where $\theta_{\lambda}=o(\lambda)$ as $\lambda\to\infty$, which was derived in [6, p. 82], is also an $L(0\leqq c)$ kernel.

The extended Phragmen kernel

$$k(t,v,c,\lambda)=e^{(c+iv)t}\Gamma\left(1-\frac{iv}{\lambda}\right)$$

which was derived in [6, p. 84], satisfies L1 and L2.

$$K(t,x,c,\lambda)=\frac{e^{ct}}{\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{-iv(x-t)}\Gamma\left(1-\frac{iv}{\lambda}\right)dv$$

and letting $w=1-iv/\lambda$ we obtain

$$K(t,x,c,\lambda)=\frac{e^{ct}}{\sqrt{2\pi}}e^{-\lambda(x-t)}\left(\frac{\lambda}{i}\right)\int_{1-i\infty}^{1+i\infty}e^{\lambda w(x-t)}\Gamma(w)\,dw$$

$$=\sqrt{2\pi}\lambda e^{ct}e^{-\lambda(x-t)}e^{-e^{-\lambda(x-t)}}$$

by [4, p. 231].

Therefore letting $y=x-t$,

$$\int_0^{\infty}e^{-at}e^{(a-c)x}|K(t,x,c,\lambda)|\,dt=\int_{-\infty}^{x}\sqrt{2\pi}\,e^{(a-c)y}\lambda e^{-\lambda y}e^{-e^{-\lambda y}}\,dy$$

which cannot be bounded if $a<c$. We will therefore only consider the possibility $a=c$. In which case

$$\begin{aligned}\int_0^\infty e^{-ct}|K(t,x,c,\lambda)|\,dt &= \sqrt{2\pi}\int_{-\infty}^{x}\lambda e^{-\lambda y}e^{-e^{-\lambda y}}dy\\ &\leqq \sqrt{2\pi}\int_{-\infty}^{\infty}\lambda e^{-\lambda y}e^{-e^{-\lambda y}}dy\\ &= \sqrt{2\pi}\,.\end{aligned}$$

Similarly

$$\int_0^\infty e^{-ct}|K(t,x,c,\lambda)|\,dx \leqq \sqrt{2\pi}$$

and therefore L3 is satisfied when $a=c$. Hence the extended Phragmen kernel is an $L(a=c)$ kernel.

An interesting result which was noted by Cooper [2, p. 233] is that for $L(a\leqq c)$ kernels it is possible to determine the abscissa of absolute convergence of the Laplace or Laplace–Stieltjes transform, $f(w)$, by considering the behaviour of $f(w)$ on any line $w=c+iv$ in the half-plane of absolute convergence. For $L(a\leqq c)$ kernels the abscissa of absolute convergence is the infimum of the values of a for which $\|F(t,c,\lambda)e^{-at};(0,\infty)\|_1$ is bounded uniformly in λ. For $L(a=c)$ the abscissa of absolute convergence is the infimum of the values of c for which $\|F(t,c,\lambda)e^{-ct};(0,\infty)\|_1$ is bounded uniformly in λ.

ON ZEROS OF INTERPOLATING POLYNOMIALS*

ROGER W. BARNARD†, WAYNE T. FORD† AND HSING Y. WANG‡

Abstract. Polynomials to be used in interpolation of digital signals are called interpolating polynomials. They may require modification to assure convergence of their reciprocals on the unit circle.

This paper concerns discrete time windowing, which consists of scaled truncation of a series such as

$$P_N(z) \overset{\Delta}{=} 1 + \sum_{m=1}^{\infty} (z^m + z^{-m}) \operatorname{sinc} \frac{m\pi}{N}, \qquad \operatorname{sinc} x \overset{\Delta}{=} \frac{\sin x}{x},$$

where $N > 1$, to obtain an expression of the form

$$P^*_{N,L}(z) \overset{\Delta}{=} z^{L-1}\left(1 + \sum_{m=1}^{L-1} (z^m + z^{-m}) c_m \operatorname{sinc} \frac{m\pi}{N}\right).$$

We delete the asterisk to write $P_{N,L}$ when each $c_m = 1$.

The zeros of $P_{N,L}$ are shown to have unit modulus for $L \leqq N$. Examples are given to show that little can be said of the zeros of $P_{N,L}$ for $L > N$. Conditions are found to define real sequences of the form, $\{c_m : 1 \leqq m < \infty\}$, so that $P^*_{N,L}$ has no zero of unit modulus. Several standard discrete time windows are shown to define real sequences which are special cases of the conditions developed.

Introduction. Polynomials to be used in interpolation of digital signals are called interpolating polynomials. These polynomials may require modification to assure convergence of their reciprocals on the unit circle. Such modification is a principal concern of this paper.

A real function, g, defined for all values of the real independent variable time, t, is called a signal. A digital signal, γ, is a real sequence, $\{\gamma_m : -\infty < m < \infty\}$, consisting of equally spaced values or samples, $\gamma_m = g(m\Delta t)$, from the signal, g, with a time increment or sample interval, Δt. Thus, the independent variable for digital signals such as γ is sample time, $m\Delta t$, or simply sample number, m.

The signal, g, is studied in terms of its classical Fourier transform, G, as a function of real frequency, ω. The digital analog of the Fourier transform consists of the study of a sequence such as γ in terms of its Z-transform, which is defined to be the power series, Γ, having γ_m as the coefficient of z^m. Frequency's digital analog comes from evaluation of Z-transforms such as Γ on the unit circle with the negative of the θ in $z = e^{i\theta}$ referred to as frequency. If the coefficients in Γ are used without any actual evaluation of $\Gamma(z)$ or g is used without computation of G, such use is said to be in the time domain. But if $\Gamma(z)$ is used with evaluation for some z of unit modulus or G is used, such use is said to be in the frequency domain.

Signals are based on even functions in a number of applications and in this paper. This restricts digital signals to self-inversive cases meaning that $\Gamma(z) = \Gamma(z^{-1})$ for $z \neq 0$. Equivalently, γ is a symmetric sequence meaning that $\gamma_m = \gamma_{-m}$ for all m.

A second signal, f, with Fourier transform, F, poses as a filter of the signal, g, if the convolution integral, $g * f$, of g and f is considered. Of course, the Fourier transform of $g * f$ is the product of the Fourier transforms, G of g and F of f. The

discrete analogy consists of the product of Z-transforms, Γ and Φ, where the latter refers to the power series with the sample, $\Phi_m = f(m\Delta t)$, taken from the filter, f, as the coefficient of z^m.

Reduction of certain frequencies is a fundamental aim in application of a filter, f, to a function, g. This can involve definition of f by the requirement that $F(\omega)$ be a constant, c, for $|\omega| < \omega_0$ but zero otherwise. If so, c can be chosen so that

$$f(t) = \operatorname{sinc} \omega_0 t, \tag{1.1}$$

where

$$\operatorname{sinc} x \overset{\Delta}{=} \frac{\sin x}{x}. \tag{1.2}$$

These equations illustrate definition of a real signal from specification of its Fourier transform. Similarly, digital signals are often defined by specification of Z-transforms.

The Fourier transform, F, of the f in (1.1) is referred to as a frequency window since it has compact support in frequency. Application of such a window to a signal, g, is known as frequency windowing. This paper concerns discrete time windowing. This consists of scaled truncation of an infinite sequence such as γ to obtain a finite sequence of the form $\{c_m \gamma_m : -L < m < L\}$ wherein the finite sequence, $\{c_m : -L < m < L\}$, is referred to as a time window.

Suppose a given digital signal, $\{b_k : -\infty < k < \infty\}$, is such that b_k is understood to correspond to the time, $kN\Delta t$, with the sample interval, $N\Delta t$, where N is a natural number such that $N > 1$. If this digital signal is to be compared with digital signals based on the smaller sample interval, Δt, the given digital signal must be interpolated to the smaller sample interval, Δt. For example, insertion of $N-1$ zeros between every b_k and b_{k+1} followed by multiplication of the Z-transform of the result by the interpolating series,

$$P_N(z) \overset{\Delta}{=} 1 + \sum_{m=1}^{\infty} (z^m + z^{-m}) \operatorname{sinc} \frac{m\pi}{N}, \tag{1.3a}$$

leads to

$$A(z) \overset{\Delta}{=} \sum_{n=-\infty}^{\infty} a_n z^n \overset{\Delta}{=} \left(\sum_{j=-\infty}^{\infty} b_j z^{jN} \right) P_N(z). \tag{1.3b}$$

Since the coefficient of z^{kN}, a_{kN}, in A comes from products of b_j and $\operatorname{sinc}(m\pi/N)$ such that $kN = jN \pm m$, it follows that $m \equiv 0 \pmod N$, $\operatorname{sinc}(m\pi/N) = 0$ for nonzero m, and $a_{kN} = b_k$. Thus, A is an interpolation of the given B.

A major purpose of this paper is to study possible alternatives to the interpolation used in (1.3a) in terms of truncation of the interpolating series in (1.3b). We consider the interpolating polynomial,

$$P_{N,L}(z) \overset{\Delta}{=} z^{L-1} \left(1 + \sum_{m=1}^{L-1} (z^m + z^{-m}) \operatorname{sinc} \frac{m\pi}{N} \right), \tag{1.4}$$

where $N > 1$.

Note that $P_{N,L}$ is a polynomial of degree $2L-2$ except that it has degree $2L-3$ and $P_{N,L}(0) = 0$ when $L \equiv 1 \pmod N$. In any case, its real coefficients imply conjugates of nonzero roots to be roots, and symmetry of coefficients implies reciprocals of

nonzero roots to be roots. Since the conjugate and the reciprocal of a root of unit modulus are equal, and the conjugate of a real root is the root itself, nonzero roots can occur in pairs. In other cases, a nonzero root, its conjugate, and their reciprocals are all different and plot as the vertices of a trapezoid in the complex plane.

We show that the zeros of $P_{N,L}$ are all of unit modulus for $L \leqq N$. Since

$$P_{N,N+1}(z) = P_{N,N}(z), \tag{1.5}$$

$P_{N,N+1}$ has a zero at the origin in addition to the zeros of unit modulus of $P_{N,N}$. We use examples to show that little can be said of the zeros of $P_{N,L}$ for $L > (N+1)$.

Conditions are then developed to define real sequences of the form, $\{c_m : 1 \leqq m < \infty\}$, so that the polynomial,

$$P^*_{N,L}(z) \overset{\Delta}{=} z^{L-1}\left(1 + \sum_{m=1}^{L-1} (z^m + z^{-m}) c_m \operatorname{sinc}\frac{m\pi}{N}\right), \tag{1.6}$$

has no zero of unit modulus. A number of standard discrete time windows are shown to define real sequences which are special cases of the conditions developed.

2. Zeros of $P_{N,L}$ for $L \leqq N$. Our study of $P_{N,L}$, for $L \leqq N$, is based on the properties of $H_{N,L}$ as defined by

$$H_{N,L}(\theta) \overset{\Delta}{=} (2\pi/N) P_{N,L}(z)/z^{L-1}\Big|_{z=e^{i\theta}}. \tag{2.1}$$

LEMMA 2.1.

$$H_{N,L}(\theta) = \int_{\theta-\pi/N}^{\theta+\pi/N} \frac{\sin[(2L-1)t/2]}{\sin(t/2)}\,dt. \tag{2.2}$$

Proof. Use the identity,

$$\begin{aligned}\int_{\theta-\pi/N}^{\theta+\pi/N} e^{imt}\,dt &= e^{im\theta}\frac{e^{im\pi/N} - e^{-im\pi/N}}{im} \\ &= \frac{\pi}{N} e^{im\theta}\frac{2\sin(m\pi/N)}{m\pi/N} = \frac{2\pi}{N} e^{im\theta}\operatorname{sinc}\frac{m\pi}{N},\end{aligned} \tag{2.3}$$

to eliminate the sinc in (1.4). Then, substitute (1.4) in (2.1) and compute

$$\begin{aligned}H_{N,L}(\theta) &= \int_{\theta-\pi/N}^{\theta+\pi/N}\left(1 + \sum_{m=1}^{L-1}(e^{imt} + e^{-imt})\right)dt \\ &= \int_{\theta-\pi/N}^{\theta+\pi/N}\left(1 + e^{it}\frac{1-e^{it(L-1)}}{1-e^{it}} + e^{-it}\frac{1-e^{-it(L-1)}}{1-e^{-it}}\right)dt \\ &= \int_{\theta-\pi/N}^{\theta+\pi/N}\left(1 + \frac{e^{it}(1-e^{it(L-1)}) - (1-e^{-it(L-1)})}{1-e^{it}}\right)dt \\ &= \int_{\theta-\pi/N}^{\theta+\pi/N}\left(1 + \frac{e^{it} - e^{itL} - 1 + e^{-it(L-1)}}{1-e^{it}}\right)dt \\ &= \int_{\theta-\pi/N}^{\theta+\pi/N}\frac{e^{i(2L-1)t/2} - e^{-i(2L-1)t/2}}{e^{it/2} - e^{-it/2}}\,dt,\end{aligned}$$

which implies (2.2). □

LEMMA 2.2. *Suppose* $0<\theta-\pi/N<\theta+\pi/N<2\pi$. *Then,*

$$\frac{dH_{N,L}(\theta)}{d\theta}=\frac{\sin[(2L-1)t/2]}{\sin(t/2)}\Bigg|_{\theta-\pi/N}^{\theta+\pi/N} \tag{2.4}$$

is zero if and only if

$$\sin(L\theta)\sin[(L-1)\pi/N]=\sin(L\pi/N)\sin[(L-1)\theta]. \tag{2.5a}$$

Proof. Differentiate (2.2) to verify (2.4). Then, set the derivative in (2.4) to zero and clear fractions to obtain

$$\begin{aligned}0&=\sin[(2L-1)(\theta+\pi/N)/2]\sin[(\theta-\pi/N)/2]\\&\quad-\sin[(2L-1)(\theta-\pi/N)/2]\sin[(\theta+\pi/N)/2]\\&\equiv\sin(L\theta)\sin[(L-1)\pi/N]\\&\quad-\sin(L\pi/N)\sin[(L-1)\theta],\end{aligned} \tag{2.5b}$$

involving a trigonometric identity which can most easily be verified by writing the sines in (2.5b) in terms of complex exponentials and combining terms on both sides to compare exponents. This completes the proof. □

LEMMA 2.3.

$$\begin{aligned}H_{N,L}(\theta)&=-(2/L)\sin(L\pi/N)\cos(L\theta)\\&\quad+2\int_0^{\pi/N}\frac{\sin(L\theta)\cos(Ls)\sin\theta-\cos(L\theta)\sin(Ls)\sin s}{\cos s-\cos\theta}\,ds\\&=2\int_0^{\pi/N}\frac{\cos(Ls)\cos[(L-1)\theta]-\cos(L\theta)\cos[(L-1)s]}{\cos s-\cos\theta}\,ds.\end{aligned} \tag{2.6}$$

Proof. Use the variable of integration, $s=t-\theta$, to write (2.2) in the form,

$$\begin{aligned}H_{N,L}(\theta)&=\int_{\theta-\pi/N}^{\theta+\pi/N}\frac{\sin(Lt)\cos(t/2)-\cos(Lt)\sin(t/2)}{\sin(t/2)}\,dt\\&=\int_{-\pi/N}^{\pi/N}\frac{\sin[L(\theta+s)]\cos[(\theta+s)/2]}{\sin[(\theta+s)/2]}-\cos[L(\theta+s)]\,ds,\end{aligned} \tag{2.7}$$

wherein the latter integrand can be written in the form,

$$\begin{aligned}\int_{-\pi/N}^{\pi/N}\cos[L(\theta+s)]\,ds&=\frac{1}{L}\sin[L(\theta+s)]\Big|_{-\pi/N}^{\pi/N}\\&=L^{-1}\{\sin[L(\theta+\pi/N)]-\sin[L(\theta-\pi/N)]\}\\&=(2/L)\sin(L\pi/N)\cos(L\theta).\end{aligned} \tag{2.8}$$

Change the integration interval from $(-\pi/N,\pi/N)$ to $(0,\pi/N)$ to write (2.7) in the form

$$
\begin{aligned}
(2.9)\quad & H_{N,L}(\theta)+(2/L)\sin(L\pi/N)\cos(L\theta) \\
&= \int_0^{\pi/N} \frac{\sin[L(\theta+s)]\cos[(\theta+s)/2]}{\sin[(\theta+s)/2]} + \frac{\sin[L(\theta-s)]\cos[(\theta-s)/2]}{\sin[(\theta-s)/2]}\,ds \\
&= \int_0^{\pi/N} \left(\frac{\cos[(\theta+s)/2]}{\sin[(\theta+s)/2]} + \frac{\cos[(\theta-s)/2]}{\sin[(\theta-s)/2]} \right) \sin(L\theta)\cos(Ls) \\
&\quad + \left(\frac{\cos[(\theta+s)/2]}{\sin[(\theta+s)/2]} - \frac{\cos[(\theta-s)/2]}{\sin[(\theta-s)/2]} \right) \cos(L\theta)\sin(Ls)\,ds \\
&= \int_0^{\pi/N} \frac{\sin(L\theta)\cos(Ls)\sin\theta - \cos(L\theta)\sin(Ls)\sin s}{\sin[(\theta+s)/2]\sin[(\theta-s)/2]}\,ds,
\end{aligned}
$$

which implies the first equality in (2.6). Observe that

$$
\sin(L\pi/N)\cos(L\theta) = L\int_0^{\pi/N} \frac{\cos(Ls)\cos(L\theta)[\cos s-\cos\theta]}{\cos s-\cos\theta}\,ds,
$$

shows that $H_{N,L}(\theta)$ is given by an integral in which the numerator of the integrand has the form,

$$
\begin{aligned}
&-\cos(Ls)\cos(L\theta)[\cos s-\cos\theta]+\sin(L\theta)\cos(Ls)\sin\theta-\cos(L\theta)\sin(Ls)\sin s \\
&\quad=\cos(Ls)[\cos(L\theta)\cos\theta+\sin(L\theta)\sin\theta]-\cos(L\theta)[\cos(Ls)\cos s+\sin(Ls)\sin s],
\end{aligned}
$$

which implies the remaining equality in (2.6). □

THEOREM 2.1. *The zeros of $P_{N,L}$ have unit modulus for $L \leqq N$.*

Proof. Set L to N in (2.5) to observe that

$$
(2.10)\qquad \frac{dH_{N,N}(\theta)}{d\theta}=0 \quad \text{iff} \quad \sin(N\theta)=0 \quad \text{iff} \quad \theta=k\pi/N.
$$

Although $\theta=k\pi/L$ is not a zero of the derivative of $H_{N,L}$, we use it to write the first equality in (2.6) in the form,

$$
\begin{aligned}
(2.11)\qquad H_{N,L}(k\pi/L) &= (-1)^{k+1}(2/L)\sin(L\pi/N) \\
&\quad +2(-1)^{k+1}\int_0^{\pi/N} \frac{\sin(Ls)\sin s}{\cos s-\cos(k\pi/L)}\,ds.
\end{aligned}
$$

Since the above integrand is positive on $(0,\pi/N)$ if $L \leqq Nk$, the integral in (2.11) is positive. Thus, $H_{N,L}(k\pi/L)$ has $(L-1)$ changes of sign as k counts from 1 to L, $P_{N,L}(z)$ has $(L-1)$ zeros in the upper half of the unit circle, $(L-1)$ conjugate zeros in the lower half of the unit circle, and the proof is complete. □

3. Zeros of $P_{N,L}$ for $L>N$. Several examples are given to show that Theorem 2.1 cannot be extended to cover $L>N$. The most trivial example,

$$
(3.1)\qquad P_{N,N+1}=zP_{N,N},
$$

has a zero at the origin in addition to the zeros of unit modulus of $P_{N,N}$.

We discuss $P_{N,L}$, for $L>N+1$, in terms of $H_{N,L}$, given in (2.1), and $F_{N,L}$, defined by

$$F_{N,L}(x) \overset{\Delta}{=} H_{N,L}(\theta)\Big|_{\cos\theta = x}. \tag{3.2}$$

Observe that each zero of $F_{N,L}$ in the interval, $(-1,1)$, implies two zeros of $H_{N,L}$, which implies two zeros of unit modulus of $P_{N,L}$.

The example,

$$\begin{aligned} H_{2,4}(\theta) &= \pi + 4\sum_{m=1}^{3} \frac{1}{m}\sin\frac{m\pi}{2}\cos m\theta \\ &= \pi + 4\cos\theta - \frac{4}{3}\cos 3\theta \\ &= \pi + 8\cos\theta - \frac{16}{3}\cos^3\theta, \end{aligned} \tag{3.3a}$$

defines

$$F_{2,4}(x) = \pi + 8x - \frac{16}{3}x^3, \qquad x = \cos\theta, \tag{3.3b}$$

which has three real roots, two in $(-1,0)$ and one in $(1,\infty)$, since it is positive at $x=-1$, $x=0$, and $x=1$, but it is negative for $x=-\frac{1}{2}$ and for large positive x. Its two roots in $(-1,0)$ force four roots of unit modulus on the polynomial,

$$\begin{aligned} P_{2,4}(z) &= \sum_{m=0}^{6} z^m \operatorname{sinc}\frac{(m-3)\pi}{2} \\ &= \frac{1}{3\pi}(-2+6z^2+3\pi z^3+6z^4-2z^6). \end{aligned} \tag{3.3c}$$

Since $P_{2,4}(0)<0$ and $P_{2,4}(1)>0$, the two remaining roots consist of one root in $(0,1)$ and its reciprocal in $(1,\infty)$.

The second example,

$$\begin{aligned} H_{2,6}(\theta) &= \pi + 4\sum_{m=1}^{5} \frac{1}{m}\sin\frac{m\pi}{2}\cos m\theta \\ &= \pi + 4\cos\theta - \frac{4}{3}\cos 3\theta + \frac{4}{5}\cos 5\theta \\ &= \pi + 4\left(3\cos\theta - \frac{16}{3}\cos^3\theta + \frac{16}{5}\cos^5\theta\right) \end{aligned} \tag{3.4a}$$

defines

$$F_{2,6}(x) = \pi + 4\left(3x - \frac{16}{3}x^3 + \frac{16}{5}x^5\right), \qquad x = \cos\theta, \tag{3.4b}$$

which has three real roots in $(-1,0)$ and two complex roots, since it has the same sign as x as $|x|\to\infty$, a positive maximum at $-\sqrt{3}/2$, a negative minimum at $-1/2$, a positive maximum at $1/2$, and a positive minimum at $\sqrt{3}/2$. The three roots of $F_{2,6}$ in

$(-1,0)$ force six roots of unit modulus on the polynomial,

$$P_{2,6}(z)=\sum_{m=0}^{10} z^m \operatorname{sinc}\frac{(m-5)\pi}{2} \tag{3.4c}$$

$$=\frac{2}{15\pi}\left(3-5z^2+15z^4+\frac{15\pi}{2}z^5+15z^6-5z^8+3z^{10}\right)$$

$$=\left(1+\frac{2}{15\pi}B(z)\right)z^5, \quad \text{where } B(z)=Q(z^{-1})+Q(z)$$

with

$$Q(z)=3z^5-5z^3+15z. \tag{3.5a}$$

Since

$$\frac{dQ}{dz}=\frac{15(z^6+1)}{z^2+1} \quad \text{and} \quad \frac{dB}{dz}=\frac{15(z^{12}-1)}{z^6(z^2+1)}, \tag{3.5b}$$

it follows that $xB(x)>0$ for nonzero real x,

$$\inf\{|B(x)|: x \text{ real}\}=|B(-1)|=26,$$

$$\sup\{1+2B(x)/(15\pi): x<0\}=1-52/(15\pi)<0,$$

and $P_{2,6}$ has no real roots. Thus, its remaining four roots must form the vertices of a trapezoid in the complex plane.

4. Zeros of $P^*_{N,L}$. We seek real sequences of the form, $\{c_m: 1\leqq m<\infty\}$, such that polynomials defined by (1.6) have no roots in $\{z:|z|=1\}$. The search will be based on using the same real sequences in defining the polynomials,

$$Q_{N,L}(z)\overset{\Delta}{=}1+2\sum_{m=1}^{L-1} c_m z^m \operatorname{sinc}\frac{m\pi}{N}, \tag{4.1}$$

which will then be such that

$$\operatorname{Re}\left[Q_{N,L}(e^{i\theta})\right]\cos(L-1)\theta=\operatorname{Re}\left[P^*_{N,L}(e^{i\theta})\right]. \tag{4.2}$$

DEFINITION 4.1. R denotes the class of functions which are analytic and of positive real part on $\{z:|z|<1\}$.

First, take L to be infinite in (4.1), set $c_m=1$ for all m, and denote the result by

$$w(\zeta)\overset{\Delta}{=}1+2\sum_{m=1}^{\infty}\zeta^m \operatorname{sinc}\frac{m\pi}{N}, \tag{4.3}$$

which will be shown below to lie in R. A classical result will then be used to develop conditions on $\{c_m: 1\leqq m<\infty\}$ to imply $Q_{N,L}\in R$. Another classical result will then be used to show that the same conditions imply that $P^*_{N,L}$, as given in (1.6), has no zeros of unit modulus. Alternative criteria for determining whether a given $\{c_m: 1\leqq m<\infty\}$ has the desired properties will then be shown.

LEMMA 4.1. *The function, w, maps $\{\zeta:|\zeta|<1\}$ onto the vertical strip bounded by $\{w:\operatorname{Re}w=0\}\cup\{w:\operatorname{Re}w=N\}$. Thus, $w\in R$.*

Proof. Compute

$$w(\zeta)=1+\frac{N}{i\pi}\sum_{m=1}^{\infty}\frac{\zeta^m}{m}(e^{im\pi/N}-e^{-im\pi/N}) \tag{4.4a}$$

$$=1+\frac{N}{i\pi}\left(\sum_{m=1}^{\infty}\frac{\zeta^m e^{im\pi/N}}{m}-\sum_{m=1}^{\infty}\frac{\zeta^m e^{-im\pi/N}}{m}\right)$$

$$=1+\frac{N}{i\pi}\left(-\ln(1-\zeta e^{i\pi/N})+\ln(1-\zeta e^{-i\pi/N})\right)$$

$$=1+\frac{N}{i\pi}\ln\frac{1-\zeta e^{-i\pi/N}}{1-\zeta e^{i\pi/N}}.$$

Since w is analytic for $|\zeta|<1$ and $w(0)=1$, it suffices to consider $w(\zeta)$ for $|z|=1$. Compute

$$\operatorname{Re} w(e^{i\Phi})=1+\operatorname{Re}\left(\frac{N}{i\pi}\ln\frac{1-e^{i\Phi-i\pi/N}}{1-e^{i\Phi+i\pi/N}}\right) \tag{4.4b}$$

$$=1+\frac{N}{\pi}\operatorname{Im}\ln\frac{e^{i(\Phi-\pi/N)/2}\left(e^{-i(\Phi-\pi/N)/2}-e^{i(\Phi-\pi/N)/2}\right)}{e^{i(\Phi+\pi/N)/2}\left(e^{-i(\Phi+\pi/N)/2}-e^{i(\Phi+\pi/N)/2}\right)}$$

$$=1+\frac{N}{\pi}\operatorname{Im}\ln\left(e^{-i\pi/N}\frac{\sin[(\Phi-\pi/N)/2]}{\sin[(\Phi+\pi/N)/2]}\right)$$

$$=\begin{cases}1+\frac{N}{\pi}\left(-\frac{\pi}{N}+\pi\right)\\ 1+\frac{N}{\pi}\left(-\frac{\pi}{N}\right)\end{cases}=\begin{cases}N, & \Phi\in(\pi/N,\ 2\pi-\pi/N),\\ 0, & \Phi\notin(\pi/N,\ 2\pi-\pi/N)\end{cases}. \qquad \square$$

LEMMA 4.2. *Let L be an integer exceeding unity. Let r_L denote the unique positive root of*

$$2r^L+r-1=0. \tag{4.5}$$

Then, $0<r_L<1$ and $r_L<r_{L+1}$. Also, $r_L>1-(2/L)\ln L$, and $r_L\to 1$ as $L\to\infty$. Adopt the definitions,

$$f(\zeta)\overset{\Delta}{=}\sum_{n=0}^{\infty}a_n\zeta^n \quad \text{and} \quad s_L(\zeta)\overset{\Delta}{=}\sum_{n=0}^{L-1}a_n\zeta^n. \tag{4.6}$$

If $f\in R$, then $\operatorname{Re}[s_L(\zeta)]>0$ on $\{\zeta:|\zeta|<r_L\}$. Moreover, the example using $a_0=1$ and $a_n=2$ for $n>0$ shows that r_L cannot be increased in the conclusion.

Proof. [2, p. 523]. $\square$

LEMMA 4.3. *Let $L>1$, $r\in(0,r_L)$ with r_L defined by* (4.5), *and f as denoted in* (4.6). *If $f\in R$, then*

$$\operatorname{Re}\left(\sum_{m=0}^{L-1}a_m r^m z^m\right)>0 \quad \text{on } \{z:|z|\leqq 1\}. \tag{4.7}$$

Proof. Set $\zeta=rz$ in partial sums of f as denoted in (4.6), and note that $|z|\leqq 1$ if and only if $|\zeta|\leqq r<r_L$. Then, Lemma 4.1 implies (4.7). $\square$

LEMMA 4.4. *Let* $\{b_n : 0 \leqq n < \infty\} \in l_1$ *such that* $b_0 \neq 0$, *and let* f *be denoted as in* (4.6). *Then*,

$$\operatorname{Re}\left(\frac{1}{b_0}\sum_{n=0}^{\infty} b_n a_n\right) \geqq 0 \tag{4.8}$$

for all $f \in R$ *if and only if*

$$\operatorname{Re}\left(\frac{1}{b_0}\sum_{n=0}^{\infty} b_n z^n\right) \geqq \frac{1}{2} \quad \text{on } \{z : |z| = 1\}. \tag{4.9}$$

Proof. [2, pp. 517–518]. □

LEMMA 4.5. *Lemma* 4.4 *remains valid with* (4.8) *replaced by*

$$\operatorname{Re}\left(\frac{1}{b_0}\sum_{n=0}^{\infty} b_n a_n z^n\right) \geqq 0 \quad \text{for } |z| < 1. \tag{4.10}$$

Proof. Clearly, validity of (4.10) for all $f \in R$ implies validity of (4.8) for all $f \in R$. It remains to show that Lemma 4.4 implies validity of (4.10) for all $f \in R$. Fix ζ with $0 < |\zeta| < 1$ and let $f \in R$. Then,

$$g_\zeta(z) \triangleq \sum_{n=0}^{\infty}\left(\frac{a_n \zeta^n}{|\zeta|^n}\right) z^n \tag{4.11}$$

satisfies $g_\zeta \in R$. Thus, (4.8) can be written in the form,

$$\operatorname{Re}\left(\frac{1}{b_0}\sum_{n=0}^{\infty}\frac{b_n a_n \zeta^n}{|\zeta|^n}\right) \geqq 0 \quad \text{for } |\zeta| \leqq 1, \tag{4.12}$$

wherein setting $|\zeta| = 1$ merely reduces (4.12) to (4.8). Let $z = \zeta/|\zeta|$ to write (4.12) in the form,

$$\operatorname{Re}\left(\frac{1}{b_0}\sum_{n=0}^{\infty} b_n a_n z^n\right) \geqq 0 \quad \text{for } |z| = 1. \tag{4.13}$$

Since $f \in R$ implies $\operatorname{Re}(a_0) \geqq 0$, (4.10) applies for $z = 0$, which combines with (4.13) to imply (4.10). □

THEOREM 4.1. *Suppose* $\{b_n : 0 \leqq n < \infty,\ b_0 = 1\}$ *is a real sequence satisfying* (4.9). *Let*

$$c_m \equiv r^m b_m, \quad \text{where } 0 \leqq r < r_L \tag{4.14}$$

with r_L *being the positive root of* (4.5). *Then*, $P^*_{N,L}$, *defined by* (1.6), *has no zeros in* $\{z : |z| = 1\}$.

Proof. Lemma 4.1 shows $w \in R$. Apply Lemma 4.5 to w to show that $f \in R$, where

$$f(\zeta) \triangleq 1 + 2\sum_{m=1}^{\infty} b_m \zeta^m \operatorname{sinc}\frac{m\pi}{N}. \tag{4.15}$$

Apply Lemma 4.3 to show that

$$Q_{N,L}(z) \triangleq 1 + 2\sum_{m=1}^{L-1} b_m r^m z^m \operatorname{sinc}\frac{m\pi}{N} \tag{4.16}$$

has positive real part on $\{z:|z|\leqq 1\}$. Since (4.14) shows (4.16) to be the same as (4.1), (4.2) implies the desired result. □

Classical tests to determine whether a given finite sequence, $\{c_m: 0<m<L\}$, can be used to define a window implying the results in Theorem 4.1 are given below.

THEOREM 4.2. *A sequence,* $\{b_m: 0\leqq m<L,\ b_0=1\}$, *initiates some infinite sequence,* $\{b_m: 0\leqq m<\infty,\ b_0=1\}$, *such that*

$$\operatorname{Re}\left(1+\sum_{m=1}^{\infty} b_m z^m\right)>\frac{1}{2} \quad \text{for } |z|<1 \tag{4.17}$$

if and only if

$$\begin{vmatrix} 1 & b_1 & \cdot & & & b_{k-1} & b_k \\ \bar{b}_1 & 1 & b_1 & \cdot & & & b_{k-1} \\ \cdot & \cdot & \cdot & \cdot & \cdot & & \\ & \cdot & \cdot & \cdot & \cdot & \cdot & \\ & & \cdot & \cdot & \cdot & \cdot & \cdot \\ \bar{b}_{k-1} & & & \cdot & \bar{b}_1 & 1 & b_1 \\ \bar{b}_k & \bar{b}_{k-1} & & & \cdot & \bar{b}_1 & 1 \end{vmatrix} \geqq 0 \tag{4.18}$$

for $0<k<L$ [6]. *Moreover,* (4.17) *is equivalent to the existence of a probability measure,* Ψ, *on* $[0,2\pi]$ *such that*

$$b_m=\frac{1}{2\pi}\int_0^{2\pi} e^{im\theta}\,d\Psi(\theta), \qquad 0\leqq m<\infty. \tag{4.19}$$

Proof. [5] for (4.18) and [7] for (4.19). □

THEOREM 4.3. *If the real sequence,* $\{b_m: 0\leqq m<L,\ b_0=1\}$, *is such that* (4.18) *is satisfied for* $0<k<L$, *let*

$$c_m=b_m\left(1-\frac{2\log L}{L}\right)^m \tag{4.20}$$

define the coefficients in (1.6). *Then* $P^*_{N,L}$ *has no zero of unit modulus.*

Proof. The inequality above (4.6) shows that (4.20) defines c_m satisfying the hypotheses of Theorem 4.1. □

5. Windows. The generalized Hamming window [4] is a standard parameterized time window which defines real sequences satisfying the conditions in Theorem 4.2. This window is defined by

$$\begin{aligned} &b_m=\alpha+(1-\alpha)\cos\frac{2\pi m}{K-1}=\alpha+(1-\alpha)\cos\frac{\pi m}{J} \\ &\text{for } K=2J+1 \quad \text{and} \quad -J=-\frac{K-1}{2}\leqq m\leqq\frac{K-1}{2}=J, \end{aligned} \tag{5.1a}$$

or

$$\begin{aligned} &b_m=\alpha+(1-\alpha)\cos\frac{2\pi(2m+1)}{2(K-1)}=\alpha+(1-\alpha)\cos\frac{\pi(2m+1)}{2J-1} \\ &\text{for } K=2J \quad \text{and} \quad -J=-\frac{K}{2}\leqq m\leqq\frac{K}{2}-1=J-1, \end{aligned} \tag{5.1b}$$

wherein α ordinarily lies in $[\frac{1}{2},1)$. The generalized Hamming window is known as the Hamming window if $\alpha=0.54$ and as the Hanning window if α is one-half.

The even case, with $K=2J$, is discarded here for lack of symmetry. Then, the generalized Hamming window becomes

$$b_m=\alpha+\frac{1-\alpha}{2}\left(e^{i\pi m/J}+e^{-i\pi m/J}\right) \tag{5.2}$$

$$=\alpha+(1-\alpha)\cos\frac{\pi m}{J} \quad \text{for } -J\leqq m\leqq J.$$

THEOREM 5.1. *Use b_m given by* (5.2) *with $J=N-1>0$ and $0<\alpha<1$. Then, $\{b_m: 0\leqq m<N-1,\ b_0=1\}$ initiates the infinite sequence, $\{b_m: 0\leqq m<\infty,\ b_0=1\}$, satisfying* (4.17) *if b_m is defined by* (5.2) *for all m.*

Proof. Compute

$$\sum_{m=0}^{\infty} b_m z^m=\frac{\alpha}{1-z}+\frac{1-\alpha}{2}\left(\frac{1}{1-ze^{i\pi/N}}+\frac{1}{1-ze^{-i\pi/N}}\right). \tag{5.3}$$

Since $(1-z)^{-1}$ maps the unit disc onto $\{w:\mathrm{Re}(w)>1/2\}$, and the bracket in (5.3) is a sum of compositions of $(1-z)^{-1}$ and rotations of the unit disc,

$$\mathrm{Re}\left(\sum_{m=0}^{\infty} b_m z^m\right)>\frac{\alpha}{2}+\frac{1-\alpha}{2}=\frac{1}{2}, \qquad |z|<1. \tag{5.4}$$

ASYMPTOTICS FOR THE GREATEST ZEROS OF ORTHOGONAL POLYNOMIALS*

ATTILA MÁTÉ†, PAUL NEVAI‡ AND VILMOS TOTIK§

Abstract. Asymptotics for the greatest zeros of symmetric orthogonal polynomials is investigated in terms of the asymptotic behavior of the recursion coefficients.

AMS(MOS) subject classification. Primary 42C05

Key words. orthogonal polynomials, zeros of polynomials

Let $d\alpha$ be a positive measure on the real line such that $\operatorname{supp}(d\alpha)$ is an infinite set and all the moments of $d\alpha$ are finite. In addition, we will also assume that all the odd moments of $d\alpha$ vanish. The corresponding orthogonal polynomials are denoted by $p_n(d\alpha)$, $n=0,1,\cdots$, where $p_n(d\alpha,x)=\gamma_n(d\alpha)x^n+\cdots$. The object of this paper is to investigate the asymptotic behavior of the greatest zero $X_n(d\alpha)$ of $p_n(d\alpha)$ in terms of the recursion coefficients $a_n(d\alpha)$ in the three-term recurrence formula

$$xp_n=a_{n+1}p_{n+1}+a_np_{n-1}$$

where $a_0(d\alpha)=0$ and

$$a_n(d\alpha)=\gamma_{n-1}(d\alpha)/\gamma_n(d\alpha), \qquad n=1,2,\cdots.$$

We will be concerned with the case when $\operatorname{supp}(d\alpha)$ is unbounded, and it is well known that this is equivalent to the unboundedness of the sequence $\{X_n(d\alpha)\}$, and the latter is equivalent to the unboundedness of $\{a_n(d\alpha)\}$. An example of particular significance is the case of the Hermite polynomials, which are orthonormal with respect to

$$dH(x)=\exp(-x^2)\,dx.$$

In this case

$$a_n(dH)=\sqrt{n/2} \tag{1}$$

and

$$\lim_{n\to\infty} X_n(dH)n^{-1/2}=\sqrt{2}$$

(see e.g. Szegö [20, p. 106 and p. 132]). G. Freud [5] considered

$$d\alpha_m(x)=\exp(-|x|^m)\,dx, \qquad m>0 \tag{2}$$

and proved

$$\lim_{n\to\infty} X_n(d\alpha_m)n^{-1/m}=\left[\sqrt{\pi}\,\frac{\Gamma(m/2)}{\Gamma((m+1)/2)}\right]^{1/m} \tag{3}$$

for $m=4$ and $m=6$. In this same paper Freud conjectured that (3) holds for every $m>0$. Freud's conjecture was proved by Rahmanov [19] for $m>1$. Another conjecture by Freud [4] states that if $d\alpha_m$ is given by (2) then

$$\lim_{n\to\infty} a_n(d\alpha_m)n^{-1/m}=\frac{1}{2}\left[\sqrt{\pi}\,\frac{\Gamma(m/2)}{\Gamma((m+1)/2)}\right]^{1/m}. \tag{4}$$

Freud [4] proved (4) for $m=4$ and $m=6$, whereas for all even integral values of m (4) was recently proved by Magnus [8]. There is an intimate connection between $X_n(d\alpha)$ and $a_n(d\alpha)$, namely

$$X_n(d\alpha)=2\max_{j_k\geq 0}\frac{\sum_{k=1}^{n}a_{n-k}(d\alpha)\,j_k j_{k+1}}{\sum_{k=1}^{n}j_k^2}, \qquad j_k \text{ real}. \tag{5}$$

This relationship was proved by Freud [5] and it is a slight improvement of a result by Chebyshev [19, p. 188]. Formula (5) arises from the Rayleigh quotient of the relevant Jacobi matrix. On the basis of (5) it is an easy exercise [5] to show that (4) implies (3). It was shown by Lew–Quarles [6] ($m=4$), Máté–Nevai [9] ($m=6$) and Máté–Nevai–Zaslavsky [10] (m even) that

$$a_n(d\alpha_m)n^{-1/m}=\frac{1}{2}\left[\sqrt{\pi}\,\frac{\Gamma(m/2)}{\Gamma((m+1)/2)}\right]^{1/m}+O(n^{-2})$$

and thus one may expect to obtain asymptotics better than (3). In fact, for the Hermite case it is known that

$$X_n(dH)n^{-1/2}=\sqrt{2}-2^{-1/2}3^{-1/3}i_1n^{-2/3}+o(n^{-2/3}), \tag{6}$$

where i_1 is the least zero of Airy's function defined as the unique solution of

$$z''+xz/3=0$$

which remains bounded as $x\to-\infty$ (see e.g. [17, p. 408] and [20, p. 132]), and this may be used to prove the following result.

THEOREM. *Suppose that all the odd moments of $d\alpha$ vanish and the recursion coefficients $a_n(d\alpha)$ satisfy*

$$a_n(d\alpha)=cn^{\delta}\left[1+o(n^{-2/3})\right], \tag{7}$$

where $c>0$ and $\delta>0$ are independent of n. Then

$$X_n(d\alpha)n^{-\delta}=2c-c3^{-1/3}(2\delta)^{2/3}i_1n^{-2/3}+o(n^{-2/3}) \tag{8}$$

where i_1 is the smallest zero of Airy's function ($i_1=3.3721\cdots$).

Remark. The underlying idea in the proof of (8) is that the problem of estimating the largest zero $X_n(d\alpha)$ of the orthogonal polynomials associated with $d\alpha$ is transformed into another problem which is essentially equivalent to estimating $X_n(H)$ and then (6) is applied. In view of the importance of the asymptotic formula (6) we recall here the outline of its proof whereas for details we refer the reader to [17] and [20]. The Hermite polynomials h_n satisfy the differential equation

$$z''+x(2\sqrt{2n+1}-x)z=0,$$

where

$$z(x)=h_n(\sqrt{2n+1}-x)\exp\bigl(-(\sqrt{2n+1}-x)^2/2\bigr).$$

This equation is almost a linearly transformed form of Airy's equation

$$z''+xz/3=0.$$

Based on this observation, Sturm's comparison theorem applied to these two differential equations yields (6).

Proof of the theorem. In order to simplify notation, we will write X_n and a_n instead of $X_n(d\alpha)$ and $a_n(d\alpha)$ respectively. First we will estimate X_n from above. Let us fix Δ such that $0<\Delta<1$ and choose $\varepsilon=\varepsilon(\Delta,\delta)$ so that $0<\varepsilon<1/2$, $\varepsilon<1/(4\delta\Delta)$ and

$$(1-x)^{\delta}\le(1-2\delta\Delta x)^{1/2},\qquad 0\le x\le 2\varepsilon, \tag{9}$$

holds. For given n we can apply (5) to find $j_k^*=j_k^*(n)$, $k=1,2,\cdots,n$, such that $j_k^*\ge 0$ and

$$\frac{1}{2}X_n=\frac{\sum_{k=1}^{n}a_{n-k}j_k^*j_{k+1}^*}{\sum_{k=1}^{n}(j_k^*)^2}.$$

Since[1]

$$\sum_{k=[\varepsilon n]}^{[2\varepsilon n]}j_k^*j_{k+1}^*\le\sum_{k=1}^{n}(j_k^*)^2,$$

there exists ν such that $[\varepsilon n]\le\nu\le[2\varepsilon n]$ and

$$\frac{j_\nu^*j_{\nu+1}^*}{\sum_{k=1}^{n}(j_k^*)^2}\le\frac{1}{\varepsilon n-1}.$$

Hence

$$\frac{1}{2}X_n\le\frac{a_{n-\nu}}{\varepsilon n-1}+\max\left\{\frac{\sum_{k=1}^{\nu-1}a_{n-k}j_k^*j_{k+1}^*}{\sum_{k=1}^{\nu}(j_k^*)^2},\frac{\sum_{k=\nu+1}^{n}a_{n-k}j_k^*j_{k+1}^*}{\sum_{k=\nu+1}^{n}(j_k^*)^2}\right\},$$

and consequently

$$\frac{1}{2}X_n\le\frac{\max_{1\le k\le n}a_{n-k}}{\varepsilon n-1}+\max\left\{\max_{j_k\ge 0}\frac{\sum_{k=1}^{[2\varepsilon n]-1}a_{n-k}j_kj_{k+1}}{\sum_{k=1}^{[2\varepsilon n]}j_k^2},\max_{[\varepsilon n]\le k\le n}a_{n-k}\right\}. \tag{10}$$

Now we will show that for sufficiently large values of n the inequality

$$\max_{[\varepsilon n]\le k\le n}a_{n-k}\le\max_{j_k\ge 0}\frac{\sum_{k=1}^{[2\varepsilon n]-1}a_{n-k}j_kj_{k+1}}{\sum_{k=1}^{[2\varepsilon n]}j_k^2} \tag{11}$$

holds. If we assume that there exists a sequence $n_1<n_2<\cdots$ such that (11) is not true for $n=n_l$ then by (10)

$$\frac{1}{2}X_n\le\frac{\max_{1\le k\le n}a_{n-k}}{\varepsilon n-1}+\max_{[\varepsilon n]\le k\le n}a_{n-k},\qquad n=n_l,$$

[1] $[z]$ denotes the integer part of z.

and thus by (7)

$$\limsup_{l\to\infty} X_{n_l}(n_l)^{-\delta} \le 2c(1-\varepsilon)^{\delta} < 2c,$$

and this contradicts

$$\lim_{n\to\infty} X_n n^{-\delta} = 2c,$$

which was proved by Freud [5, Thm. 7] whenever (7) holds. Having proved (11), we obtain from (7) and (10) the inequality

$$\frac{1}{2} X_n n^{-\delta} \le c \max_{j_k \ge 0} \frac{\sum_{k=1}^{[2\varepsilon n]-1} (1-k/n)^{\delta} j_k j_{k+1}}{\sum_{k=1}^{[2\varepsilon n]} j_k^2} + o(n^{-2/3}), \tag{12}$$

so that by (9)

$$\frac{1}{2} X_n n^{-\delta} \le c \max_{j_k \ge 0} \frac{\sum_{k=1}^{[2\varepsilon n]-1} (1-2\delta\Delta k/n)^{1/2} j_k j_{k+1}}{\sum_{k=1}^{[2\varepsilon n]} j_k^2} + o(n^{-2/3}).$$

Introducing the notation $N = [n/(2\delta\Delta)]$, we can rewrite the previous inequality as

$$\frac{1}{2} X_n n^{-\delta} \le c\sqrt{\frac{2}{N}} \max_{j_k \ge 0} \frac{\sum_{k=1}^{[2\varepsilon n]-1} \sqrt{(N-k)/2}\, j_k j_{k+1}}{\sum_{k=1}^{[2\varepsilon n]} j_k^2} + o(n^{-2/3}).$$

Taking (1) and (5) into consideration, we obtain

$$X_n n^{-\delta} \le c\sqrt{\frac{2}{N}}\, X_N(dH) + o(n^{-2/3}),$$

and thus (6) yields

$$X_n n^{-\delta} \le 2c - c3^{-1/3} i_1 N^{-2/3} + o(n^{-2/3}).$$

Hence

$$X_n n^{-\delta} \le 2c - c3^{-1/3}(2\delta)^{2/3} i_1 n^{-2/3}\Delta^{2/3} + o(n^{-2/3}),$$

and since $0 < \Delta < 1$ is arbitrary we can let Δ tend to 1 to obtain the upper estimate

$$X_n n^{-\delta} \le 2c - c3^{-1/3}(2\delta)^{2/3} i_1 n^{-2/3} + o(n^{-2/3}). \tag{13}$$

Estimating X_n from below can be achieved along lines similar to the previous arguments. We pick $\Delta > 1$ and choose $\varepsilon = \varepsilon(\Delta, \delta)$ such that $0 < \varepsilon < 1/2$, $\varepsilon < \delta\Delta$, $\varepsilon < 1/(4\delta\Delta)$ and

$$(1-2\delta\Delta x)^{1/2} \le (1-x)^{\delta}, \qquad 0 \le x \le 2\varepsilon/(\delta\Delta). \tag{14}$$

Let $N = [n/(2\delta\Delta)]$. Then we can apply (12) with $d\alpha = dH$ and $n = N$ to obtain

$$\frac{1}{2} X_N(dH) N^{-1/2} \le \frac{1}{\sqrt{2}} \max_{j_k \ge 0} \frac{\sum_{k=1}^{[2\varepsilon N]-1} (1-k/N)^{1/2} j_k j_{k+1}}{\sum_{k=1}^{[2\varepsilon N]} j_k^2} + o(N^{-2/3}).$$

Since $N = [n/(2\delta\Delta)]$ and (14) holds, we get

$$\frac{1}{2} X_N(dH) N^{-1/2} \le \frac{n^{-\delta}}{\sqrt{2}} \max_{j_k \ge 0} \frac{\sum_{k=1}^{[n\varepsilon/(\delta\Delta)]-1} (n-k)^{\delta} j_k j_{k+1}}{\sum_{k=1}^{[n\varepsilon/(\delta\Delta)]} j_k^2} + o(N^{-2/3}),$$

and therefore by (5) and (7)

$$X_N(dH)N^{-1/2} \leq \frac{n^{-\delta}}{c\sqrt{2}} X_n + o(n^{-2/3}).$$

Now the inequality

$$X_n n^{-\delta} \geq 2c - c3^{-1/3}(2\delta)^{2/3} i_1 n^{-2/3} + o(n^{-2/3}) \tag{15}$$

follows immediately from (6) by letting $\Delta \to 1$. In view of (13) and (15) the Theorem has completely been proved.

There exist several orthogonal polynomial systems whose recursion coefficients satisfy (7) and thus (8) can be applied to find asymptotics for $X_n(d\alpha)$.

The associated Pollaczek polynomials are orthogonal with respect to

$$d\alpha(x) = |\Gamma(\lambda+\gamma+ix)|^2 |{}_2F_1(1-\lambda+ix, \gamma; \gamma+\lambda+ix; -1)|^{-2} dx, \qquad -\infty < x < \infty,$$

where either $2\lambda+\gamma > 0$, $\gamma \geq 0$ or $2\lambda+\gamma > 1$, $\gamma > -1$ [2], [18]. For these polynomials the recursion coefficients are given by

$$a_n(d\alpha) = \frac{1}{2}\sqrt{(n+\gamma)(n+2\lambda+\gamma-1)} = \frac{n}{2}\left[1 + O(n^{-1})\right],$$

and thus

$$X_n(d\alpha)/n = 1 - 6^{-1/3} i_1 n^{-2/3} + o(n^{-2/3}). \tag{16}$$

For the case $\gamma = 0$, that is for

$$d\alpha(x) = |\Gamma(\lambda+ix)|^2 dx, \qquad -\infty < x < \infty, \tag{17}$$

Freud [5] gave an estimate for $X_n(d\alpha)$ that is weaker than (16). The measure associated with the symmetric Meixner polynomials [2] is closely related to (16).

The Associated Hermite Polynomials are orthogonal with respect to

$$d\alpha(x) = \exp(-x^2)\left|\gamma \int_0^\infty t^{\gamma-1} \exp(-2ixt - t^2)\, dt\right|^{-2} dx, \qquad -\infty < x < \infty,$$

where $\gamma \geq 0$ [1], and their recursion coefficients satisfy

$$a_n(d\alpha) = \sqrt{\frac{n+\gamma}{2}},$$

so that

$$X_n(d\alpha)n^{-1/2} = \sqrt{2} - 2^{-1/2}3^{-1/3} i_1 n^{-2/3} + o(n^{-2/3}). \tag{18}$$

When $\gamma = 0$ these polynomials are the Hermite polynomials.

The Hermite–Sonine Polynomials are orthogonal with respect to

$$d\alpha(x) = |x|^\lambda \exp(-x^2)\, dx, \qquad -\infty < x < \infty, \tag{19}$$

$\lambda > -1$ [2], [20] and in this case

$$a_n(d\alpha) = \sqrt{\frac{n+\theta_n}{2}} \tag{20}$$

where $\theta_{2m} = 0$, $\theta_{2m+1} = \lambda$. Thus $X_n(d\alpha)$ again satisfies (18).

The Freud polynomials are orthogonal with respect to

$$d\alpha(x)=|x|^{\lambda}\exp\left(-|x|^{m}\right)dx, \qquad -\infty<x<\infty,$$

where $\lambda>-1$ and $m>0$.

CONJECTURE.

$$a_n(d\alpha)=\frac{1}{2}\left[\sqrt{\pi}\,\frac{\Gamma(m/2)}{\Gamma((m+1)/2)}\right]^{1/m} n^{1/m}\left[1+O(n^{-1})\right]. \tag{21}$$

In view of (19) and (20) this holds for $m=2$. For $m=4$, $\lambda>-1$ this was proved by Lew–Quarles [6]. As mentioned before (21) also holds for $m=6$, $\lambda=0$ [9] and $m=$ even integer, $\lambda=0$ [10]. Thus

$$X_n(d\alpha)n^{-1/m}=\left[\sqrt{\pi}\,\frac{\Gamma(m/2)}{\Gamma((m+1)/2)}\right]^{1/m}\left(1-6^{-1/3}m^{-2/3}i_1n^{-2/3}+o(n^{-2/3})\right)$$

for $m=2, 4$, $\lambda>-1$ and m even, $\lambda=0$.

Finally, we point out that polynomials that are orthogonal on a half infinite line such as the Laguerre polynomials may be transformed by a quadratic change of the variable into symmetric orthogonal polynomials on the real line, and thus our theorem can be used to determine the size of their greatest zeros as well. Further recent results on the behavior of zeros of orthogonal polynomials are given in [3], [7], [11]–[16], [19] and [21].

One of the referees of this paper suggested finding explicit expression for the error term in (8) or at least an expression for an appropriate bound of the error term in (8). In [17, p. 408] F. W. J. Olver does provide such error analysis for the zeros of the Hermite polynomials. Naturally such a result would help to assess the computational feasibility of the approximation. At this time, however, we are unable to produce nontrivial error bounds in (8). Nonetheless we expect to return to this problem in a subsequent paper. We thank all the referees for their valuable remarks.

ORTHOGONAL POLYNOMIALS, MEASURES AND RECURRENCE RELATIONS*

JOANNE DOMBROWSKI† AND PAUL NEVAI‡

Abstract. Properties of measures associated with orthogonal polynomials are investigated in terms of the coefficients of the three term recurrence formula satisfied by the orthogonal polynomials.

AMS(MOS) subject classification. Primary 43C05

Key words. orthogonal polynomials, recurrence relations, Szegö's theory

1. Introduction. Let $d\alpha$ be a positive measure on the real line with finite moments and infinite support, and let $\{p_n\}_{n=0}^{\infty}$, $p_n(x)=\gamma_n x^n+\cdots$, $\gamma_n>0$, be the system of orthonormal polynomials associated with $d\alpha$. The polynomials p_n satisfy the recurrence formula

$$xp_n=a_{n+1}p_{n+1}+b_n p_n+a_n p_{n-1}, \qquad n=0,1,\cdots, \tag{1}$$

where $p_{-1}=0$, $p_0=\gamma_0$, $a_0=0$, $a_n=\gamma_{n-1}/\gamma_n$ and

$$b_n=\int_{-\infty}^{\infty} xp_n^2(x)\,d\alpha(x).$$

By J. Favard's theorem [10, p. 60] every system of polynomials generated by (1) where $a_n>0$ $(n=1,2,\cdots)$ and $b_n\in\mathbb{R}$ is in fact a system of orthonormal polynomials. The corresponding measure $d\alpha$ is uniquely determined if and only if the associated moment problem has a unique solution, and the latter holds if, say, both sequences $\{a_n\}$ and $\{b_n\}$ are bounded. Recently there has been an upsurge in research activity concerning the determination of the relationship between orthogonal polynomials, recurrence relations and measures. Several such papers are listed in the references. In particular, R. Askey and M. Ismail [1, p. 102] asked whether it is true that if

$$a_n=\frac{1}{2}+\frac{c}{n}+O(n^{-2}) \quad \text{and} \quad b_n=0 \tag{2}$$

where $c>0$ then the absolutely continuous portion of the corresponding measure $d\alpha$ is in Szegö's class which means that $\log\alpha'(\cos t)\in L^1$. One of the main goals of this paper is to show that the Askey–Ismail problem can essentially be solved. More precisely, it follows from Theorem 3 below that if (2) is replaced by

$$a_n=\frac{1}{2}+\frac{c}{n}+\frac{d}{n^2}+o(n^{-2}) \quad \text{and} \quad b_n=0$$

where $c>0$ and $d\in\mathbb{R}$ then $\log\alpha'(\cos t)\in L^1$. While we suspect that condition (2) fails to imply the integrability of $\log\alpha'(\cos t)$, we do not have evidence supporting our claim at the present time. Let us point out that Theorem 2 in fact yields $\alpha'(x)\geqq \text{const}\sqrt{1-x^2}$, $|x|<1$, if only $a_n\downarrow 1/2$ and $b_n=0$. The latter is quite a surprise if compared with J. Shohat's result [26, p. 50] claiming that if $\operatorname{supp}(d\alpha)=[-1,1]$ then $\log\alpha'(\cos t)\in L^1$ if

and only if

$$\sum_{k=1}^{\infty}\left(a_k-\frac{1}{2}\right)<\infty, \qquad \sum_{k=1}^{\infty} b_k<\infty$$

and

$$\sum_{k=1}^{\infty}\left\{\left(a_k-\frac{1}{2}\right)^2+b_k^2\right\}<\infty.$$

The natural way to connect the recursion coefficients with the measure is via Stieltjes transforms (see e.g. [1]). However, it seems that this approach is feasible only when the recursion coefficients are given in terms of explicitly defined expressions such as rational functions of n. The general cases can better be handled by techniques introduced on one side in [5]–[9] and on the other side in [15], [16], [18], [19] and [20].

If p_n is generated by (1), then we define S_n by

$$S_n(x)=\sum_{k=0}^{n}\left\{\left[a_{k+1}^2-a_k^2\right]p_k^2(x)+a_k\left[b_k-b_{k-1}\right]p_{k-1}(x)p_k(x)\right\}. \tag{3}$$

All of our results are based on the formula

$$S_n(x)=a_{n+1}^2\left[p_n^2(x)-\frac{x-b_n}{a_{n+1}}p_n(x)p_{n+1}(x)+p_{n+1}^2(x)\right] \tag{4}$$

proved in [8]. (Caution: the notation in [8] is somewhat different!) The second of us believes that the significance of (4) cannot be overestimated, and it will play a fundamental role in future research on general orthogonal polynomials (see e.g. [22]). The other ingredient of this paper comes from [16] where the necessary spectral analysis was accomplished.

In order not to interrupt our forthcoming discussion, we first prove the following technical proposition. In what follows a_+ denotes the positive part of a and $\log^+$ and $\log^-$ are also defined in the usual way.

LEMMA 1. *Let* $\{a_n\}$ *and* $\{b_n\}$ *satisfy* $a_{n+1}\geqq\frac{1}{2}(1+|b_n|)$ *for* $n>N$ *and let* p_n *and* S_n *be defined by* (1) *and* (3) *respectively. Then*

$$(1-x^2)p_{n+1}^2(x)\leqq 4S_n(x), \qquad |x|\leqq 1, \tag{5}$$

$$(1-x^2)p_n^2(x)\leqq 4S_n(x), \qquad |x|\leqq 1, \tag{6}$$

$$\max_{|x|\leqq 1}p_{n+1}^2(x)\leqq 4(n+2)^2\max_{|x|\leqq 1}|S_n(x)|, \tag{7}$$

$$\max_{|x|\leqq 1}p_n^2(x)\leqq 4(n+1)^2\max_{|x|\leqq 1}|S_n(x)|, \tag{8}$$

$$0\leqq S_{n+1}(x)\leqq S_n(x)\exp\left\{4\frac{\left[a_{n+2}^2-a_{n+1}^2\right]_+ +a_{n+1}|b_{n+1}-b_n|}{1-x^2}\right\}, \qquad |x|\leqq 1, \tag{9}$$

and

$$\max_{|x|\leqq 1}S_{n+1}(x)\max_{|x|\leqq 1}S_n(x)\cdot\exp\left\{4(n+2)^2\left(\left[a_{n+2}^2-a_{n+1}^2\right]_+-a_{n+1}|b_{n+1}-b_n|\right)\right\} \tag{10}$$

hold for $n>N$.

Proof. By (4)

$$S_n(x)=a_{n+1}^2\left[p_n(x)-\frac{x-b_n}{2a_{n+1}}p_{n+1}(x)\right]^2+\frac{1}{4}\left[4a_{n+1}^2-(x-b_n)^2\right]p_{n+1}^2(x)$$

and

$$S_n(x)=a_{n+1}^2\left[p_{n+1}(x)-\frac{x-b_n}{2a_{n+1}}p_n(x)\right]^2+\frac{1}{4}\left[4a_{n+1}^2-(x-b_n)^2\right]p_n^2(x).$$

If $2a_{n+1}\geqq 1+|b_n|$ then $4a_{n+1}^2-(x-b_n)^2\geqq 1-x^2$ for $|x|\leqq 1$. Thus (5) and (6) are satisfied. Inequalities (7) and (8) follow from (5), (6) and Bernstein's theorem [17, p. 139]. Writing

$$S_{n+1}=S_n\left[a_{n+2}^2-a_{n+1}^2\right]p_{n+1}^2+a_{n+1}[b_{n+1}-b_n]p_np_{n+1}$$

and applying (5)–(8), inequalities (9) and (10) follow immediately.

THEOREM 1. *If* $\lim_{n\to\infty}=\frac{1}{2}$, $\lim_{n\to\infty}b_n=0$ *and*

$$\sum_{n=0}^{\infty}\{|a_{n+1}-a_n|+|b_{n+1}-b_n|\}<\infty \tag{11}$$

then the orthogonal polynomials p_n *generated by* (1) *and the corresponding measure* $d\alpha$ *satisfy*

(12)

$$\sum_{k=0}^{\infty}\{[a_{k+1}^2-a_k^2]p_k^2(x)+a_k[b_k-b_{k-1}]p_{k-1}(x)p_k(x)\}=\frac{\sqrt{1-x^2}}{2\pi\alpha'(x)},\qquad -1<x<1,$$

and the convergence is uniform on every closed subinterval of $(-1,1)$.

Proof. Theorem 1 follows immediately from (3), (4) and

$$\lim_{n\to\infty}\left[p_n^2(x)-\frac{x-b_n}{a_{n+1}}p_n(x)p_{n+1}(x)+p_{n+1}^2(x)\right]=\frac{2\sqrt{1-x^2}}{\pi\alpha'(x)}$$

which holds uniformly on every closed subinterval of $(-1,1)$ if (11) is satisfied [16].

THEOREM 2. *Let* $\{a_n\}_{n=1}^{\infty}$ *and* $\{b_n\}_{n=0}^{\infty}$ *satisfy* $a_{n+1}\geqq\frac{1}{2}(1+|b_n|)$ *for* $n>N$, $\lim_{n\to\infty}a_n=\frac{1}{2}$, $\lim_{n\to\infty}b_n=0$ *and*

$$\sum_{n=1}^{\infty}n^2\{[a_{n+1}-a_n]_+ +|b_{n+1}-b_n|\}<\infty.$$

Then there exist a constant $K>0$ *such that for the orthogonal polynomials* p_n *defined by* (1) *and for the associated measure* $d\alpha$ *we have*

$$\sqrt{1-x^2}\,|p_n(x)|\leqq K,\qquad -1\leqq x\leqq 1, \tag{13}$$

$n=1,2,\cdots$, *and*

$$\alpha'(x)\geqq K^{-1}\sqrt{1-x^2},\qquad -1\leqq x\leqq 1. \tag{14}$$

Proof. Repeated application of (10) shows that the sequence $\{S_n\}$ is uniformly bounded in $[-1,1]$ and then (13) follows from (6) whereas (14) follows from Theorem 1, (3) and (4).

Remark 1. The sharpness of Theorem 2 may best be illustrated by the ultraspherical polynomials which are orthogonal with respect to $d\alpha(x)=(1-x^2)^{\varepsilon}dx$ in $[-1,1]$. For these polynomials

$$a_n=\frac{1}{2}+\frac{1-4\varepsilon^2}{16}\frac{1}{n^2}+\frac{\text{const}}{n^3}+O(n^{-4})\quad\text{and}\quad b_n=0$$

so that the conditions of Theorem 2 are satisfied if and only if $|\varepsilon| \leqq \frac{1}{2}$ whereas (14) holds if and only if $\varepsilon \leqq \frac{1}{2}$.

THEOREM 3. *Let* $\{a_n\}_{n=1}^{\infty}$ *and* $\{b_n\}_{n=0}^{\infty}$ *satisfy* $a_{n+1} \geqq \frac{1}{2}(1+|b_n|)$ *for* $n > N$, $\lim_{n\to\infty} a_n = \frac{1}{2}$, $\lim_{n\to\infty} b_n = 0$ *and*

$$\sum_{k=1}^{\infty} n\{[a_{n+1}-a_n]_+ + |b_{n+1}-b_n|\} < \infty.$$

Let $d\alpha$ *be the measure associated with the orthogonal polynomials defined by* (1). *Then*

$$d\alpha(x) = w(x)\,dx + \textit{mass points outside } (-1,1) \tag{15}$$

where w *is positive and continuous in* $(-1,1)$, w *vanishes outside* $[-1,1]$ *and* w *belongs to Szegö's class, that is*

$$\int_0^{\pi} |\log w(\cos t)|\,dt < \infty. \tag{16}$$

Remark 2. If $\Sigma n\{|a_n - \frac{1}{2}| + |b_n|\} < \infty$ then the number of mass points in $d\alpha$ is finite and all such mass points are located outside $[-1,1]$ (see [4] and [11]).

Proof of Theorem 3. By the conditions $\Sigma(|a_{n+1}-a_n| + |b_{n+1}-b_n|) < \infty$ holds as well so that by the Theorem in [16] and by Blumenthal's result (see e.g. [18, Thm. 3.3.7, p. 23]) formula (15) holds with $w(>0) \in C(-1,1)$ and $\operatorname{supp}(w) = [-1,1]$. Therefore only (16) needs to be proved. Let δ_n be defined by

$$\delta_n = 4\left(\left[a_{n+2}^2 - a_{n+1}^2\right]_+ + a_{n+1}|b_{n+1}-b_n|\right).$$

Then by the assumptions made

$$\sum_{1}^{\infty} n\delta_n < \infty, \tag{17}$$

and applying (9) and (10) with $n > N$, we obtain

$$\begin{aligned}
&\int_0^{1-(n+1)^2} \frac{\log^+ S_{n+1}(x)}{\sqrt{1-x}}\,dx \\
&\quad \leqq \int_0^{1-n^{-2}} \frac{\log^+ S_n(x)}{\sqrt{1-x}}\,dx + \delta_n \int_1^{1-n^{-2}} \frac{dx}{(1-x)^{3/2}} \\
&\qquad + \log^+\left\{\max_{|x|\leqq 1} |S_{n+1}(x)|\right\} \int_{1-n^{-2}}^{1-(n+1)^{-2}} \frac{dx}{\sqrt{1-x}} \\
&\quad = \int_0^{1-n^{-2}} \frac{\log^+ S_n(s)}{\sqrt{1-x}}\,dx \\
&\qquad + 2(n-1)\delta_n + 2\left(\frac{1}{n}\right)\frac{1}{n+1} \log^+\left\{\max_{|x|\leqq 1} S_{n+1}(x)\right\} \\
&\quad \leqq \int_0^{1-n^{-2}} \frac{\log^+ S_n(x)}{\sqrt{1-x}}\,dx + 2(n-1)\delta_n + \frac{2}{n} \log^+\left\{\max_{|x|\leqq 1} S_n(x)\right\} \\
&\qquad - \frac{2}{n+1} \log^+\left\{\max_{|x|\leqq 1} S_{n+1}(x)\right\} + \frac{2(n+2)^2}{n}\delta_n.
\end{aligned}$$

Therefore

$$\int_0^{1-(n+1)^{-2}} \frac{\log^+ S_{n+1}(x)}{\sqrt{1-x}}\,dx \leqq \int_0^{1-n^{-2}} \frac{\log^+ S_n(x)}{\sqrt{1-x}}\,dx + 18n\delta_n + \frac{2}{n}\log^+\left\{\max_{|x|\leqq 1} S_n(x)\right\} - \frac{2}{n+1}\log^+\left\{\max_{|x|\leqq 1} S_{n+1}(x)\right\}$$

from which

$$\int_0^{1-(n+1)^{2}} \frac{\log^+ S_{n+1}(x)}{\sqrt{1-x}}\,dx \leqq \int_0^{1-(N+1)^{2}} \frac{\log^+ S_{n+1}(x)}{\sqrt{1-x}}\,dx + 18\sum_{k=N+1}^{n} k\delta_k + \frac{2}{N+1}\log^+\left\{\max_{|x|\leqq 1} S_{N+1}(x)\right\}$$

follows. Now letting $n\to\infty$ and applying (3), (17), Theorem 1 and Fatou's lemma, we see that

$$\int_0^{\pi/2} \log^- w(\cos t)\,dt > -\infty.$$

By similar arguments

$$\int_{\pi/2}^{\pi} \log^- w(\cos t)\,dt > -\infty$$

holds as well. By Jensen's inequality

$$\int_0^{\pi} \log w(\cos t)\,dt < \infty$$

and thus Theorem 3 has completely been proved.

2. Applications.

A. Ya. L. Geronimus [12]–[14] raised and solved the following problem. Let $m\geqq 0$ be a fixed integer and let $\{b_k\}_{k=0}^{\infty}$ and $\{a_k\}_{k=1}^{\infty}$ $(a_k>0)$ be given sequences such that $b_k=0$ for $k\geqq m$ and $a_k=\frac{1}{2}$ for $k>m$. Let $\{p_n\}_{n=0}^{\infty}$ be the orthogonal polynomial system generated by (1) and let $d\alpha$ be the corresponding measure. The problem is to find $d\alpha$. We will show that on the basis of our results $d\alpha$ can easily be found. It follows from (3) and (4) that

$$4S_n = p_n^2 - 2xp_n p_{n+1} + p_{n+1}^2, \qquad n\geqq m, \tag{18}$$

and

$$S_n = S_m, \qquad n\geqq m. \tag{19}$$

Thus by Theorem 1 and 3 and by Remark 2,

$$d\alpha(x) = \frac{2}{\pi}\frac{\sqrt{1-x^2}}{p_m^2(x) - 2xp_m(x)p_{m+1}(x) + p_{m+1}^2(x)}\chi(x) + \sum_{l=1}^{M} J_l\delta(x-x_l) \tag{20}$$

where χ is the characteristic function of $[-1,1]$ and x_l's are the mass points with mass $J_l>0$. It is well known [27] that for an arbitary system of orthogonal polynomials if the associated moment problem has a unique solution then x is a mass point for $d\alpha$ with

mass J if and only if $\Sigma p_k^2(x)<\infty$ and then

(21)

$$\frac{1}{J}=\sum_{k=0}^{\infty}p_k^2(x)=\lim_{k\to\infty}a_{k+1}\left[p'_{k+1}(x)p_k(x)-p_{k+1}(x)p'_k(x)\right]$$

$$=\lim_{k\to\infty}a_{k+1}\left[p_{k+1}(x)/p_k(x)\right]'p_k^2(x)=-\lim_{k\to\infty}a_{k+1}\left[p_k(x)/p_{k+1}(x)\right]'p_{k+1}^2(x).$$

Therefore by (18) and (19) the mass points x_l are zeros of S_m and hence $M\leqq 2m+2$. However not all zeros of S_m are in fact mass points. Applying the recurrence formula (1) and (3)–(4) we obtain

$$4S_m=p_{n+1}^2-p_np_{n+2},\qquad n\geqq m \tag{22}$$

so that

$$\frac{p_{n+1}}{p_n}=\frac{p_{m+1}}{p_m},\quad n\geqq m,\quad \text{if } S_m=0. \tag{23}$$

On the other hand, by (18)

$$\frac{p_{m+1}}{p_m}=x\pm\sqrt{x^2-1}\quad \text{if } S_m=0 \tag{24}$$

(here $\sqrt{x^2-1}>0$ if $x>1$ and $\sqrt{x^2-1}<0$ if $x<-1$). Thus by (21) x is a mass point if and only if $S_m(x)=0$ and $|p_{m+1}(x)|<|p_m(x)|$. By (22)

$$4S'_m=-\left(p_n/p_{n+1}\right)'p_{n+1}^2\frac{p_{n+2}}{p_{n+1}}-\left(p_{n+2}/p_{n+1}\right)'p_{n+1}^2\frac{p_n}{p_{n+1}},\qquad n\geqq m,$$

if $S_m=0$ so that by (21), (23) and (24)

$$2S'_m(x_l)=J_l^{-1}\left(x_l-\sqrt{x_l^2-1}\right)-J_l^{-1}\left(x_l+\sqrt{x_l^2-1}\right)=-2J_l^{-1}\sqrt{x_l^2-1}\,.$$

Thus the mass points x_l in (20) are those zeros of $p_m^2-2xp_mp_{m+1}+p_{m+1}^2$ for which $|p_{m+1}(x_l)|<|p_m(x_l)|$ and the corresponding mass J_l is given by

$$J_l=\frac{-\sqrt{x_l^2-1}}{S'_m(x_l)}=\left|\frac{\sqrt{x_l^2-1}}{S'_m(x_l)}\right|.$$

B. The previous analysis can be applied to the case when

$$\lim_{n\to\infty}\left|a_n-\frac{1}{2}\right|^{1/n}=0\quad\text{and}\quad\lim_{n\to\infty}|b_n|^{1/n}=0.$$

Without going into details we point out that in this case one can prove

$$\limsup_{n\to\infty}|p_n(x)|^{1/n}<\infty$$

uniformly on every compact set in the complex plane, and thus

$$S(x)=\lim_{n\to\infty}S_n(x)$$

is an entire function. The corresponding measure $d\alpha$ can be written as

$$d\alpha(x)=\frac{1}{2\pi}\frac{\sqrt{1-x^2}}{S(x)}\chi(x)\,dx+\sum_{x_l\in Z}\left|\frac{\sqrt{x_l^2-1}}{S'(x_l)}\right|\delta(x-x_l)$$

where χ is the characteristic function of $[-1,1]$ and Z is the collection of those zeros x_l of S for which $\lim_{n\to\infty}|p_{n+1}(x_l)/p_n(x_l)|<1$. Of course, Z is a finite set.

C. The Pollaczek polynomials satisfy (1) with

$$a_n^2=\frac{1}{4}\frac{(n+c)(n+2\lambda+c-1)}{(n+\lambda+a+c)(n+\lambda+a+c-1)},\qquad n=1,2,\cdots,$$

and

$$b_n=-\frac{b}{n+\lambda+a+c},\qquad n=0,1,2,\cdots,$$

where the parameters a, b, c and λ are chosen so that $b_n\in\mathbb{R}$ and $a_n>0$. Pollaczek [23] (see also [3]) investigated the case when either $a>|b|$, $2\lambda+c>0$, $c\geqq 0$ or $a>|b|$, $2\lambda+c\geqq 1$, $c>-1$ and determined that $d\alpha$ is absolutely continuous. Hence $d\alpha$ is completely described by (16). The explicit expression for α' [3, p. 185] shows that α' is not Szegö's class in this case. Since

$$a_n=\frac{1}{2}-\frac{a}{2n}+\frac{\text{const}}{n^2}+O(n^{-3})$$

holds, we see that the conditions of Theorem 2 are satisfied provided that $a<0$, $b=0$, and consequently

$$\alpha'(x)\geqq K^{-1}\sqrt{1-x^2},\qquad -1\leqq x\leqq 1,$$

with a suitably chosen positive constant K if $a<0$ and $b=0$. In particular, $\log\alpha'(\cos t)\in L^1$ in this case. Examples of Pollaczek polynomials with not necessarily absolutely continuous measures have been investigated in [1], [2], [24], and [29].

D. Let $\{a_n\}_{n=1}^{\infty}$ satisfy $0<a_n\leqq\frac{1}{2}$, $\lim_{n\to\infty}a_n=\frac{1}{2}$ and

$$\sum_{k=1}^{\infty}|a_{k+1}-a_k|<\infty,$$

and let $b_n=0$ for every n. Let $d\alpha$ be the measure associated with the orthogonal polynomials p_n which are defined by (1). It is well known that in this case $\operatorname{supp}(d\alpha)=[-1]$ (see e.g. [18, Thm. 3.3.7, p. 23]). Let us show that ± 1 are not mass points of $d\alpha$. If x is a mass point, then by (21) $\lim_{n\to\infty}|p_n(x)|=0$ so that there exists n_0 such that $|p_n(x)|\leqq p_{n_0}(x)$ for every n and $|p_n(x)|<|p_{n_0}(x)|$ for $n<n_0$. By the recurrence formula

$$|xp_{n_0}(x)|\leqq a_{n_0+1}|p_{n_0+1}(x)|+a_{n_0}|p_{n_0-1}(x)|<|p_{n_0}(x)|$$

and hence $|x|<1$, that is $x\neq\pm 1$. It has been shown in both [8] and [16] that $d\alpha$ is absolutely continuous in $(-1,1)$. Therefore $d\alpha$ is absolutely continuous on the whole real line and by Theorem 1

$$d\alpha(x)=\frac{1}{2\pi}\frac{\sqrt{1-x^2}}{\sum_{k=0}^{\infty}\left[a_{k+1}^2-a_k^2\right]p_k^2(x)}\chi(x)\,dx$$

where χ is the characteristic function of $[-1,1]$. By the previously quoted theorem of Shohat [26, p. 50] $\log \alpha'(\cos t) \in L^1$ if and only if $\Sigma(a_k - \frac{1}{2}) < \infty$.

E. If there exists N such that $a_n > a_{n+1}$ for $n > N$ and $\lim_{n\to\infty} a_n = \frac{1}{2}$ and if $b_n = 0$ for every n, then the conditions of Theorem 2 are satisfied. Hence $\alpha'(x) \geqq K^{-1}\sqrt{1-x^2}$, $|x| \leqq 1$, holds in this case.

ON A CLASS OF SUPERLINEAR STURM–LIOUVILLE PROBLEMS WITH ARBITRARILY MANY SOLUTIONS*

BERNHARD RUF† AND SERGIO SOLIMINI‡

Abstract. We derive multiplicity results for autonomous superlinear ODE's of the form

$$-u''(x)=g(u(x))+t, \qquad x\in(0,\pi), \quad t\in R,$$
$$u(0)=u(\pi)=0,$$

with $g'(-\infty)<+\infty$ and $g'(+\infty)=+\infty$.

We show that for any given $n\in N$ there exist at least n solutions of the problem if t is sufficiently negative. The proof is carried out by using variational methods jointly with a rearrangement argument.

Key words. superlinear Sturm–Liouville problem, multiple solutions, variational problem, mountain pass solution, Steiner symmetrization

AMS(MOS) subject classifications. Primary 34B15; secondary 35A15

1. Introduction. We consider here the solvability of ordinary differential equations with superlinear nonlinearities of the following type:

$$-u''(x)=g(u(x))+t, \quad x\in(0,\pi), \qquad u(0)=u(\pi)=0, \tag{1}$$

with

$$\lim_{s\to+\infty}\frac{g(s)}{s}=+\infty \quad \text{and} \quad \limsup_{s\to-\infty}\frac{g(s)}{s}<1=\lambda_1,$$

i.e., the nonlinearity crosses *all* eigenvalues $\lambda_k=k^2$, $k\in N$, of the eigenvalue problem

$$-v''(x)=\lambda v(x), \quad x\in(0,\pi), \qquad v(0)=v(\pi)=0. \tag{2}$$

It is easy to see that (1) admits no solution if t is bigger than some t_0. On the other hand the results of E. N. Dancer [4] (see also [1], [5], [6]) ensure in particular that (1) admits at least two solutions for t smaller than t_0. We recall also the results of C. Scovel [12] for the equation

$$-u''=6u^2+t \quad \text{in } (0,\pi), \qquad u(0)=u(\pi)=0. \tag{3}$$

He has shown that for all $k\in N$ there exist values $t_k<\cdots<t_1$ such that for $t<t_k$ there exist k solutions of (3).

The aim of this paper is to prove such a result for equation (1) under general assumptions on g. The key idea to arrive at this result is the following: it is easy to see that (1) has a negative solution which is a local minimum of the associated functional. A second solution can then be found by the mountain pass theorem. We shall show that this mountain pass solution must change sign if t is large enough negative. A "rearrangement" of the minimizing paths then shows that the mountain pass solution

‡ International School for Advanced Studies, 33014 Trieste, Italy.

has in fact precisely one sign change. Finally, doing the same on the intervals $(0,\pi/n)$, we then show that these solutions can be joined to obtain solutions having $2n-1$ nodes.

We point out that it is essential for our method that equation (1) is autonomous (including that t is a constant). The nonautonomous equation as well as, of course, the corresponding partial differential equation, remain therefore open problems.

2. Statement of the result. We consider (1) under the following assumptions on g: $(g_1)\, g \in C^1(\mathbb{R})$ with

$$\limsup_{s \to -\infty} g'(s) =: g^- < 1, \qquad \lim_{s \to +\infty} g'(s) = +\infty,$$

$(g_2)\, g \in C^1(\mathbb{R})$ with

$$\limsup_{s \to -\infty} g'(s) < +\infty, \qquad \lim_{s \to +\infty} g'(s) = +\infty.$$

Of course (g_1) is a stronger assumption than (g_2) and it is the situation in which we are mainly interested. We shall assume the condition (g_1) throughout the paper until the proof of Theorem 1.

Our goal is to prove the following theorem:

THEOREM 1. *Assume* (g_2) *holds. Then for any* $k \in N$ *there exists* $t_k \in R$ *such that for* $t < t_k$ *problem* (1) *has at least* k *distinct solutions.*

Remark 2. In Theorem 1, when (g_1) holds, we actually prove that there exist a negative solution, and solutions with $1,3,5,\cdots,2k-1$ nodes. We shall also discuss the possible existence of positive solutions of (1).

We remark that if (g_1) holds, then there exists a constant t_0 such that for $t > t_0$ (1) has no solution. This follows from the following calculation:

Since $g(s) - g^- \cdot s \geqq -c$, $\forall s \in \mathbb{R}$, we have for $t > c$ and any solution u of (1)

$$-u'' - g^- u = (g - g^-)(u) + t > 0$$

and hence $u > 0$ by the maximum principle, since $g^- < 1$. Multiplying this equation by $\sin x$, we get

$$\begin{aligned}(1-g^-)(u,\sin x) &= ((g-g^-)(u),\sin x) + (t,\sin x) \\ &\geqq ((1-g^-)u,\sin x) - (d,\sin x) + (t,\sin x)\end{aligned}$$

which implies $d > t$. Hence there exists no solution for $t > d$.

On the other hand, if (g_1) does not hold, i.e. if $g^- < \lambda_1$, then the above estimate is not valid, and one then expects solutions for arbitrarily large t. In fact, for the following closely related equation

$$-u'' = \lambda u + (u^+)^p + t \sin x, \quad x \in (0,\pi), \qquad u(0) = u(\pi),$$

where $p > 1$, one has the following result (see B. Ruf and P. N. Srikanth [11]): If $\lambda \in (\lambda_k, \lambda_{k+1})$, then there exist at least $2k+2$ solutions for any $t > 0$.

It is to be expected that the same result holds for the inhomogeneity t instead of $t \sin x$ and for more general nonlinearities g with $g^- \in (\lambda_k, \lambda_{k+1})$, $\lim_{s \to +\infty}(g(s)/s) = +\infty$. □

We shall use variational methods on the space $E=H_0^1(0,\pi)$. We work with the functional I: $E\to\mathbb{R}$

$$I(u):=1/2\int_0^\pi |u'|^2-\int_0^\pi G(u)-t\int_0^\pi u,$$

where $G(s)=\int_0^s g(t)\,dt$ is the primitive of g.

It is clear that $I\in C^2(E,\mathbb{R})$, and we have

LEMMA 3. *The functional I satisfies the Palais–Smale condition, i.e. any sequence $(u_n)\subset E$ with $I(u_n)$ bounded and $I'(u_n)_{n\to\infty}\to 0$ in E', contains a convergent subsequence.*

Proof. Since $g^-<1$ we can find a constant $a\in(g^-,1)$ and a constant M such that $g(s)>as-M$, $\forall s<0$. Let (u_n) be a sequence satisfying the hypothesis, and set $r_n=-u_n''-g(u_n)-t$, which converges to zero in H^{-1}. Multiplying r_n by $u_n^-:=\max\{-u,0\}$ we get

$$\left|-\int_0^\pi u_n''u_n^- -\int_0^\pi (g(u_n)+t)u_n^-\right|\leqq C\|u_n^-\|_E$$

from which we get

$$\left|\int_{[u_n<0]}|u_n'|^2-\int_{[u_n<0]}(au_n^2-Mu_n)\right|\leqq C_1\|u_n^-\|_E$$

and hence

$$\|u_n^-\|_E^2-a\|u_n^-\|_E^2\leqq C_2\|u_n^-\|_E.$$

Therefore $\|u_n^-\|_E\leqq C$, $\forall n\in N$, and hence also $\forall\|u_n^-\|_{C^0}\leqq C$, $\forall n\in N$. This means that the u_n are bounded from below, and hence also $g(u_n)$ is bounded from below. Therefore there exists a $b>1$ (by (g_1)) such that

$$g(u_n)\geqq bu_n-M\quad\forall n\in N.$$

Now we multiply r_n by $\sin x$ and get the estimate

$$\int_0^\pi \sin x(g(u_n)-u_n)\,dx\leqq C.$$

Using the estimate for g we then obtain

$$\int_0^\pi \sin x(b-1)u_n\,dx\leqq C,$$

i.e.,

$$\int_0^\pi \sin x\cdot u_n\leqq C\quad\forall n\in N,$$

and then also $\int_0^\pi \sin x\cdot g(u_n)\leqq C$, $\forall n\in N$. Since $g(u_n)$ is bounded below, we finally get

$$\int_0^\pi \sin x|g(u_n)|\leqq C\quad\forall n\in N.$$

Let G be the Green's operator of $-\ddot{u}$ with the associated Green's function K. Then

$$u_n=G(g(u_n)+t+r_n)=\int_0^\pi K(x,y)(g(u_n(y))+t+r_n(y))\,dy.$$

It is easily seen that $K(x,y)$ satisfies the estimate

$$0 \leqq K(x,y) \leqq C \cdot \sin y.$$

Using this in the above equation, we obtain

$$u_n \leqq \int_0^\pi C \cdot \sin y \, |g(u_n(y))| + \int_0^\pi K(x,y)(t + r_n(y))\, dy \leqq \text{const} \quad \forall n \in N.$$

From this one concludes by standard arguments that (u_n) contains a convergent subsequence. □

We point out that we have actually proved that if $I'(u_n) \to 0$ in E', then (u_n) is precompact. Therefore we have in particular proved that the set of the solutions of (1), for a given t, is compact. This shows that Theorem 1 is in some sense optimal when (g_1) holds; in fact one cannot generically expect to get infinitely many solutions of (1) for the same value of t.

3. A priori estimates. We first recall how a negative solution of (1), which is a local minimum of I, can be found.

In fact, choosing $t < -g(0)$, we see that zero is a supersolution of (1). By J. Kazdan and F. W. Warner [7] we can fix a negative subsolution $\underline{u}$. Using arguments as in H. Hofer [6] and D. G. De Figueiredo and S. Solimini [5] one then proves the existence of a local minimum of I in $[\underline{u}, 0]$. We remark that from the subsequent arguments it will follow that any negative solution is a local minimum.

LEMMA 4. *For k, $\varepsilon \in R_+$ given, there exists $T(k,\varepsilon) \in R$ such that if $t < T(k,\varepsilon)$, then $u < -k$ on $[\varepsilon, \pi - \varepsilon]$ for any negative solution u of* (1).

Proof. Fix $k, \varepsilon \in R_+$. Now choose $t < 0$ such that

$$\sup_{[-k,0]} g(s) < -\frac{1}{2}t, \qquad (4k/-t)^{1/2} < \varepsilon.$$

We set

$$x_1 := \inf\left\{ x \in [0,\pi] \mid u(x) \leqq -k \text{ or } u(x) = \min_{s \in [0,\pi]} u(s) \right\}.$$

We estimate u on $[0, x_1]$. Note that in x_1 we have $u'(x_1) \leqq 0$ and $u(x_1) \geqq -k$, and that $\ddot{u} > -t/2$ in $[0, x_1]$. By the Taylor formula we therefore have

$$u(x) \geqq u(x_1) + u'(x_1)(x - x_1) - \frac{t}{4}(x - x_1)^2 \geqq -k - \frac{t}{4}(x - x_1)^2.$$

Setting $x = 0$, we get $0 \geqq -k - (t/4)x_1^2$, and hence $x_1 \leqq (4k/-t)^{1/2} < \varepsilon$.

Doing the same arguments on the other end of the interval, we find that if $x_2 = \sup\{ x \in [0,\pi] \mid u(x) \leqq -k \text{ or } u(x) = \min_{[0,\pi]} u \}$, then $x_2 \geqq \pi - \varepsilon$.

Finally we note that $u \leqq -k$ in the interval (x_1, x_2), because otherwise we get a local maximum $\bar{x}$ with $u(\bar{x}) \geqq -k$ which would imply $\ddot{u}(\bar{x}) > -\frac{1}{2}t > 0$: a contradiction.

PROPOSITION 5. *Assume (g_1). Then there exists a constant $\tau \in R$ such that for $t < \tau$ equation* (1) *has exactly one negative solution.*

Proof. We have only to show that for τ sufficiently negative there is at most one negative solution. Let us assume that there are two, say u_1 and u_2. Subtracting the two equations, we have

$$-(u_2 - u_1)'' = g(u_2) - g(u_1). \tag{4}$$

Set

$$a(x):=\begin{cases}\dfrac{g(u_2(x))-g(u_1(x))}{u_2(x)-u_1(x)} & \text{if } u_2(x)\neq u_1(x),\\ g'(u_1(x)) & \text{if } u_2(x)=u_1(x).\end{cases}$$

Now we choose $k\in N$ such that $s<-k$ implies $|(g'(s))^+-(g_-)^+|<\delta$, for some $\delta>0$. By Lemma 3 we now have for $t<T(k,\varepsilon)$

$$\int_0^\pi |(a(x))^+-(g^-)^+|<\delta\pi+2\varepsilon\cdot m,$$

where $m=\sup_{s\in R^-}|g'(s)|$.

We rewrite (4) as follows:

$$-(u_2-u_1)''=a(x)(u_2-u_1). \tag{5}$$

But the eigenvalues μ_i of

$$-v''=\mu a(x)v \tag{6}$$

are all strictly bigger than one, if we choose $\delta>0$ and $\varepsilon>0$ sufficiently small; this follows by A. Manes and A. M. Micheletti [9], since $(a(x))^+\to(g_-)^+<1$ in $L^1(0,\pi)$, and $(a(x))^+\geqq a(x)$. This shows that $u_2=u_1$. □

We now turn to the discussion of the existence of positive solutions. We shall show in the next proposition that (1) has no *strictly* positive solution for t large negative. This result is based on and generalizes a recent nonexistence result of M. Ramaswamy [10]. On the other hand, we shall show that there is a negatively diverging sequence of values of t for which (1) has positive solutions which have (degenerate) zeros in $(0,\pi)$. Finally, we remark that the autonomous character of the equation (1) is essential for the nonexistence result; in fact, we will construct a superlinearity for which (1), with t replaced by $t\sin x$, has a strictly positive solution for arbitrarily large negative t.

PROPOSITION 6. *There exists $t^*\in R$ such that* (1) *has no strictly positive solution for $t<t^*$.*

Proof. Let t be given, and let u be a strictly positive solution of (1). We set

$$\beta=\inf\{s\in R^+\mid -g(s)=t\},\qquad \alpha=\inf\{x\in(0,\pi)\mid u(x)=\beta\}.$$

Note that u is symmetric around $\pi/2$; this follows since by the unique solvability of the Cauchy problem every stationary point x of u is a symmetry point. Therefore the only stationary point of u is $\pi/2$, and u is strictly increasing in $(0,\pi/2)$.

We want to give upper estimates of α and $\pi/2-\alpha$.

First, we consider $v=u-u(\alpha)$ as a solution on $(\alpha,\pi-\alpha)$ of the equation

$$-v''=-u''=g(u)+t=\frac{g(u)-g(u(\alpha))}{u-u(\alpha)}v,\qquad v(\alpha)=v(\pi-\alpha)=0. \tag{7}$$

Since $v\geqq 0$ in $(\alpha,\pi-\alpha)$ it follows that the first eigenvalue of the coefficient $(g(u(x))-g(u(\alpha)))/(u(x)-u(\alpha))$, which we denote by $\mu_1((g(u)-g(u(\alpha)))/(u-u(\alpha)))$ (see e.g. [9]), is equal to one. But we have for all $x\in(\alpha,\pi-\alpha)$

$$\frac{g(u(x))-g(u(\alpha))}{u(x)-u(\alpha)}=g'(\xi)$$

for some $\xi > \mu(\alpha)$. Hence, if we let $g(u(\alpha)) = -t \to +\infty$, we get $u(\alpha) \to +\infty$ and hence $\xi \to +\infty$ which implies $|g'(\xi)| \to \infty$ by assumption. Therefore

$$(g(u)-g(u(\alpha)))/(u-u(\alpha)) \to +\infty$$

uniformly for $t \to -\infty$. This implies that the length of $[\alpha, \pi-\alpha]$ tends to zero as $t \to -\infty$ (see [9]).

To obtain an estimate for α, we consider $w(x) = (x/\alpha)u(\alpha) - u(x)$ on $[0,\alpha]$ as a solution of the equation

$$\begin{aligned} -w'' = u'' = -t - g(u) &= \frac{g(u(\alpha))-g(u)}{(x/\alpha)u(\alpha)-u} w, \\ w(0) = w(\alpha) &= 0. \end{aligned} \tag{8}$$

Since $u'' = -t - g(u) \geqq 0$, because $u < \beta$, u is convex in $[0,\alpha]$ and therefore $w > 0$, hence

$$\mu_1\left(\frac{g(u(\alpha))-g(u(x))}{(x/\alpha)u(\alpha)-u(x)} \right) = 1 \quad \text{on } [0,\alpha].$$

But, since $g(u(\alpha)) > g(u(x))$ by the choice of α,

$$\frac{g(u(\alpha))-g(u(x))}{(x/\alpha)u(\alpha)-u(x)} \geqq \frac{g(u(\alpha))-g(u(x))}{u(\alpha)-u(x)}.$$

Fixing $\delta := \inf\{s \in R^+ \mid g(s) \geqq -1/2t\}$ we get for $u(x) < \delta$:

$$\frac{g(u(\alpha))-g(u(x))}{u(\alpha)-u(x)} \geqq \frac{1}{2} \frac{g(u(\alpha))}{u(\alpha)}.$$

On the other hand, for $u(x) \geqq \delta$ we have

$$\frac{g(u(\alpha))-g(U(x))}{u(\alpha)-u(x)} = g'(\xi)$$

for some $\xi \geqq u(x) \geqq \delta$. Hence we get in any case that

$$\frac{g(u(\alpha))-g(u)}{(x/\alpha)u(\alpha)-u} \to \infty \quad \text{uniformly for } t \to -\infty,$$

since $t \to -\infty$ implies $g(u(\alpha))/u(\alpha) \to +\infty$ and $\delta \to +\infty$. Therefore we conclude that also $\alpha \to 0$ as $t \to -\infty$.

We have shown that for $t \to -\infty$ $\alpha \to 0$ and $\alpha \to \pi/2$. This contradiction shows that there cannot exist a positive solution for t large negative. □

Remark 7. The above proof works on any interval. If on the other hand a certain interval is given, the condition $\lim_{s \to +\infty} g'(x) = +\infty$ could be relaxed to a suitable finite lower estimate of this limit. Our proof in fact shows that with the assumption $g'(s)_{s \to +\infty} \to +\infty$ the length of an interval on which there exists a strictly positive solution tends to zero for $t \to -\infty$.

This remark leads to the observation that Proposition 5 is not true if we omit the requirement that u is a strictly positive solution. In fact one has:

PROPOSITION 8. *There exists a sequence* $t_{n(n \to \infty)} \to -\infty$ *such that* (1) *has a positive solution* (*with interior degenerate zeros*) *for* $t = t_n$.

Proof. For given t consider the Cauchy problem

$$-u'' = g(u) + t, \qquad u(0) = u'(0) = 0. \tag{9}$$

Multiplying this equation by u' and integrating, we get

$$-|u'|^2 = G(u) + tu, \tag{10}$$

where $G(s) = \int_0^s g(t)\,dt$ denotes the primitive of g. Also, since g is asymptotically monotone, we have the relation

$$G(s) < g(s)\cdot s \quad \text{for } s \text{ large.} \tag{11}$$

Let now $\bar{s} \in R^+$ be the smallest value such that $G(\bar{s}) = t\bar{s}$. Then, assuming $t < -g(0)$, the solution of (9) starts monotonically increasing in zero, and by (10) it grows monotonically until it either reaches the value $\bar{s}$, or it tends monotonically to some limit. However, this last case is not possible, since this limit has to be $\bar{s}$ (since $u'(t)$ must tend to zero for $t \to -\infty$) and then

$$-u''(x) = g(u(x)) + t \to g(\bar{s}) + t > 0,$$

for t large negative, because this implies $\bar{s}$ large, and hence $g(\bar{s}) > G(\bar{s})/\bar{s} = -t$. Such an estimate for u'' is clearly impossible.

Therefore u must reach $\bar{s}$ in some finite point, say $x(t)/2$, and since this value is then again a symmetry point, we have that u is a positive solution on $[0, x(t)]$.

Finally, since u is a strictly positive solution on $[0, x(t)]$, the Remark 7 implies that $x(t) \to 0$ for $t \to -\infty$, and one sees easily that $x(t)$ depends continuously on t. Therefore there exists a sequence $t_n \to -\infty$ such that $x(t_n) = \pi/n$, for n large enough, and hence we can join the solutions on $[0, \pi/n]$ to obtain positive solutions on $[0, \pi]$ having degenerate zeros in the points $j\pi/n$, $0 \leqq j \leqq n$. □

Remark 9. The autonomous character of (1) is essential for Proposition 8. In fact, the following construction leads to a convex superlinearity f satisfying (g_1) and such that for

$$-u''(x) = f(u(x)) + t\sin x, \qquad u(0) = u(\pi) = 0 \tag{12}$$

the proposition does not hold.

We construct a sequence of asymptotically positively homogeneous problems; we choose a strictly convex function f_0 with $\lambda_1 < f_0'(+\infty) < \lambda_2$. By A. C. Lazer and P. J. McKenna [8] and S. Solimini [13, §2] there exists $t_0 < 0$ such that the corresponding problem (12_0) has a strictly positive solution u_0. Setting $m_0 = \max_{x \in [0,\pi]} u_0(x)$, we choose a strictly convex function f_1 with

$$f_1(s) \quad \begin{cases} = f_0(s), & s < m_0, \\ \text{strictly convex with } \lambda_2 < f_0'(+\infty) < \lambda_3. \end{cases}$$

For the problem (12_1) there then exists $t_1 < -1$ such that there exists a strictly positive solution u_1, with $m_1 = \max_{x \in [0,\pi]} u_1(x)$. Repeating this argument, we can find a strictly convex function f_n, $\forall n \in N$, such that (12_n) has a strictly positive solution u_n for $t_n \leqq -n$, and u_n is also a solution for (12_m), for $m > n$, and for the problem (12) with $f = \sup_{n \in N}\{f_n\}$.

4. A solution with one sign change. Here we want to show that the mountain pass solution can be assumed to have exactly one sign change.

For given t, we choose $r \in R^+$ such that

$$I(r\cdot \sin x) \leqq I(\underline{u}),$$

where $\underline{u}$ is the negative solution of (1). Now let

$$\Gamma = \{\gamma \in C([0,1], E) \mid \gamma(0) = \underline{u}, \gamma(1) = r \sin x\}$$

and set

$$C = \inf_{\gamma \in \Gamma[0,1]} \max I(\gamma(t)) > I(\underline{u}). \tag{13}$$

By the mountain pass theorem as given in A. Ambrosetti and P. Rabinowitz [2] one has in particular the following result.

THEOREM. *Let* $(\gamma_n) \subset \Gamma$ *such that*

$$\max_{[0,1]} I(\gamma_n(t))_{n \to \infty} \to C.$$

Then there exists a subsequence (γ_{n_k}) *such that one can find a sequence* (u_{n_k}) *with* $u_{n_k} \in \gamma_{n_k}$ *and* $u_{n_k} \to u$, *where* u *is a critical point of* I *at level* C.

We introduce the following class of functions:

$$\mathscr{S} = \{u \in E \mid (u(x) > 0, u(y) < 0) \Rightarrow x < y,$$
$$(u(x) > 0, u(y) > 0,\ x < z < y) \Rightarrow u(z) \geqq \min\{u(x), u(y)\}\}.$$

Note that if we find a solution v in $\mathscr{S}$ at level C, then this solution has exactly one nodal point. In fact, v cannot be negative, since by Proposition 5 there exists only one negative solution of (1), and it is at a lower level. Moreover, for t large negative, v cannot be positive, since by Proposition 6 it has to have interior zeros which contradicts the second requirement of $\mathscr{S}$. Finally, the condition of $\mathscr{S}$ says that v can have at most one sign change.

Note that $\mathscr{S}$ is closed for the pointwise convergence (and therefore in E).

We now introduce a procedure which will assign to any $u \in E$ a set of "rearranged" functions lying in $\mathscr{S}$.

We denote by σ: $E \to H^1(R)$ the *Steiner symmetrization* of a positive function in E around zero, i.e. for $u \in E$, $u \geqq 0$, $\sigma(u)$ is the unique function which is even, nonincreasing on $[0, \infty)$ and such that

$$\text{meas}\{x \mid \sigma(u(x)) \geqq y\} = \text{meas}\{x \mid u(x) \geqq y\}, \qquad \forall y \in R,$$

where meas A stands for the Lebesgue measure of A. $\sigma(u)$ satisfies

(a) For h: $[0, \infty) \to R$ continuous: $\int_R h(\sigma(u))\,dx := \int_R h(u)\,dx$

(b) $\sigma(u) \in H^1(R)$,

$$\int_R \left|\frac{d\sigma(u)}{dx}\right|^2 dx \leqq \int_R \left|\frac{du}{dx}\right|^2 dx,$$

(c) σ is strongly continuous in the H^1-norm (see J. M. Coron [3]).

We introduce some more notation. For $u \in E$, let $\alpha_+ = \mu\{u > 0\}$ and $\alpha_- = \mu\{u < 0\}$. Then $\alpha_+ + \alpha_- \leqq \pi$, and we can define the following set

$$\mathscr{P}(u) = \Big\{(p_+, p_-) \in [0,\pi]^2 \mid d(p_\pm, \{0,\pi\})$$
$$\geqq \frac{1}{2}\alpha_\pm, d(p_+, p_-) \geqq \frac{1}{2}(\alpha_+ + \alpha_-),\ p_+ \leqq p_-\Big\}.$$

Clearly, $\mathscr{P}(u)$ is nonempty and convex.

For $u \in E$ and $(p_+, p_-) \in \mathscr{P}(u)$ we now define

$$s(u, p_+, p_-) = \begin{cases} \pm[\sigma(u^{\pm})](x - p_{\pm}) & \text{if } d(x, p_{\pm}) \leqq \frac{1}{2}\alpha_{\pm}, \\ 0 & \text{otherwise} \end{cases}$$

and we set

$$S(u) = \bigcup_{(p_+, p_-) \in \mathscr{P}(u)} \{s(u, p_+, p_-)\}.$$

By the properties of the Steiner symmetrization we have

$$I(v) \leqq I(u) \quad \forall v \in S(u).$$

PROPOSITION 10. *Let $(u_n) \subset E$ be a sequence with $u_n \to u$ in E, and let $(p_+^n, p_-^n) \in \mathscr{P}(u_n)$ with $p_{\pm}^n \underset{n \to \infty}{\to} p_{\pm}$. Then $(p_+, p_-) \in \mathscr{P}(u)$ and*

$$v_n = s(u_n, p_+^n, p_-^n) \to v = s(u, p_+, p_-) \quad \text{in } E.$$

Proof. Since $u \to u^{\pm}$, σ and the translation operator are continuous in E, the result follows easily.

COROLLARY 11. *For any $u \in E$ the set $S(u)$ is connected in E.*

Proof. The map $s(u, \cdot, \cdot)$: $\mathscr{P}(u) \to E$ is continuous by Proposition 10, and since $\mathscr{P}(u)$ is convex, we obtain that $S(u)$ is connected.

COROLLARY 12. *If $(u_n) \subset E$ is a sequence with $u_n \to u$ in E, and $v_n \in S(u_n)$, then there exists a subsequence (v_{n_k}) with $v_{n_k} \to v$ in E for some $v \in S(u)$.*

Proof. Since $v_n = s(u_n, p_+^n, p_-^n)$ for some $(p_+^n, p_-^n) \in \mathscr{P}(u_n)$ we can choose a convergent subsequence $(p_+^{n_k}, p_-^{n_k}) \to (p_+, p_-)$ and apply Proposition 10 to obtain

$$v_{n_k} \to v = s(u, p_+, p_-).$$

PROPOSITION 13. *If γ is connected in E, then also $\bigcup_{u \in \gamma} S(u)$ is connected.*

Proof. Take any two closed sets C_1, C_2 with $\bigcup_{u \in \gamma} S(u) = C_1 \cup C_2$ and $C_1 \cap C_2 \cap \bigcup_{u \in \Gamma} S(u) = \varnothing$. For $u \in \gamma$ we have $S(u) \in C_1$ or $S(u) \in C_2$, since $S(u)$ is connected. Now let $\gamma_i = \{u \in \gamma \mid S(u) \subset C_i\}$, $i = 1, 2$. The γ_i are relatively closed because if $(u_n) \subset \gamma_i$ with $u_n \to u$ then there exists $(v_n) \subset S(u_n) \cap C_i$ of which a subsequence (v_{n_k}) converges to $v \in S(u)$ by Proposition 10. But since C_i is closed we have $v \in C_i$ and hence $S(u) \subset C_i$. By construction we have $\gamma_1 \cup \gamma_2 = \gamma$ with $\gamma_1 \cap \gamma_2 = \varnothing$. Therefore $\gamma = \gamma_i$ with $i = 1$ or $i = 2$, since γ is connected, and hence $\bigcup_{\gamma} S(u) \subset C_i$, for $i = 1$ or 2.

PROPOSITION 14. *Fix $t < -f(0)$ and let C be the critical value given in* (13). *Then there exists a critical point u with $I(u) = C$ and $u \in \mathscr{S}$.*

Proof. By the definition of C we can pick a sequence $\gamma_n \subset \Gamma$ such that $\max_{t \in [0, \pi]} I(\gamma_n(t))_{n \to \infty} \to C$. We have seen that $\bigcup_{u \in \gamma_n} S(u)$ is connected and that $\sup I(\bigcup_{u \in \gamma_n} S(u)) \leqq \sup I(\gamma_n(t))$, $\forall n \in N$. We can find an open, connected neighborhood A_n of $\bigcup_{\gamma_n} S(u)$ such that $d(x, \bigcup_{\gamma_n} S(u)) \leqq 1/n$, $\forall x \in A_n$ and that $\sup I(A_n) \leqq \sup I(\gamma) + 1/n$. Therefore one finds a path $\tilde{\gamma}_n \subset A_n$ with $\tilde{\gamma}_n(0) = \underline{u}$ and $\tilde{\gamma}_n(1) = r \cdot \sin x$ and such that

$$\sup_{t \in [0, 1]} I(\tilde{\gamma}_n(t)) \leqq \sup_{t \in [0, 1]} I(\gamma_n(t)) + \frac{1}{n}, \quad \forall n \in N.$$

By the mountain pass theorem we can therefore find a sequence $u_{n_k} \in \tilde{\gamma}_{n_k}$ with $u_{n_k} \to u$, where u is again a critical point at level C. Since moreover $d(u_{n_k}, \mathscr{S}) \leqq 1/n$ and $\mathscr{S}$ is closed, we have $u \in \mathscr{S}$. □

By our previous remarks we have therefore found a solution u with exactly one sign change, provided t is sufficiently negative.

5. Joining of solutions defined on $(0,\pi/n)$. The purpose of proving the existence of solutions which have exactly one sign change is that such solutions (if they are defined on a suitable sub-interval, say $(0,\pi/n)$) can be joined to solutions having many nodes. This is based on the following observation.

LEMMA 15. *Let u be a solution of* (1), *and let $x\in(0,\pi]$ be a zero of u. Then* $|u'(x)|=|u'(0)|$.

Proof. Multiplying (1) by u' we have

$$-\frac{1}{2}\frac{d}{dx}|u'(x)|^2=\frac{d}{dx}(F(u(x))+tu(x)).$$

Therefore (choosing $F(0)=0$) by integration

$$\frac{1}{2}|u'(x)|^2=\frac{1}{2}|u'(0)|^2-F(u(x))-tu(x).$$

Hence, if $u(x)=0$: $|u'(x)|=|u'(0)|$. □

We are now in the position to complete the proof of Theorem 1.

Proof of Theorem 1. First assume (g_1) and let $k\in N$ be given. Consider (1) on the interval $(0,\pi/m)$, $m=1,\cdots,k-1$. Choosing t smaller than some T (depending on k), we find solutions u_m on $(0,\pi/m)$ which change sign exactly once (Proposition 14). By Lemma 15 we know that $u_m'(0)=u_m'(\pi/m)$. Therefore, u_m can be extended to $(0,\pi)$ by setting

$$\tilde{u}_m(x)=\begin{cases}u(x), & x\in(0,\pi/m),\\ u\left(x-\dfrac{\pi}{m}\right), & x\in(\pi/m,2\pi/m),\\ u\left(x-\dfrac{\pi(m-1)}{m}\right), & x\in\left(\dfrac{\pi(m-1)}{m},\pi\right).\end{cases}$$

Hence we obtain the negative solution on $(0,\pi)$ and $k-1$ solutions having $2m-1$ $(m=1,\cdots,k-1)$ sign changes, respectively.

If we replace (g_1) by (g_2) then the argument works for large m and therefore the statement of the theorem still holds. □

Acknowledgment. We should like to thank E. N. Dancer and O. Kavian for their kind help and stimulating discussions.

Note added in proof. A similar result has been obtained simultaneously by A. Castro and R. Shivaji, Multiple solutions for a Dirichlet problem with jumping nonlinearities, to appear in the Proceedings of Conference on Diff. Equations, Arlington, Texas, 1984.

CHARACTERIZATIONS OF THE FRIEDRICHS EXTENSIONS OF SINGULAR STURM–LIOUVILLE EXPRESSIONS*

HANS G. KAPER†, MAN KAM KWONG†‡ AND ANTON ZETTL†‡

Abstract. A method is presented to characterize selfadjoint realizations of a singular Sturm–Liouville differential expression on a finite interval, where the singularities are of limit-circle type.

Key words. Sturm–Liouville differential operators, singularities of limit-circle type, selfadjoint realizations, Friedrichs extension

AMS(MOS) subject classifications. Primary 34B25, 47E05

1. Introduction. In this article we present a new method for defining selfadjoint realizations of a certain class of singular Sturm–Liouville differential expressions

$$\tau = -\frac{d}{dt}p(t)\frac{d}{dt} + q(t) \tag{1}$$

on a finite interval (a,b). We assume throughout that p and q are measurable and real-valued functions on (a,b) which satisfy the minimal conditions

$$p^{-1}, q \in L^1_{\text{loc}}(a,b). \tag{2}$$

Moreover, we assume that p is positive,

$$p(t) > 0 \quad \text{a.e. on } (a,b). \tag{3}$$

Thus, τ is a quasi-differential expression in the sense of Naimark [1, §V.1]. A function $\bar{y}$ is said to be a solution of the equation $\tau y = 0$ if (i) $\bar{y}$ is absolutely continuous on (a,b), (ii) $p\bar{y}'$ is equal a.e. on (a,b) to an absolutely continuous function (which, with a slight abuse of notation, we denote by the symbol $p\bar{y}'$), and (iii) the identity $-(p\bar{y}')'(t) + q(t)\bar{y}(t) = 0$ holds a.e. on (a,b).

The right endpoint b is said to be a regular endpoint for τ if

$$p^{-1}, q \in L^1(c,b) \quad \text{for some } c \in (a,b). \tag{4}$$

Similarly, the left endpoint a is regular if

$$p^{-1}, q \in L^1(a,c) \quad \text{for some } c \in (a,b). \tag{5}$$

If both endpoints are regular, then the differential expression τ is called regular; otherwise, it is called singular. Note that, for τ to be regular, neither p^{-1} nor q need to be bounded on (a,b).

All solutions $\bar{y}$ of a regular Sturm–Liouville equation $\tau y = 0$ are continuous on $[a,b]$, and the same property holds for the function $p\bar{y}'$. Hence, boundary values can be assigned to these functions. The characterization of those boundary conditions which

*Received by the editors August 17, 1984, and in revised form February 23, 1985. This work was supported by the Applied Mathematical Sciences Research Program (KC-04-02) of the Office of Energy Research of the U. S. Department of Energy under Contract W-31-109-ENG-38.

give rise to selfadjoint realizations of a regular differential expression in the Hilbert space $L^2(a,b)$ is well known and can be found, for example, in the monographs by Akhiezer and Glazman [2, Appendix II] and Naimark [1, §5.18].

The study of singular differential expressions is considerably more difficult. The solutions of a singular Sturm–Liouville equation $\tau y = 0$ generally exhibit singularities near the endpoints, so one cannot assign boundary values there. Weyl [3] has developed a theory for the construction of selfadjoint realizations of singular differential expressions, which is based on a distinction between singularities of limit-circle type and those of limit-point type. The characterizations are, however, not concrete and therefore difficult to apply. The same remarks can be made for the theory developed by Titchmarsh [4].

In this article we present a new method for characterizing selfadjoint realizations of singular Sturm–Liouville differential expressions τ of the form (1), where q is bounded and the singularity at either endpoint is of limit-circle type. We limit the discussion to the case of one singular endpoint; the extension of the method to cases where both endpoints are singular is straightforward. Specifically, we assume that the coefficients p and q satisfy, in addition to (2), (3), and (4), the conditions

$$\int_t^b p^{-1}(s)\,ds = O\big((t-a)^{-\gamma}\big) \quad \text{as } t \downarrow a, \quad \gamma \in \left(0, \frac{1}{2}\right), \tag{6}$$

$$q \in L^\infty(a,b). \tag{7}$$

Thus, b is a regular endpoint and a is a singular endpoint for τ. For bounded potentials q, the condition (6) is both necessary and sufficient for the singularity at a to be of limit-circle type.

A selfadjoint realization of τ in $L^2(a,b)$ requires the specification of two boundary conditions, one at the regular endpoint b and one at the singular endpoint a. At b we impose a condition of the usual type,

$$B_1 y(b) + B_2(py')(b) = 0, \qquad B_1^2 + B_2^2 \neq 0. \tag{8}$$

Given such a condition, there are an infinite number of conditions at a which give rise to a selfadjoint realization of τ in $L^2(a,b)$. The particular condition

$$\lim_{t \downarrow a} y(t) \text{ exists and is finite} \tag{9}$$

is known to generate a selfadjoint realization which coincides with the Friedrichs extension of the minimal operator in $L^2(a,b)$ associated with τ. Although the condition (9) is often referred to as the "natural" one, relating it to the Weyl or Titchmarsh theory of singular Sturm–Liouville problems is nontrivial.

As we will demonstrate, (9) is but one of several equivalent characterizations of the same selfadjoint realization of τ. These characterizations follow in a systematic way from a particular representation of the elements in the domain of the maximal operator defined by τ. The procedure sheds some light on the role that the particular condition (9) plays within the general framework of Weyl's theory.

2. Characterization of the Friedrichs extension. Let $\phi : (a,b) \to \mathbb{R}$ be defined by the expression

$$\phi(t) = 1 + \int_t^b p^{-1}(s)\,ds, \qquad t \in (a,b). \tag{10}$$

Then $\phi \in L^2(a,b)$, because (a,b) is finite and p satisfies (6). Furthermore, $\phi(t) \geqq 1$ for all $t \in (a,b)$ and $\phi'(t) = -p^{-1}(t)$ a.e. on (a,b).

Let M be the maximal operator associated with τ,

$$My = \tau y, \qquad y \in \operatorname{dom} M, \tag{11}$$

where $\operatorname{dom} M = \{ y \in L^2(a,b) : y \text{ and } py' \text{ locally absolutely continuous on } (a,b) \text{ and } \tau y \in L^2(a,b)\}$. The following lemma gives a representation of the elements of $\operatorname{dom} M$.

LEMMA 1. *For every $y \in \operatorname{dom} M$ there exist two constants c and d and an element $g \in L^2(a,b)$, such that*

$$y(t) = c\phi(t) + d + \int_a^t (\phi(t) - \phi(s)) g(s)\, ds, \qquad t \in (a,b), \tag{12}$$

$$y'(t) = -cp^{-1}(t) - p^{-1}(t) \int_a^t g(s)\, ds, \qquad t \in (a,b). \tag{13}$$

Proof. Because q is bounded, $\operatorname{dom} M$ consists of those $y \in L^2(a,b)$ for which y and py' are locally absolutely continuous on (a,b) and $(py')' \in L^2(a,b)$. Hence, for every $y \in \operatorname{dom} M$ there exists a $g \in L^2(a,b)$ such that $-(py')' = g$. Integration of this identity gives the representations (12) and (13). □

Selfadjoint realizations T of τ are obtained by restricting M. The restrictions result in constraints on the element g and the constants c and d in the representation (12). The boundary condition (8) imposes one such constraint, viz.,

$$(B_1 - B_2)c + B_1 d = \int_a^b (B_1 - B_2 - B_1\phi(s)) g(s)\, ds. \tag{14}$$

Another constraint is obtained by imposing a "boundary condition" at the singular endpoint. For example, the condition (9) leads to the constraint $c = 0$. The following lemma explores the ramifications of this constraint.

LEMMA 2. *Let $y \in \operatorname{dom} M$. Then the following conditions are equivalent*:

(i) *y has a representation of the form* (12) *with* $c = 0$;
(ii) *y is bounded on (a,b)*;
(iii) $\lim_{t \downarrow a} y(t)$ *exists and is finite*;
(iv) $\lim_{t \downarrow a} (t-a)^{\gamma} y(t) = 0$;
(v) $\lim_{t \downarrow a} (py')(t) = 0$;
(vi) $\lim_{t \downarrow a} (t-a)^{-\alpha} (py')(t) = 0$ *for any* $\alpha \in (0, \frac{1}{2})$;
(vii) $p^{1/2} y' \in L^2(a,b)$;
(viii) $(t-a)^{-\alpha/2} p^{1/2} y' \in L^2(a,b)$ *for any* $\alpha \in (0, \frac{1}{2})$;
(ix) $y' \in L^1(a,b)$.

Proof. (i) $\Leftrightarrow$ (ii). Elementary estimates yield the inequalities

$$\left| \int_a^t (\phi(t) - \phi(s)) g(s)\, ds \right| \leqq \phi(t) \left| \int_a^t g(s)\, ds \right| + \left| \int_a^t \phi(s) g(s)\, ds \right| \tag{15}$$

$$\leqq \left[\phi(t)(t-a)^{1/2} + \|\phi\| \right] \|g\|.$$

Because of (6), $\phi(t)(t-a)^{1/2}$ tends to zero as $t \downarrow a$, so there exists a positive constant C such that, for any $g \in L^2(a,b)$,

$$\left| \int_a^t (\phi(t) - \phi(s)) g(s)\, ds \right| \leqq C \|g\|, \qquad t \in (a,b). \tag{16}$$

Every $y \in \operatorname{dom} M$ has a representation of the form (12), where the integral obeys the inequality (16). Clearly, y is bounded on (a,b) if and only if $c=0$.

(i) $\Leftrightarrow$ (iii). A more careful estimate of the second term in (15) yields the inequality

$$\left|\int_a^t (\phi(t)-\phi(s))g(s)\,ds\right| \leqq \left[\phi(t)(t-a)^{1/2}+\left(\int_a^t \phi^2(s)\,ds\right)^{1/2}\right]\|g\|. \tag{17}$$

Because of (6), there exists a positive constant C such that $\phi(s) \leqq C(s-a)^{-\gamma}$ for s sufficiently close to a. Thus we find that, for any $g \in L^2(a,b)$, we have the more refined estimate

$$\left|\int_a^t (\phi(t)-\phi(s))g(s)\,ds\right| \leqq \psi(t)\|g\|, \qquad t \in (a,b), \tag{18}$$

where ψ is independent of g, ψ is bounded on (a,b) and $\psi(t)=O((t-a)^{1/2-\gamma})$ as $t \downarrow a$. Every $y \in \operatorname{dom} M$ has a representation of the form (12), where the integral tends to zero like $(t-a)^{1/2-\gamma}$ as $t \downarrow a$. Clearly, $y(t)$ tends to a finite limit as $t \downarrow a$ if and only if $c=0$.

(i) $\Leftrightarrow$ (iv). The proof is similar to the proof of the previous equivalence.

(i) $\Leftrightarrow$ (v). For any $g \in L^2(a,b)$ we have

$$\left|\int_a^t g(s)\,ds\right| \leqq (t-a)^{1/2}\|g\|, \qquad t \in (a,b). \tag{19}$$

Representing y as in (12), so py' is given by (13), we see that $(py')(t)$ tends to zero as $t \downarrow a$ if and only if $c=0$.

(i) $\Leftrightarrow$ (vi). The equivalence follows immediately from the proof of the previous equivalence.

(i) $\Leftrightarrow$ (vii). According to Lemma 1, we have for any $y \in \operatorname{dom} M$,

$$p^{1/2}(t)y'(t) = -cp^{-1/2}(t) - p^{-1/2}(t)\int_a^t g(s)\,ds, \qquad t \in (a,b), \tag{20}$$

for some constant c and some $g \in L^2(a,b)$. Now, using (19),

$$\int_a^b p^{-1}(t)\left|\int_a^t g(s)\,ds\right|^2 dt \leqq \|g\|^2 \int_a^b p^{-1}(t)(t-a)\,dt.$$

The last integral is bounded:

$$\int_a^b p^{-1}(t)(t-a)\,dt = -\int_a^b \phi'(t)(t-a)\,dt = -(b-a)+\int_a^b \phi(t)\,dt = C,$$

so

$$\int_a^b p^{-1}(t)\left|\int_a^t g(s)\,ds\right|^2 dt \leqq C\|g\|^2.$$

The second term in the right member of (20) defines therefore an element of $L^2(a,b)$. The first term, on the other hand, does not, unless $c=0$. Consequently, $p^{1/2}y' \in L^2(a,b)$ if and only if $c=0$.

(i) $\Leftrightarrow$ (viii). We use the representation (20) of $p^{1/2}y'$ and observe that

$$\int_a^b (t-a)^{-\alpha}p^{-1}(t)\left|\int_a^t g(s)\,ds\right|^2 dt \leqq \|g\|^2 \int_a^b p^{-1}(t)(t-a)^{1-\alpha}dt.$$

The last integral is still bounded if $\alpha \in (0, \frac{1}{2})$, so

$$\int_a^b (t-a)^{-\alpha} p^{-1}(t) \left| \int_a^t g(s)\, ds \right|^2 dt \leqq C \| g \|^2.$$

The expression $(t-a)^{-\alpha/2} p^{-1/2}(t) \int_a^t g(s)\, ds$ defines therefore an element of $L^2(a,b)$ as long as $\alpha \in (0, \frac{1}{2})$. On the other hand, the expression $(t-a)^{-\alpha/2} p^{-1/2}(t)$ clearly does not define an element of $L^2(a,b)$ if $\alpha \in (0, \frac{1}{2})$, so the function $t \mapsto (t-a)^{-\alpha/2} p^{1/2}(t) y'(t)$ with $\alpha \in (0, \frac{1}{2})$ belongs to $L^2(a,b)$ if and only if $c = 0$.

(i) $\Leftrightarrow$ (ix). According to Lemma 1 we have, for any $y \in \operatorname{dom} M$,

$$y'(t) = -cp^{-1}(t) - p^{-1}(t) \int_a^t g(s)\, ds, \qquad t \in (a,b), \tag{21}$$

for some constant c and some $g \in L^2(a,b)$. Now,

$$\int_a^b \left| p^{-1}(t) \int_a^t g(s)\, ds \right| dt \leqq \int_a^b p^{-1}(t) \int_a^t |g(s)|\, ds\, dt$$

$$= \int_a^b |g(s)| \int_s^b p^{-1}(t)\, dt\, ds \leqq \| g \|^2 \left(\int_a^b \left(\int_s^b p^{-1}(t)\, dt \right)^2 ds \right)^{1/2}.$$

The last integral is bounded, so the second term in the right member of (21) defines an element of $L^1(a,b)$. The first term does not, unless $c = 0$. Hence, $y' \in L^1(a,b)$ if and only if $c = 0$. □

Lemma 2 shows that the domain of the maximal operator M can be restricted in many equivalent ways. Let T be defined by

$$Ty = My, \qquad y \in \operatorname{dom} T, \tag{22}$$

where $\operatorname{dom} T = \{ y \in \operatorname{dom} M : y$ satisfies (8) and any one of the conditions (i)–(ix) of Lemma 2$\}$.

THEOREM 3. *T is selfadjoint in $L^2(a,b)$.*

Proof. Let $f, g \in \operatorname{dom} T$. Then

$$(Tf, g) = [f, g]_a^b + (f, Tg),$$

where

$$[f, g] = -(pf')\bar{g} + f(p\bar{g}').$$

The bilinear form $[\cdot, \cdot]$ vanishes at b, because f and g satisfy the boundary condition (9). It also vanishes at a, as one verifies most easily using the conditions (iii) and (v) of Lemma 2. Hence, T is symmetric.

It follows from Lemma 1 and the definition of T that M, the maximal operator, is a one-dimensional extension of T. Furthermore, M is a two-dimensional extension of the minimal operator associated with τ. Since T is symmetric, we have $T^* \supset T$. But T^* cannot be a proper extension of T, because then T^* would coincide with M; hence, $T^* = T$. □

The operator T coincides with the Friedrichs extension of the minimal operator associated with the differential expression τ. Hence, we have established several equivalent characterizations of the Friedrichs extension. In the special case of the Legendre differential operator, a proof of the equivalence of the condition (iii), (v) and (vii) of Lemma 2 can be found in Akhiezer and Glazman [2, Appendix II, §9]; the other characterizations appear to be new. The simple characterization given by the condition (i) of Lemma 2 appears to be particularly interesting.

STÄCKEL-EQUIVALENT INTEGRABLE HAMILTONIAN SYSTEMS*

C. P. BOYER†, E. G. KALNINS‡ AND W. MILLER, JR.§

Abstract. The Stäckel transform is a mapping of the commuting constants of the motion (corresponding to a separable coordinate system) for one completely integrable classical or quantum Hamiltonian system to the constants of the motion for another such system. Here the transform is defined and given an intrinsic characterization, and a large family of nontrivial examples is worked out of systems which are "Stäckel equivalent". Among the simplest examples are geodesic flow on an n-dimensional ellipsoid with distinct axes, which is equivalent to the motion of a mass point on the unit sphere in R^{n+1} under the influence of a quadratic potential with distinct eigenvalues, and the Kepler (Coulomb) problem in three dimensions which is equivalent to the pseudo-Coulomb problem.

Key words. Stäckel transform, Hamiltonian system, separation of variables

AMS(MOS) subject classifications. Primary 35A22, 35J05, 58F05, 70H20

Introduction. It has long been known that the Hamiltonian systems corresponding to geodesic flow on an n-dimensional ellipsoid in R^{n+1} with distinct axes and to the motion of a mass point on the unit sphere in R^{n+1} under the influence of a quadratic potential with distinct eigenvalues are both completely integrable [1], [2]. The original proofs were based on Jacobi's separation of variable techniques for solution of the Hamilton–Jacobi equation. With the recent discovery of many examples of completely integrable Hamiltonian systems which are not separable and the attempt to develop a general theory for all such systems, interest in the old (separable) examples has revived, [3], [4]. Now, however, the emphasis is on the explicit construction of the algebraic constants of the motion for these systems in the cotangent bundle of R^{n+1}. (This was not done by Jacobi.)

Uhlenbeck [5] and Devaney [6] appear to have been the first to discover and utilize the algebraic constants of the motion for the sphere problem. In [3] Moser developed a geometric approach to the ellipsoid and sphere systems in which he was able to derive the algebraic constants of the motion for both systems without using separation of variables. He made the interesting observation that the two systems are closely related: under the "hodograph transformation" $p_i \to -x^i$, $x^i \to p_i$ the constants of the motion for one go to the constants of the motion for the other. (The relationship persists for the quantum mechanical analogies of these systems where the hodograph transformation is replaced by the Fourier transform; see the "sphere model" in [7].)

This striking correspondence between two physically distinct separable systems motivated the authors of the present work to study the relationship of these systems from the viewpoint of separation of variables. (This makes good sense since there is a one-to-one relationship between separable coordinates for a system and certain involutive families of constants of the motion for the system. Separable coordinates have a coordinate-free characterization.) Our study has led us to the concept of the Stäckel

transform, which maps the constants of the motion for one orthogonal separable system to the constants of the motion for another orthogonal separable system. Two systems related by a sequence of Stäckel transforms are said to be Stäckel equivalent. Interestingly this equivalence, while intrinsic has no general connection with the hodograph transform.

The basic idea behind the Stäckel transform is related to the Jacobi metric in analytical dynamics [8, p. 172]. Let $H(\mathbf{y},\mathbf{p})$ be a Hamiltonian, quadratic in the momenta p_i, and $V(\mathbf{y})$ a scalar potential such that the Hamilton–Jacobi equation $H+V=E$ is separable in the orthogonal coordinates $\{x^i\}$. Then the Hamilton–Jacobi equation $V^{-1}H=E$ is also separable in these coordinates for the new Hamiltonian $V^{-1}H$. This invertible transform $H\to V^{-1}H$ can be defined intrinsically, i.e., independent of coordinates, by extending it to the involutive family of constants of the motion that characterize $\{x^i\}$.

In §1 we review the intrinsic characterizations of orthogonal coordinate separation for the Hamilton–Jacobi and Helmholtz (Schrödinger) equations in terms of second order symmetries of these equations. In §2 we define the Stäckel transform between two Hamiltonian systems, first in a coordinate dependent manner and then intrinsically (Theorem 3). In §3 we work out a family of (nontrivial) examples of Stäckel equivalent systems, one of the simplest of which is the pair of systems discussed by Moser. In each case one of the systems consists of the n-dimensional geodesic flat space or constant curvature Hamiltonian with an added separable potential. The other system is either of the same type or is an induced Hamiltonian on an n-dimensional coordinate hypersurface in $(n+1)$-dimensional flat space. The explicit algebraic integrals for each of these systems are not worked out here but can be obtained directly from the results of [9].

Finally, in §4 we show that the classical mechanics ideas of §2 can be carried over to quantum mechanics without difficulty. We conclude with an intrinsic characterization of Stäckel equivalence for quantum mechanical systems.

All functions treated in this paper are assumed to be locally analytic.

1. Intrinsic characterization of separation. Let V^n be an n-dimensional (local) pseudo-Riemannian manifold and $\hat{V}^n$ the associated cotangent bundle ($n\geqq 2$). If $(y^1,\cdots,y^n)$ is a local coordinate system on V^n then $(y^1,\cdots,y^n,\ p_1,\cdots,p_n)$ is the corresponding canonical system of coordinates on $\hat{V}^n$. If the metric ds^2 on V^n takes the form

$$ds^2=\sum g_{ij}dy^i dy^j$$

on V^n, then the Hamiltonian H on $\hat{V}^n$ can be written as

$$H(\mathbf{y},\mathbf{p})=\sum g^{ij}(\mathbf{y})\,p_i p_j \tag{1.1}$$

and the Laplace–Beltrami operator is expressed as

$$\Delta=\frac{1}{\sqrt{g}}\sum \partial_i\left(\sqrt{g}\,g^{ij}\partial_j\right) \tag{1.2}$$

where $g=\det(g_{ij})$, and $\sum_j g^{ij}g_{jk}=\delta^i_k$.

The *Hamilton–Jacobi equation* is

$$H\left(y^i,\partial_j S\right)\equiv\sum_{i,j} g^{ij}\partial_i S\partial_j S=E \tag{1.3}$$

and the *Helmholtz equation* is

$$\Delta\psi(y^i)=E\psi(y^i). \tag{1.4}$$

Our interest is in additively separable orthogonal coordinate systems for (1.3) and multiplicatively R-separable orthogonal coordinate systems for (1.4). We know that the orthogonal coordinate system $\{x^i\}$ is additively separable for (1.3) if and only if the metric

$$ds^2=\sum_i H_i^2(dx^i)^2 \tag{1.5}$$

is in Stäckel form [10] (see (2.1)). Furthermore, there is the following intrinsic characterization of variable separation [11], [12]:

THEOREM 1. *Necessary and sufficient conditions for the existence of an orthogonal separable coordinate system* $\{x^i\}$ *for the Hamilton–Jacobi equation* (1.3) *are that there exist n quadratic functions* $G_k=\sum_{i,j} g^{ij}_{(k)} p_i p_j$, $(G_1=H)$ *on* $\hat{V}^n$ *such that*

1) $\{G_k, G_l\}=0$, $1\leqq k, l\leqq n$.

2) *The set* $\{G_k\}$ *is linearly independent* (*as n quadratic forms*).

3) *There is a basis* $\{\omega_{(j)}: 1\leqq j\leqq n\}$ *of simultaneous eigenforms for the* $\{G_k\}$.

(*Here we follow the definitions of Eisenhart* [13] *for the roots and eigenforms of a quadratic form with respect to a metric.*)

If conditions 1)–3) are satisfied, then there exist functions $g^j(x)$ such that $\omega_{(j)}=g^j dx^j$, $j=1,\cdots,n$. (Here $\{\ ,\ \}$ is the Poisson bracket on V^n.) The separable solutions of (1.3) are characterized by the equations $G_k(x^i,\partial_j S)=\lambda_j$, $j=1,\cdots,n_j$ $(\lambda_1=E)$ where the λ_j are the separation parameters.

Recall that a function $V(\mathbf{x})$ is a *Stäckel multiplier* with respect to a Stäckel form metric $ds^2=\sum H_i^2(dx^i)^2$ provided the metric $d\hat{s}^2=V ds^2$ is also in Stäckel form [14].

PROPOSITION. *Let* $ds^2=\sum H_i^2(dx^i)^2$ *be a Stäckel form metric. The following are equivalent*:

1) $V(\mathbf{x})$ *is a Stäckel multiplier.*

2) *There exist functions* $\psi_j=\psi_j(x^j)$ *such that*

$$V(\mathbf{x})=\sum_{j=1}^{n}\psi_j(x^j)H_j^{-2}.$$

3) *The function* $V(\mathbf{x})$ *satisfies*

$$\partial_{jk}V-\partial_j V\partial_k\log H_j^{-2}-\partial_k V\partial_j\log H_k^{-2}=0, \qquad j\neq k, \qquad j,k=1,\cdots,n. \tag{1.6}$$

Here $\partial_j=\partial_{x^j}$.

In this paper we shall be concerned with the Hamilton–Jacobi equation with potential,

$$\sum_{i,j} g^{ij}(\mathbf{y})\partial_i S\partial_j S+V(\mathbf{y})=E. \tag{1.7}$$

The technical conditions for additive separation of this equation in the orthogonal coordinates $\{x^i\}$ are that a) the metric ds^2, (1.5), is in Stäckel form with respect to these coordinates and b) the potential V is a Stäckel multiplier in the coordinates $\{x^i\}$.

Theorem 1 extends to the following intrinsic characterization of variable separation for (1.7) [15].

THEOREM 2. *Necessary and sufficient conditions for the existence of an orthogonal additive separable coordinate system* $\{x^i\}$ *for the Hamilton–Jacobi equation with potential* $H(\mathbf{y}, \partial_i S)+V(\mathbf{y})=E$ *are that there exist* n *quadratic functions* $G_k=\sum_{i,j} h^{ij}_{(k)} p_i p_j$, $(G_1=H)$ *and* n *functions* $V_k(\mathbf{y})$, $(V_1=V)$ *on* $\hat{V}^n$ *such that*

1) $\{G_k+V_k, G_l+V_l\}=0$, $1\leqq k, l\leqq n$.

2) *The set* $\{G_k\}$ *is linearly independent* (*as n quadratic forms*).

3) *There is a basis* $\{\omega_{(j)}: 1\leqq j\leqq n\}$ *of simultaneous eigenforms for the* $\{G_k\}$.

The separable solutions are characterized by the equations $G_k(x^i_j \partial_j S)+V_k(\mathbf{x})=\lambda_k$, $k=1, \cdots, n$, $(\lambda_1=E)$ *where the* λ_k *are the separation parameters.*

Here the eigenforms $\omega_{(j)}$ are related to the separable coordinates dx^j by $\omega_{(j)}=g^j(\mathbf{x})dx^j$ where g^j is a nonzero function. The above results are easily proved by slight modifications of the proof of [16, Thm. 3].

2. Stäckel equivalence. Let H be a quadratic Hamiltonian on a $2n$-dimensional symplectic manifold, $\{x^i\}$ be an orthogonal separable coordinate system for the Hamilton–Jacobi equation $H(x^i, \partial_j S)=E$ and $V(\mathbf{x})$, $W(\mathbf{x})$ be two nonzero Stäckel multipliers for H in the coordinates $\{x^i\}$. Then the Hamilton–Jacobi equation

$$H\left(x^i, \partial_j S\right)+V(\mathbf{x})=E$$

separates in the coordinates $\{x^i\}$ and so does the equation

$$H'\left(x^i, \partial_j S\right)+W^{-1}V=E$$

where $H'=W(x)^{-1}H$ is a Hamiltonian on a new manifold $\hat{V}^n$. (Indeed, $W^{-1}V$ is a Stäckel multiplier for H'.) We say that $H'+W^{-1}V$ is a *Stäckel transform* of $H+V$.

We first examine the significance of Stäckel transforms in terms of Stäckel matrices. Now $H=\sum_{i=1}^n H_i^{-2} p_i^2$ is in Stäckel form, i.e., there exists an $n\times n$ invertible matrix $S=(S_{ji}(x^j))$ such that

$$H_j^{-2}=(S^{-1})^{nj}, \qquad j=1, \cdots, n \tag{2.1}$$

where S^{-1} is the multiplicative inverse of S. Since W is a Stäckel multiplier for H there exist functions $l_i(x^i)$ such that

$$W(\mathbf{x})=\sum_{j=1}^{n} l_j(x^j) H_j^{-2}. \tag{2.2}$$

It follows easily that $W^{-1}H$ is in Stäckel form with $n\times n$ Stäckel matrix

$$S'=\begin{pmatrix} & l_1(x^1) \\ S_{j\alpha}(x^j) & \vdots \\ & l_n(x^n) \end{pmatrix}, \qquad 1\leqq j\leqq n, \quad 1\leqq \alpha\leqq n-1. \tag{2.3}$$

Thus the Stäckel transform consists in the replacement of the nth column of S by the column vector $(l_1(x^1), \cdots, l_n(x^n))$. (We have singled out the nth column by convention. More generally, we shall see that the replacement of any column in a Stäckel matrix by a new column vector $(l_1(x^1), \cdots, l_n(x^n))$ defines a Stäckel transform so long as the new matrix is nonsingular, i.e., so long as the corresponding potential is nonzero.)

A more sophisticated approach to the Stäckel transform is through the roots $\rho_k^{(i)}$ of the quadratic functions G_i which characterize the separable coordinates, Theorems 1

and 2. As is well known, the symmetries G_i take the form

$$G_i = \sum_{j=1}^{n} \rho_j^{(i)} H_j^{-2} p_j^2, \qquad i = 1, \cdots, n \tag{2.4}$$

where $G_1 = H$, $\rho_j^{(1)} = 1$ and, ([16], [13, Appendix 13])

$$\partial_q \rho_k^{(i)} = \left(\rho_q^{(i)} - \rho_k^{(i)}\right) \partial_q \log H_k^{-2}, \qquad q, k = 1, \cdots, n. \tag{2.5}$$

If $W(\mathbf{x}) = \sum_{j=1}^{n} l_j(x^j) H_j^{-2}$ is a Stäckel multiplier for H, then it is straightforward to show that the functions

$$W_i(\mathbf{x}) = \sum_{j=1}^{n} l_j(x^j) \rho_j^{(i)} H_j^{-2} \tag{2.6}$$

satisfy the conditions $\{G_i + W_i, G_k + W_k\} = 0$, $W_1 = W$ and characterize the separable coordinates $\{x^i\}$, as shown in Theorem 2.

A set of roots $\rho_k^{(i)'}$ corresponding to the transformed Hamiltonian $W^{-1}H$ is given by

$$\rho_k^{(i)'} = W \rho_k^{(i)} - W_i + 1, \qquad i = 1, \cdots, n. \tag{2.7}$$

This follows easily from

LEMMA 1. *Let $(\rho_1(x), \cdots, \rho_n(x))$ be a solution of the system*

$$\partial_q \rho_k = (\rho_q - \rho_k) \partial_q \log H_k^{-2}, \qquad q, k = 1, \cdots, n \tag{2.8}$$

where $H = \sum_{i=1}^{n} H_i^{-2} p_i^2$ is in Stäckel form. Then

$$\rho_k' = \sum_{i=1}^{n} l_i(x^i)(\rho_k - \rho_i) H_i^{-2} + 1, \qquad k = 1, \cdots, n$$

is a solution of the system

$$\partial_q \rho_k' = \left(\rho_q' - \rho_k'\right) \partial_q \log\left(H_k^{-2}/W\right) \tag{2.9}$$

where $W = \sum_{i=1}^{n} l_i(x^i) H_i^{-2}$.

Finally, the Stäckel transform has an intrinsic characterization.

THEOREM 3. *Let $(G_i, V_i : i = 1, \cdots, n)$ be a set of quadratic polynomials and potentials corresponding to an orthogonal coordinate system $\{x^i\}$ for the Hamiltonian $H + V \equiv G_1 + V_1$ $(V \not\equiv 0)$, i.e.,*

1) $\{G_k + V_k, G_l + V_l\} = 0$, $1 \leqq k, l \leqq n$.

2) *The set of quadratic forms $\{G_k\}$ is linearly independent.*

3) *There is a basis $\{\omega_{(j)} : 1 \leqq j \leqq n\}$ of simultaneous eigenforms for the $\{G_k\}$.*

Suppose the system (G_i, W_i) also satisfies conditions 1)–3) *with the same basis of eigenforms. Then the system (G_i', V_i') where*

$$\begin{aligned} G_j' &= G_j - W_j W_1^{-1} G_1 + W_1^{-1} G_1, \\ V_j' &= V_j - W_j V_1 / W_1 + V_1 / W_1, \qquad j = 1, \cdots, n \end{aligned} \tag{2.10}$$

satisfies conditions 1)–3) *and corresponds to the orthogonal coordinate system $\{x^i\}$ for the Hamiltonian $G' + V' \equiv G_1' + V_1'$. In particular, $\{G_k' + V_k', G_l' + V_l'\} = 0$.*

Proof. It is clear that the system (G_i', V_i'), defined by (2.10), satisfies conditions 2) and 3). Condition 1) for the systems (G_i, V_i), (G_i, W_i) is equivalent to the requirements

a) $\{G_k, G_l\} = 0$,

b) $\{G_k, V_l\} + \{V_k, G_l\} = 0$, $\{G_k, W_l\} + \{W_k, G_l\} = 0$, $1 \leqq k,\ l \leqq n$.

It is straightforward to show that a) and b) together with the properties $\{L, M_1 + M_2\} = \{L, M_1\} + \{L, M_2\}$, $\{L, M\} = -\{M, L\}$ and $\{L, M_1 M_2\} = M_1\{L, M_2\} + \{L, M_1\} M_2$ of the Poisson bracket for functions $L(\mathbf{x}, \mathbf{p})$, $M_i(\mathbf{x}, \mathbf{p})$ imply $\{G_1', G_j'\} = 0$ and $\{G_j', G_l'\} = 0$, $2 \leqq j,\ l \leqq n$. Furthermore $\{G_k', V_l'\} + \{V_k', G_l'\} = 0$. Q.E.D.

The Stäckel transform is invertible in the following sense.

COROLLARY 1. *Let H, G_i, V_i, V and G_i', V_i', W, W_i be defined as in Theorem* 3. *Let $U = W^{-1}$. Then U is a Stäckel multiplier for $G_1' + V_1' = W^{-1}H + W^{-1}V$ in the orthogonal separable coordinates $\{x^i\}$, corresponding to $(G_i',\ V_i' : i = 1, \cdots, n)$. Furthermore the transformed system is identical to (G_i, V_i).*

For computational convenience the preceding results have been expressed in terms of an explicit basis G_i of quadratic forms and an associated basis V_i, W_i of potentials. However, the results are clearly basis free: they apply to an n-dimensional vector space $\mathscr{K}$ of quadratic forms K in involution, and associated potentials $V_K(\mathbf{x})$, $W_K(\mathbf{x})$. The maps $K \to V_K$, $K \to W_K$ are linear. Furthermore we can extend the definition of the Stäckel transform by noting that any nonsingular quadratic form $\mathscr{K}_0 \in \mathscr{K}$ for which $W_{K_0} \not\equiv 0$ can serve as a *Hamiltonian* with which to define a transform. Thus a given space $\mathscr{K}$ is associated with many different Hamilton–Jacobi equations. It is this simple observation which leads to the most interesting applications of the Stäckel transform.

Let $\mathscr{K}$ and $\mathscr{L}$ be two n-dimensional vector spaces of quadratic forms in involution, each of which has a simultaneous eigenbasis of differential forms. We say that $\mathscr{L}$ is *Stäckel equivalent* to $\mathscr{K}$ if there is a finite sequence of Stäckel transforms $a_1, \cdots, a_t$ such that $\mathscr{L} = a_t \circ a_{t-1} \circ \cdots \circ a_1(\mathscr{K})$. (If b is a Stäckel transform of $\mathscr{K}$ and a is a Stäckel transform of $b(\mathscr{K})$ then $a \circ b$ *is the composition which maps* $\mathscr{K}$ *to* $a(b(\mathscr{K}))$.) We are associating the potential $V_K \equiv 0$ with each of $\mathscr{K}$ and $\mathscr{L}$. It is clear from Corollary 1 that Stäckel equivalence is a true equivalence relation.

THEOREM 4. *Let $\mathscr{K}$ and $\mathscr{L}$ be n-dimensional vector spaces of quadratic forms in involution, each of which has a simultaneous eigenbasis of differential forms. Then $\mathscr{L}$ is Stäckel equivalent to $\mathscr{K}$ if and only if $\mathscr{K}$ and $\mathscr{L}$ have the same eigenbasis.*

Proof. Suppose $\mathscr{L}$ and $\mathscr{K}$ are Stäckel equivalent. Since a space of quadratic forms and its Stäckel transform have the same eigenforms, it follows that $\mathscr{L}$ and $\mathscr{K}$ must have the same eigenforms.

Conversely, suppose $\mathscr{K}$ and $\mathscr{L}$ have the same eigenforms. It follows from Theorem 1 that there exist coordinates $(x^1, \cdots, x^n)$ such that the basis of eigenforms is $(dx^1, \cdots, dx^n)$. Thus $\mathscr{K}$ and $\mathscr{L}$ correspond to $n \times n$ Stäckel matrices $S_{\mathscr{K}}$ and $S_{\mathscr{L}}$ in the same coordinates. Let $\mathbf{k}_i(x^i)$, $\mathbf{l}_i(x^i)$ be the ith column vector in $S_{\mathscr{K}}$, $S_{\mathscr{L}}$, respectively. Note that an elementary column transformation of $S_{\mathscr{K}}$ in which column $\mathbf{k}_i$ is replaced by $\mathbf{k}_i + \alpha \mathbf{k}_h$, where α is a constant and $h < i$, leads to another Stäckel matrix associated to the same Hamiltonian $K = K_1$ and the same coordinates. (Indeed such a transformation merely corresponds to a change of basis forms K_j, $j = 2, \cdots, n$.) The same remarks hold for $S_{\mathscr{L}}$.

By using the elementary column transformations if necessary, we can always choose $S_{\mathscr{K}}$ and $S_{\mathscr{L}}$ such that the following properties hold: each matrix S_j, $0 \leqq j \leqq n$ where $S_j = (\mathbf{l}_1(x^1), \mathbf{l}_2(x^2), \cdots, \mathbf{l}_j(x^j), \mathbf{k}_{j+1}(x^{j+1}), \cdots, \mathbf{k}_n(x^n))$, $j = 1, \cdots, n-1$, $S_0 = S_{\mathscr{L}}$, $S_n = S_{\mathscr{K}}$ is nonsingular and each matrix element $(S^{-1})_j^{ih}$, $(0 \leqq j \leqq n,\ 1 \leqq i, h \leqq n)$ is nonzero. From the remarks following (2.3) we see that the replacement $S_j \to S_{j-1}$ defines a Stäckel transform a_j and $\mathscr{L} = a_1 \circ \cdots \circ a_n(\mathscr{K})$. Q.E.D.

COROLLARY 2. *If $\mathscr{L}$ and $\mathscr{K}$ are Stäckel equivalent then $\mathscr{K}$ can be mapped to $\mathscr{L}$ by a sequence of at most n Stäckel transforms.*

It is a consequence of Theorem 4 that (roughly speaking) *any* orthogonal separable coordinate system on an n-dimensional pseudo-Riemannian manifold is Stäckel equivalent to any such system on another n-manifold. The primary practical and theoretical interest of Stäckel equivalence concerns systems that are equivalent via a single Stäckel transform.

The following construction, a special case of the general Stäckel transform, constitutes an important application of transform methods to the study of Hamiltonian systems. Let H be a quadratic Hamiltonian on a $2n$-dimensional symplectic manifold $\hat{V}_n$ and suppose the Hamilton–Jacobi equation

$$H(x^i, \partial_j S) - \lambda W(\mathbf{x}) + V(\mathbf{x}) = E, \qquad W \not\equiv 0 \tag{2.11}$$

separates in the orthogonal coordinates $\{x^i\}$ for all values of the parameter λ. Then $H(x^i, p_j) = \sum_{i=1}^n H_i^{-2} p_i^2$ is in Stäckel form and the potentials W, V are Stäckel multipliers for H. Furthermore, via Theorem 3, this separable system is characterized by n linearly independent quadratic forms $G_k(\mathbf{x}, \mathbf{p})$ on $\hat{V}_n$ and $2n$ potentials $W_k(\mathbf{x}), V_k(\mathbf{x})$, $k = 1, \cdots, n$ such that $G_1 \equiv H$, $W_1 \equiv W$, $V_1 \equiv V$ and the family $\{G_k - \lambda W_k + V_k\}$ is in involution with respect to the Poisson bracket. The separable complete integral $S(\mathbf{x}; \lambda; \mathbf{E}) = \sum S_i(x^i; \lambda; \mathbf{E})$ of (2.11) is characterized by the equations

$$G_k(x^i; \partial_j S) - \lambda W_k(x) + V_k(x) = E_k, \qquad k = 1, \cdots, n \tag{2.12}$$

with $E_1 = E$. Dividing (2.11) by the nonzero Stäckel multiplier $W(\mathbf{x})$, we obtain the transformed Hamilton–Jacobi equation

$$W^{-1}H - EW^{-1} + W^{-1}V = \lambda \tag{2.13}$$

where now E is considered as a parameter and λ is the "energy". Clearly (2.13) admits the same separable complete integral $S(\mathbf{x}; \lambda; \mathbf{E})$ as does (2.11), with separation parameters $\lambda, E_2, \cdots, E_n$. Furthermore the separable solutions are now characterized by the Hamiltonian $W_1^{-1}G_1 - EW_1^{-1} + W_1^{-1}V_1$ and the constants of the motion

$$(G_k - W_1^{-1}W_k G_1) + EW_1^{-1}W_k + (V_k - V_1 W_1^{-1} W_k), \qquad k = 2, \cdots, n. \tag{2.14}$$

This corresponds to a special case of Theorem 5.

This special Stäckel transform can be very useful when both the systems (2.12) and (2.13), (2.14) correspond to spaces of physical or geometrical interest: one of the systems may prove more tractable than the other. In particular, the Stäckel transform does not, in general, preserve the symmetry algebra of a Hamilton–Jacobi equation so one system may have a higher degree of symmetry than the other.

In the following section we will derive a number of examples of Hamiltonian systems on flat spaces and spaces of constant curvature that are related by Stäckel transforms.

3. Examples. We begin the section with some simple low-dimensional cases where Stäckel transforms appear and are useful. This will be followed by a derivation of families of examples associated with constant curvature spaces in n dimensions.

One of the simplest examples is associated with the Coulomb problem [17]. The Hamilton–Jacobi equation for this problem (expressed in Cartesian coordinates x^i) is

$$p_1^2 + p_2^2 + p_3^2 - \frac{q}{r} = E, \qquad r = \left[\sum_{i=1}^{3} (x^i)^2 \right]^{1/2}. \tag{3.1}$$

Here q is a real parameter. This equation separates in spherical coordinates (r,θ,φ). The associated pseudo-Coulomb problem

$$r\left(p_1^2+p_2^2+p_3^2\right)-Er=q \tag{3.2}$$

also separates in these coordinates, where now E is considered as a parameter and q is the "energy". Here (3.2) is obtained as a Stäckel transform of (3.1) by the potential r^{-1}. Although (3.1) and (3.2) are equivalent, (3.2) is more tractible from a symmetry point of view. Indeed for (3.2) the fundamental constants of the motion (the angular momentum vector and the Laplace–Runge–Lenz vector) form a 6-dimensional symmetry algebra isomorphic to $O(4)$. However for (3.1) the corresponding constants of the motion fail to generate a finite-dimensional algebra under the Poisson bracket [17]. Similar comments apply for the quantum Kepler problem [18].

For our next example we use the fact that if $ds^2=\sum_{i=1}^n H_i^2(dx^i)^2$ is in Stäckel form and $\partial_{x^n}H_j=0$ for all j then H_n^{-2} is a Stäckel multiplier for the reduced Hamiltonian associated with the $(n-1)$-dimensional space $ds'^2=\sum_{i=1}^{n-1} H_i^2(dx^i)^2$ and coordinates $x^1,\cdots,x^{n-1}$. (This follows directly from the Levi–Civita conditions [13, p. 265].) Let $H=p_1^2+p_2^2+p_3^2$ be the Hamiltonian for three-dimensional Euclidean space (expressed in Cartesian coordinates x^i) and pass to parabolic coordinates

$$x^1=\xi\eta\cos\theta,\ x^2=\xi\eta\sin\theta,\qquad x^3=\tfrac{1}{2}\left(\xi^2-\eta^2\right). \tag{3.3}$$

The Hamilton–Jacobi equation for these orthogonal separable coordinates takes the form

$$H=\frac{1}{\xi^2+\eta^2}\left(p_\xi^2+p_\eta^2\right)+\frac{1}{\xi^2\eta^2}p_\theta^2=E. \tag{3.4}$$

Since θ is an ignorable variable, corresponding to a complete separable integral we have $p_\theta=\lambda$, a separation parameter. Now the potential $\xi^{-2}\eta^{-2}$ is a Stäckel multiplier for the reduced Hamiltonian $(\xi^2+\eta^2)^{-1}(p_\eta^2+p_\xi^2)$. Dividing by this multiplier, we can recast $H=E_1$ in the form

$$\frac{\xi^2\eta^2}{\xi^2+\eta^2}\left(p_\xi^2+p_\eta^2\right)+\xi^2\eta^2p_\varphi^2=-\lambda^2=E' \tag{3.5}$$

where $p_\varphi=\sqrt{-E}$. (Here, we must make the restriction that both E and E' are negative.) Now (3.5) is just the Hamilton–Jacobi equation for the hyperboloid

$$t^2-x^2-y^2-z^2=1,\qquad t>1. \tag{3.6}$$

Indeed the coordinates are related by

$$x=\frac{\varphi}{\xi\eta},\quad y=\frac{1}{2}\left(\frac{\xi}{\eta}-\frac{\eta}{\xi}\right),\quad t+z=\frac{1}{\xi\eta},\quad t-z=\frac{\left(\xi^2+\eta^2\right)^2}{4\xi\eta}+\frac{\varphi^2}{\xi\eta}. \tag{3.7}$$

Note that the Hamilton–Jacobi equations for these two geometrically distinct problems have essentially the same solutions.

For a more sophisticated example we consider the Hamiltonian $H=p_1^2+p_2^2-\lambda(z_1^2+z_2^2)$ on Euclidean two-space, expressed in terms of the Cartesian coordinates z_1, z_2. In terms of elliptic coordinates x_1, x_2 the Hamilton–Jacobi equation is separable

and the separation is characterized by

(3.8)

$$H=G_1=-4\left(\frac{(e_1-x_1)(e_2-x_1)}{x_1-x_2}p_{x_1}^2+\frac{(e_1-x_2)(e_2-x_2)}{x_2-x_1}p_{x_2}^2\right)+\lambda(x_1+x_2)=E_1,$$

$$G_2=-4\left(\frac{x_2(e_1-x_1)(e_2-x_1)}{x_1-x_2}p_{x_1}^2+\frac{x_1(e_1-x_2)(e_2-x_2)}{x_2-x_1}p_{x_2}^2\right)+\lambda x_1x_2=E_2.$$

Here $e_1<e_2$ are real constants and for fixed z_1, z_2 with $z_1z_2\neq 0$ the corresponding elliptic coordinates x_i are uniquely chosen such that $x_1<e_1<x_2<e_2$ and $x_i=\mu$ is a solution of

$$\frac{z_1^2}{e_1-\mu}+\frac{z_2^2}{e_2-\mu}=1.$$

Now consider the case $e_1=e$, $e_2=0$ and note that x_1x_2 is a Stäckel multiplier for G_2. Dividing by this multiplier, we can write $G_2=E_2$ in the form

$$H'=4\left(\frac{x_1-e}{x_1-x_2}p_{x_1}^2+\frac{x_2-e}{x_2-x_1}\right)p_{x_2}^2+\frac{E_2}{x_1x_2}=\lambda. \tag{3.9}$$

This is just the Hamilton–Jacobi equation, expressed in parabolic coordinates, corresponding to two-dimensional Euclidean space with an added potential. In Cartesian coordinates z_i, $H'=\lambda$ where

$$H'=p_1^2+p_2^2+\frac{E_2}{2ez_2-z_1^2}. \tag{3.10}$$

Here for given z_1, z_2 with $z_1\neq 0$ the corresponding parabolic coordinates x_i are uniquely chosen such that $x_1<e<x_2<0$ and $x_i=\mu$ is a solution of

$$2z_2-\mu+\frac{z_1^2}{\mu-e}=0.$$

For the case $e_1e_2\neq 0$ it is still true that x_1x_2 is a Stäckel multiplier for G_2. Dividing by the multiplier we can rewrite $G_2=E_2$ in the form

$$H''=-4\left(\frac{(e_1-x_1)(e_2-x_1)}{x_1(x_1-x_2)}p_{x_1}^2+\frac{(e_1-x_2)(e_2-x_2)}{x_2(x_2-x_1)}p_{x_2}^2\right)-\frac{E_2}{x_1x_2}=-\lambda. \tag{3.11}$$

This is the Hamilton–Jacobi equation in parabolic coordinates induced on the paraboloid

$$2z_3-\frac{z_1^2}{e_1}-\frac{z_2^2}{e_2}=0$$

in three-dimensional Euclidean space by the potential $E_2(z_1^2+z_2^2-2z_3(e_1+e_2)-e_1e_2)^{-1}$.

Since many of our examples concern coordinate hypersurfaces corresponding to orthogonal separable coordinate systems, we will briefly digress to discuss the induced Riemannian structure on such hypersurfaces. Let V^n be a local pseudo-Riemannian manifold and $\hat{V}^n$ the associated cotangent bundle. Let H be the Hamiltonian on $\hat{V}^n$

and suppose the Hamilton–Jacobi equation $H(x^i, \partial_j S) = E$ separates in the orthogonal coordinates $(x^1, \cdots, x^n)$. By Theorem 1 these coordinates can be associated to an involutive family $\{G_i : i = 1, \cdots, n\}$ of quadratic forms on $\hat{V}^n$ where $H = G_1$. The metric, expressed in the separable coordinates, is

$$ds^2 = \sum_{j=1}^{n} H_j^2(\mathbf{x})(dx^j)^2. \tag{3.12}$$

Now consider the pseudo-Riemannian manifold Z^{n-1} obtained by restricting V^n to a coordinate hypersurface, say $x^n = c$, c a constant. The induced metric on Z^{n-1} is

$$d\tilde{s}^2 = \sum_{j=1}^{n=1} H_j^2(\tilde{\mathbf{x}}, c)(dx^j)^2, \qquad \tilde{\mathbf{x}} = (x^1, \cdots, x^{n-1}). \tag{3.13}$$

Similarly, we can identify the cotangent bundle $\hat{Z}^{n-1}$ as a restriction of $\hat{V}^n$. If $(\mathbf{x}, \mathbf{p})$ are local symplectic coordinates on $\hat{V}^n$, then $(\tilde{\mathbf{x}}, \tilde{\mathbf{p}})$ are local coordinates on $\hat{Z}^{n-1}$, where $\tilde{\mathbf{p}} = (p_1, \cdots, p_{n-1})$ and for the restriction we set $x^n = c$, $p_n = 0$. The pullback of the quadratic forms G_i to $\hat{Z}^{n-1}$ is

$$\tilde{G}_i = \sum_{j=1}^{n-1} \rho_j^{(i)}(\tilde{\mathbf{x}}, c) H_j^{-2}(\tilde{x}, c) p_j^2, \qquad i = 1, \cdots, n \tag{3.14}$$

and $\{\tilde{G}_i, \tilde{G}_l'\} = 0$, $1 \leqq i$, $l \leqq n$, where $\{\cdot, \cdot\}'$ is the Poisson bracket on $\hat{Z}^{n-1}$. The Hamilton–Jacobi equation for Z^{n-1}

$$\tilde{H}(\tilde{x}, \partial_j W) = H(\tilde{\mathbf{x}}, c, \partial_j W, 0) = E, \qquad j = 1, \cdots, n-1, \tag{3.15}$$

separates in the coordinates $(x^1, \cdots, x^{n-1})$ and these coordinates are uniquely associated with the $(n-1)$-dimensional involutive family spanned by the forms $\tilde{G}_i$, $i = 1, \cdots, n$.

We see that an orthogonal separable coordinate system $\{x^1, \cdots, x^n\}$ for V^n leads to orthogonal separable systems and corresponding involutive families of quadratic forms for all of the pseudo-Riemannian manifolds induced on the coordinate hypersurfaces.

Our basic example is the "generic" separable system $\{x^1, \cdots, x^n\}$ on V^n with metric

$$ds^2 = \sum_{j=1}^{n} \frac{\prod_{i \neq j}(x^i - x^j)(dx^j)^2}{f(x^j)} \tag{3.16}$$

where f is a nonzero function of a single variable. (At this point we shall not be precise about the range of values permitted to the x^j.) It is evident that this system is separable. Indeed the columns of the Stäckel matrix can be chosen as

$$\mathbf{l}_i(\mathbf{x}) = \begin{pmatrix} \dfrac{(x^1)^{i-1}}{f(x^1)} \\ \vdots \\ \dfrac{(x^n)^{i-1}}{f(x^n)} \end{pmatrix}, \qquad i = 1, \cdots, n. \tag{3.17}$$

It is not difficult to show [9] that V^n is a space of nonzero constant curvature if and only if $(d^{n+1}/du^{n+1})f(u)=c$, a nonzero constant. Furthermore, V^n is flat if and only if $(d^{n+1}/du^{n+1})f(u)=0$. If V^n is Euclidean, then f is a polynomial of order $n-1$ or n.

Note that the Hamiltonian in these coordinates can be taken to be

$$G_1=\sum_{j=1}^{n}\frac{f(x^j)}{\Pi_{i\neq j}(x^i-x^j)}p_j^2 \tag{3.18}$$

and the quadratic form obtained by expanding the Stäckel matrix on the 1st column is

$$G_n=\sum_{j=1}^{n}\frac{f(x^j)\Pi_{i\neq j}(x^i)}{\Pi_{i\neq j}(x^i-x^j)}p_j^2. \tag{3.19}$$

For convenience we choose the coordinate hypersurface Z^{n-1} in the normalized form: $x^n=0$. Then the metric on Z^{n-1} in the separable coordinates $(x^1,\cdots,x^{n-1})$ is

$$d\tilde{s}^2=-\sum_{j=1}^{n-1}\frac{x^j\Pi_{i\neq j}(x^i-x^j)(dx^j)^2}{f(x^j)} \tag{3.20}$$

and the Hamiltonian is

$$\tilde{G}_1=-\sum_{j=1}^{n-1}\frac{f(x^j)}{x^j\Pi_{i\neq j}(x^i-x^j)}p_j^2 \tag{3.21}$$

where now $i<n$. Note that $\tilde{G}_n\equiv 0$.

Making use of the identities

$$\sum_{l=1}^{n}\frac{(x^l)^k}{\Pi_{i\neq l}(x^l-x^i)}=\begin{cases}0, & k=0,1,\cdots,n-2,\\ 1, & k=n-1,\\ \sum_{l=1}^{n}x^l, & k=n,\end{cases} \tag{3.22}$$

for the case $k=n$, we see that the potential

$$V_1=-\sum_{j=1}^{n}x^j \tag{3.23}$$

is a Stäckel multiplier for the Hamiltonian G_1. Furthermore, using (3.11) for $k=n-1$, we see that the potential V_n associated with V_1 is

$$V_n=-x^1x^2\cdots x^n. \tag{3.24}$$

It follows that V_n is a Stäckel multiplier for G_n and the Stäckel transform

$$K=V_n^{-1}G_n=-\sum_{j=1}^{n}\frac{f(x^j)}{x^j\Pi_{i\neq j}(x^i-x^j)}p_j^2 \tag{3.25}$$

is the Hamiltonian for the coordinate hypersurface Z^n in V_{n+1}, with metric (3.16), same f, n replaced by $n+1$ (compare with (3.21)). We have shown that (for all f) the system generated by the Hamiltonian G_1, (3.18), in V^n is Stäckel equivalent to the system generated by the Hamiltonian K, (3.25), in Z^n. We can consider Z^n as an n-dimensional hypersurface in V^{n+1}.

All of the examples where f is a polynomial of order $\leqq n+1$ occur as hypersurfaces in $(n+1)$-dimensional flat space. Well known is the case [9], [10]

$$f(u)=(u-e_1)(u-e_2)\cdots(u-e_{n+1}), \qquad e_1<e_2<\cdots<e_{n+1}. \tag{3.26}$$

Here the embedding space is Euclidean space E^{n+1} with Cartesian coordinates $\mathbf{z}=(z_1,\cdots,z_{n+1})$ and metric

$$ds^2=dz_1^2+\cdots+dz_{n+1}^2. \tag{3.27}$$

We now consider the unit sphere S^n in E^{n+1},

$$z_1^2+z_2^2+\cdots+z_{n+1}^2=1. \tag{3.28}$$

The metric on S^n is obtained by restricting ds^2 to (3.28). The appropriate coordinates on S^n are elliptic spherical coordinates $(x^1,\cdots,x^n)$ defined as follows, [3], [9]: through each point $\hat{\mathbf{z}}\in S^n$ with no $\hat{z}_i=0$ there pass exactly n confocal cones

$$\sum_{i=1}^{n+1}\frac{z_i^2}{e_i-\lambda}=0, \tag{3.29}$$

corresponding to the parameters $\lambda=x^1,\cdots,x^n$ where

$$e_1<x^1<e_2<x^2<e_3<\cdots<x^n<e_{n+1}. \tag{3.30}$$

Indeed we have the identity in λ

$$\sum_{i=1}^{n+1}\frac{z_i^2}{e_i-\lambda}=\frac{\prod_{j=1}^{n}(x^j-\lambda)}{\prod_{l=1}^{n+1}(e_l-\lambda)}. \tag{3.31}$$

The metric on S^n expressed in the elliptic spherical coordinates x^i takes the form $-\frac{1}{4}$ times (3.16) with f given by (3.26) [9]. Comparing coefficients of λ^{-2} in the Laurent series expansions for both sides of (3.31), we obtain the result

$$V_1=-\sum_{j=1}^{n}x^j=\sum_{i=1}^{n+1}e_iz_i^2-\sum_{l=1}^{n+1}e_l. \tag{3.32}$$

Since the constant Σe_l can be absorbed into E for the Hamilton–Jacobi equation $G_1+V_1=E$, we can consider the separable potential V_1 as a quadratic potential in Cartesian coordinates.

Now we consider elliptic coordinates in E^{n+1}. Through each point $\mathbf{z}\in E^{n+1}$ with no $z_i=0$ there pass exactly $n+1$ confocal ellipsoids [3], [19]

$$\sum_{i=1}^{n+1}\frac{z_i^2}{e_i-\lambda}=1 \tag{3.33}$$

corresponding to the parameters $\lambda=x^0,\cdots,x^n$ where

$$x^0<e_1<x^1<e_2<\cdots<x^n<e_{n+1}. \tag{3.34}$$

We have the identity in λ

$$1-\sum_{i=1}^{n+1}\frac{z_i^2}{e_i-\lambda}=\prod_{j=1}^{n+1}\frac{(\lambda-x^{j-1})}{(\lambda-e_j)}. \tag{3.35}$$

Suppose $e_1 > 0$ and consider the ellipsoid Z^n obtained by setting $x^0 = 0$. It is straightforward via (3.14) to show that the induced metric on this hypersurface is

$$d\tilde{s}^2 = -\frac{1}{4}\sum_{j=1}^{n} \frac{x^j \Pi_{i\neq j}(x^i - x^j)(dx^j)^2}{f(x^j)}$$

where f is given by (3.26). This shows that the Hamiltonian system on the sphere S^n (elliptic spherical coordinates) is Stäckel equivalent to the Hamiltonian system on the ellipsoid (elliptic coordinates). (Moser [3] has demonstrated that these two systems are equivalent via the hodograph transformation, see also [4]. Similarly, the "sphere model" in [7, Chap. 3] displays the equivalence of these systems for the Helmholtz equation. However, the following Stäckel equivalent systems are not equivalent via the hodograph transform.)

We now consider the cases where $\deg f = n+1$ and f has repeated roots, or $\deg f \leqq n$. In each case we will compute the expression of the separable potential $V_1 = -\Sigma_{j=1}^n x^j$ in terms of "natural" cartesian coordinates $\{z^i\}$ and identify the coordinate hypersurfaces in terms of cartesian coordinates. The method we follow, a limit procedure based on (3.31), was pioneered by Bôcher [19] and refined by two of the authors [20]. The results are complete except that determination of the range of the coordinates is left to the reader. (The "natural" coordinates z_i, y_i may be complex but the separable coordinates and the roots will be real.)

Consider first the case $\dim f = n+1$, where f has roots e_J of multiplicities $N_1, \cdots, N_P$, $\Sigma_{J=1}^P N_J = n+1$. Then, as shown in [17], the identity (3.31) is modified to

$$\sum_{J=1}^{P}\sum_{j=1}^{N_J} \frac{S_{j+1}^J}{(\lambda - e_J)^{N_J+1-j}} = \frac{\Pi_{j=1}^n(\lambda - x^j)}{\Pi_{J=1}^P(\lambda - e_J)^{N_J}} \tag{3.36}$$

where $S_{j+1}^J = \Sigma_i Y_i^J Y_{j+1-i}^J$. Here

$$\sum_i z_i^2 = \sum_J S_{N_J+1}^J = \sum_J \sum_j \left(z_j^J\right)^2 = 1$$

where

(i) $N_J = 2p$ (even),

$$Y_j^J = \frac{1}{\sqrt{2}}\left(z_j^J - iz_{N_J+1-j}^J\right), \qquad Y_{2P+1-j}^J = \frac{1}{\sqrt{2}}\left(z_j^J + iz_{N_J+1-j}^J\right), \qquad j = 1, \cdots, p,$$

(ii) $N_J = 2p+1$ (odd), as above but $Y_{p+1}^J = z_{p+1}^J$.

Here the coordinates Y_i^J are real. Equating coefficients of λ^{-2} on both sides of (3.36), we obtain

$$\sum_j x^j - \sum_J N_J e_J = \sum_{J=1}^{P}\left(S_{N_J}^J + e_J S_{N_J+1}^J\right). \tag{3.37}$$

It follows from (3.26) that the coordinate curves are given by

$$\sum_{J=1}^{P}\sum_{j=1}^{N_J} \frac{S_{j+1}^J}{(\lambda - e_j)^{N_J+1-j}} = 0. \tag{3.38}$$

We can take $z_1 = z_1^1$, $z_2 = z_2^1, \cdots, z_{N_1} = z_{N_1}^1$, $z_{N_1+1} = z_1^2, \cdots, z_n = z_{N_P}^P$.

For example, if $N_1=2$, and $N_j=1$ for $1<j\leqq n-1$ we have

$$\sum_j x^j-2e_1-\sum_{j=2}^{n} e_j=e_1\left(z_1^2+z_2^2\right)+\frac{1}{2}\left(z_1+iz_2\right)^2+\sum_{j=2}^{n} e_j z_{j+1}^2.$$

To treat the case $\deg f\leqq n$, we start from the basic identity [19], [20]

$$\sum_{j=1}^{n+2}\frac{y_j^2}{(\lambda-e_j)}=\left(-\sum_{j=1}^{n+2} e_j y_j^2\right)\frac{\prod_{j=1}^{n}(\lambda-x^j)}{\prod_{l=1}^{n+2}(\lambda-e_l)} \tag{3.39}$$

for general cyclidic coordinates x^j. Here the y_j are hyperspherical coordinates ($\Omega\equiv\sum_{j=1}^{n+2}y_j^2=0$), related to cartesian coordinates z_i by formulas

$$z_i=y_i/\left(\sqrt{-1}\,y_{n+1}+y_{n+2}\right),\qquad i=1,\cdots,n. \tag{3.40}$$

(Note: There is some freedom in the choice of y_{n+1}, y_{n+2}.) Now suppose that $n+2$ roots e_l degenerate to roots with multiplicities $N_1,\cdots,N_P$ where $\sum_J N_J=n+2$. As shown in [20], formula (3.39) then becomes

$$\sum_{J=1}^{P}\sum_{j=1}^{N_J}\frac{S_{j+1}^J}{(\lambda-e_J)^{N_J+1-j}}=\left(-\sum_J e_J S_{N_J+1}^J\right)\frac{\prod_{j=1}^{n}(\lambda-x^j)}{\prod_{J=1}^{P}(\lambda-e_J)^{N_J}} \tag{3.41}$$

and $\Omega=\sum_J S_{N_J+1}^J=0$. At this point it is convenient to set $\lambda=-1/\lambda'$, $x^j=-1/x'^j$, $e_J=-1/e_J'$ so that (3.41) becomes

$$\sum_{J=1}^{P}\sum_{j=1}^{N_J-1}\frac{S_{j+1}^J}{(\lambda'-e_J')^{N_J+1-j}}(\lambda')^{N_J-1-j}\left(e_J'\right)^{N_J+1-j}+\sum_{J=1}^{P}\frac{S_{N_J+1}^J}{(\lambda'-e_J')} \tag{3.42}$$

$$=\frac{\left(\sum_J\left(1/e_J'\right)S_{N_J+1}^J\right)}{\left(\prod_{j=1}^{n}x'^j\right)}\cdot\frac{\left(\prod_{J=1}^{P}\left(e_J'\right)^{N_J}\right)}{\prod_{j=1}^{P}(\lambda'-e_J)^{N_J}}\prod_{j=1}^{n}(\lambda'-x'^j).$$

Here we have added $\lambda'\Omega$ to the left-hand side of this equation and restricted λ' to the domain $|\lambda'|>|e_j|$, $\forall j$.

Following Bôcher's procedures, to obtain the coordinate curves corresponding to f with $\deg f\leqq n$ and distinct roots of multiplicities $N_2,\cdots,N_P$ respectively, we let $e_1'\to\infty$ in (3.42). (Here, we are assuming $N_1\geqq 2$.) We use the notation $[\overset{\infty}{N}_1,N_2,\cdots,N_P]$ to denote this coordinate system. The result is easily seen to be

(3.43)

$$\sum_{j=1}^{N_1-1}S_{j+1}^1(-\lambda')^{N_1-j-1}+\sum_{J=2}^{P}\sum_{j=1}^{N_J-1}\frac{S_{j+1}^J}{(\lambda'-e_J')^{N_J-j+1}}\left(\lambda' e_J'\right)^{N_J-j+1}\lambda'^{-2}+\sum_{J=2}^{P}\frac{S_{N_J+1}^J}{(\lambda'-e_J')}$$

$$=\frac{\left(\sum_{J=2}^{P}\left(1/e_J'\right)S_{N_J+1}^J\right)}{\prod_{j=1}^{n}x'^j}\frac{\left(\prod_{J=2}^{P}\left(e_J'\right)^{N_J}\right)}{\prod_{J=2}^{P}\left(\lambda'-e_J'\right)^{N_J}}(-1)^{N_1}\prod_{j=1}^{n}(\lambda'-x'^j).$$

Equating coefficients of $(\lambda')^{N_1-2}$ on each side of this identity, we obtain

$$S_2^1=\frac{\left(\sum_{J=2}^{P}(1/e_J')S_{N_J+1}^J\right)\left(\prod_{J=2}^{P}(e_J')^{N_J}\right)}{\prod_{j=1}^{n}x'^j} \tag{3.44}$$

Equating coefficients of $(\lambda')^{N_1-3}$ and making use of the condition $\Omega=0$, we have

$$\sum_{j=1}^{n}x'^j-\sum_{J=2}^{P}N_Je_J'=\begin{cases}\dfrac{S_3^1}{S_2^1}, & N_1\geqq 3,\\[2ex] \dfrac{S_3^1}{S_2^1}, & N_1=2.\end{cases} \tag{3.45}$$

Here $S_2^1=(y_1^1)^2$, $S_3^1=2y_1^1y_2^1$.

For $N_1>3$ we can define hyperspherical coordinates $\tilde{y}_j^J$ so that

$$\sqrt{2}\,y_1^1=\tilde{y}_1^1-\sqrt{-1}\,\tilde{y}_{N_1}^1,\qquad \sqrt{2}\,y_2^1=\tilde{y}_2^1-\sqrt{-1}\,\tilde{y}_{N_1-1}^1 \tag{3.46}$$

and (of course)

$$\sum_{J=1}^{P}\sum_{j=1}^{N_J}\left(\tilde{y}_j^J\right)^2=0.$$

Passing to Cartesian coordinates z_j^J via (3.40), we can obtain the linear potential

$$\frac{S_3^1}{S_2^1}=\sqrt{2}\left(z_2^1-\sqrt{-1}\,z_{N_1-1}^1\right).$$

This potential will be real only for a pseudo-Euclidean space.

For $N_1=3$ we can set $y_2^1=\tilde{y}_2^1$ and, from (3.46), (3.40), achieve the linear potential

$$\frac{S_3^1}{S_2^1}=\sqrt{2}\,z_2^1.$$

Finally, for $N_1=2$ we can obtain the oscillator potential

$$\frac{S_3^1}{S_2^1}=\sum_{J=2}^{P}\sum_{j=1}^{N_J}\left(z_j^J\right)^2=\sum_{l=1}^{n}(z_l)^2.$$

Thus all the potentials V_1 correspond to either linear or oscillator potentials in terms of Cartesian coordinates. The coordinate hypersurface $x=x^i$ for $[\overset{\infty}{N}_1,N_2,\cdots,N_P]$ is given by

$$\sum_{j=1}^{N_1-1}S_{j+1}^1(-x^i)^{N_1-j-1}+\sum_{J=2}^{P}\sum_{j=1}^{N_J-1}\frac{S_{j+1}^J}{\left(x^i-e_J\right)^{N_J-j+1}}\left(x^ie_J\right)^{N_J-j+1}(x^i)^{-2}$$
$$+\sum_{J=2}^{P}\frac{S_{N_J+1}^J}{\left(x^i-e_j\right)}=0. \tag{3.47}$$

Note that since $S^1_{N_1+1}$ does not occur explicitly in (3.47), hyperspherical coordinates y_l can always be chosen such that this hypersurface is quadratic in terms of the associated cartesian coordinates in E^{n+1}.

4. Stäckel equivalence for Schrödinger equations. Here we work out the appropriate modification of the results of §2 for the Schrödinger (or Helmholtz) equation with velocity dependent potential. On V^n this equation can be written in the form

$$\mathscr{H}\psi \equiv \Delta\psi + Q\cdot\nabla\psi + V\psi = E\psi \tag{4.1}$$

where Δ is the Laplacian

$$\Delta = \frac{1}{\sqrt{g}} \sum_{i,j=1}^{n} \partial_i\left(\sqrt{g}\, g^{ij}\partial_j\right),$$

and

$$Q\cdot\nabla\psi = \sum_{i,j=1}^{n} Q_i g^{ij}\partial_j\psi. \tag{4.2}$$

Here, $Q_i(\mathbf{y})$ is a covariant vector and $V(\mathbf{y})$ is a scalar function. Applying the definitions and techniques of [16], [21], we obtain the following necessary and sufficient conditions for multiplicative R-separability of (4.1) in the orthogonal coordinates $\{x^i\}$, $(\psi = e^R\prod_{j=1}^n \psi^{(j)}(x^j))$:

1) the metric $ds^2 = \sum_i H_i^2 (dx^i)^2$ is in Stäckel form,

2) there is a function Q such that $Q_i = \partial_i Q$ in the coordinates $\{x^j\}$,

3) $\sum_{i=1}^n H_i^{-2}(R_{ii} - 2R_i^2) + V$ is a Stäckel multiplier where

$$-2R_i = \partial_i \log\left(H_1\cdots H_n/H_i^2\right) + Q_i, \qquad R_{ii} = \partial_i R_i. \tag{4.3}$$

If conditions 1)–3) are satisfied, then $R_i = \partial_i R$.

Now suppose that the Schrödinger equation (4.1) R-separates in the orthogonal coordinates $\{x^j\}$. In these coordinates (4.1) takes the form

$$\sum_i \left\{ \frac{1}{\sqrt{g}}\partial_i\left[\left(\sqrt{g}\, H_i^{-2}\right)\partial_i\right] + Q_i H_i^{-2}\partial_i \right\}\psi + V\psi = E\psi, \tag{4.4}$$

where $\sqrt{g} = H_1 H_2 \cdots H_n$. Let $W \neq 0$ be a Stäckel multiplier for the metric $ds^2 = \sum H_i^2 (dx^i)^2$. Our basic observation is that the Schrödinger equation

$$W^{-1}[\Delta + Q\cdot\nabla + V]\psi = E\psi \tag{4.5}$$

i.e.,

$$[\Delta' + Q'\cdot\nabla + W^{-1}V]\psi = E\psi \tag{4.6}$$

is also R-separable in the coordinates $\{x^j\}$. Here Δ' is the Laplace operator corresponding to the metric $W\,ds^2$. We say that $\Delta' + Q'\cdot\nabla + W^{-1}V$ is a *Stäckel transform* of $\Delta + Q\cdot\nabla + V$.

Variable R-separation for (4.1) can be characterized intrinsically.

THEOREM 5. *Necessary and sufficient conditions for the existence of an orthogonal R-separable coordinate system $\{x^i\}$ for the Schrödinger equation* (4.1) *are that there exist n second-order differential operators*

$$\mathscr{A}_k = \Delta_k + \sum_{i,j=1}^{n} \partial_{yi} Q g^{ij}_{(k)} \partial_{yj} + V_k, \qquad k = 1,\cdots,n, \tag{4.7}$$

($\mathscr{A}_1=\mathscr{H}$) on V^n where

$$\Delta_k=\frac{1}{\sqrt{g}}\sum_{i,j=1}^{n}\partial_{yi}\left(\sqrt{g}\,g^{ij}_{(k)}\partial_{yj}\right) \tag{4.8}$$

and $\Delta_1=\Delta$ such that

1) $[\mathscr{A}_k,\mathscr{A}_l]\equiv\mathscr{A}_k\mathscr{A}_l-\mathscr{A}_l\mathscr{A}_k=0$, $1\leqq k,l\leqq n$.

2) *The set $\{G_k: k=1,\cdots,n\}$ is linearly independent as n quadratic forms on $\hat{V}^n$, where*

$$G_k=\sum_{i,j=1}^{n}g^{ij}_{(k)}p_ip_j.$$

3) *There is a basis $\{\omega_{(j)}: 1\leqq j\leqq n\}$ of simultaneous eigenforms for the $\{G_k\}$.*

If conditions 1)–3) *are satisfied, then there exist functions $g^j(\mathbf{x})$ such that $\omega_{(j)}=g^j\,dx^j$.* (*Note that the division* (4.7) *of $\mathscr{H}_k$ into three terms is coordinate independent. Indeed the operators Δ_k are in self-adjoint form with respect to the measure on V^n given in local coordinates by $\sqrt{g}\,dy^1\cdots dy^n$ whereas Q and V_k $V(_1=V)$ are scalar valued functions on V^n.*)

Proof. Suppose the operators satisfy conditions 1)–3). Comparing coefficients of third derivative terms in $[\mathscr{A}_k,\mathscr{A}_l]=0$, we obtain $\{G_k,G_l\}=0$. It follows from Theorem 1 and comparison of second derivative terms that there exists an orthogonal coordinate system $\{x^i\}$ such that

$$\mathscr{A}_k=\sum_{i=1}^{n}\rho_i^{(k)}H_i^{-2}(\partial_{ii}+f_i\partial_i)+\sum_{i=1}^{n}Q_i\rho_i^{(k)}H_i^{-2}\partial_i+V_k. \tag{4.9}$$

Here $f_i=\partial_i\log(H_1\cdots H_n/H_i^2)$, $\partial_i=\partial_{x^i}$, $Q_i=\partial_{x^i}Q$ and the functions $\rho_i^{(k)}(\mathbf{x})$ satisfy conditions (2.4), (2.5).

At this point it is convenient to perform the similarity transformation

$$\mathscr{A}_k\leftrightarrow\tilde{\mathscr{A}}_k=e^{-R}\mathscr{A}_ke^{R} \tag{4.10}$$

where $-2\partial_iR=f_i+Q_i$. We find

$$\tilde{\mathscr{A}}_k=\sum_i\rho_i^{(k)}H_i^{-2}\partial_{ii}+\tilde{V}_k \tag{4.11}$$

where

$$\tilde{V}_k=V_k+\sum_i\rho_i^{(k)}H_i^{-2}\left(R_{ii}-2R_i^2\right). \tag{4.12}$$

Comparison of the coefficients of ∂_l in $[\tilde{\mathscr{A}}_1,\tilde{\mathscr{A}}_k]=0$ leads to

$$\partial_l\tilde{V}_k=\partial_l\left(\rho_l^{(k)}T\right),\qquad 2\leqq k\leqq n \tag{4.13}$$

where

$$T=V+\sum_iH_i^{-2}\left(R_{ii}-2R_i^2\right). \tag{4.14}$$

Since $\partial_{lj}\tilde{V}_k = \partial_{jl}\tilde{V}_k$ we see from (2.5) and (4.13) that

$$\partial_{jl}T = \partial_j T \partial_l \log H_j^{-2} + \partial_l T \partial_j \log H_l^{-2}, \qquad j \neq l.$$

Thus T is a Stäckel multiplier and (4.1) R-separates in the orthogonal coordinates $\{x^i\}$.

Conversely, if (4.1) R-separates in the orthogonal coordinates $\{x^i\}$ then there exist functions $\psi_l(x^l)$ such that $T = \sum_l \psi_l(x^l) H_l^{-2}$ where T is given by (4.14). It is straightforward to verify that the operators $\mathscr{A}_k = e^R \tilde{\mathscr{A}}_k e^{-R}$ defined by (4.11), (4.12) with

$$\tilde{V}_k = \sum_l \rho_l^{(k)} \psi_l(x^l) H_l^{-2},$$

satisfy conditions 1)–3). Q.E.D.

Shapovalov [15] has stated without proof a theorem which implies Theorem 5.

COROLLARY 3. *Let* $\{\mathscr{A}_k : k = 1, \cdots, n\}$ *satisfy conditions* 1)–3) *of Theorem* 5 *and let* $\{W_k : k = 1, \cdots, n\}$ *be a set of scalar valued functions on* V^n *such that* $W_1 \neq 0$ *and*

$$\{G_k + W_k, G_l + W_l\} = 0, \qquad 1 \leqq k, l \leqq n. \tag{4.15}$$

Then the system $\{\mathscr{A}'_k\}$ *where*

$$\mathscr{A}'_j = \mathscr{A}_j - W_j W_1^{-1} \mathscr{A}_1 + W_1^{-1} \mathscr{A}_1, \qquad j = 1, \cdots, n$$

also satisfies conditions 1)–3) *and corresponds to the orthogonal coordinate system* $\{x^i\}$ *for the Schrödinger operator* $\mathscr{H}' = \mathscr{A}'_1$. *In particular* $\{\mathscr{A}'_k, \mathscr{A}'_l\} = 0$.

This is the operator analogue of Theorem 3 and is proved in a similar manner.

In analogy to (2.12) there is a special case of the Stäckel transform for Schrödinger equations in which the formal eigenfunctions are preserved by the transform. Consider the eigenvalue equations $\mathscr{A}_k \psi = E_k \psi$, $k = 1, \cdots, n$, corresponding to the R-separable equation ($E_1 = E$)

$$\frac{1}{\sqrt{g}} \sum_{i=1}^{n} \partial_i \left(g^{ii} \sqrt{g}\, \partial_i \right) \psi + (V - \lambda W)\psi = E\psi, \tag{4.16}$$

in the orthogonal coordinates $\{x^j\}$. Here λ is a parameter and

$$\mathscr{A}_k = \frac{1}{\sqrt{g}} \sum_{i=1}^{n} \partial_i \left(a_{(k)}^{ii} \sqrt{g}\, \partial_i \right) + V_k - \lambda W_k. \tag{4.17}$$

Suppose the quadratic form $\{a_{(l)}^{ii}\}$ is nonsingular and $W_l \neq 0$. Then W_l is a Stäckel multiplier for this form and the equation

$$\frac{1}{W_k \sqrt{g}} \sum \partial_i \left(a_{(l)}^{ii} \sqrt{g}\, \partial_i \right) \psi + \left(\frac{V_l}{W_l} - \frac{E}{W_l} \right) \psi = \lambda \psi \tag{4.18}$$

admits the same R-separable solutions as does (4.16). Here (4.18) can be cast in the self-adjoint from

$$\frac{1}{\sqrt{a W_l^n}} \sum_{i=1}^{n} \partial_i \left(\frac{a_{(l)}^{ii}}{W_l} \sqrt{a W_l^n}\, \partial_i \right) \Theta + (\tilde{V} - E\tilde{W})\Theta = \lambda \Theta \tag{4.19}$$

where $a^{-1}=\prod_{j=1}^{n} a_{(l)}^{jj}$, $\tilde{W}=W_l^{-1}$,

$$\tilde{V}=\sum_{j=1}^{n}\left(\frac{a_{(l)}^{jj}}{W_l}\left[S_{jj}+S_j^2+\partial_j \ln\left(\sqrt{g}\cdot S_j\right)\right]+\frac{\partial_j a_{(l)}^{jj}}{W_l}S_j\right) \tag{4.20}$$

and

$$\psi=e^S\Theta, \qquad e^S=\left[\frac{W_l^{n-2}a}{g}\right]^{1/4}. \tag{4.21}$$

Thus the Stäckel transform takes R-separable solutions ψ of (4.16) on the manifold V^n to R-separable solutions Θ of (4.19) on a manifold $V^{n'}$.

Note that the natural metric on V^n with respect to which the $\mathscr{A}_k$ are formally self-adjoint is $\sqrt{g}\,d\mathbf{x}$. Similarly the natural metric on $V^{n'}$ is $\sqrt{W_l^n a}\,d\mathbf{x}$. A formal computation yields

$$\int\psi\bar{\psi}\sqrt{g}\,d\mathbf{x}=\int\Theta\bar{\Theta}\frac{\sqrt{W_l^n a}}{W_l}\,d\mathbf{x}$$

or $(W_l\psi,\psi)=\langle\Theta,\Theta\rangle$ where $(\cdot,\cdot)$, and $\langle\cdot,\cdot\rangle$ are the inner products on V^n, $V^{n'}$ respectively. Thus the inner product, hence the spectral resolution for the operators $\mathscr{A}_k$ is in general not preserved by a Stäckel transform. However, in particular cases the spectrum is preserved, e.g., the transform from the Coulomb to the pseudo-Coulomb problem where the Virial Theorem [18] shows that the discrete spectrum is unchanged.

INTEGRABILITY OF KLEIN–GORDON EQUATIONS*

PETER A. CLARKSON†, J. BRYCE McLEOD‡, PETER J. OLVER§ AND ALFRED RAMANI¶

Abstract. Using the Painlevé test, it is shown that the only integrable nonlinear Klein–Gordon equations $u_{xt}=f(u)$ with f a linear combination of exponentials are the Liouville, sine-Gordon (or sinh-Gordon) and Mikhailov equations. In particular, the double sine-Gordon equation is not integrable.

Key words. completely integrable, Painlevé property, Klein–Gordon equation

AMS(MOS) subject classifications. Primary 35Q20, 34A20

In [7], two of the present authors (J. B. M. and P. J. O.) considered the problem of which nonlinear Klein–Gordon equations

$$u_{xt}=f(u) \tag{1}$$

are completely integrable. They referred to the Ablowitz–Ramani–Segur (ARS) conjecture, [2], [3] which states that if a partial differential equation is integrable by the inverse scattering transform (IST) method, then all its reductions to ordinary differential equations have the Painlevé property, i.e., all their moveable singularities are poles. It was shown in [7] that if $f(u)$ is a linear combination of exponentials, the only equations of type (1) whose corresponding ordinary differential equation for travelling wave solutions

$$u(x,t)=w(\xi)=w(x-ct),$$

arising from the invariance of (1) under the group of translations, has the Painlevé property, are those of the form

$$u_{xt}=c_2e^{2\beta u}+c_1e^{\beta u}+c_{-1}e^{-\beta u}+c_{-2}e^{-2\beta u} \tag{2}$$

for constants $c_2,\cdots,c_{-2}$. In fact the singularities of u are not really poles, but rather "pure logarithms" in the sense that u_x, u_t and $\exp(\beta u)$ have only poles. This extension was included in the ARS conjecture as originally stated.

A paradox apparently remained; namely that the form (2), which does include the well-known Liouville equation (only one nonzero c_i), the sine-Gordon equation ($c_2=c_{-2}=0$, $c_1=-c_{-1}$, $\beta=i$) and the Mikhailov equation ($c_1=c_{-2}=0$), [8], [9], [12] all of which are known to be completely integrable, also includes the double sine-Gordon equation ($c_2=-c_{-2}$, $c_1=-c_{-1}$, $\beta=i$), which is *not* integrable. Indeed numerical studies have shown that its travelling wave solutions do not behave like solitons under collisions, [1]. This apparent problem, however, is easily resolved if one considers a second one-parameter group of symmetries of (1),

$$(x,t)\to(\lambda x,\lambda^{-1}t), \qquad \lambda>0,$$

leading to a different form

$$u(x,t)=w(xt)=w(\xi)$$

for the group-invariant solutions. Then w satisfies the ordinary differential equation

$$\xi w''+w'=f(w) \tag{3}$$

where $\xi=xt$.

In order to apply the ARS conjecture, we need to analyze the singularities of solutions of (3) in the case f has the form (2). To eliminate logarithmic singularities, set $v=\exp(\beta w)$, so v satisfies

$$v''=\frac{v'^2}{v}-\frac{v'}{\xi}+\frac{c_2v^3+c_1v^2+c_{-1}+c_{-2}v^{-1}}{\xi}. \tag{4}$$

All second order ordinary differential equations with the Painlevé property have been classified by Painlevé and Gambier and can be reduced, through a change of variables, to one of fifty canonical forms—see [5]. An obvious candidate to reduce (4) to is the equation

$$w''=\frac{w'^2}{w}-\frac{w'}{z}+\frac{\alpha w^2+\beta}{z}+\gamma w^3+\frac{\delta}{w}, \tag{5}$$

which is canonical form number 13 in [5, p. 335]. Thus we need to determine when (4) can be reduced to the canonical form (5). The change of variables

$$\xi=z^p, \qquad v=z^qw \tag{6}$$

reduces (4) to

$$w''=\frac{w'^2}{w}-\frac{w'}{z}+\sum b_nw^{n+1}z^{nq+p-2}, \tag{7}$$

where the sum is on $n=2,1,-1$ and -2 (but not 0!) and the b_n's and c_n's are related by irrelevant powers of p.

In order for (7) to agree with (5), we need to have all of the following four conditions to hold:

a) either $b_2=0$ or $2q+p-2=0$;
b) either $b_1=0$ or $q+p-2=-1$;
c) either $b_{-1}=0$ or $-q+p-2=-1$;
d) either $b_{-2}=0$ or $-2q+p-2=0$.

Clearly this is not possible if all the b_n's are nonzero. If only one b_n is nonzero, there are no difficulties. The original equation was the Liouville equation $u_{xt}=e^{\beta u}$, which is integrable using the Bäcklund transformation

$$w_x=u_x+\exp\frac{\beta}{2}(u+w), \qquad w_t=-u_t-\frac{2}{\beta}\exp\frac{\beta}{2}(u-w)$$

with w satisfying $w_{xt}=0$, [4]. Alternatively, we can set

$$u=\frac{1}{\beta}\log\left[2v_xv_te^v/(e^v-1)^2\beta\right],$$

leading to $v_{xt}=0$. If $b_2=b_{-2}=0$, $b_1b_{-1}\neq 0$ then (4) is already in the canonical form (6) with $\gamma=\delta=0$, $\alpha\beta\neq 0$, so no change of variable is required, i.e., $p=1$, $q=0$. This is the case of the sine (and sinh-) Gordon equations, which are integrable by inverse scattering methods. If $b_1=b_{-1}=0$, $b_2b_{-2}\neq 0$, then we again have the sine-Gordon equation, but we have made a different choice for defining v in terms of u. This should not alter the Painlevé character of the equation, and indeed $p=2$, $q=0$ will satisfy conditions a)–d). Curiously enough this reduces (4) to a canonical form (5) with $\alpha=\beta=0$, $\gamma\delta\neq 0$, which is *not* the same as above. This shows that the same equation can be reduced by different changes of variables to *different* canonical forms.

If $b_1=b_{-2}=0$, $b_2b_{-1}\neq 0$ (or, respectively, $b_{-1}=b_2=0$, $b_1b_{-2}\neq 0$), then we have the Mikhailov equation

$$u_{xt}=be^{2\beta u}+b'e^{-\beta u},$$

which was shown to be integrable by a 3×3 matrix scattering problem, [8], [9], [12]. In this case, conditions a)–d) have the solution $p=\frac{4}{3}$, $q=\frac{1}{3}$ (respectively $p=\frac{4}{3}$, $q=-\frac{1}{3}$), and hence this reduction of Mikhailov's equation does have the Painlevé property.

Finally, if $b_1b_2\neq 0$, even if $b_{-2}=b_{-1}=0$, one would need $p=0$, $q=1$ for a)–d) to be satisfied. But this is not an acceptable change of variables as ξ would not really depend on z. Thus we cannot reduce (4) to the canonical form (5) if $b_1b_2\neq 0$ whatever the values of b_{-1} and b_{-2}. By symmetry, the same holds if $b_{-1}b_{-2}\neq 0$ no matter what values b_1 and b_2 have. Of course, this does not completely prove that (4) in this case does not have the Painlevé property since (6) is not the only possible choice of change of variables and it may be possible to reduce (4) to some other canonical form. Indeed, we have just seen that starting with $b_1=b_{-1}=0$, $b_2b_{-2}\neq 0$, the change of variables (6) with $p=2$, $q=0$ is a rather contrived way to reduce (4) to the canonical form (5) compared with the more obvious choice $v=w^2$. To check that if $b_1b_2\neq 0$, equation (4) does not have the Painlevé property, one could study the behavior of its singularities and show that they are not pure poles, or, alternatively, follow through Painlevé's deviation of the fifty canonical forms, as in [5], and see that it does not fall into one of these categories.

Instead of doing this, however, it is just as easy to check the Painlevé property for the partial differential equation (2) directly, using the method introduced by Weiss et al. [10], [11], and improved by Kruskal [6]. First set $v=\exp(\beta u)$, so (2) becomes

$$vv_{xt}=v_xv_t+c_2v^4+c_1v^3+c_{-1}v+c_{-2}. \tag{8}$$

Suppose $v(x,t)$ is singular along the curve

$$\psi(x,t)=x+\varphi(t)=0$$

with φ arbitrary. Let us expand v near this curve in a Laurent series

$$v=\psi^r\sum_{n=0}^{\infty}\alpha_n(t)\psi^n. \tag{9}$$

Without loss of generality, we can suppose $c_2\neq 0$. (If $c_2=0$, $c_{-2}\neq 0$ change variables by replacing v by $1/v$; if $c_2=c_{-2}=0$, change v to v^2 if $c_1\neq 0$ and v^{-2} if only $c_{-1}\neq 0$.) Balancing the lowest powers of ψ in both sides of (8), we have one possible solution $r=-1$. Equating the coefficients of ψ^{-4}, we get

$$2\alpha_0^2\frac{d\varphi}{dt}=\alpha_0^2\frac{d\varphi}{dt}+c_2\alpha_0^4,$$

so

$$c_2\alpha_0^2=\frac{d\varphi}{dt}. \tag{10}$$

Substituting (9) into (8) and identifying the coefficients of ψ^{n-4} gives an equation for all of the α_n's except α_2 which does not appear when one equates the coefficients of ψ^{-2}. Indeed $n=2$ is the "resonance" in the ARS terminology, [3]. More precisely, the coefficient of ψ^{-3} is

$$2\alpha_0\alpha_1\frac{d\varphi}{dt}-\alpha_0\frac{d\alpha_0}{dt}=-\alpha_0\frac{d\alpha_0}{dt}+4c_2\alpha_0^3\alpha_1+c_1\alpha_0^3,$$

which by (10) gives the expression

$$\alpha_1=-c_1/2c_2 \tag{11}$$

for α_1. At order ψ^{-2}, we find

$$2\alpha_0\alpha_2\frac{d\varphi}{dt}-\alpha_1\frac{d\alpha_0}{dt}=-2\alpha_0\alpha_2\frac{d\varphi}{dt}+6c_2\alpha_0^2\alpha_1^2+4c_2\alpha_0^3\alpha_2+3c_1\alpha_0^2\alpha_1.$$

By (10), (11) all the terms cancel except for $\alpha_1 d\alpha_0/dt$, the value of which is

$$\alpha_1\frac{d\alpha_0}{dt}=-\frac{c_1}{4c_2^{3/2}}\frac{d^2\varphi/dt^2}{\sqrt{d\varphi/dt}}.$$

If this quantity does not vanish, one cannot find an expansion for v in the form (9). Terms of the form

$$\psi(\alpha_2+\tilde{\alpha}_2\log\psi)$$

are needed at that order, and at higher and higher orders in ψ one will need higher and higher powers of logarithms of ψ. Such an expansion is not of Painlevé type.

In [7] the proof of the ARS conjecture was done by first showing that the solution $v(x,t)$ must be meromorphic when both x and t are allowed to assume complex values. This was then specialized to gain the required Painlevé property of group-invariant solutions. It also immediately gives the modification of the ARS conjecture by Weiss et al. [10], [11] which predicts that an equation will not be integrable if some nonpolar singularity exists on a line $\psi(x,t)=x+\varphi(t)=0$ for φ arbitrary. In particular, if $d^2\varphi/dt^2\neq 0$, then c_1 must vanish. This leads to an understanding of the result of [7]. For translation-invariant solutions, we have only straight lines $x=\lambda t+k$, so $d^2\varphi/dt^2=0$ in this case, and a nonvanishing α_1 does not pose any difficulty. Alternatively, the original ARS conjecture for the scale-invariant solutions would also lead to the same conclusion $c_1=0$.

So far we did not find any restrictions on c_{-1} and c_{-2}. However, if c_{-2} does not vanish, a similar argument shows that $c_{-1}=0$, namely we look at solutions with the

$$v=\alpha_0\psi+\alpha_1\psi^2+\cdots,$$

which, because of the coefficient v multiplying the highest derivative v_{xt} in (9) may be singular when $v=0$. Indeed, if $c_{-1}\neq 0$ one finds that it is a singular logarithmic point, with logarithms first entering at order ψ^3.

In conclusion the analysis of the singular behavior of solutions shows that the solutions are meromorphic along arbitrary curves if and only if $b_1b_2=0$ and $b_{-1}b_{-2}=0$. We conclude that the only possible integrable cases are the Liouville, sine-Gordon

(sinh-Gordon) and Mikhailov equations, in perfect agreement with the known integrable character of these equations and the nonintegrable character of the double sine-Gordon equation, as suggested by numerical studies of its solutions.

ON THE INFINITELY MANY SOLUTIONS OF A SEMILINEAR ELLIPTIC EQUATION*

C. JONES† AND T. KÜPPER‡

Abstract. A dynamical systems approach is developed for studying the spherically symmetric solutions of $\Delta u+f(u)=0$, where $f(u)$ grows like $|u|^{\sigma}u$ as $|u|\to\infty$. Various scalings are introduced to elucidate the singular behavior near the center and at infinity. The solutions of interest appear as trajectories in a three-dimensional phase space with a different amount of oscillation around a certain invariant axis. Using this oscillation, solutions with a prescribed number of zeros can be found when $\sigma<4/(n-2)$.

Key words. spherically symmetric solution, oscillation properties, dynamical systems

AMS(MOS) subject classifications. Primary 35P30, 35P05, 34B15, 34F15

1. Introduction. Variational arguments have been very successful in finding solutions of semilinear elliptic equations. Strauss [16] proved, by a nonlinear minimax argument, that a certain class of equations on $\mathbb{R}^n$ have infinitely many solutions. Berestycki and Lions [2] proved the same type of result allowing more general nonlinearities. A canonical example is given by the equation

$$\Delta_x u+|u|^{\sigma}u+\lambda u=0, \tag{1.1}$$

where Δ_x = Laplacian in $x\in R^n (n>1)$, $\lambda<0$, $\sigma>0$ and one is interested in classical L^2 solutions. Any of the above-mentioned results applied to this example guarantees the existence of infinitely many spherically symmetric solutions if $\sigma<4/(n-2)$.

Equation (1.1) is the standing wave equation for many nonlinear evolution equations, for instance the nonlinear Schrödinger, heat and wave equations. In nonlinear optics, this Schrödinger equation arises as a simplification to the Maxwell–Bloch equations. The solutions described in this paper may be relevant to some recent work on the behavior of an optical ring cavity, see McLaughlin, Moloney and Newell [11].

It has long been suspected that these infinitely many solutions are ordered, in some sense, by the number of zeros of the solution in the radial variable. Nehari [13] and Ryder [15] proved results that cover the case $n=3$, but the general case has remained open. The variational proofs mentioned above give only information about the energy values of the solutions and tell us nothing about the shape of their graphs.

In this paper we take a dynamical systems approach so as to realize the number of zeros as a geometrical property in phase space. Using this, we are able to prove for a large class of problems the existence of solutions with a prescribed number of zeros.

Spherically symmetric solutions of the equation

$$\Delta u+f(u)=0 \tag{1.2}$$

satisfy the ordinary differential equation

$$u_{rr}+\frac{n-1}{r}u_r+f(u)=0, \tag{1.3}$$

where r is the radial variable. We shall look for solutions of (1.3) that satisfy the boundary conditions

$$u_r(0)=0, \tag{1.4}$$

$$\lim_{r\to+\infty} u(r)=0. \tag{1.5}$$

Condition (1.4) is necessary to have a regular solution of (1.2), while (1.5) is forced (it turns out) by looking for an L^2 solution.

We make the following assumptions about $f(u)$:

(1) $f:\mathbb{R}\to\mathbb{R}$ is C^1.

(2) $f(u)=k(u)|u|^\sigma u+g(u)$, where

$$k(u)=\begin{cases} k_+ & \text{if } u\geqq 0,\\ k_- & \text{if } u<0,\end{cases} \quad \text{and } k_+>0,\ k_->0,$$

$$g(u)=0\big(|u|^\gamma\big),\quad g'(u)=0\big(|u|^{\gamma-1}\big) \quad \text{as } |u|\to+\infty, \quad \text{for some } \gamma<\sigma+1.$$

(3) $f(0)=0$, $f'(0)<0$ and if u is the smallest positive number for which $\int_0^u f(s)\,ds=0$, then u is not a critical point; similarly for the largest negative number for which

$$\int_0^u f(s)\,ds=0.$$

Remarks. (1) The function $f(u)=|u|^\sigma u+\lambda u$ with $\lambda<0$ and $\sigma>0$ is easily seen to satisfy these hypotheses.

(2) It is convenient to write $f(u)=k_\pm|u|^\sigma u+g(u)$, with the understanding that $k_\pm$ is k_+ if $u\geqq 0$ and k_- if $u<0$.

(3) Condition (3) seems a little strange and it is rather annoying that we need it. It says that in the phase portrait when $n=1$, 0 has two homoclinic orbits, one in the right half plane and the other in the left. This condition can be weakened somewhat as will be remarked in §4.

This paper is devoted to the proof of the following theorem.

THEOREM. *If $n>1$ and $\sigma<4/(n-2)$ then given m there is a solution of* (1.3)–(1.5), *$u(r)$ on $[0,\infty)$ with exactly m zeros in $[0,\infty)$. If $n=2$ these solutions exist for any σ.*

The relationship between σ and the space dimension n is the most subtle aspect of this problem. The Pohozaev [14] identity tells us that we cannot expect solutions to exist if $\sigma>4/(n-2)$. The variational proofs use the condition $\sigma<4/(n-2)$ for the compactness of a certain operator. It is interesting to see how the condition enters in the dynamical systems arguments.

Another drawback of the variational argument is that it needs the nonlinear term to be odd. This is not needed in our proof.

In §2 the basic framework in which we work will be given and explained. The basic idea of how the oscillation (number of zeros) is measured using a winding number in the plane is given in §3. This winding number idea is then used in §4 to obtain curves for the problem near $+\infty$ that have the necessary oscillation. Using some simple estimates, this is sufficient to obtain the solutions in the case $\sigma<2/(n-2)$ or $n=2$. This is done in §5. The full result is proved in §6; it needs another transformation and a much deeper understanding of the behavior near $r=0$.

2. Basic framework. Firstly, convert (1.3) to a system

$$u' = v, \qquad v' = -\frac{n-1}{r}v - f(u), \qquad ' = \frac{d}{dr}. \tag{2.1}$$

As $r \to +\infty$, (2.1) looks like the system when $n = 1$. We need to use this information in a concrete way. To do this, introduce the transformation

$$\rho = \frac{r}{r+1}. \tag{2.2}$$

Equation (2.1) then becomes

$$\begin{aligned} u' &= v, \\ v' &= -\frac{(n-1)(1-\rho)}{\rho}v - f(u), \qquad ' = \frac{d}{dr}. \\ \rho' &= (1-\rho)^2, \end{aligned} \tag{2.3}$$

Notice that the independent variable is still r, but r as a dependent variable has been changed. The plane $\rho = 1$ is now invariant ($\rho' = 0$) and carries the flow of (2.1) with $n = 1$. Equation (2.3) is, however, still singular at $\rho = 0$. This can be corrected by a change of independent variable which has the effect of multiplying the equation by ρ, call the new independent variable t

$$\begin{aligned} u' &= \rho v, \\ v' &= -(n-1)(1-\rho)v - \rho f(u), \qquad ' = \frac{d}{dt}. \\ \rho' &= \rho(1-\rho)^2, \end{aligned} \tag{2.4}$$

The plane $\rho = 1$ is still invariant and carries the flow associated to (2.1) with $n = 1$. The phase portrait for the example of $f(u) = |u|^a u + \lambda u$ is shown in Fig. 1.

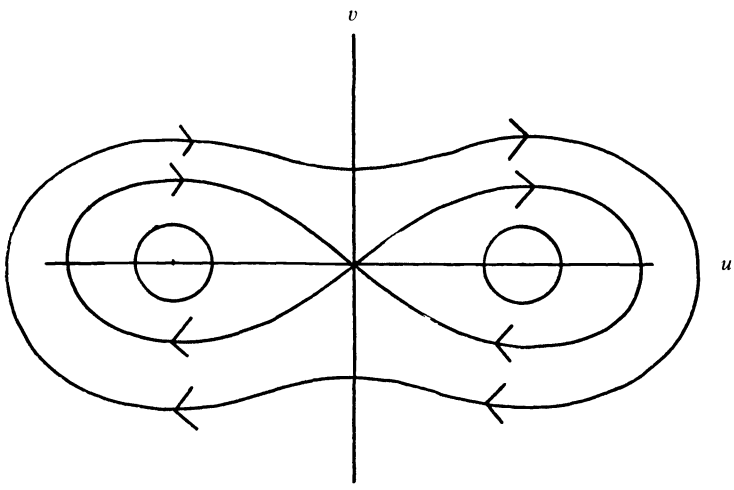

FIG. 1

From the assumption about $f(u)$, 0 must be a saddle and have two homoclinic orbits as shown in Fig. 2. However there may be more than one critical point inside each loop and there may be other critical points outside.

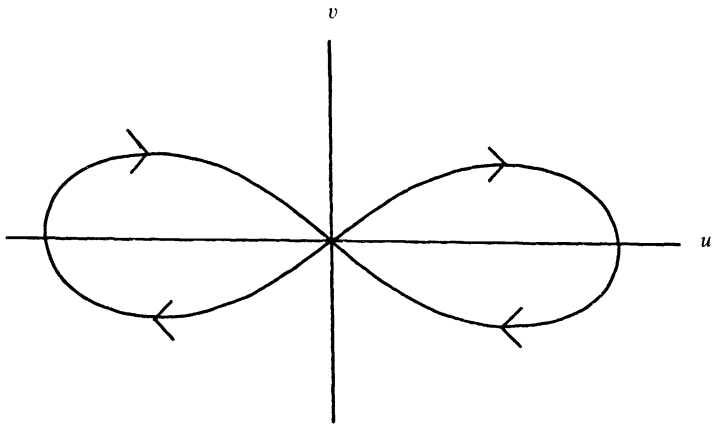

FIG. 2

If $\rho = 0$, the flow is that of the equation

$$u' = 0, \qquad v' = -(n-1)v, \tag{2.5}$$

for which the u-axis is a line of stable critical points. Notice that each vertical line is invariant. The flow is shown in Fig. 3.

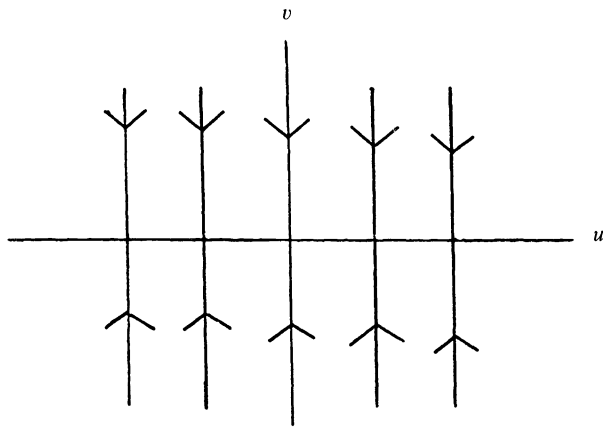

FIG. 3

The natural phase space for the problem (2.4) is $\mathbb{R}^2 \times [0,1]$. The plane $\rho = 0$ corresponds to $r = 0$ and $\rho = 1$ to $r = +\infty$. So the boundary conditions (1.4), (1.5) translate to looking for an orbit $(u(s), v(s), \rho(s))$ that satisfies

$$\lim_{s \to -\infty} (u(s), v(s), \rho(s)) = (a, 0, 0) \tag{2.6}$$

for some $a \neq 0$, and

$$\lim_{s \to +\infty} (u(s), v(s), \rho(s)) = (0,0,1). \tag{2.7}$$

In the full phase space such an orbit connects a critical point on the u-axis in $\rho = 0$ to the point $(0,0)$ in $\rho = 1$. The number of zeros is the number of times that the orbit crosses the plane $u = 0$. From the direction of the vector field on this plane, it can be seen that this corresponds to the number of oscillations around the invariant line $u = v = 0$. Therefore we are looking for solutions of the kind depicted in Fig. 4, where the amount of oscillation is prescribed.

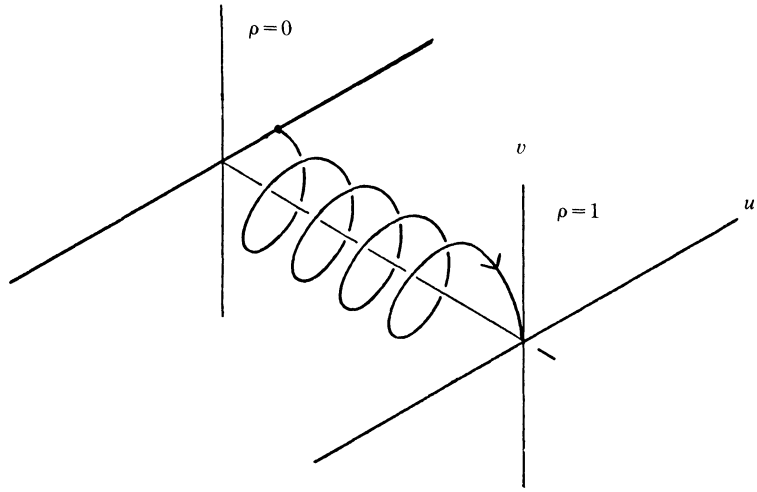

FIG. 4

The first step towards finding an orbit of the kind described above is to analyse the local behavior near the critical points to be connected.

The linearisation of (2.4) at $(0,0,1)$ is

$$\begin{pmatrix} 0 & 1 & 0 \\ -f'(0) & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{2.8}$$

whose eigenvalues are 0, $\pm(-f'(0))^{1/2}$. The associated eigenvectors are $(0,0,1)$, $(1, \pm(-f'(0))^{1/2}, 0)$. These are the eigenvalues and eigenvectors of the one-dimensional system (Fig. 2) and a neutral eigenvalue whose eigenvector points away from the plane $\rho = 1$.

We can construct the center-stable manifold W^{cs}_{loc} at $(0,0,1)$. It is a small two-dimensional surface which contains a piece of the stable manifold of $(0,0)$ in $\rho = 1$, see Fig. 5.

It is easy to check that in a sufficiently small neighborhood of $(0,0,1)$, if $x = (u,v,\rho) \in W^{cs}_{loc}$ then $x \cdot t$ (the solution of (2.4) starting at x) tends to $(0,0,1)$ as $t \to +\infty$.

Therefore W^{cs}_{loc} contains points whose orbits satisfy the correct boundary condition (2.7).

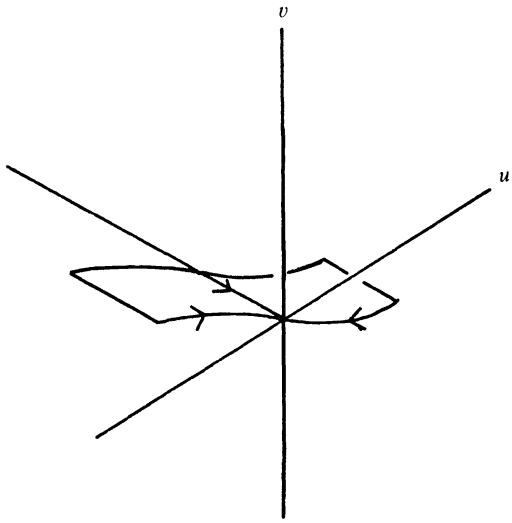

FIG. 5

At a critical point in the $\rho = 0$ plane, the linearisation is

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1-n & f(a) \\ 0 & 0 & 1 \end{pmatrix}. \tag{2.9}$$

The eigenvalues of this matrix are 0, $1-n$, 1. The stable eigenvector is $(0,1,0)$. The eigenvectors associated to 0 and 1 are $(1,0,0)$ and $(0, -f(a)/n, 1)$ respectively. The unstable manifold points into the $\rho > 0$ space. This unstable manifold (call it $W^{u}_{loc}(a)$) corresponds to the unique solution of (1.3) that satisfies $u(0) = a$. This could actually be used as a proof of the uniqueness.

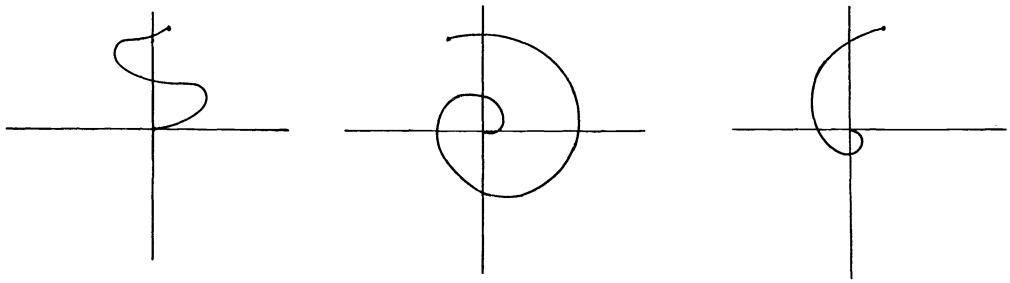

FIG. 6

Near a, these unstable manifolds can be collected together in the center-unstable manifold, W^{cu}_{loc}, see Fig. 6. These manifolds are unique because they are negatively invariant; see Jones [9] for this type of argument. The idea here is that if there were two

surfaces with center-unstable behavior, the complementary stable direction would tear them apart (in backward time).

Now set $W^0=\bigcup_{\alpha\in\mathbb{R}} W^u_{\text{loc}}(a)$. W^0 is then a surface containing the line $\{(u,v,\rho): v=\rho=0\}$. It contains all the solutions to the original problem which are regular at $r=0$.

The argument will proceed by iterating W^{cs}_{loc} of $(0,0,1)$ in backward time and making it intersect W^0. Part of the problem is that we cannot get an estimate on how far W^0 extends in the ρ direction that is uniform in a.

3. Winding number. In this section we define a winding number for a certain type of curve in $\mathbb{R}^2$. It will then be shown how we use this to measure the oscillation of solutions.

Let C be a curve in $\mathbb{R}^2$, that is C is given by a function $\phi:[s_0,s_1]\to\mathbb{R}^2$.

DEFINITION. C is called an admissible curve if the following are satisfied:

(1) ϕ is continuous and $\phi(s)\neq 0$ for all $s\in(s_0,s_1]$.

(2) $\phi(s_0)=0$ and a tangent vector to C exists at s_0.

This last condition says that

$$\lim_{s\to s_0}\frac{\phi(s)}{s-s_0}$$

exists and is nonzero; we shall always denote it ψ_0.

The main point about an admissible curve is that we can assign an angle to each point on it, $\theta(x)$ according to the rules:

(1) $\theta(\phi(s_0))=\arg(\psi_0)$ (argument of ψ_0), where $\arg(\psi_0)\in[0,2\pi)$.

(2) $\theta(\phi(s))$ is continuous in $s\in[s_0,s_1]$.

This is possible from the definition of admissibility. If $\phi(s)$ is written as $r(s)e^{i\theta(s)}$, where a suitable branch for $\theta(s)$ is chosen, then

$$r(s)e^{i\theta(s)}/(s-s_0)\to\psi_0$$

as $s\to s_0$. If $\psi_0=r_0e^{i\theta_0}$, we have $r(s)/(s-s_0)\to r_0$ and $\theta(s)\to\theta_0$.

DEFINITION. The winding number of an admissible curve C is then defined to be

$$I(C)=\left[\frac{1}{2}\left(\frac{2\theta(\phi(s_1))}{\pi}+1\right)\right]-\left[\frac{1}{2}\left(\frac{2\theta(\phi(s_0))}{\pi}+1\right)\right]$$

where $[x]=$ greatest integer less than or equal to x.

This rather strange looking definition becomes less mysterious when it is noticed that the function

$$\frac{1}{2}\left(\frac{2x}{\pi}+1\right)$$

maps the points $-\pi/2$, $\pi/2$, $3\pi/2,\cdots$ into the points $0,1,2,\cdots$, respectively. Thus this winding number counts the net number of crossings of the vertical axis in $\mathbb{R}^2$. For example, the curves in Fig. 6 have winding numbers 0, 3 and -2.

This winding number does not measure the exact number of crossings of the vertical axis by these curves. It seems then that this number could only be used to obtain a lower bound on the number of zeros and not give the exact number. However, it turns out that the winding of the relevant curves gives the exact number of zeros. The

curve used is not the solution but a curve on W^{cs}. It is the power of this method that the topological winding of this curve determines the exact number of zeros of the solution with initial value at the end point of this curve. See Proposition 3.5 below.

It is convenient to give a covering space interpretation to this winding number as then the action of the flow as a homotopy can be viewed easily. The problem of dealing with curves that go to 0 but have well defined tangent vectors there can be dealt with by blowing up the origin and then using the covering space of this space.

Consider polar co-ordinates on $\mathbb{R}^2\setminus\{0\}$. This is a mapping of $\mathbb{R}^2\setminus\{0\}$ to $\mathbb{R}^+\times S^1$, $(s,\theta)\in\mathbb{R}^+\times S^1$ and $\mathbb{R}^+=\{r\in\mathbb{R}: r>0\}$. $\mathbb{R}^+\times S^1$ can be completed to $\mathbb{R}^+\times S^1$ by adding on the set $r=0$. Let $j:\mathbb{R}^2\setminus\{0\}\to\mathbb{R}^+\times S^1$ be the inclusion given by polar co-ordinates. Set $X=\mathbb{R}^+\times S^1$.

Let C be an admissible curve in $\mathbb{R}^2$. We claim that a curve $\hat{C}$ in X can be naturally associated to C as follows. If C is given by $\phi:[s_0,s_1]\to\mathbb{R}^2$, $\hat{C}$ will be given by $\hat{\phi}:[s_0,s_1]\to X$. For $s\in(s_0,s_1]$, define

$$\hat{\phi}(s)=j(\phi(s)).$$

For $s=s_0$, set $\hat{\phi}(s_0)=(0,\arg\psi_0)$, where ψ_0 is the tangent vector to C at s_0. To check this is continuous; for s near s_0, write $\phi(s)=r(s)\exp\{i\theta(s)\}$. Then

$$j(\phi(s))=(r(s),\theta(s))\to\Big(0,\lim_{s\to s_0}\theta(s)\Big).$$

But

$$\lim_{s\to s_0}\phi(s)/(s-s_0)=\psi_0$$

and

$$\phi(s)/(s-s_0)=\{r(s)/(s-s_0)\}\exp\{i\theta(s)\}.$$

This implies that if $\psi_0=\rho\exp\{i\gamma\}$, then

$$\theta(s)\to\gamma \quad \text{as } s\to s_0.$$

The space $X=\mathbb{R}^+\times S^1$ admits $\tilde{X}=\mathbb{R}^+\times\mathbb{R}$ as a covering space. Since we wish to measure crossings of the v-axis, it is convenient to use a covering map that sends vertical lines at integer intervals to the lines $\theta=\pi/2,3\pi/2,\cdots$. If $(r,x)\in\tilde{X}$, such a map is:

$$p(r,x)=\left(r,2\pi\left(\frac{2x-1}{4}-\left[\frac{2x-1}{4}\right]\right)\right). \tag{3.1}$$

The line $x=0$ is sent to $\theta=3\pi/2$ and $x=1$ to $\theta=\pi/2$, etc.

From standard covering space theory, see Munkres [12], the curve $\hat{C}$ can be lifted to a curve $\tilde{C}$ in $\tilde{X}$ and this is unique given the choice of starting point. For each $q\in p^{-1}(\phi(s_0))$, there is a unique curve $\tilde{C}$ so that $p(\tilde{C})=\hat{C}$.

The winding number of C, $I(C)$, is now determined by the number of crossings of lines $x=0,\pm1,\pm2,\cdots$ that $\tilde{C}$ makes. If $\tilde{C}$ is given by $\tilde{\phi}:[s_0,s_1]\to\tilde{X}$ and

$$\tilde{\phi}(s)=(r(s),x(s)),$$

then this is

$$I(C)=[\tilde{x}(s_1)]-[\tilde{x}(s_0)].$$

It is easy to check that this is independent of the choice of $\tilde{\phi}(s_0)$.

Now consider how maps on $\mathbb{R}^2$ lift to this covering space. This will lead to lifting homotopies.

Let $\Phi:\mathbb{R}^2\to\mathbb{R}^2$ be continuous and satisfy:

(1) $\{0\}$ and $\mathbb{R}^2\setminus\{0\}$ are preserved;

(2) Φ is differentiable at $x=0$ and $D\Phi(0)$ is nonsingular.

There is naturally associated to such a Φ a map $\hat{\Phi}:X\to X$ so that

$$\hat{\Phi}(j(x))=j(\Phi(x))$$

for $x\in\mathbb{R}^2\setminus\{0\}$. Recall that $j:\mathbb{R}^2\setminus\{0\}\to\mathbb{R}^+\times S^1=X^0$ is the polar co-ordinates map. It is trivial to define Φ^0 on X^0 to commute with j,

$$\Phi(r,\theta)=(R(r,\theta),\gamma(r,\theta))$$

where

$$\Phi(re^{i\theta})=R(r,\theta)\exp\{i\gamma(r,\theta)\}.$$

Since Φ is differentiable at 0

$$\lim_{r\to 0}\frac{1}{r}\Phi(re^{i\theta})=D\Phi(0)e^{i\theta}.$$

Since $D\Phi(0)$ is nonsingular

$$\lim_{r\to 0}\frac{R(r,\theta)}{r}$$

is nonzero and

$$\lim_{r\to 0}\gamma(r,0)=\arg\{D\Phi(0)e^{i\theta}\}. \tag{3.2}$$

It follows that Φ^0 can be extended to X by setting

$$\Phi(0,\theta)=\arg\{D\Phi(0)e^{i\theta}\}.$$

Φ is thus continuous in r and θ separately. Further $R(r,\theta)\to 0$ uniformly in θ since Φ is continuous at 0 and (3.2) is uniform in θ from the definition of differentiability. It follows that Φ is continuous on X.

Now consider the case of a homotopy $\Phi:\mathbb{R}^2\times[a,b]\to\mathbb{R}^2$ under the following assumptions:

(1) $\{0\}$ and $\mathbb{R}^2\setminus\{0\}$ are preserved by Φ_t for each t. ($\Phi_t(x)=\Phi(x,t)$).

(2) Φ_t is differentiable at $x=0$, for $t\in[a,b]$. $D_x\Phi_t(0)$ is nonsingular and continuous in t.

(3) $|\Phi_t(x+h)-\Phi_t(x)-D_x\Phi_t(0)h|\to 0$ uniformly in $t\in[a,b]$.

DEFINITION. A homotopy $\Phi:\mathbb{R}^2\times[a,b]\to\mathbb{R}^2$ is called admissible if (1)–(3) above are satisfied.

Let $\hat{j}(\mathbb{R}^2\setminus\{0\})\times[0,1]\to X\times[0,1]$ be $j\times id$.

PROPOSITION 3.1. *If Φ is an admissible homotopy, then there exists a homotopy $\hat{\Phi}:X\times[0,1]\to X$ such that*

$$\hat{\Phi}\circ\hat{j}=j\circ\Phi \tag{3.3}$$

on $(\mathbb{R}^2\setminus\{0\})\times[0,1]$.

Proof. The above considerations about a map on $\mathbb{R}^2$ guarantee that Φ_t is defined for each t and (3.3) is satisfied. It remains to show that $\hat{\Phi}$ is continuous. From the above reasoning $\hat{\Phi}_t$ is continuous in (r,θ). Since $D_x\Phi_t(0)$ is continuous in t, $\hat{\Phi}_t$ is continuous in t for fixed (r,θ). Joint continuity then follows from (3).

The space $X=\mathbb{R}^+\times S^1$ is covered by $\tilde{X}=\mathbb{R}^+\times\mathbb{R}$ as mentioned earlier. From standard covering space theory, $\hat{\Phi}$ lifts to a homotopy $\tilde{\Phi}$ on $\tilde{X}$. So

$$\tilde{\Phi}:\tilde{X}\times[0,1]\to\tilde{X}.$$

Let C be an admissible curve and Φ an admissible homotopy. It is obvious that $\Phi_t(C)$ is also an admissible curve, for any $t\in[a,b]$. Since C is not a closed curve, $I(\Phi_t(C))$ can change with t. This is measured in $\tilde{X}$ by $\tilde{\Phi}_t(\tilde{C})$.

Let $A\subset\tilde{X}$ be given by

$$A=\{(r,x):x\in\mathbb{Z}\}.$$

The proof of the following proposition is immediate from the winding number.

PROPOSITION 3.2. *If* $\tilde{\Phi}_t(\tilde{\phi}(s_0))\in A$ *and* $\tilde{\Phi}_t(\tilde{\phi}(s_1))\in A$ *for all* $t\in[a,\tau]$ *then*

$$I(\Phi_t(C))=I(\Phi_0(C)).$$

The next task is to relate this number and homotopy to the flow of (2.4).

Let $w=(u,v,\rho)\in\mathbb{R}^2\times[0,1]$, in the notation of (2.4). Rewrite (2.4) as

$$w'=F(w),\qquad '=\frac{d}{dt}. \tag{3.4}$$

From the assumption that $f(u)$ is C^1, $F(w)$ is easily seen to be C^1 on $\mathbb{R}^2\times(0,1)$. Let $\psi(x,t)$ be the flow operator for (3.4). Now restrict x to lie in the set $\{\rho=\gamma\}\simeq\mathbb{R}^2$ for some $\gamma\in(0,1)$.

We claim that $\psi(x,t)$ is defined for all $t\in\mathbb{R}$. For $t>0$, this follows from the fact that energy is decreasing for (2.1). Set

$$H(u,v)=\frac{v^2}{2}+\int_0^u f(s)\,ds; \tag{3.5}$$

then along orbits of (2.1)

$$\frac{dH}{dr}=-\frac{(n-1)}{r}v^2.$$

Consequently in forward r, the solution to (2.1) with $(u(r_0),v(r_0))=(u_0,v_0)$, is constrained to lie inside $H(u,v)=H(u_0,v_0)$ and so exist for all $r\geqq 0$. This property then transfers easily to (2.3) and (2.4). That solutions to (3.4) exist for $t<0$ follows from Corollary 5.1 to be proved in §5. This gives an a priori estimate to solutions of (2.1) with $r\leqq r_0$.

Consider Ψ as a map on $\{\rho=\gamma\}\times[a,b]$ some $a,b\in\mathbb{R}$. From the above it is defined and continuous with values in $\mathbb{R}^2\times[0,1]$. Let $\pi:\mathbb{R}^2\times[0,1]\to\mathbb{R}^2$ be the natural projection and set $\Phi=\pi\circ\Psi$. Now consider Φ as a homotopy on $\mathbb{R}^2$,

$$\Phi:\mathbb{R}^2\times[0,1]\to\mathbb{R}^2 \tag{3.6}$$

with the understanding that the domain $\mathbb{R}^2$ depends on γ.

We must check that Φ is an admissible homotopy. Condition (1) is satisfied because $u=v=0$ is a solution of the equation. Since Φ is a restriction of the solution operator of (3.4), (2) follows because F is C^1. (3) is the only condition that is not

immediate. But the fact that the difference quotient of the solution operator approaches the derivative uniformly on compact intervals of t is part of the proof that it converges. In particular it follows from the proof of Theorem 3.1 in Hartman [8, p. 98]. (3) would follow easily from assuming that f is C^2 but in our main example

$$f(u)=|u|^{\sigma}u+\lambda u,$$

f may only be C^1 at $u=0$, if $0<\sigma<1$. We have proved the following proposition.

PROPOSITION 3.3. *Φ is an admissible homotopy.*

Recall W^{cs}_{loc} from §2; this is the local center-stable manifold of $(0,0,1)$ for (2.4). It consists of orbits that satisfy the desired boundary condition at $+\infty$. Let

$$W^{cs}=\bigcup_{t\leqq 0} W^{cs}_{loc}\cdot t=\bigcup_{t\leqq 0}\Psi(W^{cs}_{loc},t).$$

W^{cs} is the global center-stable manifold. The main curves whose winding number will be measured are ones that lie in $W^{cs}\cap\{\rho=\gamma\}$.

Let $x\in W^{cs}\cap\{\rho=\gamma\}$ and C_x be a compact curve in $W^{cs}\cap\{\rho=\gamma\}$ joining x to $(0,0)$. In other words, if C_x is given by $\phi:[s_0,s_1]\to\{\rho=\gamma\}$, $\phi(s_0)=0$ and $\phi(s_1)=x$. We claim that such a curve C_x is admissible.

Because the manifold W^{cs}_{loc} for (2.4) is unique, it contains a piece of the curve $u=v=0$ for ρ near 1. This line separates W^{cs}_{loc} into two pieces

$$W^{cs}_{loc}=W^R\cup W^L$$

where $W^R\subset\{u>0\}$ and $W^L\subset\{u<0\}$. The point $x\in W^{cs}_{loc}\cdot t$ some t, and therefore it lies in $W^R\cdot t$ or $W^L\cdot t$. Assume without loss of generality that $x\in W^R\cdot t$ and that $C_x\setminus\{\phi(s_0)\}\subset W^R\cdot t$.

Now ϕ is clearly continuous and $\phi(s)\neq 0$ for $s\neq s_0$. We only have to show that a tangent vector exists at s_0. $C_x\cdot t\subset W^R$ and $\phi(s_0)\cdot t\in\{(0,0)\}\times[0,1]$. Since ρ' is independent of u and v in (2.4) $(C_x\setminus\{\phi(s_0)\})\cdot t\subset W^R\cap\{\rho=\bar\gamma\}$ some $\bar\gamma$. Since W^{cs}_{loc} is smooth and transverse to $\{\rho=\bar\gamma\}$, $W^R\cap\{\rho=\bar\gamma\}$ is a one-dimensional curve in $\{\rho=\bar\gamma\}$ and has a tangent vector at $(0,0)$. It therefore follows that $C_x\cdot t$ does also. It is now easy to see that C_x has a tangent vector at s_0 and we have proved the following proposition.

PROPOSITION 3.4. *If C_x is a continuous, compact curve in $W^{cs}\cap\{\pi=\gamma\}$ given by $\phi:[s_0,s_1]\to\{\rho=\gamma\}$ with $\phi(s_0)=0$ and $\phi(s_1)=x\neq 0$, then C_x is admissible.*

If $x\in W^{cs}$, the solution to (2.4), $x(t)$ with $x(0)=x$ satisfies $x(t)\to(0,0,1)$ as $t\to+\infty$. The reason our approach works is the following proposition.

PROPOSITION 3.5. *If C_x is a curve as described in Proposition* 3.4, *then*

$$I(C_x)=\text{number of zeros of } u(t) \text{ in the solution } x(t),\ t\in[0,\infty).$$

Remark. This proposition is not obvious because C_x is not the solution curve, it is a curve in W^{cs}.

Proof. $C_x\subset W^{cs}\cap\{\rho=\gamma\}$, we can apply the homotopy Φ derived from the flow. If τ is a large positive number, then

$$I(\Phi_\tau(C_x))=0 \tag{3.7}$$

since $\Phi_\tau(C_x)\subset W^R$ (or W^L). From Proposition 3.2 there exists $t\in[0,\tau]$ with $\tilde\Phi_t(\tilde\phi(s_0))$ or $\tilde\Phi_t(\tilde\phi(s_1))$ in the set A.

The tangent vector to $W^R \cap \{\rho = \bar{\gamma}\} \cdot t$, for all $t < 0$, lies in the set $\{u > 0\}$. This can be seen by checking the vector field on $u = 0$ and $H(u,v) = 0$ for (2.3), see Fig. 7. Notice that it points for large $\bar{\gamma}$ and $t = 0$ into the region between the bulb $H(u,v) = 0$ and $\{u = 0,\ v < 0\}$.

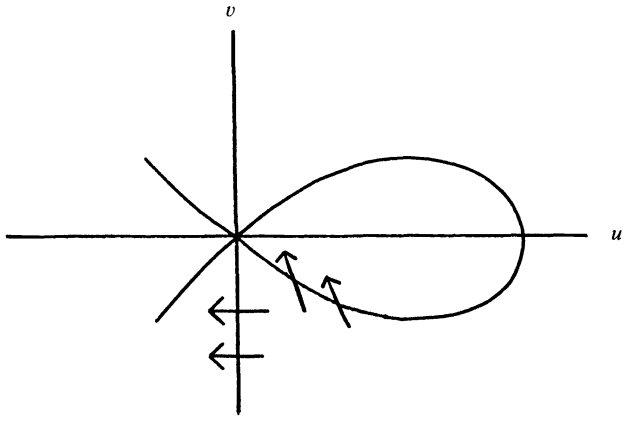

FIG. 7

It follows that $\hat{\Phi}_t(\hat{\phi}(s_0))$ never crosses $\theta = \pi/2$ or $\theta = 3\pi/2$. Consequently $\tilde{\Phi}_t(\tilde{\phi}(s_0)) \in A$ for all $t \in [0,\tau]$.

Therefore $\tilde{\Phi}_t(\tilde{\phi}(s_1)) \in A$ for some $t \in [0,\tau]$. In fact it must cross A at least $I(C_x)$ times for $t \in [0,\tau]$, from (3.7).

Now $\tilde{\Phi}_t(\tilde{\phi}(s_1)) \in \tilde{X} \times [0,1]$ and $p(\tilde{\Phi}_t(\tilde{\phi}(s_1))) = \Phi_t(\phi(s_1)) = \Phi_t(x) = \pi(\psi_t(x))$. But $\psi_t(x) = w(t)$ is the solution of (2.4) satisfying $w(0) = x$. If $\tilde{\Phi}_t(\tilde{\phi}(s_1)) \in A$ then $\Phi_t(x) \in \{u = 0\}$, which means that if $w(t) = (u(t), v(t), \rho(t))$ u has a zero at that value of t. The direction of the vector field of (2.4) on the v-axis is determined by $u' = \rho v$. Since we can assume $\rho > 0$, it is as given in Fig. 8.

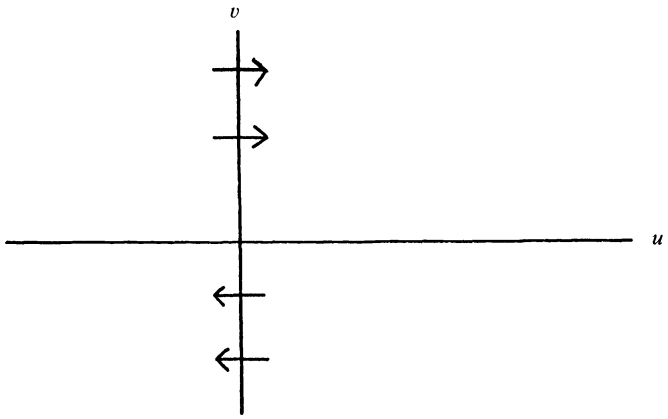

FIG. 8

A solution can only cross $v=0$ with angle decreasing in forward time. In the covering space, $\tilde{\Phi}_t(\tilde{\phi}(s_1))$ can only cross a line A with decreasing horizontal co-ordinate. It then follows that it must cross exactly $I(C_x)$ times. Therefore $u(t)$, $t\in[0,\infty)$, has $I(C_x)$ zeros.

As a consequence of the proof above we can see that $I(\Phi_t(C_x))$ can only increase as t decreases with $t<0$.

PROPOSITION 3.6. *If C_x is a curve as described in Proposition* 3.4, *$I(\Phi_t(C_x))$ is a decreasing function of t, for all $t\in\mathbb{R}$.*

4. Behavior near $+\infty$. The proof of the theorem will proceed by iterating W^{cs}_{loc} of $(0,0,1)$, in backward time and ensuring that it eventually intersects W^0. The zeros of the solution will be obtained by constructing curves in W^{cs} with a certain amount of winding. It was proved in §3 that the winding of such a curve determines exactly the number of zeros of the solution starting at the end point. In this section we shall prove the existence of curves in W^{cs} with arbitrarily large winding number.

Recall the basic equation (2.4):

$$\begin{aligned} u' &= \rho v, \\ v' &= -(n-1)(1-\rho)v - \rho f(u), \\ \rho' &= \rho(1-\rho)^2. \end{aligned}$$

Let $W\subset\mathbb{R}^2\times[0,1]$ be given by

$$W=\{(u,v,\rho): 1-\gamma\leqq\rho\leqq 1\},$$

$\gamma>0$ is fixed.

We claim that W is a Wazewski set in backward time, see Conley [5] for definition. Let

$$\begin{aligned} W^0 &= \{x\in W: x\cdot t\in W \text{ some } t<0\}, \\ W^+ &= \{x\in W: x\cdot(t,0]\notin W \text{ for all } t<0\}. \end{aligned}$$

For W to be a Wazewski set, it suffices that W and W^+ be closed in $\mathbb{R}^2\times[0,1]$. Since $W^+=\{(u,v,\rho):\rho=1-\gamma\}$, this is obvious. The point about a Wazewski set is that one can define a continuous map $R: W^0\to W^+$ as follows. For $x\in W^0$, let

$$\tau(x)=\sup\{t<0: x\cdot t\notin W\},$$

and set $R(x)=x\cdot\tau(x)$. Wazewski's principle says that $R(x)$ is a retract of W^0 to W^+. It maps a point $x\in W^0$ to the place where it first leaves W.

Now choose γ so that $W^{cs}\cap\{\rho=1-\gamma\}$ is nonempty. In fact $W^{cs}\cap\{\rho=1-\gamma\}$ will be a curve containing $(0,0)$. Let Γ be a continuous curve in W^{cs} satisfying the conditions:

(1) $(0,0,1-\gamma)\in\Gamma$.

(2) $\Gamma\setminus\{(0,0,1-\gamma)\}\subset\{u>0\}$.

(3) There exists exactly one point $\bar{y}$ in $\Gamma\cap\{\rho=1\}$, see Fig. 9.

The set $\Gamma^0=\Gamma\setminus\{\bar{y}\}\subset W^0$ and so we can restrict R to Γ^0 as a continuous map; it is then obvious that $R(\Gamma^0)\subset W^{cs}$. The following lemma is what we need about the behavior near $\rho=1$ ($r=+\infty$) for the existence theorem.

LEMMA 4.1. *There exists $x\in R(\Gamma^0)\subset W^{cs}$ such that $C_x\subset R(\Gamma^0)$ and $I(C_x)$ is arbitrarily large.*

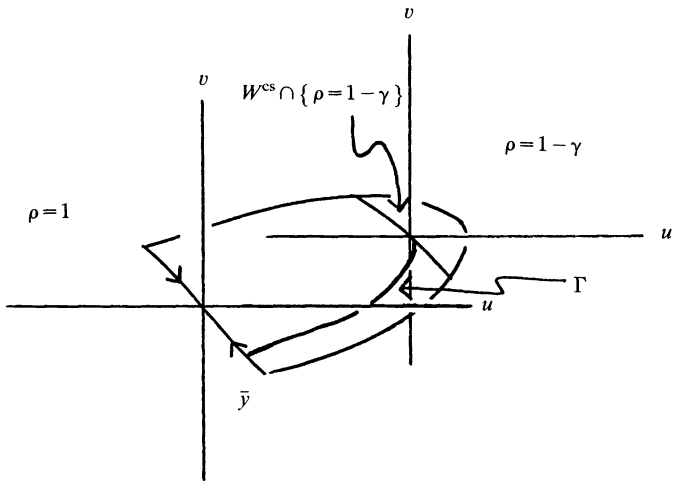

FIG. 9

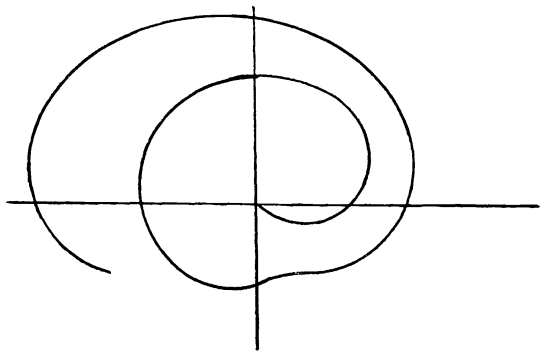

FIG. 10

The lemma says that $R(\Gamma^0)$ contains curves as shown in Fig. 10.

The idea is that because of energy dissipation, the solutions will move outside the "bow-tie" of $\{\rho = 1\}$ but the oscillation in $\{\rho = 1\}$ will cause them to rotate around $(0,0)$. There is, however, a nontrivial estimate to be made. Since the solutions are moving away from $\{\rho = 1\}$, it is a little delicate to check that the oscillation can still be forced on them.

Recall from §2 that $(0,0,1)$ has one negative, one positive and one zero eigenvalue. Let E^s, E^u and E^c be the associated eigenspaces, with (y,z,τ) as the co-ordinates given by the decomposition $E^s \oplus E^u \oplus E^c$. We can assume that $\tau = 1-\rho$. There is a local center-unstable manifold W^{cu}_{loc} given by

$$y = g_1(z,\tau)$$

in a neighborhood of $(0,0,0)$. W^{cs}_{loc} is given by $z = g_2(y,\tau)$. Now change co-ordinates on $\mathbb{R}^2 \times [0,1]$ so that near $(0,0,1)$, W^{cu}_{loc} and W^{cs}_{loc} become orthogonal planes. Near $(0,0,1)$

these could be:

$$\zeta = y - g_1(z, 1-\rho),$$
$$\eta = z - g_2(y, 1-\rho),$$
$$\tau = 1-\rho.$$

Near the origin the equations now take the form

$$\begin{aligned} \zeta' &= \alpha\zeta + f_1(\zeta,\eta,\tau), \\ \eta' &= \beta\eta + f_2(\zeta,\eta,\tau), \\ \tau' &= -(1-\tau)\tau^2 \end{aligned} \tag{4.1}$$

where $\alpha < 0$, $\beta > 0$ and $f_i(\zeta,\eta,\tau) = O(|\zeta|+|\eta|+|\tau|)$, $i = 1$ or 2. The relevant parts of the new phase portrait are depicted in Fig. 11.

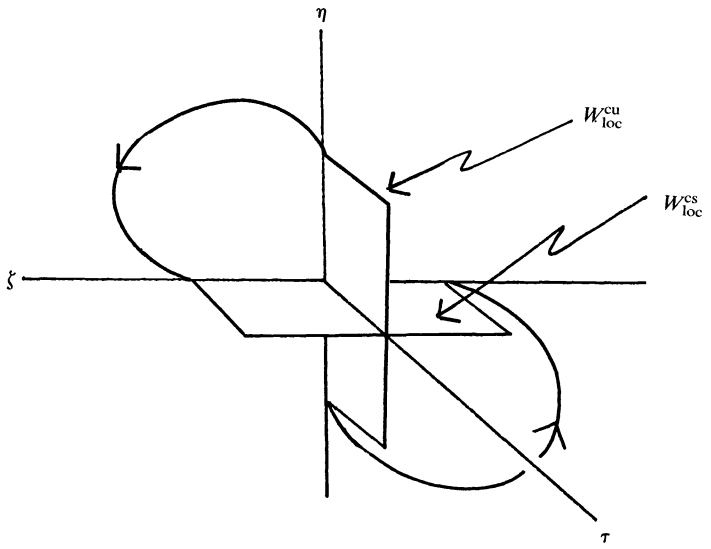

FIG. 11

Set $V = V(\varepsilon,\delta) = [-\varepsilon,\varepsilon]\times[-\varepsilon,\varepsilon]\times[0,\delta]$ in (ζ,η,τ) space. If ε is small enough, V is a backwards Wazewski set. We shall need some notation

$$z_1^+ = W^u_{loc} \cap \{\eta = \varepsilon\}, \qquad z_2^+ = W^u_{loc} \cap \{\eta = -\varepsilon\},$$
$$z_1^- = W^s_{loc} \cap \{\zeta = \varepsilon\}, \qquad z_2^- = W^s_{loc} \cap \{\zeta = -\varepsilon\}.$$

It is clear that these sets are just single points. Recall that $W^s_{loc} = W^{cs}_{loc} \cap \{\tau = 0\}$. Let D_1^+ be a neighborhood of z_1^+ in $\{\eta = \varepsilon\}$ and D_1^- a neighborhood of z_1^- in $\{\zeta = \varepsilon\}$. Define D_2^+ and D_2^- similarly, see Fig. 12.

Let $P: V^0 \to V^+$ be the Wazewski map for V, where V^0 and V^+ have the analogous meaning to W^0 and W^+. P is defined on $D_1^+ \setminus \{z_1^+\}$ and $D_2^+ \setminus \{z_2^+\}$. We can also define a map $Q: D_1^- \to \{\eta = \varepsilon\}$ as follows. Let $T(z_1^-)$ be determined by $z_1^- \cdot T(z_1^-) = z_1^+$. If $\pi(\zeta,\eta,\tau) = \eta$ and Φ is still the flow,

$$\pi(\Phi(z,t)) = \varepsilon$$

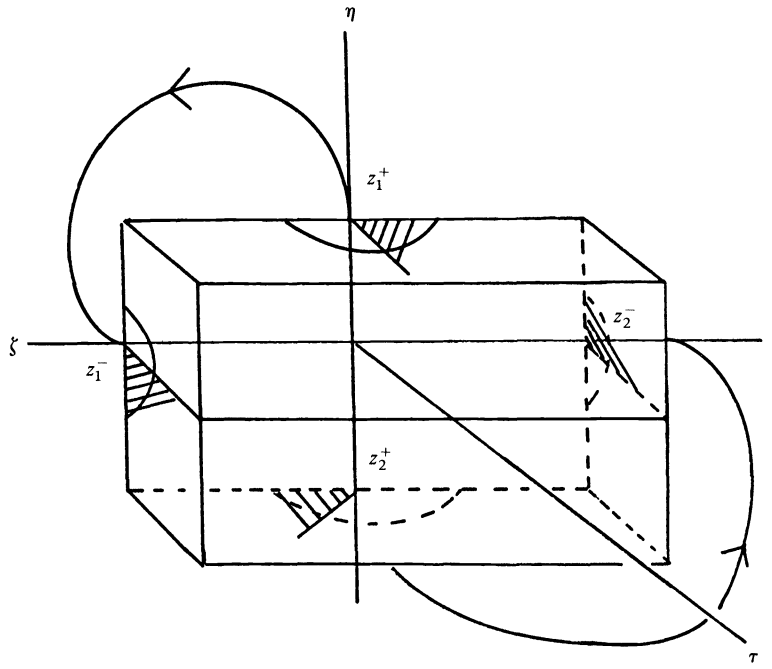

FIG. 12

can be solved, t as a function of z, near $(z_1^-, T(z_1^-))$. This follows from the implicit function theorem, knowing that the vector field is transverse to $\eta = \varepsilon$. Let the solution be denoted $T = T(z)$. Now restrict D_1 to lie inside the domain of $T(z)$ and set

$$Q_1(z) = z \cdot T(z).$$

Similarly define Q_2 on D_2^-.

We shall need an estimate on what Q_1, Q_2 do outside the box and one on what P does inside. Let $K_a^1 = \{(\zeta, \eta, \tau)\colon \eta = \varepsilon \text{ and } \zeta \leqq -a\tau\}$, $K_a^2 = \{(\zeta, \eta, \tau)\colon \eta = \varepsilon \text{ and } \zeta \geqq a\tau\}$, see Fig. 12.

LEMMA 4.2. *If D_1^- is small enough,*

$$Q_1(D_1^- \cap \{\eta \leqq 0\}) \subset K_a^1.$$

LEMMA 4.3. *If D_2^- is small enough,*

$$Q_2(D_2^- \cap \{\eta \geqq 0\}) \subset K_a^2.$$

LEMMA 4.4. *If D_1^+ is small enough, then any set $A \subset K_a^1 \cap D_1^+$ with $z_1^+ \notin A$ satisfies*

$$P(A) \subset \{\zeta = -\varepsilon\} \cap \{\eta \geqq 0\} \cap D_2^-$$

where D_2^- is some prescribed neighborhood of z_2^-.

LEMMA 4.5. *If D_2^+ is small enough, then any set $A \subset K_a^2 \cap D_2^+$ with $z_2^+ \notin A$ satisfies*

$$P(A) \subset \{\zeta = \varepsilon\} \cap \{\eta \leqq 0\} \cap D_1^-$$

where D_1^- is a prescribed neighborhood of z_1^-.

We shall only prove Lemmas 4.2 and 4.4; 4.3 and 4.5 only involve changing notation. We shall do 4.4 first.

Proof of Lemma 4.4. The set $\{\eta=\varepsilon\}\setminus\{z_1^+\}\subset V^0$, therefore P is defined on A. Since $\eta=0$ and $\zeta=0$ are invariant relative to V, it is clear that $P(A)\subset\{\eta\geqq 0\}\cap\{\zeta\leqq 0\}$. The lemma will follow from proving the following two facts; a is fixed and positive:

(1) If D_1^+ is small enough, $P(K_a^1\cap D_1^+)$ lies in a prescribed neighborhood of $\{\tau=0\}$.

(2) If $z_k\to z_1^+$ and $\{z_k\}\subset K_a^1$ then $P(z_k)\to z_1^+$.

Note that (2) does not trivially follow from the continuity of P because P is not defined at z_1^+. We firstly prove (1). This is the key estimate, for it says that the influence of the flow in $\{\tau=0\}$ is stronger than that of τ'.

Let $z=(\zeta_0,\eta_0,\tau_0)\in K_a$, some $a>0$. Define

$$T_\tau(z)=\inf\{|t|: t<0 \text{ and } z\cdot t\in\{\tau=\delta\}\},$$
$$T_\zeta(z)=\inf\{|t|: t<0 \text{ and } z\cdot t\in\{\zeta=-\varepsilon\}\}.$$

(1) follows from showing that

$$T_\zeta(z)/T_\tau(z)\to 0 \quad \text{as } z\to z_1^+, \tag{4.2}$$

for then the orbit $z\cdot t$ will reach $\zeta=-\varepsilon$ before it reaches $\tau=\delta$, and this will be true for any δ, making $|z-z_1^+|$ small enough.

From (4.1)

$$\zeta'=\alpha\zeta+f_1(\zeta,\eta,\tau), \tag{4.3}$$

with $\alpha<0$. On any orbit of interest $\zeta\leqq 0$. Since $\zeta=0$ is invariant,

$$f_1(\zeta,\eta,\tau)=\zeta g(\zeta,\eta,\tau)$$

where $g(\zeta,\eta,\tau)$ can be made as small as desired by making V small. Therefore

$$\frac{d\zeta}{dt}\geqq\frac{\alpha}{2}\zeta.$$

Integrating, we have

$$\int_{-\varepsilon}^{\zeta_0}\frac{d\zeta}{\alpha\zeta}\geqq\int_{-T_\zeta}^{0}\frac{1}{2}dt$$

so,

$$\frac{2}{\alpha}\ln\frac{\zeta_0}{-\varepsilon}\geqq T_\zeta.$$

This is the estimate on T_ζ. For τ we have from (4.1) in V, $\tau'\geqq-\tau^2$ and so

$$\int_\delta^{\tau_0}\frac{d\tau}{\tau^2}\geqq-\int_{T_\tau}^{0}dt$$

which gives

$$-\frac{1}{\tau_0}+\frac{1}{\delta}\geqq -T_\tau$$

or,

$$T_\tau\geqq\frac{1}{\tau_0}-\frac{1}{\delta}\geqq\frac{1}{2\tau_0},$$

if τ_0 is chosen so that $\delta > 2\tau_0$, for instance. But then

$$T_\zeta / T_\tau \leqq \frac{4\tau_0}{\alpha} \ln \left| \frac{\zeta_0}{\varepsilon} \right|.$$

Since $z \in K_a$, $|\zeta_0| \geqq a\tau_0$, and so

$$T_\zeta / T_\tau \leqq \frac{4a\zeta_0}{\alpha} \ln \left| \frac{\zeta_0}{\varepsilon} \right|$$

as $z \to z_1^+$, $\zeta_0 \to 0$ and the right-hand side (which is positive) tends to 0. This proves (1).

It then follows that $P(z_k) \to \{\tau = 0\}$ in the sense that all limit points lie in $\{\tau = 0\}$. For (2) it suffices to show that any such limit point is z_1^+. Suppose $P(z_k) \to \tilde{z}$ where $\tilde{z} \neq z_2^-$; then $\tilde{z}$ has coordinates $(-\varepsilon, \tilde{\eta}, 0)$ for some $\tilde{\eta} \neq 0$. But such a point lies in the range of P, so $P(\hat{z}) = \tilde{z}$, for some $\hat{z} \in \{\eta = \varepsilon\} \cap \{\tau = 0\} \cap \{-\varepsilon \leqq \zeta < 0\}$. By continuity of the flow we would then have $z_k \to \hat{z}$, but $\hat{z} \neq z_1^+$ which is a contradiction.

Proof of Lemma 4.2. Recall that $Q_1 : D_1^- \to \{\eta = \varepsilon\}$ and $Q_1(z_1^-) = z_1^+$. We shall compute $\partial Q_1 / \partial w$ in two different directions w. Let $g(z)$ be the vector field of (4.1) at $z = (\zeta, \eta, \rho)$. We claim the lemma follows from proving the following:

(1) $\partial Q_1 / \partial w \times g(z_1^+) = (a_1, a_2, a_3)$ has $a_1 > 0$ and $a_3 > 0$ if $w = (0, 0, 1)$.

(2) $\partial Q_1 / \partial w \times g(z_1^+) = (b_1, b_2, b_3)$ has $b_3 > 0$ if $w = (0, -1, 0)$.

To see that these prove the lemma, consider the images of the curves $\eta = 0$, $\zeta = -\varepsilon$ and $\tau = 0$, $\zeta = -\varepsilon$ inside the neighborhood D_1^-. Q_1 maps these to curves in $\{\eta = \varepsilon\}$ emanating from z_1^+. Further the region $\{\eta \leqq 0\} \cap D_1^-$ is mapped under Q_1 to a region bounded by these two curves, since Q is one-to-one. If D_1^- is small enough, it easily follows from the information about the tangent vectors in (1) and (2) that this region lies in K_a^1 some $a > 0$, see Fig. 13 of $\eta = \varepsilon$. The shaded area is $Q_1(\{\eta \leqq 0\} \cap D_1^-)$. To see this, one has to calculate the cross product with the vector field at this point, but notice the vector field is only nonzero in the second component at z_1^+.

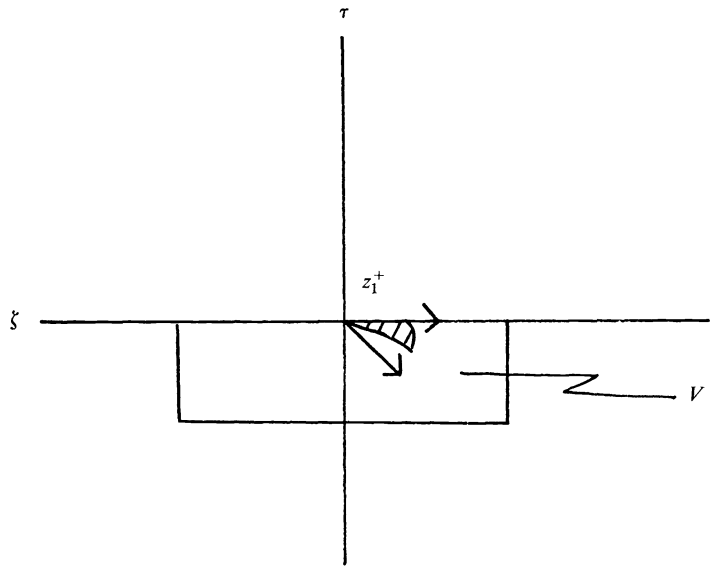

FIG. 13

To prove (1) and (2), calculate:

$$\frac{\partial Q_1}{\partial w} = D_z\Phi(z,\tau(z))w + \frac{\partial \Phi}{\partial t}(z,\tau(z))(\nabla\tau(z)\cdot w);$$

recall that Φ is the flow. Now

$$\frac{\partial Q_1}{\partial t} \times g(z_1^+) = D_z\Phi(z,\tau(z))w \times g(z_1^+) \tag{4.4}$$

since $(\partial\Phi/\partial t)(z_1^-,\tau(z_1^-)) = g(z_1^+)$. So it suffices to compute the right-hand side of (4.4) which is the same as

$$D_z\Phi(z,t)w \times \frac{\partial \Phi}{\partial t}(z,t)\Big|_{(z_1^-,\tau(z_1^-))}. \tag{4.5}$$

We can now see why information about the tangent vectors is obtained through the cross product with $g(z_1^+)$ as in (1) and (2). The problem is that Q_1 is not exactly the flow, but it differs from the flow by something in the direction of the flow and this drops out when crossed with the vector field. (4.5) can be computed using the equation of variations.

Both $D_z\Phi(z,t)w$ and $(\partial\Phi/\partial t)(z,t)$ satisfy the equation of variation of (4.1). It is most convenient to work with this back in (u,v,ρ) variables. It is:

$$\begin{pmatrix} \delta u \\ \delta v \\ \delta\rho \end{pmatrix}' = \begin{pmatrix} 0 & \rho & v \\ -\rho f'(u) & -(n-1)(1-\rho) & (n-1)v - f(u) \\ 0 & 0 & (1-\rho)^2 - 2\rho(1-\rho) \end{pmatrix} \begin{pmatrix} \delta u \\ \delta v \\ \delta\rho \end{pmatrix}. \tag{4.6}$$

Since the orbit through z_1^+ has $\rho = 1$, we can simplify (4.6) to:

$$\begin{aligned} \delta u' &= \delta v + v\delta\rho, \\ \delta v' &= -f'(u)\delta u + \{(n-1)v - f(u)\}\delta\rho, \\ \delta\rho' &= 0. \end{aligned} \tag{4.7}$$

In these co-ordinates, we can write

$$\begin{aligned} D_z\Phi(z,t) &= (\delta u_2(t), \delta v_2(t), c), \\ \frac{\partial \Phi}{\partial t}(z,t) &= (\delta u_1(t), \delta v_1(t), 0) \end{aligned}$$

where $c = -1$ for (1) and $c = 0$ for (2). Note that c is independent of t because of $\delta\rho' = 0$ in (4.7). Now compute

$$D_z\Phi(z,t) \times \frac{\partial \Phi}{\partial t}(z,t) = (-(c\delta v_1), (c\delta u_1), (\delta u_2\delta v_1 - \delta v_2\delta u_1)). \tag{4.8}$$

With $c = -1$, projecting into $\{\tau = 0\}$, (4.8) has co-ordinates $(\delta v_1, -\delta u_1)$. In the $\tau = 0$ plane this is orthogonal to the vector field at z_1^+, in a counterclockwise direction. Since the transformation to (ζ,η) co-ordinates is orientation preserving, (a_1,a_2) lies in a counterclockwise direction from $g(z_1^+)$ and so $a_1 > 0$.

We need to show that for each of the values of w: $(0,0,1)$ and $(0,-1,0)$, the third component is negative, since τ reverses the orientation of ρ. Let $\omega = \delta u_2\delta v_1 - \delta v_2\delta u_1$ and compute, using (4.7),

$$\omega' = -cv^2(n-1).$$

In case (1), $c=-1$ and $\omega'>0$. For (2) $\omega'=0$. It remains to compute the values at $t=0$. This can be done back in (ζ,η,τ) co-ordinates. Since the change of co-ordinates preserves orientation in $\tau=0$, the sign of ω is the same in each co-ordinate system.

For (1), ω is the third component of $(0,0,1)\times g(z_1^-)$, which is zero. For (2), we have $(0,-1,0)\times g(z_1^-)$ and $g(z_1^-)$ has zero second and third components. Moreover its first component is positive. It follows that $\omega<0$ at $t=0$.

In both cases at $t=\tau(z_1^-)$, $\omega<0$ as desired.

Proof of Lemma. 4.1. Using these results, we can prove Lemma 4.1. It suffices to find for given N, $\tilde{x}\in\Gamma^0$ so that $\tilde{x}\cdot[-T,0]\subset W$ and if $\tilde{x}\cdot t=(u(t), v(t), \rho(t))$ then $u(t)$ has at least N zeros in $[-T,0]$. Clearly there exists a smallest $\tilde{T}>T$ so that $\tilde{x}\cdot\tilde{T}\in\{\rho=1-\gamma\}$, set $\tilde{x}\cdot(-\tilde{T})=x$. From Proposition 3.5, $I(C_x)=$number of zeros of $u(t)$, $t\in[-\tilde{T},0]$, which is bigger than N.

To find such an $\tilde{x}$, work in (δ,η,τ) variables. Recall Γ is a curve in W^{cs}_{loc} joining W^{s}_{loc} and some point on the ρ-axis, not $(0,0,1)$. In (δ,η,τ) variables we can assume this includes a piece of $\{\eta=0\}\cap V$ and this piece is a curve converging to the ζ-axis. It follows that we can pick $z\in\Gamma^0$ so that, for some $t_0<0$, $z\cdot t_0\in D_1^-\cap\{\eta\leqq 0\}$; for any neighborhood D_1^- of z_1^-, obviously z depends on D_1^-. Now apply Q_1, by Lemma 4.2 $Q_1(z\cdot t_0)\in K_a^1$ for some $z>0$, and by continuity it lies in a prescribed D_1^+, neighborhood of z_1^+. Therefore there exists t_1, so that $z\cdot t_1\in K_a^1\cap D_1^+$. Now apply P, through Lemma 4.2, $P(z\cdot t_1)\in\{\delta=-\varepsilon\}\cap\{\eta\geqq 0\}\cap D_2^-$. So there exists t_2 such that $z\cdot t_2\in\{\delta=-\varepsilon\}\cap\{\eta\leqq 0\}\cap D_2^-$.

We now have a z so that the orbit $z\cdot[t_2,0]$ rotates around one half-time, through a neighborhood of z_1^- to a neighborhood of z_2^-. It is also clear that $\tau<0$ on this orbit. Notice the important fact that back in (u,v,ρ) co-ordinates $u(t)$ must have a zero between the neighborhood of z_1^+ and that of z_2^-.

Lemma 4.3 can now be applied to $z\cdot t_2$, to obtain t_3 so that $z\cdot t_3\in K_a^2\cap D_2^+$, obviously making D_1^- smaller again if necessary. Then apply Lemma 4.5 to obtain t_4 so that $z\cdot t_4\in\{\delta=\varepsilon\}\cap\{\eta\leqq 0\}\cap D_1^-$, with a possibly different D_1^-. Now a full circuit has been made and $u(t)$ has two zeros. This argument can now be repeated to obtain an arbitrarily large number of zeros.

5. Completion of proof when $\sigma<2/(n-2)$. Recall that we are working with the equation (2.4) in the phase space $\mathbb{R}^2\times[0,1]$. So long as $n>1$, Lemma 4.1 guarantees the existence of a curve $C_x\subset R(\Gamma^0)\subset W^{cs}$ with $I(C_x)$ arbitrarily large. This lies in the set $\{\rho=1-\gamma\}$. The flow operator (3.5) can then be applied to this set. We shall apply it with large negative t so as to pull W^{cs} back to $\rho=0$. We need an estimate to guarantee that Φ is defined and to see how $\Phi_t(C_x)$ can grow in $\mathbb{R}^2$.

It suffices to prove the estimate for the original equation.

LEMMA 5.1. *If $u(r)$ is a solution (with $n>2$) of*

$$u''+\frac{n-1}{r}u'+f(u)=0,\qquad u(r_0)=u_0,\quad u'(r_0)=v_0 \tag{5.1}$$

where $f(u)$ is C^1 and $F(u)=\int_0^u f(s)\,ds$ is bounded below, then there exist C_1, C_2 so that, if $r<r_0$

$$|u(r)|\leqq C_1 r^{2-n} \tag{5.2}$$

and

$$|u'(r)|\leqq C_2 r^{1-n} \tag{5.3}$$

where C_1, C_2 are constants depending on (u_0, v_0), uniformly on compact sets of (u_0, v_0) values for fixed $r_0 \in (0, \infty)$.

Proof. Rewrite (5.1) as

$$(r^{n-1}u')' + r^{n-1}f(u) = 0;$$

multiply by $r^{n-1}u'$,

$$\left\{\frac{1}{2}(r^{n-1}u')^2\right\}' + r^{2n-2}f(u)u' = 0.$$

Now integrate from r_0 to r,

$$\frac{1}{2}(r^{n-1}u')^2 - \frac{1}{2}(r_0^{n-1}v_0)^2 + \int_{r_0}^{r} r^{2n-2}f(u)u' = 0.$$

Integrating by parts, with $F(u) = \int_0^u f(s)\,ds$, gives

$$\frac{1}{2}(r^{n-1}u')^2 = \frac{1}{2}(r_0^{n-1}v_0)^2 - r^{2n-2}F(u)\Big|_{r_0}^{r} + (2n-2)\int_{r_0}^{r} F(u(s))s^{2n-3}\,ds.$$

Since $F(u)$ is bounded below, we can find $k > 0$ so that $F(u) \geqq -k$; then if $r \leqq r_0$

$$\frac{1}{2}(r^{n-1}u')^2 \leqq k_1 + kr^{2n-2} + k(2n-2)\int_r^{r_0} s^{2n-3}\,ds \leqq k_2 \tag{5.4}$$

where k_1, k_2 depend on u_0, v_0 and r_0. From this, (5.3) easily follows and an integration from r to r_0 gives (5.2).

COROLLARY 5.1. *Under the same assumptions as in Lemma* 5.1, *if* $(u(t), v(t), \rho(t))$ *satisfy* (2.4) *with* $(u(0), v(0), \rho(0)) = (u_0, v_0, \rho_0)$, $0 < \rho_0 < 1$ *then there exist constants* C_1, C_2 *such that*

$$|u(t)| \leqq C_1[\rho(t)]^{2-n}, \tag{5.5}$$

$$|v(t)| \leqq C_2[\rho(t)]^{1-n} \tag{5.6}$$

for all $t \in (-\infty, 0]$, *where* C_1 *and* C_2 *depend uniformly on compact sets of* (u_0, v_0) *values with fixed* ρ_0.

Proof. Lemma 5.1 gives the estimate on solutions of (2.1) and therefore on solutions of (2.3) with $\rho = r/(r+1)$. Now reset the parametrisation to get the appropriate estimate on solutions of (2.4).

If $n = 2$, the above still holds but now with $|\ln r|$ replacing r^{2-n}.

LEMMA 5.2. *If* $u(r)$ *is a solution of*

$$u'' + \frac{1}{r}u' + f(u) = 0, \qquad u(r_0) = u_0, \quad u'(r_0) = v_0 \tag{5.7}$$

where $f(u)$ *is* C^1 *and* $F(u) = \int_0^u f(s)\,ds$ *is bounded below, then there exists* C_1, C_2 *so that if* $r \leqq r_0$

$$|u(r)| \leqq C_1|\ln r| \tag{5.8}$$

and

$$|u'(r)| \leqq C_2(1/r) \tag{5.9}$$

where C_1 *and* C_2 *depend uniformly on* (u_0, v_0) *over a compact set if* $r_0 \in (0, \infty)$ *is fixed.*

Proof. All the reasoning in the proof of Lemma 5.1 holds up to (5.4). This immediately gives (5.9) and an integration gives (5.8).

COROLLARY 5.2. *With the assumptions of Lemma* 5.2 *and the set-up of Corollary* 5.1, *the estimates*

$$|u(t)| \leqq C_1 |\ln \rho(t)|, \tag{5.10}$$

$$|v(t)| \leqq C_2 (1/\rho(t)) \tag{5.11}$$

hold under the same conditions as in Corollary 5.1.

It now follows from Corollaries 5.1 and 5.2 and the equation $\rho' = \rho(1-\rho)^2$ that, so long as $n > 1$, the flow operator (3.5) of (2.4) can be applied to the $\{\rho = 1-\gamma\}$ slice for $t \in [T, 0]$, and $T < 0$. Moreover

$$I(\Phi_t(C_x)) \geqq I(C_x) \tag{5.12}$$

from Proposition 3.6.

Because of the growth condition (2) on $f(u)$, $F(u)$ is bounded below and the above corollaries can be applied. If $n > 2$, it follows that $\Phi_t(C_x)$ lies in a set in $\mathbb{R}^2$ of the form

$$\left[-C_1\rho^{2-n}, C_1\rho^{2-n}\right] \times \left[-C_2\rho^{1-n}, C_2\rho^{1-n}\right],$$

and if $n = 2$ in a set of the form

$$\left[-C_1|\ln\rho|, C_1|\ln\rho|\right] \times \left[-C_2(1/\rho), C_2(1/\rho)\right].$$

We must now analyse the manifold at the other end. Pick $u_0 > 0$ so that if $u \geqq u_0$

$$k_1 u^{\sigma+1} \leqq f(u) \leqq k_2 u^{\sigma+1}; \tag{5.13}$$

this can clearly be done from the conditions on $f(u)$. Now choose ρ_0 so that $W_0^{cu} \cap \{\rho = \rho_0\}$ contains a curve L_0 with $(0,0) \in L_0$, $L_0 \subset \{y \geqq 0\}$ and if $(u(t), v(t), \rho(t))$ is the nontrivial solution of (2.4) with $u(t) \to u_0$ as $t \to -\infty$, $\rho(T_0) = \rho_0$ then $u(T_0) \in L_0$. This can be done as W_0^{cu} can be constructed by a finite number of local center-unstable manifolds out to u_0. We can now state the lemma we need to prove.

LEMMA 5.3. *For each* $\rho \in [0, \rho_0]$, *there is a connected curve* $K_\rho \subset W_0^{cu}$ *with* ρ *fixed on it such that*

(1) $K_\rho \subset \{u \geqq 0\}$,

(2) $(0,0) \in K_\rho$,

(3) $K_\rho \cap \{u = c\rho^{-2/\sigma}\} \neq \varnothing$ *for some* $C > 0$ *independent of* ρ.

Proof. Return to the original system again:

$$u'' + \frac{n-1}{r} u' + f(u) = 0, \tag{5.14}$$

and let

$$u(\gamma, 0) = \gamma. \tag{5.15}$$

For each fixed r sufficiently small, either

$$u(\gamma, r) > \frac{\gamma}{2} \tag{5.16}$$

for all $\gamma \in [u_0, \infty)$, or there exists a $\tilde{\gamma}$ such that

$$u(\tilde{\gamma}, r) = \frac{\tilde{\gamma}}{2} \tag{5.17}$$

and (5.16) holds for all $\gamma \in [u_0, \tilde{\gamma})$. If (5.16) is false, then choosing a minimal γ for which (5.17) holds, continuity of $u(\gamma, r)$ guarantees that (5.16) holds on $[u_0, \tilde{\gamma})$, as it does at u_0.

Corresponding to $u(\gamma, r)$ there is a solution of (2.4), $(u(t), v(t), \rho(t))$ with $\lim_{t \to -\infty} u(t) = u_0$. Set $R_0 = \rho_0/(1-\rho_0)$. For fixed $r \in (0, R_0]$ if (5.16) happens for all $\gamma \in [u_0, \infty)$ then the lemma obviously holds at the associated value of ρ.

Suppose then that there exists a γ for which

$$u(\gamma, r) = \gamma. \tag{5.18}$$

The lemma will follow from finding a constant C for which

$$\gamma \geqq C r^{-2/\sigma}. \tag{5.19}$$

Using the usual Green's function, we can rewrite (if $n > 2$)

$$u(\gamma, r) = \gamma - \left(\int_0^r s\left(1 - (s/r)^{n-2}\right) f(u(\gamma, s))\, ds \right) / (n-2). \tag{5.20}$$

If (5.18) holds, then

$$\frac{\gamma}{2} = \left(\int_0^r s\left(1 - (s/r)^{n-2}\right) f(u(\gamma, s))\, ds \right) / (n-2).$$

Assuming that $\gamma \geqq u_0$

$$\frac{\gamma}{2} \leqq \left(\int_0^r s\left(1 - (s/r)^{n-2}\right) ds \right) \left(k_2 \gamma^{\sigma+1} / (n-2) \right),$$

from which it follows that

$$r^2 \gamma^{\sigma} \geqq n / k_2,$$

and the lemma holds. If $n = 2$, (5.20) is replaced by

$$u(\gamma, r) = \gamma - \int_0^r s(\ln - \ln s) f(u(\gamma, s))\, ds;$$

after repeating the above manipulations we arrive at the same estimate,

$$r^2 \gamma^{\sigma} \geqq 2 / k_2.$$

Translating back to (u, v, ρ) space, the lemma is proved.

We now have enough information to prove the theorem in the cases

(1) $\sigma < 2/(n-2)$, $n > 2$,

(2) $n = 2$.

For case (1), to construct the solution with m zeros where m is even, apply the flow to a curve C_x with $I(C_x) > m$. Choose t large negative so that $\rho(t) \leqq \rho_0$, then $\Phi_t(C_x)$ lies in the region where K_ρ is defined. Now $\Phi_t(C_x)$ lies in a strip about the

v-axis of width $C_1[\rho(t)]^{2-n}$ from (5.5) and K_ρ extends out at least to $C\rho^{-2/\sigma}$ (Lemma 5.3). Set $\rho=\rho(t)$, and then the condition that these intersect if t is large enough negative is that $2-n>-2/\sigma$, or $\sigma<2/(n-2)$, see Fig. 14.

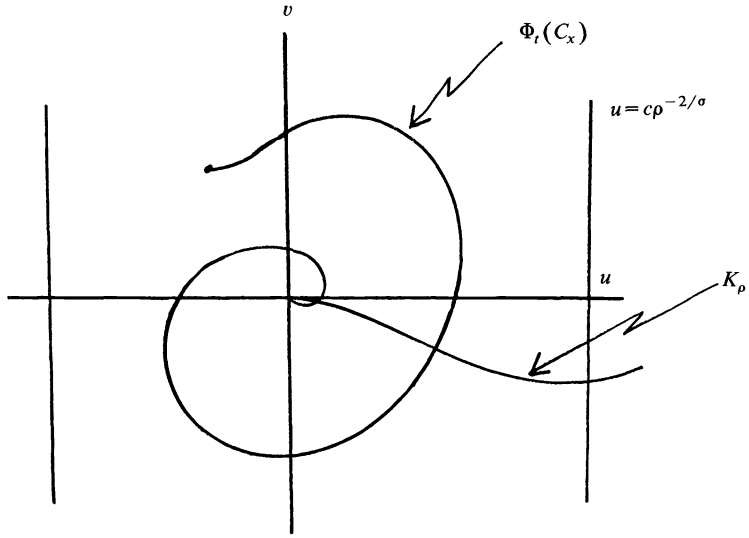

FIG. 14

To check the winding, $I(\Phi_t(C_x))>m$ and so it must intersect K_ρ at a point y so that the piece of $\Phi_t(C_x)$ between y and $(0,0)$ has winding number j, for each j even between 0 and M.

To be more precise, choose t so that

$$C_1[\rho(t)]^{2-n}<C[\rho(t)]^{-2/\sigma}, \tag{5.21}$$

which can be done if $\sigma<2/(n-2)$. Let $\phi(s)$, $s\in[s_0,s_1]$ be a parametrisation of $\Phi_t(C_x)$. Denote by C_s the curve ϕ restricted to $[s_0,s]$. We can find $q=q(j)$ so that $\phi(q)\in\{u=0\}$ and $I(C_q)=j$ for all $0<j\leqq m$. Moreover

$$I(C_s)\leqq j$$

for $s\in[q(j),q(j+1)]$. Let $j<m$ and even, then ϕ restricted to $[q(j),q(j+1)]$ is a curve connecting the negative v-axis to the positive v-axis with the angle making a net increase. Also it stays inside the strip

$$-C_1[\rho(t)]^{2-n}\leqq u\leqq C_1[\rho(t)]^{2-n}.$$

From (5.21), the strip

$$0\leqq u\leqq C_1[\rho(t)]^{2-n}$$

is divided into two components by the curve $K_{\rho(t)}$. In order to increase its angle, therefore, $\phi(s)$ must cross $K_{\rho(t)}$ for some $s\in[q(j),q(j+1)]$. We thus have an intersection of $\Phi_t(C_x)$ with K_ρ at winding number j.

It follows from Proposition 3.5 that the solution starting at this point has exactly j zeros. One checks easily that ρ_0 can be chosen so that it picks up no more zeros on $[0, R_0]$.

For the case of no zeros, we must analyse the tangent vectors of $\Phi_t(C_x)$ and K_ρ at the origin. The tangent vector to $\Phi_t(C_x)$ is always sandwiched between the negative v-axis and the unstable manifold in quadrant four for the $n=1$ case, see §3. However, the tangent vector to K_ρ becomes tangent to the u-axis and so an intersection is forced again if t is large enough negative.

To obtain the solutions with an odd number of zeros, one constructs the curve K_ρ in the left half-plane with the symmetric properties.

For the case $n=2$, observe that the analogue to (5.21) is

$$C_1|\ln \rho(t)| < C[\rho(t)]^{-2/\sigma}$$

which can be satisfied for any σ if t is large enough negative, making ρ small.

6. Completion of proof when $2/(n-2) \leqq \sigma < 4/(n-2)$, $n \neq 2$. The proof of §5 will only work when $\sigma < 2/(n-2)$. It is tempting to try to improve the estimates to prove the full theorem. However, this is not possible; we shall see by the end of this section that the ones given in §5 are, in some sense, the best possible.

The idea of the above proof was to see how far out in the u-direction a slice, in some $\{\rho = \bar{\rho}\}$ plane, of the manifold W_0^{cu} can be extended. In terms of the original problem (1.3), the solutions that satisfy (1.4) end up as the curves on this manifold. If their graphs are drawn u against r, it is well known that these graphs form an envelope, see Fig. 15. In other words they do not fill out the (u,r) plane, at least now while staying positive. Back in (u,v,ρ) space, we can imagine an envelope that marks the edge of the manifold W_0^{cu}. If one can guarantee that some backward iteration of W_{loc}^{cs} gets inside this envelope, existence could be proved, see Fig. 16.

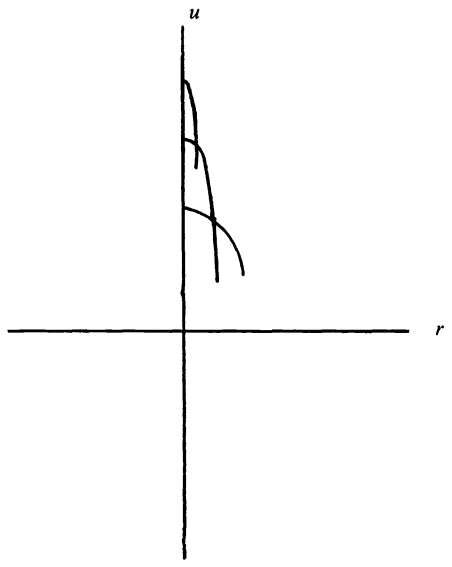

FIG. 15

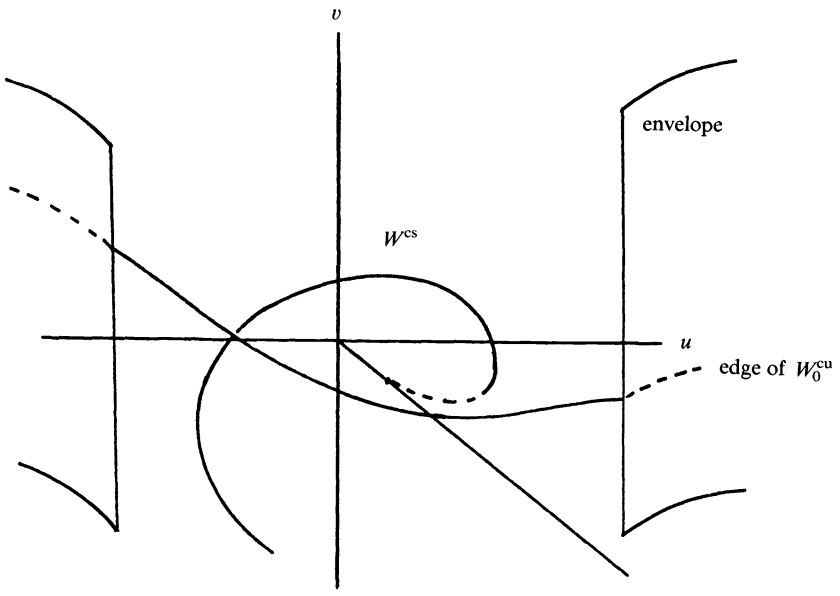

FIG. 16

However, the best general growth estimate one can obtain for these equations is r^{2-n} and the envelope actually grows at the rate $r^{-2/\sigma}$. Hence it looks as if the result of §5 is the best possible. The paradox is resolved by realising that W_0^{cu} does not end at the envelope!

To understand the behavior of W_0^{cu}, we must analyse the limit $r=0$ more carefully. In fact we shall scale so as the envelope stays bounded.

The transformation needed is the Emden–Fowler transformation. This has been used to analyse the pure power and similar cases, see Fowler [7], Chandrasekhar [4], Joseph and Lundgren [10]. Here we shall retrieve the phase planes obtained by these authors as limit systems of a three-dimensional problem.

Consider again the original equation

$$u''+\frac{n-1}{r}u'+f(u)=0.$$

Transform this by

$$y=r^t u, \qquad r=e^s,$$

where $\tau=2/\sigma$. One obtains

$$\ddot{y}+(n-2-2\tau)\dot{y}+\tau(\tau+2-n)y+h(y)y^{\sigma+1}+r^{2+\tau}g(r^{-\tau}y)=0, \qquad \dot{} = \frac{d}{ds},$$

where

$$h(y)=\begin{cases} k_+ & \text{if } y>0, \\ -k_- & \text{if } y\leqq 0, \end{cases}$$

recalling that $f(u)=h(u)|u|^{\sigma+1}+g(u)$, see §1.

We introduce $p=r^{\alpha}$, where α is chosen so that $0<\alpha<\tau$, and write (6.1) as an autonomous system.

$$\begin{aligned}&\dot{y}=z,\\ &\dot{z}=-(n-2-2\tau)z-\tau(\tau+2-n)y-h(y)y^{\sigma+1}-p^{(2+\tau)/\alpha}g(p^{-\tau/\alpha}y),\\ &\dot{p}=\alpha p.\end{aligned}\tag{6.2}$$

This is defined for $p>0$. Now define $q(p,y)$:

$$q(p,y)=\begin{cases}p^{(2+\tau)/\alpha}g(p^{-\tau/\alpha}y) & \text{if } p>0,\\ 0 & \text{otherwise.}\end{cases}\tag{6.3}$$

Consider the system

$$\begin{aligned}&\dot{y}=z,\\ &\dot{z}=-(n-2-2\tau)z-\tau(\tau+2-n)y-h(y)y^{\sigma+1}-q(p,y),\\ &\dot{p}=\alpha p.\end{aligned}\tag{6.4}$$

Note that $p=0$ corresponds to $r=0$ or $s\to-\infty$. We need to check that the right-hand side is C^1. It suffices to check that q is C^1 near $p=0$.

From the assumptions on g given in §1, the following two quantities

$$g(p^{-\tau/\alpha}y)/p^{-\tau\gamma/\alpha}=H_1(p,y)\tag{6.5}$$

and

$$g'(p^{-\tau/\alpha}y)/p^{-\tau(\gamma-1)/\alpha}=H_2(p,y)\tag{6.6}$$

are bounded as $p\to0$ and the bound is uniform over compact sets of y values.

To show that q is continuous, it suffices to show that $q(p,y)\to0$ as $p\to0$ and that this is locally uniform in y. But if $p\neq0$

$$q(p,y)=P^{(2+\tau-\tau\gamma)/\alpha}H_1(p,y).$$

Since $\gamma<\sigma+1$, $2+\tau-\tau\gamma>0$, and so $q(p,y)\to0$ as $p\to0$ uniformly on compact sets of y values. It follows that q is continuous at $p=0$.

To check the derivatives, if $p>0$

$$\frac{\partial q}{\partial y}=p^{(2+\tau)/\alpha-\tau/\alpha}g'(p^{-\tau/\alpha}y)=p^{(2+\tau-\tau-\tau(\gamma-1))/\alpha}H_2(p,y).$$

As above $2+\tau-\tau\gamma>0$ and so $\partial q/\partial y\to0$ as $p\to0$.

To compute $\partial q/\partial p$ at $p=0$, the limit

$$\lim_{p\to0}p^{(2+\tau)/\alpha-1}g(p^{-\tau/\alpha}y)$$

must exist.

$$p^{(2+\tau)/\alpha-1}g(p^{-\tau/\alpha}y)=p^{(2+\tau-\tau\gamma-\alpha)/\alpha}H_1(p,y),$$

and so the above limit exists if

$$2+\tau-\tau\gamma>\alpha\tag{6.7}$$

and is 0. Equation (6.7) is possible for some choice of α so long as

$$2+\tau-\tau\gamma>0$$

which is equivalent to $\gamma<\sigma+1$.

$\partial q/\partial p$ will be continuous if it converges to 0 as $p \to 0$. If $p > 0$

$$\frac{\partial q}{\partial p} = p^{(2+\tau)/\alpha - 1} g\left(p^{-\tau/\alpha} y\right) + p^{2/\alpha - 1} g'\left(p^{-\tau/\alpha} y\right) y.$$

The first term tends to zero as above. The second term is easily seen to converge to zero if (6.7) is satisfied.

This means that the system (6.4) is a C^1 system on $\mathbb{R}^2 \times [0, \infty)$. The plane $p = 0$ is invariant and contains the information about $r = 0$. The next step is to understand the structure of this phase portrait at and near $p = 0$.

The point $(0,0,0)$ is a critical point for (6.4). Linearising at this point, we obtain the matrix

$$\begin{pmatrix} 0 & 1 & 0 \\ -\tau(\tau+2-n) & -(n-2-2\tau) & 0 \\ 0 & 0 & \alpha \end{pmatrix}. \tag{6.8}$$

The eigenvalues of this matrix are τ, $\tau - n + 2$ and α. The associated eigenvectors are $(1, \tau, 0)$, $(1, \tau - n + 2, 0)$ and $(0,0,1)$, respectively. The eigenvalues τ and α are always positive, while

$$\tau - n + 2 > 0$$

if

$$\sigma < 2/(n-2)$$

and $\tau - n + 2 \leqq 0$ if $\sigma \geqq 2/(n-2)$. If we assume $\sigma \geqq 2/(n-2)$, we can form the local unstable manifold $W^{\mathrm{u}}_{\mathrm{loc}}$ to $(0,0,0)$ for (6.4), associated to the two eigenvalues τ and α.

As mentioned at the beginning, if $n = 2$, this method becomes considerably harder to apply but the results of §5 give the theorem.

As usual, set

$$W^{\mathrm{u}} = \bigcup_{t \geqq 0} W^{\mathrm{u}}_{\mathrm{loc}} \cdot t.$$

The reason that this technique works is that W^{u} is mapped back to W^{cu}_0 in (u, v, θ) co-ordinates. The transformation from (y, z, p) to (u, v, ρ), call it G, defined on $\mathbb{R}^2 \times (0, \infty)$ is given by

$$u = p^{-\tau/\alpha} y, \quad v = p^{-(\tau+1)/\alpha}(z - \tau y), \quad \rho = p^{1/\alpha}/\left(1 + p^{1/\alpha}\right).$$

This takes solution curves of (6.4) to those of (2.4).

LEMMA 6.1. $G(W^{\mathrm{u}} \cap \{p \geqq 0\}) \subset W^{\mathrm{cu}}_0$.

Proof. The lemma states that if (y_0, z_0, p_0) is an initial condition for (6.4) with solution $(y(s), z(s), p(s)) \to (0,0,0)$ as $s \to -\infty$, then $G(y_0, z_0, p_0) = (u_0, v_0, \rho_0)$ has a solution $(u(t), v(t), \theta(t))$ to (2.4) with $u(t) \to \gamma$, some $\gamma \in \mathbb{R}$, as $t \to -\infty$. It suffices to show that $u(t)$ is bounded as $t \to -\infty$.

Inside $W^{\mathrm{u}}_{\mathrm{loc}}$, there lies a strong unstable manifold that is one-dimensional; call this $W^{\mathrm{su}}_{\mathrm{loc}}$. It is tangent to the eigenvector $(1, \tau, 0)$ and clearly lies in the invariant plane $p = 0$. Choosing co-ordinates (ζ, η) on $W^{\mathrm{u}}_{\mathrm{loc}}$ so that the p-axis and $W^{\mathrm{su}}_{\mathrm{loc}}$ become axes in that order, it follows easily (see Fenichel [6]) that

$$|\eta(s)| \leqq c e^{\tau s}, \quad \text{some } c > 0$$

as $s \to -\infty$, for any solution on W^{u}_{loc}. Since the eigenvector for τ has a nonzero y component, it follows that

$$|y(s)| \leqq ce^{\tau s}, \quad \text{some } c > 0$$

as $s \to -\infty$. But $u = r^{-\tau} y = e^{-\tau s} y(s)$; so this implies that $|u(s)|$ is bounded as $s \to -\infty$, as desired.

We shall use this lemma to deduce the behavior of W_0^{cu} by understanding W^{u}. The relevant properties about W^{u} will be obtained by the same idea as used in §4, namely to study the limit system and then to view the full problem as a perturbation of this. The next task then is to analyse the system in the $p = 0$ invariant plane.

Restricting (6.4) to $p = 0$,

$$\dot{y} = z, \qquad \dot{z} = (2\tau - n + 2)z + \tau(n - 2 - \tau)y - h(y)y^{\sigma+1}. \tag{6.9}$$

Set $F(y) = \int_0^y (\tau(n-2-\tau)\eta - h(\eta)\eta^{\sigma+1})\,d\eta$ and

$$H(y,z) = \frac{z^2}{2} - F(y); \tag{6.10}$$

then H is the Hamiltonian for (6.9) if the dissipative term is absent, which happens when $2\tau - n + 2 = 0$, or

$$\sigma = 4/(n-2).$$

In general,

$$\dot{H} = (2\tau - n + 2)z^2$$

and $\dot{H} > 0$ if $\sigma < 4/(n-2)$, $\dot{H} < 0$ if $\sigma > 4/(n-2)$. The three-phase portraits are shown in Fig. 17.

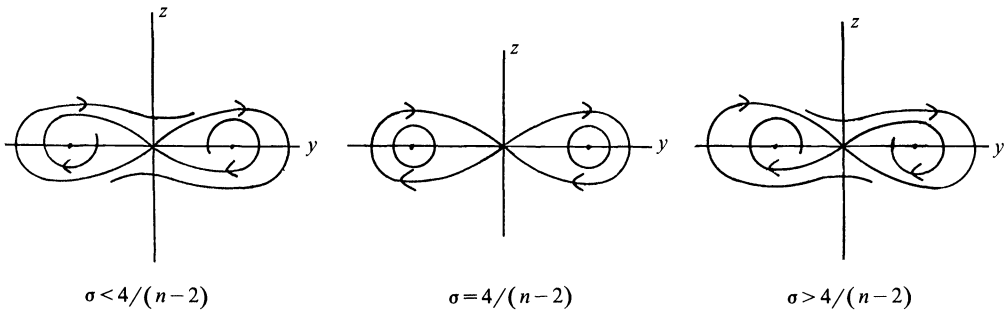

FIG. 17

This is the structure that changes at the critical value of σ. The important point is that the unstable manifold switches from oscillating about the origin to spiralling into one of the right-hand critical points. This is in Joseph and Lundgren [10].

The fact that the unstable manifold spirals out in the subcritical case will perturb to the desired information for W^{u}_{loc} in the full system. The phase portrait depicted for $\sigma < 4/(n-2)$ in Fig. 17 only holds if $\sigma > 2/(n-2)$. At $\sigma = 2/(n-2)$, all those critical points collide at the origin. We need to prove then that this spiralling always occurs if $n \neq 2$.

Let $\tilde{W}^u_{loc}$ be the local unstable manifold at $(0,0)$ for (6.9). Set $\tilde{W}^u = \cup_{s \geqq 0} \tilde{W}^u_{loc} \cdot s$. If $x \in \tilde{W}^u$, there exists an s so that $x \in W^u_{loc} \cdot s$. Let D_x be the curve in $\tilde{W}^u_{loc} \cdot s$ joining x to $(0,0)$. D_x is clearly an admissible curve.

LEMMA 6.2. *If $\sigma < 4/(n-2)$ and $n \neq 2$, then given $m \in \mathbb{Z}^+$, there exists $x \in W^u$ so that $I(D_x) < -m$.*

Proof. $\tilde{W}^u$ is the union of two solutions and $(0,0)$. We must show that each of these solutions oscillates infinitely often about 0 in a clockwise direction. It suffices to show that if $(y(s_0), z(s_0)) \in \{z > 0\} \cap \{H > 0\}$ for some s_0, then there is an $s > s_0$ for which $z(s) = 0$ and at the smallest such $s > s_0$, $y(s) > 0$. This says that any orbit in the upper half plane must leave it at some future time through the positive y-axis. This, together with the symmetric statement about the lower half plane, proves the lemma.

Firstly we prove that if $z(s) \neq 0$ for all $s > s_0$ then $y(s)$ becomes infinite, i.e. given k there exists $s > s_0$ so that $y(s) > k$. Suppose $|y(s)| \leqq k$ for all $s \geqq s_0$; then from (6.9),

$$\frac{d}{ds}\left(e^{-(2\tau - n + 2)s} z\right) \leqq C$$

for some constant $C > 0$. But then $z(s)$ cannot blow up in finite time. Suppose $z(s) \to +\infty$ as $s \to +\infty$; then $y(s) \to +\infty$ as $s \to +\infty$ also. It follows that $z(s)$ stays bounded. But then $\omega(y(s_0), z(s_0))$ is nonempty. Since $\dot{H} > 0$ there are no periodic orbits so, by Poincaré–Bendixson, $\omega(y(s_0), z(s_0))$ must contain a critical point. But since all the critical points lie in $H < 0$ (this is just the point $(0,0)$ if $\sigma < 2/(n-2)$), this contradicts the fact that $H > 0$ on the orbit. Therefore $y(s)$ must become unbounded.

Suppose that for any given k, there exists $\tilde{s}$ so that $y(\tilde{s}) = k^{1/\sigma}$. Set $z = \delta w$ in (6.9) to obtain

$$\dot{y} = \delta w, \qquad \dot{w} = (2\tau - n + 2)w - y\left(|y|^\sigma - \tau(n - 2 - \tau)\right)/\delta. \tag{6.11}$$

Let $\theta = \arctan(w/y)$, computing

$$\dot{\theta} = (2\tau - n + 2)\sin\theta\cos\theta - \cos^2\theta\left(|y|^\sigma - \tau(n - 2 - \tau)\right)/\delta - \delta\sin^2\theta. \tag{6.12}$$

Since $|y|^\sigma > k$

$$\dot{\theta} < (2\tau - n + 2)\sin\theta\cos\theta - (k/\delta)\cos^2\theta - \delta\sin^2\theta + (\tau(n - 2 - \tau)/\delta)\cos^2\theta.$$

Now let $\delta = k^{1/2}$,

$$\dot{\theta} < -\delta^{1/2} + C$$

where C is some constant bounded independently of δ if it is large. But then there exists an s so that $\theta(s) = 0$ by choosing k large enough. This means $z(s) = 0$.

Checking the vector field on $z = 0 \cap \{H > 0\}$ shows that when $z(s) = 0$ for the first time, $y(s) > 0$. This proves the lemma.

In the same spirit as §4, we now show that this winding property can be inherited by $W^u \cap \{p = \gamma\}$ for small enough γ.

Define the Wazewski set

$$W = \{(y, z, p) : p \in [0, \gamma]\}.$$

This is clearly a Wazewski set in forward time if γ is small. Choose γ small enough so that $W^u_{loc} \cap \{p = \gamma\}$ is a one-dimensional curve. Let Γ be a curve $\phi : [\gamma_0, \gamma_1] \to W^u_{loc} \cap \{0 \leqq p \leqq \gamma\}$ such that $\phi(b) \in \{p = 0\}$, $\phi([a, b]) \subset \{y > 0\}$ and $\phi(a) = (0, 0, \gamma)$. Set $\Gamma^0 = \Gamma \setminus \{\phi(b)\}$; then $\Gamma^0 \subset W^0$ since $p' = \alpha p$. If $R : W \to W^-$ is the Wazewski map, set

$\Omega = R(\Gamma^0)$. Obviously Ω is a continuous curve in $\{p=\gamma\}$, so it can be considered as a curve in $\mathbb{R}^2$. With $\psi(s)=R(\phi(s))$, which is defined for $s\in[a,b)$, and $D_s=\psi([0,s))$ we claim the following are true of Ω.

LEMMA 6.3. *Under the assumptions of Lemma* 6.2

(1) $(0,0)\in\Omega$ *and* Ω *is admissible.*

(2) *For all* s, $I(D_s)\leqq 0$.

(3) *Given* $m\in\mathbb{Z}^+$, *there exists an* s *so that* $I(D_s)<-m$.

In order to prove Lemma 6.1, we need a set of propositions that are analogous to Propositions 3.3–3.6. The proofs are essentially the same as in that case, only with appropriate reversal of direction.

Let D_x be a connected curve in $W^u\cap\{p=p_0\}$ with $0\leqq p_0\leqq\sigma$, $\psi:[\gamma_0,\gamma_1]\to\{p=p_0\}$ such that $\psi(b)=x$ and $\psi(a)=(0,0)$.

PROPOSITION 6.1. *Any* D_x *as described above is admissible. Let* $(y(s),\ z(s),\ p(s))$ *be the solution satisfying* $(y(0),\ z(0),\ p(0))=x$.

PROPOSITION 6.2. $-I(D_x)=$ *number of zeros of* $y(s)$ *in* $(-\infty,0]$.

Notice the minus sign, $I(D_x)$ is in fact negative. The flow of (6.4) restricted to $\{p=p_0\}$ any $0\leqq p_0\leqq\gamma$ determines a homotopy

$$\Psi:\mathbb{R}^2\times[a,b]\to\mathbb{R}^2 \tag{6.13}$$

with any $a<b<0$. It is well defined because it is a scaling of the original flow which was well defined.

PROPOSITION 6.3. Ψ *is an admissible homotopy.*

PROPOSITION 6.4. $I(\psi_t(D_x))$ *is a decreasing function of* t.

Proof of Lemma 6.3. (1) is obvious as the tangent vector Ω at $(0,0)$ is a tangent vector to W^u_{loc}. By continuity of the flow if $x=(y(0),\ z(0),\ p(0))$ is close enough to $p=0$ it stays close for an arbitrarily long time. Therefore by Lemma 6.2 it has an arbitrarily large number of zeros; by Proposition 6.2, $-I(D_s)$ can be made arbitrarily large. This proves (3).

To prove (2), suppose this were not true; apply the flow (6.13) ψ_t to D_s. From Proposition 6.4 $I(\psi_t(D_s))>0$ for all $t<0$. But for sufficiently large negative t, $\psi_t(D_s)\subset W^u_{\text{loc}}$ and $I(\psi_t(D_s))=0$. This contradiction proves (2) and therefore the lemma.

The transformation back to (u,v,ρ) co-ordinates, namely G takes Ω to a curve $G(\Omega)$ with the same properties at Ω. In other words $G(\Omega)$ is admissible, $I(G(D_s))\leqq 0$ for all s and there exists s so that $I(G(D_s))$ is an arbitrarily large negative number. This follows because the transformation (6.8) is orientation preserving and maps the z-axis to the v-axis.

Now apply the flow Φ (3.6) of (2.4) to C_x back to $\bar\rho=\gamma^{1/4}/(1+\gamma^{1/\alpha})$. If t is such that $\Phi_t(C_x)\subset\{\rho=\bar\rho\}$, let $E_x=\Phi_t(C_x)$. Intersections between E_x and $G(\Omega)$ are solutions of the problem. We want to find intersections that supply the desired number of zeros.

Let us work in the covering space of $\mathbb{R}^2$ as described in §3 with the covering map given by (3.1). Lift both E_x and $G(\Omega)$ to this space $\tilde X$. Let the lift of $G(\Omega)$ be called Y, choose it so that the end point lies in the interval $[0,1]$ on the x-axis. Y is then a curve, from the above mentioned properties of $G(\Omega)$ (Lemma 6.3), that does not intersect the line $x=1$ but intersects $x=0$ and $x=-m$ for every $m\in\mathbb{Z}^+$.

Now suppose $I(E_x)=k$, and k can be made arbitrarily large. Let E_x be given by $\phi:[s_0,s_1]\to\mathbb{R}^2$. The lift of E_x, say $\tilde E_x$, is determined by the choice of interval in which $\tilde\phi(s_0)$ lives, in other words by the choice of N for which $\tilde\phi(s_0)\in[N,N+1]$.

Now Y divides the covering space $\tilde{X}$ into two components. If $(0,\eta)$ is the end-point of Y on $\{r=0\}$, i.e. the x-axis (r is the radial variable in polar co-ordinates on phase space), then $\{(r,x): r=0,\ x<\eta\}$ lies in one component and each line $x=K$, with $k>0$ lies in the other.

With N, k as above, $\tilde{\phi}(S_1)$ must lie in $k+N\leqq x\leqq k+N+1$. It follows that if $k+N\geqq 1$ and $N\leqq 0$ then this lift of E_x must intersect the curve $G(\Omega)$. Each N supplies a different solution corresponding to such an intersection point, call one determined by a choice of N, J_N. Notice that we can find J_N for $|N|$ arbitrarily large as k can be chosen arbitrarily large. We must prove that the solution J_N has $|N|$ zeros.

LEMMA 6.4. *J_N has $|N|$ zeros.*

Proof. Let δ be the intersection point between $G(\Omega)$ and $\tilde{E}_x$. Let B^+ be the portion of $\tilde{E}_x$ between δ and $\tilde{\phi}(S_0)$; similarly B^- is the portion between δ and $\tilde{\phi}(s_1)$. It is obvious that

$$I(B^+)+I(B^-)=|N|.$$

Let $(u(t),\ v(t),\ \rho(t))$ be the solution of (2.4) satisfying

$$(u(0),\ v(0),\ \rho(0))=\left(p(\zeta),\ p_0^{1/4}\left(1+p_0^{1/4}\right)\right);$$

then $I(B^+)=$ number of zeros of $u(t)$ in $[0,\infty)$ and $I(B^-)=$ number of zeros of $u(t)$ in $(-\infty,0]$. Since N is any element of $\mathbb{Z}^+$, we are done.

Remark. This limiting phase portrait shows that the growth estimates of §5 are the best possible. The eigenvalue other than τ at $(0,0)$ is $\tau-n+2$; coming in at this direction would correspond to growth at the rate r^{2-n}, which is the estimate obtained in §5. The envelope corresponds to a curve that stays bounded in the scaled variables. In fact it is tangent to W^u at the first time it turns around. It therefore grows like $r^{-2/\sigma}$.

Acknowledgments. The first author thanks Prof. Hermann Flaschka for showing him an unpublished manuscript of his and Keener's which was influential on this work. He also thanks Prof. Paul Fife for some helpful conversations on the estimate in §5.

A MAXIMUM PRINCIPLE FOR AN ELLIPTIC SYSTEM AND APPLICATIONS TO SEMILINEAR PROBLEMS*

DJAIRO G. DE FIGUEIREDO† AND ENZO MITIDIERI‡

Abstract. The Dirichlet problem in a bounded region for elliptic systems of the form

$$(*) \qquad -\Delta u = f(x,u) - v, \qquad -\Delta v = \delta u - \gamma v$$

is studied. For the question of existence of positive solutions the key ingredient is a maximum principle for a linear elliptic system associated with (*). A priori bounds for the solutions of (*) are proved under various types of growth conditions on f. Variational methods are used to establish the existence of pairs of solutions for (*).

Key words. elliptic systems, maximum principle, a priori estimates, positive solutions, monotone iteration method, mountain pass theorem

AMS(MOS) subject classifications. Primary 35J65, 35J50, 47H15

Introduction. In this paper we propose to discuss the elliptic system

$$(0.1) \qquad -\Delta u = f(x,u) - v, \qquad -\Delta v = \delta u - \gamma v \quad \text{in } \Omega,$$

where Ω is a bounded smooth domain in R^N, $N \geqq 2$, subject to Dirichlet boundary conditions $u = v = 0$ on $\partial\Omega$. The solutions (u,v) of this problem represent steady state solutions of reaction diffusion systems of interest in biology, namely systems of the form

$$(0.2) \qquad u_t = D_1 \Delta u + f(u) - v, \qquad v_t = D_2 \Delta v + \varepsilon(u - \gamma v)$$

where D_1, D_2, ε and γ are positive constants, and one looks for solutions $u(t,x)$, $v(t,x)$ defined in $(0,\infty)\times\Omega$, subject to Dirichlet boundary conditions on $(0,\infty)\times\partial\Omega$. The type of nonlinearities which are of importance in the applications will be described in the Examples I and II below. System (0.2) shows that both species may diffuse. In this sense it is an extension of the well-known FitzHugh–Nagumo system, which serves as a model for nerve conduction, cf. [5] or Hastings [7]. We also mention Koga–Kuramoto [10], where the complete system (0.2) appears and steady state solutions are discussed. There is an extensive bibliography in this subject. We mention three additional papers, which are more closely related to the investigation presented here, namely Rothe–de Mottoni [13], Rothe [14] and Lazer–McKenna [11].

In the applications the constants γ and δ, which appear in system (0.1), are taken to be *positive*. So we shall make this assumption throughout this paper. It follows then that the second equation in (0.1) can be solved for v in terms of u. Let us denote by B its solution operator under Dirichlet boundary conditions. That is, given u, we define

Bu as the solution of the problem $-\Delta v+\gamma v=\delta u$ in Ω, $v=0$ on $\partial\Omega$. Thus our problem becomes the one of finding u such that

$$-\Delta u+Bu=f(x,u) \quad \text{in } \Omega, \qquad u=0 \quad \text{on } \partial\Omega. \tag{0.3}$$

We observe that the left side of (0.3) contains a local (differential) operator $-\Delta$, and a nonlocal (integral) operator B. This fact gives rise to quite interesting questions. It is essential at the outset to understand the operator $-\Delta+B$. In §1 we study its spectral properties and establish a maximum principle for solutions of linear equations like

$$-\Delta u+Bu-\lambda u=g(x) \quad \text{in } \Omega, \qquad u=0 \quad \text{on } \partial\Omega, \tag{0.4}$$

where the real parameter λ is restricted to certain ranges depending on γ, δ and the region Ω. In §2 we establish a priori bounds for solutions of (0.3) under the main assumption that the nonlinearity f at ∞ is below the smallest eigenvalue of the operator $-\Delta+B$; this assumption will be stated precisely as condition (f2) and it characterizes a class of systems which are here called sublinear. The two examples below, which were treated by previous authors [9], [11], [13] and [14], are included in the classes studied in the present paper. Their results are therefore sharpened as far as ranges of the parameters involved and signs of the solutions.

Example I. $f(u)=\lambda u-g(u)$, where λ is a real parameter larger than the first eigenvalue of the operator $-\Delta+B$, and g is a function behaving like u^3, but not necessarily odd; cf. [11], [13], [14].

Example II. $f(u)=u(u-a)(1-u)$, where a is such that $0<a<1/2$. This is the sort of nonlinearity arising in the FitzHugh–Nagumo equations, [5], [9].

The a priori bounds obtained in §2 will be needed in an essential way to perform appropriate truncations of the nonlinearity f, so the problem could be treated by variational methods. This will be done in §5.

In §3 we discuss a class of systems whose model nonlinearity is the one given by Example I. Using the results of §1 we are able to establish the existence of a positive and a negative solution. This result complements a previous one by Lazer and McKenna [11], who proved the existence of two nontrivial solutions by topological degree arguments. Their method, however, does not yield the signs of the solutions obtained. The maximum principle for equations like (0.4) becomes very useful in this respect.

In §4 we sketch a result on the existence of positive solutions for a superlinear elliptic system. Results similar to the ones known for the scalar case hold true in view of the aforementioned maximum principle. The question of the a priori bounds for positive solutions of superlinear elliptic systems may be a hard one. If the growth of the nonlinearity at $+\infty$ is at most like $(N+1)/(N-1)$, for $N\geqq 3$, then the results of Brézis–Turner [2] extend readily. The range $[(N+1)/(N-1), (N+2)/(N-2)]$ poses serious difficulties. The methods used in de Figueiredo–Lions–Nussbaum [3] to treat the scalar case rely on the results of Gidas–Ni–Nirenberg [6], which are not available as yet for the type of systems studied here. We remark that Troy [15] has extended some of the results in [6] to systems. However, Troy's systems do not include the ones we are concerned with. Also in §4 we prove a nonexistence result basing it on our extension to systems of the well-known Pohozaev's identity.

In §5 we consider a class of systems whose model nonlinearity is the one given in Example II. Using the Mountain Pass Theorem of Ambrosetti–Rabinowitz [1], we establish Theorem 5.1 on the existence of two nontrivial solutions for such systems, extending a previous result of Klaasen–Mitidieri [9]. This result shows clearly the relevance of the volume of Ω and of the parameters γ and δ on the existence questions.

It also exhibits the importance of a large positive parameter λ on the existence of two positive solutions for the system

$$-\Delta u=\lambda f(x,u)-v, \qquad -\Delta v=\delta u-\gamma v, \quad \text{in } \Omega$$

subject to Dirichlet boundary conditions, and the nonlinearity f is of the type given by Example II. This relates to the scalar case studied in Rabinowitz [12].

The contents of this paper are as follows:

1. The operator $-\Delta+B$.
2. A priori bounds for solutions of sublinear elliptic systems.
3. Existence of positive solutions.
4. Remarks on a superlinear system.
5. Existence of two nontrivial solutions for a class of sublinear systems.

1. The operator $-\Delta+B$. Consider the linear Dirichlet problem

$$-\Delta v+\gamma v=\delta u \quad \text{in } \Omega, \qquad v=0 \quad \text{in } \partial\Omega, \tag{1.1}$$

where $\Omega\subset R^N$ is a bounded and smooth domain, γ and δ are positive constants. Let us denote by B its solution operator: $v=Bu$. It is well known that

$$B:L^2(\Omega)\to H^2(\Omega)\cap H_0^1(\Omega); \quad B:L^p(\Omega)\to W^{2,p}(\Omega); \quad B:C^\alpha(\bar\Omega)\to C^{2+\alpha}(\bar\Omega).$$

Let us define the operator

$$T\equiv -\Delta+B:L^2(\Omega)\to L^2(\Omega), \quad \text{with } D(T)=H^2(\Omega)\cap H_0^1(\Omega).$$

Clearly T is symmetric, that is, $(Tu_1,u_2)=(u_1,Tu_2)$ for all $u_1,u_2\in D(T)$, where $(\ ,\ )$ denotes the L^2 inner product. Using the L^2 regularity theory, one can prove that T is a closed operator. Let us denote by $0<\lambda_1<\lambda_2\leqq\lambda_3\leqq\cdots$ the eigenvalues of $-\Delta$ under Dirichlet boundary conditions, and by ϕ_k the corresponding eigenfunctions. Then it is easily verified that

$$\hat\lambda_k=\lambda_k+\frac{\delta}{\gamma+\lambda_k}, \qquad k=1,2,\cdots \tag{1.2}$$

are eigenvalues of T. Moreover the same ϕ_k's defined above are their corresponding eigenfunctions. Since (ϕ_k) is a complete orthonormal set in L^2, it is readily shown that the $\hat\lambda_k$'s are the *only* eigenvalues of T. We shall prove in the sequel that in fact the *spectrum* $\sigma(T)$ of T *consists precisely of these eigenvalues*. For each λ in the resolvent set $\rho(T)$ of T, let us denote by $T_\lambda=(T-\lambda I)^{-1}$ its corresponding resolvent operator.

LEMMA 1.1 (a representation formula of the resolvent operator for some values of λ). *Suppose that the real numbers a and b satisfy the following conditions*

$$a>-\lambda_1, \quad \gamma+b>-\lambda_1, \quad b\neq 0, \quad \textit{and} \tag{1.3}$$

$$b\gamma+\delta=ab. \tag{1.4}$$

Then $\lambda=-a-b$ is in the resolvent set $\rho(T)$ and

$$T_\lambda=\left[1-b(\gamma+b-\Delta)^{-1}\right](a-\Delta)^{-1}. \tag{1.5}$$

Proof. With $\lambda=-a-b$, one can write

$$T-\lambda I=(a-\Delta)+b\left[\frac{b\gamma+\delta}{b}-\Delta\right](\gamma-\Delta)^{-1}.$$

Using condition (1.4) above, one obtains

$$T-\lambda I=(a-\Delta)\left[1+b(\gamma-\Delta)^{-1}\right]=(a-\Delta)(\gamma-\Delta)^{-1}(\gamma+b-\Delta).$$

Finally using condition (1.3), it follows that

$$T_\lambda=(\gamma+b-\Delta)^{-1}(\gamma-\Delta)(a-\Delta)^{-1},$$

which readily gives (1.5). □

Remark 1.1. A calculation shows that λ, taken in the ranges indicated below, are representable as $\lambda=-a-b$, with a and b satisfying (1.3) and (1.4):

(i) All $\lambda\leqq-\gamma-2\sqrt{\delta}$. These λ's correspond to $b>0$.

(ii) If $\gamma+\lambda_1>\sqrt{\delta}$, there are some additional values of λ, namely $2\sqrt{\delta}-\gamma\leqq\lambda<\lambda_1+\delta/(\gamma+\lambda_1)$. These λ's correspond to b negative in the range $-\lambda_1-\gamma<b<-\delta/(\gamma+\lambda_1)$.

Remark 1.2 (*monotonicity of the sequence* $\hat{\lambda}_k$). We observe that $\gamma+\lambda_1>\sqrt{\delta}$ implies that $\hat{\lambda}_1<\hat{\lambda}_2\leqq\hat{\lambda}_3\leqq\cdots$. Of course one does not have in general such a monotonicity of the eigenvalues $\hat{\lambda}_k$. Clearly $\gamma+\lambda_1>\sqrt{\delta}$ is not a necessary condition, since it in fact implies the stronger statement that the function $s\mapsto s+\delta/(\gamma+s)$ is monotonically increasing in the whole halfline $[\lambda_1,\infty)$. A necessary and sufficient condition for this monotonicity involves also the second eigenvalue λ_2, namely $\delta<(\gamma+\lambda_1)(\gamma+\lambda_2)$.

COROLLARY 1.2 (compactness of T_λ). *For all* $\lambda\in\rho(T)$, *the resolvent operator* T_λ *is compact.*

Proof. For any $\lambda,\mu\in\rho(T)$ one has the resolvent equation

$$T_\mu-T_\lambda=(\mu-\lambda)T_\mu T_\lambda.$$

So if T_λ is compact for some λ, then it is compact for all λ's in the resolvent set. By the previous lemma T_λ is compact for $\lambda\leqq-\gamma-2\sqrt{\delta}$. □

The following result is an immediate consequence of Lemma 1.1 and Remark 1.1 above.

COROLLARY 1.3 (positiveness of T_λ for some values of λ). *If* $\gamma+\lambda_1>\sqrt{\delta}$, *then* T_λ *is positive for all* $2\sqrt{\delta}-\gamma\leqq\lambda<\hat{\lambda}_1$.

Remark 1.3. The positiveness of T_λ is a *maximum principle* for the equation

$$-\Delta v+Bv-\lambda v=u \quad \text{in } \Omega, \qquad v=0 \quad \text{on } \partial\Omega.$$

It says that if $u\in L^2$ and $u\geqq0$ a.e., then $v\geqq0$ a.e. In fact, it follows from the representation formula (1.5) that a *strong maximum principle* holds. Namely, if $u\in C^0(\Omega)$ and $u\geqq0$ in Ω, then $v>0$ in Ω and the outward normal derivative $(\partial v/\partial\nu)<0$. (Recall that Ω is being assumed to be smooth. So the interior sphere condition is satisfied.)

Remark 1.4. If $\gamma>2\sqrt{\delta}$, then the condition $\gamma+\lambda_1>\sqrt{\delta}$ is automatically satisfied, and Corollary 1.3 says that in this case T_λ is positive for λ in an interval which contains 0. In general one cannot expect that T_0 be positive. Indeed, if $\gamma=\delta=1$, then Corollary 1.3 says that T_λ is positive for $1\leqq\lambda<\hat{\lambda}_1$.

PROPOSITION 1.4. *The spectrum* $\sigma(T)$ *of* T *consists of precisely the eigenvalues* $\hat{\lambda}_k$.

Proof. We have seen above that the point spectrum $P\sigma(T)=\{\hat{\lambda}_k:k=1,2,\cdots\}$. Let $\lambda\notin P\sigma(T)$. Then $T-\lambda I$ is one-to-one. If we show that $T-\lambda I$ is onto, it follows by the Closed Graph Theorem that $\lambda\in\rho(T)$. Thus we claim that the equation $Tu-\lambda u=v$ has a solution u for each given $v\in L^2$. Taking $\mu\in\rho(T)$, we see that this equation is equivalent to $Tu-\mu u=(\lambda-\mu)u+v$, or

$$u=(\lambda-\mu)T_\mu u+T_\mu v. \tag{1.6}$$

By the Fredholm alternative (1.6) is solvable iff the homogeneous equation $u=(\lambda-\mu)T_\mu u$ has only the solution $u=0$. But this is actually the case, since this homogeneous equation is equivalent to $Tu=\lambda u$. Recall that $\lambda\notin P\sigma(T)$. □

Remark 1.5. The above proposition follows also from general results in functional analysis. Namely, since T is a self-adjoint operator, it follows that its residual spectrum $R\sigma(T)$ is empty. Next, since $-\Delta-\lambda$ is Fredholm for every $\lambda\in C$, it follows that $-\Delta+B-\lambda$ is also Fredholm for all $\lambda\in C$. Consequently the continuous spectrum $C\sigma(T)$ is also empty.

Remark 1.6 (*a useful inequality*). Let $\tilde{\lambda}$ denote the smallest of the eigenvalues $\hat{\lambda}_k$. We have seen above that $\tilde{\lambda}=\hat{\lambda}_1$ if $\gamma+\lambda_1>\sqrt{\delta}$. We assert that

$$(Tu,u)\geqq\tilde{\lambda}\|u\|^2_{L^2},\qquad \forall u\in D(T). \tag{1.7}$$

Indeed, since (ϕ_k) is a complete orthonormal set in L^2, we can write $u=\sum\alpha_k\phi_k$ where $\alpha_k=(u,\phi_k)$. So

$$(Tu,u)=\sum\alpha_k(Tu,\phi_k)=\sum\alpha_k(u,T\phi_k)=\sum\alpha_k^2\hat{\lambda}_k,$$

from which the claim follows. A similar argument shows that

$$\int|\nabla u|^2+(Bu,u)\geqq\tilde{\lambda}\|u\|^2_{L^2},\qquad \forall u\in H_0^1. \tag{1.8}$$

Remark 1.7 (*uncoupling of systems and maximum principles*). The usual maximum principle for systems, as well as the maximum principle proved here, seems to be related with the possibility of uncoupling the elliptic system. To make precise our observation, let us look at the linear elliptic system

$$-\Delta u=au+bv+f(x),\qquad -\Delta v=cu+dv+g(x) \tag{1.9}$$

subject to Dirichlet boundary conditions: $u=v=0$ on $\partial\Omega$, where Ω is some bounded domain in R^N, and a, b, c and d are real constants. Suppose that $b\neq 0$ and $c\neq 0$; otherwise the problem trivializes. The uncoupling of system (1.9) is possible if the matrix of the coefficients

$$M=\begin{bmatrix} a & b\\ c & d\end{bmatrix}$$

has two distinct eigenvalues, μ_1 and μ_2. Such a condition is equivalent to

$$(a-d)^2+4bc>0. \tag{1.10}$$

Of course this is the case if b and c both have the same sign. However, to infer the signs of u and v from the signs of the corresponding functions in the uncoupled system, one requires that both b and c be positive. This gives the usual maximum principle for systems. On the other hand, if b and c have opposite signs, the uncoupling is still possible provided a and d "compensate" for the negativeness of bc. Through some calculations one can prove the following result, which essentially gives our maximum principle.

PROPOSITION 1.5. *In addition to* (1.10) *assume that* $bc<0$, $c(a-d)>0$, $\mu_1<\hat{\lambda}_1$ *and* $\mu_2<\hat{\lambda}_1$. *Then if* $f\geqq 0$, $g\geqq 0$ *and* $cf\geqq(a-\mu_1)g$, *it follows that the solutions* u *and* v *of* (1.9) *are positive in* Ω.

2. A priori bounds for solutions of sublinear elliptic systems. Let us consider the elliptic system

$$-\Delta u=f(x,u)-v,\qquad -\Delta v=\delta u-\gamma v\quad \text{in } \Omega, \tag{2.1}$$

where Ω is a bounded smooth domain in R^N, subject to Dirichlet boundary conditions. We always assume that γ and δ are *positive constants*. The nonlinearity f is subject to the following conditions:

(f1) $f:\bar{\Omega}\times R\to R$ is locally Lipschitzian,

(f2) $\limsup_{|s|\to\infty}(f(x,s)/s)<\tilde{\lambda}$ (uniformly in Ω), where $\tilde{\lambda}$ denotes the smallest eigenvalue of the operator $-\Delta+B$ studied in §1.

Condition (f2) characterizes system (2.1) as being *sublinear*.

Examples. 1) $f(u)=\lambda u-h(u)u$, where h is a C^1 function such that $h(0)=0$, $h'(s)s>0$ for all $s\neq 0$ and $\liminf_{s\to\pm\infty}h(s)>\lambda$, (for instance $h(s)=s^2$). This is the case considered in [11] and [14].

2) $f(u)=u(u-a)(1-u)$, where $0<a<1$. This is the type of nonlinearity that appears in the FitzHugh–Nagumo equations; cf. [5], [9].

Remark 2.1. By a solution of (2.1) we mean a classical solution. That is, a pair of functions (u,v) which are in $C^2(\Omega)\cap C^0(\bar{\Omega})$ and which are 0 on $\partial\Omega$. We observe that if, $u,v\in H_0^1(\Omega)\cap C^0(\bar{\Omega})$ satisfy (2.1) in the distribution sense, then by a bootstrap argument it follows that $u,v\in C^{2,\alpha}(\bar{\Omega})$. We remark that in general one cannot drop the hypothesis that u and v are in $C^0(\bar{\Omega})$ in order to be able to bootstrap. However, this would be possible provided one assumes some growth condition on f.

In order to obtain the a priori bound for the solutions of (2.1), we shall assume either one of the conditions below.

(f3) $\lim_{|s|\to\infty}(f(x,s)/|s|^p)=0$, where $1<p<(N+2)/(N-2)$, if $N\geq 3$, and $1<p<\infty$, if $N=2$,

(f4) $\limsup_{|s|\to\infty}(f(x,s)/s)<-\delta/\gamma$,

where the limits are uniform in Ω.

Remark 2.2. In the scalar case (i.e. $-\Delta u=f(x,u)$) condition (f4) corresponds to $f(x,s)<0$ for $s>\beta>0$ and $f(x,s)>0$ for $s<-\beta$, where β is some real number.

PROPOSITION 2.1. *Under hypotheses* (f1), (f2) *and* (f3), *the solutions of* (2.1) *are a priori bounded in* L^∞.

Proof. It follows from (f2) that there exist $0<\mu<\tilde{\lambda}$ and $M>0$ such that

$$f(x,s)\leq\mu s+M,\quad \text{for } 0\leq s<\infty,\qquad f(x,s)\geq\mu s-M\quad \text{for } -\infty<s<0. \tag{2.2}$$

The second equation in (2.1) can be solved for v in terms of u. And in this way system (2.1) is equivalent to the equation

$$-\Delta u+Bu=f(x,u), \tag{2.3}$$

using the notation of §1. So we need only to prove bounds on u. The corresponding bounds on v are obtained immediately from the second equation in (2.1). Multiplying (2.3) by u, integrating by parts and using (1.8), we obtain

$$\tilde{\lambda}\int u^2\leq\int|\nabla u|^2+\int(Bu)u=\int f(x,u)u. \tag{2.4}$$

Next we estimate the last term in (2.4) using (2.2)

$$\int f(x,u)u\leq\mu\int u^2+M\int|u| \tag{2.5}$$

which implies $\int u^2\leq C$. (We shall use the same C to denote different constants.) Using (2.4) and (2.5) again and recalling that B is a bounded linear operator in L^2, we conclude that $\int|\nabla u|^2\leq C$. It follows from (f3) that given $\varepsilon>0$ there exists $C_\varepsilon>0$ such that

$$|f(x,s)|\leq\varepsilon|s|^p+C_\varepsilon.$$

Finally using this inequality and invoking L^p estimates and the Sobolev imbedding theorem, we conclude that there exist a constant $\hat{C}$ such that $\|u\|_{L^\infty} \leqq \hat{C}$. □

Remark 2.3. We emphasize that the dependence of $\hat{C}$ on f is through the constants μ, M and C_ε. So if we change f for $|s| \geqq \hat{C}$ maintaining μ, M and C_ε, the new equation (2.3) with this modified f has the same solutions of the original equation (2.3). This fact will be used in §5.

The following result was proved by Rothe [14] and Lazer and McKenna [11] under less general hypotheses on f. The main idea in the proof below is taken from those papers.

PROPOSITION 2.2. *Under hypotheses* (f1), (f2) *and* (f4), *the solutions of* (2.1) *are a priori bounded in* L^∞.

Proof. (i) We first claim that for $u \in C^0(\bar{\Omega})$, with $u = 0$ on $\partial\Omega$, one has

$$\frac{\delta}{\gamma} \min u \leqq (Bu)(x) \leqq \frac{\delta}{\gamma} \max u, \qquad x \in \Omega. \tag{2.6}$$

Indeed we know that $v = Bu$ satisfies the equation

$$v = \frac{1}{\gamma}\Delta v + \frac{\delta}{\gamma} u. \tag{2.7}$$

Let us prove the first inequality in (2.6). If $v \geqq 0$ that inequality is trivially true. So let us assume that for $x_1 \in \Omega$ we have $v(x_1) = \min v < 0$. Then $\Delta v(x_1) \geqq 0$ and (2.7) implies that $v(x_1) \geqq (\delta/\gamma) u(x_1)$, from which the first inequality in (2.6) follows readily. In a similar way we prove the second inequality in (2.6).

(ii) It follows from (f4) that there exist positive constants k and m such that

$$\frac{f(x,s)}{s} \leqq -k < -\frac{\delta}{\gamma}, \qquad |s| \geqq m. \tag{2.8}$$

We claim that $\|u\|_{L^\infty} \leqq m$ for all solutions u of (2.1). Indeed, suppose by contradiction that $\|u\|_{L^\infty} = M > m$ for some solution u. It follows from (2.6), using the first equation in (2.1) that

$$\frac{\delta}{\gamma} \min u \leqq \Delta u + f(x,u) \leqq \frac{\delta}{\gamma} \max u. \tag{2.9}$$

If there is $x_0 \in \Omega$ such that $u(x_0) = M$, we obtain from (2.9) and (2.8) that

$$-\frac{\delta}{\gamma} M \leqq f(x_0, u(x_0)) \leqq -k u(x_0) = -kM,$$

which is impossible. In a similar way we arrive to a contradiction if $u(x) = -M$ for some $x \in \Omega$. □

Next we discuss the question of bounds for positive solutions of the system (2.1). As remarked before we need only to obtain bounds on u, and then corresponding bounds on v follow readily.

PROPOSITION 2.3. *In addition to* (f1) *assume the following condition*:

(f5) *there exists a constant* $m > 0$ *such that* $f(x,s) = 0$ *for* $s \geqq m$.

Then all nonnegative solutions u of (2.3) *are bounded above by m.*

Proof. Given a solution u of (2.1), define the function ω as $\omega(x) = u(x) - m$ for $u(x) > m$ and $\omega(x) = 0$ for $u(x) \leqq m$. Such a ω belongs to $H_0^1(\Omega)$. So it follows from (2.3) that

$$\int |\nabla \omega|^2 + (Bu, \omega) = \int f(x,u)\omega. \tag{2.10}$$

In view of (f5) and the fact that $(Bu)(x)>0$ for $x\in\Omega$, we conclude from (2.10) that $\int|\nabla\omega|^2=0$, which implies $\omega=0$. □

Remark 2.4. This proposition will be used as follows. Suppose that the function f is such that there is an $m>0$ for which $f(x,m)=0$. Then we consider system (2.1) with f replaced by a new function $\tilde{f}$ defined as f for $s\leqq m$ and as 0 for $s>m$. If for this new system we could find a nonnegative solution u, then by the proposition above such a u would be indeed a solution of the original system.

Remark 2.5. Now if $f(x,s)=f(s)$ satisfies (f2), $f(0)\geqq 0$ and $f(s)>0$ for $0<s<\varepsilon$, then either there is an $m>0$ such that $f(m)=0$ or f satisfies (f3). In the first case we treat the problem as in the previous remark. In the second case we proceed as in Proposition 2.1 and obtain an a priori bound on positive solutions.

Remark 2.6. Similar statements can be made for nonpositive solutions u.

Remark 2.7. *A sufficient condition for all (eventual) nontrivial solutions of* (2.1) *to be positive.* Assume that $\gamma+\lambda_1>\sqrt{\delta}$ and that $f(x,u)\geqq\alpha u$ for all u, where $-\gamma+2\sqrt{\delta}\leqq\alpha<\hat{\lambda}_1$. Then *the nontrivial solutions* u of (2.1) *are positive in* Ω. From (2.3) we obtain $-\Delta u+Bu\geqq\alpha u$, and the result follows readily by Corollary 1.3.

Remark 2.8. The previous condition applied to Example 2 gives interesting conclusions. Indeed, we can in this case compute explicitly the value of m in (2.8). Then truncate f outside $|s|\geqq m$ in such a way that the new f has derivative equals to $-a$ for $|s|>m$. By Proposition 2.2 the solutions of (2.1) with this new f are the same as the solutions of the original equation. Moreover, from the way the truncation is done, it follows (by a straightforward calculation) that now $f(u)\geqq -au$, (where we are denoting also by f the truncated function) provided $\delta/\gamma<a$. So the previous sufficient condition applies. Summarizing, *the solutions of* (2.1), *in the case of Example* 2, *are positive if*

$$\frac{\delta}{\gamma}<sa\leqq\gamma-2\sqrt{\delta}\,. \tag{2.11}$$

Observe that, if (2.11) is assumed, then the condition $\gamma+\lambda_1>\sqrt{\delta}$ is automatically satisfied, cf. Remark 1.4. We remark that no solution of (2.3) in this example can be nonpositive (i.e. $u\leqq 0$ in Ω). In fact the solutions in general change sign.

3. Existence of positive solutions. We consider again system (2.1) of the previous section or its equivalent expression in the form of equation (2.3). In this section we examine the question of existence of a positive solution under an additional condition on the nonlinearity f at 0. In order to simplify the presentation in the sequel, we suppose that f does not depend on x. The case when f depends also on x can also be treated by the method used here; under appropriate conditions on f similar results may be obtained. So we assume the next condition.

(f6) $\liminf_{s\to 0}(f(s)/s)>\hat{\lambda}_1$.

Examples. Condition (f6) is satisfied, for instance, if (i) $f(0)>0$, or (ii) $f(s)$ is C^1 and $f'(0)>\hat{\lambda}_1$. A special case of (ii) was considered in [11].

THEOREM 3.1. *Assume that* $\gamma+\lambda_1>\sqrt{\delta}$. *In addition to conditions* (f1), (f2) *and* (f6), *suppose that* f *is* C^1 *for* $s\geqq 0$ *and*

$$\inf\{f'(s):0\leqq s<\beta\}\geqq-\gamma+2\sqrt{\delta}\,, \tag{3.1}$$

where $\beta\leqq+\infty$ *is the first positive zero of* $f(s)$. *Then equation* (2.3) *has a positive solution* u, *or equivalently, system* (2.1) *has a pair* (u,v) *of positive solutions.*

Remark 3.1. The hypothesis $\gamma+\lambda_1>\sqrt{\delta}$ in Theorem 3.1 implies that $\tilde{\lambda}=\hat{\lambda}_1$. Recall also that under this hypothesis $-\gamma+2\sqrt{\delta}<\hat{\lambda}_1$, and so we can make use of Corollary 1.3. The condition on the differentiability of f can be relaxed and in consequence (3.1) has to be replaced by an appropriate one-sided Lipschitz condition.

Proof of Theorem 3.1. (i) It follows from (f6) that there exist $\nu > \hat{\lambda}_1$ and $s_0 > 0$ such that $f(s) \geqq \nu s$ for $0 \leqq s \leqq s_0$. Thus $\varepsilon\phi_1$ is a subsolution of (2.3) for all ε such that $0 < \varepsilon < \varepsilon_0 = s_0 / \max \phi_1$.

(ii) If $\beta < \infty$ then $\omega(x) \equiv \beta$ in Ω is a supersolution of (2.3). If $\beta = +\infty$ we construct a supersolution ω for (2.3) as follows. It follows from (f2) that there exist $-\gamma + 2\sqrt{\delta} < \mu < \hat{\lambda}_1$ and $C > 0$ such that $f(s) \leqq \mu s + C$. We then take ω as the solution of $-\Delta\omega + B\omega = \mu\omega + C$ in Ω, $\omega = 0$ on $\partial\Omega$. In view of Corollary 1.3, $\omega > 0$ in Ω and $\varepsilon > 0$ can be chosen in such a way that $\varepsilon\phi_1 < \omega$ in Ω.

(iii) So (2.3) possesses an ordered pair of a sub- and a supersolution. Now in order to apply the method of monotone iteration, it is still required that (a) $T_\lambda = (-\Delta + B - \lambda I)^{-1}$ be a positive operator for some real number λ, and (b) the function $s \to f(s) - \lambda s$, for the same λ, be nondecreasing in the interval $[0, \max \omega]$. These two requirements are accomplished if one chooses $\lambda = -\gamma + 2\sqrt{\delta}$. Indeed, (a) then follows by Corollary 1.3 and (b) follows from (3.1). Therefore the method of monotone iteration can be applied and one obtains a solution of (2.3) in the interval $[\varepsilon\phi_1, \omega]$.

Remark 3.2. It should be remarked that besides (f2) no growth condition is required on f.

Remark 3.3. A statement similar to Theorem 3.1 holds true for the existence of negative solutions of (2.1). In this case, condition (3.1) is replaced by

$$(3.1)^- \qquad \inf\{f'(s) : \beta' < s \leqq 0\} \geqq -\gamma + 2\sqrt{\delta}$$

where $-\infty \leqq \beta' < 0$ is the first negative zero of $f(s)$. In order to prove such a result, we can reduce it to the situation of Theorem 3.1 by the substitution $z = -u$.

Example. $f(u) = au - u^3$ with $a > 0$. In this case $\beta = \sqrt{a}$, and $\min\{f'(s) : 0 \leqq u \leqq \beta\} = -2a$. So conditions (f6) and (3.1) are satisfied if $\hat{\lambda}_1 < a \leqq \gamma/2 - \sqrt{\delta}$. We then see that in this example there are values of a for which (2.3) has a positive solution provided

$$(3.2) \qquad \hat{\lambda}_1 < \gamma/2 - \sqrt{\delta}\,.$$

Clearly this is the case for instance if γ is large. This is also the case if $\gamma > (\sqrt{3} + 1)\sqrt{\delta}$ and Ω is a sufficiently large ball. Indeed, for large balls λ_1 is essentially zero and this last inequality implies readily condition (3.2). Clearly in this example there is also a negative solution, namely $-u$, where u is the positive solution.

Comparison with the results of Lazer–McKenna. In [11] the following system is studied

$$(3.3) \qquad -k\Delta u = \lambda u - h(u)u - v, \qquad -\Delta v + v = u \quad \text{in } \Omega$$

subject to Dirichlet boundary conditions. Under certain conditions on k, λ and h it is proved that

$$(3.4) \qquad -k\Delta u + (1 - \Delta)^{-1} u = \lambda u - h(u)u,$$

which is an equivalent form of (3.3), has exactly three solutions. In [11] a topological degree argument is used, which does not give the sign of the two nontrivial solutions. Under essentially the same hypotheses, our Theorem 3.1 says that one of these solutions is positive and the other is negative. Our precise result is the following. We state only the one corresponding to the existence of a positive solution. A similar one can be drawn for the existence of a negative solution.

COROLLARY 3.2. *Under the assumptions below, equation* (3.4) *has a positive solution*:

$$1+\lambda_1 > 1/\sqrt{k}\,, \tag{3.5}$$

$$h\in C^1(R,R), \quad h(0)=0 \quad h'(s)s>0 \quad \forall s\neq 0, \tag{3.6}$$

$$k\lambda_1+\frac{1}{1+\lambda_1}<\lambda, \tag{3.7}$$

$$\sup\{h'(s)s+h(s): 0\leqq s\leqq\beta\}\leqq\lambda+k-2\sqrt{k}\,, \tag{3.8}$$

where β *is the only positive solution of* $h(s)=\lambda$. (*Observe that* β *could be* $+\infty$.)

Remark 3.4. If $h'(s)$ is nondecreasing, then $\beta<\infty$ and (3.8) simplify to $\beta h'(\beta)\leqq k-2\sqrt{k}$. So positive solutions of (3.4) exist if the *diffusion rate k is large.*

4. Remarks on a superlinear system. Consider the elliptic system

$$-\Delta u=f(u)-v, \qquad -\Delta v=\delta u-\gamma v \quad \text{in } \Omega, \tag{4.1}$$

subject to Dirichlet boundary conditions, with $\gamma,\delta>0$ and $-\gamma+2\sqrt{\delta}<0$. Assume the following conditions on the nonlinearity f:

(f1)′ $f: R^+\to R^+$ locally Lipschitzian,

(f7) $\liminf_{s\to+\infty}(f(s)/s)>\hat{\lambda}_1$,

(f8) $\limsup_{s\to 0}(f(s)/s)<\hat{\lambda}_1$,

(f9) $\lim_{s\to+\infty}(f(s)/s^\sigma)=0$ where $1<\sigma\leqq(N+1)/(N-1)$, if $N\geqq 3$ and $1<\sigma<\infty$, if $N=2$.

As seen in the previous section, (4.1) is equivalent to

$$-\Delta u+Bu=f(u). \tag{4.2}$$

Under the hypotheses above we may proceed as in the scalar case (cf. Brézis–Turner [2]) and we prove that (4.2) has a positive solution. Condition (f9) is used to get a priori bounds for the positive solutions of (4.2). We do not know how to proceed in order to obtain such bounds in the case when $(N+1)/(N-1)<\sigma<(N+2)/(N-2)$ and $N\geqq 3$. The results of [3] for the scalar case are not immediately extended to this case. For that purpose, the first step would be to see how the results of Gidas–Ni–Nirenberg [6] look (if at all!) in this case. We remark that the extension obtained by Troy [15] does not cover the type of systems studied in this paper.

Remark 4.1. The condition $-\gamma+2\sqrt{\delta}<0$ is used in order to guarantee that the operator $T_0\equiv(-\Delta+B)^{-1}$ is positive. If this condition is not satisfied, but one has $\gamma+\lambda_1>\sqrt{\delta}$, everything still works provided $\hat{\lambda}_1$ in the right sides of assumptions (f7) and (f8) is replaced by $\hat{\lambda}_1-\gamma+2\sqrt{\delta}$.

Nonexistence of positive solutions in the case when $f(u)=u^p$, *for* $p\geqq(N+2)/(N-2)$ *and* $N\geqq 3$. As in the scalar case this is proved using an identity of the Pohozaev type. The function $f(u)=u^p$ for $u\geqq 0$ is extended as $f(u)=0$ for $u<0$. Then it follows from Remark 2.7 that all eventual solutions u and v of (4.1) are positive in Ω, provided we assume that $-\gamma+2\sqrt{\delta}<0$. Consequently the nonexistence of nontrivial solutions for system (4.1) (in *star-shaped* domains Ω) with such an f follows readily from the two lemmas below.

LEMMA 4.1. *Let u and v be solutions of* (4.1). *Then the following identity holds*

$$2N\int F(u)-(N-2)\int uf(u)-2\int uv-\frac{2}{\delta}\int|\nabla v|^2=\oint(x\cdot\nu)\left[|\nabla u|^2-\frac{1}{\delta}|\nabla v|^2\right] \tag{4.3}$$

where $F(s)=\int_0^s f$ *and* $\int$ *denotes* (*volume*) *integral over* Ω *and* $\oint$ (*surface*) *integral over* $\partial\Omega$. *Here* ν *denotes the outward unit normal.*

LEMMA 4.2. *Let u and v be solutions of* (4.1). *Assume that* $-\gamma+2\sqrt{\delta}<0$. *Then* $u-(1/\sqrt{\delta})v$ *is positive in* Ω *and*

$$\frac{\partial u}{\partial \nu}<\frac{1}{\sqrt{\delta}}\frac{\partial v}{\partial \nu}<0 \quad \text{on } \partial\Omega.$$

To conclude this section, we prove the two lemmas above.

Proof of Lemma 4.1. First we use the general form of Pohozaev's identity for solutions of the $-\Delta u=g(x,u)$ in Ω and $u=0$ on $\partial\Omega$; see [3]. This identity will be applied separately to the first and second equations in (4.1). Observe that for the first equation, $g(x,s)=f(s)-v(x)$, and for the second equation, $g(x,s)=\delta u(x)-\gamma s$. Then we obtain the following two identities

$$2N\int[F(u)-uv]-2\int(x\cdot\nabla v)u-(N-2)\int[f(u)-v]u=\oint(x\cdot\nu)|\nabla u|^2, \tag{4.4}$$

$$2N\int\left[\delta uv-\frac{1}{2}\gamma v^2\right]+2\delta\int(x\cdot\nabla u)v-(N-2)\int[\delta u-\gamma v]v=\oint(x\cdot\nu)|\nabla v|^2. \tag{4.5}$$

(If one prefers to ignore [3], identities (4.4) and (4.5) may be obtained in the standard way Pohozaev's identities are proved. Use the multiplier $x\cdot\nabla u$ in the first equation of (4.1) and $x\cdot\nabla x$ in the second.) It follows from the divergence theorem that

$$\int(x\cdot\nabla v)u+\int(x\cdot\nabla u)v=-N\int uv. \tag{4.6}$$

Next dividing (4.5) through by δ, subtracting the result from (4.4) and using (4.6), we obtain

$$2N\int F(u)-(N-2)\int uf(u)-4\int uv+\frac{2\gamma}{\delta}\int v^2=\oint(x\cdot\nu)\left[|\nabla u|^2-\frac{1}{\delta}|\nabla v|^2\right]. \tag{4.7}$$

Now it follows from the second equation in (4.1) that

$$\int|\nabla v|^2=\delta\int uv-\gamma\int v^2. \tag{4.8}$$

Taking (4.8) into (4.7), we obtain the identity (4.3). □

Proof of Lemma 4.2. It follows from $-\gamma+2\sqrt{\delta}<0$ that there exists a real number k such that $\sqrt{\delta}<k<\gamma-\sqrt{\delta}$. Using (4.1), it is easy to check that

$$(-\Delta+k)\left(u-\frac{1}{\sqrt{\delta}}v\right)\geqq 0 \quad \text{in } \Omega$$

from which the assertion of the lemma follows. Observe that we know that all (eventual) solutions of (4.1) would be positive. □

5. Existence of two nontrivial solutions for a class of sublinear systems. Let us once more consider system (2.1) under conditions (f1), (f2), (f3) or (f4). As in previous sections we discuss, instead of system (2.1), its equivalent form given by equation (2.3). In this section we propose to treat the question of existence of solutions of (2.3) by a variational argument. So we look for the critical points of the functional

$$\Phi(u)=\frac{1}{2}\int|\nabla u|^2+\frac{1}{2}(Bu,u)-\int F(x,u) \tag{5.1}$$

where $F(x,s)=\int_0^s f(x,\xi)\,d\xi$. Although this functional is well defined in H_0^1 if we assume (f3), this is not the case if (f4) is assumed instead. Observe that both (f2) and (f4) restrict f only in one direction. So some truncation has to be done. The existence of a priori bounds on the solutions of (2.3) in either case ((f3) or (f4) assumed), as proved in §2, allows us to truncate the nonlinearity f in such a way that the functional Φ is *well defined* in H_0^1 and it is *bounded from below*. Indeed, if case (f3) is assumed, we choose an appropriate $\tilde{C}>\hat{C}$ and do this truncation for $|s|\geqq\tilde{C}$ (see Proposition 2.1 and Remark 2.3) preserving μ, M and C_ε and in such a way that $\lim_{|s|\to\infty}(f(x,s)/s)=l$ where $0<l<\tilde{\lambda}$. In case we assume (f4) the truncation is done for $|s|\geqq m$ (see Proposition 2.2), and in such a way that $\lim_{|s|\to\infty}(f(x,s)/s)=-k$, where the constant k is given in (2.8). The truncation so done has the very essential feature that the new equation (2.3) with this truncated function has the same solutions as the solutions of the original equation (2.3).

One sees immediately that $\Phi: H_0^1(\Omega)\to R$ is C^1 and

$$(\Phi'(u),\omega)_{H^1}=\int\nabla u\cdot\nabla\omega+\int(Bu)\omega-\int f(x,u)\omega. \tag{5.2}$$

So the critical points of Φ are the H_0^1 solutions of (2.3). By a bootstrap argument it follows that these solutions are in fact in $C^{2,\alpha}(\bar{\Omega})$.

LEMMA 5.1. *The functional Φ defined above satisfies the Palais–Smale condition.*

Proof. (i) In view of Poincaré's inequality we may consider H_0^1 endowed with the inner product $(u,\omega)_{H^1}=\int\nabla u\cdot\nabla\omega$. It is well known that the nonlinear operator $\tilde{f}: H_0^1\to H_0^1$ defined by $(\tilde{f}(u),\omega)_{H^1}=\int f(x,u)\omega$, $\forall\,\omega\in H_0^1$, is compact. (Recall that f has linear growth in view of the truncation.) On the other hand the (linear) operator $\tilde{B}: H_0^1\to H_0^1$ defined by $(\tilde{B}u,\omega)_{H^1}=\int(Bu)\omega$ is also compact. This follows readily from the compact imbedding of H_0^1 in L^2. Consequently $\Phi'=I+\tilde{B}-\tilde{f}$, that is, Φ' is of the form identity + compact operator. Thus to prove the Palais–Smale condition, it is enough to show that any sequence $(u_n\in H_0^1)$ such that $|\Phi(u_n)|\leqq C$ and $\Phi'(u_n)\to 0$ in H_0^1 possesses a subsequence (denoted again by u_n) such that $\|u_n\|_{H^1}\leqq C$.

(ii) It follows from $\Phi'(u_n)\to 0$ that given $\varepsilon_n\downarrow 0$ there exists a subsequence of (u_n) (denoted again by u_n) such that

$$\left|\int\nabla u_n\cdot\nabla\omega+\int(Bu_n)\omega-\int f(x,u_n)\omega\right|\leqq\varepsilon_n\|\omega\|_{H^1}. \tag{5.3}$$

Now using (5.3) with $\omega=u_n$ and estimating with the help of (1.8), we get

$$\tilde{\lambda}\int|u_n|^2\leqq\int f(x,u_n)u_n+\varepsilon_n\|u_n\|_{H^1}. \tag{5.4}$$

From the properties of the truncated f we obtain from (5.4)

$$\int u_n^2\leqq C+C\varepsilon_n\|u_n\|_{H^1}. \tag{5.5}$$

Next from $|\Phi(u_n)|\leqq C$ we infer that

$$\int|\nabla u_n|^2\leqq\int(Bu_n)u_n+2\int|F(x,u_n)|+C \tag{5.6}$$

and finally using the properties of the truncated f, we obtain from (5.6) and (5.5) that $\int|\nabla u_n|^2\leqq C+C\varepsilon_n\|u_n\|_{H^1}$ which proves that $\|u_n\|_{H^1}\leqq C$. □

Remark 5.1. It follows immediately from the previous remarks that system (2.1) has *at least one solution* under hypotheses (f1), (f2), and (f3) or (f4). Indeed, since Φ is C^1 functional, bounded below and satisfying the Palais–Smale condition, it follows that it has a global minimum u_1, $\Phi(u_1)=\inf\{\Phi(u): u\in H_0^1\}$. One cannot expect in general the existence of more solutions. Indeed if $f(u)=\lambda u$ with $\lambda<\tilde{\lambda}$, equation (2.3) in this case has only the trivial solution! So some additional assumption is necessary.

Now we treat a problem which is superlinear at 0, in the sense that the condition below holds:

(f10) f is differentiable at 0, $f(x,0)=0$, and $f'(x,0)<\tilde{\lambda}$.

Example 2 in §2 satisfies condition (f10).

THEOREM 5.2. *Assume conditions* (f1), (f2), (f3) *or* (f4), *and* (f10). *In addition suppose that there exists* $\xi>0$ *such that*

$$F(\xi)\geqq F(s) \quad \forall\, 0\leqq s\leqq \xi, \tag{5.7}$$

$$\frac{2F(\xi)}{\xi^2} > \min\left\{ \frac{1}{R^2}\frac{(1+t)^2}{t^2}\frac{(1+t)^N-1}{2-(1+t)^N}+\frac{\delta}{\gamma}\frac{(1+t)^N}{2-(1+t)^N} : 0<t<2^{1/N}-1 \right\} \tag{5.8}$$

where R *denotes the radius of the largest ball contained in* Ω. *Then equation* (2.3) *has at least two nontrivial solutions.*

Remark 5.2. Condition (5.8) is the analogue of a condition introduced by one of the authors (D.G.F.) in [4] for the scalar case. We remark that if there is a $\xi>0$ such that $F(\xi)>0$ then the condition is satisfied (for example if Ω is a large ball and δ is very small). The special case of Example 2 was studied by Klaasen and Mitidieri [9]. Condition (5.8) follows readily from their conditions: (i) Ω to be a large ball, and (ii) $\gamma/\delta>9/(2a^2-5a+2)$.

Proof. It suffices to prove that there exists $\tilde{u}\in H_0^1$ such that $\Phi(\tilde{u})<0$. Once this is done, we see that the global minimum u_1 of Φ is a nontrivial solution since $\Phi(u_1)=\inf\Phi<0$. The second solution is obtained immediately by an application of the Mountain Pass Theorem of Ambrosetti–Rabinowitz [1], since 0 is a strict local minimum in view of assumption (f10). In order to see that there are points in H_0^1 where the functional Φ is negative we consider the functions u_t below. We may assume that the ball centered at 0 with radius R is contained in Ω, where R is the radius of the largest ball contained in Ω. Defining

$$u_t(x)=\begin{cases} \xi & \text{if } \|x\|\leqq R/(1+t), \\ \xi\left[1-\dfrac{1+t}{tR}\left(\|x\|-\dfrac{R}{1+t}\right)\right] & \text{if } \dfrac{R}{1+t}\leqq\|x\|\leqq R, \\ 0 & \text{if } x\in\Omega\setminus B_R(0), \end{cases}$$

the result follows by a calculation from conditions (5.7) and (5.8). □

ON THE EIGENVALUE PROBLEM FOR COUPLED ELLIPTIC SYSTEMS*

ROBERT STEPHEN CANTRELL† AND KLAUS SCHMITT‡

Abstract. We consider the eigenvalue problem

$$\begin{aligned} L_k u_k &= \lambda \sum_{i=1}^{r} m_{ki} u_i \quad \text{in } \Omega, \\ u_k &= 0 \qquad\qquad\quad \text{on } \partial\Omega, \end{aligned}$$

where Ω is a bounded domain in $\mathbb{R}^n$, $n \geqq 1$, with smooth boundary $\partial\Omega$ and for $k = 1, \cdots, r$, L_k is a second order uniformly elliptic operator. The coupling coefficients are such that $m_{ij} \geqq 0$, $i \neq j$ and for at least one k, $m_{kk}^{+} \neq 0$. We establish the existence of positive characteristic values with associated positive solutions. We also investigate the multiplicity of such characteristic values and establish bifurcation results for nonlinear perturbations of the linear problem.

Key words. coupled elliptic systems, eigenvalue problems, bifurcation in nonlinear systems

1. Introduction.

Consider the eigenvalue problem

$$\begin{aligned} L_k u_k &= \lambda \sum_{i=1}^{r} m_{ki} u_i \quad \text{in } \Omega, \\ u_k &= 0 \qquad\qquad\quad \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

where Ω is a bounded domain in $\mathbb{R}^n$, $n \geqq 1$, with smooth boundary $\partial\Omega$, and for $k = 1, \cdots, r$

$$L_k = \sum_{i,j=1}^{n} a_{ij}^{k} \frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{n} a_i^k \frac{\partial}{\partial x_i} + a_0^k \tag{1.2}$$

is a uniformly elliptic differential operator of second order with coefficients continuous on $\bar{\Omega}$ and $a_0^k(x) \geqq 0$, $x \in \bar{\Omega}$. The coefficients m_{ki}, $1 \leqq k$, $i \leqq r$ are also assumed to belong to $C^0(\bar{\Omega}, \mathbb{R})$. The parameter $\lambda \in \mathbb{R}$ is assumed to be positive.

In a recent paper, P. Hess [11] showed that if $m_{ij} \geqq 0$, $i \neq j$ and if for at least one k, $m_{kk}^{+} \neq 0$, then (1.1) has a positive characteristic value with associated nontrivial solution $u = \operatorname{col}(u_1, \cdots, u_r) \in K = \{ v \in C^0(\bar{\Omega}, \mathbb{R}^r)\colon\ v_i \geqq 0,\ 1 \leqq i \leqq r \}$. The purpose of this paper is to examine this important result more closely. We obtain a somewhat more detailed understanding of the multiplicity and character of the nontrivial solutions to (1.1), leading to results on bifurcation questions for associated nonlinear eigenvalue problems.

† Department of Mathematics and Computer Science, University of Miami, Coral Gables, Florida 33124.

‡ Department of Mathematics, University of Utah, Salt Lake City, Utah 84112.

To this end, we shall begin by proving the main result of Hess [11] in a slightly different way, relying on ideas employed earlier by the second author in [18]. We then give an extension of the result to the multiparameter problem

$$\begin{aligned} L_k u_k &= \lambda_k \sum_{i=1}^{r} m_{ki} u_i \quad \text{in } \Omega, \\ u_k &= 0 \qquad\qquad\qquad\quad \text{on } \partial\Omega, \quad k = 1, \cdots, r. \end{aligned} \tag{1.3}$$

Together with some conditions for the uniqueness and simplicity of such characteristic values of (1.1), our result on (1.3) explains how multiplicities greater than one occur in a number of cases. Finally, we apply these results to the problem of positive solutions to nonlinear eigenvalue problems, including the problem of coexistence steady states in the Volterra–Lotka competition model with diffusion, recently studied by Cosner and Lazer [8].

2. Main results. Let L_k, $1 \leqq k \leqq r$ also denote the realization of L_k in $C_0^0(\bar{\Omega}, \mathbb{R})$ subject to Dirichlet boundary conditions. Then L_k: $C_0^0(\bar{\Omega}, \mathbb{R}) \supset \operatorname{dom}(L_k) \to C_0^0(\bar{\Omega}, \mathbb{R})$ is invertible, with compact inverse. Furthermore, L_k^{-1} is a positive operator with respect to the cone of nonnegative functions. Denote by M the matrix $M = (m_{ij})$, $1 \leqq i, j \leqq r$ and think of M as a multiplication operator. (Recall that $m_{ij} \geqq 0$ if $i \neq j$.) Then (1.1) may be written as

$$Lu = \lambda M u, \tag{2.1}$$

where

$$L = \begin{bmatrix} L_1 & & 0 \\ & \ddots & \\ 0 & & L_r \end{bmatrix}, \qquad u = \begin{bmatrix} u_1 \\ \vdots \\ u_r \end{bmatrix},$$

and L^{-1} is a compact operator on $C_0^0(\bar{\Omega}, \mathbb{R}^r)$ which is positive with respect to the cone K in $C_0^0(\bar{\Omega}, \mathbb{R}^r)$, i.e. $L^{-1}(K) \subset K$.

Let us choose $\mu > 0$ such that all elements on the main diagonal of $M + \mu I = M + \mu$, where I is the $r \times r$ identity matix, are positive. Then (2.1) is equivalent to

$$(L + \lambda\mu) u = \lambda (M + \mu) u, \tag{2.2}$$

and since μ and λ are positive $(L + \mu\lambda)^{-1}$ is also a compact operator positive with respect to K. Thus (2.2) is equivalent to

$$u = \lambda (L + \lambda\mu)^{-1} (M + \mu) u. \tag{2.3}$$

We let $A_\lambda = \lambda (L + \lambda\mu)^{-1} (M + \mu)$. The following result then holds.

LEMMA 2.1. *Let $r(A_\lambda)$ denote the spectral radius of A_λ. Then the mapping $\lambda \to r(A_\lambda)$ is continuous on $(0, \infty)$ with $\lim_{\lambda \to 0^+} r(A_\lambda) = 0$.*

Proof. The map A_λ depends continuously on λ in the strong operator topology. Since the family $\{A_\lambda\}$ is a compact family, it follows from a result of Nussbaum [13] that the map $\lambda \to r(A_\lambda)$ is continuous.

LEMMA 2.2. *Assume $m_{kk}^+ \neq 0$ for some $k \in \{1, \cdots, r\}$. Then there exists $\lambda > 0$ such that $r(A_\lambda) \geqq 1$.*

Proof. According to Hess–Kato [12], there exists $\lambda > 0$ and $u_k \in C_0^0(\bar{\Omega}, \mathbb{R})$, $u_k(x) > 0$, $x \in \Omega$ such that

$$L_k u_k = \lambda m_{kk} u_k.$$

Letting $u=\operatorname{col}(0,\cdots,u_k,0,\cdots,0)$ one gets $Lu\leqq\lambda Mu$. Thus $(L+\lambda\mu)u\leqq\lambda(M+\mu)u$. Hence for this value of λ

$$u\leqq\lambda(L+\lambda\mu)^{-1}(M+\mu)u,$$

i.e. $u\leqq A_\lambda u$.

Iterating this inequality, we get $u\leqq A_\lambda^n u$, and since the C_0^0 norm is monotone with respect to the cone K, we get

$$|u|\leqq|A_\lambda^n||u|.$$

Hence $1\leqq|A_\lambda^n|^{1/n}$. Thus $r(A_\lambda)\geqq 1$.

THEOREM 2.3. *Let $m_{kk}^+\neq 0$ for some $k\in\{1,2,\cdots,r\}$. Then there exists a smallest $\bar\lambda>0$ and $u\in K\setminus\{0\}$ such that*

$$u=A_{\bar\lambda}u,$$

i.e. $Lu=\bar\lambda Mu$.

Proof. Since $r(A_\lambda)$ is continuous and $r(A_\lambda)\to 0$ as $\lambda\to 0$ and since by Lemma 2.2, there exists λ such that $r(A_\lambda)\geqq 1$, it follows that there exists a smallest $\bar\lambda$ such that

$$r(A_{\bar\lambda})=1.$$

Since $A_{\bar\lambda}$ is positive and compact and K is total one may employ the theorem of Krein–Rutman (see [2]) to conclude that there exists $u\in K\setminus\{0\}$ such that

$$u=r(A_{\bar\lambda})u=A_{\bar\lambda}u,$$

i.e., $Lu=\bar\lambda Mu$.

COROLLARY 2.4. *If $\lambda>0$ is any other characteristic value, then $\lambda\geqq\bar\lambda$.*

Proof. Let λ be a characteristic value. Then there is $u\neq 0$ such that $u=A_\lambda u$. Iterating, one obtains $u=A_\lambda^n u$. Hence $1\leqq|A_\lambda^n|^{1/n}$, implying that $r(A_\lambda)\geqq 1$. The result then follows from the proof of Theorem 2.3.

Now consider (1.3). Assume that $(\lambda_1,\cdots,\lambda_r)$ is restricted to a ray emanating from the origin of $\mathbb{R}^r$ into the positive cone. Theorem 2.3 then obtains in most cases. To see this, observe that if $(\lambda_1,\cdots,\lambda_r)$ is as restricted, (1.3) is equivalent to

$$Lu=t\tilde M u, \tag{2.4}$$

where

$$\tilde M=\begin{bmatrix}\lambda_1^0 & & \\ & \ddots & \\ & & \lambda_r^0\end{bmatrix}M,\qquad t\in I,$$

$\lambda_1^0\geqq 0$ and $(\lambda_1^0)^2+\cdots+(\lambda_r^0)=1$. The result follows provided $\tilde m_{kk}^+=\lambda_k^0 m_{kk}^+\neq 0$ for some $k\in\{1,2,\cdots,r\}$.

Suppose now that $\lambda=(\lambda_1,\cdots,\lambda_r)$ is such that $\lambda_i\geqq 0$ and $|\lambda|^2>0$. Define

$$A_\lambda=|\lambda|^2\left(L+|\lambda|^2\mu\right)^{-1}(\tilde M+\mu)$$

with

$$\tilde M=\frac{1}{|\lambda|^2}\begin{bmatrix}\lambda_1 & & \\ & \ddots & \\ & & \lambda_r\end{bmatrix}M.$$

If $|\lambda^0|^2=1$, and $\lambda_i^0>0$, $i=1,\cdots,r$, we define $F(\lambda^0)=\bar{t}(\lambda^0)$, where $\bar{t}>0$ is the smallest number such that $r(A_{\bar{t}\lambda^0})=1$. There are a number of conditions under which the function F is continuous. In particular, we have the following result.

THEOREM 2.5. *F is continuous at $\lambda^0\in(\mathbb{R}_+)^r\cap S^{r-1}$ provided any one of the following conditions holds*:

i) *$m_{ij}\geqq 0$ for $i,j=1,\cdots,k$.*

ii) *If $F(\lambda^0)=\bar{t}\lambda^0$, then $\bar{t}$ is the only positive number t such that $u=A_{t\lambda^0}u$ has a nontrivial solution $u\in K$.*

Proof. In case (i), $r(A_{t\lambda^0})$ is a nondecreasing function of t, $t\geqq 0$. The result follows from an application of a result of Nussbaum [13]. In case (ii), one uses a simple compactness argument.

3. Coupling and multiplicity. In this section we investigate the question of uniqueness and multiplicity of the characteristic values of (1.1). We begin with the following lemma.

LEMMA 3.1. *Suppose $\mu\geqq 0$ is chosen so that all entries of the matrix $M+\mu$ are nonnegative and that there exists $x_0\in\Omega$ such that $(M+\mu)(x_0)$ is irreducible. Then if $Lu=\lambda Mu$ and $u\in K\setminus\{0\}$, then in fact $u\in\operatorname{int}K$ (where* int *is with respect to the $C^1(\bar{\Omega})$ topology).*

Proof. Since $Lu=\lambda Mu$ we have that

$$(L+\lambda\mu)u=\lambda(M+\mu)u,$$

and componentwise

$$(L_i+\lambda\mu)u_i=\lambda\sum_{j=1}^{r}(m_{ij}+\mu\delta_{ij})u_j\geqq 0.$$

It then follows from the Hopf maximum principle that for each $i\in\{1,\cdots,r\}$, either $u_i\equiv 0$ on $\bar{\Omega}$ or $u_i(x)>0$, for all $x\in\Omega$.

Since $u\in K\setminus\{0\}$, there must be at least one $i_0\in\{1,\cdots,r\}$ such that $u_{i_0}(x)>0$ on Ω. If there is no other such i, $(M+\mu)(x_0)$ has a one-dimensional invariant subspace, contradicting the assumption of irreducibility. Hence there is $i_1\in\{1,\cdots,r\}$, $i_1\neq i_0$ such that $u_{i_1}(x)>0$ on Ω. If i_0 and i_1 are the only such, then $(M+\mu)(x_0)$ has a two-dimensional invariant subspace, again a contradiction. Iterating this argument now guarantees $u_i(x)>0$ on Ω for $i=1,\cdots,r$. It further follows from [10, Lemma 3.4] that $\partial u_i/\partial\nu$ is negative on $\partial\Omega$ for each i, proving the result.

THEOREM 3.2. *Suppose there are $\mu\geqq 0$ and $x_0\in\Omega$ such that $(M+\mu)(x_0)$ is irreducible. Then if $\bar{\lambda}$ is as in Theorem* 2.3, *$\bar{\lambda}$ is a geometrically simple eigenvalue.*

Proof. Suppose u and v are nontrivial solutions of (1.1) with $u\in K$. Lemma 3.1 implies $u\in\operatorname{int}K$. Hence for small δ, $u-\delta v\in\operatorname{int}K$. Let $\delta^*=\sup\{\delta>0\colon u-\delta v\in\operatorname{int}K\}$, $\delta_*=\inf\{\delta<0\colon u-\delta v\in\operatorname{int}K\}$. Since $v\neq 0$ at least one of δ^* or δ_* must be finite. With no loss of generality, assume $\delta^*<\infty$. Then $u-\delta^*v\in\partial K$. Lemma 3.1 implies $u\equiv\delta^*v$.

LEMMA 3.3. *Suppose there are $\mu\geqq 0$ and $x_0\in\Omega$ such that $(M+\mu)(x_0)$ is irreducible. Then if $\bar{\lambda}$ is as in Theorem* 2.3, *$(I-A_{\bar{\lambda}})^2z=0$ implies $(I-A_{\bar{\lambda}})z=0$.*

Proof. Suppose $(I-A_{\bar{\lambda}})^2z=0$. Then Theorem 3.2 implies that $(I-A_{\bar{\lambda}})z=cu$, where $u=A_{\bar{\lambda}}u$. Let $A_{\bar{\lambda}}^*$ denote the Banach space adjoint of $A_{\bar{\lambda}}$ considered in $C_0(\bar{\Omega},\mathbb{R}^r)$. The Krein–Rutman theorem implies there is a continuous linear functional f^* (with $f^*(K)\subset[0,\infty]$ and $f^*(\operatorname{int}K)\subset(0,\infty)$) such that $A_{\bar{\lambda}}^*f^*=f^*$. Hence

$$f^*z-f^*A_{\bar{\lambda}}z=cf^*(u)$$

which implies $0=cf^*(u)$. Hence, since $u\in\operatorname{int}K$, $c=0$.

THEOREM 3.4. *Suppose* $m_{ii} \geqq 0$ *for* $i = 1, \cdots, r$. *Then if* $M(x_0)$ *is irreducible for some* $x_0 \in \Omega$ *and* $\bar{\lambda}$ *is as in Theorem* 2.3, $\bar{\lambda}$ *is an algebraically simple eigenvalue and the only positive eigenvalue admitting a solution* u, *where* $u \in K$.

Proof. That $\bar{\lambda}$ is an algebraically simple eigenvalue is a consequence of Lemma 3.3. Suppose now $\lambda' > \bar{\lambda}$ is such that $v = \lambda' L^{-1} M v$, with $v \in K$. Then Lemma 3.1 implies $v \in \operatorname{int} K$. Furthermore, since $r(A_\lambda)$ is a strictly increasing function of λ, $r(A_{\lambda'}) > 1$. The Krein–Rutman theorem implies the existence of $\tilde{v} \in K \setminus \{0\}$ such that $r(A_{\lambda'})\tilde{v} = A_{\lambda'}\tilde{v}$. Applying Lemma 3.1 to the equation

$$L\tilde{v} = \frac{\lambda'}{r(A_{\lambda'})} M\tilde{v},$$

we conclude that in fact $\tilde{v} \in \operatorname{int} K$. For $\delta > 0$ and sufficiently small, $v - \delta\tilde{v} \in \operatorname{int} K$. Let $\delta^* = \sup\{\delta > 0 \colon v - \delta\tilde{v} \in \operatorname{int} K\}$. Since $\tilde{v} \in \operatorname{int} K$, $\delta^* < \infty$ and $v - \delta^*\tilde{v} \in K$, i.e., $\delta^*\tilde{v} \leqq v$. Hence $\delta^* r(A_{\lambda'})\tilde{v} = \delta^* A_{\lambda'} v \leqq A_{\lambda'} v = v$. It follows that $\delta^* r(A_{\lambda'}) \leqq \delta^*$, and so $r(A_{\lambda'}) \leqq 1$, a contradiction.

We do not know in general whether Theorem 3.4 remains valid if the assumption $m_{ii} \geqq 0$ for $i = 1, \cdots, r$ is removed. However, with some additional restrictions on the system (1.1), the theorem remains valid. As we shall see, the restrictions are substantial. Nevertheless, the result is quite useful from the point of view of applications to nonlinear analysis. Before stating the result, we give two lemmas which will be needed in the proof.

LEMMA 3.5. *Suppose that* $m_{ij}(x) \leqq 1/r$, $i \neq j$, *and that* $-1 \leqq m_{ii} \leqq -1 + 1/r$ *for* $j, i = 1, \cdots, r$. *Then there is no positive eigenvalue for* (1.1) *admitting a solution in* $K \setminus \{0\}$.

Proof. The result follows from an application of the maximum principle. See [14, pp. 188–192].

LEMMA 3.6. *Let* $m_{ii} + 1 > 0$ *for* $i = 1, \cdots, r$, *let* $M + I$ *be irreducible, and assume there is* $\lambda > 0$ *and* $u \in K \setminus \{0\}$ *such that* $Lu = \lambda Mu$. *Then* $N((I - \lambda L^{-1}M)^2) = N(I - \lambda L^{-1}M) = \langle u \rangle$, *whenever* $L^{-1}M = ML^{-1}$.

Proof. That $N(I - \lambda L^{-1}M) = \langle u \rangle$ follows from the fact that $u \in \operatorname{int} K$ (see Lemma 3.1). Consider $\lambda(L + \lambda)^{-1}(M + 1)$. By the proof of Theorem 3.4, $r(\lambda(L + \lambda)^{-1}(M + 1)) = 1$. If A_λ^* denotes the Banach space adjoint of $\lambda(L + \lambda)^{-1}(M + 1)$, the Krein–Rutman theorem guarantees the existence of continuous linear functional f^* such that $A_\lambda^* f^* = f^*$ and such that $f^*(\operatorname{int} K) \subset (0, \infty)$.

Suppose $(L - \lambda M)^2 x = 0$. Then $Lx - \lambda Mx = cu$, for some $c \in \mathbb{R}$. Hence $(L + \lambda)x - \lambda(M + 1)x = cu$, or equivalently, $x - \lambda(L + \lambda)^{-1}(M + 1)x = c(L + \lambda)^{-1}u$. It follows that $f^*x - f^*(\lambda(L + \lambda)^{-1}(M + 1)x) = cf^*((L + \lambda)^{-1}u)$. Now $f^*(\lambda(L + \lambda)^{-1}(M + 1)x) = (A_\lambda^* f^*)x = f^*x$. So $0 = cf^*((L + \lambda)^{-1}u)$. Since $u \in \operatorname{int} K$, $c = 0$.

Finally, if $L^{-1}M = ML^{-1}$ and $(I - \lambda L^{-1}M)^2 x = 0$, then a simple computation shows $(L - \lambda M)^2 x = 0$. Hence $(L - \lambda M)x = 0$, or equivalently, $(I - \lambda L^{-1}M)x = 0$.

Remark 3.7. We note that in Lemma 3.6 that we do not need $m_{ii} > 0$ for some $i \in \{1, 2, \cdots, r\}$.

THEOREM 3.8. *Suppose that the conditions of Theorem* 2.3 *are satisfied. In addition, assume*

(i) $m_{ij} \leqq 1/r$, *if* $i \neq j$;

(ii) $-1/2r < m_{ii} < 1/2r$, *for* $i = 1, \cdots, r$.

If $L^{-1}M = ML^{-1}$, $(M + I)$ *is irreducible, and if* $\bar{\lambda}$ *is as in Theorem* 2.3, *then* $\bar{\lambda}$ *is a simple eigenvalue for* (1.1) *and the only positive eigenvalue admitting a solution* u, *with* $u \in K \setminus \{0\}$.

Remark 3.9. (a) Since (1.1) may be rescaled, conditions (i) and (ii) above are restrictions only on the relative sizes of the diagonal versus off-diagonal terms of the matrix M. The commutativity condition requires that $L_i = L_j$ for $i,j = 1,\cdots,r$, and that M be constant, although M may have negative entries on its main diagonal.

(b) The proof relies on an "unfolding" of the problem in a manner analogous to that employed in [12]. We also obtain partial results in case $(M+I)(x_0)$ is irreducible for some $x_0 \in \Omega$ (dropping the commutativity assumption).

Proof of Theorem 3.8. Assume initially only that M satisfies conditions (i) and (ii) of the hypotheses and that $(M+I)(x_0)$ is irreducible for some $x_0 \in \Omega$. Let $\lambda > 0$ and $t \in \mathbb{R}$ and define $A_{\lambda,t}$ by

$$A_{\lambda,t} = \lambda(L+\lambda)^{-1}(M-t+1).$$

We first observe that there is $t^* \in (0, 1-1/2r)$ such that $A_{\lambda,t}$ is a positive operator for $\lambda > 0$ and $t \leq t^*$ and that the equation

$$u = A_{\lambda,t}u \tag{3.1}$$

has no solution with $\lambda > 0$, $t = t^*$, and $u \in K\setminus\{0\}$. To see that this is the case, consider

$$-\frac{1}{2r} < \min_{x\in\bar{\Omega}} m_{ii}(x) \leqq \max_{x\in\bar{\Omega}} m_{ii}(x) < \frac{1}{2r}$$

for some $i \in \{1,2,\cdots,r\}$. It follows that if $0 < t < 1-1/2r$, then $\min_{x\in\bar{\Omega}} m_{ii}(x) - t > -1$, and that if $t > \max_{x\in\bar{\Omega}} m_{ii}(x) + 1 - \frac{1}{r}$, then $\max_{x\in\bar{\Omega}} -m_{ii}(x) - t \leqq -1 + 1/r$. Since

$$\max_{x\in\bar{\Omega}} m_{ii}(x) + 1 - \frac{1}{r} < \frac{1}{2r} + 1 - \frac{1}{r} = 1 - \frac{1}{2r},$$

our observation follows from Lemma 3.5.

Next observe that if $t \leqq 0$, Theorem 2.3 implies that there exists a smallest positive number $\bar{\lambda}(t)$ such that (3.1) has a solution $u \in K\setminus\{0\}$. If $t = t^*$, no such number exists. We now define a function $f\colon (-\infty, t^*] \to [0,\infty)$ by

$$f(t) = \begin{cases} 1/\bar{\lambda}(t) & \text{provided } \bar{\lambda}(t) \text{ exists,} \\ 0 & \text{otherwise.} \end{cases}$$

Suppose now $t < t' \leqq t^*$ and there exists $\lambda(t') > 0$ and $u \in K\setminus\{0\}$ such that

$$u = \lambda(t')\big(L+\lambda(t')\big)^{-1}(M-t'+1)u.$$

Since $0 < m_{ii} - t' + 1 < m_{ii} - t + 1$ for $i = 1,\cdots,r$, we have

$$u \leqq \lambda(t')\big(L+\lambda(t')\big)^{-1}(M-t+1)u.$$

It follows that $\bar{\lambda}(t)$ exists and $\bar{\lambda}(t) \leqq \bar{\lambda}(t')$. Furthermore, if $f(t') = 0$, $f(t) = 0$ for $t \in [t', t^*]$. Hence f is a monotonic nonincreasing function and, as such, can have at most a countable number of discontinuities.

Suppose now that $\lambda_0 > 0$, $t_0 < t^*$, and $u \in K\setminus\{0\}$ such that

$$u = \lambda_0(L+\lambda_0)^{-1}(M-t_0+1)u.$$

Lemma 3.1 implies that $u \in \operatorname{int} K$. It follows from Lemma 3.3 that 1 is a simple eigenvalue of $\lambda_0(L+\lambda_0)^{-1}(M-t_0+1)$ and that $r(\lambda_0(L+\lambda_0)^{-1}(M-t_0-1)) = 1$. Since $r(\lambda(L+\lambda)^{-1}(M-t+1))$ depends continuously on λ and t, a perturbation theory

argument will show that if $\alpha(\lambda,t)=r(\lambda(L+\lambda)^{-1}(M-t+1))$, α is an analytic function of (λ,t) in a neighborhood of(λ_0,t_0). Furthermore, one may choose an eigenfunction $u(\lambda,t)$ corresponding to $\alpha(\lambda,t)$ so that $u(\lambda,t)$ is analytic in (λ,t) also. (The perturbation theory argument necessary can be adapted from [17, pp. 57–64]. We note only that the simplicity of the eigenvalue 1 of $\lambda_0(L+\lambda_0)^{-1}(M-t_0+1)$ is essential to the argument.) Let us now consider the equation

$$\alpha u=\lambda(L+\lambda)^{-1}(M-t+1)u. \tag{3.2}$$

Differentiating (3.2) with respect to t and evaluating at (λ_0,t_0) we obtain

$$\begin{aligned}&\alpha_t(\lambda_0,t_0)u(\lambda_0,t_0)+u_t(\lambda_0,t_0)\\&\quad=\lambda_0(L+\lambda_0)^{-1}(M-t_0+1)u_t(\lambda_0,t_0)-\lambda_0(L+\lambda_0)^{-1}u(\lambda_0,t_0).\end{aligned} \tag{3.3}$$

Let $A^*_{\lambda_0,t_0}$ be the Banach space adjoint of A_{λ_0,t_0}. The Krein–Rutman Theorem implies that there is a continuous linear functional f^* (with $f^*(\operatorname{int}K)\subset(0,\infty)$) such that $f^*A_{\lambda_0,t_0}=A^*_{\lambda_0,t_0}f^*=f^*$. Applying f^* to (3.3) yields

$$\alpha_t(\lambda_0,t_0)f^*(u(\lambda_0,t_0))=-\lambda_0 f^*\left[(L+\lambda_0)^{-1}u(\lambda_0,t_0)\right]. \tag{3.4}$$

Since $u(\lambda_0,t_0)\in\operatorname{int}K$, $\alpha_t(\lambda_0,t_0)\neq 0$. The Implicit Function Theorem implies the existence of $\delta>0$ and a smooth function g: $(\lambda_0-\delta,\lambda_0+\delta)\to\mathbb{R}$ such that $g(\lambda_0)=t_0$ and $\alpha(\lambda,g(\lambda))=1$.

Since f is nonincreasing, if $t_1<t_2$ and $f(t_1)=f(t_2)>0$, then $f(t)\equiv f(t_1)=1/\bar{\lambda}(t_1)$ for $t\in[t_1,t_2]$. So $\alpha(\bar{\lambda}(t_1),t)=1$ for $t\in[t_1,t_2]$ by Lemma 3.3. But for any $t_0\in(t_1,t_2)$, the preceding argument shows that the solution set to $\alpha(\lambda,t)=1$ is expressible as a function of λ in a neighborhood of $(\bar{\lambda}(t_1),t_0)$, a contradiction. Hence f is strictly decreasing so long as it remains positive.

Let $t^{**}\in(0,1-1/2r)$ be given by $t^{**}=\inf\{t\leqq t^*\colon f(t)=0\}$ and also let $\gamma=\lim_{t\to-\infty}f(t)$ and $0\leqq\omega=\inf\{f(t)\colon f(t)>0\}$. Since f is strictly decreasing, it has an inverse h defined from a subset of (ω,γ) into $(-\infty,t^{**})$. We claim that this function h is extendable to a continuous function $\tilde{h}$: $(0,\gamma)\to(-\infty,t^{**})$ such that if $s\in(0,\gamma)$, $\alpha(1/s,\tilde{h}(s))=1$.

Let us now establish this claim. Let $t_0<t^{**}$ and let

$$L_0=\lim_{t\to t_0^-}f(t)\geqq\lim_{t\to t_0^+}f(t)=R_0>0.$$

It follows from [13] that

$$\alpha\left(\frac{1}{L_0},t_0\right)=1\quad\text{and}\quad\alpha\left(\frac{1}{R_0},t_0\right)=1.$$

The minimality of $\bar{\lambda}(t_0)$ implies that $L_0=f(t_0)$. Notice that if $t\leqq-1/2r$, Theorem 3.4 implies that $L_0=R_0$. So if $L_0>R_0$, $t_0\in(-1/2r,t^{**})$. Furthermore, the Implicit Function Theorem may be applied as before at $(1/L_0,t_0)$ and $(1/R_0,t_0)$, giving functions g_1 and g_2 respectively. Notice that: if $\lambda\in[1/L_0,1/R_0]$ and $g_1(\lambda)$ is defined, then Theorem 3.4 and the minimality of $\bar{\lambda}(t)$ for $t>t_0$ implies that $g_1(\lambda)\in[-1/2r,t_0]$, and similarly for $g_2(\lambda)$. By [13], $g_1(\lambda)$ and $g_2(\lambda)$ can be extended on $[1/L_0,1/R_0]$. Since $A_{\tilde{\lambda},t}$ is monotonic in t for fixed $\tilde{\lambda}$, so must $r(A_{\tilde{\lambda},t})$ be. Hence if $g_1(\lambda)\neq g_2(\lambda)$ for some $\lambda\in[1/L_0,1/R_0]$, $\alpha(\lambda,t)=1$ for t between $g_1(\lambda)$ and $g_2(\lambda)$, a contradiction to the Implicit Function Theorem. Hence $\tilde{h}$ may be defined on $[R_0,L_0]$ by $\tilde{h}(s)=g_1(1/s)$.

We have now shown the existence of $\tilde{h}$ on (ω,γ). If $\omega=0$, there is nothing more to do. If $\omega>0$, then $\alpha(1/\omega,t^{**})=1$ and the Implicit Function Theorem guarantees the existence of a g as before with $g(\lambda)\in[-1/2r,t^{**}]$ and $\alpha(\lambda,g(\lambda))=1$. Since $g(\lambda)\in[-1/2r,t^{**}]$, it again follows from the continuity of the spectral radius [13] that g is extendable to $(1/\omega,\infty)$. Defining $\tilde{h}(s)=g(1/s)$ for $s\in(0,\omega)$ completes the verification of the claim.

Now assume that $L^{-1}M=ML^{-1}$. Suppose there is a $t_0\in(-1/2r,t^{**})$ such that $L_0>R_0$. Now $1/L_0=\bar{\lambda}(t_0)<1/R_0<\bar{\lambda}(t)$ for $t>t_0$. Lemma 3.6 implies there exists a $\delta\in(0,1)$ such that the Leray–Schauder indices $\operatorname{ind}_{LS}(I-(1+\delta)\bar{\lambda}(t_0)L^{-1}(M-t_0))$ and $\operatorname{ind}_{LS}(I-(1-\delta)\bar{\lambda}(t_0)L^{-1}(M-t_0))$ are defined and unequal. We may also assume that $\delta>0$ is sufficiently small so that $((1+\delta)\bar{\lambda}(t_0)<1/R_0$. The homotopy invariance property of the Leray–Schauder degree guarantees that

$$\operatorname{ind}_{LS}\big(I-(1+\delta)\bar{\lambda}(t_0)L^{-1}(M-t)\big)\neq\operatorname{ind}_{LS}\big(I-(1-\delta)\bar{\lambda}(t_0)L^{-1}(M-t)\big)$$

for $t\in(t_0,t_0+\varepsilon)$ for $\varepsilon>0$ and sufficiently small. Hence for $t\in(t_0,t_0+\varepsilon)$ there exist $0<\lambda<\bar{\lambda}(t)$ with $N(I-\lambda L^{-1}(M-t))\neq\{0\}$, a contradiction. Hence $L_0=R_0$ and so f is continuous on $(-\infty,t^{**})$. A similar argument gives $\lim_{t\to t^{**}}f(t)=0$ in this case.

The uniqueness assertion of the theorem is now evident from the Implicit Function Theorem and the monotonicity of $r(A_{\lambda,t})$ in t.

COROLLARY 3.10. *Suppose M satisfies* (i) *and* (ii) *of Theorem* 3.8 *and $(M+I)(x_0)$ is irreducible for some $x_0\in\Omega$. Then if $\tilde{h}$, $A_{\lambda,t}$, and γ are as in the proof of Theorem* 3.8, *then the set* $\{(\lambda,t)\in(0,\infty)\times(-\infty,t^{**}]\colon u=A_{\lambda,t}u \text{ for some } u\in K\setminus\{0\}\}=\{(\lambda,h(\frac{1}{\lambda}))\colon \lambda\in(\frac{1}{\gamma},\infty)\}$.

The requirement that $(M+\mu)(x_0)$ be irreducible for some $x_0\in\Omega$ represents a rather strong coupling in the equations of the system. The other extreme is an uncoupled system, i.e. $m_{ij}\equiv 0$ on Ω if $i\neq j$. Both, however, may be viewed as special cases of the following.

Condition 3.11. There is a finite sequence of row and column interchanges under which M is equivalent to a matrix of the form

$$\begin{bmatrix} M_1 & & \\ & \ddots & \\ & & M_l \end{bmatrix} \tag{3.5}$$

where M_i is an $r_i\times r_i$ matrix, with $r_1+\cdots+r_l=r$. Furthermore, (2.1) is equivalent (under an appropriate relabelling of the u_i's) to the collection of systems

$$L_iv_i=\lambda M_iv_i,\quad i=1,\cdots,l \tag{3.6}$$

where

$$v_i=\begin{bmatrix} w_1 \\ \vdots \\ w_{r_i} \end{bmatrix}$$

has the property that $v_i\in\partial K_i$ and v_i a solution of (3.6) implies $v_i\equiv 0$.

As is evident, not all systems of the form (1.1) satisfy Condition 3.11. However, there are sufficient conditions other than the above special cases under which Condition 3.11 holds. We will not dwell on these here.

Suppose now Condition 3.11 is satisfied. Let k_i, $i=1,\cdots,l$ be defined as follows: $k_1=0$, $k_i=\Sigma_{j<i}r_j$, $i=2,\cdots,l$. Then (1.3) can be equivalently expressed as

$$(3.7)\qquad \begin{bmatrix} L_{k_i+1} & & \\ & \ddots & \\ & & L_{k_i+r_i} \end{bmatrix}\begin{bmatrix} u_{k_i+1} \\ \vdots \\ u_{k_i+r_i} \end{bmatrix} = \begin{bmatrix} \lambda_{k_i+1} & & \\ & \ddots & \\ & & \lambda_{k_i+r_i} \end{bmatrix}\begin{bmatrix} m_{k_i+1,k_i+1} & \cdots & m_{k_i+1,k_i+r_i} \\ \vdots & & \vdots \\ m_{k_i+r_i,k_i+1} & \cdots & m_{k_i+r_i,k_i+r_i} \end{bmatrix}\begin{bmatrix} u_{k_i+1} \\ \vdots \\ u_{k_i+r_i} \end{bmatrix},$$

$i=1,\cdots,l$. Let F_i denote the function of Theorem 2.5 relative to (3.6) (i). We have the following result, which is similar in spirit to the results of [6].

THEOREM 3.12. *Suppose Condition* 3.11 *holds and that for each* $i=1,\cdots,l$, *there exists* $d(i)\in\{1,\cdots,r_i\}$ *such that* $(m_{k_i+d(i),k_i+d(i)})^+\neq 0$. *Assume also that* (ii) *of Theorem* 2.5 *holds for* $\{(\lambda_{k_{i+1}},\cdots,\lambda_{k_i+r_i})\in\mathbb{R}^{r_i}_+\colon |(\lambda_{k_{i+1}},\cdots,\lambda_{k_i+r_i})|=1\}$. *Then the set* $\{(\lambda_1,\cdots,\lambda_r)\in\mathbb{R}^r_+\colon$ (3.6) *has nontrivial solution in* $K\}=\cup_{i=1}^{l}T_i$, *where* $T_i=(\mathbb{R}_+)^{k_i}\times \operatorname{im}(F_i)\times(\mathbb{R}_+)^{r-(k_i+r_i)}$. *Furthermore, the geometric multiplicity of* $(\lambda_1,\cdots,\lambda_r)$ *is precisely the number of sets* T_i *of which* $(\lambda_1,\cdots,\lambda_r)$ *is a member.*

Proof. The result follows easily from Theorem 2.5, the results of §3, and the definition of Condition 3.11.

We conclude this section with a brief examination of the system

$$(3.8)\qquad L_1u=\lambda(u+v),\qquad L_2v=\lambda v.$$

(3.8) is a typical example of a system for which Condition 3.11 fails to hold. Multiplicity results for more general upper-triangular nonsymmetric matrices M may be obtained in a manner analogous to that which follows. To this end, consider

$$(3.9)\qquad L_1u=\lambda(u+v),\qquad L_2v=\mu v.$$

Let λ_1 and λ_2 represent the first eigenvalues for L_1 and L_2, respectively. If (3.8) has a nontrivial cone solution, either $v\equiv 0$ or $\mu=\lambda_2$. In the first case, $\lambda=\lambda_1$. If $\mu=\lambda_2$, however, it follows from the results of [12] that a nontrivial solution $\binom{u}{v}$ with $u>0$ and $v>0$ (note that $u=0$ implies $v=0$) is possible only in case $\lambda<\lambda_1$. In particular, it follows that if $\lambda_1=\lambda_2$, then $\lambda=\lambda_1=\lambda_2$ is a characteristic value of (3.8) which is geometrically but not algebraically simple.

4. Bifurcation results. In [11], Hess combined the result of Theorem 2.3 with the methods of [3] to obtain a bifurcation result for the nonlinear eigenvalue problem

$$(4.1)\qquad Lu=\lambda A(u).$$

Here $A\colon K\to C_0(\bar{\Omega};\mathbb{R}^r)$ is the Nemytskii operator associated with a continuous function $a\colon \bar{\Omega}\times\overline{(\mathbb{R}^+)^r}\to\mathbb{R}^r$. He assumed that a satisfies the following conditions:

$$(4.2)\qquad a(x,0)=0,\qquad x\in\bar{\Omega}.$$

(4.3) There exists an $r\times r$ matrix m of functions $m_{kl}\in C(\bar{\Omega};\mathbb{R})$ such that

$$a(x,\sigma)=m(x)\sigma+o(|\sigma|)$$

as $|\sigma|\to 0$, $\sigma\in(\mathbb{R}^+)^r$ (uniformly for $x\in\bar{\Omega}$).

(4.4) There exists a number $\alpha \geqq 0$ such that

$$a(x,\sigma) \geqq -\alpha\sigma$$

for $(x,\sigma) \in \bar{\Omega} \times (\mathbb{R}^+)^r$.

Under the above conditions, Hess showed that if $\Sigma^+ = \{(\lambda,u) \in \mathbb{R} \times C_0^0(\bar{\Omega},\mathbb{R}^r)$: $\lambda > 0$, $u \in K$, $Lu = \lambda A(u)\}$, Σ^+ contains an unbounded component Σ_0 emanating from $(\lambda^*,0)$, where $\lambda^* \geqq \bar{\lambda}$ ($\bar{\lambda}$ as in Theorem 2.3). He also identified certain cases when $\lambda^* = \bar{\lambda}$ (namely $m_{kl} \geqq 0$ for k, $l = 1,\cdots,r$ or $m_{kl} \equiv 0$ if $k \neq l$).

Our results show that if $(M+\mu)(x_0)$ is irreducible for some $x_0 \in \Omega$, then, at least locally, if $(\lambda,u) \in \Sigma_0$ and $u \neq 0$, then $u \in \operatorname{int} K$. Furthermore, if a is independent of x and $L_i = L_j$ for $i,j = 1,\cdots,r$, Theorem 3.8 implies that also in this case $\lambda^* = \bar{\lambda}$.

We now establish some results on the multidimensionality of the nontrivial bifurcating solutions for nonlinear analogues of (1.3). The principal techniques for establishing such are the theorems of Alexander and Antman [1] and Fitzpatrick, Massabo, and Pejsachowitz [9]. Both results require that one work in an open subset of $\mathbb{R}^r \times E$, E an appropriate Banach space. (In this case, $[C_0^{1,\alpha}(\bar{\Omega},\mathbb{R})]^r$ is suitable, where $0 < \alpha < 1$, provided the coefficients of L_k and the m_{kl} are in $C^\alpha(\bar{\Omega},\mathbb{R})$. A precise definition of the spaces is found in [10].) A formulation based on [3] is not immediate. We therefore consider

$$Lu = \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_r \end{bmatrix} Mu + H(\lambda_1,\cdots,\lambda_r,u), \tag{4.5}$$

where H: $R^r \times R^r \to R^r$ is continuous, cone-preserving and $H(\lambda_1,\cdots,\lambda_r,w_1,\cdots,w_r) = o(|(w_1,\cdots,w_r)|)$ (uniformly for $(\lambda_1,\cdots,\lambda_r)$ in compact subsets of R^r). It follows from [5] that the techniques of [1] are applicable to (4.5) provided $(\lambda_1,\cdots,\lambda_r)$ is an algebraically simple characteristic value of (1.3).

THEOREM 4.1. *Suppose there is $k \in \{1,\cdots,r\}$ such that $m_{kk}^+ \neq 0$ and that for $\mu \geqq 0$ and sufficiently large $(M+\mu)(x_0)$ is nonnegative irreducible for some $x_0 \in \Omega$. (If $\mu \geqq 0$ is required, assume that the conditions of Theorem* 3.8 *also hold.) Suppose that $H(\lambda_1,\cdots,\lambda_r,-u) = -H(\lambda_1,\cdots,\lambda_r,u)$ and that F is as in Theorem* 2.5. *Then there emanates from $\operatorname{im} F \times \{0\} \cap (\mathbb{R}_+)^r \times E$ a connected set S of solutions to* (4.5) *such that*

(i) $(\lambda_1,\cdots,\lambda_r,u) \in S$ *implies either* $u \in \operatorname{int}$ *or* $(\lambda_1,\cdots,\lambda_r,u) \in \operatorname{im} F \times \{0\}$;

(ii) $S \setminus (\operatorname{im} F \times \{0\})$ *is of topological dimension at least r at every point.*

Remark 4.2. (i) For a precise definition of topology dimension, see [1] and its references.

(ii) If $(\lambda_1,\cdots,\lambda_r)$ is restricted to a ray emanating from the origin of $\mathbb{R}^r$, the global bifurcation alternatives of Rabinowitz [15] hold. (See also [9].) It then follows that S is unbounded in the sense that $S \cap \partial((\mathbb{R}_+)^r \times C_0(\bar{\Omega},\mathbb{R}^r)) \neq \varnothing$.

(iii) The oddness condition on H is a representative condition guaranteeing the existence of "small" positive solutions. Certainly, other such conditions are possible.

COROLLARY 4.3. *Suppose Condition* 3.11 *holds with $l > 1$. Consider* (4.5) *and assume H of* (4.5) *has the form*

$$H(\lambda_1,\cdots,\lambda_r,u_1,\cdots,u_r) = \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_r \end{bmatrix} \tilde{H}(u_1,\cdots,u_r).$$

Consider the problem

$$(4.6)\qquad \begin{bmatrix} L_1 & & \\ & \ddots & \\ & & L_{r_1} \end{bmatrix} \begin{bmatrix} u_1 \\ \vdots \\ u_{r_1} \end{bmatrix} = \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_{r_1} \end{bmatrix} M_1 \begin{bmatrix} u_1 \\ \vdots \\ u_{r_1} \end{bmatrix} + \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_{r_1} \end{bmatrix} H^*(u_1, \cdots, u_{r_1}),$$

where

$$H^*(u_1, \cdots, u_{r_1}) = \begin{bmatrix} \tilde{H}_1(u_1, \cdots, u_{r_1}, 0, \cdots, 0) \\ \vdots \\ \tilde{H}_{r_1}(u_1, \cdots, u_{r_1}, 0, \cdots, 0) \end{bmatrix}.$$

Suppose that if $(\lambda_1, \cdots, \lambda_{r_1}, u_1, \cdots, u_{r_1})$ *is a solution of* (4.6) *then* $(\lambda_1, \cdots, \lambda_{r_1}, \lambda_{r_1+1}, \cdots, \lambda_r, u_1, \cdots, u_{r_1}, 0, \cdots, 0)$ *is a solution of* (4.5) *for any choice of* $\lambda_{r_1+1}, \cdots, \lambda_r$. *Then if* M_1, H^* *and* F_1 *satisfy the hypotheses of Theorem* 4.1 *with respect to* (4.6), *there emanates from* $[\operatorname{im} F_1 \times (\mathbb{R}^+)^{r-r_1}] \times \{0\} \subset (\mathbb{R}^+)^r \times [C_0^{1,\alpha}(\bar{\Omega}, \mathbb{R})]^{r_1} \times \{0\}$ *a connected set of cone solutions to* (4.5) *such that* $(\lambda_1, \cdots, \lambda_r, u_1, \cdots, u_{r_1}, 0, \cdots, 0) \in S$ *and* $(u_1, \cdots, u_{r_1}) \neq 0$ *implies* $(u_1, \cdots, u_{r_1}) \in \operatorname{int} K_1$. *Furthermore,* $S \setminus ([\operatorname{im} F_1 \times (\mathbb{R}^+)^{r-r_1}] \times \{0\})$ *has a topological dimension at least r at every point.*

Proof. If $(\lambda_{r_1+1}, \cdots, \lambda_r)$ are considered fixed, Theorem 4.1 guarantees the existence of a set $\tilde{S}$ of solutions to (4.6) as above with topological dimension at least r_i. Then $S = \tilde{S} \times (\mathbb{R}^+)^{r-r_1}$.

Corollary 4.3 raises the obvious question: do there exist other "small" positive solutions with $(u_{r_1+1}, \cdots, u_r$ not identically zero) bifurcating from $[\operatorname{im} F_1 \times (\mathbb{R}^+)^{r-r_1}] \times \{0\}$? The answer is no, provided $(\lambda_1, \cdots, \lambda_r)$ is algebraically simple (with respect to all of M) and H is sufficiently well behaved. More precisely, we have the following result.

COROLLARY 4.4. *Suppose* $(\lambda_1, \cdots, \lambda_r) \in \operatorname{im} F_1 \times (\mathbb{R}^+)^{r-r_1}$ *is as in Corollary* 4.3 *and that*

$$\dim N\left[I - \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_r \end{bmatrix} L^{-1}M\right] = \dim N\left[\left(I - \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_r \end{bmatrix} L^{-1}M\right)^2\right] = 1.$$

Suppose also that there exists a continuous monotonic function $G\colon \mathbb{R}^+ \to \mathbb{R}^+$ *such that* $G(0) = 0$ *and for all* $v, w \in E = [C_0^{1,\alpha}(\bar{\Omega}, \mathbb{R})]^r$

$$\|\tilde{H}(v_1, \cdots, v_r) - \tilde{H}(w_1, \cdots, w_r)\|_E \leqq G\big(\|(v_1, \cdots, v_r)\|_E + \|(w_1, \cdots, w_r)\|_E\big)\|(v_1, \cdots, v_r) - (w_1, \cdots, w_r)\|_E.$$

Then near $(\lambda_1, \cdots, \lambda_r, 0, \cdots, 0)$ *in* $(\mathbb{R}^+)^r \times E$, *the solution set of* (4.5) *is as described by Corollary* 4.3.

Proof. The result follows from the generalization [1, Thm. 3.12] to several parameters of the global bifurcation theorem of Rabinowitz [16, Thm. 1.19].

We conclude this article by demonstrating the applicability of Corollaries 4.3 and 4.4 to the question of stable coexistence states in the Volterra–Lotka competition model with diffusion, recently studied by Cosner and Lazer [8], among others. The model in question is as follows:

$$\begin{aligned} -\Delta u &= au - bu^2 - cuv, \\ -\Delta v &= dv - euv - fv^2, \end{aligned} \tag{4.7}$$

with $u(x)$ and $v(x)$ the population densities of the competing species at $x \in \Omega$, an open bounded smooth domain in $\mathbb{R}^n$, subject to $u \equiv 0 \equiv v$ on $\partial\Omega$. a and d, b and f and c and e are assumed to be positive constants, representing growth rates, self-regularization and competition, respectively, with positive diffusion coefficients normalized to 1. The only solutions to (4.7) with physical significance are those with $u \geqq 0$, $v \geqq 0$.

We will now consider (4.7) as a bifurcation problem with a and d acting as parameters and b, c, e, f considered fixed. Let λ_1 be the first eigenvalue of $-\Delta$ (relative to Ω and zero boundary conditions). Then if F_1 and F_2 are as in Theorem 3.8 relative to

$$-\Delta u = au, \qquad -\Delta v = bv, \tag{4.8}$$

then $\operatorname{im}(F_1) \times R = \{(a,d)\colon a = \lambda_1\}$ and $R \times \operatorname{im}(F_2) = \{(a,d)\colon d = \lambda_1\}$.

Consider the problem

$$\begin{aligned} -\Delta u &= au - bu^2 \quad \text{in } \Omega, \\ u &\equiv 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{4.9}$$

As noted in [8], (4.9) has a unique positive solution for all $a > \lambda_1$. In fact, one may realize these positive solutions as one of the two branches guaranteed by [16, Thm. 1.19]. To see this, note that the nonlinearity in the problem

$$\begin{aligned} -\Delta u &= au - bu|u|, \quad \text{in } \Omega, \\ u &\equiv 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{4.10}$$

is odd. Since the eigenfunction corresponding to λ_1 is of one sign and since $f(x) = x|x|$ is continuously differentiable at $x = 0$, a positive branch for (4.10) is guaranteed at least locally. This branch coincides with solutions to (4.9). One may then use the uniqueness of the positive solutions, upper and lower solution techniques, the maximum principle, and global Rabinowitz bifurcation theory [15] to guarantee the continuation of the branch. Corollary 4.3 and Corollary 4.4 may now be applied. As a result, the only cone solution to (4.7) possible in a sufficiently small neighborhood of $(\lambda_1, d, 0, 0)$, $d \neq \lambda_1$, or of $(a, \lambda_1, 0, 0)$, $a \neq \lambda_1$, are of the form $(a, d, u, 0)$ or $(a, d, 0, v)$, respectively. Thus $a > \lambda_1$, $d > \lambda_1$ does not give a sufficient condition for stable coexistence states if $a \neq d$. This result strongly suggests stable coexistence states should be in general viewed as a secondary bifurcation phenomenon, as is the case in [4] and [7].

Note. It has been observed by one of the referees for this paper that the use of irreducibility in Lemma 3.1 is similar to that in the paper, G. J. Habeitler and M. A. Martino, *Existence theorems and spectral theory for the multigroup diffusion model*, Proc. Symposia in Applied Mathematics XI. Nuclear Reactor Theory, American Mathematical Society, Providence, RI, 1961, pp. 127–139.

A DENSITY DEPENDENT DIFFUSION EQUATION IN POPULATION DYNAMICS: STABILIZATION TO EQUILIBRIUM*

M. BERTSCH† AND D. HILHORST‡

Abstract. We study an evolution problem corresponding to the nonlinear diffusion equation $u_t = \Delta\varphi(u) + \operatorname{div}(u \operatorname{grad} v)$ with no flux boundary conditions. This problem has a continuum of stationary solutions. We prove the existence and uniqueness of the solution of the evolution problem and construct a Lyapunov functional in order to show that the solution stabilizes as $t \to \infty$.

Key words. nonlinear degenerate diffusion equation, large time behavior, Lyapunov functional, population dynamics

AMS(MOS) subject classifications. Primary 35K60, 35K65, 35B40, 34D20

1. Introduction. Let Ω be a bounded domain in $\mathbb{R}^N (N \geqq 1)$ with smooth boundary $\partial\Omega$. We consider the nonlinear evolution problem

$$\text{(P)} \qquad \begin{aligned} &u_t = \Delta\varphi(u) + \operatorname{div}(u \operatorname{grad} v) && \text{in } \Omega \times \mathbb{R}^+, \\ &\frac{\partial}{\partial \nu}\varphi(u) + u\frac{\partial v}{\partial \nu} = 0 && \text{on } \partial\Omega \times \mathbb{R}^+, \\ &u(x,0) = u_0(x) && \text{in } \Omega. \end{aligned}$$

Here ν denotes the outward normal at $x \in \partial\Omega$, the function φ is a smooth function such that $\varphi(0)=0$, $\varphi'(s)>0$ for $s>0$ and $\varphi'(0)=0$, the initial function $u_0 \in L^\infty(\Omega)$ is nonnegative and $v \in W^{1,\infty}(\Omega)$ is a given function (for the precise assumptions we refer to §3).

In §2, we show how Problem P arises in the theory of population dynamics in the case that $\varphi(s) = \frac{1}{2}s^2$ and interpret some of our results in terms of the geographical location of two biological populations.

This paper is divided into two main parts. In Part I (§§4–6) we discuss the large time behaviour of the solution of Problem P. In Part II (§§7–9) we collect the basic results about Problem P: existence, uniqueness and regularity of the solution.

In Part I we prove that the solution $u(t; u_0)$ of Problem P stabilizes to equilibrium. Let E denote the set of equilibrium solutions; then there exists a function $q \in E$ such that

$$u(t; u_0) \to q \quad \text{in } C(\bar{\Omega}) \text{ as } t \to \infty$$

where q satisfies

$$\int_\Omega q\,dx = \int_\Omega u_0\,dx.$$

‡Present address: CNRS, Laboratoire d'Analyse Numérique, Université de Paris-Sud, 91405 Orsay, France.

In addition we give a characterization of E: we show that E coincides with the set

$$S = \{ w \in C(\bar{\Omega}) : w \geqq 0 \text{ in } \Omega, \text{ and for every } x \in \Omega \text{ either } w(x) = 0 \text{ or } \Phi(w) + v = \text{constant in a neighbourhood of } x \}. \tag{1.1}$$

Here

$$\Phi(s) = \int_0^s \frac{\varphi'(\tau)}{\tau}\, d\tau, \qquad s \geqq 0. \tag{1.2}$$

The proof of these results is given in §§4 and 5. In §4 we show that solutions of Problem P satisfy a contraction property in $L^1(\Omega)$. In §5 we follow an idea of Osher and Ralston [18] and exploit this contraction property, combined with the structure of the set S, to construct a Lyapunov functional. A remarkable detail of the proof is that we do not study the elliptic problem to prove that $E = S$. Also this fact follows from the contraction property and the structure of the set S.

In §6 we extend the above results to the case when the natural boundary condition is replaced by a homogeneous Dirichlet condition.

In Part II, we show that Problem P has a unique solution in some generalized sense. In §7 we construct a solution $u(t; u_0)$ of Problem P as the limit of solutions of related uniformly parabolic problems. It turns out that the set $\{u(t; u_0); t \geqq 1\}$ is precompact in $C(\bar{\Omega})$, thanks to a regularity result of DiBenedetto [7].

In order to show that the solution of Problem P is unique, we are led to use another sequence of regularized problems, following closely a method of Kalashnikov [12], [13]. This is done in §8.

Finally, in §9, we give the corresponding results about the Dirichlet problem.

Studies concerning the existence and uniqueness of the solution of problems related to Problem P have also been done by Aronson, Crandall and Peletier [3], Diaz and Kersner [6], Gagneux [10], Madaune [17] and Touré [21].

There exists an extensive literature about the large time behaviour of solutions of degenerate parabolic equations. However there are not many articles where one constructs a Lyapunov functional in order to establish the stabilization to equilibrium. We have already mentioned the work of Osher and Ralston [18]. Such a method is also used by Aronson, Crandall and Peletier [3], Schatzman [20] and Alikakos and Rostamian [1], [2].

2. Biological context. Problem P arises in the theory of population dynamics. Consider a population in a finite habitat Ω which consists of two different groups, for instance age groups. Let $u(x,t)$ and $v(x,t)$ denote the density of these groups. In order to model their evolution with time, Gurtin and Pipkin [11] propose the following system of equations:

$$u_t = \operatorname{div}(u \operatorname{grad}(u+v)) \quad \text{in } \Omega \times \mathbb{R}^+,$$
$$v_t = k \operatorname{div}(v \operatorname{grad}(u+v)) \quad \text{in } \Omega \times \mathbb{R}^+,$$

where k is some positive constant. The flow of the populations is described by the dispersal velocities: $\operatorname{grad}(u+v)$ for the u-individuals and $k \operatorname{grad}(u+v)$ for the v-individuals. In particular, when the parameter k is small, the v-individuals disperse much slower than the u-individuals.

In this article, we study the problem in the limit $k = 0$. The second equation yields at once that v is constant in time; there remains the equation in u which coincides with the differential equation in Problem P if we set $\varphi(s) = \frac{1}{2}s^2$. The boundary condition expresses the fact that no individuals can leave or enter the habitat.

An interesting consequence of our results is the following. It follows from (1.1) that, for any nonconstant function $v(x)$, the set $E=S$ contains a nontrivial function $q(x)$ such that

$$q\equiv 0 \quad \text{in } \Omega_0\subset\Omega, \qquad q>0 \quad \text{in } \Omega\setminus\Omega_0$$

for some nonempty subset Ω_0. If $u_0\leqq q$ in Ω, then $u(t;u_0)\leqq q$ in Ω for all $t>0$. In particular

$$u(t;u_0)\equiv 0 \quad \text{in } \Omega_0 \text{ for } t\geqq 0.$$

From a biological point of view this phenomenon of *localization* is interesting: the v-individuals can stop the spread of the u-individuals.

A detailed analysis of this model in one space dimension was given in [4].

3. Preliminaries. Let us first state the precise hypotheses on φ, u_0 and v and give a definition of a solution of Problem P.

H1. $\varphi\in C^3(\mathbb{R}^+)\cap C^1(\overline{\mathbb{R}^+})$, $\varphi(0)=\varphi'(0)=0$, $\int_0^1 \tau^{-1}\varphi'(\tau)\,d\tau<\infty$, $\varphi'(s)>0$ for $s>0$, $\varphi''(s)\geqq 0$ for $s\in(0,s_0)$ for some $s_0>0$.

H2a. $v\in W^{1,\infty}(\tilde{\Omega})$ for some smooth domain $\tilde{\Omega}\supset\bar{\Omega}$, and $\Delta v\geqq -M$ in $\tilde{\Omega}$ in the sense of distributions for some $M>0$.

H2b. If $N\geqq 2$, $v\in W^{2,p}(\tilde{\Omega})$ for some $p>N$.

H2c. v has finitely many local strict minima.

H3. If $N=1$ either $\varphi(s)=\frac{1}{2}s^2$ or $v''\in L^1(\Omega)$.

H4. $u_0\in L^\infty(\Omega)$, $u_0\geqq 0$ a.e. in Ω.

We use the notation $Q_t=\Omega\times(0,t]$ for $t>0$ and $Q=\Omega\times\mathbb{R}^+$.

DEFINITION 3.1. We say that a function $u\colon [0,\infty)\to L^1(\Omega)$ is a *generalized solution* of Problem P if it satisfies:

(i) $u\in C([0,t];L^1(\Omega))\cap L^\infty(Q_t)$ for all $t>0$,

(ii) $\int_\Omega u(t)\psi(t)=\int_\Omega u_0\psi(0)+\int\int_{Q_t}\{\varphi(u)\Delta\psi+u\psi_t-u\operatorname{grad}v\operatorname{grad}\psi\}$ for all $t>0$ and all $\psi\in C^{2,1}(\bar{Q})$ such that $\psi\geqq 0$ in Q and $\partial\psi/\partial\nu=0$ on $\partial\Omega\times\mathbb{R}^+$.

A generalized subsolution (resp. supersolution) of Problem P is defined by (i) and (ii) with equality replaced by $\leqq$ (resp. $\geqq$).

In the sequel we shall often omit the word generalized.

In Part II, we shall prove the following results. We suppose that the hypotheses H1, H2a and and H4 are satisfied.

PROPOSITION 3.2. *There exists a unique solution of Problem* P.

PROPOSITION 3.3. (regularity). *Let u be the solution of Problem* P. *Then $u\in C(\bar{\Omega}\times(0,\infty))$ and the set $\{u(t);t\geqq 1\}$ is bounded and equicontinuous. Furthermore if $u_0\in C(\bar{\Omega})$, then $u\in C(\bar{\Omega}\times[0,\infty))$.*

PROPOSITION 3.4. (comparison principle). *Let $\underline{u}(t)$ and $\bar{u}(t)$ be respectively a subsolution and a supersolution of Problem* P *with initial functions $\underline{u}_0$ and $\bar{u}_0$ such that $\underline{u}_0\leqq\bar{u}_0$. Then $\underline{u}(t)\leqq\bar{u}(t)$ in Ω for $t\geqq 0$.*

Part I

4. Contraction in $L^1(\Omega)$. In this section we prove a contraction theorem which turns out to be our main tool when studying the asymptotic behaviour of $u(t)$ as $t\to\infty$.

THEOREM 4.1. *Let $u_1(t)$ and $u_2(t)$ be the solutions of Problem* P *with initial functions u_{01} and u_{02} respectively and suppose that the hypotheses* H1, H2a *and* H4 *are satisfied.*

(i) *Then*

$$\|u_1(t)-u_2(t)\|_{L^1(\Omega)} \leqq \|u_{01}-u_{02}\|_{L^1(\Omega)} \quad \text{for any } t>0.$$

(ii) *Let v satisfy in addition the hypotheses* H2b *and* H3. *If u_{01} and $u_{02} \in C(\bar{\Omega})$ and if there exists a connected subdomain $U \subset \Omega$ such that*

$$\text{(4.1)} \quad \text{and} \quad \begin{aligned} &u_{01}>0, \quad u_{02}>0 \quad \text{in } \bar{U} \\ &u_{01}-u_{02} \text{ changes sign in } U, \end{aligned}$$

then

$$\|u_1(t)-u_2(t)\|_{L^1(\Omega)} < \|u_{01}-u_{02}\|_{L^1(\Omega)} \quad \text{for any } t>0.$$

Remark 4.2. Condition (4.1) is necessary because the parabolic equation in Problem P is degenerate at points where $u=0$.

Due to the degeneracy of the equation and the fact that v is not smooth, the proof of Theorem 4.1 is fairly technical. The idea of the proof is due to Osher and Ralston [18].

Proof of (i). In Part II of this article we show that we can approximate $u_i (i=1,2)$ by solutions of uniformly parabolic problems: let $u_{i\varepsilon} (\varepsilon>0)$ be the classical solution of the problem

$$\begin{aligned} &u_t = \Delta \varphi_\varepsilon(u) + \operatorname{div}(u \operatorname{grad} v_\varepsilon) && \text{in } \Omega \times \mathbb{R}^+, \\ &\frac{\partial}{\partial \nu} \varphi_\varepsilon(u) + u \frac{\partial v_\varepsilon}{\partial \nu} = 0 && \text{on } \partial\Omega \times \mathbb{R}^+, \\ &u(x,0) = u_{0i\varepsilon}(x) && \text{in } \Omega, \end{aligned}$$

where φ_ε is a smooth function such that $\varphi_\varepsilon'(s) \geqq c(\varepsilon)>0$ for $s \geqq 0$ and $\varphi_\varepsilon(s) \to \varphi(s)$ uniformly on compact subsets of $[0,\infty)$ and where v_ε and $u_{0i\varepsilon}$ are smooth functions such that $v_\varepsilon \to v$ in $H^1(\Omega)$ and $u_{0i\varepsilon} \to u_{0i}$ in $L^2(\Omega)$ as $\varepsilon \downarrow 0$. In part II we show that $\{u_{i\varepsilon}\}$ is uniformly bounded and equicontinuous in compact subsets of $\bar{\Omega} \times (0,\infty)$. Using in addition the uniqueness of the solution $u_i (i=1,2)$, we conclude that

$$\text{(4.2)} \qquad u_{i\varepsilon}(t) \to u_i(t) \quad \text{in } C(\bar{\Omega}) \text{ as } \varepsilon \to 0 \text{ for } t>0, \quad i=1,2.$$

We define

$$z_\varepsilon(x,t) = u_{1\varepsilon}(x,t) - u_{2\varepsilon}(x,t), \qquad x \in \bar{\Omega}, \quad t \geqq 0.$$

Then z_ε is the solution of the linear problem

$$\text{(L}_\varepsilon\text{)} \qquad \begin{aligned} &z_t = \Delta(a_\varepsilon z) + \operatorname{div}(z \operatorname{grad} v_\varepsilon) && \text{in } \Omega \times \mathbb{R}^+, \\ &\frac{\partial}{\partial \nu}(a_\varepsilon z) + z \frac{\partial v_\varepsilon}{\partial \nu} = 0 && \text{on } \partial\Omega \times \mathbb{R}^+, \\ &z(x,0) = z_{0\varepsilon}(x) \equiv u_{01\varepsilon}(x) - u_{02\varepsilon}(x) && \text{in } \Omega, \end{aligned}$$

where

$$a_\varepsilon(x,t) = \int_0^1 \varphi_\varepsilon'(\theta u_{1\varepsilon}(x,t) + (1-\theta) u_{2\varepsilon}(x,t))\, d\theta.$$

For smooth initial functions $z_{0\varepsilon}$ which satisfy the compatibility conditions at $\partial\Omega \times \{0\}$, the existence of a unique solution $z_\varepsilon \in C^{2,1}(\bar{Q})$ of Problem L_ε is proved in [16, Thm. 5.3, p. 320]. Below we shall need an existence and uniqueness result if $z_{0\varepsilon}$ is

merely continuous in $\bar{\Omega}$. To obtain this result we can proceed in the same way as we sketched above (and as we shall prove in §7) for the more difficult nonlinear and degenerate Problem P: we approximate $z_{0\varepsilon}$ uniformly by smooth initial functions $z_{0\varepsilon n}$ $(n=1,2,\cdots)$. Then the corresponding solutions $z_{\varepsilon n}$ are uniformly bounded and equicontinuous in $\bar{\Omega}\times[0,t]$ for $t>0$ and $z_{\varepsilon n}$ converges uniformly to a generalized solution $z_\varepsilon \in C(\bar{\Omega}\times[0,t])$ of Problem L_ε as $n\to\infty$. By standard regularity results [16], [8], $z_\varepsilon \in C^{2,1}(\Omega\times(0,t])$. In addition these solutions satisfy the comparison principle; in particular they are uniquely determined by the initial function. The proof rests on the same test function argument which is used in §8 for the nonlinear problem and which is extremely easy in this linear case.

For any initial function $z_0\in C(\bar{\Omega})$, we denote the unique solution of Problem L_ε by $z_\varepsilon(t)=T_\varepsilon(t)z_0$. We set $a^+=\max\{a,0\}$ and $a^-=\max\{-a,0\}$. Then for any $t>0$

$$\begin{aligned}
\|z_\varepsilon(t)\|_{L^1(\Omega)}-\|z_{0\varepsilon}\|_{L^1(\Omega)} &= \|T_\varepsilon(t)z_{0\varepsilon}^+ - T_\varepsilon(t)z_{0\varepsilon}^-\|_{L^1(\Omega)} - \|z_{0\varepsilon}\|_{L^1(\Omega)} \\
&= \int_\Omega \Big\{ \max_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm - \min_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm \Big\}\, dx - \|z_{0\varepsilon}\|_{L^1(\Omega)} \\
&= \int_\Omega \Big\{ \max_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm + \min_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm \Big\}\, dx - \int_\Omega (z_{0\varepsilon}^+ + z_{0\varepsilon}^-)\, dx \\
-2\int_\Omega \min_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm\, dx &= \int_\Omega \{T_\varepsilon(t)z_{0\varepsilon}^+ + T_\varepsilon(t)z_{0\varepsilon}^- - z_{0\varepsilon}^+ - z_{0\varepsilon}^-\}\, dx \\
-2\int_\Omega \min_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm\, dx &= -2\int_\Omega \min_{+,-} T_\varepsilon(t)z_{0\varepsilon}^\pm\, dx,
\end{aligned}$$

since

$$\int_\Omega T_\varepsilon(t)z_{0\varepsilon}^\pm\, dx = \int_\Omega z_{0\varepsilon}^\pm\, dx.$$

It follows from the comparison principle that $T_\varepsilon(t)z_{0\varepsilon}^\pm \geqq 0$. Thus for any $\varepsilon>0$

$$\|u_{1\varepsilon}(t)-u_{2\varepsilon}(t)\|_{L^1(\Omega)} - \|u_{01\varepsilon}-u_{02\varepsilon}\|_{L^1(\Omega)} \leqq 0. \tag{4.3}$$

Clearly Theorem 4.1 (i) follows from (4.2) and (4.3).

Proof of Theorem 4.1(ii). Let $u_{i\varepsilon}(i=1,2)$ and z_ε be defined as above. Since $u_{0i}\in C(\bar{\Omega})$ we may assume that $u_{0i\varepsilon}=u_{0i}$. Let $\delta>0$, and write

$$z_\varepsilon(t)=T_\varepsilon^\delta(t)z_\varepsilon(\delta) \quad \text{for } t\geqq\delta.$$

Then, by the proof of (i),

$$\|z_\varepsilon(t)\|_{L^1(\Omega)} - \|z_\varepsilon(\delta)\|_{L^1(\Omega)} = -2\int_\Omega \min_{+,-}\big(T_\varepsilon^\delta(t)z_\varepsilon^\pm(\delta)\big), \qquad t\geqq\delta,$$

and it is enough to prove that, for sufficiently small values of δ, there exists a $t_1=t_1(\delta)>\delta$ such that

$$\int_\Omega \min_{+,-}\big(T_\varepsilon^\delta(t)z_\varepsilon^\pm(\delta)\big) \geqq \eta(t,\delta)>0 \quad \text{for } t\in(\delta,t_1)$$

for all small $\varepsilon>0$.

Consider the Cauchy–Dirichlet problem

$$(\tilde{\mathrm{L}}_\varepsilon^\delta)\qquad \begin{aligned} &z_t=\Delta(a_\varepsilon z)+\operatorname{div}(z\operatorname{grad} v_\varepsilon) && \text{in } \tilde{U}\times(\delta,\infty),\\ &z=0 && \text{on } \partial\tilde{U}\times(\delta,\infty),\\ &z(\cdot,\delta)=z_\varepsilon^{\pm}(\delta) && \text{in } \tilde{U}, \end{aligned}$$

where $\tilde{U}\subset U$ is such that $\operatorname{dist}(\tilde{U},\delta U)>0$ and $z_{0\varepsilon}=u_{01}-u_{02}$ changes sign in $\tilde{U}$. We denote the solution of Problem $\tilde{L}_\varepsilon^\delta$ by

$$\tilde{z}_\varepsilon^{\pm}(t)=\tilde{T}_\varepsilon^\delta(t)z_\varepsilon^{\pm}(\delta)\quad \text{in } \tilde{U}\times(\delta,\infty).$$

Then, by the maximum principle,

$$\tilde{T}_\varepsilon^\delta(t)z_\varepsilon^{\pm}(\delta)\leqq T_\varepsilon^\delta(t)z_\varepsilon^{\pm}(\delta)\quad \text{in } \tilde{U}\times(\delta,\infty).$$

Thus, it is enough to prove that

$$\int_{\tilde{U}} \min_{+,-}\left(\tilde{T}_\varepsilon^\delta(t)z_\varepsilon^{\pm}(\delta)\right)\geqq\eta(t,\delta)>0\quad \text{for } t\in(\delta,t_1) \tag{4.4}$$

for every $\varepsilon\in(0,\varepsilon_0)$ for some $\varepsilon_0>0$.

This will be done by means of the following lemma, which is an immediate consequence of Harnack's inequality [16, p. 209–210].

LEMMA 4.3. *Let $\varepsilon_0>0$ and $t_1>\delta>0$ be constants, and let the following assumptions be satisfied for all $\varepsilon\in(0,\varepsilon_0)$:*

(a) $\|\tilde{T}_\varepsilon^\delta(t)z_\varepsilon^{\pm}(\delta)\|_{L^\infty(\tilde{U})}\geqq\mu_0>0$ *for* $t\in[\delta,t_1]$,

(b) *when* $N=1$, *then* $\|a_\varepsilon\|_{L^\infty(\delta,t_1;H^1(U))}\leqq C$ *and* $\|v_\varepsilon\|_{W^{1,\infty}(U)}\leqq C$,

(c) *when* $N\geqq 2$, *then* $\|a_\varepsilon\|_{L^\infty(\delta,t_1;W^{1,\infty}(U))}\leqq C$ *and* $\|v_\varepsilon\|_{W^{2,p}(U)}\leqq C$,

(d) $a_\varepsilon\geqq\alpha_0>0$ *in* $\bar{U}\times[\delta,t_1]$, *for some constants* $\mu_0>0$, $C>0$, $\alpha_0>0$ *and* $p>N$.

Then, for all $\varepsilon\in(0,\varepsilon_0)$

$$\tilde{T}_\varepsilon^\delta(t)z_\varepsilon^{\pm}(\delta)\geqq\mu(x,t;\delta)>0\quad \text{in } \tilde{U}\times(\delta,t_1]$$

for some function μ which does not depend on ε.

Assuming that (a), (b), (c) and (d) are satisfied for small $\delta>0$, (4.4) follows. Thus, to complete the proof we need to verify these conditions.

In view of Proposition 3.3 and the assumption $u_{0i}\in C(\bar{\Omega})$, we have $u_i\in C(\bar{\Omega}\times[0,\infty))$. Hence there exists a $t_0>0$ such that $u_i>0$ in $\bar{U}\times[0,t_0]$ and $z(t)=u_1(t)-u_2(t)$ changes sign in $\tilde{U}$ for $t\in[0,t_0]$. Since $u_{i\varepsilon}\to u_i$ and $z_\varepsilon\to z$ in $C(\bar{\Omega}\times[0,t_0])$ there exist positive numbers μ_0, ν_0 and ε_0 such that for all $\varepsilon\in(0,\varepsilon_0)$

$$u_{i\varepsilon}\geqq\nu_0\quad \text{in } \bar{U}\times[0,t_0],\quad i=1,2, \tag{4.5}$$

and

$$\left\|z_\varepsilon^{\pm}(t)\right\|_{L^\infty(\tilde{U})}\geqq 2\mu_0\quad \text{for } t\in[0,t_0]. \tag{4.6}$$

By (4.5) and the definition of a_ε, condition (d) is satisfied on $\bar{U}\times[0,t_0]$.

Let $\delta\in(0,t_0)$ be fixed.

When $N=1$, Lemma 7.7 below, combined with (4.5), implies that $u_{i\varepsilon}$ is uniformly bounded in $L^\infty(\delta,t_0;H^1(U))$. Hence it follows from the definition of a_ε that condition (b) is satisfied for all $t_1\in(\delta,t_0]$ (the hypothesis H3 is necessary in the proof of Lemma 7.7).

When $N \geqq 2$ we may assume that v_ε is uniformly bounded in $W^{2,p}(\Omega)$. It follows from (4.5) and [16, Thm. 3.1, p. 437] that $u_{i\varepsilon}$ is uniformly bounded in $L^\infty(\delta, t_0, W^{1,\infty}(U))$. Thus condition (c) is satisfied for all $t_1 \in (\delta, t_0]$.

It remains to show that for some $t_1 \in (\delta, t_0]$ condition (a) is satisfied. In view of the conditions (b) and (c), which we proved to be satisfied for $t_1 \in (\delta, t_0]$ we deduce from [16, Thm. 7.1, p. 181] that $\tilde{T}_\varepsilon^\delta(t) z_\varepsilon^\pm(\delta)$ is uniformly bounded in $\tilde{U} \times [\delta, t_0]$. In addition, (4.5) and [16, Thm. 1.1, p. 419] imply that $u_{i\varepsilon}(\delta)$ is uniformly Hölder continuous in $\tilde{U}$. Finally it follows from [16, Thm. 10.1., p. 204] that $T_\varepsilon^\delta(t) z_\varepsilon^\pm(\delta)$ is Hölder continuous in $\tilde{U} \times [\delta, t_0]$, uniformly with respect to $\varepsilon \in (0, \varepsilon_0)$. Hence, by (4.6), there exists a $t_1 \in (\delta, t_0]$ such that condition (a) of Lemma 4.3 is satisfied for all $\varepsilon \in (0, \varepsilon_0)$.

This completes the proof of Theorem 4.1.

5. Stabilization to equilibrium. In the present section we prove the main result of this paper, namely that u stabilizes to equilibrium as $t \to \infty$.

Let the set E be defined by

$$E = \left\{ q \in C(\bar{\Omega}) \colon q \geqq 0 \text{ and } \int_\Omega (\varphi(q)\Delta\eta - q \operatorname{grad} v \operatorname{grad} \eta) = 0 \right.$$
$$\left. \text{for all } \eta \in C^2(\bar{\Omega}) \text{ with } \frac{\partial \eta}{\partial \nu} = 0 \text{ on } \partial\Omega \right\}.$$

It follows from the definition of a solution of Problem P (Definition 3.1) that

$$E = \{ q \in C(\bar{\Omega}) \colon q \geqq 0 \text{ and } u(t; q) = q \text{ for } t \geqq 0 \}. \tag{5.1}$$

Let S be defined by (1.1).

THEOREM 5.1. *If the hypotheses* H1, H2abc, H3 *and* H4 *are satisfied, then*:

(i) $E = S$.

(ii) *There exists a function* $q \in E$ *such that*

$$u(t; u_0) \to q \quad \text{in } C(\bar{\Omega}) \text{ as } t \to \infty$$

where q *satisfies*

$$\int_\Omega q\,dx = \int_\Omega u_0\,dx. \tag{5.2}$$

Remark 5.2. For some functions v and initial functions u_0, condition (5.2) characterizes q completely (see [4]).

The main tools in the proof of Theorem 5.1 are the contraction property which we proved in §4, and the following lemma about the structure of the set S.

LEMMA 5.3. *Let* $q \in C(\bar{\Omega})$ *be nonnegative. Then either* $q \in S$, *or there exists a function* $w \in S$ *such that* $w - q$ *changes sign in a connected subdomain* $U \subset \Omega$ *such that* w, $q > 0$ *in* $\bar{U}$.

Thus S is a continuum in the space of nonnegative continuous functions on $\bar{\Omega}$.

Proof of Lemma 5.3. Suppose that there is no $w \in S$ such that $w - q$ changes sign in some connected subdomain $U \subset \Omega$ such that w, $q > 0$ in $\bar{U}$. We shall prove that $q \in S$.

If $q \equiv 0$ in Ω, then $q \in S$. So let $q(x_1) > 0$ for some $x_1 \in \Omega$. We set $C_1 = \Phi(q(x_1)) + v(x_1)$, where the function Φ is defined by (1.2). Let $P_1 \subset \bar{\Omega}$ be the connected component of the set $\{ x \in \bar{\Omega} \colon v(x) < C_1 \}$ which contains x_1. We claim that

$$\Phi(q(x)) = C_1 - v(x) \quad \text{in } P_1. \tag{5.3}$$

Suppose that P_1 contains a point where $\Phi(q) < C_1 - v$. Then

$$\Phi(q(\tilde{x})) + v(\tilde{x}) = C_1 - \varepsilon_0 \quad \text{and} \quad q(\tilde{x}) > 0$$

for some $\tilde{x} \in P_1$ and $\varepsilon_0 > 0$. Let $\tilde{P}_\varepsilon \subset P_1 (0 < \varepsilon < \varepsilon_0)$ be the connected component of the set $\{x \in \bar{\Omega}: v(x) < C_1 - \varepsilon\}$ which contains $\tilde{x}$. We fix $\varepsilon \in (0, \varepsilon_0)$ so small, that $\tilde{P}_\varepsilon$ contains x_1. Define w by

$$\Phi(w(x)) = \begin{cases} C_1 - \varepsilon - v(x) & \text{for } x \in \tilde{P}_\varepsilon, \\ 0 & \text{for } x \in \bar{\Omega} \setminus \tilde{P}_\varepsilon. \end{cases}$$

Then $w \in S$. Let Γ be a curve in $\tilde{P}_\varepsilon$ which connects $\tilde{x}$ and x_1. Since $w > 0$ on Γ, and since, by construction, $w - q$ changes sign on Γ, there exists a connected closed subset $\Gamma_0 \subset \Gamma$ such that

$$w, q > 0 \text{ on } \Gamma_0 \text{ and } w - q \text{ changes sign on } \Gamma_0.$$

Hence there exists a neighbourhood $\bar{U}$ of Γ_0 in $\tilde{P}_\varepsilon$, where $w, q > 0$ and $w - q$ changes sign. Thus we have a contradiction and P_1 does not contain points where $\Phi(q) < C_1 - v$.

A similar, but easier proof yields that P_1 does not contain points where $\Phi(q) > C_1 - v$, and (5.3) follows.

If $\bar{P}_1 = \bar{\Omega}$ or if $q \equiv 0$ in $\bar{\Omega} \setminus P_1$, then $q \in S$. So suppose that $q(x_2) > 0$ in $\Omega \setminus P_1$. Set $C_2 = \Phi(q(x_2)) + v(x_2)$ and let $P_2 \subset \bar{\Omega}$ be the connected component of the set $\{x \in \bar{\Omega}: C_2 - v(x) > 0\}$ which contains x_2. Then again we conclude that

$$\Phi(q(x)) = C_2 - v(x) \quad \text{in } P_2$$

and clearly $P_1 \cap P_2 = \varnothing$.

Continuing this process, we construct sets, P_i, $i = 1, 2, \cdots$. Since v has a local strict minimum in each connected P_i and since the number of local strict minima of v in Ω is finite, this process is finite. Thus $q \in S$.

Proof of Theorem 5.1(i). We first show that $S \subset E$. Let $w \in S$. Since v has a finite number of local strict mimima, it follows from (1.1) that there exist a finite number of continuous functions $\Phi_i(x)$ $(i = 1, \cdots, i_0)$ with connected and mutually disjoint support such that

$$\Phi(w(x)) = \sum_{i=1}^{i_0} \Phi_i(x) \tag{5.4}$$

and

$$\Phi_i(x) = C_i - v(x) \quad \text{for } x \in \operatorname{supp} \Phi_i$$

for some constants C_i. Since $v \in W^{1,\infty}(\Omega)$ it follows (see for instance [14, Thm. A1, p. 50]) that $\Phi(w(\cdot)) \in W^{1,\infty}(\Omega)$ and

$$\operatorname{grad} \Phi(w) = \begin{cases} -\operatorname{grad} v & \text{in } \{x: w(x) > 0\}, \\ 0 & \text{elsewhere.} \end{cases}$$

Then, by standard theory, $\varphi(w(\cdot)) \in W^{1,\infty}(\Omega)$ and

$$\operatorname{grad} \varphi(w) = \begin{cases} -w \operatorname{grad} v & \text{in } \{x: w(x) > 0\}, \\ 0 & \text{elsewhere.} \end{cases} \tag{5.5}$$

Let $\eta \in C^2(\bar{\Omega})$ with $\partial\eta/\partial\nu = 0$ on $\partial\Omega$. Then, by (5.5),

$$\int_\Omega (\varphi(w)\Delta\eta - w \operatorname{grad} v \operatorname{grad}\eta) = -\int_\Omega (\operatorname{grad}\varphi(w) + w \operatorname{grad} v)\operatorname{grad}\eta = 0.$$

Thus $w \in E$.

Next we show that $E \subset S$. Let $q \in E$ and suppose that $q \notin S$. Then, by Lemma 5.3, there exists a $w \in S$ such that $w - q$ changes sign in a connected subdomain $U \subset \Omega$ in which w, $q > 0$. Since $q \in E$ and $w \in S \subset E$, it follows from (5.1) and Theorem 4.1(ii) that

$$\|q - w\|_{L^1(\Omega)} = \|u(t;q) - u(t;w)\|_{L^1(\Omega)} < \|q - w\|_{L^1(\Omega)}, \qquad t > 0.$$

Thus we have obtained a contradiction and $q \in S$.

Remark 5.4. When $N = 1$, Theorem 5.1(i) follows at once by integrating the differential equation (see [4]).

Proof of Theorem 5.1(ii). We define the ω-limit set

$$\omega(u_0) = \{ w \in L^1(\Omega) : \text{there exists a sequence } t_n \to \infty \text{ such that } u(t_n) \to w \text{ in } L^1(\Omega) \text{ as } t_n \to \infty \}.$$

By Proposition 3.3, the set $\{u(t;u_0); t \geqq 1\}$ is precompact in $C(\bar{\Omega})$ (and hence in $L^1(\Omega)$). Thus $\omega(u_0)$ is nonempty and $\omega(u_0) \subset C(\bar{\Omega})$.

Let $q \in \omega(u_0)$. We show first that q satisfies (5.2), then that $q \in E$, and finally that $\omega(u_0) = \{q\}$.

Setting $\psi(x,t) \equiv 1$ in Definition 3.1, we find that

$$\int_\Omega u(t;u_0) = \int_\Omega u_0 \quad \text{for all } t > 0$$

and (5.2) follows.

In order to show that $q \in E$, we argue by contradiction: suppose that $q \notin E$. Then, by Theorem 5.1(i), $q \notin S$. Thus, by Lemma 5.3, there exists a function $w \in S$ such that $q - w$ changes sign in a connected subdomain $U \subset \Omega$ in which q, $w > 0$. We use w to define the functional V: $L^1(\Omega) \to [0, \infty)$:

$$V(u) = \|u - w\|_{L^1(\Omega)}, \qquad u \in L^1(\Omega).$$

Since $w \in E$, it follows from Theorem 4.1(i) that the solution $u(t)$ of Problem P satisfies

$$V(u(t_1)) \leqq V(u(t_2)) \quad \text{for all } t_1 \geqq t_2 \geqq 0.$$

Thus V is a Lyapunov functional for Problem P. Since $u \in C([0,\infty);\ L^1(\Omega))$ and V is continuous, it follows from [5, Prop. 2.1 and 2.2] that $u(t;q) \in \omega(u_0)$ and that V is constant on $\omega(u_0)$. Hence

$$V(u(t;q)) = V(q) \quad \text{for all } t \geqq 0. \tag{5.6}$$

On the other hand, since q and $w \in C(\bar{\Omega})$, it follows from the choice of w and Theorem 4.1(ii) that

$$V(u(t;q)) < V(q) \quad \text{for all } t > 0$$

which contradicts (5.6). Thus $q \in E$.

Finally we show that $\omega(u_0) \equiv \{q\}$.

Suppose that $\tilde{q}\in\omega(u_0)$ and that $u(t_n;u_0)\to q$ as $t_n\to\infty$ and $u(s_n;u_0)\to\tilde{q}$ as $s_n\to\infty$ where the sequences $\{t_n\}$ and $\{s_n\}$ are chosen such that $s_n<t_n$ for all $n\geqq 1$. Then, using Theorem 4.1(i), we find that

$$\|q-\tilde{q}\|_{L^1(\Omega)}=\lim_{n\to\infty}\|u(t_n;u_0)-\tilde{q}\|_{L^1(\Omega)}$$
$$\leqq\lim_{n\to\infty}\|u(s_n;u_0)-\tilde{q}\|_{L^1(\Omega)}=0.$$

Thus $\tilde{q}=q$, which completes the proof of Theorem 5.1.

6. The Dirichlet problem. In this section we show how the results about Problem P can be extended to the case of homogeneous Dirichlet boundary conditions. We consider the problem

$$(\mathrm{P}_D)\qquad\begin{aligned} &u_t=\Delta\varphi(u)+\operatorname{div}(u\operatorname{grad}v) && \text{in } \Omega\times\mathbb{R}^+,\\ &u=0 && \text{on } \partial\Omega\times\mathbb{R}^+,\\ &u(x,0)=u_0(x) && \text{in } \Omega.\end{aligned}$$

We define a (generalized) solution $u(t;u_0)$ of Problem P_D in a similar way as for Problem P, taking test functions $\psi\in C^{2,1}(\bar{Q})$ such that $\psi=0$ on $\partial\Omega\times\mathbb{R}^+$. The Propositions 3.2, 3.3 and 3.4 as well as Theorem 4.1 remain valid in the case of Problem P_D. In particular

$$u(t;u_0)\in C(\bar{\Omega}) \text{ and } u(t;u_0)=0 \text{ on } \partial\Omega \text{ for } t>0. \tag{6.1}$$

Let the set of steady-state solutions, E_D, be defined by

$$E_D=\{q\in C(\bar{\Omega}):\ q\geqq 0 \text{ and } \textstyle\int_\Omega(\varphi(q)\Delta\eta-q\operatorname{grad}v\operatorname{grad}\eta)=0$$
$$\text{for all } \eta\in C^2(\bar{\Omega}) \text{ such that } \eta=0 \text{ on } \partial\Omega\}.$$

LEMMA 6.1. *Let E be defined as in* §5. *Then $E_D\subset E$.*

Proof. Let $q\in E_D$. Then

$$u(t;q)=q \quad \text{for } t>0. \tag{6.2}$$

Let $\tilde{u}(t;q)$ denote the solution of Problem P with initial function q. Since, by (6.1) and (6.2),

$$\tilde{u}(t;q)\geqq u(t;q)=q=0 \quad \text{on } \partial\Omega\times\mathbb{R}^+,$$

$\tilde{u}(t;q)$ is a supersolution of Problem P_D. Hence, by (6.2),

$$\tilde{u}(t;q)\geqq q \quad \textit{in } \Omega\times\mathbb{R}^+. \tag{6.3}$$

On the other hand we have that

$$\int_\Omega\tilde{u}(t;q)\,dx=\int_\Omega q\,dx, \qquad t\geqq 0.$$

Combined with (6.3) this yields $\tilde{u}(t;q)=q$ for $t\geqq 0$. Thus $q\in E$. We define S_D by

$$S_D=\{q\in S, \text{ such that } q=0 \text{ on } \partial\Omega\},$$

where S is defined by (1.1). In what follows we prove the following theorem.

THEOREM 6.2. *Let the hypotheses* H1, H2abc, H3 *and* H4 *be satisfied. Then*:
(i) $E_D = S_D$.
(ii) E_D *contains a maximal element* $q_{\max}$, *i.e.* $q \leqq q_{\max}$ *in* Ω *for any* $q \in E_D$.
(iii) *There exists a function* $q \in E_D$ *such that* $u(t; u_0) \to q$ *in* $C(\bar{\Omega})$ *as* $t \to \infty$.
If in addition $u_0 \leqq q_{\max}$, *then* q *satisfies* $\int_\Omega q\,dx = \int_\Omega u_0\,dx$.

Proof. (i) By Lemma 6.1 and Theorem 5.1(i), $E_D \subset S$. Hence $E_D \subset S_D$. The proof of the inclusion $S_D \subset E_D$ is identical to the proof of $S \subset E$, given in §5. Thus $E_D = S_D$.

(ii) Let $C > \|v\|_{L^\infty(\Omega)}$ be constant and let $w \in S$ be defined by $\Phi(w(x)) = C - v(x)$, $x \in \bar{\Omega}$. Then $w > 0$ in $\bar{\Omega}$ and it follows from the definition of the set S_D that $q \leqq w$ in Ω for any $q \in S_D$. Hence, by (i),

$$q \leqq w \quad \text{in } \Omega \text{ for any } q \in E_D. \tag{6.4}$$

Since $w \in S = E$, w is a supersolution of Problem P_D. Hence the solution $u(t; w)$ of Problem P_D is nonincreasing in t and we may define

$$0 \leqq p(x) = \lim_{t \to \infty} u(x, t; w), \qquad x \in \bar{\Omega}.$$

By (6.4) and the comparison principle

$$q \leqq p \quad \text{in } \Omega \text{ for any } q \in E_D. \tag{6.5}$$

Below we prove that $p \in E_D$. Then the result follows at once from (6.5), with $q_{\max} = p$.

Let $\eta(x) \geqq 0$ be a smooth test function on $\bar{\Omega}$ such that $\eta = 0$ on $\partial\Omega$. Then $u = u(\cdot; w)$ satisfies

$$\int_\Omega u(t)\eta = \int_\Omega w\eta + \iint_{Q_t} (\varphi(u)\Delta\eta - u \operatorname{grad} v \operatorname{grad} \eta).$$

Thus

$$\frac{d}{dt}\int_\Omega u(t)\eta = \int_\Omega (\varphi(u(t))\Delta\eta - u(t)\operatorname{grad} v \operatorname{grad} \eta). \tag{6.6}$$

Since $u(t; w)$ decreases to p as $t \to \infty$, the left-hand side of (6.6) is nonpositive and there exists a sequence $t_n \to \infty$ such that

$$\frac{d}{dt}\int_\Omega u(t_n)\eta \to 0 \quad \text{as } t_n \to \infty. \tag{6.7}$$

On the other hand, the right-hand side of (6.6) converges to

$$\int_\Omega (\varphi(p)\Delta\eta - p \operatorname{grad} v \operatorname{grad} \eta) \quad \text{as } t_n \to \infty.$$

Hence, by (6.6) and (6.7),

$$\int_\Omega (\varphi(p)\Delta\eta - p \operatorname{grad} v \operatorname{grad} \eta) = 0$$

and thus $p \in E_D$.

(iii) Given an initial function u_0, one can find a function $w \in S$ such that $u_0 \leqq w$ in Ω. Using the above argument and the comparison principle, we find that

$$\limsup_{t \to \infty} u(x, t; u_0) \leqq q_{\max}(x), \qquad x \in \Omega.$$

Hence

$$q \in \omega(u_0) \text{ implies that } q \leqq q_{\max}. \tag{6.8}$$

In order to prove that $u(t;u_0)$ stabilizes to equilibrium, we use the same arguments as for the proof of Theorem 5.1(ii), but now based on the fact that S_D is a continuum between zero and $q_{\max}$, on (6.8), and on the contraction property of u. If furthermore $u_0 \leqq q_{\max}$, then the solution $\tilde{u}(t;u_0)$ of Problem P satisfies $\tilde{u}(t;u_0) \leqq q_{\max}$ for $t \geqq 0$ and in particular $\tilde{u}(t,u_0)=0$ on $\partial\Omega \times \mathbb{R}^+$. Thus $\tilde{u}(t;u_0)$ coincides with the solution $u(t;u_0)$ of Problem P_D (see Lemma 9.3 below). Then, if $q=\lim_{t\to\infty} u(t;u_0)$, we have, by Theorem 5.1(ii)

$$\int_\Omega q\,dx = \int_\Omega u_0\,dx.$$

Part II

7. Existence and regularity. In this section we prove the existence of a solution of Problem P which satisfies this problem in a somewhat stronger sense than that of Definition 3.1. We first recall some usual definitions and then give an alternative definition of a solution, involving the gradient of $\varphi(u)$. The existence proof itself is based on the study of uniformly parabolic problems which are related to Problem P.

We denote by $L^2(0,T;H^1(\Omega))$ the Hilbert space with inner product

$$(u,v)_{L^2(0,T;H^1(\Omega))} = \iint_{Q_T} uv + \iint_{Q_T} \operatorname{grad} u \operatorname{grad} v$$

and by $V_2(Q_T)$ the Banach space with norm

$$|u|^2_{V_2(Q_T)} = \operatorname*{ess\,sup}_{0\leqq t\leqq T} \int_\Omega u^2(t) + \iint_{Q_T} (\operatorname{grad} u)^2.$$

DEFINITION 7.1. We say that $u\colon [0,\infty) \to L^1(\Omega)$ is a *weak solution* of Problem P if it satisfies

(i) $u \in C([0,t];L^1(\Omega)) \cap L^\infty(Q_t)$ for all $t \in (0,\infty)$;

(ii) $\varphi(u) \in V_2(Q_t)$ for all $t \in (0,\infty)$;

(iii) $\int_\Omega u(t)\psi(t) = \int_\Omega u_0\psi(0) + \int_0^t \int_\Omega \{u\psi_t - (\operatorname{grad}\varphi(u) + u \operatorname{grad} v)\operatorname{grad}\psi\}$ for all $\psi \in C^1(\overline{Q})$ and all $t \in (0,\infty)$.

LEMMA 7.2. *A weak solution of Problem* P *is a generalized solution as well.*

Proof. Take $\psi \in C^{2,1}(\overline{Q})$ with $\partial\psi/\partial\nu = 0$ on $\partial\Omega \times \mathbb{R}^+$ and integrate by parts.

In what follows, we show that Problem P has a weak solution. To that purpose, we consider the problems

$$\begin{aligned} &u_t = \Delta\varphi_\varepsilon(u) + \operatorname{div}(u \operatorname{grad} v_\varepsilon) && \text{in } Q_T, \\ &\frac{\partial}{\partial\nu}\varphi_\varepsilon(u) + u\frac{\partial v_\varepsilon}{\partial\nu} = 0 && \text{on } \partial\Omega \times (0,T], \\ &u(x,0) = u_{0\varepsilon}(x) && \text{in } \Omega, \end{aligned}$$

where

$$\varphi_\varepsilon \in C^\infty(\mathbb{R}^+), \qquad \varphi_\varepsilon(0)=0,\ \varphi_\varepsilon'(s) \geqq C(\varepsilon) > 0 \quad \text{for } s \in [0,K],$$
$$(\varphi_\varepsilon^{-1}(s))' \leqq (\varphi^{-1}(s))' \text{ for } s \in [0,\varphi(2K)]$$

where K is the uniform L^∞-bound of u_ε that we find in Lemma 7.4 below and φ_ε and φ_ε' converge to φ and φ' on all compact subsets of $\mathbb{R}^+$ as $\varepsilon \downarrow 0$, where

$$v_\varepsilon \in C^\infty(\bar{\Omega}), \quad \|v_\varepsilon\|_{C^1(\bar{\Omega})} \leqq C \quad \text{for some constant } C > 0,$$
$$\|v_\varepsilon\|_{C(\bar{\Omega})} \leqq \|v\|_{L^\infty(\Omega)} \text{ and } \|v_\varepsilon - v\|_{H^1(\Omega)} \to 0 \quad \text{as } \varepsilon \downarrow 0,$$

and where

$$u_{0\varepsilon} \in C^\infty(\bar{\Omega}), \ 0 \leqq u_{0\varepsilon} \leqq \|u_0\|_{L^\infty(\Omega)},$$

$u_{0\varepsilon}$ satisfies the compatibility condition

$$\frac{\partial}{\partial \nu} \varphi_\varepsilon(u_{0\varepsilon}) + u_{0\varepsilon} \frac{\partial v_\varepsilon}{\partial \nu} = 0 \text{ on } \partial\Omega$$

and $\|u_{0\varepsilon} - u_0\|_{L^2(\Omega)} \to 0$ as $\varepsilon \downarrow 0$.

Since it is standard that one can construct the approximations φ_ε of the function φ having the properties indicated above, we do not do it here. On the other hand we construct explicitly in an appendix approximations v_ε and $u_{0\varepsilon}$ of the functions v and u_0.

To begin with, we give a comparison principle, which turns out to be basic in the study of Problems P_ε and P.

LEMMA 7.3. *Let u_1 and $u_2 \in C^{2,1}(\bar{Q}_T)$ be two solutions of Problem P_ε with initial functions $u_{01} \leqq u_{02}$. Then $u_1(t) \leqq u_2(t)$.*

Proof. Let $z = u_1 - u_2$. Then z satisfies the linear problem L_ε which we discussed in §4 and Lemma 7.3 follows from the comparison principle for that problem.

Before proving the existence of a solution of Problem P, we first give some a priori estimates.

LEMMA 7.4. *Let $u_\varepsilon \in C^{2,1}(\bar{Q}_T)$ be a solution of Problem P_ε. Then*

$$0 \leqq u_\varepsilon \leqq K \quad \text{in } \bar{Q}_T \tag{7.1}$$

where the constant K does not depend on T.

The lower bound in (7.1) is obvious. The upper bound follows from the construction of time-dependent supersolutions, which are uniformly bounded with respect to ε. We leave the details to the reader.

LEMMA 7.5. *Problem P_ε has a unique classical solution $u_\varepsilon \in C^{2+\alpha}(\bar{Q}_T)$ for each $\alpha \in (0,1)$.*

Proof. See [16, Thm. 7.4, p. 491].

In what follows we give some more a priori estimates for u_ε.

LEMMA 7.6. *Let $0 \leqq t - \tau < t < T$. Then there exists $C(\tau) > 0$ such that*

$$\int_{t-\tau}^{t} \int_\Omega (\operatorname{grad} \varphi_\varepsilon(u_\varepsilon))^2 \leqq C(\tau).$$

In particular the constant $C(\tau)$ does not depend on T or on ε.

The proof is immediate if we multiply the differential equation by $\varphi_\varepsilon(u_\varepsilon)$ and integrate by parts over $\Omega \times (t, t+\tau)$.

Next we give an estimate which is useful for the proof of Theorem 4.1(ii); we adapt a proof from Gagneux [10].

LEMMA 7.7. *We suppose that either* $\varphi(s)=s|s|/2$ *or* $\Delta v \in L^1(\Omega)$. *Then*

$$\|\varphi_\varepsilon(u_\varepsilon)\|_{L^\infty(T-\tau,T;H^1(\Omega))} \leqq C(\tau), \qquad 0<\tau\leqq T. \tag{7.2}$$

The constant $C(\tau)$ *does not depend on* T.

Proof. We first show that for $0\leqq t-\tau<t\leqq T$, the following estimate holds

$$\int_{t-\tau}^{t}\int_\Omega \varphi_\varepsilon'(u_\varepsilon)(\operatorname{grad} u_\varepsilon)^2 \leqq C(\tau). \tag{7.3}$$

For that purpose we multiply the differential equation by u_ε and integrate by parts; we obtain

$$\frac{1}{2}\int_\Omega u_\varepsilon^2(t)-\frac{1}{2}\int_\Omega u_\varepsilon^2(t-\tau)+\int_{t-\tau}^{t}\int_\Omega \varphi_\varepsilon'(u_\varepsilon)(\operatorname{grad} u_\varepsilon)^2=\int_{t-\tau}^{t}\int_\Omega \operatorname{grad} v_\varepsilon \operatorname{grad}\left(\frac{1}{2}u_\varepsilon^2\right).$$

When (i): $\varphi(s)=s^2/2$, we have

$$\int_{t-\tau}^{t}\int_\Omega \operatorname{grad} v_\varepsilon \operatorname{grad}\left(\frac{1}{2}u_\varepsilon^2\right) \leqq C\sqrt{\tau}\,\|\varphi(u_\varepsilon)\|_{L^2(t-\tau,t;H^1(\Omega))} \leqq C(\tau)$$

by Lemma 7.4; and when (ii): $\Delta v\in L^1(\Omega)$, then

$$\int_{t-\tau}^{t}\int_\Omega \operatorname{grad} v_\varepsilon \operatorname{grad}\left(\frac{1}{2}u_\varepsilon^2\right)=\int_{t-\tau}^{t}\int_{\partial\Omega}\frac{u_\varepsilon^2}{2}\frac{\partial v_\varepsilon}{\partial \nu}-\int_{t-\tau}^{t}\int_\Omega \Delta v_\varepsilon \frac{u_\varepsilon^2}{2}\leqq C(\tau)$$

which completes the proof of (7.3).

For the rest of the proof we refer to [10].

We shall need a result of DiBenedetto [7, Thm. 6.2] to deduce a strong estimate, namely the equicontinuity of u_ε.

LEMMA 7.8(i). *For every* $\tau>0$ *there exists a continuous nondecreasing function* $\omega_\tau(\cdot)$, $\omega_\tau(0)=0$ *such that*

$$|u_\varepsilon(x_1,t_1)-u_\varepsilon(x_2,t_2)|\leqq \omega_\tau\left(|x_1-x_2|+|t_1-t_2|^{1/2}\right)$$

for all $(x_i,t_i)\in\bar\Omega T\times[\tau,T]$, $i=1,2$. *The function* ω_τ *does not depend on* T *and* ε.

(ii) *If* $u_0\in C(\bar\Omega)$, *then* $\{u_\varepsilon\}$ *is equicontinuous on* $\bar\Omega\times[0,T]$.

We are now in a position to prove the existence theorem.

THEOREM 7.9. *We suppose that* H1 *and* H4 *are satisfied and that* $v\in W^{1,\infty}(\Omega)$. *Then there exists a weak solution of Problem* P *which satisfies*

$$0\leqq u\leqq C \quad \text{on } Q_T$$

and is continuous in any set $\bar\Omega\times[\tau,T]$ *with* $\tau>0$. *The constant* C *and the modulus of continuity do not depend on* T.

Proof. From the estimates above we deduce that there exist a function $u\in L^\infty(Q_T)\cap C(\bar\Omega\times(0,T])$ and a subsequence of $\{u_\varepsilon\}$ which we denote again by $\{u_\varepsilon\}$ such that

(i) $u_\varepsilon\to u$ uniformly on all sets of the form $\bar\Omega\times[\tau,T]$ with $\tau>0$ (by Lemma 7.8),

(ii) $u_\varepsilon\to u$ strongly in $L^2(Q_T)$ and a.e. (this is a consequence of (i) and the uniform bound of u_ε in $L^\infty(\Omega)$),

(iii) $\varphi_\varepsilon(u_\varepsilon)\to\varphi(u)$ weakly in $L^2(0,T;H^1(\Omega))$ (this follows from Lemma 7.6; one checks that the limit is $\varphi(u)$ by observing that by (ii) and Lebesgue's dominated convergence theorem $\varphi_\varepsilon(u_\varepsilon)\to\varphi(u)$ strongly in $L^2(Q_T)$),

(iv) $u_\varepsilon \operatorname{grad} v_\varepsilon \to u \operatorname{grad} v$ strongly in $L^1(Q_T)$.

It remains to check that u is a solution of Problem P. It is easy to deduce from (i)–(iv) that u satisfies the integral equation in Definition 3.1 since u_ε satisfies a similar equation. Also $u \in C((0,T];\ L^1(\Omega))$. In order to show that $\|u(t)\|_{L^1(\Omega)}$ is continuous at zero we use the contraction Theorem 4.1(i). Let $\tilde{u}_\varepsilon$ be a solution of Problem P with initial function $u_{0\varepsilon}$ obtained as a limit of solutions of Problem P_ε. Then

$$\|u(t)-u_0\|_{L^1(\Omega)} \leqq \|u(t)-\tilde{u}_\varepsilon(t)\|_{L^1(\Omega)} + \|\tilde{u}_\varepsilon(t)-u_{0\varepsilon}\|_{L^1(\Omega)} + \|u_{0\varepsilon}-u_0\|_{L^1(\Omega)}.$$

Let $\eta > 0$ be arbitrary. Since $u_{0\varepsilon}$ converges to u_0 in $L^1(\Omega)$, one can fix ε such that $\|u_{0\varepsilon}-u_0\|_{L^1(\Omega)} \leqq \eta/3$. Then by Theorem 4.1 $\|u(t)-\tilde{u}_\varepsilon(t)\|_{L^1(\Omega)} \leqq \eta/3$. Finally we deduce from Lemma 7.8 (ii) that one can find t_0 such that $\|\tilde{u}_\varepsilon(t)-u_{0\varepsilon}\|_{L^1(\Omega)} \leqq \eta/3$ for all $t \leqq t_0$.

Remark 7.10. If the function φ is defined on $\mathbb{R}$ with $\varphi'(s) > 0$ for $s < 0$, the condition $u_0 \geqq 0$ is not necessary to obtain the results of §7.

8. Uniqueness of the solution. In order to show that the solution of Problem P is unique, we apply a method due to Kalashnikov [13] which consists of comparing an arbitrary solution of Problem P with a solution obtained as the limit of a sequence of classical solutions of the parabolic equation in Problem P. We do so below and for technical reasons which will appear later we impose the condition $\Delta v \geqq -M$ in the sense of distributions.

We approximate Problem P in two steps, first by the problem

$$(P_n)\qquad \begin{aligned} &u_t = \Delta\varphi(u) + \operatorname{div}(u \operatorname{grad} v) && \text{in } Q_T,\\ &\frac{\partial}{\partial \nu}\varphi(u) + u\frac{\partial v}{\partial \nu} = \frac{A}{n}e^{-Mt} && \text{on } \partial\Omega \times (0,T],\\ &u(x,0) = u_{0n}(x) := u_0(x) + \frac{1}{n} && \text{in } \Omega, \end{aligned}$$

which in turn we approximate by the problem

$$(P_{nj})\qquad \begin{aligned} &u_t = \Delta\varphi(u) + \operatorname{div}(u \operatorname{grad} v_j) && \text{in } Q_T,\\ &\frac{\partial}{\partial \nu}\varphi(u) + u\frac{\partial v_j}{\partial \nu} = \frac{A}{n}e^{-Mt} && \text{on } \partial\Omega \times (0,T],\\ &u(x,0) = u_{0j}(x) + \frac{1}{n} && \text{in } \Omega, \end{aligned}$$

where

$$\begin{aligned} &v_j \in C^\infty(\bar{\Omega}), \qquad \|v_j\|_{C^1(\bar{\Omega})} \leqq C_1 \quad \text{for some constant } C_1 > 0,\\ &\Delta v_j \geqq -M \text{ and } \|v_j - v\|_{H^1(\Omega)} \to 0 \quad \text{as } j \to \infty, \end{aligned}$$

where the constant A is such that $A \geqq C_1$ and

$$u_{0j} \in C^{2+\alpha}(\bar{\Omega}), \qquad 0 \leqq u_{0j} \leqq C_2 \quad \text{for some constant } C_2 > 0,$$

u_{0j} satisfies the compatibility condition

$$\varphi'\left(u_{0j} + \frac{1}{n}\right)\frac{\partial u_{0j}}{\partial \nu} + \frac{\partial v_j}{\partial \nu}u_{0j} + \frac{1}{n}\left(\frac{\partial v_j}{\partial \nu} - A\right) = 0 \quad \text{on } \partial\Omega$$

and is such that $\|u_{0j}-u_0\|_{L^2(\Omega)} \to 0$ as $j \to \infty$.

We show in the appendix that one can construct such functions v_j and u_{0j}.

We first give uniform upper and lower bounds for the solution u_{nj} of Problem P_{nj}; the fact that u_{nj} turns out to be bounded away from zero ensures that Problem P_{nj} is uniformly parabolic.

LEMMA 8.1. *Let $u_{nj} \in C^{2,1}(\overline{Q}_T)$ be a solution of Problem P_{nj}. Then, for n large enough,*

$$\frac{1}{n} e^{-Mt} \leqq u_{nj}(x,t) \leqq C \quad \text{for all } (x,t) \in \overline{Q}_T$$

where the constant C does not depend on time.

The main tool of the proof is the following comparison principle which is an immediate generalization of Lemma 7.3.

LEMMA 8.2. *Let u_1 and $u_2 \in C^{2,1}(\overline{Q}_T)$ and assume that u_1 and u_2 are positive on $\overline{Q}_T$. If*

$$\Delta\varphi(u_1) + \operatorname{div}(u_1 \operatorname{grad} v_j) - u_{1t} \geqq \Delta\varphi(u_2) + \operatorname{div}(u_2 \operatorname{grad} v_j) - u_{2t} \quad \text{in } Q_T,$$

$$\frac{\partial}{\partial \nu}\varphi(u_1) + u_1 \frac{\partial v_j}{\partial \nu} \leqq \frac{\partial}{\partial \nu}\varphi(u_2) + u_2 \frac{\partial v_j}{\partial \nu} \quad \text{on } \partial\Omega \times (0,T]$$

$$u_1(x,0) \leqq u_2(x,0) \quad \text{in } \Omega.$$

Then

$$u_1 \leqq u_2 \quad \text{in } \overline{Q}_T.$$

Proof of Lemma 8.1. One easily checks that $s^-(x,t) := (1/n)e^{-Mt}$ is a subsolution of Problem P_{nj}, and hence, by Lemma 8.2, $u_n \geqq (1/n)e^{-Mt}$.

On the other hand, one can construct a supersolution of the form

$$s^+(x,t) = \Phi^{-1}\big(C - v_j - e^{-Mt}h(x)\big),$$

where h is a smooth function such that $1 \leqq h \leqq 2$, and where the constant C is chosen large enough. Omitting the details here we find that $u_{nj} \leqq s^+ \leqq \Phi^{-1}(C)$.

By the method of §7 one can obtain further a priori estimates for solutions of the Problems P_{nj} and P_n and use them to show that a subsequence $\{u_{nj}\}$ of solutions of Problems P_{nj} converge to a generalized solution of Problem P_n as $j \to \infty$ and then that a subsequence $\{u_{\tilde{n}}\}$ of solutions of Problems $P_{\tilde{n}}$ converge to a solution of Problem P. In addition, following DiBenedetto again, we find that the sequence $\{u_{nj}\}$ is equicontinuous. In particular one can show that there exists a solution u of Problem P and a subsequence of the solutions u_n of Problems P_n (which we denote again by $\{u_n\}$) which converge to u as $n \to \infty$. Below we use this construction to prove the following result.

THEOREM 8.3. *We suppose that the hypotheses* H1, H2a *and* H4 *are satisfied. Let u be the solution of Problem* P *obtained above and let $\underline{u}$ (resp. $\bar{u}$) be a subsolution (resp. supersolution) of P with initial function $\underline{u}_0$ (resp. $\bar{u}_0$). Then for every $t \in (0,T]$ we have that*

$$\int_\Omega (\underline{u}(t) - u(t))^+ \leqq \int_\Omega (\underline{u}_0 - u_0)^+ \tag{8.1}$$

and

$$\int_\Omega (u(t) - \bar{u}(t))^+ \leqq \int_\Omega (u_0 - \bar{u}_0)^+. \tag{8.2}$$

COROLLARY 8.4. *If the hypotheses* H1, H2a *and* H4 *are satisfied, Problem* P *has a unique solution.*

COROLLARY 8.5. *Let* $\underline{u}(t)$ *and* $\bar{u}(t)$ *be respectively a subsolution and a supersolution of Problem* P *with initial functions* $\underline{u}_0$ *and* $\bar{u}_0$ *such that* $\underline{u}_0 \leqq \bar{u}_0$. *Then* $\underline{u}(t) \leqq \bar{u}(t)$ *for every* $t \in (0, T]$.

Proof of Theorem 8.3. The proof follows closely that of Diaz and Kersner [6]. Let ψ be a test function. Then

$$\int_\Omega (\underline{u}-u_n)(t)\psi(t) - \int_\Omega (\underline{u}_0 - u_{0n})\psi(0)$$

$$\leqq \int_0^t \int_\Omega \{(\underline{u}-u_n)(t)\psi_t + (\varphi(\underline{u})-\varphi(u_n))\Delta\psi - (\underline{u}-u_n)\operatorname{grad} v \operatorname{grad}\psi\}$$

$$- \frac{A}{n}\int_0^t \int_{\partial\Omega} e^{-Mt}\psi$$

$$\leqq \int_0^t \int_\Omega (\underline{u}-u_n)\{\psi_t + A_n\Delta\psi - \operatorname{grad} v \operatorname{grad}\psi\}$$

where

$$A_n(x,t) = \int_0^1 \varphi'(\theta\underline{u}(x,t) + (1-\theta)u_n(x,t))\,d\theta.$$

Since $u_n \geqq (1/n)e^{-Mt}$, there exists $\varepsilon(n) > 0$ such that $A_n \geqq \varepsilon(n) > 0$. We now define a sequence of smooth functions $A_{nj} \geqq \varepsilon(n)$ such that

$$A_{nj} \to A_n \quad \text{strongly in } L^2(Q_T) \text{ as } j \to \infty.$$

Let ψ_{nj} be the solution of the problem

$$(\mathrm{L}_{nj}) \qquad \begin{aligned} &\psi_t + A_{nj}\Delta\psi - \operatorname{grad} v_j \operatorname{grad}\psi = 0 && \text{in } \Omega\times(0,t),\\ &\frac{\partial\psi}{\partial\nu} = 0 && \text{on } \partial\Omega\times[0,t),\\ &\psi(x,t) = \chi(x) && \text{in } \Omega, \end{aligned}$$

where χ is a smooth function such that $0 \leqq \chi \leqq 1$. As a consequence of the maximum principle we have that $0 \leqq \psi_{nj} \leqq 1$. We set $\psi = \psi_{nj}$. Then

$$(8.3) \quad \int_\Omega (\underline{u}-u_n)\chi \leqq \int_\Omega (\underline{u}_0 - u_{0n})^+ + \int_0^t \int_\Omega (\underline{u}-u_n)\{(A_n - A_{nj})\Delta\psi_{nj} - (\operatorname{grad} v - \operatorname{grad} v_j)\operatorname{grad}\psi_{nj}\}.$$

In what follows we first keep n fixed. In order to show that the second term of the right-hand side of (8.3) vanishes as $j \to \infty$, it is sufficient to prove that there exists a constant $C(n,t)$ such that

$$(8.4) \qquad \int_0^t \int_\Omega (\operatorname{grad}\psi_{nj})^2 \leqq C(n,t) \quad \text{and} \quad \int_0^t \int_\Omega (\Delta\psi_{nj})^2 \leqq C(n,t).$$

These estimates follow from multiplying the differential equation in Problem L_{nj} by $\Delta\psi_{nj}$ and integrating it on $\Omega\times(0,t)$. For details we refer to Aronson, Crandall and Peletier [3] where a similar calculation is made. Inequality (8.3) together with (8.4)

yields

$$\int_\Omega (\underline{u}(t)-u_n(t))\chi \leqq \int_\Omega (\underline{u}_0-u_{0n})^+$$

for all smooth χ such that $0\leqq\chi\leqq 1$ and hence, since $u_{0n}\to u_0$ in $C(\bar{\Omega})$ and $u_n\to u$ in $C(\bar{Q}_T)$, we have

$$\int_\Omega (\underline{u}(t)-u(t))\chi \leqq \int_\Omega (\underline{u}_0-u_0)^+. \tag{8.5}$$

Next we consider a sequence of smooth functions χ_m such that χ_m converges in $L^2(\Omega)$ to a limit $\bar{\chi}$ defined by

$$\bar{\chi}(x)=\begin{cases}1 & \text{in } \{x|\underline{u}(x,t)\geqq u(x,t)\},\\ 0 & \text{elsewhere.}\end{cases}$$

Taking $\chi=\chi_m$ in (8.5) and letting $m\to\infty$ yield (8.1). Finally one can show (8.2) in a similar way.

9. Some remarks about the Dirichlet problem. In this section we give results about the existence, uniqueness and regularity of solutions of Problem P_D, which we introduced in §6. Because the proofs are quite similar to those given in §8, we omit them here.

THEOREM 9.1 (existence + regularity). *Let* H1 *and* H4 *be satisfied and let* $v\in W^{1,\infty}(\Omega)$. *Then Problem* P_D *possesses a solution* u *which is uniformly bounded in* Q *and which is continuous in any set* $\bar{\Omega}\times[\tau,T]$ *with* $\tau>0$. *The modulus of continuity does not depend on* T.

THEOREM 9.2 (uniqueness + comparison principle). *Let* H1, H2a *and* H4 *be satisfied. Then*:

(i) *Problem* P_D *possesses at most one solution.*

(ii) *Let* $\underline{u}(t)$ *and* $\bar{u}(t)$ *be respectively a subsolution and a supersolution of Problem* P_D *with respect to the initial functions* $\underline{u}_0$ *and* $\bar{u}_0$. *If* $\underline{u}_0\leqq\bar{u}_0$ *in* Ω, *then* $\underline{u}(t)\leqq\bar{u}(t)$ *in* Ω *for* $t\geqq 0$.

Finally we give a lemma which relates solutions of the Neumann problem which vanish on $\partial\Omega$ to solutions of the Dirichlet problem.

LEMMA 9.3. *If the solution* $u(t;u_0)$ *of Problem* P *satisfies* $u(t;u_0)=0$ *on* $\partial\Omega$ *for any* $t\geqq 0$, *then* $u(t;u_0)$ *is a solution of Problem* P_D.

Proof. Let $\psi\in C^{2,1}(\bar{Q})$ with $\psi=0$ on $\partial\Omega\times\mathbb{R}^+$. Then $u(t;u_0)$ satisfies the integral equality (iii) of Definition 7.1. Integrating by parts yields

$$\int_\Omega u(t)\psi(t)=\int_\Omega u_0\psi(0)-\int_0^t\int_{\partial\Omega}\varphi(u)\frac{\partial\psi}{\partial\nu}$$

$$+\int_0^t\int_\Omega\{\varphi(u)\Delta\psi+u\psi_t-u\operatorname{grad}v\operatorname{grad}\psi\}.$$

Since $\varphi(u)=0$ on $\partial\Omega\times\mathbb{R}^+$, the second term at the right-hand side vanishes. Thus $u(t;u_0)$ is a solution of Problem P_D.

Appendix. In this appendix we collect various approximation results which are used in this article.

A1. *Approximation of* v.

LEMMA A1. *Let* $v\in W^{1,\infty}(\Omega)$. *Then there exists a sequence* $\{v_\varepsilon\}\subset C^\infty(\bar{\Omega})$ *such that* $\|v_\varepsilon\|_{C^1(\bar{\Omega})}\leqq C$, $\|v_\varepsilon\|_{C(\bar{\Omega})}\leqq\|v\|_{L^\infty(\Omega)}$ *and* $\|v_\varepsilon-v\|_{H^1(\Omega)}\to 0$ *as* $\varepsilon\downarrow 0$.

Proof. Let $\tilde{\Omega} \supset \Omega$ with $\operatorname{dist}(\Omega, \partial\tilde{\Omega}) > 0$. Then one can extend v by a function $\tilde{v} \in W^{1,\infty}(\tilde{\Omega})$ such that $\tilde{v} = v$ in Ω and $\|\tilde{v}\|_{L^\infty(\tilde{\Omega})} \leqq \|v\|_{L^\infty(\Omega)}$. We define the function

$$\rho(x) = \begin{cases} 0 & \text{if } |x| \geqq 1, \\ C\exp\left\{\dfrac{1}{|x|^2 - 1}\right\} & \text{if } |x| < 1, \end{cases}$$

where C is a constant such that $\int_{\mathbb{R}^n} \rho(x)\,dx = 1$. Let

$$v_\varepsilon(x) = \varepsilon^{-N} \int_{\tilde{\Omega}} \rho\left(\frac{x-y}{\varepsilon}\right) \tilde{v}(y)\,dy \quad \text{for } x \in \tilde{\Omega}.$$

In particular note that $\|v_\varepsilon\|_{C(\bar{\Omega})} \leqq \|v\|_{L^\infty(\Omega)}$. Let us suppose that $\varepsilon < \operatorname{dist}(\Omega, \partial\tilde{\Omega})$. Then it is a standard result (see for instance Kufner et al. [15]) that

$$\operatorname{grad} v_\varepsilon(x) = \varepsilon^{-N} \int_{\tilde{\Omega}} \rho\left(\frac{x-y}{\varepsilon}\right) \operatorname{grad} v(y)\,dy \quad \text{for } x \in \Omega. \tag{A.1}$$

Then $\|\operatorname{grad} v_\varepsilon\|_{C(\bar{\Omega})} \leqq \|\operatorname{grad} v\|_{L^\infty(\tilde{\Omega})}$ and $\|v_\varepsilon - v\|_{W^{1,p}(\Omega)} \to 0$ as $\varepsilon \downarrow 0$ for every $p \in [1, \infty)$.

LEMMA A2. *Let $v \in W^{1,\infty}(\tilde{\Omega})$ be such that $\Delta v \geqq -M$ in the sense of distributions in $\tilde{\Omega} \supset \Omega$ with $\operatorname{dist}(\Omega, \partial\tilde{\Omega}) > 0$. Then there exists a sequence $\{v_\varepsilon\} \subset C^\infty(\bar{\Omega})$ such that $\|v_\varepsilon\|_{C^1(\bar{\Omega})} \leqq C$, $\Delta v_\varepsilon \geqq -M$ in Ω and $\|v_\varepsilon - v\|_{H^1(\Omega)} \to 0$ as $\varepsilon \downarrow 0$.*

Proof. In view of the proof of Lemma A1, it remains to show that $\Delta v_\varepsilon \geqq -M$. From (A.1) we deduce that

$$\Delta v_\varepsilon(x) = \varepsilon^{-N} \left\langle \Delta v(y), \rho\left(\frac{x-y}{\varepsilon}\right) \right\rangle \quad \text{for } x \in \Omega$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $H_0^1(\tilde{\Omega})$ and $H^{-1}(\tilde{\Omega})$. In particular, since $\Delta v \geqq -M$ we have that for $x \in \Omega$

$$\Delta v_\varepsilon(x) \geqq -\varepsilon^{-N} M \int_{\tilde{\Omega}} \frac{\rho(x-y)}{\varepsilon}\,dy = -\varepsilon^{-N} M \int_{\mathbb{R}} \rho\left(\frac{u}{\varepsilon}\right) du = -M$$

which yields the result.

A2. *Approximation of u_0.*

LEMMA A3. *Let $u_0 \in L^\infty(\Omega)$ with $u_0 \geqq 0$ a.e. and let v_ε, $v_j \in C^\infty(\bar{\Omega})$ be such that $\|v_\varepsilon\|_{C^1(\bar{\Omega})}$, $\|v_j\|_{C^1(\bar{\Omega})} \leqq C$. Then*

(i) *There exists a sequence $\{u_{0\varepsilon}\} \subset C^\infty(\bar{\Omega})$ such that $0 \leqq u_{0\varepsilon} \leqq \|u_0\|_{L^\infty(\Omega)}$, $u_{0\varepsilon}$ satisfies the compatibility condition*

$$\varphi_\varepsilon'(u_{0\varepsilon}) \frac{\partial u_{0\varepsilon}}{\partial \nu} + u_{0\varepsilon} \frac{\partial v_\varepsilon}{\partial \nu} = 0 \text{ on } \partial\Omega \quad \text{and} \quad \|u_{0\varepsilon} - u_0\|_{L^2(\Omega)} \to 0 \text{ as } \varepsilon \downarrow 0.$$

(ii) *There exists a sequence $\{u_{0j}\} \subset C^\infty(\bar{\Omega})$ such that $0 \leqq u_{0j} \leqq C$, u_{0j} satisfies the compatibility condition*

$$\varphi'\left(u_{0j} + \frac{1}{n}\right) \frac{\partial u_{0j}}{\partial \nu} + \frac{\partial v_j}{\partial \nu} u_{0j} + \left(\frac{\partial v_j}{\partial \nu} - A\right) \Big/ n = 0$$

where A is a given constant and $\|u_{0j} - u_0\|_{L^2(\Omega)} \to 0$ as $j \to \infty$.

Proof. Since (i) is practically a special case of (ii) we only prove (ii). We define

$$\tilde{u}_{0j}(x) = j^n \int_\Omega \rho(j(x-y)) u_0(y)\,dy$$

and note that $0 \leqq \tilde{u}_{0j} \leqq \|u_0\|_{L^\infty(\Omega)}$. Let B be a positive constant. It follows from Friedman [9, p. 39] that one can find a function $w_j \in C^\infty(\bar{\Omega})$ such that

$$w_j\Big|_{\partial\Omega} = B \text{ and } \frac{\partial w_j}{\partial \nu}\Big|_{\partial\Omega} = \frac{-1}{\varphi'(B+n^{-1})}\left(\frac{\partial v_j}{\partial \nu}B + \left(\frac{\partial v_j}{\partial \nu} - A\right)/n\right).$$

Also, since $\operatorname{grad} v_j$ is bounded in $C(\bar{\Omega})$ uniformly in j we have that $\|w_j\|_{C(\bar{\Omega})} \leqq C$. Since $B > 0$, there exists $\tilde{\Omega}_j \subset \Omega$ with $\operatorname{dist}(\tilde{\Omega}_j, \partial\Omega) > 0$ such that $w_j > 0$ on $\Omega \setminus \tilde{\Omega}_j$. Finally we choose $\Omega_{1j} \subset \Omega_{2j} \subset \Omega$, such that $\operatorname{dist}(\Omega_{2j}, \partial\Omega) > 0$, $\operatorname{dist}(\Omega_{1j}, \partial\Omega_{2j}) > 0$, $\Omega_{1j} \supset \tilde{\Omega}_j$ and $\operatorname{meas}(\Omega \setminus \Omega_{1j}) \leqq 1/j$. We define

$$u_{0j}(x) = \begin{cases} \tilde{u}_{0j}(x) & \text{if } x \in \Omega_{1j}, \\ \xi_j(x)\tilde{u}_{0j}(x) + (1-\xi_j(x))w_j(x) & \text{if } x \in \Omega_{2j} \setminus \Omega_{1j}, \\ w_j(x) & \text{if } x \in \Omega \setminus \Omega_{2j}, \end{cases}$$

where ξ_j is a C^∞ function such that

$$\xi_j(x) \in \begin{cases} 1 & \text{if } x \in \Omega_{1j}, \\ [0,1] & \text{if } x \in \Omega_{2j} \setminus \Omega_{1j}, \\ 0 & \text{if } x \in \Omega \setminus \Omega_{2j}. \end{cases}$$

We have that $u_{0j} \in C^\infty(\bar{\Omega})$. Also

$$\|u_{0j} - u_0\|_{L^2(\Omega)} \leqq \|u_{0j} - \tilde{u}_{0j}\|_{L^2(\Omega)} + \|\tilde{u}_{0j} - u_0\|_{L^2(\Omega)}.$$

$\|\tilde{u}_{0j} - u_0\|_{L^2(\Omega)}$ can be made arbitrarily small by choosing j large enough. The term $\|u_{0j} - \tilde{u}_{0j}\|_{L^2(\Omega)}$ is bounded by $(1/j)(\|u_0\|_{L^\infty(\Omega)} + \|w_j\|_{L^\infty(\Omega)})$, which tends to zero as $j \to \infty$.

Acknowledgments. The authors are greatly indebted to Professor M. E. Gurtin for suggesting this problem to them and for many discussions. They wish to express their thanks to Professor L. A. Peletier whose advice has been invaluable for the completion of this work.

THE WELL-POSEDNESS OF THE KURAMOTO–SIVASHINSKY EQUATION*

EITAN TADMOR†

Abstract. The Kuramoto–Sivashinsky equation arises in a variety of applications, among which are modeling reaction-diffusion systems, flame-propagation and viscous flow problems. It is considered here, as a prototype to the larger class of generalized Burgers equations: those consist of quadratic nonlinearity and arbitrary linear parabolic part. We show that such equations are well-posed, thus admitting a unique smooth solution, continuously dependent on its initial data. As an attractive alternative to standard energy methods, existence and stability are derived in this case, by "patching" in the large short time solutions without "loss of derivatives".

Key words. Kuramoto–Sivashinsky equation, fixed point iterations, existence, uniqueness, stability

AMS(MOS) subject classifications. Primary 35Q20; secondary 35K55

1. Introduction.

The equation referred to in the title is of the form

$$\frac{\partial \phi}{\partial t}+|\nabla \phi|^2+\Delta \phi+\Delta^2 \phi=0.$$

This equation was independently advocated by Kuramoto [2], in connection with reaction-diffusion systems, and by Sivashinsky [4], modeling flame propagation; it also arises in the context of viscous film flow [5] and bifurcating solutions of the Navier–Stokes equations.[1]

In this paper we study the well-posedness question associated with the one-dimensional version of the Kuramoto–Sivashinsky equation (abbreviated hereafter as the K-S equation)

$$\frac{\partial \phi}{\partial t}+\left(\frac{\partial \phi}{\partial x}\right)^2+\frac{\partial^2 \phi}{\partial x^2}+\frac{\partial^4 \phi}{\partial x^4}=0. \tag{1.1}$$

It is shown that the Cauchy problem connected with (1.1) is well-posed: the K-S equation admits a unique smooth solution, continuously dependent on its initial data. In fact, all the results quoted below equally apply to the more general equation

$$\frac{\partial \phi}{\partial t}+\left(\frac{\partial \phi}{\partial x}\right)^2=P\left(\frac{\partial}{\partial x}\right)\phi=0, \tag{1.2a}$$

with a linear part, strongly parabolic of arbitrary order $\nu>\frac{3}{2}$,

$$\operatorname{Re}\hat{P}(i\xi)\geqq \text{Const}\cdot|\xi|^{\nu}, \qquad |\xi|\to\infty. \tag{1.2b}$$

[1] G. Sivashinsky, private communication.

Existence and stability results given here, are obtained by modifying Taylor's recipe, [6, p. 96], for treating the existence question in the special case of Burgers equation, $\hat{P}(i\xi)=\xi^2$. According to that recipe, roughly speaking, dissipation is used to compensate nonlinearity, so that short time solutions can be constructed without running into the familiar phenomenon of "loss of derivatives". Coupled with an L^2-decay estimate, short time solutions are then "patched" together, in the large. A study along these lines is carried out in §2 below, where existence and stability questions are treated in connection with the K-S equation. Existence and uniqueness in this case were previously proved by energy methods, see e.g., Aimar and Penel [1], Nicolaenko and Scheurer [3]. The technical details are avoided in §2: these are postponed to §4, all proved by virtue of a single standard estimate on the *linear* dissipative part of the equation, given in §3.

The above study thus suggests itself, with handling arbitrary linear dissipative parts. In §5 we conclude by quoting the corresponding results to such generalized Burgers equations.

2. Existence and stability. We start by putting the K-S equation in a conservative form: we differentiate (1.1), obtaining that the new decayed variable $u\equiv u(x,t;\ \eta)=e^{-\eta t}\partial\phi/\partial x$, $\eta>0$, satisfies

$$\frac{\partial u}{\partial t}+e^{\eta t}\frac{\partial(u^2)}{\partial x}+\eta u+\frac{\partial^2 u}{\partial x^2}+\frac{\partial^4 u}{\partial x^4}=0; \tag{2.1a}$$

a solution for the initial value problem (2.1a) is sought, $u(t)$, $t\geqq 0$, subject to initial condition

$$u(x,t=0)=f(x). \tag{2.1b}$$

Both the pure Cauchy problem, $-\infty<x<\infty$, and the periodic problem, say $-\pi/2\leqq x\leqq\pi/2$, are discussed. We explicitly treat the first infinite case by means of Fourier expansion; the somewhat simpler periodic case can be likewise handled, using Fourier series instead.

If we let $\hat{P}(i\xi)\equiv\hat{P}(i\xi;\ \eta)=\eta-\xi^2+\xi^4$ denote the symbol associated with the spatial linear part of (2.1a) and let $\hat{Q}(\xi,t)\equiv\hat{Q}(\xi,t;\ \eta)=e^{-t\hat{P}(i\xi;\eta)}$ be its transformed solution operator, then by Duhammel's principle (2.1) admits the following integral representation

$$u(t)=Q(t;\ \eta)*f+\int_0^t e^{\eta\tau}\cdot Q(t-\tau;\ \eta)*\frac{\partial}{\partial x}\big(u^2(\tau)\big)\,d\tau. \tag{2.2}$$

Abbreviate the right-hand side of (2.2) by $\mathbf{J}_\eta[u;\ f]$; to simplify notation, we will occasionally suppress the explicit dependence on the initial data, thus writing

$$\mathbf{J}_\eta[u]\equiv\mathbf{J}_\eta[u;\ f]=Q(t;\ \eta)*f+\int_0^t e^{\eta\tau}\cdot Q(t-\tau;\ \eta)*\frac{\partial}{\partial x}\big(u^2(\tau)\big)\,d\tau. \tag{2.3}$$

The question of existence of a solution for (2.1) is now transformed into that of a fixed point solution for $\mathbf{J}_\eta[u]$. Fixing T, $T>0$, we seek a fixed point solution for $\mathbf{J}_\eta[u]$ in $L^\infty([0,T],\ L^2)$, equipped with the standard norm $\|u\|=\sup_{0\leqq t\leqq T}|u(\cdot;\ t)|$.[2] The existence of such a fixed point solution is guaranteed, at least for a short time, as a consequence of

[2] We adopt the notation of single bars to denote spatial norming; for example, $|w|_{H^s}=(\int(1+|\xi|^2)^s|\hat{w}(\xi)|^2\,d\xi)^{1/2}$. Similarly, double bars are reserved to space-time norming; for example, $\|w\|_s=\sup_{0\leqq t\leqq T}|w(\cdot,t)|_{H^s}$. In particular, $|w|=|w|_{H^0}=(\int w^2(x)\,dx)^{1/2}$, $\|w\|=\|w\|_0$.

LEMMA 2.1 (short time contraction). *Given v, w in $L^\infty([0,T], L^2)$ and $\mathbf{J}_\eta[\cdot]=\mathbf{J}_\eta[\cdot;f]$ as in (2.3). Then, there exists a constant $\eta_0 \geqq 0$, such that for $\eta \geqq \eta_0$ we have,*

$$\|\mathbf{J}_\eta[v]-\mathbf{J}_\eta[w]\| \leqq M(T;\eta)\cdot(\|v\|+\|w\|)\cdot\|v-w\|. \tag{2.4a}$$

Here, $M(T;\eta)$ is given by,

$$M(T;\eta)=2e^{\eta T}\cdot T^{1/8}. \tag{2.4b}$$

By virtue of Lemma 2.1 we find

COROLLARY 2.2 (short time boundedness). *Set $T=T_1$, $T_1>0$, such that*

$$4M(T_1;\eta)\cdot|f|<1. \tag{2.5a}$$

Then, for $\eta \geqq \eta_0$ we have,

$$\|\mathbf{J}_\eta^{[n]}[f]\| \leqq 2|f|, \qquad n=0,1,\cdots. \tag{2.5b}$$

Thus, the fixed point iterations, $\mathbf{J}_\eta^{[n]}[f]$ remain inside the origin centered ball of radius $2|f|$. Hence—since by Lemma 2.1 $\mathbf{J}_\eta[\cdot]$ contracts inside that ball, having a Lipschitz constant $4M(T_1;\eta)\cdot|f|<1$—the existence of a fixed point solution for $\mathbf{J}_\eta[u]$ follows, at least for a short time interval, $0 \leqq t \leqq T_1$. Furthermore, *the length of that existence interval, T_1, depends on no higher than the initial L^2-norm.* This latter fact plays a central role in the foregoing analysis; in particular, it enables the local solution just constructed, to be continued to a global one, with the help of

LEMMA 2.3 (large time decay). *Let $u(t;\eta)\equiv u(x,t;\eta)$ be a solution of (2.1). Then, there exists a constant $\eta_0 \geqq 0$, such that for $\eta \geqq \eta_0$ we have*

$$|u(t_2;\eta)| \leqq e^{-(\eta-\eta_0)(t_2-t_1)}\cdot|u(t_1;\eta)|, \qquad 0 \leqq t_1 \leqq t_2 \leqq T. \tag{2.6}$$

Verification of Lemma 2.3 is straightforward: multiplying (2.1a) by $u(x,t;\eta)$, integrating by parts while noting the vanishing contribution of the nonlinear term,[3] we find

$$1/2\,\frac{d}{dt}|u(t)|^2=-\eta|u(t)|^2+\left|\frac{\partial u}{\partial x}(t)\right|^2-\left|\frac{\partial^2 u}{\partial x^2}(t)\right|^2;$$

invoking the Parseval relation, the last equality yields

$$1/2\,\frac{d}{dt}|u(t)|^2 \leqq \max_\xi(-\hat{P}(i\xi;\eta))\cdot|u(t)|^2,$$

and integration finally leads us to (2.6) with $\eta_0=\frac{1}{4}$. We remark that in the periodic case, $-\pi/2 \leqq x \leqq \pi/2$, one can invoke instead Poincaré's inequality,

$$\int_{-\pi/2}^{\pi/2}\left|\frac{\partial u}{\partial x}\right|^2=\int_{-\pi/2}^{\pi/2}\left[\frac{\partial u}{\partial x}-\frac{1}{\pi}\cdot\int_{-\pi/2}^{\pi/2}\frac{\partial u}{\partial x}\right]^2 \leqq \int_{-\pi/2}^{\pi/2}\left|\frac{\partial^2 u}{\partial x^2}\right|^2,$$

leading, in a similar way, to (2.6) with $\eta_0=0$. Observe that in general the exponential growth bound, η_0, may depend on the period.

To conclude the existence of solution in the large, we now fix η, $\eta \geqq \eta_0$, with appropriately chosen η_0 in either the finite or infinite case; then, short time

[3] With the infinite pure Cauchy problem, $u(x,t)$ is required to vanish at $x=\pm\infty$, indeed, $|u(t)|_{H^1}<\infty$ according to Theorem 2.6 below.

solutions—constructed according to Lemma 2.1—can be successively "patched" together, over time intervals which—according to Lemma 2.3—are of a *fixed* (non-shrinking) length T_1. Integrating, we obtain a global solution for the K-S equation, $\phi=\phi(x,t)$; the solution so obtained is—up to integration factor—unique. Thus we finally arrive at

THEOREM 2.4 (existence). *The* K-S *equation* (1.1), *with prescribed initial data* $\phi(t=0)$ *in* H^1, *admits a unique solution*, $\phi=\phi(x,t)$, *which satisfies*,

$$\left|\frac{\partial\phi}{\partial x}(t)\right|\leqq e^{\eta_0 T}\cdot\left|\frac{\partial\phi}{\partial x}(t=0)\right|,\qquad 0\leqq t\leqq T<\infty. \tag{2.7}$$

In fact, $\phi(t)$, $t\geqq 0$, belongs to H^1: a further L^2 estimate needed here, is discussed in §4 below.

The global solution referred to in Theorem 2.4, is constructed by patching together short time solutions, using a single L^2 a priori estimate. Such a patching procedure differs from existence proofs via standard energy methods, e.g., [1], [3], where higher a priori estimates are called for. Instead, we rely here on having a derivative-free Lipschitz contraction factor, so that short time solutions can be constructed, without running into the familiar phenomenon of "loss of derivatives". We note that solving the integrodifferential equation (2.2) by fixed point iterations results in the existence of a solution satisfying the original *differential* equation (2.1), in a *weak* sense. Concerning the existence of such a solution under a stronger topology, one observes that (2.1a) contains two destabilizing sources: the focusing effect ("loss of derivatives") caused by the nonlinear term, and the exponential divergence of the second order dissipative term. It is the balance of these two terms by the fourth-order dissipation, which leads us to the important derivative-free Lipschitz contraction factor in this case. Making a finer study of that balance, we are able to conclude that the solution constructed above is, in fact, smooth enough to be interpreted as a classical one. To this end, we sharpen Lemma 2.1, stating

LEMMA 2.5 (short time contraction). *Given* v, w *in* $L^\infty([0,T],\ H^s)$ $s\geqq 0$, *and* $\mathbf{J}_\eta[\cdot]=\mathbf{J}_\eta[\cdot;\ f]$ *as in* (2.3). *Then*, *there exists a constant* $\eta_0\geqq 0$, *such that for* $\eta\geqq\eta_0$ *we have*,

$$\|\mathbf{J}_\eta[v]-\mathbf{J}_\eta[w]\|_{s+2}\leqq 2^s\cdot M(T;\ \eta)\cdot(\|v\|_s+\|w\|_s)\cdot\|v-w\|_s. \tag{2.8}$$

Thus, each fixed point iteration gives us a smoother *correction*. In particular, setting s to be zero, we find on account of Corollary 2.2 that $\{\mathbf{J}_\eta^{[n]}[f]\}_{n\geqq 0}$ form a Cauchy sequence in the $L^\infty([0,T_1],\ H^2)$—origin centered ball of radius $2|f|$. Hence, the fixed point iterations $\mathbf{J}_\eta^{[n]}[f]$ converge to a unique, short time solution, $u=u(x,t)$ in $L^\infty([0,T_1],\ H^2)$. Thanks to the L^2-decay estimate in Lemma 2.3, such short time solutions can be patched in the large as before, integrated once and yielding

THEOREM 2.6 (existence). *The* K-S *equation* (1.1), *with prescribed initial data* $\phi(t=0)$ *in* H^3, *admits a unique solution*, $\phi=\phi(x,t)$, *which satisfies*,

$$\left|\frac{\partial\phi}{\partial x}(t)\right|_{H^2}\leqq\frac{5}{4}e^{\alpha T}\cdot\left|\frac{\partial\phi}{\partial x}(t=0)\right|_{H^2},\qquad 0\leqq t\leqq T\leqq\infty. \tag{2.9}$$

Finally, we turn to examine the question of stability: allowing the initial data to vary as well, we have the final extension to the short time contraction lemma, which now reads

LEMMA 2.7 (short time contraction). *Given v, w in $L^\infty([0,T],\ H^s)$ with $f=v(t=0)$, $g=w(t=0)$ in H^{s+2}. Then, there exists a constant $\eta_0\geqq 0$ such that for $\eta\geqq\eta_0$ we have,*

$$\|\mathbf{J}_\eta[v;\ f]-\mathbf{J}_\eta[w;\ g]\|_{s+2} \leqq |f-g|_{H^{s+2}}+2^s\cdot M(t;\ \eta)\cdot(\|v\|_s+\|w\|_s)\cdot\|v-w\|_s. \tag{2.10}$$

Now let $v(t)=\mathbf{J}_\eta[v(t);\ v(t=0)]$, $w(t)=\mathbf{J}_\eta[w(t);\ w(t=0)]$ be two different fixed point solutions of (2.1a), whose initial data $f=v(t=0)$ and $g=w(t=0)$ are assumed to be in H^2; according to Theorem 2.6, $u(t)$ and $v(t)$ belong to H^2 later on, $t\geqq 0$, and as a consequence of Lemma 2.7 with $s=0$, we have short time stability

$$|v(t)-w(t)|_{H^2}\leqq\frac{1}{1-M(T_1;\ \eta)\cdot(|f|+|g|)}|v(t=0)-w(t=0)|_{H^2},\qquad 0\leqq t\leqq T_1.$$

Successive application of the last inequality yields the desired stability result, which we state as our final

THEOREM 2.8 (stability). *Let ϕ, ψ be two different solutions of the* K-S *equation* (1.1), *with initial data $\phi(t=0)$, $\psi(t=0)$ lying in H^3. Then, there exist constants C and $\beta\geqq 0$ (both may depend on $|(\partial\phi/\partial x)(t=0)|+|(\partial\psi/\partial x)(t=0)|$), such that the following estimate holds*:

$$\left|\frac{\partial\phi}{\partial x}(t)-\frac{\partial\psi}{\partial x}(t)\right|_{H^2}\leqq C\cdot e^{\beta t}\cdot\left|\frac{\partial\phi}{\partial x}(t=0)-\frac{\partial\psi}{\partial x}(t=0)\right|_{H^2},\qquad 0\leqq t\leqq T\leqq\infty. \tag{2.11}$$

3. An estimate on the dissipative kernel. The following classical estimate is in the heart of the matter.

LEMMA 3.1. *Given $\omega(x)$ in W_p^m, $1\leqq p\leqq 2$, and real r, $r\geqq\frac{1}{2}-1/p$. Then, there exist constants, $C=C_{p,r}$ and $\eta_0\geqq 0$, such that for $\eta\geqq\eta_0$ we have,*

$$|Q(t;\ \eta)*\omega|_{H^{m+r}}\leqq C\cdot e^{-(\eta-\eta_0)t}\cdot t^{-(r-1/2+1/p)/4}\cdot|\omega|_{W_p^m}. \tag{3.1}$$

Remark. We adopt here the standard notation, W_p^m, to denote the L^p-type Sobolev space of order m, consisting of those functions whose derivatives up to order m belong to L^p. (Although not specifically referred to, a fractional Sobolev space with nonintegral m should be interpreted as a Besov space: to comply with notation, we therefore restrict attention to integral orders, with the understanding that final results can be interpolated into Besov space.)

For completeness, we include here a short calculation verifying (3.1): setting $\mu=p/(2-p)$ and letting μ' be its conjugate, $1/\mu+1/\mu'=1$; then the Hölder inequality yields

$$|Q(t;\ \eta)*\omega|_{H^{m+r}}\leqq\left[\int_{-\infty}^{\infty}\left(1+|\xi|^2\right)^{\mu r}e^{-2\mu t(\eta-\xi^2+\xi^4)}d\xi\right]^{1/2\mu} \times\left[\int_{-\infty}^{\infty}\left(1+|\xi|^2\right)^{\mu' m}|\hat{\omega}(\xi)|^{2\mu'}d\xi\right]^{1/2\mu'}. \tag{3.2}$$

Since by the Hausdorff–Young inequality the Fourier transform is of type $(2\mu',\ (2\mu')'=p)$, the second factor on the right of (3.2), $|\hat{\omega}|_{W_{2\mu'}^m}$, does not exceed

$$\left[\int_{-\infty}^{\infty}\left(1+|\xi|^2\right)^{\mu' m}|\hat{\omega}(\xi)|^{2\mu'}d\xi\right]^{1/2\mu'}\leqq(2\pi)^{1/2-1/p}\cdot|\omega|_{W_p^m}. \tag{3.3}$$

Next, we split the first factor on the right of (3.2),

$$e^{-\eta t}\left[\int_{-\infty}^{\infty}\left(1+|\xi|^2\right)^{\mu r}e^{-2\mu t(\xi^4-\xi^2)}d\xi\right]^{1/2\mu}=e^{-\eta t}\left[\int_{|\xi|\leq\sqrt{2}}\cdots+\int_{|\xi|>\sqrt{2}}\cdots\right]^{1/2\mu};$$

the first of the two integrals admits a pessimistic bound of

$$\int_{|\xi|\leq\sqrt{2}}\left(1+|\xi|^2\right)^{\mu r}e^{-2\mu t(\xi^4-\xi^2)}d\xi\leq 2\sqrt{2}\,3^{\mu r}e^{\mu t/2},$$

while the second one is estimated by

$$\int_{|\xi|>\sqrt{2}}\left(1+|\xi|^2\right)^{\mu r}e^{-2\mu t(\xi^4-\xi^2)}d\xi$$

$$\leq 2^{\mu r+1}\int_{\xi=0}^{\infty}\xi^{2\mu r}e^{-\mu t\xi^4}d\xi=2^{\mu r-1}\Gamma\left(\frac{2\mu r+1}{4}\right)(\mu t)^{-(2\mu r+1)/4}.$$

Added together, we find that the first factor on the right of (3.2), does not exceed

$$\left[\int_{-\infty}^{\infty}\left(1+|\xi|^2\right)^{\mu r}e^{-2\mu t(\eta-\xi^2+\xi^4)}d\xi\right]^{1/2\mu} \tag{3.4}$$

$$\leq B_{p,r}\cdot e^{-(\eta-\eta_0)t}\cdot t^{-(2\mu r+1)/8\mu},\qquad \eta_0=\frac{1}{4},$$

with Stirling's formula giving us a bound of

$$B_{p,r}=(4\pi e)^{1/2\mu}3^{r/2}\left(r+\frac{1}{p}\right)^{r-1/2+1/p}.$$

Recalling that $(2\mu')'=p$, (3.2), (3.3) and (3.4) yield the required estimate (3.1) with $C_{p,r}=(2\pi)^{1/2-1/p}B_{p,r}$.

Remark 1. In the *infinite* case under consideration, an exponential growth bound, $\eta_0=\frac{1}{4}$, was found. In general, η_0 may depend on the period, in the spirit of an earlier remark; for example, $\eta_0=0$, in the π-periodic case.

Remark 2. For future reference, we quote here the constants $C_{p,r}$ in two special cases: as can be readily verified, $C_{2,0}=1$ (indeed, such an estimate also follows by a straightforward integration by parts, essentially contained in the verification of Lemma 2.3 above); also, by sharpening the above pessimistic bounds, one finds $C_{1,3}<8$.

4. Proof of main results. We first study the operator $\mathbf{J}_\eta[\cdot;\ \cdot]$ introduced in (2.3), whose fixed point solutions are sought. Equipped with Lemma 3.1, we are able to derive the following summary stability estimate

$$\text{(S)}\quad \left|\mathbf{J}_\eta[v(t);\ f]-\mathbf{J}_\eta[w(t);\ g]\right|_{H^{s+2}}\leq e^{-(\eta-\eta_0)t}\cdot|f-g|_{H^{s+2}}$$

$$+2^{s+1}\cdot e^{\eta t}\cdot t^{1/8}\cdot\sup_{0\leq\tau\leq t}|v(\tau)+w(\tau)|_{H^s}\cdot\sup_{0\leq\tau\leq t}|v(\tau)-w(\tau)|_{H^s}.$$

To verify (S)—assuming the quantities on the right are finite and $\eta\geq\eta_0$—we consider the difference

$$\mathbf{J}_\eta[v(t);\ f]-\mathbf{J}_\eta[w(t);\ g]=Q(t;\ \eta)*(f-g)$$

$$+\int_0^t e^{\eta\tau}\cdot Q(t-\tau;\ \eta)*\frac{\partial}{\partial x}\left(v^2(\tau)-w^2(\tau)\right)d\tau,$$

so that after taking norms on both sides we have

$$\left|\mathbf{J}_\eta[v(t);\, f]-\mathbf{J}_\eta[w(t);\, g]\right|_{H^{s+2}} \leqq |Q(t;\,\eta)*(f-g)|_{H^{s+2}} + \int_0^t e^{\eta\tau}\cdot\left|Q(t-\tau;\,\eta)*\frac{\partial}{\partial x}\left(v^2(\tau)-w^2(\tau)\right)\right|_{H^{s+2}} d\tau.$$

Now applying Lemma 3.1 with respect to both terms on the right of the last inequality: the first term with $(r,p,m)=(0,2,s+2)$, and the second one with $(r,p,m)=(3,1,s-1)$; recalling the earlier quoted constants $C_{2,0}=1$ and $C_{1,3}<8$, we find

$$\left|\mathbf{J}_\eta[v(t);\, f]-\mathbf{J}_\eta[w(t);\, g]\right|_{H^{s+2}} \leqq e^{-(\eta-\eta_0)t}\cdot|f-g|_{H^{s+2}} + 8\cdot\int_0^t e^{\eta\tau}\cdot e^{-(\eta-\eta_0)(t-\tau)}\cdot(t-\tau)^{-7/8}\cdot\left|\frac{\partial}{\partial x}\left(v^2(\tau)-w^2(\tau)\right)\right|_{W_1^{s-1}} d\tau.$$

The last integral bounds the interaction between the linear dissipative part of the equation, and the nonlinear differentiated quadratic term; the loss of derivative due to the latter is compensated here by dissipation, weighted with the L^1 topology. In order to return to the usual L^2 setup, we apply the Leibniz rule and Cauchy–Schwarz inequality to find

$$\left|\frac{\partial}{\partial x}\left(v^2(\tau)-w^2(\tau)\right)\right|_{W_1^{s-1}} \leqq 2^{s+1}\cdot|v(\tau)+w(\tau)|_{H^s}\cdot|v(\tau)-w(\tau)|_{H^s}.$$

Inserted into the last integral and carrying out the integration, we end up with the required estimate (S).

We now turn to prove the results in §2, starting with:

Short time contractions (Lemma 2.1, Lemma 2.5, Lemma 2.7). Taking supremum over both sides of the (S) estimate with varying t, $0\leqq t\leqq T$, and equipped with the notation of

$$M(T;\,\eta)=2e^{\eta T}\cdot T^{1/8}$$

in (2.4b), we find

$$\left\|\mathbf{J}_\eta[v;\, f]-\mathbf{J}_\eta[w;\, g]\right\|_{s+2} \leqq |f-g|_{H^{s+2}}+2^s\cdot M(T;\,\eta)\cdot\left(\|v\|_s+\|w\|_s\right)\cdot\|v-w\|_s,$$

so that Lemma 2.7 follows. Taking the special case $f=g$ proves Lemma 2.5, and further setting $s=0$, yields Lemma 2.1,

$$\left\|\mathbf{J}_\eta[v]-\mathbf{J}_\eta[w]\right\| \leqq \left\|\mathbf{J}_\eta[v]-\mathbf{J}_\eta[w]\right\|_2 \leqq M(T;\,\eta)\cdot\left(\|v\|+\|w\|\right)\cdot\|v-w\|.$$

(Observe that in the case of Lemma 2.1, where no gain of derivatives is involved, one can in fact improve the contraction factor $M(T;\,\eta)$ to be $\frac{2}{7}e^{\eta T}T^{7/8}$.)

An immediate consequence of Lemma 2.1 is the following:

Short time boundedness (Corollary 2.2). Setting $v=\mathbf{J}_\eta^{[n-1]}[f]$ and $w=0$ in Lemma 2.1, we find

$$\left\|\mathbf{J}_\eta\left[\mathbf{J}_\eta^{[n-1]}(f)\right]\right\| \leqq \left\|\mathbf{J}_\eta[v;\, f]-\mathbf{J}_\eta[w=0;\, f]\right\|+\left\|\mathbf{J}_\eta[w=0;\, f]\right\| \leqq M(T;\,\eta)\cdot\left\|\mathbf{J}_\eta^{[n-1]}[f]\right\|^2+\|Q(t;\,\eta)*f\|.$$

We now consider a temporal interval of length T_1 such that $4M(T_1;\ \eta)\cdot|f|<1$: assuming $\|\mathbf{J}_\eta^{[n-1]}[f]\|\leqq 2|f|$ in that interval, then together with Lemma 3.1 taking $(r,p,m)=(0,2,0)$, we obtain

$$\left\|\mathbf{J}_\eta^{[n]}[f]\right\|\leqq 4M(T_1;\ \eta)|f|\cdot|f|+|f|\leqq 2|f|,$$

and Corollary 2.2 follows by induction.

Owing to the last two results in the small, one may construct fixed point solutions, $u(t)$, as local solutions over time intervals $[T_N,T_{N+1}]$ $N=0,1,2,\cdots$, such that $4M(T_{N+1}-T_N;\ \eta)\cdot|u(T_N)|<1$. Thanks to the large L^2-estimate in Lemma 2.3, the local solutions just constructed can be patched in the large, over *fixed* length time intervals, $T_N=NT_1$, $N=0,1,\cdots$, obtaining

Existence. (Theorem 2.4, Theorem 2.6). Given the initial data $\phi(t=0)$ in H^1, we set $f=(\partial\phi/\partial x)(t=0)$ for the initial value problem (2.1); let $u(t)$, $t\geqq 0$, be its global solution, constructed according to the above recipe. Integrated once, we obtain a solution for the K-S equation, $\phi(x,t)=\int^x u(\xi,t)\,d\xi$, which satisfies—choosing $\eta=\eta_0$ in Lemma 2.3—

$$\left|\frac{\partial\phi}{\partial x}(t)\right|\leqq e^{\eta_0 T}\cdot\left|\frac{\partial\phi}{\partial x}(t=0)\right|,\qquad 0\leqq t\leqq T.$$

This proves Theorem 2.4. In order to show that $u=\partial\phi/\partial x$ possesses a certain degree of smoothness, at least that of the initial data, we appeal to the short time contraction estimate in Lemma 2.5 with $s=0$:

$$\left\|\mathbf{J}_\eta[v]-\mathbf{J}_\eta[w]\right\|_2\leqq M(T;\ \eta)\cdot(\|v\|+\|w\|)\cdot\|v-w\|.$$

Consider first the time interval $[0,T=T_1]$ and let $u=\mathbf{J}_\eta[u]$ the fixed point solution there; choosing $v=u$ and $w=0$, we find

$$\|u\|_2=\left\|\mathbf{J}_\eta[u]\right\|_2\leqq M(T_1;\ \eta)\|u\|^2+\|Q*f\|_2.$$

Using Lemma 2.3 and Lemma 3.1 with $(r,p,m)=(0,2,2)$, we end up with

$$\|u\|_2\leqq M(T_1;\ \eta)|f|^2+|f|_2^2\leqq\frac{5}{4}|f|_2.$$

Successive application of the last inequality over the accumulated patching intervals, implies

$$|u(t;\ \eta)|_{H^2}\leqq\left(\frac{5}{4}\right)^{t/T_1+1}\cdot|f|_{H^2}.$$

Choosing $\eta=\eta_0$, Theorem 2.6 now follows with $\alpha=\eta_0+\ln(\frac{5}{4})$,

$$\left|\frac{\partial\phi}{\partial x}(t)\right|_{H^2}\leqq\frac{5}{4}e^{\alpha T}\cdot\left|\frac{\partial\phi}{\partial x}(t=0)\right|_{H^2},\qquad 0\leqq t\leqq T<\infty.$$

Remark. We note that the above solution $\phi=\phi(x,t)$ lies, in fact, in the same Sobolev space the initial data belong to, H^s, $0\leqq s\leqq 2$. This follows from a complementing L^2-estimate which we now derive: multiplying (1.1) by ϕ and integrating by parts, we find

$$\frac{1}{2}\frac{d}{dt}|\phi(t)|^2\leqq\left|\frac{\partial\phi}{\partial x}(t)\right|^2-\left|\frac{\partial^2\phi}{\partial x^2}(t)\right|^2+|\phi(t)|_{L^\infty}\cdot\left|\frac{\partial\phi}{\partial x}(t)\right|^2.$$

We interpolate in a somewhat nonstandard way, $|\phi|_{L^\infty} \leq \varepsilon|\phi| + C \cdot \varepsilon^{-1} \cdot |\phi_x|$, so that by appropriately choosing $\varepsilon = \gamma \cdot |(\partial\phi/\partial x)(t)|^{-2}$, the last inequality implies

$$\frac{1}{2}\frac{d}{dt}|\phi(t)|^2 \leq \gamma \cdot |\phi(t)|^2 + \gamma^{-1}K,$$

with $K = K(|(\partial\phi/\partial x)(t)|)$. Thanks to Lemma 2.3, we can control

$$K\left(\left|\frac{\partial\phi}{\partial x}(t)\right|\right) \leq K\left(\left|\frac{\partial\phi}{\partial x}(t=0)\right|\right),$$

and L^2-boundedness now follows

$$|\phi(t)| \leq e^{\gamma t} \cdot \left[|\phi(t=0)| + \gamma^{-1} \cdot K\left(\left|\frac{\partial\phi}{\partial x}(t=0)\right|\right)\right],$$

with arbitrarily small exponential growth factor γ, $\gamma > 0$. Regarding the periodic case, $-\pi/2 \leq x \leq \pi/2$, one may subtract the average

$$\bar{\phi}(t) = \frac{1}{\pi}\int_{-\pi/2}^{\pi/2} \phi(x,t)\,dx,$$

so that by invoking Poincaré's inequality for $\phi(t) - \bar{\phi}(t)$ rather than interpolating, we find

$$|\phi(t) - \bar{\phi}(t)| \leq |\phi(t=0) - \bar{\phi}(t=0)| + K\left(\left|\frac{\partial\phi}{\partial x}(t=0)\right|\right) \cdot t^{1/2}.$$

5. A generalized Burgers equation. The results of the last sections were so organized, in order to emphasize that the only a priori estimate required for the proofs, concerns the linear dissipative part of the equation, see Lemma 3.1. Hence, the following generalization can be easily worked out.

We consider the generalized Burgers equation

$$\frac{\partial u}{\partial t} + \frac{\partial(u^2)}{\partial x} + P\left(\frac{\partial}{\partial x}\right)u = 0 \tag{5.1a}$$

whose linear part, $\partial/\partial t + P(\partial/\partial x)$, is assumed strongly parabolic of order ν,

$$\operatorname{Re}\hat{P}(i\xi) \geq \text{Const} \cdot |\xi|^\nu, \qquad |\xi| \to \infty. \tag{5.1b}$$

Regarding the corresponding kernel, $\hat{Q}(t;\ \eta) = e^{-t(\eta + \hat{P}(i\xi))}$, we have, in analogy with Lemma 3.1,

$$|Q(t;\ \eta) * \omega|_{H^{m+r}} \leq C \cdot e^{-(\eta - \eta_0)t} \cdot t^{-(r - 1/2 + 1/p)/\nu} \cdot |\omega|_{W_p^m}. \tag{5.2}$$

In particular, considering $Q(t;\ \eta)$ operating from L^1 to H^{1+s}, it is found to have an operator norm with an *integrable* singularity, $t^{-(s+3/2)/\nu}$, provided $s < \nu - \frac{3}{2}$. Arguments similar to those introduced in §2, then lead us to

THEOREM 5.1. *Let u, v be two different solutions of the generalized Burgers equation* (5.1), *with initial data lying in H^s, $s < \nu - 3/2$. Then, there exist constants, C and $\beta \geq 0$* (*both may depend on $|u(t=0)| + |v(t=0)|$*), *such that the following estimate holds*:

$$|u(t) - v(t)|_{H^s} \leq C \cdot e^{\beta t} \cdot |u(t=0) - v(t=0)|_{H^s}. \tag{5.3}$$

We end up noting that the above recipe suggests itself, in studying the all important question regarding the long-time behavior of solutions for (5.1).

Remark. The special case $P(\partial/\partial x)=(-\partial^2/\partial x^2)^{\nu/2}$ can be considered as a one-dimensional degenerate case of the formal d-dimensional Navier–Stokes equations; global regularity in the latter case follows with dissipativity of order $\nu>1+d/2$, (see, e.g., Rose and Sulem, J. de Physique, 39 (1978), pp. 441–484). In either way, one finds $\nu=\frac{3}{2}$ as the critical order of dissipativity which guarantees regularity in the one-dimensional case, $d=1$.

HOPF BIFURCATION IN TWO-COMPONENT FLOW*

M. RENARDY† AND D. D. JOSEPH‡

Abstract. The stability of viscosity-stratifed bicomponent flow has been studied by long wave asymptotics, by short wave asymptotics and numerically. These studies have shown that interfacial instabilities arise from the viscosity difference between the two fluids. If the surface tension between the fluids is nonzero, then Hopf type bifurcatinos leading to traveling interfacial waves are expected. In this paper, we prove a rigorous theorem establishing the existence of bifurcating solutions of this nature.

Key words. two-component flow, Hopf bifurcation

AMS(MOS) subject classifications. Primary 35B32, 35Q10, 76E05, 76V05

1. Introduction. The stability of two-component parallel shear flows has been analyzed by long-wave asymptotics [5], [16], short-wave asymptotics [6], [13] and numerically [11], [13]. These studies show that, if the fluids have different viscosities, then instabilities can arise at all Reynolds numbers.

This raises the question of possible alternative flow patterns which might be stable. Yih [16] has conjectured that wavy interfaces might develop. The analysis of Hooper and Boyd [6] reveals a crucial difference between the cases of zero and nonzero surface tension between the fluids. If the surface tension is zero, then sufficiently short waves are always unstable, i.e., there is an infinite number of unstable modes. This situation is very much unlike the usual problems of bifurcation theory, and we believe it is possible that no smooth interface, steady or unsteady, would be stable in this situation. (In reality, of course, the surface tension is not zero, but there will be instability for very short waves when the surface tension is small and the Reynolds number is large. We think that this instability mechanism may be relevant in the formation of emulsions.)

In the case of nonzero surface tension, however, one can establish a bifurcation theorem. If the bifurcation turns out supercritical, this provides a basis for Yih's conjecture. Whether or not the bifurcation is supercritical will in general have to be decided by a numerical calculation. To our knowledge, such calculations have not yet been done. The computations referred to above concern only the eigenvalues of the linearized problems. For the sake of simplicity, we confine attention to plane Couette flow, but it is clear that similar techniques can be applied to more complicated geometries such as concentric flow in pipes or between rotating cylinders. We consider plane Couette flow of two fluids with equal density, but different viscosities, and an interface parallel to the plates. Periodic boundary conditions are imposed in the streamwise direction. Evidently, this configuration is stable at rest. If there is a flow,

however, then instabilities can develop [6], [16]. Since, however, surface tension will damp short waves, there can be only a finite number of unstable modes. Generically, as the flow rate is increased, one specific mode will be the first to become unstable. Since the eigenvalues are complex, one expects a bifurcation of the Hopf type [7], leading to traveling interfacial waves.

The Hopf bifurcation thoerem in infinite dimensions [4], [8]–[10], [14] relies on coercive estimates for the linearized equations. For one-component free surface flows such estimates were derived by Beale [2], [3], and we shall, in §3, derive analogous estimates for two-component flow. Our proof differs from Beale's and is slightly simpler. Using these coercive estimates, we can then establish a bifurcation theorem in §4. In §§5–8, we outline an algorithm for the computation of bifurcating solutions.

2. Formulation of the problem. We consider two-dimensional flow of two fluids with different viscosities and equal densities between parallel plates; see Fig. 1. The motion in each fluid is described by the Navier–Stokes equations:

$$\left.\begin{aligned} &\rho(\dot{\mathbf{u}}+(\mathbf{u}\cdot\nabla)\mathbf{u})=\eta_1\Delta\mathbf{u}-\nabla p,\\ &\nabla\cdot\mathbf{u}=0,\end{aligned}\right\} \qquad 0<y<h(x), \tag{2.1}$$

$$\left.\begin{aligned} &\rho(\dot{\mathbf{v}}+(\mathbf{v}\cdot\nabla)\mathbf{v})=\eta_2\Delta\mathbf{v}-\nabla q,\\ &\nabla\cdot\mathbf{v}=0,\end{aligned}\right\} \qquad h(x)<y<1. \tag{2.2}$$

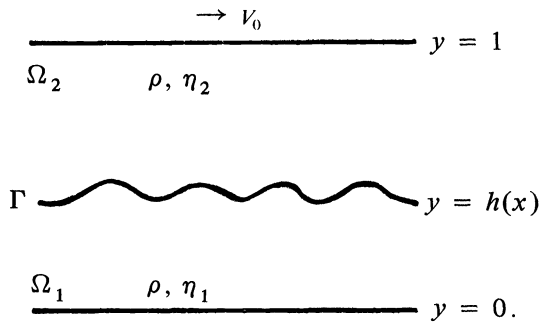

FIG. 1

We have no slip conditions at the walls:

$$\mathbf{u}=0 \qquad \text{at } y=0, \tag{2.3}$$

$$\mathbf{v}=(V_0,0) \qquad \text{at } y=1. \tag{2.4}$$

Across the interface, there must be continuity of velocity,

$$\mathbf{u}=\mathbf{v} \quad \text{at } y=h(x), \tag{2.5}$$

continuity of shear stress

$$(2.6)\quad \eta_1\left\{(1-h'^2)\left(\frac{\partial u_2}{\partial x}+\frac{\partial u_1}{\partial y}\right)+2h'\left(\frac{\partial u_2}{\partial y}-\frac{\partial u_1}{\partial x}\right)\right\}$$
$$=\eta_2\left\{(1-h'^2)\left(\frac{\partial v_2}{\partial x}+\frac{\partial v_1}{\partial y}\right)+2h'\left(\frac{\partial v_2}{\partial y}-\frac{\partial v_1}{\partial x}\right)\right\} \quad \text{at } y=h(x),$$

and balance of the normal stress difference by surface tension

$$(2.7)\quad 2\eta_1\frac{\partial u_2}{\partial y}-p-2h'\eta_1\left(\frac{\partial u_2}{\partial x}+\frac{\partial u_1}{\partial y}\right)+h'^2\left(2\eta_1\frac{\partial u_1}{\partial x}-p\right)$$
$$=2\eta_2\frac{\partial v_2}{\partial y}-q-2h'\eta_2\left(\frac{\partial v_2}{\partial x}+\frac{\partial v_1}{\partial y}\right)+h'^2\left(2\eta_2\frac{\partial v_1}{\partial x}-q\right)$$
$$+T\frac{h''}{(1+h'^2)^{1/2}} \quad \text{at } y=h(x).$$

Here T is the surface tension parameter. Finally, we have the kinematic boundary condition

$$(2.8)\qquad \dot{h}+u_1h'=u_2.$$

We are interested in solutions to (2.1)–(2.8) which have a given period L in the x-direction and are periodic in t. We denote by Ω_1 the set $\{(x,y)\,|\,0\leqq x|L,\ 0\leqq y\leqq h(x)\}$, by Ω_2 the set $\{(x,y)\,|\,0\leqq x\leqq L, h(x)\leqq y\leqq 1\}$ and by Γ the interface $\{(x,y)\,|\,0\leqq x\leqq L, y=h(x)\}$. The spaces $H^k(\Omega_1)$, $H^k(\Omega_2)$, $H^k(\Gamma)$ consist of those functions which have k square integrable derivatives and satisfy periodic boundary conditions in the x-direction.

3. The linearized problem. In this chapter, we obtain coercive estimates on the linear problem, which we shall need later. We put $V_0=0$ and linearize (2.1)–(2.8) at the rest state $\mathbf{u}=\mathbf{v}=0$, with a flat interface $h=h_0$. We include inhomogeneous terms in (2.1), (2.2), (2.6) and (2.7). The goal of this section is to derive estimates for a resolvent operator, i.e. the time dependence is assumed to be exponential, and $\partial/\partial t$ can be replaced by a constant factor λ. This leads to the problem:

$$(3.1)\quad \left.\begin{aligned}\lambda\rho\mathbf{u}&=\eta_1\Delta\mathbf{u}-\nabla p+\mathbf{f}_1,\\ \nabla\cdot\mathbf{u}&=0,\end{aligned}\right\} \qquad 0<y<h_0$$

$$(3.2)\quad \left.\begin{aligned}\lambda\rho\mathbf{v}&=\eta_2\Delta\mathbf{v}-\nabla q+\mathbf{f}_2\\ \nabla\cdot\mathbf{v}&=0,\end{aligned}\right\} \qquad h_0<y<1,$$

$$(3.3)\quad \mathbf{u}=0, \qquad y=0,$$

$$(3.4)\quad \mathbf{v}=0, \qquad y=1,$$

$$(3.5)\quad \mathbf{u}=\mathbf{v}, \qquad y=h_0,$$

$$(3.6)\quad \eta_1\left(\frac{\partial u_2}{\partial x}+\frac{\partial u_1}{\partial y}\right)-\eta_2\left(\frac{\partial v_2}{\partial x}+\frac{\partial v_1}{\partial y}\right)=f_3, \qquad y=h_0,$$

$$(3.7)\quad 2\eta_1\frac{\partial u_2}{\partial y}-p-2\eta_2\frac{\partial v_2}{\partial y}+q-Th''=f_4, \qquad y=h_0,$$

$$(3.8)\quad \lambda h=u_2, \quad y=h_0.$$

We seek solutions periodic in x with period L, and of course the same periodicity is assumed for $\mathbf{f}_1, \mathbf{f}_2$, f_3 and f_4. Our goal is the following estimate:

THEOREM 3.1. *Let* $\gamma > 0$. *For* $\mathrm{Re}\lambda \geqq \gamma$, *the following estimate holds for solutions of* (3.1)–(3.8):

$$
\begin{aligned}
(3.9)\qquad & \|\mathbf{u}\|_{H^2(\Omega_1)} + \|\mathbf{v}\|_{H^2(\Omega_2)} + \|p\|_{H^1(\Omega_1)} + \|q\|_{H^1(\Omega_2)} + |\lambda|\|\mathbf{u}\|_{L^2(\Omega_1)} \\
& \quad + |\lambda|\|\mathbf{v}\|_{L^2(\Omega_2)} + \|h\|_{H^{5/2}(\Gamma)} + |\lambda|\|h\|_{H^{3/2}(\Gamma)} \\
& \quad \leqq C\left[\|\mathbf{f}_1\|_{L^2(\Omega_1)} + \|\mathbf{f}_2\|_{L^2(\Omega_2)} + \|f_3\|_{H^{1/2}(\Gamma)} + |\lambda|^{1/4}\|f_3\|_{L^2(\Gamma)} + \|f_4\|_{H^{1/2}(\Gamma)}\right].
\end{aligned}
$$

(*Here C can depend on* γ *but not on* λ.)

Proof. We multiply (3.1) by $\bar{\mathbf{u}}$ (the complex conjugate of $\mathbf{u}$), and (3.2) by $\bar{\mathbf{v}}$, add them and integrate over the domain. Integrating by parts, and using the boundary and interface conditions, we find

$$
\begin{aligned}
(3.10)\qquad & \lambda\rho\left(\|\mathbf{u}\|_{L^2}^2 + \|\mathbf{v}\|_{L^2}^2\right) + \frac{1}{2}\eta_1\langle\mathbf{u},\mathbf{u}\rangle + \frac{1}{2}\eta_2\langle\mathbf{v},\mathbf{v}\rangle + \bar{\lambda}T\|h'\|_{L^2}^2 \\
& \quad = (\mathbf{f}_1, \bar{\mathbf{u}})_{L^2} + (\mathbf{f}_2, \bar{\mathbf{v}})_{L^2} + \int_0^L f_3\bar{u}_1(y = h_0)\,dx + \int_0^L f_4\bar{u}_2(y = h_0)\,dx.
\end{aligned}
$$

Here $\langle\mathbf{u},\mathbf{u}\rangle = \int (\nabla\mathbf{u} + (\nabla\mathbf{u})^T) : (\nabla\bar{\mathbf{u}} + (\nabla\bar{\mathbf{u}})^T)$.

Since $\mathbf{u}$ is divergence free, u_2 has a trace on the interface whose $H^{-1/2}$-norm can be bounded by $\|\mathbf{u}\|_{L^2(\Omega_1)}$ [15], hence the last term on the right side can be bounded by $\|f_4\|_{H^{1/2}(\Gamma)}\|\mathbf{u}\|_{L^2(\Omega_1)}$. The third term is bounded by

$$
\|f_3\|_{L^2(\Gamma)}\|\mathbf{u}\|_{L^2(\Gamma)} \leqq \|f_3\|_{L^2(\Gamma)}\|\mathbf{u}\|_{L^2(\Omega_1)}^{1/2}\|\mathbf{u}\|_{H^1(\Omega_1)}^{1/2}.
$$

We assume that the right side of (3.9) is bounded by a constant of order one, and we wish to bound the left side. From (3.10), we immediately obtain bounds for $\|\mathbf{u}\|_{H^1}$, $\|\mathbf{v}\|_{H^1}$, $\|h\|_{H^1}$ (we have used Korn's inequality here).

In the following, we make repeated use of the following estimates

$$
\begin{aligned}
(3.11)\qquad & \|\mathbf{u}\|_{H^2} + \|\mathbf{v}\|_{H^2} + \|p\|_{H^1} + \|q\|_{H^1} \\
& \quad \leqq C\left(\|\mathbf{f}_1\|_{L^2} + \|\mathbf{f}_2\|_{L^2} + \|f_3\|_{H^{1/2}} + |\lambda|\|h\|_{H^{3/2}} + |\lambda|\|\mathbf{u}\|_{L^2} + |\lambda|\|\mathbf{v}\|_{L^2}\right),
\end{aligned}
$$

$$
(3.12)\qquad \|h\|_{h^{5/2}} \leqq C\left(\|\mathbf{u}\|_{H^2} + \|\mathbf{v}\|_{H^2} + \|p\|_{H^1} + \|q\|_{H^1} + \|f_4\|_{H^{1/2}}\right),
$$

$$
(3.13)\qquad \|h\|_{H^{3/2}} \leqq \|h\|_{H^1}^{2/3}\|h\|_{H^{5/2}}^{1/3}.
$$

Estimate (3.11) follows from (3.1)–(3.6) and (3.8), which form an elliptic system in the sense of Agmon, Douglis and Nirenberg [1]. This can be seen as follows: We can formally regard (3.1), (3.2) as being posed in the same domain by mapping the strip occupied by fluid 2 onto the strip occupied by fluid 1. We do this in such a way that the interface is mapped onto itself and the solid boundaries are mapped onto each other. This yields a system for the six unknowns $(u_1, u_2, p, v_1, v_2, q)$, which are now defined on the same domain. That the Stokes equations are an elliptic system is well known. The same holds of course for two sets of Stokes equations. It is also well known that Dirichlet boundary conditions satisfy the complementing condition. Showing the complementing nature of the interface condition is a straightforward calculation, which we omit. Equation (3.12) is a trivial consequence of (3.7) and the trace theorem, and (3.13) follows from the convexity property of Sobolev norms.

In the following, we start from the energy equation and then use (3.11)–(3.13) in an iterative fashion to obtain better and better estimates. This will lead to the following preliminary result.

Lemma 3.2. *For any* $\varepsilon > 0$, *the following quantities can be estimated by the right-hand side of* (3.9) (*with constants allowed to depend on* ε):

$$\|h\|_{H^1}|\lambda|^{1-\varepsilon},\quad \|\mathbf{u}\|_{L^2}|\lambda|^{1-\varepsilon},\quad \|\mathbf{v}\|_{L^2}|\lambda|^{1-\varepsilon},\quad \|\mathbf{u}\|_{H^1}|\lambda|^{1/2-\varepsilon},\quad \|\mathbf{v}\|_{H^1}|\lambda|^{1/2-\varepsilon},$$
$$\left(\|\mathbf{u}\|_{H^2}+\|p\|_{H^1}\right)|\lambda|^{-1/2-\varepsilon},\quad \left(\|\mathbf{v}\|_{H^2}+\|q\|_{H^1}\right)|\lambda|^{-1/2-\varepsilon}.$$

Proof. We prove by induction that

$$(3.14)_n \qquad \|h\|_{H^1} \leqq C|\lambda|^{2^n/3^n-1},$$

$$(3.15)_n \qquad \|\mathbf{u}\|_{L^2},\ \|\mathbf{v}\|_{L^2} \leqq C|\lambda|^{2^n/3^n-1},$$

$$(3.16)_n \qquad \|\mathbf{u}\|_{H^1},\ \|\mathbf{v}\|_{H^1} \leqq C|\lambda|^{1/2(2^n/3^n-1)},$$

$$(3.17)_n \qquad \|\mathbf{u}\|_{H^2}+\|p\|_{H^1},\ \|\mathbf{v}\|_{H^2}+\|q\|_{H^1} \leqq C|\lambda|^{1/2+2^n/3^n}.$$

Obviously the lemma follows by letting $n \to \infty$. We already have (3.14)–(3.16) for $n=0$. By combining (3.11)–(3.13), we obtain

$$(3.18)\quad \|\mathbf{u}\|_{H^2}+\|p\|_{H^1}+\|\mathbf{v}\|_{H^2}+\|q\|_{H^1}$$
$$\leqq C\Big[\|\mathbf{f}_1\|_{L^2}+\|\mathbf{f}_2\|_{L^2}+\|f_3\|_{H^{1/2}}+|\lambda|\|\mathbf{u}\|_{L^2}+|\lambda|\|\mathbf{v}\|_{L^2}$$
$$+|\lambda|\|h\|_{H^1}^{2/3}\cdot\left(\|\mathbf{u}\|_{H^2}+\|\mathbf{v}\|_{H^2}+\|p\|_{H^1}+\|q\|_{H^1}+\|f_4\|_{H^{1/2}}\right)^{1/3}\Big].$$

With $\beta=\|\mathbf{u}\|_{H^2}+\|p\|_{H^1}+\|\mathbf{v}\|_{H^2}+\|q\|_{H^1}$, we find, using $(3.14)_n$–$(3.16)_n$

$$(3.19)\qquad \beta \leqq C\left(1+|\lambda|^{2^n/3^n}+|\lambda|^{2^{n+1}/3^{n+1}+1/3}\left(\beta+c'\right)^{1/3}\right).$$

From this, $(3.17)_n$ follows easily.

Next, we wish to show that $(3.14)_{n+1}$–$(3.16)_{n+1}$ follow from $(3.17)_n$. Using (3.8), the trace theorem and the convexity property of Sobolev norms, we find

$$(3.20)\qquad \|h\|_{H^1} \leqq \frac{C}{|\lambda|}\sqrt{\|\mathbf{u}\|}_{H^2}\sqrt{\|\mathbf{u}\|}_{H^1}.$$

Moreover (3.10) implies

$$(3.21)\qquad \|\mathbf{v}\|_{H^1}+\|\mathbf{u}\|_{H^1} \leqq C\left(\|\mathbf{u}\|_{L^2}+\|\mathbf{v}\|_{L^2}+|\lambda|^{-1/4}\|\mathbf{u}\|_{L^2}^{1/2}\|\mathbf{u}\|_{H^1}^{1/2}\right)^{1/2},$$

and

$$(3.22)$$
$$\|\mathbf{v}\|_{L^2}+\|\mathbf{u}\|_{L^2} \leqq C\Big[\|h\|_{H^1}+|\lambda|^{-1/2}\left(\|\mathbf{u}\|_{L^2}+\|\mathbf{v}\|_{L^2}+|\lambda|^{-1/4}\|\mathbf{u}\|_{L^2}^{1/2}\|\mathbf{u}\|_{H^1}^{1/2}\right)^{1/2}\Big].$$

With $x=\|\mathbf{u}\|_{H^1}+\|\mathbf{v}\|_{H^1}$, $y=\|\mathbf{u}\|_{L^2}+\|\mathbf{v}\|_{L^2}$ and using $(3.17)_n$, we find that (3.21), (3.22) take the following form

$$(3.23)\qquad x \leqq C\left(y^{1/2}+|\lambda|^{-1/8}x^{1/4}y^{1/4}\right),$$

$$(3.24)\qquad y \leqq C\left(|\lambda|^{2^{n-1}/3^n-3/4}x^{1/2}+|\lambda|^{-1/2}y^{1/2}+|\lambda|^{-5/8}y^{1/4}x^{1/4}\right).$$

From (3.23) it follows that $x \leqq Cy^{1/2}$ or $x \leqq C|\lambda|^{-1/6}y^{1/3}$, depending on whether the first or second term on the right is bigger. In the first case, (3.24) yields

$$y \leqq C\left(|\lambda|^{2^{n-1}/3^n - 3/4} y^{1/4} + |\lambda|^{-1/2} y^{1/2} + |\lambda|^{-5/8} y^{3/8}\right). \tag{3.25}$$

From this $(3.15)_{n+1}$ is immediate. In the second case, we get

$$y \leqq C\left(|\lambda|^{2^{n-1}/3^n - 3/4 - 1/12} y^{1/6} + |\lambda|^{-1/2} y^{1/2} + |\lambda|^{-5/8 - 1/24} y^{1/3}\right). \tag{3.26}$$

From this, $(3.15)_{n+1}$ is also immediate. From $(3.15)_{n+1}$ and (3.21) follows $(3.16)_{n+1}$, and using (3.20) and $(3.17)_n$ we find $(3.14)_{n+1}$. This concludes the proof of the lemma.

We now return to the proof of Theorem 3.1.

To proceed further, we take difference quotients in the x-direction. These satisfy the same equations (3.1)–(3.8) with the f's replaced by their difference quotients. From (3.10), we then see that the H^1-norms of all x-derivatives of $\mathbf{u}$ and $\mathbf{v}$ can be estimated by terms of order 1. The divergence condition now yields

$$\|u_2\|_2, \|v_2\|_2 \leqq C.$$

Equation (3.8) and the trace theorem imply that $\|h\|_{H^{3/2}} \leqq C/|\lambda|$, and from (3.11), and Lemma 3.2 we conclude that

$$\|\mathbf{u}\|_{H^2} + \|\mathbf{v}\|_{H^2} + \|p\|_{H^1} + \|q\|_{H^1} \leqq C|\lambda|^{\varepsilon}.$$

Using this in (3.20), we get $\|h\|_{H^1} \leqq C|\lambda|^{-5/4+\varepsilon}$, and by inserting this in (3.21), (3.22), we find $\|\mathbf{u}\|_{L^2} + \|\mathbf{v}\|_{L^2} \leqq C/|\lambda|$. By using (3.11) again, we obtain the theorem.

Remarks. We have so far only given estimates for a solution that was assumed to exist and have the regularity implied by the left-hand side of (3.9). Such estimates show that (3.1)–(3.8) for $\mathrm{Re}\lambda \geqq \gamma > 0$ is solvable for a closed set of f's (in the topology indicated by the right side of (3.9)). Solvability for a dense set of f's can be shown in a straightforward manner by separation of variables. (Separation of variables leads to a system of ODE's, and it is easy to show that a Fredholm alternative holds for these ODE's. The absence of eigenfunctions follows from the energy equation.) From this we see that in fact, for any λ with $\mathrm{Re}\lambda > 0$, (3.1)–(3.8) has a unique solution. Inequality (3.9) holds uniformly in any closed subset of any right half-plane, if this subset contains no eigenvalues. Moreover, by compactness, the number of eigenvalues is countable, and there can be only finitely many in any bounded set. Equation (3.10) implies that all eigenvalues have negative real parts.

4. Bifurcation to travelling waves. It is convenient to use a domain mapping which takes the domain occupied by each fluid to a fixed one. The most straightforward way to construct such a mapping is to stretch or contract vertical lines. We shall in addition transform the velocity fields in such a way that the divergence condition is preserved and (2.8) reduces to the linearized form even in the nonlinear case. In doing this, we essentially follow Beale [2].

Let $y = h_0$ be the flat interface of the rest state, and let $y = h(x,t)$ be the actual interface, which we assume periodic in x with period L.

Let P be any linear extension operator that maps functions $h(\zeta) \in H^s(\Gamma)$, into functions $\tilde{h}(\zeta,\eta)$ such that $\tilde{h}(\zeta,h_0) = h(\zeta)$ and $\tilde{h} \in H^{s+1/2}(\Omega)$ (P exist according to the trace theorem). For simplicity, we also assume that P takes $h \equiv h_0$ to $\tilde{h} \equiv h_0$. Let then $f_0(\eta)$ be a C^∞-function of η such that $f_0 = 1$ near $\eta = h_0$ and $f_0 = 0$ near $\eta = 0$ and $\eta = 1$. Define $\bar{h}(\zeta,\eta,t) = \tilde{h}(\zeta,\eta,t)\cdot f_0(\eta) + h_0(1 - f_0(\eta))$.

We now define

$$\theta(\zeta,\eta,t)=\left(\zeta,\eta\cdot\frac{\bar{h}(\zeta,\eta,t)}{h_0}\right). \tag{4.1}$$

Evidently, θ maps the strip $0\leqq\eta\leqq h_0$ to Ω_1, and the strip $h_0\leqq\eta\leqq 1$ to Ω_2. The velocities are transformed as follows:

$$u_i(\theta(\zeta,\eta,t))=\frac{\partial\theta_i}{\partial\zeta_j}\tilde{u}_j/J, \tag{4.2}$$

where J is the Jacobian of θ. Of course, $\mathbf{v}$ in Ω_2 is transformed in the same way. Explicitly, (4.2) reads

$$\mathbf{u}=\left(\frac{\bar{h}}{h_0}+\eta\frac{\bar{h}_\eta}{h_0}\right)^{-1}\left(\tilde{u}_1,\eta\frac{\bar{h}_\zeta}{h_0}\tilde{u}_1+\left(\frac{\bar{h}}{h_0}+\eta\frac{\bar{h}_\eta}{h_0}\right)\tilde{u}_2\right). \tag{4.3}$$

Formula (4.2) is set up in such a way that $\mathbf{u}$, $\mathbf{v}$ are divergence-free in the x, y-plane, if $\tilde{\mathbf{u}}$, $\tilde{\mathbf{v}}$ are divergence-free in the ζ, η-plane. Moreover, (2.8) now assumes the simple form

$$\dot{h}(\zeta,t)=\tilde{u}_2(\zeta,h_0,t). \tag{4.4}$$

It is also clear that (2.5) does not change its form, i.e. $\mathbf{u}=\mathbf{v}$ at $y=h(x)$ simply becomes $\tilde{\mathbf{u}}=\tilde{\mathbf{v}}$ at $\eta=h_0$. The boundary conditions at the walls are also preserved. When these substitutions are inserted into (2.1)–(2.8), we obtain a new set of equations, which we do not write down explicitly. We shall refer to these new equations as (2.1)*–(2.8)*. If we have a flat interface $h=h_0$, then of course (4.3) reads $\mathbf{u}=\tilde{\mathbf{u}}$, and (2.1)*–(2.8)* have the same form as (2.1)–(2.8).

Plane Couette flow is the following solution of (2.1)–(2.8):

$$\hat{h}(x)\equiv h_0,\ \hat{u}_1=\frac{\eta_2 V_0}{\eta_1+h_0(\eta_2-\eta_1)}y,\quad \hat{u}_2=0,\quad \hat{v}_1=\frac{\eta_1 V_0 y+V_0 h_0(\eta_2-\eta_1)}{\eta_1+h_0(\eta_2-\eta_1)},$$
$$\hat{v}_2=0,\quad \hat{p}=0,\quad \hat{q}=0.$$

We can linearize at this solution, and obtain a set of linearized equations analogous to (3.1)–(3.8). As usual, we call λ an eigenvalue, if the homogeneous linearized problem has nontrivial solutions. The estimates in §3 imply that, for $V_0=0$ (rest), there is a countable sequence of eigenvalues, all in a sector of the left half plane bounded away from the imaginary axis. All these eigenvalues have finite multiplicity and Fredholm index zero. Estimates like those in §3 can easily be extended to the linearization at Couette flow with finite V_0. If we linearize (2.1)–(2.8) at this flow, then there are a number of terms perturbing (3.1)–(3.8). All these terms are relatively compact except the one resulting from u_1h' in (2.8). This latter term vanishes in a frame moving with the fluid on the interface. Standard perturbation theory [12] can now be used to show that estimates like in §3 hold for λ in any closed set that lies in a right half plane and contains no eigenvalues. However, there can, and as [6], [16] show, there will be a finite number of eigenvalues with positive real parts if V_0 is large enough. Generically, there will be a critical value V_{0c}, such that, for $V_0<V_{0c}$, all eigenvalues have negative real parts, but a pair of simple complex conjugate eigenvalues crosses the imaginary axis transversally as V_0 increases past V_{0c}. Let us denote these imaginary eigenvalues by $\pm i\omega_0$.

We introduce the following substitutions in (2.1)*–(2.8)*:

$$\tau=\omega t,\quad \mathbf{u}^*=\tilde{\mathbf{u}}-\hat{\mathbf{u}}(V_0),\quad \mathbf{v}^*=\tilde{\mathbf{v}}-\hat{\mathbf{v}}(V_0),\quad h^*=(h-h_0)\frac{\omega}{\omega_0}.$$

We use the following notation for function space: $H^k_{\Omega_1}$ denotes the space of functions defined on $-\infty<\zeta<\infty$, $0\leqq\eta\leqq h_0$, which have period L in ζ and H^k-regularity. Similarly, we define $H^k_{\Omega_2}$. Finally H^k_Γ is the set of k times differentiable periodic functions depending on ζ alone.

$H^k(X)$ denotes the spaces of all 2π-periodic functions defined on $-\infty<\tau<\infty$, taking values in X, and having k square integrable derivatives.

For the analysis of (2.1)*–(2.8)*, we choose the following space V:

$$\begin{aligned}V=\Big\{&(\mathbf{u}^*,\mathbf{v}^*,p,q,h^*)\,|\,\mathbf{u}^*\in H^1\big(H^2_{\Omega_1}\big)\cap H^2\big(L^2_{\Omega_1}\big),\ v^*\in H^1\big(H^2_{\Omega_2}\big)\cap H^2\big(L^2_{\Omega_2}\big),\\ &p\in H^1\big(H^1_{\Omega_1}\big),\ q\in H^1\big(H^1_{\Omega_2}\big),\ h^*\in H^1\big(H^{5/2}_\Gamma\big)\cap H^2\big(H^{3/2}_\Gamma\big);\\ &\operatorname{div}\mathbf{u}^*=0,\ \operatorname{div}\mathbf{v}^*=0,\\ &\iint_{\Omega_1}p+\iint_{\Omega_2}q=0,\ \mathbf{u}^*=0 \text{ at } \eta=0,\ \mathbf{v}^*=0 \text{ at } \eta=1,\ \mathbf{u}^*=\mathbf{v}^* \text{ at}\\ &\qquad\eta=h_0,\ \omega_0\frac{\partial h^*}{\partial\tau}=\mathbf{u}^* \text{ at } \eta=h_0,\ \int_0^L h^*(\zeta)\,d\zeta=0\Big\}.\end{aligned}$$

Functions in this space have sufficient regularity such that all the nonlinearities in (2.1)*–(2.8)* are defined. We can now prove a Hopf bifurcation result based on the implicit function theorem. This relies essentially on an iterative scheme which at each stage solves the linearized problem with the nonlinear terms as inhomogeneities. It is important that such an iteration takes the space V into itself, i.e. that by inverting the linearized operator we gain at least as much regularity as we lose by evaluating the nonlinear terms. This is guaranteed by the coercive estimate of Theorem 3.1. In this way, we obtain the following.

THEOREM 4.1. *Assume that, at $V_0=V_{0c}$, there is a pair of algebraically simple complex conjugate eigenvalues $\pm i\omega_0$, $\omega_0\neq 0$, and no other eigenvalue is an integral multiple of $i\omega_0$. Moreover, assume that those eigenvalues cross the imaginary axis transversally, i.e. if $\lambda(V_0)$ denotes the branch of eigenvalues for which $\lambda(V_{0c})=i\omega_0$, then $(d/dV_0)\operatorname{Re}\lambda(V_0)\,|_{V_0=V_{0c}}\neq 0$. Then there is an analytic branch of nontrivial time-periodic solutions $(\mathbf{u}^*(\varepsilon),\mathbf{v}^*(\varepsilon),p(\varepsilon),q(\varepsilon),h^*(\varepsilon))=:Y(\varepsilon)$, such that $Y(\varepsilon)\in V$ is a solution of (2.1)*–(2.8)* for $V_0=V_0(\varepsilon)$ with temporal frequency $\omega=\omega(\varepsilon)$. For $\varepsilon=0$, we have $V_0=V_{0c}$, $\omega=\omega_0$ and $Y=0$. This branch of periodic solutions is unique except for phase shift or changes of parametrization.*

If, at $V_0=V_{0c}$, all eigenvalues other than $\pm i\omega_0$ have negative real parts and we have $\frac{d}{dV_0}\operatorname{Re}\lambda(V_0)\,|_{V_0=V_{0c}}>0$, then the bifurcating periodic solutions are stable if $V_0(\varepsilon)>V_{0c}$ for small $\varepsilon\neq 0$, and unstable if $V_0(\varepsilon)<V_{0c}$.

Remark. It is easy to show higher regularity of the bifurcating solutions by choosing function spaces of higher regularity for the bifurcation analysis.

5. Reduction of the bifurcation problem to local form. In the previous two sections, we have provided the analytical tools and the estimates needed to establish a bifurcation theorem. In the following, we now describe an algorithm for calculating approximations to this bifurcating solution.

As before, we study bifurcation from plane Couette flow, and we consider the velocity of the upper plate as the bifurcation parameter. Plane Couette flow is the following solution of (2.1)–(2.8):

$$
\begin{aligned}
&\hat{h}(x)=h_0,\\
&\hat{u}_1=\frac{\eta_2 V_0 y}{\eta_1+h_0(\eta_2-\eta_1)},\\
&\hat{u}_2=0, \qquad \hat{p}=0,\\
&\hat{v}_1=\frac{[\eta_1 y+h_0(\eta_2-\eta_1)]V_0}{\eta_1+h_0(\eta_2-\eta_1)},\\
&v_2=0, \qquad q=0.
\end{aligned}
\tag{5.1}
$$

For the bifurcation problem, it is convenient to introduce new variables representing the perturbation of this solution. We therefore replace u_1 and v_1 by $u_1+\hat{u}_1$, $v_1+\hat{v}_1$, where $\hat{u}_1$, $\hat{v}_1$ are given by formula (5.1) in the regions $0\leqq y\leqq h(x,t)$ and $h(x,t)\leqq y\leqq 1$, respectively. Moreover, we set

$$
h(x,t)=h_0+\delta(x,t), \tag{5.2}
$$

and $\delta(x,t)$ has zero mean value as a function of x. With this change of variables, (2.1) and (2.2) take the form

$$
\rho\left[\dot{\mathbf{u}}+\hat{u}_1\frac{\partial \mathbf{u}}{\partial x}+\mathbf{e}_x u_2\frac{\partial \hat{u}_1}{\partial y}+(\mathbf{u}\cdot\nabla)\mathbf{u}\right]=\eta_1\Delta\mathbf{u}-\nabla p, \quad 0\leqq y\leqq h(x,t), \quad \operatorname{div}\mathbf{u}=0, \tag{5.3}
$$

$$
\rho\left[\dot{\mathbf{v}}+\hat{v}_1\frac{\partial \mathbf{v}}{\partial x}+\mathbf{e}_x v_2\frac{\partial \hat{v}_1}{\partial y}+(\mathbf{v}\cdot\nabla)\mathbf{v}\right]=\eta_2\Delta\mathbf{v}-\nabla q, \quad h(x,t)\leqq y\leqq 1, \quad \operatorname{div}\mathbf{v}=0. \tag{5.4}
$$

On the walls, we have

$$
\mathbf{u}=0 \text{ at } y=0, \qquad \mathbf{v}=0 \text{ at } y=1. \tag{5.5}
$$

In the normal and shear stress conditions, the terms replaced by $\hat{u}_1$, $\hat{v}_1$ are such that they cancel. Moreover, $h'=\delta'$, so h can be replaced by δ. Across the interface $y=h(x,t)$, we thus obtain the following conditions resulting from (2.6) and (2.7)

$$
\begin{aligned}
&(1-\delta'^2)\eta_1\left(\frac{\partial u_2}{\partial x}+\frac{\partial u_1}{\partial y}\right)+2\eta_1\delta'\left(\frac{\partial u_2}{\partial y}-\frac{\partial u_1}{\partial x}\right)\\
&\qquad=(1-\delta'^2)\eta_2\left(\frac{\partial v_2}{\partial x}+\frac{\partial v_1}{\partial y}\right)+2\eta_2\delta'\left(\frac{\partial v_2}{\partial y}-\frac{\partial v_1}{\partial x}\right),
\end{aligned}
\tag{5.6}
$$

$$
\begin{aligned}
&2\eta_1\frac{\partial u_2}{\partial y}-p-2\delta'\eta_1\left(\frac{\partial u_2}{\partial x}+\frac{\partial u_1}{\partial y}\right)+\delta'^2\left(2\eta_1\frac{\partial u_1}{\partial x}-p\right)\\
&\qquad=2\eta_2\frac{\partial v_2}{\partial y}-q-2\delta'\eta_2\left(\frac{\partial v_2}{\partial x}+\frac{\partial v_1}{\partial y}\right)+\delta'^2\left(2\eta_2\frac{\partial v_1}{\partial x}-q\right)+T\delta''/(1+\delta'^2)^{1/2}.
\end{aligned}
\tag{5.7}
$$

The condition (2.5) is replaced by

$$u_1 - v_1 = \hat{v}_1(h_0+\delta) - \hat{u}_1(h_0+\delta) = \frac{(\eta_1-\eta_2)\delta V_0}{\eta_1 + h_0(\eta_2-\eta_1)}, \tag{5.8}$$

$$u_2 = v_2. \tag{5.9}$$

Equation (5.8) shows that, for $\eta_1 \neq \eta_2$ and $V_0 \neq 0$, $\delta(x,t)$ can be eliminated and expressed by the jump in the x-component of velocity at $y = h_0 + \delta(x,t)$. Finally, equation (2.8) assumes the form

$$\dot{\delta} + \hat{u}_1(h_0)\delta' + u_1\delta' + \frac{\eta_2 V_0 \delta\delta'}{\eta_1 + h_0(\eta_2-\eta_1)} = u_2. \tag{5.10}$$

Our bifurcation problem is now given by (5.1)–(5.10). The null solution corresponds to plane Couette flow. We consider δ in (5.6), (5.7) and (5.10) as having been eliminated from (5.8), and look for solutions $(\mathbf{u}, \mathbf{v}, p, q)$ which are periodic in x.

6. The spectral problem and its adjoint. The spectral problem for the stability of the null solution is

$$\rho\left[\lambda\mathbf{u} + \hat{u}_1 \frac{\partial \mathbf{u}}{\partial x} + \mathbf{e}_x u_2 \hat{u}_1'\right] + \nabla p - 2\eta_1 \operatorname{div} \underline{\underline{D}}[\mathbf{u}] = 0, \quad 0 \leqq y \leqq h_0, \quad \operatorname{div}\mathbf{u} = 0, \tag{6.1}$$

$$\rho\left[\lambda\mathbf{v} + \hat{v}_1 \frac{\partial \mathbf{v}}{\partial x} + \mathbf{e}_x v_2 \hat{v}_1'\right] + \nabla q - 2\eta_2 \operatorname{div} \underline{\underline{D}}[\mathbf{v}] = 0, \quad h_0 \leqq y \leqq 1, \quad \operatorname{div}\mathbf{v} = 0. \tag{6.2}$$

Here $\underline{\underline{D}}[\mathbf{u}]$ is the symmetric part of $\nabla\mathbf{u}$. $\hat{u}_1'$ and $\hat{v}_1'$ denote derivatives with respect to h, while h' and δ' will continue to denote derivatives with respect to x. On the walls we have

$$\mathbf{u} = 0 \text{ at } y = 0, \qquad \mathbf{v} = 0 \text{ at } y = 1. \tag{6.3}$$

From (5.8), we have $\delta = k(u_1 - v_1)$, where $k = (\eta_1 + (\eta_2 - \eta_1)h_0)/V_0(\eta_1 - \eta_2)$.

By inserting this into the remaining interface conditions and linearizing, we find the following conditions at $y = h_0$:

$$u_2 - v_2 = 0, \tag{6.4}$$

$$2\eta_1 D_{12}[\mathbf{u}] - 2\eta_2 D_{12}[\mathbf{v}] = 0, \tag{6.5}$$

$$-p + 2\eta_1 D_{22}[\mathbf{u}] + q - 2\eta_2 D_{22}[\mathbf{v}] - Tk(u_1'' - v_1'') = 0, \tag{6.6}$$

$$\left(\lambda + \hat{u}(h_0)\frac{\partial}{\partial x}\right) k(u_1 - v_1) - u_2 = 0. \tag{6.7}$$

We turn next to the computation of the spectral problem, which is adjoint to (6.1)–(6.7). We multiply (6.1) by $\bar{\mathbf{u}}^*$, (6.2) by $\bar{\mathbf{v}}^*$, the complex conjugates of the adjoint velocities, and integrate the resulting expressions over their domain of definition. We assume periodicity in x with period L, and integrate by parts using periodicity, solenoidality

and (6.3) to derive

$$(6.8)\qquad \int_{\Omega_1}\left\{\rho\lambda\bar{\mathbf{u}}^*-\rho\hat{u}_1\frac{\partial\bar{\mathbf{u}}^*}{\partial x}+\rho\bar{u}_1^*\hat{u}_1'\mathbf{e}_y-2\eta_1\operatorname{div}\underline{\underline{D}}[\bar{\mathbf{u}}^*]\right\}\cdot\mathbf{u}\,dx\,dy$$

$$+\int_{\Omega_2}\left\{\rho\lambda\bar{\mathbf{v}}^*-\rho\hat{v}_1\frac{\partial\bar{\mathbf{v}}^*}{\partial x}+\rho\bar{v}_1^*\hat{v}_1'\mathbf{e}_y-2\eta_2\operatorname{div}\underline{\underline{D}}[\bar{\mathbf{v}}^*]\right\}\cdot\mathbf{v}\,dx\,dy$$

$$-\int_{\Omega_1}p\operatorname{div}\bar{\mathbf{u}}^*-\int_{\Omega_2}q\operatorname{div}\bar{\mathbf{v}}^*$$

$$=-\int_0^L\{(-q+2\eta_2D_{22}[\mathbf{v}])\bar{v}_2^*-(-p+2\eta_1D_{22}[\mathbf{u}])\bar{u}_2^*$$

$$+2\eta_2\bar{v}_1^*D_{12}[\mathbf{v}]-2\eta_2v_1D_{12}[\bar{\mathbf{v}}^*]-2\eta_2v_2D_{22}[\bar{\mathbf{v}}^*]$$

$$+2\eta_1u_1D_{12}[\bar{\mathbf{u}}^*]-2\eta_1\bar{u}_1^*D_{12}[\mathbf{u}]+2\eta_1u_2D_{22}[\mathbf{u}^*]\}\,dx.$$

By considering special forms of $\mathbf{u}$, $\mathbf{v}$, p, q, we find that in $0\leqq y\leqq h_0$, we have

$$(6.9)\qquad \rho\lambda\bar{\mathbf{u}}^*-\rho\hat{u}_1\frac{\partial\bar{\mathbf{u}}^*}{\partial x}+\rho\mathbf{e}_y\bar{u}_1^*\hat{u}_1'-2\eta_1\operatorname{div}\underline{\underline{D}}[\bar{\mathbf{u}}^*]=-\nabla\bar{p}^*,\qquad \operatorname{div}\bar{\mathbf{u}}^*=0,$$

whilst in $h_0\leqq y\leqq 1$,

$$(6.10)\qquad \rho\lambda\bar{\mathbf{v}}^*-\rho\hat{v}_1\frac{\partial\bar{\mathbf{v}}^*}{\partial x}+\rho\mathbf{e}_y\bar{v}_1^*\hat{v}_1'-2\eta_2\operatorname{div}\underline{\underline{D}}[\bar{\mathbf{v}}^*]=-\nabla q^*,\qquad \operatorname{div}\bar{\mathbf{v}}^*=0.$$

We insert (6.9) and (6.10) back into (6.8), and compute

$$\int_{\Omega_1}\mathbf{u}\cdot\nabla\bar{p}^*\,dx\,dy+\int_{\Omega_2}\mathbf{v}\cdot\nabla\bar{q}^*\,dx\,dy=\int_0^L(\bar{p}^*u_2-\bar{q}^*v_2)\,dx.$$

This term is added to the right-hand side of (6.8), leading to

$$(6.11)\qquad 0=\int_0^L\{(-q+2\eta_2D_{22}[\mathbf{v}])\bar{v}_2^*+(p-2\eta_1D_{22}[\mathbf{u}])\bar{u}_2^*$$

$$+(\bar{q}^*-2\eta_2D_{22}[\bar{\mathbf{v}}^*])v_2+(-\bar{p}^*+2\eta_1D_{22}[\bar{\mathbf{u}}^*])u_2$$

$$+2\eta_2\bar{v}_1^*D_{12}[\mathbf{v}]-2\eta_1\bar{u}_1^*D_{12}[\mathbf{u}]$$

$$+2\eta_1u_1D_{12}[\bar{\mathbf{u}}^*]-2\eta_2v_1D_{12}[\bar{\mathbf{v}}^*]\}\,dx.$$

We use (6.6) to reduce the first line of (6.11), (6.4) for the second line and (6.5) for the third line. Thus we find

$$(6.12)\quad 0=\int_0^L\{(-q+2\eta_2D_{22}[\mathbf{v}])(\bar{v}_2^*-\bar{u}_2^*)-T\delta''\bar{u}_2^*$$

$$+u_2(\bar{q}^*-2\eta_2D_{22}[\bar{\mathbf{v}}^*]-\bar{p}^*+2\eta_1D_{22}[\bar{\mathbf{u}}^*])$$

$$+(\bar{v}_1^*-\bar{u}_1^*)2\eta_1D_{12}[\mathbf{u}]$$

$$+(u_1-v_1)\cdot2\eta_1D_{12}[\bar{\mathbf{u}}^*]+v_1(2\eta_1D_{12}[\bar{\mathbf{u}}^*]-2\eta_2D_{12}[\bar{\mathbf{v}}^*])\}\,dx.$$

We next write

$$\int_0^L \delta'' \bar{u}_2^* \, dx = \int_0^L \delta \bar{u}_2^{*\prime\prime} \, dx,$$

and set $\delta = k(u_1 - v_1)$, $u_2 = (\lambda + \hat{u}(h_0)\partial/\partial x)k(u_1 - v_1)$.

This leads to

$$\begin{aligned} 0 = \int_0^L \Big\{ & \big(-q + 2\eta_2 D_{22}[\mathbf{v}]\big)\big(\bar{v}_2^* - \bar{u}_2^*\big) \\ & + (u_1 - v_1)\Big\langle -Tk\bar{u}_2^{*\prime\prime} + \Big(\lambda - \hat{u}(h_0)\frac{\partial}{\partial x}\Big)k\big(\bar{q}^* - 2\eta_2 D_{22}[\bar{\mathbf{v}}^*] \\ & \qquad - \bar{p}^* + 2\eta_1 D_{22}[\bar{\mathbf{u}}^*]\big) + 2\eta_1 D_{12}[\bar{\mathbf{u}}^*]\Big\rangle \\ & + \big(\bar{v}_1^* - \bar{u}_1^*\big)\cdot 2\eta_1 D_{12}[\mathbf{u}] + v_1\big(2\eta_1 D_{12}[\bar{\mathbf{u}}^*] - 2\eta_2 D_{12}[\bar{\mathbf{v}}^*]\big)\Big\} \, dx. \end{aligned}$$

This yields the following four conditions on $y = h_0$:

$$2\eta_1 D_{12}[\bar{\mathbf{u}}^*] = 2\eta_2 D_{12}[\bar{\mathbf{v}}^*], \tag{6.13}$$

$$\bar{u}_1^* = \bar{v}_1^*, \tag{6.14}$$

$$\bar{u}_2^* = \bar{v}_2^*, \tag{6.15}$$

$$\begin{aligned} -Tk\bar{u}_2^{*\prime\prime} + \Big(\lambda - \hat{u}(h_0)\frac{\partial}{\partial x}\Big)k\big(\bar{q}^* - 2\eta_2 D_{22}[\bar{\mathbf{v}}^*] \\ - \bar{p}^* + 2\eta_1 D_{22}[\bar{\mathbf{u}}^*]\big) + 2\eta_1 D_{12}[\bar{\mathbf{u}}^*] = 0. \end{aligned} \tag{6.16}$$

Thus the adjoint problem is given by the differential equations (6.9), (6.10), the Dirichlet conditions $\bar{\mathbf{u}}^* = 0$, $\bar{\mathbf{v}}^* = 0$ on the walls and conditions (6.13)–(6.16) on the interface.

It is easy to establish a necessary and sufficient condition for the solvability of the inhomogeneous problem corresponding to (6.1)–(6.7). Suppose that the zeros on the right of the first equation in (6.1) and (6.2) and on the right of (6.4)–(6.7) are replaced by

$$\mathbf{g}_1(x,y), \quad \mathbf{g}_2(x,y), \quad g_3(x), \quad g_4(x), \quad g_5(x), \quad g_6(x), \tag{6.17}$$

respectively. This inhomogeneous problem is solvable if and only if the data (6.17) are orthogonal to the kernel of the adjoint, that is, when (6.17) is such that

$$\begin{aligned} & \int_{\Omega_1} \mathbf{g}_1 \cdot \bar{\mathbf{u}}^* \, dx\, dy + \int_{\Omega_2} \mathbf{g}_2 \cdot \bar{\mathbf{v}}^* \, dx\, dy \\ & \quad = \int_0^L \big\{ g_3\big(\bar{q}^* - 2\eta_2 D_{22}[\bar{\mathbf{v}}^*]\big) + g_4 \bar{u}_1^* + g_5 \bar{u}_2^* \\ & \qquad + g_6\big(\bar{q}^* - 2\eta_2 D_{22}[\bar{\mathbf{v}}^*] - \bar{p}^* + 2\eta_1 D_{22}[\bar{\mathbf{u}}^*]\big)\big\} \, dx. \end{aligned} \tag{6.18}$$

We are interested in the neighborhood of a critical point, where a loss of stability occurs. There is a critical plate velocity $V_0 = \hat{V}_0$ such that the real part of λ vanishes, and $\lambda = i\omega_0$. We put

$$V_0 = \hat{V}_0(1 + R),$$

so criticality is when $R=0$. We get Hopf bifurcation when the loss of stability is strict

$$\operatorname{Re} \left.\frac{\partial \lambda}{\partial R}\right|_{R=0} \neq 0.$$

Let

$$\zeta_0 = \begin{cases} \mathbf{u} & \text{in } \Omega_1 (y < h_0), \\ \mathbf{v} & \text{in } \Omega_2 (y > h_0) \end{cases}$$

be a right eigenvector satisfying (6.1)–(6.7) at criticality. Then $\bar{\zeta}_0$ is the right eigenvector belonging to $-i\omega_0$. $\bar{\zeta}_0^*$ and ζ_0^* are the left eigenvectors belonging to $i\omega_0$ and $-i\omega_0$.

7. Domain perturbations and Hopf bifurcation. We have already demonstrated that Couette flow can bifurcate into a time-periodic solution in which we have travelling interfacial waves. To compute this solution we would, following Lindstedt, map the solution into a fixed frequency domain (2π periodic in s)

$$\omega \, dt = ds,$$

and replace

$$(\dot{\mathbf{u}}, \dot{\mathbf{v}}, \dot{\delta}) \quad \text{with } \omega \left(\frac{\partial \mathbf{u}}{\partial s}, \frac{\partial \mathbf{v}}{\partial s}, \frac{\partial \delta}{\partial s} \right) \tag{7.1}$$

in (5.3), (5.4) and (5.10). We then map our problem into a fixed spatial domain, using a one-to-one linear mapping, which takes boundary points into boundary points

$$y = \left(h(x,t) - h_0\right) \frac{y_0 - 1}{h_0 - 1} + y_0 \begin{cases} h \leqq y \leqq 1, \\ h_0 \leqq y_0 \leqq 1, \end{cases} \tag{7.2}_1$$

and

$$y = \left(1 + \frac{h(x,t) - h_0}{h_0}\right) y_0 \begin{cases} 0 \leqq y \leqq h(x,t), \\ 0 \leqq y_0 \leqq h_0. \end{cases} \tag{7.2}_2$$

We then change variables, putting $x = x_0$ and $y = \tilde{y}(x_0, y_0)$, where $\tilde{y}$ is defined by (7.2) in (5.3)–(5.10). The form of these equations changes under the change of variables. However, following ideas introduced by Joseph [18], [19] we find many simplifications. We shall now explain these simplifications.

First we introduce an amplitude parameter which is conveniently set as a projection

$$\varepsilon = [\mathbf{u}, \mathbf{z}^*],$$

where

$$[\mathbf{a}, \mathbf{b}] \overset{\text{def}}{=} \frac{1}{2\pi} \int_0^{2\pi} \langle \mathbf{a}, \mathbf{b} \rangle \, ds,$$

and $\langle \mathbf{a}, \mathbf{b} \rangle$ are integrals over both regions of the type displayed in (6.8). We are working in the frame of Iooss-Joseph [17, §VIII. 3] and

$$\mathbf{z}^* = e^{is} \zeta_0^*, \tag{7.3}$$

where ζ_0^* is the left eigenvector at criticality which was introduced at the end of the last section.

The bifurcating solution may be computed in a series of powers of ε. Thus

$$\omega(\varepsilon)=\omega_0+\frac{\varepsilon^2}{2}\omega_2+\frac{\varepsilon^4}{4!}\omega_4+\cdots, \tag{7.4}$$

$$V_0(\varepsilon)=\hat{V}_0\left(1+\frac{\varepsilon^2}{2}\hat{V}_2+\frac{\varepsilon^4}{4!}\hat{V}_4+\cdots\right). \tag{7.5}$$

It follows from the classical theory of Hopf bifurcation that ω and V_0 are even functions of ε. We have assumed this in writing (7.4) and (7.5). Moreover,

$$\left.\begin{matrix}\mathbf{u}(x,y,s,\varepsilon)\\ \mathbf{v}(x,y,s,\varepsilon)\\ p(x,y,s,\varepsilon)\\ q(x,y,s,\varepsilon)\end{matrix}\right\}=\sum_{l=0}^{\infty}\frac{\varepsilon^{l+1}}{(l+1)!}\begin{matrix}\mathbf{u}^{[l]}(x_0,y_0,s)\\ \mathbf{v}^{[l]}(x_0,y_0,s)\\ p^{[l]}(x_0,y_0,s)\\ q^{[l]}(x,y,s).\end{matrix} \tag{7.6}$$

The functions of x and y are defined in deformed domains with a wavy interface $h(x,s,\varepsilon)-h_0=\delta(x,s,\varepsilon)$. The functions of x_0 and y_0 were defined in the reference domain with a flat interface at $y_0=h$. The perturbation of the interface $\delta(x,s,\varepsilon)$ can be eliminated from (5.8); that is,

$$\delta(x,s,\varepsilon)=k(u_1-v_1)(x,s,\varepsilon)$$

is an identity for all x, s, ε. The square brackets on the left of (7.6) indicate differentiation following the mapping evaluated at $\varepsilon=0$. For example,

$$\begin{aligned}\mathbf{u}^{[n]}(x_0,y_0,s)&=\left.\frac{d^n}{d\varepsilon^n}\right|_{\varepsilon=0}u(x,y,s,\varepsilon)\\ &=\frac{\partial^n}{\partial\varepsilon^n}u(x_0,y(x_0,y_0,s,\varepsilon),s,\varepsilon).\end{aligned} \tag{7.7}$$

There is a simple differential calculus for domain perturbations. The partial derivatives, holding x_0,y_0 fixed, at $\varepsilon=0$ are also important. For these

$$\mathbf{u}^{\langle n\rangle}(x_0,y_0,s,\varepsilon)=\left[\frac{\partial^n}{\partial\varepsilon^n}u(x_0,y_0,s,\varepsilon)\right]_{\varepsilon=0}. \tag{7.8}$$

The two types of derivatives are related by the chain rule

$$\begin{aligned}&\mathbf{u}^{[1]}=\mathbf{u}^{\langle 1\rangle}+y^{\langle 1\rangle}\frac{\partial\mathbf{u}^{\langle 0\rangle}}{\partial y},\\ &\mathbf{u}^{[2]}=\mathbf{u}^{[2]}+2y^{\langle 1\rangle}\frac{\partial\mathbf{u}^{\langle 1\rangle}}{\partial y}+\left(y^{\langle 1\rangle}\right)^2\frac{\partial^2\mathbf{u}^{\langle 0\rangle}}{\partial y^2}+y^{\langle 2\rangle}\frac{\partial\mathbf{u}^{\langle 0\rangle}}{\partial y},\\ &\mathbf{u}^{[n]}(x_0,y_0,s)=\mathbf{u}^{\langle n\rangle}(x_0,y_0,s)+\text{lower order terms},\end{aligned} \tag{7.9}$$

where

$$y^{\langle n\rangle}(x_0,y_0,s)=\begin{cases}\delta^{\langle n\rangle}(x_0,s)\dfrac{y_0-1}{h_0-1}, & h_0\leqq y_0\leqq 1,\\ \delta^{\langle n\rangle}(x_0,s)\dfrac{y_0}{h_0}, & 0\leqq y_0\leqq h_0.\end{cases} \tag{7.10}$$

On the free surface $y_0 = h_0$ of the reference domain, we have

$$y^{\langle n\rangle}(x_0, h_0, s) = \delta^{\langle n\rangle}(x_0, s). \tag{7.11}$$

The equations governing the coefficients in (7.6) are very complicated because the differential operators with derivatives with respect to x and y in the field equations must be reexpressed by derivatives with respect to x_0, y_0 under the change of variables $x,\ y \to x_0,\ y_0$. Since this mapping is invertible we can continue (7.6) as

$$\left.\begin{matrix}\mathbf{u}(x,y,s,\varepsilon)\\ \mathbf{v}(x,y,s,\varepsilon)\\ \text{etc.}\end{matrix}\right\} = \sum_{l=0}^{\infty} \frac{\varepsilon^{l+1}}{(l+1)!} \begin{matrix}\mathbf{u}^{[l]}(x, y_0(x,y,s,\varepsilon), s)\\ \mathbf{v}^{[l]}(x, y_0(x,y,s,\varepsilon), s)\\ \text{etc.}\end{matrix} \tag{7.12}$$

Fortunately it is never necessary to solve the complicated equations which govern the derivatives $[l]$ on the right of (7.6). In fact we need only to do much simpler calculations for the partial derivatives $\langle l\rangle$. When the partial derivatives $\langle l\rangle$ are known the total derivatives $[l]$ may be computed by the chain rule (7.9). The point of simplicity of partial derivatives is that they do not perturb the operators which are defined on region Ω_1 and Ω_2, below and above the free surfaces, see [18] and [19]. For example,

$$\operatorname{div} \mathbf{u}^{\langle n\rangle}(x_0, y_0, s) = \frac{\partial u_1^{\langle n\rangle}}{\partial x_0} + \frac{\partial u_2^{\langle n\rangle}}{\partial y_0} = 0, \tag{7.13}$$

whereas

$$\operatorname{div} \mathbf{u}^{[n]}(x_0, y_0, s) \neq 0.$$

The same type of simplification holds for the perturbation equations which arise from (7.1), (5.3) and (5.4). For example,

$$\rho\left[\omega_0 \frac{\partial \mathbf{u}^{\langle 2\rangle}}{\partial s} + \hat{u}_1 \frac{\partial \mathbf{u}^{\langle 2\rangle}}{\partial x} + \mathbf{e}_x u_2^{\langle 2\rangle} \hat{u}_1' + \hat{u}_1^{\langle 2\rangle} \frac{\partial \mathbf{u}^{\langle 0\rangle}}{\partial x} + \mathbf{e}_x u_2^{\langle 0\rangle} \hat{u}_1'^{\langle 2\rangle} + \mathbf{u}^{\langle 1\rangle} \cdot \nabla \mathbf{u}^{\langle 1\rangle} + \omega_2 \frac{\partial \mathbf{u}^{\langle 0\rangle}}{\partial s}\right] = \eta_1 \Delta \mathbf{u}^{\langle 2\rangle} - \nabla p^{\langle 2\rangle}. \tag{7.14}$$

The unknowns here are $\mathbf{u}^{\langle 2\rangle}$, $p^{\langle 2\rangle}$, ω_2 and $\hat{V}_2$.

It is not possible to avoid the total derivatives $[l]$ in (5.6)–(5.10) because these are defined on a manifold, the interface, and not in a region. The interface conditions are of the form

$$g(x, y = h(x,s,\varepsilon), s, \varepsilon) = 0 \tag{7.15}$$

and the perturbation of $y = h$ with ε cannot be avoided. In fact the interface conditions are identities on the interface so that tangential derivatives on them vanish (see [19]).

The following is a recipe for perturbations of the domain in bifurcation problems. First, we introduce the frequency $\omega(\varepsilon)$ into (5.3), (5.4) and (5.10) using (7.1). We then insert the series (7.4), (7.5) and the series

$$\left.\begin{matrix}\mathbf{u}(x_0,y_0,s,\varepsilon)\\ \mathbf{v}(x_0,y_0,s,\varepsilon)\\ p(x_0,y_0,s,\varepsilon)\\ q(x_0,y_0,s,\varepsilon)\\ \delta(x_0,s,\varepsilon)\end{matrix}\right\} = \sum_{l=0} \frac{\varepsilon^{l+1}}{(l+1)!} \begin{matrix}\mathbf{u}^{\langle l\rangle}(x_0,y_0,s),\\ \mathbf{v}^{\langle l\rangle}(x_0,y_0,s),\\ p^{\langle l\rangle}(x_0,y_0,s),\\ q^{\langle l\rangle}(x_0,y_0,s),\\ \delta^{\langle l\rangle}(x_0,s)\end{matrix} \tag{7.16}$$

into $\operatorname{div}\mathbf{u}=\operatorname{div}\mathbf{v}=0$, (5.3), (5.4) and (5.5) and identify the perturbation equations. These equations hold in the reference domain. To get the equations which govern the interface conditions (5.6)–(5.10) we insert the series (7.6) and identify. Then we express the derivatives $[l]$ with partial derivatives $\langle l\rangle$, using the chain rule. The perturbation equations arising from interface conditions are thus defined on the flat interface $y=h_0$.

The series on the right of (7.16) may be expressed on the deformed domain by inverting the mapping, as in (7.12). In fact, the series on the right of (7.16) is equal to the series on the right of (7.6), though the partial sums of these two series are not equal (see equations of [18]).

8. Solvability of the perturbation equations. We must solve perturbation problems of the following form:

(i) All functions of s are 2π periodic in s.

(ii) All functions of $x=x_0$ are L periodic in x_0.

(iii) In the region $0\leqq y_0\leqq h_0$,

$$\frac{\partial u_1^{\langle n\rangle}}{\partial x_0}+\frac{\partial u_2^{\langle n\rangle}}{\partial y_0}=0, \tag{8.1}$$

$$\rho\left[\omega_0\frac{\partial u_1^{\langle n\rangle}}{\partial s}+\hat{u}\frac{\partial \mathbf{u}^{\langle n\rangle}}{\partial x_0}+\mathbf{e}_x u_2^{\langle n\rangle}\hat{u}'\right]-\eta_1\Delta\mathbf{u}^{\langle n\rangle}+\nabla p^{\langle n\rangle}=\theta_1(\omega_n,\hat{V}_n,x_0,s). \tag{8.2}$$

(iv) In the region $h_0\leqq y_0\leqq 1$ we have the same equations with $\mathbf{v}^{\langle n\rangle}(x_0,y_0,s)$, $\hat{v}(y_0)$, $q^{\langle n\rangle}$ and $\boldsymbol{\theta}_2$ replacing $\mathbf{u}^{\langle n\rangle}$, $\hat{u}$, $p^{\langle n\rangle}$ and $\boldsymbol{\theta}_1$.

(v) $u^{\langle n\rangle}=0$ at $y_0=0$, $v^{\langle n\rangle}=0$ at $y_0=1$.

(vi) On the interface $y=h_0+\delta$, we have by (5.8)

$$\delta=k[[u_1]],\ [[u_1]]\overset{\text{def}}{=}u_1-v_1. \tag{8.3}$$

We have eliminated δ from the interface equations (5.6), (5.7) and (5.10) with (8.3). Of course

$$\delta^{\langle n\rangle}=k\left[\left[u_1^{\langle n\rangle}\right]\right]\quad\text{on } y_0=h_0.$$

(vii) The four interface conditions on $y_0=h_0$ are of the form

$$u_2^{\langle n\rangle}-v_2^{\langle n\rangle}=\theta_3(\hat{V}_n,x_0,s),$$

$$\eta_1 D_{12}[\mathbf{u}^{\langle n\rangle}]-\eta_2 D_{12}[\mathbf{v}^{\langle n\rangle}]=\theta_4(\hat{V}_n,x_0,s),$$

$$-p^{\langle n\rangle}+2\eta_1 D_{22}[\mathbf{u}^{\langle n\rangle}]+q^{\langle n\rangle}-2\eta_2 D_{22}[\mathbf{v}^{\langle n\rangle}]-kT\frac{\partial^2}{\partial x_0^2}\left[\left[u_1^{\langle n\rangle}\right]\right]=\theta_5(\hat{V}_n,x_0,s),$$

$$k\left(\omega_0\frac{\partial}{\partial s}+\hat{u}_1(k_0)\frac{\partial}{\partial x_0}\right)\left[\left[u_1^{\langle n\rangle}\right]\right]-u_2^{\langle n\rangle}=\theta_6(\omega_n,\hat{V}_n,x_0,s).$$

The inhomogeneous terms θ are linear in the unknown parameters ω_n and $\hat{V}_n$ and are otherwise known from computations at orders $l<n$.

These inhomogeneous problems can be solved uniquely in the space orthogonal to the null space of the adjoint operator introduced at the begining of §6. This null space is two-dimensional and is spanned by

$$\mathbf{z}^*\quad\text{and}\quad\bar{\mathbf{z}}^*$$

defined by (7.3) and explained in Iooss and Joseph [17, §VIII.3]. There are therefore two solvability conditions to be used in the determination of the parameters ω_n and $\hat{V}_n$.

GLOBAL HOPF BIFURCATION FOR VOLTERRA INTEGRAL EQUATIONS*

BERNOLD FIEDLER†

Abstract. This paper investigates global bifurcation of time periodic orbits for autonomous systems of integral equations of convolution type depending on a real parameter λ. An easy criterion for global bifurcation is derived: if—for simplicity—there exists only one stationary, nondegenerate solution for all λ, then it is sufficient that the linear unstable dimensions for λ near $-\infty$ resp. $+\infty$ differ from each other.

The theorem requires the integral kernels to be integrable with some exponential weight. The proof then relies on approximation by ordinary differential equations.

Applications are given to oscillations in a model for epidemics, and to a model for circular neural nets.

Key words. bifurcation, periodic solutions, integral equations, epidemics, neural nets

AMS(MOS) subject classifications. Primary 45D05, 45L05, 45M99

Introduction. Periodic oscillations are a quite common feature of many models in mathematical biology which take the form of integral equation systems

$$x(t)=\int_0^\infty a_\lambda(s)f_\lambda(x(t-s))\,ds, \quad x\in\mathbb{R}^m, \quad \lambda\in I=[\alpha,\beta] \tag{0.1}$$

see e.g. [10], [11], [16], [22], [33], or of integro-differential systems

$$x'(t)=\int_0^\infty a_\lambda(s)f_\lambda(x(t-s))\,ds, \tag{0.2}$$

see e.g. [4], [8], [9], [22], [23], [26], [30], [31], [34]. A frequent approach to detect such oscillations is local Hopf bifurcation theory with respect to a parameter λ: the stationary (i.e. t-independent) solutions x are computed first and various conditions on the linearized equation for some $\lambda=\lambda_0$ yield small amplitude periodic solutions. Such theorems are available at a considerable level of generality and technical perfection [5], [8], [12], [16], [20], [21], [26], [32]. However, there are two main drawbacks to this approach:

- the assumptions on the linearization are difficult to check, restricting applicability to very special kernels, and
- conclusions are obtained only in a small neighborhood of the bifurcation point.

Taking a global point of view we attack both problems simultaneously, concentrating on integral equation (0.1). We define a global Hopf index H (see Definition 1.6) which requires only some information on the linearizations at $\lambda=\alpha$ and $\lambda=\beta$. Our Main Theorem 3.1 states: if

$$H\neq 0 \tag{0.3}$$

then there is a global continuum Z of pairs (λ, x) with x a periodic solution of (0.1). Here "global" means that

- Z is unbounded, or
- the virtual periods of the nonstationary periodic solutions on Z are unbounded, or
- Z contains (λ, x) with x nonstationary periodic, $\lambda = \alpha$ or $\lambda = \beta$.

We call q a virtual period of x, if q is the minimal period of a pair (x, y) where y solves the linearized equation

$$(0.1)' \qquad y(t) = \int_0^\infty a_\lambda(s) f_\lambda'(x(t-s)) y(t-s)\, ds,$$

see Definition 2.1. Note that x may have several virtual periods, but at least the minimal period of x is always a virtual period. Unlike the set of all periods, the set of all virtual periods of x is bounded (Lemma 2.3).

We briefly outline the proof to clarify the role of virtual periods. Our starting point is a corresponding theorem for ordinary differential equations. This theorem relies heavily on ideas of Alligood, Chow, Mallet-Paret and Yorke [2], [3], [7], [27], who also introduced a notion of virtual period. A global theorem involving the Hopf index H was proved by the author [15] in an analytic semigroup setting using generic approximations—a method where virtual periods seem both natural and indispensable. To extend our theory to integral equations we avoid flow concepts like [12], [18] because we were unable to develop a generic theory for equations of the form (0.1). Rather, in §1 we approximate the kernel $a_\lambda(s)$ by exponential sums. For exponential sum kernels (0.1) reduces to an ordinary differential equation and [15] applies. Limits of periodic solutions yield periodic solutions of (0.1). In §2 we establish the crucial fact that limits of virtual periods are again virtual periods. If we replace "virtual" by "minimal", this is no longer true. In §3 we piece everything together and comment on our result.

Of course, there are also some drawbacks to our theorem. In applications, it seems to be difficult to obtain upper bounds on (minimal) periods, in general. Actually this difficulty goes back to the original paper by Alexander and Yorke [0] who started global Hopf bifurcation for ODEs. The problem persists in more recent work [6], [24], [25] and is only slightly diminished in our approach: there is an example of a bifurcation which is global in the sense of [0] but not in ours, see [1]. At present there is one other method to avoid this difficulty, using Poincaré return maps of cones and some fixed point theory, see [4], [19], [20], [30], [31], [34] for example. This method requires detailed information on the nonlinear flow; it works for scalar equations and a very few special systems. Another serious drawback, which we hope to overcome soon, is the following: we cannot allow for stationary bifurcations, because we exclude characteristic value zero of the linearization.

There are many applications of our theorem. For §4, we selected just two to demonstrate the necessary adaptations of our theory and the comparative ease in computing the global Hopf index H. We can also treat integro-differential systems (0.2), but only for kernels which are L^1 with respect to an exponential weight. At present our results do not include delay equations, or the claims of [6].

1. Approximation by ordinary differential equations. In this section we analyze approximations of the integral equation (IE)

$$(1.1) \qquad x(t) = \int_0^\infty a_\lambda(s) f_\lambda(x(t-s))\, ds =: (a_\lambda * f_\lambda(x))(t), \qquad \lambda \in I = [\alpha, \beta]$$

by ordinary differential equations in $\mathbb{R}^n$

$$(1.2)_n \qquad \dot{y} = g_\lambda^n(y),$$

letting the dimension n tend to infinity. In particular we relate eigenvalues of the linearization of the ODE $(1.2)_n$ to the characteristic roots of the linearization of IE (1.1). As a consequence we can define a Hopf index $H(a,f)$ of (1.1) as the limit

$$H(a,f) := \lim_{n\to\infty} H(g^{(n)})$$

of the Hopf indices $H(g^{(n)})$ of equations $(1.2)_n$. Along our way, we develop the technical frame and state a compactness result for later reference.

We fix some notation. For kernels $a_\lambda, b \in L^1(\mathbb{R}^+, M(m,\mathbb{R}))$, a_λ depending continuously on λ, and for $\gamma \geqq 0$, $I=[\alpha,\beta]$ a compact interval, $\alpha<\beta$, we define

$$|b|_\gamma := \int_0^\infty |b(s)| \exp(\gamma s)\, ds, \qquad \|a\|_\gamma := \sup_{\lambda\in I} |a_\lambda|_\gamma,$$

as weighted norms with corresponding spaces

$$L^1_\gamma := \left\{ b \in L^1(\mathbb{R}^+, M(m,\mathbb{R})) \,|\, |b|_\gamma < \infty \right\},$$
$$A_\gamma(I) := \left\{ a : I\times\mathbb{R}^+ \to M(m,\mathbb{R}) \,|\, \|a\|_\gamma < \infty \right\}.$$

We assume that

$$\begin{aligned} &a \in A_\gamma(\mathbb{R}) \text{ with some } \gamma>0 \quad \text{and} \\ &f \in F := C^0\big(I, BC^1(\mathbb{R}^m,\mathbb{R}^m)\big), \quad \text{i.e.,} \\ &f_\lambda \in BC^1(\mathbb{R}^m,\mathbb{R}^m) \text{ depends continuously on } \lambda\in I. \end{aligned} \tag{1.3}$$

Here C^k (BC^k) denotes the space of functions with (uniformly bounded) continuous derivatives up to order k, endowed with the standard sup-norm. By C_0, we will denote continuous functions with compact support. As a solution space of equation (1.1) we consider

$$x \in X := BC^0(\mathbb{R},\mathbb{R}^m).$$

We call $x\in X$ periodic if $x(t+p)=x(t)$ for some $p>0$ and all real t, including stationary solutions which admit any real p as a period. By assumption (1.3), all periodic solutions of (1.1) are in X. It is not necessary to introduce a phase space of past histories for IE (1.1) if we concentrate on periodic solutions only. Thus, we avoid the technicalities of defining semiflows for (1.1) but we also lose concepts like Poincaré-maps and Floquet-multipliers.

Let us state compactness. Using [28] we know the following.

LEMMA 1.1. *Let $y_n \in X$ of period p_n satisfy the (not necessarily autonomous) equation*

$$(1.4)_n \qquad y_n(t) = b^n * g^n(\cdot, y_n)(t) := \int_0^\infty b^n(s)\, g^n(t-s, y_n(t-s))\, ds$$

and assume

(i) *b^n converges to b in L^1;*

(ii) *g^n converges to g in $BC^0(\mathbb{R}\times\mathbb{R}^m,\mathbb{R}^m)$ and $g^n(\cdot,y)$ are periodic with periods independent of y and uniformly bounded with respect to n;*

(iii) *p_n converges to $p_\infty<\infty$.*

Then (y_n) has a subsequence converging in X to y with period p_∞ and y satisfies the limiting equation

$$(1.4)_\infty \qquad y = b * g(\cdot, y). \qquad \square$$

We turn to approximation of kernels by exponential sums. Let e_j be the exponential $e_j(s) := \exp(-js)$, and $P_\gamma(I) \subset A_\gamma(I)$ be the subset of finite sums of functions

$$(\lambda, s) \to p_j(\lambda) e_{\gamma+j}(s)$$

with $p_j \in C^0(I, M(m, \mathbb{R}))$, $j \in \mathbb{N}$.

LEMMA 1.2. *$P_\gamma(I)$ is dense in $A_\gamma(I)$.*

Proof. Because multiplication by e_γ is an isomorphism from L^1 to L^1_γ, we prove only the case $\gamma = 0$. Further we may restrict our attention to $m = 1$. I is compact and we allow for continuous $p_j(\lambda)$, hence, fixing λ, we only have to prove: for any $b \in L^1(\mathbb{R}^+, \mathbb{R})$ and for any $\varepsilon > 0$ there exist real coefficients p_j, $j = 1, \cdots, n$ such that $p := \sum p_j e_j$ satisfies

$$|b - p|_{L^1(\mathbb{R}^+, \mathbb{R})} < \varepsilon. \tag{1.5}$$

To prove (1.5), we note that $C_0(\mathbb{R}^+, \mathbb{R})$ is dense in $L^1(\mathbb{R}^+, \mathbb{R})$; hence we may assume that b is continuous and has compact support in $\mathbb{R}^+$. Let

$$b^*(\sigma) := \sigma^{-1} b(-\log \sigma) \in C^0([0,1], \mathbb{R})$$

with the obvious definition $b^*(0) := 0$. By the Stone-Weierstraß approximation theorem, there exists a polynomial $p^*(\sigma) := \sigma^{-1} \sum p_j \sigma^j$ such that

$$\max_{\sigma \in [0,1]} |b^*(\sigma) - p^*(\sigma)| < \varepsilon.$$

For $s = -\log \sigma$ this implies

$$|b(s) - p(s)| = |\sigma b^*(\sigma) - \sigma p^*(\sigma)| < \varepsilon \exp(-s)$$

and integration over $s \in \mathbb{R}^+$ yields (1.5). □

In the next lemma we show that IE (1.1) is equivalent to an ODE, if the kernel a is an exponential sum (i.e. if $a \in P_\gamma(I)$).

LEMMA 1.3. *Let* $a_\lambda = \sum p_j(\lambda) e_{j+\gamma} \in P_\gamma(I)$, $j = 1, \cdots, n$, $\xi = (\xi_1, \cdots, \xi_n)$, $g^n_\lambda = (g_{1,\lambda}, \cdots, g_{n,\lambda})$ *with*

$$g_{j,\lambda}(\xi) := p_j(\lambda) f_\lambda(\xi_1 + \cdots + \xi_n) - (j+\gamma)\xi_j. \tag{1.6}$$

Define the respective transformations

$$x := \sum \xi_j, \qquad \xi_j := p_j(\lambda) \cdot (e_{j+\gamma} * f_\lambda(x)). \tag{1.7}$$

Then, for each $\lambda \in I$, $x \in X$ is a solution of IE (1.1) *iff ξ is a bounded solution of* ODE $(1.2)_n$.

The proof consists of an obvious calculation and is omitted. □

Combining Lemmata 1.1–1.3 the following proposition is immediate.

PROPOSITION 1.4. *Let a and f satisfy assumption* (1.3). *Then, for each $\lambda \in I$, there is a sequence $a^n_\lambda \in P_\gamma(I)$ of exponential sum kernels, converging to a_λ in $A_\gamma(I)$, such that solutions $x^n \in X$ of*

$$x^n = a^n_\lambda * f_\lambda(x^n) \tag{$1.1)_n$}$$

correspond by transformation (1.7) *to bounded solutions ξ^n of*

$$\dot{\xi}^n = g^n_\lambda(\xi^n), \tag{$1.2)_n$}$$

and the stationary (t-independent) solutions of $(1.1)_n$ *and* (1.1) *are the same.*

In particular, if ξ^n *are periodic solutions of* $(1.2)_n$ *with periods* p_n *converging to* $p_\infty \in \mathbb{R}^+$, *then there is a subsequence of the* x^n *converging in* X *to a periodic solution* x *of* (1.1) *with period* p_∞. □

Now we investigate the behavior of eigenvalues resp. characteristic roots under the approximation from Proposition 1.4. Let $x(t) \equiv x_0$ be a stationary solution of (1.1), then the linearized equation is

$$(1.1)' \qquad y = a_\lambda * \big(f'_\lambda(x_0)\cdot y\big).$$

Values $\mu \in \mathbb{C}$, such that (1.1)′ has a nontrivial solution

$$y(t) = e^{\mu t} y_0,$$

are called *characteristic roots* of (λ, x_0). Let $\hat{a}_\lambda(\mu) := \int_0^\infty \exp(-\mu s) a_\lambda(s)\, ds$ denote the Laplace transform of a_λ (defined for $\operatorname{Re}\mu \geqq -\gamma$); then characteristic roots (with $\operatorname{Re}\mu > -\gamma$) are the zeros of the characteristic function

$$(1.8) \qquad \chi(\mu) = \det\big(1 - \hat{a}_\lambda(\mu)\cdot f'_\lambda(x_0)\big).$$

By analyticity of $\chi(\mu)$, we may assign a multiplicity to each characteristic root μ. For $a_\lambda \in P_\lambda(I)$, linearization commutes with the equivalence transformation from IE (1.1) to ODE (1.2), by Lemma 1.3. Hence we may also associate the linearization

$$(1.2)' \qquad \dot{\eta} = g'_\lambda(\xi_0)\eta$$

to (λ, x_0) and consider the eigenvalues of $g'_\lambda(\xi_0)$, where ξ_0 corresponds to x_0 by (1.7).

LEMMA 1.5. *In the situation described above, the characteristic roots* μ *of* (1.1) *at* (λ, x_0) *with* $\operatorname{Re}\mu > -\gamma$ *are exactly the eigenvalues* μ' *of* (1.2)′ *with* $\operatorname{Re}\mu' > -\gamma$, *with equal algebraic multiplicities.*

Proof. The considerations above prove the lemma except for the claim that algebraic multiplicities are equal. To complete the proof, we directly compute χ and the characteristic polynomial π of $g'_\lambda(\xi_0)$. Absorbing $f'_\lambda(x_0)$ into a_λ, we may assume $f'_\lambda(x_0) = id$. Further, we may omit the index λ.

With $a = \sum p_j e_{j+\gamma}$, $q_j(\mu) := (j+\gamma+\mu)^{-1} p_j = p_j \cdot \hat{e}_{j+\gamma}$ we first obtain

$$\chi(\mu) = \det\big(1 - \textstyle\sum q_j(\mu)\big).$$

Next we compute π, doing some determinant manipulations:

$$\begin{aligned}
\pi(\mu) &= \det\big(g'(\xi_0) - \mu\big) = \det\big(p_i - (j+\gamma+\mu)\delta_{ij}\big)_{i,j} \\
&= \prod_k (k+\gamma+\mu)\cdot \det\big(q_i - 1\cdot\delta_{ij}\big)_{i,j} \\
&= \pm \prod_k (k+\gamma+\mu)\cdot \det\Big(\sum_j q_j - 1\Big) \\
&= \pm \prod_k (k+\gamma+\mu)\cdot \chi(\mu),
\end{aligned}$$

and the lemma is proved. □

Finally, we introduce the Hopf index, using our ODE approximations. First we need some more notation and assumptions. Let (λ_0, x_0) be a stationary solution of IE (1.1) with corresponding linearization (1.1)′ and characteristic function χ; cf. (1.8). We assume

$$(1.9) \qquad \chi(0) \neq 0 \text{ at any stationary solution } (\lambda_0, x_0).$$

In particular, this excludes secondary bifurcation of stationary solutions; the stationary solutions are given as branches $(\lambda, x^j(\lambda))$, parametrized by λ with j labeling the branches. On occasion, we also denote the characteristic function at $(\lambda, x^j(\lambda))$ by $\chi^j_\lambda(\mu)$. Further we call (λ_0, x_0) a *center* if $\chi = 0$ has pure imaginary roots; let $C \subset I \times X$ denote the set of centers of (1.1). We assume

(1.10) the set C of centers does not contain points (λ, x) with $\lambda \in \partial I = \{\alpha, \beta\}$.

Let

$E^j(\lambda)$: number of characteristic roots with positive real part at $(\lambda, x^j(\lambda))$, counting multiplicities.

DEFINITION 1.6. We define the global Hopf index of integral equation (1.1) to be

$$H = H(I) := \frac{1}{2} \cdot \sum_j (-1)^{E^j(\alpha)} \cdot (E^j(\beta) - E^j(\alpha)). \tag{1.11}$$

Choose an exponential approximation of a by $a^n \in {}_\gamma(\mathbb{R})$ such that

$$a^n \underset{n}{\to} a \quad \text{in } A_\gamma(I)$$

and Proposition 1.4 holds. We define $H_n(I)$ by (1.11), corresponding to a^n, for $n \geqq n_0$ large enough that assumptions (1.9) and (1.10) above hold for equation $(1.1)_n$, too. By Lemma 1.5 we may equivalently interpret the characteristic roots contributing to $E^j_n(\lambda)$ for a^n as eigenvalues of the associated ODE.

PROPOSITION 1.7. *Under assumptions* (1.3), (1.9) *and* (1.10), *the global Hopf index is well-defined and satisfies*

$$H(I) = \lim_{n \to \infty} H_n(I).$$

Proof. By definition, we only have to show

$$E(\lambda) = \lim_{n \to \infty} E_n(\lambda),$$

at any stationary solution (λ, x_0) of (1.1), $\lambda \in \partial I$ (by Proposition 1.4, (1.1) has the same stationary solutions as $(1.1)_n$). Suppressing the argument λ, we note that E_n is the number of roots of

$$\chi_n = \det(1 - \hat{a}_n(\cdot))$$

with positive real part, if we put $f'_\lambda(x_0) = 1$ without loss of generality. For any $\varepsilon > 0$, by continuity, there exists $n_0(\varepsilon)$ such that for all $n \geqq n_0(\varepsilon)$

$$|\chi_n(\mu) - \chi(\mu)| < \varepsilon \quad \text{for } \operatorname{Re}\mu \geqq 0.$$

Now $\chi \neq 0$ on the imaginary axis, and $\lim_{|\mu| \to \infty} \chi(\mu) = 1$ for $\operatorname{Re}\mu \geqq 0$, by the Riemann–Lebesgue lemma, hence zeros of χ in $\{\operatorname{Re}\mu \geqq 0\}$ are in some compact subset of $\{\operatorname{Re}\mu > 0\}$. By uniform convergence of the analytic functions χ_n to χ,

$$E_n = E$$

for $\varepsilon > 0$ small enough and $n \geqq n_0(\varepsilon)$, and the proof is complete. □

2. Virtual periods. We develop a notion of virtual periods for periodic solutions of integral equations, without referring to flow concepts, Poincaré maps etc.. Our definition is consistent with the virtual periods introduced by Alligood, Mallet-Paret and

Yorke [2], [3], [27] in an ODE setting. We show that virtual periods are well behaved under limits, i.e. the limit of virtual periods is again a virtual period. Then we prove that any orbit has only finitely many virtual periods, and finally we analyze the behavior of virtual periods on branches of stationary solutions, using analyticity. Throughout this section let assumptions (1.3) on a, f and (1.9): $\chi(0)\neq 0$ be satisfied.

DEFINITION 2.1. Given a periodic solution $x(\cdot)$ of integral equation

$$x = a * f(x) \tag{1.1}$$

we call $q>0$ *a virtual period of* x if q is the prime (minimal) period $p(x,y)$ of a pair (x,y), where y is a periodic solution of the linearized equation

$$y = a * (f'(x(\cdot))y). \tag{1.1}'$$

Recall that we regard stationary solutions as periodic with "minimal period" $p := 0$. Setting $y := 0$, the prime period is always a virtual period; however, $x(\cdot)$ may have several virtual periods (see Proposition 2.2 below). Floquet-theory, along with Lemma 1.3 on the correspondence between ODEs and IEs, tells us that our definition of virtual periods coincides with the one given in [2], [3], [27] for ODEs, if $a\in P_\gamma$ is an exponential sum kernel.

In [7], [27] it was shown that a limit of *minimal* periods is a *virtual* period. The most useful property of virtual periods in our approach is a generalization of this result: we prove that a limit of *virtual* periods is again a *virtual* period. Because of the independent significance of the next proposition, we emphasize that the proof does not use Assumption (1.9) $\chi(0)\neq 0$; but this fact is not exploited in the present paper.

PROPOSITION 2.2. *Let* x_n *be periodic solutions of*

$$x_n = a_n * f_n(x_n) \tag{1.1}_n$$

with a virtual period $q_n>0$. *For* $n\to\infty$ *assume that*

$$\begin{aligned} a_n &\to a && \text{in } L^1,\\ f_n &\to f && \text{in } BC^1,\\ x_n &\to x && \text{in } X = BC^0,\\ q_n &\to q_\infty && \text{in } \mathbb{R}. \end{aligned}$$

Then q_∞ *is a virtual period of* x, *in particular* q_∞ *is positive.*

Proof. The proof is rather involved; we give an outline first. We construct two solutions η_1 and η_2 of the linearized equation (1.1)′ such that (x,η_1,η_2) has minimal period $p(x,\eta_1,\eta_2)=q_\infty>0$. This is sufficient because $p(\eta_1,\eta_2)=p(\alpha_1\eta_1+\alpha_2\eta_2)$ for almost every $\alpha_1,\alpha_2\in\mathbb{R}$. In the first step we construct η_1, involving limits of x_n, such that

$$p(x,\eta_1)=p_\infty,$$

where $p_\infty=\lim p_n$, $p_n := p(x_n)$. In our second step we construct η_2. This involves limits of solutions y_n of the linearized equation (1.1)′ with $p(x,y_n)=q_n$, $|y_n|=0$ or 1. Finally we prove that indeed

$$p(x,\eta_1,\eta_2)=q_\infty>0.$$

Note that in our proof we may assume that $p_n>0$ eventually; otherwise, for x_n stationary, we consider the linearized equations for y_n directly replacing x_n by y_n in the proof.

For later reference we introduce some notation. For periodic $\phi \in X$ we denote

$p(\phi)$: the minimal period of ϕ,
$P(\phi)$: the set of all periods of ϕ,
$S(t)\phi := \phi(\cdot + t)$, the shift on X,
$\delta_n^\sigma := |(S(\sigma p_n)x_n - x_n)|_X > 0$ for $p_n > 0$, $\sigma \in \mathbb{Q} \setminus \mathbb{Z}$,
$x_n^\sigma := (S(\sigma p_n)x_n - x_n)/\delta_n^\sigma$,
$z_n := (x_n, y_n)$,
$\varepsilon_n^\tau := |S(\tau q_n)z_n - z_n|_{X \times X} > 0$ for $\tau \in \mathbb{Q} \setminus \mathbb{Z}$,
$y_n^\tau := (S(\tau q_n)y_n - y_n)/\varepsilon_n^\tau$.

Step 1: *Construction of* η_1. We claim that, after restriction to an appropriate subsequence,

$$x^\sigma := \lim_n x_n^\sigma \tag{2.1}$$

exists and satisfies the linearized equation (1.1)′ at x, provided that $\sigma \in \mathbb{Q} \setminus \mathbb{Z}$ satisfies the admissibility condition

$$\sigma p_\infty \in P(x). \tag{2.2}$$

For admissible σ (possibly an empty set) we then show

$$\sigma p_\infty \notin P(x^\sigma). \tag{2.3}$$

We choose η_1 as a finite linear combination

$$\eta_1 := \sum_\sigma \alpha_\sigma x^\sigma$$

with admissible σ, such that $p(\eta_1) = p(x^\sigma, \sigma \text{ admissible})$ and we finally show

$$p(x, \eta_1) = p_\infty.$$

Existence of x^σ follows from our compactness Lemma 1.1: by admissibility (2.2) we have $\lim_n \delta_n^\sigma = 0$ and therefore

$$x_n^\sigma = a_n * (f_n'(x_n)x_n^\sigma) + o(1),$$

which yields convergence and

$$x^\sigma = a * (f'(x)x^\sigma).$$

We prove indirectly that $\sigma p_\infty \notin P(x^\sigma)$: choose $k \in \mathbb{N}$ such that $k\sigma \in \mathbb{Z}$ and compute

$$\begin{aligned} 0 &= \lim_n (S(k\sigma p_n)x_n - x_n)/\delta_n^\sigma \\ &= \lim_n \sum_{j=0}^{k-1} (S((j+1)\sigma p_n)x_n - S(j\sigma p_n)x_n)/\delta_n^\sigma \\ &= \sum S(j\sigma p_\infty)x^\sigma = kx^\sigma, \end{aligned}$$

if we assume $\sigma p_\infty \in P(x^\sigma)$ in the last equality. This is a contradiction to $|x^\sigma|_X = 1$. Note that (2.3) implies $p_\infty > 0$, hence $q_\infty > 0$. Further, x^σ cannot be stationary.

We show that $p(x,\eta_1)=p_\infty$. If there is no admissible σ, then $\sigma p_\infty \in P(x)$ implies $\sigma \in \mathbb{Z}$, i.e. p_∞ is the minimal period of x and we may choose $\eta_1 \equiv 0$. If there are admissible σ then (2.2), (2.3) imply that

$$\mathbb{Z}p_\infty = P(x) \cap \bigcap_{\sigma \text{ adm}} P(x^\sigma). \tag{2.4}$$

To see that, note that p_∞ is contained in the right-hand side by construction. Vice versa: $\mathbb{Q}p_\infty$ contains the right-hand side; but if $\alpha p_\infty \in P(x) \cap \bigcap P(x^\sigma)$, $\alpha \in \mathbb{Q}$, then $\alpha \in \mathbb{Z}$, or else $\alpha \in \mathbb{Q}\setminus\mathbb{Z}$ is admissible and therefore $\alpha p_\infty \notin P(x^\alpha)$: a contradiction. This proves (2.4). Now $P(x^\sigma)$ is discrete for all σ, therefore a finite intersection over σ is sufficient in (2.4). The corresponding σ provide η_1, as desired.

Step 2: *Construction of* η_2. This step is somewhat similar to the last one, replacing x_n by y_n. We claim that

$$y := \lim y_n, \qquad y^\tau := \lim y_n^\tau \tag{2.1}'$$

exist, y satisfies (1.1)′, and y^τ satisfies (1.1)′ if $\tau \in \mathbb{Q}\setminus\mathbb{Z}$ is admissible, i.e.

$$\tau q_\infty \in \mathbb{Z}p_\infty \cap P(z) \tag{2.2}'$$

where $z=(x,y)$. For admissible τ we show

$$\tau q_\infty \notin P(y^\tau) \tag{2.3}'$$

and choose η_2 as a finite linear combination of z^τ such that finally

$$p(x,\eta_1,\eta_2) = q_\infty.$$

Convergence of y_n is trivial. However, some care is needed with y^τ to insure that y^τ satisfies the linearization (1.1)′; this explains the $\mathbb{Z}p_\infty$ in condition (2.2)′ which in turn made step 1 indispensable. By $\tau q_\infty \in P(z)$ the ε_n^τ go to zero. In addition $\tau q_\infty \in \mathbb{Z}p_\infty$, $p_\infty > 0$ implies that $\tau q_n \in \mathbb{Z}p_n$, eventually. Therefore,

$$S(\tau q_n)x_n = x_n, \quad \varepsilon_n^\tau = |S(\tau q_n)y_n - y_n|_X, \quad |y_n^\tau| = 1$$

and we may compute that

$$\begin{aligned} y_n^\tau &= a_n * \big(S(\tau q_n)\big(f_n'(x_n)y_n\big) - f_n'(x_n)y_n\big)/\varepsilon_n^\tau \\ &= a_n * \big(f_n'(S(\tau q_n)x_n)S(\tau q_n)y_n - f_n'(x_n)y_n\big)/\varepsilon_n^\tau \\ &= a_n * \big(f_n'(x_n)y_n^\tau\big) \end{aligned}$$

indeed satisfies the linearization (1.1)′.

We prove (2.3)′ as in Step 1, replacing (p,x,δ,σ) by (q,y,ε,τ).

Finally we show that $p(x,\eta_1,\eta_2)=q_\infty$. If there is no admissible τ, then

$$\tau q_\infty \in \mathbb{Z}p_\infty \cap P(z)$$

implies $\tau \in \mathbb{Z}$ and we may choose $\eta_2 = y$ to obtain $p(x,\eta_1,y)=q_\infty$. If there are admissible τ, (2.2)′ and (2.3)′ imply

$$\mathbb{Z}q_\infty = \mathbb{Z}p_\infty \cap P(z) \cap \bigcap_{\tau \text{ adm}} P(y^\tau)$$

as before. By $p_\infty > 0$, there are only finitely many admissible $\tau \in (0,1)$ anyway. Choosing η_2 as an appropriate linear combination of the corresponding y^τ and y completes the proof. □

In view of Lemma 1.3 on the correspondence between integral equations and ordinary differential equations, the virtual period Proposition 2.2 also holds for ODEs, of course.

In §3 we consider global bifurcation and one alternative will be that arbitrarily large virtual periods occur. Such a statement is significant only if we show that for any single orbit the virtual periods are bounded.

LEMMA 2.3. *Let x be a periodic or stationary solution of*

$$x = a * f(x). \tag{1.1}$$

Then the virtual periods of x are a bounded set.

Moreover, suppose x is stationary. Then x has a (positive) virtual period iff x is a center. More precisely: q is a virtual period of x, iff q is the (positive) least common multiple of numbers $2\pi/\beta_k$, where $\{\pm i\beta_\nu \mid \nu = 1, \cdots, j\}$ are the pure imaginary characteristic roots of x and k ranges over a subset of $\{1, \cdots, j\}$. In particular, x has at most $2^j - 1$ distinct virtual periods.

Proof. Let y be a periodic solution of the linearized equation

$$y = a * f'(x)y \tag{1.1}'$$

such that p is the period of x and $q = p(x,y)$ is a virtual period of x. The case $p = 0$, i.e. x stationary, is elementary and well be treated first. For nonstationary x, we use that (1.1)′ defines a linear evolution system on an exponentially weighted history space, i.e. we rely on a (linear) flow concept. The evolution will be α-condensing, thus proving boundedness of the virtual periods.

For stationary x, let

$$y(t) = \sum_{r \in \mathbb{Z}} y_r \exp(ir\beta t) \qquad \beta := 2\pi/q,$$

be the Fourier series for y. From (1.1)′ we see that

$$y_r = 0 \quad \text{or} \quad \chi(ir\beta) = 0.$$

Hence r shows up in the Fourier series, iff $r\beta = \pm\beta_k$ for some k and the claims are immediate.

For x with period $p > 0$, let Y be the set of continuous functions

$$y_0 : (-\infty, 0] \to \mathbb{R}^m,$$

such that for γ as in (1.3)

$$\|y_0\|_\gamma := \sup_{s \leqq 0} |y_0(s)| \exp(\gamma s) < \infty,$$

and let Y_s be the set of $y_0 \in Y$ such that

$$y_0(0) = a * \big(f'(S(s)x)\, y_0\big)(0).$$

Obviously, Y and Y_s are Banach spaces and (1.1)′ defines a solution operator

$$U(t,s) : Y_s \to Y_t,$$

see [28]. Because x is p-periodic, $T := U((j+1)p, jp)$ is independent of j, maps Y_0 into itself, and

$$y = S(q)y = T^n y, \tag{2.5}$$

if $n := q/p$ and y is interpreted, by restriction, as an element of Y_0.

We claim that the spectral radius r_e of the essential spectrum of T is at most $\exp(-p\gamma) < 1$. Then y lies in the generalized eigenspaces of T for some eigenvalues which are nth roots of unity. But T has at most finitely many eigenvalues on the unit circle; hence n and consequently q is bounded.

To prove the claim, we apply Nussbaum's formula [29] which states

$$r_e = \lim_{n\to\infty} (\alpha(T^n))^{1/n},$$

where $\alpha(T^n)$ is the Hausdorff measure of noncompactness of $T^n(B_1)$. To compute α we split T^n into a sum

$$T^n = S_n + K_n,$$

where S_n is roughly a shift and K_n is compact. To be specific, we define

$$(S_n y_0)(t) := \begin{cases} y_0(t+np), & -\infty < t \leqq -np, \\ (-n+1-t/p)\, y_0(0) & \text{for } -np \leqq t \leqq (-n+1)p, \\ 0, & (-n+1)p \leqq t \leqq 0, \end{cases} \tag{2.6}$$

$$(K_n y_0)(t) := \begin{cases} 0, & -\infty < t \leqq -np, \\ w(t+np) - (-n+1-t/p)\, y_0(0) & \text{for } -np \leqq t \leqq (-n+1)p, \\ w(t+np), & (-n+1)p \leqq t \leqq 0, \end{cases}$$

where w is the solution of the Volterra equation

$$w(t) = \int_0^t a(t-s) f'(x(s)) w(s)\, ds + h(t),$$

$$h(t) := \int_{-\infty}^0 a(t-s) f'(x(s))\, y_0(s)\, ds.$$

Note that w exists in $BC(\mathbb{R}_0^+)$ and defines the continuation of $y_0 \in Y_0$ as a solution of (1.1)', hence $S_n + K_n = T^n$. Unfortunately, S_n and K_n map into Y, not necessarily into Y_0. But choosing a projection P_0 onto Y_0 (which has codimension 1 in Y), we may write

$$T^n = P_0 S_n + P_0 K_n.$$

By compactness of K_n [28], and because $\operatorname{codim} Y_0 = 1$, we may compute

$$\alpha(T^n) = \alpha(P_0 S_n) = \alpha(S_n)$$

[13], [29]. For S_n we estimate

$$\begin{aligned} |S_n y_0|_\gamma &= \sup_{t\leqq 0} |(S_n y_0)(t)| \cdot \exp(\gamma t) \\ &\leqq \max_{\tau\in[0,p]} (1-\tau/p) \exp(\gamma\tau) \cdot \exp(-\gamma np) \cdot |y_0|_\gamma \\ &= c \exp(-\gamma pn) \cdot |y_0|_\gamma, \end{aligned}$$

this implies $\alpha(T^n) \leqq c \exp(-\gamma p n)$, hence

$$r_e = \lim_n \alpha(T^n)^{1/n} \leqq \exp(-p\gamma) < 1,$$

and the proof is complete. □

We conclude this section with a technical lemma on virtual periods of branches of stationary solutions. Recall that $\chi_\lambda^j(\mu)$ denotes the characteristic function (1.8) at the jth stationary branch $(\lambda, x^j(\lambda))$. We assume that

(2.7) for each j, the map

$$(\lambda, \mu) \to \chi_\lambda^j(\mu)$$

is analytic for $(\lambda, x^j(\lambda))$ in a neighborhood of the set C of centers and for $\operatorname{Re}\mu > -\gamma$.

LEMMA 2.4. *Let Assumption* (2.7) *be satisfied. Then there exists a constant* c_0 *such that the set*

$$J(c_0) := \{(\lambda, x) \in C \mid \textit{all virtual periods of } (\lambda, x) \textit{ are } < c_0\}$$

is dense in C.

Proof. For simplicity of notation we focus on just one stationary branch $(\lambda, 0)$ and think of C as a subset of $\mathbb{R}$. In [15, Lemma 4.8] we gave a proof which holds for ODEs, where

$$\chi_\lambda(\mu) = \det(\mu - f_\lambda'(0)).$$

We use Lemma 2.3 to rephrase $J(c_0)$ in terms of zeros of χ. By the Riemann–Lebesgue lemma, the imaginary parts of characteristic values are bounded on C. The only difference to the ODE case is the fact that χ_λ is not polynomial in μ any more. We remedy this drawback locally by application of the Weierstraß preparation theorem, leaving the zeros unchanged. Then we use the proof of [15, Lemma 4.8] to complete our proof. □

3. Global Hopf bifurcation. In this section we present our main abstract result, i.e. we obtain global bifurcation of periodic orbits if the Hopf index H of Definition 1.6 is nonzero

(3.1) $$H \neq 0.$$

We discuss our result and indicate some easy generalizations.

MAIN THEOREM 3.1. *Let* a *and* f *satisfy the following assumptions*:

(1.3) $a \in A_\gamma$ *for some positive exponential weight* γ *and* $f \in F$ (*differentiability*);

(1.9) *the stationary branches are parametrized over* λ *in the compact interval* $I = [\alpha, \beta]$;

(1.10) *there are no centers* (λ, x) *with* $\lambda = \alpha$ *or* $\lambda = \beta$;

(2.7) *the characteristic function* $\chi_\lambda(\mu)$ *is analytic in* (λ, μ);

and—the most important assumption—

(3.1) *the Hopf index* H *is nonzero.*

Then there exists a continuum $Z \subset I \times X$ *consisting of stationary centers and nonstationary periodic solutions* (λ, x) *of*

(1.1) $$x = a_\lambda * f_\lambda(x)$$

such that Z contains both a center and nonstationary periodic solutions and Z is global, i.e. Z contains nonstationary periodic solutions (λ, x) with

(3.2) *arbitrarily large norm of $x \in X$, or*

(3.3) *arbitrarily large virtual period of $x \in X$, or*

(3.4) $\lambda = \alpha$, *or* $\lambda = \beta$ *on the boundary of* I.

We postpone the proof to give a discussion first. By Definition 2.1 virtual periods are some multiples of the minimal period; however, for each (λ, x) in Z the virtual periods of (λ, x) are a finite bounded set (Lemma 2.3). It seems unlikely that we may replace "virtual period" by "minimal period" in conclusion (3.3), except for ODEs of dimension $\leqq 4$. Note that we do not require the periods to become unbounded in a continuous fashion, in contrast to [0], [6], [24], [25]. Actually we have to allow for jumps of the virtual periods by factors of 2 as becomes clear from the proof for ODEs (see e.g. [15, Thm. 4.7]). Technically, the advantage of virtual periods is the fact that limits of virtual periods are again virtual periods (Proposition 2.2).

Using Proposition 2.2 for stationary limiting x only, we could also obtain a global Hopf bifurcation result in the spirit of Alexander and Yorke [0] by our approximation process. In contrast to their result, we do not require any detailed analysis at the centers (e.g. concerning multiplicities of pure imaginary eigenvalues, resonance conditions etc.). All the necessary information sits in the index H. In [0], a bounded continuum of periodic orbits is also called "global", if it just connects centers. Our conclusion above is stronger: we do not call such a continuum global.

By Assumption (1.9) we exclude bifurcations within the class of stationary solutions. This severe drawback already shows up in the ODE case. It is connected to the fact that the index $H = H(f)$ is not homotopy invariant with respect to the families f. We will analyze this problem in a future paper, concentrating on the ODE situation.

Analyticity of the characteristic function χ may be dropped and the proof simplifies, if we assume e.g. that the set C of centers is discrete. In our abstract result, however, we want to use only minimal information on C.

For technical convenience we require f to be bounded and I to be compact. We can drop both restrictions, if we replace Assumption (1.10) by

(1.10)′ the set C of centers of f is bounded in $\mathbb{R} \times X$.

We sketch the necessary modifications. Let $\psi_n \in C^1(\mathbb{R}, \mathbb{R})$ be strictly increasing, $\psi_n(\rho) = \rho$ for $|\rho| \leqq n-1$ and $\psi_n(\rho) = n$ for $|\rho| \geqq n$. Define cut-off approximations f_n of $f: \mathbb{R} \times \mathbb{R}^m \to \mathbb{R}^m$ by

$$f_n(\lambda, x) := f\left(\psi_n(\lambda),\ \psi_n(|x|) \cdot \frac{x}{|x|}\right).$$

By Assumption (1.10)′ the centers C_n of f_n coincide with C for n large enough. Applying Theorem 3.1 to f_n, $I_n := [-n, n]$, we obtain global periodic continua $Z_n \subset I_n \times X$ bifurcating from $C_n = C$. In the proof of our theorem (Step 2) we will indicate how to obtain a limiting global continuum $Z \subset \mathbb{R} \times X$ of f from Z_n as $n \to \infty$. Here global means that Z contains both a center and nonstationary periodic solutions (λ, x) with arbitrarily large

(3.2)′ norm in $\mathbb{R} \times X$ or

(3.3)′ virtual period of $x \in X$.

The variants $I = [\alpha, \infty)$, $I = (-\infty, \beta]$ can be treated similarly.

Our theorem holds for various other autonomous integral equations of convolution type as well. Some examples are

$$x = g(a_1 * f_1(x), \cdots, a_k * f_k(x)),$$
$$\dot{x} = a * f(x),$$

and various other combinations. We just have to give a technical frame, where compactness (Lemma 1.1) and an ODE approximation (Proposition 1.4) holds. However, it is not clear how our results extend to abstract integral equations, e.g. in Hilbert space.

Proof (*Main Theorem* 3.1). We give an outline first. We approximate the original equation

$$x = a_\lambda * f_\lambda(x) \tag{1.1}$$

by integral equations with exponential sum kernels

$$x = a_\lambda^n * f_\lambda(x) \tag{1.1}_n$$

which in turn are equivalent to ODEs

$$\dot{y} = g_\lambda^n(y), \tag{1.2}_n$$

as summarized in Proposition 1.4. In Step 1 we use a global bifurcation result for ODEs (cf. [15]), to construct large continua Z_k^n of periodic solutions of $(1.1)_n$; these continua are getting more and more "global" as $k \in \mathbb{N}$ increases. In Step 2 we pass to the limit $n \to \infty$ and obtain continua Z_k of periodic solutions of the original equation (1.1). Step 3 shows that Z_k is not contained in the set of centers C for k large enough. Defining

$$Z := \bigcup_k Z_k$$

will finish the proof.

Step 1: *properties of* Z_k^n. We consider $k \geqq k_0$ with k_0 large enough that B_{k_0} contains C. Then, by Proposition 1.7, the Hopf index $H_n(k)$ of ODE $(1.2)_n$ on B_k satisfies

$$0 \neq H = \lim_{n \to \infty} H_\nu(k) = H_n(k) \quad \text{for } n \geqq n_0(k),$$

where, for any k, $B_k := \{(\lambda, x) \in I \times X \mid |x|_X \leqq k\}$ with boundary $\partial B_k := \{(\lambda, x) \in I \times X \mid \lambda = \alpha \text{ or } \lambda = \beta \text{ or } |x| = k\}$. Consider $k \geqq k_0$ with k_0 large enough, such that B_{k_0} contains all stationary solutions of f and C is contained in the interior $B_{k_0} - \partial B_{k_0}$. Note that k_0 exists by Assumptions (1.3) and (1.10). By Proposition 1.7 the Hopf index H_n of ODE $(1.2)_n$ satisfies

$$0 \neq H = \lim_{\nu \to \infty} H_\nu = H_n \quad \text{for } n \geqq n_0.$$

The approximation leaves the set of stationary solutions unchanged, no eigenvalues zero occur in B_k for $n \geqq n_0$. From the proof of [15, Thm. 4.7] we conclude that there exist continua $Z_k^n \subset I \times X$ of centers and nonstationary periodic solutions of $(1.1)_n$ with the following properties:

(3.5) $Z_k^n \subset B_k$ and the prime periods on Z_k^n are $\leqq 2k$,

(3.6) Z_k^n contains a center z^n of $(1.1)_n$, independently of k,

(3.7) Z_k^n is compact and connected,

(3.8) if $Z_k^n \cap \partial B_k$ is empty, then there is a continuum $Z_k'^n \subset Z_k^n$ such that

(i) any element of $Z_k'^n$ has some virtual period $\geqq c_0$ where c_0 was defined in Lemma 2.4, and

(ii) any interval $[\tau, 2\tau] \subset [c_0, 2k]$ contains a virtual period of an element of $Z_k'^n$.

The Z_k^n, $Z_k'^n$ correspond to the continua Z_k, Z_k' which were constructed in [15]: any element $(\lambda,y)\in I\times\mathbb{R}^m$ of Z_k is reinterpreted as an element $(\lambda,y(t))\in I\times X$, attaching the orbit to it. Properties (3.5), (3.6), (3.8) are read off from properties [15, (4.9)–(4.12)] of the corresponding snakes. The assumption [15, (1.2)] on C^4 differentiability of g^n may be dropped for ODEs, using smoothed generic approximations. Assumption [15, (4.5)] on analyticity was not used in the construction of Z_k, Z_k'. Thus existence of Z_k^n is established.

Step 2: *construction of* $Z_k=$"lim" Z_k^n. We define

$$Z_k := \bigcap_{\nu\geqq n_0}\left(\overline{\bigcup_{n\geqq\nu} Z_k^n}\right)$$

$$= \left\{ z \mid z=\lim z_{n_j} \text{ for some sequences } n_j\to\infty,\ z_{n_j}\in Z_k^{n_j}\right\}.$$

Obviously, $Z_k\subset B_k$ is closed. By (3.5) and compactness Lemma 1.1, the set Z_k consists of periodic solutions of IE (1.1) with period $\leqq 2k$, and Z_k is compact. Restricting the whole approximation process to a subsequence of $n\in\mathbb{N}$ from now on, we may also assume that the $z^n\in Z_k^n$ from (3.6) converge to

$$z_0 := \lim_{n\to\infty} z^n\in C,$$

which implies $z_0\in Z_k$ for all $k\geqq k_0$.

Moreover Z_k is connected: otherwise we would have a partition $Z_k=Z'\cup Z''$ into disjoint, nonempty, compact subsets with $z_0\in Z''$ and $\alpha := \frac{1}{2}\operatorname{dist}(Z',Z'')>0$. By definition of Z_k there exists ν_0 such that for all $\nu>\nu_0$ we have

$$\alpha>\operatorname{dist}\left(Z_k^\nu,Z_k\right)=\operatorname{dist}\left(Z_k,Z'\cup Z''\right).$$

Now $z_0\in Z''$ implies that $z^\nu\in Z_k^\nu\cap N_\alpha(Z'')$ for large ν and the open α-neighborhood $N_\alpha(Z'')$. Hence $Z_k^\nu\cap N_\alpha(Z')=\varnothing$, because Z_k^ν is connected. This is a contradiction to $Z'\neq\varnothing$, therefore Z_k is connected.

Step 3: *centers in* Z_k. We claim that Z_k is not contained in the set of centers C. Analyticity is used only in this step. We consider two cases.

CASE 1. There exists a sequence $n_j\to\infty$ (which may depend on k) such that $Z_k^{n_j}\cap\partial B_k$ is nonempty.

Then $Z_k\cap\partial B_k$ is nonempty and Z_k is not contained in $C\subset B_k-\partial B_k$, for $k\geqq k_0$.

CASE 2. For all $n\geqq n_0(k)$, $Z_k^n\cap\partial B_k$ is empty.

Then (3.8), (i) and (ii) are satisfied, i.e. the virtual periods are large on a continuum $Z_k'^n$. Analogously to Z_k, we construct a continuum Z_k' of solutions of (1.1) with large virtual periods: by (3.8), (ii) there exist z_k^n in $Z_k'^n$ with some virtual period in $[c_0,2c_0]$. Passing to subsequences we may assume that

$$z_k := \lim_{n\to\infty} z_k^n$$

exists. We define

$$Z_k' := \bigcap_{\nu\geqq n_0(k)}\overline{\bigcup_{n\geqq\nu} Z_k'^n}$$

and z_k is an element of the compact connected set Z_k'. Moreover the virtual period Proposition 2.2 implies that (3.8), (i)–(ii) remains valid if we replace $Z_k'^n$ by $Z_k'\subset Z_k$.

We show that $Z_k' \not\subset C$, by contradiction. If $Z_k' \subset C$ then Z_k' consists of just one point z_k because, by Lemma 2.4, the set $J(c_0)$ defined there is dense in C and has empty intersection with the connected set Z_k', by (3.8)(i). But then, by (3.8)(ii), the point z_k has at least 2^j different virtual periods for $k \geqq k_0$ if we choose

$$k_0 > 2^{2^j} c_0.$$

This is a contradiction to Lemma 2.3, if we choose $2j$ to be a uniform bound on C for the number of characteristic roots of χ on the imaginary axis: then $z_k \in C$ has less than 2^j distinct virtual periods.

Step 4: *finale for* Z. We define the set Z of centers and nonstationary periodic solutions of IE (1.1) as

$$Z := \bigcup_{k \geqq k_0} Z_k.$$

By Step 2, the connected sets Z_k have the center z_0 in common, hence Z is connected. By Step 3, Z is not contained in C. Again by Step 3, Z_k contains a *nonstationary* periodic solution z which lies on ∂B_k (Case 1), or has a virtual period between $2^{-2^j-1}k$ and $2k$ (Case 2). Therefore Z is global, i.e. Z satisfies (3.2) or (3.3), and the proof is complete. □

4. Applications. We indicate applications of our abstract global bifurcation Theorem 3.1 to two problems arising in mathematical biology. We compute the Hopf index on suitably chosen intervals I of the parameter λ. In the first problem we have to adapt the solution space X to the biological situation. Our results are stated as corollaries to Theorem 3.1.

The first example is drawn from Diekmann, Montijn [11] and Gripenberg [16], [17] and was the original motivation of our work. The scalar equation, arising in epidemiology, reads [11]

$$x(t) = \lambda \cdot \left(1 - \int_{t-1}^{t} x(s)\,ds\right) \cdot \int_{-\infty}^{t} b(t-s)x(s)\,ds; \tag{4.1}$$

and we assume $b \geqq 0$ has integral 1 and is in A_γ for some $\gamma > 0$. The parameter λ relates to the total population size, $x(s) \geqq 0$ counts the individuals which are newly infected at time s, and $b(\tau)$ measures the infective force of an individual, which was infected τ units of time ago, on susceptible individuals (see [11] for more details and references). Let

$$\xi_1(t) := \int_{t-1}^{t} x(s)\,ds,$$

$$\xi_2(t) := \int_{-\infty}^{t} b(t-s)x(s)\,ds,$$

$$g(\xi_1, \xi_2) := (1-\xi_1)\xi_2.$$

Use (4.1) to replace $x = \lambda g(\xi_1, \xi_2)$ in the definition of ξ_1, ξ_2 to obtain the equivalent system

$$\xi = \lambda a * f(\xi), \quad \text{where} \tag{4.2}$$

$$\xi = \begin{pmatrix} \xi_1 \\ \xi_2 \end{pmatrix}, \quad f = \begin{pmatrix} g \\ g \end{pmatrix}, \quad a = \begin{pmatrix} 1_{[0,1]} & 0 \\ 0 & b \end{pmatrix}.$$

Thus (4.1) is put into the general form (1.1) discussed before. As a solution space for (4.1) we consider the subset

$$x \in X := BC^0(\mathbb{R}, \mathbb{R}^+)$$

of the Banach space $BC^0(\mathbb{R}, \mathbb{R})$ i.e. we admit positive solutions x only.

Let us analyze the stationary solutions and characteristic equation of (4.1). In X, the only stationary solution is

$$x^0(\lambda) = 1 - 1/\lambda, \qquad \lambda > 1$$

(we exclude the branch $x(\lambda) \equiv 0 \notin X$), with corresponding characteristic function

$$\chi_\lambda(\mu) = 1 + (\lambda - 1)\mu^{-1} \cdot (1 - \exp(-\mu)) - \hat{b}(\mu).$$

We discuss the limits $\lambda \searrow 1$ and $\lambda \to \infty$ in order to compute the Hopf index along $x^0(\lambda)$. The limit $\lambda \searrow 1$ is regular, $\mu = 0$ is the only zero of $\chi_1(\mu)$ with $\operatorname{Re}\mu \geqq 0$. This simple zero continues to $\mu = \mu(\lambda)$ near $\lambda = 1$ and from

$$\mu'(1) = \left(\hat{b}'(0)\right)^{-1} = -\left(\int_0^\infty s b(s)\, ds\right)^{-1} < 0$$

we conclude that

$$\lim_{\lambda \searrow 1} E^0(\lambda) = 0 \tag{4.3}$$

(the "unstable dimensions" $E^j(\lambda)$ were introduced just before Definition 1.6). The limit $\lambda \to \infty$ is also easy [11]: with $\beta := 1/(\lambda - 1)$, $\chi = 0$ is equivalent to

$$\eta(\beta, \mu) := \beta(1 - \hat{b}(\mu)) + \mu^{-1}(1 - \exp(-\mu)) = 0 \tag{4.4}$$

where $\eta : \mathbb{R} \times \mathbb{C} \to \mathbb{C}$ is analytic. Note that $\eta(0, \mu_k) = 0$ at the simple zeros $\mu_k = k \cdot 2\pi i$, $k \in \mathbb{Z} \setminus \{0\}$. By the implicit function theorem, these zeros have continuations $\mu_k(\beta)$ for small $|\beta|$ with derivative

$$\mu_k'(0) = -\left(D_\mu \eta(0, \mu_k)\right)^{-1} D_\beta \eta(0, \mu_k) = -\mu_k^{-1}(1 - \hat{b}(\mu_k)).$$

In the notation of [11], $b_k := 2 \operatorname{Im} \hat{b}(\mu_k)$, we obtain

$$\operatorname{Re}\mu_k'(0) = \frac{b_k}{4k\pi}.$$

This implies that

$$E^0(\lambda_0) > 0 \quad \text{for large } \lambda_0 > 1, \tag{4.5}$$

if at least one of the numbers b_k is positive.

We check the assumptions of our Main Theorem 3.1 for $\lambda \in I := [1 + \varepsilon, \lambda_0]$ and $\varepsilon > 0$ sufficiently small. We get around the boundedness assumption on f as in our remarks on Theorem 3.1. Obviously, $b \in A_\gamma$ implies $a \in A_\gamma$. Assumption (1.9) is satisfied: we obtain a stationary branch $x^0(\lambda)$ with $\chi_\lambda(0) = \lambda - 1 \neq 0$. The set C of centers is discrete. To see that we write $\mu = i\tau$ and solve equation (4.4) for β, obtaining

$$\beta = \Phi(\tau)$$

with $\Phi(\tau) := -(1-\exp(-i\tau))\cdot(i\tau(1-\hat{b}(i\tau)))^{-1}$. The curve Φ is analytic for $\tau>0$ and $\operatorname{Im}\Phi \not\equiv 0$ because $\Phi(2\pi k)=0$, $\operatorname{Im}\Phi'(2\pi k)\neq 0$ provided that $b_k\neq 0$. Together with $\Phi(\tau)\to 0$ for $\tau\to\infty$ this proves C is discrete. Hence we may pick λ_0 large enough such that (4.5) is valid and no centers occur on ∂I, i.e. Assumption (1.10) holds. By Definition 1.6 of the Hopf index, (4.3) and (4.5) imply

$$H=\frac{1}{2}(-1)^{E^0(1+\varepsilon)}\cdot\left(E^0(\lambda_0)-E^0(1+\varepsilon)\right)=\frac{1}{2}E^0(\lambda_0)>0,$$

i.e. Assumption (3.1) holds. Analyticity of $\chi_\lambda(\mu)$ (cf. (2.7)) is trivial. Applying Theorem 3.1 we obtain the following.

COROLLARY 4.1. *Let the kernel b in equation* (4.1) *be nonnegative with integral normalized to one, $b\in A_\gamma$ for some positive γ, and*

$$b_k := 2\int_0^\infty b(s)\,\sin(2\pi k s)\,ds>0$$

for some $k\in\mathbb{N}$.

Then one of the following holds:

(4.6) *For any large enough λ_0 which does not occur in the discrete set C of centers there exists a nonstationary periodic solution $x\in X=BC^0(\mathbb{R},\mathbb{R}^+)$ of equation* (4.1); *or*

(4.7) *there exists a $\lambda_0>1$ and a continuum $Z\subset(1,\lambda_0)\times X$ consisting of centers and nonstationary periodic solutions of* (4.1) *such that Z is global, i.e. Z contains nonstationary periodic solutions (λ,x) with*
- *arbitrarily large norms of x, or*
- *arbitrarily large virtual periods.*

Proof. Our previous remarks prove that a global continuum $Z_\varepsilon\subset[1+\varepsilon,\lambda_0]\times X$ exists, if we can exclude the possibility that Z_ε terminates at a periodic orbit in $[1+\varepsilon,\lambda_0]\times\partial X$. From Gripenberg [17] it is immediate that 0 is the only periodic orbit in ∂X.

If $(\lambda,0)$ is in $\overline{Z}_\varepsilon$ with virtual periods staying bounded on Z, then $(\lambda,0)$ is a center, $\lambda\neq 1$ and there is a periodic solution $y\geqq 0$, $|y|=1$ of the linearized equation

$$y=\lambda b * y.$$

Taking averages over a period, we obtain a contradiction to $\lambda\neq 1$, $\int b=1$. Thus $(\lambda,0)\notin\overline{Z}$ and Theorem 3.1 applies on $[1+\varepsilon,\lambda_0]\times X$.

Letting $\varepsilon\to 0$, we can in fact obtain a global continuum $Z=$"lim" Z_ε in $[1,\lambda_0]\times X$ as was indicated in our remarks following Theorem 3.1; cf. also Step 2 in the proof of Theorem 3.1.

Note that (4.1) cannot have nontrivial periodic orbits at $\lambda=1$, to complete the proof of the corollary. □

Under the stronger but epidemiologically reasonable assumption that there is a constant C such that $b\leqq C\cdot 1_{[0,1]}$ it is easy to see that all periodic solutions in X have norm at most $\lambda\cdot C$. Then Corollary 4.1 holds even if we drop the alternative "Z is unbounded" in (4.7).

Our second example concerns a model for circular neural nets, cf. an der Heiden [22]. The system reads

$$x_j=\lambda h_j * f_j(x_{j-1}),\qquad j=1,\cdots,m \tag{4.8}$$

with $x_0 := x_m$. We assume

(4.9) the kernels $h_j \geqq 0$ have integral normalized to 1, and $h_j \in A_\gamma$ for some $\gamma > 0$ and all j; the C^1-nonlinearities f_j satisfy $f_j(\xi) \neq 0$ for $\xi \neq 0$, $f_j(0) = 0$ and $c := \Pi_j f_j'(0) < 0$.

Systems (4.8) with $\lambda > 0 > c$ are called "repressible" in [22]. We give a general discussion of the Hopf index H first and specify kernels h_j later. Our result shows how *delays* in the kernels cause global Hopf bifurcation.

This time we work directly in the setting of equation (1.1), $I = [0, \lambda_0]$. The only stationary solution of system (4.8) is the zero solution (by Assumption 4.9), and the characteristic equation reads

$$\chi_\lambda(\mu) = 1 - \lambda^m \cdot c \prod_j \hat{h}_j(\mu) = 0.$$

Obviously, $\chi_\lambda(0) = 1 - \lambda^m c \neq 0$.

For $\lambda = 0$ we trivially obtain $\chi(\mu) \equiv 1$, hence

$$E(\lambda = 0) = 0. \tag{4.10}$$

Obviously, nonstationary periodic solutions do not exist for $\lambda = 0$.

Analysis for $\lambda = \lambda_0 > 0$ is much more involved. Introducing $\beta := \lambda^{-m}$, $\mu = i\tau$ and $\Phi(\tau) := c \cdot \Pi \hat{h}_j(i\tau)$, the characteristic equation reads

$$\Phi(\tau) = \beta. \tag{4.11}$$

As before, Φ is analytic. Therefore $\Phi(0) = c$, $\operatorname{Im} \Phi'(0) \neq 0$ implies that $\operatorname{Im} \Phi \not\equiv 0$ and the set C of centers is discrete, by real analyticity of $\tau \to \operatorname{Im} \Phi(\tau)$. However, C may be unbounded.

In our first example, we have discussed the case that Φ has a real zero. This time, let us assume $\Phi(\tau) \neq 0$ for all real τ. To compute

$$E(\lambda_0)$$

we may perturb Φ slightly, such that $\Phi'(\tau) \neq 0$ whenever $\Phi(\tau) \in \mathbb{R}^+$. In that case, all imaginary characteristic roots $\mu = i\tau$ are simple and (4.11) may be solved for $\mu = \mu(\beta)$, locally, with

$$\operatorname{sgn} \operatorname{Re} \mu'(\beta) = -\operatorname{sgn} \operatorname{Im} \tau'(\beta) = \operatorname{sgn} \operatorname{Im} \Phi'(\tau). \tag{4.12}$$

This equality tells us how $E(\lambda)$ relates to the winding number $n(\Phi, 0)$ around 0 of the complex valued curve $\Phi : \mathbb{R} \to \mathbb{C} \setminus \{0\}$. For $(\lambda_0, 0) \notin C$ and $\beta_0 := \lambda_0^{-m}$ let $\tau_0 > 0$ be maximal (Riemann–Lebesgue lemma) such that $\Phi(\tau_0) \in [\beta_0, \infty)$. Then all imaginary characteristic roots $\mu = i\tau$ on $C \cap ([0, \lambda_0] \times \{0\})$ satisfy $|\tau| \leqq \tau_0$ and contribute to the left-hand side of (4.12) for some $\tau \in [-\tau_0, \tau_0]$, adding up to $E(\lambda_0)$. The right-hand sides add up almost to the winding number $n(\Phi([-\tau_0, \tau_0]), 0)$ with a possible difference of at most one. Thus we have proved

$$|E(\lambda_0) - n(\Phi([-\tau_0, \tau_0]), 0)| \leqq 1. \tag{4.13}$$

We apply our Main Theorem 3.1 with $\lambda \in I = [0, \lambda_0]$ just as with our first example. By (4.10), we know that on $[0, \lambda_0] \times X$

$$H = \frac{1}{2} E(\lambda_0),$$

and (4.13) helps us to compute this quantity.

Before we specify particular kernels we summarize our result as follows.

COROLLARY 4.2. *Let Assumption* (4.9) *be satisfied for the repressible system* (4.8). *In addition suppose that for* $\lambda=\lambda_0>0$ *the winding number* $n(\Phi,0)$ *satisfies*

$$|n(\Phi([-\tau_0,\tau_0]),0)|>1. \tag{4.14}$$

Then the conclusion of Theorem 3.1 *holds for system* (4.8) *on* $[0,\lambda_0]\times X$. *Obviously,* (3.4) $\lambda=\alpha=0$ *is impossible, i.e. nonstationary periodic orbits do not exist at* $\lambda=0$.

As a simple example we specify the following *delaying* kernels

$$h_j(s)=\begin{cases}0 & \text{for } 0\leqq s<\zeta_j,\\ b_j(s-\zeta_j) & \text{for } \zeta_j\leqq s<\infty,\end{cases} \tag{4.15}$$

$$b_j(s):=p_j(s)\exp(-\gamma_j s),$$

with $\gamma_j>0$, $\zeta_j\geqq 0$, $\Sigma\zeta_j>0$ and nonzero polynomials $p_j\geqq 0$ on $[0,\infty)$. We check Assumption (4.14) on the winding number of Φ. We compute

$$\begin{aligned}\Phi(\tau)&=\prod_j f_j'(0)\hat{h}_j(i\tau)\\ &=c\cdot\prod_j\hat{b}_j(i\tau)\cdot\exp\Big(-i\tau\sum_j\zeta_j\Big)\\ &=c\cdot\prod_j\hat{p}_j(\gamma_j+i\tau)\cdot\exp\Big(-i\tau\sum_j\zeta_j\Big)\\ &=c\cdot\prod_j q_j\big(1/(\gamma_j+i\tau)\big)\cdot\exp\Big(-i\tau\sum_j\zeta_j\Big),\end{aligned}$$

where q_j are polynomials related to p_j. Thus

$$\Phi(\tau)=cq(\tau)\exp\Big(-i\tau\sum_j\zeta_j\Big),$$

with $\arg(q(\tau))$ being uniformly bounded for $\tau\in\mathbb{R}$ (we take $\arg(q(\tau))$ continuous as a function of τ). By equation (4.11), the set C of centers is therefore unbounded and

$$\lim_{\tau_0\to\infty} n(\Phi([-\tau_0,\tau_0]),0)=-\infty.$$

Hence Corollary 4.2 applies for all sufficiently large $\lambda_0>0$. This result is not affected by a possible finite number of real zeros of Φ.

Following our previous analysis we could treat other kernels (e.g. step functions) as well. Also, small self-inhibition or self-excitation in (4.8) does not change our results.

Finally, we note that Gripenberg's example [16], [17] can be treated along the lines of our second example. With regard to $\Phi(\tau)$, (4.1) is rather special because it yields infinitely many zeros of Φ.

Acknowledgments. The author is indebted to W. Jäger, K. Schumacher and H. Thieme for teaching him some integral equations with patience and enthusiasm, to O. Diekmann who initiated this research by his questions, and to the referees for their constructive criticism.

Note added in proof. Above we announce a result on global Hopf bifurcation if Assumption (1.9) is violated. This accounts for degenerate stationary solutions and their bifurcations. The corresponding ODE theory is developed in B. Fiedler, *Global Hopf bifurcation of two parameter flows*, Arch. Rational Mech. Anal., to appear. By ODE-approximation, this theory carries over to Volterra integral equations as considered in the present paper.

KINETIC EQUATIONS WITH REFLECTING BOUNDARY CONDITIONS*

C. V. M. VAN DER MEE† AND V. PROTOPOPESCU‡

Abstract. A general abstract model of time-independent kinetic equations on the half-line is presented. The existence and uniqueness of the solution is proved under specified incoming flux and nonmultiplying boundary reflection processes. An iterative method is formulated for computing in principle the solution by using the solution of the analogous problem without reflection. In many concrete cases (e.g. neutron transport, BGK model in rarefied gas dynamics, etc.) the available explicit expression for the latter provides the actual solution of the general problem. Possible generalizations and open problems are briefly discussed.

Key words. kinetic theory, transport equation, reflection

AMS(MOS) subject classifications. Primary 82A70; secondary 45A25

1. Introduction. In recent years substantial progress has been reported on the existence and uniqueness theory for the solution of boundary value problems of the type

$$T\psi'(x) = -A\psi(x), \qquad x \in \mathbb{R}_+, \tag{1.1}$$

$$Q_+\psi(0) = \mathscr{R}JQ_-\psi(0) + \phi_+, \tag{1.2}$$

$$\|\psi(x)\| = O(1) \qquad (x \to \infty), \tag{1.3}$$

where T is an injective self-adjoint operator, Q_+ and Q_- the orthogonal projections onto the maximal positive and negative T-invariant subspaces and A a positive self-adjoint (bounded or unbounded) Fredholm operator. The operators $\mathscr{R}$ and J as well as the precise meaning of the norm in (1.3) will be specified later. This boundary value problem models a variety of time-independent transport phenomena in semi-infinite media with boundary conditions appropriate to incoming flux specification and, if $\mathscr{R}$ is nonzero, to a (partial) reflection at the boundary. In most instances, however, it has been assumed that $\mathscr{R}=0$ (absence of reflection), and in this case the solution ψ, whenever unique, is represented in the form

$$\psi(x) = e^{-xT^{-1}A}E\phi_+, \qquad x \in \mathbb{R}_+. \tag{1.4}$$

In this direction we note the important contributions of Hangelbroek [14], Lekkerkerker [16], Beals [1, 2], van der Mee [19] and Greenberg et al. [13]. Only recently such a theory has been developed with full account of boundary reflection processes ($\mathrm{R} \equiv 0$). Namely, Beals and Protopopescu [3], [4] obtained an existence and uniqueness theory

for the Fokker–Planck equation

$$(1.5)\quad v\frac{\partial\psi}{\partial x}(x,v)=\frac{\partial^2\psi}{\partial v^2}(x,v)-v\frac{\partial\psi}{\partial x}(x,v),\qquad x\in\mathbb{R}_+,\quad v\in\mathbb{R},$$

$$(1.6)\quad \psi(0,v)=\alpha\psi(0,-v)+\beta\int_{-\infty}^{0}\sigma(v'\to v)\psi(0,v')\,dv'+\phi_+(v),\qquad v\in\mathbb{R}_+,$$

$$(1.7)\quad \lim_{x\to\infty}\{\psi(x,v)/x\}=b.$$

For general σ's the existence proof required a condition which will turn out to be automatically satisfied. Maslova [17], [18] published related results on the linearized Boltzmann equation with a sufficiently regular intermolecular potential. Greenberg and van der Mee [12] formulated a related radiative transfer problem in an abstract setting, but their result deals with (1.1) on a finite interval. The abstract approach was recently followed by van der Mee [20], who announced some results on this problem.

The paper is organized as follows. For the reader's convenience in §2 we provide a brief but fairly complete review of the existence and uniqueness theory for the solution of (1.1)–(1.3). Section 3 contains the procedure of *computing* the solution of the problem with reflection from the solution of the same problem without reflection ($\mathscr{R}=0$). This iterative scheme can be implemented whenever the albedo operator E in (1.4) is known explicitly, which is actually the case for a large class of problems. Namely, if A is a compact perturbation of the identity, an expression for E in terms of generalized Chandrasekhar **H**-functions [9] has been given by van der Mee [21], thereby generalizing a plethora of results obtained before for specific models (neutron transport, radiative transfer, BGK models, etc.). In some cases the iterative procedure can also be derived from a half-range completeness result involving **H**-functions (cf. [7], for instance). At present, no explicit representation is known for the albedo operator E in the case of the Fokker–Planck model (1.5)–(1.7) and more general Sturm–Liouville problems.

2. Existence and uniqueness theory. In the present section we provide a brief but fairly complete review of the existence and uniqueness theory for the solution of (1.1)–(1.3). In order to explain the later introduction of a number of concepts, we present the overall flavor of the theory by first considering T bounded and A strictly positive and neglecting reflection processes, which is relevant to radiative transfer in absorbing atmospheres [9] and neutron transport in submultiplying reactors [7]. Using semigroup theory, one may naturally write solutions to (1.1) in the form

$$\psi(x)=e^{-xT^{-1}A}\psi(0),\qquad 0\leqq x<\infty,$$

where $\psi(0)$ must be chosen in the subspace corresponding to the nonnegative part of the spectrum of the evolution operator $T^{-1}A$ in order that the above semigroup expression makes sense and condition (1.3) is fulfilled. On fitting the boundary condition (1.2) where $\mathscr{R}=0$, one must require $Q_+\psi(0)=\varphi_+$. If one would formulate an analogous boundary value problem for $x\in(+\infty,0)$, one should require that $\psi(0)$ be chosen in the subspace corresponding to the nonpositive part of the spectrum of $T^{-1}A$ and $Q_-\psi(0)=\varphi_-$. In a natural way one may thus express the unique solvability of both half-space problems, for $x\in(0,\infty)$ and for $x\in(-\infty,0)$, in terms of the invertibility of the operator V, which maps the nonnegative (resp. nonpositive) spectral subspace of $T^{-1}A$ into the ranges of the projections $Q_\pm$ onto forward (resp. backward) "fluxes". As a matter of fact, $V\psi(0)=\varphi_+$, $E=V^{-1}$ is called the albedo operator and formula (1.4) arises as the obvious result. Below we shall review the existence and uniqueness theory

along the above set up (which originates from Hangelbroek [14]) in some detail, since the unboundedness of T, the appearance of a nonzero null space of A and the absence of compactness assumptions on A cause technical difficulties and necessitate the introduction of some novel notions.

Let us now drop the above restrictions on T and A. Let T be an injective self-adjoint operator and A a positive self-adjoint operator with closed range $\mathrm{Ran}A$ and null space $\mathrm{Ker}A$ of finite dimension, both defined on the complex Hilbert space H. For the sake of convenience we assume A to be bounded, but at the end of this work we shall discuss how to remove this restriction. We then define the zero root subspace

$$Z_0=\{h\in H/\exists n\in\mathbb{N}:(T^{-1}A)^n h=0\}, \tag{2.1}$$

and assume $Z_0\subset D(T)$. It can then be proved (cf. [13]; the result there extends to unbounded T) that Z_0 has a finite dimension and $Z_0=\mathrm{Ker}(T^{-1}A)^2$. Here we also assume that Z_0 is nondegenerate in the following sense:

$$\{h\in Z_0/(Th,k)=0 \text{ for all } k\in Z_0\}=\{0\}.$$

In fact, this assumption is automatically satisfied. (If T is bounded, see [13]).

PROPOSITION 2.1. *We have the following decompositions*:

$$Z_0\oplus(T[Z_0])^{\perp}=H, \tag{2.2}$$

$$T[Z_0]\oplus Z_0^{\perp}=H, \tag{2.3}$$

$$Z_0^{\perp}=\overline{T\{(T[Z_0])^{\perp}\}}=A\{(T[Z_0])^{\perp}\}. \tag{2.4}$$

Moreover, Z_0 and $(T[Z_0])^{\perp}$ are $T^{-1}A$-invariant subspaces and there exists a unique operator S on $(T[Z_0])^{\perp}$ such that

$$T^{-1}A=(T^{-1}A|_{Z_0})\oplus S^{-1}. \tag{2.5}$$

The operator S is self-adjoint with respect to the positive definite inner product on $(T[Z_0])^{\perp}$ given by

$$(h,k)_A=(Ah,k). \tag{2.6}$$

For isotropic neutron transport in a conservative medium, where Z_0 can be constructed explicitly, this Proposition 2.1 is due to Lekkerkerker [16]. It later appeared in more abstract form in [19], [13], [2].

Let us introduce H_T as the Hilbert space obtained by completing $D(T)$ with respect to the inner product

$$(h,k)_T=(|T|h,k).$$

Let us assume that there exists a unitary and self-adjoint operator J on H, which leaves invariant $D(T)$ and satisfies

$$TJ=-JT, \qquad AJ=JA.$$

Then J extends from $D(T)$ to a unitary and self-adjoint operator on H_T, as also do the orthogonal projections Q_+ and Q_- of H onto the maximal positive and negative T-invariant subspaces, respectively. We shall require the *reflection operator* to be a bounded operator on $Q_+[H]$, which leaves invariant $D(T)$, and satisfies the identity

$$T\mathscr{R}=\mathscr{R}^{\dagger}T \tag{2.7}$$

for some bounded operator $\mathscr{R}^+$ on H. Putting

$$\mathscr{R}h \overset{\text{def}}{=} J\mathscr{R}Jh, \qquad h \in Q_-[H],$$

we extend $\mathscr{R}$ to a bounded operator on H, which automatically commutes with J, leaves invariant $D(T)$ and extends from $D(T)$ to a bounded operator on H_T. In order that the operator $\mathscr{R}$ models a nonmultiplying reflection process at the boundary, we also assume that $\mathscr{R}$ extends to a contraction on H_T:

$$(|T|\mathscr{R}h, \mathscr{R}h) \leqq (|T|h, h), \qquad h \in D(T).$$

For later use we include the following result, derived by Beals [1] for injective and certain noninjective A, and generalized by Greenberg et al. [13].

THEOREM 2.2. *For every $\phi_+ \in Q_+[H_T]$ there exists at least one continuous function $\psi\colon [0,\infty) \to H_T$, which is continuously differentiable on $(0,\infty)$ and satisfies the equations*

$$T\psi'(x) = -A\psi(x), \qquad x \in \mathbb{R}_+, \tag{2.8}$$

$$Q_+\psi(0) = \phi_+, \tag{2.9}$$

$$\|\psi(x)\|_T = O(1) \qquad (x \to \infty). \tag{2.10}$$

The number of linearly independent solutions of the homogeneous $(\phi_+ = 0)$ problem coincides with the maximal number of linearly independent vectors $h_1, \cdots, h_k \in \operatorname{Ker} A$ satisfying $(Th_i, h_j) = 0$ for $i \neq j$ and $(Th_i, h_i) < 0$ for $i = 1, 2, \cdots, k$.

In fact, it is possible to construct at least one "albedo operator" E, which is a bounded strictly positive self-adjoint operator on H_T, such that

$$\psi(x) = e^{-xT^{-1}A}PE\phi_+ + (I-P)E\phi_+ \tag{2.11}$$

is a solution of (2.8)–(2.10). Here P is the continuous extension from $D(T)$ to H_T of the projection of H onto $(T[Z_0])^\perp$ along Z_0 (cf. (2.1)), while

$$\|I - E\|_{H_T} < 1 \tag{2.12}$$

(cf. [13], where it is shown that $\sigma(E) \subset (0,2)$). Evidently we must then have $(I-P)E\phi_+ \in \operatorname{Ker} A$ for all $\phi_+ \in Q_+[H_T]$.

The solution of the existence problem for (1.1)–(1.3) is provided by the following

THEOREM 2.3. *For every $\phi_+ \in Q_+[H_T]$ there exists at least one continuous function $\psi\colon [0,\infty) \to H_T$, which is continuously differentiable on $(0,\infty)$ and satisfies the equations*

$$T\psi'(x) = -A\psi(x), \qquad x \in \mathbb{R}_+, \tag{2.13}$$

$$Q_+\psi(0) = \mathscr{R}JQ_-\psi(0) + \phi_+, \tag{2.14}$$

$$\|\psi(x)\|_T = O(1) \qquad (x \to \infty). \tag{2.15}$$

Proof. Consider the operator

$$S_{\mathscr{R}} = I + \mathscr{R}J(I-E).$$

Because of the estimate

$$\|S_{\mathscr{R}} - I\|_{H_T} \leqq \|\mathscr{R}\|_{H_T}\|J\|_{H_T}\|I-E\|_{H_T} < 1, \tag{2.16}$$

the operator $S_{\mathscr{R}}$ is bounded and invertible on H_T. Consider the function

$$\psi(x) = e^{-xT^{-1}A}PES_{\mathscr{R}}^{-1}\phi_+ + (I-P)ES_{\mathscr{R}}^{-1}\phi_+, \qquad 0 \leqq x < \infty.$$

Then ψ is a continuous function from $[0,\infty)$ into H_T, which is bounded and continuously differentiable on $(0,\infty)$ and satisfies (2.13), since $(I-P)ES_{\mathscr{R}}^{-1}\phi_+ \in \operatorname{Ker} A$. Notice that $S_{\mathscr{R}}$ maps $Q_+[H_T]$ onto itself. We now have

$$\begin{aligned}(Q_+ - \mathscr{R}JQ_-)\psi(0) &= (Q_+ - \mathscr{R}JQ_-)ES_{\mathscr{R}}^{-1}\phi_+ \\ &= (Q_+ - \mathscr{R}JQ_-)EQ_+S_{\mathscr{R}}^{-1}\phi_+ = (Q_+ - \mathscr{R}JQ_-EQ_+)S_{\mathscr{R}}^{-1}\phi_+ \\ &= (Q_+ + \mathscr{R}JQ_-(I-E)Q_+)S_{\mathscr{R}}^{-1}\phi_+ = Q_+S_{\mathscr{R}}Q_+S_{\mathscr{R}}^{-1}\phi_+ = \phi_+,\end{aligned}$$

and therefore (2.14) is satisfied. □

Remark. As far as one considers only operators A which do not have negative definite parts and whose kernel is finite-dimensional, the most general boundary condition to be imposed at infinity reads

$$\exists n \geqq 0: \|\psi(x)\|_T = 0(x^n)(x \to \infty). \tag{2.17}$$

This is the case for conservative neutron transport [16] and for the Fokker–Planck equation [4], where the root subspace as defined by (2.1) is two-dimensional and $n=1$. This implies that for large x the solution behaves as $f_1 + f_2 x$. (Here the vectors f_1 and f_2 are functions depending on the angular (for neutron transport) or velocity (for the Fokker–Planck equation) variable, but in more general cases they may contain some other variables as well, depending on the complexity of the operators T and A.) For the kinetic (transport) problems usually occurring in physical situations the solution $f_1 + f_2 x$ is called normal (or Chapman–Enskog) and the vectors in the root subspace are related to the (reduced) hydrodynamical description, valid far from the boundary. Because the boundary condition (2.17) is more general than (2.15), existence of solutions is clear. For the two types of boundary condition at infinity the number of linearly independent solutions might be different if normal solutions occur.

Let us now define P as the projection onto $(T[Z_0])^{\perp}$ along Z_0 and PP_+ (resp. PP_-) as the projection onto the maximal positive (resp. negative) S-invariant subspace along the direct sum of Z_0 and the maximal negative (resp. positive) S-invariant subspace. Here positivity and negativity relate to the inner product (2.6) and essential use has been made of the Spectral Theorem for S (cf. Proposition 2.1). As a consequence,

$$(TPP_+h,h) = (SPP_+h,h)_A \geqq 0, \qquad (TPP_-k,k) = (SPP_-k,k)_A \leqq 0, \tag{2.18}$$

where strict positivity and negativity hold for $h \in \operatorname{Ran} PP_+$ and $k \in \operatorname{Ran} PP_-$. Then PP_+ and PP_- extend to bounded projections on H_T (cf. [1],[13]). Next put

$$M_{\mp,} = [\operatorname{Ran} PP_{\pm} \oplus \operatorname{Ker}(Q_{\pm} - \mathscr{R}JQ_{\mp})] \cap Z_0 \tag{2.19}$$

for the notions concerning indefinite inner product spaces we are going to use we refer to [5].

LEMMA 2.4. *We have*

$$(Th,h) \leqq 0, \qquad h \in M_{-,\mathscr{R}}.$$

If $\|\mathscr{R}\|_{H_T} < 1$, *or under the weaker assumption*

$$\operatorname{Ker}(Q_+ - \mathscr{R}JQ_-) \cap Z_0 = \{0\}, \tag{2.20}$$

we have

$$(Th,h) < 0, \qquad 0 \neq h \in M_{-,\mathscr{R}}.$$

Proof. For $h \in M_{-,\mathscr{R}}$ we first determine $g \in \operatorname{Ran} PP_+$ and $k \in \operatorname{Ker}(Q_+ - \mathscr{R}JQ_-)$ such that $h = g + k$. Since $h \in Z_0$ and $g \in (T[Z_0])^\perp$, we have $(Th, g) = 0$. Hence,

$$(Th,h)+(Tg,g)=(Tk,k)=\|Q_+k\|_T^2-\|Q_-k\|_T^2$$
$$=\|\mathscr{R}JQ_-k\|_T^2-\|Q_-k\|_T^2\leqq-\left(I-\|\mathscr{R}\|_{H_T}^2\right)\|Q_-k\|_T^2.$$

Since $(Tg,g)=(Sg,g)_A \geqq 0$ (cf. (2.18)), we have $(Th,h)\leqq 0$. Moreover, if $(Th,h)=0$, then $g=0$ and either $\|\mathscr{R}\|_{h_T}=1$ or $Q_-k=0$; the latter would imply $k=\mathscr{R}JQ_-k+Q_-k = 0$ and $h=0$. Hence, if $\|\mathscr{R}\|_{H_T}<1$, we have $(Th,h)<0$ for $0\neq h\in M_{-,\mathscr{R}}$. The latter conclusion can also be drawn under the weaker assumption (2.20). □

In the same way we can prove that

$$(Th,h)<0, \qquad h\in M_{-,\mathscr{R}}\cap \operatorname{Ker}A,$$

provided

$$\operatorname{Ker}(Q_+-\mathscr{R}JQ_-)\cap\operatorname{Ker}A=\{0\}. \tag{2.21}$$

THEOREM 2.5. *Under the condition* (2.21) *the number of linearly independent solutions of the homogeneous* $(\phi_+=0)$ *problem* (2.13)–(2.15) *coincides with the maximal number of linearly independent vectors* $h_1,\cdots,h_k\in\operatorname{Ker}A$ *satisfying* $(Th_i,h_j)=0$ *for* $i\neq j$ *and* $(Th_i,h_i)<0$ *for* $i=1,2,\cdots,k$.

Proof. Denoting by $\mathscr{R}^*$ the adjoint of $\mathscr{R}$ in H, we easily compute

$$(T[M_{\mp,\mathscr{R}}])^\perp=\left[(T\operatorname{Ran}PP_\pm)^\perp\cap\operatorname{Ran}T^{-1}\left(Q_\pm-Q_\mp J\mathscr{R}^*\right)\right]+(T[Z_0])^\perp$$
$$=\left[(\operatorname{Ran}PP_\mp\oplus Z_0)\cap\operatorname{Ran}\left(Q_\pm+Q_\mp J(\mathscr{R}^\dagger)^*\right)T^{-1}\right]+(T[Z_0])^\perp$$
$$=\left\{\left[\operatorname{Ran}PP_\mp\oplus\operatorname{Ran}\left(Q_\pm+Q_\mp J(\mathscr{R}^\dagger)^*\right)\right]\cap Z_0\right\}\cap(T[Z_0])^\perp.$$

Here we have used the intertwining property $T\mathscr{R}=\mathscr{R}^\dagger T$ and the fact that the operator $Q_\pm+Q_\mp J(\mathscr{R}^\dagger)^*$ is a bounded projection on H and therefore has closed range. For $g\in\operatorname{Ran}PP_-$ and $k=(Q_++Q_-J(\mathscr{R}^\dagger)^*)l$ we obtain

$$(Th,h)+(Tg,g)=(Tk,k)=\|Q_+k\|_T^2-\|Q_-k\|_T^2=\|Q_+l\|_T^2-\left\|Q_-J(\mathscr{R}^\dagger)^*l\right\|_T^2$$
$$\geqq\left(1-\left\|(\mathscr{R}^\dagger)^*\right\|_{H_T}^2\right)\|Q_+l\|_T^2\geqq 0,$$

because $(\mathscr{R}^\dagger)^*$ is a contraction in H_T:

$$0\leqq\left((\mathscr{R}^\dagger)^*h,h\right)_T=\left((Q_+-Q_-)h,\mathscr{R}(Q_+-Q_-)h\right)_T\leqq\|\mathscr{R}\|_{H_T}^2\|h\|_T^2\leqq\|h\|_T^2.$$

We now obtain

$$(Th,h)\geqq 0, \qquad h\in(T[M_{-,\mathscr{R}}])^\perp\cap Z_0.$$

Since Z_0 is nondegenerate with respect to the indefinite inner product

$$[h,k]=(Th,k), \tag{2.22}$$

$M_{-,\mathscr{R}}$ is negative and $(T[M_{-,\mathscr{R}}])^\perp\cap Z_0$ is positive, the subspace $M_{-,\mathscr{R}}$ is maximal negative with respect to this inner product. Under the condition (2.21) the subspace $M_{-,\mathscr{R}}\cap\operatorname{Ker}A$ then is strictly negative and maximal in this respect among the subspaces

of $\mathrm{Ker}\,A$. Because the linear span of the vectors $h_1,\cdots,h_k$ in the statement of this theorem is also a maximal strictly negative subspace of $\mathrm{Ker}\,A$ and the dimension of such a subspace does not depend on its specific choice, we must have $\dim(M_{-,\mathscr{R}}\cap \mathrm{Ker}\,A)=k$. Finally, if ψ is a solution of (2.13)–(2.15) with $\phi_+=0$, then necessarily $(I-P)\psi(0)\in M_{-,\mathscr{R}}\cap \mathrm{Ker}\,A$. □

Under the condition (2.21) we find the same existence and uniqueness result as for $\mathscr{R}=0$, which we easily see on comparing Theorems 2.2 and 2.5. If one would drop condition (2.21), the homogeneous ($\phi_+=0$) problem (2.13)–(2.15) in general has more linearly independent solutions than is to be expected from the above theorem. As an example, consider the case $\mathscr{R}=I$, which describes *purely specular reflection*. First we observe that every $k\in H_T$, which satisfies $Q_+k=\mathscr{R}JQ_-k$ for $\mathscr{R}=I$, has the property

$$(Tk,k)=\|Q_+k\|_T^2-\|Q_-k\|_T^2=\|JQ_-k\|_T^2-\|Q_-k\|_T^2=0,$$

since J is a unitary operator on H_T. If such a vector k would belong to the space $\mathrm{Ran}\,PP_+\oplus\mathrm{Ker}\,A$, as it should be if it were the initial value of a solution ψ, then $k=-g+h$ for some $g\in\mathrm{Ran}\,PP_+$ and $h\in\mathrm{Ker}\,A$. Since $Q_+k=JQ_-k$ implies

$$Jk=JQ_+k+JQ_-k=J(JQ_-k)+Q_+k=k,$$

and therefore $Jg=g$ and $Jh=h$, the property $g=Jg\in\mathrm{Ran}\,PP_-$ would give rise to $g=0$ and thus $k\in\mathrm{Ker}\,A$, whence $k\in\mathrm{Ker}\,A\cap\mathrm{Ker}(I-J)$. Conversely, every such k would fulfill the condition $JQ_-k=Q_+Jk=Q_+k$ and therefore be an initial value of some solution ψ. Thus the constant functions $\psi(x)=k$, where $k=Jk\in\mathrm{Ker}\,A$, are the solutions of the homogeneous ($\phi_+=0$) problem (2.13)–(2.15) with $\mathscr{R}=I$.

Remark. The analogue of Theorem 2.5 for the kinetic equation (2.13) with boundary conditions (2.14) and (2.17) can easily be obtained by repeating the arguments with Z_0 instead of $\mathrm{Ker}\,A$. It then appears that under the assumption (2.20) the number of linearly independent solutions of the homogeneous ($\phi_+=0$) problem coincides with the maximal number of linearly independent vectors $h_1,\cdots,h_k\in Z_0$ satisfying $(Th_i,h_j)=0$ for $i\neq j$ and $(Th_i,h_i)<0$ for $i=1,2,\cdots,k$, which is the same result as for $\mathscr{R}=0$. In the case of purely specular reflection ($\mathscr{R}=I$) this number generally is larger and in fact equals the dimension of the subspace $Z_0\cap\mathrm{Ker}(I-J)$ of "even" root subspace vectors. In general, for $Z_0\neq\mathrm{Ker}\,A$ one will find a larger measure of nonuniqueness of the solution than for the problem (2.13)–(2.15), which can be accounted for by considering the normal solutions f_1+f_2x.

3. An iteration procedure. Let us consider a suitable bounded strictly positive albedo operator E on H_T, such that $\psi(0)=E\phi_+$ yields a solution of (2.8)–(2.10). Such an operator always exists and satisfies (2.12). It is unique, if and only if $(Th,h)\geqq 0$ for all $h\in\mathrm{Ker}\,A$ (cf. Theorem 2.2). Using the norm estimate (2.16), we may write a solution of (2.13)–(2.15) as follows:

$$\psi(x)=e^{-xT^{-1}A}PEg_+ +(I-P)Eg_+,\qquad x\in\mathbb{R}_+,$$

where

$$g_+=S_{\mathscr{R}}^{-1}\phi_+=\sum_{n=0}^{\infty}(-1)^n[\mathscr{R}j(I-E)]^n\phi_+; \tag{3.1}$$

the series is absolutely convergent in the norm of H_T, uniformly in ϕ_+ on bounded subsets of $Q_+[H_T]$. We may therefore compute g_+ by iterating the vector equation

$$g_+ +\mathscr{R}J(I-E)g_+=\phi_+ \tag{3.2}$$

on $Q_+[H_T]$. Depending on the choice of the albedo operator E—unique if and only if $(Th,h)\geqq 0$ for $h\in \operatorname{Ker}A$—, different solutions are generated. In order to find all solutions, especially in the cases where they are nonunique, one should still solve the homogeneous ($\phi_+=0$) problem (2.13)–(2.15). For instance, if $\operatorname{Ker}A\neq\{0\}$ and $Jh=h$ for all $h\in\operatorname{Ker}A$, which occurs for the Fokker–Planck example (1.5)–(1.7) (disregarding for the moment that this model does not satisfy the boundedness assumption on A), we would have $(Th,h)=(TJh,Jh)=-(JTh,Jh)=-(Th,h)=0$ for all $h\in\operatorname{Ker}A$. This would imply existence of a unique albedo operator and therefore the generation by iteration of one solution only. Nevertheless the problem is nonuniquely solvable and the homogeneous problem should be solved as well. A similar remark applies to the solution of (2.13) with boundary conditions (2.14) and (2.17).

Let us consider the case when A is a compact perturbation of the identity satisfying

$$\exists 0<\alpha<1:\operatorname{Ran}(I-A)\subset\operatorname{Ran}|T|^{\alpha},\qquad Z_0\subset D\big(|T|^{2+\alpha}\big), \tag{3.3}$$

which occurs in one-speed and symmetric multigroup neutron transport (cf. [19]), and several BGK models in rarefied gas dynamics. If we choose a closed subspace $\mathbb{B}\supset\operatorname{Ran}(I-A)$, which may be chosen finite-dimensional if $I-A$ has finite rank, and operators $\pi:H\to\mathbb{B}$ and $j:\mathbb{B}\to H$ such that πj is the identity on $\mathbb{B}$ and $j\pi$ the orthogonal projection of H onto $\mathbb{B}$, a representation for E can be found in terms of generalized Chandrasekhar **H**-functions. More precisely, if $\sigma(\cdot)$ denotes the resolution of the identity of the self-adjoint operator T, we have (see [21])

$$E\phi_+=\phi_+ +\int_{-\infty}^{0}\int_{0}^{\infty}\frac{\nu}{\nu-\mu}\sigma(d\mu)(I-A)j\mathbf{H}_l(-\mu)\mathbf{H}_r(\nu)\pi\sigma(d\nu)\phi_+, \tag{3.4}$$

where $\mathbf{H}_l(-\mu)$ and $\mathbf{H}_r(\nu)$ are solutions of the nonlinear integral equations

$$\mathbf{H}_l(z)^{-1}=I-z\int_0^{\infty}(z+t)^{-1}\mathbf{H}_r(t)\pi\sigma(dt)(I-A)j, \tag{3.5}$$

$$\mathbf{H}_r(z)^{-1}=I-z\int_0^{\infty}(z+t)^{-1}\pi\sigma(-dt)(I-A)j\mathbf{H}_l(t). \tag{3.6}$$

The solutions and their inverses must be analytic for $\operatorname{Re}z>0$ and continuous for $\operatorname{Re}z\geqq 0$. If $\operatorname{Ker}A\neq\{0\}$, the continuity of $\mathbf{H}_l$ and $\mathbf{H}_r$ at infinity must be replaced by a weaker requirement. (The precise description of such requirements was not given in [21].) Equation (3.2) then has the form

$$g_+-\int_{\substack{-\infty\\(\mu)}}^{0}\int_{\substack{0\\(\nu)}}^{\infty}\frac{\nu}{\nu-\mu}\mathscr{R}J\sigma(d\mu)(I-A)j\mathbf{H}_l(-\mu)\mathbf{H}_r(\nu)\pi\sigma(d\nu)g_+=\phi_+. \tag{3.7}$$

On solving the **H**-equations (3.5)–(3.6) we may compute g_+ by iteration. It should be noted that the above expression (3.4) for E was formulated for $\phi_+\in Q_+[H]$, but allows continuous extension to $\phi_+\in Q_+[H_T]$.

Let us consider the specific example of the scalar BGK model. The existence and uniqueness theory for this example without reflection is immediate from [1], and has also been published by Kaper [15]. For a combination of specular and diffuse reflection (no absorption) solutions were obtained before by Cercignani [8], using expansion with respect to increasing powers of the accommodation coefficient α. Let $L_2(\mathbb{R})_\delta$ be the Hilbert space of complex measurable functions on $\mathbb{R}$ with inner product

$$(h,k)=\int_{-\infty}^{\infty}h(v)\overline{k(v)}\,d\delta(v),\qquad d\delta(v)=\pi^{-1/2}e^{-v^2}dv,$$

and define T, Q_+, Q_-, A, $\mathscr{R}$ and J as follows:

$$(Th)(v)=vh(v), \qquad (Ah)(v)=h(v)-\pi^{-1/2}\int_{-\infty}^{\infty} h(v')e^{-(v')^2}dv',$$

$$(Q_+h)(v)=\begin{cases} h(v), & v>0,\\ 0, & v<0,\end{cases} \qquad (Q_-h)(v)=\begin{cases} 0, & v>0,\\ h(v), & v<0,\end{cases}$$

$$(Jh)(v)=h(-v), \qquad (\mathscr{R}h)(v)=\alpha h(v)+2\beta\pi^{-1/2}\int_0^{\infty} v'h(v')e^{-(v')^2}dv',$$

where $\mathscr{R}$ is defined on $\operatorname{Ran} Q_+$ and $\alpha,\beta\geqq 0$ with $\alpha+\beta\leqq 1$. This model satisfies the assumptions of the previous section and existence is assured. First we solve the **H**-equation (i.e., (3.5)–(3.6) with $\mathbf{H}_l=\mathbf{H}_r$ and $\mathbb{B}=\{\text{constant functions}\}$)

$$\mathbf{H}(z)^{-1}=1-\frac{z}{\sqrt{\pi}}\int_0^{\infty}(z+t)^{-1}\mathbf{H}(t)e^{-t^2}dt,$$

requiring a solution such that $\mathbf{H}$ and $\mathbf{H}^{-1}$ are analytic for $\operatorname{Re} z>0$, continuous for $\operatorname{Re} z\geqq 0$ and satisfying $\mathbf{H}(z)=O(z)$ for $z\to\infty$ with $\operatorname{Re} z\geqq 0$. We find

$$(E\phi_+)(v)=\begin{cases}\phi_+(v), & v>0,\\ \dfrac{1}{\sqrt{\pi}}\displaystyle\int_0^{\infty}\frac{v'}{b'-v}\mathbf{H}(-v)\mathbf{H}(v')\phi_+(v')e^{-(v')^2}dv', & v<0.\end{cases}$$

Therefore, we write (3.2) in the form

$$g_+(v)-\frac{\alpha}{\sqrt{\pi}}\int_0^{\infty}\frac{v'}{v'+v}\mathbf{H}(v)\mathbf{H}(v')g_+(v')e^{-(v')^2}dv'$$

$$-\frac{2\beta}{\pi}\int_0^{\infty}\int_0^{\infty}\frac{vv'}{v'+v}\mathbf{H}(v)\mathbf{H}(v')g_+(v')e^{-[v^2+(v')^2]}dv'\,dv=\phi_+(v),$$

which has to be solved by iteration. The initial value of the solution is then given by $\psi(0,v)=g_+(v)$ for $v>0$ and by

$$\psi(0,v)=\frac{1}{\sqrt{\pi}}\int_0^{\infty}\frac{v'}{v'-v}\mathbf{H}(-v)\mathbf{H}(v')g_+(v')e^{-(v')^2}dv'$$

for $v<0$.

For the isotropic Lorentz gas (neutron transport) the calculation has been carried out for various combinations of selective, specular and diffuse boundary conditions (cf. [10], [11]) yielding interesting and sometimes striking conclusions about their influence on the boundary layer structure, density profile at the wall, validity of Fick's law, etc. For instance, the selective reflection of slow particles and absorption of fast ones leads to an accumulation of particles near the wall and a reversal of the density gradient (interpreted in terms of Fick's law, as equivalent to a negative diffusion coefficient [11]). For the Fokker–Planck equation such selective boundary conditions have been investigated numerically by Burschka and Titulaer [6]. We remark that in general (e.g. for so-called selective boundary conditions [6], [11]) the operator $\mathscr{R}$ is not self-adjoint in H_T. Since only the contraction property of $\mathscr{R}$ plays a role in all derivations and not whether it is self-adjoint, our existence, uniqueness and iteration results also apply to selective boundary conditions.

4. Discussion.

4.1. Generalization to unbounded A. Hitherto we have assumed that A is a bounded operator. For many applications, especially the ones involving BGK models in rarefied gas dynamics, this is sufficient. The Fokker–Planck model (1.5)–(1.7), however, does not satisfy these assumptions. We shall therefore point out what type of hypotheses on T and A, with A unbounded, would entail a repetition of the previous arguments.

Let us assume that T is (bounded or unbounded) injective self-adjoint on H, and let us define Q_+, Q_- and H_T as before. Suppose A is a positive self-adjoint operator with closed range and finite-dimensional kernel, possibly unbounded, such that $D(T) \cap D(A)$ is dense in H. On defining Z_0 as before and repeating the previous hypotheses on Z_0, we may derive Proposition 2.1. It should be noted that $T^{-1}A$, with $D(T^{-1}A) = \{h \in D(A)/Ah \in \operatorname{Ran} T\}$, is closable, but not necessarily closed. Still we may derive the decompositions (2.2) and (2.3) where $T^{-1}A|_{Z_0}$ is closed (and even bounded) and $T^{-1}A$ and S^{-1} should be replaced by their respective closures. As a result, S will be a closed *symmetric* operator with respect to the inner product (2.6). We shall assume that S is, in fact, self-adjoint on the completion of $(T[Z_0])^{\perp} \cap D(A)$ (which is dense in H, due to the density of $D(T) \cap D(A)$) with respect to (2.6). By H_A we shall denote the direct sum of this completion and Z_0. Since A has a closed range and a finite-dimensional kernel, H_A is densely imbedded in H. We define H_K as the direct sum of Z_0 and the completion of $D(T) \cap H_A (\supset D(T) \cap D(A))$ with respect to the inner product

$$(h,k)_K = (|S|h,k)_A,$$

where the absolute value of S is taken in H_A. As before, we define the projections P, PP_+ and PP_- on H_A (and not on H) and extend them continuously to projections on H_K (and not on H_T).

If A is bounded, we may identify H_A and H (which is a trivial observation) as well as H_K and H_T (see [1]; cf. [13] for a different proof). The existence and uniqueness theory has then been developed in §2. For a large class of models on $L_2(a,b)$, where T is a multiplication by an indefinite weight function and A is a Sturm–Liouville type differential operator, it has been proved by Beals [2] that the Hilbert spaces H_T and H_K are completions of $D(T) \cap D(A)$ with respect to equivalent inner products and can be identified. Moreover, for the models Beals considered the previous assumptions on T and A, including the self-adjointness assumption on S, are satisfied. As for bounded A, we may then develop the theory of §2 and the first paragraph of §3 for these indefinite Sturm–Liouville problems and essentially the same results are found. Moreover, for these cases the operator S is bounded self-adjoint on $H_A \cap (T[Z_0])^{\perp}$ (which is due to more specific assumptions on T and A) and even compact. A specific example of such a model is the Fokker–Planck equation (1.5)–(1.7). For this example the equivalence proof of H_T and H_K is contained in [3]. It should be noticed that Theorem 2.3 answers in the affirmative the existence issue raised in [4], thereby making redundant the condition imposed there to enforce existence of solutions (namely, the condition $Bl \in \operatorname{cls}\{Bu_n : n > 0\}$ in [4]).

4.2. The albedo operator for indefinite Sturm–Liouville problems. It is by no means clear how to proceed finding the albedo operator E for (1.5)–(1.7) and other Sturm–Liouville type models. One way, suggested by the approach in [4], is to use the completeness of the eigenfunctions $(u_n)_{0 \neq n \in \mathbb{Z}}$ of $T^{-1}A$ at the nonzero eigenvalues $(\lambda_n)_{0 \neq n \in \mathbb{Z}}$, where we order these by $\ldots \leqq \lambda_{-2} \leqq \lambda_{-1} < 0 < \lambda_1 \leqq \lambda_2 \leqq \ldots$ and take

account of multiplicities. (It should be noted that under weak oscillation conditions on A these eigenvalues are simple). We add an orthogonal basis $u_{0,1}, \cdots, u_{0,l}$ of a given maximal positive subspace N_+ of $\operatorname{Ker} A$ (i.e., $(Tu_{0,i}, u_{0,i}) \geqq 0$). The full-range completeness property implies that every vector $h \in PP_+[H_K] \oplus N_+$ can be expanded as the series

$$h = \sum_{i=1}^{l} \xi_{0,i} u_{0,i} + \sum_{n=1}^{\infty} \xi_n u_n. \tag{4.1}$$

Half-range completeness (for the problem without reflection) amounts to the possibility of expanding every vector $g_+ \in Q_+[H_T]$ (where $H_K \simeq H_T$) as

$$g_+ = \sum_{i=1}^{l} \eta_{0,i} Q_+ u_{0,i} + \sum_{n=1}^{\infty} \eta_n Q_+ u_n;$$

here Q_+ is the restriction to the interval I_+ where the indefinite weight is positive. (For (1.5)–(1.7) we have $I_+ = \mathbb{R}_+$). *Assuming* the existence of a nonnegative weight function $\mathbf{H}$ on I_+ satisfying

$$\int_{I_+} u_{0,i}(v) u_{0,j}(v) \mathbf{H}(v)\, dv = \delta_{i,j} \theta_{0,i} \qquad \theta_{0,i} > 0, \tag{4.2}$$

$$\int_{I_+} u_n(v) u_m(v) \mathbf{H}(v)\, dv = \delta_{n,m} \theta_n, \qquad \theta_n > 0, \tag{4.3}$$

$$\int_{I_+} u_{0,i}(v) u_n(v) \mathbf{H}(v)\, dv = 0, \tag{4.4}$$

we can easily evaluate the (unique) albedo operator E such that

$$EQ_+[H_T] = PP_+[H_K] \oplus N_+.$$

Indeed, on expanding $h = Eg_+$ with $g_+ \in Q_+[H_T]$ as the series (4.1) we obtain

$$g_+ = Q_+ E g_+ = \sum_{i=1}^{l} \xi_{0,i} Q_+ u_{0,i} + \sum_{n=1}^{\infty} \xi_n Q_+ u_n. \tag{4.5}$$

Using (4.2)–(4.4), we then easily derive

$$Eg_+ = \sum_{i=1}^{l} \theta_{0,i}^{-1} \left(\int_{I_+} u_{0,i}(v) g_+(v) \mathbf{H}(v)\, dv \right) u_{0,i} + \sum_{n=1}^{\infty} \theta_n^{-1} \left(\int_{I_+} u_n(v) g_+(v) \mathbf{H}(v)\, dv \right) u_n.$$

If the weight function $\mathbf{H}$ on I_+ is known, the boundary value problem with reflection can again be solved by iterating (3.2), using (4.6). At present even the existence (let alone the computation) of such a weight function is an open problem.

ON A PROBLEM IN THE POLYMER INDUSTRY: THEORETICAL AND NUMERICAL INVESTIGATION OF SWELLING*

A. FASANO†, G. H. MEYER‡ AND M. PRIMICERIO†

Abstract. A recent model for the penetration of solvents into polymers leads to a parabolic free boundary problem with unusual boundary conditions. It is shown that the model equations are well posed, and some qualitative features of the free boundary are established. A numerical method for the free boundary problem is suggested and its convergence is proved. A numerical calculation is included to illustrate the theoretical results.

1. Introduction. This paper deals with a mathematical model proposed in [2] for the penetration of solvents into polymers. Further comments on this model may be found in [1], [3] and [4].[1] A related but more involved and mathematically unresolved model for swelling may be found in [10] where multiple phases are allowed.

While we confine our analysis to the particular case of constant solvent concentration at the polymer surface, the one-dimensional theory presented here is comprehensive and includes existence, uniqueness, regularity and other qualitative properties of the solution, asymptotic estimates and a convergent numerical algorithm. These analytic results may prove useful for model verification.

Let us sketch the physical problem.

Consider a slab of a glassy polymer (e.g., poly (methyl methacrylate)) in contact with a solvent (n-alkyl alcohol). It is observed that if the solvent concentration exceeds some threshold value, then the solvent moves into the polymer, creating a swollen layer in which the solvent diffuses according to Fick's law. The boundary between the swollen region and the glassy region obeys an empirical penetration law, relating its velocity with the (unknown) value assumed on it by the solvent concentration. An additional condition on the free boundary is obtained imposing mass conservation, i.e., equating the mass density current to the product of the solvent concentration and the velocity of the free boundary.

Assuming that the swelling process occurs instantaneously at the penetration surface and choosing a frame of reference in which the swollen region is at rest, the above scheme leads to the following statement.

Problem (P). *Find a triple* (T,s,c) *such that* $T>0$, $s\in C^1[0,T]$, $c\in C^{2,1}(D_T)\cap C(\bar{D}_T)$, $D_T=\{(x,t): 0<x<s(t),\ 0<t<T\}$, c_x *continuous up to* $x=s(t)$, *and such that*

$$c_{xx}-c_t=0, \qquad (x,t)\in D_T, \tag{1.1}$$

$$s(0)=0, \tag{1.2}$$

$$c(0,t)=1, \qquad 0<t<T, \tag{1.3}$$

$$\dot{s}(t)=f[c(s(t),t)], \qquad 0<t<T, \tag{1.4}$$

$$c_x(s(t),t)=-\dot{s}(t)[c(s(t),t)+q], \qquad 0<t<T. \tag{1.5}$$

*Received by the editors July 11, 1984, and in revised form March 28, 1985. This work was partly supported by USA-ERO under contract DAJA 45-83-C-0053 and the National Science Foundation under grant MCS 8302548.

[1]Some preliminary results were communicated at the conference on Applied Nonlinear Functional Analysis, Berlin 1981 and at the Seminar on Mathematics and Industry, Oberwolfach 1983.

In (1.1)–(1.5) nondimensional variables are used and physical constants are normalized to 1. In (1.5) q is a given nonnegative constant, representing the threshold concentration for penetration. By $c(x,t)$ we denote the excess concentration, normalized to 1 at $x=0$, so that the normalized solvent concentration is represented by $c+q$. Condition (1.4) describes the penetration law. Throughout the paper the function f will be supposed to satisfy the following assumptions:

$$\text{(F)} \qquad f\in C^1(0,1], \qquad f'(c)>0 \quad \text{for } c\in(0,1], \qquad f(0)=0.$$

(Indeed the form for $f(c)$ proposed in [2] is αc^m, $m>0$.)

As a consequence, (1.4) can be written as

$$(1.4') \qquad c(s(t),t)=\Phi(\dot{s}(t)),$$

where $\Phi=f^{-1}$ also satisfies (F).

The plan of the paper is the following. In §2 a priori estimates are obtained for a class of auxiliary problems. Such estimates are used in §3 to prove local existence of a smooth solution. A general uniqueness theorem is then proved in the same section. In §4 it is proved that the solution can be continued over an arbitrarily large time interval, that it depends continuously on the data f,q, and that the free boundary is a C^2 convex curve. The asymptotic behavior of the free boundary is investigated in §5, showing its crucial dependence on q and on the modulus of continuity of $f(c)$ near $c=0$. Section 6 is devoted to setting up a numerical scheme based on the sweep method introduced in [8] for a time discretization of (1.1)–(1.5). Numerical results are presented in §7.

Of course, it makes sense to consider different boundary conditions for the model studied here and also to investigate different models which have been proposed for the same phenomenon. This will be the objective of further research.

2. An auxiliary problem. Let $r(t)\in C^1[0,T]\cap C^2(0,T)$ be such that

$$(2.1) \qquad r(0)=0,$$

$$(2.2) \qquad \dot{r}(0)=f(1),$$

$$(2.3) \qquad 0\leqq\dot{r}(t)\leqq f(1) \quad \text{in } [0,T],$$

$$(2.4) \qquad |\ddot{r}(t)|\leqq K \quad \text{in } (0,T),$$

and consider the problem of finding $c\in C^{2,1}(D)\cap C(\bar{D})$, c_x continuous up to $x=r(t)$, $t\in(0,T)$, such that

$$(2.5) \qquad c_{xx}-c_t=0 \quad \text{in } D\equiv\{(x,t): 0<x<r(t), 0<t<T\},$$

$$(2.6) \qquad c(0,t)=1, \qquad 0<t<T,$$

$$(2.7) \qquad c_x(r(t),t)=-\dot{r}(t)[q+\Phi(\dot{r}(t))], \qquad 0<t<T.$$

We have immediately

PROPOSITION 2.1. *Problem* (2.5)–(2.7) *has a unique solution.*

Proof. See, e.g. [5]. □

Next, we prove

PROPOSITION 2.2. *Under assumptions* (2.1)–(2.4), *the solution of* (2.5)–(2.7) *is such that*

$$(2.8) \qquad 1>c(x,t), \qquad 0<x\leqq r(t), \quad 0<t\leqq T,$$

$$(2.9) \qquad 0>c_x(x,t)>-f(1)[q+1] \quad \text{in } \bar{D}\setminus\{0,0\}.$$

Proof. To prove (2.8), it suffices to recall the maximum principle and the sign of $c_x(r(t),t)$. Since $c(x,t)$ attains its maximum on $x=0$, we have $c_x(0,t)<0$ and the first inequality (2.8) follows from the maximum principle. Moreover, $c_{xx}(0,t)=0$. Thus c_x attains its minimal value on $x=r(t)$, and this proves (2.9). □

At this point we note $\dot{r}(t)\geqq f(1)-KT$, we fix $\dot{r}_0<f(1)$ and we reduce T, if necessary, in order to have

$$\dot{r}(t)\geqq \dot{r}_0, \qquad 0\leqq t\leqq T. \tag{2.10}$$

We prove

PROPOSITION 2.3. *Under assumptions* (2.1)–(2.4) $c\in C^{2,1}(\bar{D})$, $c_{xt}\in C(\bar{D}\setminus(0,0))$, *and there exists a constant M depending on f, and on K such that*

$$|c_t(x,t)|\leqq Mt \quad \text{in } D. \tag{2.11}$$

Proof. Note that c_t coincides with the solution $w(x,t)$ of the heat equation in D with boundary conditions

$$w(0,t)=0, \qquad 0<t<T, \tag{2.12}$$

$$[w_x+\dot{r}(t)w]_{x=r(t)}=-\ddot{r}(t)[q+\Phi(\dot{r}(t))+\Phi'(\dot{r}(t))\dot{r}(t)]\equiv F(t), \qquad 0<t<T. \tag{2.13}$$

We have that $w\in C(\bar{D})$ and that

$$\min\Big[0, \inf_{0<t<T} F(t)/\dot{r}_0\Big]\leqq w(x,t)\leqq \max\Big[0, \sup_{0<t<T} F(t)/\dot{r}_0\Big] \quad \text{in } D. \tag{2.14}$$

But this implies

$$|w_x(r(t),t)|\leqq \sup|F(t)|+f(1)\sup|F(t)|/\dot{r}_0\equiv\Psi \tag{2.15}$$

and finally

$$|w(x,t)|\leqq \Psi r(t)\leqq \Psi f(1)t \quad \text{in } D. \tag{2.16}$$

This proves (2.11). □

Now, we investigate how the solution of (2.5)–(2.7) depends on $r(t)$. Let $r_1(t)$, $r_2(t)$ satisfy (2.1)–(2.4) and let $c_1(x,t)$, $c_2(x,t)$ be the corresponding solutions of (2.5)–(2.7). We have

PROPOSITION 2.4. *Under the assumptions above, constants* $T_0>0$ *and* $N>0$ *can be found such that for any* $T\in(0,T_0)$

$$|c_1(r_1(t),t)-c_2(r_2(t),t)|\leqq N\|r_1-r_2\|_{C^1(0,T)}T, \qquad 0<t<T. \tag{2.17}$$

Proof. Let

$$\lambda(t)=\inf(r_1(t),r_2(t)),$$
$$\mu(t)=\sup(r_1(t),r_2(t))$$

and

$$D^*\equiv\{(x,t): 0<x<\lambda(t), 0<t<T\}.$$

Moreover we reduce, if necessary, T in order to have

$$\dot{r}_i(t)\geqq \dot{r}_0, \qquad t\in[0,T], \quad i=1,2.$$

The absolute value of the difference $v(x,t)=c_1(x,t)-c_2(tx,t)$ is dominated in D^* by the solution $V(x,t)$ of the heat equation with boundary data

$$V(0,t)=0, \qquad 0<t<T,$$
$$V_x(\lambda(t),t)=C\|r_1-r_2\|_{C^1(0,T)}+Mt\|r_1-r_2\|_{C[0,T]}, \qquad 0<t<T,$$

where $C=q+\max_{y\in[i_0,f(1)]}\Phi'(y)$. This implies

$$|v(\lambda(t),t)|\leqq(C+Mt)\|r_1-r_2\|_{C^1(0,T)}\cdot f(1)t, \qquad 0<t<T. \tag{2.18}$$

As a consequence of (2.18) we have in $(0,T)$

$$|c_1(r_1(t),t)-c_2(r_2(t),t)|\leqq(C+Mt)f(1)\|r_1-r_2\|_{C^1(0,T)}+f(1)(1+q)\|r_1-r_2\|_{C(0,T)}$$

thus proving (2.17). □

3. Local existence. Uniqueness. Let $\gamma(t)$ be a positive nonincreasing function defined for $t>0$ and possibly diverging for $t\to 0^+$. Denote by $X(K,T,\gamma)$ the set of functions $r(t)$ satisfying (2.1)–(2.4) and such that, for some $\alpha\in(0,1]$

$$|\dot r(t_1)-\dot r(t_2)|\leqq\gamma(\tau)(t_1-t_2)^{\alpha/2}, \qquad 0<\tau\leqq t_2\leqq t_1\leqq T. \tag{3.1}$$

Note that the set X is closed in $C^1(0,T)$.

For any $r\in X$ let c be the solution of (2.5)–(2.7). Then, define the transformation $\tilde r=\mathscr{C}r$ as follows

$$\tilde r(0)=0, \qquad \dot{\tilde r}(t)=f(c(r(t),t)), \quad 0<t<T. \tag{3.2}$$

Note that the domain of f is $[0,1]$. Thus, (3.2) makes sense only when $c(r(t),t)\geqq 0$ (remember $c<1$ by (2.8)). But from (2.9) and (2.3) we have

$$c(r(t),t)\geqq 1-[f(1)]^2(q+1)t.$$

This means that we can reduce T, if necessary, in order to have

$$c(r(t),t)\geqq c_0, \qquad 0<t<T \tag{3.3}$$

for some $c_0>0$.

Now we prove

THEOREM 3.1. *There exist K,T,γ such that the transformation $\tilde r=\mathscr{C}r$ is a contractive mapping of $X(K,T,\gamma)\subset C^1(0,T)$ into itself.*

Proof. Since (2.1)–(2.3) are satisfied by construction, to prove that $\mathscr{C}$ maps X into itself, we only need to prove that $\tilde r$ satisfies (2.4) and (3.1) for suitable K,T,γ.

We have

$$\ddot{\tilde r}(t)=[c_x(r(t),t)\dot r(t)+c_t(r(t),t)]f'(c(r(t),t)), \qquad 0<t<T. \tag{3.4}$$

Using (2.9) and (2.11), we find

$$|\ddot{\tilde r}(t)|\leqq\{[f(1)]^2(q+1)+Mt\}C_1, \qquad 0<t<T, \tag{3.5}$$

where $C_1=\max_{[c_0,1]}f'(c)$. Take e.g. $K=2C_1[f(1)]^2(q+1)$ and T such that

$$MT\leqq[f(1)]^2(q+1).$$

Then (3.4) yields

$$|\ddot{\tilde r}(t)|\leqq K, \qquad 0<t<T.$$

To estimate the Hölder norm of $\ddot{r}(t)$ we need to estimate the norm of $c_x(x,t)$ in the space $C^{1+\alpha}$. This is accomplished as follows. Define $z(x,t)=c_x(x,t)+\dot{r}(t)[q+\Phi(\dot{r}(t))]$, which solves

$$
\begin{aligned}
&z_{xx}-z_t=-\ddot{r}(t)\left[q+\Phi(\dot{r}(t))+\Phi'(\dot{r}(t))\dot{r}(t)\right] \quad \text{in } D,\\
&z_x(0,t)=0, \qquad 0<t<T,\\
&z(r(t),t)=0, \qquad 0<t<T.
\end{aligned} \tag{3.6}
$$

For any $\tau\in(0,T)$ transform the domain $0<x<r(t)$, $\tau/2<t<T$ into the rectangle $(0,1)\times(\tau/2,T)$ by the transformation $y=x/r(t)$ and apply the standard Schauder estimates (e.g. [7, Thm. 5.2, p. 561]) to the transformed function $\hat{z}(y,t)$, in the rectangle $(1/2,1)\times(\tau/2,T)$. We find

$$
\|z\|_{C^\alpha}\leqq\bar{\gamma}(\tau), \quad \text{in } \left(\tfrac{1}{2},1\right)\times(\tau,T), \tag{3.7}
$$

where $\bar{\gamma}$ depends on K, on f, on T, and on τ (and α). Thus, defining $\gamma(t)$ as suggested by (3.7), $\tilde{r}$ will satisfy (3.1). The final step in proving Theorem 3.1 is to prove the contractive character of $\mathscr{C}$. But this is an immediate consequence of (2.17) and of (3.2) because

$$
\|\tilde{r}_1-\tilde{r}_2\|_{C^1(0,T)}\leqq C_1NT\|r_1-r_2\|_{C^1(0,T)}
$$

and it suffices to reduce T, if necessary, to conclude the proof. □

Hence a $T_0>0$ can be found such that the following theorem holds.

THEOREM 3.2. *Problem* (P) *admits a solution for* $T\leqq T_0$. *Moreover,* $c\in C^{2,1}(\bar{D}_T)$, $c_{xt}\in C(\bar{D}_T\setminus\{0,0\})$, $s\in C^2[0,T]$.

Proof. This is a straightforward consequence of Theorem 3.1 and of Banach's fixed point theorem. The regularity properties of c and s follow from Proposition 2.3 and the definition of X. □

A monotone dependence lemma will be useful in proving the uniqueness theorem. Let c_i, s_i, $i=1,2$, solve the problems

$$
c_{ixx}-c_{it}=0, \qquad 0<x<s_i(t), \quad t_i<t<T, \tag{3.8}
$$

with initial conditions $s_i(t_i)=0$ and satisfying boundary conditions (1.3)–(1.5) in the time intervals (t_i,T). We have

LEMMA 3.3. *If* $t_1<t_2$, *then*

$$
s_1(t)>s_2(t), \qquad t_2<t<T. \tag{3.9}
$$

Proof. Note that the transformation

$$
u(x,t)=-\int_x^{s(t)}\left[c(y,t)+q\right]dy, \tag{3.10}
$$

carries (1.1)–(1.5) into the following Stefan-like problem:

$$
u_{xx}-u_t=0 \qquad \text{in } D_T, \tag{3.11}
$$

$$
s(0)=0, \tag{3.12}
$$

$$
u_x(0,t)=1+q, \qquad 0<t<T, \tag{3.13}
$$

$$
u(s(t),t)=0, \qquad 0<t<T, \tag{3.14}
$$

$$
u_x(s(t),t)=\Phi(\dot{s}(t))+q, \qquad 0<t<T. \tag{3.15}
$$

Consider the function $u_i(x,t)$ obtained from $c_i(x,t)$ by means of (3.10). Assume that there exists a first time t_0 such that $s_1(t_0)=s_2(t_0)$ and hence

$$\dot{s}_1(t_0)\leqq\dot{s}_2(t_0). \tag{3.16}$$

Standard use of the maximum principle applied to the difference u_1-u_2 leads to a contradiction of (3.16). □

Now we can prove uniqueness.

THEOREM 3.4. *Problem* (P) *cannot have two distinct solutions with the same* T.

Proof. Let (T,s,c) and (T,σ,γ) be two solutions and consider

$$s_n^{\pm}(t)=s(t\pm 1/n),\qquad c_n^{\pm}(x,t)=c(x,t\pm 1/n).$$

Note that s_n^+, c_n^+ and s_n^-, c_n^- are solutions corresponding to initial data $s_n^+(-1/n)=0$ and $s_n^-(1/n)=0$, respectively. According to Lemma 3.3

$$s_n^-(t)<\sigma(t)<s_n^+(t),\qquad 1/n<t<T-1/n.$$

Letting n tend to infinity concludes the proof to the theorem. □

Remark 3.5. As a consequence of Theorems 3.2 and 3.4, we have that for any solution of problem (P) a T_0 can be found such that $c\in C^{2,1}(\bar{D}_{T_0})$, $c_{xt}\in C(\bar{D}_T LT_0\setminus\{0,0\})$, $s\in C^2[0,T_0]$.

4. Regularity, convexity, global existence, continuous dependence. Before proving global existence, let us perform an a priori analysis on the solutions of problem (P).

PROPOSITION 4.1. *Assume* s,c *solve problem* (P) *for a given* $T<+\infty$. *Then, there exists* $c_0=c_0(T)>0$ *such that*

$$c_0<c(x,t)<1,\qquad 0<x\leqq s(t),\quad 0<t<T, \tag{4.1}$$

$$0<f(c_0)\equiv\dot{r}_0\leqq\dot{s}(t)\leqq f(1),\qquad 0\leqq t<T, \tag{4.2}$$

$$0>c_x(x,t)>-f(1)[q+1],\quad \text{in } D_T. \tag{4.3}$$

Proof. If $c(x,t)$ attains the value 0 (necessarily at $x=s(t)$) for the first time at some point $(s(t_0),t_0)$, one would have $c_x(s(t_0),t_0)=0$, contradicting the boundary point principle. This yields $c\geqq c_0$, $\dot{s}\geqq\dot{r}_0$. The last inequalities in (4.1), (4.2) follow as in the proof of Proposition 2.2. The same is true for inequality (4.3). □

Now we prove

THEOREM 4.2. *Let* (T,s,c) *be a solution to problem* (P). *Then* $s\in C^2[0,T]$. *Moreover, if* $f\in C^\infty(0,1]$ *then* $s\in C^\infty(0,T)$.

Proof. This result can be proved either directly, or by applying the iterative technique introduced in [9] to the equivalent problem (3.11)–(3.15), with (3.15) written more conveniently as $\dot{s}(t)=f[u_x(s(t),t)-q]$. Following the second way, start from $t_0\in(0,T)$ and conclude step by step that the derivatives up to u_{xt} are Hölder continuous on $x=s(t)$ for $t\in(t_0,T)$]. At this point the continuity of f' ensures the continuity of $\ddot{s}$. If $f\in C^\infty(0,1]$ the same procedure can be iterated indefinitely, thus concluding that $s\in C^\infty(0,T]$. The continuity of $\ddot{s}(t)$ at $t=0$ is already known (see Remark 3.5). □

At this point, we can prove the convexity of the free boundary.

THEOREM 4.3. *Assume* (T,s,c) *solve Problem* (P). *Then*

$$\ddot{s}(t)<0,\qquad 0\leqq t\leqq T. \tag{4.4}$$

Proof. Theorem 4.2 yields the continuity of c_t in $\overline{D}_T$ and the continuity of c_{xt} in $\overline{D}_T \setminus \{0,0\}$. Hence the function

$$v(x,t) = [\ln(c+q)]_{xx}$$

is continuous in $\overline{D}_T$ and v_x is continuous in $\overline{D}_T \setminus \{0,0\}$. Note that

$$v_{xx} + 2[\ln(c+q)]_x v_x + 2v^2 - v_t = 0 \quad \text{in } D_{T_0} \tag{4.5}$$

and that

$$v(0,t) = -[c_x/(c+q)]^2\big|_{x=0} < 0,$$
$$v(s(t),t) = \ddot{s}(t)\Phi'(\dot{s})/(q+\Phi(\dot{s})).$$

Owing to the continuity of $\ddot{s}(t)$ for $t=0$, we can assert that $\ddot{s}(t)$, and consequently $v(s(t),t)$, is negative in some interval $[0,t_0)$ (recall that $\ddot{s}(0) = -f^1(1)f^2(1)(1+q) < 0$).

The maximum principle (e.g in the form of [6, Thm. 5, p. 39]) applied with some care to (4.5) implies that if $v(s(t),t)$ vanishes for the first time at some $t_0 > 0$, then $v(x,t) < 0$ in D_{t_0}. Therefore equation (4.5) is such that the boundary point principle (see e.g. [6, Thm. 14, p. 49]) can be applied, yielding $v_x(s(t_0),t_0) > 0$. However, $v_x(s(t),t) = \dot{s}(t)\Phi'(\dot{s})\ddot{s}(t)/(q+\Phi(\dot{s}))$, contradicting $\ddot{s}(t_0) = 0$. □

COROLLARY 4.4. *Under the same assumptions*

$$c_t(x,t) > 0, \qquad 0 < x \leqq s(t), \quad 0 < t < T_0, \tag{4.6}$$

$$c_{xt}(0,t) > 0, \qquad 0 < t < T_0. \tag{4.7}$$

Proof. Indeed, as in the proof of Proposition 2.3, we write the problem solved by $w = c_t$ for which we have the estimate (2.14). But, (4.4) implies $F(t) \geqq 0$, whence $c_t \geqq 0$ in $\overline{D}_T$. At this point (4.6) follows by the strong maximum principle. Since $c_t(0,t) = 0$, (4.7) follows by the boundary point principle. □

COROLLARY 4.5. *Under the same assumptions*

$$\ddot{s}(t) \geqq -[f(1)]^2 \cdot [q+1] \cdot \max_{\eta \in [c_0,1]} f'(\eta), \qquad 0 < t < T_0. \tag{4.8}$$

Proof. Since

$$\ddot{s}(t) = f'(c(s(t),t))[c_x \dot{s} + c_t]_{x=s(t)}, \qquad 0 < t < T_0, \tag{4.9}$$

(4.8) follows from (4.2), (4.3), (4.6). □

Remark 4.6. Estimate (4.6) can be obtained independently of (4.4), by simply noting that the use of both the free boundary conditions enables us to write the boundary problem for $w = c_t$ replacing (2.13) by

$$[w\dot{s} + w_x]_{x=s(t)} = -\frac{d}{dt}[f(c)(q+c)]_{s=s(t)},$$

i.e.

$$[w_x + (\dot{s} + f + (1+c)f')w]_{x=s(t)} = -[c_x \dot{s}\{f + (q+c)f'\}]_{x=s(t)}.$$

Since the r.h.s. is nonnegative, (4.6) follows from the maximum principle.

THEOREM 4.7. *Problem* (P) *admits a solution for arbitrary* $T > 0$.

Proof. Assume there exists a $T^* > 0$ such that the solution (whose local existence was proved in Theorem 3.2) cannot be continued beyond T^*. We have that

$$\lim_{t \to T^*_-} s(t), \qquad \lim_{t \to T^*_-} \dot{s}(t)$$

both exist, because of the monotonicity of s and $\dot{s}$ (see Proposition 4.1 and Theorems 4.2, 4.3). Consider the free boundary problem

$$u_{xx}-u_t=0, \qquad 0<x<s(t), \quad T^*<t<\hat{T},$$

with boundary data given by (3.13)–(3.15) (in the time interval $(T^*,\hat{T})$) and "initial" data given by the limits for $t\to T^*-$ of $s(t)$ and of $\int_x^{s(t)}[c(\xi,t)+q]\,d\xi$. This problem has a unique solution (for suitable $\hat{T}>T^*$), provided $\Phi'(\dot{s}(T^*))\neq 0$ (see [5]). This fact is guaranteed by (4.2) and by assumption (F). Hence the theorem. □

Finally, we want to investigate the dependence of the solution on the data. Assume f_1, f_2 (both satisfying assumption (F)) and q_1, q_2 (both satisfying $0\leqq q_i\leqq Q$) are data for problem (1.1)–(1.5) and let $s_i(t)$, $c_i(x,t)$ be the corresponding solutions in a given interval $(0,T)$. We know that s_1 and s_2 are the fixed points of operators $\mathscr{C}_1$ and $\mathscr{C}_2$ mapping the same set $X(\overline{K},\overline{T},\overline{\gamma})$ into itself.

Now, the contractive character of operator $\mathscr{C}(f,q)$ does not depend on the pair f_i, q_i but only on Q, $\dot{r}_0$.

Moreover, $\mathscr{C}$ depends continuously on $|q_1-q_2|+\|f_1-f_2\|_{C^1(0,\overline{T})}$. Beyond $\overline{T}$, the continuous dependence follows from the results of [5], applied to the problem solved by $u(x,t)$ defined according to (4.15). Thus we have proved:

THEOREM 4.8. *The solution of problem* (P) *depends continuously upon the data* q,f.

5. Asymptotic estimates. Let $s(t)$, $c(x,t)$ solve problem (P) for any $T>0$. Then, Green's identity

$$0=\int\int_{D_t} x(c_{xx}-c_t)\,dx\,d\tau=\oint_{\partial D_t}\left[(xc_x-c)\,d\tau+xc\,dx\right], \qquad t>0,$$

gives

$$\frac{1}{2}qs^2(t)-t+\int_0^{s(t)} xc(x,t)\,dx+\int_0^t c(s(\tau),\tau)d\tau=0, \qquad t>0. \tag{5.1}$$

Moreover we have

PROPOSITION 5.1. *The following estimates hold in* D_T, $\forall T>0$.

$$c(x,t)\leqq 1+x[\Phi(\dot{s}(t))-1]/s(t), \tag{5.2}$$

$$c(x,t)\geqq \Phi(\dot{s}(t))-\dot{s}(t)[\Phi(\dot{s}(t))+q](x-s(t)). \tag{5.3}$$

Proof. Both inequalities follow from the convexity of the curve, representing $c(x,t)$ as a function of x, for any $t>0$ (see Theorem 4.3). □

Now, we prove

THEOREM 5.2.

$$\lim_{t\to+\infty} s(t)=+\infty, \tag{5.4}$$

$$\lim_{t\to+\infty} \dot{s}(t)=0. \tag{5.5}$$

Proof. The existence of both limits is a consequence of the monotonicity of $s,\dot{s}$. Also $c(s(t),t)$ and $c(x,t)$ have limits for $t\to+\infty (c_t>0, dc(s(t),t)/dt<0)$.

Let (5.4) be false; then $-t$ and possibly $\int_0^t c(s(\tau),\tau)\,d\tau$ are the only terms in (5.1) going to infinity as $t\to+\infty$. But $c(s(t),t)$ tends monotonically to zero like $\dot{s}(t)$, and hence the two terms are of different order. This proves (5.4).

To prove (5.5), just note that the compatibility of (5.2) and (5.3) in $x=0$ requires

$$\Phi(\dot{s}(t))[1+s(t)\dot{s}(t)]+qs(t)\dot{s}(t)\leqq 1. \tag{5.6}$$

Note that this argument applies also when $q=0$. □

THEOREM 5.3. *If* $q>0$, *then*

$$s(t)\leqq\sqrt{\frac{2t}{q}} \quad \text{as } t\to+\infty. \tag{5.7}$$

If $q\geqq 0$, *then*

$$s(t)\geqq\sqrt{\frac{2}{q+1/3}}\sqrt{t}\,[1-\varepsilon^2(t)], \tag{5.8}$$

where $\lim_{t\to+\infty}\varepsilon^2(t)=0$.

Proof. To prove (5.7), it suffices to use the positivity of c and (5.1). To prove (5.8), we note that (5.2) implies

$$\int_0^{s(t)} xc(x,t)\,dx\leqq\frac{s^2(t)}{2}+\frac{s^2(t)}{3}[\Phi(\dot{s}(t))-1].$$

Hence, from (5.1) we have

$$\left[\frac{1}{3}\Phi(\dot{s}(t))+\frac{1}{2}q+\frac{1}{6}\right]s^2(t)\geqq t\left[1-\frac{1}{t}\int_0^t\Phi(\dot{s}(\tau))\,d\tau\right]. \tag{5.9}$$

But $\Phi(\dot{s}(t))$ and $(1/t)\int_0^t\Phi(\dot{s}(\tau))\,d\tau$ tend to zero as $t\to+\infty$; hence (5.8) follows. □

Now, we want to investigate the case $q=0$. To this aim, we need to know the behaviour of $\Phi(z)$ near $z=0$. To be specific, we will assume that

$$\Phi(z)=\alpha z^{1/m} \quad \text{for some } \alpha,\ m>0. \tag{5.10}$$

We can prove

THEOREM 5.4. *Let* $q=0$ *and* (5.10) *hold. Then*

$$s(t)\leqq\left(\frac{2}{\alpha}\right)^{m/(2m+1)}\left(\frac{2m+1}{m+1}\right)^{1/(2m+1)}t^{(m+1)/(2m+1)}. \tag{5.11}$$

Proof. From (5.1) we have

$$\int_0^{s(t)} xc(x,t)\,dx-t<0.$$

Since $c(x,t)>\Phi(\dot{s}(t))$, this implies

$$\Phi(\dot{s}(t))s^2(t)\leqq 2t. \tag{5.12}$$

Using (5.9), we have

$$\alpha^m s^{2m}(t)\dot{s}(t)\leqq 2^m t^m,$$

whence (5.11) follows by integration. □

Numerical calculations (see next section) show that the right-hand side of (5.8) is a good approximation of $s(t)$ for t sufficiently large. In this respect it is of some interest to estimate the term $\varepsilon^2(t)$ in (5.8). To this end we can utilize the inequality

$$\dot{s}(t)\leqq\min\left[(qs(t))^{-1},(\alpha s(t))^{-m/(1+m)}\right], \tag{5.13}$$

following from (5.6), (5.10). From (5.9) it follows that

$$(5.14)\qquad s(t)\geqq\sqrt{\frac{2}{q+1/3}}\sqrt{t}\left\{1-\frac{1}{t}\int_0^t\Phi(\dot{s}(\tau))\,d\tau-2\Phi(\dot{s}(t))/(3q+1)\right\}^{1/2}.$$

For some fixed $t_0>0$ the quantity in braces is less than 1 and approaches 1 for t_0 large. Let us write it $1-\delta$ and use the consequent estimate in (5.13) to get upper bounds for $\dot{s}(t)$. Now use such bounds in turn in (5.14) to conclude the following

(i) If $q=0$, then

$$\varepsilon^2(t)\cong\alpha\frac{m+2}{2m+1}\left[6\alpha^2(1-\delta)t\right]^{-1/2(1+m)}.$$

(ii) If $q>0$, then

$$\varepsilon^2(t)\cong\alpha\left(\frac{m}{2m-1}+\frac{1}{3q+1}\right)q^{-1/m}\left(\frac{q+1/3}{2(1-\delta)}\right)^{1/2m}t^{-1/2m},\qquad m>\tfrac{1}{2},$$

for $m=\frac{1}{2}$, $\varepsilon^2(t)$ behaves like $(\log t)/t$ and for $m<\frac{1}{2}$ like $1/t$.

6. The numerical method. In this section will be shown the convergence of a numerical scheme based on the method introduced in [8] for one-dimensional parabolic free boundary problems with arbitrary implicit or explicit free boundary conditions.

In this method the continuous problem is time discretized and solved at successive time levels as a sequence of free boundary problems for ordinary differential equations. Specifically, at the time level $t=t_n$ with $t_n-t_{n-1}=\Delta t$ the solution $\{C_n(x),S_n\}$ is computed as the exact solution of the discretized equations

$$(6.1)\qquad C_n''-\frac{1}{\Delta t}(C_n-C_{n-1})=0,\qquad 0<x<S_n,$$

$$(6.2)\qquad C_n(0)=1,$$

$$(6.3)\qquad \frac{S_n-S_{n-1}}{\Delta t}=f(C_n(S_n)),\qquad S_0=S(0)=0,$$

$$(6.4)\qquad C_n'(S_n)=-\frac{S_n-S_{n-1}}{\Delta t}(q+C_n(S_n)).$$

In (6.1) the function $C_{n-1}(x)$ is supposed to be defined over $[0,+\infty)$, and S_{n-1} is supposed to be known as well. The free boundary problem (6.1)–(6.4) is conveniently solved with the method of invariant imbedding (sweep method). We write (6.1) as a first order system over $(0,S_n)$

$$(6.5)\qquad C_n'=V_n,$$

$$(6.6)\qquad V_n'=\frac{1}{\Delta t}(C_n-C_{n-1})$$

and exploit the observation that C_n and V_n are related through the Riccati transformation

$$(6.7)\qquad C_n(x)=R(x)V_n(x)+W_n(x),$$

where

$$(6.8)\qquad R'=1-\frac{1}{\Delta t}R^2,\qquad R(0)=0,$$

$$(6.9)\qquad W_n'=-\frac{R(x)}{\Delta t}(W_n-C_{n-1}(x)),\qquad W_n(0)=1.$$

The functions R and W are solutions of well defined initial value problems and may be considered available. The free boundary S_n is determined such that the triple C_n, V_n, S_n simultaneously satisfies (6.3), (6.4), and (6.7). Elimination of C_n and V_n from (6.4) and (6.7) shows that S_n must be a root of the scalar equation

$$\sigma_n(x) \equiv (x - S_{n-1})/\Delta t - f\left[(W_n(x) - qR(x)(x - S_{n-1})/\Delta t)(1 + R(x)(x - S_{n-1})/\Delta t)^{-1}\right] = 0 \tag{6.10}$$

(extend f as an odd function). Given S_n, we set

$$C_n(S_n) = \frac{W_n(S_n) - R(S_n)\dot{S}_n q}{1 + R(S_n)\dot{S}}, \tag{6.11}$$

so that

$$\dot{S}_n \equiv \frac{S_n - S_{n-1}}{\Delta t} = f(C_n(S_n)), \tag{6.12}$$

and

$$C_n'(S_n) \equiv V_n(S_n) = -\frac{S_n(W_n(S_n) + q)}{1 + R(S_n)\dot{S}_n}. \tag{6.13}$$

Thus, the triple $\{C_n(S_n), V_n(S_n), S_n\}$ is an exact solution of (6.3), (6.4) and (6.7). We remark that depending on Δt and q the functional $\sigma_n(x)$ may have a root smaller than S_{n-1}. Such a root would correspond to a negative concentration $C_n(S_n)$ and is not admissible. We shall therefore agree to choose for S_n the smallest root of $\sigma_n(x) = 0$ on (S_{n-1}, ∞). Such a root will be shown to exist.

Once S_n has been determined, one can find V_n by integrating backward over $[0, S_n)$ the reverse sweep equation

$$V_n' = \frac{1}{\Delta t}\left[R(x)V_n + W_n(x) - C_{n-1}(x)\right] \tag{6.14}$$

with $V_n(S_n)$ given by (6.13). The concentration $C_n(x)$ at time level T_n is obtained from (6.7). Finally, $C_n(x)$ is extended over $[S_n, \infty)$ as C^1 linear function. For the initial concentration we shall use

$$C_0(x) = 1 + C_0' x = 1 - f(1)(q+1)x.$$

Assuming f satisfies (F), §1, we will derive some estimates of the solution $\{C_n, S_n\}$ to (6.1)–(6.4). Such estimates correspond to the bounds obtained in previous sections for the solution of the continuous problem.

LEMMA 6.1. *There exists a solution S_n of* (6.10) *on* (S_{n-1}, ∞) *and* C_n *satisfies* $0 < C_n \leqq 1$ *on* $[0, S_n]$ *and* $C_n' < 0$ *on* $[0, \infty)$.

Proof. We note that $C_0(S_0) = 1$ and $C_0' < 0$. Assume next that $C_{n-1}(S_{n-1}) > 0$ and $C_{n-1}' < 0$. We observe from $R(x) > 0$ on $(0, \infty)$ and

$$(W_n - C_{n-1})' = \frac{R(x)}{\Delta t}(W_n - C_{n-1}) - C_{n-1}',$$

$(W_n - C_{n-1})(0) = 0$ that $W > C_{n-1}$ on $(0, \infty)$ and $W_n' \leqq 0$ on $[0, \infty)$. Moreover $\sigma_n(S_{n-1}) = -f(W_n(S_{n-1})) \leqq -f(C_{n-1}(S_{n-1})) < 0$ and

$$\lim_{x \to \infty} \sigma_n(x) = \infty.$$

Thus there must be a point $S_n > S_{n-1}$ where $\sigma_n(S_n)=0$, $C_n(S_n)>0$ and $C_n'(S_n)<0$. The linear equation (6.14) now assures that $V_n<0$ and that $0<C_n\leqq 1$ on $[0,S_n]$. Hence the lemma is true for all n. □

We remark that the monotonicity of $R(x)$ and $W_n(x)$ assures that $\sigma_n'>0$ (S_{n-1},∞). We also note that

$$0<S_n-S_{n-1}=f(C_n(S_n))\Delta t\leqq f(1)\Delta t. \tag{6.15}$$

LEMMA 6.2. $-f(1)(q+1)\leqq C_n'(x)<0$ *on* $[0,\infty)$.

Proof. The upper bound is guaranteed by Lemma 6.1. The lower bound is obtained by applying the maximum principle to

$$\left(C_n'\right)''-\frac{1}{\Delta t}C_n'=-\frac{1}{\Delta t}C_{n-1}',$$
$$C_n''(0)=0,\qquad C_n'(S_n)=-f(C_n(S_n))(q+C_n(S_n))$$

from which it follows that

$$\min C_n'\geqq\min\left\{\min C_{n-1}', C_n'(S_n)\right\}.$$

Since $C_n'(S_n)\geqq -f(1)(q+1)$ and $C_0'=-f(1)(q+1)$ the lemma is proved. □

LEMMA 6.3. $0\leqq C_n-C_{n-1}\leqq f(1)^2(q+1)\Delta t$ *on* $[0,S_n]$ *for* $n=1,2,\cdots$.

Proof. We observe from Lemma 6.2 that $(C_1-C_0)'\geqq 0$ so that $C_1-C_0\geqq 0$. Let us assume that $C_{n-1}-C_{n-2}\geqq 0$ and consider the problem satisfied by C_n-C_{n-1} on $(0,S_n)$:

$$(C_n-C_{n-1})''-\frac{1}{\Delta t}(C_n-C_{n-1})=\begin{cases}-\dfrac{1}{t}(C_{n-1}-C_{n-2}), & x\in(0,S_{n-1}),\\ 0, & x\in(S_{n-1},S_n)\end{cases}$$
$$(C_n-C_{n-1})(0)=0,$$
$$(C_n-C_{n-1})'(S_n)=-f(C_n)(q+C_n)\big|_{S_n}+f(C_{n-1})(q+C_{n-1})\big|_{S_{n-1}}.$$

The maximum principle assures that its solution has no negative minimum on the half open interval $[0,s_n)$ and no positive maximum on (S_{n-1},S_n). At a positive maximum on $(0,S_{n-1}]$ the maximum principle yields $C_n-C_{n-1}\leqq\max[C_{n-1}-C_{n-2}]$. Let us now consider the remaining case when C_n-C_{n-1} has an extremum at S_n. The boundary condition can be rewritten with the mean value theorem as

$$(C_n-C_{n-1})'(S_n)=-\left[f'(\xi)(q+\xi)+f(\xi)\right]\cdot\left[(C_n-C_{n-1})(S_n)+C_{n-1}(S_n)-C_{n-1}(S_{n-1})\right]$$

for some $\xi>0$. Since $C_{n-1}(S_n)-C_{n-1}(S_{n-1})<0$ by Lemma 6.2 this boundary condition rules out a negative minimum at S_n. Hence $C_n-C_{n-1}\geqq 0$ on $[0,S_n]$. Suppose finally that C_n-C_{n-1} assumes its maximum at S_n. Then $(C_n-C_{n-1})'(S_n)\geqq 0$ so that the boundary condition implies that

$$0\leqq(C_n-C_{n-1})(S_n)\leqq C_{n-1}(S_{n-1})-C_{n-1}(S_n)=C_{n-1}'(\eta)(S_{n-1}-S_n)$$
$$\leqq f(1)^2(q+1)\Delta t\quad\text{for some }\eta\in(S_{n-1},S_n).$$

Since this argument already applies to C_1-C_0 on $[0,S_1]$ the lemma follows by induction. □

We note from

$$C_n(S_n)-C_{n-1}(S_{n-1})=C_n(S_n)-C_{n-1}(S_n)+C_{n-1}(S_n)-C_{n-1}(S_{n-1})$$

that

$$C_{n-1}(S_n)-C_{n-1}(S_{n-1})\leqq C_n(S_n)-C_{n-1}(S_{n-1})\leqq C_n(S_n)-C_{n-1}(S_n)$$

so that

$$|C_n(S_n)-C_{n-1}(S_{n-1})|\leqq f(1)^2(q+1)\Delta t. \tag{6.16}$$

LEMMA 6.4. $|(C_n-C_{n-1})'|\leqq K\Delta t$ *for* $n=1,2,\cdots$.

Proof. Let $Q_n=C_n'$ then it follows from Lemma 6.3 and $f(1)^2(q+1)\geqq (Q_n-Q_{n-1})'=(1/\Delta t)(C_n-C_{n-1})\geqq 0$ on $[S_{n-1},S_n)$ that Q_n-Q_{n-1} is increasing on $[S_{n-1},S_n]$. We also note that as in Lemma 6.3

$$(Q_n-Q_{n-1})(S_n)=-[f'(\xi)(q+\xi)+f(\xi)](C_n(S_n)-C_{n-1}(S_{n-1}))$$

so that by (6.16)

$$|(Q_n-Q_{n-1}(S_n)|\leqq f(1)^2(q+1)\Delta t\cdot\max_{\xi\in[0,1]}[f'(\xi)(q+\xi)+f(\xi)]\equiv K_1\Delta t$$

and

$$|(Q_n-Q_{n-1})(S_n)|\leqq K_1\Delta t+f(1)^3(q+1)\Delta t\equiv K\Delta t.$$

These estimates imply in particular that

$$|Q_1-Q_0|\leqq K\Delta t.$$

Finally, we apply the maximum principle to

$$(Q_n-Q_{n-1})''-\frac{1}{\Delta t}(Q_n-Q_{n-1})=-\frac{1}{\Delta t}(Q_{n-1}-Q_{n-2})\quad\text{on } (0,S_{n-1}),$$
$$(Q_n-Q_{n-1})'(0)=0$$

to conclude $|Q_n-Q_{n-1}|\leqq\max\{|(Q_n-Q_{n-1})(S_{n-1})|,\max|Q_{n-1}-Q_{n-2}|\}$ and hence that $|Q_n-Q_{n-1}|\leqq K\Delta t$ for all n. □

We observe that it is a consequence of these lemmas that

$$|C_n-C_{n-1}|\leqq\tilde{K}\Delta t$$

for some $\tilde{K}>0$ on compact subsets of $[0,\infty)$. In fact, suppose $\tilde{x}>S_n$ then

$$C_n(\tilde{x})-C_{n-1}(\tilde{x})=C_n(S_n)-C_{n-1}(S_n)+[C_n'(S_n)-C_{n-1}'(S_n)](\tilde{x}-S_n).$$

The desired inequality now follows from Lemmas 6.3 and 6.4. For arbitrary but fixed T let us define the interpolating functions $S_N(t)$ on $[0,T]$ and $C_N(x,t)$ on $[0,f(1)]\times[0,T]$ given by

$$S_N(t)=S_{n-1}+\frac{S_n-S_{n-1}}{\Delta t}(t-t_{n-1}),\qquad t\in[t_{n-1},t_n),$$
$$C_N(x,t)=C_{n-1}(x)+\frac{C_n(x)-C_{n-1}(x)}{\Delta t}(t-t_{n-1}),\qquad t\in[t_{n-1},t_n)$$

where $\Delta t = T/N$. It follows from (6.15) and from Lemmas 6.2, 6.3 and 6.4 that both S_N, C_N and $\partial C_N/\partial x$ are uniformly bounded and Lipschitz continuous on $[0,T]$ and $[0,f(1)T]\times[0,T]$. By the Ascoli–Arzela theorem a subsequence of $\{S_N, C_N\}$ will converge uniformly to Lipschitz continuous limit functions $\{s(t), c(x,t)\}$ defined for $0 \leqq t \leqq T$ and $0 \leqq x \leqq f(1)T$. Moreover, $(\partial c/\partial x)(x,t)$ is Lipschitz continuous and the uniform limit of $\partial C_N/\partial x$.

LEMMA 6.5. *The limit function $s(t)$ has a Lipschitz continuous derivative.*

Proof. Let $t \in (0,T]$ be arbitrary and set $\Delta t = t/N$. Define

$$Q(t) = \int_0^t f(c(s(\tau),\tau))\, d\tau,$$

then dQ/dt is Lipschitz continuous because f is continuously differentiable and c and s themselves are Lipschitz continuous. Let $\{C_n, S_N\}$ denote a convergent subsequence. Then by construction

$$S_N(t) = \Delta t \sum_{i=1}^{N} (S_i - S_{i-1}) = \Delta t \sum_{i=1}^{N} f(C_i(S_i)) = \Delta t \sum_{i=1}^{N} f(C_N(S_N(t_i),t_i)).$$

It now follows from

$$Q(t) - S_N(t) = \left[\int_0^t f(c(s(\tau),\tau))\, d\tau - \Delta t \sum_{i=1}^{N} f(c(s(t_i),t_i))\right]$$

$$+ \Delta t \sum_{i=1}^{N} [f(c(s(t_i),t_i)) - f(C_N(S_N(t_i),t_i))]$$

that $\lim_{N\to\infty}[Q(t) - S_N(t)] = 0$. Indeed, the first bracket on the right is the difference between the integral and its Riemann sum approximation and hence vanishes as $\Delta t \to 0$. The second bracket vanishes because C_N and S_N converge uniformly to Lipschitz continuous limit functions.

We have thus shown that the limit functions s and c satisfy

$$\dot{s}(t) = f(c(s(t),t)).$$

It also is readily seen that

$$\frac{\partial c}{\partial x}(s(t),t) = -f(c(s(t),t))(q + c(s(t),t))$$

since

$$\frac{\partial C_N}{\partial x}(S_N(t),t) = -f(C_N(S_N(t),t))(q + C_N(S_N(t),t))$$

at each point of the partition $\{t_i\}$ associated with N. Since these points are dense in $[0,T]$ as $N \to \infty$ and the convergence of $\partial C_N/\partial x$, C_N and S_N is uniform, it follows immediately that the limit functions c, s also satisfy the second boundary condition (1.5).

To conclude that the whole sequence of interpolating functions converges, it is enough to recall the uniqueness of the solution to problem (P), see Theorem 3.4.

7. A numerical example. The algorithm of the preceding section is used to examine numerically the asymptotic estimates (5.7), (5.8) for the special case of $m = 2$ and $q = 1$. All calculations are carried out with the research code of [8] as follows. For a

given interval $[0, X]$ a variable but time independent mesh with grid points $\{x_k\}_{k=0}^{N}$ is imposed with $x_i = X(i/N)^2$ so that the mesh points cluster near the origin where the free boundary moves fast. The time step Δt is variable and increases with time. For the Riccati equation (6.8) the analytic solution

$$R(x, \Delta t) = \sqrt{\Delta t} \tanh \frac{x}{\sqrt{\Delta t}}$$

is used, while the linear equation (6.9) is integrated with the trapezoidal rule. The function $\sigma_n(x)$ is evaluated at successive mesh points of the grid beyond S_{n-1} until it changes sign between, say, x_l and x_{l+1}. The free boundary S_n is now determined as the root of the quadratic interpolant through $\sigma(x_{l-1})$, $\sigma(x_l)$ and $\sigma(x_{l+1})$. The equation (6.14) is also integrated with the trapezoidal rule, first from S_n to x_l and then backward over the fixed mesh. The numerical methods for these equations are known to converge as $\Delta x \to 0$. The results obtained are reasonably stable with respect to changes in the mesh. However, if run times are to be minimized, then a Crank–Nicolson time discretization and a higher order Adams–Moulton space integration are suggested.

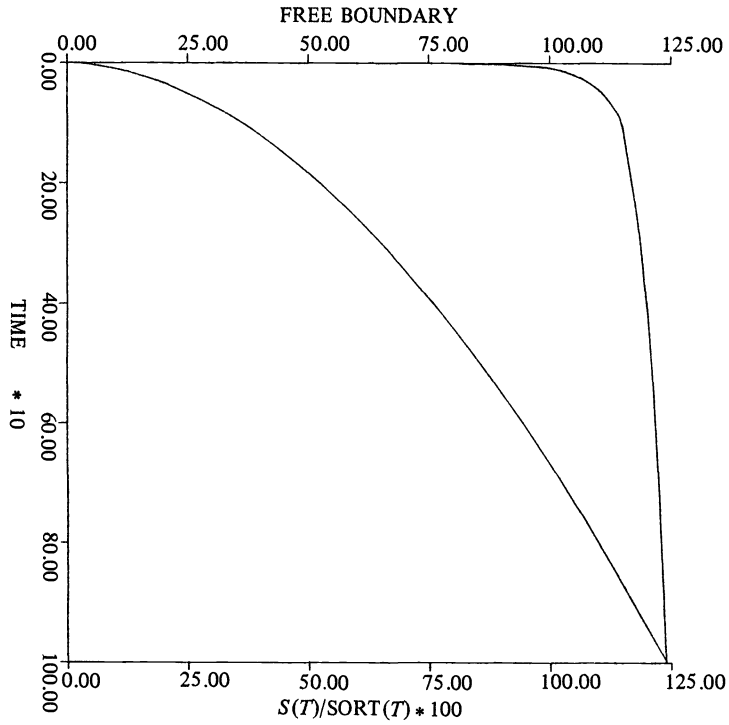

FIG. 1. *Plot of the free boundary and its asymptotic behavior for* $q=1$, $m=2$. $X=140$, $N=6000$ *with* 100 *equal time steps for each of the intervals* $[0,1]$, $[1,10]$, $[10,100]$, $[100,10000]$, *and* $[1000,10000]$. *Total execution time on the Cyber* 855 *was* 200*s*.

Figure 1 shows a plot of the free boundary $s(t)$ for $t \in [0, 10000]$ and $\phi(t) = s(t)/\sqrt{t}$. The computed values satisfy the inequalities

$$\sqrt{1.5}\,(1-\varepsilon^2(10000)) \leqq \sqrt{1.5} \equiv 1.225 \leqq \phi(10000) = 1.24 \leqq \sqrt{2} = 1.41,$$

as well as $\phi'(10000) \approx 4.18 \cdot 10^{-6}$ and $s'(10000) \approx 6.62 \cdot 10^{-3}$. Thus the lower bound (5.8) appears to be quite good.

ON FUNCTIONS REPRESENTABLE AS A SUPREMUM OF A FAMILY OF SMOOTH FUNCTIONS II*

Y. YOMDIN†

Abstract. The classes S_m^q of functions $f(x)$, representable as $\sup_t h(x,t)$, where t is an m-dimensional parameter and h is a C^q-smooth function of x and t, are studied. Considering the "massiveness" of the sets S_m^q in appropriate functional spaces, we show that these classes really differ for different q and m.

Studying geometric invariants of maximum functions, related to the critical values of smooth mappings involved, we give explicit examples of functions in S_m^q which are not representable as the maximum of k times differentiable families when k is sufficiently large.

1. Introduction. Functions, represented as a supremum of families of a certain type, arise naturally in many questions of analysis and optimization (see e.g. [1], [5], [6], [13] and many others). In [7], [9], [12] the class $H(D)$ has been considered of functions f on the domain $D \subset R^n$, representable as $f(x) = \sup_{h \in Q} h(x)$, $x \in D$, where Q is a bounded in a C^2-norm family of twice differentiable functions on D. The functions $f \in H(D)$ have many nice properties, both geometric and analytic. One important point is that the consideration of families of C^k-smooth functions, bounded in C^k-norm, for $k > 2$, does not restrict the class H. In fact, it is shown in [7], [9] that $H(D)$ can be described as the class of all f, representable as $f(x) = \sup_{p \in P} p(x)$, where P is a bounded subset in the space of all the quadratic polynomials on R^n.

Another important class of maximum functions appears when we assume that the family Q is smoothly parametrized.

Let $S_m^q(D)$ denote the set of functions r, representable as $f(x) = \max_{t \in T^m} h(x,t)$, where T^m is a compact m-dimensional smooth manifold and h: $D \times T^m \to R$ is a q-times continuously differentiable function, $q \geq 2$. Clearly, $S_m^q(D) \subset H(D)$.

Precise information on the local structure of "generic" functions in $S_m^q(D)$ has been obtained by methods of Singularities theory (see e.g. [1], [5], [12], [13]).

However, the following important question seems to be untouched: Do the classes S_m^q really depend on q and m? This question is especially interesting in view of the independence of the class H above of the smoothness of functions involved.

In the present paper we answer this question, showing in many cases noncoincidence of S_m^q for different q and m, although our results are not strong enough to separate these classes completely.

Two different approaches are used: first we study the "massiveness" of the sets S_m^q in appropriate functional spaces, in a way similar to that used in [4], [10] for the problem of representability and approximations by means of compositions. This method allows us to separate classes S_m^q, but does not give explicit examples.

Another approach is based on the study of geometric invariants of maximum functions. These invariants are related to the structure of the set of critical values of the smooth family that defines the maximum function. In this way we obtain explicit examples of functions in $S_m^q \setminus S_{m'}^{q'}$.

To give the flavor of these examples, we state here the following theorem which will be proved in §4 below.

*Received by the editors December 1, 1983, and in revised form October 4, 1984.

THEOREM 4.4. *Let $f(x)$ be a convex piecewise linear function of the single variable $x\in[0,1]$, with the countable number of "edges". Let $\delta_1<\delta_2<\cdots<\delta_i<\cdots$ be the slopes of these edges, and let $\alpha_i=\delta_{i+1}-\delta_i$. Then f can be represented in a form*

$$f(x)=\max_{t\in[0,1]} a(t)x+b(t), \qquad x\in[0,1],$$

with $a(t)$ and $b(t)$ k times continuously differentiable functions on $[0,1]$, if and only if $\sum_{i=1}^{\infty}\alpha_i^{1/k}<\infty$.

There are many open questions, concerning the structure of maximum functions, some of which we discuss in the last section.

2. ε-entropy of sets of maximum functions. Let $D\subset R^n$ be a bounded closed domain. For $q=p+\alpha$, $p\geqq 1$ -an integer, $0<\alpha\leqq 1$, we denote by $C^q(D)$ the space of p times continuously differentiable functions g on D, whose derivatives of order p satisfy the Hölder condition

$$(*) \qquad \|d^p g(x)-d^p g(y)\|\leqq L\|x-y\|^{\alpha},$$

with some constant L.

Let

$$M_i(g)=\max_{y\in D}\|d^i g(y)\|, \qquad i=0,\cdots,p,$$

$$M_q(g)=\inf L \quad \text{in } (*).$$

(We consider all the Euclidean spaces R^s and the spaces of their linear and multilinear mappings with the usual Euclidean norms.)

For $c>0$ denote by $C^q(D,c)$ the set of all g in $C^q(D)$ with $M_i(g)\leqq c$, $i=0,\cdots,p,q$.

Let F be a relatively compact set in a metric space X. For some $\varepsilon>0$ a set $F^*\subset X$ is called an ε-net of F if for any $z\in F$ there exists $z^*\in F^*$ with $d(z,z^*)\leqq\varepsilon$, where d denotes the distance in X.

Denote by $N_\varepsilon(F)$ the number of elements in a minimal ε-net of F. The number $H_\varepsilon(F)=\log_2 N_\varepsilon(F)$ is called the ε-entropy of the set F. It is convenient also to define the number $\mathrm{fd}(F)$ as $\overline{\lim}_{\varepsilon\to 0}\log_2 H_\varepsilon(F)/\log_2(1/\varepsilon)$.

The notion of entropy arises in a natural way in connection with various problems of analysis (see e.g. [4], [10], [14], [16]).

In this section the metric space X is the space $C(D)$ of continuous functions on D with the uniform norm. Now we turn back to maximum functions. Without loss of generality we can assume that the parameter manifold T^m is the unit m-dimensional cube I^m. For $c>0$ denote by $S_m^q(D,c)$ the set of functions f on D, representable as $f(x)=\max_t h(x,t)$, with $h\in C^q(D\times I^m,c)$. Clearly, for any $c>0$, $S_m^q(D,c)$ is a compact subset in $C(D)$.

THEOREM 2.1. *For any $c>0$,*

$$\frac{n+m}{q+2m/n}\leqq \mathrm{fd}\left(S_m^q(D,c)\right)\leqq\frac{n+m}{q}.$$

Proof. Consider the mapping μ: $C(D\times I^m)\to C(D)$, defined by $\mu(h)=f$, $f(x)=\max_{t\in I^m}h(x,t)$. Clearly, μ does not increase the distance. From the definition of ε-entropy we obtain that for any relatively compact set $F\subset C(D\times I^m)$, $H_\varepsilon(\mu(F))\leqq H_\varepsilon(F)$.

Since $S_m^q(D,c)=\mu(C^q(D\times I^m,c))$ and since according to [10, Thm. 2.2.1], $\mathrm{fd}(C^q(D\times I^m,c))=(n+m)/q$, we obtain the right-hand side inequality.

To obtain the lower bound for $\mathrm{fd}(S_m^q(D,c))$ it is sufficient to find in this set a suitable number of functions, any two of which differ at least by 2ε in C-norm.

Let us fix some $\delta>0$ and let $\delta'=\frac{1}{2}\delta^{1+m/n}$. Let $Z_\delta\subset R^n$ denote the net of points of the form $z=(k_1\delta,k_2\delta,\cdots,k_n\delta)$, $k_i\in Z$.

Consider also the points $z'_\alpha\in R^n$ of the form $(k_1\delta',\cdots,k_n\delta')$, $1\leqq k_i\leqq[\delta/\delta']$, indexed in some fixed way, $1\leqq\alpha\leqq[\delta/\delta']^n$. Finitely, let $z''_\beta\in I^m$ be the points of the form $(k_1\delta,\cdots,k_m\delta)$, $0\leqq k_i\leqq[1/\delta]$, indexed in some fixed way, $1\leqq\beta\leqq[1/\delta]^m$.

Since $\delta/\delta'=2(1/\delta)^{m/n}$, $[\delta/\delta']^n\sim 2^n(1/\delta)^m>[1/\delta]^m$ for δ sufficiently small, we can fix some one-to-one mapping ω from the set of indices β into the set of indices α.

Now consider in $R^m\times I^m$ the net of points y of the form $y=(z+z'_{\omega(\beta)},z''_\beta)$, $z\in Z_\delta$, $1\leqq\beta\leqq[1/\delta]^m$, and let y_ξ, $1\leqq\xi\leqq K(\delta)$, denote those from the points y, whose projections x_ξ on R^n belong to D. Since D has a nonempty interior, $K(\delta)\geqq K'(1/\delta)^{n+m}$, with some $K'>0$, not depending on δ.

We shall use below only the following property of points y_ξ: they form a net in $D\times I^m$ with the distance at least δ between any two points, while their projections x_ξ form a net in D with the distance at least δ' between any two points.

Let ϕ: $R\to R$ be a C^∞-smooth even function with the following properties:

i. $\phi(s)=1-s^2$ for $|s|\leqq\frac{1}{2}$;

ii. $\phi(s)=0$ for $|s|\geqq 1$;

iii. $\phi(s)$ is a decreasing function of $|s|$ for $\frac{1}{2}\leqq|s|\leqq 1$.

Let ψ: $R^{n+m}\to R$ be defined by $\psi(y)=\phi(\|y\|)$. Denote by M $2^q\cdot\max M_i(\psi)$, $i=1,\cdots,p+1$.

Now for any subset $\kappa\subset\{1,\cdots,K(\delta)\}$ define the function ψ_κ: $D\times I^m\to R$ as follows: for $y=(x,t)\in D\times I^m$

$$\psi_\kappa(y)=\frac{c}{M}\delta^q\sum_{\xi\in\kappa}\psi\left(\frac{2}{\delta}(y-y_\xi)\right).$$

Clearly, ψ_κ is a C^∞ function, and since the supports of $\psi((2/\delta)(y-y_\xi))$ are disjoint for different ξ by property ii of ϕ, we see that $\psi_\kappa\in C^q(D\times I^m,c)$.

Now consider the corresponding maximum function $f_\kappa=\mu(\psi_\kappa)$, which by definition belongs to $S_m^q(D,c)$.

LEMMA 2.2. *For* $\kappa\neq\kappa'$, $\|f_\kappa-f_{\kappa'}\|_C\geqq(c/M)\delta^{q+2m/n}$.

Proof. Since the supports of $\psi((2/\delta)(y-y_\xi))$ are disjoint, we have:

$$f_\kappa(x)=\frac{c}{M}\delta^q\max_{\xi\in\kappa}\max_{t\in I^m}\psi\left(\frac{2}{\delta}(y-y_\xi)\right)=\frac{c}{M}\delta^q\max_{\xi\in\kappa}\phi\left(\frac{2}{\delta}\|x-x_\xi\|\right),$$

by construction of function ψ.

Now assume that $\kappa\setminus\kappa'\neq\phi$ and fix some $\eta\in\kappa\setminus\kappa'$. Then

$$f_\kappa(x_\eta)=\frac{c}{M}\delta^q\phi(0)=\frac{c}{M}\delta^q,$$

by property i of ϕ. On the other hand, for any $\xi \neq \eta$,

$$\phi\left(\frac{2}{\delta}\|x_\eta - x_\xi\|\right) = 1 - \left(\frac{2}{\delta}\|x_\eta - x_\xi\|\right)^2 \leqq 1 - 4\left(\frac{\delta'}{\delta}\right)^2,$$

since $\|x_\eta - x_\xi\| \geqq \delta'$ for $\xi \neq \eta$. Hence

$$f_{\kappa'}(x_\eta) \leqq \frac{c}{M}\delta^q - \frac{c}{M}\delta^q 4\left(\frac{\delta'}{\delta}\right)^2 = f_\kappa(x_\eta) - \frac{c}{M}\delta^{q+2m/n}.$$

Therefore $\|f_\kappa - f_{\kappa'}\|_C \geqq \|f_\kappa(x_\eta) - f_{\kappa'}(x_\eta)\| \geqq (c/M)\delta^{q+2m/n}$. This completes the proof of Lemma 2.2. We now return to the proof of Theorem 2.1.

Given $\varepsilon > 0$ let $\delta = (3M\varepsilon/c)^{1/(q+2m/n)}$. Then $(c/M)\delta^{q+2m/n} = 3\varepsilon$ and by Lemma 2.2 all the functions f_κ form the 3ε-separated net in $S_m^q(D,c)$. Since the number of elements in this net is equal to

$$2^{K(\delta)} \geqq 2^{K'(1/\delta)^{n+m}} = 2^{K''(1/\varepsilon)^{(n+m)/(q+2m/n)}},$$

we have

$$H_\varepsilon(S_m^q(D,c)) \geqq K''(1/\varepsilon)^{(n+m)/(q+2m/n)}.$$

Theorem 2.1 is proved.

As an immediate consequence of Theorem 2.1 we obtain the main result of this section:

THEOREM 2.3. *Let D be a compact domain in R^n. Then for any m, q and m', q', such that $(n+m)/(q+2m/n) > (n+m')/q'$, the set of functions in $S_m^q(D) \subset C(D)$ not belonging to $S_{m'}^{q'}(D)$, is a set of second category. In particular, this set is everywhere dense in $S_m^q(D)$.*

Proof. Clearly, $S_{m'}^{q'}(D) = \bigcup_{N=1}^{\infty} S_{m'}^{q'}(D,N)$. By Theorem 2.1 for any ball Ω in $C(D)$, $\mathrm{fd}(S_m^q(D) \cap \Omega) \geqq (n+m)/(q+2m/n)$. But by the same theorem, $\mathrm{fd}(S_{m'}^{q'}(D,N)) \leqq (n+m')/q' < (n+m)/(q+2m/n)$. Since $S_{m'}^{q'}(D,N) \cap S_m^q(D)$ is closed, it is therefore a nowhere dense subset in S_m^q.

Now we give some corollaries, showing what classes S_m^q can be separated by means of Theorem 2.3.

COROLLARY 2.4. *For given $D \subset R^n$ and m and for any q and $q' > q + 2m/n$, $S_m^{q'}(D) \subsetneqq S_m^q(D)$. In particular, if $n > 2m$, then for any $q' > q$, $S_m^{q'}(D) \subsetneqq S_m^q(D)$.*

Proof. For $q' > q + 2m/n$, $(n+m)/q' < (n+m)/(q+2m/n)$.

COROLLARY 2.5. *For given $D \subset R^n$, q and m, and for any $m' < m - 2n(n+m)/(2n+qm)$, $S_{m'}^q(D) \subsetneqq S_m^q(D)$. In particular, for $q > (2n^2-1)/m + 2n$, $S_{m'}^q(D) \subsetneqq S_m^q(D)$ for any $m' < m$, and for $q > 2n^2 + 2n - 1$, $S_{m'}^q(D) \subsetneqq S_{m''}^q(D)$ for any $m' < m''$.*

Proof. For $m' < m - 2n(n+m)/(2n+qm)$, $(n+m')/q < (n+m)/(q+2m/n)$. For $q > (2n^2-1)/m + 2n$, $2n(n+m)/(2n+qm) < 1$. Finitely, for $q > 2n^2 + 2n - 1$, the last inequality is satisfied for any m.

We can use the result of Theorem 2.1 also to compare $S_m^q(D)$ with $C^k(D)$. Indeed, by [10, Thm. 2.2.1], $\mathrm{fd}\, C^k(D) = n/k$, and repeating the proof of Theorem 2.3 we obtain the following:

COROLLARY 2.6. *For $(n+m)/q < n/k$, the set of k times continuously differentiable functions on D not belonging to $S_m^q(D)$, is a set of the second category and, in particular, is everywhere dense in the uniform topology.*

Notice that Corollaries 2.4, 2.5 and 2.6 do not give explicit examples of functions, not representable as a maximum of a suitably smooth family. Below we give such examples for any situation, covered by Corollary 2.6.

3. Critical values of maximum functions. Let $f\colon D \to R^s$ be a continuous mapping. The point $x \in \mathring{D}$ is called a critical point of f, if the first differential $df(x)$ exists and is equal to zero. Let $\Sigma(f)$ be the set of all the critical points of f and let $\Delta(f)=f(\Sigma(f)) \subset R^s$ be the set of critical values of f. (Actually, $\Sigma(f)$ is the set of critical points of rank zero of f, in the usual terminology).

A well-known and widely used property of critical values of differentiable mappings is given by the Morse–Sard theorem (see [3], [8]): if the mapping is sufficiently smooth, the set of its critical values has the Lebesgue measure (or, more precisely, the Hausdorff measure of an appropriate dimension) zero.

In [14] the stronger property of critical values has been established: let A be a bounded subset in R^s. The entropy dimension of A, $\dim_e A$ is defined as

$$\dim_e A = \inf\left\{ \beta\colon \exists K, \forall \varepsilon > 0,\ \varepsilon \leqq 1,\ N_\varepsilon(A) \leqq K\left(\frac{1}{\varepsilon}\right)^\beta \right\},$$

where $N_\varepsilon(A)$, as above, is the number of elements in a minimal ε-net of A in R^s.

For "nice" sets the entropy dimension coincides with the Hausdorff dimension $\dim_h$ and with the topological dimension. For any A $\dim_e A \geqq \dim_h A$, and the important advantage of the entropy dimension, which we shall use below, is that it allows us to distinguish countable sets, while the Hausdorff dimension of any countable set is zero.

The following result has been obtained in [14]:

THEOREM 5.4. [14]. *Let $D \subset R^n$ be a compact domain and let $f\colon D \to R^s$ be a C^q-mapping. Then*

$$\dim_e \Delta(f) \leqq \frac{n}{q}.$$

(The Morse–Sard theorem, in its general form, proved in [3], gives the same bound for the Hausdorff dimension of $\Delta(f)$.)

It turns out that also the critical values of the function, representable as a maximum of a smooth family, cannot form a set which is too large. More precisely, we have:

THEOREM 3.1. *Let $D \subset R^n$ be a compact domain. For any $f \in S_m^q(D)$,*

$$\dim_e \Delta(f) \leqq \frac{n+m}{q}.$$

Proof. Let $f(x)=\max_{t \in I^m} h(x,t)$, $h \in C^q(D \times I^m)$.

Before proving Theorem 3.1 we state and prove a lemma.

LEMMA 3.2. *Let $x_0 \in D$ be a critical point of f and let $t_0 \in I^m$ be such that $f(x_0)=h(x_0,t_0)$. Then $(x_0,t_0) \in D \times I^m$ is a critical point of h.*

Proof. Since $h(x_0,t)$ attains its maximum with respect to t at t_0, we have $d_t h(x_0,t_0)=0$.

By the definition of critical points, f is differentiable at x_0 and $df(x_0)=0$. But then from the expression of the generalized differential of maximum functions (see [2]) it follows immediately that $d_x h(x_0,t_0)=0$.

Proof of Theorem 3.1. By Lemma 3.2 any critical value $f(x_0)$ of f is a critical value $h(x_0,t_0)$ of h, i.e., $\Delta(f) \subset \Delta(h)$. But by Theorem 5.4 [14], $\dim_e \Delta(h) \leqq (n+m)/q$.

Now to obtain examples of functions, nonrepresentable as maximum, we note that for any $\gamma < n/k$, by [14, Thm. 5.6], the function $g \in C^k(D)$ can be built, with $\dim_e \Delta(g) \geqq \gamma$. By Theorem 3.1, g does not belong to any $S_m^q(D)$, with $(n+m)/q < \gamma$; and therefore, we get explicit examples of nonrepresentable functions in any situation, covered by Corollary 2.6.

In particular, let g_n: $I^n \to R$, $g_n \in C^{n-1}(I^n)$ be the Whitney function with $\Delta(g) = [0,1]$. (See [11].)

Since $\dim_e [0,1] = 1$, we have proved:

COROLLARY 3.3. *$g_n \notin S_m^q(I^n)$ for $q > n+m$.*

Notice that in all the constructions above it is sufficient to use the Hausdorff dimension of the sets of critical values. However, using the specific properties of the entropy dimension we can give examples of very simple functions, not representable as maximum:

Let ψ_k: $[0,1] \to R$ be defined as $\psi_k(x) = x^k \cos(1/x)$. $\psi_k \in C^{[k/2]-1}([0,1])$ and the critical values of ψ_k form the sequence

$$\omega\left(-\left(\frac{1}{\pi}\right)^k\right), \omega\left(\left(\frac{1}{2\pi}\right)^k\right), \cdots, \omega\left((-1)^i\left(\frac{1}{i\pi}\right)^k\right), \cdots,$$

where ω: $[-1,1] \to [-1,1]$ is a Lipschitzian homeomorphism. Hence $\dim_e \Delta(\psi_k) = 1/(k+1)$ (see e.g. [15]). This proves:

COROLLARY 3.4. *$\psi_k \notin S_m^q([0,1])$ for $q > (k+1)(m+1)$.*

4. Maxima of smooth families of linear functions. In this section we give simple examples of convex functions nonrepresentable as a maximum of a sufficiently smooth family of linear functions. Once more we reduce the question of representability to the properties of critical values of some differentiable mappings. But here, in constrast to section 3, the arising sets of critical values are a priori at most countable. Thus the Morse–Sard theorem gives no information in this case and the use of the entropy dimension and the stronger [14, Thm. 5.4] becomes essential. In fact, this theorem was found in the attempt to give criteria for representability of convex functions as the maximum of linear ones.

Let D be a convex compact domain in R^n. We consider a cone $Q(D)$ of convex functions f on D, which are extendable to convex functions on R^n and whose graphs $\Gamma(f)$ over D are polyhedra with possibly countable number of faces.

We study the representability of $f \in Q(D)$ as $f = \max_{t \in I^m} l_t$, where for $x = (x_1, \cdots, x_n) \in R^n$

$$l_t(x) = a_1(t)x_1 + \cdots + a_n(t)x_n + b(t), \quad \text{with } a_1, \cdots, a_n, b \in C^q(I^m).$$

Denote the set of functions in $Q(D)$, representable in this form, by $Q_m^q(D)$.

Let L be a hyperplane in $R^n \times R$ with a nondegenerate projection on R^n. L is a graph of the linear function $l_L(x) = a_1(L)x_1 + \cdots + a_n(L)x_n + b(L)$. Denote the point $(a_1(L), \cdots, a_n(L)) \in R^n$ by $\delta(L)$.

For a given $f \in Q(D)$ let $\delta(F) \subset R^n$ be the set of $\delta(\gamma)$, where γ runs through all the faces of $\Gamma(f)$. $\delta(f)$ is at most countable bounded subset in R^n.

THEOREM 4.1. *For any $f \in Q_m^q(D)$, $\dim_e \delta(F) \leqq (m/q)$.*

Proof. Write f as $\max l_t$, $l_t(x) = a_1(t)x_1 + \cdots + a_n(t)x_n + b(t)$, and for each face γ of $\Gamma(f)$ find some $t_\gamma \in I^m$, such that γ is a graph of l_{t_γ}.

LEMMA 4.2. *For any face γ of $\Gamma(f)$, t_γ is a critical point of each of functions $a_1, \cdots, a_n, b$.*

Proof. Let $x^0, x^1, \cdots, x^n$ be the vertices of some nondegenerate simplex in the projection of γ on R^n. Since at each x^i, $f(x^i)=l_{t_\gamma}(x^i)=\max_t l_t(x^i)$, we have $d_t l_t(x^i)\,|_{t=t_\gamma}=0$, or

$$d_t a_1(t_\gamma)x_1^i+\cdots+d_t a_n(t_\gamma)x_n^i+d_t b(t_\gamma)=0, \qquad i=0,\cdots,n.$$

But since $x^0,\cdots,x^n$ are the vertices of a nondegenerated simplex, this linear system has only the zero solution. This proves the lemma.

Thus if we define the mapping Φ: $I^m\to R^n$ by $\Phi(t)=(a_1(t),\cdots,a_n(t))$, any point t_γ is a critical point of Φ and $\delta(\gamma)=\Phi(t_\gamma)$ is a critical value of Φ. Hence $\delta(f)\subset\Delta(\Phi)$, and since by Theorem 5.4 [14] $\dim_e\Delta(\Phi)\leqq m/q$, Theorem 4.1 is proved.

Now consider, for instance, the set $\Delta_\alpha\subset R^n$, consisting of points of the form

$$\left(\frac{1}{k_1^\alpha},\frac{1}{k_2^\alpha},\cdots,\frac{1}{k_n^\alpha}\right), \qquad k_i=1,2,\cdots,$$

$\alpha>0$. We have $\dim_e\Delta_\alpha=n/(\alpha+1)$ (see e.g. [15]). One can easily find functions $f_\alpha\in Q(I^n)$ with $\delta(f)=\Delta_\alpha$. We obtain the following:

COROLLARY 4.3. *$f_\alpha\notin Q_m^q(I^n)$ for $m/q<n/(\alpha+1)$.*

Using the metric invariant V_β, defined in [15], one can give a more precise version of Theorem 4.1. We shall consider only one special case, where the question of representability can be answered completely. This is the case of Theorem 4.4 which was stated in the introduction. We repeat that statement here.

Let $f\in Q([0,1])$ be a function, for which $\delta(f)$ is a sequence $\delta_1<\delta_2<\cdots<\delta_i<\cdots$ and let $\alpha_i=\delta_{i+1}-\delta_i$.

THEOREM 4.4. *The function f can be represented as $f(x)=\max_{t\in[0,1]}a(t)x+b(t)$, $x\in[0,1]$, with a and b k times continuously differentiable functions on $[0,1]$, if and only if $\Sigma_{i=1}^\infty\alpha_i^{1/k}<\infty$.*

Proof. If f has a required representation, then, by Lemma 4.2, $\delta(f)=\{\delta_1,\delta_2,\cdots\}\subset\Delta(a)$. But then by [15, Thm. 4.1], $\Sigma_{i=1}^\infty\alpha_i^{1/k}<\infty$.

Now assume that $\Sigma_{i=1}^\infty\alpha_i^{1/k}<\infty$. In the proof of [15, Thm. 4.1] it is shown that we can find the function a: $[0,1]\to R$ with the following properties:

(i) $a\in C^\infty([0,1))$ and all the derivatives of a up to order k at $t\in[0,1)$ tend to zero as t tends to 1 (and, in particular, a is k times continuously differentiable on $[0,1]$.)

(ii) a increases on $[0,1]$.

(iii) There is a sequence of points $t_1, t_2,\cdots$ in $[0,1)$, converging to 1, such that $a(t_i)=\delta_i$ and all the derivatives of a at t_i vanish, $i=1,2,\cdots$.

Using $a(t)$ and f, we define $b(t)$ as follows: $b(t)$ is the constant term in the equation of the support line to the graph $\Gamma(f)$ with the slope $a(t)$.

Clearly, $f(x)=\max_t a(t)x+b(t)$. It remains to prove that b is k times continuously differentiable on $[0,1]$.

Let (x_i,y_i) be the coordinates of the vertex of $\Gamma(f)$, belonging to the edges of $\Gamma(f)$ with the slopes δ_i and δ_{i+1}, $i=1,2,\cdots$. Then for $\delta_i\leqq a(t)\leqq\delta_{i+1}$, i.e. for $t_i\leqq t\leqq t_{i+1}$, $b(t)=y_i-a(t)x_i$. Hence $b(t)$ is C^∞-smooth on each segment $[t_i,t_{i+1}]$, and its derivatives coincide with the derivatives of $a(t)$ up to a coefficient $-x_i$. But by the condition (iii), all the derivatives of a vanish at t_i. Hence $b\in C^\infty([0,1])$. Since by i, all the derivatives of $a(t)$ up to order k tend to zero as t tends to 1, the same is true for $b(t)$ and hence b is a k times continuously differentiable function on $[0,1]$.

5. Some open questions. Of course, the results above are far from being complete. However, they show that there is a rich variety of interesting phenomena concerning the maxima of smooth families, as well as various connections with the deep properties of smooth mappings.

Theorem 2.1 gives bounds for the functional dimension fd of the sets of maximum functions. What is the precise value of $\mathrm{fd}(S_m^q(D,c))$?

Notice also that the invariants obtained in §§2 and 3 involve both the smoothness q and the dimension of the parameter space m. Can one find invariants of maximum functions, separating the influence of these factors?

There is a similarity between the study of maximum functions above and the study of functions, representable by means of compositions of functions of some fixed class (see [10], [16]). In both cases the consideration of the ε-entropy allows us to prove the existence of nonrepresentable functions, while the study of some invariants, related to critical values, gives explicit examples of such functions. Are there direct connections between these two problems?

The necessary condition for the representability of a polyhedral convex function as a maximum of a smooth family of linear functions, given by Theorem 4.1, is very close to a sufficient one (see Theorem 4.4). However, for an arbitary convex function (not necessarily polyhedral), the method used here breaks down. Can one define invariants of a general convex function, responsible for the representability of this function as a maximum of a smooth family of linear functions?[1]

The maximum functions of smooth families have nice differentiability properties, which can be formulated, in particular, in terms of their generalized derivatives (both in sense of distributions—see [12], and in sense of optimization theory—see [2], [6], [7], [9]). Can one give criteria of representability in these terms? In particular, can one find function spaces appropriate for the treatment of maximum functions?

We focus on one question, in particular concerning the differentiability properties of maximum functions. A continuous function $f\colon R^n \to R$ is said to have the kth differential at x_0, if there exists a polynomial $P\colon R^n \to R$ of degree k, such that $\|f(x)-P(x)\| = o(\|x-x_0\|^k)$. Convex functions are known to have the second differential almost everywhere. Is it true that functions in $S_m^k(D)$ have the kth differential almost everywhere in D? Some variant of this question (for finite families) is considered in [17].[2]

Acknowledgment. The author would like to thank Y. Kanai for useful discussions and the Max-Planck-Institut für Mathematik, where this paper was written, for its kind hospitality.

POSITIVITY OF THE POISSON KERNEL FOR THE CONTINUOUS q-JACOBI POLYNOMIALS AND SOME QUADRATIC TRANSFORMATION FORMULAS FOR BASIC HYPERGEOMETRIC SERIES*

GEORGE GASPER† AND MIZAN RAHMAN‡

Abstract. A nonterminating extension of the Sears–Carlitz quadratic transformation formula for a well-posed ${}_3\phi_2$ series with an arbitrary argument is obtained as a sum of two balanced ${}_5\phi_4$ series. This is then extended to a very well-poised ${}_5\phi_4$ series with arbitrary argument. These results are used to derive some generating functions for the q-Wilson polynomials $p_n(x;\ a,b,c,d;\ q)$ when $ad=bc$ and an expression for the Poisson kernel $K_t(x,y;\ a,b,c,bc/a;\ q)$ as a sum of three sums of very well-poised ${}_{10}\phi_9$ series which clearly demonstrates its positivity for $0\leqq t<1$, $0\leqq q<1$ in the continuous q-Jacobi case when $a=q^{\alpha/2+1/4}$, $b=q^{\alpha/2+3/4}$, $c=-q^{\beta/2+1/4}$ and $\alpha,\beta>-1$. Additional quadratic transformation formulas are derived, along with q-analogues of Watson's and Whipple's summation formulas.

Key words. q-Wilson polynomials, continuous q-Jacobi polynomials, Sears–Carlitz formula, quadratic transformations of basic hypergeometric series, q-analogues of Watson's and Whipple's summation theorems, Bailey's transformation formulas, generating functions, Poisson kernel

1. Introduction.

Recently we showed [9] how Rogers' linearization formula for the continuous q-ultraspherical polynomials $C_n(x;\ \beta\,|\,q)$, defined below, could be used to derive an ${}_8\phi_7$ basic hypergeometric series representation for the Poisson kernel $P_t(x,y;\ \beta\,|\,q)$ for these polynomials from which one could easily see that this kernel is positive for $-1\leqq x,y\leqq 1$, $0\leqq t,q<1$ when $0\leqq\beta<1$. In analogy with the limiting ultraspherical polynomial case we conjectured that $P_t(x,y;\ \beta\,|\,q)$ should also be positive when $1<\beta<q^{-1/2}$. It was in trying to prove this conjecture and to give conditions under which the Poisson kernel for the continuous q-Jacobi polynomials $P_n^{(\alpha,\beta)}(x\,|\,q)$ is positive that we were led to consider the quadratic transformations and generating functions derived in this paper.

In particular, after first introducing our notation in §2, we shall prove in §3, that the Sears–Carlitz formula [14, (4.1)], [8, (2.4)],

$$(1.1)\quad {}_3\phi_2\left[\begin{matrix}a,\ b,\ c\\ aq/b,\ aq/c\end{matrix};q,\ \frac{aqx}{bc}\right]$$

$$=\frac{(ax;\ q)_\infty}{(x;\ q)_\infty}\ {}_5\phi_4\left[\begin{matrix}\sqrt{a},\ -\sqrt{a},\ \sqrt{aq},\ -\sqrt{aq},\ aq/bc\\ aq/b,\ aq/c,\ ax,\ q/x\end{matrix};q,\ q\right]$$

*Received by the editors November 8, 1983, and in revised form August 29, 1985.

‡Department of Mathematics and Statistics, Carleton University, Ottawa, Ontario, Canada K1S 5B6. The work of this author was supported in part by the Natural Sciences and Engineering Research Council under grant A6197.

where $a=q^{-n}$, $n=0,1,\cdots$, has a nonterminating extension of the form

$$(1.2)\quad {}_3\phi_2\left[\begin{matrix}a, b, c\\ aq/b, aq/c\end{matrix};q, \frac{aqx}{bc}\right]$$

$$=\frac{(ax;q)_\infty}{(x;q)_\infty}\,{}_5\phi_4\left[\begin{matrix}\sqrt{a}, -\sqrt{a}, \sqrt{aq}, -\sqrt{aq}, aq/bc\\ aq/b, aq/c, ax, q/x\end{matrix};q, q\right]$$

$$+\frac{(a;q)_\infty(aq/bc;q)_\infty(aqx/b;q)_\infty(aqx/c;q)_\infty}{(aq/b;q)_\infty(aq/c;q)_\infty(aqx/bc;q)_\infty(x^{-1};q)_\infty}$$

$$\cdot\,{}_5\phi_4\left[\begin{matrix}x\sqrt{a}, -x\sqrt{a}, x\sqrt{aq}, -x\sqrt{aq}, aqx/bc\\ aqx/b, aqx/c, xq, ax^2\end{matrix};q, q\right].$$

An analogous quadratic transformation formula, (3.5) below, is derived for the series

$$(1.3)\quad {}_5\phi_4\left[\begin{matrix}a, q\sqrt{a}, -q\sqrt{a}, b, c\\ \sqrt{a}, -\sqrt{a}, aq/b, aq/c\end{matrix};q, \frac{t\sqrt{aq}}{bc}\right],$$

which plays a crucial role in our derivation in §6 of a representation for the Poisson kernel for the continuous q-Jacobi polynomials as a sum of three sums of balanced ${}_{10}\phi_9$ series from which its positivity for $0\leq t,q<1$ is obvious when $\alpha,\beta>-1$; thus, also proving the above-mentioned conjecture for the continuous q-ultraspherical polynomials.

We shall also derive quadratic transformations of the type that transform series with base q^2 to series with base q, such as

(1.4)

$${}_2\phi_1\left[\begin{matrix}a^2, b^2\\ a^2q^2/b^2\end{matrix};q^2, \frac{x^2q^2}{b^4}\right]=\frac{(aq/b^2;q)_\infty(x^2q/b^2;q)_\infty}{(q/b^2;q)_\infty(ax^2q/b^2;q)_\infty}$$

$$\cdot\frac{(a^2x^2q/b^2;q^2)_\infty(q/b^2;q^2)_\infty(q^2/b^2;q^2)_\infty(a^2x^2q^2/b^4;q^2)_\infty}{(x^2q/b^2;q^2)_\infty(a^2q/b^2;q^2)_\infty(a^2q^2/b^2;q^2)_\infty(x^2q^2/b^4;q^2)_\infty}$$

$$\cdot\,{}_8\phi_7\left[\begin{matrix}ax^2/b^2;q\sqrt{\cdot}, -q\sqrt{\cdot}, a, x, -x, xq^{1/2}/b, -xq^{1/2}/b\\ \sqrt{\cdot}, -\sqrt{\cdot}, x^2q/b^2, axq/b^2, -axq/b^2, axq^{1/2}/b, -axq^{1/2}b\end{matrix};q, \frac{aq}{b^2}\right],$$

where $|aq/b^2|<1$, and give q-analogues of the well-known quadratic summation formulas of Watson [5, p. 16].

$$(1.5)\quad {}_3F_2\left[\begin{matrix}a, b, c\\ \frac{1}{2}(a+b+1), 2c\end{matrix};1\right]=\frac{\Gamma(\frac{1}{2})\Gamma(\frac{1}{2}+c)\Gamma(\frac{1+a+b}{2})\Gamma(\frac{1-a-b+c}{2})}{\Gamma(\frac{1+a}{2})\Gamma(\frac{1+b}{2})\Gamma(\frac{1-a}{2}+c)\Gamma(\frac{1-b}{2}+c)}$$

and Whipple [5, p. 16]

$$(1.6)\quad {}_3F_2\left[\begin{matrix}a, 1-a, b\\ c, 2b+1-c\end{matrix};1\right]=\frac{\pi\Gamma(c)\Gamma(2b+1-c)2^{1-2b}}{\Gamma(\frac{a+c}{2})\Gamma(b+\frac{a+1-c}{2})\Gamma(\frac{1+c-a}{2})\Gamma(b+1-\frac{a+c}{2})}.$$

The open square root symbol used in (1.4) and elsewhere is an abbreviation for the square root of the top left-hand member of the series, with the understanding that the same square root is used throughout.

2. Notation. Let $|q|<1$. As usual, a ${}_{r+1}\phi_r$ basic hypergeometric series with base q is defined by

$$(2.1)\qquad {}_{r+1}\phi_r\left[\begin{matrix}a_1,a_2,\cdots,a_{r+1}\\ b_1,\cdots,b_r\end{matrix};q,\ z\right]=\sum_{n=0}^{\infty}\frac{(a_1;\ q)_n(a_2;\ q)_n\cdots(a_{r+1};\ q)_n}{(q;\ q)_n(b_1;\ q)_n\cdots(b_r;\ q)_n}z^n,$$

whenever the series converges (e.g., if $|z|<1$) where the q-shifted factorials are defined by

$$(a;\ q)_n=\begin{cases}1, & n=0,\\ (1-a)(1-aq)\cdots(1-aq^{n-1}), & n=1,2,\cdots.\end{cases}$$

We also let $(a;\ q)_\infty=(1-a)(1-aq)(1-aq^2)\ldots$. To simplify the notation we will also write $(a)_n$ and $(a)_\infty$ in place of $(a;\ q)_n$ and $(a;\ q)_\infty$, respectively, and omit the base q symbol in the ${}_{r+1}\phi_r$ series when the base is q, so that only the z term appears after the semicolon.

As in Askey and Wilson [4] we define the continuous q-ultraspherical polynomials $C_n(x;\ \beta\,|\,q)$ by

$$(2.2)\qquad C_n(x;\ \beta\,|\,q)=\frac{(\beta^2)_n\beta^{-n/2}}{(q)_n}\,{}_4\phi_3\left[\begin{matrix}q^{-n},\ q^n\beta^2,\ \beta^{1/2}e^{i\theta},\ \beta^{1/2}e^{-i\theta}\\ \beta q^{1/2},\ -\beta q^{1/2},\ -\beta\end{matrix};q\right]$$

and the continuous q-Jacobi polynomials $P_n^{(\alpha,\beta)}(x\,|\,q)$ by

$$(2.3)\qquad P_n^{(\alpha,\beta)}(x\,|\,q)=\frac{(q^{\alpha+1})_n}{(q)_n}\,{}_4\phi_3\left[\begin{matrix}q^{-n},\ q^{n+\alpha+\beta+1},\ q^{\alpha/2+1/4}e^{i\theta},\ q^{\alpha/2+1/4}e^{-i\theta}\\ q^{\alpha+1},\ -q^{\alpha/2+\beta/2+1/2},\ -q^{\alpha/2+\beta/2+1}\end{matrix};q\right],$$

where, as elsewhere, $x=\cos\theta$. It should be noted that $C_n(x;\ q^{\alpha+1/2}\,|\,q)$ is a constant multiple of $P_n^{(\alpha,\alpha)}(x\,|\,q)$ and that the polynomial

$$(2.4)\qquad P_n^{(\alpha,\beta)}(x;\ q)=\frac{(q^{\alpha+1})_n(-q^{\beta+1})_n}{(q)_n(-q)_n}\,{}_4\phi_3\left[\begin{matrix}q^{-n},\ q^{n+\alpha+\beta+1},\ q^{1/2}e^{i\theta},\ q^{1/2}e^{-i\theta}\\ q^{\alpha+1},\ -q^{\beta+1},\ -q\end{matrix};q\right],$$

which was considered in Rahman [13] and Gasper [11], is a constant multiple of $P_n^{(\alpha,\beta)}(x\,|\,q^2)$, as Askey and Wilson showed in [4, §4].

Since the above polynomials are constant multiples of the q-Wilson polynomials [4]

$$(2.5)\qquad p_n(x;\ a,b,c,d;\ q)={}_4\phi_3\left[\begin{matrix}q^{-n},\ abcdq^{n-1},\ ae^{i\theta},\ ae^{-i\theta}\\ ab,\ ac,\ ad\end{matrix};q\right],$$

we shall initially consider these polynomials. Askey and Wilson [4, Thm. 2.2] proved for $-1<q<1$ that if a, b, c, d are real (or if complex, appear in conjugate pairs) and

$\max(|a|, |b|, |c|, |d|)<1$ then these polynomials satisfy the orthogonality relation

$$\int_{-1}^{1} p_n(x; a,b,c,d; q)p_m(x; a,b,c,d; q)w(x; a,b,c,d; q)\,dx=\frac{\delta_{m,n}}{h_n}, \tag{2.6}$$

where

$$w(x; a,b,c,d; q) = \frac{(e^{2i\theta})_\infty(e^{-2i\theta})_\infty \csc\theta}{(ae^{i\theta})_\infty(ae^{-i\theta})_\infty(be^{i\theta})_\infty(be^{-i\theta})_\infty(ce^{i\theta})_\infty(ce^{-i\theta})_\infty(de^{i\theta})_\infty(de^{-i\theta})_\infty}, \tag{2.7}$$

and

$$\begin{aligned} h_n &= h_n(a,b,c,d; q) \\ &= \frac{(abcdq^{-1})_n(1-abcdq^{2n-1})(ab)_n(ac)_n(ad)_n a^{-2n}}{(1-abcdq^{-1})(bc)_n(bd)_n(cd)_n(q)_n} \\ &\quad \cdot \frac{(ab)_\infty(ac)_\infty(ad)_\infty(bc)_\infty(bd)_\infty(cd)_\infty(q)_\infty}{2\pi(abcd)_\infty}. \end{aligned} \tag{2.8}$$

They also gave the orthogonality relation for cases when $a>1$, $0<q<1$, and some positive discrete masses have to be added to the weight function (see [4, Thm. (2.4)]).

From (2.8) the Poisson kernel

$$\begin{aligned} &P_t(x,y; a,b,c,d; q) \\ &\quad = \sum_{n=0}^{\infty} t^n h_n(a,b,c,d; q)p_n(x; a,b,c,d; q)p_n(y; a,b,c,d; q) \end{aligned} \tag{2.9}$$

is a positive multiple of the sum

$$\begin{aligned} &K_t(x,y; a,b,c,d; q) \\ &\quad = \sum_{n=0}^{\infty} \frac{(abcdq^{-1})_n(1-abcdq^{2n-1})}{(q)_n(1-abcdq^{-1})} \\ &\quad\quad \cdot \frac{(ab)_n(ac)_n(ad)_n}{(bc)_n(bd)_n(cd)_n} a^{-2n}t^n p_n(x; a,b,c,d; q)p_n(y; a,b,c,d; q), \end{aligned} \tag{2.10}$$

when a, b, c, d are real and their pairwise products have absolute value less than one, which is the case we consider in this paper.

Another notation that we shall use is that of a q-integral defined by

$$\int_a^b f(u)\,d_q u=\int_0^b f(u)\,d_q u-\int_0^a f(u)\,d_q u, \tag{2.11}$$

where

$$\int_0^a f(u)\,d_q u=a(1-q)\sum_{n=0}^{\infty} f(aq^n)q^n$$

whenever the series converges, which will simplify our proofs in §§4 to 6.

3. Quadratic transformations. To derive formula (1.2) we first observe that from a transformation formula due to Bailey [6, (1)] it follows that

(3.1)

$$
{}_5\phi_4\left[\begin{matrix} a, b, c, dq^n, q^{-n} \\ aq/b,\ aq/c,\ aq^{1-n}/d,\ b^2c^2d^2q^{n-2}/a^2 \end{matrix}; q\right]
$$

$$
= \frac{(aq^{2-n}/bcd)_n (a^3q^{3-2n}/b^2c^2d^2)_n}{(a^2q^{2-n}/bcd)_n (a^2q^{3-2n}/b^2c^2d^2)_n}
$$

$$
\cdot {}_{12}\phi_{11}\left[\begin{matrix} a^2q^{1-n}/bcd,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ aq^{1-n}/cd, \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ aq/b, \end{matrix}\right.
$$

$$
\begin{matrix} aq^{1-n}/bd,\ aq/bc,\ \sqrt{a},\ -\sqrt{a},\ \sqrt{aq}, \\ aq/c,\ aq^{1-n}/d,\ a^{3/2}q^{2-n}/bcd,\ -a^{3/2}q^{2-n}/bcd,\ a^{3/2}q^{3/2-n}/bcd, \end{matrix}
$$

$$
\left.\begin{matrix} -\sqrt{aq},\ a^3q^{3-n}/b^2c^2d^2,\ q^{-n} \\ -a^{3/2}q^{3/2-n}/bcd,\ bcd/aq,\ a^2q^2/bcd \end{matrix}; q\right].
$$

Letting $n \to \infty$ we get

$$
{}_3\phi_2\left[\begin{matrix} a, b, c \\ aq/b,\ aq/c \end{matrix}; \frac{d}{a}\right] = \frac{(bcd/aq)_\infty}{(bcd/a^2q)_\infty} \lim_{n\to\infty} {}_{12}\phi_{11}[\cdots]. \tag{3.2}
$$

To find the limit on the right side of (3.2) we follow the procedure in Bailey [5, p. 28] of first assuming n to be an odd integer, splitting up the ${}_{12}\phi_{11}$ series into two halves, reversing the second series, and then letting $n \to \infty$. This yields

(3.3)

$$
\lim_{n\to\infty} {}_{12}\phi_{11}[\cdots] = {}_5\phi_4\left[\begin{matrix} \sqrt{a},\ -\sqrt{a},\ \sqrt{aq},\ -\sqrt{aq},\ aq/bc \\ aq/b,\ aq/c,\ bcd/aq,\ a^2q^2/bcd \end{matrix}; q\right]
$$

$$
- \frac{bcd}{a^2q} \frac{(bcd/a^2)_\infty (cd/a)_\infty (bd/a)_\infty (aq/bc)_\infty (a)_\infty}{(d/a)_\infty (aq/b)_\infty (aq/c)_\infty (bcd/aq)_\infty (a^2q^2/bcd)_\infty}
$$

$$
{}_5\phi_4\left[\begin{matrix} d/a,\ bcd/qa^{3/2},\ -bcd/qa^{3/2},\ bcd/q^{1/2}a^{3/2},\ -bcd/q^{1/2}a^{3/2} \\ cd/a,\ bd/a,\ bcd/a^2,\ b^2c^2d^2/a^3q^2 \end{matrix}; q\right].
$$

Replacing d by a^2xq/bc in (3.2) and (3.3) we immediately get (1.2). With Bailey's formula (3.1) known for over 40 years (his paper was accepted for Proceedings of London Mathematical Society in 1943) it is surprising how such a simple derivation of (1.2) could have escaped notice for so long.

Bailey even had a formula [6, (2)] which gives an analogue of (3.1) in the form

(3.4)

$$
{}_7\phi_6\left[\begin{matrix} a,\ q\sqrt{a}\,,\ -q\sqrt{a}\,,\ b,\ c,\ dq^n,\ q^{-n} \\ \sqrt{a}\,,\ -\sqrt{a}\,,\ aq/b,\ aq/c,\ aq^{1-n}/d,\ b^2c^2d^2q^n/a^2 \end{matrix};q\right]
$$

$$
=\frac{(a^3q^{2-2n}/b^2c^2d^2)_{n-1}(aq^{-n}/bcd)_n(1-a^3q/b^2c^2d^2)}{(a^2q^{2-n}/bcd)_n(a^2q^{1-2n}/b^2c^2d^2)_n}
$$

$$
\cdot\,{}_{12}\phi_{11}\left[\begin{matrix} a^2q^{1-n}/bcd,\ q\sqrt{\cdot}\,,\ -q\sqrt{\cdot}\,,\ aq^{1-n}/cd,\ aq^{1-n}/bd,\ aq/bc, \\ \sqrt{\cdot}\,,\ -\sqrt{\cdot}\,,\ aq/b,\ aq/c,\ aq^{1-n}/d, \\ \sqrt{aq}\,,\ -\sqrt{aq}\,,\ q\sqrt{a}\,,\ -q\sqrt{a}\,, \\ a^{3/2}q^{3/2-n}/bcd,\ -a^{3/2}q^{3/2-n}/bcd,\ a^{3/2}q^{1-n}/bcd,\ -a^{3/2}q^{1-n}/bcd, \\ a^3q^{1-n}/b^2c^2d^2,\ q^{-n} \\ bcdq/a,\ a^2q^2/bcd \end{matrix};q\right].
$$

Taking the limit $n\to\infty$ as described above and replacing d by $a^{3/2}q^{1/2}t/bc$ we obtain for the ${}_5\phi_4$ in (1.3) that

(3.5)

$$
{}_5\phi_4\left[\begin{matrix} a,\ q\sqrt{a}\,,\ -q\sqrt{a}\,,\ b,\ c \\ \sqrt{a}\,,\ -\sqrt{a}\,,\ aq/b,aq/c \end{matrix};\frac{t\sqrt{aq}}{bc}\right]
$$

$$
=\frac{(1-t^2)(tq\sqrt{aq})_\infty}{(t/\sqrt{aq})_\infty}\,{}_5\phi_4\left[\begin{matrix} \sqrt{aq}\,,\ -\sqrt{aq}\,,\ q\sqrt{a}\,,\ -q\sqrt{a}\,,\ aq/bc \\ aq/b,\ aq/c,\ t^{-1}q\sqrt{aq}\,,\ tq\sqrt{aq} \end{matrix};q\right]
$$

$$
+\frac{(aq)_\infty(aq/bc)_\infty(\sqrt{aq}\,t/b)_\infty(\sqrt{aq}\,t/c)_\infty}{(aq/b)_\infty(aq/c)_\infty(\sqrt{aq}\,t/bc)_\infty(t^{-1}\sqrt{aq}\,)_\infty}
$$

$$
\cdot\,{}_5\phi_4\left[\begin{matrix} t,\ -t,\ t\sqrt{q}\,,\ -t\sqrt{q}\,,\ \sqrt{aq}\,t/bc \\ \sqrt{aq}\,t/b,\ \sqrt{aq}\,t/c,\ qt^2,\ t\sqrt{q/a} \end{matrix};q\right].
$$

It should be noted that by replacing a, b, c in (3.5) by q^a, q^b, q^c and letting $q\to 1-$ we obtain the quadratic transformation [5, Ex. 6, p. 97]. Similarly, it can be shown that the quadratic transformation [5, Ex. 4(iv) p. 97] is a limit of (1.2).

In terms of the q-integral notation formula (1.2) is equivalent to

(3.6)
$$
{}_3\phi_2\left[\begin{matrix} a,\ b,\ c \\ aq/b,\ aq/c \end{matrix};\frac{aqx}{bc}\right]
$$

$$
=\frac{(a)_\infty(aq/bc)_\infty}{s(1-q)(q)_\infty(aq/b)_\infty(aq/c)_\infty(q/x)_\infty(x)_\infty}
$$

$$
\cdot\int_{xs}^{s}\frac{(qu/xs)_\infty(qu/s)_\infty(aqu/bs)_\infty(aqu/cs)_\infty(axu/s)_\infty}{(\sqrt{a}\,u/s)_\infty(-\sqrt{a}\,u/s)_\infty(\sqrt{aq}\,u/s)_\infty(-\sqrt{aq}\,u/s)_\infty(aqu/bcs)_\infty}\,d_qu
$$

and (3.5) is equivalent to

(3.7)

$$
{}_5\phi_4\left[\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b, c \\ \sqrt{a}, -\sqrt{a}, aq/b, aq/c \end{matrix}; \frac{t\sqrt{aq}}{bc}\right]
$$

$$
= \frac{1-t^2}{s(1-q)} \frac{(aq)_\infty (aq/bc)_\infty}{(q)_\infty (aq/b)_\infty (aq/c)_\infty (t/\sqrt{aq})_\infty (t^{-1}q\sqrt{aq})_\infty}
$$

$$
\cdot \int_{st/\sqrt{aq}}^{s} \frac{(q\sqrt{aq}\,u/st)_\infty (qu/s)_\infty (aqu/bs)_\infty (aqu/cs)_\infty (tq\sqrt{aq}\,u/s)_\infty}{(\sqrt{aq}\,u/s)_\infty (-\sqrt{aq}\,u/s)_\infty (q\sqrt{a}\,u/s)_\infty (-q\sqrt{a}\,u/s)_\infty (aqu/bcs)_\infty} d_q u
$$

where s is arbitrary.

It should also be observed that by replacing c by cq^{-n} in (3.1) and (3.4), letting $n \to \infty$, and then setting $d = aq/cx$, we obtain the quadratic transformations

(3.8)

$$
{}_2\phi_1\left[\begin{matrix} a, b \\ aq/b \end{matrix}; \frac{qx}{b^2}\right] = \frac{(qx/b)_\infty (aqx^2/b^2)_\infty}{(aqx/b)_\infty (qx^2/b^2)_\infty}
$$

$$
\cdot {}_8\phi_7\left[\begin{matrix} ax/b, q\sqrt{\cdot}, -q\sqrt{\cdot}, x, \sqrt{a}, -\sqrt{a}, \sqrt{aq}, -\sqrt{aq} \\ \sqrt{\cdot}, -\sqrt{\cdot}, aq/b, \sqrt{a}\,qx/b, -\sqrt{a}\,qx/b, \sqrt{aq}\,x/b, -\sqrt{aq}\,x/b \end{matrix}; \frac{qx}{b^2}\right]
$$

and

(3.9)

$$
{}_4\phi_3\left[\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b \\ \sqrt{a}, -\sqrt{a}, aq/b \end{matrix}; \frac{x}{b^2 q}\right]
$$

$$
= \frac{(ax^2/b^2)_\infty (x/bq)_\infty}{(aqx/b)_\infty (x^2/b^2 q)_\infty}
$$

$$
\cdot {}_8\phi_7\left[\begin{matrix} ax/b, q\sqrt{\cdot}, -q\sqrt{\cdot}, x, \sqrt{aq}, -\sqrt{aq}, q\sqrt{a}, -q\sqrt{a} \\ \sqrt{\cdot}, -\sqrt{\cdot}, aq/b, \sqrt{aq}\,x/b, -\sqrt{aq}\,x/b, \sqrt{a}\,x/b, -\sqrt{a}\,x/b \end{matrix}; \frac{x}{b^2 q}\right]
$$

provided that $|qx/b^2| < 1$ in (3.8) and $|x/b^2 q| < 1$ in (3.9) whenever the series do not terminate.

Our derivation of (1.4) and a more general transformation depends on the use of the Sears [14] summation formula

(3.10)

$$
\frac{(e)_\infty (f)_\infty}{(a)_\infty (b)_\infty (c)_\infty} {}_3\phi_2\left[\begin{matrix} a, b, c \\ e, f \end{matrix}; q\right]
$$

$$
- \frac{q}{e} \frac{(q^2/e)_\infty (fq/e)_\infty}{(aq/e)_\infty (bq/e)_\infty (cq/e)_\infty} {}_3\phi_2\left[\begin{matrix} aq/e, bq/e, cq/e \\ q^2/e, fq/e \end{matrix}; q\right]
$$

$$
= \frac{(e)_\infty (q/e)_\infty (f/a)_\infty (f/b)_\infty (f/c)_\infty}{(a)_\infty (b)_\infty (c)_\infty (aq/e)_\infty (bq/e)_\infty (cq/e)_\infty}
$$

where $abcq=ef$. Set $e=-q$, $b=-c$, replace a by aq^r, $r=0,1,2,\cdots$, multiply both sides of (3.10) by

$$\frac{(x^2;\,q^2)_r(y^2;\,q^2)_r}{(-q;\,q)_r(x^2y^2b^2;\,q^2)_r}b^{2r}q^r,$$

use $(a^2;\,q^2)_r=(a;\,q)_r(-a;\,q)_r$, and sum over r from 0 to ∞ to get

(3.11)

$$\frac{(-1)_\infty(-q)_\infty(-ab)_\infty(ab)_\infty(b^2)_\infty}{(a)_\infty(b)_\infty(-b)_\infty(-a)_\infty(b)_\infty(-b)_\infty}\,{}_3\phi_2\left[\begin{matrix}a^2,\ x^2,\ y^2\\ a^2b^2,\ x^2y^2b^2\end{matrix};q^2,\ qb^2\right]$$

$$=\frac{(-q)_\infty(ab^2)_\infty}{(a)_\infty(b)_\infty(-b)_\infty}\sum_{j=0}^{\infty}\frac{(a)_j(b)_j(-b)_j}{(q)_j(-q)_j(ab^2)_j}q^j\,{}_3\phi_2\left[\begin{matrix}q^{-2j},\ x^2,\ y^2\\ x^2y^2b^2,\ b^{-2}q^{2-2j}\end{matrix};q^2,\ q^2\right]$$

$$+\frac{(-q)_\infty(-ab^2)_\infty}{(-a)_\infty(-b)_\infty(b)_\infty}\sum_{j=0}^{\infty}\frac{(-a)_j(-b)_j(b)_j}{(q)_j(-q)_j(-ab^2)_j}q^j\,{}_3\phi_2\left[\begin{matrix}q^{-2j},\ x^2,\ y^2\\ x^2y^2b^2,\ b^{-2}q^{2-2j}\end{matrix};q^2,\ q^2\right].$$

Since the ${}_3\phi_2$ series on the r.h.s. can be summed by using [16; (IV.4)]

$$(3.12)\qquad {}_3\phi_2\left[\begin{matrix}a,\ b,\ q^{-n}\\ c,\ ab/cq^{n-1}\end{matrix};q,\ q\right]=\frac{(c/a;\,q)_n(c/b;\,q)_n}{(c;\,q)_n(c/ab;\,q)_n}$$

with the base q replaced by q^2, it follows from (3.11) that

(3.13)

$${}_3\phi_2\left[\begin{matrix}a^2,\ x^2,\ y^2\\ a^2b^2,\ x^2y^2/b^2\end{matrix};q^2,\ qb^2\right]$$

$$=\frac{(-a;\,q)_\infty(ab^2;\,q)_\infty(b^2;\,q^2)_\infty}{(-1;\,q)_\infty(b^2;\,q)_\infty(a^2b^2;\,q^2)_\infty}\,{}_5\phi_4\left[\begin{matrix}a,\ bx,\ -bx,\ by,\ -by\\ -q,\ ab^2,\ bxy,\ -bxy\end{matrix};q,\ q\right]$$

$$+\frac{(a;\,q)_\infty(-ab^2;\,q)_\infty(b^2;\,q^2)_\infty}{(-1;\,q)_\infty(b^2;\,q)_\infty(a^2b^2;\,q^2)_\infty}\,{}_5\phi_4\left[\begin{matrix}-a,\ -bx,\ bx,\ -by,\ by\\ -q,\ -ab^2,\ -bxy,\ bxy\end{matrix};q,\ q\right].$$

Setting $y=ab$, this reduces to

(3.14)

$${}_2\phi_1\left[\begin{matrix}a^2,\ x^2\\ a^2b^4x^2\end{matrix};q^2,\ qb^2\right]$$

$$=\frac{(-a;\,q)_\infty(ab^2;\,q)_\infty(b^2;\,q^2)_\infty}{(-1;\,q)_\infty(b^2;\,q)_\infty(a^2b^2;\,q^2)_\infty}\,{}_4\phi_3\left[\begin{matrix}a,\ bx,\ -bx,\ -ab^2\\ -q,\ ab^2x,\ -ab^2x\end{matrix};q,\ q\right]$$

$$+\frac{(a;\,q)_\infty(-ab^2;\,q)_\infty(b^2;\,q^2)_\infty}{(-1;\,q)_\infty(b^2;\,q)_\infty(a^2b^2;\,q^2)_\infty}\,{}_4\phi_3\left[\begin{matrix}-a,\ -bx,\ bx,\ ab^2\\ -q,\ -ab^2x,\ ab^2x\end{matrix};q,\ q\right].$$

Using Bailey's [5, p. 69] transformation formula, namely,

(3.15)

$$
{}_8\phi_7\left[\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b, c, d, e, f \\ \sqrt{a}, -\sqrt{a}, aq/b, aq/c, aq/d, aq/e, aq/f \end{matrix}; \frac{a^2q^2}{bcdef}\right]
$$

$$
= \frac{(aq)_\infty (aq/de)_\infty (aq/df)_\infty (aq/ef)_\infty}{(aq/d)_\infty (aq/e)_\infty (aq/f)_\infty (aq/def)_\infty}\, {}_4\phi_3\left[\begin{matrix} aq/bc, d, e, f \\ aq/b, aq/c, def/a \end{matrix}; q\right]
$$

$$
+ \frac{(aq)_\infty (aq/bc)_\infty (d)_\infty (e)_\infty (f)_\infty (a^2q^2/cdef)_\infty (a^2q^2/bdef)_\infty}{(aq/b)_\infty (aq/c)_\infty (aq/d)_\infty (aq/e)_\infty (aq/f)_\infty (a^2q^2/bcdef)_\infty (def/aq)_\infty}
$$

$$
\cdot {}_4\phi_3\left[\begin{matrix} aq/de, aq/df, aq/ef, a^2q^2/bcdef \\ aq^2/def, a^2q^2/bdef, a^2q^2/cdef \end{matrix}; q\right],
$$

we obtain

(3.16)
$$
{}_2\phi_1\left[\begin{matrix} a^2, x^2 \\ a^2b^4x^2 \end{matrix}; q^2, qb^2\right]
$$

$$
= \frac{(b^2x^2; q)_\infty (abx; q)_\infty (-abx; q)_\infty (ab^2; q)_\infty (b^2; q^2)_\infty}{(ab^2x^2; q)_\infty (bx; q)_\infty (-bx; q)_\infty (b^2; q)_\infty (a^2b^2; q^2)_\infty}
$$

$$
\cdot {}_8\phi_7\left[\begin{matrix} ab^2x^2q^{-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, a, x, -x, bx, -bx \\ \sqrt{\cdot}, -\sqrt{\cdot}, b^2x^2, ab^2x, -ab^2x, abx, -abx \end{matrix}; q, ab^2\right].
$$

By Heine's second transformation [2],

(3.17)
$$
{}_2\phi_1\left[\begin{matrix} a^2, x^2 \\ a^2b^4x^2 \end{matrix}; q^2, qb^2\right]
$$

$$
= \frac{(a^2b^2q; q^2)_\infty (b^4x^2; q^2)_\infty}{(b^2q; q^2)_\infty (a^2q^4x^2; q^2)_\infty}\, {}_2\phi_1\left[\begin{matrix} a^2, qb^{-2} \\ a^2b^2q \end{matrix}; q^2, b^4x^2\right]
$$

and hence by using (3.17) and (3.16) and replacing b by $\sqrt{q}/b$ we get formula (1.4). If $a = \pm q^{-n}$, $n = 0, 1, \cdots$, then one of the terms on the r.h.s. of (3.14) drops out and, by (3.17), we get a formula equivalent with Verma's formula (2.5) in [17].

The only tools that we need to derive q-analogues of Watson's (1.5) and Whipple's (1.6) summation formulas are the q-analogue of Dixon's formula [16, (IV.6)]

(3.18)
$$
{}_4\phi_3\left[\begin{matrix} A, -q\sqrt{A}, B, C \\ -\sqrt{A}, Aq/B, Aq/C \end{matrix}; \frac{q\sqrt{A}}{BC}\right]
$$

$$
= \frac{(Aq)_\infty (q\sqrt{A}/C)_\infty (q\sqrt{A}/B)_\infty (Aq/BC)_\infty}{(Aq/B)_\infty (Aq/C)_\infty (q\sqrt{A})_\infty (q\sqrt{A}/BC)_\infty}, \qquad |q\sqrt{A}/BC| < 1,
$$

and the following limit case of Jackson's transformation formula [16, (3.4.2.4)]

(3.19)

$$
{}_8\phi_7\left[\begin{matrix} A, q\sqrt{A}, -q\sqrt{A}, B, C, D, E, F \\ \sqrt{A}, -\sqrt{A}, Aq/B, Aq/C, Aq/D, Aq/E, Aq/F \end{matrix}; \frac{A^2q^2}{BCDEF}\right]
$$

$$
= \frac{(Aq)_\infty (Aq/EF)_\infty (A^2q^2/BCDE)_\infty (A^2q^2/BCDF)_\infty}{(Aq/E)_\infty (Aq/F)_\infty (A^2q^2/BCD)_\infty (A^2q^2/BCDEF)_\infty}
$$

$$
\cdot {}_8\phi_7\left[\begin{matrix} A^2q/BCD, q\sqrt{\cdot}, -q\sqrt{\cdot}, Aq/CD, Aq/BD, Aq/BC, E, F \\ \sqrt{\cdot}, -\sqrt{\cdot}, Aq/B, Aq/C, Aq/D, A^2q^2/BCDE, A^2q^2/BCDF \end{matrix}; \frac{Aq}{EF}\right],
$$

provided that $|A^2q^2/BCDEF|<1$ and $|Aq/EF|<1$ whenever the series do not terminate.

If we now set $A=-F=-a$, $B=-C=b$, and $D=-E=c$, then the l.h.s. of (3.19) reduces to the ${}_4\phi_3$ series

$$
{}_4\phi_3\left[\begin{matrix} a^2, -aq^2, b^2, c^2 \\ -a, a^2q^2/b, a^2q^2/c^2 \end{matrix}; q^2, \frac{aq^2}{b^2c^2}\right]
$$

which, by (3.18), sums to

$$
\frac{(a^2q^2;\, q^2)_\infty (aq^2/c^2;\, q^2)_\infty (aq^2/b^2;\, q^2)_\infty (a^2q^2/b^2c^2;\, q^2)_\infty}{(a^2q^2/b^2;\, q^2)_\infty (a^2q^2/c^2;\, q^2)_\infty (aq^2;\, q^2)_\infty (aq^2/b^2c^2;\, q^2)_\infty}.
$$

Hence it follows from (3.19) that

(3.20)
$$
{}_8\phi_7\left[\begin{matrix} -a^2q/b^2c, q\sqrt{\cdot}, -q\sqrt{\cdot}, aq/bc, -aq/bc, aq/b^2, -c, a \\ \sqrt{\cdot}, -\sqrt{\cdot}, -aq/b, aq/b, -aq/c, a^2q^2/b^2c^2, -aq^2/b^2c \end{matrix}; q, \frac{q}{c}\right]
$$

$$
= \frac{(aq/c;\, q)_\infty (-q;\, q)_\infty (-a^2q^2/b^2c;\, q)_\infty (aq^2/b^2c^2;\, q)_\infty}{(-aq;\, q)_\infty (q/c;\, q)_\infty (a^2q^2/b^2c^2;\, q)_\infty (-aq^2/b^2c;\, q)_\infty}
$$

$$
\cdot \frac{(a^2q^2;\, q^2)_\infty (aq^2/b^2;\, q^2)_\infty (aq^2/c^2;\, q^2)_\infty (a^2q^2/b^2c^2;\, q^2)_\infty}{(a^2q^2/b^2;\, q^2)_\infty (a^2q^2/c^2;\, q^2)_\infty (aq^2;\, q^2)_\infty (aq^2/b^2c^2;\, q^2)_\infty}.
$$

Replacing aq/b^2, aq/bc, and c by b, c, and $\sqrt{abq}/c$, respectively, we obtain the following q-analogue of (1.5):

(3.21)

$$
{}_8\phi_7\left[\begin{matrix} -c\sqrt{ab/q}, q\sqrt{\cdot}, -q\sqrt{\cdot}, a, b, c, -c, -c^{-1}\sqrt{abq} \\ \sqrt{\cdot}, -\sqrt{\cdot}, -c\sqrt{bq/a}, -c\sqrt{aq/b}, -\sqrt{abq}, \sqrt{abq}, c^2 \end{matrix}; q, \frac{c\sqrt{q}}{\sqrt{ab}}\right]
$$

$$
= \frac{(c\sqrt{aq/b}\,;\, q)_\infty (-q;\, q)_\infty (-c\sqrt{abq}\,;\, q)_\infty (c^2/a;\, q)_\infty}{(-aq;\, q)_\infty (c\sqrt{q/ab}\,;\, q)_\infty (c^2;\, q)_\infty (-c\sqrt{bq/a}\,;\, q)_\infty}
$$

$$
\cdot \frac{(a^2q^2;\, q^2)_\infty (bq;\, q^2)_\infty (qc^2/b^2;\, q^2)_\infty (c^2;\, q^2)_\infty}{(abq;\, q^2)_\infty (ac^2q/b^2;\, q^2)_\infty (aq^2;\, q^2)_\infty (c^2/a;\, q^2)_\infty}, \qquad \left|\frac{c^2q}{ab}\right|<1.
$$

To obtain a q-analogue of Whipple's summation formula (1.6) we apply (3.19) to the ${}_8\phi_7$ in (3.20) by identifying A, B, C, D, E, and F with $-a^2q/b^2c$, $-aq/bc$, aq/b^2, a, aq/bc and $-c$, respectively. This yields a summation formula for an ${}_8\phi_7$ which on replacing a, b, c by bc/q, a, c/b, respectively, gives the desired formula

$$(3.22)\quad {}_8\phi_7\left[\begin{matrix} -b, q\sqrt{\cdot}, -q\sqrt{\cdot}, a, q/a, b, -bq/c, -c/b \\ \sqrt{\cdot}, -\sqrt{\cdot}, -bq/a, -ab, -q, c, b^2q/c \end{matrix}; q, b\right]$$

$$= \frac{(-c;q)_\infty(-bq;q)_\infty(ab;q)_\infty(b^2q/ac;q)_\infty}{(b;q)_\infty(b^2q/c;q)_\infty(-ac;q)_\infty(-bq/a;q)_\infty}$$

$$\cdot \frac{(a^2c^2;q^2)_\infty(cq/a;q^2)_\infty(ab^2q/c;q^2)_\infty(b^2;q^2)_\infty}{(c^2;q^2)_\infty(a^2b^2;q^2)_\infty(acq;q^2)_\infty(b^2q/ac;q^2)_\infty}, \qquad |b|<1.$$

Additional summation formulas for ${}_8\phi_7$ series follow by applying the transformation formula (3.19) to formulas (3.21) and (3.22).

It should be noted that if we set a or b in (3.21) equal to q^{-n}, $n=0,1,\cdots$, then we obtain Theorem 1 in Andrews [3] by means of Watson's [16, (3.4.1.5)] transformation formula

$$(3.23)\quad {}_8\phi_7\left[\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b, c, d, e, q^{-n} \\ \sqrt{a}, -\sqrt{a}, aq/b, aq/c, aq/d, aq/e, aq^{n+1} \end{matrix}; \frac{aq^{n+2}}{bcde}\right]$$

$$= \frac{(aq)_n(aq/de)_n}{(aq/d)_n(aq/e)_n}\,{}_4\phi_3\left[\begin{matrix} aq/bc, d, e, q^{-n} \\ de/aq^n, aq/b, aq/c \end{matrix}; q\right].$$

Similarly, Theorem 2 in Andrews [3] follows by applying (3.23) to the case $a=q^{-n}$ of (3.22).

In the next section we will need to use the fact that Sears' summation formula (3.10) is equivalent to the formula

$$(3.24)\quad \int_a^b \frac{(qu/a)_\infty(qu/b)_\infty(cu)_\infty}{(du)_\infty(eu)_\infty(fu)_\infty}\,d_qu$$

$$= \frac{b(1-q)(q)_\infty(bq/a)_\infty(a/b)_\infty(c/d)_\infty(c/e)_\infty(c/f)_\infty}{(ad)_\infty(ae)_\infty(af)_\infty(bd)_\infty(be)_\infty(bf)_\infty},$$

where $c=abdef$, which is also equivalent to the q-beta formula (1.3) in Al-Salam and Verma [1]. Likewise, Bailey's transformation formula (3.15) is equivalent to

$$(3.25)\quad \int_a^b d_qu \frac{(qu/a)_\infty(qu/b)_\infty(cu)_\infty(du)_\infty}{(eu)_\infty(fu)_\infty(gu)_\infty(hu)_\infty}$$

$$= \frac{b(1-q)(q)_\infty(bq/a)_\infty(a/b)_\infty(cd/eh)_\infty(cd/fh)_\infty(cd/gh)_\infty(bc)_\infty(bd)_\infty}{(ae)_\infty(af)_\infty(ag)_\infty(be)_\infty(bf)_\infty(bg)_\infty(bh)_\infty(bcd/h)_\infty}$$

$$\cdot {}_8\phi_7\left[\begin{matrix} bcd/hq, q\sqrt{\cdot}, -q\sqrt{\cdot}, be, bf, bg, c/h, d/h \\ \sqrt{\cdot}, -\sqrt{\cdot}, cd/eh, cd/fh, cd/gh, bd, bc \end{matrix}; cd/befg\right],$$

where $cd=abefgh$. It should also be observed that formula (IV.15) in [16] for the sum of two ${}_8\phi_7$ series is equivalent to

(3.26)

$$\int_a^b \frac{(qu/a)_\infty (qu/b)_\infty (u/\sqrt{a})_\infty (-u/\sqrt{a})_\infty (qu/c)_\infty (qu/d)_\infty (qu/e)_\infty (qu/f)_\infty}{(u)_\infty (qu/\sqrt{a})_\infty (-qu/\sqrt{a})_\infty (bu/a)_\infty (cu/a)_\infty (du/a)_\infty (eu/a)_\infty (fu/a)_\infty} d_q u$$

$$= \frac{a(q-1)(q)_\infty (aq/b)_\infty (b/a)_\infty (aq/cd)_\infty}{(b)_\infty (c)_\infty (d)_\infty (e)_\infty (f)_\infty}$$

$$\cdot \frac{(aq/ce)_\infty (aq/de)_\infty (ae/cf)_\infty (aq/df)_\infty (aq/ef)_\infty}{(bc/a)_\infty (bd/a)_\infty (be/a)_\infty (bf/a)_\infty},$$

where $a^2q=bcdef$, which has (3.24) as a limit case.

As usual, in (3.26) and other formulas it is assumed that no zero factors appear in the denominator.

4. Some generating functions for q-Wilson polynomials. Here, as an introduction to the method that we will apply to the Poisson kernel, we first consider the simpler sum

$$G_t(x;\, a,b,c,d;\, q) = \sum_{n=0}^{\infty} \frac{(abcd/q)_n (ad)_n}{(q)_n (bc)_n} \left(\frac{t}{a}\right)^n p_n(x;\, a,b,c,d;\, q), \tag{4.1}$$

which, by the asymptotic formula for the q-Wilson polynomials in Ismail and Wilson [12, (1.13)], converges for $|t|<1$ when $-1<x<1$. Unfortunately, if the ${}_4\phi_3$ series representation for $p_n(x;\, a,b,c,d;\, q)$ in (2.5) is used in (4.1), then we cannot change the order of summation and sum over n since, due to the term q^{-n} in the numerator of the ${}_4\phi_3$ series, this leads to a divergent series when $t\neq 0$. This divergence problem also keeps us from applying the product formulas in Gasper and Rahman [10] to the Poisson kernel (2.9). To overcome this difficulty in (4.1) we can either use (3.23) to write the q-Wilson polynomial in terms of a ${}_8\phi_7$ in which q^{-n} also appears in the denominator or write it as an appropriate sum of ${}_4\phi_3$ or ${}_8\phi_7$ series. Here we shall employ the q-integral representation

(4.2)

$$p_n(x;\, a,b,c,d;\, q)$$

$$= A(\theta) \frac{(bc)_n}{(ad)_n} \int_{qe^{i\theta}/d}^{qe^{-i\theta}/d} \frac{(abcdu/q)_\infty (due^{i\theta})_\infty (due^{-i\theta})_\infty (q/u)_n}{(cdu/q)_\infty (bdu/q)_\infty (adu/q)_\infty (abcdu/q)_n} \left(\frac{adu}{q}\right)^n d_q u,$$

where

$$A(\theta) = \frac{2id}{q(1-q)(q)_\infty (ab)_\infty (ac)_\infty (bc)_\infty (de^{i\theta})_\infty (de^{-i\theta})_\infty w(x;\, a,b,c,d;\, q)}$$

with $x=\cos\theta$, which follows from formula (3.3) in Al-Salam and Verma [1] and is equivalent to a representation as a sum of two ${}_4\phi_3$ series.

After substituting (4.2) into (4.1) we can now sum over n to obtain

$$(4.3)\qquad G_t(x;\,a,b,c,d;\,q)=A(\theta)\int_{qe^{i\theta}/d}^{qe^{-i\theta}/d}\frac{(abcdu/q)_\infty(due^{i\theta})_\infty(due^{-i\theta})_\infty}{(adu/q)_\infty(bdu/q)_\infty(cdu/q)_\infty}\cdot{}_2\phi_1\left[\begin{matrix}abcd/q,\ q/u\\ abcdu/q\end{matrix};\frac{dtu}{q}\right]d_qu.$$

From (3.6),

$$(4.4)\qquad {}_2\phi_1\left[\begin{matrix}abcd/q,\ q/u\\ abcdu/q\end{matrix};\frac{dtu}{q}\right]=\frac{(abcd/q)_\infty(\alpha u/q)_\infty}{(1-q)(q)_\infty(abcdu/q)_\infty(\alpha)_\infty(\alpha q/dt)_\infty(dt/\alpha)_\infty}\cdot\int_{dt/\alpha}^{1}\frac{(\alpha qv/dt)_\infty(qv)_\infty(abcduv/q)_\infty(\alpha dtv/q)_\infty}{(\alpha v/\sqrt{q})_\infty(-\alpha v/\sqrt{q})_\infty(-\alpha v)_\infty(\alpha uv/q)_\infty}d_qv,$$

with $\alpha=(abcd)^{1/2}$. Using (4.4) in (4.3) and changing the order of integration gives

$$(4.5)\qquad G_t(x;\,a,b,c,d;\,q)=\frac{A(\theta)(abcd/q)_\infty}{(1-q)(q)_\infty(\alpha)_\infty(\alpha q/dt)_\infty(dt/\alpha)_\infty}\cdot\int_{dt/\alpha}^{1}d_qv\frac{(\alpha qv/dt)_\infty(qv)_\infty(\alpha dtv/q)_\infty}{(\alpha v/\sqrt{q})_\infty(-\alpha v/\sqrt{q})_\infty(-\alpha v)_\infty}\cdot\int_{qe^{i\theta}/d}^{qe^{-i\theta}/d}d_qu\frac{(\alpha u/q)_\infty(abcduv/q)_\infty(due^{i\theta})_\infty(due^{-i\theta})_\infty}{(adu/q)_\infty(bdu/q)_\infty(cdu/q)_\infty(\alpha uv/q)_\infty}.$$

At this point if in addition to the assumption that $-1<a,\ b,\ c,\ d<1$, we assume $ad=bc$ then the last integral in (4.5) can be evaluated via (3.24) to give

$$(4.6)\qquad G_t(x;\,a,b,c,bc/a;\,q)=\frac{(b^2c^2/q)_\infty(ae^{i\theta})_\infty(ae^{-i\theta})_\infty}{(1-q)(q)_\infty(bc)_\infty(aq/t)_\infty(t/a)_\infty(ab)_\infty(ac)_\infty}\cdot\int_{t/a}^{1}d_qv\frac{(aqv/t)_\infty(qv)_\infty(b^2c^2tv/aq)_\infty(abv)_\infty(acv)_\infty}{(bcv/\sqrt{q})_\infty(-bcv/\sqrt{q})_\infty(-bcv)_\infty(ave^{i\theta})_\infty(ave^{-i\theta})_\infty}$$

$$=\frac{(b^2c^2t/aq)_\infty}{(t/a)_\infty}\,{}_5\phi_4\left[\begin{matrix}bc/\sqrt{q},\ -bc/\sqrt{q},\ -bc,\ ae^{i\theta},\ ae^{-i\theta}\\ ab,\ ac,\ aq/t,\ b^2c^2t/aq\end{matrix};q\right]+\frac{(bct/a)_\infty(b^2c^2/q)_\infty(bt)_\infty(ct)_\infty(ae^{i\theta})_\infty(ae^{-i\theta})_\infty}{(a/t)_\infty(bc)_\infty(ab)_\infty(ac)_\infty(te^{i\theta})_\infty(te^{-i\theta})_\infty}\cdot{}_5\phi_4\left[\begin{matrix}bct/a\sqrt{q},\ -bct/a\sqrt{q},\ -bct/a,\ te^{i\theta},\ te^{-i\theta}\\ bt,\ ct,\ tq/a,\ b^2c^2t^2/a^2q\end{matrix};q\right].$$

Since

$$(4.7)\quad P_n^{(\alpha,\beta)}(x\,|\,q)=\frac{(q^{\alpha+1})_n}{(q)_n}p_n(x;\ q^{\alpha/2+1/4},\ q^{\alpha/2+3/4},\ -q^{\beta/2+1/4},\ -q^{\beta/2+3/4};\ q)$$

by (2.3), for the continuous q-Jacobi polynomials the sum of two ${}_5\phi_4$ series in (4.6) reduces to a sum of two ${}_4\phi_3$ series and it then follows from (3.15) that

(4.8)

$$G_t(x;\ a,b,c,d;\ q)=\frac{(bt/\sqrt{q})_\infty(bc^2t/\sqrt{q})_\infty(-bcte^{i\theta}/\sqrt{q})_\infty(-bcte^{-i\theta}/\sqrt{q})_\infty}{(-ct)_\infty(-b^2ct/q)_\infty(te^{i\theta})_\infty(te^{-i\theta})_\infty}$$

$$\cdot\,{}_8\phi_7\left[\begin{matrix}-b^2ct/q^2,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ -ct/\sqrt{q},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ b^2/\sqrt{q},\ bc^2t/\sqrt{q},\end{matrix}\right.$$

$$\left.\cdot\,\begin{matrix}-b/c\sqrt{q},\ -bc/\sqrt{q},\ be^{i\theta}/\sqrt{q},\ be^{-i\theta}/\sqrt{q}\\ bt/\sqrt{q},\ -bcte^{-i\theta}/\sqrt{q},\ -bcte^{i\theta}/\sqrt{q}\end{matrix}\ ;\ -ct\sqrt{q}\right]$$

with

$$(4.9)\qquad a=q^{\alpha/2+1/4},\quad b=q^{\alpha/2+3/4},\quad c=-q^{\beta/2+1/4},\quad d=-q^{\beta/2+3/4}.$$

If $\alpha=\beta$, then the r.h.s. of (4.8) degenerates to

$$\frac{(te^{i\theta}q^{\beta+1/2})_\infty(te^{-i\theta}q^{\beta+1/2})_\infty}{(te^{i\theta})_\infty(te^{-i\theta})_\infty},$$

giving a well-known generating function for the continuous q-ultraspherical polynomials.

Now consider

$$(4.10)\quad K_t(x;\ a,b,c,d;\ q)=\sum_{n=0}^{\infty}\frac{(abcd/q)_n(1-abcdq^{2n-1})}{(q)_n(1-abcdq^{-1})}$$

$$\cdot\,\frac{(ab)_n(ac)_n(ad)_n}{(bc)_n(bd)_n(cd)_n}a^{-2n}t^n p_n(x;\ a,b,c,d;\ q),$$

which is the kernel (2.10) with $p_n(y;\ a,b,c,d;\ q)$ replaced by 1, and converges for $|t|<|a|$ when $-1<x<1$. By employing the above method with (3.7) replaced by (3.6) and using the fact that (via [15, (8.3)])

$$p_n(x;\ a,b,c,d;\ q)=\frac{(bd)_n(cd)_n}{(ab)_n(ac)_n}\left(\frac{a}{d}\right)^n p_n(x;\ d,c,b,a;\ q)$$

we find that

(4.11) $K_t(x;\, a,b,ad/b,d;\, q)$

$$=\frac{(1-t^2)(adqt)_\infty}{(t/ad)_\infty}\,{}_5\phi_4\left[\begin{matrix} ad\sqrt{q}\,,\ -ad\sqrt{q}\,,\ -ad,\ de^{i\theta},\ de^{-i\theta} \\ bd,\ ad^2/b,\ adqt,\ adq/t \end{matrix};q\right]$$

$$+\frac{(t)_\infty(bt/a)_\infty(dt/b)_\infty(a^2d^2)_\infty(de^{i\theta})_\infty(de^{-i\theta})_\infty}{(ad/t)_\infty(ad)_\infty(bd)_\infty(ad^2/b)_\infty(te^{i\theta}/a)_\infty(te^{-i\theta}/a)_\infty}$$

$$\cdot\,{}_5\phi_4\left[\begin{matrix} t\sqrt{q}\,,\ -t\sqrt{q}\,,\ -t,\ te^{i\theta}/a,\ te^{-i\theta}/a \\ bt/a,\ dt/b,\ qt/ad,\ qt^2 \end{matrix};q\right].$$

As above, for the continuous q-Jacobi polynomials it follows from (4.11) and (3.15) that

(4.12)

$$K_t(x;\, a,b,c,d;\, q)=\frac{(1-t^2)(adqt)_\infty(dt/a)_\infty(-dte^{i\theta})_\infty(-dte^{-i\theta})_\infty}{(-t)_\infty(-d^2t)_\infty(te^{i\theta}/a)_\infty(te^{-i\theta}/a)_\infty}$$

$$\cdot\,{}_8\phi_7\left[\begin{matrix} -d^2t/q,\ q\sqrt{\cdot}\,,\ -q\sqrt{\cdot}\,,\ -t\sqrt{q}\,,\ -d/aq,\ -ad,\ de^{i\theta},\ de^{-i\theta} \\ \sqrt{\cdot}\,,\ -\sqrt{\cdot}\,,\ d^2/\sqrt{q}\,,\ adqt,\ dt/a,\ -dte^{-i\theta},\ -dte^{i\theta} \end{matrix};-tq^{1/2}\right]$$

when (4.9) holds. The transformation formula (3.19) can be applied to the ${}_8\phi_7$ series in (4.8) and (4.12) to give cases in which these generating functions are positive, but we shall not do so here, since we are primarily concerned with the positivity of the Poisson kernel.

5. The kernel $K_t(x, y; a, b, c, d; q)$. Let $x=\cos\theta$, $y=\cos\phi$, $0\leqq t<1$, $0\leqq q<1$, and let a, b, c, d be real. Since, by (4.2),

(5.1)

$$p_n(x;\, a,b,c,d;\, q)\,p_n(y;\, a,b,c,d;\, q)$$

$$=B(\theta,\phi)\frac{(cd)_n(bd)_n}{(ab)_n(ac)_n}\int_{qe^{i\theta}/b}^{qe^{-i\theta}/b}d_qu\,\frac{(abcdu/q)_\infty(bue^{i\theta})_\infty(bue^{-i\theta})_\infty}{(abu/q)_\infty(bcu/q)_\infty(bdu/q)_\infty}$$

$$\cdot\int_{qe^{i\phi}/c}^{qe^{-i\phi}/c}d_qv\,\frac{(abcdv/q)_\infty(cve^{i\phi})_\infty(cve^{-i\phi})_\infty}{(acv/q)_\infty(bcv/q)_\infty(cdv/q)_\infty}\,\frac{(q/u)_n(q/v)_n}{(abcdu/q)_n(abcdv/q)_n}\left(\frac{a^2bcuv}{q^2}\right)^n,$$

with

(5.2)

$$B(\theta,\phi)=B(\theta,\phi;\, a,b,c,d;\, q)$$

$$=\frac{-4bc[w(x;\, a,b,c,d;\, q)w(y;\, a,b,c,d;\, q)]^{-1}}{[q(1-q)(q)_\infty(ad)_\infty]^2(ab)_\infty(ac)_\infty(bd)_\infty(cd)_\infty|(be^{i\theta})_\infty(ce^{i\phi})_\infty|^2},$$

it follows from (2.10) that

$$K_t(x,y;\,a,b,c,d;\,q)$$

$$= B(\theta,\phi)\int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u\,\frac{(abcdu/q)_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty}{(abu/q)_\infty (bcu/q)_\infty (bdu/q)_\infty}$$

$$\cdot \int_{qe^{i\phi}/c}^{qe^{-i\phi}/c} d_q v\,\frac{(abcdv/q)_\infty (cve^{i\phi})_\infty (cve^{-i\phi})_\infty}{(acv/q)_\infty (bcv/q)_\infty (cdv/q)_\infty}$$

$$\cdot {}_6\phi_5\left[\begin{matrix} abcd/q,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ q/u,\ q/v,\ ad \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ abcdu/q,\ abcdv/q,\ bc \end{matrix};\ \frac{bcuvt}{q^2}\right].$$

At this point we have to assume that

$$ad = bc, \tag{5.4}$$

so that the above ${}_6\phi_5$ reduces to a ${}_5\phi_4$ to which we can apply formula (3.5) or (3.7). Here we shall apply formula (3.5) since, as we shall see, the first ${}_5\phi_4$ on the r.h.s. of (3.5) leads to a single sum of a terminating ${}_{10}\phi_9$ series. This yields

(5.5)

$$K_t(x,y;\,a,b,c,bc/a;\,q)$$

$$= B(\theta,\phi;\,a,b,c,bc/a;\,q)(1-t^2)\frac{(bcqt)_\infty}{(t/bc)_\infty}$$

$$\cdot \sum_{k=0}^{\infty} \frac{(b^2c^2)_{2k}q^k}{(q)_k (bcqt)_k (bcq/t)_k} \int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u\,\frac{(b^2c^2uq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty}{(abu/q)_\infty (bcu/q)_\infty (b^2cu/aq)_\infty}$$

$$\cdot \int_{qe^{i\phi}/c}^{qe^{-i\phi}/c} d_q v\,\frac{(b^2c^2vq^{k-1})_\infty (cve^{i\phi})_\infty (cve^{-i\phi})_\infty (b^2c^2uv/q^2)_\infty}{(acv/q)_\infty (bcv/q)_\infty (bc^2v/aq)_\infty (b^2c^2uvq^{k-2})_\infty}$$

$$+ B(\theta,\phi;\,a,b,c,bc/a;\,q)\frac{(b^2c^2)_\infty}{(bc/t)_\infty} \sum_{k=0}^{\infty} \frac{(t^2)_{2k}q^k}{(q)_k (qt/bc)_k (qt^2)_k}$$

$$\cdot \int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u\,\frac{(bcutq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty}{(abu/q)_\infty (bcu/q)_\infty (b^2cu/aq)_\infty}$$

$$\cdot \int_{qe^{i\phi}/c}^{qe^{-i\phi}/c} d_q v\,\frac{(bcvtq^{k-1})_\infty (cve^{i\phi})_\infty (cve^{-i\phi})_\infty (b^2c^2uv/q^2)_\infty}{(acv/q)_\infty (bcv/q)_\infty (bc^2v/aq)_\infty (bcuvtq^{k-2})_\infty}.$$

From (3.15),

(5.6)

$$\int_{qe^{i\phi}/c}^{qe^{-i\phi}/c} d_q v \frac{(b^2c^2vq^{k-1})_\infty (cve^{i\phi})_\infty (cve^{-i\phi})_\infty (b^2c^2uv/q^2)_\infty}{(acv/q)_\infty (bcv/q)_\infty (bc^2v/aq)_\infty (b^2c^2uvq^{k-2})_\infty}$$

$$= \frac{q(1-q)(q)_\infty (b^2c/a)_\infty (ab)_\infty (bc)_\infty (e^{2i\phi})_\infty (e^{-2i\phi})_\infty}{2ci\sin\phi (b^2ce^{-i\phi})_\infty (ae^{i\phi})_\infty (be^{i\phi})_\infty (bce^{i\phi}/a)_\infty (bce^{-i\phi}/a)_\infty}$$

$$\cdot \frac{(b^2ce^{-i\phi}q^k)_\infty (b^2cue^{-i\phi}/q)_\infty}{(ae^{-i\phi})_\infty (be^{-i\phi})_\infty (b^2cue^{-i\phi}q^{k-1})_\infty}$$

$$\cdot {}_8\phi_7\left[\begin{matrix} b^2ce^{-i\phi}/q, q\sqrt{\cdot}, -q\sqrt{\cdot}, bce^{-i\phi}/a, be^{-i\phi}, q/u, ae^{-i\phi}, q^{-k} \\ \sqrt{\cdot}, -\sqrt{\cdot}, ab, bc, b^2cue^{-i\phi}/q, b^2c/a, b^2ce^{-i\phi}q^k \end{matrix}; b^2cue^{i\phi}q^{k-1}\right]$$

$$= \frac{q(1-q)}{2ci}(q)_\infty (ab)_\infty (bc)_\infty (b^2c/a)_\infty (ce^{i\phi})_\infty (ce^{-i\phi})_\infty w(y; a,b,c,bc/a; q)$$

$$\cdot \frac{(b^2cu/aq)_k}{(b^2c/a)_k} {}_4\phi_3\left[\begin{matrix} q^{-k}, q/u, ae^{i\phi}, ae^{-i\phi} \\ ab, bc, a/b^2cuq^{k-2} \end{matrix}; q\right]$$

by (3.23). Hence

(5.7)

$$\int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u \frac{(b^2c^2uq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty}{(abu/q)_\infty (bcu/q)_\infty (b^2cu/aq)_\infty} \int_{qe^{i\phi}/c}^{qe^{-i\phi}/c} d_q v \cdots$$

$$= \frac{q(1-q)}{2ci}(q)_\infty (ab)_\infty (bc)_\infty (b^2c/a)_\infty (ce^{i\phi})_\infty (ce^{-i\phi})_\infty w(y; a,b,c,bc/a; q)$$

$$\cdot \sum_{j=0}^{k} \frac{(q)_k (ae^{i\phi})_j (ae^{-i\phi})_j}{(q)_j (q)_{k-j} (ab)_j (bc)_j (b^2c/a)_k} \left(\frac{b^2c}{aq}\right)^j$$

$$\cdot \int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u \frac{(b^2c^2uq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty (q/u)_j u^j}{(abu/q)_\infty (bcu/q)_\infty (a^{-1}b^2cuq^{k-j-1})_\infty}$$

$$= -\frac{[q(1-q)(q)_\infty (bc)_\infty]^2 (ab)_\infty (ac)_\infty (b^2c/a)_\infty (bc^2/a)_\infty}{4bc(bc)_k (b^2c/a)_k (bc^2/a)_k}$$

$$\cdot \left|(be^{i\theta})_\infty (ce^{i\phi})_\infty (bca^{-1}e^{i\theta})_k\right|^2 w(x; a,b,c,bc/a; q) w(y; a,b,c,bc/a; q)$$

$$\cdot \sum_{j=0}^{k} \frac{(q^{-k})_j (a/bc^2q^{k-1})_j \left|(ae^{i\phi})_j\right|^2}{(q)_j (ab)_j \left|(ae^{i\theta}/bcq^{k-1})_j\right|^2} q^j$$

$$\cdot {}_4\phi_3\left[\begin{matrix} q^{-j}, b^2c^2q^{k-1}, ce^{i\theta}, ce^{-i\theta} \\ ac, bc, bc^2a^{-1}q^{k-j} \end{matrix}; q\right]$$

by using (3.15) and (3.23) as in (5.6). Consequently, the first term on the r.h.s. of (5.5) gives

$$(5.8)\qquad (1-t^2)\frac{(bcqt)_\infty}{(t/bc)_\infty}\sum_{k=0}^{\infty}\frac{(-bc)_k\left(bc\sqrt{q}\right)_k\left(-bc\sqrt{q}\right)_k\left|\left(bca^{-1}e^{i\theta}\right)_k\right|^2}{(q)_k\left(bc^2/a\right)_k\left(b^2c/a\right)_k(bcqt)_k(bcq/t)_k}q^k$$

$$\cdot\sum_{j=0}^{k}\frac{\left(q^{-k}\right)_j\left(a/bc^2q^{k-1}\right)_j\left|\left(ae^{i\theta}\right)_j\right|^2}{(q)_j(ab)_j\left|\left(ae^{i\theta}/bcq^{k-1}\right)_j\right|^2}q^j$$

$$\cdot\,{}_4\phi_3\left[\begin{matrix}q^{-j},\ b^2c^2q^{k-1},\ ce^{i\theta},\ ce^{-i\theta}\\ ac,\ bc,\ bc^2a^{-1}q^{k-j}\end{matrix};q\right].$$

Transforming the above ${}_4\phi_3$ via [15, (8.3)], the sum over j in (5.8) becomes

(5.9)

$$\sum_{j=0}^{k}\frac{\left(q^{-k}\right)_j\left(b^{-1}c^{-1}q^{1-k}\right)_j\left|\left(ae^{i\phi}\right)_j\right|^2q^j}{(q)_j(bc)_j\left|\left(ae^{i\theta}/bcq^{k-1}\right)_j\right|^2}\,{}_4\phi_3\left[\begin{matrix}q^{-j},\ b^2c^2q^{k-1},\ ae^{i\theta},\ ae^{-i\theta}\\ ab,\ ac,\ bcq^{k-j}\end{matrix};q\right]$$

$$=\sum_{j=0}^{k}\frac{\left(q^{-k}\right)_j\left|\left(ae^{i\phi}\right)_j\right|^2q^j}{(q)_j(bc)_j\left(a^2/bcq^{k-1}\right)_j}\,{}_8\phi_7\left[\begin{matrix}a^2/bcq^k,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ a/b^2cq^{k-1},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ ab,\end{matrix}\right.$$

$$\left.\begin{matrix}a/bc^2q^{k-1},\ ae^{i\theta},\ ae^{-i\theta},\ q^{-j}\\ ac,\ ae^{-i\theta}/bcq^{k-1},\ ae^{i\theta}/bcq^{k-1},\ a^2/bcq^{k-j-1}\end{matrix};bcq^j\right]$$

$$=\sum_{m=0}^{k}\frac{\left(a^2/bcq^k\right)_m\left(q\sqrt{\cdot}\right)_m\left(-q\sqrt{\cdot}\right)_m\left(a/b^2cq^{k-1}\right)_m\left(a/bc^2q^{k-1}\right)_m\left|\left(ae^{i\theta}\right)_m\right|^2}{(q)_m\left(\sqrt{\cdot}\right)_m\left(-\sqrt{\cdot}\right)_m(ab)_m(ac)_m(bc)_m\left(a^2/bcq^{k-1}\right)_{2m}\left|\left(ae^{i\theta}/bcq^{k-1}\right)_m\right|^2}$$

$$\cdot(-1)^mq^{m(m+1)/2}(bc)^m\left(q^{-k}\right)_m\left|\left(ae^{i\phi}\right)_m\right|^2$$

$$\cdot\,{}_3\phi_2\left[\begin{matrix}q^{m-k},\ ae^{i\phi}q^m,\ ae^{-i\phi}q^m\\ bcq^m,\ a^2/bcq^{k-2m-1}\end{matrix};q\right]$$

$$=\frac{\left|\left(bce^{i\phi}/a\right)_k\right|^2}{(bc)_k\left(bc/a^2\right)_k}\,{}_{10}\phi_9\left[\begin{matrix}a^2/bcq^k,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ a/b^2cq^{k-1},\ a/bc^2q^{k-1},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ ab,\ ac,\end{matrix}\right.$$

$$\left.\begin{matrix}ae^{i\theta},\ ae^{-i\theta},\ ae^{i\phi},\ ae^{-i\phi},\ q^{-k}\\ ae^{-i\theta}/bcq^{k-1},\ ae^{i\theta}/bcq^{k-1},\ ae^{-i\phi}/bcq^{k-1},\ ae^{i\phi}/bcq^{k-1},\ a^2q/bc\end{matrix};q\right]$$

by (3.23) and (3.12).

Hence, the first term on the r.h.s. of (5.5) equals

(5.10)

$$(1-t^2)\frac{(bcqt)_\infty}{(t/bc)_\infty}\sum_{k=0}^{\infty}\frac{(-bc)_k(bc\sqrt{q})_k(-bc\sqrt{q})_k|(bce^{i\theta}/a)_k(bce^{i\phi}/a)_k|^2q^k}{(q)_k(bc^2/a)_k(b^2c/a)_k(bc)_k(bc/a^2)_k(bcqt)_k(bcq/t)_k}$$

$$\cdot{}_{10}\phi_9\left[\begin{matrix}a^2/bcq^k, q\sqrt{\cdot}, -q\sqrt{\cdot}, a/b^2cq^{k-1}, a/bc^2q^{k-1}, ae^{i\theta},\\ \sqrt{\cdot}, -\sqrt{\cdot}, ab, ac, ae^{-i\theta}/bcq^{k-1},\end{matrix}\right.$$

$$\left.\begin{matrix}ae^{-i\theta}, ae^{i\phi}, ae^{-i\phi}, q^{-k}\\ ae^{i\theta}/bcq^{k-1}, ae^{-i\phi}/bcq^{k-1}, ae^{i\phi}/bcq^{k-1}, a^2q/bc\end{matrix};q\right].$$

Let us now compute the second term on the r.h.s. of (5.5). From (3.15),

(5.11)

$$\int_{qe^{i\phi}/c}^{qe^{-i\phi}/c}d_qv\frac{(bcvtq^{k-1})_\infty(cve^{i\phi})_\infty(cve^{-i\phi})_\infty(b^2c^2uv/q^2)_\infty}{(acv/q)_\infty(bcv/q)_\infty(bc^2v/aq)_\infty(bcuvtq^{k-2})_\infty}$$

$$=\frac{q(1-q)}{2ci}(q)_\infty(ab)_\infty(bc)_\infty(b^2c/a)_\infty|(ce^{i\phi})_\infty|^2w(y;a,b,c,bc/a;q)$$

$$\cdot\frac{(btq^ke^{-i\phi})_\infty(b^2cuq^{-1}e^{-i\phi})_\infty}{(butq^{k-1}e^{-i\phi})_\infty(b^2ce^{-i\phi})_\infty}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}b^2ce^{-i\phi}/q, q\sqrt{\cdot}, -q\sqrt{\cdot}, bce^{-i\phi}/a, be^{-i\phi}, q/u, bct^{-1}q^{-k}, ae^{-i\phi}\\ \sqrt{\cdot}, -\sqrt{\cdot}, ab, bc, b^2cue^{-i\phi}/q, btq^ke^{-i\phi}, b^2c/a\end{matrix};butq^{k-1}e^{i\phi}\right].$$

Unfortunately, since this ${}_8\phi_7$ does not terminate we cannot apply formula (3.23) to it as in (5.6). However, we can still apply (3.15) to it to obtain

$$\int_{qe^{i\phi}/c}^{qe^{-i\phi}/c}d_qv\ldots$$

$$=\frac{q(1-q)(q)_\infty(bc)_\infty(b^2cu/aq)_\infty(abutq^k)_\infty(tbq^k/a)_\infty|(be^{i\phi})_\infty(ce^{i\phi})_\infty|^2}{2ci(b/a)_\infty(butq^{k-1}e^{i\phi})_\infty(butq^{k-1}e^{-i\phi})_\infty}$$

$$\cdot w(y;a,b,c,bc/a;q)\,{}_4\phi_3\left[\begin{matrix}tq^k, bcu/q, ae^{i\phi}, ae^{-i\phi}\\ bc, aq/b, abutq^{k-1}\end{matrix};q\right]$$

$$+\frac{q(1-q)(q)_\infty(bcu/q)_\infty(b^2c/a)_\infty(tq^k)_\infty(b^2utq^{k-1})_\infty|(ae^{i\phi})_\infty(ce^{i\phi})_\infty|^2}{2ci(a/b)_\infty(butq^{k-1}e^{i\phi})_\infty(butq^{k-1}e^{-i\phi})_\infty}$$

$$\cdot w(y;a,b,c,bc/a;q)\,{}_4\phi_3\left[\begin{matrix}tbq^k/a, b^2cu/aq, be^{i\phi}, be^{-i\phi}\\ bq/a, b^2c/a, b^2utq^{k-1}\end{matrix};q\right].$$

Therefore,

(5.12)

$$\int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u \frac{(bcutq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty}{(abu/q)_\infty (bcu/q)_\infty (b^2cu/aq)_\infty} \int_{qe^{i\theta}/c}^{qe^{-i\theta}/c} d_q v \dots$$

$$= \frac{q(1-q)(q)_\infty}{2ci(b/a)_\infty} (bc)_\infty (btq^k/a)_\infty \left|(be^{i\phi})_\infty (ce^{i\phi})_\infty\right|^2 w(y;\, a,b,c,bc/a;\, q)$$

$$\cdot \sum_{r=0}^{\infty} \frac{(tq^k)_r \left|(ae^{i\phi})_r\right|^2 q^r}{(q)_r (bc)_r (aq/b)_r}$$

$$\cdot \int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u \frac{(bcutq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty (abutq^{k+r-1})_\infty}{(abu/q)_\infty (bcuq^{r-1})_\infty (butq^{k-1}e^{i\phi})_\infty (butq^{k-1}e^{-i\phi})_\infty}$$

$$+ \frac{q(1-q)(q)_\infty}{2ci(a/b)_\infty} (b^2c/a)_\infty (tq^k)_\infty \left|(ae^{i\phi})_\infty (ce^{i\phi})_\infty\right|^2 w(y;\, a,b,c,bc/a;\, q)$$

$$\cdot \sum_{r=0}^{\infty} \frac{(btq^k/a)_r \left|(be^{i\phi})_r\right|^2 q^r}{(q)_r (bq/a)_r (b^2c/a)_r}$$

$$\cdot \int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} \frac{(bcutq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty (b^2utq^{k+r-1})_\infty}{(abu/q)_\infty (butq^{k-1}e^{i\phi})_\infty (butq^{k-1}e^{-i\phi})_\infty (b^2cuq^{r-1}/a)_\infty}.$$

Since, by (3.15) and (3.19),

$$\int_{qe^{i\theta}/b}^{qe^{-i\theta}/b} d_q u \frac{(bcutq^{k-1})_\infty (bue^{i\theta})_\infty (bue^{-i\theta})_\infty (abutq^{k+r-1})_\infty}{(abu/q)_\infty (bcuq^{r-1})_\infty (butq^{k-1}e^{i\phi})_\infty (butq^{k-1}e^{-i\phi})_\infty}$$

$$= \frac{q(1-q)}{2bi\sin\theta} \frac{(q)_\infty (acq^r)_\infty \left|(e^{2i\theta})_\infty\right|^2 (atq^k e^{i\phi})_\infty (ctq^{k+r}e^{i\phi})_\infty}{(actq^{k+r}e^{i\phi-i\theta})_\infty \left|(tq^k e^{i\theta+i\phi})_\infty (ae^{i\theta})_\infty (cq^r e^{i\theta})_\infty\right|^2}$$

$$\cdot \frac{(ctq^k e^{-i\theta})_\infty (atq^{k+r}e^{-i\theta})_\infty}{(tq^k e^{i\phi-i\theta})_\infty} {}_8\Phi_7\left[\begin{matrix} actq^{k+r-1}e^{i\phi-i\theta},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ tq^k e^{i\phi-i\theta}, \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ acq^r, \\ aq^r e^{i\phi},\ cq^r e^{-i\theta},\ ce^{i\phi},\ ae^{-i\theta} \\ ctq^k e^{-i\theta},\ atq^k e^{i\phi},\ atq^{k+r}e^{-i\theta},\ ctq^{k+r}e^{i\phi} \end{matrix};\, tq^k e^{i\theta-i\phi}\right]$$

$$= \frac{q(1-q)}{2bi} w(x;\, a,b,c,bc/a;\, q)(q)_\infty (ac)_\infty (tq^k)_\infty \left|(be^{i\theta})_\infty (bca^{-1}e^{i\theta})_\infty\right|^2$$

$$\cdot \frac{\left|(atq^k e^{i\phi})_\infty (ctq^k e^{i\theta})_\infty (ce^{i\theta})_r\right|^2}{\left|(tq^k e^{i\theta+i\phi})_\infty (tq^k e^{i\theta-i\phi})_\infty\right|^2 (actq^k)_\infty (ac)_r (tq^k)_r}$$

$$\cdot {}_8\Phi_7\left[\begin{matrix} actq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ tq^{k-r},\ ae^{i\theta},\ ae^{-i\theta},\ ce^{i\phi},\ ce^{-i\phi} \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ acq^r,\ ctq^k e^{-i\theta},\ ctq^k e^{i\theta},\ atq^k e^{-i\phi},\ atq^k e^{i\phi} \end{matrix};\, tq^{k+r}\right],$$

the first term on the r.h.s. of (5.12) equals

(5.13)

$$-\frac{[q(1-q)(q)_\infty]^2}{4bc}w(x;\,a,b,c,bc/a;\,q)w(y;\,a,b,c,bc/a;\,q)_\infty(ac)_\infty(bc)_\infty$$

$$\cdot\frac{(tq^k)_\infty(btq^k/a)_\infty\left|(be^{i\phi})_\infty(ce^{i\phi})_\infty(be^{i\theta})_\infty(bce^{i\theta}/a)_\infty(atq^ke^{i\phi})_\infty(ctq^ke^{i\theta})_\infty\right|^2}{(b/a)_\infty(actq^k)_\infty\left|(tq^ke^{i\theta+i\phi})_\infty(tq^ke^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot\sum_{r=0}^{\infty}\frac{\left|(ae^{i\phi})_r(ce^{i\theta})_r\right|^2q^r}{(q)_r(ac)_r(bc)_r(aq/b)_r}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}actq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ tq^{k-r},\ ae^{i\theta},\ ae^{-i\theta},\ ce^{i\phi},\ ce^{-i\phi}\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ acq^r,\ ctq^ke^{-i\theta},\ ctq^ke^{i\theta},\ atq^ke^{-i\phi},\ atq^ke^{i\phi}\end{matrix};\,tq^{k+r}\right].$$

Similarly, since

$$\int_{qe^{i\theta}/b}^{qe^{-i\theta}/b}d_qu\,\frac{(bcutq^{k-1})_\infty(bue^{i\theta})_\infty(bue^{-i\theta})_\infty(b^2utq^{k+r-1})_\infty}{(abu/q)_\infty(butq^{k-1}e^{i\phi})_\infty(butq^{k-1}e^{-i\phi})_\infty(b^2cuq^{r-1}/a)_\infty}$$

$$=\frac{q(1-q)}{2bi\sin\theta}\,\frac{(q)_\infty(bcq^r)_\infty\left|(e^{2i\theta})_\infty\right|^2(btq^{k+r}e^{-i\theta})_\infty}{(bctq^{k+r}e^{i\phi-i\theta})_\infty(tq^ke^{i\phi-i\theta})_\infty}$$

$$\cdot\frac{(ctq^ke^{-i\theta})_\infty(atq^ke^{i\phi})_\infty(bca^{-1}tq^{k+r}e^{i\phi})_\infty}{\left|(ae^{i\theta})_\infty(bca^{-1}q^re^{i\theta})_\infty(tq^ke^{i\theta+i\phi})_\infty\right|^2}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}bctq^{k+r-1}e^{i\phi-i\theta},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ bq^re^{i\phi},\ bca^{-1}q^re^{-i\theta},\ tq^ke^{i\phi-i\theta},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ ctq^ke^{-i\theta},\ atq^ke^{i\phi},\ bcq^r,\\ \qquad\qquad ae^{-i\theta},\ ce^{i\phi}\\ bca^{-1}tq^{k+r}e^{i\phi},\ btq^{k+r}e^{-i\theta}\end{matrix};\,tq^ke^{i\theta-i\phi}\right]$$

$$=\frac{q(1-q)}{2bi\sin\theta}\,\frac{(q)_\infty(bcq^r)_\infty(ba^{-1}tq^{k+r})_\infty\left|(e^{2i\theta})_\infty(atq^ke^{i\phi})_\infty(ctq^ke^{i\theta})_\infty\right|^2}{(actq^k)_\infty\left|(ae^{i\theta})_\infty(bca^{-1}q^re^{i\theta})_\infty(tq^ke^{i\theta+i\phi})_\infty(tq^ke^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}actq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ ab^{-1}tq^{k-r},\ ae^{i\theta},\ ae^{-i\theta},\ ce^{i\phi},\ ce^{-i\phi}\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bcq^r,\ ctq^ke^{-i\theta},\ ctq^ke^{i\theta},\ atq^ke^{-i\phi},\ atq^ke^{i\phi}\end{matrix};\,ba^{-1}tq^{k+r}\right],$$

the second term on the r.h.s. of (5.12) equals

(5.14)

$$-\frac{[q(1-q)(q)_\infty]^2}{4bc}w(x;\,a,b,c,bc/a;\,q)w(y;\,a,b,c,bc/a;\,q)(bc)_\infty(b^2c/a)_\infty$$

$$\cdot\frac{(tq^k)_\infty(ba^{-1}tq^k)_\infty\left|(ae^{i\phi})_\infty(be^{i\theta})_\infty(ce^{i\theta})_\infty(ce^{i\phi})_\infty(atq^ke^{i\phi})_\infty(ctq^ke^{i\theta})_\infty\right|^2}{(a/b)_\infty(actq^k)_\infty\left|(tq^ke^{i\theta+i\phi})_\infty(tq^ke^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot\sum_{r=0}^{\infty}\frac{\left|(be^{i\phi})_r(bca^{-1}e^{i\theta})_r\right|^2q^r}{(q)_r(bc)_r(bq/a)_r(b^2c/a)_r}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}actq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ ab^{-1}tq^{k-r},\ ae^{i\theta},\ ae^{-i\theta},\ ce^{i\phi},\ ce^{-i\phi}\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bcq^r,\ ctq^ke^{-i\theta},\ ctq^ke^{i\theta},\ atq^ke^{-i\phi},\ atq^ke^{i\phi}\end{matrix};ba^{-1}tq^{k+r}\right].$$

At this stage it is possible to apply (3.19) to the ${}_8\phi_7$ series in (5.13) and (5.14) to get a representation for $K_t(x,y;\,a,b,c,bc/a;\,q)$ as the sum (5.10) plus two double sums of ${}_8\phi_7$ series which shows that this kernel is nonnegative in the continuous q-Jacobi case (4.9) for $\alpha,\beta>-1$ when $0\leqq t<q^{1/2}$. But in order to handle the full range $0\leqq t<1$ we need to use the deeper procedure in the next section.

6. Positivity of $P_t(x,y;\,a,\,b,\,c,\,bc/a;\,q)$. The above-mentioned procedure involves first using (3.15) to see that the ${}_8\phi_7$ series in (5.13) equals

$$\frac{(actq^k)_\infty(atq^k/c)_\infty\left|(aq^re^{i\phi})_\infty\right|^2}{(acq^r)_\infty(aq^r/c)_\infty\left|(atq^ke^{i\phi})_\infty\right|^2}\,{}_4\phi_3\left[\begin{matrix}ctq^k/a,\ tq^{k-r},\ ce^{i\phi},\ ce^{-i\phi}\\ c/aq^{r-1},\ ctq^ke^{i\theta},\ ctq^ke^{-i\theta}\end{matrix};q\right]$$

$$+\frac{(actq^k)_\infty(ctq^k/a)_\infty(tq^{k-r})_\infty\left|(ce^{i\phi})_\infty(atq^{k+r}e^{i\theta})_\infty\right|^2}{(acq^r)_\infty(tq^{k+r})_\infty(c/aq^r)_\infty\left|(ctq^ke^{i\theta})_\infty(atq^ke^{i\phi})_\infty\right|^2}$$

$$\cdot{}_4\phi_3\left[\begin{matrix}atq^k/c,\ tq^{k+r},\ aq^re^{i\phi},\ aq^re^{-i\phi}\\ ac^{-1}q^{r+1},\ atq^{k+r}e^{i\theta},\ atq^{k+r}e^{-i\theta}\end{matrix};q\right]$$

and the ${}_8\phi_7$ series in (5.14) equals

$$\frac{(actq^k)_\infty(atq^k/c)_\infty\left|(bq^re^{i\phi})_\infty\right|^2}{(bcq^r)_\infty(bq^r/c)_\infty\left|(atq^ke^{i\phi})_\infty\right|^2}\,{}_4\phi_3\left[\begin{matrix}ctq^k/a,\ ab^{-1}tq^{k-r},\ ce^{i\phi},\ ce^{-i\phi}\\ c/bq^{r-1},\ ctq^ke^{i\theta},\ ctq^ke^{-i\theta}\end{matrix};q\right]$$

$$+\frac{(actq^k)_\infty(ctq^k/a)_\infty(ab^{-1}tq^{k-r})_\infty\left|(ce^{i\phi})_\infty(btq^{k+r}e^{i\theta})_\infty\right|^2}{(bcq^r)_\infty(ba^{-1}tq^{k+r})_\infty(c/bq^r)_\infty\left|(ctq^ke^{i\theta})_\infty(atq^ke^{i\phi})_\infty\right|^2}$$

$$\cdot{}_4\phi_3\left[\begin{matrix}atq^k/c,\ ba^{-1}tq^{k+r},\ bq^re^{i\phi},\ bq^re^{-i\phi},\\ bc^{-1}q^{r+1},\ btq^{k+r}e^{i\theta},\ btq^{k+r}e^{-i\theta}\end{matrix};q\right].$$

Using the above in (5.13) and (5.14) and writing

$$V(x,y) \equiv -\frac{[q(1-q)(q)_\infty]^2}{4bc} w(x;\, a,b,c,bc/a;\, q)w(y;\, a,b,c,bc/a;\, q)$$

it follows by regrouping that we can write the r.h.s. of (5.12) in the form $G_1(x,y)+G_2(x,y)$ with

(6.1)

$$G_1(x,y) = \frac{V(x,y)(b^2c/a)_\infty |(ae^{i\phi})_\infty (be^{i\phi})_\infty (ce^{i\phi})_\infty (be^{i\theta})_\infty (ce^{i\theta})_\infty (ctq^k e^{i\theta})_\infty|^2}{(b/c)_\infty (a/b)_\infty |(tq^k e^{i\theta+i\phi})_\infty (tq^k e^{i\theta-i\phi})_\infty|^2}$$

$$\cdot (btq^k/a)_\infty (atq^k/c)_\infty (tq^k)_\infty \sum_{r=0}^{\infty} \frac{(b/c)_r |(bce^{i\theta}/a)_r|^2 q^r}{(q)_r (bq/a)_r (b^2c/a)_r}$$

$$\cdot {}_4\phi_3\left[\begin{matrix} ctq^k/a,\ ab^{-1}tq^{k-r},\ ce^{i\phi},\ ce^{-i\phi} \\ c/bq^{r-1},\ ctq^k e^{i\theta},\ ctq^k e^{-i\theta} \end{matrix};\, q\right]$$

$$+ \frac{V(x,y)(bc)_\infty |(ae^{i\phi})_\infty (be^{i\phi})_\infty (ce^{i\phi})_\infty (be^{i\theta})_\infty (bce^{i\theta}/a)_\infty (ctq^k e^{i\theta})_\infty|^2}{(a/c)_\infty (b/a)_\infty |(tq^k e^{i\theta+i\phi})_\infty (tq^k e^{i\theta-i\phi})_\infty|^2}$$

$$\cdot (btq^k/a)_\infty (atq^k/c)_\infty (tq^k)_\infty \sum_{r=0}^{\infty} \frac{(a/c)_r |(ce^{i\theta})_r|^2 q^r}{(q)_r (bc)_r (aq/b)_r}$$

$$\cdot {}_4\phi_3\left[\begin{matrix} ctq^k/a,\ tq^{k-r},\ ce^{i\phi},\ ce^{-i\phi} \\ c/aq^{r-1},\ ctq^k e^{i\theta},\ ctq^k e^{-i\theta} \end{matrix};\, q\right]$$

and

(6.2)

$$G_2(x,y) = \frac{V(x,y)(b^2c/a)_\infty |(ae^{i\phi})_\infty (ce^{i\phi})_\infty (ce^{i\phi})_\infty (be^{i\theta})_\infty (ce^{i\theta})_\infty (btq^k e^{i\theta})_\infty|^2}{(c/b)_\infty (a/b)_\infty |(tq^k e^{i\theta+i\phi})_\infty (tq^k e^{i\theta-i\phi})_\infty|^2}$$

$$\cdot (ctq^k/a)_\infty (atq^k/b)_\infty (tq^k)_\infty \sum_{r=0}^{\infty}\sum_{s=0}^{\infty} \frac{(btq^k/a)_{r+s} |(be^{i\phi})_{r+s}|^2}{(q)_r (q)_s |(btq^k e^{i\theta})_{r+s}|^2}$$

$$\cdot \frac{(atq^k/c)_s |(bce^{i\theta}/a)_r|^2 (b/atq^{k-1})_r}{(bq/c)_{r+s} (bq/a)_r (b^2c/a)_r} (ac^{-1}tq^{k+1})^r q^s$$

$$+ \frac{V(x,y)(bc)_\infty |(be^{i\phi})_\infty (ce^{i\phi})_\infty (ce^{i\phi})_\infty (be^{i\theta})_\infty (bce^{i\theta}/a)_\infty (atq^k e^{i\theta})_\infty|^2}{(b/a)_\infty (c/a)_\infty |(tq^k e^{i\theta+i\phi})_\infty (tq^k e^{i\theta-i\phi})_\infty|^2}$$

$$\cdot (btq^k/a)_\infty (ctq^k/a)_\infty (tq^k)_\infty \sum_{r=0}^{\infty}\sum_{s=0}^{\infty} \frac{(tq^k)_{r+s} |(ae^{i\phi})_{r+s}|^2}{(q)_r (q)_s |(atq^k e^{i\theta})_{r+s}|^2}$$

$$\cdot \frac{(atq^k/c)_s (t^{-1}q^{1-k})_r |(ce^{i\theta})_r|^2}{(aq/c)_{r+s} (aq/b)_r (bc)_r} (ac^{-1}tq^{k+1})^r q^s.$$

By changing the orders of summation in both parts of $G_1(x,y)$ and using (3.15) it follows that

(6.3)

$$G_1(x,y)=\frac{V(x,y)(bc^2/a)_\infty\left|(ae^{i\phi})_\infty(be^{i\phi})_\infty(ce^{i\phi})_\infty(be^{i\theta})_\infty(be^{i\theta})_\infty(ctq^ke^{i\theta})_\infty\right|^2}{(a/c)_\infty(b/c)_\infty\left|(tq^ke^{i\theta+i\phi})_\infty(tq^ke^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot(btq^k/a)_\infty(atq^k/c)_\infty(tq^k)_\infty\sum_{j=0}^{\infty}\frac{(ctq^k/a)_j\left|(ce^{i\phi})_j(qb^{-1}e^{i\theta})_j\right|^2}{(q)_j(cq/b)_j(aq/b^2c)_j\left|(ctq^ke^{i\theta})_j\right|^2}$$

$$\cdot\frac{(atq^k/b)_j}{(cq/a)_j}q^k\,{}_8\phi_7\left[\begin{matrix}b^2c/aq^{j+1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ bctq^{k-1},\ bca^{-1}e^{i\theta},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ b/atq^{k+j-1},\ be^{-i\theta}q^{-j},\end{matrix}\right.$$

$$\left.\begin{matrix}bca^{-1}e^{-i\theta},\ b/cq^j,\ q^{-j}\\ be^{i\theta}q^{-j},\ bc^2/a,\ b^2c/a\end{matrix};t^{-1}q^{1-k}\right].$$

By using (3.23) to write the above ${}_8\phi_7$ as a multiple of the series

$${}_4\phi_3\left[\begin{matrix}q^{-j},\ c/atq^{k-1},\ bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta}\\ bc^2/a,\ cq/a,\ b/atq^{k+j-1}\end{matrix};q\right]$$

and then using it again to write this ${}_4\phi_3$ as a multiple of the series

$${}_8\phi_7\left[\begin{matrix}bc^2a^{-1}tq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ tq^k,\ bctq^{k-1},\ bca^{-1}e^{i\theta},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bc^2/a,\ cq/a,\ ctq^ke^{-i\theta},\end{matrix}\right.$$

$$\left.\begin{matrix}bca^{-1}e^{-i\theta},\ q^{-j}\\ ctq^ke^{i\theta},\ bc^2a^{-1}tq^{k+j}\end{matrix};cb^{-1}q^{j+1}\right]$$

we find that the sum over j in (6.3) equals

(6.4)

$$\sum_{j=0}^{\infty}\frac{(ctq^k/a)_j\left|(ce^{i\phi})_j\right|^2}{(q)_j(cq/b)_j(bc^2tq^k/a)_j}q^j\sum_{r=0}^{j}\frac{(bc^2a^{-1}tq^{k-1})_r(q\sqrt{\cdot})_r(-q\sqrt{\cdot})_r}{(q)_r(\sqrt{\cdot})_r(-\sqrt{\cdot})_r}$$

$$\cdot\frac{(tq^k)_r(bctq^{k-1})_r\left|(bca^{-1}e^{i\theta})_r\right|^2(q)_j(-1)^r(cq/b)^r}{(bc^2/a)_r(cq/a)_r\left|(ctq^ke^{i\theta})_r\right|^2(bc^2a^{-1}tq^{k+j})_r(q)_{j-r}}q^{r(r-1)/2}$$

$$=\sum_{r=0}^{\infty}\frac{(bc^2a^{-1}tq^{k-1})_r(q\sqrt{\cdot})_r(-q\sqrt{\cdot})_r(tq^k)_r(bctq^{k-1})_r(ctq^k/a)_r\left|(ce^{i\phi})_r\right|^2}{(q)_r(\sqrt{\cdot})_r(-\sqrt{\cdot})_r(bc^2/a)_r(cq/a)_r(cq/b)_r\left|(ctq^re^{i\theta})_r\right|^2}$$

$$\cdot\frac{\left|(bca^{-1}e^{i\theta})_r\right|^2}{(bc^2tq^k/a)_{2r}}(-1)^r\left(\frac{cq}{b}\right)^r q^{r(r+1)/2}\,{}_3\phi_2\left[\begin{matrix}ca^{-1}tq^{k+r},\ cq^re^{i\phi},\ cq^re^{-i\phi}\\ cb^{-1}q^{r+1},\ bc^2a^{-1}tq^{k+2r}\end{matrix};q\right].$$

Fortunately, we can now apply (3.10) to the above ${}_3\phi_2$ to show that it equals

$$\frac{(b/cq^r)_\infty (bcq^r)_\infty \left|(bca^{-1}tq^{k+r}e^{i\phi})_\infty\right|^2}{(btq^k/a)_\infty (bc^2a^{-1}tq^{k+2r})_\infty \left|(be^{i\phi})_\infty\right|^2}$$
$$+ bc^{-1}q^{-r}\frac{(ca^{-1}tq^{k+r})_\infty (b/cq^{r-1})_\infty (b^2ca^{-1}tq^{k+r})_\infty \left|(cq^re^{i\phi})_\infty\right|^2}{(cb^{-1}q^{r+1})_\infty (bc^2a^{-1}tq^{k+2r})_\infty (btq^k/a)_\infty \left|(be^{i\phi})_\infty\right|^2}$$
$$\cdot {}_3\phi_2\left[\begin{matrix} btq^k/a,\ be^{i\phi},\ be^{-i\phi} \\ b/cq^{r-1},\ b^2ca^{-1}tq^{k+r}\end{matrix};q\right].$$

Using this in (6.4) we obtain that the sum over j in (6.3) equals

(6.5)

$$\frac{(b/c)_\infty (bc)_\infty \left|(bca^{-1}tq^ke^{i\phi})_\infty\right|^2}{(btq^k/a)_\infty (bc^2tq^k/a)_\infty \left|(be^{i\phi})_\infty\right|^2}$$
$$\cdot {}_{10}\phi_9\left[\begin{matrix} bc^2a^{-1}tq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ tq^k, \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bc^2/a, \\ bctq^{k-1},\ bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta},\ ce^{i\phi},\ ce^{-i\phi},\ ctq^k/a \\ cq/a,\ ctq^ke^{-i\theta},\ ctq^ke^{i\theta},\ bca^{-1}tq^ke^{-i\phi},\ bca^{-1}tq^ke^{i\phi},\ bc\end{matrix};q\right]$$
$$- \frac{(b/c)_\infty (ctq^k/a)_\infty (b^2ctq^k/a)_\infty \left|(ce^{i\phi})_\infty\right|^2}{(c/b)_\infty (bc^2tq^k/a)_\infty (btq^k/a)_\infty \left|(be^{i\phi})_\infty\right|^2}$$
$$\cdot \sum_{j=0}^{\infty}\frac{(btq^k/a)_j \left|(be^{i\phi})_j\right|^2}{(q)_j (bq/c)_j (b^2ctq^k/a)_j}q^j$$
$$\cdot {}_8\phi_7\left[\begin{matrix} bc^2a^{-1}tq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ tq^k,\ bctq^{k-1},\ bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta},\ c/bq^j \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bc^2/a,\ cq/a,\ ctq^ke^{-i\theta},\ ctq^ke^{i\theta},\ b^2ca^{-1}tq^{k+j}\end{matrix};q^{j+1}\right]$$

by a change in order of summation.

Let us now consider $G_2(x,y)$. From (6.2)

(6.6)

$$G_2(x,y) = \frac{V(x,y)(b^2c/a)_\infty \left|(ae^{i\phi})_\infty (ce^{i\phi})_\infty (ce^{i\phi})_\infty (be^{i\theta})_\infty (ce^{i\theta})_\infty (btq^ke^{i\theta})\right|^2}{(c/b)_\infty (a/b)_\infty \left|(tq^ke^{i\theta+i\phi})_\infty (tq^ke^{i\theta-i\phi})_\infty\right|^2}$$
$$\cdot (ctq^k/a)_\infty (atq^k/b)_\infty (tq^k)_\infty$$
$$\cdot \sum_{j=0}^{\infty}\frac{(btq^k/a)_j (atq^k/c)_j \left|(be^{i\phi})_j\right|^2}{(q)_j (bq/c)_j \left|(btq^ke^{i\theta})_j\right|^2}q^j$$
$$\cdot {}_4\phi_3\left[\begin{matrix} q^{-j},\ b/atq^{k-1},\ bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta} \\ bq/a,\ b^2c/a,\ c/atq^{k+j-1}\end{matrix};q\right]$$

$$+\frac{V(x,y)(bc)_\infty\left|(be^{i\phi})_\infty(ce^{i\phi})_\infty(ce^{i\phi})_\infty(be^{i\theta})_\infty(bca^{-1}e^{i\theta})_\infty(atq^ke^{i\theta})_\infty\right|^2}{(b/a)_\infty(c/a)_\infty\left|(tq^ke^{i\theta+i\phi})_\infty(tq^ke^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot(btq^k/a)_\infty(ctq^k/a)_\infty(tq^k)_\infty\sum_{j=0}^{\infty}\frac{(tq^k)_j(atq^k/c)_j\left|(ae^{i\phi})_j\right|^2}{(q)_j(aq/c)_j\left|(atq^ke^{i\theta})_j\right|^2}q^j$$

$$\cdot{}_4\phi_3\left[\begin{matrix}q^{-j},\ t^{-1}q^{1-k},\ ce^{i\theta},\ ce^{-i\theta}\\ bc,\ aq/b,\ c/atq^{k+j-1}\end{matrix};q\right].$$

Using (3.23), the first ${}_4\phi_3$ on the r.h.s. of (6.6) equals

(6.7)

$$\frac{\left|(btq^ke^{i\theta})_j\right|^2}{(atq^k/c)_j(b^2ctq^k/a)_j}{}_8\phi_7\left[\begin{matrix}b^2ca^{-1}tq^{k-1},\ q\sqrt{\cdot},\ -\sqrt{\cdot},\ bctq^{k-1},\ tq^k,\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bq/a,\ b^2c/a,\\ bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta},\ q^{-j}\\ btq^ke^{-i\theta},\ btq^ke^{i\theta},\ b^2ca^{-1}tq^{k+j}\end{matrix};bc^{-1}q^{j+1}\right]$$

$$=\frac{(b^2ca^{-1}tq^{k+j})_\infty(ac^{-1}tq^{k+j})_\infty\left|(b^2a^{-1}q^{j+1}e^{i\theta})_\infty\right|^2}{(bc^{-1}q^{j+1})_\infty(b^3ca^{-2}q^{j+1})_\infty\left|(btq^{k+j}e^{i\theta})_\infty\right|^2}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}b^3ca^{-2}q^j,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ b^2cq^j/a,\ ba^{-1}q^{j+1},\ b/atq^{k-1},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bq/a,\ b^2c/a,\ b^2ca^{-1}tq^{k+j},\\ bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta}\\ b^2a^{-1}q^{j+1}e^{-i\theta},\ b^2a^{-1}q^{j+1}e^{i\theta}\end{matrix};ac^{-1}tq^k\right]$$

by (3.19). Our reason for choosing the above ${}_8\phi_7$ from among all the other possibilities will be clear from (6.12) and (6.11) below. Since the second ${}_4\phi_3$ on the r.h.s. of (6.6) equals

(6.8)
$$\frac{(aq/c)_j(b/atq^{k+j-1})_j}{(aq/b)_j(c/atq^{k+j-1})_j}\left(\frac{c}{b}\right)^j{}_4\phi_3\left[\begin{matrix}q^{-j},\ t^{-1}q^{1-k},\ be^{i\theta},\ be^{-i\theta}\\ bc,\ aq/c,\ b/atq^{k+j-1}\end{matrix};q\right]$$

$$=\frac{(aq/c)_j\left|(atq^ke^{i\theta})_j\right|^2}{(aq/b)_j(atq^k/c)_j(abtq^k)_j}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}abtq^{k-1},\ q\sqrt{jdot},\ -q\sqrt{\cdot},\ atq^k/c,\ bctq^{k-1},\\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bc,\ aq/c,\\ be^{i\theta},\ be^{-i\theta},\ q^{-j}\\ atq^ke^{-i\theta},\ atq^ke^{i\theta},\ abtq^{k+j}\end{matrix};ab^{-1}q^{j+1}\right],$$

the second sum over j on the r.h.s. of (6.6) equals

$$(6.9)\quad \sum_{r=0}^{\infty} \frac{(abtq^{k-1})_r(q\sqrt{\cdot})_r(-q\sqrt{\cdot})_r(atq^k/c)_r(bctq^{k-1})_r(tq^k)_r(-1)^r q^{r(r+1)/2}}{(q)_r(\sqrt{\cdot})_r(-\sqrt{\cdot})_r(bc)_r(aq/c)_r(aq/b)_r(abtq^k)_{2r}} \cdot \frac{|(ae^{i\phi})_r(be^{i\theta})_r|^2}{|(atq^k e^{i\theta})_r|^2}\left(\frac{aq}{b}\right)^r {}_3\phi_2\left[\begin{matrix} tq^{k+r}, aq^r e^{i\phi}, aq^r e^{-i\phi} \\ ab^{-1}q^{r+1}, abtq^{k+2r}\end{matrix}; q\right]$$

by a change in order of summation. We can apply (3.10) to the above ${}_3\phi_2$ to find that it equals

$$\frac{(b/aq^r)_\infty(abq^r)_\infty|(btq^{k+r}e^{i\phi})_\infty|^2}{(abtq^{k+2r})_\infty(btq^k/a)_\infty|(be^{i\phi})_\infty|^2} - \frac{(tq^{k+r})_\infty(b/aq^r)_\infty(b^2tq^{k+r})_\infty|(aq^r e^{i\phi})_\infty|^2}{(aq^r/b)_\infty(btq^k/a)_\infty(abtq^{k+2r})_\infty|(be^{i\phi})_\infty|^2} {}_3\phi_2\left[\begin{matrix} btq^k/a, be^{i\phi}, be^{-i\phi} \\ b/aq^{r-1}, b^2tq^{k+r}\end{matrix}; q\right].$$

Hence, from (6.9), the second sum over j on the r.h.s. of (6.6) equals

(6.10)

$$\frac{(ab)_\infty(b/a)_\infty|(btq^k e^{i\phi})_\infty|^2}{(abtq^k)_\infty(btq^k/a)_\infty|(be^{i\phi})_\infty|^2} {}_{10}\phi_9\left[\begin{matrix} abtq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, atq^k/c, \\ \sqrt{\cdot}, -\sqrt{\cdot}, bc, \\ bctq^{k-1}, tq^k, be^{i\theta}, be^{-i\theta}, ae^{i\phi}, ae^{-i\phi} \\ aq/c, ab, atq^k e^{-i\theta}, atq^k e^{i\theta}, btq^k e^{-i\phi}, btq^k e^{i\phi}\end{matrix}; q\right]$$

$$- \frac{(b/a)_\infty(tq^k)_\infty(b^2tq^k)_\infty|(ae^{i\phi})_\infty|^2}{(a/b)_\infty(abtq^k)_\infty(btq^k/a)_\infty|(be^{i\phi})_\infty|^2} \sum_{j=0}^{\infty} \frac{(btq^k/a)_j|(be^{i\phi})_j|^2}{(q)_j(bq/a)_j(b^2tq^k)_j} q^j \cdot {}_8\phi_7\left[\begin{matrix} abtq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, atq^k/c, bctq^{k-1}, be^{i\theta}, be^{-i\theta}, a/bq^j \\ \sqrt{\cdot}, -\sqrt{\cdot}, bc, aq/c, atq^k e^{-i\theta}, atq^k e^{i\theta}, b^2tq^{k+j}\end{matrix}; q^{j+1}\right]$$

by a change in order of summation.

Combining (6.3), (6.5), (6.6), (6.7) and (6.10) we obtain that

(6.11)

$$G_1(x,y)+G_2(x,y)=\frac{V(x,y)(tq^k)_\infty(bc)_\infty|(ce^{i\phi})_\infty(be^{i\theta})_\infty|^2}{|(tq^k e^{i\theta+i\phi})_\infty(tq^k e^{i\theta-i\phi})_\infty|^2} \cdot \left\{\frac{(bc^2/a)_\infty(atq^k/c)_\infty}{(a/c)_\infty(bc^2tq^k/a)_\infty}|(ae^{i\phi})_\infty(be^{i\theta})_\infty(ctq^k e^{i\theta})_\infty(bca^{-1}tq^k e^{i\phi})_\infty|^2 \cdot {}_{10}\phi_9\left[\begin{matrix} bc^2a^{-1}tq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, \\ \sqrt{\cdot}, -\sqrt{\cdot}, \\ tq^k, bctq^{k-1}, ctq^k/a, ce^{i\phi}, ce^{-i\phi}, bca^{-1}e^{i\theta}, bca^{-1}e^{-i\theta} \\ bc^2/a, cq/a, bc, bca^{-1}tq^k e^{-i\phi}, bca^{-1}tq^k e^{i\phi}, ctq^k e^{-i\theta}, ctq^k e^{i\theta}\end{matrix}; q\right]\right.$$

$$+\frac{(ab)_\infty(ctq^k/a)_\infty}{(c/a)_\infty(abtq^k)_\infty}\left|(ce^{i\phi})_\infty(bca^{-1}e^{i\theta})_\infty(atq^ke^{i\theta})_\infty(btq^ke^{i\phi})_\infty\right|^2$$

$$\cdot{}_{10}\phi_9\left[\begin{matrix}abtq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, atq^k/c, bctq^{k-1}, tq^k, be^{i\theta}, be^{-i\theta},\\ \sqrt{\cdot}, -\sqrt{\cdot}, bc, aq/c, ab, atq^ke^{-i\theta}, atq^ke^{i\theta},\\ ae^{i\phi}, ae^{-i\phi}\\ btq^ke^{-i\phi}, btq^ke^{i\phi}\end{matrix};q\right]\Bigg\}$$

$$+\frac{V(x,y)(tq^k)_\infty(ctq^k/a)_\infty\left|(ae^{i\phi})_\infty(ce^{i\phi})_\infty(ce^{i\phi})_\infty(be^{i\theta})_\infty\right|^2}{\left|(tq^ke^{i\theta+i\phi})_\infty(tq^ke^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot\Bigg\{\frac{(b^2c/a)_\infty(atq^k/c)_\infty(b^2ctq^k/a)_\infty(atq^k/b)_\infty}{(a/b)_\infty(c/b)_\infty(b/c)_\infty(b^3cq/a^2)_\infty}\left|(ce^{i\theta})_\infty(b^2a^{-1}qe^{i\theta})_\infty\right|^2$$

$$\cdot\sum_{j=0}^{\infty}\frac{(btq^k/a)_j(b^3cq/a^2)_j\left|(be^{i\phi})_j\right|^2}{(q)_j(b^2ctq^k/a)_j\left|(b^2a^{-1}qe^{i\theta})_j\right|^2}q^j$$

$$\cdot{}_8\phi_7\left[\begin{matrix}b^3ca^{-2}q^j, q\sqrt{\cdot}, -q\sqrt{\cdot},\\ \sqrt{\cdot}, -\sqrt{\cdot},\\ b^2cq^j/a, ba^{-1}q^{j+1}, b/atq^{k-1}, bca^{-1}e^{i\theta}, bca^{-1}e^{-i\theta}\\ bq/a, b^2c/a, b^2ca^{-1}tq^{k+j}, b^2a^{-1}q^{j+1}e^{-i\theta}, b^2a^{-1}q^{j+1}e^{i\theta}\end{matrix};ac^{-1}tq^k\right]$$

$$-\frac{(bc)_\infty(b^2tq^k)_\infty(tq^k)_\infty}{(a/b)_\infty(c/a)_\infty(abtq^k)_\infty}\left|(bca^{-1}e^{i\theta})_\infty(atq^ke^{i\theta})_\infty\right|^2$$

$$\cdot\sum_{j=0}^{\infty}\frac{(btq^k/a)_j}{(q)_j(bq/a)_j}\frac{\left|(be^{i\phi})_j\right|^2}{(b^2tq^k)_j}q^j$$

$$\cdot{}_8\phi_7\left[\begin{matrix}abtq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, atq^k/c, bctq^{k-1}, a/bq^j,\\ \sqrt{\cdot}, -\sqrt{\cdot}, bc, aq/c, b^2tq^{k+j},\\ be^{i\theta}, be^{-i\theta}\\ atq^ke^{-i\theta}, atq^ke^{i\theta}\end{matrix};q^{j+1}\right]$$

$$-\frac{(bc^2/a)_\infty(atq^k/c)_\infty(b^2ctq^k/a)_\infty}{(a/c)_\infty(c/b)_\infty(bc^2tq^k/a)_\infty}\left|(be^{i\theta})_\infty(ctq^ke^{i\theta})_\infty\right|^2$$

$$\cdot\sum_{k=0}^{\infty}\frac{(btq^k/a)_j}{(q)_j(bq/c)_j}\frac{\left|(be^{i\phi})_j\right|^2}{(b^2ctq^k/a)_j}q^j$$

$$\cdot{}_8\phi_7\left[\begin{matrix}bc^2a^{-1}tq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, bctq^{k-1}, c/bq^j,\\ \sqrt{\cdot}, -\sqrt{\cdot}, cq/a, b^2ca^{-1}tq^{k+j},\\ tq^k, bca^{-1}e^{i\theta}, bca^{-1}e^{-i\theta}\\ bc^2/a, ctq^ke^{-i\theta}, ctq^ke^{i\theta}\end{matrix};q^{j+1}\right]\Bigg\}.$$

Now, we need but observe that, by Bailey [6, (5.1)], the last ${}_8\phi_7$ in (6.11) equals

(6.12)

$$\frac{(a/c)_\infty (b^2c/a)_\infty (atq^k/b)_\infty (bc^2tq^k/a)_\infty \left|(ce^{i\theta})_\infty (b^2a^{-1}q^{j+1}e^{i\theta})_\infty\right|^2}{(a/b)_\infty (bc^2/a)_\infty (bc^{-1}q^{j+1})_\infty \left|(be^{i\theta})_\infty (ctq^ke^{i\theta})_\infty\right|^2}$$

$$\cdot {}_8\phi_7\left[\begin{matrix} b^3ca^{-2}q^j,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ b^2cq^j/a,\ ba^{-1}q^{j+1},\ b/atq^{k-1} \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bq/a,\ b^2c/a,\ b^2ca^{-1}tq^{k+j}, \end{matrix}\right.$$

$$\left.\begin{matrix} bca^{-1}e^{i\theta},\ bca^{-1}e^{-i\theta} \\ b^2a^{-1}q^{j+1}e^{-i\theta},\ b^2a^{-1}q^{j+1}e^{i\theta} \end{matrix};\ ac^{-1}tq^k\right]$$

$$- \frac{(bc)_\infty (a/c)_\infty (tq^k)_\infty (ba^{-1}q^{j+1})_\infty (bc^2tq^k/a)_\infty (b^2tq^{k+j})_\infty}{(c/a)_\infty (bc^2/a)_\infty (abtq^k)_\infty (atq^k/c)_\infty (bc^{-1}q^{j+1})_\infty (b^2c^{-1}atq^{k+j})_\infty}$$

$$\cdot \frac{\left|(atq^ke^{i\theta})_\infty (bca^{-1}e^{i\theta})_\infty\right|^2}{\left|(be^{i\theta})_\infty (ctq^ke^{i\theta})_\infty\right|^2} \cdot \frac{(c/b)_\infty (bq/c)_\infty}{(a/b)_\infty (bq/a)_\infty}$$

$$\cdot {}_8\phi_7\left[\begin{matrix} abtq^{k-1},\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ atq^k/c,\ bctq^{k-1},\ a/bq^j,\ be^{i\theta},\ be^{-i\theta} \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ bc,\ aq/c,\ b^2tq^{k+j},\ atq^ke^{-i\theta},\ atq^ke^{i\theta} \end{matrix};\ q^{j+1}\right],$$

from which it fortunately follows that the second expression in braces on the r.h.s. of (6.11) equals zero.

Hence, combining (5.5), (5.10), and (6.11) with the above observation we finally get our desired formula.

(6.13)

$$K_t(x,y;\ a,b,c,bc/a;\ q) = (1-t^2)\frac{(bcqt)_\infty}{(t/bc)_\infty}$$

$$\cdot \sum_{k=0}^{\infty} \frac{(-bc)_k}{(q)_k} \frac{(bc\sqrt{q})_k (-bc\sqrt{q})_k \left|(bca^{-1}e^{i\theta})_k (bca^{-1}e^{i\phi})_k\right|^2 q^k}{(bc^2/a)_k (b^2c/a)_k (bc)_k (bca^{-2})_k (bcqt)_k (bcq/t)_k}$$

$$\cdot {}_{10}\phi_9\left[\begin{matrix} a^2/bcq^k,\ q\sqrt{\cdot},\ -q\sqrt{\cdot},\ a/b^2cq^{k-1},\ a/bc^2q^{k-1},\ q^{-k}, \\ \sqrt{\cdot},\ -\sqrt{\cdot},\ ab,\ ac,\ a^2q/bc,\ ab^{-1}c^{-1}q^{1-k}e^{-i\theta}, \end{matrix}\right.$$

$$\left.\begin{matrix} ae^{i\theta},\ ae^{-i\theta},\ ae^{i\phi},\ ae^{-i\phi} \\ ab^{-1}c^{-1}q^{1-k}e^{i\theta},\ ab^{-1}c^{-1}q^{1-k}e^{-i\phi},\ ab^{-1}c^{-1}q^{1-k}e^{i\phi} \end{matrix};\ q\right]$$

$$+ \frac{(t)_\infty (at/c)_\infty (b^2c^2)_\infty \left|(ae^{i\phi})_\infty (be^{i\theta})_\infty (cte^{i\theta})_\infty (bca^{-1}te^{i\phi})_\infty\right|^2}{(ab)_\infty (ac)_\infty (bc)_\infty (a/c)_\infty (b^2c/a)_\infty (bc^2t/a)_\infty (bc/t)_\infty \left|(te^{i\theta+i\phi})_\infty (te^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot \sum_{k=0}^{\infty} \frac{(-t)_k (t\sqrt{q})_k (-t\sqrt{q})_k (bc^2t/a)_k \left|(te^{i\theta+i\phi})_k (te^{i\theta-i\phi})_k\right|^2}{(q)_k (qt/bc)_k (qt^2)_k (at/c)_k \left|(cte^{i\theta})_k (bca^{-1}te^{i\phi})_k\right|^2} q^k$$

$$\cdot {}_{10}\phi_9\left[\begin{matrix} bc^2a^{-1}tq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, tq^k, bctq^{k-1}, ca^{-1}tq^k, bca^{-1}e^{i\theta}, \\ \sqrt{\cdot}, -\sqrt{\cdot}, bc^2/a, cq/a, bc, ctq^ke^{-i\theta}, \end{matrix} \right.$$

$$\left. \begin{matrix} bca^{-1}e^{-i\theta}, ce^{i\phi}, ce^{-i\phi} \\ ctq^ke^{i\theta}, bca^{-1}tq^ke^{-i\phi}, bca^{-1}tq^ke^{i\phi} \end{matrix} ; q \right]$$

$$+ \frac{(t)_\infty (ct/a)_\infty (b^2c^2)_\infty \left|(ce^{i\phi})_\infty (bca^{-1}e^{i\theta})_\infty (ate^{i\theta})_\infty (bte^{i\phi})_\infty\right|^2}{(ac)_\infty (bc)_\infty (bc^2/a)_\infty (b^2c/a)_\infty (c/a)_\infty (abt)_\infty (bc/t)_\infty \left|(te^{i\theta+i\phi})_\infty (te^{i\theta-i\phi})_\infty\right|^2}$$

$$\cdot \sum_{k=0}^{\infty} \frac{(-t)_k (t\sqrt{q})_k (-t\sqrt{q})_k (abt)_k \left|(te^{i\theta+i\phi})_k (te^{i\theta-i\phi})_k\right|^2}{(q)_k (qt/bc)_k (qt^2)_k (ct/a)_k \left|(ate^{i\theta})_k (bte^{i\phi})_k\right|^2} q^k$$

$$\cdot {}_{10}\phi_9\left[\begin{matrix} abtq^{k-1}, q\sqrt{\cdot}, -q\sqrt{\cdot}, tq^k, bctq^{k-1}, ac^{-1}tq^k, be^{i\theta}, be^{-i\theta}, ae^{i\phi}, ae^{-i\phi} \\ \sqrt{\cdot}, -\sqrt{\cdot}, ab, aq/c, bc, atq^ke^{-i\theta}, atq^ke^{i\theta}, btq^ke^{-i\phi}, btq^ke^{i\phi} \end{matrix} ; q \right].$$

By inspection it is obvious from (6.13) that if $0 \leqq t < 1$, $0 < q < 1$, and (4.9) holds with $\alpha, \beta > -1$, then $K_t(x,y;\ a,b,c,bc/a;\ q)$ and hence the Poisson kernel $P_t(x,y;\ a,b,c,bc/a;\ q)$ for the continuous q-Jacobi polynomials are positive when $-1 \leqq x,y \leqq 1$.

INEQUALITIES AND NUMERICAL BOUNDS FOR ZEROS OF ULTRASPHERICAL POLYNOMIALS*

SHAFIQUE AHMED†, MARTIN E. MULDOON‡ AND RENATO SPIGLER§

Abstract. We improve previous results concerning the monotonicity in λ of $f(\lambda)x_{nk}^{(\lambda)}$ where $x_{nk}^{(\lambda)}$ is a positive zero of the ultraspherical polynomial $P_n^{(\lambda)}(x)$, and $f(\lambda)$ is a suitably chosen positive increasing function. The range of validity is extended to $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$ rather than $0 \leqq \lambda \leqq 1$. In a certain sense the results are the best obtainable by the methods used. Some new elementary bounds for the zeros are obtained and compared with known results. An inequality for $\partial(\log x_{nk}^{(\lambda)})/\partial\lambda$ is also derived.

Key words. ultraspherical polynomials, zeros, inequalities, monotonicity, Sturm comparison theorem

AMS(MOS) subject classifications. Primary 33A65; secondary 34C10

1. Introduction. The study of zeros of special functions is of interest not only because of its mathematical aspects but also due to its many applications. The zeros of classical orthogonal polynomials may be interpreted as equilibrium configurations of certain one-dimensional systems [3], [12]. For instance the x-zeros $x_{nk}^{(\lambda)}$, $k=1,2,\cdots,n$, of the ultraspherical polynomial $P_n^{(\lambda)}(x)$ can be thought of as the positions of equilibrium of $n(\geqq 2)$ unit electrical charges in the interval $(-1,1)$ in the field generated by two identical charges of magnitude $\lambda/2+1/4$ placed at 1 and -1 [12, pp. 140–142]. Thus, the study of the variation of $x_{nk}^{(\lambda)}$ with λ and of bounds for $x_{nk}^{(\lambda)}$ corresponds to the physical problem of how the position of equilibrium of the n unit charges varies with λ and how much they can be displaced by changing λ. The physical interpretation makes it clear that the positive zeros move to the left when λ is increased; this agrees with a theorem of Stieltjes [9], [12, p. 121].

In this paper we use Sturmian methods to improve some previously known results [2], [7], [8] concerning the monotonicity of $f(\lambda)x_{nk}^{(\lambda)}$. From this we are able to derive some new elementary bounds for the zeros. In many cases these bounds are sharper than existing elementary bounds and, in some cases, generally for the smallest positive zero, they are sharper than existing bounds involving zeros of Bessel functions.

2. A preliminary theorem. Although the Sturm comparison theorem [10] is almost 150 years old, its value in providing information about zeros of special functions has not always been appreciated fully; see, for example, the remarks in Watson's treatise [13, p. 517]. It is largely to G. Szegö that we owe the obervation that Sturm methods can provide quite sharp results; see [12, Chap. 6] and R. Askey's notes following [11] in Szegö's collected papers.

An old result, due to Stieltjes [9], [12, p. 121] asserts that each positive zero $x_{nk}^{(\lambda)}$ of $P_n^{(\lambda)}(x)$ *decreases* as λ increases, for n, k fixed. On the other hand, R. Spigler [8] proved essentially the following theorem.

*Received by the editors September 20, 1984. This work was supported partially by the Natural Sciences and Engineering Research Council of Canada and by Consiglio Nazionale delle Ricerche, Italy.

THEOREM 2.1. *The function* $f(\lambda)x_{nk}^{(\lambda)}$ *increases with* $\lambda, \lambda \in I$, *where* I *is some interval, for every function* $f(\lambda)$ *which satisfies* $f(\lambda)>0$, $f'(\lambda)>0$, $f'(\lambda)$ *continuous for* $\lambda \in I$ *and*

$$(2.1)\qquad (f^2-x^2)\left[2(n+\lambda)^2 f'-(2n+1)f\right]f+2x^2(n+\lambda)(f^2-x^2)$$
$$+ff'(1+2\lambda-2\lambda^2)(f^2+x^2)+x^2ff'\geqq 0, \qquad 0<x<f(\lambda).$$

In [8] only the case $I=(0,1)$ was considered. However, an examination of the proof reveals that we may take I to be any interval included in $[-\frac{1}{2}, \frac{3}{2}]$ possibly including one or both of its endpoints.

Theorem 2.1 was proved in [8] by applying a version of the Sturm comparison theorem [4] to the differential equation obtained by applying the scaling $x \to x/f(\lambda)$ to the equation satisfied by

$$u_\lambda(x)=(1-x^2)^{\lambda/2+1/4}P_n^{(\lambda)}(x).$$

The coefficient $\psi_\lambda(x)$ in the scaled equation

$$(2.2)\qquad u_\lambda''+\psi_\lambda(x)u_\lambda=0$$

was shown to be a monotonically decreasing function of λ using the condition (2.1). Spigler [8] called a function $f(\lambda)$ "acceptable" if it satisfies the hypotheses placed on f in Theorem 2.1 (in the special case where $I=(0,1)$). He then used (2.1) to derive the sufficient condition

$$(2.3)\qquad \frac{f'(\lambda)}{f(\lambda)} \geqq \frac{2n+1}{2(n+\lambda)^2}, \qquad 0<\lambda<1,$$

for the increase of $f(\lambda)x_{nk}^{(\lambda)}$ on $0<\lambda<1$ for an acceptable f. The results [8]

$$(2.4)\qquad \left|\frac{\partial\left(\log x_{nk}^{(\lambda)}\right)}{\partial\lambda}\right| \leqq \frac{f'(\lambda)}{f(\lambda)}, \qquad 0<\lambda<1,$$

and

$$(2.5)\qquad 1<\frac{x_{nk}^{(\lambda)}}{x_{nk}^{(\lambda+\varepsilon)}}<\frac{f(\lambda+\varepsilon)}{f(\lambda)}, \qquad 0<\lambda<\lambda+\varepsilon<1,$$

valid *for every acceptable* f showed that the most desirable f is one which minimizes the ratio $f'(\lambda)/f(\lambda)$. Correspondingly, the best results of the type (2.4) and (2.5) in [8] were obtained by taking the equality sign in (2.3). This leads, apart from a multiplicative constant, to

$$(2.6)\qquad f(\lambda)=\exp\left\{\frac{(2n+1)\lambda}{2n(n+\lambda)}\right\}.$$

The inequality

$$(2.7)\qquad \frac{x_{nk}^{(\lambda)}}{x_{nk}^{(\lambda+\varepsilon)}}<1+\frac{\varepsilon}{\lambda}$$

obtained in [7] corresponds to (2.5) with $f(\lambda)=\lambda$. However the right-hand side here becomes infinite as $\lambda \to 0$. Following a suggestion of R. Askey, S. Ahmed [2] considered functions of the form $(\lambda+m)^{1/2}$. Our results generalize those of [2].

In [8], use was made of the *sufficient* condition (2.3) for a function satisfying the other hypotheses in Theorem 2.1 to satisfy (2.1) also. Here we use instead (3.7) below which is, in a certain sense, both necessary and sufficient. In this way, we obtain inequalities of the type (2.4) and (2.5) which are the "best" that can be obtained by "the Sturm method plus scaling" in the sense that we discover the "acceptable" f's for which $f'(\lambda)/f(\lambda)$ is smallest on $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$. (Here we use the word "acceptable" in a wider sense than Spigler [8] who considered only $0 < \lambda < 1$.)

3. The best acceptable function. Our main goal here is to prove the following result.

THEOREM 3.1. *For $n \geqq 2$ let $x_{nk}^{(\lambda)}$ denote the kth x-zero in decreasing order of $P_n^{(\lambda)}(x)$. Then, for $k = 1, \cdots, [n/2]$,*

$$[2n^2+1+2\lambda(2n+1)]^{1/2} x_{nk}^{(\lambda)}$$

increases as λ increases, $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$.

Proof. It is simply a matter of checking that the condition (2.1), with equality sign, is satisfied for $0 \leqq x \leqq f(\lambda)$, $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$, where

$$f(\lambda) = [2n^2+1+2\lambda(2n+1)]^{1/2}. \tag{3.1}$$

To see this, we divide (2.1) by $[f(\lambda)]^4$ and obtain, after some algebraic manipulation,

$$\frac{f'(\lambda)}{f(\lambda)} \geqq F\left(\frac{x^2}{f^2}\right), \qquad 0 < x < f(\lambda), \tag{3.2}$$

where

$$F(u) = \frac{(1-u)[2(n+1)-2u(n+\lambda)]}{2(n+\lambda)^2(1-u)+(1+2\lambda-2\lambda^2)(1+u)+u}. \tag{3.3}$$

It is clear that the denominator here is positive for $0 < u < 1$, $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$.

In order that (3.2) hold *for every* x in $(0, f(\lambda))$ it is necessary and sufficient that

$$f'(\lambda)/f(\lambda) \geqq \sup_{0<u<1} F(u). \tag{3.4}$$

However we can show that

$$\sup_{0<u<1} F(u) = F(0). \tag{3.5}$$

To prove (3.5) we note that it is equivalent to

$$\frac{a-(a+b)u+bu^2}{A-Bu} \leqq \frac{a}{A}, \qquad 0 < u < 1 \tag{3.6}$$

where $a = 2n+1$, $b = 2(n+\lambda)$,

$$A = 2(n+\lambda)^2+1+2\lambda-2\lambda^2, \qquad B = -2\left[1+\lambda-\lambda^2-(n+\lambda)^2\right]$$

and it is easy to see that a necessary and sufficient condition for this is that $A \geqq B$ or that $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$. Thus for these values of λ, (3.4) is equivalent to

$$\frac{f'(\lambda)}{f(\lambda)} \geqq \frac{2n+1}{2(n+\lambda)^2+1+2\lambda-2\lambda^2} \tag{3.7}$$

and it is easy to see that this holds with the equality sign when $f(\lambda)$ is given by (3.1). This completes the proof of Theorem 3.1.

The method of proof shows that the choice (3.1) for $f(\lambda)$ is, apart from constant factors, the one which *minimizes* $f'(\lambda)/f(\lambda)$ subject to the hypotheses of Theorem 2.1 applied to the interval $I=[-\frac{1}{2},\frac{3}{2}]$ and so it is the best "acceptable" function for this interval.

From Theorem 3.1 we get

COROLLARY 3.1. *If* $n\geqq 2$, $-\frac{1}{2}\leqq\lambda<\lambda+\varepsilon<\frac{3}{2}$, $k=1,2,\ldots[n/2]$, *we have*

$$1<\frac{x_{nk}^{(\lambda)}}{x_{nk}^{(\lambda+\varepsilon)}}<\left[1+\frac{\varepsilon}{\lambda+(2n^2+1)/[2(2n+1)]}\right]^{1/2}.$$

We also have, as in [8], from (2.4) and (3.7):

COROLLARY 3.2. *A "best" estimate for the derivative of* $x_{nk}^{(\lambda)}$ *is given by*

$$\left|\frac{\partial\left(\log x_{nk}^{(\lambda)}\right)}{\partial\lambda}\right|<\frac{2n+1}{2(2n+1)\lambda+2n^2+1}$$

where $-\frac{1}{2}\leqq\lambda\leqq\frac{3}{2}$, $k=1,2,\cdots,[n/2]$.

4. Numerical bounds for $x_{nk}^{(\lambda)}$, $0<\lambda<1$. The decreasing character of $x_{nk}^{(\lambda)}$, as a function of λ, enables us to provide *upper and lower bounds* for this quantity whenever the zeros of two other ultraspherical polynomials $P_n^{(\lambda_1)}(x)$ and $P_n^{(\lambda_2)}(x)$, with $\lambda_1<\lambda<\lambda_2$, are known. When $\lambda_1=0$, $\lambda_2=1$ we have the Chebyshev polynomials; in this way Stieltjes was able to show that

$$\cos\frac{k\pi}{n+1}<x_{nk}^{(\lambda)}<\cos\frac{(2k-1)\pi}{2n}, \tag{4.1}$$

for $0<\lambda<1$ [9], [12, p. 122].

The monotonic increasing character of $f(\lambda)x_{nk}^{(\lambda)}$, where $f(\lambda)$ is given by (3.1), enables us to get sharper results. In fact we have

$$\frac{f(\lambda_1)}{f(\lambda)}x_{nk}^{(\lambda_1)}<x_{nk}^{(\lambda)}<\frac{f(\lambda_2)}{f(\lambda)}x_{nk}^{(\lambda_2)} \tag{4.2}$$

where $-\frac{1}{2}\leqq\lambda_1<\lambda<\lambda_2\leqq\frac{3}{2}$, $k=1,2,\cdots,[n/2]$. In particular with $\lambda_1=0$, $\lambda_2=1$ we get the following result.

THEOREM 4.1. *For* $0<\lambda<1$ *and* $k=1,2,\cdots,[n/2]$ *we have*

$$x_{nk}^{(\lambda)}<\left[\frac{2n^2+4n+3}{2n^2+1+2\lambda(2n+1)}\right]^{1/2}\cos\frac{k\pi}{n+1} \tag{4.3}$$

and

$$x_{nk}^{(\lambda)}>\left[\frac{2n^2+1}{2n^2+1+2\lambda(2n+1)}\right]^{1/2}\cos\frac{(2k-1)\pi}{2n}. \tag{4.4}$$

G. Szegö [12, §6.6] summarizes the various known elementary bounds for $x_{nk}^{(\lambda)}$, including some obtained by Sturm methods. The best such *upper* bound, among those available in [12] is

$$x_{nk}^{(\lambda)}<\cos\left[\frac{k-(1-\lambda)/2}{n+\lambda}\pi\right],\qquad 0<\lambda<1, \tag{4.5}$$

and the best such *lower* bounds are

$$x_{nk}^{(\lambda)} > \cos\frac{k\pi}{n+1}, \qquad \frac{1}{2} \leqq \lambda < 1, \tag{4.6}$$

and

$$x_{nk}^{(\lambda)} > \cos\left\{\frac{(k+\lambda-1/2)\pi}{n+2\lambda}\right\}, \qquad 0 < \lambda \leqq \frac{1}{2}. \tag{4.7}$$

In the special case $\lambda = \frac{1}{2}$ (Legendre polynomials) some calculations which we performed in the range $n = 2$ to 15 indicate that our lower bound (4.4) is quite sharp and generally better than (4.6) and (4.7) for all except the first (largest) one or two zeros, while our upper bound (4.3) is better than (4.5) for at most the last (smallest) zero. Thus, for example, our bounds lead to

$$0.20111 < x_{15,7}^{(1/2)} < 0.20126 \tag{4.8}$$

while (4.5) and (4.6) lead to

$$0.19509 < x_{15,7}^{(1/2)} < 0.20130.$$

We note that (4.1) would have given only

$$0.195090 < x_{15,7}^{(1/2)} < 0.207912.$$

Calculations for other values of λ $(0 < \lambda < 1)$ confirm the pattern; our lower bounds are better than (4.6) and (4.7) for most zeros except the largest while our upper bounds are better than (4.5) only for the smallest zeros. There does not appear to be any easy way to decide a priori on the relative sharpness of these elementary bounds. In Table 1 we provide some further numerical comparison of our bounds with (4.5) to (4.7).

TABLE 1

n	k	L	L_s	U	U_s

The columns headed L and U give the (lower and upper) bounds for $x_{nk}^{(1/2)}$ *obtained using our formulas* (4.3) *and* (4.4). *The columns headed* L_s *and* U_s *give the bounds obtained by using* (4.5) *and* (4.6) (*or* (4.7)). *An asterisk indicates the cases where our bounds are better.*

We can hardly expect our bounds to compare as well with those involving nonelementary functions. Szegö [11] showed that for $0 < \lambda < 1$, $k = 1, 2, \cdots, [n/2]$,

$$x_{nk}^{(\lambda)} < \cos\frac{j_{\lambda-1/2,k}}{\left[(n+\lambda)^2 + (1-4/\pi^2)\lambda(1-\lambda)\right]^{1/2}} \tag{4.9}$$

where $j_{\lambda-1/2,k}$ is the kth positive zero of the Bessel function $J_{\lambda-1/2}(x)$, while L. Gatteschi [5] provided the lower bound

$$x_{nk}^{(\lambda)} > \cos \frac{j_{\lambda-1/2,k}}{\left[(n+\lambda)^2+\lambda(1-\lambda)/3\right]^{1/2}} \tag{4.10}$$

for the same range. Some calculations indicate that our elementary bounds (4.3), (4.4) are sometimes sharper than (4.9), (4.10) but only in the case of the smallest zeros. Thus, for example, (4.3) and (4.4) give

$$0.14885 < x_{10,5}^{(1/2)} < 0.14889$$

while (4.9) and (4.10) give

$$0.148788 < x_{10,5}^{(1/2)} < 0.149204.$$

5. Bounds outside the range $0<\lambda<1$. It is clear from (4.2) that we also have, for $1<\lambda\leqq\frac{3}{2}$,

$$x_{nk}^{(\lambda)} > \left[\frac{2n^2+4n+3}{2n^2+1+2\lambda(2n+1)}\right]^{1/2} \cos\frac{k\pi}{n+1} \tag{5.1}$$

and for $1\leqq\lambda<\frac{3}{2}$

$$x_{nk}^{(\lambda)} < \left[\frac{2n^2+6n+4}{2n^2+1+2\lambda(2n+1)}\right] x_{nk}^{(3/2)}. \tag{5.2}$$

The corresponding inequalities for $-\frac{1}{2}\leqq\lambda\leqq 0$ are

$$x_{nk}^{(\lambda)} > \left[\frac{2n^2-2n}{2n^2+1+2\lambda(2n+1)}\right]^{1/2} x_{nk}^{(-1/2)}, \qquad -\frac{1}{2}<\lambda\leqq 0 \tag{5.3}$$

and

$$x_{nk}^{(\lambda)} < \left[\frac{2n^2+1}{2n^2+1+2\lambda(2n+1)}\right]^{1/2} \cos\frac{(2k-1)\pi}{2n}, \qquad -\frac{1}{2}\leqq\lambda<0. \tag{5.4}$$

All of the above inequalities hold for $k=1,2,\cdots,[n/2]$. It is noteworthy that (5.1) and (5.4) are reversed forms of (4.3) and (4.4). Laforgia [6] has shown that inequalities (4.9) and (4.10), which become equalities for $\lambda=1$, are reversed for $\lambda>1$ so it is of interest to compare the elementary lower bound (5.1) with the reversed form of (4.10) in the range $1<\lambda\leqq\frac{3}{2}$. Some calculations which we have performed in the case $n=10$ and various values of λ indicate that the elementary bound (5.1) is sharper only in the case of the smallest zero ($k=5$ in this example). The upper bound (5.2) is not elementary but it involves the zeros of $P_n^{(3/2)}(x)$ which are the same as those of the *derivative* $P'_{n+1}(x)$ *of the Legendre polynomial* and some of these have been tabulated [1, p. 920].

In particular, the inequality (5.3) and, more especially the elementary inequality (5.4), are noteworthy in that they provide simple bounds corresponding to *negative values of* λ. There do not appear to be many such bounds in the literature.

6. Concluding remarks. 1. Since Laforgia's reversed forms of (4.9), (4.10) are valid for *all* $\lambda>1$, the question arises as to whether some of our monotonicity properties or

elementary bounds can be extended to all values of $\lambda > 1$. We have seen that our method of proof *cannot* furnish such an extension since inequality (3.6) fails to hold for $\lambda > 3/2$. However the example

$$x_{21}^{(\lambda)} = [2(\lambda+1)]^{-1/2}$$

shows that, for $\varepsilon > 0$, $(\lambda+1-\varepsilon)^{1/2} x_{21}^{(\lambda)}$ increases on the interval $-1+\varepsilon < \lambda < \infty$. Examining the proof in §3 we see that if we take $\lambda > \frac{3}{2}$ the inequality (2.1) breaks down for x close to $f(\lambda)$. The condition $0 < x < f(\lambda)$ arises from the fact that the positive zeros lie in $(0,1)$. If we have a better upper bound for a zero say $0 < x_{nk}^{(\lambda)} < x_0 < 1$ then we would need the condition (2.1) only for $0 < x < x_0 f(\lambda)$ with a corresponding enlargement of the set of values of λ for which our results hold. Since we have many such upper bounds including those proved here, our results can in fact be improved in this way though it does not seem to be possible to get them for *all* positive λ.

2. In the case of $x_{21}^{(\lambda)}$, not only do our methods not give the whole λ-interval, they do not in fact give the factor $(\lambda+1-\varepsilon)^{1/2}$ for small $\varepsilon > 0$. Using our method we need (2.1) to hold as $x \to 0^+$ i.e., we need

$$[(2n+1)(n+2\lambda)-(n-1)] f'(\lambda) \geqq (2n+1) f(\lambda). \tag{6.1}$$

If we let $f(\lambda) = (\lambda+\beta)^{1/2}$, we see that (6.1) requires us to have $\beta \leqq \frac{9}{10}$.

3. In [8] it was shown that $\lambda^{\alpha} x_{nk}^{(\lambda)}$ increases with λ, $0 < \lambda < 1$, provided

$$\alpha \geqq \max_{n \geqq 1} \frac{2n+1}{8n} = \frac{3}{8}.$$

Actually, since only the cases $n \geqq 2$ arise, it could be deduced from the work in [8] that this holds for

$$\alpha \geqq \max_{n \geqq 2} \frac{2n+1}{8n} = \frac{5}{16}.$$

However the results of the present paper, in particular the condition (3.7), show that it is sufficient to have

$$\alpha \geqq \max \frac{2n+1}{2(2n+1)+2n^2+1} = \frac{5}{19}.$$

4. $P_4^{(\lambda)}(x)$ is a constant multiple of

$$4(\lambda+2)(\lambda+3)x^4 - 12(\lambda+2)x^2 + 3.$$

Hence $[x_{41}^{(\lambda)}]^2$ and $[x_{42}^{(\lambda)}]^2$ are given by

$$\left[3 \pm \sqrt{9 - 3(\lambda+3)/(\lambda+2)}\,\right] / [2(\lambda+3)].$$

From this it follows that $(\lambda+3)^{1/2} x_{41}^{(\lambda)}$ *increases* while $(\lambda+3)^{1/2} x_{42}^{(\lambda)}$ *decreases* on $(-3/2, \infty)$. Thus, it would be of interest to obtain monotonicity results like Theorem 3.1 in which the square root factor depends on k as well as on n. Such results would lead to elementary bounds of the form (4.3), (4.4) in which the square root factors as well as the arguments of the cosine terms depend on k.

A NOTE TO THE PAPER OF AHMED, MULDOON AND SPIGLER*

ÁRPÁD ELBERT† AND ANDREA LAFORGIA‡

Abstract. We give a simplified proof of a theorem proved in [*Inequalities and numerical bounds for zeros of ultraspherical polynomials*, this Journal, 17 (1986) pp. 1000–1007].

Key words. zeros of ultraspherical polynomials, Sturm comparison theorem

AMS(MOS) subject classifications. Primary 33A45; secondary 34C10

S. Ahmed, M. E. Muldoon and R. Spigler proved the following result [2].

THEOREM. *For $n \geqq 2$ let $x_{nk}^{(\lambda)}$ denote the kth x-zero in decreasing order of $P_n^{(\lambda)}(x)$. Then for $k = 1, 2, \cdots, [n/2]$*

$$[2n^2+1+2\lambda(2n+1)]^{1/2} x_{nk}^{(\lambda)}$$

increases as λ increases, $-\frac{1}{2} \leqq \lambda \leqq \frac{3}{2}$.

The proof of the theorem given in [2] was based on a result due to Spigler, proved as a consequence of a version of the Sturm comparison theorem given in [1].

The aim of this note is to provide a shorter and easier proof of the theorem above.

Proof. The function $u(x) = (1-x^2)^{\lambda/2+1/4} P_n^{(\lambda)}(x)$ satisfies the differential equation [3, p. 81]

$$\frac{d^2u}{dx^2} + p(\lambda, x)u = 0,$$

where

$$p(\lambda, x) = \frac{(n+\lambda)^2}{1-x^2} + \frac{1/2+\lambda-\lambda^2+x^2/4}{(1-x^2)^2}.$$

Let $t = f(\lambda)x$, where

$$f(\lambda) = [2n^2+1+2\lambda(2n+1)]^{1/2}.$$

Then the function $U(t) = u(x)$ satisfies the differential equation

$$\frac{d^2U}{dt^2} + \tilde{P}(\lambda, t)U = 0,$$

with

$$\tilde{P}(\lambda, t) = [f(\lambda)]^{-2} p\left(\lambda, \frac{t}{f(\lambda)}\right).$$

The authors in [2] have this result. Making the substitution

$$t^2=\sigma, \qquad f^2=\varphi=2n^2+1+2\lambda(2n+1)$$

we get

$$P(\lambda,\varphi,\sigma)=\tilde{P}(\lambda,t)=\frac{(n+\lambda)^2}{\varphi-\sigma}+\frac{\varphi(1/2+\lambda-\lambda^2)+\sigma/4}{(\varphi-\sigma)^2}.$$

As in [2] we intend to apply the version of the Sturm comparison theorem proved in [1]. To this end we need to show that the function $P(\lambda,\varphi,\sigma)$ defined above decreases as λ increases, $-\frac{1}{2}\leqq\lambda\leqq\frac{3}{2}$. Since

$$\frac{dP}{d\lambda}=\frac{\partial P}{\partial\lambda}+\frac{\partial P}{\partial\varphi}\varphi', \qquad 0\leqq\sigma<\varphi$$

we get

$$(\varphi-\sigma)^3\frac{dP}{d\lambda}=A\sigma^2+B\sigma+C, \tag{1}$$

where

$$A=2(n+\lambda), \qquad B=-(4n+2\lambda+1)\varphi+\left[\lambda^2-\lambda-1+(n+\lambda)^2\right]\varphi',$$
$$C=(2n+1)\varphi^2+\left[\lambda^2-\lambda-1/2-(n+\lambda)^2\right]\varphi\varphi'.$$

The quadratic polynomial (1) is strictly convex.

Therefore, in order to show that $dP/d\lambda\leqq 0$ we have to check the sign of this polynomial only at $\sigma=0$ and $\sigma=\varphi$. By the definition of σ we obtain $C=0$. At $\sigma=\varphi$ the polynomial assumes the value

$$\varphi(2n+1)(4\lambda^2-4\lambda-3)=\varphi(2n+1)(2\lambda+1)(2\lambda-3)$$

which is clearly negative if $-\frac{1}{2}<\lambda<\frac{3}{2}$.

The proof of the theorem is complete.

Acknowledgment. We are indebted to Professor Richard A. Askey for the careful reading of the manuscript.

A NEW PROOF OF WATSON'S PRODUCT FORMULA FOR LAGUERRE POLYNOMIALS VIA A CAUCHY PROBLEM ASSOCIATED WITH A SINGULAR DIFFERENTIAL OPERATOR*

C. MARKETT†

Abstract. Watson's product formula for Laguerre polynomials L_n^α for $\alpha > -\frac{1}{2}$ as well as its limiting case for $\alpha = -\frac{1}{2}$ have served for defining a generalized translation operator [1]. In this paper we proceed just the other way. The Laguerre translation operator will be introduced as the solution of an associated Cauchy problem for each $\alpha \geqq -\frac{1}{2}$. A main task consists in finding the corresponding Riemann function explicitly. The Laguerre product formula then follows as a corollary. The paper concludes with a comparison between the translation operators associated with the Laguerre series and the Hankel transform.

Key words. Bessel function, Cauchy problem, generalized translation operator, Hankel transform, Laguerre polynomial, product formula, Riemann function, Sturm–Liouville differential equation

1. Introduction, survey of approach. Let for $\alpha > -1$, $x \geqq 0$, and $n \in \mathbb{P} = \{0, 1, 2, \cdots\}$ the Laguerre polynomials, Laguerre functions, and the Bessel functions be defined by

$$L_n^\alpha(x) = \sum_{k=0}^{n} \binom{n+\alpha}{n-k} \frac{(-x)^k}{k!},$$

$$y_n^\alpha(x) = e^{-x^2/2} L_n^\alpha(x^2)/L_n^\alpha(0),$$

$$j_\alpha(x) = 2^\alpha \Gamma(\alpha+1) x^{-\alpha} J_\alpha(x) = \sum_{k=0}^{\infty} \frac{\Gamma(\alpha+1)(-1)^k (x/2)^{2k}}{k!\Gamma(k+\alpha+1)},$$

respectively. The product formula for Laguerre polynomials due to Watson [32] can be written in the form

$$y_n^\alpha(x) y_n^\alpha(t) = \frac{\Gamma(\alpha+1)}{\Gamma(\alpha+1/2)\Gamma(1/2)} \int_0^\pi y_n^\alpha\left([x^2+t^2+2xt\cos\theta]^{1/2}\right) \cdot j_{\alpha-1/2}(xt\sin\theta)\sin^{2\alpha}\theta\, d\theta \qquad (\alpha > -\tfrac{1}{2},\ x, t \geqq 0). \tag{1.1}$$

The limiting formula for α tending to $-\frac{1}{2}$,

$$y_n^{-1/2}(x) y_n^{-1/2}(t) = \frac{1}{2}\left\{ y_n^{-1/2}(|x-t|) + y_n^{-1/2}(x+t) \right\} - \frac{xt}{2} \int_0^\pi y_n^{-1/2}\left([x^2+t^2+2xt\cos\theta]^{1/2}\right) J_1(xt\sin\theta)\, d\theta, \tag{1.2}$$

was first proved by Boersma, cf. [23] for his proof and another proof by the author.

Watson proved the identity (1.1) by special function arguments using the generating functions of the Laguerre polynomials and their products as well as an integral representation of Bessel functions due to Gegenbauer. Later, a group theoretical proof for $\alpha \in \mathbb{P}$ was given by Peetre [24]: If one associates the Weyl transform with the k-dimensional Heisenberg group, the so-called twisted convolution of two functions is introduced in such a way that the convolution is mapped by the Weyl transform onto an ordinary product of the Weyl transforms of the functions. Peetre showed that the restriction of the Weyl transform to rotation invariant functions is the Laguerre transform with $\alpha = k-1$, and the restriction of the twisted convolution is the Laguerre convolution. This immediately yields the product formula.

Another proof is due to Koornwinder [20] who deduces the product formula for $\alpha > 0$ from his Laguerre addition formula by integration. The assertion for $-\frac{1}{2} < \alpha \leqq 0$ then follows by analytic continuation with respect to α. Koornwinder obtains his addition formula as a limit of the addition formula for the so-called disk polynomials which for its part was found in case $\alpha \in \mathbb{N}$ independently by Šapiro [28] and Koornwinder [16] by interpreting the disk polynomials as spherical functions on the homogeneous spaces $SU(\alpha+2)/SU(\alpha+1)$. Again, analytic continuation leads to the general formula. Thus one may say that Koornwinder's proof of (1.1) also has a group theoretical source.

Each of these proofs is of its own interest since each illustrates a different aspect of special function theory. The main purpose of the present paper is to give another analytic proof for the Laguerre product formula which works for each $\alpha \geqq -\frac{1}{2}$ at once. Our starting point is the fact that the Laguerre functions y_n^α are the eigenfunctions of the Sturm–Liouville differential equation (S.-L. DE)

$$\frac{d}{dx}\left[x^{2\alpha+1}\frac{d}{dx}u(x)\right]+(\lambda x^{2\alpha+1}-x^{2\alpha+3})u(x)=0 \qquad (0 \leqq x < \infty) \tag{1.3}$$

for the eigenvalues $\lambda_n = 4n+2\alpha+2$, satisfying the boundary conditions

$$u(0)=1, \qquad \int_0^\infty |u(x)|^2 x^{2\alpha+1}dx < \infty.$$

DE(1.3) follows from the more familiar S.-L. DE for the Laguerre polynomials [30]

$$\frac{d}{dx}\left[e^{-x}x^{\alpha+1}\frac{d}{dx}L_n^\alpha(x)\right]+ne^{-x}x^\alpha L_n^\alpha(x)=0 \qquad (n \in \mathbb{P})$$

by an appropriate transformation. In operational notation it can also be written as

$$D_{q,x}^\alpha(u,x)+\lambda u(x)=0, \qquad D_{q,x}^\alpha = \frac{d^2}{dx^2}+\frac{2\alpha+1}{x}\frac{d}{dx}-q(x) \tag{1.4}$$

with the potential function given by $q(x)=x^2$. The Laguerre translation $T_{L,t}^\alpha(f,x)$ of a sufficiently smooth function $f(x)$ can then be introduced as the solution $u(x,t)$ of the Cauchy problem

$$\begin{aligned} &\left(D_{q,x}^\alpha - D_{q,t}^\alpha\right)u(x,t)=0 \qquad (0<t\leqq x), \\ &u(x,0)=f(x), \qquad u_t(x,0)=\frac{\partial}{\partial t}u(x,t)\Big|_{t=0}=0 \qquad (x>0), \end{aligned} \tag{1.5}$$

where $q(x)=x^2$, and where $u(x,t)$ is extended symmetrically in x and t to $0<x<t$. By solving this problem we will establish the following kernel representation of the Laguerre translation (see also [1] and [12] with a slight change of notation).

THEOREM 1. *For $\alpha \geqq -\frac{1}{2}$ the solution $u(x,t)=T^{\alpha}_{L,t}(f;x)$ of the Cauchy problem* (1.5) *is given by*

$$T^{\alpha}_{L,t}(f;\,x)=\begin{cases}\displaystyle\int_0^{\infty} f(z)K^{\alpha}_L(x,t,z)z^{2\alpha+1}dz, & \alpha>-\frac{1}{2},\\[2ex] \displaystyle\frac{1}{2}\{f(|x-t|)+f(x+t)\}+\int_0^{\infty} f(z)K_L^{-1/2}(x,t,z)\,dz, & \alpha=-\frac{1}{2},\end{cases}$$

where the kernel functions K^{α}_L are

$$K^{\alpha}_L(x,t,z)=\begin{cases}\displaystyle\frac{\Gamma(\alpha+1)}{\Gamma(\alpha+1/2)\Gamma(1/2)}(xtz)^{-2\alpha}\rho^{2\alpha-1}j_{\alpha-1/2}(\rho), & \alpha>-\frac{1}{2},\\[2ex] \displaystyle-\frac{1}{4}xtz\,j_1(\rho), & \alpha=-\frac{1}{2}\end{cases}\tag{1.6}$$

for $|x-t|<z<x+t$, and $K^{\alpha}_L(x,t,z)=0$ elsewhere, with the notation

$$\begin{aligned}\rho(x,t,z)&=\frac{1}{2}\left(2[x^2t^2+x^2z^2+t^2z^2]-x^4-t^4-z^4\right)^{1/2}\\ &=\frac{1}{2}\left(\left[(x+t)^2-z^2\right]\left[z^2-(x-t)^2\right]\right)^{1/2}.\end{aligned}\tag{1.7}$$

The proof will be given in §5. For $\alpha\geqq 0$ the domain of the translation operator $T^{\alpha}_{L,t}$ can be extended to the weighted Lebesgue space

$$L^1_{w(2\alpha+1)}=\left\{f;\ \|f\|_{L^1_{w(2\alpha+1)}}=\int_0^{\infty}|f(x)|x^{2\alpha+1}dx<\infty\right\}$$

(cf. [12]). Applying Theorem 1 to the Laguerre functions y^{α}_n, $n\in\mathbb{P}$, one obtains

$$y^{\alpha}_n(x)y^{\alpha}_n(t)=T^{\alpha}_{L,t}(y^{\alpha}_n;\,x)\qquad\left(x,t>0,\alpha\geqq-\frac{1}{2}\right),$$

which provides the desired proof of the product formulas (1.1), (1.2).

The foregoing way of introducing generalized translation operators goes back to Delsarte [7], [8], who studied the Cauchy problem (1.5) in case $q(x)\equiv 0$. Many authors have continued and extended his work. For example, Levitan [22] and Povzner [25] considered the particular case $\alpha=-\frac{1}{2}$ of (1.5), imposing certain growth conditions on the potential q. Other generalizations were made by Leblanc, Hutson and Pym, as well as by Chébli; cf. [4] for references. For example, Chébli [5] proceeds from the partly more general differential operator

$$D^A_x=\frac{1}{A(x)}\frac{\partial}{\partial x}\left[A(x)\frac{\partial}{\partial x}\right]\qquad(0<x<\infty)$$

where, apart from a convexity property for $A(x)$, he assumes that $A\in C^2(0,\infty)$, $A(0)=0$, $A(x)>0$ for $x>0$, and $A'(x)/A(x)=\alpha/x+B(x)$, B being continuous at 0.

In order to solve a Cauchy problem of the form (1.5), Riemann's method can be used provided the corresponding Riemann function can be determined explicitly (cf. §2). Of course, the latter task is the main obstacle here. The interesting feature of this approach to a translation operator is that it can also cover variants of the classical translations which arise from slight variations of the potential function q in (1.5). In fact, once the Riemann function of a differential equation (1.5) is found for some fixed

potential q_0, it may be possible to handle the solutions of (1.5) for other q without knowing their Riemann functions explicitly, e.g., by estimating the Riemann functions in terms of the old one.

Braaksma and de Snoo [4] have proceeded this way, starting from the Cauchy problem (1.5) with $q_0 \equiv 0$ (cf. also [3]). Its solution defines the well-known "Hankel translation"

$$T^{\alpha}_{H,t}(f;\, x) = \begin{cases} \displaystyle\int_0^{\infty} f(z) K^{\alpha}_H(x,t,z) z^{2\alpha+1} dz, & \alpha > -\frac{1}{2}, \\ \displaystyle\frac{1}{2}\{f(|x-t|)+f(x+t)\}, & \alpha = -\frac{1}{2}, \end{cases} \tag{1.8}$$

where

$$K^{\alpha}_H(x,t,z) = \frac{\Gamma(\alpha+1)}{\Gamma(\alpha+1/2)\Gamma(1/2)} (xtz)^{-2\alpha} (\rho(x,t,z))^{2\alpha-1}$$

if $|x-t| < z < x+t$, and $K^{\alpha}_H(x,t,z) = 0$ elsewhere, with ρ given by (1.7). See [2], [6], [13], [15], also for applications in harmonic analysis of the Hankel transform. By varying the potential and the corresponding Riemann function (cf. (4.7), (4.9)) Braaksma and de Snoo derived estimates of the kernels of a class of generalized translations. This class does not contain the Laguerre translation whose potential is $q(x) = x^2$ since, among other conditions, the potentials q admitted in [4] have to vanish at infinity. So our final purpose is to determine the Riemann function associated with the Laguerre translation (cf. §4, in particular, (4.11), (4.13)) and thus to provide a new starting point ($q_0(x) = x^2$ instead of $q_0(x) \equiv 0$) for the same procedure. In a forthcoming paper it will be shown that in this way one can indeed obtain norm estimates for a class of translations in some neighborhood of the Laguerre case.

At this point let us make some further remarks concerning product formulas for orthogonal systems and their relation to other important formulas in the field as, e.g., to addition formulas and Laplace type integral representations. In particular, we will take the Jacobi polynomial systems as examples which have been extensively studied. While product and addition formulas for the ultraspherical polynomials are well known for quite a time, the respective formulas for the Jacobi polynomials were found by Koornwinder within the last decade. See, e.g., [18], [19], and, for the historical background, also the introductory survey paper of Koornwinder's thesis [17]. He gave several different proofs, some of which are group theoretic in nature, while others are analytic. It turns out that, for Jacobi polynomials, one of the four properties: Laplace representation, product formula, degenerate and ordinary addition formula implies the three others [19]. This may be a general feature, also for other orthogonal systems. Let us mention only one analytic proof of the product formula [18]. It also proceeds from a partial differential equation, but now of elliptic type, i.e., from the biaxially symmetric potential equation

$$\left(D^{\beta}_{0,x} + D^{\alpha}_{0,t}\right) F(x,t) = 0, \tag{1.9}$$

where the same differential operators appear as in the Hankel case (cf. (1.4)). Solving (1.9) in two different ways leads, after some transformations, to Bateman's bilinear sum which expresses the product of the Jacobi polynomials $P^{\alpha,\beta}_n(x) P^{\alpha,\beta}_n(t)$ as a linear combination of the terms $(x+t)^k P^{\alpha,\beta}_k((1+xt)/(x+t))$. An application to the Laplace type integral representations of the Jacobi polynomials (which can be derived from the corresponding formula for the ultraspherical polynomials by means of fractional integration) then yields the Jacobi product formula immediately.

2. Translation and Riemann function. We begin with a brief review of Riemann's method (cf. [27] and, e.g., [4], [10]). The Cauchy problem (1.5) can be reformulated so as to have homogeneous initial conditions. To this end we set $v(x,t)=u(x,t)-f(x)$, so that, with the notation $D^{\alpha}_{q,x,t}=D^{\alpha}_{q,x}-D^{\alpha}_{q,t}$,

$$\begin{aligned} &D^{\alpha}_{q,x,t}v(x,t)=-D^{\alpha}_{q,x,t}f(x) \qquad (0<t\leqq x),\\ &v(x,0)=0, \quad v_t(x,0)=0 \quad (x>0). \end{aligned} \tag{2.1}$$

Denote by $A_q(\xi,\tau;\ x,t)$ the Riemann function associated with the operator

$$D^{\alpha}_{q,\xi,\tau}=\frac{\partial^2}{\partial\xi^2}-\frac{\partial^2}{\partial\tau^2}+\frac{2\alpha+1}{\xi}\frac{\partial}{\partial\xi}-\frac{2\alpha+1}{\tau}\frac{\partial}{\partial\tau}-[q(\xi)-q(\tau)],$$

i.e., $A_q(\xi,\tau;x,t)=v^*(\xi,\tau;x,t)$ where v^* solves the characteristic boundary value problem

(2.2)

$$\begin{aligned} &\left(D^{\alpha}_{q,\xi,\tau}\right)^*v^*(\xi,\tau)\\ &\quad=v^*_{\xi\xi}-v^*_{\tau\tau}-\left(\frac{2\alpha+1}{\xi}v^*\right)_{\xi}+\left(\frac{2\alpha+1}{\tau}v^*\right)_{\tau}-[q(\xi)-q(\tau)]v^*=0\\ &\qquad\qquad \text{if } (\xi,\tau)\in\Delta_{xt}=\{(\xi,\tau);\ 0<\tau<t,\ x-t+\tau<\xi<x+t-\tau\},\\ &v^*_{\xi}+v^*_{\tau}=\left(\alpha+\frac{1}{2}\right)\left(\frac{1}{\xi}+\frac{1}{\tau}\right)v^* \quad \text{if } \xi-\tau=x-t,\\ &v^*_{\xi}-v^*_{\tau}=\left(\alpha+\frac{1}{2}\right)\left(\frac{1}{\xi}-\frac{1}{\tau}\right)v^* \quad \text{if } \xi+\tau=x+t,\\ &v^*(x,t;\ x,t)=1. \end{aligned}$$

Applying Green's theorem to

$$v^*D^{\alpha}_{q,\xi,\tau}v=v^*D^{\alpha}_{q,\xi,\tau}v-v\left(D^{\alpha}_{q,\xi,\tau}\right)^*v^*,$$

and choosing for the region of integration the triangle $\Delta_{xt,\varepsilon}$ with vertices $R(x,t)$ and $P_{\varepsilon}(x-t+\varepsilon,\varepsilon)$, $Q_{\varepsilon}(x+t-\varepsilon,\varepsilon)$ for some $\varepsilon>0$, one obtains

$$\begin{aligned} &\iint_{\Delta_{xt,\varepsilon}} v^*D^{\alpha}_{q,\xi,\tau}v\,d\xi\,d\tau\\ &\quad=\int_{\partial\Delta_{xt,\varepsilon}}\left[\left(v^*v_{\tau}-vv^*_{\tau}+\frac{2\alpha+1}{\tau}vv^*\right)d\xi+\left(v^*v_{\xi}-vv^*_{\xi}+\frac{2\alpha+1}{\xi}vv^*\right)d\tau\right]\\ &\quad=(vv^*)_{P_{\varepsilon}}+(vv^*)_{Q_{\varepsilon}}-2(vv^*)_R+\int_{x-t+\varepsilon}^{x+t-\varepsilon}\left(v^*v_{\tau}-vv^*_{\tau}+\frac{2\alpha+1}{\tau}vv^*\right)\Big|_{\tau=\varepsilon}d\xi. \end{aligned}$$

Here $(vv^*)_{P_{\varepsilon}}$ denotes the value of vv^* at the vertex P_{ε}, etc. Under the assumption that v^* and $((2\alpha+1)/\tau)v^*-v^*_{\tau}$ remain continuous on $\Delta_{xt,\varepsilon}$ for ε tending to $0+$, this leads in the limit to

$$v(x,t)=-\frac{1}{2}\iint_{\Delta_{xt}} v^*D^{\alpha}_{q,\xi,\tau}v\,d\xi\,d\tau \qquad \left(\alpha\geqq-\frac{1}{2}\right),$$

in view of the initial data of v. As will be shown in §§4 and 5, the two continuity conditions are satisfied if $q(x)=x^2$. In view of (2.1), one can replace $v(\xi,\tau)$ by $-f(\xi)$

in the last integral, so that a second application of Green's theorem yields

$$v(x,t)=\frac{1}{2}\iint_{\Delta_{xt}} v^* D^{\alpha}_{q,\xi,\tau} f\,d\xi\,d\tau$$

$$=\frac{1}{2}\{(fv^*)_{P_0}+(fv^*)_{Q_0}\}-(fv^*)_R+\frac{1}{2}\lim_{\varepsilon\to 0+}\int_{x-t+\varepsilon}^{x+t-\varepsilon}\left(\frac{2\alpha+1}{\tau}v^*-v^*_\tau\right)\Big|_{\tau=\varepsilon} f\,d\xi.$$

Since $(v^*)_R=1$, and $(v^*)_{P_0}=(v^*)_{Q_0}=0$ if $\alpha>-\frac{1}{2}$, and $=1$ if $\alpha=-\frac{1}{2}$ (cf. (4.12), (4.13)), one finally derives

$$u(x,t)=v(x,t)+f(x)$$

$$=\begin{cases}\displaystyle\int_{x-t}^{x+t} f(\xi)w^{\alpha}_q(x,t,\xi)\,d\xi, & \alpha>-\frac{1}{2},\\ \displaystyle\frac{1}{2}\{f(x-t)+f(x+t)\}+\int_{x-t}^{x+t} f(\xi)w^{\alpha}_q(x,t,\xi)\,d\xi, & \alpha=-\frac{1}{2},\end{cases}$$

for $0<t\leqq x$, where

$$w^{\alpha}_q(x,t,\xi)=\frac{1}{2}\lim_{\tau\to 0+}\left\{\frac{2\alpha+1}{\tau}A^{\alpha}_q(\xi,\tau;\,x,t)-\frac{\partial}{\partial\tau}A^{\alpha}_q(\xi,\tau;\,x,t)\right\} \tag{2.3}$$

$$=-\frac{1}{2}\lim_{\tau\to 0+}\left\{\tau^{2\alpha+1}\frac{\partial}{\partial\tau}\left[\tau^{-2\alpha-1}A^{\alpha}_q(\xi,\tau;\,x,t)\right]\right\}.$$

For $0<x<t$, set $u(x,t)=u(t,x)$. If $w^{\alpha}_q(x,t,\xi)$ is symmetric with respect to x and t for each $|x-t|<\xi<x+t$, the kernel of the corresponding generalized translation is then given by

$$K^{\alpha}_q(x,t,\xi)=\xi^{-2\alpha-1}w^{\alpha}_q(x,t,\xi). \tag{2.4}$$

This relation will be the basis of the proof of Theorem 1 in §5.

In view of the importance of Riemann's method [27] for various problems concerning partial differential equations, many authors have tried to determine as many Riemann functions as possible in closed form. For example, there are contributions by Chaundy, Cohn, Copson, Henrici, Vekua, and, particularly in recent years, by Bauer, Florian, Lanckau, Püngel, Wahlberg, and Wallner, cf. e.g. [21], [26], [31] and the literature cited there. Here, one essential step is to introduce appropriate auxiliary variables for representing the Riemann function, the number of which increases with the generality of the underlying PDE. For example, let us take the boundary value problem, which will be of particular interest in the following (cf. §4),

$$\begin{aligned} &V_{\zeta\eta}-\left[C_0+C_1(\zeta-\eta)^{-2}\right]V=0, \qquad C_0,\,C_1=\text{const.},\\ &V(\zeta,\eta_0;\,\zeta_0,\eta_0)=V(\zeta_0,\eta;\,\zeta_0,\eta_0)=1.\end{aligned} \tag{2.5}$$

Its solution follows at once from a result of Henrici [14] by changing the variable η into $-\eta$. With the two auxiliary variables

$$w_0=(\zeta-\zeta_0)(\eta-\eta_0), \qquad w=w_0\left[(\zeta-\eta)(\zeta_0-\eta_0)\right]^{-1} \tag{2.6a}$$

the solution is given as the confluent hypergeometric function

$$V(\zeta,\eta;\,\zeta_0,\eta_0)=\Xi_2(p,1-p;\,1;\,w,C_0w_0) \tag{2.6b}$$

$$=\sum_{n=0}^{\infty}\sum_{k=0}^{\infty}\frac{(p)_n(1-p)_n}{(n+k)!n!k!}w^n(C_0w_0)^k,$$

where $|w|<1$, w_0 is arbitrary, and $p(1-p)=C_1$. This can also be derived from more general results of Lanckau [21], Püngel [26], and Wallner [31]. Let us mention that Püngel gave his Riemann function in a somewhat different form, namely as a power series expansion in powers of w_0 with coefficients being polynomials of several variables. When applied to our example (2.5), his result reduces to

$$V(\zeta,\eta;\zeta_0,\eta_0)=\sum_{k=0}^{\infty} Q^k(v)\frac{(w_0)^k}{k!^2}, \qquad v=\frac{w}{w_0},$$

$$Q^k(v)=\sum_{n=0}^{k}\binom{k}{n}(p)_n(1-p)_n C_0^{k-n}v^n,$$

which coincides with (2.6b).

3. Auxiliary results. We collect some properties of the hypergeometric function to be used in the sequel. (See, e.g., [9], [29].) The transformations

(3.1a) $$F(a,b;\,c;\,z)=(1-z)^{-a}F\left(a,c-b;\,c;\,\frac{z}{z-1}\right)$$

(3.1b) $$F(a,b;\,c;\,z)=(1-z)^{-b}F\left(c-a,b;\,c;\,\frac{z}{z-1}\right) \qquad \left(|z|<1,\ \left|\frac{z}{z-1}\right|<1\right),$$

(3.1c) $$F(a,b;\,c;\,z)=(1-z)^{c-a-b}F(c-a,c-b;\,c;\,z) \qquad (|z|<1)$$

are due to Euler as is the integral representation

$$F(a,b;\,c;\,z)=\frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)}\int_0^1 t^{b-1}(1-t)^{c-b-1}(1-tz)^{-a}dt$$

for $\operatorname{Re}c>\operatorname{Re}b>0$, $|\arg(1-z)|<\pi$. The Gauss summation theorem reads

$$F(a,b;\,c;\,1)=\frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} \qquad (c\neq 0,-1,\cdots;\ \operatorname{Re}c>\operatorname{Re}(a+b)).$$

Moreover, one has

$$\frac{d}{dz}F(a,b;\,c;\,z)=\frac{ab}{c}F(a+1,b+1;\,c+1;\,z),$$

$$F(a,b;\,c;\,z)=\frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}F(a,b;\,a+b+1-c;\,1-z)$$

$$+\frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(c)\Gamma(b)}(1-z)^{c-a-b}F(c-a,c-b;\,c-a-b+1;\,1-z)$$

if $a+b<c<a+b+1$, $c\neq 0,-1,-2,\cdots$, and for $a,b\neq 0,-1,-2,\cdots$,

$$F(a,b;\,a+b;\,z)=\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{n!n!}[k_{n,0}-\log(1-z)](1-z)^n,$$

$$F(a,b;\,a+b+1;\,z)=\frac{\Gamma(a+b+1)}{\Gamma(a+1)\Gamma(b+1)}-(1-z)\frac{\Gamma(a+b+1)}{\Gamma(a)\Gamma(b)}\cdot$$

$$\sum_{n=0}^{\infty}\frac{(a+1)_n(b+1)_n}{(n+1)!n!}[k_{n,1}-\log(1-z)](1-z)^n,$$

where $k_{n,j}=\psi(n+1)+\psi(n+1+j)-\psi(a+n+j)-\psi(b+n+j)$ $(j=0,1)$. Hence the behavior of F for $z\to 1-$ can be described by

(3.2a)

$$|F(a,b;\ c;\ z)-F(a,b;\ c;\ 1)|$$

$$\leqq C\begin{cases}\left|\dfrac{ab\Gamma(c)\Gamma(c-a-b-1)}{\Gamma(c-a)\Gamma(c-b)}\right|(1-z) & \text{if } c>a+b+1,\\ \left|\dfrac{\Gamma(a+b+1)}{\Gamma(a)\Gamma(b)}\right|(1-z)\log\left(\dfrac{1}{1-z}\right) & \text{if } c=a+b+1,\\ \left|\dfrac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)}\right|(1-z)^{c-a-b} & \text{if } a+b<c<a+b+1,\end{cases}$$

$$F(a,b;\ a+b;\ z)=\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\log\left(\frac{1}{1-z}\right)+O(1)\qquad(z\to 1-). \tag{3.2b}$$

The following lemma can be considered as a generalization of Euler's transformation.

LEMMA 1. *For $n\in\mathbb{P}$, $a<1$, $0\leqq\phi\leqq 1$, $\chi\geqq 0$, the function*

$$S(n,a;\ \phi,\chi)=\sum_{k=0}^{\infty}F(n+a,k;\ k+n+1;\ \phi)\frac{n!(-\chi)^k}{k!(k+n)!}$$

satisfies

$$|S(n,a;\ \phi,\chi)|\leqq\begin{cases}1, & a\leqq\dfrac{1}{2},\\ 1+\dfrac{\chi}{(1-a)(2-a)}, & \dfrac{1}{2}<a<1.\end{cases} \tag{3.3}$$

Moreover, if $a\leqq\frac{1}{2}$, $b>0$, $c>0$, $|z|<1$, and $|z/(z-1)|<1$, there holds

$$\sum_{n=0}^{\infty}\left\{\sum_{k=0}^{\infty}\frac{n!(-\chi)^k}{k!(k+n)!}\right\}\frac{(a)_n(b)_n}{(c)_n n!}z^n$$

$$=(1-z)^{-a}\sum_{n=0}^{\infty}S\left(n,a;\ \frac{z}{z-1},\chi\right)\frac{(a)_n(c-b)_n}{(c)_n n!}\left(\frac{z}{z-1}\right)^n. \tag{3.4}$$

Proof. Concerning (3.3), insert

$$F(n+a,k;\ k+n+1;\ 1)=\frac{(k+n)!\Gamma(1-a)}{n!\Gamma(k+1-a)}\qquad(a<1)$$

to deduce $S(n,a;\ 1,\chi)=j_{-a}(2\sqrt{\chi})$, from which the assertion for $\phi=1$ follows by means of the estimate of the Bessel functions [33, 3.31(1), (2)]

$$|j_\nu(x)|\leqq\begin{cases}1, & \nu\geqq-\dfrac{1}{2},\\ 1+\dfrac{x^2}{4(\nu+1)(\nu+2)}, & -1<\nu<-\dfrac{1}{2}\end{cases}\qquad(x\geqq 0). \tag{3.5}$$

Now let $0 \leqq \phi < 1$. In view of Euler's integral representation one has

$$S(n,a;\ \phi,\chi) = 1 + \int_0^1 \left\{ \sum_{k=1}^{\infty} \frac{(-\chi)^k t^{k-1}}{k!(k-1)!} \right\} g_{n,\phi}(t)\, dt,$$

where $g_{n,\phi}(t) = (1-t)^n (1-t\phi)^{-n-a}$. Interpreting the inner sum as the derivative of j_0, summation by parts gives

$$S(n,a;\ \phi,\chi) = j_0(2\sqrt{\chi})(1-\phi)^{-a}\delta_{n,0} - \int_0^1 j_0(2\sqrt{\chi t})\, g'_{n,\phi}(t)\, dt,$$

$\delta_{n,0}$ being Kronecker's symbol. In case $a \leqq 0$,

$$g'_{n,\phi}(t) = -[n(1-\phi) - a\phi(1-t)](1-t)^{n-1}(1-t\phi)^{-n-a-1}$$

is nonpositive on $0 \leqq t \leqq 1$ for each $n \in \mathbb{P}$, $0 \leqq \phi < 1$, so that, in view of (3.5),

$$|S(n,a;\ \phi,\chi)| \leqq (1-\phi)^{-a}\delta_{n,0} - \int_0^1 g'_{n,\phi}(t)\, dt \equiv 1 \qquad (\chi \geqq 0).$$

In the remaining cases $0 < a < 1$ we use

$$\begin{aligned} F(n+a,k;\ k+n+1;\ \phi) &= (1-\phi)^{1-a} F(n+1,k-a+1;\ k+n+1;\ \phi) \\ &= (1-\phi)^{1-a} \frac{\Gamma(k+n+1)}{\Gamma(k-a+1)\Gamma(n+a)} \int_0^1 t^{k-a}(1-t)^{n+a-1}(1-t\phi)^{-n-1} dt \end{aligned}$$

to deduce

$$S(n,a;\ \phi,\chi) = (1-\phi)^{1-a} \frac{\Gamma(n+1)}{\Gamma(n+a)\Gamma(1-a)} \cdot \int_0^1 j_{-a}(2\sqrt{\chi t})\, t^{-a}(1-t)^{n+a-1}(1-t\phi)^{-n-1} dt. \tag{3.6}$$

Applying (3.5) once more, one has

$$|S(n,a;\ \phi,\chi)| \leqq (1-\phi)^{1-a} F(n+1,1-a;\ n+1;\ \phi) \equiv 1$$

for $0 < a \leqq \frac{1}{2}$ and, for $\frac{1}{2} < a < 1$,

$$\begin{aligned} |S(n,a;\ \phi,\chi)| &\leqq 1 + (1-\phi)^{1-a} \frac{\chi}{(n+1)(2-a)} F(n+1,2-a;\ n+2;\ \phi) \\ &\leqq 1 + \frac{\chi}{(1-a)(2-a)}. \end{aligned}$$

This completes the proof of (3.3). To verify (3.4), we generalize a proof of Euler's transformation (3.1a) as given in [29, §1.7.1]. Setting

$$\frac{(a)_n (b)_n}{(c)_n n!} = \frac{(a)_n}{n!} F(-n,c-b;\ c;\ 1) = \sum_{j=0}^{n} \frac{(a)_j (c-b)_j (j+a)_{n-j} (-1)^j}{(c)_j j!(n-j)!}$$

for $b>0$, $c>0$, $n\in\mathbb{P}$, the left-hand side of (3.4) becomes

$$\sum_{n=0}^{\infty}\left\{\sum_{k=0}^{\infty}\frac{n!(-\chi)^k}{k!(k+n)!}\right\}\left\{\sum_{j=0}^{n}\frac{(a)_j(c-b)_j(j+a)_{n-j}(-1)^j}{(c)_j j!(n-j)!}\right\}z^n$$

$$=\sum_{j=0}^{\infty}\left\{\sum_{n=j}^{\infty}\left[\sum_{k=0}^{\infty}\frac{n!(-\chi)^k}{k!(k+n)!}\right]\frac{(j+a)_{n-j}}{(n-j)!}z^{n-j}\right\}\frac{(a)_j(c-b)_j}{(c)_j j!}(-z)^j.$$

By an index transformation, an interchange of summations and an application of (3.1a), the term in curly brackets can be written as

$$\sum_{k=0}^{\infty}\left[\sum_{n=0}^{\infty}\frac{(j+a)_n(n+j)!}{(n+j+k)!n!}z^n\right]\frac{(-\chi)^k}{k!}$$

$$=\sum_{k=0}^{\infty}F(j+a,j+1;\ k+j+1;\ z)\frac{j!(-\chi)^k}{(k+j)!k!}$$

$$=(1-z)^{-a-j}\sum_{k=0}^{\infty}F\left(j+a,k;\ k+j+1;\ \frac{z}{z-1}\right)\frac{j!(-\chi)^k}{(k+j)!k!},$$

which proves (3.4). □

4. The Riemann function associated with the Laguerre translation. In the characteristic boundary value problem (2.2) we choose the Laguerre potential $q(\xi)=\xi^2$ and substitute

$$\begin{aligned}\zeta(\xi,\tau)&=\frac{1}{4}(\xi+\tau)^2, \qquad \zeta_0=\zeta(x,t),\\ \eta(\xi,\tau)&=\frac{1}{4}(\xi-\tau)^2, \qquad \eta_0=\eta(x,t).\end{aligned}\tag{4.1}$$

Dropping the asterisk, we obtain

$$\begin{aligned}&v_{\zeta\eta}+\left(\frac{\alpha+1/2}{\zeta-\eta}v\right)_{\zeta}-\left(\frac{\alpha+1/2}{\zeta-\eta}v\right)_{\eta}-v=0 \quad \text{if } (\zeta,\eta)\in\Delta_{\zeta_0\eta_0},\\ &v_{\zeta}=\frac{\alpha+1/2}{\zeta-\eta}v \quad \text{if } \eta=\eta_0,\\ &v_{\eta}=-\frac{\alpha+1/2}{\zeta-\eta}v \quad \text{if } \zeta=\zeta_0,\\ &v(\zeta_0,\eta_0;\ \zeta_0,\eta_0)=1\end{aligned}\tag{4.2}$$

for $\alpha\geqq-\frac{1}{2}$, where now

$$\Delta_{\zeta_0\eta_0}=\{(\zeta,\eta);\ \eta_0<\eta<\zeta_0,\ \eta<\zeta<\zeta_0\}.$$

The boundary conditions in (4.2) can also be written as

$$v(\zeta,\eta;\ \zeta_0,\eta_0)=\left(\frac{\zeta-\eta}{\zeta_0-\eta_0}\right)^{\alpha+1/2} \quad \text{if } \eta=\eta_0 \text{ or } \zeta=\zeta_0.\tag{4.3}$$

We further use the transformation

$$v(\zeta,\eta;\ \zeta_0,\eta_0)=\left(\frac{\zeta-\eta}{\zeta_0-\eta_0}\right)^{\alpha+1/2}V(\zeta,\eta;\ \zeta_0,\eta_0)\tag{4.4}$$

to turn (4.2) into its selfadjoint form

$$V_{\zeta\eta}+\left[\frac{\alpha^2-1/4}{(\zeta-\eta)^2}-1\right]V=0 \quad \text{if } (\zeta,\eta)\in\Delta_{\zeta_0\eta_0}, \tag{4.5}$$
$$V(\zeta,\eta;\,\zeta_0,\eta_0)=1 \quad \text{if } \eta=\eta_0 \text{ or } \zeta=\zeta_0.$$

As a pattern for solving this problem we consider the corresponding boundary value problem for the Riemann function of the Hankel case

$$(V_H^\alpha)_{\zeta\eta}+\frac{\alpha^2-1/4}{(\zeta-\eta)^2}V_H^\alpha=0 \quad \text{if } (\zeta,\eta)\in\Delta_{\zeta_0\eta_0},$$
$$V_H^\alpha(\zeta,\eta;\,\zeta_0,\eta_0)=1 \quad \text{if } \eta=\eta_0 \text{ or } \zeta=\zeta_0.$$

(Throughout the paper the subscripts H and L stand for Hankel and Laguerre, respectively.) Its solution can be represented using one auxiliary variable only:

$$V_H^\alpha(\zeta,\eta;\,\zeta_0,\eta_0)=F\left(\frac{1}{2}+\alpha,\frac{1}{2}-\alpha;\,1;\,w\right), \qquad w=\frac{(\zeta-\zeta_0)(\eta-\eta_0)}{(\zeta-\eta)(\zeta_0-\eta_0)}.$$

But while the hypergeometric function F converges in the unit disk only, the argument $w(\zeta,\eta;\,\zeta_0,\eta_0)$ ranges over the whole negative semiaxis when (ζ,η) ranges over $\Delta_{\zeta_0\eta_0}$. To establish the complete solution by analytic continuation one therefore has to use Euler's transformations (3.1a) and (3.1b) according to $\alpha\leqq 0$ or $\alpha>0$. Hence, setting

$$\chi=(\zeta_0-\zeta)(\eta-\eta_0), \quad \psi=(\zeta_0-\eta)(\zeta-\eta_0), \quad \phi=\frac{\chi}{\psi}=\frac{w}{w-1} \tag{4.6}$$

and returning to v via (4.4) again, one obtains

$$v_H^\alpha(\zeta,\eta;\,\zeta_0,\eta_0) \tag{4.7}$$
$$=\begin{cases}\dfrac{\zeta-\eta}{(\zeta_0-\eta_0)^{2\alpha}}\psi^{\alpha-1/2}F\left(\dfrac{1}{2}-\alpha,\dfrac{1}{2}-\alpha;\,1;\,\phi\right), & \alpha>0,\\[2ex] (\zeta-\eta)^{2\alpha+1}\psi^{-\alpha-1/2}F\left(\dfrac{1}{2}+\alpha,\dfrac{1}{2}+\alpha;\,1;\,\phi\right), & -\dfrac{1}{2}\leqq\alpha\leqq 0.\end{cases}$$

Notice that ϕ vanishes on the characteristics $\eta=\eta_0$ and $\zeta=\zeta_0$, in accordance with (4.3). If $(\zeta,\eta)\in\Delta_{\zeta_0\eta_0}$ tends to the initial line $\zeta=\eta$, ϕ tends to $1-$, and the asymptotic behavior of the hypergeometric function implies that the Riemann function v_H^α is still continuous on $\eta_0<\zeta=\eta<\zeta_0$ with

$$v_H^\alpha(\zeta,\zeta;\,\zeta_0,\eta_0)=\begin{cases}0, & \alpha>-\dfrac{1}{2},\\[2ex] 1, & \alpha=-\dfrac{1}{2}.\end{cases} \tag{4.8}$$

When substituting (4.1) into (4.7) and (4.8), the Riemann function of the Hankel case in the sense of (2.2) is finally given for $(\xi,\tau)\in\overline{\Delta_{xt}}$ by

$$A_H^\alpha(\xi,\tau;\,x,t)=v_H^\alpha\left(\frac{1}{4}(\xi+\tau)^2,\frac{1}{4}(\xi-\tau)^2;\,\frac{1}{4}(x+t)^2,\frac{1}{4}(x-t)^2\right). \tag{4.9}$$

Returning to problem (4.5), we use the solution (2.6) of (2.5) for the case $C_0=1$ and $C_1=\frac{1}{4}-\alpha^2$ to get

$$V_L^\alpha(\zeta,\eta;\,\zeta_0,\eta_0)=\sum_{n=0}^{\infty}\left\{\sum_{k=0}^{\infty}\frac{n!(-\chi)^k}{k!(k+n)!}\right\}\frac{(1/2+\alpha)_n(1/2-\alpha)_n}{n!n!}w^n$$

$$=\sum_{n=0}^{\infty}j_n(2\sqrt{\chi})\frac{(1/2+\alpha)_n(1/2-\alpha)_n}{n!n!}w^n$$

for those ζ, η for which the series converges absolutely, i.e., for $|w|<1$. In the particular cases $\alpha=-\frac{1}{2}$ and $\alpha=\frac{1}{2}$, the result reduces to

$$V_L^{\pm 1/2}(\zeta,\eta;\,\zeta_0,\eta_0)=j_0(2\sqrt{\chi})=J_0\left(2\sqrt{(\zeta_0-\zeta)(\eta-\eta_0)}\right) \tag{4.10}$$

which is known as the Riemann function of the telegraph equation $V_{\zeta\eta}-V=0$, cf., e.g. [10, p. 133].

In order to obtain the solution for each $w\leqq 0$ by analytic continuation, we now have to apply (3.4) of Lemma 1. Choosing $a=\frac{1}{2}+\alpha$, $b=\frac{1}{2}-\alpha$ if $-\frac{1}{2}\leqq\alpha\leqq 0$, and $a=\frac{1}{2}-\alpha$, $b=\frac{1}{2}+\alpha$ if $\alpha>0$, as well as $c=1$, and inverting the transformation (4.4), it follows for $(\zeta,\eta)\in\Delta_{\zeta_0\eta_0}$ that

(4.11)

$$v_L^\alpha(\zeta,\eta;\,\zeta_0,\eta_0)$$

$$=\begin{cases}\dfrac{\zeta-\eta}{(\zeta_0-\eta_0)^{2\alpha}}\psi^{\alpha-1/2}\displaystyle\sum_{n=0}^{\infty}S\left(n,\frac{1}{2}-\alpha;\,\phi,\chi\right)\frac{(1/2-\alpha)_n(1/2-\alpha)_n}{n!n!}\phi^n, & \alpha>0,\\[2ex] (\zeta-\eta)^{2\alpha+1}\psi^{-\alpha-1/2}\displaystyle\sum_{n=0}^{\infty}S\left(n,\frac{1}{2}+\alpha;\,\phi,\chi\right)\frac{(1/2+\alpha)_n(1/2+\alpha)_n}{n!n!}\phi^n, & -\frac{1}{2}\leqq\alpha\leqq 0,\end{cases}$$

where

$$S\left(n,\frac{1}{2}\pm\alpha;\,\phi,\chi\right)=\sum_{k=0}^{\infty}F\left(n+\frac{1}{2}\pm\alpha,k;\,k+n+1;\,\phi\right)\frac{n!(-\chi)^k}{k!(k+n)!}.$$

Notice that $v_H^\alpha(\zeta,\eta;\,\zeta_0,\eta_0)$ in (4.7) is of the same form as (4.11) except for the factors $S(n,\frac{1}{2}\pm\alpha;\,\phi,\chi)$. As in the Hankel case, v_L^α depends continuously on the boundary conditions (4.3). Since $S(n,1/2-|\alpha|,\phi,\chi)$ tends to $j_{|\alpha|-1/2}(2\sqrt{\chi})$ for each $n\in\mathbb{P}$ if ϕ tends to $1-$, v_L^α has a continuous extension to the initial line $\eta_0<\zeta=\eta<\zeta_0$, and

$$v_L^\alpha(\zeta,\zeta;\,\zeta_0,\eta_0)=\begin{cases}0, & \alpha>-\dfrac{1}{2},\\[2ex] J_0\left(2\sqrt{(\zeta_0-\zeta)(\zeta-\eta_0)}\right), & \alpha=-\dfrac{1}{2}.\end{cases} \tag{4.12}$$

After substituting (4.1) into (4.11) and (4.12) one obtains the final version of the Riemann function in the Laguerre case,

$$A_L^\alpha(\xi,\tau;\,x,t)=v_L^\alpha\left(\frac{1}{4}(\xi+\tau)^2,\,\frac{1}{4}(\xi-\tau)^2;\,\frac{1}{4}(x+t)^2,\,\frac{1}{4}(x-t)^2\right), \tag{4.13}$$

when $(\xi,\tau)\in\overline{\Delta_{xt}}$.

5. The kernel of the Laguerre translation, proof of Theorem 1. In view of (2.3) and (2.4), the kernel of the Laguerre translation can be derived from the representation of the Riemann function by

$$
\begin{aligned}
&w_L^\alpha(x,t,\xi) = -\frac{1}{2}\lim_{\tau\to 0+} G_L^\alpha(\tau),\\
&G_L^\alpha(\tau) = G_L^\alpha(\tau;\, x,t,\xi) = \tau^{2\alpha+1}\frac{\partial}{\partial\tau}\left[\tau^{-2\alpha-1}A_L^\alpha(\xi,\tau;\, x,t)\right].
\end{aligned}
\tag{5.1}
$$

The main purpose of this paragraph is to prove somewhat more than needed for the proof of Theorem 1, namely an asymptotic expansion of $G_L^\alpha(\tau)$ for $\tau\to 0+$ (see (5.11)).

Again, let us first consider the Hankel case. Setting

$$
\begin{aligned}
&\phi(\xi,\tau;\, x,t) = \chi(\xi,\tau;\, x,t)/\psi(\xi,\tau;\, x,t),\\
&\chi(\xi,\tau;\, x,t) = \frac{1}{16}\left[(x+t)^2-(\xi+\tau)^2\right]\left[(\xi-\tau)^2-(x-t)^2\right],\\
&\psi(\xi,\tau;\, x,t) = \frac{1}{16}\left[(x+t)^2-(\xi-\tau)^2\right]\left[(\xi+\tau)^2-(x-t)^2\right],
\end{aligned}
$$

(cf. (4.1), (4.6)) and writing the Riemann function (4.9) in the form

$$
\begin{aligned}
&A_H^\alpha(\xi,\tau;\, x,t) = a_H^{|\alpha|}(\xi,\tau;\, x,t)\cdot\begin{cases}\xi\tau(xt)^{-2\alpha}, & \alpha>0,\\ (\xi\tau)^{2\alpha+1}, & -\frac{1}{2}\leqq\alpha\leqq 0,\end{cases}\\
&a_H^\gamma(\xi,\tau;\, x,t) = \psi^{\gamma-1/2}F\left(\frac{1}{2}-\gamma,\frac{1}{2}-\gamma;\,1;\,\phi\right)\qquad(\gamma\geqq 0),
\end{aligned}
\tag{5.2}
$$

the kernel of the Hankel translation is given by

$$
\begin{aligned}
&w_H^\alpha(x,t,\xi) = -\frac{1}{2}\lim_{\tau\to 0+} G_H^\alpha(\tau),\\
&G_H^\alpha(\tau) = \tau^{2\alpha+1}\frac{\partial}{\partial\tau}\left[\tau^{-2\alpha-1}A_H^\alpha(\xi,\tau;\, x,t)\right]\\
&\qquad = \begin{cases}\xi(xt)^{-2\alpha}\left\{-2\alpha\, a_H^\alpha(\tau)+\tau\frac{\partial}{\partial\tau}a_H^\alpha(\tau)\right\}, & \alpha>0,\\ (\xi\tau)^{2\alpha+1}\frac{\partial}{\partial\tau}a_H^{-\alpha}(\tau), & -\frac{1}{2}\leqq\alpha\leqq 0.\end{cases}
\end{aligned}
$$

For $\alpha=-\frac{1}{2}$ and $\alpha=\frac{1}{2}$ one immediately obtains

$$
G_H^{-1/2}(\tau)=0,\qquad G_H^{1/2}(\tau)=-\xi(xt)^{-1}.
$$

In the remaining cases, the asymptotic expansion of $G_H^\alpha(\tau)$ for $\tau\to 0+$ can essentially be deduced from

LEMMA 2. *Let* $\gamma\geqq 0$ *and let* $\psi_0=\psi(\xi,0;\, x,t)$. *Then*

$$
\text{(i)}\qquad a_H^\gamma(\tau) = \frac{\Gamma(2\gamma)}{\Gamma^2(\gamma+1/2)}\psi_0^{\gamma-1/2}+\begin{cases}O(\tau^{2\gamma}), & 0<\gamma<\frac{1}{2},\\ O(\tau), & \gamma>\frac{1}{2}\ (\tau\to 0+),\end{cases}
$$

(ii)

$$\frac{\partial}{\partial\tau}a_H^{\gamma}(\tau)=\begin{cases}-\dfrac{\Gamma(1-2\gamma)}{\Gamma^2(1/2-\gamma)}\psi_0^{-\gamma-1/2}(\xi xt)^{2\gamma}\tau^{2\gamma-1}+\mathcal{O}(\tau^{2\gamma}), & 0\leqq\gamma\leqq\dfrac{1}{2},\\ O(\tau^{2\gamma-1}), & \dfrac{1}{2}<\gamma<1,\\ O\left(\tau\log\dfrac{1}{\tau}\right), & \gamma=1,\\ O(\tau), & \gamma>1 \qquad (\tau\to 0+).\end{cases}$$

Proof. By definition, one has

$$1-\phi=\psi^{-1}\xi\tau xt, \qquad \phi'(\tau)=\psi^{-1}\left[\chi'(\tau)-\phi\psi'(\tau)\right],$$
$$\chi'(\tau)=-\frac{1}{2}\xi xt+\frac{\tau}{4}(\xi^2+x^2+t^2-\tau^2), \qquad \psi'(\tau)=\frac{1}{2}\xi xt+\frac{\tau}{4}(\xi^2+x^2+t^2-\tau^2).$$

The differentiability of ψ and (3.2) immediately implies the assertion of part (i). Concerning part (ii), an application of

$$\begin{aligned}&F\left(\frac{1}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right)+\left(\frac{1}{2}-\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{3}{2}-\gamma;2;\phi\right)\cdot\phi\\ &\qquad=F\left(\frac{3}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right),\\ &F\left(\frac{3}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right)+\left(\frac{1}{2}-\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{3}{2}-\gamma;2;\phi\right)\\ &\qquad=\left(\frac{3}{2}-\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{5}{2}-\gamma;2;\phi\right)(1-\phi),\\ &F\left(\frac{3}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right)-\left(\frac{1}{2}-\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{3}{2}-\gamma;2;\phi\right)\\ &\qquad=\left(\frac{1}{2}+\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{1}{2}-\gamma;2;\phi\right)\end{aligned}$$

for $\phi<1$ leads to

$$\begin{aligned}&\frac{\partial}{\partial\tau}a_H^{\gamma}(\tau)\\ &\quad=\left(\gamma-\frac{1}{2}\right)\psi^{\gamma-3/2}\psi'(\tau)F\left(\frac{1}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right)\\ &\qquad\qquad+\psi^{\gamma-1/2}\left(\frac{1}{2}-\gamma\right)^2F\left(\frac{3}{2}-\gamma,\frac{3}{2}-\gamma;2;\phi\right)\phi'(\tau)\\ &\quad=\left(\gamma-\frac{1}{2}\right)\psi^{\gamma-3/2}\Big\{\psi'(\tau)F\left(\frac{3}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right)\\ &\qquad\qquad-\left(\frac{1}{2}-\gamma\right)\chi'(\tau)F\left(\frac{3}{2}-\gamma,\frac{3}{2}-\gamma;2;\phi\right)\Big\}\\ &\quad=\left(\gamma-\frac{1}{2}\right)\psi^{\gamma-3/2}\Big\{\frac{1}{2}\xi xt\left(\frac{3}{2}-\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{5}{2}-\gamma;2;\phi\right)(1-\phi)\\ &\qquad\qquad+\frac{\tau}{4}(\xi^2+x^2+t^2-\tau^2)\left(\frac{1}{2}+\gamma\right)F\left(\frac{3}{2}-\gamma,\frac{1}{2}-\gamma;2;\phi\right)\Big\}.\end{aligned}$$

The assertion then follows by (3.1c) and (3.2). For $0 \leqq \gamma < \frac{1}{2}$, in particular, the first term in curly brackets gives

$$\frac{1}{2}\xi xt\left(\frac{3}{2}-\gamma\right)\frac{\Gamma(2-2\gamma)}{\Gamma(3/2-\gamma)\Gamma(5/2-\gamma)}(1-\phi)^{2\gamma-1}+O\big((1-\phi)^{2\gamma}\big) \qquad (\phi\to 1-)$$

$$=\frac{\Gamma(1-2\gamma)}{\Gamma(1/2-\gamma)\Gamma(3/2-\gamma)}\psi_0^{1-2\gamma}(\xi xt)^{2\gamma}\tau^{2\gamma-1}+O(\tau^{2\gamma}) \qquad (\tau\to 0+),$$

while the second term can be neglected. □

An application of Lemma 2 now yields

$$(5.3)\quad G_H^\alpha(\tau)=-\frac{\Gamma(2\alpha+1)}{\Gamma^2(\alpha+1/2)}\xi(xt)^{-2\alpha}\left(\frac{1}{16}\big[(x+t)^2-\xi^2\big]\big[\xi^2-(x-t)^2\big]\right)^{\alpha-1/2}$$

$$+\begin{cases} O(\tau) & \text{if } \alpha>\frac{1}{2} \text{ or } -\frac{1}{2}<\alpha\leqq 0\\ O(\tau^{2\alpha}) & \text{if } 0<\alpha<\frac{1}{2}\end{cases} \qquad (\tau\to 0+).$$

In the Laguerre case, we write the Riemann function (4.13) in a form analogous to (5.2),

$$A_L^\alpha(\xi,\tau;\,x,t)=a_L^{|\alpha|}(\xi,\tau;\,x,t)\cdot\begin{cases}\xi\tau(xt)^{-2\alpha}, & \alpha>0,\\ (\xi\tau)^{2\alpha+1}, & -\frac{1}{2}\leqq\alpha\leqq 0,\end{cases}$$

$$a_L^\gamma(\xi,\tau;\,x,t)=\psi^{\gamma-1/2}\sum_{n=0}^{\infty}S\left(n,\frac{1}{2}-\gamma;\,\phi,\chi\right)\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n \qquad (\gamma\geqq 0).$$

Thus, $G_L^\alpha(\tau)$ in (5.1) can be expressed by

$$(5.4)\qquad G_L^\alpha(\tau)=\begin{cases}\xi(xt)^{-2\alpha}\left\{-2\alpha\, a_L^\alpha(\tau)+\tau\frac{\partial}{\partial\tau}a_L^\alpha(\tau)\right\}, & \alpha>0,\\ (\xi\tau)^{2\alpha+1}\frac{\partial}{\partial\tau}a_L^{-\alpha}(\tau), & -\frac{1}{2}\leqq\alpha\leqq 0.\end{cases}$$

When $\alpha=-\frac{1}{2}$ or $\alpha=\frac{1}{2}$, use $a_L^{1/2}(\tau)=j_0(2\sqrt{\chi})$ to get

$$(5.5)\qquad \begin{aligned} G_L^{-1/2}(\tau)&=-j_1\big(2\sqrt{\chi}\big)\chi'(\tau),\\ G_L^{1/2}(\tau)&=-\xi(xt)^{-1}\big\{j_0\big(2\sqrt{\chi}\big)+\tau j_1\big(2\sqrt{\chi}\big)\chi'(\tau)\big\}.\end{aligned}$$

Otherwise, the following analogue of Lemma 2 will be needed.

LEMMA 3. *Let* $\gamma\geqq 0$ *and let* $\psi_0=\chi_0=\psi(\xi,0;\,x,t)$. *Then*

(i)

$$a_L^\gamma(\tau)=\frac{\Gamma(2\gamma)}{\Gamma^2(\gamma+1/2)}\psi_0^{\gamma-1/2}j_{\gamma-1/2}\big(2\sqrt{\chi_0}\big)+\begin{cases}O(\tau^{2\gamma}), & 0<\gamma<\frac{1}{2},\\ O(\tau), & \gamma>\frac{1}{2}\end{cases} \qquad (\tau\to 0+),$$

(ii)

$$\frac{\partial}{\partial\tau}a_L^{\gamma}(\tau)=\begin{cases}-\dfrac{\Gamma(1-2\gamma)}{\Gamma^2(1/2-\gamma)}\dfrac{(\xi xt)^{2\gamma}}{\psi_0^{\gamma+1/2}}j_{-\gamma-1/2}\left(2\sqrt{\chi_0}\right)\tau^{2\gamma-1}+\begin{cases}O\left(\log\dfrac{1}{\tau}\right), & \gamma=0,\\ O(1), & 0<\gamma<\dfrac{1}{2},\end{cases}\\ O(1), \qquad \gamma>\dfrac{1}{2}\end{cases}\qquad(\tau\to 0+).$$

Proof. First we consider the cases $\gamma>\frac{1}{2}$ of part (i). By the mean value theorem, for each $n,k\in\mathbb{P}$ there exist $\tilde{\phi}\in(\phi,1)$ such that

$$\begin{aligned}F\left(n+\frac{1}{2}-\gamma,k;\ n+k+1;\ \phi\right)&=F\left(n+\frac{1}{2}-\gamma,k;\ n+k+1;\ 1\right)-\frac{(n+1/2-\gamma)k}{n+k+1}\\&\quad\cdot F\left(n+\frac{3}{2}-\gamma,k+1;\ n+k+2;\ \tilde{\phi}\right)(1-\phi)\\&=\frac{\Gamma(n+k+1)\Gamma(\gamma+1/2)}{\Gamma(n+1)\Gamma(k+\gamma+1/2)}-\frac{(n+1/2-\gamma)k\Gamma(n+k+1)}{\Gamma(k+1)\Gamma(n+1)}\\&\quad\cdot\int_0^1 t^k(1-t)^n(1-t\tilde{\phi})^{-n-3/2+\gamma}dt(1-\phi).\end{aligned}$$

So one has

$$\begin{aligned}&\left|S\left(n,\frac{1}{2}-\gamma;\ \phi,\chi\right)-j_{\gamma-1/2}(2\sqrt{\chi})\right|\\&=\left|\left(n+\frac{1}{2}-\gamma\right)\int_0^1\sum_{k=1}^{\infty}\frac{(-\chi t)^k}{(k-1)!k!}(1-t)^n(1-t\tilde{\phi})^{-n-3/2+\gamma}dt(1-\phi)\right|\\&\leqq\left|n+\frac{1}{2}-\gamma\right|\chi\int_0^1\left|j_1(2\sqrt{\chi t})\right|t\left(\frac{1-t}{1-t\tilde{\phi}}\right)^n(1-t\tilde{\phi})^{\gamma-3/2}dt(1-\phi)\\&\leqq C\left|n+\frac{1}{2}-\gamma\right|\chi(1-\phi)\end{aligned}$$

with a constant C depending only on γ, and consequently

$$\begin{aligned}&\left|a_L^{\gamma}(\tau)-\psi^{\gamma-1/2}F\left(\frac{1}{2}-\gamma,\frac{1}{2}-\gamma;1;\phi\right)j_{\gamma-1/2}(2\sqrt{\chi})\right|\\&\qquad\leqq C\psi^{\gamma-1/2}\chi\left|F\left(\frac{1}{2}-\gamma,\frac{3}{2}-\gamma;1;\phi\right)\right|(1-\phi)\leqq C(1-\phi).\end{aligned}$$

For $0<\gamma<\frac{1}{2}$, we use the representation (3.6) of $S(n,a;\ \phi,\chi)$ with $a=\frac{1}{2}-\gamma$ and the identity

$$\sum_{n=0}^{\infty}\frac{(1/2-\gamma)_n}{n!}\left(\frac{[1-t]\phi}{1-t\phi}\right)^n=\left(1-\frac{[1-t]\phi}{1-t\phi}\right)^{\gamma-1/2}=\left(\frac{1-\phi}{1-t\phi}\right)^{\gamma-1/2}\tag{5.6}$$

to obtain

$$\sum_{n=0}^{\infty} S\Big(n, \frac{1}{2}-\gamma;\ \phi, \chi\Big)\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n$$

$$= \frac{(1-\phi)^{\gamma+1/2}}{\Gamma(1/2-\gamma)\Gamma(1/2+\gamma)}\int_0^1 j_{\gamma-1/2}\big(2\sqrt{\chi t}\big)t^{\gamma-1/2}(1-t)^{-1/2-\gamma}(1-t\phi)^{-1}$$

$$\cdot \sum_{n=0}^{\infty}\frac{(1/2-\gamma)_n}{n!}\left(\frac{[1-t]\phi}{1-t\phi}\right)^n dt$$

$$= \frac{(1-\phi)^{2\gamma}}{\Gamma(1/2-\gamma)\Gamma(1/2+\gamma)}\int_0^1 j_{\gamma-1/2}\big(2\sqrt{\chi t}\big)t^{\gamma-1/2}(1-t)^{-1/2-\gamma}(1-t\phi)^{-1/2-\gamma}dt.$$

Again by the mean value theorem, for each $0 \leqq t \leqq 1$ there exists $s(t) \in (t,1)$ such that

$$j_{\gamma-1/2}\big(2\sqrt{\chi t}\big) = j_{\gamma-1/2}\big(2\sqrt{\chi}\big) + \frac{\chi}{\gamma+1/2}j_{\gamma+1/2}\big(2\sqrt{\chi s(t)}\big)(1-t).$$

By (3.5) this gives

$$\left|a_L^{\gamma}(\tau) - \psi^{\gamma-1/2}(1-\phi)^{2\gamma}F\Big(\frac{1}{2}+\gamma, \frac{1}{2}+\gamma; 1;\ \phi\Big)j_{\gamma-1/2}\big(2\sqrt{\chi}\big)\right|$$

$$\leqq \psi^{\gamma-1/2}\chi\frac{(1-\phi)^{2\gamma}}{\Gamma(1/2-\gamma)\Gamma(3/2+\gamma)}$$

$$\cdot \int_0^1 \left|j_{\gamma+1/2}\big(2\sqrt{\chi s(t)}\big)\right| t^{\gamma-1/2}(1-t)^{1/2-\gamma}(1-t\phi)^{-1/2-\gamma}dt$$

$$\leqq \psi^{\gamma-1/2}\chi\frac{1/2-\gamma}{1/2+\gamma}(1-\phi)^{2\gamma}F\Big(\frac{1}{2}+\gamma, \frac{1}{2}+\gamma; 2;\ \phi\Big)$$

$$\leqq C(1-\phi)^{2\gamma}.$$

In view of the asymptotic expansions

$$\psi^{\gamma-1/2} = \psi_0^{\gamma-1/2} + O(\tau), \qquad j_{\gamma-1/2}\big(2\sqrt{\chi}\big) = j_{\gamma-1/2}\big(2\sqrt{\chi_0}\big) + O(\tau),$$

and

$$(1-\phi)^{2\gamma}F\Big(\frac{1}{2}+\gamma, \frac{1}{2}+\gamma; 1;\ \phi\Big) = F\Big(\frac{1}{2}-\gamma, \frac{1}{2}-\gamma; 1;\ \phi\Big)$$

$$= \frac{\Gamma(2\gamma)}{\Gamma^2(\gamma+1/2)} + \begin{cases} O\big((1-\phi)^{2\gamma}\big), & 0<\gamma<\frac{1}{2}, \\ O(1-\phi), & \gamma>\frac{1}{2} \end{cases}$$

for $\tau \to 0+$, the assertion of Lemma 3(i) then follows.

Concerning part (ii), term by term differentiation for $\phi<1$ is justified by Lemma 1, (3.3), so that

(5.7)

$$\frac{\partial}{\partial\tau}a_L^{\gamma}(\tau)=\left(\gamma-\frac{1}{2}\right)\psi^{\gamma-3/2}\psi'(\tau)\sum_{n=0}^{\infty}S\left(n,\frac{1}{2}-\gamma;\ \phi,\chi\right)\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n$$
$$+\psi^{\gamma-1/2}\phi'(\tau)\sum_{n=1}^{\infty}S\left(n,\frac{1}{2}-\gamma;\ \phi,\chi\right)\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^{n-1}$$
$$+\psi^{\gamma-1/2}\sum_{n=0}^{\infty}\frac{\partial}{\partial\tau}S\left(n,\frac{1}{2}-\gamma;\ \phi,\chi\right)\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n$$

and

$$\frac{\partial}{\partial\tau}S\left(n,\frac{1}{2}-\gamma;\ \phi,\chi\right)$$
$$=\phi'(\tau)\left(n+\frac{1}{2}-\gamma\right)\sum_{k=0}^{\infty}kF\left(n+\frac{3}{2}-\gamma,k+1;\ n+k+2;\ \phi\right)\frac{n!(-\chi)^k}{k!(k+n+1)!}$$
$$-\chi'(\tau)\sum_{k=0}^{\infty}F\left(n+\frac{1}{2}-\gamma,k+1;\ n+k+2;\ \phi\right)\frac{n!(-\chi)^k}{k!(k+n+1)!}.$$

An index transformation in the second term of (5.7), together with the relation

$$\left(n+\frac{1}{2}-\gamma\right)F\left(n+\frac{3}{2}-\gamma,k;\ n+k+2;\ \phi\right)+kF\left(n+\frac{3}{2}-\gamma,k+1;\ n+k+2;\ \phi\right)$$
$$=(n+k+1)F\left(n+\frac{3}{2}-\gamma,k;\ n+k+1;\ \phi\right)-\left(\gamma+\frac{1}{2}\right)F\left(n+\frac{3}{2}-\gamma,k;\ n+k+2;\ \phi\right),$$

then give

$$\frac{\partial}{\partial\tau}a_L^{\gamma}(\tau)$$
$$=\left(\gamma-\frac{1}{2}\right)\psi^{\gamma-3/2}\psi'(\tau)\sum_{n=0}^{\infty}S\left(n,\frac{1}{2}-\gamma;\ \phi,\chi\right)\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n$$
$$+\left(\frac{1}{2}-\gamma\right)\psi^{\gamma-1/2}\phi'(\tau)\sum_{n=0}^{\infty}S\left(n,\frac{3}{2}-\gamma;\ \phi,\chi\right)\frac{(1/2-\gamma)_n(3/2-\gamma)_n}{n!n!}\phi^n$$
$$+\left(\gamma-\frac{1}{2}\right)\left(\gamma+\frac{1}{2}\right)\psi^{\gamma-1/2}\phi'(\tau)\sum_{n=0}^{\infty}S\left(n+1,\frac{1}{2}-\gamma;\ \phi,\chi\right)\frac{(1/2-\gamma)_n(3/2-\gamma)_n}{(n+1)!n!}\phi^n$$
$$-\psi^{\gamma-1/2}\chi'(\tau)\sum_{n=0}^{\infty}\left\{\sum_{k=0}^{\infty}F\left(n+\frac{1}{2}-\gamma,k+1;\ n+k+2;\ \phi\right)\frac{n(-\chi)^k}{k!(k+n+1)!}\right\}$$
$$\cdot\frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n$$
$$=A_1+A_2+A_3+A_4,$$

say. When estimating the four terms separately, they turn out to be of the same order if $\gamma > \frac{1}{2}$, while for $0 \leqq \gamma < \frac{1}{2}$ the second term turns out to be the main one. Indeed, since

$$|A_1| \leqq \psi^{\gamma-3/2}\left|\left(\gamma-\frac{1}{2}\right)\psi'(\tau)\left|F\left(\frac{1}{2}-\gamma, \frac{1}{2}-\gamma; 1; \phi\right)\right.\right.,$$

$$|A_3| \leqq C_\gamma \psi^{\gamma-1/2}\left|\left(\gamma-\frac{1}{2}\right)\left(\gamma+\frac{1}{2}\right)\phi'(\tau)F\left(\frac{1}{2}-\gamma, \frac{3}{2}-\gamma; 2; \phi\right)\right|$$

where the constant C_γ equals 1 for $0 \leqq \gamma < \frac{1}{2}$, and

$$|A_4| \leqq \psi^{\gamma-1/2}|\chi'(\tau)| \sum_{n=0}^{\infty} \int_0^1 |j_0(2\sqrt{\chi t})|(1-t)^n(1-t\phi)^{-n-1/2+\gamma}dt \cdot \frac{(1/2-\gamma)_n(1/2-\gamma)_n}{n!n!}\phi^n$$

$$\leqq \psi^{\gamma-1/2}|\chi'(\tau)|F\left(\frac{1}{2}-\gamma, \frac{1}{2}-\gamma; 1; \phi\right) \cdot \begin{cases} \dfrac{1}{\gamma+1/2}, & 0 \leqq \gamma < \dfrac{1}{2}, \\ 1, & \gamma \geqq \dfrac{1}{2} \end{cases}$$

it follows for $i = 1, 3, 4$ that

$$A_i = \begin{cases} O\left(\log \dfrac{1}{\tau}\right), & \gamma = 0, \\ O(1), & \gamma > 0 \end{cases} \qquad (\tau \to 0+). \tag{5.8}$$

For $\gamma > \frac{1}{2}$, A_2 is of the same order since, in view of (3.3),

$$|A_2| \leqq \left(\gamma-\frac{1}{2}\right)\psi^{\gamma-1/2}|\phi'(\tau)| \cdot \sum_{n=0}^{\infty} \frac{|(1/2-\gamma)_n(3/2-\gamma)_n|}{n!n!}\phi^n \cdot \begin{cases} 1+\dfrac{\chi}{\gamma^2-1/4}, & \dfrac{1}{2} < \gamma < 1, \\ 1, & \gamma \geqq 1 \end{cases} \tag{5.9}$$

$$= O(1) \qquad (\tau \to 0+).$$

It remains to consider A_2 in case $0 \leqq \gamma < \frac{1}{2}$. Euler's transformation and integral representation give

$$S\left(n, \frac{3}{2}-\gamma; \phi, \chi\right)$$

$$= (1-\phi)^{\gamma-1/2} \sum_{k=0}^{\infty} F\left(k+\gamma-\frac{1}{2}, n+1; k+n+1; \phi\right)\frac{n!(-\chi)^k}{k!(k+n)!}$$

$$= 1 + (1-\phi)^{\gamma-1/2}\frac{n!}{(3/2-\gamma)_n\Gamma(3/2-\gamma)} \cdot \sum_{k=1}^{\infty} \int_0^1 t^{k+\gamma-3/2}(1-t)^{n-\gamma+1/2}(1-t\phi)^{-n-1}dt\frac{(-\chi)^k}{\Gamma(k+\gamma-1/2)k!}.$$

Inserting this into A_2 and interchanging the order of summation we have

$$A_2=\left(\frac{1}{2}-\gamma\right)\psi^{\gamma-1/2}\phi'(\tau)$$
$$\cdot\left[F\left(\frac{1}{2}-\gamma,\frac{3}{2}-\gamma;1;\phi\right)+\frac{1}{\Gamma(3/2-\gamma)}(1-\phi)^{\gamma-1/2}\right.$$
$$\cdot\sum_{k=1}^{\infty}\left\{\sum_{n=0}^{\infty}\frac{(1/2-\gamma)_n}{n!}\int_0^1 t^{k+\gamma-3/2}(1-t)^{n-\gamma+1/2}(1-t\phi)^{-n-1}dt\phi^n\right\}$$
$$\left.\cdot\frac{(-\chi)^k}{\Gamma(k+\gamma-1/2)k!}\right],$$

and, by (5.6), the sum in curly brackets equals

$$(1-\phi)^{\gamma-1/2}\int_0^1 t^{k+\gamma-3/2}(1-t)^{-\gamma+1/2}(1-t\phi)^{-\gamma-1/2}dt$$
$$=(1-\phi)^{\gamma-1/2}\frac{\Gamma(k+\gamma-1/2)\Gamma(3/2-\gamma)}{\Gamma(k+1)}F\left(\gamma+\frac{1}{2},k+\gamma-\frac{1}{2};k+1;\phi\right).$$

Using the transformation

$$F\left(\frac{1}{2}-\gamma,\frac{3}{2}-\gamma;1;\phi\right)=(1-\phi)^{2\gamma-1}F\left(\gamma+\frac{1}{2},\gamma-\frac{1}{2};1;\phi\right)$$

and applying Euler's integral representation once more, one obtains

$$A_2=\left(\frac{1}{2}-\gamma\right)\psi^{\gamma-1/2}\phi'(\tau)(1-\phi)^{2\gamma-1}\sum_{k=0}^{\infty}F\left(\gamma+\frac{1}{2},k+\gamma-\frac{1}{2};k+1;\phi\right)\frac{(-\chi)^k}{\Gamma^2(k+1)}.$$

Using now (3.2a), $1-\phi=\psi^{-1}\xi\tau xt$ and $\phi'(\tau)=-\psi_0^{-1}\xi xt+O(\tau)$, $\tau\to 0+$, we arrive at

$$A_2=\frac{\Gamma(1-2\gamma)}{\Gamma^2(1/2-\gamma)}\psi^{\gamma-1/2}\phi'(\tau)(1-\phi)^{2\gamma-1}j_{-\gamma-1/2}(2\sqrt{\chi})+\begin{cases}O\left(\log\frac{1}{\tau}\right), & \gamma=0,\\ O(1), & 0<\gamma<\frac{1}{2},\end{cases}$$

(5.10)

$$=-\frac{\Gamma(1-2\gamma)}{\Gamma^2(1/2-\gamma)}\psi_0^{-\gamma-1/2}(\xi xt)^{2\gamma}j_{-\gamma-1/2}\left(2\sqrt{\chi_0}\right)\tau^{2\gamma-1}+\begin{cases}O\left(\log\frac{1}{\tau}\right), & \gamma=0,\\ O(1), & 0<\gamma<\frac{1}{2}\end{cases}$$

as $\tau\to 0+$. By (5.8), (5.9), and (5.10), the proof of Lemma 3 is complete. □

Applying Lemma 3 for $\gamma=|\alpha|$ to the right-hand side of (5.4) and observing (5.5), the desired asymptotic expansions now follow:

$$G_L^\alpha(\tau)=-\frac{\Gamma(2\alpha+1)}{\Gamma^2(\alpha+1/2)}\xi(xt)^{-2\alpha}\psi_0^{\alpha-1/2}j_{\alpha-1/2}\left(2\sqrt{\chi_0}\right) \tag{5.11}$$

$$+\begin{cases} O(\tau), & \alpha\geqq\frac{1}{2},\\ O(\tau^{2\alpha}), & 0<\alpha<\frac{1}{2},\\ O\left(\tau\log\frac{1}{\tau}\right), & \alpha=0,\\ O(\tau^{2\alpha+1}), & -\frac{1}{2}<\alpha<0 \end{cases} \qquad (\tau\to 0+),$$

$$G_L^{-1/2}(\tau)=\frac{1}{2}\xi xt\,j_1\left(2\sqrt{\chi_0}\right)+O(\tau) \qquad (\tau\to 0+),$$

where $\psi_0=\chi_0=\frac{1}{16}[(x+t)^2-\xi^2][\xi^2-(x-t)^2]$. In view of (5.1) we thus have found that

(5.12)

$$w_L^\alpha(x,t,\xi)=\begin{cases} \dfrac{\Gamma(2\alpha+1)}{\Gamma^2(\alpha+1/2)}\xi(2xt)^{-2\alpha}(\rho(x,t,\xi))^{2\alpha-1}j_{\alpha-1/2}(\rho(x,t,\xi)), & \alpha>-\frac{1}{2},\\ -\dfrac{1}{4}\xi xt\,j_1(\rho(x,t,\xi)), & \alpha=-\frac{1}{2}, \end{cases}$$

where ρ is given by (1.7).

Proof of Theorem 1. Using (2.4) and Legendre's duplication formula, the kernel representation (1.6) is an immediate consequence of (5.12). □

6. A comparison between the Laguerre and the Hankel translations. There is a deep relation between the geometrical interpretations of both translations. In fact the Laguerre translation plays the same role in the rotation invariant case of the Weyl transform on a higher dimensional Heisenberg group as the Hankel translation does with respect to the rotation invariant case of the ordinary Fourier transform in several variables [24].

But while the Hankel translation is a positive operator, the Laguerre translation obviously is not. Nevertheless, it follows from the estimate (3.5) of the Bessel functions that, for each $\alpha\geqq 0$, the respective translation kernels are related by

$$|K_L^\alpha(x,t,z)|\leqq K_H^\alpha(x,t,z) \qquad (0<x,t,z<\infty).$$

Consequently, the operator norms of the translations satisfy

$$\|T_{L,t}^\alpha\|_{[L^1_{w(2\alpha+1)}]}\leqq\|T_{H,t}^\alpha\|_{[L^1_{w(2\alpha+1)}]}=1 \qquad (\alpha\geqq 0,\ t\geqq 0),$$

and, in fact, it can be shown that equality holds [12]. To our opinion this is a surprising result which seems to indicate that even nonpositive translation operators may show a favourable norm behavior.

In addition to the numerous relations between the Laguerre and Hankel cases mentioned in the preceding paragraphs, it is to be noted that the Riemann functions themselves are closely related to each other by

$$|A_L^\alpha(\xi,\tau;\,x,t)|\leqq A_H^\alpha(\xi,\tau;\,x,t) \tag{6.1}$$

provided $\alpha \geqq -\frac{1}{2}$ and $(\xi,\tau)\in\overline{\Delta_{xt}}$. This follows from (4.9), (4.13) by observing that the factors $S(n,\frac{1}{2}-|\alpha|;\phi,\chi)$ are uniformly bounded by 1 in view of Lemma 1.

We finally mention two different formal representations of the translation kernels as a "triple product integral" and a "triple product sum", which reflect the formal difference arising from the continuous and discrete spectrum of the S.-L. DE (1.4) for $q\equiv 0$ and $q(x)=x^2$, respectively. These are

$$K_H^\alpha(x,t,z)=[2^\alpha\Gamma(\alpha+1)]^{-2}\int_0^\infty j_\alpha(xu)\,j_\alpha(tu)\,j_\alpha(zu)\,u^{2\alpha+1}\,du,$$

$$K_L^\alpha(x,t,z)=\sum_{k=0}^{\infty}\frac{2\Gamma(k+\alpha+1)}{\Gamma^2(\alpha+1)\Gamma(k+1)}\,y_k^\alpha(x)\,y_k^\alpha(t)\,y_k^\alpha(z)$$

if $|x-t|<z<x+t$. This can also be compared with the kernel representation of the Jacobi translation given by Gasper [11, (2.2)] as a sum over triple products of Jacobi polynomials as well as an integral of a triple product of Bessel functions.

Acknowledgment. The author would like to thank Professor E. Görlich for helpful comments and suggestions.

AN ANALYTICAL EXPRESSION FOR COEFFICIENTS ARISING WHEN IMPLEMENTING A TECHNIQUE FOR INDEFINITE INTEGRATION OF PRODUCTS OF SPECIAL FUNCTIONS*

JEAN C. PIQUETTE†

Abstract. In an earlier article [*Technique for evaluating indefinite integrals involving products of certain special functions*, Jean C. Piquette and A. L. Van Buren, SIAM J. Math. Anal., 15 (1984), pp. 845–855], a new analytical technique for evaluating indefinite integrals involving special functions was described. The technique replaces the integral by an inhomogeneous set of coupled first-order differential equations. This coupled set does not explicitly contain the special functions of the integrand, and any particular solution of the set is sufficient to obtain an analytical result for the indefinite integral. The present article gives an analytical expression for the functional coefficients arising in the coupled set. Thus, the process of obtaining the coupled set is reduced to evaluation of the analytical expression. This formula is therefore valuable in creating a general algorithm for analytically evaluating indefinite integrals of special functions. Such an algorithm could be used to mechanically generate the coupled differential equations, and could be readily implemented on a digital computer using a symbolic manipulation program.

Key words. antidifferentiation, ordinary differential equations, systems series expansion

AMS(MOS) subject classifications. Primary 34A30, 41A58

1. Introduction. A previous article [1] presented an analytical technique for evaluating indefinite integrals of the form

$$I=\int dx\, f(x)\prod_{i=1}^{m} R_{\mu_i}^{(i)}(x), \tag{1}$$

where $R_{\mu_i}^{(i)}(x)$ is the ith type of special function of order μ_i obeying the set of recurrence relations

$$R_{\mu+1}^{(i)}(x)=a_\mu(x)R_\mu^{(i)}(x)+b_\mu(x)R_{\mu-1}^{(i)}(x), \tag{2a}$$

$$DR_\mu^{(i)}(x)=c_\mu(x)R_\mu^{(i)}(x)+d_\mu(x)R_{\mu-1}^{(i)}(x). \tag{2b}$$

Here a_μ, b_μ, c_μ, and d_μ are known functions corresponding to $R_\mu^{(i)}$. The symbol D represents d/dx. The function $f(x)$ and the product $\prod R_\mu^{(i)}$ are both assumed continuous (or with at most a finite number of discontinuities) over an interval $[x_1,x_2]$, insuring that the integral I exists in the same interval. The technique is a generalization of one used by Sonine [2] (described by Watson [3]) to evaluate indefinite integrals involving products of Bessel functions. Reference [1] extended the technique to include most of the special functions of physics, including Legendre functions, Hermite functions, Laguerre funtions, etc. The technique replaces the integral which is to be evaluated by an inhomogeneous set of coupled first-order differential equations. The coupled set does not explicitly contain any of the special functions $R_\mu^{(i)}$, and *any particular solution* of the set is sufficient to yield an analytical expression for the integral I.

*Received by the editors January 22, 1985, and in revised form June 30, 1985.
† Naval Research Laboratory, Orlando, Florida 32856-8337.

The method of [1] assumes that the integral I of (1) may be represented by the expression

$$I=\sum_{p_1=0}^{1}\sum_{p_2=0}^{1}\cdots\sum_{p_m=0}^{1}A_{p_1p_2,\cdots,p_m}(x)\prod_{i=1}^{m}R^{(i)}_{\mu_i+p_i}(x), \tag{3}$$

where the 2^m coefficients $A_{p_1,p_2,\cdots,p_m}(x)$ are functions to be determined. The technique replaces the integral I with the coupled set of differential equations

$$f(x)\delta_{0,p}=DA_p+\sum_{[q]}B_{pq}A_q, \tag{4}$$

where δ is a Kronecker delta defined to be zero unless $p_1=p_2=\cdots=p_m=0$. In (4), the shorthand notations $A_p\equiv A_{p_1,p_2,\cdots,p_m}(x)$ and $B_{pq}\equiv B_{p_1,p_2,\cdots,p_m,q_1,q_2,\cdots,q_m}(x)$ have been used. Also, the notation $\Sigma_{\{q\}}$ represents the multiple summations

$$\sum_{q_1=0}^{1}\sum_{q_2=0}^{1}\cdots\sum_{q_m=0}^{1}.$$

The functions B_{pq} are described in [1] as being known functions resulting from repeated applications of the relations of (2) and the regrouping of terms in the form $\Pi_{i=1}^{m}R^{(i)}_{\mu_i+p_i}$. As of the writing of [1], no general analytical expression for the coefficients B_{pq} was available. However, due to the advent of symbolic manipulation computer programs (such as MACSYMA, SMP, REDUCE, MAPLE, etc.), such a formula would reduce the problem of generating the coupled set (4) from the indefinite integral of (1) to a mechanical process (i.e., evaluation of a formula). Since a particular solution to the coupled set may be easier to obtain than directly performing the indefinite integral, the availability of a formula to generate the required coupled set in an algorithmic way is of interest. This formula is obtained in the present article.

2. An analytical expression for the coefficients B_{pq}. Rather than working directly with the recurrence relations (2), it is more convenient to use the equivalent set

$$DR^{(i)}_{\mu}(x)=a'_{\mu}(x)R^{(i)}_{\mu}(x)+b'_{\mu}(x)R^{(i)}_{\mu+1}(x), \tag{5a}$$

$$DR^{(i)}_{\mu+1}(x)=c'_{\mu}(x)R^{(i)}_{\mu}(x)+d'_{\mu}(x)R^{(i)}_{\mu+1}(x), \tag{5b}$$

where

$$a'_{\mu}(x)\equiv c_{\mu}(x)-\frac{a_{\mu}(x)d_{\mu}(x)}{b_{\mu}(x)}, \qquad c'_{\mu}(x)\equiv d_{\mu+1}(x),$$

$$b'_{\mu}(x)\equiv d_{\mu}(x)/b_{\mu}(x), \qquad d'_{\mu}(x)\equiv c_{\mu+1}(x).$$

The special case where $b_{\mu}=0$ (discussed extensively in [1]) is excluded here.

The desired expression for B_{pq} is now obtained in the following way: The logarithmic derivative of the expression $\Pi_{i=1}^{m}R^{(i)}_{\mu_i+p_i}(x)$ is first computed and simplified using recurrence relations (5). It is next necessary to express the quantity

$$\sum_{\{p\}}A_pD\prod_{i=1}^{m}R^{(i)}_{\mu_i+p_i}(x)$$

in terms of expressions of the form $\Pi_{i=1}^{m} R^{(i)}_{\mu_i+p_i}(x)$. The desired expression for B_{pq} is obtained by comparing the result of the above computation with second term on the right-hand side of [1, eq. (10)]. The result is

$$(6)\qquad B_{pq}=\sum_{j=1}^{m}\left[\left(a'_{\mu_j}(x)\prod_{l=1}^{m}\delta_{q_l,p_l}+c'_{\mu_j}(x)\prod_{l=1}^{m}\delta_{q_l,p_l+\delta_{lj}}\right)\delta_{p_j,0}\right.$$
$$\left.+\left(b'_{\mu_j}(x)\prod_{l=1}^{m}\delta_{q_l,p_l-\delta_{lj}}+d'_{\mu_j}(x)\prod_{l=1}^{m}\delta_{q_l,p_l}\right)\delta_{p_j,1}\right],$$

where a'_μ, b'_μ, c'_μ, and d'_μ are defined above. Although the number of coefficients B_{pq} becomes large even for small values of m (this number being equal to 2^{2m}), this presents no difficulty to the new symbol manipulation computer programs which routinely evaluate symbolic expressions containing thousands of terms. [1] discusses the procedure necessary to obtain a series solution (involving a *single summation index*) for the unknown integral. This process could also be implemented mechanically using a symbol manipulation program. In fact, I have recently implemented [1, eq. (10)], replacing B_{pq} with (6) above, using the SMP© computer program. This implementation has enabled generation of the relevant differential equations to occur in a few minutes, compared with the several hours normally required when implemented using paper and pencil. Hence, combining the technique of [1] and the formula of (6) above, it should generally be possible to obtain a simple series representation for integrals of the type (1). Of course, if a closed-form particular solution of the coupled set (4) is found, then a closed-form analytical expression for the integral of (1) results via (3).

RECURRENCE RELATIONS FOR THE COEFFICIENTS IN JACOBI SERIES SOLUTIONS OF LINEAR DIFFERENTIAL EQUATIONS*

STANISŁAW LEWANOWICZ†

Abstract. A method is presented for obtaining recurrence relations for the coefficients in Jacobi series solutions of linear ordinary differential equations with polynomial coefficients.

Key words. Jacobi series, Jacobi coefficients, recurrence relations, difference operators, linear differential equation

AMS(MOS) subject classifications. Primary 42C10, 39A70, 65L05, 65L10

1. Introduction. A function defined in the interval $\langle -1,1\rangle$ and satisfying the required conditions (see, e.g., [3, v. 1, §10.19] or [11, v. 1, §8.3]) may be expanded into a series uniformly convergent in this interval with respect to the Jacobi polynomials (in short: the *Jacobi series*):

$$f=\sum_{k=0}^{\infty} a_k^{(\alpha,\beta)}[f]P_k^{(\alpha,\beta)} \qquad (\alpha>-1,\beta>-1). \tag{1.1}$$

Here $P_k^{(\alpha,\beta)}$ is the usual notation for the kth Jacobi polynomial, and

$$a_k^{(\alpha,\beta)}[f]=\frac{(2k+\lambda)k!\Gamma(k+\lambda)}{2^{\lambda}\Gamma(k+\alpha+1)\Gamma(k+\beta+1)}\int_{-1}^{1}(1-x)^{\alpha}(1+x)^{\beta}P_k^{(\alpha,\beta)}(x)f(x)\,dx \tag{1.2}$$

$$(k=0,1,\cdots)$$

where

$$\lambda=\alpha+\beta+1.$$

Some alternative forms for the coefficients (1.2) are available for many elementary and special functions (see, e.g., [11, v. 2, §9.3]). In particular, if f belongs to the hypergeometric family, $a_k^{(\alpha,\beta)}[f]$ is also of this type and obeys a difference equation of the form

$$\sum_{j=0}^{r} A_j(k)\psi_{k+j}=B(k), \tag{1.3}$$

in which A and B are rational in k [11, v. 2, §12.4], [10]. In this case, equation (1.3) serves as the basis for a very efficient numerical procedure for the calculation of $a_k^{(\alpha,\beta)}[f]$ (see [11, v. 2, §12.5] or [17, Ex. 7.2]).

A simple and universal method for deriving a recurrence relation for the coefficients $a_k^{(\alpha,\beta)}[f]$ may be applied in the case where the function f satisfies the linear differential equation

$$\sum_{m=0}^{n} p_m f^{(m)}=q \tag{1.4}$$

* Received by the editors April 15, 1985.
† Institute of Computer Science, University of Wrocław, 51-151 Wrocław, Poland.

of order n, with suitable initial or boundary conditions. In (1.4) p_0, $p_1, \cdots, p_n$ are polynomials, and the coefficients $a_k^{(\alpha,\beta)}[q]$ are known. The main idea of this method should be ascribed to Clenshaw [1]. We restate Clenshaw's result briefly. We assume the *Chebyshev series* expansion for f:

$$f=\frac{1}{2}t_0[f]T_0+\sum_{k=0}^{\infty} t_k[f]T_k \tag{1.5}$$

and similar expansions for the derivatives, where T_k is the Chebyshev polynomial

$$T_k(x)=\frac{k!}{(1/2)_k}P_k^{(-1/2,-1/2)}(x). \tag{1.6}$$

Here we use the Pochhammer symbol

$$(a)_k=\Gamma(a+k)/\Gamma(a).$$

The following identities can be deduced from basic difference properties of the Chebyshev polynomials [1]:

$$t_{k-1}[f^{(m+1)}]-t_{k+1}[f^{(m+1)}]=2kt_k[f^{(m)}], \tag{1.7}$$

$$t_k[x^s f^{(m)}]=2^{-s}\sum_{j=0}^{s}\binom{s}{j}t_{k-s+2j}[f^{(m)}], \tag{1.8}$$

for nonnegative integers m and s. The above equations are then applied to the differential equation (1.4) to obtain a system of finite difference equations for the coefficients $\{t_k[f^{(m)}]\}$ $(m=0,1,\cdots,n)$. Many authors (Fox [4], Fox and Parker [5], Geddes [6], Horner [7], Morris and Horner [13], Olaofe [14], Paszkowski [15]) have proposed modifications and improvements of Clenshaw's method, which lead to a single difference equation or recurrence relation for the principal coefficients $\{t_k[f]\}$.

Paszkowski ([15, §13]) has raised the problem of constructing the recurrence relation which has the lowest order among all such relations following from (1.4), (1.7) and (1.8). The complete solution to this problem, even in the more general case of the *Gegenbauer series* expansion

$$f=\sum_{k=0}^{\infty} g_k^{(\nu)}[f]C_k^{(\nu)} \qquad (\nu>-1/2), \tag{1.9}$$

where $C_k^{(\nu)}$ is the Gegenbauer polynomial

$$\begin{aligned} C_k^{(\nu)}&=\frac{(2\nu)_k}{(\nu+1/2)_k}P_k^{(\nu-1/2,\nu-1/2)} \qquad (\nu\neq 0),\\ C_k^{(0)}&=\lim_{\nu\to 0}\nu^{-1}C_k^{(\nu)}, \end{aligned} \tag{1.10}$$

was given by Lewanowicz [8]. A generalization of Clenshaw's method, in which (1.6) was replaced by (1.9), has been given by Elliott [2].

The case of the unsymmetric Jacobi polynomial expansion (1.1), for which $\alpha\neq\beta$, was discussed in [9]; the proposed optimum algorithm provides a recurrence relation of minimum order among all such equations which can be obtained from the differential equation (1.4), using basic difference and differential properties of the Jacobi polynomials (see (3.1), (3.2)).

In the present paper we describe another method for constructing a recurrence relation for the coefficients (1.2). The new method, though not optimum in general, seems to have some important advantages over the algorithms of papers [8] and [9]. First, the recurrence relation and its order are given by explicit formulae. Second, the components of these formulae are expressed in terms of the coefficients of the differential equation

$$\sum_{m=0}^{n} (q_m f)^{(m)} = q, \tag{1.11}$$

where

$$q_m = \sum_{j=m}^{n} (-1)^{j-m} \binom{j}{m} p_j^{(j-m)}, \tag{1.12}$$

which is equivalent to (1.4) (see, e.g., [15], p. 231). Last, the new procedure involves much less computational effort. Also, it could well be programmed in a language for symbolic computation; in this connection, see [6] and [16].

The main result of the paper is given in §4. The special cases of Gegenbauer and Chebyshev expansions are discussed in §5. Section 6 contains an illustrative example.

In the sequel we shall use the notation [9]

$$b_k[f] \equiv b_k^{(\alpha,\beta)}[f] = \frac{\Gamma(k+\alpha+1)}{\Gamma(k+\lambda)(2k+\lambda-1)_3} a_k^{(\alpha,\beta)}[f]. \tag{1.13}$$

We call $b_k[f]$ the *Jacobi coefficients* of the function f. It will be convenient to use coefficients with negative indices. We assume that if $\alpha \neq \beta$, or $\alpha = \beta$ but $2\alpha+1$ is not an integral $\geqq 0$, then

$$b_{-k}^{(\alpha,\beta)}[f] = 0 \quad \text{for } k = 1,2,\cdots, \tag{1.14}$$

and if $\alpha = \beta$ and $2\alpha+1 = m$ is a nonnegative integer, we define [2]

$$b_{-k}^{(\alpha,\alpha)}[f] = \begin{cases} 0 & \text{for } k = 1,2,\cdots,m-1, \\ b_{k-m}^{(\alpha,\alpha)}[f] & \text{for } k \geqq m. \end{cases} \tag{1.15}$$

The quantities

$$c_k[f] \equiv c_k^{(\nu)}[f] = 2\left(k+\nu-\frac{1}{2}\right) b_k^{(\nu-1/2,\nu-1/2)}[f] \tag{1.16}$$

are called the *Gegenbauer coefficients* of f. It can be seen that

$$c_k^{(\nu)}[f] = \begin{cases} \dfrac{\sqrt{\pi}}{\Gamma(\nu)(k+\nu)} g_k^{(\nu)}[f] & (\nu \neq 0), \\ \dfrac{\sqrt{\pi}}{4} t_k[f] & (\nu = 0). \end{cases}$$

2. Difference operators. The results given in the following sections are expressed in terms of a certain type of linear operator. Let $\mathscr{S}$ denote the linear space of all "doubly infinite" sequences of complex numbers, with addition of sequences and scalar multiplication defined as usual. Obviously $\mathscr{S}$ is the space of all complex-valued func-

tions defined on the set of all integers. Let $\mathscr{S}_{\text{rat}}$ denote the set of all *rational* functions $s\in\mathscr{S}$.

Consider the set $\mathscr{S}^*$ of all linear operators mapping $\mathscr{S}$ into itself. For $T\in\mathscr{S}^*$ and $\{z_k\}\in\mathscr{S}$, we denote the kth coordinate of the sequence $T\{z_k\}\in\mathscr{S}$ by Tz_k, so that $T\{z_k\}=\{Tz_k\}$. The *zero operator*, the *identity operator* and the *mth shift operator* in $\mathscr{S}^*$ are denoted by θ, I and E^m, respectively. Then we have

$$Iz_k=z_k,\quad \theta z_k=0,\quad E^m z_k=z_{k+m} \tag{2.1}$$

for every $\{z_k\}\in\mathscr{S}$. Clearly, $E^0=I$.

Let $\mathscr{L}$ be the set of all operators $L\in\mathscr{S}^*$ such that

$$L=\sum_{j=0}^{r}\lambda_j(k)E^{u+j}, \tag{2.2}$$

where $r\geqq 0$ and u are integers, and $\lambda_0,\lambda_1,\cdots,\lambda_r\in\mathscr{S}_{\text{rat}}$. Every nonzero operator $L\in\mathscr{L}$ can be expressed in the form (2.2) with $\lambda_0\not\equiv 0$ and $\lambda_r\not\equiv 0$. The number $r=r(L)$ is referred to as the *order* of the operator L, while λ_j are called the coefficients of L. The elements of the set $\mathscr{L}$ are known as *difference operators*.

Let $L\in\mathscr{L}$ be defined by (2.2) and let $M\in\mathscr{L}$ be such that

$$M=\sum_{j=0}^{t}\mu_j(k)E^{v+j}.$$

We define the *product* of L and M to be the operator

$$LM=\sum_{i=0}^{r}\lambda_i(k)\sum_{j=0}^{t}\mu_j(k+u+i)E^{u+v+i+j}.$$

It can be seen that under this definition of multiplication, with addition defined in a natural manner, $\mathscr{L}$ forms a ring with identity I.

Let $L\in\mathscr{L}$ and $\omega\in\mathscr{S}$. The equation $Lz_k=\omega(k)$ is the *recurrence relation* for the sequence $\{z_k\}\in\mathscr{S}$; the *order of the recurrence relation* is the order of the difference operator L.

3. Properties of the Jacobi coefficients. The well-known difference properties of the Jacobi polynomials,

$$\begin{aligned}(2k+\lambda-1)_3 xP_k^{(\alpha,\beta)}(x)&=2(k+\alpha)(k+\beta)(2k+\lambda+1)P_{k-1}^{(\alpha,\beta)}(x)\\&\quad+(\alpha^2-\beta^2)(2k+\lambda)P_k^{(\alpha,\beta)}(x)\\&\quad+2(k+1)(k+\lambda)(2k+\lambda-1)P_{k+1}^{(\alpha,\beta)}(x),\end{aligned}$$

$$\begin{aligned}2\Big[(k+\lambda-1)_2(2k+\lambda-1)\frac{d}{dx}P_{k+1}^{(\alpha,\beta)}(x)&+(\alpha-\beta)\\&\cdot(k+\lambda-1)(2k+\lambda)\frac{d}{dx}P_k^{(\alpha,\beta)}(x)\\&-(k+\alpha)(k+\beta)(2k+\lambda+1)\frac{d}{dx}P_{k-1}^{(\alpha,\beta)}(x)\Big]\\&=(k+\lambda-1)(2k+\lambda-1)_3P_k^{(\alpha,\beta)}(x)\end{aligned}$$

(see, e.g., [3, v. 2, §10.8] or [11, v. 1, §8]) imply the following basic identities for the Jacobi coefficients [9]:

$$Xb_k[f]=b_k[xf(x)], \tag{3.1}$$

$$Db_k[f']=b_k[f]. \tag{3.2}$$

Here X and D are difference operators,

$$X=\sum_{j=0}^{2}\xi_j(k)E^{j-1}, \tag{3.3}$$

$$D=\sum_{j=0}^{2}\delta_j(k)E^{j-1}, \tag{3.4}$$

and ξ_j, δ_j are rational functions,

$$\begin{aligned}&\delta_0(k)=2(k+\alpha)(2k+\lambda-3)/\gamma(k), \qquad \delta_1(k)=2(\alpha-\beta)(2k+\lambda)/\gamma(k),\\ &\delta_2(k)=-2(k+\beta+1)(2k+\lambda+3)/\gamma(k), \qquad \gamma(k)=(2k+\lambda-1)_3,\end{aligned} \tag{3.5}$$

$$\xi_0(k)=k\delta_0(k), \quad \xi_1(k)=\frac{1-\lambda}{2}\delta_1(k), \quad \xi_2(k)=-(k+\lambda)\delta_2(k). \tag{3.6}$$

From (3.1) and (3.2) we deduce the more general equations

$$p(X)b_k[f]=b_k[pf] \qquad (p \text{ a polynomial}), \tag{3.7}$$

$$D^ib_k[f^{(i)}]=b_k[f]. \tag{3.8}$$

Powers of the operators X and D may be obtained by the following procedure. Let $\Lambda\in\mathscr{L}$, $\Lambda=\sum_{j=0}^{2}\lambda_j(k)E^{j-1}$. Then we have

$$\Lambda^i=\sum_{j=0}^{2i}\lambda_{ij}(k)E^{j-i} \qquad (i\geqq 0),$$

where $\lambda_{ij}\in\mathscr{S}_{\text{rat}}$, $\lambda_{00}(k)\equiv 1$, and

$$\lambda_{ij}(k)=\lambda_0(k)\lambda_{i-1,j}(k-1)+\lambda_1(k)\lambda_{i-1,j-1}(k)+\lambda_2(k)\lambda_{i-1,j-2}(k+1)$$
$$(j=0,1,\cdots,2i;\lambda_{i,-2}=\lambda_{i,-1}=\lambda_{i,2i+1}=\lambda_{i,2i+2}\equiv 0)$$

for $i\geqq 1$. Moreover, if Λ has the *symmetry property* $\lambda_j(k)=\lambda_{2-j}(-k-\lambda)(j=0,1,2)$ then Λ^i also has this property: $\lambda_{ij}(k)=\lambda_{i,2i-j}(-k-\lambda)(j=0,1,\cdots,2i)$. Note that D and X have the symmetry property.

DEFINITION 3.1. Let

$$A_m^{(\varepsilon)}=I+\tau_m^{(\varepsilon)}(k)E,$$
$$Q_m^{(\varepsilon)}=kI-(k+\lambda+m+1)\tau_m^{(\varepsilon)}(k)E,$$

where $\varepsilon=\pm 1$, $m=0,1,\cdots$, and

$$\tau_m^{(-1)}(k)=\frac{(2k+\lambda+1)_3}{(2k+\lambda+m+1)_2(2k+\lambda-1)}, \qquad \tau_m^{(1)}(k)=-\frac{k+\beta+1}{k+\alpha+1}\tau_m^{(-1)}(k).$$

Further, let

$$\begin{aligned} S_{ij}^{(\varepsilon)} &= I && (i<j),\\ &= A_i^{(\varepsilon)} S_{i-1,j}^{(\varepsilon)} && (i \geqq j \geqq 0),\\ P_h^{(\varepsilon)} &= S_{h-1,0}^{(\varepsilon)} && (h \geqq 0),\\ R_m^{(\varepsilon)} &= I && (m=0),\\ &= Q_{m-1}^{(\varepsilon)} R_{m-1}^{(\varepsilon)} && (m \geqq 1). \end{aligned}$$

In virtue of [9, Lemma 3.5], we have

$$A_0^{(\varepsilon)}(X+\varepsilon I) = Q_0^{(\varepsilon)} D \qquad (\varepsilon = \pm 1). \tag{3.9}$$

It can be checked that

$$A_m^{(\varepsilon)} Q_{m-1}^{(\varepsilon)} = Q_m^{(\varepsilon)} A_{m-1}^{(\varepsilon)} \qquad (m \geqq 1). \tag{3.10}$$

LEMMA 3.1. *The identity*

$$P_i^{(\varepsilon)} b_k[\omega_\varepsilon^i f] = R_i^{(\varepsilon)} b_k[f], \tag{3.11}$$

where $\omega_\varepsilon = (x+\varepsilon)(d/dx)$, *holds for* $\varepsilon = \pm 1$ *and* $i = 0, 1, \cdots$.

Proof (by induction on i). For $i=0$ equation (3.11) is obviously true. Now, we have

$$P_1^{(\varepsilon)} b_k[\omega_\varepsilon f] = A_0^{(\varepsilon)}(X+\varepsilon I) b_k[f'] = Q_0^{(\varepsilon)} D b_k[f'] = R_1^{(\varepsilon)} b_k[f],$$

as can be seen using Definition 3.1, (3.9) and (3.4). Assume that (3.11) holds for a certain i ($i \geqq 1$). We obtain

$$P_{i+1}^{(\varepsilon)} b_k[\omega_\varepsilon^{i+1} f] = A_i^{(\varepsilon)} P_i^{(\varepsilon)} b_k[\omega_\varepsilon^i(\omega_\varepsilon f)] = A_i^{(\varepsilon)} R_i^{(\varepsilon)} b_k[\omega_\varepsilon f].$$

From (3.10) we deduce that

$$A_i^{(\varepsilon)} R_i^{(\varepsilon)} = Q_i^{(\varepsilon)} Q_{i-1}^{(\varepsilon)} \cdots Q_1^{(\varepsilon)} P_1^{(\varepsilon)},$$

which together with the result of the first part of the proof leads to

$$P_{i+1}^{(\varepsilon)} b_i[\omega^{i+1} f] = R_{i+1}^{(\varepsilon)} b_k[f]. \qquad \square$$

DEFINITION 3.2. Let

$$H_m^{(\varepsilon)} = H + m(X+\varepsilon I) \qquad (m = 0, 1, \cdots),$$

$$V_i^{(\varepsilon)} = \begin{cases} I & (i=0), \\ V_{i-1}^{(\varepsilon)} H_i^{(\varepsilon)} & (i = 1, 2, \cdots), \end{cases}$$

where $\varepsilon = \pm 1$ and

$$H = (k-1)_2 \delta_0(k) E^{-1} - k(k+\lambda)\delta_1(k) I + (k+\lambda)_2 \delta_2(k) E.$$

LEMMA 3.2. *For every* $m = 0, 1, \cdots$ *and* $\varepsilon = \pm 1$ *we have*

$$b_k[\omega_\varepsilon^m \{(x-\varepsilon)^m f(x)\}] = V_m^{(\varepsilon)} b_k[f]. \tag{3.12}$$

Proof. It can be checked (see [9]) that

$$b_k[(x^2-1) f'(x)] = H b_k[f]. \tag{3.13}$$

We also need the identity

$$\omega_\varepsilon\{(x-\varepsilon)^{m+1}f(x)\}=(x-\varepsilon)^m\{(x^2-1)f'(x)+(m+1)(x+\varepsilon)f(x)\} \tag{3.14}$$
$$(m=0,1,\cdots).$$

Equation (3.12) holds trivially for $m=0$. Assuming that it is true for a certain m ($m\geqq 0$), and making use of (3.14) and (3.13), we obtain

$$b_k\left[\omega_\varepsilon^{m+1}\{(x-\varepsilon)^{m+1}f(x)\}\right]=V_m^{(\varepsilon)}b_k\left[(x^2-1)f'(x)+(m+1)(x+\varepsilon)f(x)\right]$$
$$=V_m^{(\varepsilon)}\{H+(m+1)(X+\varepsilon I)\}b_k[f]=V_{m+1}^{(\varepsilon)}b_k[f]. \quad \square$$

4. Recurrence relation for the Jacobi coefficients. The main result of this paper is contained in Theorem 4.1 below. We shall need one more lemma.

LEMMA 4.1. *For every $r=0,1,\cdots$ and $\varepsilon=\pm 1$ we have*

$$\frac{d^r}{dx^r}\{(x+\varepsilon)^r f(x)\}=\sum_{h=0}^{r}\beta_h^{(r)}\omega_\varepsilon^{r-h}f(x), \tag{4.1}$$

where $\omega_\varepsilon=(x+\varepsilon)(d/dx)$,

$$\beta_h^{(r)}=(-1)^h\binom{r}{h}B_h^{(r+1)} \qquad (h=0,1,\cdots,r), \tag{4.2}$$

and $B_m^{(a)}$ are generalized Bernoulli numbers defined implicitly by

$$\left(\frac{t}{e^t-1}\right)^a=\sum_{m=0}^{\infty}\frac{t^m}{m!}B_m^{(a)}.$$

Proof. We start with the identity [11, v. 1, Eq. 2.8(16)]

$$(y+1)_r=\sum_{h=0}^{r}\beta_h^{(r)}y^{r-h}.$$

Combining this with [11, v. 1, Eq. 2.9(4)]

$$\frac{d^r}{dz^r}\{z^r g(z)\}=\prod_{i=1}^{r}(\omega+i)g(z),$$

where $\omega=z(d/dz)$, we obtain

$$\frac{d^r}{dz^r}\{z^r g(z)\}=\sum_{h=0}^{r}\beta_h^{(r)}\omega^{r-h}g(z). \tag{4.3}$$

For $\varepsilon\in\{-1,1\}$, let $z=x+\varepsilon$ and $f(x)=g(x+\varepsilon)$. Obviously, $\omega_\varepsilon f(x)=\omega g(z)$ and (4.1) is simply a transcription of (4.3). $\square$

The quantities (4.2) can be calculated recursively using formulae (cf. [11, v. 1, Eq. 2.8(7)])

$$\begin{aligned}&\beta_h^{(r)}=\beta_h^{(r-1)}+r\beta_{h-1}^{(r-1)} \qquad (r=1,2,\cdots;h=0,1,\cdots),\\ &\beta_0^{(r)}=1, \quad \beta_{r+1}^{(r)}=0 \qquad (r\geqq 0).\end{aligned} \tag{4.4}$$

THEOREM 4.1. *Let f be a function satisfying the differential equation*

$$\sum_{m=0}^{n} (q_m f)^{(m)} = q \tag{4.5}$$

of order n, where $q_0, q_1, \cdots, q_n$ are polynomials, and assume that $f^{(n)}$ can be expanded into a uniformly convergent Jacobi series. Let e_{im} be an integer $\geqq 0$ such that the equation

$$q_m(x) = (x+1)^{e_{1m}}(x-1)^{e_{-1m}} u_m(x) \qquad (m = 1, 2, \cdots, n; q_m \not\equiv 0) \tag{4.6}$$

holds for a polynomial u_m, $u_m(\pm 1) \neq 0$; let

$$s_i = \max\left\{ \max_{1 \leqq m \leqq n,\, q_m \not\equiv 0} (m - e_{im}), 0 \right\} \qquad (i = \pm 1), \tag{4.7}$$

and let $\varepsilon \in \{-1, 1\}, s, \sigma$ and d be integers,

$$\varepsilon = \begin{cases} 1 & \text{for } s_1 \leqq s_{-1}, \\ -1 & \text{for } s_1 > s_{-1}, \end{cases} \tag{4.8}$$

$$s = s_\varepsilon, \quad \sigma = s_{-\varepsilon}, \quad d = \sigma - s. \tag{4.9}$$

Finally, define the polynomials

$$\phi_h(x) = \sum_{i=s+h}^{n} \beta_{i-s-h}^{(i-s)} (x+\varepsilon)^{s-i} q_i(x) \quad \text{for } h = 0, 1, \cdots, n-s, \tag{4.10}$$

$$\psi_j(x) = (x-\varepsilon)^{-j} \phi_{j+d}(x) \quad \text{for } j = 1, 2, \cdots, n-\sigma. \tag{4.11}$$

Then we have the recurrence relation

$$Lb_k[f] = \rho(k), \tag{4.12}$$

where

$$L = P_d^{(\varepsilon)} \sum_{m=0}^{s-1} D^{s-m} q_m(X) + \sum_{h=0}^{d} S_{d-1,h}^{(\varepsilon)} R_h^{(\varepsilon)} \phi_h(X) + R_d^{(\varepsilon)} \sum_{j=1}^{n-\sigma} V_j^{(\varepsilon)} \psi_j(X), \tag{4.13}$$

and

$$\rho(k) = P_d^{(\varepsilon)} D^s b_k[q]. \tag{4.14}$$

(The notation used is that of Definitions 3.1 *and* 3.2.*) The order of this relation is expressed by the formula*

$$r = s_{-1} + s_1 + 2 \max_{0 \leqq m \leqq n,\, q_m \not\equiv 0} (\deg(q_m) - m). \tag{4.15}$$

Proof. Equation (4.5) implies that

$$\sum_{m=0}^{n} b_k\left[(q_m f)^{(m)}\right] = b_k[q].$$

Applying the operator D^s, where s is defined in (4.9), to both sides of the above equation, and using (3.7) and (3.8), we obtain

$$\sum_{m=0}^{s-1} D^{s-m} q_m(X) b_k[f] + \sum_{m=s}^{n} b_k\left[(q_m f)^{(m-s)}\right] = D^s b_k[q]. \tag{4.16}$$

Now, it readily follows from (4.7)–(4.9) that $e_{\varepsilon m} \geqq m-s \geqq m-\sigma$. Hence the formulae (4.10) and (4.11) actually define polynomials. Let $v_m(x)=(x+\varepsilon)^{s-m} q_m(x)$ for $m=s, s+1, \cdots, n$. Using Lemma 4.1 we transform the second sum on the l.h.s. of (4.16):

$$\begin{aligned}\sum_{m=s}^{n} b_k\left[(q_m f)^{(m-s)}\right] &= \sum_{r=0}^{n-s} b_k\left[\left\{(x+\varepsilon)^r v_{s+r}(x) f(x)\right\}^{(r)}\right] \\ &= \sum_{r=0}^{n-s} \sum_{h=0}^{r} \beta_h^{(r)} b_k\left[\omega_\varepsilon^{r-h}(v_{s+r} f)\right] = \sum_{h=0}^{n-s} b_i\left[\omega_\varepsilon^h(\phi_h f)\right].\end{aligned}$$

In the last expression, ϕ_h is the polynomial defined in (4.10).

Let ε and d be the integers defined in (4.8) and (4.9), respectively. Applying the operator $P_d^{(\varepsilon)}$ to both sides of (4.16) and making use of Lemma 3.1 and of (3.7), we obtain

$$\begin{aligned}&\left\{P_d^{(\varepsilon)} \sum_{m=0}^{s-1} D^{s-m} q_m(X) + \sum_{h=0}^{d} S_{d-1,h}^{(\varepsilon)} R_h^{(\varepsilon)} \phi_h(X)\right\} b_k[f] \\ &\qquad + R_d^{(\varepsilon)} \sum_{h=d+1}^{n-s} b_k\left[\omega_\varepsilon^{h-d}(\phi_h f)\right] = P_d^{(\varepsilon)} D^s b_k[q].\end{aligned} \tag{4.17}$$

Using (4.11) and Lemma 3.2, we deduce that

$$\sum_{h=d+1}^{n-s} b_k\left[\omega_\varepsilon^{h-d}(\phi_h f)\right] = \sum_{j=1}^{n-\sigma} b_k\left[\omega_\varepsilon^j\left\{(x-\varepsilon)^j \psi_j(x) f(x)\right\}\right] = \sum_{j=1}^{n-\sigma} V_j^{(\varepsilon)} \psi_j(X) b_k[f].$$

Noting this result in (4.17), equation (4.12) follows, in which the operator $L \in \mathscr{L}$ and the function $\rho \in \mathscr{S}$ are given by (4.13) and (4.14), respectively.

As we remarked in §1, the differential equation (4.5) is equivalent to the equation

$$\sum_{m=0}^{n} p_m f^{(m)} = q$$

of order n, where p_m are polynomials. Now, we have seen that the recurrence relation (4.12) is obtained by the use of the operator $P = P_d^{(\varepsilon)} D^s$ which satisfies

$$P \sum_{m=0}^{n} b_k\left[p_m f^{(m)}\right] = L b_k[f],$$

where L is the operator (4.13). According to [9, Lemma 4.2], the order of the operator L is equal to

$$r = r(P) + 2 \max_{0 \leqq m \leqq n,\, p_m \not\equiv 0} (\deg(p_m) - m).$$

It can be checked that, without affecting its validity, we may replace p_m by q_m in the above expression. As $r(P)=r(P_d^{(\varepsilon)})+r(D^s)=d+2s=s+\sigma$, we obtain the formula (4.15). □

The recurrence relation (4.12) takes a particularly simple form in the case where neither $x+1$ nor $x-1$ divides the coefficient $q_n(x)$ in the equation (4.5). Namely, equations (4.13) and (4.14) then become

$$L=\sum_{m=0}^{n} D^{n-m}q_m(X) \tag{4.18}$$

and

$$\rho(k)=D^n b_k[q],$$

respectively. The operator (4.18) has the order

$$2n+2\Big(\max_{0\leqq m\leqq n,\, q_m\not\equiv 0}(\deg(q_m)-m)\Big). \tag{4.19}$$

In the case under consideration our method is equivalent to the Paszkowski-type method described in [9, §5], which like most other algorithms [4–7], [12–15]) does *not* analyse the form of the coefficients of (4.5) but leads "blindly" to a recurrence relation of the *maximum* order (4.19). (Obviously, (4.19) is the upper bound for (4.15).)

There are two other special cases. First, if $q_m(x)=(x^2-1)^m w_m(x)$, where w_m is a polynomial ($m=0,1,\cdots,n$), then (4.13)–(4.15) reduce to

$$\begin{aligned} L&=\sum_{j=0}^{n} V_j^{(1)}\psi_j(X),\\ \rho(k)&=b_k[q],\\ r&=2\max_{0\leqq m\leqq n,\, w_n\not\equiv 0}(\deg(w_m)+m), \end{aligned}$$

where

$$\psi_j(x)=\sum_{m=j}^{n}\beta_{m-j}^{(m)}(x-1)^{m-j}w_m(x).$$

Second, when for $\varepsilon\in\{-1,1\}$, $q_m(x)=(x+\varepsilon)^m v_m(x)$, where v_m is a polynomial ($m=0,1,\cdots,n$) and $q_n(-\varepsilon)\neq 0$, we have

$$\begin{aligned} L&=\sum_{h=0}^{n} S_{n-1,h}^{(\varepsilon)}R_h^{(\varepsilon)}\phi_h(X),\\ \rho(k)&=P_n^{(\varepsilon)}b_k[q],\\ r&=n+2\max_{0\leqq m\leqq n,\, v_m\not\equiv 0}\deg(v_m), \end{aligned}$$

where

$$\phi_h(x)=\sum_{m=h}^{n}\beta_{m-h}^{(m)}v_m(x)\qquad(h=0,1,\cdots,n).$$

Finally, a symmetry property of the equation (4.12) should be noted which seems to be useful for checking purposes.

THEOREM 4.2. *Operator* (4.13) *can be written in the form*

$$L=\mu_d^{(\varepsilon)}(k)\sum_{i=0}^{r}\lambda_i(k)E^{i-u} \qquad (r=r(L))$$

in which

$$u=s+\max_{0\leqq m\leqq n,\, q_m\not\equiv 0}\bigl(\deg(q_m)-m\bigr),$$

$$\mu_d^{(-1)}(k)=(k+\alpha+1)_d\mu_d^{(1)}=\begin{cases}1 & (d=0),\\ (2k+\lambda-1)^{-1} & (d=1),\\ \bigl[(2k+\lambda-1)(2k+\lambda+d+1)_{d-2}\bigr]^{-1} & (d>1),\end{cases}$$

and $\lambda_0, \lambda_1, \cdots, \lambda_r \in \mathscr{S}_{\text{rat}}$ *are such that*

$$\lambda_{r-i}(k)=(-1)^{\eta}\lambda_i(-k-\lambda-d) \qquad (i=0,1,\cdots,r),$$

where

$$\eta=\begin{cases}d & (d\leqq 1),\\ d-1 & (d>1).\end{cases}$$

Proof. We give a short sketch of the proof. Let P represent any of the following operators:

$$P_d^{(\varepsilon)}, \quad R_d^{(\varepsilon)}, \quad S_{d-1,h}^{(\varepsilon)}R_h^{(\varepsilon)} \qquad (h=0,1,\cdots,d).$$

It can be shown by induction on d that

$$P=\mu_d^{(\varepsilon)}(k)\sum_{i=0}^{d}\pi_i(k)E^i$$

in which $\pi_0, \pi_1, \cdots, \pi_d \in \mathscr{S}_{\text{rat}}$ are such that

$$\pi_{d-i}(k)=(-1)^{\eta}\pi_i(-k-\lambda-d) \qquad (i=0,1,\cdots,d).$$

Further, let T stand for any of the operators

$$\sum_{m=0}^{s-1}D^{s-m}q_m(X), \quad \sum_{j=1}^{n-\sigma}V_j^{(\varepsilon)}\psi_j(X), \quad \phi_h(X) \qquad (h=0,1,\cdots,d).$$

From a symmetry property of the operators $V_j^{(\varepsilon)}$ and of the powers of D and X, it can be seen that

$$T=\sum_{j=0}^{2t}\tau_j(k)E^{j-t}$$

in which

$$t=s+\max_{m\in M,\, q_m\not\equiv 0}\bigl(\deg(q_m)-m\bigr),$$

and the coefficients τ_j satisfy

$$\tau_{2t-j}(k)=\tau_j(-k-\lambda) \qquad (j=0,1,\cdots,2l).$$

Here M is the set $\{0,1,\cdots,s-1\}$, or $\{\sigma+1,\sigma+2,\cdots,n\}$, or $\{s+h,s+h+1,\cdots,n\}$ $(h=0,1,\cdots,d)$, respectively.

Now, it can be checked that

$$PT=\mu_d^{(\varepsilon)}(k)\sum_{l=0}^{d+2t}\chi_l(k)E^{l-t}$$

in which χ_l are such that

$$\chi_{d+2t-l}(k)=(-1)^{\eta}\chi_l(-k-\lambda-d)\qquad(l=0,1,\cdots,d+2l).$$

Substituting this in (4.13) gives the theorem. □

5. Recurrence relation for the Gegenbauer coefficients. The special case $\alpha=\beta$ of the Jacobi series (1.1) is of particular importance. As has already been remarked in §1, it is then more convenient to deal with the Gegenbauer series (1.9) or the Chebyshev series (1.5). A recurrence relation for the Gegenbauer coefficients (1.16) can be constructed by a method analogous to that used in §4. However, in the present section we obtain neater looking results.

First of all, the basic identities (3.1), (3.2) may be replaced by

$$\bar{X}c_k[f]=c_k[xf(x)],\tag{5.1}$$

$$\bar{D}c_k[f']=c_k[f],\tag{5.2}$$

in which

$$\bar{X}=2^{-1}(k+\nu)^{-1}\{kE^{-1}+(k+2\nu)E\},$$
$$\bar{D}=2^{-1}(k+\nu)^{-1}\{E^{-1}-E\},\qquad \nu=\alpha+\tfrac{1}{2}.$$

We have

$$p(\bar{X})c_k[f]=c_k[pf]\qquad(p\text{ a polynomial}),\tag{5.3}$$

$$\bar{D}^ic_k[f^{(i)}]=c_k[f].\tag{5.4}$$

Note that [8]

$$\bar{D}^i=2^{-i}(k+\nu-i)_{2i+1}^{-1}\sum_{m=0}^{i}\rho_{im}(k+\nu)E^{2m-i},\tag{5.5}$$

where

$$\rho_{im}(\kappa)=(-1)^m\binom{i}{m}(\kappa-i)_m(\kappa-i+2m)(\kappa+m+1)_{i-m}\qquad(m=0,1,\cdots,i).$$

Further,

$$\bar{X}^i=2^{-i}\sum_{j=0}^{i}\xi_{ij}(k+\nu)E^{2j-i},$$

where

$$\xi_{ij}(k)=\binom{i}{j}\qquad(j=0,1,\cdots,i)$$

for $\nu=0$ and

$$\xi_{00}(\kappa)=1,$$
$$\xi_{ij}(\kappa)=\kappa^{-1}\{(\kappa-\nu)\xi_{i-1,j}(\kappa-1)+(\kappa+\nu)\xi_{i-1,j-1}(\kappa+1)\}$$
$$(j=0,1,\cdots,i;\, i\geqq 1;\, \xi_{i-1,-1}=\xi_{i-1,i}=0)$$

for $\nu\neq 0$ (ibid.).

DEFINITION 5.1. For any $m=0,1,\cdots$ and $\varepsilon=\pm 1$ we define

$$\overline{A}_m^{(\varepsilon)}=I-\varepsilon\tau_m(k)E,$$
$$\overline{Q}_m^{(\varepsilon)}=kI+\varepsilon(k+2\nu+m+1)\tau_m(k)E,$$

where

$$\tau_m(k)=(2k+2\nu+1)_2/(2k+2\nu+m+1)_2.$$

Further, let

$$\overline{S}_{ij}^{(\varepsilon)}=\begin{cases} I & (i<j),\\ \overline{A}_i^{(\varepsilon)}\overline{S}_{i-1,j}^{(\varepsilon)} & (i\geqq j\geqq 0),\end{cases}$$
$$\overline{P}_m^{(\varepsilon)}=\overline{S}_{m-1,0}^{(\varepsilon)} \qquad (i\geqq 0),$$
$$\overline{R}_i^{(\varepsilon)}=\begin{cases} I & (i=0),\\ \overline{Q}_i^{(\varepsilon)}\overline{R}_{i-1}^{(\varepsilon)} & (i>0).\end{cases}$$

Finally, let

$$\overline{H}_m^{(\varepsilon)}=\overline{H}+m(\overline{X}+\varepsilon I) \qquad (m=1,2,\cdots;\varepsilon=\pm 1),$$
$$\overline{V}_i^{(\varepsilon)}=\begin{cases} I & (i=0),\\ \overline{V}_{i-1}^{(\varepsilon)}\overline{H}_i^{(\varepsilon)} & (i\geqq 1),\end{cases}$$

where

$$\overline{H}=2^{-1}(k+\nu)^{-1}\{(k-1)_2E^{-1}-(k+2\nu)_2E\}.$$

Lemmata 3.1 and 3.2 now have the following analogues.

LEMMA 5.1. *For any $i\geqq 0$ and $\varepsilon=\pm 1$ we have*

$$\overline{P}_i^{(\varepsilon)}c_k[\omega_\varepsilon^i f]=\overline{R}_i^{(\varepsilon)}c_k[f],$$

where $\omega_\varepsilon=(x+\varepsilon)(d/dx)$.

LEMMA 5.2. *For any $j\geqq 0$ and $\varepsilon=\pm 1$ we have the identity*

$$c_k[\omega_\varepsilon^j\{(x-\varepsilon)^j f(x)\}]=\overline{V}_j^{(\varepsilon)}c_k[f].$$

Finally, we have the following

THEOREM 5.1. *Let f be a function satisfying the differential equation* (4.5) *of order n and such that its nth derivative can be expanded into the uniformly convergent Gegenbauer series. We then have the recurrence relation*

$$\overline{L}c_k[f]=\overline{\rho}(k), \tag{5.6}$$

where

$$\overline{L}=\overline{P}_d^{(\varepsilon)}\sum_{m=0}^{s-1}\overline{D}^{s-m}q_m(\overline{X})+\sum_{h=0}^{d}\overline{S}_{d-1,h}^{(\varepsilon)}\overline{R}_h^{(\varepsilon)}\phi(\overline{X})+\overline{R}_d^{(\varepsilon)}\sum_{j=1}^{n-\sigma}\overline{V}_j^{(\varepsilon)}\psi_j(\overline{X}),$$

$$\overline{\rho}(k)=\overline{P}_d^{(\varepsilon)}\overline{D}^s c_k[q],$$

and the symbols $\varepsilon, s, \sigma, d, \phi_h, \psi_j$ *have the meaning given in Theorem* 4.1. *The order of the relation* (5.6) *is expressed by* (4.15). *Operator* $\overline{L}$ *can be written in the form*

$$\overline{L}=\mu(k)\sum_{i=0}^{r}\lambda_i(k)E^{i-u}, \qquad r=r(L),$$

in which

$$u=s+\max_{0\leqq m\leqq n,\, q_m\not\equiv 0}(\deg(q_m)-m),$$

$$\mu(k)=\begin{cases}1 & (d=0),\\ 1/(2k+2\nu+d+1)_{d-1} & (d>0),\end{cases}$$

and $\lambda, \lambda_1, \cdots, \lambda_r \in \mathscr{S}_{\mathrm{rat}}$ *are such that*

$$\lambda_{r-i}(k)=\eta\varepsilon^d\lambda_i(-k-2\nu-d) \qquad (i=0,1,\cdots,r),$$

where $\eta=0$ *for* $d=0$ *and* $\eta=-1$ *for* $d>0$.

From (4.5), we have the identity

$$\sum_{m=0}^{n}c_k\left[(q_m f)^{(m)}\right]=c_k[q].$$

Applying the operator $\overline{D}^n$ to both sides of the above equation and using (5.3) and (5.4), we obtain another recurrence relation obeyed by $\{c_k[f]\}$, namely

$$\left\{\sum_{m=0}^{n}\overline{D}^{n-m}q_m(\overline{X})\right\}c_k[f]=\overline{D}^n c_k[q] \tag{5.7}$$

or, in view of (5.5),

$$\left\{\sum_{m=0}^{n}2^m(k+\nu-n)_m(k+\nu-m+1)_m\sum_{i=0}^{n-m}\rho_{n-m,i}(k+\nu)E^{2i-n+m}q_m(\overline{X})\right\}c_k[f]$$

$$=\sum_{m=0}^{n}\rho_{nm}(k+\nu)c_{k-n+2m}[q].$$

The described procedure is equivalent to the generalized Paszkowski algorithm ([8]; or [17, p. 196 ff]). Clearly, equation (5.7) has order (4.19). Equations (5.6) and (5.7) coincide if and only if the coefficient q_n in (4.5) has no linear factors of the form $(x+1)$ or $(x-1)$.

6. Example. The generalized hypergeometric function

$$F(z)={}_{p+1}F_p\left(\begin{matrix}\gamma_1,\gamma_2,\cdots,\gamma_{p+1}\\ \varepsilon_1,\varepsilon_2,\cdots,\varepsilon_p\end{matrix}\middle|z\right) \qquad \left(\mathrm{Re}\left(\sum\gamma_i-\sum\varepsilon_i\right)<0\right) \tag{6.1}$$

satisfies the differential equation [3, v. 1, §4.2], or [11, v. 1, §5.1]

$$\left\{ z \prod_{i=1}^{p+1} (\omega+\gamma_i) - \omega \prod_{j=1}^{p} (\omega+\varepsilon_j-1) \right\} Y(z)=0 \qquad \left(\omega = z\frac{d}{dz}\right)$$

which can also be written in the form

$$u_0 Y(z) + \sum_{m=1}^{p} (u_m z - v_m) z^{m-1} Y^{(m)}(z) + (z-1) z^p Y^{(p+1)}(z) = 0, \tag{6.2}$$

where u_m, v_m are constants. Therefore, the function

$$f_p(x) = F\left(\frac{1+x}{2}\right) \qquad (-1 \leqq x \leqq 1) \tag{6.3}$$

satisfies

$$u_0 y(x) + \sum_{m=1}^{p} (u_m x - w_m)(x+1)^{m-1} y^{(m)}(x) + (x-1)(x+1)^p y^{(p+1)}(x) = 0, \tag{6.4}$$

where $w_m = u_m - 2v_m$ $(m=1,2,\cdots,p)$.

It is known [11, v. 2, §9] that the function (6.3) can be expanded in the Jacobi series (1.1) and that

$$a^{(\alpha,\beta)}[f_p] = \frac{\prod_{i=1}^{p+1} (\gamma_i)_k}{(k+\lambda)_k \prod_{j=1}^{p} (\varepsilon_j)_k} p+2F p+1\left(\begin{matrix} k+\beta+1, k+\gamma_1, \cdots, k+\gamma_{p+1} \\ 2k+\lambda+1, k+\varepsilon_1, \cdots, k+\varepsilon_p \end{matrix} \middle| 1 \right). \tag{6.5}$$

We need the following alternative form of (6.4):

$$\lambda_0 y + \sum_{m=1}^{p+1} \left\{ (\lambda_m x + \mu_m)(x+1)^{m-1} y \right\}^{(m)} = 0,$$

where $\lambda_{p+1} = -\mu_{p+1} = 1$ (cf. (1.11), (1.12)). By virtue of Theorem 4.1 we have the recurrence relation

$$L_p b_k^{(\alpha,\beta)}[f_p] = 0$$

of order $p+1$ satisfied by the Jacobi coefficients of the function (6.3), where

$$L_p = \lambda_0 P_{p-1}^{(1)} D + \sum_{h=0}^{p-1} S_{p-2,h}^{(1)} R_h^{(1)} (\eta_h + X + \theta_h I) + R_{p-1}^{(1)} H_1^{(1)},$$

and

$$\eta_h = \sum_{l=h+1}^{p+1} \beta_{l-h-1}^{(l-1)} \lambda_l, \qquad \theta_h = \sum_{l=h+1}^{p+1} \beta_{l-h-1}^{(l-1)} \mu_l.$$

In particular, the Jacobi coefficients of the function

$$f_2(x) = {}_3F_2\left(\begin{matrix} \gamma_1, \gamma_2, \gamma_3 \\ \varepsilon_1, \varepsilon_2 \end{matrix} \middle| \frac{1+x}{2} \right)$$

obey the third-order recurrence relation

$$L_2 b_k^{(\alpha,\beta)}[f_2] = 0, \tag{6.6}$$

where

$$L_2 = A_0^{(1)}\{\lambda_0 D + (\lambda_1+\lambda_2+2)X + (\mu_1+\mu_2-2)I\} + Q_0^{(1)}\{H + (\lambda_2+4)X + (\mu_2-2)I\},$$

and

$$\begin{aligned}
&\lambda_0 = \sigma_1 - \sigma_2 + \gamma_1\gamma_2\gamma_3 - 1, \qquad \lambda_1 = \sigma_2 - 3\sigma_1 + 7,\\
&\lambda_2 = \sigma_1 - 6, \qquad \mu_1 = \sigma_2 - 3\sigma_1 - 2\varepsilon_1\varepsilon_2 + 4\varepsilon_1 + 4\varepsilon_2 - 1,\\
&\mu_2 = \sigma_1 - 2\varepsilon_1 - 2\varepsilon_2 + 1, \qquad \sigma = \gamma_1+\gamma_2+\gamma_3,\\
&\sigma_2 = \gamma_1\gamma_2 + \gamma_1\gamma_3 + \gamma_2\gamma_3.
\end{aligned}$$

Remark that an equivalent result is furnished by the optimum method of [9]. On the other hand, we have recently shown [10] that the quantities (6.5) satisfy the recurrence relation

$$\sum_{i=0}^{p+1} A_i(k)\, a_{k+i}^{(\alpha,\beta)}[f_p] = 0 \tag{6.7}$$

of order $p+1$, where the coefficients $A_i(k)$ are expressed in terms of hypergeometric functions of unit argument. We have checked that, for $p=2$, (6.7) is equivalent to (6.6).

Acknowledgment. The author would like to thank Professors S. Paszkowski and M. J. D. Powell for helpful comments.

INVARIANT CURVES FOR MAPPINGS*

HAL L. SMITH†

Abstract. The main result of this paper concerns a smooth map T of a Banach space X into itself which has an unstable fixed point x_0. We prove that if the spectral radius λ_0 of the Frechet derivative of T at x_0 is an eigenvalue which exceeds one and appropriate additional assumptions hold, then there is a smooth invariant curve emanating from x_0 which might be called the "most unstable manifold" of x_0. The curve is parametrized by a smooth function satisfying a functional equation involving T and λ_0. This result is shown to be especially useful when the map T possesses certain monotonicity conditions. In this case, the curve can be shown to be monotone and to terminate on a stable fixed point of T.

Key words. unstable manifold of a fixed point, functional equation, smooth linearization

Introduction. In 1901, motivated by the work of Poincaré on the stability of periodic solutions of ordinary differential equations, T. Hadamard [4] published a short note in which he showed that the unstable manifold of a hyperbolic fixed point of a smooth diffeomorphism T of the plane can be obtained as the limit of a sequence of curves generated by successively applying T to a suitable initial curve. In fact, his result is more general. He assumed that

$$T(x,y)=(sx+F(x,y),s'y+\Phi(x,y)),$$

where F and Φ have Taylor developments about the origin beginning with quadratic terms, $s>1$, $|s'|<s$. He then shows that if C is a curve which can be parametrized by $y=y(x)$ with $|dy/dx|\leqq\alpha$, then $C_n\equiv T^n(C)$ converges to an invariant curve for the map T (T^n denotes the n-fold composition of T with itself: $T\circ T\circ\cdots\circ T, n$ times). Since s' is not assumed to satisfy $|s'|<1$, nor $s'\neq 1$, this invariant curve, in general, will lie in the unstable manifold of the fixed point; it might be called (part of) the "most unstable manifold" of the fixed point.

The purpose of this paper is to prove a general version of this result, obtaining a "most unstable" invariant curve emanating from an unstable fixed point for a smooth map. We will also find a parametrization of this invariant curve which effectively linearize the action of T on the curve. The following is a special case of our main theorem.

THEOREM. *Let T: $X\to X$ be a smooth map of a real Banach space X into itself having a fixed point x_0. Let $A\equiv DT(x_0)$ be the derivative of T at x_0 and assume that $Ae_0=\lambda_0 e_0$ where $e_0\notin\overline{R(A-\lambda_0 I)}$ and $\lambda_0>1$ is the spectral radius of A. Then there exists a unique smooth function y: $[0,\infty)\to X$, $y(t)=x_0+te_0+O(t^2)$ as $t\to 0$, with the following properties.*

I. $y(t)=T(y(\lambda_0^{-1}t))$ $t\geqq 0$.

II. $y(t)=\lim_{n\to\infty}T^n(x_0+\lambda_0^{-n}te_0)$.

III. *If T is a diffeomorphism then y is a one-to-one immersion ($y'(t)\neq 0$) and $y(t)$ is not a fixed point of T (or periodic point) for any $t>0$.*

*Received by the editors June 22, 1984, and in revised form February 14, 1985. This paper was presented at the International Conference on Qualitative Theory of Differential Equations, Edmonton, Alberta, Canada, June 1984.

†Department of Mathematics, Arizona State University, Tempe, Arizona 85287.

In II, T^n again denotes the n-fold composition $T \circ T \circ T \circ \cdots \circ T$, n times, of T with itself. We will use this notation throughout the rest of the paper without further comment.

If we let C be the curve in X parametrized by $y, C = \{y(t): t \geqq 0\}$, then the functional relation I can be interpreted in terms of the commuting diagram of maps

$$\begin{array}{ccc} C & \xrightarrow{T} & C \\ {\scriptstyle y}\uparrow & & \uparrow{\scriptstyle y} \\ [0,\infty) & \xrightarrow[t \to \lambda_0 t]{} & [0,\infty) \end{array}$$

In other words, the parametrization y of C effects a linearization of T on C. One may view the functional relations I in a different vein by setting $f(s) = y(\lambda_0^s)$, $-\infty < s < \infty$, yielding the functional equation $f(s) = T(f(s-1))$.

The finite-dimensional version of the theorem can be obtained from existing results. First observe that the existence of y: $[0,\infty) \to X$ in the theorem follows by continuation from the existence of y: $[0,\varepsilon) \to X$, $\varepsilon > 0$, satisfying I, II and III. Hence, the issue is the local existence of y for t near zero. By using [11, Thm. 5.1], one obtains the existence of a local C^2 unstable manifold for T, which by a C^2 change of variables can be taken to be a neighborhood of x_0 in an affine subspace of X. Then, a result of Hartman ([5, Exercise 8.2, p. 246]) can be applied to the restriction of T to the unstable manifold yielding a C^1 change of coordinates near x_0 on the unstable manifold so that in the new coordinates, T (restricted to unstable subspace) can be represented by its linear part. This result is easily seen to imply our theorem.

Our motivation for proving the above theorem stems from dynamical systems theory. One may imagine that T is the Poincaré map associated with a flow. The unstable fixed point x_0 may represent an equilibrium solution or periodic orbit for the flow. In certain situations, one may be able to conclude that the invariant curve C, emanating from x_0, asserted to exist by our theorem, is precompact in the phase space X. In such cases, one can assert (see Remark 2 following Theorem 1.1) that the limit set

$$\Lambda = \left\{ x: x = \lim_{n \to \infty} y(t_n), t_n \to \infty \right\}$$

is nonempty, compact, connected and an invariant set for T. It may contain fixed points of T, periodic points, a closed curve or more exotic strange attractors. Those familiar with dynamical systems theory will have a ready supply of examples. In recent studies of chaotic motion and strange attractors, a standard technique has been to locate saddle fixed points of suitable diffeomorphisms and to numerically approximate the unstable manifold. For example, in (see in particular, [3, Figs. 2.2.7 and 2.2.8]) it is conjectured that the strange attractor in the periodically perturbed Duffing equation is the closure of such an unstable manifold corresponding to the Poincaré map.

In a different direction, Pounder and Rogers [7] study the difference equation $(x_n, y_n) = T_a(x_{n-1}, y_{n-1})$ associated with the mapping $T_a(x,y) = (y, ay(1-x))$. This equation is equivalent to the "delayed" logistic equation $y_{n+1} = ay_n(1-y_{n-1})$. They obtain an existence proof of an invariant curve, $C_\infty(a)$, for T_a, emanating from the saddle $(0,0)$ for $a > 1$ by techniques very similar to ours. Their numerical calculations of $C_\infty(a)$ for various values of a are particularly interesting, (see especially [3, Figs. 2a–c and 5–12]) showing clearly the complex behavior to be expected of the invariant curve $C = C_\infty(a)$ of our theorem. In [7, Fig. 2a] the set Λ consists of another fixed point with

C joining the two fixed points, $1<a<\frac{5}{4}$. For larger values of $\frac{5}{4}<a<2$, Λ is the same fixed point but C spirals around this fixed point. For $2<a\leqq 2.20$, C wraps around a closed invariant curve for T, then $\Lambda=S^1$. For $a\simeq 2.27$, the curve C loops back to the origin infinitely many times and it appears clear that the outer loop of C is contained in Λ in this case.

We envision that an important application of our result will be to discrete dynamical systems generated by a monotone map T. A monotone map is one which preserves a partial ordering on the space X, induced, for example, by a cone in X. Such maps arise naturally as Poincaré maps for ordinary differential equations, for which the Kamke theorem [12] applies, the so-called competitive and cooperative systems of Hirsch [12], [13] (see also Selgrade [8] and [16], [17]) and for parabolic partial differential equations which generate monotone flows in suitable function spaces via maximum principle arguments (see [14], [15]). If x_0 is an unstable fixed point of a monotone map T, the spectral assumptions of our theorem can often be verified by the Perron–Frobenius theorem in finite dimensions or the Krein–Rutman theorem in infinite dimesions. In §2 we give sufficient conditions for the function y of our theorem to be monotone with respect to the usual ordering on R^+ and the partial ordering on X, in case T is monotone. This result leads to the dichotomy: either C is monotone and unbounded or C joins x_0 to a semi-stable fixed point, x_∞, of T and C is tangent at x_∞ to the eigenvector corresponding to the dominant eigenvalue of $DT(x_\infty)$. This result provides the key tool for our analysis of periodic competitive and cooperative systems in future publications [16], [17].

1. Main results. Before stating and proving our main results, we establish some notation. We will introduce various Banach spaces in what follows and will reserve $|\cdot|$ for the norm. Since we also will consider Banach spaces whose elements are Banach space-valued functions there is the potential for confusion over which norm is being used. In all cases we have attached subscripts to function-space norms in order to reduce the chance for confusion. If Z is a Banach space and $r>0$ we write $B_r(0)$ for the open ball about zero of radius r, $B_r(0)=\{z\in Z\colon |z|<r\}$, and $\overline{B_r(0)}$ for the closure of $B_r(0)$ in Z. If T is a map from a Banach space X to a Banach space Y, we call T a C^n map if it possesses n continuous derivatives at all points of its domain.

THEOREM 1.1. *Let X be a real, Banach space, $\Omega\subseteq X$ an open set and $T\colon \Omega\to X$ be a C^1-map with fixed point $x_0\in\Omega$. Let T be C^2 in a neighborhood of x_0. Let $A\equiv DT(x_0)$ have spectral radius λ_0 and assume*

(a) $\lambda_0>1$,

(b) $Ae_0=\lambda_0 e_0$, $e_0\notin\overline{R(A-\lambda_0 I)}$.

Then there exists t_0, $0<t_0\leqq\infty$ and a unique C^1 function $y\colon [0,t_0)\to X$ with the properties

(i) $y(t)=x_0+te_0+O(t^2)$ *as* $t\to 0$,

(ii) $y(t)=T(y(\lambda_0^{-1}t))$, $0\leqq t<t_0$,

(iii) $x_n(t)\equiv T^n(x_0+\lambda_0^{-n}te_0)$, $n=0,1,2,\cdots$ *satisfies* $x_n\to y$ *uniformly on compact sets and* $x_n'(t)\to y'(t)$ *on* $[0,t_0)$,

(iv) *either* $t_0=+\infty$ *or* t_0 *is maximal with the property that* $y(t)\in\Omega$, $0<t<\lambda_0^{-1}t_0$,

(v) *if T is a diffeomorphism than $y\colon [0,t_0)\to X$ is an injective immersion* ($y'(t)\neq 0$).

Before proceeding to the proof, it is convenient to make the following remarks.

Remark 1. Condition (b) of Theorem 1.1 may seem strange. It implies the existence of a decomposition of $X=\operatorname{span} e_0+Z$, where Z is a closed subspace of T, which reduces A ($AZ\subset Z$). This, in fact, is all we use in the proof. Condition (b) will hold, for example, if λ_0 is a simple pole of $(A-\lambda I)^{-1}$ and e_0 is any nonzero vector in $N(A-\lambda_0 I)$.

Remark 2. Assume $t_0 = +\infty$ and $C = \{y(t)\colon t \geqq 0\}$ lies in a compact subset of X, for example, X might be finite-dimensional and C bounded. Let $\Lambda = \{x\colon x = \lim_{n\to\infty} y(t_n), \{t_n\}_{n=1}^{\infty}$ an arbitrary sequence satisfying $\lim t_n = +\infty\}$. It is easily seen that Λ is a nonempty, compact, connected, invariant set for T.

Remark 3. When T is a diffeomorphism, the map y is one-to-one and $y(t)$ is not a periodic point of T for any $T > 0$. Both properties can fall spectacularly if T is not one-to-one. An interesting example is given by $T\colon R \to R$ defined by $x \to 3x - 4x^3$, which lies $T(0) = 0$ and $DT(0) = 3$. Corresponding to $e_0 = +1$, $y\colon [0, \infty) \to R$ of Theorem 1.1 is given by $y(t) = \sin t$ since $\sin t = 3\sin(t/3) - 4(\sin(t/3)^3$. The set Λ of limit points of $y(t)$ is the invariant set $[-1, 1]$ for T. It can be seen that $T|_{[-1,1]}\colon [-1,1] \to [-1,1]$ exhibits Li–Yorke chaos [10] with periodic points of every period, an uncountable set of a-periodic trajectories and an invariant probability measure (ergodic [18]) $(1/\pi)\,dx/\sqrt{1-x^2}$. All this follows from the observation that $h\colon [-1,1] \to [-1,1]$ defined by $h(x) = \sin(\pi x/2)$ is a homeomorphism providing a conjugacy between $T|_{[-1,1]}$ and the piecewise linear map $S\colon [-1,1] \to [-1,1]$ defined by

$$S = \begin{cases} -3t - 2, & -1 \leqq t < -\frac{1}{3}, \\ 3t, & -\frac{1}{3} \leqq t < \frac{1}{3}, \\ -3t + 2, & \frac{1}{3} \leqq t \leqq 1. \end{cases}$$

Note that if $t_0 = 2 \cdot 3^{-3}$ and $t_i = S^i(t_0)$, then $t_3 < t_0 < t_1 < t_2$, establishing Li–Yorke chaos [10]. It is clear that S preserves Lebesgue measure.

Clearly, in this example, explicit knowledge of the function y was of great help in determining the dynamics of the difference equation $x_{n+1} = T(x_n)$. It is interesting to speculate on whether the dynamics of other difference equations generated by one-dimensional maps might be illuminated by this approach, although it is clearly too much to hope that y can be explicitly found in general. If, for example, T is a simple polynomial map, for example, $T(x) = rx(1-x)$, fixing the origin with $T'(0) = r$, $r > 1$, it may be convenient to allow x to be complex: $T\colon C \to C$. It is then not difficult to see that there is an entire function $y\colon C \to C$ with an essential singularity at ∞, $y(z) = z + O(|z|^2)$ as $|z| \to 0$, such that $y(z) = T(y(r^{-1}z))$ (see Proposition 1.4 or [7]). Although y is not a homeomorphism in general, it is surjective and one has the following commutative diagram

$$\begin{array}{ccc} C & \xrightarrow{\quad} & C \\ {\scriptstyle y}\downarrow & {\scriptstyle z \to rz} & \downarrow{\scriptstyle y} \\ C & \xrightarrow[\quad T \quad]{} & C \end{array}$$

Hence the iterates $w_{n+1} = T(w_n)$, $w_0 = y(z_0)$ are $w_n = y(r^n z_n)$.

Remark 4. There are many different properties of a map T which will insure that $t_0 = +\infty$. We mention only one. If there exists a closed invariant set K for T, $K \subset \Omega$, $(T(K) \subset K)$ such that for some $\varepsilon > 0$, $x_0 + te_0 \in K$ for $0 \leqq t \leqq \varepsilon$ then $t_0 = +\infty$ and $y(t) \in K$ for $t \geqq 0$. In order to see this, observe that $y(t) \in K$ by (iii) for $[0, t_0)$. But then, by (iv), $t_0 = +\infty$.

Remark 5. If T is a diffeomorphism, the hypotheses of Theorem 1.1 may hold for T^{-1} if T has a smallest eigenvalue. More precisely, if $\lambda_0 \in (0,1)$ is a simple eigenvalue of $DT(x_0)$ with corresponding eigenvector e_0 and $\inf\{|\lambda|\colon \lambda \in \sigma(DT(x_0)) - \{\lambda_0\}\} \geqq \lambda_0$ then one can apply Theorem 1.1. to T^{-1} to obtain the existence of a map $y\colon [0, t_0) \to X$ such that $y(\lambda_0 t) = T(y(t))$.

Remark 6. The smoothness assumptions on T of Theorem 1.1 may be relaxed. We use only that $DT(x)$ is uniformly Lipschitz continuous in a neighborhood of x_0. If T is only continuous on X, differentiable at x_0, and $r(x)=T(x)-x_0-A(x-x_0)$ satisfies (1.6) of Proposition 1.3 below, then a continuous y: $[0,t_0)\to X$ exists satisfying (ii) and (iii) except that the convergence may not be uniform on compact sets if $\dim X=+\infty$. (C^1 functions are uniformly continuous on bounded sets whereas continuous functions are not generally uniformly continuous on bounded subsets of infinite-dimensional spaces.)

Before proceeding to the proof of Theorem 1.1 we present a simple example. Let T: $R^2\to R^2$ be given by $T(z)=z^2$ where we have identified R^2 with C. Consider the fixed point $z_0=1$ of T where $DT(1)=\left(\begin{smallmatrix}2 & 0\\ 0 & 2\end{smallmatrix}\right)$. For every $\theta\in[0,2\pi]$, $e_\theta\equiv e^{i\theta}$ is an eigenvalue and the corresponding function y_0: $[0,\infty]\to R^2$, the existence of which is asserted in Theorem 1.1, is given by $y_\theta(t)=\exp(e_\theta t)$. As θ runs over $[0,2\pi)$ the curves $C_\theta=\{y_\theta(t)\colon \geqq 0\}$ cover $R^2-\{0\}$.

We begin the proof of Theorem 1.1 by establishing the existence of $y(t)$ satisfying (i), (ii) and (iii) for small t.

LEMMA 1.2. *Assume the hypotheses of Theorem* 1.1. *Then there exist* $\tau>0$ *and a* C^1 *function* y: $[0,\tau]\to\Omega$ *such that* (i), (ii) *and* (iii) *of Theorem* 1.1 *hold.*

Proof. It follows from our assumptions on A that there exists $f_0\in N(A^*-\lambda_0 I)$, where A^*: $X^*\to X^*$ is the adjoint of A on the dual space X^* of X, such that $f_0(e_0)=1$. The projection P: $X\to X$ defined by $Px=f_0(x)e_0$ leads to a decomposition of X: $X=\operatorname{lin}\{e_0\}+Z$, $Z=(I-P)X$, where $\operatorname{lin}\{e_0\}$ is the linear span of e_0, which reduces A: $A=\lambda_0 I+B$, B: $Z\to Z$. We may choose an equivalent norm on Z so that the corresponding operator norm of B satisfies $\|B\|<\lambda_0^2$ (spectral radius of $B\leqq\lambda_0$). For $x\in X$, we write $x=ue_0+z$, $u\in R$, $z\in Z$ and $|x|=|u|+|z|$ where $|u|$ is the absolute value of u.

We assume w.l.o.g. that $x_0=0$. If $Tx_0=x_0$ then $\bar S(x)=T(x+x_0)-x_0$ satisfies $\bar S(0)=0$, $D\bar S(0)=A$.

Write, for $x=ue_0+z$

$$T(x)=T_1(u,z)e_0+T_2(u,z)$$

where T_1: $R\times Z$ and T_2: $R\times Z\to Z$ satisfy

$$T_1(u,z)=\lambda_0 u+r_1(u,z),\qquad T_2(u,z)=Bz+r_2(u,z)$$

and $r_i(0,0)=0$, $Dr_i(0,0)=0$. Our assumption that T is C^2 in a neighborhood of 0 implies that there exists C, $\delta>0$ such that

$$\sum_{i=1}^{2}\|Dr_i(u_1,z_1)=Dr_i(u_2,xz_2)\|\leqq C\left[|u_1-u_2|+|z_1-z_2|\right] \tag{1.1}$$

provided $|u_i|+|z_i|\leqq\delta$, $i=1,2$.

One easily verifies that (1.1) implies that

$$\sum_{i=1}^{2}|Dr_i(x_1)h_1-Dr_i(x_2)h_2|\leqq C\left[\max_i|x_i||h_1-h_2|+\max_i|h_i||x_1-x_2|\right], \tag{1.2}$$

$$x_i=(u_i,z_i)\quad h_i=(h_{i1},h_{i2})$$

provided $|x_i|\leqq\delta$, $i=1,2$.

We seek a function $y(t)=te_0+o(t)$ satisfying (ii). Setting

$$y(t)=(t+\eta(t))e_0+z(t),\ z(t)\in Z,$$

(ii) will hold if and only if

$$\eta(t)=\lambda_0\eta(\lambda_0^{-1}t)+r_1(\lambda_0^{-1}t+\eta(\lambda_0^{-1}t),z(\lambda_0^{-1}t)), \tag{1.3a}$$

$$z(t)=Bz(\lambda_0^{-1}t)+r_2(\lambda_0^{-1}t+\eta(\lambda_0^{-1}t),z(\lambda_0^{-1}t)). \tag{1.3b}$$

We will solve (1.3) for (η,z) by the contraction mapping theorem.Let $\tau>0$ and let

$$C_\tau^1=\{x(t)=(\eta(t),z(t))\in C^1([0,\tau],X):$$
$$(\eta(0),z(0))=0,|\eta'(t)|+|z'(t)|\leqq Mt \text{ for some } M>0\}.$$

One can verify that C_τ^1 is a Banach space when equipped with the norm $|\cdot|_\tau$ defined by

$$|x|_\tau\equiv\sup_{0<t\leqq\tau}\frac{|\eta'(t)|+|z'(t)|}{t}.$$

Note the inequalities

$$|\eta'(t)|+|z'(t)|\leqq|x|_\tau t,\qquad |\eta(t)|+|z(t)|\leqq|x|_\tau\frac{t^2}{2}. \tag{1.4}$$

We define the linear operator L on C_τ^1 by

$$(Lx)(t)\equiv(\lambda_0\eta(\lambda_0^{-1}t),Bz(\lambda_0^{-1}t)),\qquad 0\leqq t\leqq\tau.$$

Since

$$(Lx)'(t)=(\eta'(\lambda_0^{-1}t),\lambda_0^{-1}Bz'(\lambda_0^{-1}t)),\qquad 0\leqq t\leqq\tau,$$

$$\begin{aligned}|(Lx)'(t)|&\leqq|\eta'(\lambda_0^{-1}t)|+\lambda_0^{-1}|Bz'(\lambda_0^{-1}t)|\\&\leqq|\eta'(\lambda_0^{-1}t)|+\lambda_0^{-1}\|B\||z'(\lambda_0^{-1}t)|\\&\leqq\max\{1,\lambda_0^{-1}\|B\|\}[|\eta'(\lambda_0^{-1}t)|+|z'(\lambda_0^{-1}t)|]\\&\leqq\max\{1,\lambda_0^{-1}\|B\|\}|x|_\tau\lambda_0^{-1}t\\&\leqq\max\{\lambda_0^{-1},\lambda_0^{-2}\|B\|\}|x|_\tau t,\end{aligned}$$

it follows that $Lx\in C_\tau^1$ and

$$\|L\|\leqq\max\{\lambda_0^{-1},\lambda_0^{-2}\|B\|\}\equiv\rho<1$$

provided $\|B\|<\lambda_0^2$.

Define an operator R on C_τ^1 by

$$R(x)=R(\eta,z)(t)\equiv(r_1(\lambda_0^{-1}t+\eta(\lambda_0^{-1}t),z(\lambda_0^{-1}t)),r_2(\lambda_0^{-1}t+\eta(\lambda_0^{-1}t),z(\lambda_0^{-1}t))).$$

Since we want to make use of the estimates (1.1) and (1.2) we define R only for those $x\in\frac{1}{\tau}$ with $|x|_\tau\leqq m$ (m and τ will be adjusted further in what follows) so that

$$|\lambda_0^{-1}t+\eta(\lambda_0^{-1}t)|+|z(\lambda_0^{-1}t)|\leqq\leqq\left(\frac{\tau}{\lambda_0}\right)\left[1+\frac{m}{2}\left(\frac{\tau}{\lambda_0}\right)\right]\leqq\delta. \tag{1.5}$$

We assume τ is small enough that the estimate above holds. Then

$$\begin{aligned}
|R(\eta,z)'(t)| &= \left|Dr_1\left(\lambda_0^{-1}t+\eta,z\right)\left(\lambda_0^{-1}+\lambda_0^{-1}\eta',\lambda_0^{-1}z'\right)\right| \\
&\quad + \left|Dr_2\left(\lambda_0^{-1}t+\eta,z\right)\left(\lambda_0^{-1}+\lambda_0^{-1}\eta',\lambda_0^{-1}z'\right)\right| \\
&\leqq C\lambda_0^{-1}\left[\left|\lambda_0^{-1}t+\eta\left(\lambda_0^{-1}tt\right)\right|+\left|z\left(\lambda_0^{-1}t\right)\right|\right]\left[\left|1+\eta'\left(\lambda_0^{-1}t\right)\right|+\left|z'\left(\lambda_0^{-1}t\right)\right|\right] \\
&\leqq C\lambda_0^{-1}\left[\lambda_0^{-1}t+m\frac{\lambda_0^{-2}t^2}{2}\right]\left[1+m\lambda_0^{-1}t\right] \\
&\leqq C\lambda_0^{-2}\left[1+\frac{m\lambda_0^{-1}\tau}{2}\right]\left[1+m\lambda_0^{-1}\tau\right]t.
\end{aligned}$$

It follows that $R(\eta,z)\in C_\tau^1$ and that $|R(\eta,z)|_\tau \leqq C\lambda_0^{-2}[1+m\lambda_0^{-1}\tau]^2, |(\eta,z)|_\tau \leqq m$.

Equation (1.3) is equivalent to $x=F(x)\equiv Lx+R(x)$, $x=(\eta,z)\in C_\tau^1$. We will show that F is a contractive self-map of $\overline{B_m(0)}\subseteq C_\tau^1$ for some m and τ. For fixed $m>0$ and τ sufficiently small that (1.5) holds we have for $|x|_\tau \leqq m$, $|F(x)|_\tau \leqq \rho m + C\lambda_0^{-2}[1+m\lambda_0^{-1}\tau]^2$. In order that F be a self-map of $\overline{B_m(0)}$ we choose

$$m=\frac{2C\lambda_0^{-2}}{1-\rho}$$

and $\tau<\min\{(\sqrt{2}-1)(1-\rho)/2C\lambda_0^3, \lambda_0(\sqrt{1+2m\delta}-1)/m\}$. The second term inside the min bracket has been chosen so that (1.5) holds while the first term insures that, together with our choice of m, F is a self map of $\overline{B_m(0)}$. We will need to choose τ possibly smaller to insure that F is a contraction.

Let $x_i=(\eta_i,z_i)\in\overline{B_m(0)}$, $i=1,2$. Then, using the estimate (1.2)

$$\begin{aligned}
&|R(x_1)'(t)-R(x_2)'(t)| \\
&= \sum_{i=1}^{2}\Big|Dr_i\left(\lambda_0^{-1}t+\eta_1\left(\lambda_0^{-1}t\right),z_1\left(\lambda_0^{-1}t\right)\right)\left(\lambda_0^{-1}+\lambda_0^{-1}\eta_1'\left(\lambda_0^{-1}\right),\lambda_0^{-1}z_1'\left(\lambda_0^{-1}t\right)\right) \\
&\qquad - Dr_i\left(\lambda_0^{-1}t+\eta_2\left(\lambda_0^{-1}t\right),z_2\left(\lambda_0^{-1}t\right)\right)\left(\lambda_0^{-1}+\lambda_0^{-1}\eta_2'\left(\lambda_0^{-1}t\right),\lambda_0^{-1}z_2'\left(\lambda_0^{-1}t\right)\right)\Big| \\
&\leqq C\Big[\lambda_0^{-1}\max_i\left|\left(\lambda_0^{-1}t+\eta_i\left(\lambda_0^{-1}t\right),z_i\left(\lambda_0^{-1}t\right)\right)\right|\left|x_i'\left(\lambda_0^{-1}t\right)-x_2'\left(\lambda_0^{-1}t\right)\right| \\
&\qquad + \max_i\left|\left(\lambda_0^{-1}+\lambda_0^{-1}\eta_i'\left(\lambda_0^{-1}t\right),\lambda_0^{-1}z_i'\left(\lambda_0^{-1}t\right)\right)\right|\left|x_1\left(\lambda_0^{-1}t\right)-x_2\left(\lambda_0^{-1}t\right)\right|\Big] \\
&\leqq C\left[\left(\lambda_0^{-1}t+m\frac{\lambda_0^{-2}t^2}{2}\right)\left(\lambda_0^{-2}t|x_1-x_2|_\tau\right)+\left(\lambda_0^{-1}+\lambda_0^{-2}tm\right)\frac{\lambda_0^{-2}t}{2}|x_1-x_2|_\tau\right] \\
&\leqq C\lambda_0^{-3}\tau\left[\left(1+\frac{m\lambda_0^{-1}\tau}{2}\right)+\frac{1}{2}\left(1+m\lambda_0^{-1}m\right)\right]|x_1-x_2|_\tau t \\
&\leqq C\lambda_0^{-3}\tau\left[\frac{3}{2}+m\lambda_0^{-1}\tau\right]|x_1-x_2|_\tau t.
\end{aligned}$$

It follows that

$$|R(x_1)-R(x_2)|_\tau \leqq C\lambda_0^{-3}\tau\left[\frac{3}{2}+m\lambda_0^{-1}\tau\right]|x_1-x_2|_\tau.$$

Hence

$$|F(x_1)-F(x_2)|_\tau \leqq \left[\rho+C\lambda_0^{-3}\tau\left[\frac{3}{2}+m\lambda_0^{-1}\tau\right]\right]|x_1-x_2|_\tau.$$

Since $\rho<1$, we can insure that the Lipschitz constant for F is smaller than one by further restricting τ if necessary. The contraction mapping theorem can now be applied completing the proof of the lemma.

Before continuing the proof of Theorem 1.1 we prove two results, Propositions 1.3 and 1.4 below, the proofs of which are very similar to the proof of Lemma 1.2. These results indicate several possible variations of Theorem 1.1. The first result, Proposition 1.3 below, shows that the smoothness assumptions on T in Lemma 1.2 can be relaxed with a corresponding loss of smoothness of y. The proof of the following lemma is so similar to the proof of Lemma 1.2 that only a sketch is given.

PROPOSITION 1.3. *Let T: $\Omega\to X$ as in Theorem* 1.1 *but assume only that T is continuous on Ω, $T(x_0)=x_0$ and $DT(x_0)=A$ exists. Let the spectral assumptions of Theorem* 1.1 *hold for A. Define $r(x)$ for x near x_0 by*

$$T(x)=x_0+A(x-x_0)r(x)$$

and suppose there exists $M,p,\delta>0$ such that

$$|r(x_1)-r(x_2)|\leqq C\left[\max_{i=1,2}\{|x_i-x_0|\}\right]^p|x_1-x_2| \tag{1.6}$$

for $|x_0-x_i|\leqq\delta$, $i=1,2$. Then there exists $\tau>0$ and a continuous function y: $[0,\tau]\to\Omega$ satisfying $y(t)=x_0+te_0+O(t^{1+p})$ as $t\to 0$, (ii) *and* (iii) *of Theorem* 1.1 *(except $x_n'\to y'$).*

Proof. The proof is very similar to that of Lemma 1.2. The estimates (1.1) and (1.2) of Lemma 1.2 are replaced by the single estimate

$$\sum_{i=1}^{2}|r_i(u_1,z_1)-r_i(u_2,z_2)|\leqq C\left[\max_{i=1,2}\{|u_i|+|z_i|\}\right]^p\cdot\left[|u_1-u_2|+|z_1-z_2|\right] \tag{1.7}$$

if $|u_i|+|z_i|\leqq\delta$, $i=1,2$, which follows from (1.6). The appropriate function space is

$$C_p=\{(\eta(t),z(t))\in C([0,\tau],X)\colon |\eta(t)|+|z(t)|\leqq Mt^{1+p}\text{ for some }M\geqq 0\}$$

with p as in (1.6). The norm on C_ρ is given by

$$|(\eta,z)|_p=\sup_{0<t\leqq\tau}\frac{|\eta(t)|+|z(t)|}{t^{1+p}}.$$

It is clear that $(C_\rho,\|_\rho)$ is a Banach space. Define L: $C_\rho\to C_\rho$ as in Lemma 1.2 and observe that $\|L\|\leqq\rho\equiv\max\{\lambda_0^{-p},\lambda_0^{-(1+p)}\|B\|\}$. Since $\|B\|<\lambda_0^{1+p}$ (this may require a different norm on Z than in Lemma 1.2), $\rho<1$. If $m>0$ is given, choose $\tau>0$ so that $\tau\lambda_0^{-1}[1+m(\tau\lambda_0^{-1})^p]\leqq\delta$. Then given $(\eta,z)\in\overline{B_m(0)}$, the estimate (1.7) can be used to show that $R(\eta,z)$, defined as in Lemma 1.2, satisfies

$$|R(\eta,z)|_p\leqq C\lambda_0^{-(1+p)}\left[1+m(\tau/\lambda_0)^p\right]^{1+p}.$$

Hence $F \equiv L+R$ is a self-map of $\overline{B_m(0)}$ provided $\rho m + C\lambda_0^{-(1+p)}[1+m(\tau/\lambda_0)^p]^{1+p} \leqq m$. As in Lemma 1.2, since $\rho<1$ and we are free to choose τ small, this inequality can be satisfied for suitable m and τ (for example, $m=2C^{-(1+p)}/1-\rho$). Now use (1.7) to calculate the contraction constant, $\rho + C\lambda_0^{-(1+p)}(\tau/\lambda_0)^p[1+-m(\tau/\lambda_0)^p]^p$, for F. For τ sufficiently small, this value is less than one.

As our final variant of Lemma 1.2, we consider the case that a complex conjugate pair of eigenvalues, $\alpha \pm i\beta$, of A are the dominant eigenvalues. This result would have a cleaner form if T were assumed to be a holomorphic map of a complex Banach space (in which case y below would be holomorphic) but in view of possible applications we continue to assume X is a real Banach space.

PROPOSITION 1.4. *Assume T: $\Omega \to X$, Ω an open subset of the Banach space X, is C^2 in a neighborhood of a fixed point x_0 of T. Let $A=DT(x_0)$ and assume*

(a) *$\lambda_0=\alpha+i\beta$ is a simple pole of the resolvent $R(\lambda,A^c)=(\lambda I-A^c)^{-1}$ and $\dim N(A^c-\lambda_0 I)<\infty$. A^c is the complexification of A.*

(b) *The spectral radius of A is $|\lambda_0|$ and $|\lambda_0|>1$.*

Then there exists $\tau>0$ and a C^1 function y: $B_\tau(0)\subseteqq R^2 \to \Omega$ such that

(i) *$y(0)=x^0$, $Dy(0)$ has rank two.*

(ii) *$y(v)=T(y(S^{-1}v))$, $v\in B_\tau(0)$ where $S=\begin{pmatrix}\alpha & -\beta\\ \beta & \alpha\end{pmatrix}$.*

Proof. By using the functional calculus of operators [2] as in the proof of Lemma 1.2, one can regard X as the direct sum

$$X=R^2+Z, \qquad x=(v,z),\ v\in R^2,\ z\in Z$$

where the decomposition reduces A: $A=S+B$, B: $Z\to Z$. Since the spectral radius of B does not exceed $|\lambda_0|$ we may choose an equivalent norm on X so that $|(v,z)|=|v|+|z|$ where $|v|$ is the Euclidean norm and $|z|$ is a norm on Z such that the operator norm $\|B\|<|\lambda_0|^2$. Note that $\|S\|=|\lambda_0|$ and $\|S^{-1}\|=|\lambda_0|^{-1}$.

Assume $x_0=0$ and write

$$T(x)=T(v,z)=(T_1(v,z),T_2(v,z))$$

where

$$T_1\colon R^2\times Z\to R^2 \quad \text{and} \quad T_2\colon R^2\times Z\to Z$$

satisfy

$$T_1(v,z)=Sv+r_1(v,z), \qquad T_2(v,z)=Bv+r_2(v,z).$$

Our assumptions on T insure that there exists δ, $C>0$ such that $|(v_i,z_i)|\leqq\delta$, $i=1,2$, implies

$$\sum_{i=1}^{2}\|Dr_i(v_1,z_1)-Dr_i(v_2,z_2)\|\leqq C|(v_1,z_1)-(v_2,z_2)|.$$

We seek y: $B_\tau(0)\subseteqq R^2\to X$ in the form $y(v)=(v+\eta(v),z(v))$ with $|(\eta(v),z(v))|=O(|v|^2)$ and such that (ii) holds. This amounts to

$$\eta(v)=S\eta(S^{-1}v)+r_1(S^{-1}v+\eta(S^{-1}v),z(S^{-1}v)),$$
$$z(v)=Bz(S^{-1}v)+r_2(S^{-1}v+\eta(S^{-1}v),z(S^{-1}v)).$$

We solve these equations as in Lemma 1.2 by the contraction mapping theorem in the function

$$C_\tau^1 = \{(\eta,z)\colon \overline{B_\tau(0)} \subseteqq R^2 \to R^2 \times Z\colon (\eta,z)$$
$$\text{is } C^1 \text{ in } \overline{B_\tau(0,0)},\ (\eta(0),z(0))=(0,0),$$
$$\text{and for some } M \geqq 0\ \|D\eta(v)\|+\|Dz(v)\| \leqq M|v|,\ v\in B_\tau(0)\}.$$

Note that $D\eta(v)\colon R^2 \to R^2$ and $Dz(v)\colon R^2 \to Z$.

A Banach space norm for C_τ^1 is

$$|(\eta,z)|_\tau = \sup_{0<|v|\leqq\tau} \frac{\|D\eta(v)\|+\|Dz(v)\|}{|v|}.$$

Observe that the inequality

$$|\eta(v)|+|z(v)| \leqq \frac{1}{2}|(\eta,z)|_\tau |v|^2$$

holds for $(\eta,z)\in C_\tau^1$. We now proceed exactly as in Lemma 1.2 (indeed, all the estimates are identical except that $|\lambda_0|$ replaces λ_0). For instance $L\colon C_\tau^1 \to C_\tau^1$ is defined by $(\bar\eta,\bar z)=L(\eta,z)=(S\eta(S^{-1}v), Bz(S^{-1}v))$. Since

$$\begin{aligned}
\|D\bar\eta(v)\|+\|D\bar z(v)\| &= \|D\eta(S^{-1}v)\|+\|BDz(S^{-1}v)S^{-1}\| \\
&\leqq \|D\eta(S^{-1}v)\|+\|B\|\|Dz(S^{-1}v)S^{-1}\| \\
&\leqq \|D\eta(S^{-1}v)\|+\|B\||\lambda_0|^{-1}\|Dz(S^{-1}v)\| \\
&\leqq \max\{1,\|B\||\lambda_0|^{-1}\}|(\eta,z)|_\tau |S^{-1}v| \\
&\leqq \max\{|\lambda_0|^{-1},\|B\||\lambda_0|^{-2}\}|(\eta,z)|_\tau |v|,
\end{aligned}$$

it follows that $\|L\| \leqq \max\{|\lambda_0|^{-1}, \|B\||\lambda_0\|^{-2}\} < 1$. We leave it to the reader to check that the other estimates hold verbatim as in Lemma 1.2.

We now complete the proof of Theorem 1.1.

Proof of Theorem 1.1. The first task is to extend our function $y\colon [0,\tau]\to\Omega$ of Proposition 1.2 as far as possible in such a way that (ii) holds. Extend y as follows if $0\leqq t\leqq\lambda_0\tau$ let $y_1(t)\equiv T(y(\lambda_0^{-1}t))$; since $0\leqq\lambda_0^{-1}t\leqq\tau$, $y(\lambda_0^{-1}t)$ is well-defined and belongs to Ω, so $y_1(t)$ is well-defined and C^1 since y and T are. Also, y_1 agrees with y on $[0,\tau]$ so $y_1(t)=T(y_1(\lambda_0^{-1}t))$ for $0\leqq t\leqq\lambda_0\tau$. However, it may happen that $y_1(t)\notin\Omega$ for all $t\in[0,\lambda_0\tau]$. Suppose that this is the case and let $\lambda_0^{-1}t_0\in(\tau,\lambda_0\tau]$ be maximal with the property that $y_1(t)\in\Omega$ for $[0,\lambda_0^{-1}t_0)$. If $0\leqq t<t_0$ define $y_2(t)=T(y_1(\lambda_0^{-1}t))$. It is again easy to see that y_2 is well-defined, C^1, and agrees with y_1 on $0\leqq t\leqq\lambda_0\tau$. Hence $y_0(t)=T(y_2(\lambda_0^{-1}t))$ for $0\leqq t<t_0$. In general, this is as far as we can extend y. If, however, $y_1(t)\in\Omega$ for $0\leqq t\leqq\lambda_0\tau$ then y_1 can be extended exactly as before to $[0,\lambda_0^2\tau]$. This completes the proof of (ii) and (iv).

In order to see that (iii) holds for $0<t<t_0$ (recall we have proved (iii) on $[0,\tau]$ in Lemma 1.2), fix $t<t_0$ and let n be such that $\lambda_0^{-n}t\leqq\tau$. We have

$$\begin{aligned}
y(t)&=T\big(y(\lambda_0^{-1}t)\big)=T\big(T\big(y(\lambda_0^{-2}t)\big)\big)=\cdots\\
&=T^n\big(y(\lambda_0^{-n}t)\big)\\
&=T^n\Big(\lim_{p\to\infty}T^p\big(\lambda_0^{-(n+p)}te_0\big)\Big)\\
&=\lim_{p\to\infty}T^{n+p}\big(\lambda_0^{-(n+p)}te_0\big)\\
&=\lim_{p\to\infty}x_{n+p}(t).
\end{aligned}$$

Since T is uniformly continuous on bounded sets, $x_n\to y$ uniformly on compact sets.

From above we have

$$\begin{aligned}
y'(t)&=D(T^n)\big(y(\lambda_0^{-n}t)\big)\lambda_0^{-n}y'(\lambda_0^{-n}t)\\
&=D(T^n)\lim_{p\to\infty}x_p(\lambda_0^{-n}t)\Big)\lambda_0^{-n}\lim_{p\to\infty}x_p'(\lambda_0^{-n}t)\\
&=\lim_{p\to\infty}D(T^n)\big(x_p(\lambda_0^{-n}t)\big)\lambda_0^{-n}x_p'(\lambda_0^{-n}t)\\
&=\lim_{p\to\infty}x_{n+p}'(t).
\end{aligned}$$

This completes the proof of (iii).

Finally, if T is a diffeomorphism and there exists $s\neq t$ such that $y(t)=y(s)$ then $T(y(\lambda_0^{-1}t))=T(y(\lambda_0^{-1}s))$ and $y(\lambda_0^{-1}t)=y(\lambda_0^{-1}s)$. After n applications of this reasoning $y(\lambda_0^{-n}t)=y(\lambda_0^{-n}s)$ which contradicts (for n sufficiently large) the fact that y is one-to-one on $[0,\varepsilon]$ for $\varepsilon>0$ sufficiently small (recall y is C^1 and $y'(0)=e\neq 0$). Since $y'(t)\neq 0$ for small t there is a maximal $t_1\leqq t_0$ such that $y'(t)=0$ on $[0,t_1)$. If $t_1<t_0$ then $y'(t_1)=0$. But then

$$0=y'(t_1)=\lambda_0 DT\big(y(\lambda_0^{-1}t_1)\big)y'(\lambda_0^{-1}t_1),$$

yet $y'(\lambda_0^{-1}t_1)\neq 0$ and $DT(y(\lambda_0^{-1}t_1))$ is nonsingular. This contradiction proves $t_1=t_0$ and $y'(t)\neq 0$ on $[0,t_0)$.

2. Some results for monotone mappings. We begin by recalling some notation and results in the theory of partially ordered spaces. Recall that a cone K in a Banach space X is a closed subset of X with the properties (i) $K+K\subset K$, (ii) $R_+\cdot K\subset K$, and (iii) $K\cap(-K)=\{0\}$. K induces a partial ordering on X via $x\leqq y$ if and only if $y-x\in K$. If $x\leqq y$ are two points in X we write $[x,y]$ for the set $\{z\in X\colon x\leqq z\leqq y\}$. A map $F\colon X\to Y$ between two Banach spaces containing cones K and C, respectively, is nondecreasing provided $F(x)\leqq_c F(y)$ in Y whenever $x\leqq_k y$ in X. A cone in a Banach space X is said to be normal if there is an equivalent nondecreasing norm on X. It is easily verified that the Fréchet derivative of a nondecreasing map $T\colon X\to X$ at a point x, $A=DT(x)$, is a so-called positive operator, that is, $A(K)\subset K$. A positive operator A is said to be strongly positive if $A^m(K\subset\{0\})\subset\operatorname{int}K$, the interior of K, for some positive integer $m\geqq 1$ (of course, this makes sense only if K has nonempty interior). In case $X=R^n$ and $K=R_+^n=\{x\colon x_i\geqq 0, 1\leqq i\leqq n\}$, a nonnegative matrix A is strongly positive if and only if all entries of A^m are positive for some integer $m\geqq 1$. In this case, the Perron–Frobenius

Theory [6] [9] implies that the spectral radius is a simple eigenvalue, greater in magnitude than any other eigenvalue, and there is a corresponding eigenvector which belongs to the interior of R^n_+. A slightly weaker assumption on $A \geqq 0$ for which the above results hold is that A be a primitive irreducible matrix (see [9]), however these ideas do not generalize nicely to infinite dimensions. For infinite-dimensional spaces X and cone $K \subset X$ with nonempty interior, strongly positive compact operators have the properties mentioned above for strongly positive matrices except possibly that there may be other parts of the spectrum in addition to the spectral radius on the circle of radius equal to the spectral radius in the complex plane [1, Thm. 3.2].

Recall that T: $X \to X$, X a Banach space, is said to be completely continuous if T maps bounded sets into precompact sets. It is well known that the Fréchet derivative of a completely continuous map is a compact linear operator.

We can now state the main results of this section.

THEOREM 2.1. *Let K be a normal cone with nonempty interior in a Banach space X. Let T: $X \to X$ be a completely continuous, nondecreasing, C^1-map, which is C^2 in a neighborhood of 0 and $T(0)=0$. Let $A=DT(0)$ be strongly positive and have spectral radius λ_0, $\lambda_0 > 1$. Then there exists a unique C^1, nondecreasing function y: $[0,\infty] \to \operatorname{int} K$ satisfying $y(t)=te_0+o(t)$ as $t \to 0$ where $Ae_0=\lambda_0$, $e_0 \in \operatorname{int} K$ and*

$$y(t)=T\big(y\big(\lambda_0^{-1}t\big)\big),\ t \geqq 0.$$

Moreover, either $|y(t)| \to +\infty$ as $t \to \infty$ or $\lim_{t\to\infty} y(t)=y_\infty \in \operatorname{int} K$ exists and $Ty_\infty = y_\infty$. In the latter case $[0,y_\infty]$ is invariant under T and $T^n_x \to y_\infty$ for every $x \in [0,y_\infty]-\{0\}$. In the former case, $|T^n x| \to +\infty$ for all $x \in K-\{0\}$.

An important extension of Theorem 2.1 can be made if $X=R^n$ and $K=R^n_+$. In this case, the complete continuity assumption in Theorem 2.1 is redundant since T is continuous. We let $\rho(A)$ stand for the spectral radius of a linear operator A.

THEOREM 2.2. *Let $X=R^n$ and $K=R^n_+$ and T: $R^n \to R^n$ satisfy the hypotheses of Theorem 2.1 and let $DT(x)$ be invertible for $x \in R^n_+$. Assume $\lim_{t\to\infty} y(t)=y_\infty$ exists and assume $A_\infty \equiv DT(y_\infty)$ is strongly positive. Then $\rho(A_\infty) \leqq 1$ and $\lim_{t\to\infty}(y'(t)/|y'(t)|)=e$ where $e \in \operatorname{int} R^n_+$ is the unique, unit norm positive eigenvector corresponding to $\rho(A_\infty)$.*

Before proceeding to the proof of the theorems we make the following remarks. First the smoothness assumptions on T in Theorem 2.1 can be relaxed as observed in Remark 6 following Theorem 1.1. Secondly, the choice of the origin as a fixed point of T in both theorems is merely for convenience. Finally, (iii) of Theorem 1.1 holds for y in both results.

For diffeomorphisms T: $R^n \to R^n$, nondecreasing with respect to the usual ordering and having the property that $DT(x)$ is strongly positive for each x, Theorems 2.1 and 2.2 allow the determination of possible "phase portraits" for the dynamics, $x_{n+1}=T(x_n)$ in case of the existence of an unstable fixed point x_0 of $T(\rho(DT(x_0))>1)$. In Fig. 1 we indicate the four possible portraits. If $e_0 \in \operatorname{int} R^n_+$ satisfies $DT(x_0)e_0=\rho(DT(x_0)e_0$, we write $y_+(t)$ for the function the existence of which is asserted in Theorem 2.1 corresponding to the eigenvector $e_0(y_+(t)=x_0+te_0+O(t^2))$ and write $y_-(t)$ for the function asserted to exist in Theorem 2.1 corresponding to $-e_0(y_-(t)=x_0-te_0+O(t^2))$. by Theorem 2.1, $y_\pm(t) \in x_0 \pm \operatorname{int} R^n_+$ for each $t>0$. The four possibilities indicated in Fig. 1 correspond to the four possible limits $\lim y_+(t)=y_\infty$ or ∞, $\lim y_-(t)=y_{-\infty}$ or ∞. It should be observed that, in case $\lim_{t\to\infty} y_+(t)=y_\infty$ exists, the fixed point y_∞ may be the limit $\lim_{t\to\infty} y_-(t)$, of a function $y_-(t)$ corresponding to another unstable fixed point of T belonging to $y_\infty + \operatorname{int} R^n_+$. A similar observation holds if $\lim_{t\to\infty} y_-(t)=y_{-\infty}$

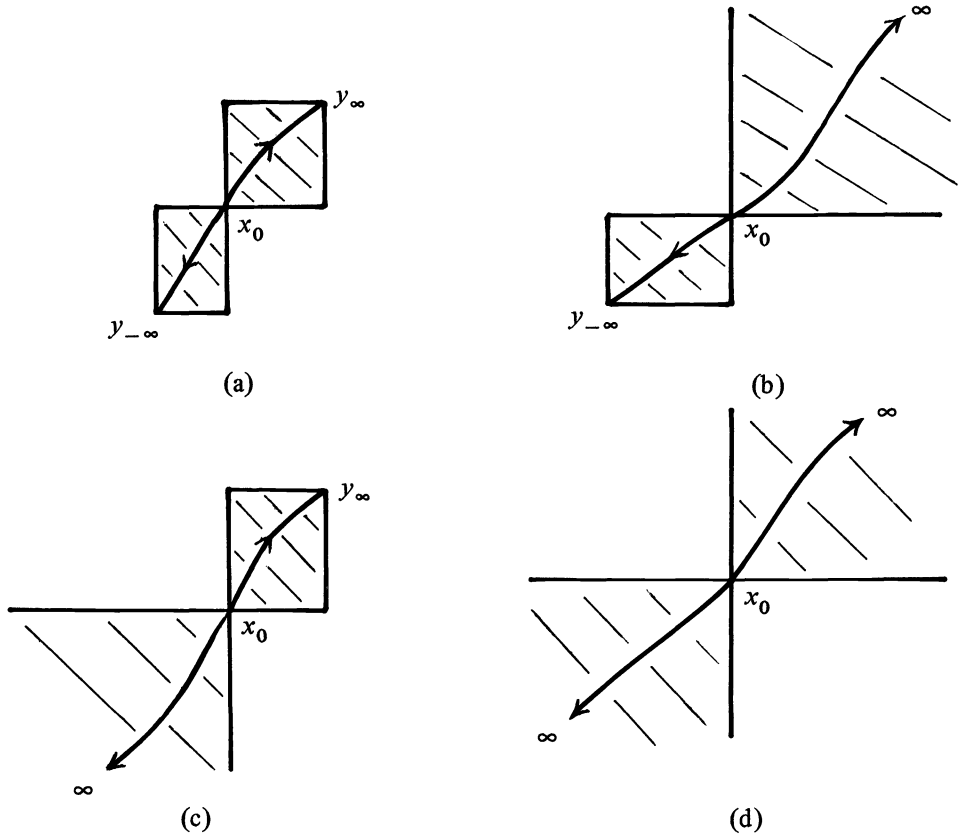

FIG. 1. *Qualitative dynamics of the iterates of* T: $R^2 \to R^2$; x_0 *is an unstable fixed point, shaded regions are included in the domains of attraction of a fixed point* $y_{-\infty}$, y_∞ *or the point at infinity,* ∞. *The solid curves are* y_+ *and* y_-.

exists. The point here is that (a), (b), and (c) of Fig. 1 may only be segments of a longer chain of such segments. A nice example of these chains occurs in the paper of Selgrade [8, see Figs. 1 and 2] where T is the time-one map for autonomous ordinary differential equation.

Finally, note that if x_0 is a a hyperbolic fixed point of T and $W^s(x_0) = \{x \in R^n: T^m(x) \to x_0 \text{ as } m \to \infty\}$ is the stable manifold then $W^s(x_0) \cap [(x_0 + R^n_+) \cup (x_0 - R^n_+)] = \{x_0\}$. This follows immediately from Theorem 2.1.

Proof of Theorem 2.1. As noted above, the spectral assumptions on A of Theorem 1.1 are satisfied by virtue of [1, Thm. 3.2] (notice that since λ_0 is a simple eigenvalue of A, λ_0 is a simple pole of $(A - \lambda I)^{-1}$, see Remark 1). By Theorem 1.1, there exists a unique function y: $[0, \infty) \to X$ satisfying the functional equation $y(t) = T(y(\lambda_0^{-1}t))t \geqq 0$. That $y(t) \in K$ follows since $T^n(\lambda_0^{-n}te_0) \in K$ for $n = 1, 2, \cdots, t \geqq 0$, and K is closed. Indeed $T^n(\lambda_0^{-n}te_0)$ is a monotone nondecreasing function of t for each $n = 1, 2, \cdots$ and thus so is $y(t)$. It is easy to see that $y(t) \in \operatorname{int} K$ for small t and since $y(t)$ is nondecreasing, it lies in $\operatorname{int} K$ for all t. If $\{y(t): 0 \leqq t < \infty\}$ is bounded then it is precompact since T is completely continuous. Let $t_n \to +\infty$ and $s_n \to +\infty$ and suppose $\lim y(t_n) = y_1$ and $\lim y(s_n) = y_2$ exist. Since $y(t)$ is monotone nondecreasing we have $y_1 \geqq y(s_n)$ for $n = 1, 2, \cdots$ so $y_1 \geqq y_2$ and similarly $y_2 \geqq y_1$. It follows that $y_1 = y_2$. Since $\{y(t): 0 < t < \infty\}$ is precompact, from every sequence $t_n \to \infty$ there is a subsequence

which converges. The above observation shows that the limit of any such subsequence is the same point. Hence $\lim_{t\to\infty} y(t)=y_\infty$ exists and is a fixed point by continuity of T. Since $y_\infty \geqq y(t)\in \operatorname{int} K$, $y_\infty \in \operatorname{int} K$. It is clear that $[0,y_\infty]$ is invariant under T since 0 and y_∞ are fixed by T and T is nondecreasing. If $x\in[0,y_\infty]\cap \operatorname{int} K$ then $y(t_0)\leqq x$ for small t_0 so $y(\lambda_0^n t_0)\leqq T^n x\leqq y_\infty$ after n applications of T to the previous inequality. Since $[0,y_\infty]$ is bounded (here we use normality of K) and T is completely continuous it follows that $T^n x\to y_\infty$. Now, if $x\in[0,y_\infty]-\{0\}$ then $T^m x\in[0,y_\infty]\cap \operatorname{int} K$ where m is such that $A^m(K-\{0\})\subseteq \operatorname{int} K$.

In case $\lim|y(t)|=+\infty$ and $x\in \operatorname{int} K$ then, again, $y(t_0)\leqq x$ for small t_0 so $y(\lambda_0^n t_0)\leqq T^n x$ as above. Since we may assume $|\cdot|$ to be nondecreasing, $|y(\lambda_0^n t_0)|\leqq|T^n x|$ for $n=1,2,\cdots$. It follows that $\lim|T^n x|=+\infty$.

Proof of Theorem 2.2. If $\rho(A_\infty)>1$ then since A_∞ is strongly positive we could use Theorem 1.1 to obtain a function y_-: $[0,\infty)\to[0,y_\infty]\cap \operatorname{int} K$ satisfying $y_-(0)=y_\infty$, $A_\infty y'_-(0)=\rho y'_-(0)$, $y_-(t)=T(y_-(\rho^{-1}t))$, $\rho=\rho(A_\infty)$. Clearly this contradicts that $[0,y_\infty]\cap \operatorname{int} K$ lies in the basin of attraction of y_∞.

Observe that $y(t)$ satisfies the functional differential equation

$$y'(t)=\lambda_0^{-1}DT\big(y(\lambda_0^{-1}t)\big)y'(\lambda_0^{-1}t) \tag{2.1}$$

and since $DT(x)$ is invertible it follows (Theorem 1.1) that $y'(t)\neq 0$ for all t. We have

$$\frac{y'(t)}{|y'(\lambda_0^{-1}t)|}=\lambda_0^{-1}A_\infty\frac{y'(\lambda_0^{-1}t)}{|y'(\lambda_0^{-1}t)|}+\lambda_0^{-1}\big[DT\big(y(\lambda_0^{-1}t)-A_\infty\big]\frac{y'(\lambda_0^{-1}t)}{|y'(\lambda_0^{-1}t)|} \tag{2.2}$$

where the second term on the right tends to zero at $t\to\infty$.

Define

$$Q=\left\{v\colon v=\lim_{n\to\infty}\frac{y'(t_n)}{|y'(t_n)|}\text{ for some sequence } t_n\to\infty\right\}.$$

To show that $\lim_{t\to\infty}(y'(t)/|y'(t)|)=e$ it suffices to show that $Q=\{e\}$. It is easy to check that Q is a nonempty compact set of unit vectors belonging to R_+^n, the latter since $y(t)$ is nondecreasing. If $v\in Q$, $v=\lim_{n\to\infty}(y'(t_n)j/|y'(t_n)|)$, it follows from putting $\lambda_0^{-1}t=t_n$ in (2.2) and taking limits that $\lim_{n\to\infty}(y'(\lambda_0 t_0)/|y'(t_n|)=\lambda_0^{-1}A_\infty v$. Hence

$$\lim_{n\to\infty}\frac{y'(\lambda_0 t_n)}{|y'(\lambda_0 t_n)|}=\frac{A_\infty v}{|A_\infty v|}\in Q.$$

We may define a continuous map f: $Q\to Q$ by $f(v)=A_\infty v/|A_\infty v|$ and observe that f is one to one since A_∞ is invertible. f is a homeomorphism of Q onto Q. For, if $v=\lim_{n\to\infty}(y'(t_n)/|y'(t_n)|)\in Q$, we may put $t=t_n$ in (2.1), divide both sides by $|y'(t_n)|$ and take limits to show that $\lim_{n\to\infty}(y'(\lambda^{-1}t_n)/|y'(t_n)|)=\lambda_0 A_\infty^{-1}v$. It follows that

$$\lim_{n\to\infty}\frac{y'(\lambda_0^{-1}t_n)}{|y'(\lambda_0^{-1}t_n)|}=\frac{A_\infty^{-1}v}{|A_\infty^{-1}v|}=v_1\in Q$$

and $f(v_1)=v$.

We now proceed to show that $f^n(v)\to e$ as $n\to\infty$ (f^n denoting n-fold composition as usual) uniformly for $v\in Q$. This is compatible with f^n: $Q\to Q$ being a homeo-

morphism for $n=1,2,\cdots$, only if $Q=\{e\}$. The principal tool in showing that $f^n(v)\to e$ as $n\to\infty$ is the fact that

$$f^n(v)=\frac{A_\infty^n v}{|A_\infty^n v|}=\frac{\rho^n}{|A_\infty^n v|}\cdot\frac{A_\infty^n}{\rho^n}v$$

and the Frobenius theorem [6, Appendix, Thm. 2.3]; $\lim_{n\to\infty}(A_\infty^n/\rho^n)=P$ where P is the projection onto the linear span of e defined $Px=(h\cdot x)e$ where $h\cdot e=1$, $A_\infty^t h=\rho h$, $h\in \operatorname{int} R_+^n$ ($\rho=\rho(A_\infty)$). Since Q is a compact subset of $R_+^n S^{n-1}$, $h\cdot x$ is bounded below by a positive constant uniformly for $x\in Q$. It follows from the above observations that $f^n(v)\to Pv/|Pv|=e$ uniformly for $v\in Q$ completing the proof of Theorem 2.2.

BREAKDOWN OF STABILITY IN SINGULARLY PERTURBED AUTONOMOUS SYSTEMS II. ESTIMATES FOR THE SOLUTIONS AND APPLICATION*

K. NIPP†

Abstract. In Nipp, [this Journal, 17 (1986), pp. 512–532] error estimates were derived for the trajectories of a singularly perturbed autonomous system. The results are extensions of a classical result due to A. N. Tikhonov. In this paper we give the transfer of those estimates to the solutions of the autonomous system and an application to a problem in biomathematics.

Special cases of our results are treated by Lebovitz and Schaar in Stud. Appl. Math., 54 (1975), pp. 229–260, 56 (1977), pp. 1–50, respectively. In order to transfer their estimates to the solutions, however, they introduce an artificial condition excluding a whole class of problems containing, e.g., the van der Pol relaxation oscillator as well as the example given in this paper.

Key words. ordinary differential equations, singular perturbations, breakdown of stability, nerve impulse equations

AMS(MOS) subject classifications. Primary 34E, 34D

1. Formulation of the problem. We first repeat the precise formulation of the problem. For introduction and motivation the reader is referred to [1].

Consider the autonomous system

$$\begin{aligned} \dot{x} &= f(x,y)+\varepsilon f^1(x,y,\varepsilon), \\ \varepsilon\dot{y} &= g(x,y)+\varepsilon g^1(x,y,\varepsilon), \end{aligned} \tag{1}$$

where x and y are m- and n-vectors, respectively, and $\varepsilon\in[0,\varepsilon_0]$, $\varepsilon_0<1$. Moreover, let all functions be sufficiently smooth in the domains considered. The corresponding reduced system is

$$\dot{x}=f(x,y), \qquad 0=g(x,y). \tag{2}$$

It is a well-known result, due to A. N. Tikhonov, that "corresponding solutions" of the systems (1) and (2) are close to each other if a certain stability assumption is satisfied (cf. [1]). We are interested in the situation where a solution of the reduced system loses its stability, and we will state a local result valid in a neighborhood of the point $(x,y)=(0,0)$ where we assume that the stability breaks down. As seen in [1] two cases ("$s<0$", "$s>0$") have to be considered depending on whether the flow along the reduced trajectory approaches the point $(0,0)$ or leads away from it. We will now state the assumptions in the first case; those in the second case are completely analogous (compare [1]).

A1. $$f_1(0,0)>0, \qquad f_k(0,0)=0 \qquad (k=2,3,\cdots,m),$$
$$g(0,0)=0.$$

Hence, there exist a domain $U\subset\mathbb{R}^{m+n}$, containing the origin, and a positive constant ρ such that $f_1(x,y)>\rho$ for $(x,y)\in U$.

* Received by the editors September 3, 1984, and in final form July 29, 1985.
† Seminar für Angewandte Mathematik, ETH-Zurich, CH-8092 Zurich, Switzerland.

A2.

$$g_y(0,0)=\begin{pmatrix} 0 & 0 & \cdots & 0 \\ 0 & & & \\ \vdots & & \bar{A} & \\ 0 & & & \end{pmatrix}$$

where all the eigenvalues of the $(n-1)\times(n-1)$ matrix $\bar{A}$ have negative real parts.

Moreover, let $\bar{y}:=(y_2,\cdots,y_n)$. As seen in [1], we may assume without loss of generality that $\bar{g}(x,y_1,\bar{y})$ has a Taylor formula beginning in y_1 with a cubic term. A2 implies that there exists a unique solution $\bar{w}(x,y_1)$ of $\bar{g}(x,y_1,\bar{y})=0$ in a neighborhood $\hat{U}\subset U$ containing the origin, having continuous partial derivatives there and satisfying $\bar{w}(0,0)=0$. For the remaining equation

$$g_1(x,y_1,\bar{w}(x,y_1))=0$$

we require

A3. There exists a function $\phi_1(x)$, which is defined and continuous for $(x_1,\bar{x})\in J\times\bar{\Omega}\subset\hat{U}$, where $J:=(s_1,0]$ for some $-1<s_1<0$, $\bar{\Omega}$ some neighborhood of $\bar{x}=0$, has continuous partial derivatives with respect to $\bar{x}$ there, and is C^1 in $J'\times\bar{\Omega}$, $J':=(s_1,0)$, satisfying

$$g_1(x,\phi_1(x),\bar{w}(x,\phi_1(x)))=0, \qquad x\in J\times\bar{\Omega},$$
$$\phi_1(0)=0,$$

and

$$\phi_1(x)=a_1(-x_1)^{\alpha}+p(x), \qquad x\in J\times\bar{\Omega},$$
$$\frac{\partial\phi_1}{\partial x_1}(x)=a_{11}(-x_1)^{\alpha-1}+p_1(x), \qquad x\in J'\times\bar{\Omega},$$

where $\alpha>0$ and a_1, $a_{11}\neq 0$, $p(0)=0$, $p(x_1,0)=o((-x_1)^{\alpha})$ and $p_1(x_1,0)=o((-x_1)^{\alpha-1})$ as $x_1\to 0^-$.

If $\alpha\geqq 1$ we suppose that $\phi_1(x)\in C^1(J\times\bar{\Omega})$.

Now let $\bar{\phi}(x):=\bar{w}(x,\phi_1(x))$ and $\phi(x):=(\phi_1,\bar{\phi})$ and consider the initial value problem

$$\frac{d\bar{x}}{dx_1}=\frac{\bar{f}(x_1,\bar{x},\phi(x_1,\bar{x}))}{f_1(x_1,\bar{x},\phi(x_1,\bar{x}))}, \qquad \bar{x}(0)=0 \tag{3}$$

for $(x_1,\bar{x})\in J\times\bar{\Omega}$.

Moreover, we introduce the following initial conditions to the system (1):

$$\begin{aligned} x(0,\varepsilon)&=x^0(\varepsilon)=X^0+O(\varepsilon),\\ y(0,\varepsilon)&=y^0(\varepsilon)=Y^0+O(\varepsilon), \end{aligned} \tag{4}$$

where X^0, Y^0 independent of ε and $(x^0(\varepsilon),y^0(\varepsilon))\in\hat{U}$, $x^0(\varepsilon)\in J'\times\bar{\Omega}$ for all $\varepsilon\in[0,\varepsilon_0]$.

We also suppose the following:

A4. The solution $\bar{U}(x_1)$ of (3) exists for $x_1\in J$, and

$$\left|\bar{x}^0(\varepsilon)-\bar{U}\left(x_1^0(\varepsilon)\right)\right|<c_0\varepsilon,$$
$$\left|y^0(\varepsilon)-V\left(x_1^0(\varepsilon)\right)\right|<c_0\varepsilon,$$

where $V(x_1):=\phi(x_1,\bar{U}(x_1))$.

There is one more condition, the essential stability condition that, together with A2, replaces the corresponding assumption in the Tikhonov case (see [1]).

A5. There are positive constants k and q such that

$$g_{1,y_1}\big(x_1, \bar{U}(x_1), V(x_1)\big) \leqq -k(-x_1)^q, \qquad x_1 \in J.$$

Let $X_1(t)$ be the solution of

$$\frac{dx_1}{dt} = f_1\big(x_1, \bar{U}(x_1), V(x_1)\big), \qquad x_1(0) = X_1^0.$$

It exists and is unique on an interval $[0, T]$, and increases there from X_1^0 to 0. Then

$$\big(X(t), Y(t)\big) := \big(X_1(t), \bar{U}(X_1(t)), V(X_1(t))\big)$$

is a solution of the reduced system (2) for $t \in [0, T]$ satisfying

$$\begin{aligned} &|X(0) - x^0(\varepsilon)| = O(\varepsilon), \\ &|Y(0) - y^0(\varepsilon)| = O(\varepsilon), \\ &X(T) = 0, \qquad Y(T) = 0. \end{aligned} \tag{5}$$

Remark. • A1–A5 imply the corresponding assumptions in [1].

• Assumption A4, which is equivalent to the condition (5) for a solution of the reduced system (2), is naturally satisfied if we consider a global problem whose reduced trajectory approaches the point $(x,y) = (0,0)$ and is stable as long as it is in a finite distance from this point.

• In order to verify A5 the asymptotic relations for $(\bar{U}(x_1), V(x_1))$ given in [1] may be used. □

In order to be able to formulate our result we need define the following nonnegative quantities:

$$\begin{aligned} \hat{\alpha} &:= \min(\alpha, 1), \\ \bar{\alpha} &:= \min(2\alpha, 1), \\ \beta &:= \begin{cases} \alpha & \text{if } \alpha < 1 \text{ and } g_1(x,y) \text{ has no linear term in } x_1 \\ 0 & \text{otherwise;} \end{cases} \end{aligned}$$

moreover, γ and ν which are defined by the estimates

$$\begin{aligned} &\big|g_{1,\bar{x}}\big(x_1, \bar{U}(x_1), V(x_1)\big)\big| \leqq C(-x_1)^{\gamma}, \\ &\big|g_{1,\bar{y}}\big(x_1, \bar{U}(x_1), V(x_1)\big)\big| \leqq C(-x_1)^{\nu}, \qquad x_1 \in J. \end{aligned}$$

In [1] we have shown that

$$\begin{aligned} &\gamma \begin{cases} \geqq \hat{\alpha} & \text{if } \alpha \geqq 1 \text{ or } g_1(x,y) \text{ has no linear term in } \bar{x}, \\ = 0 & \text{otherwise,} \end{cases} \\ &\nu \geqq \hat{\alpha}. \end{aligned}$$

2. The main result. Under the assumptions A1–A5 the following result holds.

THEOREM 1. *If q satisfies*

$$q < \min(1 + \gamma, \bar{\alpha} + \nu)$$

then for $|x^0(\varepsilon)|$, $|y^0(\varepsilon)|$ *sufficiently small there exist positive constants* C *and* $\varepsilon_1 \leqq \varepsilon_0$ *such that the solution* $(x(t,\varepsilon),y(t,\varepsilon))$ *of the initial value problem* (1), (4) *exists at least for* $t \in [0, T - C\varepsilon^{q}*]$, *where* $q^* := 1/(q_1+q-\beta)$, $q_1 := 1-\hat{\alpha}+q$, *and*

$$|x(t,\varepsilon)-X(t)| < \begin{cases} C\varepsilon \log(T-t)^{-1}, & q_1 = 1, \\ C\varepsilon(T-t)^{1-q_1}, & q_1 > 1, \end{cases}$$

$$|y_1(t,\varepsilon)-Y_1(t)| < C\varepsilon(T-t)^{-q_1},$$

$$|\bar{y}(t,\varepsilon)-\bar{Y}(t)| < \begin{cases} C\varepsilon \log(T-t)^{-1}, & q_1 = 1, \\ C\varepsilon(T-t)^{\bar{\alpha}-q_1}, & q_1 > 1 \end{cases}$$

for $t \in [0, T - C\varepsilon^{q}*]$, $\varepsilon \in [0, \varepsilon_1]$. □

Proof. We want to apply [1, Thm. 2]. Consider the initial value problem

$$\begin{aligned} &\frac{d\bar{x}}{dx_1} = F(x_1,\bar{x},y) + \varepsilon F^1(x_1,\bar{x},y,\varepsilon), \qquad \bar{x}\big(x_1^0(\varepsilon),\varepsilon\big) = \bar{x}^0(\varepsilon), \\ &\varepsilon\frac{dy}{dx_1} = G(x_1,\bar{x},y) + \varepsilon G^1(x_1,\bar{x},y,\varepsilon), \qquad y\big(x_1^0(\varepsilon),\varepsilon\big) = y^0(\varepsilon), \end{aligned} \tag{6}$$

where $F := \bar{f}/f_1$, $G := g/f_1$, F^1 and G^1 are defined for $(x,y) \in U$. Let $(\bar{u}(x_1,\varepsilon), v(x_1,\varepsilon))$ be the solution of (6). By means of [1, Thm. 2] it exists for $x_1 \in J^* := [x_1^0(\varepsilon), -c\varepsilon^{q}*]$ if $|x_1^0(\varepsilon)|$ is taken small enough. And let $\tilde{x}_1(t,\varepsilon)$ be the solution of

$$\frac{dx_1}{dt} = f_1\big(x_1,\bar{u}(x_1,\varepsilon),v(x_1,\varepsilon)\big) + \varepsilon f_1^1\big(x_1,\bar{u}(x_1,\varepsilon),v(x_1,\varepsilon),\varepsilon\big), \qquad x_1(0,\varepsilon) = x_1^0(\varepsilon).$$

Then the following identity holds

$$(x(t,\varepsilon),y(t,\varepsilon)) = \big(\tilde{x}_1(t,\varepsilon),\bar{u}\big(\tilde{x}_1(t,\varepsilon),\varepsilon\big),v\big(\tilde{x}_1(t,\varepsilon),\varepsilon\big)\big)$$

as long as $\tilde{x}_1(t,\varepsilon) \in J^*$. Moreover, assumption A1 implies that $x_1(t,\varepsilon)$ is an, in t, increasing function there. Since this is also true for the reduced solution $X_1(t)$ (cf. §1), we may consider the inverse functions which satisfy the following integral equations. To save writing we put $s := x_1$, $s^0 := x_1^0(\varepsilon)$, $S^0 := X_1^0$, $s^* := -c\varepsilon^{q}*$, and without loss of generality we suppose that $S^0 > s^0$ for all $\varepsilon \in [0, \varepsilon_0]$.

$$X_1^{-1}(s) = \int_{S^0}^{s} \frac{d\sigma}{f_1\big(\sigma,\bar{U}(\sigma),V(\sigma)\big)}, \qquad s \in [S^0, 0],$$

$$\begin{aligned} x_1^{-1}(s,\varepsilon) &= \int_{s^0}^{s} \frac{d\sigma}{f_1\big(\sigma,\bar{u}(\sigma,\varepsilon),v(\sigma,\varepsilon)\big) + \varepsilon f_1^1\big(\sigma,\bar{u}(\sigma,\varepsilon),v(\sigma,\varepsilon),\varepsilon\big)}, \qquad s \in [s^0, s^*] \\ &= \int_{s^0}^{s} \frac{d\sigma}{f_1\big(\sigma,\bar{U}(\sigma)+z(\sigma,\varepsilon),V(\sigma)+w(\sigma,\varepsilon)\big) + \varepsilon f_1^1(\cdots)}. \end{aligned}$$

We define $X_1^{-1}(s) \equiv 0$ for $s < S^0$. Hence (cf. A1), for ε small enough there are positive constants M_1 and M_2 such that

$$|x_1^{-1}(s,\varepsilon) - X_1^{-1}(s)| < M_1\varepsilon + M_2\int_{s^0}^{s} \big(|z(\sigma,\varepsilon)| + |w(\sigma,\varepsilon)|\big)\,d\sigma.$$

Applying [1, Thm. 2] and integrating yields

$$\left|x_1^{-1}(s,\varepsilon)-X_1^{-1}(s)\right|<M_1\varepsilon+M_3\varepsilon\psi(s)<\hat{M}\varepsilon\psi(s),\qquad s\in[s^0,s^*]$$

where

$$\psi(s):=\begin{cases}\log(-s)^{-1}, & q_1=1,\\ (-s)^{1-q_1}, & q_1>1.\end{cases}$$

This situation is sketched in Fig. 1.

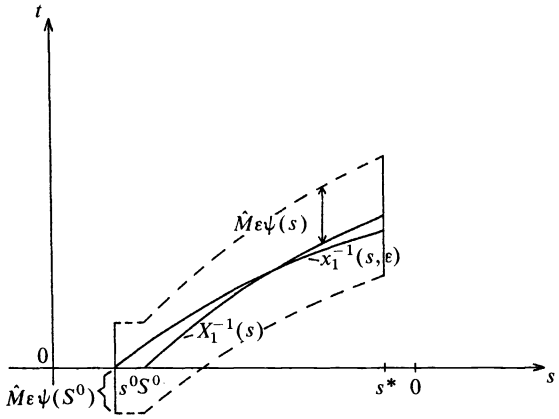

FIG. 1

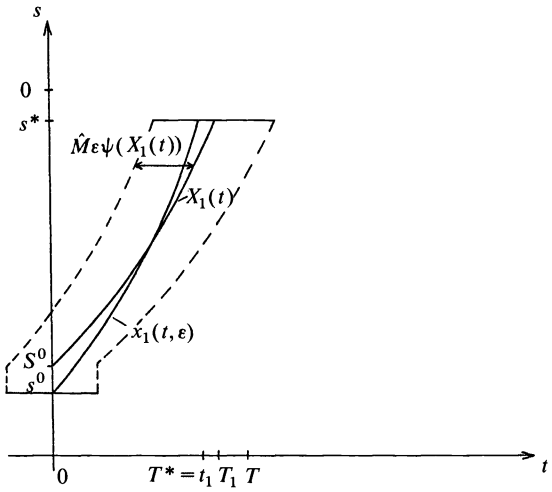

FIG. 2

The time T was defined by $T=X_1^{-1}(0)$. Moreover let

$$T_1(\varepsilon):=X_1^{-1}(s^*),$$
$$t_1(\varepsilon):=x_1^{-1}(s^*,\varepsilon),$$
$$T^*(\varepsilon):=\min(T_1,t_1).$$

It can easily be seen that there is $d>0$ such that

$$T^* \geqq T - d\varepsilon^{q*}.$$

Thus, for the functions $x_1(t,\varepsilon)$, $X_1(t)$ we obtain the situation sketched in Fig. 2. We now want to derive an estimate for $|x_1(t,\varepsilon)-X_1(t)|$ out of this picture. $X_1(t)$ provides a diffeomorphism from $[0,T]$ onto $[S^0,0]$ with inverse X_1^{-1}.

We first consider the lower boundary of the tube (see Fig. 3) and we put

$$r(t,\varepsilon) := \begin{cases} X_1(t) - X_1(\hat{t}(t,\varepsilon)), & T_0^* \leqq t \leqq T_1, \\ X_1(t) - s^0, & 0 \leqq t < T_0^*. \end{cases}$$

$r(t,\varepsilon)$ is a positive, continuous function on both intervals.

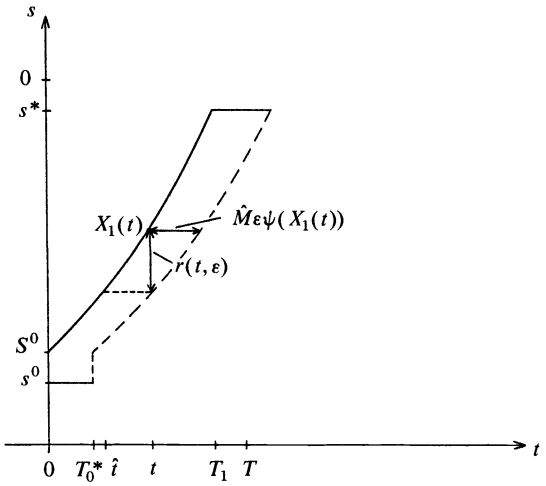

FIG. 3

The mean value theorem implies that

$$r(t,\varepsilon) = \dot{X}_1(\tau)\hat{M}\varepsilon\psi(X_1(\hat{t})) \quad \text{for some } \tau \in [\hat{t},t], t \in [T_0^*, T_1].$$

Hence, since $\psi(X_1(\hat{t})) < \psi(X_1(t))$ for $\hat{t} < t$, we have

$$r(t,\varepsilon) \leqq \tilde{M}\varepsilon\psi(X_1(t)) \quad \text{for } t \in [T_0^*, T_1].$$

For $t \in [0, T_0^*)$ we have

$$\begin{aligned} r(t,\varepsilon) &\leqq r(T_0^*,\varepsilon) + S^0 - s^0 \\ &\leqq K\varepsilon\psi(S^0) + O(\varepsilon) \leqq \tilde{K}\varepsilon\psi(S^0) \leqq \tilde{K}\varepsilon\psi(X_1(t)). \end{aligned}$$

Hence, there is $M_l > 0$ such that

$$r(t,\varepsilon) \leqq M_l\varepsilon\psi(X_1(t)) \quad \text{for } t \in [0, T_1].$$

The upper part of the tube (see Fig. 4) is slightly more difficult.

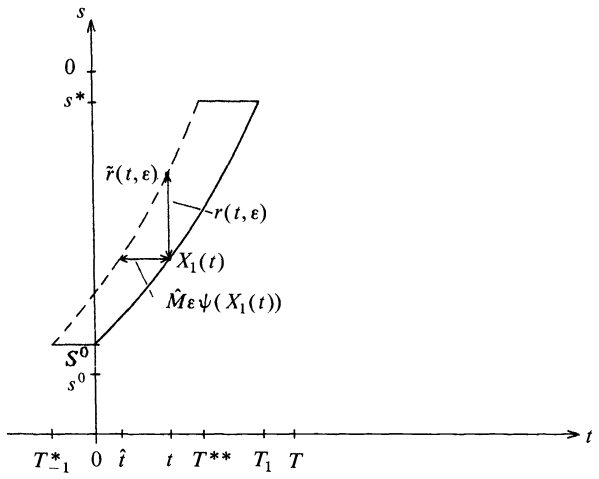

FIG. 4

The function $\tilde{r}(t,\varepsilon)$ (the upper boundary of the tube) is C^1 and increasing for $t\in[T^*_{-1}, T^{**}]$. This follows from the fact that the function $\tilde{r}^{-1}(s,\varepsilon)$ (the lower boundary of the tube in Fig. 1) is given by

$$\tilde{r}^{-1}(s,\varepsilon)=X_1^{-1}(s)-\hat{M}\varepsilon\psi(s) \quad \text{for } s\in[S^0,s^*],$$

and hence C^1 and increasing there with positive derivative. Therefore

$$r(t,\varepsilon):=\tilde{r}(t,\varepsilon)-\tilde{r}(\hat{t},\varepsilon)=\dot{\tilde{r}}(\tau,\varepsilon)\hat{M}\varepsilon\psi(X_1(t)) \quad \text{for some } \tau\in[\hat{t},t],\ t\in[0,T^{**}].$$

For $t\in[T^{**},T_1]$ we have for some $\tau<T^{**}$

$$\begin{aligned} r(t,\varepsilon)&\leqq r(T^{**},\varepsilon)=\dot{\tilde{r}}(\tau,\varepsilon)\hat{M}\varepsilon\psi(X_1(T^{**}))\\ &\leqq\dot{\tilde{r}}(\tau,\varepsilon)\hat{M}\varepsilon\psi(X_1(t)).\end{aligned}$$

Hence, since $\dot{\tilde{r}}(\tau,\varepsilon)$ is bounded for all possible τ there is $M_u>0$ such that

$$r(t,\varepsilon)\leqq M_u\varepsilon\psi(X_1(t)) \quad \text{for } t\in[0,T_1].$$

And we finally obtain that

$$|x_1(t,\varepsilon)-X_1(t)|<M_1\varepsilon\psi(X_1(t)) \quad \text{for } t\in[0,T^*]. \tag{7}$$

Since $X_1(T)=0$ and $\dot{X}_1(T)>0$ we have

$$X_1(t)=-M(T-t)+o(T-t), \qquad (T-t)\to 0^+.$$

Therefore, we finally obtain for T small enough (which can always be achieved by taking $|x_1^0|$ small enough) the following estimate:

$$|x_1(t,\varepsilon)-X_1(t)|<K_1\varepsilon\psi(T-t) \quad \text{for } t\in[0,T-d\varepsilon^{q*}].$$

For the remaining x-components we get from this result and again by means of [1, Thm. 2]:

$$\begin{aligned}|\bar{x}(t,\varepsilon)-\overline{X}(t)| &= |\bar{u}(x_1(t,\varepsilon),\varepsilon)-\overline{U}(X_1(t))| \\ &\leqq |\bar{u}(x_1(t,\varepsilon),\varepsilon)-\bar{u}(X_1(t),\varepsilon)|+|\bar{u}(X_1(t),\varepsilon)-\overline{U}(X_1(t))| \\ &< K|x_1(t,\varepsilon)-X_1(t)|+c\varepsilon\psi(X_1(t)) \\ &< \overline{K}\varepsilon\psi(T-t), \qquad t\in[0,T-d\varepsilon^{q*}].\end{aligned}$$

We now consider the y_1-component which is the most delicate one.

$$\begin{aligned}|y_1(t,\varepsilon)-Y_1(t)| &= |v_1(x_1(t,\varepsilon),\varepsilon)-V_1(X_1(t))| \\ &\leqq |v_1(x_1(t,\varepsilon),\varepsilon)-V_1(x_1(t,\varepsilon))|+|V_1(x_1(t,\varepsilon))-V_1(X_1(t))|.\end{aligned}$$

The first term can again be estimated by [1, Thm. 2]:

$$|v_1(x_1(t,\varepsilon),\varepsilon)-V_1(x_1(t,\varepsilon))|<c\varepsilon(-x_1(t,\varepsilon))^{-q_1}.$$

For the second term we obtain for each $t\in[0,T^*]$ by the mean-value theorem

$$|V_1(x_1)-V_1(X_1)|=|V_1'(x_1^*)||x_1-X_1|$$

for some x_1^* lying between x_1 and X_1. From [1] we know that $V_1'(s)=O((-s)^{\beta_1})$, $\beta_1=\min(\alpha-1,0)$, for $s\in[s^0,0)$. Hence

$$|V_1'(x_1^*)|\leqq N(-x_1^*)^{\beta_1}$$

and, since (7) implies that there is $\hat{N}>0$ such that for $\nu<0$

$$(-x_1(t,\varepsilon))^{\nu}\leqq\hat{N}(-X_1(t))^{\nu} \quad \text{for } t\in[0,T^*]$$

and ε sufficiently small, we get

$$\begin{aligned}|V_1(x_1(t,\varepsilon))-V_1(X_1(t))| &\leqq \tilde{N}\varepsilon(-X_1(t))^{\beta_1}\psi(X_1(t)) \\ &< N_1\varepsilon(-X_1(t))^{-q_1}, \qquad t\in[0,T^*].\end{aligned}$$

Therefore

$$\begin{aligned}|y_1(t,\varepsilon)-Y_1(t)| &< \hat{C}\varepsilon(-X_1(t))^{-q_1} \\ &< C_1\varepsilon(T-t)^{-q_1} \quad \text{for } t\in[0,T-d\varepsilon^{q*}].\end{aligned}$$

In a similar way, it can be shown that for ε small enough

$$|\bar{y}(t,\varepsilon)-\overline{Y}(t)|<\overline{C}\varepsilon\hat{\psi}(T-t) \quad \text{for } t\in[0,T-d\epsilon^{q*}],$$

where

$$\hat{\psi}(s):=\begin{cases}\log(-s)^{-1}, & q_1=1,\\ (-s)^{\bar{\alpha}-q_1}, & q_1>1.\end{cases}$$

This completes the proof of Theorem 1. □

3. Application to the nerve impulse equations of E. C. Zeeman. In [5] Zeeman suggests the following qualitative model for the local nerve impulse

$$\begin{aligned} \dot{x}_1 &= -1-x_2, \\ \dot{x}_2 &= -2x_2-2y, \\ \varepsilon\dot{y} &= -\left(x_1+x_2y+y^3\right), \end{aligned} \tag{8}$$

where x_1 corresponds to the potential of the membrane surrounding the axon of the neuron, and x_2 and y are correlated with the permeabilities of the membrane to potassium and sodium ions, respectively. Putting $\varepsilon=0$ in (8) we obtain the reduced system

$$\begin{aligned} \dot{x}_1 &= -1-x_2 =: f_1(x_1,x_2,y), \\ \dot{x}_2 &= -2x_2-2y =: f_2(x_1,x_2,y), \\ 0 &= -\left(x_1+x_2y+y^3\right) =: g(x_1,x_2,y), \end{aligned} \tag{9}$$

which defines a flow on the surface M: $g(x_1,x_2,y)\equiv 0$. M is sketched in Fig. 5. The fold curves $\tilde{C}^+$ and $\tilde{C}^-$ on M are given by

$$g_y = -\left(x_2+3y^2\right)=0.$$

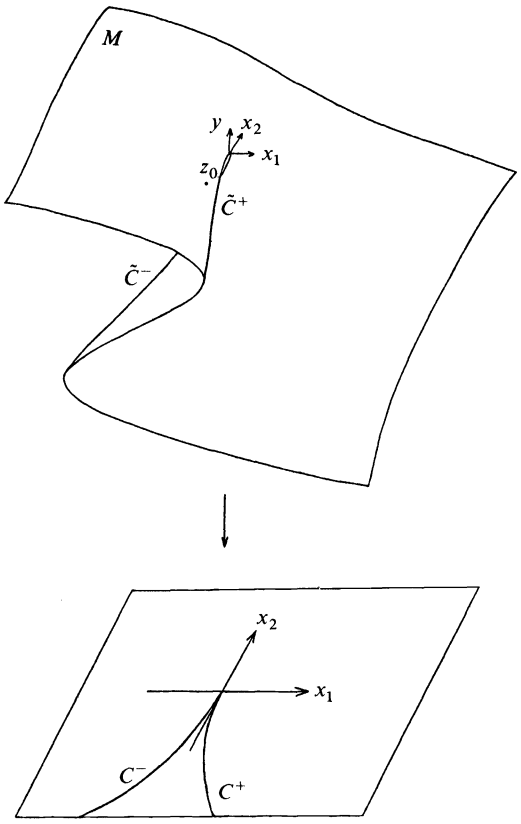

FIG. 5

When projected onto the (x_1, x_2)-plane they form a cusp defined by

$$27x_1^2 + 4x_2^3 = 0,$$

i.e. the curves C^+, C^- are given by

$$C^{\pm}: x_1 = \pm \frac{2}{3\sqrt{3}}(-x_2)^{3/2}, \qquad x_2 \leqq 0.$$

Outside the cusp M is single-sheeted, and inside it is 3-sheeted. Since the stability of these sheets as reduced manifolds of the system (8) is defined by $g_y < 0$ we find that the upper and lower sheet are stable (attractors) and the middle sheet is unstable (repellor).

The system (8) has one equilibrium point $z_0 = (0, -1, 1)$ which of course lies on M. To leading order in ε the eigenvalues of the Jacobian at z_0 are $-\frac{2}{\varepsilon}$, $e^{i2\pi/3}$, $e^{i4\pi/3}$, which in particular means that z_0 is a focus of the reduced flow on M. In Fig. 6 we have sketched the vector field of (8) on M. The curves $\tilde{A}, \tilde{B}, \tilde{C}$ on M are defined as follows:

$$\tilde{A}: f_2 = 0,$$
$$\tilde{B}: f_1 = 0,$$
$$\tilde{C}: g_y = 0 \text{ (fold curves)}.$$

It is easily verified that the projections A, B, C onto the (x_1, x_2)-plane look like indicated in Fig. 6.

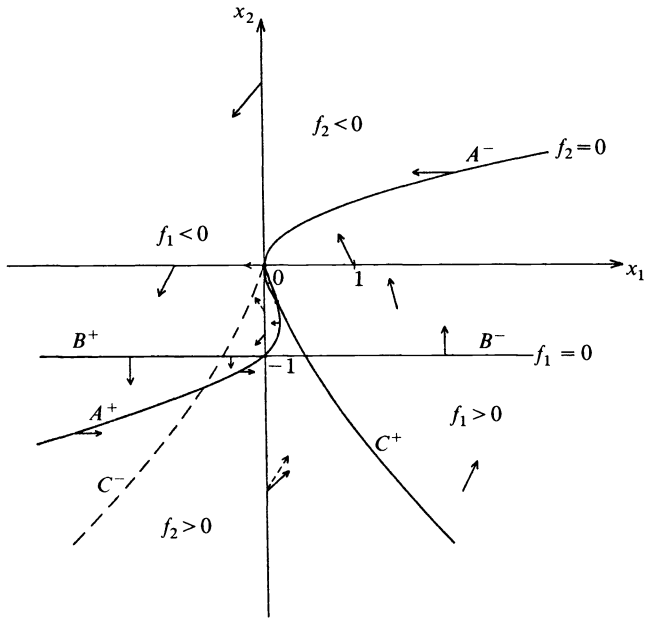

FIG. 6

In a finite distance away from M the vectors of the vector field of (8) are of length $O(1/\varepsilon)$ and hence for $\varepsilon \ll 1$ almost parallel to the y-axis. This means that the trajectory through such points drops into an ε-dependent vicinity of a stable sheet of M almost

instantaneously. It is plausible that the trajectory stays close to M as long as it does not encounter a point on a fold curve.

In the biological model, while no message is passing through the neuron, the membrane surrounding the axon is polarized, and the potential remains constant representing the stable equilibrium. As a message moves along the axon it triggers off a rapid depolarization of the membrane which causes the potential to increase suddenly. When the message has passed, the membrane repolarizes slowly, representing the smooth return to the equilibrium.

In the mathematical model (8), what happens if a trigger increases x_1 away from the equilibrium point z_0? A phase plane discussion (see Fig. 6) suggests that there are essentially two cases

(a) $x_1^0 \leqq \frac{2}{3\sqrt{3}}$,

(b) $x_1^0 > \frac{2}{3\sqrt{3}}$.

The value $x_1^0 = 2/3\sqrt{3}$ is a threshold for the trigger. In the case (a) the trajectory through $(x_1^0, -1, 1)$ will drop onto the upper sheet of M and in the case (b) onto the lower sheet of M. Then, the following situations may arise, depending on the size of x_1^0:

(A) (i) The trajectory spirals back into the equilibrium.
(ii) It encounters a point on the fold curve $\tilde{C}^+$ and drops down onto the lower sheet of M ($\rightarrow(B)$).

(B) (i) It slowly returns to the upper sheet of M and spirals into the equilibrium.
(ii) The trajectory encounters a point on the fold curve $\tilde{C}^-$ and drops onto the upper sheet of M and spirals into the equilibrium.

The case (B)(i) of course is the one that describes the biological model as sketched above. We, however, want to consider the case A(ii), B(i) which contains, from a mathematical point of view, all possible difficulties lying in this (mathematical) model. And we want to show that a trajectory of (8) is indeed approximated by jumps into an ε-dependent neighborhood of a stable sheet of M and trajectories (on M) of the reduced system (9). To be even more precise, we are going to prove rigorously that a trajectory of (8) (as well as the corresponding solution) is approximated by trajectories (solutions) of a sequence of reduced systems. Three different situations may arise:

—the reduced trajectory lies on a stable sheet of M,
—it encounters a point on a fold curve of M,
—it is "perpendicular" to M.

Hence without loss of generality we may consider a trajectory of (8) that starts in a neighborhood of a point on a fold curve. For convenience, we take the point $z^1 := (2, -3, 1)$ on $\tilde{C}^+$.

Let Γ^+ be the reduced trajectory of (9) through z^1 lying on the upper (stable) sheet of M. It is well defined for $x_1 \leqq 2$ in a neighborhood of z^1. Moreover, let $(X_1(t), X_2(t), Y(t))$ be the corresponding solution of (9) with initial conditions (at $t=0$) $Z^0 := (X_1^0, X_2^0, Y^0)$ on Γ^+ sufficiently close to z^1. It exists for $t \in (T_-, T)$, where $T_- < 0$ and $T > 0$ such that $(X_1(T), X_2(T), Y(T)) = z^1$.

We introduce local coordinates near z^1 by means of

$$x_1 = 2 + 2\hat{s} - 4x,$$
$$x_2 = -3 + 4\hat{s} + 2x,$$
$$y = 1 + \hat{y}.$$

Then the transformed equation (8) satisfies A1 and M is locally given by

$$\hat{s}=h(x,\hat{y})=-\frac{-2x+2x\hat{y}+3\hat{y}^2+\hat{y}^3}{6+4\hat{y}}.$$

Moreover, the fold curve $\tilde{C}^+$ has the (local) representation $(h(x,\varphi(x)),x,\varphi(x))$ for $x\in U(0)$, where the smooth function $\varphi(x)$ is such that

$$h_{\hat{y}}(x,\varphi(x))=0 \quad \text{for } x\in U(0),$$

with $\varphi(0)=0$.

In order that A3 holds we need one more transformation

$$\hat{s}=s+h(x,\varphi(x)), \qquad \hat{y}=v+\varphi(x).$$

In these new coordinates $\tilde{C}^+$ has the (local) representation $(0,x,0)$, $x\in U(0)$, and (8) now reads

$$\begin{aligned}
\dot{s}&=1-2s+\rho(x,v),\\
\dot{x}&=-\frac{1}{5}(v+\varphi(x)),\\
\varepsilon\dot{v}&=G(s,x,v)+\varepsilon\kappa(x,v)
\end{aligned} \tag{10}$$

where the smooth functions ρ, κ vanish at $(x,v)=(0,0)$ and

$$G(s,x,v)=-\left[(6+4\varphi(x))s+4sv+(3+3\varphi(x))v^2+v^3\right].$$

Therefore, M in these new coordinates is locally given by

$$-s=\frac{(3+3\varphi(x))v^2+v^3}{6+4\varphi(x)+4v}.$$

Taking the positive square root on both sides we obtain an equation in $\sqrt{-s},x,v$ that satisfies the IFT. Hence, we find that there is a continuous function $\phi(s,x)$ defined for $s\in(s_1,0]$, $x\in\Omega(0)$, which is in $C^1((s_1,0)\times\Omega)$ and has a continuous partial derivative with respect to x also for $s=0$, and which satisfies

$$\begin{aligned}
&G(s,x,\phi(s,x))=0 \quad \text{for } s\in(s_1,0],\ x\in\Omega,\\
&\phi(0,0)=0,
\end{aligned}$$

and

$$\begin{aligned}
&\phi(s,x)=\sqrt{-2s}+h.o.t.,\\
&\phi_s(s,x)=-\frac{1}{\sqrt{-2s}}+h.o.t., \qquad s\to 0^-,\quad |x|\to 0.
\end{aligned}$$

Hence, the upper (stable) sheet of M is locally given by $v=\phi(s,x)$ and A3 is satisfied with $\alpha=\frac{1}{2}$.

Let us now consider the following initial conditions to (10)

$$\begin{aligned}
s(0,\varepsilon)&=s^0(\varepsilon)=S^0+O(\varepsilon),\\
x(0,\varepsilon)&=x^0(\varepsilon)=X^0+O(\varepsilon),\\
v(0,\varepsilon)&=v^0(\varepsilon)=V^0+O(\varepsilon),
\end{aligned} \tag{11}$$

where (S^0, X^0, V^0) is the point Z^0 in the new coordinates, i.e. we start in an ε-dependent neighborhood of the reduced trajectory Γ^+ and close to the point z^1 on $\tilde{C}^+$ (such that the initial point lies in the s- and x-domain considered above). Then A4 is satisfied, and from

$$G_v(s,x,v) = -\left(4s + (6+6\varphi(x))v + 3v^2\right) \qquad \text{(which also implies A2)}$$

and by applying the estimates (27), (28) of [1] we find that A5 holds with $q = \frac{1}{2}$. In the same way we obtain $\beta = 0$, $\gamma = 1$.

Thus, all assumptions of Theorem 1 [1, Thm. 2] are satisfied, and we have the following result for the phase-plane trajectory of the IVP (10), (11):

$$\begin{aligned} &|x(s,\varepsilon) - X(s)| < c\varepsilon \log(-s)^{-1}, \\ &|v(s,\varepsilon) - V(s)| < c\varepsilon(-s)^{-1}, \end{aligned} \qquad s \in [s^0(\varepsilon), -c\varepsilon^{2/3}] \tag{12}$$

where $(X(s), V(s))$ is the trajectory of the reduced problem (the reduced trajectory Γ^+ in the new coordinates). Going back to the original variables we have for the corresponding solution of (8)

$$\begin{aligned} &|x_1(t,\varepsilon) - X_1(t)| < C\varepsilon \log(T-t)^{-1} &&< \hat{C}\varepsilon \log \varepsilon^{-1}, \\ &|x_2(t,\varepsilon) - X_2(t)| < C\varepsilon \log(T-t)^{-1} && \qquad\qquad t \in [0, T - C\varepsilon^{2/3}]. \\ &|y(t,\varepsilon) - Y(t)| < C\varepsilon(T-t)^{-1} &&\leqq \varepsilon^{1/3}, \end{aligned} \tag{13}$$

Hence, the reduced solution (trajectory) ceases to be an approximation in an ε-dependent neighborhood of the point z^1 where the stability breaks down. Guided by the algorithm presented in [2] we introduce the following shift scaling transformation

$$\begin{aligned} x_1 &= 2 + \varepsilon^{2/3} u_1, \\ x_2 &= -3 + \varepsilon^{2/3} u_2, \\ y &= 1 + \varepsilon^{1/3} q, \\ t &= T + \varepsilon^{2/3} \sigma, \end{aligned}$$

which means a blowing up of that neighborhood and takes (8) into

$$\begin{aligned} \frac{du_1}{d\sigma} &= 2 - \varepsilon^{2/3} u_2, \\ \frac{du_2}{d\sigma} &= 4 - 2\varepsilon^{1/3} q - 2\varepsilon^{2/3} u_2, \\ \frac{dq}{d\sigma} &= -\left(u_1 + u_2 + 3q^2\right) - \varepsilon^{1/3}\left(u_2 q + q^3\right). \end{aligned} \tag{14}$$

Let $(u_1(\sigma,\varepsilon), u_2(\sigma,\varepsilon), q(\sigma,\varepsilon))$ be the solution of (14) that satisfies

$$\begin{aligned} u_1(-\hat{\sigma},\varepsilon) &= \varepsilon^{-2/3}\left[x_1(T - \hat{\sigma}\varepsilon^{2/3},\varepsilon) - 2\right], \\ u_2(-\hat{\sigma},\varepsilon) &= \varepsilon^{-2/3}\left[x_2(T - \hat{\sigma}\varepsilon^{2/3},\varepsilon) + 3\right], \\ q(-\hat{\sigma},\varepsilon) &= \varepsilon^{-1/3}\left[y(T - \hat{\sigma}\varepsilon^{2/3},\varepsilon) - 1\right], \end{aligned} \tag{15}$$

for some $\hat{\sigma} \geqq C$. A solution of the reduced system corresponding to (14) satisfies

$$\begin{aligned} &U_1(\sigma) = 2\sigma + U_1^0, \qquad U_2(\sigma) = 4\sigma + U_2^0, \\ &\dot{Q} = -6\sigma - 3Q^2 - \left(U_1^0 + U_2^0\right). \end{aligned} \tag{16}$$

Taking $U_1^0 = U_2^0 = 0$ it can be shown that

$$\begin{aligned} |u_1(-\hat{\sigma},\varepsilon) - U_1(-\hat{\sigma})| &= O(\varepsilon^{1/3}\log\varepsilon^{-1}), \\ |u_2(-\hat{\sigma},\varepsilon) - U_2(-\hat{\sigma})| &= O(\varepsilon^{1/3}\log\varepsilon^{-1}), \end{aligned} \qquad \varepsilon \to 0.$$

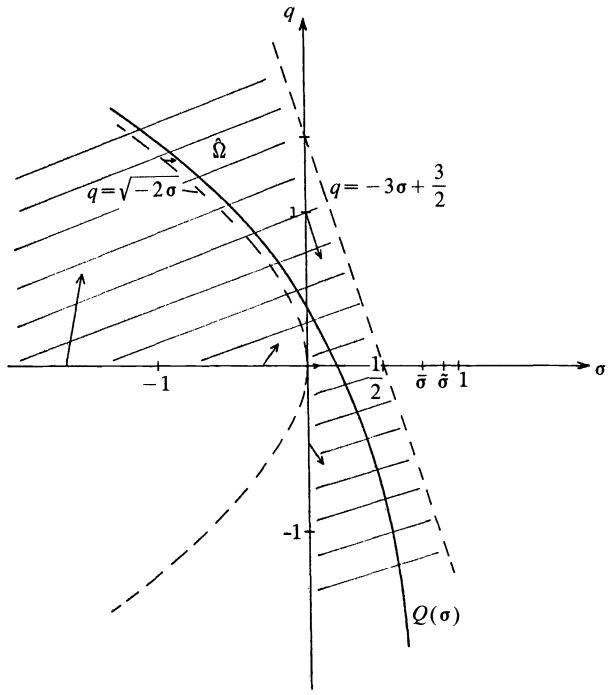

FIG. 7

Equation (16) is discussed in Fig. 7. The domain $\hat{\Omega}$ sketched there is invariant, i.e. every solution $Q(\sigma,\sigma_0,Q^0)$ with $(\sigma_0,Q^0)\in\hat{\Omega}$ stays in $\hat{\Omega}$ for all $\sigma\in(\sigma_0,\sigma_+)$, where (σ_-,σ_+), $\sigma_+ > 0$, is its maximal domain of existence. Moreover, it follows that $Q(\sigma,\sigma_0,Q^0)\to-\infty$ for $\sigma\to\sigma_+$. Since (13) implies

$$|q(-\hat{\sigma},\varepsilon) - \sqrt{2\hat{\sigma}}| < 1$$

we know that $q(-\hat{\sigma},\varepsilon)\in\hat{\Omega}$ for $\hat{\sigma}$ large enough. Hence, applying standard arguments (Gronwall lemma) we obtain that there is $0<\bar{\sigma}<\frac{5}{6}$ such that for ε sufficiently small the solution of (14) with initial conditions (15) exists at least for $\sigma\in[-\hat{\sigma},\bar{\sigma}]$ and

$$q(\bar{\sigma},\varepsilon) < -1. \tag{17}$$

Equation (16) can be transformed into Airy's equation which is linear of second order (see e.g. [2, Ex. 1]). Let $Q(\sigma)$ be the solution of (16) based on the first one of the two linearly independent solutions of Airy's equation. Then, it can be shown that

$$Q(\sigma) = \sqrt{-2\sigma} + O\big((-\sigma)^{-1}\big), \qquad \sigma\to-\infty$$

and

$$|q(-\hat{\sigma},\varepsilon)-Q(-\hat{\sigma})|<1 \quad \text{for } \hat{\sigma} \text{ large enough.}$$

Moreover, $Q(\sigma)$ has a pole at $\sigma=\tilde{\sigma}\cong 0.892$, and hence behaves as sketched in Fig. 7. Thus, by means of the same arguments as before we obtain for our solution $(x_1(t,\varepsilon),x_2(t,\varepsilon),y(t,\varepsilon))$ of (8) that for every $c_2\in(0,\tilde{\sigma}-\bar{\sigma}]$ there exists $M>0$ such that

$$\begin{aligned} &|x_1(t,\varepsilon)-\tilde{X}_1(t)|<M\varepsilon\log\varepsilon^{-1},\\ &|x_2(t,\varepsilon)-\tilde{X}_2(t)|<M\varepsilon\log\varepsilon^{-1}, \qquad t\in\left[T-\hat{\sigma}\varepsilon^{2/3},T+(\tilde{\sigma}-c_2)\varepsilon^{2/3}\right],\\ &|y(t,\varepsilon)-\tilde{Y}(t)|<M\varepsilon^{1/3}, \end{aligned} \tag{18}$$

where $(\tilde{X}_1(t),\tilde{X}_2(t),\tilde{Y}(t))$ is the reduced solution $(U_1(\sigma),U_2(\sigma),Q(\sigma))$ expressed in the original variables.

By means of this second approximation, we have passed the delicate point $z^1\in\tilde{C}^+$. We are still in an ε-dependent neighborhood, however.

Again we proceed as motivated in [2] and introduce the new shift scaling transformation

$$\begin{aligned} u_1&=2\tilde{\sigma}+\varepsilon^{1/3}v_1,\\ u_2&=4\tilde{\sigma}+\varepsilon^{1/3}v_2,\\ q&=\varepsilon^{-1/3}w,\\ \sigma&=\tilde{\sigma}+\varepsilon^{1/3}\tau, \end{aligned}$$

that takes (14) into

$$\begin{aligned} \frac{dv_1}{d\tau}&=2-4\varepsilon^{2/3}\tilde{\sigma}-\varepsilon v_2,\\ \frac{dv_2}{d\tau}&=4-2w-8\varepsilon^{2/3}\tilde{\sigma}-2\varepsilon v_2,\\ \frac{dw}{d\tau}&=-3w^2-w^3-\varepsilon^{2/3}(6\tilde{\sigma}+4\tilde{\sigma}w)-\varepsilon(v_1+v_2+v_2w). \end{aligned} \tag{19}$$

Let $(v_1(\tau,\varepsilon),v_2(\tau,\varepsilon),w(\tau,\varepsilon))$ be the solution of (19) satisfying

$$\begin{aligned} v_1(-\varepsilon^{-1/3}c_2,\varepsilon)&=\varepsilon^{-1}\left[x_1\left(T+\varepsilon^{2/3}(\tilde{\sigma}-c_2),\varepsilon\right)-(2+\varepsilon^{2/3}2\tilde{\sigma})\right],\\ v_2(-\varepsilon^{-1/3}c_2,\varepsilon)&=\varepsilon^{-1}\left[x_2\left(T+\varepsilon^{2/3}(\tilde{\sigma}-c_2),\varepsilon\right)+3-\varepsilon^{2/3}4\tilde{\sigma}\right],\\ w(-\varepsilon^{-1/3}c_2,\varepsilon)&=y\left(T+\varepsilon^{2/3}(\tilde{\sigma}-c_2),\varepsilon\right)-1. \end{aligned}$$

From (17) we know that $w(-\varepsilon^{-1/3}c_2,\varepsilon)<-\varepsilon^{1/3}$. Typical solutions of the reduced w-equation are sketched in Fig. 8. A solution $W(\tau,W^0)$, $W(0,W^0)=W^0$, with $W^0\in(-3,0)$ exists for $\tau\in(-\infty,\infty)$ and approaches 0 geometrically for $\tau\to-\infty$ and -3 exponentially for $\tau\to+\infty$. By using "phase-plane" arguments in the (w,τ)-plane and Gronwall type results it can be shown that $(v_1(\tau,\varepsilon),v_2(\tau,\varepsilon),w(\tau,\varepsilon))$ exists for $\tau\in[-c_2\varepsilon^{-1/3},\varepsilon^{-1/3}]$. Moreover, there is $c_3\in(0,1)$ such that

$$\begin{aligned} v_1(\tau,\varepsilon)&=O(\tau),\\ v_2(\tau,\varepsilon)&=O(\tau), \qquad \tau\in\left[c_3\varepsilon^{-1/3},\varepsilon^{-1/3}\right].\\ w(\tau,\varepsilon)&=-3+O(\varepsilon^{2/3}), \end{aligned}$$

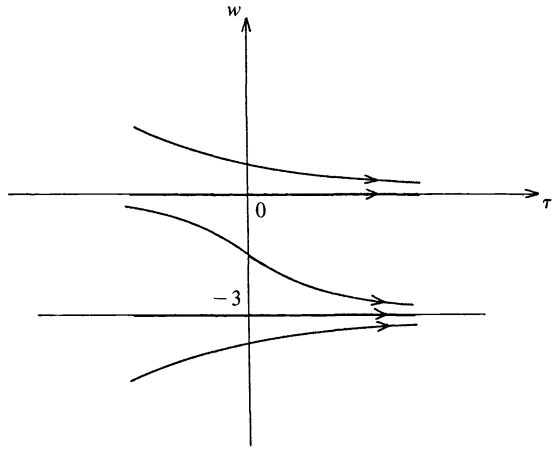

FIG. 8

Thus in the original variables we have

$$
\begin{aligned}
&x_1\big(T+\varepsilon^{2/3}(\tilde{\sigma}+1),\varepsilon\big)=2+O(\varepsilon^{2/3}),\\
&x_2\big(T+\varepsilon^{2/3}(\tilde{\sigma}+1),\varepsilon\big)=-3+O(\varepsilon^{2/3}),\\
&y\big(T+\varepsilon^{2/3}(\tilde{\sigma}+1),\varepsilon\big)=-2+O(\varepsilon^{2/3}).
\end{aligned}
\tag{20}
$$

The point $z^2:=(2,-3,-2)$ lies on the lower (stable) sheet of the surface M. Hence, we have proved up to now that (and how) the trajectory of our solution $(x_1(t,\varepsilon),x_2(t,\varepsilon),y(t,\varepsilon))$ of (8) has dropped off the upper sheet of M down to the lower one. It drops down almost instantaneously (time $O(\varepsilon^{2/3})$) and almost vertically ($O(\varepsilon^{2/3})$-neighborhood of $(x_1,x_2)=(2,-3)$).

We again consider the original system (8) now together with the initial conditions (20). By simple phase plane arguments (compare Fig. 6) it can be shown that the trajectory of the corresponding reduced problem (lying on the lower sheet of M) crosses the curve $\tilde{A}^-$, follows $\tilde{A}^-$ into a neighborhood of the origin where it leaves $\tilde{A}^-$ now being on the upper sheet of M. Then it crosses $\tilde{A}^+$ and follows $\tilde{A}^+$ into a neighborhood of the point $(0,-1,1)$ and finally spirals into this point on M which is a stationary point (focus) of the reduced system. Hence, the corresponding reduced solution $(\bar{X}_1(t),\bar{X}_2(t),\bar{Y}(t))$ exists for all $t\geqq T+\varepsilon^{2/3}(\tilde{\sigma}+1)$ and since the trajectory stays on the stable sheets of M we may apply the Tikhonov theorem (cf. [1]) on every finite t-interval $[T+\varepsilon^{2/3}(\tilde{\sigma}+1),c]$. Taking also into account that $z_0=(0,-1,1)$ is an asymptotically stable equilibrium solution of the full system (8) we thus obtain for ε small enough the following result on the unbounded t-interval:

$$
\begin{aligned}
&|x_1(t,\varepsilon)-\bar{X}_1(t)|<K\varepsilon^{2/3}\\
&|x_2(t,\varepsilon)-\bar{X}_2(t)|<K\varepsilon^{2/3}\quad \text{for every } t\geqq T+\varepsilon^{2/3}(\tilde{\sigma}+1).\\
&|y(t,\varepsilon)-\bar{Y}(t)|<K\varepsilon^{2/3}
\end{aligned}
$$

This was the final step. Summarizing, we have proved that the solution $(x_1(t,\varepsilon),x_2(t,\varepsilon),y(t,\varepsilon))$ we have considered of the system (8) exists for all $t\geqq 0$ and its trajectory behaves as sketched in Fig. 9. The motion is slow as long as the trajectory is

close to a stable sheet of M. The jump from the upper sheet of M to the lower one happens in a fast time scale.

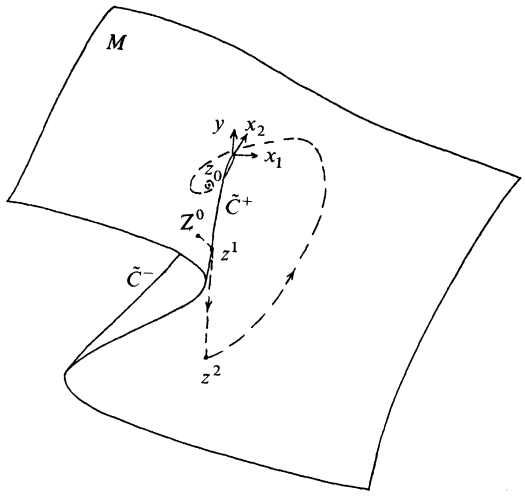

FIG. 9

4. The case "$x_1 > 0$". This case is characterized by the fact that the flow along a stable reduced trajectory of (2) leads away from the origin, the point where the stability assumption is violated (see [1]). Also in this case, the estimates for the trajectories of (1) given in [1, Thm. 3] carry over to the solutions and in a way completely analogous to the proof of Theorem 1. For completeness, we state these estimates, but without formulating the precise Theorem 2 corresponding to [1, Thm. 3] and without proof.

Let $(\bar{u}(x_1,\varepsilon), v(x_1,\varepsilon))$ and $(\bar{U}(x_1), V(x_1))$ be trajectories of (1) and (2), respectively, that satisfy [1, Thm. 3] and let c, δ and q^* be the quantities defined there. Moreover, let $(x(t,\varepsilon), y(t,\varepsilon))$ and $(X(t), Y(t))$ be the corresponding solutions obtained by introducing the time t in the way (compare §§1, 2)

$$x_1(0,\varepsilon) = s^*(\varepsilon), \qquad X_1(0) = S^*(\varepsilon)$$

with

$$s^*(\varepsilon) = c\varepsilon^{q^*} \quad \text{and} \quad |s^* - S^*| = O(\varepsilon^{\delta}).$$

Then, if the parameter q_1 in [1, Thm. 3] is taken such that $q_1 > 1 - \hat{\alpha}$ (i.e. $q^* < \delta$), there are positive constants C and c_1 such that the following estimates hold for T_1 and ε small enough:

$$\begin{aligned}
&|x(t,\varepsilon) - X(t)| < C\varepsilon^{\delta}, \\
&|y_1(t,\varepsilon) - Y_1(t)| < C\varepsilon^{\delta}\left(c_1\varepsilon^{q^*} + t\right)^{-q_1}, \\
&|\bar{y}(t,\varepsilon) - \bar{Y}(t)| < C\varepsilon^{\delta}\left(c_1\varepsilon^{q^*} + t\right)^{\bar{\omega}-q_1},
\end{aligned}$$

for $t \in [0, T_1]$.

Examples for this case "$x_1 > 0$" (as well as for "$x_1 < 0$") are the situations treated in [3], [4].

ON THE GLOBAL REPRESENTATION OF THE SOLUTIONS OF SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS HAVING AN IRREGULAR SINGULARITY OF RANK ONE IN ∞ BY SERIES IN TERMS OF CONFLUENT HYPERGEOMETRIC FUNCTIONS*

THEO KURTH† AND DIETER SCHMIDT†

Abstract. A general second-order linear differential equation having an irregular singularity of rank one in ∞ is considered. It is shown that the solutions of this equation can be represented by series in terms of confluent hypergeometric functions which describe the full analytic behavior at the singular point ∞.

Key words. global representations, singular ODEs, series, confluent hypergeometric functions

Introduction. In the theory of complex ordinary differential equations a study of the global behavior of the solutions is one of the most interesting and difficult problems. A specific problem of this kind consists in finding global representations for the solutions which describe their full analytic behavior. In the present paper we want to treat this question for the case of the general second-order linear differential equation (DE) having an irregular singular point of rank one in ∞, which is of the form

$$y''+f(z)y'+g(z)y=0,$$

where f and g are holomorphic in ∞. There is a very extensive literature on this DE since the fundamental papers of Horn [5] in 1908 and Birkhoff [1] in 1913. (See e.g. [12], [6], [7], [8], [4].)

By a transformation of variables the above DE takes the following *normal form*

$$y''+\left(\frac{1}{z}+\frac{a(z)}{z^2}\right)y'+\left(1+\frac{2i\kappa}{z}+\frac{b(z)}{z^2}\right)y=0, \tag{0.1}$$

where κ is a complex constant and $a(z)$, $b(z)$ are functions being holomorphic in a full neighborhood $r<|z|\leqq\infty$ of infinity. We shall restrict our considerations to the DE (0.1).

It is well known that the solutions of the DE (0.1) are holomorphic functions on the Riemann surface of $\ln z$ over $r<|z|<\infty$, which possess in each sector $|\arg z-\pi/2-n\pi|<\pi/2$, $(n\in\mathbb{Z})$ a characteristic asymptotic behavior as $|z|\to\infty$. (See e.g. [11], pp. 232–236.) Our main aim is to obtain for these solutions global representations which are valid on the whole Riemann surface and which completely reflect the asymptotic behavior for $|z|\to\infty$ as well as the transition behavior in the case of analytic continuation around ∞.

A central role in our consideration plays the special case of the DE (0.1) with $a(z)$ equal to 0 and $b(z)$ equal to a constant $-\mu^2$:

$$y''+\frac{1}{z}y'+\left(1+\frac{2i\kappa}{z}-\frac{\mu^2}{z^2}\right)y=0. \tag{0.2}$$

*Received by the editors August 21, 1984, and in revised form July 31, 1985

This DE is—up to a simple transformation of variables—the confluent hypergeometric DE. The solutions of this DE—the confluent hypergeometric functions—are very well known. Using a lot of these well known facts and taking advantage of the very close relationship between the DEs (0.1) and (0.2), we can show that the solutions of the DE (0.1) are to be represented by series in terms of confluent hypergeometric functions, and that these representations are global ones possessing all the desired properties. A very specific property of these series, which underlines their usefulness, is that essentially only one set of coefficients is needed for the expansion of different solutions of the DE (0.1).

An immediate cause for the present consideration results from the study of special functions of mathematical physics, where expansions of "higher" special functions in terms of "simple" special functions have played a central role at all times. It is just this field from which we have obtained essential stimulations. In this connection we should mention, above all, the corresponding considerations of Meixner and Schäfke in Chapter 3 of their book on Mathieu and spheroidal functions [9, pp. 289–300], where spheroidal functions are expanded in terms of Bessel and Hankel functions. As far as the whole organization and the analytic methods of this paper are concerned there is a close relationship with the paper [16] of the second author.

This paper is divided into two main sections. Section 1 contains preliminary results: in §1.1 and §1.2 we introduce the fundamental notations for the DEs (0.1) and (0.2) and give some elementary, respectively well-known statements. In §1.3 we make available a suitable version of a theorem of F. W. Schäfke on expansions in terms of Whittaker functions, which serves as a main tool in our analysis, and in the following we draw some important conclusions on the coefficients of such expansions. In §1.4 we prove a theorem on the asymptotic behavior of series in terms of confluent hypergeometric functions, which surely is interesting by itself. This theorem is a generalization of a corresponding result of Meixner and Schäfke [9, pp. 95–97]. Section 2 contains the main results on the representation of the solutions of the DE (0.1) in terms of confluent hypergeometric functions. In §2.1 we transform the DE (0.1) into sequence spaces. In §2.2 we prove the fundamental result concerning the asymptotic behavior of the expansion coefficients which ensures the global convergence of all series. Section 2.3 finally contains the definition and a detailed discussion of the solutions of the DE (0.1) by means of their series representations.

Three final remarks are to be made:

1) Our analysis of the DE (0.1) also furnishes the *existence* of asymptotic solutions of the DE (0.1), certainly under the use of the very strong expansion theorem in §1.3. Another method to obtain the main results of this paper is to base all considerations on the existence of asymptotic solutions and to use the principle of analytic equivalence. (See [6]–[8]).

2) All series representations in this paper are only valid in the case that the characteristic exponents ν of the DE (0.1) fulfill $2\nu \notin \mathbb{Z}$ ("*normal case*"). A treatment of the exceptional case $2\nu \in \mathbb{Z}$ in the frame of our methods would require a more recent expansion theorem of F. W. Schäfke in [15, pp. 134–135], which is based on the general results in 1.1.11 of [10].

3) In principle, it should be possible to extend the methods of this paper also to general DEs of higher rank, but considerable efforts are to be made: First, one has to find an adequate set of "special" DEs being analytic equivalent to the "general" DE. Secondly, one has to establish for these special DEs all the results corresponding to those for equation (0.2) which are contained in §§1.2, 1.3 and 1.4.

1. Preliminary results.

1.1. General remarks on the DE (0.1); notation. In the following let Ω denote the annulus $\{z\in\mathbb{C}\,|\,r<|z|<\infty\}$ and $\hat{\Omega}$ the Riemann surface of $\ln z$ over Ω.[1] The vector space of holomorphic functions in $\hat{\Omega}$ is then denoted by $\mathscr{H}(\hat{\Omega})$.

For $y\in\mathscr{H}(\hat{\Omega})$ we define

$$L_\kappa y := \left(z\frac{d}{dz}\right)^2 y+(z^2+2i\kappa z)y, \tag{1.1}$$

where $\kappa\in\mathbb{C}$, and

$$Gy := \frac{d}{dz}(g_1\cdot y)+g_2\cdot y, \tag{1.2}$$

where the coefficients $g_1 := a$ and $g_2 := b-da/dz$ are holomorphic functions in $\Omega\cup\{\infty\}$. L_κ and G are linear operators in $\mathscr{H}(\hat{\Omega})$, in terms of which the DE (0.1) then reads

$$Dy := L_\kappa y+Gy=0. \tag{D}$$

The solution space of (D), which we denote in the following by $\mathfrak{N}(D)$, is a two-dimensional subspace of $\mathscr{H}(\hat{\Omega})$.

The following remark is to be easily verified:

(1.3) *Let $y_1,y_2\in\mathfrak{N}(D)$. Then the Wronskian*

$$w[y_1,y_2] := y_1\cdot\frac{d}{dz}y_2-y_2\cdot\frac{d}{dz}y_1$$

has the form

$$w[y_1,y_2](z)=[y_1,y_2]\cdot z^{-1}\cdot\exp\left(\int_z^\infty g_1(\zeta)\zeta^{-2}d\zeta\right),$$

where $[y_1,y_2]\in\mathbb{C}$. $[\cdot,\cdot]$ is a nontrivial alternating bilinear form on $\mathfrak{N}(D)$.

Defining for $y\in\mathscr{H}(\hat{\Omega})$

$$(\phi y)(z) := y(e^{2\pi i}\cdot z)\qquad(z\in\hat{\Omega}), \tag{1.4}^2$$

we obtain a linear operator ϕ in $\mathscr{H}(\hat{\Omega})$ which maps $\mathfrak{N}(D)$ onto itself: $\phi(\mathfrak{N}(D))=\mathfrak{N}(D)$. The restriction $\phi|_{\mathfrak{N}(D)}$ is then called the "*monodromy operator of the DE (D)*". It is one of the fundamental quantities of the DE (D). Further, one defines $\nu\in\mathbb{C}$ to be a "*characteristic exponent of the DE (D)*", iff $\exp(2\pi i\nu)$ is an eigenvalue of the monodromy operator $\phi|_{\mathfrak{N}(D)}$. This means especially that there exists a nontrivial solution y of (D) belonging to

$$\mathfrak{U}_\nu := (\phi-e^{2\pi i\nu})^{-1}(\{0\})=\{z^\nu\cdot h\,|\,h:\Omega\to\mathbb{C}\text{ holomorphic}\}. \tag{1.5}$$

A solution of this kind is called "*Floquet solution of the DE (D) with respect to the characteristic exponent ν*".

Let the set of all characteristic exponents of (D) be denoted by Ξ. Ξ is then characterized by

$$\nu\in\Xi\Leftrightarrow\cos 2\pi\nu=\frac{1}{2}\operatorname{trace}\phi\Big|_{\mathfrak{N}(D)}. \tag{1.6}$$

---

[1] For the sake of briefness we use the same symbol z for the point $(r,\varphi)\in\hat{\Omega}$ as well as for its projection $re^{i\varphi}\in\Omega$.

[2] For $z=(r,\varphi)$, $x=(\rho,\psi)\in\hat{\Omega}$ let $z\cdot x := (r\cdot\rho,\varphi+\psi)\in\hat{\Omega}$.

Thus, for any $\nu \in \Xi$ we have $\Xi = (\nu + \mathbb{Z}) \cup (-\nu + \mathbb{Z})$. For the sake of completeness we give a short proof of (1.6), using the nontrivial alternating form $[\cdot, \cdot]$ in (1.3): Let y_1, y_2 be a fundamental set of solutions of (D) with $[y_1, y_2] = 1$. We then have

$$(*) \qquad \det \phi|_{\mathfrak{N}(D)} = [\phi y_1, \phi y_2], \qquad \operatorname{trace} \phi|_{\mathfrak{N}(D)} = [\phi y_1, y_2] + [y_1, \phi y_2].$$

Since the Wronskian $w[y_1, y_2]$ is holomorphic in Ω, we obtain

$$w[\phi y_1, \phi y_2] = \phi(w[y_1, y_2]) = w[y_1, y_2]$$

and therefore

$$(**) \qquad \det \phi|_{\mathfrak{N}(D)} = [\phi y_1, \phi y_2] = [y_1, y_2] = 1.$$

Since the eigenvalues $\lambda = \exp(2\pi i \nu)$ of $\phi \mid_{\mathfrak{N}(D)}$ are determined by

$$\lambda^2 - \lambda \cdot \operatorname{trace} \phi|_{\mathfrak{N}(D)} + \det \phi|_{\mathfrak{N}(D)} = 0,$$

we immediately obtain (1.6).

It should be observed, however, that the representation of $\operatorname{trace} \phi \mid_{\mathfrak{N}(D)}$ in (*) does not provide an elementary means of calculating the characteristic exponents of (D).

Finally it turns out to be convenient introducing for $\nu \in \mathbb{C}$ the operator

$$(1.7) \qquad Q_\nu := \frac{1}{2\pi i}(\phi - e^{2\pi i \nu}).$$

Obviously, for $\nu \in \mathbb{C}$ and $y \in \mathscr{H}(\hat{\Omega})$

$$(1.8.1) \qquad \frac{\sin 2\pi\nu}{\pi} y = Q_{-\nu} y - Q_\nu y.$$

Moreover, for $\nu \in \Xi$ and $y \in \mathfrak{N}(D)$

$$(1.8.2) \qquad Q_{\mp\nu} y \in \mathfrak{U}_{\pm\nu} \cap \mathfrak{N}(D).$$

In the "*normal case*" of the DE (D) where

$$2\nu \notin \mathbb{Z} \text{ for (one and hence for all) } \nu \in \Xi$$

the formula (1.8.1) thus yields a unique representation of each $y \in \mathfrak{N}(D)$ in terms of Floquet solutions.

1.2. Floquet and asymptotic solutions of the DE (0.2). In terms of the operator L_κ the DE (0.2) can be written in the form

$$(D_\mu) \qquad D_\mu y := L_\kappa y - \mu^2 y = 0,$$

where $\kappa, \mu \in \mathbb{C}$. By the transformations

$$y(z) = e^{\mp iz} \cdot z^\mu \cdot u(x), \qquad x = \pm 2iz,$$

this DE is equivalent to the confluent hypergeometric DE

$$xu'' + (c - x)u' - au = 0,$$

where $a = \frac{1}{2} \mp \kappa + \mu$, $c = 1 + 2\mu$.

Introducing a slightly modified Φ function

$$\tilde{\Phi}(a;\, c;\, x) := \sum_{n=0}^{\infty} \frac{(a)_n}{\Gamma(c+n)} \frac{x^n}{n!} \qquad (x \in \mathbb{C}),$$

where $(a)_n = \Gamma(a+n)/\Gamma(a) = a(a+1)\cdots(a+n-1)$, we obtain by

$$I_{\kappa,\mu}(z) := e^{-iz} \cdot z^{\mu} \cdot \tilde{\Phi}\left(\frac{1}{2} - \kappa + \mu;\, 1+2\mu;\, 2iz\right) \tag{1.9}$$

a solution of the DE (D_μ). $\tilde{\Phi}$ being holomorphic with respect to (x,a,c); the same is true for $I_{\kappa,\mu}$ with respect to (z,κ,μ). Obviously, $I_{\kappa,\mu}$ belongs to $\mathfrak{U}_\mu$ and is hence a Floquet solution of (D_μ), if $\neq 0$; this is especially true for $2\mu \notin \mathbb{Z}$.

Since the DE (D_μ) is invariant under the substitution $\mu \to -\mu$, we obtain by $I_{\kappa,-\mu}$ a second solution of (D_μ), which now belongs to $\mathfrak{U}_{-\mu}$ and is $\neq 0$ for $2\mu \notin \mathbb{Z}$. Therefore, in the case of $2\mu \notin \mathbb{Z}$, $I_{\kappa,\mu}$ and $I_{\kappa,-\mu}$ constitute a fundamental set of solutions.

Introducing the Ψ function (see e.g. [3, p. 255]), we obtain by

$$H^{\pm}_{\kappa,\mu}(z) := (2e^{\mp \pi i/2})^{1/2 \pm \kappa + \mu} \cdot e^{\pm iz} \cdot z^{\mu} \cdot \Psi\left(\frac{1}{2} \pm \kappa + \mu;\, 1+2\mu;\, 2e^{\mp \pi i/2} \cdot z\right) \tag{1.10}$$

solutions of the DE (D_μ), which possess the asymptotic expansions

$$H^{\pm}_{\kappa,\mu}(z) \sim e^{\pm iz} \cdot z^{-1/2 \mp \kappa} \sum_{m=0}^{\infty} \frac{(1/2 \pm \kappa + \mu)_m (1/2 \pm \kappa - \mu)_m}{m!} \cdot (\pm 2iz)^{-m} \tag{1.11}$$

as $|z| \to \infty$ within the sectors $|\arg z \mp \pi/2| < 3\pi/2$. Here—and also in the following—let the upper and lower signs always be taken simultaneously.

The different asymptotic behavior of $H^{+}_{\kappa,\mu}$ and $H^{-}_{\kappa,\mu}$ implies that these functions constitute a fundamental set of solutions of the DE (D_μ) without any restrictions to the values of κ and μ.

The functions $H^{\pm}_{\kappa,\mu}$ possess the following representations as Laplace integrals

$$H^{\pm}_{\kappa,\mu}(z) = e^{\pm iz} \cdot z^{1/2 \mp \kappa} \cdot \int_0^{\infty \cdot e^{-i\xi}} e^{-zt}\, {}_2F_1\left(\frac{1}{2} \pm \kappa + \mu,\, \frac{1}{2} \pm \kappa - \mu;\, 1;\, \pm \frac{t}{2i}\right) dt, \tag{1.12}$$

which are valid for $z \in \hat{\Omega}$ with $|\arg z - \xi| < \pi/2$ where $\xi \in \mathbb{R}$ with $|\xi \mp \pi/2| < \pi$. This follows e.g. from [3, p. 273] by transformations, but may also be easily verified directly. Using (1.12) as definition, one immediately finds (1.11) by means of Watson's lemma. (See e.g. [11, p. 114] or [14, p. 40]).

From (1.12) we also obtain that the $H^{\pm}_{\kappa,\mu}$ are holomorphic with respect to (z,κ,μ) and satisfy

$$H^{\pm}_{\kappa,-\mu} = H^{\pm}_{\kappa,\mu} \tag{1.13}$$

In the very special situation of the DE (D_μ) one can determine the connection between the Floquet solutions $I_{\kappa,\pm\mu}$ and the asymptotic solutions $H^{\pm}_{\kappa,\mu}$ explicitly. Defining

$$I^{\pm}_{\kappa,\mu} := Q_{-\mu} H^{\pm}_{\kappa,\mu}, \tag{1.14}$$

we obtain by (1.8.1)

$$\frac{\sin 2\pi\mu}{\pi} H^{\pm}_{\kappa,\mu} = I^{\pm}_{\kappa,\mu} - I^{\pm}_{\kappa,-\mu} \tag{1.15}$$

and by (1.8.2) $I^{\pm}_{\kappa,\mu}\in \mathfrak{U}_{\mu}\cap \mathfrak{U}(D_{\mu})$. Using the connection formula between the Φ and Ψ functions (see e.g. [3, p. 257]) we finally find

$$I^{\pm}_{\kappa,\mu}=-(2e^{\mp \pi i/2})^{1/2\pm\kappa+\mu}\cdot\frac{1}{\Gamma(1/2\pm\kappa-\mu)}\cdot I_{\kappa,\mu}. \tag{1.16}$$

1.3. Series in terms of Floquet solutions of the DE (0.2). Throughout this section let $\nu\in\mathbb{C}$ with $2\nu\notin\mathbb{Z}$ and $\frac{1}{2}-\kappa+\nu\notin\mathbb{Z}$. The first condition implies $\mathfrak{U}_{\nu}\cap\mathfrak{U}_{-\nu}=\{0\}$ and both together $I^{\pm}_{\kappa,\mu}\neq 0$ for $\mu\in\pm\nu+\mathbb{Z}$.

For any two functions $y^{\pm}\in\mathfrak{U}_{\pm\nu}$ the product $y^{+}\cdot y^{-}$ is a holomorphic function on Ω. Hence we can define

$$\langle y^{+},y^{-}\rangle:=\langle y^{-},y^{+}\rangle:=\frac{1}{2\pi i}\oint_{|z|=\rho} y^{+}(z)y^{-}(z)\frac{dz}{z} \tag{1.17}$$

with an arbitrary $r<\rho<\infty$. Obviously, this expression is linear with respect to y^{+} and y^{-}.

Since the operator L_{κ} commutes with ϕ, the spaces $\mathfrak{U}_{\pm\nu}$ are invariant under L_{κ}. One easily verifies for $y^{\pm}\in\mathfrak{U}_{\pm\nu}$

$$\langle L_{\kappa}y^{+},y^{-}\rangle=\langle y^{+},L_{\kappa}y^{-}\rangle. \tag{1.18}$$

The results of the preceding section show that both eigenvalue problems

$$L_{\kappa}y^{\pm}=\lambda y^{\pm}\qquad(\lambda\in\mathbb{C};\ 0\neq y\in\mathfrak{U}_{\pm\nu})$$

possess the same eigenvalues, namely $\lambda=\mu^{2}$ with $\mu\in\nu+\mathbb{Z}$, and that the corresponding eigenfunctions are just $I^{+}_{\kappa,\mu}\in\mathfrak{U}_{\nu}$ and $I^{-}_{\kappa,-\mu}\in\mathfrak{U}_{-\nu}$. Using (1.18) as well as (1.16) and (1.9) then yields

$$\langle I^{+}_{\kappa,\mu+n},I^{-}_{\kappa,-\mu}\rangle=\delta_{n,0}\cdot\varepsilon_{\kappa,\mu}\qquad(\mu\in\nu+\mathbb{Z},\ n\in\mathbb{Z}) \tag{1.19}$$

where $\delta_{n,m}$ denotes the Kronecker symbol and

$$\varepsilon_{\kappa,\mu}:=e^{-i\pi(\kappa+\mu)}\cdot\frac{\sin\pi(1/2-\kappa+\mu)}{\pi}\cdot\frac{\sin 2\pi\mu}{\pi\mu}\neq 0\qquad(\mu\in\nu+\mathbb{Z}). \tag{1.20}$$

We now state a theorem which ensures the expansion of any function $y^{\pm}\in\mathfrak{U}_{\pm\nu}$ in terms of the eigenfunctions $I^{\pm}_{\kappa,\pm\mu}$ $(\mu\in\nu+\mathbb{Z})$. This theorem, which is fundamental for the following analysis, can be deduced easily from a corresponding theorem on expansions in terms of Whittaker functions found by F. W. Schäfke. (See e.g. [13, p. 177] or [14, p. 228].)

(1.21) THEOREM. *Each $y^{\pm}\in\mathfrak{U}_{\pm\nu}$ has an expansion*

$$y^{\pm}(z)=\sum_{\mu\in\pm\nu+\mathbb{Z}} c_{\mu}\cdot I^{\pm}_{\kappa,\mu}(z)\qquad(z\in\hat{\Omega}), \tag{1.21.1}$$

which converges absolutely and uniformly on compact subsets of $\hat{\Omega}$. The coefficients are uniquely determined by

$$c_{\mu}\cdot\varepsilon_{\kappa,\pm\mu}=\langle y^{\pm},I^{\mp}_{\kappa,-\mu}\rangle\qquad(\mu\in\pm\nu+\mathbb{Z}). \tag{1.21.2}$$

Moreover, the following asymptotic formula for the $I^{\pm}_{\kappa,\mu}$ holds. (See e.g. [13, p. 180] or [14, p. 245].)

(1.22) *Let for* $\mu \in \pm\nu + \mathbb{Z}$ *the functions* $g_{\kappa,\mu}: \mathbb{C} \to \mathbb{C}$ *be defined by*

$$I^{\pm}_{\kappa,\mu}(z) =: -(2e^{\mp i\pi/2})^{1/2\pm\kappa+\mu} \cdot \frac{z^{\mu}}{\Gamma(1+2\mu)\Gamma(1/2\pm\kappa-\mu)} g_{\kappa,\mu}(z).$$

Then

$$g_{\kappa,\pm\nu+n}(z) = 1 + O\left(\frac{1}{n}\right) \qquad (|n| \to \infty)$$

uniformly on compact subsets of $\mathbb{C}$.

Theorem (1.21) serves as a main tool to transform and study the DE (D) in suitable sequence spaces. For this purpose we make the following preliminary remarks.

Let $y^{\pm} \in \mathfrak{U}_{\pm\nu}$ and let $(c_{\mu})_{\mu \in \pm\nu+\mathbb{Z}}$ be the corresponding sequences of coefficients determined by (1.21.2). From (1.22) we obtain then

$$\lim_{n\to\infty} \left(|c_{\pm\nu+n}| \cdot (n!)^{-1}\right)^{1/n} = 0 \tag{1.23.1}$$

and

$$\limsup_{n\to\infty} \left(|c_{\pm\nu-n}| \cdot n!\right)^{1/n} \leqq \frac{r}{2}. \tag{1.23.2}$$

On the other hand, let $(c_{\mu})_{\mu \in \pm\nu+\mathbb{Z}}$ be sequences which behave like (1.23.1) and (1.23.2). Using (1.22) again, we find that the corresponding series (1.21.1) converge and define functions $y^{\pm} \in \mathfrak{U}_{\pm\nu}$. Moreover, the sequences $(c_{\mu})_{\mu \in \pm\nu+\mathbb{Z}}$ can be obtained back by (1.21.2). Introducing thus the vector spaces

$$\tilde{\mathfrak{U}}_{\pm\nu} := \left\{ c \in \mathbb{C}^{\pm\nu+\mathbb{Z}} \mid c \text{ behaves like (1.23.1) and (1.23.2)} \right\},$$

we have just seen that these are through (1.21.1), (1.21.2) isomorphic to $\mathfrak{U}_{\pm\nu}$, respectively.

For studying the DE (D) in $\tilde{\mathfrak{U}}_{\pm\nu}$, it becomes necessary to find the corresponding representations of the operators L_{κ} and G in $\tilde{\mathfrak{U}}_{\pm\nu}$. More generally, we consider an arbitrary differential operator of the form

$$Sy := \sum_{j=0}^{m} s_j \left(\frac{d}{dz}\right)^j y \qquad (y \in \mathscr{H}(\hat{\Omega})), \tag{1.24}$$

where $m \in \mathbb{N}$ and the coefficients s_j $(j = 0, \cdots, m)$ are holomorphic in Ω. Since S and ϕ commute, the spaces $\mathfrak{U}_{\pm\nu}$ are invariant under S. Hence, S has a representation in $\tilde{\mathfrak{U}}_{\pm\nu}$ which we denote by $\tilde{S}$. Letting $c = (c_{\mu})_{\mu \in \pm\nu+\mathbb{Z}} \in \tilde{\mathfrak{U}}_{\pm\nu}$ and $d = (d_{\mu})_{\mu \in \pm\nu+\mathbb{Z}} := \tilde{S}c \in \tilde{\mathfrak{U}}_{\pm\nu}$, we immediately obtain by (1.21)

$$d_{\mu} = \frac{1}{\varepsilon_{\kappa,\pm\mu}} \cdot \sum_{l\in\mathbb{Z}} \left\langle SI^{\pm}_{\kappa,\mu+l}, I^{\mp}_{\kappa,-\mu} \right\rangle \cdot c_{\mu+l} \qquad (\mu \in \pm\nu + \mathbb{Z}). \tag{1.25}$$

An important role in the following analysis plays the explicit knowledge of the representations of the special operators $1/z \cdot$ and d/dz in $\tilde{\mathfrak{U}}_{\pm\nu}$. These result from the following three-term recurrence relations

$$\begin{aligned} \frac{\mu}{z} I^{\pm}_{\kappa,\mu} &= \frac{i}{2}\left(\mp \frac{\mu \pm \kappa + 1/2}{\mu + 1/2} I^{\pm}_{\kappa,\mu+1} + \frac{2\kappa\mu}{\mu^2 - 1/4} I^{\pm}_{\kappa,\mu} \pm \frac{\mu \mp \kappa - 1/2}{\mu - 1/2} I^{\pm}_{\kappa,\mu-1} \right), \\ \frac{d}{dz} I^{\pm}_{\kappa,\mu} &= \frac{i}{2}\left(\pm \frac{\mu \pm \kappa + 1/2}{\mu + 1/2} I^{\pm}_{\kappa,\mu+1} + \frac{\kappa}{\mu^2 - 1/4} I^{\pm}_{\kappa,\mu} \pm \frac{\mu \mp \kappa - 1/2}{\mu - 1/2} I^{\pm}_{\kappa,\mu-1} \right), \end{aligned} \tag{1.26}$$

which can readily be obtained from [2, p. 82].

By the use of (1.26) we derive

(1.27) PROPOSITION. *Let S be an operator of the form* (1.24) *with coefficients s_j being holomorphic in $\Omega \cup \{\infty\}$. Then for $\mu \in \pm\nu + \mathbb{Z}$ and $n \in \mathbb{Z}$*

$$\frac{\Gamma(1/2 \pm \kappa - \mu - n)}{\Gamma(1/2 \pm \kappa - \mu)} \left\langle SI^{\pm}_{\kappa,\mu+n}, I^{\mp}_{\kappa,-\mu} \right\rangle = \frac{\Gamma(1/2 \pm \kappa - \mu)}{\Gamma(1/2 \pm \kappa - \mu - n)} \left\langle SI^{\mp}_{\kappa,-\mu-n}, I^{\pm}_{\kappa,\mu} \right\rangle.$$

The proof follows in several steps:

1) For $S = identity$ the formula is trivial by (1.19). For $S = 1/z \cdot$ and $S = d/dz$ it can directly be verified by using (1.26) and (1.19). In the first case both sides vanish for $|n| \geqq 1$ and in the latter for $|n| \geqq 2$.

2) Let now S_1 and S_2 be operators of the form (1.24) for which the formula (1.27) is valid. Obviously, it holds then for $S_1 + S_2$, too. A straightforward calculation using (1.25) shows that it also holds for $S_2 \circ S_1$.

3) According to 1) and 2) formula (1.27) is valid for operators of the form (1.24) where the s_j are polynomials in $1/z$. But then the general case immediately follows by a simple limiting process.

We finally prove

(1.28) PROPOSITION. *Let $0 < \tau < \rho < \infty$. Then for each $l \in \mathbb{Z}$ there exists a constant $\gamma_l = \gamma_l(\tau, \rho) > 0$ such that for all $k \in \mathbb{N}$ and all $n \in \mathbb{Z}$*

$$\left| \frac{1}{\varepsilon_{\kappa,\nu\pm n}} \left\langle z^{-k} I^{\pm}_{\kappa,\pm\nu+l}, I^{\mp}_{\kappa,\mp\nu-n} \right\rangle \right| \leqq \gamma_l \cdot \frac{\rho^{|n|}}{|n|!} (2\tau)^{-k}.$$

For $n \leqq N$ the inequality follows directly with (1.17) and (1.22) by estimating the integral at $|z| = 2\tau$. The case $n > N$ then can be reduced to the former case by means of (1.27). Here N has to be chosen large enough such that (1.27) is applicable.

1.4. Series in terms of asymptotic solutions of the DE (0.2). Throughout this section let $\nu, \kappa \in \mathbb{C}$ be arbitrary. We prove in the following

(1.29) THEOREM. *Let $(c_n) \in \mathbb{C}^{\mathbb{Z}}$ satisfy*

$$\limsup_{n \to \pm\infty} \left(|c_n| \cdot |n|! \right)^{1/|n|} \leqq \frac{r}{2}.$$

Then the series

$$H^{\pm}(z) := \sum_{n \in \mathbb{Z}} c_n \cdot H^{\pm}_{\kappa,\nu+n}(z) \qquad (z \in \hat{\Omega}) \tag{1.29.1}$$

define holomorphic functions in $\hat{\Omega}$ which possess the asymptotic expansions

$$H^{\pm}(z) \sim e^{\pm iz} \cdot z^{-1/2 \mp \kappa} \cdot \sum_{m=0}^{\infty} \frac{\tilde{c}^{\pm}_m}{m!} \cdot (\pm 2iz)^{-m} \tag{1.29.2}$$

as $|z| \to \infty$ within the sectors $|\arg z \mp \pi/2| < 3\pi/2$, where the coefficients $\tilde{c}^{\pm}_m$ are given by

$$\tilde{c}^{\pm}_m := \sum_{n \in \mathbb{Z}} c_n \cdot \left(\frac{1}{2} \pm \kappa + \nu + n \right)_m \cdot \left(\frac{1}{2} \pm \kappa - \nu - n \right)_m. \tag{1.29.3}$$

By the use of (1.15) and (1.22) it follows that the series (1.29.1) converge absolutely and uniformly on compact subsets of $\hat{\Omega}$ and hence define holomorphic functions in $\hat{\Omega}$. It remains to prove the asymptotic behavior. This may be done by representing $H^{\pm}$ as a Laplace integral and then applying Watson's lemma.

To simplify the following consideration let us assume that $c_n = 0$ for $n < N$, where $N \in \mathbb{N}$ with $\mathrm{Re}(\frac{1}{2} \pm \kappa + \nu + N) \geqq 1$. This means no restriction since by (1.13) one achieves at once $c_n = 0$ for $n < 0$ and the remaining finite series can be tackled directly by means of (1.11).

The representation (1.12) of $H^{\pm}_{\kappa,\mu}$ suggests that one study the series

$$f^{\pm}(\zeta) := \sum_{n=N}^{\infty} c_n \, {}_2F_1\left(\frac{1}{2} \pm \kappa + \nu + n, \, \frac{1}{2} \pm \kappa - \nu - n; \, 1; \, \zeta\right) \tag{1.30}$$

for $\zeta \in \mathbb{C} \setminus [1, +\infty[$. In view of this we prove

(1.31) LEMMA. *Let $a, b \in \mathbb{C}$ and $m \in \mathbb{N}$ with $\mathrm{Re}\, a \geqq 1$ and $m \geqq -\mathrm{Re}\, b$. Further, let $0 < \delta < 1$, $0 < \varphi < \pi/2$, $4 < \sigma < \infty$. Then there exist constants $0 < M < \infty$, $0 < \gamma < \infty$ and $1 < \rho < \infty$ such that for all $\zeta \in \mathbb{C}$ with $|\zeta| \leqq \delta$ or $\varphi \leqq \arg \zeta \leqq 2\pi - \varphi$ and for all $n \in \mathbb{N}$*

$$|{}_2F_1(a+n, \, b-n; \, 1; \, \zeta)| \leqq M \cdot \begin{cases} \sigma^n |\zeta|^{n+m} & (|\zeta| \geqq \rho), \\ \gamma^n & (|\zeta| \leqq \rho). \end{cases}$$

Proof. For $\zeta \in \mathbb{C} \setminus [1, +\infty[$ and $n \in \mathbb{N}$ the following integral representation is valid:

$${}_2F_1(a+n, \, b-n; \, 1; \, \zeta) = \frac{e^{i\pi(a+n)}}{2\pi i} \int_{\mathfrak{C}} t^{a-1} \cdot (1-t)^{-a} \cdot (1-t\zeta)^{-b} \cdot \left(\frac{t}{1-t}(1-t\zeta)\right)^n dt.$$

Here $\mathfrak{C}$ is a contour starting and ending at 0 and encircling 1 once in the positive sense which, moreover, is to be suitably chosen with respect to ζ. All powers are to be taken with their principal values near the initial point $t = 0$. (See e.g. [3, p. 60].)

A convenient choice for our purposes is given by the contour $\mathfrak{C}_\varepsilon$ (with $0 < \varepsilon < 1$) comprising the line segments $\overline{0\varepsilon}$ and $\overline{\varepsilon 0}$ together with the circle $|\zeta - 1| = 1 - \varepsilon$ taken in the positive sense. We intend to estimate the four factors of the integrand separately along $\mathfrak{C}_\varepsilon$. To this end let for the present $0 < \varepsilon < 1$ and $0 < \rho < \infty$ be arbitrary.

Then, for $t \in \mathfrak{C}_\varepsilon$

$$(\alpha) \qquad |t| \leqq 2 - \varepsilon, \qquad 1 - \varepsilon \leqq |1 - t| \leqq 1.$$

Furthermore, for $t \in \mathfrak{C}_\varepsilon$ and $\zeta \in \mathbb{C}$

$$(\beta 1) \qquad |1 - t\zeta| \leqq 2|\zeta| \qquad \text{if } |\zeta| \geqq \rho \geqq \frac{1}{\varepsilon},$$

$$(\beta 2) \qquad |1 - t\zeta| \leqq 1 + (2-\varepsilon)\rho \qquad \text{if } |\zeta| \leqq \rho,$$

as well as

$$(\gamma 1) \qquad |1 - t\zeta| \geqq \sin\varphi \qquad \text{if } 0 \leqq t \leqq \varepsilon, \quad \varphi \leqq \arg\zeta \leqq 2\pi - \varphi,$$

$$(\gamma 2) \qquad |1 - t\zeta| \geqq \rho\varepsilon - 1 \qquad \text{if } |t-1| \geqq 1 - \varepsilon, \quad |\zeta| \geqq \rho > \frac{1}{\varepsilon},$$

$$(\gamma 3) \qquad |1 - t\zeta| \geqq 1 - \delta(2-\varepsilon) \qquad \text{if } |\zeta| \leqq \delta,$$

$$(\gamma 4) \qquad |1 - t\zeta| \geqq \sin\frac{\varphi}{2} \qquad \text{if } \varphi \leqq \arg\zeta \leqq 2\pi - \varphi, \quad 1 - \varepsilon \leqq \sin\frac{\varphi}{2},$$

and

$$(\gamma 5) \qquad |\arg(1 - t\zeta)| \text{ bounded in each of the latter four cases.}$$

To prove the first inequality in (1.31), we choose $0<\varepsilon_1<1$ with $2(2-\varepsilon_1)/(1-\varepsilon_1)<\sigma$ and after that $1/\varepsilon_1<\rho<\infty$. Estimating the integral along $\mathfrak{C}_{\varepsilon_1}$ by the use of (α), $(\beta 1)$ $(\gamma 1)$, $(\gamma 2)$ and $(\gamma 5)$ then yields the desired result. To prove the second inequality in (1.31), we choose now $0<\varepsilon_2<1$ with $\delta\cdot(2-\varepsilon_2)<1$ and $1-\varepsilon_2\leqq\sin(\varphi/2)$. Estimating the integral along $\mathfrak{C}_{\varepsilon_2}$ by the use of (α), $(\beta 2)$, $(\gamma 3)$, $(\gamma 4)$ and $(\gamma 5)$ then yields the inequality for $|\zeta|\leqq\rho$. This completes the proof of the lemma.

We continue now in the proof of (1.29). Lemma (1.31) shows that the series (1.30) converge absolutely and uniformly on compact subsets of $\mathbb{C}\setminus[1,+\infty[$ and hence define holomorphic functions $f^{\pm}:\mathbb{C}\setminus[1,+\infty[\to\mathbb{C}$. One readily verifies the following power series representation at 0:

$$(*)\qquad f^{\pm}(\zeta)=\sum_{m=0}^{\infty}\frac{\tilde{c}_m^{\pm}}{m!}\frac{\zeta^m}{m!}\qquad(|\zeta|<1).$$

Using the first inequality in (1.31) again, one obtains, on the other hand, for arbitrary $0<\varphi<\pi/2$ and $r<\tilde{r}<\infty$ the inequality

$$(**)\qquad |f^{\pm}(\zeta)|\leqq\exp(2\tilde{r}|\zeta|),$$

being valid for all $\zeta\in\mathbb{C}$ with $\varphi\leqq\arg\zeta\leqq 2\pi-\varphi$ and $|\zeta|\geqq\rho$, where $1<\rho<\infty$ is to be chosen sufficiently large. Obviously, the right member in $(**)$ is also a bound for all partial sums of the series (1.30). This especially permits one to interchange summation and integration in the situation (1.29.1), (1.12) by means of the Lebesgue dominated convergence theorem and finally leads to the Laplace integral

$$(1.32)\qquad H^{\pm}(z)=e^{\pm iz}\cdot z^{1/2\mp\kappa}\cdot\int_0^{\infty\cdot e^{-i\xi}}e^{-zt}\cdot f^{\pm}\left(\pm\frac{t}{2i}\right)dt,$$

which is then valid for $z\in\hat{\Omega}$ with $\mathrm{Re}\,ze^{-i\xi}>r$ where $\xi\in\mathbb{R}$ with $|\xi\mp\pi/2|<\pi$.

Having $(*)$ and $(**)$ available, one can now immediately apply Watson's lemma onto the situation (1.32). This yields then the asymptotic expansions (1.29.2) as $|z|\to\infty$ within the half-planes $\mathrm{Re}\,ze^{-i\xi}>r$ where $\xi\in\mathbb{R}$ with $|\xi\mp\pi/2|<\pi$. To obtain the asymptotic expansion within the full sectors $|\arg z\mp\pi/2|<3\pi/2$, one has to choose an appropriate covering.

2. The global representation of the solutions of the DE (0.1) by series in terms of solutions of the DE (0.2). Throughout this chapter we assume that the DE (D) is in the "normal case", which means $2\nu\notin\mathbb{Z}$ for (one and hence for all) $\nu\in\Xi$. Then, for every $\nu\in\Xi$, we have $\frac{1}{2}-\kappa+\nu\notin\mathbb{Z}$ or $\frac{1}{2}+\kappa+\nu\notin\mathbb{Z}$ (since the sum of both quantities is $2\nu+1\notin\mathbb{Z}$). Considering $\nu\in\Xi\Leftrightarrow-\nu\in\Xi$, we may thus assume that a

$$\nu\in\Xi\text{ with }2\nu\notin\mathbb{Z}\quad\text{and}\quad\frac{1}{2}-\kappa+\nu\notin\mathbb{Z}$$

is chosen and fixed for the following. (This is done with regard to the unrestricted applicability of the results in §1.3). We then especially have $\Xi=(\nu+\mathbb{Z})\cup(-\nu+\mathbb{Z})$.

2.1. Transformation of the DE (0.1) into sequence spaces. According to (1.8.1), (1.8.2) each $y\in\mathfrak{N}(D)$ has a (unique) representation $y=y^{+}+y^{-}$ with $y^{\pm}\in\mathfrak{U}_{\pm\nu}\cap\mathfrak{N}(D)$. We shall thus consider in the following always (pairs of) functions $y^{\pm}\in\mathfrak{U}_{\pm\nu}$.

Let $y^{\pm}\in\mathfrak{U}_{\pm\nu}\cap\mathfrak{N}(D)$. Then, according to §1.3, the corresponding sequences $(c_\mu)_{\mu\in\pm\nu+\mathbb{Z}}\in\tilde{\mathfrak{U}}_{\pm\nu}$ defined by (1.21.2) are solutions of the equation

$$\tilde{L}_\kappa c+\tilde{G}c=0,$$

which can also be written in the more explicit form

$$\mu^2 \cdot c_\mu + \frac{1}{\varepsilon_{\kappa,\pm\mu}} \cdot \sum_{l\in\mathbb{Z}} \left\langle G I^{\pm}_{\kappa,\mu+l}, I^{\mp}_{\kappa,-\mu} \right\rangle \cdot c_{\mu+l} = 0, \qquad (\mu \in \pm\nu + \mathbb{Z}). \tag{2.1}$$

This follows immediately from (1.25) with $S = L_\kappa$ and $S = G$; the off-diagonal terms of $\tilde{L}_\kappa$ vanish due to $L_\kappa I^{\pm}_{\kappa,\mu} = \mu^2 I^{\pm}_{\kappa,\mu}$ and (1.19).

In the following, we also need the converse statement: Let the sequences $(c_\mu)_{\mu\in\pm\nu+\mathbb{Z}}$ be solutions of (2.1) belonging to $\tilde{\mathfrak{U}}_{\pm\nu}$, which means by (1.23) that they have the asymptotic behavior (1.23.1) and (1.23.2). Then, according to §1.3, the corresponding functions $y^{\pm} \in \mathfrak{U}_{\pm\nu}$ defined by (1.21.1) are solutions of (D), so $y^{\pm} \in \mathfrak{U}_{\pm\nu} \cap \mathfrak{N}(D)$.

The main aim of the following analysis is to improve the asymptotic behavior (1.23.1) for the solutions of the equation (2.1). This means to show that the solutions of (2.1) belong to other specific sequence spaces. We thus have to put the equation into a suitable form such that it can also be treated in the other sequence spaces in question.

For this purpose we define, for the moment only for sequences $c = (c_\mu)_{\mu\in\pm\nu+\mathbb{Z}} \in \tilde{\mathfrak{U}}_{\pm\nu}$,

$$(Tc)_\mu := \frac{1}{\mu} c_\mu, \tag{2.2}$$

$$(Ac)_\mu := \frac{1}{\varepsilon_{\kappa,\pm\mu}} \cdot \sum_{l=-1}^{1} \left\langle \frac{1}{z} \cdot I^{\pm}_{\kappa,\mu+l},\ I^{\mp}_{\kappa,-\mu} \right\rangle \cdot c_{\mu+l}, \tag{2.3}$$

$$(Bc)_\mu := \frac{1}{\mu \cdot \varepsilon_{\kappa,\pm\mu}} \cdot \sum_{l=-1}^{1} \left\langle \frac{d}{dz} \cdot I^{\pm}_{\kappa,\mu+l},\ I^{\mp}_{\kappa,-\mu} \right\rangle \cdot c_{\mu+l}, \tag{2.4}$$

$$(G_m c)_\mu := \frac{1}{\varepsilon_{\kappa,\pm\mu}} \cdot \sum_{l\in\mathbb{Z}} \left\langle g_m I^{\pm}_{\kappa,\mu+l},\ I^{\mp}_{\kappa,-\mu} \right\rangle \cdot c_{\mu+l}. \tag{2.5}$$

$(\mu \in \pm\nu + \mathbb{Z})$

Obviously, the sequences Tc, Ac, Bc and $G_m c$ belong to $\tilde{\mathfrak{U}}_{\pm\nu}$ and, hence, T, A, B and G_m are operators in $\tilde{\mathfrak{U}}_{\pm\nu}$. With the notation of §1.3 we especially have

$$T^2 = \tilde{L}_k^{-1}, \quad A = \left(\widetilde{\frac{1}{z}\cdot}\right), \quad B = T \circ \left(\widetilde{\frac{d}{dz}}\right), \quad G_m = \left(\widetilde{g_m \cdot}\right).$$

Thus, (2.1) is equivalent to

$$c + T \circ (B \circ G_1 + T \circ G_2) c = 0. \tag{2.6}$$

2.2. Solution of the DE (0.1) in sequence spaces. Let $0 < \rho < \infty$. By means of

$$\omega_1(n) := \frac{\rho^{|n|}}{|n|!}, \qquad \omega_2(n) := \frac{|n|!}{\rho^{|n|}} \qquad (n \in \mathbb{Z})$$

we define for $j = 1, 2$ the sequence spaces

$$\mathfrak{M}_j^{\pm} := \left\{ (c_\mu) \in \mathbb{C}^{\pm\nu+\mathbb{Z}} \,\middle|\, \exists \gamma > 0 \text{ s.t. } |c_{\pm\nu+n}| \leqq \gamma \cdot \omega_j(n),\ (n \in \mathbb{Z}) \right\}$$

and for $c = (c_\mu) \in \mathfrak{M}_j^{\pm}$ respectively the norms

$$\|c\|_j := \min\left\{ \gamma \geqq 0 \,\middle|\, |c_{\pm\nu+n}| \leqq \gamma \cdot \omega_j(n),\ (n \in \mathbb{Z}) \right\}.$$

Obviously, the $\mathfrak{M}_j^{\pm}$ (with corresponding norm $\|\cdot\|_j$) are Banach spaces and

$$\mathfrak{M}_1^{\pm} \hookrightarrow \mathfrak{M}_2^{\pm} \quad \text{continuously imbedded.}$$

We intend to study the equation (2.6) in the spaces $\mathfrak{M}_j^{\pm}$, $(j=1,2)$. We thus show at first

(2.7) PROPOSITION. *The formulas* (2.2), (2.3) *and* (2.4) *define continuous operators* T, A *and* B *in each of the spaces* $\mathfrak{M}_j^{\pm}$ $(j=1,2)$.

Proof. The case (2.2) is obvious. Since the cases (2.3) and (2.4) are quite analogous, we restrict ourselves to the case (2.3). Let $c=(c_\mu)\in\mathfrak{M}_j^{\pm}$. Using (1.26) we obtain for $\mu\in\pm\nu+\mathbb{Z}$

$$(Ac)_\mu = \pm\frac{i}{2}\left(1\mp\frac{\kappa}{\mu+1/2}\right)\frac{c_{\mu+1}}{\mu+1}+\frac{i\kappa}{\mu^2-1/4}c_\mu\mp\frac{i}{2}\left(1\pm\frac{\kappa}{\mu-1/2}\right)\cdot\frac{c_{\mu-1}}{\mu-1}.$$

This immediately yields the inequality

$$|(Ac)_{\pm\nu+n}|\leqq\frac{1}{2\rho}\cdot\sigma_n\cdot\omega_j(n)\cdot\|c\|_j \qquad (n\in\mathbb{Z}), \tag{2.8.1}$$

where the σ_n are independent of c and

$$\mathbb{R}^+\ni\sigma_n\to 1 \qquad (|n|\to\infty). \tag{2.8.2}$$

Especially, for $c\in\mathfrak{M}_j^{\pm}$

$$Ac\in\mathfrak{M}_j^{\pm} \quad\text{and}\quad \|Ac\|_j\leqq\frac{1}{2\rho}\cdot\sup_{n\in\mathbb{Z}}\sigma_n\cdot\|c\|_j.$$

The case (2.5) is more difficult. We shall essentially show that like the g_m are power series in $1/z$ the corresponding G_m are power series in A.

We consider for $N\in\mathbb{N}$ the projection P_N which we define for $c=(c_\mu)\in\mathfrak{M}_j^{\pm}$ by

$$(P_Nc)_{\pm\nu+n} := \begin{cases} c_{\pm\nu+n} & (|n|>N),\\ 0 & (|n|\leqq N).\end{cases}$$

Obviously, the P_N are continuous operators in $\mathfrak{M}_j^{\pm}$ satisfying

$$\|P_N\|_j\leqq 1 \quad\text{and}\quad \|1-P_N\|_j\leqq 1.$$

Here, $\|\cdot\|_j$ denotes the corresponding operator norm. From (2.8.1) and (2.8.2) we immediately obtain

(2.9) COROLLARY. *To each* $0<\tau<\rho$ *there exists a* $N\in\mathbb{N}$ *with*

$$\|A\circ P_N\|_j\leqq\frac{1}{2\tau}.$$

We can prove now

(2.10) PROPOSITION. *In the case* $r/2<\rho<\infty$ *the formula* (2.5) *defines continuous operators* G_1 *and* G_2 *in each of the spaces* $\mathfrak{M}_j^{\pm}$ $(j=1,2)$.

Proof. Let $r/2<\tau<\sigma<\rho$ be fixed and $N\in\mathbb{N}$ be chosen to τ according to (2.9).

(i) Using (1.25), one readily finds for $k\in\mathbb{N}$ and $c=(c_\mu)\in\mathfrak{M}_j^{\pm}$

$$(A^kc)_\mu=\frac{1}{\varepsilon_{\kappa,\pm\mu}}\cdot\sum_{|l|\leqq k}\left\langle z^{-k}I^{\pm}_{\kappa,\mu+l},\ I^{\mp}_{\kappa,-\mu}\right\rangle\cdot c_{\mu+l} \qquad (\mu\in\pm\nu+\mathbb{Z}). \tag{2.11}$$

Estimating with (1.28), this yields for $c=(c_\mu)\in\operatorname{range}(1-P_N)$

$$|(A^k c)_{\pm\nu+n}|\leqq\Big(\sum_{|l|\leqq N}\gamma_l\cdot|c_{\pm\nu+l}|\Big)\cdot\omega_1(n)\cdot(2\sigma)^{-k}\qquad(n\in\mathbb{Z}),$$

where $\gamma_l=\gamma_l(\sigma,\rho)$. Thus there is a constant $1\leqq\tilde\gamma<\infty$ with

$$\|A^k\circ(1-P_N)\|_j\leqq\tilde\gamma\cdot(2\sigma)^{-k}. \tag{2.12}$$

By induction now immediately follows

$$\|A^k\|_j\leqq\tilde\gamma\cdot(2\tau)^{-k}\cdot\prod_{j=1}^{k}\Big(1+\Big(\frac{\tau}{\sigma}\Big)^j\Big)\leqq\gamma\cdot(2\tau)^{-k}\qquad(k\in\mathbb{N}), \tag{2.13}$$

where $\gamma:=\tilde\gamma\cdot\exp(\tau/(\sigma-\tau))$. For $k=0$ this is true on account of $\tilde\gamma\geqq1$. For the step "$k\to k+1$" we estimate by the use of (2.12) and (2.9)

$$\begin{aligned}\|A^{k+1}\|_j&\leqq\|A^k\|_j\|A\circ P_N\|_j+\|A^{k+1}\circ(1-P_N)\|_j\\&\leqq\tilde\gamma\cdot(2\tau)^{-k}\cdot\prod_{j=1}^{k}\Big(1+\Big(\frac{\tau}{\sigma}\Big)^j\Big)\cdot\frac{1}{2\tau}+\tilde\gamma\cdot(2\sigma)^{-k-1}.\end{aligned}$$

(ii) Expanding the g_m into power series

$$g_m(z)=:\sum_{k=0}^{\infty}g_k^m\cdot z^{-k}\qquad(r<|z|\leqq\infty),$$

we obtain

$$\sum_{k=0}^{\infty}|g_k^m|\cdot(2\tau)^{-k}=:\gamma_m<\infty.$$

By the use of (1.25), (2.11) and (2.13) then follow for $c=(c_\mu)\in\mathfrak{M}_j^{\pm}$ and $\mu=\pm\nu+n$

$$\begin{aligned}|(G_m c)_\mu|&\leqq\frac{1}{|\varepsilon_{\kappa,\pm\mu}|}\cdot\sum_{l\in\mathbb{Z}}\sum_{k\geqq|l|}|g_k^m|\Big|\big\langle z^{-k}I^{\pm}_{\kappa,\mu+l},\,I^{\mp}_{\kappa,-\mu}\big\rangle\Big|\cdot|c_{\mu+l}|\\&\leqq\sum_{k=0}^{\infty}|g_k^m|\cdot\frac{1}{|\varepsilon_{\kappa,\pm\mu}|}\cdot\sum_{|l|\leqq k}\Big|\big\langle z^{-k}I^{\pm}_{\kappa,\mu+l},\,I^{\mp}_{\kappa,-\mu}\big\rangle\Big|\cdot|c_{\mu+l}|\\&\leqq\Big(\sum_{k=0}^{\infty}|g_k^m|\cdot\|A^k\|_j\Big)\cdot\|c\|_j\cdot\omega_j(n)\leqq\gamma\cdot\gamma_m\cdot\|c\|_j\cdot\omega_j(n).\end{aligned}$$

Thus, for $c\in\mathfrak{M}_j^{\pm}$,

$$G_m c\in\mathfrak{M}_j^{\pm}\quad\text{and}\quad\|G_m c\|_j\leqq\gamma\cdot\gamma_m\cdot\|c\|_j.$$

According to (2.7) and (2.10) we can consider equation (2.6) now in $\mathfrak{M}_1^{\pm}$ as well as in $\mathfrak{M}_2^{\pm}$, provided that $r/2<\rho$. We prove

(2.14) PROPOSITION. *Let $r/2<\rho<\infty$. Then each solution of* (2.6) *belonging to $\mathfrak{M}_2^{\pm}$ already belongs to $\mathfrak{M}_1^{\pm}$.*

Proof. By the definition of T immediately follows $\|P_N\circ T\|_j\to0$ for $N\to\infty$. Hence we can choose $N\in\mathbb{N}$ such that $\|P_N\circ T\|_j\cdot\|B\circ G_1+T\circ G_2\|_j<1$. Applying P_N to (2.6) and adding $(1-P_N)c$ on both sides gives

$$(1-P_N)c=\big(1+(P_N\circ T)\circ(B\circ G_1+T\circ G_2)\big)c. \tag{$*$}$$

Since the left side of (*) obviously belongs to $\mathfrak{M}_1^{\pm}$ and the operator on the right side of (*) is, by the above choice of N, invertible in $\mathfrak{M}_1^{\pm}$ as well as in $\mathfrak{M}_2^{\pm}$, c necessarily belongs to $\mathfrak{M}_1^{\pm}$.

Finally, we apply the result of (2.14) to our special situation where we have a solution c of (2.6) belonging to $\tilde{\mathfrak{U}}_{\pm\nu}$. Choosing an arbitrary $(r/2)<\rho<\infty$, we obviously have $c\in\tilde{\mathfrak{U}}_{\pm\nu}\subset\mathfrak{M}_2^{\pm}$ and hence by (2.14) obtain $c\in\mathfrak{M}_1^{\pm}$. We summarize the essential facts in the following

(2.15) THEOREM. *Let* $y^{\pm}\in\mathfrak{U}_{\pm\nu}\cap\mathfrak{N}(D)$ *and let* $(c_\mu)_{\mu\in\pm\nu+\mathbb{Z}}$ *be the corresponding coefficients defined by* (1.21.2). *Then*

$$\limsup_{|n|\to\infty}\left(|c_{\pm\nu+n}|\cdot|n|!\right)^{1/n}\leqq\frac{r}{2}. \tag{2.15.1}$$

2.3. Floquet and asymptotic solutions of the DE (0.1). Let $0\neq y^{\pm}\in\mathfrak{U}_{\pm\nu}\cap\mathfrak{N}(D)$. According to (1.21) we have

$$y^{\pm}(z)=\sum_{\mu\in\pm\nu+\mathbb{Z}}c_\mu I^{\pm}_{\kappa,\mu}(z)\qquad(z\in\hat{\Omega}) \tag{2.16}$$

where the coefficients $(c_\mu)_{\mu\in\pm\nu+\mathbb{Z}}$ are given by (1.21.2). As shown in the last section, these coefficients possess the asymptotic behavior (2.15.1). We can thus define

$$\hat{y}^{\pm}(z):=\sum_{\mu\in\pm\nu+\mathbb{Z}}c_{-\mu}I^{\mp}_{\kappa,\mu}(z)=\sum_{\mu\in\pm\nu+\mathbb{Z}}\hat{c}_\mu I^{\pm}_{\kappa,\mu}(z)\qquad(z\in\hat{\Omega}) \tag{2.17}$$

where—by (1.16)—

$$\hat{c}_\mu:=c_{-\mu}\cdot 4^{\mp\kappa}\cdot\left(e^{\pm i\pi/2}\right)^{1+2\mu}\cdot\frac{\Gamma(1/2\pm\kappa-\mu)}{\Gamma(1/2\mp\kappa-\mu)}\qquad(\mu\in\pm\nu+\mathbb{Z}). \tag{2.17.1}$$

Obviously, $\hat{y}^{\pm}\in\mathfrak{U}_{\pm\nu}$. Multiplying (2.1) with

$$4^{\pm\kappa}\cdot\left(e^{\mp i\pi/2}\right)^{1-2\mu}\cdot\frac{\Gamma(1/2\mp\kappa+\mu)}{\Gamma(1/2\pm\kappa+\mu)}$$

and using (1.27) with $S=G$ one readily finds that $(\hat{c}_\mu)_{\mu\in\pm\nu+\mathbb{Z}}$ is a solution of (2.1) in $\tilde{\mathfrak{U}}_{\pm\nu}$. Hence, according to §2.1, $\hat{y}^{\pm}\in\mathfrak{U}_{\pm\nu}\cap\mathfrak{N}(D)$.

Since $y^{\pm}\neq 0$, there exist (unique) constants $\xi^{\pm}\in\mathbb{C}$ such that

$$\hat{y}^{\pm}(z)=\pm\frac{e^{\pi i\nu}}{2\sin\pi(1/2+\kappa-\nu)}\cdot\xi^{\pm}\cdot y^{\pm}(z)\qquad(z\in\hat{\Omega}). \tag{2.18}$$

This immediately implies

$$\xi^{\pm}\cdot c_\mu=\frac{2\pi i\cdot 4^{\mp\kappa}}{\Gamma(1/2\mp\kappa+\mu)\Gamma(1/2\mp\kappa+\mu)}\cdot c_{-\mu}\qquad(\mu\in\pm\nu+\mathbb{Z}), \tag{2.19}$$

which obviously is a connection formula between the coefficients of y^{+} and y^{-}. Using (2.19) twice gives

$$\xi^{+}\cdot\xi^{-}=-4\sin\pi\left(\frac{1}{2}+\kappa-\nu\right)\sin\pi\left(\frac{1}{2}+\kappa+\nu\right)=-2(\cos(2\pi\nu)+\cos(2\pi\kappa)). \tag{2.20}$$

A short calculation then yields

$$1+\frac{e^{2\pi i\nu}\cdot\xi^{+}\cdot\xi^{-}}{4\sin^2(1/2+\kappa-\nu)}=\frac{e^{\pi i(\kappa+\nu-1/2)}\cdot\sin 2\nu\pi}{\sin\pi(1/2+\kappa-\nu)}\neq 0. \tag{*}$$

We define now for $z \in \hat{\Omega}$

$$\frac{\sin 2\pi\nu}{\pi}(H^+(z), H^-(z)) := (y^+(z), y^-(z)) \cdot \begin{pmatrix} 1 & \frac{e^{\pi i\nu}\cdot\xi^+}{2\sin\pi(1/2+\kappa-\nu)} \\ \frac{e^{\pi i\nu}\cdot\xi^-}{2\sin\pi(1/2+\kappa-\nu)} & -1 \end{pmatrix}. \tag{2.21}$$

Since y^+ and y^- constitute a fundamental set of solutions of (D), also H^+ and H^- do so on account of $(*)$. By the use of (2.18), (2.17) and (1.15) we obtain the representations

$$H^{\pm}(z) = \sum_{\mu \in \pm\nu + \mathbb{Z}} c_\mu \cdot H^{\pm}_{\kappa,\mu}(z) \qquad (z \in \hat{\Omega}). \tag{2.22}$$

(1.29) then shows that the $H^{\pm}$ possess the asymptotic expansions

$$H^{\pm}(z) \sim e^{\pm iz}\cdot z^{\mp\kappa - 1/2}\cdot \sum_{m=0}^{\infty} \frac{\tilde{c}_m^{\pm}}{m!}(\pm 2iz)^{-m} \tag{2.23}$$

as $|z| \to \infty$ within the sectors $|\arg z \mp \pi/2| < 3\pi/2$, where the coefficients are given by

$$\tilde{c}_m^{\pm} := \sum_{\mu \in \pm\nu + \mathbb{Z}} c_\mu \cdot \left(\frac{1}{2} \pm \kappa + \mu\right)_m \cdot \left(\frac{1}{2} \pm \kappa - \mu\right)_m. \tag{2.23.1}$$

Inserting the asymptotic series (2.23) into the Wronskian we arrive after a short calculation at

$$[H^+, H^-] = -2i \cdot \tilde{c}_0^+ \cdot \tilde{c}_0^-.$$

Since H^+ and H^- constitute a fundamental system, we have $[H^+, H^-] \neq 0$ and thus obtain

$$\tilde{c}_0^{\pm} = \sum_{\mu \in \pm\nu + \mathbb{Z}} c_\mu \neq 0.$$

This makes it possible to normalize the solutions $y^{\pm}$ and $H^{\pm}$. A quite natural choice is $\tilde{c}_0^{\pm} = 1$. By this, $y^{\pm}$ and $H^{\pm}$ become uniquely determined. We summarize the results concerning the $H^{\pm}$.

(2.24) THEOREM. *There is a unique fundamental set of solutions H^+ and H^- of the DE (D) having a representation of the form* (2.22), *where the coefficients $(c_\mu)_{\mu \in \Xi}$ satisfy* (2.15.1) *and*

$$\sum_{\mu \in \pm\nu + \mathbb{Z}} c_\mu = 1. \tag{2.24.1}$$

The $H^{\pm}$ possess the asymptotic expansions (2.23), (2.23.1). *Furthermore, the coefficients of H^+ and H^- satisfy the connection formula* (2.19), *where*

$$\xi^{\pm} = \sum_{\mu \in \mp\nu + \mathbb{Z}} \frac{2\pi i \cdot 4^{\mp\kappa}}{\Gamma(1/2 \mp \kappa + \mu)\Gamma(1/2 \mp \kappa - \mu)} c_\mu. \tag{2.24.2}$$

The formula (2.24.2) follows by summing up (2.19) and using (2.24.1).

Introducing the *monodromy matrix* U of the fundamental set of solutions H^+ and H^- through

$$(\phi H^+(z),\phi H^-(z)) =: (H^+(z),H^-(z))\circ U \qquad (z\in\hat{\Omega}), \tag{2.25}$$

a short calculation using (2.21) and (*) yields

$$U=\begin{pmatrix} -e^{-2\pi i\kappa} & -e^{-\pi i\kappa}\cdot\xi^+ \\ -e^{-\pi i\kappa}\cdot\xi^- & 2\cos 2\pi\nu + e^{-2\pi i\kappa}\end{pmatrix}. \tag{2.25.1}$$

The formulas (2.25.1) and (2.20) show the actual meaning and the fundamental importance of the quantities $\xi^{\pm}$.

We shall now call attention to the special case where H^+ or H^- itself is a Floquet solution. A preliminary result which is closely related to this question is the following:

$$\Xi=\left(\frac{1}{2}+\kappa+\mathbb{Z}\right)\cup\left(\frac{1}{2}-\kappa+\mathbb{Z}\right) \quad \text{if and only if } \xi^+\cdot\xi^-=0. \tag{2.26}$$

This is obvious by (2.20). A more detailed information is contained in

(2.27) THEOREM. *A necessary and sufficient condition for $H^{\pm}$ to be a Floquet solution is $\xi^{\mp}=0$. In this case*

$$c_{\mp\kappa-1/2+n}=0 \qquad (\mathbb{Z}\ni n\geqq 1)$$

and hence

$$\begin{aligned} H^{\pm}(z) &= \sum_{n=0}^{\infty} c_{\mp\kappa-1/2-n}\cdot H^{\pm}_{\kappa,\pm\kappa+1/2+n}(z) \\ &= \frac{\pm\pi}{\sin 2\pi\kappa}\sum_{n=0}^{\infty} c_{\mp\kappa-1/2-n} I^{\pm}_{\kappa,\mp\kappa-1/2-n}(z). \end{aligned}$$

Moreover, the corresponding asymptotic expansion actually converges in $\hat{\Omega}$ and represents $H^{\pm}$.

The last statement follows from the fact that in this case $z^{1/2\pm\kappa}\cdot e^{\mp iz}\cdot H^{\pm}(z)$ is holomorphic in $\Omega\cup\{\infty\}$. The other statements follow directly by (2.21), (2.19) and (1.15), (1.16).

The following remark shall clarify the actual dependence of our functions on the previous choice of ν. Obviously, all definitions and calculations only depend on $\nu\in\Xi$ modulo 1, but some of them essentially use the assumptions $\frac{1}{2}-\kappa+\nu\notin\mathbb{Z}$. Regarding especially the solutions $H^{\pm}$, one easily sees that these are uniquely determined by their asymptotic behavior and hence are independent of ν. Then, by (2.25), (2.25.1), also the $\xi^{\pm}$ are independent of ν.

Since the $H^{\pm}$ are independent of the previous choice of ν, we can give an appropriate definition of Floquet solutions depending on the $H^{\pm}$, which is in full accordance with the definition (1.14).

For $\mu\in\Xi$ let

$$I^{\pm}_{\mu} := Q_{-\mu}H^{\pm}. \tag{2.28}$$

By (1.8.1), (1.8.2) then follows

$$\frac{\sin 2\pi\mu}{\pi}\cdot H^{\pm}=I_{\mu}^{\pm}-I_{-\mu}^{\pm},\qquad I_{\mu}^{\pm}\in\mathfrak{U}_{\pm\mu}\cap\mathfrak{N}(D). \tag{2.28.1}$$

Especially, for $\mu\in\Xi$ with $\frac{1}{2}-\kappa+\mu\notin\mathbb{Z}$, we obtain from (2.28.1), (2.21) and (2.18)

$$I_{\pm\mu}^{\pm}=y^{\pm}\neq 0;\ I_{\mp\mu}^{\pm}=\tilde{y}^{\mp}\qquad(\neq 0\Leftrightarrow\xi^{\mp}\neq 0). \tag{2.28.2}$$

We close our considerations with a few *remarks* concerning the practicality of our representations and their relation to other recent results on the subject.

Our series representations of the solutions of the DE (D) depend at first on the characteristic exponents $\nu\in\Xi$ and secondly on (essentially) one set of coefficients $(c_{\mu})_{\mu\in\pm\nu+\mathbb{Z}}$.

The characteristic exponents are determined by (2.20) through the quantities $\xi^{\pm}$. This fact—but even more their fundamental role as coefficients of the monodromy matrix U—makes it desirable having a method to compute the $\xi^{\pm}$. Unfortunately, (2.24.2) is not accessible for a direct computation because the $(c_{\mu})_{\mu\in\pm\nu+\mathbb{Z}}$ are not available. But (2.24.2) together with (2.23.1) yields the following limit-formula for the $\xi^{\pm}$

$$\lim_{n\to\infty}\frac{\tilde{c}_n^{\pm}}{\Gamma(n\pm 2\kappa)\cdot n!}=\frac{1}{2\pi i}\cdot 4^{\mp\kappa}\cdot\xi^{\mp}. \tag{2.29}$$

Since the coefficients $\tilde{c}_n^{\pm}$ of the asymptotic expansion (2.23) can be calculated recursively in a well-known manner, this formula provides an explicit method to determine approximately the $\xi^{\pm}$ (and thus the characteristic exponents $\nu\in\Xi$ and the monodromy matrix U). (2.29) is exactly the formula obtained by Jurkat–Lutz–Peyerimhoff in [6], resp. [7], [8] for calculating the so-called *Birkhoff invariants* of the DE (D), which are essentially ξ^{+} and ξ^{-}. Another method to determine the $\xi^{\pm}$ is to be found in Hinton [4].

Once knowing the characteristic exponents $\nu\in\Xi$, the coefficients $(c_{\mu})_{\mu\in\pm\nu+\mathbb{Z}}$ of our expansions are then uniquely determined by equation (2.1) and conditions (1.23.1), (1.23.2), (2.24.1). Unfortunately, equation (2.1) is, in general, not recursively solvable. The situation is nearly the same as for calculating the coefficients of the Laurent expansion of the Floquet solutions $y^{\pm}$. But this is not at all astonishing: Knowing the power series expansion of the $I_{\kappa,\mu}^{\pm}$ explicitly, one can express the Laurent coefficients of the $y^{\pm}$ through our coefficients c_{μ} and vice versa. Nevertheless, if the coefficients g_1 and g_2 of the DE (D) are polynomials in $1/z$, equation (2.1) becomes a difference-equation, which can be solved recursively with respect to the conditions (1.23.1), (1.23.2). Herein are included many types of confluent Fuchsian DEs which are of interest in the theory of higher special functions.

DISCONJUGACY AND COMPARISON THEOREMS FOR SECOND-ORDER LINEAR SYSTEMS*

W. J. KIM†

Abstract. Sufficient conditions for disconjugacy and disfocality are obtained for the second-order system $y''+Ay=0$, where A is an $n\times n$ matrix. Also proved are comparison theorems for disfocality through a generalization of the Riccati equation method originally used by Hille (Trans. Amer. Math. Soc., 64 (1948), pp. 234–252) for the case $n=1$.

1. Introduction. The second-order systems to be studied in this paper are of the form

$$y''+Ay=0, \qquad A=(a_{ij})_{i,j=1}^{n}, \tag{1}$$

where $A=A(x)$ is an $n\times n$ matrix with real elements which are continuous on an x-interval I, and y is an n-dimensional column vector. The system (1) is said to be *disconjugate* on the interval I if, for every pair of points a, $b\in I$, $a<b$, the only solution y satisfying the two-point boundary condition $y(a)=y(b)=0$ is the trivial one. On the other hand, if the only solution of (1) satisfying the condition $y(a)=y'(b)=0$, $a,b\in I$, $a<b$, is the trivial solution, then (1) is said to be *right-disfocal* on I. Similarly, we shall say that (1) is *left-disfocal* on I if no nontrivial solution satisfies the condition $y'(a)=y(b)=0$, $a,b\in I$, $a<b$.

The concepts of disconjugacy and disfocality defined for the second-order system (1) are closely related to the concepts of suborthogonality and nonoscillation that Nehari [13] defined for the first-order system

$$z'+Pz=0, \qquad P=(p_{ij})_{i,j=1}^{n}. \tag{2}$$

A nontrivial solution vector $z=\mathrm{col}(z_1,\cdots,z_n)$ of (2) is said to be *oscillatory* on an interval I if $z_k(x_k)=0$ for some $x_k\in I$, $k=1,\cdots,n$. The system (2) is said to be *oscillatory* if it has at least one oscillatory solution vector; otherwise, it is said to be *nonoscillatory* on I. The first-order system (2) is said to be *suborthogonal* on I if, for any nontrivial solution vector z and for any pair of points $s,t\in I$, the inner product $(z(s),z(t))\equiv\sum_{k=1}^{n}z_k(s)z_k(t)>0$ [13].

Suppose that $y=\mathrm{col}(y_1,\cdots,y_n)$ is a solution of (1). If we put $w=\mathrm{col}(y_1,\cdots,y_n,y_1',\cdots,y_n')$, the second-order system reduces to the first-order system

$$w'+Cw=0, \qquad C=\begin{pmatrix}0 & -\mathrm{I}\\ A & 0\end{pmatrix}, \tag{3}$$

where I is the $n\times n$ identity matrix. If (1) has a nontrivial solution $y=\mathrm{col}(y_1,\cdots,y_n)$ such that $y(a)=y(b)=0$, $a,b\in I$, $a<b$, then $y_i(a)=y_i(b)=0$, $i=1,\cdots,n$, and by Rolle's theorem, $y_i'(x_i)=0$ for some x_i, $a<x_i<b$, $i=1,\cdots,n$. This means that every component of w has a zero on I, i.e., (3) is oscillatory on I. Hence, any nonoscillation theorems for (3) may be useful in establishing explicit disconjugacy criteria for (1).

*Received by the editors January 10, 1984, and in revised form November 12, 1984.

†Department of Applied Mathematics and Statistics, State University of New York, Stony Brook, New York 11794.

Indeed, a nonoscillation theorem for (3) leads to a condition guaranteeing that at least one of the functions $y_1,\cdots,y_n,\ y_1',\cdots,y_n'$ does not vanish on I if $y=\operatorname{col}(y_1,\cdots,y_n)$ is a nontrivial solution of (1). In particular, any nonoscillation theorems for (3) lead to right- and left-disfocality criteria of (1). Furthermore, right- and left-disfocality of (1) are also implied by the suborthogonality of (3).

In 1930 Morse [12] studied the selfadjoint second-order systems in the setting of the calculus of variations and obtained extensions of the classical Sturm separation and comparison theorems [16]. Following his pioneering work, many results of similar type appeared in the literature [15]. Recently, in a series of papers [1]–[4], Ahmad and Lazer investigated the system (1) concerning the sign properties of the components of extremal solutions and comparison theorems for disconjugacy. Their results involved conditions imposed on the elements a_{ij} of the coefficient matrix A, while the earlier results had been stated in terms commonly encountered in the variational problems such as the positive semidefiniteness of certain matrices. Keener and Travis [9] also studied the Sturmian properties of (1) using the theory of μ_0-positive operators defined on a Banach space.

The purpose of this paper is to establish disconjugacy criteria and comparison theorems involving disfocality for the second-order system (1). In §2 we shall prove two sufficient conditions for disconjugacy (Theorems 1 and 2), one of which was obtained by noting the connection between the systems (1) and (3). In §3 we discuss comparison and separation theorems for the right- and left-disfocality of (1) (Theorems 4 and 6). These comparison theorems are proved by generalizing the method of the Riccati equation first used by Hille for the second-order equations [8], which was later adapted to higher-order equations by Nehari [14] and others [7], [11].

2. Disconjugacy criteria. Let $y=\operatorname{col}(y_1,\cdots,y_n)$ be a solution of (1) and put

$$w=\operatorname{col}(w_1,\cdots,w_{2n})=\operatorname{col}(\varepsilon y_1,\cdots,\varepsilon y_n,\ y_1',\cdots,y_n'),$$

for some $\varepsilon>0$. Then

$$w'=Bw, \tag{4}$$

where

$$B=B(x,\varepsilon)=\begin{pmatrix} 0 & \varepsilon \mathrm{I} \\ -\varepsilon^{-1}A(x) & 0 \end{pmatrix},$$

and I is the $n\times n$ identity matrix. According to a result of Nehari [13], (4) is nonoscillatory on the interval $I=[a,b]$ if

$$\int_a^b \|B\|\,dx<\pi/2,$$

where $\|B\|$ denotes the matrix norm $\sup_{\|z\|=1}\|Bz\|$ and $\|z\|$ is the Euclidean norm of vector z. As was pointed out in the preceding section, the nonoscillation of (4) implies that every nontrivial solution y of (1) possesses the property that at least one of the $2n$ functions $y_1,\cdots,y_n,\ y_1',\cdots,y_n'$ does not vanish on I, i.e., (1) is a fortiori disconjugate and right- and left-disfocal on I.

Put $u=\operatorname{col}(w_1,\cdots,w_n)$ and $v=\operatorname{col}(w_{n+1},\cdots,w_{2n})$. Then

$$\|Bw\|^2=(Bw,Bw)=\varepsilon^2\|v\|^2+\varepsilon^{-2}\|Au\|^2$$

$$\leqq\varepsilon^2\|v\|^2+\varepsilon^{-2}\|A\|^2\|u\|^2$$

$$\leqq\max\left(\varepsilon^2,\varepsilon^{-2}\|A\|^2\right)\|w\|^2;$$

consequently,

$$\|B\|\leqq\max\left(\varepsilon,\varepsilon^{-1}\|A\|\right),$$

and we have proved the following result.

THEOREM 1. *Let a and b, $a<b$, be points of the interval I. If*

$$\int_a^b\max\left(\varepsilon,\varepsilon^{-1}\|A(x)\|\right)dx<\pi/2,$$

for some $\varepsilon>0$, then every nontrivial solution y of the second-order system (1) *has the property that at least one component of y or y' does not vanish on $[a,b]$; in particular,* (1) *is disconjugate and right- and left-disfocal on $[a,b]$.*

If $\|A(x)\|$ is constant, the inequality condition in the above theorem is equivalent to $\|A(x)\|<\pi^2/4(b-a)^2$.

Next we shall establish a disconjugacy criterion of a different nature. Here we shall be concerned with a symmetric interval of the type $(-c,c)$. This is not an essential restriction because disconjugacy and zero properties are preserved under a translation.

THEOREM 2. *The system* (1) *is disconjugate on $I=(-c,c)$ if*

$$\frac{1}{2}\left(c^2-|x|^2\right)\sum_{j=1}^{n}|a_{kj}(x)|\leqq 1,\qquad x\in(-c,c), \tag{5}$$

$k=1,\cdots,n$.

Proof. Suppose that (1) is not disconjugate on $(-c,c)$. Then there exist a nontrivial solution $y=\operatorname{col}(y_1,\cdots,y_n)$ and a pair of points a and b, $-c<a<b<c$, such that $y_k(a)=y_k(b)=0$, $k=1,\cdots,n$. For each component y_k which is twice continuously differentiable and vanishes at a and b on $(-c,c)$, it is easily confirmed that

$$y_k(x)=(b-x)\int_a^x(b-t)^{-2}\int_b^t(b-s)\,y_k''(s)\,ds\,dt$$

[5], [10]. Let

$$|y_k''(x_k)|=\max_{a\leqq x\leqq b}|y_k''(x)|,$$

$k=1,\cdots,n$. Then we have for $a\leqq x\leqq b$,

$$|y_k(x)|\leqq|y_k''(x_k)||b-x|\int_a^x|b-t|^{-2}\int_b^t|b-s||ds||dt|$$

$$=\frac{1}{2}|y_k''(x_k)||b-x||a-x|.$$

Since $|b-x||a-x|<(c^2-|x|^2)$, $a\leqq x\leqq b$, we get the inequality

$$|y_k(x)|\leqq\frac{1}{2}|y_k''(x_k)|\left(c^2-|x|^2\right),\qquad a\leqq x\leqq b, \tag{6}$$

where the strict inequality holds unless $|y_k''(x_k)|=0$, $k=1,\cdots,n$. Note that $|y_k''(x_k)|=0$ if and only if $y_k\equiv 0$, due to the condition $y_k(a)=y_k(b)=0$. If we put

$$|y_m''(x_m)|\equiv\max_{1\leqq j\leqq n}|y_j''(x_j)|,$$

then $|y_m''(x_m)|>0$ since $y\not\equiv 0$. From the system (1),

$$|y_m''(x)|\leqq\sum_{j=1}^{n}|a_{mj}(x)||y_j(x)|;$$

in particular, for $x=x_m$,

$$0<|y_m''(x_m)|\leqq\sum_{j=1}^{n}|a_{mj}(x_m)||y_j(x_m)|. \tag{7}$$

Hence, there must exist an l, $1\leqq l\leqq n$, for which $|a_{ml}(x_m)||y_l(x_m)|>0$. For such an l, $y_l(x)\not\equiv 0$ and $y_l''(x_l)\neq 0$; therefore,

$$|y_l(x)|<\frac{1}{2}|y_l''(x_l)|\left(c^2-|x|^2\right),\qquad a\leqq x\leqq b, \tag{6'}$$

from (6). Substituting (6) and (6′) with $x=x_m$ in (7), we get

$$\begin{aligned}|y_m''(x_m)|&<\frac{1}{2}\left(c^2-|x_m|^2\right)\sum_{j=1}^{n}|a_{mj}(x_m)||y_j''(x_m)|\\&\leqq\frac{1}{2}\left(c^2-|x_m|^2\right)|y_m''(x_m)|\sum_{j=1}^{n}|a_{mj}(x_m)|,\end{aligned}$$

i.e.,

$$1<\frac{1}{2}\left(c^2-|x_m|^2\right)\sum_{j=1}^{n}|a_{mj}(x_m)|,$$

contrary to (5). This completes the proof.

3. Comparison theorems. In this section we shall frequently consider an interval of the form $I=[a,\omega)$, where ω may or may not be finite. If the system (1) is not right [left]-disfocal on $[a,\omega)$, we define $\eta(A,b)[\phi(A,b)]$, $a\leqq b<\omega$, to be the infimum of c, $b\leqq c<\omega$, such that there exists a nontrivial solution y of (1) satisfying $y(b)=y'(c)=0$ [$y'(b)=y(c)=0$]. Then there exists a nontrivial solution y of (1) satisfying $y(b)=y'(\eta(A,b))=0$ [$y'(b)=y(\phi(A,b))=0$]. If, on the other hand, (1) is right [left]-disfocal on $[a,\omega)$, we put $\eta(A,b)=\omega[\phi(A,b)=\omega]$ for all b.

Let $y_j=\mathrm{col}(y_{1j},\cdots,y_{nj})$, $j=1,\cdots,n$, be the solution vectors of (1) satisfying

$$y_{ij}(b)=0,\qquad y_{ij}'(b)=\delta_{ij}, \tag{8}$$

$i,j=1,\cdots,n$, for a fixed b, $a\leqq b<\omega$. Put $Y=(y_{ij})_{i,j=1}^{n}$ and $S=Y(Y'^{-1})$. If the system (1) is right-disfocal on $[b,\omega)$, the determinant of Y' does not vanish on $[b,\omega)$; therefore, S is continuously differentiable on $[b,\omega)$, and

$$S'=Y'Y'^{-1}+Y(Y'^{-1})'=\mathrm{I}+Y(-Y'^{-1}Y''Y'^{-1})$$

$$=\mathrm{I}+Y\left[-Y'^{-1}(-AY)Y'^{-1}\right]=\mathrm{I}+SAS,$$

i.e., S satisfies the matrix-matrix equation

$$S'=\mathrm{I}+SAS, \qquad S(b)=0. \tag{9}$$

Conversely, we assert that $\det Y'\neq 0$ as long as (9) has a continuous solution. Since $\det Y'(x)$ is a continuous function of x and $\det Y'(b)=1$, $\det Y'$ does not vanish on some right neighborhood N of the point b; that is, Y' is invertible on N. Therefore, YY'^{-1} is defined on N; moreover, $S=YY'^{-1}$ due to the uniqueness of solutions of the initial value problem (9) [6]. Suppose that $\det Y'$ vanishes at some point: Let x_0, $b<x_0<\omega$, be the first point to the right of b at which $\det Y'$ vanishes, while S remains continuous at x_0. Then the span G of the row vectors of $Y'(x_0)$ is at most $n-1$ dimensional, and there exists a nontrivial vector $\alpha=(\alpha_1,\cdots,\alpha_n)$ which is orthogonal to G, i.e.,

$$\sum_{j=1}^{n}\alpha_j y'_{ij}(x_0)=0, \tag{10}$$

$i=1,\cdots,n$. On the interval $[b,x_0)$ we have $S=YY'^{-1}$, which may be written as $SY'=Y$; indeed, this equality holds on $[b,x_0]$, because S, Y and Y' are continuous on $[b,x_0]$. Hence, for a fixed $x\in[b,x_0]$, the row vectors $(y_{k1},\cdots,y_{kn})$, $k=1,\cdots,n$, of Y are contained in the span of the row vectors of Y'. In particular, for $x=x_0$, every row vector $(y_{k1}(x_0),\cdots,y_{kn}(x_0))$, $k=1,\cdots,n$, of $Y(x_0)$ is contained in G. Since the vector α is orthogonal to G, it is orthogonal to the row vectors of $Y(x_0)$:

$$\sum_{j=1}^{n}\alpha_j y_{ij}(x_0)=0, \qquad i=1,\cdots,n. \tag{11}$$

Putting

$$y=\sum_{j=1}^{n}\alpha_j y_j, \qquad y_j=\mathrm{col}(y_{1j},\cdots,y_{nj}),$$

$j=1,\cdots,n$, we see that y is a nontrivial solution of the system (1). However, (10) and (11) require that $y(x_0)=y'(x_0)=0$, which cannot be satisfied unless y is the trivial solution. This contradiction proves that $\det Y'$ cannot vanish at x_0.

Thus we have proved the following theorem.

THEOREM 3. *Let b be a point on the interval $I=[a,\omega)$. Every nontrivial solution y of* (1) *with $y(b)=0$ has the property that $y'\neq 0$ on $[b,c)$, $a\leqq b<c\leqq\omega$, if and only if the Riccati system* (9) *has a continuous solution on $[b,c)$.*

In order to obtain the desired comparison theorems, we shall study the differential system satisfied by the components s_{ij} of the matrix $S=(s_{ij})_{i,j=1}^{n}$ in (9). As a first step, we need to determine the growth properties of s_{ij} in the right neighborhood of the

point b. Since

$$\det Y' = \sum_{\pi \in P} (\operatorname{sgn} \pi)\, y'_{1\pi(1)} y'_{2\pi(2)} \cdots y'_{n\pi(n)},$$

where P is the set of all permutations of the integers between 1 and n, the cofactor of y'_{ij} may be obtained from the above formula by setting $y'_{ij}=1$ and $y'_{ik}=0$, $k=1,\cdots,$ $j-1$, $j+1,\cdots,n$. Evidently, the cofactor of y'_{ij} is the sum of the products of the form

$$\pm y'_{1k_1} \cdots y'_{i-1,k_{i-1}} y'_{i+1,k_{i+1}} \cdots y'_{nk_n}, \tag{12}$$

where $1 \leqq k_m \leqq n$, $k_m \neq j$, $m=1,\cdots,i-1$, $i+1,\cdots,n$. Hence, every term in the sum contains a factor y'_{rs}, $r \neq s$, unless $i=j$. If $i=j$, the sum contains exactly one term of the form (12) for which $k_m=m$, $m=1,\cdots,i-1$, $i+1,\cdots,n$, and all the other terms contain a factor y_{rs}, $r \neq s$. Therefore, the diagonal and the off-diagonal elements of the inverse Y'^{-1} are, respectively, unity and zero at b. Furthermore, we see from (8) that the diagonal elements of Y have zeros of order exactly 1 at b, while the off-diagonal elements have zeros of order at least 2 at b. Consequently, simple computations show that the diagonal elements of $S=YY'^{-1}$ have zeros of order exactly 1 at b and the off-diagonal elements have zeros of order at least 2 at b.

From (9) we have $s_{ii}(b)=0$, $s'_{ii}(b)=1$, which implies that $s_{ii}>0$ on $(b,b+\varepsilon)$ for some $\varepsilon>0$, $i=1,\cdots,n$. On the other hand, for the off-diagonal element s_{ij}, $i \neq j$,

$$s'_{ij}(x) = \sum_{k=1}^{n} \sum_{m=1}^{n} a_{km}(x) s_{ik}(x) s_{mj}(x),$$

where the term $a_{ij}(x)s_{ii}(x)s_{jj}(x)$ is easily seen to be dominating as $x \to b+$, provided $a_{ij}(b) \neq 0$. This is because the term $a_{ij}s_{ii}s_{jj}$ has a zero of order exactly 2 at b if $a_{ij}(b) \neq 0$, while the other terms have zeros of order at least 3 at b. In particular, if $a_{ij}(b)>0$, $i \neq j$, then $s'_{ij}(x)>0$ on $(b,b+\varepsilon)$ for some $\varepsilon>0$. Thus, we have the following lemma.

LEMMA 1. *Let b be a point on the interval $I=[a,\omega)$. Then the solution matrix S of* (9) *is positive on $(b,b+\varepsilon)$ for some $\varepsilon>0$ if $a_{ij}(b)>0$, $i \neq j$.*

The condition $a_{ij}(b)>0$, $i \neq j$, in the above lemma may be relaxed. In view of the zero properties of the components s_{ij} at b, we may merely require that a_{ij} be nonnegative in a right neighborhood of b and $a_{ij}(x)=O((x-b)^{\lambda})$ for some λ, $0 \leqq \lambda < 1$, as $x \to b+$, $i \neq j$.

Another result needed for our proof is an extended version of [14, Lemma 3.2], which follows when a few obvious changes are made in the original proof.

LEMMA 2 [14, Lemma 3.2]. *Let $P_r(w_1,\cdots,w_m,t)$ and $P_r^*(w_1,\cdots,w_m,t)$ be two sets of polynomials in the variables $w_1,\cdots,w_m$ whose coefficients are nonnegative and continuous on $[a,\omega)$, $r=1,\cdots,m$. Suppose that*

$$\int_a^t P_r(w_1,\cdots,w_m,s)\,ds \leqq \int_a^t P_r^*(w_1,\cdots,w_m,s)\,ds, \qquad t \in [a,\omega),$$

for any set of nonnegative continuous functions $w_1,\cdots,w_m$ defined on $[a,\omega)$, $r=1,\cdots,m$. If there exist nonnegative differentiable functions $W_1,\cdots,W_m$ defined on $[a,\omega)$ satisfying the inequality

$$W_r' \geqq P_r^*(W_1,\cdots,W_m,t), \qquad W_r(a)=\alpha_r \geqq 0,$$

$r=1,\cdots,m$, *then the differential system*

$$w_r'=P_r(w_1,\cdots,w_m,t), \qquad w_r(a)=\beta_r, \qquad \alpha_r\geqq\beta_r\geqq 0,$$

$r=1,\cdots,m$, *has a continuous solution* $(w_1,\cdots,w_m)$ *on* $[a,\omega)$ *and* $w_r(t)\leqq W_r(t)$, $r=1,\cdots,m$, *on* $[a,\omega)$.

Let $B=B(x)$ be an $n\times n$ matrix with real elements which are continuous on the x-interval $[a,\omega)$. We shall prove a comparison theorem for (1) and the system

$$y''+By=0, \qquad B=(b_{ij})_{i,j=1}^{n}, \tag{13}$$

by applying Lemma 2 to the corresponding Riccati systems

$$S'=\mathrm{I}+SAS, \qquad S(c)=\alpha\geqq 0, \qquad c\in[a,\omega), \tag{14}$$

$$T'=\mathrm{I}+TBT, \qquad T(c)=0, \qquad c\in[a,\omega). \tag{15}$$

THEOREM 4. *Let* $A=(a_{ij})_{i,j=1}^{n}$ *and* $B=(b_{ij})_{i,j=1}^{n}$ *be matrices with real elements which are continuous on an interval* $[a,\omega)$. *Assume that* $0\leqq b_{ij}\leqq a_{ij}$, $i,j=1,\cdots,n$, *on* $[b,\omega)$ *for some* b, $a\leqq b<\omega$, *and that* $a_{ij}(b)>0$, $i\neq j$. *Then* $\eta(B,c)\geqq\eta(A,b)$, $a\leqq b\leqq c<\omega$.

Proof. If y is a nontrivial solution of the system (1) satisfying $y(b)=0$, then $y'(x)\neq 0$, $b\leqq x<\eta(A,b)$. Thus, the Riccati system (9) has a continuous solution S on $[b,\eta(A,b))$ by Theorem 3. The solution S is positive on $(b,b+\varepsilon)$ for some $\varepsilon>0$ by Lemma 1; therefore, S is positive throughout the interval $(b,\eta(A,b))$ due to the nonnegativity of the coefficients of the system (9). Hence, on the interval $[c,\eta(A,b))$, $b\leqq c<\eta(A,b)$, S is continuous and satisfies (14) with $\alpha=S(c)$. From Lemma 2 and the inequalities $0\leqq b_{ij}\leqq a_{ij}$, $i,j=1,\cdots,n$, we conclude that (15) possesses a nontrivial solution T which is continuous on $[c,\eta(A,b))$. It follows finally from Theorem 3 that the system (13) is right-disfocal on $[c,\eta(A,b))$, i.e., $\eta(B,c)\geqq\eta(A,b)$.

If $\eta(A,b)\leqq c<\omega$, the inequality holds trivially.

We remark that the following "separation theorem" results when $A=B$ in Theorem 4: Let $A=(a_{ij})_{i,j=1}^{n}$ be a matrix with real elements which are continuous on $[a,\omega)$. Assume that $a_{ij}\geqq 0$, $i,j=1,\cdots,n$, on some interval $[b,\omega)$, $a\leqq b<\omega$, and that $a_{ij}(b)>0$, $i\neq j$. If $b\leqq x_1<x_2<\eta(A,b)$, then the system (1) has no nontrivial solution y such that $y(x_1)=y'(x_2)=0$, i.e., $\eta(A,c)\geqq\eta(A,b)$, $b\leqq c<\omega$.

There are parallel results for left-disfocality, which we summarize below. Let $u_j=\mathrm{col}(u_{1j},\cdots,u_{nj})$, $j=1,\cdots,n$, be the solutions of (1) satisfying

$$u_{ij}(b)=\delta_{ij}, \qquad u_{ij}'(b)=0,$$

for some fixed point b, $a\leqq b<\omega$, $i,j=1,\cdots,n$. Put $U=(u_{ij})_{i,j=1}^{n}$ and $V=-U'U^{-1}$. If the system (1) is left-disfocal on $[b,\omega)$, $\det U$ does not vanish on $[b,\omega)$. Hence, V is continuously differentiable on $[b,\omega)$ and

$$V'=A+V^2, \qquad V(b)=0. \tag{16}$$

Conversely, $\det U$ does not vanish on $[b,\omega)$ if (16) has a continuous solution V on $[b,\omega)$. The proof is omitted because it is similar to the preceding case of right-disfocality. To recapitulate, we have

THEOREM 5. *Let* b *be a point on the interval* $I=[a,\omega)$. *Every nontrivial solution* y *of* (1) *with* $y'(b)=0$ *does not vanish on* $[b,c)$, $a\leqq b<c\leqq\omega$, *if and only if the Riccati system* (16) *has a continuous solution on* $[b,c)$.

Due to the form of the Riccati system (16)—the coefficient matrix A appears by itself—the proof of the comparison theorem for this case is substantially simpler, and the resulting theorem involves inequality conditions imposed on the integrals of the coefficients, rather than on the coefficients themselves.

THEOREM 6. *Let* $A=(a_{ij})_{i,j=1}^{n}$ *and* $B=(b_{ij})_{i,j=1}^{n}$ *be matrices with nonnegative, real elements which are continuous on* $[a,\omega)$. *If* $a_{ij}(b)>0$ *and*

$$\int_c^t b_{ij}(s)\,ds \leqq \int_c^t a_{ij}(s)\,ds, \qquad c \leqq t < \omega, \tag{17}$$

$i,j=1,\cdots,n$, *for some* b *and* c, $a \leqq b \leqq c < \omega$, *then* $\phi(B,c) \geqq \phi(A,b)$.

Proof. By Theorem 5, the Riccati system has a continuous solution V on $[b,\phi(A,b))$. Since $V(b)=0$ and $V'(b)=A(b)>0$, $V>0$ on $(b,b+\varepsilon)$, for some $\varepsilon>0$, and therefore $V>0$ on $(b,\phi(A,b))$ due to the nonnegativity of a_{ij}. If $\phi(A,b) \leqq c$, then the inequality $\phi(B,c) \geqq \phi(A,b)$ holds trivially. If $b \leqq c < \phi(A,b)$, the solution V satisfies

$$V' = A + V^2, \qquad V(c) \geqq 0.$$

From (17) and Lemma 2, we deduce that the system

$$W' = B + W^2, \qquad W(c) = 0,$$

has a continuous solution W on $[c,\phi(A,b))$. Therefore, according to Theorem 5, every nontrivial solution y of the second-order system $y''+By=0$, $y'(c)=0$, is such that $y \neq 0$ on $[c,\phi(A,b))$, i.e., $\phi(B,c) \geqq \phi(A,b)$.

By putting $A=B$ in the above comparison theorem, we again obtain a separation theorem. However, all we can conclude in this case is that the system (1) has no nontrivial solution y such that $y'(c)=y(d)=0$, $b \leqq c < d < \phi(A,b)$, where c is the lower limits of the integrals in (17). If (17) holds for all c, $b \leqq c < \omega$—as in the case $b_{ij} \leqq a_{ij}$, $i,j=1,\cdots,n$—then the above separation theorem is valid for any two points b and c, $b \leqq c < d < \phi(A,b)$.

EVOLUTION PROBLEMS WITH HYSTERESIS IN THE SOURCE TERM*

A. VISINTIN†

Abstract. Jump conditions having a hysteresis effect are introduced to model some inertial mechanisms which yield criteria of control of systems. Examples can be found in biology, chemistry, engineering, and economics.

Both orientations of the hysteresis loops are considered, corresponding to "delay" and "anticipation" between input and output variables.

Existence results are proved for parabolic and hyperbolic problems and also for the Stefan problem with a term of this type in the second member. A regularizing effect is exhibited by the "jump with delay" condition.

Key words. variational problem, hysteresis, existence results

1. Introduction.

1) We introduce a simple *hysteresis* relationship between two functions of time: $u(t)$, $w(t)$. Fix ρ_1, $\rho_2 \in \mathbb{R}$ with $\rho_1 < \rho_2$. Let $u \in C^0([0,T])$ and w^0 be given such that

$$\begin{array}{ll} \text{if } u(0) \leqq \rho_1, & \text{then } w^0 = -1; \\ \text{if } u(0) \geqq \rho_2, & \text{then } w^0 = 1; \\ \text{if } \rho_1 < u(0) < \rho_2, & \text{then } w^0 = -1 \text{ or } 1. \end{array} \tag{1.1}$$

We say that the function w: $[0,T] \to \{-1,1\}$ fulfills a *jump condition with delay* if

$$\begin{array}{l} w(0) = w^0; \\ \text{if } u(t) \leqq \rho_1 \ (u(t) \geqq \rho_2, \text{ respectively}) \text{ then } w(t) = -1 \ (w(t) = 1, \text{ respectively}) \\ \forall t \in [0,T]; \\ w \text{ can jump from } -1 \text{ to } 1 \text{ (from } 1 \text{ to } -1, \text{ respectively) at time } t \text{ only if} \\ u(t) = \rho_2 \ (\rho_1, \text{ respectively}), \text{ these are the only discontinuities of } w. \end{array} \tag{1.2}$$

This means that for any $t \in [0,T[$ if $w(t) = -1$ ($w(t) = 1$, respectively) then w remains constant for $\tau > t$ as long as $u(\tau) < \rho_2$ ($u(\tau) > \rho_1$, respectively); if u reaches ρ_2 (ρ_1, respectively), then w jumps to 1 (-1, respectively), where it remains till u reaches ρ_1 (ρ_2, respectively), and so on. Here delay is meant with respect to the usual condition taking place in any fixed point of $[\rho_1, \rho_2]$: the jump is delayed w.r.t. u, not w.r.t. time.

2) Examples of hysteresis relations of this type are quite common in technology, for instance a thermostat which is switched on or off according to temperature, but with an inertial behavior in its dependence on the latter, so that actually the switching off value ρ_2 is greater than the swtiching on one ρ_1. A different model for problems with thermostats has been studied by Glashoff and Sprekels in [1], [2].

Another example is given by an irrigation model; here u represents water saturation, $w+1$ is the intensity of a water source due to irrigation and (1.2) corresponds to a

* Received by the editors December 7, 1982, and in final revised form November 15, 1984. This work has been supported by the Deutsche Forschungsgemeinschaft through the Sonderforschungsbereich 123.

† Institut für Angewandte Mathematik, Universität Heidelberg, Im Neuenheimer Feld 294, 6900 Heidelberg 1, West Germany. Permanent address: Istituto di Analisi Numerica del C.N.R., c.so C. Alberto 5, 27100-Pavia, Italy.

control criterion for switching the water source either on or off according to the water saturation (see [9, p. 488]).

Further examples arise in biology and chemistry, as in the model studied by Hoppensteadt and Jäger in [3], [4] and treated here in §6.

Mathematical models for hysteresis phenomena have been studied by Krasnosel'skiĭ and Pokrovskiĭ (see [5], [6], e.g.) and by the present author (see [10]–[13]).

3) It can be useful to compare (1.2) with the usual jump relationship. The latter is monotone, but its graph is not maximal monotone; thus the graph of the corresponding operator $u \mapsto w = \operatorname{sign}(u)$ is not closed with respect to the strong topology of $C^0([0,T])$ for u and the weak star topology of $L^\infty(0,T)$ for w. Consequently one is induced to work with the closure of this graph, that is to replace the sign function by the sign graph.

Similarly the functional $u \mapsto w$ defined by (1.2) (for any compatible w^0) is not closed with respect to the strong topology of $C^0([0,T])$ for u and the weak star topology of $L^\infty(0,T)$ for w. Therefore we shall study the form of its closure with respect to these topologies.

The couples $(u,w) \in C^0([0,T]) \times L^\infty(0,T)$ which belong to this closure fulfill the following conditions:

(1.3)
$-1 \leqq w(t) \leqq 1$;
if $u(t) < \rho_1$ ($u(t) > \rho_2$, respectively), then $w(t) = -1$ ($w(t) = 1$, respectively);
if $\rho_1 < u(t) < \rho_2$, then w is constant in a neighborhood of t;
if $u(t) = \rho_1$ ($u(t) = \rho_2$, respectively), then $w(t)$ is nonincreasing (nondecreasing, respectively) in a neighborhood of t (see Fig. 1).

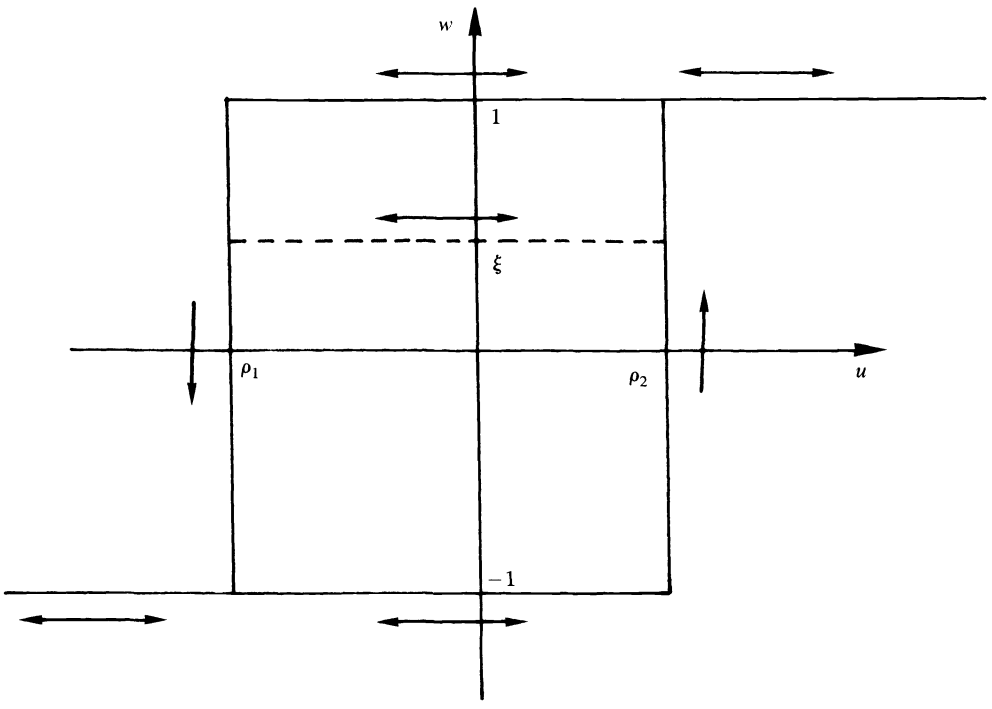

FIG. 1. *Arrows indicate the direction of movement of* $(u(t), w(t))$ *as* t *increase.* $\xi \in [-1,1]$ *is generic.*

Indeed by means of small perturbations of $u(t)$ where this reaches ρ_1 (ρ_2, respectively) as a local minimum (maximum, respectively), we get perturbed w's which attain the constant values -1 or 1 as long as $\rho_1 < u(t) < \rho_2$; then by weak star convergence in $L^\infty(0,T)$ we can get any w which attains arbitrary constant values betweeen -1 and 1 as long as $\rho_1 < u(t) < \rho_2$.

We note that any w fulfilling (1.2) has bounded total variation in $[0,T]$: $w \in BV(0,T)$; thus the initial condition is meaningful and $w' \in C^0([0,T])$. Indeed w has a variation equal to 2 just when u reaches one of the thresholds ρ_1, ρ_2 and moreover the uniformly continuous function u can have just a finite number of oscillations between ρ_1 and ρ_2. Also any w fulfilling (1.3) has bounded total variation in $[0,T]$.

We introduce some notation:

$$\alpha(\xi) \equiv (\xi-\rho_2)^+ - (\xi-\rho_1)^-, \quad \beta(\xi) \equiv \xi - \alpha(\xi) \quad \forall \xi \in \mathbb{R}; \tag{1.4}$$

$$S(\eta) \equiv \begin{cases} \{-1\} & \text{if } \eta < 0, \\ [-1,1] & \text{if } \eta = 0 \\ \{1\} & \text{if } \eta > 0, \end{cases} \quad \forall \eta \in \mathbb{R}; \tag{1.5}$$

$$R(\eta) \equiv \begin{cases}]-\infty, 0[& \text{if } \eta = \rho_1, \\ \{0\} & \text{if } \rho_1 < \eta < \rho_2 \\ [0, +\infty[& \text{if } \eta = \rho_2, \end{cases} \quad \forall \eta \in [\rho_1, \rho_2]. \tag{1.6}$$

It is easy to check that (1.3) entails

$$\int_0^T w[\alpha(u) - v]\, dt \geqq \int_0^T (|\alpha(u)| - |v|)\, dt \quad \forall v \in L^1(0,T), \tag{1.7}$$

i.e.

$$w \in S(\alpha(u)) \quad \text{in }]0,T[. \tag{1.8}$$

Conditions (1.3) imply also

$$_{(C^0([0,T]))'}\langle w', \beta(u) - v \rangle_{C^0([0,T])} \geqq 0 \quad \forall v \in C^0([0,T]) \text{ such that } \rho_1 \leqq v \leqq \rho_2, \tag{1.9}$$

i.e.,

$$w' \in R(\beta(u)) \quad \text{in } (C^0([0,T]))'; \tag{1.10}$$

the latter is equivalent to

$$w' \in S^{-1}\left(\frac{2}{\rho_2 - \rho_1} \left[\beta(u) - \frac{\rho_1 + \rho_2}{2} \right] \right), \quad \text{i.e.} \quad \frac{2}{\rho_2 - \rho_1} \left[\beta(u) - \frac{\rho_1 + \rho_2}{2} \right] \in S(w'), \tag{1.11}$$

which is to be understood as follows

$$\frac{2}{\rho_2 - \rho_1} {}_{C^0([0,T])}\left\langle \beta(u) - \frac{\rho_2 + \rho_1}{2}, w' - v \right\rangle_{(C^0([0,T]))'} \geqq \int_0^T (|w'| - |v|) \quad bav \in (C^0([0,T]))' \tag{1.12}$$

(here $\int_0^T |v|$ denotes the total mass of v in $[0,T]$); this can be easily deduced by (1.3). (We point out that calculations are simplified in the case of $\rho_1 = -1$, $\rho_2 = 1$.) (1.7) and (1.9) express the property (1.3) in variational form. We weaken the compatibility

condition (1.1) requiring just that

$$\text{(1.13)}\qquad \begin{aligned} &\text{if } u(0)<\rho_1 \ (u(0)>\rho_2, \text{ respectively}), \text{ then } w^0=-1 \ (w^0=1, \text{ respectively});\\ &\text{if } \rho_1\leqq u(0)\leqq\rho_2, \text{ then } -1\leqq w(0)\leqq 1; \end{aligned}$$

then for any compatible couple $(u,w^0)\in C^0([0,T])\times[-1,1]$ we consider the set of the $w\in BV(0,T;[-1,1])$ such that $w(t)\to w^0$ as $t\to 0^+$, (1.7) and (1.9) hold.

For any fixed w^0 this multivalued correspondence $u\mapsto w$ is closed with respect to the strong topology of $C^0([0,T])$ for u and the weak star topology of $BV(0,T)$ for w; hence it is the closure of the functional defined by (1.2).

So far we have assumed the couple (ρ_1,ρ_2) to be fixed; an interesting generalization is obtained as follows. Set $\mathscr{P}\equiv\{\rho=(\rho_1,\rho_2)\in\mathbb{R}^2\mid\rho_1<\rho_2\}$; let $u\in C^0([0,T])$ and for any ρ let w_ρ denote the function w defined by (1.2) and corresponding to an initial datum w_ρ^0 compatible with u in the sense of (1.1); let μ be a measure over $\mathscr{P}$; then we can consider the functional $u\mapsto w=\int_{\mathscr{P}} w_\rho\,d\mu_\rho$; this corresponds to the classical Preisach model introduced for ferromagnetism and has been studied in [12], for example,

4) After considering hysteresis (delay), we take into account the inverse effect, namely *anticipation*.

Let u: $[0,T]\to\mathbb{R}$ be absolutely continuous; we shall say that a measurable function $w(t)$ fulfills a *jump condition with anticipation* if a.e. in $]0,T[$

$$\text{(1.14)}\qquad \begin{aligned} &\text{if } u(t)<\rho_1 \ (u(t)>\rho_2, \text{ respectively}) \text{ then } w(t)=-1 \ (w(t)=1, \text{ respectively}),\\ &\text{if } \rho_1\leqq u(t)\leqq\rho_2, \text{ then } w(t)\in S(u'(t)) \text{ (see Fig. 2)} \end{aligned}$$

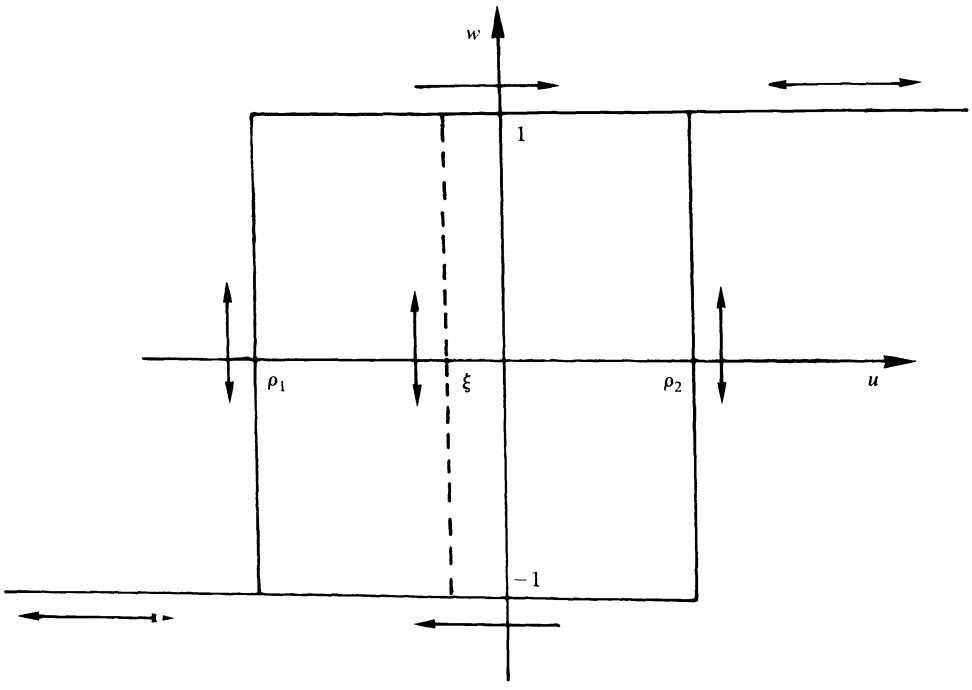

FIG. 2. *Arrows indicate the direction of movement of* $(u(t), w(t))$ *as* t *increases.* $\xi\in[\rho_1,\rho_2]$ *is generic.*

or equivalently

$$\begin{aligned} &w\in S(\alpha(u)) \quad \text{a.e. in }]0,T[,\\ &w\in S\big(\beta(u)'\big) \quad \text{a.e. in }]0,T[\end{aligned} \tag{1.15}$$

or also

$$w\in S\big(\alpha(u)+\beta(u)'\big) \quad \text{a.e. in }]0,T[. \tag{1.16}$$

Note that here no initial condition is required for w; moreover the graph of the multivalued functional $u\mapsto w$ is closed with respect to the strong topology of $W^{1,1}(0,T)$ for u and the weak star topology of $L^\infty(0,T)$ for w.

If $\rho_1=-1$ and $\rho_2=1$, then the behavior of $(u(t),w(t))$ in (1.7), (1.9) and in (1.14) are reciprocally inverse in $[-1,1]^2$; in particular the esterior loop is covered with opposite orientations in the two cases.

5) Anticipation corresponds to the case in which in a certain range the output w depends on the trend of the input u, not on its value. Examples of this situation can be found in sociology, economics, and so on. For instance delay and anticipation in the sense introduced above are possible attitudes of economical operators; here w may represent a decision ($w=1$ for Yes, $w=-1$ for No, say), whereas u may be a measure of the advantages offered by the operation under consideration.

In this last case and in the example of irrigation the dependence $u\mapsto w$ corresponds to a criterion of control, whereas in the example of thermostat it describes the behavior of a system. In some cases, for instance that of the economical operator, it may be possible to choose between the strategy of delay and that of anticipation (and also to select the thresholds ρ_1, ρ_2). If the input u is continuous in time, then the delay criterion offers the advantage of bounding the total variation of the output w; for instance in the model of irrigation the number of interventions on the irrigation system will be finite. On the other hand, if the input is absolutely continuous in time, then the anticipation criterion allows to take advantage of the forecast offered to some extent by the inertia of the variable u.

6) Let D be a bounded domain of $\mathbb{R}^n$ ($N\geqq 1$). We shall deal with PDE's of the form

$$u_t-\Delta u+w-f \quad \text{in } Q\equiv D\times]0,T[; \tag{1.17}$$

$$\begin{aligned} &u_t-\Delta u=g && \text{in } Q,\\ &\frac{\partial u}{\partial \nu}+w=h && \text{on } \Sigma\equiv \partial D\times]0,T[; \end{aligned} \tag{1.18}$$

$$u_{tt}-\Delta u+w=f \quad \text{in } Q; \tag{1.19}$$

where f, g, h are data, $\Delta\equiv\sum_{i=1}^N \partial^2/\partial x_i^2$ and $\partial/\partial\nu$ denotes the outward normal derivative.

Each of these equations will be coupled with either the hysteresis or the anticipation relationships introduced above. We also consider a Stefan problem with hysteresis in the source; this corresponds to coupling the hysteresis relation with the system

$$\begin{aligned} &(u+\lambda\chi)_t-\Delta u+w=f && \text{in } Q;\\ &\chi\in H(u) && \text{in } Q, \end{aligned} \tag{1.20}$$

where λ is a positive constant representing latent heat and H denotes the Heaviside graph ($H(\xi)=\{0\}$ if $\xi<0$, $H(0)=[0,1]$, $H(\xi)=\{1\}$ if $\xi>0$).

The present author has already studied hysteresis in connection with PDE's (see [10], [11], [12] and [13] for a survey). In particular in [11] existence and approximation results were proved for (1.7), (1.9) coupled with the equation

$$(u+w)_t-\Delta u=f \quad \text{in } Q, \tag{1.21}$$

with suitable initial and boundary condition. This setting generalizes the weak formulation of the Stefan problem.

Here we shall prove existence results for (the weak formulations of) equations (1.17), (1.18) and (1.19), each one coupled with the hysteresis relation (1.7), (1.9) (problems (P1), (P2), (P3), respectively; §2), for the same equations coupled with the anticipation relation (1.15) (problems (P4), (P5), (P6), respectively; §3) and for the Stefan problem with hysteresis in the source, i.e. (1.20) coupled with (1.7), (1.9) (problem (P7), §5). We also give several complementary results.

Finally in §6 we consider the problem studied by Hoppensteadt and Jäger in [3], [4]. There a system of two diffusion equations is coupled with a hysteresis relationship of the form (1.2). We replace the latter by the weaker condition (1.3), i.e. with the system (1.7), (1.9), and prove existence of a variational solution of the problem.

We stress that the formulation of the hysteresis relation we give here is different from that used by Jäger in [4].

For all of these problems the uniqueness of the solution is an open question. We are just able to prove the weaker result of Proposition 8.

2. Jump with delay.

1) Set $V=H_0^1(D)$, Hilbert space with norm $\|v\|_V=(\int_D|\overline{\nabla}v|^2dx)^{1/2}$, and $A\colon V\to V'$ defined by ${}_{V'}\langle Au,v\rangle_V=\int_D\overline{\nabla}u\cdot\overline{\nabla}v\,dx\ \forall u,\ v\in V$. Let

$$f\in L^2(0,T,V'); \tag{2.1}$$

$$u^0\in L^2(D) \text{ and } w^0\in L^\infty(D), \text{ such that } w^0\in S(\alpha(u^0)) \text{ a.e. in } D. \tag{2.2}$$

We introduce a weak formulation of (1.17), (1.3).

(P1) Find $u\in L^2(0,T,V)\cap H^1(0,T,V')$ ($\subset C^0([0,T];L^2(D))$) and $w\in L^\infty(Q)$ such that $\beta(u(x,\cdot))\in C^0([0,T])$, $w(x,\cdot)\in BV(0,T)$ a.e. in D and

$$w\in S(\alpha(u)) \quad \text{a.e. in } Q, \tag{2.3}$$

$$({}_{C^0([0,T])'}\langle w_t,\beta(u)-v\rangle_{C^0([0,T])}\geqq 0 \quad \forall v\in C^0([0,T]) \text{ such that } \rho_1\leqq v\leqq\rho_2, \text{ a.e. in } D, \tag{2.4}$$

$$\lim_{t\to 0^+}[w(x,t)-w^0(x)]\cdot[\beta(u^0(x))-v]\geqq 0 \quad \forall v\in[\rho_1,\rho_2], \text{ a.e. in } D, \tag{2.5}$$

$$u_t+Au+w=f \quad \text{in } V', \quad \text{a.e. in }]0,T[, \tag{2.6}$$

$$u(x,0)=u^0(x) \quad \text{a.e. in } D. \tag{2.7}$$

THEOREM 1. *Assume that* (2.2) *holds and that*

$$u^0 \in V; \tag{2.8}$$

$$f = f_1 + f_2, \quad f_1 \in L^2(Q), \quad f_2 \in W^{1,1}(0,T;V'). \tag{2.9}$$

Then problem (P1) *has at least one solution such that moreover*

$$u \in H^1(0,T;L^2(D)) \cap C_S^0([0,T];V); \tag{2.10}$$

$$w \in L^2(D; BV(0,T)). \tag{2.11}$$

We recall the definition of the space of scalarly continuous functions with values in a Banach space B:

$$C_S^0([0,T];B) = \{ v\colon [0,T] \to B \mid \forall \varphi \in B',\ t \mapsto {}_B\langle v(t), \varphi \rangle_{B'} \text{ is continuous in } [0,T] \}. \tag{2.12}$$

Throughout this paper u and w are regarded as functions of t with values into a space of functions of x, as well as functions of x with values into a space of functions of t.

Proof. (i) *Approximation.* Let $m \in \mathbb{N}$, $k = T/m$. Set

$$\begin{aligned} &f_m^n = f_{1m}^n + f_{2m}^n, \qquad f_{1m}^n(x) = \frac{1}{k} \int_{(n-1)k}^{nk} f_1(x,t)\,dt \quad \text{a.e. in } D; \\ &f_{2m}^n = f_2(nk) \quad \text{in } V', \text{ for } n = 1, \cdots, m; \end{aligned} \tag{2.13}$$

$$K(\xi,\eta) = \begin{cases} \{-1\} & \text{if } \xi < \rho_1 \\ [-1,\eta] & \text{if } \xi = \rho_1 \\ \{\eta\} & \text{if } \rho_1 < \xi < \rho_2 \\ [\eta,1] & \text{if } \xi = \rho_2 \\ \{1\} & \text{if } \xi > \rho_2 \end{cases} \quad \forall \xi \in \mathbb{R}, \forall \eta \in [-1,1]. \tag{2.14}$$

$(\mathrm{P1})_m$ Find $u_m^n \in V$, $w_m^n \in L^\infty(D)$ for $n = 1, \cdots, m$, such that, setting $u_m^0 = u^0$, $w_m^0 = w^0$ a.e. in D,

$$\frac{u_m^n - u_m^{n-1}}{k} + Au_m^n + w_m^n = f_m^n \quad \text{in } V', \text{ for } n = 1, \cdots, m, \tag{2.15}$$

$$w_m^n \in K(u_m^n, w_m^{n-1}) \quad \text{a.e. in } D, \text{ for } n = 1, \cdots, m. \tag{2.16}$$

$\forall m \in \mathbb{N}$ $(\mathrm{P1})_m$ can be solved step by step. Fix $n \in \{1, \cdots, m\}$ and assume that u_m^{n-1}, w_m^{n-1} are known. $K(\cdot, w_m^{n-1}(x))$ is a maximal monotone graph a.e. in D. Therefore (2.15) is equivalent to the minimization of a coercive, strictly convex, lower semicontinuous functional $V \to \mathbb{R}$; this problem has a unique solution u_m^n (which can be approximated by standard space-discretization methods).

(ii) *Estimates.* Take a generic $l \in \{1, \cdots, m\}$, multiply (2.15) by $u_m^n - u_m^{n-1}$ and sum for $n = 1, \cdots, l$. Notice that

$$\sum_{n=1}^{l} \int_D \frac{u_m^n - u_m^{n-1}}{k} \left(u_m^n - u_m^{n-1}\right) dx = k \sum_{n=1}^{l} \left\| \frac{u_m^n - u_m^{n-1}}{k} \right\|^2_{L^2(D)}, \tag{2.17}$$

$$\sum_{n=1}^{l} \int_D w_m^n \left(u_m^n - u_m^{n-1}\right) dx \geqq -k \sum_{n=1}^{l} \left\| \frac{u_m^n - u_m^{n-1}}{k} \right\|_{L^1(D)}, \tag{2.18}$$

$$\begin{aligned} \sum_{n=1}^{l} {}_{V'}\langle A u_m^n, u_m^n - u_m^{n-1} \rangle_V &= \sum_{n=1}^{l} \int_D \overline{\nabla} u_m^n \cdot \overline{\nabla} \left(u_m^n - u_m^{n-1}\right) dx \\ &\geqq \frac{1}{2} \sum_{n=1}^{l} \left(\|u_m^n\|_V^2 - \|u_m^{n-1}\|_V^2 \right) = \frac{1}{2} \|u_m^l\|_V^2 - \frac{1}{2} \|u^0\|_V^2, \end{aligned} \tag{2.19}$$

$$\sum_{n=1}^{l} \int_D f_{1m}^n \left(u_m^n - u_m^{n-1}\right) dx \leqq \|f_1\|_{L^2(Q)} \left(k \sum_{n=1}^{l} \left\| \frac{u_m^n - u_m^{n-1}}{k} \right\|^2_{L^2(D)} \right)^{1/2}, \tag{2.20}$$

$$\begin{aligned} &\sum_{n=1}^{l} {}_{V'}\langle f_{2m}^n, u_m^n - u_m^{n-1} \rangle_V \\ &\quad = {}_{V'}\langle f_{2m}^n, u_m^l \rangle_V - {}_{V'}\langle f_{2m}^1, u^0 \rangle_V - \sum_{n=1}^{l} {}_{V'}\langle f_{2m}^n - f_{2m}^{n-1}, u_m^{n-1} \rangle_V \\ &\quad \leqq \text{Const.} \|f_{2m}\|_{W^{1,1}(0,T;V')} \max_{n=0,\cdots,l} \|u_m^n\|_V. \end{aligned} \tag{2.21}$$

Using Gronwall's lemma we get

$$k \sum_{1}^{m} {}_n \left\| \frac{u_m^n - u_m^{n-1}}{k} \right\|^2_{L^2(D)} \leqq C; \tag{2.22}$$

$$\max_{n=0,\cdots,m} \|u_m^n\|_V \leqq C \tag{2.23}$$

(throughout this paper we shall denote positive constants independent of m by C and C_i's). Note that by (2.16)

$$\begin{cases} w_m^n - w_m^{n-1} & \text{only if } u_m^n \geqq \rho_2 \\ w_m^n < w_m^{n-1} & \text{only if } u_m^n \leqq \rho_1 \quad \text{a.e. in } D, \text{ for } n = 1, \cdots, m. \\ |w_m^n - w_m^{n-1}| \leqq 2, \end{cases} \tag{2.24}$$

This yields

$$\sum_{1}^{m} {}_n |w_m^n - w_m^{n-1}| \leqq \frac{2}{\rho_2 - \rho_1} \sum_{1}^{m} {}_n |u_m^n - u_m^{n-1}| + 2 \quad \text{a.e. in } D, \tag{2.25}$$

whence

$$\left\| \sum_{1}^{m} {}_n |w_m^n - w_m^{n-1}| \right\|_{L^2(D)} \leqq \frac{2}{\rho_2 - \rho_1} \left\| \sum_{1}^{m} {}_n |u_m^n - u_m^{n-1}| \right\|_{L^2(D)} + 2(\text{meas } D)^{1/2}. \tag{2.26}$$

Let $u_m(x,t)$ denote the function obtained by linear interpolation of the values $u_m(x,nk)=u_m^n(x)$ for $n=0,\cdots,m$ a.e. in D; define w_m similarly. Set $\hat{u}_m(x,t)=u_m^n(x)$, $\hat{w}_m(x,t)=w_m^n(x)$ a.e. in D and $\hat{f}_m(t)=f_m^n$ in V' if $(n-1)k<t\leqq nk$, for $n=1,\cdots,m$. (2.15) becomes

$$u_{mt}+A\hat{u}_m+\hat{w}_m=\hat{f}_m \quad \text{in } V', \text{ a.e. in }]0,T[. \tag{2.27}$$

(2.22), (2.23) and (2.26) yield

$$\|u_m\|_{H^1(0,T;L^2(D))\cap L^\infty(0,T;V)}\leqq C, \tag{2.28}$$

(2.29)

$$\|w_m\|_{L^2(D;BV(0,T))}=\|w_m\|_{L^2(D;W^{1,1}(0,T))}\leqq\frac{2}{\rho_2-\rho_1}\|u_m\|_{L^2(D;W^{1,1}(0,T))}+2(\operatorname{meas}D)^{1/2}$$

$$\leqq\frac{2\sqrt{T}}{\rho_2-\rho_1}\|u_m\|_{H^1(0,T;L^2(D))}+2(\operatorname{meas}D)^{1/2}\leqq C,$$

moreover of course

$$\|w_m\|_{L^\infty(Q)}\leqq C,\ \|\hat{w}_m\|_{L^\infty(Q)}\leqq C. \tag{2.30}$$

(iii) *Limit.* By the above estimates there exist u, w such that, possibly taking subsequences,

$$u_m\to u \text{ in } H^1(0,T;L^2(D)) \text{ weak, in } L^\infty(0,T;V) \text{ weak star;} \tag{2.31}$$

$$\hat{u}_m\to 0 \text{ in } H^r(0,T;L^2(D)) \text{ weak } \forall r<\tfrac{1}{2}, \text{ in } L^\infty(0,T;V) \text{ weak star;} \tag{2.32}$$

$$w_m\to w \text{ in } L^2(D;BV(0,T)) \text{ weak star;} \tag{2.33}$$

$$w_m\to w,\ \hat{w}_m\to w \text{ in } L^\infty(Q) \text{ weak star.} \tag{2.34}$$

Taking $m\to\infty$ in (2.27) we get (2.6). As α and β are Lipschitz continuous we have

$$\alpha(\hat{u}_m)\to\alpha(u) \text{ in } H^r(0,T;L^2(D)) \text{ weak } \forall r<\tfrac{1}{2}, \text{ in } L^\infty(0,T;V) \text{ weak star;} \tag{2.35}$$

$$\beta(u_m)\to\beta(u) \text{ in } H^1(0,T;L^2(D)) \text{ weak, in } L^\infty(0,T;V) \text{ weak star.} \tag{2.36}$$

By (2.16)

$$w_m^n\in S(\alpha(u_m^n)) \quad \text{a.e. in } D, \text{ for } n=1,\cdots,m, \tag{2.37}$$

that is,

$$\hat{w}_m\in S(\alpha(\hat{u}_m)) \quad \text{a.e. in } Q. \tag{2.38}$$

Hence $\forall v\in L^1(Q)$

$$\iint_Q \hat{w}_m[\alpha(u_m)-v]\,dx\,dt\geqq\iint_Q\left(|\alpha(\hat{u}_m)|-|v|\right)dx\,dt, \tag{2.39}$$

whence taking $m\to\infty$ and using (2.34), (2.35)

$$\iint_Q w[\alpha(u)-v]\,dx\,dt\geqq\iint_Q\left(|\alpha(u)|-|v|\right)dx\,dt, \tag{2.40}$$

that is, (2.3).

Notice that (2.16) yields

$$w_m^n - w_m^{n-1} \in R\big(\beta(u_m^n)\big) \quad \text{a.e. in } D, \text{ for } n=1,\cdots,m. \tag{2.41}$$

Take a generic $v \in H^1(0,T,L^2(D))$ such that $\rho_1 \leqq v \leqq \rho_2$ a.e. in Q and $v(x,T) = \beta(u(x,T))$ a.e. in D; set $v_m^n(x) = v(x,nk)$ if $(n-1)k < t \leqq nk$ for $n=1,\cdots,m$ and denote the linear interpolate of these values by v_m. By (2.41)

$$0 \leqq \sum_1^m{}_n \int_D \big(w_m^n - w_m^{n-1}\big)\cdot\big(\beta(u_m^n) - v_m^n\big)\,dx = \iint_Q w_{mt}\cdot\big(\beta(\hat{u}_m) - \hat{v}_m\big)\,dx\,dt, \tag{2.42}$$

that is

$$0 \leqq \iint_D {}_{(C^0([0,T]))'}\langle w_{mt}, \beta(u_m) - v_m\rangle_{C^0([0,T])}\,dx + \iint_Q w_{mt}\cdot\big(\beta(u_m) - \beta(\hat{u}_m) + v_m - \hat{v}_m\big)\,dx\,dt. \tag{2.43}$$

The inclusion $H^1(Q) \subset L^2(D; C^0([0,T]))$ is compact, hence by (2.36) we have $\beta(u_m) \to \beta(u)$ in $L^2(D; C^0([0,T]))$ strong and $\beta(u_m) - \beta(\hat{u}_m) \to 0$ in $L^2(D; L^\infty(0,T))$ strong; the same convergence properties hold for v_m and $v_m - \hat{v}_m$; moreover by (2.33) $w_{mt} \to w_t$ in $L^2(D; (C^0([0,T]))')$ weak star and by (2.29) $\|w_{mt}\|_{L^2(D;\, L^1(0,T))} \leqq C$. Therefore taking $m \to \infty$ in (2.42) we get

$$0 \leqq \int_D {}_{(C^0([0,T]))'}\langle w_t, \beta(u) - v\rangle_{C^0([0,T])}\,dx + 0, \tag{2.44}$$

whence (2.4).

Finally $u \in C_S^0([0,T]; V)$ is entailed by the following result.

LEMMA 1. *Let X, Y be two Banach spaces, $X \subset Y$ with continuous injection, X being reflexive. Then*

$$L^\infty(0,T;X) \cap C_S^0([0,T]; Y) = C_S^0([0,T]; X). \tag{2.45}$$

Proof. Cf. [8, Chap. 3, §8.4]. □

PROPOSITION 1. *Assume that* (2.2), (2.8) *hold and that moreover*

$$f(0) + \Delta u^0 - w^0 \in L^2(D), \tag{2.46}$$

$$f = f_1 + f_2 \quad \text{with } f_1 \in W^{1,1}\big(0,T; L^2(D)\big), \qquad f_2 \in H^1(0,T; V'). \tag{2.47}$$

Then the problem (P1) *has at least one solution such that moreover*

$$u \in W^{1,\infty}\big(0,T; L^2(D)\big) \cap H^1(0,T; V), \tag{2.48}$$

$$w \in L^2\big(D; BV(0,T)\big). \tag{2.49}$$

Proof. It is sufficient to show stronger a priori estimates on the solutions u_m's of the approximated problems $(\mathrm{P1})_m$'s. $\forall m \in \mathbb{N}$, set

$$z_m^n = \frac{u_m^n - u_m^{n-1}}{k}, \quad \omega_m^n = \frac{w_m^n - w_m^{n-1}}{k}, \quad g_m^n = \frac{f_m^n - f_m^{n-1}}{k} \quad \text{for } n=1,\cdots,m;$$

set also $z_m^0 = f(0) + \Delta u^0 - w^0$ a.e. in D. Taking the incremental ratio w.r.t. time in (2.15), we get

$$\frac{z_m^n - z_m^{n-1}}{k} + A z_m^n + \omega_m^n = g_m^n \quad \text{in } V', \quad \text{for } n=1,\cdots,m. \tag{2.50}$$

Take a generic $l\in\{1,\cdots,m\}$, multiply (2.50) by kz_m^n and sum for $n=1,\cdots,l$. Notice that, as $w_m^n\in K(u_m^n,w_m^{n-1})$ and by the monotonicity of K. w.r.t. its first argument, we have

$$\omega_m^n z_m^n=\frac{w_m^n-w_m^{n-1}}{k}\cdot\frac{u_m^n-u_m^{n-1}}{k}\geqq 0 \quad \text{a.e. in } D, \text{ for } n=1,\cdots,m. \tag{2.51}$$

Thus by developments analogous to (2.17)–(2.21) and still by Gronwall's lemma we get

$$\max_{n=0,\cdots,m}\|z_m^n\|_{L^2(D)}\leqq C; \tag{2.52}$$

$$k\sum_1^m\|z_m^n\|_V^2\leqq C, \tag{2.53}$$

i.e.

$$\|u_m\|_{W^{1,\infty}(0,T;L^2(D))\cap H^1(0,T;V)}\leqq C. \tag{2.54}$$ □

2) We are going to introduce a weak formulation of (1.3), (1.18).

Assume that $\Gamma\equiv\partial D$ is a variety piecewise of class C^1, that D is only on one side of Γ. Set $W=H^1(D)$, Hilbert space with norm $\|v\|_W=[\int_D(v^2+|\overline{\nabla}v|^2)dx]^{1/2}$. Introduce the trace operator γ: $W\to H^{1/2}(\Gamma)$ (cf. [8, Chap. 1]) and, after identification of $L^2(\Gamma)$ with its dual, denote its adjoint by γ^*:

$$\begin{aligned}&\gamma^*\colon H^{-1/2}(\Gamma)\to W' \quad \forall v\in H^{-1/2}(\Gamma),\ \forall z\in W,\\ &{}_{W'}\langle\gamma^*v,z\rangle_W={}_{H^{-1/2}(\Gamma)}\langle v,\gamma z\rangle_{H^{1/2}(\Gamma)};\end{aligned} \tag{2.55}$$

in particular

$${}_{W'}\langle\gamma^*v,z\rangle_W=\int_\Gamma v\cdot\gamma z\,d\sigma \quad \forall v\in L^2(\Gamma),\ \forall z\in W. \tag{2.56}$$

Let (2.1) hold and

(2.57) $u^0\in L^2(D)\cap W^{1,1}(D)$ and $w^0\in L^\infty(\Gamma)$ such that $w^0\in S(\alpha(\gamma u^0))$ a.e. on Γ.

(P2) Find $u\in L^2(0,T;W)\cap H^1(0,T;W')$ $(\subset C^0([0,T];L^2(D)))$ and $w\in L^\infty(\Sigma)$ such that $\beta(\gamma u(\sigma,\cdot))\in C^0([0,T])$, $w(\sigma,\cdot)\in BV(0,T)$ a.e. on Γ and

(2.58) $w\in S(\alpha(\gamma u))$ a.e. on Σ,

(2.59) ${}_{(C^0([0,T]))'}\langle w_t,\beta(\gamma u)-v\rangle_{C^0([0,T])}\geqq 0$

$\forall v\in C^0([0,T])$ such that $\rho_1\leqq v\leqq\rho_2$, a.e. on Γ;

(2.60) $\lim_{t\to 0^+}[w(\sigma,t)-w^0(\sigma)]\cdot[\beta(u^0(\sigma))-v]\geqq 0$ $\forall v\in[\rho_1,\rho_2]$ a.e. on Γ;

(2.61) $u_t+Au+\gamma^*w=f$ in W' a.e. in $]0,T[$;

(2.62) $u(\sigma,0)=u^0(\sigma)$ a.e. on Γ.

THEOREM 2. *Assume that* (2.8), (2.47), (2.57) *hold and that*

$$f(0)+Au^0+\gamma^*w^0\in L^2(D). \tag{2.63}$$

Then problem (P2) *has at least one solution such that moreover*

$$u\in W^{1,\infty}(0,T;L^2(D))\cap H^1(0,T;W), \tag{2.64}$$

$$w\in L^2(\Gamma,BV(0,T)). \tag{2.65}$$

Proof. $\forall m \in \mathbb{N}$ we introduce to mean a time-discretized problem $(P2)_m$ similar to $(P1)_m$; also $(P2)_m$ has one (and only one) solution. Taking the incremental ration w.r.t. time in the approximate equation and using the procedure of Proposition 1, we get the following estimates

$$\|u_m\|_{W^{1,\infty}(0,T;L^2(D))\cap H^1(0,T;W)} \leqq C; \tag{2.66}$$

$$\|\hat{u}_m\|_{H^r(0,T;W)} \leqq C \quad \forall r < \tfrac{1}{2}. \tag{2.67}$$

The approximate equation has the form

$$u_{mt} + A\hat{u}_m + \gamma^* \hat{w}_m = \hat{f}_m \quad \text{in } W', \text{ a.e. in }]0,T[\tag{2.68}$$

(notations are as in the proof of Theorem 1). (2.25) yields

$$\begin{aligned} \|w_m\|_{L^2(\Gamma;BV(0,T))} &= \|w_m\|_{L^2(\Gamma;W^{1,1}(0,T))} \\ &\leqq \frac{2}{\rho_2 - \rho_1} \|\gamma u_m\|_{L^2(\Gamma;W^{1,1}(0,T))} + 2(\mathrm{meas}(\Gamma))^{1/2} \\ &\leqq C_1 \|u_m\|_{H^1(0,T;W)} + C_2 \leqq C. \end{aligned} \tag{2.69}$$

Therefore there exist u, w such that

$$u_m \to u \quad \text{in } W^{1,\infty}(0,T;L^2(D)) \text{ weak star, in } H^1(0,T;W) \text{ weak}; \tag{2.70}$$

$$\hat{u}_m \to u \quad \text{in } H^r(0,T;W) \text{ weak } \forall r < \tfrac{1}{2}; \tag{2.71}$$

$$w_m \to w \quad \text{in } L^2(\Gamma;BV(0,T)) \text{ weak star}; \tag{2.72}$$

$$w_m \to w,\ \hat{w}_m \to w \quad \text{in } L^\infty(Q) \text{ weak star}. \tag{2.73}$$

Taking $m \to \infty$ in (2.68) we get (2.61). (2.70) yields

$$\gamma u_m \to \gamma u \quad \text{in } H^1(0,T;H^{1/2}(\Gamma)) \text{ weak} \tag{2.74}$$

and as α and β are Lipschitz-continuous we get also

$$\alpha(\gamma \hat{u}_m) \to \alpha(\gamma u) \quad \text{in } H^r(0,T;L^2(\Gamma)) \cap L^2(0,T;H^{1/2}(\Gamma)) \text{ weak}, \ \forall r < \tfrac{1}{2}; \tag{2.75}$$

$$\beta(\gamma u_m) \to \beta(\gamma u) \quad \text{in } H^1(0,T;L^2(\Gamma)) \cap L^2(0,T;H^{1/2}(\Gamma)) \text{ weak}. \tag{2.76}$$

This allows us to prove (2.59) and (2.60) by a procedure analogous to that of the proof of Theorem 1. □

Remark. (2.63) is equivalent to the existence of a positive constant C such that

$$\left| {}_{V'}\langle f(0) + Au^0 + \gamma^* w^0, v \rangle_V \right| \leqq C \|v\|_{L^2(D)} \quad \forall v \in V; \tag{2.77}$$

thus if $f(0) \in V'$ is of the form

$${}_{V'}\langle f(0), v \rangle_V = \int_D \varphi \cdot v \, dx + {}_{H^{-1/2}(\Gamma)}\langle \psi, \psi v \rangle_{H^{1/2}}(\Gamma) \quad \forall v \in V \tag{2.78}$$

with $\varphi \in L^2(D)$ and $\psi \in H^{-1/2}(\Gamma)$, then (2.63) is equivalent to

$$\begin{aligned} &-\Delta u^0 + \varphi \in L^2(D) \quad \text{i.e. } \Delta u^0 \in L^2(D); \\ &\frac{\partial u^0}{\partial \nu} + w^0 + \psi = 0 \quad \text{in } H^{-1/2}(\Gamma). \end{aligned} \tag{2.79}$$

Remark. Theorems 1 and 2 can be extended to the case in which $D_t - \Delta$ is replaced by a nonlinear strictly parabolic operator.

3) We shall give a weak formulation of (1.3), (1.19). We introduce the interpolation spaces $H_{00}^{1/2}(D) = [L^2(D), V]_{1/2}$, $(H_{00}^{1/2}(D))' = [V', L^2(D)]_{1/2}$ as in [8, Chap. 1]. Assume that (2.1) and (2.2) hold with moreover

$$u^0 \in H_{00}^{1/2}(D); \tag{2.80}$$

let

$$u^1 \in \left(H_{00}^{1/2}(D)\right)'. \tag{2.81}$$

(P3) Find $u \in L^2(0,T;V) \cap H^2(0,T;V')$ and $w \in L^\infty(Q)$ such that $w(x,\cdot) \in BV(0,T)$ a.e. in D and

$$w \in S(\alpha(u)) \text{ a.e. in } Q; \tag{2.82}$$

$$_{(C^0([0,T]))'}\langle w_t, \beta(u) - v\rangle_{C^0([0,T])} \geqq 0 \tag{2.83}$$

$$\forall v \in C^0([0,T]) \text{ such that } \rho_1 \leqq v \leqq \rho_2, \qquad \text{a.e. in } D;$$

$$\lim_{t \to 0^+} \left[w(x,t) - w^0(x)\right] \cdot \left[\beta(u^0(x)) - v\right] \geqq 0 \quad \forall v \in [\rho_1, \rho_2], \text{ a.e. in } D; \tag{2.84}$$

$$u_{tt} + Au + w = f \quad \text{in } V', \text{ a.e. in }]0,T[; \tag{2.85}$$

$$u(x,0) = u^0(x) \quad \text{a.e. in } D; \tag{2.86}$$

$$u_t(x,0) = u^1(x) \quad \text{in } V'. \tag{2.87}$$

Remark. $u \in L^2(0,T;V) \cap H^2(0,T;V')$ entails $u \in H^1(0,T;L^2(D))$, hence $\beta(u(x,\cdot)) \in C^0([0,T])$ a.e. in D; moreover $L^2(0,T;V) \cap H^1(0,T;L^2(D)) \subset C^0([0,T]; H_{00}^{1/2}(D))$ and $H^1(0,T;L^2(D)) \cap H^2(0,T;V') \subset C^1([0,T]; (H_{00}^{1/2}(D))')$. Therefore (2.83), (2.86) and (2.87) are meaningful; furthermore (2.83) can be written equivalently in the form (1.15) a.e. in D, as $\beta(u) \in W^{1,1}(0,T)$ a.e. in D.

THEOREM 3. *Assume that* (2.1), (2.2) *hold and that*

$$u^0 \in V; \tag{2.88}$$

$$u^1 \in L^2(D). \tag{2.89}$$

Then problem (P3) *has at least one solution such that*

$$u \in C_S^1([0,T]; L^2(D)) \cap C_S^0([0,T]; V); \tag{2.90}$$

$$w \in L^2(D; BV(0,T)) \tag{2.91}$$

(*where* $C_2^1([0,T]; L^2(D)) = \{v \in C_S^0([0,T]; L^2(D)) \mid v_t \in C_S^0([0,T]; L^2(D))\}$).

Proof. Let $m \in \mathbb{N}$, $k = T/m$. Set

$$f_m^n = \frac{1}{k} \int_{(n-1)k}^{nk} f(t)\, dt \text{ in } V' \quad \text{for } n = 1, \cdots, m. \tag{2.92}$$

Remember the definition (2.14).

$(P3)_m$ Find $u_m^n \in V$, $w_m^n \in L^2(D)$ for $n = 1, \cdots, m$ such that, setting $u_m^0 = u^0$, $w_m^0 = w^0$, $z_m^0 = u^1$, $z_m^n = (u_m^n - u_m^{n-1})/k$ for $n = 1, \cdots, m$ a.e. in D,

$$\frac{z_m^n - z_m^{n-1}}{k} + Au_m^n + w_m^n = f_m^n \quad \text{in } V', \text{ for } n = 1, \cdots, m; \tag{2.93}$$

$$w_m^n \in K\left(u_m^n, w_m^{n-1}\right) \text{ a.e. in } D, \text{ for } n = 1, \cdots, m. \tag{2.94}$$

$\forall m \in \mathbb{N}$, $(P3)_m$ has one (and only one) solution, which can be constructed step by step as for $(P1)_m$.

Take a generic $l \in \{1, \cdots, m\}$, multiply (2.93) by $u_m^n - u_m^{n-1}$ and sum for $n = 1, \cdots, l$. Notice that

$$(2.95)\quad \sum_{n=1}^{l} \int_D \frac{z_m^n - z_m^{n-1}}{k} \cdot \left(u_m^n - u_m^{n-1}\right) dx$$

$$= \sum_{n=1}^{l} \int_D \left(z_m^n - z_m^{n-1}\right) z_m^n dx$$

$$\geqq \frac{1}{2} \sum_{n=1}^{l} \left(\left\| z_m^n \right\|_{L^2(D)}^2 - \left\| z_m^{n-1} \right\|_{L^2(D)}^2 \right) = \frac{1}{2} \left\| z_m^l \right\|_{L^2(D)}^2 - \frac{1}{2} \left\| u^1 \right\|_{L^2(D)}^2.$$

Thus by (2.17)–(2.21) we get (2.23) and

$$(2.96)\quad \max_{n=0,\cdots,m} \left\| \frac{u_m^n - u_m^{n-1}}{k} \right\|_{L^2(D)} \leqq C.$$

Therefore, using the notation of the proof of Theorem 1, we have (2.31)–(2.34) and

$$(2.97)\quad u_m \to u \quad \text{in } W^{1,\infty}\left(0, T; L^2(D)\right) \text{ weak star.}$$

The rest of the proof follows as in (2.35)–(2.44); just remark that by (2.85) $u_{tt} \in L^\infty(0, T; V')$, hence $u_t \in L^\infty(0, T; L^2(D)) \cap C^0([0, T]; V') \subset C_S^0([0, T]; L^2(D))$ by Lemma 1. □

3. Jump with anticipation.

1) Let (2.1) hold and

$$(3.1)\quad u^0 \in L^2(D).$$

We introduce a weak formulation of (1.17), (1.15).

(P4) Find $u \in L^2(0, T; V) \cap H^1(0, T; V')$ $(\subset C^0([0, T]; L^2(D)))$ and $w \in L^\infty(Q)$ such that $\beta(u) \in W^{1,1}(0, T; L^1(D))$ and

$$(3.2)\quad w \in S(\alpha(u)) \qquad \text{a.e. in } Q;$$

$$(3.3)\quad w \in S(\beta(u)_t) \qquad \text{a.e. in } Q;$$

$$(3.4)\quad u_t + Au + w = f \qquad \text{in } V', \text{ a.e. in }]0, T[,$$

$$(3.5)\quad u(x, 0) = u^0(x) \qquad \text{a.e. in } D.$$

THEOREM 4. *Assume that* (2.8) *holds and that*

$$(3.6)\quad f \in L^2(Q).$$

Then problem (P4) *has at least one solution such that moreover*

$$(3.7)\quad u \in H^1\left(0, T; L^2(D)\right) \cap C_S^0\left([0, T]; V\right) \cap L^2\left(0, T; H^2(D)\right).$$

Proof. Set

$$(3.8)\quad L(\xi, \eta) = S(\xi - \beta(\eta)) \quad \forall \xi, \eta \in \mathbb{R}.$$

Let $m \in \mathbb{N}$, $k = T/m$. Set

$$(3.9)\quad f_m^n(x) = \frac{1}{k} \int_{(n-1)k}^{nk} f(x, t)\, dt \quad \text{a.e. in } D, \text{ for } n = 1, \cdots, m.$$

$(P4)_m$ Find $u_m^n \in V$, $w_m^n \in L^\infty(D)$ for $n=1,\cdots,m$, such that, setting $u_m^0 = u^0$ a.e. in D,

$$\frac{u_m^n - u_m^{n-1}}{k} + Au_m^n + w_m^n = f_m^n \quad \text{in } V', \text{ for } n=1,\cdots,m; \tag{3.10}$$

$$w_m^n \in L\left(u_m^n, u_m^{n-1}\right) \quad \text{a.e. in } D, \text{ for } n=1,\cdots,m. \tag{3.11}$$

$\forall m \in \mathbb{N}$, $(P4)_m$ has one (and only one) solution, which can be constructed step by step as for $(P1)_m$. A priori estimates (2.22) and (2.23) can be obtained by the procedure (2.17)–(2.21); but here there is no reason for having (2.26). Using the notation introduced in the proof of Theorem 1, (3.10) can be written in the form

$$u_{mt} + A\hat{u}_m + \hat{w}_m = \hat{f}_m \quad \text{in } V', \text{ a.e. in }]0,T[; \tag{3.12}$$

as $\|\hat{f}_m\|_{L^2(Q)} \leqq C$, comparison in (3.12) yields $\|A\hat{u}_m\|_{L^2(Q)} \leqq C$, whence

$$\|\hat{u}_m\|_{L^2(0,T;H^2(D))} \leqq C. \tag{3.13}$$

Therefore there exist u, w, ξ such that, possibly taking subsequences

$$u_m \to u \quad \text{in } H^1(0,T;L^2(D)) \cap L^2(0,T;H^2(D)) \text{ weak}, \quad \text{in } L^\infty(0,T;V) \text{ weak star}; \tag{3.14}$$

$$\hat{u}_m \to u \quad \text{in } H^r(0,T;L^2(D)) \cap L^2(0,T;H^2(D)) \text{ weak } \forall r < \tfrac{1}{2}, \quad \text{in } L^\infty(0,T;V) \text{ weak star}; \tag{3.15}$$

$$w_m \to w \text{ and } \hat{w}_m \to w \quad \text{in } L^\infty(Q) \text{ weak star}; \tag{3.16}$$

$$u_m(T) \to \xi \quad \text{in } V \text{ weak}. \tag{3.17}$$

Thus also (2.35) and (2.36) hold; by (3.11) we have (2.37), whence (3.2) by the procedure (2.38)–(2.40). Let π denote the operator which extends any function defined in $[0,T]$ with value 0 in $\mathbb{R}\setminus[0,T]$; (3.12) can be written in the form

(3.18)

$$(\pi u_m)_t + \pi A\hat{u}_m + \pi\hat{w}_m = \pi\hat{f}_m + u_m(0)\delta_0(t) - u_m(T)\delta_0(t-T) \quad \text{in } (\mathcal{D}(0,T;V))'$$

(where δ_0 denotes the Dirac mass in 0); taking $m \to \infty$ we get

$$(\pi u)_t + Au + \pi w = f + u^0\delta_0(t) - \xi\delta_0(t-T) \quad \text{in } (\mathcal{D}(0,T;V))' \tag{3.19}$$

whence (3.4), (3.5) and

$$u(T) = \xi \quad \text{a.e. in } D. \tag{3.20}$$

Notice that, by the regularity of f, (3.4) can be written in the form

$$u_t - \Delta u + w = f \quad \text{a.e. in } Q. \tag{3.21}$$

Besides the notation introduced in the proof of Theorem 1, let $b_m(x,t)$ denote the function obtained by linear interpolation of the values $b_m(x,nk) = \beta(u_m^n(x))$ for $n = 0,\cdots,m$ a.e. in D. As β is Lipschitz-continuous, by (3.14) we have

$$b_m \to \beta(u) \quad \text{in } H^1(0,T;L^2(D)) \text{ weak, in } L^\infty(0,T;V) \text{ weak star}. \tag{3.22}$$

(3.11) yields

$$w_m^n \in S\left(\alpha\left(u_m^n\right)\right) \quad \text{for } n=1,\cdots,m; \tag{3.23}$$

$$w_m^n \in S\left(\beta\left(u_m^n\right) - \beta\left(u_m^{n-1}\right)\right) \quad \text{for } n=1,\cdots,m; \tag{3.24}$$

therefore

(3.25)

$$\sum_{n=1}^{m}\int_D w_m^n\big(u_m^n-u_m^{n-1}\big)\,dx$$

$$=\sum_{n=1}^{m}\int_D w_m^n\big[\beta(u_m^n)-\beta(u_m^{n-1})\big]\,dx+\sum_{n=1}^{m}\int_D w_m^n\big[\alpha(u_m^n)-\alpha(u_m^{n-1})\big]\,dx$$

$$\geqq\sum_{n=1}^{m}\|\beta(u_m^n)-\beta(u_m^{n-1})\|_{L^1(D)}+\sum_{n=1}^{m}\big(\|\alpha(u_m^n)\|_{L^1(D)}-\|\alpha(u_m^{n-1})\|_{L^1(D)}\big)$$

$$=k\sum_{n=1}^{m}\left\|\frac{\beta(u_m^n)-\beta(u_m^{n-1})}{k}\right\|_{L^1(D)}+\|\alpha(u_m^n)\|_{L^1(D)}-\|\alpha(u^0)\|_{L^1(D)};$$

thus multiplying (3.10) by $u_m^n-u_m^{n-1}$ and summing for $n=1,\cdots,m$, we get

$$\|u_{mt}\|^2_{L^2(Q)}+\frac{1}{2}\|\hat u_m(T)\|^2_V-\frac{1}{2}\|u^0\|^2_V+\|b_{mt}\|_{L^1(Q)}+\|\alpha(u_m(T))\|_{L^1(D)}$$
$$-\|\alpha(u^0)\|_{L^1(D)}\leqq\iint_Q\hat f_m\cdot u_{mt}\,dx\,dt,\tag{3.26}$$

whence taking $m\to\infty$ and using the lower semicontinuity of norms

$$\|u_t\|^2_{L^2(Q)}+\frac{1}{2}\|u(T)\|^2_V-\frac{1}{2}\|u^0\|^2_V+\|\beta(u)_t\|_{L^1(Q)}+\|\alpha(u(T))\|_{L^1(D)}$$
$$-\|\alpha(u^0)\|_{L^1(D)}\leqq\iint_Q f\cdot u_t\,dx\,dt.\tag{3.27}$$

Now multiply (3.4) by $u_t\in L^2(Q)$ and integrate w.r.t. space and time; using (3.2) we get

$$\|u_t\|^2_{L^2(Q)}+\frac{1}{2}\|u(T)\|^2_V-\frac{1}{2}\|u^0\|^2_V+\iint_Q w\cdot\beta(u)_t\,dx\,dt$$
$$+\|\alpha(u(T))\|_{L^1(D)}-\|\alpha(u^0)\|_{L^1(D)}=\iint_Q fu_t\,dx\,dt;\tag{3.28}$$

the comparison of the last two formulae yields

$$\iint_Q w\beta(u)_t\,dx\,dt\geqq\|\beta(u)_t\|_{L^1(D)}\tag{3.29}$$

whence, as $|w|\leqq1$ a.e. in Q,

$$\iint_Q w(\beta(u)_t-v)\,dx\,dt\geqq\iint_Q\big(|\beta(u)_t|-|v|\big)\,dx\,dt\quad\forall v\in L^1(Q)\tag{3.30}$$

that is (3.3). Finally by Lemma 1 we get $u\in C^0_S([0,T];V)$. □

PROPOSITION 2. *Assume that* (2.8) *and* (2.9) *hold. Then problem* (P4) *has at least one solution such that moreover*

$$u \in H^1(0,T;L^2(D)) \cap C_S^0([0,T];V). \tag{3.31}$$

Proof. As for Theorem 4, with the exception of (3.13); hence a priori u_m and $\hat{u}_m$ do not converge in $L^2(0,T;H^2(D))$ weak and the equation (3.4) does not hold a.e. in Q. Therefore in this case the multiplication of (3.4) by $u_t \notin L^2(0,T;V)$ is only formal. In order to make it rigorous, convolution with a regularizing kernel can be used, as in [7, Chap. 1, §1.8] (we shall give more details about this technique in the proof of Theorem 6). □

We give a regularity result.

PROPOSITION 3. *Assume that* (2.8), (2.46) *and* (2.47) *hold. Then* (P4) *has at least one solution such that moreover*

$$u \in W^{1,\infty}(0,T;L^2(D)) \cap H^1(0,T;V). \tag{3.32}$$

Proof. For the solutions of the approximate problems $(P3)_m$'s the stronger a priori estimate (2.54) can be proved as for Proposition 1 (notice that (2.51) holds also in this case). Thus we get in particular $u \in H^1(0,T;V)$; hence (3.4) can be multiplied by u_t.

2) We introduce another weak formulation of (1.17), (1.15). Let (2.8) and (2.9) hold.

(P4)′ Find $u \in H^1(0,T;L^2(D)) \cap L^\infty(0,T;V)$ $(\subset C_S^0([0,T];V))$ such that

$$\iint_Q \left[u_t(\alpha(u)-v)+\overline{\nabla} u\cdot\overline{\nabla}(\alpha(u)-v)\right]dx\,dt+\iint_Q \left(|\alpha(u)|-|v|\right)dx\,dt \leqq \int_0^T {}_{V'}\langle f,\alpha(u)-v\rangle_V dt \quad \forall v\in L^2(0,T;V), \tag{3.33}$$

$$\begin{aligned}&\iint_Q u_t(u_t-v)\,dx\,dt+\frac{1}{2}\int_D\left(|\overline{\nabla} u(T)|^2-|\nabla u^0|^2\right)dx-\iint_Q \overline{\nabla} u\cdot\overline{\nabla} v\,dx\,dt\\ &\quad+\iint_Q\left(|\beta(u)_t|-|v|\right)dx\,dt+\int_D\left(|\alpha(u(T))|-|\alpha(u^0)|\right)dx\\ &\leqq \iint_Q f_1(u_t-v)\,dx\,dt+{}_{V'}\langle f_2(T),u(T)\rangle_V-{}_{V'}\langle f_2(0),u^0\rangle_V\\ &\quad-\int_0^T {}_{V'}\langle f_{2t},u\rangle_V dt-\int_0^T\langle f_2,v\rangle_V dt \quad \forall v\in L^2(0,T;V).\end{aligned} \tag{3.34}$$

Remark. A system of variational inequalities was used also in [11] for the weak formulation of (1.3) coupled with (1.20).

PROPOSITION 4. *Assume that* (2.8) *and* (2.9) *hold. Then problem* (P4)′ *has at least one solution.*

Proof. Quite similar to that of Theorem 4. □

PROPOSITION 5. *Assume that* (2.8) *holds and that*

$$f \in L^2(Q) \cap W^{1,1}(0,T;V'). \tag{3.35}$$

Then any solution of problem (P4) *also solves* (P4)′.

Proof. (3.2) and (3.4) are equivalent to (3.33). As $f-w \in L^2(Q)$ then $u \in H^1(0,T;L^2(D)) \cap L^2(0,T;H^2(D))$ and (3.4) can be written in the form

$$u_t-\Delta u+w=f \quad \text{a.e. in } Q. \tag{3.36}$$

Multiply this by $u_t - v \in L^2(Q)$, for a generic $v \in L^2(0,T;V)$; notice that

$$(3.37) \qquad \iint_Q -\Delta u u_t \, dx\, dt = \iint_Q \overline{\nabla} u \cdot \overline{\nabla} u_t \, dx\, dt = \frac{1}{2} \int_D \left(|\overline{\nabla} u(T)|^2 - |\overline{\nabla} u^0|^2 \right) dx,$$

and that by (3.2), (3.3)

$$(3.38) \qquad \iint_Q w(u_t - v)\, dx\, dt = \iint_Q w\alpha(u)_t \, dx\, dt + \iint_Q w(\beta(u)_t - v)\, dx\, dt$$

$$\geqq \int_D \left(|\alpha(u(T))| - |\alpha(u^0)| \right) dx + \iint_Q \left(|\beta(u)_t| - |v| \right) dx\, dt;$$

thus we get (3.34). □

3) Assume that (2.1) and (3.1) hold. We introduce a weak formulation of (1.18), (1.15).

(P5) Find $u \in L^2(0,T;W) \cap H^1(0,T;W')$ $(\subset C^0([0,T];L^2(D)))$ and $w \in L^\infty(\Sigma)$ such that $\beta(\gamma u) \in W^{1,1}(0,T;L^1(\Gamma))$ and

$$(3.39) \qquad w \in S(\alpha(\omega)) \qquad \text{a.e. on } \Sigma;$$

$$(3.40) \qquad w \in S(\beta(\gamma u)_t) \qquad \text{a.e. on } \Sigma;$$

$$(3.41) \qquad u_t + Au + \gamma^* w = f \qquad \text{in } W', \text{ a.e. in }]0,T[;$$

$$(3.42) \qquad u(x,0) = u^0(x) \qquad \text{a.e. in } D.$$

Remark. It is possible to introduce a different setting, analogous to problem (P4)′, and to prove results similar to Propositions 4 and 5.

THEOREM 5. *Assume that* (2.8), (2.47) *and* (2.63) *hold. Then problem* (P5) *has at least one solution such that moreover*

$$(3.43) \qquad u \in W^{1,\infty}(0,T;L^2(D)) \cap H^1(0,T;W).$$

Proof. $\forall m \in \mathbb{N}$ we introduce a time-discretized problem $(P5)_m$ similar to $(P4)_m$; also $(P5)_m$ has one (and only one) solution, which can be constructed step by step. Taking the incremental ratio in the approximate equation and using a procedure similar to that of Proposition 1, we get the a priori estimates (2.66), (2.67) for the equation (2.68). Therefore there exist u, w such that possibly taking subsequences (2.70), (2.71) and (2.73) hold. Taking $m \to \infty$ in (2.68) we get (3.41). We have also (2.75) and (2.76). Therefore we can show (3.39) and (3.40) by a procedure similar to that used in the proof of Theorem 4 (just notice that the regularity $u \in H^1(0,T;W)$ is sufficient for multiplying (3.41) by u_t). □

4) Assume that (2.1), (2.80) and (2.81) hold. We introduce a weak formulation of (1.19), (1.15).

(P6) Find $u \in L^2(0,T;V) \cap H^2(0,T;V')$ and $w \in L^\infty(Q)$ such that

$$(3.44) \qquad w \in S(\alpha(u)) \qquad \text{a.e. in } Q;$$

$$(3.45) \qquad w \in S(\beta(u)_t) \qquad \text{a.e. in } Q;$$

$$(3.46) \qquad u_{tt} + Au + w = f \qquad \text{in } V', \text{ a.e. in }]0,T[;$$

$$(3.47) \qquad u(x,0) = u^0(x) \qquad \text{a.e. in } D;$$

$$(3.48) \qquad u_t(x,0) = u^1(x) \qquad \text{in } V'.$$

See the remark following (P3).

THEOREM 6. *Assume that* (2.1), (2.88) *and* (2.89) *hold. Then problem* (*P*6) *has at least one solution such that moreover*

$$u \in C_S^1([0,T];L^2(D)) \cap C_S^0([0,T];V). \tag{3.49}$$

Proof. $\forall m \in \mathbb{N}$ we introduce a time discretized problem $(P6)_m$ similar to $(P3)_m$, with (2.94) replaced by (3.11); also $(P6)_m$ has one (and only one) solution. Using the notations introduced in the proof of Theorem 1, the approximated equation can be written in the form

$$u_{mtt} + A\hat{u}_m + \hat{w}_m = \hat{f}_m \quad \text{in } V', \text{ for } n = 1, \cdots, m. \tag{3.50}$$

Multiplying the discretized equation by $u_m^n - u_m^{n-1}$, summing for $n = 1, \cdots, l$ and using (2.17)–(2.21) and (2.95) we get

$$\|u_m\|_{W^{1,\infty}(0,T;L^2(D)) \cap L^\infty(0,T;V)} \leqq C, \tag{3.51}$$

$$\|\hat{u}_m\|_{L^\infty(0,T;V)} \leqq C. \tag{3.52}$$

Fix a generic $\tilde{t} \in]0,t]$. By the above estimates there exist u, w, ξ, η such that possibly taking subsequences

$$u_m \to u \quad \text{in } W^{1,\infty}(0,T;L^2(D)) \cap L^\infty(0,T;V) \text{ weak star,} \tag{3.53}$$

$$\hat{u}_m \to u \quad \text{in } L^\infty(0,T;V) \text{ weak star;} \tag{3.54}$$

$$w_m \to w,\ \hat{w}_m \to w \quad \text{in } L^\infty(Q) \text{ weak star;} \tag{3.55}$$

$$u_m(\tilde{t}) \to \xi \quad \text{in } V \text{ weak;} \tag{3.56}$$

$$u_{mt}(\tilde{t}) \to \eta \quad \text{in } L^2(D) \text{ weak.} \tag{3.57}$$

By the procedure of (3.18)–(3.20), we get (3.46) and

$$\eta = u_t(\tilde{t}) \quad \text{a.e. in } D; \tag{3.58}$$

integrating (3.50) w.r.t. time and repeating the same procedure we obtain

$$\xi = u(\tilde{t}) \quad \text{a.e. in } D. \tag{3.59}$$

Multiplying (3.50) by $u_{mt} \in L^2(0,T;V)$ and integrating in $]0,\tilde{t}[$ we get (cf. (3.25), (3.26))

(3.60)

$$\frac{1}{2}\|u_{mt}(\tilde{t})\|_{L^2(D)}^2 - \frac{1}{2}\|u^1\|_{L^2(D)}^2 + \frac{1}{2}\|u_m(\tilde{t})\|_V^2 - \frac{1}{2}\|u^0\|_V^2 + \int_0^{\tilde{t}} \|b_{mt}\|_{L^1(D)} d\tau + \|\alpha(u_m(\tilde{t}))\|_{L^1(D)} - \|\alpha(u^0)\|_{L^1(D)} \leqq \int_0^{\tilde{t}} {}_{V'}\langle f_m, u_{mt}\rangle_V d\tau,$$

whence taking $m \to \infty$ and using lower semicontinuity of norms

(3.61)

$$\frac{1}{2}\|u_t(\tilde{t})\|_{L^2(D)}^2 - \frac{1}{2}\|u^1\|_{L^2(D)}^2 + \frac{1}{2}\|u(\tilde{t})\|_V^2 - \frac{1}{2}\|u^0\|_V^2 + \int_0^{\tilde{t}} \|\beta(u)_t\|_{L^1(D)} d\tau + \|\alpha(u(\tilde{t}))\|_{L^1(D)} - \|\alpha(0)\|_{L^1(D)} \leqq \int_0^{\tilde{t}} d\tau \int_D f_1 u_t dx + {}_{V'}\langle f_2(\tilde{t}), u(\tilde{t})\rangle_V - {}_{V'}\langle f_2(0), u^0\rangle_V - \int_0^{\tilde{t}} {}_{V'}\langle f_{2t}, u\rangle_V d\tau$$

and this last holds for any $\tilde{t}\in]0,T[$ (though the extracted subsequences may depend on $\tilde{t}$). Now we would like to multiply (3.46) by u_t and to integrate w.r.t. time (similarly to the procedure used in the proof of Theorem 4); but this is only formal, as $u_t\notin L^2(0,T;V)$ a priori. In order to make this rigorous, convolution with a regularizing kernel can be used; by the procedure of [7, Chap. 1, §1.8], one gets

$$\begin{aligned}(3.62)\quad &\frac{1}{2}\|u_t(\tilde{t})\|^2_{L^2(D)}-\frac{1}{2}\|u_t(t)\|^2_{L^2(D)}+\frac{1}{2}\|u(\tilde{t})\|^2_V-\frac{1}{2}\|u(t)\|^2_V\\ &\quad+\int_t^{\tilde{t}}d\tau\int_D w\beta(u)_t dx+\|\alpha(u(\tilde{t}))\|_{L^1(D)}-\|\alpha(u(t))\|_{L^1(D)}\\ &=\int_t^{\tilde{t}}d\tau\int_D f_1u_t dx+{}_{V'}\langle f_2(\tilde{t}),u(\tilde{t})\rangle_V-{}_{V'}\langle f_2(t),u(t)\rangle_V-\int_t^{\tilde{t}}{}_{V'}\langle f_{2t},u\rangle_V d\tau\\ &\qquad\qquad\text{a.e. for } t,\ \tilde{t}\in]0,T[.\end{aligned}$$

Now let $t\to 0$. By Lemma 1 $u_t\in C^0_S([0,T);L^2(D))$ and $u\in C^0_S([0,T];V)$, hence $u_t(t)\to u^1$ in $L^2(D)$ weak, $u(t)\to u^0$ in V weak; therefore by the lower semicontinuity of norms we get

$$\begin{aligned}(3.63)\quad &\frac{1}{2}\|u_t(\tilde{t})\|^2_{L^2(D)}-\frac{1}{2}\|u_1\|^2_{L^2(D)}+\frac{1}{2}\|u(\tilde{t})\|^2_V-\frac{1}{2}\|u^0\|^2_V\\ &\quad+\int_0^{\tilde{t}}d\tau\int_D w\beta(u)_t dx+\|\alpha(u(\tilde{t}))\|_{L^1(D)}-\|\alpha(u^0)\|_{L^1(D)}\\ &\geqq\int_0^{\tilde{t}}d\tau\int_D f_1u_t dx+{}_{V'}\langle f_2(\tilde{t}),u(\tilde{t})\rangle_V-{}_{V'}\langle f_2(0),u^0\rangle_V-\int_0^{\tilde{t}}{}_{V'}\langle f_{2t},u\rangle_V d\tau\\ &\qquad\qquad\text{a.e. for } \tilde{t}\in]0,T[;\end{aligned}$$

comparing (3.61) with (3.63) we get

$$(3.64)\qquad \int_0^{\tilde{t}}d\tau\int_D w\beta(u)_t dx\geqq\int_0^{\tilde{t}}\|\beta(u)_t\|_{L^1(D)}d\tau\quad\text{a.e. for } \tilde{t}\in]0,T[$$

whence (3.30), i.e. (3.45) □

Remark. As the system (1.15) is equivalent to (1.16), in (P4) we can replace (3.42), (3.44) by

$$(3.65)\qquad w\in S(\alpha(u)+\beta(u)_t)\quad\text{a.e. in } Q;$$

eliminating w by (3.4) and (3.65) we get

$$(3.66)\qquad u_t+Au+S(\alpha(u)+\beta(u)_t)\ni f\quad\text{in } V',\ \text{a.e. in }]0,T[.$$

Formally a solution u of (3.66) can be interpreted as a fixed-point for the application

$$(3.67)\quad \bar{u}\to\tilde{u}\quad\text{such that } \tilde{u}_t+A\tilde{u}+S(\tilde{u}-\beta(\bar{u})+\beta(\bar{u})_t)\ni f\quad\text{in } V',\ \text{a.e. in }]0,T[$$

as well as for

$$(3.68)\quad \bar{u}\to\tilde{u}\quad\text{such that } \tilde{u}_t+A\tilde{u}+S(\alpha(\bar{u})-\alpha(\bar{u})_t+\tilde{u}_t)\ni f\quad\text{in } V',\ \text{a.e. in }]0,T[$$

(where in both cases we have used the fact that $\alpha+\beta=$ Identity). (3.67) ((3.68)) corresponds to a variational inequality of the first type (of the second type, respectively). Therefore (3.66) can be regarded as a nonstandard nonstandard quasi-variational inequality.

4. Other results. Let ρ_1 and ρ_2 run along two sequences converging to the same limit, which we can assume to be zero: $\rho_{ij}\to 0$ as $j\to\infty$, for $i=1,2$; moreover let $\rho_{1j}\leqq\rho_{2j}\forall j$. Accordingly $\forall j\in\mathbb{N}$ define α_j and β_j similarly to (1.8) and define $(\tilde{\mathrm{P}}1)_j$ as (P1) with α and β replaced by α_j and β_j.

PROPOSITION 6. *Assume that* (2.1) *holds and that*

$$\forall j\in\mathbb{N}\quad w_j^0\in L^\infty(D)\ \text{and}\ w_j^0\in S\big(\alpha_j(u^0)\big)\quad a.e.\ \text{in}\ D; \tag{4.1}$$

$\forall j\in\mathbb{N}$ *let* u_j *be a solution of* $(\tilde{\mathrm{P}}1)_j$ (*existing by Theorem* 1). *Then*

$$u_j\to u\ \text{in}\ L^2(0,T;V)\cap H^1(0,T;V^1)\ \text{weak}, \tag{4.2}$$

where u *is the unique solution of the following variational inequality*:

Find $u\in L^2(0,T;V)\cap H^1(0,T;V')$ $(\subset C^0([0,T];L^2(D)))$ *such that*

$$\ {}_{V'}\langle u_t,u-v\rangle_V+\int_D\overline{\nabla}u\cdot\overline{\nabla}(u-v)\,dx+\int_D\big(|u|-|v|\big)\,dx\leqq{}_{V'}\langle f,u-v\rangle_V \tag{4.3}$$

$$\forall v\in V\ a.e.\ \text{in}\ ]0,T[;$$

$$u(x,0)=u^0(x)\quad a.e.\ \text{in}\ D. \tag{4.4}$$

Proof. $\forall j\in\mathbb{N}$, multiplying the corresponding (2.6) by u_j and integrating w.r.t. time, by a standard procedure (cf. (2.17)–(2.21)) we get

$$\|u_j\|_{L^\infty(0,T;L^2(D))\cap L^2(0,T;V)}\leqq\text{constant independent of } j \tag{4.5}$$

and then by comparison in (2.6)

$$\|u_j\|_{H^1(0,T;V')}\leqq\text{constant independent of } j. \tag{4.6}$$

Therefore there exists u such that, possibly taking a subsequence,

$$u_j\to u\quad\text{in}\ L^2(0,T;V)\cap H^1(0,T;V')\ \text{weak}; \tag{4.7}$$

hence

$$u_j\to u\quad\text{in}\ L^2(Q)\ \text{strong}, \tag{4.8}$$

whence, since $\lim_{j\to\infty}\alpha_j=$ identity uniformly in $\mathbb{R}$,

$$\alpha_j(u_j)\to u\quad\text{in}\ L^2(Q)\ \text{strong}. \tag{4.9}$$

$\forall j\in\mathbb{N}$, multiplying the corresponding (2.6) by u_j-v for a generic $v\in V$ and integrating w.r.t. time we get

$$\begin{aligned}\frac{1}{2}\|u_j(T)\|^2_{L^2(D)}-\frac{1}{2}\|u^0\|^2_{L^2(D)}-\int_0^T{}_{V'}\langle u_{jt},v\rangle_V dt+\|u_j\|^2_{L^2(0,T;V)}\\ -\iint_Q\overline{\nabla}u_j\cdot\overline{\nabla}v\,dx+\iint_Q w_j(u_j-v)\,dx=\int_0^T{}_{V'}\langle f,u_j-v\rangle_V dt.\end{aligned} \tag{4.10}$$

Notice that by (2.4) and (4.9)

$$\begin{aligned}&\lim_{j\to\infty}\iint_Q w_j(u_j-v)\,dx\,dt\\ &\quad=\lim_{j\to\infty}\iint_Q w_j\big(\alpha_j(u_j)-v\big)\,dx\,dt+\lim_{j\to\infty}\iint_Q w_j\big(u_j-\alpha_j(u_j)\big)\,dx\,dt\\ &\quad\geqq\iint_Q\big(|u|-|v|\big)\,dx\,dt;\end{aligned} \tag{4.11}$$

therefore taking the inferior limit as $j\to\infty$ in (4.10) we get

$$(4.12)\quad \frac{1}{2}\|u(T)\|^2_{L^2(D)}-\frac{1}{2}\|u^0\|^2_{L^2(D)}-\int_0^T {}_{V'}\langle u_t,v\rangle_V dt+\|u\|^2_{L^2(0,T;V)}$$
$$-\int_Q \overline{\nabla} u\cdot\overline{\nabla} v\,dx\,dt+\iint_Q (|u|-|v|)\,dx\,dt\leqq\int_0^T {}_{V'}\langle f,u-v\rangle_V dt\quad \forall v\in V,$$

which is equivalent to (4.3) and (4.4). Uniqueness of the solution of (4.3), (4.4) entails the convergence of the whole sequence $\{u_j\}_{j\in\mathbb{N}}$. □

PROPOSITION 7. *Assume that* (2.1) *and* (2.2) *hold. If*

$$(4.13)\qquad f\leqq 0 \text{ in } \mathcal{D}'(Q),\quad \rho_2\geqq 0,\quad u^0\leqq\rho_2 \text{ a.e. in } D,$$

then for any solution of problems (P1), (P2), (P3), *and* (P4)

$$(4.14)\qquad u\leqq\rho_2 \text{ a.e. in } D.$$

Similarly if $f\geqq 0$ *in* $\mathcal{D}'(Q)$, $\rho_1\leqq 0$, $u^0\geqq\rho_1$ *a.e. in* D, *then* $u\geqq\rho_1$ *a.e. in* D.

Proof. For problem (P1) it is sufficient to multiply (2.6) against $(u-\rho_2)^+$ in the first case, by $-(u-\rho_1)^-$ in the second one, then to integrate in time. Proof is quite similar for (P2), (P3) and (P4). □

For all of the above problems, uniqueness is an open question. We are just able to prove the following result.

PROPOSITION 8. *Assume that* (2.1), (2.2), (2.8) *hold and that*

$$(4.15)\qquad f=0 \text{ a.e. in } Q,\ \rho_1\leqq 0\leqq\rho_2,\ \rho_1\leqq u^0\leqq\rho_2 \text{ a.e. in } Q.$$

Then problem (P4) *has at most one solution such that* $u\in H^1(0,T;V)$.

Proof. Let (u_1,w_1), (u_2,w_2) be two solutions of (P4). By Proposition 7 $\rho_1\leqq u_i\leqq\rho_2$ a.e. in Q, hence $\beta(u_i)=u_i$ a.e. in Q for $i=1,2$. Take the difference of (2.6) written for u_1 and u_2, multiply it by $(u_1-u_2)_t\in L^2(0,T;V)$ and integrate w.r.t. time. Notice that as $w_i\in S(\beta(u_i)_t)$ $(i=1,2)$,

$$(4.16)\quad \iint_Q (w_1-w_2)\cdot(u_1-u_2)_t\,dx\,dt=\iint_Q (w_1-w_2)\cdot(\beta(u_1)_t-\beta(u_2)_t)\,dx\,dt\geqq 0;$$

thus by standard calculations we get $(u_1-u_2)_t=0$ a.e. in Q. □

Remark. All of the previous developments for problems (P1)–(P6) extend in a natural way to the case in which the normalized output w is replaced by $a(x,t)w$ with $a\in L^\infty(Q)$ ($a\in L^\infty(\Sigma)$ in (P2), (P5)), $a>0$ a.e. in Q (on Σ, respectively).

5. Stefan problem with hysteresis in the source. We remind that we denote by H the Heaviside graph, by λ the latent heat of water; if u represents temperature then $u+\lambda\chi\in u+\lambda H(u)$ has the physical meaning of enthalpy. We denote the inverse of $\xi\mapsto\xi+\lambda H(\xi)$ by l: $l(\xi)=(\xi-\lambda)^+-\xi^-\ \forall\xi\in\mathbb{R}$. Assume that (2.1) holds and let

$$(5.1)\quad \zeta^0\in\big(H^{1/2}_{00}(D)\big)'\cap L^1(D),\ w^0\in L^\infty(D) \text{ such that } w^0\in S\big(\alpha\big(l(\zeta^0)\big)\big) \text{ a.e. in } D$$

(ζ^0 and $l(\zeta^0)$ will represent initial enthalpy and initial temperature, respectively). We introduce a weak formulation of a two-phase Stefan problem with hysteresis in the source (see (1.7), (1.9), (1.20)):

(P7). Find $u\in L^2(0,T;V)$, $\chi\in L^\infty(Q)$, $w\in L^\infty(Q)$ such that $u+\lambda\chi\in H^1(0,T;V')$, $\beta(u(x,\cdot))\in C^0([0,T])$, $w(x,\cdot)\in BV(0,T)$ a.e. in D and

$$w\in S(\alpha(u)) \quad \text{a.e. in } Q, \tag{5.2}$$

$$_{(C^0[(0,T)])'}\langle w_t,\beta(u)-v\rangle_{C^0[(0,T)]}\geqq 0 \quad \forall v\in C^0[(0,T)] \text{ such that } \rho_1\leqq v\leqq\rho_2, \text{ a.e. in } D, \tag{5.3}$$

$$\lim_{t\to 0^+}\left[w(x,t)-w^0(x)\right]\cdot\left[\beta(u^0(x))-v\right]\geqq 0 \quad \forall v\in[\rho_1,\rho_2], \text{ a.e. in } D \tag{5.4}$$

$$\chi\in H(u) \quad \text{a.e. in } Q; \tag{5.5}$$

$$(u+\lambda\chi)_t+Au+w=f \quad \text{in } V', \text{ a.e. in }]0,T[; \tag{5.6}$$

$$(u+\lambda\chi)|_{t=0}=\zeta^0 \quad \text{in } V'. \tag{5.7}$$

Remark. $u+\lambda\chi\in L^2(Q)\cap H^1(0,T;V')\subset C^0([0,T];\ (H_{00}^{1/2}(D))')$, hence (5.7) is meaningful.

THEOREM 7. *Assume that* (2.8), (2.9) *and* (5.1) *hold. Then problem* (P7) *has at least one solution such that moreover*

$$u\in H^1(0,T;L^2(D))\cap L^\infty(0,T;V); \tag{5.8}$$

$$w\in L^2(D;BV(0,T)). \tag{5.9}$$

Proof. Let $m\in\mathbb{N}$, $k=T/m$. Define f_m^n and K as in (2.13), (2.14).

$(P7)_m$ Find $u_m^n\in V$, $\chi_m^n\in L^\infty(D)$, $w_m^n\in L^\infty(D)$ such that, setting $u_m^0=l(\zeta^0)$, $\chi_m^0=\zeta^0-l(\zeta^0)$, $w_m^0=w^0$ in D,

$$\frac{u_m^n-u_m^{n-1}}{k}+\frac{\chi_m^n-\chi_m^{n-1}}{k}+Au_m^n+w_m^n=f_m^n \quad \text{n } V', \text{ for } n=1,\cdots,m, \tag{5.10}$$

$$\chi_m^n\in H(u_m^n) \quad \text{a.e. in } D, \text{ for } n=1,\cdots,m; \tag{5.11}$$

$$w_m^n\in K(u_m^n,w_m^{n-1}) \quad \text{a.e. in } D, \text{ for } n=1,\cdots,m. \tag{5.12}$$

$\forall m\in\mathbb{N}$ $(P7)_m$ has one (and only one) solution, which can be constructed step by step as for $(P1)_m$; indeed, by the monotonicity of H, also in this case at every step a coercive, strictly convex, lower semicontinuous functional $V\to\mathbb{R}$ is to be minimized.

Multiply (5.10) by $u_m^n-u_m^{n-1}$ and sum for $n=1,\cdots,l$, for a generic $l\in\{1,\cdots,m\}$; notice that the monotonicity of H yields

$$\sum_{n=1}^{l}\int_D\frac{\chi_m^n-\chi_m^{n-1}}{k}\left(u_m^n-u_m^{n-1}\right)dx\geqq 0; \tag{5.13}$$

thus by (2.17)–(2.21) we get (2.22), (2.23).

We use the notation of the proof of Theorem 1. Moreover by χ_m we denote the function obtained by linear interpolation of the values $\chi_m^n(x,nk)=\chi_m^n(x)$ for $n=0,\cdots,m$, a.e. in D; set also $\hat\chi_m(x,t)=\chi_m^n(x)$ a.e. in D if $(n-1)k<t\leqq nk$ for $n=1,\cdots,m$. (5.10) can be written in the form

$$u_{mt}+\lambda\chi_{mt}+A\hat u_m+\hat w_m=\hat f_m \text{ in } V', \quad \text{a.e. in }]0,T[; \tag{5.14}$$

we have a priori estimates (2.28)–(2.30). Therefore there exist u, χ, w such that possibly by taking subsequences (2.31)–(2.34) hold and moreover

$$\chi_m\to\chi \quad \text{in } L^\infty(Q) \text{ weak star.} \tag{5.15}$$

We have $\hat{\chi}_m \in H(\hat{u}_m)$ a.e. in Q; hence by (2.31) and by a standard monotonicity technique we get (5.5). The rest of the proof follows as for Theorem 1. □

It does not seem trivial to extend Theorems 2, 4, 5 to the case in which the linear operator $u \mapsto u_t + Au$ is replaced by $u \mapsto u_t + \lambda\chi_t + Au$ where $\chi \in H(u)$, as in the Stefan problem.

A result analogous to Proposition 6 holds for (P7), too.

6. A parabolic system with hysteresis. Hoppensteadt and Jäger have modelled and numerically studied a biological phenomenon exhibiting hysteresis (cf. [3], [4]). They formulated the following parabolic system

$$u_{it} - D_i \Delta u_i + c_i s = 0 \qquad (i = 1,2), \tag{6.1}$$

where D_i and c_i are positive constants, $u_i \geqq 0$ $(i = 1,2)$; s is related to (u_1, u_2) as follows: the quadrant $(\mathbb{R}^+)^2$ is parted into three sets by two disjoint curves on which s is switched from 0 to 1 and conversely; let $\Gamma_1(\Gamma_2)$ correspond to the switching off (on) curve (see Fig. 3). We can assume Γ_1 and Γ_2 to be level curves of a "smooth" function φ: $(\mathbb{R}^+)^2 \to \mathbb{R}$; that is $\Gamma_i = \{(u_1, u_2) \mid \varphi(u_1, u_2) = \rho_i\}$ $(i = 1,2)$ with ρ_1, $\rho_2 \in \mathbb{R}$. If $\rho_1 < \rho_2$, then the relation between $2s - 1$ and $\varphi(u_1, u_2)$ is the same as that between w and u in (1.2). Therefore the system (6.1) can be studied similarly to the single equation (1.17).

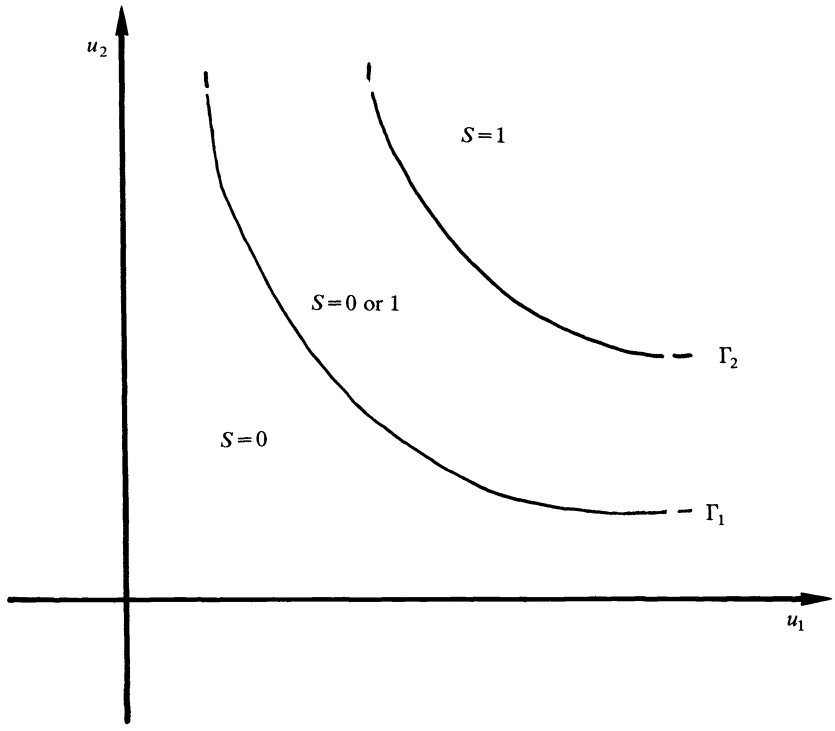

FIG. 3

In the biological phenomenon considered by Hoppensteadt and Jäger, the u_i's represent the concentrations of substances ("nutrients") which activate the growth of another substance ("bacteria"). This last diffuses slowly and reacts fast, so that one can use the ordinary differential equation $b_t = c_0 s$, where b represents the concentration of bacteria and c_0 is a positive constant. Due to the threshold effect in the dependence of

s on (u_1, u_2), some spatial structures appear in the distribution of b. This is analogous to the Liesegang phenomenon arising in chemistry, in which nutrients and bacteria are replaced by ions. The above model has also been confirmed by numerical tests (cf. [3], [4]).

Let $\tilde{V}=(H^1(\Omega))^2$, $\tilde{H}=(L^2(D))^2$; identifying $\tilde{H}$ with its dual $\tilde{H}'$, we get the Hilbert triple $\tilde{V}\subset\tilde{H}=\tilde{H}'\subset\tilde{V}'$, with dense and compact inclusions. Let A: $\tilde{V}\to\tilde{V}'$ be linear, continuous, symmetric and coercive (so that $u\mapsto({}_{\tilde{V}'}\langle Au,u\rangle_{\tilde{V}})^{1/2}$ defines a norm equivalent to $\|u\|_{\tilde{V}}$); let $f\in L^2(0,T;\tilde{V}')$ and $u^0\in\tilde{V}'$. Moreover let $c=(c_1,c_2)\in(\mathbb{R}^+)^2$ and φ: $(\mathbb{R}^+)^2\to\mathbb{R}$ continuous.

(P8) Find $u=(u_1,u_2)\in L^2(0,T;\tilde{V})\cap H^1(0,T;\tilde{V}')$ and $w\in L^\infty(Q)$ such that, setting $z=\varphi(u)$ a.e. in Q,

$$\beta(z(x),\cdot)\in C^0([0,T]),\ w(x,\cdot)\in BV(0,T)\quad\text{a.e. in } D; \tag{6.2}$$

$$w\in S(\alpha(z))\quad\text{a.e. in } Q; \tag{6.3}$$

$$({}_{C^0([0,T])'}\langle w_t,\beta(z)-v\rangle_{C^0([0,T])}\geqq 0 \qquad \forall v\in C^0([0,T])\text{ such that }\rho_1\leqq v\leqq\rho_2,\text{ a.e. in } D; \tag{6.4}$$

$$\lim_{t\to 0^+}\left[w(x,t)-w^0(x)\right]\cdot\left[\beta(u^0(x))-v\right]\geqq 0\quad\forall v\in[\rho_1,\rho_2],\quad\text{a.e. in } D \tag{6.5}$$

$$u_t+Au+c\frac{w+1}{2}=f\quad\text{in }\tilde{V}',\text{ a.e. in }]0,T[; \tag{6.6}$$

$$u(x,0)=u^0(x)\quad\text{a.e. in } D. \tag{6.7}$$

Remark that (6.6) corresponds to (2.6) setting

$$ {}_{\tilde{V}'}\langle Au,v\rangle_{\tilde{V}}=\int_D\left(D_1\overline{\nabla}u_1\cdot\overline{\nabla}v_1+D_2\overline{\nabla}u_2\cdot\overline{\nabla}v_2\right)dx,$$

$$ {}_{\tilde{V}'}\langle f,v\rangle_{\tilde{V}}=\int_\Gamma\left(D_1\frac{\partial u_1}{\partial\nu}\cdot v_1+D_2\frac{\partial u_2}{\partial\nu}\cdot v_2\right)d\sigma$$

a.e. in $]0,T[$ $\forall v=(v_1,v_2)\in V$ and $s=(w+1)/2$.

THEOREM 8. *Assume that*

$$\varphi\text{ is Lipschitz-continuous and monotone with respect to each of its arguments}; \tag{6.8}$$

$$u^0\in\tilde{V}; \tag{6.9}$$

$$f=f_1+f_2,\quad f_1\in L^2(0,T;\tilde{H}),\quad f_2\in W^{1,1}(0,T;\tilde{V}). \tag{6.10}$$

Then problem (P8) *has at least one solution such that moreover*

$$u\in H^1(0,T;\tilde{H})\cap C_S^0([0,T];\tilde{V}), \tag{6.11}$$

$$w\in L^2(D;BV(0,T)). \tag{6.12}$$

Proof. Similar to that of Theorem 1. An approximated problem $(P8)_m$ analogous to $(P1)_m$ can be introduced, with (2.16) replaced by

$$w_m^n\in K\left(\varphi(u_m^n),w_m^{n-1}\right)\quad\text{a.e. in } D,\text{ for } n=1,\cdots,m. \tag{6.13}$$

By (6.8) $K(\varphi(\cdot),w_m^{n-1}(x))$ is a maximal monotone operator a.e. in D; therefore also $(P8)_m$ has one (and only one) solution, which can be constructed step by step. A priori estimates (2.22), (2.23) can be proved also here (obviously with $L^2(D)$ and V replaced by $\tilde{H}$ and $\tilde{V}$, respectively).

We use the notation introduced in the proof of Theorem 1. Moreover by $z_m(x,t)$ we denote the function obtained by linear interpolation of the values $z_m(x,nk)=\varphi(u_m^n(x))$ for $n=0,\cdots,m$, a.e. in D; set $\hat{z}_m(x,t)=\varphi(u_m^m(x))$ a.e. in D if $(n-1)k<t\leqq nk$ for $n=1,\cdots,m$. Thus the approached equation can be written in the form (2.27) and also (2.28) holds. Then by (6.8) we have

$$\|z_m\|_{H^1(0,T;\tilde{H})\cap L^\infty(0,T;\tilde{V})}\leqq C \tag{6.14}$$

whence as in (2.29)

$$\|w_m\|_{L^2(D;BV(0,T))}\leqq C. \tag{6.15}$$

Therefore there exist u, z, w such that, possibly taking subsequences, (2.31)–(2.34) hold and

$$z_m\to z \text{ in } H^1(0,T;\tilde{H})\cap L^\infty(0,T;\tilde{V}) \text{ weak star.} \tag{6.16}$$

This last and (2.31) yield

$$z=\varphi(u) \quad \text{a.e. in } D. \tag{6.17}$$

The rest of the proof follows as in (2.35)–(2.44). □

Acknowledgment. The author is indebted to the referees for several useful suggestions.

ON THE FRACTAL DIMENSION OF ATTRACTORS FOR VISCOUS INCOMPRESSIBLE FLUID FLOWS*

J.-M. GHIDAGLIA†

Abstract. We prove that attractors associated to various equations of viscous incompressible fluid flows have finite fractal dimension and lie in the set of C^∞-functions. The first part of this article consists in an abstract formulation of our results; then in the second part, we apply these results to Navier–Stokes equations with nonhomogeneous boundary conditions to N.S.E. on a Riemannian manifold, to thermo-hydraulic equations and finally to magnetohydrodynamic equations.

Key words. Navier–Stokes equations, long-time behavior, attractors, fractal dimension

Introduction. The equations which describe the motion of a viscous fluid can be viewed as an infinite dynamical system. However from a physical point of view it is admitted that this motion depends on a finite number of degrees of freedom. This is a physical evidence for laminar flows (observed for small Reynolds numbers) which correspond mathematically to the existence of a stable steady state. For large Reynolds numbers, the phenomenon of Turbulence occurs and the interpretation becomes somewhat more complicated (both physically and mathematically).

D. Ruelle and F. Takens [28] attribute Turbulence to strange attractors. These sets represent the behaviour of the flow since after some transient period they trap the motion. Thus in a certain sense, attractors carry all the information contained in the external excitation. This feature is characteristic of dissipative systems.

Proving that attractors have finite dimension is a way to give a mathematical sense to the physical concept of finite number of degrees of freedom. In 1979, C. Foias and R. Temam [14] proved that attractors associated to Navier–Stokes equations have finite dimension and more recently M. Sermange and R. Temam [29] have investigated the magnetohydrodynamic equations. Using completely different methods, various authors have obtained bounds for the dimension of attractors which have physical interest (i.e. in terms of nondimensional physical numbers) in case of Navier–Stokes equations with homogeneous boundary condition: C. Foias and R. Temam [15], P. Constantin and C. Foias [8], P. Constantin, C. Foias and R. Temam [10], D. Ruelle [26], E. Lieb [23], P. Constantin, C. Foias, O. Manley and R. Temam [9], R. Temam [33] (this reference contains a quasi optimal result for 2D-N.S.E.) and in a special case of thermo-hydraulic equations, D. Ruelle [27].

In this article we shall study various situations arising in fluid mechanics of viscous incompressible fluid flows. We successively consider the motion of a fluid dragged by moving walls (Navier–Stokes equations with nonhomogeneous boundary conditions), the motion of a fluid on a Riemannian manifold (motivated by a meteorological model for the circulation of the atmosphere), the motion of a fluid submitted to buoyancy effects (thermo-hydraulic equations). Finally we consider the motion of a resistive fluid (magnetohydrodynamic equations).

*Received by the editors November 14, 1984, and in revised form April 5, 1985.
†Laboratoire d'Analyse Numérique, Université Paris-Sud, 91405 Orsay, France.

The plan is as follows. In the first part, we consider in §1.1, an abstract equation (generalizing the usual Navier–Stokes equation where $\mathfrak{R}=0$):

$$\frac{d\phi}{dt}+\mathfrak{A}\phi+\mathfrak{B}(\phi,\phi)+\mathfrak{R}\phi=\mathfrak{F}, \tag{0.1}$$

and briefly recall the well-known results of existence and uniqueness. Estimates, uniform with respect to time, are stated in §1.2. They extend those obtained by C. Guillopé [20] for the Navier–Stokes equations with homogeneous boundary conditions. In §1.3, which contains the main results of the first part, we introduce with C. Foias and R. Temam [14], R. Temam [31], a notion of functional invariant set and attractor. Then we prove that the attractors have finite fractal dimension and lie in a set of regular functions. In the second part we show how the results of the first part apply to the situations mentioned previously, namely Navier–Stokes equations (N.S.E.) with nonhomogeneous boundary conditions (§2.1), N.S.E. on a Riemannian manifold (§2.2), thermo-hydraulic equations (§2.3) and finally M. H. D. equations (§2.4).

In a subsequent work we shall derive bounds for the dimension of attractors in term of nondimensional physical numbers similar to those obtained by P. Constantin, C. Foias, O. Manley and R. Temam [9] in the case of the Navier–Stokes equations.

This work summarizes a thesis [16] prepared at the Laboratoire d'Analyse Numérique of the University of Paris-Sud at Orsay, France.

1. Review of known results and complements.

1.1. The abstract framework. Let $\mathfrak{v}$ be a separable Hilbert space topologically included in a Hilbert space $\mathfrak{H}$ with compact injection; we denote by $(\cdot,\cdot)$ and $|\cdot|$ the scalar product and the norm on $\mathfrak{H}$ and by $|\cdot|_{\mathfrak{v}}$ the norm on $\mathfrak{v}$. We suppose that $\mathfrak{v}$ is dense in $\mathfrak{H}$ and thus, identifying $\mathfrak{H}$ with its dual, we have the usual injections

$$\mathfrak{v}\subset\mathfrak{H}\subset\mathfrak{v}'. \tag{1.1}$$

We shall also denote by $(\cdot,\cdot)$ the pairing between $\mathfrak{v}$ and $\mathfrak{v}'$.

Let $\mathfrak{A}$ be a self-adjoint linear operator, continuous form $\mathfrak{v}$ into $\mathfrak{v}'$, such that $(\alpha>0)$:

$$(\mathfrak{A}\phi,\phi)\geqq\alpha|\phi|_{\mathfrak{v}}^2 \quad \forall\phi\in\mathfrak{v}. \tag{1.2}$$

For convenience we shall use in the sequel the norm $\|\phi\|\equiv(\mathfrak{A}\phi,\phi)^{1/2}$ on $\mathfrak{v}$. This norm is equivalent to $|\cdot|_{\mathfrak{v}}$.

Let $\mathfrak{R}$ be a linear continuous operator from $\mathfrak{v}$ into $\mathfrak{v}'$ which maps $D(\mathfrak{A})\equiv\{\phi\in\mathfrak{v},\ \mathfrak{A}\phi\in\mathfrak{H}\}$ into $\mathfrak{H}$ and such that there exist $\theta_1,\theta_2\in[0,1[$ and two positive constants K_1 and K_2 satisfying

$$|\mathfrak{R}\phi|\leqq K_1\|\phi\|^{1-\theta_1}|\mathfrak{A}\phi|^{\theta_1} \quad \forall\phi\in D(\mathfrak{A}); \tag{1.3}$$

$$|(\mathfrak{R}\phi,\phi)|\leqq K_2\|\phi\|^{1+\theta_2}|\phi|^{1-\theta_2} \quad \forall\phi\in\mathfrak{v}. \tag{1.4}$$

Finally let $\mathfrak{B}$ be a bilinear continuous operator from $\mathfrak{v}\times\mathfrak{v}$ into $\mathfrak{v}'$ and $D(\mathfrak{A})\times D(\mathfrak{A})$ into $\mathfrak{H}$ such that

$$(\mathfrak{B}(\phi,\psi),\psi)=0 \quad \forall\phi,\psi\in\mathfrak{v}; \tag{1.5}$$

and there exist $\theta_3, \theta_4 \in [0,1[$ and $K_3, K_4 > 0$ satisfying

$$|(\mathfrak{B}(\phi_1,\phi_2),\phi_3)| \leqq K_3 \|\phi_1\| \|\phi_2\| \|\phi_3\|^{\theta_3} |\phi_3|^{1-\theta_3} \quad \forall \phi_i \in \mathfrak{v}, \tag{1.6}$$

$$|\mathfrak{B}(\phi_1,\phi_2)| + |\mathfrak{B}(\phi_2,\phi_1)| \leqq K_4 \|\phi_1\| \|\phi_2\|^{1-\theta_4} |\mathfrak{A}\phi_2|^{\theta_4} \quad \forall \phi_1 \in \mathfrak{v} \quad \forall \phi_2 \in D(\mathfrak{A}). \tag{1.7}$$

Flow of strong solutions. Given $\phi^0 \in \mathfrak{v}$ and $\mathfrak{F} \in L^\infty(0,T;\mathfrak{H})$ with $T>0$, the initial value problem

$$\frac{d\phi}{dt} + \mathfrak{A}\phi + \mathfrak{B}(\phi,\phi) + \mathfrak{R}\phi = \mathfrak{F}, \tag{1.8}$$

$$\phi(0) = \phi^0, \tag{1.9}$$

has a unique solution on $[0, T_1(\|\phi^0\|)]$ $(0 < T_1 \leqq T)$ such that

$$\phi \in \mathfrak{C}([0,T_1];\mathfrak{v}) \cap L^2(0,T_1;D(\mathfrak{A})) \tag{1.10}$$

where $T_1 = T_1(\|\phi^0\|)$ depends on $\|\phi^0\|$ and the other data $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{R}$, $\mathfrak{F}$; more precisely there exists a positive constant C_1 depending only on the operators $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{R}$ and $\mathfrak{F}$ such that

$$T_1(\rho) \geqq \frac{C_1}{(1+\rho^2)^{1/(1-\theta_4)}}, \tag{1.11}$$

$$\sup_{0 \leqq t \leqq T_1} \|\phi(t)\| \leqq 1 + 2\|\phi^0\|. \tag{1.12}$$

DEFINITION 1.1. We say that ϕ is a strong solution of (1.1.8) on an interval I if $\phi \in C(I;V) \cap L^2_{\text{loc}}(I;D(\mathfrak{A}))$.

If $\mathfrak{B}$ satisfies in addition: there exist $\theta_5 \in [0,1[$, $K_5 > 0$, such that

$$|\mathfrak{B}(\phi_1,\phi_2)| \leqq K_5 \|\phi_1\|^{1-\theta_5} |\phi_1|^{\theta_5} \|\phi_2\|^{1-\theta_5} |\mathfrak{A}\phi_2|^{\theta_5} \quad \forall \phi_1 \in \mathfrak{v}, \quad \forall \phi_2 \in D(\mathfrak{A}); \tag{1.13}$$

we can take $T_1 = T$ i.e. we have existence for all time. These results are well known in the case of Navier–Stokes equations (C. Foias and G. Prodi [13], J. L. Lions [24], R. Temam [31, 32], $\cdots$); the details of the proofs, for the equation considered here, are given in [16].

1.2. Time uniform estimates. We denote by $\mathfrak{v}_m = D(\mathfrak{A}^{m/2})$ the scale of Hilbert spaces endowed with the norm $\|\phi\|_m \equiv |\mathfrak{A}^{m/2}\phi|$.

We introduce a family of Hilbert spaces $\{\mathfrak{E}_m\}_{m \in \mathbb{N}}$, with

$$\mathfrak{E}_{m+1} \subset \mathfrak{E}_m \quad \forall m \in \mathbb{N}, \tag{2.1}$$

the injection being continuous,

$$\begin{aligned} &\mathfrak{v}_m \text{ is a closed subspace of } \mathfrak{E}_m, \forall m \in \mathbb{N}, \text{ the norm} \\ &\text{induced by } \mathfrak{E}_m \text{ on } \mathfrak{v}_m \text{ being equivalent to } \|\cdot\|_m. \end{aligned} \tag{2.2}$$

We assume that $\mathfrak{E}_0 = \mathfrak{H}$ and

$$\mathfrak{A}^{-1} \text{ is continuous from } \mathfrak{E}_m \text{ into } \mathfrak{E}_{m+2} \cap \mathfrak{v} \quad \forall m \geqq 0. \tag{2.3}$$

We make the following assumptions on $\mathfrak{B}$ and $\mathfrak{R}$:

(2.4) $\mathfrak{R}$ is continuous from $\mathfrak{E}_{m+1}$ into $\mathfrak{E}_m$, $m \geqq 1$;

(2.5) $\mathfrak{B}$ is continuous from $\mathfrak{E}_{m+1} \times \mathfrak{E}_{m+1}$ into $\mathfrak{E}_m$, $m \geqq 1$.

The following theorem was first proved by C. Guillopé [20] for Navier–Stokes equations with homogeneous boundary conditions. The proof in our more general case can be found in [16].

Let $m \in \mathbb{N}$ and $l = [(m/2)]$.

THEOREM 2.1. *If* $\mathfrak{F}$ *satisfies*

(2.6) $$\mathfrak{F}^{(j)} \in \mathfrak{C}_b([0, +\infty[;\ \mathfrak{E}_{m-2j-2}), \qquad j = 0, \cdots, l-1,$$

(2.7) $$\mathfrak{F}^{(l)} \in \mathfrak{C}_b([0, +\infty[;\ \mathfrak{v}_{m-2l-1}),$$

then every solution of (1.1.7) *such that*

(2.8) $$\phi \in L^\infty(t_0, +\infty;\ \mathfrak{v}), \qquad t_0 \geqq 0,$$

satisfies

(2.9) $$\phi^{(j)} \in \mathfrak{C}_b([t_1, +\infty[;\ \mathfrak{E}_{m-2j}) \quad \forall t_1 > t_0, \quad j = 0, \cdots, l.$$

The notation $\mathfrak{C}_b([a,b[;\ X)$ means $\mathfrak{C}([a,b[;\ X) \cap L^\infty(a,b;\ X)$ and the proof of this theorem shows that the norm of the $\phi^{(j)}$ in $\mathfrak{C}_b([t_1, +\infty[,\ \mathfrak{E}_{m-2j})$ depends on the operators $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{R}$, on the different norms of the $\mathfrak{F}^{(j)}$ in the spaces appearing in (1.2.6)–(1.2.7), on the norm of ϕ in $L^\infty(t_0, +\infty;\ \mathfrak{v})$ on j, t_0 and t_1.

Remark 2.1. When $\mathfrak{A} + \mathfrak{R}$ is $\mathfrak{v}$-coercive (i.e. there exists $\eta > 0$ such that $((\mathfrak{A} + \mathfrak{R})\phi, \phi) \geqq \eta \|\phi\|^2$, $\forall \phi \in \mathfrak{v}$) and when (1.1.13) is satisfied, it is shown in [16, p. 35] that the strong solution of (1.1.7)–(1.1.8) satisfies (1.2.8) with $t_0 = 0$.

1.3. Fractal dimension of an attractor. This section contains the main results of the first part. It is organized as follows. In a first time we show a squeezing property for the flow of strong solutions in the sense of C. Foias and R. Temam [14] (Theorem 1.3.1). Then we define functional invariant sets and attractors. We prove for these sets a regularity like property (Theorem 1.3.2) and finally we establish (Theorem 1.3.3) that invariant sets, bounded in $\mathfrak{v}$, have finite fractal dimension. In the previous works on the dimension of attractors ([14], [11], [4], [26], [23], $\cdots$) the authors have proved that the Hausdorff dimension of these sets is finite. P. Constantin, C. Foias and R. Temam [10] are the first who have shown that, for Navier–Stokes equations with homogeneous boundary conditions, the fractal dimension of attractors is finite (note that this notion of dimension is stronger than that of the Hausdorff dimension).

Squeezing property. We first introduce some notations. The operator $\mathfrak{A}$ is an isomorphism from $D(\mathfrak{A})$ onto $\mathfrak{H}$; $\mathfrak{A}^{-1}$ is a self-adjoint and compact operator on $\mathfrak{H}$. Thus $\mathfrak{A}$ possesses an orthonormal family of eigenvectors $\{\xi_j\}_{j \geqq 1}$, which is complete in $\mathfrak{H}$. The increasing sequence of eigenvalues of $\mathfrak{A}$ is denoted by $\{\lambda_j\}_{j \geqq 1}$ and we also denote by P_m the projector in $\mathfrak{H}$ onto the space spanned by $\xi_1, \cdots, \xi_m$. When $\dim \mathfrak{v} = \infty$ (we shall only consider this case) the sequence λ_j is infinite and

(3.1) $$\lim_{j \to +\infty} \lambda_j = +\infty.$$

In this section we assume that $\mathfrak{R}$ is linear and continuous from $\mathfrak{v}$ onto $\mathfrak{H}$ (i.e. $\theta_1=\theta_2=0$ in (1.1.3), (1.1.4)):

$$|\mathfrak{R}\psi|\leqq K_1\|\psi\| \quad \forall\psi\in\mathfrak{v}. \tag{3.2}$$

Let ϕ_1, ϕ_2 be two strong solutions of (1.1.7) on some interval $[0,T]$; $i=1,2$:

$$\frac{d\phi_i}{dt}+\mathfrak{A}\phi_i+\mathfrak{B}(\phi_i,\phi_i)+\mathfrak{R}\phi_i=\mathfrak{F}, \tag{3.3}_i$$

$$\phi_i(0)=\phi_i^0, \tag{3.4}_i$$

where ϕ_i^0 is given in $\mathfrak{v}$ and

$$\mathfrak{F}\in L^\infty(0,T;\ \mathfrak{H}). \tag{3.5}$$

Since strong solutions belong to $\mathfrak{C}([0,T];\ \mathfrak{v})$, we set

$$R=\max_{i=1,2}\Big(\sup_{t\in[0,T]}\|\phi_i(t)\|\Big). \tag{3.6}$$

THEOREM 3.1. *Under the previous hypotheses, there exist C_1 and C_2 depending only on $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{R}$, R, T and $\mathfrak{F}$ such that for every $m\geqq 1$ and every $t\in[0,T]$ the following alternative holds*:

$$\textit{either (i)}\ |\phi_1(t)-\phi_2(t)|\leqq\sqrt{2}\,|P_m(\phi_1(t)-\phi_2(t))|,$$
$$\textit{or (ii)}\ |\phi_1(t)-\phi_2(t)|\leqq C_1\exp(-C_2\lambda_{m+1}\cdot t)|\phi_1^0-\phi_2^0|.$$

The proof given here is inspired from P. Constantin, C. Foias and R. Temam [10].

It should be noted that the constant $\sqrt{2}$ appearing in (i) could be any real number strictly larger than 1.

In the following the positive constants C_i depend only on $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{R}$, R, T and on the norm of $\mathfrak{F}$ in $L^\infty(0,T;\ \mathfrak{H})$ (denoted $|\mathfrak{F}|_\infty$). Before proving Theorem 3.1 we establish:

LEMMA 3.1. *Under the assumption of Theorem* 1.3.1; *if $\phi_1^0\neq\phi_2^0$ then $\phi_1(t)\neq\phi_2(t)$ for every $t\in[0,T]$ and for $0\leqq t\leqq\tau\leqq T$, we have*

$$\frac{\|\phi_1(t)-\phi_2(t)\|^2}{|\phi_1(t)-\phi_2(t)|^2}\geqq\frac{\|\phi_1(\tau)-\phi_2(\tau)\|^2}{|\phi_1(\tau)-\phi_2(\tau)|}\exp\big(-C_3(\tau-t)^{1-\theta_4}\big). \tag{3.7}$$

Proof. We set $\psi=\phi_1-\phi_2$. From $(1.3.3)_{i=1,2}$ we deduce

$$\frac{d\psi}{dt}+\mathfrak{A}\psi+\mathfrak{B}(\phi_1,\psi)+\mathfrak{B}(\psi,\phi_2)+\mathfrak{R}\psi=0, \tag{3.8}$$

$$\psi(0)=\phi_1^0-\phi_2^0. \tag{3.9}$$

Denoting by $B(t)$ the time dependent operator

$$B(t)\xi=\mathfrak{B}(\phi_1(t),\xi)+\mathfrak{B}(\xi,\phi_2(t))+\mathfrak{R}\xi \quad \forall\in\mathfrak{v}; \tag{3.10}$$

from (1.1.6), (1.3.2) and from the fact that strong solutions belong to $L^2(0,T;\ D(\mathfrak{A}))$, we deduce that

$$B(t)\in L^2(0,T;\ \mathfrak{L}(\mathfrak{v},\mathfrak{H})). \tag{3.11}$$

Now according to C. Bardos and L. Tartar [6] the equation

$$\frac{d\psi}{dt}+\mathfrak{A}\psi+B(t)\psi=0,$$

with $B(t)$ satisfying (1.3.11) possesses the backward uniqueness property (note that (1.3.8) is ill-posed for $t<0$). Then if $\psi(0)\neq 0$, $\psi(t)\neq 0$, $0\leqq t\leqq T$. This proves the first part of the lemma.

We can set $\Lambda(t)=\|\psi(t)\|^2/|\psi(t)|^2$. According to (1.3.8) and to the identity $(\mathfrak{A}\psi-\Lambda\psi,\psi)=0$ we deduce that

$$\frac{1}{2}\frac{d\Lambda}{dt}+\frac{|\mathfrak{A}\psi-\Lambda\psi|^2}{|\psi|^2}=-\frac{(\mathfrak{R}\psi+\mathfrak{B}(\phi_1,\psi)+\mathfrak{B}(\psi,\phi_2),\ \mathfrak{A}\psi-\Lambda\psi)}{|\psi|^2}. \tag{3.12}$$

Now thanks to (1.1.3) and (1.1.6) we can majorize the r.h.s. of (1.3.12) by

$$\left[K_1+K_4\left(\|\phi_1\|^{1-\theta_4}|\mathfrak{A}\phi_1|^{\theta_4}+\|\phi_2\|^{1-\theta_4}|\mathfrak{A}\phi_2|^{\theta_4}\right)\right]\frac{\|\psi\|}{|\psi|}\cdot\frac{|\mathfrak{A}\psi-\Lambda\psi|}{|\psi|}.$$

We denote by σ the term between the brackets, and then

$$\frac{1}{2}\frac{d\Lambda}{dt}+\frac{|\mathfrak{A}\psi-\Lambda\psi|^2}{|\psi|^2}\leqq\sigma\frac{\|\psi\|}{|\psi|}\cdot\frac{|\mathfrak{A}\psi-\Lambda\psi|}{|\psi|}\leqq\frac{1}{2}\sigma^2\Lambda+\frac{1}{2}\frac{|\mathfrak{A}\psi-\Lambda\psi|^2}{|\psi|^2}.$$

Thus we have

$$\frac{d\Lambda}{dt}\leqq\sigma^2\Lambda \tag{3.13}$$

which yields by integration

$$\Lambda(t)\geqq\Lambda(\tau)\exp-\int_\tau^t\sigma^2(s)\,ds. \tag{3.14}$$

We estimate now this last integral. Thanks to Young's inequality

$$\int_\tau^t\|\phi_i\|^{2(1-\theta_4)}|\mathfrak{A}\phi_i|^{2\theta_4}ds\leqq\left(\int_\tau^t\|\phi_i\|^2ds\right)^{1-\theta_4}\left(\int_\tau^t|\mathfrak{A}\phi_i|^2ds\right)^{\theta_4},$$

$$\leqq(t-\tau)^{1-\theta_4}R^{2(1-\theta_4)}\left(\int_\tau^t|\mathfrak{A}\phi_i|^2ds\right)^{\theta_4}.$$

Thus in order to deduce (1.3.7) from (1.3.14) we must majorize $(\int_\tau^t|\mathfrak{A}\phi_i|^2ds)^{\theta_4}$. For that purpose we take the scalar product in $\mathfrak{H}$ of $(1.3.3)_i$ with $\mathfrak{A}\phi_i$:

$$\frac{1}{2}\frac{d}{dt}\|\phi_i\|^2+|\mathfrak{A}\phi_i|^2\leqq K_1\|\phi_i\|^{1-\theta_1}\cdot|\mathfrak{A}\phi_i|^{1+\theta_1}+K_4\|\phi_i\|^{2-\theta_4}\cdot|\mathfrak{A}\phi_i|^{1+\theta_4}+|\mathscr{F}|_\infty|\mathfrak{A}\phi_i|$$

(we have used (1.1.3) and (1.1.6)).

By applications of Young's inequality we deduce that

$$\frac{d}{dt}\|\phi_i\|^2+|\mathfrak{A}\phi_i|^2\leqq C_4,$$

from which we get by integration: $\int_0^T |\mathfrak{A}\phi_i|^2\,ds \leqq C_5$. Thus

$$\int_\tau^t \sigma^2(s)\,ds \leqq C_3(\tau - t)^{1-\theta_4}. \tag{3.15}$$

This completes the proof of Lemma 3.1.

Proof of Theorem 3.1. We take the scalar product in $\mathfrak{H}$ of (1.3.8) with ψ: (we use (1.1.5))

$$\frac{1}{2}\frac{d}{dt}|\psi|^2 + \|\psi\|^2 = -(\mathfrak{R}\psi,\psi) - ((\mathfrak{B}(\psi,\phi_2),\psi)$$

by (1.1.7) and (1.3.2)

$$\leqq \left[K_1 + K_4\|\phi_2\|^{1-\theta_4}|\mathfrak{A}\phi_2|^{\theta_4}\right]\|\psi\||\psi|$$

$$\leqq \frac{1}{2}\sigma^2|\psi|^2 + \frac{1}{2}\|\psi\|^2.$$

We obtain

$$\frac{d}{dt}|\psi|^2 + (\Lambda - \sigma^2)|\psi|^2 \leqq 0,$$

and thanks to (1.3.7) (τ is fixed)

$$\frac{d}{dt}|\psi|^2 + \left(\Lambda(\tau)\exp\left(-C_3\tau^{1-\theta_4}\right) - \sigma^2\right)|\psi|^2 \leqq 0.$$

By integration from 0 to τ we get

$$|\psi(\tau)|^2 \leqq |\psi(0)|^2 \exp\left(-\tau\Lambda(\tau)\exp\left(-C_3\tau^{1-\theta_4}\right)\right) + \int_0^\tau \sigma^2(s)\,ds\Big). \tag{3.16}$$

First case: $|Q_m\psi(\tau)| \leqq |P_m\psi(\tau)|$, then (i) is satisfied.
Second case: $|Q_m\psi(\tau)| > |P_m\psi(\tau)|$, then

$$\Lambda(\tau) \geqq \frac{\|P_m\psi(\tau)\|^2}{|Q_m\psi(\tau)|^2 + |P_m\psi(\tau)|^2} \geqq \frac{\lambda_{m+1}|Q_m\psi(\tau)|^2}{|Q_m\psi(\tau)|^2 + |Q_m\psi(\tau)|^2} = \frac{\lambda_{m+1}}{2}$$

and from (1.3.15) and (1.3.16) we deduce (ii) with τ instead of t. □

Remark 3.1. From (1.3.15), (1.3.16), and $\Lambda(\tau) \geqq \lambda_1$ we deduce the following property of continuous dependence w.r. to the initial value ϕ^0 for the flow $\{\phi(t)\}_{t\in[0,T]}$:

There exists a constant C_7 depending only on $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{R}$, R, T and $|\mathscr{F}|_\infty$ such that

$$|\phi_1(t) - \phi_2(t)| \leqq C_7|\phi_1(0) - \phi_2(0)| \quad \forall t \in [0,T]. \tag{3.17}$$

Functional invariant sets, attractors. Let be given $\mathfrak{F} \in \mathfrak{H}$. For every $\phi^0 \in \mathfrak{v}$, as recalled in §1.1.1., the problem

Find $\phi \in \mathfrak{C}([0, T_1(\|\phi^0\|)];\ \mathfrak{v}) \cap L^2(0, T_1(\|\phi^0\|),\ D(\mathfrak{A}))$ such that

$$\frac{d\phi}{dt} + \mathfrak{A}\phi + \mathfrak{B}(\phi,\phi) + \mathfrak{R}\phi = \mathfrak{F}, \tag{3.18}$$

$$\phi(0) = \phi^0, \tag{3.19}$$

possess a unique solution which will be denoted by $S(t)\phi^0 \equiv \phi(t)$. This defines a nonlinear semi-group on $\mathfrak{v}$, continuous w.r. to the $\mathfrak{H}$ norm (see (1.3.17)).

DEFINITION 3.1. A functional invariant set X is a subset of $\mathfrak{v}$ such that

i) for every $\phi^0 \in X$, (1.3.18)–(1.3.19) possess a solution for all time (i.e. $\phi \in \mathfrak{C}([0, +\infty[; \mathfrak{v})$);

ii) $S(t)X = X$, $\forall t \geqq 0$.

Remark 3.2. As mentioned previously, the problem (1.3.18)–(1.3.19) is in general ill-posed for $t < 0$. Nevertheless for $\phi^0 \in X$, where X is a functional invariant set, this problem is well-posed for $t \in \mathbb{R}$. Indeed from (ii) of Definition 1.3.1 we deduce that for every $n \in \mathbb{N}$, there exist $\phi_n^0 \in X$ such that $S(n)\phi_n^0 = \phi^0$. Now for $t < 0$ and $n = [-t]$, we set $S(-t)\phi^0 = S(n+1-t)\phi_{n+1}^0$. Note that this definition is not ambiguous thanks to the backward uniqueness property pointed out at the beginning of the proof of Lemma 1.3.1. □

Examples.

(i) Let $\{\phi_1, \cdots, \phi_k\}$ be a set of steady-state solutions of (1.3.18); then $X = \{\phi_1, \cdots, \phi_k\}$ is functional invariant.

(ii) If $T > 0$ is such that $\phi(T) = \phi^0$ then the orbit $X = \{\phi(t),\ 0 \leqq t \leqq T\}$ is a functional invariant set.

(iii) Proposition 3.1 will exhibit a functional invariant set which is attracting in a certain sense. We do not know if this set is trivial (i.e. of the form (i)). □

An attractor is an invariant set attracting the trajectories which fall in its basin of attraction:

DEFINITION 3.2. An attractor is a functional invariant set X which possesses a neighbourhood in $\mathfrak{v}$, $\mathfrak{O}$, such that for every $\phi^0 \in \mathfrak{O}$, the distance from $S(t)\phi^0$ to X in $\mathfrak{v}$ tends to zero.

Remark 3.3. A. V. Babin and M. I. Vishik [4], [5] have proved the existence of an attractor in the case of two-dimensional Navier–Stokes equations in a rectangle with periodic boundary conditions (these equations can be written under the form (1.3.18)). In [4] it is showed that the dimension of that attractor grows at least like the inverse of the aspect ratio—the ratio of the length and the width of the strip.

Remark 3.4. The previous definitions were given in case of a constant excitation $\mathfrak{F}$. We can also consider the case of forced oscillation: $\mathfrak{F} \in L^\infty(0, +\infty; \mathfrak{H})$ and $\mathfrak{F}$ is T-periodic ($T > 0$). In this case we must substitute to the continuous semi-group $\{S(t)\}_{t \geqq 0}$ the distance one $\{S(nT)\}_{n \in \mathbb{N}}$ (see also Remark 3.7).

PROPOSITION 3.1. *Suppose that* $\mathfrak{B}$ *fulfills* (1.1.13) *and that* $\mathfrak{A} + \mathfrak{R}$ *is* $\mathfrak{v}$*-coercive* (*see Remark* 1.1.1). *For every* $\phi^0 \in \mathfrak{v}$ *and* $\mathfrak{F} \in \mathfrak{H}$, *there exists a functional invariant set* $X(\phi^0, \mathfrak{F})$, *bounded in* $D(\mathfrak{A})$, *such that*

$$\lim_{t \to +\infty} d_{\mathfrak{v}}\big(S(t)\phi^0, X\big) = 0. \tag{3.20}$$

Proof. As mentioned in Remark 1.1.1, under the above hypotheses, the problem (1.3.18)–(1.3.19) possesses a solution $\phi \in \mathfrak{C}([0, +\infty[; \mathfrak{v})$ and moreover $\phi \in L^\infty(0, +\infty; \mathfrak{v})$. We set $X(\phi^0, \mathfrak{F}) = \bigcap_{\tau \geqq 0} \{\overline{\phi(s),\ s > \tau}\}^{\mathfrak{H}}$, and remark that $\phi \in X$ is equivalent to the existence of a sequence of real numbers $(s_j)_{j \geqq 1}$ such that

$$\lim_{j \to +\infty} s_j = +\infty, \qquad \lim_{j \to +\infty} \big|S(s_j)\phi^0 - \psi\big| = 0. \tag{3.21}$$

Since $\phi \in L^\infty(0, +\infty; \mathfrak{v})$, we deduce from Theorem 1.2.1 with $m = 2$ that $\phi \in L^\infty(1, +\infty, \mathfrak{E}_2)$ and by (1.2.2) it results that X is bounded in $D(\mathfrak{A})$ (see also Remark 1.3.5).

We prove now (ii) of Definition 1.3.1. Let be $t>0$ and $\phi\in S(t)X$. There exist $\psi\in S$ and $(s_j)_{j\geq 1}$ satisfying $\phi=S(t)\psi$ and $\phi(s_j)\to\psi$ in $\mathfrak{H}$. By continuity of $S(t)$ we have $\phi(s_j+t)\to\phi$ in $\mathfrak{H}$ and thus $\phi\in X: S(t)X\subset X$. Conversely, let $\phi\in X$. There exists $(s_j)_{j\geq 1}$ such that $\phi(s_j)\to\phi$ in $\mathfrak{H}$. We set $\sigma_j=s_j-t$ where $t>0$ is fixed; the sequence $(\phi(\sigma_j))$ is bounded in $D(\mathfrak{A})$, by compactness we can extract from $(\phi(\sigma_j))$ a subsequence $(\phi(\sigma_{j'}))$ which converges to some limit ψ in $\mathfrak{H}$. We have $\phi(s_{j'})=S(t)\phi(\sigma_{j'})\to S(t)\psi$ in $\mathfrak{H}$ and since the sequence $(\phi(s_{j'}))$ is extracted from $(\phi(s_j))$ we have $\phi(s_{j'})\to\phi$ in $\mathfrak{H}$. Thus $S(t)\psi=\phi$ and then $\phi\in S(t)X: X\subset S(t)X$.

It remains to show that the distance in $\mathfrak{v}$ from X to $S(t)\phi^0$ tends to zero. If it were not the case, there would exist some $\varepsilon_0>0$ and a sequence (t_j), $t_j\to+\infty$, such that $d_{\mathfrak{v}}(\phi(t_j), X)\geq\varepsilon_0$. But the sequence $(\phi(t_j))$ is bounded in $D(\mathfrak{A})$ and thus relatively compact in $\mathfrak{v}$. We can extract a subsequence $(\phi(t_{j'}))$ which converges to some limit ψ w.r. to the $\mathfrak{v}$-norm and since (1.3.21) is satisfied, $\psi\in X$. The function $d_{\mathfrak{v}}(\cdot, X)$ is continuous on $\mathfrak{v}$; thus $d(\psi, X)\geq\varepsilon_0$ which contradicts $\psi\in X$.

Remark 3.5. Assume that $\mathfrak{F}\in\mathfrak{E}_{m_0}$ for some $m_0\geq 0$, and then according to Theorem 1.2.1 with $m=m_0$, $X(\phi^0,\mathfrak{F})$ is bounded in $\mathfrak{E}_{m_0+2}$ and

$$\lim_{t\to+\infty} d_{\mathfrak{E}_{m_0+1}}\big(S(t)\phi^0, X\big)=0.$$

Regularity. In all the applications that we have in view, the operator $\mathfrak{A}$ is in a certain sense an elliptic differential operator of even order. Thus the spaces $\mathfrak{v}_m$ (and $\mathfrak{E}_m$) are spaces of functions more regular as m increases (think that $\mathfrak{E}_m$ is approximately a space of functions whose mth distributional derivative is still a function). The next result shows that functional invariant sets (and thus attractors) are as regular as $\mathfrak{F}$.

THEOREM 3.2. *Let $\mathfrak{F}\in\bigcap_{m\geq 0}\mathfrak{E}_m$, and then every functional invariant set, X, is included in $\bigcap_{m\geq 0}\mathfrak{E}_m$. Moreover if X is bounded in $\mathfrak{v}$, then X is bounded in $\mathfrak{E}_m$ for every $m\geq 0$.*

Proof. Let $\psi\in X$, and then there exists $T>0$ and $\phi^0\in\mathfrak{v}$ such that ϕ, the solution of (1.3.18)–(1.3.19), satisfies $\phi(T)=\psi$ and $\phi\in C([0,T];\ \mathfrak{v})$. Then according to R. Temam [30], we have $\phi(T)\in\mathfrak{E}_m$, for every $m\in\mathbb{N}$.

If X is bounded in $\mathfrak{v}$, then for every $\phi^0\in X$ the flow $\phi(t)$ satisfies (1.2.8) with $t_0=0$. Thus Theorem 1.2.1 applies for every $m\in\mathbb{N}$ and ϕ is bounded in $\mathfrak{E}_m$ by a constant which does not depend on ϕ^0. This proves the last part of Theorem 3.2. □

Remark 3.6. Assuming only that $\mathfrak{F}\in\mathfrak{E}_{m_0}$, for some $m_0\in\mathbb{N}$, we obtain that $X\subset\mathfrak{E}_{m_0+2}$. And when X is bounded in $\mathfrak{v}$, X is bounded in $\mathfrak{E}_{m_0+2}$.

Finite dimension. We show that functional invariant sets, bounded in $\mathfrak{v}$, have finite dimension. We first introduce the definition of fractal dimension (see B. Mandelbrot [25]):

DEFINITION 3.3. Let Y be a subset of a metric space X. For every $\delta>0$, the minimal number of open balls of radius equals to δ which is necessary to cover Y is denoted by $N_Y(\delta)$ (this number can be infinite). We set ($\gamma\in\mathbb{R}_+^*$):

$$\mu_F(Y,\gamma)=\limsup_{\varepsilon\to 0} N_Y(\varepsilon)\varepsilon^\gamma.$$

If there exists $\delta\geq 0$ such that $\mu_F(Y,\gamma)<+\infty$, Y has finite fractal dimension and its dimension is the number

$$\inf\{\gamma\geq 0,\ \mu_F(Y,\gamma)<+\infty\}.$$ □

THEOREM 3.3. *Every functional invariant set, bounded in* $\mathfrak{v}$, *has finite fractal dimension.*

Proof. Let be R such that $\|\phi\| \leqq R$ for every ϕ in X, the functional invariant set considered here. We also fix $T>0$.

According to Theorem 1.3.1, for every ϕ and ψ in $\mathfrak{v}$ we have

$$(3.22)\quad |S(T)\phi - S(T)\psi| \leqq C_1 \exp(-C_2\lambda_{m+1}T)|\phi-\psi| + \sqrt{2}\,|P_m(S(T)\phi - S(T)\psi)| \quad \forall \phi, \psi \in \mathfrak{v}, \|\phi\| \leqq R, \|\psi\| \leqq R.$$

And thanks to (1.3.17)

$$(3.23)\quad |S(T)\phi - S(T)\psi| \leqq C_7|\phi-\psi| \quad \forall \phi, \psi \in \mathfrak{v}, \|\phi\| \leqq R, \|\psi\| \leqq R.$$

Let $\eta \in]0,1[$, and from (1.3.1) and (1.3.22) we deduce that there exist a constant C_8 $(=\sqrt{2})$ and a continuous projector on $\mathfrak{H}$ of finite dimension Π $(=P_m$, with m such that $\eta \leqq C_1 \exp(-C_2\lambda_{m+1}t))$ such that

$$(3.24)\quad |S(T)\phi - S(T)\psi| \leqq \eta|\phi-\psi| + C_8|\Pi(S(T)\phi - S(T)\psi)|.$$

We shall prove that Theorem 1.3.3 is a consequence of (1.3.23) and (1.3.24).

Let there be given $\gamma>0$ and $\varepsilon>0$. Since X is relatively compact in $\mathfrak{H}$, it can be covered by a finite number of open balls $\{B_i\}_{1 \leqq i \leqq N}$ of radius ε. The ball B_i is supposed centered at $\phi_i \in X$. From $S(T)X \supset X$ we deduce that $X \subset \bigcup_{i=1}^{N} S(T)(B_i \cap X)$.

Let there be given ϕ in $S(T)(B_i \cap X)$, and thanks to (1.3.23) and (1.3.24) we have $(\psi_i = S(T)\phi_i)$

$$(3.25)\quad |\phi - \psi_i| \leqq \eta\varepsilon + C_8|\Pi(\phi - \psi_i)|,$$

$$(3.26)\quad |\phi - \psi| \leqq C_7\varepsilon.$$

We construct a new covering of X. For i fixed, according to (1.3.26), $\Pi(S(T)(B_i \cap X))$ is included in a ball of $\Pi(\mathfrak{H})$ of radius $2C_7\varepsilon$. Let be $\tilde{B}_i^1, \cdots, \tilde{B}_i^P$ a minimal covering of $\Pi(S(t)(B_i \cap X))$ by balls of radius $r_1 = (1-\eta)/4C_8\varepsilon$. We have $p \leqq l_m(r_1/2C_7\varepsilon) = l_m((1-\eta)/2C_7C_8)$, where $l_m(\rho)$ is the minimal number of balls of radius ρ which is necessary to cover the unit ball of $\mathbb{R}^m$. We set $G_i^k = S(T)(B_i \cap X) \cap \Pi^{-1}(\tilde{B}_i^k)$. According to (1.3.25), G_i^k is included in a closed ball, centered at ψ_i, of radius $\leqq \eta\varepsilon + C_8 r_1 = (1+3\eta)/4\varepsilon$. Thus we can include G_i^k in an open ball B_i^k of radius $(1+\eta)\varepsilon/2$. Let us now summarize what we have done. Starting from a generic covering of X by balls of radius ε, $\{B_i\}_{1 \leqq i \leqq N}$, we have constructed a new covering $\{B_i^k\}_{1 \leqq i \leqq N, 1 \leqq k \leqq \rho}$, by balls of radius $(1+\eta)\varepsilon/2$ $(<\varepsilon)$. Thus we have: $N_X((1+\eta)\varepsilon/2) \leqq p \cdot N_X(\varepsilon)$. Denoting by $\phi(\varepsilon) = N_X(\varepsilon)\varepsilon^\gamma$, we get from this last inequality that $\phi((1+\eta)/2\varepsilon) \leqq l_m(\eta/8C_7C_8) \cdot ((1+\eta)/2)^\gamma \phi(\varepsilon)$. We claim that if $l_m((1-\eta)/8C_7C_8)((1+\eta)/2)^\gamma < 1$ i.e. if

$$(3.27)\quad \gamma > \gamma_0 = \frac{\log l_m((1-\eta)/8C_4C_5)}{\log 2/(1+\eta)},$$

we have $\limsup_{\varepsilon \to 0} \phi(\varepsilon) = 0$ and thus the fractal dimension of X is not greater than γ_0.

It remains to prove our claim. We set $\delta = (1+\eta)/2$ and $\chi = l_m((1-\eta)/8C_4C_5) \cdot ((1+\eta)/2)^\gamma$. We have $\phi(\delta\varepsilon) \leqq \chi\phi(\varepsilon)$ thus by iteration $\phi(\varepsilon) \leqq \chi^j \phi(\delta^{-j}\varepsilon)$, $\forall j \in \mathbb{N}$.

Taking $j = 1 + [\log\varepsilon/\log\delta]$, $\phi(\delta^{-j}\varepsilon) \leqq \sup_{1 \leqq \rho \leqq \delta^{-1}} \phi(\rho) \leqq \delta^{-\gamma} N_X(1) < +\infty$ and $\phi(\varepsilon) \leqq \chi^j \delta^{-\gamma} N_X(1)$ tends to 0 with ε. □

Remark 3.7. (Continuation of Remark 1.3.4): Theorems 1.3.1, 1.3.2 and 1.3.3 are also valid in case of forced oscillations.

2. Applications. In this part we illustrate the abstract results of the first part by four applications in fluid mechanics. The four following sections are set in the same way: after writing the set of equations coming from physics, we give the functional setting that allows us to use the results of the first part. Then we state in each particular situation the results obtained in §1.3.

2.1. Nonhomogeneous Navier–Stokes equations. Many of the results obtained here were proved by C. Foias and R. Temam [14]. Nevertheless we need to present them in order to introduce some notations and to check the hypotheses of the abstract framework, which will be subsequently useful.

We consider the motion of a viscous incompressible fluid which fills some bounded region Ω. The velocity $u(x,t)$ and pressure $p(x,t)$, are determined by the set of equations

$$\begin{aligned} &\frac{\partial u}{\partial t}-\nu\Delta u+(u\cdot\nabla)u+\nabla p=h && \text{in } \Omega\times\mathbb{R}_+,\\ &\operatorname{div} u=0 && \text{in } \Omega\times R_+,\\ &u(x,t)=\psi(x) && \text{on } \Gamma\times\mathbb{R}_+,\\ &u(x,0)=u^0(x) && \text{in } \Omega; \end{aligned} \tag{1.1}$$

where ν is the viscosity of the fluid, h is an external force acting on the fluid and $\psi(x)$ is the velocity of the boundary Γ of Ω (we have taken the density equal to 1).

2.1.1. Functional setting. We assume that Ω is an open connected bounded set in $\mathbb{R}^d$ ($d=2$ or 3) and that

$$\Gamma \text{ is a } C^\infty\text{-manifold of dimensional } d-1 \text{ and } \Omega \text{ is locally located on one side of } \Gamma, \tag{1.2}$$

$$\Gamma \text{ has a finite number of connected components denoted } \Gamma_1,\cdots,\Gamma_k. \tag{1.3}$$

Let H and V be the closures in $L^2(\Omega)^d$ and $H_0^1(\Omega)^d$ respectively of

$$\mathcal{N}=\left\{v\in\mathfrak{D}(\Omega)^d,\ \operatorname{div} v=0\right\}$$

where $H_0^m(\Omega)$ denotes the closure of $\mathfrak{D}(\Omega)$ (the space of C^∞ functions with compact support in Ω) in the Sobolev L^2-space $H^m(\Omega)$ of order m.

The spaces H and V are endowed with the scalar products

$$(u,v)=\int_\Omega u_i v_i dx \quad\text{and}\quad ((u,v))=\int_\Omega D_j u_i D_j v_i dx$$

respectively. We set also $|u|=(u,u)^{1/2}$ and $\|u\|=((u,u))^{1/2}$. The injection from V into H is dense, continuous and compact (thanks to Rellich's lemma). Let A be the operator from V into V' defined by

$$\langle Au,v\rangle=((u,v)).$$

We set

$$E_0 = H \quad \text{and} \quad E_m = H^m(\Omega)^d \cap H, \qquad m \geqq 1 \tag{1.4}$$

and according to the regularity properties of Stokes operator A (see R. Temam [32], J. M. Ghidaglia [17]):

$$A^{-1} \text{ is a continuous operator from } \mathfrak{E}_m \text{ into } \mathfrak{E}_{m+2} \cap V. \tag{1.5}$$

For u, v, w in $H^1(\Omega)^d$ we set

$$b(u,v,w) = \int_\Omega u_j (D_j v_k) w_k \, dx. \tag{1.6}$$

We have the following property for b (see R. Temam [31]):

$$\begin{aligned} &b \text{ is continuous on } H^{s_1}(\Omega)^d \times H^{s_2+1}(\Omega)^d \times H^{s_3}(\Omega)^d, \text{ where } s_i \geqq 0 \text{ and} \\ &s_1 + s_2 + s_3 > \frac{d}{2} \quad \text{if one of the } s_i = \frac{d}{2}, \\ &s_1 + s_2 + s_3 \geqq \frac{d}{2} \quad \text{otherwise.} \end{aligned} \tag{1.7}$$

Let $u, v, w \in V$, we set $B(u,v) \in V' : \langle B(u,v), w \rangle = b(u,v,w)$, then

$$B \text{ is continuous from } E_{m+1} \times E_{m+1} \text{ into } E_m \text{ for } m \geqq 1. \tag{1.8}$$

The following result (see R. Temam [32] for the proof) will be useful to find an appropriate $\bar{u} \in H^1(\Omega)^d$ such that $\bar{u}_{|\Gamma} = \psi$.

LEMMA 1.1. *Let $\psi \in H^{1/2}(\Gamma)^d$ be given such that (n is the unit outward normal on Γ)*

$$\int_{\Gamma_i} \psi \cdot n \, d\Gamma = 0, \qquad i = 1, \cdots, k. \tag{1.9}$$

There exists $\bar{u} \in H^1(\Omega)$ such that

i) $\bar{u}_{|\Gamma} = \psi$ *(in the sense of traces on Γ),*

ii) $\operatorname{div} \bar{u} = 0$,

iii) $|b(v, \bar{u}, v)| \leqq \nu \|v\|^2/2$, $\forall v \in V$.

Moreover, for every $m \in \mathbb{N}$, if $\psi \in H^{m+1/2}(\Gamma)^d$, $\bar{u} \in H^{m+1}(\Omega)^d$.

Using now the classical projection on divergence free fields (see J. L. Lions [24], R. Temam [32], $\cdots$) we deduce that (2.1.1) is equivalent to the initial value problem for $\phi = u - \bar{u}$ ($\bar{u}$ is given by Lemma 2.1.1):

$$\frac{d\phi}{dt} + \nu A\phi + B(\phi,\phi) + R\phi = f, \tag{1.10}$$

$$\phi(0) = \phi^0, \tag{1.11}$$

where $R \in \mathfrak{L}(V, V')$ is defined by

$$\langle R\phi, \xi \rangle = b(\phi, \bar{u}, \xi) + b(\bar{u}, \phi, \xi) \quad \forall \xi \in V. \tag{1.12}$$

2.1.2. Fractal dimension for attractors. We briefly show that the operators introduced previously satisfy the assumptions of the first part.

Suppose that $\psi \in H^{3/2}(\Gamma)$ satisfies (2.1.9); then according to Lemma 2.1.1, (2.1.7) and (2.1.12), R satisfies (1.3.2) and B satisfies (1.1.6) with $\theta_3 = \frac{1}{2}$. Note that (1.1.5) is the well-known property of orthogonality of b. The estimate (1.1.7), with $\theta_4 = \frac{1}{2}$, results from (2.1.7) and from (cf. S. Agmon [1]):

$$|\phi|^2_{L^\infty(\Omega)} \leqq C\|\phi\||A\phi| \quad \forall \phi \in D(A).$$

Remark 1.1. When $\Omega \subset \mathbb{R}^2$, according to (2.1.7), (1.1.13) is satisfied with $\theta_5 = \frac{1}{2}$. On the other hand, thanks to the choice of $\bar{u}$ (Lemma 2.1.1):

$$((\nu A + R)\phi, \phi) \geqq \frac{\nu}{2}\|\phi\|^2 \quad \forall \phi \in V.$$

As mentioned in Remark 1.2.1, the problem (2.1.10)–(2.1.11) possesses a unique strong solution for $t \in [0, +\infty[$ which is bounded in $H^1(\Omega)^2$. Note also that, according to Proposition 1.3.1, for every $u^0 \in V$ and $h \in L^2(\Omega)^d$, there exists a functional invariant set $X(u^0, h)$, bounded in $H^2(\Omega)^d$, such that the distance from $u(t)$ to X in $H^1(\Omega)^d$ tends to zero when t goes to $+\infty$. □

THEOREM 1.1. *Assume that $h \in \mathfrak{C}^\infty(\bar{\Omega})^d$ and $\psi \in \mathfrak{C}^\infty(\Gamma)^d$; then every functional invariant set, X, lies in $\mathfrak{C}^\infty(\bar{\Omega})^d$. Moreover if X is bounded in $H^1(\bar{\Omega})^d$, then X is bounded in $H^m(\Omega)^d$ for every $m \geqq 0$.*

Proof. From the hypotheses on h and ψ we deduce that $f \in \bigcap_{m \geqq 0} E_m$ and $\bar{u} \in \mathfrak{C}^\infty(\bar{\Omega})^d$. It follows then that R maps E_{m+1} into E_m; thus Theorem 1.3.2 applies.

From Theorem 1.3.3 we deduce:

THEOREM 1.2. *Every functional invariant set, bounded in $H^1(\Omega)^d$, has finite fractal (and Hausdorff) dimension.*[1]

2.2. Navier–Stokes equations on a manifold. This application is motivated by the modelisation of geophysical flows. Assuming that the velocities are horizontal and proportional to the distance from the center of the Earth, this flow can be viewed as a viscous incompressible flow on the 2D-sphere S^2 (see for instance A. Avez and Y. Bamberger [3]). In the following analysis this case corresponds to $M = S^2$ and the metric g is that induced by the 3-Euclidean space. Note that in this case the following assumption (2.2.4) is a well-known property of sphere with even dimension.

It should be observed that Navier–Stokes equations with periodic boundary conditions correspond to $M = T^n$ (n-dimensional torus) endowed with the flat metric ($g_{ij} = \delta_{ij}$).

2.2.1. Geometric preliminaries. Let M be an n-dimensional compact, connected and oriented Riemannian manifold without boundary.

We denote by g the Riemannian metric on M: g is a C^∞-field of symmetric and bilinear forms on the tangent spaces:

$$g(x; u, v) = g(x; v, u) \quad \forall x \in M, \quad \forall u, \quad v \in T_x M$$

where $T_x M$ is the tangent space at M in x,

$$g(x; u, u) > 0 \quad \forall x \in M, \quad \forall u \in T_X M, \quad u \neq 0.$$

[1] Recall that if a set has finite fractal dimension then it has finite Hausdorff dimension. The converse is false.

Letting $(x^1, \cdots, x^n)$ be a coordinate system on M, we set

$$g_{ij} = g\left(x; \frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j}\right), \qquad G = \det(g_{ij}),$$

and denote by

$$(u \mid v) = g_{ih} u^i u^j$$

the scalar product on $T_X M$ induced by g and $|\cdot|$ the corresponding norm.

The inverse of g_{ij} is denoted by $g^{ij}: g_{ij} g^{jk} = \delta_i^k$. Thanks to g_{ij} and g^{ij} we can:
assign to u (vector), $\tilde{u}$ (covector) by $(\tilde{u})_i = g_{ij} u^j$,
assign to ω (covector), $\hat{\omega}$ (vector) by $(\hat{\omega})^i = g^{ij} \omega_j$.

In the sequel we shall omit the $\sim$ and the $\wedge$ and use subscripts for covariant index and superscripts for contravariant index.

2.2.2. Differential operators, Sobolev spaces. We denote by $C^\infty(M)$ (resp. $C^\infty(TM)$) the space of C^∞-functions (resp. C^∞-vector field) on M.

Gradient of a function. We associate to $p \in C^\infty(M)$, the element $\nabla p \in C^\infty(TM)$:

$$(\nabla p)^i = g^{ij} \frac{\partial p}{\partial x^j}.$$

Total derivative of a vector field. Let $u \in C^\infty(TM)$ and D the Levi–Cività connection (see (2.2.1) for the expression in a coordinate system),

$$(\nabla u)_i^j = D_i u^j.$$

Divergence of a vector field. The divergence is the contraction of the total derivative

$$\operatorname{div} u = D_i u^i.$$

Laplacian on $\mathfrak{C}(TM)$.

$$(\Delta u)^i = g^{kl} D_k D_l u^i \quad \forall u \in C^\infty(TM).$$

In order to give the expression of these differential operators in a coordinate system, we introduce Christoffel's symbols:

$$\{i \quad j \quad k\} = \frac{1}{2}\left(\frac{\partial g_{jk}}{\partial x^i} + \frac{\partial g_{ik}}{\partial x^j} - \frac{\partial g_{ij}}{\partial x^k}\right),$$

$$\left\{\begin{matrix} k \\ i\, j \end{matrix}\right\} = g^{kl}\{ijl\}.$$

The expression of the covariant derivation is then

$$D_i u^j = \frac{\partial u_j}{\partial x^i} + \left\{\begin{matrix} j \\ i\, k \end{matrix}\right\} u^k. \tag{2.1}$$

2.2.3. Navier–Stokes equations on M. With the previous notation, Navier–Stokes equations on M read (see D. Ebin and J. Marsden [12]):

$$\frac{\partial u}{\partial t} - \nu \Delta u + D_u u + \nabla p = f, \tag{2.2}$$

$$\operatorname{div} u = 0, \tag{2.3}$$

where f is a tangent vector field, the unknowns u (the velocity) and p (the pressure) being respectively a tangent vector field and a scalar field.

Let us introduce Stokes operator on M. We set

$$\mathcal{N}=\{u\in C^\infty(TM),\ \operatorname{div}u=0\},$$

and let H and V be the closures in $\mathbb{L}^2$ and $\mathbb{H}^1$ respectively of $\mathfrak{v}$ (for Sobolev spaces on manifolds the reader is referred to T. Aubin [2]). These spaces are endowed with the scalar products

$$(u,v)=\int(uv)\,dM \qquad (dM=\sqrt{G}\,dx^1\cdots dx^n)$$

and

$$((u,v))_1=\int(u\,|\,v)\,dM+\int(\nabla u\,|\,\nabla v)\,dM$$

respectively. We set also $\|u\|_1=((u,u))_1^{1/2}$.

Let A be the operator from V into V' defined by

$$\langle Au,v\rangle=\int(\nabla u\,|\,\nabla v)\,dM \quad \forall u,\ v\in V.$$

The next proposition gives a condition which is sufficient to insure the coercivity of A:

PROPOSITION 2.1. *The semi-norm*

$$|u|_1=\left(\int|\nabla u|^2\,dM\right)^{1/2}$$

reduces to a norm equivalent to $\|\cdot\|_1$ *on* $\mathbb{H}^1$ *if the metric* g *does not locally split under the form* $g'+dy_n^2$ *where* g' *depends only on* $n-1$ *variables.* □

This proposition is a consequence of the de Rham decomposition theorem (see S. Kobayashi and K. Nomizu [21]). For further details see [16]. It is also proved in this last reference that under the topological condition:

(2.4) Every continuous vector field on M, vanishes at least at one point,

the semi-norm $|\cdot|_1$ is equivalent to $\|\cdot\|_1$.

Let v be given in $\mathfrak{v}$. The scalar product in $\mathbb{L}^2$ of (2.2.2) with v yields since $\operatorname{div}v=0$:

$$\frac{\partial}{\partial t}(u\,|\,v)+\nu\langle Au,v\rangle+\langle B(u,u),\,v\rangle=(f\,|\,v),$$

where we set

$$\langle B(u,v),\,w\rangle=\int(D_u v\,|\,w)\,dM \quad \forall u,\ v,\ w\in\mathfrak{E}(TM).$$

With this notation, (2.2.2)–(2.2.3) turn out to be equivalent to the differential equation for u:

$$\frac{du}{dt}+\nu Au+B(u,u)=f. \tag{2.5}$$

2.2.4. Fractal dimension of attractors. The verification of the fact that the previous functional setting is compatible with the hypotheses of the first part (when dimension of $M=2$ or 3) is similar to that of the case of Navier–Stokes equations (here $\mathfrak{R}\equiv 0$). The details are given in [16].

Remark 2.1. When $\dim M=2$, (1.1.13) is satisfied with $\theta_5=\frac{1}{2}$. According to Remark 1.2.1, for every $f\in L^\infty(0,+\infty;\ H)$ and $u^0\in V$ the initial value Problem for (2.2.5) with $u(0)=u^0$ possesses a strong solution which is bounded in $\mathbb{H}^1$. Note also that Proposition 1.3.1 applies in this case. □

We deduce from the results of §1.3:

THEOREM 2.1. *Assume that $f\in C^\infty(TM)$; then every functional invariant set, X, lies in $C^\infty(TM)$. Moreover, if X is bounded in $\mathbb{H}^1$, then X is bounded in $\mathbb{H}^m$ for every $m\geqq 0$.*

THEOREM 2.2. *Every functional invariant set, bounded in $\mathbb{H}^1$, has finite fractal (and Hausdorff) dimension.*

2.3. Thermo-hydraulic equations. We consider the motion of a viscous incompressible fluid, subjected to thermal effects, which fills some bounded region Ω. In the Boussinesq approximation the velocity $u(x,t)$, pressure $p(x,t)$ and temperature $\theta(x,t)$ are determined, in case of homogeneous boundary conditions, by the equations (see Chandrasekhar [7]):

$$
\begin{aligned}
&\frac{\partial u}{\partial t}+(u\cdot\nabla)u-\nu\Delta u+\sigma\theta+\nabla p=f,\\
&\frac{\partial \theta}{\partial t}+(u\cdot\nabla)\theta-\kappa\Delta\theta=s,\\
&\operatorname{div} u=0,\\
&u(x,t)=0 \quad \text{on } \partial\Omega\times\mathbb{R}_+,\\
&\theta(x,t)=0 \quad \text{on } \partial\Omega\times\mathbb{R}_+;
\end{aligned}
\tag{3.1}
$$

where κ denotes the Fourier coefficient of the fluid and σ is a fixed vector in $\mathbb{R}^d$ pointing vertically downwards.

2.3.1. Functional setting. We supplement some notations to that of the §2.1.1. The orthogonal projector in $L^2(\Omega)^d$ onto H is denoted by P. The operator $-\Delta$ on $H_0^1(\Omega)$ is denoted by A_1 and we define $B_1\in\mathfrak{L}(V\times H_0^1(\Omega),\ H^{-1}(\Omega))$ by

$$\langle B_1(U,\theta),\ \eta\rangle=\int_\Omega u_i\frac{\partial\theta}{\partial x_i}\eta\,dx.$$

We set

$$\mathfrak{H}=H\times L^2(\Omega),\qquad \mathfrak{v}=V\times H_0^1(\Omega);$$

these spaces are endowed with the scalar products

$$(\phi_1,\phi_2)=\int_\Omega(u_1\cdot u_2+\theta_1\cdot\theta_2)\,dx,$$

and

$$((\phi_1,\phi_2))=\nu\int_\Omega\nabla u_1:\nabla u_2\,dx+\kappa\int_\Omega\nabla\theta_1\cdot\nabla\theta_2\,dx$$

respectively, where ϕ_i denotes the pair $\{u_i,\theta_i\}$.

We introduce the operators $\mathfrak{A}\in\mathfrak{L}(\mathfrak{v},\mathfrak{v}')$, $B\in\mathfrak{L}(\mathfrak{v}\times\mathfrak{v},\mathfrak{v}')$ and $\mathfrak{R}\in\mathfrak{L}(\mathfrak{v},\mathfrak{v}')$:

$$\langle \mathfrak{A}\phi_1,\phi_2\rangle=((\phi_1,\phi_2)),$$

$$\langle \mathfrak{B}(\phi_1,\phi_2),\phi_3\rangle=\int_\Omega (u_1\cdot\nabla)u_2u_3\,dx+\int_\Omega (u_1\cdot\nabla)\theta_2\theta_3\,dx,$$

$$\langle \mathfrak{R}\phi_1,\phi_2\rangle=\int_\Omega \theta_1\sigma\cdot u_2\,dx.$$

With these notations and $\mathfrak{F}=(f,s)$ equations (2.3.1) read

$$\frac{d\phi}{dt}+\mathfrak{A}\phi+\mathfrak{B}(\phi,\phi)+\mathfrak{R}\phi=\mathfrak{F}.$$

2.3.2. Fractal dimension of attractors. The verification of the fact that the previous functional setting is compatible with the hypotheses of the first part is similar to that of the case of Navier–Stokes equation. The details are given in [16].

Remark 3.1. When $\Omega\subset\mathbb{R}^2$, (1.1.3) is satisfied with $\theta_5=\frac{1}{2}$. In general $\mathfrak{A}+\mathfrak{R}$ is not $\mathfrak{v}$-coercive, but studying the system equivalent to (2.3.1), obtained by multiplying the evolution equation of θ by a large constant, we change $\mathfrak{A}$ to make $\mathfrak{A}+\mathfrak{R}$ $\mathfrak{v}$-coercive. Thus Proposition 1.3.1 applies also in this case. Note that in case of nonhomogeneous boundary condition on the temperature, the trick mentioned previously does not apply but, as proved in [16], the conclusions of Remark 1.2.1 and Proposition 1.3.1 still hold. □

We deduce from the results of §1.3:

THEOREM 3.1. *Assume that* $f\in\mathfrak{C}^\infty(\bar\Omega)^d$ *and* $s\in\mathfrak{C}^\infty(\bar\Omega)$; *then every functional invariant set,* X, *lies in* $\mathfrak{C}^\infty(\bar\Omega)^{d+1}$. *Moreover if* X *is bounded in* $H^1(\Omega)^{d+1}$, *then* X *is bounded in* $H^m(\Omega)^{d+1}$ *for every* $m\geqq 0$.

THEOREM 3.2. *Every functional invariant set, bounded in* $H^1(\Omega)^d$, *has finite fractal (and Hausdorff) dimension.*

2.4. Magnetohydrodynamic equations. In this section we briefly give the functional setting that allows us to apply the results of the first part to M. H. D. equations. Most of the results which issue from this application are contained in M. Sermange and R. Temam [29]. Nevertheless we have presented them in order to emphasize the generality of the abstract framework.

We consider the motion of a viscous incompressible and resistive fluid. The velocity $u(x,t)$, pressure $p(u,t)$ and the magnetic field $B(x,t)$ are determined by the equations (see L. Landau and E. Lifchitz [22]):

$$\begin{aligned}
&\frac{\partial u}{\partial t}+(u\cdot\nabla)u-\frac{1}{Re}\Delta u-(B\cdot\nabla)B+\nabla\left(p+\frac{1}{2}B^2\right)=f,\\
&\frac{\partial B}{\partial t}+(u\cdot\nabla)B+\frac{1}{Rm}\operatorname{curl}(\operatorname{curl}B)-(B\cdot\nabla)u=0,\\
&\operatorname{div}u=0,\qquad \operatorname{div}B=0,\\
&u=0,\quad B\cdot n=0\ \text{ and }\ (\operatorname{curl}B)\times n=0\quad\text{on }\Gamma,
\end{aligned}\tag{4.1}$$

where n is the unit normal on Γ. The two positive numbers Re and Rm appearing in (2.4.1) are respectively the Reynolds number and the magnetic Reynolds number.

We assume, in addition to the hypothesis of §2.1.1 that Ω is simply connected (this assumption is not essential) and introduce the space

$$\tilde V=\left\{B\in H^1(\Omega)^d,\ \operatorname{div}B=0,\ B\cdot n=0\right\}.$$

We set $\mathfrak{H}=H\times H$ and $\mathfrak{v}=V\times\tilde{V}$. If we denote by ϕ the pair $\{u,B\}$ and introduce the operators $\mathfrak{A}\in\mathfrak{L}(\mathfrak{v},\mathfrak{v}')$, $\mathfrak{B}\in\mathfrak{L}(\mathfrak{v}\times\mathfrak{v},\mathfrak{v}')$:

$$\langle\mathfrak{A}\phi_1,\phi_2\rangle=\frac{1}{Re}\int_\Omega\nabla u_1\nabla u_2\,dx+\frac{1}{Rm}\int_\Omega\operatorname{curl}B_1\cdot\operatorname{curl}B_2\,dx,$$

$$\langle\mathfrak{B}(\phi_1,\phi_2),\phi_3\rangle=\int_\Omega\left[(u_1\cdot\nabla)u_2u_3-(B_1\cdot\nabla)B_2u_3+(u_1\cdot\nabla)B_2B_3-(B_1\cdot\nabla)u_2B_3\right]dx;$$

Equations (2.4.1) can be written under the form

$$\frac{d\phi}{dt}+\mathfrak{A}\phi+\mathfrak{B}(\phi,\phi)=\mathfrak{F}.$$

Therefore we can, in the same way as in the previous applications, derive the following regularity and finite dimension results for attractors for M.H.D. equations:

THEOREM 4.1. *Assume that $f\in\mathfrak{C}^\infty(\bar{\Omega})^d$ and then every functional invariant set, X, lies in $\mathfrak{C}^\infty(\bar{\Omega})^{2d}$. Moreover if X is bounded in $H^1(\Omega)^{2d}$, then X is bounded in $H^m(\Omega)^{2d}$ for every $m\geqq 0$.*

THEOREM 4.2. *Every functional invariant set, bounded in $H^1(\Omega)^{2d}$, has finite fractal (and Hausdorff) dimension.*

Remark 4.1. We have considered for the sake of simplicity the homogeneous case (i.e. $\mathfrak{R}=0$). The nonhomogeneous case that could be treated like it has been done for Navier–Stokes equations.

EXISTENCE AND CONTROL OF PLASMA EQUILIBRIUM IN A TOKAMAK*

J. BLUM†, T. GALLOUET† AND J. SIMON†

Abstract. The "Tokamak" is a machine where the plasma is confined inside a toroidal vessel by the magnetic field due to currents in external coils. In the present Tokamaks the free plasma boundary is a flux line which is in contact with a given limiter. We first give a simplified model for the plasma axisymmetric equilibrium. We prove, under suitable assumptions on the limiter, the existence of such an equilibrium for given external currents. We then establish the existence of external currents for which the domain aoccupied by the plasma is as close as possible to a given domain. For this problem, which is formulated as an optimal control problem, the first order necessary optimality conditions are obtained by introducing a suitable adjoint state.

Introduction. A model which describes the equilibrium of a plasma in a toroidal machine (a Tokamak) is studied here. The plasma current is obtained by magnetic induction from a primary circuit made of poloidal field coils. In the present Tokamaks the volume occupied by the plasma inside the vacuum vessel is limited by the presence of a "limiter". The configuration is supposed to be axisymmetric, so that the problem can be reduced to a two-dimensional one in the meridian section of the torus.

Section 1 is devoted to the establishment of the model for the plasma axisymmetric equilibrium. Section 2 deals with an annex mathematical problem. In §3 the existence of a solution for the equilibrium problem formulated in §1 is studied. The control of the plasma shape by the external currents is treated in §4.

1. The plasma equilibrium model.

1.1. The Maxwell equations in an axisymmetric configuration. The magnetic induction $\mathbf{B}$ and the current density $\mathbf{j}$ verify the following Maxwell equations:

$$\operatorname{div}\mathbf{B}=0, \tag{1}$$

$$\mathbf{rot}\left(\frac{\mathbf{B}}{\mu}\right)=\mathbf{j}, \tag{2}$$

where μ is the magnetic permeability.

We restrict the problem to the study of axisymmetric configurations, so that in cylindrical coordinates (r,z,φ) the vectors $\mathbf{B}$ and $\mathbf{j}$ are independent of the angle φ.

Equation (1) can then be written

$$\frac{1}{r}\frac{\partial}{\partial r}(rB_r)+\frac{\partial B_z}{\partial z}=0. \tag{3}$$

From (3) one deduces the existence of a scalar function $\psi(r,z)$ called the poloidal flux, such that

$$B_r=-\frac{1}{r}\frac{\partial\psi}{\partial z},\qquad B_z=\frac{1}{r}\frac{\partial\psi}{\partial r}. \tag{4}$$

* Received by the editors November 10, 1983, and in final revised form February 19, 1985.
† Laboratoire d'Analyse Numérique de Paris VI et du CNRS, 4, Place Jussieu, 75230 Paris Cedex 05, France.

From (2) and (4), one can deduce the following partial differential equation for $\psi(r,z)$

$$\mathscr{L}\psi = j_\varphi \tag{5}$$

with

$$\mathscr{L} = -\frac{\partial}{\partial r}\left(\frac{1}{\mu r}\frac{\partial}{\partial r}\right) - \frac{\partial}{\partial z}\left(\frac{1}{\mu r}\frac{\partial}{\partial z}\right)$$

and where j_φ is the toroidal component of the current density (i.e. the φ-component of $\mathbf{j}$).

Let us restrict ourselves to air-transformer Tokamaks, so that μ is constant and equal to the magnetic permeability μ_0 of the vacuum ($\mu_0 = 1$ in Gaussian units). Therefore the operator $\mathscr{L}$ is a linear elliptic operator.

The current density j_φ in the right-hand side of (5) is equal to 0 everywhere except in the coils C_i and in the plasma P.

1.2. Equilibrium conditions for the plasma. In the first Tokamaks (T3, TFR, $\cdots$) the plasma was inside a perfect superconducting shell, on which ψ was constant. The eddy currents on this shell generated the magnetic field necessary to ensure plasma equilibrium (cf. [10], [14]). Simplified models of plasma equilibrium inside a perfect superconducting shell have been studied in [17], [18], [1]. In the present Tokamaks (JET, TFTR, $\cdots$) there is no more superconducting shell and the plasma shape is determined by the currents in the external coils. The plasma is inside a vacuum region V, whose boundary ∂V is the vacuum vessel (see Fig. 1). The plasma boundary is a flux line (ψ = constant). Since an arbitrary constant can be added to ψ according to its definition (4), we can assume that $\psi = 0$ on the plasma boundary. Therefore the plasma domain is defined in the following way

$$P = \{ x \in V \text{ such that } \psi(x) > 0 \}. \tag{6}$$

The plasma particles (electrons and ions) follow the flux lines; they are stopped when they touch the limiter D, which is a piece of metal inside V. This contact condition between the plasma and the limiter can be written

$$P \cap D = \varnothing, \qquad \partial P \cap D \neq 0. \tag{7}$$

In fact the aim of the limiter is to prevent the plasma from touching the vacuum vessel (that is to ensure $\partial P \cap \partial V = \varnothing$).

The plasma is in equilibrium when the kinetic pressure force $\mathbf{grad}\, p$ (p is the plasma kinetic pressure) is equal to the magnetic pressure force ($\mathbf{j} \wedge \mathbf{B}$)

$$\mathbf{grad}\, p = \mathbf{j} \wedge \mathbf{B}. \tag{8}$$

The toroidal plasma current density j_φ can then be deduced from (2), (4) and (8), and it is given by the Grad–Shafranov relation (cf. [7], [13])

$$j_\varphi(r,\psi) = r\frac{\partial p}{\partial \psi} + \frac{1}{2\mu_0 r}\frac{\partial f^2}{\partial \psi} \tag{9}$$

with $f = rB_\varphi$, where B_φ is the toroidal component of $\mathbf{B}$. The functions p and f are the solutions of parabolic diffusion equations, which depend on the shape of the flux lines. These "queer" differential equations (cf. [8]) will not be considered here and, as in [18], we assume, for the sake of simplicity, that j_φ is proportional to ψ in the plasma P. The

proportionality constant λ is unknown here and is determined by the fact that the total plasma current I_p is given (I_p is assumed to be positive). The plasma current density can then be written, with (6),

$$j_\varphi = \lambda \psi^+ 1_V, \qquad I_P = \lambda \int_V \psi^+ \, dx, \tag{10}$$

with $\psi^+ = \sup(\psi, 0)$ and 1_V is the characteristic function of the vacuum region V.

1.3. The equations for the poloidal flux ψ. Physically the problem is set in $R^+ \times R$. But we can restrict it to an open bounded subset Ω of $R^+ \times R$, with a regular boundary $\Gamma = \partial\Omega$, and such that

$$\Omega \subset \{ x = (r,z), r \geqq \underline{r} \} \quad \text{with } \underline{r} > 0.$$

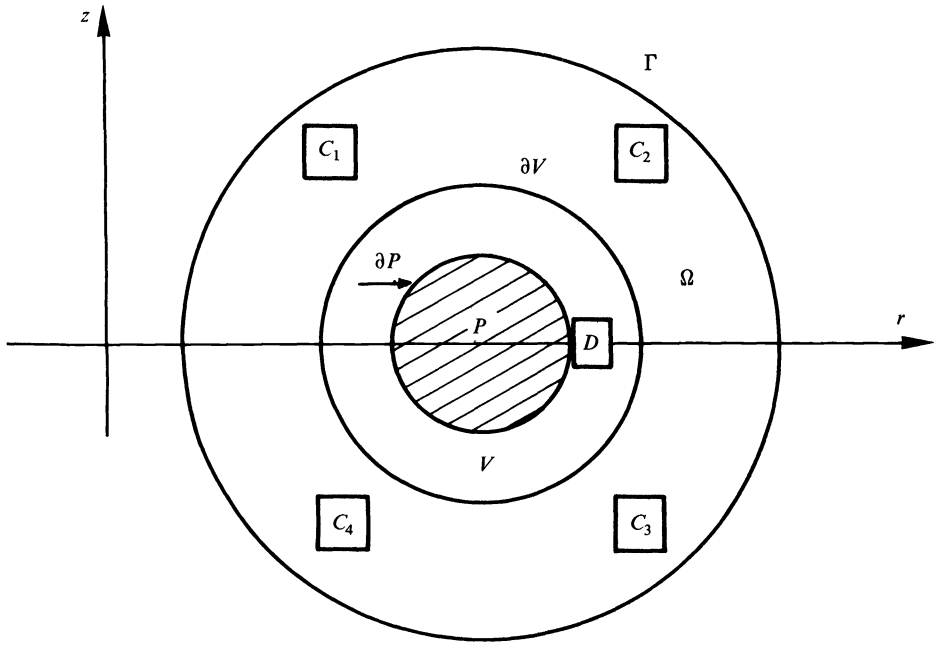

FIG. 1. *The cross section Ω of the torus.*

If Γ is taken sufficiently far from the vacuum vessel and from the coils, then ψ can be assumed to be constant on Γ. Therefore the equations for ψ will be set in such a bounded domain Ω.

The vacuum region V is an open subset of Ω and its boundary ∂V is the vacuum vessel. The sections of the coils $C_1, \cdots, C_k$ are closed subsets of Ω, pairwise disjoint and which do not intersect V. The section D of the limiter is a closed subset of V.

From (5), (7) and (10), one can deduce the equations for the pair (ψ, λ)

$$\begin{aligned} &\mathcal{L}\psi = \lambda \psi^+ 1_V + j \quad \text{in } \Omega, \\ &I_p = \lambda \int_V \psi^+ \, dx, \\ &\psi \text{ is a constant on } \Gamma \end{aligned} \tag{11}$$

and

$$\sup_{x\in D}\psi(x)=0, \tag{12}$$

where j is the external current density, whose support is $\cup_i C_i$. For a continuous function ψ satisfying (11), equation (12) is clearly equivalent to the contact conditions (7), since, by the maximum principle, ψ has no local maximum on D.

Remark 1. From (11) it is clear that, if there exists a zone of positivity of ψ outside V, there is no plasma in this zone.

Remark 2. For a pair (ψ,λ) satisfying (11) and (12), the plasma boundary ∂P may intersect ∂V (see Fig. 2). In this case ∂P is no longer the flux line $\{\psi=0\}$ and this solution is not interesting from a physical point of view. It shows that the limiter D is not correctly located, because in this case it does not prevent the plasma from touching the vacuum vessel ∂V.

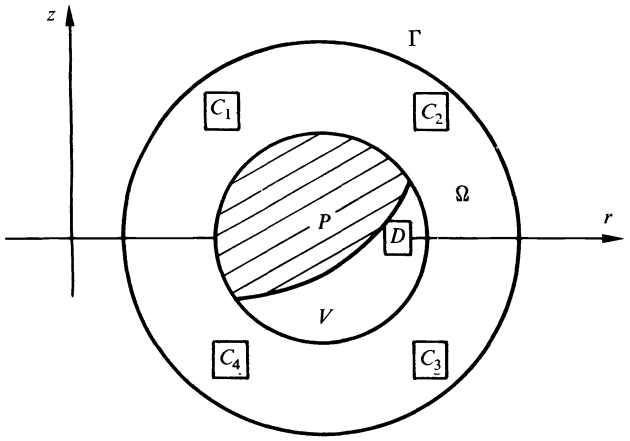

FIG. 2. *A nonphysical solution of equations* (11)–(12).

In §3, we are going to establish under suitable assumptions on D, the existence of (at least) one pair $(\psi,\lambda)\in C^0(\bar{\Omega})\times R$ solution of (11) and (12). In order to prove this, an annex problem will first be studied in §2, namely the existence of a solution of (11), for λ given.

2. An annex problem.

2.1. An existence result. One defines

$$H_c^2(\Omega)=\{v\in H^2(\Omega) \text{ such that } v \text{ is constant on } \Gamma\}.$$

Let us recall that, according to Sobolev's theorem, $H^2(\Omega)\subset C^0(\bar{\Omega})$.

If $\nu>0$, $I>0$ and $f\in L^2(\Omega)$ are given, we are going to study the solutions u of

$$\begin{aligned} &u\in H_c^2(\Omega),\\ &\mathcal{L}u=\nu u^+ 1_V+f \quad \text{in } \Omega,\\ &I=\nu\int_V u^+\,dx. \end{aligned} \tag{13}$$

Many papers have been devoted to the case $f=0$, $V=\Omega$ which corresponds to the plasma equilibrium in a perfect superconducting shell. Particularly existence results have been established by R. Temam [18] and by H. Berestycki–H. Brezis [1] using methods of minimization of suitable functionals and also in [1] using the topological degree of J. Leray–J. Schauder [9].

Following [1] the topological degree method will be used here, because it enables one to prove, in addition to the existence of a solution for each value of the parameters ν, I and f, that there exists a connected set of solutions, when ν is varying. More precisely the following theorem will be proved in §2.6:

THEOREM 1. *For every $I>0$ and $f\in L^2(\Omega)$, there exists a set $\mathscr{C}$ of pairs (u,ν) satisfying* (13) *such that $\mathscr{C}$ is connected in $H_c^2(\Omega)\times R^+$, and such that ν spans $R^+-\{0\}$ when (u,ν) spans $\mathscr{C}$.*

To prove this result, the existence and uniqueness of a solution u of (13) will first be established when ν is sufficiently small, and a priori estimates on the solutions of (13) will be given.

2.2. Uniqueness for ν small. Let $\mu_1, \mu_2 \cdots$ be the sequence of the eigenvalues of the problem

$$\mathscr{L}v=\mu 1_V v, \qquad v\in\mathscr{V}$$

where $\mathscr{V}=\{v\in H_c^2(\Omega)$ such that $\int_\Omega \mathscr{L}v\,dx=0\}$.

LEMMA 1. *If $0<\nu<\mu_2$, equation* (13) *has at most one solution.*

Remark 3. Let $\lambda_1, \lambda_2 \cdots$ be the sequence of the eigenvalues of the problem

$$\mathscr{L}v=\lambda 1_V v, \qquad v\in H_0^1(\Omega).$$

We have: $\mu_1=0$ and $0<\lambda_1<\mu_2\leqq\lambda_2$ (cf. for example [6]).

Let us recall that in the case $f=0$, $V=\Omega$, Lemma 1 is still true with λ_2 instead of μ_2 (cf. [11] and [18]).

Proof of Lemma 1. This result is essentially in H. Berestycki–H. Brezis [1, Thm. 4]. Let us prove it in the following way: let u_1 and u_2 be two distinct solutions of (13). Their difference $w=u_2-u_1$ satisfies

$$\mathscr{L}w=\nu\rho 1_V w, \qquad w\in\mathscr{V} \tag{14}$$

where

$$\rho(x)=\begin{cases}\dfrac{u_2^+(x)-u_1^+(x)}{u_2(x)-u_1(x)} & \text{if } u_2(x)-u_1(x)\neq 0,\\ 0 & \text{if } u_2(x)-u_1(x)=0.\end{cases}$$

Let $\nu_1^\rho, \nu_2^\rho, \cdots$ be the nondecreasing sequence of the eigenvalues of (14). These eigenvalues are nonincreasing as ρ increases. Since $0\leqq\rho\leqq 1$ one has $\nu_2^\rho\geqq\mu_2$. Since $\nu<\mu_2$ one has necessarily $\nu=\nu_1^\rho=0$, which is impossible. □

2.3. A priori estimates.

LEMMA 2. *Every solution u of* (13) *satisfies*

$$|u|_{H^2(\Omega)}\leqq C\left(\nu^2+\frac{1}{\nu}\right)\left(I+\frac{1}{I}\right)\left(1+|f|_{L^2(\Omega)}\right)^2$$

where C only depends on Ω and V.

Since the operator $\mathscr{L}$ is uniformly elliptic with regular coefficients in $\bar{\Omega}$, $\mathscr{L}$ is an isomorphism from $H_0^1(\Omega)\cap H^2(\Omega)$ onto $L^2(\Omega)$. Its inverse operator is denoted K.

For every $s\leqq 0$, there exists $\theta_s\in R$ (depending only on Ω) such that

$$|Kv|_{H^{s+2}(\Omega)}\leqq\theta_s|v|_{H^s(\Omega)},\qquad \forall v\in L^2(\Omega). \tag{15}$$

Proof of Lemma 2. Let u be a solution of (13). Its (constant) value on Γ is denoted u_Γ and we set $P(u)=\{x\in V \text{ such that } u(x)>0\}$. Then we have

$$u=u_\Gamma+\nu K(u^+1_V)+K(f). \tag{16}$$

i) *Upper bound on* $(u-u_\Gamma)$ *in* $L^2(\Omega)$. One has: $|u^+1_V|_{L^1(\Omega)}=I/\nu$; therefore it follows from Sobolev's theorem that

$$|u^+1_V|_{H^{-2}(\Omega)}\leqq C_1\frac{I}{\nu}.$$

Using (15) we deduce

$$|u-u_\Gamma|_{L^2(\Omega)}\leqq C_2\big(I+|f|_{L^2(\Omega)}\big). \tag{17}$$

ii) *Upper bound on* $|u_\Gamma|$. If $u_\Gamma\leqq 0$, we have in $P(u)$

$$2|u_\Gamma|u^+\leqq\big(u^++|u_\Gamma|\big)^2=|u-u_\Gamma|^2,$$

and, integrating on $P(u)$, we deduce

$$2|u_\Gamma|\frac{I}{\nu}\leqq|u-u_\Gamma|^2_{L^2(\Omega)}.$$

If $u_\Gamma\geqq 0$ one has

$$u_\Gamma\leqq|u-u_\Gamma|+u^+ \text{ in } \Omega$$

and, integrating on V, one deduces

$$u_\Gamma|V|\leqq|\Omega|^{1/2}|u-u_\Gamma|_{L^2(\Omega)}+\frac{I}{\nu}.$$

In both cases, using the upper bound on $(u-u_\Gamma)$, one obtains

$$|u_\Gamma|\leqq C_3\Big(\nu+\frac{1}{\nu}\Big)\Big(I+\frac{1}{I}\Big)\big(1+|f|_{L^2(\Omega)}\big)^2.$$

iii) *Upper bound on* u *in* $H^2(\Omega)$. From (15) and (16), one has

$$|u|_{H^2(\Omega)}\leqq|u_\Gamma||\Omega|^{1/2}+\nu\theta_0|u|_{L^2(\Omega)}+\theta_0|f|_{L^2(\Omega)}.$$

The lemma follows from the estimates on $|u-u_\Gamma|_{L^2(\Omega)}$ and $|u_\Gamma|$.

2.4. Transformation of (13). According to the Lax–Milgram theorem, for every $w\in L^2(\Omega)$ there exists a unique $q\in H_c^1(\Omega)$ such that

$$\int_\Omega\left(\frac{1}{r}\nabla q\cdot\nabla v+qv\right)dx=\int_\Omega wv\,dx\quad\forall v\in H_c^1(\Omega),$$

where $H_c^1(\Omega)=\{v\in H^1(\Omega)$ such that v s constant on $\Gamma\}$. One easily verifies that q is the unique solution in $H_c^2(\Omega)$ of

$$\mathscr{L}q+q=w, \qquad \int_\Omega \mathscr{L}q\,dx=0.$$

A linear continuous operator from $L^2(\Omega)$ into $H_c^2(\Omega)$ is then defined by $Lw=q$.

The Lax–Milgram theorem gives also the existence (and the uniqueness) of a solution $\phi\in H_c^1(\Omega)$ of

$$\int_\Omega \left(\frac{1}{r}\nabla\phi\cdot\nabla v+\phi v\right)dx=-\left(I+\int_\Omega f\,dx\right)v_\Gamma \quad \forall v\in H_c^1(\Omega).$$

In fact ϕ is the solution in $H_c^2(\Omega)$ of

$$\mathscr{L}\phi+\phi=0, \qquad \int_\Omega \mathscr{L}\phi\,dx=I+\int_\Omega f\,dx.$$

One defines an operator H from $H_c^2(\Omega)$ into itself by (ν is fixed)

$$H(u)=\phi+L(\nu u^+1_V+f+u).$$

From this definition it is easy to prove the following lemma.

LEMMA 3. *The problem* (13) *is equivalent to*

$$u\in H_c^2(\Omega), \qquad u-H(u)=0. \tag{18}$$

The operator H is compact from $H_c^2(\Omega)$ into itself. Therefore one can define, according to J. Leray–J. Schauder [9, §13, p. 60] the index of the solutions of (18).

Using results of [9], we will prove in §2.5 that, if ν is sufficiently small, there exists a unique solution of (18), with a nonzero index, and we will deduce from this in §2.6 the existence of a connected set $\mathscr{C}$ of solutions (u,ν) of (13) with the properties that ν spans $\mathbb{R}^+-\{0\}$ when (u,ν) spans $\mathscr{C}$.

2.5. Existence of a solution for small ν and computation of its index.

LEMMA 4. *There exists* $\alpha>0$, *which depends only on* Ω, V *and* f, *such that when* $0<\nu\leqq\alpha$, *the problem* (18) *has a unique solution* u_ν, *and the index of* u_ν *is equal to* -1.

This lemma will be proved by transforming continuously, with the help of a parameter t, equation (18) so as to obtain an equation having a unique solution k, whose index is easily computable.

Proof. Let α and ν be two constants such that: $0<\nu\leqq\alpha<\mu_2$.

i) *Transformation of* (18). There exists a unique real number b such that $k=\phi+b$ satisfies

$$\nu\int_V k^+\,dx=I. \tag{19}$$

One defines a function G from $H_c^2(\Omega)\times[0,1]$ into $H_c^2(\Omega)$ by

$$G(v,t)=t\phi+(1-t)k+L\big(\nu v^+1_V+v+tf-(1-t)(\nu k^+1_V+k)\big).$$

Then the equation

$$w\in H_c^2(\Omega), \qquad w-G(w,t)=0 \tag{20}$$

is equivalent to

$$
\begin{aligned}
&w \in H_c^2(\Omega),\\
&\mathscr{L}w = \nu w^+ 1_V + tf + (1-t)(\mathscr{L}k - \nu k^+ 1_V),\\
&\nu \int_V w^+ \, dx = I.
\end{aligned} \tag{21}
$$

For $t=1$, (21) is equivalent to (13) and therefore to (18).

For every t, Lemma 1 shows that there exists at most one solution w. Moreover the operator $v \to G(v,t)$ is compact from $H_c^2(\Omega)$ into itself; therefore one can define the index of the solution w, when this solution exists.

ii) *The case* $t=0$. *Existence of a solution and computation of its index.* As k is a solution of (21), it satisfies (20). We are going to compute its index relatively to this equation.

The condition (19) shows that α can be chosen small enough so that, when $\nu \leqq \alpha$, one has $k>0$ in $\bar{\Omega}$.

Then, in a neighbourhood of k (note that $H^2(\Omega) \hookrightarrow C^0(\bar{\Omega})$), w is positive and $G(w,0)=k+\nu L[(w-k)1_V]+L(w-k)$.

It follows that $G(\cdot,0)$ is Frechet differentiable at the point k, and its derivative is the operator $v \to L(\nu 1_V v + v)$.

According to [9, Conclusion, p. 56], the index of k for equation (20) is equal to the index of 0 for the equation $z - L(\nu 1_V z + z) = 0$ in $H_c^2(\Omega)$, when this latter index exists. This equation is equivalent to

$$
\mathscr{L}z = \nu 1_V z, \qquad \int_\Omega \mathscr{L}z \, dx = 0.
$$

Its eigenvalues are the μ_i defined in §2.2. Since $0=\mu_1<\nu<\mu_2$ and μ_1 is a simple eigenvalue, this index exists and is equal to (-1).

This proves that the index of k for equation (20) is equal to -1.

iii) *Existence of a solution for* $t=1$. The function G: $H_c^2(\Omega)\times[0,1] \to H_c^2(\Omega)$ is continuous, the functions $t \to G(v,t)$ are equicontinuous and, for every t, $v \to G(v,t)$ is compact.

Lemma 2 shows that the possible solutions w of (21), and consequently of (20), are bounded (in $H_c^2(\Omega)$) independently of t.

Then, according to [9], there exist a solution of (20) for $t=1$ and its index is equal to the index of k relatively to (20) for $t=0$.

As $G(\cdot,1)=H$ this proves Lemma 4. □

2.6. Proof of Theorem 1. Let $\underline{\nu}$ and $\bar{\nu}$ be two real numbers such that $0<\underline{\nu} \leqq \alpha < \bar{\nu}$ where α is given by Lemma 4. The operator H defined in §2.4 depending on ν, one defines a function F from $H_c^2(\Omega)\times[\underline{\nu},\bar{\nu}]$ into $H_c^2(\Omega)$ by $F(v,\nu)=H(v)$.

Lemma 3 shows that (13) is equivalent to

$$
u \in H_c^2(\Omega), \qquad u - F(u,\nu) = 0. \tag{22}
$$

Lemma 2 shows that the solutions of (22) are bounded (in $H_c^2(\Omega)$) independently of ν.

Moreover F is continuous, the functions $\nu \to F(v,\nu)$ equicontinuous when v remains in a bounded set, and for every ν the function $v \to F(v,\nu)$ is compact.

Finally for $\nu=\alpha$ the total index of the solutions of (22) is equal to -1 according to Lemma 4.

Theorem 1 of J. Leray–J. Schauder [9] proves then that there exists a set $\mathscr{C}_{\underline{\nu},\bar{\nu}}$ of pairs (u,ν) satisfying (22) such that $\mathscr{C}_{\underline{\nu},\bar{\nu}}$ is connected in $H_c^2(\Omega)\times\mathbb{R}^+$ and such that ν spans $[\underline{\nu},\bar{\nu}]$ when (u,ν) spans $\mathscr{C}_{\underline{\nu},\bar{\nu}}$.

For every positive integer n, setting $\underline{\nu}=\alpha/n$ and $\bar{\nu}=n\alpha$, one obtains a connected set $\mathscr{C}^n$. Since each $\mathscr{C}^n$ contains the point (u_α,α), the reunion $\mathscr{C}$ of all the $\mathscr{C}^n$ is connected, and ν attains in $\mathscr{C}$ all positive values.

This proves Theorem 1. □

2.7. Lower bound of the solutions for small ν.

LEMMA 5. *If* $\nu\leqq I/d(I+|f|_{L^2(\Omega)})$, *then every solution* u *of* (13) *satisfies*

$$u\geqq\frac{I}{\nu|\Omega|}-d'\big(I+|f|_{L^2(\Omega)}\big)\quad \text{in } \bar{\Omega},$$

where d *and* d' *only depend on* Ω.

Proof. One has (recall that $P(u)=\{x\in V,u(x)>0\}$)

$$\int_{P(u)}(u-u_\Gamma)\,dx\leqq\int_\Omega|u-u_\Gamma|\,dx\leqq|\Omega|^{1/2}|u-u_\Gamma|_{L^2(\Omega)},$$

and from (17) it follows that

$$\frac{I}{\nu}-u_\Gamma|P(u)|\leqq d\big(I+|f|_{L^2(\Omega)}\big).$$

If $I/\nu\geqq d(I+|f|_{L^2(\Omega)})$ one has $u_\Gamma\geqq 0$ and, since $|P(u)|\leqq|\Omega|$, it comes

$$u_\Gamma\geqq\frac{I}{\nu|\Omega|}-\frac{d}{|\Omega|}\big(I+|f|_{L^2(\Omega)}\big).$$

The maximum principle shows that $K(u^+1_V)\geqq 0$ where the operator K has been defined in §2.3. It follows from (15) that $|K(f)|_{L^\infty(\Omega)}\leqq d_1|f|_{L^2(\Omega)}$ and, with (16) one has

$$u\geqq\frac{I}{\nu|\Omega|}-\frac{d}{|\Omega|}\big(I+|f|_{L^2(\Omega)}\big)-d_1|f|_{L^2(\Omega)}.$$ □

2.8. An estimate on $P(u)$ for large ν.

LEMMA 6. *Assume that* $\mathrm{Supp}(f)\cap V=\varnothing$. *Then there exists* C *depending only on* Ω *such that for every* $\nu>0$ *and* u *solution of* (13) *one has* $B(x_0,C/\sqrt{\nu})\not\subset P(u)$, *for every* $x_0\in\Omega$ (*where* $B(x_0,R)$ *designates the ball centered on* x_0 *and of radius* R).

Proof. Let us suppose that there exists a ball B, of radius R, included in $P(u)$. Then

$$\mathscr{L}u=\nu u \quad \text{in } B,$$
$$u\geqq 0 \quad \text{on } \partial B.$$

Let $\lambda_1(B)$ be the first eigenvalue of

$$\mathscr{L}\varphi=\lambda\varphi,\qquad \varphi\in H_0^1(B)$$

and let φ_1 be a related positive eigenfunction. Then,

$$\nu\int_B u\varphi_1\,dx=\int_B \mathscr{L}u\varphi_1\,dx=\int_B u\mathscr{L}\varphi_1\,dx+\int_{\partial B}\frac{u}{r}\frac{\partial\varphi_1}{\partial n}\,d\sigma$$

$$=\lambda_1(B)\int_B u\varphi_1\,dx+\int_{\partial B}\frac{u}{r}\frac{\partial\varphi_1}{\partial n}\,d\sigma,$$

whence

$$(\nu-\lambda_1(B))\int_B u\varphi_1\,dx=\int_{\partial B}\frac{u}{r}\frac{\partial\varphi_1}{\partial n}\,d\sigma\leqq 0.$$

This implies $\nu\leqq\lambda_1(B)$.

Since $\lambda_1(B)<C^2/R^2$ (where C is a constant depending only on Ω), Lemma 6 is proved. □

3. Existence of solutions for (11)–(12).

3.1. An existence result. The aim of this section is to find a solution (ψ,λ) of equations (11)–(12). The total plasma current I_p and the external current density j are given such that

$$\text{(23)}\qquad \begin{aligned} &I_p>0,\\ &j\in L^2(\Omega),\quad \operatorname{supp} j\cap V=\varnothing. \end{aligned}$$

Let us set, in (13), $f=j$ and $I=I_p$. According to Theorem 1, one can define a unique set C^* by

> C^* is the greatest set of pairs $(u,\nu)\in H_c^2(\Omega)\times\mathbb{R}^+$ satisfying (13), such that C^* is connected in $H_c^2(\Omega)\times\mathbb{R}^+$, and such that ν spans $\mathbb{R}^+-\{0\}$ when (u,ν) spans C^*.

Let us recall from Lemma 1 that if $0<\nu<\mu_2$ there is a unique solution $u=u_\nu$ of (13). Then $(u_\nu,\nu)\in C^*$.

THEOREM 2. *Assume* (23) *and*

$$\text{(24)}\qquad \textit{there exists } (v,\gamma)\in C^* \textit{ such that } v\leqq 0 \textit{ in } D.$$

Then there exists a pair $(\psi,\lambda)\in H_c^2(\Omega)\times\mathbb{R}^+$, *solution of* (11)–(12).

Proof of Theorem 2. Since $u\to\sup_{x\in D}u(x)$ is continuous from $C^0(\bar{\Omega})$ (and therefore from $H_c^2(\Omega)$) into $\mathbb{R}$, the set

$$\left\{\sup_{x\in D}u(x),(u,\nu)\in C^*\right\}\text{ is connected in }\mathbb{R}.$$

Lemma 5 shows that there exists β, $0<\beta<\mu_2$, such that $\sup_{x\in D}u(x)\geqq 0$. By hypothesis (24) one has $\sup_{x\in D}v(x)\leqq 0$. Then there exists $(\psi,\lambda)\in C^*$ with $\sup_{x\in D}\psi(x)=0$. The pair (ψ,λ) satisfies (11)–(12). □

Remark 4. Condition (24) is hard to verify in practice. Letting (v,γ) be a solution of (13), it is an open problem to know if $(v,\gamma)\in C^*$, except if $\gamma<\mu_2$. Indeed in this latter case, from the uniqueness of Lemma 1, one has $(v,\gamma)\in C^*$.

Remark 5. Every pair $(u,\nu)\in C^*$ defines an admissible zone for the limiter D. Indeed if $D\subset V\setminus P(u)$, there exists a solution of (11)–(12). This zone is not empty as

soon as $\nu > \lambda'_1$ where λ'_1 is the first eigenvalue of the Dirichlet problem for the operator $\mathscr{L}$ in$V$. (Note that $\lambda'_1 < \mu_2$).

Another possibility to verify (24) is to study the behaviour of $P(u)$, for (u,ν) solution of (13), as $\nu \to +\infty$. This is done in the next sections 3.2 and 3.3.

3.2. Existence by infinitesimal change of the limiter. For two closed subsets E, F of R^2 we recall the definition of the Hausdorff distance from E to F

$$d_H(E,F) = \mathrm{Sup}\left\{ \sup_{x\in E} d(x,F);\ \sup_{x\in F} d(x,E) \right\}.$$

THEOREM 3. *Let $\tilde{D}$ be a closed subset of V, and $\varepsilon > 0$. Then there exists a closed subset D of V such that*

i) $d_h(\tilde{D}, D) \leqq \varepsilon$.

ii) *There exists* $(\psi,\lambda) \in H_c^2(\Omega)\times\mathbb{R}^+$, *solution of* (11)–(12).

Proof of Theorem 3. We can assume that $\varepsilon < d(\tilde{D}, \Omega\setminus V)$. From Theorem 1, there exists $(u,\nu) \in C^*$ such that $\nu = C^2/\varepsilon^2$, where C is defined by Lemma 6. From Lemma 6 one has $B(x,\varepsilon) \not\subset P(u)$ for every $x \in \tilde{D}$. Set $D = \overline{U_{x\in\tilde{D}} B(x,\varepsilon)} \setminus P(u)$. One has $D \subset V$, $d_H(D,\tilde{D}) \leqq \varepsilon$, D closed. Moreover, $u \leqq 0$ on D; then from Theorem 2 we deduce ii). □

Remark 6. The case of punctual limiters.

Let $\omega = \{ d \in V$ such that there exists $(\psi,\lambda) \in H_c^2(\Omega)\times\mathbb{R}^+$ solution of (11)–(12) with $D = \{d\}\}$. Then ω is dense in V.

Indeed in Theorem 3 if $\tilde{D}$ is reduced to a single point, then in the proof D can be chosen as a single point.

Remark 7. The cylindrical case. If the machine is cylindrical instead of toroidal, the operator $\mathscr{L}$ is replaced by $-\Delta$. In this case if Ω is a ball centered at 0 and if $V = \Omega$, $j = 0$, then there exists a solution of (11)–(12) iff $0 \notin D$. then the set ω in Remark 6 is $\Omega\setminus\{0\}$.

An example for which the existence holds only for some convenient values of the inducing current j in one single coil C_1 is given in J. Simon [15].

3.3. Open questions. In order to prove condition (24) in Theorem 2 it would be interesting to know the answer to the following questions.

Open question 1. Is the set of pairs (u,ν) satisfying (13) connected in $C^0(\bar{\Omega})\times\mathbb{R}^+$?

On the other hand, we can define "variational solutions" of (13) as in [18]. Indeed, let us set for $v \in H_c^1(\Omega)$

$$E(v) = \int_\Omega \left(\frac{1}{r} |\nabla v|^2 - \nu |v^+|^2 1_V - 2jv \right) dx + 2\left(I_p + \int_\Omega j\,dx \right) v_\Gamma.$$

By using a simple adaptation of the method of R. Temam [18] one can prove that for every $\nu > 0$, E reaches its minimum on the set $K = \{ v \in H_c^1(\Omega),\ \int_V v^+\,dx = I_p/\nu \}$. Moreover each minimizing point of E on K is a solution, called "variational solution", of (13).

By an adaptation of the method of L. Caffarelli–A. Friedman [4] (where $V = \Omega$, $j = 0$) one may prove that, for every variational solution u, $\dim P(u) \to 0$ as $\nu \to \infty$, and $P(u)$ is asymptotically located on the set $\partial V^+ = \{ x \in \bar{V}, r(x) \geqq r(y)\ \forall y \in V \}$.

Therefore condition (24) is satisfied if one can answer positively to the following question.

Open question 2. Is the set of pairs (u,ν) such that u is a variational solution connected in $C^0(\bar{\Omega})\times\mathbb{R}^+$?

At last for some particular geometries and currents it is perhaps also possible to answer positively to the next question.

Open question 3. For ν large enough does (13) have a unique solution? This is not always the case. Indeed the counterexample given by D. G. Schaeffer [12] relative to the operator $-\Delta$, can be adapted to the operator $\mathscr{L}$.

3.4. Computational aspects. More sophisticated models can be written for the axisymmetric equilibrium in a Tokamak, including a more general law for the plasma current density and a nonlinear operator $\mathscr{L}$; indeed, in an iron-transformer Tokamak, the nonlinearity of $\mathscr{L}$ is due to the fact that the constant μ_0 is replaced by a function $\mu(|\nabla\psi|)$. These models are numerically solved in [2] by a finite element method and by iterative algorithms for the nonlinearities; they are applied to the simulation of the axisymmetric equilibrium configurations in TFR 600 (Tokamak of Fontenay-aux-Roses) and JET (Joint European Torus).

4. Control of the plasma shape.

4.1. Formulation of the problem. Let us assume that the current density is homogeneous in each coil C_i and let I_i be the total current flowing in C_i; then j can be written

$$j=\sum_{i=1}^{k}\frac{I_i}{|C_i|}1_{C_i},$$

where $|C_i|$ denotes the Lebesgue measure of C_i and k the number of coils. One intends to determine the currents I_i in the coils C_i, so that the plasma boundary ∂P is as close as possible to a desired boundary Σ. In order to achieve this, we want to realize "at best" $\psi=0$ on Σ. Therefore we shall minimize the following cost-function

$$J(\psi)=\int_{\Sigma}\psi^2 d\sigma$$

on the set Ψ of the solutions of (11)–(12) when the currents I_i are varying, i.e.,

$$\Psi=\left\{\psi\in C^0(\bar{\Omega}),\ \text{such that } \exists\lambda>0,\ I_1,\cdots,I_k,\ \text{so that } (\psi,\lambda) \text{ satisfy (11)–(12)}\right\}.$$

Let us mention that the total plasma current I_p is fixed. We are looking for a solution $\psi\in\Psi$ of the following optimal control problem

$$J(\psi)=\inf_{\tilde{\psi}\in\Psi}J(\tilde{\psi}). \tag{25}$$

Notice that since there is only a finite number k of control parameters, the minimum of J will generally be different from 0 and ∂P will not be exactly identical to Σ. It is reasonable to assume that Σ is in contact with the limiter D, because the plasma boundary must satisfy this condition. But this hypothesis will not be used in the following. On the other hand we shall use the following hypothesis

$$\Omega-\bigcup_{i=1}^{k}C_i \text{ is connected; } \Sigma \text{ is the boundary of a regular open subset of } V. \tag{26}$$

4.2. An a priori estimate.

LEMMA 7. *Every solution* $\psi\in C^0(\bar{\Omega})$ *of* (11) *satisfies*

$$\sum_{i=1}^{k}|I_i|+|\psi_\Gamma|\leqq e\left(I_p+\sqrt{j(\psi)}\right)$$

where the constant e only depends on Ω, Σ, $C_1,\cdots,C_k$.

Proof of Lemma 7. From (16) it follows that $\psi=\psi_\Gamma+K(\lambda\psi^+1_V)+K(j)$. One has $|\lambda\psi^+1_V|_{L^1(\Omega)}=I_p$. Since $L^1(\Omega)\hookrightarrow H^{-s}(\Omega)$, for all $s>1$, it follows from (15) that, taking some $s\in\left]1,\frac{3}{2}\right[$, one has

$$|K(\lambda\psi^+1_V)|_{H^{-s+2}(\Omega)}\leqq e_1 I_p.$$

Since $|\psi|_{L^2(\Sigma)}=\sqrt{j(\psi)}$, and since the trace operator is linear continuous from $H^2(\Omega)$ into $L^2(\Sigma)$, one deduces

$$|K(j)+\psi_\Gamma|_{L^2(\Sigma)}\leqq e_2 I_p+\sqrt{j(\psi)}\,.$$

Let $\bar v$ be the mean value of the function v on Σ, i.e. $\bar v=(1/|\Sigma|)\int_\Sigma v\,d\sigma$. One has $|\bar v|_{L^2(\Sigma)}\leqq|v|_{L^2(\Sigma)}$. Let us set $g=K(j)-\overline{K(j)}$. Then

$$|g|_{L^2(\Sigma)}\leqq 2|K(j)+\psi_\Gamma|_{L^2(\Sigma)}\leqq 2\left(e_2 I_p+\sqrt{J(\psi)}\right).$$

i) We shall now prove that there exists $e_3>0$ such that

$$|g|_{L^2(\Sigma)}\geqq e_3\sum_i|I_i|.$$

Let us suppose that $|g|_{L^2(\Sigma)}=0$, i.e. $g=0$ on Σ. One has $\mathscr{L}g=j$ which is zero in $\Omega-\bigcup_i C_i$. Then, with (26), we deduce that $g=0$ on $\Omega-\bigcup_i C_i$.

Then for each i, one has

$$I_i=\int_{C_i} j\,dx=\int_{C_i}\mathscr{L}g\,dx=-\int_{\partial C_i}\frac{1}{r}\frac{\partial g}{\partial n}\,d\sigma=0.$$

Then the function $(I_1,\cdots,I_k)\to|g|_{L^2(\Sigma)}$ is a norm on $\mathbb{R}^k$. This proves the existence of the constant e_3.

ii) It remains to bound ψ_Γ. We have

$$|\psi_\Gamma|\leqq|\overline{K(j)}+\psi_\Gamma|+|\overline{K(j)}|$$

and

$$|\overline{K(j)}+\psi_\Gamma|\leqq|\Sigma|^{-1/2}|K(j)+\psi_\Gamma|_{L^2(\Sigma)},$$

$$|\overline{K(j)}|=\left|\sum_i\frac{I_i}{|C_i|}\overline{K(1_{C_i})}\right|\leqq e_4\sum_i|I_i|,$$

whence

$$|\psi_\Gamma|\leqq\left(|\Sigma|^{-1/2}+\frac{2e_4}{e_3}\right)|K(j)+\psi_\Gamma|_{L^2(\Sigma)}\leqq e_5\left(I_p+\sqrt{J(\psi)}\right).$$

4.3. Existence of an optimal control. We assume here that λ remains bounded when j and ψ_Γ are bounded. More precisely

(27) For every $a>0$ and $\psi\in\Psi$ such that $\sum_i|I_i|+|\psi_\Gamma|\leqq a$ one has $\lambda\leqq A$,

where A depends on a, Ω, V, I_p and on the C_i.

Remark 8. We can show that (27) is satisfied if equation (13) has only variational solutions, and in particular if, for every ν and f there exists a unique solution of (13).

THEOREM 4. *Assume that* $\Psi \neq \varnothing$ *and that* (26) *and* (27) *are verified. Then there exists a solution* ψ_0 *of* (25).

Proof. Let $\{\psi^n\}$ be a minimizing sequence of J in Ψ, i.e.,

$$J(\psi^n) \to \inf_{\psi \in \Psi} J(\psi) \quad \text{as } n \to \infty.$$

Let λ^n and $I_1^n, \cdots, I_k^n$ be the proportionality coefficient and the currents relative to ψ^n.

Lemma 7 shows that I_i^n and ψ_Γ^n are bounded independently of n.

Then j^n is bounded in $L^2(\Omega)$ and Lemma 5 shows that there exists $b>0$, independent of n, such that $\lambda^n \geqq b$ (otherwise ψ_Γ^n would not be bounded).

Moreover assumption (27) shows that $\lambda^n \leqq B$. Then Lemma 2 shows that the ψ^n are bounded in $H^2(\Omega)$.

The imbedding of $H^2(\Omega)$ into $C^0(\bar{\Omega})$ being compact, one can extract a subsequence, still denoted ψ^n such that as $n \to +\infty$

$$\psi^n \to \psi_0 \quad \text{in } C^0(\bar{\Omega}),$$
$$\lambda^n \to \lambda_0, \qquad I_i^n \to I_i^0.$$

Passing to the limit in the equations (11) and (12) relative to ψ^n, one shows that $\psi_0 \in \Psi$. Moreover $J(\psi^n) \to J(\psi_0)$, therefore ψ_0 verifies (25).

Remark 9. *Control of the variational solutions*. Let Ψ_{var} be the subset of Ψ constituted by the variational solutions. Assume that $\Psi_{\text{var}} \neq \varnothing$ and (26) is satisfied. Then there exists $\psi_0 \in \Psi_{\text{var}}$ such that

$$J(\psi_0) = \inf_{\psi \in \Psi_{\text{var}}} J(\psi).$$

This is a consequence of Remark 8, and of the fact that a limit of variational solutions is itself a variational solution.

4.4. Differentiation of a solution with respect to the currents in the coils. If (ψ, λ) is a solution of (11)–(12) relative to $j = \sum_i I_i (1_{C_i}/|C_i|)$, we intend to find, in a neighbourhood of (ψ, λ), a solution which depends continuously on the currents.

For this it is enough to find a solution which depends continuously on each current. Let us consider the variation with respect to I_1.

We assume (this assumption may be weakened as we shall see later) that

(28) D is reduced to a point d.

For every $t \in R$, one looks for a solution of (11) and (12) relative to $j_t = j + t 1_{C_1}/|C_1|$, i.e. for a solution of

$$\begin{aligned} &\psi_t \in H_c^2(\Omega), \qquad \lambda_t > 0, \\ &\mathcal{L}\psi_t - \lambda_t \psi_t^+ 1_V = j_t, \\ &\int_\Omega \mathcal{L}\psi_t \, dx = I_p + \int_\Omega j_t \, dx, \\ &\psi_t(d) = 0, \end{aligned} \tag{29}$$

such that $t \to (\psi_t, \lambda_t)$ is differentiable. (With $(\psi_0, \lambda_0) = (\psi, \lambda)$.)

First let us differentiate formally this equation so as to obtain the equations satisfied by the derivative $\psi' = \partial\psi_t/\partial t$, $\lambda' = \partial\lambda_t/\partial t$ at the point $t=0$. We set $P = \{x \in V, \psi(x) > 0\}$. One obtains

$$
\begin{aligned}
&\psi' \in H_c^2(\Omega), \qquad \lambda' \in \mathbb{R}, \\
&\mathscr{L}\psi' - \lambda 1_P \psi' - \lambda' \psi^+ 1_V = \frac{1_{C_1}}{|C_1|}, \\
&\int_\Omega \mathscr{L}\psi' \, dx = 1, \\
&\psi'(d) = 0.
\end{aligned} \tag{30}
$$

We are going to prove this "formal" differentiation by using the implicit function theorem. To do this we introduce the eigenvalue problem

$$
\begin{aligned}
&\varphi \in \mathscr{V} = \left\{ v \in H_c^2(\Omega), \int_\Omega \mathscr{L} v \, dx = 0 \right\}, \\
&\mathscr{L}\varphi = \nu 1_P \varphi.
\end{aligned} \tag{31}
$$

If λ is not an eigenvalue of (31), one defines the unique function φ_1 by

$$
\varphi_1 \in \mathscr{V}, \qquad \mathscr{L}\varphi_1 - \lambda 1_P \varphi_1 = \psi^+ 1_V. \tag{32}
$$

THEOREM 5. *The pair* $(\psi, \lambda) \in H_c^2(\Omega) \times R$ *being a solution of* (11)–(12), *one assumes that*

$$
\nabla\psi(x) \neq 0 \text{ for every } x \in \bar{V} \text{ such that } \psi(x) = 0, \tag{33}
$$

$$
\lambda \text{ is not an eigenvalue of } (31) \text{ and } \varphi_1(d) \neq 0. \tag{34}
$$

Then, for every small enough t, *there exists a unique solution of* (29) *such that* $t \to (\psi_t, \lambda_t)$ *is continuously differentiable into* $H_c^2(\Omega) \times \mathbb{R}$ *and such that* $(\psi_0, \lambda_0) = (\psi, \lambda)$.

The derivative for $t=0$ *is the unique solution* (ψ', λ') *of* (30).

Remarks 10.

i) From (29) one can deduce that $\psi \in C^1(\bar{\Omega})$ and (33) is therefore meaningful.

ii) Let us assume that $\lambda < \mu_2$, where μ_2 is defined in §2.2. Then λ is not an eigenvalue of (31).

Indeed, as it has been seen in the proof of Lemma 1, the first eigenvalue of (31) is zero, and the second is larger than μ_2.

Remark. Analogous results of derivability have been obtained by A. Dervieux [5], for the equilibrium problem without inductive currents, vacuum vessel nor limiter.

Proof of Theorem 5. Let $p > 2$ be given and let us set $X = \{v \in W_c^{2,p}(\Omega), v(d) = 0\}$. Provided with the norm of $W^{2,p}(\Omega)$, X is a Banach space included in $C^1(\bar{\Omega})$.

One defines F: $R \times X \times R \to L^p(\Omega) \times \mathbb{R}$ by

$$
F(t; v, b) = \left(\mathscr{L} v - b v^+ 1_V - j_t, \int_\Omega \mathscr{L} v \, dx - I_p - \int_\Omega j_t \, dx \right).
$$

One looks for a solution of $F(t; \psi_t, \lambda_t) = 0$ in the neighbourhood of the solution (ψ, λ) relative to $t=0$. The implicit function theorem gives the announced results, provided

that one verifies the following properties:

(35) There exists a neighbourhood $\mathcal{V}'$ of ψ in X such that $F \in C^1(\mathbb{R} \times \mathcal{V}' \times \mathbb{R}, L^p(\Omega) \times \mathbb{R})$.

(36) The derivative $A = (\partial F/\partial(v,b))(0;\psi,\lambda)$ is an isomorphism from $X \times \mathbb{R}$ onto $L^p(\Omega) \times \mathbb{R}$.

i) *Proof of* (35). The only difficulty comes from the nonlinear term $v^+ 1_V$. The function $v \to v^+ 1_V$ is differentiable from $W^{2,p}(\Omega)$ into $L^p(\Omega)$ at any point w such that the measure of $\{x \in V, w(x) = 0\}$ is zero, and its derivative is the function $G(w)$: $v \to 1_{P_w} v$ where $P_w = \{x \in V, w(x) > 0\}$ (cf. for example [6] for the proof of these points).

To prove (35), we have to verify that:

(37) for every $w \in \mathcal{V}'$ the measure of the set $\{x \in V, w(x) = 0\}$ is zero,

(38) $G \in C^0(\mathcal{V}', \mathcal{L}(W^{2,p}(\Omega); L^p(\Omega)))$.

From the assumption (33) it follows that there exists a neighbourhood of ψ in $C^1(\bar{\Omega})$, and therefore a neighbourhood $\mathcal{V}'$ of ψ in X such that $\forall w \in \mathcal{V}'$, one has

$$\nabla w(x) \neq 0 \text{ for any } x \in \bar{V} \text{ such that } w(x) = 0.$$

This yields (37) since, according to G. Stampacchia [16], one has

$$1_{w=0} \nabla w = 0 \quad \text{a.e. in } V.$$

Moreover, when $w_n \to w$ in $\mathcal{V}'$ one has, since the measure of $\{x \in V, w(x) = 0\}$ is zero, $1_{P_{w_n}} \to 1_{P_w}$ in $L^1(\Omega)$. Therefore, for any $v \in W^{2,p}(\Omega)$, one has

$$\left| (1_{P_{w_n}} - 1_{P_w}) v \right|_{L^p(\Omega)} \leqq \left| 1_{P_{w_n}} - 1_{P_w} \right|^{1/p}_{L^1(\Omega)} |v|_{L^\infty(\Omega)}$$

which yields (38).

ii) *Proof of* (36). The operator $A \in \mathcal{L}(X \times \mathbb{R}; L^p(\Omega) \times \mathbb{R})$ is defined by

$$A(\varphi, \mu) = \left(\mathcal{L}\varphi - \lambda 1_P \varphi - \mu \psi^+ 1_V, \int_\Omega \mathcal{L}\varphi \, dx \right).$$

One has to show that, for every $(g,a) \in L^p(\Omega) \times \mathbb{R}$, there exists a unique solution (φ, μ) of

$$\begin{aligned} &\varphi \in W_c^{2,p}(\Omega), \qquad \mu \in \mathbb{R}, \\ &\mathcal{L}\varphi - \lambda 1_P \varphi - \mu \psi^+ 1_V = g, \\ &\int_\Omega \mathcal{L}\varphi \, dx = a, \\ &\varphi(d) = 0. \end{aligned} \tag{39}$$

Since λ is not an eigenvalue of (31) there exists a unique function φ_2 such that

$$\begin{aligned} &\varphi_2 \in H_c^2(\Omega), \\ &\mathcal{L}\varphi_2 - \lambda 1_P \varphi_2 = g, \\ &\int_\Omega \mathcal{L}\varphi_2 \, dx = a. \end{aligned}$$

It is clear that φ_1 and φ_2 belong to $W_c^{2,p}(\Omega)$; therefore (φ,μ) is a solution of (39) if and only if

$$\varphi=\mu\varphi_1+\varphi_2, \qquad \varphi(d)=0. \tag{40}$$

Since one has supposed $\varphi_1(d)\neq 0$, (40) (and therefore (39)) has a unique solution (φ,μ). This proves (36). □

Remark 11. In Theorem 5, we have assumed that D is reduced to one point. This assumption is not necessary. In fact if D is constituted by a finite number of points and if we assume that the maximum of ψ on D is reached at a unique point, it is easy to see that Theorem 5 is still true.

More generally let us suppose that D is a closed subset of V, with a regular boundary and that the maximum of ψ on D is reached at a unique point d. Then one can prove a result, which is similar to that of Theorem 5. By using additional assumptions, in particular that the curvatures of the boundaries of P and D at the point d are different, one can show that ψ_t reaches its maximum at a point d_t which depends regularly on t. The derivative of $t\to\psi_t$ for $t=0$ is still given by (30).

4.5. Optimality conditions. In this paragraph we still assume that D is reduced to a point d (this hypothesis can be weakened as we have seen in the remark at §4.4).

Let ψ_0 be an optimal control, i.e. a solution of (25). Thus there exists a unique $\lambda_0>0$ and unique currents $I_1^0,\cdots,I_k^0$ such that (ψ_0,λ_0) satisfies (11) and (12).

One denotes by δ_d the Dirac measure at point d, and δ_Σ the measure on Σ defined by

$$(\delta_\Sigma,v)=\int_\Sigma v\,d\sigma \quad \forall v\in C^0(\bar\Omega).$$

(σ is the 1-dimensional Lebesgue measure on Σ). We set $P_0=\{x\in V,\psi_0(x)>0\}$.

THEOREM 6. *We assume that* (ψ_0,λ_0) *satisfies the assumptions* (33) *and* (34). *Then there exists a unique solution* q *of*

$$\begin{aligned} &q\in W_c^{1,p'}(\Omega) \quad \textit{where } 1<p'<2,\\ &\mathcal{L}q-\lambda_0 1_{P_0}q=\psi_0\delta_\Sigma-\left(\lambda_0\int_{P_0}q\,dx+\int_\Sigma\psi_0\,d\sigma\right)\delta_d,\\ &\int_V q\psi_0^+\,dx=0, \end{aligned} \tag{41}$$

and one has the following necessary optimality condition

$$\frac{1}{|C_i|}\int_{C_i}q\,dx=q_\Gamma \quad \forall i.$$

Proof of Theorem 6 .

i) *Differentiation of the cost function.* Theorem 5 enables to define in a unique way, for t small enough, a solution (ψ_t,λ_t) of (11)–(12) relative to $j_t=j_0+t1_{C_1}/|C_1|$.

Since ψ_0 is optimal one has

$$\int_\Sigma\psi_t^2\,d\sigma\geqq\int_\Sigma\psi_0^2\,d\sigma \quad \forall t.$$

Since $t \to \psi_t$ is differentiable into $H_c^2(\Omega)$, one has

$$\int_\Sigma \psi_0 \psi' \, d\sigma = 0 \tag{42}$$

where (ψ', λ') is the unique solution of (30) (relative to $(\psi, \lambda) = (\psi_0, \lambda_0)$).

By introducing an appropriate adjoint state, we are going to transform this condition (42).

ii) *Definition of the adjoint state q.* As it has been mentioned in the part ii) of the proof of Theorem 5, the operator A which is defined by

$$A(\varphi, \mu) = \left(\mathscr{L}\varphi - \lambda_0 1_{P_0} \varphi - \mu \psi_0^+ 1_V, \int_\Omega \mathscr{L}\varphi \, dx \right)$$

is linear continuous from $X \times \mathbb{R}$ onto $L^p(\Omega) \times \mathbb{R}$. Let us recall that $X = \{ v \in W_c^{2,p}(\Omega), v(d) = 0 \}$.

The adjoint operator A^* of A is therefore linear continuous from $L^{p'}(\Omega) \times \mathbb{R}$ onto $X' \times \mathbb{R}$ with $p' = p/(p-1)$.

As the embedding of X into $C^0(\bar{\Omega})$ is continuous, the measure $\psi_0 \delta_\Sigma$ is an element of X'. Then one defines (q, h) in a unique way by $A'(q, h) = (\psi_0 \delta_\Sigma, 0)$, i.e. by

$$\begin{aligned} &q \in L^{p'}(\Omega), \qquad h \in \mathbb{R}, \\ &\int_\Omega q \left(\mathscr{L}\varphi - \lambda_0 1_{P_0} \varphi - \mu \psi_0^+ 1_V \right) dx + h \int_\Omega \mathscr{L}\varphi \, dx = \int_\Sigma \psi_0 \varphi \, d\sigma \quad \forall \varphi \in X, \ \mu \in \mathbb{R}. \end{aligned} \tag{43}$$

When v spans $W_c^{2,p}(\Omega)$, $v - v(d)$ spans X and then (43) is equivalent to

$$\begin{aligned} &q \in L^{p'}(\Omega), \qquad h \in \mathbb{R}, \\ &\int_\Omega q \left(\mathscr{L}v - \lambda_0 1_{P_0} v \right) dx + h \int_\Omega \mathscr{L}v \, dx = \int_\Sigma \psi_0 v \, d\sigma - v(d) \left[\lambda_0 \int_{P_0} q \, dx + \int_\Sigma \psi_0 \, d\sigma \right], \\ &\int_V q \psi_0^+ \, dx = 0 \quad \forall v \in W_c^{2,p}(\Omega). \end{aligned} \tag{44}$$

iii) *Characterization* (41) *of q.* Let us set

$$\mu = \lambda_0 1_{P_0} q + \psi_0 \delta_\Sigma - \left(\lambda_0 \int_{P_0} q \, dx + \int_\Sigma \psi_0 \, d\sigma \right) \delta_d.$$

One has $\mu \in W^{-1,p'}(\Omega)$ since the measures belong to this space.

Let us consider the solution η of

$$\eta \in W_0^{1,p'}(\Omega), \qquad \mathscr{L}\eta = \mu, \tag{45}$$

and let us assume for a while that η is the unique solution of

$$\eta \in L^{p'}(\Omega), \quad \int_\Omega \eta \mathscr{L}v \, dx = (\mu, v) \quad \forall v \in W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega). \tag{46}$$

Since $q + h$ satisfies (46), one has $q + h = \eta$, which establishes (41).

Reciprocally if q satisfies (41) one has $q - q_\Gamma = \eta$, then for $h = -q_\Gamma$ the pair (q, h) satisfies (44), therefore (41) has a unique solution.

iv) *Equivalence of* (45) *and* (46). Let us first prove that η satisfies (46). One sets $v = v_1 + v_2$ where v_1 equals zero in a neighbourhood of Γ and v_2 equals zero in a neighbourhood of $\Sigma \cup \{d\}$. If $v_1 \in \mathcal{D}(\Omega)$ one has

$$\int_\Omega \eta \mathcal{L} v_1 \, dx = (\mathcal{L}\eta, v_1)_{\mathcal{D}'(\Omega)\times\mathcal{D}(\Omega)} = (\mu, v_1)$$

and by density one obtains this same result for every $v_1 \in W_c^{2,p}(\Omega)$, such that v_1 equals zero in a neighbourhood of Γ.

Moreover, as $\mu = \lambda_0 1_{p_0} q$ in the support S of v_2 one has $\eta \in W^{2,p'}(S)$ and

$$\int_\Omega \eta \mathcal{L} v_2 \, dx = \int_S \eta \mathcal{L} v_2 \, dx = \int_S \mathcal{L}\eta v_2 \, dx = (\mu, v_2).$$

By adding these equalities one obtains (44).

It remains to verify that (44) has a unique solution. Indeed the difference w of two solutions satisfies $w \in L^{p'}(\Omega)$ and

$$\int_\Omega w \mathcal{L} v \, dx = 0 \quad \forall v \in Y$$

where $Y = W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$.

As $\mathcal{L}$ is an isomorphism from Y onto $L^p(\Omega)$, its adjoint $\mathcal{L}^*$ is an isomorphism from $L^{p'}(\Omega)$ onto Y'. One has

$$(\mathcal{L}^* w, v)_{Y'\times Y} = 0 \quad \forall v \in Y;$$

therefore $\mathcal{L}^* w = 0$ and $w = 0$.

v) *Necessary optimality condition.* From the definition of (q,h) one has

$$A^*(q,h)\cdot(\psi',\lambda') = (\psi_0 \delta_\Sigma, 0)\cdot(\psi',\lambda') = \int_\Sigma \psi_0 \psi' \, d\sigma.$$

Moreover, from the definition (30) of (ψ',λ') one has

$$(q,h)\cdot A(\psi',\lambda') = (q,h)\left(\frac{1_{C_1}}{|C_1|}, 1\right) = \frac{1}{|C_1|}\int_{C_1} q \, dx + h.$$

Then the optimality condition (42) shows that

$$\frac{1}{|C_1|}\int_{C_1} q \, dx = -h = q_\Gamma.$$

One can of course replace C_1 by any coil C_i, whence the announced result.

Remark 12. A sequential quadratic method is used in [3] in order to solve numerically this optimal control problem and it is applied to the control of the plasma shape in the Tokamaks JET and TORE SUPRA.

Acknowledgment. The authors are very thankful to Dr. H. Berestycki for many valuable comments on this paper.

THE SCALAR RIEMANN PROBLEM IN TWO SPATIAL DIMENSIONS: PIECEWISE SMOOTHNESS OF SOLUTIONS AND ITS BREAKDOWN*

W. B. LINDQUIST†

Abstract. Consider the scalar quasilinear equation

$$\frac{\partial u(t,x)}{\partial t}+\sum_{i=1}^{n}\frac{\partial f_i(u(t,x))}{\partial x_i}=0,$$

for $n=1,2$, $f_i\in C^2$: $R\to R$. For $n=2$, we define the two-dimensional Riemann problem and show the unique (in the sense of Kružkov) solutions are piecewise smooth for $f_1\equiv f_2\equiv f$, f purely convex or having a single inflection point. A mechanism leading to a presumed loss of piecewise smoothness is presented for f having three or more inflection points. The analysis is based on a study of the generalization of the one-dimensional Riemann problem to allow for initial data having a finite number of jump discontinuities with constant data or rarefaction waves between jumps.

Key words. Riemann problems, hyperbolic equations

AMS(MOS) subject classifications. Primary 35C05; secondary, 35B65, 35L65

1. Introduction.

Consider the Cauchy problem for the scalar quasilinear equation

$$\frac{\partial u(t,x)}{\partial t}+\sum_{i=1}^{n}\frac{\partial f_i(u(t,x))}{\partial x_i}=0,\qquad n=1,2,$$
$$u(0,x)=u_0(x),\tag{1.1}$$

with f_i: $\mathbf{R}\to\mathbf{R}\in C^2$. For two spatial dimensions, we define the Riemann problem and show that the unique (in the sense of Kružkov) solutions are piecewise smooth for $f_1\equiv f_2\equiv f$, f having at most one inflection point. The assumption $f_1=f_2$ appears to be natural from the point of view of applications. This sufficiency condition follows from a detailed analysis of a generalization of the Riemann problem in one dimension to allow for initial data having a finite number of jump discontinuities where the data between points of jump is allowed to contain rarefaction waves as defined below. For these generalized one-dimensional Riemann problems, we show the unique (in the sense of Kružkov) solutions are piecewise smooth if the initial data has a single jump discontinuity and f_1 is restricted to at most two inflection points. If the initial data has more than a single jump discontinuity we show that restricting f_1 to at most one inflection point guarantees a piecewise smooth solution.

We present a construction based on a function f_1 having three inflection points which shows a possible breakdown of piecewise smoothness for the associated one-dimensional Riemann problem. The implication of this example is that the scalar Riemann problem in two dimensions can presumably fail to have piecewise smooth solutions for nonconvex $f_2\equiv f_1$ having three inflection points.

A bounded measurable function $u(t,x)$ is a *weak solution* of (1.1) in the strip $\Pi_T \equiv [0,T]\times \mathbf{R}^n$ if

$$\iint_{\Pi_T} dt\,dx\left[u\frac{\partial\phi}{dt}+\sum_{i=1}^{2} f_i(u)\frac{\partial\phi}{\partial x_i}\right]+\int_{i=0} dx \quad u_0(x)\phi(0,x)=0, \tag{1.2}$$

for all $\phi\in C_0^\infty(\Pi_T)$. A function is a weak solution in the large if it is a weak solution for all T. For initial data $u_0(x)$ in the class of bounded, measurable functions Kružkov [2] has shown the existence and uniqueness of a bounded measurable function which is a weak solution to (1.1).[1] The uniqueness (entropy) condition satisfied by this weak solution is [2]

$$\iint_{\Pi_T} dt\,dx\,\operatorname{sign}(u-k)\left\{(u-k)\frac{\partial\phi}{\partial t}+\sum_{i=1}^{2}\left(f_i(u)-f_i(k)\right)\frac{\partial\phi}{\partial x_i}\right\}\geqq 0, \tag{1.3}$$

for any real constant k and any $\phi\in C_0^\infty(\Pi_T)$ such that $\phi\geqq 0$. This uniqueness condition characterizes the allowed discontinuities in the weak solution.

Define a *regular point* of the weak solution u as a point p for which $\partial u/\partial t$ and $\partial u/\partial x_i$ exist and are continuous in a neighbourhood of p, and at which the differential form of (1.1) is satisfied. The function u shall be termed *smooth* in an open neighbourhood N if each point $p\in N$ is a regular point. Let a *smooth* surface of codimension i in $\mathbf{R}^n\times\mathbf{R}^+$ be a surface at each point p of which a unique (modulo minus signs) i-dimensional space of normals exist and for which the normal space varies continuously as the point p is varied over the surface. A *piecewise smooth surface* is defined by induction on the codimension i, as the union of a finite number of smooth surfaces with piecewise smooth boundaries of codimension $i+1$; each of the finite number of pieces being everywhere the boundary of the same codimension i surfaces. A *piecewise smooth* solution $u\in\mathbf{R}^n\times\mathbf{R}^+$ is defined as a function that is smooth except on a discontinuity set that consists of piecewise smooth surfaces. A *point of jump* is a point p of discontinuity of a function u for which the discontinuity is a simple jump in u, i.e. locally the point p lies on a smooth codimension 1 surface of discontinuity and the one sided limits $u^-=\lim_{\varepsilon\to 0^+} u(p-\varepsilon n)$ and $u^+=\lim_{\varepsilon\to 0^+} u(p+\varepsilon n)$, where n is the unit normal to the smooth discontinuity surface at p, exist at p. A singular point of u which is not a point of jump shall be termed an *irregular* point.

Using integration by parts, the arbitrariness of ϕ and appropriate choices of the constant k, it can be shown that (1.3) is equivalent to two conditions for points of jump p in whose neighbourhood the unique weak solution u is piecewise smooth:

$$n\cdot\left[u^+-u^-,\vec{f}(u^+)-\vec{f}(u^-)\right]=0, \tag{1.4}$$

and

$$n\cdot\left[k-u^-,\vec{f}(k)-\vec{f}(u^-)\right]\geqq 0, \tag{1.5}$$

where $\vec{f}$ stands for the vector $[f_1,f_2]$. In (1.5) n is oriented such that $u^-\leqq u^+$ and k is any constant such that $u^-\leqq k\leqq u^+$. As a consequence of (1.4), (1.5) also holds with u^- replaced by u^+. Equation (1.4) will be denoted the jump condition for the discontinuity at p and (1.5) the entropy condition. In $\mathbf{R}^1\times\mathbf{R}^+$ (1.4) is the familiar Rankine–Hugoniot

[1] Kružkov's proof holds for $n\geqq 1$ spatial dimensions. Here only $n\leqq 2$ concerns us.

condition and (1.5) is equivalent to the entropy condition of Oleĭnik [5]. The advantage of equations (1.4) and (1.5) over (1.3) is that the former are local conditions which will allow construction of piecewise smooth global solutions by piecing together local solutions which individually obey (1.4) and (1.5).

A weak solution $u \in \mathbf{R}^n \times \mathbf{R}^+$ to (1.1) which is piecewise smooth and whose discontinuity sets are piecewise smooth surfaces of points of jump obeying (1.4) and (1.5) then satisfies (1.3) and is therefore the unique Kružkov solution to (1.1).

The existence and uniqueness theory gives little insight into the actual form of the weak solution. In $\mathbf{R}^1 \times \mathbf{R}^+$, insight is provided by analysis of the Riemann problem whose solution is piecewise smooth and can be derived in terms of a nonlinear wave analysis. It can be shown (see, for example, Lax [3] and the references therein) that these nonlinear waves consist of rarefaction and shock waves. The initial motivation of this paper was to consider the natural generalization of the Riemann problem in two dimensions and investigate its solution in terms of two-dimensional waves which, by implication, is a restriction to the set of piecewise smooth solutions. In this paper we determine a sufficient condition for which the solution to the two-dimensional Riemann problem is piecewise smooth. In a companion paper [4] we investigate the form of these solutions in terms of nonlinear waves. For the case $f_1 = f_2 \equiv f$, the sufficiency condition consists of restricting f to at most one inflection point. We conjecture that if the number of inflection points of f is at least three, the solution to the generalized Riemann problem defined in one dimension (and hence for the Riemann problem in two dimensions) may fail to be piecewise smooth. Our argument for this is presented in §2.

The generalizations of the one-dimensional Riemann problem to allow multiple jumps and restricted smooth variation in the initial data are presented in §§2 and 3. In §4, the two-dimensional Riemann problem is defined and a sufficiency condition for piecewise smooth solutions obtained.

2. The one-dimensional Riemann problem. Throughout this paper the notation $q'(p)$ or $(q(p))'$ shall denote $dq(p)/dp$ for any function q of a single variable p.

We first discuss the familiar results for the one-dimensional Riemann problem to introduce notation and reformulate results in a manner that will allow generalization. The scalar quasilinear equation (1.1) in one spatial dimension ($f_1 \equiv f, x_1 \equiv x$) with initial data

$$u(0,x) = \begin{cases} u_l & \text{for } x < x_0, \\ u_r & \text{for } x > x_0, \end{cases} \tag{2.1}$$

defines the *one-dimensional Riemann problem*.

The Riemann problem (1.1), (2.1) is invariant under the similarity transformation $(t, x - x_0) \to (ct, c(x - x_0))$, $c > 0$.[2] Hence the solution is constant along the straight lines $(x - x_0)/t = constant$. In a neighbourhood of a point in which the Riemann problem solution is smooth, (1.1) implies that the solution will be constant along the straight lines

$$\frac{x - x_c}{t - t_c} = f'(u), \qquad t \geq t_c, \tag{2.2}$$

[2] This scale invariance is one of the essential features of the Riemann problem.

which are denoted *characteristics*. Characteristics shall be denoted (u,t_c,x_c) where (t_c,x_c) is the origin point of the characteristic given by (2.2). For the Riemann problem (1.1) (2.1), $t_c=0$ for all characteristics.

Let $p=(t_p,x_p)$ be a point on a characteristic (u_1,t_1,x_1). Let $\hat{n}$ be a normal to the characteristic at p. By the smoothness of u there exists δ_p such that each point $p+\varepsilon\hat{n}$, where $-\delta_p\leqq\varepsilon\leqq\delta_p$, lies on a characteristic. Let $(u_\varepsilon,t_\varepsilon,x_\varepsilon)$ denote such a characteristic. Then (u_1,t_1,x_1) is a *rarefaction wave* if the lines defined by the characteristics (u_1,t_1,x_1) and $(u_\varepsilon,t_\varepsilon,x_\varepsilon)$ intersect at some $t\leqq t_p$. This condition generalizes the concept of the familiar centered rarefaction wave for which $t_\varepsilon=t_1$, $x_\varepsilon=x_1$, to noncentered rarefaction waves which appear in the generalized Riemann problem solutions and also generalizes to a definition of rarefaction waves in two spatial dimensions.

A *rarefaction fan* is an open set in the t,x plane all points of which belong to rarefaction waves.

A *shock* is defined as a smooth curve of points of jump in the t,x plane at each point of which the conditions (1.4) and (1.5) are satisfied. A shock curve (wave) will be denoted $(u_l(t),u_r(t),t_s,x_s)$ where $u_l(t)$ is the limit value of the solution u to the left of the shock wave at time $t>t_s$, u_r is the corresponding right limit, and (t_s,x_s) is the origin point of the shock wave. For the Riemann problem (1.1) (2.1), $t_s=0$, $x_s=x_0$.

A *constant state* is a domain (connected open set) in the t,x plane over which the solution is constant.

Let $f(u)\in C^2$: $\mathbf{R}\to\mathbf{R}$. Let $\{u_1,u_2\}$ denote a closed interval where

$$\{u_1,u_2\}\equiv\begin{cases}[u_1,u_2] & \text{if } u_1<u_2,\\ [u_2,u_1] & \text{if } u_1>u_2.\end{cases} \tag{2.3}$$

A *rarefaction interval of* f shall denote an interval which satisfies either

$$f''(u)>0 \quad \text{if } u_1<u_2 \text{ for every } u\in\{u_1,u_2\}, \tag{2.4a}$$

or

$$f''(u)<0 \quad \text{if } u_1>u_2 \text{ for every } u\in\{u_1,u_2\}. \tag{2.4b}$$

Let $E(u_1,u_2;u)$: $\mathbf{R}\to\mathbf{R}$ denote the convex envelope function for $f(u)$ restricted to the interval $\{u_1,u_2\}$ of f such that

$$E(u_1,u_2;u)\equiv\begin{cases}\text{upper convex envelope from } u_1 \text{ to } u_2, & \text{if } u_1>u_2,\\ \text{lower convex envelope from } u_1 \text{ to } u_2 & \text{if } u_1<u_2.\end{cases} \tag{2.5}$$

Let $C(u_1,u_2;u)$: $\mathbf{R}\to\mathbf{R}$ denote the linear map restricted to the domain interval $\{u_1,u_2\}$ such that

$$\begin{aligned}C(u_1,u_2;u_1)&=f(u_1),\\ C(u_1,u_2;u_2)&=f(u_2),\end{aligned} \tag{2.6}$$

i.e. for all u in $\{u_1,u_2\}$,

$$\frac{dC(u_1,u_2;u)}{du}=\frac{f(u_2)-f(u_1)}{u_2-u_1}.$$

Denote the restriction of the function $f(u)$ to the subinterval $\{u_1,u_2\}$ by $f(u_1,u_2;u)$.

THEOREM 2.1 (Oleĭnik [5]). *Consider the Riemann problem* (1.1), (2.1). *Assume* $f(u)\in C^2$: $\mathbf{R}\to\mathbf{R}$ *such that f has a finite number of inflection points. Then the unique, entropy obeying solution connecting the states* u_l *and* u_r *is determined solely from* $E(u_l,u_r;u)$, *as described below. Further, the solution is piecewise smooth, with a single irregular point corresponding to the discontinuity at* x_0 *in the initial data.*

The convex envelope function $E(u_l,u_r;u)$ uniquely divides the interval $\{u_l,u_r\}$ into rarefaction intervals separated by intervals corresponding to the linear chord segments of E. Each rarefaction interval corresponds to a rarefaction fan in the solution. The fans are centered on $t=0$, $x=x_0$ and each rarefaction wave has a unique value u corresponding to a state in a rarefaction interval. The slope of the rarefaction wave $(v,0,x_0)$ is given by $f'(v)$. Each linear chord in E covering an interval $\{u_1,u_2\}$ corresponds to a shock wave $(u_1,u_2,0,x_0)$. The solution is bordered on the left by the single constant state $u=u_l$ and on the right by $u=u_r$. No constant states appear within the solution except for these two bounding constant states, which are the states u_l and u_r of the initial data. The speeds of the nonlinear waves found in the solution increase continuously from left to right along the x direction. Fig. 2.1a shows an upper convex envelope drawn between two states for the function $f(u)$ illustrated. Figure 2.1b illustrates the corresponding Riemann solution in t,x space, with the three shocks (in this case) represented as dark lines.

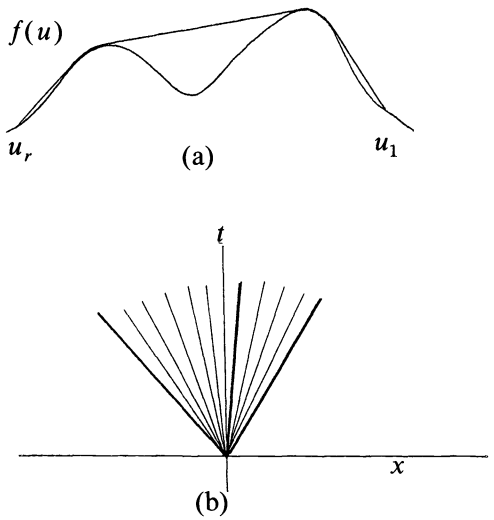

FIG. 2.1. (a) *The upper convex envelope drawn between two points* u_l *and* u_r *for an illustrative function f.* (b) *The Riemann solution in the* t,x *plane based on* (a). *Dark lines represent shock waves, light lines are rarefaction waves.*

A solution given by Theorem 2.1 shall be referred to, for brevity, as the *Oleĭnik solution to* $\{u_l,u_r\}$ centered on x_0.

2.1. The generalized Riemann problem for initial data with a single point of discontinuity. Let $h(x_1,x_2,u_1,u_2;x)$: $\mathbf{R}\to\mathbf{R}$ be a continuous, differentiable, 1-1 mapping from the interval $[x_1,x_2]$ of the real axis onto a rarefaction interval $\{u_1,u_2\}$ of f such

that

$$h(x_1,x_2,u_1,u_2;x_1)=u_1, \qquad h(x_1,x_2,u_1,u_2;x_2)=u_2. \tag{2.7}$$

Further, assume that the derivative of h is bounded and bounded away from 0. Then its inverse map exists, is 1-1, onto, and has derivatives bounded away from 0. Denote the inverse map by

$$h^{-1}(x_1,x_2,u_1,u_2;u).$$

Where no ambiguity exists the notation for these maps shall be shortened to $h(x)$ and $h^{-1}(u)$.

Let $f(u)\in C^2$: $\mathbf{R}\to\mathbf{R}$ such that $f''(u)=0$ at a finite number of points. Let $\{a,b\}$ and $\{c,d\}$ be rarefaction intervals of $f(u)$.

DEFINITION 2.2. The Cauchy problem

$$\frac{\partial u(x,t)}{\partial t}+\frac{\partial f(u(x,t))}{\partial x}=0, \tag{2.8}$$

with initial data

$$u(x)=\begin{cases} a, & x\leqq x_l,\\ h_l(x_l,x_0,a,b;x), & x_l<x<x_0,\\ h_r(x_0,x_r,c,d;x), & x_0<x<x_r,\\ d, & x_r\leqq x, \end{cases} \tag{2.9}$$

will be denoted as a Cauchy problem with generalized Riemann data (generalized Riemann problem, for short). The unique solution to (2.8) and (2.9) obeying (1.4) and (1.5) shall be referred to as the generalized Oleĭnik solution.

THEOREM 2.3. *Let $f(u)\in C^2$: $\mathbf{R}\to\mathbf{R}$ such that $f''(0)$ for at most two values of u. Then the generalized Oleĭnik solution to* (2.8), (2.9) *is piecewise smooth; it consists of two constant states, rarefaction fans, at most three shock waves*[3] *and at most two irregular points. A rarefaction wave either originates at $t=0$ on the interval $[x_l,x_r]$ or tangentially to a shock line at $t>0$ and either terminates on a shock line or propagates undisturbed for all t. At most two points can be irregular, the initial discontinuity point in the data $(t=0,x=x_0)$ or the meeting point of three shocks.*[3]

2.1.1. Proof of Theorem 2.3. The following definitions will prove useful. Let $\{u_1,u_2\}$ be a rarefaction interval of f and $h(x_1,x_2,u_1,u_2;x)$ a map as in (2.7). At each point $x\in[x_1,x_2]$ construct the rarefaction wave $(u,0,x)$ with

$$x(t)=x+f'(h(x))t.$$

The set of waves thus constructed on $[x_1,x_2]$ form a rarefaction fan which shall be referred to as the *rarefaction fan determined by* $h(x_1,x_2,u_1,u_2;x)$.

[3] By definition of a shock wave as a smooth curve, the occurrences of either two shock lines interacting to produce a single shock curve, or a single shock curve splitting into two shock curves, are each described as involving three shock waves.

Let $\{u_1, u_2\}$ be a rarefaction interval of f. For every u in $\{u_1, u_2\}$ construct the rarefaction wave $(u, 0, x_0)$ with

$$x(t) = x_0 + f'(u)t.$$

The set of waves thus constructed form a rarefaction fan which shall be referred to as *determined at x_0 by the interval $\{u_1, u_2\}$*.

Let $\{a, b\}$ be a rarefaction interval of f. Let $h(\rho_0, \rho_1, a, b; \rho)$ be a map as in (2.7) from the real interval $[\rho_0, \rho_1]$ to $\{a, b\}$. Construct a curve segment $(t(\rho), x(\rho))$ from (t_0, x_0) to (t_1, x_1) in the t, x plane such that

$$\begin{aligned} (t_0, x_0) &\equiv (t(\rho_0), x(\rho_0)), \\ (t_1, x_1) &\equiv (t(\rho_1), x(\rho_1)), \\ \frac{dx(\rho)}{dt(\rho)} &= f'(h(\rho_0, \rho_1, a, b; \rho)). \end{aligned}$$

At each point $(t(\rho), x(\rho))$ construct the rarefaction wave $(h(\rho), t(\rho), x(\rho))$. Then the set of waves constructed on the curve segment form a rarefaction fan which shall be referred to as the *rarefaction fan determined by the curve $(t(\rho), x(\rho))$*.

LEMMA 2.4. *Let N be a rarefaction fan in the t, x plane for some solution $u(t, x)$. Let $[x_1, x_2]$ be an interval in N parallel to the x-axis at some time t such that the rarefaction wave passing through the point (t, x_1) has value $u = u_1$ and the rarefaction wave passing through the point (t, x_2) has value $u = u_2$. Then $\{u_1, u_2\}$ is a rarefaction interval of f and the fan defines a continuous*, 1-1 *mapping $h'(x_1, x_2, u_1, u_2; x)$: $\mathbf{R} \to \mathbf{R}$ from $[x_1, x_2]$ onto $\{u_1, u_2\}$ whose derivatives are bounded and bounded away from* 0.

The proof for Lemma 2.4 follows from the definition of a rarefaction wave. □

The proof for Theorem 2.3 is constructive. All possible Cauchy data (2.9) fall into four classes:

C1. $\{a, b\}$ and $\{c, d\}$ are not disjoint, $f'' > 0$ on $\{a, b\} \cup \{c, d\}$,
C2. $\{a, b\}$ and $\{c, d\}$ are not disjoint, $f'' < 0$ on $\{a, b\} \cup \{c, d\}$,
C3. $\{a, b\}$ and $\{c, d\}$ are disjoint, $b > c$,
C4. $\{a, b\}$ and $\{c, d\}$ are disjoint, $b < c$.

Classes C3 and C4 can each be divided into four subgroups:

S1: $a < b$, $c < d$,
S2: $a > b$, $c > d$,
S3: $a < b$, $c > d$,
S4: $a > b$, $c < d$.

For classes C1, C2 there are no inflection points of f in the interval $[a, d]$. For subgroups S1 and S2 of classes C3 and C4 there are either 0 or 2 inflection points in the interval $[a, d]$. Subgroups S3 and S4 of classes C3 and C4 contain one inflection point in the interval $[a, d]$. Theorem 2.3 will be proven for the case of 0 and 1 inflection point in the interval $[a, d]$ of f. The proof for the case of two inflection points will be omitted for brevity.

f has zero inflection points. Restriction of f to no inflection points implies initial data from either classes C1, C2 or subgroups S1 or S2 of C3 and C4. We study data of classes C1, C3.S1 and C3.S2; the proofs for classes C2, C4.S1 and C4.S2 follow analogously.

Class C1. There are four arrangements of initial data in the class C1:

$$\begin{aligned} &\text{C1.A1:} \quad a<c<b<d,\\ &\text{C1.A2:} \quad a<c<d<b,\\ &\text{C1.A3:} \quad c<a<d<b,\\ &\text{C1.A4:} \quad c<a<b<d. \end{aligned}$$

The generalized Oleĭnik solution to Cauchy data of type C1.A1 is examined below.

Let $\{a,b\}$ and $\{c,d\}$ be rarefaction intervals of type C1.A1. Consider maps $h_l(x_l,x_0,a;b;x)$ and $h_r(x_0,x_r,c,d;x)$ as in (2.7). Construct the rarefaction fans determined by $h_l(x)$ and $h_r(x)$. Then through each point $p\equiv(t,x)$ in the plane such that

$$x_0+f'(c)t\leqq x\leqq x_0+f'(b)t$$

there passes a unique rarefaction wave originating from the interval $[x_l,x_0]$ and a unique rarefaction wave originating from the interval $[x_0,x_r]$, thus defining respectively the unique values $u_l(p)$ and $u_r(p)$.

Consider the curve $(t,x(t))$ defined implicitly by

$$x(t)=x_0+\int_0^t \frac{dx}{dt}\,dt, \tag{2.10}$$

where

$$\frac{dx}{dt}=\frac{f(u_l(t))-f(u_r(t))}{u_l(t)-u_r(t)}, \tag{2.11}$$

with $u_l(t)$ and $u_r(t)$ determined from

$$x(t)=h_l^{-1}(x_l,x_0,a,b;u_l(t))+f'(u_l(t))t, \tag{2.12}$$

$$x(t)=h_r^{-1}(x_0,x_r,c,d;u_r(t))+f'(u_r(t))t. \tag{2.13}$$

We remark that for $\{a,b\}$ and $\{c,d\}$ of type C1.A1, the set of equations (2.10) through (2.13) are well defined for all t and the curve $(t,x(t))$ is smooth.

PROPOSITION 2.5. *For the curve* $(t,x(t))$ *defined by* (2.10) *through* (2.13):

1) $du_l(t)/dt<0$, $du_r(t)/dt>0$, $\forall t>0$.

2) *There exists* $g\in[c,b]$ *such that* $u_l(t)\to g$, $u_r(t)\to g$ *as* $t\to\infty$.

3) *The curve defined in* (2.10) *through* (2.13) *considered as a curve of points of jump* $u_l(t)\to u_r(t)$ *obeys* (1.4) *and* (1.5).

Proof. Note

$$\begin{aligned} &f''(u_l(t))>0, \qquad \big(h_l^{-1}(u)\big)'>0 \quad \forall u_l(t) \text{ on } [a,b],\\ &f''(u_r(t))>0, \qquad \big(h_r^{-1}(u)\big)'>0 \quad \forall u_r(t) \text{ on } [c,d]. \end{aligned}$$

Equations (2.12) and (2.13) yield

$$\big[f'(u_l(t))-f'(u_r(t))\big]t=h_r^{-1}(u_r(t))-h_l^{-1}(u_l(t)). \tag{2.14}$$

For $t>0$, the positivity of the right-hand side of (2.14) implies

$$f'(u_l(t))-f'(u_r(t))>0. \tag{2.15}$$

By the requirement that $\{a,b\}$ and $\{c,d\}$ be of class C1.A1, (2.15) implies (using 2.11)

$$f'(u_l(t))>\frac{dx}{dt}>f'(u_r(t)). \tag{2.16}$$

Therefore, the time derivatives of (2.12) and (2.13),

$$\frac{dx}{dt} = \left[\left(h_l^{-1}(u_l)\right)' + f''(u_l)t\right]u_l'(t) + f'(u_l), \tag{2.17}$$

$$\frac{dx}{dt} = \left[\left(h_r^{-1}(u_r)\right)' + f''(u_r)t\right]u_r'(t) + f'(u_r), \tag{2.18}$$

lead to the conclusion

$$u_l'(t) < 0, \qquad u_r'(t) > 0 \quad \forall t. \tag{2.19}$$

Further (2.16) and (2.19) imply the existence of $g \in [c,b]$ such that as $t \to \infty$,

$$u_l(t) \to g, \quad u_r(t) \to g, \quad \frac{dx}{dt} \to f'(g).$$

By construction, the curve $(t,x(t))$ considered as a curve of points of jump obeys (1.4). It is easy to verify that the entropy condition (1.5) is also satisfied. From Proposition 2.5 note that the strength of the shock decreases monotonically to zero as $t \to \infty$. □

All rarefaction waves originating in the interval

$$h_l^{-1}(g) \leqq x \leqq h_r^{-1}(g)$$

for the construction in Proposition 2.5 intersect the curve $(t,x(t))$. Terminate these waves at the curve. All rarefaction waves originating in the intervals

$$h_l^{-1}(a) \leqq x \leqq h_l^{-1}(g),$$
$$h_r^{-1}(g) \leqq x \leqq h_r^{-1}(d),$$

propagate unimpeded for all $t > 0$. The rarefaction fans and shock curve thus defined by this construction shall be said to be *determined by the functions* $h_l(x_l, x_0, a, b; x)$ *and* $h_r(x_0, x_r, c, d; x)$.

PROPOSITION 2.6. *Let* $\{a,b\}$ *and* $\{c,d\}$ *be as in* C1.A1. *Then the generalized Oleĭnik solution* $u(t,x)$ *to* (2.8) (2.9) *is given by*:

the constant state $u = a$ *for* $x \leqq x_l + f'(a)t$, $t \geqq 0$;

the shock curve and rarefaction fans determined by $h_l(x)$ *and* $h_r(x)$ *for* $x_l + f'(a)t < x < x_r + f'(d)t$, $t \geqq 0$;

the constant state $u = d$ *for* $x_r + f'(d)t \leqq x$, $t \geqq 0$.

The proof follows immediately from Proposition 2.5. □

A sketch of this solution is given in Fig. 2.2.

The generalized Oleĭnik solutions to Cauchy data of types C1.A2 through C1.A4 have exactly the same structure as for C1.A1. For each, the strength of the single shock curve $(t,x(t))$ decreases monotonically to zero as $t \to \infty$, and $dx/dt \to f'(g)$ where for

C1.A2: $c < g \leqq d$,
C1.A3: $a < g \leqq d$,
C1.A4: $a < g \leqq b$.

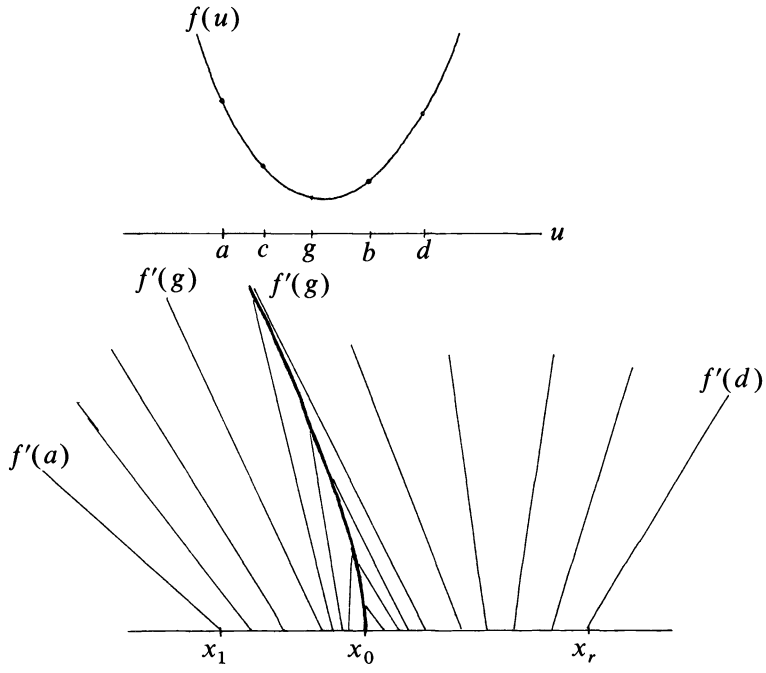

FIG. 2.2. *A sketch of the solution (lower figure) for a particular case of initial data (upper figure) for a generalized Riemann problem with f having no inflection point. The dark line is the shock wave. Important rarefaction lines have been labelled by their speeds.*

Class C3.S1: no inflection point. Let $\{a,b\}$ and $\{c,d\}$ be rarefaction intervals of type C3.S1 such that for every $v\in\{a,b\}$, $w\in\{c,d\}$.

$$E(v,w;u)=C(v,w;u).$$

Then $f'(v)>f'(w)$ for every choice v,w. Consider the curve $(t,x(t))$ implicitly defined by (2.10) through (2.13). Statement 1 of Proposition 2.5 follows from (2.14) through (2.19). However, the disjointness of the intervals implies there exists finite times $t_l>0$, $t_r>0$ such that $u_l(t_l)=a$ and $u_r(t_r)=d$. For all $t>t_l$ let $u_l(t)\equiv a$ and for all $t>t_r$ let $u_r(t)\equiv d$. With this extension, (2.10) through (2.13) are defined for all t. The curve $(t,x(t))$ thus defined, considered as a curve of points of jump $u_l(t)\to u_r(t)$ obeys the conditions (1.4) and (1.5). In contrast to class C1 data, the shock strength attains a constant value, $|a-d|$, as $t\to\infty$.

All rarefaction waves originating from the interval $[x_l,x_r]$ intersect the shock curve and are terminated there. The shock curve and rarefaction fans so defined (together with the bounding constant states $u=a$, $u=d$ will also be referred to as *determined by the functions* $h_l(x)$ *and* $h_r(x)$ since their definition is merely an extension of the usage defined after Proposition 2.5.

PROPOSITION 2.7. *Let* $\{a,b\}$ *and* $\{c,d\}$ *be disjoint rarefaction intervals on f such that for all* $v\in\{a,b\}$, $w\in\{c,d\}$

$$E(v,w;u)=C(v,w;u).$$

Then the generalized Oleĭnik solution to (2.8) (2.9) *is given by constructing the shock curve and rarefaction fans determined by* $h_l(x_l,x_0,a,b;x)$ *and* $h_r(x_0,x_r,c,d;x)$.

Proof. The above construction proves this proposition for rarefaction intervals in class C3.S1, where the condition $f''>0$ was used implicitly in (2.17) and (2.18). With trivial modifications, analogous arguments can be used to prove this proposition for appropriate data in classes C3 and C4.

Class C3.S2: *no inflection point.* Data of class C3.S2 insures $f'(b)\leqq f'(c)$.

PROPOSITION 2.8. *Let* $\{a,b\}$ *and* $\{c,d\}$ *be rarefaction intervals of* f *of class* C3. *Further assume* $f'(b)\leqq f'(c)$. *Then the generalized Oleĭnik solution* $u(t,x)$ *to* (2.8) (2.9) *is*:

the constant state $u(t,x)=a$ *for* $x<x_l+f'(a)t$, $t\geqq 0$;

the rarefaction wave determined by $h_l(x_l,x_0,a,b;x)$ *for*

$$x_l+f'(a)t<x<x_0+f'(b)t, \qquad t\geqq 0;$$

the Oleĭnik solution to $\{b,c\}$ *centered on* x_0 *for* $x_0+f'(b)t<x<x_0+f'(c)t$, $t\geqq 0$;

the rarefaction wave determined by $h_r(x_0,x_r,c,d;x)$ *for*

$$x_0+f'(c)t<x<x_r+f'(d)t, \qquad t\geqq 0,$$

and the constant state $u(t,x)=d$ *for* $x<x_r+f'(d)t$, $t\geqq 0$.

Proof. The proof is trivial; the condition $f'(b)\leqq f'(c)$ guarantees that the rarefaction waves determined by h_l and h_r do not interact.

Thus all solutions for allowed Cauchy data with f restricted to have no inflection point are piecewise smooth, with at most a single shock and at most a single irregular point at $(t=0,x=x_0)$.

f has one inflection point. Restriction of f to a single inflection point implies initial data from subgroups S3 or S4 of C3 and C4. We study data of C3.S3 and C3.S4; the proofs for C4.S3 and C4.S4 follow analogously.

Class C3.S3.

LEMMA 2.9. *Let* f, $\{a,b\}$, *and* $\{b^*,a^*\}$ *be chosen such that*: $\{a,b\}$ *is a rarefaction interval of* f *on which* $f''(u)>0$, $\{b^*,a^*\}$ *is a rarefaction interval of* f *on which* $f''(u)<0$, $a^*<b$, *and*

$$E(b,b^*;u)=C(b,b^*;u), \quad f'(b^*)=\frac{dC(b,b^*;u)}{du},$$
$$E(a,a^*;u)=C(a,a^*;u), \quad f'(a^*)=\frac{dC(a,a^*;u)}{du}.$$

For every $v\in\{a,b\}$ *there exists* $w(v)\in\{b^*,a^*\}$ *such that*

$$E(v,w(v);u)=C(v,w(v);u), \qquad f'(w(v))=\frac{dC(v,w(v);u)}{du}.$$

Then

1) $w(v)$ *is a* 1-1 *map from* $\{a,b\}$ *onto* $\{b^*,a^*\}$,

2) $f''(w(v))dw(v)/dv=(f'(w(v))-f'(v))/(w(v)-v)$.

Proof. 1) This follows from the definition of $w(v)$.

2) For all $v\in(a,b)$, δv sufficiently small,

$$f(w(v))-f(v)=f'(w(v))[w(v)-v], \tag{2.20}$$
$$f(w(v+\delta v))-f(v+\delta v)=f'(w(v+\delta v))[w(v+\delta v)-v-\delta v]. \tag{2.21}$$

Subtracting (2.20) from (2.21), arranging terms and taking $\delta v \to 0$

$$f'(w(v))\frac{dw(v)}{dv} - f'(v) = f''(w(v))\frac{dw(v)}{dv}w(v) + f'(w(v))\frac{dw(v)}{dv} - f''(w(v))\frac{dw(v)}{dv}v - f'(w(v)),$$

from which the conclusion 2) follows. □

Let $\{a,b\}$ and $\{b^*,a^*\}$ be as in Lemma 2.9. Let $h_l(x_l,x_0,a,b;x)$ be the usual map from the rarefaction interval $\{a,b\}$ to $[x_l,x_0]$. Consider the curve $(t,x(t))$ defined by

$$x(t) = x_0 + \int_0^t \frac{dx}{dt}\,dt, \tag{2.10}$$

$$\frac{dx(t)}{dt} = f'(w(u_l(t))), \tag{2.22}$$

with $w(u_l(t))$ defined in Lemma 2.9 and $u_l(t)$ defined by

$$x(t) = h_l^{-1}(x_l,x_0,a,b;u_l(t)) + f'(u_l(t))t. \tag{2.12}$$

There exists a finite time $t_l > 0$ at which $u_l(t_l) = a$ and

$$\frac{dx}{dt} = f'(w(a)) = f(a^*).$$

For every $t > t_l$ let $u_l(t) = a$. Then (2.10), (2.12) and (2.22) are defined for all t.

PROPOSITION 2.10. *The curve defined by* (2.10), (2.12) *and* (2.22) *considered as a curve of points of jump* $u_l \to w(u_l)$ *obeys* (1.4) *and* (1.5).

Proof. Follows from the construction. □

Construct the rarefaction fan determined by h_l. If a wave from this fan intersects the above shock curve, terminate the wave on the curve. For a point $(t_b,x(t_b))$ on this shock curve where $0 \leqq t_b \leqq t_l$, there exists a uniquely defined $u_r(t_b) = w(u_l(t_b))$. Also note from (2.22) and Lemma 2.9

$$x''(t) = f''(w(u_l))w'(u_l)u_l'(t) = \frac{f'(w(u_l)) - f'(u_l)}{w(u_l) - u_l}u_l'(t) < 0. \tag{2.23}$$

The rarefaction fan determined by this curve can therefore be constructed. Note further that the "left bounding" wave $(a^*,t,x(t))$ of the fan propagates parallel to the shock curve.

The two rarefaction fans and shock wave, together with the bounding constant state $u = a$, thus constructed from (2.10), (2.12), (2.22) and (2.23) shall be denoted *as determined by the function* $h_l(x)$ *and the state* $u = b^*$.

Let f have a single inflection point and $\{a,b\}$ and $\{c,d\}$ be rarefaction intervals of type C3.S3. Then there exists a rarefaction interval $\{b^*,a^*\}$ as described in Lemma 2.9. Three possibilities exist for the orientation of $\{c,d\}$ with respect to $\{b^*,a^*\}$:

Case 1. $\{c,d\}$ and $\{b^*,a^*\}$ are disjoint with $d \geqq a^*$.

Case 2. $\{c,d\}$ and $\{b^*,a^*\}$ are disjoint with $c \leqq b^*$.

Case 3. $\{c,d\}$ and $\{b^*,a^*\}$ are not disjoint.

For the case $d \geqq a^*$, the generalized Oleĭnik solution $u(t,x)$ to (2.8) (2.9) is given by Proposition 2.7.

For the case $c \leqq b^*$, the generalized Oleĭnik solution $u(t,x)$ to (2.8) (2.9) is given by the following:

The constant state $u=a$, two rarefaction fans and the shock curve determined by the function $h_l(x)$ and the state $u=b^*$ for $x \leqq f'(b^*)t$, $t>0$.

The rarefaction wave determined at x_0 by the interval $\{c,b^*\}$ for $f'(b^*)t \leqq x \leqq f'(c)t$, $t>0$.

The rarefaction wave determined by $h_r(x)$ for $f'(c)t \leqq x \leqq f'(d)t$, $t>0$.

The constant state $u=d$ for $f'(c)t \leqq x$, $t>0$.

This solution is sketched in Fig. 2.3.

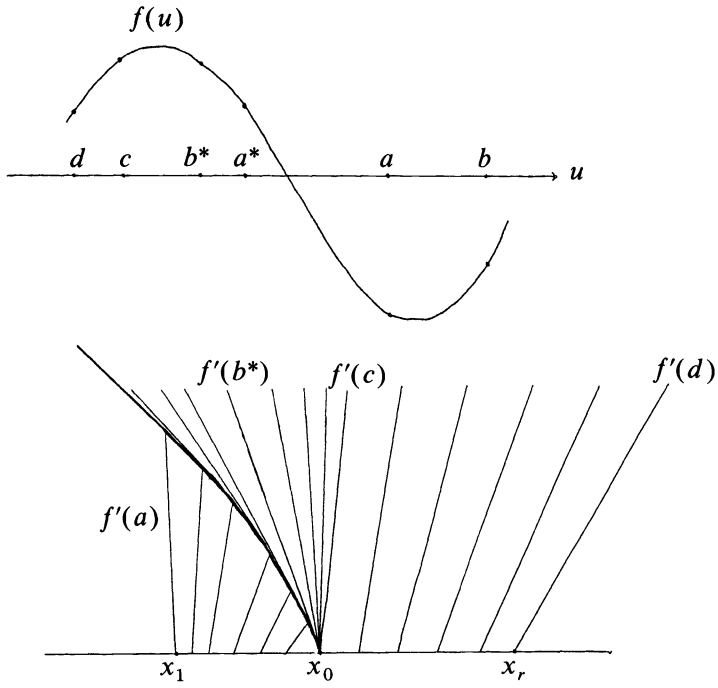

FIG. 2.3. *A sketch of the solution (lower figure) for a particular case of initial data (upper figure) for a generalized Riemann problem with f having a single inflection point. The dark line is the shock wave. Important rarefaction lines have been labelled by their speeds.*

For the case in which $\{c,d\}$ and $\{b^*,a^*\}$ are not disjoint we remark that the generalized Oleĭnik solution can be described by a solution similar to case 1 above for $0 \leqq t \leqq t_g$ and by a solution similar to case 2 for $t_g < t$. The time t_g is determined by the propagation of a rarefaction wave for some state $u=g$ where $g \in \{b^*,a^*\} \cap \{c,d\}$.

Class C3.S4. Lemma 2.9 and Proposition 2.10 can be written analogously for data of type C3.S4, with the arguments revolving around an interval $\{c^*,d^*\}$. Again the construction of a solution to the generalized Riemann problem can be broken into three cases and dealt with as above.

The solutions for classes C4.S3 and C4.S4 follow in the same manner. Thus we have shown that the solutions to the generalized Riemann problem for f having at most a single inflection point are piecewise smooth and consist of at most a single shock wave and at most a single irregular point (at x_0).

f has two inflection points. In the interest of brevity, we omit the solution for the case of f having two inflection points. The method of proof is repetitive to that presented above. The proof shows that in addition to solutions with a single shock, either two shock waves can be present for all $t>0$ or three shock waves can appear in the solution (i.e., a single shock which is present for $0 \leqq t \leqq t_s$ which then "splits", via interaction with rarefaction waves, into two shocks which are present for $t_s \leqq t$).

2.2. A conjecture on loss of piecewise smoothness for more than two inflection points. The constructive proof given for Theorem 2.3 is not readily extendable to f having three inflection points since the number of cases to be considered is large. In fact, we argue that for $f(u)$ having three or more inflection points, the solution need not be piecewise smooth. An example is sketched below in which a solution having a countably infinite number of arbitrarily small smooth pieces may occur.

Let $\{a,b\}$ and $\{c,d\}$ be rarefaction intervals of $f(u)$ as illustrated in the lower left hand side of Fig. 2.4. $f(u)$ has three inflection points in the interval $[d,b]$. Consider the corresponding generalized Riemann problem (2.8), (2.9). Using the construction methods of the proof of Theorem 2.3, it is seen that the generalized Oleĭnik solution initially has a single shock curve determined by $h_l(x)$ and $h_r(x)$ starting at x_0 with slope $dC(b,c;u)/du$. The rates at which the left and right states $u_l(t)$ and $u_r(t)$ change

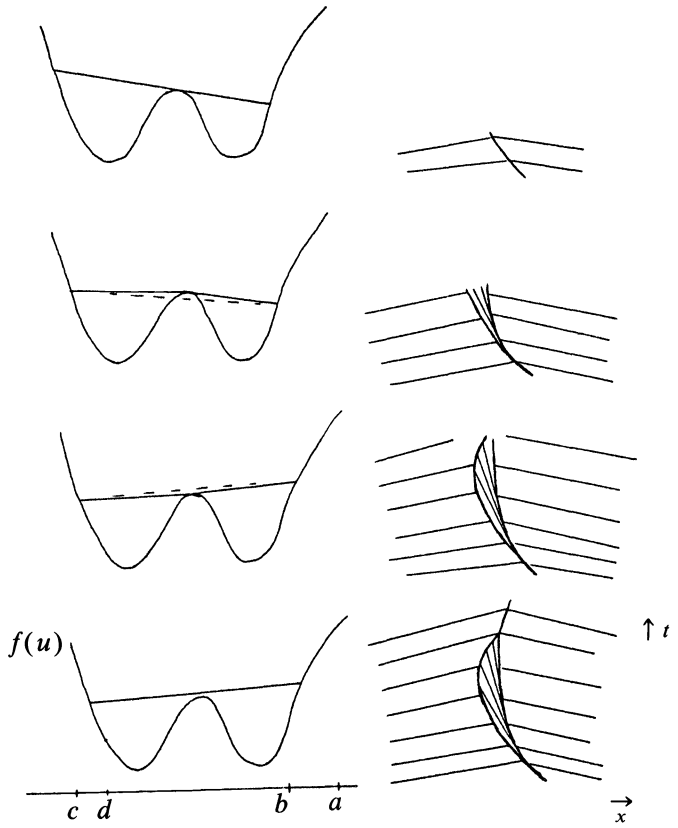

FIG. 2.4. *Formation of a single "bubble" in a solution. The dotted lines in the middle diagrams on the right emphasise the nonlinearity of the convex envelope.*

along the shock curve depend on the functions $h_l(x)$ and $h_r(x)$. Given $\{c,d\}$ (and hence $\{a,b\}$), $[x_0,x_r]$ and $h_r(x)$, it is possible to determine $h_l(x)$ and $[x_l,x_r]$ such that for all time $t>0$

$$E(u_l(t),u_r(t);u)=C(u_l(t),g(t);u)\cup C(g(t),u_r(t);u), \tag{2.24}$$

where

$$f'(g(t))=\frac{\partial C(u_l(t),g(t);u)}{\partial t}=\frac{\partial C(g(t),u_r(t);u)}{\partial t}. \tag{2.25}$$

The convex envelope (2.24), though consisting of two chords, defines a single shock line and represents a metastable balance between a single and a two shock configuration. This construction can be perturbed to create a single "bubble"; that is a time interval $t_1<t<t_2$ over which the shock separates into two shocks as is illustrated on the right in Fig. 2.4. This is accomplished by adjustment of the rate at which the rarefaction waves (i.e. adjustment of the respective h functions) enter the shock waves from the extreme left and right. The above construction can be iterated to produce a second bubble starting at t_3 by adjusting (slowing) the rate $h_l'(x)$ appropriately. It has not as yet been determined if, for a given set of intervals $\{a,b\}$, $\{c,d\}$, $[x_l,x_0]$, and $[x_0,x_r]$, it is possible to construct a sequence of generalized Riemann problems, where the ith problem is characterized by the choice of functions $h_l^i(x)$, $h_r^i(x)$, for which the solution to the ith problem has i such bubbles. If this was possible, the solution to the limiting problem obtained as $i\to\infty$ would not be piecewise smooth. We note it is certainly possible to create an infinite sequence of such problems if only $\{a,b\}$, $\{c,d\}$, and $[x_r,x_0]$ are held constant and the interval $[x_0,x_l]$ is allowed to vary with i. It remains to be proven that such a sequence of problems can be chosen such that $[x_0,x_l]$ also remains fixed.

3. The generalized Riemann problem for initial data with multiple points of discontinuity. Let $x_l<x_0<x_1<\cdots<x_n<x_r$. Consider (2.8) with initial data

$$u(0,x)=\begin{cases} u_l, & x<x_l,\\ h_l(x_l,x_0,u_l,u_0;x), & x_l<x<x_0,\\ h_j(x_j,x_{j+1},u_j,u_{j+1};x), & x_j<x<x_{j+1}, \quad j=0,1,\cdots,n-1,\\ h_r(x_n,x_r,u_n,u_r;x), & x_n<x<x_r,\\ u_r, & x_r\leqq x, \end{cases} \tag{3.1}$$

where $h_l(x)$, $h_j(x)$, $h_r(x)$ are as in (2.7), and $\{u_l,u_0\}$, $\{u_0,u_1\},\cdots,\{u_n,u_r\}$ are rarefaction intervals of f. The Cauchy problem (2.8), (3.1) is an extension of the definition of the generalized Riemann problem to include multiple initial discontinuities.

THEOREM 3.1. *The solution to* (2.8) *with initial data* (3.1) *for* $f\in C^2$: $\mathbf{R}\to\mathbf{R}$ *having at most one inflection point is piecewise smooth. There are no more than* $(n+1)!$ *shocks in the solution and no more than* $(n+1)!$ *irregular points.*

The restriction to either zero or one inflection point for $f(u)$ guarantees that when two shocks interact a single shock is produced. Thus given a finite number m of initial discontinuities, the number of shocks in the solution remains bounded by $m!$ and the solution will be piecewise smooth. For f having two or more inflection points there is no a priori bound on the growth of the number of shocks in time since an interaction of two (incoming) shocks can conceivably give rise to two or more (outgoing) shocks (or to

a single shock which later splits via interaction with rarefaction waves into two or more shocks) and the possibility of generating a solution that is richer in structure than piecewise smooth exists. It is only through the decrease in variation of the solution (ie. the decrease in shock strength with in time) that such a bound may be possible. Such a bound on the growth rate of shock number combined with a general statement for the >2 inflection point case of §2 is required for a more general statement on the piecewise smoothness of the solution to the generalized Riemann problem for initial data with multiple points of discontinuity.

Theorem 3.1 will be proven by finite induction on n in (3.1). The case $n=0$ is the generalized Riemann of §2.1. The case $n=1$ is given below. It suffices to illustrate the salient points of the general induction step.

Proof of Theorem 3.1 *for* $n=1$. Consider (2.8) under three possible cases of Cauchy data:

$$u(x)=\begin{cases} u_l, & x\leqq x_l,\\ h_l(x_l,x_0,u_l,u_0;x), & x_l<x<x_0,\\ h_0(x_0,x_1,u_0,u_1;x), & x_0<x<x_1,\\ u_1, & x_1\leqq x,\end{cases} \tag{3.2}$$

$$u(x)=\begin{cases} u_0, & x\leqq x_0,\\ h_0(x_0,x_1,u_0,u_1;x), & x_0<x<x_1,\\ h_r(x_1,x_r,u_1,u_r;x), & x_1<x<x_r,\\ u_r, & x_r\leqq x,\end{cases} \tag{3.3}$$

$$u(x)=\begin{cases} u_l, & x\leqq x_l,\\ h_l(x_l,x_0,u_l,u_0;x), & x_l<x<x_0,\\ h_0(x_0,x_1,u_0,u_1;x), & x_0<x<x_1,\\ h_r(x_1,x_r,u_1,u_r;x), & x_1<x<x_r,\\ u_r & x_r\leqq x.\end{cases} \tag{3.4}$$

From §2, construct the solutions to (3.2) and (3.3), denoting them $u_L(t,x)$ and $u_R(t,x)$ respectively. Denote the solution to (3.4) as $u_C(t,x)$. The following four (exhaustive but not mutually exclusive) possibilities exist for the solutions u_L and u_R:[4]

P1) There exists a rarefaction wave $(v,0,x_v)$ common to both solutions with $v\in\{u_0,u_1\}$, $x_v\in(x_0,x_1)$ which propagates unimpeded for all t.

P2) Both u_L and u_R have a shock curve and there exists a point $p_2=(t_2,x_2)$ common to the shock curve of each solution for some $t_2>0$.

P3) u_L has a shock curve, denoted $(u_l^1(t),u_r^1(t),x)$ and $u_r^1(t_3)=u_1$ for $t_3>0$.

P4) u_R has a shock curve, denoted $(u_l^2(t),u_r^2(t),x)$ and $u_r^2(t_4)=u_0$ for some $t_4>0$.

---

[4]As x_0 and x_1 are spatially separated, intuitively M_C is expected to be composed thusly:

$M_C=$ left piece of $M_L\cup$ piece due interaction of waves x_0 and $x_1\cup$ right piece of M_R.

Conditions P1 through P4 characterize the interactions between waves from x_0 and x_1.

If P1 holds (if neither solution has a shock wave, then condition P1 holds) then

$$u_C(x,t) \equiv \begin{cases} u_L(x,t) & \text{if } x \leqq x_v + f'(v)t, \\ u_R(x,t) & \text{if } x > x_v + f'(v)t, \end{cases} \tag{3.5}$$

is the unique solution to (2.8) (3.1) obeying (1.4) and (1.5).

If P1 does not hold let $t_{\min}$ denote the minimum of the existing values t_2, t_3, t_4.

If $t_{\min} = t_2$ then let $\Sigma_L^0 \equiv (u_l^0(t), u_r^0(t), 0, x_0)$ and $\Sigma_R^1 \equiv (u_l^1(t), u_r^1(t), 0, x_1)$ denote the shock waves propagating respectively from x_0 in u_L and x_1 in u_R. Then for $t \leqq t_2$

$$u_C(x,t) \equiv \begin{cases} u_L(x,t) & \text{if } x \leqq h_0^{-1}(v_2) + f'(v_2)t, \\ u_R(x,t) & \text{if } x > h_0^{-1}(v_2) + f'(v_2)t, \end{cases} \tag{3.6}$$

where $v_2 = u_r^0(t_2) = u_l^1(t_2)$ is in the interval $\{u_0, u_1\}$. For $t > t_2$, $u_C(x,t)$ is the generalized Oleĭnik solution to (2.8) with initial data (at t_2)

$$u(t_2,x) = \begin{cases} u_l, & x \leqq x_l^{t_2}, \\ h_l^{t_2}(x_l^{t_2}, x_2, u_l, u_l^1(t_2); x), & x_l^{t_2} < x < x_2, \\ h_r^{t_2}(x_2, x_r^{t_2}, u_r^2(t_2), u_r; x), & x_2 < x < x_r^{t_2}, \\ u_r, & x_r^{t_2} \leqq x, \end{cases}$$

where

$$x_l^{t_2} = x_l + f'(u_l)t_2, \qquad x_r^{t_2} = x_r + f'(u_r)t_2.$$

$h_l^{t_2}(x)$ is defined by the rarefaction interval $\{u_l, u_l^1(t_2)\}$ where $u_l^1(t_2)$ is the left limit of u at (t_2, x_2) for the shock curve Σ_0 in u_C propagating from x_0 in (3.6). (Σ_0 is identical with Σ_L^0 for $0 \leqq t \leqq t_2$.) Similarly $h_r^{t_2}(x)$ is defined by the rarefaction interval $\{u_r, u_r^2(t_2)\}$ where $u_r^2(t_2)$ is the right limit of u at (t_2, x_2) for the shock curve Σ_1 propagating from x_1. (Σ_1 is identical with Σ_L^1 for $0 \leqq t \leqq t_2$.)

If $t_{\min} = t_3$, let $x_3 = x_1 + f'(u_1)t$. There exist two possibilities for the solution u_C if u_R has a shock wave. (If u_R has no shock the solution for u_C is deduced easily from the discussion below.) These two possibilities are either that u_R has a leftmost rarefaction fan

a) centered at the point x_1 (Fig. 3.1a),

b) determined by the shock wave Σ_1 originating at $(0, x_1)$ (Fig. 3.1b).

We note that in either case this leftmost rarefaction fan in u_R is a smooth continuation of the rightmost rarefaction fan in the solution u_L for $t \leqq t_3$. For $t \leqq t_3$, let

$$u_C(t,x) = \begin{cases} u_L(t,x), & x \leqq x_1 + f'(u_1)t, \\ u_R(t,x), & x \geqq x_1 + f'(u_1)t. \end{cases} \tag{3.7}$$

At (t_3, x_3) the shock Σ_0 originating from $(0, x_0)$ encounters the first rarefaction wave from the solution for $x > x_3$. For case a) above, the shock Σ_0 is determined for $t > t_3$ by the rarefaction fan determined by $h_l(x_l, x_0, u_l, u_0; x)$ and the rarefaction fan centered on $(0, x_1)$. Denote the curve followed by the shock Σ_0 for $t > t_3$ as $(t, x_{\Sigma_0}(t))$. Then, for case a),

$$u_C(t,x) = \begin{cases} u_L, & x < x_{\Sigma_0}(t), \\ u_R, & x > x_{\Sigma_0}(t), \end{cases} \qquad t > t_3. \tag{3.8}$$

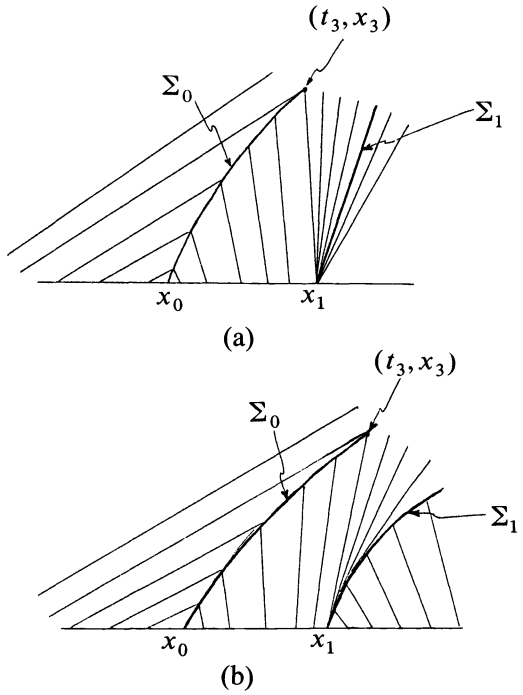

FIG. 3.1. *Two possibilities encountered under case* P3 *described in the text. Dark lines are shock waves, light lines are rarefaction waves.*

In case b) the shock Σ_0 is determined for $t > t_3$ by the rarefaction fan determined by $h_l(x_l, x_0, u_l, u_0; x)$ and the rarefaction fan determined by the shock line Σ_1. In either case a) or b), the resulting shock, Σ_0 hits the shock Σ_1 at some time $t_5 > t_3$ or it does not. If it does not, the solution for all $t > t_3$ is given by (3.8). If it does, the solution for $t_3 \leqq t \leqq t_5$ is given by (3.8) and for $t \geqq t_5$ by the solution to a generalized Riemann problem of the type discussed in §2.1. It is to be noted that the solution is C^1 continuous at t_3 (ie. all waves propagate continuously from $t_3 - \varepsilon$ to $t_3 + \varepsilon$ and all waves except the interacting shock lines are C^1 continuous at t_5.

If $t_{\min} = t_4$, an analogous construction to that for case P3 holds.

In all cases the constructed solution u_C is thus piecewise smooth. The general induction step for Theorem 3.1 follows the above argument with a more complicated notation. □

4. The two-dimensional Riemann problem. For convenience we shall use the notation $f_1 \equiv f$, $f_2 \equiv g$, $x_1 \equiv x$, $x_2 \equiv y$ for the discussion in two spatial dimensions.

DEFINITION 4.1. The Cauchy problem (1.1) with initial data piecewise constant on a finite number of wedges focused on a single point in the x, y plane shall be referred to as the *two-dimensional Riemann problem*. Without loss of generality, this point can be taken to be the point $x = 0$, $y = 0$.

For the case $g \equiv f$, under the 45° rotation $2\xi = x + y$, $2\eta = y - x$, (1.1) becomes

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial \xi} = 0. \tag{4.1}$$

From (4.1) we see that the solution can be obtained along each $\eta = constant$ plane independent of other η. In particular, this implies the solutions obtained in the $\eta < 0$ half space can be obtained independently of the solutions in the $\eta > 0$ half; by the symmetry of the problem, no new solutions will be found in the $\eta < 0$ half space that are not found in the upper. We therefore restrict our discussion to the half space $\eta > 0$ ($y > x$). The solution in the plane $\eta = 0$ is discussed in Lemma 4.4.

In the $\eta > 0$ half space, the solution in each $\eta = constant$ plane is just that for a generalized Riemann problem in one dimension.

LEMMA 4.2. *Let $u(t,\xi,\eta_0)$ denote the generalized Riemann problem solution in the $\eta = \eta_0 > 0$ plane. Then the solution $u(t,\xi,\eta_1)$ to the generalized Riemann problem in the η_1 plane ($\eta_1 > 0$) is just a similarity solution of $u(t,\xi,\eta_0)$ given by*

$$u(ct, c\xi + b(c), \eta_1) = u(t,\xi,\eta_0), \tag{4.2}$$

where $c = \eta_1/\eta_0$.

Proof. If $v_0(\xi)$ is the initial data for the generalized Riemann problem on η_0, then $w_0(\zeta \equiv c\xi + b(c)) = v_0(\xi)$ is the initial data for the generalized Riemann problem on η_1 where $c = \eta_1/\eta_0$ and $b(c)$ is given by the wedge pattern of the two-dimensional Riemann problem. Further, the function $u(\tau \equiv ct, \zeta \equiv c\xi + b, \eta_1 \equiv c\eta_0) \equiv u(t,\xi,\eta_0)$ is a weak solution of the generalized Riemann problem on η_1 having initial data w_0. □

Thus the solution to the two-dimensional Riemann problem (4.1) in the $\eta > 0$ half space is found from a mapping M: $\mathbf{R}^1 \to \mathbf{R}^2$ which is similarity transformation in t,ξ,η and therefore continuous onto the domain $t > 0$, ξ, $\eta > 0$.

THEOREM 4.3. *The unique (in the sense of Kružkov) solution in the plane $\eta > 0$ ($y > x$), to (1.1) with initial data that is piecewise constant on a finite number of wedges focused on a single point in the plane, with $f_1 \equiv f_2 \equiv f$, $f \in C^2$: $\mathbf{R} \to \mathbf{R}$, f having at most one inflection point, is*

a) *piecewise smooth,*

b) *composed of nonlinear waves and constant states which are the images under a similarity map M defined by Lemma 4.2 of the rarefaction and shock waves and constant states of a generalized Riemann problem in one dimension,*

c) *composed of curves of irregular points corresponding to images under the map M of the irregular points in the one-dimensional Riemann problem.*

Proof. Follows immediately from Lemma 4.2 and Theorem 3.1. □

LEMMA 4.4. a) *If the half line $\eta = 0$, $\xi < 0$ is not a line of discontinuity of the initial data (i.e., is not a wedge line) the waves incident upon the corresponding half plane $t > 0$, $\xi < 0$, $\eta = 0$ are continuous across the half plane.*

b) *If the half line $\eta = 0$, $\xi < 0$ is a line of discontinuity (constant jump) of the initial data, it remains a half plane $t > 0$, $\xi < 0$, $\eta = 0$ of (in general variable) jump discontinuity in the solution.*

Proof. a) Follows from taking the limit $\eta \to 0$ of the solution in either half plane.

b) Follows from taking the limit of solutions for which the wedge line in the initial data is displaced slightly from the $\eta = 0$ axis. □

Similar statements hold for the half line $\eta = 0$, $\xi > 0$.

Although the map M provides a means of constructing the solution to the two-dimensional Riemann problem, it is not a convenient method of doing so. In particular it is a method that will not generalize to cases $f \neq g$ where no appeal to a one-dimensional analysis can be made. We propose that the correct method of dealing with the general solution to the two-dimensional Riemann problem is to identify the general

two-dimensional nonlinear waves. In [4] we identify these waves for the case $f \equiv g$ and use the construction method initiated by Guckenheimer [1] and Wagner [6] to piece these waves together into entropy obeying solutions.

5. Concluding remarks. The condition $f_1 \equiv f_2 \equiv f$, $f \in C^2$: $\mathbf{R} \to \mathbf{R}$, f having at most one inflection point has been shown to be sufficient to guarantee that the solution to the two-dimensional Riemann problem is piecewise smooth. A construction has been presented detailing a presumed mechanism for loss of piecewise smoothness if f has three or more inflection points.

The Riemann problem in one dimension has been generalized to include a finite number of discontinuities and smooth "rarefaction" variation in the initial data. Sufficiency conditions based upon the number of inflection points in the convection function f have been obtained which guarantee piecewise smoothness of the solution to the generalized problem.

Acknowledgments. The author wishes to thank Professor James Glimm for suggesting this problem and for his guidance on several issues of this paper. Thanks also to Jonathan Goodman for several helpful discussions.

ON THE IDENTIFICATION OF PARAMETERS IN GENERAL VARIATIONAL INEQUALITIES BY ASYMPTOTIC REGULARIZATION*

K.-H. HOFFMANN† AND J. SPREKELS†

Abstract. A method for the identification of parameters in a general class of variational inequalities from the knowledge of the solutions is proposed. The method consists of embedding the original problem into a sequence of regularizing equations. An a priori estimate is fundamental to prove that limit points of the regularizing sequence are solutions of the original problem. The method is applied to various applications, in particular, to the dam problem and to linear elasticity with friction.

Key words. distributed parameter identification, variational inequalities, regularization, inverse problems

1. Introduction. Starting point for the present paper was the following identification problem which is considered in [3]:

(1.1) Given $u^* \in \mathring{H}^1(\Omega) \cap H^{1,\infty}(\Omega)$ and $f^* \in H^{-1}(\Omega)$, find a matrix $a^* = (a_{ij}^*)$ with entries $a_{ij}^* \in L^\infty(\Omega)$, such that $-\nabla \cdot (a^* \nabla u^*) = f^*$.

This problem is closely related to a problem which occurs in oil field exploration (see [4]). In [3] a method for the solution of (1.1) was proposed which consists in trying to obtain (1.1) as asymptotic steady-state of a regularizing system of approximating parameter-dependent problems. The basic idea was to construct the regularized equations in such a way that a Lyapunov-type a priori estimate holds from which convergence results can be derived.

In [3] this technique was specified and applied numerically. A slightly different regularization was used in [6]. In [7] the above idea was applied to compartment models for ordinary differential equations.

In this paper we give a general functional analytic framework for the technique under which the results of [3], [6], [7] can be subsumed. Moreover, we show that the method may be used for identifying the system coefficients of various other problems involving partial differential equations, among those the problem of identifying the permeability matrix in the dam problem from measurements of the pressure and the problem of the coefficients of elasticity in linear elasticity from measurements of the displacements.

The paper is organized as follows. In §2 our method is formulated in functional analytic framework and is applied to general elliptic variational inequalities. Convergence and stability results are proved. The method used here differs slightly from that used in the previous papers [3], [6], [7]. In §3 we extend some of the results of §2 to the problem of identifying parameters in evolution equations. The concluding §4 brings various applications.

2. Stationary variational inequalities. We now define our general functional analytic setting. Let the separable and reflexive Banach space V be dense with continuous

*Received by the editors February 16, 1984, and in revised form February 14, 1985.
† Universität Augsburg, Memminger Strasse 6, 8900 Augsburg, West Germany.

embedding in the Hilbert space H. Then $V \subset H \subset V^*$ with dense and continuous embedding where V^* is the dual of V. The dual pairing between elements of V^* and V is denoted by $\langle \cdot, \cdot \rangle$. By C we denote some nonempty, closed and convex subset of V. Moreover, let X denote another Hilbert space with the inner product $[\cdot, \cdot]$. The norms of the above spaces are denoted by $\|\cdot\|_V$, $\|\cdot\|_H$, $\|\cdot\|_{V^*}$, $\|\cdot\|_X$. Finally, we assume that $(X_0, \|\cdot\|_{X_0})$ is another Banach space such that X_0 is a dense subspace of X.

We then consider the parameter identification problem:

(P) Given $u^* \in D(S) \cap C$ and $f^* \in V^*$, find $a^* \in X$ with $(a^*, u^*) \in D(A_2)$ such that there is a $w^* \in S(u^*)$ which satisfies the variational inequality

$$\langle w^* + A_1(a^*) + A_2(a^*, u^*) - f^*, v - u^* \rangle + \Psi(v) - \Psi(u^*) \geqq 0 \quad \forall v \in C. \tag{2.1}$$

Here and throughout we assume:

(A1) $S : D(S) \subset V \to 2^{V^*}$ is a maximal monotone graph with $u^* \in \operatorname{int} D(S)$.

(A2) $A_1 : X \to V^*$ is linear and bounded.

(A3) $A_2 : D(A_2) \subset X \times V \to V^*$ is a bilinear map such that

(i) $(X_0 \times V) \subset D(A_2)$,

(ii) $|\langle A_2(a,u), v \rangle| \leqq \gamma_1 \|a\|_{X_0} \|u\|_V \|v\|_V$, $\forall a \in X_0$, $u, v \in V$, for some $\gamma_1 > 0$.

(A4) $\Psi : V \to \mathbb{R}$ is continuous and convex.

Remark 1. $u^* \in \operatorname{int} D(S)$ implies that S is locally bounded at u^* (see [8, p. 31, Lemma 2.3]).

Remark 2. From (A3ii) follows that $A_2(a_n, u_n) \to A_2(a, u)$ weakly in V^* if $(a_n, u_n) \in X_0 \times V$ and $\|a_n - a\|_{X_0} \to 0$, $\|u_n - u\|_V \to 0$.

In §4 the above assumptions are verified for various applications. We assume:

(A5) (P) has at least one solution $a^* \in X_0$ such that $\langle A_2(a^*, u - v), u - v \rangle \geqq \delta \|u - v\|_V^2$, $\forall u, v \in C$, for some $\delta > 0$ (uniform monotonicity on C).

We now introduce a sequence of systems of variational inequalities the solutions of which shall for $n \to \infty$ converge to a solution of a finite-dimensional analogue of (P).

To this end, let V_N and W_M be finite-dimensional subspaces of V and X_0 such that:

(A6) $u^* \in V_N$.

(A7) $\langle A_1(a) + A_2(a, u), v \rangle = 0$, whenever $a \in W_M^{\perp}$, $u \in C$, and $v \in C - C$. Here $W_M^{\perp} := \{ z \in X_0 : [z, \eta] = 0 \ \forall \eta \in W_M \}$.

Whereas (A6) is easily verified, the compatibility condition (A7) is not obvious. We refer to §4.

Now let $\varepsilon > 0$ be arbitrary. For fixed $h > 0$ we consider the problem:

(P_h) Given $(a_0, u_0) \in W_M \times (D(S) \cap C \cap V_N)$, find $(a_n, u_n) \in W_M \times (D(S) \cap C \cap V_N)$ such that there exists $w_n \in S(u_n)$ $(n \in \mathbb{N})$ with

$$\left\langle \varepsilon \frac{u_{n+1} - u_n}{h} + w_{n+1} + A_1(a_{n+1}) + A_2(a_{n+1}, u_{n+1}) - f^*, v - u_{n+1} \right\rangle + \Psi(v) - \Psi(u_{n+1}) \geqq 0 \quad \forall v \in C \cap V_N, \tag{2.2}$$

$$\left[\frac{a_{n+1} - a_n}{h}, \eta \right] = \langle A_1(\eta) + A_2(\eta, u_{n+1}), u_{n+1} - u^* \rangle \quad \forall \eta \in W_M. \tag{2.3}$$

Let us postpone the question of solvability and assume that $\{(a_n, u_n)\}_{n \geqq 0}$ solves (P_h). We derive an a priori estimate which is fundamental for all subsequent considerations.

To this end, put $q_n := u_n - u^*$, $r_n := a_n - a^*$.

Substitution of $v := u^*$ into (2.2) and $v := u_{n+1}$ into (2.1) gives:

$$\left\langle \varepsilon \frac{q_{n+1}-q_n}{h} + w_{n+1} + A_1(a_{n+1}) + A_2(a_{n+1}, u_{n+1}) - f^*,\ q_{n+1} \right\rangle + \Psi(u_{n+1}) - \Psi(u^*)$$

$$\leqq 0 \leqq \Psi(u_{n+1}) - \Psi(u^*) + \left\langle w^* + A_1(a^*) + A_2(a^*, u^*) - f^*, q_{n+1} \right\rangle,$$

whence

$$(2.4) \quad 0 \geqq \left\langle \varepsilon \frac{q_{n+1}-q_n}{h},\ q_{n+1} \right\rangle + \delta \|q_{n+1}\|_V^2 + \left\langle A_1(r_{n+1}) + A_2(r_{n+1}, u_{n+1}),\ q_{n+1} \right\rangle,$$

where the monotonicity of S and (A5) were used. Let P denote the $[\cdot,\cdot]$-orthogonal projection onto the closed subspace W_M of X. Substitution of $\eta := a_{n+1} - Pa^*$ into (2.3) yields by (A7) and $a^* - Pa^* \in W_M^{\perp}$:

$$\begin{aligned} 0 &= \left[\frac{a_{n+1}-a_n}{h},\ r_{n+1} \right] + \left[\frac{a_{n+1}-a_n}{h},\ a^* - Pa^* \right] \\ &\quad - \left\langle A_1(r_{n+1}) + A_2(r_{n+1}, u_{n+1}),\ q_{n+1} \right\rangle \\ &\quad + \left\langle A_1(Pa^* - a^*) + A_2(Pa^* - a^*, u_{n+1}),\ q_{n+1} \right\rangle \\ &= \left[\frac{r_{n+1}-r_n}{h},\ r_{n+1} \right] - \left\langle A_1(r_{n+1}) + A_2(r_{n+1}, u_{n+1}) q_{n+1} \right\rangle. \end{aligned}$$

Addition to (2.4) gives:

$$0 \geqq \left\langle \varepsilon \frac{q_{n+1}-q_n}{h},\ q_{n+1} \right\rangle + \left[\frac{r_{n+1}-r_n}{h},\ r_{n+1} \right] + \delta \|q_{n+1}\|_V^2.$$

Hence, from standard arguments, for all $n \geqq 0$,

$$(2.5) \qquad \varepsilon \|q_{n+1}\|_H^2 + \|r_{n+1}\|_X^2 + 2\delta h \|q_{n+1}\|_V^2 \leqq \varepsilon \|q_n\|_H^2 + \|r_n\|_X^2,$$

and upon summation,

$$(2.6) \qquad \frac{\varepsilon}{2h} \|q_{n+1}\|_H^2 + \frac{1}{2h} \|r_{n+1}\|_X^2 + \delta \sum_{k=0}^{n} \|q_{k+1}\|_V^2 \leqq \frac{\varepsilon}{2h} \|q_0\|_H^2 + \frac{1}{2h} \|r_0\|_X^2.$$

Hence we have proved the a priori estimate

$$(2.7) \qquad \sup_{n \in \mathbb{N}} \left[\varepsilon \|q_n\|_H^2 + \|r_n\|_X^2 \right] + 2\delta h \sum_{k=1}^{\infty} \|q_k\|_V^2 \leqq C < \infty,$$

where C depends on ε, a_0, u_0, u^*, a^*, but not on h, V_N, W_M.

Remark 3. Note that (2.7) holds for any solution $a^* \in X_0$ such that $A_2(a^*, \cdot)$ is uniformly monotone on $C \cap V_N$.

THEOREM 2.1. *Let the assumptions* (A1)–(A7) *hold. Then there is an* $h_0 > 0$ *such that* (P_h) *has a solution* $\{(a_n, u_n)\}_{n \geqq 0}$ *whenever* $0 < h \leqq h_0$.

The proof uses the following general result on variational inequalities (see [8, p. 197, Satz 2.7]).

THEOREM 2.2. *Let* B *be a reflexive Banach space and* $K \subset B$, $K \neq \emptyset$, *be closed and convex. Let* $g : K \to \mathbb{R}$ *be convex and lower semicontinuous. Moreover, let* $P_1 : D(P_1) \subset B \to 2^{B^*}$ *be maximal monotone, and let* $P_2 : K \to B^*$ *be continuous, bounded, pseudomonotone and coercive with respect to* $\Theta \in B^*$. *Moreover, let the following conditions hold*:

$$(2.8) \qquad \operatorname{int} D(P_1) \cap D(\partial g) \neq \emptyset,$$

$$\partial(g+\chi_K)=\partial g+\partial\chi_K, \tag{2.9}$$

$$K\cap \operatorname{int} D(P_1+\partial g)\neq\varnothing. \tag{2.10}$$

Then there is a $u\in K$ *such that for some* $w\in P_1(u)$:

$$\langle w+P_2(u),\, v-u\rangle+g(v)-g(u)\geqq 0 \quad \forall v\in K. \tag{2.11}$$

(*The terms bounded, pseudomonotone, coercive have the usual meaning*; *cf.* [8]; χ_K *is the characteristic function of* K *and* ∂ *the subgradient*).

Proof of Theorem 2.1. Let $W_M := \operatorname{span}\{\Psi_1,\cdots,\Psi_M\}$ with $[\Psi_i,\Psi_j]=\delta_{ij}$, $\forall i,\ j$. We conclude inductively. So let (a_k,u_k), $0\leqq k\leqq n$, already be constructed. We consider:

$$\left[\frac{a-a_n}{h},\,\eta\right]-\langle A_1(\eta)+A_2(\eta,u),\, u-u^*\rangle=0 \quad \forall\eta\in W_M. \tag{2.12}$$

Given $u\in C$, (2.12) has the unique solution

$$a=a_n+h\sum_{k=1}^{M}\langle A_1(\Psi_k)+A_2(\Psi_k,u),\, u-u^*\rangle\Psi_k. \tag{2.13}$$

Hence the solution of (2.2), (2.3) is equivalent to finding $u\in D(S)\cap C\cap V_N$ such that with some $w\in S(u)$:

(2.14)

$$\left\langle \varepsilon\frac{u-u_n}{h}+w+A_1(a)+A_2(a,u)-f^*,\, v-u\right\rangle+\Psi(v)-\Psi(u)\geqq 0 \quad \forall v\in C\cap V_N,$$

with a given by (2.13).

We apply Theorem 2.2 with the following specifications:

$$B=V,\quad K=C\cap V_N,\quad P_1=S,\quad g(v)=\Psi(v)-\left\langle\frac{\varepsilon}{h}u_n+f^*,\, v\right\rangle,$$

$$P_2(u):=\frac{\varepsilon}{h}u+A_1(a_n)+h\sum_{k=1}^{M}\langle A_1(\Psi_k)+A_2(\Psi_k,u),\, u-u^*\rangle A_1(\Psi_k)$$

$$+A_2(a_n,u)+h\sum_{k=1}^{M}\langle A_1(\Psi_k)+A_2(\Psi_k,u),\, u-u^*\rangle A_2(\Psi_k,u).$$

K is closed and convex, and $u^*\in K$. P_1 is maximal monotone. By (A1), $u^*\in\operatorname{int} D(P_1)$ and $u^*\in D(\partial g)$ from the continuity of Ψ which yield (2.8). Moreover g and χ_K are proper convex functionals, and g is continuous at u^* which lies in the effective domains of g and χ_K. Hence (2.9) holds (see [8, p. 125, Satz 5.16]). Finally, $V=D(\partial g)$ and thus $D(P_1+\partial g)=D(P_1)$. Hence (2.10) follows from $u^*\in K\cap\operatorname{int} D(P_1)$.

It remains to show that P_2 has the required properties.

α) $P_2: K\to V^*$ is bounded: This follows from (A3ii) and:

$$\|P_2(u)\|_{V^*}\leqq\frac{\varepsilon}{h}\|u\|_{V^*}+\|A_1(a_n)\|_V+\gamma_1\|a_n\|_{X_0}\|u\|_V$$

$$+h\sum_{k=1}^{M}\left\{\|A_1(\Psi_k)\|_{V^*}+\gamma_1\|\Psi_k\|_{X_0}\|u\|_V\right\}$$

$$\cdot\|u-u^*\|_V\left\{\gamma_1\|\Psi_k\|_{X_0}\|u\|_V+\|A_1(\Psi_k)\|_{V^*}\right\}.$$

β) $P_2: K \to V^*$ is continuous: This follows from a lengthy but straightforward computation which uses the bilinearity of A_2 and (A3ii) as essential tools.

γ) $P_2: K \to V^*$ is pseudomonotone: Let $\{u_m\} \subset K$ be given with $u_m \to u$ weakly in V and $\limsup \langle P_2(u_m), u_m - u \rangle \leqq 0$. From $\dim W_M < \infty$ it follows that $u_m \to u$ strongly in V and hence by β): $P_2(u_m) \to P_2(u)$ strongly in V^*. Hence for all $w \in V$:

$$\langle P_2(u), u - w \rangle \leqq \liminf \langle P_2(u_m), u_m - w \rangle .$$

δ) $P_2: K \to V^*$ is coercive with respect to $\Theta \in B^*$ whenever $0 < h \leqq h_0$, where $h_0 > 0$ does not depend on n: Let $u \in K$. We then have by (A3ii):

$$\begin{aligned}
\langle P_2(u), u \rangle &= \frac{\varepsilon}{h} \|u\|_H^2 + \langle A_1(a_n), u \rangle + \langle A_2(a_n, u), u \rangle \\
&\quad + h \sum_{k=1}^{M} \langle A_1(\Psi_k) + A_2(\Psi_k, u), u - u^* \rangle \langle A_1(\Psi_k) + A_2(\Psi_k, u), u \rangle \\
&\geqq \frac{\varepsilon}{h} \|u\|_H^2 - \|A_1(a_n)\|_{V^*} \|u\|_V - \gamma_1 \|a_n\|_{X_0} \|u\|_V^2 \\
&\quad + h \sum_{k=1}^{M} \left[\langle A_1(\Psi_k) + A_2(\Psi_k, u), u \rangle - \frac{1}{2} \langle A_1(\Psi_k) + A_2(\Psi_k, u), u^* \rangle \right]^2 \\
&\quad - \frac{h}{4} \sum_{k=1}^{M} \langle A_1(\Psi_k) + A_2(\Psi_k, u), u^* \rangle^2 .
\end{aligned}$$

Since (a_n, u_n) solves (2.2), (2.3), the a priori estimate (2.7) yields that $\{a_n\}$ is bounded in X by a constant which does not depend on n. This together with the finite dimension of W_M, V_N, the boundedness of A_1 and (A3ii) yields:

$$\begin{aligned}
\langle P_2(u), u \rangle &\geqq \left(C_1 \frac{\varepsilon}{h} - \gamma_1 C_2 - \frac{h}{4} \gamma_1^2 \sum_{k=1}^{M} \|\Psi_k\|_{X_0}^2 \|u^*\|_V^2 \right) \|u\|_V^2 \\
&\quad - \left(C_3 + \frac{h}{2} C_4 \sum_{k=1}^{M} \gamma_1 \|\Psi_k\|_{X_0}^2 \|u^*\|_V^2 \right) \|u\|_V - \frac{h}{4} \sum_{k=1}^{M} \langle A_1(\Psi_k), u^* \rangle^2 .
\end{aligned}$$

Now choose $h_0 > 0$ so small that the expression in the first bracket becomes positive, which is possible independently of n. Then it follows that $\langle P_2(u), u \rangle > 0$ for $\|u\|_V \geqq R$, R sufficiently large, which proves the coercivity. This concludes the proof. □

THEOREM 2.3. *Let* (A1)–(A7) *hold, and let* $0 < h \leqq h_0$ ($h_0 > 0$ *as in Theorem* 2.1). *Let* $\{(a_n, u_n)\}_{n \geqq 0}$ *solve* (P_h). *Then it follows that*:

(i) $u_n \to u^*$, *strongly in* V.

(ii) *Every subsequence of* $\{a_n\}$ *has a cluster point* $a_\infty \in W_M$ *such that with some* $w_\infty \in S(u^*)$

(2.15)

$$\langle w_\infty + A_1(a_\infty) + A_2(a_\infty, u^*) - f^*, v - u^* \rangle + \Psi(v) - \Psi(u^*) \geqq 0 \quad \forall v \in C \cap V_N$$

(*i.e.*, a_∞ *solves the finite dimensional analogue of* (P)).

(iii) *If* $\Psi \equiv 0$, $C = V$, $S(u^*) = \{w_\infty\}$, *and* $\|u - v\|_H \leq \text{const} \cdot \|u - v\|_V \ \forall u, v \in V$ *then the whole sequence* $\{a_n\}$ *converges to some* $a_\infty \in W_M$ *such that* (2.15) *holds.*

Proof. Equation (2.7) implies (i). Moreover $\{a_n\}$, and hence any subsequence $\{a_m\}$, is bounded in X and has a weak cluster point $a_\infty \in X$. From $\dim W_M < \infty$ it follows without loss of generality that $\|a_m - a_\infty\|_{X_0} \to 0$ and thus $a_\infty \in W_M$.

By (A1) S is locally bounded at u^* (compare Remark 1). Since $\|u_m - u^*\|_V \to 0$, we may assume that $w_m \to w_\infty \in V^*$ weakly-star, and by reflexivity of V, weakly. The maximal monotonicity of S implies $w_\infty \in S(u^*)$ (compare [8, p. 33, Lemma 2.12]).

We show the validity of (2.15). To this end, consider (2.2). From $\|u_m - u^*\|_V \to 0$ and $\|a_m - a_\infty\|_{X_0} \to 0$ it follows by Remark 2 that $A_2(a_m, u_m) \to A_2(a, u)$ weakly in V^*. By (A2), $A_1 : X \to V^*$ is continuous, and thus $A_1(a_m) \to A_1(a_\infty)$ strongly in V^*. Moreover, $\Psi(u_{m+1}) \to \Psi(u^*)$, by (A4). Passing to the limit as $m \to \infty$ in (2.2) gives (2.15).

It remains to show (iii). Let $\Psi \equiv 0$, $C = V$ and $S(u^*) = \{w_\infty\}$. Then (2.1) is equivalent to the equation

$$w_\infty + A_1(a^*) + A_2(a^*, u^*) - f^* = \Theta, \tag{2.16}$$

and (2.15) reads

$$\left\langle w_\infty + A_1(a_\infty) + A_2(a_\infty, u^*) - f^*,\ v \right\rangle = 0 \quad \forall v \in V_N. \tag{2.17}$$

The solution set $L(V_N) := \{a_\infty \in X_0$: (2.17) holds$\}$ is an affine subspace of X_0, and $a^* \in L(V_N)$. Moreover, for every $\hat{a} \in L(V_N)$ such that $A_2(\hat{a}, \cdot)$ is uniformly monotone on $C \cap V_N$, the a priori estimate (2.7) is valid (compare Remark 3).

Now let $\hat{a} \in L(V_N)$ be arbitrary where $A_2(\hat{a}, \cdot)$ is uniformly monotone on $C \cap V_N$. Then by (2.5) there exists

$$l := \lim_{n \to \infty} \left(\varepsilon \|u_n - u^*\|_H^2 + \|a_n - \hat{a}\|_X^2 \right). \tag{2.18}$$

But $\|u_n - u^*\|_V^2 \to 0$, and thus $\|u_n - u^*\|_H^2 \to 0$, i.e.,

$$l = \lim_{n \to \infty} \|a_n - \hat{a}\|_X^2. \tag{2.19}$$

Now let $a_\infty^1, a_\infty^2 \in W_M$ be any two limit points of $\{a_n\}$. Then

$$\|a_\infty^1 - \hat{a}\|_X^2 = \|a_\infty^2 - \hat{a}\|_X^2. \tag{2.20}$$

For $\hat{a} := a^* + \lambda(a_\infty^1 - a_\infty^2) \in L(V_N)$ and sufficiently small $|\lambda| > 0$ the operator $A_2(\hat{a}, \cdot)$ is uniformly monotone on $C \cap V_N$. Hence

$$\|a_\infty^1 - a^* - \lambda(a_\infty^1 - a_\infty^2)\|_X^2 = \|a_\infty^2 - a^* - \lambda(a_\infty^1 - a_\infty^2)\|_X^2 \quad \text{or} \quad \|a_\infty^1 - a_\infty^2\|_X^2 = 0.$$

Thus $\{a_n\}$ has a unique limit point for $n \to \infty$. □

Remark 4. For numerical purposes it is noteworthy that the convergence of $\|a_n - a_\infty\|_{X_0}$ can be accelerated by a proper choice of the scaling factor ε.

Remark 5. Under the conditions of (iii) we have form $u^* \in V_N$:

$$\begin{aligned} \left\langle A_1(a_\infty) + A_2(a_\infty, u^*),\ u^* \right\rangle &= \left\langle f^* - w_\infty,\ u^* \right\rangle \\ &= \left\langle A_1(a^*) + A_2(a^*, u^*),\ u^* \right\rangle. \end{aligned}$$

Hence if $A_1 = \Theta$ and $u^* \neq \Theta$, then $\left\langle A_2(a_\infty, u^*),\ u^* \right\rangle > 0$ which means that $A_2(a_\infty, \cdot)$ is positive definite at u^*.

Next we show that limit points a_∞ of (P_h) are stable against perturbations in the initial data if $A_2(a_\infty, \cdot)$ is uniformly monotone on C and a_∞ is unique. However, for technical reasons we have to impose the assumption $A_1 = \Theta$. Also, the admissible set of parameters h has to be restricted.

THEOREM 2.4. *Let* (A1)–(A7) *hold with* $A_1 = \Theta$. *Assume initial data* $(a_0^\lambda, u_0^\lambda)$, $|\lambda| \leqq \lambda_0$, *are given such that*

$$a_0^\lambda \to a_0^0, \qquad u_0^\lambda \to u_0^0 \quad \text{as } \lambda \to 0. \tag{2.21}$$

Then there is an $\hat{h} \in (0, h_0]$ *such that for* $0 < h \leqq \hat{h}$ *the following assertion holds: If* $\{a_n^\lambda, u_n^\lambda\}_{n \geqq 0}$ *solves* (P_h) *with initial data* $(a_0^\lambda, u_0^\lambda)$, $|\lambda| \leqq \lambda_0$, *and if* a_∞^λ *is any cluster point of* $\{a_n^\lambda\}$, *then*

$$\lim_{\lambda \to 0} a_\infty^\lambda = a_\infty^0, \tag{2.22}$$

provided the whole sequence $\{a_n^0\}$ *converges to* a_∞^0 *and* $A_2(a_\infty^0, \cdot)$ *is uniformly monotone on* C.

Proof. Let $0 < h \leqq h_0$. From (2.2), (2.3) there follows:

$$\left\langle \varepsilon \frac{u_{n+1}^\lambda - u_n^\lambda}{h} + w_{n+1}^\lambda + A_2\left(a_{n+1}^\lambda, u_{n+1}^\lambda\right) - f^*,\ v - u_{n+1}^\lambda \right\rangle + \Psi(v) - \Psi\left(u_{n+1}^\lambda\right) \geqq 0 \tag{2.23}$$

$$\forall v \in C \cap V_N,$$

with some $w_{n+1}^\lambda \in S(u_{n+1}^\lambda)$,

$$\left[\frac{a_{n+1}^\lambda - a_n^\lambda}{h},\ \eta \right] - \left\langle A_2\left(\eta, u_{n+1}^\lambda\right),\ u_{n+1}^\lambda - u^* \right\rangle = 0 \quad \forall \eta \in W_M. \tag{2.24}$$

Let $y_n^\lambda := u_n^\lambda - u_n^0$, $r_n^\lambda := a_n^\lambda - a_n^0$, $q_n^\lambda := u_n^\lambda - u^*$. Then it follows:

$$\left\langle \varepsilon \frac{u_{n+1}^\lambda - u_n^\lambda}{h} + w_{n+1}^\lambda + A_2\left(a_{n+1}^\lambda, u_{n+1}^\lambda\right) - f^*,\ u_{n+1}^\lambda - u_{n+1}^0 \right\rangle + \Psi\left(u_{n+1}^\lambda\right) - \Psi\left(u_{n+1}^0\right)$$

$$\leqq 0 \leqq \left\langle \varepsilon \frac{u_{n+1}^0 - u_n^0}{h} + w_{n+1}^0 + A_2\left(a_{n+1}^0, u_{n+1}^0\right) - f^*,\ u_{n+1}^\lambda - u_{n+1}^0 \right\rangle$$

$$+ \Psi\left(u_{n+1}^\lambda\right) - \Psi\left(u_{n+1}^0\right),$$

whence

$$0 \geqq \left\langle \varepsilon \frac{y_{n+1}^\lambda - y_n^\lambda}{h},\ y_{n+1}^\lambda \right\rangle + \left\langle A_2\left(a_{n+1}^0, y_{n+1}^\lambda\right),\ y_{n+1}^\lambda \right\rangle$$

$$+ \left\langle A_2\left(r_{n+1}^\lambda, u_{n+1}^\lambda\right),\ y_{n+1}^\lambda \right\rangle.$$

Putting $\eta := r_{n+1}^\lambda$ in (2.24) yields:

$$0 = \left[\frac{r_{n+1}^\lambda - r_n^\lambda}{h},\ r_{n+1}^\lambda \right] + \left[\frac{a_{n+1}^0 - a_n^0}{h},\ r_{n+1}^\lambda \right]$$

$$- \left\langle A_2\left(r_{n+1}^\lambda, u_{n+1}^\lambda\right),\ y_{n+1}^\lambda \right\rangle - \left\langle A_2\left(r_{n+1}^\lambda, u_{n+1}^\lambda\right),\ q_{n+1}^0 \right\rangle$$

$$= \left[\frac{r_{n+1}^\lambda - r_n^\lambda}{h},\ r_{n+1}^\lambda \right] - \left\langle A_2\left(r_{n+1}^\lambda, u_{n+1}^\lambda\right),\ y_{n+1}^\lambda \right\rangle - \left\langle A_2\left(r_{n+1}^\lambda, y_{n+1}^\lambda\right),\ q_{n+1}^0 \right\rangle.$$

Addition gives:

$$0 \geqq \left\langle \varepsilon \frac{y_{n+1}^\lambda - y_n^\lambda}{h},\ y_{n+1}^\lambda \right\rangle + \left[\frac{r_{n+1}^\lambda - r_n^\lambda}{h},\ r_{n+1}^\lambda \right] + \left\langle A_2\left(a_{n+1}^0, y_{n+1}^\lambda\right),\ y_{n+1}^\lambda \right\rangle - \left\langle A_2\left(r_{n+1}^\lambda, y_{n+1}^\lambda\right),\ q_{n+1}^0 \right\rangle. \tag{2.25}$$

From (A3ii) we have for every $v \in V$:

$$\left| \left\langle A_2\left(a_\infty^0, v\right),\ v \right\rangle - \left\langle A_2\left(a_{n+1}^0, v\right),\ v \right\rangle \right| \leqq \gamma_1 \left\| a_{n+1}^0 - a_\infty^0 \right\|_{X_0} \|v\|_V^2.$$

Hence there exists a $\hat{\rho} > 0$ and an $n_0 \in \mathbb{N}$ such that:

$$\left\langle A_2\left(a_{n+1}^0, y_{n+1}^\lambda\right),\ y_{n+1}^\lambda \right\rangle \geqq \hat{\rho} \left\| y_{n+1}^\lambda \right\|_V^2 \quad \forall n \geqq n_0. \tag{2.26}$$

Using $\dim W_M < \infty$ we obtain for $n \geqq n_0$:

$$\begin{aligned} &\left\langle \varepsilon \frac{y_{n+1}^\lambda - y_n^\lambda}{h},\ y_{n+1}^\lambda \right\rangle + \left[\frac{r_{n+1}^\lambda - r_n^\lambda}{h},\ r_{n+1}^\lambda \right] \\ &\qquad \leqq -\hat{\rho} \left\| y_{n+1}^\lambda \right\|_V^2 + \gamma_1 \left\| r_{n+1}^\lambda \right\|_{X_0} \left\| y_{n+1}^\lambda \right\|_V \left\| q_{n+1}^0 \right\|_V \\ &\qquad \leqq -\hat{\rho} \left\| y_{n+1}^\lambda \right\|_V^2 + \hat{\rho} \left\| y_{n+1}^\lambda \right\|_V^2 + \frac{1}{4\hat{\rho}} \gamma_1^2 C_1^2 \left\| r_{n+1}^\lambda \right\|_X^2 \left\| q_{n+1}^0 \right\|_V^2 \\ &\qquad \leqq C \left(\frac{\varepsilon}{h} \left\| y_{n+1}^\lambda \right\|_H^2 + \frac{1}{h} \left\| r_{n+1}^\lambda \right\|_X^2 \right) \left\| q_{n+1}^0 \right\|_V^2. \end{aligned}$$

Now we put

$$\left(\phi_{n+1}^\lambda\right)^2 := \frac{\varepsilon}{h} \left\| y_{n+1}^\lambda \right\|_H^2 + \frac{1}{h} \left\| r_{n+1}^\lambda \right\|_X^2.$$

Then

$$\frac{\varepsilon}{h} \left\langle y_n^\lambda,\ y_{n+1}^\lambda \right\rangle + \frac{1}{h} \left[r_n^\lambda, r_{n+1}^\lambda \right] \leqq \phi_n^\lambda \phi_{n+1}^\lambda,$$

and hence,

$$\left(\phi_{n+1}^\lambda\right)^2 \leqq \phi_n^\lambda \phi_{n+1}^\lambda + \gamma_{n+1} \left(\phi_{n+1}^\lambda\right)^2, \quad \text{where } \gamma_{n+1} := C \left\| q_{n+1}^0 \right\|_V^2$$

or

$$\phi_{n+1}^\lambda (1 - \gamma_{n+1}) \leqq \phi_n^\lambda \quad \forall n \geqq n_0.$$

By (2.7) we may assume that $0 \leqq \gamma_{n+1} \leqq \kappa < 1$, $n \geqq n_0$. Hence $\phi_{n+1}^\lambda \leqq (1 + \sigma_{n+1}) \phi_n^\lambda$, $n \geqq n_0$, where

$$\sigma_{n+1} := \frac{\gamma_{n+1}}{1 - \gamma_{n+1}} \leqq \sigma \left\| q_{n+1}^0 \right\|_V^2 \quad \text{for some } \sigma > 0.$$

Induction yields for any $p \in \mathbb{N}$:

$$\phi_{n_0+p}^\lambda \leqq \prod_{k=1}^{p} \left(1 + \sigma_{n_0+k}\right) \phi_{n_0}^\lambda.$$

But

$$\prod_{k=1}^{p}\left(1+\sigma_{n_0+k}\right) \leqq \prod_{k=1}^{p}\exp(\sigma_{n_0+k}) = \exp\left(\sum_{k=1}^{p}\sigma_{n_0+k}\right)$$

$$\leqq \exp\left(\sigma\sum_{k=1}^{\infty}\left\|q_k^0\right\|_V^2\right),$$

which is finite by (2.7). Thus

$$\phi_n^\lambda \leqq \text{const}\cdot\phi_{n_0}^\lambda \quad \text{for all } n\geqq n_0,\ |\lambda|\leqq\lambda_0. \tag{2.27}$$

Next we show that $\lim_{\lambda\to 0}\phi_{n_0}^\lambda = 0$. From (2.25) we have for any $n\leqq n_0$:

$$\left(\phi_{n+1}^\lambda\right)^2 \leqq \phi_n^\lambda\phi_{n+1}^\lambda + \gamma_1\left\|a_{n+1}^0\right\|_{X_0}\left\|y_{n+1}^\lambda\right\|_V^2 + \gamma_1\left\|r_{n+1}^\lambda\right\|_{X_0}\left\|y_{n+1}^\lambda\right\|_V\left\|q_{n+1}^0\right\|_V.$$

By (2.7) the real sequences $\{\|a_{n+1}^0\|_{X_0}\}$ and $\{\|q_{n+1}^0\|_V\}$ are bounded. Thus

$$\left(\phi_{n+1}^\lambda\right)^2 \leqq \phi_n^\lambda\phi_{n+1}^\lambda + C_1\left\|y_{n+1}^\lambda\right\|_H^2 + C_2\left\|r_{n+1}^\lambda\right\|_X^2 \leqq \phi_n^\lambda\phi_{n+1}^\lambda + Ch\left(\phi_{n+1}^\lambda\right)^2.$$

Choosing $h<\hat{h} := 1/C$ yields

$$\phi_{n+1}^\lambda \leqq \frac{1}{1-Ch}\phi_n^\lambda,$$

and thus

$$\phi_{n_0}^\lambda \leqq \left(\frac{1}{1-Ch}\right)^{n_0}\phi_0^\lambda,$$

whence $\lim_{\lambda\to 0}\phi_{n_0}^\lambda = 0$.

The proof is now easily finished: Since a_∞^λ is a cluster point of $\{a_n^\lambda\}$ we have $a_{n_k}^\lambda \to a_\infty^\lambda$ for some subsequence $\{a_{n_k}^\lambda\}$.

Since a_∞^0 is the unique limit point of $\{a_n^0\}$ it follows that $a_{n_k}^0 \to a_\infty^0$, and thus

$$\left\|a_\infty^\lambda - a_\infty^0\right\|_X = \lim_{k\to\infty}\left\|a_{n_k}^\lambda - a_{n_k}^0\right\|_X \leqq C\cdot\phi_{n_0}^\lambda,$$

from which the assertion follows. □

Remark 6. a_∞^0 is uniquely determined under the assumptions of Theorem 2.3 (iii).

Finally we discuss the situation as $\dim V_N\to\infty$. To this end, let $\{V_N\}_{N\geqq 2}$ be a sequence of subspaces of V such that $u_0, u^*\in V_N$, $\forall N\geqq 2$. Assume to each N there is a subspace $W_{M(N)}$ of X_0 of (smallest) dimension $M(N)$ such that $a_0\in W_{M(N)}$ and such that (A7) holds.

Let

$$V_N\subset V_{N+1} \quad \forall N\geqq 2, \quad \bigcup_{N=2}^{\infty} V_N \text{ is dense in } V. \tag{A8}$$

By Theorem 2.3 for any $N\geqq 2$ there exists an $a_\infty^N\in W_{M(N)}$ such that with some $w_\infty^N\in S(u^*)$

$$\left\langle w_\infty^N + A_1\left(a_\infty^N\right) + A_2\left(a_\infty^N, u^*\right) - f^*,\ v-u^*\right\rangle + \Psi(v) - \Psi(u^*) \geqq 0 \quad \forall v\in C\cap V_N. \tag{2.28}$$

The a priori estimate (2.7) gives that $\{a_\infty^N\}$ is bounded in X (recall that the constant C does not depend on V_N and W_M). Thus a subsequence, again denoted by $\{a_\infty^N\}$, converges weakly in X to some $a_\infty \in X$.

Let us assume

(A9) $X \times \{u^*\} \subset D(A_2)$, and $a_n \to a$ weakly in X implies $A_2(a_n, u^*) \to A_2(a, u^*)$ weakly in V^*.

Then $(a_\infty, u^*) \in D(A_2)$. We show that a_∞ is a solution of (P).

By the boundedness of $S(u^*)$ we may assume that $w_\infty^N \to w^*$ weakly in V^* whence $w^* \in S(u^*)$ by the maximal monotonicity. Moreover, from $a_\infty^N \to a_\infty$ weakly in X follows $A_1(a_\infty^N) \to A_1(a_\infty)$ weakly in V^* since every continuous linear mapping is weakly sequentially continuous. We assume further:

(A10) $(V, \|\cdot\|)$ is a Hilbert space, i.e., $\|\cdot\|_V$ is induced by an inner product $(\cdot, \cdot)$ on V.

Now let $v \in C$ be arbitrary. By (A8) there is a sequence $v_N \in V_N$ with $\|v_N - v\|_V \to 0$.

Let P_C denote the $(\cdot, \cdot)$-orthogonal projection operator onto C. As C is closed and convex, P_C is nonexpansive. Thus, $\|v - P_C v_N\|_V \leqq \|v - v_N\|_V \to 0$, as $N \to \infty$, and also, $P_C v_N - u^* \to v - u^*$, strongly in V.

We have

$$\begin{aligned}
&\left\langle w^* + A_1(a_\infty) + A_2(a_\infty, u^*) - f^*,\ v - u^* \right\rangle + \Psi(v) - \Psi(u^*) \\
&\quad = \left[\left\langle w_\infty^N + A_1(a_\infty^N) + A_2(a_\infty^N, u^*) - f^*,\ P_C v_N - u^* \right\rangle + \Psi(P_C v_N) - \Psi(u^*) \right] \\
&\qquad + \left[\left\langle w^* - w_\infty^N + A_1(a_\infty) - A_1(a_\infty^N) + A_2(a_\infty, u^*) - A_2(a_\infty^N, u^*),\ P_C v_N - u^* \right\rangle \right] \\
&\qquad + \Psi(v) - \Psi(P_C v_N) + \left[\left\langle w^* + A_1(a_\infty) + A_2(a_\infty, u^*) - f^*,\ v - P_C v_N \right\rangle \right].
\end{aligned}$$

The first bracket is nonnegative by (2.28), and the second and third brackets approach 0 as $N \to \infty$. Hence passing to the limit as $N \to \infty$ yields

$$\left\langle w^* + A_1(a_\infty) + A_2(a_\infty, u^*) - f^*,\ v - u^* \right\rangle + \Psi(v) - \Psi(u^*) \geqq 0 \quad \forall v \in C,$$

i.e. a_∞ solves (P).

Putting things together we obtain:

THEOREM 2.5. *Let* (A1)–(A10) *hold. If* $\{a_\infty^N\}$ *denotes a sequence of limit points of the solution of* $(P_{h(N)})$, *then each subsequence has a weak cluster point in X which solves* (P).

3. Equations of evolution. We now extend some of the results of the preceding section to equations of evolution type. The notations have the same meaning as in §2. The vector-valued Sobolev spaces $L^2(0, T; H)$, $L^2(0, T; V)$, $L^2(0, T; X)$, $L^2(0, T; V^*)$ and $L^\infty(0, T; X_0)$ together with their norms are defined as usual. Clearly $L^2(0, T; V) \subset L^2(0, T; H) \subset L^2(0, T; V^*)$ with dense and continuous embedding. The dual pairing between elements of $L^2(0, T; V^*)$ and $L^2(0, T; V)$ is denoted by $\langle \cdot | \cdot \rangle$; i.e., for $w \in L^2(0, T; V^*)$ and $v \in L^2(0, T; V)$ we have

$$\langle w | v \rangle = \int_0^T \langle w(t), u(t) \rangle \, dt. \tag{3.1}$$

The inner product $[\cdot | \cdot]$ in the Hilbert space $L^2(0, T; X)$ is defined by

$$[w | v] := \int_0^T [w(t), v(t)] \, dt, \qquad w, v \in L^2(0, T; X). \tag{3.2}$$

Finally we set

$$W^1(0,T;\ V,H) := \Big\{ u \in L^2(0,T;\ V) : u \text{ has a generalized derivative } \frac{du}{dt} \in L^2(0,T;\ V^*) \Big\}. \tag{3.3}$$

As is well known, $W^1(0,T;\ V,H)$ is a Banach space with the norm

$$\|u\|_{W^1} := \|u\|_{L^2(0,T;V)} + \left\| \frac{du}{dt} \right\|_{L^2(0,T;V^*)}. \tag{3.4}$$

Recall that $u \in W^1(0,T;\ V,H)$ implies $u \in C(0,T;\ H)$ (possibly after a modification on a set of zero measure). Now let

$$C := \{ v \in W^1(0,T;\ V,H) : v(0) = \Theta \}. \tag{3.5}$$

An appropriate identification problem for an evolution process is;

(P) Given $u^* \in C$ and $f^* \in L^2(0,T;\ V^*)$, find $a^* \in L^2(0,T;\ X)$ with $(a^*,u^*) \in D(A_2)$ such that there exists $w^* \in S(u^*)$ with

$$\left\langle \frac{du^*}{dt} + w^* + A_1(a^*) + A_2(a^*,u^*) - f^* \,\middle|\, v - u^* \right\rangle + \Psi(v) - \Psi(u^*) \geqq 0 \quad \forall v \in C. \tag{3.6}$$

In correspondence with the assumptions of §2 we assume:

(A1)* $S : D(S) \subset L^2(0,T;\ V) \to 2^{L^2(0,T;V^*)}$ is a maximal monotone graph with $u^* \in \operatorname{int} D(S)$.

(A2)* $A_1 : L^2(0,T;\ X) \to L^2(0,T;\ V^*)$ is linear and bounded.

(A3)* $A_2 : D(A_2) \subset L^2(0,T;\ X) \times L^2(0,T;\ V) \to L^2(0,T;\ V^*)$ is a bilinear map such that

(i) $L^\infty(0,T;\ X_0) \times L^2(0,T;\ V) \subset D(A_2)$,

(ii)

$$\big| \langle A_2(a,u) \,|\, v \rangle \big| \leqq \gamma_1 \|a\|_{L^\infty(0,T;X_0)} \|u\|_{L^2(0,T;V)} \|v\|_{L^2(0,T;V)},$$

$\forall a \in L^\infty(0,T;\ X_0)$, $u, v \in L^2(0,T;\ V)$, for some $\gamma_1 > 0$.

(A4)* $\Psi : L^2(0,T;\ V) \to \mathbb{R}$ is convex and continuous.

Remark 7. The condition $u^*(0) = \Theta$ is merely a normalization.

Remark 8. The operator d/dt with $D(d/dt) := \{ u \in W^1(0,T;\ V,H) : u(0) = \Theta \}$ is maximal monotone from $L^2(0,T;\ V)$ into $L^2(0,T;\ V^*)$.

But as $D(d/dt)$ has empty interior in $L^2(0,T;\ V)$ it appears that the techniques of §2 do not apply unchanged.

Remark 9. If $\|a_n - a\|_{L^\infty(0,T;X_0)} \to 0$ and $\|u_n - u\|_{L^2(0,T;V)} \to 0$, then $A_2(a_n,u_n) \to A_2(a,u)$ weakly in $L^2(0,T;\ V^*)$.

We proceed in close analogy to §2. To this end, let V_N and W_M denote finite-dimensional subspaces of $W^1(0,T;\ V,H)$ and $L^\infty(0,T;\ X_0)$ with

(A5)* $u^* \in V_N$.

(A6)* $\langle A_1(a) + A_2(a,u) \,|\, v \rangle = 0$, $\forall a \in W_M^\perp$, $u, v \in V_N$.

Here $W_M^\perp := \{ z \in L^\infty(0,T;\ X_0) : [z|\eta] = 0, \forall \eta \in W_M \}$.

Condition (A5) is replaced by

(A7)* (P) has at least one solution $a^* \in L^\infty(0,T;\ X_0)$ such that

$$\langle A_2(a^*, u - v) \,|\, u - v \rangle \geqq \delta \|u - v\|^2_{L^2(0,T;V)}$$

$\forall u, v \in L^2(0,T;\ V)$, for some $\delta > 0$.

Now let $\varepsilon>0$ be arbitrary and $h>0$ be fixed. We consider:

(P_h) Given $(a_0,u_0)\in W_M\times(D(S)\cap C\cap V_N)$, find $(a_n,u_n)\in W_M\times(D(S)\cap C\cap V_N)$, $n\in\mathbb{N}$, such that there exists $w_n\in S(u_n)$ with

$$\left\langle \varepsilon\frac{u_{n+1}-u_n}{h}+\frac{d}{dt}u_{n+1}+w_{n+1}+A_1(a_{n+1})+A_2(a_{n+1},u_{n+1})-f^* \mid v-u_{n+1}\right\rangle + \Psi(v)-\Psi(u_{n+1})\geqq 0 \quad \forall v\in C\cap V_N, \tag{3.7}$$

$$\left[\frac{a_{n+1}-a_n}{h}\middle|\eta\right]-\left\langle A_1(\eta)+A_2(\eta,u_{n+1})\mid u_{n+1}-u^*\right\rangle=0 \quad \forall \eta\in W_M. \tag{3.8}$$

With the same technique as in §2 one arrives at the inequality

$$0\geqq\left\langle \varepsilon\frac{q_{n+1}-q_n}{h}\middle|q_{n+1}\right\rangle+\left[\frac{r_{n+1}-r_n}{h}\middle|r_{n+1}\right]+\delta\|q_{n+1}\|^2_{L^2(0,T;V)} +\frac{1}{2}\|q_{n+1}(T)\|^2_H.$$

Here it was used that $q_{n+1}(0)=\Theta$ and thus

$$\left\langle\frac{d}{dt}q_{n+1}\middle|q_{n+1}\right\rangle=\int_0^T\left\langle\frac{d}{dt}q_{n+1}(t),\,q_{n+1}(t)\right\rangle dt =\frac{1}{2}\int_0^T\frac{d}{dt}\|q_{n+1}(t)\|^2_H dt=\frac{1}{2}\|q_{n+1}(T)\|^2_H.$$

As in §2 there follows:

$$\varepsilon\|q_{n+1}\|^2_{L^2(0,T;H)}+\|r_{n+1}\|^2_{L^2(0,T;X)}+2\delta h\|q_{n+1}\|^2_{L^2(0,T;V)} +h\|q_{n+1}(T)\|^2_H\leqq\varepsilon\|q_n\|^2_{L^2(0,T;H)}+\|r_n\|^2_{L^2(0,T;X)}, \tag{3.9}$$

and

$$\sup_{n\in\mathbb{N}}\left\{\varepsilon\|q_n\|^2_{L^2(0,T;H)}+\|r_n\|^2_{L^2(0,T;X)}\right\}+2\delta h\sum_{k=1}^{\infty}\|q_k\|^2_{L^2(0,T;V)} +h\sum_{k=1}^{\infty}\|q_k(T)\|^2_H\leqq C<+\infty, \tag{3.10}$$

where C depends on ε, a_0, u_0, a^*, u^*, but not on h, W_M, V_N.

In analogy to Theorem 2.1 we have:

THEOREM 3.1. *Let* (A1)*–(A7)* *hold. Then there is an* $h_0>0$ *such that* (P_h) *has a solution* $\{(a_n,u_n)\}_{n\geqq 0}$ *for* $0<h\leqq h_0$.

Proof. Let $W_M:=\operatorname{span}\{\Psi_1,\cdots,\Psi_M\}$ with $[\Psi_i|\Psi_j]=\delta_{ij}$, $\forall i,\ j$. Let (a_k,u_k), $0\leqq k\leqq n$, be already constructed. As in the proof of Theorem 2.1 the existence of (a_{n+1},u_{n+1}) is equivalent to the solvability of

$$\left\langle\varepsilon\frac{u-u_n}{h}+w+\frac{du}{dt}+A_1(a)+A_2(a,u)-f^*\mid v-u\right\rangle+\Psi(v)-\Psi(u)\geqq 0,$$

$\forall v\in V_N\cap C$, for some $w\in S(u)$, where

$$a=a_n+h\sum_{k=1}^{M}\left\langle A_1(\Psi_k)+A_2(\Psi_k,u)\mid u-u^*\right\rangle\Psi_k. \tag{3.11}$$

We apply Theorem 2.2 with

$$B := L^2(0,T;\, V), \qquad K := C \cap V_N,$$
$$P_1 := S + \frac{d}{dt}, \qquad g(v) = \Psi(v) - \left\langle \frac{\varepsilon}{h} u_n + f^* \,\middle|\, v \right\rangle,$$

and

$$\begin{aligned} &P_2 : K \to B^*, \\ &P_2(u) := \frac{\varepsilon}{h} u + A_1(a_n) + A_2(a_n, u) \\ &\qquad + h \sum_{k=1}^{M} \left\langle A_1(\Psi_k) + A_2(\Psi_k, u) \,|\, u - u^* \right\rangle \cdot \{ A_1(\Psi_k) + A_2(\Psi_k, u) \}. \end{aligned} \tag{3.12}$$

Clearly $K \neq \varnothing$, and K is convex. Now C is closed in $W^1(0,T;\, V,H)$, and since $K = C \cap V_N$ is contained in the finite-dimensional subspace V_N of $W^1(0,T;\, V,H)$, K is a closed subset of $B = L^2(0,T;\, V)$.

Moreover, S and d/dt are maximal monotone, and $D(d/dt) \cap \operatorname{int} D(S) \ni u^*$. Thus $P_1 = S + d/dt$ is maximal monotone. Finally it is easily checked that P_2 is bounded, continuous, pseudomonotone and coercive with respect to Θ (provided h_0 is sufficiently small, compare the proof of Theorem 2.1). The assertion follows from Theorem 2.2.

THEOREM 3.2. *Let* (A1)*–(A7)* *hold, and let* $0 < h \leqq h_0$. *Let* $\{(a_n, u_n)\}_{n \geqq 0}$ *solve* (P_h). *Then it follows that*:

(i) $\|u_n - u^*\|^2_{L^2(0,T;V)} + \|u_n(T) - u^*(T)\|^2_H \to 0$, *as* $n \to \infty$.

(ii) *Every subsequence of* $\{a_n\}$ *has a cluster point* $a_\infty \in W_M$ *such that with some* $w_\infty \in S(u^*)$

$$\left\langle w_\infty + A_1(a_\infty) + A_2(a_\infty, u^*) + \frac{du^*}{dt} - f^* \,\middle|\, v - u^* \right\rangle + \Psi(v) - \Psi(u^*) \geqq 0 \quad \forall v \in C \cap V_N. \tag{3.13}$$

Proof. (3.10) implies (i). Moreover, any subsequence $\{a_m\}$ has a weak cluster point $a_\infty \in L^2(0,T;\, X)$. Hence we may assume $a_m \to a_\infty$ weakly in $L^2(0,T;\, X)$.

From $\dim W_M < \infty$ follows $\|a_m - a_\infty\|_{L^\infty(0,T;X_0)} \to 0$ and hence $a_\infty \in W_M$. As in the proof of Theorem 2.3 we may assume that $w_m \to w_\infty \in S(u^*)$, weakly in $L^2(0,T;\, V^*)$. From Remark 10 we have

$A_2(a_m, u_m) \to A(a_\infty, u^*)$, weakly in $L^2(0,T;\, V^*)$,

$A_1(a_m) \to A_1(a_\infty)$, weakly in $L^2(0,T;\, V^*)$, by (A2)*.

Relation (3.7) yields for every $v \in C \cap V_N$:

$$\begin{aligned} 0 \leqq \lim_{m \to \infty} \Bigg\{ \Bigg\langle & \varepsilon \frac{u_{m+1} - u_m}{h} + \frac{d}{dt} u_{m+1} + w_{m+1} + A_1(a_{m+1}) \\ & + A_2(a_{m+1}, u_{m+1}) - f^* \,\Big|\, v - u_{m+1} \Bigg\rangle + \Psi(v) - \Psi(u_{m+1}) \Bigg\} \\ = \Big\langle & w_\infty + A_1(a_\infty) + A_2(a_\infty, u^*) - f^* \,\Big|\, v - u^* \Big\rangle + \Psi(v) - \Psi(u^*) \\ & + \lim_{m \to \infty} \left\langle \frac{d}{dt} u_{m+1} \,\middle|\, v - u_{m+1} \right\rangle. \end{aligned}$$

From $v \in W^1(0,T;\, V,H)$ and $u_{m+1} \in C$ there follows:

$$\left\langle \frac{d}{dt}(u_{m+1}-u^*)\middle| v \right\rangle = \int_0^T \left\langle \frac{d}{dt}(u_{m+1}-u^*)(t),\, v(t) \right\rangle dt$$

$$= -\int_0^T \left\langle \frac{d}{dt} v(t),\, u_{m+1}(t)-u^*(t) \right\rangle dt$$

$$+ \left\langle u_{m+1}(T)-u^*(t),\, v(T) \right\rangle \to 0,$$

as $m \to \infty$. Moreover,

$$\left\langle \frac{d}{dt} u_{m+1} \middle| u_{m+1} \right\rangle = \frac{1}{2}\|u_{m+1}(T)\|_H^2 - \frac{1}{2}\|u_{m+1}(0)\|_H^2$$

$$\to \frac{1}{2}\|u^*(T)\|_H^2 - \frac{1}{2}\|u^*(0)\|_H^2 = \left\langle \frac{d}{dt} u^* \middle| u^* \right\rangle,$$

again by (i). Hence (3.13) holds. □

It should be clear that a result which essentially resembles part (iii) of Theorem 2.3 can be proved. Also an analogue of the stability result of Theorem 2.4 is easily established. For the sake of shortness we omit an explicit statement of the result. Instead we turn over our interest to the applications.

4. Applications. In all our applications let $\Omega \subset \mathbb{R}^N$ be open and bounded with a sufficiently smooth boundary $\partial\Omega$. For the sake of shortness we confine ourselves to only some typical examples. There are many other applications in which the developed methods apply as well.

Example 1. Consider the problem:

(4.1) Given $u^* \in \mathring{H}^1(\Omega) \cap H^{1,\infty}(\Omega)$ and $f^* \in H^{-1}(\Omega)$, find a matrix $a^* = (a_{ij}^*)$ with entries $a_{ij}^* \in L^2(\Omega)$ such that: $-\nabla \cdot (a^* \nabla u^*) = f^*$.

This problem was treated extensively in [3], [6]. We make the following specifications: $V = \mathring{H}^1(\Omega)$, $H = L^2(\Omega)$, $V^* = H^{-1}(\Omega)$, $X = \{a = (a_{ij}) : a_{ij} \in L^2(\Omega), \forall i,\, j\}$, $X_0 = \{a \in X : a_{ij} \in L^\infty(\Omega), \forall i,\, j\}$, $C = V$, $\Psi \equiv 0$, $A_1 = \Theta$, $S = \Theta$ and $A_2(a,u) := -\nabla \cdot (a \nabla u)$.

Then (A1), (A2), (A4) are trivial. A_2 is bilinear, and Poincaré's inequality yields (A3ii). (A5) is reasonable from the physical viewpoint. Now, for all $a \in W_M^\perp$:

$$\langle A_2(a,u),\, v \rangle = \int_\Omega \nabla v \cdot (a \nabla u)\, dx = [a, \nabla v \nabla u^T],$$

where the inner product $[\cdot,\cdot]$ of X is given by:

$$[a,b] := \sum_{i,j=1}^N \int_\Omega a_{ij} b_{ij}\, dx.$$

Hence (A7) can be satisfied if only

$$\nabla v \nabla u^T \in W_M \quad \forall u,\, v \in V_N. \tag{4.2}$$

This is possible if $V_N \subset \mathring{H}^1(\Omega) \cap H^{1,\infty}(\Omega)$. Also (A8) can be satisfied since $\mathring{H}^1(\Omega) \cap H^{1,\infty}(\Omega)$ is dense in $\mathring{H}^1(\Omega)$. Finally, from $u^* \in H^{1,\infty}(\Omega)$ it follows that $\nabla v \nabla u^{*T} \in X$ whenever $v \in \mathring{H}^1(\Omega)$. This implies (A9), since from $v \in \mathring{H}^1(\Omega)$ and $a_n \to a$ weakly in X

we get

$$\langle A_2(a_n-a,u^*),\, v\rangle = \int_\Omega \nabla v\cdot\big((a_n-a)\nabla u^*\big)\,dx = \big[a_n-a,\nabla v\nabla u^{*T}\big]\to 0.$$

(A10) is obviously satisfied as well.

Hence the theory of §2 applies. Numerical calculations can be found in [3]. Physical applications are given by stationary states of time-dependent phenomena, such as:

(i) fluid flow through porous media: u = pressure, a = permeability of the medium;
(ii) electricity: u = potential, a = conductivity;
(iii) heat conduction: u = temperature, a = thermal conductivity.

Example 2 (*other boundary conditions*). Let $\sigma^*\in L^\infty(\partial\Omega)$ be nonnegative with $\sigma^*(x)\geqq\sigma>0$ on $\Gamma\subset\partial\Omega$ where meas $(\Gamma)>0$. $\partial/\partial n_a^*$ is the outer conormal derivative at $\partial\Omega$ with respect to the matrix a^*. We consider

(4.3) Given $u^*\in H^{1,\infty}(\Omega)$, $f^*\in L^2(\Omega)$ and $g^*\in H^{-1/2}(\partial\Omega)$, find $a^*\in X$ such that for all $v\in H^1(\Omega)$:

$$\int_\Omega \nabla v\cdot(a^*\nabla u^*)\,dx+\int_\Gamma \sigma^* v u^*\,ds=\int_\Omega f^* v\,dx+\int_{\partial\Omega} g^* v\,ds.$$

Note that from the trace theorems (see [9]) the injection $H^1(\Omega)\to H^{1/2}(\partial\Omega)$ is continuous.

Obviously (4.3) is a weak formulation of

$$(4.4)\qquad -\nabla\cdot(a^*\nabla u^*)=f^* \quad \text{in } \Omega, \qquad \sigma^* u^*+\frac{\partial u^*}{\partial n_a^*}=g^* \quad \text{on } \partial\Omega.$$

We set $V=H^1(\Omega)$, $H=L^2(\Omega)$, $V^*=(H^1(\Omega))^*$, X, X_0 as in Example 1, $A_1=\Theta$, $S=\Theta$, $C=V$, and $\Psi(v):=-\int_{\partial\Omega} g^* v\,ds$, which is convex and continuous by the trace theorems. Next we define A_2 by

$$\langle A_2(a,u),\, v\rangle := \int_\Omega \nabla v\cdot(a\nabla u)\,dx+\int_\Gamma \sigma^* uv\,ds.$$

Since $\sigma^*\geqq\sigma>0$ on a set of positive measure,

$$\|v\|^2 := \int_\Omega |\nabla v|^2 dx+\int_\Gamma \sigma^* |v|^2 ds$$

defines a norm on $H^1(\Omega)$ which is equivalent to $\|\cdot\|_{H^1(\Omega)}$. Hence (A3) follows from

$$\begin{aligned}|\langle A_2(a,u),\, v\rangle| &\leqq C\left(\int_\Omega |\nabla v\cdot\nabla u|dx+\int_\Gamma \sigma^* |uv|\,ds\right)\\ &\leqq C\|u\|\|v\|\leqq \text{const.}\cdot\|u\|_{H^1(\Omega)}\|v\|_{H^1(\Omega)},\end{aligned}$$

if $a\in X_0$, $u,v\in V$.

The other conditions are satisfied as in Example 1. Hence the theory of §2 applies.

Example 3 (*dam problem*). We consider stationary fluid flows through a porous medium $\Omega\subset\mathbb{R}^N$. $\partial\Omega$ is the union of three disjoint sets: Γ^+ (boundary to water reservoirs), Γ^0 (boundary to the atmosphere) and Γ^- (boundary to the impervious ground). See Fig. 1. Let Ω be inhomogeneous and unisotropic, and let Γ^+ be nonempty and relatively open in $\Gamma^+\cup\Gamma^0$.

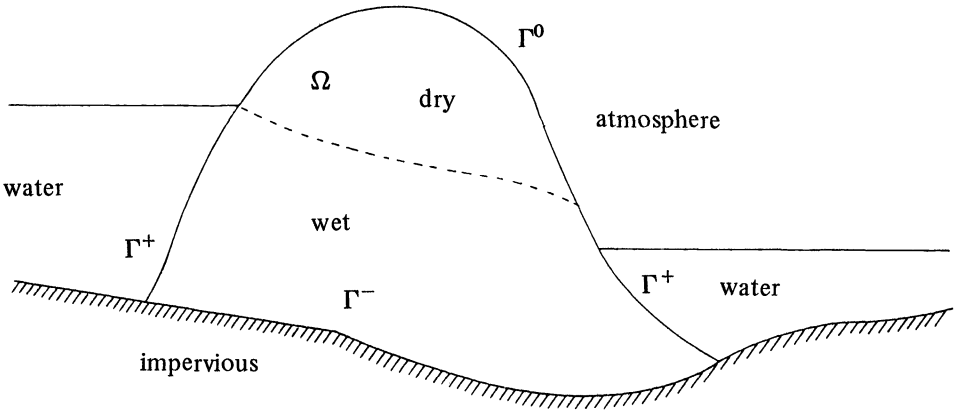

FIG. 1

Assuming the boundary data for pressure u are given by

$$g^* \in H^1(\Omega) \cap H^{1,\infty}(\Omega), \qquad g^* \geqq 0, \tag{4.5}$$

and introducing

$$M(g^*) := \{ v \in H^1(\Omega) : v = g^* \text{ on } \Gamma^+,\ v \leqq g^* \text{ on } \Gamma^0 \},$$

the problem of finding the free boundary between the wet and dry parts of Ω leads to solving:

(4.6) Given $a^* \in X_0$, find $u^* \in M(g^*)$ with $u^* \geqq 0$ and $\gamma^* \in L^\infty(\Omega)$ with $0 \leqq \gamma^* \leqq 1$ and $\gamma^* = 1$ in $\{u^* > 0\}$ such that for all $v \in M(g^*)$:

$$\int_\Omega \nabla(v - u^*) \cdot a^*(\nabla u^* + \gamma^* \vec{e})\, dx \geqq 0.$$

Here X_0, X are as in Example 1, and $\vec{e} = (0, \cdots, 0, 1)$ stands for the gravitational direction. The problem (4.6) has a solution with $u^* \in M(g^*) \cap L^\infty(\Omega)$. For this and a detailed description of the physical background we refer to [1], [2]. We remark that $\{u^* > 0\}$ is the saturated region and that $\{\gamma^* = 0\}$ is the dry part of Ω.

Now set

$$V := \{ v \in H^1(\Omega) : v = 0 \text{ on } \Gamma^+ \}, \qquad K := \{ v \in V : v \leqq 0 \text{ on } \Gamma^0 \}.$$

Then (4.6) can be rewritten as

$$\int_\Omega \nabla(v - u^*) \cdot a^*(\nabla u^* + \nabla g^* + \gamma^* \vec{e})\, dx \geqq 0 \quad \forall v \in K, \tag{4.7}$$

where $u^* \in K$, $u^* \geqq -g^*$. The corresponding parameter identification problem is to reconstruct the permeability matrix:

(4.8) Given $u^* \in K \cap L^\infty(\Omega)$ with $u^* \geqq -g^*$ and $\gamma^* \in L^\infty(\Omega)$ with $0 \leqq \gamma^* \leqq 1$ and $\gamma^* = 1$ in $\{u^* > -g\}$, find $a^* \in X$ such that (4.7) holds.

We show that the theory of §2 applies. $(V, \|\cdot\|_{\mathring{H}^1(\Omega)})$ is a separable and reflexive Banach space with dense and continuous embedding into $H = L^2(\Omega)$. X, X_0 are as in Example 1. Moreover, $f^* = \Theta$, $S = \Theta$, $\Psi \equiv 0$, and $C := K$ is nonempty, closed and convex.

Since $g^* \in H^{1,\infty}(\Omega)$, $\gamma^* \in L^\infty(\Omega)$ the linear mapping A_1 defined by

$$\langle A_1(a), v\rangle := \int_\Omega \nabla v \cdot \big(a\big(\nabla g^* + \gamma^* \vec{e}\big)\big)\, dx \quad \forall v \in V,$$

is bounded. Moreove, the bilinear mapping A_2,

$$\langle A_2(a,u), v\rangle := \int_\Omega \nabla v \cdot (a \nabla u)\, dx \quad \forall v \in V,$$

satisfies (A3). As in Example 1, condition (A7) is fulfilled if only

$$\nabla v\big(\nabla u + \nabla g^* + \gamma^* \vec{e}\big)^T \in W_M \quad \forall u, v \in V_N. \tag{4.9}$$

This is possible if $V_N \subset H^{1,\infty}(\Omega)$ which by (A6) necessitates $u^* \in H^{1,\infty}(\Omega)$.

Example 4 (*linear elasticity*). We follow the lines of [5] and use the notation therein, in particular, the summation convention.

Let $\Omega \subset \mathbb{R}^3$ be the region occupied by an inhomogeneous elastic body with (sufficiently smooth) boundary $\partial\Omega$. Assume Ω is at equilibrium under the influence of forces which are distributed over Ω or act on $\partial\Omega$. We confine ourselves to the static (i.e. time-independent) case. The equations are

$$-\frac{\partial}{\partial x_j}\big(a^*_{ijkh}(x)\varepsilon_{kh}(u)\big) = f_i^* \quad \text{in } \Omega, \qquad i = 1,2,3. \tag{4.10}$$

Here

$$\varepsilon_{ij}(u) := \frac{1}{2}\left(\frac{\partial}{\partial x_i}u_j + \frac{\partial}{\partial x_j}u_i\right), \qquad i = 1,2,3,$$

are the components of the linearized strain tensor in dependence on the displacement vector $u = (u_1, u_2, u_3)$. The vector field $f^* = (f_1^*, f_2^*, f_3^*) \in (L^2(\Omega))^3$ represents a volume density of prescribed forces. $a^*_{ijkh} = a^*_{jihk} = a^*_{khij}$, i, j, k, $h = 1$, 2, 3, are the space-dependent coefficients of elasticity which satisfy the ellipticity condition

(4.11) $a^*_{ijkh}(x)\phi_{ij}\phi_{kh} \geqq \delta \phi_{ij}\phi_{ij}$, a.e. on Ω, for some $\delta > 0$, whenever (ϕ_{ij}) is a (3×3)-matrix.

Typical boundary conditions are (if no friction is present):

$$\partial\Omega = \Gamma_U \cup \Gamma_F, \quad \Gamma_U \cap \Gamma_F = \varnothing, \quad \operatorname{meas}(\Gamma_U) > 0, \tag{4.12}$$

$$u_i = U_i^* \in H^{1/2}(\partial\Omega) \quad \text{on } \Gamma_U, \qquad i = 1,2,3, \tag{4.13}$$

$$\sigma_{ij} n_j = F_i^* \in L^2(\Gamma_F) \quad \text{on } \Gamma_F, \qquad i = 1,2,3. \tag{4.14}$$

Here $n = (n_1, n_2, n_3)$ is the outer unit normal at $\partial\Omega$, $F^* = (F_1^*, F_2^*, F_3^*)$ represents a surface density of forces prescribed on Γ_F, and the components σ_{ij} of the stress tensor are linked to the components of the linearized strain tensor by

$$\sigma_{ij} = a^*_{ijkh}\varepsilon_{kh}(u), \qquad i,j = 1,2,3. \tag{4.15}$$

Now $(H^1(\Omega))^3 = \{v = (v_1, v_2, v_3) : v_i \in H^1(\Omega)\}$ is a Banach space when endowed with the norm

$$\|v\|_{(H^1(\Omega))^3} := \left[\int_\Omega \left\{ v_i v_i + \frac{\partial}{\partial x_j} v_i \frac{\partial}{\partial x_j} v_i \right\} dx\right]^{1/2}$$

By the trace theorem, $U^*=(U_1^*, U_2^*, U_3^*)$ is the trace of a function in $(H^1(\Omega))^3$ which is denoted by U^*, too. The substitution $u=u-U^*$ yields

$$(4.10)^* \qquad -\frac{\partial}{\partial x_j}\left(a_{ijkh}^*(x)\varepsilon_{kh}(u+U^*)\right)=f_i^* \quad \text{in } \Omega, \quad i=1,2,3;$$

$$(4.13)^* \qquad u_i=0 \quad \text{on } \Gamma_U, \qquad i=1,2,3;$$

$$(4.14)^* \qquad a_{ijkh}^*\varepsilon_{kh}(u+U^*)=F_i^*, \qquad i=1,2,3 \quad \text{on } \Gamma_F.$$

Now we define:

$$H := \left(L^2(\Omega)\right)^3,$$
$$V := \left\{v\in\left(H^1(\Omega)\right)^3 : v_i=0, \text{ on } \Gamma_U,\ i=1,2,3\right\},$$
$$X := \left\{a=(a_{ijkh}) : a_{ijkh}\in L^2(\Omega),\ 1\leqq i,\ j,\ k,\ h\leqq 3\right\},$$
$$X_0 := \left\{a\in X : a_{ijkh}\in L^\infty(\Omega),\ 1\leqq i,\ j,\ k,\ h\leqq 3\right\}.$$

X is a Hilbert space when endowed with the inner product

$$(4.16) \qquad [a,b] := \int_\Omega a_{ijkh}b_{ijkh}\,dx.$$

From Korn's inequality it follows (see [5]) that

$$\|v\|_V := \left[\int_\Omega \varepsilon_{ij}(v)\varepsilon_{ij}(v)\,dx\right]^{1/2}$$

defines a norm on V which is equivalent to $\|\cdot\|_{(H^1(\Omega))^3}$.

Now easy calculations using Green's formula (see [5]) show that (4.10)*, (4.12), (4.13)*, (4.14)* is equivalent to:

Given $a^*\in X_0$, $U^*\in(H^1(\Omega))^3$, $f^*\in H$, $F^*\in(L^2(\Gamma_F))^3$, find $u^*\in V$ such that for all $v\in V$:

$$(4.17) \qquad \int_\Omega a_{ijkh}^*\varepsilon_{kh}(u^*+U^*)\varepsilon_{ij}(v)\,dx=\int_\Omega f_i^*v_i\,dx+\int_{\Gamma_F}F_i^*v_i\,ds.$$

Expression (4.17) admits a unique solution ([5, p. 118, Thm. 3.5]). The corresponding identification problem consists in reconstructing the coefficients of elasticity from measurements of the displacements:

(4.18) Given $u^*\in V\cap(H^{1,\infty}(\Omega))^3$, $U^*\in(H^{1,\infty}(\Omega))^3$, $f^*\in H$, $F^*\in(L^2(\Gamma_F))^3$, find $a^*\in X$ with (4.17).

It is easy to check that the assumptions of §2 can be satisfied with the specifications

$$S=\Theta, \quad C=V, \quad \Psi(v) := -\int_{\Gamma_F}F_i^*v_i\,ds,$$

and A_1, A_2 defined by putting for all $v\in V$

$$\langle A_1(a), v\rangle := \int_\Omega a_{ijkh}\varepsilon_{kh}(U^*)\varepsilon_{ij}(v)\,dx,$$

$$\langle A_2(a,u), v\rangle := \int_\Omega a_{ijkh}\varepsilon_{kh}(u)\varepsilon_{ij}(v)\,dx.$$

In this case the assumption (A7) is satisfied if

$$\left(\varepsilon_{ij}(v)\varepsilon_{kh}(u+U^*)\right)\in W_M \quad \forall u,\, v\in V_N.$$

This is possible for $V_N\subset(H^{1,\infty}(\Omega))^3$.

Example 5 (*linear elasticity with friction*). Let in Example 4 the boundary condition (4.14) be replaced by a condition of friction type:

$$(4.14)^{**}\qquad \begin{aligned} &\sigma_N = F_N^* \quad \text{on } \Gamma_F,\\ &|\sigma_T| < \mathbf{F}|F_N^*| \Rightarrow u_T = \Theta,\\ &|\sigma_T| = \mathbf{F}|F_N^*| \Rightarrow \text{there is } \lambda\geqq 0 \text{ such that } u_T = -\lambda\sigma_T. \end{aligned}$$

Let $\operatorname{meas}(\Gamma_F)>0$. $\mathbf{F}\in L^\infty(\Gamma_F)$ is the friction coefficient, and $F_N^*\in L^\infty(\Gamma_F)$ is given. We assume $\mathbf{F}(x)\geqq \mathbf{F}_0>0$, a.e. on Γ_F. The normal stress $\sigma_N=\sigma_{ij}n_jn_i$ is a scalar, and $\sigma_T:=(\sigma_{1T},\sigma_{2T},\sigma_{3T})$ is given by $\sigma_{iT}:=\sigma_{ij}n_j-\sigma_Nn_i$.

Moreover, for $v\in(H^1(\Omega))^3$ we have

$$\begin{aligned} &v_N := v_in_i \text{ (normal displacement, scalar)},\\ &v_T := v-v_Nn \text{ (tangential displacement, vector)}. \end{aligned}$$

Again replacing u by $u-U^*$ one obtains (see [5]) that (4.10), (4.12), (4.13), (4.14)** are (formally) equivalent to:

(4.19) Given $a^*\in X_0$, $f^*\in H$, $U^*\in(H^1(\Omega))^3$, $F_N^*\in L^\infty(\Gamma_F)$ and $\mathbf{F}\in L^\infty(\Gamma_F)$, find $u^*\in V$ such that

$$\int_\Omega a^*_{ijkh}\varepsilon_{kh}(u^*+U^*)\varepsilon_{ij}(v-u^*)\,dx+j(v+U^*)-j(u^*+U^*)$$

$$\geqq \int_\Omega f_i^*(v_i-u_i^*)\,dx+\int_{\Gamma_F}F_N^*(v_N-u_N^*)\,ds \quad \forall v\in V.$$

Here j is the continuous and convex functional

$$(4.20)\qquad j(v):=\int_{\Gamma_F}\mathbf{F}|F_N^*|\,|v_T|\,ds.$$

It should be clear how the corresponding identification problem is formulated and how it fits into the framework of §2.

Remark 10. We have not given any examples for equations of evolution. In [7] the simplest case of identifying the system matrix of a system of ordinary differential equations is treated, and numerical results are given.

It should be clear from the preceding examples how for example the problem of reconstructing a time-dependent thermal conductivity matrix in a linear heat conduction problem can be fitted into the setting of §3.

REAL CONTINUED FRACTIONS AND ASYMPTOTIC EXPANSIONS*

BURNETT MEYER†

Abstract. Let $\mathbf{K}(a_n(x)/b_n(x))$ be a continued fraction, where $a_n(x)$ and $b_n(x)$ are polynomials with nonnegative coefficients, in a real variable x. Let the continued fraction correspond at $x=0$ to a formal power series in x or at $x=\infty$ to a formal power series in x^{-1}. Conditions are given which insure that the corresponding series are asymptotic expansions of the functions to which the odd and even parts of the continued fraction converge as $x\to 0+$ or as $x\to+\infty$.

Key words. continued fraction, asymptotic expansion, correspondence of power series

AMS(MOS) subject classifications. Primary 30B70, 30E15, 40A15

In this paper the author continues his study of a question posed by Jones and Thron [2, p.331]: Let a formal power series $\sum c_k z^{-k}$ be given, and let $\mathbf{K}(a_n(z)/b_n(z))$ be a continued fraction that corresponds to the above series at $z=\infty$ and that converges to a holomorphic function $f(z)$ in a region D with $z=\infty$ on its boundary. Is the given series the asymptotic expansion of $f(z)$ at $z=\infty$, with respect to D? A similar question can be asked if the correspondence is at $z=0$.

1. Preliminaries. We use the notation $\mathbf{K}_{n=1}^{\infty}(a_n/b_n)$ for the continued fraction

$$\frac{a_1}{b_1}+\frac{a_2}{b_2}+\cdots+\frac{a_n}{b_n}+\cdots.$$

In the following two definitions, asymptotic expansions and correspondence will be defined at a finite point z_0, with the modifications necessary for $z_0=\infty$ put in parentheses.

DEFINITION [1, p. 359]. Let f be a function defined on a set S in the complex plane with $z=z_0$ $(z=\infty)$ a limit point of S. Let $L=\sum_{k=0}^{\infty}c_k(z-z_0)^k$ $(L=\sum_{k=0}^{\infty}c_k z^{-k})$ be a formal power series in $z-z_0$ (z^{-1}). Let $G_n(z)=\sum_{k=0}^{n}c_k(z-z_0)^k$ $(G_n(z)=\sum_{k=0}^{n}c_k z^{-k})$. Then L is the asymptotic expansion of f as $z\to z_0$ $(z\to\infty)$, $z\in S$, if $f(z)-G_n(z)=O((z-z_0)^{n+1})$ $(f(z)-G_n(z)=O(z^{-n-1}))$, as $z\to z_0$ $(z\to\infty)$, $z\in S$, for $n=0,1,2,\cdots$.

DEFINITION [2, p. 149]. Let $\{f_n\}$ be a sequence of complex-valued functions of a complex variable z, each holomorphic at $z=z_0$ $(z=\infty)$. Let $L=\sum_{k=0}^{\infty}c_k(z-z_0)^k$ $(L=\sum_{k=0}^{\infty}c_k z^{-k})$ be a formal power series in $z-z_0$ (z^{-1}), and let

$$G_m(z)=\sum_{k=0}^{m}c_k(z-z_0)^k\qquad\left(G_m(z)=\sum_{k=0}^{m}c_k z^{-k}\right).$$

The sequence $\{f_n\}$ is said to *correspond* to L at $z=z_0$ $(z=\infty)$, with order of correspondence ν_n, if there exists a sequence $\{\nu_n\}$ of positive integers such that $\nu_n\to\infty$ and

$$f_n(z)-G_{\nu_n-1}(z)=O\big((z-z_0)^{\nu_n}\big)\qquad\big(f_n(z)-G_{\nu_n-1}(z)=O(z^{-\nu_n})\big)$$

as $z=z_0$ $(z\to\infty)$.

*Received by the editors April 15, 1985.
†Department of Mathematics, University of Colorado, Boulder, Colorado 80309.

A continued fraction is said to correspond to a formal power series if the sequence of its approximants corresponds to the series.

THEOREM 1 [4, p. 48]. *If $a_n>0$ and $b_n>0$ for all n, then the even approximants of $\mathbf{K}(a_n/b_n)$ form an increasing sequence, with limit k. The odd approximants form a decreasing sequence with limit K, and $0<k\leqq K<\infty$.*

The following lemma is probably not new, but the author is unable to find a reference.

LEMMA 1. *Let $\sum_{k=0}^{\infty}c_k(z-z_0)^k$ be a formal power series and let $G_m(z)=\sum_{k=0}^{m}c_k(z-z_0)^k$. If $f(z)-G_m(z)=O((z-z_0)^{m+1})$ as $z\to z_0$, $z\in S$ holds for $m=m_1$, then it holds for all nonnegative $m\leqq m_1$.*

Proof.

$$\left|f(z)-G_{m_1}(z)\right|=\left|f(z)-G_{m_1-1}(z)-c_{m_1}(z-z_0)^{m_1}\right|.$$

So there is a constant γ_{m_1+1} such that

$$\left|f(z)-G_{m_1-1}(z)\right|-\left|c_{m_1}(z-z_0)^{m_1}\right|\leqq\gamma_{m_1+1}\left|z-z_0\right|^{m_1+1}.$$

Hence, $f(z)-G_{m_1-1}(z)=O((z-z_0)^{m_1})$ as $z\to z_0$, $z\in S$. The proof is completed by repetition of the argument. □

The analogous lemma for $z_0=\infty$ is similarly proved.

2. The following theorem is an improvement on [3, Thm. 1].

THEOREM 2. *Let $\{f_n\}$ be a sequence of functions, holomorphic at z_0 and meromorphic in a domain D, with $z_0\in D$. Let z_0 be a limit point of a set $S\subset D$. Let $\{f_n\}$ correspond at z_0 to a formal power series $L=\sum_{k=0}^{\infty}c_k(z-z_0)^k$, and let $\nu_1\leqq\nu_2\leqq\cdots\leqq\nu_n\leqq\cdots$, with $\nu_n\to\infty$, where ν_n is the order of correspondence. If there exist a function f, defined on S, and positive constants k_n $(n=0,1,2,\cdots)$ such that*

$$\left|f(z)-f_n(z)\right|\leqq k_n\left|f_{n+1}(z)-f_n(z)\right| \tag{1}$$

for $z\in S$ and $n=0,1,2,\cdots$, then L is the asymptotic expansion of f as $z\to z_0$, $z\in S$.

Proof. Let $G_n(z)=\sum_{k=0}^{n}c_k(z-z_0)^k$. Then

$$\begin{aligned}\left|f(z)-G_n(z)\right|&\leqq\left|f(z)-f_n(z)\right|+\left|f_n(z)-G_n(z)\right|\\&\leqq k_n\left|f_{n+1}(z)-f_n(z)\right|+\left|\beta(z-z_0)^{\mu_n}+\cdots\right|,\end{aligned}$$

where $\mu_n=\min(\nu_n,n+1)$. Thus, $f(z)-G_n(z)=O((z-z_0)^{\mu_n})$ as $z\to z_0$, $z\in S$, for $n=0,1,2,\cdots$.

So

$$\begin{aligned}&\left|f(z)-G_{\mu_n-1}(z)-c_{\mu_n}(z-z_0)^{\mu_n}-\cdots-c_n(z-z_0)^n\right|\\&\qquad\leqq k_n\left|\alpha(z-z_0)^{\mu_n}+\cdots\right|+\left|\beta(z-z_0)^{\mu_n}+\cdots\right|.\end{aligned}$$

Thus, $f(z)-G_{\mu_n-1}(z)=O((z-z_0)^{\mu_n})$ as $z\to z_0$, $z\in S$, for $n=0,1,2,\cdots$. Since $\mu_n\to\infty$, we apply Lemma 1 to obtain

$$f(z)-G_{m-1}(z)=O\big((z-z_0)^m\big)\quad\text{as } z\to z_0,\ z\in S,\text{ for } m=0,1,2,\cdots.$$

(In the above proof we assumed $\nu_n<n+1$. If $\nu_n\geqq n+1$, the proof is easier.) □

A similar theorem can be proved for the case $z_0=\infty$, considering expansions of the form $\sum_{k=0}^{\infty} c_k z^{-k}$.

Also, the right side of (1) may be replaced by $k_n|f_n(z)-f_{n-1}(z)|$. See [3].

3. Real continued fractions. We now consider the real continued fraction $\mathbf{K}(a_n(x)/b_n(x))$, where a_n and b_n are polynomials in a real variable x. We will obtain simple "rules of thumb" for concluding that the corresponding power series at 0 or at ∞ are the asymptotic expansions of the limits of the continued fraction as $x\to 0+$ or as $x\to+\infty$, respectively.

Given the polynomial $P(x)=a_n x^n+\cdots+a_0$, $a_n\neq 0$, $n\geqq 0$. Let $d(P)=n$, the degree of P. Denote the degree of the nonzero term of P of *lowest* degree by $l(P)$. We call a polynomial nonnegative if all its coefficients are nonnegative.

THEOREM 3. *Let $a_n(x)$ and $b_n(x)$ be nonnegative polynomials. If $l(b_n(x))=0$ for all n and if $\sum_{k=1}^{n} l(a_k(x))\to\infty$ as $n\to\infty$, then the power series corresponding to $\mathbf{K}(a_n(x)/b_n(x))$ at $x=0$ is the asymptotic expansion of the limits of the odd and even parts of the continued fraction as $x\to 0+$.*

Proof. Let the nth approximant of the continued fraction be denoted by $f_n(x)=A_n(x)/B_n(x)$. Since $l(b_n)=0$, it is easily shown by induction, using the recursion formula for B_n [2, p. 20], that the constant term of $B_n(x)$ is >0. Now, by the determinant formula [2, p. 20]

$$\frac{A_{n+1}}{B_{n+1}}-\frac{A_n}{B_n}=\frac{(-1)^n\prod_{k=1}^{n+1}a_k(x)}{B_n(x)B_{n+1}(x)}=\frac{P(x)}{Q(x)}, \tag{2}$$

where $l(P(x))=\sum_{k=1}^{n+1} l(a_k(x))$ and $Q(x)$ is a polynomial with constant term >0. Therefore, the continued fraction corresponds to a power series, with order of correspondence $\sum_{k=1}^{n+1} l_k$.

By Theorem 1, the odd and even parts of the continued fraction converge to functions g_1 and g_2, respectively. The following inequalities hold:

$$f_{2n}(x)\leqq g_2(x)\leqq g_1(x)\leqq f_{2n+1}(x)$$

for $n=1,2,\cdots$ and $x>0$. Thus,

$$|g_k(x)-f_n(x)|\leqq|f_{n+1}(x)-f_n(x)|$$

for $k=1,2$, $n=1,2,\cdots$, and $x>0$. By Theorem 2 the corresponding series is the asymptotic expansion of g_1 and of g_2 as $x\to 0+$. □

We note that Theorem 3 applies to all positive C-fractions (not just the *regular* positive C-fractions), SITZ fractions, g-fractions, associated continued fractions for which the k_n are negative and the l_n are positive, and positive T-fractions. See [2, pp. 386–394] for definitions of these kinds of continued fractions.

THEOREM 4. *Let $a_n(x)$ and $b_n(x)$ be nonnegative polynomials of degrees d_n and e_n, respectively. Then the power series in z^{-1} corresponding to $\mathbf{K}(a_n(x)/b_n(x))$ at $x=\infty$ is the asymptotic expansion of the continued fraction as $x\to+\infty$, provided*

$$h_n=2\sum_{k=1}^{n} e_k+e_{n+1}-\sum_{k=1}^{n+1} d_k\to\infty \tag{3}$$

as $n\to\infty$. If $d_n\leqq e_n$ for all n, condition (3) may be replaced by the simpler condition $\sum_{k=1}^{n+1} e_k\to\infty$ as $n\to\infty$.

Proof. We use the notation of Theorem 3. Using induction and the recursion formula for B_n, we can prove that $d(B_n) \geqq e_1 + e_2 + \cdots + e_n$. We again use formula (2). We have $d(P) = \sum_{k=1}^{n+1} d_k$ and $d(Q) \geqq 2\sum_{k=1}^{n} e_k + e_{n+1}$. Thus, the continued fraction corresponds to a power series in z^{-1}, with order of correspondence $\geqq h_n$. The remainder of the proof is similar to the proof of Theorem 3. □

Theorem 4 applies to modified S-fractions, H-fractions if all the b_n are positive, J-fractions if all the c_n^2 are negative and all the d_n are positive, and positive T-fractions. And, of course, Theorems 3 and 4 apply to many continued fractions that have not been classified and given names.

4. An example. The continued fraction

$$\frac{1}{1} + \frac{x}{1} + \frac{x}{1} + \frac{2x}{1} + \frac{2x}{1} + \frac{3x}{1} + \cdots$$

corresponds at $x = 0$ to the series $\sum_{n=0}^{\infty} (-1)^n n! x^n$. [1, p. 519] By Theorem 4.58 in [2, p. 136], it follows that the continued fraction converges for all positive x. So, by Theorem 3, the series is the asymptotic expansion of the limit of the continued fraction, which is

$$\int_0^{\infty} \frac{e^{-s}\, ds}{1 + xs},$$

as $x \to 0+$.

BOREL SUMMABILITY AND CONVERGING FACTORS FOR SOME EVERYWHERE DIVERGENT SERIES*

AVRAM SIDI†

Abstract. In this work we deal with the problem of interpretation of certain classes of everywhere divergent power series within the framework of Borel summability, and derive asymptotic expansions for their partial sums and/or their converging factors when the number of terms in the partial sums goes to infinity.

Key words. divergent series, Borel summability, converging factors, asymptotic expansion

AMS(MOS) subject classifications. Primary 34E05, 40A05, 40D15, 40G10, 65B05, 65B10

1. Introduction. Consider the formal power series $F(\zeta):=\sum_{r=1}^{\infty}a_r\zeta^r$ whose terms are of the form

$$a_r=r^p w(r)(r!)^m, \tag{1.1}$$

where $p\geqq 0$ and $m\geqq 1$ are integers, and $w(r)$ is such that

$$w(r)\sim\sum_{i=0}^{\infty}\frac{w_i}{r^{i+\sigma}}\quad\text{as } r\to\infty,\quad\text{for some } \sigma>0, \tag{1.2}$$

with w_i being some constants independent of r. Obviously $F(\zeta)$ does not converge for any value of ζ. In this work we shall be concerned with the interpretation of the "sum" of $F(\zeta)$, and with the asymptotics of the converging factor of the partial sum $A_n(\zeta)=\sum_{i=1}^{n}a_i\zeta^i$ in the limit $n\to\infty$, for ζ fixed. This problem arises when one tries to apply the t or u transformation of Levin [4] to the sequence $A_j(\zeta)$, $j=1,2,\cdots$, to obtain an approximation to the "sum" of $F(\zeta)$, or to the anti-limit of the sequence $\{A_j(\zeta)\}$.

The t and u transformations are nonlinear methods for accelerating the convergence of a slowly converging sequence to its limit, or for effecting convergence of a diverging sequence to its anti-limit. There is ample numerical evidence (see the numerical examples given in [10]) that suggests that in order for the t (or u) transformation to be efficient on a sequence B_i, $i=1,2,\cdots$, B_i has to be of the form

$$B_{r-1}=B+R_r f(r), \tag{1.3}$$

where B is the limit or anti-limit of $\{B_i\}$, and $f(r)$ should be such that

$$f(r)\sim\sum_{i=0}^{\infty}\frac{\beta_i}{r^i}\quad\text{as } r\to\infty \tag{1.4}$$

and $R_r=r^{\lambda}b_r$, where $b_1=B_1$, $b_r=B_r-B_{r-1}$, $r\geqq 2$, and $\lambda=0$ for the t transformation (or $\lambda=1$ for the u transformation). From the conjectured behavior of B_i in (1.3) and (1.4), it follows that

$$b_{r+1}=c(r)b_r, \tag{1.5}$$

* Received by the editors October 19, 1982, and in revised form February 21, 1985.
† Computer Science Department,Technion–Israel Institute of Technolgy, Haifa, Israel.

where

$$c(r)=\frac{1+r^{\lambda}f(r)}{(r+1)^{\lambda}f(r+1)}\sim\sum_{i=0}^{\infty}\frac{c_i}{r^{i-q}}\quad\text{as } r\to\infty, \tag{1.6}$$

with q being an integer. The solution of (1.5) and (1.6) is known to be, see [3, p. 70], of the form $b_r=x^r v(r)(r!)^q$, with $v(r)$ being such that $v(r)\sim\sum_{i=0}^{\infty}v_i/r^{i+\alpha}$ as $r\to\infty$, for some α, cf. (1.1) and (1.2). With the help of [7, Thm. 6.1], it has been proved in [8, Thm. 2.2] that when $q=0$, and $\lim_{i\to\infty}B_i$ exists, i.e. $|x|>1$, the B_i satisfy (1.3) and (1.4). When $\lim_{i\to\infty}B_i$ does not exist, i.e., $|x|>1$ or $|x|\geqq 1$, it is not known, in general, whether (1.3) and (1.4) still hold, although, under certain circumstances, the techniques of the present work can be used to show that they do. This will be indicated at the end of §2. Using the technique of the proof of [8, Thm. 2.2], (1.3) and (1.4) can be shown to hold for all integers $q\leqq -1$ and for all x, since for this case $\lim_{i\to\infty}B_i$ exists for all x. For $q>0$, in which case $\lim_{i\to\infty}B_i$ does not exist for any x, no result like (1.3) and (1.4) is known in general, and precisely this is the subject of the present work. For $q=1$, (1.3) and (1.4) have been shown to hold for two special cases, see [9].

In the present work we actually show that under certain conditions, $A_i(\zeta)$ is of the form

$$A_{r-1}(\zeta)=A(\zeta)+a_r\zeta^r g(r,\zeta), \tag{1.7}$$

where $A(\zeta)$ is the Borel-type sum of $F(\zeta)$ (to be defined later), and the converging factor $g(r,\zeta)$ has an asymptotic expansion of the form

$$g(r,\zeta)\sim\sum_{i=0}^{\infty}\frac{g_i(\zeta)}{r^i}\quad\text{as } r\to\infty, \tag{1.8}$$

with $g_i(\zeta)$ being polynomials in ζ^{-1}. We also note that all of the numerical examples of everywhere divergent series considered in [11, Tables A3 and A4] are of the form above with $q>0$, and for these examples Levin's transformations produce accurate approximations to their Borel-type sums.

A similar but less general approach to the interpretation of divergent series has been introduced by Dingle in a series of papers, and this approach is summarized in his book [2, Chaps. XXI and XXII]. Dingle is concerned with summing the remainder series $\sum_{i=r}^{\infty}a_i\zeta^i$ for fixed r, whereas our main concern is with the asymptotics of it as $r\to\infty$. Olver's book [6, Chap. 14] contains another approach to the estimation of $\sum_{i=r}^{\infty}a_i\zeta^i$ that was introduced by Stieltjes, and developed further by Airy and J. C. P. Miller; see [6] for further references. Again our problem is different than that considered in Olver's book.

2. Theory.

LEMMA 2.1. *Define*

$$Q_k(r,z)=\left(z\frac{d}{dz}\right)^k\frac{z^r}{1-z}. \tag{2.1}$$

Then

$$Q_k(r,z)=\frac{\sum_{i=0}^{k}g_{k,i}(r)z^{r+i}}{(1-z)^{k+1}}, \tag{2.2}$$

where $g_{k,i}(r)$ are polynomials of degree k in r, satisfying

$$(2.3)\qquad \begin{aligned} &g_{k,0}(r)=r^k, \qquad g_{k,k}(r)=(1-r)^k,\\ &g_{k,i}(r)=(r+i)g_{k-1,i}(r)+(k-r-i+1)g_{k-1,i-1}(r), \qquad i=1,\cdots,k-1. \end{aligned}$$

Proof. Equation (2.3) follows easily by induction on k, starting with $k=0$ and $g_{0,0}(r)=1$. □

THEOREM 2.2. *Let a_r be expressible in the form*

$$(2.4)\qquad a_r=r^p w(r)\prod_{i=1}^{m}(\mu_i r+\nu_i)!,$$

where we assume that $p\geqq 0$ is an integer,

$$(2.4a)\qquad w(r)=\int_0^\infty e^{-rt}\varphi(t)\,dt, \qquad r\geqq 1,$$

for some function $\varphi(t)$ such that $\int_0^\infty e^{-t}|\varphi(t)|\,dt<\infty$, and μ_i and ν_i satisfy

$$(2.4b)\qquad \mu_i>0, \quad \mu_i+\nu_i>-1, \quad i=1,\cdots,m.$$

Obviously the power series $F(\zeta):=\sum_{r=1}^\infty a_r\zeta^r$ diverges for all $\zeta\neq 0$. For $0<\theta_0<\pi$ define the bounded sectors $S(\rho,\theta_0)$ in the ζ-plane by

$$(2.5)\qquad S(\rho,\theta_0)=\left\{\zeta=|\zeta|e^{i\theta}\colon |\zeta|\leqq\rho,\ \theta_0\leqq\theta\leqq 2\pi-\theta_0\right\}.$$

Then $F(\zeta)$ is the asymptotic expansion of its Borel-type sum

$$(2.6)\qquad \mathcal{F}(\zeta)=\int_0^\infty\cdots\int_0^\infty \psi(\vec{t})\left(z\frac{d}{dz}\right)^p\left(\frac{z}{1-z}\right)\prod_{i=0}^{m}dt_i,$$

as $\zeta\to 0$, uniformly in $S(\rho,\theta_0)$, for each finite ρ, where $\vec{t}=(t_0,t_1,\cdots,t_m)$, and

$$(2.6a)\qquad \psi(\vec{t})=\exp\left(-\sum_{i=1}^{m}t_i\right)\left(\prod_{i=1}^{m}t_i^{\nu_i}\right)\varphi(t_0),$$

$$(2.6b)\qquad z=\zeta e^{-t_0}\prod_{i=1}^{m}t_i^{\mu_i}.$$

The function $\mathcal{F}(\zeta)$ is analytic in the ζ-plane cut along $[0,\infty)$.

Remarks. (1) If $\varphi(t)\sim\sum_{i=0}^\infty\varphi_i t^{i+\sigma-1}$ as $t\to 0+$, with $\sigma>0$, the application of Watson's lemma, see [6, p. 71], yields $w(r)\sim\sum_{i=0}^\infty\varphi_i(i+\sigma-1)!/r^{i+\sigma}$ as $r\to\infty$, and this is exactly of the form given in (1.2) with $w_i=\varphi_i(i+\sigma-1)!$, $i=0,1,\cdots$. Furthermore, if we take $\mu_i=1$, $\nu_i=0$, $i=1,\cdots,m$, then we are back at (1.1) and (1.2).

(2) There is no loss of generality in assuming $\mu_i+\nu_i>-1$ in (2.4b). For, if $\mu_i+\nu_i>-1$ is not satisfied for all i, we can consider the series $F'(\zeta):=\sum_{r=1}^\infty a'_r\zeta^r$, where $a'_r=a_{r+k}$, with k being chosen such that $\mu_i+(k\mu_i+\nu_i)>-1$, $1\leqq i\leqq m$. Note that $F(\zeta)=A_k(\zeta)+\zeta^k F'(\zeta)$.

(3) The Borel-type sum $\mathcal{F}(\zeta)$ given in (2.6) is obtained by substituting (2.9) (see proof below) in $\sum_{r=1}^\infty a_r\zeta^r$, interchanging the summation with all the integrations, and then summing the geometric-type series $M(z)=\sum_{r=1}^\infty r^p z^r$ to obtain $M(z)=(zd/dz)^p(z/(1-z))$. It can be shown that the Borel sum of $F(\zeta)$, namely $\int_0^\infty e^{-t}(\sum_{r=1}^\infty a_r t^r\zeta^r/r!)\,dt$, see [3, p. 78], is its Borel-type sum when $m=1$, $\mu_1=1$, and $\nu_1=0$.

(4) If in (2.4) $r^p w(r)=Cr^{p'}$, where C is a constant and $p'=p-1\geqq 0$, then the Borel-type sum in (2.6) reduces to that obtained from (2.6) by omitting the integration with respect to t_0 after $\varphi(t_0)$ in $\psi(\vec{t})$ has been replaced by C, p has been replaced by p', and the factor e^{-t_0} has been deleted from z. This can be shown by observing that actually $w(r)=C/r$, thus $\varphi(t_0)=C$, and performing the integral with respect to t_0, reducing (2.6) to an m-dimensional integral.

Proof. Using the fact that

$$\frac{z}{1-z}=z+z^2+\cdots+z^{r-1}+\frac{z^r}{1-z}, \tag{2.7}$$

we have

$$\left(z\frac{d}{dz}\right)^p\frac{z}{1-z}=\sum_{j=1}^{r-1}j^p z^j+Q_p(r,z). \tag{2.8}$$

Letting z be as in (2.6b), and substituting (2.8) in (2.6), and using the fact that

$$j^p\int_0^\infty\cdots\int_0^\infty\psi(\vec{t})z^j\prod_{i=0}^m dt_i=a_j\zeta^j,\qquad j=1,2,\cdots, \tag{2.9}$$

we obtain

$$\mathscr{F}(\zeta)=A_{r-1}(\zeta)+U_r(\zeta), \tag{2.10}$$

where

$$U_r(\zeta)=\int_0^\infty\cdots\int_0^\infty\psi(\vec{t})Q_p(r,z)\prod_{i=0}^m dt_i. \tag{2.11}$$

From Lemma 2.1

$$Q_p(r,z)=\frac{\sum_{i=0}^p g_{p,i}(r)z^{r+i}}{(1-z)^{p+1}}. \tag{2.12}$$

It is easy to see that

$$|1-z|\geqq\sin\theta_0,\quad \text{all } \zeta\in S(\rho,\theta_0),\quad \text{all } \rho>0. \tag{2.13}$$

Substituting (2.12) in (2.11), taking the modulus of both sides, and using (2.13), we obtain

$$\begin{aligned}|U_r(\zeta)|\leqq(\sin\theta_0)^{-p-1}&\sum_{i=0}^p|g_{p,i}(r)||\zeta^{r+i}|\\&\times\left(\prod_{j=1}^m[\mu_j(r+i)+\nu_j]!\right)\int_0^\infty e^{-(r+i)t}|\varphi(t)|\,dt,\end{aligned} \tag{2.14}$$

which, for all $\zeta\in S(\rho,\theta_0)$, becomes

$$|U_r(\zeta)|\leqq K_r|\zeta|^r, \tag{2.15}$$

with K_r being *independent* of ζ. This proves the first part of the theorem. The second part of the theorem is obvious. □

We now go on to analyze the "remainder" term $U_r(\zeta)$ in the limit $r\to\infty$.

THEOREM 2.3. *Assume that all the conditions of Theorem* 2.2 *are satisfied, and, in addition,* $\varphi(t)$ *is continuous in a neighborhood of* 0 *except possibly at* 0, *and satisfies*

$$\varphi(t)\sim\varphi_0 t^{\sigma-1} \quad \text{as } t\to 0^+, \quad \text{for some } \sigma>0. \tag{2.16}$$

Then, for any integer $k\geqq 0$,

$$U_r(\zeta)=-\sum_{j=0}^{k-1} a_{r-1-j}\zeta^{r-1-j}+0\left(a_{r-1-k}\zeta^{r-1-k-p}\right) \quad \text{as } r\to\infty, \tag{2.17}$$

uniformly in ζ *for* $\zeta\in S(\rho,\theta_0)$, *for each finite* ρ.

Proof. Expressing $Q_p(r,z)$ (see (2.1)) in the form

$$Q_p(r,z)=-\left(z\frac{d}{dz}\right)^p\frac{z^{r-1}}{1-1/z}, \tag{2.18}$$

and making use of (2.7) with z replaced by $1/z$, we have, for any integers $k\geqq 1$ and $N\geqq k$,

$$Q_p(r,z)=-\sum_{j=0}^{N-1}(r-1-j)^p z^{r-1-j}+Q_p(r-N,z). \tag{2.19}$$

Substituting (2.19) in (2.11), and invoking (2.9), we obtain

$$U_r(\zeta)=-\sum_{j=0}^{N-1} a_{r-1-j}\zeta^{r-1-j}+U_{r-N}(\zeta). \tag{2.20}$$

Now $U_{r-N}(\zeta)$ satisfies (2.14) with r replaced by $r-N$. By (2.16), we conclude that

$$\begin{aligned}&\int_0^\infty e^{-rt}\varphi(t)\,dt\sim\varphi_0(\sigma-1)!/r^\sigma && \text{as } r\to\infty,\\ &\int_0^\infty e^{-rt}|\varphi(t)|\,dt\sim|\varphi_0|(\sigma-1)!/r^\sigma && \text{as } r\to\infty,\end{aligned} \tag{2.21}$$

see [6, p. 81]. Also, $g_{p,i}(r)=O(r^p)$ as $r\to\infty$, by Lemma 2.1. Consequently, for $\zeta\in S(\rho,\theta_0)$

$$|U_{r-N}(\zeta)|\leqq 0\left(r^{p-\sigma}|\zeta|^{r-N}\prod_{j=1}^{m}\left[\mu_j(r-N+p)+\nu_j\right]!\right) \quad \text{as } r\to\infty, \tag{2.22}$$

uniformly in ζ. Similarly

$$a_{r-N+p}\sim\varphi_0 r^{p-\sigma}\prod_{j=1}^{m}\left[\mu_j(r-N+p)+\nu_j\right]! \quad \text{as } r\to\infty. \tag{2.23}$$

Comparing (2.22) and (2.23), we obtain

$$|U_{r-N}(\zeta)|\leqq 0\left(a_{r-N+p}|\zeta|^{r-N}\right) \quad \text{as } r\to\infty, \tag{2.24}$$

uniformly in ζ for all $\zeta\in S(\rho,\theta_0)$.

Finally, by choosing $N=k+p+1$, and recalling that (see (2.23) above)

$$\lim_{r\to\infty}\frac{a_{r-j}}{a_r}=0, \qquad j=1,2,\cdots, \tag{2.25}$$

(2.17) follows. □

COROLLARY 2.4. *If* $\sum_{i=1}^{m}\mu_i=\mu$, *where* μ *is a positive integer, and if* $\varphi(t)$ *also satisfies*

$$\varphi(t)\sim\sum_{i=0}^{\infty}\varphi_i t^{i+\sigma-1}\quad \text{as } t\to 0^+,\quad \text{for some } \sigma>0, \tag{2.26}$$

then $U_r(\zeta)$ *is of the form*

$$U_r(\zeta)\sim a_r\zeta^r\sum_{i=0}^{\infty}\frac{\beta_i(\zeta)}{r^{i+\mu}}\quad \text{as } r\to\infty, \tag{2.27}$$

with $\beta_i(\zeta)$ *being polynomials in* ζ^{-1}. *Furthermore* (2.27) *is uniformly valid in* ζ *for* $\zeta\in T=S(\rho,\theta_0)\backslash\{\zeta\colon |\zeta|<\varepsilon\}$, *for any* $\varepsilon>0$.

Proof. As mentioned in the remark following the statement of Theorem 2.1, (2.4) and (2.26) imply that $w(r)\sim\sum_{i=0}^{\infty}\varphi_i(i+\sigma-1)!/r^{i+\sigma}$ as $r\to\infty$. This, together with the result

$$x^{\beta-\alpha}\frac{(x+\alpha)!}{(x+\beta)!}\sim 1+\sum_{i=1}^{\infty}\frac{c_i}{x^i}\quad \text{as } x\to\infty, \tag{2.28}$$

c_i being some constants independent of x (see [1, p. 257, formula 6.1.47]), give

$$\frac{a_{r-1-j}}{a_r}\sim r^{-\mu(1+j)}\left[1+\sum_{i=1}^{\infty}\frac{d_i^{(j)}}{r^i}\right]\quad \text{as } r\to\infty, \tag{2.29}$$

where $d_i^{(j)}$ are constants independent of r. Upon substituting (2.29) in (2.17), we obtain

$$U_r(\zeta)=a_r\zeta^r\left[\sum_{i=0}^{\mu(k+1)-1}\frac{\beta_i(\zeta)}{r^{i+\mu}}+O\left(\frac{1}{r^{\mu(k+1)}}\right)\right]\quad \text{as } r\to\infty, \tag{2.30}$$

with $\beta_i(\zeta)$ being given by

$$\beta_{j\mu+i}(\zeta)=-\sum_{l=0}^{j}d_{l\mu+i}^{(j-l)}\zeta^{-j+l-1},\quad 0\leqq i\leqq\mu-1,\quad j=0,1,\cdots, \tag{2.31}$$

where $d_0^{(j)}=1$, $j=0,1,\cdots$; hence $\beta_0(\zeta)=-\zeta^{-1}$. This completes the proof of the corollary. □

Remark. Under the conditions stated in the corollary above, we have actually shown that the partial sums of the everywhere divergent series $F(\zeta):=\sum_{r=1}^{\infty}a_r\zeta^r$ are of the form given in (1.7) and (1.8), with $A(\zeta)=\mathscr{F}(\zeta)$, the Borel-type sum of $F(\zeta)$, and $g_i(\zeta)=0$, $0\leqq i\leqq\mu-1$.

As an example, consider one of the series given in [11, Table A3], namely $\sum_{r=1}^{\infty}(-1)^{r-1}c_r/x^r$, with $c_1=2$ and $c_r=c_{r-1}(2r-3)^2$, $r\geqq 2$. Therefore, $(-1)^{r-1}c_r/x^r=a_r\zeta^r$, with $\zeta=-4/x$ and $a_r=-[(r-3/2)!]^2/(2\pi)$, $r\geqq 1$. That is to say, $\mu_1=\mu_2=1$, $\nu_1=\nu_2=-3/2$, and $r^p w(r)=Cr^{p'}$ with $C=-1/(2\pi)$ and $p'=p-1=0$ in Remark (4) following (2.6b). Consequently,

$$\mathscr{F}(\zeta)=-\frac{\zeta}{2\pi}\int_0^{\infty}\int_0^{\infty}e^{-(t_1+t_2)}\frac{(t_1t_2)^{-1/2}}{1-\zeta t_1t_2}\,dt_1\,dt_2.$$

By making the transformation of variables $t_1=\sqrt{x}\,t\cos^2\theta$, $t_2=\sqrt{x}\,t\sin^2\theta$, and performing the integral with respect to θ, we obtain

$$\mathscr{F}(\zeta)=\frac{2}{\sqrt{x}}\int_0^\infty e^{-\sqrt{x}t}\frac{dt}{(1+t^2)^{1/2}}=\frac{\pi}{\sqrt{x}}\left[\mathbf{H}_0(\sqrt{x})-Y_0(\sqrt{x})\right],$$

where $\mathbf{H}_\nu(z)$ is the Struve function of order ν [1, p. 496, formula 12.1.8]. The numerical result given in [11] for $x=4$ is another indication that the u-transformation produces approximations to $\mathscr{F}(\zeta)$.

Finally, we note that when $\mu_i=\nu_i=0$, $1\leqq i\leqq m$, in Theorem 2.2, $\mathscr{F}(\zeta)$ converges for $|\zeta|<1$ and diverges for $|\zeta|>1$. Thus, $\mathscr{F}(\zeta)$ represents an analytic function $u(\zeta)$ within the unit circle. Equation (2.6) now becomes

$$\mathscr{F}(\zeta)=\int_0^\infty \varphi(t)\left[z\frac{d}{dz}\right]^p\frac{z}{1-z}\,dt,\quad z=\zeta e^{-t}. \tag{2.32}$$

Since this time $\mathscr{F}(\zeta)$ is analytic in the ζ-plane cut along $[1,\infty)$, it represents the analytic continuation of $u(\zeta)$ outside the unit circle. Furthermore, (2.10) holds with (2.11) replaced by

$$U_r(\zeta)=\int_0^\infty \varphi(t)Q_p(r,z)\,dt. \tag{2.33}$$

Let us now assume that $\varphi(t)$ satisfies (2.26). Then substituting (2.12) in (2.33), and applying Watson's lemma for $r\to\infty$, after some manipulation of the asymptotic expansions that arise, we obtain (2.27) with $\mu=0$ there. Of course, in this case the $\beta_i(\zeta)$ are not necessarily polynomials in ζ^{-1}. In addition, (2.27) with $\mu=0$ holds for all $\zeta\notin[1,\infty)$, for which $F(\zeta)$ converges or diverges. The details are left to the interested reader.

3. Further developments. The results of the previous section have been based mainly on the assumptions of Theorem 2.2, namely (2.4) to (2.4b). It is these assumptions that enable one to express the Borel-type sum $\mathscr{F}(\zeta)$ of $F(\zeta)$ as in (2.6) to (2.6b). One important feature of (2.6) is the function $Q_p(1,z)=(zd/dz)^p(z/(1-z))$, which is very easy to handle. Actually this function has simple expansions about $z=0$ and $z=\infty$, and it is these expansions that lead to the results of Theorem 2.2, Theorem 2.3, and Corollary 2.4. In this section we seek to generalize the conditions of Theorem 2.2 in a way that will enable us to retain the function $Q_p(1,z)$. We note that the developments of this section can readily be applied to generalized hypergeometric functions.

THEOREM 3.1. *Let a_r be expressible in the form*

$$a_r=r^P w(r)\prod_{i=1}^{m}(\mu_i r+\nu_i)!\prod_{j=1}^{n}B\left(\kappa_j r+\lambda_j+1,\bar{\kappa}_j r+\bar{\lambda}_j+1\right), \tag{3.1}$$

where p, $w(r)$, μ_i, and ν_i are exactly as in Theorem 2.2,

$$\kappa_j\geqq 0,\quad \bar{\kappa}_j\geqq 0,\quad \kappa_j+\bar{\kappa}_j>0,\quad \kappa_j+\lambda_j>-1,\quad \bar{\kappa}_j+\bar{\lambda}_j>-1,\qquad j=1,\cdots,n, \tag{3.1a}$$

and $B(b,c)$ is the beta function defined by

$$B(b,c)=\int_0^1 \tau^{b-1}(1-\tau)^{c-1}d\tau=\frac{(b-1)!(c-1)!}{(b+c-1)!},\qquad \mathrm{Re}\,b>0,\qquad \mathrm{Re}\,c>0. \tag{3.1b}$$

It is clear that the power series $F(\zeta) := \sum_{r=1}^{\infty} a_r \zeta^r$ *diverges for all* $\zeta \neq 0$. *Define* $S(\rho, \theta_0)$ *again as in Theorem* 2.2. *Then* $F(\zeta)$ *is the asymptotic expansion of its Borel-type sum*

$$\mathscr{F}(\zeta) = \underbrace{\int_0^{\infty} \cdots \int_0^{\infty}}_{m+1 \text{ times}} \underbrace{\int_0^{1} \cdots \int_0^{1}}_{n \text{ times}} \psi(\vec{t}, \vec{\tau}) Q_p(1, z) \prod_{i=0}^{m} dt_i \prod_{j=1}^{n} d\tau_j, \tag{3.2}$$

as $\zeta \to 0$, *uniformly in* $S(\rho, \theta_0)$, *for each finite* ρ, *where* $\vec{t} = (t_0, t_1, \cdots, t_m)$, $\vec{\tau} = (\tau_1, \cdots, \tau_n)$, *and*

$$\psi(\vec{t}, \vec{\tau}) = \exp\left(- \sum_{i=1}^{m} t_i \right) \left(\prod_{i=1}^{m} t_i^{\nu_i} \right) \varphi(t_0) \left(\prod_{j=1}^{n} \left[\tau_j^{\lambda_j} (1 - \tau_j)^{\bar{\lambda}_j} \right] \right), \tag{3.2a}$$

$$z = \zeta e^{-t_0} \left(\prod_{i=1}^{m} t_i^{\mu_i} \right) \left(\prod_{j=1}^{n} \left[\tau_j^{\kappa_j} (1 - \tau_j)^{\bar{\kappa}_j} \right] \right), \tag{3.2b}$$

with the integrals over t_i, $0 \leqq i \leqq m$ *being from* 0 *to* ∞ *and those over* τ_j, $1 \leqq j \leqq n$, *from* 0 *to* 1. *The function* $\mathscr{F}(\zeta)$ *is analytic in the* ζ*-plane cut along* $[0, \infty)$.

Proof. Similar to that of Theorem 2.2. □

Remark. If in (3.1) $r^p w(r) = C r^{p'}$, where C is a constant and $p' = p - 1 \geqq 0$, then the Borel-type sum of $\mathscr{F}(\zeta)$ in (3.2) reduces to that obtained from (3.2) by omitting the integration with respect to t_0 after $\varphi(t_0)$ in $\psi(\vec{t}, \vec{\tau})$ has been replaced by C, and p by p', and the factor e^{-t_0} has been deleted from z. (cf. Remark (4) following statement of Theorem 2.2.)

THEOREM 3.2. *Assume that all the conditions of Theorem* 3.1 *are satisfied, and, in addition,* $\varphi(t)$ *is as in Theorem* 2.3. *Then, for any integer* $k \geqq 0$,

$$U_r(\zeta) = \mathscr{F}(\zeta) - A_{r-1}(\zeta) = - \sum_{j=0}^{k-1} a_{r-1-j} \zeta^{r-1-j} + O\left(a_{r-1-k} \zeta^{r-1-k-p} \right) \quad \text{as } r \to \infty, \tag{3.3}$$

uniformly in ζ *for* $\zeta \in S(\rho, \theta_0)$ *for each finite* ρ.

Proof. Similar to that of Theorem 2.3. □

COROLLARY 3.3. *If* $\sum_{i=1}^{m} \mu_i = \mu$, *where* μ *is an integer, and if* $\varphi(t)$ *is as in Corollary* 2.4, *then* $U_r(\zeta)$ *is of the form given in* (2.27), *with* $\beta_i(\zeta)$ *being polynomials in* ζ^{-1} *again.* (2.27) *is uniformly valid in* ζ *for* $\zeta \in T$.

Proof. Using Stirling's formula, it can be shown that for $r \to \infty$

$$B(\kappa r + \lambda, \bar{\kappa} r + \bar{\lambda}) \sim \begin{cases} \left[\dfrac{\kappa^{\kappa} \bar{\kappa}^{\bar{\kappa}}}{(\kappa + \bar{\kappa})^{\kappa + \bar{\kappa}}} \right]^r \displaystyle\sum_{i=0}^{\infty} \frac{e_i}{r^{i+1/2}} & \text{if } \kappa > 0, \quad \bar{\kappa} > 0, \\ \displaystyle\sum_{i=0}^{\infty} \frac{e_i'}{r^{i+\bar{\lambda}}} & \text{if } \kappa > 0, \quad \bar{\kappa} = 0, \end{cases} \tag{3.4}$$

where e_i and e_i' are constants independent of r. With the help of (3.4), the proof of this corollary can now be accomplished as that of Corollary 2.4. □

Note. The results above are applicable to series $F(\zeta)$ for which

$$a_r = r^p w(r) \frac{\prod_{i=1}^{m'} (\varepsilon_i r + \delta_i)!}{\prod_{i=1}^{n'} (\varepsilon_i r + \bar{\delta}_i)!}, \tag{3.5}$$

with p and $w(r)$ as before, $\varepsilon_i > 0$, $\varepsilon_i + \delta_i > -1$, $\bar{\delta}_i > \delta_i$, $1 \leqq i \leqq n'$, $m' > n'$. This is so since a_r can be expressed as in (3.1), due to the fact that

$$\frac{(\varepsilon r+\delta)!}{(\varepsilon r+\bar{\delta})!} = \frac{B(\varepsilon r+\delta+1, \bar{\delta}-\delta)}{(\bar{\delta}-\delta-1)!}. \tag{3.6}$$

There is no loss of generality in assuming that $\bar{\delta}_i > \delta_i$, $1 \leqq i \leqq n'$, for if $\bar{\delta}_i \leqq \delta_i$ for some i, say $i = q$, then $(\varepsilon_q r + \bar{\delta}_q)!$ and r^p in (3.5) can be replaced by $[\varepsilon_q r + (k\varepsilon_q + \bar{\delta}_q)]!$ and the polynomial $r^p \prod_{j=1}^{k} (\varepsilon_q r + j\varepsilon_q + \bar{\delta}_q)$ respectively, such that $\hat{\delta}_q = k\varepsilon_q + \bar{\delta}_q > \delta_q$. In general, we can express a_r as $a_r = \sum_{j=1}^{k} h_j a_r^{(j)}$, where

$$a_r^{(j)} = r^{p+j} w(r) \frac{\prod_{i=1}^{m'} (\varepsilon_i r + \delta_i)!}{\prod_{i=1}^{n'} (\varepsilon_i r + \hat{\delta}_i)!}, \qquad 1 \leqq j \leqq k,$$

with $\hat{\delta}_i > \delta_i$, $1 \leqq i \leqq n'$. Now we apply Theorem 3.1, Theorem 3.2 and Corollary 3.3 to each of the series $\sum_{r=1}^{\infty} h_j a_r^{(j)} \zeta^r$ and add the results. The overall result is that Theorem 3.1, Theorem 3.2 and Corollary 3.3 hold for the series $F(\zeta) := \sum_{r=1}^{\infty} a_r \zeta^r$, even though $\bar{\delta}_i > \delta_i$ is not satisfied for all $1 \leqq i \leqq n'$. Thus our results can be applied to the generalized hypergeometric functions ${}_pF_q$, where

$${}_pF_q\left(\begin{matrix} \alpha_1, \cdots, \alpha_p \\ \rho_1, \cdots, \rho_q \end{matrix} \middle| \zeta \right) = \sum_{k=0}^{\infty} \frac{\prod_{h=1}^{p} (\alpha_h)_k \zeta^k}{\prod_{h=1}^{q} (\rho_h)_k k!}$$

with $(c)_k = \Gamma(c+k)/\Gamma(c)$, $k = 0, 1, \cdots$, see [5, p. 155], when $p > q+1$.

Note also that the representation given in (3.2) is somewhat related to the beta transform described in [5, p. 160].

As an example, we consider the asymptotic series $\sum a_r \zeta^r$ with

$$a_r = (\alpha)_{r-1} (1+\alpha-\beta)_{r-1} / (n-1)! \quad \text{and} \quad \zeta = -1/x.$$

That is to say, a_r is expressible as

$$a_r = -\frac{(r+\alpha-\beta-1)! B(r+\alpha-1, 1-\alpha)}{(-\alpha)!(\alpha-1)!(\alpha-\beta)!}.$$

By the remark above, $\mathscr{F}(\zeta)$ can be expressed as a double integral that can be reduced to a one-dimensional integral, which, by using some relations among the confluent hypergeometric functions of different parameters, can be shown to be $-x^{\alpha-1} U(\alpha, \beta, x)$. Again [11, Table A3] contains numerical results for different values of α, β, and x, that indicate that the u-transformation produces approximations to $\mathscr{F}(\zeta)$.

4. Concluding remarks. We have shown that under the conditions stated in Corollary 2.4 and Corollary 3.3, the partial sums $A_{r-1}(\zeta) = \sum_{i=1}^{r-1} a_i \zeta^i$ of the everywhere divergent series $F(\zeta) := \sum_{i=1}^{\infty} a_i \zeta^i$ are of the form (1.7) and (1.8), where $A(\zeta)$ is the Borel-type sum of $F(\zeta)$. As mentioned in the introduction to this work, most of the examples of everywhere divergent series considered in [11] satisfy the requirements of Corollary 2.4 and Corollary 3.3; furthermore, after some tedious calculations, involving manipulation of (2.6) and (3.2), one observes for all these examples, that the numbers obtained by applying Levin's t or u transformation to $A_i(\zeta)$, are approximations to the Borel-type sum of $F(\zeta)$. In view of this observation, we conjecture that for the kind of series considered in Corollary 2.4 and Corollary 3.3, Levin's t and u transformations produce approximations that converge to the Borel-type sums of these series.

NIELSEN'S GENERALIZED POLYLOGARITHMS*

K. S. KÖLBIG†

Abstract. Properties (in particular functional relations and special values) of the functions

$$(-1)^{n+p-1}(n-1)!p!S_{n,p}(z)=\int_0^1 \log^{n-1}t\log^p(1-zt)\frac{dt}{t},$$

$$(-1)^{n+p-1}(n-1)!p!L_{n,p}(z)=\int_0^z \log^{n-1}t\log^p(1-t)\frac{dt}{t},$$

$$(-1)^{n-1}(n-1)!p!M_{n,p}(z)=\int_0^z \log^{n-1}t\log^p(1+t)\frac{dt}{t},$$

which play a role in the computation of higher order radiative corrections in quantum electrodynamics, are discussed for complex z and positive integers n and p. The first function is a generalization of the well-known polylogarithms ($p=1$). The discussion is based on results published by Nielsen early this century in a little-known monograph.

Key words. Nielsen's generalized polylogarithms, polylogarithms, Spence functions, logarithmic integrals, Riemann zeta functions, Stirling numbers of the first kind

AMS(MOS) subject classification. Primary 33A70

1. Introduction.

A certain class of logarithmic integrals, the so-called polylogarithms, defined by

$$Li_n(x)=\frac{(-1)^{n-1}}{(n-2)!}\int_0^1 \log^{n-2}t\log(1-xt)\frac{dt}{t}, \qquad (n\geqq 2), \tag{1.1}$$

has been investigated in the past by many mathematicians, including Euler, Kummer, Abel and Spence. In particular, their properties with respect to transformations of the variable were established for several special cases, for example, for the dilogarithm ($n=2$) and the trilogarithm ($n=3$). A special property of these functions is the relation

$$Li_n(1)=\zeta(n) \tag{1.2}$$

where $\zeta(n)$ is the Riemann zeta function of integer argument.

At the beginning of this century, the Danish mathematician Niels Nielsen collected the known results into a monograph [20], and introduced a new class of functions, namely

$$S_{n,p}(z)=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^1 \log^{n-1}t\log^p(1-zt)\frac{dt}{t}, \tag{1.3}$$

defined for positive integers n,p, and complex $z=x+iy$. The function $\log\zeta$ is understood to lie on its principal sheet, and we define

$$\log\xi=\lim_{\varepsilon\to 0+}\log(\xi+i\varepsilon)=\log|\xi|+i\pi \quad \text{if } \xi<0. \tag{1.4}$$

* Received by the editors September 10, 1984.

Because of the fact that

$$S_{n-1,1}(z)=Li_n(z),$$

these functions are generalizations of the polylogarithms (1.1). It is likely that Nielsen undertook his research on $S_{n,p}(z)$ in the hope of finding expressions for $\zeta(2k+1)$ similar to those known for $\zeta(2k)$, and results for

$$\beta(2k)=\sum_{j=0}^{\infty}\frac{(-1)^j}{(2j+1)^{2k}} \qquad (k=1,2,\cdots), \tag{1.5}$$

similar to those known for $\beta(2k+1)$. At least he remarked [20, pp. 131, 204] that he was not able to obtain such results from his relations for $S_{n,p}(z)$.

Nielsen's monograph [20] contains many formulae for $S_{n,p}(z)$ and for two related functions $L_{n,p}(z)$ and $M_{n,p}(z)$, in particular involving transformations of the argument z. Although most of his formulae are correct (apart from misprints) for complex $z=x+iy$ with $y\neq 0$, the direct replacement of z by real x may lead to discrepancies when the functions involved are complex-valued for real x. This fact has been overlooked in [12]. As far as the author knows, these formulae have never found their way into any of the relevant handbooks, and it seems that the only reference to this monograph until about fifteen years ago was in the book of Lewin [16]. About this time, however, it became apparent that Nielsen, although he did not succeed in finding results for $\zeta(2k+1)$ and $\beta(2k)$, had introduced a class of functions which are of importance in certain applications, in particular in quantum electrodynamics (see, for example, [2], [3], [6], [15], [18], [19]). With this application in mind, functional relations for $S_{n,p}(z)$ were presented in [12], together with a method for computing $S_{n,p}(z)$ accurately (12–14 digits) for real $z=x$ and $n+p\leqq 5$. Also some of Nielsen's ideas, in particular on the special values $s_{n,p}=S_{n,p}(1)$ and on a similar integral, have been investigated further [12], [13], [14]. Jacobs and Lambert [11] have developed a method for computing $S_{1,1}(z)$ and $S_{2,1}(z)$ for complex values of z, and Barlow [4] has considered the computation of $S_{n,p}(z)$ for complex z by continued fraction approximants.

An explanation for the fact that Nielsen's monograph remained undiscovered for so long lies perhaps in the fact that it was published in a journal which (at least for mathematicians and physicists) was little-known and not easy to obtain. Further, it contains an unusually large number of misprints and, as we shall see, genuine errors. It is, however, far from being out-of-date or without interest. Integrals of this type or even, in some respects, more general, such as

$$\int_0^1 \frac{\log^m t\log^n(1-t)\log^p(1+t)}{D(t)}\,dt$$

where m,n, and p are nonnegative integers, and $D(t)=t$, $1-t$, or $1+t$, play a role in the evaluation of Feynman and relativistic phase space integrals, as is indicated by the recent publication of a table by Gastmans and Troost [7]. These authors also discuss certain special values of the polylogarithms, a problem which Nielsen investigated in a more general way for his functions, and give a table of infinite series related to polylogarithmic integrals.

Therefore, for historical and practical reasons, it is perhaps worthwhile to give a systematic and critical presentation of the more important part of Nielsen's work on generalized polylogarithms, which until now has not been generally accessible. For

example, Lewin [17, p. 199], in a new edition of [16], remarked that it was not possible for him to give a discussion of the general results obtained by Nielsen, although he cites Nielsen's monograph many times. Also, the table of Gröbner and Hofreiter [9, pp. 71–73] contains a chapter on "Euler's dilogarithm and its generalisations" and a reference to [20], but only formulae for $p=1$ are given there.

In the presentation which follows, we shall follow the original monograph fairly closely, but on some occasions we shall present new results or proofs; for example, certain constants appearing in the functional equation relating $S_{n,p}(z)$ to $S_{\nu,\rho}(1/z)$ will be expressed in terms of known constants. Special attention will also be given to the correct representation of the functional relations for real arguments.

2. Basic formulae. Nielsen's generalized polylogarithms can be defined by [12], [20]

$$S_{n,p}(z)=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^1 \log^{n-1}t\log^p(1-zt)\frac{dt}{t} \tag{2.1}$$

$$=\sum_{j=0}^{\infty}\frac{(-1)^j S_{p+j}^{(p)}}{(p+j)!(p+j)^n}z^{p+j} \qquad (|z|\leqq 1) \tag{2.2}$$

$$=\frac{(-1)^{n-1}}{(n-1)!p!}\left[\frac{\partial^{n+p-1}}{\partial\beta^{n-1}\partial\alpha^p}\frac{1}{\beta}{}_2F_1(\alpha,\beta;\beta+1;z)\right]_{\alpha=\beta=0} \tag{2.3}$$

where

$${}_2F_1(\alpha,\beta;\gamma;z)=\frac{\Gamma(\gamma)}{\Gamma(\beta)\Gamma(\gamma-\beta)}\int_0^1 t^{\beta-1}(1-t)^{\gamma-\beta-1}(1-tz)^{-\alpha}dt$$

is the Gaussian hypergeometric function, and

$$S_k^{(m)}=\sum_{i=0}^{k-m}\frac{1}{i!}\binom{k-1+i}{k-m+i}\binom{2k-m}{k-m-i}\sum_{j=0}^{i}(-1)^i\binom{i}{j}^{k-m+i}$$

are the Stirling numbers of the first kind in Schlömilch's representation [5, p. 216], generated by [1], [5, p. 212]

$$\log^m(1+x)=m!\sum_{k=m}^{\infty}S_k^{(m)}\frac{x^k}{k!} \qquad (|x|<1). \tag{2.4}$$

In this paper, we shall use Nielsen's notation

$$S_n(z)=S_{n-1,1}(z)$$

instead of the notation $Li_n(z)$ introduced by Lewin [16], [17].

It follows from the series definition (2.2) that, for the polylogarithms,

$$S_n(z)=\sum_{j=1}^{\infty}\frac{z^j}{j^n}=\frac{z}{1^n}+\frac{z^2}{2^n}+\frac{z^3}{3^n}+\cdots \qquad (|z|\leqq 1)\quad (n>1). \tag{2.5}$$

For $n=1$ and $n=0$, we have as degenerate cases

$$S_1(z)=-\log(1-z),\quad S_0(z)=\frac{z}{1-z},\quad (|z|<1). \tag{2.6}$$

For $p>1$, the series (2.2) becomes considerably more complicated. By writing [5, p. 217]

$$S_{j+2}^{(2)}=(-1)^j(j+1)!\sum_{k=1}^{j+1}\frac{1}{k}, \tag{2.7}$$

$$S_{j+3}^{(3)}=(-1)^j(j+2)!\left[\left(\sum_{k=1}^{j+2}\frac{1}{k}\right)^2-\sum_{k=1}^{j+2}\frac{1}{k^2}\right], \tag{2.8}$$

we find, for example

$$S_{n,2}(z)=\frac{z^2}{2^{n+1}}+\left(1+\frac{1}{2}\right)\frac{z^3}{3^{n+1}}+\left(1+\frac{1}{2}+\frac{1}{3}\right)\frac{z^4}{4^{n+1}}+\cdots, \tag{2.9}$$

$$S_{n,3}(z)=\frac{1}{2}\left[\left(1+\frac{1}{2}\right)^2-\left(1+\frac{1}{4}\right)\right]\frac{z^3}{3^{n+1}} + \frac{1}{2}\left[\left(1+\frac{1}{2}+\frac{1}{3}\right)^2-\left(1+\frac{1}{4}+\frac{1}{9}\right)\right]\frac{z^4}{4^{n+1}}+\cdots. \tag{2.10}$$

From (2.1) and (2.2) one may easily obtain

$$\frac{d}{dz}S_{n,p}(\alpha z)=\begin{cases}\dfrac{(-1)^p}{p!}\dfrac{1}{z}\log^p(1-\alpha z), & (n=1),\\[2ex] \dfrac{1}{z}S_{n-1,p}(\alpha z), & (n\geqq 2),\end{cases} \tag{2.11}$$

$$\begin{aligned} S_{n,p}(\alpha z)&=\int_0^z\frac{1}{\zeta}S_{n-1,p}(\alpha\zeta)\,d\zeta, \qquad (n\geqq 1),\\ S_{n,p}(z)&=\frac{1}{p!p^n}z^p+O(z^{p+1}), \qquad (z\to 0),\end{aligned} \tag{2.12}$$

and from (5.12) below,

$$S_{n,p}(z)=\frac{(-1)^p}{(n+p)!}\log^{n+p}(-z)+O\left(\log^{n-1}(-z)\right), \quad (z\to\infty).$$

In order to derive his relations, Nielsen introduces in addition the functions

$$L_{n,p}(z)=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^z\log^{n-1}t\log^p(1-t)\frac{dt}{t}, \qquad (n\geqq 1, p\geqq 1), \tag{2.13}$$

$$M_{n,p}(z)=\frac{(-1)^{n-1}}{(n-1)!p!}\int_0^z\log^{n-1}t\log^p(1+t)\frac{dt}{t}, \qquad (n\geqq 1, p\geqq 1). \tag{2.14}$$

Using the binomial theorem, it is easy to see that

$$S_{n,p}(z)=\sum_{j=0}^{n-1}\frac{\log^j z}{j!}L_{n-j,p}(z), \tag{2.15}$$

$$L_{n,p}(z)=\sum_{j=0}^{n-1}\frac{(-1)^j\log^j z}{j!}S_{n-j,p}(z), \tag{2.16}$$

and

$$(-1)^p S_{n,p}(-z)=\sum_{j=0}^{n-1}\frac{\log^j z}{j!}M_{n-j,p}(z), \tag{2.17}$$

$$M_{n,p}(z)=(-1)^p\sum_{j=0}^{n-1}\frac{(-1)^j\log^j z}{j!}S_{n-j,p}(-z). \tag{2.18}$$

In particular,

$$L_{1,p}(z)=S_{1,p}(z),\qquad M_{1,p}(z)=(-1)^p S_{1,p}(-z). \tag{2.19}$$

The values of $S_{n,p}(z)$ for $z=1,-1$ and $\frac{1}{2}$ are of special interest. These values are real, and we define

$$\begin{aligned} s_{n,p}&=S_{n,p}(1)=L_{n,p}(1),\\ \sigma_{n,p}&=(-1)^p S_{n,p}(-1)=M_{n,p}(1),\\ a_{n,p}&=S_{n,p}(\tfrac{1}{2}). \end{aligned} \tag{2.20}$$

We also write

$$s_n=s_{n-1,1},\quad \sigma_n=\sigma_{n-1,1},\quad a_n=a_{n-1,1}.$$

Properties of $s_{n,p}$, $\sigma_{n,p}$ and $a_{n,p}$ are discussed in §9. For the moment, we note only that $s_{n,p}$ can be expressed in $\zeta(k)$, that

$$s_{n,p}=s_{p,n}, \tag{2.21}$$

which follows from the definition integral (2.1) by partial integration, and that

$$s_n=\zeta(n),\qquad \sigma_n=(1-2^{1-n})\zeta(n), \tag{2.22}$$

which follows from (2.5), using well-known properties of the Riemann zeta function.

3. Some analytical properties of $S_{n,p}(z)$, $L_{n,p}(z)$, and $M_{n,p}(z)$. With the general definition of the logarithm function, $S_{n,p}(z)$, $L_{n,p}(z)$, and $M_{n,p}(z)$ are multi-valued functions of z. By restricting $\log\zeta$ to its principal sheet, using (1.4), and cutting the z-plane appropriately, we obtain single-valued functions which are holomorphic at all finite points z with the exception of the branch-cuts. In the remainder of this section, we define these cuts along sections of the real axis $z=x$ and describe the behavior of these functions on this axis, in particular on the cuts. These properties will be required later.

3.1. $S_{n,p}(z)$. In this case, we have as branch points $z=1$ and $z=\infty$, and we cut the z-plane along the real axis from $x=1$ to ∞. For $x\leqq 1$, $S_{n,p}(x)$ is real. For the behavior on the cut, we have from (1.3) and (1.4)

$$\begin{aligned} &\lim_{\varepsilon\to 0+} S_{n,p}(x-i\varepsilon)=S_{n,p}(x),\\ &\lim_{\varepsilon\to 0+} S_{n,p}(x+i\varepsilon)=S^*_{n,p}(x), \end{aligned}\qquad (x>1), \tag{3.1}$$

where the asterisk denotes the complex conjugate. Therefore, $S_{n,p}(z)$ is, on the cut, continuous from below.

3.2. $L_{n,p}(z)$ $(n>1)$. Because of (2.19), we can make the restriction $n>1$. As branch points, we find $z=0$, $z=1$ and $z=\infty$, and we cut the z-plane along the real axis from $x=1$ to ∞, and from $x=0$ to $-\infty$. For $0\leqq x\leqq 1$, $L_{n,p}(x)$ is real. On the cuts, we have from (2.16),

$$\begin{aligned} &\lim_{\varepsilon\to 0+} L_{n,p}(x+i\varepsilon)=L_{n,p}(x),\\ &\lim_{\varepsilon\to 0+} L_{n,p}(x-i\varepsilon)=L^{*}_{n,p}(x), \end{aligned} \qquad (x<0), \tag{3.2}$$

and

$$\begin{aligned} &\lim_{\varepsilon\to 0+} L_{n,p}(x-i\varepsilon)=L_{n,p}(x),\\ &\lim_{\varepsilon\to 0+} L_{n,p}(x+i\varepsilon)=L^{*}_{n,p}(x), \end{aligned} \qquad (x>1), \tag{3.3}$$

so that $L_{n,p}(z)$ is continuous from above for $x<0$, and continuous from below for $x>1$.

3.3. $M_{n,p}(z)$. From (2.19) and (3.1), we find for $n=1$ that the branch points are $z=-1$ and $z=\infty$, and we cut the z-plane from $x=-1$ to $-\infty$. On the cut, we have

$$\begin{aligned} &\lim_{\varepsilon\to 0+} M_{1,p}(x+i\varepsilon)=M_{1,p}(x),\\ &\lim_{\varepsilon\to 0+} M_{1,p}(x-i\varepsilon)=M^{*}_{1,p}(x), \end{aligned} \qquad (x<-1), \tag{3.4}$$

so that $M_{1,p}(z)$ is continuous from above for $x<-1$. For $x\geqq -1$, $M_{1,p}(x)$ is real.

For $n>1$, we find from (2.18)

$$\lim_{\varepsilon\to 0+} M_{n,p}(x\pm i\varepsilon)=(-1)^{p}\sum_{j=0}^{n-1}\frac{(-1)^{j}\log^{j}(x\pm i\varepsilon)}{j!}S_{n-j,p}(-x\mp i\varepsilon).$$

Because of (1.4) and (3.1), it follows that $M_{n,p}(z)$ has branch points at $z=0$ and $z=\infty$, and we cut the z-plane from $x=0$ to $-\infty$. Then

$$\begin{aligned} &\lim_{\varepsilon\to 0+} M_{n,p}(x+i\varepsilon)=M_{n,p}(x),\\ &\lim_{\varepsilon\to 0+} M_{n,p}(x-i\varepsilon)=M^{*}_{n,p}(x), \end{aligned} \qquad (x<0). \tag{3.5}$$

For $x\geqq 0$, $M_{n,p}(x)$ is real. Thus, $M_{n,p}(z)$ is continuous from above for $x<0$ $(n\geqq 1, p\geqq 1)$.

4. A lemma. In order to establish some of the functional relations for the generalized polylogarithms, Nielsen needs the following

LEMMA. *Let the complex quantities* x_j, y_j $(j=1,\cdots,n)$, *and* α, *for* $n=1,2,3,\cdots$, *be related by*

$$x_n=\sum_{j=0}^{n-1}\frac{\alpha^{j}}{j!}y_{n-j}. \tag{4.1}$$

Then

$$y_n=\sum_{j=0}^{n-1}(-1)^{j}\frac{\alpha^{j}}{j!}x_{n-j}, \tag{4.1a}$$

and

$$\text{(4.1b)}\qquad \sum_{j=0}^{n-1}\frac{\alpha^j}{j!}\binom{n+r-j-1}{r}y_{n+r-j}=\sum_{m=0}^{r}(-1)^m\frac{\alpha^m}{m!}\binom{n+r-m-1}{r-m}x_{n+r-m}.$$

Proof. The first result (4.1a) is well known. Nielsen obtains (4.1a) by using relations between integrals (see Lewin [17, p. 266]), but mentions that it can be proved directly. An elementary proof follows from the well-known binomial inversion theorem [21, p. 45], namely

$$a_n=\sum_{j=0}^{n}\binom{n}{j}b_{n-j},\qquad b_n=\sum_{j=0}^{n}(-1)^j\binom{n}{j}a_{n-j},$$

by setting $a_0=b_0=0$ and

$$a_k=k!\alpha^{-k}x_k,\qquad b_k=k!\alpha^{-k}y_k.$$

Note that, for fixed p, $L_{n,p}(x)$, $S_{n,p}(x)$, and $M_{n,p}(x)$, $(-1)^pS_{n,p}(-x)$ are, according to (2.15)–(2.18) pairs of functions related by this lemma.

In order to prove (4.1b), Nielsen uses a form of Vandermonde's convolution theorem (see, for example, Riordan [21, pp. 8–10]), namely

$$\text{(4.2)}\qquad \sum_{m=0}^{r}(-1)^m\binom{j}{m}\binom{n+r-m-1}{r-m}=\binom{n-j+r-1}{r},$$

in particular

$$\text{(4.3)}\qquad \sum_{m=0}^{r}(-1)^m\binom{n+k}{m}\binom{n+r-m-1}{r-m}=0,\qquad (0\leqq k\leqq r-1).$$

Denoting the left-hand side of (4.1b) by $A_{n,r}$, we obtain, using (4.2),

$$\text{(4.4)}\qquad A_{n,r}=\sum_{j=0}^{n-1}\frac{\alpha^j}{j!}\sum_{m=0}^{r}(-1)^m\binom{j}{m}\binom{n+r-m-1}{r-m}y_{n+r-j}$$

$$=\sum_{m=0}^{r}(-1)^m\frac{\alpha^m}{m!}\binom{n+r-m-1}{r-m}\sum_{j=0}^{n-m-1}\frac{\alpha^j}{j!}y_{n+r-m-j}.$$

From (4.1), we have

$$\text{(4.5)}\qquad \sum_{j=0}^{n-m-1}\frac{\alpha^j}{j!}y_{n+r-m-j}=x_{n+r-m}-\alpha^{n-m}\sum_{k=0}^{r-1}\frac{\alpha^k}{(n-m+k)!}y_{r-k}.$$

Substituting (4.5) into (4.4), we find as coefficient for y_{r-k} the expression

$$-\frac{\alpha^{n+k}}{(n+k)!}\sum_{m=0}^{r}(-1)^m\binom{n+k}{m}\binom{n+r-m-1}{r-m},\qquad (0\leqq k\leqq r-1)$$

which vanishes by (4.3). The result (4.1b) follows immediately.

5. The transformations $z \to 1-z$ and $z \to 1/z$. Nielsen was able to find many formulae relating the functions $S_{n,p}(z)$, $L_{n,p}(z)$, and $M_{n,p}(z)$ for different arguments. He proved these relations mainly by considering indefinite integrals for $L_{n,p}(z)$ and $M_{n,p}(z)$, for example by writing

$$L_{n,p}(z) = \frac{(-1)^{n+p-1}}{(n-1)!p!} \int \log^{n-1} z \log^p(1-z) \frac{dz}{z} + C,$$

and fixing the constant in the resulting expression by considering special values.

In the following, we shall prove these formulae of Nielsen by using the definitions (2.13) and (2.14) of $L_{n,p}(z)$ and $M_{n,p}(z)$. We start with

5.1. The reflection $z \to 1-z$. We split the range of integration in (2.13), and obtain by partial integration, for $\operatorname{Im} z \neq 0$, using (2.20),

$$\begin{aligned} L_{n,p}(z) &= s_{n,p} + \frac{(-1)^{n+p-1}}{(n-1)!p!} \int_1^z \log^{n-1} t \log^p(1-t) \frac{dt}{t} \\ &= s_{n,p} + \frac{(-1)^{n+p-1}}{n!p!} \log^n z \log^p(1-z) \\ &\quad - \frac{(-1)^{n+p-1}}{(p-1)!n!} \int_0^{1-z} \log^{p-1} t \log^n(1-t) \frac{dt}{t}, \end{aligned}$$

which gives

$$L_{n,p}(z) + L_{p,n}(1-z) = s_{n,p} - \frac{(-1)^{n+p}}{n!p!} \log^n z \log^p(1-z) \tag{5.1}$$

as the reflection formula for the function $L_{n,p}(z)$. Using (2.15) yields

$$S_{n,p}(z) = \sum_{j=0}^{n-1} \frac{\log^j z}{j!} \left\{ s_{n-j,p} - L_{p,n-j}(1-z) - \frac{(-1)^{n+p-j}}{(n-j)!p!} \log^{n-j} z \log^p(1-z) \right\} \tag{5.2}$$

whence, using (2.16) and a well-known property of the binomial coefficients,

$$\begin{aligned} S_{n,p}(z) &= \sum_{j=0}^{n-1} \frac{\log^j z}{j!} \left\{ s_{n-j,p} - \sum_{k=0}^{p-1} \frac{(-1)^k \log^k(1-z)}{k!} S_{p-k,n-j}(1-z) \right\} \\ &\quad + \frac{(-1)^p}{n!p!} \log^n z \log^p(1-z). \end{aligned} \tag{5.3}$$

Equation (5.3) is the reflection formula for the generalized polylogarithms. In the case of polylogarithms ($p=1$), this equation reduces to

$$S_n(z) = \sum_{j=0}^{n-2} \frac{\log^j z}{j!} \{ s_{n-j} - S_{1,n-j-1}(1-z) \} - \frac{1}{(n-1)!} \log^{n-1} z \log(1-z). \tag{5.4}$$

Note that the reflection $z \to 1-z$ for $S_{n,p}(z)$ as expressed by (5.3) remains within the set of generalized polylogarithms (apart from known constants and logarithms). Equation (5.4) shows, however, that it is not possible to represent the reflection for the polylogarithms within the set of these functions if $n \geqq 3$. Thus, for the trilogarithm, one

has

$$S_3(z)=s_3-S_{1,2}(1-z)+\log z\,[s_2-S_2(1-z)]-\tfrac{1}{2}\log^2 z\log(1-z). \tag{5.5}$$

This relation contains the function $S_{1,2}(1-z)$ which is not a polylogarithm. It is interesting to note, however, that the reflection formula provides an expression for the particular generalized polylogarithms $S_{1,p}(z)$ in terms of ordinary polylogarithms, since we have

$$S_{1,p}(z)=\frac{(-1)^p}{p!}\int_0^1 \log^p(1-zt)\frac{dt}{t}=s_{p+1}+\frac{(-1)^p}{p!}\log z\log^p(1-z) - \sum_{k=0}^{p-1}(-1)^k\log^k\frac{(1-z)}{k!}S_{p-k+1}(1-z). \tag{5.6}$$

We now consider the case $z=x$ real. By setting $z=x+i\varepsilon$ it follows from (3.2), (3.3) and (1.4) that, for $x<0$, (5.1) remains unchanged, while for $x>1$, both sides must be replaced by their complex conjugate. From this and the fact that $L_{n,p}(x)$ is real for $0\leqq x\leqq 1$, we see that (5.1) remains valid, as it stands, for arbitrary real $z=x$. By a similar argument, this is also true for (5.3) relating $S_{n,p}(z)$ to $S_{\nu,\rho}(1-z)$, and for the special case (5.4). Therefore, the restriction $\operatorname{Im} z\neq 0$ made above is no longer necessary.

5.2. The inversion $z\to 1/z$. This case is more complicated. We follow Nielsen in first establishing an inversion formula for $M_{n,p}(z)$ but instead of considering indefinite integrals for $M_{n,p}(z)$ and $M_{n,p}(1/z)$ as he does, we start with the definition integral (2.14), which gives for $\operatorname{Im} z\neq 0$, using (2.20),

$$\begin{aligned}
M_{n,p}(z)&=\sigma_{n,p}+\frac{(-1)^{n-1}}{(n-1)!p!}\int_1^z \log^{n-1}t\log^p(1+t)\frac{dt}{t}\\
&=\sigma_{n,p}-\frac{1}{(n-1)!p!}\int_1^{1/z}\log^{n-1}t\,[\log(1+t)-\log t]^p\frac{dt}{t}\\
&=\sigma_{n,p}-\frac{1}{(n-1)!p!}\sum_{k=0}^{p-1}(-1)^k\binom{p}{k}\int_1^{1/z}\log^{n+k-1}t\log^{p-k}(1+t)\frac{dt}{t}\\
&\quad-\frac{(-1)^p}{(n-1)!p!}\int_1^{1/z}\log^{n+p-1}t\,\frac{dt}{t}\\
&=\sigma_{n,p}-(-1)^n\sum_{k=0}^{p-1}\binom{n+k-1}{k}\sigma_{n+k,p-k}\\
&\quad+(-1)^n\sum_{k=0}^{p-1}\binom{n+k-1}{k}M_{n+k,p-k}\left(\frac{1}{z}\right)-\frac{(-1)^n}{(n+p)(n-1)!p!}\log^{n+p}z.
\end{aligned}$$

Denoting the constant part by $C_{n,p}$, we have

$$M_{n,p}(z)=C_{n,p}+(-1)^n\sum_{k=0}^{p-1}\binom{n+k-1}{k}M_{n+k,p-k}\left(\frac{1}{z}\right)-\frac{(-1)^n}{(n+p)(n-1)!p!}\log^{n+p}z \tag{5.7}$$

$$(\operatorname{Im} z\neq 0,\ \text{or}\ \operatorname{Im} z=0\ \text{and}\ \operatorname{Re} z\geqq 0).$$

Formula (5.7) is also valid for real $z=x\geqq 0$, in which case it is real. For $x<0$, we set $z=x+i\varepsilon$ and obtain with the help of (1.4) and (3.5) the relation

$$M_{n,p}(x)=C_{n,p}+(-1)^n\sum_{k=0}^{p-1}\binom{n+k-1}{k}M^*_{n+k,p-k}\left(\frac{1}{x}\right) - \frac{(-1)^n}{(n+p)(n-1)!p!}\log^{n+p}x, \qquad (x \text{ real}). \tag{5.8}$$

This equation enables us to express the constants (where the sum is zero for $p=1$)

$$C_{n,p}=(1-(-1)^n)\sigma_{n,p}-(-1)^n\sum_{k=1}^{p-1}\binom{n+k-1}{k}\sigma_{n+k,p-k} \tag{5.9}$$

in terms of known constants. This will be discussed further in §7.

In order to establish the inversion formula for the generalized polylogarithms $S_{n,p}(z)$, we start from (5.7) and write, using (2.17)

(5.10)

$$(-1)^pS_{n,p}(-z)=\sum_{j=0}^{n-1}\frac{\log^j z}{j!}(-1)^{n-j}\sum_{k=0}^{p-1}\binom{n-j+k-1}{k}M_{n-j+k,p-k}\left(\frac{1}{z}\right) - \frac{1}{p!}\log^{n+p}z\sum_{j=0}^{n-1}\frac{(-1)^{n-j}}{(n-j+p)(n-j-1)!j!}+\sum_{j=0}^{n-1}\frac{\log^j z}{j!}C_{n-j,p}.$$

The coefficient of $\log^{n+p}z$ can be written as [8, No. 3.191 3]

(5.11)

$$-\frac{1}{p!}\sum_{j=0}^{n-1}\frac{(-1)^{n-j}}{(n-j+p)(n-j-1)!j!}=\frac{1}{p!(n-1)!}\int_0^1\sum_{j=0}^{n-1}(-1)^{n-j}\binom{n-1}{j}u^{n-j+p-1}du =\frac{1}{p!(n-1)!}\int_0^1 u^p(1-u)^{n-1}du=\frac{1}{(n+p)!}.$$

We now apply Lemma (4.1b) and write, remembering that $M_{n,p}(z)$ and $(-1)^pS_{n,p}(-z)$ are related through (4.1),

$$\sum_{j=0}^{n-1}(-1)^j\frac{\log^j z}{j!}\binom{n-j+k-1}{k}M_{n-j+k,p-k}\left(\frac{1}{z}\right) =(-1)^{p-k}\sum_{m=0}^{k}\frac{\log^m z}{m!}\binom{n+k-m-1}{k-m}S_{n+k-m,p-k}\left(-\frac{1}{z}\right)$$

whence, replacing z by $-z$ in (5.10)

$$S_{n,p}(z)=(-1)^n\sum_{k=0}^{p-1}(-1)^k\sum_{m=0}^{k}\frac{\log^m(-z)}{m!}\binom{n+k-m-1}{k-m}S_{n+k-m,p-k}\left(\frac{1}{z}\right) +(-1)^p\left\{\sum_{j=0}^{n-1}\frac{\log^j(-z)}{j!}C_{n-j,p}+\frac{1}{(n+p)!}\log^{n+p}(-z)\right\}. \tag{5.12}$$

It is easy to see that (5.12) is also valid for real $z=x$ if $x\leqq 0$. In this case it contains only real functions. For $x>0$, we proceed analogously to the case of $M_{n,p}(z)$, set $z=x+i\varepsilon$ and obtain, using (1.4) and (3.1),

(5.13)

$$S_{n,p}(x)=(-1)^n\sum_{k=0}^{p-1}(-1)^k\sum_{m=0}^{k}\frac{\log^m(-x)}{m!}\binom{n+k-m-1}{k-m}S^*_{n+k-m,p-k}\left(\frac{1}{x}\right)$$

$$+(-1)^p\left\{\sum_{j=0}^{n-1}\frac{\log^j(-x)}{j!}C_{n-j,p}+\frac{1}{(n+p)!}\log^{n+p}(-x)\right\}\qquad (x \text{ real}).$$

Note that the imaginary parts cancel for $0\leqq x\leqq 1$. Further, since $S_{\nu,\rho}(1/x)$ is real for $x\geqq 1$, it follows that the imaginary part of $S_{n,p}(x)$ for $x\geqq 1$ comes only from $\log(-x)$. Using (1.4) in (5.13) and taking the imaginary part (with empty sums equal to zero) gives[1]

(5.14)

$$\frac{1}{\pi}\operatorname{Im}S_{n,p}(x)=(-1)^n\sum_{k=1}^{p-1}(-1)^k\sum_{m=1}^{k}\binom{n+k-m-1}{k-m}S_{n+k-m,p-k}\left(\frac{1}{x}\right)$$

$$\times\sum_{j=0}^{[(m-1)/2]}(-1)^j\frac{\pi^{2j}}{(2j+1)!(m-2j-1)!}\log^{m-2j-1}x$$

$$+(-1)^p\sum_{m=1}^{n-1}C_{n-m,p}\sum_{j=0}^{[(m-1)/2]}(-1)^j\frac{\pi^{2j}}{(2j+1)!(m-2j-1)!}\log^{m-2j-1}x$$

$$+(-1)^p\sum_{j=0}^{[(n+p-1)/2]}(-1)^j\frac{\pi^{2j}}{(2j+1)!(n+p-2j-1)!}\log^{n+p-2j-1}x.$$

Equation (5.14) shows that, for $p>1$, $\operatorname{Im}S_{n,p}(x)$ is expressible, apart from logarithms and (known) constants, in terms of $S_{\nu,\rho}(\xi)$ $(n\leqq\nu\leqq n+p-2, 1\leqq\rho\leqq p-1)$ in the interval $0<\xi\leqq 1$.

For the polylogarithms, we obtain as a special case from (5.12), (5.9) and (2.22)

(5.15) $$S_n(z)+(-1)^nS_n\left(\frac{1}{z}\right)$$

$$=-\frac{1}{n!}\log^n(-z)-\sum_{j=0}^{n-2}\frac{1}{j!}\left(1+(-1)^{n-j}\right)\left(1-2^{1-n+j}\right)s_{n-j}\log^j(-z),$$

where for real $z=x$, $S_n(1/x)$ has to be replaced by $S_n^*(1/x)$.

As in the case of reflection, the inversion (5.12) has the remarkable property of remaining within the set of generalized polylogarithms. In contrast to the case of reflection, the inversion (5.15) for the polylogarithms also remains within the set of these functions.

---

[1] Note that this formula differs by a factor -1 from the expression given in [12], owing to the fact that, for real $z=x$, (5.12) had been erroneously used instead of (5.13), and a convention different from (1.4) had been introduced in order to overcome resulting contradictions. Because of this, the function computed by the Algol program for $S_{n,p}(x)$ in [12] is in fact $S^*_{n,p}(x)$ according to our present definition. For $n=p=1$, formula (5.14) agrees with Lewin [17, p. 2].

6. Bilinear transformations of the argument. If we consider the reflection $P_1(z)=1-z$ and the inversion $P_2(z)=1/z$ as belonging to the group of bilinear transformations

$$P(z)=\frac{\alpha z+\beta}{\gamma z+\delta}$$

with real coefficients and $\alpha\delta-\beta\gamma\neq 0$, we see that they generate a subgroup

$$P_j(z)=z,\quad 1-z,\quad \frac{1}{z},\quad \frac{1}{1-z},\quad \frac{z-1}{z},\quad \frac{z}{z-1}$$

($j=0,1,\cdots,5$). By repeated use of (5.3) and (5.12) it is then possible to find formulae for

$$S_{n,p}\left(\frac{1}{1-z}\right),\quad S_{n,p}\left(\frac{z-1}{z}\right),\quad S_{n,p}\left(\frac{z}{z-1}\right)$$

which will contain, apart from logarithms and known constants, only generalized polylogarithms. These formulae become soon very complicated, and we leave a more systematic investigation to further research. By the above procedure one can, in principle, find a (complicated) expression for $S_{2,2}(z)$ in terms of polylogarithms. Lewin [17, p. 204] has given a formula from which such an expression can be derived.

Nielsen also discusses the following bilinear transformations of the argument of the function $L_{n,p}(z)$.

6.1. The transformation $z\to 1/(1+z)$. From the definition integral (2.13) we find, for $\operatorname{Im} z\neq 0$,

(6.1)

$$\begin{aligned}L_{n,p}\left(\frac{1}{1+z}\right)&=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^{1/(1+z)}\log^{n-1}t\log^p(1-t)\frac{dt}{t}\\&=s_{n,p}-\frac{1}{(n-1)!p!}\int_0^z\log^{n-1}(1+t)[\log(1+t)-\log t]^p\frac{dt}{1+t}\\&=s_{n,p}-\frac{1}{(n-1)!p!}\sum_{k=0}^{p}(-1)^k\binom{p}{k}\int_0^z\log^{n+p-k-1}(1+t)\log^k t\frac{dt}{1+t}.\end{aligned}$$

Using (2.14), and taking into account that

$$\frac{\binom{p}{k}}{(n-1)!p!(n+p-k)}=\frac{\binom{n+p-k-1}{n-1}\binom{n+p}{k}}{(n+p)!},$$

yields, after integration by parts,

(6.2)

$$\begin{aligned}L_{n,p}\left(\frac{1}{1+z}\right)&=s_{n,p}-\frac{1}{(n+p)!}\sum_{k=0}^{p}(-1)^k\binom{n+p-k-1}{n-1}\binom{n+p}{k}\log^k z\log^{n+p-k}(1-z)\\&\quad-\sum_{k=1}^{p}\binom{n+p-k-1}{n-1}M_{k,n+p-k}(z)\qquad(\operatorname{Im} z\neq 0,\text{ or }\operatorname{Im} z=0\text{ and }\operatorname{Re} z\geqq -1).\end{aligned}$$

Both sides of formula (6.2) are real for $z=x\geqq 0$. Further, it follows from (1.4) and (3.3) that (6.2) remains valid for real $z=x$ if $-1\leqq x\leqq 0$. For $z=x<-1$, however, we see from (3.2) that $L_{n,p}(1/(1+z))$ has to be replaced by $L^*_{n,p}(1/(1+z))$.

6.2. The transformation $z\to z/(1+z)$. In this case, we have from (2.13) for $\operatorname{Im} z\neq 0$ and $n>1$

$$L_{n,p}\left(\frac{z}{1+z}\right)=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^{z/(1+z)}\log^{n-1}t\log^p(1-t)\frac{dt}{t}$$

$$=\frac{1}{(n-1)!p!}\left\{\int_0^z[\log(1+t)-\log t]^{n-1}\log^p(1+t)\frac{dt}{t}\right.$$

$$\left.-\int_0^z[\log(1+t)-\log t]^{n-1}\log^p(1+t)\frac{dt}{1+t}\right\}.$$

Hence by comparison with (6.1),

$$L_{n,p}\left(\frac{z}{1+z}\right)=L_{p+1,n-1}\left(\frac{1}{1+z}\right)-s_{p+1,n-1}$$

$$+\frac{1}{(n-1)!p!}\sum_{k=0}^{n-1}(-1)^k\binom{n-1}{k}\int_0^z\log^{n+p-k-1}(1+t)\log^k t\frac{dt}{t}$$

and, using (2.14) and (2.21),

(6.3)

$$L_{n,p}\left(\frac{z}{1+z}\right)-L_{p+1,n-1}\left(\frac{1}{1+z}\right)=-s_{n-1,p+1}+\sum_{k=0}^{n-1}\binom{n+p-k-1}{p}M_{k+1,n+p-k-1}(z)$$

$$(\operatorname{Im} z\neq 0,\text{ or }\operatorname{Im} z=0\text{ and }\operatorname{Re} z\geqq -1).$$

For $n=1$, we have directly from (2.13):

(6.4)
$$L_{1,p}\left(\frac{z}{1+z}\right)=\frac{1}{p!}\left\{\int_0^z\log^p(1+t)\frac{dt}{t}-\int_0^z\log^p(1+t)\frac{dt}{1+t}\right\}$$

$$=M_{1,p}(z)-\frac{1}{(p+1)!}\log^{p+1}(1+z)$$

or, by (2.19),

(6.5)
$$S_{1,p}\left(\frac{z}{1+z}\right)=(-1)^pS_{1,p}(-z)-\frac{1}{(p+1)!}\log^{p+1}(1+z)$$

$$(\operatorname{Im} z\neq 0,\text{ or }\operatorname{Im} z=0\text{ and }\operatorname{Re} z\geqq -1).$$

As in the case of formula (6.2), we see by setting $z=x+i\varepsilon$ and using (1.4), (3.2) and (3.3) that the left-hand side of (6.2) must be replaced, for real $z=x<-1$, by

$$L^*_{n,p}\left(\frac{z}{1+z}\right)-L^*_{p+1,n-1}\left(\frac{1}{1+z}\right).$$

Since $L_{1,p}(z/(1+z))=S_{1,p}(z/(1+z))$ is real for $x\geqq -1$, the formula obtained by replacing the left-hand sides of (6.4) and (6.5) by their conjugates are valid for all real $z=x$.

6.3. The transformation $z \to (a+z)/(b+z)$. This transformation is a generalization of the transformation $z \to z/(1+z)$. The formula obtained by Nielsen [20, §13(7)] is incorrect, and, as we shall see in §9, it was this error which led him to wrong conclusions on the nature of the special values $\sigma_{n,p} = (-1)^p S_{n,p}(-1)$.

We have from the definition integral (2.13) for $a \neq b$, $\operatorname{Im} z \neq 0$, and $n > 1$,

$$L_{n,p}\left(\frac{a+z}{b+z}\right) = \frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^{(a+z)/(b+z)} \log^{n-1} t \log^p(1-t)\frac{dt}{t}$$

$$= s_{n,p} + \frac{(-1)^{n+p}}{(n-1)!p!}(b-a)\int_z^\infty \log^{n-1}\left(\frac{a+t}{b+t}\right)\log^p\left(\frac{b-a}{b+t}\right)\frac{dt}{(a+t)(b+t)}$$

$$= s_{n,p} + \frac{(-1)^{n+p}}{(n-1)!p!}\left\{\int_z^\infty \log^{n-1}\left(\frac{a+t}{b+t}\right)\log^p\left(\frac{b-a}{b+t}\right)\frac{dt}{a+t}\right.$$

$$\left. - \int_z^\infty \log^{n-1}\left(\frac{a+t}{b+t}\right)\log^p\left(\frac{b-a}{b+t}\right)\frac{dt}{b+t}\right\}.$$

Denoting the integrals by J_1 and J_2, and substituting $\tau = (b-a)/(a+t)$ and $\tau = (b-a)/(b+t)$ in J_1 and J_2, respectively, we obtain, using (2.14),

$$J_1 = (-1)^{n+p-1}\int_0^{(b-a)/(a+z)} \log^{n-1}(1+\tau)\log^p\left(\frac{1+\tau}{\tau}\right)\frac{d\tau}{\tau}$$

$$= (-1)^{n+p-1}\sum_{k=0}^{p}(-1)^k\binom{p}{k}\int_0^{(b-a)/(a+z)} \log^{n+p-k-1}(1+\tau)\log^k\tau\frac{d\tau}{\tau}$$

$$= (-1)^{n+p-1}p!(n-1)!\sum_{k=0}^{p}\binom{n+p-k-1}{n-1}M_{k+1,n+p-k-1}\left(\frac{b-a}{a+z}\right).$$

Similarly, by (2.13),

$$J_2 = \int_0^{(b-a)/(b+z)} \log^{n-1}(1-\tau)\log^p\tau\frac{d\tau}{\tau}$$

$$= (-1)^{n+p-1}p!(n-1)!L_{p+1,n-1}\left(\frac{b-a}{b+z}\right).$$

Therefore

(6.6)

$$L_{n,p}\left(\frac{a+z}{b+z}\right) = s_{n,p} - \sum_{k=0}^{p}\binom{n+p-k-1}{n-1}M_{k+1,n+p-k-1}\left(\frac{b-a}{a+z}\right) + L_{p+1,n-1}\left(\frac{b-a}{b+z}\right)$$

$$(\operatorname{Im} z \neq 0).$$

This formula corrects Nielsen's formula [20, §13(7)], in which

$$\text{the term} \quad L_{p+1,n-1}\left(\frac{b-a}{b+z}\right) \quad \text{reads} \quad L_{n,p}\left(\frac{b-a}{b+z}\right).$$

For real $z = x$, formula (6.6) has to be adjusted in accordance with the results of §3. This will depend on the values of a and b.

Comparing formula (6.3) with (6.6) for $a=0$ and $b=1$, we obtain a relation between $M_{\nu,\rho}(z)$ and $M_{\nu,\rho}(1/z)$, namely $(n>1)$

$$(6.7)\qquad \sum_{k=0}^{n-1}\binom{n+p-k-1}{p}M_{k+1,n+p-k-1}(z)$$
$$+\sum_{k=0}^{p}\binom{n+p-k-1}{n-1}M_{k+1,n+p-k-1}\left(\frac{1}{z}\right)=s_{n,p}+s_{n-1,p+1}.$$

$(\operatorname{Im} z\neq 0$, or $\operatorname{Im} z=0$ and $\operatorname{Re} z\geqq 0)$.

For real $z=x<0$, $M_{k+1,n+p-k-1}(1/z)$ has to be replaced by $M^{*}_{k+1,n+p-k-1}(1/z)$.

6.4. A sum containing $L_{n,p}(z/(1+z))$. Nielsen closes his section on bilinear transformations of the argument by considering a sum containing $L_{\nu,\rho}(z/(1+z))$. This sum can be expressed in terms of (ordinary) polylogarithms. To avoid divergent integrals, we introduce the functions $(0<\varepsilon<1)$

$$(6.8)\qquad \left.\begin{matrix}L^{\varepsilon}_{n,p}(z)\\(-1)^{p}M^{\varepsilon}_{n,p}(z)\end{matrix}\right\}=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_{\varepsilon}^{z}\log^{n-1}t\log^{p}(1\mp t)\frac{dt}{t}$$

and write

$$(-1)^{j}k!L^{\varepsilon}_{k-j+1,j}(\zeta)=(-1)^{j}k!\frac{(-1)^{k}}{(k-j)!j!}\int_{\varepsilon}^{\zeta}\log^{k-j}t\log^{j}(1-t)\frac{dt}{t}.$$

Thus, by summation,

$$\sum_{j=0}^{k}(-1)^{j}L^{\varepsilon}_{k-j+1,j}(\zeta)=\frac{(-1)^{k}}{k!}\sum_{j=0}^{k}(-1)^{j}\binom{k}{j}\int_{\varepsilon}^{\zeta}\log^{k-j}t\log^{j}(1-t)\frac{dt}{t}$$
$$=\frac{(-1)^{k}}{k!}\int_{\varepsilon}^{\zeta}\log^{k}\left(\frac{t}{1-t}\right)\frac{dt}{t}.$$

Setting $\zeta=z/(1+z)$, and making the substitution $\tau=t/(1-t)$, we obtain, with $\varepsilon'=\varepsilon/(1-\varepsilon)$,

$$\sum_{j=0}^{k}(-1)^{j}L^{\varepsilon}_{k-j+1,j}\left(\frac{z}{1+z}\right)=\frac{(-1)^{k}}{k!}\int_{\varepsilon'}^{z}\log^{k}\tau\frac{d\tau}{\tau(1+\tau)}$$
$$=\frac{(-1)^{k}}{(k+1)!}\left[\log^{k+1}z-\log^{k+1}\varepsilon'\right]-\frac{(-1)^{k}}{k!}\int_{\varepsilon'}^{z}\log^{k}\tau\frac{d\tau}{1+\tau}.$$

By partial integration, using (6.8)

$$\int_{\varepsilon'}^{z}\log^{k}\tau\frac{d\tau}{1+\tau}=\log^{k}z\log(1+z)-\log^{k}\varepsilon'\log(1+\varepsilon')+(-1)^{k}k!M^{\varepsilon'}_{k,1}(z).$$

Further, from (6.8),

$$L^{\varepsilon}_{k+1,0}\left(\frac{z}{1+z}\right)=\frac{(-1)^{k}}{(k+1)!}\left[\log^{k+1}\left(\frac{z}{1+z}\right)-\log^{k+1}\varepsilon\right].$$

Collecting these results, we see that the divergent parts cancel for $\varepsilon \to 0$, and we obtain

$$\sum_{j=1}^{k} (-1)^j L_{k-j+1,j}\left(\frac{z}{1+z}\right) = \frac{(-1)^k}{(k+1)!}\left[\log^{k+1} z - \log^{k+1}\left(\frac{z}{1+z}\right)\right] - \frac{(-1)^k}{k!}\log^k z \log(1+z) - M_{k,1}(z) \tag{6.9}$$

or, using (2.18) and replacing k by $n-1$,

$$\sum_{m=0}^{n-2} (-1)^m L_{n-m-1,m+1}\left(\frac{z}{1+z}\right) = \frac{(-1)^n}{n!}\left[\log^n z - \log^n\left(\frac{z}{1+z}\right)\right] - \sum_{j=0}^{n-1} \frac{(-1)^j \log^j z}{j!} S_{n-j}(-z). \tag{6.10}$$

As in the case of formula (6.2), the left-hand side of (6.10) has to be replaced by its conjugate for real $z = x < -1$.

7. The constants $C_{n,p}$. We now return to the constants $C_{n,p}$ defined by (5.9). Because no relation seems to be known which expresses $\sigma_{n,p} = (-1)^p S_{n,p}(-1)$ for arbitrary $n \geqq 1$, $p \geqq 1$ in terms of known constants, Nielsen did not, apart from giving a formula for $C_{2n-1,2}$ in terms of $\zeta(q)$, investigate relation (5.9) further. For some small values of n or p, however, expressions for $C_{n,p}$ are known [12] in addition to $C_{2n-1,2}$, namely

$$\begin{aligned} &C_{1,p} = \zeta(p+1), \qquad (p = 1,2,3,4), \\ &C_{2n,1} = 0, \qquad (n \geqq 1), \\ &C_{3,1} = -C_{2,2} = \frac{7}{4}\zeta(4) = \frac{7}{360}\pi^4, \\ &C_{2,3} = -C_{3,2} = -\zeta(2)\zeta(3) - \zeta(5). \end{aligned} \tag{7.1}$$

The question arises whether it is possible to express $C_{n,p}$ for all n and p, in terms of known constants. This is indeed the case, as is shown by the following

THEOREM 1. *Let δ_{ij} be the Kronecker symbol; let $\varepsilon_m = 1$ if m is even, $\varepsilon_m = 0$ if m is odd, and let $s_{\nu,\rho} = S_{\nu,\rho}(1)$. Then, for integer n,p $(n \geqq 1, p \geqq 1)$*

$$C_{n,p} = (-1)^{n+p-1} \sum_{k=0}^{p-1} (-1)^k \left(1 - (-1)^n \delta_{k0}\right) \binom{n+k-1}{k} \times \sum_{j=0}^{[(n+k-1)/2]} (-1)^j \frac{\pi^{2j}}{(2j)!} s_{n+k-2j,p-k} + (-1)^{[(n+p)/2]+n} \varepsilon_{n+p} \frac{\pi^{n+p}}{(n+p)(n-1)!p!}. \tag{7.2}$$

Proof. We set $x=-1$ in (5.8) and obtain, using (1.4),

$$C_{n,p}=M_{n,p}(-1)-(-1)^n\sum_{k=0}^{p-1}\binom{n+k-1}{k}M^*_{n+k,p-k}(-1)+(-1)^n\frac{(i\pi)^{n+p}}{(n+p)(n-1)!p!}.$$

From (2.18), we have

$$M_{n,p}(-1)=(-1)^p\sum_{j=0}^{n-1}\frac{(-i\pi)^j}{j!}s_{n-j,p}. \tag{7.3}$$

Therefore

(7.4)

$$C_{n,p}=(-1)^{n+p-1}\Bigg\{\sum_{k=0}^{p-1}(-1)^k\binom{n+k-1}{k}\sum_{j=0}^{n+k-1}\frac{(i\pi)^j}{j!}s_{n+k-j,p-k} -(-1)^n\sum_{j=0}^{n-1}(-1)^j\frac{(i\pi)^j}{j!}s_{n-j,p}\Bigg\} +(-1)^n\frac{(i\pi)^{n+p}}{(n+p)(n-1)!p!}.$$

On taking the real part of (7.4), Theorem 1 follows. In addition, we obtain from the imaginary part a relation between the $s_{\nu,\rho}$, namely

$$\sum_{k=0}^{p-1}(-1)^k\left(1+(-1)^n\delta_{k0}\right)\binom{n+k-1}{k}\sum_{j=0}^{[(n+k-2)/2]}(-1)^j\frac{\pi^{2j+1}}{(2j+1)!}s_{n+k-2j-1,p-k} +(-1)^{[(n+p-1)/2]+p}\left(\varepsilon_{n+p}-1\right)\frac{\pi^{n+p}}{(n+p)(n-1)!p!}=0.$$

It has been shown in [12], [13], [20] that $s_{\nu,\rho}$ can be expressed by a homogeneous polynomial in $s_q=\zeta(q)$ $(2\leqq q\leqq\nu+\rho)$, with rational coefficients, where $\zeta(q)$ is the Riemann zeta function. This polynomial is of degree $\nu+\rho$, if $\zeta(q)$ is defined to be of degree q and if the degree of a product is the sum of the degree of its factors. Since even powers of π can, through [8, No. 9.616]

$$\pi^{2m}=\frac{(2m)!\zeta(2m)}{2^{2m-1}|B_{2m}|}$$

be expressed in terms of $\zeta(q)$ and the Bernoulli numbers B_{2m}, one has the remarkable fact that $C_{n,p}$ can be expressed by a polynomial in $\zeta(q)$ $(2\leqq q\leqq n+p)$ which is of the same type as the polynomial for $s_{n,p}$.

A short table of $C_{n,p}$ $(1\leqq n\leqq 5, 1\leqq p\leqq 5)$ is given in Table 1. This table has been computed by REDUCE [10] from the expressions for $s_{r,m}$ given in [13]. For the special case $n=1$, we find from (5.9) and Theorem 3 in §9 that

$$C_{1,p}=2\sigma_{1,p}+\sum_{k=1}^{p-1}\sigma_{k+1,p-k}=\zeta(p+1), \qquad (p\geqq 1), \tag{7.5}$$

which gives, with (7.2), another relation between the $s_{\nu,\rho}$.

TABLE 1

$$C_{1,1}=\zeta(2)=\frac{\pi^2}{6} \qquad C_{2,1}=0$$

$$C_{1,2}=\zeta(3) \qquad C_{2,2}=-6\zeta^2(2)+\frac{53}{4}\zeta(4)=-\frac{7}{360}\pi^4$$

$$C_{1,3}=\zeta(4)=\frac{\pi^4}{90} \qquad C_{2,3}=-\zeta(2)\zeta(3)-\zeta(5)$$

$$C_{1,4}=\zeta(5) \qquad C_{2,4}=-\frac{25}{6}\zeta^3(2)+\frac{21}{2}\zeta(2)\zeta(4)-\frac{1}{2}\zeta^2(3)-\frac{163}{48}\zeta(6)$$

$$C_{1,5}=\zeta(6)=\frac{\pi^6}{945} \qquad C_{2,5}=-\frac{5}{2}\zeta^2(2)\zeta(3)-\zeta(2)\zeta(5)+\frac{21}{4}\zeta(3)\zeta(4)-2\zeta(7)$$

$$C_{3,1}=6\zeta^2(2)-\frac{53}{4}\zeta(4)=\frac{7}{360}\pi^4$$

$$C_{3,2}=\zeta(2)\zeta(3)+\zeta(5)$$

$$C_{3,5}=\frac{23}{8}\zeta^4(2)-\frac{17}{2}\zeta^2(2)\zeta(4)+\frac{1}{2}\zeta(2)\zeta^3(3)+\frac{531}{16}\zeta(2)\zeta(6)+2\zeta(3)\zeta(5)-\frac{175}{8}\zeta^2(4)-\frac{939}{64}\zeta(8)$$

$$C_{4,1}=0$$

$$C_{4,2}=3\zeta(2)\zeta(4)-\frac{73}{8}\zeta(6)=-\frac{31}{7560}\pi^6$$

$$C_{4,3}=-12\zeta^2(2)\zeta(3)-2\zeta(2)\zeta(5)+\frac{53}{2}\zeta(3)\zeta(4)-2\zeta(7)$$

$$C_{4,4}=-2\zeta^4(2)+\frac{35}{4}\zeta^2(2)\zeta(4)-\zeta(2)\zeta^2(3)-\frac{205}{4}\zeta(2)\zeta(6)-2\zeta(3)\zeta(5)+\frac{131}{4}\zeta^2(4)+\frac{1357}{64}\zeta(8)$$

$$C_{4,5}=-\frac{25}{3}\zeta^3(2)\zeta(3)-23\zeta^2(2)\zeta(5)+\frac{45}{2}\zeta(2)\zeta(3)\zeta(4)-5\zeta(2)\zeta(7)-\frac{1}{3}\zeta^3(3)-\frac{545}{48}\zeta(3)\zeta(6)+\frac{201}{4}\zeta(4)\zeta(5)-\frac{23}{3}\zeta(9)$$

$$C_{5,1}=-\frac{3}{2}\zeta(2)\zeta(4)+\frac{73}{16}\zeta(6)=\frac{31}{15120}\pi^6$$

$$C_{5,2}=6\zeta^2(2)\zeta(3)+\zeta(2)\zeta(5)-\frac{53}{4}\zeta(4)+\zeta(7)$$

$$C_{5,3}=\zeta^4(2)-\frac{35}{8}\zeta^2(2)\zeta(4)+\frac{1}{2}\zeta(2)\zeta^2(3)+\frac{755}{16}\zeta(2)\zeta(6)+\zeta(3)\zeta(5)-\frac{281}{8}\zeta^2(4)-\frac{1261}{64}\zeta(8)$$

$$C_{5,4}=\frac{25}{6}\zeta^3(2)\zeta(3)+\frac{53}{2}\zeta^2(2)\zeta(5)-15\zeta(2)\zeta(3)\zeta(4)+5\zeta(2)\zeta(7)+\frac{1}{6}\zeta^3(3)+\frac{205}{12}\zeta(3)\zeta(6)-\frac{233}{4}\zeta(4)\zeta(5)+\frac{19}{3}\zeta(9)$$

$$C_{5,5}=\frac{73}{120}\zeta^5(2)+\frac{109}{24}\zeta^3(2)\zeta(4)+\frac{41}{4}\zeta^2(2)\zeta^2(3)+\frac{4405}{96}\zeta^2(2)\zeta(6)+4\zeta(2)\zeta(3)\zeta(5)-62\zeta(2)\zeta^2(4)$$
$$+\frac{1659}{32}\zeta(2)\zeta(8)-\frac{45}{2}\zeta^2(3)\zeta(4)+5\zeta(3)\zeta(7)-\frac{3385}{96}\zeta(4)\zeta(6)+\frac{5}{2}\zeta^2(5)-\frac{22177}{640}\zeta(10)$$

8. Some integrals involving $S_{n,p}(z)$. We now consider some integrals containing $S_{n,p}(z)$ in the integrand which were discussed by Nielsen. From the differentiation rule (2.11) for $S_{n,p}(x)$ we see immediately that

$$\int S_{n-1,p}(z)S_{n,p}(z)\frac{dz}{z}=\frac{1}{2}S_{n,p}^2(z), \qquad (n\geqq 2). \tag{8.1}$$

By repeated partial integration we obtain for $k<n-1$, (note the misprints in Nielsen's formulae [20, p. 190])

$$\int S_{n-1,p}(z)S_{n,p}(z)\frac{dz}{z}=\sum_{j=1}^{k}(-1)^{j-1}S_{n-j,p}(z)S_{n+j,p}(z)$$
$$+(-1)^k\int S_{n-k-1,p}(z)S_{n+k,p}(z)\frac{dz}{z}.$$

Therefore

(8.2)

$$(-1)^k \int S_{n-k-1,p}(z) S_{n+k,p}(z) \frac{dz}{z} = \frac{1}{2} S_{n,p}^2(z) + \sum_{j=1}^{k} (-1)^j S_{n-j,p}(z) S_{n+j,p}(z)$$

$$= \frac{1}{2}(-1)^k \sum_{j=0}^{2k} (-1)^j S_{n-k+j,p}(z) S_{n+k-j,p}(z).$$

Using the definitions (2.6) of $S_0(z)$ and $S_1(z)$, and rule (2.12), we obtain, by repeated partial integration, for $\alpha \neq 1$ and $|z|<1$,

$$\int z^\alpha S_n(z)\,dz = z^{\alpha+1} \sum_{j=0}^{n-1} (-1)^j \frac{S_{n-j}(z)}{(\alpha+1)^{j+1}} + \frac{(-1)^n}{(\alpha+1)^n} \int \frac{z^{\alpha+1}}{1-z}\,dz \tag{8.3}$$

$$= z^{\alpha+1} \sum_{j=0}^{n-2} \frac{(-1)^j S_{n-j}(z)}{(\alpha+1)^{j+1}} + \frac{(-1)^n}{(\alpha+1)^n}(z^{\alpha+1}-1)\log(1-z)$$

$$+ \frac{(-1)^{n-1}}{(\alpha+1)^n} \int \frac{1-z^{\alpha+1}}{1-z}\,dz,$$

and hence, using [8, No. 8.361 7], we obtain the definite integral

(8.4)

$$\int_0^1 x^{\alpha-1} S_n(x)\,dx = \sum_{j=0}^{n-2} \frac{(-1)^j s_{n-j}}{\alpha^{j+1}} + \frac{(-1)^{n-1}}{\alpha^n}[\psi(\alpha+1)+\gamma], \qquad (\mathrm{Re}\,\alpha > -1),$$

where $\psi(x)$ is the logarithmic derivative of the gamma function and γ is Euler's constant. In particular, for $\alpha = m > 0$ an integer,

$$\int_0^1 x^{m-1} S_n(x)\,dx = \sum_{j=0}^{n-2} \frac{(-1)^j s_{n-j}}{m^{j+1}} + \frac{(-1)^{n-1}}{m^n} \sum_{k=1}^{m} \frac{1}{k}. \tag{8.5}$$

Lewin [17, p. 308] gives (8.4) and (8.5) for $n=2$.

Equation (8.5), together with the power series expansion (2.5), allows us to compute

$$\phi(x) = \int_0^1 S_q(tx) S_n(t) \frac{dt}{t} = \sum_{m=1}^{\infty} \frac{x^m}{m^q} \int_0^1 t^{m-1} S_n(t)\,dt. \tag{8.6}$$

Using (8.5) and the series (2.5) and (2.9), we obtain

$$\phi(x) = \sum_{j=0}^{n-2} (-1)^j s_{n-j} \sum_{m=1}^{\infty} \frac{x^m}{m^{q+j+1}} - (-1)^n \sum_{m=1}^{\infty} \left(\sum_{k=1}^{m} \frac{1}{k} \right) \frac{x^m}{m^{q+n}} \tag{8.7}$$

$$= \sum_{j=0}^{n-2} (-1)^j s_{n-j} S_{q+j+1}(x) - (-1)^n \big(S_{n+q+1}(x) + S_{n+q-1,2}(x) \big).$$

Some other integrals containing $S_n(x)$ can be found in [12] and [15].

9. Values of $S_{n,p}(z)$ for special arguments z.

9.1. The integrals $s_{n,p}=S_{n,p}(1)$. As has been shown in [13], the homogeneous polynomial in $\zeta(q)$ for the integrals

$$s_{n,p}=\frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^1 \log^{n-1}t\log^p(1-t)\frac{dt}{t} \tag{9.1}$$

can be written in the form

$$s_{n,p}=(-1)^{n+p-1}\sum_{\nu=0}^{n-1} b_{n-\nu-1}\sum_{\rho=0}^{p}\binom{\nu+\rho+1}{\rho}b_{p-\rho}a_{\nu+\rho+1}$$

where [8, No. 8.321]

$$a_k=-\frac{1}{k}\sum_{m=1}^{k}(-1)^m\zeta(m)a_{k-m},\qquad b_k=\frac{1}{k}\sum_{m=1}^{k}(-1)^m\zeta(m)b_{k-m},$$

are the coefficients in the power series for $1/\Gamma(1+x)$ and $\Gamma(1+x)$ respectively, and where $a_0=b_0=1$ and $\zeta(1)\equiv\gamma$ by definition. In order to derive this expression, the well-known relation [8, No. 9.122 1]

$${}_2F_1(\alpha,\beta;\beta+1;1)=\frac{\Gamma(1-\alpha)\Gamma(1+\beta)}{\Gamma(1-\alpha+\beta)} \tag{9.2}$$

is essential.

9.2. The integrals $\sigma_{n,p}=(-1)^pS_{n,p}(-1)$. The problem of evaluating

$$\sigma_{n,p}=\frac{(-1)^{n-1}}{(n-1)!p!}\int_0^1 \log^{n-1}t\log^p(1+t)\frac{dt}{t} \tag{9.3}$$

seems to be far more difficult. This difficulty is related to the apparent nonexistence of a relation for ${}_2F_1(\alpha,\beta;\beta+1;-1)$ similar to (9.2). Nielsen claimed that he had succeeded in representing $\sigma_{n,p}$ by $\zeta(q)$ if $n+p$ is odd, but, as we shall see, his proof is erroneous. Those relations between $\sigma_{n,p}$ and $s_{n,p}$ which can be deduced from relations given in the previous sections are of such a special nature that it is not easy to see how they could be used, for example, to derive an expression for $\sigma_{n,p}$ in terms of $\zeta(k)$. On the contrary, it seems likely that, in the general case, no such relations exist. (Barlow [4] states, without giving a reference, that "$S_{n,p}(-1)$, $S_{n,p}(\frac{1}{2})$ and $S_{n,p}(1)$ are easily evaluated analytically from equation [(2.1)]".)

Nielsen did, however, find a closed formula for the case $p=2$, n odd, which seems to be the most general result known for $\sigma_{n,p}$. He proved the following

THEOREM 2. *Let $\zeta(k)$ be the Riemann zeta function for integer argumnent. Then for $n\geqq 0$*

$$\begin{aligned}\sigma_{2n+1,2}&=\frac{1}{2(2n)!}\int_0^1 \log^{2n}t\log^2(1+t)\frac{dt}{t}\\ &=\frac{1}{2}\left[1-(2n+1)(1-2^{-2n-2})\right]\zeta(2n+3)\\ &\quad+\sum_{j=1}^{n}(1-2^{1-2j})\zeta(2j)\zeta(2n-2j+3).\end{aligned} \tag{9.4}$$

The sum is zero if $n=0$.

Proof. Nielsen's proof, which is full of misprints, starts from the inversion formula (5.12) for $z=1$ and $p=2$. After applying Lemma (4.1a), he obtains an expression for $C_{2n-1,2}$. He then takes the real part and compares his result with the power series expansion of both sides of the relation

$$\pi \csc \pi x = \pi \cot \pi x \cos \pi x + \pi \sin \pi x.$$

Theorem 1 allows us to shorten this proof. From (5.9), we have

$$\sigma_{2n-1,2} = \frac{1}{2}\left[C_{2n-1,2} - (2n-1)\sigma_{2n+1}\right].$$

Hence, for $n=1$, using (7.1) and (2.22),

$$\sigma_{1,2} = \frac{1}{2}(C_{1,2} - \sigma_3) = \frac{1}{2}(s_3 - \sigma_3) = \frac{1}{8}\zeta(3).$$

For $n \geqq 2$, we obtain, using (7.2),

$$\sigma_{2n-1,2} = \frac{1}{2}\left\{2\sum_{j=0}^{n-1}(-1)^j \frac{\pi^{2j}}{(2j)!} s_{2n-2j-1,2} - (2n-1)\sum_{j=0}^{n-1}(-1)^j \frac{\pi^{2j}}{(2j)!} s_{2n-2j+1} - (2n-1)\sigma_{2n+1}\right\}. \tag{9.5}$$

With the help of [13], [20],

$$s_{m,2} = \frac{1}{2}\left[(m+1)s_{m+2} - \sum_{k=2}^{m} s_k s_{m-k+2}\right], \qquad (m \geqq 2) \tag{9.6}$$

$$s_{1,2} = s_3,$$

(9.5) can be written as

$$\sigma_{2n-1,2} = \frac{1}{2}\left\{-\sum_{j=0}^{n-1}(-1)^j \frac{\pi^{2j}}{2j(2j-2)!} s_{2n-2j+1} - \sum_{j=0}^{n-2}(-1)^j \frac{\pi^{2j}}{(2j)!} \sum_{k=2}^{2n-2j-1} s_k s_{2n-2j-k+1} + s_{2n+1} - (2n-1)\sigma_{2n+1}\right\}.$$

Noting the symmetry in the double sum, and reordering, gives

$$\sigma_{2n-1,2} = \frac{1}{2}\left\{\sum_{j=1}^{n-1}\left[(-1)^{j-1}\frac{\pi^{2j}}{2j(2j-2)!} - 2\sum_{k=0}^{j-1}(-1)^k \frac{\pi^{2k}}{(2k)!} s_{2j-2k}\right] \times s_{2n-2j+1} + s_{2n+1} - (2n-1)\sigma_{2n+1}\right\}.$$

Referring to (7.2), we see that the expression in square brackets equals $C_{2j-1,1} = 2\sigma_{2j}$, hence

$$\sigma_{2n-1,2} = \sum_{j=1}^{n-1} \sigma_{2j} s_{2n-2j+1} + \frac{1}{2}\left[s_{2n+1} - (2n-1)\sigma_{2n+1}\right], \tag{9.7}$$

and Theorem 2 follows on replacing n by $n+1$ and using (2.22).

Formula (9.4) shows that $\sigma_{2n+1,2}$ can be expressed by a homogeneous polynomial of degree $2n+3$ in $\zeta(q)$ $(2 \leqq q \leqq 2n+3)$, with rational coefficients. In contrast to the expressions for $s_{n,p}$ and $C_{n,p}$, however, all coefficients of terms which contain more than two factors vanish. A short table of $\sigma_{2n+1,2}$ is given in Table 2.

TABLE 2

Let

$$I_n = \sigma_{2n+1,2} = \frac{1}{2(2n)!}\int_0^1 \log^{2n} t \log^2(1+t)\frac{dt}{t}.$$

Then

$$I_0 = \frac{1}{8}\zeta(3)$$
$$I_1 = \frac{1}{2}\zeta(2)\zeta(3) - \frac{29}{32}\zeta(5)$$
$$I_2 = \frac{1}{2}\zeta(2)\zeta(5) + \frac{7}{8}\zeta(3)\zeta(4) - \frac{251}{128}\zeta(7)$$
$$I_3 = \frac{1}{2}\zeta(2)\zeta(7) + \frac{31}{32}\zeta(3)\zeta(6) + \frac{7}{8}\zeta(4)\zeta(5) - \frac{1529}{512}\zeta(9)$$
$$I_4 = \frac{1}{2}\zeta(2)\zeta(9) + \frac{127}{128}\zeta(3)\zeta(8) + \frac{7}{8}\zeta(4)\zeta(7) + \frac{31}{32}\zeta(5)\zeta(6) - \frac{8183}{2048}\zeta(11)$$
$$I_5 = \frac{1}{2}\zeta(2)\zeta(11) + \frac{511}{512}\zeta(3)\zeta(10) + \frac{7}{8}\zeta(4)\zeta(9) + \frac{127}{128}\zeta(5)\zeta(8) + \frac{31}{32}\zeta(6)\zeta(7) - \frac{40949}{8192}\zeta(13)$$

For a discussion of Nielsen's work on $\sigma_{n,p}$ for other values of n and p, it is perhaps useful to quote his monograph [20, pp. 199–202, translated from the German]. He starts with formula (2.22) for σ_n and continues that

> a similar result is not available for the more general numbers $\sigma_{n,p}\cdots$, if $p>1$. On the contrary, it seems that these numbers cannot, in general, be expressed in closed form by the numbers s_k. In any case, I have found such an expression only when $n+p$ is odd.

After having proved Theorem 2, he continues

> On the values $\sigma_{n,p}$, we still have to prove that, for $n \geqq 2$,
>
> (N1) $$\sigma_{p,n} = (-1)^{p-1}\binom{n+p-1}{n}\sigma_{1,n+p-1} + \sum_{q=0}^{p-2}(-1)^q\binom{n+q}{n}s_{n+q+1,p-q-1}.$$
>
> For this purpose, we set $x=1$ in (2) and obtain
>
> (N2) $$s_{n,p} = \sum_{q=0}^{p}\binom{n+p-q-1}{n-1}\sigma_{q+1,n+p-q-1},$$
>
> which easily gives formula (N1) by induction. Setting $n=2$ and $p=2n-1$ in (N1) yields
>
> (N3) $$\sigma_{2n-1,2} = \binom{2n+1}{2}\sigma_{1,2n} + \sum_{q=0}^{2n-3}(-1)^q\binom{q+2}{q}s_{q+3,2n-q-2}.$$
>
> Therefore, because of [(9.4)] and (N1), we can deduce the following theorem:
>
> For $n+p$ odd, the value $\sigma_{n,p}$ is a homogeneous polynomial of degree $n+p$ in $s_2, s_3, \cdots, s_{n+p}$ with rational coefficients, provided s_r is of degree r.
>
> In order to find the numbers $\sigma_{n,p}$ also for $n+p$ even, one needs only to express the numbers $\sigma_{1,2n-1}$ by s_r, in which I did not succeed.

A numerical check for small n and p shows, however, that (N2) cannot be correct as it stands. In addition, formula (N2), which represents, for given $n+p$, a system of $n+p-1$ linear equations in the $n+p-1$ unknowns $\sigma_{\nu,\rho}$, is not symmetric with respect

[2] There is an obvious misprint in the equation number referenced.

to n and p, as it should be according to (2.21). Further, for $n=1$ it contains a quantity $\sigma_{n+p,0}$ which is undefined. However, it is easy to see the origin of (N2) in spite of the misprint in the equation number referenced. It lies in Nielsen's incorrect equation corresponding to (6.6), which gives, for $a=0$, $b=1$, $z=1$, the relation (N2) as a special case.

A correct relation between $s_{n,p}$ and $\sigma_{\nu,\rho}$ is given by the following

THEOREM 3. *The numbers* $s_{n,p}=S_{n,p}(1)$ *and* $\sigma_{\nu,\rho}=(-1)^{\rho}S_{\nu,\rho}(-1)$ *are linearly related through*

$$s_{n,p}=\sum_{j=1}^{n}\binom{n+p-j-1}{p-1}\sigma_{j,n+p-j}+\sum_{j=1}^{p}\binom{n+p-j-1}{n-1}\sigma_{j,n+p-j}. \tag{9.8}$$

Proof. From (5.1), we obtain for $z=\frac{1}{2}$

$$L_{n,p}\left(\frac{1}{2}\right)+L_{p,n}\left(\frac{1}{2}\right)=s_{n,p}-\frac{\log^{n+p}2}{n!p!}$$

and from (6.2) for $z=1$, using (2.21),

$$L_{n,p}\left(\frac{1}{2}\right)+L_{p,n}\left(\frac{1}{2}\right)=2s_{n,p}-\left[\binom{n+p-1}{n-1}+\binom{n+p-1}{p-1}\right]\frac{\log^{n+p}2}{(n+p)!}$$
$$-\sum_{j=1}^{n}\binom{n+p-j-1}{p-1}\sigma_{j,n+p-j}-\sum_{j=1}^{p}\binom{n+p-j-1}{n-1}\sigma_{j,n+p-j}.$$

Theorem 3 follows by comparison.

Note that (9.8) is symmetric in n and p. This relation for $s_{n,p}$ was given in [12] without proof. Note also that setting $z=1$ in formula (6.7), derived from the correct equation (6.6) merely yields an equation equivalent to equation (9.8), as can be seen from elementary properties of binomial coefficients.

It seems puzzling that Nielsen should have published such an obviously incorrect equation as (N2), when the correct relation follows easily from his relations for $L_{n,p}(z)$.[3] However, by introducing (N1) into (N2) and performing some manipulations with binomial coefficients, it can be shown that (N1) is indeed the solution of the linear system (N2) for $\sigma_{\nu,\rho}$. This suggests that the more special formula (N3) for $\sigma_{1,2n}$ is also incorrect, a fact which is easily verified by a numerical check using small values of n, after correcting an obvious misprint in (N3).

By comparing (N2) and (9.8), we see that Nielsen was misled by the (wrong) triangular structure of (N2), which enabled him to solve his system in closed form. On the other hand, the correct system (9.8) does not allow a solution $\sigma_{n,p}$ in terms of $s_{\nu,\rho}$ (and therefore of $\zeta(q)$). For $n+p\geqq 4$, the system (9.8) consists of $[(n+p)/2]$ equations with either $n+p-2$ ($n+p$ even) or $n+p-3$ ($n+p$ odd) unknowns, so that for $n+p\geqq 6$ there are more unknowns than equations. The cases $n+p=4$ and $n+p=5$, where one has as many equations as unknowns, namely two, result in a vanishing determinant, yielding the single equations

$$2\sigma_{1,3}+\sigma_{2,2}=\frac{\pi^4}{720}, \qquad 2\sigma_{1,4}+\sigma_{2,3}=\frac{31}{32}\zeta(5)-\frac{1}{2}\zeta(2)\zeta(3). \tag{9.9}$$

The cases $n+p=2$ and $n+p=3$ are trivial.

[3] One could imagine that Nielsen, or somebody else at the time might have recognized this error later. However, a search through the volumes of *Nova Acta Leopoldina* and *Oversigt Danske Vidensk. Selsk. Forh.* up to 1918 shows no published erratum or remark relating to Nielsen's paper. As far as the author knows, no collected papers of Nielsen exist (cf. the list of known collected papers in Struik [22, p. 196]).

When examining other relations of §§5 and 6, one realizes that there seems to be an inherent difficulty in getting relations which could be used to compute $\sigma_{n,p}$ in terms of $s_{\nu,\rho}$. This is true in particular for the (singular) system (5.9) of linear equations for the unknowns $\sigma_{\nu,\rho}$. Therefore, it seems likely that, not only are Nielsen's relations (N1) and (N3) incorrect, but that no such relation exists. An unsuccessful computer search through relations of the form

$$\left.\begin{matrix}|\sigma_{1,4}|\\ |\sigma_{2,3}|\end{matrix}\right\} = \frac{p_1}{p_2}\zeta(2)\zeta(3)+\frac{p_3}{p_4}\zeta(5),$$

with integers p_i in the range $-50 \leqq p_1 \leqq 50$, $1 \leqq p_2 \leqq 50$, $0 \leqq p_3 \leqq 50$, $1 \leqq p_4 \leqq 50$ supports this conclusion.

9.3. The integrals $a_{n,p} = S_{n,p}(\frac{1}{2})$. The problem of evaluating

$$a_{n,p} = \frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^1 \log^{n-1} t \log^p\left(1-\frac{1}{2}t\right)\frac{dt}{t} \tag{9.10}$$

apparently faces obstacles similar to those found for the evaluation of $\sigma_{n,p}$; in particular, because no closed expression seems to be known for ${}_2F_1(\alpha,\beta;\beta+1;\frac{1}{2})$. A result which can easily be obtained from formulae treated in the previous sections is the following

THEOREM 4. *For $n \geqq 1$ and $p \geqq 1$, the numbers $a_{n,p}$ can be expressed in terms of $\sigma_{\nu,\rho}$ and $\log 2$, through the relation*

$$a_{n,p} = \sum_{j=0}^{n-1}(-1)^j\frac{\log^j 2}{j!}\sum_{k=1}^{n-j}\binom{n+p-j-k-1}{p-1}\sigma_{k,n+p-j-k} + (-1)^n\frac{\log^{n+p}2}{(n+p)!}. \tag{9.11}$$

Proof. From (6.2) with $z=1$ and (2.16) with $z=\frac{1}{2}$ it follows that

$$\sum_{i=0}^{n-1}\frac{\log^j 2}{j!}a_{n-j,p} = s_{n,p} - \frac{1}{(n+p)!}\binom{n+p-1}{n-1}\log^{n+p}2 - \sum_{k=1}^{\infty}\binom{n+p-k-1}{n-1}\sigma_{k,n+p-k}.$$

Applying Lemma (4.1a) and using (5.11) yields

$$a_{n,p} = \sum_{j=0}^{n-1}\frac{(-1)^j\log^j 2}{j!}\left\{s_{n-j,p} - \sum_{k=1}^{p}\binom{n+p-j-k-1}{n-j-1}\sigma_{k,n+p-j-k}\right\} + (-1)^n\frac{\log^{n+p}2}{(n+p)!}. \tag{9.12}$$

Replacing $s_{n-j,p}$ by (9.8) gives Theorem 4.

As a special case, we obtain for $p=1$,

$$a_n = \sum_{j=0}^{n-2}\frac{(-1)^j\log^j 2}{j!}\sum_{k=1}^{n-j-1}\sigma_{k,n-j-k} - (-1)^n\frac{\log^n 2}{n!}, \qquad (n \geqq 2). \tag{9.13}$$

In particular, for $n=2$,

$$a_2=-\int_0^1 \log\left(1-\frac{1}{2}t\right)\frac{dt}{t}=\sigma_{1,1}-\frac{1}{2}\log^2 2=\frac{\pi^2}{12}-\frac{1}{2}\log^2 2, \tag{9.14}$$

which is a well-known formula due to Euler (attributed to Landen by Lewin [17, p. 6]); and for $n=3$,

$$a_3=\int_0^1 \log t\log\left(1-\frac{1}{2}t\right)\frac{dt}{t}=\frac{7}{8}\zeta(3)-\frac{\pi^2}{12}\log 2+\frac{1}{6}\log^3 2. \tag{9.15}$$

For $n=4$, we have, using (9.9),

$$a_4=\frac{\pi^4}{90}+\frac{\pi^2}{24}\log^2 2-\frac{7}{8}\zeta(3)\log 2-\frac{1}{24}\log^4 2-\sigma_{1,3}. \tag{9.16}$$

The appearance of the quantity $\sigma_{1,3}$, for which no closed formula seem to be known, makes it impossible to compute

$$a_4=-\frac{1}{2}\int_0^1 \log^2 t\log\left(1-\frac{1}{2}t\right)\frac{dt}{t}$$

from (9.13).

From the power series (2.5) we have

$$a_n=\sum_{j=1}^{\infty}\frac{1}{2^j j^n}. \tag{9.17}$$

Therefore

$$a_2=\sum_{j=1}^{\infty}\frac{1}{2^j j^2}=\frac{\pi^2}{12}-\frac{1}{2}\log^2 2 \tag{9.18}$$

$$a_3=\sum_{j=1}^{\infty}\frac{1}{2^j j^3}=\frac{7}{8}\zeta(3)-\frac{\pi^3}{12}\log 2+\frac{1}{6}\log^3 2 \tag{9.19}$$

and, trivially, $a_0=1$, $a_1=\log 2$. Formula (9.19) had been found by Legendre.

It seems puzzling that (9.17) should exist in closed form only for $n=0,1,2,3$. Knowing a_4 for example would allow us to obtain, from (9.16) and (9.9), expressions for $\sigma_{1,3}$ and $\sigma_{2,2}$. This in turn, together with a knowledge of a_5, would make possible a computation of $\sigma_{1,4}$ and $\sigma_{2,3}$ from (9.12), (9.4) and (9.9). Levine et al. [15] and Gastmans and Troost [7] therefore consider a_4 and a_5 as "new" constants. This makes it possible to express more kinds of logarithmic integrals in "closed" form.

Another special case is $n=1$. Here we find from (9.11) that

$$a_{1,p}=\frac{(-1)^p}{p!}\int_0^1 \log^p\left(1-\frac{1}{2}t\right)\frac{dt}{t}=\sigma_{1,p}-\frac{\log^{p+1}2}{(p+1)!}. \tag{9.20}$$

Note that Nielsen's remark [20, p. 203] that $a_{1,2p}$ can be expressed in terms of $\log 2$ and $\zeta(q)$ $(2 \leqq q \leqq 2p+1)$, is probably incorrect, being a consequence of the incorrect formula (N3).

From (2.7), (9.4) and (9.20), one finds

$$a_{1,2} = \sum_{j=0}^{\infty} \frac{(-1)^j S_{j+2}^{(2)}}{(j+2)!(j+2)} \frac{1}{2^{j+2}}$$

$$= \sum_{j=2}^{\infty} \frac{1}{2^j j^2} \left(1 + \frac{1}{2} + \cdots + \frac{1}{j-1}\right) = \frac{1}{8}\zeta(3) - \frac{1}{6}\log^3 2$$

or

$$\int_0^1 \log^2\left(1 - \frac{1}{2}t\right) \frac{dt}{t} = \frac{1}{4}\zeta(3) - \frac{1}{3}\log^3 2. \tag{9.21}$$

Nielsen also gave two relations between $a_{1,n}$ and $a_{p,1}$. From (5.1) and (2.16), we obtain for $z = \frac{1}{2}$,

$$a_{1,n} = s_{n+1} - \sum_{j=0}^{n-1} \frac{\log^j 2}{j!} a_{n-j+1} - \frac{1}{n!}\log^{n+1} 2. \tag{9.22}$$

With the help of Lemma (4.1a) and a well-known relation for the binomial coefficients, (9.22) can be inverted to give

$$a_n = \sum_{j=0}^{n-2} \frac{(-1)^j \log^j 2}{j!} (s_{n-j} - a_{1,n-j-1}) - (-1)^n \frac{\log^n 2}{(n-1)!}. \tag{9.23}$$

Acknowledgment. I would like to thank Dr. B. Schorr for a critical reading of the manuscript and for helpful discussions.

p-ARY SEQUENCY AND ORDERINGS OF THE CHRESTENSON FUNCTIONS*

ZHANG GONGLI†

Abstract. A physical interpretation of the concept of the p-ary sequency is presented. A definition of p-ary sequency is given according to the interpretation. Expressions of p-ary natural (generalized Hadamard), p-ary sequency, and p-adic ordered Chrestenson functions are established in a systematic way, and they are related to the p-adic code and the p-ary Gray code. Mutual mappings of different ordered Chrestenson functions are discussed.

Key words. Chrestenson function, p-ary sequency, ordering, Gray code, Walsh function

1. Introduction. Much interest in multiple-valued devices, logic, and digital circuits has been evidenced in the past decade. The Chrestenson functions [1], which take multiple complex values, are compatible with p-ary numerical systems, and they have been applied to the design and optimization of multiple-valued logic networks [2], [3], [4]. In order to introduce the Chrestenson functions well to engineering, where p-ary digital techniques are employed, the present author showed that the sums of the real and imaginary parts of the Chrestenson functions also form a set of complete orthogonal functions [5]. We call them the RMV Walsh functions. Because the RMV Walsh functions take real multiple values, they are readily represented by physical means, e.g., voltage levels, as is necessary for system implementation. S-H Chang and T. Joseph [6] introduced the generalized concept of symmetry and sequence for the Chrestenson functions, and they presented orderings of the functions according to the symmetry and sequency. However, further development is necessary.

2. The p-ary sequency. For the Walsh functions the sequency, which is generalized frequency, is defined as "one-half the average number of zero crossings per unit of time" [7]. However, the definition is not applicable to the Chrestenson functions. In [6] sequency is generalized as the measure of oriented phase shift, but the physical interpretation of the concept is not given. The phase number or sequency number has not so obvious a meaning as the number of zero crossings.

It is known that for a given natural number m the Chrestenson functions [1] $\mathrm{CH}_w^p(t)$ are defined as

$$\mathrm{CH}_w^p(t)=\exp\left(2\pi i p^{-1}\mathbf{w}^T\mathbf{t}\right) \tag{1}$$

where

$$w=0,1,\cdots,p^{m-1},\quad w=\sum_{s=0}^{m-1} w_s p^{m-1-s},\quad \mathbf{w}=[w_0 w_1\cdots w_{m-1}]^T;$$

$$t\in[0,1),\quad t=\sum_{s=0}^{\infty} t_s p^{-s-1},\quad \mathbf{t}=[t_0 t_1\cdots t_{m-1}]^T,\quad i^2=-1;$$

$$J_p=\{0,1,\cdots,p-1\},\quad t_s, w_s\in J_p,\quad p \text{ is a fixed integer},\quad p>1.$$

We would interpret variable t as time measured in seconds. To interpret the concept of sequency for Chrestenson functions, we begin by considering the physical interpretation of frequency for the exponential and trigonometric functions. Speaking more generally, we view that these functions are intimately related to the circular motions of particles, with which Newtonian (classical) mechanics deals. The exponential functions $\exp(2\pi iwt)$, $w=0,1,2,\cdots$, mathematically describe circular motion of a unit vector around the origin in the complex plane, as shown in Fig. 1. The unit vector projected onto the real axis yields $\cos(2\pi wt)$, while the projection onto the imaginary axis yields $\sin(2\pi wt)$. Whenever one uses the term frequency and angular shift of $\exp(2\pi iwt)$, $\sin(2\pi wt)$ and $\cos(2\pi wt)$, one refers implicitly to the circular motion described by these functions. The usual physical interpretation of frequency is the "number of cycles per unit time" [7]. It is just the definition of frequency, and its unit is "cps" or Hz. Note that the motion of the unit vector described by the exponential functions is continuous and differentiable, and the motion can be understood with the aid of Newtonian mechanics, which deals with forces, masses and motions of particles. The time t (function variable) is interpreted as the topology of continuum just as shown in the expressions for exponential functions. In other words, t has the same topology as the real numbers. From the point of view of mathematics the exponential functions represent a mapping of the real number t on the number axis in the interval $[0,1)$ onto the unit circle in the complex plane as shown in Fig. 1. The time t in the expressions for exponential functions is a continuous (analogue) variable.

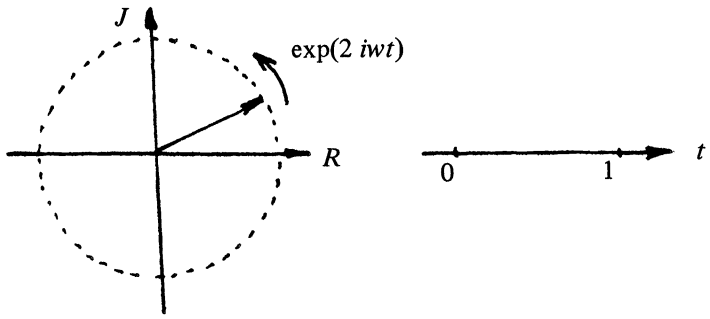

FIG. 1. *The motion of the unit vector described by the exponential functions.*

Similarly the Chrestenson functions may be said to describe mathematically the circular motion of a unit vector around the origin in the complex plane; but the circular motion described by the Chrestenson functions cannot be understood with the aid of Newtonian mechanics, if we view the motion as that of a particle. The unit vector transitionally moves discontinuously around the origin while the variable t increases from 0 to 1. The angular shift θ (in radians) of the position occupied by the unit vector is only an integer times the basis $\theta=2\pi/p$, i.e., $\theta=0,\ 2\pi/p,\ 2\times 2\pi/p,\cdots$. For example, if $p=3$ the three positions which the unit vector can occupy are shown in Fig. 2.

It is clear that the positions occupied by the unit vector are quantized. The unit vector moves instantaneously from one position to another without spending any time. The motion of the unit vector can be interpreted with the aid of quantum mechanics, which shows us that the transition from one position, form, or state to another is possible. The Chrestenson functions represent another mapping of the real number t on the number axis in the inverval $[0,1)$ onto the unit circle, but in the expression for

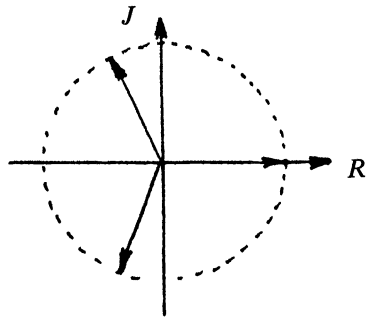

FIG. 2. *The three positions of the unit vector.*

Chrestenson functions the continuous time variable t, which has been quantized in the p-ary numerical system, becomes a digital variable. The discontinuous and transitional motion of the unit vector is related to the idea that the time t is regarded as having a p-adic topology for the Chrestenson functions.

The "cycle" for the Chrestenson functions thus has an obvious meaning according to the above interpretation. We interpret the sequency of a Chrestenson function as the "average number of cycles made by the rotating unit vector, the motion of which is described by the Chrestenson function, per unit of time". It is also the definition of p-ary sequency. The concept of p-ary sequency, which has a broader meaning, is applicable to the trigonometric, exponential, Walsh, and RMV Walsh functions if the function describing the motion of the unit vector is a corresponding function. The unit of p-ary sequency is the same as the one of frequency, i.e., "cps" or Hz. It is easy to see that p-ary sequency is a generalized concept of frequency and sequency.

We now show how the notion of p-ary sequency applies to the Walsh functions ($p=2$). Because $p=2$, the unit vector occupies only two positions, which are $\theta_1=2n\pi$ and $\theta_2=(2n+1)\pi$, $n=0,1,2,\cdots$. With θ_1 the value of the Walsh function equals 1, and with θ_2 its value is -1. If a Walsh function has one sign change (from 1 to -1 or the reverse) at t_1, $t_1\in[0,1)$, the corresponding angular shift of the unit vector equals π at t_1. Suppose N is the average number of sign changes (zero crossings) of the Walsh function per unit of time: according to the definition of p-ary sequency the sequency of the Walsh function would be

$$S=N\pi/2\pi=N/2. \tag{2}$$

It is just "one-half the average number of zero crossings per unit of time". Therefore, with $p=2$ the p-ary sequency and the sequency for the Walsh functions are identical.

It will be proved later that if $w=(w=0,1,\cdots,p^m-1)$ is the index of a p-ary sequency ordered Chrestenson function, the p-ary sequency s of the Chrestenson function is

$$S=[(p-1)w/p]^* \tag{3}$$

where $[a]^*$ denotes the least integer $\geqq a$.

3. Orderings of the Chrestenson functions. The question about the ordering of Walsh functions has been investigated by some authors [8], [9]. The merits and disadvantages of different orderings are discussed by Yuen [10]. There are three orderings for the Chrestenson functions, which correspond to the dyadic (Paley), natural

(Hadamard), and sequency (Walsh) ordering of Walsh functions. They are p-adic, p-ary natural (generalized Hadamard), and p-ary sequency.

Suppose w_H, w_G, and w_P express the indexes of the generalized Hadamard, p-ary sequency, and p-adic ordered Chrestenson functions respectively, and their p-adic code, p-ary Gray code [11], and bit-reversed p-adic code are represented as $(w_0 w_1 \cdots w_{m-1})$, $(g_0 g_1 \cdots g_{m-1})$, and $(h_0 h_1 \cdots h_{m-1})$, respectively. Then

$$h_s = w_{m-1-s}, \tag{4}$$

$$g_s = w_s \ominus w_{s-1}, \tag{5}$$

$$w_s = \sum_{k=0}^{s} g_k, \tag{6}$$

$$w_A = \sum_{s=0}^{m-1} w_s p^{m-1-s} \tag{7}$$

where $\ominus$ denotes subtraction modulo p and $\sum$ denotes summation modulo p.

$$A \in \{H, G, P\} \quad \text{and} \quad w_A = 0, 1, \cdots p^m - 1.$$

3.1. Generalized Hadamard ordering. The generalized Hadamard ordering is the one which was originally employed by H. E. Chrestenson [1]. The generalized Hadamard ordered Chrestenson functions $\mathrm{CH}^p_{w_H}(t)$ are expressible by using the bit-reversed p-adic code $(h_0 h_1 \cdots h_{m-1})$ of w_H as

$$\mathrm{CH}^p_{w_H}(t) = \exp\left((2\pi i/p) \sum_{s=0}^{m-1} h_{m-1-s} t_s \right). \tag{8}$$

Substituting (4) in (8), we find

$$\mathrm{CH}^p_{w_H}(t) = \exp\left((2\pi i/p) \sum_{s=0}^{m-1} w_s t_s \right). \tag{9}$$

If $[\mathrm{CH}_m]$ denotes the matrix whose w_Hth row is $[\mathrm{CH}^p_{w_H}(0)\ \mathrm{CH}^p_{w_H}(p^{-m}) \cdots \mathrm{CH}^p_{w_H}((p^m - 1)p^{-m})]$ for $w_H = 0, 1, \cdots, p^m - 1$, it is easily shown that [6]

$$[\mathrm{CH}_m] = [\mathrm{H}_m], \tag{10}$$

where $[\mathrm{H}_m]$ is the generalized Hadamard matrix of order m

$$[\mathrm{H}_1] = \begin{bmatrix} r^0 & r^0 & \cdots & r^0 \\ r^0 & r^1 & \cdots & r^{p-1} \\ \cdots & & & \\ r^0 & r^{p-1} & \cdots & r^1 \end{bmatrix}, \tag{11}$$

$$[\mathrm{H}_2] = [\mathrm{H}_1] \otimes [\mathrm{H}_1], \tag{12}$$

$$[\mathrm{H}_m] = [\mathrm{H}_{m-1}] \otimes [\mathrm{H}_1] \tag{13}$$

where $\otimes$ denotes the Kronecker product and $r = \exp(2\pi i/p)$.

3.2. *p*-Ary sequency ordering. The sequency ordered Chrestenson functions $\mathrm{CH}^p_{w_G}(t)$ are defined by using the p-ary Gray code $(g_0 g_1 \cdots g_{m-1})$ of w_G as

$$\mathrm{CH}^p_{w_G}(t) = \exp\left((2\pi i/p) \sum_{s=0}^{m-1} g_{m-1-s} t_s \right). \tag{14}$$

Substituting (5) in (14), we get

$$\text{(15)}\qquad \mathrm{CH}^{p}_{w_G}(t)=\exp\left((2\pi i/p)\sum_{s=0}^{m-1}(w_{m-1-s}\ominus w_{m-2-s})t_s\right).$$

Now we prove that the Chrestenson functions defined by (14) are ordered according to the p-ary sequency. As already mentioned, the p-ary sequency S of a Chrestenson function equals the angular shift (measured in radians) of the unit vector, the motion of which is described by the Chrestenson function over $[0,1)$, divided by 2π. For $\mathrm{CH}^{p}_{w_G}(t)$, the angular shift θ over $[0,1)$ is determined by

$$\text{(16)}\qquad \theta=\sum_{q=0}^{p^m-2}(2\pi/p)\left(\sum_{s=0}^{m-1}g_{m-1-s}t_{q+1,s}\ominus\sum_{s=0}^{m-1}g_{m-1-s}t_{q,s}\right)+\phi$$

where $q=\sum_{s=0}^{m-1}t_{q,s}p^{m-1-s}$, $t_{q,s}\in J_p$ and ϕ is the angular shift at $t=0$. We have

$$\text{(17)}\qquad \theta=(2\pi/p)\sum_{q=0}^{p^m-2}\left[\sum_{s=0}^{m-1}g_{m-1-s}(t_{q+1,s}\ominus t_{q,s})\right]+\phi.$$

According to the construction of the p-adic code of t, as shown in Table 1 for $p=3$, $m=3$, it is not difficult to see that

$$\text{(18)}\qquad \begin{aligned}\theta=(2\pi/p)\big[&(p^m-p^{m-1})g_0+(p^{m-1}-p^{m-2})(g_0\oplus g_1)\\&+\cdots+(p-1)(g_0\oplus g_1\oplus 2/\oplus g_{m-1})\big]+\phi,\end{aligned}$$

where $\oplus$ denotes addition modulo p. Substituting (6) in (18), we have

$$\text{(19)}\qquad \theta=(2\pi/p)(p-1)(p^{m-1}w_0+p^{m-2}w_1+\cdots+w_{m-1})+\phi$$

$$\text{(20)}\qquad =(2\pi/p)(p-1)\sum_{s=0}^{m-1}w_s p^{m-1-s}+\phi.$$

By (7),

$$\text{(21)}\qquad \theta=2\pi(p-1)w_G/p+\phi.$$

Therefore,

$$\text{(22)}\qquad S=\theta/2\pi=(p-1)w_G/p+\phi/2\pi.$$

TABLE 1

The values of $(t_{q+1}\ominus st_{q,s})$ *for* $p=3$, $m=3$.

t,q	t_0	t_1	t_2	$(t_{q+1}\ominus t_{q,s})$			t,q	t_0	t_1	t_2	$(t_{q+1}\ominus t_{q,s})$		
				$s=0$	1	2					$s=0$	1	2
0	0	0	0	0	0	1	14	1	1	2	0	1	1
1	0	0	1	0	0	1	15	1	2	0	0	0	1
2	0	0	2	0	1	1	16	1	2	1	0	0	1
3	0	1	0	0	0	1	17	1	2	2	1	1	1
4	0	1	1	0	0	1	18	2	0	0	0	0	1
5	0	1	2	0	1	1	19	2	0	1	0	0	1
6	0	2	0	0	0	1	20	2	0	2	0	1	1
7	0	2	1	0	0	1	21	2	1	0	0	0	1
8	0	2	2	1	1	1	22	2	1	1	0	0	1
9	1	0	0	0	0	1	23	2	1	2	0	1	1
10	1	0	1	0	0	1	24	2	2	0	0	0	1
11	1	0	2	0	1	1	25	2	2	1	0	0	1
12	1	1	0	0	0	1	26	2	2	2			
13	1	1	1	0	0	1							

The angular shift ϕ at $t=0$ would be determined, while the Chrestenson function is extended with period 1, i.e.,

$$\mathrm{CH}^{p}_{w_G}(t)=\mathrm{CH}^{p}_{w_G}(t+1). \tag{23}$$

It is easy to see that the ϕ is the angle shift from θ_1 (corresponding to $\mathrm{CH}^{p}_{w_G}(1-p^{-m})$) to θ_2 (corresponding to $\mathrm{CH}^{p}_{w_G}(0)$). So

$$S=[(p-1)w_G/p]^*. \tag{24}$$

The formula (24) shows that the larger the index w_G, the larger the corresponding p-ary sequency, and the $\mathrm{CH}^{p}_{w_G}(t)$ $(w_G=0,1,\cdots,p^m-1)$ are ordered according to the p-ary sequency. The p-ary sequencies of the Chrestenson functions for $p=3$, $m=3$, are shown in Table 2.

TABLE 2

The p-ary sequencies of the Chrestenson functions for $p=3$, $m=3$.

w_G	p-ary Gray code	$(\theta-\phi)$ (π)	S	w_G	p-ary Gray code	$(\theta-\phi)$ (π)	S
0	000	0	0	14	101	28	10
1	001	2	1	15	111	30	10
2	002	4	2	16	112	32	11

4	010	8	3	18	210	36	12
5	011	10	4	19	211	38	13
6	021	12	4	20	212	40	14
7	022	14	5	21	222	42	14
8	020	16	6	22	220	44	15
9	120	18	6	23	221	46	16
10	121	20	7	24	201	48	16
11	122	22	8	25	202	50	17
12	102	24	8	26	200	52	18
13	100	26	9				

3.3. *p*-Adic ordering. Using the p-adic code $(w_0w_1\cdots w_{m-1})$ of index w_p, we define the p-adic ordered Chrestenson functions $\mathrm{CH}^{p}_{w_p}(t)$ as

$$\mathrm{CH}^{p}_{w_p}(t)=\exp\left((2\pi i/p)\sum_{s=0}^{m-1} w_{m-1-s}t_s\right). \tag{25}$$

S-H Chang and T. Joseph [6] pointed out that the p-adic code $(w_0w_1\cdots w_{m-1})$ is the p-ary symmetry index for the $\mathrm{CH}^{p}_{w_p}(t)$, and that the vector

$$\left[\mathrm{CH}^{p}_{w_p}(0)\ \mathrm{CH}^{p}_{w_p}(p^{-m})\cdots\mathrm{CH}^{p}_{w_p}((p^m-1)p^{-m})\right]$$

can be written from left to right by using the p-ary symmetry index without referring to any other member of the set of Chrestenson functions. In [6] the p-adic ordered Chrestenson functions are called ordered according to the p-ary symmetry. We note that for the otherwise ordered Chrestenson functions the p-ary symmetry holds true, but the symmetry index is indifferent. The symmetry index of the generalized Hadamard ordered Chrestenson functions is the bit-reversed p-adic code, and the p-ary Gray code corresponds to the p-ary symmetry index of p-ary sequency ordered Chrestenson functions.

4. Mutual mappings of differently ordered Chrestenson functions. The exponential functions $\exp(2\pi iwt)$ are a character group of the topologic group of the real numbers. Since we may consider real numbers to be points on the real line which has only one dimension, the exponential functions have one ordering. On the other hand, the Chrestenson functions are a character group of the p-adic group, and the p-tuple vectors which belong to the p-adic group form a space which has p dimensions. Therefore, the Chrestenson functions can be ordered in many different ways.

Now we give a representation of the Chrestenson functions, ordering them according to the parameter matrix Q_A

$$\mathrm{CH}^{p}_{w_A}(t)=\exp\big((2\pi i/p)\mathbf{w}_A^T Q_A \mathbf{t}\big), \tag{26}$$

where A_A is an invertible symmetric matrix,

$$Q_A=[q_{ij}], \qquad i,j=0,\cdots,m-1, \quad q_{ij}\in J_P;$$
$$w_A=\sum_{s=0}^{m-1} w_s p^{m-1-s}, \quad \mathbf{w}_A=[w_0 w_1 \cdots w_{m-1}]^T, \quad \mathbf{t}=[t_0 t_1 \cdots t_{m-1}]^T.$$

All multiplication and addition operations in the calculation of $\mathbf{w}_A^T Q_A \mathbf{t}$ are performed modulo p. The ordering of the Chrestenson functions is determined by the matrix Q_A; the three matrices corresponding to the p-ary sequency, p-adic, and generalized Hadamard orderings are shown in Table 3.

TABLE 3

The matrices corresponding to the three orderings.

$$Q_H=\begin{bmatrix} 1 & & & \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{bmatrix} \qquad Q_G=\begin{bmatrix} & & & p-1 & 1 \\ & & \iddots & 1 & \\ & \iddots & \iddots & & \\ p-1 & \iddots & & & \\ 1 & & & & \end{bmatrix} \qquad Q_P=\begin{bmatrix} & & & & 1 \\ & & & \iddots & \\ & & 1 & & \\ & \iddots & & & \\ 1 & & & & \end{bmatrix}$$

Generalized Hadamard $\qquad$ p-ary sequency $\qquad$ p-adic

It is easy to see that the conversion from one ordering to another order is the same as the conversion from one code to the other code. Suppose $\mathbf{w}_H$, $\mathbf{w}_G$, and $\mathbf{w}_P$ are vectors formed by the p-adic code $(w_0 w_1 \cdots w_{m-1})$ of the indices w_H, w_G, and w_P, respectively. For example, if the p-adic code of w_H is (211), $\mathbf{w}_H=[211]^T$. The mutual mappings of the three orderings are represented as

$$\mathbf{w}_B^T=\mathbf{w}_A^T Q_A Q_B^{-1}, \tag{27}$$

where A, $B\in\{H,G,P\}$.

For example, let $p=3$, $m=3$; then

$$Q_H=\begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \end{bmatrix}, \quad Q_G=\begin{bmatrix} & 2 & 1 \\ 2 & 1 & \\ 1 & & \end{bmatrix}, \quad Q_P=\begin{bmatrix} & & 1 \\ & 1 & \\ 1 & & \end{bmatrix}$$

and

$$Q_H^{-1}=Q_H, \quad Q_P^{-1}=Q_P, \quad Q_G^{-1}=\begin{bmatrix} & & 1 \\ & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}.$$

Suppose $w_H = 8$; then $\mathbf{w}_H = [022]^T$,

$$\mathbf{w}_G^T = [022] \times \begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \end{bmatrix} \times \begin{bmatrix} & & 1 \\ & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} & & 1 \\ & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} = [211],$$

$$\mathbf{w}_P^T = [022] \times \begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \end{bmatrix} \times \begin{bmatrix} & & 1 \\ & 1 & \\ 1 & & \end{bmatrix} = [220].$$

Using (7), we have $w_G = 22$, $w_P = 24$.

The mutual mappings of other Chrestenson functions are analogous to the mutual mappings of the foregoing three ordered functions.

5. Discussion. The Chrestenson functions correspond to the discontinuous circular motion of the unit vector around the origin in the complex plane. The p-ary sequency of the Chrestenson functions is analogous to frequency. Among the orderings of the functions there are three important orderings, which are generalized Hadamard, p-ary sequency and p-adic. The merits and disadvantages of the three orderings are analogous to those of the Walsh functions [10]. It is convenient to use the p-adic ordered Chrestenson functions for mathematical discussions, while the generalized Hadamard ordered functions are applicable to fast transform. p-Ary sequency ordered Chrestenson functions, the indices of which have a transparent physical interpretation, would be applied to communication engineering, p-ary sequency filtering, and so on, just as sequency ordered Walsh functions [7].

Acknowledgments. The author is grateful to Prof. Fan Changxin of Northwest Telecommunication Engineering Institute, China and Prof. Hu Zhengming of Beijing Institute of Posts and Telecommunications for their helpful suggestions.

ANOTHER CONJECTURED q-SELBERG INTEGRAL*

MIZAN RAHMAN†

Abstract. Using Askey and Wilson's q-beta type integral, a q-extension of Selberg's n-dimensional integral is given as a conjecture and is proved for $n=2$.

Key words. Selberg's integral, Askey–Wilson integral, Sears' summation formula, basic hypergeometric series, quadratic transformation-formula, Macdonald–Morris conjectures

1. Introduction. In a little-known paper published in a Norwegian journal, A. Selberg [14] gave the following important result:

$$(1.1)\qquad \int_{-1}^{1}\cdots\int_{-1}^{1}\prod_{i=1}^{n}(1-x_i)^{\alpha}(1+x_i)^{\beta}\prod_{1\le i\le j\le n}|x_j-x_i|^{2\gamma}\,dx_1\cdots dx_n$$

$$=\prod_{j=1}^{n}2^{\alpha+\beta+1+(n-1)\gamma}\frac{\Gamma(\alpha+1+(j-1)\gamma)\Gamma(\beta+1+(j-1)\gamma)\Gamma(j\gamma+1)}{\Gamma(\alpha+\beta+2+(n+j-2)\gamma)\Gamma(\gamma+1)},$$

$$\operatorname{Re}\alpha>-1,\quad \operatorname{Re}\beta>-1,\quad \operatorname{Re}\gamma>-\left[\frac{1}{n},\frac{\operatorname{Re}(\alpha+1)}{n-1},\frac{\operatorname{Re}(\beta+1)}{n-1}\right],\quad n\ge 2.$$

In view of the particular extension we wish to propose, we have expressed the integrals on the interval $[-1,1]$ instead of $[0,1]$ and this explains an additional factor $2^{\alpha+\beta+1+(n-1)\gamma}$ on the right-hand side.

Once an important result is found, it is natural to look for extensions. Selberg's integral is a mutidimensional beta integral, so there may be extensions in each of the ways that Euler's beta integral has been extended. One way to extend the beta integral is as a sum, either like the hypergeometric distribution on an equally spaced set of points, or on a set of points whose ratio is constant. Included in the latter is Thomae's q-integral representation of the q-gamma function and Ramanujan's ${}_1\psi_1$ sum. See [15], [2]. Askey [3] discovered some extensions of Selberg's integral of this type, and was able to prove some of them in two dimensions. In a different direction, Macdonald [8] conjectured some constant term identities that are truncated versions of some of his earlier identities, Morris [9] made some further conjectures, and Macdonald reformulated Morris' conjectures so they made sense for the affine root systems [8]. For affine BC_n Macdonald's conjecture is equivalent to an integral with an absolutely continuous measure that extends Selberg's integral. For BC_1 Askey [4] proved this conjecture and the related integral was a new extension of Euler's integral. There is a

similar extension of Euler's integral with four free parameters in addition to q, which was found by Askey and Wilson [5]:

(1.2)

$$\int_{-1}^{1} \frac{h(x;1)h(x;-1)h(x;q^{1/2})h(x;-q^{1/2})}{h(x;a)h(x;b)h(x;c)h(x;d)} \frac{dx}{\sqrt{1-x^2}}$$

$$= \frac{2\pi(abcd;q)_\infty}{(q;q)_\infty(ab;q)_\infty(ac;q)_\infty(ad;q)_\infty(bc;q)_\infty(bd;q)_\infty(cd;q)_\infty}$$

$$= \kappa(a,b,c,d), \text{ say,}$$

where

$$(a;q)_\infty = \prod_{n=0}^{\infty}(1-aq^n), \qquad |q|<1, \tag{1.3}$$

and

$$h(x;a) = \prod_{n=0}^{\infty}(1-2axq^n+a^2q^{2n}) = (ae^{i\theta};q)_\infty(ae^{-i\theta};q)_\infty, \qquad x=\cos\theta, \tag{1.4}$$

the parameters being subject to the restriction

$$\max(|q|,|a|,|b|,|c|,|d|)<1. \tag{1.5}$$

It is natural to ask if this can be used to extend the Selberg integral. That (1.2) is an extension of Euler's integral can be seen by specializing the parameters in a number of different ways and then taking the limit $q\to 1$. Following Askey and Wilson [5], we take

$$0<q<1, \quad a=q^{\alpha/2+1/4}, \quad b=aq^{1/2}, \quad c=-q^{\beta/2+1/4}, \quad d=cq^{1/2}, \quad \alpha,\beta>-1. \tag{1.6}$$

Then, using the notation

$$(a;q)_\alpha = \frac{(a;q)_\infty}{(aq^\alpha;q)_\infty}, \tag{1.7}$$

(1.2) can be written as

(1.8)

$$\int_{-1}^{1} \left|(e^{i\theta};q)_{\alpha/2+1/4}(e^{i\theta}q^{1/2};q)_{\alpha/2+1/4}(-e^{i\theta};q)_{\beta/2+1/4}(-e^{i\theta}q^{1/2};q)_{\beta/2+1/4}\right|^2 \frac{dx}{\sqrt{1-x^2}}$$

$$= \frac{2\pi(-q^{1/2};q)_{(\alpha+\beta)/2}(-q;q)^2_{(\alpha+\beta)/2}(-q^{1/2};q)_{(\alpha+\beta+2)/2}}{\Gamma_q^2(1/2)} \frac{\Gamma_q(\alpha+1)\Gamma_q(\beta+1)}{\Gamma_q(\alpha+\beta+2)}.$$

In (1.8) we have used the identity

$$(q^{1/2};q)_\infty(-q^{1/2};q)_\infty(-q;q)_\infty = 1 \tag{1.9}$$

and the q-gamma function

$$\Gamma_q(x)=\frac{(q;q)_\infty}{(q^x;q)_\infty}(1-q)^{1-x},\quad \lim_{q\to 1}\Gamma_q(x)=\Gamma(x),\quad 0<q<1. \tag{1.10}$$

Observing that $\lim_{q\to 1}(z;q)_a=\lim_{q\to 1}\Sigma_{n=0}^{\infty}(q^{-a};q)_n(zq^a)^n/(q;q)_n=(1-z)^a$, and so

$$\lim_{q\to 1}\left|(e^{i\theta};q)_a\right|^2=2^a(1-\cos\theta)^a,\qquad \lim_{q\to 1}(-q^a;q)_b=2^b, \tag{1.11}$$

it is easily seen that (1.8) goes to the familiar beta integral in the limit $q\to 1$.

One can also see by similar arguments that

$$\lim_{q\to 1}\left|(q^{1/2}e^{i\theta+i\phi};q)_\gamma(q^{1/2}e^{i\theta-i\phi};q)_\gamma\right|^2=2^{2\gamma}|\cos\theta-\cos\phi|^{2\gamma}, \tag{1.12}$$

where γ is a real number. This provides the important clue to a possible extension of the discriminant $\Pi_{1\le i<j\le n}|x_j-x_i|^{2\gamma}$ in (1.1). Note that the limit on the right-hand side of (1.12) would be the same if we replaced $q^{1/2}$ by an arbitrary power of q. It turns out, however, that the integrals do not reduce to a compact formula without the $q^{1/2}$. It seems reasonable, therefore, to start with the following q-extension of the left-hand side of (1.1)

$$\int_{-1}^{1}\cdots\int_{-1}^{1}\prod_{j=1}^{n}w\left(x_j;a,aq^{1/2},b,bq^{1/2}\right)\cdot\prod_{1\le k<l\le n}\left|(q^{1/2}e^{i\theta_k+i\theta_l};q)_\gamma(q^{1/2}e^{i\theta_k-i\theta_l};q)_\gamma\right|^2 dx_1\cdots dx_n, \tag{1.13}$$

where

$$w\left(x_j;a,aq^{1/2},b,bq^{1/2}\right)=\frac{h(x_j;1)h(x_j;-1)h\left(x_j;q^{1/2}\right)h\left(x_j;-q^{1/2}\right)}{h(x_j;a)h\left(x_j;aq^{1/2}\right)h(x_j;b)h\left(x_j;bq^{1/2}\right)}\left(1-x_j^2\right)^{-1/2},\qquad x_j=\cos\theta_j. \tag{1.14}$$

At the moment we are unable to handle the integral for a γ that is not a nonnegative integer. So we shall assume that $\gamma=N$, $N=0,1,2,\cdots$. We will show that

$$\begin{aligned}\int_{-1}^{1}\int_{-1}^{1}w(x;a,aq^{1/2},b,bq^{1/2})w(y;a,aq^{1/2},b,bq^{1/2})&\cdot\left|(q^{1/2}e^{i\theta+i\phi};q)_N(q^{1/2}e^{i\theta-i\phi};q)_N\right|^2dx\,dy\\&=\prod_{j=1}^{2}\frac{2\pi}{(q;q)_\infty^2(1-ab)(abq^{1/2+(j-1)N};q)_\infty^2(abq^{1+(j-1)N};q)_\infty^2}\\&\cdot\prod_{j=1}^{2}\frac{(a^2b^2q^{jN+1};q)_\infty(q^{N+1};q)_\infty(q;q)_\infty}{(a^2q^{1/2+(j-1)N};q)_\infty(b^2q^{1/2+(j-1)N};q)_\infty(q^{jN+1};q)_\infty},\end{aligned} \tag{1.15}$$

where $x=\cos\theta$, $y=\cos\phi$.

We shall carry out the computations in two steps. In §2 we shall do integration over y and complete the second integration over x in §3. In §4 we shall state the n-dimensional result as a conjecture and examine the situation when we replace the

parameters as in (1.6) but also replace $e^{i\theta_j}$ by q^{ix_j} in the integrand and then take the limit $q\to 1$.

2. Evaluation of a single integral. We shall start by computing a somewhat more general integral

(2.1)

$$\int_{-1}^{1} w(y;a,b,c,d)(zq^{1/2}e^{i\phi};q)_r(zq^{1/2}e^{-i\phi};q)_r(q^{1/2}e^{i\phi}/z;q)_s(q^{1/2}e^{-i\phi}/z;q)_s\,dy$$
$$=S_{r,s}(z;a,b,c,d), \text{ say,}$$

where z is arbitrary and r,s are nonnegative integers. The formulas that we shall immediately need are the q-integral representations of Sears' summation formula [12], [1], [7]

(2.2)

$$\int_a^b \frac{(qu/a;q)_\infty(qu/b;q)_\infty(cu;q)_\infty}{(fu;q)_\infty(gu;q)_\infty(hu;q)_\infty}\,d_qu$$
$$=\frac{b(1-q)(q;q)_\infty(bq/a;q)_\infty(a/b;q)_\infty(c/f;q)_\infty(c/g;q)_\infty(c/h;q)_\infty}{(af;q)_\infty(ag;q)_\infty(ah;q)_\infty(bf;q)_\infty(bg;q)_\infty(bh;q)_\infty}$$

where $c=abfgh$, and of Bailey's formula [6, 8.5(3)] for the sum of two balanced and nonterminating balanced ${}_4\phi_3$'s in terms of a very well-poised ${}_8\phi_7$:

(2.3)

$$\int_a^b \frac{(qu/a;q)_\infty(qu/b;q)_\infty(cu;q)_\infty(du;q)_\infty}{(eu;q)_\infty(fu;q)_\infty(gu;q)_\infty(hu;q)_\infty}\,d_qu$$
$$=\frac{b(1-q)(q;q)_\infty(bq/a;q)_\infty(a/b;q)_\infty}{(ae;q)_\infty(af;q)_\infty(ag;q)_\infty}$$
$$\cdot\frac{(cd/eh;q)_\infty(cd/fh;q)_\infty(cd/gh;q)_\infty(bc;q)_\infty(bd;q)_\infty}{(be;q)_\infty(bf;q)_\infty(bg;q)_\infty(bh;q)_\infty(bcd/h;q)_\infty}$$
$$\cdot{}_8\phi_7\left[\begin{matrix}bcd/hq, q(bcd/hq)^{1/2}, -q(bcd/hq)^{1/2}, be, bf, bg, c/h, d/h\\ (bcd/hq)^{1/2}, -(bcd/hq)^{1/2}, cd/eh, cd/fh, cd/gh, bd, bc\end{matrix};q,\frac{cd}{befg}\right],$$

where $cd=abefgh$; see also [7, (3.25)].

The q-integrals in (2.2) and (2.3) are defined by

(2.4)
$$\int_0^a f(u)\,d_qu=a(1-q)\sum_{n=0}^{\infty}f(aq^n)q^n,$$
$$\int_a^b f(u)\,d_qu=\int_0^b f(u)\,d_qu-\int_0^a f(u)\,d_qu,$$

and the basic hypergeometric series ${}_{r+1}\phi_r$ by

(2.5)
$${}_{r+1}\phi_r\left[\begin{matrix}a_1,a_2,\cdots,a_{r+1}\\ b_1,\cdots,b_r\end{matrix};q,z\right]=\sum_{n=0}^{\infty}\frac{(a_1;q)_n(a_2;q)_n\cdots(a_{r+1};q)_n}{(q;q)_n(b_1;q)_n\cdots(b_r;q)_n}z^n,$$

provided $|z|<1$ if the series does not terminate.

A third formula that we shall find useful is the integral representation of an ${}_8\phi_7$ found by Nassrallah and Rahman [10]

$$(2.6)\quad \int_{-1}^{1} (w;\lambda,\mu,\nu,\rho)\frac{h(x;\tau)}{h(x;\sigma)}\,dx$$

$$=\frac{2\pi(\lambda\mu\nu\rho;q)_\infty(\lambda\mu\nu\sigma;q)_\infty(\lambda\tau;q)_\infty}{(q;q)_\infty(\lambda\mu;q)_\infty(\lambda\nu;q)_\infty(\lambda\rho;q)_\infty(\lambda\sigma;q)_\infty(\mu\nu;q)_\infty(\mu\rho;q)_\infty}$$

$$\cdot\frac{(\mu\tau;q)_\infty(\nu\tau;q)_\infty}{(\mu\sigma;q)_\infty(\nu\rho;q)_\infty(\nu\sigma;q)_\infty(\lambda\mu\nu\tau;q)_\infty}$$

$$\cdot{}_8\phi_7\left[\begin{matrix}\lambda\mu\nu\tau q^{-1}, q(\lambda\mu\nu\tau q^{-1})^{1/2}, -q(\lambda\mu\nu\tau q^{-1})^{1/2}, \lambda\mu, \lambda\nu, \mu\nu, \tau\rho^{-1}, \tau\sigma^{-1} \\ (\lambda\mu\nu\tau q^{-1})^{1/2}, -(\lambda\mu\nu\tau q^{-1})^{1/2}, \nu\tau, \mu\tau, \lambda\tau, \lambda\mu\nu\rho, \lambda\mu\nu\sigma\end{matrix};q,\rho\sigma\right],$$

see also [11].

Using (2.2), we find that

$$(2.7)\quad \frac{h(y;q^{1/2}/z)}{h(y;d)h(y;fq^{1/2}/z)}$$

$$=\frac{(f^{-1};q)_\infty(q^{1/2}/zd;q)_\infty}{fq^{1/2}z^{-1}(1-q)(q;q)_\infty(dz/fq^{1/2};q)_\infty(fq^{3/2}/dz;q)_\infty(dfq^{1/2}/z;q)_\infty}$$

$$\cdot\int_d^{fq^{1/2}/z}\frac{(qu/d;q)_\infty(uzq^{1/2}/f;q)_\infty(uq^{1/2}/z;q)_\infty}{(u/df;q)_\infty h(y;u)}\,d_qu.$$

Hence

$$(2.8)\quad \int_{-1}^{1} w(y;a,b,c,d)(ze^{i\phi}q^{1/2};q)_r(ze^{-i\phi}q^{1/2};q)_r\frac{h(y;q^{1/2}/z)}{h(y;fq^{1/2}/z)}\,dy$$

$$=\frac{(f^{-1};q)_\infty(q^{1/2}/dz;q)_\infty}{fq^{1/2}z^{-1}(1-q)(q;q)_\infty(dz/fq^{1/2};q)_\infty(fq^{3/2}/dz;q)_\infty(dfq^{1/2}/z;q)_\infty}$$

$$\cdot\int_d^{fq^{1/2}/z}\frac{(qu/d;q)_\infty(uzq^{1/2}/f;q)_\infty(uq^{1/2}/z;q)_\infty}{(u/df;q)_\infty}\,d_qu$$

$$\cdot\int_{-1}^{1} w(y;a,b,c,u)\frac{h(y;zq^{1/2})}{h(y;zq^{r+1/2})}\,dy.$$

By (2.6) we can now express the y-integral on the right-hand side as a very well-poised ${}_8\phi_7$ which terminates because of the assumption that r is a nonnegative integer, and consequently expressible as a balanced and terminating ${}_4\phi_3$ via Watson's formula [6, 8.5(2)]. Thus the y-integral on the right of (2.8) simplifies to

$$(2.9)\quad \frac{2\pi(azq^{1/2};q)_r(zq^{1/2}/a;q)_r(abcu;q)_\infty}{(q;q)_\infty(ab;q)_\infty(ac;q)_\infty(bc;q)_\infty(au;q)_\infty(bu;q)_\infty(cu;q)_\infty}$$

$$\cdot{}_4\phi_3\left[\begin{matrix}q^{-r}, ab, ac, au \\ azq^{1/2}, aq^{1/2-r}/z, abcu\end{matrix};q,q\right].$$

Substituting this into (2.8) the right-hand side becomes

(2.10)

$$\frac{2\pi(f^{-1};q)_\infty(q^{1/2}/dz;q)_\infty(azq^{1/2};q)_r(zq^{1/2}/a;q)_r}{fq^{1/2}z^{-1}(1-q)(q;q)_\infty^2(ab;q)_\infty(ac;q)_\infty(bc;q)_\infty(dz/fq^{1/2};q)_\infty(fq^{3/2}/dz;q)_\infty(dfq^{1/2}/z;q)_\infty}$$

$$\cdot\sum_{j=0}^{r}\frac{(q^{-r};q)_j(ab;q)_j(ac;q)_j}{(q;q)_j(azq^{1/2};q)_j(aq^{1/2-r}/z;q)_j}q^j$$

$$\cdot\int_d^{fq^{1/2}/z}\frac{(qu/d;q)_\infty(uzq^{1/2}/f;q)_\infty(uq^{1/2}/z;q)_\infty(abcuq^j;q)_\infty}{(bu;q)_\infty(cu;q)_\infty(u/df;q)_\infty(auq^j;q)_\infty}d_qu$$

$$=\frac{2\pi(bq^{1/2}/z;q)_\infty(cq^{1/2}/z;q)_\infty(qf/z^2;q)_\infty}{(q;q)_\infty(ab;q)_\infty(ac;q)_\infty(bc;q)_\infty(cd;q)_\infty}$$

$$\cdot\frac{(bcdfq^{1/2}/z;q)_\infty(azq^{1/2};q)_r(zq^{1/2}/a;q)_r}{(dfq^{1/2}/z;q)_\infty(bfq^{1/2}/z;q)_\infty(cfq^{1/2}/z;q)_\infty(bcfq/z^2;q)_\infty}$$

$$\cdot\sum_{j=0}^{r}\frac{(q^{-r};q)_j(ab;q)_j(ac;q)_j(abcfq^{1/2+j}/z;q)_\infty}{(q;q)_j(azq^{1/2};q)_j(aq^{1/2-r}/z;q)_j(afq^{1/2+j}/z;q)_\infty}q^j$$

$$\cdot{}_8\phi_7\left[\begin{matrix}bcf/z^2,q(bcf/z^2)^{1/2},-q(bcf/z^2)^{1/2},bfq^{1/2}/z,\\(bcf/z^2)^{1/2},-(bcf/z^2)^{1/2},cq^{1/2}/z,bq^{1/2}/z,\end{matrix}\right.$$

$$\left.\begin{matrix}cfq^{1/2}/z,q^{1/2}/dz,bc,q^{1/2-j}/az\\bcdfq^{1/2}/z,qf/z^2,abcfq^{1/2+j}\end{matrix};q,adq^j\right],$$

by (2.3). We now replace f by q^s, use [6, 8.5(3)] and simplify to get

(2.11)

$$S_{r,s}(z;a,b,c,d)$$

$$=\kappa(a,b,c,d)\frac{(azq^{1/2};q)_r(zq^{1/2}/a;q)_r(bq^{1/2}/z;q)_s(cq^{1/2}/z;q)_s(ad;q)_s}{(abcd;q)_s}$$

$$\cdot\sum_{j=0}^{r}\frac{(q^{-r};q)_j(ab;q)_j(ac;)_j(adq^s;q)_j}{(q;q)_j(azq^{1/2};q)_j(aq^{1/2-r}/z;q)_j(abcdq^s;q)_j}q^i$$

$$\cdot{}_4\phi_3\left[\begin{matrix}q^{-s},bc,q^{1/2}/dz,q^{1/2-j}/az\\bq^{1/2}/z,cq^{1/2}/z,q^{1-j-s}/ad\end{matrix};q,q\right].$$

The ${}_4\phi_3$ series on the right is balanced and terminating, so we may apply Sears' transformation formula [13]

(2.12)

$${}_4\phi_3\left[\begin{matrix}q^{-n},a,b,c\\d,e,f\end{matrix};q,q\right]$$

$$=\frac{(aq^{1-n}/e;q)_n(aq^{1-n}/f;q)_n}{(e;q)_n(f;q)_n}\left(\frac{bc}{d}\right)^n{}_4\phi_3\left[\begin{matrix}q^{-n},a,d/b,d/c\\d,aq^{1-n}/e,aq^{1-n}/f\end{matrix};q,q\right],$$

$def=abcq^{1-n}$, as often as necessary. Application of this formula twice in an order that should be obvious from the reduction, yields the following:

(2.13)

$$
{}_4\phi_3\left[\begin{matrix} q^{-s}, bc, q^{1/2}/dz, q^{1/2-j}/az \\ bq^{1/2}/z, cq^{1/2}/z, q^{1-j-s}/ad \end{matrix}; q, q\right]
$$

$$
= \frac{(aq^{1/2+j}/z;q)_s (q^{1/2}/az;q)_s (azq^{1/2};q)_j (abcdq^j;q)_s}{(bq^{1/2}/z;q)_s (cq^{1/2}/z;q)_s (azq^{1/2-s};q)_j (adq^j;q)_s} q^{-js}
$$

$$
\cdot {}_4\phi_3\left[\begin{matrix} q^{-s}, abq^j, acq^j, adq^j \\ abcdq^j, aq^{1/2+j}/z, azq^{1/2-s+j} \end{matrix}; q, q\right].
$$

Substituting this into (2.11) and simplifying the coefficients, we obtain

(2.14)

$$
S_{r,s}(z;a,b,c,d)
$$

$$
= \kappa(a,b,c,d)(azq^{1/2};q)_r (zq^{1/2}/a;q)_r (aq^{1/2}/z;q)_s (q^{1/2}/az;q)_s
$$

$$
\cdot \sum_{j=0}^{r} \sum_{k=0}^{s} \frac{(q^{-r};q)_j (q^{-s};q)_k (aq^{1/2+s}/z;q)_j (ab;q)_{j+k} (ac;q)_{j+k} (ad;q)_{j+k}}{(q;q)_j (q;q)_k (aq^{1/2-r}/z;q)_j (abcd;q)_{j+k} (aq^{1/2}/z;q)_{j+k} (azq^{1/2-s};q)_{j+k}}
$$

$$
\cdot q^{j+k-js}.
$$

We now transform the summation variables by setting $j+k=l$, $k=l-j$. The double sum in (2.14) becomes

(2.15)

$$
\sum_{l=0}^{r+s} \frac{(q^{-s};q)_l (ab;q)_l (ac;q)_l (ad;q)_l}{(q;q)_l (abcd;q)_l (aq^{1/2}/z;q)_l (azq^{1/2-s};q)_l} q^l {}_3\phi_2\left[\begin{matrix} q^{-l}, q^{-r}, aq^{1/2+s}/z \\ aq^{1/2-r}/z, q^{1+s-l} \end{matrix}; q, q\right]
$$

$$
= \sum_{l=0}^{r+s} \frac{(q^{-s};q)_l (ab;q)_l (ac;q)_l (ad;q)_l}{(q;q)_l (abcd;q)_l (aq^{1/2}/z;q)(azq^{1/2-s};q)_l} q^l \frac{(aq^{1/2}/z;q)_l (q^{-r-s};q)_l}{(aq^{1/2-r}/z;q)_l (q^{-s};q)_l}
$$

$$
= {}_4\phi_3\left[\begin{matrix} q^{-r-s}, ab, ac, ad \\ abcd, aq^{1/2-r}/z, azq^{1/2-s} \end{matrix}; q, q\right],
$$

by Jackson's formula [6, 8.4(1)] for the sum of a balanced and terminating ${}_3\phi_2$ series. Thus we have

(2.16)

$$
S_{r,s}(z;a,b,c,d)
$$

$$
= \kappa(a,b,c,d)(azq^{1/2};q)_r (zq^{1/2}/a;q)_r (aq^{1/2}/z;q)_s (q^{1/2}/az;q)_s
$$

$$
\cdot {}_4\phi_3\left[\begin{matrix} q^{-r-s}, ab, ac, ad \\ abcd, aq^{1/2-r}/z, azq^{1/2-s} \end{matrix}; q, q\right].
$$

Reversing the series on the right and simplifying, we find

(2.17)

$$S_{r,s}(z;a,b,c,d)=\kappa(a,b,c,d)\frac{(ab;q)_{r+s}(ac;q)_{r+s}(ad;q)_{r+s}}{(abcd;q)_{r+s}}a^{-r-s}z^{r-s}q^{(r+s)/2-rs}$$
$$\cdot{}_4\phi_3\left[\begin{matrix}q^{-r-s},q^{1-r-s}/abcd,zq^{1/2-s}/a,q^{1/2-r}/az\\ q^{1-r-s}/ab,q^{1-r-s}/ac,q^{1-r-s}/ad\end{matrix};q,q\right]$$
$$=\kappa(a,b,c,d)\frac{(ab;q)_{r+s}(bc;q)_{r+s}}{(abcd;q)_{r+s}}(bd;q)_{r+s}b^{-r-s}z^{r-s}q^{(r+s)/2-rs}$$
$$\cdot{}_{\phi 3}\left[\begin{matrix}q^{-r-s},q^{1-r-s}/abcd,zq^{1/2-s}/b,q^{1/2-r}/bz\\ q^{1-r-s}/ba,q^{1-r-s}/bc,q^{1-r-s}/bd\end{matrix};q,q\right],$$

the last line following from the previous one by (2.12). Replacing b,c,d by $aq^{1/2}$, b, $bq^{1/2}$, respectively, we finally obtain

(2.18)

$$S_{r,s}(z;a,aq^{1/2},b,bq^{1/2})$$
$$=\kappa(a,aq^{1/2},b,bq^{1/2})\frac{(a^2q^{1/2};q)_{r+s}(abq^{1/2};q)_{r+s}(abq;q)_{r+s}}{(a^2b^2q;q)_{r+s}}a^{-r-s}z^{r-s}q^{-rs}$$
$$\cdot{}_4\phi_3\left[\begin{matrix}q^{-r-s},q^{-r-s}/a^2b^2,zq^{-s}/a,q^{-r}/az\\ q^1z-r-s/a^2,q^{1/2-r-s}/ab,q^{-r-s}/ab\end{matrix};q,q\right].$$

The ${}_4\phi_3$ series on the right of (2.18) has a structure that enables us to apply a quadratic transformation formula due to Askey and Wilson [5, (4.22)]

$$(2.19)\qquad {}_4\phi_3\left[\begin{matrix}q^{-2n},a^2q^{2n},b^2q,c^2\\ -a,-aq,b^2c^2q^2\end{matrix};q^2,q^2\right]={}_4\phi_3\left[\begin{matrix}q^{-n},aq^n,b^2q,c^2\\ -a,bcq,-bcq\end{matrix};q,q\right].$$

Use of this in (2.18) followed by yet another application of (2.12) and some simplifications leads to

(2.20)

$$S_{r,s}(z;a,aq^{1/2},b,bq^{1/2})$$
$$=\kappa(a,aq^{1/2},b,bq^{1/2})\frac{(a^2q^{1/2};q)_{r+s}(abq^{1/2};q)_{r+s}(abq;q)_{r+s}}{(a^2b^2q;q)_{r+s}}$$
$$\cdot\frac{(bq^{1/4};q^{1/2})_{r+s}(-q^{1/2};q^{1/2})_{r+s}}{(-aq^{1/4};q^{1/2})_{r+s}(abq^{(r+s+1)/2};q^{1/2})_{r+s}}z^{r-s}q^{(r+s)^2/4-rs}$$
$$\cdot{}_4\phi_3\left[\begin{matrix}q^{-(r+s)/2},-q^{-(r+s)/2}/ab,q^{1/4+(s-r)/2}/z,zq^{1/4+(r-s)/2}\\ -q^{1/2},q^{1/4-(r+s)/2}/a,q^{1/4-(r+s)/2}/b\end{matrix};q^{1/2},q^{1/2}\right].$$

3. Proof of (1.15). It should be clear from (2.1) and (1.15) that we now need to evaluate the integral

$$\int_{-1}^{1} w(x;a,aq^{1/2},b,bq^{1/2})S_{N,N}(e^{i\theta};a,aq^{1/2},b,bq^{1/2})\,dx \equiv I_N, \quad \text{say.} \tag{3.1}$$

From (2.20) we have

(3.2)

$$S_{N,N}(e^{i\theta};a,aq^{1/2},b,bq^{1/2}) = \kappa(a,aq^{1/2},b,bq^{1/2}) \cdot \frac{(a^2q^{1/2},q)_{2N}(abq^{1/2};q)_{2N}(abq;q)_{2N}(bq^{1/4};q^{1/2})_{2N}(-q^{1/2};q^{1/2})_{2N}}{(a^2b^2q;q)_{2N}(-aq^{1/4};q^{1/2})_{2N}(abq^{N+1/2};q^{1/2})_{2N}} \cdot {}_4\phi_3\left[\begin{matrix} q^{-N}, -q^{-N}/ab, q^{1/4}e^{i\theta}, q^{1/4}e^{-i\theta} \\ q^{1/4-N}/a, q^{1/4-N}/b, -q^{1/2} \end{matrix}; q^{1/2}, q^{1/2}\right].$$

So we need to consider the integral

$$\int_{-1}^{1} w(x;a,aq^{1/2},b,bq^{1/2})(q^{1/4}e^{i\theta};q^{1/2})_m(q^{1/4}e^{-i\theta};q^{1/2})_m\,dx \equiv T_m, \quad \text{say,} \quad m=0,1,2,\cdots,N. \tag{3.3}$$

Using the identity

$$(a;q)_{2n} = (a;q^2)_n(aq;q^2)_n, \tag{3.4}$$

we find that when m is even

$$\left|(q^{1/4}e^{i\theta};q^{1/2})_m\right|^2 = \left|(q^{1/2}e^{i\theta};q)_{m/2}(q^{3/4}e^{i\theta};q)_{m/2}\right|^2, \tag{3.5}$$

and when m is odd

$$\left|(q^{1/4}e^{i\theta};q^{1/2})_m\right|^2 = \left|(q^{1/4}e^{i\theta};q)_{(m+1)/2}(q^{3/4}e^{i\theta};q)_{(m-1)/2}\right|^2. \tag{3.6}$$

Using (2.20), (3.4) and the identity

$$(a^2;q^2)_n = (a;q)_n(-a;q)_n, \tag{3.7}$$

we can easily show that

$$\begin{aligned} T_m &= S_{m/2,m/2}(q^{-1/4};a,aq^{1/2},b,bq^{1/2}), \quad m \text{ even} \\ &= S_{(m+1)/2,(m-1)/2}(q^{-1/4};a,aq^{1/2},b,bq^{1/2}), \quad m \text{ odd} \\ &= \kappa(a,aq^{1/2},b,bq^{1/2})(aq^{1/4};q^{1/2})_m(bq^{1/4};q^{1/2})_m(-q^{1/2};q^{1/2})_m \\ &\qquad (-abq^{1/2};q^{1/2})_m. \end{aligned} \tag{3.8}$$

From (3.1), (3.2), (3.3) and (3.8) we then have

$$I_N = \kappa^2(a,aq^{1/2},b,bq^{1/2})\frac{(a^2q^{1/2};q)_{2N}(abq^{1/2};q)_{2N}(abq;q)_{2N}}{(a^2b^2q;q)_{2N}} \cdot \frac{(bq^{1/4};q^{1/2})_{2N}(-q^{1/2};q^{1/2})_{2N}}{(-aq^{1/4};q^{1/2})_{2N}(abq^{N+1/2};q^{1/2})_{2N}} \cdot {}_4\phi_3\left[\begin{matrix} q^{-N}, -q^{-N}/ab, aq^{1/4}, bq^{1/4} \\ -abq^{1/2}, q^{1/4-N}/a, q^{1/4-N}/b \end{matrix}; q^{1/2}, q^{1/2}\right]. \tag{3.9}$$

This ${}_4\phi_3$ is summable. We have

(3.10)

$$
\begin{aligned}
&{}_4\phi_3\left[\begin{matrix} q^{-N}, -q^{-N}/ab, aq^{1/4}, bq^{1/4} \\ -abq^{1/2}, q^{1/4-N}/a, q^{1/4-N}/b \end{matrix}; q^{1/2}, q^{1/2}\right] \\
&\quad = \frac{(a^2q^{1/2};q^{1/2})_{2N}(abq^{1/2};q^{1/2})_{2N}}{(q^{1/4-N}/a;q^{1/2})_{2N}(q^{1/4-N}/b;q^{1/2})_{2N}}\left(\frac{q^{-N-1/4}}{a^2b}\right)^{2N} \\
&\qquad \cdot {}_4\phi_3\left[\begin{matrix} q^{-N}, a^2b^2q^{N+1/2}, aq^{1/4}, -aq^{1/4} \\ a^2q^{1/2}, abq^{1/2}, -abq^{1/2} \end{matrix}; q^{1/2}, q^{1/2}\right], \qquad \text{by (2.12)} \\
&\quad = \frac{(a^2q^{1/2};q^{1/2})_{2N}(abq^{1/2};q^{1/2})_{2N}}{(q^{1/4-N}/a;q^{1/2})_{2N}(q^{1/4-N}/b;q^{1/2})_{2N}}\left(\frac{q^{-N-1/4}}{a^2b}\right)^{2N} \\
&\qquad \cdot {}_4\phi_3\left[\begin{matrix} q^{-N}, a^2q^{1/2}, a^2q^{1/2}, a^2b^2q^{N+1/2} \\ a^2q^{1/2}, a^2q, a^2b^2q \end{matrix}; q, q\right] \qquad \text{by (2.19)} \\
&\quad = \frac{(a^2q^{1/2};q^{1/2})_{2N}(abq^{1/2};q^{1/2})_{2N}}{(q^{1/4-N}/a;q^{1/2})_{2N}(q^{1/4-N}/b;q^{1/2})_{2N}}\left(\frac{q^{-N-1/4}}{a^2b}\right)^{2N} \\
&\qquad \cdot \frac{(q^{1/2};q)_N(q^{1/2-N}/b^2;q)_N}{(a^2q;q)_N(q^{-N}/a^2b^2;q)_N} \\
&\quad = \frac{(a^2q^{1/2};q^{1/2})_{2N}(abq^{1/2};q^{1/2})_{2N}}{(aq^{1/4};q^{1/2})_{2N}(bq^{1/4};q^{1/2})_{2N}} \cdot \frac{(b^2q^{1/2};q)_N(q^{1/2};q)}{(a^2b^2q;q)_N(a^2q;q)_N}.
\end{aligned}
$$

Substituting this into (3.9), using (3.4), (3.7) and the definition of κ given in (1.2), we obtain (1.15).

4. The conjecture for the *n*-dimensional integral and the limiting cases. Our conjecture for the n-dimensional integral (1.13) is now clear from the form of (1.15):

$$
\begin{aligned}
(4.1)\quad &\int_{-1}^{1}\cdots\int_{-1}^{1}\prod_{j=1}^{n} w(x_j;a,aq^{1/2},b,bq^{1/2}) \\
&\qquad \cdot \prod_{1\le k<l\le n}\left|(q^{1/2}e^{i(\theta_k+\theta_l)};q)_N(q^{1/2}e^{i(\theta_k-\theta_l)};q)_N\right|^2 dx_1dx_2\cdots dx_n \\
&= \prod_{j=1}^{n}\frac{2\pi}{(q;q)_\infty^2(1-ab)(abq^{1/2+(j-1)N};q)_\infty^2(abq^{1+(j-1)N};q)_\infty^2} \\
&\qquad \cdot \prod_{j=1}^{n}\frac{(a^2b^2q^{1+(n+j-2)N};q)_\infty(q^{N+1};q)_\infty(q;q)_\infty}{(a^2q^{1/2+(j-1)N};q)_\infty(b^2q^{1/2+(j-1)N};q)_\infty(q^{jN+1};q)_\infty}.
\end{aligned}
$$

If we now take $0<q<1$, set $a=q^{\alpha/2+1/4}, b=-q^{\beta/2+1/4}$ and use (1.7), (1.9) and (1.10), we can also express it in the form

(4.2)

$$\int_{-1}^{1}\cdots\int_{-1}^{1}\prod_{j=1}^{n}\left|\left(e^{i\theta_j};q\right)_{\alpha/2+1/4}\left(q^{1/2}e^{i\theta_j};q\right)_{\alpha/2+1/4}\left(-e^{i\theta_j};q\right)_{\beta/2+1/4}\left(-q^{1/2}e^{i\theta_j};q\right)_{\beta/2+1/4}\right|^2\left(1-x_j^2\right)^{-1/2}$$

$$\cdot\prod_{1\le k<l\le n}\left|\left(q^{1/2}e^{i(\theta_k+\theta_l)};q\right)_N\left(q^{1/2}e^{i(\theta_k-\theta_l)};q\right)_N\right|^2 dx_1\,dx_2\cdots dx_n$$

$$=\prod_{j=1}^{n}\frac{2\pi\left(-q^{1/2};q\right)_{N(j-1)+(\alpha+\beta+2)/2}^2\left(-q;q\right)_{N(j-1)+(\alpha+\beta)/2}^2}{\Gamma_q^2(1/2)\left(1+q^{(\alpha+\beta+1)/2}\right)}$$

$$\cdot\prod_{j=1}^{n}\frac{\Gamma_q(\alpha+1+(j-1)N)\Gamma_q(\beta+1+(j-1)N)\Gamma_q(jN+1)}{\Gamma_q(\alpha+\beta+2+(n+j-2)N)\Gamma_q(N+1)}.$$

In this form it is clear that the limit of (4.2) is the Selberg formula (1.1). It is also clear from (4.2) that we have a conjecture for the constant term in the expansion of

$$\prod_{i=1}^{n}\left(x_i;q\right)_a\left(1/x_i;q\right)_a\left(-x_i;q\right)_b\left(-1/x_i;q\right)_b$$

$$\cdot\prod_{1\le i<j\le n}\left(qx_ix_j;q^2\right)_c\left(q/x_ix_j;q^2\right)_c\left(qx_i/x_j;q^2\right)_c\left(qx_j/x_i;q^2\right)_c.$$

However, there is no need for us to take b negative. We may, in fact, express the integral on the left of (4.1) in the form

$$\int_0^{\pi}\cdots\int_0^{\pi}\prod_{j=1}^{n}\left|\frac{\left(e^{2i\theta_j};q\right)}{\left(ae^{i\theta_j};q^{1/2}\right)_\infty\left(be^{i\theta_j};q^{1/2}\right)_\infty}\right|^2$$

$$\cdot\prod_{1\le j<k\le n}\left|\left(q^{1/2}e^{i(\theta_j+\theta_k)};q\right)_N\left(q^{1/2}e^{i(\theta_j-\theta_k)};q\right)_N\right|^2 d\theta_1\,d\theta_2\cdots d\theta_n,$$

so that if we now set

(4.3) $$a=q^{\alpha/2+1/4},\qquad b=q^{\beta/2+1/4},\qquad 0<q<1,$$

and transform the integral by setting $e^{i\theta_j}=q^{ix_j}$, that is, $\theta_j=x_j\log q$, then (4.1) gives

(4.4)

$$(\log q)^n\int_0^{\pi/\log q}\cdots\int_0^{\pi/\log q}\prod_{j=1}^{n}\left|\frac{\left(q^{2ix_j};q\right)_\infty}{\left(q^{\alpha/2+1/4+ix_j};q^{1/2}\right)_\infty\left(q^{\beta/2+1/4+ix_j};q^{1/2}\right)_\infty}\right|^2$$

$$\prod_{1\le j<k\le n}\left|\left(q^{1/2+ix_j+ix_k};q\right)_N\left(q^{1/2+ix_j-ix_k};q\right)_N\right|^2 dx_1\,dx_2\cdots dx_n$$

$$=\prod_{j=1}^{n}\frac{2\pi}{(q;q)_\infty^2\left(1-q^{(\alpha+\beta+1)/2}\right)\left(q^{(\alpha+\beta+2)/2+(j-1)N};q\right)_\infty^2\left(q^{(\alpha+\beta+3)/2+(j-1)N};q\right)_\infty^2}$$

$$\cdot\prod_{j=1}^{n}\frac{\left(q^{\alpha+\beta+2+(n+j-2)N};q\right)_\infty\left(q^{N+1};q\right)_\infty(q;q)_\infty}{\left(q^{\alpha+1+(j-1)N};q\right)_\infty\left(q^{\beta+1+(j-1)N};q\right)_\infty\left(q^{jN+1};q\right)_\infty}.$$

Using (1.10), this can also be written as

(4.5)

$$\left(\frac{\log q}{q-1}\right)^n (-1)^n \int_0^{\pi/\log q} \cdots \int_0^{\pi/\log q} \cdot \prod_{j=1}^{n} \left| \frac{\Gamma_q(\alpha/2+1/4+ix_j)\Gamma_q(\alpha/2+3/4+ix_j)\Gamma_q(\beta/2+1/4+ix_j)\Gamma_q(\beta/2+3/4+ix_j)}{\Gamma_q(2ix_j)} \right|^2$$

$$\cdot \prod_{1\le j<k\le n} \left| \frac{\Gamma_q(N+1/2+ix_j+ix_k)\Gamma_q(N+1/2+ix_j-ix_k)}{\Gamma_q(1/2+ix_j+ix_k)\Gamma_q(1/2+ix_j-ix_k)} \right|^2 dx_1 dx_2 \cdots dx_n$$

$$= \prod_{j=1}^{n} \frac{2\pi(1-q)\Gamma_q^2((\alpha+\beta+2)/2+(j-1)N)\Gamma_q^2((\alpha+\beta+3)/2+(j-1)N)}{(1-q^{(\alpha+\beta+1)/2})}$$

$$\cdot \prod_{j=1}^{n} \frac{\Gamma_q(\alpha+1+(j-1)N)\Gamma_q(\beta+1+(j-1)N)\Gamma q(jN+1)}{\Gamma_q(\alpha+\beta+2+(n+j-2)N)\Gamma_q(N+1)}.$$

If we now take the limit $q\to 1$ and use the duplication formula for the gamma function, we get the Mellin–Barnes type multiple integral

(4.6)

$$\int_0^\infty \cdots \int_0^\infty \prod_{j=1}^{n} \left| \frac{\Gamma(\alpha+1/2+2ix_j)\Gamma(\beta+1/2+2ix_j)}{\Gamma(2ix_j)} \right|^2$$

$$\cdot \prod_{1\le j<k\le n} \left|(1/2+ix_j+ix_k)_N (1/2+ix_j-ix_k)_N\right|^2 dx_1 dx_2 \cdots dx_n$$

$$= 2^{-2n(1+(n-1)N)} \prod_{j=1}^{n} \frac{\Gamma^2(\alpha+\beta+2+2(j-1)N)\Gamma(\alpha+1+(j-1)N)}{(\alpha+\beta+1)\Gamma(N+1)\Gamma(\alpha+\beta+2+(n+j-2)N)}$$

$$\frac{\Gamma(\beta+1+(j-1)N)\Gamma(jN+1)}{(\alpha+\beta+1)\Gamma(N+1)\Gamma(\alpha+\beta+2+(n+j-2)N)}$$

as a conjecture which is true if (4.1) is.

Acknowledgment. I am grateful to Professor R. Askey for making many important suggestions that I have freely used throughout the paper and for sending me a copy of Dyson's translation of Selberg's paper.

q-WILSON FUNCTIONS OF THE SECOND KIND*

MIZAN RAHMAN†

Abstract. The q-Wilson function of the second kind is defined as a Hilbert transform of the q-Wilson polynomials and is shown to be expressible as a very well-poised ${}_8\phi_7$ series. This is used to find the leading terms in the asymptotic expansions of the q-Wilson polynomials and functions of the second kind on the interval $-1<x<1$.

Key words. q-Wilson polynomials, functions of the second kind, very-well-poised basic hypergeometric series, asymptotic properties

AMS(MOS) subject classifications. Primary 33A15, 33A65

1. Introduction. Let $\{p_n(x)\}_{n=0}^{\infty}$ be a set of polynomials orthogonal with respect to a positive measure $d\alpha(x)$ on the real line having support within a finite interval $[a,b]$. Then a corresponding function of the second kind is defined by

$$q_n(z)=\int_a^b \frac{p_n(t)}{z-t}\,d\alpha(t), \qquad z\notin[a,b]. \tag{1.1}$$

We are interested in the functions that correspond to the q-Wilson polynomials defined by

$$p_n\equiv p_n(x;a,b,c,d)={}_4\phi_3\left[\begin{matrix}q^{-n},abcdq^{n-1},ae^{i\theta},ae^{-i\theta}\\ ab,ac,ad\end{matrix};q,q\right], \tag{1.2}$$

where $-1\leqq x=\cos\theta\leqq 1$, and the basic hypergeometric series on the right is given by

$${}_{r+1}\phi_r\left[\begin{matrix}a_1,a_2,\cdots,a_{r+1}\\ b_1,\cdots,b_r\end{matrix};q,x\right]=\sum_{k=0}^{\infty}\frac{(a_1,a_2,\cdots,a_{r+1};q)_k}{(q,b_1,\cdots,b_r;q)_k}x^k, \tag{1.3}$$

with

$$(a_1,a_2,\cdots,a_j;q)_k=(a_1;q)_k(a_2;q)_k\cdots(a_j;q)_k, \tag{1.4}$$

$$(a;q)_k=\frac{(a;q)_\infty}{(aq^k;q)_\infty}, \qquad (a;q)_\infty=\prod_{n=0}^{\infty}(1-aq^n). \tag{1.5}$$

Askey and Wilson [1] showed that

$$\int_{-1}^{1} w(x)p_m(x)p_n(x)\,dx=h_n^{-1}\delta_{m,n}, \tag{1.6}$$

where

$$w(x)=(1-x^2)^{-1/2}\frac{h(x;1)h(x;-1)h(x;\sqrt{q})h(x;-\sqrt{q})}{h(x;a)h(x;b)h(x;c)h(x;d)}, \tag{1.7}$$

$$h(x;a)=\prod_{n=0}^{\infty}(1-2axq^n+a^2q^{2n})=(ae^{i\theta},ae^{-i\theta};q)_\infty, \tag{1.8}$$

$$h_n=\kappa^{-1}(a,b,c,d)\frac{(abcdq^{-1};q)_n(1-abcdq^{2n-1})(ab,ac,ad;q)_n}{(q;q)_n(1-abcdq^{-1})(cd,bd,bc;q)_n}a^{-2n}, \tag{1.9}$$

with

$$\kappa(a,b,c,d)=\frac{2\pi(abcd;q)_\infty}{(q,ab,ac,ad,bc,bd,cd;q)_\infty}, \tag{1.10}$$

and

$$\max(|q|,|a|,|b|,|c|,|d|)<1. \tag{1.11}$$

In §2 we shall compute $q_n(z)$ by using (1.2) and $d\alpha(x)=w(x)dx$. Once the computation is done for $z\notin[-1,1]$ we shall be able to define an appropriate q-Wilson function of the second kind for $-1<x<1$ by making use of the well-known properties:

$$q_n(x)=\frac{1}{2}[q_n(x+i0)+q_n(x-i0)], \tag{1.12}$$

$$p_n(x)w(x)=-\frac{1}{2\pi i}[q_n(x+i0)-q_n(x-i0)]. \tag{1.13}$$

In §3 we shall discuss some asymptotic properties of $p_n(x)$ and $q_n(x)$ when $x\neq\pm1$.

2. q-Wilson function of the second kind. In (1.1) let us replace z by $\frac{1}{2}(z+z^{-1})=x$, say, and assume that $|z|<1$. If $t=\cos\phi$, then we may write

$$x-\cos\phi=\frac{1}{2z}(1-ze^{i\phi})(1-ze^{-i\phi})=\frac{1}{2z}\frac{h(t;z)}{h(t;qz)}. \tag{2.1}$$

Hence

$$\begin{aligned} q_n(x)&=2z\int_{-1}^{1}w(t;a,b,c,d)\frac{h(t;qz)}{h(t;z)}p_n(t;a,b,c,d)\,dt \\ &=2z\sum_{k=0}^{n}\frac{(q^{-n},abcdq^{n-1};q)_k q^k}{(q,ab,ac,ad;q)_k}\int_{-1}^{1}w(t;aq^k,b,c,d)\frac{h(t;qz)}{h(t;z)}\,dt. \end{aligned} \tag{2.2}$$

By [7, eq. (3.6)]

$$\begin{aligned} &\int_{-1}^{1}w(t;aq^k,b,c,d)\frac{h(t;qz)}{h(t;z)}\,dt \\ &=\kappa(a,b,c,d)\frac{(bcdz,bzq,czq,dzq;q)_\infty}{(bcdzq,bz,cz,dz;q)_\infty}\frac{(ab,ac,ad;q)_k}{(abcd;q)_k} \\ &\quad\cdot{}_8\phi_7\left[\begin{matrix}bcdz,q\sqrt{\ },-q\sqrt{\ },bc,bd,cd,q,zq^{1-k}/a\\ \sqrt{\ },-\sqrt{\ },dzq,czq,bzq,bcdz,abcdq^k\end{matrix};q,azq^k\right], \end{aligned} \tag{2.3}$$

where the symbol $\sqrt{\ }$ indicates a square root over the top left-hand parameter which, in this case, is $bcdz$. After some simplifications and an easily justifiable interchange in the order of summations, (2.2) and (2.3) give

$$q_n(x)=2z\kappa(a,b,c,d)\frac{(bcdz,bzq,czq,dzq;q)_\infty}{(bcdzq,bz,cz,dz;q)_\infty}\sum_{l=0}^{\infty}\left(\frac{1-bcdzq^{2l}}{1-bcdz}\right)$$
$$\cdot\frac{(bc,bd,cd,zq/a;q)_l}{(dzq,czq,bzq,abcd;q)_l}(az)^l\,{}_3\phi_2\left[\begin{matrix}q^{-n},abcdq^{n-1},a/z\\ abcdq^l,aq^{-l}/z\end{matrix};q,q\right]. \tag{2.4}$$

The ${}_3\phi_2$ series on the right is balanced and terminating and so is summable by Jackson's formula [3, (8.4)] with sum

$$\frac{(q^{1-n+l},bcdzq^l;q)}{(abcdq^l,zq^{1-n+l}/a;q)_n}$$

which vanishes unless $l\geqq n$. Replacing l by $l+n$ in (2.4) and simplifying, we obtain

$$q_n(x)=2z\kappa(a,b,c,d)\frac{(bzq,czq,dzq;q)_\infty}{(bz,cz,dz;q)_\infty}\frac{(bc,bd,cd;q)_n}{(bzq,czq,dzq;q)_n}(az)^n$$
$$\cdot\frac{(q;q)_n(bcdzq^n;q)_{n+1}}{(abcd;q)_{2n}}$$
$$\cdot{}_8\phi_7\left[\begin{matrix}bcdzq,q\sqrt{\ },-q\sqrt{\ },bdq^n,cdq^n,q^{n+1},bcq^n,zq/a\\ \sqrt{\ },-\sqrt{\ },czq^{n+1},bzq^{n+1},bcdzq^n,dzq^{n+1},abcdq^{2n}\end{matrix};q,za\right]. \tag{2.5}$$

Using Bailey's two-term transformation formula [4, (4.3)] for a very well-poised ${}_8\phi_7$ series, we transform the ${}_8\phi_7$ above to the following:

$$\frac{(bcdzq^{2n+1},qz^2,adq^n,abczq^n;q)_\infty}{(az,dzq^{n+1},abcdq^{2n},bcz^2q^{n+1};q)_\infty}$$
$$\cdot{}_8\phi_7\left[\begin{matrix}bcz^2q^n,q\sqrt{\ },-q\sqrt{\ },bz,cz,zq/a,zq/d,bcq^n\\ \sqrt{\ },-\sqrt{\ },czq^{n+1},bzq^{n+1},abczq^n,bcdzq^n,qz^2\end{matrix};q,adq^n\right].$$

Substituting this in (2.5) and simplifying the coefficients, we get

$$q_n(x)=\frac{4\pi z(qz^2;q)_\infty}{(ab,ac,ad,az,bz,cz,dz;q)_\infty}\frac{(abczq^n,bcdzq^n,bzq^{n+1},czq^{n+1},adq^n;q)_\infty}{(bcq^n,bdq^n,cdq^n,q^{n+1},bcz^2q^{n+1};q)_\infty}(az)^n$$
$$\cdot{}_8\phi_7\left[\begin{matrix}bcz^2q^n,q\sqrt{\ },-q\sqrt{\ },bz,cz,zq/a,zq/d,,bcq^n\\ \sqrt{\ },-\sqrt{\ },czq^{n+1},bcq^{n+1},abczq^n,bcdzq^n,qz^2\end{matrix};q,adq^n\right]. \tag{2.6}$$

We now define the q-Wilson function of the second kind:

$$Q_n(z;a,b,c,d)=\frac{1-z^2}{4\pi z}\frac{(az,bz,cz,dz,a/z,b/z,c/z,d/z;q)_\infty}{(z^2,z^{-2};q)_\infty}$$
$$\cdot\frac{(ab,ac,ad;q)_n}{(bc,bd,cd;q)_n}a^{-n}q_n(x) \tag{2.7}$$

$$= \frac{(abczq^n, bcdzq^n, bzq^{n+1}, czq^{n+1}; q)_\infty (a/z, b/z, c/z, d/z; q)_\infty}{(bc, bd, cd, abq^n, acq^n, q^{n+1}, bcz^2q^{n+1}; q)_\infty (z^{-2}; q)_\infty} z^n$$

$$\cdot {}_8\phi_7\left[\begin{matrix} bcz^2q^n, q\sqrt{\ }, -q\sqrt{\ }, bz, cz, zq/a, zq/d, bcq^n \\ \sqrt{\ }, -\sqrt{\ }, czq^{n+1}, bzq^{n+1}, abczq^n, bcdzq^n, qz^2 \end{matrix}; q, adq^n\right].$$

By (1.11), the ${}_8\phi_7$ series is convergent for all z and so the second expression on the right side of (2.7) defines $Q_n(z; a, b, c, d)$ for all z, excluding the poles. The factors in front of $q_n(x)$ in the first expression may appear a bit mysterious at this stage, but the eventual simplifications and symmetries will justify their use. It can be verified through a set of lengthy but straightforward calculations that $Q_n(z; a, b, c, d)$ satisfies the second order divided difference equation of Askey and Wilson [1, (5.16)], implying that it is the right q-analogue of the Jacobi function of the second kind.

Now, by Bailey's formula [4, (5.1)],

(2.8)

$$ {}_8\phi_7\left[\begin{matrix} bcz^2q^n, q\sqrt{\ }, -q\sqrt{\ }, bz, cz, zq/a, zq/d, bcq^n \\ \sqrt{\ }, -\sqrt{\ }, czq^{n+1}, bzq^{n+1}, abczq^n, bcdzq^n, qz^2 \end{matrix}; q, adq^n\right]$$

$$= \frac{(bcz^2q^{n+1}, bdq^n, cdq^n, q^{n+1}, z^{-2}, ab, ac, bc; q)_\infty}{(abcz, bcdzq^n, bzq^{n+1}, czq^{n+1}, b/z, c/z, a/z, dq^n/z; q)_\infty}$$

$$\cdot {}_8\phi_7\left[\begin{matrix} abczq^{-1}, q\sqrt{\ }, -q\sqrt{\ }, az, bz, cz, abcdq^{n-1}, q^{-n} \\ \sqrt{\ }, -\sqrt{\ }, bc, ac, ab, q^{1-n}z/d, abczq^n \end{matrix}; q, q/dz\right]$$

$$- \frac{(bcz^2q^{n+1}, abcq^n/z, bcdq^n/z, bq^{n+1}/z, cq^{n+1}/z, dzq^n, q^{1-n}/dz; q)_\infty}{(bcq^{n+1}/z^2, abczq^n, bcdzq^n, bzq^{n+1}, czq^{n+1}, dq^n/z, zq^{1-n}/d; q)_\infty}$$

$$\cdot \frac{(z^{-2}, qz/d, az, bz, cz; q)_\infty}{(z^2, q/dz, a/z, b/z, c/z; q)_\infty}$$

$$\cdot {}_8\phi_7\left[\begin{matrix} bcq^n z^{-2}, q\sqrt{\ }, -q\sqrt{\ }, b/z, c/z, q/az, q/dz, bcq^n \\ \sqrt{\ }, -\sqrt{\ }, cq^{n+1}/z, bq^{n+1}/z, abcq^n/z, bcdq^n/z, qz^{-2} \end{matrix}; q, adq^n\right]$$

and, by Watson's formula [3, (8.5)],

(2.9)
$$ {}_8\phi_7\left[\begin{matrix} abczq^{-1}, q\sqrt{\ }, -q\sqrt{\ }, az, bz, cz, abcdq^{n-1}, q^{-n} \\ \sqrt{\ }, -\sqrt{\ }, bc, ac, ab, q^{1-n}z/d, abczq^n \end{matrix}; q, q/dz\right]$$

$$= \frac{(abcz, q^{1-n}/ad; q)_n}{(bc, q^{1-n}z/d; a)_n} {}_4\phi_3\left[\begin{matrix} q^{-n}, abcdq^{n-1}, az, a/z \\ ab, ac, ad \end{matrix}; q, q\right]$$

$$= \frac{(abcz, ad; q)_n}{(bc, d/z; q)_n} (az)^{-n} p_n(x; a, b, c, d).$$

Using (2.8) and (2.9) in (2.7), we get

(2.10)
$$Q_n(z; a, b, c, d) = \frac{(ab, ac, ad; q)_n}{(bc, bd, cd; q)_n} a^{-n} p_n(x; a, b, c, d) - Q_n(z^{-1}; a, b, c, d).$$

The symmetry of this formula implies that this is valid for both $|z|<1$, and $|z|>1$. Use of (2.7) in (1.12) and (1.13) now yields

$$q_n(x;a,b,c,d)=\pi i w(x)\left[Q_n(e^{i\theta};a,b,c,d)-Q_n(e^{-i\theta};a,b,c,d)\right], \tag{2.11}$$

$$p_n(x;a,b,c,d)=\frac{(bc,bd,cd;q)_n}{(ab,ac,ad;q)_n}a^n\left[Q_n(e^{i\theta};a,b,c,d)+Q_n(e^{-i\theta};a,b,c,d)\right] \tag{2.12}$$

where $x=\cos\theta$, $0<\theta<\pi$, and $q_n(x;a,b,c,d)$ is the q-Wilson function of the second kind on $-1<x<1$. Note that (2.10) is just the analytic continuation of (2.12) and so it was not really necessary to use (2.8) and (2.9). However, it is interesting to see that Bailey's three-term transformation formula [4, (5.1)] for a very-well-poised ${}_8\phi_7$ series produces the same result.

Askey, Koornwinder and Rahman [2] used a special case of $q_n(x;a,b,c,d)$ by defining the q-ultraspherical functions of the second kind as follows:

$$D_n(\cos\theta;\beta|q)=\frac{4}{w_\beta(\cos\theta|q)}\sum_{k=0}^{\infty}b(k,n;\beta)\cos(n+2k+1)\theta, \tag{2.13}$$

where

$$w_\beta(\cos\theta|q)=\csc\theta\prod_{n=0}^{\infty}\frac{1-2(2\cos^2\theta-1)q^n+q^{2n}}{1-2(2\cos^2\theta-1)\beta q^n+\beta^2q^{2n}}, \tag{2.14}$$

$$b(k,n;\beta)=\frac{(\beta,\beta q;q)_\infty}{(q,\beta^2;q)_\infty}\frac{(\beta^2;q)_n(q\beta^{-1};q)_k(q;q)_{n+k}}{(q;q)_n(q;q)_k(\beta q;q)_{n+k}}\beta^k. \tag{2.15}$$

Since there is no apparent similarity between (2.13) and the expression on the right of (2.7), it is of interest to see how (2.7) and (2.11) give rise to (2.13) in the ultraspherical case.

Let us set $z=e^{i\theta}$, $a=-d=\sqrt{q}$ and $b=-c=\beta$ in (2.7) to get

(2.16)

$$Q_n(e^{i\theta};\sqrt{q},\beta,-\beta,-\sqrt{q})=\frac{(-\beta^2e^{i\theta}q^{n+1/2},\beta^2e^{i\theta}q^{n+1/2},\beta e^{i\theta}q^{n+1},-\beta e^{i\theta}q^{n+1};q)_\infty}{(\beta q^{n+1/2},-\beta q^{n+1/2},q^{n+1},-\beta^2e^{2i\theta}q^{n+1};q)_\infty}$$

$$\cdot\frac{(\sqrt{q}e^{-i\theta},-\sqrt{q}e^{-i\theta},\beta e^{-i\theta},-\beta e^{-i\theta};q)_\infty}{(-\beta^2,-\beta\sqrt{q},\beta\sqrt{q},e^{-2i\theta};q)_\infty}$$

$$\cdot e^{in\theta}\cdot{}_8\phi_7\left[\begin{matrix}-\beta^2e^{2i\theta}q^n,q\sqrt{\ },-q\sqrt{\ },\beta e^{i\theta},-\beta e^{i\theta},\sqrt{q}e^{i\theta},-\sqrt{q}e^{i\theta},-\beta^2q^n\\ \sqrt{\ },-\sqrt{\ },-\beta e^{i\theta}q^{n+1},\beta e^{i\theta}q^{n+1},-\beta^2e^{i\theta}q^{n+1/2},\beta^2e^{i\theta}q^{n+1/2},qe^{2i\theta}\end{matrix};q,-q\right]$$

$$=\frac{(\beta e^{i\theta}q^{n+1},-\beta e^{i\theta}q^{n+1},\beta^2q^n,e^{i\theta}q^{n+3/2},\sqrt{q}e^{-i\theta},-\sqrt{q}e^{-i\theta},\beta e^{-i\theta},-\beta e^{-i\theta};q)_\infty}{(-\beta^2,\beta\sqrt{q},-\beta\sqrt{q},\beta q^{n+1/2},-\beta q^{n+1/2},q^{n+1},-q^{n+1},q^{n+2}e^{2i\theta},e^{-2i\theta};q)_\infty}$$

$$\cdot e^{in\theta}\cdot{}_8\phi_7\left[\begin{matrix}q^{n+1}e^{2i\theta},q\sqrt{\ },-q\sqrt{\ },qe^{i\theta}/\beta,-qe^{i\theta}/\beta,q^{n+1},\sqrt{q}e^{i\theta},-\sqrt{q}e^{i\theta}\\ \sqrt{\ },-\sqrt{\ },\beta e^{i\theta}q^{n+1},-\beta e^{i\theta}q^{n+1},qe^{2i\theta},e^{i\theta}q^{n+3/2},-e^{i\theta}q^{n+3/2}\end{matrix};q,\beta^2q^n\right],$$

by [4, (4.3)]. Now we shall need to use the following quadratic transformation formula recently found by Gasper and Rahman [5].

$$(2.17)\quad {}_8\phi_7\left[\begin{matrix} ax^2/b^2, q\sqrt{\ }, -q\sqrt{\ }, x, -x, x\sqrt{q}/b, -x\sqrt{q}/b, a \\ \sqrt{\ }, -\sqrt{\ }, axq/b^2, -axq/b^2, ax\sqrt{q}/b, -ax\sqrt{q}/b, qx^2/b^2 \end{matrix}; q, aq/b^2\right]$$
$$= \frac{(q/b^2, aqx^2/b^2; q)_\infty}{(aq/b^2, qx^2/b^2; q)_\infty} \frac{(qx^2/b^2, q^2a^2/b^2, qa^2/b^2, q^2x^2/b^4; q^2)_\infty}{(q/b^2, q^2/b^2, qa^2x^2/b^2, q^2a^2x^2/b^4; q^2)_\infty}$$
$$\cdot {}_2\phi_1\left[\begin{matrix} a^2, b^2 \\ a^2q^2/b^2 \end{matrix}; q^2, q^2x^2/b^4\right],$$

provided $|aq/b^2|<1$, $|qx/b^2|<1$. Setting $a=q^{n+1}$, $b=q/\beta$, $x=qe^{i\theta}/\beta$ in (2.17) and substituting in (2.16), we get

$$(2.18)\quad Q_n(e^{i\theta}; \sqrt{q}, \beta, -\beta, -\sqrt{q})$$
$$= -2i\sin\theta \frac{(\beta^2, \beta^2q^{2n+2}, \beta^2e^{2i\theta}, \beta^2e^{-2i\theta}; q^2)_\infty}{(\beta^4, q^{2n+2}, e^{2i\theta}, e^{-2i\theta}; q^2)} e^{i(n+1)\theta}$$
$$\cdot {}_2\phi_1\left[\begin{matrix} q^{2n+2}, q^2/\beta^2 \\ \beta^2q^{2n+2} \end{matrix}; q^2, \beta^2e^{2i\theta}\right].$$

In deriving this we have made frequent use of the identities

$$(2.19)\quad (a;q)_\infty = (a;q^2)_\infty (aq;q^2)_\infty,$$
$$(a^2;q^2)_\infty = (a;q)_\infty (-a;q)_\infty.$$

From (2.11) and (2.18) we then have

(2.20)

$$q_n(x; \sqrt{q}, \beta, -\beta, -\sqrt{q})$$
$$= 4\pi \frac{(\beta^2, \beta^2q^{2n+2}; q^2)_\infty}{(\beta^4, q^{2n+2}; q^2)_\infty} \sum_{k=0}^{\infty} \frac{(q^{2n+2}, q^2/\beta^2; q^2)_k}{(q^2, \beta^2q^{2n+2}; q^2)_k} \beta^{2k} \cos(n+1+2k)\theta$$
$$= 4\pi \frac{(\beta^2, \beta^2q^2; q^2)_\infty}{(q^2, \beta^4; q^2)_\infty} \sum_{k=0}^{\infty} \frac{(q^2\beta^{-2}; q^2)_k (q^2; q^2)_{n+k}}{(q^2; q^2)_k (\beta^2q^2; q^2)_{n+k}} \beta^{2k} \cos(n+1+2k)\theta$$
$$= \frac{(q^2; q^2)_n}{(\beta^4; q^2)_n} \pi w_{\beta^2}(\cos\theta | q^2) D_n(\cos\theta; \beta^2 | q^2).$$

3. Asymptotic properties. Following Ismail and Wilson [6] let us denote

$$(3.1)\quad A(z) = (az, bz, cz, dz; q)/(z^2; q)_\infty.$$

Then it is clear from (2.7) that

$$(3.2)\quad Q_n(z; a, b, c, d) \sim z^n A(z^{-1})/(bc, bd, cd; q)_n,$$

as $n \to \infty$, uniformly for x, a, b, c, d in compact sets avoiding the poles $z^2 = q^{-k}$, $k = 0, 1, 2, \cdots$. Using (2.12) we get

$$(3.3) \qquad a^{-n}(ab, ac, ad; q)_n p_n(x; a, b, c, d)$$
$$\sim z^n A(z^{-1}) + z^{-n} A(z) = 2|A(e^{i\theta})|\cos(n\theta - \phi), \qquad n \to \infty,$$

where $\phi = \arg A(e^{i\theta})$, $0 < \theta < \pi$, $|q| < 1$. This agrees with (1.13) of [6] for $x \neq \pm 1$ and inside the ellipse with foci ± 1 and vertices $\pm 1/2[|q|^{1/2} + |q|^{-1/2}]$. By (3.2) and (2.11) we also get the leading term in the asymptotic expansion of the q-Wilson function of the second kind:

$$(3.4) \qquad (bc, bd, cd; q)_n q_n(x; a, b, c, d) \sim -2\pi w(x)|A(e^{i\theta})|\sin(n\theta - \phi),$$

as $n \to \infty$ for x restricted as above.

ERRATUM AND ADDENDUM: ANALYTIC FUNCTIONS RELATED TO THE DISTRIBUTIONS OF EXPONENTIAL GROWTH*

RICHARD D. CARMICHAEL†

Abstract. Analytic functions in tubes which were previously shown to have distributional boundary values on the distinguished boundary of the tube are now shown to have boundary values on the topological boundary of the tube as well.

Key words. analytic functions in tubes, distributions of exponential growth, distributional boundary value

AMS(MOS) subject classifications. Primary 32A07, 32A10, 32A40, 46F20

1. Correction. In the final printing of [1, p. 1063] the lines between equations (8.8) and (8.9), which are correct as printed, were printed again after (8.9) to the end of the paragraph. The lines in [1, p. 1063] directly after (8.9) to the end of the paragraph should be as follows:

with this Fourier transform being in the L^2 sense. But $m>0$ is arbitrary in (8.9) and independent of the arbitrary compact subcone $C'\subset C$. Thus it follows that (8.9) holds for $z\in T^{C'}$, C' being an arbitrary compact subcone of C, since for arbitrary $z\in T^{C'}$ we can choose $m>0$ such that $z\in T(C';\ m)$. Since we now know (8.9) holds for $z\in T^{C'}$, then (8.1) follows immediately from this. Now that we have (8.1), the conclusions (8.2) and (8.3) follow by exactly the same type of analysis used in the proof of Theorem 7.1 to prove (7.3) and (7.4).

The remainder of [1, p. 1063] is correct as printed beginning with the paragraph which starts at line 11 ↑.

2. Addition. Let C be an open connected cone in $\mathbb{R}^n$ and let C' be an arbitrary compact subcone of C. If a function $f(z)$ is analytic in $T^{C'}=\mathbb{R}^n+iC'$ for every compact subcone C' of C then $f(z)$ is analytic in the whole of $T^C=\mathbb{R}^n+iC$; for if $z=x+iy\in T^C$, there exists a compact subcone C' of C such that $z\in T^{C'}$ with $y=\mathrm{Im}(z)$ on the interior of C' since C is open. Thus an equivalent definition of the functions $F_p(A;\ C)$ of [1, p. 1053] is that $f(z)\in F_p(A;\ C)$ if and only if $f(z)$ is analytic in T^C and satisfies [1, (6.4), p. 1053] for every compact subcone C' of C and for all $m>0$. In [1, Thm. 8.1, p. 1062] we have [1, (8.1) and (8.2)] holding for $z=x+iy\in T^{C'}$, $C'\subset C$. But the n-tuple α of nonnegative integers, the function $g(t)$, and the distribution $V=D_t^{\alpha}(g(t))\in\mathscr{K}_1'$ in the proof of [1, Thm. 8.1] are all independent of compact subcones $C'\subset C$ (and of the arbitrary $m>0$) as noted in [1, p. 1063, lines 22–23 ↓]. We have that the right side of both [1, (8.1) and (8.2)] are well defined for all $y\in C$. Thus [1, (8.1) and (8.2)] holding for $z\in T^{C'}$ for every compact subcone $C'\subset C$ implies that

*Received by the editors March 18, 1985. This material is based upon work supported by the National Science Foundation under grant DMS-8418435.

[1, (8.1) and (8.2)] hold for all $z \in T^C$ since $f(z)$ is actually analytic in the whole of T^C here. Additionally [1, (8.3)] holds for $y = \mathrm{Im}(z) \in C$ with $|y| \leqq Q$.

Now let y_0 denote any point in $\mathbb{R}^n$. An easy adaptation of the proof of [1, Lemma 5.9, p. 1052] yields that if $V \in \mathscr{K}_r'$, $r \geqq 1$, then

$$\lim_{\substack{y \to y_0 \\ y \in \mathbb{R}^n}} \exp(-2\pi\langle y, t\rangle) V_t = \exp(-2\pi\langle y_0, t\rangle) V_t \tag{1}$$

in the strong (and weak) topology of $\mathscr{K}_r'$. ($V \in \mathscr{K}_r'$, $r \geqq 1$, implies $(\exp(-2\pi\langle y, t\rangle)V_t) \in \mathscr{K}_r'$ for any $y \in \mathbb{R}^n$ because $\exp(-2\pi\langle y, t\rangle)$ is a multiplier in $\mathscr{K}_r$, $r \geqq 1$, as a function of $t \in \mathbb{R}^n$.) But the Fourier transform defined by [1, (4.2), p. 1044] is a strongly continuous mapping from $\mathscr{K}_r'$ onto K_r'; thus by (1) and the fact that [1, (8.2)] actually holds for all $z = x + iy \in T^C$, as noted in the preceding paragraph, we have

$$\lim_{\substack{y \to y_0 \\ y \in C}} f(x+iy) = \mathscr{F}\left[\exp(-2\pi\langle y_0, t\rangle) V_t\right] \in K_r', \quad r \geqq 1, \tag{2}$$

in the strong (and weak) topology of K_r', $r \geqq 1$, for y_0 being any point on the topological boundary of the cone C. The limit (2) is obtained unrestrictedly, that is independently of how $y \to y_0$, $y \in C$, and is also obtained uniquely. Thus the boundary value conclusion [1, (8.4)] can be replaced by the more general boundary value conclusion obtained in (2) above which yields that the functions $f(z) \in F_1(A;\ C)$, $A \geqq 0$, considered in [1, Theorem 8.1] obtain strong K_r', $r \geqq 1$, boundary values on the topological boundary of the tube T^C as well as on the distinguished boundary $\{x + iy : x \in \mathbb{R}^n, y = \bar{0}\}$ of the tube. (If $y_0 = \bar{0}$, the origin in $\mathbb{R}^n$, (2) reduces to [1, (8.4)].)

The conclusions in [1, Thms. 8.2, 8.4, 9.1, and 9.2] correrssponding to [1, (8.1), (8.2), and (8.3)], where applicable, also hold for $z \in T^C$ ($\in T^{O(C)}$), and [1, (8.10) and (9.2)] hold for all $z \in T^C$. In each of these theorems the boundary value result can be replaced by the more general conclusion (2) for y_0 being any point on the topological boundary of C ($O(C)$).

PERIODIC SOLUTIONS OF PERIODIC COMPETITIVE AND COOPERATIVE SYSTEMS*

HAL L. SMITH†

Abstract. The periodic solutions, their basins of attraction and invariant manifolds are considered for periodic systems of differential equations which are cooperative or competitive following Hirsch. Competitive and cooperative mappings are introduced which possess the essential features of the Poincaré map for such systems. The geometrical properties of these mappings and the discrete dynamical system they generate are the objects of study. The main tools in this study are the Perron–Frobenius theory of positive matrices and invariant manifold theory. A complete description of the "phase portrait" of the discrete dynamical system generated by an orientation preserving planar cooperative map is obtained.

Key words. periodic solutions, Poincaré map, order preserving diffeomorphism, invariant manifold

Introduction. Many mathematical models in the biological sciences give rise to systems of differential equations

$$\begin{aligned} x_i' &= F_i(x,t), \qquad 1 \leqq i \leqq n, \\ x &= (x_1, x_2, \cdots, x_n) \end{aligned} \tag{0.1}$$

which have quite special properties. Two types of systems which have recently received considerable attention in the literature [10], [11], [12], [15] will be referred to as cooperative and competitive following Hirsch [5]. System (0.1) is cooperative if

$$\frac{\partial F_i}{\partial x_j} \geqq 0, \qquad i \neq j$$

and competitive if the reverse inequalities hold. Applied mathematicians working with particular cooperative or competitive autonomous systems typically found that the asymptotic behavior consisted of convergence to equilibrium (particularly for cooperative systems, e.g., [11] but see [15] for a counterexample in the competitive case). However, any thoughts that competitive and cooperative systems might be immune to the plague of ever more complex and chaotic attractors which the dynamical systems people have discovered had to be scrapped following the note of Smale [12]. Smale showed that any vector field on the standard $(n-1)$-simplex in R^n can be embedded in a smooth competitive vector field on R^n for which the simplex is an attractor. Discouraging as this result might seem for proving any general results for competitive or cooperative systems, it suggests that these systems can behave no worse than general systems in one fewer dimension. In essence, this is what Hirsch showed in [5], [6]. In this series of important papers, many key ideas were introduced.

The above-mentioned work focuses on autonomous systems. We are interested in (0.1) when F_i is periodic in the time variable (of normalized period 2π). Periodic systems (0.1) arise naturally in population biology when day-night cycles or seasonal variation in parameters are accounted for.

*Received by the editors September 18, 1984, and in revised form July 8, 1985.

Autonomous systems are, of course, periodic and hence all the limitations of Smale's result on any general theory for periodic competitive or cooperative systems are present. Indeed, one expects periodic systems to be less well behaved since they may be viewed as an autonomous system in one more dimension, $S^1 \times R^n$. The first important results for periodic competitive systems were obtained by de Mottoni and Schiaffino [10] who considered periodic two-dimensional Lotka–Volterra systems. They translated properties of competitive planar systems (0.1) to properties of the associated Poincaré map, T, defined by: $x(0) \xrightarrow{T} x(2\pi)$. The most important properties are that T^{-1} preserves the usual partial ordering on R^2 and T is orientation preserving. They then analysed the discrete dynamical system $x_{n+1} = Tx_n$, showing that all orbits $\{T^n x\}_{n \geqq 0}$ tend to fixed points of T. In other words, all solutions of (0.1) are asymptotic to 2π-periodic solutions. In addition, they showed that the nontrivial fixed points of T lie on a separatrix curve: a monotone invariant curve for T forming part of the boundary of the domain of replusion of the trivial fixed point. While de Mottoni and Schiaffino considered only the periodic Lotka–Volterra equations, their arguments were quite general, as pointed out by J. Hale and S. Somolinos [3].

The purpose of this paper is to study the periodic solutions of periodic competitive and cooperative systems (0.1), their respective domains of attraction and invariant manifolds. Following [10], our approach will be to study the geometrical properties of the discrete dynamical system generated by the Poincaré map for (0.1). In the language of discrete dynamical systems, the focus of our work is on fixed points and periodic points of what we term competitive or cooperative mappings. In this sense, the scope of our work is much less ambitious than that of Hirsch [5], [6] since we do not consider the more general problem of determining properties of the limit set $\Lambda(x) = \{y : y = \lim_{i \to \infty} T^{n_i} x$, $\{T^{n_i} x\}$ a convergent subsequence of $\{T^n x\}_{n \geqq 0}\}$ of an orbit $\{T^n x\}_{n \geqq 0}$ (see §2, Proposition L for an exception). In future work we intend to consider this much deeper problem.

The organization of this paper and our main results will be briefly described. In §1 we introduce the Poincaré map for competitive and cooperative periodic systems (0.1) and present some more or less known results concerning these maps, the most important of which are derived from results of Kamke (see [2]) and Hirsch [6]. For a cooperative periodic system (0.1), these properties are, in the above order, that T preserves the usual coordinate wise ordering on R^n ($x < y$ if and only if $x_i < y_i$, $1 \leqq i \leqq n$) and, if $D_x F$ is an irreducible matrix, then $D_x T$ is a positive matrix (all entries are positive). If (0.1) is a competitive system, then T^{-1} enjoys the above properties. Proofs are presented for some of the less well-known results for completeness.

In §2, we introduce the class of cooperative mappings. These maps are diffeomorphisms defined on a neighborhood of R^n_+, the nonnegative orthant, which map the interior, $\dot{R}^n_+$, of R^n_+ into itself, preserve the usual coordinate wise ordering and have the property that the Jacobian derivative of the map evaluated at every positive fixed point is strongly positive (some positive power of the matrix has all positive entries). Included in this class of mappings are the Poincaré maps of cooperative periodic systems (0.1) provided $D_x F$ is irreducible. Nontrivial cooperative maps are shown to have a minimal fixed point which, if it lies in $\dot{R}^n_+$ and is hyperbolic, must be asymptotically stable. We examine the geometry of the basin of attraction of stable fixed points x of a cooperative map T obtaining useful results on the intersection of the basin of attraction of x with the two cones $x + R^n_+$ and $x - R^n_+$. One of these results (Proposition 2.3) implies that if the intersection of the basin of attraction with $x + R^n_+$ is bounded then the boundary of this set, relative to $x + R^n_+$, contains at least one fixed point of T.

Generically, these latter fixed points are unstable. Our main contribution in §2 is the application of a result of the author [13, Thm. 2.2] concerning unstable fixed points of order preserving mappings to cooperative maps. The Perron–Frobenius theory of nonnegative matrices [7], [14] plays a fundamental role in this result and others in this work. Essentially, this result asserts that to each unstable fixed point $x_1 > 0$ of a cooperative map T there are two invariant curves $C^+ \subset x_1 + R^n_+$ and $C^- \subset (x_1 - R^n_+) \cap R^n_+$ issuing from x_1 and parametrized by monotone increasing, respectively decreasing, functions of the half line $[0, \infty)$. C^- connects x_1 to another fixed point x_0, $x_0 < x_1$, which is generically stable and C^+ either connects x_1 to infinity or to another fixed point x_2, $x_2 > x_1$, which is generically stable (the latter necessarily occurs if all orbits, $\{T^n x\}_{n \geqq 0}$, are bounded). In addition, x_0 attracts all points in $[x_0, x_1]$ except x_1 and x_2 attracts all points of $[x_1, x_2]$ except x_1 under iteration by T (if $x \leqq y$, $[x,y] = \{z : x \leqq z \leqq y\}$). In other words, an unstable fixed point x_1 of T must lie on the common boundary of the basins of attraction of two distinct stable fixed points x_0 and x_2, $x_0 < x_1 < x_2$. This result, Theorem 2.5, together with earlier mentioned results, indicates that the fixed point set of T together with the invariant curves C^+ and C^- associated with each unstable fixed point form a tree-like structure with the minimal fixed point at the base.

The results of §2, while providing useful information about the fixed point set of a cooperative map, provide an incomplete description of the dynamics generated by cooperative mappings. This is inevitable, of course, in view of Smale's result. For orientation preserving cooperative mappings in two dimensions, however, we can completely describe the "phase portrait" for the discrete dynamical system under the following reasonable conditions: (A) the minimal fixed point is positive (lies in $\dot{R}^2_+$), (B) all fixed points are hyperbolic and (C) all orbits $\{T^n x\}_{n \geqq 0}$ are bounded. This complete description is possible because (i) every orbit tends to a fixed point of T and (ii) the structure of the fixed point set, including basins of attraction of stable fixed points, can be completely described. Both results rely heavily on the Jordan curve theorem. The fact that in two dimensions every bounded orbit of a cooperative map tends to a fixed point was first recognized by de Mottoni and Schiaffino [10] (see also Hale and Somolinos [3]). Although they observed the property for competitive maps, their arguments are easily transformed to the case of cooperative maps. Our ability to completely describe the structure of the fixed point set as well as the basins of attraction of stable fixed points stems from the earlier mentioned result on monotone invariant curves issuing from unstable fixed points together with a description of the stable manifold of a saddle fixed point. The stable manifold of a saddle fixed point x of T lies in the second and fourth quadrant centered at x and can be divided into two pieces, one lying in each quadrant. Each piece emanates from x in such a way that it can be parametrized by a map of an interval of the real line into R^2, the components of which are monotone, one increasing the other decreasing. Each of the pieces of the stable manifold either connects the saddle point to a fixed point (repeller), becomes unbounded, or intersects a coordinate axis. This global result, Theorem 4.5, provides the component parts of the "separatrix" curves forming the common boundary of the basins of attraction of two stable fixed points. Our main result, Theorem 4.8, synthesizes the earlier results and provides the complete description of the fixed point set and basins of attraction. This description goes roughly as follows. The stable fixed points make up a totally ordered finite or infinite set $\{y_k\}$, $0 < y_1 < y_2 < \cdots < y_k < \cdots$. Each interval $[y_k, y_{k+1}]$ contains an odd number of unstable fixed points (saddles and repellers) lying on a smooth curve S^k. The curve S^k can be parametrized by either of

the coordinate variables in terms of the other in a monotone decreasing fashion and S^k separates R^2_+ into two components. The odd number of fixed points lying in $[y_k, y_{k+1}]$ can be ordered $x^k_1, \cdots, x^k_{2n_k+1}$ from left to right on S^k with the odd indexed x^k being saddles and the even indexed x^k being repellers. S^k consists of the union of the stable manifolds of the saddle fixed points x^k_{2l+1}, $1 \leqq l \leqq n_k$, together with the repellets x^k_{2j}, $1 \leqq j \leqq n_k$. Finally, the S^k, $k \geqq 1$ are pairwise nonintersecting and S^k forms the upper boundary of the basin of y_k (see Fig. 4.8).

The above results for orientation preserving planar cooperative maps are presented in §4. In §3, immediately following our results on general cooperative maps in §2, we introduce the class of competitive maps. These are diffeomorphisms defined on a neighborhood of R^n_+ which map $\dot{R}^n_+$ into itself, map the boundary of R^n_+ into itself and whose additional properties are most easily, but somewhat inaccurately, described by stating that its inverse is a cooperative map. In fact the results of §3 are obtained by applying the results of §2 to the inverse of the competitive map. The main difficulty with this approach is that the domain of the inverse of a competitive map may not include R^n_+. The inverse of a competitive map is a cooperative map which maps the boundary of R^n_+ into itself and hence must fix the origin (Proposition 3.1). In addition, one expects that there will be nontrivial fixed points of a competitive map on the boundary of R^n_+ and that these will be important (recall the competitive exclusion principle of population biology). Despite this fact, we consider primarily the positive fixed points of competitive maps. The reason for this is that in applications, competitive systems (0.1) typically have the property that each portion of a subspace of R^n spanned by a proper subset of the standard basis vectors which makes up the boundary of R^n_+ is itself invariant for (0.1). In other words, the Poincaré map for a competitive periodic system (0.1) preserves each of these "faces" of R^n_+ and, when restricted to any particular face, is a competitive map. Such maps we term "competitive in each face" Since a fixed point of a map, which is competitive in each face, that lies on the boundary of R^n_+ must lie in the (relative) interior of some lower dimensional face of R^n_+, our results on positive fixed points of competitive maps will apply to the restriction of the map to the appropriate face.

A positive fixed point x of a competitive map T will be an unstable fixed point of T^{-1} if any part of the spectrum of $DT(x)$ lies interior to the unit circle. This simple observation indicates that the main result of §2 on stable fixed points of cooperative mappings, will apply quite generally to positive fixed points of competitive maps. One of the consequences of the main result of §3 (Theorem 3.5) will be that, if all fixed points are hyperbolic, every positive fixed point x_1 is either a repeller (all eigenvalues of the Jacobian exceed unity in modulus) or there is a repeller x_0 in R^n_+, $x_0 < x_1$ and a monotone invariant curve for the map T joining x_0 and x_1. Moreover every point of $[x_0, x_1]$ except x_1 lies in the domain of repulsion of x_1 (the basin of attraction of x_0 under T^{-1}). An important class of competitive maps consists of the Poincaré maps of competitive periodic systems (0.1) for which the divergence of the time dependent vector field $F = (F_i)$ is nonpositive. For these maps, Liouville's theorem [4] implies that $\det DT(x) \leqq 1$ for every positive fixed point x of T. As a consequence, T cannot have any positive repelling fixed point and hence a positive fixed point x_1 of T can exist only if there exists a repeller x_0, $x_0 < x_1$, lying on the boundary of R^n_+. One can also show in this case that no two positive fixed points can be related (more generally, two positive fixed points can be related only if the smaller is a repeller or a repeller lies between them).

We have not attempted in this paper to describe the complete phase portrait of a planar orientation preserving competitive map. While the results of §§2 and 4 would be

useful in such a description, the complete description does not immediately follow from the analogous description for the cooperative case (Theorem 4.8) because of our assumption there that the minimal fixed point is positive. One of the reasons for not attempting in this work a description of the dynamics of planar orientation preserving competitive maps is that such a description would depend on both the stability properties of the zero fixed point and on the number of nontrivial fixed points on each of the two coordinate axes neither of which are constrained. It would be reasonable from an applications viewpoint to assume the existence of at most one nontrivial fixed point on each coordinate axis. In any case, the description would break down into several cases. One such case has essentially already been treated by de Mottoni and Schiaffino [10] and Hale and Somolinos [3]. In a future paper, we plan to consider the phase portrait of orientation preserving maps which are competitive in each face in both two and three dimensions in much more detail. The results of our work here will provide the necessary tools for this future study.

1. Competitive and cooperative systems: The Poincaré map. Consider the 2π-periodic system of differential equations

$$x' = F(t,x) = F(t+2\pi,x), \qquad x \in R^n \tag{1.1}$$

to be defined for $(t,x) \in R \times U$ where U is some open neighborhood of $R^n_+ = \{x : x_i \geqq 0, 1 \leqq i \leqq n\}$. We assume F is continuous on its domain and F is C^2 in x for each $t \in R$.

Following Hirsch [5] and Hale and Somolinos [3], we call (1.1)

$$\text{(strictly) competitive if } \frac{\partial F_i}{\partial x_j} \leqq 0 \quad \text{for } i \neq j, \quad (<),$$

$$\text{(strictly) cooperative if } \frac{\partial F_i}{\partial x_j} \geqq 0 \quad \text{for } i \neq j, \quad (>).$$

The inequalities are assumed to hold for all $(t,x) \in R \times R^n_+$. Note that if (1.1) is competitive (cooperative) then the time reversed system

$$y' = -F(-t,y) \tag{1.2}$$

which has solutions $y(t) = x(-t)$ where $x(t)$ satisfies (1.1), is cooperative (competitive).

It is convenient to introduce the following notation. For vectors x and y in R^n we write $x \leqq y$ $(x < y)$ if $x_i \leqq y_i$ $(x_i < y_i)$, $1 \leqq i \leqq n$. If $x \leqq y$, let $[x,y]$ denote the set $\{z \in R^n : x \leqq z \leqq y\}$. We let $R^n_+ = \{x \in R^n : x \geqq 0\}$ and $\dot{R}^n_+ = \{x \in R^n : x > 0\}$. We say x and y are weakly related in case $x \leqq y$ or $y \leqq x$, related if $x < y$ or $y < x$, and unrelated if they are not related. If A is an $n \times n$ matrix we write $A \geqq 0$ $(A > 0)$ if every $a_{ij} \geqq 0$ $(a_{ij} > 0)$. Let $\phi(t,s,x)$ be the solution map for (1.1), i.e., $x(t) = \phi(t,s,x)$ is the maximally extended solution of (1.1) satisfying $x(s) = x$.

In the applications, it is typical for cooperative systems to have the property that if $x(0) \in R^n_+$ then $x(t) \in \dot{R}^n_+$ for $t > 0$ but $x(t) \notin R^n_+$ for $t < 0$, that is, typically boundary points of R^n_+ are strict ingress points of R^n_+ (see [4]). On the other hand, it is typical of competitive systems that each coordinate axis and each of the faces of various dimensions making up the boundary of R^n_+ are invariant sets for (1.1). Hence, in so far as solutions exist in both forward and backward time for (1.1), $\dot{R}^n_+$ is invariant for (1.1) in the competitive case but only forward invariant $(t \geqq 0)$ for the cooperative case. We will make this difference a part of our hypotheses.

Standing hypothesis (SH). If (1.1) is competitive, $s \in R$, $x_0 > 0$ then domain $\phi(\cdot, s, x_0)$ contains $[s, \infty)$ and $\phi(t, s, x_0) > 0$ for all t in the domain of ϕ. If (1.1) is cooperative, $s \in R$, $x_0 > 0$, then domain $\phi(\cdot, s, x_0)$ contains $[s, \infty)$ and $\phi(t, s, x_0) > 0$ for all $t \geqq s$.

In particular, we are assuming the solutions of (1.1) in both cases can be extended into the future but no assumptions are made concerning their extendibility into the past.

Our goal is to draw general conclusions about how periodic solutions of (1.1) are situated. It is important, in order to make our conclusions as generally applicable as possible, to restrict our consideration to solutions of (1.1) which lie in $\dot{R}^n_+$. While this restriction may appear to ignore important (and sometimes all) the interesting periodic behavior, we point out that our results can usually be applied to the lower dimensional hyperplanes forming the boundary of R^n_+ (see §3).

The fundamental result for competitive and cooperative systems is due to Kamke which we state as follows [2].

THEOREM A. *Let $x(t)$ and $y(t)$ be solutions of* (1.1) *on* $[a, b]$.

(i) *If* (1.1) *is cooperative and $x(a) < y(a)$ then $x(b) < y(b)$.*

(ii) *If* (1.1) *is competitive and $x(b) < y(b)$ then $x(a) < y(a)$.*

Note that (ii) is equivalent to the corresponding versions in Hirsch [5] or Hale and Somolinos [3]. It follows from Theorem A and continuity of solutions with respect to initial conditions that the strict inequalities in (i) can be replaced by inequalities; a corresponding result may be obtained in (ii). In two dimensions, Theorem A has the following corollary, the proof of which the reader may easily supply.

COROLLARY B. *Let $n = 2$. Let $z(t)$ and $y(t)$ be solutions of* (1.1), $y_i(t) = z_i(t) + h_i(t)$.

(i) *If* (1.1) *is cooperative and $h_1(a)h_2(a) < 0$ then it cannot be the case that $h_1(a)h_1(b) < 0$ and $h_2(a)h_2(b) < 0$.*

(ii) *If* (1.1) *is competitive and $h_i(a) \geqq 0$, $h_j(a) \leqq 0$, then $h_i(b) \geqq 0$ and $h_j(b) \leqq 0$, $\{i, j\} = \{1, 2\}$. If $h_1(a)h_2(a) > 0$ then it cannot be the case that $h_1(a)h_1(b) < 0$ and $h_2(a)h_2(b) < 0$.*

Another corollary of Theorem 1 will be useful in our study of competitive systems.

COROLLARY C. *Let* (1.1) *be competitive, $t_1 \geqq 0$, $x_0 \in R^n_+$ and $x_1 = \phi(t_1, 0, x_0)$. Then* $\phi(t_1, 0, [0, x_0]) \supset [0, x_1]$.

Proof. Let $x \in [0, x_1]$ and let $z(t)$ be the maximal solution of (1.2) satisfying $z(-t_1) = x$. Since $y(t) \equiv \phi(-t, 0, x_0)$, $-t_1 \leqq t \leqq 0$, and $z(t)$ satisfy (1.2) and $y(-t_1) = x_1 \geqq x = z(-t_1)$, Theorem A together with (SH) imply that $z(t)$ is defined on $[-t_1, 0]$ and $y(t) \geqq z(t)$, $-t_1 \leqq t \leqq 0$. One easily shows that $z_0 = z(0) \leqq x_0$ satisfies $\phi(t_1, 0, z_0) = x$.

Note that Corollary C implies that $\phi(t, 0, 0) \equiv 0$.

We now consider the variational equation for (1.1) corresponding to a solution $\phi(t, 0, x)$, $x > 0$, namely

$$X' = D_x F(t, \phi(t, 0, x))\, X, \qquad X(0) = I. \tag{1.3}$$

Let $\Phi(t, x)$ be the (fundamental) matrix solution of (1.3), i.e., $\Phi(t, x) = D_x \phi(t, 0, x)$. The result below appears in Hirsch [6] but a slightly weaker version may be found in Krasnosel'skii [8]. An $n \times n$ matrix $A = (a_{ij})$ is irreducible if whenever the set $\{1, 2, \cdots, n\}$ is expressed as the union of two disjoint proper subsets S, S', then for every $i \in S$ there exists j and k in S', such that $a_{ij} \neq 0$ and $a_{ki} \neq 0$. This means that the linear transformation A does not map into itself any nonzero proper linear subspace spanned by a subset of the standard basis vectors.

THEOREM D. (i) *If* (1.1) *is cooperative* (*competitive*) *then* $\Phi(t,x)\geqq 0$ ($\Phi^{-1}(t,x)\geqq 0$) *for* $t\geqq 0$.

(ii) *If* $D_xF(t,z)$ *is irreducible for all* t *and* $z>0$ *and* (1.1) *is cooperative* (*competitive*) *then* $\Phi(t,x)>0$($\Phi^{-1}(t,x)>0$) *for* $t>0$.

Actually, only the cooperative case appears in Hirsch [6] but the competitive case of Theorem D follows immediately from applying the results of the cooperative case to the adjoint equation corresponding to (1.3), which is cooperative if (1.1) is competitive, thus deducing that the transpose of $\Phi(t,x)^{-1}$ is nonnegative (positive).

It is worth noting that $D_xF(t,z)$ is irreducible if (1.1) is either strictly competitive or strictly cooperative.

We will refer to (1.1) as "cooperative (competitive) and irreducible" if (1.1) is cooperative (competitive) and $D_xF(t,z)$ is irreducible for $t\in R$ and $z>0$. Actually, we do not require the strong result that $\Phi(t,x)>0$ for $t>0$, $x>0$ but only that for each $x>0$, $\Phi(t,x)>0$ for large t. This property is referred to by Hirsch [6] as "$\phi(t,s,x)$ has eventually positive derivatives". Similarly, if (1.1) is competitive we need only require that $\Phi(t,x)^{-1}>0$ for large t. While there are advantages to assuming the weaker condition (the property is inherited by nearby systems), it does not appear to be readily verifiable in applications.

As noted by Hirsch [6], systems (1.1) which are cooperative (competitive) and irreducible possess stronger monotonicity properties.

COROLLARY E. *Let* $x_1\geqq 0$, $x_2>0$ *be distinct and* $x_1\leqq x_2$.

(i) *If* (1.1) *is cooperative and irreducible, then* $\phi(t,0,x_1)<\phi(t,0,x_2)$ *for* $t>0$.

(ii) *If* (1.1) *is competitive and irreducible, then* $\phi(0,t,x_1)<\phi(0,t,x_2)$ *for* $t>0$.

Proof. For (i), note that

$$\phi(t,0,x_2)-\phi(t,0,x_1)=\int_0^1\Phi(t,sx_2+(1-s)x_1)\,ds(x_2-x_1).$$

For (ii), note that $x=\phi(0,t,\phi(t,0,x))$ so

$$\phi(0,t,x_2)-\phi(0,t,x_1)=\int_0^1\Phi^{-1}(t,\phi(0,t,sx_2+(1-s)x_1))\,ds(x_2-x_1).$$

In either case, the result follows from Theorem D.

Another property that (1.1) may possess in either the competitive or cooperative case is that

$$\operatorname{div}F(t,x)\leqq 0,\qquad (t,x)\in R\times\dot{R}^n_+ \tag{1.4}$$

where div denotes the divergence of the time-dependent vector field F. In case (1.4) holds, Liouville's theorem [4] states that

$$0<\det\Phi(t,x)\leqq 1. \tag{1.5}$$

We will see that (1.5) has particularly strong consequences for competitive systems.

We are now ready to define the primary object of study in this paper, the Poincaré map. The Poincaré map for (1.1) is defined for $x\in R^n_+$ as follows

$$T(x)=\phi(2\pi,0,x).$$

It is well known that T is a C^2 orientation preserving diffeomorphism defined on a neighborhood of R^n_+ whose fixed points and periodic points (x is a periodic point of T of period p if $T^px=x$ and $T^jx\neq x$ for $1\leqq j\leqq p-1$) correspond to 2π, periodic solutions or $2\pi p$-periodic solutions of (1.1).

Theorem A and Corollary E have the following implication for the Poincaré map T.

COROLLARY F. (i) *If* (1.1) *is cooperative and* $0 \leqq x_1 < x_2$ *then* $T(x_1) < T(x_2)$. *If* (1.1) *is also irreducible, the conclusion holds if* $0 \leqq x_1 \leqq x_2$, $x_1 \neq x_2$ *and* $x_2 > 0$.

(ii) *If* (1.1) *is competitive,* $x_i \geqq 0$, $i = 1, 2$, *and* $T(x_1) < T(x_2)$ *then* $x_1 < x_2$. *If* (1.1) *is also irreducible, the conclusion holds if* $Tx_2 > 0$ *and* $Tx_1 \leqq Tx_2$, $x_1 \neq x_2$.

One can view (ii), which we will do, as asserting that $T^{-1}: T(R^n_+) \to R^n_+$, $T^{-1}(x) = \phi(0, 2\pi, x)$ is monotone in the sense of (i). It will be important to have the following information concerning the domain $T(R^n_+)$, of T^{-1} which follows from Corollary C.

COROLLARY G. *Let* (1.1) *be competitive,* $x_0 \geqq 0$, *and* $x_1 = T(x_0)$. *Then* $T([0, x_0]) \supset [0, x_1]$.

In other words, if $x_1 \in T(R^n_+)$ then $[0, x_1] \subset T(R^n_+)$ and if $x \notin T(R^n_+)$ then $y \notin T(R^n_+)$ if $y \geqq x$.

Theorem D(i) or Corollary F imply that the derivative, $DT(x) = \Phi(2\pi, x)$, of T satisfies $DT(x) \geqq 0$ in the cooperative case and $[DT(x)]^{-1} = D(T^{-1})(Tx) \geqq 0$ in the competitive case.

LEMMA H. *Let* (1.1) *be cooperative* (*competitive*) *and irreducible. If* $\phi(t, 0, x_0)$, $x_0 > 0$, *is a* $2\pi j$*-periodic solution of* (1.1) *for some positive integer* j, *i.e.,* $T^j(x_0) = x_0$, *then*

$$(1.6)\qquad \begin{aligned} &\text{(a)} \quad \left[D(T^j)(x_0)\right] > 0 \quad \textit{if (1.1) is cooperative,} \\ &\text{(b)} \quad \left[D(T^{-j})(x_0)\right] > 0 \quad \textit{if (1.1) is competitive.} \end{aligned}$$

Proof. Assume first that (1.1) is cooperative. Then $T^j(x) = \phi(2j\pi, 0, x)$ so by the chain rule and the fact that $T^j(x_0) = x_0$ we have

$$\Phi(2j\pi, x_0) = D_x \phi(2j\pi, 0, x_0) = D(T^j)(x_0).$$

The matrix on the left is assumed to be positive.

If (1.1) is competitive and $T^j(x_0) = x_0$ for $x_0 > 0$ then it follows that $\phi(t, 0, x_0)$ is defined for all $t \in R$. Hence T^{-j} is defined in a neighborhood of x_0. Since $T^{-j}(x_0) = x_0$ we have

$$\left[D(T^{-j})(x_0)\right] = \left[D(T^j)(x_0)\right]^{-1} = \left[\Phi(2j\pi, x_0)\right]^{-1} > 0.$$

We remark that if in Lemma H, irreducible is replaced by "ϕ has eventually positive derivatives" then 1.6 (a) and (b) are modified only by the need to raise the bracketed matrix to a sufficiently large positive integer power in order to have positivity.

Lemma H has important implications for the stability of $2\pi j$-periodic solutions of (1.1). The primary reason for the usefulness of Lemma H is that it allows the application of the Perron–Frobenius theory of positive matrices [7], [14].

THEOREM I. *If* $A \geqq 0$ *is an* $n \times n$ *matrix for which* $A^p > 0$ *for some positive integer* p *then* $\rho(A)$, *the spectral radius of* A, *is a positive simple eigenvalue of* A *strictly exceeding in modulus all other eigenvalues of* A. *Moreover, there exist* $x > 0$ *such that* $Ax = \rho(A)x$ *and* x *is the unique eigenvector of* A (*up to scalar multiple*) *which lies in* R^n_+.

Recall that a fixed point x_0 of a smooth map T is asymptotically stable if the spectral radius of $DT(x_0)$, $\rho(x_0) \equiv \rho(DT(x_0))$, is less than one and unstable if $\rho(x_0)$ is larger than one. If (1.1) is cooperative and irreducible, then Lemma H implies that the derivative of the Poincaré map T at x_0 satisfies $DT(x_0) > 0$ if $x_0 > 0$ and by Theorem I, $\rho(x_0)$ is a simple eigenvalue of $DT(x_0)$ with corresponding eigenspace spanned by a

positive vector. This property will prove to be important in our study of cooperative maps in §2. If (1.1) is competitive and irreducible, then the derivative of the inverse of the Poincaré map will have the property that its spectral radius is a simple eigenvalue with positive eigenvector.

We have now accumulated the results which will be essential in our study of periodic solutions of competitive and cooperative systems (1.1). Our approach will be to study the Poincaré map T. The cooperative case will be considered in greater detail since the competitive case can be treated by applying the results of the cooperative case to T^{-1}. We do, however, consider an important result for the competitive case where (1.1) satisfies the nonpositive divergence condition (1.4) (see §3). In addition, we will largely restrict our attention to fixed points of T and consider explicitly periodic points of T only briefly. The rationale for this is that the conditions we place on T in the results to follow will apply also to T^j for each positive integer j. Thus, by replacing T in the results of §2, by T^j one obtains results concerning periodic points. Having said this, we make some remarks concerning periodic points of T. First, in dimensions one and two, all periodic points in either the competitive or cooperative case are fixed points, i.e., all periodic solutions whose period is an integer multiple of 2π are in fact 2π-periodic. In one dimension this is trivial, all periodic scalar equations are cooperative and T is strictly increasing. In two dimensions the result is not so trivial. It is contained in results proved by de Mottoni and Schiaffino [10] and in greater generality by Hale and Somolinos [3] (see §4). Our second point is the following.

PROPOSITION J. *Let* (1.1) *be competitive or cooperative, let* x_0 *be a periodic point of period* $j>1$ *for* T (*i.e.* $\phi(t,0,x_0)$ *is* $2j\pi$*-periodic*), *and let* $x_i=T^i(x_0)(x_i(t)=\phi(t+2i\pi,0,x_0))$ $i=0,1,2,\cdots,j-1$. *Then no two distinct points* x_i *and* x_j *can be weakly related* (*no two distinct solutions* $x_i(t)$ *and* $x_j(t)$ *can be weakly related for any* t).

Proof. Consider the cooperative case (the competitive case may be treated by considering T^{-1}). If $x_r\leqq x_s$ for distinct integers $r,s\in\{0,1,\cdots,j-1\}$, say $r<s$, then on applying T^{j-r} to the inequality we obtain $x_0\leqq T^p(x_0)$, $p=s-r\in\{1,2,\cdots,j-1\}$. But then $x_0\leqq T^p(x_0)\leqq T^{2p}(x_0)\leqq\cdots\leqq T^{np}(x_0)\leqq\cdots$ and equality cannot occur in any inequality. On the other hand, the points $T^{np}(x_0)$, $n=1,2,\cdots$ all belong to $\{x_i\}_{i=0}^{j-1}$ so they must repeat, i.e., there exists $n,m,n-m>1$ such that

$$T^{mp}(x_0)\leqq T^{(m+1)p}(x_0)\leqq\cdots\leqq T^{np}(x_0)=T^{mp}(x_0).$$

This implies that

$$T^{mp}(x_0)=T^{(m+1)p}(x_0)=\cdots=T^{np}(x_0),$$

a contradiction.

For dimensions larger than two, cooperative or competitive systems (1.1) can have periodic solutions of minimal period $2\pi j$, $j>1$, as well as far more bizarre attractors. This is a consequence of a result of Smale [12] which states that any smooth vector field on the standard $(n-1)$-simplex in R^n_+ can be extended to a smooth competitive vector field on R^n.

Our final comment on periodic points is to point out that a positive stable 2π-periodic solution of a one-parameter family of cooperative irreducible systems can participate in only two types of bifurcation, namely, it can coalesce with another 2π-periodic solution and disappear at a critical value of the parameter or it can persist, throwing off another 2π-periodic solution as it loses stability at a critical value of the parameter. The other possible bifurcations are forbidden by Lemma H and Theorem I: the largest characteristic multiplier in modulus is necessarily positive.

We close this section with two results which are obvious modifications of similar results of Hirsch [5], [6] for the autonomous case. Let T be the Poincaré map for (1.1). If $x_0 \geqq 0$ we write $O^+(x_0)=\{T^n(x_0): n=0,1,2,\cdots\}$ for the forward orbit and $\Lambda(x_0)$ for the set of limit points of $O^+(x_0)$, that is, $\Lambda(x_0)=\{x: x=\lim_{i\to\infty} T^{n_i}x$, where $\{n_i\}_{i=1}^{\infty}$ is a subsequence of the natural numbers$\}$.

PROPOSITION K. *Let* (1.1) *be cooperative and* $O^+(x_0)$ *be a bounded orbit and suppose* $T^n(x_0) \leqq T^m(x_0)$ *for distinct nonnegative integers* n, m. *Then either* $O^+(x_0)$ *is a periodic orbit or* $\Lambda(x_0)$ *is a periodic orbit.*

Proof. If $T^n(x_0)=T^m(x_0)$, then $O^+(x_0)$ is a periodic orbit. Suppose $T^n(x_0) \leqq T^m(x_0)$ but equality does not hold. Then by Proposition J, $O^+(x_0)$ is not a periodic orbit. We assume $n>m$, i.e., $n=m+p$, the other case is similar. Then $T^p(T^m(x_0)) \leqq T^m(x_0)$ so $T^{lp}(T^m(x_0)) \leqq T^{(l-1)p}(T^m(x_0))$, $l=1,2,\cdots$. Since $O^+(x_0)$ is bounded, $y=\lim_{l\to\infty} T^{lp+m}(x_0)$ exists. By continuity of T, $T^p(y)=y$, and $\lim_{l\to\infty} T^{lp+m+r}(x_0) = T^r(y)$ for $r=1,2,\cdots,p-1$. It follows that $\Lambda(x_0)$ is the periodic orbit $\{T^r(y)\}_{r=0}^{p-1}$.

The following result generalizes Proposition J.

PROPOSITION L. *Let* (1.1) *be cooperative and* $O^+(x_0)$ *be a bounded orbit. Then no two elements of* $\Lambda(x_0)$ *can be related.*

Proof. We may assume $O^+(x_0)$ is not a periodic orbit by Proposition J. Suppose $x,y \in \Lambda(x_0)$ and $x<y$. It follows that there exist two distinct integers n and m such that $T^n(x_0)<T^m(x_0)$. By Proposition K, $\Lambda(x_0)$ is a periodic orbit. But then we have a contradiction to Proposition J.

If (1.1) is cooperative and irreducible, then "related" can be replaced by "weakly related" in Proposition L. This follows since $T\Lambda \subset \Lambda$ and if $x \leqq y$ then $T^n x < T^n y$ for some positive integer n.

2. Fixed points of cooperative maps: Invariant manifolds and basins of attraction. In this section we consider C^2 diffeomorphisms defined on a neighborhood of R_+^n which map $\dot{R}_+^n$ into itself and satisfy

(M) $0 \leqq x < y$ implies $Tx < Ty$, and

(SP) $x>0$ and $T(x)=x$ implies $DT(x)^p>0$ for some positive integer p depending on x.

We will call such maps cooperative. It will be assumed without further mention that all maps T in this section are cooperative but in one of our results we will assume the stronger monotonicity assumption

(SM) $0 \leqq x \leqq y$, $x \neq y$ and $y>0$ implies $T^p(x)<T^p(y)$ for large positive integers p.

Recall that if T is the Poincaré map of a C^2 cooperative system (1.1), then (M) holds. If, in addition, (1.1) is irreducible (or has eventually monotone derivatives) then (SM) and (P) hold for T by Corollary F and Lemma H respectively.

The focus of this section is to describe the manner in which the positive fixed points together with their domains of attraction and invariant manifolds are situated in R_+^n. We begin by observing that, in the interesting case, a cooperative map has a minimal fixed point though it may not be positive.

PROPOSITION 2.1. *Either* $|T^n x| \to \infty$ *as* $n \to \infty$ *for every* $x \geqq 0$ *or* T *has a minimal fixed point* $x_m=\lim_{n\to\infty} T^n 0$, *i.e.*, $Tx=x$ *implies* $x \geqq x_m$. $T^n x \to x_m$ *as* $n \to \infty$ *for all* $x \in [0, x_m]$.

Proof. We have $0 \leqq T0 \leqq T^2 0 \leqq \cdots \leqq T^n 0 \leqq \cdots$. The first alternative occurs if $|T^n 0| \to \infty$ while the latter occurs if $\{T^n 0\}_{n\geqq 0}$ is bounded. If $0 \leqq x \leqq x_m$ then $T^p 0 \leqq T^p x \leqq x_m$ for every p so $T^p x \to x_m$ as $p \to \infty$.

The following result will be useful. It follows immediately from (SM) but we prefer to assume only (M) and (SP).

LEMMA 2.2. *Let* $x_0>0$, $x\geqq 0$ *be distinct points and assume* $Tx_0=x_0$. *If* $x\geqq x_0$ ($x\leqq x_0$) *then* $T^p x>x_0$ ($T^p x<x_0$) *for large positive integers* p.

Proof. Suppose $x\geqq x_0$ and let $h=x-x_0\geqq 0$. Since $T^p(x_0+th)=x_0+tD(T^p)(x_0)h+o(t)$ as $t\to 0$, it follows that $t^{-1}(T^p(x_0+th)-x_0)=(DT(x_0)^p h+O(t))$ for small positive t so by (SP), $t^{-1}(T^p(x_0+th)-x_0)>0$ for small positive t, p as in (SP). Hence $T^p(x_0+th)>x_0$ for small t and $x_0<T^p(x_0+th)\leqq T^p(x_0+h)=T^p(x)$.

Lemma 2.2 implies that two nonnegative fixed points of T, at least one of which is positive, are related if they are weakly related. This observation will be important.

We begin our study of positive fixed points of T by establishing some notation. Let $x_0>0$ be a fixed point of T and let $B(x_0)=\{x\geqq 0: T^n x\to x_0 \text{ as } n\to\infty\}$. Let $B^+(x_0)=B(x_0)\cap(x_0+R^n_+)$ and $B^-(x_0)=B(x_0)\cap[0,x_0]$ denote respectively those points in $B(x_0)$ for which $x\geqq x_0$ and $x\leqq x_0$. Let $S^+(x_0)$ denote the boundary of $B^+(x_0)$ considered as a subset of the space x_0+R^n and $S^-(x_0)$ denote the boundary of $B^-(x_0)$ considered as a subset of the space $[0,x_0]$. We drop x_0 from the notation when no confusion will result. Each of the sets B, B^+, B^-, S^+ and S^- is mapped into itself by T. In the following result, some simple properties are derived concerning the sets B, B^+, B^-, S^+ and S^-. We do not assume x_0 is asymptotically stable but in that case, B contains a neighborhood of x_0.

PROPOSITION 2.3. *Let* $x_0>0$ *be a fixed point of* T. *Then*

(a) *If* $x_i\in B$, $i=1,2$, $x_1\leqq x_2$ *then* $[x_1,x_2]\in B$.

(b) *If* $x_2\in S^+$ *and* $x_0\leqq x_1<x_2$ *then* $x_1\in B^+$. *If* $x_1\in S^-$ *and* $x_1<x_2\leqq x_0$ *then* $x_2\in B^-$.

(c) *If* B^+ *contains the intersection of a ball centered at* x_0 *with* $x_0+R^n_+$ *then either* B^+ *is unbounded or* S^+ *is homeomorphic to the* $n-1$ *simplex and contains a fixed point of* T. *If* B^- *contains the intersection of a ball centered at* x_0 *with* $x_0-R^n_+$ *and if* $\partial R^n_+\cap[0,x_0]$ *is contained in the interior of* $[0,x_0]-B^-$ *relative to* $[0,x_0]$ *then* S^- *is homeomorphic to the* $n-1$ *simplex and contains a fixed point of* T.

Proof. (a) follows from $T^n x_1\leqq T^n x\leqq T^n x_2$, $n=1,2,\cdots$, which holds if $x_1\leqq x\leqq x_2$.

The first assertion in (b) follows from the observation that there exists a ball centered at x_2 with the property that all of its points x satisfy $x>x_1$. But one of these points necessarily lies in B^+ so, by (a), $x_1\in B^+$. The second assertion is proved similarly.

If B^+ is bounded, then S^+ is nonempty. In fact for every $h\geqq 0$, $|h|=1$ there is a unique (by (a)) value, t_h, of $t>0$ such that $x_0+t_h h\in S^+$. It is easy to see that $h\to t_h$ is continuous so S^+ is homeomorphic to the $n-1$ simplex. Since $T(S^+)\subset S^+$, the Brouwer fixed point theorem implies S^+ contains a fixed point of T. The assertion concerning S^- is proved in a similar fashion.

If (SM) holds for T then S^+ and S^- can be continuously parametrized by points of the set obtained by projecting S^+ (S^-) orthogonally along a standard basis vector onto an $(n-1)$-dimensional face of ∂R^n_+. For the statement of the result, we require the following notation. For $i=1,2,\cdots,n$, let $H_i(x_0)=\{x: x_i=(x_0)_i\}$, $H^+(x_0)=H_i(x_0)\cap(x_0+R^n_+)$, $H^-(x_0)=H_i(x_0)\cap(x_0-R^n_+)$ and $P_i: R^n\to H_i(x_0)$ be the orthogonal projection onto $H_i(x_0)$ along the ith standard bases vector e_i (see Fig. 2.1). We drop x_0 from the notation when it is clear to which fixed point we refer. In the following result we assume x_0 is an asymptotically stable fixed point in order to avoid a more lengthy statement. All that is required is that B^+ (B^-) contains the intersection of a ball about x_0 with $x_0+R^n_+$ ($x_0-R^n_+$).

PROPOSITION 2.4. *Let* (SM) *hold and* $x_0>0$ *be an asymptotically stable fixed point of* T. *If* $S^+\neq\phi$ (*i.e.*, $B^+\neq x_0+R^n_+$), *then no two distinct elements of* S^+ *can be weakly related nor can they have the same projection onto* H_i *along* e_i *for* $1\leqq i\leqq n$. *For* $1\leqq i\leqq n$,

$P_i(S^+)$ contains $[x_1, x_2]$ whenever $x_1 \leqq x_2$ belong to $P_i(S^+)$. There exists a continuous function $h_i^+ : P_i(S^+) \to R^+$, strictly decreasing in the sense that $x_1 \leqq x_2$, $x_1 \neq x_2$ implies $h_i^+(x_1) > h_i^+(x_2)$, such that $S^+ = \{x + h_i^+(x)e_i : x \in P_i(S^+)\}$.

If $\partial R_+^n \cap [0, x_0]$ is contained in the interior of $[0, x_0] - B^-$ relative to $[0, x_0]$ then no two distinct elements of S^- can be weakly related nor can they have the same projection onto H_i along e_i for $1 \leqq i \leqq n$. For $1 \leqq i \leqq n$, $P(S^-)$ contains $[x_1, x_2]$ whenever $x_1 \leqq x_2$ belong to $P_i(S^-)$. There exists a continuous function $h_i^- : P_i(S^-) \to R^-$, strictly decreasing in the sense that $x_1 \leqq x_2$, $x_1 \neq x_2$ implies $h_i^-(x_2) < h_i^-(x_1)$, such that $S^- = \{x + h_i^-(x)e_i : x \in P_i(S^-)\}$.

Proposition 2.4 implies that $P_i : S^+ \to P_i(S^+)$ is a homeomorphism, the inverse of which is the monotone map $x \to x + h_i^+(x)e_i$. Figure 2.1 below depicts the geometry of the sets S^+ and S^- for a two-dimensional competitive map T satisfying (SM).

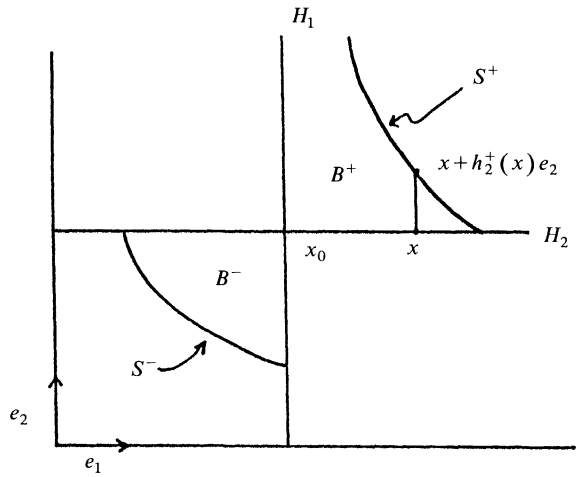

FIG. 2.1. *A possible configuration of the sets B^+, S^+, B^-, S^- for the stable fixed point x_0 of T which is consistent with Proposition* 2.4 *in two dimensions.*

Proof. Suppose $x_1, x_2 \in S^+$, $x_1 \neq x_2$ and $x_1 \leqq x_2$. Then $T^p x_1, T^p x_2 \in S^+$ and $x_0 \leqq T^p x_1 < T^p x_2$ by (SM). This contradicts Proposition 2.3 (b). Note that if $x_2 \in S^+$ and $x_0 \leqq x_1 \leqq x_2$ where x_1 is distinct from x_2 then the above argument shows (by Proposition 2.3 (b)) that $T^p x_1 \in B^+$ for large p and hence $x_1 \in B^+$. Suppose now that x_1 and x_2 are distinct points of S^+ and $P_i x_1 = P_i x_2$ for some i. Then it follows that x_1 and x_2 are related which contradicts the assertion proved above. Let $x_j = P_i y_j$ where $y_j \in S^+$, $j = 1, 2$, are distinct points. Suppose $x_1 \leqq x_2$ and write $y_j = x_j + h_i^+(x_j)e_i$, $j = 1, 2$, where $h_i^+(x_j) \geqq 0$ since $x_j \leqq y_j$, $j = 1, 2$. If $h_i^+(x_1) \leqq h_i^+(x_2)$ then clearly $y_1 \leqq y_2$ contradicting the assertion proved above. Hence $h_i^+(x_1) > h_i^+(x_2)$ proving h_i^+ is strictly decreasing. Note that if $x_2 \neq y_2$ then $x_2 \leqq y_2$ so $x_2 \in B^+$. If $x \in [x_1, x_2]$ is distinct from x_2, then it follows that $x \in B^+$. If $x \notin P_i(S^+)$ then $x + te_i \in B^+$ for all $t > 0$. But $y_1 = x_1 + h_i^+(x_1)e_1 \leqq x + te_1$ for large t, implying that $y_1 \in B^+$ (Proposition 2.3 (a)). This contradiction proves $x \in P_i(S^+)$ whenever $x_1 \leqq x \leqq x_2$ and $x_1, x_2 \in P_i(S^+)$. All that remains to be proved is the continuity of h_i^+. Let $x_n \to x$ as $n \to \infty$ where x_n, $x \in P_i(S^+)$, $n = 1, 2, \cdots$. Let $h_i^+(x_{n_j}) \to \alpha \in [0, \infty)$ as $n_j \to \infty$ where $\{x_{n_j}\}$ is a subsequence of $\{x_n\}$. Since S^+ is closed, $x + \alpha e_i \in S^+$. But then $\alpha = h_i^+(x)$. One sees that $\limsup_{n \to \infty} h_i^+(x_n) < \infty$ as follows. If $t > h_i^+(x)$ then $x + te_i \notin S^+ \cup B^+$. Since $S^+ \cup B^+$ is closed, it follows that $x_n + te_i \notin S^+ \cup B^+$ for all large n. One then must conclude that $h_i^+(x_n) < t$ for these large n. It follows that h_i^+ is continuous. The arguments for S^- are omitted since they parallel those above.

We now turn our attention to fixed points $x>0$ of T satisfying $\rho(x)>1$. Recall, $\rho(x)=\rho(DT(x))$ is the spectral radius of $DT(x)$. Such fixed points are unstable. The following theorem is one of the main results of this paper. In large part, its proof is contained in [13].

THEOREM 2.5. *Let $x_1>0$ be a fixed point of T with $\rho_1=\rho(x_1)>1$ and $DT(x_1)e_1=\rho_1 e_1$ where $e_1>0$. Then there exists a C^1 function $y_+:[0,\infty)\to \dot{R}^n_+$ satisfying*

(A_+) $y_+(t)=x_1+te_1+O(t^2)$ *as* $t\to 0$.

(B_+) $0\leqq t_1<t_2$ *implies* $y_+(t_1)<y_+(t_2)$.

(C_+) $y_+(t)=T(y_+(\rho_1^{-1}t))$, $t\geqq 0$.

(D_+) *Either* $\lim_{t\to\infty}|y_+(t)|=\infty$ *or* $\lim_{t\to\infty}y_+(t)=x_2>x_1$. *In the latter case,* $Tx_2=x_2$, $\rho(x_2)\leqq 1$ *and* $\lim_{t\to\infty}(y'_+(t)/|y'_+(t)|)=e_2>0$ *where* $DT(x_2)e_2=\rho(x_2)e_2$.

(E_+) *If* $\lim_{t\to\infty}|y_+(t)|=\infty$ *then* $|T^nx|\to\infty$ *as* $n\to\infty$ *for all* $x\geqq x_1$, $x\neq x_1$.
If $\lim_{t\to\infty}y_+(t)=y_2$ *then* $T^nx\to x_2$ *as* $n\to\infty$ *for all* $x\neq x_1$, $x\in[x_1,x_2]$.

There exists a C^1 function $y_-:[0,\infty)\to\dot{R}^n_-$ satisfying

(A_-) $y_-(t)=x_1-te_1+O(t^2)$ *as* $t\to 0$.

(B_-) $0\leqq t_1<t_2$ *implies* $y_-(t_2)<y_-(t_1)$.

(C_-) $y_-(t)=T(y_-(\rho_1^{-1}t))$, $t\geqq 0$.

(D_-) $\lim_{t\to\infty}y_-(t)=x_0\geqq 0$ *exists,* $Tx_0=x_0$ *and* $\rho(x_0)\leqq 1$. *If $DT(x_0)$ satisfies* (SP) (*e.g.* $x_0>0$) *then* $\lim_{t\to\infty}(y'_-(t)/|y'_-(t)|)=e_0>0$ *where* $DT(x_0)e_0=\rho(x_0)e_0$.

(E_-) $x\neq x_1$, $x\in[x_0,x_1]$ *implies* $T^nx\to x_0$ *as* $n\to\infty$.

Essentially, Theorem 2.5 asserts that a positive unstable fixed point x_1 is joined by two smooth monotone curves, each invariant under T, to two semi-stable fixed points x_0 and x_2 where $0\leqq x_0<x_1<x_2\leqq\infty$. Moreover, the basin of attraction of x_0 includes $[x_0,x_1]$ except for x_1 and the basin of attraction of x_2 includes $[x_1,x_2]$ except for x_1. The two fixed points x_0 and x_2 are asymptotically stable if they are hyperbolic. Observe that if all orbits $O^+(x)$ are bounded then $x_2=\lim_{t\to\infty}y_+(t)$ is finite.

The functional equation which $y_+(t)$ satisfies can be interpreted as follows. Let $C^+=\{y_+(t):t\geqq 0\}$ be the invariant curve joining x_1 to x_2 (or infinity). Then (C_+) asserts that the following diagram of mappings commutes

$$\begin{array}{ccc} C^+ & \xrightarrow{\quad T\quad} & C^+ \\ {\scriptstyle y^+}\uparrow & & \uparrow{\scriptstyle y^+} \\ [0,\infty) & \xrightarrow[t\mapsto\rho_1 t]{} & [0,\infty) \end{array}.$$

In other words, the parametrization y_+ of C^+ affects a linearization of T on C^+. We write C^- for the curve parametrized by y_-. Similar comments apply to C^-.

Proof. As mentioned above, most of the assertions of Theorem 2.5 are contained in [13, Thm. 2.2]. We consider here only those assertions which are not contained in [13]. Of the assertions concerning $y_+(t)$, the strict inequality $y_+(t_1)<y_+(t_2)$ in (B_+) requires proof. In [13] we proved $y_+(t_1)\leqq y_+(t_2)$. The stronger inequality certainly holds for small t by virtue of (A_+). But then, by (C_+), $y_+(t_2)-y_+(t_1)=T^n(y_+(\rho_1^{-n}t_2))-T^n(y_+(\rho_1^{-n}t_1))$ for $n=1,2,\cdots$ and since T^n preserves the strong inequality and $y_+(\rho_1^{-n}t_2)>y_+(\rho_1^{-n}t_1)$ for large n, we deduce that $y_+(t_2)>y_+(t_1)$. The assertions concerning $y_-(t)$ follow for the most part from [13] and the above (apply [13, Thm. 2.2] to $F(x)=x_1-T(x_1-x)$). One assertion which does not follow from [13] is that $y_-(t)$ exists satisfying (A_-), (B_-), (C_-) for all $t>0$, that is, the assertion that $t_0=+\infty$ of [13, Thm. 1.1 (iv)] needs to be verified. Assume $t_0<\infty$, i.e., assume y_- is defined on $[0,t_0)$ satisfying (A_-), (B_-) and (C_-) with $y_-(t)\in\dot{R}^n_+$ holding for $0\leqq t<\rho_1^{-1}t_0$. Since

t_0 is maximal with this property [13, Thm. 1.1(iv)], we have $y_-(\rho_1^{-1}t_0)\in\partial R_+^n$, but then since $y_-(\rho_1^{-1}t_0)=T(y_-(\rho_1^{-2}t_0))$ by continuity of T and $y_-(\rho_1^{-2}t_0)>0$ we have a contradiction to the invariance of $\dot{R}_+^n$ under T. It follows that $t_0=\infty$ and that $0<y_-(t)<x_1$ for $t>0$. Since $y_-(t)$ is bounded below $\lim_{t\to\infty}y_-(t)=x_0\geqq 0$ exists. $Tx_0=x_0$ by continuity of T. (E_-) follows from $\lim_{t\to\infty}y_-(t)=x_0$ as in [13]. If $x_0>0$ then $\rho(x_0)\leqq 1$ for otherwise Theorem 2.5 applied to x_0 yields a contradiction to (E_-). If $x_0\in\partial R_+^n$ one must work harder to show $\rho(x_0)\leqq 1$. In this case we know that $DT(x_0)$ is nonsingular and $DT(x_0)\geqq 0$. By a simple argument involving the normal form of a reducible matrix, we can extend [14, Thm. 2.7] to conclude that there exists a nonzero vector $v\geqq 0$ such that $DT(x_0)v=\rho(x_0)v$ and v does not lie in the range of $DT(x_0)-\rho(x_0)I$. Now one can apply [13, Thm. 1.1] to conclude that if $\rho(x_0)>1$ there exists a monotone curve $z:[0,\infty)\to[x_0,x_1]$, $z(t)=x_0+tv+O(t^2)$ as $t\to 0$, $z(t_1)\leqq z(t_2)$ if $t_1\leqq t_2$ and satisfying (ii), (iii) and $z(t)\to x_1$ as $t\to\infty$. Note (iii) implies that $t_0=\infty$, $z(t)\in[x_0,x_1]$ and $z(\cdot)$ is monotone. Again we have contradicted (E_-).

The positioning of the stable manifold of x_1, $W^s(x_1)=\{x\in\dot{R}_+^n: T^n(x)\to x_1\}$, if nontrivial, was considered by Selgrade [11] for cooperative autonomous systems. Below we state the analogue of this result for mappings which follows immediately from Theorem 2.5.

PROPOSITION 2.6. *Assume x_1 is a hyperbolic, positive fixed point of T with $\rho(x_1)>1$ but assume part of the spectrum of $DT(x_1)$ lies inside the unit circle in the complex plane. Then*

$$W^s(x_1)\cap\left[(x_1+R_+^n)\cup(x_1-R_+^n)\right]=\{x_1\}$$

i.e., no point of $W^s(x_1)$ is weakly related to x_1 other than x_1 itself.

Note that if x is a hyperbolic positive fixed point of the Poincaré map for a cooperative system (1.1) which satisfies the nonpositive divergence condition (1.4) and if $\rho(x)>1$ then it follows immediately that $W^u(x)$ is nontrivial in case $n>1$ since $\det DT(x)\leqq 1$.

If in Theorem 2.5 we make the generic assumption that x_0 and x_2 (if it exists) are hyperbolic fixed points of T, then it follows that they are asymptotically stable. Even in the case that, e.g., $\rho(x_2)=1$ one can obtain information about the stability of x_2. The reason for this is that x_2 possesses a one-dimensional monotone, center manifold which is tangent at x_2 to a positive vector. Our results are contained in the following.

THEOREM 2.7. *Let x_2 be a positive fixed point of T and suppose $\rho(x_2)=1$. Then exactly one of the following holds*:

(i) *T has fixed points $x>x_2$ arbitrarily near x_2.*

(ii) *$B^+(x_2)$ contains the intersection of a ball centered at x_2 with $x_2+R_+^n$.*

(iii) *There is a C^1 curve $C^+\subset x_2+\dot{R}_+^n$ emanating from x_2 which coincides near x_2 with a portion of a center manifold of T at x_2. C^+ is a strictly increasing curve ($x\neq y$, x, $y\in C^+$ then either $x<y$ or $y<x$) which is invariant under T and $Tx>x$ for every $x\in C^+$, $x\neq x_2$. Either C^+ is unbounded in which case $|T^nx|\to\infty$ as $n\to\infty$ for every $x\geqq x_2$ distinct from x_2 or C^+ is bounded and there exists a unique point x_3 satisfying $x_3=\lim_{n\to\infty}T^nx$, independent of $x\in C^+$ distinct from x_2. Moreover x_3 is a fixed point of T, $\rho(x_3)\leqq 1$, and $x_3=\lim_{n\to\infty}T^nx$ for every $x\in[x_2,x_3]$ distinct from x_2.*

Some remarks concerning Theorem 2.7 are in order. In order that its statement not be prohibitively long, Theorem 2.7 describes the situation for $x_2+R_+^n$. An analogous set of alternatives holds for $x_2-R_+^n$ (note x_2 is not necessarily the x_2 of Theorem 2.5). The main difference is that for the analogous assertion corresponding to (iii), $C^-\subset x_2-\dot{R}_+^n$ cannot be unbounded and hence must connect x_2 to a fixed point $x_1<x_2$.

In case x_2 arises from Theorem 2.5 (D_+) and if (ii) of Theorem 2.7 holds, then it follows from the center manifold theorem [1], [9] that x_2 is asymptotically stable, that is, $B(x_2)$ contains a neighborhood of x_2. A similar statement can be made concerning x_0 of Theorem 2.5.

Of course, a one-dimensional center manifold for T containing x_2 exists regardless of which of (i)–(iii) hold. It is most useful in case (iii). It is well known [9] that, in general, there is not a unique center manifold for T corresponding to the fixed point x_2. Our proof of (iii) actually shows that each local center manifold can be extended for $x \geqq x_2$ to a curve C^+. Thus C^+ is not unique. However, Theorem 2.7 implies that if one C^+ is unbounded, then all are unbounded and if one C^+ joins x_2 to x_3 then all such C^+ join x_2 to x_3.

Proof. Suppose (i) does not hold. By (P) and Theorem I there is a positive vector e such that $DT(x_2)e = e$. Since one is a simple eigenvalue and there are no other eigenvalues of $DT(x_2)$ on the unit circle in the complex plane, it follows from the center manifold theorem [1], [9] that there is a C^1, one-dimensional center manifold, tangent at x_2 to e which is locally invariant under T. It follows that we may find a C^1 parametrization (e.g. by arclength) $\hat{x}:[0,\varepsilon) \to x_1 + \dot{R}^n_+$, $\hat{x}(0) = x_2$, $\hat{x}'(0) = e$, of a portion of a center manifold which lies in $x_2 + \dot{R}^n_+$. We assume ε has been chosen so small that $x'(t) > 0$ on $[0,\varepsilon)$. Since T satisfies (M) and the center manifold is locally invariant for T, there exists $\varepsilon_0 \leqq \varepsilon$ sufficiently small so that for each $t \in (0,\varepsilon_0)$ there exists a unique $s \equiv h(t) \in (0,\varepsilon)$ such that $T(x(t)) = x(s)$. One easily sees that $h:[0,\varepsilon_0) \to [0,\varepsilon)$ is strictly increasing and C^1. Our assumption that (i) does not hold implies that either $h(t) < t$ for $0 < t < \varepsilon_0$ or $h(t) > t$ for $0 < t < \varepsilon_0$. In the first case, it is clear from the monotonicity of T that $T^n(x(t)) \to x_2$ as $n \to \infty$ monotonely for every fixed $t \in [0,\varepsilon_0)$. It follows that $B^+(x_2)$ contains $x(t)$ for $0 \leqq t < \varepsilon_0$. It must also contain $[x_2, x]$ for each $x \in B^+(x_2)$ by a familiar argument. Since $x(t) > x_2$ for $0 < t < \varepsilon_0$, we see that the first case, namely that $h(t) < t$, $0 < t < \varepsilon_0$ implies that (ii) holds. The last assertion of (ii) follows from Proposition 2.3.

We now show that the second possibility, $h(t) > t$, $0 < t < \varepsilon_0$ implies that (iii) holds. Fix $t_0 \in (0,\varepsilon_0)$ and for each $n = 0,1,2,\cdots$, define $\hat{x}_n:[0,t_0] \to x_2 + R^n_+$ by $\hat{x}_n(t) = T^n(\hat{x}(t))$, $C_n = \{x : x = \hat{x}_n(t),\ 0 \leqq t \leqq t_0\}$ and $C^+ = \bigcup_{n \geqq 0} C_n$. Observe that $\hat{x}_n$ is C^1 and increasing for each n since $\hat{x}$ is C^1 and increasing and T is C^2 and satisfies (M). We show that $C_0 \subsetneqq C_1 \subsetneqq C_2 \subsetneqq \cdots \subsetneqq C_n \cdots$. Since $C_n = T^n(C_0)$ it suffices to show that $C_0 \subsetneqq C_1$. But $C_0 = \{x : x = \hat{x}(t),\ 0 \leqq t \leqq t_0\}$ and $C_1 = \{x : x = T(\hat{x}(t)),\ 0 \leqq t \leqq t_0\} = \{x : x = \hat{x}(h(t)),\ 0 \leqq t \leqq t_0\} = \{x : x = \hat{x}(t),\ 0 \leqq t \leqq h(t_0)\}$ where $h(t_0) > t_0$. It follows that C^+ is a C^1 curve. Let $x \neq x_2$, $x \in C^+$. Then $x = T^n(\hat{x}(t))$ for some $n \geqq 0$ and $t \in [0,t_0]$ so $Tx = T^{n+1}(\hat{x}(t)) = T^n\hat{x}(h(t)) > T^n(\hat{x}(t)) = x$ since h, $\hat{x}$ and T are increasing. Let $y \neq x_2$, $y \in C^+$, be distinct from x. Then there exists an integer m and distinct values of t, t_x and t_y such that $x = T^m(\hat{x}(t_x))$ and $y = T^m(\hat{x}(t_y))$. Since t_x and t_y are related, it follows that x and y are related. If C^+ is unbounded, then it follows that $|T^n x| \to \infty$ as $n \to \infty$ for $x \in C^+$ distinct from x_2. We want to show that this also holds for $x \geqq x_2$ distinct from x_2. Let $x \geqq x_2$ be distinct from x_2. By Lemma 2.2 there is a positive integer n such that $T^n x > x_2$. It then follows that there exists $y \in C^+$, $y \neq x_2$, such that $T^n x > y$ and hence $T^{n+p}x > T^p y$. The desired conclusion follows from $|T^p y| \to \infty$ as $p \to \infty$. If, on the other hand, C^+ is bounded and $x \in C^+$, $x \neq x_2$, then $x < Tx < T^2x < \cdots$ so $\lim_{n\to\infty} T^n x$ exists. Let $y \in C^+$ be distinct from x_2 and x. If $y > T^n x$ for every n then $y \geqq \lim_{n\to\infty} T^n x$. Since $\lim_{n\to\infty} T^n x$ is a fixed point of T it follows that C^+ contains a fixed point distinct from x_2 which contradicts that $Tx > x$ for $x \in C^+$, $x \neq x_2$. Hence it must be the case that $y < T^n x$ for some integer n and so $\lim_{n\to\infty} T^n y \leqq \lim_{n\to\infty} T^n x$. The symmetry in the argument above implies $\lim T^n x \leqq \lim T^n y$ and so

the limit, x_3, is independent of $x \in C^+$, $x \neq x_2$. By continuity of T, x_3 is a fixed point. Let $x \in [x_2, x_3]$, $x \neq x_2$. By Lemma 2.2 and monotonicity of T it follows that $x_2 < T^n x \leqq x_3$ for large n. But then, for such an n, $T^n x > y$ for some $y \in C^+$ so $T^p y < T^{n+p} \leqq x_3$. Since $T^p y \to x_3$ it follows that $T^n x \to x_3$.

Consider how the results of this section can be combined to give a geometric description of the set of fixed points of a cooperative map T, their domains of attraction and their associated invariant manifolds. We briefly sketch such a description in the case that all fixed points are hyperbolic, there are no unbounded orbits and x_m, the minimal fixed point, is positive. If $x_m > 0$, it follows from Theorem 2.5 that $\rho(x_m) < 1$ so x_m is asymptotically stable. If $B^+(x_m) = x_m + R^n_+$ then $B(x_m) = R^n_+$ by Proposition 2.3, x_m is a global attractor. If $B^+(x_m) \neq x_m + R^n_+$, one expects that the boundary $S^+(x_m)$ will contain fixed points of T. If $B^+(x_m)$ is bounded then by Proposition 2.3, $S^+(x_m)$ will contain at least one fixed point. Such a fixed point x_1 must be unstable with $\rho(x_1) > 1$. In case $\rho(x_1)$ is the only point of the spectrum of $DT(x)$ exceeding one in modulus, then the $(n-1)$-dimensional stable manifold $W^s(x_1)$ must form part of $S^+(x_m)$. Every fixed point of T on $S^+(x_m)$ must be connected to x_m by an invariant monotone curve C^- emanating from the fixed point and belonging to $B^+(x_m)$. The curve C^- must be tangent at x_m to the positive eigenvector for $DT(x_m)$ corresponding to the simple eigenvalue $\rho(x_m)$. If there is more than one fixed point on $S^+(x_m)$, each of the curves C^- are thus tangent at x_m. Each fixed point x_1 of T on $S^+(x_m)$ is connected to another asymptotically stable fixed point $x_2 > x_1$ by an invariant monotone curve C^+ emanating from x_1 and contained in $B^-(x_2)$ by Theorem 2.5. Moreover, $[x_m, x_1] \backslash \{x_1\} \subset B^+(x_m)$ for every such fixed point $x_1 \in S^+(x_m)$ and $[x_1, x_2] \backslash \{x_1\} \subset B^-(x_2)$. It may happen that more than one fixed point on $S^+(x_m)$ is connected by a C^+ to the same fixed point x_2. In that case, each C^+ connecting a fixed point on $S^+(x_m)$ to x_2 is tangent at x_2 to the positive eigenvector for $DT(x_2)$.

Now each of these secondary stable fixed points x_2 can take the place of x_m in the previous scenario. Thus one obtains a cascading sequence of these stable-unstable-stable cells forming a tree-like structure with x_m at its base. In §4 we will obtain additional information for two-dimensional cooperative maps which will allow us to describe completely their "phase portrait".

3. Fixed points of competitive maps. In this brief section we examine how the fixed points of competitive maps and their invariant manifolds are situated by applying the results of the previous section to the inverse map. A map T will be called a competitive map if T is a C^2 diffeomorphism defined on a neighborhood of R^n_+ satisfying $Tx > 0$ if and only if $x > 0$ and

(MI) $x_1, x_2 \geqq 0$ and $Tx_1 < Tx_2$ imply $x_1 < x_2$

and

(SPI) $x > 0$ and $T(x) = x$ implies $DT(x)^{-p} > 0$ for some positive integer p depending on x.

(MI) and (SPI) will be assumed without further mention but we will briefly note a result requiring the stronger monotonicity assumption

(SMI) $x_1 \geqq 0$, $x_2 > 0$ and $Tx_1 \leqq Tx_2$ implies $x_1 < x_2$.

If T is the Poincaré map of a C^2 competitive system (1.1) then (MI) holds. If, in addition, (1.1), is irreducible then (SPI) and (SMI) hold for T by Corollary F and Lemma H respectively. Of course, (MI), (SPI) and (SMI) imply that T^{-1}, the inverse of T, satisfies (M), (SP) and (SM) of the previous section except that T^{-1} is defined only in a neighborhood of $T(R^n_+)$. In case T is the Poincaré map of a competitive system (1.1) then Corollary G implies that $[0, x] \subset T(R^n_+)$ whenever $x \in T(R^n_+)$.

We note that competitive maps necessarily fix the origin as might be expected from the remark following Corollary C.

PROPOSITION 3.1. *Let T be a competitive map. Then $T0=0$. If x_1 and x_2 are distinct fixed points of T, at least one of which is positive, then $x_1 \leqq x_2$ implies $x_1 < x_2$.*

Proof. $T(\partial R^n_+) \subset \partial R^n_+$ together with the smoothness of T and the fact that $DT(0)$ is nonsingular imply $T0=0$. The second assertion follows from Lemma 2.2 applied to T^{-1}.

As previously mentioned, the results of the previous section concerning cooperative maps can be immediately applied to T^{-1} to obtain results for competitive maps. It is not our intention to translate each of the results of the previous section to a corresponding result for competitive maps. Instead, we select a few such results which are likely to be of interest for competitive Poincaré maps. Keep in mind as we proceed that if T is a competitive map and $Tx=x$ then T^{-1} is defined in a neighborhood of x, $T^{-1}x=x$ and the spectrum of $D(T^{-1})(x)$ is obtained from the spectrum of $DT(x)$ by inverting: $\lambda \to \lambda^{-1}$. If x is a positive fixed point of T, let $\mu(x)=[\rho(D(T^{-1}))(x)]^{-1}$. By (SPI) and Theorem I, $\mu(x)^{-1}$ is a simple eigenvalue of $D(T^{-1})(x)=(DT(x))^{-1}$ with positive eigenvector and all other eigenvalues have smaller modulus. It follows that $\mu(x)$ is the (strictly) smallest eigenvalue of $DT(x)$ in modulus and it has a positive corresponding eigenvector.

If x is a positive fixed point of T with $\mu(x)>1$ then, of course, x is a totally unstable fixed point of T and it is an asymptotically stable fixed point of T^{-1}. Consequently, Proposition 2.3 (and Proposition 2.4 if (SMI) holds) can be applied to obtain information concerning the domain of repulsion for x and its boundary. It is much more likely, however, that $\mu(x)<1$. In fact, if a competitive system (1.1) has a nonpositive divergence ((1.4) holds) then every positive fixed point of its Poincaré map satisfies $\mu<1$.

LEMMA 3.2. *If $n>1$ and $x>0$ is a fixed point of T and $\det(DT(x)) \leqq 1$ then $\mu(x)<1$.*

Proof. If $\mu(x) \geqq 1$ then since $\mu(x)$ is the (strictly) smallest eigenvalue it follows that the products of the eigenvalues of $DT(x)$ with corresponding multiplicities strictly exceeds ($n>1$) one which contradicts $\det(DT(x)) \leqq 1$.

If $\mu(x)<1$ for a positive fixed point x of T then the spectral radius of $D(T^{-1})(x)$ exceeds one and Theorem 2.5 can be applied to T^{-1} to obtain the following result.

THEOREM 3.3. *Let x_1 be a positive fixed point of T with $\mu_1=\mu_1(x_1)<1$ and $DT(x_1)e_1=\mu_1 e_1$ where $e_1>0$. Then there exists t_0, $0<t_0 \leqq \infty$, and a C^1 function $y_+ : [0,t_0) \to \dot{R}^n_+$ satisfying*

(A_+) *$y_+(t)=x_1+te_1+O(t^2)$ as $t \to 0$.*

(B_+) *$0<t_1<t_2<t_0$ implies $y_+(t_1)<y_+(t_2)$.*

(C_+) *$T(y_+(t))=y_+(\mu_1 t)$, $0<t<t_0$.*

(D_+) *Either $\lim_{t \to t_0+}|y_+(t)|=\infty$ or $\lim_{t \to t_0+} y_+(t)=x_2$. In the latter case, $t_0=\infty$, $Tx_2=x_2$, $\mu(x_2) \geqq 1$ and $\lim_{t \to \infty}(y'_+(t)/|y'_+(t)|)=e_2>0$ where $DT(y_2)e_2=\mu(x_2)e_2$.*

(E_+) *If $\lim_{t \to t_0+}|y_+(t)|=\infty$ then for all $x \geqq x_1$, $x \neq x_1$, either there exists N such that $T^{-\bar{n}}x \in T(R^n_+)$, $0 \leqq \bar{n} \leqq N$ and $T^{-(\bar{n}+1)}x \notin T(R^n_+)$ or $T^{-\bar{n}}x \in T(R^n_+)$ for all $\bar{n}$ and $|T^{-\bar{n}}x| \to \infty$ as $\bar{n} \to \infty$. If $\lim_{t \to \infty} y_+(t)=x_2$ then $T^{-\bar{n}}x \to x_2$ as $\bar{n} \to \infty$ for all $x \neq x_1$, $x \in [x_1,x_2]$.*

There exists a C^1 function $y_- : [0,\infty) \to \dot{R}^n_+$ satisfying

(A_-) *$y_-(t)=x_1-te_1+O(t^2)$ as $t \to 0$.*

(B_-) *$0 \leqq t_1<t_2$ implies $y_-(t_2)<y_-(t_1)$.*

(C_) $T(y_-(t))=y_-(\mu_1 t)$, $t\geqq 0$.

(D_) $\lim_{t\to\infty} y_-(t)=x_0\geqq 0$ *exists,* $Tx_0=x_0$ *and* $\mu(x_0)\geqq 1$. *If* $DT(x_0)$ *satisfies* (SPI) (*e.g.* $x_0>0$) *then* $\lim_{t\to\infty}-(y'_-(t)/|y'_-(t)|)=e_0>0$ *where* $DT(x_0)e_0=\mu(x_0)e_0$.

(E_) $x\neq x_1$, $x\in[x_0,x_1]$ *implies* $T^{-n}x\to x_0$ *as* $n\to\infty$.

As an immediate corollary of Theorem 3.3 (E_) observe that no positive asymptotically stable fixed point x_1 of T can exist unless T possesses a corresponding fixed point $x_0\leqq x_1$ which satisfies $\mu(x_0)\geqq 1$. Ignoring the nongeneric possibility $\mu(x_0)=1$, one may say that x_0 is a repeller: all of the eigenvalues of the Jacobian at x_0 exceed unity in modulus.

In view of the fact that $\mu(x)<1$ is typical for a positive fixed point (and necessary if $\det DT(x)\leqq 1$), Theorem 3.3 will play a more fundamental role for competitive maps than its counterpart, Theorem 2.5, played for cooperative maps. The assertions (A_)–(E_) will be most useful in general. Let us write $C^+=\{y_+(t):0\leqq t<t_0\}$ and $C^-=\{y_-(t):t\geqq 0\}$ for the two invariant curves the existence of which is asserted in Theorem 3.3. We call special attention to the fact that assertions made in (E_+) and (E_) concern T^{-1} and not T itself. For example, in (E_) the set $[x_0,x_1]$ is mapped into itself by T^{-1} and the orbit, under T^{-1}, of every point except x_1 of $[x_0,x_1]$ limits on x_0 but $[x_0,x_1]$ is not necessarily mapped into itself by T. It is also important to reemphasize that when either of the curves C^+ or C^- connect x_1 to a fixed point x_2 or x_0, then that fixed point must be quite unstable since the smallest eigenvalue of the Jacobian must be greater than or equal to one. One might expect that for a typical application there are few such ($\mu\geqq 1$) unstable fixed points. Indeed, suppose that T is the Poincaré map for a competitive irreducible system satisfying the nonpositive divergence condition (1.4). Then by Lemma 3.2, every positive fixed point x of T has $\mu(x)<1$. This observation excludes the possibility that $\lim_{t\to\infty} y_+(t)=x_2$ in (D_+) and that $x_0>0$ in (D_) of Theorem 3.3. One can, in fact, say slightly more.

PROPOSITION 3.4. *Let* T *be a competitive map with the property that* $\mu(x)<1$ *for each of its positive fixed points. Then no pair of positive fixed points of* T *can be weakly related and every positive fixed point* x_1 *is joined by the curve* C^- *to a fixed point* x_0 *of* T *on* ∂R^n_+. *Moreover,* $\mu(x_0)\geqq 1$ *and* $T^{-\bar n}x\to x_0$ *as* $\bar n\to\infty$ *for every* $x\in[x_0,x_1]$ *distinct from* x_1.

Proof. If $0<x_0\leqq x_2$ where x_0 and x_2 are fixed points of T, then $x_0<x_2$ by Proposition 3.1 and Theorem 3.2 (D_+) applied to x_0 implies the existence of a fixed point $x_1\in[x_0,x_2]$ with $\mu(x_1)\geqq 1$. Indeed, the curve C^+ obtained from Theorem 3.2 applied to x_0 must satisfy $C^+\subset[x_0,x_2]$ by Remark 3 following Theorem 1.1 in [13]. The first assertion is established. The second assertion is a restatement of Theorem 3.2 (E_).

Anyone who has worked with competitive systems (1.1) in applications knows that typically each face $H_I^+=\{x\geqq 0:x_i=0,\ i\in I\}$, $I\subseteq\{1,2,\cdots,n\}$, making up the boundary of R^n_+ is invariant under (1.1). In such a case, the Poincaré map will map each H_I^+ into itself. We will call a competitive map T "competitive in each face" if T is a competitive map when restricted to each face H_I^+ (where $\leqq$ and $<$ are now relative to H_I). Of course, each of the results of this section may be applied to each of the faces H_I^+ if T is competitive in each face. For example, if T is competitive in each face, then no face H_I^+ can have a fixed point x_1 belonging to the interior of H_I^+ (relative to H_I) which is asymptotically stable for $T|_{H_I^+}:H_I^+\to H_I^+$ unless $T|_{H_I^+}$ possesses a fixed point $x_0\leqq x_1$ in H_i^+ which satisfies $\mu_{H_I^+}(x_0)\geqq 1$ where $\mu_{H_I^+}(x_0)$ is the smallest eigenvalue of $D(T|_{H_I^+})(x_0)=DT(x_0)|_{H_I^+}:H_I\to H_I$.

If T is competitive in each face, then each of the coordinate axes is invariant under T. It follows that $DT(0)$ is a diagonal matrix. In many applications to ecology where competitive systems arise, each coordinate of x represents the population density of a particular organism and typically each organism is assumed to be viable in the sense that if none of its competitors are present, then it will grow, at least when it is scarce. The mathematical translation of this last statement is that if $DT(0) = \operatorname{diag}\{\lambda_1, \lambda_2, \cdots, \lambda_n\}$ then $\lambda_i \geqq 1$, $1 \leqq i \leqq n$. Typically, one expects 0 to be the only fixed point of T for which $\mu \geqq 1$ and thus all fixed points of T will be connected to 0 by a curve C^-.

An immediate corollary of Theorem 3.3 is the following.

PROPOSITION 3.5. *Assume x_0 is a hyperbolic, positive fixed point of a competitive map T with $\mu(x_0) < 1$ and $\rho(DT(x_0)) > 1$. Then no point of the unstable manifold $W^u(x_0) = \{x : T^{-\bar{n}}x \to x_0 \text{ as } \bar{n} \to \infty\}$ is weakly related to x_0 except x_0 itself.*

In future work we intend to consider in greater detail the dynamics generated by maps which are competitive in each face in low dimensions ($n = 2$ and 3).

4. Cooperative planar maps. In this section we continue our investigation of cooperative maps, focusing on the two-dimensional case. The results obtained in this section may be applied to the inverse of a competitive planar map.

In addition to the results of §2, we will show that the dynamics of a planar orientation preserving cooperative map are "trivial" in the sense that all bounded orbits tend to fixed points. This result was obtained by de Mottoni and Schiaffino [10] for competitive maps and we essentially reproduce their proof with minor modifications. We also show that the center-stable manifold of every fixed point contains two monotone invariant curves each of which either tends to infinity or limits on another fixed point of T. Armed with these additional results together with those of §2, we will be able to describe completely the "phase portrait" for a planar orientation preserving cooperative map which satisfies (A) the minimal fixed point x_m is positive, (B) all fixed points are hyperbolic and (C) all orbits are bounded. A rather rich structure will become apparent for the set of fixed points and their basins of attraction. These results are contained in Theorem 4.8, the main result of this section.

Some additional notation will prove useful. Let Q_i, $i = 1, 2, 3, 4$ denote the usual open quadrants in R^2 in counter clockwise order with increasing i, e.g., $Q_1 = \{(x_1, x_2) : x_i > 0,\ i = 1, 2\}$. For $x \geqq 0$ denote by $Q_i(x)$ the set $(x + Q_i) \cap R^2_+$, that is, the portion of the ith quadrant centered at x which lies in R^2_+.

The manner in which orientation enters the study of cooperative maps may be seen in the following result. First, observe that if T is cooperative then $T(Q_i(x)) \subset Q_i(Tx)$ for $i = 1, 3$.

LEMMA 4.1. *Let T be cooperative and $x > 0$. If T is orientation preserving, then $T(Q_2(x)) \cap Q_4(Tx)$ and $T(Q_4(x)) \cap Q_2(Tx)$ are empty. If T is orientation reversing, then $T(Q_2(x)) \cap Q_2(Tx)$ and $T(Q_4(x)) \cap Q_4(Tx)$ are empty.*

Proof. The result is easily established by considering the images under T of the following curves. $E_1 = \{(t, 0) : t \geqq 0\}$, $E_2 = \{(0, t) : t \geqq 0\}$, $H_1 = \{(t, b) : t \geqq 0\}$ and $H_2 = \{(a, t) : t \geqq 0\}$ where $x = (a, b)$. Each of the curves has been parametrized in such a way as to be monotone nondecreasing. Each of the image curves $T(E_1)$, $T(E_2)$, $T(H_1)$ and $T(H_2)$ are monotone nondecreasing and $T(H_i)$, $i = 1, 2$ lie in $\overline{Q_1(Tx)} \cup \overline{Q_3(Tx)}$. The proposition follows easily from the fact that the boundary of $T(Q_2(x))$ consists of a portion of each of the curves $T(H_1)$, $T(H_2)$ and $T(E_2)$ and the fact that the relative relation of the pairs of curves $T(E_1)$, $T(E_2)$ and $T(H_1)$ and $T(H_2)$ are preserved or reserved depending on whether T is orientation preserving or reversing.

PROPOSITION 4.2. *If T is a cooperative orientation preserving map and $x>0$ then $T(Q_i(x))\cap Q_i(Tx)$ $i=1,3$ and $T(Q_j(x))\cap Q_k(Tx)=\phi$, $j\neq k$, $j,k\in\{2,4\}$.*

Proposition 4.2 has the important implication that the orbit of x, $0^+(x)$ has eventually monotone (with respect to n) components. This line of argument was first used by de Mottoni and Schiaffino in the competitive case and our proof below is merely a mirror image of theirs.

THEOREM 4.3. *Let T be cooperative and orientation preserving, $x=(x_1,x_2)>0$ and $x_n=T^nx=(x_1^{(n)},x_2^{(n)})$, $n=0,1,2,\cdots$. Then there exists $N=N(x)$, a positive integer, such that for $n\geqq N$ both $x_1^{(n)}$ and $x_2^{(n)}$ are monotone sequences.*

Proof. Either there exists a nonnegative integer M such that $T^Mx\leqq T^{N+1}x(T^{N+1}x\leqq T^Nx)$ or it must be the case that $T^{n+1}x\in Q_2(T^nx)\cup Q_4(T^nx)$ for all $n\geqq 0$. In the former case, $T^nx\leqq T^{n+1}x(T^{n+1}x\leqq T^nx)$ for all $n\geqq N$ and the theorem follows. In the latter case we may assume $Tx\in Q_2(x)$ (the case $Tx\in Q_4(x)$ is treated similarly). It follows from Lemma 4.1 that $T^2x\in T(Q_2(x))$ does not lie in $Q_4(Tx)$ and so must be an element of $Q_2(Tx)$. Proceeding by induction on n, one shows $T^{n+1}x\in Q_2(T^nx)$ $n=0,1,2,\cdots$. The result follows easily in this case (in fact $N=0$).

The upshot of Theorem 4.3 is that the dynamics of cooperative orientation preserving maps is "trivial", all bounded orbits are either fixed points or tend to fixed points. Though the dynamics may be "trivial", we will show that the fixed point set of an orientation preserving cooperative map together with their domains of attraction have a rich and beautiful structure.

COROLLARY 4.4. *Let T be cooperative and orientation preserving and let $x>0$. Then either $|T^nx|\to\infty$ as $n\to\infty$ or there exists a fixed point $x_1\geqq 0$ of T for which $T^nx\to x_1$ as $n\to\infty$.*

If T is a cooperative map, it may not be the case that T^2 is cooperative. The problem is that (SP) may not hold for T^2. In case (SP) holds for T^2 so it is cooperative, then T^2 is cooperative and orientation preserving. Hence T^2 has trivial dynamics. In this way, one can treat orientation reversing cooperative maps: their bounded orbits approach period two points (which might be fixed points) of T.

Let $x>0$ be a fixed point of an orientation preserving cooperative map T. Since $DT(x)$ satisfies (SP), the spectrum of $DT(x)$ consists of distinct positive eigenvalues η, ρ where $\rho=\rho(DT(x))$ is the spectral radius and $\eta<\rho$. Corresponding to ρ there is a positive eigenvector e_1. This eigenvector, being (to within scalar multiple) the unique nonnegative eigenvector of $DT(x)$ by Theorem 1, it follows that we may select an eigenvector e_2 corresponding to η which lies in Q_2 or Q_4 as we please. In case $\rho>1$, Theorem 2.5 implies the existence of two monotone invariant curves for T: $C^+\subset Q_1(x)$ and $C^-\subset Q_3(x)$. The following result states that if $\eta<1$ then there are two monotone invariant curves for T: $C^l\subset Q_2(x)$ and $C^r\subset Q_4(x)$.

THEOREM 4.5. *Let x_1 be a positive fixed point of an orientation preserving cooperative map T and suppose $\eta_1=\eta(x_1)$, the smaller positive eigenvalue of $DT(x_1)$ satisfies $\eta_1<1$. Let $DT(x_1)e_2=\eta_1e_2$ where the eigenvector $e_2\in Q_2$. Then there exist t_l, $0<t_l\leqq\infty$ and a C^1 function $y_l\colon[0,t_l)\to Q_2(x_1)$ satisfying*

- (A$_l$) *$y_l(t)=x_1+te_2+O(t^2)$ as $t\to 0$.*
- (B$_l$) *$0<t<s<t_l$ implies $y(s)-y(t)\in Q_2$.*
- (C$_l$) *$T(y_l(t))=y_l(\eta_1t)$, $0\leqq t<t_l$, and either $t_l=\infty$ or $y_l(t_l+)$ lies on the vertical coordinate axis.*
- (D$_l$) *If $t_l=\infty$ then either $\lim_{t\to\infty}y_l(t)=\infty$ or $\lim_{t\to\infty}y_l(t)=x_l\in Q_2(x_1)$. In the latter case, $Tx_l=x_l$ and, if $x_l>0$, then $\eta(x_l)\geqq 1$ and $\lim_{t\to\infty}(y_l'(t)/|y_l'(t)|)$ is an eigenvector for $DT(x_l)$ corresponding to $\eta(x_l)$.*

(E_l) *If* $x \geqq y_l(t)$ *for some* $t \in (0, t_l)$ *then* $T^n x \geqq y_l(\eta_1^n t)$ *for* $n = 1, 2, \cdots$.
If $x \leqq y_l(t)$ *for some* $t \in (0, t_l)$ *then* $T^n x \leqq y_l(n_1^n t)$ *for* $n = 1, 2, \cdots$.

There exist t_r, $0 < t_r \leqq \infty$ *and a* C^1 *function* $y_r : [0, t_r) \to Q_4(x_1)$ *satisfying*

(A_r) $y_r(t) = x_1 - te_2 + O(t^2)$ *as* $t \to 0$.

(B_r) $0 < t < s < t_r$ *implies* $y_r(s) - y_r(t) \in Q_4$.

(C_r) $T(y_r(t)) = y_r(\eta_1 t)$ $0 \leqq t < t_r$, *and either* $t_r = \infty$ *or* $y_r(t_r+)$ *lies on the horizontal coordinate axis.*

(D_r) *If* $t_r = \infty$ *then either* $\lim_{t\to\infty} y_r(t) = \infty$ *or* $\lim_{t\to\infty} y_r(t) = x_r \in Q_4(x_1)$. *In the latter case,* $Tx_r = x_r$ *and, if* $x_r > 0$ *then* $\eta(x_r) \geqq 1$ *and* $\lim_{t\to\infty} (y_r'(t)/|y_r'(t)|)$ *is an eigenvector for* $DT(x_r)$ *corresponding to* $\eta(x_r)$.

(E_r) *If* $x \geqq y_r(t)$ *for some* $t \in (0, t_r)$ *then* $T^n x \geqq y_r(\eta_1^n t)$ *for* $n = 1, 2, \cdots$.
If $x \leqq y_r(t)$ *for some* $t \in (0, t_r)$ *then* $T^n x \geqq y_r(\eta_1^n t)$ *for* $n = 1, 2, \cdots$.

Before proceeding to the proof of Theorem 4.5 we comment on its assertions which clearly parallel those of Theorem 2.5. Figure 4.1 illustrates the possible configurations of the curve $C^l \equiv \{ y_l(t) : 0 \leqq t < t_l \}$ which lies in the center-stable manifold of the fixed point x_1 of T. The curve $C^r \equiv \{ y_r(t) : 0 \leqq t < t_r \}$ has a similar set of possibilities which are independent of those of C^l. In case the curve C^l connects x_1 to a positive fixed point x_l, see Fig. 4.1 (b), (D_l) asserts that the smallest eigenvalue of the Jacobian of T at x_l is larger than or equal to one. In other words, x_l is a repeller if it is hyperbolic.

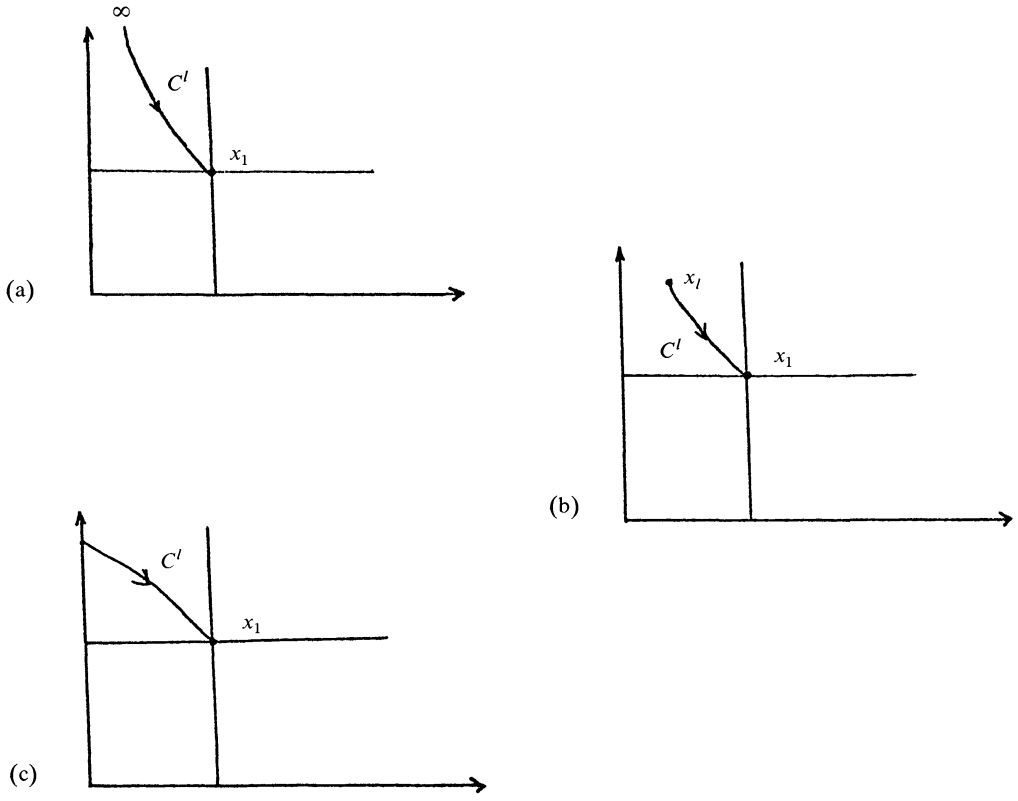

FIG. 4.1. *The possible configurations of* C^l. *In* (a) $t_l = \infty$ *and* $\lim_{t\to\infty} y_l(t) = \infty$; *in* (b) $t_l = \infty$ *and* $\lim_{t\to\infty} y_l(t) = x_l$. (c) *illustrates two possibilities: either* $t_l = \infty$ *and* $\lim_{t\to\infty} y_l(t) = x_l \in \partial R_+^2$ *or* $t_l < \infty$ *and* $y_l(t_l+)$, *which cannot be a fixed point, lies on* ∂R_+^2.

The assertions (E_l) and (E_r) will prove to be especially important. Since $y_l(\eta_1^n t) \to x_1$ as $n \to \infty$, if $x \geqq y_l(t)$ then any limit points of $\{T^n x\}_{n \geqq 0}$ must lie in $\overline{Q_1(x_1)}$. Similar remarks hold for the other cases.

Proof. Let E_1 and E_2 denote the horizontal and vertical coordinate axis respectively. Since T satisfies (M), $T(E_i)$, $i=1,2$, are monotone curves forming the boundary of $T(Q_1)$. See Fig. 4.2 depicting these sets. Consider $T^{-1}: T(Q_1) \to Q_1$ which fixes x_1 and for which $\rho(D(T^{-1})(x_1)) = \eta_1^{-1} > 1$. Applying [13, Thm. 1.1] to T^{-1} with eigenvector $e_2 \in Q_2(x_1)$, we obtain t_l, $0 < t_l \leqq \infty$ and a C^1 function $y_l: [0, t_l) \to T(Q_1)$ satisfying $y_l(t) = x_1 + te_2 + O(t^2)$ as $t \to 0$, $y_l(t) = T^{-1}(y_l(\eta_1 t))$, $0 \leqq t < t_l$, and $t_l = \infty$ or t_l is maximal with the property that $y_l(t) \in T(Q_1)$, $0 \leqq t < \eta_1 t_l$. Since $y_l'(t) \in Q_2$ for sufficiently small $t > 0$, $y_l(t) \in Q_2(x_1)$ and (B_l) hold for small t. Suppose $0 < t < s < t_l$ and $y_l(t)$ and $y_l(s)$ are weakly related, e.g., $y_l(t) \leqq y_l(s)$. Then $T(y_l(t)) \leqq T(y_l(s))$ so $y_l(\eta_1 t) \leqq y_l(\eta_1 s)$. After n applications of T one has $y_l(\eta_1^n t) \leqq y_l(\eta_1^n s)$ which contradicts, for large enough n $(\eta_1^n \ll 1)$, that B_l holds for small t. Now let $F: \{(t,s): 0 < t < s < t_l\} \to R^2 \setminus \{0\}$ be defined by $F(t,s) = y_l(s) - y_l(t)$. F is a continuous function satisfying Image $F \subset Q_2 \cup Q_4$ by the argument just presented. Since B_l holds for small t, Image $F \cap Q_2 \neq \varnothing$. But Image F must be connected and so it must be the case that Image $F \subset Q_2$. Hence (B_l) holds and $y_l(t) \in Q_2(x_1)$, $0 < t < t_l$. Now, if $t_l < \infty$ then (B_l) implies the existence of $y_l(t_l+) \in Q_2(x_1)$ and since $t_l > 0$ is maximal with the property that $y_l(t) \in T(Q_1)$, $0 \leqq t < \eta_1 t_l$, it follows that $y_l(\eta_1 t_l) \in \partial T(Q_1) = T(E_1) \cup T(E_2)$. Since $y_l(\eta_1 t_l) \in Q_2(x_1)$, $y_l(\eta_1 t_l) \in T(L_2)$ (see Fig. 4.1). Hence $y_l(t_l+) \in E_2$. This completes the proof of (C_l). If $t_l = \infty$ then (B_l) implies the first assertion of (D_l). Clearly $Tx_l = x_l$. Before proving the remainder of (D_l) we observe that (E_l) follows trivially from (C_l) and (M). Now suppose $x_l > 0$ and $\eta(x_l) < 1$. But then we could apply Theorem 4.5 $(A_r) \to (E_r)$ to x_l. This contradicts (E_l) (draw a picture!). The last assertion of (D_l) can be verified as in [13, Thm. 2.2]. The proof of $(A_r) \to (E_r)$ follows a similar pattern.

Theorem 2.5, Corollary 4.4 and Theorem 4.5 can be used to describe the "phase portrait" for a planar orientation preserving cooperative map satisfying

A. The minimal fixed point, x_m, is positive.

B. Every fixed point is hyperbolic.

C. All forward orbits, $O^+(x)$, are bounded.

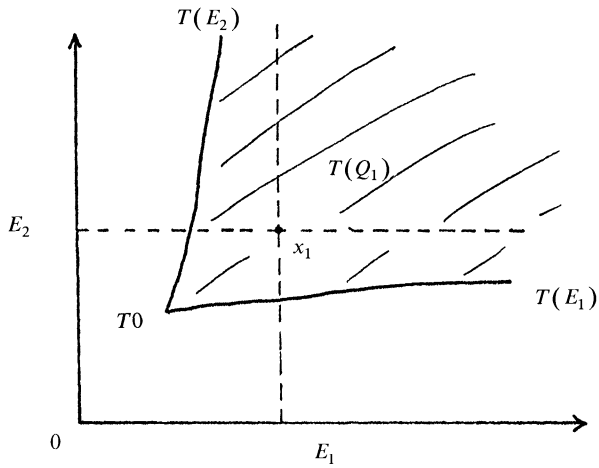

FIG. 4.2. *The configuration of $T(E_i)$, $i=1,2$ and $T(Q_1)$. Note $T0$ need not be positive as depicted. Each curve $T(E_i)$ is monotone.*

In view of B, a fixed point x of T must be either (i) stable: $0<\eta<\rho<1$, (ii) a saddle point: $0<\eta<1<\rho$, or (iii) a repeller: $1<\eta<\rho$. If x is a positive fixed point of T and either stable or a saddle point, we will write $C^l(x)$ and $C^r(x)$ for the two monotone invariant curves emanating from x which are asserted to exist by Theorem 4.5. Similarly, if x is a saddle point or a repeller, we write $C^-(x)$ and $C^+(x)$ for the monotone invariant curves emanating from x described in Theorem 2.5. Observe that, by B and C, a $C^-(x)$ and $C^+(x)$ always lead to a stable fixed point while if a $C^l(x)$ or $C^r(x)$ lead to a fixed point, then that fixed point must be a repeller. We will establish the following propositions assuming that A–C hold.

PROPOSITION 4.6. *If y_1 is a stable positive fixed point then either $B^+(y_1)=\overline{Q_1(y_1)}$ or $S^+(y_1)$ is the graph of a C^1 monotone decreasing curve in $\overline{Q_1(y_1)}$. $S^+(y_1)$ contains an odd number of fixed points $x_1, x_2, \cdots, x_{2n+1}$ ordered from left to right on $S^+(y_1)$ (see Fig. 4.3). The odd indexed points are saddles and the even indexed points are repellers. $S^+(y_1)$ consists of the curves $C^l(x_i)$, $C^r(x_i)$, $i=1,3,5,\cdots,2n-1$ together with their limit points $x_2, x_4, \cdots, x_{2n}$.*

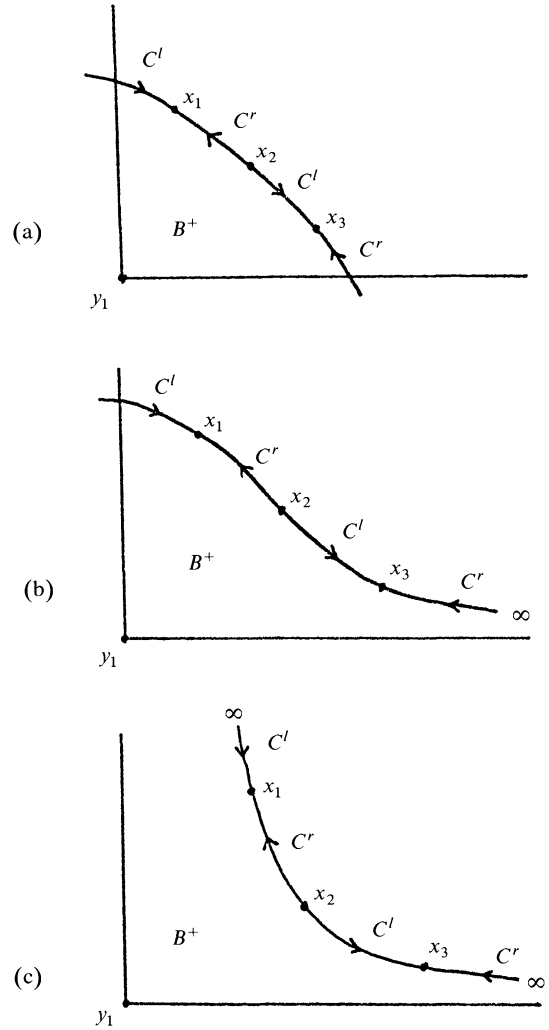

FIG. 4.3. *The set $S^+(y_1)$ in case $2n+1=3$.*

PROPOSITION 4.7. *If y_1 is a stable fixed point, $B^+(y_1) \neq \overline{Q_1(y_1)}$, and $x_1, x_2, \cdots, x_{2n+1}$ are the fixed points of T on $S^+(x)$ as in Proposition* 4.6, *then each of the curves $C^-(x_i)$, $1 \leqq i \leqq 2n+1$, is asymptotic to y_1 and tangent at y_1 to the positive eigenvector for $DT(y_1)$ (corresponding to $\rho(y_1)$). All the curves $C^+(x_i)$, $1 \leqq i \leqq 2n+1$, are asymptotic to the same stable fixed point $y_2 > x_i$, $1 \leqq i \leqq 2n+1$. Each curve $C^+(x_i)$ is tangent at y_2 to the positive eigenvector for $DT(y_2)$. The curve $C^l(y_2) \subset Q_2(y_2)$ either leaves $\overline{Q_1(y_1)}$ by crossing its vertical boundary or remains in $Q_1(y_1)$ tending to infinity. The curve $C^r(y_2) \subset Q_4(y_2)$ either leaves $\overline{Q_1(y_1)}$ by crossing its horizontal boundary or remains in $Q_1(y_1)$ tending to infinity. (See Fig.* 4.4.)

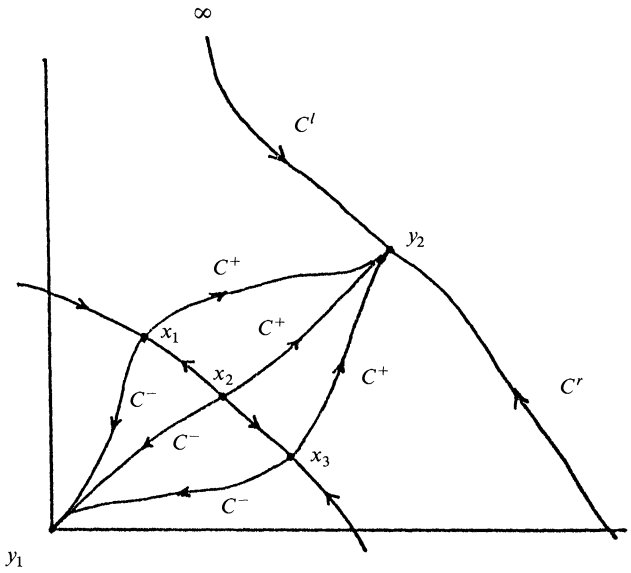

FIG. 4.4. *The curves $C^+(x_i)$, $C^-(x_i)$, $C^r(y_2)$ and $C^l(y_2)$ are added to Fig.* 4.3(a). *The reader may easily supply these curves to Fig.* 4.3(b) *and* (c). *Note that no two distinct pair of the various curves can intersect so if $C^l(x_1)$ is unbounded in $Q_1(y_1)$ then so is $C^l(y_2)$.*

Propositions 4.6 and 4.7 describe what we might refer to as a basic cell $[y_1, y_2]$ with y_1 and y_2 being stable fixed points. Inside the cell there are an odd number of unstable fixed points lying on a smooth monotone decreasing curve (only part of which may lie in $[y_1, y_2]$). The proofs of Propositions 4.6 and 4.7 will be deferred to the end of this section while we consider how to construct the global phase portrait. We will show that the fixed point set of T consists of a finite or infinite totally ordered sequence of such basic units and we will describe precisely the basis of attraction of each of the stable fixed points. In order to achieve this goal, we proceed from the bottom up, so to speak, beginning with the minimal fixed point $y_1 \equiv x_m$. In Fig. 4.5 below, we indicate the possible configurations of the curves $C^l(y_1)$ and $C^r(y_1)$. Observe that since all fixed points x of T satisfy $x \geqq y_1$, the quadrants $\overline{Q_2(y_1)}$ and $\overline{Q_4(y_1)}$ are fixed point free while $\overline{Q_3(y_1)} \subset B^-(y_1)$.

By Propositions 4.6 and 4.7, either $B^+(y_1) = \overline{Q_1(y_1)}$ or we can add one of our basic units as in Fig. 4.4 to Fig. 4.5. In case $B^+(y_1) = \overline{Q_1(y_1)}$, then $B(y_1) = \overline{Q}_1$, all orbits tend to y_1. If $B^+(y_1) \neq \overline{Q_1(y_1)}$ so that Propositions 4.6 and 4.7 apply, there are two issues to consider. First, where do the curves $C^l(x_1)$, $C^l(y_2)$, $C^r(x_{2n+1})$ and $C^r(y_2)$ go if they leave $\overline{Q_1(y_1)}$? Secondly, are there unaccounted-for fixed points of T belonging to the various regions partitioned by the curves which we have described so far?

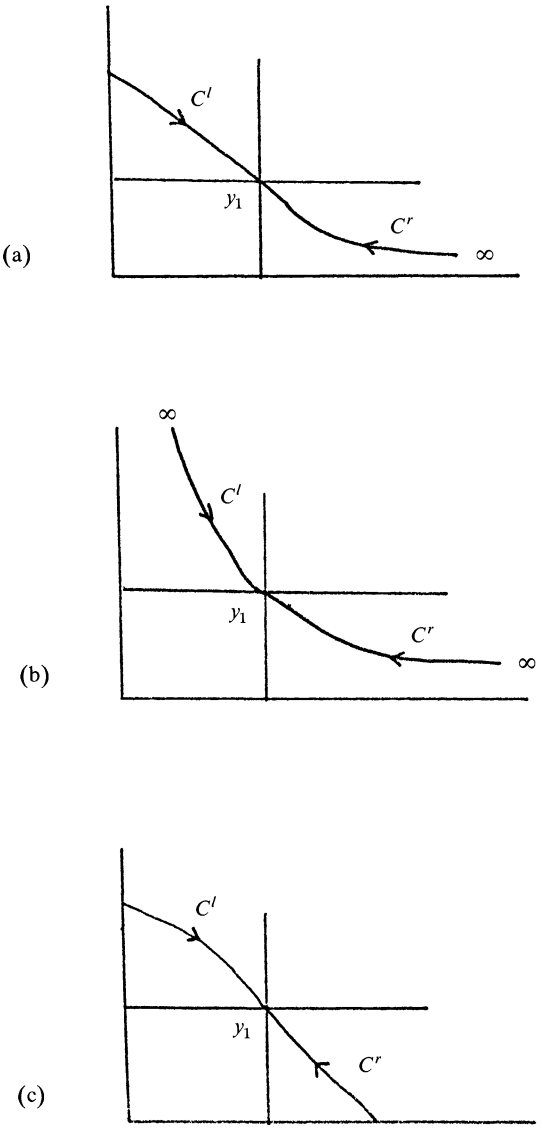

FIG. 4.5. *Configurations of $C^l(y_1)$ and $C^r(y_1)$ for the minimal fixed point y_1. $\overline{Q_2(y_1)}$, $\overline{Q_3(y_1)}$ and $\overline{Q_4(y_1)}$ are fixed point free.*

Beginning with the first question, recall that $C^l(x_1)$ either leaves $\overline{Q_1(y_1)}$ through the vertical boundary or remains in $Q_1(y_1) \cap Q_2(x_1)$ tending to infinity. In the latter case there is nothing more to say but in case $C^l(x_1)$ leaves $\overline{Q_1(y_1)}$, Theorem 4.5 and the fact that $\overline{Q_2(y_1)}$ is fixed point free leave only two alternatives. Either $C^l(x_1)$ tends to infinity in $Q_2(y_1) \cap Q_2(x_1)$ or $C^l(x_1)$ terminates on the vertical coordinate axis. Since $C^l(x_1)$ cannot intersect $C^l(y_1)$, the latter alternative can only occur if $C^l(y_1)$ terminates on the vertical coordinate axis as in Fig. 4.5(a). The three other curves are treated in similar fashion. The number of possibilities for each of these curves prevents a catalogue of all possibilities. In Fig. 4.6 below we combine Figs. 4.5 and 4.4 together with the observations above.

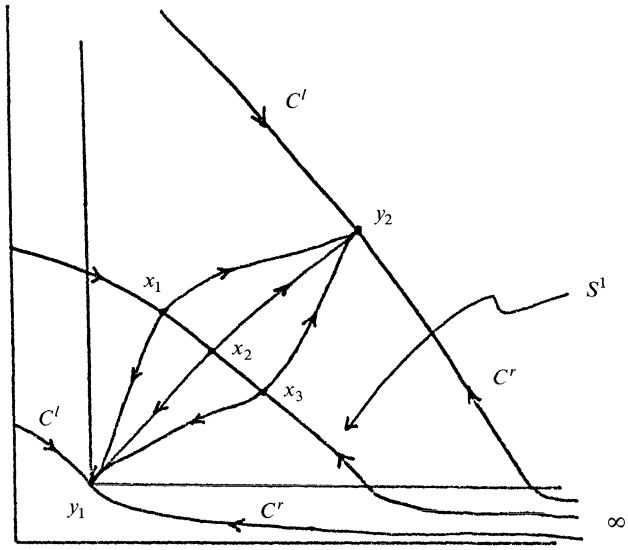

FIG. 4.6. *Figs.* 4.5(a) *and* 4.4 *are combined. The curves* $C^l(y_2)$ *and* $C^r(y_2)$ *are also featured. Note the curve* $S^1 = C^l(x_1) \cup C^r(x_1) \cup C^l(x_3) \cup C^r(x_3)$ *forms the boundary between the* $B(y_1)$ *and* $B(y_2)$.

Let S^1 denote the curve consisting of $C^l(x_1) \cup C^r(x_1) \cup C^l(x_3) \cup C^r(x_3) \cup \cdots \cup C^r(x_{2n+1})$ (see Fig. 4.6). S^1 is a C^1 monotone decreasing curve which disconnects R^2_+ into two components, a lower one, L^1, and an upper one, U^1. We will soon see that $B(y_1) = L^1$. First though we must address the second question raised above. Consider the lower left-hand component whose upper boundary is $C^l(y_2) \cup C^r(y_2)$. This region may be further partitioned into $4n+5$ separate regions formed by $C^l(y_1)$, $C^r(y_1)$, $C^l(y_2)$, $C^r(y_2)$ and the $C^+(x_i)$, $C^-(x_i)$ for odd i. Can there be a fixed point in any one of these open regions? We argue that there cannot be any fixed points in these regions. A formal proof would proceed case by case through each region, systematically using (E_+) and (E_-) of Theorem 2.5 and (E_l) and (E_r) of Theorem 4.5. We proceed less formally considering a sample case and leaving the remainder to the reader. Consider the open region, V, bounded by $C^l(x_1)$, a portion of the vertical coordinate axis, $C^l(y_2)$ and $C^+(x_1)$ (see Fig. 4.7 below). This region is mapped into itself by T. There can be no fixed points of T in $V \cap [x_1, y_2]$ by Theorem 2.5 (E_+). There can be no fixed points in $V \cap Q_2(x_1)$ by Theorem 4.5 (E_l). There can be no fixed points of T in $Q_2(y_2) \cap V$ by Theorem 4.5 (E_l). This exhausts the region. Indeed, one can show that the orbit of every point of V tends to y_2 by using the above arguments. The other regions can be treated in similar fashion; note that each is mapped into itself by T.

We show $L^1 = B(y_1)$ as follows. Each of the $(4n+5)$ regions are mapped into themselves by T. Corollary 4.4, the fact that each open region is fixed point free, and the fact that y_1 is the only stable fixed point in L^1 complete the argument.

We now state the main result of this section, completely describing the dynamics of an orientation preserving cooperative map in the case that A., B. and C. hold.

THEOREM 4.8. *Let* T *be an orientation preserving cooperative map satisfying* A., B. *and* C. *and assume* $B(x_m) \neq R^2_+$. *Then the set of fixed points is either infinite or odd in number and can be described as follows. The subset of stable fixed points is totally ordered* $0 < x_m \equiv y_1 < y_2 < \cdots < y_n \cdots$. *In each order interval* $[y_k, y_{k+1}]$, $k = 1, \cdots$, *there are an*

odd number of unrelated fixed points $x_1^k, x_2^k, \cdots, x_{2n_k+1}^k$ *lying on a* C^1 *monotone decreasing separatrix curve* S^k *and ordered from left to right on* S^k. *For each fixed point* x_i^k, $C^-(x_i^k)$ *and* $C^+(x_i^k)$ *tend to* y_k *and* y_{k+1} *respectively and are tangent at these points to the positive eigenvector of* $DT(y_k)$ *or* $DT(y_{k+1})$. *The odd indexed fixed points* x_{2i+1}^k *are saddle points and the even indexed fixed points are repellers.* $S^k = C^l(x_1) \cup C^r(x_1) \cup C^l(x_3) \cup C^r(x_3) \cup \cdots \cup C^l(x_{2n+1}) \cup C^r(x_{2n+1}) \cup \{x_2, x_4, \cdots, x_{2n}\}$ *and* S^k *separates* R_+^2 *into two components. If* L^k *denotes the lower left component of* R_+^2 *and* U^k *the upper right component of* R_+^2 *the boundary of which is* S^k *then* $B(y_1) = L^1$, $B(y_k) = L^k \cap U^{k-1}$, $k > 1$, *unless the sequence of stable fixed points terminates at* y_p. *In the latter case* $B(y_p) = U^{p-1}$.

See Fig. 4.8 below for a possible scenario.

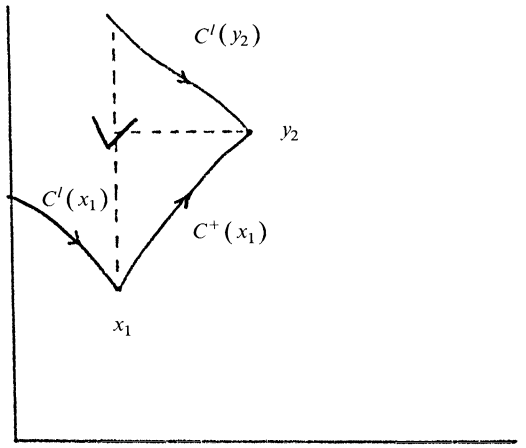

FIG. 4.7. *The region V in the case that* $C^l(x_1)$ *intersects the vertical coordinate axis.*

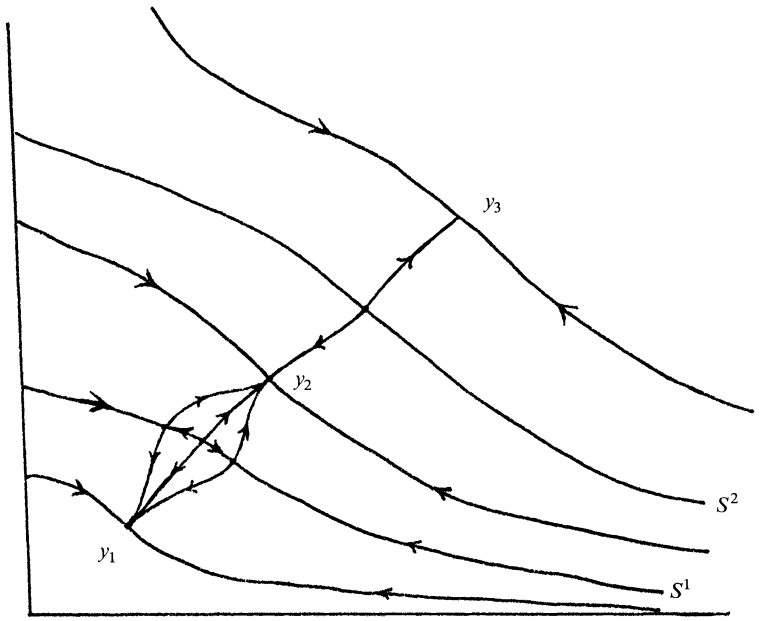

FIG. 4.8. *A phase portrait consistent with Theorem* 4.8. *There are three stable fixed points* y_1, y_2, y_3 *with separatrices* S^1 *and* S^2 *separating* $B(y_1)$, $B(y_2)$ *and* $B(y_3)$. *The interval* $[y_1, y_2]$ *contains three unstable fixed points on* S^1 *and* $[y_2, y_3]$ *contains one unstable fixed point on* S^2.

Theorem 4.8 is proved by successively employing Propositions 4.6 and 4.7 together with arguments using Theorem 2.5 (E_+), (E_-) and Theorem 4.5 (E_l) and (E_r) to insure regions bounded by the various curves are fixed point free. For example, the region lying above $C^l(y_2)$ in $Q_2(y_2)$ must be shown to be fixed point free as well as the region lying above $C^r(y_2)$ in $Q_4(y_2)$. Theorem 4.5 (E_l) and (E_r) respectively can be used to show that these regions are fixed point free. Now only $\overline{Q_1(y_2)}$ needs to be considered and Propositions 4.6 and 4.7 can be applied.

We end this section with the proofs of Proposition 4.6 and 4.7.

Proof of Proposition 4.6. Suppose $B^+(y_1) \neq \overline{Q_1(y_1)}$. Let $x \in S^+(y_1)$ and $\bar{x} = \lim_{n\to\infty} T^n x$ (the limit exists by C. and Corollary 4.4). Then $\bar{x} \in S^+(y_1)$, $T\bar{x} = \bar{x}$ and $\bar{x}$ is a saddle point. Observe that $\bar{x} \in Q_1(y_1)$ and $C^l(\bar{x}) \cap \overline{Q_1(y_1)}$ and $C^r(\bar{x}) \cap \overline{Q_1(y_1)}$ are contained in $S^+(y_1)$. If $C^l(\bar{x})$ has a limit point z in $\overline{Q_1(y_1)}$, then it is a repelling fixed point which lies in $S^+(y_1)$ and $C^l(\bar{x})$ is tangent at z to the eigenvector for $DT(z)$ corresponding to $\eta(z)$. A similar statement holds for $C^r(\bar{x})$. The first assertion of Proposition 4.6 is established by piecing together the curves $C^l(\bar{x})$ and $C^r(\bar{x})$ keeping in mind Proposition 2.3 (note that every ray $y_1 + th$, $h > 0$, intersects $S^+(y_1)$ in one point). $S^+(y_1)$ is C^1 because where a $C^r(\bar{x}_1)$ meets a $C^l(\bar{x}_2)$ at a repelling fixed point, the two curves are tangent to the same eigendirection by Theorem 4.5.

Now, either $S^+(y_1)$ intersects both boundary lines of $\overline{Q_1(y_1)}$, in which case $S^+(y_1)$ contains a finite number of fixed points by B. none of which can lie on the boundary lines, or $S^+(y_1)$ is unbounded. In either case the set of fixed points on $S^+(y_1)$ must lie discretely on $S^+(y_1)$, they cannot accumulate, and they must alternate between saddle and repeller. Now each such fixed point has $\rho > 1$ and so by Theorem 2.5 and C. each fixed point on $S^+(y_1)$ has a monotone invariant curve C^+ emanating from it and connecting the fixed point to a stable fixed point. In Proposition 4.7, we will show that all of the curves C^+ tend to the *same* fixed point. Since each of these curves C^+ is monotone, it would be impossible for the set of fixed points of T on $S^+(y_1)$ to be unbounded.

Proof of Proposition 4.7. In view of Theorem 2.5 and C., only the assertion that all the curves $C^+(x_i)$ are asymptotic to the same fixed point and the final assertion concerning $C^l(y_2)$ and $C^r(y_2)$ require proof. Consider a particular $x_i \in S^+(y_1)$ and the limit point z_i of $C^+(x_i)$ which exists by C. The fixed point z_i is stable and the curve $C^r(z_i)$ must, by Theorem 4.5, lie in $Q_4(z_i)$ and either (a) tends to infinity monotonely in $Q_1(y_1)$, (b) leaves $Q_1(y_1)$ be crossing the horizontal boundary or (c) has a limit point which is a fixed point and lies in $Q_1(y_1)$. We rule out the possibility (c) as follows. If $C^r(z_i)$ limits on a fixed point $u_i \in Q_1(y_1) \cap Q_4(z_i)$ then u_i is a repeller (Theorem 4.5) so consider $C^-(u_i)$. $C^-(u_i) \subset Q_3(u_i)$ cannot intersect $S^+(y_1)$ nor can it leave $Q_1(y_1)$. Moreover $C^-(u_i)$ can not have its limit fixed point on $S^+(y_1)$ because this limit point must be stable. It follows that the limit point of $C^-(u_i)$ lies outside $B^+(y_1) \cup S^+(y_1)$ but in $Q_1(y_1)$. Let this point be v_i, a stable fixed point, and consider $C^l(v_i)$. In Fig. 4.9 below we sketch the curves and fixed points discussed above. The curve $C^l(v_i)$ cannot cross any of the previously mentioned curves so it must have a limit point $w_i \in Q_2(v_i)$ below $C^+(x_i)$. Since w_i is a repeller and $C^+(w_i)$ cannot cross any of the curves previously mentioned, it must limit on a stable fixed point. We may clearly continue this reasoning producing an inward spiral $C^+, C^r, C^-, C^l, C^+, C^r, C^-, C^l, \cdots$ (see Fig. 4.9). The limit fixed points on these successive curves must accumulate. This violates B. Hence we see that possibility (c) cannot occur. Similar reasoning applies to $C^l(z_i)$: either it tends to infinity in $Q_1(y_1)$ or leaves $Q_1(y_1)$. See Fig. 4.10 below. But now, in view of Fig. 4.9, consider z_{i-1} and z_{i+1} the limit points of $C^+(x_{i-1})$ and $C^+(x_{i+1})$

respectively. These curves cannot cross $C^l(z_i)$ or $C^r(z_i)$. If $z_{i-1} \neq z_i$ then z_{i-1} must lie in the region bounded by $S^+(y_1)$, $C^+(x_i)$ and $C^l(z_i)$. Since $C^r(z_{i-1})$ cannot cross any of these curves, we have a contradiction to the fact that $C^r(z_{i-1})$ must be either unbounded or leave $Q_1(y_1)$. Thus we must have $z_{i-1} = z_i = z_{i+1}$.

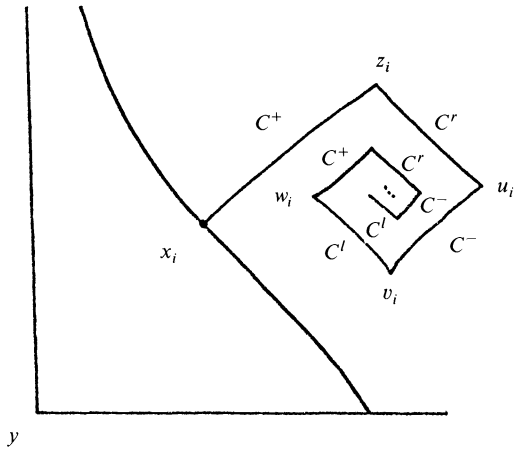

FIG. 4.9. *Inward spiral* C^+, C^r, C^-, C^l, $C^+, \cdots$.

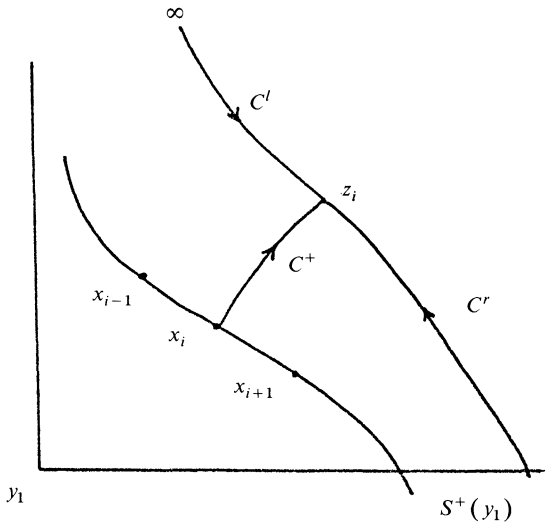

FIG. 4.10. *The sets* $C^l(z_i)$ *and* $C^r(z_i)$. *Where can* $C^l(z_{i+1})$ *and* $C^r(z_{i-1})$ *go?*

PERIODIC SOLUTIONS OF FORCED NONLINEAR SECOND ORDER EQUATIONS: SYMMETRY AND BIFURCATIONS*

M. FÜRKOTTER† AND H. M. RODRIGUES‡

Abstract. The authors are concerned with the equation $\ddot{u}+u=g(u,p)+\mu f(t)$, where p, μ are small parameters, f is an even, continuous π-periodic function, g is an odd smooth function of u, such that $g(u,p)=O(|pu|+|u^3|)$, as p and u go to zero. The main results are that, under certain conditions, the small 2π-periodic solutions maintain some symmetry properties of the forcing function $f(t)$, when $\mu\neq 0$. Some other interesting results describe the changes in the number of such solutions as p and μ vary in a small neighborhood of the origin. The authors use the approach of alternative problems.

Key words. periodic solutions, symmetry, bifurcation, nonlinear equations, small solutions

1. Introduction.

We are concerned with the equation

$$\ddot{u}+u=g(u,p)+\mu f(t) \tag{1.1}$$

where p, μ are small parameters, f is an even continuous periodic function and g is sufficiently smooth.

Our main results are that if g is odd in u and small near $(u,p)=(0,0)$, f is π-periodic and some conditions are satisfied, then the small 2π-periodic solutions of (1.1) maintain some symmetry properties of the forcing function $f(t)$, when $\mu\neq 0$. We also find the bifurcation curves and describe the changes of the number of such solutions as (p,μ) varies in a small neighborhood of the origin.

Hale–Rodrigues [3], [1] studying Duffing's equation, $\ddot{u}+u=pu-u^3+\mu\cos t$, showed that the only small 2π-periodic solutions are even functions of t, if $\mu\neq 0$. They also stated the same result for a general even forcing function with minimal periodic 2π under the condition $\int_0^{2\pi} f(s)\cos s\,ds\neq 0$.

Rodrigues–Vanderbauwhede [4] generalized this result for equations like (1.1), where f satisfies the former hypothesis and $g(u,p)=O(|pu|+u^2)$ as (u,p) goes to $(0,0)$. They also presented an abstract version for equations in Banach spaces. Vanderbauwhede [5], [6] also considers problems related to the above ones in an abstract form.

Many authors look for solutions of nonlinear equations in classes of functions defined by symmetry conditions. For instance, some of them consider equations similar to (1.1) with f 2π-periodic, and just prove that there are 2π-periodic solutions $u(t)$, which are even functions of t, or equivalently, $\dot{u}(0)=0$. But Hale, Vanderbauwhede and Rodrigues in the cited papers went further and proved that, under certain conditions, these are the only small 2π-periodic solutions.

Taking the same attitude of the last three authors, we study the small 2π-periodic solutions of (1.1), but assume that f has minimal period π. In this case the condition of Hale–Rodrigues, $\int_0^{2\pi} f(s)\cos s\,ds\neq 0$, no longer holds and in addition to the even solutions, solutions with other symmetries may arise. The main features of this paper

are to find a set of small 2π-periodic solutions of (1.1) and to prove that these are the only feasible solutions.

In §2, using the Lyapunov–Schmidt method, we show that symmetries in (1.1) imply symmetries in the solution of the auxiliary equation.

In §3, under the conditions

$$g(u,p)=pu+\alpha u^3+\cdots,\alpha\int_0^{2\pi}[(\mathscr{K}f)(t)]^2\cos 2t\,dt\neq 0,$$

we prove that the only small 2π-periodic solutions of (1.1) are such that either $u(t)$ or $u(t-\pi/2)$ is even in t, if $\mu\neq 0$, where $\mathscr{K}f$ indicates the π-periodic solutions of $\ddot{u}+u=f(t)$. As an example we analyse the equation $\ddot{u}+u=pu+u^3+\mu(1+\cos 2t)$.

However, our main results and the harder part of this work are in §4. If $f(t+\pi/2)=-f(t)$ the condition of §3 on $\mathscr{K}f$ is not satisfied. In this case $f(t-\pi/2)$ is even and $f(t\pm\pi/4)$ is odd in t. We show that, if a certain coefficient is not zero, the only small 2π-periodic solutions $u(t)$ of (1.1) are such that $u(t)$ or $u(t-\pi/2)$ is even or $u(t\pm\pi/4)$ is odd in t, if $\mu\neq 0$. This is stated in Theorem 4.2. We call special attention to Theorem 4.1, which was not easy to state and plays an important role in the proof of Theorems 4.2 and 4.3. The calculations indicate that the bifurcation equations are more degenerate when more symmetries are presented in (1.1). As an example we analyse the equation $\ddot{u}+u=pu+u^3+\mu\cos 2t$.

In §§3 and 4 we give, in Theorems 3.2 and 4.3 respectively, a complete description of the bifurcation curves and of the number of small 2π-periodic solutions, as (p,μ) varies in a small neighborhood of the origin.

It is not our aim to discuss all the possible cases, but at the end of §4 and below we give some indications of what can be expected when some of our assumptions are not satisfied, for example, when g is not odd and when f has other periods.

An application which can be reduced to (1.1) is the equation of a forced pendulum $\ddot{v}+(g/L)\sin v=\sigma f(wt)$ where σ is small, w is close to $w_0=\sqrt{g/L}$, f is π-periodic and we look for $2\pi/w$-periodic solutions. If we let $u(t)\overset{\text{def}}{=}v(t/w)$ and $w_0^2/w^2\overset{\text{def}}{=}1-p$ we get an equation like (1.1).

It is convenient to point out that the conditions to be verified in our main theorems usually do not involve hard calculations, because they can be computed as long as one knows the forcing function and a few terms of Taylor expansion of the nonlinearity.

Equation (2.5b) is important for the determination of the admissible phases. After this is done the problem is reduced to the analysis of the equation (2.5a) which will provide the "amplitude" r and the bifurcation diagram.

If $g(u,p)$ is odd in u and f is $2\pi/n$-periodic, even, and not odd harmonic, our conjecture is that, in general, there exists an integer $m=m(n)$, with $m(1)=0$, $m(n)>0$ if $n>1$, such that (2.5b) is given by

$$G(r,\phi,p,\mu)=\begin{cases} r^m\mu\sin n\phi(\rho_n+\cdots) & \text{if } n \text{ is odd,}\\ r^m\mu^2\sin n\phi(\rho_n+\cdots) & \text{if } n \text{ is even,}\end{cases}$$

where $\rho_n=\rho_n(f,g)$, ρ_n does not depend on ϕ and depends only on finitely many coefficients of the Taylor expansion of $g(u,0)$ around 0.

If $g(u,p)$ is odd in u, f is even and $f(t+\pi/n)=-f(t)$, our conjecture is that generically, there exists an integer $m=m(n)$, with $m(1)=0$, $m(n)>0$ if $n>1$, such that

equation (2.5b) is given by

$$G(r,\phi,p,\mu)=\begin{cases} r^m\mu\sin n\phi(\eta_n+\cdots) & \text{if } n \text{ is odd,}\\ r^m\mu^2\sin 2n\phi(\eta_n+\cdots) & \text{if } n \text{ is even,}\end{cases}$$

where $\eta_n=\eta_n(f,g)$, η_n does not depend on ϕ and depends only on finitely many coefficients of the Taylor expansion of $g(u,0)$ around 0.

The analysis of some examples indicates evidences that if g is odd in u and factor term is $\sin n\phi$ the the factor term in r is r^{n-1}, that is $m=n-1$.

If we do not assume that g is odd in u, a broader conjecture is that, generically, if f is even and $2\pi/n$-periodic then there exist integers m, p, q, which depend on n such that

$$G(r,\phi,p,\mu)=r^m\mu^p\sin q\phi(\xi_n+\cdots)$$

where ξ_n depends only on finitely many coefficients of the Taylor expansion of $g(u,0)$ around 0 and $m>1$ if $n>1$.

When ρ_n (η_n or ξ_n) does not vanish, we can discuss the existence of some special solutions.

In any of the above cases, for $n>1$, $r=0$ would give rise to the $2\pi/n$-periodic solution.

2. The auxiliary and the bifurcation equations. Consider the equation

$$\ddot{u}+u=g(u,p)+\mu f(t) \tag{1.1}$$

where (p,μ) varies in a small neighborhood of the origin, and the following hypotheses:

(A_1) f is a real π-periodic, even function, continuous on R.

(B_1) g is a C^∞ real function defined in a neighborhood of $(u,p)=(0,0)$, odd in u, and $g(u,p)=pu+\alpha u^3+O(|pu^3|+|u^5|)$ as (p,μ) goes to $(0,0)$. In fact it would be enough to assume that g is sufficiently smooth.

If $u(t)$ is a 2π-periodic solution of (1.1), then there are $r\in R$ and $\phi\in(-\pi/2,\pi/2]$, such that $u(t)=r\cos(t-\phi)+x(t)$, where

$$\int_0^{2\pi}x(t)\cos t\,dt=\int_0^{2\pi}x(t)\sin t\,dt=0.$$

If we let $u(t+\phi)\overset{\text{def}}{=}r\cos t+v(t)$, then $v(t)$ is a solution of

$$\begin{aligned}&\ddot{v}+v=g(r\cos t+v,\ p)+\mu f(t+\phi),\\ &\int_0^{2\pi}v(t)\cos t\,dt=\int_0^{2\pi}v(t)\sin t\,dt=0.\end{aligned} \tag{2.1}$$

Let $\mathscr{P}$ be the space of all 2π-periodic real functions, continuous on R, with the norm $\|w\|=\sup_{0\le t\le 2\pi}|w(t)|$, and let $\mathscr{P}^{(2)}$ be the space of all 2π-periodic real functions, with the second derivative continuous on R, with the norm $\|w\|=\sup\{|w^{(j)}(t)|,\ 0\le t\le 2\pi,\ j=0,1,2\}$.

On these spaces we consider the projection

$$(Pw)(t)\overset{\text{def}}{=}\frac{\cos t}{\pi}\int_0^{2\pi}w(s)\cos s\,ds+\frac{\sin t}{\pi}\int_0^{2\pi}w(s)\sin s\,ds. \tag{2.2}$$

The Fredholm alternative implies that the equation $\ddot{u}+u=h(t)$, with h in $\mathscr{P}$, has a solution in $\mathscr{P}^{(2)}$ if and only if $Ph=0$. Moreover, if $Ph=0$ then there exists a unique solution $u(t)$ in $\mathscr{P}^{(2)}$, of this equation, such that $Pu=0$. We indicate this solution by $\mathscr{K}h$. From the variation of constants formula, we obtain

$$\mathscr{K}h=(I-P)\left[-\cos(\cdot)\int_0^{(\cdot)}h(s)\sin s\,ds+\sin(\cdot)\int_0^{(\cdot)}h(s)\cos s\,ds\right]. \tag{2.3}$$

Following the usual procedure of the Lyapunov–Schmidt method (see [2]), the problem is reduced to that of finding v in $\mathscr{P}^{(2)}$ for the following system of equations,

$$\begin{aligned}&\text{(a) } v=\mathscr{K}(I-P)[g(r\cos(\cdot)+v,\ p)+\mu f(\cdot+\phi)],\\ &\text{(b) } P[g(r\cos(\cdot)+v,\ p)+\mu f(\cdot+\phi)]=0.\end{aligned} \tag{2.4}$$

The equations (a) and (b) are called the auxiliary and bifurcation equation, respectively. It follows from the implicit function theorem that (2.4a) has a unique small solution for (p,μ) in a small neighborhood of the origin. We denote this solution by $v^*(t)=v^*(r,\phi,p,\mu)(t)$. If we substitute in (2.4b), we obtain the following equations:

$$\begin{aligned}&\text{(a) } F(r,\phi,p,\mu)\overset{\text{def}}{=}\frac{1}{\pi}\int_0^{2\pi}g(r\cos s+v^*(r,\phi,p,\mu)(s),\ p)\cos s\,ds=0,\\ &\text{(b) } G(r,\phi,p,\mu)\overset{\text{def}}{=}\frac{1}{\pi}\int_0^{2\pi}g(r\cos s+v^*(r,\phi,p,\mu)(s),\ p)\sin s\,ds=0\end{aligned} \tag{2.5}$$

The following lemma gives information about some symmetries and estimates of v^*.

LEMMA 2.1. *If hypotheses* (A_1) *and* (B_1) *are satisfied, then the solution* v^* *of* (2.4a) *has the following properties*:

$$v^*(r,\phi,p,\mu)(t)=v^*(-r,\phi,p,\mu)(t-\pi), \tag{2.6}$$

$$v^*(r,\phi,p,\mu)(t)=-v^*(r,\phi,p,-\mu)(t-\pi), \tag{2.7}$$

$$v^*(0,\phi,p,\mu)(t)\ \textit{is } \pi\textit{-periodic in } t, \tag{2.8}$$

$$v^*(0,\phi,p,\mu)(t-\phi)\ \textit{is even in } t \textit{ and independent of } \phi, \tag{2.9}$$

$$v^*(r,0,p,\mu)(t),\ v^*(r,\pi/2,p,\mu)(t) \textit{ and } v^*(r,\phi,p,0)(t) \textit{ are even functions of } t, \tag{2.10}$$

$$v^*(0,\phi,p,\mu)=\mu\mathscr{K}f(\cdot+\phi)+O(|p\mu|+|\mu|^3) \textit{ as } (p,\mu) \textit{ goes to } (0,0), \tag{2.11}$$

$$v^*(r,\phi,p,\mu)=v^*(0,\phi,p,\mu)+rS(r,\phi,p,\mu) \textit{ where } S(r,\phi,p,\mu)=O(|r|^2+|\mu|) \textit{ as } (r,p,\mu) \textit{ goes to } (0,0,0). \tag{2.12}$$

Proof. Properties (2.6) to (2.10) follow essentially from the fact that the auxiliary equation is invariant under certain transformations.

To prove (2.11) it suffices to observe that

$$v^*(0,\phi,0,0)\equiv 0,\quad \frac{\partial v^*}{\partial\mu}(0,\phi,0,0)=\mathscr{K}f(\cdot+\phi),$$

$$\frac{\partial^2 v^*}{\partial\mu^2}(0,\phi,0,0)=0,\quad \frac{\partial v^*}{\partial p}(0,\phi,0,0)=0.$$

To get (2.12) we define

$$S(r,\phi,p,\mu) \overset{\text{def}}{=} r^{-1}\left[v^*(r,\phi,p,\mu)-v^*(0,\phi,p,\mu)\right] \quad \text{if } r\neq 0,$$

$$S(0,\phi,p,\mu) \overset{\text{def}}{=} \frac{\partial v^*}{\partial r}(0,\phi,p,\mu),$$

and observe that $S(r,\phi,p,0)=O(r^2)$. □

The next lemma is related to the bifurcation equation (2.5).

LEMMA 2.2. *Suppose hypotheses* (A_1), (B_1) *are satisfied. Then* F *and* G *given in* (2.5) *are odd in* r, *even in* μ *and* $G(r,\phi,p,0)\equiv 0$, *for* (r,p,μ) *in a small neighborhood of the origin.*

Proof. The first part follows from (2.6) and the second part is a consequence of (2.7) and (2.10). □

LEMMA 2.3. *Suppose hypotheses* (A_1), (B_1) *are satisfied. Then, for* (r,p,μ) *in a small neighborhood of the origin,* $G(r,\phi,p,\mu)=r\mu^2\sin 2\phi(\rho+\cdots)$, *where*

$$\rho=-3\alpha(2\pi)^{-1}\int_0^{2\pi}(\mathscr{K}f(\tau))^2\cos 2\tau\,d\tau$$

and $\cdots$ *indicates terms of order* $O(|p|+|\mu|+|r|)$, *uniformly with respect to* ϕ, *as* (r,p,μ) *goes to* $(0,0,0)$.

Proof. From (2.10) it follows that

$$G(r,0,p,\mu)\equiv 0 \quad \text{and} \quad G\left(r,\frac{\pi}{2},p,\mu\right)\equiv 0. \tag{2.13}$$

Applying (2.13) and Lemma 2.2 we obtain $G(r,\phi,p,\mu)=r\mu^2\sin 2\phi H(r,\phi,p,\mu)$, where H is a smooth function.

From (2.12) and (B_1) it follows that

$$G(r,\phi,p,\mu)=\pi^{-1}\left[3\alpha r^2\int_0^{2\pi}\cos^2 s\,v^*(s)\sin s\,ds+3\alpha r\int_0^{2\pi}\cos s\left(v^*(s)\right)^2\sin s\,ds\right.$$
$$\left.+\alpha\int_0^{2\pi}\left(v^*(s)\right)^3\sin s\,ds+o\left(r^2+\mu^2\right)\right].$$

By (2.11) and (2.12),

$$\frac{\partial^3 G}{\partial\mu^2\partial r}(0,\phi,0,0)=-\frac{3\alpha}{\pi}\sin 2\phi\int_0^{2\pi}(\mathscr{K}f(\tau))^2\cos 2\tau\,d\tau.$$

From this expression we obtain the value of ρ and this completes the proof of our lemma. □

3. The non odd-harmonic case. In this section we give conditions on the nonlinear term and on the forcing function in such a way that the only small 2π-periodic solutions $u(t)$ of (1.1) are such that, either $u(t)$ or $u(t-\pi/2)$ is an even function of t. We also descibe the bifurcation diagram. As an example we consider the equation $\ddot{u}+u=pu+u^3+\mu(1+\cos 2t)$.

THEOREM 3.1. *Suppose hypotheses* (A_1), (B_1) *are satisfied and that* $\alpha\int_0^{2\pi}(\mathscr{K}f(\tau))^2\cos 2\tau\,d\tau\neq 0$, *where* $\mathscr{K}f$ *is the* π*-periodic solution of* $\ddot{u}+u=f(t)$. *Then the only small* 2π*-periodic solutions* $u(t)$ *of* (1.1) *are such that either* $u(t)$ *or* $u(t-\pi/2)$ *is an even function of* t, *for* (p,μ) *in a small neighborhood of the origin and* $\mu\neq 0$.

Proof. By Lemma 2.3, $G(r,\phi,p,\mu)=r\mu^2\sin 2\phi(\rho+\cdots)$. We see that $r=0$ solves $G(r,\phi,p,\mu)=0$. Since in this case, $u(t)=v^*(0,\phi,p,\mu)(t-\phi)$, it follows from (2.9) that $u(t)$ is even in t. For $\mu\neq 0$, since $\rho\neq 0$, the only left possibility is that $\sin 2\phi=0$. This implies $\phi=0,\ \pi/2$, because we have assumed that ϕ is in $(-\pi/2,\pi/2]$. Recalling that $u(t)=r\cos(t-\phi)+v^*(r,\phi,p,\mu)(t-\phi)$, it follows from (2.10) that for $\phi=0$, $u(t)$ is even in t. For $\phi=\pi/2$, we have, from (2.7) that $v^*(r,\pi/2,p,\mu)(t-\pi)=v^*(-r,\pi/2,p,\mu)(t)$. Then $u(t-\pi/2)=r\cos(t-\pi)+v^*(-r,\pi/2,p,\mu)(t)$ is an even function of t, as a consequence of (2.10). □

We should point out that the above theorem still does not prove the existence of 2π-periodic solutions, because the first bifurcation equation was not solved yet. It only states that if some solution exists it must have the mentioned properties.

Now we turn to (2.5a). By using hypothesis (B_1), we let $g(u,p)\overset{\text{def}}{=}pu+\alpha u^3+pu^3h_1(u,p)+u^5h_2(u)$, where h_1, h_2 are smooth functions. If we write

$$h_1(r\cos t+v^*(r,\phi,p,\mu)(t),\ p)=h_1(v^*(0,\phi,p,\mu)(t),\ p)+O(r),$$

$$h_2(r\cos t+v^*(r,\phi,p,\mu)(t))=h_2(v^*(0,\phi,p,\mu)(t))+O(r)$$

and use (2.12), (2.8), (2.11), we can show that, $F(r,\phi,p,\mu)=r[p+\frac{3}{4}\alpha r^2+3\alpha\lambda\mu^2+o(|p|+r^2+\mu^2)]$, where

$$\lambda=\lambda(\phi)=\frac{1}{2\pi}\left[\int_0^{2\pi}(\mathscr{K}f(\tau))^2\,d\tau+\cos 2\phi\int_0^{2\pi}((\mathscr{K}f)(\tau))^2\cos 2\tau\,d\tau\right]. \tag{3.1}$$

It is clear that $r=0$ solves $F(r,\phi,p,\mu)=0$ and we already know that this will give rise to a π-periodic solution of (1.1).

Let $J(r,\phi,p,\mu)\overset{\text{def}}{=}r^{-1}F(r,\phi,p,\mu)$ if $r\neq 0$ and $J(0,\phi,p,\mu)\overset{\text{def}}{=}F_r(0,\phi,p,\mu)$. In order to find the multiple roots of $J=0$, we must solve the system

$$\begin{aligned} J(r,\phi,p,\mu)&=p+\frac{3}{4}\alpha r^2+3\alpha\lambda\mu^2+\cdots=0,\\ J_r(r,\phi,p,\mu)&=\frac{3}{2}\alpha r+\cdots=0, \end{aligned} \tag{3.2}$$

where $\cdots$ indicates higher order terms.

Since $\det(\partial J,J_r)/\partial(p,r))=\frac{3}{2}\alpha$ for $r=p=\mu=0$ from the implicit function theorem, it follows from (3.2) that for $\alpha\neq 0$, p and r can be solved for as functions of μ in a neighborhood of the origin, for $\phi=0$ and $\phi=\pi/2$. But Lemma 2.2 implies that $F(r,\phi,p,\mu)$ is an odd function of r. This shows that $J_r(0,\phi,p,\mu)\equiv 0$. Thus $r\equiv 0$ is the function of μ given above. The functions $p=p(\mu)$ can be found by solving $J(0,\phi,p,\mu)=p+3\alpha\lambda\mu^2+o(|p|+|\mu|^2)=0$, and we obtain $p=-3\alpha\lambda\mu^2+O(\mu^4)$.

If we assume that $\alpha\int_0^{2\pi}\cos 2\tau[(\mathscr{K}f)(\tau)]^2\,d\tau\neq 0$, an analysis of (3.1) shows that $\lambda_1\overset{\text{def}}{=}\lambda(0)$ and $\lambda_2\overset{\text{def}}{=}\lambda(\pi/2)$ are nonzero and distinct. Then we have two bifurcation curves, Γ_1 and Γ_2, for $\phi=0$ and $\phi=\pi/2$, respectively, given by

$$\begin{aligned} \Gamma_1:&\quad p=-3\alpha\lambda_1\mu^2+O(\mu^4),\\ \Gamma_2:&\quad p=-3\alpha\lambda_2\mu^2+O(\mu^4). \end{aligned}$$

Using the fact that J is quadratic in r, we can prove that when we cross each bifurcation curve we gain or lose two solutions. In Fig. 3.1 we show the bifurcation diagram with the number of 2π-periodic solutions of (1.1), in a neighborhood of the origin, when λ_1, λ_2 and α are positive. Thus, we have proved the following.

THEOREM 3.2. *Suppose* (A_1), (B_1) *are satisfied and that* $\alpha\int_0^{2\pi}\cos 2\tau[(\mathscr{K}f)(\tau)]^2 d\tau \neq 0$, *where* $\mathscr{K}f$ *is the* π*-periodic solution of* $\ddot{u}+u=f(t)$. *Then there exist two bifurcation curves* Γ_1 *and* Γ_2, *in the plane* (p,μ), *given by* $p=-3\alpha\lambda_1\mu^2+O(\mu^4)$ *and* $p=-3\alpha\lambda_2\mu^2+O(\mu^4)$, *respectively, where* λ_1 *and* λ_2 *are obtained from* (3.1), *for* $\phi=0$, *and* $\phi=\pi/2$, *respectively. These curves divide a neighborhood of the origin into three regions, as shown in Fig.* 3.1. *In* S_1 *there is only one* 2π*-periodic solution which is in fact* π*-periodic. In* S_2 *there are two solutions with minimum period* 2π *and one with period* π. *In* S_3 *there are four solutions with minimum period* 2π *and one with period* π. *In* Γ_1 *we have only one* 2π*-periodic solution, which is in fact* π*-periodic; and in* Γ_2 *we have three* 2π*-periodic solutions, but one of them is* π*-periodic. All of the above information is concerned with small solutions, for* $\mu\neq 0$.

Example 3.1. Let us consider (1.1) with $f(t)=1+\cos 2t$ and $g(u,p)=pu+u^3$. In this case we have Duffing's equation. The calculation shows that $\rho=1$, $\lambda_1=\lambda(0)=\frac{13}{18}$, $\lambda_2=\lambda(\pi/2)=\frac{25}{18}$ and the bifurcation curves are given by $\Gamma_1: p=-\frac{13}{6}\mu^2+O(\mu^4)$, $\Gamma_2: p=-\frac{25}{6}\mu^2+O(\mu^4)$ and the picture is shown in Fig. 3.1.

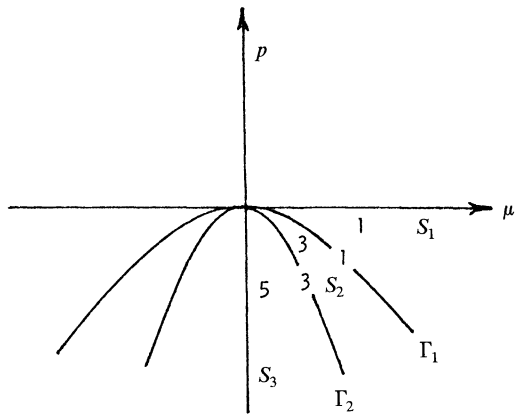

FIG. 3.1

4. The odd-harmonic case. This section contains our main results and is the most difficult part of this paper. The reason for the difficulty is that more symmetries are present in (1.1) and as a consequence, the bifurcation equation is more degenerate.

In this part we will assume more restrictive conditions on the forcing function and on the nonlinearity.

(A_2) $f: R\to R$ is an even continuous function and $f(t+\pi/2)=-f(t)$, for all t in R.

(B_2) g is a real C^∞ function, defined in a neighborhood of the origin, $g(u,p)=pu+\alpha u^3+\nu u^5+O(|pu^3|+|u^7|)$ and g is odd in u.

Besides the information given by Lemma 2.1, we have in this case the following properties of the solution of the auxiliary equation (2.4a).

LEMMA 4.1. *Suppose* (A_2), (B_2) *are satisfied. Then, for all* t *in* R,

$$v^*(0,\phi,p,\mu)(t+\pi/2)=-v^*(0,\phi,p,\mu)(t). \tag{4.1}$$

Furthermore, $v^*(r,\pi/4,p,\mu)(t-\pi/2)$ *is odd in* t.

The proof follows the same ideas as for Lemma 2.1.

Remark. Besides the above information, we need in this section the following properties which follow easily from Lemma 2.1 under the assumptions (A_1), (B_1).

$$\frac{\partial v^*}{\partial r}(0,\phi,p,\mu)(t+\pi) = -\frac{\partial v^*}{\partial r}(0,\phi,p,\mu)(t), \tag{4.2}$$

$$\frac{\partial^2 v^*}{\partial r^2}(0,\phi,p,\mu)(t) \text{ is } \pi\text{-periodic in } t. \tag{4.3}$$

It was not easy to discover the representation stated in the next theorem. It plays an important role in the proof of our main results.

THEOREM 4.1. *Suppose* (B_1) *and* (B_2) *are satisfied. Then* $(\partial v^*/\partial r)(0,\phi,p,\mu)(t-\phi) = a(t)\cos(t-\phi)+b(t)\sin(t-\phi)$, *where* $a=a(p,\mu)$, $b=b(p,\mu)$ *are* $\pi/2$*-periodic functions, independent of* ϕ *and with mean value zero. Furthermore* $a=a(t)$ *and* $b=b(t)$ *are, respectively, even and odd in* t.

Proof. Let $M_\phi \overset{\text{def}}{=} \{ y(\cdot,\phi)\in\mathscr{P}^{(2)} : y(t,\phi)=a(t)\cos(t-\phi)+b(t)\sin(t-\phi)$, where a and b are $C^{(2)}$, $\pi/2$-periodic functions, with mean value zero, a is even and b is odd$\}$.

Next, we prove that M_ϕ is a closed subspace of $\mathscr{P}^{(2)}$. Let $y_n(t,\phi)=a_n(t)\cos(t-\phi)+b_n(t)\sin(t-\phi)$ be such that $y_n(\cdot,\phi)\to y(\cdot,\phi)$ in $\mathscr{P}^{(2)}$. An easy calculation shows that

$$\begin{aligned} a_n(t) &= y_n(t,\phi)\cos(t-\phi) - y_n(t+\pi/2,\phi)\sin(t-\phi), \\ b_n(t) &= y_n(t,\phi)\sin(t-\phi) + y_n(t+\pi/2,\phi)\cos(t-\phi). \end{aligned} \tag{4.4}$$

Then (a_n) and (b_n) are convergent in $\mathscr{P}^{(2)}$. Let a and b be their limits.

Relations (4.4) imply that $y(t,\phi)=a(t)\cos(t-\phi)+b(t)\sin(t-\phi)$. The other properties which define M_ϕ are easily verified.

Now we observe that $(\partial v^*/\partial r)(0,\phi,p,\mu)(t-\phi)$ is a solution of the equation

$$\ddot{x}+x = (I-P)\left[\frac{\partial g}{\partial u}\big(v^*(0,\phi,p,\mu)(\cdot-\phi),\ p\big)(\cos(\cdot-\phi)+x)\right].$$

We define $H:\mathscr{P}^{(2)}\to\mathscr{P}$ by

$$Hy = \mathscr{K}(I-P)\left[\frac{\partial g}{\partial u}\big(v^*(0,\phi,p,\mu)(\cdot-\phi),\ p\big)(\cos(\cdot-\phi)+y)\right].$$

Our next purpose is to prove that H leaves M_ϕ invariant. As a first step we claim that if $\alpha(t)$, $\beta(t)$ are $C^{(2)}$, $\pi/2$-periodic functions, $\alpha(t)$ is even, $\beta(t)$ is odd and if we assume that β has mean value zero, then

$$z(\cdot,\phi) \overset{\text{def}}{=} (I-P)(\alpha(\cdot)\cos(\cdot-\phi)+\beta(\cdot)\sin(\cdot-\phi))$$

is an element of M_ϕ. This follows from

$$z(t,\phi) = \left[\alpha(t) - (2\pi)^{-1}\int_0^{2\pi}\alpha(s)\,ds\right]\cos(t-\phi)+\beta(t)\sin(t-\phi).$$

Using the above claim, (B_1), Lemma 2.1 and Lemma 4.1, we can prove that

$$(I-P)\left[\frac{\partial g}{\partial u}\big(v^*(0,\phi,p,\mu)(\cdot-\phi),\ p\big)(\cos(\cdot-\phi)+y(\cdot-\phi))\right]$$

belongs to M_ϕ if $y(\cdot-\phi)$ is in M_ϕ.

Now, we prove that if $y(\cdot,\phi)$ is in M_ϕ, the $\mathscr{K}y(\cdot,\phi)$ is in M_ϕ. Since $\mathscr{K}$ is linear we will prove it for $y(t,\phi)=a(t)\cos(t-\phi)$ and the other part follows in a similar way.

By computing $\mathscr{K}y(\cdot,\phi)$, we obtain $\mathscr{K}y(\cdot,\phi)(t)=A(t)\cos(t-\phi)+B(t)\sin(t-\phi)$, where

$$A(t)=\frac{1}{2}\Bigg\{\Bigg[-\cos 2t\int_0^t a(s)\sin 2s\,ds-(2\pi)^{-1}\int_0^{2\pi}\cos 2s\,ds\int_0^s a(u)\sin 2u\,du$$

$$-\frac{1}{2\pi}\cos 2t\int_0^{2\pi}ds\int_0^s a(u)\sin 2u\,du\Bigg]$$

$$+\Bigg[\sin 2t\int_0^t a(s)\cos 2s\,ds-\frac{1}{2\pi}\int_0^{2\pi}\sin 2s\,ds\int_0^s a(u)\cos 2u\,du\Bigg]\Bigg\}.$$

$$B(t)=\frac{1}{2}\Bigg\{\int_0^t a(s)\,ds-\Bigg[\sin 2t\int_0^t a(s)\sin 2s\,ds-\frac{1}{2\pi}\sin 2t\int_0^{2\pi}ds\int_0^s a(u)\sin 2u\,du\Bigg]$$

$$-\cos 2t\int_0^t a(s)\cos 2s\,ds\Bigg\}.$$

With the identity

$$\frac{1}{2\pi}\int_0^{\pi}ds\int_0^s a(u)\sin 2u\,du=\int_0^{\pi/2}a(s)\sin 2s\,ds,$$

we prove that $A(t)$ and $B(t)$ are $\pi/2$-periodic. The remaining properties, which define M_ϕ, follow in a natural way. This concludes the proof that $\mathscr{K}y(\cdot,\phi)$ belongs to M_ϕ and so H leaves M_ϕ invariant.

Moreover, H is a uniform contraction with respect to (p,μ) in a neighborhood of the origin and ϕ in $(-\pi/2\pi/2]$.

From the contraction fixed point principle it follows that H has a unique fixed point in a small neighborhood of the origin in $\mathscr{P}^{(2)}$. Since M_ϕ is itself a Banach space and it is invariant under H, it follows that the fixed point must be in M_ϕ and this completes the proof that $(\partial v^*/\partial r)(0,\phi,p,\mu)(t-\phi)$ has the desired form. □

LEMMA 4.2. *Suppose hypotheses* (A_2), (B_2) *are satisfied. Then for* (r,p,μ) *in a small neighborhood of the origin*

$$G(r,\phi,p,\mu)=r^3\mu^2\sin 4\phi(\eta+\cdots), \tag{4.5}$$

where

$$\eta=\frac{1}{12\pi}\Bigg\{-27\alpha^2\int_0^{2\pi}\Big[\mathscr{K}(I-P)\Big((\mathscr{K}f(\cdot))^2\cos(\cdot)\Big)\Big](s)\cos 3s\,ds \tag{4.6}$$

$$-27\alpha^2\int_0^{2\pi}(\mathscr{K}f)(\tau)\mathscr{K}[(\mathscr{K}f)(\cdot)\cos 2(\cdot)](s)\cos 2s\,ds$$

$$+27\alpha^2\int_0^{2\pi}(\mathscr{K}f)(\tau)\mathscr{K}[(\mathscr{K}f)(\cdot)\sin 2(\cdot)](s)\sin 2s\,ds$$

$$+\Big[\frac{9}{16}\alpha^2-15\nu\Big]\int_0^{2\pi}[\mathscr{K}f(\tau)]^2\cos 4\tau\,d\tau\Bigg\},$$

$\mathscr{K}$ *is given by* (2.3) *and* $\cdots$ *indicates terms of order* $O(|p|+|\mu|+|r|)$, *uniformly on* ϕ, *as* (r,p,μ) *goes to* $(0,0,0)$.

Proof. From the last statement of Lemma 4.1, and (2.10), it follows that

$$G(r,\phi,p,\mu)\equiv 0 \quad \text{for } \phi=0,\ \pi/2,\ \pi/4. \tag{4.7}$$

Now we claim that

$$\frac{\partial G}{\partial r}(0,\phi,p,\mu)\equiv 0. \tag{4.8}$$

In fact, from Theorem 4.1,

$$\begin{aligned}\frac{\partial G}{\partial r}(0,\phi,p,\mu)&=\frac{1}{\pi}\int_0^{2\pi} g_u(v^*(0,\phi,p,\mu)(s-\phi),\ p)\frac{\partial v^*}{\partial r}(0,\phi,p,\mu)(s-\phi)\sin(s-\phi)\,ds\\&=\frac{1}{\pi}\int_0^{2\pi} g_u(v^*(0,\phi,p,\mu)(s-\phi),\ p)[a(s)\cos(s-\phi)+b(s)\sin(s-\phi)]\sin(s-\phi)\,ds\\&=\frac{1}{2\pi}\int_0^{2\pi} g_u(v^*(0,\phi,p,\mu)(s-\phi),\ p)(a(s)\sin 2(s-\phi)-b(s)\cos 2(s-\phi))\,ds\\&\quad+\frac{1}{2\pi}\int_0^{2\pi} g_u(v^*(0,\phi,p,\mu)(s-\phi),\ p)b(s)\,ds.\end{aligned}$$

Since $g_u(u,p)$ is even in u, from (4.1) it follows that $g_u(v^*(0,\phi,p,\mu)(s-\phi),\ p)$ is $\pi/2$-periodic in s. If we add to this the fact that a and b are $\pi/2$-periodic and that $\sin 2(s-\phi)$ and $\cos 2(s-\phi)$ change sign, when we change s by $s+\pi/2$, we conclude that the last but one integral vanishes. To prove that the last integral vanishes we use (2.9) and the fact that b is odd. This completes the proof of (4.8).

From Lemma 2.2, $G(r,\phi,p,\mu)$ is odd in r, even in μ and $G(r,\phi,p,0)\equiv 0$. If we use this information with (4.7) and (4.8), we can prove that there is a smooth function $S(r,\phi,p,\mu)$ such that $G(r,\phi,p,\mu)=r^3\mu^2\sin 4\phi S(r,\phi,p,\mu)$.

Since $g(u,0)=\alpha u^3+\nu u^5+O(u^7)$, we obtain

$$\begin{aligned}\frac{\partial^5}{\partial\mu^2\partial r^3}G(0,\phi,0,0)=\pi^{-1}\Big\{&18\alpha\int_0^{2\pi}\frac{\partial 3v^*}{\partial\mu^2\partial r}(0,\phi,0,0)(s)\cos^2 s\sin s\,ds\\&+36\alpha\int_0^{2\pi}\frac{\partial v^*}{\partial\mu}(0,\phi,0,0)(s)\frac{\partial^3 v^*}{\partial\mu\partial r^2}(0,\phi,0,0)(s)\sin s\cos s\,ds\\&+6\alpha\int_0^{2\pi}\left[\frac{\partial v^*}{\partial\mu}(0,\phi,0,0)(s)\right]^2\frac{\partial^3 v^*}{\partial r^3}(0,\phi,0,0)(s)\sin s\,ds\\&+120\nu\int_0^{2\pi}\left[\frac{\partial v^*}{\partial\mu}(0,\phi,0,0)(s)\right]^2\cos^3 s\sin s\,ds\Big\}.\end{aligned} \tag{4.9}$$

But

$$\frac{\partial^3 v^*}{\partial\mu^2\partial r}(0,\phi,0,0)=6\alpha\mathscr{K}(I-P)\big[(\mathscr{K}f(\cdot+\phi))^2\cos(\cdot)\big], \tag{4.10}$$

$$\frac{\partial v^*}{\partial\mu}(0,\phi,0,0)=\mathscr{K}f(\cdot+\phi), \tag{4.11}$$

$$\frac{\partial^3 v^*}{\partial\mu\partial r^2}(0,\phi,0,0)=6\alpha\mathscr{K}(I-P)\big[\mathscr{K}f(\cdot+\phi)\cos^2(\cdot)\big], \tag{4.12}$$

$$\frac{\partial^3 v^*}{\partial r^3}(0,\phi,0,0)=-\frac{3}{16}\alpha\cos 3(\cdot). \tag{4.13}$$

If we substitute (4.10)–(4.13) in (4.9), use the change $s=\tau-\phi$ in the integrals and take into account that $(\mathscr{K}(I-P)f)(t-\phi)=(\mathscr{K}(I-P)f(\cdot-\phi))(t)$ and $(\mathscr{K}f)(t-\phi)=(\mathscr{K}f(\cdot-\phi))(t)$, we obtain

$$\frac{\partial^5}{\partial\mu^2\partial r^3}G(0,\phi,0,0)=\frac{1}{\pi}\sin 4\phi\Big\{-27\alpha^2\int_0^{2\pi}\mathscr{K}(I-P)\big[(\mathscr{K}f(\cdot))^2\cos(\cdot)\big](\tau)\cos 3\tau\,d\tau$$
$$-27\alpha^2\int_0^{2\pi}(\mathscr{K}f)(\tau)\mathscr{K}\big[(\mathscr{K}f)(\cdot)\cos 2(\cdot)\big](\tau)\cos 2\tau\,d\tau$$
$$+27\alpha^2\int_0^{2\pi}(\mathscr{K}f)(\tau)\mathscr{K}\big[(\mathscr{K}f)(\cdot)\sin 2(\cdot)\big](\tau)\sin 2\tau\,d\tau$$
$$+\Big(\frac{9}{16}\alpha^2-15\nu\Big)\int_0^{2\pi}((\mathscr{K}f)(\tau))^2\cos 4\tau\,d\tau\Big\}.$$

This completes the proof of the lemma and gives the expression for η. □

Remark 4.1. It should be pointed out that the expression (4.6), which defines η, can be computed as long as we know the forcing function and the coefficients α and ν respectively of third and fifth order, of the Taylor expansion of $g(u,0)$ in u, around 0.

The next theorem is our main result. It claims that, under certain conditions, the small 2π-periodic solutions of (1.1) maintain some symmetry properties of the forcing function.

THEOREM 4.2. *Suppose hypotheses* (A_2), (B_2) *are satisfied and* $\eta\neq 0$, *where* η *is given by* (4.6). *Then the only small* 2π*-periodic solutions of* (1.1) *are such that* $u(t)$ *or* $u(t-\pi/2)$ *is even or* $u(t\pm\pi/4)$ *is odd in* t *for* (ρ,μ) *small and* $\mu\neq 0$.

Proof. From Lemma 4.2, $G(r,\phi,p,\mu)=r^3\mu^2\sin 4\phi(\eta+\cdots)$. We see that $r=0$ solves $G(r,\phi,p,\mu)=0$ and we already know that it will give rise to a π-periodic solution $u(t)$ of (1.1). Since $\eta\neq 0$, for $\mu\neq 0$ the only possibility left is that $\sin 4\phi=0$. This implies $\phi=0$, $\pi/2$, $\pm\pi/4$, because we have assumed that ϕ is in $(-\pi/2,\pi/2]$.

As in §3, Theorem 3.1, we can show that for $\phi=0$, the solution $u(t)$ is even in t and for $\phi=\pi/2$, $u(t-\pi/2)$ is even in t.

For $\phi=\pi/4$ since $u(t)=r\cos(t-\pi/4)+v^*(r,\pi/4,p,\mu)(t-\pi/4)$, from the last statement of Lemma 4.1 it follows that $u(t-\pi/4)$ is odd in t. The case $\phi=-\pi/4$ is similar. This completes the proof of our theorem. □

Now we turn to the analysis of the first bifurcation equation.

If we proceed as in the proof of Theorem 3.2, we see that bifurcation curves will be obtained by solving $J(0,\phi,p,\mu)=0$. The next lemma helps us to understand that equation.

LEMMA 4.3. *Suppose* (A_2), (B_2) *are satisfied. Then* $J(0,\phi,p,\mu)$ *is independent of* ϕ.

Proof. Using the definition of J,

$$J(0,\phi,p,\mu)=\frac{1}{\pi}\int_0^{2\pi}g_u\big(v^*(0,\phi,p,\mu)(s),\ p\big)\Big(\cos s+\frac{\partial v^*}{\partial r}(0,\phi,p,\mu)(s)\Big)\cos s\,ds.$$

If we let $s=\tau-\phi$ and proceed as in the proof of (4.8), by using (4.1) and Theorem 4.1 we obtain

$$J(0,\phi,p,\mu)=\frac{1}{2\pi}\Big(\int_0^{2\pi}g_u\big(v^*(0,\phi,p,\mu)(\tau-\phi),\ p\big)\,d\tau\Big)$$
$$+\int_0^{2\pi}g_u\big(v^*(0,\phi,p,\mu)(\tau-\phi)a(\tau)\,d\tau\big),$$

where $a(\tau)$ is given as in Theorem 4.1. Using (2.9) and Theorem 4.1, we see that $J(0,\phi,p,\mu)$ is independent of ϕ. □

The next theorem is very interesting and it describes the changes of the number of the small 2π-periodic solutions of (1.1) as (p,μ) crosses the bifurcation curve.

THEOREM 4.3. *Suppose* (A_2), (B_2) *are satisfied and* η, *given by* (4.6), *is nonzero. Then there exists a unique bifurcation curve* Γ, *given by* $p=-3\alpha\lambda\mu^2+O(\mu^4)$, *where* $\lambda=(2\pi)^{-1}\int_0^{2\pi}(\mathscr{K}f(s))^2\,ds$ *and* $\mathscr{K}f$ *is the* π*-periodic solution of* $\ddot{u}+u=f(t)$. *The curve* Γ *divides a neighborhood of the origin, in the plane* (p,μ) *into two regions* S_1, S_2, *as shown in Fig.* 4.1 *for* $\alpha,\lambda>0$. *For* (p,μ) *in* S_1 *there is a unique* 2π*-periodic solution of* (1.1), *which is in fact* π*-periodic. In* S_2 *there are nine* 2π*-periodic solutions; only one of them is* π*-periodic. In* Γ *there is a unique* 2π*-periodic solution of* (1.1), *which is in fact* π*-periodic.*

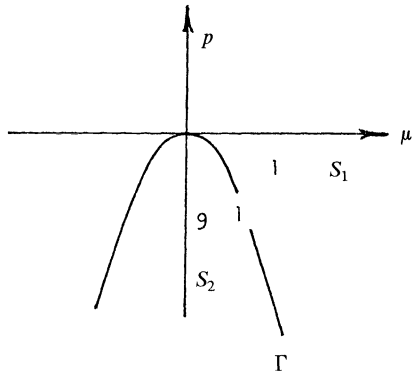

FIG. 4.1

All of the above information is concerned with small solutions of (1.1), *for* $\mu\neq 0$.

Proof. We proceed as in the proof of Theorem 3.2, by solving the equation

$$J(0,\phi,p,\mu)=p+3\alpha\lambda\mu^2+\cdots=0$$

where λ is given as in (3.1).

From (A_2) it follows that $\mathscr{K}f(\tau+\pi/2)=-\mathscr{K}f(\tau)$, and then

$$\lambda=\lambda(\phi)=\frac{1}{2\pi}\left[\int_0^{2\pi}(\mathscr{K}f(\tau))^2\,d\tau+\cos 2\phi\int_0^{2\pi}(\mathscr{K}f(\tau))^2\cos 2\tau\,d\tau\right]$$

$$=\frac{1}{2\pi}\int_0^{2\pi}(\mathscr{K}f(\tau))^2\,d\tau,$$

which shows that λ is independent of ϕ. Since, from Lemma 4.3, $J(0,\phi,p,\mu)$ is independent of ϕ, we conclude by implicit function theorem, that the bifurcation curve is the same for $\phi=0$, $\pi/2$, $\pm\pi/4$ and it is given by $p=-3\alpha\lambda\mu^2+O(\mu^4)$.

Since $J(r,\phi,p,\mu)$ is quadratic in r we see that for each phase, $\phi=0$, $\pi/2$, $\pm\pi/4$, when we cross Γ, we gain or lose two solutions, $u(t)=r\cos(t-\phi)+v^*(r,\phi,p,\mu)(t-\phi)$, of (1.1) of minimum period 2π, besides the π-periodic one. This completes the proof of our theorem. □

The bifurcation is not so degenerate as it appears. In fact the above proof shows that, besides the π-periodic solution, for each fixed phase $\phi=0$, $\pi/2$, $\pm\pi/4$, we have a quadratic bifurcation in r.

Example 4.1. Consider the equation $\ddot{u}+u=pu+u^3+\mu\cos 2t$. In this case $\eta=-\frac{11}{8}$, $\lambda=\frac{1}{18}$, all the assumptions of Theorem 4.2 and Theorem 4.3 are satisfied and Γ is given by $p=-\frac{1}{6}\mu^2+O(\mu^4)$.

Example 4.2. Consider the equation of a forced pendulum $\ddot{v}+(g/L)\sin v=\sigma\cos 2w\tau$, where w varies near $w_0=\sqrt{g/L}$ and σ is small. With the changes $u(t)\overset{\text{def}}{=}v(t/w)$, $w_0^2/w^2\overset{\text{def}}{=}1-p$ and $\mu\overset{\text{def}}{=}\sigma/w^2$ the above equation is reduced to $\ddot{u}+u=g(u,p)+\mu\cos 2t$, where, $g(u,p)=pu+(u^3/3!)-(u^5/5!)+O(|pu^3|+|u^7|)$. In this case $\eta=-\frac{1}{32}$, $\lambda=\frac{1}{18}$, all the assumptions of Theorem 4.2 and Theorem 4.3 are satisfied and Γ is given by $p=-\frac{1}{36}\mu^2+O(\mu^4)$.

5. Final remarks. As we said in the Introduction, we do not intend to exhaust all the possible cases, but we give below some indications about what can be expected when some of our assumptions are not satisfied. Some preliminary calculations show that the ideas of our work can be used to solve other cases not included here.

1. Suppose that g is not odd in u, but $g(u,p)=pu+\alpha u^2+O(|pu^2|+|u^3|)$. Some calculations indicate that the bifurcation equations are given by

$$F(r,\phi,p,\mu)=r\left[p+\tfrac{5}{6}\alpha^2r^2+\alpha\lambda\mu+\cdots\right]=0,$$
$$G(r,\phi,p,\mu)=r\mu\sin 2\phi(\xi+\cdots)=0,$$

where

$$\lambda=\int_0^{2\pi}\mathscr{K}f(s)\,ds+\cos 2\phi\int_0^{2\pi}\mathscr{K}f(s)\cos 2s\,ds,$$
$$\xi=-\frac{\alpha}{\pi}\int_0^{2\pi}\mathscr{K}f(s)\cos 2s\,ds.$$

Thus, if $\xi\neq 0$ the only small 2π-periodic solutions $u(t)$ of (1.1) must satisfy either $u(t)$ is even in t or $u(t-\pi/2)$ is even in t, for $\mu\neq 0$.

The analysis of the first bifurcation equation furnishes the bifurcation curves.

2. Our approach should help to explain the case when the forcing function is even and $(2\pi/n)$-periodic, where n is a positive integer. For instance, some calculations for the example $\ddot{u}+u=pu+u^3+\mu\cos 3t$, show that the bifurcation equations are given by

$$F(r,\phi,p,\mu)=r\left[p+\tfrac{3}{4}r^2+\tfrac{3}{128}\mu^2+\cdots\right]=0,$$
$$G(r,\phi,p,\mu)=r^2\mu\sin 3\phi\left(\tfrac{3}{32}+\cdots\right)=0$$

and the only small 2π-periodic solutions $u(t)$ must satisfy either $u(t)$ is even or $u(t\pm\pi/3)$ is even in t.

Acknowledgment. We are grateful to a referee for valuable comments, in particular for a remark about the conjecture presented in the Introduction.

MULTIPLICITY OF SOLUTIONS OF NONLINEAR BOUNDARY VALUE PROBLEMS*

D. C. HART[†§], A. C. LAZER[‡] AND P. J. MCKENNA[†]

Abstract. Sharp results for the number of solutions of a one-dimensional nonlinear Neumann boundary value problem are given, in terms of the range of its linearization, and the projection of the source term onto the principle eigenfunction.

Key words. nonlinear Neumann problems, jumping nonlinearities, multiple solutions, bifurcations, scaling, perturbation, phase plane

AMS(MOS) subject classifications. Primary 34B15; secondary 35J65

1. There have been many investigations in recent years of nonlinear boundary value problems for equations of the form

$$\Delta u + g(u) = h(x) \tag{1}$$

under assumptions on the behavior of g at infinity:

$$\lim_{x \to -\infty} \frac{g(x)}{x} = a \quad \text{and} \quad \lim_{x \to +\infty} \frac{g(x)}{x} = b, \tag{2}$$

called asymptotically sublinear, linear, or superlinear if a and b are zero, finite, or infinite. Let $\lambda_1 < \lambda_2 \leqq \lambda_3 \cdots$ denote the eigenvalues of the linear problem

$$\Delta v + \lambda v = 0 \tag{3}$$

with, for example, Dirichlet boundary conditions. One may then investigate the effect of relationships between a, b and the $\{\lambda_i\}$. We suppose $a < b$ (so that g is what Fučik [8] terms a "jumping nonlinearity"); the cases $a < b$ and $b < a$ are equivalent under change of variables. If $\lambda < a \leqq g' \leqq b < \lambda_{n+1}$ for some n, then there is a unique solution of the Dirichlet problem (or the Neumann problem) for (1), for any smooth g and h; see, for example [5, Chap. 3].

Amann and Hess [1] and Dancer [6] have shown that if we decompose h as $s\phi_1 + h_1$, where ϕ_1 is the positive normalized eigenfunction for λ_1 and h_1 is orthogonal to ϕ_1 (in L^2), then there exists $S_0 = S_0(h_1)$ such that no solution exists for $s < S_0$, but (at least) two solutions exist for any $s > S_0$, if $a < \lambda_1 < b$. If also $b < \lambda_2$ and $g \in C^2$, with $g'' > 0$, then Berger and Podolak [4] have shown that there are exactly two solutions for $s > S_0$ (and exactly one at $s = S_0$); this extends to an earlier result of Ambrosetti and Prodi [2].

In [12], Lazer and McKenna conjecture that whenever $a<\lambda_1$, $\lambda_n<b<\lambda_{n+1}$ and h is as above, then for sufficiently large s there are at least $2n$ distinct solutions. Some partial results are given in [7], [10], [14], [17]. They have proved this for the one-dimensional case in [13]. The present authors have extended that result in [9], to show that if $a\in(\lambda_k,\lambda_{k+1})$ and $b\in(\lambda_n,\lambda_{n+1})$, for some integers $n>k\geqq 1$ (and a technical "nonresonance" condition on a,b is satisfied), then the number of solutions of

$$u''+g(u)=s\sin t+h_1(t), \tag{4a}$$

$$u(0)=u(\pi)=0, \tag{4b}$$

for large positive s, plus the number of solutions for large negative s, is at least $2(n-k+1)$.

In this note we discuss the corresponding one-dimensional Neumann problem,

$$u''+g(u)=s+h(t), \tag{5a}$$

$$u'(0)=0=u'(\pi). \tag{5b}$$

The eigenvalues of the corresponding linear problem (3) are then just the squares of integers. We verify the conjecture, and show that the estimate for the number of solutions is sharp in the asymptotically linear or sublinear cases, for any smooth h.

We assume without further mention a nondegeneracy condition, in the statement of our theorems: that g' does not vanish on an interval. If this condition were violated, the theorems would remain true if the phrase "any s" were replaced throughout by "any s such that $g(u)-s$ does not vanish on an interval." Our main result is the following.

THEOREM 1. *Suppose* $g\in C^1(R)$, *that* $\lim_{u\to-\infty}g'(u)=a$, $\lim_{u\to+\infty}g'(u)=b$, *where* $b\in((n-1)^2,n^2)$ *for some integer* $n\geqq 1$. *If* $a<0$, *then for any* $h\in C^1([0,\pi])$, *there exists* $S_0>0$ *such that for any* $s>S_0$, (5) *has exactly* $2n$ *solutions. If* $a\in((k-1)^2,k^2)$, *for some integer* k, $0<k<n$, *and* $a^{-1/2}+b^{-1/2}$ *is not twice the reciprocal of an integer, then for any* $h\in C^1([0,\pi])$, *there exists* $S_+>0$ *and* $S_-<0$ *such that the number of solutions of* (5) *for any* $s<S_-$ *plus the number of solutions of* (5) *for any* $s>S^+$ *is exactly* $2(n-k+1)$.

Note that we include the equilibrium solutions in our count. Our method is to use scaling arguments to reduce the asymptotically linear case to a perturbation of the autonomous piecewise linear case, which we analyze by phase plane methods.

For the superlinear case, we have the following.

THEOREM 2. *Suppose* $g\in C^1(R)$, *that* $\lim_{u\to-\infty}g'(u)=a$, *for some* $a\in[-\infty,\infty)$, *and that* $\lim_{u\to+\infty}g'(u)=+\infty$. *Then for any positive integer* n *there exists* S_n *such that for* $s>S_n$, *there exists* $\eta>0$ *such that if* $h\in C^0([0,\pi])$ *and* $\|h\|_{C^0}<\eta$, *then* (5) *has at least* $2n$ *solutions. Further, there exist* $S_-<0$ *such that* $s<S_-$ *implies, for small enough* h, *at least* $2k$ *solutions when* $a\in((k-1)^2,k^2)$.

If we do not assume that $\lim_{u\to+\infty}g'(u)$ exists, but only retain the idea that $g'(u)$ increases from negative to positive as u increases, we still have the following.

THEOREM 3. *Let* $g\in C^1(R)$, *and suppose there exist numbers* $R_a<R_b$ *and* $a<0<b$ *such that* $u<R_a$ *implies that* $g'(u)<a$, *and* $u>R_b$ *implies that* $g'(u)>b$. *Assume that* $b>(n-1)^2$ *for some integer* $n\geqq 1$. *Then there exist* $S>0$ *such that for any* $s>S$, *there exists* $\eta>0$ *such that* $\|h\|_{C^0}<\eta$ *implies that* (5) *has at least* $2n$ *solutions.*

Finally, we note that these results would not be altered by the introduction of a "sufficiently small" dissipative term, $\varepsilon u'$, in (5). The plan of the papers is as follows: in §2, we establish the lower bounds on the number of solutions as given in Theorems 1, 2,

and 3. In §3, we establish the upper bound on the number of solutions as given in Theorem 1 for piecewise linear autonomous equations. In §4, we show that we can reduce the general situations of Theorem 1 to perturbations of the problem treated in §3.

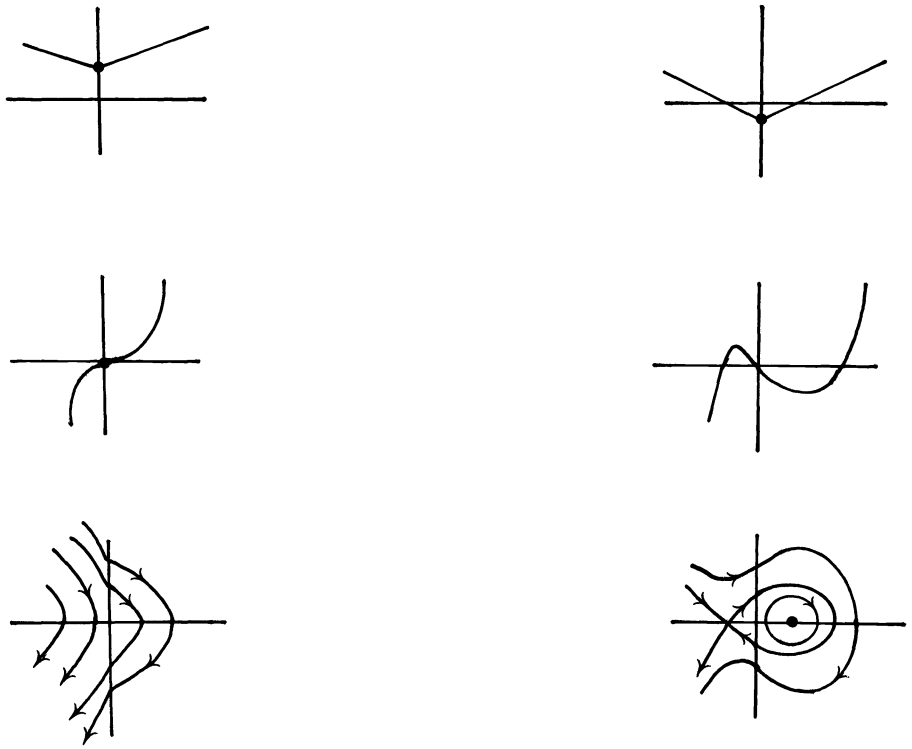
2. Solutions to the autonomous equation (h = constant)

$$u''+g(u)=s, \tag{6a}$$

$$u'(0)=0=u'(\pi), \tag{6b}$$

lie in the level curves of the conserved "energy" $E=\frac{1}{2}(u')^2+V(u)$, where the "potential" $V(u)=\int^u [g(t)-s]\,dt$ (see for example [3] or [11]). Solutions of the Neumann problem (6) are simply segments of 2π-periodic trajectories. Any periodic solution lies in a "well" of the potential, that is, a neighborhood of a local minimum of V. These minima, in general, are just the solutions of $g(u)=s$ such that $g'(u)>0$ (see Fig. 1b). At such an equilibrium point C (a "center"), the period tends to $2\pi(g'(c))^{-1/2}$, the period of the linearization of the vector field

$$u'=v, \qquad v'=s-g(u) \tag{7}$$



(a) $s<0$. (b) $s>0$.

FIG. 1

at the constant solution $u=C$. Note that if g' is monotone there can be only one such well, so just one center C. Further, by choice of s we may drive C toward positive or negative infinity (for a,b not zero), and so control $g'(C)$. Note also that the nondegeneracy hypothesis, that g' does not vanish on an interval, implies that $g(u)-s$ does not vanish on an interval but at discrete points; this is the only use we make of this hypothesis.

Suppose that the hypotheses of Theorem 3 are satisfied; for some numbers $R_a<R_b$, $g'(u)<a<0$ if $u<R_a$, and $g'(u)>b>0$ if $u>R_b$, where $b>(n-1)^2$ for some positive integer n. Then there must be at exactly two equilibria for s large, since $g(u)\to\infty$ as $u\to\pm\infty$; let C be the larger, and S the smaller. Then as the energy E increases from $V(C)$ to $V(S)$, the periods go from $2\pi(g'(C))^{-1/2}$ to infinity; hence if s is such that $g'(C)>(n-1)^2$, there exists a $(2\pi/k)$-periodic trajectory $(u_k(t),v_k(t))$ of (7) for each integer k between 1 and $n-1$. Hence the Neumann problem (6) has at least $2n$ solutions (including the constant solutions $u\equiv C$ and $u\equiv S$), obtained by requiring that $v_k(0)=0$. Let $\phi(t,u_0,v_0)=(u(t,u_0,v_0),\ v(t,u_0,v_0))$ be the time-t map (the flow) for the solution of (7) with initial conditions $u(0)=u_0$, $v(0)=v_0$. Then for some neighborhood of $u_k(0)$, where $u_k(t)$ is a solution of the Neumann problem (6), $\phi(\pi)$ carries the u-axis across itself, with a zero at $u_k(\pi)$. If h is C^0-small, then the time-π map for (5) must also carry the u-axis across itself, and thus (5) also has a solution (near the solution $u_k(t)$ of (6)). The persistence of the constant solutions follows from the inverse function theorem, in the standard way [5]. This proves Theorem 3, and Theorem 2 for $a<0$.

We now treat the case $a>0$ of Theorem 2. If $\lim_{u\to-\infty}g'(u)=a\in((k-1)^2,k^2)$ for an integer $k\geqq 1$, and $\lim_{u\to+\infty}g'(u)=+\infty$, then $g(u)=s$ has a unique solution $C=C(s)$ for large positive s, and also for large negative s; all solutions are then periodic. Choose S_n such that $g'(C)>n^2$ for $s>S_n$; then the periods of (6) approach some value less than $2\pi/n$, as the solutions approach C. Since n may be arbitrary, we need only show that the greatest period is bounded below. Let $x=u-C$ and $f(x)=g(x+C)-s$, so that (6a) becomes $x''+f(x)=0$, where $f(0)=0$. Introduce polar coordinates by $x=r\cos\theta$, $y=x'/\omega=r\sin\theta$, where we treat ω as a free parameter. Then

$$\theta'=(xy'-yx')/r^2=-\omega\left[1-\left(1-\frac{g(x)}{\omega^2x}\right)\left(\frac{x}{r}\right)^2\right]. \tag{8}$$

Let the right side of (8) define $-F(\omega,r,\theta)$. Take $\omega=\sqrt{a}$, and consider a segment of a trajectory with $\theta(0)=5\pi/4$, $\theta(T)=3\pi/4$, so x/r is bounded below, and take R so large that $|1-f(x)/ax|<1$, for $x\leqq x(0)=-R/\sqrt{2}$. Then $|\theta'|\leqq\sqrt{a}(1+|1-f(x)/ax|\cos^2\theta)\leqq 2\sqrt{a}$ and the time T elapsed on this trajectory segment exceeds $\pi/4\sqrt{a}$. The range of periods for (6a) contains $(2\pi/n,\pi/4\sqrt{a})$, so as n increases, the number of solutions of (6) increases without bound.

We now take $S_-<0$ so that for $s<S_-$, $|1-f(x)/ax|<\varepsilon$, for all $x\leqq 0$. We want to show that $k-1$ 2π-periodic solutions exist when $(k-1)^2<\lim_{u\to-\infty}g'(u)<k^2$. The periods of trajectories near C approach $2\pi(g'(C))^{-1/2}$, so exceed $2\pi/k$ for ε sufficiently small. On the other hand, we claim that as the energy goes to infinity, the periods become less than $\pi/(k-1)$ since (i) the time-elapsed for $x<0$ is less than $\pi/(k-1)$, and (ii) the time elapsed for $x>0$ is going to zero. The first assertion may be seen from (8), with $\omega=\sqrt{a}$ again; we have $|\theta'|=\sqrt{a}(1-\varepsilon\cos^2\theta)$, and if ε is so small that $k-1<\sqrt{a}(1-\varepsilon)$, then $T<\pi/(k-1)$.

We now show (ii), that the time T^+ for $x>0$ may be made arbitrarily small. Note that $T^+=2\int_0^{\pi/2}d\theta/F(\omega,r,\theta)$, where F was defined in equation (8). Thus if g is increased (keeping $g(0)=0$) then F is also increased, so that T^+ is decreased. Now

define x_j by requiring $g'(x)>(j+1)^2$ for all $x\geqq x_j$, and define $\theta_j(r)=\cos^{-1}(x_j/r)$ for $r\geqq x_j$. If g is monotone, then $x_{k-1}<0<x_k$ (since $g'(0)\in((k-1)^2,k^2)$; let j^* denote the least $j\geqq -1$ such that $x_{j+1}\geqq 0$). Notice that $\theta_{j+1}<\theta_j$ and $\theta_j\to 0$ as $j\to\infty$, for fixed r, and that $\theta_j(r)\to\pi/2$ as $r\to\infty$, for any j. Given $\varepsilon>0$, choose $n>j_*$ such that $\pi/n<\varepsilon/2$; then choose R so large that for any $r>R$, $\pi/2-\theta_n<\varepsilon/4$. Since $|f'(0)-a|<\varepsilon$, the time for θ to go from $\pi/2$ to θ_n is less than $\varepsilon/4a$, on a trajectory with $r(0)>R$; the time from θ_n to 0 is less than $\varepsilon/4$; and thus $T^+<\varepsilon$.

Finally, a C^0-small nonautonomous perturbation h is treated as in the case $a<0$ above. This completes the proof of Theorem 2.

3. Consider now the piecewise linear function $g(u)=au$ for $u<0$, $g(u)=bu$ for $u>0$; we write $g(u)=bu^+-au^-$. Then (6) becomes

$$u''+bu^+-au^-=s, \tag{9a}$$

$$u'(0)=0=u'(\pi). \tag{9b}$$

We consider two cases, (i) $a<0$ and $(n-1)^2<b<n^2$, and (ii) $(k-1)^2<a<k^2$, $(n-1)^2<b<n^2$.

In the former ($a<0$) case, the graphs of $g(u)-s$, $V_s(u)$, and the phase portrait are as in Fig. 1. There are no periodic solutions if $s<0$. If $s>0$, the period of the strictly positive orbits is $2\pi/\sqrt{b}$; we show below that as the energy increases from zero, the period tends continuously and monotonically to infinity. Hence there are $n-1$ nonstationary 2π-periodic solutions if $n-1<\sqrt{b}<n$, and the Neumann problem (9) has exactly $2n$ solutions.

In the case $\sqrt{a}\in(k-1,k)$ and $\sqrt{b}\in(n-1,n)$ for some integrals $n>k\geqq 1$, the situation is as depicted in Fig. 2. All solutions are periodic and consist of solutions of the two linear problems, pieced together along $x=0$. If $s=0$, all have period $\pi(a^{-1/2}+b^{-1/2})$. There are positive solutions for $s>0$, which have period $2\pi b^{-1/2}$, and negative solutions for $s<0$ with period $2\pi a^{-1/2}$. Using (8), one finds the period of a solution of both signs passing through $(u,u')=(0,I)$, $I>0$, to be $2((\pi-\theta_a)a^{-1/2}+\theta_b b^{-1/2})$, where $\tan\theta_a=-Ia^{1/2}/s$, and $\tan\theta_b=-Ib^{1/2}/s$ (θ_a and θ_b are in $[0,\pi]$). The period is then easily seen to be continuous and strictly monotone (increasing with I for $s>0$, decreasing for $s<0$), with range $(2\pi b^{-1/2},\pi(a^{-1/2}+b^{-1/2}))$ for $s>0$ and $(\pi(a^{-1/2}+b^{-1/2}),2\pi a^{-1/2})$ for $s<0$. Since we have assumed that $a^{-1/2}+b^{-1/2}$ is not twice the reciprocal of an integer, the number of solutions of (9) for s positive, plus the number for s negative, is therefore exactly $2(n-k+1)$, as claimed.

4. We treat the asymptotically linear problem (5) as a perturbation of the autonomous piecewise-linear problem (9), via rescaling. Let $u=|s|v$, so that (9a) becomes

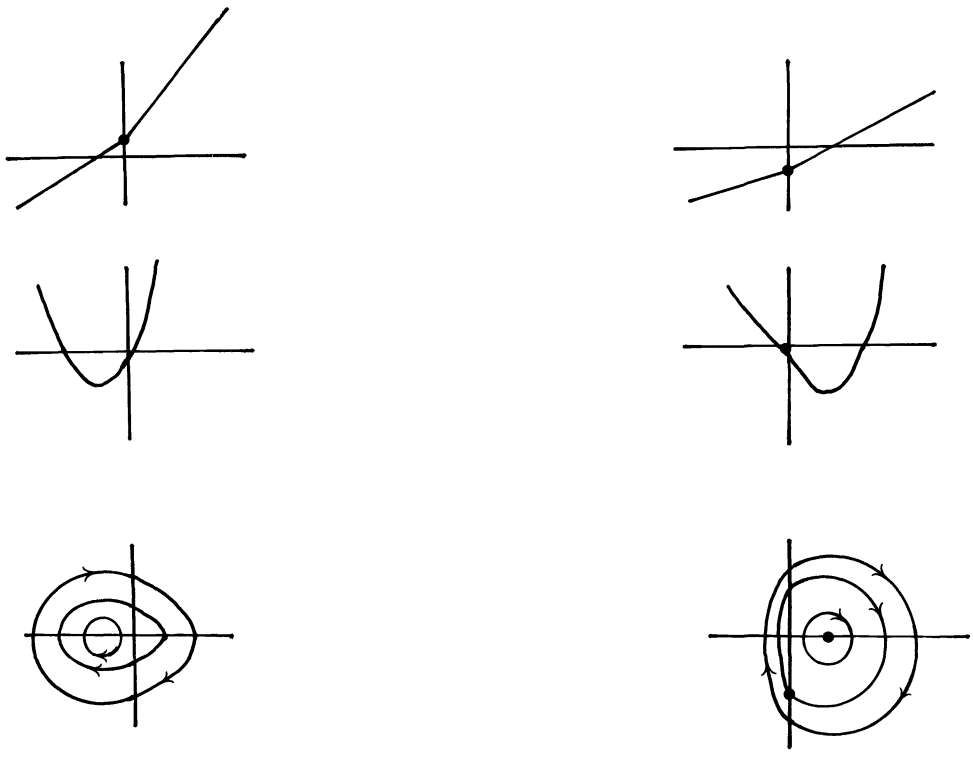
$$v''+bv^+-av^-=\pm 1 \tag{10}$$

and (5a) becomes

$$v''+bv^+-av^-\big(bv^+-av^--g(|s|v)/|s|\big)=\pm 1+h(x)/|s|. \tag{11}$$

We want to show that (11) differs from (10) by a C^1-small term for $|s|$ large, since then their solutions are C^1-close. If $\theta_E(t)$ is the angular coordinate on the solution of (9) with energy E and with $\theta(0)=\pi$, then near solutions of the Neumann problem, $\theta_E(\pi)$ carries the negative x-axis to a smooth curve which is differentiably transverse to the positive x-axis. Hence any map C^1-close to θ_E does the same. We therefore see that for

any given a, b and s, any C^1 perturbation of (9) has the same number of solutions. (We remark that the permissible size of such a perturbation decreases as a or b approach an eigenvalue n^2, for fixed s, or as b is increased.)



(a) $s<0$. (b) $s>0$.

FIG. 2. $(k-1)^2<a<k^2$, $(n-1)^2<b<n^2$.

If v is a solution of (10), the trajectory (v,v') in phase space is bounded away from the center $(C/|s|,0)$ if s is bounded above, and its size is bounded above if s is bounded below. We require $|s|$ to be so large that $\|h\|_{C^1}<\eta/2|s|$, and likewise $\|bv^+-av^--g(|s|v)/|s|\|_{C^1}<\eta/2|s|$, for any v in an annulus $r_1<\|(v,v')-(C,0)\|<r_2$. We will treat $s>0$; the other case is similar. For $v>0$, we then have $bv^+-av^--g(sv)/s=v(b-g(sv)/sv)$. Since v is bounded (for $s>S_0$, say, where S_0 is such that $g'(C)$ exceeds n^2 by $\frac{1}{2}(b-n^2)$ for all $s>S_0$), and $g(u)/u\to b$ as $u\to\infty$, it follows that $\|v(b-qg(sv)/sv)\|_{C^1}\to 0$ as $s\to\infty$. Likewise for $v<0$, $v(a-g(sv)/sv)\to 0$. This gives C^0-smallness (for large positive s); C^1-smallness follows, as $v>0$ implies $(bv^+-av^--g(sv)/s)'=b-g'(sv)\to 0$ as $s\to\infty$, similarly for $v<0$. Thus (5) has exactly as many solutions as (9), and the proof of Theorem 1 is completed.

The term $h(x)$ is of course no problem above, under the assumption that $\lim_{x\to+\infty}g'(x)$ exists and is finite. Under the assumptions of Theorem 2, however, the $|s|$ required above increases as η decreases, as b increases; so if $g'(x)$ is unbounded, then for fixed $\|h\|_{C^1}$, we may be forced to choose s large to arrange that $\|h\|_{C^1}/|s|<\eta$, but then find $g'(C)$ (the "b" above) so large that η must be still smaller.

GLOBAL BIFURCATION OF POSITIVE SOLUTIONS IN SOME SYSTEMS OF ELLIPTIC EQUATIONS*

J. BLAT† AND K. J. BROWN†

Abstract. In this paper the structure of the nonnegative steady-state solutions of a system of reaction-diffusion equations arising in ecology is investigated. The equations model a situation in which a predator species and a prey species inhabit the same region and the interaction terms are of Holling–Tanner type so that the predator has finite appetite. Prey and predator birth-rates are treated as bifurcation parameters and the theorems of global bifurcation theory are adapted so that they apply easily to the system. Thus ranges of parameters are found for which there exist nontrivial steady-state solutions.

Key words. reaction-diffusion equations, multiple steady states, global bifurcation, predator-prey

AMS(MOS) subject classifications. Primary 35J65, 32B32, 92A17

1. Introduction. In this paper we study the nonnegative steady-state solutions of the reaction-diffusion system

$$u_t(x,t)-d_1\Delta u(x,t)=au-a_1u^2-a_2uv/(1+mu), \tag{1.1}$$

$$v_t(x,t)-d_2\Delta v(x,t)=bv-b_1v^2+b_2uv/(1+mu)$$

for $x\in D$ and $t\geqq 0$ where D is a bounded region in $\mathbb{R}^n$ $(n=1,2,3)$ with smooth boundary together with boundary conditions

$$u(x,t)=0=v(x,t) \quad \text{for all } x\in\partial D \text{ and } t\geqq 0. \tag{1.2}$$

Equation (1.1) models a situation in which a prey and a predator species with population densities $u(x,t)$ and $v(x,t)$ respectively inhabit the region D. It is assumed that both species diffuse, i.e., move from points of high to points of low population density; the Laplacian terms in (1.1) correspond to this diffusion, the constants d_1 and d_2 giving the rates at which the species diffuse. It is also assumed that in the absence of other species and of diffusion that both species would grow logistically. Thus, in the absence of other factors, the rate of increase of the prey population is given by $au-a_1u^2$. If u is small, this increase is approximately equal to au and the constant a is termed the birth rate of the prey. Because of limited natural resources, the prey population will decrease in size if it becomes too large; we assume throughout that the constant $a_1>0$ so that $au-a_1u^2<0$ for sufficiently large u. Similarly the constant b is termed the birth rate of v and we assume that the constant $b_1>0$. The term $a_2uv/(1+mu)$ represents the rate at which the prey is consumed by the predator and is usually referred to as the Holling–Tanner interaction term; as is reasonable this term increases as either u or v increases. In the classical equations of ecology the corresponding term is simply a_2uv. This classical interaction term has the defect that for a fixed predator population $\lim_{u\to\infty}a_2uv=\infty$ which implies that predators must be capable of consuming prey at an infinitely great rate. For the Holling–Tanner interaction term, however, $\lim_{u\to\infty}a_2uv/(1+mu)=a_2v/m$ and this difficulty does not arise. We assume throughout that the constants $a_2,b_2>0$.

*Received by the editors January 2, 1985.

In [2] we used a decoupling technique to study the steady-state solutions of the classical equations of ecology, viz.

$$-d_1\Delta u = au - a_1u^2 - a_2uv, \qquad -d_2\Delta v = bv - b_1v^2 + b_2uv \tag{1.3}$$

with Dirichlet boundary conditions. The general idea is to regard v as a fixed function in the first equation in (1.3) and solve for u, denoting the solution by $u(v)$, i.e., $u(v)$ is the solution of

$$-d_1\Delta u + a_2vu = au - a_1u^2 \quad \text{on } D, \qquad u|_{\partial D} = 0. \tag{1.4}$$

The solutions of (1.4) are easy to describe and a suitable $u(v)$ can be defined. Then $u(v)$ is substituted into the second equation in (1.3) to give a single equation for v. Treating b as a bifurcation parameter and using the results of global bifurcation theory, fairly detailed results are obtained about the solutions of (1.3).

If we fix v in the first equation with the Holling–Tanner interaction term, it seems considerably harder to analyze the solutions of the corresponding equation for u, viz.,

$$-d_1\Delta u = au - a_1u^2 - \frac{a_2uv}{1+mu} \quad \text{on } D, \quad u|_{\partial D} = 0$$

and we are no longer able to use our decoupling technique. In this paper we study nontrivial steady-state solutions of a simplified version of (1.1), i.e.,

$$\begin{aligned} -\Delta u &= au - a_1u^2 - a_2uv/(1+mu) \quad \text{on } D, \qquad u|_{\partial D} = 0, \\ -\Delta v &= bv - b_1v^2 + b_2uv/(1+mu) \quad \text{on } D, \qquad v|_{\partial D} = 0 \end{aligned} \tag{1.5}$$

by applying bifurcation theory directly to the system (1.5). Note that we assume $d_1 = d_2 = 1$; this is done simply for notational convenience and it is straightforward to adapt our proofs to deal also with the general case of unequal diffusion coefficients. If we assume that all the other constants in (1.5) are fixed and treat a as a bifurcation parameter, we can show that (1.5) is equivalent to an operator equation of the form $w - T(a,w) = 0$ where $w = (u,v)$. In the existing literature global bifurcation theorems of the type we require seem only to apply in the cases where the Fréchet derivative $T_w(a,0) = aAw$ (see Rabinowitz [11]) or $T_w(a,0) = aA_1w + A_2w$ (see Chow and Hale [4]) where A, A_1 and A_2 are linear operators. In some situations which we encounter $T_w(a,0)$ depends on a in a more complicated way and in §3 we give a formulation of some standard theorems on bifurcation which can be applied easily to all the cases in which we are interested. In §2 we discuss results we shall require later on linear problems and on the trivial solutions of (1.5). In §§4 and 5 we treat b and a respectively as bifurcation parameters.

We work throughout with Dirichlet boundary conditions. Our results also apply to the more ecologically reasonable cases of Neumann and Robin boundary conditions. However Dirichlet boundary conditions present the hardest mathematical problem and so we concentrate our attention on these. In the case of Neumann boundary conditions all the steady-state solutions we obtain are spatially homogeneous.

A number of other studies have been made on the existence of steady-state solutions of the classical equations of ecology. In Dancer [7] index theory is used to give necessary and sufficient conditions for the existence of nontrivial solutions. Leung [9] has obtained existence and uniqueness results by using iteration methods. Local bifurcation methods for the classical equations describing competing species are used in Cantrell and Cosner [3].

2. Preliminaries. It is well known that the linear eigenvalue problem

$$-\Delta\phi=\lambda\phi \quad \text{on } D, \qquad \phi=0 \quad \text{on } \partial D$$

has an infinite sequence of eigenvalues $\{\lambda_n\}$ such that $0<\lambda_1<\lambda_2\leqq\lambda_3\cdots$ with corresponding eigenfunctions $\phi_1,\phi_2,\phi_3,\cdots$ where $\phi_1(x)>0$ for $x\in D$. Suppose that $q: D\to\mathbb{R}$ is smooth. Then the linear eigenvalue problem

$$-\Delta u+qu=\lambda u \quad \text{on } D, \qquad u=0 \quad \text{on } \partial D \tag{2.1}$$

also has an infinite sequence of eigenvalues which are bounded below. We denote the ith eigenvalue of (2.1) by $\lambda_i(q)$. It is known that $\lambda_1(q)$ is a simple eigenvalue and that the corresponding eigenfunctions do not change sign on D. Clearly $\lambda_1(0)=\lambda_1$ and $\lambda_1(q)$ is an increasing function of q.

If 0 is not an eigenvalue of (2.1), then we can define a corresponding solution operation K, i.e., Kf is the unique solution of

$$-\Delta u+qu=f \quad \text{on } D, \qquad u=0 \quad \text{on } \partial D$$

i.e., K is the inverse of the differential operator $L=-\Delta+q$ associated with Dirichlet boundary conditions. It is well known (see e.g. Amann [1] and Sattinger [12]) that $K: C^1(D)\to C^1(D)$ and $K: L_2(D)\to L_2(D)$ is a compact operator and that $K: C^\alpha(D)\to C_0^{2+\alpha}(D)$ is an isomorphism ($C_0^{2+\alpha}(D)=\{u\in C^{2+\alpha}(D): u(x)=0 \text{ for } x\in\partial D\}$).

Consider now the nonlinear boundary value problem

$$-\Delta u+qu=au-a_1u^2 \quad \text{on } D, \qquad u=0 \quad \text{on } \partial D \tag{2.2}$$

where q is as above and a and a_1 are real numbers with $a_1>0$. It is known that if $a\leqq\lambda_1(q)$ then $u=0$ is the only nonnegative solution of (2.2) whereas if $a>\lambda_1(q)$ then (2.2) has a solution u which is positive on D. Since $u\to(au-a_1u^2)/u$ is a decreasing function, it follows that (see Cohen and Laetsch [5]) for each fixed $a>\lambda_1(q)$ there is a unique solution of (2.2) which is positive on D.

Suppose now that $q=0$. We denote the unique positive solution of

$$-\Delta u=au-a_1u^2 \quad \text{on } D, \qquad u|_{\partial D}=0 \tag{2.3}$$

where $a>\lambda_1$ by u_a. In the (a,u) plane, i.e., $\mathbb{R}\times C^1(D)$, the curve of solutions $a\to u_a$ bifurcates from the zero solution when $a=\lambda_1$. The linearized operator corresponding to u_a is the differential operator L where

$$Lu(x)=-\Delta u(x)-au(x)+2a_1u_a(x)u(x)$$

associated with Dirichlet boundary conditions.

LEMMA 2.1. *All eigenvalues of L are strictly positive.*

Proof. Since

$$-\Delta u_a+(a_1u_a-a)u_a=0 \quad \text{on } D, \qquad u_a|_{\partial D}=0, \tag{2.4}$$

u_a is a positive eigenfunction of $-\Delta+(a_1u_a-a)$ corresponding to the eigenvalue 0 and so $\lambda_1(a_1u_a-a)=0$. Hence $\lambda_1(2a_1u_a-a)>0$ and the result is proved.

We now show that u_a depends continuously on a. Define $F: (\lambda_1,\infty)\times C_0^{2+\alpha}(D)\to C^\alpha(D)$ by

$$F(s,u)=-\Delta u-su+a_1u^2.$$

Clearly F is a C^1 function and $F(s,u_s)=0$ for all $s>\lambda_1$. Choose and fix $a>\lambda_1$. If we denote the Fréchet derivative $F_u(a,u_a)$ by L, then $L: C_0^{2+\alpha}(D)\to C^{\alpha}(D)$ such that $Lu=-\Delta u-au+2a_1u_au$. By Lemma 2.1 L is an isomorphism and so by the Implicit Function Theorem there exists a C^1 function $\phi:\mathbb{R}\to C_0^{2+\alpha}(D)$ defined on a neighbourhood of a such that $\phi(a)=u_a$ and $F(s,\phi(s))=0$. However, $F(s,u)=0$ has the unique solution (s,u_s) close to (a,u_a) and so $\phi(s)=u_s$. This $s\to u_s$ is a C^1 map from $\mathbb{R}$ to $C_0^{2+\alpha}(D)$.

Let $\eta_a=du_a/da$. Differentiation of (2.4) with respect to a and interchange of order of the smooth derivatives involved show that

$$-\Delta\eta_a+(2a_1u_a-a)\eta_a=u_a>0 \quad \text{on } D,$$

i.e.

$$L\eta_a>0 \quad \text{on } D, \qquad \eta_a|_{\partial D}=0.$$

Since by Lemma 2.1 the principal eigenvalue of L on D is positive, there exists a region $\hat{D}$ containing $\overline{D}$ such that the principal eigenvalue of L with Dirichlet boundary conditions on $\hat{D}$ is positive; the corresponding principal eigenfunction ϕ is such that ϕ and $L\phi$ are strictly positive on $\overline{D}$. Hence it follows from the generalized maximum principle (see [10, Chap. 2, Thm. 10]) that η_a/ϕ does not have a nonpositive minimum in D and so $\eta_a>0$. Thus we have

LEMMA 2.2. *The map $a\to u_a$ is a C^1 map from (λ_1,∞) to $C_0^{2+\alpha}(D)$ and, if $\eta_a=du_a/da$, then $\eta_a(x)>0$ for all x in D.*

In a similar way we can define and establish the corresponding properties of v_b, the unique positive solution of

$$-\Delta v=bv-b_1v^2 \quad \text{on } D, \qquad v|_{\partial D}=0$$

when $b>\lambda_1$.

We now discuss the trivial solutions of (1.5). Clearly for all values of a and b there is the zero solution i.e. $u=0$ and $v=0$. When $a>\lambda_1$, there is the semi-trivial solution $u=u_a$ and $v=0$ and, when $b>\lambda_1$, there is the semi-trivial solution $u=0$ and $v=v_b$. We prove the existence of nontrivial solutions by studying the bifurcations which occur from branches of semi-trivial solutions. For this purpose it is necessary to obtain some a priori information about solutions of (1.5).

LEMMA 2.3. *If $a>\lambda_1$, then $(a-\lambda_1)\phi/a_1\leqq u_a\leqq a/a_1$ where ϕ is the principal eigenfunction of $-\Delta$ such that* $\max\phi=1$.

Proof. It is easy to check that $(a-\lambda_1)\phi/a_1$ and a/a_1 are sub and supersolutions of (2.3). But u_a is the unique positive solution of (2.3) and so must lie between the sub- and supersolution.

LEMMA 2.4. *If (u,v) is a nonnegative solution of* (1.5) *such that u is not identically zero, then $a>\lambda_1$.*

Proof. Since u satisfies the first equation in (1.5), it follows that $-\Delta u<au$ on D. Multiplying by u and integrating over D shows that $\int_D|\nabla u|^2dx<a\int_D u^2dx$. But by Poincaré's Inequality $\int_D|\nabla u|^2dx\geqq\lambda_1\int_D u^2dx$ and so $a>\lambda_1$.

The above lemma shows that the prey cannot coexist with the predator if its birth rate is too low. The next lemma gives a priori bounds on the population densities in terms of the birth rates.

LEMMA 2.5. *Suppose (u,v) is a nonnegative solution of* (1.5) *such that $u\not\equiv 0$ and $v\not\equiv 0$. Then*

(i) *$u\leqq u_a$ and $v\leqq b_1^{-1}[b+b_2a/(a_1+ma)]$;*

(ii) *if $b>\lambda_1$, then $v\geqq v_b$.*

Proof. (i) Since $u \not\equiv 0$, it follows that $a > \lambda_1$ and so (2.3) has the unique positive solution u_a. Clearly u is a subsolution of (2.3) and there exist arbitrarily large supersolutions of (2.3). Hence u_a must be greater than or equal to the subsolution u.

As v satisfies the equation

$$-\Delta v = [b - b_1 v + b_2 u/(1+mu)]v \quad \text{on } D \tag{2.5}$$

and $u \leqq u_a \leqq a/a_1$, we have that

$$-\Delta v \leqq [b - b_1 v + ab_2/(a_1 + ma)]v$$

and so $\Delta v > 0$ whenever $v > b_1^{-1}[b + b_2 a/(a_1 + ma)]$ $(= B$ say.) Thus it is impossible that v has a local maximum at x_0 where $v(x_0) > B$ and so we obtain the required upper bound for v.

(ii) Regarding u as a fixed function, v is the unique positive solution of (2.5) with Dirichlet boundary conditions. Clearly v_b is a subsolution of (2.5) and, as there are arbitrarily large constant supersolutions of (2.5), it follows that $v \geqq v_b$.

Finally in this section we make a preliminary investigation of bifurcation from the branch of trivial solutions of the form $u = u_a$, $v = 0$. Writing $u = u_a - U$ and $v = V$, it is easy to check that (u, v) is a nonnegative solution of (1.5) if and only if $0 \leqq U \leqq u_a$, $V \geqq 0$ and (U, V) satisfies

$$\begin{aligned} -\Delta U &= aU - 2a_1 u_a U + a_2 u_a V/(1+mu_a) + f(a, x, U, V), \\ -\Delta V &= bV + b_2 u_a V/(1+mu_a) + g(a, x, U, V) \end{aligned} \tag{2.6}$$

where f and g are smooth functions on $[\lambda_1, \infty) \times D \times \mathbb{R} \times \mathbb{R}$ such that

$$\begin{aligned} f(a, x, U, V) &= a_1 U^2 + a_2[(u_a - U)V/(1 + m(u_a - U)) - u_a V/(1+mu_a)], \\ g(a, x, U, V) &= -b_1 V^2 + b_2[(u_a - U)V/(1 + m(u_a - U)) - u_a V/(1+mu_a)] \end{aligned}$$

for $U \leqq u_a(x) + \frac{1}{2}m^{-1}$. Let $F: (\lambda_1, \infty) \times C^1(D) \times C^1(D) \to C^1(D)$ be defined by

$$[F(a, U, V)](x) = f(a, x, U(x), V(x))$$

and let G be the similar operator corresponding to g. Clearly F and G are continuous and the Fréchet derivatives $F_{(U,V)}(a, 0, 0)$ and $G_{(U,V)}(a, 0, 0)$ are zero. Then equation (2.6) can be written as

$$\begin{aligned} U &= aKU - 2a_1 K(u_a U) + a_2 K[u_a V/(1+mu_a)] + KF(a, U, V), \\ V &= bKV + b_2 K[u_a V/(1+mu_a)] + KG(a, U, V) \end{aligned} \tag{2.7}$$

where K is the inverse of $-\Delta$ with Dirichlet boundary conditions. Clearly (2.7) has the solution $U = 0$, $V = 0$ for all values of a and b and to find possible bifurcation points from the branch of zero solutions it is necessary to investigate the linearisation

$$\begin{aligned} U &= aKU - 2a_1 K(u_a U) + a_2 K[u_a V/(1+mu_a)], \\ V &= bKV + b_2 K[u_a V/(1+mu_a)]. \end{aligned} \tag{2.8}$$

3. Bifurcation theory. Since the dependence of the linearisation (2.8) on a and b is quite complicated, it is necessary to reformulate some of the standard theorems of bifurcation before we can apply them to our equations.

Let X be a Banach space and let $T:\mathbb{R}\times X\to X$ be a compact, continuously differentiable operator such that $T(a,0)=0$. Suppose we can write T as

$$T(a,u)=K(a)u+R(a,u) \tag{3.1}$$

where $K(a)$ is a linear compact operator and the Fréchet derivative $R_u(a,0)=0$. We investigate bifurcation phenomena for the equation

$$u=T(a,u) \tag{3.2}$$

treating a as a bifurcation parameter.

THEOREM 3.1. *Suppose* $(a,0)$ *is a bifurcation point of* (3.2). *Then*

(i) $K(a)$ *has eigenvalue* 1;

(ii) *if* $\{(a_n,u_n)\}$ *is a sequence of nontrivial solutions such that* $a_n\to a$ *and* $u_n\to 0$, *then there exists a subsequence of* $\{u_n\}$, *again denoted by* $\{u_n\}$, *such that* $u_n/\|u_n\|\to u_0$ *where* u_0 *is an eigenvector of* $K(a)$ *corresponding to the eigenvalue* 1.

Proof. Since $u_n-T(a_n,u_n)=0$ for all n, we have that

$$u_n-T_u(a,0)u_n=\int_0^1\left[T_u(a_n,su_n)u_n-T_u(a,0)u_n\right]ds.$$

Let $v_n=u_n/\|u_n\|$. Then

$$v_n-K(a)v_n=\int_0^1\left[T_u(a_n,su_n)v_n-T_u(a,0)v_n\right]ds.$$

As $n\to\infty$, the integral term $\to 0$ and so $\lim_{n\to\infty}(v_n-K(a)v_n)=0$. Since $\{v_n\}$ is bounded and $K(a)$ is compact, there exists a subsequence such that $\{K(a)v_n\}$ is convergent. Hence there exists a subsequence of $\{v_n\}$ converging to u_0 say. As $\|v_n\|=1$ for all n, $u_0\neq 0$ and clearly $u_0-K(a)u_0=0$.

We now give a sufficient condition for bifurcation to occur and at the same time obtain a global bifurcation result. First we recall the notions of multiplicity of an eigenvalue and the index of a fixed point.

Let $K:X\to X$ be a compact linear operator and let λ_0 be a nonzero eigenvalue of K. Then the null space of $K-\lambda_0 I$ denoted by $N(K-\lambda_0 I)$ is nonempty. We define the generalized null space of λ_0 as $M(K;\lambda_0)=\bigcup_{p=1}^{\infty}N(K-\lambda_0 I)^p$. It is well known that

$$N(K-\lambda_0 I)\subseteq N(K-\lambda_0 I)^2\subseteq N(K-\lambda_0 I)^3\subseteq\cdots$$

and that there exists P such that $N(K-\lambda_0 I)^p\subsetneq N(K-\lambda_0 I)^{p+1}$ for $p<P$ but $N(K-\lambda_0 I)^P=N(K-\lambda_0 I)^{P+1}=N(K-\lambda_0 I)^{P+2}=\cdots$ and so

$$M(K;\lambda_0)=\bigcup_{p=1}^{P}N(K-\lambda_0 I)^p.$$

Thus $\dim M(K;\lambda_0)<\infty$ and we define the algebraic multiplicity of λ_0 as equal to $\dim M(K;\lambda_0)$. If λ_0 has algebraic multiplicity 1, we say that λ_0 is a simple eigenvalue. Clearly λ_0 is a simple eigenvalue if and only if $\dim N(K-\lambda_0 I)=\dim N(K-\lambda_0 I)^2=1$. It is easy to show that $N(K-\lambda_0 I)=N(K-\lambda_0 I)^2$ if and only if $N(K-\lambda_0 I)\cap R(K-\lambda_0 I)=\{0\}$ where $R(K-\lambda_0 I)$ denotes the range space of $K-\lambda_0 I$. Thus λ_0 is a simple eigenvalue of K if and only if $\dim N(K-\lambda_0 I)=1$ and $N(K-\lambda_0 I)\cap R(K-\lambda_0 I)=\{0\}$.

Suppose now that $I-K: X \to X$ is a bijection. Then it is well known that the Leray Schauder degree $\deg(I-K,B,0)=(-1)^p$ where B is a ball centre 0 in X and $p=$ sum of the algebraic multiplicities of the eigenvalues of K which are >1 (see Krasnoselskii [8]). Suppose $T: X \to X$ is a compact differentiable operator. If x_0 is an isolated fixed point of T, we define the index of T at x_0 as $i(T,x_0)=\deg(I-T,B,x_0)$ where B is a ball centre x_0 such that x_0 is the only fixed point of T in B. If x_0 is a fixed point of T such that $I-T'(x_0)$ is invertible, then x_0 is an isolated fixed point of T and

$$i(T,x_0)=\deg(I-T,B,x_0)=\deg\big(I-T'(x_0),\hat{B},0\big)$$

where B is a sufficiently small ball centre x_0 and $\hat{B}$ is a ball centre 0.

We now state the result we shall use on global bifurcation. Suppose $T: \mathbb{R}\times X \to X$ is as given by (3.1).

THEOREM 3.2. *Let a_0 be such that $I-K(a)$ is invertible if $0<|a-a_0|<\varepsilon$ for some $\varepsilon>0$. Suppose $i(T(a,\cdot),0)$ is constant on $(a_0-\varepsilon,a_0)$ and on $(a_0,a_0+\varepsilon)$ such that, if $a_0-\varepsilon<a_1<a_0<a_2<a_0+\varepsilon$, then $i(T(a_1,\cdot),0)\neq i(T(a_2,\cdot),0)$. Then there exists a continuum C in the $(a-u)$-plane of solutions of* (3.2) *such that one of the following alternatives holds*

(i) *C joins $(a_0,0)$ to $(\hat{a},0)$ where $I-K(\hat{a})$ is not invertible.*

(ii) *C joins $(a_0,0)$ to ∞ in $\mathbb{R}\times X$.*

The above results can be proved by using exactly the same argument as in Rabinowitz [11]. The index $i(T(a,\cdot),0)$ can be calculated by investigating the eigenvalues of $K(a)$.

4. Structure of solutions with b as bifurcation parameter. In this section we shall regard b as a bifurcation parameter and suppose that all other constants are fixed. For all values of b we have the branch of zero solutions of (1.5) $S_0=\{(b,0,0): b\in\mathbb{R}\}$. When b crosses λ_1, there bifurcates from S_0 the branch of semi-trivial solutions $S_1=\{(b,0,v_b): b>\lambda_1\}$. Lemma 2.4 shows that, when a is fixed $\leqq\lambda_1$, then all nonnegative solutions of (1.5) lie on either S_0 or S_1. For the rest of this section we suppose that a is fixed $>\lambda_1$ so that we also have the branch of semi-trivial solutions $S_2=\{(b,u_a,0): b\in\mathbb{R}\}$. We show that there is a continuum of nontrivial solutions (i.e. in which neither u nor v is identically zero) joining S_1 and S_2.

First we use the result of Crandall and Rabinowitz [6] on bifurcation from a simple eigenvalue to obtain a local result on bifurcation from S_2. Motivated by (2.7), we define $T: \mathbb{R}\times C^1(D)\times C^1(D)\to C^1(D)\times C^1(D)$ by $T(b,u,v)=(aKu-2a_1K(u_au)+a_2K[u_av/(1+mu_a)]+KF(a,u,v),\ bKv+b_2K[u_av/(1+mu_a)]+KG(a,u,v))$ where K is the inverse of $-\Delta$ with Dirichlet boundary conditions. Let $H=I-T$. Then $H(b,u,v)=0$ with $0\leqq u\leqq u_a$ and $v\geqq 0$ if and only if (b,u_a-u,v) is a nonnegative solution of (1.5). It is easy to see that H is a C^1 function with $H(b,0,0)=0$. Straightforward computations show that H has Fréchet derivative

(4.1)

$$H_{(u,v)}(b,0,0)(\phi,\psi)$$
$$=\big(\phi-aK\phi+2a_1K(u_a\phi)-a_2K[u_a\psi/(1+mu_a)],\ \psi-bK\psi-b_2K[u_a\psi/(1+mu_a)]\big).$$

For notational convenience let $q(x)=u_a(x)/(1+mu_a(x))$. Let $b_0=\lambda_1(-b_2q)$ and let ψ_1 denote a corresponding nonnegative principal eigenfunction corresponding to principal eigenvalue b_0 of

$$-\Delta\psi-b_2q\psi=b\psi \quad \text{on } D, \qquad \psi|_{\partial D}=0.$$

It is easy to check that $N(H_{(u,v)}(b_0,0,0))=\operatorname{span}\{(\phi_1,\psi_1)\}$ where $\phi_1=a_2K_1[q\psi_1]$ and K_1 denotes the inverse of $-\Delta-a+2a_1u_a$ with Dirichlet boundary conditions. Thus $\dim N(H_{(u,v)}(b_0,0,0))=1$. It follows from the properties of compact operators that the codimension of $R(H_{(u,v)}(b_0,0,0))=1$.

Using (4.1), it is easy to see that the Fréchet derivative

$$H_{b,(u,v)}(b_0,0,0)(\phi_1,\psi_1)=(0,-K\psi_1).$$

Suppose that $(0,-K\psi_1)\in R(H_{(u,v)}(b_0,0,0))$. Then there exists $\psi\in C^1(D)$ such that

$$\psi-bK\psi-b_2K[q\psi]=-K\psi_1$$

and so

$$-\Delta\psi-b\psi-b_2q\psi=-\psi_1. \tag{4.2}$$

Multiplying (4.2) by ψ_1 and integrating over D shows that $\int_D\psi_1^2\,dx=0$ and this is impossible. Thus $(0,-K\psi_1)\notin R(H_{(u,v)}(b_0,0,0))$.

We have shown that H satisfies all the hypotheses of Theorem 1.7 of [6]. Thus there exists a real interval $(-\varepsilon,\varepsilon)$ and functions $b:(-\varepsilon,\varepsilon)\to\mathbb{R}$, $u,v:(-\varepsilon,\varepsilon)\to C^1(D)$ such that the nontrivial zeros of H close to $(b_0,0,0)$ lie on the curve $\{(b(s),s\phi_1+su(s),s\psi_1+sv(s)):-\varepsilon<s<\varepsilon\}$ where $b(0)=b_0$, $u(0)=v(0)=0$. It follows that for the system of equations (1.5) bifurcation occurs from the branch of semi-trivial solutions S_2 at $(b_0,u_a,0)$ and close to the bifurcation point the nontrivial solutions lie on the curve $\{(b(s),u_a-s\phi_1-su(s),s\psi_1+sv(s)):-\varepsilon<s<\varepsilon\}$. Points on the curve with $s>0$ correspond to nontrivial, nonnegative solutions of (1.5).

We now investigate the global nature of the above curve of nontrivial, nonnegative solutions in the $b-(u,v)$ plane, i.e., in $\mathbb{R}\times C^1(D)\times C^1(D)$. Theorems 4.1 and 4.2 give limitations on the values of b for which such solutions can exist.

THEOREM 4.1. *If (b,u,v) be a nontrivial, nonnegative solution of* (1.5), *then $b>b_0$ (i.e. $b>\lambda_1(-b_2q)$).*

Proof. We have that

$$-\Delta v-\left[b_2u/(1+mu)\right]v=bv-b_1v^2.$$

Since $u\leqq u_a$, it follows that

$$-\Delta v-b_2qv\leqq bv-b_1v^2.$$

Multiplying by v and integrating over D, we obtain

$$-\int_D(\Delta v+b_2qv)v\,dx<b\int_D v^2\,dx.$$

By the spectral theorem

$$-\int_D(\Delta v+b_2qv)v\,dx\geqq b_0\int_D v^2\,dx$$

and so it follows that $b>b_0$.

The above result shows that the bifurcation of nonnegative solutions from S_2 at $(b_0,u_a,0)$ must be to the right. The next result shows that the branch of nontrivial solutions cannot extend too far to the right.

THEOREM 4.2. *There exists $M>0$ such that, if (b,u,v) is a nontrivial, nonnegative solution of* (1.5), *then $b\leqq M$.*

Proof. By Lemma 2.3 $v_b \geqq (b-\lambda_1)\phi/b_1$ where ϕ is the principal eigenfunction of $-\Delta$ with $\sup\phi = 1$. If α is a positive constant, it follows that $\lim_{b\to\infty}\lambda_1(\alpha v_b) = \infty$ (see [2, Thm. 3.4]). Choose M such that $\lambda_1(a_1a_2v_b/(a_1+ma)) > a$ whenever $b > M$.

Suppose (b,u,v) is a nontrivial, nonnegative solution of (1.5). Then u is a nontrivial solution of

$$-\Delta u + [a_2v/(1+mu)]u = au - a_1u^2$$

and so $a > \lambda_1(a_2v/(1+mu))$. Since $v \leqq v_b$ and $u \leqq a/a_1$, it follows that $a > \lambda_1(a_1a_2v_b/(a_1+ma))$. Hence we must have that $b < M$.

We now show that T satisfies the hypotheses of our global bifurcation result, i.e., Theorem 3.2. We can write T as

$$T(b,u,v) = K(b)(u,v) + R(b,u,v)$$

where $K(b)$ is the compact linear operator such that $K(b)(u,v) = (aKu - 2a_1K(u_au) + a_2K(qv),\ bKv + b_2K(qv))$ and $K(b)$ and $R(b,u,v)$ satisfy the conditions given at the start of §3.1. In order to show that the hypotheses of Theorem 3.2 are satisfied, we must calculate the index $i(T(b,\cdot),0)$ when b is close to b_0. This index is equal to $(-1)^\beta$ where β is the sum of the algebraic multiplicities of eigenvalues of $K(b) > 1$.

Suppose that $\mu > 0$ is an eigenvalue of $K(b)$. Then there exists a nonzero function v such that

$$bKv + b_2K(qv) = \mu v$$

and so

$$-\mu\Delta v - b_2qv = bv \quad \text{on } D, \qquad v = 0 \quad \text{on } \partial D, \tag{4.3}$$

i.e. b is an eigenvalue of (4.3). Conversely, if $\mu \geqq 1$ and b is an eigenvalue of (4.3) with corresponding eigenfunction v, then (u,v) is an eigenfunction of $K(b)$ corresponding to the eigenvalue μ where u is the unique solution of

$$-\mu\Delta u - au + 2a_1u_au = a_2qv \quad \text{on } D, \qquad u = 0 \quad \text{on } \partial D.$$

Note that, since all eigenvalues of $-\Delta - a + 2a_1u_a$ are positive by Lemma 2.1 and $\mu > 1$, it follows that $-\mu\Delta - a + 2a_1u_a$ is invertible. The eigenvalues of (4.3) form an increasing sequence $\gamma_1(\mu) < \gamma_2(\mu) \leqq \gamma_3(\mu) \leqq \cdots$ and the variational characterisation of eigenvalues shows that $\mu \to \gamma_i(\mu)$ is a continuous increasing function. Thus $\mu \geqq 1$ is an eigenvalue of $K(b)$ if and only if $b = \gamma_i(\mu)$ for some μ. Clearly $\gamma_i(1) = \lambda_i(-b_2q)$.

Suppose that $b < b_0$, i.e., $b < \lambda_1(-b_2q)$. Hence $b < \gamma_1(1)$ and so $b < \gamma_i(\mu)$ for $i = 1, 2, \cdots$ and $\mu \geqq 1$. Hence $K(b)$ has no eigenvalues > 1 and so $i(T(b,\cdot),0) = 1$.

Suppose $b_0 < b < \lambda_2(-b_2q)$. Then $\gamma_1(1) < b < \gamma_2(1)$. Since $\mu \to \gamma_1(\mu)$ is increasing with $\lim_{\mu\to\infty}\gamma_1(\mu) = \infty$, there exists a unique $\mu > 1$ (μ_1 say) such that $b = \gamma_1(\mu_1)$. Since $b < \gamma_2(1)$, it follows that $b < \gamma_i(\mu)$ for $i = 2, 3, \cdots$ and $\mu \geqq 1$. Thus μ_1 is the only eigenvalue of $K(b)$ which is greater than 1. We now show that μ_1 is a simple eigenvalue of $K(b)$. The discussion above shows that $N(K - \mu_1 I) = \text{span}\{(\phi,\psi)\}$ where ψ is the principal eigenfunction corresponding to the eigenvalue b of

$$-\mu_1\Delta v - b_2qv = bv \quad \text{on } D, \qquad v = 0 \quad \text{on } \partial D$$

and $\phi = a_2K_1[q\psi]$ and K_1 denotes the inverse of $-\mu_1\Delta - a + 2a_1u_a$. Thus $\dim N(K(b) - \mu_1 I) = 1$. Suppose that $(\phi,\psi) \in R(K(b) - \mu_1 I)$. Then there exists v such that

$$bKv + b_2K(qv) - \mu_1 v = \psi.$$

Hence

$$-\mu_1\Delta v - bv - b_2qv = -\Delta\psi = -\mu_1^{-1}(b\psi + b_2q\psi) \quad \text{on } D.$$

Multiplying by ψ and integrating over D shows that $\int_D (b+b_2q)\psi^2\,dx = 0$ which is impossible. Hence $R(K(b)-\mu_1 I)\cap N(K(b)-\mu_1 I)=\{0\}$ and so μ_1 is a simple eigenvalue of $K(b)$. Thus $i(T(b,\cdot),0)=-1$ whenever $b_0 < b < \lambda_2(-b_2q)$.

Therefore Theorem 3.2 can be applied to T. Thus there exists a continuum C_0 of solutions of $(u,v)=T(b,u,v)$ in the $b-(u,v)$ plane, i.e., in $\mathbb{R}\times C^1(D)\times C^1(D)$ emanating from $(b_0,0,0)$ and either joining with $(\hat{b},0,0)$ where $I-K(\hat{b})$ is not invertible or joining with ∞. Close to the bifurcation point all solutions lie on the curve whose existence we proved by using the Crandall and Rabinowitz theorem. Let C_1 be the maximal continuum of solutions contained in $C_0 - \{(b(s), s\phi_1 + su(s), s\psi_1 + sv(s)) : -\varepsilon < s \leqq 0\}$. Then close to the bifurcation point $(b_0,0,0)$ C_1 consists of the curve $\{(b(s), s\phi_1 + su(s), s\psi_1 + sv(s)) : 0 < s < \varepsilon\}$ and it can be shown by a reflection argument exactly as in Rabinowitz [11] that C_1 either satisfies one of the same alternatives as C_0 or contains a pair of points of the form (b,u,v) and $(b,-u,-v)$ where $(u,v)\neq(0,0)$. Let $C=\{(b,u_a-u,v):(b,u,v)\in C_1\}$. Clearly, if $u,v\geqq 0$ and $(b,u,v)\in C$, then (b,u,v) is a solution of system (1.5). Let

$$P_1 = \{u\in C^1(D) : u(x) > 0 \text{ for } x\in D \text{ and } \partial u/\partial n(x) < 0 \text{ for } x\in\partial D\}$$

and let

$$P = \{(b,u,v) : b\in\mathbb{R} \text{ and } u,v\in P_1\}.$$

Clearly $C\subset P$ in a neighbourhood of the bifurcation point $(b_0,u_a,0)$. However

THEOREM 4.3. *$C-\{(b_0,u_a,0)\}$ is not contained in P.*

Proof. Suppose $C-\{(b_0,u_a,0)\}$ is contained in P; we shall obtain a contradiction. By the previous discussion the continuum $C-\{(b_0,u_a,0)\}$ must

(i) contain points of the form (b,u_a-u,v) and $(b,u_a+u,-v)$ or

(ii) join up with a bifurcation point of the form $(\hat{b},u_a,0)$ where $\hat{b}\neq b_0$ and $I-K(\hat{b})$ is not invertible or

(iii) join $(b_0,u_a,0)$ with ∞.

Since the continuum is contained in P neither (i) nor (ii) is possible. By Theorem 4.1 and Theorem 4.2 we must have that $b_0 < b < M$ whenever $(b,u,v)\subset C$. Therefore by Lemma 2.5 there exists a constant $M_1>0$ such that $|u(x)|$, $|v(x)|\leqq M_1$ for all $x\in D$ whenever $(b,u,v)\in C$. It follows from standard bootstrapping arguments that C is bounded in $\mathbb{R}\times C^1(D)\times C^1(D)$ and so (iii) is also impossible. This is a contradiction and so the continuum is not contained in P.

THEOREM 4.4. *C joins with S_1.*

Proof. Since $C-\{(b_0,u_a,0)\}$ is not contained in P, there exists $(\hat{b},\hat{u},\hat{v})\in [C-\{(b_0,u_a,0)\}]\cap\partial P$ which is the limit of a sequence $\{(b_n,u_n,v_n)\}\subseteq C\cap P$. As $(\hat{b},\hat{u},\hat{v})\in\partial P$, either $\hat{u}\in\partial P_1$ or $\hat{v}\in\partial P_1$.

Suppose $\hat{v}\in\partial P_1$. Then $\hat{v}(x)\geqq 0$ for $x\in D$ and either $\hat{v}(x)=0$ for some $x\in D$ or $\partial\hat{v}/\partial n(x)=0$ for some $x\in\partial D$. It follows from the second equation in system (1.5) that

$$-\Delta\hat{v} + \left[M - b + b_1\hat{v} - b_2\hat{u}/(1+m\hat{u})\right]\hat{v} = M\hat{v}\geqq 0 \quad \text{on } D$$

where M is a constant chosen sufficiently large so that the term in the square brackets is positive for all $x\in D$. It follows from the maximum principle that $\hat{v}\equiv 0$. A similar but simpler argument shows that if $\hat{u}\in\partial P_1$ then $\hat{u}\equiv 0$. Thus $\hat{u}\equiv 0$ or $\hat{v}\equiv 0$.

Suppose that $\hat{u} \equiv 0$ and $\hat{v} \equiv 0$. Then $(\hat{b}, \hat{u}, \hat{v})$ lies on the branch of trivial solutions $S_0 = \{(b,0,0) : b \in \mathbb{R}\}$. The only nontrivial, nonnegative solutions which are close to S_0 lie on the semi-trivial branch $S_1 = \{(b,0,v_b) : b \geqq \lambda_1\}$ and so there cannot exist a sequence in P converging to $(\hat{b},0,0)$. Hence either $\hat{u}$ or $\hat{v}$ is nonzero.

Suppose that $\hat{u}$ is nonzero and $\hat{v} \equiv 0$. Then $(\hat{b}, \hat{u}, \hat{v})$ lies on $S_2 = \{(b, u_a, 0) : b \in \mathbb{R}\}$ and so is a bifurcation point on S_2 from which bifurcate nontrivial and nonnegative solutions. Therefore by Theorem 3.1 $\hat{b}$ is such that 1 is an eigenvalue of $K(\hat{b})$ with corresponding eigenfunctions which are nonnegative on D. If (u,v) is a nonnegative eigenfunction corresponding to $\hat{b}$, then v satisfies

$$-\Delta v - b_2 q v = \hat{b} v \quad \text{on } D, \qquad v = 0 \quad \text{on } \partial D$$

and since v is nontrivial and nonnegative, it follows that $\hat{b} = \lambda_1(-b_2 q) = b_0$ and this is impossible.

Thus the only remaining possibility is that $\hat{v}$ is nonzero and $\hat{u} \equiv 0$. In this case $(\hat{b}, \hat{u}, \hat{v})$ must lie on S_1. Hence C joins up with S_1.

It is possible to use our methods to analyze the bifurcation which occurs when C joins up with S_1. The arguments involved are very similar to those we develop in the next section and so we omit the details here. In fact C joins S_1 when b is such that $a = \lambda_1(a_2 v_b)$ (when $b = b_1$ say). The argument in Theorem 4.4 shows that, if $(b,u,v) \in C \cap \partial P$, then $(b,u,v) \in S_1$. Thus C provides a continuum of nontrivial, nonnegative solutions joining $(b_0, u_a, 0)$ on S_2 to the point $(b_1, 0, \hat{v})$ on S_1. In particular we can conclude

THEOREM 4.5. *The system of equations* (1.5) *has a nontrivial, nonnegative solution provided* $b_0 < b < b_1$.

5. Structure of solutions with a as bifurcation parameter. We now treat a as a bifurcation parameter and assume that all the other constants are fixed. The decoupling technique of [2] works in this case. Suppose $b > \lambda_1$. Then (1.5) has a continuum of semi-trivial solutions $S_1 = \{(a,0,v_b) : a \in \mathbb{R}\}$ and it can be proved as in [2] that there is a continuum C of nontrivial, nonnegative solutions bifurcating from S_1 at $(\lambda_1(a_2 v_b), 0, v_b)$ such that C does not join up with any other continuum and goes to ∞ as $a \to \infty$. Thus the following result holds.

THEOREM 5.1. *If* $b > \lambda_1$, *then the system of equations* (1.5) *has a nontrivial, nonnegative solution provided* $a > \lambda_1(a_2 v_b)$.

The above result could also be established by using an argument similar to that of the preceding section.

Suppose now that $b < \lambda_1$. In this case we have the continuum of trivial solutions $S_0 = \{(a,0,0) : a \in \mathbb{R}\}$ and the continuum of semi-trivial solutions $S_1 = \{(a, u_a, 0) : a \geqq \lambda_1\}$. In [2], using decoupling techniques for the classical predator-prey equations it was shown that the stability of the semi-trivial solution $(u_a, 0)$ changes as a is increased and this indicates that a continuum of nontrivial, nonnegative solutions bifurcates from S_1. We now use bifurcation techniques similar to those of the preceding section to make a direct investigation of this continuum for the more complicated system (1.5).

As we are linearizing about the same solution as in the previous section, bifurcation seems likely to occur at values of a such that $b = \lambda_1(-b_2 u_a/(1 + m u_a))$. Modifying our notation slightly from that used in the previous section in order to highlight the dependence on a, we let $q_a(x) = u_a(x)/(1 + m u_a(x))$. Since u_a is an increasing function of a, q_a is also an increasing function of a. Clearly $q_a(x) \leqq m^{-1}$ for all a. Hence $\lambda_1(-b_2 q_a)$ is a decreasing function of a and $\lambda_1(-b_2 q_a) \geqq \lambda_1 - b_2/m$ for all a. Thus

$\lim_{a\to\infty}\lambda_1(-b_2q_a)$ exists and $\lim_{a\to\infty}\lambda_1(-b_2q_a)\geqq\lambda_1-b_2/m$. By Lemma 2.3 u_a converges uniformly to ∞ on any compact subset of D and so b_2q_a converges uniformly to b_2/m. If ϕ denotes the principal eigenfunction of $-\Delta$ with zero boundary conditions such that $\int_D\phi^2\,dx=1$, then $\int_D|\nabla\phi|^2\,dx=\lambda_1$. Since $\lim_{a\to\infty}\int_D b_2q_a\phi^2\,dx=b_2/m\int_D\phi^2\,dx=b_2/m$, it follows that

$$\lim_{a\to\infty}\int_D\left(|\nabla\phi|^2-b_2q_a\phi^2\right)dx=\lambda_1-b_2/m.$$

Hence by the variational characterisation of eigenvalues $\lim_{a\to\infty}\lambda_1(-b_2q_a)\leqq\lambda_1-b_2/m$.

Thus we have shown

LEMMA 5.1. $\lim_{a\to\infty}\lambda_1(-b_2q_a)=\lambda_1-b_2/m$.

Our first theorem shows that if the predator birth rate is too low then no nontrivial solutions exist. This result differs from what occurs in the classical case where, however negative the predator birth rate, nontrivial solutions exist provided the prey birth rate is sufficiently large.

THEOREM 5.2. *If* (a,u,v) *is a nonnegative solution of* (1.5) *with* $v\not\equiv 0$, *then* $b>\lambda_1-b_2/m$.

Proof. Since

$$-\Delta v-\left[b_2u/(1+mu)\right]v=bv-b_1v^2,$$

it follows that

$$-\Delta v-b_2/mv\leqq bv-b_1v^2.$$

Multiplying by v and integrating over D, we obtain

$$-\int_D\Delta v\cdot v\,dx-b_2/m\int_D v^2\,dx<b\int_D v^2\,dx.$$

Since $-\int_D\Delta v\cdot v\,dx\geqq\lambda_1\int_D v^2\,dx$, it follows that $b>\lambda_1-b_2/m$.

The above theorem shows that, if we fix $b\leqq\lambda_1-b_2/m$, there can be no bifurcation of nontrivial solutions from S_1. From now on we suppose that b is fixed such that $b>\lambda_1-b_2/m$. Since $a\to\lambda_1(-b_2q_a)$ is a decreasing function which equals λ_1 when $a=\lambda_1$ and tends to λ_1-b_2/m as $a\to\infty$, there is a unique value of $a>\lambda_1$, say α, such that $b=\lambda_1(-b_2q_\alpha)$. We show that bifurcation from S_1 occurs at $(\alpha,u_\alpha,0)$.

Motivated by equation (2.7) as in the previous section but now interested in varying a rather than b, we define $T:\mathbb{R}\times C^1(D)\times C^1(D)\to C^1(D)\times C^1(D)$ by

$$T(a,u,v)$$
$$=\left(aKu-2a_1K(u_au)+a_2K(q_av)+KF(a,u,v),\ bKv+b_2K(q_av)+KG(a,u,v)\right)$$

and let $H=I-T$. Then $H(a,u,v)=0$ with $0\leqq u\leqq u_a$ and $v\geqq 0$ if and only if (a,u_a-u,v) is a nonnegative solution of (1.5). Clearly $H(a,0,0)=0$ and it follows from Lemma 2.2 that H is a C^1 function. The Fréchet derivative with respect to (u,v) is

$$H_{(u,v)}(a,0,0)(\phi,\psi)=\left(\phi-aK\phi+2a_1K(u_a\phi)-a_2K(q_a\psi),\ \psi-bK\psi-b_2K(q_a\psi)\right).$$

We have that $N(H_{(u,v)}(\alpha,0,0))=\operatorname{span}\{(\phi_1,\psi_1)\}$ where ψ_1 is a nonnegative eigenfunction corresponding to the principal eigenvalue b $(=\lambda_1(-b_2q_\alpha))$ of

$$-\Delta\psi-b_2q_\alpha\psi=b\psi\quad\text{on } D,\qquad \psi|_{\partial D}=0$$

and $\phi_1 = a_2 K_1(q_\alpha \psi_1)$ where K_1 denotes the inverse of $-\Delta - a + 2a_1 u_a$ with Dirichlet boundary conditions. Thus $\dim N(H_{(u,v)}(\alpha,0,0)) = 1$ and it follows that the codimension of $R(H_{(u,v)}(\alpha,0,0)) = 1$.

It is easy to check that further differentiation with respect to a gives

$$H_{a,(u,v)}(\alpha,0,0)(\phi_1,\psi_1)$$

$$= \left(-K\phi_1 + 2a_1 K(u'_\alpha \phi_1) - a_2 K\left[\psi_1 u'_\alpha/(1+mu_\alpha)^2\right],\ -b_2 K\left[\psi_1 u'_\alpha/(1+mu_\alpha)^2\right]\right)$$

where $u'_a = du_a/da$. Suppose that $H_{a,(u,v)}(\alpha,0,0)(\phi_1,\psi_1) \in R(H_{(u,v)}(\alpha,0,0))$. Then there exists v such that

$$v - bKv - b_2 K(q_\alpha v) = -b_2 K\left[\psi_1 u'_\alpha/(1+mu_\alpha)^2\right]$$

and so

$$-\Delta v - bv - b_2 q_a v = -b_2 \psi_1 u'_\alpha/(1+mu_\alpha)^2.$$

Multiplying by ψ_1 and integrating over D shows that

$$0 = -b_2 \int_D u'_\alpha \psi_1^2/(1+mu_\alpha)^2\, dx.$$

But by Lemma 2.2 u'_α is positive on D and so we have a contradiction.

Thus the hypotheses of the Crandall–Rabinowitz theorem are satisfied and so there exists a curve of nontrivial, nonnegative solutions of (1.5) bifurcating from S_1 at $(\alpha, u_\alpha, 0)$. We shall investigate the global nature of this continuum. First we show that bifurcation of nonnegative solutions is to the right.

THEOREM 5.3. *If (a,u,v) is a nontrivial, nonnegative solution of* (1.5), *then $a > \alpha$.*

Proof. Suppose $a \leqq \alpha$. Then $b = \lambda_1(q_\alpha) \leqq \lambda_1(q_a)$. But by Theorem 4.1 system (1.5) has nontrivial, nonnegative solutions only when $b > \lambda_1(q_a)$. Thus, if (a,u,v) is nontrivial, $a > \alpha$.

We now compute $i(T(a,\cdot),0)$ so that we can apply our global bifurcation result. This index is $(-1)^\beta$ where β is the sum of the algebraic multiplicities of the eigenvalues of $K(a) > 1$ where $K(a)$ is the compact linear operator

$$K(a)(u,v) = \left(aKu - 2a_1 K(u_a u) + a_2 K(q_a v),\ bKv + b_2 K(q_a v)\right).$$

If $\mu > 0$ is an eigenvalue of $K(a)$, then b must be an eigenvalue of

$$-\mu\Delta v - b_2 q_a v = \lambda v \quad \text{on } D, \qquad v|_{\partial D} = 0. \tag{5.1}$$

Conversely, if $\mu \geqq 1$ and b is an eigenvalue of (5.1) with corresponding eigenfunction v, then (u,v) is an eigenfunction of $K(a)$ corresponding to the eigenvalue μ where $u = (-\mu\Delta - a + 2a_1 u_a)^{-1} v$, the inverted differential operator corresponding to zero boundary conditions.

Suppose that $a < \alpha$ and $\mu \geqq 1$ is an eigenvalue of $K(a)$. Then b is an eigenvalue of (5.1) and, since $\mu \geqq 1$, it follows that $b >$ the least eigenvalue of $-\Delta - b_2 q_a$, i.e. $b > \lambda_1(-b_2 q_a)$. But $b = \lambda_1(-b_2 q_\alpha) < \lambda_1(-b_2 q_a)$ and this is a contradiction. Hence, if $a < \alpha$, $K(a)$ has no eigenvalues > 1 and so $i(T(a,\cdot),0) = 1$.

Now suppose that a is such that $\lambda_1(-b_2q_a)<b<\lambda_2(-b_2q_a)$, i.e. a lies in an open interval with left-hand end point α. An argument similar to that used in the preceding section shows that $K(a)$ has a unique eigenvalue μ_1 which is greater than 1 and that this eigenvalue is simple. Therefore $i(T(a,\cdot),0)=-1$ and so Theorem 3.2 can be applied to T.

By arguments similar to those used in the preceding section it can be proved that there exists a continuum C in $\mathbb{R}\times C^1(D)\times C^1(D)$ emanating from $(\alpha,u_\alpha,0)$ such that

(i) if $(a,u,v)\in C$, then $(u_a-u,v)=T(a,u_a-u,v)$;

(ii) if $(a,u,v)\in C$ and $u,v\geqq 0$, then (a,u,v) is a solution of (1.5);

(iii) close to the bifurcation point $(\alpha,u_\alpha,0)$, C consists of the points (a,u,v) on the curve given by the Crandall and Rabinowitz theorem with $v\geqq 0$.

We now show that C does not join up with any other continuum but extends to $a=\infty$.

THEOREM 5.4. (i) *If* $(a,u,v)\in C-\{(\alpha,u_\alpha,0)\}$, *then* $u,v\in P_1$, *i.e.* $u,v>0$ *on* D *and* $\partial u/\partial n$, $\partial v/\partial n<0$ *on* ∂D.

(ii) $\{a:(a,u,v)\in C\}=[\alpha,\infty)$.

Proof. (i) Suppose that C contains a point $(a,u,v)\neq(\alpha,u_\alpha,0)$ which lies outside of P. Then there exists a point $(\hat a,\hat u,\hat v)\in C-\{(\alpha,u_\alpha,0)\}\cap\partial P$ which is the limit of a sequence of points $\{(a_n,u_n,v_n)\}$ in $C\cap P$. It follows as in the previous section that $\hat u\equiv 0$ or $\hat v\equiv 0$.

Suppose that $\hat u\equiv 0$ and $\hat v\equiv 0$. Then $(\hat a,\hat u,\hat v)=(\hat a,0,0)$ and so $(\hat a,\hat u,\hat v)$ lies on the trivial branch of solutions S_0. The only nontrivial, nonnegative solutions which are close to S_0 lie on the semi-trivial branch $S_1=\{(a,u_a,0):a\geqq\lambda_1\}$ and so there cannot exist a sequence in $C\cap P$ converging to $(\hat a,\hat u,\hat v)$. Therefore it is impossible that both $\hat u$ and $\hat v$ are identically zero.

Suppose that $\hat u\equiv 0$. Then

$$-\Delta\hat v=b\hat v-b_1\hat v^2 \quad \text{on } D, \qquad \hat v|_{\partial D}=0$$

and so, since $b<\lambda_1$, $\hat v\equiv 0$. Therefore $\hat u$ is not identically zero.

Suppose that $\hat v\equiv 0$. Then $(\hat a,\hat u,\hat v)\in S_1$ and there bifurcate from $(\hat a,\hat u,\hat v)$ nontrivial, nonnegative solutions. Therefore by Theorem 3.1 $\hat a$ is such that 1 is an eigenvalue of $K(\hat a)$ with corresponding eigenfunctions which are nonnegative on D. Thus $\hat a$ must be such that $b=\lambda_1(-b_2q_a)$ when $a=\hat a$. Hence $\hat a=\alpha$ and $(\hat a,\hat u,\hat v)=(\alpha,u_\alpha,0)$ which is impossible.

Therefore, if $(a,u,v)\in C-\{(\alpha,u_\alpha,0)\}$, then $(a,u,v)\in P$.

(ii) C must satisfy one of the three alternatives discussed in the preceding section. Because of (i) above, C contains no pairs of points of the form (a,u_a-u,v) and $(a,u_a+u,-v)$ and C cannot join up with another bifurcation point of the form $(a,u_a,0)$ on S_1. Hence C joins $(\alpha,u_\alpha,0)$ to ∞. By Theorem 5.3 we have that $a\geqq\alpha$ whenever $(a,u,v)\in C$. Lemmas 2.3 and 2.5 show that there exist a constant $M_1(a)$ such that, if $(a,u,v)\in C$, then $|u(x)|$, $|v(x)|<M_1(a)$ for all $x\in D$. Bootstrapping arguments imply that there exists a constant $M(a)$ such that $\|u\|$, $\|v\|<M(a)$ where $\|\ \|$ denotes the norm in $C^1(D)$. Hence the only way for C to approach ∞ in $\mathbb{R}\times C^1(D)\times C^1(D)$ is by a becoming unbounded. Since $\{a:(a,u,v)\in C\}$ is connected, it must equal $[\alpha,\infty)$.

Thus we obtain the following theorem on the existence of solutions of (1.5) to complement Theorem 5.2.

THEOREM 5.5. *Suppose* $b>\lambda_1-b_2/m$. *Then* (1.5) *has a nontrivial, nonnegative solution if and only if* $a>\alpha$ *where* $b=\lambda_1(-b_2q_\alpha)$ *i.e. if and only if* a *is sufficiently large so that* $b>\lambda_1(-b_2q_a)$.

SYMMETRY IN AN OVERDETERMINED FOURTH ORDER ELLIPTIC BOUNDARY VALUE PROBLEM*

ALLAN BENNETT†

Abstract. Let Ω be a bounded domain in $\mathbb{R}^N$ for which the following boundary value problem has a classical solution: $\Delta(\Delta u)=-1$ in Ω; $u=\partial u/\partial n$ on $\partial\Omega$; $\Delta u=c$ (constant) on $\partial\Omega$. We show that Ω must be an open ball and that u must be radially symmetric about the center of Ω. This result is analogous to that of Serrin (Arch. Rat. Mech. Anal., 43 (1971), pp. 304–318) and Weinberger (Arch. Rat. Mech. Anal., 43 (1971), pp. 319–320) for the problem $\Delta u=-1$ in Ω, $u=0$ and $\partial u/\partial n=c$ on $\partial\Omega$. Our result is obtained from a maximum principle for fourth order elliptic equations and several applications of Green's theorem. We then obtain two characterizations of open balls by means of integral identities—the first depends on our result and the second on that of Serrin and Weinberger.

Key words. maximum principle, radial symmetry

AMS(MOS) subject classification. Primary 35J

In 1971, J. Serrin [3] and H. Weinberger [4] proved that if Ω is a bounded domain in $\mathbb{R}^N$ with smooth boundary and if the solution to the problem

$$\Delta u=-1 \quad \text{in } \Omega, \tag{1a}$$

$$u=0 \quad \text{on } \partial\Omega \tag{1b}$$

has the property that $\partial u/\partial n$ is equal to a constant c on $\partial\Omega$, then Ω is a ball of radius $|Nc|$ and the solution to (1) is radially symetric about the center.

Serrin's proof is based on the Hopf maximum principle [2] and on a device of moving parallel planes to a critical position and then showing that the solution is symmetric about the limiting plane. This method can be extended to a more general second order elliptic problems. Weinberger's argument, however, is much more elementary. It also uses the maximum principle but relies on Green's theorem to establish certain identities which make it possible to solve for all second derivatives of the solution to (1). Unfortunately, Weinberger's argument does not extend to the more general results of [3]. However, the argument in [4] can be modified to establish the following theorem:

THEOREM. *Let Ω be a bounded domain in $\mathbb{R}^N$ with $C^{4+\varepsilon}$ boundary $\partial\Omega$, and suppose that the following overdetermined problem has a solution u in $C^4(\bar{\Omega})$:*

$$\Delta(\Delta u)=-1 \quad \textit{in } \Omega, \tag{2a}$$

$$u=\frac{\partial u}{\partial n}=0 \quad \textit{on } \partial\Omega, \tag{2b}$$

$$\Delta u\equiv c \quad \textit{on } \partial\Omega \ (c \textit{ constant}). \tag{2c}$$

Then Ω is an open ball of radius $[|c|(N^2+2N)]^{1/2}$, and

$$u(x)=\frac{-1}{2N}\left\{\frac{1}{4}(N+2)(Nc)^2+\frac{Nc}{2}r^2+\frac{1}{4(N+2)}r^4\right\}, \tag{2d}$$

where r denotes the distance from x to the center of Ω.

* Received by the editors January 22, 1985 and in final form September 30, 1985.
† Department of Mathematics, Cornell University, Ithaca, New York 14853.

This result has a corollary which allows a characterization of open balls in $\mathbb{R}^N$ by means of an integral identity:

COROLLARY. *Let D be a bounded domain in $\mathbb{R}^N$ with $C^{4+\varepsilon}$ boundary ∂D, and suppose that there is a real constant M so that*

$$\int_D B\,dx = M \oint_{\partial D} \frac{\partial B}{\partial n}\,dS \tag{3}$$

holds for any function B in $C^4(\bar{D})$ satisfying $\Delta(\Delta B)=0$ in D and $B=0$ on ∂D. Then D is an open ball, and

$$M = \frac{1}{|D|}\int_D |\nabla \psi|^2\,dx, \tag{4}$$

where $|D|$ is the N-dimensional volume of D and ψ satisfies $\Delta\psi = 1$ in D and $\psi = 0$ on ∂D.

Before proving these results, let us make some remarks about notation to be used. We shall use $u_{,i}$ and $u_{,ij}$ to denote, respectively, $\partial u/\partial x_i$ and $\partial^2 u/\partial x_i \partial x_j$. A superscript will denote a vector coordinate—for example, n^i is the ith coordinate of the (outward) unit normal vector to a surface at a given point. Finally, repeated indices indicate a summation with respect to that index, for example,

$$u_{,ii} = \Delta u = \sum_{i=1}^{N} \frac{\partial^2 u}{\partial x_i^2}.$$

Proof of Theorem. Suppose that $u \in C^4(\bar{\Omega})$ is a solution of the overdetermined problem (2). We first consider the following lemmas:

LEMMA 1 [1]. *The function*

$$\Phi := \frac{N-4}{N+2}u + \frac{N-4}{2(N+2)}(\Delta u)^2 + u_{,ij}u_{,ij} - \nabla u \cdot \nabla(\delta u) \tag{5}$$

assumes its maximum value on $\partial\Omega$.

LEMMA 2. *The following identity holds*:

$$\int_\Omega u\,dx = \frac{-N}{N+4}c^2|\Omega|. \tag{6}$$

To prove Lemma 1, it suffices to show that $\Delta\Phi \geqq 0$ in Ω. Routine calculation gives

$$\Delta\Phi = 2u_{,ijk}u_{,ijk} - \frac{6}{N+2}|\nabla(\Delta u)|^2. \tag{7}$$

To show that the right side of (7) is nonnegative, note that for any real number γ:

$$\sum_{i,j,k}\left[u_{,ijk} - \gamma\{(\Delta u)_{,i}\delta_{jk} + (\Delta u)_{,j}\delta_{ik} + (\Delta u)_{,k}\delta_{ij}\}\right]^2 \geqq 0 \tag{8}$$

or

$$u_{,ijk}u_{,ijk} - 6\gamma|\nabla(\Delta u)|^2 + 3\gamma^2(N+2)|\nabla(\Delta u)|^2 \geqq 0. \tag{9}$$

The discriminant of this quadratic expression in γ must then satisfy

$$36|\nabla(\Delta u)|^4 - 12(N+2)|\nabla(\Delta u)|^2 u_{,ijk}u_{,ijk} \leqq 0, \tag{10}$$

which is equivalent to $\Delta\Phi \geqq 0$. This yields the conclusion of Lemma 1.

The proof of Lemma 2 requires several applications of Green's theorem and the boundary condition in (2). First note that

$$\Delta\left[\Delta\left(r\frac{\partial u}{\partial r}\right)\right]=r\frac{\partial}{\partial r}[\Delta(\Delta u)]+4\Delta(\Delta u)=-4, \tag{11}$$

where r is the distance from a fixed origin. From (11) we obtain:

$$\begin{aligned}\int_\Omega\left[4u-r\frac{\partial u}{\partial r}\right]dx&=\int_\Omega\left[-u\Delta\Delta\left(r\frac{\partial u}{\partial r}\right)+r\frac{\partial u}{\partial r}\Delta\Delta u\right]dx \\ &=-\oint_{\partial\Omega}\Delta u\frac{\partial}{\partial n}\left(r\frac{\partial u}{\partial r}\right)dS=-c\oint_{\partial\Omega}\frac{\partial}{\partial n}\left(r\frac{\partial r}{\partial n}\frac{\partial u}{\partial n}\right)dS \\ &=-c\oint_{\partial\Omega}r\frac{\partial r}{\partial n}\frac{\partial^2 u}{\partial n^2}\,dS=-c^2\oint_{\partial\Omega}r\frac{\partial r}{\partial n}\,dS=-c^2N\cdot|\Omega|.\end{aligned} \tag{12}$$

An application of Green's theorem gives

$$\int_\Omega r\frac{\partial u}{\partial r}\,dx=-N\int_\Omega u\,dx, \tag{13}$$

so that (12) and (13) yield Lemma 2.

Our next step is to show that Φ is constant in Ω. We note that on $\partial\Omega$,

$$u_{,ij}u_{,ij}=\frac{\partial^2 u}{\partial n^2}n^in^j\frac{\partial^2 u}{\partial n^2}n^in^j=\left(\frac{\partial^2 u}{\partial n^2}\right)^2. \tag{14}$$

Lemma 1 and the boundary conditions (2) give

$$\Phi=\frac{3Nc^2}{2(N+2)}\quad\text{on }\partial\Omega,\qquad \Phi\leqq\frac{3Nc^2}{2(N+2)}\quad\text{in }\Omega. \tag{15}$$

By Lemma 2 and Green's theorem, we see that

$$\int_\Omega\Phi\,dx=\frac{-3(N+4)}{2(N+2)}\int_\Omega u\,dx=\frac{3Nc^2}{2(N+2)}\cdot|\Omega|. \tag{16}$$

Thus, by (15) and (16), $\Phi\equiv 3Nc^2/(2(N+2))$ in $\bar{\Omega}$. This implies that $\Delta\Phi$ vanishes identically in $\bar{\Omega}$. Therefore each term of the sum in (8) vanishes when $\gamma=1/(N+2)$. By differentiating each term with respect to x_k and adding, we obtain

$$u_{,ijkk}=(\Delta u)_{,ij}=\frac{1}{N+2}\left[2(\Delta u)_{,ij}-\delta_{ij}\right] \tag{17}$$

or

$$(\Delta u)_{,ij}=\frac{-1}{N}\delta_{ij}. \tag{18}$$

Now by (17) and analyticity of solutions of (2a), we have $\Delta u(x)=(1/2N)(A-|x-a|^2)$ in $\bar{\Omega}$, where A is the maximum value of Δu in $\bar{\Omega}$ and $\Delta u(a)=A$. By the boundary conditions (2c), we see that Ω is an open ball of radius $(A-2cN)^{1/2}$ centered at a. The boundary conditions (2b) then yield the radially symmetric solution (2d) and the additional relation $A=-cN^2$. This completes the proof of the theorem.

Proof of the corollary. Let $u \in C^4(\bar{D})$ be the solution of the problem

$$\Delta(\Delta u) = 1 \quad \text{in } D, \qquad u = \frac{\partial u}{\partial n} = 0 \quad \text{on } \partial D. \tag{19}$$

Then for any function B satisfying the hypothesis of the corollary, we have

$$M \int_{\partial D} \frac{\partial B}{\partial n}\, dS = \int_D B\, dx = \int_D \Delta(\Delta u) = -\oint_{\partial D} \Delta u \frac{\partial B}{\partial n}\, dS. \tag{20}$$

The last equality in (20) follows from several applications of Green's theorem and from the boundary value problems satisfied by u and B. We see now from (20) that

$$0 = \oint_{\partial D} \frac{\partial B}{\partial n}(M + \Delta u). \tag{21}$$

Let B be the solution of class $C^4(\bar{D})$ to the problem

$$\Delta(\Delta B) = 0 \quad \text{in } D, \qquad B = 0 \quad \text{and} \quad \frac{\partial B}{\partial n} = M + \Delta u \quad \text{on } \partial D. \tag{22}$$

It is immediate from (21) that $\Delta u = -M$ on ∂D, so that the theorem implies that D is an open ball. The exact value of M can be determined by replacing B in (3) by ψ in (4) and using an argument similar to the one above. Q.E.D.

To conclude this note, let us consider the analogue of the preceding corollary for harmonic functions. If D is an open ball in $\mathbb{R}^N$ and $h \in C^2(\bar{D})$ is harmonic in D, then the mean value theorem for harmonic functions implies that the average value of h over D and the average value of h on ∂D are both equal to the value of h at the center of D. Using the Serrin–Weinberger theorem, we can prove the following proposition: If Ω is a bounded domain in $\mathbb{R}^N$ with $C^{2+\varepsilon}$-boundary $\partial\Omega$ and if

$$\frac{1}{|\Omega|} \int_\Omega h = \frac{1}{|\partial\Omega|} \oint_{\partial\Omega} h \tag{23}$$

for each function in $C^2(\bar{\Omega})$ satisfying $\Delta h = 0$ in Ω, then Ω is an open ball. (Here, $|\partial\Omega|$ is the surface area of $\partial\Omega$.)

Proof. Let $u \in C^2(\bar{\Omega})$ satisfy $\Delta u = 1$ in Ω and $u = 0$ on $\partial\Omega$. Then:

$$\int_\Omega h = \int_\Omega h \Delta u = \int_\Omega u \Delta h + \oint_{\partial\Omega} \left[h \frac{\partial u}{\partial n} - u \frac{\partial h}{\partial n} \right] = \oint_{\partial\Omega} h \frac{\partial u}{\partial n} \tag{24}$$

$$= \frac{|\Omega|}{|\partial\Omega|} \oint_{\partial\Omega} h.$$

Therefore, we see that

$$0 = \oint_{\partial\Omega} h \left[\frac{\partial u}{\partial n} - \frac{|\Omega|}{|\partial\Omega|} \right]. \tag{25}$$

Now choose $h \in C^2(\bar{\Omega})$ so that $\Delta h = 0$ in Ω and $h = \partial u/\partial n - |\Omega|/|\partial\Omega|$ on $\partial\Omega$. Then (26) implies that $\partial u/\partial n| = |\Omega|/|\partial\Omega|$ on $\partial\Omega$, and the Serrin–Weinberger result completes the proof of the proposition. Q.E.D.

ON A SINGULAR NONLINEAR ELLIPTIC PROBLEM*

SÔNIA M. GOMES†

Abstract. Elliptic boundary value problems of the form $Lu=k(x)u^{-\alpha}$ in Ω and $u=0$ on the boundary of Ω are studied where L is given in the divergence form, $\alpha>0$ and $k(x)$ is a nonnegative measurable real function. Existence in $C^1(\bar{\Omega})$ and uniqueness of a solution $u\geqq 0$ are established for the equivalent fixed point problem $u(x)=\int_\Omega G(x,s)k(s)[u(s)]^{-\alpha}ds$, where $G(x,s)$ is the Green's function for the Dirichlet problem associated to L in Ω. Various inequalities for $G(x,s)$ are proved and a study is made of the action of the integral operator defined by the kernel G on unbounded functions with a prescribed growth near the boundary.

Introduction. This paper concerns positive solutions of elliptic boundary value problems of the form:

$$\text{(0.1)}\qquad \begin{aligned} &Lu(x)=-\sum_{i,j=1}^{n}\frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}u(x)\right)=f(x,u(x)) \quad \text{for } x\in\Omega,\\ &u(x)=0 \quad \text{for } x\in\partial\Omega, \end{aligned}$$

where Ω is a bounded region in R^n, $n\geqq 3$ and $\partial\Omega$ is the boundary of Ω. We will consider nonlinearities of the form:

$$f(x,u)=k(x)u^{-\alpha}, \qquad \alpha>0$$

where $k(x)$ is a nonnegative measurable real function.

The main point of study here, besides the existence and uniqueness, is the behavior of solutions near $\partial\Omega$, where f is singular.

We say that $u(x)$ is a solution of (0.1) if u satisfies

$$\text{(0.2)}\qquad u(x)=\int_\Omega G(x,s)k(s)[u(s)]^{-\alpha}ds$$

where $G(x,s)$ is the Green's function for the Dirichlet problem for the equation $Lu=h$ in Ω.

In §1 we establish various inequalities for $G(x,s)$. Using these inequalities, we will study in §2 the action of the integral operator defined by the kernel G on functions $h(x)$ which tend to infinity as $x\to\partial\Omega$ in a way we will make precise later.

The fixed point problem (0.2) may not have solutions in $H_0^1(\Omega)$. However, under appropriate assumptions, we will prove in §3 the existence and uniqueness of a solution $u(x)$ of (0.2), continuously differentiable in $\bar{\Omega}$. For this purpose, we seek a solution written in the form $u(x)=\Phi(x)\Psi(x)$, where $\Phi\in C^1(\bar{\Omega})\cap C^2(\Omega)$ satisfies $L\Phi(x)=1$ for $x\in\Omega$ and $\Phi(x)=0$ for $x\in\partial\Omega$. The new unknown $\Psi(x)$ must satisfy

$$\text{(0.3)}\qquad \Psi(x)=\int_\Omega \frac{G(x,s)k(s)}{\Phi(x)[\Phi(s)]^{\alpha}}[\Psi(s)]^{-\alpha}ds.$$

*Received by the editors March 30, 1984, and in revised form February 25, 1985.

†Instituto de Pesquisas Espaciais (INPE), Departamento de Energia Espacial, (12.201) São José dos Campos, S.P., Brazil.

Consequently, instead of (0.2), we have a new fixed point problem, that is, $\Psi = T \circ F(\Psi)$, where $F(\Psi)=[\Psi(x)]^{-\alpha}$ and T is the operator defined by the kernel

$$N(x,s)=\frac{G(x,s)k(s)}{\Phi(x)[\Phi(s)]^{\alpha}}.$$

We determine $\Psi \in C(\bar{\Omega})$, bounded away from zero.

With this process we are "avoiding the nonlinear singularity" but, on the other hand, we have to deal with an integral operator with a "bad" kernel. However, we still have that $T: C(\bar{\Omega}) \to C(\bar{\Omega})$ is a completely continuous operator.

By using this idea, in [5] we have already proved analogous results for the particular case of the sphere and $L=-\Delta$.

Singular differential equations like (0.1) arise in the theory of heat conduction in electrically conducting materials as discussed in [3]. In that paper the authors treat the existence question for the equation

$$u_t - \Delta u = f(x,t,u), \quad x \in \Omega \subset \mathbb{R}^n, \quad t>0,$$

coupled with initial and boundary conditions for a class of functions f which are nonincreasing in u. Assuming that $f(x,t,r) \to f(x,r)$ as $t \to \infty$, they obtain classical solutions of the corresponding elliptic boundary value problem upon letting $t \to \infty$.

Later, the existence of classical solutions was obtained in [9] for elliptic operators L more general than the Laplacian and for a class of functions $f(x,r)$ with no monotonicity assumption. The uniqueness was also obtained under appropriate assumptions.

In [2] the authors considered generalized solutions by means of a nonlinear eigenvalue problem. They assume the continuity of the coefficients of L and f, that $f(x,r)$ is bounded from above for $r>1$ and that $f(x,r) \to \infty$ as $r \to 0^+$, uniformly for $x \in \bar{\Omega}$. For $f(x,r)=f(r)$ they obtained bounds for the rate at which $u(x) \to 0$ when $x \to \partial\Omega$ and for $\|\operatorname{grad} u(x)\|$.

It is also interesting to observe that for $\Omega=(0,1) \subset \mathbb{R}$, the problem (0.1) appears in the study of similarity solutions of one-dimensional initial value problems for diffusion equations of the type $u_t=(k(x)|u_x|^{N-1}u_x)_x$, $N>0$ (cf. [1]).

Singular equations like (0.3) have been treated in [8] where the existence of solutions of

$$u(x)=\int_0^1 K(x,s)[u(s)]^{-\alpha} ds$$

is studied for $\alpha=1$ and for positive semidefinite symmetric kernels $K(x,s)$ satisfying $\int_0^1 K(x,s)\,ds \geqq \delta > 0$. That work was generalized for $\alpha>0$ in [6] but, in both papers, $K(x,s)$ is supposed to be continuous for $0 \leqq x,\ s \leqq 1$.

1. Inequalities for the Green's function. Let $\Omega \subset \mathbb{R}^n$, $n \geqq 3$ be a bounded region of class C^2. We consider a linear differential operator L defined by

$$Lu = -\sum_{i=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}u\right),$$

where $a_{ij} \in C^{2,\lambda}(\bar{\Omega})$ for some $0<\lambda<1$ and $a_{ij}=a_{ji}$.

The operator L is assumed to be uniformly elliptic in the sense that there exists a constant $\gamma>0$ such that

$$\gamma \sum_{i=1}^{n} \xi_i^2 \leqq \sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \leqq \gamma^{-1} \sum_{i=1}^{n} \xi_i^2$$

for all $x \in \bar{\Omega}$ and $\xi \in R^n$.

In what follows C is a generic constant which may be different at different places. The function $d(x)$ will denote the distance from x to $\partial\Omega$.

Let $G(x,y)$ be the Green's function of the Dirichlet problem for the equation $Lu=h$ in Ω. Under the above hypothesis the function G can be shown to exist with the following properties (cf. [7]):

(a) $G(x,y)$ is continuous in the variables x and y, x and y in Ω, with $x\neq y$, together with its first and second derivatives with respect to x_i.

(b) $L_x G(x,y)=0$ in Ω for $x\neq y$.

(c) $G(x,y)=0$ for $x\in\partial\Omega$.

(d) $G(x,y)=G(y,x)$.

Furthermore,

(1.1) (e) $G=O(\|x-y\|)^{2-n}$ uniformly in $\bar{\Omega}$.

First we will prove the following further properties of $G(x,y)$.

THEOREM 1.1. *For $x,y\in\Omega, x\neq y$, the Green's function $G(x,y)$ verifies*:

$$G(x,y)\leqq Cd(x)\|x-y\|^{1-n}, \tag{1.2}$$

$$\|\operatorname{grad}_x G(x,y)\|\leqq C\|x-y\|^{1-n}, \tag{1.3}$$

$$\|\operatorname{grad}_x G(x,y)\|\leqq Cd(y)\|x-y\|^{-n}, \tag{1.4}$$

where the constant C depends only on Ω and L.

In [10, Thm. 2.3], the author proves these inequalities for $L=-\Delta$ in Lyapunov–Dini regions. We will use the same idea of his proof.

Proof of Theorem 1.1. First we observe that if D is the region defined by

$$D=\left\{x=(x',x_n);\ x'\in R^{n-1},\ \|x'\|<1 \text{ and } -1+\sqrt{1-\|x'\|^2}<x_n<2\right\},$$

then there is some $s_0<1$ such that regions D_s congruent to D shrunk by a factor $1/s$ can be placed at every point $x_0\in\partial\Omega$ in such a way that the bent part intersects $\partial\Omega$ at this point only and the symmetry axis is along the normal, for all $s<s_0$.

Let $y\in\Omega$ be fixed. If $d(x)\geqq s_0$ we have

$$d(x)\geqq s_0\geqq Cd\geqq C\|x-y\|$$

where $d=$ diameter of Ω. Hence, by (1.1),

$$G(x,y)\leqq C|x-y|^{2-n}\leqq Cd(x)\|x-y\|^{1-n}.$$

The same type of argument holds if $d(x)<s_0$ but $\|x-y\|<2d(x)$. Thus it is sufficient to consider the case $d(x)<s_0$ and $d(x)<1/2\|x-y\|$. Let $x_0\in\partial\Omega$ be such that $d(x)=\|x-x_0\|$. At x_0 we place a region D_s as above, where

$$s=\begin{cases}\|x-y\|/4 & \text{if } \|x-y\|<4s_0,\\ s_0 & \text{otherwise.}\end{cases}$$

We may assume that $x_0=(0,s/2)$ and that the direction of the normal to Ω at x_0 is the x_n-axis. In this way $B\cap\bar{\Omega}=\{x_0\}$ where B is the ball $B_{s/2}(0)$.

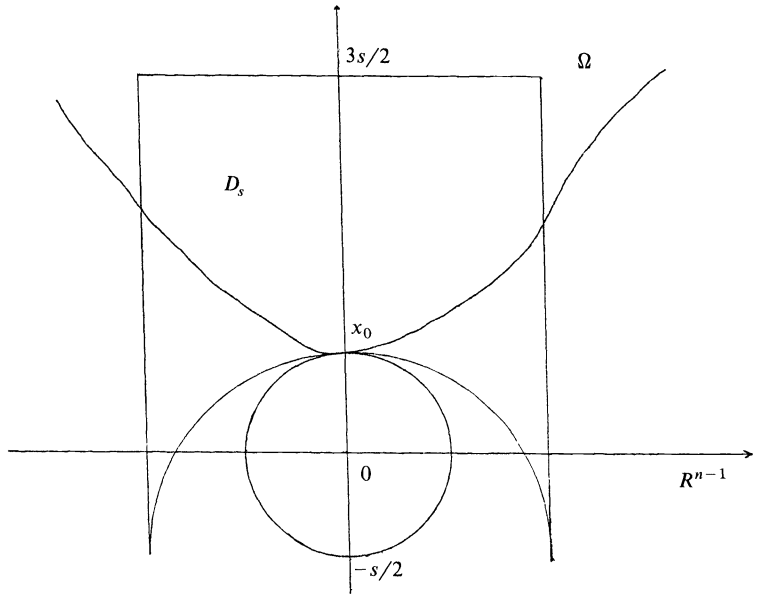

FIG. 1

We will construct "local barriers" at x_0 as follows. For suitable positive constants β_s and p, the function

$$w_s(x)=\beta_s\left[(s/2)^{-p}-\|x\|^{-p}\right]$$

satisfies:

$$\begin{aligned} &Lw_s\geqq 0 \quad \text{in } D_s\cap\Omega,\\ &w_s\geqq 1 \quad \text{in } \partial D_s\cap\Omega,\\ &w_s\geqq 0 \quad \text{in } \partial\Omega\cap D_s. \end{aligned} \tag{1.5}$$

Indeed:

$$Lw_s(x)=\beta_s p\|x\|^{-p-4}\left\{(p+2)\sum_{i,j=1}^{n}a_{ij}(x)x_ix_j - \|x\|^2\left[\sum_{i=1}^{n}a_{ii}(x)+\sum_{i,j=1}^{n}\frac{\partial}{\partial x_i}a_{ij}(x)x_j\right]\right\}.$$

Since the coefficients of L are bounded, there is a positive constant Λ such that

$$Lw_s(x)\geqq\beta_s p\|x\|^{-p-2}\left[(p+2)^{\gamma}-\Lambda(1+2s)\right].$$

Now, if p is sufficiently large so that $(p+2)\gamma-\Lambda(1+2s)\geqq 0$ for all $s\leqq s_0$, then $Lw_s(x)\geqq 0$ in $D_s\cap\Omega$ as asserted. If $x\in\partial D_s\cap\Omega$ then $\|x\|\geqq s$ and thus $w_s(x)\geqq \beta_s s^{-p}(2^p-1)=1$ provided $\beta_s=s^p/(2^p-1)$. If ν is the unit normal to Ω at the boundary point x_0 in the inward direction, then we also can see that

$$w_s(x_0+t\nu)\leqq Cts^{-1},$$

where the constant C is independent of s. Indeed,

$$w_s(x_0+t\nu)=\beta_s\left[(s/2)^{-p}-(t+s/2)^{-p}\right]=f_s(t);$$

$f_s'(t)=\beta_s p(t+s/2)^{-p-1}\geqq 0$ and $f_s''(t)=-\beta_s p(p+1)(t+s/2)^{-p-2}\leqq 0$. Hence $f_s(t)/t \leqq f_s'(0)=ps^{-p-1}2^{p+1}s^p/(2^p-1)=ps^{-1}2^{p+1}/(2^p-1)\leqq 4ps^{-1}$. It is easy to see that the distance from y to D_s is greater than $\|x-y\|/4$ which implies that

$$G(z,y)\leqq C\|x-y\|^{2-n} \quad \text{for } z\in\partial D_s\cap\Omega.$$

Now, we define $v(z)=w_s(z)-G(z,y)/C\|x-y\|^{2-n}$. In view of (1.5), we have

$$Lv=Lw_s\geqq 0 \quad \text{in } D_s\cap\Omega, \qquad v\geqq 0 \quad \text{in } \partial(D_s\cap\Omega).$$

Hence, $v(z)\geqq 0$ in $D_s\cap\Omega$. In particular, for $z=x=x_0+d(x)\nu$ we have that $w_s(x)\leqq Cd(x)s^{-1}$ and hence

$$G(x,y)\leqq C\|x-y\|^{2-n}w_s(x)\leqq C\|x-y\|^{2-n}d(x)s^{-1}.$$

If $\|x-y\|<4s_0$ then $s^{-1}=4/\|x-y\|$ and

$$G(x,y)\leqq Cd(x)\|x-y\|^{1-n}.$$

Otherwise,

$$G(x,y)\leqq Cd(x)\|x-y\|^{1-n}\|x-y\|/s_0\leqq Cd(x)\|x-y\|^{1-n},$$

and (1.2) is proved.

To prove (1.3), we consider first the points x such that $d(x)>\|x-y\|$. Let $B=B_r(x)$ where $r=\|x-y\|/4$. Since $G(x,y)$ belongs to $C^{2,\lambda}(B)$ (cf. [4, Thm. 6.13]) and in view of [4, Cor. 6.3], we can assert that

$$\|x-y\|\|\operatorname{grad}_x G(x,y)\|\leqq C\sup_{z\in B}G(z,y)$$

where C depends on the ellipticity constant γ and on the $C^{\lambda}(\bar{\Omega})$ bounds on the coefficients of L (as well as on n).

Hence,

$$\begin{aligned}\|\operatorname{grad}_x G(x,y)\|&\leqq C\|x-y\|^{-1}\sup_{z\in B}\|z-y\|^{2-n}\\ &\leqq C\|x-y\|^{-1}\|x-y\|^{2-n}\\ &=C\|x-y\|^{1-n}.\end{aligned}$$

If $d(x)\leqq\|x-y\|$ we consider $B=B_r(x)$ with $r=d(x)/4$. By the same argument we have

$$\begin{aligned}\|\operatorname{grad}_x G(x,y)\|&\leqq C[d(x)]^{-1}\sup_{z\in B}G(z,y)\\ &\leqq C[d(x)]^{-1}\sup_{z\in B}d(z)\|z-y\|^{1-n}\\ &\leqq C\sup_{z\in B}\|z-y\|^{1-n}\\ &\leqq C\|x-y\|^{1-n}.\end{aligned}$$

To prove (1.4), we first show that for fixed $x \in \Omega$

$$\frac{\partial}{\partial x_i} G(x,y) \to 0 \quad \text{as } y \to \partial\Omega.$$

Let $\rho > 0$, small enough such that

$$G(x,z) \geqq \frac{1}{2} \|x-z\|^{2-n} \quad \text{for } \|x-z\| = \rho.$$

Now, let $t \in \mathbb{R}$ with $|t| < \rho/2$. Hence, for $\|x-z\| = \rho$ and for some $\tilde{x}$ in the segment $[x, x+te_i]$ we have

$$\left| \frac{G(x+te_i,z) - G(x,z)}{t} \right| = \|\operatorname{grad}_x G(\tilde{x},z)\| \leqq C\|\tilde{x}-z\|^{1-n}$$

$$\leqq C\|x-z\|^{1-n}$$

$$\leqq C\rho^{-1} G(x,z).$$

Since this difference quotient is zero for $z \in \partial\Omega$, this inequality holds also for $z \in \Omega - B$ where $B = B_\rho(x)$. Therefore, if $y \in \Omega - B$ we have that

$$|\partial/\partial x_i G(x,y)| = \lim_{t \to 0} \left| \frac{G(x+te_i,y) - G(x,y)}{t} \right|$$

$$\leqq C\rho^{-1} G(x,y).$$

Hence

$$\frac{\partial}{\partial x_i} G(x,y) \to 0 \quad \text{as } d(y) \to 0.$$

Next, since $L_y \partial/\partial x_i G(x,y) = 0$ and using (1.3), the inequality (1.4) follows as in the proof of (1.2).

2. Consider the integral operator defined by the kernel $G(x,y)$. The proof of the following lemma is analogous to that of [4, Lemma 4.1] and it is a consequence of (1.1) and (1.3).

LEMMA 2.1. *Let $h : \Omega \to R$ be a bounded measurable function. If $v(x)$ is the function defined by*

$$v(x) = \int_\Omega G(x,s) h(s)\, ds,$$

then

$$v \in C^1(\bar{\Omega}),$$

$$\frac{\partial}{\partial x_i} v(x) = \int_\Omega \frac{\partial}{\partial x_i} G(x,s) h(s)\, ds \quad \textit{for all } x \in \bar{\Omega}.$$

As we said in the introduction, we will study here the behavior of the function $v(x)$ when the function h goes to infinity on the boundary. More precisely, the inequalities (1.2)–(1.4) will allow us to consider unbounded functions h with the following condition on their growth near $\partial\Omega$.

(2.1) There is some $0 \leqq \tau < 1$ such that $[d(x)]^\tau h(x) \in L^\infty(\Omega)$.

THEOREM 2.2. *If* $h:\Omega\to R$ *is a measurable function that satisfies* (2.1) *and* $v(x)=\int_\Omega G(x,s)h(s)\,ds$, *then*:

$$v\in C^1(\bar\Omega), \tag{2.2}$$

$$\frac{\partial}{\partial x_i}v(x)=\int_\Omega \frac{\partial}{\partial x_i}G(x,s)h(s)\,ds \quad \textit{for all } x\in\bar\Omega. \tag{2.3}$$

Proof of Theorem 2.2. By virtue of (1.1) the function v is well defined. In what follows, we will use several times the inequalities (1.2), (1.3) and (1.4). Let $w(x)=\int_\Omega \partial/\partial x_i G(x,s)h(s)\,ds$. First we will prove that w is well defined for $x\in\bar\Omega$.

(i) If $x\in\Omega$ and $r<d(x)$, we have:

$$|w(x)|\leqq C\left[\int_{\|x-s\|<r}\|x-s\|^{1-n}|h(s)|\,ds+r^{1-n}\int_{\|x-s\|\geqq r}|h(s)|\,ds\right]$$

$$\leqq C\left[\int_{\|x-s\|<r}\|x-s\|^{1-n}ds+r^{1-n}\int_{\|x-s\|\geqq r}[d(s)]^{-\tau}ds\right]<\infty.$$

(ii) If $x\in\partial\Omega$ and $r>0$, we have:

$$|w(x)|\leqq C\left[\int_{\|x-s\|<r}[d(s)]^{1-\tau}\|x-s\|^{-n}ds+\int_{\|x-s\|\geqq r}[d(s)]^{-\tau}\|x-s\|^{1-n}ds\right]$$

$$\leqq C\left[\int_{\|x-s\|<r}\|x-s\|^{1-n-\tau}ds+r^{1-n}\int_{\|x-s\|\geqq r}[d(s)]^{-\tau}ds\right]<\infty.$$

Next, we define $h_\varepsilon(x)=h(x)\eta(d(x)/\varepsilon)$ where η is the characteristic function of the interval $[1,+\infty)$; that is, $\eta(t)=1$ if $t\geqq 1$ and $\eta(t)=0$ if $t<1$. Now h_ε is bounded and thus, the function

$$v_\varepsilon(x)=\int_\Omega G(x,s)h_\varepsilon(s)\,ds$$

is in $C^1(\bar\Omega)$ and $\partial/\partial x_i v_\varepsilon(x)=\int_\Omega \partial/\partial x_i G(x,s)h_\varepsilon(s)\,ds=w_\varepsilon(x)$ for all $x\in\bar\Omega$.

$$v(x)-v_\varepsilon(x)=\int_{\Omega_\varepsilon}G(x,s)h(s)\,ds \quad \text{where } \Omega_\varepsilon=\{x\in\Omega;\ d(x)<\varepsilon\}.$$

Hence,

$$|v(x)-v_\varepsilon(x)|\leqq\int_{\Omega_\varepsilon}G(x,s)|h(s)|\,ds\leqq\int_{\Omega_\varepsilon}[d(s)]^{1-\tau}\|x-s\|^{1-n}ds$$

$$\leqq C\varepsilon^{1-\tau}.$$

Now,

$$w(x)-w_\varepsilon(x)=\int_{\Omega_\varepsilon}\frac{\partial}{\partial x_i}G(x,s)h(s)\,ds.$$

Thus,

(i) If $d(x)>2\varepsilon$ and $s\in\Omega_\varepsilon$ then $\|x-s\|\geqq\varepsilon>d(s)$ and

$$|w(x)-w_\varepsilon(x)|\leqq C\int_{\Omega_\varepsilon}[d(s)]^{1-\tau}\|x-s\|^{-n}ds$$

$$\leqq C\int_{\Omega_\varepsilon}\|x-s\|^{1-n-\tau}ds$$

$$\leqq C\left[\int_{\|x-s\|<d}\|x-s\|^{p(1-n-\tau)}ds\right]^{1/p}\mu(\Omega_\varepsilon)^{1/q}$$

where $p>1$ is such that $p(n-1+\tau)<n$, $q=p/(p-1)$, $d=$ diameter of Ω and μ is the Lebesgue measure.

(ii) If $d(x)\leqq\varepsilon$ we shall consider a partition of Ω_ε as follows:

$$A_1=\{s\in\Omega_\varepsilon;\ \|x-s\|<2d(x) \text{ and } d(s)<\tfrac{1}{2}d(x)\},$$
$$A_2=\{s\in\Omega_\varepsilon;\ \|x-s\|<2d(x) \text{ and } d(s)\geqq\tfrac{1}{2}d(x)\}, \quad \text{and}$$
$$A_3=\Omega_\varepsilon-(A_1\cup A_2).$$

In this way we have:

$$|w(x)-w_\varepsilon(x)|\leqq I_1+I_2+I_3 \quad \text{where } I_j=\int_{A_j}|\partial/\partial x_i G(x,s)h(s)|\,ds.$$

$$I_1\leqq C[d(x)]^{1-n-\tau}\int_{A_1}ds\leqq C[d(x)]^{1-\tau}\leqq C\varepsilon^{1-\tau},$$

$$I_2\leqq C\int_{A_2}[d(s)]^{-\tau}\|x-s\|^{1-n}ds\leqq C[d(x)]^{-\tau}\int_{A_2}\|x-s\|^{1-n}ds\leqq C[d(x)]^{1-\tau}$$
$$\leqq C\varepsilon^{1-\tau},$$

$$I_3\leqq C\int_{A_3}[d(s)]^{1-\tau}\|x-s\|^{-n}ds\leqq C\int_{A_3}\|x-s\|^{1-n-\tau}ds$$
$$\leqq C\left[\int_{\|x-s\|<d}\|x-s\|^{p(1-n-\tau)}ds\right]^{1/p}\mu(\Omega_\varepsilon)^{1/q}.$$

For the last inequality we used the fact that if $s\in A_3$, that is $\|x-s\|\geqq 2d(x)$, then

$$d(s)=\|s-s_0\|\leqq\|s-x_0\|\leqq\|x-s\|+\|x-x_0\|=\|x-s\|+d(x)$$
$$\leqq\|x-s\|+1/2\|x-s\|=3/2\|x-s\|,$$

where x_0 and s_0 are in $\partial\Omega$.

So, we have proved that $|v(x)-v_\varepsilon(x)|\leqq C\varepsilon^{1-\tau}$ and $|w(x)-w_\varepsilon(x)|\leqq C\mu(\Omega_\varepsilon)^{1/q}$. Consequently v_ε and w_ε converge to v and to w respectively as $\varepsilon\to 0$. Hence, $v\in C^1(\bar{\Omega})$ and $\partial/\partial x_i v=w$ and the theorem is proved.

Remark. The first assertion of Theorem 2.2 above is well known under more restrictive assumptions; for example if $h\in L^p(\Omega)$, $p>n$. Assuming also that h satisfies the condition (2.1) the Holder continuity of the grad v is stated in [10] for $v\in C^2(\Omega)$. However, in the proof of Theorem 3.1 below, we will need, not only the regularity condition (2.2), but also an integral representation for grad v, as stated in (2.3).

3. The main theorem. In view of Theorem 2.2 above, we observe that if $u(x)$ is a solution of (0.2) and $k(x)[u(x)]^{-\alpha}$ verifies the condition (2.1) then $u \in C^1(\bar{\Omega})$. In this case, since $\partial/\partial\nu u(x) > 0$ for all $x \in \partial\Omega$, there are positive numbers θ and Θ such that $\theta d(x) \leqq u(x) \leqq \Theta d(x)$. Consequently, $k(x)[d(x)]^{-\alpha} \leqq Ck(x)[u(x)]^{-\alpha}$ and $k(x)[d(x)]^{-\alpha}$ also verifies (2.1). Conversely, we will prove in the present section the existence and uniqueness of a solution $u(x)$ of (0.2), $u(x)$ continuously differentiable in $\bar{\Omega}$, provided that $k(x)[d(x)]^{-\alpha}$ verifies (2.1).

Let $\Phi \in C^1(\bar{\Omega}) \cap C^2(\Omega)$ be the solution of

$$\begin{aligned} L\Phi(x) &= 1 \quad \text{for } x \in \Omega, \\ \Phi(x) &= 0 \quad \text{for } x \in \partial\Omega. \end{aligned}$$

We observe that $\Phi(x) = \int_\Omega G(x,s)\,ds$ and that $\partial/\partial\nu\Phi(x) > 0$ for all $x \in \partial\Omega$.

As mentioned in the introduction, we will seek a solution in the form $u(x) = \Phi(x)\Psi(x)$ where $\Psi(x)$ must satisfy (0.3); that is, the fixed point problem $\Psi = T \circ F(\Psi)$ where $F(\Psi)(x) = [\Psi(x)]^{-\alpha}$ and

$$Tw(x) = \int_\Omega \frac{G(x,s)k(s)}{\Phi(x)[\Phi(s)]^\alpha} w(s)\,ds.$$

We will determine the existence and uniqueness of the fixed point $\Psi \in \mathring{K}$ where $\mathring{K} = \{v \in C(\bar{\Omega});\ v(x) > 0 \text{ for all } x \in \bar{\Omega}\}$ is the cone of the positive functions. For this purpose we will prove first the following theorem:

THEOREM 3.1. *If $k(x)[d(x)]^{-\alpha}$ verifies the condition* (2.1), *then $T: C(\bar{\Omega}) \to C(\bar{\Omega})$ is a completely continuously linear operator that preserves $\mathring{K}$.*

Proof of Theorem 3.1. The complete continuity of the operator T in $C(\bar{\Omega})$ is satisfied if it can be represented in the form

$$Tw(x) = \int_\Omega N(x,s)w(s)\,ds$$

where the kernel function $N(x,s)$ verifies the following condition:

$$\lim_{y \to x} \int_\Omega |N(x,s) - N(y,s)|\,ds = 0 \quad \text{for all } x \in \bar{\Omega}. \tag{3.1}$$

For this purpose we define for $s \in \Omega$

$$N(x,s) = \begin{cases} \dfrac{G(x,s)k(s)}{\Phi(x)[\Phi(s)]^\alpha} & \text{for } x \in \Omega, \\ \dfrac{\partial/\partial\nu G(x,s)k(s)}{\partial/\partial\nu\Phi(x)[\Phi(s)]^\alpha} & \text{for } x \in \partial\Omega. \end{cases}$$

LEMMA 3.2. *Under the hypothesis of Theorem* 3.1 *and for all $x \in \bar{\Omega}$ we have*:

$$\lim_{y \to x} N(y,s) = N(x,s), \tag{3.2}$$

$$\lim_{y \to x} \int_\Omega N(y,s)\,ds = \int_\Omega N(x,s)\,ds. \tag{3.3}$$

Proof of Lemma 3.2. Since $\Phi \in C^2(\Omega)$ and $G \in C^2(\Omega - \{s\})$, we need to verify (3.2) only for $x \in \partial\Omega$. By virtue of the continuity of grad Φ and grad G up to the boundary of Ω, we have:

$$G(x+t\nu,s) = \frac{\partial}{\partial \nu} G(x,s)t + E_1(x,t);$$

$$\Phi(x+t\nu) = \frac{\partial}{\partial \nu}\Phi(x)t + E_2(x,t),$$

where $\lim_{t\to 0} E_i(x,t)/t = 0$ uniformly for $x \in \partial\Omega$. Therefore, given $\varepsilon > 0$ there exists $\delta_1 > 0$ such that for all $x \in \partial\Omega$ and for $0 \leqq t \leqq \delta_1$:

$$|N(x+t\nu,s) - N(x,s)|$$

$$= k(s)|\Phi(s)|^{-\alpha} \left| \frac{\partial/\partial\nu\Phi(x) E_1(x,t)/t - \partial/\partial\nu G(x,s) E_2(x,t)/t}{|\partial/\partial\nu\Phi(x)|^2 + \partial/\partial\nu\Phi(x) E_2(x,t)/t} \right|$$

$$< \varepsilon/2.$$

Since the direction of the normals is a continuous function on $\partial\Omega$, there exists $\delta_2 > 0$ such that $|N(y,s) - N(x,s)| < \varepsilon/2$ for x and $y \in \partial\Omega$ with $\|x-y\| < \delta_2$. Hence, given $x \in \partial\Omega$ and $\varepsilon > 0$, let $y \in \bar{\Omega}$ be such that $\|x-y\| < \delta$, where $\delta = \min\{\delta_1, \delta_2/4\}$. If $\bar{y} \in \partial\Omega$ verifies $d(y) = \|y - \bar{y}\|$ then,

$$\|x - \bar{y}\| \leqq \|x-y\| + \|y-\bar{y}\| \leqq 2\|x-y\| < 2\delta \leqq \delta_2/2 < \delta_2.$$

Thus,

$$|N(x,s) - N(y,s)| \leqq |N(x,s) - N(\bar{y},s)| + |N(\bar{y},s) - N(y,s)| < \varepsilon.$$

To prove (3.3), we proceed as in the proof of (3.2) observing that $\int_\Omega N(x,s)\,ds = \Gamma(x)/\Phi(x)$ for $x \in \Omega$ and $\int_\Omega N(x,s)\,ds = \partial/\partial\nu\Gamma(x)/\partial/\partial\nu\Phi(x)$ for $x \in \partial\Omega$, where

$$\Gamma(x) = \int_\Omega \frac{G(x,s)k(s)}{[\Phi(s)]^\alpha} ds \in C^1(\bar{\Omega}).$$

Completion of the proof of Theorem 3.1. Now, (3.1) follows as a consequence of (3.2) and (3.3) and the fact that if the functions g and $g_m \in L^1(\Omega)$ are such that $g_m(x) \to g(x)$ a.e. and $\int_\Omega |g_m(s)|\,ds \to \int_\Omega |g(s)|\,ds$ then $\int_\Omega |g_m(s) - g(s)|\,ds \to 0$. To conclude the proof of Theorem 3.1, we consider $w(x) \in \mathring{K}$. $Tw(x) = \int_\Omega N(x,s)w(s)\,ds$ is a continuous function in $\bar{\Omega}$, $Tw(x) \geqq 0$ and $Tw(x) = 0$ if and only if $N(x,s) \equiv 0$. But this takes place only if $k(x) \equiv 0$. So, Tw is a strictly positive continuous function in $\bar{\Omega}$, that is, $Tw \in \mathring{K}$, and the Theorem 3.1 is proved.

Now, for $0 < \varepsilon \leqq 1$ we define $f_\varepsilon(t) = \varepsilon^{-\alpha}$ for $t \leqq \varepsilon$ and $f_\varepsilon(t) = t^{-\alpha}$ for $t > \varepsilon$. If $F_\varepsilon : C(\bar{\Omega}) \to C(\bar{\Omega})$ is such that $F_\varepsilon w(x) = f_\varepsilon(w(x))$, then it follows immediately from the Theorem 3.1 above, that $T \circ F_\varepsilon : \mathring{K} \to \mathring{K}$ is a continuous and compact nonlinear operator. Under these conditions we will prove:

LEMMA 3.3. *There exists a unique function* $\Psi_\varepsilon \in \mathring{K}$ *such that*

$$T \circ F_\varepsilon(\Psi_\varepsilon) = \Psi_\varepsilon.$$

Furthermore, if $0 < \varepsilon \leqq \bar{\varepsilon} \leqq 1$ *then* $\Psi_{\bar{\varepsilon}} \leqq \Psi_\varepsilon$.

Proof of Lemma 3.3. Let $R \geqq 1$ be a number such that $1/R \leqq \int_\Omega N(x,s)\,ds \leqq R$, for all $x \in \bar{\Omega}$. For all $w \in \mathring{K}$, $T \circ F_\varepsilon(w) \leqq R\varepsilon^{-\alpha}$. If we define $w_2(x) = R\varepsilon^{-\alpha}$, then $T \circ F_\varepsilon(w_2) \geqq R^{-1-\alpha}\varepsilon^{\alpha^2}$, and if $w_1(x) = R^{-1-\alpha}\varepsilon^{\alpha^2}$, then $T \circ F_\varepsilon(w_1) \leqq w_2$. So, $T \circ F_\varepsilon : [w_1, w_2] \to [w_1, w_2]$ where $[w_1, w_2] = \{w \in C(\bar{\Omega});\ w_1(x) \leqq w(x) \leqq w_2(x) \text{ for all } x \in \bar{\Omega}\}$. Now, the existence of

$\Psi_\varepsilon \in [w_1, w_2]$, fixed point of $T \circ F_\varepsilon$, is a consequence of Schauder's Theorem. The uniqueness of Ψ_ε is a consequence of the Maximum Principle (cf. [4, Thm. 8.8]). Indeed, if $\Psi_{\varepsilon,1}$ and $\Psi_{\varepsilon,2}$ are two fixed points and $h(x) = \Phi(x)\Psi_{\varepsilon,1}(x) - \Phi(x)\Psi_{\varepsilon,2}(x)$, then $h \in H_0^1(\Omega)$ (in fact, $h \in C^1(\bar{\Omega})$, cf. Theorem 2.2) and

$$Lh(x) = k(x)[\Phi(x)]^{-\alpha}[f_\varepsilon(\Psi_{\varepsilon,1}(x)) - f_\varepsilon(\Psi_{\varepsilon,2}(x))].$$

Let A be the open set $\{x \in \Omega;\ \Psi_{\varepsilon,1}(x) > \Psi_{\varepsilon,2}(x)\}$. For $x \in \partial A$ $h(x) = 0$ and $Lh(x) \leqq 0$ in A. Hence, $h(x) \leqq 0$ in A. But this is a contradiction, unless $A = \varnothing$.

In the same way, if $0 < \varepsilon \leqq \bar{\varepsilon} \leqq 1$, $A = \{x \in \Omega;\ \Psi_\varepsilon(x) > \Psi_{\bar{\varepsilon}}(x)\}$ and $h(x) = \Phi(x)\Psi_{\bar{\varepsilon}}(x) - \Phi(x)\Psi_\varepsilon(x)$ then $h \in H_0^1(\Omega)$ and

$$\begin{aligned} Lh(x) &= k(x)[\Phi(x)]^{-\alpha}[f_{\bar{\varepsilon}}(\Psi_{\bar{\varepsilon}}(x)) - f_\varepsilon(\Psi_\varepsilon(x))] \\ &\leqq k(x)[\Phi(x)]^{-\alpha}[f_\varepsilon(\Psi_{\bar{\varepsilon}}(x)) - f_\varepsilon(\Psi_\varepsilon(x))]. \end{aligned}$$

Hence, $h(x) = 0$ for $x \in \partial A$ and $Lh(x) \leqq 0$ in A and so, $h(x) \leqq 0$ in A which is a contradiction, unless $A = \varnothing$.

We are now in a position to prove our main theorem:

THEOREM 3.4. *If $k(x)[d(x)]^{-\alpha}$ verifies the condition* (2.1), *then the problem* (0.2) *has a unique solution u and $u \in C^1(\bar{\Omega})$.*

Proof of Theorem 3.4. As a consequence of Lemma 3.3 above we have that $\Psi_\varepsilon(x) \geqq \Psi_1(x) \geqq R^{-1-\alpha}$ for $0 < \varepsilon \leqq 1$. Therefore, if $\varepsilon = R^{-1-\alpha}$ and $\Psi = \Psi_\varepsilon$, then $F_\varepsilon(\Psi) = F(\Psi)$ and $T \circ F(\Psi) = T \circ F_\varepsilon(\Psi) = \Psi$. Now, if $u(x) = \Phi(x)\Psi(x)$ then u verifies (0.2). The uniqueness of u follows from the uniqueness of Ψ. In view of Theorem 2.2 we conclude that $u \in C^1(\bar{\Omega})$.

Acknowledgment. The author wishes to thank Professor Pedro Nowosad from Instituto de Matemática Pura e Aplicada(CNPq)–Rio de Janeiro, for suggesting the present problem and for the encouragement given to her.

ELLIPTIC PROBLEMS ON UNBOUNDED DOMAINS*

RAINER JANßEN†

Abstract. This paper considers elliptic boundary value problems on unbounded domains with possibly unbounded boundary using the variational method. Since a nonvanishing harmonic function is not square integrable on R^n, the construction of solutions in the usual Sobolev spaces, so successful for bounded domains, must fail. Kudrjavcev [8], [9] showed how to circumvent this difficulty by introducing weighted Sobolev spaces. See Besov et al. [3] for a survey on this method. Benci, Fortunato [2], Cantor [4], Janßen [5], Mäulen [10], Owen [15], Vogelsang [16], and others, apparently independently, have seized upon this method for treating elliptic problems on unbounded domains. This paper generalizes the method in two directions: 1) We treat operators of all orders with Dirichlet, Neumann and mixed boundary conditions. 2) We impose none of the usual restrictions on the coefficients of the operator (e.g. that they should converge to a constant as $|x|\to\infty$). The main tools are variants of the Poincaré and Friedrichs inequality, respectively, and compact embeddings in weighted Sobolev spaces.

Key words. elliptic boundary value problems, unbounded domains, weighted Sobolev spaces

AMS(MOS) subject classifications. Primary 35J20, 26A86

1. Introduction and notation.

As mentioned in the abstract, we consider elliptic boundary value problems in weighted Sobolev spaces. Before we give the definition of these spaces let us fix some notation.

From now on let Ω denote an open set in R^n with boundary $\partial\Omega$. Furthermore, let

$$C_0^\infty := \{f:\Omega\to R \mid f \text{ infinitely often differentiable with compact support in } \Omega\},$$

$$C^\infty := \{f:\Omega\to R \mid f \text{ infinitely often differentiable in } \Omega\},$$

$$D_i f := \frac{\partial f}{\partial x_i}, \qquad i=1,\cdots,n,$$

$$D^\alpha f := \frac{\partial^{|\alpha|}}{\partial x_1^{\alpha_1}\cdots\partial x_n^{\alpha_n}}, \quad \text{where } \alpha=(\alpha_1,\cdots,\alpha_n)\in(N_0)^n, \quad |\alpha|=\sum_{i=1}^n \alpha_i.$$

A positive-real valued, function ρ is called a weight function. If ρ is a weight function and $k\in N$, then

$$(f,g)_{k,\rho} := \sum_{|\alpha|\leqq k}\int_\Omega \rho^{-2k+2|\alpha|} D^\alpha f D^\alpha g\, dx$$

defines a scalar product on $C_0^\infty(\Omega)$. The completion with respect to the appropriate norm is called $\overset{0}{W}{}^{k,\rho}(\Omega)$; hence

$$\overset{0}{W}{}^{k,\rho}(\Omega) := \overline{C_0^\infty(\Omega)}^{\|\cdot\|_{k,\rho}}.$$

Similarly we define

$$W_c^{k,\rho}(\Omega) := \overline{C_0^\infty(R^n)|_\Omega}^{\|\cdot\|_{k,\rho}},$$

$$W^{k,\rho}(\Omega) := \overline{C^\infty}^{\|\cdot\|_{k,\rho}},$$

*Received by the editors December 19, 1984, and in revised form June 30, 1985.
† Wissenschaftliches Zentrum der IBM, Tiergartenstrasse 15, 6900 Heidelberg, West Germany.

where $C_0^\infty(R^n)|_\Omega$ denotes the space of restrictions of functions in $C_0^\infty(R^n)$ to Ω. For $x=(x_1,\cdots,x_n)\in R^n$ we need the following three norms

$$|x|_1=\sum_1^n |x_i|, \quad |x|_2=\left(\sum_1^n x_i^2\right)^{1/2}, \quad |x|_\infty=\max_{i=1,\cdots,n}|x_i|.$$

$L_q(\Omega)$ denotes the usual Lebesgue space with $\|f\|_q := (\int_\Omega |f|^q dx)^{1/q}$.

Remark 1.1. It is clear that $\overset{0}{W}{}^{k,\rho}\subset W_c^{k,\rho}\subset W^{k,\rho}$. The functions in $W_c^{k,\rho}$ need not vanish on the boundary as the functions in $\overset{0}{W}{}^{k,\rho}$ but contrary to $W^{k,\rho}$ there is a kind of growth condition at infinity.

Let us now sketch the plan of the paper. In the next section we prove variants of the Poincaré lemma and apply this to study the Dirichlet problem. The third section is devoted to compact imbeddings and their applications. In the last section we shall study the Neumann problem. There we shall again prove suitable variants of the Poincaré lemma, this time for functions which do not necessarily vanish on the boundary. In most existence theorems we shall get explicit bounds for the norm of the solution operator.

2. Dirichlet problem on unbounded domains. The Poincaré lemma states that for bounded domains Ω there exists a constant depending only on the diameter of Ω such that for all $f\in C_0^\infty(\Omega)$ $\int f^2 dx \leqq \text{const}\int |\nabla f|^2 dx$. It is easy to see that this is false, in general, for unbounded domains. We prove now some variants for the weighted spaces.

LEMMA 2.1. *Let ρ be a locally Lipschitz-continuous weight function with $\rho(x)\geqq|x|_\infty$ on Ω. Furthermore, let $k\in N$ and $q,\delta\in R$ with $q>1$ and $\delta>0$. Then either of the two conditions*

$$\text{(i)} \qquad 1-\frac{qk\sum_1^n D_i\rho(x)x_i}{n\rho(x)}\geqq\delta \quad \textit{for all } x\in\Omega,$$

$$\text{(ii)} \qquad 1-\frac{qk\sum_1^n D_i\rho(x)x_i}{n\rho(x)}\leqq-\delta \quad \textit{for all } x\in\Omega$$

implies that for all $f\in C_0^\infty(\Omega)$

$$\|f\rho^{-k}\|_q\leqq\frac{q}{n\delta}\sum_1^n\|(D_if)\rho^{-k+1}\|_q.$$

Proof. Integration by parts implies

$$\int\left|\frac{f}{\rho^k}\right|^q dx=+\frac{1}{n}\sum_1^n\int\left|\frac{f}{\rho^k}\right|^q dx=-\frac{1}{n}\sum_1^n\int\operatorname{sign}(f)D_i\left(\frac{f}{\rho^k}\right)\left|\frac{f}{\rho^k}\right|^{q-1}x_i dx$$

$$=-\frac{q}{n}\sum_1^n\int\operatorname{sign}(f)\left(\frac{D_if}{\rho}-\frac{kfD_i\rho}{\rho^{k+1}}\right)\left|\frac{f}{\rho^k}\right|^{q-1}x_i dx.$$

Hence we have the identity

$$\text{(1)} \qquad \int\left[1-\frac{qk\sum D_i\rho x_i}{n\rho}\right]\left|\frac{f}{\rho^k}\right|^q dx=-\frac{q}{n}\sum\int\frac{\operatorname{sign}(f)x_i}{\rho}\frac{D_if}{\rho^{k-1}}\left|\frac{f}{\rho^k}\right|^{q-1}dx.$$

(i) In this case the left side is $\geqq \delta \int |f/\rho^k|^q dx$. Since $|\operatorname{sign}(f) x_i|/\rho \leqq 1$ the Hölder inequality for $q_1, q_2 > 1$, $1/q_1 + 1/q_2 = 1$ implies that

$$\int \left|\frac{f}{\rho^k}\right|^q dx \leqq \frac{q}{n\delta} \sum_1^n \left(\int \left| \frac{D_i f}{\rho^{k-1}} \right|^{q_1} dx \right)^{1/q_1} \cdot \left(\int \left| \frac{f}{\rho^k} \right|^{(q-1)q_2} dx \right)^{1/q_2}.$$

Choosing $q_1 = q$, $q_2 = q/(q-1)$ and dividing by $(\int |f/\rho^k|^q dx)^{(q-1)/q}$, we get the assertion.

(ii) In this case the left side is $\leqq -\delta \int |f/\rho^k|^q dx$. We divide by $-\delta$ and get

$$\int \left|\frac{f}{\rho^k}\right|^q dx \leqq \frac{q}{\delta n} \sum_1^n \int \frac{\operatorname{sign}(f) x_i}{\rho} \cdot \frac{D_i f}{\rho^{k-1}} \left| \frac{f}{\rho^k} \right|^{q-1} dx$$

$$\leqq \frac{q}{\delta n} \sum_1^n \int \left| \frac{D_i f}{\rho^{k-1}} \right| \cdot \left| \frac{f}{\rho^k} \right|^{q-1} dx.$$

Now the assertion follows as in case (i). Q.E.D.

Remark 2.2. Of course we did not need the assumption $k \in N$ in the proof of Lemma 2.1. Furthermore, it should be noted that in case $\rho(x)$ grows stronger than $O(|x|)$ the estimate $|\operatorname{sign}(f) x_i/\rho| \leqq 1$ is not sharp. This observation leads one to sharper estimates and yields essential improvements for second-order operators (see Janßen [6]).

THEOREM 2.3. *Let* Ω, p, k, n, δ *fulfill any of the following conditions*:

(i) $\rho(x) = (1 + |x|_1)^\alpha$, $\alpha \geqq 1$, $n - 2\alpha k > 0$, $\delta = (n - 2\alpha k)/n$.

(ii) $\rho(x) = (1 + |x|_1)^\alpha$, $\alpha \geqq 1$, $n - 2\alpha k < 0$, $\delta = (2\alpha k - n)/(n + 2\alpha k)$, $r = 2n/(2\alpha k - n)$, $\Omega \subset \{x \mid |x|_1 \geqq r\}$.

(iii) $2k < n$, $\rho(x) = (|x|_1 + c) \ln(|x|_1 + c)$, $c = \exp(4k/(n-2k))$, $\delta = (n-2k)/(2n)$.

(iv) $2k > n$, $\rho(x) = (|x|_1 + c) \ln(|x|_1 + c)$, $\delta = (2k-n)/(2n)$, *let* r, c *be chosen such that for* $|x|_1 \geqq r$ *we have* $|x|_1 \ln(|x|_1 + c) + |x|_1 \geqq ((2k+n)/4k)(|x|_1 + c) \ln(|x|_1 + c)$ *and* $\Omega \subset \{x \mid |x| \geqq r\}$.

(v) $\rho(x) = x_1$, $\Omega \subset R_+ \times R^{n-1}$, $\delta = (2k-1)/\sqrt{n}$.

(vi) $\Omega = R_+ \times R_+$, $\rho(x) = \operatorname{dist}(x, \partial\Omega)^\alpha = \min(x_1, x_2)^\alpha$, $2\alpha k \neq n = 2$, $\delta = (n - 2\alpha k)/n$.

Then for all $f \in \overset{0}{W}{}^{k,\rho}(\Omega)$

$$\int_\Omega \left(\frac{f}{\rho^k} \right)^2 dx \leqq \frac{4}{n\delta^2} \sum_1^n \int_\Omega \left(\frac{D_i f}{\rho^{k-1}} \right)^2 dx.$$

Proof. (i) $D_i \rho = \alpha (1 + |x|_1)^{\alpha - 1} \operatorname{sign} x_i$ implies that

$$1 - \frac{2k}{n\rho} \sum_1^n D_i \rho x_i = 1 - \frac{2\alpha k}{n} \frac{|x|_1}{1 + |x|_1} \geqq 1 - \frac{2\alpha k}{n} = \delta.$$

Now Lemma 2.1 implies that (after squaring both sides) for all $f \in C_0^\infty(\Omega)$

$$\int \left(\frac{f}{\rho^k} \right)^2 dx \leqq \frac{4}{n^2\delta^2} \left(\sum_1^n \left(\int \left(\frac{D_i f}{\rho^{k-1}} \right)^2 dx \right)^{1/2} \right)^2 \leqq \frac{4}{n\delta^2} \sum_1^n \int \left(\frac{D_i f}{\rho^{k-1}} \right)^2 dx.$$

Since $C_0^\infty(\Omega)$ lies dense in $\overset{0}{W}{}^{k,\rho}(\Omega)$, this gives our assertion.

(ii) As above we get

$$1 - \frac{2k}{n\rho} \sum_1^n D_i \rho x_i = 1 - \frac{2\alpha k}{n} \frac{|x|_1}{1 + |x|_1} \leqq 1 - \frac{2\alpha k}{n} \frac{r}{1 + r} = -\delta.$$

Now multiply by -1 and proceed as in (i).

(iii)

$$1-\frac{2k\sum D_i\rho x_i}{n\rho}=1-\frac{2k}{n}\,\frac{|x|_1(\ln(|x|_1+c)+1)}{(|x|_1+c)\ln(|x|_1+c)}$$

$$\geqq 1-\frac{2k}{n}\left(1+\frac{1}{\ln c}\right)=\delta.$$

(iv)

$$1-\frac{2k\sum D_i\rho x_i}{n\rho}\leqq 1-\frac{2k}{n}\,\frac{2k+n}{4k}=-\delta.$$

(v) Since

$$\int\left(\frac{f}{x_1^k}\right)^2 dx=-2\int D_1\left(\frac{f}{x_1^k}\right)\cdot\frac{f}{x_1^k}\cdot x_1\,dx$$

$$=-2\int\frac{D_1 f}{x_1^{k-1}}\cdot\frac{f}{x_1^k}dx+2k\int\left(\frac{f}{x_1^k}\right)^2 dx,$$

we get

$$\int\left(\frac{f}{x_1^k}\right)^2=\frac{2}{2k-1}\int\frac{D_1 f}{x_1^{k-1}}\,\frac{f}{x_1^k}\,dx\leqq\frac{2}{2k-1}\left(\int\left(\frac{D_1 f}{x_1^{k-1}}\right)^2 dx\right)^{1/2}\cdot\left(\int\left(\frac{f}{x_1^k}\right)^2 dx\right)^{1/2}.$$

We divide by $\|fx_1^{-k}\|_2$, square both sides and thus get the assertion.

(vi) We have

$$\rho(x)=\begin{cases}x_1^\alpha & \text{if } x_1\leqq x_2,\\ x_2^\alpha & \text{else,}\end{cases}$$

$$D_1\rho(x)=\begin{cases}\alpha x_1^{\alpha-1} & \text{if } x_1\leqq x_2,\\ 0 & \text{else,}\end{cases}\qquad D_2\rho(x)=\begin{cases}0 & \text{if } x_1\leqq x_2,\\ \alpha x_2^{\alpha-1} & \text{else.}\end{cases}$$

Now $\sum D_i\rho x_i=\alpha\rho$ and hence

$$1-\frac{2k}{n\rho}\sum D_i\rho x_i=1-\frac{2\alpha k}{n}=\delta.$$

Lemma 2.1 then implies the assertion as usual. Q.E.D.

Remark 2.4. (i) If the assertion of Theorem 2.3 holds for a weight function ρ and if $\tilde\rho$ is any other (not necessarily continuous) weight function such that $c_1\rho(x)\leqq\tilde\rho(x)\leqq c_2\rho(x)$ for all $x\in\Omega$ and some constants $c_1,c_2>0$, then an inequality of the same type as in Theorem 2.3 holds for $\tilde\rho$—only the constant $4n^{-1}\delta^{-2}$ has to be changed!

(ii) Mazja [11] studies Poincaré-type inequalities using capacity theory. But the constants appearing in his conditions are hard to compute or even prove finite, especially in the critical cases $n\leqq 2k$.

(iii) Using a suitable transformation of the coordinates, we can of course replace the condition on Ω in Theorem 2.3(ii) and (iv) by $\overline{\Omega}\neq R^n$.

The next examples show that the conditions on Ω cannot be relaxed, at least for $k=1$.

Example 2.5. (i) Let $n=1$ and ρ be a weight function which is less or equal than one on the interval $[-1,1]$. We consider the functions

$$f_m(x) := \begin{cases} m & \text{if } x\in[0,1], \\ m-(x-1) & \text{if } x\in(1,m+1), \\ 0 & \text{if } x\geqq m+1, \\ f_m(-x) & \text{if } x\leqq 0. \end{cases}$$

Then for all $m\in N$

$$\int_{-\infty}^{\infty} f_m^2\rho^{-2}\,dx \geqq \int_{-1}^{1} f_m^2\,dx = 2m^2 \quad \text{and} \quad \int_{-\infty}^{\infty} (f_m')^2\,dx \leqq 2m.$$

Hence there cannot exist any locally bounded weight functions ρ and any constant K such that for all $f\in C_0^\infty(R)$

$$\int_{-\infty}^{\infty} f^2\rho^{-2}\,dx \leqq K\int_{-\infty}^{\infty} (f')^2\,dx.$$

(ii) Now let $n=2$ and ρ be a weight function which is smaller than or equal to one on the unit ball $K(0,1)$. For $m\in N$, $r\in R_+$ we define

$$g_m(r) := \begin{cases} m & \text{if } r\in[0,1], \\ m-\ln r & \text{if } r\in(1,\exp m), \\ 0 & \text{if } r\geqq \exp m. \end{cases}$$

Then

$$\int_{R^2} g_m(|x|)^2\rho^{-2}(x)\,dx \geqq \pi m^2 \quad \text{and} \quad \sum_1^2 \int_{R^2} \big(D_i g_m(|x|)\big)^2\,dx = w\pi m$$

and again there cannot exist any locally bounded weight function ρ and any constant K such that for all $f\in C_0^\infty(R^2)$

$$\int_{R^2} f^2\rho^{-2}\,dx \leqq K\sum_1^2 \int_{R^2} (D_i f)^2\,dx.$$

COROLLARY 2.6. *Let $\Omega\subset R^n$, ρ be a weight function, $k_0\in N$. If Ω, p, k, n fulfill for any $k\leqq k_0$ any of the conditions of Theorem* 2.3, *then there exists a constant K, which can be computed explicitly, such that for all $f\in \overset{0}{W}{}^{k,\rho}(\Omega)$*

$$\sum_{|\alpha|=k_0} \|D^\alpha f\|_2^2 \leqq \sum_{|\alpha|\leqq k_0} \|\rho^{-k_0+|\alpha|}D^\alpha f\|_2^2 \leqq K \sum_{|\alpha|=k_0} \|D^\alpha f\|_2^2.$$

Proof. The proof follows immediately from Theorem 2.3 by induction. Q.E.D.

We shall now apply our theorems to the Dirichlet problem on unbounded domains. The proof follows the philosophy of J. Wloka (see [18]).

THEOREM 2.7. *Let Ω, ρ, k, n fulfill the assumptions of Corollary* 2.6. *Furthermore, let $Au := \sum_{|\alpha|,|\beta|\leqq k}(-1)^{|\alpha|}D^\alpha(a_{\alpha\beta}D^\beta u)$, where the matrix $(a_{\alpha\beta})_{|\alpha|=|\beta|=k}$ is assumed to be uniformly positive definite and*

(i) $a_{\alpha\beta}\in L_\infty$ *for* $|\alpha|=|\beta|=k$,

(ii) $a_{\alpha\beta}=0$ *for* $k<|\alpha|+|\beta|<2k$,

(iii) $D^\gamma(a_{\alpha\beta})\rho^{2k-|\beta+\alpha-\gamma|}\in L_\infty$ *for* $|\alpha|+|\beta|\leqq k$, $\gamma\leqq\alpha$.

Set

$$a(u,v) := \sum_{|\alpha|,|\beta| \leqq k} \int_\Omega a_{\alpha\beta} D^\beta u D^\alpha v \, dx.$$

Then there exists a $\lambda_0 > 0$ *such that for all* $\lambda > \lambda_0$ *and all* $f \in (\overset{0}{W}{}^{k,\rho}(\Omega))^*$ *there is exactly one* $u \in \overset{0}{W}{}^{k,\rho}(\Omega)$ *such that for all* $v \in \overset{0}{W}{}^{k,\rho}(\Omega)$

$$b(u,v) := a(u,v) + \lambda \int_\Omega uv\rho^{-2k} dx = \langle f, v \rangle_{\overset{0}{W}{}^{k,\rho}}.$$

The operator $A + \lambda\rho^{-2k}: \overset{0}{W}{}^{k,\rho} \to (\overset{0}{W}{}^{k,\rho})^*$ *is a topological isomorphism.*

Proof. b is for all $\lambda \in R$ a continuous bilinear form. From the assumptions on the coefficients and Corollary 2.6 we conclude that

$$(2) \qquad a(u,u) = \sum_{|\alpha|=|\beta|=k} \int a_{\alpha\beta} D^\beta u D^\alpha u \, dx + \sum_{|\alpha|+|\beta|<k} \int a_{\alpha\beta} D^\beta u D^\alpha u \, dx$$

$$\geqq c_1 \sum_{|\alpha|=k} \|D^\alpha u\|_2^2 - c_2 \sum_{|\alpha|+|\beta|<k} \sum_{\gamma<\alpha} \int \left| D^\gamma(a_{\alpha\beta}) D^{\beta+\alpha-\gamma} u \cdot u \right| dx$$

$$\geqq c_3 \|u\|_{k,\rho}^2 - c_4 \|u\|_{k,\rho} \cdot \|u\rho^{-k}\|_2,$$

where c_i are positive constants. Now let $c_3 > \delta > 0$ and $\varepsilon := 2(c_3 - \delta)c_4^{-1}$; then

$$(3) \qquad c_4 \|u\|_{k,\rho} \|u\rho^{-k}\|_2 \leqq c_4 \varepsilon 2^{-1} \|u\|_{k,\rho}^2 + c_4 (2\varepsilon)^{-1} \|u\rho^{-k}\|_2^2$$

$$= (c_3 - \delta)\|u\|_{k,\rho}^2 + c_4^2 (4(c_3 - \delta))^{-1} \|u\rho^{-k}\|_2^2.$$

For any $\lambda > \lambda_0 := c_4^2 (4c_3)^{-1}$ exists a $\delta > 0$, such that $\lambda \geqq c_4^2 (4(c_3 - \delta))^{-1}$. For this δ it follows from (2), (3) that $b(u,u) \geqq \delta \|u\|_{k,\rho}^2$, i.e. b is coercive. The Lax–Milgram lemma (see e.g. Oden, Reddy [13]) gives us then the assertion. Q.E.D.

Remark 2.8. (i) λ_0 can be computed explicitly using Corollary 2.6 and bounds on the coefficients.

(ii) The conditions on $a_{\alpha\beta}$ for $|\alpha| + |\beta| < 2k$ will be weakened considerably in the next section. But then we use compactness arguments and shall not be able to compute λ_0 any more.

(iii) We can also treat mixed boundary conditions in this way. For an example see Janßen [5].

3. Compact imbeddings. In this section we study compact imbeddings and some of their consequences. We shall need some geometric properties of Ω and the weight function ρ, which we shall provide in the next definitions and lemmata.

DEFINITION 3.1. Let $l \in N$, $0 \leqq \kappa \leqq 1$ (for $l = 0$ only $\kappa = 0$ or 1).

(i) The function $f:\Omega\to R$ belongs to $C^{(l,\kappa)}(\Omega)$, if the numbers

$$\sup_{x\in\Omega}|D^\alpha f(x)|, \qquad |\alpha|\leqq l,$$

$$\sup_{x,y\in\Omega}\frac{|D^\alpha f(x)-D^\alpha f(y)|}{|x-y|}, \qquad |\alpha|\leqq l-1,$$

$$\sup_{x,y\in\Omega}\frac{|D^\alpha f(x)-D^\alpha f(y)|}{|x-y|^\kappa}, \qquad |\alpha|=l.$$

are all finite.

(ii) A one-to-one mapping $T:\Omega\to\Omega'\subset R^n$ is called a $C^{(l,\kappa)}$-diffeomorphism if the components of T resp. T^{-1} belong to $C^{(l,\kappa)}(\Omega)$ resp. $C^{(l,\kappa)}(\Omega')$ and for $l\geqq 1$ $0<c_1\leqq|\det(\partial T/\partial x)(x)|\leqq c_2<\infty$ for all $x\in\Omega$.

(iii) $\Omega\subset R^n$ is called (l,κ)-smooth if for all $x\in\partial\Omega$ there exists a neighbourhood U_x such that U_x is (l,κ)-diffeomorphic to the unit cube W at which (all mappings are one-to-one, onto)

$$\partial\Omega\cap U_x\to W\cap\{x_n=0\},$$
$$\Omega\cap U_x\to W\cap\{x_n>0\},$$
$$C\bar{\Omega}\cap U_x\to W\cap\{x_n<0\}.$$

LEMMA 3.2. *Let $T:\Omega\to\Omega'$ be a $C^{(L,\kappa)}$-diffeomorphism. Then the pullback operators*

$$*T: W^{l,\rho}(\Omega')\to W^{l,\rho\circ T}(\Omega), \qquad u\to u\circ T$$

$$*T^{-1}: W^{l,\rho\circ T}(\Omega)\to W^{l,\rho}(\Omega'), \qquad u\to u\circ T^{-1}$$

are continuous for $l\leqq L+\kappa$ and hence

$$W^{l,\rho}(\Omega')\cong W^{l,\rho\circ T}(\Omega).$$

Proof. Analogous to the case $\rho\equiv 1$, see e.g. Wloka [18, p. 86ff], or Adams [1]. Q.E.D.

DEFINITION 3.3. A weight function $\rho:R^n\to R_+$ is called translation, and dilation invariant (td-function) if for all $K_0>0$ and all $x_0\in R^n$ there exists a constant K_1 such that for the mapping $T:R^n\to R^n$, $T(x)=K_0(x-x_0)$ and all $x\in R^n$ $K_1^{-1}\rho(Tx)\leqq\rho(x)\leqq K_1\rho(Tx)$, where K_1 as a function of K_0, x_0 is locally bounded.

LEMMA 3.4. (i) $1+|x|$ *and* $\ln(|x|+2)$ *are td-functions.*

(ii) *If ρ_1, ρ_2 are td-functions, then the same is true for $\rho_1\cdot\rho_2$, ρ_1^c for any $c>0$ and also any weight-function ρ with $c_1^{-1}\rho_1<\rho<c_1\rho_1$, $c_1>0$ is a td-function.*

(iii) *If ρ is a td-function and $f:R^+\to R^+$ increasing, then $f\circ\rho$ is a td-function.*

Proof. Left to the reader.

LEMMA 3.5. *Let $M\in R_+$, $K_0\in R_+$ and $x_0\in R^n$ such that $K_0+|x_0|\leqq M$. If ρ is a td-function, $T(x):=K_0(x-x_0)$ and $\Omega':=T\Omega$, then for all $l\in N$, $W^{l,\rho}(\Omega)\cong W^{l,\rho}(\Omega')$. The norms of the pullback operators depend only on l and M.*

Proof. T is a C^∞-diffeomorphism. Lemmata 3.2 and 3.4(ii) imply $W^{l,\rho}(\Omega)\cong W^{l,\rho}(\Omega')$ and the continuity of the pullback operators. Since by Definition 3.3 K_1 as a function of K_0, x_0 is locally bounded, the norms depend only on M (and of course 1). Q.E.D.

LEMMA 3.6. *Let $T:\Omega\to\Omega'$ be a $C^{(L,\kappa)}$-diffeomorphism, $L+\kappa\geqq 1$. If $\rho(x)=f(1+|x|)$, $f:R_+\to R_+$ increasing, then for all $l\leqq L+\kappa$, $W^{l,\rho}(\Omega)\cong W^{l,\rho}(\Omega')$.*

Proof. ρ is a td-function; hence by 3.5, without loss of generality, $0\in\Omega\cap\Omega'$, $T(0)=0$. T, T^{-1} are Lipschitz continuous; hence there exists a $K_1>0$ such that $K_1^{-1}|x|\leqq|Tx|\leqq K_1|x|$. Since f is increasing, it follows that $\rho(K_1^{-1}x)\leqq\rho(Tx)\leqq\rho(K_1x)$. Since ρ is dilation invariant, there exists $K_2>0$ such that $K_2^{-1}\rho(x)\leqq\rho(Tx)\leqq K_2\rho(x)$ and Lemma 3.2 gives us the assertion. Q.E.D.

Before we proceed, let us fix some more notation. If $k\in N$, ρ is a weight function on Ω, then $M_{k,\rho}$ denotes the operator which assigns to any measurable $f:\Omega\to R$ the function $M_{k,\rho}(f):=\rho^{-k}\cdot f$. If $\phi:\Omega\to R$ is measurable, then $M_\phi(f):=\phi\cdot f$. Let $\Sigma\subset\{x\in R^n\,|\,|x|=1\}$, $x_0\in R^n$, $r_0>0$, then

$$S(x_0,r_0,\Sigma):=\{x_0+t\cdot\sigma\,|\,r_0\leqq t,\ \sigma\in\Sigma\}.$$

For $a\geqq 1$ we introduce the following abbreviation, where $\rho(x)=\tilde\rho(|x|)$ (for shortness $\rho(|x|)$)

$$I(a,n,k,\rho):=\int_a^\infty\frac{\int_1^u v^{1-n}\rho^{2(k-1)}(v)\,dv}{\rho^{2k}(u)}\cdot u^{n-1}\,du.$$

Furthermore, we shall need the following well-known theorem due to Kolmogoroff (for a proof see Yoshida [19] or Voigt and Wloka [17]):

$K\subset L_2(\Omega)$ is relatively compact iff the following three conditions hold:

(K1) K is bounded in $L_2(\Omega)$;

(K2) $\lim_{h\to 0}\int_\Omega|f(x+h)-f(x)|^2dx=0$ uniformly for all $f\in K$;

(K3) $\lim_{a\uparrow\infty}\int_{|x|>a}|f(x)|^2dx=0$ uniformly for all $f\in K$.

LEMMA 3.7. *Let $\Omega=S(0,1,\Sigma)$, $k\in N$, ρ be a weight function with $\rho(x):=\tilde\rho(|x|)$ (for shortness $\rho(|x|)$) and $f\in C^\infty(\Omega)$ with $\|f\|_{k,\rho}\leqq 1$ and $f(\sigma)=0$ for $\sigma\in\Sigma$. Then*

$$\int_{\Omega\cap\{|x|>a\}}f^2(x)\rho^{-2k}(x)\,dx\leqq I(a,n,k,\rho).$$

Proof. We introduce polar coordinates $x=T(u,\alpha_1,\cdots,\alpha_{n-1})$.

$$\begin{aligned}
x_1&=u\cos\alpha_1,\\
x_2&=u\sin\alpha_1\cos\alpha_2,\\
&\vdots\\
x_{n-1}&=u\sin\alpha_1\cdots\sin\alpha_{n-2}\cos\alpha_{n-1},\\
x_n&=u\sin\alpha_1\cdots\sin\alpha_{n-2}\sin\alpha_{n-1},
\end{aligned}$$

where $0\leqq u<\infty$, $0\leqq\alpha_{n-1}\leqq 2\pi$, $0\leqq\alpha_i\leqq\pi$ for $i=1,\cdots,n-2$ and set $\tilde f:=f\circ T$. Since $\tilde f(1,\alpha_1,\cdots,\alpha_{n-1})=0$ for $(\alpha_1,\cdots,\alpha_{n-1})\in T^{-1}(1,\Sigma)=:\tilde\Sigma$ we have for $x=T(u,\alpha_1,\cdots,\alpha_{n-1})\in\Omega$ that

$$\tilde f(u,\alpha_1,\cdots,\alpha_{n-1})=\int_1^u\frac{\partial\tilde f}{\partial v}(v,\alpha_1,\cdots,\alpha_{n-1})\,dv.$$

This implies that

$$\begin{aligned}
|\tilde f(u,\alpha_1,\cdots,\alpha_{n-1})|^2&=\left|\int_1^u\frac{\partial\tilde f}{\partial v}(v,\alpha_1,\cdots,\alpha_{n-1})\,dv\right|^2\\
&=\left(\int_1^u\frac{|(\partial\tilde f/\partial v)(v,\alpha_1,\cdots,\alpha_{n-1})|^2}{\rho^{2(k-1)}(v)}\cdot v^{(n-1)/2}\cdot\rho^{(k-1)}(v)\cdot v^{(1-n)/2}\,dv\right)^2\\
&\leqq F(u,n,k,\rho)\int_1^\infty\frac{|(\partial\tilde f/\partial v)(v,\alpha_1,\cdots,\alpha_{n-1})|^2}{\rho^{2(k-1)}(v)}\cdot v^{n-1}\,dv
\end{aligned}$$

where $F(u,\ n,\ k,\ \rho) := \int_1^u v^{1-n}\rho^{2(k-1)}(v)\,dv$. We multiply both sides of the inequality by $\Pi_1^{n-2}(\sin\alpha_i)^{n-i-1}$, integrate with respect to $\alpha_1,\cdots,\alpha_{n-1}$ over $\tilde{\Sigma}$ and since

$$\left|\frac{\partial\tilde{f}}{\partial v}(y)\right|^2 \leqq \left(\sum_1^n \left|\frac{\partial f}{\partial x_i}(Ty)\right|^2\right)\left(\sum_1^n \left|\frac{\partial T_i}{\partial v}(y)\right|^2\right) \leqq \sum \left|\frac{\partial f}{\partial x_i}(Ty)\right|^2$$

and $\|f\|_{k,\rho}\leqq 1$ we arrive after a coordinate transformation on the right side at

$$\int\cdots\int_{\tilde{\Sigma}} |\tilde{f}(u,\alpha_1,\cdots,\alpha_{n-1})|^2 \prod_1^{n-2}(\sin\alpha_i)^{n-i-1}\,d\alpha_1\cdots d\alpha_{n-1} \leqq F(u,\ n,\ k,\ \rho).$$

Multiplying by $u^{n-1}\rho^{-2k}(u)$, integrating with respect to u from a to ∞ and transforming the coordinates on the left side, we finally get the assertion. Q.E.D.

LEMMA 3.8. *If ρ, k, n fulfill any of the following conditions*

(i) $2k>n$, $\rho(x)=(|x|+2)\ln(|x|+2)$,

(ii) $\rho(x)=(|x|+1)^c$, $c>\max(1,n/2k)$,

(iii) $\rho(x)=(|x|+2)^c\cdot\ln(|x|+2)$, $c>1$, $n=2kc$,

then ρ is a td-function, $\rho^{-k}\in L_2(R^n)$ and $\lim_{a\to\infty} I(a,n,k,\rho)=0$.

Proof. Lemma 3.4 implies that all functions are td-functions. In all three cases we easily see that $\int_0^\infty \rho^{-2k}(u)u^{n-1}\,du<\infty$ and hence $\rho^{-k}\in L_2(R^n)$.

(i) Set $F(u,n,k,\rho)=\int_1^u v^{1-n}\rho^{2(k-1)}(v)\,dv$; then

$$F(u,n,k,\rho)\leqq c_1\int_1^u v^{1-n+2(k-1)}(\ln(v+2))^{2(k-1)}\,dv.$$

Since $2k>n$ we have $m := 1-n+2(k-1)\geqq 0$ and hence

$$\frac{F(u,n,k,\rho)}{\rho^{2k}(u)} \leqq c_1\frac{\int_1^u v^m\,dv}{u^{2k}\ln^2(u+2)} \leqq c_2\frac{u^{m+1-2k}}{\ln^2(u+2)} = c_2\frac{u^{-n}}{\ln^2(u+2)}.$$

For $a\geqq 2$ this implies that

$$I(a,n,k,\rho)\leqq c_3\int_a^\infty \frac{1}{u\ln^2 u}\,du = \frac{c_3}{\ln a} \overset{a\to\infty}{\to} 0.$$

(ii) Now we define $m := 1-n+2(k-1)c$. Then

$$F(u,n,k,\rho)\leqq c_4\int_1^u v^m\,dv.$$

Case 1. $m<-1$. Then $F(u,n,k,\rho)\leqq c_4$ and hence $I(a,n,k,\rho)\leqq c_4\int_a^\infty u^{n-2kc-1}\,du\to 0$ for $a\to\infty$ since $n-2kc-1<-1$.

Case 2. $m=-1$. Then $F(u,n,k,\rho)\leqq c_4\ln u$ and hence $I(a,n,k,\rho)\leqq c_4\int_a^\infty \ln(u)\cdot u^{n-2kc-1}\,du\leqq c_5\int_a^\infty u^{-1-\delta}\,du\to 0$ for $a\to\infty$ where we choose $\delta>0$ such that $\ln u\leqq c_5u^\delta/c_4$ and $n-2kc-1\leqq -1-2\delta$.

Case 3. $m>-1$. Then $F(u,n,k,\rho)\leqq c_6u^{m+1}$ and $I(a,n,k,\rho)\leqq c_6\int_a^\infty u^{-2c+1}\,du\to 0$ for $a\to\infty$, since $-2c+1<-1$.

(iii) For $a\geqq 2$ we get

$$I(a,n,k,\rho)\leqq c_7\int_a^\infty \frac{\int_1^\infty v^{1-2c}\,dv}{u^{2kc}\ln^2 u}\cdot u^{n-1}\,du \leqq c_7\int_a^\infty \frac{1}{u\ln^2 u}\,du = \frac{c_7}{\ln a} \overset{a\to\infty}{\to} 0.$$ Q.E.D.

THEOREM 3.9. *Let ρ, k, n fulfill any of the conditions of Lemma 3.8. Then $M_{k,\rho}: W^{k,\rho}(R^n)\to L_2(R^n)$ is a linear, continuous and injective operator with dense range which maps bounded into relatively compact sets. (Henceforth we shall call a mapping with these properties a compact imbedding.)*

Proof. Obviously, $M_{k,\rho}$ is linear, continuous, injective and has dense image. Let $\phi_1 \in C_0^\infty(R^n)$ with $\operatorname{supp}\phi_1 \subset K(0,2)$ and $\phi_1(x)=1$ for $x \in K(0,1)$. Since

$$M_{\phi_1}: W^{k,\rho}(R^n) \to \overset{0}{W}{}^{k,\rho}(K(0,2)) \cong \overset{0}{W}{}^{k}(K(0,2))$$

is continuous, we get from the imbedding theorems on bounded domains that

$$M_{k,\rho} \circ M_{\phi_1}: W^{k,\rho}(R^n) \to L_2(K(0,2)) \subset L_2(R^n)$$

is compact. If we define $\phi_2 := 1-\phi_1$, then the derivatives of ϕ_2 have compact support and since the weight functions are bounded from above and below by positive constants, it follows that

$$M_{\phi_2}: W^{k,\rho}(R^n) \to \overset{0}{W}{}^{k,\rho}(R^n \backslash K(0,1))$$

is continuous. Since $M_{k,\rho} = M_{k,\rho} \circ M_{\phi_1} + M_{k,\rho} \circ M_{\phi_2}$, it suffices to show that

$$M_{k,\rho}\big(M_{\phi_2}(K)\big) \subset L_2(R^n \backslash K(0,1))$$

is relatively compact where $K := \{f \in W^{k,\rho} \mid \|f\|_{k,\rho} \leqq 1\}$.

Now (K1) is immediate and (K3) follows from Lemmata 3.7, 3.8. Since M_{ϕ_2} is continuous, there exists $c_1 > 0$ such that

$$M_{\phi_2}(K) \subset \overline{\{f \in C^\infty(R^n) \mid \|f\|_{k,\rho} \leqq c_1,\ \operatorname{supp} f \subset R^n \backslash K(0,1)\}}^{\|\cdot\|_{k,\rho}}.$$

So let $f \in C^\infty(R^n)$, $\|f\|_{k,\rho} \leqq c_1$, $\operatorname{supp} f \subset R^n \backslash K(0,1)$. Then

$$\begin{aligned}
&\int |M_{k,\rho}(f)(x+h) - M_{k,\rho}(f)(x)|^2\, dx \\
&= \int \left| \frac{f(x+h)}{\rho^k(x+h)} - \frac{f(x)}{\rho^k(x)} \right|^2 dx \\
&= \int \left| \frac{f(x+h)\rho^k(x) - f(x)\rho^k(x) + f(x)\rho^k(x) - f(x)\rho^k(x+h)}{\rho^k(x+h)\rho^k(x)} \right|^2 dx \\
&\leqq 2\int \left| \frac{f(x+h)-f(x)}{\rho^k(x+h)} \right|^2 + \left(\frac{f(x)}{\rho^k(x)} \right)^2 \left| \frac{\rho^k(x)-\rho^k(x+h)}{\rho^k(x+h)} \right|^2 dx \\
&\leqq 2\int \left\{ \frac{\left(\int_0^1 \langle \nabla f(x+th) \mid h \rangle\, dt \right)^2}{\rho^{2k}(x+h)} + \left(\frac{f(x)}{\rho^k(x)} \right)^2 \frac{\left(\int_0^1 \langle \nabla \rho^k(x+th) \mid h \rangle\, dt \right)^2}{\rho^{2k}(x+h)} \right\} dx \\
&\leqq 2|h|^2 c_2 \int_0^1 \int \left\{ \frac{|\nabla f(x+th)|^2}{\rho^{2(k-1)}(x+th)} + \left(\frac{f(x)}{\rho^k(x)} \right)^2 \right\} dx\, dt \qquad \text{(since } \rho \text{ is a td-function)} \\
&\leqq c_3 |h|^2 \to 0 \quad \text{for } |h| \to 0
\end{aligned}$$

where c_3 does not depend on f (only on c_1, k, ρ). This implies (K2) and hence the assertion is proved. Q.E.D.

COROLLARY 3.10. *Let $\Omega \subset R^n$, k, n, ρ as in Theorem 3.9. Then $M_{k,\rho}$: $\overset{0}{W}{}^{k,\rho}(\Omega) \to L_2(\Omega)$ is a compact imbedding.*

Proof. Let $F_\Omega: \overset{0}{W}{}^{k,\rho}(\Omega) \to \overset{0}{W}{}^{k,\rho}(R^n)$ be the natural continuation operator (zero outside Ω) and $R_\Omega: L_2(R^n) \to L_2(\Omega)$ the restriction mapping. Then F_Ω, R_Ω are continuous and hence

$$M_{k,\rho}^{\Omega} = R_\Omega \circ M_{k,\rho}^{R^n} \circ F_\Omega$$

is compact by Theorem 3.9. Q.E.D.

If there is a continuation operator for the spaces $W^{k,\rho}$, i.e. a continuous, linear mapping $F_\Omega: W^{k,\rho}(\Omega) \to W^{k,\rho}(R^n)$ with $Fu(x) = u(x)$ for all $x \in \Omega$, $u \in C^k(\Omega) \cap W^{k,\rho}(\Omega)$, we can easily transfer Corollary 3.10 to these spaces. We now give some examples where such an operator exists.

LEMMA 3.11. *Let* $\Omega = \{x \in R^n \mid x_n > 0\}$. *Then there exists a continuation operator.*

Proof. Use the method of Hestenes, see Adams [1], Wloka [18]. Q.E.D.

Remark 3.12. By multiple application of Hestenes' construction we can of course also construct continuation operators for orthants and similar domains, e.g. $\{x \in R^3 \mid x_1 > 0 \text{ and } x_2 > 0\}$.

LEMMA 3.13. (i) *Let* Ω *be* $C^{(k,\kappa)}$*-diffeomorphic to a domain* Ω' *for which there exists a continuation operator for* $l \leqq k + \kappa$. *Then there exists also a continuation operator for* Ω *and* $l \leqq k + \kappa$.

(ii) *Let* Ω *be* (k, κ)*-smooth with bounded boundary. Then there exists a continuation operator.*

Proof. (i) $F_\Omega := {}^*T \circ F_{\Omega'} \circ {}^*T^{-1}$ (see Lemma 3.2).

(ii) Cover $\partial\Omega$ by small neighbourhoods U_j, $j = 1, \cdots, m$ from Lemma 3.2(iii). Then (with $U_0 = \Omega$) we have $\overline{\Omega} \subset \bigcup_{j=0}^{m} U_j$. Let α_j, $j = 0, \cdots, m$ be the appropriate partition of the unity. Then α_0 is equal to one outside $\bigcup_1^m U_j$; hence all derivations of α_0 (and of course those of α_j, $j = 1, \cdots, m$) vanish outside a bounded ball and hence $|D^\beta \alpha_j \circ \rho^l|$ stays uniformly bounded. This implies that $M_{\alpha_j}: W^{l,\rho}(U_j \cap \Omega) \to W^{l,\rho}(\Omega)$ is continuous and their norm is uniformly bounded. By (i) we can extend $\alpha_j f$ for $j = 1, \cdots, m$ to $U_j (f \in W^{l,\rho}(\Omega))$. Adding these local extensions to $\alpha_0 f$, we get an extension with support in $\bigcup_{j=0}^{m} U_j$ and can extend by zero to the whole space. Q.E.D.

THEOREM 3.14. *Let* $\Omega = \bigcup_1^N \Omega_i$, *where there exists a continuation operator for each* Ω_i *and* ρ, k, n *fulfill the conditions of Lemma* 3.8. *Then* $M_{k,\rho}: W^{k,\rho}(\Omega) \to L_2(\Omega)$ *is a compact imbedding.*

Proof. For $N = 1$, analogous to Corollary 3.10. For $N > 1$ let $(\phi_j)_{j \in N} \subset W_{k,\rho}(\Omega)$ with $\|\phi_j\|_{k,\rho} \leqq 1$. Then $\phi_j \in W^{k,\rho}(\Omega_i)$, $i = 1, \cdots, N$ and there exist (eventually after passing to some convergent subsequence several times) $\psi_i \in L_2(\Omega_i)$ such that $M_{k,\rho}\phi_j \to \psi_i$ in $L_2(\Omega_i)$. Now define

$$\psi := \psi_i \quad \text{on } \Omega_i \setminus \bigcup_{l=1}^{i-1} \Omega_l, \qquad i = 1, \cdots, N.$$

Then $M_{k,\rho}\phi_j \to \psi$ in $L_2(\Omega)$ and $M_{k,\rho}$ is compact. Q.E.D.

For $n > 2k$ the conditions on the weight function are very restrictive (see Lemma 3.8). This defect can be removed if we add a decay condition at infinity, i.e. we consider now the spaces $W_c^{k,\rho}$.

LEMMA 3.15. *Let* $n > 2k$ *and* $c > 1$ *be such that* $n > 2kc + 2(1 - c)$. *If* $\Omega = S(0, 1, \Sigma)$ *and* $\rho(x) = (1 + |x|)^c$ *then*

$$\int_{\Omega \cap \{|x| \geqq a\}} \left(\frac{f(x)}{\rho^k(x)} \right)^2 dx \to 0 \quad \text{as } a \to \infty$$

uniformly for all $f \in W_c^{k,\rho}(\Omega)$ *with* $\|f\|_{k,\rho} \leqq 1$.

Proof. Let $f \in C_0^\infty(R^n)|_\Omega$, introduce polar coordinates $x = T(u, \alpha_1, \cdots, \alpha_{n-1})$ and set $\tilde{f} := f \circ T$. Then

$$\tilde{f}(u, \alpha_1, \cdots, \alpha_{n-1}) = \int_u^\infty \frac{\partial \tilde{f}}{\partial v}(v, \alpha_1, \cdots, \alpha_{n-1})\, dv.$$

Similar to Lemma 3.7 this implies that

$$\int_{\Omega \cap \{|x| \geqq a\}} \frac{f^2(x)}{\rho^{2k}(x)}\, dx \leqq \int_a^\infty \frac{G(u,n,k,\rho)}{\rho^{2k}(u)} u^{n-1}\, du$$

where $G(u,n,k,\rho) := \int_u^\infty v^{1-n} \rho^{2(k-1)}(v)\, dv$. Since

$$\int_a^\infty \frac{G(u,n,k,\rho)}{\rho^{2k}(u)} u^{n-1}\, du \leqq c_1 a^{2-2c}$$

the assertion follows from $c > 1$. Q.E.D.

THEOREM 3.16. *Let $n > 2k$, $d > 1$, $n > 2kd + 2(1-d)$, $\rho(x) = (1 + |x|)$. Then*

(i) *$M_{k,\rho}: W_c^{k,\rho}(R^n) \to L_2(R^n)$ is a compact imbedding.*

(ii) *If $\Omega = \bigcup_1^N \Omega_i$ and for each Ω_i exists a continuation operator, then $M_{k,\rho}: W_c^{k,\rho}(\Omega) \to L_2(\Omega)$ is a compact imbedding.*

(iii) *For any $\Omega \subset R^n$ $M_{k,\rho}: W_c^{k,\rho}(\Omega) \to L_2(\Omega)$ is a compact imbedding.*

Proof. Analogous to that of Theorem 3.9, Corollary 3.10 and Theorem 3.14, using Lemma 3.15 instead of Lemmata 3.7, 3.8. Q.E.D.

THEOREM 3.17. *Let $M_{j,\rho}: W^{j,\rho}(\Omega) \to L_2(\Omega)$ be compact for $1 \leqq j \leqq k$. Then for any $\varepsilon > 0$ there exists a $c(\varepsilon) > 0$ such that for all $f \in W^{k,\rho}(\Omega)$*

$$\sum_{|\alpha| \leqq k-1} \| D^\alpha f \rho^{-k+|\alpha|} \|_2 \leqq \varepsilon \| f \|_{k,\rho} + c(\varepsilon) \| f \rho^{-k} \|_2$$

(*similar for* $\overset{0}{W}{}^{k,\rho}$, $W_c^{k,\rho}$).

Proof. Suppose the assertion wrong. Then there exist $\varepsilon > 0$ and a sequence $f_m \in W^{k,\rho}$ with $\|f_m\|_{k,\rho} = 1$ such that for all $m \in N$

$$(*) \qquad \sum_{|\alpha| \leqq k-1} \| D^\alpha f_m \rho^{-k+|\alpha|} \|_2 > \varepsilon + m \| f_m \rho^{-k} \|_2.$$

From the compactness it follows that there exists a subsequence (again denoted by f_m) and $g_\alpha \in L_2$ such that $D^\alpha f_m \rho^{-k+|\alpha|} \to g_\alpha$ for $|\alpha| \leqq k-1$. We define $h_\alpha := g_\alpha \rho^{k+|\alpha|}$. Then $D_\alpha h_0 = h_\alpha$ in the sense of distributions. Since $\|f_m\|_{k,\rho} \leqq 1$ $(*)$ implies that $\|f_m \rho^{-k}\| \to 0$ and $g_0 = 0$. Hence h_0 and also $h_\alpha = 0$ for $|\alpha| \leqq k-1$. Going to the limit in $(*)$ this implies that $0 > \varepsilon$ and this is the desired contradiction. Q.E.D.

Remark 3.18. (i) Theorem 3.17 is a generalization of Ehrling's lemma (see Wloka [18]).

(ii) Benci and Fortunato [2] prove an imbedding theorem of the following kind: Let $\phi := \psi \cdot \rho^{-k}$, $\psi(x) \to 0$ for $|x| \to \infty$ then $M_\phi: \overset{0}{W}{}^{k,\rho} \to L_2$ is compact. This result can also be applied to study Fredholm properties of elliptic operators but from it we cannot derive Ehrling's lemma or variants of Poincaré's lemma for functions not vanishing on the boundary (see §4).

(iii) Imbedding theorems for weighted Sobolev spaces have also been studied by Otelbaev [14]. Contrary to our result, there ρ^{-k} has to grow sufficiently fast.

As an application of these imbedding theorems we study again the Dirichlet problem.

THEOREM 3.19. *Let* Ω, ρ, k, n *fulfill the conditions of Corollary* 2.6 *and Theorem* 3.17. *Furthermore, let* $Au := \sum_{|\alpha|,|\beta| \leq k}(-1)^{|\alpha|} D^{\alpha}(a_{\alpha\beta} D^{\beta} u)$ *where* $(a_{\alpha\beta})_{|\alpha|=|\beta|=k}$ *is uniformly strict positive definite and* $a_{\alpha\beta}\rho^{2k-|\alpha|-|\beta|} \in L_{\infty}$. *Again let* $a(u,v) := \sum \int a_{\alpha\beta} D^{\beta} u D^{\alpha} v \, dx$; *then it follows that*

(i) *There exists* λ_0 *such that for all* $f \in (\overset{0}{W}{}^{k,\rho}(\Omega))^*$ *and for all* $\lambda > \lambda_0$ *exists one and only one* $u \in \overset{0}{W}{}^{k,\rho}(\Omega)$ *such that for all* $v \in \overset{0}{W}{}^{k,\rho}(\Omega)$

$$b_{\lambda}(u,v) := a(u,v) + \lambda \int uv\rho^{-2k} dx = \langle f, v \rangle_{k,\rho}.$$

(ii) $A + \lambda\rho^{-2k} : \overset{0}{W}{}^{k,\rho}(\Omega) \to (\overset{0}{W}{}^{k,\rho}(\Omega))^*$ *is an isomorphism for all* $\lambda > \lambda_0$.

(iii) $A : \overset{0}{W}{}^{k,\rho}(\Omega) \to (\overset{0}{W}{}^{k,\rho}(\Omega))^*$ *is a Fredholm operator with index zero.*

(iv) *There exist only countably many* λ *such that* $Av + \lambda\rho^{-2k} v = 0$ *admits a nontrivial solution. These eigenvalues have no finite accumulation point.*

Proof. b is continuous and from Corollary 2.6 and Theorem 3.17 we get

$$a(u,u) \geqq c_1 \| u \|^2_{k,\rho} - c_2 \| u\rho^{-k} \|_2, \qquad c_1 > 0.$$

Set $\lambda_0 = c_2$. Then the Lax–Milgram lemma implies (i), (ii). Since $M_{k,\rho}$ is continuous it follows that the dual mapping $M^*_{k,\rho} : L^*_2 \to (\overset{0}{W}{}^{k,\rho})^*$ is also continuous; hence $\overline{M}_{k,\rho} = M^*_{k,\rho} \circ M_{k,\rho}$ is compact. Identifying $L_2 = L^*_2$, it is easy to see that $M^*_{k,\rho} f = f\rho^{-k}$; hence $\overline{M}_{k,\rho} f = \rho^{-2k} f$. Define $L := A + \lambda\overline{M}$, $\lambda > \lambda_0$. Then $A = L - \lambda\overline{M}$. Since L is an isomorphism by (ii) and $\overline{M}$ is compact, (iii) follows. Now the Riesz–Schauder theory applies to the operator $I + \mu L^{-1} \circ \overline{M}$. This implies (iv). Q.E.D.

4. The Neumann problem on unbounded domains. In order to study the Neumann problem by the variational method, we need suitable variants of the Poincaré lemma. On bounded domains we have (see Nečas [12], Wloka [18])

$$\| f \|^2_{W^k} \leqq \text{const} \left(\sum_{|\alpha|=k} \int |D^{\alpha} f|^2 dx + \sum_{|\alpha|<k} \left| \int D^{\alpha} f \, dx \right|^2 \right).$$

We first apply the compactness theorems of the last section to get a generalization for weighted spaces. Then we get it for convex domains and compute the constants explicitly. Furthermore, we prove generalizations of Friedrich's inequality. As an application we study the Neumann problem. Before we begin with this program, let us fix a notation. By Q_l, $l \in N_0$ we denote the set of all polynomials in $x \in R^n$ of degree less than or equal to l. For a multiindex $\alpha \in (N_0)^n$ we denote by q_a the monom $q_{\alpha}(x) := x^{\alpha}$.

THEOREM 4.1. (i) *Let* Ω, k, n, ρ *be such that* $M_{j,\rho} : W^{j,\rho}(\Omega) \to L_2(\Omega)$ *are compact for* $1 \leqq j \leqq k$. *Furthermore, let* $\rho^{-l} \in L_2(\Omega)$ *for some* $l \geqq 1$ *and let there exist a set* $I \subset \{ \alpha \in (N_0)^n \mid |\alpha| < k \}$ *such that* $W^{k,\rho}(\Omega) \cap Q_{k-1} = \text{span}\{ q_{\alpha} \mid \alpha \in I \}$. *Then there exists a constant* $c > 0$ *such that for all* $u \in W^{k,\rho}(\Omega)$

$$\| u \|^2_{k,\rho} \leqq c \left(\sum_{|\alpha|=k} \int_{\Omega} |D^{\alpha} u|^2 dx + \sum_{\alpha \in I} \left| \int_{\Omega} D^{\alpha} u \rho^{-k-l+|\alpha|} dx \right|^2 \right).$$

(ii) *The assertion remains true if we replace everywhere in* (i) $W^{k,\rho}$ *by* $W^{k,\rho}_c$.

Proof. (i) If the assertion is wrong there exists a sequence $u_m \in W^{k,\rho}$, $\|u_m\|_{k,\rho}=1$ such that

$$1 > m\left(\sum_{|\alpha|=k}\int |D^\alpha u_m|^2\,dx + \sum_{\alpha\in I}\left|\int D^\alpha u_m \rho^{-k-l+|\alpha|}\,dx\right|^2\right). \tag{1}$$

This implies that $\|D^\alpha u_m\|_2 \to 0$ for $m\to\infty$, $|\alpha|=k$. As in Theorem 3.17 we get functions g_α such that $\|D^\alpha u_m \rho^{-k+|\alpha|} - g_\alpha\|_2 \to 0$ for $m\to\infty$ and $|\alpha|<k$. We define $h_\alpha := g_\alpha \rho^{k-|\alpha|}$ for $|\alpha|<k$ and $h_\alpha = 0$ for $|\alpha|=k$. Then $D^\alpha h_0 = h_\alpha$ for $|\alpha|<k$ and from $D^\alpha h_0 = 0$ for $|\alpha|=k$ we get $h_0 \in Q_{k-1}$. Since $\rho^{-l}\in L_2$ (1) implies that

$$\int D^\alpha h_0 \rho^{-k-l+|\alpha|}\,dx = 0 \quad \text{for } \alpha\in I. \tag{2}$$

Since $h_0 = \lim u_m$ (in $W^{k,\rho}$) we see that on the one hand $\|h_0\|_{k,\rho}=1$ and on the other hand $h_0 = \sum_{\alpha\in I} a_\alpha q_\alpha$, $a_\alpha \in R$; hence (2) implies $h_0 = 0$. This is the desired contradiction.

(ii) Obvious. Q.E.D.

Now we are going to prove another variant of this type of inequality where we shall be able to compute the constants explicitly.

THEOREM 4.2. *Let Ω be a convex domain, ρ a convex function and $\rho \geq 1+|x|$, $\rho^{-1}|x| \in L_2$ and set $\rho_1 := \||x|\rho^{-1}\|_2^2$, $\rho_2 := \|\rho^{-1}\|_2^2$; $\rho_3 := \|\rho^{-k}\|_2^2$. Then for all $u \in W^{k,\rho}(\Omega)$*

$$\int_\Omega (u\rho^{-k})^2\,dx \leqq \frac{2^n(\rho_1+\rho_2)}{\rho_3}\int_\Omega \frac{|\nabla u|^2}{\rho^{2(k-1)}}\,dx + \frac{1}{\rho_3}\left(\int_\Omega \frac{u}{\rho^{2k}}\,dx\right)^2.$$

Proof. From $u(y)-u(x) = \int_0^1 \langle \nabla u(x+t(y-x))\,|\,(y-x)\rangle\,dt$ we get

$$u(y)^2 - 2u(y)u(x) + u(x)^2 \leqq \int_0^1 |\nabla u(x+t(y-x))|^2\,|y-x|^2\,dt.$$

Multiplying by $\rho^{-2k}(x)\rho^{-2k}(y)$ and integrating with respect to x, y yields

$$\begin{aligned} 2\int\rho^{-2k}\,dx\int (u\rho^{-k})^2\,dx - 2\left(\int u\rho^{-2k}\,dx\right)^2 \\ \leqq 2\int_0^1\int\int \frac{|\nabla u(x+t(y-x))|^2|x|^2}{\rho^{2k}(x)\rho^{2k}(y)}\,dx\,dy\,dt \\ + 2\int_0^1\int\int \frac{|\nabla u(x+t(y-x))|^2|y|^2}{\rho^{2k}(x)\rho^{2k}(y)}\,dx\,dy\,dt. \end{aligned} \tag{3}$$

We estimate the first summand in (3); the second is treated analogously. Set $\Phi(t,x,y) := x+t(y-x)$; then from the assumptions on ρ it follows that

$$\begin{aligned} &\int_0^{1/2}\int\int \frac{|\nabla u(\Phi(t,x,y))|^2|x|^2}{\rho^{2k}(x)\rho^{2k}(y)}\,dx\,dy\,dt \\ &\leqq \int_0^{1/2}\int \rho^{-2}(y)\int \frac{|\nabla u(\Phi(t,x,y))|^2}{(\rho(x)\rho(y))^{2(k-1)}}\,dx\,dy\,dt \\ &\leqq \int_0^{1/2}\int \rho^{-2}(y)\int \frac{|\nabla u(\Phi(t,x,y))|^2}{\rho(\Phi(t,x,y))^{2(k-1)}}\,dx\,dy\,dt =: I_1. \end{aligned}$$

The mapping $\Phi(t,\cdot,y):\Omega\to\Phi(t,\Omega,y)=:\Omega_{t,y}\subset\Omega$ is differentiable and bijective for all $t\in[0,\frac{1}{2}]$, $y\in\Omega$. The inverse is $\Phi(t,\cdot,y)^{-1}(x):=(z-ty)/(1-t)$. For the determinant of the Jacobian of this inverse we have $|J_{t,y}^{-1}|=(1-t)^{-n}\leqq 2^n$ for all $t\in[0,\frac{1}{2}]$. We transform the coordinates and obtain

$$I_1=\int_0^{1/2}\int_\Omega \rho^{-2}(y)\int_{\Omega_{t,y}}\frac{|\nabla u(z)|^2}{\rho(z)^{2(k-1)}}\left|J_{t,y}^{-1}\right|dz\,dy\,dt$$

$$\leqq 2^n\int_0^{1/2}\int_\Omega \rho^{-2}(y)\int\frac{|\nabla u(z)|^2}{\rho(z)^{2(k-1)}}\,dz\,dy\,dt$$

$$=2^{n-1}\rho_2\int\frac{|\nabla u(z)|^2}{\rho(z)^{2(k-1)}}\,dz.$$

Furthermore, we have

$$\int_{1/2}^1\int\int\frac{|\nabla u(\Phi(t,x,y))|^2|x|^2}{\rho^{2k}(x)\rho^{2k}(y)}\,dy\,dx\,dt$$

$$\leqq\int_{1/2}^1\int\frac{|x|^2}{\rho^2(x)}\int\frac{|\nabla u(\Phi(t,x,y))|^2}{\rho(\Phi(t,x,y))^{2(k-1)}}\,dy\,dx\,dt=:I_2.$$

Now we consider the transformation $\Phi(t,x,\cdot)$. For the determinant of the Jacobian of the inverse we have $|J_{t,x}^{-1}|=t^{-n}\leqq 2^n$ for all $t\in[\frac{1}{2},1]$ and $x\in\Omega$. A similar reasoning as above implies

$$I_2\leqq 2^{n-1}\rho_1\int\frac{|\nabla u(z)|^2}{\rho^{2(k-1)}(z)}\,dz.$$

The same estimates hold for the second summand in (3). Adding these estimates we obtain the conclusion. Q.E.D.

COROLLARY 4.3. *Let Ω, ρ be as above; then there exists a constant c_k such that for all $u\in W^{k,\rho}(\Omega)$*

$$\|u\|_{k,\rho}^2\leqq c_k\left(\sum_{|\alpha|=k}\|D^\alpha u\|_2^2+\sum_{|\alpha|<k}\left(\int_\Omega D^\alpha u\rho^{-2k+2|\alpha|}dx\right)^2\right).$$

Proof. Simple induction. Q.E.D.

We now turn to Friedrich's inequality. In this inequality appear some boundary integrals. So before we can proceed, we need a trace theorem for weighted spaces in order to ascertain that these integrals exist.

DEFINITION 4.4. The boundary $\partial\Omega$ of a set $\Omega\subset R^n$ is called uniformly locally finite Lipschitz continuous (ulf L) if there exist numbers L, α, $\beta>0$ and $K\in N$ as well as a covering $\{U_i\}_{i\in N}$ of $\partial\Omega$ such that

(i) At most K different U_i have a nonvoid intersection, i.e., $U_{j(1)},\cdots,U_{j(K+1)}\in\{U_i\}$ implies $\bigcap_{k=1}^{K+1}U_{j(k)}=\varnothing$.

(ii) For all U_i there exists an orthogonal transformation $A_i:R^n\to R^n$ ($y_1,\cdots,y_n$ are the new coordinates) and a uniformly Lipschitz continuous (with Lipschitz constant

L, independent of i) mapping $a_i: R^{n-1} \to R$ such that for $W_\alpha := \{(y_1, \cdots, y_{n-1}) \mid |y_j| \leqq \alpha\}$ we have

$$U_i \cap \partial\Omega = \{(y_1, \cdots, y_n) \mid (y_1, \cdots, y_{n-1}) \in W_\alpha,\ y_n = a_i(y_1, \cdots, y_{n-1})\},$$

$$U_i \cap \Omega = \{(y_1, \cdots, y_n) \mid (y_1, \cdots, y_{n-1}) \in W_\alpha,$$
$$a_i(y_1, \cdots, y_{n-1}) < y_n < a_i(y_1, \cdots, y_{n-1}) + \beta\},$$

$$U_i \cap C\bar{\Omega} = \{(y_1, \cdots, y_n) \mid (y_1, \cdots, y_{n-1}) \in W_\alpha,$$
$$a_i(y_1, \cdots, y_{n-1}) - \beta < y_n < a_i(y_1, \cdots, y_{n-1})\}.$$

LEMMA 4.5. *Let B, $B_i \in \text{Borel}(R^n)$, μ be a measure on* Borel(R^n). *If $B = \bigcup_{i=1}^{\infty} B_i$ and at most K different B_i have a nonvoid intersection, then $\sum_1^\infty \mu(B_i) \leqq K\mu(B)$.*

Proof. Let $P(m) := \{P_j\}_{j \in J}$ be a pavement of $\bigcup_1^m B_i$, i.e., the P_j are pairwise disjoint and

(i) for all P_j exists a $B_{i(j)}$, such that $P_j \subset B_{i(j)}$,
(ii) $B_i = \bigcup_{P \in B_i} P$,
(iii) $\bigcup_1^m B_i = \bigcup_{P \in P(m)} P$.

Then it follows that

$$\sum_1^m \mu(B_i) = \sum_1^m \sum_{P \subset B_i} \mu(P) \leqq K \sum_{P \in P(m)} \mu(P) = K \cdot \mu\left(\bigcup_{P \in P(m)} P \right) \leqq K \cdot \mu(B)$$

for all $m \in N$ and hence the assertion. Q.E.D.

THEOREM 4.6. *Let Ω have a ulfL-boundary and $\rho \geqq 1$ be a td-function. Then there exists a continuous, linear mapping $T: W^{k,\rho}(\Omega) \to L_{2,\rho^{-k}}(\partial\Omega)$ such that for all functions $u \in C^k(\bar{\Omega}) \cap W^{k,\rho}(\Omega)$ there holds $Tv = v \mid_{\partial\Omega}$.*

Proof. We work with the new coordinates $(y_1, \cdots, y_n)$ and set $y' = (y_1, \cdots, y_{n-1})$. Now fix $i \in N$ and $U_i^+ := \{y \mid y' \in W_\alpha,\ a_i(y') < y_n < a_i(y') + \beta\}$ and let $u \in C^k(\bar{\Omega}) \cap W^{k,\rho}(\Omega)$ then for $(y', z) \in U_i^+$

$$u(y', a_i(y')) = -\int_{a_i(y')}^{z} D_n u(y', y_n)\, dy_n + u(y', z)$$

and hence

$$u(y', a_i(y'))^2 \leqq 2\beta \int_{a_i(y')}^{a_i(y') + \beta} |D_n u(y', y_n)|^2 dy_n + 2u(y', z)^2.$$

We divide by $\rho^{2k}(y', a_i(y'))$ and since $\rho \geqq 1$ is a td-function

$$\frac{u(y', a_i(y'))^2}{\rho^{2k}(y', a_i(y'))} \leqq 2c_1\beta \int_{a_i(y')}^{a_i(y') + \beta} \frac{|D_n u(y', y_n)|^2}{\rho^{2(k-1)}(y', y_n)}\, dy_n + 2c_2 \frac{u(y', z)^2}{\rho^{2k}(y', z)}.$$

Integrating over y' and z, we conclude

$$\beta \int_{W_\alpha} \frac{u(y', a_i(y'))^2}{\rho^{2k}(y', a_i(y'))}\, dy' \leqq 2c_1\beta^2 \int\int_{U_i^+} \frac{|D_n u(y', y_n)|^2}{\rho^{2(k-1)}(y', y_n)}\, dy_n dy'$$
$$+ 2c_2 \int\int_{U_i^+} \frac{u(y', z)^2}{\rho^{2k}(y', z)}\, dz\, dy'.$$

The surface element is $ds=(1+\sum_{j=1}^{n-1}(D_j a_i)^2)^{1/2}dy'$ and since $|D_j a_i|\leqq L$ (see Definition 4.4), A_i orthogonal we obtain after transforming back to the old coordinates

$$\int_{U_i\cap\partial\Omega} u^2\rho^{-2k}ds\leqq c_3\|u\|^2_{W^{k,\rho}(U_i\cap\Omega)}$$

and hence (c_3 is independent of i)

$$\int_{\partial\Omega} u^2\rho^{-2k}ds\leqq c_3\sum_i\|u\|^2_{W^{k,\rho}(U_i\cap\Omega)}.$$

Lemma 4.5 implies the assertion. Q.E.D.

THEOREM 4.7. (i) *Let Ω have ulfL-boundary and $M_{j,\rho}: W^{j,\rho}(\Omega)\to L_2(\Omega)$ be compact for $1\leqq j\leqq k$. Furthermore, let $\rho^{-l}\in L_2$ for some $l\geqq 1$, $I\subset\{\alpha\in(N_0)^n\,|\,|\alpha|<k\}$ such that $Q_{k-1}\cap W^{k,\rho}(\Omega)=\operatorname{span}\{q_\alpha\,|\,\alpha\in I\}$ and there exists no polynomial which vanishes identically on $\partial\Omega$. Then*

$$\left(\sum_{|\alpha|=k}\int_\Omega|D^\alpha u|^2dx+\int_{\partial\Omega}u^2\rho^{-2k}ds\right)^{1/2}$$

is an equivalent Hilbert space norm on $W^{k,\rho}(\Omega)$.

(ii) *If we replace everywhere $W^{k,\rho}$ by $W_c^{k,\rho}$ the same statement holds.*

Proof. (i) From Theorem 4.1 we see that $(\sum_{|\alpha|=k}\|D^\alpha u\|_2^2)^{1/2}$ is equivalent to the quotient norm on $W^{k,\rho}(\Omega)/Q_{k-1}$ and from the assumptions on $\partial\Omega$ it follows that $\int_{\partial\Omega}u^2\rho^{-2k}ds$ is a norm on the finite dimensional space $Q_{k-1}\cap W^{k,\rho}(\Omega)$. This readily implies that $\|u\|^2:=\sum_{|\alpha|=k}\|D^\alpha u\|_2^2+\int_{\partial\Omega}u^2\rho^{-2k}ds$ is a Hilbert space norm on $W^{k,\rho}(\Omega)$—it remains only to prove the completeness of $W^{k,\rho}$ with respect to this norm. Since the imbedding $(W^{k,\rho}(\Omega),\|\cdot\|_{k,\rho})\to(W^{k,\rho}(\Omega),\|\cdot\|)$ is continuous by Theorem 4.6 and bijective, the assertion follows from the isomorphism theorem of Banach.

(ii) Obvious. Q.E.D.

Now we shall prove variants of Friedrich's inequality without using compactness theorems. Again we shall be able to compute the constants.

LEMMA 4.8. *Let Ω have ulfL-boundary and denote for any $x\in\partial\Omega$ by $v(x)=(v_1(x),\cdots,v_n(x))$ the normed outer normal. We assume that there exists $M>0$ such that $|\langle v(x),(x)\rangle|\leqq M$ for all $x\in\partial\Omega$. Now let $\rho\geqq|x|$, $\delta>0$, $k\in N$. Then either of the following two conditions*

$$\text{(i)}\qquad 1-\frac{2k\sum D_i\rho x_i}{n\rho}\geqq\delta>0\quad\text{for all } x\in\Omega,$$

$$\text{(ii)}\qquad 1-\frac{2k\sum D_i\rho x_i}{n\rho}\leqq-\delta<0\quad\text{for all } x\in\Omega$$

implies that for all $u\in W_c^{k,\rho}(\Omega)$

$$\int_\Omega\left(\frac{u}{\rho^k}\right)^2dx\leqq\frac{4}{(n\delta)^2}\sum_1^n\int_\Omega\left|\frac{D_iu}{\rho^{k-1}}\right|^2dx+\frac{2M}{n\delta}\int_{\partial\Omega}\left(\frac{u}{\rho^k}\right)^2ds.$$

Proof. Let $u\in C_0^\infty(R^n)\,|_\Omega$. Then by Gauss' integral theorem

$$\int_\Omega\left(\frac{u}{\rho^k}\right)^2dx=-\frac{2}{n}\sum_1^n\int_\Omega\left[\frac{D_iu}{\rho^k}-\frac{kuD_i\rho}{\rho^{k+1}}\right]\frac{u}{\rho^k}x_idx+\frac{1}{n}\sum_1^n\int_{\partial\Omega}v_i(x)\left(\frac{u}{\rho^k}\right)^2x_ids$$

and hence

(4)

$$\int_\Omega \left(\frac{u}{\rho^k}\right)^2 \left[1 - \frac{2k\sum D_i \rho x_i}{n\rho}\right] dx = -\frac{2}{n}\sum \int_\Omega \frac{D_i u}{\rho^{k-1}} \cdot \frac{u}{\rho^k} \cdot \frac{x_i}{\rho}\, dx + \int_{\partial\Omega} \frac{\langle v(x), x\rangle}{n} \left(\frac{u}{\rho^k}\right)^2 ds.$$

(i) In this case (4) implies

$$\int_\Omega \left(\frac{u}{\rho^k}\right)^2 dx \leqq \frac{2}{n\delta}\sum \int_\Omega \left|\frac{D_i u}{\rho^{k-1}} \cdot \frac{u}{\rho^k}\right| dx + \frac{M}{n\delta}\int_{\partial\Omega}\left(\frac{u}{\rho^k}\right)^2 ds$$

$$\leqq \frac{2}{(n\delta)^2}\sum \int_\Omega \left(\frac{D_i u}{\rho^{k-1}}\right)^2 dx + \frac{1}{2}\int_\Omega \left(\frac{u}{\rho^k}\right)^2 dx + \frac{M}{n\delta}\int_{\partial\Omega}\left(\frac{u}{\rho^k}\right)^2 ds$$

and hence the assertion.

(ii) We estimate in (4) on the left side from above by $-\delta \int u^2 \rho^{-2k}\, dx$, divide by $-\delta$ and proceed as in (i). Q.E.D.

Remark 4.9. If Lemma 4.8, case (i) for all $x \in \partial\Omega$ $\langle v(x), x\rangle \leqq 0$—as is the case e.g. for $S(0, r_0, \Sigma)$—we can omit the boundary integrals in the assertion of Lemma 4.8. To see this, consider again the identity (4).

THEOREM 4.10. *Let Ω fulfill the conditions of Lemma* 4.8. *Furthermore, let Ω, ρ, j, n for all $j \leqq k$ fulfill one of the conditions of Theorem* 2.3. *Then for all $u \in W_c^{k,\rho}(\Omega)$*

$$\sum_{|\alpha|=k} \|D^\alpha u\|_2^2 \leqq \|u\|_{k,\rho}^2 \leqq \sum_{|\alpha|=k_0} \|D^\alpha u\|_2^2 + \sum_{|\alpha|<k} c_\alpha \int_{\partial\Omega}\left(\frac{D^\alpha u}{\rho^{k-|\alpha|}}\right)^2 ds.$$

Proof. By induction from Lemma 4.8 and the proof of Theorem 2.3. Q.E.D.

As an application we consider the following Neumann problem for an elliptic operator of order $2k$: Find $u \in W^{k,\rho}(\Omega)$ such that for all $v \in W^{k,\rho}(\Omega)$

$$(5) \qquad a(u,v) := \sum_{|\alpha|=|\beta|=k} \int_\Omega a_{\alpha\beta} D^\beta u(x) D^\alpha v(x)\, dx = \int_\Omega f(x) v(x)\, dx.$$

THEOREM 4.11. *Let $a_{\alpha\beta} \in L_\infty$, $(a_{\alpha\beta})_{|\alpha|=|\beta|=k}$ uniformly positive definite and $f\rho^k \in L_2(\Omega)$. Furthermore, let ρ be convex and $\rho^{-1}\cdot(1+|x|) \in L_2(R^n)$. We assume that there exists a convex set $\tilde{\Omega}$ and a (l,κ)-diffeomorphism $T: \tilde{\Omega} \to \Omega$ with $1 \leqq l+\kappa$ such that the matrix*

$$B := \left(B_{\alpha\beta}(T)\right)_{|\alpha|,|\beta|<k},\ B_{\alpha\beta}(T) := \int_{\tilde{\Omega}} D^\alpha\left(q_\beta \circ T\right)(y)\rho^{-2k+|\alpha|}(y)\, dy$$

is invertible. Then problem (5) *admits a solution u iff for all $q \in Q_{k-1}$ $\int_\Omega q \cdot f\, dx = 0$. This solution is unique in $W^{k,\rho}(\Omega)/Q_{k-1}$ and*

$$\|u\|_{W^{k,\rho}/Q_{k-1}} \leqq c\|f\rho^k\|_{L_2},$$

where c can be computed explicitly.

Proof. $\rho^{-1}(1+|x|) \in L_2$ implies $Q_{k-1} \subset W^{k,\rho}$ is well defined. Denote by $Q_{k-1}^\perp$ the orthogonal complement of Q_{k-1} then $Q_{k-1}^\perp \cong W^{k,\rho}/Q_{k-1}$ and the norms can be identified. Hence we may denote the norm on the quotient space by $\|\cdot\|_{k,\rho,\perp}$. Applying Lemma 3.6, Theorem 4.2 and Lemma 3.2, we obtain for all $v \in W^{k,\rho}(\Omega)$

$$\|v\|_{k,\rho}^2 \leqq c_1\left(\sum_{|\alpha|=k} \|D^\alpha v\|_2^2 + \sum_{|\alpha|<k}\left|\int_{\tilde{\Omega}} D^\alpha(v\circ T)(y)\rho^{-2k+|\alpha|}(y)\, dy\right|^2\right).$$

If $q := \Sigma_{|\beta|<k} d_\beta q_\beta \in Q_{k-1}$, $d_\beta \in R$, then

$$\|v\|^2_{k,\rho,\perp} \leqq \|v+q\|^2_{k,\rho}$$

$$\leqq c_1 \left(\sum_{|\alpha|=k} \int_\Omega |D^\alpha v|^2 dx + \sum_{|\alpha|<k} \left| c_\alpha(v) + \sum_{|\beta|<k} d_\beta B_{\alpha\beta}(T) \right|^2 \right)$$

where $c_\alpha := \int_{\tilde{\Omega}} D^\alpha (v \circ T)(y) \rho^{-2k+|\alpha|}(y)\, dy$. Since B is invertible there exists a vector d such that $-c(v) := Bd$ and hence

$$\|v\|^2_{k,\rho,\perp} \leqq c_1 \sum_{|\alpha|=k} \int_\Omega |D^\alpha v|^2 dx.$$

Now let u be a solution of (5). Then for all $q \in Q_{k-1}$ and all $v \in W^{k,\rho}(\Omega)$

$$a(u,v) = a(u, v+q) = \int fv\, dx + \int fq\, dx$$

and $\int fq\, dx = 0$. If on the other hand $\int fq\, dx$ for all $q \in Q_{k-1}$ then $\int fv\, dx$ is a continuous, linear functional on $Q^\perp_{k-1}$. Since there appear only derivations of order k $a(u,v)$ is a continuous, bilinear form on $Q^\perp_{k-1}$. Furthermore, $a(u,u) \geqq c_2 \Sigma_{|\alpha|=k} \|D^\alpha u\|^2_2 \geqq c_2 c_1^{-1} \|u\|^2_{k,\rho,\perp}$ and the Lax–Milgram lemma concludes the proof. Q.E.D.

Remark 4.12. (i) Analogously, we might apply the other inequalities to get existence theorems for problem (5). In some cases the decay condition $u \in W^{k,\rho}_c$ suffices to ensure the existence of a unique solution, e.g. in the situation of Theorems 4.10, 4.1 if $Q_{k-1} \cap W^{k,\rho}(\Omega) = \{0\}$.

(ii) The coercivity estimates can be used to prove the convergence of approximate solutions computed on bounded domains. Also they can be applied to get stochastic representations of solutions to the second-order Dirichlet problem (see Janßen [7]).

EXISTENCE AND UNIQUENESS OF SOLUTIONS TO THE COMPRESSIBLE REYNOLDS LUBRICATION EQUATION*

MICHEL CHIPOT† AND MITCHELL LUSKIN‡

Abstract. We prove the existence of a solution to the compressible Reynolds lubrication equation and we show that our solution is unique in the class of nonnegative solutions (under some additional hypotheses, we prove that our solution is unique among all weak solutions). We also prove the strong result that the mapping from the boundary data to the solution is monotonic.

Key words. compressible Reynolds lubrication equation, nonlinear elliptic boundary value problem

AMS(MOS) subject classifications. Primary 76N99, 35J65

1. Introduction. The compressible Reynolds lubrication equation [7, p. 63] is the nonlinear elliptic partial differential equation

$$\begin{aligned} &6\mu \mathbf{V}\cdot\nabla(Ph)=\nabla\cdot(h^3P\nabla P), \qquad x=(x_1,x_2)\in\Omega,\\ &P=P_a, \qquad x\in\partial\Omega, \end{aligned} \tag{1.1}$$

which gives the pressure, $P=P(x)$, that develops in a layer of air of thickness, $h=h(x)$, which is confined between two solid bodies when the average of the velocities of the upper and lower bodies is $\mathbf{V}=(V_1,V_2)$. The air is assumed to be isothermal and to be an ideal gas (the density is taken to be proportional to the pressure) [7]. Here, $\mu>0$ is the dynamic viscosity of the fluid, $\Omega\subseteq\mathbb{R}^2$ is the region (with smooth boundary, $\partial\Omega$) where the upper and lower bodies are in proximity, and $P_a>0$ is the ambient pressure.

When the thickness of a gaseous fluid layer is of the order of the molecular mean free path of the gas, then the compressible Reynolds equation becomes a poor model for the pressure in the fluid layer. In many applications in the modeling of the mechanical systems of magnetic recording the following modified Reynolds equation [3] has been found to be a good model equation for predicting the pressure in the fluid layer

$$\begin{aligned} &6\mu \mathbf{V}\cdot\nabla(Ph)=\nabla\cdot(h^3P\nabla P)+\nabla\cdot\left(6\lambda_a h^2P_a\nabla P\right), \qquad x\in\Omega,\\ &P=P_a, \qquad x\in\partial\Omega. \end{aligned} \tag{1.2}$$

Here $\lambda_a\geqq 0$ is the mean free path of the gas at ambient pressure. Note that $\lambda_a=0$ gives the compressible Reynolds equation (1.1) and all the analysis and results which we give for the modified Reynolds equation, (1.2), are valid for the modified Reynolds equation, (1.1), unless we state otherwise.

We assume only that $h=h(x)$ is a Lipschitz continuous function such that for positive constants $h_{\min}, h_{\max}$, and H we have the bounds

$$\begin{aligned} &0<h_{\min}\leqq h(x)\leqq h_{\max}, \qquad x\in\Omega, \\ &|\nabla h(x)|\leqq H, \qquad \text{a.e. } x\in\Omega. \end{aligned} \tag{1.3}$$

We prove the existence of a nonnegative weak solution to the Reynolds equation (1.2), and we prove that this solution is unique in the class of nonnegative functions. We actually prove the stronger result that the mapping S: $P_a\to P(x)$ from the boundary data to the solution satisfies the monotonicity result

$$P_a\geqq Q_q \text{ implies } P(x)\geqq Q(x) \quad \text{for all } x\in\Omega$$

where $Q=S(Q_a)$. Moreover, if

$$\mathbf{V}\cdot\nabla h\leqq 0,$$

we prove that our solution to the Reynolds equation (1.1) is unique among all weak solutions.

We note that the implicit function theorem has been used in [5] to obtain the existence of solutions to (1.1) for small values of the velocity, $V=(V_1^2+V_2^2)^{1/2}$. However, our techniques give the existence and uniqueness of solutions to (1.1) for all values of $\mathbf{V}$.

In the mechanical systems of magnetic recording, the pressure developed in the fluid layer is coupled to the deformation of the confining solid bodies (such as a disk or a tape) [8]. In a forthcoming paper, we will give an analysis of the system of coupled partial differential equations for the pressure and the deformation. In this case, h will depend on the deformation and the present results will be useful there.

2. Existence of solutions. In what follows, the $L^2(\Omega)$ inner product for real-valued functions ψ, $\zeta\in L^2(\Omega)$ is denoted by

$$(\psi,\zeta)=\int_\Omega \psi(x)\zeta(x)\,dx$$

with corresponding norm

$$\|\psi\|^2=(\psi,\psi).$$

If ψ, ζ: $\Omega\to\mathbb{R}^2$, then the $L^2(\Omega)$ inner product for ψ, $\zeta\in L^2(\Omega)$ is similarly denoted by

$$(\psi,\zeta)=\int_\Omega \psi(x)\cdot\zeta(x)\,dx$$

with corresponding norm

$$\|\psi\|^2=(\psi,\psi),$$

where $\psi(x)\cdot\zeta(x)$ denotes the usual Euclidean inner product in $\mathbb{R}^2$. Also, we define the Sobolev spaces

$$\begin{aligned} H^1(\Omega)&=\{\psi\in L^2(\Omega)\mid\nabla\psi\in L^2(\Omega)\}, \\ H_0^1(\Omega)&=\{\psi\in H^1(\Omega)\mid\psi\equiv 0 \text{ on } \partial\Omega\}, \end{aligned}$$

with norm

$$\|\psi\|^2_{H^1(\Omega)} = \|\psi\|^2 + \|\nabla\psi\|^2,$$

where equality on the boundary is understood in the trace sense [1].

We first prove the existence of a solution to (1.2). Set $\Lambda = 6\mu V$ and $\lambda = 6\lambda_a P_a$ and introduce the dependent variable

$$u = \frac{1}{2}P^2 + \frac{\lambda}{h}P.$$

If P is a nonnegative solution to (1.2), then we see that u is a nonnegative solution to

$$\begin{aligned} &\nabla\cdot(h^3\nabla u) = \nabla\cdot(\beta(x,u)\Lambda - \lambda\beta(x,u)\nabla h(x)), \qquad x\in\Omega, \\ &u(x) = \frac{1}{2}P_a^2 + \frac{\lambda}{h(x)}P_a \equiv u_a(x), \qquad x\in\partial\Omega, \end{aligned} \tag{2.1}$$

where

$$\beta(x,u) = \begin{cases} -\lambda + \sqrt{\lambda^2 + 2h^2 u}, & u \geqq 0, \\ 0, & u \leqq 0. \end{cases}$$

Conversely, if u is a nonnegative of (2.1), then

$$P(x) = -\frac{\lambda}{h(x)} + \sqrt{\lambda^2/h(x)^2 + 2u(x)}$$

is a nonnegative solution to (1.2). Thus, we shall show that (2.1) has a nonnegative solution.

We set

$$\alpha(x,u) = \beta(x,u)\Lambda - \lambda\beta(x,u)\nabla h(x).$$

We define a weak solution, u, to the problem:

$$\begin{aligned} &\nabla\cdot(h^3(x)\nabla u) = \nabla\cdot\alpha(x,u), \qquad x\in\Omega, \\ &u = \varphi, \qquad x\in\partial\Omega, \end{aligned} \tag{2.2}$$

for $\varphi\in H^1(\Omega)$ to be u such that

$$\begin{aligned} &u - \varphi \in H_0^1(\Omega), \\ &\int_\Omega h^3(x)\nabla u\cdot\nabla\xi\,dx = \int_\Omega \alpha(x,u)\cdot\nabla\xi\,dx, \qquad \xi\in H_0^1(\Omega). \end{aligned} \tag{2.3}$$

Using the inequality $\sqrt{A} + \sqrt{B} \geqq \sqrt{A+B}$, it is easy to check that

$$\begin{aligned} &|\beta(x,v)|^2 \leqq 2h^2|v|, \qquad x\in\Omega, \quad v\in\mathbb{R}, \\ &|\beta(x,v) - \beta(x,w)|^2 \leqq 2h^2|v-w|, \qquad x\in\Omega, \quad v,w\in\mathbb{R}. \end{aligned}$$

Hence for some constants c_1, c_2 we have

$$\begin{aligned} &|\alpha(x,v)|^2 \leqq c_1|v|, \qquad x\in\Omega, \quad v\in\mathbb{R}, \\ &|\alpha(x,v) - \alpha(x,w)|^2 \leqq c_2|v-w|, \qquad x\in\Omega, \quad v,w\in\mathbb{R}. \end{aligned} \tag{2.4}$$

We shall prove the following theorem.

THEOREM 1. *There exists a weak solution to* (2.2).

In §3, we shall prove that a (weak) solution u, to (2.1) is nonnegative almost everywhere. Thus, we can define

$$P(x)=\frac{-\lambda}{h(x)}+\sqrt{\lambda^2/h(x)^2+2u(x)} \tag{2.5}$$

to be a weak solution to (1.2). Hence, we have the following theorem.

THEOREM 2. *There exists a nonnegative, weak solution, P, to* (1.2).

We now turn to the proof of Theorem 1. We shall use the Schauder fixed point theorem. We denote by T: $L^2(\Omega)\to L^2(\Omega)$ the map $u=T(v)$ where $u\in H^1(\Omega)$ is the solution to $u=\varphi$ on $\partial\Omega$,

$$\int_\Omega h^3(x)\nabla u\cdot\nabla\xi\,dx=\int_\Omega \alpha(x,v)\cdot\nabla\xi\,dx,\qquad \xi\in H_0^1(\Omega). \tag{2.6}$$

The Schauder fixed point theorem states that if T is continuous and if there exists a closed, convex set B such that $T(B)\subset B$ and $\overline{T(B)}$ is compact, then there exists a fixed point, $u\in B$, of T, i.e., $T(u)=u$. We note that a fixed point of T is a weak solution of (2.2).

Set

$$B_R=\{v\in L^2(\Omega)\,|\,\|v\|\leqq R\}.$$

We shall show that there exists a positive constant R_1 such that

$$T(B_R)\subseteq B_R \quad \text{if } R\geqq R_1.$$

Further, we shall show that there exists a positive constant, $c_3=c_3(R)$, such that

$$\|T(v)\|_{H^1(\Omega)}\leqq c_3,\qquad v\in B_R. \tag{2.7}$$

Thus, it follows from Rellich's theorem [1] that $\overline{T(B_R)}$ is compact.

The conditions (2.6) are equivalent to the conditions

$$\begin{aligned} &u-\varphi\in H_0^1(\Omega),\\ &\int_\Omega h^3(x)\nabla(u-\varphi)\cdot\nabla\xi\,dx=-\int_\Omega h^3(x)\nabla\varphi\cdot\nabla\xi\,dx\\ &\qquad\qquad +\int_\Omega \alpha(x,v)\cdot\nabla\xi\,dx,\qquad \xi\in H_0^1(\Omega). \end{aligned} \tag{2.8}$$

It follows from standard elliptic theory [2] that (2.8) has a unique solution, $u\in H^1(\Omega)$. (Note that $\alpha(x,v)\in L^2(\Omega)$ thanks to (2.4).) We can set $\xi=u-\varphi$ in (2.8) and use the Cauchy-Schwarz inequality to obtain the bound (see (1.3))

$$\|\nabla(u-\varphi)\|\leqq c\big(\|\nabla\varphi\|+\|\alpha(x,v)\|\big). \tag{2.9}$$

Here and in what follows, c will denote a positive constant which can change from equation to equation. Now it follows from (2.4) that

$$\|\alpha(x,v)\|\leqq c_1^{1/2}\|v\|_{L^1(\Omega)}\leqq c_1^{1/2}|\Omega|^{1/2}\|v\|^{1/2}, \tag{2.10}$$

where $|\Omega|$ is the measure of Ω. Hence, we obtain from (2.9) and the triangle inequality

$$\|\nabla u\| \leqq \|\nabla \varphi\| + \|\nabla(u-\varphi)\| \leqq c\left(\|\nabla \varphi\| + \|v\|^{1/2}\right). \tag{2.11}$$

Also,

$$\|\psi\| \leqq \nu^{-1/2}\|\nabla \psi\|, \qquad \psi \in H_0^1(\Omega), \tag{2.12}$$

where $\nu > 0$ is the smallest eigenvalue of the problem

$$\begin{aligned} -\Delta\psi &= \nu\psi, && x \in \Omega, \\ \psi &= 0, && x \in \partial\Omega. \end{aligned}$$

Now

$$\|u\| \leqq \|\varphi\| + \|u-\varphi\| \leqq \|\varphi\| + \nu^{1/2}\|\nabla(u-\varphi)\|. \tag{2.13}$$

Thus, it follows from (2.9), (2.10), and (2.13) that there exists positive constants c_4 and c_5 such that

$$\|u\| \leqq c_4\|\varphi\|_{H^1(\Omega)} + c_5\|v\|^{1/2}. \tag{2.14}$$

We see from (2.14) that $\|v\| \leqq R$ implies that $\|u\| \leqq R$ if $R \geqq R_1$ where

$$R_1 = \left(\frac{c_5 + \sqrt{c_5^2 + 4c_4\|\varphi\|_{H^1(\Omega)}^2}}{2} \right).$$

Thus, $T(B_R) \subseteq B_R$ if $R \geqq R_1$. Further, it follows from (2.11) that there exists $c_3 = c_3(R)$ such that

$$\|T(v)\|_{H^1(\Omega)} \leqq c_3(R), \qquad v \in B_R.$$

All of the hypotheses of Schauder's theorem have now been satisfied except for the continuity of T. It follows from (2.6) that for $v, w \in L^2(\Omega)$,

$$T(v) - T(w) \in H_0^1(\Omega),$$

$$\int_\Omega h^3(x)\nabla(T(v)-T(w))\cdot\nabla\xi\,dx = \int_\Omega (\boldsymbol{\alpha}(x,v)-\boldsymbol{\alpha}(x,w))\cdot\nabla\xi\,dx, \qquad \xi \in H_0^1(\Omega). \tag{2.15}$$

Thus, we can set $\xi = T(v) - T(w)$ above to obtain

$$\|\nabla(T(v)-T(w))\| \leqq c\|\boldsymbol{\alpha}(x,v)-\boldsymbol{\alpha}(x,w)\|. \tag{2.16}$$

Now by (2.5)

$$\|\boldsymbol{\alpha}(x,v)-\boldsymbol{\alpha}(x,w)\| \leqq c_2^{1/2}\|v-w\|_{L^1(\Omega)} \leqq c_2^{1/2}|\Omega|^{1/2}\|v-w\|^{1/2}.$$

Hence, it follows from (2.12), (2.16), and (2.17) that

$$\|T(v)-T(w)\| \leqq \|v-w\|^{1/2},$$

i.e., T is Hölder continuous with exponent $1/2$. This completes the proof that T has a fixed point.

Remark. One could weaken the assumption (2.4) in various directions and still get a solution of (2.3).

3. Uniqueness of solutions. In this section, we prove a uniqueness and monotonicity result for weak solutions to the problem (2.2). More precisely, we have:

THEOREM 3. *The weak solution to* (2.2) *is unique. Further, suppose that* u_1 *is a weak solution to* (2.2) *corresponding to boundary data* φ_1 *and* u_2 *is a weak solution to* (2.2) *corresponding to boundary data* φ_2. *If* $\varphi_1 \geqq \varphi_2$ *a.e. on* $\partial\Omega$, *then* $u_1 \geqq u_2$ *a.e. in* Ω.

Proof. The uniqueness of weak solutions clearly follows from the monotonicity result. We will use here an argument due to Carillo and Chipot. See [4] for a variant.

We assume that $\varphi_1 \geqq \varphi_2$ a.e. on $\partial\Omega$. First, we prove that for all $\zeta \in C^\infty(\bar{\Omega})$ and $\zeta > 0$ we have

$$\int_{[u_1 - u_2 > 0]} h^3(x)\nabla(u_2 - u_1)\cdot\nabla\zeta - (\alpha(x,u_2) - \alpha(x,u_1))\cdot\nabla\zeta\, dx \leqq 0 \tag{3.1}$$

where

$$[u_2 - u_1 > 0] = \{x \in \Omega \mid u_2(x) - u_1(x) > 0\}.$$

To do that, we consider for $\varepsilon > 0$

$$\xi = \min\left(\frac{(u_2 - u_1)^+}{\varepsilon}, \zeta\right) \tag{3.2}$$

where

$$\psi^+(x) = \max(\psi(x), 0).$$

Note that $\xi \in H_0^1(\Omega)$ since for $x \in \partial\Omega$,

$$\xi(x) = \min\left(\frac{(\varphi_2 - \varphi_1)^+}{\varepsilon}, \zeta\right) = 0.$$

It follows from subtracting (2.3) with $u = u_2$ from (2.3) with $u = u_1$ that

$$\int_\Omega h^3(x)\nabla(u_2 - u_1)\nabla\xi - (\alpha(x,u_2) - \alpha(x,u_1))\cdot\nabla\xi\, dx = 0, \tag{3.3}$$

which for ξ given by (3.2) is equivalent to

$$\begin{aligned}\int_{[u_2 - u_1 > \varepsilon\zeta]} & h^3(x)\nabla(u_2 - u_1)\nabla\zeta - (\alpha(x,u_2) - \alpha(x,u_1))\cdot\nabla\zeta\, dx \\ & + \frac{1}{\varepsilon}\int_{[0 < u_2 - u_1 \leqq \varepsilon\zeta]} h^3(x)|\nabla(u_2 - u_1)|^2 dx \\ & - \frac{1}{\varepsilon}\int_{[0 < u_2 - u_1 \leqq \varepsilon\zeta]} (\alpha(x,u_2) - \alpha(x,u_1))\cdot\nabla(u_2 - u_1)\, dx = 0\end{aligned} \tag{3.4}$$

where

$$[u_2 - u_1 > \varepsilon\zeta] = \{x \in \Omega \mid u_2(x) - u_1(x) > \varepsilon\zeta\}$$

and the other sets $[\cdot]$ are defined likewise. We estimate the last integral above by

$$
\begin{aligned}
I &\equiv \int_{[0<u_2-u_1\leqq\varepsilon\zeta]} (\boldsymbol{\alpha}(x,u_2)-\boldsymbol{\alpha}(x,u_1))\cdot\nabla(u_2-u_1)\,dx \\
&\leqq \left(\int_{[0<u_2-u_1\leqq\varepsilon\zeta]} h(x)^{-3}|\boldsymbol{\alpha}(x,u_2)-\boldsymbol{\alpha}(x,u_1)|^2\,dx\right)^{1/2} \\
&\quad\times\left(\int_{[0<u_2-u_1\leqq\varepsilon\zeta]} h^3(x)|\nabla(u_2-u_1)|^2\,dx\right)^{1/2} \qquad (3.5)\\
&\leqq \frac{1}{4}\int_{[0<u_2-u_1\leqq\varepsilon\zeta]} h(x)^{-3}|\boldsymbol{\alpha}(x,u_2)-\boldsymbol{\alpha}(x,u_1)|^2\,dx \\
&\quad+\int_{[0<u_2-u_1\leqq\varepsilon\zeta]} h^3(x)|\nabla(u_2-u_1)|^2\,dx.
\end{aligned}
$$

Using the estimate (3.5) in (3.4) we obtain from (1.3) and (2.4)

$$
\begin{aligned}
&\int_{[u_2-u_1>\varepsilon\zeta]} h^3(x)\nabla(u_2-u_1)\nabla\zeta-(\boldsymbol{\alpha}(x,u_2)-\boldsymbol{\alpha}(x,u_1))\cdot\nabla\zeta\,dx \qquad (3.6)\\
&\qquad\leqq \frac{1}{4\varepsilon}\int_{[0<u_2-u_1\leqq\varepsilon\zeta]} h(x)^{-3}|\boldsymbol{\alpha}(x,u_2)-\boldsymbol{\alpha}(x,u_1)|^2\,dx \\
&\qquad\leqq \frac{c_2M}{4h_{\min}^3}\int_{[0<u_2-u_1\leqq\varepsilon\zeta]} dx
\end{aligned}
$$

where $M=\max\zeta$. Now the measure of the set $[0<u_2-u_1\leqq\varepsilon\zeta]$ goes to zero as $\varepsilon\to 0$. Thus, the estimate (3.1) follows from (3.6).

Now set $\mathbf{n}=(n_1,n_2)\equiv(-\Lambda_2,\Lambda_1)$ and $s>0$. We then set

$$
\zeta(x_1,x_2)=W-\exp(s(n_1x_1+n_2x_2)) \qquad (3.7)
$$

where W is a constant chosen large enough so that $\zeta>0$. If we set ζ from (3.7) in (3.1) we obtain (see the definition of $\boldsymbol{\alpha}$)

$$
\int_{[u_2-u_1>0]} h^3(x)\nabla(u_2-u_1)\nabla\zeta+\lambda(\beta(x,u_2)-\beta(x,u_1))\nabla h\cdot\nabla\zeta\,dx\leqq 0 \qquad (3.8)
$$

since $\boldsymbol{\Lambda}\cdot\nabla\zeta=0$ for all $x\in\Omega$. Now it follows from integration by parts that

$$
\begin{aligned}
\int_{[u_2-u_1>0]} h^3(x)\nabla(u_2-u_1)\nabla\zeta\,dx &= \int_\Omega h^3(x)\nabla(u_2-u_1)^+\nabla\zeta\,dx \qquad (3.9)\\
&= -\int_\Omega (u_2-u_1)^+\nabla\cdot(h^3(x)\nabla\zeta)\,dx \\
&= -\int_{[u_2-u_1>0]} (u_2-u_1)\nabla\cdot(h^3(x)\nabla\zeta)\,dx.
\end{aligned}
$$

So, from (3.8) we obtain

$$
\int_{[u_2-u_1>0]} (u_2-u_1)\left[-\nabla\cdot(h^3(x)\nabla\zeta)+g(x)\nabla h\cdot\nabla\zeta\right]dx\leqq 0
$$

where

$$g(x)=\begin{cases}\dfrac{\lambda(\beta(x,u_2(x)))-\beta(x,u_1(x))}{(u_2(x)-u_1(x))} & \text{if } u_2(x)\neq u_1(x),\\ 0 & \text{if } u_2(x)=u_1(x).\end{cases}$$

If $\lambda=0$, then $g=0$. Further, from the definition of β, for $\lambda\neq 0$

$$|\beta(x,v)-\beta(x,w)|\leqq\frac{h_{\max}^2}{\lambda}|v-w|,\quad x\in\Omega,\quad v,w\in\mathbb{R}.$$

Thus, $g\in L^\infty(\Omega)$. Also, we have that

$$\begin{aligned}-\nabla\cdot\big(h^3(x)\nabla\zeta\big)+g(x)\nabla h\cdot\nabla\zeta&\\ =-h^3(x)\Delta\zeta-\nabla h^3\cdot\nabla\zeta+g(x)\nabla h\cdot\nabla\zeta&\\ =\exp\big(s(n_1x_1+n_2x_2)\big)\big[h^3(x)s^2n^2+(\nabla h^3\cdot\mathbf{n})s-g(x)(\nabla h\cdot\mathbf{n})s\big]&\end{aligned}$$

where $n^2=n_1^2+n_2^2$. Hence, it follows that for s sufficiently large

$$-\nabla\cdot\big(h^3(x)\nabla\zeta\big)+g(x)\nabla h\cdot\nabla\zeta>0 \tag{3.10}$$

for all $x\in\Omega$. The inequalities (3.9) and (3.10) thus allow us to conclude that $(u_2-u_1)^+=0$ a.e. This concludes the proof of Theorem 3.

4. Nonnegativity and regularity of solutions. We have

$$\boldsymbol{\alpha}(x,0)=0,\qquad x\in\Omega. \tag{4.1}$$

Thus, Theorem 3 allows us to conclude that the weak solution, u, to (2.2) with boundary data $\varphi>0$ on $\partial\Omega$ is nonnegative, i.e., $u\geqq 0$ a.e. in Ω. (Take $\varphi_1=\varphi$, $u_1=u$, $\varphi_2=0$, $u_2=0$ in Theorem 3.) Thus, we have the following result.

COROLLARY 1. *If $\varphi>0$ a.e. in $\partial\Omega$, the weak solution, u, to* (2.2) *satisfies $u\geqq 0$ a.e. in Ω.*

If $\lambda\neq 0$ and $h(x)\in C^\infty(\bar\Omega)$, then $\boldsymbol{\alpha}(x,v)$ has bounded derivatives of all orders for $v\geqq 0$. Hence, the standard techniques for the analysis of the regularity of solutions to elliptic boundary value problems [2], [6] can be used to prove that u is a smooth, classical solution to (2.1). However, if $\lambda=0$, then $\boldsymbol{\alpha}(x,v)$ is not differentiable at $v=0$, and it is necessary to show that u is bounded away from zero to be able to prove that u is smooth. Thus, we demonstrate the following theorem which gives a condition on h which guarantees that u is bounded away from zero.

COROLLARY 2. *If $\varphi\geqq\Phi>0$ on $\partial\Omega$ where Φ is a constant and if*

$$\nabla\cdot\boldsymbol{\alpha}(x,\Phi)\leqq 0,\qquad x\in\Omega,$$

then the weak solution, u, to (2.2) *satisfies the bound $u\geqq\Phi>0$ on Ω.*

Proof. We will use the method of Theorem 3 with $\varphi_1=\varphi$, $u_1=u$, $\varphi_2=\Phi$, $u_2=\Phi$. Now $u_2=\Phi$ is not the weak solution of (2.2) with boundary data, $\varphi_2=\Phi$, but we have instead by integration by parts that for all $\zeta\in H_0^1(\Omega)$, $\zeta\geqq 0$,

$$\int_\Omega h^3(x)\nabla u_2\cdot\nabla\zeta-\boldsymbol{\alpha}(x,u_2)\cdot\nabla\zeta\,dx=\int_\Omega\nabla\cdot\boldsymbol{\alpha}(x,\Phi)\zeta\,dx\leqq 0. \tag{4.2}$$

From (4.2) we obtain in place of (3.3) that

$$\int_\Omega h^3(x)\nabla(u_2-u_1)\cdot\nabla\zeta\,dx-(\alpha(x,u_2)-\alpha(x,u_1))\cdot\nabla\zeta\,dx\leqq 0 \tag{4.3}$$

for all $\zeta\in H_0^1(\Omega)$, $\zeta\geqq 0$.

The proof of Corollary 2 now follows from the observation that the inequality (4.3) can replace the equality (3.3) in the argument of Theorem 3.

An argument similar to that given in Corollary 2 can be used to prove the following result.

COROLLARY 3. *If* $0\leqq\varphi\leqq\Phi$ *on* $\partial\Omega$ *and if*

$$\nabla\cdot\alpha(x,\Phi)\geqq 0,\qquad x\in\Omega,$$

then the weak solution, u, *to* (2.2) *satisfies the bound* $0\leqq u\leqq\Phi$ *on* Ω.

Note that the technique of Corollary 2 and Corollary 3 could provide some other comparison results by choosing φ_2 and u_2 to satisfy a suitable differential inequality. The bound given in Corollary 2 allows the standard regularity theory for elliptic partial differential equations [2], [6] to be used to prove the following theorem.

COROLLARY 4. *Assume that the boundary of* Ω, $\partial\Omega$, *is infinitely differentiable, that* $h\in C^\infty(\bar\Omega)$, *and that*

$$\Lambda\cdot\nabla h\leqq 0,\qquad x\in\Omega. \tag{4.4}$$

Then the Reynolds lubrication equation (1.1) *has a nonnegative classical solution,* P, *such that* $P\in C^\infty(\bar\Omega)$ *and such that* P *is unique in the class of nonnegative solutions.*

We note that it is proven in [5] under the hypothesis (4.4) that solutions to (1.1) are positive, smooth, and unique in the class of smooth solutions. Our results here prove that such a solution exists and that the stronger bound of Corollary 2 holds. Further, if (4.4) holds, the following result proves that our solution to (1.1) is unique in the class of weak solutions.

COROLLARY 5. *Assume that* P *is a weak solution to* (1.1) *in the sense that* $P\equiv P_a>0$ *on* $\partial\Omega$ *and*

$$\int_\Omega h^3P\nabla P\cdot\nabla\xi-Ph\Lambda\cdot\nabla\xi\,dx=0,\qquad \xi\in H_0^1(\Omega), \tag{4.5}$$

where $P, P^2\in H^1(\Omega)$. *If* (4.4) *holds, then* $P>0$ *a.e. in* Ω.

Proof. Take $\xi=P^-=\min(P,0)\in H_0^1(\Omega)$. Then by (4.5)

$$\begin{aligned}\int_\Omega h^3P\nabla P\cdot\nabla P^- - Ph\Lambda\cdot\nabla P^-\,dx &\\ =\int_\Omega h^3P^-|\nabla P^-|^2+\frac{1}{2}h\Lambda\cdot\nabla(P^-)^2\,dx &\\ =\int_\Omega h^3P^-|\nabla P^-|^2-\frac{1}{2}(\Lambda\cdot\nabla h)(P^-)^2\,dx=0.&\end{aligned} \tag{4.6}$$

Hence, by (4.4),

$$\int_\Omega h^3P^-|\nabla P^-|^2\,dx=\frac{1}{2}\int_\Omega(\Lambda\cdot\nabla h)(P^-)^2\,dx\leqq 0.$$

Thus, $P^-=0$ a.e. in Ω.

ON THE RELATION BETWEEN COEFFICIENT AND BOUNDARY VALUES FOR SOLUTIONS OF WEBSTER'S HORN EQUATION*

WILLIAM W. SYMES†

Abstract. Webster's horn equation is a normalized version of the one-dimension linear acoustic wave equation. It has been used extensively as a simple model for plane wave propagation in layered systems, and particularly as the arena for much work on the relation between the acoustic impedance (coefficient) and the surface response or seismogram (boundary value) in theoretical seismology (this is the simplest so-called seismic reflection inverse problem). The question of continuous dependence of the solution on the coefficient arises naturally in this context, particularly in connection with perturbational techniques.

We study the dependence of boundary values for solutions of Webster's horn equation on its coefficient. For suitable choice of topologies (Sobolev spaces), we show that the map from coefficient to boundary values is a C^1-diffeomorphism.

Introduction. Various wave propagation problems in a plane-stratified half-space $\{z>0\}$ lead to *Webster's horn equation*:

$$(\eta(z)\partial_t^2-\partial_z\eta(z)\partial_z)u(z,t)=0 \tag{0.1}$$

where the coefficient η is generally called an impedance, and is related to the mechanical properties of the medium (see [5] or [26] for a derivation and discussion of (0.1) in linear acoustics and elastodynamics).

We impose the boundary and initial conditions

$$\partial_z u(0,\cdot)=f, \tag{0.2}$$

$$u(\cdot,t)\equiv 0, \qquad t\ll 0, \tag{0.3}$$

where the Neumann datum f vanishes for $|t|$ large, so that the resulting disturbance is transient.

The conditions (0.1), (0.2), (0.3) form a well-posed initial boundary value problem in the half-space $(z>0)$, even for distribution datum f. Therefore, specification of η and f determines for instance the values of u on $\{z=0\}$. We define

$$\tau_f(\eta)=\partial_t u(0,\cdot). \tag{0.4}$$

Our aim in this paper is to establish the properties of τ_f as a map between suitable function spaces. Note that

$$\tau_f(\eta)=f*\tau_\delta(\eta).$$

Thus properties of τ_f follow from properties of τ_δ via well-known facts about convolution. Therefore, we restrict our attention to the choice $f=-\delta$ (the so-called impulse-response case). Our main result is that $\tau=\tau_{-\delta}$ is a Lipschitz homeomorphism, in the following sense.

We may rewrite (0.1) as

$$(0.1') \qquad \left(\partial_t^2 - \partial_z^2 - \sigma\partial_z\right)u = 0$$

with $\sigma = \partial_z \log \eta$ (the *reflectivity* in seismic parlance), and normalize $\eta(0) = 1$, by scaling u, so

$$\eta(z) = \exp\left\{\int_0^z \sigma\right\}.$$

We can view τ as a functional of σ instead, i.e. redefine

$$(0.4') \qquad \tau(\sigma) = \partial_t u(0, \cdot).$$

Note that the boundary value $u(o,t)$, $0 \leqq t \leqq 2T$, depends on the coefficient η (or σ) only in $0 \leqq z \leqq T$, since the signal propagation speed of (0.1) is one. The solution of (0.1), (0.2) and (0.3) is constructed by well-known methods (see below) for smooth η (or σ), so we can view τ initially as a map: $C^\infty[0,T] \to C^\infty[0,2T]$.

We can now state our three major results:

THEOREM 0.1. *For $\sigma \in C^\infty[0,T]$, there exist constants β and C^*, depending only on $\|\sigma\|_{L^2[0,T]}$ and on T, so that for $\tilde{\sigma} \in C^\infty[0,T]$ with $\|\sigma - \tilde{\sigma}\|_{L^2[0,T]} < \beta$ we have*

$$\|\tau(\sigma) - \tau(\tilde{\sigma})\|_{L^2[0,2T]} \leqq C^* \|\sigma - \sigma^*\|_{L^2[0,T]}.$$

So τ extends to a locally Lipschitz map:

$$L^2[0,T] \to L^2[0,2T].$$

THEOREM 0.2. *For $\sigma \in L^2[0,T]$, $g = \tau(\sigma) \in L^2[0,2T]$, there exist α and $C_* > 0$ depending only on $\|\sigma\|_{L^2[0,T]}$ and on T, for which*

$$\|\tilde{g} - g\|_{L^2[0,2T]} < \alpha$$

implies that $\tilde{g} = \tau(\tilde{\sigma})$ for a unique $\tilde{\sigma} \in L^2[0,T]$, with

$$\|\sigma - \tilde{\sigma}\|_{L^2[0,T]} < C_* \|g - \tilde{g}\|_{L^2[0,2T]}.$$

Actually Theorems 0.1 and 0.2 were the main results of our previous paper [21]. The arguments used in [21], however, suffered from two major drawbacks: they depend on

(i) a characterization of the range of τ; and

(ii) Lipschitz estimates for the time-like Cauchy problem.

Neither (i) nor (ii) is available in similar higher-dimensional problems. In the present treatment, we have reformulated the results so that the Lipschitz constants and domains of validity depend only on local quantities, thus avoiding (i). Also, we have revised the main step in the proof ("downward continuation") so that the time-like Cauchy problem no longer plays an explicit role. As a by-product of our analysis, we obtain a stronger result:

THEOREM 0.3. *τ is a C^1-diffeomorphism of $L^2[0,T]$ into $L^2[0,2T]$.*

As intended, the new approach has allowed us to establish carefully formulated analogues of Theorems 0.1, 0.2, and 0.3 for similar higher-dimensional problems: see [22] and references cited therein.

In the remainder of this introduction, we shall:

(i) explain the origin of our interest in the map τ;

(ii) briefly discuss related literature;

(iii) describe the main components of our analysis;

(iv) outline the organization of the paper.

Our interest in the properties of τ_f is motivated by the *impedance profile inversion problem*, which is a model for many inverse (or coefficient—or medium—identification) problems in wave propagation. In the impedance profile inversion problem, a propagating plane-wave disturbance (measured by u) is introduced into a medium $\{z>0\}$ (modeled by (0.1)) by means of a boundary excitation (imposed traction, pressure drop, etc., modeled by (0.2)), assumed quiescent in the past ((0.3)). The inhomogeneities in the medium ($\eta \neq$ constant) set up reflected waves, which reach the surface and result in a nonzero rate of change of the boundary value of u ($\tau_f(\sigma) = \partial_t u(0,\cdot)$). From this latter data, one is to infer the structure of the medium (i.e. $\eta(z)$, $z>0$).

In our notation, we formulate the impedance profile inversion problem as follows: given data g and f, find η (or $\sigma = \partial_z \log \eta$) so that the functional equation

$$\tau_f(\sigma) = g \tag{0.5}$$

is satisfied.

This problem and its generalizations are models for many interesting data-pocessing technologies, the best-known being the seismic reflection method in petroleum prospecting. Correspondingly, inverse problems in wave propagation have a large and rapidly growing literature, much of it concerned with impedance profile inversion and simple variants (layered-medium problems). Therefore, it seems surprising that the properties of the map τ_f have seldom been addressed in any substantial way, even though many authors have recommended perturbation or optimization techniques for (0.5) and its generalizations, which require properties such as differentiability (see [7], [13], and references cited there). Even continuity of τ and its inverse has been addressed in only a few papers (see [21], [6], [11], [1], and in the context of spectral inverse problems [14]). The issue is serious, as any measurement modeled by τ is inevitably contaminated with noise, and τ and τ^{-1} are *not* continuous with respect to some apparently natural domain and range metrics (see [11] for discontinuity examples in impedance profile inversion, and [23] for different examples of nondifferentiability of τ and τ^{-1} in higher-dimensional problems). Moreover, many approaches to impedance profile inversion do not generalize in any obvious way to higher-dimensional (nonlayered) problems.

Our approach in this paper is a modification of the *downward continuation* (or "layered-stripping") method, which really goes back to the geophysical work of Goupillaud [12] and Kunetz [15] in the early 1960s. A number of authors recently have developed reliable computational techniques for impedance profile inversion based on this idea ([17], [4], [3], [19], [9], [2], [20]).

The main tools used in the present study (and in [21]) are:

(I) *The transport equation*. The progressing wave expansion ([8, Chap. VI, §4, esp. pp. 633–655], also [23, §2], and [10, pp. 42–45]) for smooth η shows that the solution of (0.1), (0.2), (0.3) with $f = -\delta$ must have a jump along the characteristic $\{z=t\}$ of magnitude

$$[u](z,z) = \eta^{-1/2}(z)$$

(with the normalization $\eta(0)=1$), and is otherwise smooth. Therefore, u solves the characteristic initial boundary value problem

$$(\partial_t^2 - \partial_z^2 - \sigma\partial_z)u = 0 \quad \text{in } \Omega := \{(z,t): 0<z<T,\ z<t<2T-z\}, \tag{0.6a}$$

$$\partial_z u(0,t) = 0, \qquad 0<t<2T, \tag{0.6b}$$

$$\lim_{\zeta \to 0^+} u(z, z+\zeta) =: \bar{u}(z) = \eta^{-1/2}(z) \tag{0.6c}$$

with

$$\eta(z)=\exp\int_0^z\sigma. \tag{0.6d}$$

In effect the use of (0.6) rather than (0.1), (0.2), (0.3) removes the propagating singularity from the problem.

(II) *Downward continuation problem.* We shall actually study a slightly more general problem than (0.6), because the generalization does not significantly increase the difficulty of the arguments and because the extended results are useful in further investigation of the inverse problem as an optimization problem with constraints on η (or σ).

We note that, if we pick $0\leqq z_0<z_1\leqq T$ and set

$$f:=\partial_z u(z_0,\cdot), \tag{0.7a}$$

$$h:=(\partial_z+\partial_t)u(z_1,\cdot), \tag{0.7b}$$

then in the region $\{(z,t): z_0\leqq z\leqq z_1,\ z\leqq t\leqq 2T-z\}$ the solution u of (0.6) satisfies

$$(\partial_t^2-\partial_z^2-\sigma\partial_z)u=0, \tag{0.8a}$$

$$\partial_z u(z_0,\cdot)=f, \tag{0.8b}$$

$$(\partial_t+\partial_z)u(z_1,\cdot)=h, \tag{0.8c}$$

$$\bar{u}(z)=\eta^{-1/2}(z). \tag{0.8d}$$

Now define, for arbitrary f, h, σ, η_0

$$\tau_0(\sigma,h,f,\eta_0):=\partial_t w(z_0,\cdot)$$

where

$$\eta(z)=\eta_0\exp\left\{\int_{z_0}^z\sigma\right\}$$

and w solves the mixed characteristic initial-boundary value problem (0.8).

We shall show in §2 that, if we regard f and η_0 as parameters, the equation

$$\tau_0(\sigma,h,f,\eta_0)=g \tag{0.9}$$

has at most one solution (σ,h) which depends continuously on f, η_0 and g. In fact, we shall show that τ_0 is Lipschitz in all variables, continuously differentiable in the first two, and we shall bound the derivative and its inverse locally. The implicit function theorem and a global uniqueness theorem then yield the result.

Note also that if we pick $z_0=0$, $z_1=T$, then $\tau_0(\sigma,0,0,1)=\tau(\sigma)$. Thus Theorems 0.1–0.3 follow from similar statements about τ_0.

The uniqueness of solutions to the functional equation for τ_0 also implies that if f is given by (0.7a), $g=\partial_t u(z_0,\cdot)$, and $\eta_0=\eta(z_0)$ from (0.6d), then the solution of (0.8) is identical to the solution of (0.6) for $z_0\leqq z\leqq z_1$. In particular, the solution (σ,h) to (0.9) *continues* σ to $[z_0,z_1]$. Also, in solving (0.8), we have implicitly constructed $\partial_t u(z_1,\cdot)$ and $\partial_z u(z_1,\cdot)$. So we can redefine g, f, and η_0, replace z_0 by z_1, and continue the procedure. This is a version of the downward continuation algorithm suited to several-dimensional generalizations.

Most inverse problems of wave propagation which model feasible experiments are ill-posed, either because of explicit band-limitation of the observed signal or because of several-dimensional effects (see [22], [23] for a discussion of the latter). This is even true

for some versions of the impedance problem with band limited data (the problem considered in this paper appears to be the sole exception). Such problems must be set as regularized (nonlinear) optimization problems, and the presence of multiple local minima becomes a possibility.

The global minimum of $\|\tau_0 - g\|$, however, is unique in a region of size proportional to $(z_1 - z_0)^{-1/2}$. This fact may be used to approximate recursively the global minimum of $\|\tau - g\|$ by a nonlinear least-squares version of downward continuation. This approach, which is a particular homotopy method for global optimization of $\|\tau - g\|$, underlies our interest in the map τ_0, and will be discussed elsewhere.

(III) *Sideways energy estimates.* The key tool in constructing derivatives and bounds for τ_0 is the estimation of

$$Q(z) := \frac{1}{2}\int_z^{2T-z} dt \left\{ (\partial_t u)^2 + (\partial_z u)^2 \right\}$$

for solutions u of (0.8). Q is a sort of vertical energy form. Its interaction with the usual energy form produces most of the important estimates. The key point is that the $1-D$ wave equation is hyperbolic as an evolution equation in z as well. This sort of argument seems to have been introduced by Rauch and Taylor [16], who used it to prove energy decay for some dissipative boundary value problems in $1+1$ dimensions. Of course, the time-like Cauchy problem is no longer hyperbolic in $1+n$ dimensions, $n>1$, so the argument breaks down, as noted in [16]. The author has recently studied regularization of the higher-dimensional time-like Cauchy problem, in such a way that "sideways" energy estimate for analogues of Q are again useful (see [22], [25]).

The paper is organized as follows:

Section 1: derivation of a number of "sideways" energy estimates.

Section 2: investigation of the downward continuation operator τ_0, proof of Theorems 0.1–0.3.

In conclusion, we note that any serious attempt to model applications such as reflection seismology by the impedance profile inversion problem sketched above runs into serious, and as yet mostly unresolved, difficulties. The gravest of these concerns the Neumann datum f, which for any realistic model is far from impulsive, and in fact tends to have very small Fourier components near both 0 and ∞ *Hz*. For the disastrous effect of the low-frequency small amplitudes on coefficient determination, and a suggestion for a partial cure, see [18]. See also, however, reference [20] in which these measurement difficulties are overcome and the solution of the impedance profile inversion problem by numerical downward continuation allows the real-time imaging of the vocal tract.

1. Energy estimates. Suppose $0 \leqq z_0 < z_1 \leqq T$, and define $\Omega = \{(z,t) : z_0 \leqq z \leqq z_1,\ z \leqq t \leqq 2T - z\}$. Thus Ω is the trapezoid obtained by intersection the double light cone, with vertices $(0,0)$, $(0,2T)$ with the strip $\{(z,t) : z_0 \leqq z \leqq z_1\}$. Suppose $u, w \in C^\infty(R^2)$, $\eta_0 \in R^+$, ω, η, σ, f, h and $\psi \in C^\infty(R)$ satisfy

$$\eta(z) = \eta_0 \exp \int_{z_0}^{z} \sigma, \qquad z_0 \leqq z \leqq z_1, \tag{1.1}$$

$$\left(\partial_t^2 - \partial_z^2 - \sigma\partial_z\right) u = \omega w \quad \text{in } \Omega, \tag{1.2a}$$

$$\partial_z u(z_0, t) = f(t), \qquad z_0 \leqq t \leqq 2T - z_0, \tag{1.2b}$$

$$(\partial_z + \partial_t) u(z_1, t) = h(t), \qquad z_1 \leqq t \leqq 2T - z_1, \tag{1.2c}$$

$$\bar{u}(z) = \psi(z), \qquad z_0 \leqq z \leqq z_1. \tag{1.2d}$$

Note: We will make use throughout of the symbol $\bar{u}$ to represent the restriction of a real-valued function of two variables to the diagonal $z=t$. We will also use the abbreviation

$$\bar{\bar{u}}(z) := u(z, 2T-z)$$

to indicate restriction to the upper boundary segment of Ω.

The problem (1.2) may be viewed as a mixed characteristic initial/boundary value problem with data σ, ω, w, f, h. A standard construction ([7], pp. 461–471) assures the existence of a solution u depending continuously on the data in various senses. The purpose of this section is to establish estimates for the boundary values of u and its restrictions to vertical line segments.

The main tools are two "energy identities." These are most easily derived by application of Stoke's theorem. The first is related to the well-known energy method ([8, pp. 438–449]); set

$$\omega_E = \frac{1}{2}\eta\left\{(\partial_t u)^2 + (\partial_z u)^2\right\} dz + \eta \partial_z u \partial_t u \, dt;$$

Stokes' theorem

$$\int_{\partial\Omega} \omega_E = \int_{\Omega} d\omega_E$$

amounts to the identity

$$\begin{aligned}(1.3)\qquad \frac{1}{2}\int_{z_0}^{z_1} \eta(\bar{u}')^2 - \frac{1}{2}\int_{z_0}^{z_1} \eta(\bar{\bar{u}}')^2 + \eta(z_1)\int_{z_1}^{2T-z_1} dt\, \partial_t u \partial_z u(z_1, t) \\ - \eta(z_0)\int_{z_0}^{2T-z_0} dt\, \partial_z u \partial_t u(z_0, t) \\ = \int_{z_0}^{z_1} dz\, \eta(z)\omega(z)\int_{z}^{2T-z} dt\, w(z,t)\partial_t u(z,t)\end{aligned}$$

where in rewriting the area integral we have made use of the form of (1.2a):

$$\left(\eta\partial_t^2 - \partial_z \eta \partial_z\right) u = \eta\omega w.$$

The second identity involves the "sideways energy" form:

$$\omega_Q = \tfrac{1}{2}\left\{(\partial_t u)^2 + \left(\partial_z u^2\right)\right\} dt + \partial_t u \partial_z u \, dz.$$

We introduce the abbreviations

$$\begin{aligned} Q(z) &:= \frac{1}{2}\int_z^{2T-z} dt \left\{(\partial_t u)^2 + (\partial_z u)^2\right\}(z,t), \\ \Omega_{a,b} &= \left\{(z,t) : z_a \leqq z \leqq z_b,\ z \leqq t \leqq 2T-z\right\} \end{aligned}$$

for $z_0 \leqq z_a < z_b \leqq z_1$. Then the identity

$$\int_{\partial\Omega_{a,b}} \omega_Q = \int_{\Omega_{a,b}} d\omega_Q$$

amounts to

$$Q(z_b)-Q(z_a)+\frac{1}{2}\int_{z_a}^{z_b}\{(\bar{u}')^2+(\bar{\bar{u}}')^2\} \tag{1.4}$$
$$=-\int_{z_a}^{z_b}dz\,\sigma(z)\int_z^{2T-z}dt(\partial_z u(z,t))^2$$
$$-\int_{z_a}^{z_b}dz\,\omega(z)\int_z^{2T-z}dt\,w(z,t)\partial_z u(z,t).$$

The identities (1.3) and (1.4) together imply a number of useful estimates on boundary values of u, corresponding to various special cases of (1.2). We make the convention in the following lemmas and their proofs that constants, which are denoted by C and which change their meaning from equation to equation, depend only on $\|\sigma\|$, η_0, T, and z_1-z_0, unless otherwise noted, and that $\|\cdot\|$ refers to the L^2-norm on the appropriate interval.

LEMMA 1.1. *Suppose in* (1.2) *that* $h=\omega\equiv 0$. *Then*

$$Q(z)\leqq C\{\|\psi'\|^2+\|f\|^2\}$$

for $z_0\leqq z\leqq z_1$.

Proof. Setting $\omega=0$ and $z_a=z$, $z_b=z_1$ in (1.4), we obtain

$$Q(z_1)+\frac{1}{2}\int_z^{z_1}(\psi')^2+\frac{1}{2}\int_z^{z_1}(\bar{\bar{u}}')^2=Q(z)-\int_z^{z_1}dz\,\sigma(z)\int_\tau^{2T-z}dt(\partial_z u)^2(\zeta,t).$$

Thus,

$$Q(z)\leqq\frac{1}{2}\int_z^{z_1}|\psi'|^2+\left\{Q(z_1)+\frac{1}{2}\int_z^{z_1}(\bar{\bar{u}}')^2\right\}+2\int_z^{z_1}d\zeta|\sigma(\zeta)|Q(\zeta).$$

So Gronwall's inequality implies

$$Q\leqq\left\{\frac{1}{2}\|\psi'\|^2+\left[Q(z_1)+\frac{1}{2}\|\bar{\bar{u}}'\|^2\right]\right\}\exp\left(2\int_{z_0}^{z_1}|\sigma|\right). \tag{1.5}$$

Since $(\partial_t+\partial_z)u(z_1,\cdot)=0$, we have

$$\partial_t u\partial_z u=-\tfrac{1}{2}\left[(\partial_t u)^2+(\partial_z u)^2\right]\quad\text{for } z=z_1.$$

Therefore (1.3) yields

$$\frac{1}{2}\int_{z_0}^{z_1}\eta(\psi')^2-\eta(z_0)\int_{z_0}^{2T-z_0}dtf(t)\partial_t u(z_0,t)=\frac{1}{2}\int_{z_0}^{z_1}\eta(\bar{\bar{u}}')^2+\eta(z_1)Q(z_1) \tag{1.6}$$
$$\geqq\eta_*\left(\frac{1}{2}\|\bar{\bar{u}}'\|^2+Q(z_1)\right)$$

where

$$\eta^*=\sup\eta(z)\leqq\eta_0\exp\int_{z_0}^{z_1}|\sigma|\leqq\eta_0\exp\{(z_1-z_0)^{1/2}\|\sigma\|\},$$
$$\eta_*=\inf\eta(z)\geqq\eta_0\exp\{-(z_1-z_0)^{1/2}\|\sigma\|\}.$$

The L.H.S. of (1.6) is bounded by

$$\eta^*\left(\frac{1}{2}\|\psi'\|^2+\|f\|Q(z_0)^{1/2}\right)\leqq\eta^*\left(\frac{1}{2}\|\psi'\|^2+\frac{k}{2}\|f\|^2+\frac{1}{2k}Q(z_0)\right)$$

for any $k>0$. Combined with (1.5) this yields

$$Q\leqq C\left\{\|\psi'\|^2+kC_2\|f\|^2+\frac{\eta^*}{2\eta_* k}Q(z_0)\right\}\exp 2\int_{z_0}^{z_1}|\sigma|.$$

Take $k=(\eta^*/\eta_*)\exp\{2\int_{z_0}^{z_1}|\sigma|\}$; then we have

$$Q\leqq C\left\{\|\psi'\|^2+\|f\|^2+\tfrac{1}{2}Q(z_0)\right\}$$

so

$$2Q(z_0)\leqq 2C\left\{\|\psi'\|^2+\|f\|^2\right\}$$

and so

$$Q\leqq 2C\left\{\|\psi'\|^2+\|f\|^2\right\}. \qquad \text{Q.E.D.}$$

LEMMA 1.2. *Suppose in* (1.2) *that* $f=h=\psi=0$. *Then,*

$$Q\leqq C(z_1-z_0)\|\omega\|^2 w^*$$

where

$$w^*=\sup\left(\int_z^{2T-z}dt w^2(z,t)\right).$$

Proof. From (1.4) we obtain

$$Q(z_1)=Q(z)-\frac{1}{2}\int_z^{z_1}(\bar{\bar{u}}')^2-\int_z^{z_1}d\zeta\sigma(\zeta)\int_\zeta^{2T-\zeta}dt(\partial_z u)^2(\zeta,t)$$
$$-\int_z^{z_1}d\zeta\omega(\zeta)\int_\zeta^{2T-\zeta}dt(w\partial_z u)(\zeta,t).$$

So

$$(1.7)\quad Q(z)\leqq Q(z_1)+\frac{1}{2}\int_{z_0}^{z_1}(\bar{\bar{u}}')^2+\int_z^{z_1}d\zeta\int_\zeta^{2T-\zeta}dt\left\{|\sigma(\zeta)|(\partial_z u)^2(\zeta,t)\right.$$
$$\left.+\|\omega(\zeta)\|w(\zeta,t)\,d_z u|\zeta,t|\right\}.$$

Identity (1.3) gives

$$-\frac{1}{2}\int_{z_0}^{z_1}\eta(\bar{\bar{u}}')^2+\eta(z_1)\int_{z_1}^{2T-z_1}dt\partial_t u\partial_z u(z_1,t)$$
$$=\int_{z_0}^{z_1}dz\eta(z)\omega(z)\int_z^{2T-z}dtw(z,t)\partial_t u(z,t).$$

As in the proof of Lemma 1.1, $\partial_t u\partial_z u=-\frac{1}{2}[(\partial_t u)^2+(\partial_z u)^2]$ at $z=z_1$, so the above implies

$$(1.8)\qquad \eta_*\left(\frac{1}{2}\int_{z_0}^{z_1}(\bar{\bar{u}}')^2+Q(z_1)\right)\leqq\eta^*\int_{z_0}^{z_1}d\zeta|\omega(\zeta)|\int_\zeta^{2T-\zeta}dt|w\partial_\tau u|(\zeta,T).$$

Now for any $\alpha > 0$

$$\int dt|w||\partial_t u| = \int dt(\alpha|w|)\left(\frac{1}{\alpha}|\partial_t u|\right) \leqq \frac{1}{2}\int dt\left(\alpha^2|w|^2 + \alpha^{-2}|\partial_t u|^2\right) \tag{1.9}$$

$$\leqq \frac{\alpha^2 w^*}{2} + \frac{\alpha^{-2}}{2}\int |\partial_t u|^2.$$

Similarly

$$\int dt|w||\partial_z u| \leqq \frac{\alpha^2 w^*}{2} + \frac{\alpha^{-2}}{2}\int y\,|\partial_z u|^2. \tag{1.10}$$

Equations (1.8), (1.9), and (1.10) combine with (1.7) to yield

$$Q(z) \leqq \int_{z_0}^{z_1} d\zeta|\omega(\zeta)|\left(1+\frac{\eta^*}{\eta_*}\right)(\alpha^2 w^* + 2\alpha^{-2}Q^*) + 2\int_{z_0}^{z_1}|\sigma|Q$$

where $Q^* := \sup_{z_0 \leqq z \leqq z_1} Q(z)$. By Gronwall,

$$Q \leqq C(\alpha^2 w^* + 2\alpha^{-2}Q^*)\left\{\int_{z_0}^{z_1}|\omega|\right\}\exp\left\{2\int_{z_0}^{z_1}|\sigma|\right\}. \tag{1.11}$$

Now if $\omega = 0$ a.e., $u \equiv 0$ by uniqueness in the mixed problem, and the assertion of the lemma holds trivially. Otherwise, set

$$\alpha^2 = 4\int_{z_0}^{z_1}|\omega|\left(\exp 2\int_{z_0}^{z_1}|\sigma|\right)$$

so that (1.11) becomes

$$Q \leqq C\left(\int_{z_0}^{z_1}|\omega|\right)^2 w^* \exp\left(4\int_{z_0}^{z_1}|\sigma|\right) + \frac{1}{2}Q^* \leqq C(z_1 - z_0)w^*\|\omega\|^2 + \frac{1}{2}Q^*$$

from which the conclusion follows immediately. Q.E.D.

LEMMA 1.3. *Suppose in* (1.2) *that* $f = \omega = \psi = 0$. *Then*

$$Q \leqq C\|h\|^2.$$

Proof. From

$$(\partial_t + \partial_z)u(z_1, \cdot) = h$$

we obtain

$$\int_{z_1}^{2T-z_1} dt\,\partial_t u \partial_z u(z_1, t) = \frac{1}{2}\int_{z_1}^{2T-z_1} h^2 - Q(z_1).$$

So the identity (1.3) reads

$$0 = \frac{1}{2}\int_{z_0}^{z_1}\eta(\bar{\bar{u}}')^2 + \eta(z_1)\left(\frac{1}{2}\int_{z_1}^{2T-z_1}h^2 - Q(z_1)\right)$$

whence

$$\frac{1}{2}\int_{z_1}^{2T-z_1}h^2 = \frac{1}{2}\int_{z_0}^{z_1}\eta(\bar{\bar{u}}')^2 + \eta(z_1)Q(z_1) \geqq \eta_*\left(\frac{1}{2}\int_{z_0}^{z_1}(\bar{\bar{u}}')^2 + Q(z_1)\right). \tag{1.12}$$

On the other hand, (1.4) gives

$$Q(z)+\int_z^{z_1} d\zeta\sigma(\zeta)\int_\zeta^{2T-\zeta} dt(\partial_z u)^2(\zeta,t)=Q(z_1)+\frac{1}{2}\int(\bar{\bar{u}}')^2. \tag{1.13}$$

Equations (1.12) and (1.13) combine to yield

$$Q(z)\leqq C\|h\|^2+\int_z^{z_1}|\sigma|Q$$

whence the result follows via Gronwall's inequality. Q.E.D.

LEMMA 1.4. *The solution of* (1.2) *satisfies*

$$Q(z)\leqq C\left\{\|\psi'\|^2+\|f\|^2+\|h\|^2+w^*\|\omega\|^2\right\}$$

in the notation of Lemmas 1.1–1.3.

Proof. This follows immediately from the previous lemmas by writing

$$u=u_1+u_2+u_3$$

and correspondingly

$$Q\leqq 3\{Q_1+Q_2+Q_3\}$$

where u_k solves the problem of Lemma 1. k, $k=1,2,3$. Q.E.D.

LEMMA 1.5. *Suppose that there exists* $k>0$ *so that for* $z_0\leqq z,\ \leqq z_1$,

$$\int_{z_0}^z|\omega|^2\leqq k\left\{\int_{z_0}^z|\psi'|^2+|\psi(0)|^2\right\}.$$

Then there exists $C>0$ *so that*

$$\|\psi'\|^2+\|h\|^2\leqq C\left\{Q(z_0)+|\psi(0)|^2\right\}.$$

Proof. From (1.4) we obtain

$$\begin{aligned}
&Q(z)+\frac{1}{2}\int_{z_0}^z(\psi')^2\\
&\leqq Q(z_0)+\int_{z_0}^z d\zeta\left\{|\sigma(\zeta)|\int_\zeta^{2T-\zeta}dt\left(\partial_z w^2(\zeta,t)\right)+\left|\omega(\zeta)\int_\zeta^{2T-\zeta}dt\,w(\zeta,t)\partial_z u(\zeta,t)\right|\right\}\\
&\leqq Q(z_0)+\int_{z_0}^z|\sigma|Q+w^*\int_{z_0}^z d\zeta|\omega(\zeta)|\left(\int_\zeta^{2T-\zeta}dt(\partial_z u)^2(\zeta,t)\right)^{1/2}\\
&\leqq Q(z_0)+\delta w^*\int_{z_0}^z|\omega|^2+\int_{z_0}^z\left(\sigma+\frac{w^*}{4\delta}\right)Q
\end{aligned}$$

for any $\delta<0$. For δ sufficiently small, the hypothesis allows us to dominate the second term on the R.H.S. by a fraction of the second term on the L.H.S., after adding a suitable multiple of $|\psi(0)|^2$, to both sides. We replace Q by $Q(z)+\frac{1}{2}\int_{z_0}^z|\psi'|^2$ on the R.H.S. under the integral sign and apply Gronwall's inequality to obtain

$$Q(z)+\frac{1}{2}\int_{z_0}^z|\psi'|^2\leqq\left\{Q(z_0)+c|\psi(0)|^2\right\}\exp\left\{\int_{z_0}^z\left(\sigma+\frac{w^*}{4\delta}\right)\right\}.$$

The proof is finished by setting $z=z_1$ and noting that

$$\int_{z_1}^{2T-z_1}|h|^2 \leqq 4Q(z_1). \qquad \text{Q.E.D.}$$

2. Proofs of the main theorems. Suppose $T>0$, $0\leqq z_0<z_1<T$, $\eta_0>0$, $\sigma\in C^\infty[z_0,z_1]$, $f\in C^\infty[z_0,2T-z_0]$, $h\in C^\infty[z_1,2T-z_1]$. Define $\eta=\eta[\sigma,\eta_0]$ by

$$\eta(z)=\eta_0\exp\int_{z_0}^{z}\sigma.$$

Thus, $\sigma=\partial_z\log\eta$ and $\eta(z_0)=h_0$. Suppose u solves the boundary value problem

(2.1a) $\quad(\partial_t^2-\partial_z^2-\sigma\partial_z)u=0 \quad$ in $\Omega:=\{(z,t): z_0\leqq z\leqq z_1,\ z\leqq t\leqq 2T-z\}$,

(2.1b) $\quad\partial_z u(z_0,t)=f(t), \qquad z_0\leqq t\leqq 2T-z_0$,

(2.1c) $\quad(\partial_t+\partial_z)u(z_1,t)=h(t), \qquad z_1\leqq t\leqq 2T-z_1$,

(2.1d) $\quad\bar{u}(z)=\eta^{-1/2}(z), \qquad z_0\leqq z\leqq z_1$.

Define

$$\tau_0(\sigma,h,f,\eta_0)(t):=\partial_t u(z_0,t), \qquad z_0\leqq t\leqq 2T-z_0.$$

τ_0 is the basic downward continuation operator. It is well-defined, as the problem (2.1) has unique solutions depending continuously on the data, by standard reasoning (see [8, Chap. V, §6]).

Our first task is the extent τ_0 continuously to square-integrable arguments.

PROPOSITION 2.1. *Suppose σ, η, f, h, η_0, u are smooth and satisfy the equations* (2.1). *Then*

$$Q(z):=\frac{1}{2}\int_z^{2T-z}dt\left\{(\partial_t u)^2+(\partial_z u)^2\right\}(z,t) \tag{2.2}$$

satisfies

$$Q(z)\leqq C\left\{\|\sigma\|^2+\|h\|^2+\|f\|^2\right\}, \qquad z_0\leqq z\leqq z_1$$

where C is exponential polynomial in η_0, $\|\sigma\|$, and z_1-z_0.

Proof. Since

$$\left\|\partial_z\eta^{-1/2}\right\|\leqq C(\eta_0,\|\sigma\|,z_1-z_0)\|\sigma\|$$

use of (2.1d) and Lemma 1.4 imply this estimate. Q.E.D.

PROPOSITION 2.2. *Suppose u_i, h_i, σ_i, η_{0i}, η_i, and f_i are smooth and satisfy* (2.1), *$i=1,2$. Let $v=u_2-u_1$ and set*

$$Q(z):=\frac{1}{2}\int_z^{2T-z}dt\left\{(\partial_t v)^2+(\partial_z v)^2\right\}(z,t);$$

then for $z_0\leqq z\leqq z_1$,

$$Q(z)\leqq C\left\{\|\sigma_1-\sigma_2\|^2+\|h_1-h_2\|^2+\|f_1-f_2\|^2+|\eta_{01}-\eta_{02}|^2\right\}$$

where C is exponential/polynomial in

$$\eta_{0i},\quad \|\sigma_i\|,\quad \|f_i\|,\quad \|h_i\|,\quad z_1-z_0, \qquad i=1,2.$$

Proof. The difference v solves the boundary value problem

$$(\partial_t^2-\partial_z^2-\sigma_1\partial_z)v=(\sigma_1-\sigma_2)\partial_z u_2 \quad \text{in } \Omega, \tag{2.3a}$$

$$\partial_z v(z_0,t)=f_2(t)-f_1(t), \qquad z_0\leqq t\leqq 2T-z_0, \tag{2.3b}$$

$$(\partial_t+\partial_z)v(z_1,t)=h_2(t)-h_1(t), \qquad z_1\leqq t\leqq 2T-z_1, \tag{2.3c}$$

$$\bar{v}(z)=\eta_2^{-1/2}(z)-\eta_1^{-1/2}(z), \qquad z_0\leqq z\leqq z_1. \tag{2.3d}$$

Note that

$$\begin{aligned}\eta_2^{-1/2}(z)-\eta_1^{-1/2}&=n_{02}^{-1/2}\left(\exp\left(-\frac{1}{2}\int_{z_0}^{z}\sigma_2\right)-\exp\left(-\frac{1}{2}\int_{z_0}^{z}\sigma_1\right)\right)\\&\quad+\left(\eta_{02}^{-1/2}-\eta_{01}^{-1/2}\right)\left(\exp\left(-\frac{1}{2}\int_{z_0}^{z}\sigma_1\right)\right)\\&=\eta_2^{-1/2}\left[\left(1-\exp\left(\frac{1}{2}\int_{z_0}^{z}(\sigma_2-\sigma_1)\right)\right)+\left(1-\eta_{02}^{1/2}\eta_{01}^{-1/2}\right)\right]\end{aligned}$$

and $\|\partial_z\eta_i^{-1/2}\|\leqq C\|\sigma_i\|$. Thus, after some manipulation,

$$\left\|\partial_z\left(\eta_2^{-1/2}-\eta_1^{-1/2}\right)\right\|\leqq C\left\{\|\sigma_2-\sigma_1\|^2+|\eta_{02}-\eta_{01}|^2\right\}^{1/2}.$$

Also Proposition 2.1 shows that

$$\int_z^{2T-z}|\partial_z u_2|^2\leqq Q(z)\leqq C(\sigma_2,\,\eta_{20},\,f_2)$$

so the conclusion follows from Lemma 1.4 with $w\to\partial_z u_2$, $\omega\to\sigma_1-\sigma_2$, $h\to h_2-h_1$, $\psi\to\eta_2^{-1/2}-\eta_1^{-1/2}$. Q.E.D.

COROLLARY 2.3. *τ_0 extends to a locally Lipschitz map*:

$$L^2[z_0,z_1]\oplus L^2[z_1,2T-z_1]_-\oplus L^2[z_0,2T-z_0]\oplus R^+\to L^2[z_0,2T\text{-}z_0].$$

More precisely, for each (σ,h,f,η_0) there exist positive constants r and k for which

$$\|\sigma-\tilde{\sigma}\|^2+\|h-\tilde{h}\|^2+\|f-\tilde{f}\|^2+|\eta_0-\tilde{\eta}_0|^2<r^2$$

implies

$$\|\tau_0(\sigma,h,f,\eta_0)-\tau_0(\tilde{\sigma},\tilde{h},\tilde{f},\tilde{\eta}_0)\|<k\left(\|\sigma-\tilde{\sigma}\|^2+\|h-\tilde{h}\|^2+\|f-\tilde{f}\|^2+|\eta_0-\tilde{\eta}_0|^2\right)^{1/2}.$$

The parameters r and k are (bounded by) functions of $\|\sigma\|$, $\|f\|$, z_1-z_0, and η_0.

Proof of Theorem 0.1. If we take $z_0=0$, $z_1=T$, the dependence of τ_0 on the second argument disappears altogether. In fact, from the definitions in the introduction,

$$\tau(\sigma)=\tau_0(\sigma,0,0,1).$$

Thus Theorem 0.1 follows immediately from Corollary 2.3. Q.E.D.

For the sake of brevity set

$$K_D := L^2[z_0,z_1]\oplus L^2[z_1,2T-z_1]\oplus L^2[z_0,2T-z_0]\oplus R^+,$$
$$K_D^\infty := C^\infty[z_0,z_1]\oplus C^\infty[z_1,2T-z_1]\oplus C^\infty[z_0,2T-z_0]\oplus R^+,$$
$$H_D := L^2[z_0,z_1]\oplus L^2[z_1,2T-z_1],$$
$$H_T := L^2[z_0,2T-z_0].$$

The formal linearization of τ_0 in (σ,h) is given by

$$D\tau_0(\sigma,h,f,\eta_0)\cdot(\sigma^1,h^1) = \partial_t u^1\big|_{z=z_0}$$

where u solves (2.1) and u^1 solves

$$(\partial_t^2-\partial_z^2-\sigma\partial_z)u^1=\sigma^1\partial_z u \quad \text{in } \Omega, \tag{2.4a}$$
$$\partial_z u^1(z_0,\cdot)=0, \tag{2.4b}$$
$$(\partial_t+\partial_z)u^1(z_1,\cdot)=h^1, \tag{2.4c}$$
$$\bar{u}^1(z)=-\frac{1}{2}\eta^{-1/2}\int_{z_0}^z\sigma^1. \tag{2.4d}$$

All of this makes sense a priori when σ, h, f, σ^1, and h^1 are smooth. The first task is to extend $D\tau_0$.

THEOREM 2.4. *For smooth* $(\sigma,h,f,\eta_0)\in K_D^\infty$, $D\tau_0$ *extends to a bounded linear map:* $H_D\to H_T$. *Moreover,*

$$\|\sigma^1\|^2+\|h^1\|^2\leqq C\|D\tau_0(\sigma,h,f,\eta_0)\cdot(\sigma^1,h^1)\|^2 \tag{2.5}$$

so in particular the range of $D\tau_0$ *is closed in* H_T.

Proof. The boundedness of $D\tau_0$, hence the existence of the extension, follow immediately from the application of Lemma 1.4 to the boundary value problem (2.4).

A simple "Poincaré inequality" argument gives

$$\int_{z_0}^z|\sigma^1|^2\leqq C\int_{z_0}^z|\partial_z\bar{u}^1|^2, \qquad z_0\leqq z\leqq z_1$$

(or see [21, inequality (13)]). Then Lemma 1.5 yields the estimate (2.5). Q.E.D.

We next study the adjoint of $D\tau_0$. Suppose that v solves the boundary value problem

$$(\eta\partial_t^2-\partial_z\eta\partial_z)v=0 \quad \text{in } \Omega, \tag{2.6a}$$
$$\partial_z v(z_0,\cdot)=\eta_0^{-1}\phi\in C^\infty[z_0,2T-z_0], \qquad \phi(2T-z_0)=0, \tag{2.6b}$$
$$(\partial_t-\partial_z)v(z_1,\cdot)=0, \tag{2.6c}$$
$$\bar{\bar{v}}\equiv 0. \tag{2.6d}$$

Then Green's theorem, i.e. integration by parts of

$$\int_{z_0}^{z_1}dz\int_z^{2T-z}dt\,\partial_t v\left(\eta\partial_t^2u^1-\partial_z\left(\eta\partial_z u^1\right)\right)$$

and repeated use of the boundary value problem (2.1) and the adjoint problem (2.6), yields the identity

$$\left\langle\phi,\ D\tau_0(\sigma,h,f,\eta^0)\cdot(\sigma^1,h^1)\right\rangle=\eta(z_1)\int_{z_1}^{2T-z_1}dt\,\partial_t v(z_1,t)\ h^1(t)$$
$$+\int_{z_0}^{z_1}dz\,\eta(z)\left\{\partial_z\bar{v}\partial_z\bar{u}^1(z)+\sigma^1\left(\int_z^{2T-z}dt\,\partial_t v(z,t)\partial_z u(z,t)\right)\right\}.$$

Now

$$\int_{z_0}^{z_1} dz\,\eta\partial_z\bar{v}\partial_z\bar{u}^1 = -\frac{1}{2}\int_{z_0}^{z_1} dz\,\eta\partial_z\bar{v}\partial_z\left(\eta^{-1/2}\int_{z_0}^{z}\sigma^1\right)$$

$$= -\frac{1}{2}\int_{z_0}^{z_1} dz\,\eta^{1/2}\partial_z\bar{v}\left(\sigma^1 - \frac{1}{2}\sigma\int_{z_0}^{z}\sigma^1\right)$$

$$= -\frac{1}{2}\int_{z_0}^{z_1} dz\,\sigma^1\left\{\eta^{1/2}\partial_z\bar{v} + \frac{1}{2}\int_{z}^{z_1}\sigma\eta^{1/2}\partial_z\bar{v}\right\}$$

whence follows the identity, valid for smooth ϕ with $\phi\,(2T-z_0)=0$,

$$D_{\tau_0}^*(\sigma,h,f,\eta_0)\phi = \left(-\frac{1}{2}\left(\eta^{1/2}\partial_z\bar{v} + \frac{1}{2}\int^{z_1}\sigma\eta^{1/2}\partial_z\bar{v}\right)\right.$$

$$\left. + \eta\int_{z}^{2T-z} dt\,\partial_t v\partial_z u,\ \eta(z_1)\partial_t v(z_1,\cdot)\right).$$

PROPOSITION 2.5. *For C depending on σ, h, f, η^0, T, and z_1-z_0, and $\phi\in C^\infty[z_0,2T-z_0]$ with $\phi(2T-z_0)=0$,*

$$\|\phi\| \leqq C\|D\tau_0^*(\sigma,h,f,\eta_0)\cdot\phi\|.$$

Proof. This argument is very similar to the proof of Lemmas 1.1, 1.3. Set

$$Q(z) = \frac{1}{2}\int_{z}^{2T-z} dt\left\{(\partial_t v)^2 + (\partial_z v)^2\right\}(z,t).$$

From the identity (1.4) we obtain

$$Q(z) = Q(z_1) + \frac{1}{2}\int_{z}^{z_1}|\partial_z\bar{v}|^2 + \int_{z}^{z_1} d\zeta\,\sigma(\zeta)\int_{\zeta}^{2T-\zeta}|\partial_z v(\zeta,t)|^2. \tag{2.7}$$

From (2.6c)

$$Q(z_1) = \int_{z_1}^{2T-z_1}|\partial_t v|^2(z_1,\cdot).$$

On the other hand, as we have assumed σ to be smooth, the operator

$$\psi \to \psi + \frac{1}{2}\eta^{-1/2}\int^{z_1}\sigma\eta^{1/2}\psi$$

is a Volterra operator of the second kind on $L^2[z_0,z_1]$ with continuous kernel, hence invertible. In particular for suitable $C>0$,

$$\|\partial_z\bar{v}\|_{L^2[z,z_1]} \leqq C\left\|-\frac{1}{2}\left(\eta^{1/2}\partial_z\bar{v} + \frac{1}{2}\int^{z_1}\sigma\eta^{1/2}\partial_z\bar{v}\right)\right\|_{L^2[z,z_1]}$$

for $z_0\leqq z\leqq z_1$.

On the other hand,

$$\left(-\frac{1}{2}\left(\eta^{1/2}\partial_z\bar{v} + \frac{1}{2}\int^{z_1}\sigma\eta^{1/2}\partial_z\bar{v}\right),\ \eta(z_1)\partial_t v(z_1,\cdot)\right)$$

$$= D\tau^*(\sigma,h,f,\eta_0)\cdot\phi - \left(\eta\int_{z}^{2T-z} dt\,\partial_t v\partial_z u,\ 0\right)$$

and

$$\int_z^{2T-z} dt\,\partial_t v\,\partial_z u \leqq CQ^{1/2}(z)$$

from Cauchy–Schwarz and Proposition 2.1. Thus

$$\begin{aligned} Q(z_1)+\frac{1}{2}\int_z^{z_1}|\partial_z\bar{v}|^2 &\leqq C\left\{\eta(z_1)^2\int_{z_1}^{2T-z_1}|\partial_t v(z_1,\cdot)|^2\right. \\ &\qquad \left. +\frac{1}{4}\int_z^{z_1}\left(\eta^{1/2}\partial_z\bar{v}+\frac{1}{2}\int^{z_1}\sigma\eta^{1/2}\partial_z\bar{v}\right)^2\right\} \\ &\leqq C\left\{\left\|D\tau^*(\sigma,h,f,\eta_0)\cdot\phi\right\|+\int_z^{z_1}d\zeta\left(\eta(\zeta)\int_\zeta^{2T-\zeta}dt\,\partial_t v\,\partial_z u\right)^2\right\} \\ &\leqq C_1\left\{\left\|D\tau^*(\sigma,h,f,\eta_0)\cdot\phi\right\|^2+C_2\int_z^{z_1}Q\right\}. \end{aligned}$$

Thus we can replace the RHS of (2.7) by

$$Q(z)\leqq C_1\left\|D\tau^*(\sigma,h,f,\eta_0)\cdot\phi\right\|^2+2\int_z^{z_1}(2|\sigma|+C_2)Q$$

whence from Gronwall's inequality

$$\|\phi\|\leqq 2Q(z_0)\leqq C\left\|D\tau^*(\sigma,h,f,\eta_0)\cdot\phi\right\|^2. \qquad \text{Q.E.D.}$$

COROLLARY 2.6. *For smooth* $(\sigma,h,f,\eta_0)\in K_D^\infty$, $D\tau(\sigma,h,f,\eta_0)$ *is a linear isomorphism:* $H_D\to H_T$. *Further, the bounds for* $\|D\tau\|$, $\|D_\tau^{-1}\|$ *depend only on* $\|\sigma\|$, $\|h\|$, $\|f\|$, η_0, T, *and* z_1-z_0.

Proof. The previous proposition shows that the adjoint $D\tau^*$ is injective, since the $\phi\in C^\infty[z_0,2T-z_0]$ with $\phi(2T-z_0)=0$ are dense in H_T. Therefore, the range of $D\tau$ is dense. We have already noted that it is closed: so $D\tau$ is surjective. Proposition 2.4 gave the required bounds. Q.E.D.

THEOREM 2.7. $D\tau$ *is a locally, Lipschitz-continuous map on* K_D^∞ *with values in* $L(H_D,H_T)$, *whence* $D\tau$ *extends to a locally Lipschitz map*

$$K_D\times H_D\to H_T.$$

Proof. Select (σ,h,f_0,η_0) and $(\tilde{\sigma},\tilde{h},\tilde{f}_0,\tilde{\eta}_0)$ in K_D^∞, and let u, $\tilde{u}$ be the corresponding solutions of (2.1). For (smooth) (σ^1,h^1) let u^1 and $\tilde{u}^1$ be the corresponding solutions of (2.4). The difference $v=\tilde{u}^1-u^1$ solves

$$(2.8a)\qquad \left(\partial_t^2-\partial_z^2-\sigma\partial_z\right)v=\sigma^1(\partial_z\tilde{u}-\partial_z u)+(\tilde{\sigma}-\sigma)\partial_z\tilde{u}^1 \quad \text{in } \Omega,$$

$$(2.8b)\qquad \partial_z v(z_0,\cdot)=0,$$

$$(2.8c)\qquad (\partial_z+\partial_t)v(z_0,\cdot)=0,$$

$$(2.8d)\qquad \bar{v}(z)=-\frac{1}{2}(\tilde{\eta}^{-1/2}-\eta^{1/2})(z)\int_{z_0}^z\sigma^1.$$

Note that

$$\left\|\partial_z\cdot\left(\tilde\eta^{-1/2}-\eta^{-1/2}\right)\int\sigma^1\cdot\right\| = \left\|\left(\partial_z\left(\tilde\eta^{-1/2}-\eta^{-1/2}\right)\right)\int\sigma^1\right\| + \left\|\left(\tilde\eta^{-1/2}-\eta^{-1/2}\right)\sigma^1\right\|$$

$$\leqq \left\|\partial_z\left(\tilde\eta^{-1/2}-\eta^{-1/2}\right)\right\|\left\|\int\sigma^1\right\|_\infty + \left\|\tilde\eta^{-1/2}-\eta^{-1/2}\right\|_\infty\left\|\sigma^1\right\|$$

$$\leqq C\|\tilde\sigma-\sigma\|\|\sigma^1\|.$$

Now Proposition 2.2 states that, for suitable C,

$$\int_z^{2T-z} dt\cdot\partial_z(\tilde u-u)(z,t)\cdot^2 \leqq C\left\{\|\tilde\sigma-\sigma\|^2+\|\tilde f-f\|^2+\|\tilde h-h\|^2+|\tilde\eta_0-\eta_0|^2\right\}.$$

Implicit in the proof of the Theorem 2.4 is the estimate

$$\int_z^{2T-z} dt\left|\partial_z\tilde u^1\right|^2(z,t)\leqq C\left\{\|\sigma^1\|^2+\|h^1\|^2\right\},$$

where C depends on $\|\tilde f_0\|$, $\|\tilde\sigma\|$, $\tilde\eta_0$, and z_1-z_0. Clearly Lemma 1.4 extends to the case in which the RHS of the wave equation is given by a sum:

$$\sum_{i=1}^N \omega_i w_i.$$

Taking $N=2$, $\omega_1=\sigma^1$, $w_1=\partial_z(\tilde u-u)$, $\omega_2=\tilde\sigma-\sigma$, $w_2=\partial_z\tilde u^1$, gives the estimate

$$\|\partial_t v(z_0,\cdot)\|\leqq C\left(\|\sigma^1\|^2+\|h^1\|^2\right)^{1/2} \cdot\left(\|\sigma-\tilde\sigma\|^2+\|h-\tilde h\|^2+\|f_0-\tilde f_0\|^2+|\eta_0-\tilde\eta_0|^2\right)^{1/2} \tag{2.9}$$

where C is bounded by a smooth function of $\|\sigma\|$, $\|\tilde\sigma\|$, $\|f_0\|$, $\|\tilde f_0\|$, η_0, $\tilde\eta_0$, and z_1-z_0. For any smooth σ, $\tilde\sigma$, etc. belonging to a bounded set in K_D, the inequality (2.9) is therefore an explicit local Lipschitz estimate. Q.E.D.

THEOREM 2.8. *For each $(\sigma,h,f,\eta_0)\in K_D$ there exist $k,r>0$ so that for $(\sigma^1,h^1)\in K_D$ with $\|\sigma^1\|^2+\|h^1\|^2=1$, and all $\varepsilon<r$,*

$$\left\|D\tau_0(\sigma,h,f_0,\eta_0)\cdot(\sigma^1,h^1)-\frac{1}{\varepsilon}\left[\tau_0\left(\sigma+\varepsilon\sigma^1,h+\varepsilon h^1,f,\eta_0\right)-\tau_0(\sigma,h,f,\eta_0)\right]\right\|<k\varepsilon.$$

Proof. Let $\tilde\sigma=\sigma+\varepsilon\sigma^1$, $\tilde h=h+\varepsilon h^1$,

$$\tilde\eta(z)=\eta_0\exp\int_{z_0}^z\tilde\sigma,\qquad \eta(z)=\eta_0\exp\int_{z_0}^z\sigma.$$

Let u solve (2.1), $\tilde u$ solve (2.1) with η, h replaced by $\tilde\eta$, $\tilde h$ and u^1 solves (2.4). Then the quantity we need to estimate is

$$\|\partial_t v(z_0,\cdot)\|$$

where

$$v=u^1-\varepsilon^{-1}(\tilde u-u)$$

solves the boundary value problem

$$(2.10a) \qquad \left(\partial_t^2 - \partial_z^2 - \sigma\partial_z\right)v = \sigma^1\partial_z(u-\tilde{u}),$$

$$(2.10b) \qquad \partial_z v(z_0,\cdot) = 0,$$

$$(2.10c) \qquad (\partial_t + \partial_z)v(z_1,\cdot) = 0,$$

$$(2.10d) \qquad \bar{v} = -\frac{1}{2}\eta^{-1/2}\sigma^1 - \frac{1}{\varepsilon}\left(\tilde{\eta}^{-1/2} - \eta^{-1/2}\right).$$

Note that

$$(2.11) \qquad \tilde{\eta}^{-1/2}(z) - \eta^{-1/2}(z) = \eta^{-1/2}(z)\left(\exp - \frac{\varepsilon}{2}\int_{z_0}^{z}\sigma^1 - 1\right)$$

$$= -\frac{\varepsilon}{2}\eta^{-1/2}(z)\int_{z_0}^{z}\sigma^1 + r(\varepsilon,z).$$

Since $\|\sigma^1\|_{L^2} \leqq 1$, $(1/\varepsilon^2)r(\varepsilon,z)$ is uniformly bounded as $\varepsilon \to 0$ by a function of η_0, $\|\sigma\|$, and $(z_1 - z_0)$. Also,

$$\frac{d}{dz}r(\varepsilon,z) = \left(\frac{d}{dz}\eta^{-1/2}(z)\right)\left\{\exp\left[\left(-\frac{\varepsilon}{2}\int_{z_0}^{z}\sigma^1\right) - 1\right] + \frac{\varepsilon}{2}\int_{z_0}^{z}\sigma^1\right\}$$

$$+ \eta^{-1/2}(z)\left\{-\frac{\varepsilon}{2}\sigma^1(z)\left[\exp\left(-\frac{\varepsilon}{2}\int_{z_0}^{z}\sigma^1\right) - 1\right]\right.$$

$$\left. - \frac{1}{2}\sigma(z)r(\varepsilon,z) - \frac{\varepsilon}{2}\sigma^1(z)\left(\tilde{\eta}^{-1/2}(z) - \eta^{-1/2}(z)\right)\right\}.$$

So (from (2.11))

$$(2.12) \qquad \left\|\frac{dr}{dz}\right\| = O(\varepsilon^2)$$

where the constant implicit in the Landau symbol depends on η_0, $\|\sigma\|$, and $z_1 - z_0$. For convenience, we shall make this dependence a convention for our use of the Landau symbol for the rest of the proof.

It follows from (2.10d), (2.11), and (2.12) that

$$\left\|\frac{d\bar{v}}{dz}\right\| = O(\varepsilon).$$

Note that the RHS of (2.10a) is of the form $\sigma^1 w$, with $\int|\sigma^1|^2 \leqq 1$ and

$$w = \partial_z(u - \tilde{u})$$

satisfying

$$\int_z^{2T-z} dt\,(w(z,t))^2 = O(\varepsilon^2)$$

according to Proposition 2.2. We are once again in position to apply Lemma 1.4. We conclude that

$$\|\partial_t v(z_0,\cdot)\| = O(\varepsilon). \qquad \text{Q.E.D.}$$

Remark. This last estimate is more than sufficient to establish that τ_0 is differentiable as a function of its first two arguments. In fact, similar estimates show that τ_0 is of class C^2 on K_D, i.e. as a function of all of its arguments. Conceivably, τ_0 is actually smooth.

PROPOSITION 2.9. *Let* $r>0$, $(\sigma^0,h^0,f^0,\eta_0^0)\in K_D$. *Set*

$$B_r=\left\{(\sigma,h)\in H_D:\|\sigma-\sigma^0\|^2+\|h-h^0\|^2\leqq r^2\right\}.$$

Then there exists $C=C(\sigma^0,h^0,f^0,\eta_0^0,r,z_1-z_0)$ *so that for any* $(\sigma,h)\in B_r$,

$$\|\sigma\|^2+\|h\|^2\leqq C\left\{\|\tau(\sigma,h,f^0,\eta_0^0)\|^2+\|f^0\|^2\right\}.$$

Proof. It follows immediately from Lemma 1.2 that

$$\|h\|^2+\frac{1}{2}\int_{z_0}^{z_1}(\bar{u}')^2\leqq C\left\{\|\tau(\sigma,h,f^0,\eta_0^0)\|^2+\|f^0\|^2\right\}$$

where C depends on $\|\sigma\|\leqq r+\|\sigma^0\|$, η_0^0, and z_1-z_0. On the other hand

$$\bar{u}'=(\eta^{-1/2})'=\left[(\eta_0^0)^{-1/2}\exp\left(-\frac{1}{2}\int\sigma\right)\right]'=-\frac{1}{2}\eta^{-1/2}\sigma$$

and

$$\begin{aligned}\eta^{-1/2}&\leqq(\eta_0^0)^{-1/2}\exp\left(-\frac{1}{2}\int_{z_0}^{z_1}|\sigma|\right)\\&\leqq(\eta_0^0)^{-1/2}\exp\left(-\frac{1}{2}(z_1-z_0)^{1/2}\|\sigma\|\right)\\&\leqq(\eta_0^0)^{-1/2}\exp\left\{-\frac{1}{2}(z_1-z_0)^{1/2}(r+\|\sigma^0\|)\right\}\end{aligned}$$

whence the conclusion follows. Q.E.D.

THEOREM 2.10. *Let* $(\sigma^0,h^0,f^0,\eta_0^0)\in K_D$. *Then there exist constants*

$$\begin{aligned}r&=r(\|\sigma^0\|,\|h^0\|,\|f^0\|,\eta_0,z_1-z_0),\\C&=C(\|\sigma^0\|,\|h^0\|,\|f^0\|,\eta_0^0,r,z_1-z_0)\end{aligned}$$

so that if $r<R$, *then*

$$|\eta_0-\eta_0^0|^2+\|f-f^0\|^2+\|g-\tau_0(\sigma^0,h^0,f^0,\eta_0^0)\|^2<r^2$$

implies that there exists a unique solution (σ,h) *of the equation*

$$\tau_0(\sigma,h,f,\eta_0)=g\in H_T. \tag{2.13}$$

Moreover,

$$\|\sigma-\sigma^0\|^2+\|h-h^0\|^2\leqq C\left\{(\eta_0-\eta_0^0)^2+\|f-f^0\|^2+\|g-\tau_0(\sigma^0,h^0,f^0,\eta^0)\|^2\right\}.$$

Proof. From Corollary 2.6, $D\tau$ is an isomorphism for smooth data. From Theorem 2.7, the lower bounds of Corollary 2.6 and Proposition 2.5 for $D\tau$ and $D\tau^*$ respectively survive the extension to $K_D\times H_D$, so $D\tau$ is a linear isomorphism for all

$(\sigma,h,f,\eta_0)\in K_D$. Now the implicit mapping theorem guarantees the local existence and continuous dependence on g, f, η_0 of solutions of the functional equation (2.13).

The uniqueness of global solutions of (2.13) follows from (a slight extension of) the results of [21]. We prefer to give an alternative proof more closely related to the arguments which we have extended to several-dimensional problems—see [22].

Suppose $(\tilde\sigma,\tilde h)\in H_D$ with $\tau(\tilde\sigma,\tilde h f,\eta_0)=\tau(\sigma,h,f,\eta_0)$. Denoting by $\tilde u$ and the relevant solutions of (2.1), we see that the difference $v=\tilde u-u$ solves

$$(\partial_t^2-\partial_z^2-\sigma\partial_z)v=(\tilde\sigma-\sigma)\partial_z\tilde u, \tag{2.14a}$$

$$\partial_z v(z_0,\cdot)=0, \tag{2.14b}$$

$$(\partial_z+\partial_t)v(z_1,\cdot)=\tilde h-h, \tag{2.14c}$$

$$\bar v(z)=\tilde\eta^{-1/2}(z)-\eta^{-1/2}(z). \tag{2.14d}$$

Write, $v=v_{\mathrm I}+v_{\mathrm{II}}$, where $v_{\mathrm I}$ solves

$$(\partial_t^2-\partial_z^2-\sigma\partial_z)v_{\mathrm I}=0$$

and (2.14b, c, d) while v_{II} solves (2.14a, b, c) and

$$\bar v_{\mathrm{II}}\equiv 0.$$

Consider for the moment (2.14) restricted to the triangle $\{(z,t): z_0\leqq z\leqq z_2,\ z\leqq t\leqq 2z_2-z\}$, where $z_2\in(z_0,z_1)$, for which the right-hand boundary condition (2.14c) plays no role. Define

$$Q_{\mathrm I}^0(z)=\int_z^{2z_2-z}dt\left\{(\partial_t v_{\mathrm I})^2+(\partial_z v_{\mathrm I})^2\right\}(z,t)$$

and similarly for Q_{II}^0. Since the Cauchy data for v vanish on $\{z=z_0\}$ by hypothesis, we have

$$Q_{\mathrm I}^0(z_0)=Q_{\mathrm{II}}^0(z_0).$$

According to Lemma 1.1,

$$\int_z^{2z_2-z}dt(\partial_z\tilde u)^2(z,t)\leqq C(\eta_0,z_2-z_0,\|\tilde\sigma\|)\|\tilde\sigma\|^2$$

whence from Lemma 1.2

$$Q_{\mathrm{II}}^0(z_0)\leqq C(\eta_0,z_2-z_0,\|\sigma\|,\|\tilde\sigma\|)\|\sigma-\tilde\sigma\|^2\|\tilde\sigma\|^2(z_2-z_0).$$

From Lemma 1.5

$$\int_{z_0}^{z_2}dz\left(\partial_2(\eta^{-1/2}-\tilde\eta^{-1/2})\right)^2\leqq C(\eta_0,z_2-z_0,\|\sigma\|)Q_{\mathrm I}^0(z_0)$$

so

$$|\eta^{-1/2}-\tilde\eta^{-1/2}|\leqq C(\eta_0,z_2-z_0,\|\sigma\|)Q_{\mathrm I}^0(z_0)^{1/2}.$$

Also

$$\sigma-\tilde\sigma=-2\eta^{1/2}\partial_z(\eta^{-1/2}-\tilde\eta^{-1/2})-(1-\eta^{1/2}\tilde\eta^{-1/2})\tilde\sigma$$

whence

$$\begin{aligned}\|\sigma-\tilde\sigma\|^2&\leqq C(\eta_0,z_2-z_0,\|\sigma\|,\|\tilde\sigma\|)Q_{\mathrm I}^0(z_0)\\&\leqq C(\eta_0,z_2-z_0,\|\sigma\|,\|\tilde\sigma\|)\|\sigma-\tilde\sigma\|^2(z_2-z_0).\end{aligned}$$

Now C is continuous in $z_2 - z_0 \to 0$, so for $z_2 - z_0$ small enough, we obtain $\sigma = \tilde{\sigma}$ $p.p.$ on $[z_0, z_2]$. Consequently the equation (2.14a) becomes homogeneous in the slab $\{z_0 \leqq z < z_2\}$, and from Lemma 1.5 we conclude that $v \equiv 0$ in this slab, in particular that v and $\partial_z v$ vanish for $z - z_2$, $z_2 \leqq t \leqq 2T - z_2$. Now we can replace z_0 by z_2 and repeat the argument. After finitely many repetitions we obtain $\sigma - \tilde{\sigma}$ on $[z_0, z_1]$, i.e. we have established global uniqueness for (2.13). Q.E.D.

Remark. This "downward continuation" or "layer-stripping" argument of course gives a (direct) uniqueness result for the (global) inverse problem, i.e. the functional equation (0.4) with $f = -\delta$.

As before, with the special choice $z_0 = 0$, $z_1 = T$, $f \equiv 0$, $\eta_0 = 1$, we obtain Theorem 0.3 as a corollary of Theorem 2.10. Since Theorem 0.2 is implied by Theorem 0.3, we have completed the proofs of our results.

HOMOGENIZATION FOR A VOLTERRA EQUATION*

HEDY ATTOUCH† AND ALAIN DAMLAMIAN‡

Abstract. A model is given for the nonlinear heat equation in a heterogeneous medium with memory. Its homogenization is carried out in two particular cases (including the linear one).

Key words. Volterra equation, homogenization, heat flow, heterogeneous material with memory

AMS(MOS) subject classifications. Primary 45D05, 73K20, 80A20, 45G10, 47H05

1. Introduction. In a heterogeneous medium with memory, a model for the heat equation (see Nohel [1]) is

$$\frac{\partial \xi}{\partial t} + \operatorname{div}_x Q = h_1, \tag{1.1}$$

where h_1 is a given diffused source term, ξ is the internal energy, and Q is the heat flux. The latter are assumed to be functionals of the temperature distribution u with "memory":

$$\xi(t,x) = b_0(x)u(t,s) + \int_{-\infty}^{t} \beta(x,t-s)u(s,x)\,ds, \tag{1.2}$$

$$Q(t,x) = -c_0(x)\sigma(x,\nabla u(t,x)) + \int_{-\infty}^{t} \gamma(x,t-s)\sigma(x,\nabla u(s,x))\,ds. \tag{1.3}$$

Equation (1.1) is considered on the product $\Omega \times (-\infty, T)$, where Ω is a bounded regular domain in R^3 (or R^N); the function σ: $\Omega \times R^N \to R^N$, $(x,r) \to \sigma(x,r)$ represents a nonlinear flux law. Its dependence upon x specifies the heterogeneity of the medium. Similarly $b_0(x)$, $\beta(x,T)$, $c_0(x)$, $\gamma(x,t)$ characterize the spatial heterogeneity of the other thermodynamical parameters.

To equation (1.1) are added boundary and initial conditions which will be specified later.

The questions considered here are:

—under what suitable set of hypotheses is equation (1.1) well posed (existence and uniqueness);

—under what further conditions can one treat the corresponding homogenization problem; in other words, if all parameters involved $(\sigma, b_0, \beta, c_0, \gamma)$ depend upon another variable ε measuring the "tightness" of the heterogeneity of the medium (typically $b_0^\varepsilon(x) = b_0(x/\varepsilon)$ where $b_0(y)$ is periodic), one can find a limit problem whose solution would be the limit of the solutions u_ε, and whose structure would be similar to (1.1), (1.2), (1.3)? We will give positive answers to both questions in particular cases only. The paper is organized as follows:

* Received by the editors February 9, 1984, and in revised form July 23, 1985. This research was sponsored by the U.S. Army under contract DAAG29-80-C-0041.

† Laboratoire de Mathématiques, Université Paris Sud, 91405 Orsay Cedex, France.

‡ Centre de Mathématiques, Ecole Polytechnique, 91128 Palaiseau Cedex, France.

In the next section (§2), we reformulate the problem in terms of a Volterra equation (i.e. with memory convolution kernels), and we make precise the hypotheses on the nonlinear term σ.

In §3 we then study what we called the splitting case, when c/c_0 is independent of the space variable x. In this situation one can apply the nice method of Crandall and Nohel [1] in order to transform the problem into a Lipschitz perturbation of a variational monotone evolution equation for which sophisticated, albeit known, techniques apply to yield a positive answer to the aforementioned questions. When dealing with the homogenization, we of course make use of various results from that theory, some of which are quite involved (see the quoted references).

In the general situation (§4) we obtain existence and uniqueness via an argument of local monotonicity combined with global estimates, both of which require some extra conditions on the various physical parameters. In §5 we give a first result for homogenization in the same framework; it is however restricted to the linear case and this for the obvious reason that we make use of the Laplace transform together with homogenization theory for complex-valued elliptic problems in order to specify the limit problem. To our knowledge, there is no result pertaining to the homogenization of the nonlinear case; any progress in that direction would be very welcome indeed.

A first approach to this type of problem appeared in Raynal [1].

2. Reformulation of the problem as a Volterra equation. Let $*$ denote the usual convolution with respect to t on $[0, +\infty[$.

As "initial" condition, we assume the history of the medium to be known for t negative. One can then rewrite (1.1), (1.2), (1.3) as:

$$\frac{\partial}{\partial t}[b_0 u + \beta * u] + \operatorname{div}_x(-c_0\sigma + \gamma * \sigma) = h \tag{2.1}$$

where σ stands for $\sigma(\cdot, \nabla u(\cdot,\cdot))$ and the right-hand side h includes the history of the system up to time zero.

It is customary to define

$$c(x,t) = c_0(x) - \int_0^t \gamma(x,s)\,ds \tag{2.2}$$

and to assume that $c(x,t)$ and $b_0(x)$ are strictly positive valued (a physical condition). With these notations (2.1) can be written as

$$b_0 u' - \operatorname{div}_x\{(c * \sigma)'\} = h - \beta_0 u - \beta' * u, \tag{2.3}$$

where "$'$" indicates a time derivative.

The initial condition becomes a Cauchy data at $t=0$:

$$u(0) = u_0 \quad \text{in } L^2(\Omega); \tag{2.4}$$

the boundary condition is taken to be compatible with the operator $-\operatorname{div}_x(\sigma(\nabla u))$, for example

$$u = 0 \quad \text{on } \partial\Omega \times (0,T). \tag{2.5}$$

Problem (2.3), (2.4), (2.5), upon integration with respect to time appears as a Volterra type integral equation (cf. 3.1).

We now make precise the type of function σ appearing here: let j: $(x,r)\in\Omega\times R^N \mapsto j(x,r)\in R^+$, be of Caratheodory type, convex and equicoercive in r. Assume further that $j(x,0)\equiv 0$; let σ be its subdifferential with respect to r and put:

$$\phi(u)=\begin{cases}\int_\Omega j(x,\nabla u(x))\,dx & \text{for } u\in W_0^{1,1}(\Omega),\\ +\infty & \text{otherwise;}\end{cases} \tag{2.6}$$

then it is shown in Attouch-Damlamian [1] that ϕ is lower semi-continuous (l.s.c.) convex on $L^2(\Omega)$; moreover, denoting by $\partial\phi$ the subdifferential of ϕ on $L^2(\Omega)$ one has:

$$v\in\partial\phi(u)\Rightarrow\begin{cases}u\in W_0^{1,1}(\Omega)\cap L^2(\Omega),\\ v=-\operatorname{div}h \text{ for some } h \text{ such that } h(x)\in\sigma(x,\nabla u(x)) \text{ a.e.}\end{cases} \tag{2.7}$$

This is the sense in which σ is used in (2.3) and it also gives a meaning to the Dirichlet condition (2.5) (when j is even with respect to r, (2.7) is actually an equivalence).

3. The splitting case. By this, we mean that c/c_0 is independent of x. Equivalently, by an obvious change of notation (for σ), c and γ can be taken independent of x (c_0 is taken to be 1).

3.1. Existence and uniqueness. Integration of (2.3) with respect to time from 0 to t yields:

$$b_0u-\operatorname{div}_x(c*\sigma)=b_0u_0-\beta*u+H \tag{3.1}$$

where H is the integral of h.

PROPOSITION 3.2. *Assume that b_0 and b_0^{-1} are in $L^\infty(\Omega)^+$, that β is in $L^\infty(\Omega;BV(0,T))$, and that γ is in $BV(0,T)$. Then equation* (3.1) *has a unique solution u in $C([0,T];L^2(\Omega))\cap L^1(0,T,W_0^{1,1}(\Omega))$. Furthermore, du/dt is in $L^2(\Omega\times(0,T))$.*

Proof. We follow here the ideas of Crandall–Nohel [1]. Let e be the resolvant kernel of γ, i.e., the solution of

$$e-\gamma-\gamma*e=0. \tag{3.3}$$

Making use of standard results for convolution equations, one obtains that e belongs to $BV(0,T)$ as soon as γ does so. Using (3.3), (2.3) becomes

$$b_0\frac{du}{dt}-\operatorname{div}_x\sigma(x,\nabla u)=G(u),\qquad u(0)=u_0, \tag{3.4}$$

where

$$G(u)=h+h*e-(\beta_0+b_0e_0)u+b_0u_0e-u*(\beta_0e+b_0e'+\beta'+e*\beta'). \tag{3.5}$$

Above $\beta_0=\beta(0)$, $e_0=e(0)$ $(=\gamma(0))$ and β', e', are the measure derivatives of β and e.

It is easy to check that G is Lipschitz continuous from $L^1(0,t;L^2(\Omega))$ into itself for each $t>0$. In order to apply a fixed point theorem (as in Crandall–Nohel [1]), we first consider the following problem for w in $C([0,T];L^2(\Omega))$:

$$b_0\frac{du}{dt}-\operatorname{div}_x\sigma(x,\partial u)=w,\qquad u(0)=u_0. \tag{3.6}$$

Now, the operator $u \mapsto -(1/b_0)\mathrm{div}_x \sigma(x, \nabla u)$ is the subdifferential of ϕ (see (2.6)) on $L^2(\Omega)$ provided the norm on $L^2(\Omega)$ is chosen with the weight function $b_0(x)$ (since b_0 and b_0^{-1} are in $L^\infty(\Omega)^+$, this is an equivalent Hilbert norm on $L^2(\Omega)$). Therefore, (3.6) can be solved with classical estimates which allow to apply the Lipschitz fixed point theorem to solve (3.4), (3.5). □

3.2. Homogenization. We now assume that $b_0^\varepsilon, c_0^\varepsilon, \gamma^\varepsilon, \beta^\varepsilon$ and σ^ε depend upon an extra parameter ε measuring the size of the heterogeneity of the medium. A typical example is the periodic case where $b_0^\varepsilon(u) = \tilde{b}_0(x/\varepsilon)$, $c_0^\varepsilon(x) = \tilde{c}_0(x/\varepsilon)$, etc. $\cdots$ where $\tilde{b}_0(y)$, $\tilde{c}_0(y), \cdots$ are Y-periodic (Y is an N-dimensional parallelepipedon). We make the following hypotheses:

$$b_0^\varepsilon \text{ and } (b_0^\varepsilon)^{-1} \text{ are bounded in } L^\infty(\Omega)^+, \tag{3.7}$$

β^ε is bounded in $L^\infty(\Omega; BV(0,T))$ and γ^ε is bounded in $BV(0,T)$. Applying Proposition 3.2, one gets

PROPOSITION 3.8. *Under hypothesis* (3.7), *there exists a unique solution* u^ε *for problem* $(3.1)_\varepsilon$ *and* u^ε *is bounded in* $C([0,T]; L^2(\Omega))$ *by a constant involving only* $|h|_{L^2(Q)}$, $|\beta_0^\varepsilon|_{L^\infty(\Omega)}$, $|b_0^\varepsilon|_{L^\infty(\Omega)}$, $|(b_0^\varepsilon)^{-1}|_{L^\infty(\Omega)}$, $|\beta^\varepsilon|_{L^\infty(\Omega; BV(0,T))}$ *and* $|\gamma^\varepsilon|_{BV(0,T)}$. □

In order to study the convergence of u^ε when ε goes to zero, we make the following extra hypotheses (3.9)–(3.13):

(3.9) $j^\varepsilon(x,r)$ is coercive in r uniformly with respect to x and ε; more precisely: $\exists K_1 > 0$, $\exists K_2 \in R$ and $p > 2N/(N+2)$ such that $j^\varepsilon(x,r) > K_1|r|^{2N/(N+2)} - K_2$.

(3.10) ϕ^ε (defined as in (2.6)) converge in the sense of Mosco[1] on $L^2(\Omega)$ to a limit denoted ϕ, which is then known to be of the same integral form, associated to a convex function j (cf. Attouch [1]). Finally $\phi(u_0)$ is assumed to be finite.

(3.11) β^ε converges in the weak star topology of $L^\infty(\Omega; BV(0,T))$ to a limit β (consequently β_0^ε converges to β_0 in the weak star topology of $L^\infty(\Omega)$; in the periodic case, β is just the average of β^ε over a period).

(3.12) b_0^ε converges to some b_0 in the weak star topology of $L^\infty(\Omega)$ and e^ε converges to some e in the weak star topology of $BV(0,T)$. Then, e is the resolvant of some γ in $BV(0,T)$ (but γ has no relationship to the weak star limit of γ^ε in $BV(0,T)$).

Consequently, the mapping G^ε (the analogue of G in (3.5)) is bounded so that $G^\varepsilon(u^\varepsilon)$ is bounded in $L^2(0,T; L^2(\Omega))$ and therefore, via the properties of the solutions of the problems $(3.6)_\varepsilon$, one can conclude (making also use of (3.10)) that

(3.13) u^ε is bounded in $L^\infty(0,T; W_0^{1,p}(\Omega))$, du^ε/dt is bounded in $L^2(0,T; L^2(\Omega))$; hence, as a consequence of Aubin's lemma (see Aubin [1]), u^ε is compact in $C([0,T]; L^2(\Omega))$.

We will show now that u^ε has only one possible limit value u when ε goes to zero, which implies that u^ε converges to u. Let therefore ε_n go to zero so that u^{ε_n} converges to some u in $C([0,T]; L^2(\Omega))$:

PROPOSITION 3.14. *Under the above hypotheses* (3.13), $G^{\varepsilon_n}(u^{\varepsilon_n})$ *converges weakly in* $L^2(\Omega \times (0,T))$ *to* $G(u)$ (*as given in* (3.5)), *and* $b_0^{\varepsilon_n}\, du^{\varepsilon_n}/dt$ *converges weakly in* $L^2(\Omega \times (0,T))$ *to* $b_0 du/dt$.

[1] For the definition and properties of this convergence, see Mosco [1] or Attouch [2].

Proof. We write ε instead of ε_n for simplicity. $b_0^\varepsilon du^\varepsilon/dt$ is bounded in $L^2(Q)$ ($Q=\Omega\times(0,T)$) and for $\varphi(x,T)$ in $D(Q)$ one has:

$$\int_Q b_0^\varepsilon \frac{du^\varepsilon}{dt}\varphi = -\int_Q b_0^\varepsilon \frac{\partial\varphi}{\partial t}u^\varepsilon \to -\int_Q b_0 \frac{\partial\varphi}{\partial t}u$$

which proves the second claim. For $G^\varepsilon(u^\varepsilon)$, each term can be treated independently; let us show convergence for the worst case: $w^\varepsilon=\beta^{\varepsilon\prime} * u^\varepsilon * e^\varepsilon$. First

$$w^\varepsilon(x,t)=\int_0^t e^\varepsilon(t-s)\int_0^s u^\varepsilon(x,s-\sigma)\,d\beta^\varepsilon(x,\sigma)\,ds$$

so that

$$|w^\varepsilon(x,\cdot)|_{L^\infty(0,T)}\leqq|e^\varepsilon|_{L^1(0,T)}|u^\varepsilon(x,\cdot)|_{L^\infty(0,T)}|\beta^\varepsilon(x,\cdot)|_{BV(0,T)},$$

and

$$|w^\varepsilon|_{L^2(\Omega;\,L^\infty(0,T))}<|e^\varepsilon|_{L^1(0,T)}|u^\varepsilon|_{L^2(\Omega;\,L^\infty(0,T))}|\beta^\varepsilon|_{L^\infty(\Omega;\,BV(0,T))}.$$

Consequently, w^ε is bounded in $L^2(\Omega;L^\infty(0,T))$ because of u^ε being bounded in $L^2(\Omega;H^1(0,T))$ is bounded in $L^2(\Omega;C([0,T]))$. By a similar argument, one checks that for almost every x in Ω, $u^\varepsilon(x,t)\to u(x,t)$ in $C([0,T])$ which will be enough to show the convergence of w^ε to the proper w in $\mathscr{D}'(Q)$ as follows: for φ in $\mathscr{D}(Q)$,

$$\langle w^\varepsilon,\varphi\rangle=-\int_\Omega\iiint\varphi'(x,t+s+\sigma)e^\varepsilon(t)u^\varepsilon(x,s)\beta^\varepsilon(x,\sigma)\,ds\,ds\,d\sigma\,dx$$

$$=\iint dt\,ds\,e^\varepsilon(t)\int\int_\Omega d\sigma\,dx\,\varphi'(x,t+s+\sigma)u^\varepsilon(x,s)\beta^\varepsilon(x,\sigma).$$

For every (t,s) the last integral converges to

$$\int d\sigma\int_\Omega\varphi'(x,t+s+\sigma)u(x,s)\beta(x,\sigma)\,dx$$

because β^ε converges to β $*$-weakly in $L^\infty(Q)$. Furthermore, Lebesgue's dominated convergence theorem applies to the (t,s) integral since the integrand is actually bounded by a constant, namely

$$|\varphi'|_\infty\cdot\sup|u^\varepsilon|_{L^\infty(0,T;\,L^2(\Omega))}\cdot\sup|\beta^\varepsilon|_{L^\infty(Q)},$$

this last factor being bounded above by $\sup|\beta^\varepsilon|_{L^\infty(\Omega,\,BV(0,T))}$ which is finite by hypothesis (3.7). □

Making now use of the convergence in the sense of Mosco of ϕ^ε to ϕ which implies a demi-closedness property (cf. Attouch [2]) one passes to the limit in

$$-\operatorname{div}\sigma^\varepsilon(x,\nabla x^\varepsilon)=G^\varepsilon(u^\varepsilon)-b_0^\varepsilon\frac{du^\varepsilon}{dt}$$

to conclude that u is a solution of

$$-\operatorname{div}\sigma(x,\nabla u)=G(u)-b_0\frac{du}{dt},\qquad u(0)=u_0. \tag{3.15}$$

Because G is as in (3.5), one concludes to the uniqueness of the solution for (3.15), hence the conclusion:

THEOREM 3.16. *Under the hypotheses* (3.7), (3.9), (3.10), (3.11), (3.12) (*and with the notation therein*), *the solution* u^ε *of problem* $(3.4)^\varepsilon$, $(3.5)^\varepsilon$ *converges uniformly in* $C([0,T];L^2(\Omega))$ *to the solution* u *of the analogous problem whose thermodynamical parameters are obtained as follows*:

β *and* b_0 *are the weak-star limits of* β^ε *and* b_0^ε *respectively*;

σ *is the elliptic homogenization of* σ^ε (*equivalent to the Mosco convergence of* ϕ^ε *to* ϕ *cf.* (3.10));

γ *is the resolvant of the weak-limit of the resolvant of* γ^ε (*these two operations do not commute*!).

4. Existence and uniqueness in the general case. We start with (2.3) again:

$$b_0u'-\operatorname{div}\big((c*\sigma)'\big)=g(u),\qquad u(0)=u_0, \tag{4.1}$$

where

$$g(u)=h-\beta_0-\beta'*u \tag{4.2}$$

is Lipschitz continuous from $L^1(0,t;L^2(\Omega))$ into itself for every positive t. Therefore, one can solve (4.1) as a Lipschitz perturbation problem (in a fashion similar to that in §3.1) provided one can solve

$$b_0\frac{du}{dt}-\operatorname{div}\big((c*\sigma)'\big)=F,\qquad u(0)=u_0 \tag{4.3}$$

for given F, via a monotonicity argument.

Here, one should notice that the method of Crandall–Nohel does not apply because c depends upon x so that div and convolution with c do not commute.

We make the following assumptions where α and k are given positive numbers:

(4.4) i) $b_0, 1/b_0, c_0, 1/c_0, \beta_0, 1/\beta_0$ are bounded by k in $L^\infty(\Omega)$ and $|u_0|_{L^2(\Omega)}<k$.

ii) $\beta'<0$ and $c'=-\gamma<0$ a.e. in Q; $\beta(T,x)$ and $c(T,x)$ are bounded below away from zero by α; $t\mapsto c(t,x)$ is continuous at $t=0$ with values in $L^\infty(\Omega)$.

iii) β'' and $c''(=-\gamma')$ are nonnegative measures for a.e. x in Ω.

iv) (2.6) holds with the following inequalities:
$\forall r,s$ in R^N,

$$\alpha|r-s|^2\leqq(\sigma(x,r)-\sigma(x,s),r-s),$$
$$|\sigma(x,r)-\sigma(x,s)|\leqq k|r-s|.$$

We start by choosing t small enough as follows:

PROPOSITION 4.5. *Let* $Au=-\operatorname{div}((c*\sigma)')=-\operatorname{div}(c_0\sigma)-\operatorname{div}(c'*\sigma)$. *For* T *small enough*, A *is maximal monotone from* $L^2(0,T;H_0^1(\Omega))=V$ *into* $L^2((0,T);H^{-1})=V'$.

Proof. We estimate

$$
\begin{aligned}
&(Au-AV,u-v)_{V',V}\\
&\quad\geqq\int_Q c_0(\sigma(x,\nabla u(x))-\sigma(x,\nabla v(x)),\nabla u(x)-\nabla v(x))\,dx\,dt\\
&\qquad+\int_Q (c'*(\sigma,x,\nabla u(x))-\sigma(x,\nabla v(x)),\nabla u(x)-\nabla v(x))\,dx\,dt\\
&\quad\geqq\alpha\int_Q c_0|\nabla u-\nabla v|^2\,dx\,dt\\
&\qquad-\int_Q |c'|*|\sigma(\nabla u)-\sigma(\nabla v)||\nabla u-\nabla v|\,dx\,dt\\
&\quad\geqq\alpha\int_Q c_0|\nabla u-\nabla v|^2\,dx\,dt\\
&\qquad-\int_\Omega dx|c'(x)|_{L^1(0,T)}|\sigma(\nabla u)-\sigma(\nabla v)|_{L^2(0,T)}|\nabla u-\nabla v|_{L^2(0,T)}\\
&\quad\geqq\alpha\int_Q c_0|\nabla u-\nabla v|^2\,dx\,dt-k|c'|_{L^\infty(\Omega;L^1(0,T))}\int_Q|\nabla u-\partial v|^2\,dx\,dt.
\end{aligned}
$$

Note now that $|c'(x)|_{L^1(0,T)}=c_0(x)-c(t,x)$ so by (4.4ii) $|c'|_{L^\infty(\omega;L^1(0,T))}$ is arbitrarily small for T arbitrarily small close to zero. For such a T, $(Au-Av,u-v)>\theta|\nabla u-\nabla v|^2_{L^2(Q)}$ for some positive number θ. Hence A is monotone. Since it is also everywhere defined and continuous on V, it is maximal. □

Now, for such a small T, $b_0d/dt+A$ is one-to-one and onto from V to V' (because of a standard nonlinear argument of coerciveness, cf. Brezis [1]). This proves local existence and uniqueness of the solution for problem (4.3), and hence for (4.1), (4.2). In order to prove global existence, we now get two a priori estimates.

PROPOSITION 4.6. *Under the above hypotheses, there is a constant* C_1 (*depending upon* α *and* k) *such that if* u *is a solution of* (4.1), (4.2), *the following holds*:

$$
|u|_{L^\infty(0,T;L^2(\Omega))}\leqq C_1\quad\text{and}\quad |j(\nabla u)|_{L^1(Q)},\ |j^*(\sigma(\nabla u))|_{L^1(Q)}\leqq C_1
$$

(*consequently* $|\nabla u|^2_{L^2(Q)}\leqq kC_1$, $\sigma|(\partial Vu)|^2_{L^2(Q)}\geqq C_1/\alpha$).

Proof. Multiply (4.1), (4.2) by $u(t)$ and integrate by parts to get

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|b_0^{1/2}u(t)|^2_{L^2(\Omega)}+|\beta_0^{1/2}u(t)|^2_{L^2(\Omega)}\\
&\qquad+\int_\Omega(\beta'*u)(t)u(t)\,dx+\int_\Omega(c_0\sigma+c'*\sigma)(t)\cdot\nabla u(t)\,dx=\int_\Omega h(t)u(t)\,dx.
\end{aligned}
\tag{4.7}
$$

Integrating on $(0,t)$ yields

$$
\begin{aligned}
&\frac{1}{2}|b_0^{1/2}u(t)|^2_{L^2(\Omega)}+\int_0^t\int_\Omega\beta_0u^2\,ds\,dx+\int_0^t\int_\Omega c_0\sigma(\nabla u(s))\nabla u(s)\,ds\,dx\\
&\qquad=\int_0^t\int_\Omega h\cdot u\,ds\,dx+\int_0^t\int_\Omega(-\beta'*u)(s)u(s)\,ds\,dx\\
&\qquad+\int_0^t\int_\Omega(-c'*\sigma)(s)\nabla u(s)\,ds\,dx+\frac{1}{2}|b_0^{1/2}u_0|^2_{L^2(\Omega)}.
\end{aligned}
\tag{4.8}
$$

By (4.4ii), one has

$$(4.9)\quad \int_0^t (-\beta' * u)(s)u(s)\,ds$$
$$\leqq \int_0^t \int_0^s -\beta'(s-\tau)\left(\frac{1}{2}|u(s)|^2+\frac{1}{2}|u(\tau)|^2\right)ds\,\tau$$
$$\leqq \int_0^t \frac{1}{2}|u(s)|^2(\beta_0-\beta(s))\,ds+\frac{1}{2}\int_0^t ds\int_0^s -\beta'(s-\tau)|u(\tau)|^2\,d\tau$$
$$\leqq \frac{1}{2}\int_0^t (\beta_0-\beta(s))|u(s)|^2\,ds+\frac{1}{2}\left(\int_0^t -\beta'(\tau)d\tau\right)\left(\int_0^t |u(\tau)|^2\,d\tau\right)$$
$$\leqq (\beta_0-\beta(t))\int_0^t u^2(s)\,ds.$$

Hence

$$(4.10)\qquad \int_0^t \int_\Omega \beta_0 u^2+(\beta' * u)u\,dx\,dx \geqq \int_\Omega \beta(x,t)\int_0^t |u(x,s)|^2\,ds\,dx.$$

A similar computation, making use of Young's inequality corresponding to j and j^*, gives

$$(4.11)\qquad \int_0^t \int_\Omega \left(c_0\sigma(\nabla u)+c' * \sigma(\nabla u)\right)\cdot\nabla u\,dx\,ds$$
$$\geqq \int_\Omega c(x,t)\int_0^t j(x,\nabla u(x,s))+j^*(x,\sigma(x,\nabla u(x,s)))\,ds\,dx.$$

Now (4.8), (4.10) and (4.11) combined give

$$\frac{1}{2}|b_0^{1/2}u(t)|^2_{L^2(\Omega)}+\int_\Omega \beta(t,x)\int_0^t u^2(s,x)\,ds\,dx$$
$$(4.12)\qquad +\int_\Omega c(t,x)\int_0^t \left(j(s,\nabla u)+j^*(x,\sigma(\nabla u))\right)ds\,dx$$
$$\leqq \int_0^t \int_\Omega hu\,ds\,dx+\frac{1}{2}|b_0^{1/2}u_0|^2_{L^2(\Omega)}.$$

A standard application of Gronwall's inequality finally yields the desired result.

PROPOSITION 4.13. *Assume the above hypotheses and that $\phi(u_0)$ is finite. Then, there is a constant C_2 (depending on c,k and $\phi(u_0)$) such that whenever u is a solution of* (4.1), (4.2) *then*

$$\left|\frac{du}{dt}\right|_{L^2(Q)}\leqq C_2,\qquad |\phi(u)|_{L^\infty(0,T)}\leqq C_2.$$

Proof. Multiply (4.1), (4.2) by du/dt to get

$$(4.14)\quad \int_0^t \int_\Omega b_0\left|\frac{du}{dt}\right|^2 dx\,dx+\int_0^t \int_\Omega \left(\beta_0 u+\beta' * u\right)\frac{du}{dt}(s)\,dx\,ds$$
$$+\int_0^t \int_\Omega \left(c_0\sigma+c' * \sigma\right)\frac{d}{dt}(\nabla u(s))\,dx\,dx=\int_0^t \int_\Omega h\frac{du}{dt}(s)\,dx\,ds.$$

In (4.14) we integrate by parts the third term as follows:

$$\int_0^t (\beta' * u)u' = u(t)\int_0^t u(s)\beta'(t-s)\,ds - \beta'(0)\int_0^t u^2(s)\,ds$$
$$- \int_0^t u(s)\int_0^s u(\sigma)\beta''(s-\sigma)\,d\sigma\,ds.$$

Making use of $\beta'' \geqq 0$, one can evaluate the last term in a way exactly similar to (4.9) above to get

$$\int_0^t (\beta'' u)\frac{du}{dt} \geqq u(t)\int_0^t u(s)\beta'(t-s)\,ds - \beta'(0)\int_0^t u^2(s)\,ds. \tag{4.15}$$

Again, similarly,

$$\int_0^t (c' * \sigma)\frac{d}{dt}(\nabla u)\,ds \geqq \nabla u(t)\cdot(c' * \sigma)(t) - c'(0)\int_0^t \sigma(s)\nabla u(s)\,ds. \tag{4.16}$$

Using (4.15), (4.16) and the following consequence of the definition of subdifferential $\sigma = \partial j$:

$$\sigma \cdot \frac{d}{dt}(\nabla u) = \frac{d}{dt} j(\nabla u), \tag{4.17}$$

(4.14) yields

(4.18)

$$\int_0^t \int_\Omega b_0 \left|\frac{du}{dt}\right|^2 dx\,ds + \frac{1}{2}\left|\beta_0^{1/2} u(t)\right|^2_{L^2(\Omega)} + \int c_0 j(\nabla u(t))\,ds$$
$$\leqq \int_0^t \int_\Omega h\frac{du}{dt}\,dx\,ds + \frac{1}{2}\left|\beta^{1/2} u_0\right|^2_{L^2(\Omega)} + \int_\Omega c_0 j(\nabla u_0)\,dx$$
$$+ \int_\Omega u(x,t)\int_0^t u(x,s)\big(-\beta'(x,t-s)\big)\,dx\,ds$$
$$+ \int_\Omega \nabla u(x,t)\int_0^t \sigma(x,\nabla u(x,s))\big(-c'(x,t-s)\big)\,ds\,dx.$$

In the right-hand side of (4.18) one can use the following bounds:

$$\text{i)} \int_\Omega \int_0^t u(t)u(s)\big(-\beta'(t-s)\big)\,dx\,ds \leqq |u|^2_{L^\infty(0,T;L^2(\Omega))}\cdot|\beta'|_{L^1(0,T;L^\infty(\Omega))}. \tag{4.19}$$

ii) By Young's inequality

$$\int_\Omega \int_0^t \sigma(s)\nabla u(t)\cdot\big(-c'(t-s)\big)\,ds\,dt$$
$$\leqq \int_\Omega j(\nabla u(t))\big(c_0 - c(t)\big) + |c'|_{L^\infty(Q)}\left|j^*(\sigma(\nabla u))\right|_{L^1(Q)}.$$

Now, confronting (4.18) and (4.19) with hypothesis (4.4ii) and Proposition (4.6), one can conclude. □

THEOREM 4.20. *Under hypotheses* (4.4), *problem* (4.1), (4.2) *has a unique solution on* $[0,T]$.

Proof. From Proposition 4.5, there is existence and uniqueness on some interval $[0,t]t>0$. But the very same proposition gives existence and uniqueness locally in time (starting from $\tau>0$, the problem is changed only insofar as G in (4.2) is modified to incorporate the history up to τ; this in no way changes the conclusion because the a priori estimates are global in time). Combining local existence and the a priori estimates (4.6) and (4.13) gives the result in a standard way. □

5. Homogenization (for the linear case). In this paragraph, b_0^ε, β^ε, c^ε and γ^ε will depend upon the parameter ε which will tend to zero; similarly, σ^ε will depend upon ε but will be assumed to be linear with respect to ∇u; hence the notation

$$\sigma^\varepsilon(x,r)=A^\varepsilon(x)r$$

where $A^\varepsilon(x)$ is a measurable function from Ω to a fixed (independent of ε) set of symmetric uniformly positive definite matrices.

We shall assume hypotheses (4.4) to be satisfied uniformly with respect to ε, so that (4.6), (4.13) and (4.20) hold uniformly in ε.

Consequently, the solutions u^ε of equations $(4.1)_\varepsilon$,$(4.2)_\varepsilon$, belong to a compact set of $C([0,T];L^2(\Omega))$ and a bounded set of

$$L^\infty\big(0,T;H_0^1(\Omega)\big)\cap W^{1,2}\big(0,T;L^2(\Omega)\big).$$

The question of homogenization for $(4.1)_\varepsilon$, $(4.2)_\varepsilon$ is: what can be said of the limit points of u^ε as ε goes to zero?

In order to simplify the notations, we shall assume that ε belongs to a sequence (still denoted ε) such that the following holds:

(5.1) u^ε converges to some u in $C([0,T];L^2(\Omega))$, in the weak-star topology of $L^\infty(0,T;H_0^1(\Omega))$ and the weak topology of $W^{1,2}(0,T;L^2(\Omega))$;

(5.2) b_0^ε converges to b_0 in the weak-star topology of $L^\infty(\Omega)$; β^ε converges to β in

$$\sigma\big(W^{1,1}(0,T;L^\infty(\Omega)),W^{-1,\infty}\big(0,T;L^1(\Omega)\big)\big).$$

Following integration on t, the Volterra equation can be written as

$$-\operatorname{div}\omega^\varepsilon=\mathscr{F}^\varepsilon, \tag{5.3}$$

where

$$\mathscr{W}^\varepsilon(x,t)=\int_0^t A^\varepsilon(x)c^\varepsilon(x,t-s)\nabla u^\varepsilon(x,s)\,ds \tag{5.4}$$

and

$$\begin{aligned}F^\varepsilon(x,t)=&-b_0^\varepsilon(x)u^\varepsilon(x,t)-\int_0^t\beta^\varepsilon(x,t-s)u^\varepsilon(x,s)\,ds\\&+\int_0^t h(x,s)\,ds+b_0^\varepsilon(x)u_0(x).\end{aligned} \tag{5.5}$$

Clearly F^ε converges to F in $C([0,T],H^{-1}(\Omega))$ and weakly in $W^{1,2}(0,T;L^2(\Omega))$, for

$$F(x,t)=b_0(x)(u_0(x)-u(x,t))+\int_0^t h(x,s)\,ds-\int_0^t\beta(x,t-s)u(x,s)\,ds. \tag{5.6}$$

On the other hand, $\mathscr{W}^\varepsilon$ is bounded in $W^{1,2}(0,T;L^2(\Omega))$. In order to characterize the possible weak limits $\mathscr{W}$ of $\mathscr{W}^\varepsilon$ (the uniqueness of which will follow, as usual from the unique solvability of the limit equation), we shall assume, after extracting another subsequence, still denoted ε, that $\mathscr{W}^\varepsilon$ converges weakly to some $\mathscr{W}$. So, going to the limit in (5.3) yields:

$$-\operatorname{div}\mathscr{W}=\mathscr{F}. \tag{5.7}$$

The main task is to find the relationship between $\mathscr{W}$ and u, which (5.4) should yield. Here, because the problem is linear, we use the Laplace transform, but to do so we extend the problem to $[0,+\infty)$ in time as follows: for $t>T$, extend β^ε by $\beta^\varepsilon(x,t)\equiv\beta^\varepsilon(x,T)$, h and γ^ε by zero (so $\sigma^\varepsilon(x,t)\equiv c^\varepsilon(x,T)$), and by Theorem 4.20 which applies to any interval $[0,T_1]$, u^ε exists for all $t\geqq 0$, but for $t>T$, the problems become simpler, as seen from (2.1):

$$b_0^\varepsilon\frac{du^\varepsilon}{dt}+\beta^\varepsilon(T)u^\varepsilon-\operatorname{div}_x A\left(c_0\nabla u^\varepsilon-\gamma*\nabla u^\varepsilon\right)=0.$$

A detailed analysis of estimates (4.6), (4.13) shows that in this particular case, $|u^\varepsilon(t)|_{H^1(\Omega)}$ grows at most exponentially in t with a rate uniform in ε. Therefore, all the Laplace transforms considered here will be convergent at least in some complex right half-plane $\operatorname{Re}\lambda>\lambda_0$.

We will denote by

$$\hat{v}(\lambda)=\int_0^{+\infty}e^{-\lambda t}v(t)\,dt \quad \text{for } \operatorname{Re}\lambda>\lambda_0$$

and (5.3), (5.4) yield $(5.8)_\varepsilon$ below since the gradient operator in x commutes with the Laplace transform.

$$\begin{aligned}&\hat{\mathscr{W}}^\varepsilon(x,\lambda)=A^\varepsilon(x)\hat{c}_\varepsilon(x,\lambda)\nabla\left(\hat{u}_\varepsilon(x,\lambda)\right),\\&-\operatorname{div}\hat{\mathscr{W}}^\varepsilon(x,\lambda)=\hat{\mathscr{F}}^\varepsilon(x,\lambda).\end{aligned} \tag{5.8}_\varepsilon$$

For fixed λ, $(5.8)_\varepsilon$ is just the homogenization problem for an elliptic operator with complex coefficients.

Upon inspection of (5.5), one sees that for every $t>0$, $\mathscr{F}^\varepsilon$ converges to $\mathscr{F}$ in $C([0,t];H^{-1}(\Omega))$ but that $\mathscr{F}^\varepsilon$ grows in H^{-1} at the same rate as u^ε does. Consequently, for each λ with $\operatorname{Re}\lambda>\lambda_0$, $\hat{\mathscr{F}}^\varepsilon(\lambda)$ converges to $\hat{\mathscr{F}}(\lambda)$ in $H^{-1}(\Omega;\mathbb{C})$. Similarly $\hat{u}_\varepsilon(\lambda)$ converges to $\hat{u}(\lambda)$ weakly in $H_0^1(\Omega;\mathbb{C})$. The sesquilinear form

$$a_\varepsilon(\lambda;u,v)=\int_\Omega\hat{c}_\varepsilon(x,\lambda)A^\varepsilon(x)\nabla u(x)\overline{\nabla v}(x)\,dx \tag{5.9}$$

is continuous coercive on $H_0^1(\Omega;\mathbb{C})$ under the hypothesis

$$\operatorname{Re}\hat{c}_\varepsilon(x,\lambda)\geqq\rho_0(\lambda)>0, \tag{5.10}$$

which we will check later.

Indeed, c_ε is bounded on Ω for each λ such that $\operatorname{Re}\lambda>0$ so a_ε is continuous and for such λ's,

$$\operatorname{Re}a_\varepsilon(\lambda;u,u)=\int_\Omega\operatorname{Re}\hat{c}_\varepsilon(x,\lambda)A^\varepsilon(x)|\nabla u(x)|^2\,dx$$

$$\geqq\alpha\int_\Omega\operatorname{Re}\hat{c}_\varepsilon(x,\lambda)|\nabla u|^2\,dx$$

since A^ε is symmetric real coercive. Incidentally, another proof of existence for the solution u^ε is thus obtained by applying Lax–Milgram's theorem for $\hat{u}^\varepsilon$.

One can now apply a compactness result for complex homogenization (see for example Sanchez-Palencia [1], Murat [1] or Bensoussan–Lions–Papanicolaou [1]). For each λ with $\mathrm{Re}\lambda > \lambda_0$, there is a matrix-valued function $D(x,\lambda)$ (independent of $\hat{\mathscr{F}}$ and $\hat{\mathscr{W}}$) such that $(5.8)_\varepsilon$ implies at the limit $\varepsilon \to 0$:

$$\begin{aligned} &-\operatorname{div}\hat{\mathscr{W}} = \hat{\mathscr{F}}, \\ &\hat{\mathscr{W}}(x,\lambda) = D(x,\lambda)\nabla\hat{u}(x,\lambda). \end{aligned} \tag{5.11}$$

In order to apply the inverse Laplace transform to (5.11), all that is needed is that $D(x,\lambda)$ be analytic in λ with at most polynomial growth at $|\lambda| \to \infty$, in which case it is the Laplace transform of a distribution of finite order in t, denoted $E(x,t)$. That D is analytic is a mere consequence of the fact that it is a limit of a sequence of analytic functions of λ, the limit being locally uniform. From the uniform boundedness of c^ε and A^ε, one can conclude that $D(x,\lambda)$ is bounded by a multiple of $(\mathrm{Re}\lambda)^{-1}$. Consequently, $E(x,t)$ is a bounded distribution of order not more than 2, on $[0, +\infty[$, with values in the cone of bounded measurable symmetric square matices on Ω.

We now check that (5.10) holds: integration by parts in

$$\mathrm{Re}\,\hat{c}_\varepsilon(x,\lambda) = \int_0^\infty e^{-(\mathrm{Re}\lambda)t}\cos(\mathrm{Im}\lambda)\,c_\varepsilon(t)\,dt \tag{5.12}$$

gives

$$\mathrm{Re}\,\hat{c}_\varepsilon(x,\lambda) = \int_0^\infty (1-\cos(t\,\mathrm{Im}\lambda))\,e^{-t\,\mathrm{Re}\lambda}\left(c_\varepsilon'' - 2\,\mathrm{Re}\lambda\,c_\varepsilon' + (\mathrm{Re}\lambda)^2 c_\varepsilon\right)dt.$$

Since $(1-\cos(t\,\mathrm{Im}\lambda))$ and $-c_\varepsilon'$ are nonnegative functions and c_ε'' is a nonnegative measure,

$$\mathrm{Re}\,\hat{c}_\varepsilon(x,\lambda) \geqq \int_0^{+\infty} (1-\cos(t\,\mathrm{Im}\lambda))\,e^{-t\,\mathrm{Re}\lambda}c_\varepsilon(t)\,dt; \tag{5.13}$$

combining (5.12) and (5.13) one gets

$$\mathrm{Re}\,\hat{c}_\varepsilon(x,\lambda) \geqq \frac{(\mathrm{Re}\lambda)^2}{1+(\mathrm{Re}\lambda)^2}\int_0^\infty e^{-t\,\mathrm{Re}\lambda}c_\varepsilon(t)\,dt. \tag{5.14}$$

But $c_\varepsilon(t) \geqq \alpha$ implies with (5.14) that $\mathrm{Re}\,\hat{c}_\varepsilon(x,\lambda) \geqq \alpha\mathrm{Re}\lambda/(1+(\mathrm{Re}\lambda)^2)$ which implies (5.10). Finally, we have proved the following theorem:

THEOREM 5.15. *Let b_0^ε, c^ε, β^ε and $\sigma^\varepsilon = A^\varepsilon$ (linear case) satisfy hypotheses* (4.4) *with α and k independent of ε. There exists a sequence ε_n converging to zero, functions $b_0(x)$, $\beta(x,t)$ and a distribution $E(x,t)$ such that the solution u^{ε_n} of the corresponding problem* (4.1), (4.2) *converges in $C([0,T];L^2(\Omega))$ to the solution u of*

$$b_0 u' - \operatorname{div}\left((E * \nabla u)'\right) = G(u). \tag{5.16}$$

b_0 and β are the weak limits of $b_0^{\varepsilon_n}$ and β^{ε_n}, and E is obtained via its Laplace transform $D(x,\lambda)$, which is the complex elliptic homogenization of $\hat{c}_{\varepsilon_n}(x,\lambda)A^{\varepsilon_n}(x)$.

Remark. Even in the case of periodic problems, where there are explicit formulas for D it is not known whether $t \mapsto E(t,x)$ is in some appropriate sense, a convex decreasing function of t, not even whether it is a function of t, as one would suspect. This is one of the problems left open in the theory, the other one being the homogenization of the nonlinear case (where the Laplace-transform cannot be used).

Acknowledgment. The authors are very grateful to Professor John Nohel who not only introduced them to nonlinear Volterra equations in general and this problem in particular, but without whose help this paper never would have been written.

A NONLINEAR SINGULAR INTEGRO-DIFFERENTIAL EQUATION ARISING IN SURFACE CHEMISTRY*

JEAN DUCHON† AND RAOUL ROBERT†

Abstract. We prove an existence-uniqueness result for the solution of a nonlinear singular integro-differential equation. This equation is an approximate model for the development, by the mechanism of volume diffusion, of a grain boundary groove on an interface separating a solid phase and a saturated fluid phase.

Key words. nonlinear integro-differential equation, special equations and problems

AMS(MOS) subject classification. Primary 35Q

Introduction. When a polycrystalline solid is heated in thermodynamical equilibrium with a fluid phase, grooves will form at the intersections of the grain boundaries and the interphase interface. These grooves have a constant dihedral angle and their dimensions roughly vary as $(\text{time})^{\alpha}$, the exponent α being determined by the dominant transport process involved.

We study here a model for the development by the mechanism of volume diffusion of such a grain boundary groove.

Referring to Mullins [6] for more details, we give a brief summary of the most important physical assumptions upon which the model is based:

1) the transport process involved in the growth of the groove is volume diffusion in the fluid phase,
2) isotropy of the interfacial free energy,
3) applicability of the Gibbs–Thompson formula relating curvature and chemical potential,
4) quasi steady-state volume diffusion,
5) negligible convection in the fluid phase,
6) the interface is taken to be initially flat.

Writing up the equations governing the groove development, we show that the groove profile has a fixed shape and linear dimensions that are proportional to $(\text{time})^{1/3}$.

This led us to study the stationary equations giving the shape of the groove. Then, we make some sort of nonlinear small slope approximation. That is, letting the curvature term be unchanged, for purposes of the diffusion problem we represent the interface as a plane.

The study of this approximate problem is a first step towards the solution of the complete problem (which is object of actual research), it gives some insight on the way the operators involved behave. On the same way the numerical resolution of the approximate problem (see [7]) enlightens our understanding of the computational processes involved in the numerical resolution of the complete problem.

From a physical point of view, the practical value of such an approximation is not obvious. Roughly speaking, the correction term created by our approximation depends linearly on the slope of the groove root (this is discussed on a physical level in [6]) whereas the correction term given by the linearization of the curvature depends

quadratically on the slope. So, for small slopes, we cannot expect a better suited quantitative model than the completely linear small slope approximation given in [6].

1. The mathematical problem and its approximation. We consider a plane section normal to the groove line and define cartesian coordinates in the plane so that the x axis coincides with the trace of the initially flat interface and the negative y axis coincides with the grain boundary. Letting $y=w(t,x)$ be the profile of the groove, we note that

$$\Omega_t=\{(x,y)\,|\,y>w(t,x)\},\qquad \partial\Omega_t=\{(x,y)\,|\,y=w(t,w)\},$$

$n(x,w(t,x))$ the unit vector normal to $\partial\Omega_t$ at $(x,w(t,x))$ and pointing out of Ω_t, $C(t,x,y)$ the concentration of solid atoms in the solvent.

Then, following Mullins [6], we write the set of equations governing the growth of the groove:

(i) $\Delta C=0$ in Ω_t (quasi steady-state diffusion),

(ii) $C=\mathrm{Co}(1-L(D^2w/(1+Dw^2)^{3/2}))$ on $\partial\Omega_t$ for $x\neq 0$ (Gibbs–Thompson formula),

(iii) $Dw(t,0\pm)=\pm m$ for all $t>0$ (constant dihedral angle),

(iv) $\partial w/\partial t=-M(1+Dw^2)^{1/2}\partial C/\partial n$ (the normal flux determines the rate of movement of the interface),

(v) $w(0,x)=0$ (initially flat interface),

where m is the slope at the groove root, D indicates differentiation with respect to x and Co, L, M are physical constants.

We seek a solution of constant shape and try the function change:

$$w(t,x)=t^{1/3}u(t^{-1/3}x),$$
$$C(t,x,y)=\mathrm{Co}\big(1-t^{-1/3}c\big(t^{-1/3}x,t^{-1/3}y\big)\big).$$

One readily sees by a straightforward computation that equations (i) $\cdots$ (v) change into the following system of stationary equations.

$$\text{(S)}\qquad \begin{aligned} &\Delta c=0 \quad \text{in } \Omega,\\ &c=L\frac{D^2u}{(1+Du^2)^{3/2}} \quad \text{on } \partial\Omega \text{ for } x\neq 0,\\ &Du(0\pm)=\pm m,\\ &u-xDu=3\,\mathrm{Co}M(1+Du^2)^{1/2}\frac{\partial c}{\partial n}, \end{aligned}$$

where $\Omega=\{(x,y)\,|\,y>u(x)\}$.

Let us identify c on $\partial\Omega$ with a function of x, i.e. $c(x)=c(x,u(x))$. We show in [4], by a study of the single layer potential, the splitting:

$$(1+Du^2)^{1/2}\frac{\partial c}{\partial n}=2\pi\Lambda^1 c+P(u)\cdot Dc,$$

where the operator Λ^s is defined by Fourier transform

$$\widehat{\Lambda^s f}(\xi)=|\xi|^s\hat{f}(\xi).$$

When u is a smooth function the operator $P(u)$ (taken on the space $L^2(\mathbb{R})$) is a compact and smoothing one whose norm, denoted $\|P(u)\|_{op}$, goes to 0 with u (in some convenient norm). When u is only Lipschitz $P(u)$ is defined by means of a singular

kernel and we can see, using deep results of Coifman, McIntosh and Meyer [1] that $\|P(u)\|_{op}$ goes to 0 as the Lipschitz constant of u goes to 0.

For a detailed study of operator $P(u)$, which falls out of the scope of this work, we refer to [4] and [1].

In the sequel we shall approxime the operator $(1+Du^2)^{1/2}\partial/\partial n$ by its "dominant part" $2\pi\Lambda^1$.

Then (S) becomes

$$\text{(E)} \qquad u - xDu - \gamma\Lambda^1 \frac{[D^2u]}{(1+Du^2)^{3/2}} = 0, \qquad Du(0\pm) = \pm m,$$

and we note $[D^2u] = D^2u - 2m\delta$, where δ is the Dirac mass in 0 and derivatives are taken in the distribution sense.

If we approximate the curvature of the interface by D^2u, (E) becomes the linear small slope approximation studied in [6].

By a change of scale in the space, we can take the constant γ to be $1/4\pi^2$ which will be a convenient choice for the sequel.

We prove here an existence and uniqueness result for the solution of equation (E). Let us briefly indicate the plan of the proof.

First step (paragraph 2). For $\varepsilon > 0$, we introduce an elliptic regularization (E_ε) of equation (E). Using a suitable linearization of (E_ε) and two estimates (A1, A2), we apply Schauder's fixed point theorem to prove that (E_ε) has a solution (Theorem 2.1).

Second step (paragraph 3). We show that equation (E) has a unique solution (Theorem 3.1) by a limit process, letting ε go to zero in (E_ε). Here the crucial point is to obtain the key estimate $|Du_\varepsilon|_\infty$ bounded. This is a consequence of some technical lemmas and three basic estimates on u_ε solution of (E_ε), (B1, B2, B3). Uniqueness is a straightforward consequence of the monotony of the nonlinear operator $-D^2u/(1+Du^2)^{3/2}$.

2. The regularized equation (E_ε). Throughout this paper we note $\operatorname{sgn}\xi$ the sign of the real number ξ and $\operatorname{Re} z$ the real part of the complex number z. Functions under consideration are real-valued. Notice that for f real valued, $\Lambda^s f$ is real valued. For s real, we note $H^s = H^s(\mathbb{R})$ the usual Sobolev's space and $\langle \cdot, \cdot \rangle$ the pairing between H^s and H^{-s}. Also we note $|f|$ the L^2-norm and $|f|_\infty$ the L^∞-norm of the function f.

We find it convenient to use the solution u_0 of the linear problem:

$$u_0 - xDu_0 - \frac{1}{4\pi^2}\Lambda^1[D^2u_0] = 0,$$
$$Du_0(0\pm) = \pm m$$

or equivalently:

$$u_0 - xDu_0 - \frac{1}{4\pi^2}\Lambda^1 D^2 u_0 = -\frac{m}{2\pi^2}\Lambda^1\delta.$$

Fourier transformation leads to the linear differential equation

$$\hat{u}_0 + D(\xi\hat{u}_0) + |\xi|^3\hat{u}_0 = -6m|\xi|,$$

and standard calculation gives the unique tempered solution:

$$\hat{u}_0(\xi) = -\frac{m}{2\pi^2\xi^2}\left(1 - e^{-|\xi|^3/3}\right).$$

We notice that u_0 is in H^1 and

$$D^2u_0=[D^2u_0]+2m\delta$$

with $[D^2u_0]$ square integrable.

We then introduce, for $\varepsilon>0$, the regularized equation

$$(E_\varepsilon)\qquad \begin{aligned} &u-xDu-\frac{1}{4\pi^2}\Lambda^1\frac{[D^2u]}{(1+Du^2)^{3/2}}-\frac{\varepsilon}{4\pi^2}\Lambda^1(D^2u-D^2u_0)=0,\\ &Du(0\pm)=\pm m. \end{aligned}$$

In this section we prove the following:

THEOREM 2.1. *Equation* (E_ε) *possesses a unique solution* u_ε *in the set* u_0+H^2. *This function is even.*

Proof. Let $u=u_0+v$, $v\in H^2$, and define

$$T(g)=\left(1-\left(1+(Du_0+g)^2\right)^{-3/2}\right)(Dg+[D^2u_0]);$$

equation (E_ε) now is:

$$\begin{aligned} &v-xDv+(1+\varepsilon)\Lambda^3v=-\frac{1}{4\pi^2}\Lambda^1T(Dv),\\ &Dv(0)=0. \end{aligned}$$

For $f\in L^2(\mathbb{R})$, we define $S(f)$ to be the unique solution $v\in H^2$ of

$$(LE_\varepsilon)\qquad v-xDv+(1+\varepsilon)\Lambda^3v=-\frac{1}{4\pi^2}\Lambda^1f.$$

Equation (E_ε) then can be written

$$\begin{aligned} &v=S(T(Dv))=\Phi(v),\\ &Dv(0)=0. \end{aligned}$$

We show now that the equation $v=\Phi(v)$ possesses an even solution in H^2. For $r\geqq 0$, let C_r be the weakly compact convex set in H^2 of even functions v such that: $|v|$, $|Dv|$, $|D^2v|\leqq r$. for r large enough, Φ maps C_r into itself as is shown by the following lemma:

LEMMA 2.2. *Let* $f\in L^2(\mathbb{R})$ *and* $v=S(f)$. *Then we have*:

(i) $|v|\leqq c|f|$,
(ii) $|Dv|\leqq c|f|$,
(iii) $|Dv|_\infty\leqq c|f|$,
(iv) $|D^2v|\leqq(1+\varepsilon)^{-1/2}|f|$,

where c *is a constant* <1.

Proof. By Fourier transformation equation (LE_ε) becomes

$$\hat v+D(\xi\hat v)+(1+\varepsilon)|\xi|^3\hat v=-\frac{1}{4\pi^2}|\xi|\hat f$$

whose unique tempered solution is given by:

$$(0)\qquad \hat v(\xi)=\frac{-1}{4\pi^2\xi^2}e^{-(1+\varepsilon)|\xi|^3/3}\int_0^\xi e^{(1+\varepsilon)|s|^3/3}s|s|\hat f(s)\,ds.$$

Schwarz's inequality shows this function is locally square integrable, since

$$\left|\int_0^\xi e^{(1+\varepsilon)|s|^3/3}s|s|\hat{f}(s)\,ds\right| \leqq \left|\int_0^\xi |\hat{f}(s)|^2\,ds\right|^{1/2}\cdot\left|\int_0^\xi s^4 e^{2(1+\varepsilon)|s|^3/3}\,ds\right|^{1/2}$$

but

$$\left|\int_0^\xi s^4 e^{2(1+\varepsilon)|s|^3/3}\,ds\right| \leqq |\xi|^5 e^{2(1+\varepsilon)|\xi|^3/3}$$

so that $|\hat{v}(\xi)| \leqq (1/4\pi^2)|\xi|^{1/2}|\hat{f}|$.

But it is not obvious from the expression (0) of $\hat{v}$ above that $v \in H^2$. Therefore we shall show inequalities (i),$\cdots$,(iv) for $\hat{f}$ C^∞ with compact support, a density argument then completes the proof of the lemma.

Estimate (A1). Multiplying equation (LE_ε) by v and integrating over $\mathbb{R}$, we get

$$|v|^2 - \int x\,Dv\,v\,dx + (1+\varepsilon)|\Lambda^{3/2}v|^2 \leqq \frac{1}{4\pi^2}|f\,||\Lambda^1 v|.$$

One easily verifies using formula (0) that this makes sense. Integration by parts gives

$$-\int x\,Dv\,v\,dx = \int D(xv)\,v\,dx = \int v^2\,dx + \int xv\,Dv\,dx,$$

whence $-\int x\,Dv\,v\,dx = \frac{1}{2}|v|^2$, and we get

$$\text{(A1)} \qquad \frac{3}{2}|v|^2 + (1+\varepsilon)|\Lambda^{3/2}v|^2 \leqq \frac{1}{4\pi^2}|f\,||\Lambda^1 v|.$$

Estimate (A2). We multiply equation (LE_ε) by $\Lambda^1 v$ and integrate over $\mathbb{R}$; it becomes

$$|\Lambda^{1/2}v|^2 - \int x\,Dv\Lambda^1 v\,dx + (1+\varepsilon)|\Lambda^2 v|^2 \leqq \frac{1}{4\pi^2}|f\,||\Lambda^2 v|.$$

Notice that $-\int x\,Dv\Lambda^1 v\,dx = \int D(\xi\hat{v})|\xi|\bar{\hat{v}}\,d\xi = 0$; then we get

$$\text{(A2)} \qquad |\Lambda^{1/2}v|^2 + \frac{1+\varepsilon}{2}|\Lambda^2 v|^2 \leqq \frac{1}{2(4\pi^2)^2}|f|^2$$

which proves (iv):

$$(1+\varepsilon)^{1/2}|D^2 v| \leqq |f|.$$

We now use estimates (A1) and (A2) to prove (i), (ii), (iii). An easy computation gives

$$|Dv|^2 \leqq \frac{8\pi^2}{3}\left(|\Lambda^{1/2}v|^2 + \frac{1}{2}|\Lambda^2 v|^2\right),$$

which together with (A2) gives

$$|Dv|^2 \leqq \frac{1}{12\pi^2}|f|^2,$$

i.e., (ii).

Using (ii), (iv) and $|Dv|_\infty \leqq 1/\sqrt{2}\,(|Dv|^2+|D^2v|^2)^{1/2}$ one gets

$$|Dv|_\infty \leqq \left(\frac{1}{2}+\frac{1}{24\pi^2}\right)^{1/2}|f|,$$

i.e., (iii).

Finally (i) is deduced from (A1) and (ii). □

One easily sees now that Φ maps c_r into itself for large r. First $\Phi(v)$ is even if v is even, and Lemma 2.2 says:

$$|\Phi(v)|, |D\Phi(v)|, |D^2\Phi(v)| \leqq c_\varepsilon |T(Dv)|$$

with $c_\varepsilon = \max(c, (1+\varepsilon)^{-1/2}) < 1$.

But $|T(Dv)| \leqq |D^2v| + |[D^2u_0]|$, so that r just has to be chosen large enough to ensure:

$$c_\varepsilon\left(r + |[D^2u_0]|\right) \leqq r.$$

Let us now prove some convenient continuity property for the operator Φ.

LEMMA 2.3. *The operator T is continuous from bounded subsets of H^1 into L^2 for the weak topologies.*

Proof. Recall $T(f) = (1-(1+(Du_0+f)^2)^{-3/2})(Df+[D^2u_0])$. Let f_n converge weakly to f in H^1. Then $f_n \to f$ uniformly on every compact and $Df_n \to Df$ weakly in L^2. An easy extra lemma says if u_n is bounded in L^∞ and $u_n \to u$ uniformly on every compact and $v_n \to v$ weakly in L^2 then $u_n v_n \to uv$ weakly in L^2. This, applied to $(1+(Du_0+f_n)^2)^{-3/2}$ and Df_n completes the proof. □

The linear operator S is continuous from L^2 into H^2, then also weakly continuous, and from Lemma 2.3, one concludes Φ is continuous on C_r for the weak topology of H^2. By Schauder's theorem, Φ has a fixed point $v_\varepsilon \in C_r$. Letting $u_\varepsilon = u_0 + v_\varepsilon$, one gets an even solution of equation (E_ε). This solution is unique (the proof of uniqueness is as in the following section in the case of equation (E)). □

3. An existence-uniqueness result for equation (E). This section is devoted to proving the following:

THEOREM 3.1. *Equation* (E) *has a unique solution u in the set $u_0 + H^2$. This solution is even.*

Proof. We let ε go to zero in equation (E_ε). Before deriving the necessary a priori estimates, we give a technical lemma.

LEMMA 3.2. *Let $h \in L^2$. There is a unique tempered function u solution of*

$$u - x\,Du = \Lambda^1 h \tag{1}$$

satisfying the estimate

$$|\Lambda^{-1}u|^2 + 3\pi^2|xu|^2 \leqq |h|^2. \tag{2}$$

If moreover $u \in L^2$, then

$$\Lambda^{-1/2}u \in L^2 \quad \text{and} \quad \langle h, u\rangle = 2|\Lambda^{-1/2}u|^2. \tag{3}$$

Proof. Applying Fourier transforms to (1) gives

$$2\hat{u} + \xi D\hat{u} = |\xi|\hat{h}; \tag{$\hat{1}$}$$

this differential equation has for particular solution

$$\hat{u}(\xi)=\xi^{-2}\int_0^{\xi} s|s|\hat{h}(s)\,ds.$$

Applying Schwarz's inequality, one sees that $|\hat{u}(\xi)|\leqq C|\xi|^{1/2}$, so $\hat{u}$ is a tempered function.

Now we show this particular solution satisfies estimate (2): first considering the case $\hat{h}$ C^∞ with compact support, the result will then follow for $h\in L^2$ by a density argument.

For such a function h, $\xi^{-1}\hat{u}$ and $D\hat{u}$ both are in L^2, and so that we can multiply equation $(\hat{1})$ by $\xi^{-1}D\bar{\hat{u}}$ and integrate over $\mathbb{R}$, we get:

$$2\int\hat{u}\,\frac{D\bar{\hat{u}}}{\xi}\,d\xi+\int|D\hat{u}|^2\,d\xi=\int\operatorname{sgn}(\xi)\hat{h}\,D\bar{\hat{u}}\,d\xi;$$

u being real, the first integral is real and we have:

$$\int\hat{u}\,D\bar{\hat{u}}\xi^{-1}\,d\xi=\int\xi^{-1}\operatorname{Re}(\hat{u}\,D\bar{\hat{u}})\,d\xi=\frac{1}{2}\int\xi^{-1}D|\hat{u}|^2\,d\xi;$$

an integration by parts performed on the last integral then gives

$$\int\hat{u}\,D\bar{\hat{u}}\xi^{-1}\,d\xi=\frac{1}{2}\int\xi^{-2}|\hat{u}|^2\,d\xi.$$

Then we have

$$|\Lambda^{-1}u|^2+4\pi^2|xu|^2\leqq 2\pi|h||xu|\leqq|h|^2+\pi^2|xu|^2,$$

which proves estimate (2).

Uniqueness is obvious here since the general solution of (1) is obtained by adding λx to the particular solution.

If u is square integrable, multiplying equation $(\hat{1})$ by $|\xi|^{-1}\bar{\hat{u}}$ gives

$$2\int\hat{u}\bar{\hat{u}}|\xi|^{-1}\,d\xi+\int\operatorname{sgn}(\xi)\,D\hat{u}\,\bar{\hat{u}}\,d\xi=\int\hat{h}\bar{\hat{u}}\,d\xi.$$

But

$$\int\operatorname{sgn}(\xi)\,D\hat{u}\,\bar{\hat{u}}\,d\xi=\int\operatorname{sgn}(\xi)\,\operatorname{Re}(D\hat{u}\bar{\hat{u}})\,d\xi=\frac{1}{2}\int\operatorname{sgn}(\xi)\,D|\hat{u}|^2\,d\xi,$$

and this last integral vanishes since $\hat{u}$ is zero at 0 and ∞ (notice $\hat{u}\in H^1$). Then we have $\langle h,u\rangle=2\int|\hat{u}|^2|\xi|^{-1}\,d\xi$, i.e. (3). □

We use Lemma 3.2 to prove the following estimates.

Estimate (B1). Equation (E_ε) writes $u-xDu=\Lambda^1 h$,[1] with

$$h=\frac{1}{4\pi^2}\left(\frac{[D^2u]}{(1+Du^2)^{3/2}}+\varepsilon D^2u-\varepsilon D^2u_0\right).$$

Lemma 3.2 then gives

$$\int\frac{[D^2u]u}{(1+Du^2)^{3/2}}\,dx+\varepsilon\langle D^2u,u\rangle-\varepsilon\langle D^2u_0,u\rangle=8\pi^2|\Lambda^{-1/2}u|^2.$$

[1] For simplicity we denote by u instead of u_ε the solution of equation (E_ε).

Integration by parts gives

$$\int \frac{[D^2u]u}{(1+Du^2)^{3/2}}\,dx = -\int \frac{Du^2}{(1+Du^2)^{1/2}}\,dx - \frac{2m}{(1+m^2)^{1/2}}u(0);$$

we have also

$$\langle D^2u_0, u\rangle = \langle [D^2u_0],\ u\rangle + 2mu(0),$$

and then

$$\text{(B1)}\quad 8\pi^2|\Lambda^{-1/2}u|^2 + \int \frac{Du^2}{(1+Du^2)^{1/2}}\,dx + \varepsilon|Du|^2 + 2m\big((1+m^2)^{-1/2}+\varepsilon\big)u(0) = -\varepsilon\langle [D^2u_0],\ u\rangle.$$

Estimate (B2). We may write equation (E_ε) as follows:

$$\Lambda^{-1}(u-xDu) - \frac{1}{4\pi^2}\frac{[D^2u]}{(1+Du^2)^{3/2}} - \frac{\varepsilon}{4\pi^2}(D^2u - D^2u_0) = 0.$$

We multiply by $-[D^2u]$ and integrate over $\mathbb{R}$. Then we need the following lemma.

LEMMA 3.3. *The solution u of* (E_ε) *satisfies*:

$$\langle \Lambda^{-1}(u-xDu),\ -[D^2u]\rangle = 4\pi^2|\Lambda^{1/2}u|^2 + 4m\Lambda^{-1}u(0).$$

Proof. We first notice that $|\xi|^{-1}\hat{u}$ is integrable, so that $\Lambda^{-1}u$ is a continuous function (vanishing to infinity) and $\Lambda^{-1}u(0)$ makes sense. Let us begin the proof with a formal computation where some of the scalar products may be undefined. One has

$$D^2u = [D^2u] + 2m\delta,$$

and then

$$\langle \Lambda^{-1}(u-xDu),\ -[D^2u]\rangle = \langle \Lambda^{-1}(u-xDu),\ -D^2u\rangle + 2m\langle \Lambda^{-1}(u-xDu),\ \delta\rangle,$$

but

$$\langle \Lambda^{-1}(u-xDu),\ -D^2u\rangle = 4\pi^2\langle u-xDu,\ \Lambda^1u\rangle = 4\pi^2|\Lambda^{1/2}u|^2 - 4\pi^2\langle xDu,\ \Lambda^1u\rangle$$

and

$$\langle \Lambda^{-1}(u-xDu),\ \delta\rangle = \langle \Lambda^{-1}(2u-D(xu)),\ \delta\rangle = 2\Lambda^{-1}u(0) - \langle \Lambda^{-1}D(xu),\ \delta\rangle.$$

Now we examine the term

$$\langle \Lambda^{-1}D(xu),\ \delta\rangle = -\int \operatorname{sgn}(\xi)\,D\hat{u}\,d\xi.$$

This last integral might be undefined since $D\hat{u}$ is only square integrable; however $\lim_{A\to\infty}\int_{-A}^{+A}\operatorname{sgn}(\xi)\,D\hat{u}d\xi = 0$ for $\hat{u}$ is in H^1 and $\hat{u}(0)=0$. Similarly $\langle xDu,\ \Lambda^1u\rangle = -\int D(\xi\hat{u})|\xi|\bar{\hat{u}}\,d\xi$.

Let us prove that

$$\lim_{A\to+\infty} \operatorname{Re}\int_{-A}^{+A} \operatorname{sgn}(\xi) D(\xi\hat{u})\xi\bar{\hat{u}}\,d\xi = 0,$$

$$\operatorname{Re}\int_{-A}^{+A} \operatorname{sgn}(\xi) D(\xi\hat{u})\xi\bar{\hat{u}}\,d\xi = \frac{1}{2}\int_{-A}^{+A} \operatorname{sgn}(\xi) D\left(\xi^2|\hat{u}|^2\right) d\xi.$$

Thus it is enough to prove that $\xi\hat{u}$ vanishes to infinity, which is a consequence of the following lemma.

LEMMA 3.4. *Let the function v satisfy a Hölder condition of order $\alpha/2$, $0<\alpha\leqq 2$. If $\xi^{1+\alpha}v$ is square integrable, then $\xi^{\alpha}v\to 0$ as $|\xi|\to\infty$.*

Proof. By contradiction. Thus assume the existence of a sequence ξ_n, $|\xi_n|\to\infty$, and $\varepsilon>0$ such that $|v(\xi_n)||\xi_n|^{\alpha}\geqq\varepsilon$. Since v satisfies a Hölder condition of order $\alpha/2$,

$$|v(\xi)-v(\xi_n)|\leqq c|\xi-\xi_n|^{\alpha/2};$$

therefore

$$|v(\xi)|\geqq|v(\xi_n)|-c|\xi-\xi_n|^{\alpha/2}.$$

Call In the interval $[\xi_n-\lambda\xi_n^{-2},\ \xi_n+\lambda\xi_n^{-2}]$, $\lambda>0$. For $\xi\in$ In, we have $|\xi-\xi_n|^{\alpha/2}\leqq\lambda^{\alpha/2}|\xi_n|^{-\alpha}$, so that a suitable choice of λ yields $|v(\xi)|\geqq\varepsilon/2|\xi_n|^{-\alpha}$.

If the In's are disjoint, which we may assume, one has

$$\int|\xi|^{2\alpha+2}|v|^2\,d\xi\geqq\sum_{n=0}^{\infty}\int_{\mathrm{In}}|\xi|^{2\alpha+2}|v|^2\,d\xi,$$

but

$$\int_{\mathrm{In}}|\xi|^{2\alpha+2}|v|^2\,d\xi\geqq\lambda\varepsilon^2/4,$$

so that the integral is divergent, which proves Lemma 3.4. □

Let us go back to the proof of Lemma 3.3.

$$\hat{u}=\hat{u}_0+\hat{v}\quad\text{and}\quad\xi\hat{u}_0=\frac{m}{2\pi^2\xi}\left(e^{-|\xi|^3/3}-1\right).$$

Thus it is enough to prove that $\xi\hat{v}$ vanishes to infinity. $\hat{u}$ and $\hat{u}_0$ belong to the space H^1; so do $\hat{v}$, which then satisfies a Hölder condition of order $\frac{1}{2}$, and applying Lemma 3.4 with $\alpha=1$ yields the desired result.

Finally, to justify the formal computation in Lemma 3.3, we compute $\left\langle\Lambda^{-1}(u-xDu),\ K_A*[D^2u]\right\rangle$, where $\hat{K}_A$ is the characteristic function of $[-A,+A]$, and take the limit $A\to\infty$. This completes the proof of Lemma 3.3. □

From Lemma 3.3 one gets the estimate

$$\text{(B2)}\qquad 4\pi^2|\Lambda^{1/2}u|^2+\frac{1}{4\pi^2}\int\frac{[D^2u]^2}{(1+Du^2)^{3/2}}\,dx+\frac{\varepsilon}{8\pi^2}\left|[D^2u]\right|^2$$

$$\leqq\frac{\varepsilon}{8\pi^2}\left|[D^2u_0]\right|^2-4m\Lambda^{-1}u(0).$$

Estimate (B3). We proceed as above but multiplying by $\Lambda^{-1}u$. Let us compute the term:

$$\langle \Lambda^{-1}(u-xDu),\ \Lambda^{-1}u\rangle = 2|\Lambda^{-1}u|^2 - \langle \Lambda^{-1}D(xu),\ \Lambda^{-1}u\rangle$$

but

$$-\langle \Lambda^{-1}D(xu),\ \Lambda^{-1}u\rangle = \int D\hat{u}\bar{\hat{u}}\xi^{-1}\,d\xi,$$

and, as in the proof of Lemma 3.2, we see that

$$\int D\hat{u}\bar{\hat{u}}\xi^{-1}\,d\xi = \frac{1}{2}|\Lambda^{-1}u|^2,$$

and therefore

$$\langle \Lambda^{-1}(u-xDu),\ \Lambda^{-1}u\rangle = \frac{5}{2}|\Lambda^{-1}u|^2.$$

Denoting

$$Bu = -\frac{1}{4\pi^2}\frac{[D^2u]}{(1+Du^2)^{3/2}},$$

one obtains

$$\frac{5}{2}|\Lambda^{-1}u|^2 + \langle Bu,\ \Lambda^{-1}u\rangle - \frac{\varepsilon}{4\pi^2}\langle D^2u,\ \Lambda^{-1}u\rangle + \frac{\varepsilon}{4\pi^2}\langle D^2u_0,\ \Lambda^{-1}u\rangle = 0.$$

Then

$$\frac{5}{2}|\Lambda^{-1}u|^2 + \varepsilon|\Lambda^{1/2}u|^2 \leqq |Bu||\Lambda^{-1}u| + \varepsilon|\Lambda^{1/2}u_0||\Lambda^{1/2}u|,$$

and finally

$$2|\Lambda^{-1}u|^2 + \frac{\varepsilon}{2}|\Lambda^{1/2}u|^2 \leqq \frac{\varepsilon}{2}|\Lambda^{1/2}u_0|^2 + \frac{1}{2}|Bu|^2. \tag{B3}$$

We now use estimates (B1), (B2), (B3) to prove Theorem 3.1. First, for every $\alpha > 0$ there is a $C\alpha \geqq 0$ such that

$$|\Lambda^{-1}u|_\infty \leqq \alpha|\Lambda^{1/2}u| + C\alpha|\Lambda^{-1}u|.$$

Taking this inequality in (B2) with $\alpha = \pi^2/m$ yields

$$2\pi^2|\Lambda^{1/2}u|^2 + \frac{1}{4\pi^2}\int \frac{[D^2u]^2}{(1+Du^2)^{3/2}}\,dx + \frac{\varepsilon}{8\pi^2}|[D^2u]|^2 \leqq A_1 + A_2|\Lambda^{-1}u|$$

for some constants A_1 and A_2.

On the other hand, we derive from (B3)

$$\sqrt{2}\,|\Lambda^{-1}u| \leqq \sqrt{\frac{\varepsilon}{2}}\,|\Lambda^{1/2}u_0| + \frac{1}{\sqrt{2}}|Bu|,$$

which together with the previous inequality and

$$\int \frac{[D^2u]^2}{(1+Du^2)^{3/2}}\,dx \geqq 16\pi^4|Bu|^2$$

gives $4\pi^2|Bu|^2 \leqq A_3 + A_4|Bu|$.

From this we deduce that $|Bu_\varepsilon|$ remains bounded and, going back to (B3), that $|\Lambda^{-1}u_\varepsilon|$ and $|\Lambda^{1/2}u_\varepsilon|$ are bounded too, and then also $|u_\varepsilon|$.

We now return to (B1) to prove the key estimate: $|Du_\varepsilon|_\infty$ is bounded.

(B1) writes readily:

$$8\pi^2|\Lambda^{-1/2}u|^2+\int\frac{Du^2}{(1+Du^2)^{1/2}}\,dx\leqq A_5+2m\left(\varepsilon+(1+m^2)^{-1/2}\right)|u(0)|. \tag{4}$$

To proceed further we need a technical lemma.

LEMMA 3.5. *For every $K>1$, there is some $C(K)\geqq 0$ such that*

$$2|u(0)|\leqq K\int\frac{Du^2}{(1+Du^2)^{1/2}}\,dx+C(K)|u|^{2/3} \tag{5}$$

for every even function $u\in H^1(\mathbb{R})$.

Proof. Let $K>1$ be fixed, there is a $\lambda>0$ for which $x^2/(1+x^2)^{1/2}\geqq|x|/K$ whenever $|x|\geqq\lambda$. Then

$$\int_0^\infty\frac{Du^2}{(1+Du^2)^{1/2}}\,dx\geqq\frac{1}{K}\int_E|Du|\,dx+\frac{1}{\sqrt{1+\lambda^2}}\int_{E^c}|Du|^2\,dx$$

where $E=\{x\geqq 0:|Du(x)|\geqq\lambda\}$.

Suppose first that u is nonincreasing for $x\geqq 0$ and let

$$u_1(x)=-\int_x^\infty\chi_E Du\,dt,\qquad u_2(x)=-\int_x^\infty\chi_{E^c}Du\,dt,$$

where χ_E is the characteristic function of the set E. Obviously $u=u_1+u_2$ and $0\leqq u_2\leqq u$. As u_2^2 is absolutely continuous on every compact and $D(u_2^2)=2u_2Du_2$, we have:

$$u_2(0)^2=-2\int_0^\infty u_2Du_2\,dx\leqq 2\left(\int_0^\infty u^2\,dx\right)^{1/2}\left(\int_{E^c}Du^2\,dx\right)^{1/2}.$$

Applying Young's inequality, we get

$$u_2(0)\leqq\frac{K}{\sqrt{1+\lambda^2}}\int_{E^c}Du^2\,dx+C(K)\left(\int_0^\infty u^2\,dx\right)^{1/3}.$$

On the other hand

$$u_1(0)=-\int_E Du\,dx$$

and since u is even this proves (5).

The general case follows by considering the function $\tilde{u}(x)=\inf_{0\leqq y\leqq x}|u(y)|$ which is nonincreasing and satisfies $|\tilde{u}(0)|=|u(0)|$. $\tilde{u}$ is absolutely continuous on every compact set since $|\tilde{u}(x)-\tilde{u}(y)|\leqq|u(y)-u(z)|$ for some $z\in[x,y]$ for which $|u(z)|$ is minimum. As $\tilde{u}(x)\leqq|u(x)|$ and $|D\tilde{u}(x)|\leqq|Du(x)|$, applying (5) to $\tilde{u}$ (extended with $\tilde{u}(-x)=\tilde{u}(x)$) proves the lemma. □

Let us return to (4); for ε small enough we may apply Lemma 3.5 choosing K such that $(m(1+m^2)^{-1/2}+m\varepsilon)K=\beta<1$. We get

$$8\pi^2|\Lambda^{-1/2}u|^2+(1-\beta)\int\frac{Du^2}{(1+Du^2)^{1/2}}\,dx\leqq\text{constant},$$

and then

$$\int \frac{Du^2}{(1+Du^2)^{1/2}}\,dx \leqq \text{constant}.$$

On the other hand, since $Du \in H^1(0, +\infty)$, we have

$$D\log(1+Du^2) = 2\frac{DuD^2u}{1+Du^2};$$

thus for $x \geqq 0$

$$\log\bigl(1+Du(x)^2\bigr) - \log(1+m^2) = 2\int_0^x \frac{Du}{(1+Du^2)^{1/4}} \frac{D^2u}{(1+Du^2)^{3/4}}\,dt;$$

then

$$\bigl|\log(1+Du^2) - \log(1+m^2)\bigr|_\infty \leqq 2\left(\int \frac{Du^2}{(1+Du^2)^{1/2}}\,dx\right)^{1/2}\left(\int \frac{[D^2u]^2}{(1+Du^2)^{3/2}}\,dx\right)^{1/2}.$$

From the estimates above, this is bounded, consequently $|Du_\varepsilon|_\infty$ is bounded and so is $|[D^2u_\varepsilon]|$.

Let now ε go to zero. If $u_\varepsilon = u_0 + v_\varepsilon$, v_ε is bounded in H^2 and, passing to a subsequence if necessary, we may further assume that $v_\varepsilon \rightharpoonup v$ weakly in H^2.

Let $u = u_0 + v$. As $[D^2u_\varepsilon] \rightharpoonup [D^2u]$ weakly in L^2 and $Dv_\varepsilon \to Dv$ weakly in H^1 (and then also uniformly on every compact), $[D^2u_\varepsilon]/(1+Du_\varepsilon^2)^{3/2}$ must converge to $[D^2u]/(1+Du^2)^{3/2}$ weakly in L^2. Thus u satisfies equation (E), and since u_ε is even, so is u. To complete the proof of Theorem 3.1, it remains only to prove uniqueness.

Let u_1, u_2 be two solutions of (E) in the space $u_0 + H^2$; we have:

$$\Lambda^{-1}[u_1 - u_2 - x(Du_1 - Du_2)] - \frac{1}{4\pi^2}\left(\frac{[D^2u_1]}{(1+Du_1^2)^{3/2}} - \frac{[D^2u_2]}{(1+Du_2^2)^{3/2}}\right) = 0.$$

Multiplying by $u_1 - u_2$ and integrating by parts gives

$$2\bigl|\Lambda^{-1/2}(u_1 - u_2)\bigr|^2 + \frac{1}{4\pi^2}\int\left(\frac{Du_1}{(1+Du_1^2)^{1/2}} - \frac{Du_2}{(1+Du_2^2)^{1/2}}\right)(Du_1 - Du_2)\,dx = 0.$$

But $x/(1+x^2)^{1/2}$ is an increasing function of x and the integral is $\geqq 0$, so then $u_1 = u_2$.

Remark. The same mechanism working on an interface with no grain boundary and arbitrary initial profile leads us to solve the initial value problem:

$$\frac{\partial w}{\partial t} - \Lambda^1 \frac{D^2w}{(1+Dw^2)^{3/2}} = 0,$$
$$w(0,x) = w_0(x).$$

An existence uniqueness result for that initial value problem is given in [5].

RECONSTRUCTION FROM RESTRICTED RADON TRANSFORM DATA: RESOLUTION AND ILL-CONDITIONEDNESS*

W. R. MADYCH[†‡] AND S. A. NELSON[†]

Abstract. Estimates are obtained for the ill-conditionedness of the inversion problem, which are independent of the method of inversion. These estimates are in terms of the resolution required of the inversion algorithm and parameters that describe the restrictions. Two kinds of restrictions are considered: the limited angle type and the exterior (hole) type.

Key words. Radon transform, limited angle, exterior problem, resolution, reconstruction, ill-conditionedness

AMS(MOS) subject classification. Primary 44A15

1. Introduction. As demonstrated by the technology of X-ray tomography, Radon transform data can be inverted quite successfully in cases where a full range of data is available. However, success has been less notable in cases of restricted data such as exterior (hole) problems and limited angle problems. Here we consider certain examples which clarify some of the difficulties that occur when the data is so restricted. From these examples we obtain estimates which give lower bounds on the ill-conditionedness of the reconstruction problem for restricted data. These estimates involve a parameter b related to resolution and constants a, r related to the restrictions; they are independent of the method of reconstruction.

In the limited angle case, Davison [2] has used a singular value decomposition to study ill-conditionedness. At the end of §2 we make an effort to relate some of his results to ours. A singular value decomposition for the exterior problem has been carried out by Quinto [6]. Since the bibliographies in [2] and [6] provide an account of work related to inversion of restricted data, we only mention a few articles of an introductory nature: [7] and [8] for general tomography; [3] and [4] for restricted problems.

Our results extend to Radon transforms $\hat{f}$ of functions f on R^n but there are technical complications. For clarity, we do the case $n=2$ first and comment on generalizations in §3. If $n=2$ then $\hat{f}$ gives the result of integrating f along lines $\langle x,u\rangle = t$. Namely,

$$\hat{f}(u,t)=\int_{-\infty}^{\infty} f(tu+sv)\,ds.$$

Here $u=(u_1,u_2)$ is a point on the unit circle S^1 in R^2 and v is either of the two unit vectors perpendicular to u. For points $x=(x_1,x_2)$ and $y=(y_1,y_2)$ in the plane R^2, $\langle x,y\rangle = x_1y_1+x_2y_2$ denotes the usual inner (dot) product. For the exterior problem the

data $\hat{f}$ is restricted to lines that miss a fixed disk. For the limited angle problem the vectors u are restricted to a fixed sector.

We let U denote the subset of $S^1 \times R$ that corresponds to these restrictions on (u,t). The distance from the point x_0 to the line $\langle x,u\rangle = t$ is $|t-\langle x_0,u\rangle|$. Thus

$$U=\{(u,t): |t-\langle x_0,u\rangle| > d\} \tag{1.1}$$

corresponds to the lines that miss the disk with center x_0 and radius d. For the limited angle case, we fix α in $(0,\pi/2)$ and take

$$U=\{(u,t): \langle u,e_1\rangle^2 \leqq \cos^2\alpha\} \tag{1.2}$$

where $e_1=(1,0)$. Note that $u=\pm(\cos\theta,\sin\theta)$, $\alpha \leqq \theta \leqq \pi-\alpha$ gives the vectors specified by (1.2).

The examples we consider are defined by

$$g_b(x)=\psi(x)e^{-ab|x|^2}\cos bx_1 \tag{1.3}$$

where $|x|^2=\langle x,x\rangle = x_1^2+x_2^2$ and a, b are positive numbers. We assume that ψ is a measurable function which is identically 1 on a disk $|x|<r$ and takes values in $[0,1]$ elsewhere. The function ψ is included in (1.3) to provide a way to make g_b vanish outside of a bounded set, but if desired, ψ may be taken to be identically 1.

Below, we assume $a>0$. However if one takes $a=0$ and takes ψ to be the indicator function for the unit disk then g_b reduces to a density that has been used in numerical tests of certain limited angle reconstruction algorithms; see [5].

We will be interested in g_b in cases where b becomes large with a and r fixed. In such cases the graph of g_b has furrows near the origin, running parallel to the x_2 axis. The spacing of the furrows is $2\pi/b$ and their length is of order $(ab)^{-1/2}$. One would expect g_b to be reasonably well reconstructed by algorithms claiming to resolve features whose size is of order $1/b$.

The following theorem shows that achieving such resolution when b is large, leads to severe demands on the accuracy of the data.

Indeed, this result gives an estimate on the accuracy required and, we stress, is independent of the inversion algorithm. Roughly speaking, it indicates that such data must be given with accuracy of order e^{-cb} in order to resolve features of size $1/b$; here c is a positive constant which depends on the geometry.

THEOREM 1.1. *Let g_b and r be as above. If U is defined by* (1.1) *with $x_0=(0,d)$, $d=\sqrt{2}\,r$ and if $a=(2\sqrt{2}\,r)^{-1}$ in* (1.3), *then for all $b>0$*

$$\sup_{(u,t)\in U} |\hat{g}_b(u,t)| \leqq 2\left(\frac{\pi}{ab}\right)^{1/2} e^{-ar^2b}. \tag{1.4}$$

Likewise, if U is defined by (1.2) *and if $a=(2r)^{-1}\sin\alpha$, then* (1.4) *again holds for all $b>0$.*

Proof. The final remark in §3 shows that for all (u,t)

$$|\hat{g}_b(u,t)| \leqq \left(\frac{\pi}{ab}\right)^{1/2}(e^{-abr^2}+e^{-abQ}) \tag{1.5}$$

where $Q=t^2+(u_2)^2(2a)^{-2}$. Thus it suffices to prove that $Q \geqq r^2$ for (u,t) in U. Since $|u|=1$, we see that $(u_1)^2 \leqq \cos^2\alpha$ implies $(u_2)^2 \geqq \sin^2\alpha$. Hence $Q \geqq (\sin\alpha)^2(2a)^{-2}=r^2$ in the case of U given by (1.2). In the other case we see from (1.1) that if (u,t) is in U then $|t-du_2| \geqq d$, which implies $t^2+(du_2)^2 \geqq d^2/2$. But this says $Q \geqq r^2$ because $d=\sqrt{2}\,r=(2a)^{-1}$.

The functions g_b can be used as building blocks to construct additional examples of densities g that satisfy (1.4). How this is done depends on whether U is given by (1.1) or (1.2).

If U is given by (1.2) then any translate of g_b will also satisfy (1.4). Superimposing such translates leads to examples like

$$g(x_1,x_2)=\int_{-1/2}^{1/2} g_b(x_1,x_2-t)\,dt. \tag{1.6}$$

For this example, the furrows are approximately of unit length when b is large. If U is given by (1.1) then other densities that satisfy (1.4) can be obtained from g_b by using rotations of the plane about the point $x_0=(0,d)$ in place of translations.

Further examples of densities that can be constructed by using the functions g_b are those of the form $f=h+cg_b$ where c is a constant and h is a suitable function. When b is large, (1.4) shows that there will only be slight differences in the U restricted Radon transform data for f and h. Since $|g_b(x)|\leqq\psi(x)e^{-ab|x|^2}$, c and h can be chosen so that f and h satisfy nonnegativity conditions or, more generally, conditions which specify a given range of values on a given subset.

2. Discussion. In this section we examine in more detail some of the implications of Theorem 1.1. We begin with some useful notation and estimates. Define $\phi_{a,b}$ on R^2 by

$$\phi_{a,b}(x_1,x_2)=\begin{cases} 1 & \text{if } \cos bx_1\geqq\tfrac{1}{2} \text{ and } ab|x|^2\leqq 1,\\ -1 & \text{if } \cos bx_1\leqq-\tfrac{1}{2} \text{ and } ab|x|^2\leqq 1,\\ 0 & \text{otherwise.}\end{cases}$$

The resemblance between $\phi_{a,b}$ and g_b is reflected in the fact that $\phi_{a,b}g_b\geqq 0$ and

$$|g_b|\geqq\frac{e^{-1}}{2}|\phi_{a,b}|\psi. \tag{2.1}$$

We will assume $abr^2\geqq 1$, so the factor of ψ in (2.1) can be dropped. The set where $|\phi_{a,b}(x)|=1$ consists of stripes inside a disk of radius $(ab)^{-1/2}$. Since the area of those stripes is at least half the area of the disk we have

$$\|\phi_{a,b}\|_p\geqq\left(\frac{\pi}{2ab}\right)^{1/p}. \tag{2.2}$$

Here $\|\ \|_p$ denotes the usual $L^p(R^2)$ norm:

$$\|f\|_p=\left\{\int|f(x)|^p\,dx\right\}^{1/p}$$

where $dx=dx_1dx_2$ is the usual measure on R^2 and the integral is taken over the whole plane.

Combining (2.1) and (2.2) gives the first inequality in

$$\frac{e^{-1}}{2}\left(\frac{\pi}{2ab}\right)^{1/p}\leqq\|g_b\|_p\leqq\left(\frac{\pi}{pab}\right)^{1/p}. \tag{2.3}$$

The second inequality follows from $|g_b(x)|\leqq e^{-ab|x|^2}$.

Now suppose V is a subset of U and A is a mapping of data $\hat{f}\,|_V$ into functions defined on some subset Ω of the plane. Here $\hat{f}\,|_V$ represents $\hat{f}$ restricted to the set V. A may be viewed as a reconstruction algorithm. For notational convenience, we denote the result of A applied to $\hat{f}\,|_V$ by Rf; symbolically $Rf = A(\hat{f}\,|_V)$. In addition, we define Rf to be 0 at points outside of Ω.

To see the implications of estimates like (1.4) let f_1 and f_2 be densities that, for some nonzero constant c, satisfy $f_1(x) - f_2(x) = cg_b(x)$ at all x in Ω and along all lines corresponding to V. If A is a reconstruction algorithm in the sense that Rf approximates f on Ω and if features of size $1/b$ are resolved, then on Ω one can expect $Rf_1 - Rf_2$ to resemble $c\phi_{a,b}$. This resemblance should be at least good enough to give an estimate such as

$$\| Rf_1 - Rf_2 \|_p \geq \frac{e^{-1}}{2} \left\{ \int_\Omega |c\phi_{a,b}(x)|^p \, dx \right\}^{1/p}.$$

This can be linked with an estimate like (2.2) if Ω is suitable. Even in the exterior case it is appropriate to assume that Ω contains the half disk D defined by $x_2 < 0$, $(x_1)^2 + (x_2)^2 < (ab)^{-1}$. Since the stripes where $|\phi_{a,b}(x)| = 1$ cover more than half the area of D, this assumption on Ω implies

$$\int_\Omega |\phi_{a,b}(x)|^p \, dx \geq \frac{\pi}{4ab}.$$

Combining the last two inequalities gives

$$\| Rf_1 - Rf_2 \|_p \geq \frac{|c|}{2e} \left(\frac{\pi}{4ab} \right)^{1/p}. \tag{2.4}$$

This difference in the reconstructions Rf_1, Rf_2 must be based on differences in the data $\hat{f}_1\,|_V$, $\hat{f}_2\,|_V$. By (1.4) the difference in the data is at most $2|c|(\pi/ab)^{1/2} e^{-ar^2 b}$. Thus to achieve (2.4), A would have to amplify such small differences between sets of data by a factor that is at least of order $(ab)^{1/2 - 1/p} e^{ar^2 b}$.

Such amplification means that, to keep the effects of noise down, the data will at least have to be accurate to roughly $O(e^{-ar^2 b})$. Note that $ar^2 = (r/2)\sin\alpha$ in the limited angle case and $ar^2 = (r/4)\sqrt{2}$ in the exterior case.

In the above discussion we have tried to minimize the assumptions made about A. For specific reconstruction algorithms A it should not be difficult to make the above considerations more precise.

For purposes of comparison with [2], we introduce some further notation. Let H_N denote the space of functions of the form $h = \chi\phi$ where χ is the indicator function of the unit disk in R^2 and ϕ is any polynomial on R^2 of degree no more than N. Let

$$\varepsilon_N(\alpha) = \min_{h \in H_N} \frac{\|\hat{h}\|_{2,\alpha}}{\|h\|_2} \tag{2.5}$$

where the denominator is the $L^2(R^2)$ norm of h and the numerator is defined by

$$\|\hat{h}\|_{2,\alpha}^2 = \frac{1}{2} \int_\alpha^{\pi - \alpha} \int_{-1}^{1} |\hat{h}(u(\theta), t)|^2 (1 - t^2)^{1/2} \, dt \, d\theta$$

with $u(\theta)=(\cos\theta,\sin\theta)$. The results in [2] imply that $\varepsilon_N(\alpha)=(\pi/N)\lambda_{N-1}(N,W)$ where $W=(\pi/2-\alpha)/\pi$ and $\lambda_{N-1}(N,W)$ is the function plotted in [2, Fig. 1]. As an analogue of $\varepsilon_N(\alpha)$ we consider

$$E_b(\alpha)=\frac{\sup|\hat{g}_b(u(\theta),t)|}{\|g_b\|_2}$$

where the sup is over $\alpha<\theta<\pi-\alpha$, $-\infty<t<\infty$ and where the parameter a in g_b is chosen so that $a=(2r)^{-1}\sin\alpha$. By (1.4) and (2.3) we have

$$E_b(\alpha)\leqq 4e\sqrt{2}\,e^{-(br\sin\alpha)/2}. \tag{2.6}$$

Figure 1 of [2] suggests that $\varepsilon_N(\alpha)$ varies with N and α in much the same way as the right side of (2.6) varies with b and α.

3. Estimates. In this section we establish the estimates that were used above and comment on extensions to higher dimensions. We use the natural n dimensional versions of the two-dimensional notation in §§1 and 2.

The k-plane transform $R_k(f)$ of a function f on R^n is defined by

$$R_k(f)(M)=\int_M f\,d\sigma$$

where M denotes any k-dimensional affine subspace of R^n, $1\leqq k\leqq n-1$ and $d\sigma$ is ordinary Euclidean measure on M. In what follows we let $q(M)$ denote the point on M that is closest to the origin. If $v_1,\cdots,v_k$ are an orthonormal basis for the subspace $M-q(M)$ then

$$R_k(f)(M)=\int\cdots\int f\left(q(M)+\sum_{i=1}^{k}s_iv_i\right)ds_1\cdots ds_k. \tag{3.1}$$

For $k=n-1$, this becomes the Radon transform and we use the notation $\hat{f}(u,t)=R_{n-1}(f)(M)$ where $M=\{x\in R^n\colon\langle x,u\rangle=t\}$.

PROPOSITION 3.1. *Let $h(x)=e^{-c|x|^2}\cos bx_1$ where b,c are positive constants and $x_1=\langle x,e_1\rangle$, $e_1=(1,0,\cdots,0)$. Then*

$$R_k(h)(M)=\left(\frac{\pi}{c}\right)^{k/2}e^{-b^2l^2(4c)^{-1}}e^{-c|q(M)|^2}\cos\left(b\langle q(M),e_1\rangle\right)$$

where $l^2=|P_Me_1|^2=\sum_{i=1}^{k}\langle v_i,e_1\rangle^2$ is the square of the length of the vector obtained by orthogonally projecting e_1 onto $M-q(M)$.

Remark. In the Radon transform case, $q(M)=tu$ and

$$|P_Me_1|^2=1-\langle u,e_1\rangle^2=\sum_{j=2}^{n}(u_j)^2.$$

Proof. If $x=q(M)+\sum_{i=1}^{k}s_iv_i$ with v_i as in (3.1), then $|x|^2=|q(M)|^2+\sum_{i=1}^{k}(s_i)^2$ and $x_1=\langle q(M),e_1\rangle+(s,a)$ where $(s,a)=\sum_{i=1}^{k}s_ia_i$ and $a_i=\langle v_i,e_1\rangle$. Thus, from (3.1)

$$R_k(h)(M)=\mathrm{Re}\int\cdots\int e^{-c|q(M)|^2}e^{-c|s|^2}e^{ib(\langle q(M),e_1\rangle+(s,a))}ds_1\cdots ds_k.$$

Applying $\int e^{-c|s|^2}e^{ib(s,a)}ds=(\pi/c)^{k/2}e^{-b^2|a|^2(4c)^{-1}}$ completes the proof.

PROPOSITION 3.2. *Let $g=\psi h$ where h is as in Proposition* 3.1 *and ψ is any measurable function on R^n taking values in the interval* $[0,1]$ *and satisfying $\psi(x)=1$ when $|x|<r$. Then*

$$|R_1(g-h)(M)|\leqq\left(\frac{\pi}{c}\right)^{1/2}e^{-cr^2} \tag{3.2}$$

while for $k\geqq 2$

$$|R_k(g-h)(M)|\leqq\frac{1}{2}\omega_{k-1}c^{-k/2}\int_{cr^2}^{\infty}e^{-u}u^{(k/2)-1}\,du \tag{3.3}$$

where ω_{k-1} denotes the area of the unit sphere in R^k.

Remark. The asymptotic expansion [1, pp. 13–14]

$$\int_z^{\infty}e^{-u}u^{q-1}\,du\sim z^q e^{-z}\left\{\frac{1}{z}+\frac{q-1}{z^2}+\frac{(q-1)(q-2)}{z^3}+\cdots\right\} \tag{3.4}$$

shows that (3.3) gives bounds much like (3.2) when cr^2 is large. If q is a positive integer (k even) then (3.4) is exact. In particular, if $k=2$ then (3.3) says

$$|R_2(g-h)(M)|\leqq\left(\frac{\pi}{c}\right)e^{-cr^2}. \tag{3.5}$$

Proof. Using the fact that $|g-h|(x)\leqq\chi(x)e^{-c|x|^2}$ where χ is the indicator function for the set $|x|\geqq r$ we see from (3.1) that

$$|R_k(g-h)(M)|\leqq J(k,c,r,|q(M)|) \tag{3.6}$$

where

$$J(k,c,r,a)=\int_{a^2+|s|^2\geq r^2}e^{-c(a^2+|s|^2)}\,ds_1\cdots ds_k. \tag{3.7}$$

We first show that for all real a

$$J(1,c,r,a)\leqq J(1,c,r,r) \tag{3.8}$$

and

$$J(k,c,r,a)\leqq J(k,c,r,0),\qquad k\geqq 2. \tag{3.9}$$

If $r^2\leqq a^2$ then the integration in (3.7) is over all of R^k and $e^{-c(a^2+s^2)}\leqq e^{-c(r^2+s^2)}$ so $J(k,c,r,a)\leqq J(k,c,r,r)$. Thus if (3.8) and (3.9) hold for $a^2\leqq r^2$ then they hold for all real a.

Assuming $r^2-a^2\geqq 0$ and changing to polar coordinates we have

$$J(k,c,r,a)=\omega_{k-1}\int_{(r^2-a^2)^{1/2}}^{\infty}e^{-c(a^2+\rho^2)}\rho^{k-1}\,d\rho$$

which becomes

$$J(k,c,r,a)=\frac{1}{2}\omega_{k-1}\int_{r^2}^{\infty}e^{-ct}(t-a^2)^{(k-2)/2}\,dt \tag{3.10}$$

after the change of variable $t=a^2+\rho^2$. If $t>r^2\geqq a^2$ then $(t-a^2)^{1/2}\leqq(t-r^2)^{1/2}$ and $(t-a^2)^{(k-2)/2}\leqq(t-0)^{(k-2)/2}$ for $k\geqq 2$. Thus (3.8) and (3.9) follow from (3.10).

To obtain (3.2) we apply (3.8) to (3.6) and note that $J(1,c,r,r)=(\pi/c)^{1/2}e^{-cr^2}$. To obtain (3.3) we apply (3.9) to (3.6) and express $J(k,c,r,0)$ using (3.10) and the change of variable $u=ct$.

Remark. To derive the inequality (1.5) write $|\hat{g}|\leqq|\hat{g}-\hat{h}|+|\hat{h}|$ and apply Propositions 3.1 and 3.2 with $c=ab$, $n=2$, $k=1$. A higher-dimensional version of (1.5) can be obtained in the same way but (3.3) gives it a messy appearance. If $n=3$, $k=2$ then (3.3) simplifies to (3.5), so that

$$|\hat{g}(u,t)|\leqq\frac{\pi}{c}\left(e^{-cr^2}+e^{-cQ}\right)$$

where $Q=b^2l^2(2c)^{-2}+t^2$. For $c=ab$ this gives the $n=3$ version of (1.5). If (1.1)–(1.3) are given $n=3$ interpretations, only two changes are needed in the statement of Theorem 1.1: take $x_0=de_0$ where e_0 is any unit vector orthogonal to e_1 and change the right side of (1.4) by replacing $(\pi/ab)^{1/2}$ with (π/ab). Concerning the proof we note that $|gt-d\langle e_0,u\rangle|\geqq d$ implies $t^2+d^2\langle e_0,u\rangle^2\geqq d^2/2$. Also, $\langle e_0,u\rangle^2+\langle e_1,u\rangle^2\leqq|u|^2=1$ so $\langle e_0,u\rangle^2\leqq 1-\langle e_1,u\rangle^2=l^2$. Thus, if (u,t) is in the set U given by (1.1) then $t^2+d^2l^2\geqq d^2/2$ and hence $Q\geqq r^2$. For the case of U given by (1.2), $Q\geqq r^2$ follows from $l^2\geqq\sin^2\alpha$.

Acknowledgment. We thank the referee for bringing reference [5] to our attention.

SIGN VARIATIONS OF THE MACDONALD IDENTITIES*

DENNIS STANTON†

Abstract. Sign variations are given for the Macdonald identities for root systems of small rank. Limiting cases of these identities give properties of the eta function. Two such formulas are explicitly given.

Key words. Macdonald identities, eta function, root systems

AMS(MOS) subject classifications. Primary 10A20; secondary 10D05, 33A70

1. Introduction. The Macdonald identities [3] are the analogues of the Weyl denominator formula for affine root systems. Dyson [2], based upon Winquist's [6] original idea, found each infinite family of these identities (except $B_n^\vee$) by a case-by-case argument. Macdonald [3] gave a uniform proof of these identities.

Dyson's proof (and Macdonald's) can be thought of as having three main steps. Let $F(x_1,\cdots,x_n)$ be the product side of the Macdonald identities. Let F have the Laurent expansion

$$F(x_1,\cdots,x_n)=\sum_m f(m_1,\cdots,m_n;q)x_1^{m_1}\cdots x_n^{m_n}. \tag{1.1}$$

These three steps are:

(I) Use the affine part of the root system to give functional equations for $F(x_1,\cdots,x_n)$ or $f(m_1,\cdots,m_n;q)$. These equations reduce the number of unknown $f(m_1,\cdots,m_n;q)$ to a finite number. This gives a fundamental domain for the lattice M in the Macdonald identities (see [3]).

(II) Use the Weyl group W of the finite root system to show that only one function, $f(0,\cdots,0;q)$, the constant term, is unknown. The simple reflections give sign-reversing involutions which show that all terms other than the orbit of W on $(0,\cdots,0)$ are zero.

(III) Find the constant term by specializing the identity in (II). This can be done by choosing special roots of unity for each x_i and using the Weyl denominator and Jacobi triple product formulas.

In this paper we shall use this proof to give new identities, called sign variations. The infinite products in $F(x_1,\cdots,x_n)$ are modified by allowing appropriate signs. Step (I) still holds. Instead of the Weyl group in (II), a subgroup related to the signs is used. This time more than orbit survives. There is one constant to be computed for each orbit. The calculations can be carried out if the rank of the root system is small.

These steps also easily prove the generalization of the Macdonald identities of type A_n due to Milne [5]. They also indicate that the Macdonald identities could have a purely bijective proof.

2. Type B_2. For Type B_2 the Macdonald identity is Winquist's identity [6], and the function $F(x,y)$ is

$$F(x,y)=(1/x)_\infty(qx)_\infty(1/y)_\infty(qy)_\infty(1/xy)_\infty(qxy)_\infty(y/x)_\infty(qx/y)_\infty, \tag{2.1}$$

where

$$(x)_\infty=(x;q)_\infty=\prod_{n=0}^{\infty}(1-xq^n). \tag{2.2}$$

(The base q will be omitted unless a base other than q is used.) The functional equations for (I) are

$$F(x,y)=-q^3x^3F(qx,y) \tag{2.3}$$

and

$$F(x,y)=-q^2y^3F(x,qy) \tag{2.4}$$

which imply that

$$f(i,j;q)=-q^if(i-3,j;q) \tag{2.5}$$

and

$$f(i,j;q)=-q^{j-1}f(i,j-3;q). \tag{2.6}$$

So the functions $f(i,j;q)$ are uniquely determined by the initial conditions at (i,j), $0\leqq i,\ j\leqq 2$.

For (II), the generators σ_1 and σ_2 of the Weyl group give

$$\sigma_1\colon\ -x^3F(x,y)=F(1/x,y) \tag{2.7}$$

and

$$\sigma_2\colon\ -xF(x,y)=yF(y,x). \tag{2.8}$$

These two equations imply

$$\sigma_1\colon\ f(i,j;q)=-f(-i-3,j;q) \tag{2.9}$$

and

$$\sigma_2\colon\ f(i,j;q)=-f(j-1,i+1;q). \tag{2.10}$$

Equations (2.9) and (2.10) give relations on the initial conditions. They can be recorded by Fig. 1: the edges of σ_1 and σ_2 are solid and dotted lines, respectively. The edges are labeled with the appropriate sign of the equality. It is clear that f is zero off the orbit of 00. Moreover, all terms in this orbit are determined by $f(0,0;q)$.

For (III), the function $F(x,y)$ is given by (II) as

(2.11)

$$F(x,y)=f(0,0;q)\sum_{i,j=-\infty}^{\infty}(-1)^{i+j}q^{(3i^2+3j^2+3i+j)/2}x^{3i}y^{3j}(1+x^2yq^{2i+j}+y^2q^{2j}-xyq^{i+j}).$$

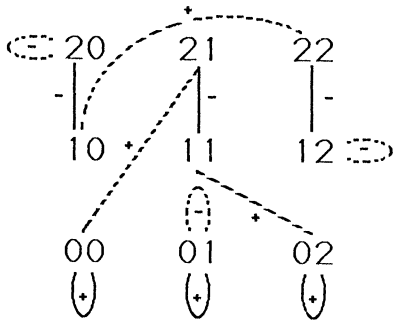

FIG. 1

We trisect (2.11) by replacing x and y independently by $-1, -\omega$, and $-\omega^2$, and summing the resulting equations. The Jacobi triple product identity then implies

$$f(0,0;q)=1/(q)_\infty^2. \tag{2.12}$$

For a sign variation, take a subset T of positive roots, and replace all infinite products $(z)_\infty$ in $F(x,y)$ involving T or $-T$ by $(-z)_\infty$. Then (I) still holds, with a possible change of sign. For (II), the subgroup $W(T)$ of W which fixes $T\cup -T$ is used. For example, if

$$F(x,y)=(1/x)_\infty(qx)_\infty(1/y)_\infty(qy)_\infty(1/xy)_\infty(qxy)_\infty(-y/x)_\infty(-qx/y)_\infty \tag{2.13}$$

then (2.3) and (2.4) hold with no minus sign. The involution σ_1 is replaced by

$$-x^2y^2F(x,y)=F(1/y,1/x), \tag{2.14}$$

and (2.8) has no minus sign. The graph that results is shown as Fig. 2. There are two orbits which survive: 00-11-02-21 and 20-12. The formula that results is

(2.15)

$$\begin{aligned} &F(x,y)\\ &=c_1(q)\sum_{i,j=-\infty}^{\infty} q^{(3i^2+3j^2+3i+j)/2}x^{3i}y^{3j}\left(1-q^{-j}/y+q^{-i-2j}/xy^2-q^{-2i-2j}/x^2y^2\right)\\ &\quad+c_2(q)\sum_{i,j=-\infty}^{\infty} q^{(3i^2+3j^2+3i+j)/2}x^{3i}y^{3j}\left(q^{-i}/x-q^{-2i-j}/x^2y\right), \end{aligned}$$

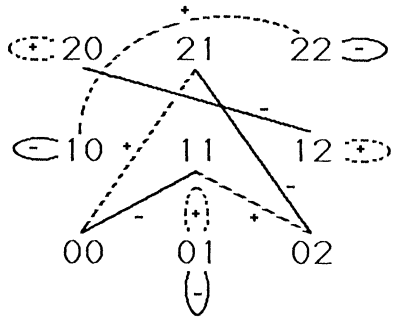

FIG. 2

where

$$c_1(q)=(q^3;q^3)_\infty(-q)_\infty/(-q^3;q^3)_\infty(q)_\infty^3 \tag{2.16}$$

and

$$c_2(q)=-2(-q^3;q^3)_\infty(q^6;q^6)_\infty/(q)_\infty^3. \tag{2.17}$$

There are two other B_2 sign variations. If

$$F(x,y)=(1/x)_\infty(qx)_\infty(1/y)_\infty(qy)_\infty(-1/xy)_\infty(-qxy)_\infty(y/x)_\infty(qx/y)_\infty, \tag{2.18}$$

then

(2.19)

$$F(x,y)=c_1(q)\sum_{i,j=-\infty}^{\infty}q^{(3i^2+3j^2+3i+j)/2}x^{3i}y^{3j}(1-q^{-j}/y-q^{-i-2j}/xy^2+q^{-2i-2j}/x^2y^2)$$

$$+c_2(q)\sum_{i,j=-\infty}^{\infty}q^{(3i^2+3j^2+3i+j)/2}x^{3i}y^{3j}(q^{-i-j}/xy-q^{-2i}/x^2),$$

where

$$c_1(q)=(q^3;q^3)_\infty(-q)_\infty/(-q^3;q^3)_\infty(q)_\infty^3 \tag{2.20}$$

and

$$c_2(q)=2(q^6;q^6)_\infty(-q^3;q^3)_\infty/(q)_\infty^3. \tag{2.21}$$

If

(2.22)

$$F(x,y)$$
$$=(-1/x)_\infty(-qx)_\infty(-1/y)_\infty(-qy)_\infty(-1/xy)_\infty(-qxy)_\infty(-y/x)_\infty(-qx/y)_\infty,$$

then

(2.23)

$$F(x,y)=c_1(q)\sum_{i,j=-\infty}^{\infty}q^{(3i^2+3j^2+3i+j)/2}x^{3i}y^{3j}(1+q^{-j}/y+q^{-i-2j}/xy^2+q^{-2i-2j}/x^2y^2)$$

$$+c_2(q)\sum_{i,j=-\infty}^{\infty}q^{(3i^2-3j^2+i+j)/2}x^{3i-1}y^{3j}(1+q^{-i}/x)(1+q^{-j}/y),$$

$$+c_3(q)\sum_{i,j=-\infty}^{\infty}q^{(3i^2+3j^2+3i-3j)/2}x^{3i}y^{3j-2},$$

where

$$c_1(q)=(q^3;q^3)_\infty^2(-q)_\infty^2/(-q^3;q^3)_\infty^2(q)_\infty^4, \tag{2.24}$$

$$c_2(q)=(q^3;q^3)_\infty(q^6;q^6)_\infty(-1)_\infty/(q)_\infty^4, \tag{2.25}$$

and

$$c_3(q)=2q^{1/2}\Big[(q^{3/2};q^3)_\infty(-q^{1/2})_\infty^2/(q^{1/2})_\infty - (-q^{3/2};q^3)_\infty(q^{1/2})_\infty^2/(-q^{1/2})_\infty\Big]/3(q)_\infty^2(q^3;q^6)_\infty^2. \tag{2.26}$$

In all of these formulas, on the sum side the orbit could be represented in another way. For example, in (2.11), the four terms could be taken as (x,y) with exponents $(3i,3j)$, $(3j-1,-3i-2)$, $(-3i-3,3j)$ and $(-3j-2,3i+1)$.

3. Types A_2, BC_1, and $B_2^\vee$. These are the remaining types which have at most three sign variations. Types G_2 and $G_2^\vee$ have 15 variations, while A_3 has 7. No infinite families of variations are given. It would appear that the appropriate constants are difficult to find in general.

Type A_2:

$$F(x,y)=(-1/x)_\infty(-qx)_\infty(1/y)_\infty(qy)_\infty(1/xy)_\infty(qxy)_\infty; \tag{3.1}$$

$$F(x,y)=c_1(q)\sum_{i,j=-\infty}^{\infty} q^{(i^2+j^2+ij+i+j)}(-1)^i(x^{2i+j}+x^{-i+j-1})y^{i+2j} + c_2(q)\sum_{i,j=-\infty}^{\infty} q^{(i^2+j^2+ij+3i+3j)}(-1)^i x^{2i+j+2}y^{i+2j+2} \tag{3.2}$$

where

$$c_1(q)=(q^3;q^3)_\infty(-q)_\infty/(-q^3;q^3)_\infty(q)_\infty^3 \tag{3.3}$$

and

$$c_2(q)=2q^3(-q^3;q^3)_\infty(q^6;q^6)_\infty/(q)_\infty^3. \tag{3.4}$$

Type BC_1:

$$F(x)=(-1/x)_\infty(-qx)_\infty(-qx^2;q^2)_\infty(-q/x^2;q^2)_\infty; \tag{3.5}$$

$$F(x)=c_1(q)\sum_{n=-\infty}^{\infty} q^{n(3n+1)/2}(x^{3n}+x^{-3n-1})+c_2(q)\sum_{n=-\infty}^{\infty} q^{3n(n+1)/2}x^{3n+1} \tag{3.6}$$

where

$$c_1(q)=(q^3;q^3)_\infty(-q^3;q^6)_\infty/(-q;q^2)_\infty(q)_\infty^2 \tag{3.7}$$

and

$$c_2(q)=2q(-q^6;q^6)_\infty(q^{12};q^{12})_\infty/(q^2;q^2)_\infty(q)_\infty. \tag{3.8}$$

Type $B_2^\vee$:

$$F(x,y)=(1/x^2;q^2)_\infty(q^2x^2;q^2)_\infty(1/y^2;q^2)_\infty(q^2y^2;q^2)_\infty(1/xy)_\infty(qxy)_\infty \times(-y/x)_\infty(-qx/y)_\infty; \tag{3.9}$$

$$F(x,y)=c_1(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+2i+2j^2+j}\left(x^{4i}y^{4j}-x^{-4j-3}y^{-4i-3}\right.$$
$$\left.-x^{-4i-4}y^{-4j-2}+x^{4j-1}y^{4i+1}\right)$$
$$+c_2(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+4i+2j^2+j}\left(x^{4i+2}y^{4j}-x^{-4j-3}y^{-4i-5}\right.$$
$$\left.-x^{-4i-6}y^{-4j-2}+x^{4j-1}y^{4i+3}\right) \tag{3.10}$$

where

$$c_1(q)=(-q^2;q^2)_\infty^5(-q)_\infty^3/(q^8;q^8)_\infty^2 \tag{3.11}$$

and

$$c_2(q)=-2q^2(-q^2;q^2)_\infty^3(-q)_\infty/(-q^2;q^4)_\infty^2(q)_\infty^2; \tag{3.12}$$

$$F(x,y)=(-1/x^2;q^2)_\infty(-q^2x^2;q^2)_\infty(1/y^2;q^2)_\infty(q^2y^2;q^2)_\infty$$
$$\times(1/xy)_\infty(qxy)_\infty(y/x)_\infty(qx/y)_\infty; \tag{3.13}$$

$$F(x,y)=c_1(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+2i+2j^2+j}(-1)^j x^{4i}\left(y^{4j}-y^{-4j-2}\right)$$
$$+c_2(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+3i+2j^2+2j}(-1)^j y^{4j+1}(x^{4i+1}+x^{-4i-5})$$
$$+c_3(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+4i+2j^2+j}(-1)^j x^{4i+2}\left(y^{4j}-y^{-4j-2}\right) \tag{3.14}$$

where

$$c_1(q)=(-q^2;q^2)_\infty^6/(q^8;q^8)_\infty^2(q;q^2)_\infty, \tag{3.15}$$

$$c_2(q)=-q(-q^2;q^2)_\infty\left[(q^{1/2})_\infty^4+(-q^{1/2})_\infty^4\right]/2(-q;q^2)_\infty^3(q^2;q^2)_\infty \tag{3.16}$$

and

$$c_3(q)=2q^2(-q^2;q^2)_\infty^6/(-q^2;q^4)_\infty^2(q^4;q^4)_\infty^2(q;q^2)_\infty; \tag{3.17}$$

$$F(x,y)=(1/x^2;q^2)(q^2x^2;q^2)_\infty(-1/y^2;q^2)_\infty(-q^2y^2;q^2)_\infty$$
$$\times(1/xy)_\infty(qxy)_\infty(y/x)_\infty(qx/y)_\infty; \tag{3.18}$$

$$F(x,y)=c_1(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+2i+2j^2+j}(-1)^i x^{4i}\left(y^{4j}+y^{-4j-2}\right)$$
$$+c_2(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+3i+2j^2+2j}(-1)^i y^{4j+1}(x^{4i+1}-x^{-4i-5})$$
$$+c_3(q)\sum_{i,j=-\infty}^{\infty} q^{2i^2+3i+2j^2+4j}(-1)^i y^{4j+3}(x^{4i+1}-x^{-4i-5}) \tag{3.19}$$

where

$$c_1(q)=\left[(q^{1/2})_\infty^4+(-q^{1/2})_\infty^4\right]/(q^2;q^2)_\infty^2(-q;q^2)_\infty^3, \tag{3.20}$$

$$c_2(q)=-q(-q^2;q^2)_\infty^6/(q^8;q^8)_\infty^2(q;q^2)_\infty, \tag{3.21}$$

and

$$c_3(q)=-2q^3(-q^2;q^2)_\infty^2(-q^4;q^4)_\infty^2/(q^2;q^2)_\infty(q)_\infty. \tag{3.22}$$

4. Remarks. One application of the Macdonald identities is to give expansions for powers of the eta function

$$\eta(q)=q^{1/24}(q)_\infty. \tag{4.1}$$

For example, if $x\to 1$ in the identity of type BC_1, then (see [3, p. 93])

$$\sum_{n\equiv 1 \pmod 6} nq^{n^2/24}=\eta(q)^5/\eta(q^2)^2. \tag{4.2}$$

If $x\to -1$ in the sign variation of BC_1 ((3.5) and (3.6)), we find

$$\sum_{n\equiv 1 \pmod 6} (-1)^{(n-1)/6}nq^{n^2/24}=\eta(q)\eta(q^2)^6\eta(q^{12})/\eta(q^4)^3\eta(q^6)^2 \tag{4.3}$$
$$+6\eta(q^2)\eta(q^3)^3\eta(q^{12})^3/\eta(q^4)\eta(q^6)^3.$$

As another example, we let $x,y\to 1$ in the sign variation (2.15) of B_2. It is easy to see that $\eta(q)^3c_1(q)$ and $\eta(q)^3c_2(q)$ can be expanded by the Jacobi triple product identity to obtain

(4.4)

$$4\eta(q)^7\eta(q^2)^2q^{-11/24}$$
$$=3\sum_{i,j,k=-\infty}^{\infty}\{i(3j-1)(3j+3i+1)+(3i+1)(3j+2)(i+j+1)\}q^{(3k^2+k+3i^2+3i+3j^2+j)/2}$$
$$-\sum_{i,j,k=-\infty}^{\infty}\{3j(3j-1)(3i-1)+(3i+1)(3i+2)(3j+2)\}q^{(3k^2+3k+3i^2+i+3j^2+j)/2}.$$

All of the sign variations can be treated in this way.

These techniques do not apply to the finite forms of the Macdonald conjectures in [4]. It is reasonable to ask if there are constant term formulas for finite forms of the sign variations. The answer is no, for in the low rank cases, such a result would imply that a well poised ${}_3F_2(-1)$ (see [1]) is evaluable.

PRODUCT AND ADDITION FORMULAS FOR THE CONTINUOUS q-ULTRASPHERICAL POLYNOMIALS*

MIZAN RAHMAN† AND ARUN VERMA‡

Abstract. Using Askey and Wilson's orthogonality relation and Rahman's product formula for Askey–Wilson polynomials a Gegenbauer-type product formula is obtained for continuous q-ultraspherical polynomials. Summation and transformation formulas for balanced hypergeometric series are then employed to derive a q-analogue of Gegenbauer's addition formula.

Key words. Rogers' q-ultraspherical polynomials, Askey–Wilson polynomials, product formula, addition formula, balanced and very-well-poised hypergeometric series, q-Saalschutz formula, Bailey's transformation formulas

AMS(MOS) subject classifications. Primary 33A65, 33A70; secondary 33A30

1. Introduction.

In 1875 Gegenbauer [9] gave the following addition formula for ultraspherical polynomials;

$$C_n^{\lambda}(\cos\psi)=\sum_{k=0}^{n} a_{k,n}^{\lambda}(\sin\theta)^k C_{n-k}^{\lambda+k}(\cos\theta)(\sin\phi)^k C_{n-k}^{\lambda+k}(\cos\phi) \cdot C_k^{\lambda-1/2}\left(\frac{\cos\psi-\cos\theta\cos\phi}{\sin\theta\sin\phi}\right), \tag{1.1}$$

where

$$a_{k,n}^{\lambda}=\frac{\Gamma(2\lambda-1)}{\Gamma^2(\lambda)}\,\frac{\Gamma^2(k+\lambda)(n-k)!(2k+2\lambda-1)2^{2k}}{\Gamma(n+k+2\lambda)} \tag{1.2}$$

and

$$C_n^{\lambda}(\cos\theta)=\sum_{k=0}^{n}\frac{(\lambda)_k(\lambda)_{n-k}}{k!(n-k)!}\cos(n-2k)\theta, \qquad 0\leqq\theta\leqq\pi. \tag{1.3}$$

See also Erdélyi [6, p. 178 (34), watch for the misprint 2^m which should be 2^{2m}], Askey [1, p. 30 (4.7), a factor of $n!/(2\lambda)_n$ is missing in the first term] or Whittaker and Watson [18, p.335, Ex. 42]. There are many proofs of this important formula, some are analytic in nature and some group theoretic. For extensive references see [1, Lecture 4]. One of the formulas that is contained in (1.1) is Gegenbauer's product formula

$$C_n^{\lambda}(\cos\theta)C_n^{\lambda}(\cos\phi)=b_n^{\lambda}\int_0^{\pi} C_n^{\lambda}(\cos\theta\cos\phi+\sin\theta\sin\phi\cos\psi)(\sin\psi)^{2\lambda-1}\,d\psi, \tag{1.4}$$

$\operatorname{Re}\lambda>0$, where

$$b_n^{\lambda}=C_n^{\lambda}(1)\left[\int_0^{\pi}(\sin\psi)^{2\lambda-1}\,d\psi\right]^{-1}=\frac{2^{1-2\lambda}\Gamma(2\lambda+n)}{\Gamma^2(\lambda)n!}, \tag{1.5}$$

see [5, p. 177, (20)] or [1, p. 30, (4.10)]. Equivalent to (1.4) is the product formula

$$\frac{C_n^\lambda(x)C_n^\lambda(y)}{C_n^\lambda(1)C_n^\lambda(1)}=\int_{-1}^{1}K(x,y,z)\frac{C_n^\lambda(z)}{C_n^\lambda(1)}\,dz, \tag{1.6}$$

where

$$K(x,y,z)=\frac{\Gamma(\lambda+1/2)}{\Gamma(\lambda)\Gamma(1/2)}\frac{(1-x^2-y^2-z^2+2xyz)^{\lambda-1}}{[(1-x^2)(1-y^2)]^{\lambda-1/2}}\quad\text{or } 0, \tag{1.7}$$

according as $1-x^2-y^2-z^2+2xyz$ is positive or negative, see [7, (1.4)] or [10].

The purpose of this paper is to obtain a q-analogue of (1.6) and then use it to derive an addition formula for Rogers' q-ultraspherical polynomials defined by

$$C_n(x;\beta\,|\,q)=\sum_{k=0}^{n}\frac{(\beta;q)_k(\beta;q)_{n-k}}{(q;q)_k(q;q)_{n-k}}\cos(n-2k)\theta,\qquad x=\cos\theta, \tag{1.8}$$

where the q-shifted factorials $(a;q)_k$ are given by

$$(a;q)_k=\frac{(a;q)_\infty}{(aq^k;q)_\infty},\qquad (a;q)_\infty=\prod_{j=0}^{\infty}(1-aq^j),\qquad |q|<1. \tag{1.9}$$

Askey and Ismail [2] have recently proved that

$$C_n(x;\beta\,|\,q)=\frac{(\beta;q)_n}{(q;q)_n}\beta^{-n/2}p_n(x;\sqrt{\beta},\sqrt{\beta q},-\sqrt{\beta},-\sqrt{\beta q}), \tag{1.10}$$

where

$$p_n(x;a,b,c,d)={}_4\phi_3\left[\begin{matrix}q^{-n},\,abcdq^{n-1},\,ae^{i\theta},\,ae^{-i\theta}\\ ab,\,ac,\,ad\end{matrix};q,q\right],\qquad x=\cos\theta \tag{1.11}$$

is the Askey–Wilson polynomial of degree n, discovered by Askey and Wilson [3], that satisfies the orthogonality relation

(1.12)

$$\int_{-1}^{1}w(x;a,b,c,d)p_m(x;a,b,c,d)p_n(x;a,b,c,d)\frac{dx}{\sqrt{1-x^2}}=h_n(a,b,c,d)\delta_{m,n},$$

with

$$w(x;a,b,c,d)=\frac{h(x;1)h(x;-1)h(x;\sqrt{q})h(x;-\sqrt{q})}{h(x;a)h(x;b)h(x;c)h(x;d)}, \tag{1.13}$$

$$h(x;a)=\prod_{n=0}^{\infty}(1-2axq^n+a^2q^{2n})=(ae^{i\theta};q)_\infty(ae^{-i\theta};q)_\infty, \tag{1.14}$$

$$h_n(a,b,c,d)=h_0(a,b,c,d)\frac{(q,cd,bd,bc;q)_n(1-abcdq^{-1})}{(abcdq^{-1},ab,ac,ad;q)_n(1-abcdq^{2n-1})}a^{2n}, \tag{1.15}$$

$$(a_1,a_2,\cdots,a_m;q)_n=\prod_{i=1}^{m}(a_i;q)_n \tag{1.16}$$

and

$$h_0(a,b,c,d)=\int_{-1}^{1} w(x;a,b,c,d)\frac{dx}{\sqrt{1-x^2}}=\frac{2\pi(abcd;q)_\infty}{(q,ab,ac,ad,bc,bd,cd;q)_\infty}, \tag{1.17}$$

provided $\max(|a|,|b|,|c|,|d|,|q|)<1$. The symbol on the right side of (1.11) is a special type of basic hypergeometric series defined by

$${}_{r+1}\phi_r\left[\begin{matrix}a_1,a_2,\cdots,a_{r+1}\\ b_1,\cdots,b_r\end{matrix};q,z\right]=\sum_{k=0}^{\infty}\frac{(a_1,a_2,\cdots,a_{r+1};q)_k}{(q,b_1,\cdots,b_r;q)_k}z^k, \tag{1.18}$$

whenever the series converges. The series becomes a polynomial of degree n in z if any one of the numerator parameters has the form q^{-n}, $n=0,1,2,\cdots$. The series (1.18) is called balanced if $z=q$ and $b_1b_2\cdots b_r=qa_1a_2\cdots a_{r+1}$; it is called well-poised if $a_2b_1=a_3b_2=\cdots=a_{r+1}b_r=qa_1$; and very-well-poised if, in addition, $b_1=\sqrt{a_1}$, $b_2=-\sqrt{a_1}$. Note that the ${}_4\phi_3$ series on the right of (1.11) is balanced.

In addition to balanced ${}_4\phi_3$ series we make fairly extensive use of very-well-poised series in this paper, so we shall adopt an economical notation:

$${}_{r+1}\phi_r\left[\begin{matrix}a,q\sqrt{a},-q\sqrt{a},a_1,a_2,\cdots,a_{r-2}\\ \sqrt{a},-\sqrt{a},aq/a_1,aq/a_2,\cdots,aq/a_{r-2}\end{matrix};q,z\right] \tag{1.19}$$

$$\equiv {}_{r+1}W_r(a;a_1,a_2,\cdots,a_{r-2};q,z).$$

In §2 we shall use a q-analogue of Koorwinder's proof [12] of his product formula for Jacobi polynomials to prove that a q-analogue of (1.6) is

$$p_n(x;a,a\sqrt{q},-a,-a\sqrt{q})\,p_n(y;a,a\sqrt{q},-a,-a\sqrt{q}) \tag{1.20}$$

$$=\int_{-1}^{1} K(x,y,z\,|\,q)\,p_n(z;a,a\sqrt{q},-a,-a\sqrt{q})\,dz,$$

where

$$K(x,y,z\,|\,q)=A^{-1}(\theta,\phi)(1-z^2)^{-1/2}w(z;ae^{i\theta+i\phi},ae^{-i\theta-i\phi},ae^{i\theta-i\phi},ae^{i\phi-i\theta}), \tag{1.21}$$

and

$$A(\theta,\phi)=h_0(ae^{i\theta+i\phi},ae^{-i\theta-i\phi},ae^{i\theta-i\phi},ae^{i\phi-i\theta}) \tag{1.22}$$

$$=\frac{2\pi(a^4;q)_\infty}{(q,a^2,a^2;q)_\infty|(a^2e^{2i\theta},a^2e^{2i\phi};q)_\infty|^2},$$

$x=\cos\theta$, $y=\cos\phi$, $0\leqq\theta\leqq\pi$, $0\leqq\phi\leqq\pi$, $\max(|a|,|q|)<1$. Note that $K(x,y,z\,|\,q)$ is positive for all $z\in(-1,1)$ and all θ,ϕ in $[0,\pi]$, unlike $K(x,y,z)$ in (1.7) which vanishes unless x,y,z satisfy certain triangle-type inequalities. However, after replacing a by q^a and then a by $\lambda/2$ we will show in §3 that

$$\lim_{q\to 1-} K(x,y,z\,|\,q)=K(x,y,z). \tag{1.23}$$

It may be pointed out that (1.20) is probably not optimal as a positive kernel for q-ultraspherical expansions since $p_n(x;q,a\sqrt{q},-a,-a\sqrt{q})$ does not equal 1 at $x=1$, although

$$\lim_{q\to 1-} p_n(x;q^{\lambda/2},q^{(\lambda+1)/2},-q^{\lambda/2},-q^{(\lambda+1)/2}) = C_n^{\lambda}(x)/C_n^{\lambda}(1).$$

In §4 we will make use of the orthogonality property (1.12) of Askey–Wilson polynomials to obtain the addition formula

(1.24)

$$\begin{aligned} &p_n(z;a,a\sqrt{q},-a,-a\sqrt{q}) \\ &= \sum_{m=0}^{n} C_{m,n}(a\mid q)e^{-mi\theta}(a^2e^{2i\theta};q)_m p_{n-m}(x;aq^{m/2},aq^{(m+1)/2},-aq^{m/2},-aq^{(m+1)/2}) \\ &\quad\cdot e^{-mi\phi}(a^2e^{2i\phi};q)_m p_{n-m}(y;aq^{m/2},aq^{(m+1)/2},-aq^{m/2},-aq^{(m+1)/2}) \\ &\quad\cdot p_m(z;ae^{i\theta+i\phi},ae^{-i\theta-i\phi},ae^{i\theta-i\phi},ae^{i\phi-i\theta}), \end{aligned}$$

where

$$C_{m,n}(a\mid q)=\frac{(q;q)_n(a^2,a^4q^n,a^4q^{-1};q)_m q^{m(m-n)}}{(q;q)_m(q;q)_{n-m}(a^2\sqrt{q},-a^2\sqrt{q},-a^2;q)_m(a^4q^{-1};q)_{2m}}. \tag{1.25}$$

Writing $x=\cos\theta$, $y=\cos\phi$, $z=\cos\psi$, replacing a by $q^{\lambda/2}$ and taking the limit $q\to 1-$ one can easily see that (1.24) goes directly to (1.1) after using the ${}_2F_1$ representation of $C_n^{\lambda}(x)$:

$$\frac{C_n^{\lambda}(x)}{C_n^{\lambda}(1)}={}_2F_1\left(-n,n+2\lambda;\lambda+\frac{1}{2};\frac{1-x}{2}\right). \tag{1.26}$$

In a subsequent paper we shall consider some special cases of (1.24) and discuss some applications.

2. Proof of the product formula (1.20). The starting point for the derivation of (1.20) is Rahman's product formula [8], [14] for Askey–Wilson polynomials which, in the q-ultraspherical case, can be written as

(2.1)

$$\begin{aligned} &p_n(x;a,a\sqrt{q},-a,-a\sqrt{q})p_n(y;a,a\sqrt{q},-a,-a\sqrt{q}) \\ &=\frac{1+a^2q^n}{1+a^2}\left(-\frac{1}{\sqrt{q}}\right)^n\sum_{k=0}^{n}\frac{(q^{-n},a^4q^n,-a\sqrt{q}e^{i\theta},-a\sqrt{q}e^{-i\theta},-a\sqrt{q}e^{i\phi},-a\sqrt{q}e^{-i\phi};q)_k}{(q,a^2\sqrt{q},-a^2\sqrt{q},-a^2\sqrt{q},-a^2q,-\sqrt{q};q)_k} \\ &\quad\cdot q^k{}_{10}W_9(-q^{-k-1/2};ae^{i\theta},ae^{-i\theta},ae^{i\phi},ae^{-i\phi},-q^{-k}/a^2,q^{1/2-k}/a^2,q^{-k};q,q). \end{aligned}$$

The important property of the very-well-poised series on the right side is that it is balanced and terminating, so we can apply Bailey's transformation formula [4, p. 68, 8.5 (1)] as often as necessary.

In particular, we have

(2.2)

$$
\begin{aligned}
&{}_{10}W_9\left(-q^{-k-1/2};ae^{i\theta},ae^{-i\theta},ae^{i\phi},ae^{-i\phi},-q^{-k}/a^2,q^{1/2-k}/a^2,q^{-k};q,q\right)\\
&\quad=\frac{\left(-\sqrt{q},-a^2\sqrt{q},-ae^{i\phi},-ae^{-i\phi};q\right)_k}{\left(-1,-a^2,-a\sqrt{q}\,e^{i\phi};-a\sqrt{q}\,e^{-i\phi};q\right)_k}\\
&\qquad\cdot{}_{10}W_9\left(-q^{-k};a\sqrt{q}\,e^{i\theta},a\sqrt{q}\,e^{-i\theta},ae^{i\phi},ae^{-i\phi},q^{1/2-k}/a^2,-q^{1/2-k}/a^2,q^{-k};q,q\right).
\end{aligned}
$$

Thus

(2.3)

$$
\begin{aligned}
&p_n\left(x;a,a\sqrt{q},-a,-a\sqrt{q}\right)p_n\left(y;a,a\sqrt{q},-a,-a\sqrt{q}\right)\\
&=\frac{1+a^2q^n}{1+a^2}(-1)^nq^{-n/2}\sum_{k=0}^{n}\frac{\left(q^{-n},a^4q^n,-a\sqrt{q}\,e^{i\theta},-a\sqrt{q}\,e^{-i\theta},-ae^{i\phi},-ae^{-i\phi};q\right)_k}{\left(q,a^2\sqrt{q},-a^2,-a^2\sqrt{q},-a^2q,-1;q\right)_k}q^k\\
&\quad\cdot{}_{10}W_9\left(-q^{-k};a\sqrt{q}\,e^{i\theta},a\sqrt{q}\,e^{-i\theta},ae^{i\phi},ae^{-i\phi},q^{1/2-k}/a^2,-q^{1/2-k}/a^2,q^{-k};q,q\right).
\end{aligned}
$$

The key step now is to use Bailey's transformation formula [17, p. 101, (3.4.1.6)] between a balanced nearly-poised ${}_5\phi_4$ series and a very-well-poised balanced ${}_{12}\phi_{11}$. In fact, we only need a special case of this formula giving a balanced nearly-poised ${}_4\phi_3$ series in terms of a balanced and very-well-poised ${}_{10}\phi_9$ series:

(2.4)

$$
\begin{aligned}
&{}_4\phi_3\left[\begin{matrix}A,B,C,q^{-k}\\Aq/B,Aq/C,B^2C^2q^{-k-1}/A\end{matrix};q,q\right]\\
&=\frac{\left(\frac{q\sqrt{Aq}}{BC},\frac{A^2q^2}{B^2C^2},\sqrt{Aq},-\frac{\sqrt{Aq}}{B},-\frac{\sqrt{Aq}}{C};q\right)_k}{\left(\frac{Aq^2}{B^2C^2},-\frac{Aq}{BC},\frac{Aq}{B},\frac{Aq}{C},-1;q\right)_k}\\
&\cdot{}_{10}W_9\left(-q^{-k};-\sqrt{Aq},-q\frac{\sqrt{Aq}}{BC},\frac{\sqrt{Aq}}{B},\frac{\sqrt{Aq}}{C},\frac{BCq^{-k-1/2}}{A},-\frac{BCq^{-k-1/2}}{A},q^{-k};q,q\right).
\end{aligned}
$$

It may be pointed out that the right side does not follow directly from Bailey's above-mentioned formula, but only after we make use of Bailey's other formula [4, p. 68, 8.5(1)].

Clearly, if we set $\sqrt{A}=-ae^{i\theta}$, $B=-\sqrt{q}\,e^{i\theta+i\phi}$, $C=-\sqrt{q}\,e^{i\theta-i\phi}$, we obtain

(2.5)
$$
\begin{aligned}
&{}_{10}W_9\left(-q^{-k};a\sqrt{q}\,e^{i\theta},a\sqrt{q}\,e^{-i\theta},ae^{i\phi},ae^{-i\phi},q^{1/2-k}/a^2,-q^{1/2-k}/a^2,q^{-k};q,q\right)\\
&\quad=\frac{\left(-1,-a^2,a^2e^{-2i\theta},-a^2\sqrt{q}\,e^{i\theta+i\phi},-a^2\sqrt{q}\,e^{i\theta-i\phi};q\right)_k}{\left(a^4,-a\sqrt{q}\,e^{i\theta},-a\sqrt{q}\,e^{-i\theta},-ae^{i\phi},-ae^{-i\phi};q\right)_k}\\
&\qquad\cdot{}_4\phi_3\left[\begin{matrix}q^{-k},a^2e^{2i\theta},-\sqrt{q}\,e^{i\theta+i\phi},-\sqrt{q}\,e^{i\theta-i\phi}\\q^{1-k}e^{2i\theta}/a^2,-a^2\sqrt{q}\,e^{i\theta-i\phi},-a^2\sqrt{q}\,e^{i\theta+i\phi}\end{matrix};q,q\right].
\end{aligned}
$$

For real a,θ,ϕ the expression on the left side of (2.5) is a real quantity, so the same must be true of the right-hand side which, however, is not self-evident. Since the ${}_4\phi_3$ series is balanced we can use an iteration of Sears' transformation formula [16]

$$(2.6)\quad {}_4\phi_3\left[\begin{matrix} q^{-k},a,b,c \\ d,e,q^{1-k}abc/de \end{matrix};q,q\right] = \frac{(e/a,de/bc;q)_k}{(e,de/abc;q)_k}\,{}_4\phi_3\left[\begin{matrix} q^{-k},a,d/b,d/c \\ d,de/bc,aq^{1-k}/e \end{matrix};q,q\right],\quad k=0,1,2,\cdots$$

to show that

$$(2.7)\quad {}_4\phi_3\left[\begin{matrix} q^{-k},a^2e^{2i\theta},-\sqrt{q}\,e^{i\theta+i\phi},-\sqrt{q}\,e^{i\theta-i\phi} \\ q^{1-k}e^{2i\theta}/a^2,-a^2\sqrt{q}\,e^{i\theta-i\phi},-a^2\sqrt{q}\,e^{i\theta+i\phi} \end{matrix};q,q\right] = \frac{(a^2,-a^2\sqrt{q}\,e^{i\phi-i\theta};q)_k}{(a^2e^{-2i\theta},-a^2\sqrt{q}\,e^{i\theta+i\phi};q)_k}\cdot{}_4\phi_3\left[\begin{matrix} q^{-k},a^2,-\sqrt{q}\,e^{i\theta+i\phi},-\sqrt{q}\,e^{-i\theta-i\phi} \\ q^{1-k}/a^2,-a^2\sqrt{q}\,e^{i\theta-i\phi},-a^2\sqrt{q}\,e^{i\phi-i\theta} \end{matrix};q,q\right].$$

Formulas (2.3), (2.5) and (2.7) then give

$$(2.8)\quad p_n(x;a,a\sqrt{q},-a,-a\sqrt{q})\,p_n(y;a,a\sqrt{q},-a,-a\sqrt{q}) = \frac{1+a^2q^n}{1+a^2}(-1)^nq^{-n/2}\sum_{k=0}^{n}\frac{(q^{-n},a^4q^n,a^2,-a^2\sqrt{q}\,e^{i\theta-i\phi},-a^2\sqrt{q}\,e^{i\phi-i\theta};q)_k}{(q,a^4,a^2\sqrt{q},-a^2\sqrt{q},-a^2q;q)_k}q^k\cdot{}_4\phi_3\left[\begin{matrix} q^{-k},a^2,-\sqrt{q}\,e^{i\theta+i\phi},-\sqrt{q}\,e^{-i\theta-i\phi} \\ q^{1-k}/a^2,-a^2\sqrt{q}\,e^{i\theta-i\phi},-a^2\sqrt{q}\,e^{i\phi-i\theta} \end{matrix};q,q\right].$$

Since by the q-Saalschutz formula [4, p. 68, 8.4(1)],

$$(2.9)\quad (-a\sqrt{q}\,e^{i\psi},-a\sqrt{q}\,e^{-i\psi};q)_k = (-a^2\sqrt{q}\,e^{i\theta-i\phi},-\sqrt{q}\,e^{i\phi-i\theta};q)_k\,{}_3\phi_2\left[\begin{matrix} q^{-k},ae^{i\theta-i\phi+i\psi},ae^{i\theta-i\phi-i\psi} \\ -a^2\sqrt{q}\,e^{i\theta-i\phi},-q^{1/2-k}e^{i\theta-i\phi} \end{matrix};q,q\right],$$

we find that, by (1.17) and (1.22)

$$(2.10)\quad \int_{-1}^{1} w(z;ae^{i\theta+i\phi},ae^{-i\theta-i\phi},ae^{i\theta-i\phi},ae^{i\phi-i\theta})(-a\sqrt{q}\,e^{i\psi},-a\sqrt{q}\,e^{-i\psi};q)_k\frac{dz}{\sqrt{1-z^2}} = (-a^2\sqrt{q}\,e^{i\theta-i\phi},-\sqrt{q}\,e^{i\phi-i\theta};q)_k\sum_{j=0}^{k}\frac{(q^{-k};q)_jq^j}{(q,-a^2\sqrt{q}\,e^{i\theta-i\phi},-q^{1/2-k}e^{i\theta-i\phi};q)_j}\cdot\int_{-1}^{1} w(z;ae^{i\theta+i\phi},ae^{-i\theta-i\phi},aq^je^{i\theta-i\phi},ae^{i\phi-i\theta})\frac{dz}{\sqrt{1-z^2}}$$

$$= A(\theta,\phi)\left(-a^2\sqrt{q}\,e^{i\theta-i\phi}, -\sqrt{q}\,e^{i\phi-i\theta}q\right)_k$$

$$\cdot {}_4\phi_3\left[\begin{matrix} q^{-k}, a^2, a^2e^{2i\theta}, a^2e^{-2i\phi} \\ -a^2\sqrt{q}\,e^{i\theta-i\phi}, a^4, -q^{1/2-k}e^{i\theta-i\phi}\end{matrix}; q, q\right]$$

$$= A(\theta,\phi)\frac{\left(a^2, -a^2\sqrt{q}\,e^{i\theta-i\phi}, -a^2\sqrt{q}\,e^{i\phi-i\theta}; q\right)_k}{\left(a^4; q\right)_k}$$

$$\cdot {}_4\phi_3\left[\begin{matrix} q^{-k}, a^2, -\sqrt{q}\,e^{i\theta+i\phi}, -\sqrt{q}\,e^{-i\theta-i\phi} \\ -a^2\sqrt{q}\,e^{i\theta-i\phi}, -a^2\sqrt{q}\,e^{i\phi-i\theta}, q^{1-k}/a^2\end{matrix}; q, q\right],$$

by (2.6). Combining (2.8) and (2.10) we then have

(2.11)

$$p_n(x; a, a\sqrt{q}, -a, -a\sqrt{q})\,p_n(y; a, a\sqrt{q}, -a, -a\sqrt{q})$$

$$= A^{-1}(\theta,\phi)\int_{-1}^{1}\frac{dz}{\sqrt{1-z^2}}w(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta})$$

$$\cdot\frac{1+a^2q^n}{1+a^2}(-1)^n q^{-n/2}{}_4\phi_3\left[\begin{matrix} q^{-n}, a^4q^n, -a\sqrt{q}\,e^{i\psi}, -a\sqrt{q}\,e^{-i\psi} \\ a^2\sqrt{q}, -a^2\sqrt{q}, -a^2q\end{matrix}; q, q\right]$$

$$= A^{-1}(\theta,\phi)\int_{-1}^{1} w(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta})$$

$$\cdot p_n(z; a, a\sqrt{q}, -a, -a\sqrt{q})\frac{dz}{\sqrt{1-z^2}} \quad \text{by (2.6).}$$

This completes the proof of (1.20). It follows from (1.20) that we have the expansion

(2.12)
$$\frac{\left(a^2; q\right)_\infty^3\left(qa^2; q\right)_\infty}{\left(a^4; q\right)_\infty^2}\left|\frac{\left(a^2e^{2i\theta}, a^2e^{2i\phi}, a^2e^{2i\psi}; q\right)_\infty}{\left(ae^{i\theta+i\phi+i\psi}, ae^{i\theta-i\phi+i\psi}, ae^{i\theta+i\phi-i\psi}, ae^{i\theta-i\phi-i\psi}; q\right)_\infty}\right|^2$$

$$\sim \sum_{n=0}^{\infty}\frac{\left(a^4; q\right)_n(1-a^2q^n)}{\left(q; q\right)_n(1-a^2)}a^{-2n}p_n(\cos\theta; a, a\sqrt{q}, -a, -a\sqrt{q})$$

$$\cdot p_n(\cos\phi; a, a\sqrt{q}, -a, -a\sqrt{q})\,p_n(\cos\psi; a, a\sqrt{q}, -a, -a\sqrt{q}).$$

By a direct computation it is shown by the authors in [15] that the " $\sim$ " sign in (2.12) can be replaced by " $=$ " for $\max(|a|, |q|) < 1$.

3. Limit of $K(x, y, z|q)$ as $q \to 1-$. Replacing a by q^a, $0 < q < 1$, in (1.21) and using the q-gamma function

(3.1)
$$\Gamma_q(x) = \frac{\left(q; q\right)_\infty}{\left(q^x; q\right)_\infty}(1-q)^{1-x}, \qquad \lim_{q\to 1-}\Gamma_q(x) = \Gamma(x),$$

it is not difficult to see that

$$\lim_{q\to 1-} K(x,y,z\,|\,q)$$

$$= \frac{\Gamma(4a)}{4\Gamma^2(2a)} \frac{\left|\sin\frac{\theta+\phi+\psi}{2}\sin\frac{\theta-\phi+\psi}{2}\sin\frac{\theta+\phi-\psi}{2}\sin\frac{\phi+\psi-\theta}{2}\right|^{2a-1}}{|\sin\theta\sin\phi|^{4a-1}}$$

$$\cdot \lim_{q\to 1-} L(\theta,\phi,\psi\,|\,q). \tag{3.2}$$

where

$$L(\theta,\phi,\psi\,|\,q)$$

$$= \frac{(\sqrt{q}\,;q)_\infty^2 |(\sqrt{q}\,e^{i\theta}, -\sqrt{q}\,e^{i\theta}, \sqrt{q}\,e^{i\phi}, -\sqrt{q}\,e^{-i\phi}, \sqrt{q}\,e^{i\psi}, -\sqrt{q}\,e^{-i\psi}; q)_\infty|^4}{|(\sqrt{q}\,e^{i(\theta+\phi+\psi)}, \sqrt{q}\,e^{i(\theta-\phi+\psi)}, \sqrt{q}\,e^{i(\theta+\phi-\psi)}, \sqrt{q}\,e^{i(\theta-\phi-\psi)}; q)_\infty|^2}. \tag{3.3}$$

Changing the base to q^2 and using the theta functions [18, Chap. 21] this can be written as

$$L(\theta,\phi,\psi\,|\,q^2)$$

$$= \left[\frac{(-q;q^2)_\infty}{(-q^2;q^2)_\infty}\right]^6 \frac{\vartheta_3^2\left(\frac{\theta}{2}\right)\vartheta_4^2\left(\frac{\theta}{2}\right)\vartheta_3^2\left(\frac{\phi}{2}\right)\vartheta_4^2\left(\frac{\phi}{2}\right)\vartheta_3^2\left(\frac{\psi}{2}\right)\vartheta_4^2\left(\frac{\psi}{2}\right)}{\vartheta_3^6\vartheta_4^2\vartheta_4\left(\frac{\theta+\phi+\psi}{2}\right)\vartheta_4\left(\frac{\theta-\phi+\psi}{2}\right)\vartheta_4\left(\frac{\phi+\psi-\theta}{2}\right)\vartheta_4\left(\frac{\theta+\phi-\psi}{2}\right)}, \tag{3.4}$$

where

$$\begin{aligned}\vartheta_3(\theta) &\equiv \vartheta_3(\theta\,|\,q) = (q^2;q^2)_\infty(-qe^{2i\theta};q^2)_\infty(-qe^{-2i\theta};q^2)_\infty,\\ \vartheta_4(\theta) &\equiv \vartheta_4(\theta\,|\,q) = (q^2;q^2)_\infty(qe^{2i\theta};q^2)_\infty(qe^{-2i\theta};q^2)_\infty\end{aligned} \tag{3.5}$$

and

$$\vartheta_3 = (-q;q^2)_\infty^2(q^2;q^2)_\infty, \qquad \vartheta_4 = (q,q)_\infty(q;q^2)_\infty. \tag{3.6}$$

Since

$$\lim_{q\to 1-} \frac{(-q;q^2)_\infty}{(-q^2;q^2)_\infty} = \sqrt{2} \tag{3.7}$$

we find that

$$\lim_{q\to 1-} K(x,y,z\,|\,q)$$

$$= \frac{2\Gamma(4a)}{\Gamma^2(2a)} \frac{\left|\sin\frac{\theta+\phi+\psi}{2}\sin\frac{\theta-\phi+\psi}{2}\sin\frac{\theta+\phi-\psi}{2}\sin\frac{\phi+\psi-\theta}{2}\right|^{2a-1}}{|\sin\theta\sin\phi|^{4a-1}}$$

$$\cdot \lim_{q\to 1-} M(\theta,\phi,\psi\,|\,q^2), \tag{3.8}$$

where

$$M(\theta,\phi,\psi\,|\,q^2) = \frac{\vartheta_3^2\left(\frac{\theta}{2}\right)\vartheta_4^2\left(\frac{\theta}{2}\right)\vartheta_3^2\left(\frac{\phi}{2}\right)\vartheta_4^2\left(\frac{\phi}{2}\right)\vartheta_3^2\left(\frac{\psi}{2}\right)\vartheta_4^2\left(\frac{\psi}{2}\right)}{\vartheta_3^6\vartheta_4^2\vartheta_4\left(\frac{\theta+\phi+\psi}{2}\right)\vartheta_4\left(\frac{\theta-\phi+\psi}{2}\right)\vartheta_4\left(\frac{\phi+\psi-\theta}{2}\right)\vartheta_4\left(\frac{\theta+\phi-\psi}{2}\right)}. \tag{3.9}$$

Using [18, p. 488, Ex. 2 and 3] we may write

$$M(\theta,\phi,\psi\,|\,q^2) = \left[1+H(\theta,\phi,\psi\,|\,q^2)\right]^{-1}, \tag{3.10}$$

where

$$H(\theta,\phi,\psi\,|\,q^2) = \sum_{i=1}^{11} A_i(\theta,\phi,\psi\,|\,q^2), \tag{3.11}$$

with

$$A_1 = \left[\frac{\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)}{\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\theta}{2}\right)}\right]^2,$$

$$A_2 = 2\frac{\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)}{\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)},$$

$$A_3 = \left[\frac{\vartheta_4\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1^2\left(\frac{\phi}{2}\right)}{\vartheta_2\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\phi}{2}\right)}\right]^2,$$

$$A_4 = \left[\frac{\vartheta_4\vartheta_1\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\phi}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)}{\vartheta_2\vartheta_3\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\phi}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)}\right]^2, \tag{3.12}$$

$$A_5 = -2\left[\frac{\vartheta_4\vartheta_1\left(\frac{\phi}{2}\right)}{\vartheta_2\vartheta_3\left(\frac{\phi}{2}\right)}\right]^2\frac{\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)}{\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\theta}{2}\right)},$$

$$A_6 = \left[\frac{\vartheta_4\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)\vartheta_2\left(\frac{\phi}{2}\right)}{\vartheta_2\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\theta}{2}\right)\vartheta_4\left(\frac{\phi}{2}\right)}\right]^2,$$

$$A_7=\left[\frac{\vartheta_4\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)\vartheta_2\left(\frac{\phi}{2}\right)}{\vartheta_2\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)\vartheta_4\left(\frac{\phi}{2}\right)}\right]^2,$$

$$A_8=-2\left(\frac{\vartheta_4}{\vartheta_2}\right)^2\frac{\vartheta_2\left(\frac{\phi}{2}\right)\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)\vartheta_2\left(\frac{\phi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)\vartheta_2\left(\frac{\psi}{2}\right)}{\vartheta_4\left(\frac{\phi}{2}\right)\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)\vartheta_4\left(\frac{\phi}{2}\right)\vartheta_3\left(\frac{\theta}{2}\right)\vartheta_4\left(\frac{\psi}{2}\right)},$$

$$A_9=\left[\frac{\vartheta_2\left(\frac{\phi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\phi}{2}\right)}{\vartheta_4\left(\frac{\phi}{2}\right)\vartheta_3\left(\frac{\theta}{2}\right)\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\phi}{2}\right)}\right]^2,$$

$$A_{10}=\left[\frac{\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1\left(\frac{\phi}{2}\right)\vartheta_2\left(\frac{\phi}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)}{\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\phi}{2}\right)\vartheta_4\left(\frac{\phi}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)}\right]^2,$$

$$A_{11}=-2\frac{\vartheta_2\left(\frac{\theta}{2}\right)\vartheta_1\left(\frac{\phi}{2}\right)\vartheta_2\left(\frac{\psi}{2}\right)\vartheta_1\left(\frac{\theta}{2}\right)\vartheta_2\left(\frac{\phi}{2}\right)\vartheta_1\left(\frac{\psi}{2}\right)\vartheta_2\left(\frac{\phi}{2}\right)\vartheta_1\left(\frac{\phi}{2}\right)}{\vartheta_4\left(\frac{\theta}{2}\right)\vartheta_3\left(\frac{\phi}{2}\right)\vartheta_4\left(\frac{\psi}{2}\right)\vartheta_3\left(\frac{\theta}{2}\right)\vartheta_4\left(\frac{\phi}{2}\right)\vartheta_3\left(\frac{\psi}{2}\right)\vartheta_4\left(\frac{\phi}{2}\right)\vartheta_3\left(\frac{\phi}{2}\right)}.$$

Using Poisson's transformation [18, p. 476]

$$\sum_{n=-\infty}^{\infty}e^{-n^2\pi t+2niz}=\frac{e^{-z^2/\pi t}}{\sqrt{t}}\sum_{n=-\infty}^{\infty}e^{-n^2\pi/t+2nz/t},\qquad \mathrm{Re}\,t>0 \tag{3.13}$$

and the definitions of the theta functions we find that, with $q=e^{-\pi t}$,

$$\begin{aligned}
\vartheta_1\left(\frac{\theta}{2}\right)&=\frac{e^{-(\pi-\theta)^2/4\pi t}}{\sqrt{t}}\sum_{n=-\infty}^{\infty}(-1)^n\exp\left[-\frac{\pi n^2}{t}-\frac{n(\pi-\theta)}{t}\right],\\
\vartheta_2\left(\frac{\theta}{2}\right)&=\frac{e^{-\theta^2/4\pi t}}{\sqrt{t}}\sum_{n=-\infty}^{\infty}(-1)^n\exp\left[-\frac{\pi n(n-\theta/\pi)}{t}\right],\\
\vartheta_3\left(\frac{\theta}{2}\right)&=\frac{e^{-\theta^2/4\pi t}}{\sqrt{t}}\sum_{n=-\infty}^{\infty}\exp\left[-\frac{\pi n(n-\theta/\pi)}{t}\right],\\
\vartheta_4\left(\frac{\theta}{2}\right)&=\frac{e^{-(\pi-\theta)^2/4\pi t}}{\sqrt{t}}\sum_{n=-\infty}^{\infty}\exp\left[-\frac{\pi n^2}{t}-\frac{n(\pi-\theta)}{t}\right],
\end{aligned} \tag{3.14}$$

see also [13, eq. (2.29)].

As $q \to 1-$ it follows that

$$
\begin{aligned}
&A_1 \simeq 1, \quad A_2 \simeq 2, \quad A_3 \simeq \left(\exp\left[\frac{\phi-\theta-\psi}{2t}\right]\right)^2, \\
&A_4 \simeq \left(\exp\left[\frac{\theta+\phi+\psi-2\pi}{t}\right]\right)^2, \qquad A_5 \simeq -2\left(\exp\left[\frac{\phi-\pi}{2t}\right]\right)^2, \\
&A_6 \simeq \left(\exp\left[\frac{\theta-\phi-\psi}{2t}\right]\right)^2, \qquad A_7 \simeq \left(\exp\left[\frac{\psi-\theta-\phi}{2t}\right]\right)^2, \\
&A_8 \simeq -2\exp\left(-\frac{\phi}{2t}\right), \quad A_9 \simeq 1, \quad A_{10} \simeq 1, \quad A_{11} \simeq -2.
\end{aligned} \tag{3.15}
$$

Thus

$$
\lim_{q \to 1-} H(\theta,\phi,\psi \mid q^2) = \begin{cases} \infty & \text{if either } \phi-\theta-\psi>0 \text{ or } \theta-\phi-\psi>0 \text{ or} \\ & \quad \psi-\theta-\phi>0 \text{ or } \theta+\phi+\psi-2\pi>0, \\ 3 & \text{if none of these is satisfied,} \end{cases} \tag{3.16}
$$

where $0 \leqq \theta, \phi, \psi \leqq \pi$.

Using (3.16) in (3.10) we find that

(3.17)

$$
\lim_{q \to 1} K(x,y,z \mid q)
$$

$$
= \begin{cases} 0 & \text{if either } \theta-\phi-\psi>0 \text{ or } \phi-\theta-\psi>0 \text{ or} \\ & \quad \psi-\theta-\phi>0 \text{ or } \theta+\phi+\psi-2\pi>0, \\ \dfrac{\Gamma(4a)}{2\Gamma^2(2a)} \dfrac{\left\{\sin\left(\frac{\theta+\phi-\psi}{2}\right)\sin\left(\frac{\phi+\psi-\theta}{2}\right)\sin\left(\frac{\psi+\theta-\phi}{2}\right)\sin\left(\frac{\theta+\phi+\psi}{2}\right)\right\}^{2a-1}}{(\sin\theta\sin\phi)^{4a-1}}, \end{cases}
$$

if none of the above inequalities is satisfied.

Setting $\lambda = 2a$ and using the duplication formula for the gamma function, it is easy to see that the right side of (3.17) reduces to that of (1.7).

4. Proof of the addition formula. Since by (1.12) the polynomials orthogonal with respect to the weight function $w(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta})$ are $p_n(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta})$, it is natural to look for an expansion of the form

$$
\begin{aligned}
&p_n(z; a, a\sqrt{q}, -a, -a\sqrt{q}) \\
&\quad = \sum_{m=0}^{n} A_{m,n}(\theta,\phi)\, p_m(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta}).
\end{aligned} \tag{4.1}
$$

Using the orthogonality relation (1.12) we get

$$
\begin{aligned}
(4.2)\qquad & h_m(ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta})A_{m,n}(\theta,\phi) \\
&= \int_{-1}^{1} w(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta}) \\
&\quad \cdot p_m(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta}) \\
&\quad \cdot p_n(z; a, a\sqrt{q}, -a, -a\sqrt{q}) \frac{dz}{\sqrt{1-z^2}} \\
&= \frac{(1+q^n a^2)}{(1+a^2)}(-1)^n q^{-n/2} S_{m,n}(\theta,\phi),
\end{aligned}
$$

say, where, by (2.6),

$$
\begin{aligned}
(4.3)\qquad S_{m,n}(\theta,\phi) &= \int_{-1}^{1} w(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta}) \\
&\quad \cdot p_m(z; ae^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta}) \\
&\quad \cdot p_n(z; -a\sqrt{q}, -a, a, a\sqrt{q}) \frac{dz}{\sqrt{1-z^2}}.
\end{aligned}
$$

By (1.11),

$$
(4.4)\qquad S_{m,n}(\theta,\phi) = \sum_{k=0}^{n}\sum_{j=0}^{m} \frac{(q^{-n}, a^4q^n; q)_k (q^{-m}, a^4q^{m-1}; q)_j q^{j+k} B_{j,k}}{(q, a^2\sqrt{q}, -a^2\sqrt{q}, -a^2q; q)_k (q, a^2, a^2e^{2i\theta}, a^2e^{2i\phi}; q)_j},
$$

where

$$
\begin{aligned}
(4.5)\qquad B_{j,k} &= \int_{-1}^{1} w(z; aq^j e^{i\theta+i\phi}, ae^{-i\theta-i\phi}, ae^{i\theta-i\phi}, ae^{i\phi-i\theta}) \\
&\quad \cdot (-a\sqrt{q}\, e^{i\psi}, -a\sqrt{q}\, e^{-i\psi}; q)_k \frac{dz}{\sqrt{1-z^2}}, \qquad z = \cos\psi.
\end{aligned}
$$

Except for the q^j factor in the first parameter in w, this integral is exactly the same as that in (2.10). Hence

$$
\begin{aligned}
(4.6)\qquad B_{j,k} &= A(\theta,\phi)(-a^2\sqrt{q}\, e^{i\theta-i\phi}, -\sqrt{q}\, e^{i\phi-i\theta}; q)_k (a^2, a^2e^{2i\theta}, a^2e^{2i\phi}; q)_j / (a^4; q)_j \\
&\quad \cdot \sum_{l=0}^{k} \frac{(q^{-k}, a^2, a^2e^{-2i\phi}, a^2q^j e^{2i\theta}; q)_l}{(q, -a^2\sqrt{q}\, e^{i\theta-i\phi}, -q^{1/2-k}e^{i\theta-i\phi}, a^4q^j; q)_l} q^l.
\end{aligned}
$$

Substituting in (4.4) we find that

$$
\begin{aligned}
(4.7)\qquad S_{m,n}(\theta,\phi) &= A(\theta,\phi) \sum_{k=0}^{n} \frac{(q^{-n}, a^4q^n, -a^2\sqrt{q}\, e^{i\theta-i\phi}, -\sqrt{q}\, e^{i\phi-i\theta}; q)_k}{(q, a^2\sqrt{q}, -a^2\sqrt{q}, -a^2q; q)_k} q^k \\
&\quad \cdot \sum_{l=0}^{k} \frac{(q^{-k}, a^2, a^2e^{2i\theta}, a^2e^{-2i\phi}; q)_l}{(q, a^4, -a^2\sqrt{q}\, e^{i\theta-i\phi}, -q^{1/2-k}e^{i\theta-i\phi}; q)_l} q^l \\
&\quad \cdot {}_3\phi_2\left[\begin{matrix} q^{-m}, a^4q^{m-1}, a^2e^{2i\theta}q^l \\ a^4q^l, a^2e^{2i\theta} \end{matrix}; q, q\right].
\end{aligned}
$$

By q-Saalschutz formula [4, p. 68, 8.4(1)], the ${}_3\phi_2$ series has the sum $(q^{1+l-m}, a^2e^{-2i\theta}; q)_m/(a^4q^l, q^{1-m}e^{-2i\theta}/a^2; q)_m$ which vanishes if $0 \leqq l \leqq m-1$. So the summation indices l and k in (4.7) both must be $\geqq m$. Replacing l and k by $l+m$ and $k+m$, respectively, and doing some straightforward simplification, we obtain

(4.8)

$$S_{m,n}(\theta,\phi) = A(\theta,\phi)\frac{\left(q^{-n}, a^4q^n, a^2, a^2e^{-2i\theta}, a^2e^{-2i\phi}; q\right)_m}{\left(a^2\sqrt{q}, -a^2\sqrt{q}, -a^2\sqrt{q}; q\right)_m (a^4; q)_{2m}} q^{m^2/2+m} a^{2m} e^{i(\theta+\phi)m}$$

$$\cdot \sum_{k=0}^{n-m} \frac{\left(q^{m-n}, a^4q^{n+m}, a^2q^m, -a^2q^{m+1/2}e^{i\theta-i\phi}, -a^2q^{m+1/2}e^{i\phi-i\theta}; q\right)_k}{\left(q, a^4q^{2m}, a^2q^{m+1/2}, -a^2q^{m+1/2}, -a^2q^{m+1}; q\right)_k} q^k$$

$$\cdot {}_4\phi_3\left[\begin{matrix} q^{-k}, a^2q^m, -\sqrt{q}\,e^{i\theta+i\phi}, -\sqrt{q}\,e^{-i\theta-i\phi} \\ q^{1-k-m}/a^2, -a^2q^{m+1/2}e^{i\theta-i\phi}, -a^2q^{m+1/2}e^{i\phi-i\theta} \end{matrix}; q, q\right].$$

Observe that the double series above is the same as that in (2.8) with n and a replaced by $n-m$ and $aq^{m/2}$, respectively. So we get

(4.9)

$$S_{m,n}(\theta,\phi) = A(\theta,\phi)\frac{\left(q^{-n}, a^4q^n, a^2, a^2e^{-2i\theta}, a^2e^{-2i\phi}; q\right)_m}{\left(a^2\sqrt{q}, -a^2\sqrt{q}, -a^2q; q\right)_m (a^4; q)_{2m}} q^{m^2/2+m} a^{2m} e^{i(\theta+\phi)m}$$

$$\cdot \frac{1+a^2q^m}{1+a^2q^n}(-1)^{n-m} q^{(n-m)/2} p_{n-m}\left(x; aq^{m/2}, aq^{(m+1)/2}, -aq^{m/2}, -aq^{(m+1)/2}\right)$$

$$\cdot p_{n-m}\left(y; aq^{m/2}, aq^{(m+1)/2}, -aq^{m/2}, -aq^{(m+1)/2}\right).$$

Using (1.15), (1.22) and (4.2), and simplifying, we finally obtain

$$A_{m,n}(\theta,\phi) = C_{m,n}(a\,|\,q)e^{-mi(\theta+\phi)}\left(a^2e^{2i\theta}, a^2e^{2i\phi}; q\right)_m \tag{4.10}$$

$$\cdot p_{n-m}\left(x; aq^{m/2}, aq^{(m+1)/2}, -aq^{m/2}, -aq^{(m+1)/2}\right)$$

$$\cdot p_{n-m}\left(y; aq^{m/2}, aq^{(m+1)/2}, -aq^{m/2}, -aq^{(m+1)/2}\right),$$

where $C_{m,n}(a\,|\,q)$ is given by (1.25). This completes the proof of the addition formula (1.24).

Acknowledgments. We would like to thank Professor G. Gasper and the referee for many valuable suggestions.

ASYMPTOTICS OF THE ASKEY–WILSON AND q-JACOBI POLYNOMIALS*

MOURAD E. H. ISMAIL†

Abstract. We derive explicit representations and complete asymptotic expansions for the Askey–Wilson ${}_4\phi_3$ polynomials and the little and big q-Jacobi polynomials. We also give an alternate proof of a Dirichlet–Mehler type formula for the continuous q-ultraspherical polynomials. We also determine the asymptotic behavior of the q-Racah polynomials.

Key words. complete asymptotic expansion, little q-Jacobi polynomials, big q-Jacobi polynomials, Askey–Wilson polynomials, Dirichlet–Mehler formula

AMS(MOS) subject classifications. Primary 33A65, 41A60

1. Introduction.

The q-shifted factorial $(a;q)_n$ is defined by

$$(a;q)_0=1, \qquad (a;q)_n=\prod_{j=1}^{n}(1-aq^{j-1}), \qquad n=\infty,1,2,\cdots,|q|<1,$$

and the basic hypergeometric factorization ${}_r\phi_{r+p-1}$ is

$${}_r\phi_{r+p-1}\left(\begin{matrix}a_1,\cdots,a_r\\ b_1,\cdots,b_{r+p-1}\end{matrix};q,x\right)=\sum_{n=0}^{\infty}\frac{(a_1;q)_n\cdots(a_r;q)_n}{(b_1;q)_n\cdots(b_{r+p-1};q)_n}\frac{[(-1)^p x]^n}{(q;q)_n}q^{p\binom{n}{2}}.$$

The Askey–Wilson ${}_4\phi_3$ polynomials [6] are

$$p_n(x)=p_n(x;a,b,c,d):={}_4\phi_3\left(\begin{matrix}q^{-n},abcdq^{n-1},az,a/z\\ ab,ac,ad\end{matrix};q,q\right), \tag{1.1}$$

where

$$z^2-2xz+1=0, \qquad |z|\leqq|z^{-1}|; \tag{1.2}$$

that is

$$z=x-\sqrt{x^2-1}, \qquad \frac{1}{z}=x+\sqrt{x^2-1}. \tag{1.3}$$

In fact, if $x=\cos\theta$, then $z=e^{-i\theta}$. The big q-Jacobi polynomials of Andrews and Askey [2], [3] are

$$P_n(x)=P_n(x;\alpha,\beta,\gamma:q):={}_3\phi_2\left(\begin{matrix}q^{-n},\alpha\beta q^{n+1},x\\ \alpha q,\gamma q\end{matrix};q,q\right), \tag{1.4}$$

* Received by the editors February 20, 1985, and in revised form August 7, 1985. This research was partially supported by the National Science Foundation under grant MCS 8313931.

† Department of Mathematics, Arizona State University, Tempe, Arizona 85287. This work was done while the author was visiting the University of Minnesota, Minneapolis, Minnesota whose hospitality and support are gratefully acknowledged.

and the little q-Jacobi polynomials are defined via

$$\Phi_n^{\alpha,\beta}(x)={}_2\phi_1\left(\begin{matrix}q^{-n},\alpha\beta q^{n+1}\\ \alpha q\end{matrix};q,qx\right). \tag{1.5}$$

Ismail and Wilson [8] determined the main term in the asymptotic expansion of the aforementioned orthogonal polynomials for fixed x and $n\to\infty$. In this paper we determine the complete asymptotic expansions of these polynomials as $n\to\infty$. The idea is to apply Cauchy's theorem to a generating function and derive a contour integral representation, and then use analytic continuation and calculus of residues to evaluate the integral. This gives rise to a Dirichlet–Mehler type formula [12] which is also a convergent asymptotic series. In §2 we investigate the asymptotics of the Askey–Wilson ${}_4\phi_3$ polynomials. We also determine the main term in the asymptotic expansion, as $N\to\infty$, of $p_n(x;a,b,c,d)$ when $ab=q^{-N}$ and $n=O(N^{1-\varepsilon})$, where ε is a fixed number in $(0,1)$. The case $q=1$ of this later result is treated heuristically in [9]. The asymptotics of the little and big q-Jacobi polynomials are in §3. In §4 we give an alternate proof of a result of Rahman and Verma [10].

The Askey–Wilson ${}_4\phi_3$ polynomials generalize the $6-j$ symbols in the sense that they contain one more parameter and the $6-j$ symbols are limiting cases of ${}_4\phi_3$ polynomials. The Askey–Wilson polynomials are also the most general orthogonal polynomials that resemble the classical polynomials of Jacobi, Hermite and Laguerre. In fact, Andrews and Askey [2] define an orthogonal family of polynomials $\{r_n(x)\}$ to be classical if and only if $r_n(x)$ is a special case or a limiting case of the ${}_4\phi_3$ orthogonal polynomials.

2. The Askey–Wilson polynomials. Ismail and Wilson [8] derived the generating function

$$\sum_{n=0}^{\infty}\frac{t^n a^{-n}(ac,q)_n(ad;q)_n}{(cd;q)_n(q;q)_n}p_n(x)={}_2\phi_1\left(\begin{matrix}a/z,b/z\\ ab\end{matrix};q,zt\right){}_2\phi_1\left(\begin{matrix}cz,dz\\ cd\end{matrix};q,t/z\right). \tag{2.1}$$

The ${}_2\phi_1$'s in (2.1) converge when $|t|<|z|$ since $|z|\leqq|z^{-1}|$. We need to continue the ${}_2\phi_1$'s in (2.1) to meromorphic functions. The appropriate transformation to apply is the q-analogue of the Pfaff–Kummer transformation, [1],

$${}_2\phi_1\left(\begin{matrix}A,B\\ C\end{matrix};q,w\right)=\frac{(Aw;q)_\infty}{(w;q)_\infty}\sum_{k=0}^{\infty}\frac{(A;q)_k(C/B;q)_k q^{k(k-1)/2}}{(q;q)_k(C;q)_k(Aw;q)_k}(-Bw)^k. \tag{2.2}$$

This transforms the right-hand side of (2.1) to

$$\frac{(at;q)_\infty(ct;q)_\infty}{(zt;q)_\infty(t/z;q)_\infty}\sum_{k,j=0}^{\infty}\frac{(az;q)_k(a/z;q)_k(cz;q)_j(c/z;q)_j}{(q;q)_k(ab;q)_k(at;q)_k(q;q)_j(cd;q)_j}\cdot\frac{(-bt)^k(-dt)^j}{(ct;q)_j}q^{\binom{k}{2}+\binom{j}{2}}.$$

The above expression is analytic in the complex plane except at the poles $t=zq^{-m}$, $t=q^{-m}/z$, $m=0,1,\cdots$. Let us denote the left-hand side of (2.1) by $F(x,t)$. This gives the integral representation

$$\frac{(ac;q)_n(ad;q)_n}{(cd;q)_n(q;q)_n}p_n(x)=\frac{a^n}{2\pi i}\int_C t^{-n-1}F(x,t)\,dt, \tag{2.3}$$

where C is a circle $|t|=p$, $p<|z|$. Now think of C as a contour around the point $t=\infty$. So C encloses all the poles of $F(x,t)$ but has the wrong orientation. Therefore, the right-hand side of (2.3) is $-\sum$ Residues. Now $t=0$ is outside the contour. Observe that

$$\operatorname{Res}\{F(x,t)/t^{n+1};t=zq^{-m}\}=-\frac{(azq^{-m};q)_\infty(czq^{-m};q)_\infty q^{nm}}{(z^2q^{-m};q)_\infty(q^{-m};q)_m(q;q)_\infty}z^{-n}$$

$$\cdot\sum_{k,j=0}^{\infty}\frac{(az;q)_k(a/z;q)_k(cz;q)_j(c/z;q)_j b^k d^j(-zq^{-m})^{k+j}}{(q;q)_k(ab;q)_k(azq^{-m};q)_k(cd;q)_j(czq^{-m};q)_j(q;q)_j}$$

$$\cdot q^{j(j-1)/2+k(k-1)/2}.$$

This gives the asymptotic formula

(2.4)

$$\frac{(ac;q)_n(ad;q)_n}{(cd;q)_n(q;q)_n}p_n(x)$$

$$=\left(\frac{a}{z}\right)^n\frac{(az;q)_\infty(cz;q)_\infty}{(z^2;q)_\infty(q;q)_\infty}\sum_{m=0}^{\infty}\frac{\left(\frac{q}{az};q\right)_m\left(\frac{q}{cz};q\right)_m}{(q;q)_m(qz^{-2};q)_m}(ac)^m q^{mn}$$

$$\cdot{}_2\phi_2\left(\begin{matrix}a/z,az\\ab,azq^{-m}\end{matrix};q,zbq^{-m}\right){}_2\phi_2\left(\begin{matrix}cz,c/z\\cd,czq^{-m}\end{matrix};q,zdq^{-m}\right)$$

$$+\text{a similar term with } z \text{ and } 1/z \text{ interchanged.}$$

The relationship (2.4) is actually an explicit representation as well as an asymptotic expansion. As $n\to\infty$ the main term on the right-hand side of (2.4) is

$$(a/z)^n\frac{(az;q)_\infty(cz;q)_\infty}{(z^2;q)_\infty(q;q)_\infty}{}_1\phi_1\left(\begin{matrix}a/z\\ab\end{matrix};q,zb\right){}_1\phi_1\left(\begin{matrix}c/z\\cd\end{matrix};q,zd\right)$$

$$+\text{a similar term with } z \text{ and } 1/z \text{ interchanged.}$$

Clearly, if r is a positive integer, then

$${}_1\phi_1\left(\begin{matrix}a/z\\ab\end{matrix};q,zb\right)=\lim_{r\to\infty}{}_2\phi_1\left(\begin{matrix}a/z,q^{-r}\\ab\end{matrix};q,zbq^r\right)=\lim_{r\to\infty}\frac{(bz;q)_r}{(ab;q)_r}=\frac{(bz;q)_\infty}{(ab;q)_\infty},$$

where we used the q-analogue of Gauss's theorem, Slater [11, p. 247]. This shows that the main term in the asymptotic expansion of the left-hand side of (2.4) is

$$\left(\frac{a}{z}\right)^n A(z)+(az)^n A(z^{-1}),$$

where

$$A(z)=\frac{(az;q)_\infty(bz;q)_\infty(cz;q)_\infty(dz;q)_\infty}{(ab;q)_\infty(cd;q)_\infty(z^2;q)_\infty(q;q)_\infty}.$$

We now consider the q-Racah case, that is the case $ab=q^{-N}$. Formula (3.2) in [8] implies

$$\frac{(ac;q)_n(ad;q)_n}{(cd;q)_n(q;q)_n}p_n(x;a,q^{-N}/a,c,d)$$

$$=a^n\sum_{k=0}^{n}\frac{(a/z;q)_{n-k}(q^{-N}/az;q)_{n-k}(cz;q)_k(dz;q)_k}{(q^{-N};q)_{n-k}(q;q)_{n-k}(cd;q)_k(q;q)_k}z^{n-2k},$$

$0\leqq n\leqq N$. Applying

$$\frac{(q^{-N}/\lambda;q)_{n-k}}{(q^{-N};q)_{n-k}}=\frac{(\lambda q;q)_N(q;q)_{N-n+k}}{(\lambda q;q)_{N-n+k}(q;q)_N}\lambda^{k-n},$$

we obtain, $0\leqq n\leqq N$,

$$\text{(2.5)}\qquad \frac{(ac;q)_n(ad;q)_n}{(cd;q)_n(q;q)_n}p_n(x;a,q^{-N}/a,c,d)$$

$$=\frac{(aqz;q)_N}{(q;q)_N}\sum_{k=0}^{n}\frac{(cz;q)_k(dz;q)_k(q;q)_{N-n+k}(a/z;q)_{n-k}}{(cd;q)_k(q;q)_k(aqz;q)_{N-n+k}(q;q)_{n-k}}\left(\frac{a}{z}\right)^k.$$

We now let $N\to\infty$, $n\to\infty$ in such a way that $n=O(N^{1-\varepsilon})$, ε is a fixed number in $(0,1)$. One can easily justify interchanging the limiting and summation processes in (2.5) and establish

$$\text{(2.6)}\qquad p_n(x;a,q^{-N}/a,c,d)\cong\frac{(a/z;q)_\infty(cd;q)_\infty}{(ac;q)_\infty(ad;q)_\infty}{}_2\phi_1\left(\begin{matrix}cz,dz\\ad\end{matrix};q,a/z\right).$$

One disadvantage of the right-hand side in (2.6) is its lack of symmetry. It should be symmetric in z and $1/z$. In order to obtain a more symmetric representation we apply the transformation (2.2) and get

$$\text{(2.7)}\qquad p_n(x;a,q^{-N}/a,c,d)\cong\frac{(cd;q)_\infty}{(ad;q)_\infty}\sum_{k=0}^{\infty}\frac{(cz;q)_k(c/z;q)_k(-ad)^k}{(q;q)_k(cd;q)_k(ac;q)_k}q^{\binom{k}{2}},$$

as $n\to\infty$, $N\to\infty$, $n=O(N^{1-\varepsilon})$. Observe that $(cz;q)_k(c/z;q)_k$ is a polynomial in x of degree k. In fact

$$(cz;q)_k(c/z;q)_k=\prod_{j=0}^{k-1}(1-2q^jcx+c^2q^{zj}).$$

3. The q-Jacobi polynomials. Ismail and Wilson [8] found the generating function

$$\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}t^n}{(\beta q;q)_n(q;q)_n}\Phi_n^{\alpha,\beta}(x)={}_2\phi_1\left(\begin{matrix}0,1/x\\ \beta q\end{matrix};q,-xt\right){}_0\phi_1\left(\begin{matrix}-\\ \alpha q\end{matrix};q,-x\alpha qt\right).$$

Applying the Pfaff–Kummer transformation (2.2) to the ${}_2\phi_1$ appearing in the above generating function, we obtain

(3.1)

$$\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}t^n}{(\beta;q)_n(q;q)_n}\Phi_n^{\alpha,\beta}(x)=\frac{1}{(-xt;q)_\infty}{}_1\phi_1\left(\begin{matrix}\beta qx\\ \beta q\end{matrix};q,-t\right){}_0\phi_1\left(\begin{matrix}-\\ \alpha q\end{matrix};q,-x\alpha qt\right).$$

The singularities of the right-hand side of (3.1) are simple poles located at $t=-q^{-m}/x$, $m=0,1,\cdots$. Let

$$\Phi(x,t)=\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}t^n}{(\beta q;q)_n(q;q)_n}\Phi_n^{\alpha,\beta}(x). \tag{3.2}$$

Cauchy's theorem implies

$$\frac{q^{n(n-1)/2}}{(\beta q;q)_n(q;q)_n}\Phi_n^{\alpha,\beta}(x)=\frac{1}{2\pi i}\int_C \Phi(x,t)t^{-n-1}\,dt, \tag{3.3}$$

where C is a circle $|t|=\rho<1/|x|$. As we did in the case of Askey–Wilson polynomials, we think of C as a contour enclosing the point at infinity in the t-plane but with a clockwise orientation. Clearly

$$\begin{aligned}&\operatorname{Res}\{t^{-n-1}\Phi(x,t);t=-q^{-m}/x\}\\&\quad=-\frac{q^{mn}(-x)^n}{(q^{-m};q)_m(q;q)_\infty}{}_0\phi_1\left(\begin{matrix}-\\ \alpha q\end{matrix};q,\alpha q^{1-m}\right){}_1\phi_1\left(\begin{matrix}\beta qx\\ \beta q\end{matrix};q,q^{-m}/x\right).\end{aligned}$$

This and (3.3) establish the explicit formula

$$\begin{aligned}&\frac{(-x)^{-n}q^{n(n-1)/2}}{(\beta q;q)_n(q;q)_n}\Phi_n^{\alpha,\beta}(x)\\&\quad=\sum_{m=0}^{\infty}\frac{q^{mn+m(m+1)/2}}{(q;q)_m(q;q)_\infty}(-1)^m{}_0\phi_1\left(\begin{matrix}-\\ \alpha q\end{matrix};q,\alpha q^{1-m}\right){}_1\phi_1\left(\begin{matrix}-\\ \beta q\end{matrix};q,q^{-m}/x\right).\end{aligned} \tag{3.4}$$

This is also an asymptotic formula as $n\to\infty$ when x is fixed. Each of the hypergeometric functions appearing on the right-hand side of (3.4) is a sum of m terms. This can be seen as follows

$$\begin{aligned}{}_0\phi_1\left(\begin{matrix}-\\ \alpha q\end{matrix};q,\alpha q^{1-m}\right)&=\lim_{\varepsilon\to 0}{}_2\phi_1\left(\begin{matrix}\frac{1}{\varepsilon},\frac{1}{\varepsilon}\\ \alpha q\end{matrix};q,\alpha\varepsilon^2q^{1-m}\right)\\&=\lim_{\varepsilon\to 0}\frac{1}{(\alpha q;q)_\infty}{}_2\phi_1\left(\begin{matrix}q^{-m},\frac{1}{\varepsilon}\\ \alpha\varepsilon q^{1-m}\end{matrix};\varepsilon\alpha q\right)\end{aligned}$$

where we used the transformation, Askey and Ismail [4, p. 67],

$${}_2\phi_1\left(\begin{matrix}a,b\\ c\end{matrix};q,x\right)=\frac{(bx;q)_\infty(c/b;q)_\infty}{(x;q)_\infty(c;q)_\infty}{}_2\phi_1\left(\begin{matrix}\frac{abx}{c},b\\ bx\end{matrix};q,c/b\right). \tag{3.5}$$

This gives

$${}_0\phi_1\left(\begin{matrix}-\\ \alpha q\end{matrix};q,\alpha q^{1-m}\right)=\frac{1}{(\alpha q;q)_\infty}\sum_{k=0}^{m}\frac{(q^{-m};q)_k}{(q;q)_k}(-\alpha)^k q^{k(k+1)/2}.$$

Furthermore,

$$
{}_1\phi_1\left(\begin{matrix}\beta xq\\ \beta q\end{matrix};q,q^{-m}/x\right)=\lim_{\varepsilon\to 0}{}_2\phi_1\left(\begin{matrix}\frac{1}{\varepsilon},\beta xq\\ \beta q\end{matrix};q,\varepsilon q^{-m}/x\right)
$$

$$
=\frac{(1/x;q)_\infty}{(\beta q;q)_\infty}\,{}_2\phi_1\left(\begin{matrix}q^{-m},\beta xq\\ 0\end{matrix};q,1/x\right).
$$

Thus we proved

$$
(3.6)\quad \frac{(-x)^{-n}q^{n(n-1)/2}}{(\beta q;q)_n(q;q)_n}\Phi_n^{\alpha,\beta}(x)=\frac{(1/x;q)_\infty}{(\beta q;q)_\infty(\alpha q;q)_\infty}\sum_{m=0}^{\infty}\frac{q^{mn+m(m+1)/2}}{(q;q)_m(q;q)_\infty}(-1)^m
$$

$$
\cdot\,{}_2\phi_1\left(\begin{matrix}q^{-m},\beta xq\\ 0\end{matrix};q,1/x\right){}_1\phi_1\left(\begin{matrix}q^{-m}\\ 0\end{matrix};q,\alpha q\right).
$$

We now treat the big q-Jacobi polynomials. Ismail and Wilson [8] obtained the generating function

$$
\sum_{n=0}^{\infty}\frac{(\gamma q;q)_n t^n}{(q;q)_n(\beta q;q)_n}P_n(x)
$$

$$
=\left(\sum_{n=0}^{\infty}\frac{(\alpha q/x;q)_n(tx)^n}{(\alpha q;q)_n(q;q)_n}\right)\left(\sum_{k=0}^{\infty}\frac{(\beta x/\gamma;q)_k(-\gamma t)^k q^{k(k+1)/2}}{(q;q)_k(\beta q;q)_k}\right),
$$

that is,

$$
(3.7)\quad \sum_{n=0}^{\infty}\frac{(\gamma q;q)_n t^n}{(q;q)_n(\beta q;q)_n}P_n(x)={}_2\phi_1\left(\begin{matrix}0,\alpha q/x\\ \alpha q\end{matrix};q,xt\right){}_1\phi_1\left(\begin{matrix}\beta x/\gamma\\ \beta q\end{matrix};q,\gamma qt\right).
$$

Applying the transformation (2.2) to the ${}_2\phi_1$ in (3.7) gives

$$
(3.8)\quad \sum_{n=0}^{\infty}\frac{(\gamma q;q)_n t^n}{(\beta q;q)_n(q;q)_n}P_n(x)=\frac{1}{(xt;q)_\infty}{}_1\phi_1\left(\begin{matrix}x\\ \alpha q\end{matrix};\alpha qt\right){}_1\phi_1\left(\begin{matrix}\beta x/\gamma\\ \beta q\end{matrix};q\gamma qt\right).
$$

The poles of the right-hand side are all simple and are located at $t=q^{-m}/x$, $m=0,1,\cdots$. The residue of t^{-n-1} times the right-hand side of (3.8) at $t=q^{-m}/x$ is

$$
\frac{-x^n q^{mn}}{(q^{-m};q)_m(q;q)_\infty}{}_1\phi_1\left(\begin{matrix}x\\ \alpha q\end{matrix};q,\frac{\alpha}{x}q^{1-m}\right){}_1\phi_1\left(\begin{matrix}\beta x/\gamma\\ q\beta\end{matrix};\frac{\gamma}{x}q^{1-m}\right).
$$

This establishes

$$
(3.9)\quad \frac{(\gamma q;q)_n(q;q)_\infty}{(\beta q;q)_n(q;q)_n}P_n(x)=x^n\sum_{m=0}^{\infty}\frac{(-1)^m q^{mn+m(m+1)/2}}{(q;q)_m}
$$

$$
\cdot\,{}_1\phi_1\left(\begin{matrix}x\\ \alpha q\end{matrix};q,\frac{\alpha}{x}q^{1-m}\right){}_1\phi_1\left(\begin{matrix}\beta x/\gamma\\ q\beta\end{matrix};q,\frac{\gamma}{x}q^{1-m}\right).
$$

Each of the ${}_1\phi_1$'s appearing in (3.9) is a sum of m terms. This follows from (3.5) since

$$
(3.10)\quad {}_1\phi_1\left(\begin{matrix}\lambda\\ \mu\end{matrix};q,\frac{\mu}{\lambda}q^{-m}\right)=\lim_{\varepsilon\to 0}{}_2\phi_1\left(\begin{matrix}\frac{1}{\varepsilon},\lambda\\ \mu\end{matrix};\varepsilon\frac{\mu}{\lambda}q^{-m}\right)=\frac{(\mu/\lambda;q)_\infty}{(\mu q)_\infty}{}_2\phi_1\left(\begin{matrix}q^{-m},\lambda\\ 0\end{matrix};q,\frac{\mu}{\lambda}\right).
$$

This enables us to transform (3.9) to

(3.11)

$$\frac{(\theta;q)_n(q;q)_\infty}{(\beta q;q)_n(q;q)_n}P_n(x)=\frac{x^n(\gamma q;q)_\infty(\alpha q/x;q)_\infty}{(\alpha q;q)_\infty(\beta q;q)_\infty}\sum_{m=1}^{\infty}\frac{(-1)^m q^{mn+m(m+1)/2}}{(q;q)_m}\cdot\left(\begin{matrix}q^{-m},x\\0\end{matrix};q,\frac{\alpha q}{x}\right)_2\phi_1\left(\begin{matrix}q^{-m},\beta x/\gamma\\0\end{matrix};q,\frac{gq}{x}\right).$$

The relationship (3.11) is an explicit representation of $P_n(x)$. The right-hand side of (3.11) is clearly an asymptotic series as $n\to\infty$.

4. The continuous q-ultraspherical polynomials. The continuous q-ultraspherical polynomials $\{C_n(x;\beta\,|\,q)\}$ have the generating function

$$\sum_{n=0}^{\infty}C_n(\cos\theta,\beta\,|\,q)t^n=\frac{(\beta te^{i\theta};q)_\infty(\beta te^{-i\theta};q)_\infty}{(te^{i\theta};q)_\infty(te^{-i\theta};q)_\infty}. \tag{4.1}$$

They were discovered by L. J. Rogers around the turn of the century and Rogers used them to prove the Rogers–Ramanujan identities. Rogers did not realize that they are orthogonal polynomials although he was well aware of the fact that they generalize the ultraspherical (or Gegenbauer) polynomials. Their orthogonality was proved only recently, [4] and [6]. Recently, Rahman and Verma [10] proved the q-integral representation

$$C_n(\cos\theta,\beta\,|\,q)=\frac{2i\sin\theta(\beta;q)_\infty^2(\beta^2;q)_n}{(1-q)w_\beta(\cos\theta\,|\,q)(q;q)_\infty(\beta^2;q)_\infty}\cdot\int_{e^{i\theta}}^{e^{-i\theta}}u^n\frac{(que^{i\theta};q)_\infty(que^{-i\theta})_\infty}{(\beta ue^{i\theta};q)_\infty(\beta ue^{-i\theta};q)_\infty}d_qu, \tag{4.2}$$

where $0<\theta<\pi$, $w_\beta(x\,|\,q)$ is the weight function

$$w_\beta(\cos\theta\,|\,q)=(e^{2i\theta};q)_\infty(e^{-2i\theta};q)_\infty/[(\beta e^{2i\theta};q)_\infty(\beta e^{-2i\theta};q)_\infty],$$

and the q-integral is defined by

$$\int_0^a f(u)\,d_qu=a(1-q)\sum_{n=0}^{\infty}f(aq^n)q^n,\int_a^b f(u)\,d_qu=\int_0^b f(u)\,d_qu-\int_0^a f(u)\,d_qu.$$

The representation (4.2) resembles the familiar Dirichlet–Mehler formula, Szegö [12]. Rahman and Verma [10] observed that (4.2) can be used to compute the complete asymptotic expansion of $C_n(\cos\theta;\beta\,|\,q)$ for large n. They also used (4.2) to derive a new generating function for the continuous q-ultraspherical polynomials and to give a simple derivation of the Poisson kernel for the continuous q-ultraspherical polynomials that Gasper and Rahman obtained earlier [7].

Applying the procedure that we used in §§2 and 3 to the generating function (4.1), we obtain

$$C_n(\cos\theta;\beta\,|\,q)=\frac{(\beta;q)_\infty(\beta e^{2i\theta};q)_\infty}{(q;q)_\infty(e^{2i\theta};q)_\infty}e^{-in\theta}{}_2\phi_1\left(\begin{matrix}q/\beta,qe^{-2i\theta}/\beta\\qe^{-2i\theta}\end{matrix};q,\beta^2q^n\right)+\text{a similar term with }\theta\text{ replaced by }-\theta. \tag{4.3}$$

The relationship (4.3) is not exactly what Rahman and Verma obtained although it serves the same purpose. Applying the transformation

$$ {}_2\phi_1\left(\begin{matrix}a,b\\c\end{matrix};q,x\right)=\frac{(abx/c;q)_\infty}{(x;q)d\infty}\,{}_2\phi_1\left(\begin{matrix}c/a,c/b\\c\end{matrix};q,abx/c\right) $$

to the basic hypergeometric functions in (4.3) transforms (4.3) to

$$ (4.4)\quad C_n(\cos\theta;\beta\,|\,q)=\frac{(\beta;q)_\infty(\beta e^{2i\theta};q)_\infty(q^{n+1};q)_\infty}{(q;q)_\infty(e^{2i\theta};q)_\infty(\beta^2q^n;q)_\infty}\,{}_2\phi_1\left(\begin{matrix}\beta e^{2i\theta},\beta\\ qe^{-2i\theta}\end{matrix};q,q^{n+1}\right). $$

Formula (4.4) is a restatement of (4.2).

Acknowledgments. I thank Mizan Rahman and Arun Verma for sending me a preprint of their paper [10] which motivated this work. Discussions with Dennis Stanton of the University of Minnesota were extremely helpful.

MONOTONICITY PROPERTIES OF THE ZEROS OF BESSEL FUNCTIONS*

ÁRPÁD ELBERT† AND ANDREA LAFORGIA‡

Abstract. For $\nu \geqq 0$ let $c_{\nu k}$ be the kth positive zero of the general cylinder function

$$C_\nu(x) = \cos\alpha J_\nu(x) - \sin\alpha Y_\nu(x), \qquad 0 \leqq \alpha < \pi$$

where $J_\nu(x)$ and $Y_\nu(x)$ denote the Bessel functions of the first and second kind, respectively. Since the notation $c_{\nu k}$ does not reflect the dependence on the values of α, it is useful to define the function $j_{\nu\kappa}$ as in [3]. The sequence $j_{\nu 1} j_{\nu 2}, \ldots$ is used to denote the sequence of the zeros of $J_\nu(x)$ corresponding to $\alpha = 0$. Now for any $\kappa \in (k-1, k)$, where k is some natural number, let $j_{\nu\kappa} = c_{\nu k}$ with $\alpha = (k-\kappa)\pi$. The correspondence between $j_{\nu k}$ and $c_{\nu k}$ is one-to-one. In this paper we are concerned with some monotonicity properties related to $j_{\nu\kappa}$. We also study the convexity (concavity) of $j_{\nu\kappa}$ showing that $j_{\nu\kappa}$ is convex with respect to κ for fixed ν and $0 \leqq \nu \leqq \frac{1}{2}$, and concave for $\nu \geqq \frac{1}{2}$.

Finally for $\nu \geqq 0$ and $\kappa > 0$ we prove that the function $\log j_{\nu\kappa}$ is concave in ν for fixed κ and concave in κ for fixed ν.

Key words. zeros of Bessel functions

AMS(MOS) subject classification. Primary 33A40

1. Introduction.

For $\nu \geqq 0$ we use $c_{\nu k}$ to denote the kth positive zero of the cylinder function

$$C_\nu(x) = J_\nu(x)\cos\alpha - Y_\nu(x)\sin\alpha, \qquad 0 \leqq \alpha < \pi$$

where $J_\nu(x)$ and $Y_\nu(x)$ are the Bessel functions of the first and second kind, respectively.

The properties of $c_{\nu k}$ have been investigated by several authors.

Recently L. Lorch has studied the determinant [4, p. 223]

$$T = \begin{vmatrix} c_{\nu k} & c_{\nu+\delta, k+h} \\ c_{\nu+\varepsilon, k+r} & c_{\nu+\delta+\varepsilon, k+h+r} \end{vmatrix} \tag{1.1}$$

for $\varepsilon, \delta \geqq 0$, h, $r = 0, 1, 2, \cdots$, $\varepsilon + r > 0$, $h + \delta > 0$ and he has proved that $T < 0$.

In this paper we are interested, among other things, in determinants of the type (1.1), and we prove a more general result than the one given by Lorch.

In [3] we introduced the notation $j_{\nu\kappa}$ to denote the function $c_{\nu k}$ as follows: let $\kappa = k - \alpha/\pi$, then $j_{\nu\kappa} = c_{\nu k}$. Now we have $j_{\nu\kappa}$ for $\nu \geqq 0$, $\kappa > 0$ and with this notation (1.1) can be rewritten in the following way

$$T = \begin{vmatrix} j_{\nu\kappa} & j_{\nu+\delta, \kappa+h} \\ j_{\nu+\varepsilon, \kappa+r} & j_{\nu+\delta+\varepsilon, \kappa+h+r} \end{vmatrix} \tag{1.2}$$

where $\nu, \kappa, \delta, h, r, \varepsilon$ are nonnegative real numbers and $\varepsilon + r > 0$, $h + \delta > 0$. We shall see that Lorch's result is true also for T in (1.2).

Concerning the function $j_{\nu\kappa}$ we know that it is increasing with respect to both the variables. For fixed κ this follows from the Watson formula [6, p. 508]

$$\frac{d}{d\nu}j_{\nu\kappa}=2j_{\nu\kappa}\int_0^\infty K_0(2j_{\nu\kappa}\sinh t)e^{-2\nu t}dt \tag{1.3}$$

where $K_0(u)$ is the modified Bessel function of order zero, which is positive. On the other hand for fixed ν we have proved in [2] that $j_{\nu\kappa}$ is strictly increasing with respect to κ. For the sake of the later reference we express this property in the form

$$j_{\nu\kappa'}>j_{\nu\kappa}, \quad \kappa'>\kappa>0, \quad \nu>-\kappa. \tag{1.4}$$

Moreover we know [5] that the sequence $\{c_{\nu,k+1}-c_{\nu,k}\}_{k=1}^{\infty}$ is strictly decreasing for $|\nu|>\frac{1}{2}$ and increasing for $|\nu|<\frac{1}{2}$. So with our notation the sequence $\{j_{\nu,\kappa+k+1}-j_{\nu,\kappa+k}\}_{k=0}^{\infty}$ is monotonic. This property suggests that the function $j_{\nu\kappa}$ is concave with respect to κ if $\nu\geqq\frac{1}{2}$ and convex for $0\leqq\nu\leqq\frac{1}{2}$. Theorem 2.2 states that this observation is true.

2. The function $j_{\nu\kappa}$ and the determinant T. For $\nu\geqq 0$ and $\kappa>0$ we consider the derivative

$$\frac{\partial}{\partial\kappa}j_{\nu\kappa}=l_{\nu\kappa}=l. \tag{2.1}$$

Since in the special case $\nu=\frac{1}{2}j_{1/2,\kappa}=\kappa\pi$ [3], we have

$$l_{1/2,\kappa}=\pi. \tag{2.2}$$

Differentiating the function $dj_{\nu\kappa}/d\nu$ given by (1.3) with respect to κ, we obtain

$$\frac{d}{d\nu}l=2l\int_0^\infty K_0(2j\sinh t)e^{-2\nu t}dt$$
$$+2j\int_0^\infty K_0'(2j\sinh t)2l\sinh te^{-2\nu t}dt$$

where $j=j_{\nu\kappa}$. An integration by parts of the second integral on the right-hand side gives

$$2l\int_0^\infty K_0'(2j\sinh t)2j\cosh t\tanh te^{-2\nu t}dt=2l\left[K_0(2j\sinh t)\tanh te^{-2\nu t}\right]_0^\infty$$
$$-2l\int_0^\infty K_0(2j\sinh t)\left[\frac{1}{\cosh^2 t}-2\nu\tanh t\right]e^{-2\nu t}dt.$$

Recalling that

$$K_0(u)=\begin{cases}O\left(\log\dfrac{1}{u}\right), & u>0, \quad u\to 0,\\ o(e^{-u}), & u\to\infty,\end{cases}$$

the first term on the right-hand side is zero; therefore by (2.1)

$$\frac{d}{d\nu}l=2l\int_0^\infty K_0(2j\sinh t)(\tanh^2 t+2\nu\tanh t)e^{-2\nu t}dt.$$

Taking into account (2.2), we have

$$(2.3)\qquad l_{\nu\kappa}=\pi\exp\left\{2\int_{1/2}^{\nu}\left[\int_0^{\infty}K_0(2j_{\mu\kappa}\sinh t)(\tanh^2 t+2\mu\tanh t)e^{-2\mu t}dt\right]d\mu\right\}.$$

A simple consequence of the formula (2.3) is the following result.

THEOREM 2.1. *For $\nu\geqq 0$ and $\kappa'>\kappa>0$ the relations*

$$j_{\nu\kappa'}-j_{\nu\kappa}\begin{cases}>\pi(\kappa'-\kappa), & \nu>\frac{1}{2},\\ =\pi(\kappa'-\kappa), & \nu=\frac{1}{2},\\ <\pi(\kappa'-\kappa), & 0\leqq\nu<\frac{1}{2}\end{cases}$$

hold.

Proof. By (2.3) we have the inequalities $l_{\nu\kappa}\gtreqless\pi$ if $\nu\gtreqless\frac{1}{2}$ respectively, and $j_{\nu\kappa'}-j_{\nu\kappa}=\int_{\kappa}^{\kappa'}l_{\nu\lambda}d\lambda$; hence the conclusion of the Theorem follows.

THEOREM 2.2. *The function $j_{\nu\kappa}$ is concave with respect to κ if $\nu\geqq\frac{1}{2}$ and convex if $0\leqq\nu\leqq\frac{1}{2}$.*

Proof. To show the concavity of the function $j_{\nu\kappa}$ with respect to κ, in the case $\nu\geqq\frac{1}{2}$, we need to show that the function $l_{\nu\kappa}=\partial j_{\nu\kappa}/\partial\kappa$ decreases as κ increases. Let $\kappa'>\kappa>0$. Then by (1.4) $j_{\nu\kappa'}>j_{\nu\kappa}$ for $\nu\geqq 0$. On the other hand the function $K_0(u)$ has the integral representation [6, p. 446]

$$K_0(u)=\int_0^{\infty}e^{-u\cosh\xi}d\xi;$$

hence $K_0(u)$ strictly decreases as u increases and by (2.3) we have $l_{\nu\kappa}>l_{\nu\kappa'}$. This gives the concavity of $j_{\nu\kappa}$ with respect to κ, for $\nu\geqq\frac{1}{2}$.

Similarly we can prove the convexity of $j_{\nu\kappa}$ with respect to κ, in the case $0\leqq\nu\leqq\frac{1}{2}$, and the proof of Theorem 2.2 is complete.

THEOREM 2.3. *For $\nu\geqq 0$ and $\kappa>0$ the function $\log j_{\nu\kappa}$ is concave in ν for fixed κ and concave in κ for fixed ν.*

Proof. The first part of the theorem follows from

$$\frac{j_{\nu+\varepsilon+\delta,\kappa}}{j_{\nu+\varepsilon,\kappa}}<\frac{j_{\nu+\delta,\kappa}}{j_{\nu\kappa}},\qquad \varepsilon,\delta>0;$$

thus we need to show that the function $H(\nu,\kappa)$ defined by

$$(2.4)\qquad H(\nu,\kappa)=\frac{j_{\nu+\delta,\kappa}}{j_{\nu\kappa}}$$

decreases as ν increases. By (1.3) we have

$$(2.5)\qquad \log H(\nu,\kappa)=2\int_{\nu}^{\nu+\delta}\left[\int_0^{\infty}K_0(2j_{\mu\kappa}\sinh t)e^{-2\mu t}dt\right]d\mu$$

and similarly

$$\begin{aligned}\log H(\nu+\varepsilon,\kappa)&=2\int_{\nu+\varepsilon}^{\nu+\varepsilon+\delta}\left[\int_0^{\infty}K_0(2j_{\mu\kappa}\sinh t)e^{-2\mu t}dt\right]d\mu\\&=2\int_{\nu}^{\nu+\delta}\left[\int_0^{\infty}(2j_{\mu+\varepsilon,\kappa}\sinh t)e^{-2(\mu+\varepsilon)t}dt\right]d\mu.\end{aligned}$$

By (1.3) $j_{\mu+\varepsilon,\kappa}>j_{\mu,\kappa}$ and since $K_0(u)$ decreases as u increases, the function in the last integral is less than the one in (2.5). This shows that $H(\nu+\varepsilon,\kappa)<H(\nu,\kappa)$ and the result follows.

For the proof of the second part we have to show the inequality

$$\frac{j_{\nu,\kappa+r+h}}{j_{\nu,\kappa+r}}<\frac{j_{\nu,\kappa+h}}{j_{\nu\kappa}}, \qquad r,h>0$$

which is equivalent to proving that the function $L(\nu,\kappa)$ defined by

$$L(\nu,\kappa)=\frac{j_{\nu,\kappa+h}}{j_{\nu\kappa}} \tag{2.6}$$

decreases as κ increases.

By (2.1) and (2.6) we have

$$\frac{\partial}{\partial\kappa}\log L(\nu,\kappa)=\frac{l_{\nu,\kappa+h}}{j_{\nu,\kappa+h}}-\frac{l_{\nu\kappa}}{j_{\nu\kappa}} \tag{2.7}$$

and we need to prove that $l_{\nu\kappa}/j_{\nu\kappa}$ decreases as κ increases. In the particular case $\nu=\frac{1}{2}$ this is trivial, because by (2.2) $l_{1/2,\kappa}=\pi$ and $j_{1/2,\kappa}=\kappa\pi$.

Now we distinguish the cases $\nu>\frac{1}{2}$ and $0\leqq\nu\leqq\frac{1}{2}$. In the first case for $r>0$ and $\kappa'=\kappa+r$ we have by (1.4) and (2.3)

$$\frac{l_{\nu\kappa'}}{j_{\nu\kappa'}}<\frac{l_{\nu\kappa'}}{j_{\nu\kappa}}<\frac{l_{\nu\kappa}}{j_{\nu\kappa}},$$

so by (2.7) the function $L(\nu,\kappa)$ decreases as κ increases, provided $\nu>\frac{1}{2}$.

The case $0\leqq\nu\leqq\frac{1}{2}$ requires more detailed investigation. By (2.1) and (2.3) we get

$$\psi(\nu,\kappa)=\frac{\partial}{\partial\kappa}\log\frac{l_{\nu\kappa}}{j_{\nu\kappa}}=-2\int_\nu^{1/2} \cdot\left[\int_0^\infty K_0'(2j_{\mu\kappa}\sinh t)2l_{\mu\kappa}\sinh t(\tanh^2 t+2\mu\tanh t)e^{-2\mu t}dt\right]d\mu-\frac{l_{\nu\kappa}}{j_{\nu\kappa}}. \tag{2.8}$$

We claim that $\psi(\nu,\kappa)<0$ for $0\leqq\nu\leqq\frac{1}{2}$. For $\nu=\frac{1}{2}$ this is trivial. We show that $\partial\psi(\nu,\kappa)/\partial\nu>0$ for $\nu>0$. Indeed by (1.3), (2.3) and (2.8) we get

$$\frac{j_{\nu\kappa}}{l_{\nu\kappa}}\frac{\partial}{\partial\nu}\psi(\nu,\kappa)=I_1+2\nu I_2 \tag{2.9}$$

where

$$I_1=4j_{\nu\kappa}\int_0^\infty K_0'(2j_{\nu\kappa}\sinh t)\sinh t\tanh^2 t\,e^{-2\nu t}dt$$

$$+2\int_0^\infty K_0(2j_{\nu\kappa}\sinh t)(1-\tanh^2 t)e^{-2\nu t}dt,$$

and

$$I_2=\int_0^\infty\left[4j_{\nu\kappa}\sinh t\tanh tK_0'(2j_{\nu\kappa}\sinh t)-2\tanh tK_0(2j_{\nu\kappa}\sinh t)\right]e^{-2\nu t}dt.$$

An integration by parts gives for $\nu > 0$

$$I_2 = \left\{ \left[4 j_{\nu\kappa} \sinh t \tanh t K_0'(2 j_{\nu\kappa} \sinh t) - 2 \tanh t K_0(2 j_{\nu\kappa} \sinh t) \right] \frac{e^{-2\nu t}}{-2\nu} \right\}_0^\infty$$
$$+ \frac{1}{2\nu} \int_0^\infty \left[4 j_{\nu\kappa} \left(\sinh t + \frac{\sinh t}{\cosh^2 t} \right) K_0'(2 j_{\nu\kappa} \sinh t) \right.$$
$$+ 8 j_{\nu\kappa}^2 \sinh^2 t K_0''(2 j_{\nu\kappa} \sinh t) - \frac{2}{\cosh^2 t} K_0(2 j_{\nu\kappa} \sinh t)$$
$$\left. - 4 j_{\nu\kappa} \sinh t K_0'(2 j_{\nu\kappa} \sinh t) \right] e^{-2\nu t} dt.$$

Recalling that $K_0'(u) = -K_1(u)$ and

$$K_1(u) = \begin{cases} O\left(\log \frac{1}{u}\right), & u > 0, \quad u \to 0, \\ o(e^{-u}), & u \to \infty \end{cases}$$

the first term on the right-hand side is zero and by (2.3) we obtain

(2.10)

$$\frac{j_{\nu\kappa}}{l_{\nu\kappa}} \frac{\partial}{\partial \nu} \psi(\nu, \kappa) = 2 \int_0^\infty \left[T_1(t) K_0(2 j_{\nu\kappa} \sinh t) + 2 j_{\nu\kappa} T_2(t) K_0'(2 j_{\nu\kappa} \sinh t) \right.$$
$$\left. + 4 j_{\nu\kappa}^2 \sinh^2 t K_0''(2 j_{\nu\kappa} \sinh t) \right] e^{-2\nu t} dt$$

where

$$T_1(t) = 1 - \tanh^2 t - \frac{1}{\cosh^2 t} = 0,$$

$$T_2(t) = \sinh t \tanh^2 t + \frac{\sinh t}{\cosh^2 t} = \sinh t.$$

Taking into account that $K_0(u)$ satisfies the differential equation [1, p. 374]

$$u^2 K'' + u K' - u^2 K = 0,$$

we have

$$\frac{\partial}{\partial \nu} \psi(\nu, \kappa) = 8 l_{\nu\kappa} j_{\nu\kappa} \int_0^\infty K_0(2 j_{\nu\kappa} \sinh t) \sinh^2 t e^{-2\nu t} dt, \tag{2.11}$$

which is clearly positive. So the function $\psi(\nu, \kappa)$ increases as ν increases and by (2.8)

$$\psi(\nu, \kappa) = \frac{\partial}{\partial \kappa} \log \frac{l_{\nu\kappa}}{j_{\nu\kappa}} \leqq \psi\left(\frac{1}{2}, \kappa\right) = \frac{-1}{\kappa} < 0, \qquad 0 \leqq \nu \leqq \tfrac{1}{2}.$$

Consequently the function $l_{\nu\kappa}/j_{\nu\kappa}$ decreases as κ increases and by (2.7) $L(\nu, \kappa)$ decreases as κ increases. The proof of Theorem 2.3 is complete.

COROLLARY 2.1. *For $\varepsilon, \delta, h, r > 0$ let T be defined by* (1.2). *If $\varepsilon + r > 0$ and $h + \delta > 0$, then $T < 0$.*

Proof. The inequality $T<0$ is equivalent to

$$H(\nu+\varepsilon,\kappa+r)L(\nu+\delta+\varepsilon,\kappa+r)<H(\nu,\kappa)L(\nu+\delta,\kappa), \tag{2.12}$$

where the functions $H(\nu,\kappa)$ and $L(\nu,\kappa)$ have been defined by (2.4) and (2.6), respectively.

So it is sufficient to show that the functions $H(\nu,\kappa)$ and $L(\nu,\kappa)$ are decreasing with respect to both the variables.

Concerning the function $H(\nu,\kappa)$ we have already shown that it is decreasing with respect to ν.

Now let us suppose $r>0$ and $\kappa'=\kappa+r$. Then by (1.4) and (2.5)

$$\log H(\nu,\kappa')=2\int_{\nu}^{\nu+\delta}\left[\int_0^{\infty}K_0(2j_{\mu\kappa'}\sinh t)e^{-2\mu t}dt\right]d\mu$$

$$<2\int_{\nu}^{\nu+\delta}\left[\int_0^{\infty}K_0(2j_{\mu\kappa}\sinh t)e^{-2\mu t}dt\right]d\mu=\log H(\nu,\kappa).$$

This shows that the function $H(\nu,\kappa)$ decreases as κ increases, provided $\delta>0$.

Let us consider the function $L(\nu,\kappa)$ defined by (2.6). The decrease of L as a function of κ has been shown. So we have to prove that $L(\nu+\delta,\kappa)<L(\nu,\kappa)$ for $\delta>0$, or equivalently

$$\frac{j_{\nu+\delta,\kappa+h}}{j_{\nu,\kappa+h}}<\frac{j_{\nu+\delta,\kappa}}{j_{\nu,\kappa}}, \qquad \delta>0.$$

By (2.4) this inequality is equivalent to $H(\nu,\kappa+h)<H(\nu,\kappa)$, which is the property proved above.

We have seen that the inequality (2.12) is equivalent to $T<0$; hence we need the sharp inequality in (2.12). Since $\varepsilon+r>0$ and $\varepsilon\geqq 0$, $r\geqq 0$, there are two possibilities: the first one, $r>0$, $\varepsilon\geqq 0$ and the second one $r=0$, $\varepsilon>0$. In the first case we have $L(\nu+\delta+\varepsilon,\kappa+r)<L(\nu+\delta,\kappa+r)<L(\nu+\delta,\kappa)$ and $H(\nu+\varepsilon,\kappa+r)\leqq H(\nu,\kappa)$ and (2.12) holds. In the second case we have the sharp inequality $H(\nu+\varepsilon,\kappa)<H(\nu,\kappa)$, and hence $T<0$. The proof of the Corollary 2.1 is complete.

Acknowledgment. We are grateful to the referee, whose constructive criticism and suggestions led to the present improved version of this paper.

THE SUMMABILITY SIGNIFICANCE OF ROOTS OF BESSEL FUNCTIONS*

E. C. OBI†

Abstract. A new semicontinuous Toeplitz (regular) matrix method of summability is developed from the (roots of) Bessel functions. Like the method of the Bessel function itself, developed by R. G. Cooke, viz.,

$$(J,v): a_{\lambda k} = 2J_{k+\nu}^2(\lambda),$$

the new method,

$$(\mathcal{O},m): t_{\nu k}^{(m)} = \beta(m,\nu)\, j_{\nu k}^{-2m}$$

(where $\beta(m,\nu)$ is explicit in m, ν), falls into the "Cesàro scope," but unlike the Cooke method, the $(\mathcal{O},m)$ limitation methods are definitely consistent with $(C,1)$ throughout the convergence field of this Cesàro means.

1. Introduction. The semicontinuous matrix of R. G. Cooke,

$$a_{\lambda k} = 2J_{k+\nu}^2(\lambda) \qquad (\lambda > 0,\ k = 1,2,\cdots),$$

where ν is fixed in $R \equiv (-\infty, \infty)$, is a Toeplitz (i.e. regular) method of summability (cf. [1]). A sequence, $z \equiv \{z_k\}$ in C (the set of complex numbers), is said to be (J,ν)-summable to $\gamma \in C$ if

$$\lim_{\lambda \to \infty} \sum_{k=1}^{\infty} 2J_{k+\nu}^2(\lambda) z_k = \gamma.$$

Thus, for example, summability $(J,0)$ would be consistent with $(C,1)$-summability for such divergent sequences as $z_k = \cos k\theta$ if $\theta \notin \{2n\pi : n = 0, \pm 1, \pm 2, \cdots\}$ is fixed (cf. [1]). The $(J, \frac{1}{2})$-method sums divergent Fourier series to their functions, a.e. on $[-\pi, \pi]$. With these and other related results of Cooke the summability significance of $J_\nu(z)$ was brought to light. Some cylinder (or their related) functions have played other classical roles in the theory of infinite matrices. It is of interest to note (in §3) that the zeros, $j_{\nu k}$, of the particular cylinder functions, $J_\nu(z)$, have a strong relationship with an important class of summability methods, viz. the *delicate* class. (We recall that there is the powerful class (cf. [2, p. 197]), consisting of those methods which are efficient for crudely divergent series—such as a power series outside the disc of convergence—but are usually ineffective for the slowly oscillating types, such as $\sum_{k=1}^{\infty}(e^{i\sqrt{k}}/\sqrt{k})$ [2, p. 197].) A summability method which is efficient for the slowly oscillating types, but normally not for the former, is said to belong to the delicate class.

If we identify the element $(\nu,k) \in R^+ \times N \equiv [0,\infty) \times \{1, 2, \cdots\}$ by the kth zero of $J_\nu(z)$, we construct explicit functions $\beta(m,\nu)$ such that for each fixed $m \in N$, the transformation, $t^{(m)}: R^+ \times N \to R^+$, defined by

$$t^{(m)}: j_{\nu k} \to \beta(m,\nu)\, j_{\nu k}^{-2m},$$

transforms the nonregular matrix $j_{\nu k}$ to a regular semicontinuous method of summability which belongs to the delicate class and which, in addition, is endowed with other desirable consistency properties. In particular, this matrix-construct of $j_{\nu k}$ is efficient

*Received by the editors May 3, 1983, and in revised form November 1, 1984.
† Department of Mathematics, University of Nigeria, Nsukka, Nigeria.

for Fourier series and has a more favorable comparison with $(C,1)$ than was shown (Cooke [1]) between (J,ν) and $(C,1)$.

2. Summability theory and roots of $J_\nu(z)$. Denote $\mathscr{S}\equiv$ the linear space of all complex sequences, $\mathbb{C}\equiv\{z\in\mathscr{S}:\lim z \text{ exists}\}$, and $\mathscr{H}\equiv$ the set of all divergent sequences of 0's and 1's. If $M\equiv(m_{\nu k})$, $\nu\geqq\nu_0>0$, $k=1,2,\cdots$, is an infinite semicontinuous complex matrix such that

$$\omega(\nu)\equiv\sum_{k=1}^{\infty}m_{\nu k}z_k \tag{1}$$

exists for all $\nu\geqq\nu_0$, then the M-transforms $\{\omega(\nu)\}_{\nu\geqq\nu_0}$ of $z\equiv\{z_k\}$ may be denoted by $w=Mz$ or by (1). Let $\mathscr{C}(M)$ be the *convergence field* of M (i.e. the linear space of those $z\in\mathscr{S}\ni\lim Mz$ exists), and let $\mathscr{P}(M)$ be the subspace of $\mathbb{C}\cap\mathscr{C}(M)$ consisting of those $z\ni\lim z=\lim Mz$. If $\mathbb{C}\subseteq\mathscr{C}(M)$, M is called a *K-matrix* (after Kojima [2, p. 4]). Those K-matrices that satisfy the following *consistency* or *regularity* property, $\mathscr{P}(M)=\mathbb{C}$, are called *Toeplitz* (or consistent, or regular, or simply T-) methods of summability, or just T-matrices. The *M-generalized limit* of z is $\lim Mz\equiv\gamma$ if γ exists and if M is Toeplitz. For a proof that the semicontinuous matrix. $a_{xk}=2J^2_{k+\nu}(x)$, with ν fixed in R, and $k\in N$, and x varying in $(0,\infty)$, is Toeplitz (regular), see [1].

Two among the best known methods which we shall have an occasion to use below are the Cesàro and the Riesz means:

$$C_{(r)}:c_{ik}=\begin{cases}\dfrac{A^{r-1}_{i-k}}{A^r_{i-1}}, & \text{if } 1\leqq k\leqq i,\\ 0 & \text{if } k>i,\ i,k=1,2,\cdots, \text{ where } A^r_0=1,\end{cases}$$

$A^r_i=(r+1)\cdots(r+i)/i!$, if $i\geqq1$ (r is real but not a negative integer); the corresponding transformation is

$$W(i)=\left(A^r_{i-1}\right)^{-1}\sum_{k=1}^{i}A^{r-1}_{i-k}z_k$$

(the notation $C_{(r)}$ and (C,r) will be used interchangeably according to convenience);

$$(\mathscr{R},r):r_{ik}=\begin{cases}\left(1-\dfrac{k}{i}\right)^r-\left(1-\dfrac{k+1}{i}\right)^r & \text{if } i-k>1,\\ 0 & \text{otherwise.}\end{cases}$$

The M-sum of a series will mean that of the sequence of its partial sums, the quantities $\lim_{\nu\to\infty}m_{\nu k}$ and $\lim_{\nu\to\infty}\Sigma_k m_{\nu k}$ are called the (first and second) characteristic numbers of M; and finally $[x]$ will denote the integral part of x. Now, using the zeros of Bessel functions, we construct a new J_ν-related regular method of summability which is of the delicate class and has the properties suggested in §1. It will be useful to define the following quantities:

$$e_m=\text{the } m\text{th Catalan number } \frac{1}{m}\binom{2m-2}{m-1};$$

$$d(m)=1-2m+\sum_{s=1}^{m}[m/s];\ h_m(\nu)=e_m(\nu+m-1)^{d(m)};$$

$$\pi_m(\nu)=4^m\sum_{s=1}^{m}(\nu+s)^{[m/s]},$$

for all $m\geqq1$, $\nu\geqq0$.

THEOREM 1. *If $j_{\nu k}$ is the kth positive root of $J_\nu(z)$, $\nu \in R^+$, $k=1,2,3,\cdots$, then each of the semicontinuous matrices generated below by $j_{\nu k}$ according to the equations,*

$$t_{\nu k}^{(m)} = \pi_m(\nu)\{h_m(\nu)\}^{-1} j_{\nu k}^{-2m}, \qquad m=1,2,3,\cdots,$$

is a Toeplitz (regular) method of summability.

(The symbol $(\mathcal{O},m)$, or $\mathcal{O}$ if m is fixed, will below denote this method, and m will be called its degree or order.)

Before the proof we first discuss a result which will be needed from the theory of Bessel functions.

Consider the Maclaurin coefficients, $\sigma_m(\nu)=\sum_{k=1}^{\infty} j_{\nu k}^{-2m}$, of the function, $\sqrt{z}\,J_{\nu+1}(\sqrt{z})/(2J_\nu(\sqrt{z}))=\sum_{m=1}^{\infty}\sigma_m(\nu)z^m$ (cf. [3, p. 528]), where for our purposes $\nu \geqq 0$. Then the product,

$$\phi_m(\nu) \equiv \left\{4^m \prod_{s=1}^{m} (\nu+s)^{[m/s]}\right\}\sigma_m(\nu),$$

is by a theorem of Kishore [3a][1] a polynomial in ν which can be represented in the form,

$$\phi_m(\nu) = \sum_{i=1}^{c(m)} 2^{m_i} \prod_{s=2}^{m-1} (\nu+s)^{a_{is}} (m \geqq 3), \qquad \phi_1=\phi_2=1, \tag{2}$$

where

$$c(m) = \sum_{s=1}^{[m/2]} c(s)c(m-s), \qquad c(1)=1,$$

$$\sum_{i=1}^{c(m)} 2^{m_i} = \frac{1}{m}\binom{2m-2}{m-1}, \quad \text{and} \quad \sum_{s=2}^{m-1} a_{is} = \deg(\phi_m) = 1-2m+\sum_{s=1}^{m}[m/s]. \tag{2a}$$

The proof of (2) may be found in [3a, p. 515].[1]

Thus $\sigma_m(\nu)$ is rational. Historically it was first used by Lord Rayleigh in his search for the numerical value for $\min_k j_{\nu k}$ when $\nu \geqq 0$ [4, p. 502].

Proof of Theorem 1. We verify that $(\mathcal{O},m)$ satisfies the Silverman–Toeplitz conditions for regularity by showing that there exists $\lambda>0$, independent of ν in $0 \leqq \nu < \infty$, such that $\sum_k t_{\nu k}^{(m)} \leqq \lambda$, and that the (first and second) characteristic numbers of $(\mathcal{O},m)$ are 0 and 1, respectively. Now take the polynomial ϕ_m. Since $\sum_{s=2}^{m-1} a_{is} = d(m)$ from (2a), we can write (2) as

$$\phi_m(\nu) = \sum_{i=1}^{c(m)} 2^{m_i} \prod_{s=1}^{d(m)} (\nu+b_{is}),$$

for some integers b_{is}, $2 \leqq b_{is} \leqq m-1$. Then on $\nu \geqq 0$,

$$0 \leqq \phi_m(\nu) \leqq (\nu+m-1)^{d(m)} \sum_{i=1}^{c(m)} 2^{m_i} = (\nu+m-1)^{d(m)} e_m = h_m(\nu);$$

[1] The notation ϕ_{2n} reads as ϕ_n after 1964.

and so,

$$\sum_k t_{\nu k}^{(m)} = \pi_m(\nu)\{h_m(\nu)\}^{-1}\sum_k j_{\nu k}^{-2m} = \pi_m(\nu)\{h_m(\nu)\}^{-1}\sigma_m(\nu)$$

$$= \phi_m(\nu)\{h_m(\nu)\}^{-1} \leqq 1 \quad \forall \nu \geqq 0.$$

Thus the first Silverman–Toeplitz condition holds for $(\mathcal{O}, m)$D with $\lambda = 1$. Next, since $j_{0k} > 2$ for all $k \geqq 1$, then using the MacCann inequality [5, pp. 101–2],

$$j_{\nu k}^2 \geqq j_{0k}^2 + \nu^2, \quad j_{\nu k}^2 > \pi^2\left(k - \tfrac{1}{4}\right)^2 + \nu^2 \quad (\nu \geqq 0), \tag{3}$$

we find that

$$0 < t_{\nu k}^{(m)} = \pi_m(\nu)\{h_m(\nu)\}^{-1} j_{\nu k}^{-2m} < 4^m \prod_{s=1}^{m} (\nu + s)^{[m/s]} / \{h_m(\nu)(4+\nu^2)^m\} \equiv f(\nu)/g(\nu),$$

where f, g are polynomials in ν, with $\deg(f) = \sum_{s=1}^m [m/s]$, and $\deg(g) = d(m) + 2m = 1 + \sum_{s=1}^m [m/s] > \deg(f)$. Therefore, $\lim_{\nu \to \infty} f(\nu)/g(\nu) = 0$, whence $\lim_{\nu \to \infty} t_{\nu k}^{(m)} = 0$.

Finally, write $\sum_k t_{\nu k}^{(m)} = \phi_m(\nu)\{h_m(\nu)\}^{-1}$, which we obtained above. Since ϕ_m and h_m have the same degrees in ν, and the same leading coefficients, e_m, it follows that $\sum_k t_{\nu k}^{(m)} \to 1$, as $\nu \to \infty$. This completes the proof. □

Now, regular methods A, P will be said to be *comparable* at $z = \{z_k\} \in \mathcal{S}$, if $z \in \mathcal{C}(A) \cap \mathcal{C}(P)$. If A, P are comparable at z, and A-sum $= P$-sum at z, we say that A and P are *consistent at* z. Thus consistency on a set X will mean consistency at all $z \in X$. On the other hand, we will describe a regular method A as being *consistent with* P at z if P-summability of $z \Rightarrow A$-summability of z to the same sum. (In case A is consistent with P everywhere in $\mathcal{S}$, we just say, "A is consistent with P." Example: if $r, r' > 0$, (C, r) and (C, r') are consistent on $\mathcal{C}(C, r) \cap \mathcal{C}(C, r')$; $(C, 2)$ is consistent with $(C, 1)$ but not vice versa. Otherwise we will specify the subset X of $\mathcal{S}$ to which the phrase refers.) Next we write, "$A \sim P$ at z" (i.e. equivalent at z), to mean that *either* both A-sum and P-sum of z exist and are equal, *or else* neither exists. If (a) $A \sim P$ at z, and (b) $Az - Pz$ is a null sequence (in case neither A-sum nor P-sum exists at z), we say that A is *absolutely equivalent* to P at z, and we write, "$A \equiv P$ at z." The example, $(C, r) \equiv (\mathcal{R}, r)$ on all of l^∞, when $r > 0$, is well known.

Once a K-method, A, is proved regular, it raises other natural and important classical questions. Does it have the Borel property?[2] Where is it consistent with some older method? What divergent sequences may it sum to their right values? What about the summability of such important series as divergent Fourier series? If $l^\infty(A)$ is the proper subspace of the nonseparable metric space l^∞ (with the usual sup metric), consisting of all the A-summable elements of l^∞, is $l^\infty(A)$ also nonseparable? And so on. Answers to these questions as they affect $(\mathcal{O}, m)$ are taken up next.

3. An efficiency theorem. Let two regular methods A, P be related as follows: (a) A is consistent with P; and (b) the sequence Az is bounded whenever Pz is bounded. Then A is said to be at least as *efficient* (or at least as *powerful*) as P. We claim that every $(\mathcal{O}, m)$ is at least as efficient as $(C, 1)$ summability.

LEMMA 1. *If $P = (p_{ik})$ is a T matrix such that for each fixed i, $kp_{ik} \to 0$, as $k \to \infty$, then*

(a) $\sum_k p_{ik} = \sum_k b_{ik}$, *where* $b_{ik} = k(p_{ik} - p_{i,k+1})$, *and*

(b) $\sum_k p_{ik} z_k = \sum_k b_{ik} S_k / k$,

[2] Does the A-transform of *almost* all divergent sequences of 0's and 1's converge to $\frac{1}{2}$? This important property is held by many well-known regular methods, but is not necessary for regularity. For a definition of "almost," see for example [2, p. 207].

whenever $z=\{z_k\}\in\mathscr{S}$ *is such that*

$$\frac{1}{k}S_k\equiv\frac{1}{k}\sum_{n=1}^{k}z_n$$

is a bounded sequence. (For this known fact, cf. [2, p. 92, no. 5].)

THEOREM 2. *The* $\mathcal{O}$*-method,* $t_{ik}^{(m)}$*, of any degree* $m\geqq 1$*, is at least as efficient as the Cesàro means* $(C,1)$ *as a method of summability.*

Proof. Fix $m\geqq 1$, and denote $\mathcal{O}\equiv(\mathcal{O},m)$ and $t_{ik}\equiv t_{ik}^{(m)}$. Now for every i fixed,

$$0<kt_{ik}=k\Pi_m(i)\{h_m(i)\}^{-1}j_{ik}^{-2m}<\Pi_m(i)\{h_m(i)\}^{-1}\pi^{-2m}k\left(k-\frac{1}{4}\right)^{-2m}\to 0$$

as $k\to\infty$, in view of the MacCann inequality (3). So,

$$\lim_k kt_{ik}=0. \tag{4}$$

Next, set $b_{ik}=k(t_{ik}-t_{i,k+1})$. Then with i fixed, $t_k\equiv t_{ik}$ is a strictly decreasing sequence of positive numbers, so that $b_{ik}>0$, $\forall k$. Since $t_{ik}>0$ is a T-matrix, $\exists\lambda>0$, independent of i, such that in view of (4) and Lemma 1(a),

$$0<\sum_k b_{ik}=\sum_k t_{ik}\leqq\lambda.$$

It is now clear that b_{ik} is a T-matrix also. Now let $\{\omega(i)\}_{i\geqq i_0}$ be the $\mathcal{O}$-transform, $\mathcal{O}_z$, of $z=\{z_k\}$, and suppose $C_{(1)}z$ is bounded. Then $(1/k)S_k$ is a bounded sequence (say by α). Therefore,

$$\omega(i)=\sum_k t_{ik}z_k=\sum_k b_{ik}S_k/k \tag{5}$$

(by Lemma 1(b)), and so $|\omega(i)|\leqq\alpha\lambda$, $\forall i$; hence $\mathcal{O}z$ is bounded.

For the consistency aspect, suppose $C_{(1)}z\to\gamma\in C$, for a given $z\in\mathscr{S}$. Then ($(1/k)S_k\to\gamma$ as $k\to\infty$, so that) (5) applies. Hence, since b_{ik} is a T-matrix, and $(1/k)S_k\to\gamma$, we must have $\omega(i)\to\gamma$ as $i\to\infty$. That is, $\lim\mathcal{O}z=\gamma$, as required. □

If A is any T-matrix at least as efficient as some (C,r), $r>0$, it can be shown (see e.g. [2, p. 213]) that $l^\infty(A)$ inherits nonseparability from l^∞; hence the separability problem raised before is settled for $(\mathcal{O},m)$. In fact, since every Cesàro means (C,r), $r>0$, satisfies just as well the particular summability properties indicated in the following corollary for $\mathcal{O}$, this corollary is therefore a necessary consequence of Theorem 2.

COROLLARY. *Let* $\mathcal{O}$ *denote* $(\mathcal{O},m)$ *for any fixed degree* $m\geqq 1$*. Then*:

(i) $\mathcal{O}$ *has the Borel property*; *in consequence this real T-matrix sums almost all* $z\in\mathscr{H}$ *to their right value* (*their Abel sum*).

(ii) *Any* $z\equiv\{c_k\}\in\mathscr{H}$ *such that the function* $f(s)$ *represented by the Taylor series* $\sum_{k=0}^{\infty}(c_k-c_{k-1})s^k(c_{-1}=0)$ *in* $|s|<1$ *has the boundary point* $s=1$ *as a regular point, or as a point of negative order,*[3] *will be summable* $(\mathcal{O})$ *to its right value* $\lim_{s\to 1^-}f(s)$*, which reduces to* $f(1)$ *if* 1 *is regular.*

(iii) *The divergent Fourier series of any* 2π*-periodic and summable function* $g(x)$*, over* $[-\pi,\pi]$*, is* $\mathcal{O}$*-summable to* $g(x)$*, a.e. on* $[-\pi,\pi]$*; this series is* $\mathcal{O}$*-summable to* $\frac{1}{2}\{g(x+0)+g(x-0)\}$ *if* x *is a jump discontinuity.*

(iv) $(\mathcal{O},m)$ *is consistent with* $(\mathscr{R},r)$ *on* l^∞*, for at least all* $r\in[0,1]$.

(v) $l^\infty(\mathcal{O})$ *retains the nonseparability of* l^∞.

[3] For such a singularity, see Dienes, *Taylor Series*, Oxford, p, 491.

Thus for example, with $z=(0, 0, 1, 0, 0, 1, 0, 0, 1, \cdots)$ whose associated Taylor series, $s^2-s^3+s^5-s^6+s^8-\cdots$, represents $f(s)=s^2/(s^2+s+1)$ on $|s|<1$, which function has 1 as a regular point, the right value for z is $f(1)=1/3$ $(=\lim_{s\to 1^-} f(s))$; hence the $\mathcal{O}$-sum of z is $1/3$. By Corollary 1, the questions raised at the close of §2 are now settled for $(\mathcal{O}, m)$.

The remaining problem, the delicacy of $(\mathcal{O}, m)$, will also be settled by Theorem 2. For since the Cesàro means, as is well known [2, p. 197], is efficient for delicately convergent series (or sequences), it follows from Theorem 2 that the $(\mathcal{O}, m)$ method of any degree $m \geqq 1$ is of the delicate class. In closing, we conjecture that for $m \geqq 2$, $(\mathcal{O}, m)$ is consistent with $(C, 2)$, or in general, for $m \geqq r$, $(\mathcal{O}, m)$ is consistent with (C, r). The case $r=1$ follows from Theorem 2. The first eight of these methods are tabulated below for reference purposes:

$$t_{ik}^{(1)}=4(i+1)/j_{ik}^2;$$

$$t_{ik}^{(2)}=4^2(i+1)^2(i+2)/j_{ik}^4;$$

$$t_{ik}^{(3)}=4^3(i+1)^3(i+2)(i+3)/2j_{ik}^6;$$

$$t_{ik}^{(4)}=4^4(i+1)^4(i+2)^2(i+4)/5j_{ik}^8;$$

$$t_{ik}^{(5)}=4^5(i+1)^5(i+2)^2(i+3)(i+5)/14j_{ik}^{10};$$

$$t_{ik}^{(6)}=4^6(i+1)^6(i+2)^3(i+3)^2(i+4)(i+6)/42(i+5)^2 j_{ik}^{12};$$

$$t_{ik}^{(7)}=4^7(i+1)^7(i+2)^3(i+3)^2(i+4)(i+5)(i+7)/132(i+6)^2 j_{ik}^{14};$$

$$t_{ik}^{(8)}=4^8(i+1)^8(i+2)^4(i+3)^2(i+4)^2(i+5)(i+6)(i+8)/429(i+7)^4 j_{ik}^{16}.$$

UNIFORM ASYMPTOTIC EXPANSIONS FOR PROLATE SPHEROIDAL FUNCTIONS WITH LARGE PARAMETERS*

T. M. DUNSTER†

Abstract. By application of the theory for second order linear differential equations with a turning point and a regular (double pole) singularity developed by Boyd and Dunster (this Journal, 17 (1986), pp. 422–450) uniform asymptotic expansions are obtained for prolate spheroidal functions for large γ. The results are uniformly valid for $0 \leqq \mu^2/\gamma^2 \leqq 1+A$ and for $A' \leqq \lambda/\gamma^2 \leqq A''$, where A, A' and A'' are arbitrary real constants such that $0 \leqq A < A' \leqq A'' < \infty$. An asymptotic relationship between λ, μ, γ and the characteristic exponent ν is then derived from the approximations for the spheroidal functions. All the error terms associated with the approximations have explicit bounds given.

Key words. spheroidal wave functions, asymptotic expansions, asymptotic representations

AMS(MOS) subject classifications. Primary 33A55, 34E05, 30E15

1. Introduction. In this paper we shall derive asymptotic approximations to solutions of the spheroidal wave equation, which we express in the form

$$(1.1) \qquad (z^2-1)\frac{d^2v}{dz^2}+2z\frac{dv}{dz}-\left(\lambda+\frac{\mu^2}{(z^2-1)}-\gamma^2(z^2-1)\right)v=0.$$

Throughout this paper we shall restrict the parameters λ, μ, γ to being real and nonnegative. We shall construct asymptotic approximations to solutions of (1.1), for large γ^2, which will be uniformly valid either for $z \equiv x$ real with $0 \leqq x < 1$ (§§2 and 6), or for z complex with $|\arg(z)| \leqq \pi/2$ (§§3, 4 and 6).

There is a fourth parameter associated with (1.1) which is a function of λ, μ, and γ. This parameter is the characteristic exponent and we shall denote it by ν.

When γ is real, solutions of (1.1) are known as prolate spheroidal functions, and in the case where ν and μ are integers they are commonly known as prolate spheroidal wave functions. Prolate spheroidal functions play an important role in many areas of mathematics and physics, and we mention in particular problems of scalar and electromagnetic scattering by a prolate spheroid. In such problems γ is generally a real constant given ab initio, and which is large in the high-frequency case.

There have been a number of approximations for prolate spheroidal wave functions with γ large obtained previously, including the work of Flammer (1957), Müller (1963), Slepian (1965), Streifer (1968), Cloizeaux and Mehta (1972), Miles (1975), and Sink and Eu (1983). These results are essentially heuristic and do not contain error bounds for the difference between the approximate and exact solutions.

The work of Miles (1975) is the most general. He considers four parametric regimes with μ fixed, μ and ν integral, and approximates solutions of (1.1) in both the angular ($0 \leqq x < 1$) and radial ($1 < x < \infty$) cases. His case (ii) is a special case of our results.

* Received by the editors November 5, 1984, and in revised form April 9, 1985. This work was supported by a Science and Engineering Research Council research studentship.

† School of Mathematics, University of Bristol, Bristol BS8 1TW, England. Present address: Department of Mathematical Sciences, The University, Dundee DD1 4HN, Scotland, U.K.

Our results differ from previous results in several significant ways. Our approximations are uniformly valid for μ ranging from 0 to $O(\gamma)$, for large γ^2 and λ, and neither ν nor μ need necessarily be an integer. The approximations either involve Bessel functions or Airy functions, and taken together they are valid over the whole of the right-half plane $|\arg(z)|\leqq\pi/2$. Also, all the approximations in this paper are complete with explicit error bounds.

It is convenient for our analysis to define at this stage new parameters α and β by

$$\alpha=\frac{\mu}{\gamma},\qquad \beta^2=\frac{\lambda}{\gamma^2} \tag{1.2}$$

and a new variable $w(z)$ by

$$w(z)=(z^2-1)^{1/2}v(z). \tag{1.3}$$

Equations (1.2) and (1.3) then transform (1.1) into the differential equation

$$\frac{d^2w}{dz^2}=\left\{\gamma^2\frac{(z^2-z_1^2)(z_2^2-z^2)}{(z^2-1)^2}-\frac{1}{(z^2-1)^2}\right\}w, \tag{1.4}$$

where for convenience we have written

$$z_1=\left[1-\tfrac{1}{2}\left((\beta^4+4\alpha^2)^{1/2}-\beta^2\right)\right]^{1/2}, \tag{1.5a}$$

$$z_2=\left[1+\tfrac{1}{2}\left((\beta^4+4\alpha^2)^{1/2}+\beta^2\right)\right]^{1/2}. \tag{1.5b}$$

In the right-half complex z-plane (1.4) is characterized by a regular singularity at $z=1$ and an irregular singularity at $z=\infty$, and for large γ has turning points at $z=z_1$ and $z=z_2$.

Assume for the moment that β is fixed and positive; we see then from (1.5b) that z_2 is real and lies in the interval $1<(1+\beta^2)^{1/2}\leqq z_2<\infty$ for $0\leqq\alpha^2<\infty$. The character of z_1 as α^2 ranges from 0 to ∞ is determined from (1.5a):

(i) $\alpha^2=0$; z_1 coalesces with the singularity at $z=1$.
(ii) $0<\alpha^2<1+\beta^2$; z_1 is real and lies in the interval $(0,1)$.
(iii) $\alpha^2=1+\beta^2$; z_1 coalesces with the turning point $-z_1$ at $z=0$.
(iv) $\alpha^2>1+\beta^2$; z_1 lies on the imaginary axis.

Our results will be uniformly valid for z_1 real and lying in any closed subinterval of $(0,1]$, and with z_2 bounded away from 1.

We impose then the following restrictions on α and β:

$$0\leqq\alpha^2\leqq 1+A, \tag{1.6a}$$

$$A'\leqq\beta^2\leqq A'', \tag{1.6b}$$

where A, A', and A'' are arbitrary real constants such that

$$0\leqq A<A'\leqq A''<\infty. \tag{1.7}$$

The spheroidal functions we approximate are $\mathrm{Ps}_\nu^{-\mu}(x,\gamma^2)$ and $\mathrm{Qs}_\nu^{-\mu}(x,\gamma^2)$ in the real variable case, and $Ps_\nu^{-\mu}(z,\gamma^2)$, $Qs_\nu^{\mu}(z,\gamma^2)$, $S_\nu^{\mu(3)}(z,\gamma)$ and $S_\nu^{\mu(4)}(z,\gamma)$ in the complex variable case. Definitions of these functions can be found in Arscott (1964, Chap. VIII) and we shall employ Arscott's notation throughout.

We shall frequently refer to the paper by Boyd and Dunster (1986) and so for brevity we shall denote this reference by B&D.

The plan of the paper is as follows. In §§2 and 3 we derive asymptotic expansions as $\gamma \to \infty$ for solutions of (1.1). These expansions are uniformly valid for $0 \leqq x < 1$ in the real variable case, and in certain domains containing the turning point $z = z_1$ and the singularity $z = 1$ in the complex variable case; in both cases the expansions will also be uniformly valid for λ, μ and γ satisfying (1.6). For this we use the theory of B&D which shows that solutions of second order linear differential equations with a turning point and a regular singularity can be approximated by expressions involving Bessel functions of large argument and variable order.

In §4 we derive asymptotic expansions as $\gamma \to \infty$ for solutions of (1.1) which hold at the second turning point $z = z_2$ and at the singularities $z = 1, \infty$. Again we assume (1.6) holds; the expansions are the standard Airy-function approximations for a turning point problem.

In §5 we establish a uniform relationship between ν and λ, μ, γ, as $\gamma \to \infty$, using the results of §3. This is useful insofar as the approximations established in §§2, 3, and 4 for the spheroidal functions involve λ, ν, μ and γ, whereas the spheroidal functions themselves are defined in terms of ν, μ, and γ only. Indeed in the case of the functions Qs and Qs (§6) a relationship between ν and λ, μ, γ is necessary to establish the uniform validity of their approximations.

In §7 we give a summary of the principal results of this paper. This summary is self-contained, in the sense that a reference is given for any term not explicitly defined in the section.

2. A uniform approximation for the spheroidal function $Ps_\nu^{-\mu}(x, \gamma^2)$. In this section we shall construct an asymptotic expansion for large γ for the spheroidal function $Ps_\nu^{-\mu}(x, \gamma^2)$, uniformly valid for $0 \leqq x < 1$ with the parameters λ, μ, γ satisfying the restrictions (1.6). We use the notation of Arscott (1964) for spheroidal functions; thus in terms of associated Legendre functions we have

$$Ps_\nu^{-\mu}(x, \gamma^2) = \sum_{r=-\infty}^{\infty} (-1)^r a_{\nu,r}^{-\mu}(\gamma^2) P_{\nu+2r}^{-\mu}(x),$$

where the coefficients a_r are given by Arscott (1964, p. 168). A second standard solution to (1.1) for $0 \leqq x < 1$ is given by

$$Qs_\nu^{-\mu}(x, \gamma^2) = \sum_{r=-\infty}^{\infty} (-1)^r a_{\nu,r}^{-\mu}(\gamma^2) Q_{\nu+2r}^{-\mu}(x),$$

and we shall establish a uniform asymptotic expansion for this function in §6 (equation (6.13)).

Following B&D (§3) we now apply the following Liouville transformation to (1.4):

$$(2.1) \qquad W(\zeta) = \left(\frac{dx}{d\zeta}\right)^{1/2} w(x), \qquad \left(\frac{d\zeta}{dx}\right)^2 = \left(\frac{4\zeta^2}{\alpha^2 - \zeta}\right) \frac{(x^2 - z_1^2)(z_2^2 - x^2)}{(1 - x^2)^2}.$$

If we take the positive square root of the second of (2.1) and integrate we obtain the following $x - \zeta$ transformation

$$(2.2) \qquad \int_{\alpha^2}^{\zeta} \frac{(\xi - \alpha^2)^{1/2}}{2\xi}\, dt = -\int_{z_1}^{x} \frac{\left[(z_1^2 - t^2)(z_2^2 - t^2)\right]^{1/2}}{1 - t^2}\, dt, \qquad (0 \leqq x \leqq z_1),$$

$$(2.3) \qquad \int_{\alpha^2}^{\zeta} \frac{(\alpha^2 - \xi)^{1/2}}{2\xi}\, d\xi = -\int_{z_1}^{x} \frac{\left[(t^2 - z_1^2)(z_2^2 - t^2)\right]^{1/2}}{1 - t^2}\, dt, \qquad (z_1 \leqq x < 1).$$

We shall denote the value of ζ at $x = 0$ by ζ_0.

Integrating (2.2) and (2.3) gives (see Gradshteyn and Ryzhik (1980, pp. 246, 247, 251))

(2.4)

$$(\zeta-\alpha^2)^{1/2}-\alpha\tan^{-1}\frac{(\zeta-\alpha^2)^{1/2}}{\alpha}=-\frac{(z_2^2-z_1^2)}{z_2}\Pi(\eta,r,t)+z_2E(\eta,t)-x\left(\frac{z_1^2-x^2}{z_2^2-x^2}\right)^{1/2},$$

$$(0\leqq x\leqq z_1),$$

$$(2.5)\qquad (-\zeta+\alpha^2)^{1/2}-\frac{1}{2}\alpha\ln\left(\frac{\alpha+(-\zeta+\alpha^2)^{1/2}}{\alpha-(-\zeta+\alpha^2)^{1/2}}\right)=z_1^2z_2F(\mathscr{X},u)-z_2E(\mathscr{X},u)$$

$$+\frac{1}{x}\{(z_2^2-x^2)(x^2-z_1^2)\}^{1/2}-\frac{z_1^2}{z_2}(z_2^2-1)\Pi(\mathscr{X},s,u),\qquad (z_1\leqq x<1),$$

with

$$(2.6)\qquad r=\frac{z_1^2(1-z_2^2)}{z_2^2(1-z_1^2)},\quad s=\frac{z_2^2-z_1^2}{z_2^2(1-z_1^2)},\quad t=\frac{z_1}{z_2},\quad u=\frac{(z_2^2-z_1^2)^{1/2}}{z_2},$$

$$\eta=\sin^{-1}\left(\frac{x}{z_1}\right)\quad\text{and}\quad\mathscr{X}=\sin^{-1}\left\{\frac{z_2}{x}\left(\frac{x^2-z_1^2}{z_2^2-z_1^2}\right)^{1/2}\right\}.$$

F, E and Π denote elliptic integrals of the first, second and third kind, definitions of which can be found in Gradshteyn and Ryzhik (1980, pp. 904, 905). Let $'$ represent differentiation with respect to ζ; with the above transformations we see that (1.3) is transformed to

$$(2.7)\qquad \frac{d^2W}{d\zeta^2}=\left\{\gamma^2\left(\frac{\alpha^2}{4\zeta^2}-\frac{1}{4\zeta}\right)-\frac{1}{4\zeta^2}+\frac{\psi(\alpha,\zeta)}{\zeta}\right\}W,$$

where

$$(2.8)\qquad \psi(\alpha,\zeta)=\dot{x}^{1/2}\frac{d^2}{d\zeta^2}(\dot{x}^{-1/2})+\frac{1}{4\zeta^2}-\left(\frac{\dot{x}}{1-x^2}\right)^2.$$

On using the second of (2.1) ψ can be expressed explicitly as

$$(2.9)\quad \psi(\alpha,\zeta)=\frac{\zeta+4\alpha^2}{16(\zeta-\alpha^2)^2}+\frac{(x^2-1)(\zeta-\alpha^2)}{16\zeta}$$

$$\cdot\left[\frac{5(4\alpha^2+\beta^4)x^2(x^2-1)}{\left(\alpha^2+\beta^2(x^2-1)-(x^2-1)^2\right)^3}-\frac{2(3\beta^2+2)x^2-2\beta^2-4}{\left(\alpha^2+\beta^2(x^2-1)-(x^2-1)^2\right)^2}\right].$$

Since β is essentially fixed (see (1.6b)) we shall for simplicity suppress any dependence of β in all functions. Thus in (2.9) $\psi(\alpha,\zeta)\equiv\psi(\alpha,\beta,\zeta)$. Before we can identify the solutions of (1.4) with those of (2.7) it is necessary for us to determine the asymptotic behavior of $\zeta(x)$ as $x\to1-$. This is achieved by comparing the limiting behavior of

both sides of (2.3) as $x\to 1-$ and $\zeta\to 0+$. First we make the splitting

$$-\int_{z_1}^{x}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}}{1-t^2}\,dt=-\int_{z_1}^{x}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}-\alpha}{1-t^2}\,dt-\alpha\int_{z_1}^{x}\frac{dt}{1-t^2}$$

and on observing that the first integral on the right-hand side is bounded as $x\to 1-$ we find that

$$1-x=a_1(\alpha)\zeta+O(\zeta^2),\qquad(\zeta\to 0+),\tag{2.10}$$

where

$$a_1(\alpha)=\frac{1}{2}\left(\frac{1-z_1}{\alpha^2}\right)(1+z_1)^{-1}e^{2+\rho_1(\alpha)},\tag{2.11}$$

with

$$\rho_1(\alpha)=\frac{2}{\alpha}\int_{z_1}^{1}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}-\alpha}{1-t^2}\,dt.\tag{2.12}$$

Note that (2.10) is uniformly valid for all values of α under consideration; when $\alpha=0$ the limiting value of (2.10), namely $1-x\sim(1/2\beta)\zeta$, applies.

From Theorem 1 of B&D, with u replaced by γ, we obtain the following solution of (2.7):

$$W_{2n+1,1}(\gamma,\alpha,\zeta)=\zeta^{1/2}J_{\gamma\alpha}(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{\gamma^{2s}}+\frac{\zeta}{\gamma}J'_{\gamma\alpha}(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{\gamma^{2s}}+\varepsilon_{2n+1,1}(\gamma,\alpha,\zeta).\tag{2.13}$$

The functions $A_s(\alpha,\zeta)$ and $B_s(\alpha,\zeta)$ are defined recursively for $s=0,1,2,\cdots$ from (2.9a, b) of B&D with $A_0(\alpha,\zeta)=1$. Bounds for the error function ε and its derivative are given by (3.8) of B&D: these bounds are somewhat complicated but their significance is explained in §3 of B&D. Two important consequences are (i) $\varepsilon_{2n+1,1}(\zeta)[\zeta^{1/2}J_{\gamma\alpha}(\gamma\zeta^{1/2})]^{-1}$ is $O(\gamma^{-2n-1})$ for large γ, uniformly with respect to ζ in the interval $(0,\zeta_0]$ and with respect to α^2 in the interval $[0,1+A]$; and (ii) $\varepsilon_{2n+1,1}(\zeta)=\zeta^{1/2}J_{\gamma\alpha}(\gamma\zeta^{1/2})O(\zeta)$ as $\zeta\to 0$. From the latter we see at once that $W_{2n+1,1}$ is recessive at $\zeta=0$ and hence is a multiple of a solution of (1.1) that is recessive at $x=1$. This solution is the spheroidal function $\mathrm{Ps}_\nu^{-\mu}(x,\gamma^2)$. From (1.1), (1.3), and (2.1) we therefore deduce that

$$\mathrm{Ps}_\nu^{-\mu}(x,\gamma^2)=C_{2n+1,1}\left(\frac{\alpha^2-\zeta}{\alpha^2-\beta^2(1-x^2)-(1-x^2)^2}\right)^{1/4}\zeta^{-1/2}W_{2n+1,1}(\gamma,\alpha,\zeta),\qquad(0\leqq x<1),\tag{2.14}$$

where the coefficient $C_{2n+1,1}$ is independent of x. To determine $C_{2n+1,1}$ we evaluate the limiting value of the ratio of the two sides of (2.14) as $x\to 1-$ and $\zeta\to 0+$. Firstly we have, from Arscott (1964, p. 171)

$$\mathrm{Ps}_\nu^{-\mu}(x,\gamma^2)=\frac{A_\nu^{-\mu}(\gamma^2)}{2^{\mu/2}\Gamma(1+\mu)}(1-x)^{\mu/2}\{1+O(1-x)\},\qquad(x\to 1-),\tag{2.15}$$

where

$$A_\nu^{-\mu}(\gamma^2)=\sum_{r=-\infty}^{\infty}(-1)^r a_{\nu,r}^{-\mu}(\gamma^2).$$

From (2.13) we see that the right-hand side of (2.14) is equal to

(2.16)

$$C_{2n+1,1}\left(\frac{\gamma}{2}\right)\frac{\zeta^{\mu/2}}{\Gamma(1+\mu)}\left(1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{\gamma^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{\gamma^{2s}}\right)(1+O(\zeta))\quad\text{as }\zeta\to 0+.$$

(In (2.16) we have used the fact that $J_\nu(x)\sim(\frac{1}{2}x)^\nu/\Gamma(\nu+1)$ as $x\to 0$, (see, for example, Olver (1974, p. 436)).)

If we divide (2.16) by (2.15) and use (2.10) we obtain the following exact expression for the coefficient $C_{2n+1,1}$:

$$A_\nu^{-\mu}(\gamma^2)\left(\frac{2a_1(\alpha)}{\gamma^2}\right)^{\mu/2}\left(1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{\gamma^{2s+1}}+\sum_{s=1}^{n}\frac{A_s(\alpha,0)}{\gamma^{2s}}\right)^{-1}. \tag{2.17}$$

We note here that there is a certain degree of arbitrariness in (2.17), insofar as there is an arbitrary integration constant λ_s associated with each of $A_s(\alpha,0)$ $(s=1,2,\cdots)$ (cf. B&D, eq. (2.9b)). A natural choice is choose them so that $A_s(\alpha,0)=0$ $(s=1,2,\cdots)$, thus removing the second series in (2.17).

3. Uniform approximations for spheroidal functions in domains containing the turning point $z=z_1$. In this section we shall construct asymptotic expansions for large γ for solutions of (1.1) with complex argument (denoted by z). The results will be uniformly valid with respect to z in certain domains containing the turning point $z=z_1$ and with parameters satisfying the restrictions of (1.6). The standard solutions we approximate in this section are $Ps_\nu^{-\mu}(z,\gamma^2)$, $S_\nu^{\mu(3)}(z,\gamma)$ and $S_\nu^{\mu(4)}(z,\gamma)$. Our notation is that of Arscott (1964, Chap. VIII, pp. 169, 170, 174); thus in terms of associated Legendre functions we have

$$Ps_\nu^{-\mu}(z,\gamma^2)=\sum_{r=-\infty}^{\infty}(-1)^r a_{\nu,r}^{-\mu}(\gamma^2)P_{\nu+2r}^{-\mu}(z),$$

and this function is recessive at $z=1$. For the S-functions we have

$$S_\nu^{\mu(j)}(z,\gamma)=\frac{(z^2-1)^{-\mu/2}z^\mu}{A_\nu^\mu(\gamma^2)}\sum_{r=-\infty}^{\infty}a_{\nu,r}^{\mu}(\gamma^2)\psi_{\nu+2r}^{(j)}(\gamma z),\qquad (j=3,4)$$

where $\psi^{(j)}$ are spherical Bessel functions. $S_\nu^{\mu(3)}$ is recessive as $z\to\infty$ for $0<\arg(z)<\pi$, and $S_\nu^{\mu(4)}$ is recessive as $z\to\infty$ for $-\pi<\arg(z)<0$.

In §6 we shall derive uniform asymptotic expansions for the spheroidal functions $Qs_\nu^\mu(z,\gamma^2)$ and $Qs_\nu^{-\mu}(x,\gamma^2)$. For brevity we shall only consider the range $|\arg(z)|\leqq\pi/2$; appropriate connection formulae for spheroidal functions can be used for other ranges of $\arg(z)$.

We use the theory of §5 of B&D. The appropriate Liouville transformation is again given by (2.1), with x replaced by z and ζ now considered as a complex variable. Integration of the second of (2.1) now yields, in place of (2.2) and (2.3), the following

z-ζ transformation

$$(3.1)\quad \int_{\alpha^2}^{\zeta} \frac{(\alpha^2-\xi)^{1/2}}{2\xi}\,d\xi = -\int_{z_1}^{x} \frac{\left[(t^2-z_1^2)(z_2^2-t^2)\right]^{1/2}}{1-t^2}\,dt, \qquad z\in\Delta,\quad \zeta\in\underline{\Delta},$$

where Δ is a certain subdomain of $|\arg(z)|\leqq\pi/2$ and $\underline{\Delta}$ is the corresponding ζ map of this domain. Equation (3.1) as it stands does not give a 1-1 mapping between z and ζ as there is a singularity in the transformation at $z=z_2$. Therefore we shall now choose a branch cut in $\underline{\Delta}$ from $\zeta=\zeta_2$ to $\zeta=-\infty$ along the negative real ζ-axis, where ζ_2 denotes the map given by (3.1) of z at $z=z_2$. With this cut we take the integrands of both sides of (3.1) to be negative when z and ζ lie in the intervals $(1,z_2)$ and $(\zeta_2,0)$ respectively, and we take them to be continuous elsewhere in Δ and $\underline{\Delta}$. Equation (3.1) now gives a continuous 1-1 mapping between the independent variables z and ζ. Domains Δ and $\underline{\Delta}$ are shown in Figs. 1a and 2; in Fig. 1a, Γ_1 and Γ_2 are conjugate curves given by

$$(3.2)\quad \operatorname{Im}\int_{z_2}^{z} \frac{\left[(t^2-z_1^2)(z_2^2-t^2)\right]^{1/2}}{1-t^2}\,dt=0.$$

A knowledge of the general configuration of the *level curves* in the ζ-plane, defined by

$$\operatorname{Im}\Phi_\mu^{(j)}(\gamma\zeta^{1/2}) \equiv \operatorname{Re}\int_{\hat{X}_\mu^2}^{\gamma^2\zeta} \frac{\left(\hat{X}_\mu^2-t\right)^{1/2}}{2t}\,dt = \text{constant},$$

is necessary in applying the theory of §5 of B&D. (A definition of $\hat{X}_\mu$ is given in the summary (equation (7.13)).) These curves are illustrated in Fig. 2. The corresponding configuration of these curves in the ζ-plane depends mainly on whether ζ_2 lies inside or outside the pear-shaped region $S_\alpha^{(0)}$ bounded by the level curve $\operatorname{Im}\Phi_\mu^{(0)}(\gamma\zeta^{1/2})=0$, or whether ζ_2 lies on this level curve. The three cases are illustrated in Figs. 1b, c, d.

It is straightforward to show that the curve $\operatorname{Im}\Phi_\mu^{(0)}(\gamma\zeta^{1/2})=0$ intersects the negative ζ-axis at $\zeta=-(1/\gamma^2)\hat{X}_\mu^2(\tau^2-1)$, where τ is the positive root of

$$(3.3a)\quad \left(\frac{\tau+1}{\tau-1}\right)-e^{2\tau}=0, \qquad (\tau=1.19968\cdots).$$

It follows then that ζ_2 will lie outside $S_\alpha^{(0)}$ iff

$$(3.3b)\quad |\zeta_2| > \frac{1}{\gamma^2}\hat{X}_\mu^2(\tau^2-1).$$

With the transformation (3.1) we obtain (2.7) with ζ a complex variable. Before we obtain solutions to this equation it is necessary for us to determine the asymptotic behavior of z, regarded as a function of ζ, as $|\zeta|\to\infty$. It is easy to see from (3.1) that

$$(3.4a)\quad z\sim \mp i|\zeta|^{1/2}, \qquad (\zeta\to-\infty\pm i0),$$

where $\pm i0$ denotes ζ above or below the cut running from $\zeta=\zeta_2$ to $\zeta=-\infty$. We will, in fact, need the next term in this asymptotic relationship, and this is not so straightforward to deduce.

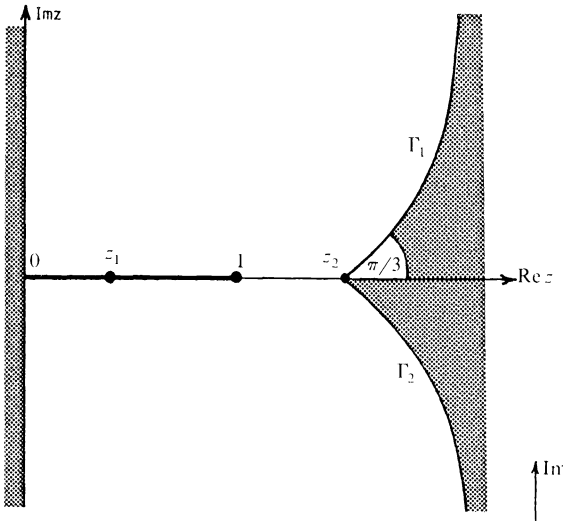

FIG. 1a. *Domain* Δ.

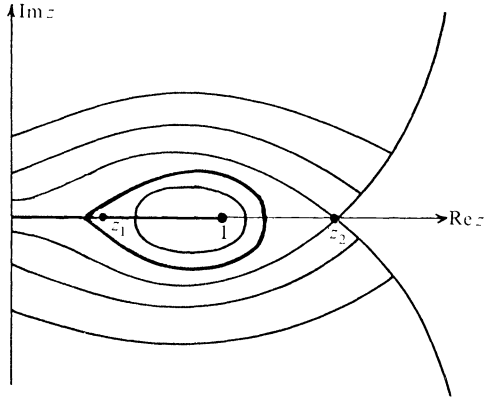

FIG. 1b. *Level curves for* $|\zeta_2|>\gamma^{-2}\hat{X}_\mu^2(\tau^2-1)$.

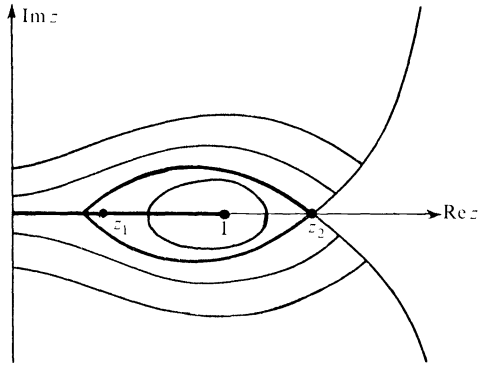

FIG 1c. *Level curves for* $|\zeta_2|=\gamma^{-2}\hat{X}_\mu^2(\tau^2-1)$.

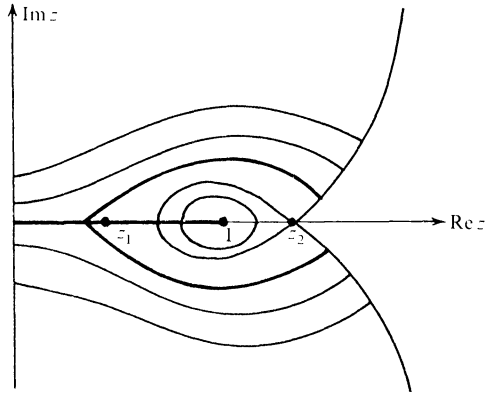

FIG. 1d. *Level curves for* $|\zeta_2|<\gamma^{-2}\hat{X}_\mu^2(\tau^2-1)$.

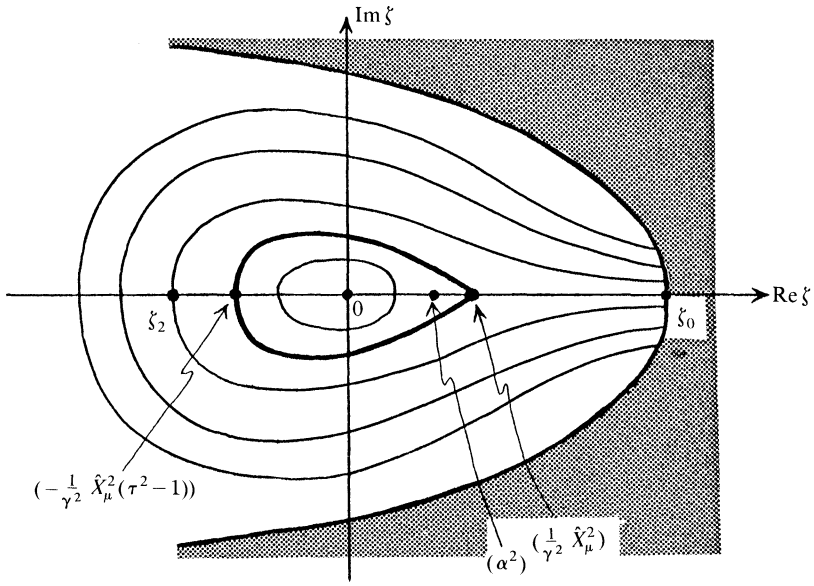

FIG. 2. *Domain* Δ *with level curves* $\operatorname{Im}\Phi_\mu^{(j)}(\gamma\zeta^{1/2})=\text{constant}$.

We first determine the asymptotic behavior of $z(\zeta)$ as $\zeta\to-\infty-i0$. If we write $\zeta=-R^2-i0$, where R is real and positive, then from (3.4a) we can write the corresponding value of $z(\zeta)$ as

$$z=iR+\tilde{z}(R) \tag{3.4b}$$

where

$$\frac{\tilde{z}(R)}{R}=o(1) \quad \text{as } R\to\infty, \tag{3.4c}$$

We shall now determine an asymptotic expression for $\tilde{z}$ as $R\to\infty$. To do so we consider the integral

$$J(R)=\int_0^{iR+\tilde{z}}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}+it^2}{1-t^2}\,dt \tag{3.5}$$

where the path of integration is shown in Fig. 3 and the branches of the square roots are the same as for (2.3). Now if we make the splitting of (3.5) as

$$J(R)=i\int_0^{iR+\tilde{z}}\frac{t^2}{1-t^2}\,dt+\int_0^{z_2}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}}{1-t^2}\,dt$$

$$+\int_{z_2}^{iR+\tilde{z}}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}}{1-t^2}\,dt$$

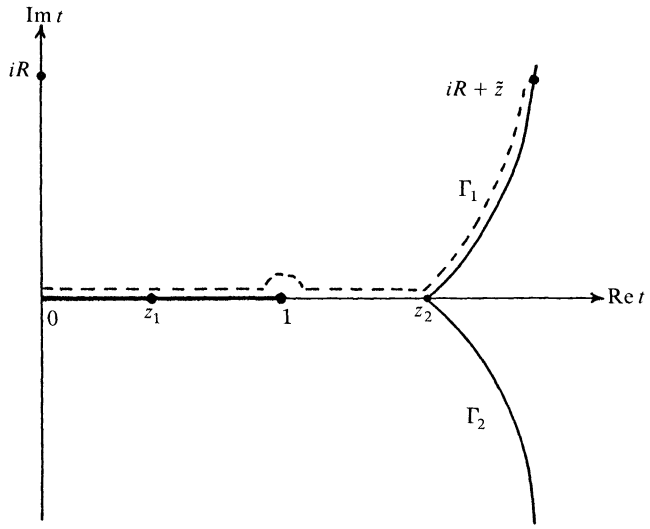

FIG. 3. *Path of integration* ----.

and equate the imaginary parts of both sides, we find on employing (3.2) that

$$\text{(3.6)}\qquad \operatorname{Im}\{J(R)\} = \operatorname{Re}\int_0^{iR+\tilde{z}} \frac{t^2}{1-t^2}\,dt + \operatorname{Im}\int_0^{z_2} \frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}}{1-t^2}\,dt$$

$$= -\tilde{z}(R) + \int_0^{z_1} \frac{\left[\left(z_1^2-t^2\right)\left(z_2^2-t^2\right)\right]^{1/2}}{1-t^2}\,dt + \frac{\alpha\pi}{2}.$$

We next show that the left-hand side of (3.6) is $o(1)$ as $R\to\infty$; we do this by observing that the integrand of (3.5) is $O(t^{-2})$ as $t\to\infty$ between the imaginary axis and Γ_1, and so from Cauchy's theorem we can deform the contour of integration of J to lie along the imaginary axis as $R\to\infty$. Thus from (3.4c) and (3.5) we have

$$J(R) = \int_0^{iR} \frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2} + it^2}{1-t^2}\,dt + o(1), \qquad (R\to\infty).$$

Since the integral of this equation is real we deduce that $\operatorname{Im}\{J(R)\} = o(1)$ as $R\to\infty$ and therefore from (3.6) we have the desired expression for $\tilde{z}$:

$$\text{(3.7a)}\qquad \tilde{z}(R) = \sigma + \frac{\alpha\pi}{2} + o(1), \qquad (R\to\infty),$$

where

$$\text{(3.7b)}\qquad \sigma = \int_0^{z_1} \frac{\left[\left(z_1^2-t^2\right)\left(z_2^2-t^2\right)\right]^{1/2}}{1-t^2}\,dt = \int_{\alpha^2}^{\zeta_0} \frac{(t-\alpha^2)^{1/2}}{2t}\,dt.$$

The same argument holds when $\zeta\to-\infty+i0$, and so from (3.4b) and (3.7a) we have

the following asymptotic behavior of $z(\zeta)$ as $|\zeta|\to\infty$:

$$z=\mp i|\zeta|^{1/2}+\sigma+\frac{\alpha\pi}{2}+o(1),\qquad(\zeta\to-\infty\pm i0). \tag{3.8}$$

An important consequence of (3.8), on using (2.9), is that the ζ-derivatives

$$\psi^{(s)}(\alpha,\zeta)=O\big(|\zeta|^{-s-1}\big),\qquad(\zeta\to-\infty\pm i0). \tag{3.9}$$

We now apply Theorem 3 of B&D, with u replaced by γ, to obtain the following pair of linearly independent solutions of (2.7) holomorphic in $\underline{\Delta}$:

(3.10)

$$W^{(j)}_{2n+1}(\gamma,\alpha,\zeta)=\zeta^{1/2}\mathscr{C}^{(j)}_{\gamma\alpha}(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{\gamma^{2s}}$$
$$+\frac{\zeta}{\gamma}\mathscr{C}^{(j)'}_{\gamma\alpha}(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{\gamma^{2s}}+\varepsilon^{(j)}_{2n+1}(\gamma,\alpha,\zeta),\qquad(j=0,1).$$

In (3.10) n is a nonnegative integer, and $\mathscr{C}^{(j)}_{\gamma\alpha}(\gamma\zeta^{1/2})$ denotes $2J_{\gamma\alpha}(\gamma\zeta^{1/2})$, $H^{(1)}_{\gamma\alpha}(\gamma\zeta^{1/2})$ for $j=0,1$ respectively. We define $\zeta^{1/2}$ here such that $0\leqq\arg(\zeta^{1/2})<\pi$.

For both solutions we associate a reference point $\tilde{\zeta}^{(j)}$ in $\underline{\Delta}$ from which error bounds on $\varepsilon^{(j)}_{2n+1}$ are determined. Since $W^{(0)}_{2n+1}$ is recessive at $\zeta=0$ we choose $\tilde{\zeta}^{(0)}=0$. For the other solution $W^{(1)}_{2n+1}$ we shall choose two reference points: $\tilde{\zeta}^{(1)}=-\infty+i0$ and $\tilde{\zeta}^{(1)}=-\infty-i0$. We shall denote $W^{(1)}_{2n+1}$ with reference point $\tilde{\zeta}^{(1)}=-\infty+i0$ by W^{+}_{2n+1} and $W^{(1)}_{2n+1}$ with reference point $\tilde{\zeta}^{(1)}=-\infty-i0$ by W^{-}_{2n+1}. Both W^{+}_{2n+1} and W^{-}_{2n+1} are expressible in the form (3.10) with $\mathscr{C}^{(1)}_{\gamma\alpha}\equiv H^{(1)}_{\gamma\alpha}$, and both are holomorphic in $\underline{\Delta}$, but the error terms (which we denote by ε^{+}_{2n+1} and ε^{-}_{2n+1}) are different in the two cases.

The error functions in (3.10) satisfy the following bounds:

(3.11a)

$$\frac{|\varepsilon^{(0)}_{2n+1}(\gamma,\alpha,\zeta)|}{\zeta^{1/2}M^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})},\ \frac{|\partial\varepsilon^{(0)}_{2n+1}(\gamma,\alpha,\zeta)/\partial\zeta|}{\frac{1}{2}\gamma N^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})+\frac{1}{2}\zeta^{-1/2}M^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})}$$
$$\leqq\frac{1}{\gamma^{2n+1}}\kappa E^{(0)}_{\gamma\alpha}(\gamma\zeta^{1/2})^{-1}\mathscr{V}_{0,\zeta}\big\{(\xi-\alpha^2)^{1/2}B_n(\xi)\big\}\exp\Big(\frac{\kappa}{\gamma}\mathscr{V}_{0,\zeta}\big\{(\xi-\alpha^2)^{1/2}B_0(\xi)\big\}\Big),$$

when $\zeta\in\underline{\Delta}$;

(3.11b)

$$\frac{|\varepsilon^{\pm}_{2n+1}(\gamma,\alpha,\zeta)|}{\zeta^{1/2}M^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})},\ \frac{|\partial\varepsilon^{\pm}_{2n+1}(\gamma,\alpha,\zeta)/\partial\zeta|}{\frac{1}{2}\gamma N^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})+\frac{1}{2}\zeta^{-1/2}M^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})}$$
$$\leqq\frac{1}{\gamma^{2n+1}}\kappa E^{(1)}_{\gamma\alpha}(\gamma\zeta^{1/2})^{-1}\mathscr{V}_{\zeta,-\infty\pm i0}\big\{(\xi-\alpha^2)^{1/2}B_n(\xi)\big\}$$
$$\times\exp\Big(\frac{\kappa}{\gamma}\mathscr{V}_{\zeta,-\infty\pm i0}\big\{(\xi-\alpha^2)^{1/2}B_0(\xi)\big\}\Big),$$

when $\zeta\in\underline{\Delta}^{\pm}$ (see Figs. 4b and 5b).

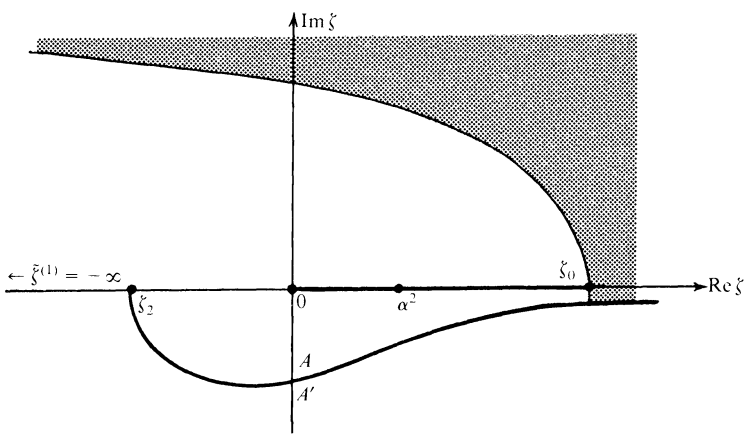

FIG. 4d. *Domain* $\underline{\Delta}^+$ *with branch cut along level curve.*

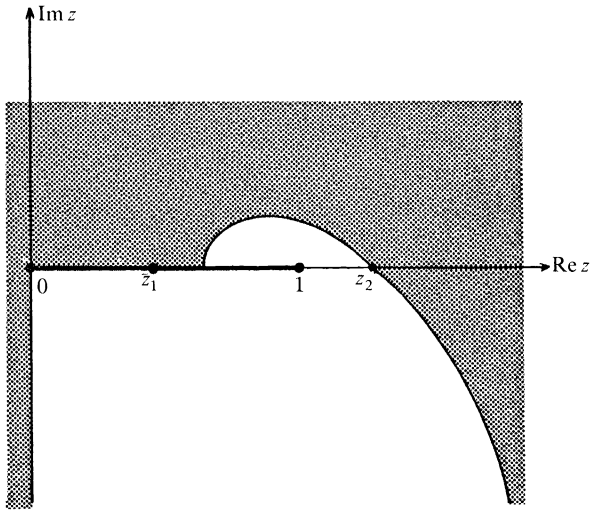

FIG. 5a. *Domain* Δ^+ *with* $|\zeta_2|<\gamma^{-2}\hat{X}_\mu^2(\tau^2-1)$.

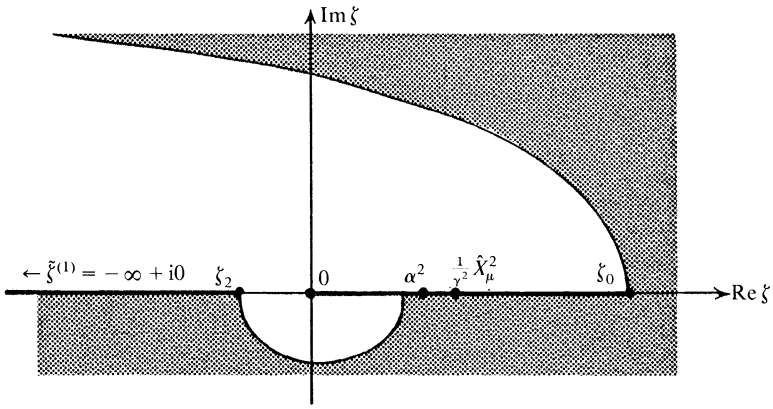

FIG. 5b. *Domain* $\underline{\Delta}^+$ *with* $|\zeta_2|<\gamma^{-2}\hat{X}_\mu^2(\tau^2-1)$.

The weight and modulus functions E, M and N, and the constant κ are defined as in §5 of B&D. All variations in (3.11a, b) are taken on progressive paths (cf. B&D, (5.14)), and their existence is a consequence of (3.9) (cf. Olver (1974, p. 445)).

We now proceed to identify the solutions (3.10) with standard spheroidal functions. Firstly $(d\zeta/dz)^{1/2}(z^2-1)^{1/2}Ps_\nu^{-\mu}(z,\gamma^2)$, considered as a function ζ, and $W_{2n+1}^{(0)}(\gamma,\alpha,\zeta)$ are both recessive at $\zeta=0$ and both are solutions of (2.7). It follows immediately that there exists a coefficient $C_{2n+1}^{(0)}$, independent of z, such that

$$(3.12)\quad Ps_\nu^{-\mu}(z,\gamma^2)=C_{2n+1}^{(0)}\left(\frac{\alpha^2-\zeta}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4}\zeta^{-1/2}W_{2n+1}^{(0)}(\gamma,\alpha,\zeta).$$

We know that (Arscott (1964, p. 171))

$$(3.13)\qquad Ps_\nu^{-\mu}(z,\gamma^2)=\frac{A_\nu^{-\mu}(\gamma^2)(z-1)^{\mu/2}}{2^{\mu/2}\Gamma(1+\mu)}\left(1+O(|z-1|)\right),\qquad (z\to 1),$$

and so from the same method of determining (2.17) we find from (3.10), (3.12) and (3.13) that

$$C_{2n+1}^{(0)}=\frac{1}{2}C_{2n+1,1}. \tag{3.14}$$

Next, we observe that $(d\zeta/dz)^{1/2}(z^2-1)^{1/2}S_\nu^{\mu(3)}(z,\gamma)$, considered as a function of ζ, and $W_{2n+1}^-(\gamma,\alpha,\zeta)$ are both recessive at $\zeta=\infty$ in $\underline{\Delta}^-$ and are both solutions of (2.7). Therefore we have the identity

$$S_\nu^{\mu(3)}(z,\gamma)=C_{2n+1}^-\left(\frac{\alpha^2-\zeta}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4}\zeta^{-1/2}W_{2n+1}^-(\gamma,\alpha,\zeta) \tag{3.15}$$

where the coefficient C_{2n+1}^- is independent of ζ.

We can conveniently determine this constant by comparing both sides of (3.15) as $\zeta\to\infty$ in $\underline{\Delta}^-$ and $z\to\infty$ in Δ^- (see Fig. 4a). For the left-hand side we have (Meixner and Schäfke (1954, p. 293))

$$S_\nu^{\mu(3)}(z,\gamma)=\frac{e^{i(\gamma z-\pi(\nu+1)/2)}}{\gamma z}\left(1+O\left(\frac{1}{z}\right)\right),\qquad (z\to\infty). \tag{3.16}$$

For the right-hand side we have the following asymptotic behavior (on using the asymptotic expression for $H_\mu^{(1)}(\gamma\zeta^{1/2})$ with large argument (Abramowitz and Stegun (1965, p. 364)):

$$C_{2n+1}^-\left(\frac{2}{\pi\gamma}\right)^{1/2}\frac{1}{|z|}e^{i(\gamma\zeta^{1/2}-\mu\pi/2-3\pi/4)}\left\{\sum_{s=0}^{n}\frac{A_s(-\infty)}{\gamma^{2s}}+\frac{1}{\gamma}\sum_{s=0}^{n-1}\frac{\tilde{B}_s(-\infty)}{\gamma^{2s}}+o(1)\right\}, \tag{3.17}$$

$$(\zeta\to-\infty-i0).$$

In (3.17) $\tilde{B}_s(-\infty)\equiv\lim_{\zeta\to-\infty}\{(-\zeta)^{1/2}B_s(\zeta)\}$. By comparing (3.16) and (3.17), and invoking (3.8) we obtain the following exact expression for C_{2n+1}^-:

$$ie^{i\chi}\left(\frac{\pi}{2\gamma}\right)^{1/2}e^{\mu\pi i/2}\left\{\sum_{s=0}^{n}\frac{A_s(-\infty)}{\gamma^{2s}}+\frac{1}{\gamma}\sum_{s=0}^{n-1}\frac{\tilde{B}_s(-\infty)}{\gamma^{2s}}\right\}^{-1} \tag{3.18}$$

where

$$\chi=\frac{\mu\pi}{2}-\frac{\nu\pi}{2}+\gamma\sigma-\frac{3\pi}{4}. \tag{3.19}$$

By the same procedure we find that

$$S_\nu^{\mu(4)}(z,\gamma)=C_{2n+1}^+\left(\frac{\alpha^2-\zeta}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4}\zeta^{-1/2}W_{2n+1}^+(\gamma,\alpha,\zeta), \tag{3.20}$$

where

$$(3.21)\qquad C_{2n+1}^{+}=ie^{-i\chi}\left(\frac{\pi}{2\gamma}\right)^{1/2}e^{\mu\pi i/2}\left\{\sum_{s=0}^{n}\frac{A_s(-\infty)}{\gamma^{2s}}+\frac{1}{\gamma}\sum_{s=0}^{n-1}\frac{\tilde{B}_s(-\infty)}{\gamma^{2s}}\right\}^{-1}.$$

We finally remark that Δ, Δ^- and Δ^+ are not the maximal regions of validity for our uniform expansions for $Ps_\nu^{-\mu}(z,\gamma^2)$, $S_\nu^{\mu(3)}(z,\gamma)$ and $S_\nu^{\mu(4)}(z,\gamma)$ respectively; if instead of choosing a branch cut along the negative ζ-axis from $\zeta=\zeta_2$ to $\zeta=-\infty$ for the $z-\zeta$ transformation (3.1) we could for instance have chosen the cut to be along the level curve passing through ζ_2 (see Fig. 4d). The extended region of validity for the asymptotic expansion for $S_\nu^{\mu(4)}$ in this case is shown in Fig. 4c. For the function $Ps_\nu^{-\mu}$ we could extend the region of the validity Δ by choosing a cut in the z-plane along the real axis from $z=z_2$ to $z=\infty$; the region of validity Δ in this case would be extended to all points in the right-half plane $|\arg(z)|\leqq\pi/2$ except points on or near this cut. The corresponding ζ-domain $\underline{\Delta}$ would in this case be a Riemann sheet.

However, if one is considering uniform expansions for any pair of $Ps_\nu^{-\mu}$, $S_\nu^{\mu(3)}$ and $S_\nu^{\mu(4)}$ in tandem the branch cut from $\zeta=\zeta_2$ to $\zeta=-\infty$ for the $z-\zeta$ transformation would seem to be the most convenient choice. Indeed this is our choice throughout this paper.

4. Uniform approximations for spheroidal functions in a domain containing the turning point $z=z_2$. In this section we establish asymptotic expansions that hold in a domain containing the second turning point $z=z_2$. The expansions are the standard Airy function approximations for a turning point problem, the theory of which is concisely presented in Olver [1974, Chap. 11].[1] As in §3 the standard solutions we consider are $Ps_\nu^{-\mu}(z,\gamma^2)$, $S_\nu^{\mu(3)}(z,\gamma)$, and $S_\nu^{\mu(4)}(z,\gamma)$. We restrict the parameters λ, μ and γ to satisfy (1.6) and we only consider values of z such that $|\arg(z)|\leqq\pi/2$. To avoid a clash of notation with §3 we shall use the notation of Olver but with each term written with a circumflex (ˆ).

From (3.02) of Olver we see that the appropriate Liouville transformation is

$$(4.1)\qquad \hat{W}(\hat{\zeta})=\left(\frac{d\hat{\zeta}}{dz}\right)^{1/2}w(z),\qquad \frac{2}{3}\hat{\zeta}^{3/2}=-\int_{z_2}^{z}\frac{\left[(t^2-z_1^2)(z_2^2-t^2)\right]^{1/2}}{t^2-1}\,dt,$$

which throws (1.4) into the form

$$(4.2)\qquad \frac{d^2\hat{W}}{d\hat{\zeta}^2}=\{\gamma^2\hat{\zeta}+\hat{\psi}(\hat{\zeta})\}\hat{W},$$

where

$$(4.3)\quad \hat{\psi}(\hat{\zeta})=\frac{5}{16\hat{\zeta}^2}-\frac{\hat{\zeta}(z^2-1)}{4}\times\left[\frac{5(4\alpha^2+\beta^4)z^2(z^2-1)}{\left(\alpha^2+\beta^2(z^2-1)-(z^2-1)^2\right)^3}-\frac{2(3\beta^2+2)z^2-2\beta^2-4}{\left(\alpha^2+\beta^2(z^2-1)-(z^2-1)^2\right)^2}\right].$$

[1] We will use the results of Olver (1974, Chap. 11) extensively in this section, and therefore we will refer to this reference simply as "Olver" to avoid undue repetition.

In the second of (4.1) we take the branches to have their principal values when $z\in(1,z_2)$ and $\hat{\zeta}\in(0,\infty)$, and to be continuous elsewhere. We see that this transformation is a continuous 1-1 map of the variables z and $\hat{\zeta}$ from the domains $\hat{Z}$ to $\underline{\hat{Z}}$ (see Figs. 6a, b). We now record the asymptotic behavior of $z(\hat{\zeta})$ as $|\hat{\zeta}|\to\infty$ in $\underline{\hat{Z}}$. Firstly, from (4.1), we find that as $\hat{\zeta}\to\infty$ in the region between the curves DC and $D'C'$ of Fig. 6b, $z(\hat{\zeta})\to 1$ such that

$$z\sim 1+a_2(\alpha)\exp\left(-\frac{4}{3\alpha}\hat{\zeta}^{3/2}\right), \qquad (\alpha>0), \tag{4.4}$$

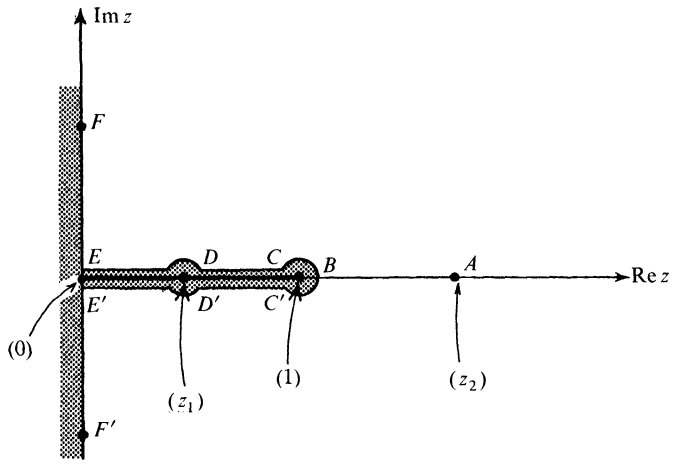

FIG. 6a. *Domain* $\hat{Z}$.

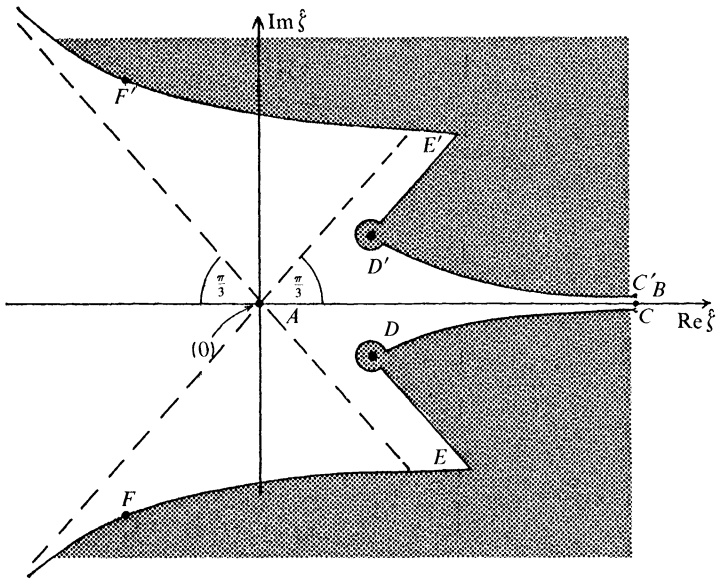

FIG. 6b. *Domain* $\underline{\hat{Z}}$.

where

$$a_2(\alpha)=2\left(\frac{z_2-1}{z_1+1}\right)e^{\rho_2(\alpha)},$$

with

$$\rho_2(\alpha)=\frac{2}{\alpha}\int_1^{z_2}\frac{\left[\left(t^2-z_1^2\right)\left(z_2^2-t^2\right)\right]^{1/2}-\alpha}{t^2-1}\,dt,$$

(cf. (2.10)). Also from (4.1) we find in a similar way to deriving (3.8) that $z\to\infty$ as $\hat{\xi}\to-\infty$, such that

$$z=\frac{2}{3}(-\hat{\xi})^{3/2}+\frac{\alpha\pi}{2}+\sigma+O\left(|\hat{\xi}|^{-3/2}\right), \tag{4.5}$$

where σ is given by (3.7b). From (4.3), (4.4) and (4.5) we see that

$$\hat{\psi}(\hat{\xi})=O(\hat{\xi}^{-2}) \tag{4.6}$$

when $\hat{\xi}\to\infty$ in both cases.

We now apply Theorem 9.1 of Olver to (4.2), with u replaced by γ, to obtain the following solutions holomorphic in $\hat{Z}$:

(4.7)

$$\hat{W}_{2n+1,j}(\gamma,\hat{\xi})=\mathrm{Ai}_j(\gamma^{2/3}\hat{\xi})\sum_{s=0}^{n}\frac{\hat{A}_s(\hat{\xi})}{\gamma^{2s}}+\frac{\mathrm{Ai}_j'(\gamma^{2/3}\hat{\xi})}{\gamma^{4/3}}\sum_{s=0}^{n-1}\frac{\hat{B}_s(\hat{\xi})}{\gamma^{2s}}+\hat{\varepsilon}_{2n+1,j}(\gamma,\hat{\xi}),$$

where n is a nonnegative integer, and

$$\mathrm{Ai}_j(z)=\mathrm{Ai}(ze^{-2\pi ij/3}),\qquad (j=0,\pm1).$$

Because of (4.6) the variations in the error bounds ((9.03) of Olver) converge in $\hat{Z}$. The reference points α_j associated with $\hat{W}_{2n+1,j}$ are taken to be $+\infty$, $\infty e^{2\pi i/3}$, $\infty e^{-2\pi i/3}$ for $j=0,1,-1$ respectively. With these choices of reference points we find from the known behavior of the Airy function at infinity that the solution $\hat{W}_{2n+1,j}$ is recessive as $\hat{\xi}\to\alpha_j$ $(j=0,\pm1)$. Therefore there exist constants $\hat{C}_{2n+1,j}(j=0,\pm1)$ such that

$$P{s}_\nu^{-\mu}(z,\gamma^2)=\hat{C}_{2n+1,0}\left(\frac{\hat{\xi}}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4}\hat{W}_{2n+1,0}(\gamma,\hat{\xi}), \tag{4.8}$$

$$S_\nu^{\mu(3)}(z,\gamma^2)=\hat{C}_{2n+1,-1}\left(\frac{\hat{\xi}}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4}\hat{W}_{2n+1,-1}(\gamma,\hat{\xi}), \tag{4.9}$$

$$S_\nu^{\mu(4)}(z,\gamma^2)=\hat{C}_{2n+1,1}\left(\frac{\hat{\xi}}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4}\hat{W}_{2n+1,1}(\gamma,\hat{\xi}), \tag{4.10}$$

since, in each of these three equations, the functions on both sides of the equation are solutions of (1.1) that share the same recessive property at $\hat{\xi}=\alpha_0$, α_{-1} and α_1 respectively.

If we set the integration constants in $\hat{W}_{2n+1,0}$ so that

$$\hat{A}_s(\infty)=0,\qquad (s=1,2,\cdots) \tag{4.11}$$

and allow z to tend to 1 (and correspondingly $\hat{\xi} \to \infty$) in (4.8) we find, on employing (3.13), (4.4), (4.7) with (1.07) of Olver, that

$$\hat{C}_{2n+1,0} = A_\nu^{-\mu}(\gamma^2) \frac{2(\mu\pi)^{1/2}}{\gamma^{1/3}\Gamma(1+\mu)} \left(\frac{a_2(\alpha)}{2}\right)^{\mu/2} \left(1 - \frac{1}{\gamma} \sum_{s=0}^{n-1} \frac{\beta_s^+}{\gamma^{2s}}\right)^{-1}, \tag{4.12}$$

where

$$\beta_s^+ = \lim_{\hat{\xi} \to \infty} \{\hat{\xi}^{1/2} \hat{B}_s(\hat{\xi})\}, \qquad (s = 0, 1, 2, \cdots).$$

Similarly on letting $\hat{\xi} \to \alpha_{-1}$ in (4.9) and $\hat{\xi} \to \alpha_1$ in (4.10), and using (3.16), (4.5), (4.7) with (1.07) of Olver, we have

$$\hat{C}_{2n+1,-1} = 2\pi^{1/2}\gamma^{-5/6} e^{i(\chi - \pi/3)} \left(1 - \sum_{s=0}^{n-1} \frac{\beta_s^-}{\gamma^{2s+1}}\right)^{-1}, \tag{4.13}$$

and

$$\hat{C}_{2n+1,1} = 2\pi^{1/2}\gamma^{-5/6} e^{-i(\chi - \pi/3)} \left(1 - \sum_{s=0}^{n-1} \frac{\beta_s^-}{\gamma^{2s+1}}\right)^{-1}, \tag{4.14}$$

where

$$\beta_s^- = \lim_{\hat{\xi} \to \infty} \{(-\hat{\xi})^{1/2} \hat{B}_s(\hat{\xi})\}, \qquad (s = 0, 1, 2, \cdots).$$

We have set the integration constants in $\hat{W}_{2n+1,-1}$ and $\hat{W}_{2n+1,1}$ so that

$$\hat{A}_s(-\infty) = 0, \qquad (s = 1, 2, \cdots).$$

5. The characteristic exponent. There are four parameters associated with the spheroidal wave equation, namely λ, μ, γ and the characteristic exponent ν. There exists a transcendental relation among the four parameters; this relation is usually expressed in two ways: ν considered as a function of λ, μ, γ, or $\lambda \equiv \lambda_\nu^\mu(\gamma^2)$ considered as a function of ν, μ, γ. In the special case $\gamma = 0$, the spheroidal wave equation degenerates to the associated Legendre equation and the transcendental relationship is known to be

$$\lambda_\nu^\mu(0) = (\nu + 2p)(\nu + 2p + 1),$$

or, alternatively

$$\nu + 2p = \tfrac{1}{2}\{(4\lambda + 1)^{1/2} - 1\}, \qquad (p \in \mathbb{Z}).$$

For general values of the parameters, however, there is no explicit relationship in the literature. But we can obtain an asymptotic relationship between ν and λ, μ, γ, for large γ and λ, using the results of §3. This is of particular importance in problems of high-frequency (γ large) scattering by prolate spheroids; as an illustration of the problem the reader is referred to a paper by Sleeman (1969).

We start by considering the well-known analytic continuation formulae (Meixner and Schäfke (1954, p. 293))

$$S_\nu^{\mu(3)}(ze^{\pi i},\gamma)=e^{-\nu\pi i}S_\nu^{\mu(4)}(z,\gamma), \tag{5.1}$$

$$S_\nu^{\mu(4)}(ze^{\pi i},\gamma)=e^{\nu\pi i}S_\nu^{\mu(3)}(z,\gamma)+2i\sin(\nu\pi)S_\nu^{\mu(4)}(z,\gamma), \tag{5.2}$$

where $S_\nu^{\mu(3,4)}(ze^{\pi i})$ denotes the value of $S_\nu^{\mu(3,4)}(z)$ after describing a negative half-circuit about infinity. We now replace the S-functions in (5.1) and (5.2) with their uniform approximations of §3 to obtain an asymptotic expression for $\sin(\nu\pi)$; as will be seen shortly it is convenient to set $z=0-i0$ in (5.1) and (5.2). Now firstly from (3.15), (3.18), (3.20) and (3.21) we have

$$S_\nu^{\mu(3,4)}(0-i0,\gamma)=C_{2n+1}e^{\pm i\chi}\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{\mp}(\gamma,\alpha,\zeta_0)\right\}, \tag{5.3}$$

and

$$S_\nu^{\mu(3,4)}(0+i0,\gamma)=C_{2n+1}e^{\pm i\chi}\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0e^{2\pi i})-\zeta_0^{-1/2}\varepsilon_{2n+1}^{\mp}(\gamma,\alpha,\zeta_0e^{2\pi i})\right\}, \tag{5.4}$$

where

$$C_{2n+1}\equiv C_{2n+1}^{-}e^{-i\chi}\left(\frac{\zeta_0-\alpha^2}{1+\beta^2-\alpha^2}\right)^{1/4}=C_{2n+1}^{+}e^{i\chi}\left(\frac{\zeta_0-\alpha^2}{1+\beta^2-\alpha^2}\right)^{1/4},$$

and

$$\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta)\equiv H_\mu^{(1)}(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}H_\mu^{(1)\prime}(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{\gamma^{2s}},\qquad(\mu=\gamma\alpha). \tag{5.5}$$

Note that in (5.4) we have used the identity

$$\zeta(0+i0)=\zeta(0-i0)e^{2\pi i}\equiv\zeta_0e^{2\pi i};$$

in other words a negative half-circuit about infinity from $0-i0$ to $0+i0$ in the z-plane corresponds to a positive circuit from ζ_0 to $\zeta_0e^{2\pi i}$ in the ζ-plane. Indeed, it is this particular property that led us to set $z=0-i0$ in (5.1) and (5.2).

In order that the error bounds (3.11b) can be applied to ε^+ and ε^- in (5.3) and (5.4) we see from Figs. 4b and 5b that we must impose the restriction on α and β that ζ_0 and $\zeta_0e^{2\pi i}$ must lie in $\underline{\Delta}^+\cap\underline{\Delta}^-$. In §3 we saw that this is equivalent to the condition (3.3b); from (3.1) one can show that (3.3b) is equivalent to the condition

$$\int_{z_1}^{z_2}\frac{\left[(t^2-z_1^2)(z_2^2-t^2)\right]^{1/2}}{t^2-1}\,dt>\frac{1}{\gamma}I(\mu), \tag{5.6a}$$

where

$$I(\mu)=\int_{\mu^2(\tau^2-1)}^{\hat{X}_\mu^2(\tau^2-1)}\frac{(\mu^2+t)^{1/2}}{2t}\,dt. \tag{5.6b}$$

From the definition of $\hat{X}_\mu$ (B&D, §5) we have $\hat{X}_\mu=\mu+O(\mu^{-1/3})$ as $\mu\to\infty$, and $\hat{X}_\mu>\mu$ for $0\leqq\mu<\infty$. It follows then that $I(\mu)$ is positive and bounded for $0\leqq\mu<\infty$.

Now if we choose the integration constants in (3.10) so that

$$A_s(\alpha,\zeta_0)=0, \qquad (s=1,2,\cdots,n),$$

and use the following relation for Hankel functions (with $^-$ denoting complex conjugate)

$$H_\mu^{(1)}(ze^{\pi i})=-e^{-\mu\pi i}H_\mu^{(2)}(z)=-e^{-\mu\pi i}\overline{H}_\mu^{(1)}(\bar{z}), \qquad (\mu \text{ real}),$$

(see, for example, Olver (1974, pp. 238, 239)), we obtain from (5.5) the following equations

$$\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)=H_\mu^{(1)}(\gamma\zeta_0^{1/2})+\frac{\zeta_0^{1/2}}{\gamma}H_\mu^{(1)\prime}(\gamma\zeta_0^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta_0)}{\gamma^{2s}}, \tag{5.7}$$

and

$$\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0e^{2\pi i})=-e^{-\mu\pi i}\overline{\mathscr{H}}_{2n+1}(\gamma,\alpha,\zeta_0). \tag{5.8}$$

From (3.19), (5.1), (5.3), (5.4), (5.8) and (A1) we derive

$$2\,\mathrm{Re}\left[e^{-i(\gamma\sigma-3\pi/4)}\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{+}(\gamma,\alpha,\zeta_0)\right\}\right]=0, \tag{5.9}$$

and therefore the *exact* relation for each n

$$\arg\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{+}(\gamma,\alpha,\zeta_0)\right\}=\gamma\sigma-\frac{\pi}{4}+p_n\pi, \tag{5.10}$$

where p_n is some integer which we determine shortly.

Next from (3.19), (5.2), (5.3), (5.4), (5.8) and (A1) we derive

$$\begin{aligned}\sin(\nu\pi)=e^{i(\gamma\sigma-\pi/4)}&\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{+}(\gamma,\alpha,\zeta_0)\right\}^{-1}\\ &\times\mathrm{Re}\left[e^{i(\mu\pi+\gamma\sigma-3\pi/4)}\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{-}(\gamma,\alpha,\zeta_0)\right\}\right],\end{aligned} \tag{5.11}$$

and on employing the relation (5.10) this reduces to the following expression for $\sin(\nu\pi)$:

$$\begin{aligned}\sin(\nu\pi)=e^{-p_n\pi i}&\left|\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{+}(\gamma,\alpha,\zeta_0)\right|^{-1}\\ &\times\mathrm{Re}\left[e^{i(\mu\pi+\gamma\sigma-3\pi/4)}\left\{\mathscr{H}_{2n+1}(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_{2n+1}^{-}(\gamma,\alpha,\zeta_0)\right\}\right].\end{aligned} \tag{5.12}$$

This is the first important result of this section. We will show shortly that $p_n=0$, provided γ is sufficiently large for each value of n. Equation (5.12) gives then an asymptotic expansion for $\sin(\nu\pi)$ for large γ. With the restrictions (1.6) and (5.6a) applying the error terms ε^+ and ε^- in this equation can be bounded by (3.11b).

Note that the Hankel functions in (5.12) are of the form

$$H_\mu^{(1)}(\mu\omega)$$

where ω is real, positive and greater than 1, and therefore they are of oscillatory nature as $\mu\to\infty$. We shall now replace these functions in (5.12) with their "Debye"-type approximations to obtain a more simple approximation for $\sin(\nu\pi)$. The price we pay for this is that the expression we obtain contains more error terms; bounds are given.

For simplicity we set $n=1$ in (5.12). The Debye approximations for the Hankel functions can be expressed as

(5.13)

$$H_{\gamma\alpha}^{(1)}(\gamma\zeta_0^{1/2})=\left(\frac{2}{\gamma\pi}\right)^{1/2}(\zeta_0-\alpha^2)^{-1/4}e^{i(\gamma\sigma-\pi/4)}\left\{1-\frac{i}{24\gamma}(3\zeta_0+2\alpha^2)(\zeta_0-\alpha^2)^{-3/2}+\delta_0\right\},$$

and

$$H_{\gamma\alpha}^{(1)\prime}(\gamma\zeta_0^{1/2})=i\left(\frac{2}{\gamma\pi}\right)^{1/2}\zeta_0^{-1/2}(\zeta_0-\alpha^2)^{1/4}e^{i(\gamma\sigma-\pi/4)}\{1+\delta_0'\}, \tag{5.14}$$

where δ_0 and δ_0' are constants which satisfy the following bounds for $\alpha^2<\zeta_0$ (Olver (1974, p. 377)):

$$|\delta_0|\leqq\frac{2}{\gamma^2}\mathscr{V}_{0,q}(U_2)\exp\left\{\frac{2}{\gamma}\mathscr{V}_{0,q}(U_1)\right\}, \tag{5.15}$$

(5.16)

$$|\delta_0'|\leqq\frac{1}{2\gamma}\zeta_0(\zeta_0-\alpha^2)^{-3/2}+\left(1+\frac{\zeta_0^2}{4\gamma^2}(\zeta_0-\alpha^2)^{-3}\right)^{1/2}\frac{2}{\gamma}\mathscr{V}_{0,q}(U_1)\exp\left\{\frac{2}{\gamma}\mathscr{V}_{0,q}(U_1)\right\},$$

with

$$q=-i(\zeta_0-\alpha^2)^{-1/2},\qquad U_1=\frac{(3q-5\alpha^2q^3)}{24},$$

and

$$U_2=\frac{81q^2-462\alpha^2q^4+385\alpha^4q^6}{1152}.$$

Now from (5.7), (5.13), (5.14) and

$$B_0(\alpha,\zeta_0)=-(\zeta_0-\alpha^2)^{-1/2}\int_{\alpha^2}^{\zeta_0}(t-\alpha^2)^{-1/2}\psi(\alpha,t)\,dt$$

(see (2.9a) of B&D) we have

$$\begin{aligned}\mathscr{H}_3(\gamma,\alpha,\zeta_0)+\zeta_0^{-1/2}\varepsilon_3^{+}(\gamma,\alpha,\zeta_0)\\ =\left(\frac{2}{\gamma\pi}\right)^{1/2}(\zeta_0-\alpha^2)^{-1/4}e^{i(\gamma\sigma-\pi/4)}\left(1-\frac{i}{\gamma}b(\alpha)\right)(1+\eta^{\pm}(\gamma,\alpha)),\end{aligned} \tag{5.17}$$

where

$$b(\alpha)=\int_{\alpha^2}^{\zeta_0}(t-\alpha^2)^{-1/2}\psi(\alpha,t)\,dt+\frac{1}{24}(3\zeta_0+2\alpha^2)(\zeta_0-\alpha^2)^{-3/2}, \tag{5.18}$$

$$\begin{aligned}\tilde{\varepsilon}^{\pm}(\gamma,\alpha)=\delta_0-\frac{i}{\gamma}\delta_0'\int_{\alpha^2}^{\zeta_0}(t-\alpha^2)^{-1/2}\psi(\alpha,t)\,dt\\ +\left(\frac{\pi\gamma}{2\zeta_0}\right)^{1/2}(\zeta_0-\alpha^2)^{1/4}e^{i(\pi/4-\gamma\sigma)}\varepsilon_3^{\pm}(\gamma,\alpha,\zeta_0),\end{aligned} \tag{5.19}$$

and

$$\eta^{\pm}(\gamma,\alpha)=\frac{\tilde{\varepsilon}^{\pm}(\gamma,\alpha)}{1-i\gamma^{-1}b(\alpha)}. \tag{5.20}$$

We see from (5.7), (5.13) and (5.14) that $p_n=0$ in (5.10) provided, for each value of n, γ is sufficiently large.

It follows then from (5.12) and (5.17) that ν satisfies

$$\sin(\nu\pi)=\left|\frac{1+\eta^{-}}{1+\eta^{+}}\right|\sin\left(\mu\pi+2\gamma\sigma-\tan^{-1}\frac{b}{\gamma}-\frac{\pi}{2}+\arg(1+\eta^{-})\right). \tag{5.21}$$

This is the second important result of this section. Note that from (5.20) and Jordan's inequality

$$|\varphi|\leqq\frac{\pi}{2}|\tan(\varphi)|, \qquad \left(0\leqq\varphi<\frac{\pi}{2}\right)$$

we obtain the following bounds for sufficiently large γ:

$$|\eta^{\pm}|\leqq|\tilde{\varepsilon}^{\pm}|, \tag{5.22}$$

$$|\arg(1+\eta^{-})|\leqq\frac{\pi}{2}|\tan(\arg(1+\eta^{-}))|\leqq\frac{\pi}{2}|\eta^{-}|. \tag{5.23}$$

Equation (5.21) then provides an asymptotic relationship between ν, λ, μ and γ, for large γ and λ, with the restrictions (1.6) and (5.6a) applying. All the error terms in (5.21) have explicit bounds under these restrictions and they are $O(1/\gamma^2)$ for large γ.

From (1.2), (1.5), (3.7b) and (5.21) we have in terms of the original parameters the relation

$$\nu_r=\theta+\varepsilon, \tag{5.24}$$

where ν_r denotes the range of numbers $-\nu-1+2r$ and $\nu+2r$ ($r=0,\pm1,\pm2,\cdots$) and where

$$\theta\equiv\mu+\frac{2}{\pi}\int_0^{z_1}\frac{\left[\gamma^2(1-t^2)^2+\lambda(1-t^2)-\mu^2\right]^{1/2}}{1-t^2}\,dt-\frac{1}{\pi}\tan^{-1}\frac{b}{\gamma}-\frac{1}{2}, \tag{5.25}$$

$$z_1=\frac{1}{\gamma}\left[\gamma^2-\frac{1}{2}\left((\lambda^2+4\mu^2\gamma^2)^{1/2}-\lambda\right)\right]^{1/2}, \tag{5.26}$$

and ε is given implicitly by the equation

$$\left|\frac{1+\eta^{-}}{1+\eta^{+}}\right|\sin(\theta\pi+\arg(1+\eta^{-}))=\sin(\theta\pi+\varepsilon\pi). \tag{5.27}$$

An upper bound for $|\sin(\varepsilon\pi)|$ is readily derived from (5.27), but we will not record details here. However, from this bound we find that

$$\sin(\varepsilon\pi)=O\left(\min\left\{\gamma^{-2}|\cos(\theta\pi)|^{-1},\gamma^{-1}\right\}\right). \tag{5.28}$$

An interesting observation from (5.27), (5.28) is that if δ is a fixed arbitrary number such that

$$|\cos(\theta\pi)|\geqq\delta>0, \tag{5.29}$$

then, for sufficiently large γ, ε is real and $O(1/\gamma^2)$, and therefore from (5.24) it is seen that ν is real in the same circumstances.

Finally, let us set $\mu=0$ in (5.24) and (5.25). We obtain in this particular case the relation

$$\nu_r \sim \frac{2}{\pi}(\gamma^2+\lambda)^{1/2} E\left(\frac{\gamma}{(\gamma^2+\lambda)^{1/2}}\right)-\frac{1}{2},$$

where E is the complete elliptic integral of the second kind (see Gradshteyn and Ryzhik (1980, p. 905)). This approximation is the same as the eigenvalue equation (3.24) of Miles (1975). (In Miles' notation $\gamma^2 \Leftrightarrow c^2$, $\nu \Leftrightarrow n$, $\lambda+\gamma^2 \Leftrightarrow \lambda$ and $\lambda/\gamma^2 \Leftrightarrow -\beta^2$.)

6. Uniform approximations for the spheroidal functions $Qs_\nu^{-\mu}(x,\gamma^2)$ and $Qs_\nu^\mu(z,\gamma^2)$. In this section we derive asymptotic expansions for large γ for the spheroidal functions Qs, Qs. The results will be uniformly valid in the real case for $0 \leqq x < 1$, and in the complex case for $z \in \Delta^+ \cap \Delta^-$ (see Figs. 4a, 5a). They will also be uniformly valid for all values of ν, λ, μ, γ satisfying the restrictions (1.6), (5.6a) and (5.29). (The last restriction will be explained shortly.)

We first turn to the problem of deriving a uniform approximation for the spheroidal function Qs. Unfortunately this function is not recessive anywhere in the complex plane and therefore we cannot identify directly with the functions given by (3.10). We overcome this difficulty by using the fact that

$$Qs_\nu^\mu(z,\gamma^2) \propto \left\{e^{\nu\pi i} S_\nu^{\mu(3)}(z,\gamma) - e^{-\nu\pi i} S_\nu^{\mu(4)}(z,\gamma)\right\}, \tag{6.1}$$

and then replacing the RHS of (6.1) with the uniform approximations of §3 for the S-functions. However, a difficulty arises in this method if ν is close to $\frac{1}{2}$ (mod 1), for then severe cancellations take place on the right-hand side of (6.1) in the domain $\Delta^+ \cap \Delta^-$ where both S-functions are dominant. (From (5.21) and (5.25) we see that $\nu \equiv \frac{1}{2}$ (mod 1) implies that $\cos(\theta\pi)$ is $O(1/\gamma^2)$ for large γ.) As Arscott (1964) remarks, the case when $\nu \equiv \frac{1}{2}$ (mod 1) is exceptional in a very large part of the theory of spheroidal functions; it appears that this case has not been treated in much detail in the literature. The results in this section are valid for ν bounded away from $\frac{1}{2}$ (mod 1) for large γ.

It follows now from (3.10), (3.15), (3.18), (3.20), (3.21) and (6.1) that there exists a constant C_{2n+1}^* such that

$$Qs_\nu^\mu(z,\gamma^2) = C_{2n+1}^* \left(\frac{\alpha^2-\zeta}{\alpha^2+\beta^2(z^2-1)-(z^2-1)^2}\right)^{1/4} \times \left\{H_\mu^{(1)}(\gamma\zeta^{1/2}) \sum_{s=0}^{n} \frac{A_s(\alpha,\zeta)}{\gamma^{2s}} + \frac{\zeta^{1/2}}{\gamma} H_\mu^{(1)\prime}(\gamma\zeta^{1/2}) \sum_{s=0}^{n-1} \frac{B_s(\alpha,\zeta)}{\gamma^{2s}} + \zeta^{-1/2}\varepsilon_{2n+1}^*(\gamma,\alpha,\zeta)\right\}, \tag{6.2}$$

where

$$\varepsilon_{2n+1}^*(\gamma,\alpha,\zeta) = \frac{1}{2i}\operatorname{cosec}(\nu\pi+\chi)\left\{e^{i(\nu\pi+\chi)}\varepsilon_{2n+1}^+(\gamma,\alpha,\zeta) - e^{-i(\nu\pi+\chi)}\varepsilon_{2n+1}^-(\gamma,\alpha,\zeta)\right\}. \tag{6.3}$$

From (3.11b) and (6.3) we have the following bounds for ε^*:

(6.4)
$$\frac{|\varepsilon^*_{2n+1}(\gamma,\alpha,\zeta)|}{\zeta^{1/2}M^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})},\ \frac{|\partial\varepsilon^*_{2n+1}(\gamma,\alpha,\zeta)/\partial\zeta|}{\frac{1}{2}\gamma N^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})+\frac{1}{2}\zeta^{-1/2}M^{(2)}_{\gamma\alpha}(\gamma\zeta^{1/2})}$$
$$\leqq \frac{\kappa E^{(1)}_{\gamma\alpha}(\gamma\zeta^{1/2})^{-1}}{2\gamma^{2n+1}|\sin(\nu\pi+\chi)|}$$
$$\times\left[\mathscr{V}_{\zeta,-\infty+i0}\left\{(\xi-\alpha^2)^{1/2}B_n(\xi)\right\}\exp\left(\frac{\kappa}{\gamma}\mathscr{V}_{\zeta,-\infty+i0}\left\{(\xi-\alpha^2)^{1/2}B_0(\xi)\right\}\right)\right.$$
$$\left.+\mathscr{V}_{\zeta,-\infty-i0}\left\{(\xi-\alpha^2)^{1/2}B_n(\xi)\right\}\exp\left(\frac{\kappa}{\gamma}\mathscr{V}_{\zeta,-\infty-i0}\left\{(\xi-\alpha^2)^{1/2}B_0(\xi)\right\}\right)\right],$$

when $\zeta\in\underline{\Delta}^+\cap\underline{\Delta}^-$ (see Figs. 4b and 5b). In deriving (6.4) we have made use of the fact that ν is real—a consequence of the restriction (5.29).

Now from (5.24) and the definition (3.19) of χ we have

$$\sin(\nu\pi+\chi)=-\cos\left(\theta\pi+\frac{1}{2}\tan^{-1}\frac{b(\alpha)}{\gamma}+\frac{\varepsilon\pi}{2}\right), \tag{6.5}$$

and so (5.29) and (6.5) give the bound

$$\frac{1}{|\sin(\nu\pi+\chi)|}\leqq\frac{1}{\delta-|\sin((1/2)\tan^{-1}(b(\alpha)/\gamma)+\varepsilon\pi/2)|}. \tag{6.6}$$

The bounds (6.4) and (6.6) together establish the uniform validity of (6.2) for $z\in\Delta^+\cap\Delta^-$. The constant of proportionality C^*_{2n+1} could be determined by comparing both sides of (6.2) as $z\to 1$ and $\zeta(z)\to 0$. However, the expression for C^*_{2n+1} derived by this method would include a constant for which only an explicit upper bound could be given (cf. B&D, eq. (4.18)).

We therefore determine C^*_{2n+1} as follows. Firstly we use the relation (Meixner and Schäfke (1954, p. 287))

(6.7)
$$i\pi\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}\mathrm{P}s^{-\mu}_\nu(y,\gamma^2)=-e^{-\mu\pi i/2}Qs^\mu_\nu(y+i0,\gamma^2)+e^{-3\mu\pi i/2}Qs^\mu_\nu(y-i0,\gamma^2),$$
$$(-1<y<1),$$

with (2.14), (6.2) and (A6) to obtain the following:

$$i\pi\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}C_{2n+1,1}\left\{\mathscr{J}_{2n+1}(\gamma,\alpha,y)+y^{-1/2}\varepsilon_{2n+1,1}(\gamma,\alpha,y)\right\} \tag{6.8}$$
$$=2e^{-3\mu\pi i/2}C^*_{2n+1}\left\{\mathscr{J}_{2n+1}(\gamma,\alpha,y)+\mathrm{Re}\left[(y+i0)^{-1/2}\varepsilon^*_{2n+1}(\gamma,\alpha,y+i0)\right]\right\},$$

where

$$\mathscr{J}_{2n+1}(\gamma,\alpha,y)\equiv J_\mu(\gamma y^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,y)}{\gamma^{2s}}+\frac{y^{1/2}}{\gamma}J'_\mu(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,y)}{\gamma^{2s}}. \tag{6.9}$$

We observe that the second term on the right-hand side of (6.8) must be recessive at $y=0$ since all other terms in this equation are recessive at $y=0$. From (6.3), (A2) and (A3) we therefore deduce that

(6.10)

$$\mathrm{Re}\big(\varepsilon^*_{2n+1}(y+i0)\big)=\int_0^y K(y,\xi)\Big[-\frac{1}{\gamma^{2n}}\big\{(\alpha^2-\xi)^{1/2}B_n(\alpha,\xi)\big\}'\xi^{1/2}J_\mu(\gamma\xi^{1/2})$$

$$+(\alpha^2-\xi)^{-1/2}\psi(\alpha,\xi)\mathrm{Re}\big(\varepsilon^*_{2n+1}(\xi+i0)\big)\Big]\,d\xi,$$

where

$$K(y,\xi)=\pi(\alpha^2-\xi)^{1/2}\big\{y^{1/2}Y_\mu(\gamma y^{1/2})\xi^{-1/2}J_\mu(\gamma\xi^{1/2})-y^{1/2}J_\mu(\gamma y^{1/2})\xi^{-1/2}Y_\mu(\gamma\xi^{1/2})\big\}.$$

This is precisely the integral equation satisfied by $\varepsilon_{2n+1,1}$ (B&D, eq. (3.3)) and therefore it follows that

$$\mathrm{Re}\big(\varepsilon^*_{2n+1}(\gamma,\alpha,y+i0)\big)=\varepsilon_{2n+1,1}(\gamma,\alpha,y).$$

From (6.8) we therefore have the *exact* relationship

$$C^*_{2n+1}=\frac{i\pi}{2}e^{3\mu\pi i/2}\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}C_{2n+1,1}. \tag{6.11}$$

We finally turn to the problem of establishing a uniform asymptotic expansion for $Qs_\nu^{-\mu}(x,\gamma^2)$ when $x\in[0,1)$. Given the relation (Meixner and Schäfke (1954, p. 287))

(6.12)

$$Qs_\nu^{-\mu}(x,\gamma^2)=\frac{\Gamma(\nu-\mu+1)}{2\Gamma(\nu+\mu+1)}\big(e^{-\mu\pi i/2}Qs_\nu^{\mu}(x+i0,\gamma^2)+e^{-3\mu\pi i/2}Q_\nu^{\mu}(x-i0,\gamma^2)\big)$$

one deduces from (6.2), (6.11) and (A6) that

$$Qs_\nu^{-\mu}(x,\gamma^2)=-\frac{\pi}{2}C_{2n+1,1}\left(\frac{\alpha^2-\zeta}{\alpha^2-\beta^2(1-x^2)-(1-x^2)^2}\right)^{1/4} \tag{6.13}$$

$$\times\Big[Y_\mu(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}Y'_\mu(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{\gamma^{2s}}$$

$$+\mathrm{Im}\big\{(\zeta+i0)^{-1/2}\varepsilon^*_{2n+1}(\gamma,\alpha,\zeta+i0)\big\}\Big].$$

7. Summary. For reference we now collect the principal results of this paper, re-expressed in terms of the original variables z (complex) or x (real), and the original parameters λ, μ, γ of the defining differential equation (1.1).

We introduce a transformed independent variable ζ that is an increasing function of x, and a continuous function of λ, μ, γ and z. When $z\equiv x$ is real with $0\leqq x<1$, ζ is

defined by equations (2.2) and (2.3). In these equations α, β, z_1 and z_2 are given by

$$\alpha=\frac{\mu}{\gamma}, \tag{7.1a}$$

$$\beta^2=\frac{\lambda}{\gamma^2}, \tag{7.1b}$$

$$z_1^2=1+\frac{\lambda}{2\gamma^2}-\frac{1}{2\gamma^2}\left(\lambda^2+4\mu^2\gamma^2\right)^{1/2}, \tag{7.2a}$$

$$z_2^2=1+\frac{\lambda}{2\gamma^2}+\frac{1}{2\gamma^2}\left(\lambda^2+4\mu^2\gamma^2\right)^{1/2}. \tag{7.2b}$$

When z is complex ζ is defined by (3.1).

Next, we introduce a function ψ which is given by (2.9). With this equation for ψ, functions $A_s(\zeta)$ and $B_s(\zeta)$ $(s=0,1,2,\cdots)$ are defined recursively by (2.9a, b) of B&D, in which the λ_s are chosen such that

$$A_s(0)=0, \qquad (s=1,2,3,\cdots). \tag{7.3}$$

The following expansions are uniformly valid for $\gamma>0$, $\mu\geqq 0$ and

$$0\leqq\frac{\mu^2}{\gamma^2}\leqq 1+A, \tag{7.4}$$

$$A'\leqq\frac{\lambda}{\gamma^2}\leqq A'', \tag{7.5}$$

where A, A' and A'' are arbitrary real constants such that $0\leqq A<A'\leqq A''<\infty$;

(7.6)

$$\mathrm{Ps}_\nu^{-\mu}(x,\gamma^2)=C_{2n+1,1}\left(\frac{\mu^2-\gamma^2\zeta}{\mu^2-\lambda(1-x^2)-\gamma^2(1-x^2)^2}\right)^{1/4}$$
$$\times\left[J_\mu(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}J_\mu'(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\gamma^{2s}}+\zeta^{-1/2}\varepsilon_{2n+1,1}(\zeta)\right],$$

(7.7)

$$Ps_\nu^{-\mu}(z,\gamma^2)=\frac{1}{2}C_{2n+1,1}\left(\frac{\mu^2-\gamma^2\zeta}{\mu^2+\lambda(z^2-1)-\gamma^2(z^2-1)^2}\right)^{1/4}$$
$$\times\left[J_\mu(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}J_\mu'(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\gamma^{2s}}+\zeta^{-1/2}\varepsilon_{2n+1}^{(0)}(\zeta)\right],$$

(7.8)

$$S_\nu^{\mu(3,4)}(z,\gamma)=C_{2n+1}^{\mp}\left(\frac{\mu^2-\gamma^2\zeta}{\mu^2+\lambda(z^2-1)-\gamma^2(z^2-1)^2}\right)^{1/4}$$
$$\times\left[H_\mu^{(1)}(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}H_\mu^{(1)\prime}(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\gamma^{2s}}+\zeta^{-1/2}\varepsilon_{2n+1}^{\mp}(\zeta)\right].$$

The coefficient $C_{2n+1,1}$ is given by

$$C_{2n+1,1}=A_\nu^{-\mu}(\gamma^2)\left(\frac{1-z_1}{\mu^2}\right)^{\mu/2}(1+z_1)^{-\mu/2}\left(1+\frac{\mu}{\gamma^2}\sum_{s=0}^{n-1}\frac{B_s(0)}{\gamma^{2s}}\right)^{-1} \tag{7.9}$$
$$\times\exp\left\{\mu+\int_{z_1}^{1}\frac{\left[\mu^2-(1-t^2)-\gamma^2(1-t^2)^2\right]^{1/2}-\mu}{1-t^2}\,dt\right\}.$$

The coefficients $C_{2n+1}^{\pm}$ are given by

$$C_{2n+1}^{\pm}=ie^{\mp i\chi}\left(\frac{\pi}{2\gamma}\right)^{1/2}e^{\mu\pi i/2}\left(\sum_{s=0}^{n}\frac{A_s(-\infty)}{\gamma^{2s}}+\frac{1}{\gamma}\sum_{s=0}^{n-1}\frac{\tilde{B}_s(-\infty)}{\gamma^{2s}}\right)^{-1}, \tag{7.10}$$

in which

$$\chi=\frac{\mu\pi}{2}-\frac{\nu\pi}{2}+\int_0^{z_1}\frac{\left[\gamma^2(1-t^2)^2+\lambda(1-t^2)-\mu^2\right]^{1/2}}{1-t^2}\,dt-\frac{3\pi}{4}, \tag{7.11}$$

and

$$\tilde{B}_s(-\infty)=\lim_{\zeta\to-\infty}\left\{(-\zeta)^{1/2}B_s(\zeta)\right\}. \tag{7.12}$$

The error term $\varepsilon_{2n+1,1}$ in (7.6) is uniformly bounded by (3.8) of B&D for $0\leqq x<1$. The error term $\varepsilon_{2n+1}^{(0)}$ is uniformly bounded by (3.11a) for $z\in\Delta$ (see Fig. 1a). The error terms $\varepsilon_{2n+1}^{\pm}$ are uniformly bounded by (3.11b) for $z\in\Delta^{\pm}$ (see Figs. 4a and 5a).

A uniform relationship between λ, μ, γ and the characteristic exponent ν is given as follows. Firstly we define $\hat{X}_\mu$ to be the smallest root of

$$J_{\hat{\mu}}(x)+Y_{\hat{\mu}}(x)=0, \tag{7.13}$$

where $\hat{\mu}$ is the real (nonnegative) solution of

$$\mu=\hat{\mu}-c(\hat{\mu}/2)^{1/3} \tag{7.14}$$

in which c denotes the negative root of smallest absolute value of the equation $\mathrm{Ai}(x)=\mathrm{Bi}(x)$ ($c=-0.36605\cdots$). Then under the restrictions (7.4), (7.5), and in addition the restriction

$$\int_{z_1}^{z_2}\frac{\left[\mu^2+\lambda(t^2-1)-\gamma^2(t^2-1)^2\right]^{1/2}}{t^2-1}\,dt>\int_{\mu^2(\tau^2-1)}^{\hat{X}_\mu^2(\tau^2-1)}\frac{(\mu^2+t)^{1/2}}{2t}\,dt, \tag{7.15}$$

where τ is defined by (3.3a), we have the following:

$$\sin(\nu\pi)=\left|H_\mu^{(1)}(\gamma\zeta_0^{1/2})+\frac{\zeta_0^{1/2}}{\gamma}H_\mu^{(1)\prime}(\gamma\zeta_0^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta_0)}{\gamma^{2s}}+\zeta_0^{-1/2}\varepsilon_{2n+1}^{+}(\zeta_0)\right|^{-1} \tag{7.16}$$
$$\times\mathrm{Re}\left[\exp\left(i\left\{\mu\pi-\frac{3\pi}{4}+\int_0^{z_1}\frac{\left[\gamma^2(1-t^2)^2+\lambda(1-t^2)-\mu^2\right]^{1/2}}{1-t^2}\,dt\right\}\right)\right.$$
$$\left.\times\left\{H_\mu^{(1)}(\gamma\zeta_0^{1/2})+\frac{\zeta_0^{1/2}}{\gamma}H_\mu^{(1)\prime}(\gamma\zeta_0^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta_0)}{\gamma^{2s}}+\zeta_0^{-1/2}\varepsilon_{2n+1}^{-}(\zeta_0)\right\}\right].$$

In (7.16) ζ_0 denotes the value of $\zeta(x)$ at $x=0$, and $B_s(\zeta)$ $(s=0,1,2,\cdots,n-1)$ are given by (2.9a, b) of B&D, with λ_s chosen such that $A_s(\zeta_0)=0$ $(s=1,2,\cdots,n)$.

Under the restrictions (7.4), (7.5), (7.15), and in addition the restriction

$$\cos\left(\mu\pi+2\int_0^{z_1}\frac{\left[\gamma^2(1-t^2)^2+\lambda(1-t^2)-\mu^2\right]^{1/2}}{1-t^2}\,dt\right)\geqq\delta>0, \tag{7.17}$$

where δ is an arbitrary fixed number, we have the following uniform asymptotic expansions:

(7.18)

$$Qs_\nu^\mu(z,\gamma^2)=\frac{i\pi}{2}e^{3\mu\pi i/2}\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}C_{2n+1,1}\left(\frac{\mu^2-\gamma^2\zeta}{\mu^2+\lambda(z^2-1)-\gamma^2(z^2-1)^2}\right)^{1/4}$$
$$\times\left[H_\mu^{(1)}(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}H_\mu^{(1)\prime}(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\gamma^{2s}}+\zeta^{-1/2}\varepsilon_{2n+1}^*(\zeta)\right],$$

(7.19)

$$Qs_\nu^{-\mu}(x,\gamma^2)=-\frac{\pi}{2}C_{2n+1,1}\left(\frac{\mu^2-\gamma^2\zeta}{\mu^2-\lambda(1-x^2)-\gamma^2(1-x^2)^2}\right)^{1/4}$$
$$\times\left[Y_\mu(\gamma\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\gamma^{2s}}+\frac{\zeta^{1/2}}{\gamma}Y_\mu'(\gamma\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\gamma^{2s}}\right.$$
$$\left.+\operatorname{Im}\left\{(\zeta+i0)^{-1/2}\varepsilon_{2n+1}^*(\zeta+i0)\right\}\right].$$

Equation (7.18) is uniformly valid for $z\in\Delta^+\cap\Delta^-$, and (7.19) is uniformly valid for $0\leqq x<1$. The error term ε_{2n+1}^* is uniformly bounded under the above-mentioned restrictions by (6.4).

Appendix. Analytic continuation of the error functions. We prove the following

$$\bar{\varepsilon}_{2n+1}^+(\gamma,\alpha,y\pm i0)=e^{\mu\pi i}\varepsilon_{2n+1}^-(\gamma,\alpha,y\mp i0),\qquad(0<y\leqq\zeta_0), \tag{A1}$$

where $^-$ denotes complex conjugate.

The error functions ε^+, ε^- are solutions of the integral equation

(A2)

$$\varepsilon_{2n+1}^\pm(\gamma,y,\zeta)=\int_{-\infty\pm i0}^{\zeta}K(\zeta,\xi)\left[-\frac{1}{\gamma^{2n}}\left\{(\xi-\alpha^2)^{1/2}B_n(\gamma,\xi)\right\}'\xi^{1/2}H_\mu^{(1)}(\gamma\xi^{1/2})\right.$$
$$\left.+(\xi-\alpha^2)^{-1/2}\psi(\alpha,\xi)\varepsilon_{2n+1}^\pm(\gamma,\alpha,\xi)\right]d\xi,$$

where

(A3)

$$K(\zeta,\xi)=\pi(\xi-\alpha^2)^{1/2}\left(\frac{\zeta}{\xi}\right)^{1/2}\left\{H_\mu^{(1)}(\gamma\zeta^{1/2})H_\mu^{(2)}(\gamma\xi^{1/2})-H_\mu^{(2)}(\gamma\zeta^{1/2})H_\mu^{(1)}(\gamma\xi^{1/2})\right\}.$$

If we set $\zeta = y \pm i0$ in (A2) and take conjugates of both sides, we have the following equation for $\bar{\varepsilon}^{+}$:

(A4)

$$\bar{\varepsilon}^{+}_{2n+1}(\gamma,\alpha,y\pm i0)=\int_{-\infty+i0}^{y\pm i0}\overline{K}(y\pm i0,\xi)\left[-\frac{1}{\gamma^{2n}}\left\{(\bar{\xi}-\alpha^2)^{1/2}B_n(\alpha,\bar{\xi})\right\}'\bar{\xi}^{1/2}\overline{H}^{(1)}_{\mu}(\gamma\xi^{1/2})\right.$$

$$\left.+(\bar{\xi}-\alpha^2)^{-1/2}\psi(\alpha,\bar{\xi})\bar{\varepsilon}^{+}_{2n+1}(\gamma,\alpha,\xi)\right]d\bar{\xi}.$$

If we make the change of variable in (A4) of

$$\omega=\bar{\xi}e^{2\pi i},\qquad (0\leqq\arg(\omega)<2\pi),$$

and use the identities

$$\overline{H}^{(1)}_{\mu}(\gamma\xi^{1/2})=-e^{\mu\pi i}H^{(1)}_{\mu}(\gamma\omega^{1/2}),$$

and $\overline{K}(y\pm i0,\xi)=K(y\mp i0,\omega)$, (see Olver (1974, pp. 238 and 239)), we find that

(A5) $$e^{-\mu\pi i}\bar{\varepsilon}^{+}_{2n+1}(\gamma,\alpha,y\pm i0)=\int_{-\infty-i0}^{y\pm i0}K(y\mp i0,\omega)$$

$$\times\left[-\frac{1}{\gamma^{2n}}\left\{(\omega-\alpha^2)^{1/2}B_n(\alpha,\omega)\right\}'\omega^{1/2}H^{(1)}_{\mu}(\gamma\omega^{1/2})\right.$$

$$\left.+(\omega-\alpha^2)^{-1/2}\psi(\alpha,\omega)e^{-\mu\pi i}\bar{\varepsilon}^{+}_{2n+1}(\gamma,\alpha,\bar{\omega}e^{2\pi i})\right]d\omega;$$

(A1) now follows from the observation that (A5) is precisely the integral equation (A2) satisfied by $\varepsilon^{-}_{2n+1}(\gamma,\alpha,y\mp i0)$.

Finally we find from (6.3) and (A1) that if ν is real (a sufficient condition is (5.29)) then the following analytic continuation formula for ε^{*} holds

(A6) $$\bar{\varepsilon}^{*}_{2n+1}(\gamma,\alpha,y+i0)=e^{\mu\pi i}\varepsilon^{*}_{2n+1}(\gamma,\alpha,y-i0).$$

Acknowledgment. The author is grateful to Dr. W. G. C. Boyd for suggesting the problem and for the invaluable help he gave during the writing of this paper.
