbb{R}. \tag{6.22}$$

The reader is referred to Kalnins and Miller (1982a) for the determination of the constants in (6.22). Since (6.18) provides us with a relation of form

$$\lambda_v=\lambda_v\left(\tilde{\Lambda}_v^E,\sigma_q\right) \tag{6.23}$$

all that has to be done for each of the σ's for $\mathrm{I}\to\mathrm{IV}\pm$, is to determine the images of the Euclidean constants of the motion in (6.21). In each case we will find an expression λ' in the enveloping algebra such that λ is determined to within a term in ε^2 i.e.

$$\lambda=\lambda'+F'\varepsilon^2. \tag{6.24}$$

(In this discussion prime is not the derivative). Since λ is a constant of the motion and λ' is in the enveloping algebra

$$\{E,\lambda\}_P=0=\{E,\lambda'+F'\varepsilon^2\}_P=\{E,F'\varepsilon\}. \tag{6.25}$$

Solving this relation with $E=P_1^2+\cdots+P_{n-1}^2-P_n^2$ we find that F' is a constant, but since ε is already on the orbit

$$\lambda=\lambda' \tag{6.26}$$

in (6.24).

The images of the Euclidean operators are displayed in Table 6.1; however one example will be done in detail to show how they are derived. Consider the term $\{M_{qb}, P_b\}$ which appears in constants of the motion in parabolic-type coordinates. The matrix form $\tilde{\Lambda}^E$ for this term is

$$\begin{pmatrix} & & -z^b/2 & & \\ & & 0 & & \\ & & \cdot & & \\ & & \cdot & & \\ -z^b/2 & 0 \quad \cdots & z^q & \cdots & 0 \\ & & \cdot & & \\ & & \cdot & & \\ & & 0 & & \end{pmatrix} \tag{6.27}$$

as it is easily checked that $\mathbf{P}^t\tilde{\Lambda}^E\mathbf{P} = \{M_{qb}, P_b\}$. From (4.30) and (4.50)

$$\begin{aligned} y^q &= z^q + \gamma_q (x^{n-1})^2/4, \\ y^b &= z^b, \qquad b \neq q. \end{aligned}$$

The calculation for the constant of the motion corresponding to $\{M_{qb}, P_b\}$ goes as follows:

$$\begin{aligned} \lambda\big(\{M_{qb}, P_b\}, \sigma = 1\big) &= \{z^q P_{y^b} - z^b P_{y^q}, P_b\} - \mathbf{P}_q^t x^{n-1} \tilde{\Lambda}^E \gamma_q \varepsilon + F\varepsilon^2 \\ &= \{M_{qb}, P_b\} - \frac{1}{4}\gamma_q (x^{n-1})^2 P_b^2 + \frac{1}{2}\gamma_q x^{n-1} P_b \varepsilon + F'\varepsilon^2 \\ &= \{M_{qb}, P_b\} - \gamma_q B_b^2/4 \end{aligned} \tag{6.28}$$

since $F' = 0$ from the discussion above. The corresponding operator for (2.1) and (*) is obtained via (6.3) but it may be unambiguously written as (6.28) by removing the tildes. Occasionally P_b has been used to represent both the Euclidean constant of the motion $\partial W/\partial z^b$ and $\partial W/\partial y^b$, a constant of the motion for the Hamilton–Jacobi equation (4.1). Sometimes, as in (6.28), we have written P_{y^b} to emphasise the difference.

TABLE 6.1
Images of Euclidean operators.

$\tilde{\Lambda}^E$	L_q			
	I	II	III	IV±
P_b^2	$P_b^2 + \gamma_b \varepsilon B_b$	$(v_q P_b - B_b)^2 + \gamma_b \varepsilon P_b$	$v_q P_b^2 - \{P_b, B_b\}$	$(v_q P_b - B_b)^2 \pm w_q^2 P_b^2$
M_{ab}^2	M_{ab}^2	M_{ab}^2	M_{ab}^2	M_{ab}^2
$\{M_{qb}, P_b\}$	$\{M_{qb}, P_b\} - \gamma_q B_b^2/4$	$\{M_{qb}, v_q P_b - B_b\} - \gamma_q P_b^2/4$	does not occur	does not occur

The results in Table 6.1 can be used to obtain the operators for any m but we will go through these results in detail for $m = 1$ and $m = 2$.

When $m = 1$ the Euclidean operator is P_1^2, and its images can be read from the row containing P_b^2 in Table 6.1 obtaining the results listed in Table 1 of the Appendix.

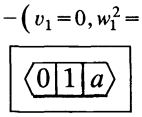
When $m=2$ the operators resulting from the unmixed systems are listed in Table 3 of the Appendix. The operators for the mixing systems are simply those of the component one-dimensional systems. For example the two Euclidean operators for (5.14) are P_1^2 and P_2^2 and by using Table 6.1 their images are

$$(v_1P_1-B_1)^2+\gamma_1\varepsilon P_1, \text{ and } -\{P_1,B_1\}. \tag{6.29}$$

Alternatively the same result is easily obtained from Table 1 of the Appendix.

In the three-dimensional case the operators have not been listed in the Appendix, but the following example will show how they are obtained. Consider system 4 of Table 6 in the Appendix.

(6.30)



The operators for ellipsoidal coordinates are easily derived from the work of Kalnins and Miller (1982a) but we also record them in Table 5. They are

$$\begin{aligned} &P_1^2+P_2^2+P_3^2,\\ &\mathbf{J}\cdot\mathbf{J}+c^2\left[(1+a)P_1^2+aP_2^2+P_3^2\right],\\ &J_2^2+aJ_3^2+c^2aP_1^2. \end{aligned} \tag{6.31}$$

Employing Table 6.1,

$$J_b^2\to J_b^2, \qquad P_b^2\to B_b^2-P_b^2, \qquad b=1,2,3 \tag{6.32}$$

so that the operators for (6.30) are

$$\begin{aligned} &\sum_b\left(B_b^2-P_b^2\right), \mathbf{J}\cdot\mathbf{J}+c^2\left[(1+a)\left(B_1^2-P_1^2\right)+a\left(B_2^2-P_2^2\right)+B_3^2-P_3^2\right],\\ &J_2^2+aJ_3^2+c^2a\left(B_1^2-P_1^2\right). \end{aligned} \tag{6.33}$$

The operators for the $m=3$ mixing types are also computed in the same fashion. For instance the operators for the mixing type (5.21) can be derived from the tables for the one- and two-dimensional cases. They are

$$B_1^2+B_2^2, \quad M_{12}^2+c^2B_1^2 \quad \text{and} \quad v_3P_3^2-\{P_3,B_3\}. \tag{6.34}$$

All R-separable systems for the $m=3$ for (*) have been characterised as commuting sets of second order partial differential operators which are members of the enveloping algebra. An immediate application for this characterisation is now given.

All separable systems on $\mathbb{R}^m$ possess the Casimir operator $\Sigma_{u=1}^m P_u^2$. If $E=0$ and our systems have form

(6.35)

then the operators corresponding to this invariant for each of the σ types are:

$$
\begin{aligned}
&\text{I} && \sum_1^m P_b^2+\gamma_1\varepsilon B_1,\\
&\text{II} && \sum_1^m B_b^2+\gamma_1\varepsilon P_1,\\
&\text{III} && \sum_1^m \{P_b,B_b\},\\
&\text{IV}\pm && \sum_1^m B_b^2\pm\sum_1^m P_b^2.
\end{aligned}
\tag{6.36}
$$

By examining the forms of the operators in (2.25)→(2.26) the following substitutions hold on the solution space of (*) when $E=0$.

$$
\sum_1^m P_b^2\to -2\varepsilon K_{-2},\quad \sum_1^m \{P_b,B_b\}\to\varepsilon D \quad\text{and}\quad \sum_1^m B_b^2\to 2\varepsilon K_2. \tag{6.37}
$$

With these substitutions, the new expressions for the operators in (6.36) are summarised in Table 6.2.

TABLE 6.2

L_1	Operator
I	$\varepsilon[\gamma_1 B_1-2K_{-2}]$
II	$\varepsilon[2K_2+\gamma_1 P_1]$
III	εD
IV±	$\varepsilon[K_2\mp K_{-2}]$

Each of the operators in Table 6.2 is first order and can be diagonalised to reduce (*) by a dimension. This feature is discussed by Miller (1977) for the one and two-dimensional heat equations. His claim, however, that this is a feature of all systems of those dimensions does not hold. For example the operators (6.29) of the splitting type (5.14) can never be made first order.

The knowledge of the operators will now be exploited to find the extra equivalences for $E=0$ that were mentioned in §5. For a system like (6.35) it is possible, as was explained in §5, to normalise γ_1 to 0 or 1. Thus there are the possibilities for L_1:

$$
\begin{aligned}
&1 \quad \text{a.} \quad \text{I} \quad (\gamma_1=0)\\
&\quad\ \ \text{b.} \quad \text{I} \quad (\gamma_1=1)\\
&2 \quad \text{a.} \quad \text{II} \quad (v_1=0,\gamma_1=0)\\
&\quad\ \ \text{b.} \quad \text{II} \quad (v_1=0,\gamma_1=1)\\
&3 \quad\ \ \text{III} \quad (v_1=0)\\
&4 \quad \text{a.} \quad \text{IV}- \quad (v_1=0,w_1^2=-1)\\
&\quad\ \ \text{b.} \quad \text{IV}+ \quad (v_1=0,w_1^2=1).
\end{aligned}
\tag{6.38}
$$

The extra equivalences occur under the action of the operator $A_3=K_{-2}-K_2$. The

adjoint action of this operator is given in Table 6.3.

TABLE 6.3
Adjoint action of A_3.

λ	$e^{s\,\mathrm{Ad}\,A_3}\lambda$
P_a	$\cos(s)P_a+\sin(s)B_a$
M_{ab}	M_{ab}
B_a	$\cos(s)B_a-\sin(s)P_a$
A_1	$A_1\cos(2s)-A_2\sin(2s)$
A_2	$A_2\cos(2s)-A_1\sin(2s)$

The adjoint action of A_3 on any element $\{L_1,L_2\}$ of the enveloping algebra is easily shown to be

$$e^{s\,\mathrm{Ad}\,A_3}(\{L_1,L_2\})=\{e^{s\,\mathrm{Ad}\,A_3}(L_1),e^{s\,\mathrm{Ad}\,A_3}(L_2)\} \tag{6.39}$$

by using (2.29). Consider the action of A_3 when $s=-\pi/4$ and for convenience let $J=e^{-\pi A_3/4}$. Then from (2.29)

$$e^{-\pi\,\mathrm{Ad}\,A_3/4}(L)=JLJ^{-1}. \tag{6.40}$$

The Euclidean operators for (∗) are

$$\tilde{\lambda}_v^E=\sum_b A_v^b P_b^2+\sum_b B_v^b\{M_{qb},P_b\}+\sum_{a<b} C_v^{ab}M_{ab}^2 \tag{6.41}$$

where $v=1,\cdots,m+1$. For case 3 in (6.38), $B_v^b=0$ always, since such terms can only appear for parabolic type coordinates. The corresponding operators as obtained from Table 6.1 are

$$\lambda_v=-\sum_b A_v^b\{P_b,B_b\}+\sum_{a<b} C_v^{ab}M_{ab}^2. \tag{6.42}$$

If the action of J is applied to these operators using Table 6.3 we obtain

$$\lambda'_v=-\sum_b A_v^b\left\{\frac{P_b}{\sqrt{2}}-\frac{B_b}{\sqrt{2}},\frac{B_b}{\sqrt{2}}+\frac{P_b}{\sqrt{2}}\right\}+\sum_{a<b} C_v^{ab}M_{ab}^2 \tag{6.43}$$

$$=\sum_b A_v^b(B_b^2-P_b^2)/2+\sum_{a<b} C_v^{ab}M_{ab}^2$$

since $P_b\to P_b/\sqrt{2}-B_b/\sqrt{2}$, $B_b\to B_b/\sqrt{2}+P_b/\sqrt{2}$ and $M_{ab}\to M_{ab}$ under the action of J. The expression obtained in (6.43) is precisely the one that would have been obtained from the same Euclidean operators for system 4a in (6.38). In similar fashion it can be shown that the systems 1a and 1b are equivalent to the systems 2a and 2b respectively under the action of

$$J^2=e^{-\pi A_3/2}. \tag{6.44}$$

We have demonstrated that the systems in (6.38) collapse to the systems 1a, 1b, 3 and 4b. The action of J on solutions of (*) is

$$
\begin{aligned}
&J\Phi(\mathbf{y},t)=\left[\frac{\sqrt{2}}{(1+t)}\right]^{m/2}\exp\left[\frac{\varepsilon\mathbf{y}\cdot\mathbf{y}}{2(1+t)}\right]\Phi\left(\frac{\sqrt{2}\,\mathbf{y}}{t+1},\frac{t-1}{t+1}\right),\\
&J^2\Phi(\mathbf{y},t)=t^{-m/2}\exp\left[\frac{\varepsilon\mathbf{y}\cdot\mathbf{y}}{2t}\right]\Phi\left(\frac{\mathbf{y}}{t},\frac{-1}{t}\right),\\
&J^4\Phi(\mathbf{y},t)=-\Phi(-\mathbf{y},t),\\
&J^8\Phi(\mathbf{y},t)=\Phi(\mathbf{y},t).
\end{aligned}
\tag{6.45}
$$

The expression for J^2 is particularly notable: it is the *Appell* transform, and its importance for the theory of the Heat equation is discussed in Widder (1975). The above work is a generalisation of that of Miller (1977) for the one and two-dimensional heat equations.

In conclusion, it is possible to exploit the conformal symmetries for unsplit systems when $E=0$ to show that some systems that look different are actually equivalent under the action of the Schrödinger group.

7. *R*-separable solutions. We now investigate the R-separable solutions of (*). To accomplish this, it is necessary to determine both the R-separation factors and the *separation equations*. The separation equations for (*) are the ordinary differential equations determining the Ψ_j functions in (2.5). From (2.7) these are the same as the corresponding functions for the Helmholtz equation (2.1). Therefore this equation is used to find the separation equations for (*). The form of (2.1) in the separable coordinates x^i can be found by using this equations local coordinate description given in (2.14). It is

$$
\begin{aligned}
\sum_{q\in Q}\frac{1}{\sigma_q}\sum_{b\in B_q}&\left[\bar{g}_q^{-1/2}\partial_b\left(\bar{g}^{bb}\bar{g}_q^{1/2}\partial_b\Psi\right)+\bar{g}^{bb}A_b^{nn}\partial_{nn}\Psi\right]\\
&+2\partial_{(n-1)n}\Psi+\frac{1}{2}\sum_{q\in Q}n(B_q)(\log\sigma_q)'\partial_n\Psi=E\Psi
\end{aligned}
\tag{7.1}
$$

where

$$
\bar{g}_q=\det(\bar{g}_{bc}),\qquad b,c\in B_q,
\tag{7.2}
$$

and A_b^{nn} is defined in (4.14). When $\Psi=\Pi_{i=1}^n\Psi_i(x^i)$ is substituted into (7.1) and the resulting equation is divided by Ψ we obtain the separation equations:

$$
\Psi_n'=\varepsilon\Psi_n,
\tag{7.3}
$$

and

$$
2\varepsilon\Psi_{n-1}'+\sum_{q\in Q}\frac{s_q}{\sigma_q}\Psi_{n-1}+\frac{\varepsilon}{2}\sum_{q\in Q}n(B_q)(\log\sigma_q)'\Psi_{n-1}=E\Psi_{n-1}.
\tag{7.4}
$$

Here s_q is the eigenvalue of the operator S_q whose action on Ψ is

$$
S_q\Psi=\sum_{b\in B_q}\left[\bar{g}_q^{-1/2}\partial_b\left(\bar{g}^{bb}\bar{g}_q^{1/2}\partial_b\Psi\right)+(\varepsilon)^2\bar{g}^{bb}A_b^{nn}\Psi\right]=s_q\Psi.
\tag{7.5}
$$

The remaining separation equations are derived from (7.5) by noticing it is the Helmholtz equation on $d\bar{s}_q^2$ with an extra term

$$\sum_{b\in B_q} (\varepsilon)^2 \bar{g}^{bb} A_b^{nn} \Psi. \tag{7.6}$$

By a simple modification of Kalnins and Miller's results for $\mathbb{R}^{n(B_q)}$ we obtain these equations.

The one-dimensional elliptic case is an exception to the general construction of the separation equations that we are about to give. The separation equation for this case is

$$\frac{d^2\Psi_1}{(dx^1)^2} + \left\{ \varepsilon^2 \left[\zeta_1 (x^1)^2/4 + \gamma_1 x^1 \right] - s_1 \right\} \Psi_1 = 0. \tag{7.7}$$

Returning to our general treatment, we can confine ourselves to a block E_r of form (4.32A) or (4.32B). For simplicity on each of these irreducible blocks the coordinates x^r, $x^{r+1}, \cdots, x^{r+n_r-1}$ are relabelled as x^1, $x^2, \cdots, x^{n_r}$ just as in our discussion of the coordinate transformations at the end of §4. The additional term contributed to the separation equations by (7.6) for the elliptic-type A coordinates x^a is

$$Z_a = -\frac{(\varepsilon)^2 c_r^4 \zeta_q}{16} (x^a)^{N_r-1} \left(x^a - \sum_{b=1}^{N_r} e_b \right), \qquad a = 1, 2, \cdots, N_r. \tag{7.8A}$$

For the parabolic-type B coordinates x^a this term is

$$Z_a = \frac{(\varepsilon)^2 c_r^3 \gamma_1}{8} (x^a)^{N_r-1} \left(x^a + \sum_{b=1}^{N_r-1} e_b \right), \qquad a = 1, 2, \cdots, N_r. \tag{7.8B}$$

The separation equations in both of these cases are

$$(P_a/Q_a)^{1/2} \frac{d}{dx^a} \left[(P_a Q_a)^{1/2} \frac{d}{dx^a} \Psi_a \right] + \left\{ \sum_{b=1}^{N_r} \frac{\Pi_{c\neq b}(e_b - e_c)}{(x^a - e_b)} t_b + \sum_{b=1}^{N_r} l_b (x^a)^{N_r-b} + Z_a \right\} \Psi_a = 0. \tag{7.9}$$

In this last equation

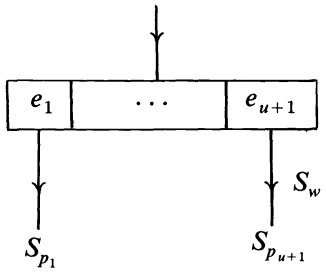
$$P_a = \prod_{b=1}^{N_r} (x^a - e_b), \qquad Q_a = \prod_{b=1}^{N_r} (x^a - e_b)^{p_b}$$
$$t_b = \begin{cases} 0, & p_b = 0 \\ j_b(j_b + p_b - 1), & p_b \neq 0 \end{cases} \tag{7.10}$$

where p_b is the dimension of the sphere S_{p_b} attached to e_b (see (4.32A) and (4.32B)). If there is no sphere attached, then $p_b = 0$. From (7.5) there is no loss in assuming $l_1 = -s_1$. The constant t_b is the eigenvalue of the Helmholtz equation on the sphere S_{p_b}.

The form of t_b given in (7.10) appears in Kalnins and Miller (1982a) and is derived from the spectral theory of the Sphere.

We now consider the separation equations for the remaining variables i.e. those on the attached spheres S_{p_b}. As was mentioned in §4 the separable systems for such spaces have been classified by Kalnins and Miller (1982a). If we trace down one of the tree graphs they use to represent these systems, it will have form (see (4.38))

(7.11)



The separation equations for the variables $x^1, \cdots, x^u$ on S_w are

$$(7.12)\qquad \left(\frac{P_a}{Q_a}\right)^{1/2}\frac{d}{dx^a}\left[(P_aQ_a)^{1/2}\frac{d}{dx^a}\Psi_a\right] + \left\{\sum_{b=1}^{u+1}\frac{\Pi_{c\neq b}(e_b-e_c)}{(x^a-e_b)}t_b+\sum_{b=1}^{u}l_b(x^a)^{u-b}\right\}\Psi_a=0, \qquad a=1,2,\cdots,u,$$

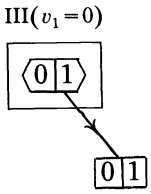
with the same definitions for P_a, Q_a and t_b except that the number of elliptic or parabolic coordinates N_r is replaced by u. We can of course take $-l_1$ as the value of the Helmholtz equation on the sphere S_w and via the spectral theory to be $-\mu(\mu+w-1)$ (see Talman (1968)). These separation equations are unaffected by the terms V_q and σ_q, and are just the same as they would be on Euclidean space.

The separation equation for x^{n-1}, (7.4), can be directly integrated:

$$(7.13)\qquad \Psi_{n-1}=\left\{\prod_{q\in Q}\sigma_q^{-n(B_q)/4}\right\}\exp\left(\frac{1}{2\varepsilon}\left[Ex^{n-1}-\sum_{q\in Q}s_q\int\frac{dx^{n-1}}{\sigma_q}\right]\right).$$

As an example consider system 9 in Table 6 of the Appendix:

(7.14)



The separation equations for this system are

$$(7.15)\quad (x^a)^{1/2}\frac{d}{dx^a}\left[x^a(x^a-1)\frac{d}{dx^a}\Psi_a\right] + \left\{\frac{j_2^2}{(x^a-1)}+-s_1x^a+l_2+\frac{(\varepsilon)^2c_r^4}{16}x^a(x^a-1)\right\}\Psi_a=0, \qquad a=1,2,$$

and

$$[x^3(x^3-1)]^{1/2}\frac{d}{dx^3}\left([x^3(x^3-1)]^{1/2}\frac{d}{dx^3}\Psi_3\right)-j_2^2\Psi_3=0. \tag{7.16}$$

Here s_1, l_2 and j_2^2 are the separation constants. These coordinates are in standard form but they could easily be transformed to the more familiar expressions in terms of cos, sinh etc. that appear in the Appendix. Indeed letting $x^3=\sin^2\vartheta$, (7.16) becomes

$$\frac{1}{4}\frac{d^2\Psi_\vartheta}{d\vartheta^2}+j_2^2\Psi_\vartheta=0.$$

We also have from (7.13)

$$\Psi_4=|x^4|^{-3/4-s_1/2\varepsilon}e^{Ex^4/2\varepsilon} \tag{7.17}$$

In order to fully determine the R-separable solutions, we now find the R-separation factor R. From (2.9) and (4.30)

$$R=-\varepsilon f=\varepsilon\sum_{q\in Q}\sum_{b\in B_q}G_{bq}. \tag{7.18}$$

If we define

$$R_r=\varepsilon\sum_{b\in E_r}G_{bq}, \tag{7.19}$$

then

$$R=\sum_{q\in Q}\sum_{r\in\mathscr{R}}R_r, \tag{7.20}$$

as a result the essential structure of the R-separation factor is solely dependent on the structure of each of the irreducible blocks E_r. Employing (4.50), it can be assume that $\gamma_{r+1}=\gamma_{r+2}=\cdots=0$, with γ_r being nonzero and zero in the parabolic and elliptic cases respectively. By using (7.18) we obtain

$$R_r=\varepsilon\left\{\frac{\sigma_q'}{4}\sum_{b\in E_r}(z^b)^2+\frac{1}{2}\gamma_r z^r\sigma_q^{1/2}\int\sigma_q^{-3/2}\right\}+\frac{\varepsilon\gamma_r^2\delta_{rq}}{8}\int\left(\int\sigma_q^{-3/2}\right)^2. \tag{7.21}$$

The last term of R_r is a function of x^{n-1} alone and so only contributes to trivial R-separation and can be absorbed in $\Psi_{n-1}(x^{n-1})$. An expression for $\Sigma(z^b)^2$ term in R_r in the separable coordinates x^k can be easily obtained from (4.41), (4.43A) and (4.43B). The expression for z^r in the x^k can be found from (4.50) since only parabolic coordinates can correspond to the linear potential term $\gamma_r z^r$. Thus it is always possible to give the R-factors in the x^k coordinates. These general expressions are summarised in Reid (1984). In each case the R-factor is independent of the variables on the spheres S_{p_b}. The R-separation factors corresponding to the unmixed types $m=1,2,3$ are given in the Appendix. The R-separation factors for the two-dimensional mixing types may be obtained simply from those for the one dimension. Similar comments apply for $m=3$.

In one and two dimensions separation equations can be solved to give known special functions. Miller (1977) lists these results and investigates some of their properties (e.g. bases and overlaps for the Schrödinger equation). In higher dimensions, however, the separation equations lead to new special functions about which little is known. Development of the properties of these functions is a problem for future research.

Conclusion. All R-separable coordinate systems have been classified and characterised in terms of the symmetry group of equation (∗). In a subsequent article we will investigate the applications of this group theoretical characterisation. Moving boundary value problems will be considered. It will be shown how the results for the potential free Schrödinger equation can be applied to equations in which the potential term need not vanish. Boyer (1974), (1976) has classified all time-independent potentials for the Schrödinger equation which admit symmetry groups. Exact forms were obtained for those potentials invariant under the Schrödinger algebra of maximal dimension. In particular he has shown how these cases: the potential free Schrödinger equation, the linear potential Schrödinger equation and the harmonic oscillator Schrödinger equations are all equivalent under the action of the Schrödinger group. Miller (1977) has shown how this equivalence is connected with the separability properties of the one and two dimensional Schrödinger equations: we will generalise his result. The programme initiated by Kalnins and Miller for the one and two-dimensional Schrödinger equations will also be pursued: deriving results about the functions arising as separated solutions of (∗), using the group theoretical characterisations of these systems.

Appendix. The main purpose of this appendix is to summarise in tabular form results concerning R-separation for $m=1,2$ and 3.

In all the tables $\sigma_{\mathrm{II}} \to \sigma_{\mathrm{IV}\pm}$ are the functions of Table 4.1, that is

$$\sigma_{\mathrm{II}} = (x^{m+1}+v)^2,$$
$$\sigma_{\mathrm{III}} = |x^{m+1}+v|,$$

and

$$\sigma_{\mathrm{IV}\pm} = \left|(x^{m+1}+v)^2 \pm w^2\right|, \qquad x^{m+1}=t. \tag{A1}$$

As we have already mentioned

$$\tau = \operatorname{sign}\left((x^{m+1}+v)^2 \pm w^2\right). \tag{A2}$$

In the tables for the unsplit systems we have ambiguously removed the subscripts from the parameters so that $v_1 \to v$, $w_1 \to w$ and $\gamma_1 \to \gamma$.

The general forms for elliptic and parabolic coordinates in (4.35) can be transformed to give their more familiar appearance in low dimensions. For example we make the transformations

$$\sqrt{x^1} \to \cosh(x^1), \qquad \sqrt{x^2} \to \cos(x^2) \tag{A3}$$

to give elliptic coordinates their "usual" appearance in Table 2. It must be remembered, however, that in higher dimensions this is not always possible. For cases like the ellipsoidal coordinates of Table 5 the general forms of (4.35) must be used. In Table 5, $J_1 = M_{32}$, $J_2 = M_{13}$, $J_3 = M_{21}$ and $\mathbf{J}\cdot\mathbf{J} = \sum_{i=1}^{3} J_i^2$.

In the tables some of the parameters e_r have been normalised. In general by making the transformations

(A4) $$x^i \to ax^i + b, \qquad e_i \to ae_i + b$$

an elliptic block

(A5) 
and become

(A6) 
TABLE 1

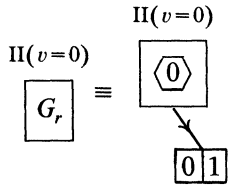
Analogous remarks apply to parabolic blocks and to those representing separable systems on the spheres S_{p_b}. As a final remark, the split types for $m=3$ may be obtained from the results for $m=1$ and $m=2$ (i.e. from Tables 1 and 3). For a brief discussion see (5.19)→(5.22).

Acknowledgments. This article is the culmination of the early work of Charles Boyer, Ernest Kalnins and Willard Miller. To all of these people, my thanks. I would like to thank Ernest Kalnins especially, for his time, suggestions and encouragement.

Notes.

Table 3. The results of Table 2 have been used to simplify the presentation of this table. For example in system 8



and $y^u=\sigma_{\mathrm{II}}^{1/2}z_r^u$ is

$$y^1=|x^3+v|x^1\cos(x^2),$$
$$y^2=|x^3+v|x^1\sin(x^2).$$

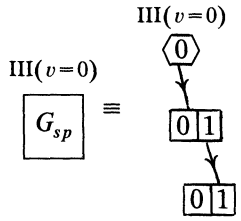
(Recall that $t=x^3$ for these systems.)

Table 4. An entry L_1 L_2 in this table corresponds to the split coordinate system

$$y^1=\sigma_{L_1}^{1/2}x^1+\frac{1}{2}\gamma_1\iint\sigma^{-3/2},$$
$$y^2=\sigma_{L_2}^{1/2}x^2+\frac{1}{2}\gamma_2\iint\sigma^{-3/2},$$
$$t=x^3,\qquad L_i\colon \mathrm{I}\to\mathrm{IV}\pm.$$

An entry L_1 in part c of Table 4 has coordinate transformations as above but with $L_1=L_2$.

Table 6. In analogy to the case $m=2$ we have used the results of Table 5 to simplify the presentation of Table 6. For instance in system 19



and $y^u=\sigma_{\mathrm{III}}^{1/2}z_{sp}^u$ is

$$y^1=|x^4+v|^{1/2}x^1\cos(x^2),$$
$$y^2=|x^4+v|^{1/2}x^1\sin(x^2)\cos(x^3),$$
$$y^3=|x^4+v|^{1/2}x^1\sin(x^2)\sin(x^3).$$

AN INTEGRAL TRANSFORM INVOLVING HEUN FUNCTIONS AND A RELATED EIGENVALUE PROBLEM*

G. VALENT†

Abstract. An integral transform involving Heun functions is obtained. When combined with the explicit solutions given by Carlitz new closed integral representations are obtained for some Heun functions. As an application we solve an eigenvalue problem related to birth and death processes obtaining the exact spectrum and eigenfunctions. A direct proof of their orthogonality and completeness is given.

1. Introduction. Heun's differential equation [1] is the most general second order differential equation with four regular singular points located at $z=0,\ 1,\ 1/k^2,\ \infty$ where we take the real parameter k^2 in the domain $\mathcal{D}_0=\{k^2 \mid 0\leqq k^2\leqq k_0^2<1\}$ for some fixed k_0.

Heun's equation is given by

$$\frac{d^2y}{dz^2}+\left(\frac{\gamma}{z}-\frac{\delta}{1-z}-\frac{\varepsilon k^2}{1-k^2z}\right)\frac{dy}{dz}+\frac{\alpha\beta k^2z+s}{z(1-z)(1-k^2z)}y=0, \tag{1.1}$$

$$\alpha+\beta=\gamma+\delta+\varepsilon-1, \tag{1.2}$$

where s is the so-called "accessory parameter".

Most of what is known about solutions of this equation is summarized in [2, p. 57]. The most important result is the existence of expansions of Heun's functions in terms of hypergeometric functions. The coefficients of such expansions obey a three term recurrence formula which makes them hard to use. Furthermore it does not seem possible to obtain explicitly the eigenvalues from such expansions.

The solutions of (1.1) which may be considered as the elliptic generalization of the hypergeometric function (in the same sense as Jacobi elliptic functions generalize the trigonometric ones) are of interest in many physical problems. Nevertheless little effort has been made to obtain explicit integral representations for them. Since the fifties, as far as we know, the main progress has been due to Carlitz [3] who obtained a finite set of nontrivial exact solutions for (1.1). (By nontrivial, we mean solutions for arbitrary values of the accessory parameter s.) It is interesting to note that he found these solutions in a study of orthogonal polynomials for which Heun's functions appear as generating functions and not in a direct analysis of (1.1).

In this article we shall give an integral transform relating two Heun's functions with different parameters. This comes about if one looks for a solution of (1.1) as a Mellin transform (in the sense of [4, p. 195]) whose kernel is itself a Heun function. Unexpectedly this transform is successful, and when combined with the explicit solutions given by Carlitz, it leads to a finite set of new integral representations for Heun's functions.

As an application we discuss thoroughly an eigenvalue problem which is relevant to the study of quadratic birth and death processes (see [5] for an introduction). Upon use of a previously derived integral representation we obtain the exact eigenvalues and eigenfunctions.

*Received by the editors January 14, 1983, and in revised form June 6, 1984.

†Laboratoire de Physique Théorique et Hautes Energies, Université Paris VII, 75251 Paris Cedex, France. The Laboratory is associated with Centre National de la Recherche Scientifique.

Contrary to the case where $k^2=0$, for nonvanishing k^2 the eigenfunctions *are no longer polynomials* with respect to the variable. Nevertheless it is possible to give a direct proof of the orthogonality of the eigenfunctions, to compute their norm and to prove their completeness in the space of square integrable functions with the weight $w(x)=(1-x)^{-1}$.

The eigenvalues display a continuous dependence for $k^2\in\mathscr{D}_0$ while for $k^2\to 1$ they all vanish, a fact related to a deep change in the nature of the spectrum which becomes continuous.

2. Connection relations for Heun functions. We shall denote a Heun function by the symbol

$$H(\alpha,\beta;\gamma,\delta,\varepsilon;k^2,s;z)\equiv H(P;k^2,s;z),$$
$$P=\{\alpha,\beta;\gamma,\delta,\varepsilon\}.$$

By a Heun function, we mean the solution of (1.1) which is holomorphic in a finite neighbourhood of $z=0$. For $\mathrm{Re}\,\gamma>0$, using the Wronskian, we readily prove that this solution is *unique*. In all that follows, we take $\mathrm{Re}\,\gamma>0$, and normalize H by

$$H(P;k^2,s;0)=1. \tag{2.1}$$

To make things more precise, we shall suppose that H is analytic in some domain $D=\{z\,||z|\leqq R\}$ with fixed (and at the moment unknown) $R>0$. R will be prescribed later.

We define a transformation of the parameters P by

$$P'=T_\alpha P\Leftrightarrow\begin{cases}\gamma'=\alpha,\\ \alpha'=\gamma,\\ \delta'=\delta+\gamma-\alpha,\\ \beta'=\beta,\\ \varepsilon'=\varepsilon+\gamma-\alpha.\end{cases} \tag{2.2}$$

This transformation is such that relation (1.2) still holds for the new parameters.

We consider the function

$$G(z)=\int_0^1 dt\,t^{c-1}(1-t)^{\gamma-c-1}H(P';k^2,s;zt)$$
$$\equiv\int_0^1 dt\,U(t)H(P';k^2,s;zt),$$

with the restrictions

$$\mathrm{Re}\,\gamma>\mathrm{Re}\,c>0. \tag{2.3}$$

Let us define the differential operator

$$\mathscr{L}_z(P)=z(1-z)(1-k^2z)\frac{d^2}{dz^2}$$
$$+\left[\gamma(1-z)(1-k^2z)-\delta z(1-k^2z)-\varepsilon k^2z(1-z)\right]\frac{d}{dz}+\alpha\beta k^2z+s.$$

We shall prove that $G(z)$ is holomorphic for $z\in D$ and is annihilated by $\mathscr{L}_z(P)$. This will imply that $G(z)$ is a Heun function with parameters P.

We divide the proof into several lemmas.

LEMMA 1. *$G(z)$ is holomorphic for $z\in D$.*

Proof. $H(P';k^2,s;zt)$ and $(\partial/\partial z)H(P';k^2,s;zt)$ are holomorphic with respect to z uniformly for $t\in[0,1]$. One has the obvious inequality

$$\left|t^{c-\alpha}(1-t)^{\gamma-c-1}\frac{\partial}{\partial z}H(P';k^2,s;zt)\right|\leqq t^{\mathrm{Re}(c-1)}(1-t)^{\mathrm{Re}(\gamma-c-1)}\left|\frac{\partial}{\partial z}H(P';k^2,s;zt_0)\right|$$

for some $t_0\in[0,1]$ and the left-hand member is integrable over $t\in[0,1]$ because of (2.3). This shows the holomorphy of $G(z)$ for $z\in D$ and the legitimacy of bringing the derivatives with respect to z inside the integral over t.

Next we prove:

LEMMA 2. $\mathscr{L}_z(P)G(z)=0, \qquad z\in D.$

Proof. Using Lemma 1, a straightforward but lengthy computation, we obtain

$$\mathscr{L}_z(P)G(z)=\int_0^1 dtU(t)M_vH(P';k^2,s;v)+A/z+B\cdot(k^2z) \tag{2.4}$$

where

$$v=zt,$$

$$M_v=v(1-v)(1-k^2v)\frac{d^2}{dv^2}+\{c-[\gamma+\delta+(\gamma+\varepsilon)k^2]v+dv^2\}\frac{d}{dv}+s+ev,$$

$$A=\int_0^1 dtU(t)\left[t(1-t)\frac{\partial^2}{\partial t^2}+(\gamma t-c)\frac{\partial}{\partial t}\right]H(P';k^2,s;v),$$

$$B=\int_0^1 dtU(t)\left\{t^2(1-t)\frac{\partial^2}{\partial t^2}+t\left(1+\alpha+\beta-\frac{dt}{k^2}\right)\frac{\partial}{\partial t}+\alpha\beta-e\cdot\frac{t}{k^2}\right\}H(P';k^2,s;v).$$

At that stage the constants c,d,e are free parameters to be adjusted later on.

As is apparent from (2.4), it is crucial for this integral transform to be successful that the coefficients A and B vanish.

Let us begin with A. Integrating by parts, we find that

$$A=-t^c(1-t)^{\gamma-c}\frac{\partial}{\partial t}H(P';k^2,s;zt)\Big|_{t=0}^{t=1} \tag{2.5}$$

since

$$U(t)=t^{c-1}(1-t)^{\gamma-c-1}.$$

On account of (2.3) and the holomorphy of Heun function, the right side of (2.5) vanishes.

We now consider B. We choose the constants c,d,e as

$$c=\alpha, \quad d=(\beta+\gamma+1)k^2, \quad e=\beta\gamma k^2$$

and integrate by parts twice to obtain

$$B=t^2(1-t)U(t)\frac{\partial}{\partial t}H(P';k^2,s;zt)+\beta t(1-t)U(t)H(P';k^2,s;zt)\Big|_{t=0}^{t=1}.$$

These terms vanish in view of (2.3) which now reads

$$\operatorname{Re}\gamma>\operatorname{Re}\alpha>0.$$

Using the values of c,d,e, we note that M_v is nothing but $\mathscr{L}_v(P')$ which precisely annihilates $H(P';k^2,s;v)$. This constitutes the proof of Lemma 2.

An immediate consequence is:

THEOREM 1. *If* 1) $\operatorname{Re}\gamma>\operatorname{Re}\alpha>0$, *and* 2) $P'=T_\alpha P$ *given by* (2.2), *then for* $z\in D$ *we have*

$$(2.6)\qquad H(P;k^2,s;z)=\frac{\Gamma(\gamma)}{\Gamma(\alpha)\Gamma(\gamma-\alpha)}\int_0^1 dt t^{\alpha-1}(1-t)^{\gamma-\alpha-1}H(P';k^2,s;zt).$$

Proof. $G(z)$ is holomorphic for $z\in D$ and is annihilated by $\mathscr{L}_z(P)$. We know that there is a unique solution to this problem which is $H(P;k^2,s;z)$ and hence $G(z)$ is related to it up to a multiplicative constant which is obtained by letting $z\to 0$ and using (2.1).

Analytic continuation will extend Theorem 1 to the complex plane with a cut along the positive real axis for $\operatorname{Re}z\geqq 1$.

Let us make some remarks on this result.

First, Erdélyi had already obtained [6] an integral equation for Heun functions. In his case, however, $P'=P$ and he deals with a kernel containing at least one hypergeometric function. His result is therefore completely different from (2.6).

Secondly, it is interesting to see what happens when $k^2\to 0$. In this case Heun functions become hypergeometric functions, and (2.6) degenerates in an integral relation due to Bateman

$${}_2F_1(a,b;c;z)=\frac{\Gamma(c)}{\Gamma(\alpha)\Gamma(c-\alpha)}\int_0^1 dt t^{\alpha-1}(1-t)^{c-\alpha-1}{}_2F_1(a,b;c;zt),\quad \operatorname{Re}c>\operatorname{Re}\alpha>0.$$

Thirdly, since $H(P';k^2,s;z)$ is a symmetric function of α and β, we can write down (2.6) with β in place of α everywhere in the right-hand member (and in that case $\operatorname{Re}\gamma>\operatorname{Re}\beta>0$).

We define

$$P'=T_\beta P\Leftrightarrow\begin{cases}\alpha'=\alpha, & \gamma'=\beta,\\ \beta'=\gamma, & \delta'=\delta+\gamma-\beta,\\ & \varepsilon'=\varepsilon+\gamma-\beta.\end{cases}$$

Combining T_α and T_β, we have

$$T_\alpha^2=T_\beta^2=\text{identity},$$
$$T_\alpha T_\beta=T_\alpha,\qquad T_\beta T_\alpha=T_\beta,$$

which shows that no new relation can be obtained by iteration.

3. Integral representations for some particular Heun functions. Let us first recall the remarkable results obtained by Carlitz [3]. We refer to the article for the derivation and we give only the results.

Consider

$$f_1=\cos\left(2\sqrt{s}\,\mathrm{sn}^{-1}(\sqrt{z}\,;k^2)\right),$$
$$f_2=\sin\left(2\sqrt{s}\,\mathrm{sn}^{-1}(\sqrt{z}\,;k^2)\right)$$

where the square root determination is taken to be positive for real positive argument.

The inverse function of the Jacobi elliptic function $\mathrm{sn}(z;k^2)$ is also multiple valued and we take the branch which vanishes for $z=0$.

One can check that f_1, f_2 are two linearly independent solutions of Heun's equations with parameters

$$\alpha=0,\quad \beta=\tfrac{1}{2},\quad \gamma=\delta=\varepsilon=\tfrac{1}{2}.$$

Putting

$$f=z^a(1-z)^b(1-k^2z)^c g,$$
$$a\left(a-\tfrac{1}{2}\right)=b\left(b-\tfrac{1}{2}\right)=c\left(c-\tfrac{1}{2}\right)=0,$$

we find, in turn, other solutions with different parameters. We list below the explicit form of Carlitz solutions normalized as in (2.1)

(3.1)

$$H\left(0,\frac{1}{2};\frac{1}{2},\frac{1}{2},\frac{1}{2};k^2,s_0;z\right)=\cos\left(2\sqrt{s_0}\,\zeta\right),$$
$$H\left(\frac{1}{2},1;\frac{3}{2},\frac{1}{2},\frac{1}{2};k^2,s_0-\frac{1+k^2}{4};z\right)=\frac{\sin\left(2\sqrt{s_0}\,\zeta\right)}{2\sqrt{s_0}\sqrt{z}},$$

$$H\left(\frac{1}{2},1;\frac{1}{2},\frac{3}{2},\frac{1}{2};k^2,s_0-\frac{1}{4};z\right)=\frac{\cos\left(2\sqrt{s_0}\,\zeta\right)}{\sqrt{1-z}},$$
$$H\left(\frac{1}{2},1;\frac{1}{2},\frac{1}{2},\frac{3}{2};k^2,s_0-\frac{k^2}{4};z\right)=\frac{\cos\left(2\sqrt{s_0}\,\zeta\right)}{\sqrt{1-k^2z}},$$

$$H\left(1,\frac{3}{2};\frac{3}{2},\frac{3}{2},\frac{1}{2};k^2,s_0-1-\frac{k^2}{4};z\right)=\frac{\sin\left(2\sqrt{s_0}\,\zeta\right)}{2\sqrt{s_0}\sqrt{z(1-z)}},$$
$$H\left(1,\frac{3}{2};\frac{3}{2},\frac{1}{2},\frac{3}{2};k^2,s_0-k^2-\frac{1}{4};z\right)=\frac{\sin\left(2\sqrt{s_0}\,\zeta\right)}{2\sqrt{s_0}\sqrt{z(1-k^2z)}},$$

$$H\left(1,\frac{3}{2};\frac{1}{2},\frac{3}{2},\frac{3}{2};k^2,s_0-\frac{1+k^2}{4};z\right)=\frac{\cos\left(2\sqrt{s_0}\,\zeta\right)}{\sqrt{(1-z)(1-k^2z)}},$$

$$H\left(\frac{3}{2},2;\frac{3}{2},\frac{3}{2},\frac{3}{2};k^2,s_0-1-k^2;z\right)=\frac{\sin\left(2\sqrt{s_0}\,\zeta\right)}{2\sqrt{s_0}\sqrt{z(1-z)(1-k^2z)}},$$

$$\zeta=\mathrm{sn}^{-1}(\sqrt{z}\,;k^2).$$

Using Theorem 1, we get four new integral representations

$$
\begin{aligned}
&H\left(\frac{1}{2},\frac{1}{2};1,0,1;k^2,s_0-\frac{k^2}{4};z\right)=\frac{1}{\pi}\int_0^1 \frac{dt}{\sqrt{t(1-t)}}\cdot\frac{\cos\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{zt};k^2)\right)}{\sqrt{1-k^2zt}},\\
&H\left(\frac{1}{2},\frac{1}{2};1,1,0;k^2,s_0-\frac{1}{4};z\right)=\frac{1}{\pi}\int_0^1 \frac{dt}{\sqrt{t(1-t)}}\cdot\frac{\cos\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{zt};k^2)\right)}{\sqrt{1-zt}},
\end{aligned}
\tag{3.2}
$$

$$
H\left(\frac{1}{2},\frac{3}{2};1,1,1;k^2,s_0-\frac{1+k^2}{4};z\right)=\frac{1}{\pi}\int_0^1 \frac{dt}{\sqrt{t(1-t)}}\cdot\frac{\cos\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{2t};k^2)\right)}{\sqrt{(1-zt)(1-k^2zt)}},
$$

$$
H\left(\frac{3}{2},\frac{3}{2};2,1,1;k^2,s_0-1-k^2;z\right)=\frac{2}{\pi}\int_0^1 \frac{dt\sqrt{t}}{\sqrt{1-t}}\cdot\frac{\sin\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{zt};k^2)\right)}{2\sqrt{s_0}\sqrt{zt(1-zt)(1-k^2zt)}}.
$$

In order to use Theorem 1, one may take $R<1$; analytic continuation extends the relations (3.2) to the whole complex plane with a cut on the real axis for $\mathrm{Re}\,z\geqq 1$. If $\alpha=\frac{1}{2}$, $\beta=1$, $\gamma=\frac{3}{2}$, $\delta=\varepsilon=\frac{1}{2}$ formula (2.6) gives an integral which can be computed and one recovers the results already given by (3.1).

Theorem 1 may generate additional formulas. For example let $\zeta=1-z$. As a function of ζ, the Heun function has the parameters

$$
P':\begin{cases}\alpha'=\alpha, & \gamma'=\delta, \quad \varepsilon'=\varepsilon, \quad k'^2=1-k^2,\\ \beta'=\beta, & \delta'=\varepsilon, \quad s'=\dfrac{s+\alpha\beta k^2}{k'^2},\end{cases}
$$

and k^2 is transformed into $-k^2/k'^2$.

Considering the solution which is holomorphic in a neighbourhood of $\zeta=0$, we can again prove Theorem 1 and obtain new integral representations.

In this example, we took $\zeta=1-z$, but any one among the 24 changes of variables given in [7, p. 577] will work. We shall not give all the related formulas which can be easily obtained.

4. Application to an eigenvalue problem. Among the integral representations obtained in (3.2), one is relevant for application to a birth and death process with quadratic transition rates (see, for instance [5] for an introduction).

One is led to the following eigenvalue problem:

$$
\left\{(1-x)\frac{d}{dx}\left[x(1-k^2x)\frac{d}{dx}\right]-\frac{k^2}{4}(1-x)-s_0\right\}y_{s_0}(x)=0 \tag{4.1}
$$

with $k^2\in\mathscr{D}_0=\{k^2\,|\,0\leqq k^2\leqq k_0^2<1\}$ (the analysis for $k^2=1$ is given in [5]). The boundary conditions are

$$
y_{s_0}(0)=1, \qquad y_{s_0}(1)=0. \tag{4.2}
$$

4.1. Eigenfunctions and eigenvectors. The first condition in (4.2) implies that the eigenfunctions are

$$
y_{s_0}(x;k^2)=H\left(\frac{1}{2},\frac{1}{2};1,0,1;k^2,s_0-\frac{k^2}{4};x\right).
$$

The other linearly independent solution is easily excluded because it has a logarithmic singularity at $x=0$.

The following lemma is essential to identify the eigenvalues.

LEMMA 3. *If $k^2\in\mathscr{D}_0$ the eigenfunctions $y_{s_0}(x;k^2)$ are continuous for $x\in[0,1]$ and one has*

$$y_{s_0}(1;k^2)=\frac{\sin\left(2\sqrt{s_0}K\right)}{\sqrt{s_0}\pi}$$

where $K(k^2)=\pi/2.\ {}_2F_1(\frac{1}{2},\frac{1}{2};1,k^2)$ is the complete elliptic integral of the first kind.

Proof. We use the integral representation of $y_{s_0}(x;k^2)$ obtained in (3.2)

$$y_{s_0}(x;k^2)=\frac{1}{\pi}\int_0^1\frac{dt}{\sqrt{t(1-t)}}\cdot\frac{\cos\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{xt}\,;k^2)\right)}{\sqrt{1-k^2xt}}. \tag{4.3}$$

The integrand is a continuous function of $x\in[0,1]$ for $t\in[0,1]$. Furthermore we have the bound

$$\frac{1}{\sqrt{t(1-t)}}\left|\frac{\cos\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{xt}\,;k^2)\right)}{\sqrt{1-k^2xt}}\right|\leqq\frac{\mathrm{ch}\left(2K\cdot\mathrm{Im}\sqrt{s_0}\right)}{\sqrt{t(1-t)(1-k^2t)}}=g(t)$$

with $g(t)$ obviously integrable for $t\in[0,1]$. Hence we get the continuity of $y_{s_0}(x;k^2)$ and

$$y_{s_0}(1;k^2)=\frac{1}{\pi}\int_0^1\frac{dt}{\sqrt{t(1-t)}}\cdot\frac{\cos\left(2\sqrt{s_0}\,\mathrm{sn}^{-1}(\sqrt{t}\,;k^2)\right)}{\sqrt{1-k^2t}}.$$

Putting $t=\mathrm{sn}^2(\theta;k^2)$, we get

$$y_{s_0}(1;k^2)=\frac{2}{\pi}\int_0^K d\theta\cos\left(2\sqrt{s_0}\theta\right)=\frac{\sin\left(2\sqrt{s_0}K\right)}{\pi\sqrt{s_0}}.$$

As a side remark the simplicity of this main result is made more transparent if in (4.3) we change the variables to

$$x=\mathrm{sn}^2(\theta;k^2),\quad xt=\mathrm{sn}^2(\psi;k^2),\quad \theta,\psi\in[0,K].$$

Then the eigenfunctions may be written

$$y_{s_0}\left(\mathrm{sn}^2(\theta;k^2);k^2\right)=\frac{2}{\pi}\int_0^\theta d\psi\frac{\mathrm{cn}(\psi;k^2)}{\sqrt{\mathrm{sn}^2(\theta;k^2)-\mathrm{sn}^2(\psi;k^2)}}\cos\left(2\sqrt{s_0}\psi\right).$$

From Lemma 3 we conclude that the eigenvalues are given by

$$(s_0)_n=\frac{n^2\pi^2}{4K^2(k^2)}=n^2\frac{K^2(0)}{K^2(k^2)},\qquad n\in\mathbb{N}^*, \tag{4.4}$$

$$\mathbb{N}^*=\{1,2,3,\cdots.\}$$

and the eigenfunctions

$$y_n(x;k^2)=\frac{1}{\pi}\int_0^1\frac{dt}{\sqrt{t(1-t)}}\cdot\frac{\cos\left((n\pi/K)\,\mathrm{sn}^{-1}(\sqrt{xt}\,;k^2)\right)}{\sqrt{1-k^2xt}}. \tag{4.5}$$

All the eigenvalues are simple.

If $k^2 \to 0$ we recover for eigenvalues n^2 with eigenfunctions ${}_2F_1(-n, n; 1, x)$ which are hypergeometric *polynomials*.

For $k^2 \in \mathscr{D}_0$ the eigenvalues exhibit a continuous dependence with respect to k^2, but if $k^2 > 0$ the eigenfunctions *are no longer polynomials* and have a complicated structure displayed by (4.5). If $k^2 \to 1$ (which lies outside $\mathscr{D}_0$) $K(k^2)$ has a logarithmic singularity and diverges. All the eigenvalues collapse to zero, an indication of a drastic change in the spectrum which becomes a continuous one (this was observed in [5]).

This is rather interesting from a differential equation theoretic point of view since we have at our disposal a soluble model where, according to the value of the parameter k^2, we can "see" the transition from a discrete spectrum to a continuous one.

One can check (4.4) using perturbation theory around $k^2 = 0$. Up to order $(k^2)^2$ the perturbation theory calculations are in agreement with (4.4).

4.2. Summation formulae for the eigenfunctions. As an interesting application of the integral representation (4.5) we have to mention the possibility of evaluating several sums involving the eigenfunctions $y_n(x; k^2)$.

Let us first give an example. We start from the series given, for instance, in [7, p. 511]

$$\mathrm{dn}(\psi; k^2) = \frac{\pi}{2K} + \frac{2\pi}{K} \sum_{n=1}^{\infty} \frac{q^n}{1+q^{2n}} \cos\left(\frac{n\pi\psi}{K}\right) = \sum_{n=0}^{\infty} \mu_n(\psi), \qquad \psi \in [0, K].$$

For $k^2 \in \mathscr{D}_0$ we have $q = e^{-\pi K'/K} < 1$ and the series is absolutely and uniformly convergent for $\psi \in [0, K]$. Furthermore it is easy to see that the series

$$\sum_{n=0}^{\infty} |\mu_n(\psi)|$$

is integrable over $[0, K]$. Hence we may multiply each term by

$$\frac{\mathrm{cn}(\psi; k^2)}{\sqrt{\mathrm{sn}^2(\theta; k^2) - \mathrm{sn}^2(\psi; k^2)}}$$

and integrate term by term from $\psi = 0$ to $\psi = \theta$. This gives

$$\frac{2}{\pi} \int_0^{\theta} d\psi \frac{\mathrm{cn}\psi\,\mathrm{dn}\psi}{\sqrt{\mathrm{sn}^2\theta - \mathrm{sn}^2\psi}} = \frac{\pi}{2K} y_0(\mathrm{sn}^2\theta) + \frac{2\pi}{K} \sum_{n=1}^{\infty} \frac{q^n}{1+q^{2n}} \cdot y_n(\mathrm{sn}^2\theta).$$

The integral on the left side equals $\pi/2$. Taking into account the relation

$$y_0(x) = {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; 1; k^2 x\right),$$

we obtain the summation formula

$$\frac{2\pi}{K} \sum_{n=1}^{\infty} \frac{q^n}{1+q^{2n}} y_n(x) = 1 - \frac{\pi}{2K} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; 1; k^2 x\right). \tag{4.6}$$

For $k^2 \in \mathscr{D}_0$ the left-hand member series is uniformly convergent for $x \in [0, 1]$. The reader can check that this series defines a C^∞ function for $x \in [0, 1]$ and that it is legitimate to differentiate it term by term. Hence differentiating (4.6) with respect to x will give new relations.

Similarly, using the known Fourier series (see [7]) for $1/\mathrm{dn}\psi$ and $\mathrm{sn}^2\psi$, we find that

$$\frac{2\pi}{K}\sum_{n=1}^{\infty}(-1)^n\frac{q^n}{1+q^{2n}}\cdot y_n(x)=\frac{k'}{\sqrt{1-k^2x}}-\frac{\pi}{2K}\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;k^2x\right),$$

$$\frac{2\pi^2}{K^2}\sum_{n=1}^{\infty}\frac{nq^n}{1-q^{2n}}\cdot y_n(x)={}_2F_1\left(-\frac{1}{2},\frac{1}{2};1;k_x^2\right)-\frac{E}{K}\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;k^2x\right),$$

where $E=E(k^2)$ is the complete elliptic integral of the second kind.

4.3. A useful integral representations for the eigenfunctions. The integral representation (4.5) for the eigenfunctions is not suited to prove their orthogonality because it does not exhibit their vanishing at $x=1$. This means that one can extract out from them a factor $1-x$ times some other integral. This is the aim of this paragraph, which follows the remark made at the end of §3.

We go back to the differential equation for the eigenfunctions, but for the moment s_0 is not supposed to be an eigenvalue

$$\frac{d^2y}{dx^2}+\left(\frac{1}{x}-\frac{k^2}{1-k^2x}\right)\frac{dy}{dx}+\frac{s_0-(k^2/4)(1-x)}{x(1-x)(1-k^2x)}y=0. \tag{4.7}$$

The change of variable $u=1-x$ gives

$$\frac{d^2y}{du^2}-\left(\frac{1}{1-u}+\frac{\hat{k}^2}{1-\hat{k}^2u}\right)\frac{dy}{du}+\frac{s_0/k'^2+(\hat{k}^2/4)u}{u(1-u)(1-\hat{k}^2u)}\cdot y=0, \tag{4.8}$$

$$\hat{k}^2=-k^2/k'^2,\qquad k'^2=1-k^2.$$

Equation (4.8) has a first solution

$$f_1(u)=H\left(\frac{1}{2},\frac{1}{2};0,1,1;\hat{k}^2,s_0/k'^2;u\right).$$

In order to get the other solution, we put

$$y=u\cdot Y$$

and obtain

$$\frac{d^2Y}{du^2}+\left(\frac{2}{u}-\frac{1}{1-u}-\frac{\hat{k}^2}{1-\hat{k}^2u}\right)\frac{dY}{du}+\frac{s_0/k'^2-1-\hat{k}^2+(9/4)\hat{k}^2u}{u(1-u)(1-\hat{k}^2u)}\cdot Y=0.$$

Hence, we take as the second solution of (4.8):

$$f_2(u)=uH\left(\frac{3}{2},\frac{3}{2};2,1,1;\hat{k}^2,\frac{s_0}{k'^2}-1-\hat{k}^2;u\right).$$

To prove the linear independence of f_1 and f_2, we examine their Wronskian which is

$$W[f_1,f_2]=f_1\frac{df_2}{du}-f_2\frac{df_1}{du}=-W_0(1-u)^{-1}(1-\hat{k}^2u)^{-1}.$$

An easy computation in the neighbourhood of $u=0$ gives $W_0=+1$ and we conclude the linear independence of f_1 and f_2.

Since (4.7) has at most two linearly independent solutions, we must have a linear relation of the form

$$y(x;k^2)=Af_2(u)+Bf_1(u), \qquad u=1-x.$$

Now we take s_0 to be an eigenvalue: since $y_n(x;k^2)$ vanishes at $x=1$ this implies $B=0$ and we are left with

$$(4.9)\qquad y_n(x;k^2)=A_n(1-x)H\left(\frac{3}{2},\frac{3}{2};2,1,1;\hat{k}^2,\left(\frac{n\pi}{2k'/K}\right)^2-1-\hat{k}^2;1-x\right),$$

where the unknown constant

$$A_n=-\frac{d}{dx}y_n(x;k^2)\Big|_{x=1}$$

is given by the following lemma:

LEMMA 4. *$y_n'(x;k^2)$ is continuous for $x\in[0,1]$ and*

$$\lim_{x\to 1}y_n'(x;k^2)=\frac{(-1)^n}{k'^2}\cdot\frac{n\pi}{2K}\cdot\frac{1+q^{2n}}{1-q^{2n}}, \qquad n\in\mathbb{N}^*, \quad k^2\in\mathscr{D}_0.$$

Proof. We start by using the integral representation (4.5). Formally, the derivative is given by

(4.10)

$$y_n'(x;k^2)=\frac{1}{\pi}\int_0^1 dt\sqrt{\frac{t}{(1-t)(1-k^2xt)^3}}$$

$$\cdot\left\{\frac{k^2}{2}\cdot\cos\left(\frac{n\pi}{K}\mathrm{sn}^{-1}(\sqrt{xt})\right)-\frac{n\pi}{2K}\sqrt{\frac{(1-k^2xt)}{xt(1-xt)}}\cdot\sin\left(\frac{n\pi}{K}\mathrm{sn}^{-1}(\sqrt{xt})\right)\right\}.$$

Our task is to justify differentiation under the integral sign.

We first observe that

$$(1-k^2xt)^{-3/2}\cos\left(\frac{n\pi}{K}\mathrm{sn}^{-1}(\sqrt{xt})\right)$$

is continuous for $x\in[0,1]$ and $t\in[0,1]$. We have the bound

$$\left|\sqrt{\frac{t}{(1-t)(1-k^2xt)^3}}\cdot\cos\left(\frac{n\pi}{K}\mathrm{sn}^{-1}(\sqrt{xt})\right)\right|\leqq\sqrt{\frac{t}{(1-t)(1-k^2t)^3}}=g(t)$$

where $g(t)$ is integrable for $t\in[0,1]$.

For the second piece, we must consider two cases: either $x\in[0,\frac{1}{2}]$ or $x\in[\frac{1}{2},1]$.

If $x\in[0,\frac{1}{2}]$ the function

$$(1-k^2xt)^{-1}\cdot(1-xt)^{-1/2}\cdot\frac{\sin((n\pi/K)\mathrm{sn}^{-1}(\sqrt{xt}))}{\sqrt{xt}}$$

is continuous for $t\in[0,1]$ provided that it takes the value $n\pi/K$ for $xt=0$. Hence its absolute value is bounded by some positive constant C

$$\left|\frac{t^{1/2}(1-t)^{-1/2}}{(1-k^2xt)}(1-xt)^{-1/2}\frac{\sin((n\pi/K)\mathrm{sn}^{-1}(\sqrt{xt}))}{\sqrt{xt}}\right|\leqq\frac{Ct^{1/2}(1-t)^{-1/2}}{(1-k^2t)}=h(t);$$

therefore $h(t)$ is integrable for $t\in[0,1]$.

If $x \in [\frac{1}{2}, 1]$ some care is required. Using the known relation

$$\mathrm{sn}^{-1}(\sqrt{v}\,;k^2) = K - \mathrm{sn}^{-1}\left(\sqrt{\frac{1-v}{1-k^2v}}\,;k^2\right), \qquad 0 \leqq v \leqq 1,$$

we write

$$\frac{\sin\left((n\pi/K)\mathrm{sn}^{-1}(\sqrt{xt}\,;k^2)\right)}{\sqrt{1-xt}} = (-1)^{n-1}\frac{\sin\left((n\pi/K)\mathrm{sn}^{-1}\left(\sqrt{(1-xt)/(1-k^2xt)}\,;k^2\right)\right)}{\sqrt{1-xt}}$$

and if we take this function to be equal to $(-1)^{n-1}n\pi/k'K$ for $xt=1$ it will be continuous for $x \in [\frac{1}{2}, 1]$ and $t \in [0,1]$ and its absolute value will be bounded by some constant D. So we obtain

$$\left|\frac{x^{-1/2}(1-t)^{-1/2}}{(1-k^2xt)} \cdot \frac{\sin\left((n\pi/K)\mathrm{sn}^{-1}(\sqrt{xt})\right)}{\sqrt{1-xt}}\right| \leqq \sqrt{2}\,D\frac{(1-t)^{-1/2}}{(1-k^2t)} = l(t)$$

where $l(t)$ is integrable for $t \in [0,1]$.

Collecting all the pieces, we conclude that $y_n'(x;k^2)$ is indeed continuously differentiable and it is legitimate to bring the derivative inside the integral.

We take in (4.10) the limit $x=1$ and put $t = \mathrm{sn}^2(\theta;k^2)$

$$y_n'(1;k^2) = \frac{1}{\pi}\int_0^K \frac{d\theta}{dn^2\theta} \cdot \cos\left(\frac{n\pi\theta}{K}\right) - \frac{n}{K}\int_0^K d\theta \frac{\mathrm{sn}\,\theta}{\mathrm{cn}\,\theta\,\mathrm{dn}\,\theta} \cdot \sin\left(\frac{n\pi\theta}{K}\right).$$

These integrals are computed using the calculus of residues and the elementary properties of the Jacobi elliptic functions. The result is Lemma 4.

To conclude this subsection, we notice that an integral representation for $f_2(u)$ has been obtained in (3.2). Combining it with (4.9), we get

$$\begin{aligned} y_n(x;k^2) &= Z_n(1-x)^{1/2}\int_0^1 dt \frac{\sin\left((n\pi/k'K)\mathrm{sn}^{-1}\left(\sqrt{t(1-x)}\,;\hat{k}^2\right)\right)}{\sqrt{(1-t)[1-t(1-x)][1-k^2t(1-x)]}}, \\ Z_n &= \frac{(-1)^{n-1}}{\pi k'}\frac{1+q^{2n}}{1-q^{2n}}. \end{aligned} \tag{4.11}$$

When $x = \mathrm{cn}^2(\theta;\hat{k}^2)$, with $\theta \in [0, k'K]$,

$$y_n\left(\mathrm{cn}^2(\theta;\hat{k}^2);k^2\right) = 2Z_n\int_0^\theta d\psi \frac{\mathrm{sn}(\psi;\hat{k}^2)}{\sqrt{\mathrm{sn}^2(\theta;\hat{k}^2) - \mathrm{sn}^2(\psi;\hat{k}^2)}} \cdot \sin\left(\frac{n\pi\psi}{k'K}\right). \tag{4.12}$$

This relation is essential for computing scalar products involving the eigenfunctions as we shall see now.

4.4. Orthogonality and norm of the eigenvectors. The scalar product for which the differential operator (4.1) is formally self-adjoint is

$$(f,g) = \int_0^1 \frac{dx}{1-x} f(x)g(x) \tag{4.13}$$

with real valued functions f, g.

We shall prove

THEOREM 2. *For $n, p \in \mathbb{N}^*$ we have*

$$(y_n, y_p) = \rho_n \delta_{np}, \qquad \rho_n = \frac{1}{2n}\left(\frac{2K}{\pi}\right)^2 \cdot \frac{1+q^{2n}}{1-q^{2n}}.$$

Proof. First, assume $k^2 > 0$. Substituting the integral representation (4.11) in (4.13), we have a triple integral

$$(4.14) \qquad (y_n, y_p) = Z_n Z_p \int_0^1 dx \int_0^1 dt \frac{\sin\left((n\pi/k'K)/\mathrm{sn}^{-1}\left(\sqrt{t(1-x)}\,;\hat{k}^2\right)\right)}{\sqrt{(1-t)[1-t(1-x)][1-k^2t(1-x)]}}$$

$$\times \int_0^1 ds \frac{\sin\left((n\pi/k'K)\mathrm{sn}^{-1}\left(\sqrt{s(1-x)}\,;\hat{k}^2\right)\right)}{\sqrt{(1-s)[1-s(1-x)][1-k^2s(1-x)]}}$$

$$= Z_n Z_p \int_0^1 dx \int_0^1 dt \int_0^1 ds U(x;t,s).$$

As already explained in the proof of Lemma 4, the function

$$\sin\left((n\pi/k'K)\mathrm{sn}^{-1}(\sqrt{v})\right)/\sqrt{1-v}$$

is continuous for $v \in [0,1]$ provided that, for $v=1$, we define it to be $(-1)^{n-1} n\pi/k'K$. Hence it is bounded by some constant D_n and we may write

$$|U(x;t,s)| \leqq D_n D_p \left[(1-t)(1-k^2t)(1-s)(1-k^2s)\right]^{-1/2}$$

a bound which implies the absolute convergence of the integral (4.14). Let

$$x = \mathrm{cn}^2(\theta;\hat{k}^2), \quad t(1-x) = \mathrm{sn}^2(\varphi;\hat{k}^2), \quad s(1-x) = \mathrm{sn}^2(\psi;\hat{k}^2), \qquad \theta, \varphi, \psi \in [0, k'K]$$

and interchange the orders of integration,

$$(y_n, y_p) = 4 Z_n Z_p \int_0^{k'K} d\varphi \sin\left(\frac{n\pi\varphi}{k'K}\right) \int_0^{k'K} d\psi \sin\left(\frac{p\pi\psi}{k'K}\right)$$

$$\times \left[\mathrm{sn}\varphi\,\mathrm{sn}\psi \int_{\sup(\varphi,\psi)}^{k'K} d\theta \frac{2\,\mathrm{cn}\theta\,\mathrm{dn}\theta}{\mathrm{sn}\theta} \frac{1}{\sqrt{(\mathrm{sn}^2\theta - \mathrm{sn}^2\varphi)(\mathrm{sn}^2\theta - \mathrm{sn}^2\psi)}}\right].$$

All the elliptic functions involved have $\hat{k}^2$ for parameter. The term in the bracket is elementary if one takes for variable $u = \mathrm{sn}^2(\theta;\hat{k}^2)$ and is equal to

$$\ln \frac{(\mathrm{sn}\varphi \cdot \mathrm{cn}\psi + \mathrm{cn}\varphi \cdot \mathrm{sn}\psi)^2}{|\mathrm{sn}^2\varphi - \mathrm{sn}^2\psi|}.$$

Coming back to elliptic functions with parameter k^2, we note that

$$(y_n, y_p) = 4k'^2 Z_n Z_p \int_0^K d\varphi \sin\left(\frac{n\pi\varphi}{K}\right) \int_0^K d\psi \sin\left(\frac{p\pi\psi}{K}\right) \ln \frac{(\mathrm{sn}\varphi \cdot \mathrm{cn}\psi + \mathrm{cn}\varphi \cdot \mathrm{sn}\psi)^2}{|\mathrm{sn}^2\varphi - \mathrm{sn}^2\psi|}.$$

In order to simplify the logarithm, we use relation (4) [16, p. 152]

$$(4.15) \qquad \frac{\mathrm{sn}\varphi \cdot \mathrm{cn}\psi + \mathrm{cn}\varphi \cdot \mathrm{sn}\psi}{\mathrm{dn}\psi - \mathrm{dn}\varphi} = \frac{1}{k^2} \cdot \frac{1 + \mathrm{dn}(\varphi - \psi)}{\mathrm{sn}(\varphi - \psi)}.$$

Putting in (4.15) $\psi=\psi'+2iK'$ and then changing ψ' to $-\psi'$ gives another relation which, when combined with (4.15), reads:

$$\frac{(\operatorname{sn}\varphi\operatorname{cn}\psi+\operatorname{cn}\varphi\operatorname{sn}\psi)^2}{\operatorname{sn}^2\varphi-\operatorname{sn}^2\psi}=\frac{1}{k^2}\cdot\frac{1+\operatorname{dn}(\varphi-\psi)}{\operatorname{sn}(\varphi-\psi)}\cdot\frac{1-\operatorname{dn}(\varphi+\psi)}{\operatorname{sn}(\varphi+\psi)}.$$

The scalar product is then transformed to

$$(y_n,y_p)=I_{np}^{(1)}+I_{np}^{(2)},$$

$$I_{np}^{(1)}=k'^2Z_nZ_p\int_{-K}^{+K}d\varphi\exp\left(\frac{in\pi\varphi}{K}\right)\int_{-K}^{+K}d\psi\exp\left(\frac{ip\pi\psi}{K}\right)\ln\left|\frac{k^2\operatorname{sn}(\varphi-\psi)}{1+\operatorname{dn}(\varphi-\psi)}\right|,$$

$$I_{np}^{(2)}=k'^2Z_nZ_p\int_{-K}^{+K}d\varphi\exp\left(\frac{in\pi\varphi}{K}\right)\int_{-K}^{+K}d\psi\exp\left(\frac{ip\pi\psi}{K}\right)\ln\left|\frac{\operatorname{sn}(\varphi+\psi)}{1-\operatorname{dn}(\varphi+\psi)}\right|.$$

The computation now becomes possible with the variables $\varphi\pm\psi$ and gives

$$I_{np}^{(1)}=\frac{2K}{\pi}k'^2Z_nZ_p\frac{(-1)^{n+p-1}}{n+p}\int_0^{2K}dx\left[\sin\left(\frac{n\pi x}{K}\right)+\sin\left(\frac{p\pi x}{K}\right)\right]\ln\left(\frac{\operatorname{sn}x}{1+\operatorname{dn}x}\right),$$

$$I_{np}^{(2)}=\begin{cases}\dfrac{2K}{\pi}k'^2Z_nZ_p\dfrac{(-1)^{n-p}}{n-p}\displaystyle\int_0^{2K}dx\left[\sin\left(\frac{p\pi x}{K}\right)-\sin\left(\frac{n\pi x}{K}\right)\right]\ln\left(\frac{\operatorname{sn}x}{1-\operatorname{dn}x}\right), & n\neq p,\\ 4Kk'^2Z_n^2\displaystyle\int_0^K dx\cos\left(\frac{n\pi x}{K}\right)\ln\left(\frac{\operatorname{sn}x}{1-\operatorname{dn}x}\right), & n=p.\end{cases}$$

The integrals of the form

$$\int_0^{2K}dx\ln\left(\frac{\operatorname{sn}x}{1\pm\operatorname{dn}x}\right)\sin\left(\frac{n\pi x}{K}\right),\qquad n\in\mathbb{N}^*$$

all vanish because their integrand is odd with respect to the point $x=K$. As a consequence, for $n\neq p$, the scalar product (y_n,y_p) vanishes.

For $n=p$, the remaining integral is computed using the calculus of residues applied to the function

$$e^{in\pi z/K}\left[\frac{\operatorname{cn}z\operatorname{dn}z}{\operatorname{sn}z}-\frac{k^2\operatorname{sn}z\operatorname{cn}z}{1-\operatorname{dn}z}\right].$$

The contour is a rectangle indented at $z=0$ and has vertices $-K$, $+K$, $+K+i\infty$, $-K+i\infty$. We obtain

$$\int_0^K dx\cos\left(\frac{n\pi x}{K}\right)\ln\left(\frac{\operatorname{sn}x}{1-\operatorname{dn}x}\right)=\frac{K}{2n}\cdot\frac{1-q^{2n}}{1+q^{2n}},\qquad n\in\mathbb{N}^*. \tag{4.16}$$

Using (4.16) and the explicit form of Z_n, we establish Theorem 2.

Recall that we assumed $k^2\in\mathscr{D}_0$, $k^2>0$. By letting $k^2\to 0$, we obtain the result

$$(y_n,y_p)=\frac{1}{2n}\delta_{np}.$$

Hence Theorem 2 is valid for $k^2\in\mathscr{D}_0$.

4.5. Completeness of the eigenfunctions. Let us begin with some definitions. We shall denote by L^2_W the linear vector space of square integrable functions with respect to the weight:

$$W(x)=(1-x)^{-1}, \qquad \|f\|=\left(\int_0^1 dx W(x) f^2(x)\right)^{1/2};$$

only real valued functions are considered. The scalar product is taken to be

$$(f,g)=\int_0^1 dx W(x) f(x) g(x).$$

Since the Lebesgue integral is used, L^2_W is a Hilbert space [10].

In this subsection we shall denote by $\hat{y}_n$ the orthonormal eigenfunctions.

LEMMA 5. $\mathscr{R}=\{(1-x)^n, n\in\mathbb{N}^*\}$ *is dense in* L^2_W *for the* L^2_W *norm.*

Proof. This result is an extension of the Stone–Weierstrass density theorem. It has been proved in a very general framework in [17] (see remark 1, p. 725 of this reference).

THEOREM 3. $\{\hat{y}_n, n\in\mathbb{N}^*\}$ *is a complete orthonormal basis in* L^2_W.

Proof. We consider the set of functions

$$h_r(\psi)=(\mathrm{sn}\psi)^{2r-1}\mathrm{cn}\psi\,\mathrm{dn}\psi, \qquad r\in\mathbb{N}^*$$

where all elliptic functions have for parameter $\hat{k}^2$. All these functions are odd, vanish at $\psi=\pm k'K$ and have a real period $2k'K$. Furthermore, they are C^∞. Hence their Fourier series converge uniformly for $\psi\in[-k'K,k'K]$:

$$\lim_{N\to\infty}\sup_{\psi\in[0,k'K]}\left|h_r(\psi)-\sum_{n=1}^{N}\xi_n(s)\sin\left(\frac{n\pi\psi}{k'K}\right)\right|=0.$$

The coefficients $\xi_n(r)$ are given by

$$\xi_n(r)=\frac{1}{k'K}\int_{-k'K}^{k'K} d\psi h_r(4)\sin\left(\frac{n\pi\psi}{k'K}\right). \tag{4.17}$$

Integrating by parts twice in (4.17), we find for ξ_n, the bound

$$|\xi_n|\leqq\frac{C^2}{n^2}, \qquad n\in\mathbb{N}^*, \quad \text{real } C. \tag{4.18}$$

From this the absolute convergence of the Fourier series follows. Hence we may multiply each term by $\mathrm{sn}\psi/\sqrt{\mathrm{sn}^2\theta-\mathrm{sn}^2\psi}$ and integrate term by term for $\psi\in[0,\theta]$. Using (4.12), we get

$$\sum_{n=1}^{\infty}\frac{\xi_n(r)\sqrt{\rho_n}}{2Z_n}\hat{y}_n(\mathrm{cn}^2\theta)=\int_0^\theta d\psi\frac{(\mathrm{sn}\psi)^{2r-1}\mathrm{sn}\psi\,\mathrm{cn}\psi\,\mathrm{dn}\psi}{\sqrt{\mathrm{sn}^2\theta-\mathrm{sn}^2\psi}}=C_r(\mathrm{sn}^2\theta)^r \quad r\in\mathbb{N}^*, \tag{4.19}$$

$\theta\in[-k'K,k'K]$, with pointwise convergence, where the C_r are known constants and ρ_n is given in Theorem 2. But we have the bound for sufficiently large n (use 4.5 for the eigenfunctions)

$$\left|\frac{\xi_n(r)\sqrt{\rho_n}}{2Z_n}\hat{y}_n(\mathrm{cn}^2\theta)\right|\leqq 2\pi k' y_0(\mathrm{cn}^2\theta).|\xi_n(r)|,$$

Since this upper bound is a convergent series (use (4.18)), we conclude that the series in (4.19) converges absolutely and uniformly for $\theta\in[-k'K,k'K]$. Then we make the change of variable $x=\mathrm{cn}^2(\theta;\hat{k}^2)$. For $\theta\in[0,k'K]$ and $x\in[0,1]$, it is continuous and one to one. This implies

$$\lim_{N\to\infty}\sup_{x\in[0,1]}\left|c_r(1-x)^r-S_N(x;r)\right|=0, \tag{4.20}$$

$$S_N(x;r)=\sum_{n=1}^{\infty}\frac{\xi_n(r)\sqrt{\rho_n}}{2Z_n}\hat{y}_n(x).$$

Hence $\{\hat{y}_n, n\in\mathbb{N}^*\}$ spans $\mathscr{B}$ with respect to the uniform convergence norm. This density property remains true for the L^2_W norm because of the bound

$$\int_0^1\frac{dx}{1-x}\left|c_r(1-x)^r-S_N(x;r)\right|^2\leqq\sup_{x\in[0,1-\eta]}\left|c_r(1-x)^r-S_N(x;r)\right|^2\cdot\ln\left(\frac{1}{\eta}\right)+\int_{1-\eta}^1\frac{dx}{1-x}\left|c_r(1-x)^r-S_N(x;r)\right|^2. \tag{4.21}$$

Since the function $c_r(1-x)^r-S_N(x;r)$ belongs to L^2_W for any value of N, the right side integral in (4.21) is absolutely continuous for $\eta\in[0,1]$. Therefore we can choose η such that this integral be as small as $\varepsilon/2$, independently of N.

Relation (4.20) shows that the other term in the right side of (4.21) can be made as small as $\varepsilon/2$ for some choice of N.

Hence the density of $\{\hat{y}_n, n\in\mathbb{N}^*\}$ in $\mathscr{B}$ with respect to the L^2_W norm is obtained. But for this norm $\mathscr{B}$ is dense in L^2_W [11]; therefore $\{\hat{y}_n, n\in\mathbb{N}^*\}$ is dense in L^2_W.

Since in a Hilbert space a spanning orthonormal set is automatically complete, Theorem 3 follows.

As a side remark we note that L^2_W has a remarkably rich structure of constructible orthogonal bases, since *for any value* $k^2\in\mathscr{D}_0$ the eigenfunctions $\{\hat{y}_n\}$ form a complete basis in L^2_W. Quite generally we may write

$$\hat{y}_n(x;k_1^2)=\sum_{r=1}^{\infty}e_{nr}(k_1^2,k_2^2)\,\hat{y}_r(x;k_2^2),\qquad k_1^2,k_2^2\in\mathscr{D}_0$$

from which, for $k_2^2=0$ we get

$$\hat{y}_n(x;k_1^2)=\sum_{r=1}^{\infty}\frac{e_{nr}(k_1^2,0)}{\sqrt{2r}}\,{}_2F_1(-r,r;1;x)$$

a series already given by Erdélyi [13, formula 9.1]. Using the integral representations for $\hat{y}_n(x;k_1^2)$, we may work out the coefficients e_{nr} appearing in this expansion: a nontrivial exercise !...

5. Conclusion. We have obtained an integral transform relating Heun functions with different sets of parameters. From this result and Carlitz explicit solutions, we have obtained new closed integral representations for some Heun functions.

Using this transformation, we have been able to solve an eigenvalue problem related to a birth and death process, obtaining the exact spectrum and eigenfunctions in a purely differential equation theoretic framework. The integral representations obtained are sufficient to give a direct proof of their orthogonality, to allow the computation of their norm and to prove their completeness in the Hilbert space L^2_W.

Let us observe that the spectrum obtained in this differential equation approach to birth and death processes is *identical* to that obtained by Stieltjes who directly solved the forward Kolmogorov equation using continued fraction techniques developed by himself (the continued fraction computation is given in [14] and its relevance to birth and death processes is fully discussed in [15]).

The identity of the eigenvalues in these two completely different approaches strongly suggests some underlying equivalence which may be extremely fruitful to develop both fields: continued fractions on one hand and new transcendental functions defined by differential equations on the other hand.

DISCRETIZED FRACTIONAL CALCULUS*

CH. LUBICH†

Abstract. For the numerical approximation of fractional integrals

$$I^\alpha f(x)=\frac{1}{\Gamma(\alpha)}\int_0^x (x-s)^{\alpha-1} f(s)\,ds \qquad (x\geqq 0)$$

with $f(x)=x^{\beta-1}g(x)$, g smooth, we study convolution quadratures. Here approximations to $I^\alpha f(x)$ on the grid $x=0,h,2h,\cdots,Nh$ are obtained from a discrete convolution with the values of f on the same grid. With the appropriate definitions, it is shown that such a method is convergent of order p if and only if it is stable and consistent of order p. We introduce fractional linear multistep methods: The αth power of a pth order linear multistep method gives a pth order convolution quadrature for the approximation of I^α. The paper closes with numerical examples and applications to Abel integral equations, to diffusion problems and to the computation of special functions.

AMS (MOS) subject classifications. Primary 26A33, 41A55, 65D25; secondary 65D20, 65R20

1. Introduction. Fractional calculus is an area having a long history whose infancy dates back to the beginnings of classical calculus, and it is an area having interesting applications. The numerical approximation of the objects of classical calculus, i.e., integrals and derivatives, has for a long time been a standard topic in numerical analysis. However, the state of the art is far less advanced for fractional integrals. Hopefully, the present work contributes to narrow this gap.

Very readable introductions to fractional calculus are given by Lavoie, Osler and Tremblay [12] and by Riesz [19]. See also the book of Oldham and Spanier [18] which contains many references and applications from different areas such as special functions of mathematical physics and diffusion equations. For easy reference we collect first some basic definitions and results.

We consider *Abel–Liouville integrals* of order α (often also called Riemann–Liouville integrals),

$$I^\alpha f(x)=\frac{1}{\Gamma(\alpha)}\int_0^x (x-s)^{\alpha-1} f(s)\,ds \qquad (x\geqq 0) \quad \text{for } \operatorname{Re}\alpha>0, \tag{1.1}$$

where Γ denotes Euler's gamma function.

$I^\alpha f(x)$ depends analytically on α (for fixed f and x). If f is k-times continuously differentiable on $[0,x]$, it can be continued analytically to α with negative real part via

$$I^\alpha f(x)=\frac{d^k}{dx^k} I^{\alpha+k} f(x) \quad \text{for } \operatorname{Re}\alpha>-k. \tag{1.2}$$

If $-k\leqq \operatorname{Re}\alpha<0$ and $f^{(j)}(0)=0$ for $j=0,1,\cdots,k-1$, then $y(x)=I^\alpha f(x)$ is the solution of the first-kind *Abel integral equation*

$$\frac{1}{\Gamma(-\alpha)}\int_0^x (x-s)^{-\alpha-1} y(s)\,ds=f(x) \qquad (x\geqq 0). \tag{1.3}$$

*Received by the editors October 18, 1983, and in revised form July 13, 1984.

†Institut für Mathematik und Geometrie, Universität Innsbruck, Technikerstraße 13, A-6020 Innsbruck, Austria.

For integer α, I^α is simply repeated integration or differentiation:

$$I^k f(x)=\int_0^x\int_0^{x_k}\cdots\int_0^{x_2} f(x_1)\,dx_1\,dx_2\cdots dx_k,$$
$$I^0 f(x)=f(x),$$
$$I^{-k} f(x)=\frac{d^k}{dx^k}f(x).$$

I^α is therefore often called *fractional integral* of order α and also denoted $D^{-\alpha}$, the *fractional derivative* of order $-\alpha$.

We extend the definition to functions $f(x)=x^{\beta-1}g(x)$, where g is sufficiently differentiable for $x\geqq 0$ and $\beta\neq 0,-1,-2,\cdots$ is arbitrary. The relation

$$\left(I^\alpha\frac{t^{\beta-1}}{\Gamma(\beta)}\right)(x)=\frac{x^{\alpha+\beta-1}}{\Gamma(\alpha+\beta)}\qquad(\mathrm{Re}\,\alpha>0,\ \mathrm{Re}\,\beta>0)\tag{1.4}$$

can be used as a definition for general $\alpha,\beta\in\mathbb{C}$, $\beta\neq 0,-1,-2,\cdots$. Expanding g as a Taylor series with Bernoulli remainder we see that $(I^\alpha t^{\beta-1}g)(x)$ is then well defined.

For the numerical approximation we wish to preserve two characteristic properties of I^α:

(i) the homogeneity of I^α

$$(I^\alpha f)(x)=x^\alpha(I^\alpha f(tx))(1);$$

(ii) the convolution structure of I^α

$$I^\alpha f=\frac{1}{\Gamma(\alpha)}t^{\alpha-1}*f.$$

So we consider *convolution quadratures*

$$I_h^\alpha f(x)=h^\alpha\sum_{j=0}^{n}\omega_{n-j}f(jh)+h^\alpha\sum_{j=0}^{s}w_{nj}f(jh)\qquad(x=nh)\tag{1.5}$$

where the convolution quadrature weights ω_n $(n\geqq 0)$ and the starting quadrature weights w_{nj} $(n\geqq 0, j=0,\cdots,s;\ s$ fixed) do not depend on h.

Because of the factor h^α we have then the homogeneity relation

$$(I_h^\alpha f)(x)=x^\alpha\big(I_{h/x}^\alpha f(tx)\big)(1).$$

Also the convolution structure is essentially preserved. It is violated only by the few correction terms of the starting quadrature which will be necessary for high order schemes. For the computation of the values $I_h^\alpha f(nh)$ $(n=0,\cdots,N-1)$ one needs only N evaluations of the function f and, using fast Fourier transform techniques, only $O(N\log N)$ additions and multiplications.

There remains the important question: How have the weights ω_n and w_{nj} to be chosen in order that $I_h^\alpha f(x)$ approximate $I^\alpha f(x)$ with a prescribed order $O(h^p)$? A complete answer is given in §2. After introducing the appropriate definitions we show in Theorem 2.5 that a convolution quadrature is convergent of order p if and only if it is stable and consistent of order p. This result is an extension of Dahlquist's [3] classical

theorem on linear multistep methods. An easy way of computing a convolution quadrature of order p is by using a pth order linear multistep method to the power α (Theorem 2.6), called a fractional linear multistep method. The proofs of the results in §2 constitute §3. In §4 we give some brief remarks on the implementation of fractional linear multistep methods. §5 contains numerical examples for some applications of fractional calculus: Abel's integral equation, diffusion in a half-space, special functions of mathematical physics.

We conclude this section with a remark on the notation: If a function $f(x)$ is undefined for $x=0$, we put for simplicity $f(0)=0$. The convolution of two functions $f(x)$, $g(x)$ defined on $x \geqq 0$ is denoted by

$$(f * g)(x)=\int_0^x f(x-s)g(s)\,ds \qquad (x \geqq 0).$$

Given a sequence $a=(a_n)_0^\infty$ we denote by

$$a(\zeta)=\sum_{n=0}^{\infty} a_n \zeta^n$$

its generating power series. We do not distinguish between a formal power series, a convergent power series and the analytical function with which it coincides in its disc of convergence. We refer to (a_n) as the coefficients of $a(\zeta)$.

2. Convergence of convolution quadratures; fractional linear multistep methods. To motivate the following definitions and results we consider first the case $\alpha=1$ in (1.1) and (1.5).

If a linear multistep method (ρ,σ) (where, as usual, ρ and σ denote the generating polynomials of the method, see e.g. Henrici [8]) is applied to the quadrature problem

$$y'(x)=f(x), \quad y(0)=0, \quad \text{i.e.} \quad y(x)=\int_0^x f(s)\,ds,$$

it is well known [17], [20], [15] that the resulting numerical solution can be written as a convolution quadrature (1.5) where the weights ω_n are the coefficients of

$$\omega(\zeta)=\frac{\sigma(1/\zeta)}{\rho(1/\zeta)}. \tag{2.1}$$

The convergence of a linear multistep method is determined by its stability and consistency (Dahlquist [3], [4], also e.g. in Henrici [8]). In terms of the quadrature weights ω_n, the method is stable if and only if ω_n are bounded. Consistency of order p can be expressed as

$$h\omega(e^{-h})=1+O(h^p).$$

In the following definitions we extend these concepts to arbitrary $\alpha \in \mathbb{C}$. Here $\omega=(\omega_n)_0^\infty$ is a convolution quadrature as in (1.5).

DEFINITION 2.1. A convolution quadrature ω is *stable* (for I^α) if

$$\omega_n=O(n^{\alpha-1}).$$

DEFINITION 2.2. A convolution quadrature ω is *consistent of order p* (for I^α) if

$$h^\alpha\omega(e^{-h})=1+O(h^p).$$

Here and in the following p is a positive integer.

Remark. For $\operatorname{Re}\alpha > 0$ this condition can be interpreted as

$$h^\alpha \sum_{j=0}^{\infty} \omega_j e^{-jh} = \frac{1}{\Gamma(\alpha)} \int_0^\infty t^{\alpha-1} e^{-t}\, dt + O(h^p),$$

that is, ω yields an $O(h^p)$ approximation to the integral of the exponential function on the interval $(0, \infty)$.

For the following it is convenient to introduce the notation

$$\Omega_h^\alpha f(x) = h^\alpha \sum_{j=0}^{n} \omega_{n-j} f(jh) \qquad (x = nh), \tag{2.2}$$

which is the convolution part of (1.5), and

$$E_h^\alpha = \Omega_h^\alpha - I^\alpha, \tag{2.3}$$

the convolution quadrature error.

DEFINITION 2.3. A convolution quadrature ω is *convergent of order p* (to I^α) if

$$\left(E_h^\alpha t^{\beta-1}\right)(1) = O(h^\beta) + O(h^p) \quad \text{for all } \beta \in \mathbb{C},\ \beta \neq 0, -1, -2, \cdots. \tag{2.4}$$

This definition is motivated by the following result.

THEOREM 2.4. *Let ω satisfy* (2.4). *Then we have*:

(i) *For every $\beta \neq 0, -1, -2, \cdots$ there exists a starting quadrature*

$$w_{nj} = O(n^{\alpha-1}) \qquad (n \geqq 0, j = 0, \cdots, s) \tag{2.5}$$

such that for any function

$$f(x) = x^{\beta-1} g(x), \quad g \text{ sufficiently differentiable}, \tag{2.6}$$

the approximation $I_h^\alpha f$ given by (1.5) *satisfies*

$$I_h^\alpha f(x) - I^\alpha f(x) = O(h^p) \tag{2.7}$$

uniformly for $x \in [a, b]$ with $0 < a < b < \infty$. (More precisely, let $\tilde{\beta} = \beta + k$ (k integer) such that $0 < \operatorname{Re}\tilde{\beta} \leqq 1$. Then

$$I_h^\alpha f(x) - I^\alpha f(x) = O(x^{\alpha+\tilde{\beta}-1} h^p) \text{ uniformly for bounded } x.) \tag{2.8}$$

(ii) *For every $\beta \neq 0, -1, -2, \cdots$ there exists a starting quadrature w_{nj} (which does not necessarily satisfy* (2.5)) *such that for any function* (2.6) *the approximation $I_h^\alpha f$ satisfies* (2.7) *uniformly for bounded x.*

Remarks. a) Trivially, (i) implies (2.4).

b) The weights w_{nj} are constructed such that $I_h^\alpha t^{q+\beta-1} = I^\alpha t^{q+\beta-1}$ for all integer $q \geqq 0$ with $\operatorname{Re}(q+\beta-1) \leqq p-1$ in (i) and (ii), and additionally those with $\operatorname{Re}(q+\alpha+\beta-1) < p$ in (ii).

c) More generally, for $\beta_1, \cdots, \beta_m$ a starting quadrature (2.5) can be given for functions $f(x) = \sum_{j=1}^m x^{\beta_j - 1} g_j(x)$, g_j sufficiently differentiable, such that (2.7) holds.

In the following we consider convolution quadratures ω for which

$$\omega(\zeta) = r_1(\zeta)^\alpha r_2(\zeta) \tag{2.9}$$

where $r_i(\zeta)$ are rational functions.

We can now give the main result of this paper.

THEOREM 2.5. *A convolution quadrature* (2.9) *is convergent of order p if and only if it is stable and consistent of order p.*

Remark. a) For the special case $\alpha = 1$, Theorem 2.5 reduces in essence to Dahlquist's convergence theorem for linear multistep methods [3], [4].

b) As the proof shows, condition (2.9) can be considerably relaxed. However, the class (2.9) is probably large enough for all practical applications.

For $\alpha = k$ a positive integer, $I^k f = II \cdots I f$ (k-times) is simply the repeated integral of f. If we take $I_h f$ to be the solution of a linear multistep method (ρ, σ) applied to $y' = f$, $y(0) = 0$ (so that $y = I f$), then the repeated method $I_h^k f = I_h \cdots I_h f$ can be rewritten as a convolution quadrature (1.5) where the weights are the coefficients of the power series $\omega(\zeta)^k$, with $\omega(\zeta)$ given by (2.1). This can be interpreted as the kth power of the multistep method. We remark that squaring linear multistep methods ($k = 2$) has been used in the literature, see e.g. Dahlquist [5] and Jeltsch [10]. The following theorem shows that one can also take fractional powers of linear multistep methods. This result is a corollary of Theorem 2.5. It provides a simple means for constructing convolution quadratures for arbitrary $\alpha \in \mathbb{C}$.

THEOREM 2.6 (fractional linear multistep methods). *Let (ρ, σ) denote an implicit linear multistep method which is stable and consistent of order p. Assume that the zeros of $\sigma(\zeta)$ have absolute value less than* 1. *Let $\omega(\zeta)$, given by* (2.1), *denote the generating power series of the corresponding convolution quadrature ω. Define $\omega^\alpha = (\omega_n^{(\alpha)})_0^\infty$ by*

$$\omega^\alpha(\zeta) = \omega(\zeta)^\alpha. \tag{2.10}$$

Then the convolution quadrature ω^α is convergent of order p (to I^α).

We conclude this section with some examples.

Example 2.7. The *fractional Euler method*, $\omega^\alpha(\zeta) = (1-\zeta)^{-\alpha}$, is of historical interest. The method reads

$$I_h^\alpha f(x) = h^\alpha \sum_{0 \le jh \le x} (-1)^j \binom{-\alpha}{j} f(x - jh). \tag{2.11}$$

For $\alpha = -k$ ($k = 1, 2, 3, \cdots$) this is just the kth backward difference quotient. Starting from this observation, Liouville [14, p. 107] had already introduced fractional derivatives by a formula similar to (2.11). Grünwald [7] and Letnikov [13] have shown that (2.11) converges to the Abel–Liouville integral $I^\alpha f(x)$ (for $\operatorname{Re}\alpha > 0$). Their proof (cf. [12, p. 248], [18, p. 51]), however, does not reveal the fact that the method yields an $O(h)$-approximation.

Example 2.8. The $(p+1)$-point backward difference formula (BDF), see e.g. Henrici [8, §5.1-4], is of order p and satisfies for $p \le 6$ the assumptions of Theorem 2.6. The *fractional* BDF *methods* given in Table 1 are therefore convergent of order p. For $\alpha = -1$ the method reduces to the usual $(p+1)$-point backward difference quotient.

TABLE 1

Generating functions for $(\mathrm{BDF}p)^\alpha$, $1 \le p \le 6$.

p	$\omega^\alpha(\zeta)$
1	$(1-\zeta)^{-\alpha}$
2	$(3/2 - 2\zeta + 1/2\zeta^2)^{-\alpha}$
3	$(11/6 - 3\zeta + 3/2\zeta^2 - 1/3\zeta^3)^{-\alpha}$
4	$(25/12 - 4\zeta + 4\zeta^2 - 4/3\zeta^3 + 1/4\zeta^4)^{-\alpha}$
5	$(137/60 - 5\zeta + 5\zeta^2 - 10/3\zeta^3 + 5/4\zeta^4 - 1/5\zeta^5)^{-\alpha}$
6	$(147/60 - 6\zeta + 15/2\zeta^2 - 20/3\zeta^3 + 15/4\zeta^4 - 6/5\zeta^5 + 1/6\zeta^6)^{-\alpha}$

Example 2.9. The *fractional trapezoidal rule*, $\omega^\alpha(\zeta)=(\frac{1}{2}(1+\zeta)/(1-\zeta))^\alpha$, is convergent of order 2 if $\operatorname{Re}\alpha\geqq 0$. Since the numerator has a zero on the unit circle, the method is not stable for $\operatorname{Re}\alpha<0$ (see (3.9), (3.10)).

Example 2.10. The following class of methods can be interpreted as generalized *Newton–Gregory formulas*.

Let γ_i denote the coefficients of

$$\sum_{i=0}^{\infty}\gamma_i(1-\zeta)^i=\left(\frac{\ln\zeta}{\zeta-1}\right)^{-\alpha}$$

(see Lemma 3.2), and put

$$\omega^\alpha(\zeta)=(1-\zeta)^{-\alpha}\left[\gamma_0+\gamma_1(1-\zeta)+\cdots+\gamma_{p-1}(1-\zeta)^{p-1}\right].$$

Then ω^α is convergent of order p (to I^α). For $\alpha=1$ this method reduces to the pth order Newton–Gregory formula (i.e. implicit Adams method), for $\alpha=-1$ to the $(p+1)$-point backward difference quotient.

3. Proofs. We give first the proof of the central result, Theorem 2.5, and of its corollary, Theorem 2.6, and finally the proof of Theorem 2.4. We begin with some preparations.

Preparations. We shall repeatedly make use of the following asymptotic expansion for binomial coefficients (cf. [6, p. 47])

$$(3.1)\quad (-1)^n\binom{-\alpha}{n}=\frac{n^{\alpha-1}}{\Gamma(\alpha)}\left[1+a_1n^{-1}+a_2n^{-2}+\cdots+a_{N-1}n^{-(N-1)}+O(n^{-N})\right]$$

where the coefficients a_j depend analytically on α. $\Omega_h^\alpha f(x)$, introduced in (2.2), can be extended to

$$\Omega_h^\alpha f(x)=h^\alpha\sum_{0\leqq jh\leqq x}\omega_j f(x-jh)\qquad(x\geqq 0),$$

which is the convolution of the sequence $h^\alpha\omega$ with f. Therefore Ω_h^α commutes with convolution

$$\Omega_h^\alpha(f*g)=(\Omega_h^\alpha f)*g,$$

if f is continuous and g is locally integrable.

This property is often shared by I^α:

$$I^\alpha(f*g)=(I^\alpha f)*g$$

which holds for locally integrable g and continuous f if $\operatorname{Re}\alpha>0$, and also for f with $f^{(j)}(0)=0$ $(j=0,\cdots,k-1)$ if $\operatorname{Re}\alpha>-k$. In this case also the convolution quadrature error $E_h^\alpha=\Omega_h^\alpha-I^\alpha$ satisfies

$$(3.2)\qquad E_h^\alpha(f*g)=(E_h^\alpha f)*g.$$

The proof of the above statements is easy and therefore omitted.

The homogeneity of I^α and $t^{\beta-1}$ yields

$$(3.3)\qquad \left(E_h^\alpha t^{\beta-1}\right)(x)=x^{\alpha+\beta-1}\left(E_{h/x}^\alpha t^{\beta-1}\right)(1).$$

Formulas (3.1)–(3.3) and an analytic continuation argument will be the essential tools in the proof of Theorem 2.5.

Proof of Theorem 2.5. We break the proof into several steps which are formulated as lemmas.

LEMMA 3.1. *If* $(E_h^\alpha t^{k-1})(1)=O(h^k)+O(h^p)$ *for* $k=1,2,3,\cdots$, *then* ω *is consistent of order* p.

In particular, convergence of order p *implies consistency of order* p.

Proof. We look first at the quadrature error for e^{t-x} (as a function of t) on the interval $[0,x]$,

$$e_h(x)=\left(E_h^\alpha e^{t-x}\right)(x)=h^\alpha \sum_{0\leqq jh\leqq x} \omega_j e^{-jh}-\left(I^\alpha e^{t-x}\right)(x).$$

As $x\to\infty$, the first expression of the difference tends to $h^\alpha\omega(e^{-h})$, and

$$\left(I^\alpha e^{t-x}\right)(x)\to 1 \qquad (x\to\infty).$$

(For $\operatorname{Re}\alpha>0$ this is immediate from the definition of Euler's gamma function. For $\operatorname{Re}\alpha\leqq 0$ it follows in the same way as in the derivation of (3.5) below, with E_h^α replaced by I^α). So we have

$$e_h(\infty)=h^\alpha\omega(e^{-h})-1. \tag{3.4}$$

We expand e^{t-x} at $t=0$,

$$e^{t-x}=\sum_{k=0}^{q}\frac{t^k}{k!}e^{-x}+\frac{1}{q!}\left(\tau^q * e^{\tau-x}\right)(t),$$

with $q+1\geqq\max\{p,p-\operatorname{Re}\alpha\}$. We write

$$e_h(x)=e_h^1(x)+e_h^2(x)$$

with

$$e_h^1(x)=e^{-x}\sum_{k=0}^{q}\frac{1}{k!}\left(E_h^\alpha t^k\right)(x).$$

By (3.3), $(E_h^\alpha t^k)(x)$ has only polynomial growth as $x\to\infty$. Hence

$$e_h^1(\infty)=0.$$

By (3.2),

$$e_h^2(x)=\frac{1}{q!}E_h^\alpha\left(t^q * e^{t-x}\right)(x)=\frac{1}{q!}\left(\left(E_h^\alpha t^q\right) * e^{t-x}\right)(x)$$

$$=\frac{1}{q!}\int_0^x e^{-s}\left(E_h^\alpha t^q\right)(s)\,ds.$$

So we obtain

$$e_h(\infty)=\frac{1}{q!}\int_0^\infty e^{-s}\left(E_h^\alpha t^q\right)(s)\,ds. \tag{3.5}$$

By (3.3) and by assumption,

$$\left(E_h^\alpha t^q\right)(s)=s^{q+\alpha}\left(E_{h/s}^\alpha t^q\right)(1)=O\left(s^{q+\alpha-p}h^p\right).$$

From (3.4) and (3.5) we obtain hence

$$h^{\alpha}\omega(e^{-h})-1=O(h^{p}),$$

i.e., consistency of order p. □

Our next aim is to give in Lemma 3.2 a characterization of consistency. We may write

$$\omega(\zeta)=(1-\zeta)^{-\mu}\tilde{\omega}(\zeta)$$

where μ is chosen such that $\tilde{\omega}(\zeta)$ is holomorphic at 1 and $\tilde{\omega}(1)\neq 0$.

Consistency implies immediately $\mu=\alpha$ and $\tilde{\omega}(1)=1$. We expand $\omega(\zeta)$ at 1:

$$\omega(\zeta)=(1-\zeta)^{-\alpha}\left[c_0+c_1(1-\zeta)+c_2(1-\zeta)^2+\cdots+c_{N-1}(1-\zeta)^{N-1}+(1-\zeta)^{N}\tilde{r}(\zeta)\right] \tag{3.6}$$

where $\tilde{r}(\zeta)$ is holomorphic at 1.

We can characterize consistency in terms of the coefficients c_i.

LEMMA 3.2. *Let γ_i denote the coefficients of $\sum_0^{\infty}\gamma_i(1-\zeta)^i=(-\ln\zeta/(1-\zeta))^{-\alpha}$. Then*

ω is consistent of order p

if and only if the coefficients c_i in (3.6) *satisfy*

$$c_i=\gamma_i \quad \text{for } i=0,1,\cdots,p-1.$$

Proof. The expression

$$h^{\alpha}\omega(e^{-h})=\left(\frac{h}{1-e^{-h}}\right)^{\alpha}\tilde{\omega}(e^{-h})$$

is $1+O(h^p)$ if and only if

$$\tilde{\omega}(e^{-h})=\left(\frac{h}{1-e^{-h}}\right)^{-\alpha}+O(h^{p}),$$

which holds if and only if

$$\tilde{\omega}(\zeta)=\left(\frac{-\ln\zeta}{1-\zeta}\right)^{-\alpha}+O((1-\zeta)^{p}).$$ □

Whether the method ω is stable depends on the remainder in the expansion (3.6). We rewrite (3.6) as

$$\omega(\zeta)=(1-\zeta)^{-\alpha}\left[c_0+c_1(1-\zeta)+\cdots+c_{N-1}(1-\zeta)^{N-1}\right]+(1-\zeta)^{N}r(\zeta) \tag{3.7}$$

where $r(\zeta)=(1-\zeta)^{-\alpha}\tilde{r}(\zeta)$.

LEMMA 3.3. *ω is stable if and only if the coefficients r_n of $r(\zeta)$ in* (3.7) *satisfy*

$$r_n=O(n^{\alpha-1}). \tag{3.8}$$

Proof. It is immediate from (3.1) that (3.8) implies $\omega_n=O(n^{\alpha-1})$. Conversely, let ω be stable. Then $\omega(\zeta)$ has no singularities in the interior of the unit disc, $|\zeta|<1$, and by (2.9) can therefore be written as

$$\omega(\zeta)=u(\zeta)\prod_{j=0}^{m}(\zeta-\zeta_j)^{-\alpha_j} \tag{3.9}$$

where the ζ_j are distinct numbers of absolute value 1 (let $\zeta_0=1, \alpha_0=\alpha$), $u(\zeta)$ is holomorphic in a neighbourhood of $|\zeta|\leqq 1$, and $u(\zeta_j)\neq 0$, $\alpha_j\neq 0, -1, -2, \cdots$. Expanding $\omega(\zeta)$ at ζ_j yields (cf. partial fraction decomposition)

$$\omega(\zeta)=\sum_{j=0}^{m}(\zeta-\zeta_j)^{-\alpha_j}p_j(\zeta-\zeta_j)+q(\zeta)$$

where p_j are polynomials, $p_j(0)\neq 0$, and $q(\zeta)$ is analytic in the interior of the unit disc and sufficiently differentiable (say, k-times) on the unit circle $|\zeta|=1$, so that its coefficients are $O(n^{-k})$, (e.g. [11, p. 24]).

It is now seen from (3.1) that

$$\omega_n=O(n^{\alpha-1}) \quad \text{if and only if } \operatorname{Re}\alpha_j\leqq\operatorname{Re}\alpha \text{ for all } j. \tag{3.10}$$

Correspondingly, $r(\zeta)$ can be represented as

$$r(\zeta)=\sum_{j=0}^{m}(\zeta-\zeta_j)^{-\alpha_j}\tilde{p}_j(\zeta-\zeta_j)+\tilde{q}(\zeta)$$

with $\tilde{p}_j$ and $\tilde{q}$ as p_j and q above.

Hence (3.10) holds also with r_n instead of ω_n. This gives (3.8). □

The trivial direction of Lemma 3.3 is used in the next lemma.

LEMMA 3.4. *Convergence implies stability.*

Proof. If ω is convergent, then it is consistent by Lemma 3.1. With $N=1$ in (3.7) we have therefore

$$\omega(\zeta)=(1-\zeta)^{-\alpha}+(1-\zeta)r(\zeta).$$

We study

$$(E_h^{\alpha}1)(1)=h^{\alpha}\sum_{j=0}^{n}\omega_{n-j}-\frac{1}{\Gamma(\alpha+1)} \qquad (hn=1).$$

$\sum_{j=0}^{n}\omega_{n-j}$ is the nth coefficient of

$$\frac{\omega(\zeta)}{1-\zeta}=(1-\zeta)^{-\alpha-1}+r(\zeta).$$

By (3.1) we have

$$(E_h^{\alpha}1)(1)=h^{\alpha}\left[\frac{n^{\alpha}}{\Gamma(\alpha+1)}+O(n^{\alpha-1})\right]+h^{\alpha}r_n-\frac{1}{\Gamma(\alpha+1)}=O(h)+h^{\alpha}r_n \qquad (hn=1)$$

which is $O(h)$ only if $r_n=O(n^{\alpha-1})$. Now Lemma 3.3 completes the proof. □

It remains to show that stability and consistency imply convergence. Let us first have a closer look at the structure of the error.

LEMMA 3.5. *Let $\alpha, \beta\in\mathbb{C}$, $\beta\neq 0, -1, -2, \cdots$. If ω is stable, then the convolution quadrature error of $t^{\beta-1}$ has an asymptotic expansion of the form*

$$(E_h^{\alpha}t^{\beta-1})(1)=e_0+e_1h+\cdots+e_{N-1}h^{N-1}+O(h^N)+O(h^{\beta}) \tag{3.11}$$

where the coefficients $e_j=e_j(\alpha,\beta,c_0,\cdots,c_j)$ depend analytically on α, β and the coefficients $c_0,\cdots,c_j$ of (3.7).

Proof. a) We need the following auxiliary result: The convolution of two sequences $u_n = O(n^\mu)$ and $v_n = O(n^\nu)$ with $\nu < \min\{-1, \mu-1\}$ satisfies

$$\sum_{j=0}^{n} u_{n-j} v_j = O(n^\mu). \tag{3.12}$$

This is seen from

$$\left| \sum_{j=0}^{n} u_{n-j} v_j \right| \leqq |u_n v_0| + |u_0 v_n| + M n^\mu \sum_{j=1}^{n-1} \left(1 - \frac{j}{n}\right)^\mu j^\nu$$

and

$$\left(1 - \frac{j}{n}\right)^\mu \leqq \begin{cases} 1 & \text{if } \mu \geqq 0 \\ (j+1)^{-\mu} & \text{if } \mu < 0 \end{cases} \quad \text{for } 1 \leqq j \leqq n-1.$$

b) For $\beta \neq 0, -1, -2, \cdots$ we obtain from (3.1) an asymptotic expansion

$$n^{\beta-1} = b_0 (-1)^n \binom{-\beta}{n} + b_1 (-1)^n \binom{-\beta+1}{n} + \cdots + b_{N-1} (-1)^n \binom{-\beta+N-1}{n} + O(n^{\beta-1-N}). \tag{3.13}$$

So we have

$$b(\zeta) := \sum_{n=1}^{\infty} n^{\beta-1} \zeta^n = b_0 (1-\zeta)^{-\beta} + b_1 (1-\zeta)^{-\beta+1} + \cdots + b_{N-1} (1-\zeta)^{-\beta+N-1} + s(\zeta)$$

where the coefficients s_n of $s(\zeta)$ satisfy

$$s_n = O(n^{\beta-1-N}). \tag{3.14}$$

c) We have to study the expression

$$h^\alpha \sum_{j=1}^{n} \omega_{n-j} (jh)^{\beta-1} \qquad (hn = 1).$$

$y_n = \sum_{j=1}^{n} \omega_{n-j} j^{\beta-1}$ is the nth coefficient of $y(\zeta) = \omega(\zeta) b(\zeta)$ which by inserting (3.7) and (3.13) can be written as

$$y(\zeta) = d_0 (1-\zeta)^{-(\alpha+\beta)} + d_1 (1-\zeta)^{-(\alpha+\beta)+1} + \cdots + d_{2N-2} (1-\zeta)^{-(\alpha+\beta)+2N-2} + \omega(\zeta) s(\zeta) + [b(\zeta) - s(\zeta)](1-\zeta)^N r(\zeta)$$

where $d_k = \sum_{j=0}^{k} b_{k-j} c_j$.

If N is chosen sufficiently large, then the coefficients of $\omega(\zeta) s(\zeta)$ and

$$[b(\zeta) - s(\zeta)](1-\zeta)^N r(\zeta) = \left[b_0 (1-\zeta)^{-\beta+N} + \cdots + b_{N-1} (1-\zeta)^{-\beta+2N-1} \right] r(\zeta)$$

are $O(n^{\alpha-1})$ by (3.1), (3.8), (3.14) and (3.12).

By (3.1) we have therefore

$$y_n = \tilde{e}_0 n^{\alpha+\beta-1} + e_1 n^{(\alpha+\beta-1)-1} + \cdots + e_N n^{(\alpha+\beta-1)-N} + O(n^{\alpha-1}).$$

This gives the desired result for

$$\left(E_h^\alpha t^{\beta-1}\right)(1)=h^{\alpha+\beta-1}y_n-\left(I^\alpha t^{\beta-1}\right)(1) \qquad (hn=1). \qquad \square$$

In Lemma 3.8 below we shall show that $e_0=\cdots=e_{p-1}=0$ if the method is stable and consistent of order p. First, we need two auxiliary results in which we restrict our attention to $\operatorname{Re}\alpha>0$.

LEMMA 3.6. *Let* $\operatorname{Re}\alpha>0$.

If $\left(E_h^\alpha t^{p-1}\right)(1)=O(h^p)$, *then* $\left(E_h^\alpha t^{\beta-1}\right)(1)=O(h^p)$ *for all* $\operatorname{Re}\beta>p$.

Proof. Let $\beta=p+\mu$. By (1.4),

$$t^{\beta-1}=\frac{\Gamma(p+\mu)}{\Gamma(p)\Gamma(\mu)}t^{p-1}*t^{\mu-1}.$$

By (3.3),

$$\left(E_h^\alpha t^{p-1}\right)(x)=O(x^{\alpha-1}h^p).$$

By (3.2),

$$E_h^\alpha\left(t^{p-1}*t^{\mu-1}\right)(1)=\left(E_h^\alpha t^{p-1}*t^{\mu-1}\right)(1)=O(h^p).$$

Hence also

$$\left(E_h^\alpha t^{\beta-1}\right)(1)=O(h^p). \qquad \square$$

Remark. $E_h^\alpha t^{p-1}$ is the Peano kernel of the quadrature ω.

LEMMA 3.7. *Let* $\operatorname{Re}\alpha>0$. *There exist numbers* $\tilde\gamma_0,\tilde\gamma_1,\tilde\gamma_2,\cdots$ (*independent of* ω) *such that the following equivalence holds for stable* ω:

$$\left(E_h^\alpha t^{q-1}\right)(1)=O(h^q) \quad \text{for } q=1,2,\cdots,p \tag{3.15}$$

if and only if the coefficients c_i *of* (3.7) *satisfy*

$$c_i=\tilde\gamma_i \quad \text{for } i=0,1,\cdots,p-1. \tag{3.16}$$

Proof. The proof proceeds by induction on p. Trivially the statement holds for $p=0$.

Assume now that Lemma 3.7 has already been proved up to order p. We shall prove it for $p+1$.

Let either of (3.15) or (3.16) hold. By the induction hypothesis, it suffices to show that c_p can be uniquely chosen such that

$$\left(E_h^\alpha t^p\right)(1)=O(h^{p+1}).$$

From Lemma 3.6 (and from Lemma 3.5 for $p=0$) we know already

$$\left(E_h^\alpha t^p\right)(1)=O(h^p). \tag{3.17}$$

For any integer n we may write

$$n^p=\sum_{k=1}^{p+1}b_k\binom{n+k-1}{n}=\sum_{k=1}^{p+1}b_k(-1)^n\binom{-k}{n}$$

so that (with $hn=1$)

$$\left(\Omega_h^\alpha t^p\right)(1)=h^\alpha\sum_{j=0}^{n}\omega_j(n-j)^ph^p=h^{p+\alpha}\sum_{k=1}^{p+1}b_k\sum_{j=0}^{n}\omega_j(-1)^{n-j}\binom{-k}{n-j}.$$

The inner sum is the nth coefficient of

$$\frac{\omega(\zeta)}{(1-\zeta)^k}=\tilde{\gamma}_0(1-\zeta)^{-\alpha-k}+\cdots+\tilde{\gamma}_{p-1}(1-\zeta)^{-\alpha+p-1-k}$$
$$+c_p(1-\zeta)^{-\alpha+p-k}+(1-\zeta)^{p+1-k}r(\zeta).$$

Using (3.1), (3.8) and (3.17) we obtain

$$(E_h^\alpha t^p)(1)=\frac{c_p-\tilde{\gamma}_p}{\Gamma(\alpha+1)}h^p+O(h^{p+1})$$

where $\tilde{\gamma}_p$ depends only on α and $\tilde{\gamma}_0,\cdots,\tilde{\gamma}_{p-1}$. Hence (3.15) holds for $p+1$ instead of p if and only if additionally $c_p=\tilde{\gamma}_p$. □

We have now arrived at the final step of the proof.

LEMMA 3.8. *Let $\alpha\in\mathbb{C}$. If ω is stable and consistent of order p, then it is also convergent of order p.*

Proof. Let first $\mathrm{Re}\,\alpha>0$. Since (3.15) implies consistency of order p by Lemma 3.1, the numbers $\tilde{\gamma}_i$ of Lemma 3.7 and $\gamma_i=\gamma_i(\alpha)$ of Lemma 3.2 are identical.

By Lemmas 3.5 and 3.6 we have then for $\mathrm{Re}\,\alpha>0$, $\mathrm{Re}\,\beta>p$

$$e_j\big(\alpha,\beta,\gamma_0(\alpha),\cdots,\gamma_j(\alpha)\big)=0\qquad(j=0,\cdots,p-1).$$

By analyticity, this holds then for *all* α, β.

If the method is consistent of order p, we have by Lemma 3.2 $c_i=\gamma_i(\alpha)$ for $i=0,\cdots,p-1$. Now Lemma 3.5 gives the result. □

We have thus completed the proof of Theorem 2.5. □

Proof of Theorem 2.6. The linear multistep method is consistent of order p, i.e.

$$h\omega(e^{-h})=1+O(h^p).$$

Taking this relation to power α yields

$$h^\alpha\omega^\alpha(e^{-h})=1+O(h^p),$$

so that ω^α is consistent of order p for I^α. Under the given assumptions on (ρ,σ) we can write

$$\omega(\zeta)=\frac{\sigma(\zeta^{-1})}{\rho(\zeta^{-1})}=\prod_{i=0}^{r}(1-\zeta_i\zeta)^{-1}v(\zeta)$$

where $v(\zeta)$ is analytic and without zeros in a neighbourhood of $|\zeta|\leqq 1$, and ζ_i are the zeros of $\rho(\zeta)$ on the unit circle. Hence

$$\omega^\alpha(\zeta)=\prod_{i=0}^{r}(1-\zeta_i\zeta)^{-\alpha}u(\zeta)$$

where $u(\zeta)=v(\zeta)^\alpha$ is analytic in a neighbourhood of $|\zeta|\leqq 1$. By (3.9) and (3.10),

$$\omega_n^{(\alpha)}=O(n^{\alpha-1})$$

so that ω^α is stable. Now Theorem 2.5 completes the proof. □

Proof of Theorem 2.4. The proof is based on a Peano kernel technique similar as in Lemmas 3.1 and 3.6.

(i) Fix $\beta \neq 0, -1, -2, \cdots$. Let the integer m such that

$$\mathrm{Re}(m+\beta-1) \leqq p < \mathrm{Re}(m+\beta).$$

A suitable starting quadrature can be chosen by putting

$$(3.18) \quad h^\alpha \sum_{j=1}^{m} w_{nj} (jh)^{q+\beta-1} + \left(E_h^\alpha t^{q+\beta-1}\right)(1) = 0 \qquad (q=0,1,\cdots,m-1;\ hn=1).$$

This gives a Vandermonde type system of equations for w_{nj} $(j=1,\cdots,m)$,

$$\sum_{j=1}^{m} w_{nj} j^{q+\beta-1} = O(n^{\alpha-1}) \quad \text{by (2.4)}.$$

Hence also

$$(3.19) \qquad w_{nj} = O(n^{\alpha-1})$$

as desired.

Let $f(x) = x^{\beta-1} g(x)$, g sufficiently differentiable. Expanding f as a fractional Taylor series with Bernoulli remainder term gives (let $f^{(\mu)} = I^{-\mu} f$)

$$(3.20) \quad f(x) = \sum_{q=0}^{N} \frac{f^{(q+\beta-1)}(0)}{\Gamma(q+\beta)} x^{q+\beta-1} + \frac{1}{\Gamma(N+\beta)} \left(t^{N+\beta-1} * f^{(N+\beta)}\right)(x).$$

If $\mathrm{Re}(N+\beta-1) > p$, then (3.3) and (2.4) yield

$$\left(E_h^\alpha t^{N+\beta-1}\right)(x) = O(x^{N-p+\alpha+\beta-1} h^p).$$

If additionally $\mathrm{Re}(N-p+\alpha+\beta) > 0$, then (3.2) and the boundedness of $f^{(N+\beta)}$ give

$$(3.21) \qquad \begin{aligned} E_h^\alpha \left(t^{N+\beta-1} * f^{(N+\beta)}\right)(x) &= \left(E_h^\alpha t^{N+\beta-1} * f^{(N+\beta)}\right)(x) \\ &= O(x^{N-p+\alpha+\beta} h^p) \end{aligned}$$

for bounded x.

By our choice of the starting quadrature ((3.18), (3.19)), by the homogeneity relation (3.3) and by (3.20), (3.21) we have

$$\begin{aligned} I_h^\alpha f(x) - I^\alpha f(x) &= E_h^\alpha f(x) + h^\alpha \sum_{j=1}^{m} w_{nj} f(jh) \\ &= O(x^{m-p+\alpha+\beta-1} h^p) + \cdots + O(x^{N-p+\alpha+\beta-1} h^p) + O(x^{N-p+\alpha+\beta} h^p) \\ &= O(x^{m-p+\alpha+\beta-1} h^p) \quad \text{uniformly for bounded } x. \end{aligned}$$

This gives (i) of Theorem 2.4 (note $\tilde{\beta} = m-p+\beta$).

(ii) If m is (3.18) is replaced by $l > m$ with $\mathrm{Re}(l-p+\alpha+\beta-1) \geqq 0$, then the corresponding starting quadrature weights satisfy

$$w_{nj} = O(n^{l-1-p+\alpha+\beta-1}),$$

and the same arguments as above show

$$I_h^\alpha f(x) - I^\alpha f(x) = O(h^p) \quad \text{uniformly for bounded } x. \qquad \square$$

4. Implementation.

4.1. Weights of fractional linear multistep methods ω^α. The coefficients of ω^α, defined by (2.10), are computed most efficiently by Fast Fourier Transform (FFT) techniques for formal power series as described by Henrici [9, §5]. The weights $\omega_0^{(\alpha)}, \cdots, \omega_{N-1}^{(\alpha)}$ are thus obtained using only $O(N \log N)$ additions and multiplications.

4.2. Starting quadrature weights w_{nj}. Multiplying (3.18) by $n^{q+\alpha+\beta-1}$ and using (1.4) we obtain

(4.1)
$$\sum_{j=1}^{s} w_{nj} j^{q+\beta-1} = \frac{\Gamma(q+\beta)}{\Gamma(\alpha+q+\beta)} n^{q+\alpha+\beta-1} - \sum_{j=1}^{n} \omega_{n-j} j^{q+\beta-1} \qquad (q=0,\cdots,s-1).$$

Exploiting the convolution structure of the right-hand side, the weights $w_{nj} (n = 1,\cdots,N$ and $j=1,\cdots,s)$ can be computed from (4.1) with $O(N \log N)$ operations, using FFT-techniques (cf. [9]).

The starting quadrature of (ii) in Theorem 2.4 can be used on short intervals. If w_{nj} of (ii) do not satisfy (2.5), then they dominate ω_n for large n, and errors in the evaluation of $f(jh)$ $(j=1,\cdots,s)$ are unduly magnified.

(As a marginal note: For large n the right-hand side of (4.1) can be computed only with large relative error, due to cancellation of leading digits. Moreover the Vandermonde system is ill-conditioned for large s. Hence the weights w_{nj} are computed with possibly low accuracy. This does, however, *not* affect the accuracy of the quadrature, since it is only important that (4.1) holds up to machine precision).

4.3. Computation of $\Omega_h^\alpha f$. After $f_j = f(jh)$ have been evaluated, the values of the convolution $\Omega_h^\alpha f(nh) = h^\alpha \sum_{j=1}^{n} \omega_{n-j} f_j (n=1,\cdots,N)$ can be computed simultaneously by FFT-techniques with only $O(N \log N)$ operations.

5. Applications and numerical examples.

5.1. Abel's integral equation. Historically, the first application of fractional calculus was probably given by Abel in his study of the tautochrone problem ([1], see also [18, p. 183]). This led him to the integral equation

$$\frac{1}{\sqrt{\pi}} \int_0^x (x-s)^{-1/2} y(s)\, ds = f(x),$$

the solution of which he found to be

$$y(x) = I^{-1/2} f(x).$$

For our numerical experiments we have used the $(\mathrm{BDF3})^{-1/2}$ method (third order backward differentiation formula to power $-\frac{1}{2}$, see Example 2.8). We give the results for the function

$$f(x) = \frac{x}{1+x}.$$

The exact solution is then given by (see [18, p. 121])

(5.1)
$$I^{-1/2} \frac{x}{1+x} = \frac{2}{\sqrt{\pi}} \sqrt{x}\, {}_2F_1\left(1, 2; \frac{3}{2}; -x\right),$$

where ${}_2F_1$ denotes the hypergeometric function. The solution at $x=1$ is $y(1)=0.4579033863$. The numerical results are given in Table 2.

TABLE 2

h	numerical solution	error	error/h^3
0.04	0.4579085018	$0.512_{10^{-5}}$	0.0799
0.02	0.4579040377	$0.651_{10^{-6}}$	0.0814
0.01	0.4579034683	$0.820_{10^{-7}}$	0.0820

5.2. Diffusion problems. As a simple example, consider the heat equation in a half-space

$$u_t = u_{xx} \qquad (x>0,\ t>0)$$

with initial condition

$$u(x,0)=0 \qquad (x>0),$$

with boundary conditions

$$u(\infty,t)=0 \qquad (t>0)$$

and either

(i) $u(0,t)=f(t)$ $(t>0)$ or

(ii) $u_x(0,t)=g(t)$ $(t>0)$ or

(iii) $u_x(0,t)=G(u(0,t))$ $(t>0)$.

The solution at the surface $x=0$ satisfies (cf. [2, App. 2 to Ch. V])

$$u(0,t) = -\frac{1}{\sqrt{\pi}}\int_0^t (t-s)^{-1/2} u_x(0,s)\,ds \qquad (t>0).$$

For boundary conditions (ii) the surface temperature $u(0,t)$ is thus obtained as $-I^{1/2}g(t)$. For boundary conditions (i) this formula is a first kind Abel integral equation for the surface flux $u_x(0,t)$, which hence equals $-I^{-1/2}f(t)$. In case (iii) we obtain a second kind Abel integral equation for $u(0,t)$. The application of fractional linear multistep methods to such equations is discussed in the author's paper [16]. The solution $u(x,t)$ can be recovered from the surface flux by

$$u(x,t) = -\frac{1}{\sqrt{\pi}}\int_0^t (t-s)^{-1/2} \exp\left(\frac{-x^2}{4(t-s)}\right) u_x(0,s)\,ds.$$

As a numerical example related to (ii), we have used the $(\mathrm{BDF4})^{1/2}$ method (see Example 2.8) to compute

$$I^{1/2}\frac{\sin\sqrt{t}}{\sqrt{\pi}} = \sqrt{t}\,J_1(\sqrt{t}), \tag{5.2}$$

where J_1 denotes the Bessel function (see [18, p. 124]). At $t=1$ the solution is $J_1(1)=0.4400505857449$. The numerical results are given in Table 3.

TABLE 3

h	numerical solution	error	error/h^4
0.04	0.4400505854008	$-0.344_{10^{-9}}$	$-0.134_{10^{-3}}$
0.02	0.4400505857240	$-0.209_{10^{-10}}$	$-0.130_{10^{-3}}$
0.01	0.4400505857436	$-0.128_{10^{-11}}$	$-0.127_{10^{-3}}$

5.3. Special functions. The relations (5.1) and (5.2) are special cases of

$$ {}_2F_1(a,b;c;x)=\frac{\Gamma(c)x^{1-c}}{\Gamma(b)}I^{c-b}\left[x^{b-1}(1-x)^{-a}\right] \quad \text{and}$$

$$ J_\mu(\sqrt{x})=\frac{2}{\sqrt{\pi}}(2\sqrt{x})^{-\mu}I^{\mu-1/2}\sin\sqrt{x}\,.$$

Among the special functions which can be represented as fractional integrals of simpler functions are: hypergeometric functions, confluent and generalized hypergeometric functions, Bessel and Struve functions, Legendre functions, elliptic integrals etc. (see [12], [18]). Convolution quadratures for their computation are particularly effective if one is interested in obtaining many values on a grid simultaneously.

Acknowledgments. The author wishes to thank E. Hairer and G. Gienger for helpful discussions, and G. Bader, P. Deuflhard and U. Nowak for their interest in this work.

THE REPRESENTATION OF FUNCTIONS AS LAPLACE AND LAPLACE–STIELTJES TRANSFORMS*

F. J. WILSON†

Abstract. We develop necessary and sufficient conditions for a function to be represented as a Laplace or Laplace–Stieltjes transform by considering the behaviour of the function on a single vertical line. Various kernels, based on ideal inversion kernels for the Fourier transform, are considered and three new inversion formulae for the Laplace transform are developed.

AMS(MOS) subject classification. Primary 44A10

Key words. Laplace transform, inversion kernel

1. Introduction. In this paper we examine criteria for a function $f(w)$ to be represented as a Laplace or Laplace–Stieltjes transform by considering the behaviour of the function on a single vertical line. We consider integral transforms of the form

$$F(t,c,\lambda)=\frac{1}{2\pi}\int_{-\infty}^{\infty} k(t,v,c,\lambda)f(c+iv)\,dv$$

where $k(t,v,c,\lambda)$ is a kernel similar in form to the ideal inversion kernels for the Fourier transform which were examined in [1] and [6].

In [2] Cooper gives necessary and sufficient conditions for a function to be represented as a Laplace transform by considering integral transforms of the form

$$F(t,c,\lambda)=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{(c+iv)t}l(v,\lambda)f(c+iv)\,dv.$$

We extend these results by considering a wider class of kernels some of which, for example the Post–Widder kernel

$$k(t,v,c,\lambda)=\left(\frac{\lambda}{\lambda-t(c+iv)}\right)^{\lambda+1},$$

cannot be written in the form $e^{(c+iv)t}l(v,\lambda)$. We also prove our results for p in the range $1\leqq p\leqq\infty$ whereas Cooper in [2], because the proofs of his main theorems depend on Fourier transform theory, has to restrict p to the range $1\leqq p\leqq 2$.

We show that, under certain conditions on $f(w)$ and the kernels $k(t,v,c,\lambda)$, the boundedness of the set $\{F(t,c,\lambda)e^{-at}\}$ in $L_p(0,\infty)$, $1<p\leqq\infty$, is necessary and sufficient for $f(w)$ to be represented as a Laplace transform and if f is the Laplace transform of a function F then F can be found by considering the weak limit of $F(t,c,\lambda)e^{-at}$ in $L_p(0,\infty)$ as $\lambda\to\infty$. Similarly for $p=1$ we show that the boundedness of the set $\{F(t,c,\lambda)e^{-at}\}$ in $L(0,\infty)$ is necessary and sufficient for $f(w)$ to be represented as a Laplace–Stieltjes transform and if f is the Laplace–Stieltjes transform of a function H then H can be found by considering the limit of $\int_0^t F(u,c,\lambda)\,du$ as $\lambda\to\infty$.

We show that the Weierstrass and Abel kernels, the Cesaro kernel of positive order and the kernel of ordinary convergence satisfy the conditions of the theorems. We then produce three new inversion formulae for the Laplace transform by showing that the following kernels

$$\left(\frac{\lambda}{\lambda - t(c+iv)}\right)^{\lambda+1} \quad \text{the Post–Widder kernel,}$$

$$\left(\frac{\lambda+\theta_\lambda}{\lambda+\theta_\lambda - t(c+iv)}\right)^{\lambda+1} \quad \text{where } \theta_\lambda = o(\lambda) \text{ as } \lambda \to \infty,$$

the extended Post–Widder kernel,

and

$$e^{(c+iv)t}\Gamma\left(1-\frac{iv}{\lambda}\right) \quad \text{the extended Phragmen kernel}$$

also satisfy the conditions of the theorems. Lastly we show that for a particular class of kernels it is possible to determine the abscissa of absolute convergence of the Laplace transform by considering the behaviour of $f(w)$ on any line in the half-plane of absolute convergence.

2. Notation. We write

$$(LF)(w) = \int_0^\infty e^{-wt} F(t)\, dt$$

and

$$(SH)(w) = \int_0^\infty e^{-wt}\, dH(t)$$

for the Laplace and Laplace–Stieltjes transforms.

For any real a we write $F \in L_p[a;(0,\infty)]$ when $F(t)e^{-at} \in L_p(0,\infty)$ and $H \in V[a,(0,\infty)]$ when H is a function of bounded variation over $(0,\infty)$ and

$$\int_0^\infty e^{-at} |dH(t)|$$

is finite. We will denote the dual of $L_p(0,\infty)$ by $L_{p'}(0,\infty)$. For $1 \leqq p < \infty$ we use the following notation for function norms

$$\|\psi(t);(0,\infty)\|_p = \left\{\int_0^\infty |\psi(t)|^p\, dt\right\}^{1/p}$$

and for $p = \infty$

$$\|\psi(t);(0,\infty)\|_\infty = \operatorname*{ess\,sup}_{0<t<\infty} |\psi(t)|$$

We write $e^{-(c+iv)t}k(t,v,c,\lambda) \to 1$ boundedly for almost all (v,t) in $(-\infty,\infty)\times(0,\infty)$ as $\lambda \to \infty$ when

$$\operatorname*{ess\,sup}_{\substack{-\infty<v<\infty \\ 0<t<\infty}} |e^{-(c+iv)t}k(t,v,c,\lambda)| < M$$

for all $\lambda > \lambda_0$, where M is a constant independent of v and t, and

$$e^{-(c+iv)t}k(t,v,c,\lambda) \to 1$$

as $\lambda \to \infty$ for almost all (v,t) in $(-\infty,\infty)\times(0,\infty)$.

We write

$$\int_0^\infty g(t,x,\lambda)\begin{Bmatrix} dt \\ dx \end{Bmatrix} \text{ is bounded uniformly in } \begin{Bmatrix} x \\ t \end{Bmatrix} \text{ and } \lambda$$

when $\int_0^\infty g(t,x,\lambda)\,dt$ is bounded uniformly in x and λ and $\int_0^\infty g(t,x,\lambda)\,dx$ is bounded uniformly in t and λ.

For the Fourier transform of $k(t,v,c,\lambda)$ with respect to v we write

$$K(t,x,c,\lambda) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-ivx}k(t,v,c,\lambda)\,dv.$$

We will denote the characteristic function of the interval (a,b) by $\chi_{(a,b)}(v)$.

In all theorems we are only concerned with $\lambda \to \infty$ so to avoid any difficulties with small values of λ we will restrict λ to the range $\lambda > \lambda_0$.

3. Necessary conditions for the representation of functions as Laplace or Laplace–Stieltjes transforms. We now show that, under certain conditions on the kernel $k(t,v,c,\lambda)$, the boundedness of the integral transform

$$F(t,c,\lambda)e^{-at} = \frac{e^{-at}}{2\pi} \int_{-\infty}^{\infty} k(t,c,v,\lambda)f(c+iv)\,dv$$

in $L_p(0,\infty)$ is a necessary condition for a function $f(w)$ to be represented as a Laplace or Laplace–Stieltjes transform.

For the theorems dealing with necessary conditions there are no restrictions on the relative values of the real numbers a and c apart from the restrictions imposed by the given function $F(t)$ and the kernel $k(t,v,c,\lambda)$ but in §4, where we prove the corresponding sufficiency theorems, we will require that $a \leqq c$.

Firstly for the case $1 < p < \infty$.

THEOREM 1. *Let $f = LF$, where $F \in L_p[a;(0,\infty)]$ and $1 < p < \infty$, and let c be a real number such that the Laplace transform, $f(w)$, converges absolutely for $w = c + iv$. As a function of v let $k(t,v,c,\lambda) \in L(-\infty,\infty)$ for all $t > 0$ and $\lambda > \lambda_0$.*

Let $\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\begin{Bmatrix} dt \\ dx \end{Bmatrix}$ be bounded uniformly in $\begin{Bmatrix} x \\ t \end{Bmatrix}$ and λ for all $\begin{Bmatrix} x>0 \\ t>0 \end{Bmatrix}$ and $\lambda > \lambda_0$. Then there exists a constant M_p such that

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_p \leqq M_p$$

uniformly in λ for all $\lambda > \lambda_0$.

Proof. By hypothesis there exist constants N_1 and N_2 such that

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dt \leqq N_1$$

and

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx \leqq N_2.$$

Now

$$F(t,c,\lambda)e^{-at} = \frac{e^{-at}}{2\pi}\int_{-\infty}^{\infty} k(t,v,c,\lambda)f(c+iv)\,dv$$

$$= \frac{e^{-at}}{2\pi}\int_{-\infty}^{\infty} k(t,v,c,\lambda)\,dv\int_0^{\infty} e^{-(c+iv)x}F(x)\,dx$$

$$= \frac{1}{\sqrt{2\pi}}\int_0^{\infty} F(x)e^{-ax}e^{-at}e^{(a-c)x}K(t,x,c,\lambda)\,dx.$$

Hence, using Holder's inequality,

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_p^p$$

$$\leqq (2\pi)^{-p/2}\int_0^{\infty} dt\left[\left\{\int_0^{\infty}|F(x)e^{-ax}|^p e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx\right\}\right.$$

$$\left.\cdot\left\{\int_0^{\infty} e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx\right\}^{p/p'}\right]$$

$$\leqq (2\pi)^{-p/2}N_2^{p/p'}\int_0^{\infty} dt\int_0^{\infty}|F(x)e^{-ax}|^p e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx$$

$$\leqq (2\pi)^{-p/2}N_2^{p/p'}\int_0^{\infty}|F(x)e^{-ax}|^p\,dx\int_0^{\infty} e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dt$$

$$\leqq (2\pi)^{-p/2}N_2^{p/p'}N_1\int_0^{\infty}|F(x)e^{-ax}|^p\,dx$$

which is bounded, since $F\in L_p[a;(0,\infty)]$, where the two interchanges of integration are justified by Fubini's theorem.

Theorem 1 also holds for $p=\infty$ and $p=1$ but we show that it is possible to prove the necessity theorem under less restrictive conditions on $k(t,v,c,\lambda)$ for these two particular cases.

Secondly for the case $p=\infty$.

THEOREM 2. *Let $f=LF$, where $F\in L_\infty[a;(0,\infty)]$, and let c be a real number such that the Laplace transform, $f(w)$, converges absolutely for $w=c+iv$. As a function of v let $k(t,v,c,\lambda)\in L(-\infty,\infty)$ for all $t>0$ and $\lambda>\lambda_0$. Let*

$$\int_0^{\infty} e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx$$

be bounded uniformly in t and λ for all $t>0$ and $\lambda>\lambda_0$. Then there exists a constant M_∞ such that

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_\infty \leqq M_\infty$$

uniformly in λ for all $\lambda>\lambda_0$.

Proof. Using the same method as in Theorem 1, we have

$$\begin{aligned}&\|F(t,c,\lambda)e^{-at};(0,\infty)\|_\infty\\&\quad=\frac{1}{\sqrt{2\pi}}\operatorname*{ess\,sup}_{0<t<\infty}\left|\int_0^\infty F(x)e^{-ax}e^{-at}e^{(a-c)x}K(t,x,c,\lambda)\,dx\right|\\&\quad\leqq\frac{1}{\sqrt{2\pi}}\|F(x)e^{-ax};(0,\infty)\|_\infty\operatorname*{ess\,sup}_{0<t<\infty}\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx\end{aligned}$$

which is bounded uniformly in λ.

Thirdly for the case $p=1$ we need to consider Laplace–Stieltjes transforms.

THEOREM 3. *Let $f=SH$, where $H\in V[a;(0,\infty)]$, and let c be a real number such that the Laplace–Stieltjes transform, $f(w)$, converges absolutely for $w=c+iv$. As a function of v let $k(t,v,c,\lambda)\in L(-\infty,\infty)$ for all $t>0$ and $\lambda>\lambda_0$. Let*

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dt$$

be bounded uniformly in x and λ for all $x>0$ and $\lambda>\lambda_0$. Then there exists a constant M_1 such that

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_1\leqq M_1$$

uniformly in λ for all $\lambda>\lambda_0$.

Proof. Using the same method as in Theorem 1, we have

$$\begin{aligned}&\|F(t,c,\lambda)e^{-at};(0,\infty)\|_1\\&\qquad=\frac{1}{\sqrt{2\pi}}\int_0^\infty dt\left|\int_0^\infty e^{-at}e^{(a-c)x}K(t,x,c,\lambda)e^{-ax}\,dH(x)\right|\\&\qquad\leqq\frac{1}{\sqrt{2\pi}}\int_0^\infty e^{-ax}|dH(x)|\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dt\end{aligned}$$

which is bounded uniformly in λ. The interchange in the order of integration being justified by Fubini's theorem.

Whilst these three theorems are adequate for most of the particular kernels that we will be considering, the kernel of ordinary convergence, $k(t,v,c,\lambda)=e^{(c+iv)t}\chi_{(-\lambda,\lambda)}(v)$, does not satisfy the conditions of the theorems, since, even for the case $a=c$,

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dx$$

is not bounded.

For the kernel of ordinary convergence we need the following necessity theorem.

THEOREM 4. *Let $f=LF$, where $F\in L_p[a;(0,\infty)]$ and $p>1$, and let c be a real number such that the Laplace transform, $f(w)$, converges absolutely for $w=c+iv$. As a function of v let $k(t,v,c,\lambda)\in L(-\infty,\infty)$ for all $t>0$ and $\lambda>\lambda_0$.*

Let the transformation S_λ be defined by

$$(S_\lambda g)(t)=\frac{1}{\sqrt{2\pi}}\int_0^\infty g(x)e^{-at}e^{(a-c)x}K(t,x,c,\lambda)\,dx$$

where $g\in L_p(0,\infty)$.

Then, if the set of transforms $\{S_\lambda\}$ *forms a bounded set of transforms from* $L_p(0,\infty)$ *into itself, there exists a constant,* M_p, *such that*

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_p \leqq M_p$$

uniformly in λ *for all* $\lambda > \lambda_0$.

Proof. The proof follows that of Theorems 1 and 2 up to the equation

$$F(t,c,\lambda)e^{-at} = \frac{1}{\sqrt{2\pi}} \int_0^\infty F(x)e^{-ax}e^{-at}e^{(a-c)x}K(t,x,c,\lambda)\,dx$$

and the result then follows directly from the hypothesis.

A similar theorem can be proved for the case $p=1$ but we do not need this theorem as the kernel of ordinary convergence does not satisfy the conditions of Theorem 4 when $p=1$ [1, p. 291].

4. Sufficient conditions for the representation of functions as Laplace or Laplace–Stieltjes transforms. We now show that, under certain conditions on $f(w)$ and the kernel $k(t,v,c,\lambda)$, the boundedness of the integral transform

$$F(t,c,\lambda)e^{-at} = \frac{e^{-at}}{2\pi} \int_{-\infty}^\infty k(t,v,c,\lambda)f(c+iv)\,dv$$

in $L_p(0,\infty)$ is a sufficient condition for a function $f(w)$ to be represented as a Laplace or Laplace–Stieltjes transform. As already mentioned in §3 we require that the value of a be restricted to $a \leqq c$.

Firstly we prove the theorem which gives sufficient conditions for a function to be represented as a Laplace transform for p in the range $1 < p \leqq \infty$.

THEOREM 5. *Let* $f(w)$ *be holomorphic in* $\mathrm{Re}\,w > c$ *and continuous in* $\mathrm{Re}\,w \geqq c$. *For every* $\delta > 0$ *let there be an* $A(\delta)$ *such that*

$$|f(w)| < Ae^{\delta|w-c|^2}$$

throughout the half-plane $\mathrm{Re}\,w > c$. *For some m let*

$$f(c+iv) = O(v^m)$$

as $|v| \to \infty$, *for every* $\delta > 0$ *let*

$$f(u) = O(e^{\delta u})$$

as $u \to \infty$ *and let*

$$|f(c+re^{i\theta})| \to 0$$

as $r \to \infty$ *for some* θ *in the range* $-\pi/2 < \theta < \pi/2$.

Let $f(c+iv) \in L(-\infty,\infty)$ *and let* $e^{-(c+iv)t}k(t,v,c,\lambda) \to 1$ *boundedly for almost all* (v,t) *in* $(-\infty,\infty)\times(0,\infty)$ *as* $\lambda \to \infty$.

For some $a \leqq c$ *let*

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_p \leqq M_p$$

uniformly in λ *for all* $\lambda > \lambda_0$.

Then, for $1 < p \leqq \infty$, $f = LF$ *where* $F \in L_p[a;(0,\infty)]$ *and* $F(t)e^{-at}$ *is the weak limit in* $L_p(0,\infty)$ *of* $F(t,c,\lambda)e^{-at}$ *as* $\lambda \to \infty$.

Proof. Let n be a nonnegative integer such that $n > m$ then for $\operatorname{Re} w > c$

$$\int_0^\infty t^n e^{-wt} F(t,c,\lambda)\,dt = \frac{1}{2\pi}\int_0^\infty t^n e^{-wt}\,dt \int_{-\infty}^\infty k(t,v,c,\lambda) f(c+iv)\,dv$$

$$\to \frac{1}{2\pi}\int_{-\infty}^\infty f(c+iv)\,dv \int_0^\infty t^n e^{-wt} e^{(c+iv)t}\,dt$$

as $\lambda \to \infty$, where the interchange in the order of integration is justified by Fubini's theorem and the limiting process by dominated convergence. Therefore

$$\int_0^\infty t^n e^{-wt} F(t,c,\lambda)\,dt \to \frac{n!}{2\pi}\int_{-\infty}^\infty \frac{f(c+iv)}{[w-(c+iv)]^{n+1}}\,dv \tag{4.1}$$

as $\lambda \to \infty$ for $\operatorname{Re} w > c$. Now by hypothesis

$$\| F(t,c,\lambda) e^{-at}; (0,\infty) \|_p \leqq M_p$$

uniformly in λ. This is a bounded set in the dual of the Banach space $L_{p'}(0,\infty)$ and is therefore relatively weakly compact. Hence there exists $F(t,c)$ such that $F(t,c)e^{-at} \in L_p(0,\infty)$ and $F(t,c)e^{-at}$ is a weak limiting point of $F(t,c,\lambda)e^{-at}$ in $L_p(0,\infty)$ as $\lambda \to \infty$. Since

$$t^n e^{-wt} e^{at} \in L_{p'}(0,\infty)$$

for $\operatorname{Re} w > a$ then as $\lambda \to \infty$ $\int_0^\infty t^n e^{-wt} F(t,c)\,dt$ is a limiting point of $\int_0^\infty t^n e^{-wt} F(t,c,\lambda)\,dt$. Hence by the above statement and (4.1) we have, for $\operatorname{Re} w > c$,

$$\int_0^\infty t^n e^{-wt} F(t,c)\,dt = \frac{n!}{2\pi}\int_{-\infty}^\infty \frac{f(c+iv)}{[w-(c+iv)]^{n+1}}\,dv$$

$$= (-1)^n f^{(n)}(w)$$

where the use of Cauchy's formula is justified by the hypothesis, since $n > m$ and $(w-c+1)^{-m} f(w)$ is bounded [3, p. 1326].

Because of the uniqueness of Laplace transforms $F(t,c)$ must be independent of the choice of c; therefore letting $F(t) = F(t,c)$, we have

$$\int_0^\infty t^n e^{-wt} F(t)\,dt = (-1)^n f^{(n)}(w)$$

for $\operatorname{Re} w > c$, where $F(t)e^{-at}$ is the weak limit in $L_p(0,\infty)$ of $F(t,c,\lambda)e^{-at}$ as $\lambda \to \infty$.

Define

$$\phi(w) = \int_0^\infty e^{-wt} F(t)\,dt;$$

then $\phi(w)$ is holomorphic in $\operatorname{Re} w > c$ and

$$\phi^{(n)}(w) = (-1)^n \int_0^\infty t^n e^{-wt} F(t)\,dt = f^{(n)}(w).$$

Therefore for $\operatorname{Re} w > c$ $\phi(w) = f(w) + p(w)$ where $p(w)$ is a polynomial of degree at most $(n-1)$. Letting $w = c + re^{i\theta}$, we have $|\phi(c+re^{i\theta})| \to 0$ as $r \to \infty$ for $-\pi/2 < \theta < \pi/2$, since $F \in L_p[a;(0,\infty)]$ and, by hypothesis, $|f(c+re^{i\theta})| \to 0$ as $r \to \infty$ for some θ in the range $-\pi/2 < \theta < \pi/2$. Hence for $\operatorname{Re} w > c$ $p(w) = 0$ and therefore $\phi(w) = f(w)$.

Hence $f(w)=\int_0^\infty e^{-wt}F(t)\,dt$ where $F\in L_p[a;(0,\infty)]$ and $F(t)e^{-at}$ is the weak limit in $L_p(0,\infty)$ of $F(t,c,\lambda)e^{-at}$ as $\lambda\to\infty$.

Secondly for the case $p=1$ we prove the theorem which gives sufficient conditions for a function to be represented as a Laplace–Stieltjes transform.

THEOREM 6. *Let $f(w)$ be holomorphic in $\operatorname{Re}w>c$ and continuous in $\operatorname{Re}w\geqq c$. For every $\delta>0$ let there be an $A(\delta)$ such that*

$$|f(w)|<Ae^{\delta|w-c|^2}$$

throughout the half-plane $\operatorname{Re}w>c$. For some m let

$$f(c+iv)=O(v^m)$$

as $|v|\to\infty$, for every $\delta>0$ let

$$f(u)=O(e^{\delta u})$$

as $u\to\infty$ and let

$$f(c+re^{i\theta})=O(1)$$

as $r\to\infty$ for some θ in the range $-\pi/2<\theta<\pi/2$.

Let $f(c+iv)\in L(-\infty,\infty)$ and let $e^{-(c+iv)t}k(t,v,c,\lambda)\to 1$ boundedly for almost all (v,t) in $(-\infty,\infty)\times(0,\infty)$ as $\lambda\to\infty$.

For some $a\leqq c$ let

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_1\leqq M_1$$

uniformly in λ for all $\lambda>\lambda_0$.

Then $f=SH$, where $H\in V[a;(0,\infty)]$ and

$$H(t)-H(0)=\lim_{\lambda\to\infty}\int_0^t F(u,c,\lambda)\,du.$$

Proof. Let n be a nonnegative integer such that $n>m$ then, as in Theorem 5, we can show that for $\operatorname{Re}w>c$ as $\lambda\to\infty$

$$\int_0^\infty t^n e^{-wt}F(t,c,\lambda)\,dt\to\frac{n!}{2\pi}\int_{-\infty}^{\infty}\frac{f(c+iv)}{[w-(c+iv)]^{n+1}}\,dv. \tag{4.2}$$

Now by hypothesis

$$\|F(t,c,\lambda)e^{-at};(0,\infty)\|_1\leqq M_1$$

uniformly in λ. Therefore $\{\int_0^t F(u,c,\lambda)e^{-au}\,du\}$ is a bounded set in the dual of the Banach space $C_0(0,\infty)$ and is therefore relatively weakly compact. Hence there exists $h(t,c)\in V(0,\infty)$ such that $h(t,c)$ is a weak limiting point of $\int_0^t F(u,c,\lambda)e^{-au}\,du$ as $\lambda\to\infty$. Therefore

$$\int_0^\infty t^n e^{-wt}e^{at}\,dh(t,c)\text{ is a limiting point of }\int_0^\infty t^n e^{-wt}F(t,c,\lambda)\,dt$$

as $\lambda\to\infty$.

Hence by the above statement, (4.2) and using Cauchy's formula, as in theorem 5, we have for $\operatorname{Re}w>c$

$$\int_0^\infty t^n e^{-wt}e^{at}\,dh(t,c)=\frac{n!}{2\pi}\int_{-\infty}^{\infty}\frac{f(c+iv)}{[w-(c+iv)]^{n+1}}\,dv=(-1)^n f^{(n)}(w).$$

Because of the uniqueness of normalised Laplace–Stieltjes transforms, $h(t,c)$ must be independent of the choice of c; therefore letting $h(t,c)=h(t)$ we have

$$\int_0^\infty t^n e^{-wt} e^{at}\, dh(t) = (-1)^n f^{(n)}(w)$$

for $\operatorname{Re} w > c$.

Define $\phi(w)=\int_0^\infty e^{-wt}e^{at}\,dh(t)$. Then $\phi(w)$ is holomorphic in $\operatorname{Re} w > c$ and

$$\phi^{(n)}(w) = (-1)^n \int_0^\infty t^n e^{-wt} e^{at}\, dh(t) = f^{(n)}(w).$$

Therefore for $\operatorname{Re} w > c$

$$\phi(w) = f(w) + p(w)$$

where $p(w)$ is a polynomial in w of degree at most $(n-1)$. Letting $w = c + re^{i\theta}$, we have

$$f(c+re^{i\theta}) = O(1) \quad \text{as } r \to \infty \quad \text{for } -\pi/2 < \theta < \pi/2,$$

since $h(t) \in V(0,\infty)$, and, by hypothesis,

$$p(c+re^{i\theta}) = O(1) \quad \text{as } r \to \infty$$

for some θ in the range $-\pi/2 < \theta < \pi/2$. Hence for $\operatorname{Re} w > c$

$$p(w) = A,$$

where A is a constant, and therefore

$$f(w) = \int_0^\infty e^{-wt} e^{at}\, dh(t) - A.$$

Now if we define

$$H(t) - H(0) = \int_0^t e^{au}\, dh(u),$$

then

$$f(w) = \int_0^\infty e^{-wt}\, dH(t) - A$$

and the constant A can be absorbed into $H(t)$ by altering the value of $H(t)$ at the origin.

Hence

$$f(w) = \int_0^\infty e^{-wt}\, dH(t)$$

where $H \in V[a;(0,\infty)]$ and

$$H(t) - H(0) = \lim_{\lambda \to \infty} \int_0^t F(u,c,\lambda)\, du.$$

Most of the particular kernels which we will be considering are of the form

$$k(t,v,c,\lambda) = e^{(c+iv)t} l(v,\lambda).$$

For kernels of this form it is possible in Theorems 5 and 6 to replace the condition $f(c+iv)\in L(-\infty,\infty)$ by the condition $l(v,\lambda)f(c+iv)\in L(-\infty,\infty)$ for all $\lambda>\lambda_0$. If, in addition, p is restricted to the range $1\leqq p\leqq 2$, then the conditions $|f(c+re^{i\theta})|\to 0$ and $f(c+re^{i\theta})=O(1)$ as $r\to\infty$ for some θ in the range $-\pi/2<\theta<\pi/2$ in Theorems 5 and 6 respectively can be omitted [2, p. 230].

5. Particular kernels. We now consider the conditions which must be satisfied by the kernels for them to be used in the theorems that we have proved.

L1. $k(t,v,c,\lambda)\in L(-\infty,\infty)$ as a function of v for all $t>0$ and $\lambda>\lambda_0$.

L2. $e^{-(c+iv)t}k(t,v,c,\lambda)\to 1$ boundedly for almost all (v,t) in $(-\infty,\infty)\times(0,\infty)$ as $\lambda\to\infty$.

L3.

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\begin{Bmatrix}dt\\dx\end{Bmatrix} \text{ is bounded uniformly in } \begin{Bmatrix}x\\t\end{Bmatrix}$$

$$\text{and } \lambda \text{ for all } \begin{Bmatrix}x>0\\t>0\end{Bmatrix} \text{ and } \lambda>\lambda_0.$$

L4. The set of transforms $\{S_\lambda\}$ forms a bounded set of transformations from $L_p(0,\infty)$ into itself, where the transformation S_λ is defined by

$$(S_\lambda g)(t)=\frac{1}{\sqrt{2\pi}}\int_0^\infty g(x)e^{-at}e^{(a-c)x}K(t,x,c,\lambda)\,dx$$

where $g\in L_p(0,\infty)$.

We say that $k(t,v,c,\lambda)$ is an $L(a\leqq c)$ kernel if it satisfies the conditions L1, L2 and either L3 or L4. If the conditions are only satisfied when $a=c$, then we write $k(t,v,c,\lambda)$ is an $L(a=c)$ kernel.

The Weierstrass kernel

$$k(t,v,c,\lambda)=e^{(c+iv)t}e^{-v^2/\lambda^2}$$

satisfies L1 and L2.

$$K(t,x,c,\lambda)=\frac{e^{ct}}{\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{-iv(x-t)}e^{-v^2/\lambda^2}\,dv$$

$$=\frac{\lambda e^{ct}}{\sqrt{2}}\exp\left\{\frac{-\lambda^2(x-t)^2}{4}\right\}.$$

Therefore letting $y=\lambda(x-t)/\sqrt{2}$,

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dt$$

$$=\exp\left\{\frac{(a-c)^2}{\lambda^2}\right\}\int_{-\infty}^{x\lambda/\sqrt{2}}\exp\left\{-\frac{1}{2}\left[y-\sqrt{2}(a-c)/\lambda\right]^2\right\}dy$$

$$\leqq\sqrt{2\pi}\exp\left\{\frac{(a-c)^2}{\lambda^2}\right\}.$$

Similarly,

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|dx$$

$$=\exp\left\{\frac{(a-c)^2}{\lambda^2}\right\}\int_{-t\lambda/\sqrt{2}}^\infty \exp\left\{-\frac{1}{2}\left[y-\sqrt{2}(a-c)/\lambda\right]^2\right\}dy$$

$$\leqq\sqrt{2\pi}\exp\left\{\frac{(a-c)^2}{\lambda^2}\right\}$$

and therefore L3 is satisfied. Hence the Weierstrass kernel is an L $(a\leqq c)$ kernel.

The Abel kernel

$$k(t,v,c,\lambda)=e^{(c+iv)t}e^{-|v|/\lambda}$$

satisfies L1 and L2.

$$K(t,x,c,\lambda)=\frac{c^{ct}}{\sqrt{2\pi}}\int_{-\infty}^\infty e^{-iv(x-t)}e^{-|v|/\lambda}dv$$

$$=\frac{2\lambda e^{ct}}{\sqrt{2\pi}}\frac{1}{1+\lambda^2(x-t)^2}.$$

Therefore letting $y=x-t$,

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|dt=\sqrt{\frac{2}{\pi}}\int_{-\infty}^x e^{(a-c)y}\frac{\lambda}{1+\lambda^2y^2}dy$$

which cannot be bounded if $a<c$. We will therefore only consider the possibility $a=c$. In which case

$$\int_0^\infty e^{-ct}|K(t,x,c,\lambda)|dt=\sqrt{\frac{2}{\pi}}\int_{-\infty}^x\frac{\lambda}{1+\lambda^2y^2}dy$$

$$\leqq\sqrt{\frac{2}{\pi}}\int_{-\infty}^\infty\frac{\lambda}{1+\lambda^2y^2}dy$$

$$=\sqrt{2\pi}.$$

Similarly $\int_0^\infty e^{-ct}|K(t,x,c,\lambda)|dx\leqq\sqrt{2\pi}$ and therefore L3 is satisfied when $a=c$. Hence the Abel kernel is an $L(a=c)$ kernel.

The Cesaro kernel of positive order

$$k(t,v,c,\lambda)=e^{(c+iv)t}\left(1-\frac{|v|}{\lambda}\right)^\alpha\chi_{(-\lambda,\lambda)}(v),\qquad\alpha>0$$

satisfies L1 and L2.

$$K(t,x,c,\lambda)=\frac{e^{ct}}{\sqrt{2\pi}}\int_{-\lambda}^\lambda\left(1-\frac{|v|}{\lambda}\right)^\alpha e^{-iv(x-t)}dv$$

$$=\sqrt{\frac{2}{\pi}}\,e^{ct}\int_0^\lambda\cos[v(x-t)]\left(1-\frac{|v|}{\lambda}\right)^\alpha dv$$

and

$$K(t,x,c,\lambda) \leqq Be^{ct}\max(\lambda,\lambda^{-\alpha}|x-t|^{-\alpha-1})$$

where B is a constant dependent on α [5, p. 30]. Therefore letting $y=x-t$,

$$\int_0^\infty e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|dt \leqq \int_{-\infty}^{x} e^{(a-c)y}B\max(\lambda,\lambda^{-\alpha}|y|^{-\alpha-1})\,dy$$

which cannot be bounded if $a<c$. We will therefore only consider the possibility $a=c$. In which case

$$\begin{aligned}\int_0^\infty e^{-ct}|K(t,x,c,\lambda)|\,dt &\leqq \int_{-\infty}^{x} B\max\left(\lambda,\lambda^{-\alpha}|y|^{-\alpha-1}\right)dy\\ &\leqq \int_{-\infty}^{\infty} B\max\left(\lambda,\lambda^{-\alpha}|y|^{-\alpha-1}\right)dy\\ &\leqq 2B\left\{\int_0^{1/\lambda} y\,dy+\int_{1/\lambda}^{\infty}\lambda^{-\alpha}y^{-\alpha-1}\,dy\right\}\\ &= 2B\left(1+\frac{1}{\alpha}\right).\end{aligned}$$

Similarly

$$\int_0^\infty e^{-ct}|K(t,x,c,\lambda)|\,dx \leqq 2B\left(1+\frac{1}{\alpha}\right)$$

and therefore L3 is satisfied when $a=c$. Hence the Cesaro kernel with $\alpha>0$ is an $L(a=c)$ kernel.

The kernel of ordinary convergence

$$k(t,v,c,\lambda)=e^{(c+iv)t}\chi_{(-\lambda,\lambda)}(v)$$

satisfies L1 and L2.

$$\begin{aligned}K(t,x,c,\lambda)&=\frac{e^{ct}}{\sqrt{2\pi}}\int_{-\lambda}^{\lambda}e^{-iv(x-t)}\,dv\\ &=\sqrt{\frac{2}{\pi}}\,e^{ct}\frac{\sin\lambda(x-t)}{x-t}.\end{aligned}$$

The kernel does not satisfy L3 even in the case $a=c$ but it does satisfy L4 for $a=c$ and $1<p\leqq 2$ since the set of transforms $\{S_\lambda\}$ forms a bounded set of transforms from $L_p(0,\infty)$ onto itself, where

$$(S_\lambda g)(t)=\frac{1}{\pi}\int_0^\infty g(x)\frac{\sin\lambda(x-t)}{x-t}\,dx,$$

for $1<p\leqq 2$ [7, p. 256]. Hence the kernel of ordinary convergence is an $L(a=c)$ kernel for $1<p\leqq 2$.

The Post–Widder kernel

$$k(t,v,c,\lambda)=\left(\frac{\lambda}{\lambda-t(c+iv)}\right)^{\lambda+1},$$

which was derived by Cooper in his work on Fourier transforms, [1, p. 292], satisfies L1 and L2.

$$K(t,x,c,\lambda)=\frac{\lambda^{\lambda+1}}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\frac{e^{-ivx}}{[\lambda-t(c+iv)]^{\lambda+1}}\,dv$$

and letting $w=\lambda-t(c+iv)$, we obtain

$$K(t,x,c,\lambda)=\frac{\lambda^{\lambda+1}}{\sqrt{2\pi}\,i|t|}e^{-\lambda x/t}e^{cx}\int_{\lambda-tc-i\infty}^{\lambda-tc+i\infty}e^{wx/t}w^{-\lambda-1}\,dw$$

$$=\frac{\sqrt{2\pi}\lambda^{\lambda+1}e^{-\lambda x/t}e^{cx}|x|^{\lambda}}{\Gamma(\lambda+1)|t|^{\lambda+1}}$$

for $x\geqq 0$ and $t\geqq 0$. L3 can only be satisfied when $a=0$, in which case

$$\int_0^{\infty}e^{-cx}|K(t,x,c,\lambda)|\,dx=\frac{\sqrt{2\pi}\lambda^{\lambda+1}}{\Gamma(\lambda+1)t^{\lambda+1}}\int_0^{\infty}e^{-\lambda x/t}x^{\lambda}\,dx$$

$$=\sqrt{2\pi}\,.$$

Similarly $\int_0^{\infty}e^{-cx}|K(t,x,c,\lambda)|\,dt=\sqrt{2\pi}$. Hence the Post–Widder kernel is an $L(0\leqq c)$ kernel.

The extended Post–Widder kernel

$$k(t,v,c,\lambda)=\left(\frac{\lambda+\theta_{\lambda}}{\lambda+\theta_{\lambda}-t(c+iv)}\right)^{\lambda+1}$$
