Now it is quite obvious that the functions u_{ε_j} converge in $L^1_{\text{loc}}(\mathbf{R};\mathbf{R})$ towards the function u and also that the functions y_{ε_j} converge uniformly on compact subsets towards the function y. It remains to prove that u is weakly thermostat controlled by y. It follows from inequalities (5) that we must have $y(t)\leqq\theta_{\text{high}}$ on $[0,T^*]$ and $y(t)\geqq\theta_{\text{low}}$ on $[T^*,T^*+S^*]$. If on the other hand there is no point $t\in[0,T]$ for which $y(t)=\theta_{\text{high}}$, then it follows that for sufficiently small numbers ε_j we have $y_{\varepsilon_j}(t)\leqq\theta_{\text{high}}-\varepsilon_j$ for all $t\in[0,T_{\varepsilon_j}]$. This implies that $v_{\varepsilon_j}(t)=y_{\varepsilon_j}(t)$ for all $t\in[0,T_{\varepsilon_j}]$ which is impossible. A similar argument for the lower bound θ_{low} shows that we actually do have a weakly controlled solution.

It remains to remove the differentiability assumption and this can be done by approximating the original kernel with differentiable ones. Thus one gets a sequence of weak solutions and an argument similar to the one used above shows that it must have a limit that is a weakly controlled periodic solution of equation (1) on **R**. □

5. Proof of Theorem 3. Let $T > S$ be two points such that $u(s) = 1$ when $s \in (S, T]$ and $u(S) = 0$. Let $\tau \in (S, T)$ be an arbitrary point. From (1) we have

$$y(T) - y(\tau) = \int_0^{T-\tau} a(s)\,ds - \int_{\mathbf{R}^+} (a(s) - a(T-\tau+s))u(\tau - s)\,ds. \tag{6}$$

Since $\int_{\mathbf{R}^+} (a(s) - a(T-\tau+s))\,ds = \int_0^{T-\tau} a(s)\,ds$ this equation shows that y is nondecreasing on the intervals where u is 1 (and by the same argument nonincreasing when u is 0). If $a(s) = 0$ when $s > \tau - S$, then $y(\tau) = 1$ which is impossible. Hence it follows from our assumptions that $a(s) - a(T-\tau+s) > 0$ if $s \in (\tau - S, \tau - S + \varepsilon)$ for some positive number ε. But this implies by (6) and the fact that $u(S) = 0$ that

$$y(T) - y(\tau) > \int_0^{T-\tau} a(s)\,ds + \int_{\mathbf{R}^+} (a(s) - a(T-\tau+s))\,ds = 0$$

and since τ was arbitrary it follows that u is strictly controlled by y at the upper limit. A similar argument can be applied to the lower limit to complete the proof. □

6. Proof of Theorem 4. We consider first the case when the functions a_1 and a_2 are of the form $a_1(t) = \sigma_1 e^{-\sigma_1 t}$ and $a_2(t) = \sigma_2 e^{-\sigma_2 t}$ for some positive numbers σ_1 and σ_2. Assume that u takes the value one on intervals of length T and is equal to zero on intervals of length S, that is $u(t) = \chi_{E_{T,S}}(t)$ where $E_{T,S}$ is given in (4). Let us denote

$$v(t) = \int_{\mathbf{R}^+} a_1(s)u(t-s)\,ds, \qquad t \in \mathbf{R}.$$

Now it is obvious that v is increasing on the intervals where u takes the value 1 and decreasing elsewhere. Differentiating both sides of (1) we have

$$y'(t) = \sigma_2(v(t) - y(t)), \qquad t \in \mathbf{R}.$$

We see that on the intervals where u is 1 the function y can have only one point where the derivative vanishes and that point must be a minimum. Hence we conclude that

$$y(t) < y(T), \qquad t \in [0, T], \tag{7}$$

provided we can show that $y(0) < y(T)$. Suppose for the moment that this has been done. Since completely monotone functions are limits of sums of exponentials we see that the relation (7) must hold in the general case too and hence the solution (y, u) is a strict solution.

Thus it remains to prove that $y(0) < y(T)$. We know that

$$v'(t) = \sigma_1(u(t) - v(t))$$

and since v is periodic with period $T + S$ one can easily solve the differential equation above and from the periodicity condition conclude that

$$v(0) = e^{-\sigma_1 S} \frac{1 - e^{-\sigma_1 T}}{1 - e^{-\sigma_1 (T+S)}},$$

$$v(T) = \frac{1 - e^{-\sigma_1 T}}{1 - e^{-\sigma_1 (T+S)}}.$$

Now we proceed to solve the function y and using the fact that this function is periodic too, we get

$$y(0)=(1-e^{-\sigma_2 T})+e^{-\sigma_2 T}y(0)-(1-v(0))\frac{\sigma_2}{\sigma_2-\sigma_1}(e^{-\sigma_1 T}-e^{-\sigma_2 T}),$$

$$y(T)=e^{-\sigma_2 S}y(T)+v(T)\frac{\sigma_2}{\sigma_2-\sigma_1}(e^{-\sigma_1 S}-e^{-\sigma_2 S}).$$

(Here we assume that $\sigma_2 \neq \sigma_1$, the case when they are equal is treated in the same manner.) If we solve $y(0)$ and $y(T)$ from these equations and insert the values of $v(0)$ and $v(T)$ obtained above, then we get the relation

$$\begin{aligned}(1-e^{-\sigma_1(T+S)})&(1-e^{-\sigma_2(T+S)})(y(T)-y(0))\\ &=(1-e^{-\sigma_2 T})(1-e^{-\sigma_2 S})(1-e^{-\sigma_1(T+S)})\\ &\quad-(1-e^{-\sigma_1 T})(1-e^{-\sigma_2 T})\frac{\sigma_2}{\sigma_2-\sigma_1}(e^{-\sigma_1 S}-e^{-\sigma_2 S})\\ &\quad-(1-e^{-\sigma_1 S})(1-e^{-\sigma_2 S})\frac{\sigma_2}{\sigma_2-\sigma_1}(e^{-\sigma_1 T}-e^{-\sigma_2 T}).\end{aligned} \tag{8}$$

Next write

$$1-e^{-\sigma_1(T+S)}=\tfrac{1}{2}(1-e^{-\sigma_1 T})(1+e^{-\sigma_1 S})+\tfrac{1}{2}(1-e^{-\sigma_1 S})(1+e^{-\sigma_1 T}) \tag{9}$$

and then observe that it is easy to verify that

$$\begin{aligned}&\frac{1}{2}(1-e^{-\sigma_2 S})(1+e^{-\sigma_1 S})-\frac{\sigma_2}{\sigma_2-\sigma_1}(e^{-\sigma_1 S}-e^{-\sigma_2 S})\\ &\quad=e^{-(\sigma_1+\sigma_2)S/2}\left(\sinh\left(\frac{(\sigma_1+\sigma_2)S}{2}\right)-\frac{\sigma_1+\sigma_2}{\sigma_1-\sigma_2}\sinh\left(\frac{(\sigma_1-\sigma_2)S}{2}\right)\right)>0.\end{aligned}$$

A similar result holds of course with S replaced by T and if these together with (9) are used in the right-hand side of the relation (8), then we obtain the desired conclusion that $y(T)>y(0)$. □

7. Proof of Theorem 5. Let T be positive, $a_m(t)=(1/m!)t^m e^{-t}$ and define

$$u_T(t)=\begin{cases}1 & \text{if } t\in(mT, mT+T],\ m \text{ even},\\ 0 & \text{otherwise.}\end{cases}$$

Let

$$y_{m,T}(t)\overset{\text{def}}{=}\int_{\mathbf{R}^+} a_m(s)u_T(t-s)\,ds, \qquad t\in\mathbf{R}$$

and

$$h_m(T)=\frac{1}{m!}(-1)^m T^{m+1}\frac{d^m}{dT^m}\left(\frac{1}{T}\frac{1}{e^T+1}\right), \qquad T>0.$$

A straightforward calculation shows that

$$y_{m,T}(0)=h_m(T), \qquad m\geqq 0, \quad T>0.$$

We need some further information about the function h_m.

LEMMA 1. *Let h_m be the function defined above. Then for each $m \geqq 0$, $h_m(0)=\frac{1}{2}$ and*

(i) $(-1)^{\lfloor m/2 \rfloor}(h_m(T)-\frac{1}{2})$ *is negative and decreasing when $T \in (0, \delta_m)$, $\delta_m > 0$,*

(ii) $h_{m+1}(T)=h_m(T)-(1/(m+1))Th'_m(T)$ *when $T>0$,*

(iii) *the function h_m has $\lfloor m/2 \rfloor$ local extrema on $(0, \infty)$ and no other points where the derivative vanishes.*

Proof. Let us first define the function $f: \mathbf{R}^+ \to \mathbf{R}^+$ by $f(T)=1/(e^T+1)$. A calculation shows that

$$h'_m(T)=\frac{1}{m!}(-1)^m T^m f^{(m+1)}(T), \qquad T \geqq 0$$

and from this relation we get the claim (ii) with the aid of a partial integration.

Next let us define

$$g_0(s) \overset{\text{def}}{=} s(1-s), \qquad s \in \mathbf{R},$$

$$g_m(s) \overset{\text{def}}{=} s(1-s)g'_{m-1}(s), \qquad m \geqq 1, \quad s \in \mathbf{R}.$$

Again it is straightforward to check that

$$h'_m(T)=-\frac{1}{m!}T^m g_m\left(\frac{1}{e^T+1}\right), \quad T \geqq 0.$$

By induction it is easy to prove that the function g_m has exactly $\lfloor m/2 \rfloor$ zeros in the interval $(0, \frac{1}{2})$ and all of these zeros are simple. This gives the assertion (iii) about the number of extreme points. To establish (i) we have only to observe that

$$g_m(\tfrac{1}{2})\begin{cases} >0 & \text{if } m \equiv 0 \bmod 4, \\ =0 & \text{if } m \equiv 1 \bmod 4, \\ <0 & \text{if } m \equiv 2 \bmod 4, \\ =0 & \text{if } m \equiv 3 \bmod 4, \end{cases} \qquad g'_m(\tfrac{1}{2})\begin{cases} =0 & \text{if } m \equiv 0 \bmod 4, \\ <0 & \text{if } m \equiv 1 \bmod 4, \\ =0 & \text{if } m \equiv 2 \bmod 4, \\ >0 & \text{if } m \equiv 3 \bmod 4. \end{cases}$$

This completes the proof of Lemma 1. □

Our next lemma says for how many values of T we get the same value for $y_{m,T}(0)$.

LEMMA 2. *Let $y_{m,T}$ be the function defined above. If $m \geqq 0$ and α is a sufficiently small positive number, then there exists $\lfloor m/4 \rfloor + 1$ different values T_j so that $y_{m,T_j}(0)=\frac{1}{2}-\alpha$ and $y_{m-1,T_j}(0)<\frac{1}{2}-\alpha$ if $m \geqq 1$.*

Proof. From Lemma 1 (i) and (iii) and the fact that $h_m(\infty)=0$ we see that the extreme point of h_2 must be a maximum. Then it is possible, using induction and (ii) in Lemma 1 to show that at all local maxima of $h_m(T)$ the value of the function is larger than $\frac{1}{2}$ and at all the minima smaller. Furthermore it follows from (i) and (iii) in Lemma 1 that h_m has exactly $\lfloor m/4 \rfloor$ local maxima on $\mathbf{R}^+$ (note that for some values of m there is one at 0). But then the desired conclusion follows directly from (ii) in Lemma 1 since immediately to the right of each maximum there is a point where $h_m(T)=\frac{1}{2}-\alpha$ and $h'_m(T)<0$. □

If now $\theta_{\text{low}}=\frac{1}{2}-\alpha$ and $\theta_{\text{high}}=1-\theta_{\text{low}}$, $m \geqq 0$ and T is such that $y_{m,T}(0)=\frac{1}{2}-\alpha$, then $(y_{m,T}, u_T)$ is a periodic strict solution of equation (1) if we can show that

$$\max_{s \in [0,T]} y_{m,T}(s)=y_{m,T}(T)>y_{m,T}(t), \qquad t \in [0, T). \tag{10}$$

This is of course the case if $m=0$ and we will show that it is also true if $y_{m,T}(0)>y_{m-1,T}(0)$. First we need a simple lemma.

LEMMA 3. *Let $m \geqq 0$, $T > 0$ and let $y_{m,T}$ be as defined above. Then $y_{m,T}$ can have at most one local extreme point on the interval* $(0, T)$.

Proof. We use induction to prove the stronger claim that there cannot be two extreme points in $(0, T)$ or one extreme point if the derivative is zero at 0. It obviously holds for $m = 0$. Assume that it also holds for $m = k-1$. We will show that it is true for $m = k$. Suppose that $y_{k,T}$ has at least two local extreme points in $(0, T)$. Since

$$y'_{k,T}(t) = y_{k-1,T}(t) - y_{k,T}(t), \tag{11}$$

and by symmetry

$$y'_{k-1,T}(0) = -y'_{k-1,T}(T),$$

this assumption implies that $y_{k-1,T}$ must have two extreme points in $(0, T)$ or one extreme point and vanishing derivative at zero. If $y_{k,T}$ has derivative equal to zero and one extreme point on $(0, T)$ then a similar argument shows that we again get a contradiction. □

To complete the proof of the theorem we see that if (10) is not satisfied then either $y'_{m,T}(0) \geqq 0$ which is impossible if $y_{m,T}(0) > y_{m-1,T}(0)$ by (11) or there are at least two local extreme points on the interval $(0, T)$. But this is impossible according to Lemma 3 and therefore the desired conclusion follows from Lemma 2. □

Acknowledgment. I would like to thank Dr. J. Prüss for introducing me to the problems considered in this paper.

EXISTENCE OF GLOBAL SOLUTIONS TO A MODEL OF A MYELINATED NERVE AXON*

CHRIS COSNER†

Abstract. The main result is a proof of the existence of solutions which are global in time for a differential equation arising in the theory of myelinated nerves. The equation differs from the usual reaction-diffusion equations occurring in nerve models in that the second derivative operator in the spatial direction is replaced at a sequence of discrete nodes by an operator defined as the jump in the first derivative in the spatial direction across the node. The nonlinear dynamics are assumed to be concentrated at the nodes. Local existence of solutions is obtained via semigroup theory; global bounds and hence global existence via energy or Lyapunov methods.

Key words. nerve axon models, global existence theory, differential/difference operators, semigroup theory, Lyapunov functions

AMS(MOS) subject classifications. 35R10, 35K57, 92A09

1. Introduction. The study of mathematical models of nerve impulse conduction has proved to be a fruitful source of interesting problems in differential equations. The purpose of this article is to prove the global existence of solutions to one such model that arises from a consideration of the effects of myelination on conduction of impulses in a nerve axon. Myelinated nerves, which include many human nerve processes, are wrapped in periodic bands of fatty myelin tissue, which acts as an insulator in damping the dynamics of the nerve axon. The dynamics of the myelinated nerve occur primarily at the gaps (known as nodes of Ranvier) between the myelin bands. The model considered here is the myelinated analogue of the simplest model for conduction in a uniform axon, the so-called reduced FitzHugh-Nagumo equation

$$\begin{aligned} &u_t = u_{xx} + f(u) \quad \text{on } (0,\infty)\times(0,\infty),\\ &u_x(0+,t) = I(t),\\ &u(x,0) = \phi(x) \end{aligned} \tag{1.1}$$

where u represents the potential across the axonal membrane, $I(t)$ a current stimulus at the end of the axon, $\phi(x)$ the initial state of the axon, and $f(u)$ describes the dynamics of the excitable membrane. The corresponding myelinated model, which we shall study in the present article, assumes nodes at integer values of x and is given by

$$\begin{aligned} &U_t = U_{xx} - gU, \quad x \in (0,\infty)\backslash\mathbb{Z}^+, \quad t>0,\\ &V_t^j = [\![U_x]\!]_j + f(V^j), \quad j\in\mathbb{Z}^+, \quad t>0,\\ &U_x(0+,t) = I(t),\\ &(U,V)|_{t=0} = (\phi_0, \psi_0) \end{aligned} \tag{1.2}$$

where $V=(V^j)_{j=1}^{\infty}$ and $[\![F]\!]_j = F(j+) - F(j-)$. In (1.2), the myelin is assumed to have the effect of limiting the dynamics of the nerve to the nodes. A discussion of the modeling leading to (1.2) is given in [2]. References on (1.2) and on models related

to (1.2) are given in [2]. Another class of models for myelinated nerves is discussed in [6]. We shall impose the following conditions on f:

$$f(0)=0, \qquad f\in C^1(\mathbb{R}) \quad \text{with } f'(x)\leqq f_0 \quad \text{on } \mathbb{R}, \tag{1.3}$$

and assume that f can be extended to a function on $\mathbb{C}$ which, if viewed as a function of two real variables, is C^1. In the actual model, f is often taken to be a cubic $f(u)=bu(a-u)(u-1)$, $b>0$, $a\in(0,1)$.

For purposes of applications, the most interesting questions about (1.2) involve threshold phenomena and propagation of impulses; those questions for the pure initial value problem are discussed in [2] and for the initial boundary problem (1.2) in work in progress by Jonathan Bell and the author. However, it is not entirely satisfactory from a mathematical point of view to leave the question of existence of solutions open; thus the question of existence is discussed here. The main result is the existence theorem for (1.2) stated at the end of § 3. To obtain a local existence result, we cast (1.2) in terms of the operator A given by $A(u,v)=(-u_{xx}+u,(-[\![u_x]\!]_j+v^j)_{j=1}^{\infty})$, where as in (1.2) u is defined on $(0,\infty)\backslash\mathbb{Z}^+$ and $v=(v^j)_{j=1}^{\infty}$, then show that when given the appropriate domain the operator A is such that abstract results from the theory of semilinear evolution equations can be applied to (1.2). The appropriate spaces on which to consider A are slightly nonstandard; those spaces and the properties of A are studied in § 2. To obtain global existence in time, a priori bounds on solutions are needed; those bounds are obtained by a Lyapunov or energy method in § 3. The analysis is somewhat similar to those done for various models of uniform (i.e., nonmyelinated) axons in [1], [3], [8]. The analysis can be extended to models more complicated than (1.2); for example it is clear from an examination of the proof that the scalar equation $V_t^j=[\![U_x]\!]_j+f(V^j)$ could be replaced by a vector equation of the form

$$\vec{V}_t^j=\vec{P}_0[\![U_x]\!]_j+\vec{f}(\vec{V}^j,\vec{W}^j), \qquad \vec{W}_t^j=\vec{h}(\vec{V}^j,\vec{W}^j)$$

(where $\vec{P}_0$ is a constant vector with positive components) with only minor changes in the analysis under appropriate hypotheses on $\vec{f}$ and $\vec{h}$. Thus, we could replace the reduced Fitzhugh-Nagumo dynamics with Hodgkin-Huxley or other more complicated dynamics at each node. The mathematical novelty of (1.2) comes mainly from the existence of nodes at which $\partial^2/\partial x^2$ is replaced by $[\![\partial^{\cdot}/\partial x]\!]$. Thus we limit our attention to (1.2) for the sake of brevity and simplicity; our methods are adequately illustrated by that simple case. In studying the operator A, we use some rather "soft" or nonconstructive methods. The author would be very interested in seeing an explicit construction of a Green's function for the linear problem $(u,v)_t+A(u,v)=(p,q)$, $(u,v)|_{t=0}=(\phi,\psi)$ with (p,q), (ϕ,ψ) given; such a construction appears to be computationally tricky. Another approach to (1.2) might be via some sort of method of lines; however, obtaining the appropriate estimates for the convergence of line methods also seems to be a delicate problem. Thus, although the methods used here are nonconstructive, they have the advantage of simplicity.

2. Linear theory. Our analysis will use some slightly unusual spaces, all consisting of pairs (p,q) where p is a complex valued function on $(0,\infty)\backslash\mathbb{Z}^+$ and $q=(q^j)_{i=1}^{\infty}$ with $q^j\in\mathbb{C}$. Let $H=\{(p,q)\colon p\in L^2[(0,\infty)\backslash\mathbb{Z}^+], q\in l^2\}$ with inner product

$$\langle (p_1,q_1),(p_2,q_2)\rangle_H=\int_{(0,\infty)\backslash\mathbb{Z}^+} p_1\bar{p}_2+\sum_{j=1}^{\infty} q_1^j\bar{q}_2^j.$$

The space H is a complex Hilbert space and can be viewed as an L^2 space generated by the appropriate measure. Let

$$X=\{(p,q)\in H\colon p',p''\in L^2[(0,\infty)\backslash\mathbb{Z}^+],\ p'\text{ absolutely continuous on }(j-1,j)\text{ for } j\in\mathbb{Z}^+,\ (\llbracket p'\rrbracket_j)_{j=1}^{\infty}\in l^2,\ \lim_{x\to j}p(x)=q^j,\text{ and } p'(0+)=0\}.$$

It is a fairly straightforward exercise in the theory of functions of a real variable to show that X is dense in H. Finally, let

$$Y=\{(p,q)\in H\colon p'\in L^2[(0,\infty)\backslash\mathbb{Z}^+],\ p\text{ absolutely continuous on }(0,\infty)\backslash\mathbb{Z}^+,\ \lim_{x\to j}p(x)=q^j\}$$

with inner product

$$\langle (p_1,q_1),(p_2,q_2)\rangle_Y=\int_{(0,\infty)\backslash\mathbb{Z}^+}(p_1'\bar{p}_2'+p_1\bar{p}_2)+\sum_{j=1}^{\infty}q_1^j\bar{q}_2^j.$$

Clearly $X\subseteq Y\subseteq H$, with $\|(u,v)\|_H\leqq\|(u,v)\|_Y$ for $(u,v)\in Y$. Let A be the operator defined by $A(p,q)=(-p''+p,-\llbracket p'\rrbracket_j+q^j)_{j=1}^{\infty}$, with $\operatorname{dom}A=X$. We will show that A generates an analytic semigroup; to see that, we will first show that A has a bounded inverse so that A is closed (since $\operatorname{dom}A=X$ is dense in H), then calculate the numerical range to see that A is m-sectorial so that A generates a holomorphic semigroup. Inverting A is equivalent to solving

$$\begin{aligned} A(u,v)&=(p,q)\in H, \qquad (u,v)\in X\\ -u''+u&=p \quad \text{on } (0,\infty)\backslash\mathbb{Z}^+,\\ -\llbracket u'\rrbracket_j+v^j&=q^j, \qquad j\in\mathbb{Z}^+,\\ u'(0+)&=0 \end{aligned} \tag{2.1}$$

in X with $\|(u,v)\|_H\leqq K\|(p,q)\|_H$ for some constant K. To solve (2.1) we first obtain a generalized solution in Y and then show that such a solution must belong to X.

We define a generalized solution of (2.1) to be an element $(u,v)\in Y$ such that for any $(w,y)\in Y$,

$$\langle (w,y),(u,v)\rangle_Y=\langle (w,y),(p,q)\rangle_H. \tag{2.2}$$

Since $|\langle (w,y),(p,q)\rangle_H|\leqq\|(w,y)\|_H\|(p,q)\|_H\leqq\|(w,y)\|_Y\|(p,q)\|_H$, the right side of (2.2) defines a bounded linear functional on $(w,y)\in Y$. By the Riesz representation theorem, there exists a unique $(u,v)\in Y$ such that (2.2) holds for any $(w,y)\in Y$. Thus, for any given $(p,q)\in Y$ we can define $B\colon H\to H$ by taking $B(p,q)$ to be the generalized solution to (2.2) corresponding to (p,q). If $(u,v)=B(p,q)\in Y$, then by (2.2), $\|B(p,q)\|_Y^2=|\langle (u,v),(u,v)\rangle_Y|=|\langle (u,v),(p,q)\rangle_H|\leqq\|(u,v)\|_Y\|(p,q)\|_H=\|B(f,g)\|_Y\|(p,q)\|_H$ so that $\|B(p,q)\|_Y\leqq\|(p,q)\|_H$. Hence $B\colon H\to Y\hookrightarrow H$ is bounded. It remains to show that B maps H into X and that any solution (u,v) to (2.2) in X satisfies $A(u,v)=(p,q)$. Showing that B maps H to X is essentially a matter of proving the regularity of generalized solutions to (2.1). Let $H^k[\Omega]$ denote the L^2-Sobolev space of functions with k weak derivatives in $L^2[\Omega]$. If $(u,v)\in Y$ then $u|_{(j-1,j)}\in H^1[(j-1,j)]$ for all $j\in\mathbb{Z}^+$. We may follow the analysis in [4, § I.15] to conclude that $u|_{(a,b)}\in H^2[(a,b)]$ for any a,b with $j-1<a<b<j$, $j\in\mathbb{Z}^+$, provided we can show that if $(u,v)\in Y$ satisfies (2.2) for a given $(p,q)\in H$, there exists a constant C such that for any $\phi\in C_0^\infty[(j-1,j)]$ we have

$$\left|\int_{(j-1,j)}\phi'\bar{u}'\right|\leqq C\|\phi\|_{L^2[(j-1,j)]}. \tag{2.3}$$

(Inequality (2.3) is essentially inequality (15.6) in [4, § I.15]; the verification that the results in [4] carry over to our situation is routine and hence omitted.) Suppose that $(u, v) \in Y$ satisfies (2.2) and $\phi \in C_0^\infty[(j-1, j)]$ with $\operatorname{supp} \phi \subseteq [a, b] \subseteq (j-1, j)$. If we extend ϕ to $(0, \infty)\backslash\mathbb{Z}^+$ by taking $\phi \equiv 0$ outside $[a, b]$ and let $\psi = (\psi^k)_{k=1}^\infty$ with $\psi^k = 0$ for all k, then $(\phi, \psi) \in Y$ and (2.2) yields

$$\int_{(j-1,j)} \phi' \bar{u}' = \int_{(j-1,j)} \phi(\bar{p} - \bar{u}) \tag{2.4}$$

so that

$$\begin{aligned} \left| \int_{(j-1,j)} \phi' \bar{u}' \right| &= \left| \int_{(j-1,j)} \phi(\bar{p} - \bar{u}) \right| \\ &\leqq (\|(p, q)\|_H + \|B(p, q)\|_H) \|\phi\|_{L^2[(j-1,j)]}, \end{aligned} \tag{2.5}$$

which establishes (2.3) since $B: H \to H$ is bounded. Hence, $u''|_{(a,b)} \in L^2[(a, b)]$ for any $[a, b] \subseteq (j-1, j)$, so by taking complex conjugates in (2.4) we have

$$-\int_{(a,b)} u'' \bar{\phi} = \overline{\int_{(a,b)} \phi' \bar{u}'} = \int_{(a,b)} \bar{\phi}(p - u)$$

for any $\phi \in C_0^\infty[(a, b)]$. Since C_0^∞ is dense in L^2, we have for any $h \in L^2[(a, b)]$

$$\int_{(a,b)} (-u'')\bar{h} = \int_{(a,b)} (p - u)\bar{h}.$$

Thus, any bounded linear functional acting on L^2 gives the same result for $-u''$ as for $p - u$, so $-u'' = p - u$ or $-u'' + u = p$ on (a, b). Since a and b may be chosen arbitrarily as long as $j - 1 < a < b < j$, and $(p - u)|_{(j-1,j)} \in L^2[(j-1, j)]$, we have $-u'' = p - u$ on $(j-1, j)$. Since $j \in \mathbb{Z}^+$ was arbitrary, $-u'' + u = p$ on $(0, \infty)\backslash\mathbb{Z}^+$ and $u'' \in L^2[(0, \infty)\backslash\mathbb{Z}^+]$, which establishes the first equation in (2.1). Since $L^2[(j-1, j)] \subseteq L^1[(j-1, j)]$ it follows that u' is absolutely continuous on $(j-1, j)$, and that $u'(b) - u'(a) = \int_{(a,b)} u''$ for any $(a, b) \subseteq (j-1, j)$. Hence we may let $a \to j-1$ or $b \to j$ to see that $u'(j-1+)$ and $u'(j-)$ are well defined. Also, since u and u'' belong to $L^2[(0, \infty)\backslash\mathbb{Z}^+]$, so does u'. Since $(u, v) \in Y$ it remains only to verify the last two equations in (2.1). Given $j \in \mathbb{Z}^+$, define $(w_j, y_j) \in Y$ by $y_j^k = \delta_{jk}$ and $w_j' = (1/h)\chi_{(j-h,j)}$ on $(j-h, j)$, $w_j' = -(1/h)\chi_{(j,j+h)}$ on $(j, j+h)$, and $w_j' = 0$ otherwise, where $h > 0$ is arbitrary; then $w_j = (1/h)(x - j + h)$ on $(j-h, j)$, $w_j = -(1/h)(x - j - h)$ on $(j, j+h)$, and $w_j = 0$ otherwise. Clearly $(w_j, y_j) \in Y$, and (2.2) yields

$$\begin{aligned} (1/h)\int_{(j-h,j)} u' + (1/h)\int_{(j-h,j)} (x-j+h)u - (1/h)\int_{(j,j+h)} u' \\ -(1/h)\int_{(j,j+h)} (x-j-h)u + v^j \\ = (1/h)\int_{(j-h,j)} (x-j+h)p - (1/h)\int_{(j,j+h)} (x-j-h)p + q^j. \end{aligned} \tag{2.6}$$

Noting that $(1/h)\int_{(j-h,j)} u' = (1/h)[u(j) - u(j-h)] \to u'(j-)$ and $(1/h)\int_{(j,j+h)} u' \to u'(j+)$ as $h \to 0$, that $|(1/h)\int_{(j-h,j)} (x-j+h)u| \leqq \int_{(j-h,j)} |u| \to 0$ as $h \to 0$ and similarly for the remaining integral terms in (2.6), we may let $h \to 0$ in (2.6) to obtain the equation $u'(j-) - u'(j+) + v^j = q^j$, which is equivalent to the second equation in (2.1), and implies that $([\![u']\!]_j)_{j=1}^\infty = v^j - q^j \in l^2$.

The last equation in (2.1) follows as above by taking $w=(1/h)(-x+h)$ on $(0, h)$, $0<h<1$, $w=0$ otherwise, $y^k=0$ for all k, using (2.1) and letting $h\to 0$.

We have shown that $B: H\to X\subseteq H$ so that $B(p, q)$ satisfies $AB(p, q)=(p, q)$ for any $(p, q)\in H$. Also, $B: H\to H$ is bounded and by our construction $BA(u, v)=(u, v)$ for $(u, v)\in X$. Since $B=A^{-1}$ is a bounded operator defined on all of H and $X=\operatorname{dom} A$ is dense in H, it follows that A is closed. (See the discussion in [7, § III.5.2].) We have thus proved the following:

LEMMA 1. *The operator A defined by $A(u, v)=(-u''+u, (-[\![u']\!]_j+v^j)_{j=1}^{\infty})$ with* $\operatorname{dom} A=X$ *is a closed operator from X to H with $A^{-1}: H\to H$ bounded.*

To apply semigroup theory in our nonlinear problem, we will show that A satisfies

$$\|(\lambda-A)^{-1}\|\leqq C/(1+|\lambda|) \quad \text{for } \operatorname{Re}\lambda\leqq 0 \tag{2.7}$$

for some constants $C, \varepsilon>0$, where $\|\ \|$ denotes the operator norm on $\mathcal{B}(H)$. (In fact, (2.7) turns out to hold for $|\arg\lambda|>(\pi/2)-\varepsilon$ for any $\varepsilon\in(0, \pi/2)$, but we will not need that stronger result.) Let $\theta(A)\subseteq\mathbb{C}$ denote the numerical range of A; that is,

$$\theta(A)=\{\langle A(u, v), (u, v)\rangle_H: (u, v)\in\operatorname{dom} A, \|(u, v)\|_H=1\}.$$

Let Γ denote the closure of $\theta(A)$, and let $\Delta=\mathbb{C}\backslash\Gamma$. We shall use the following lemma, which is essentially a special case of Theorem V.3.2 in [7] applied to A.

LEMMA 2. *Suppose that A is closed and Δ is connected. For $\lambda\in\Delta$, $A-\lambda$ has nullity 0 and constant deficiency. If the deficiency is 0, then Δ is contained in the resolvent set of A and*

$$\|(\lambda-A)^{-1}\|\leqq 1/\operatorname{dist}(\lambda, \Gamma) \tag{2.8}$$

where $\operatorname{dist}(\lambda, \Gamma)$ *is the distance from λ to Γ in $\mathbb{C}$.*

To apply Lemma 2, we must calculate the numerical range of A. We have for $(u, v)\in X$ that

$$\begin{aligned}\langle A(u, v), (u, v)\rangle &= \int_{(0,\infty)\backslash\mathbb{Z}^+}(u''+u)\bar{u}+\sum_{j=1}^{\infty}(-[\![u']\!]_j+v^j)\bar{v}^j\\ &= \int_{(0,\infty)\backslash\mathbb{Z}^+}(|u'|^2+|u|^2)+\sum_{j=1}^{\infty}u'(j+)\bar{u}(j+)\\ &\quad -\sum_{j=1}^{\infty}u'(j-)\bar{u}(j-)-\sum_{j=1}^{\infty}[\![u']\!]_j\bar{v}^j+\sum_{j=1}^{\infty}|v^j|^2.\end{aligned}$$

Since $u(j+)=u(j-)=v^j$ for $(u, v)\in X$, the middle three terms on the right side of the second equation drop out, leaving

$$\begin{aligned}\langle A(u, v), (u, v)\rangle &= \int_{(0,\infty)\backslash\mathbb{Z}}(|u'|^2+|u|^2)+\sum_{j=1}^{\infty}|v^j|^2\\ &=\|(u, v)\|_Y^2\geqq\|(u, v)\|_H^2.\end{aligned}$$

Since $\|(u, v)\|_H=1$ in the definition of $\theta(A)$, we have $\theta(A)\subseteq[1, \infty)$ and $\Gamma\subseteq[1, \infty)$. Hence $\Delta=\mathbb{C}\backslash\Gamma$ is connected, and since $A^{-1}\in\mathcal{B}(H)$, A has deficiency zero on Δ. Thus Lemma 2 applies, and (2.7) follows immediately from (2.8) and some elementary geometry.

3. Existence. To solve (1.2) we recast it in terms of the operator A defined in § 2 and apply a result from the theory of abstract evolution equations. First, we rewrite

(1.2) as a pure initial value problem. Let $\sigma(x) \in C_0^\infty[[0,\infty)\backslash\mathbb{Z}^+]$ be such that $\sigma'(0+) = -1$ and $\operatorname{supp}\sigma \subseteq [0, 1/2)$. Let $u = U + \sigma(x)I(t)$ and $v = V$; then (u, v) satisfies

$$\begin{aligned} &u_t - u_{xx} + u = (1-g)u + (g\sigma - \sigma_{xx})I + \sigma I_t,\\ &v_t^j - [\![u_x]\!]_j + v^j = v^j + f(v^j),\\ &(u, v)|_{t=0} = (\phi, \psi) \equiv (\phi_0 + \sigma(x)I(0), \psi_0),\\ &u_x(0+) = 0. \end{aligned} \tag{3.1}$$

Letting $h(x, t) = (g\sigma - \sigma_{xx})I + \sigma I_t$, we may rewrite (3.1) as

$$\begin{aligned} &\frac{d}{dt}(u, v) + A(u, v) = F(t, (u, v)),\\ &(u, v)|_{t=0} = (\phi, \psi), \end{aligned} \tag{3.2}$$

where $F(t, (u, v)) = ((1-g)u + h, (v^j + f(v^j))_{j=1}^\infty)$. We will want $(\phi, \psi) \in \operatorname{dom} A = X$; also, we will want to differentiate (3.2) with respect to t, so we require

$$(\phi_0, \psi_0) \in X, \quad \phi_0'(0+) = I(0), \quad I(t) \in C^3[[0, \infty)]. \tag{3.3}$$

To solve (3.2) we use a form of a result due independently to Sobolevski and Tanabe (see [4, § II.16] and [5]); the present formulation is taken from [3, Thm. 1].

LEMMA 3. *Let A be a closed linear operator on a Banach space E such that* (2.7) *holds. Suppose that $F(t, p)$ is a function on $[0, T_0) \times E$ such that for some constants $\alpha, \eta \in (0, 1)$ and for any $R > 0$ there exists a constant $C(R)$ for which*

$$\|F(t_1, A^{-\alpha}p_1) - F(t_2, A^{-\alpha}p_2)\|_E \leqq C(R)[|t_1 - t_2|^\eta + \|p_1 - p_2\|_E] \tag{3.4}$$

for all $t_1, t_2 \in [0, T_0]$, $p_1, p_2 \in E$ with $\|p_1\|_E, \|p_2\|_E < R$. Then for any $p_0 \in \operatorname{dom} A$ and each $R > \|A^\sigma p_0\|_E$, there exists a $t^* = t^*(R, \|A^\alpha p_0\|_E) > 0$ such that the problem

$$\frac{dp}{dt} + Ap = F(t, p), \qquad p(0) = p_0 \tag{3.5}$$

has a unique solution in $[0, t^*]$. Furthermore, if there exists a constant $R' > 0$ such that for any solution p of (3.5) *in $[0, T_1]$, $T_1 \leqq T_0$, we have $\|Ap\|_E < R'$, then we may choose $R > R'$ and thus apply the local existence assertion of this lemma on $[0, t^*]$, $[t^*, 2t^*]$, and so on until $[0, T_0]$ is exhausted.*

Since the operator A in (3.2) was already shown to be closed and to satisfy (2.7), we need only establish (3.4) for the function F in (3.2) to conclude the local existence of solutions to (1.2). Let $(w_k, y_k) = A^{-\alpha}(u_k, v_k)$ for $k = 1, 2$. If $\|(u_k, v_k)\|_H < R$ for $k = 1, 2$, $|y_k^j| \leqq \|y_k\|_{l^2} \leqq \|(w_k, y_k)\|_H \leqq \|A^{-\alpha}\|R$, so

$$\begin{aligned} \|(f(y_1^j) - f(y_2^j))_{j=1}^\infty\|_{l^2} &\leqq \sup_{|y| < \|A^{-\alpha}\|R} |f'(y)|\,\|y_1 - y_2\|_{l^2}\\ &\leqq C_0(R)\|(w_1 - w_2, y_1 - y_2\|_H\\ &\leqq C_0(R)\|A^{-\alpha}\|\;\|(u_1, v_1) - (u_2, v_2)\|_H. \end{aligned} \tag{3.6}$$

We have

$$\begin{aligned} &\|F(t_1, A^{-\alpha}(u_1, v_1)) - F(t_2, A^{-\alpha}(u_2, v_2))\|_H\\ &\quad = \|F(t_1, (w_1, y_1)) - F(t_2, (w_2, y_2))\|_H\\ &\quad = \|((1-g)(w_1 - w_2) + h(t_1) - h(t_2), (y_1^j - y_2^j + f(y_1^j) - f(y_2^j))_{j=1}^\infty)\|_H\\ &\quad \leqq |1-g|\;\|(w_1 - w_2, 0)\|_H + \|(h(t_1) - h(t_2), 0\|_H\\ &\qquad + \|(0, (y_1^j - y_2^j + f(y_1^j) - f(y_2^j))_{j=1}^\infty)\|_H. \end{aligned} \tag{3.7}$$

Since $\|(w,0)\|_H \leqq \|(w,y)\|_H$, $\|(0,y)\|_H \leqq \|(w,y)\|_H$ and $\|(0,y)\|_H = \|(y^j)_{j=1}^\infty\|_{l^2}$, it follows from (3.6) and (3.7) that

$$\begin{aligned}\|F(t_1, A^{-\alpha}(u_1, v_1)) - F(t_2, A^{-\alpha}(u_2, v_2))\|_H &\leqq \|(h(t_1)-h(t_2), 0)\|_H \\ &\quad + (|1+g| + C_0(R))\|A^{-\alpha}\| \, \|(u_1, y_1) - (u_2, y_2)\|_H.\end{aligned} \tag{3.8}$$

Since $\sigma \in C_0^\infty([0,\infty)\mathbb{Z}^+)$ with supp $\sigma \in [0, 1/2]$ and $I(t) \in C^3([0,\infty))$, (3.4) follows from (3.8) with $\eta \in (0,1)$ arbitrary. Thus, the local existence of solutions to (1.2) is established.

To obtain global existence we must bound $\|A(u,v)\|_H$ for any solution to (3.2). Since only the situation with (ϕ, ψ) real valued is of physical interest, we shall assume that to be the case, so that (u, v) is real valued also. To bound $\|A(u,v)\|_H$ it is sufficient to bound $\|(u,v)\|_H$, $\|(h,0)\|_H$ and $\|(u_t, v_t)\|_H$, since if $\|(u,v)\|_H \leqq M$ then $|v^j| \leqq M$ so by (1.2) $|f(v^j)| \leqq \sup_{|y|<M} |f'(y)| \, |v^j|$ and thus $\|(0, (f(v^j))_{j=1}^\infty\|_H \leqq \sup_{|y|<M} |f'(y)| \, \|(0,v)\|_H$. Because we assume the initial data $(\phi, \psi) \in \operatorname{dom} A$, the proof of Lemma 3 and the smothness of F imply the existence of continuous first and second time derivatives in H for any solution (u, v) of (3.2); see the discussion following Theorem 2 in [5]. We obtain the necessary bounds via a Lyapunov or energy functional; the method is similar to those used in [1], [3], [8]. Let

$$\begin{aligned}E(t) &= \frac{1}{2}(\|(u,v)\|_H^2 + \|(u,v)_t\|_H^2) \\ &= \frac{1}{2}\int_{(0,\infty)\setminus\mathbb{Z}^+} [u^2 + u_t^2] + \frac{1}{2}\sum_{j=1}^\infty [(v_t^j)^2 + (v^j)^2].\end{aligned}$$

We have

$$\begin{aligned}E'(t) &= \int_{(0,\infty)\setminus\mathbb{Z}^+} (uu_t + u_t u_{tt}) + \sum_{j=1}^\infty v_t^j v_{tt}^j + v^j v_t^j \\ &= \int_{(0,\infty)\setminus\mathbb{Z}^+} [u(u_{xx} - gu + h) + u_t(u_{xxt} - gu_t + h_t)] \\ &\quad + \sum_{j=1}^\infty [v_t^j [\![u_{xt}]\!]_j + f'(v^j)(v_t^j)^2 + v^j [\![u_x]\!]_j + f(v^j)v^j] \\ &= -\int_{(0,\infty)\setminus\mathbb{Z}} [u_x^2 + gu^2 + u_{xt}^2 + gu_t^2] \\ &\quad + \int_{(0,\infty)\setminus\mathbb{Z}} [hu + h_t u_t] + \sum_{j=1}^\infty f'(v^j)(v_t^j)^2 + f(v^j)v^j\end{aligned} \tag{3.9}$$

where we have used the fact that (u, v), $(u, v)_t \in X$, so that $u(j+, t) = u(j-, t) = v^j(t)$ and $u_t(j+, t) = u_t(j-, t) = v_t^j(t)$ as in the computation of the numerical range of A following Lemma 2. Using Cauchy's inequality and (1.2) we have from (3.9)

$$\begin{aligned}E'(t) &\leqq -\int_{(0,\infty)\setminus\mathbb{Z}^+} (u_x^2 + u_{xt}^2) + [(1/2) - g]\int_{(0,\infty)\setminus\mathbb{Z}^+} (u^2 + u_t^2) \\ &\quad + (1/2)\int_{(0,\infty)\setminus\mathbb{Z}^+} (h^2 + h_t^2) + f_0 \sum_{j=1}^\infty (v^j)^2 + (v_t^j)^2].\end{aligned} \tag{3.10}$$

From (3.10) and the properties of h, it follows immediately that $E'(t) \leqq K_1 + K_2 E(t)$ for some constants K_1, K_2 that do not depend on (u, v), as long as (u, v) exists. We already have the existence of a local solution to (3.2); so choose $\varepsilon > 0$ such that a solution to (3.2) exists on $[0, T_2)$ for some $T_2 > \varepsilon$. We can now apply Lemma 3 again with initial data $(u(\varepsilon), v(\varepsilon)) \in X$. By our differential inequality for E, we have $E(t) \leqq K_3(t) + E(\varepsilon)\, e^{K_2 t}$ with $K_3(t)$ bounded on any fixed interval in t. By our assumptions on σ and I, $\|(h, 0)\|_H$ is bounded on any fixed interval $[0, T_1]$. Since $2E(t)$ bounds $\|(u, v)\|_H$ and $|(u, v)_t\|_H$, we have as noted above that $\|A(u, v)\|_H$ is bounded on any subinterval of $[\varepsilon, T_0]$ for which the solution exists; the bound depends only on K_2, K_3, and $E(\varepsilon)$. Hence we have the necessary bound for global existence of solutions on $[\varepsilon, T_0]$ and hence on $[0, T_0]$ by Lemma 3. Since $T_0 > 0$ was arbitrary, our solution must exist for all $t > 0$. We have thus proved the following.

THEOREM. *If* $(\phi_0, \psi_0) \in X$ *and conditions* (1.2), (3.3) *hold, then the problem* (1.2) *has a unique solution* (U, V) *for all* $t > 0$.

Acknowledgment. The author wishes to thank Jonathan Bell for much useful discussion and correspondence.

THE BLOW-UP TIME FOR SOLUTIONS OF NONLINEAR HEAT EQUATIONS WITH SMALL DIFFUSION*

AVNER FRIEDMAN† AND ANDREW A. LACEY‡

Abstract. Consider a nonlinear heat equation $u_t - \varepsilon\Delta u = f(u)$ in a cylinder $\{x \in \Omega,\ t > 0\}$, with u vanishing on the lateral boundary and $u = \phi_\varepsilon(x)$ initially ($\phi_\varepsilon \geqq 0$). Denote by T_ε the blow-up time for the solution. Asymptotic estimates are obtained for T_ε as $\varepsilon \to 0$.

Key words. nonlinear heat equation, blow-up of solutions

AMS(MOS) subject classifications. Primary 35K55; secondary 35B25

Introduction. Consider the system

$$u_t - \varepsilon\Delta u = f(u) \qquad (x \in \Omega, t > 0), \tag{0.1}$$

$$u(x,t) = 0 \qquad (x \in \partial\Omega, t > 0), \tag{0.2}$$

$$u(x,0) = \phi(x) \qquad (x \in \Omega) \tag{0.3}$$

where $\phi(x)$ is continuous and nonnegative, $f(s)$ is positive and increasing for $s \geqq 0$, and $1/f$ is integrable. Denote by T_ε the time when the solution blows up. Denote by T_0 the time when the solution of

$$v'(t) = f(v(t)) \qquad (t > 0), \tag{0.4}$$

$$v(0) = \phi(x_0) \tag{0.5}$$

blows up, where $\phi(x_0) = \max_{x \in \bar{\Omega}} \phi(x)$. We are interested in estimating T_ε as $\varepsilon \to 0$. If $\Delta\phi(x_0) < 0$ then we prove that

$$c\varepsilon < T_\varepsilon - T_0 < C\varepsilon \tag{0.6}$$

where c, C are positive constants. More generally, if

$$\phi(x) \sim \phi(x_0) - c_0|x - x_0|^{2\alpha} \quad \text{as } x \to x_0$$

for some positive numbers c_0 and α, then

$$c\varepsilon^\alpha < T_\varepsilon - T_0 < C\varepsilon^\alpha. \tag{0.7}$$

The forms of the constants c, C in (0.6), (0.7) will be given quite explicitly.

We also consider the case where $\phi(x)$ varies with ε. Suppose

$$\phi_\varepsilon(x) = \begin{cases} \phi_0(x) + \Phi\left(\dfrac{x}{\varepsilon^\beta}\right) & \text{if } \dfrac{x}{\varepsilon^\beta} \in B_1, \\ \phi_0(x) & \text{if } \dfrac{x}{\varepsilon^\beta} \notin B_1 \end{cases}$$

where $B_1 = \{y;\ |y| < 1\}$, $\Phi(y) \geqq 0$, $\Phi(y) = 0$ if $y \in \partial B_1$, $\Phi \in C^0(\bar{B}_1)$, and let

$$\phi_0(0) = \max_{\Omega} \phi, \qquad \Phi(0) = \max_{B_1} \Phi.$$

‡ Heriot-Watt University, Edinburgh, Scotland.

Denote by T^* and T_* the blow-up times for the solutions of (0.4), (0.5) corresponding to $\phi_0(0)$ and $\phi_0(0)+\Phi(0)$. Then if $\beta \neq \frac{1}{2}$, $T_\varepsilon \to T_0$ as $\varepsilon \to 0$, where

$$T_0 = T_* \quad \text{if } \beta < \tfrac{1}{2}, \qquad T_0 = T^* \quad \text{if } \beta > \tfrac{1}{2}; \tag{0.8a}$$

also

$$T_* < \varliminf_{\varepsilon \to 0} T_\varepsilon \leqq \varlimsup_{\varepsilon \to 0} T_\varepsilon < T^* \quad \text{if } \beta = \tfrac{1}{2}. \tag{0.8b}$$

Notice that if $\phi_0(0) < \max_\Omega \phi_0$ then the asymptotic behavior of T_ε does not depend on Φ.

The assertion (0.6) is proved in § 1, (0.7) is proved in § 2 and (0.8) is proved in § 3.

We finally mention that recent literature on blow-up of solutions of nonlinear heat equations can be found in [1]-[5] and in the references given there.

1. The estimate (0.6). Let Ω be a bounded domain in $\mathbb{R}^n$ whose boundary $\partial\Omega$ is locally a Lipschitz graph. For any $s > 0$ set

$$\Omega_s = \Omega \times \{0 < t < s\}, \qquad \partial\Omega_s = \partial\Omega \times \{0 < t < s\}$$

and consider the parabolic problem

$$L_\varepsilon u_\varepsilon \equiv \frac{\partial u_\varepsilon}{\partial t} - \varepsilon \Delta u_\varepsilon - f(u_\varepsilon) = 0 \quad \text{in } \Omega_\infty, \tag{1.1}$$

$$u_\varepsilon = 0 \quad \text{on } \partial\Omega_\infty, \tag{1.2}$$

$$u_\varepsilon(x, 0) = \phi(x) \quad \text{for } x \in \Omega \tag{1.3}$$

where

$$\begin{gathered} \phi \in C^2(\Omega) \cap C^0(\bar{\Omega}), \qquad \phi(x) \geqq 0, \\ \phi = 0 \quad \text{on } \partial\Omega \end{gathered} \tag{1.4}$$

and $f(s)$ satisfies

$$\begin{gathered} f(s) > 0, \quad f'(s) > 0, \quad f''(s) \geqq 0 \quad \text{if } s \geqq 0, \\ \int^\infty \frac{ds}{f(s)} < \infty; \end{gathered} \tag{1.5}$$

at the end of § 3 we shall extend all the results to the case where $f(0) = 0$.

It is easily seen that there exists a unique function $\zeta(s)$ and a positive number s_0 such that

$$\begin{gathered} \frac{d\zeta}{ds} = -f(\zeta) \quad \text{if } 0 < s < s_0, \\ \zeta(s) \to \infty \quad \text{if } s \to 0, \qquad \zeta(s_0 - 0) = 0. \end{gathered} \tag{1.6}$$

Clearly

$$\zeta' < 0, \qquad \zeta'' < 0. \tag{1.7}$$

The inverse function ζ^{-1} satisfies

$$(\zeta^{-1})'(s) = -\frac{1}{f(s)}. \tag{1.8}$$

The most interesting examples for f are

$$f(s)=e^s, \text{ and then } \zeta(s)=-\log s,\ \zeta^{-1}(s)=e^{-s}, \tag{1.9}$$

$$\begin{gathered} f(s)=(s+\lambda)^p(\lambda>0, p>1), \text{ and then} \\ \zeta(s)=\alpha s^{-1/(p-1)}-\lambda,\ \zeta^{-1}(s)=\frac{1}{p-1}(s+\lambda)^{1-p} \qquad (\alpha=(p-1)^{-1/(p-1)}); \end{gathered} \tag{1.10}$$

the case $\lambda=0$ is considered at the end of § 3.

For any $\bar{x}\in\Omega$ consider

$$\frac{dv}{dt}=f(v) \quad \text{for } t>0, \qquad v(0)=\phi(\bar{x})$$

and denote the solution by $u_{\bar{x}}(t)$. The solution must blow up in finite time $T_{\bar{x}}$ and

$$u_{\bar{x}}(t)=\zeta(T_{\bar{x}}-t). \tag{1.11}$$

Taking $t=0$ we get $\phi(\bar{x})=\zeta(T_{\bar{x}})$, or

$$T_{\bar{x}}=\zeta^{-1}(\phi(\bar{x})). \tag{1.12}$$

Notation. We denote $T_{\bar{x}}$ by $T(\phi(\bar{x}))$, and we denote the blow-up time for the solution u_ε of (1.1)-(1.3) by T_ε.

THEOREM 1.1. *Let $\phi(x_0)=\max_{x\in\Omega}\phi(x)$, $x_0\in\Omega$. Then*

$$T_\varepsilon \geqq T(\phi(x_0)). \tag{1.13}$$

Proof. The function $v(t)=u_{x_0}(t)$ satisfies

$$v_t-\Delta v=f(v) \quad \text{in } \Omega_{T_{x_0}},$$

and $v\geqq u_\varepsilon$ on the parabolic boundary. Hence, by comparison, $v>u_\varepsilon$ in $\Omega_{T_{x_0}}$. Since $u_\varepsilon\geqq 0$ it follows that u_ε cannot blow up in time smaller than T_{x_0}.

In the sequel we shall obtain a much more refined estimate than (1.13).

THEOREM 1.2. *Let x_0 be any point in Ω such that $\phi(x_0)=\max_{x\in\Omega}\phi(x)$. Then*

$$T_\varepsilon \leqq T(\phi(x_0))+\varepsilon T(\phi(x_0))\frac{|\Delta\phi(x_0)|}{f(\phi(x_0))}+o(\varepsilon) \tag{1.14}$$

as $\varepsilon\to 0$.

Proof. We shall construct a subsolution of the form

$$w(x,t)=\zeta(V(x,t)-t).$$

Using (1.6) and the fact that $\zeta''>0$, we have

$$\begin{aligned} w_t-\varepsilon\Delta w-f(w) &= \zeta'(V-t)(V_t-1-\varepsilon\Delta V)-\varepsilon\zeta''(V-t)|\nabla V|^2-f(\zeta(V-t)) \\ &\leqq -f(\zeta(V-t))(V_t-\varepsilon\Delta V). \end{aligned}$$

Taking

$$V(x,t)=U(x,\varepsilon t)$$

where $U(x,\tau)$ satisfies

$$U_\tau=\Delta U,$$

we conclude that w is a subsolution.

We choose the initial and boundary conditions for U such that

$$(1.15)\qquad \begin{aligned} &U(x,0)=\zeta^{-1}(\phi(x)) \quad \text{if } x\in\Omega,\\ &U(x,\tau)=\frac{\tau}{\varepsilon}+s_0 \quad \text{if } x\in\partial\Omega, \qquad 0<\tau<C\varepsilon \end{aligned}$$

where C is a positive constant. Then

$$\zeta(U(x,0))=\phi(x)=u_\varepsilon(x,0) \quad \text{if } x\in\Omega,$$

$$\zeta\left(U(x,\tau)-\frac{\tau}{\varepsilon}\right)=0 \quad \text{if } x\in\partial\Omega, \quad 0<\tau<C\varepsilon,$$

so that $w=u_\varepsilon$ on the parabolic boundary of Ω_C. The maximum principle then gives

$$(1.16)\qquad u_\varepsilon(x,t)\geqq\zeta(U(x,\varepsilon t)-t) \quad \text{if } t<C.$$

Notice that the boundary values of U are bounded, i.e.,

$$0\leqq U(x,\tau)\leqq C+s_0 \quad \text{if } x\in\partial\Omega, \quad \tau\leqq C\varepsilon.$$

Hence we can write

$$(1.17)\qquad U(x_0,\varepsilon t)=U(x_0,0)+\varepsilon tU_\tau(x_0,0)+o(\varepsilon)$$

where $o(\varepsilon)/\varepsilon\to 0$ as $\varepsilon\to 0$, uniformly in t if $0<t<C$.

The function w blows up at time $\leqq\tilde{t}$ where $\tilde{t}$ satisfies

$$U(x_0,\varepsilon\tilde{t})-\tilde{t}=0.$$

Choosing $C>U(x_0,0)+1$ we see, upon recalling (1.17), that $\tilde{t}$ is determined by

$$\tilde{t}(1-\varepsilon U_\tau(x_0,0))=U(x_0,0)+o(\varepsilon)$$

or, since $U_\tau=\Delta U$,

$$\tilde{t}=U(x_0,0)+\varepsilon U(x_0,0)\Delta U(x_0,0)+o(\varepsilon).$$

In view of (1.16) we also have $T_\varepsilon\leqq\tilde{t}$, and recalling (1.15), (1.12) and the fact that

$$\Delta\zeta^{-1}(\phi(x))=-\frac{\Delta\phi(x)}{f(\phi(x))} \quad \text{at } x=x_0$$

(by (1.18) and $\nabla\phi(x_0)=0$), the assertion (1.14) follows.

THEOREM 1.3. *Let ϕ achieve its maximum at the unique point $x_0\in\Omega$ and suppose that $\Delta\phi(x_0)<0$. Then*

$$(1.18)\qquad T_\varepsilon\geqq T(\phi(x))+\varepsilon\gamma(\phi(x_0))|\Delta\phi(x_0)|+o(\varepsilon)$$

as $\varepsilon\to 0$, where $\gamma(\phi(x_0))$ is defined by

$$(1.19)\qquad \gamma(\phi(x_0))=\max_{0<\lambda<\zeta^{-1}(\phi(x_0))}\lambda/f(\zeta(\zeta^{-1}(\phi(x_0))-\lambda)).$$

Remark 1.1. In case (1.9), the combined estimates (1.14) and (1.18) become

$$(1.20)\qquad \tfrac{1}{4}\varepsilon\, e^{-2\phi(x_0)}|\Delta\phi(x_0)|+o(\varepsilon)\leqq T_\varepsilon\leqq\varepsilon\, e^{-2\phi(x_0)}|\Delta\phi(x_0)|+o(\varepsilon).$$

Proof. Taking $x_0=0$ we first construct a supersolution of the form

$$w=\zeta(\zeta^{-1}(\phi(0))-t)+W(x,t), \qquad 0<t<C$$

where $C \in (0, T(\phi(0)))$ is to be chosen,

$$W(x,t) = Z(x, \varepsilon t)$$

and $Z(x, \tau)$ satisfies

$$\begin{aligned} &Z_\tau = \Delta Z \quad \text{if } x \in \Omega, \quad 0 < \tau < C\varepsilon, \\ &Z(x,0) = \phi(x) - \phi(0) \quad \text{if } x \in \Omega, \\ &Z(x,\tau) = \phi(x) - \phi(0) \quad \text{if } x \in \partial\Omega, \quad 0 < \tau < C\varepsilon. \end{aligned}$$

Clearly $Z \leqq 0$, whence

$$\begin{aligned} L_\varepsilon w &= w_t - \varepsilon \Delta w - f(w) \\ &= f(\zeta(\zeta^{-1}(\phi(0)) - t)) + W_t - \varepsilon \Delta W - f(w) \\ &= f(\zeta(\zeta^{-1}(\phi(0)) - t)) - f(\zeta(\zeta^{-1}(\phi(0)) - t) + W) \geqq 0. \end{aligned}$$

Also

$$w(x,0) = \phi(0) + (\phi(x) - \phi(0)) = u_\varepsilon(x) \quad \text{if } x \in \Omega$$

and

$$w(x,t) = \zeta(\zeta^{-1}(\phi(0)) - t) + \phi(x) = \phi(0) \geqq 0 \quad \text{if } x \in \partial\Omega,$$

since $\zeta(\zeta^{-1}(\phi(0)) - t) \geqq \phi(0)$ and $\phi(x) = 0$ for $x \in \partial\Omega$.

It follows that

$$u_\varepsilon \leqq w \quad \text{if } x \in \Omega, \quad 0 < t < C. \tag{1.21}$$

We now choose μ arbitrarily small and η small enough depending on μ so that

$$-\Delta\phi(x) > -\Delta\phi(0) - \mu \quad \text{if } |x| < \eta.$$

Then

$$Z \leqq (\Delta\phi(0) + \mu)\tau + o(\tau) \quad \text{as } \tau \to 0 \quad \text{for } |x| < \eta,$$

while $Z \leqq 0$ if $|x| \geqq \eta$. It follows that, for $\varepsilon \to 0$,

$$\begin{aligned} u_\varepsilon(x,c) \leqq w(x,C) &= \zeta(\zeta^{-1}(\phi(0)) - C) + W(x,C) \\ &\leqq \zeta(\zeta^{-1}(\phi(0)) - C) + (\Delta\phi(0) + \mu)C + o(\varepsilon). \end{aligned}$$

Denote by $\tilde{u}(x,t)$ the solution of (1.1), (1.2) for $t > C$ with $\tilde{u}(x, C) = w(x, C)$ and denote by $\tilde{T}$ the blow-up time for $\tilde{u}$. From a comparison of the form (1.13),

$$\begin{aligned} T_\varepsilon &\geqq \tilde{T} \geqq C + \zeta^{-1}\{\max_{\Omega} u_\varepsilon(\cdot, C)\} \\ &\geqq C + \zeta^{-1}\{\zeta(\zeta^{-1}(\phi(0)) - C + (\Delta\phi(0) + \mu)\varepsilon C + o(\varepsilon)\} \\ &= C + (\zeta^{-1}(\phi(0)) - C) - \varepsilon C(\Delta\phi(0) + \mu)/f(\zeta(\zeta^{-1}(\phi(0)) - C)) + o(\varepsilon) \quad \text{(by (1.18))} \\ &= T(\phi(0)) - \varepsilon C(\Delta\phi(0) + \mu)/f(\zeta(\zeta^{-1}(\phi(0)) - C)) + o(\varepsilon). \end{aligned}$$

But as this holds for μ arbitrarily small and $\Delta\phi(0) < 0$,

$$T_\varepsilon \geqq T(\phi(0)) + \varepsilon|\Delta\phi(0)|C/f(\zeta(\zeta^{-1}(\phi(0)) - C)) + o(\varepsilon).$$

Choosing $C = C_M \in (0, \zeta^{-1}(\phi(0)))$, which maximizes the coefficient of ε, assertion (1.18) follows with $\gamma(\phi(x_0))$ defined by (1.19).

Remark 1.2. Theorem 1.1 does not require the assumption that $\phi \in C^2(\Omega)$; Theorems 1.2 and 1.3 require only that $\phi \in C^2$ in a neighborhood of x_0.

Remark 1.3. If $\phi(x)$ achieves its maximum at several points x_i, then in assertion (1.18) one should replace $|\Delta\phi(x_0)|$ by $\min_i |\Delta\phi(x_i)|$; the proof is the same as before.

2. The cases $\Delta\phi_0(x_0)=0$ or $-\infty$. Consider the case where at a point x_0 of maximum of ϕ

$$\phi(x) \geqq \phi(x_0) - c_0|x-x_0|^{2\alpha} \quad \text{if } x \to x_0 \tag{2.1}$$

where c_0 is a positive constant and $\alpha > 0$, $\alpha \neq 1$; the assumption that $\phi \in C^2(\Omega)$ made in § 1 is dropped (cf. Remark 1.2). The inequality (2.1) is taken in the usual sense that

$$\liminf_{x \to x_0} \frac{\phi(x)-\phi(x_0)}{|x-x_0|^{2\alpha}} \geqq -c_0.$$

THEOREM 2.1. *If* (2.1) *holds then*

$$T_\varepsilon \leqq T(\phi(x_0)) + \kappa_\alpha c_0 \varepsilon^\alpha \{\zeta^{-1}(\phi(x_0)\}^\alpha / f(\phi(x_0)) + o(\varepsilon^\alpha) \tag{2.2}$$

as $\varepsilon \to 0$, *where* κ_α *is a universal positive constant, defined by* (2.3) *below.*

Proof. We proceed as in the proof of Theorem 1.2. The only difference occurs when we analyze the behavior of the function $U(x_0, \tau)$. Using the relation

$$\int_\Omega \frac{e^{-(|x-\xi|^2/4\tau)}}{(4\pi\tau)^{n/2}} |\xi - x_0|^{2\alpha}\, d\xi = \kappa_\alpha \tau^\alpha + o(\tau^\alpha) \quad \text{as } \tau \to 0 \tag{2.3}$$

in the representation of $U(x_0, \tau)$ by means of Green's function, we get

$$U(x_0, \tau) \leqq \zeta^{-1}(\phi(x_0)) - \kappa_\alpha c_0 \tau^\alpha + o(\tau^\alpha) \quad \text{as } \tau \to 0.$$

The blow-up time for the subsolution w is $\leqq \tilde{t}$ where

$$\tilde{t} = U(x_0, \varepsilon\tilde{t}) \leqq T(\phi(x_0)) + \kappa_\alpha c_0 \zeta^{-1}(\phi(x_0)) \varepsilon^\alpha \tilde{t}^\alpha + o(\tilde{t}^\alpha),$$

from which the assertion (2.2) follows.

We next obtain a lower bound on T_ε, assuming that

$$\phi(x) \leqq \phi(x_0) - c_0|x-x_0|^{2\alpha} \quad \text{as } x \to x_0. \tag{2.4}$$

As before, the assumption $\phi \in C^2(\Omega)$ is dropped.

THEOREM 2.2. *Assume that* ϕ *achieves its maximum at the unique point* x_0 *and that* (2.4) *holds for some* $c_0 > 0$ *and* $\alpha > 0$. *Then*

$$T_\varepsilon \geqq T(\phi(x_0) + \kappa_\alpha c_0 \varepsilon^\alpha \gamma_\alpha(\phi(x_0)) + o(\varepsilon^\alpha) \tag{2.5}$$

as $\varepsilon \to 0$, *where* $\gamma_\alpha(\phi(x_0))$ *is defined by*

$$\gamma_\alpha(\phi(x_0)) = \max_{0<\lambda<\zeta^{-1}(\phi(x_0))} \lambda^\alpha / f(\zeta(\zeta^{-1}(\phi(x_0)) - \lambda)). \tag{2.6}$$

Proof. We proceed as in the proof of Theorem 1.3, modified as in the proof of Theorem 2.1, to obtain the local behavior of Z:

$$Z(x, \tau) = -\kappa_\alpha c_0 \tau^\alpha + o(\tau^\alpha) \quad \text{as } \tau \to 0.$$

The blow-up time for the supersolution $\tilde{u}$, applicable for $T > C$, is

$$\tilde{T} = T(\phi(x_0)) + \kappa_\alpha c_0 \varepsilon^\alpha / f(\zeta(\zeta^{-1}(\phi(x_0)) - C)) + o(\varepsilon^\alpha);$$

the assertions (2.5) and (2.6) now readily follow.

Remark 2.1. If

$$\phi(x) \sim \phi(x_0) - c_0|x-x_0|^\alpha \quad \text{as } x \to x_0$$

then from Theorems 2.1 and 2.2 we obtain

$$T(\phi(x_0)) + \kappa_\alpha c_0 \varepsilon^\alpha \gamma_\alpha(\phi(x_0)) + o(\varepsilon^\alpha) \leqq T_\varepsilon$$
$$\leqq T(\phi(x_0)) + \kappa_\alpha c_0 \varepsilon^\alpha \{\zeta^{-1}(\phi(x_0))\}^\alpha / f(\phi(x_0)) + o(\varepsilon^\alpha).$$

In particular, for the special case $f(s) = e^s$,

$$e^{-\phi(x_0)} + \frac{\alpha^\alpha}{(1+\alpha)^{1+\alpha}} \kappa_\alpha c_0 \varepsilon^\alpha \, e^{-(1+\alpha)\phi(x_0)} + o(\varepsilon^\alpha) \leqq T_\varepsilon$$
$$\leqq e^{-\phi(x_0)} + \kappa_\alpha c_0 \varepsilon^\alpha \, e^{-(1+\alpha)\phi(x_0)} + o(\varepsilon^\alpha).$$

3. Proof of (0.8). In this section we consider the case where ϕ depends on the parameter ε, say $\phi = \phi_\varepsilon$. The function ϕ_ε is a sum of two functions:

$$\phi_\varepsilon(x) = \phi_0(x) + \Phi_\varepsilon(x) \tag{3.1}$$

where

$$\Phi_\varepsilon(x) = \begin{cases} \Phi\left(\dfrac{x}{\varepsilon^\beta}\right) & \text{if } |x| < \varepsilon^\beta, \\ 0 & \text{if } |x| > \varepsilon^\beta, \qquad \beta > 0, \end{cases} \tag{3.2}$$

and

$$\phi_0(0) = \max_{x \in \Omega} \phi(x), \qquad 0 \in \Omega. \tag{3.3}$$

We assume that

$$\begin{gathered} \Phi \in C^0(\bar{B}_1), \quad \Phi \geqq 0, \quad \Phi(0) = \max_{x \in \bar{B}_1} \Phi(x), \\ \Phi = 0 \quad \text{on } \partial B_1, \\ \Phi \in C^2(B_\rho) \quad \text{for some } \rho > 0 \end{gathered} \tag{3.4}$$

where $B_\rho = \{x; |x| < \rho\}$, and set

$$\phi_0 = \phi(0), \qquad \Phi_0 = \Phi(0).$$

To avoid a trivial case we assume that $\Phi_0 > 0$.

Introduce the blow-up times

$$T^* = T(\phi_0), \qquad T_* = T(\phi_0 + \Phi_0); \tag{3.5}$$

clearly $T_* < T^*$.

THEOREM 3.1. (i) *If* $\beta < \frac{1}{2}$ *then* $T_\varepsilon \to T_*$ *as* $\varepsilon \to 0$; (ii) *if* $\beta > \frac{1}{2}$ *then* $T_\varepsilon \to T^*$ *as* $\varepsilon \to 0$; (iii) *if* $\beta = \frac{1}{2}$ *then* $T_0^- \equiv \lim_{\varepsilon \to 0} T_\varepsilon$ *and* $T_0^+ = \overline{\lim}_{\varepsilon \to 0} T_\varepsilon$ *satisfy* $T_* < T_0^- \leqq T_0^+ < T^*$.

Proof. For simplicity consider first the case where $\phi_0 \equiv 0$. Let $\tilde{\Phi}(x)$ be a function satisfying: $\tilde{\Phi}(0) = \Phi(0)$, $\tilde{\Phi} \geqq \Phi_\varepsilon$, $\tilde{\Phi} = 0$ on $\partial\Omega$. By comparison

$$u_{0,\varepsilon} \leqq u_\varepsilon \leqq u_{1,\varepsilon}$$

where $u_{0,\varepsilon}$, $u_{1,\varepsilon}$ are the solutions of (1.1)-(1.3) corresponding to $\phi \equiv 0$ and $\phi \equiv \tilde{\Phi}$ respectively. Since, by Theorems 1.1 and 1.2, the blow-up times $T_{i,\varepsilon}$ corresponding to u_i satisfy

$$T_{0,\varepsilon} \to T^*, \qquad T_{1,\varepsilon} \to T_* \quad \text{as } \varepsilon \to 0,$$

it follows that

$$T_* \leqq \varliminf_{\varepsilon \to 0} T_\varepsilon \leqq \varlimsup_{\varepsilon \to 0} T_\varepsilon \leqq T^*. \tag{3.6}$$

In order to prove (i) it suffices to show that

$$\varlimsup_{\varepsilon \to 0} T_\varepsilon \leqq T_*. \tag{3.7}$$

To do this we construct a subsolution w of the form

$$w(x, t) = \zeta(V(x, t) - t)$$

where

$$V(x, t) = U\left(\frac{x}{\varepsilon^\beta}, \frac{\varepsilon t}{\varepsilon^{2\beta}}\right)$$

and $U(u, \tau)$ satisfies

$$\begin{aligned} &U_\tau = \Delta U \quad \text{if } y \in \mathbb{R}^n, \quad \tau > 0,\\ &\zeta(U(y, 0)) = \Phi(y) \quad \text{if } |y| < 1,\\ &\zeta(U(y, 0)) = 0 \quad \text{if } |y| > 1,\\ &\zeta(U(y, \tau)) = 0 \quad \text{if } |y| = 1. \end{aligned}$$

As in the proof of Theorem 1.2, w is a subsolution and $u_\varepsilon \geqq w$. Hence $T_\varepsilon \leqq \tilde{T}_\varepsilon$ where $\tilde{T}_\varepsilon$ is the blow-up time for w. Further, $\tilde{T}_\varepsilon \leqq \tilde{t}$ where $\tilde{t}$ satisfies

$$\tilde{t} \sim V\left(0, \frac{\varepsilon \tilde{t}}{\varepsilon^{2\beta}}\right) = \zeta^{-1}(\Phi_0) + O(\varepsilon^{1-2\beta})$$

since V_t is continuous about (0, 0). The estimate (3.7) now immediately follows.

To prove (ii) it suffices, in view of (3.6), to show that

$$\varliminf_{\varepsilon \to 0} T_\varepsilon \geqq T^*. \tag{3.8}$$

We proceed similarly to the proof of Theorem 1.3, to construct a supersolution w of the form

$$w = W(x, t) + ta$$

where a is a positive constant,

$$W(x, t) = U\left(\frac{x}{\varepsilon^\beta}, \frac{\varepsilon t}{\varepsilon^{2\beta}}\right)$$

and $U(y, \tau)$ satisfies

$$\begin{aligned} &U_\tau = \Delta U \quad \text{if } y \in \mathbb{R}^n, \quad \tau > 0,\\ &U(y, 0) = \Phi(y) \quad \text{if } |y| < 1,\\ &U(y, 0) = 0 \quad \text{if } |y| > 1. \end{aligned}$$

By the maximum principle $0 \leqq W \leqq \Phi_0$. Hence

$$w_t - \varepsilon \Delta w - f(w) = a - f(W + ta) > 0$$

if $a > 1 + f(\Phi_0)$, $t \leqq b$, provided b is some small positive number. It follows that

$$u_\varepsilon \leqq w \quad \text{in } \Omega_b.$$

Since $U(y, \tau) \leqq C\tau^{-n/2}$, we have

$$w \leqq at + C(t\varepsilon^{1-2\beta})^{-n/2}.$$

Noting that

$$t_0 \equiv \varepsilon^{(2\beta-1)n/(n+2)} < b$$

if ε is small enough, we get

$$u_\varepsilon(x, t_0) \leqq w(x, t_0) < C\varepsilon^{(2\beta-1)n/(n+2)}. \tag{3.9}$$

Using comparison for $t > t_0$, we conclude from (3.9) (by (1.8), (1.9)) that

$$u(x, t) \leqq \zeta(\zeta^{-1}(C\varepsilon^{(2\beta-1)n/(n+2)}) - t + t_0).$$

The right-hand side blows up at time $\sim \tilde{t}$ where

$$\begin{aligned} \tilde{t} &= t_0 + \zeta^{-1}(C\varepsilon^{(2\beta-1)n/(n+2)}) \\ &= t_0 + T^* + (\zeta^{-1})'(0)C\varepsilon^{(2\beta-1)n/(n+2)}. \end{aligned}$$

Consequently

$$T_\varepsilon > T^* + O(\varepsilon^{(2\beta-1)n/(n+2)}),$$

from which (3.8) follows.

To prove (iii) let $v_\varepsilon(x, t) = u(x\sqrt{\varepsilon}, t)$. Then

$$\begin{aligned} &\frac{\partial v_\varepsilon}{\partial t} - \Delta v_\varepsilon = f(v_\varepsilon) \quad \text{if } x \in \Omega_\varepsilon \equiv \frac{1}{\sqrt{\varepsilon}}\Omega, \quad 0 < t < T_\varepsilon, \\ &v_\varepsilon(x, 0) = \Phi(x) \quad \text{if } |x| < 1, \\ &v_\varepsilon = 0 \text{ on the remaining part of the parabolic boundary of } \Omega_\varepsilon \times (0, T_\varepsilon). \end{aligned} \tag{3.10}$$

It is clear that $v_\varepsilon \uparrow W$ where

$$\begin{aligned} &W_t - \Delta W = f(W) \quad \text{in } \mathbb{R}^n x(0, \tilde{T}), \\ &W(x, 0) = \Phi(x) \quad \text{if } |x| < 1, \\ &W(x, 0) = 0 \quad \text{if } |x| > 1 \end{aligned} \tag{3.11}$$

where $\tilde{T}$ is the blow up time of W, and $T_\varepsilon \downarrow T_0$ where $T_0 \geqq \tilde{T}$. We shall first prove that

$$\tilde{T} > T_* \tag{3.12}$$

and, consequently, $T_0 > T_*$.

Let $\Psi(x) \equiv \Psi_0(|x|) \geqq \Phi(x)$ be such that $\Psi_0(1) = 0$, $\Psi_0'(r) \leqq 0$ and $\Psi_0(0) = \Phi_0$. Denote by $\tilde{u}$ the corresponding solution of (3.11) which is obtained by limit of problems analogous to (3.10). Then $\tilde{u}$ is symmetric about the origin, i.e., $\tilde{u} = U(r, t)$, and it is decreasing in r, by the maximum principle applied to $\partial\tilde{u}/\partial r$. Further, by the maximum principle applied to $\partial\tilde{u}/\partial x_i$ we get that $\partial\tilde{u}/\partial x_i < 0$ in $\{x_i > 0\} \times \{t > 0\}$, and

$$\frac{\partial^2 \tilde{u}}{\partial x_i^2} < 0 \quad \text{on } \{x_i = 0\} \times \{t > 0\};$$

in particular,

$$\Delta \tilde{u}(0, t) < 0.$$

It follows that $\tilde{U}(t) \equiv U(0, t)$ satisfies

$$\tilde{U}' < f(\tilde{U}).$$

Hence the blow-up time $\tilde{t}$ of U satisfies

$$\tilde{t} > \zeta^{-1}(\Psi(0)) = \zeta^{-1}(\Phi_0) = T_*.$$

Since $W \leqq \tilde{u}$ (by comparison), it follows that $\tilde{T} \geqq \tilde{t} > T_*$, and (3.12) is thereby proved.

In order to complete the proof of (iii) it remains to show that $T_0 < T_*$. We proceed as in Theorem 1.2 with $\varepsilon = 1$, taking

$$w = \zeta(V(x, t) - t)$$

where

$$V_t = \Delta V \quad \text{if } |x| < 1, \quad t > 0,$$
$$V(x, 0) = \zeta^{-1}(\Phi(x)) \quad \text{if } |x| < 1,$$
$$V(x, t) = 0 \quad \text{if } |x| = 1, \quad t > 0.$$

Then w is a subsolution and $u \geqq w$ in $\{|x| < 1, t > 0\}$. It follows that $T_\varepsilon \leqq \tilde{t}$ where

$$V(0, \tilde{t}) = \tilde{t}. \tag{3.13}$$

Since $\Phi \geqq 0$ we have

$$\zeta^{-1}(\Phi) \leqq \zeta^{-1}(0) = T^*.$$

Also, $\zeta^{-1}(\Phi(0)) < T^*$ since $\Phi(0) > 0$. Applying the strong maximum principle we conclude that

$$V(x, t) < T^* \quad \text{if } |x| < 1, \quad t > 0$$

and, in particular,

$$V(0, \tilde{t}) < T^*. \tag{3.14}$$

Combining (3.13), (3.14) we deduce that $\tilde{t} < T^*$ and, consequently,

$$\overline{\lim_{\varepsilon \to 0}}\, T_\varepsilon \leqq t < T^*.$$

So far we have proved Theorem 3.1 in the case $\phi_0 \equiv 0$. The same proof extends with minor changes to the case $\phi_0 \not\equiv 0$. The only difference is that now we cannot assert that the corresponding function $v_\varepsilon(x, t) = u(x\sqrt{\varepsilon}, t)$ is monotonically increasing to W and that consequently $\lim T_\varepsilon$ exists (if $\phi_\varepsilon(x)$ is decreasing in every radial direction then $v_\varepsilon(x, t)$ is still increasing in ε).

Remark 3.1. If condition (3.3) is not satisfied, then the blow-up times corresponding to ϕ_0 and ϕ_ε coincide, i.e., the "spike" Φ_ε does not affect the blow-up time for small ε.

Remark 3.2. Theorem 3.1 clearly extends to the case of several spikes of the type Φ_ε with different β's.

Remark 3.3. *The case* $f(0)=0$. So far we have assumed that $f(0)>0$ and consequently $s_0<\infty$. This was needed in the proofs for upper bounds on T_ε (e.g. Theorems 1.2 and 2.1). Consider now the case $f(0)=0$ and assume that for all ε small enough

$$f(\phi)+\varepsilon\Delta\phi \geqq 0 \quad \text{in } \Omega. \tag{3.15}$$

Then, by the maximum principle $\partial u_\varepsilon/\partial t \geqq 0$. It follows that for some small ball $B_\rho(x_0)$ with center x_0 and radius ρ we have

$$u_\varepsilon \geqq \tilde{c} > 0 \text{ on the parabolic boundary of } B_\rho(x_0)\times(0, T_\varepsilon). \tag{3.16}$$

We can now modify the proofs of Theorems 1.2 and 2.1 by constructing subsolutions w only in $B_\rho(x_0)\times(0, t)$; since $\zeta^{-1}(\tilde{c})$ is well defined, the proofs can be extended with just trivial changes.

A CRITERION FOR BLOW-UP OF SOLUTIONS TO SEMILINEAR HEAT EQUATIONS*

HAMID BELLOUT†

Abstract. We prove that for the parabolic initial value problem $u_t = \Delta u + \delta f(u)$ there is a finite time blow-up of the solution, provided δ is greater than the upper bound to the spectrum of the steady state problem and (f/f') is concave. An upper bound of the blow-up time is given. The proof is based on a comparison with a subsolution to the parabolic initial value problem.

Key words. blow-up, parabolic, comparison, supersolution

AMS(MOS) subject classification. 35K55

1. The main result. We are interested in the finite time blow-up of the solution to the ·problem:

$$u_t = \Delta u + \delta f(u) \quad \text{in } Q_T, \tag{1.1}$$

$$u(x, 0) = u_0(x) \quad \text{in } D, \tag{1.2}$$

$$\alpha u_\nu + \beta u = 0 \quad \text{on } \Gamma \tag{1.3}$$

where D is a bounded domain in R^n with $C^{2,\mu}$ boundary and

$$Q_T = D \times (0, T), \qquad \Gamma = \partial D \times (0, T),$$

u_0 is a positive continuous function on $\bar{D}$, ν is the outward normal to D, δ is a positive number (which is called the scaled Damköhler number in the combustion theory [3, p. 3]) and α, β are real numbers satisfying

$$\alpha \geqq 0, \quad \beta \geqq 0, \quad \alpha + \beta > 0.$$

Let $R_+ = \{0 < s < \infty\}$. We shall need the following conditions:

$$f \in C^3([0, \infty)), \quad f(0) > 0, \quad f' > 0 \quad \text{on } R_+, \tag{1.4}$$

$$\left(\frac{f}{f'}\right)'' \leqq 0 \quad \text{and} \quad M \equiv \int_0^\infty \frac{ds}{f(s)} < \infty, \tag{1.5}$$

$$\left(\frac{sf'(s)}{f(s)}\right)' \geqq 0 \quad \text{on } R_+. \tag{1.6}$$

By standard results (see, for instance, [7]) there exists a unique positive solution $u(x, t)$ of (1.1)-(1.3) for $0 \leqq t < T$ with either T finite or $+\infty$. If $T < \infty$ then

$$\|u(\cdot, t)\|_{C^0(\bar{D})} \to \infty \quad \text{as } t \to T;$$

in this case we say that there is a finite time blow-up.

Under assumption (1.4), it is well known (Amann [2]) that there is a critical value δ^* such that, for any δ less than δ^*, there is a positive classical solution to the steady state problem:

$$\Delta u + \delta f(u) = 0 \quad \text{in } D, \tag{1.7}$$

$$\alpha u_\nu + \beta u = 0 \quad \text{on } \partial D, \tag{1.8}$$

* Received by the editors June 17, 1985; accepted for publication (in revised form) May 13, 1986.

† Department of Mathematics, Purdue University, West Lafayette, Indiana 47907.

while, for δ greater than δ^*, such a solution does not exist. We will need the following definition.

DEFINITION. The spectrum of (1.7), (1.8) is the set of numbers $\delta > 0$ such that a positive classical solution of (1.7), (1.8) exists.

THEOREM 1.[1] *Assume that f satisfies conditions* (1.4), (1.5), *and that if $\alpha \neq 0$ and $\beta \neq 0$ then f also satisfies* (1.6). *If $\delta > \delta^*$ then the solution of* (1.1)-(1.3) *blows up in finite time T, and*

$$(1.9) \qquad T \leqq \frac{4M(2\delta^* + \delta')}{\delta'(4\delta^* + \delta')} \cdot \left[1 - \left[\frac{4\delta^* + \delta'}{2(2\delta^* + \delta')}\right]^{1/2}\right]^{-1} \quad \textit{where } \delta' = \delta - \delta^*.$$

The proof is given in § 2 and is based on comparison of u with a subsolution to the problem (1.1)-(1.3).

The conditions on f are satisfied by a large class of functions such as e^u and $(A+u)^p$ $(p > 1, A > 0)$, as well as functions with growth like $u \cdot (Lnu)^2$.

A. A. Lacey proved that

(i) If $\delta < \delta^*$ then there is blow-up infinite time if u_0 is not "too small" in the average norm;

(ii) If $\delta > \delta^*$ and δ^* is in the spectrum, then the solution of problem (1.1)-(1.3) blows up in finite time.

Although he does not require that $(f/f')'' \leqq 0$, as we did, his condition that δ^* be in the spectrum has been proved only for "small" dimension n, and then only for the Dirichlet problem (see [4]). Thus, in the case of $(A+u)^p$, he requires that $n \leqq 4$ and, for e^u, that $n \leqq 9$.

2. Auxiliary lemmas. Let

$$g(t) = a^2 t^2,$$

$$a = \frac{\delta'}{M} \frac{4\delta^* + \delta'}{4(2\delta^* + \delta')} \left[1 - \left[\frac{4\delta^* + \delta'}{2(2\delta^* + \delta')}\right]^{1/2}\right],$$

$$T_1 = \frac{1}{a},$$

and consider the problem

$$(2.1) \qquad v_t = \Delta v + \delta g(t) f(v) \quad \text{in } Q_T,$$

$$(2.2) \qquad \alpha v_\nu + \beta v = 0 \quad \text{on } \Gamma,$$

$$(2.3) \qquad v(x, 0) = 0 \quad \text{in } D.$$

The local existence, uniqueness and regularity of a solution v to the problem (2.1)-(2.3) follow from Theorem 6.1 of [7, p. 452]. Furthermore, v ceases to exist only by becoming infinite. We want to prove that v blows up at finite time $\leqq T_1$. Without loss of generality, we can assume that v is finite in $D \times [0, T_1)$; then v is $C^{6,3}_{x,t}(\bar{D} \times [0, T_1))$, and $v_t/f(v)$ is in $C^{2,1}_{x,t}(\bar{D} \times [0, T_1))$.

LEMMA 1. *There holds*

$$\left(\frac{v_t}{f(v)}\right)_t \geqq 0 \quad \forall t \leqq T_1.$$

In the special case $f(s) = s^\gamma$ the lemma is due to F. B. Weissler [8]. However, our method of proof is different.

[1] The author expresses his thanks to Professor A. Friedman for suggesting this theorem.

Proof. Dividing (2.1) by $f(v)$ we get

$$\frac{v_t}{f(v)}=\frac{\Delta v}{f(v)}+\delta g.$$

Taking $w=\int_0^v ds/f(s)$, we have that w satisfies

$$w_t=\Delta w+(\nabla w)^2 f'(v)+\delta g(t). \tag{2.4}$$

Since

$$\begin{aligned}((\nabla w)^2 f'(v))_{tt} &= (2\nabla w_t\cdot\nabla w f'+(\nabla w)^2 w_t f''f)_t\\ &=2\nabla w_{tt}\cdot\nabla w f'+2(\nabla w_t)^2 f'+4\nabla w_t\cdot\nabla w w_t f'f\\ &\quad+(\nabla w)^2 w_{tt} f''f+(\nabla w)^2(w_t)^2 f'''f+(\nabla w)^2(w_t)^2 f''f'f,\end{aligned}$$

if we differentiate (2.4) twice with respect to t, we find that the function

$$z\equiv\left(\frac{v_t}{f(v)}\right)_t=w_{tt}$$

satisfies

$$\begin{aligned}L(z)&\equiv z_t-\Delta z-2f'\cdot\nabla z\cdot\nabla w-f''f(\nabla w)^2 z\\ &=\delta g''+(\nabla w)^2(w_t)^2(f'''f^2+f''f'f)+2(\nabla w_t)^2 f'+4\nabla w_t\cdot\nabla w w_t f''f.\end{aligned}$$

Using

$$|\nabla w_t\cdot\nabla w\cdot w_t|\leqq\frac{1}{2}\left[\varepsilon(\nabla w)^2(w_t)^2+\frac{1}{\varepsilon}(\nabla w_t)^2\right]$$

we obtain

$$L(z)\geqq\delta g''+(\nabla w)^2(w_t)^2(f'''f^2+f''f'f-2\varepsilon f''f)+2(\nabla w_t)^2\left(f'-\frac{1}{\varepsilon}f''f\right).$$

Taking $\varepsilon=(f''f/f')$ we get

$$\begin{aligned}L(z)&\geqq\delta g''+(\nabla w)^2(w_t)^2\left[f'''f^2+f''f'-2\frac{f''^2f^2}{f'}\right]\\ &=\delta g''-(\nabla w)^2 f'^2 f\left(\frac{f}{f'}\right)'',\end{aligned}$$

and by assumption (1.5),

$$L(z)\geqq\delta g''>0. \tag{2.5}$$

From (2.3) and the definition of z we have that

$$z(x,0)=0. \tag{2.6}$$

If $\alpha=0$ (respectively, $\beta=0$) then $z(x,t)=0$ (respectively, $z_\nu(x,t)=0$) on Γ.

Since the coefficients of L remain bounded as long as v is bounded, we conclude by the maximum principle that

$$z(x,t)\geqq 0\quad\forall t<T_1.$$

Consider now the case $\alpha \neq 0$, $\beta \neq 0$ and let $b = \beta/\alpha$. Then from (2.2) we have

$$v_\nu = -bv.$$

Differentiating with respect to t and dividing by f we obtain

$$\frac{v_{\nu t}}{f} = -b\frac{v_t}{f}. \tag{2.7}$$

On the other hand,

$$\left(\frac{v_t}{f}\right)_\nu = \frac{v_{\nu t}}{f} - \frac{v_t v_\nu f'}{f^2} = \frac{v_{\nu t}}{f} + bv \cdot \frac{v_t}{f}\frac{f'}{f},$$

so that

$$\frac{v_{\nu t}}{f} = \left(\frac{v_t}{f}\right)_\nu - bv\frac{v_t}{f}\frac{f'}{f}.$$

Substituting into (2.7) we obtain

$$\left(\frac{v_t}{f}\right)_\nu^e = b\frac{v_t}{f}\left(v\frac{f'}{f} - 1\right).$$

Since $w_t = v_t/f$, we then have

$$w_{\nu t} = bw_t\left(v\frac{f'}{f} - 1\right),$$

and differentiating with respect to t we get

$$\begin{aligned} w_{tt\nu} &= bw_{tt}\left(v\frac{f'}{f} - 1\right) + bw_t\left[w_t f' + vw_t f'' - vw_t\frac{f'^2}{f}\right] \\ &= bw_{tt}\left(v\frac{f'}{f} - 1\right) + b(w_t)^2 f'\left[1 + v\left(\frac{f''}{f'} - \frac{f'}{f}\right)\right]. \end{aligned}$$

Since $z = w_{tt}$, this yields

$$z_\nu = bz\left(v\frac{f'}{f} - 1\right) + b(w_t)^2 f' v \cdot \left(Ln\left(v\frac{f'}{f}\right)\right) \geqq bz\left(v\frac{f'}{f} - 1\right) \tag{2.8}$$

where condition (1.6) was used.

Since $v(x, 0) = 0$, there exists an $\varepsilon > 0$ such that the coefficient of z in (2.8) is negative in $\bar{D} \times (0, \varepsilon)$. From (2.5), (2.6), (2.8) we deduce by the strong maximum principle that $z > 0$ in $\bar{D} \times (0, \varepsilon)$.

Suppose z takes negative values in $D \times (0, T_1)$. Then let t^* be the smallest positive time where z has a zero. By (2.5), $z(x, t^*) > 0$ in the interior of D. Thus $z(x, t^*)$ has a zero at a point $x^* \in \partial D$, and by the maximum principle

$$z_\nu(x^*, t^*) < 0.$$

On the other hand, from (2.8), $z_\nu(x^*, t^*) \geqq 0$, a contradiction. This completes the proof that

$$z \geqq 0 \quad \text{in } D \times (0, T_1).$$

LEMMA 2. *There exists a point x_0 in D such that*

$$v(x_0, t) \to \infty \quad \textit{as } t \to T_1.$$

Proof. Let

$$t_0 = \frac{1}{a}\left[\frac{4\delta^* + \delta'}{2(2\delta^* + \delta')}\right]^{1/2}.$$

Then

$$g(t_0)\left(\delta^* + \frac{\delta'}{2}\right) = \delta^* + \frac{\delta'}{4}$$

and, at $t = t_0$, we have

$$v_t = \Delta v + \left(\delta^* + \frac{\delta'}{4}\right) f(v) + \frac{\delta'}{2} g(t_0) f(v). \tag{2.9}$$

Since $\delta' > 0$, the steady state problem (1.7), (1.8) has no solution for $\delta = \delta^* + (\delta'/4)$. By Theorem 1 of [1] the problem (1.7), (1.8) has no positive subsolution; thus there exists x_0 such that at the point (x_0, t_0),

$$\Delta v + \left(\delta^* + \frac{\delta'}{4}\right) f(v) > 0.$$

From (2.9) we therefore have that

$$\frac{v_t}{f(v)} \geqq \frac{\delta'}{2} g(t_0)$$

at the point (x_0, t_0). Also, by Lemma 1

$$\frac{v_t}{f(v)} \geqq \frac{\delta'}{2} g(t_0) \tag{2.10}$$

at (x_0, t) for any $t \geqq t_0$.

Integrating (2.10) with respect to t, $t \in (t_0, T_1)$, we get

$$\int_0^{v(x_0, T_1)} \frac{ds}{f(s)} \geqq \frac{\delta'}{2} g(t_0)(T_1 - t_0).$$

By the choice of T_1, we have that

$$\frac{\delta'}{2} g(t_0)(T_1 - t_0) = M$$

and thus $v(x_0, t) \to \infty$ as $t \to T_1$.

2.1. Proof of Theorem 1. Since $g(t) \leqq 1$ for $t \leqq T_1$, v satisfies

$$v_t \leqq \Delta v + \delta f(v) \quad \text{in } Q_{T_1}.$$

The function $w = u - v$ satisfies

$$w_t \geqq \Delta w + \gamma w, \quad w(x, 0) = 0, \quad \alpha w_\nu + \beta w = 0,$$

where $\gamma = f'(\theta u + (1 - \theta) v)$, and γ is a bounded function as long as u and v are both bounded. By the maximum principle, we conclude that $w \geqq 0$ and $u \geqq v$. Consequently, u blows up at some time $\leqq T_1$.

Remark. Theorem 1 holds for more general equations such as

$$u_t = \Delta u + \sum_{i=0}^{n} a_i(x) i_{x_i} + \delta f(u) + \gamma |\nabla u|^2 \qquad (\gamma \in R^1);$$

the result of [1], [2] used in the proof of Theorem 1 has been generalized to the quasilinear case in [5].

LIMITING PROFILES IN CONTAMINANT TRANSPORT THROUGH POROUS MEDIA*

C. J. VAN DUYN† AND J. M. DE GRAAF‡

Abstract. In this paper the following degenerate nonlinear diffusion problem is investigated:

$$\beta(u)_t + u_x = u_{xx}, \qquad t>0, \quad -\infty<x<\infty,$$

$$u(x,0) = u_0(x), \qquad -\infty<x<\infty.$$

For a special choice of β ($\beta(u) = u + u^p$, $p>0$) the equation describes the one-dimensional transport of contaminant in a fluid flow through a homogeneous saturated porous medium.

Here the large time behaviour of the solution of the above problem is studied for more general β. It turns out that, depending upon the shape of β (convex or concave) and the values $u_0(-\infty)$ and $u_0(+\infty)$, the solution converges to a travelling wave g of the form $g(x-at)$ or to a function ω^* of the form $\omega^*(x/(t+1))$.

Key words. degenerate diffusion, large time behaviour, porous media

AMS(MOS) subject classifications. Primary 35B40, 35B50

1. Introduction. Consider the flow of an incompressible fluid through a homogeneous saturated porous medium. It is assumed that the flow is steady-state, one-dimensional and directed in what is chosen to be the positive x-axis. Suppose the fluid is contaminated by a solute, whose concentration C is defined as the mass of solute per unit volume of solution.

If no chemical reactions occur between the solute and the surrounding solid part of the porous medium, then the transport of the contaminant is determined by convection, molecular diffusion and mechanical dispersion; see Bear [1] or Freeze and Cherry [5].

But when chemical reactions do occur, this has to be taken into account when describing the transport process. In this reactive case, let S denote the mass of chemical constituent adsorbed on the solid matrix per unit mass of solid. If the boundary conditions and flow conditions are such that both S and C can be assumed constant in planes perpendicular to the x-axis, which implies $C = C(x, t)$ and $S = S(x, t)$, then mass-conservation for the contaminant leads to the equation (see [1])

$$C_t + \frac{\rho_b}{n} S_t + vC_x = DC_{xx} \tag{1.1}$$

where t and x denote, respectively, a time and a space coordinate, the subscripts t and x denote differentiation with respect to these variables, ρ_b is the bulk mass density of the porous medium, n is the porosity, v is the average fluid velocity and D is the coefficient which incorporates molecular diffusion and mechanical dispersion.

In view of our assumptions, all coefficients in (1.1) can be viewed as being constant and positive. The term $(\rho_b/n)S_t$ in (1.1) represents the change in concentration on the porous matrix caused by adsorption or desorption.

The adsorption reactions for contaminant in groundwater are normally considered as being very rapid with respect to the flow velocity. In view of this, the amount of

* Received by the editors November 5, 1984; accepted for publication (in revised form) April 8, 1986.

† Department of Mathematics and Informatics, Delft University of Technology, Delft, The Netherlands.
‡ Mathematical Institute, University of Leiden, Leiden, The Netherlands.

contaminant that is adsorbed by the solid is commonly assumed to be a function of the concentration in the fluid:

$$S = f(C). \tag{1.2}$$

For a particular contaminant and porous material, (1.2) is determined by laboratory experiments. Since these experiments are normally carried out on soil-samples at constant temperature, relations such as (1.2) are known as *isotherms*. An important example is the Freundlich isotherm, when (1.2) is given by

$$S = K_d C^p, \tag{1.3}$$

where K_d and p are positive constants.

Substitution of the isotherm (1.2) into (1.1) leads to the partial differential equation

$$\left(C + \frac{\rho_b}{n} f(C)\right)_t + vC_x = DC_{xx}. \tag{1.4}$$

This contaminant transport equation is frequently encountered in the groundwater literature (e.g. Bolt [2], further references given there). In particular many numerical models, which are often designed for prediction capabilities, are based on (1.4) or on higher dimensional and more complicated versions of it. When the first author was at the Delft Soil Mechanics Laboratory, he did contaminant transport calculations with a model which is based on a numerical approximation of (1.4) with f given by (1.3). He made the following observations.

Let $p \in (0, 1)$ and let C be kept at some positive value far upstream and at zero far downstream. Then the numerical results indicate that when t increases the contaminant profile C converges towards a travelling front, which moves at a constant velocity. However, reversing the boundary conditions, thus keeping C at zero far upstream and at a positive value far downstream, the numerical results show a flattening profile when t increases.

Note that the first choice of boundary conditions describes the situation where polluted groundwater is contaminating the (originally clean) soil. The second choice corresponds to the situation where polluted soil is washed by uncontaminated groundwater.

For values of $p > 1$, the situation seems to be the reverse of the case $p \in (0, 1)$. Then the numerical calculations indicate a travelling front, which increases from zero (upstream) to some constant positive value (downstream) and a flattening profile when the boundary conditions are reversed.

Inspired by these observations, we study in this paper the large time behaviour of solutions of the initial value problem and of a boundary value problem related to (1.4). We do this for more general isotherms f.

Before we proceed, notice that when f is given by (1.3), (1.4) can be rescaled to an equation with only one parameter. For general f this cannot be done. However, the coefficients in (1.4) are constant and positive and remain fixed throughout this paper. Therefore, we set all coefficients in (1.4) equal to one. Furthermore, let C be denoted by u and define

$$\beta(s) = s + f(s) \quad \text{for } s \geqq 0. \tag{1.5}$$

We consider two problems.

The Cauchy problem.

$$\text{I}\begin{cases} (\beta(u))_t + u_x = u_{xx} & \text{in } S_T, \quad (1.6) \\ u(\cdot, 0) = u_0(\cdot) & \text{on } \mathbb{R}, \quad (1.7) \end{cases}$$

where $S_T=\{(x,t):x\in\mathbb{R}, 0<t\leqq T\}$ in which T is some fixed positive number which eventually will tend to infinity.

The Cauchy-Dirichlet problem.

$$\begin{array}{ll} (1.8) & \\ (1.9) & \\ (1.10) & \end{array}\quad \text{II}\begin{cases}(\beta(u))_t+u_x=u_{xx} & \text{in } H_T,\\ u(0,t)=u^0 & 0<t\leqq T,\\ u(\cdot,0)=u_0(\cdot) & \text{on } \mathbb{R}^+,\end{cases}$$

where $H_T=\{(x,t):x\in\mathbb{R}^+, 0<t\leqq T\}$.

With respect to the function β we assume the following hypotheses.

H1. $\beta:[0,M]\to[0,\infty)$ for some $M>0$ satisfies

(i) $\beta\in C([0,M])\cap C^1((0,M])$; $\beta(0)=0$ and $\beta(s)>0$ on $(0,M]$;

(ii) $\beta'(s)>0$ on $(0,M]$ and $\lim_{s\downarrow 0}(1/(\beta'(s)))$ exists;

(iii) β'' exists and is locally Hölder continuous on $(0,M]$ with exponent $\mu\in(0,1)$;

(iv) $(\beta\cdot\beta'')/(\beta')^2\in L^1(0,M]$.

The initial function u_0 from Problem I is chosen such that H2 is satisfied.

H2. $u_0:\mathbb{R}\to[0,M]$ is uniformly Lipschitz continuous on $\mathbb{R}$.

With respect to the initial function u_0 from Problem II we assume the following.

H2$^+$. $u_0:[0,\infty)\to[0,M]$ satisfies

(i) $u_0\in C([0,\infty))$;

(ii) u_0 is uniformly Lipschitz continuous on $\mathbb{R}^+$;

(iii) $u_0(0)=u^0$, where $u^0\in[0,M]$ is constant.

Equation (1.6) is a nonlinear second order equation of parabolic type. Since $\beta'(s)$ may tend to infinity when s tends to zero, this equation can degenerate at points where its solution vanishes. Therefore we cannot expect Problem I and Problem II to have classical solutions for all admissible choices of β and thus we introduce the notion of weak solutions.

Definition I. $u:\bar{S}_T\to\mathbb{R}$ is a weak solution of Problem I if

(i) $u\in C(\bar{S}_T)$ and u is uniformly bounded and nonnegative;

(ii) u has a bounded generalized derivative with respect to x;

(1.11) (iii) $\iint_{S_T}\{\phi_x(u-u_x)+\phi_t\beta(u)\}\,dx\,dt+\int_{\mathbb{R}}\phi(x,0)\beta(u_0(x))\,dx=0$ for all $\phi\in C^1(S_T)$ which vanish for large $|x|$ and $t=T$.

Definition II. $u:\bar{H}_T\to\mathbb{R}$ is a weak solution of Problem II if

(i) $u\in C(\bar{H}_T)$ and u is uniformly bounded and nonnegative;

(ii) $u(0,t)=u^0$ for all $t\in[0,T]$;

(iii) u has a bounded generalized derivative with respect to x;

(1.12) (iv) $\iint_{H_T}\{\phi_x(u-u_x)+\phi_t\beta(u)\}\,dx\,dt+\int_{\mathbb{R}^+}\phi(x,0)\beta(u_0(x))\,dx=0$ for all $\phi\in C^1(\bar{H}_T)$ which vanish for $x=0$, for large x and for $t=T$.

The hypotheses on β and u_0 assure the existence of a unique weak solution of Problem I and Problem II in $\bar{S}_T$ and $\bar{H}_T$, respectively, for every $T>0$. This solution is a classical solution of (1.6) in a neighbourhood of a point in S_T or H_T where $u>0$, see Gilding [7] and Gilding and Peletier [8].

To study the asymptotic behaviour for $t\to\infty$ of solutions of Problem I and Problem II we set $M=1$ in H1, H2 and H2$^+$, for convenience. With respect to the initial function $u_0:\mathbb{R}\to[0,1]$ from the Cauchy problem we assume the following.

H3. The limits $\lim_{x\to-\infty}u_0(x)=u^-$ and $\lim_{x\to+\infty}u_0(x)=u^+$ exist.

In particular we consider the following two cases:

$$\text{BC1: } u^-=0 \quad\text{and}\quad u^+=1,$$

$$\text{BC2: } u^-=1 \quad\text{and}\quad u^+=0.$$

Similarly, the initial function $u_0:[0,\infty)\to[0,1]$ from the Cauchy-Dirichlet problem satisfies:

H3$^+$. The limit $\lim_{x\to+\infty} u_0(x)=u^+$ exists.

As for the Cauchy problem, we consider the following two cases:

$$\text{BC1}^+\text{: } u^0=0 \quad\text{and}\quad u^+=1,$$

$$\text{BC2}^+\text{: } u^0=1 \quad\text{and}\quad u^+=0.$$

In § 2 we study the existence of travelling wave solutions of (1.6). In particular we look for solutions g of the form $g(x-at)$ $(a>0)$ with $g(-\infty)=u^-$ and $g(+\infty)=u^+$. It will turn out that for given u^- and u^+ the existence of such travelling waves depends critically upon the shape of β. In fact we shall show that (1.6) has a travelling wave solution g with $u^-=0$ and $u^+=1$ (respectively $u^-=1$ and $u^+=0$) if and only if $\beta(s)<\beta(1)\cdot s$ for all $s\in(0,1)$ (respectively $\beta(s)>\beta(1)\cdot s$ for all $s\in(0,1)$). This travelling wave solution is unique modulo translations.

The convergence of solutions of Problem I towards these travelling waves was studied by Osher and Ralston in [10]. In fact, making the additional hypothesis

$$(1.13)\qquad \int_{-\infty}^{0} |\beta(u_0(x))-\beta(u^-)|\,dx<\infty \quad\text{and}\quad \int_{0}^{\infty} |\beta(u_0(x))-\beta(u^+)|\,dx<\infty,$$

Osher and Ralston proved the next theorem with semigroup methods.

THEOREM 1. *Let assumptions* H1, H2, H3 *and* (1.13) *hold and suppose* u_0 *and* β *are such that there exists a travelling wave* $g(x-at)$. *Then the solution* u *of Problem* I *converges to* g *in the following sense*:

$$\lim_{t\to\infty}\int_{-\infty}^{\infty} |\beta(u(x,t))-\beta(g(x-y-at))|\,dx=0,$$

where $y\in\mathbb{R}$ *is such that* $\int_{-\infty}^{\infty}\{\beta(u_0(x))-\beta(g(x-y))\}\,dx=0$.

The convergence of solutions of Problem II, with u_0 satisfying BC2$^+$ and with β such that $0<\beta'<\infty$, was studied by Khusnytdinova in [9]. She obtained exponential convergence towards a travelling wave. However, her proof depends critically upon the upper bound of β' on $[0,1]$.

In §§ 3 and 4 we study Problem I when u_0 and β are such that no travelling wave exists. To be definite we shall assume that u_0 satisfies BC1 and that $\beta''<0$. To investigate the behaviour of the solution of this problem as $t\to\infty$ it will be convenient to change to the new independent variables

$$\eta:=\frac{x}{t+1},\qquad \tau:=\log(t+1).$$

Then $u(x,t)$ is a weak solution of Problem I if and only if $w(\eta,\tau):=u(x,t)$ is a weak solution of the transformed problem;

$$P\begin{cases}(\beta(w))_\tau+(1-\eta\beta'(w))w_\eta=e^{-\tau}w_{\eta\eta} & \text{in } S_{T'}, \qquad (1.14)\\ w(\cdot,0)=u_0(\cdot) & \text{on } \mathbb{R} \qquad (1.15)\end{cases}$$

where $S_{T'}=\{(\eta,\tau)\colon \eta\in\mathbb{R}, 0<\tau\leqq T'\}$ and $T'=\log(T+1)$.

Here a weak solution is a function that satisfies the following.

DEFINITION. $w:\bar{S}_{T'}\to\mathbb{R}$ is a weak solution of Problem P if

(i) $w\in C(\bar{S}_{T'})$ and w is uniformly bounded and nonnegative;

(ii) w has a bounded generalized derivative with respect to η;

(1.16) (iii) $\iint_{S_{T'}} \{\beta(w)\phi_\tau + [w - \eta\beta(w) - w_\eta e^{-\tau}]\phi_\eta - \beta(w)\phi\}\, d\eta\, d\tau$
$+\int_{\mathbb{R}} \beta(u_0(\eta))\phi(\eta, 0)\, d\eta = 0$
for all $\phi \in C^1(\bar{S}_{T'})$ which vanish for large $|\eta|$ and for $\tau = T'$.

To prove our results we need the following additional hypotheses on the functions β and u_0.

H4. (i) $\beta \in C^\alpha([0,1])$ for some $\alpha \in (0,1)$;
(ii) $-\beta''/(\beta')^2 \geqq \nu > 0$ on $(0,1)$ for some $\nu > 0$;
(iii) β''' exists and $(\beta''' \cdot \beta')/(\beta'')^2 < 2$ on $(0,1)$.

H5. There exist constants $k_1 > 1/\alpha$, $k_2 > 1$ such that
(1.17) (i) $u_0(x) = O((-x)^{-k_1})$ when $x \to -\infty$,
(1.18) (ii) $u_0(x) - 1 = O(x^{-k_2})$ when $x \to +\infty$.
Here α is the Hölder exponent defined in H4.

We shall show that $w(\eta, \tau)$ converges, as $\tau \to \infty$, to a function w^* which is a solution of the reduced problem:

$$\bar{P}_\infty \begin{cases} (1 - \eta\beta'(w))\dfrac{dw}{d\eta} = 0 & \text{on } \mathbb{R}, \\ w(-\infty) = 0, & w(+\infty) = 1. \end{cases}$$

Using the notation $u^*(x,t) = w^*(\eta)$ we prove the following theorem.

THEOREM 2. *Suppose β and u_0 satisfy* H1 *and* H4, *respectively* H2 *and* H5. *Let $u(x,t)$ be the weak solution of Problem* I. *Then the following estimate holds*:

$$\sup_{x \in \mathbb{R}} |\beta(u(x,t)) - \beta(u^*(x,t))| \leqq (t+1)^{-\alpha/(\alpha+1)}(A_1 + A_2 \log(t+1))^{\alpha/(\alpha+1)}$$

for all $t \geqq 0$, where A_1 and A_2 are positive constants.

Remark. In the case of the Freundlich isotherm, with $K_d = 1$ in (1.3) for convenience, $\beta(s) = s + s^p$. Then when $p \in (0,1)$ Theorem 2 implies that

$$\sup_{x \in \mathbb{R}} |\beta(u(x,t)) - \beta(u^*(x,t))| \leqq (t+1)^{-p/(p+1)}(A_1 + A_2 \log(t+1))^{p/(p+1)}$$

for all $t \geqq 0$.

For this choice of β the function w^* is explicitly known and is given by (3.8) in § 3. In terms of the variables x and t, u^* behaves as in Fig. 1. Indeed this gives a limiting profile, which becomes flatter when t increases.

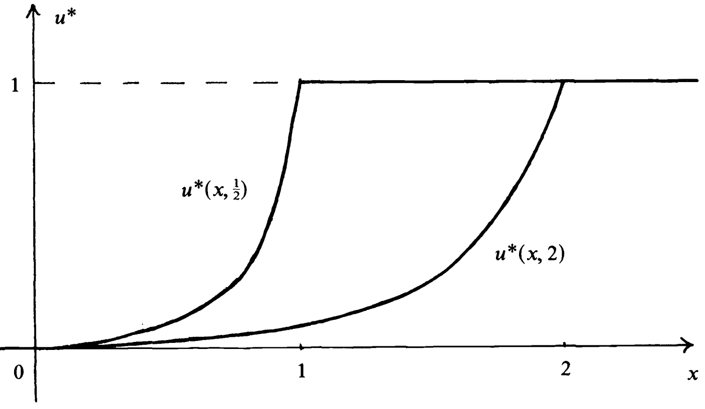

FIG. 1. *The function u^* for the case $\beta(s) = s + s^{1/2}$.*

For the Cauchy-Dirichlet problem we have a similar result. We make the following assumption on the initial function u_0.

H5$^+$. There exists a constant $k_0 > 1/\alpha$ such that

$$u_0(x) - u^+ = O(x^{-k_0}) \quad \text{when } x \to +\infty. \tag{1.19}$$

Then the following theorem can be proved.

THEOREM 3. *Suppose* β *satisfies* H1, H4 *and* u_0 *satisfies* H2$^+$, H5$^+$. *Let* $u(x, t)$ *be the weak solution of Problem* II. *Then the following estimate holds*:

$$\sup_{x\in\mathbb{R}} |\beta(u(x,t)) - \beta(u^*(x,t))| \leqq (t+1)^{-\alpha/(\alpha+1)}(A_1^+ + A_2^+ \log(t+1))^{\alpha/(\alpha+1)}$$

for all $t \geqq 0$, *where* A_1^+ *and* A_2^+ *are positive constants and* $u^*(x, t) = w^*(\eta)$ *with* w^* *the solution of* P_∞.

Finally note that Theorems 2 and 3 only partially answer the questions raised by the numerical computations. In particular, when u_0 satisfies the boundary conditions BC2 or BC2$^+$ and when $\beta(s) = s + s^p$ with $p > 1$, our results do not apply. With respect to the convergence towards travelling waves, it is of interest to generalize the results of Khusnytdinova [9] for the Cauchy-Dirichlet problem and to obtain convergence estimates for the Cauchy problem studied by Osher and Ralston [10]. We leave these questions for future study.

2. Travelling waves. In this section we study the existence and uniqueness of travelling wave solutions of Problem I.

DEFINITION. The pair (a, g) with $a \in \mathbb{R}$ and $g: \mathbb{R} \to [0, 1]$ is called a travelling wave solution of Problem I if

(i) $\beta(g)$ and g' are absolutely continuous on $\mathbb{R}$;

(ii) $a(\beta(g))' - g' = -g''$ a.e. on $\mathbb{R}$;

(iii) $g(-\infty) = 0$; $g(+\infty) = 1$ (in case BC1);
$g(-\infty) = 1$; $g(+\infty) = 0$ (in case BC2).

THEOREM 4. *Let* β *satisfy assumption* H1(i). *Then*

(i) *Problem* I *has a unique travelling wave solution* (a, g) *satisfying* BC1 *if and only if* $\beta(s) < \beta(1) \cdot s$ *for all* $s \in (0, 1)$.

(ii) *Problem* I *has a unique travelling wave solution* (a, g) *satisfying* BC2 *if and only if* $\beta(s) > \beta(1) \cdot s$ *for all* $s \in (0, 1)$.

Remarks. (1) The uniqueness in the theorem must be understood modulo translations. (2) The unique speed a of the travelling wave in the theorem is given by $a = 1/(\beta(1))$.

Proof. We shall only prove part (ii) of the theorem because part (i) can be handled in exactly the same way.

Define $\eta := x - at$. Then if (a, g) is a travelling wave solution of Problem I, a and g satisfy

$$a(\beta(g))' - g' = -g'' \quad \text{a.e. on } \mathbb{R}, \tag{2.1}$$

$$g(-\infty) = 1, \qquad g(+\infty) = 0, \tag{2.2}$$

where primes denote differentiation. Integration of (2.1) yields

$$a\beta(g(\eta)) - g(\eta) + A = -g'(\eta) \quad \text{for } \eta \in \mathbb{R}, \tag{2.3}$$

where A is a constant. Because g' is continuous we have

$$g(\eta + h) - g(\eta) = hg'(\eta + \theta h) = h(-a\beta(g(\eta + \theta h)) + g(\eta + \theta h) - A)$$
$$(0 < \theta(\eta) < 1, h > 0).$$

Taking the limit $\eta \to +\infty$ respectively $\eta \to -\infty$ in this expression we find

$$0 = a\beta(0) - 0 + A \quad \text{and} \quad 0 = a\beta(1) - 1 + A.$$

Since $\beta(0) = 0$, $A = 0$ and hence for the speed a we have

$$a = \frac{1}{\beta(1)}. \tag{2.4}$$

Substituting a and A in (2.3) we derive the following equation for g

$$g' = g - \frac{1}{\beta(1)} \cdot \beta(g) \quad \text{on } \mathbb{R}. \tag{2.5}$$

Since $\beta \in C^1((0, 1])$ it follows from (2.5) that when $g(\eta_0) > 0$ for some $\eta_0 \in \mathbb{R}$, there exists a neighbourhood of the point η_0 where g is a classical solution.

Suppose that

$$\beta(s) > \beta(1) \cdot s \quad \text{on } (0, 1). \tag{$*$}$$

Then (2.5) has a unique (modulo translations) solution given by

$$\int_{1/2}^{g(\eta)} \frac{ds}{s - (\beta(s)/\beta(1))} = \eta,$$

where we have chosen $g(0) = 1/2$.

Note that the solution vanishes for finite $\eta > 0$ if and only if $(\beta(s) - s\beta(1))^{-1} \in L^1(0, \frac{1}{2})$. Furthermore, since $(\beta(s) - s\beta(1))^{-1} \notin L^1(\frac{1}{2}, 1)$, $g(\eta) < 1$ on $\mathbb{R}$ and $g(\eta)$ tends to 1 as $\eta \to -\infty$.

Next suppose that there exist points where ($*$) does not hold. It is clear from (2.5) that if $\beta(\hat{g}) < \beta(1) \cdot \hat{g}$ at some point $\hat{g} \in (0, 1)$, then a travelling wave which satisfies (2.2) cannot exist. If $\beta(\hat{g}) = \beta(1) \cdot \hat{g}$ at some point $\hat{g} \in (0, 1)$, then it follows from the local uniqueness of solutions of (2.5) that the only solution for which $g(\eta_0) = \hat{g}$ at some point $\eta_0 \in \mathbb{R}$ is the constant solution $g = \hat{g}$ and hence (2.2) is not satisfied.

Finally note that if (a, g) is a travelling wave solution, then g is the weak solution of Problem I (for an appropriate choice of u_0). The proof follows by direct calculation. □

Remark. Suppose there exists a $s_0 \in (0, 1)$ where β' does not exist and where $\beta(s_0) = \beta(1) \cdot s_0$. Then if β is Lipschitz continuous on $[0, 1]$, the standard uniqueness result for ordinary differential equations gives that a travelling wave does not exist. If on the other hand $\beta(s) - \beta(1)s = O(|s - s_0|^\sigma)$ with $\sigma \in (0, 1)$, then a travelling wave can still be constructed. However for this case there is no uniqueness.

In the case of the Freundlich isotherm $f(s) = s^p$, we have the following.

Example. Choose $\beta(s) = s + s^p$ with $0 < p < 1$. Then β satisfies H1 and $\beta'' < 0$. Therefore we are in case (ii) of Theorem 4, so we know that a travelling wave solution (a, g) exists with $g(-\infty) = 1$, $g(+\infty) = 0$ and $a = 1/2$.

For this choice of β we can explicitly calculate the travelling wave

$$g(\eta) = \begin{cases} [1 - e^{\lambda(\eta - \eta_0)}]^{1/(1-p)} & \text{if } \eta < \eta_0 \\ 0 & \text{if } \eta \geqq \eta_0 \end{cases} \quad \text{for some } \eta_0,$$

where $\eta = x - t/2$ and $\lambda = (1 - p)/2$.

A trivial consequence of Theorem 4 is the following.

COROLLARY 1. *Suppose β satisfies* H1(i) *and β'' exists and is of one sign. Then*

(i) *Problem* I *has a unique travelling wave solution (a, g) satisfying* BC1 *if and only if $\beta''(s) > 0$ for all $s \in (0, 1)$.*

(ii) *Problem* I *has a unique travelling wave solution (a, g) satisfying* BC2 *if and only if $\beta''(s) < 0$ for all $s \in (0, 1)$.*

3. The function w^*. In this section we study the problem:

$$P_\infty \begin{cases} (1-\eta\beta'(w))\dfrac{dw}{d\eta}=0 & \text{on } \mathbb{R}, \\ w(-\infty)=0, & w(+\infty)=1, \end{cases}$$

where the prime denotes differentiation with respect to the argument of β. The solution of this problem arises in the study of the large time behaviour of solutions of Problem P (or Problem I) in the case where u_0 satisfies BC1 and $\beta''<0$. This will be treated in § 4.

DEFINITION. $w^*:\mathbb{R}\to\mathbb{R}$ is a weak solution of Problem P_∞ if it satisfies

(i) w^* is absolutely continuous on $\mathbb{R}$ and $0 \leqq w^* \leqq 1$;

(ii) $w^*(-\infty)=0$; $w^*(+\infty)=1$;

(iii) $\int_{\mathbb{R}} \{(w^*-\eta\beta(w^*))\phi_\eta - \beta(w^*)\phi\}\, d\eta = 0$
for all $\phi \in C^1(\mathbb{R})$ which vanish for large $|\eta|$.

THEOREM 5. *If β satisfies* H1(i, ii) *and β' is monotone decreasing, then Problem P_∞ has one and only one weak solution.*

Proof. Let w^* be a weak solution of Problem P_∞. Then it follows from (iii) and the continuity of β that

$$\frac{d}{d\eta}(w^*-\eta\beta(w^*)) = -\beta(w^*) \quad \text{on } \mathbb{R} \tag{3.1}$$

and $(w^*-\eta\beta(w^*)) \in C^1(\mathbb{R})$. Integrating (3.1) with respect to η from η_1 to η_2 gives

$$[w^*(\eta_2)-\eta_2\beta(w^*(\eta_2))]-[w^*(\eta_1)-\eta_1\beta(w^*(\eta_1))] = -\int_{\eta_1}^{\eta_2} \beta(w^*(s))\, ds. \tag{3.2}$$

Suppose that $w^*(\eta_1)=w^*(\eta_2)$ and $w^*(\eta)>w^*(\eta_1)$ on (η_1, η_2) (respectively $w^*(\eta) < w^*(\eta_1)$ on (η_1, η_2)). Then (3.2) yields

$$(\eta_2-\eta_1)\beta(w^*(\eta_1)) = \int_{\eta_1}^{\eta_2} \beta(w^*(s))\, ds,$$

which gives a contradiction. This means that w^* is nondecreasing, i.e.,

$$\frac{dw^*}{d\eta} \geqq 0 \quad \text{a.e. on } \mathbb{R}. \tag{3.3}$$

Next we assume that $w^*(\eta_0)>0$ for some $\eta_0<0$. Then $w^*>0$ in a neighbourhood N of η_0 with $N \subset \mathbb{R}^-$. Using the smoothness of β in (3.1) it follows that

$$(1-\eta\beta'(w^*))\frac{dw^*}{d\eta}=0 \quad \text{a.e. in } N.$$

But $1-\eta\beta'(w^*)>1$ in N. Therefore $(dw^*)/d\eta=0$ a.e. in N, which implies that $w^* \equiv 0$ on $\overline{\mathbb{R}^-}$.

Define

$$\eta^* := \sup\{\eta \in \mathbb{R}\colon w^*(\eta) = 0\}. \tag{3.4}$$

Then $\eta^* \geqq 0$ and w^* satisfies

$$w^*(\eta)\begin{cases} =0 & \text{if } \eta \leqq \eta^*, \\ >0 & \text{if } \eta > \eta^*. \end{cases} \tag{3.5}$$

Furthermore

$$(1 - \eta\beta'(w^*))\frac{dw^*}{d\eta} = 0 \quad \text{a.e. on } (\eta^*, \infty). \tag{3.6}$$

Finally we show that w^* is strictly increasing when $0 < w^* < 1$. Suppose not; then there exist points $\eta^* < \eta_1 < \eta_2 < \eta_3 < \eta_4$ such that $(dw^*)/d\eta > 0$ a.e. on $(\eta_1, \eta_2) \cup (\eta_3, \eta_4)$, and $w^*(\eta) \equiv \alpha_0 > 0$ on $[\eta_2, \eta_3]$. Then from (3.6) we have

$$\frac{1}{\eta_2} = \beta'(w^*(\eta_2)) = \beta'(\alpha_0) = \beta'(w^*(\eta_3)) = \frac{1}{\eta_3},$$

which proves the assertion.

Thus if $\tilde{\eta}$ is such that $1 - \tilde{\eta}\beta'(1) = 0$, we may conclude that a weak solution of Problem P_∞ is of the form

$$w^*(\eta)\begin{cases} =0 & \text{on } (-\infty, \eta^*], \\ \text{satisfies } 1 - \eta\beta'(w^*) = 0 & \text{on } (\eta^*, \tilde{\eta}), \\ =1 & \text{on } [\tilde{\eta}, \infty). \end{cases} \tag{3.7}$$ □

Remark. The number η^* in (3.4) is given by

$$\eta^* = \lim_{s \downarrow 0} \frac{1}{\beta'(s)}.$$

Example. In the case $\beta(s) = s + s^p$ with $0 < p < 1$ we can calculate w^* explicitly and find

$$w^*(\eta) = \begin{cases} 0 & \text{if } \eta \leqq 0, \\ \left(\dfrac{p\eta}{1-\eta}\right)^{1/(1-p)} & \text{if } 0 < \eta < \dfrac{1}{1+p}, \\ 1 & \text{if } \eta \geqq \dfrac{1}{1+p}. \end{cases} \tag{3.8}$$

4. Convergence to the function $u^*(x, t)$ for the Cauchy problem. In this section we study the asymptotic behaviour as $t \to \infty$ of the solution $u(x, t)$ of Problem I when u_0 satisfies BC1 and $\beta'' < 0$. From the corollary in § 2 we know that Problem I does not have a travelling wave solution in this case.

Throughout this section we assume that β satisfies H1 and H4 and u_0 satisfies H2 and H5.

Set

$$\eta = \frac{x}{t+1} \quad \text{and} \quad \tau = \log(t+1) \tag{4.1}$$

and consider the transformed problem

$$P\begin{cases}(\beta(w))_\tau+(1-\eta\beta'(w))w_\eta=e^{-\tau}w_{\eta\eta} & \text{in } S_T,\\ w(\cdot,0)=u_0(\cdot) & \text{on } \mathbb{R}.\end{cases}$$

The main result of this section is the following.

PROPOSITION 1. *Let $w(\eta,\tau)$ be the weak solution of Problem P with β satisfying* H1, H4 *and u_0 satisfying* H2, H5. *Let $w^*(\eta)$ be the weak solution of Problem P_∞. Then the following integral estimate holds*:

$$\int_{-\infty}^{\infty}|\beta(w(\eta,\tau))-\beta(w^*(\eta))|\,d\eta\leqq(C_1+C_2\tau)\,e^{-\tau} \tag{4.2}$$

for all $\tau\in[0,T']$, where C_1 and C_2 are positive constants.

Proof. The proof consists of two parts. In the first part we approximate the initial function u_0 by a sequence of smooth positive functions $\{u_{0n}\}$. Then we consider the family of problems $\{P_n\}$ obtained from Problem P by using u_{0n} as the initial function. Next we show that the classical solution w_n of the corresponding Problem P_n converges towards a function w_n^* as $\tau\to\infty$, where w_n^* is an approximation of w^*.

In the second part we let n tend to infinity and obtain the desired integral estimate (4.2).

Without loss of generality we may assume that u_0 is nondecreasing. In the case where u_0 is nonmonotone, two nondecreasing functions ψ_1 and ψ_2 can always be found such that $\psi_1\leqq u_0\leqq\psi_2$ on $\mathbb{R}$. Then if Proposition 1 holds for the monotone initial functions ψ_1 and ψ_2, it follows by a maximum principle argument (see [7]) that the integral estimate (4.2) also holds in the case of arbitrary initial functions u_0.

Part 1. Because the initial function u_0 is uniformly Lipschitz continuous and nondecreasing on $\mathbb{R}$ we can construct a sequence of smooth functions $\{u_{0n}\}_{n=1}^{\infty}$ such that $u_{0n}\to u_0$ as $n\to\infty$, uniformly on $\mathbb{R}$, and where every function u_{0n} satisfies

(i) $u_{0n}\in C^\infty(\mathbb{R})$ and $0\leqq u_{0n}'\leqq M^*$ (for some constant $M^*>0$, independent of n),

(ii) $u_{0n}(-\infty)=1/n$; $u_{0n}(+\infty)=1$.

Now consider for each $n\in\mathbb{N}$ the approximate problem:

$$P_n\begin{cases}(\beta(w))_\tau+(1-\eta\beta'(w))w_\eta=e^{-\tau}w_{\eta\eta} & \text{in } S_T,\\ w(\cdot,0)=u_{0n}(\cdot) & \text{on } \mathbb{R}.\end{cases} \tag{4.3}$$

This problem has a unique solution $w_n\in C^{3+\mu}(\bar{S}_{T'})$, with $\mu\in(0,1)$ as given in H1(iii), and $1/n\leqq w_n\leqq 1$. This follows directly from the observation that w_n is the transformed of u_n, where u_n is the unique classical solution of Problem I with initial function u_{0n} (see e.g. van Duyn and Ye [4]).

We want to show that w_n tends to an approximation of w^* as $\tau\to\infty$, where this approximation is defined by

$$w_n^*=\max\left\{w^*,\frac{1}{n}\right\},\qquad n\in\mathbb{N}. \tag{4.4}$$

Note that the function w_n^* satisfies

$$\begin{aligned}&(1-\eta\beta'(w_n^*))\frac{dw_n^*}{d\eta}=0\quad\text{a.e. on }\mathbb{R},\\ &w_n^*(-\infty)=\frac{1}{n},\qquad w_n^*(+\infty)=1.\end{aligned} \tag{4.5}$$

In order to prove the convergence of w_n to w_n^* we need the following lemma.

LEMMA 1. *There exists a constant $M_0 > 0$ such that for all $n \in \mathbb{N}$*

$$0 \leqq w_{n\eta} \leqq M_0 \quad \text{in } S_{T'}.$$

Proof. Differentiate (4.3) with respect to η. Then $v := w_{n\eta}$ satisfies the following problem;

$$P'_n \begin{cases} \beta'(w_n)v_\tau + (1-\eta\beta'(w_n))v_\eta + \left\{ -\dfrac{\beta''(w_n)}{\beta'(w_n)} v - \beta'(w_n) \right\} v \\ \qquad + \dfrac{\beta''(w_n)}{\beta'(w_n)} e^{-\tau} v v_\eta = e^{-\tau} v_{\eta\eta} \quad \text{in } S_{T'}, \\ v(\cdot, 0) = u'_{0n}(\cdot) \qquad\qquad \text{on } \mathbb{R}. \end{cases}$$

It is known that $0 \leqq u'_{0n} \leqq M^*$. Then obviously $\underline{v} \equiv 0$ is a subsolution for Problem P'_n. Furthermore the function $\bar{v} \equiv M_0$, with $M_0 = \max\{M^*, 1/\nu\}$, is a supersolution for Problem P'_n. This follows from H4(ii). Then Cosner [3, Lemma 1] implies that $0 \leqq w_{n\eta} \leqq M_0$, where the constant M_0 does not depend on n and τ.

To investigate the asymptotic behaviour of w_n for large $|\eta|$ we construct a time-independent sub- and supersolution.

LEMMA 2. (i) *There exist constants $\gamma > 0$, $1 < k < k_2$, $\eta_0 > 1$ such that the function $\underline{s}_n(\eta)$, for each $n \in \mathbb{N}$ defined by*

$$\underline{s}_n(\eta) := \begin{cases} \dfrac{1}{n}, & \eta \leqq \eta_0 \\ \max\left\{\dfrac{1}{n}, 1 - \gamma(\eta - \eta_0)^{-k}\right\}, & \eta > \eta_0, \end{cases} \tag{4.6}$$

satisfies: $\underline{s}_n$ *is continuous on* $\mathbb{R}$ *and* $w_n(\cdot, \tau) \geqq \underline{s}_n(\cdot)$ *on* $\mathbb{R}$ *for all* $0 \leqq \tau \leqq T'$ *and for all* $n \in \mathbb{N}$.

(ii) *There exist constants $\tilde{\gamma} > 0$, $1/\alpha < \tilde{k} < k_1$, $\eta_1 < -1$ such that the function $\bar{s}_n(\eta)$, for each $n \in \mathbb{N}$ defined by*

$$\bar{s}_n(\eta) := \begin{cases} 1, & \eta \geqq \eta_1, \\ \min\left\{1, \tilde{\gamma}(-\eta + \eta_1)^{-\tilde{k}} + \dfrac{1}{n}\right\}, & \eta < \eta_1, \end{cases} \tag{4.7}$$

satisfies: $\bar{s}_n$ *is continuous on* $\mathbb{R}$ *and* $w_n(\cdot, \tau) \leqq \bar{s}_n(\cdot)$ *on* $\mathbb{R}$ *for all* $0 \leqq \tau \leqq T'$ *and for all* $n \in \mathbb{N}$.

Proof. For each $n \in \mathbb{N}$ the approximating initial functions u_{0n}, used in Problem P_n, are given by

$$u_{0n}(x) = \int_{\mathbb{R}} \rho_n(x-y) u_0^+(y)\, dy.$$

Here $u_0^+ = \max\{u_0, 1/n\}$ and $\rho_n(x) = n\rho(nx)$, where $\rho \in C^\infty(\mathbb{R})$ is such that $\operatorname{Supp} \rho = [-1, 1]$, $\rho(x) \geqq 0$ on $\mathbb{R}$ and $\|\rho\|_{L^1(\mathbb{R})} = 1$.

Below we use the following property of the functions u_{0n}: for any increasing function f defined on $\mathbb{R}$, let $f^+ = \max\{f, 1/n\}$. Then for each $x_0 \geqq 1$ we have:

(a) If $u_0 \geqq f$ on $\mathbb{R}$, then $u_{0n}(x) \geqq f^+(x - x_0)$ for all $n \in \mathbb{N}$ and for all $x \in \mathbb{R}$;

(b) If $u_0 \leqq f$ on $\mathbb{R}$, then $u_{0n}(x) \leqq f^+(x + x_0)$ for all $n \in \mathbb{N}$ and for all $x \in \mathbb{R}$.

We shall only prove part (i) of Lemma 2. The proof of part (ii) is almost identical and is therefore omitted.

Choose constants $\gamma > 0$, $k > 1$, $\hat{\eta} \geqq (\beta'(1))^{-1}(1 + (k+1)\gamma^{-1/k})$ such that $\mu_0(\eta) \geqq 1 - \gamma(\eta - \hat{\eta})^{-k}$ for $\eta > \hat{\eta}$. Because μ_0 satisfies H5 this is possible if we choose $k < k_2$.

Next let $\eta^* = \hat{\eta} + \gamma^{1/k}$ and define

$$\underline{s}(\eta) := \begin{cases} 0, & \eta \leqq \eta^*, \\ 1 - \gamma(\eta - \hat{\eta})^{-k}, & \eta > \eta^*. \end{cases}$$

From property (a) we know that there exists a constant $\xi_0 > 1$ such that $u_{0n}(\eta) \geqq \underline{s}(\eta - \xi_0)$ on $\mathbb{R}$. Thus if we choose in (4.6) $\eta_0 = \hat{\eta} + \xi_0$, then $u_{0n}(\eta) \geqq \underline{s}_n(\eta)$ on $\mathbb{R}$. Furthermore if

$$\mathscr{L}u := (\beta(u))_\tau + (1 - \eta\beta'(u))u_\eta - e^{-\tau}u_{\eta\eta},$$

then an elementary computation shows that $\mathscr{L}\underline{s}_n \leqq 0$ for $\eta > \bar{\eta}$. Applying [3, Lemma 1] to the difference $w_n - \underline{s}_n$, part (i) of the lemma follows immediately. □

Thus Lemma 2 gives

$$\underline{s}_n(\cdot) \leqq w_n(\cdot, \tau) \leqq \bar{s}_n(\cdot) \quad \text{on } \mathbb{R} \tag{4.8}$$

for all $\tau \in [0, T']$ and for all $n \in \mathbb{N}$.

From (4.8) and H1(i) we may now conclude that $(\beta(w_n(\cdot, \tau)) - \beta(w_n^*(\cdot))) \in L^1(\mathbb{R})$ for all $\tau \in [0, T']$.

To estimate

$$\|\beta(w_n(\tau)) - \beta(w_n^*)\|_{L^1(\mathbb{R})} := \int_{-\infty}^{\infty} |\beta(w_n(\eta, \tau)) - \beta(w_n^*(\eta))| \, d\eta$$

it will be convenient to consider the following auxiliary problem:

$$\tilde{P}_n \begin{cases} (\beta(w))_\tau + (1 - \eta\beta'(w))w_\eta = e^{-\tau}w_{\eta\eta} & \text{in } H^{\tilde{\eta}}_{T'}, \\ w(\tilde{\eta}, \tau) = 1, \qquad 0 < \tau \leqq T', \\ w(\cdot, 0) = \tilde{u}_{0n}(\cdot) \quad \text{on } (-\infty, \tilde{\eta}), \end{cases}$$

where $H^{\tilde{\eta}}_{T'} = \{(\eta, \tau)\colon \eta \in (-\infty, \tilde{\eta}),\ 0 < \tau \leqq T'\}$. In this problem $\tilde{\eta}$ is chosen such that $w^*(\tilde{\eta}) = 1$ and $w^*(\eta) < 1$ if $\eta < \tilde{\eta}$, thus $\tilde{\eta} = 1/\beta'(1)$ (see § 3). The function $\tilde{u}_{0n}$ is given by $\tilde{u}_{0n} = \max\{u_{0n}, w_n^*\}$.

We want to transform Problem $\tilde{P}_n$ into one in which the differential equation has bounded coefficients and in which the boundary condition is essentially unchanged. To this end we set

$$y = (\eta - \tilde{\eta})\, e^\tau \quad \text{and} \quad t = e^\tau - 1.$$

Then $w(\eta, \tau)$ is a classical solution of Problem $\tilde{P}_n$ if and only if $h(y, t) := w(\eta, \tau)$ is a classical solution of the problem

$$\begin{aligned} &(\beta(h))_t + (h - \tilde{\eta}\beta(h))_y = h_{yy} \quad \text{in } H_T^- = (-\infty, 0) \times (0, T], \\ &h(0, t) = 1, \qquad 0 < t \leqq T, \\ &h(y, 0) = \tilde{u}_{0n}(y + \tilde{\eta}) \quad \text{on } (-\infty, 0). \end{aligned}$$

Now this problem has a unique classical solution $h_n \in C^{2,1}(H_T^-) \cap C(\overline{H_T^-})$ (see e.g. [7]). Then $v_n(\eta, \tau) := h_n(y, t)$ is the unique solution of Problem $\tilde{P}_n$ such that $v_n \in C^{2,1}(H^{\tilde{\eta}}_{T'}) \cap (\overline{H^{\tilde{\eta}}_{T'}})$ and $1/n \leqq v_n \leqq 1$.

If we define the function $\tilde{w}_n$ as

$$\tilde{w}_n(\eta, \tau) := \begin{cases} v_n(\eta, \tau) & \eta < \tilde{\eta}, \\ 1 & \eta \geqq \tilde{\eta}, \end{cases}$$

then by a maximum principle argument we have

$$\tilde{w}_n \geqq w_n \quad \text{in } \overline{S_{T'}}. \tag{4.9}$$

Furthermore it can be proved by direct calculation that w_n^* is a subsolution for Problem $\tilde{P}_n$, where we use the fact that β satisfies H4(iii). Also it can be shown that $\bar{s}_n(\eta)$ is a supersolution for Problem $\tilde{P}_n$. Therefore

$$w_n^*(\cdot) \leqq \tilde{w}_n(\cdot, \tau) \leqq \bar{s}_n(\cdot) \quad \text{on } \mathbb{R} \tag{4.10}$$

for all $\tau \in [0, T']$ and for all $n \in \mathbb{N}$.

Now it follows from (4.8), (4.10) and the definition of $\underline{s}_n$, $\bar{s}_n$ that $(\beta(\tilde{w}_n(\cdot, \tau)) - \beta(w_n(\cdot, \tau))) \in L^1(\mathbb{R})$ and $(\beta(\tilde{w}_n(\cdot, \tau)) - \beta(w_n^*(\cdot))) \in L^1(\mathbb{R})$ for all $\tau \in [0, T']$.

Since

$$\begin{aligned} \|\beta(w_n(\tau)) - \beta(w_n^*)\|_{L^1(\mathbb{R})} \leqq \|\beta(w_n(\tau)) - \beta(\tilde{w}_n(\tau))\|_{L^1(\mathbb{R})} \\ + \|\beta(\tilde{w}_n(\tau)) - \beta(w_n^*)\|_{L^1(\mathbb{R})}, \end{aligned} \tag{4.11}$$

it is sufficient to find estimates for the norms on the right-hand side of (4.11).

LEMMA 3. (i) $\|\beta(w_n(\tau)) - \beta(\tilde{w}_n(\tau))\|_{L^1(\mathbb{R})} \leqq (B_0 + B_1\tau)\, e^{-\tau}$ *for all* $\tau \in [0, T']$, *where* B_0 *and* B_1 *are constants independent of* n. (ii) $\|\beta(\tilde{w}_n(\tau)) - \beta(w_n^*)\|_{L^1(\mathbb{R})} \leqq (B_2 + B_3\tau)\, e^{-\tau}$ *for all* $\tau \in [0, T']$, *where* B_2 *and* B_3 *are constants independent of* n.

Proof. (i) The function $\tilde{w}_n$ satisfies

$$(\beta(\tilde{w}_n))_\tau + (1 - \eta\beta'(\tilde{w}_n))\tilde{w}_{n\eta} = e^{-\tau}\tilde{w}_{n\eta\eta} \quad \text{on } \mathbb{R}|\{\tilde{\eta}\} \times (0, T'].$$

The function w_n satisfies

$$(\beta(w_n))_\tau + (1 - \eta\beta'(w_n))w_{n\eta} = e^{-\tau}w_{n\eta\eta} \quad \text{on } \mathbb{R} \times (0, T'].$$

Subtraction and integration with respect to η from $-\infty$ to ∞ yields

$$\begin{aligned} &\frac{d}{d\tau}\|\beta(\tilde{w}_n) - \beta(w_n)\|_{L^1(\mathbb{R})} + (\tilde{w}_n - w_n)|_{\eta=-\infty}^{\infty} \\ &\qquad - \eta\{\beta(\tilde{w}_n) - \beta(w_n)\}|_{\eta=-\infty}^{\infty} + \|\beta(\tilde{w}_n) - \beta(w_n)\|_{L^1(\mathbb{R})} \\ &\quad = e^{-\tau}\{(\tilde{w}_n - w_n)_\eta|_{\eta=-\infty}^{\tilde{\eta}-} + (\tilde{w}_n - w_n)_\eta|_{\eta=\tilde{\eta}+}^{\infty}\}. \end{aligned} \tag{4.12}$$

Because (4.8) and (4.10) hold and because k, $\tilde{k} > 1$ in (4.6), (4.7) respectively, the third term on the left-hand side of (4.12) vanishes. Then, using Lemma 1 and Lemma 2, we find

$$\begin{aligned} &\frac{d}{d\tau}\|\beta(\tilde{w}_n) - \beta(w_n)\|_{L^1(\mathbb{R})} + \|\beta(\tilde{w}_n) - \beta(w_n)\|_{L^1(\mathbb{R})} \\ &\quad \leqq e^{-\tau}\{\tilde{w}_{n\eta}(\tilde{\eta}^-, \tau) - \tilde{w}_{n\eta}(-\infty, \tau) + C_0\} \end{aligned} \tag{4.13}$$

for all $\tau \in (0, T']$, where the constant C_0 does not depend on n. For each $n \in \mathbb{N}$ the solution v_n of Problem $\tilde{P}_n$ satisfies $v_{n\eta}(\tilde{\eta}, \tau) \geqq 0$ for $\tau \in [0, T']$ and $v_{n\eta}(\eta, 0) \geqq 0$ for $\eta \in (-\infty, \tilde{\eta}]$, except possibly at the points where $u_{0n} = w_n^*$. It then follows from a maximum principle argument that $v_{n\eta} = \tilde{w}_{n\eta} \geqq 0$ in $H_{T'}^{\tilde{\eta}}$. Moreover, using (4.10), we see that

$$\tilde{w}_{n\eta}(\tilde{\eta}^-, \tau) \leqq \frac{dw_n^*(\tilde{\eta}^-)}{d\eta}$$

for all $\tau \in (0, T']$ and for all $n \in \mathbb{N}$.

Therefore the right-hand side of (4.13) can be estimated uniformly with respect to n, which implies that there exists a constant C such that

$$\frac{d}{d\tau}\|\beta(\tilde{w}_n)-\beta(w_n)\|_{L^1(\mathbb{R})}+\|\beta(\tilde{w}_n)-\beta(w_n)\|_{L^1(\mathbb{R})}\leqq Ce^{-\tau} \tag{4.14}$$

for all $\tau\in(0, T']$ and for all $n\in\mathbb{N}$.

From this, inequality (i) follows immediately.

(ii) The proof of this inequality is almost identical and will be omitted. □

Next use (4.11) and Lemma 3 to find

$$\|\beta(w_n(\tau))-\beta(w_n^*)\|_{L^1(\mathbb{R})}\leqq(C_1+C_2\tau)\,e^{-\tau} \tag{4.15}$$

for all $\tau\in[0, T']$, where C_1 and C_2 are constants independent of n.

Part 2. The convergence of $\{w_n\}$ to the weak solution w of Problem P as $n\to\infty$.

From Lemma 1 it follows that

$$|w_n(\eta_1, \tau)-w_n(\eta_2, \tau)|\leqq M_0|\eta_1-\eta_2| \tag{4.16}$$

for all (η_1, τ), $(\eta_2, \tau)\in\bar{S}_{T'}$ and for all $n\in\mathbb{N}$.

Next consider the sequence of rectangles $D_m:=(-m, m)\times(0, T')$ with $m\in\mathbb{N}$. Then by a result of Gilding [6] about the Hölder continuity of solutions of parabolic equations

$$|w_n(\eta, \tau_1)-w_n(\eta, \tau_2)|\leqq C(m)|\tau_1-\tau_2|^{1/2} \quad \text{in } D_m \tag{4.17}$$

for all $n\in\mathbb{N}$ and for all (η, τ_1) and $(\eta, \tau_2)\in D_m$ with $|\tau_1-\tau_2|\leqq 1$. Thus, for each $m\geqq 1$, the set of functions $\{w_n(\eta, \tau)\}$ is bounded ($0\leqq w_n(\eta, \tau)\leqq 1$ in $\bar{S}_{T'}$) and equicontinuous on D_m. Hence the Arzela–Ascoli Theorem implies the existence of a subsequence $\{w_{n_k}\}$ and a function $w_m\in C(\bar{D}_m)$ such that $w_{n_k}\to w_m$ as $n_k\to\infty$, uniformly on $\bar{D}_m$. Then, by a diagonal process, it follows that there exists a function w, defined on $\bar{S}_{T'}$, and a convergent subsequence $\{w_{n_j}(\eta, \tau)\}$ such that $w_{n_j}\to w$ as $j\to\infty$, pointwise on $\bar{S}_{T'}$. Since this convergence is uniform on every bounded subset of $\bar{S}_{T'}$, the limit function w is continuous on $\bar{S}_{T'}$.

To show that the function $w(\eta, \tau)$ is a weak solution of Problem P we must check properties (i), (ii) and (iii) in the definition of weak solution. Because the proof is standard (see e.g. [4]), we shall omit it here.

Finally we derive the integral estimate (4.2).

Because $|\beta(w_n)-\beta(w_n^*)|\leqq(\beta(\tilde{w}_n)-\beta(w_n))+(\beta(\tilde{w}_n)-\beta(w_n^*))$ and (4.8), (4.10) hold, we have

$$|\beta(w_n)-\beta(w_n^*)|\leqq\begin{cases}\beta(1)-\beta(\underline{s}_n), & \eta\geqq\tilde{\eta},\\ 2\left\{\beta(\bar{s}_n)-\beta\left(\dfrac{1}{n}\right)\right\}, & \eta<\tilde{\eta}.\end{cases} \tag{4.18}$$

Using the assumptions H1(i), H4(i) on β and the definition of $\underline{s}_n$, $\bar{s}_n$ (given in (4.6) and (4.7)) it is clear that the right-hand side of (4.18) can be estimated, uniformly in n, by an L^1-function which is $O(\eta^{-k})$ for $\eta\to\infty$ and $O((-\eta)^{-\bar{k}\alpha})$ for $\eta\to-\infty$. Then if we take the limit $n\to\infty$ in the estimates in Lemma 3 and use the Dominated Convergence Theorem, we find

$$\|\beta(w(\tau))-\beta(w^*)\|_{L^1(\mathbb{R})}\leqq(C_1+C_2\tau)\,e^{-\tau}$$

for all $\tau\in[0, T']$, where C_1 and C_2 are positive constants independent of n.

This proves Proposition 1. □

To derive a pointwise estimate from the integral estimate (4.2) we need the following lemma.

LEMMA 4. *Let ϕ be a function defined on $\mathbb{R}$, satisfying $\phi(x) \geqq 0$ on $\mathbb{R}$ and $|\phi(x) - \phi(x_0)| \leqq A|x - x_0|^\alpha$ on $\mathbb{R}$, where A and α are positive constants. Furthermore, suppose*

$$\int_{-\infty}^{\infty} \phi(x)\, dx \leqq l.$$

Then

$$\sup_{x \in \mathbb{R}} \phi(x) \leqq l^{\alpha/(\alpha+1)} A^{1/(\alpha+1)} \left(\frac{\alpha+1}{\alpha}\right)^{\alpha/(\alpha+1)}.$$

Proof. The proof is similar to the proof of Lemma 3 in Gilding and Peletier [8]. □

PROPOSITION 2. *Let β and u_0 satisfy* H1, H4, *respectively,* H2, H5. *Then if $w(\eta, \tau)$ is the weak solution of Problem P and $w^*(\eta)$ is the weak solution of Problem P_∞, the following estimate holds*:

$$\sup_{\eta \in \mathbb{R}} |\beta(w(\eta, \tau)) - \beta(w^*(\eta))| \leqq [e^{-\tau}(A_1 + A_2 \tau)]^{\alpha/(\alpha+1)}$$

for all $\tau \in [0, T']$, where A_1 and A_2 are positive constants.

Proof. Because w is uniformly Lipschitz continuous with respect to η, which is a direct consequence of (4.16), and β satisfies H4(i), we have

$$|\beta(w(\eta, \tau)) - \beta(w(\eta_0, \tau))| \leqq C|\eta - \eta_0|^\alpha$$

for η, $\eta_0 \in \mathbb{R}$ and for all $\tau \in [0, T']$, where C is a positive constant. The same is true for the function w^*

$$|\beta(w^*(\eta)) - \beta(w^*(\eta_0))| \leqq C^*|\eta - \eta_0|^\alpha$$

for η, $\eta_0 \in \mathbb{R}$ and for some positive constant C^*.

Now apply Lemma 4 with $\phi(\eta) = |\beta(w(\eta, \tau)) - \beta(w^*(\eta))|$ and Proposition 2 is proved. □

Finally, let $u^*(x, t) = w^*(\eta)$, where w^* is the weak solution of Problem P_∞.

Since the result of Proposition 2 does not depend on T', Theorem 2 follows immediately.

5. Convergence to the function $u^*(x, t)$ for the Cauchy–Dirichlet problem.

In this section we give results on the asymptotic behaviour of the solution of the Cauchy-Dirichlet problem II when u_0 satisfies the boundary condition $\mathrm{BC1}^+$ and $\beta'' < 0$.

Furthermore we assume that β satisfies H1, H4 and u_0 satisfies $\mathrm{H2}^+$, $\mathrm{H5}^+$.

As in § 4 we use transformation (4.1) and consider the transformed problem:

$$P^+ \begin{cases} (\beta(w))_\tau + (1 - \eta\beta'(w))w_\eta = e^{-\tau} w_{\eta\eta} & \text{in } H_{T'}, \\ w(0, \tau) = 0, \quad 0 < \tau \leqq T', \\ w(\cdot, 0) = u_0(\cdot) & \text{on } \mathbb{R}^+, \end{cases}$$

where $H_{T'} = \{(\eta, \tau) : \eta \in \mathbb{R}^+, 0 < \tau \leqq T'\}$, $T' = \log(T + 1)$ and $w(\eta, \tau) = u(x, t)$.

The reduced problem

$$P_\infty^+ \begin{cases} (1 - \eta\beta'(w)) \dfrac{dw}{d\eta} = 0 \quad \text{on } \mathbb{R}^+, \\ w(0) = 0, \quad w(+\infty) = 1 \end{cases}$$

has a unique weak solution w^* (as in § 3).

The following proposition holds.

PROPOSITION 3. *Let w be the weak solution of Problem P^+ and let w^* be the weak solution of Problem P^+_∞. Suppose β satisfies* H1, H4 *and u_0 satisfies* H2$^+$, H5$^+$. *Then*

$$\sup_{\eta\in\mathbb{R}^+} |\beta(w(\eta,\tau))-\beta(w^*(\eta))| \leqq [e^{-\tau}(A1^+ + A2^+\tau)]^{\alpha/(\alpha+1)}$$

for all $\tau\in[0, T']$, where $A1^+$ and $A2^+$ are positive constants.

Proof. The proof is essentially the same as the proof of Proposition 2. The main difference is the following. When introducing the approximate Problem P_n in $H_{T'}$, with solution w_n, one needs a uniform bound with respect to n on $w_{n\eta}$ at $\eta=0$. This bound is obtained by observing that

$$\frac{1}{n} \leqq w_n(\eta,\tau) \leqq \min\left\{\frac{1}{n} + M\eta, 1\right\}$$

for all $(\eta, \tau)\in H_{T'}$ and for all $n\in\mathbb{N}$. Here the constant M is chosen such that $M=\max\{M^*, (1/\tilde{\eta})\}$, where $\tilde{\eta}=1/(\beta'(1))$ as defined in § 3. The rest of the proof will be omitted. □

Again define $u^*(x,t)=w^*(\eta)$; then an immediate consequence of Proposition 3 is Theorem 3.

Acknowledgment. The authors are greatly indebted to Professor L. A. Peletier for his assistance with this work.

GLOBAL EXISTENCE AND BOUNDEDNESS IN REACTION-DIFFUSION SYSTEMS*

SELWYN L. HOLLIS†, ROBERT H. MARTIN, JR.† AND MICHEL PIERRE‡

Abstract. In many applications, systems of reaction-diffusion equations arise in which the nature of the nonlinearity in the reaction terms renders ineffective the standard techniques (such as invariant sets and differential inequalities) for establishing global existence, boundedness, and asymptotic behavior of solutions. In this paper we prove global existence and uniform boundedness for a class of reaction-diffusion systems involving two unknowns in which an a priori bound is available for one component as long as solutions exist. Among this class of systems is the so-called Brusselator, a model from the study of instabilities in chemical processes.

Key words. reaction-diffusion systems, global existence, stability

AMS (MOS) subject classifications. 35K45, 35B35

Introduction. It is well known that the addition of diffusion in a reaction system can cause the loss of stability properties of equilibrium solutions. This follows from the fact that the subtraction of a positive diagonal matrix from a square matrix can increase the maximum real part of the eigenvalues. In general, it does not seem to be known whether adding diffusion in a reaction system (or changing the diffusion coefficients in a reaction-diffusion system) can affect the global existence of solutions. In some situations general results on invariant sets and differential inequalities may be applied to establish global existence as well as estimate the growth of solutions. However, the class of equations under consideration here cannot be effectively analyzed by these general methods.

A typical type of system that can be studied with the methods of this paper is a reaction-diffusion equation of the form

$$u_t = d_1\Delta u - uv^\beta, \qquad v_t = d_2\Delta v + uv^\beta \tag{1}$$

with various homogeneous boundary conditions and nonnegative initial data, where Ω is a bounded region in $\mathbb{R}^n$, Δ is the Laplacian, $\beta \geqq 1$, and d_1, $d_2 > 0$. N. Alikakos [1] established global existence and $\mathscr{L}^\infty$-bounds of solutions when $1 \leqq \beta < (n+2)/n$. K. Masuda [8] shows that solutions to this system exist globally for every $\beta \geqq 1$ and, in addition, shows that the solutions converge as $t \to \infty$. One should note that the global existence assertion is immediate if $\beta = 1$ and also if $d_1 = d_2$ (for if $d_1 = d_2$ and $w \equiv u + v$, then $w_t = d_1\Delta w$, and it easily follows that u and v remain uniformly bounded since $u, v \geqq 0$). On the other hand, if $d_1 \neq d_2$, the global boundedness is not obvious; one can even show that there is no global $\mathscr{L}^\infty$ estimate in terms of $\|u_0\|_\infty$ and $\|v_0\|_\infty$ for t large if $d_2 = 0$ (see § 5).

A second illustration is the Brusselator, a model of a certain chemical morphogenetic process due to Turing [12], which has the form

$$\begin{aligned} &u_t = d_1\Delta u - uv^2 + Bv, && \\ &v_t = d_2\Delta v + uv^2 - (B+1)v + A, && x \in \Omega, \quad t > 0, \\ &u(x,t) = B/A,\ v(x,t) = A, && t > 0, \quad x \in \partial\Omega \end{aligned} \tag{2}$$

with nonnegative initial data where A, B, d_1 and d_2 are positive constants. This system is discussed for $\Omega=(0,1)$ in Prigogine and Nicolis [10]. Except for inhomogenous boundary conditions, (2) is very similar to (1) with $\beta=2$. In [6], H. Lange proved that solutions to (2) with $\Omega=(0,1)$ exist globally, *provided* that the diffusion coefficients satisfy

$$(d_1-d_2)^2/(4d_1d_2)<[1+B^2/(4A^2)]^{-1}.$$

Observe that this result may be regarded as a perturbation of the routinely deduced fact that nonnegative solutions to (2) exist globally when $d_1=d_2$ (for if $d_1=d_2$ and $w\equiv u+v$, then $w_t=d_1w_{xx}+A-v\leqq d_1w_{xx}+A$). Auchmuty and Nicolis [2] proved the global existence of solutions to (2) for spatial dimension 1 and arbitrary d_1, $d_2>0$. A proof of global existence and boundedness for solutions of (2) with Neumann boundary conditions; d_1, $d_2>0$; and spatial dimension $n\leqq 3$ may be found in Rothe [11]. Our results show that nonnegative solutions to (2) exist globally and remain uniformly bounded for the stated boundary conditions, arbitrary spatial dimensions, and d_1, $d_2>0$.

The present paper is organized as follows: 1, The main results; 2, Semigroup formulation and local existence; 3, Preliminary estimates; 4, Proof of the theorems; 5, An example and a counterexample.

1. The main results. Throughout this paper it is assumed that Ω is a bounded domain in $\mathbb{R}^n$ with smooth boundary $\partial\Omega$. Also, Δ is the Laplacian operator on Ω and $\partial/\partial n$ denotes the outward normal derivative on $\partial\Omega$. We consider the reaction-diffusion system

$$(1.1)\qquad \begin{array}{lll} \text{(a)} & \begin{array}{l} u_t=d_1\Delta u+f(t,u,v),\\[4pt] v_t=d_2\Delta v+g(t,u,v),\end{array} & x\in\Omega,\quad t>0,\\[12pt] \text{(b)} & \begin{array}{l} \alpha_1u+(1-\alpha_1)\dfrac{\partial u}{\partial n}=\beta_1,\\[8pt] \alpha_2v+(1-\alpha_2)\dfrac{\partial v}{\partial n}=\beta_2,\end{array} & x\in\partial\Omega,\quad t>0,\\[12pt] \text{(c)} & u=u_0,\ v=v_0, & x\in\Omega,\quad t=0\end{array}$$

where the following basic hypotheses are assumed to hold:

(H1) d_1, d_2, α_1, α_2, β_1 and β_2 are constants with $d_1, d_2>0$; β_1, $\beta_2\geqq 0$; and either $0<\alpha_1$, $\alpha_2<1$, $\alpha_1=\alpha_2=1$, or $\alpha_1=\alpha_2=0$. Also, $\beta_1=\beta_2=0$ if $\alpha_1=\alpha_2=0$;

(H2) f and g are continuously differentiable functions from $[0,\infty)^3$ into $\mathbb{R}$ with $f(t,0,\eta)\geqq 0$ and $g(t,\xi,0)\geqq 0$ for all t, ξ, $\eta\geqq 0$;

(H3) Both u_0 and v_0 are measurable on Ω and there is an $M_0>0$ such that $0\leqq u_0(x)$, $v_0(x)\leqq M_0$ for all $x\in\Omega$.

PROPOSITION 1. *Suppose that* (H1)-(H3) *are satisfied. Then* (1.1) *has a unique, noncontinuable* (*classical*) *solution* (u,v) *on* $\Omega\times[0,T^*)$, *and there are continuous functions* N_1, $N_2:[0,T^*)\to[0,\infty)$ *such that*

$$(1.2)\qquad 0\leqq u(x,t)\leqq N_1(t),\qquad 0\leqq v(x,t)\leqq N_2(t)\quad \text{for } (x,t)\in\Omega\times[0,T^*).$$

Moreover, if $T^*<\infty$ *then*

$$(1.3)\qquad \limsup_{t\uparrow T^*}\ \sup_{x\in\Omega}\{|u(x,t)|+|v(x,t)|\}=\infty.$$

This local existence result follows from the basic existence theory for abstract semilinear differential equations (see, e.g., Henry [4] or Pazy [9]). Since some modifications of these results are needed, the ideas of the proof are included in § 2. In general, (H1)-(H3) are not sufficient to insure that solutions to (1.1) exist for all $t \geqq 0$. The purpose of this paper is to give sufficient conditions guaranteeing that $T^* = \infty$ in Proposition 1. In addition, we establish a result on the uniform boundedness of solutions on $\Omega \times [0, \infty)$.

THEOREM 1. *In addition to* (H1)-(H3) *suppose that*

(H4) *The function* N_1 *in* (1.2) *is bounded if* $T^* < \infty$;

(H5) *There is a* $\gamma \geqq 1$ *and a continuous* $L_0: [0, \infty)^2 \to [0, \infty)$ *such that* $|g(t, \xi, \eta)| \leqq L_0(t, r)(1+\eta)^\gamma$ *for all* $t, \xi, \eta \geqq 0$ *with* $\xi \leqq r$;

(H6) *There is a continuous* $\mu_0: [0, \infty)^2 \to [0, \infty)$ *such that* $f(t, \xi, \eta) + g(t, \xi, \eta) \leqq \mu_0(t, r)$ *for all* $t, \xi, \eta \geqq 0$ *with* $\xi \leqq r$.

Then the solution (u, v) *exists on* $\Omega \times [0, \infty)$ *and* (1.2) *holds with* $T^* = \infty$.

Remark 1. Condition (H4) says that in each bounded t interval, $u(\cdot, t)$ remains uniformly bounded so long as the solution to (1.1) exists. This is the case, for example, if $f(t, \xi, \eta) \leqq \mu_1(t)\xi + \mu_2(t)$ for all $t, \xi, \eta \geqq 0$, where $\mu_1, \mu_2: [0, \infty) \to [0, \infty)$ are continuous.

THEOREM 2. *In addition to the suppositions in Theorem* 1, *suppose that there is an* $\bar{N}_1 > 0$ *and for each* $r > 0$ *there are numbers* $L_\infty(r)$ *and* $\mu_\infty(r)$ *such that*

$$N_1(t) \leqq \bar{N}_1, \quad L_0(t, r) \leqq L_\infty(r), \quad \mu_0(t, r) \leqq \mu_\infty(r) \quad \textit{for all } t \geqq 0.$$

If $\alpha_2 = 0$, *assume also that* $\mu_\infty(r) \equiv 0$. *Then, there is an* $\bar{N}_2$ *such that* $N_2(t) \leqq \bar{N}_2$ *for all* $t \geqq 0$, *and so the solution to* (1.1) *is uniformly bounded on* $\Omega \times [0, \infty)$.

2. Semigroup formulation and local existence. For each $p \in (1, \infty)$ and $j \in \{1, 2\}$ define $A_{j,p}$ on $\mathscr{L}^p(\Omega)$ by

$$\begin{aligned} &A_{j,p}w = d_j \Delta w \quad \text{for } w \in \mathscr{D}(A_{j,p}), \quad \text{and} \\ &\mathscr{D}(A_{j,p}) = \left\{ w \in W^{2,p}(\Omega) \colon \alpha_j w + (1-\alpha_j)\frac{\partial w}{\partial n} = 0 \text{ on } \partial\Omega \right\} \end{aligned} \tag{2.1}$$

where $W^{2,p}(\Omega)$ is the usual Sobolev space and d_j, α_j are as in (H1). It is well known that $A_{j,p}$ generates a compact, analytic semigroup $\mathscr{T}_{j,p} = \{\mathscr{T}_{j,p}(t) \colon t \geqq 0\}$ of bounded linear operators on $\mathscr{L}^p(\Omega)$, and that

$$|\mathscr{T}_{j,p}(t)w|_p \leqq e^{\omega t}|w|_p \quad \text{for } t \geqq 0, \quad w \in \mathscr{L}^p(\Omega) \tag{2.2}$$

where $\omega < 0$ if $\alpha_j > 0$, $\omega = 0$ if $\alpha_j = 0$, and

$$|w|_p \equiv \left[\int_\Omega |w(x)|^p \, dx\right]^{1/p}.$$

For each $\alpha > 0$ and $\lambda > \omega$ the fractional powers $(\lambda I - A_{j,p})^{-\alpha}$ exist and are injective, bounded linear operators on $\mathscr{L}^p(\Omega)$ (see Pazy [9]). For each $\alpha > 0$ define $B_{j,p}^{-\alpha} = (-A_{j,p})^{-\alpha}$ if $\alpha_j > 0$, $B_{j,p}^{-\alpha} = (I - A_{j,p})^{-\alpha}$ if $\alpha_j = 0$, and $B_{j,p}^{\alpha} = (B_{j,p}^{-\alpha})^{-1}$. Recall that $\mathscr{D}(B_{j,p}^{\alpha})$ is a Banach space with the graph norm $|w|_\alpha = |B_{j,p}^{\alpha} w|_p$, and that, for $\alpha > \beta \geqq 0$, $\mathscr{D}(B_{j,p}^{\alpha})$ is a dense subspace of $\mathscr{D}(B_{j,p}^{\beta})$ with the inclusion $\mathscr{D}(B_{j,p}^{\alpha}) \subset \mathscr{D}(B_{j,p}^{\beta})$ compact (we use the convention $\mathscr{D}(B_{j,p}^{0}) = \mathscr{L}^p(\Omega)$). Also (see Henry [4, p. 40]),

$$\begin{aligned} &\text{if } \alpha > n/(2p) \text{ then } \mathscr{D}(B_{j,p}^{\alpha}) \subset \mathscr{L}^\infty(\Omega), \text{ and} \\ &|w|_\infty \leqq M_{\alpha,p}|B_{j,p}^{\alpha} w|_p \text{ for all } w \in \mathscr{D}(B_{j,p}^{\alpha}). \end{aligned} \tag{2.3}$$

In addition, the following properties are satisfied by $\mathcal{T}_{j,p}$ and $B_{j,p}^{\alpha}$; a proof can be found in Pazy [9, p. 74].

LEMMA 1. *Suppose that $\mathcal{T}_{j,p}$ and $B_{j,p}^{\alpha}$ are as above. Then*

(i) *$\mathcal{T}_{j,p}(t)$: $\mathcal{L}^p(\Omega)\to\mathcal{D}(B_{j,p}^{\alpha})$ for all $t>0$,*

(ii) *$|B_{j,p}^{\alpha}\mathcal{T}_{j,p}(t)w|_p\leqq C_{\alpha,p}t^{-\alpha}e^{\omega t}|w|_p$ for $t>0$ and $w\in\mathcal{L}^p(\Omega)$, and*

(iii) *$\mathcal{T}_{j,p}(t)B_{j,p}^{\alpha}w=B_{j,p}^{\alpha}\mathcal{T}_{j,p}(t)w$ for $t>0$, $w\in\mathcal{D}(B_{j,p}^{\alpha})$.*

In order to use a modification of a local existence result in Henry [4], we write (1.1) as an integral equation system via variation of constants. So define F and G on $[0,\infty)\times\mathcal{L}^{\infty}(\Omega)^2$ by

$$(2.4)\qquad \begin{aligned}&[F(t,w_1,w_2)](x)=f(t,w_1(x),w_2(x))\\&[G(t,w_1,w_2)](x)=g(t,w_1(x),w_2(x))\end{aligned}\quad \text{for } x\in\Omega,\quad t>0,\quad w_1,w_2\in\mathcal{L}^{\infty}(\Omega),$$

and let z_j satisfy

$$(2.5)\qquad \Delta z_j=0\quad\text{on }\Omega,\qquad \alpha_j z_j+(1-\alpha_j)\frac{\partial z_j}{\partial n}=\beta_j\quad\text{on }\partial\Omega$$

where $z_j=0$ if $\alpha_j=0$ (and hence $\beta_j=0$—see (H1)). By variation of constants (see Pazy [9]) it follows that if (u,v) is a solution in $\mathcal{L}^p(\Omega)\times\mathcal{L}^p(\Omega)$ to the system

$$(2.6)\qquad \begin{aligned}u(t)&=\mathcal{T}_{1,p}(t)(u_0-z_1)+z_1+\int_0^t\mathcal{T}_{1,p}(t-s)F(s,u(s),v(s))\,ds,\\ v(t)&=\mathcal{T}_{2,p}(t)(v_0-z_2)+z_2+\int_0^t\mathcal{T}_{2,p}(t-s)G(s,u(s),v(s))\,ds\end{aligned}$$

then $u(x,t)\equiv[u(t)](x)$, $v(x,t)\equiv[v(t)](x)$ is the solution to (1.1). Of course, z_1 and z_2 reflect the possibility of the inhomogeneous boundary conditions in (1.1b), and clearly $z_j=0$ whenever $\beta_j=0$.

Proof of Proposition 1. Select $\alpha\in(0,1)$ and $p>1$ so that (2.3) holds and use the techniques in Henry [4, § 3.3], modified to take into account the inhomogeneous terms, to show the existence of a unique noncontinuable soltuion (u,v) to (2.6) for

$$(u_0-z_1,v_0-z_2)\in\mathcal{D}(B_{1,p}^{\alpha})\times\mathcal{D}(B_{2,p}^{\alpha}).$$

Also, $u(t)$ and $v(t)$ have nonnegative values on Ω since $f(t,0,\eta)\geqq 0$ and $g(t,\xi,0)\geqq 0$ for all $t,\xi,\eta\geqq 0$ (see, e.g., Lightbourne and Martin [7]). Application of the results of Ball [3, Thm. 3.1] shows that (u,v) is defined on an interval of the form $[0,T^*)$, and that

$$(2.7)\qquad \begin{aligned}&\text{if } T^*<\infty,\text{ then } |B_{1,p}^{\alpha}(u(t)-z_1)|_p+|B_{2,p}^{\alpha}(v(t)-z_2)|_p\to\infty \text{ as } t\uparrow T^*,\text{ and}\\ &\limsup_{t\uparrow T^*}\textstyle\int_0^t(t-s)^{-\alpha}[|F(s,u(s),v(s))|_p+|G(s,u(s),v(s))|_p]\,ds=\infty.\end{aligned}$$

For each $T,R>0$ there is an $M(T,R)>0$ such that

$$|f(t,\xi,\eta)|,|g(t,\xi,\eta)|\leqq M(T,R)\quad\text{for } t\in[0,T],\quad \xi,\eta\in[0,R].$$

Hence,

$$(2.8)\qquad \begin{aligned}&|F(t,w_1,w_2)|_{\infty},|G(t,w_1,w_2)|_{\infty}\leqq M(T,R)\\ &\text{whenever } t\in[0,T]\text{ and } w_1,\ w_2\in\mathcal{L}^{\infty}(\Omega)\text{ with } |w_1|_{\infty},|w_2|_{\infty}\leqq R.\end{aligned}$$

Since the function $\psi(t)\equiv \mathcal{T}_{j,p}(t)(w_j-z_j)+z_j$ satisfies

$$\psi_t=d_j\Delta\psi \quad \text{on } \Omega\times(0,\infty),$$

$$\alpha_j\psi+(1-\alpha_j)\frac{\partial\psi}{\partial n}=\beta_j \quad \text{on } \partial\Omega\times(0,\infty),$$

$$\psi(0)=w_j \quad \text{on } \Omega,$$

application of the maximum principle yields

$$\text{(2.9)} \qquad |\mathcal{T}_{j,p}(t)(w_j-z_j)+z_j|_\infty \leqq R \quad \text{for all } t\geqq 0 \text{ whenever } |z_j|_\infty,\ |w_j|_\infty\leqq R.$$

If $0\leqq t_1<T^*$, $|z_j|_\infty\leqq R_1<R_2$ and $|u(t_1)|_\infty$, $|v(t_1)|_\infty\leqq R_1$, then by (2.8) and (2.9)

$$\begin{aligned}|u(t)|_\infty&=|\mathcal{T}_{1,p}(t-t_1)(u(t_1)-z_1)+z_1+\int_{t_1}^{t}\mathcal{T}_{1,p}(t-s)F(s,u(s),v(s))\,ds|_\infty\\ &\leqq|\mathcal{T}_{1,p}(t-t_1)(u(t_1)-z_1)+z_1|_\infty+\int_{t_1}^{t}|\mathcal{T}_{1,p}(t-s)F(s,u(s),v(s))|\,ds\\ &\leqq R_1+(t-t_1)M(T^*,R_2)\end{aligned}$$

so long as $|u(s)|_\infty$, $|v(s)|_\infty\leqq R_2$ for $s\in[t_1,t]$. A similar estimate holds for $|v(t)|_\infty$, and, taking $R_2=R_1+1$, it follows that

(2.10) if $0\leqq t_1<T^*$ and $|u(t_1)|_\infty$, $|v(t_1)|_\infty\leqq R_1$ where $R_1\geqq\max\{|z_1|_\infty,|z_2|_\infty\}$, then $T^*-t_1>M(T^*,R_1+1)^{-1}$, and $|u(t)|_\infty$, $|v(t)|_\infty\leqq R_1+1$ for $t\in[t_1,t_1+M(T^*,R_1+1)^{-1}]$.

Now suppose that $T^*<\infty$. Then (2.7) implies that

$$\begin{aligned}\infty&=\limsup_{t\uparrow T^*}|F(t,u(t),v(t))|_p+|G(t,u(t),v(t))|_p\\ &\leqq C\limsup_{t\uparrow T^*}|F(t,u(t),v(t))|_\infty+|G(t,u(t),v(t))|_\infty.\end{aligned}$$

Hence by (2.8)

$$\limsup_{t\uparrow T^*}|u(t)|_\infty+|v(t)|_\infty=\infty.$$

This, combined with (2.10), shows that

$$|u(t)|_\infty+|v(t)|_\infty\to\infty \quad \text{as } t\uparrow T^* \text{ if } T^*<\infty.$$

Each of the assertions in Proposition 1 follows whenever

$$(u_0-z_1,v_0-z_2)\in\mathcal{D}(B_{1,p}^{\alpha})\times\mathcal{D}(B_{2,p}^{\alpha}).$$

Suppose now that $(u_0,v_0)\in\mathcal{L}^\infty(\Omega)^2$ and let $\{(u_0^k,v_0^k)\}_1$ be a sequence in $\mathcal{D}(B_{1,p}^{\alpha})\times\mathcal{D}(B_{2,p}^{\alpha})$ such that u_0^k, $v_0^k\geqq 0$ and

$$|u_0^k-u_0|_p,\ |v_0^k-v_0|_p\to 0 \quad \text{as } k\to\infty.$$

By the first equation in (2.6) and the properties of $B_{1,p}$ stated in Lemma 1, it follows that

$$|B_{1,p}^{\beta}(u^k(t)-z_1)|_p\leqq C_\beta t^{-\beta}|u_0^k-z_1|_p+\int_0^t C_\beta(t-s)^{-\beta}|F(s,u^k(s),v^k(s))|_p\,ds$$

for all $t \in [0, T_k^*)$. If $R_1 \geqq |z_1|_\infty, |z_2|_\infty$ is chosen so that $R_1 \geqq |u_0^k|_\infty, |v_0^k|_\infty$ for all $k \geqq 1$, then it follows from (2.10) that if $\delta = M(R_1, R_1+1)^{-1}$ then $T_k^* > \delta$ for all $k \geqq 1$. From these estimates one can deduce the existence of a $\bar{C}_\beta$ such that

$$|B_{1,p}^\beta(u^k(t) - z_1)|_p \leqq \bar{C}_\beta t^{-\beta} \quad \text{for all } t \in [0, \delta], k \geqq 1 \text{ and } \alpha \leqq \beta < 1$$

and, similarly,

$$|B_{2,p}^\beta(v^k(t) - z_2)|_p \leqq \bar{C}_\beta t^{-\beta} \quad \text{for all } t \in [0, \delta], k \geqq 1 \text{ and } \alpha \leqq \beta < 1.$$

Because of the compact embedding of $\mathscr{D}(B_{j,p}^\beta)$ in $\mathscr{D}(B_{j,p}^\alpha)$ for $\alpha < \beta < 1$ and the compactness of $T_{j,p}$, it follows, by selecting a subsequence and relabeling if necessary, that

$$\lim_{k\to\infty} |u^k(t) - u(t)|_p = \lim_{k\to\infty} |v^k(t) - v(t)|_p = 0$$

for $t \in [0, \delta]$ and that (u, v) is a solution to (2.6) on $[0, \delta]$ with $u(t) - z_1 \in \mathscr{D}(B_{1,p}^\alpha)$ and $v(t) - z_2 \in \mathscr{D}(B_{2,p}^\alpha)$ for $0 < t \leqq \delta$ (see, e.g., Lemmas 6 and 7 in Lightbourne and Martin [7]). By replacing $[0, T^*)$ with $[\delta, T^*)$ and (u_0, v_0) with $(u(\delta), v(\delta))$ and using the results already established when $u_0 - z_1 \in \mathscr{D}(B_{1,p}^\alpha)$ and $v_0 - z_2 \in \mathscr{D}(B_{2,p}^\alpha)$, Proposition 1 follows.

3. Preliminary estimates. For $0 \leqq \tau < T < \infty$ let $Q_{\tau,T} = \Omega \times (\tau, T)$ and for $q \in [1, \infty)$ let $\mathscr{L}^q(Q_{\tau,T})$ be the space of measurable $\phi: Q_{\tau,T} \to \mathbb{R}$ with

$$\|\phi\|_{q,\tau,T} \equiv \left[\int_{Q_{\tau,T}} |\phi(x, t)|^q \, dx \, dt\right]^{1/q} < \infty.$$

Observe that if $\phi \in \mathscr{L}^q(Q_{\tau,T})$ then $\phi(\cdot, t) \in \mathscr{L}^q(\Omega)$ for almost all $t \in (\tau, T)$, $t \mapsto \phi(\cdot, t)$ is measurable, and that

$$\|\phi\|_{q,\tau,T} = \left[\int_\tau^T |\phi(\cdot, t)|_q^q \, dt\right]^{1/q}.$$

Throughout this section we assume that $\theta \in \mathscr{L}^q(Q_{\tau,T})$ and that $\phi: Q_{\tau,T} \to \mathbb{R}$ is the solution to

$$\text{(3.1)} \qquad \begin{aligned} &\phi_t = -d_2 \Delta \phi - \theta, && x \in \Omega, \quad t \in (\tau, T), \\ &\alpha_2 \phi + (1 - \alpha_2) \frac{\partial \phi}{\partial n} = 0, && x \in \partial\Omega, \quad t \in (\tau, T), \\ &\phi = 0, && x \in \Omega, \quad t = T \end{aligned}$$

where d_2 and α_2 are as in (H1). If $\bar{\phi}(x, t) \equiv \phi(x, T - t)$ and $\bar{\theta}(x, t) \equiv \theta(x, T - t)$ for $(x, t) \in \Omega \times (0, T - \tau)$, then

$$\text{(3.2)} \qquad \begin{aligned} &\bar{\phi}_t = d_2 \Delta \bar{\phi} + \bar{\theta}, && x \in \Omega, \quad t \in (0, T - \tau), \\ &\alpha_2 \bar{\phi} + (1 - \alpha_2) \frac{\partial \bar{\phi}}{\partial n} = 0, && x \in \partial\Omega, \quad t \in (0, T - \tau), \\ &\bar{\phi} = 0, && x \in \Omega, \quad t = 0. \end{aligned}$$

The maximum principle implies that $\bar{\phi} \geqq 0$ (and hence $\phi \geqq 0$) whenever $\theta \geqq 0$. Thus it follows immediately that $\partial\phi/\partial n \leqq 0$ on $\partial\Omega \times (\tau, T)$ whenever $\theta \geqq 0$.

LEMMA 2. *Suppose that $q \in (1, \infty)$, $\theta \in \mathscr{L}^q(Q_{\tau,T})$ and ϕ is the solution to* (3.1). *Then there is a constant $C(q, T-\tau)$ (independent of θ) such that*

$$\|\phi\|_{q,\tau,T}, \|\Delta\phi\|_{q,\tau,T} \leqq C(q, T-\tau)\|\theta\|_{q,\tau,T}. \tag{3.3}$$

Also, $C(q, T-\tau)$ can be chosen so that

$$|\phi(\cdot, \tau)|_q \leqq C(q, T-\tau)\|\theta\|_{q,\tau,T}. \tag{3.4}$$

Proof. The estimates in (3.3) follow directly from Theorem 9.1 of Ladyzenskaja et al. [5, p. 341]. Applying variation of constants to (3.2) and using (2.2) and Hölder's inequality we have, taking p conjugate to q,

$$\begin{aligned} |\phi(\cdot, \tau)|_q = |\bar{\phi}(\cdot, T-\tau)|_q &= \left| \int_0^{T-\tau} \mathscr{T}_{2,q}(T-\tau-s)\bar{\theta}(\cdot, s)\, ds \right|_q \\ &\leqq \int_0^{T-\tau} |\bar{\theta}(\cdot, s)|_q\, ds \\ &\leqq (T-\tau)^{1/p}\|\theta\|_{q,\tau,T} \end{aligned}$$

and (3.4) follows by taking $C(q, T-\tau) \geqq (T-\tau)^{1/p}$.

In order to obtain uniform boundedness of solutions to (1.1), we need to control the dependence on $T-\tau$ of the constants in Lemma 2.

LEMMA 3. *Under the assumptions of Lemma 2, there is a $\bar{C}(q)$ such that*

$$|P\phi(\cdot,\tau)|_q, \|P\phi\|_{q,\tau,T}, \|\Delta\phi\|_{q,\tau,T} \leqq \bar{C}(q)\|\theta\|_{q,\tau,T}$$

where we set

$$P\phi(\cdot, t) = \begin{cases} \phi(\cdot, t) & \text{if } \alpha_2 \neq 0, \\ \phi(\cdot, t) - |\Omega|^{-1} \int_\Omega \phi(x, t)\, dx & \text{if } \alpha_2 = 0 \end{cases}$$

for $t \in (\tau, T)$. Thus, if $\alpha_2 \neq 0$, one can assume that $C(q, T-\tau) \leqq \bar{C}(q)$ in Lemma 2.

Proof. Note first that C can be chosen so that

$$C(q, T-\tau) \leqq C(q, T'-\tau) \quad \text{if } T' \geqq T > \tau \geqq 0. \tag{3.5}$$

Suppose that $\theta_1 \in \mathscr{L}^q(Q_{\tau,T})$ and define $\theta_2 \in \mathscr{L}^q(Q_{\tau,T})$ by $\theta_2 = \theta_1$ on $Q_{\tau,T}$ and $\theta_2 = 0$ on $Q_{T,T'}$. Then $\|\theta_1\|_{q,\tau,T} = \|\theta_2\|_{q,\tau,T'}$ and if ϕ_1 and ϕ_2 are solutions to (3.1) with $\theta = \theta_1$ and $\theta = \theta_2$, respectively, then $\phi_2 = \phi_1$ on $Q_{\tau,T}$. Thus, by (3.3),

$$\|\phi_1\|_{q,\tau,T} \leqq \|\phi_2\|_{q,\tau,T'} \leqq C(q, T'-\tau)\|\theta_2\|_{q,\tau,T'} = C(q, T'-\tau)\|\theta_1\|_{q,\tau,T}.$$

Since the same estimate holds for $\|\Delta\phi_1\|_{q,\tau,T}$ and $|\phi_1(\cdot, \tau)|_q$, we see that (3.5) is true. Let us first assume that $\alpha_2 \neq 0$. Then (2.2) holds with $\omega = -\delta < 0$. By variation of constants

$$\begin{aligned} |\phi(\cdot, \tau)|_q = |\bar{\phi}(\cdot, T-\tau)|_q &= \left| \int_0^{T-\tau} \mathscr{T}_{2,q}(T-\tau-s)\bar{\theta}(\cdot, s)\, ds \right| \\ &\leqq \int_0^{T-\tau} e^{-\delta(T-\tau-s)}|\bar{\theta}(\cdot, s)|_q\, ds \\ &\leqq \left[\int_0^{T-\tau} e^{-p\delta(T-\tau-s)}\, ds \right]^{1/p} \left[\int_0^{T-\tau} |\bar{\theta}(\cdot, s)|_q^q\, ds \right]^{1/q} \\ &\leqq (p\delta)^{-1/p}\|\theta\|_{q,\tau,T} \end{aligned}$$

where $p^{-1}+q^{-1}=1$. Therefore,

$$|\phi(\cdot,\tau)|_q \leqq k_q\|\theta\|_{q,\tau,T}. \tag{3.6}$$

This shows that the constant in (3.4) may be chosen independent of $T-\tau$. Again by variation of constants

$$\begin{aligned}\|\phi\|_{q,\tau,T}^q &= \int_0^{T-\tau} |\bar\phi(\cdot,t)|_q^q\,dt\\ &= \int_0^{T-\tau}\left|\int_0^t \mathcal{T}_{2,q}(t-s)\bar\theta(\cdot,s)\,ds\right|_q^q dt\\ &\leqq \int_0^{T-\tau}\left\{\int_0^t e^{-\delta(t-s)}|\bar\theta(\cdot,s)|_q\,ds\right\}^q dt.\end{aligned}$$

Let us set $y(s)=|\bar\theta(\cdot,s)|_q$, By Hölder's inequality

$$\int_0^t e^{-\delta(t-s)}y(s)\,ds \leqq \left[\int_0^t e^{-\delta(t-s)}y(s)^q\,ds\right]^{1/q}\left[\int_0^t e^{-\delta(t-s)}\,ds\right]^{1/p},$$

and the last integral is bounded above by δ^{-1}. Hence

$$\begin{aligned}\|\phi\|_{q,\tau,T}^q &\leqq \delta^{-q/p}\int_0^{T-\tau}\int_0^t e^{-\delta(t-s)}y(s)^q\,ds\,dt\\ &= \delta^{-q/p}\int_0^{T-\tau} y(s)^q\int_s^{T-\tau} e^{-\delta(t-s)}\,dt\,ds\end{aligned}$$

where the last integral is bounded above by δ^{-1}. This implies that

$$\|\phi\|_{q,\tau,T}^q \leqq \delta^{-q}\|\theta\|_{q,\tau,T}^q \tag{3.7}$$

and shows that the constant in the estimate for $\|\phi\|_{q,\tau,T}$ in (3.3) may be chosen independent of $T-\tau$.

To show the same for $\|\Delta\phi\|_{q,\tau,T}$, we argue as follows. Let A be an even regular function on $\mathbb{R}$ such that

$$0\leqq A\leqq 1, \qquad A\equiv 1 \quad \text{on } (0,1), \qquad A\equiv 0 \quad \text{on } [2,\infty).$$

For $t_0\geqq 2$, set $\psi(t,x)=A(t-t_0)\bar\phi(t,x)$ where $\bar\phi$ is defined for $t\geqq 0$ by (3.2). Then

$$\begin{aligned}&\psi_t = d_2\Delta\psi + A(t-t_0)\bar\theta + A'(t-t_0)\bar\phi, && x\in\Omega, \quad t>t_0-2,\\ &\alpha_2\psi+(1-\alpha_2)\frac{\partial\psi}{\partial n}=0, && x\in\partial\Omega, \quad t>t_0-2,\\ &\psi(t_0-2)=0.\end{aligned}$$

Set $C(q)=C(q,4)$. By Lemma 2,

$$\begin{aligned}\|\Delta\psi\|_{q,t_0-2,t_0+2}^q &\leqq C(q)^q(\|\bar\theta\|_{q,t_0-2,t_0+2}+\|A'\|_\infty\|\bar\phi\|_{q,t_0-2,t_0+2})^q\\ &\leqq 2^qC(q)^q(\|\bar\theta\|_{q,t_0-2,t_0+2}^q+\|A'\|_\infty^q\|\bar\phi\|_{q,t_0-2,t_0+2}^q).\end{aligned}$$

By the choice of A,

$$\|\Delta\psi\|_{q,t_0-2,t_0+2}^q \geqq \|\Delta\psi\|_{q,t_0-1,t_0+1}^q \geqq \|\Delta\bar\phi\|_{q,t_0-1,t_0+1}^q.$$

Applying these inequalities with $t_0=2,4,\cdots,2k,\cdots$ and summing over k, we obtain

$$\|\Delta\bar\phi\|_{q,1,\infty}^q \leqq 2^qC(q)^q(\|\bar\theta\|_{q,0,\infty}^q+\|A'\|_\infty^q\|\bar\phi\|_{q,0,\infty}^q).$$

Using again Lemma 2 on (0, 1), we deduce that

$$\|\Delta\bar{\phi}\|^q_{q,0,\infty} \leqq (2^q+1)C(q)^q(\|\bar{\theta}\|^q_{q,0,\infty} + \|A'\|^q_\infty \|\bar{\phi}\|^q_{q,0,\infty}).$$

Combining this with (3.7) yields

$$\|\Delta\bar{\phi}\|_{q,0,\infty} \leqq \bar{C}(q)\|\bar{\theta}\|_{q,0,\infty}$$

where $\bar{C}(q) = (2^q+1)^{1/q}C(q)(q + \|A'\|^q_\infty \delta^{-q})^{1/q}$. Applying this with $\bar{\theta} = 0$ for $t \geqq T-\tau$ yields the required estimate.

Assume now that $\alpha_2 = 0$. For $\psi \in \mathscr{L}^q(\Omega)$ set

$$\hat{\psi} = |\Omega|^{-1}\int_\Omega \psi \quad \text{and} \quad P\psi = \psi - \hat{\psi}.$$

If ϕ and θ are as in (3.1), then $\hat{\phi}_t = -\hat{\theta}$ since $\partial\phi/\partial n = 0$ on $\partial\Omega$, and

$$\begin{aligned} &(P\phi)_t = -d_2\Delta(P\phi) - P\theta, && x \in \Omega, \quad t \in (0, T-\tau), \\ &\frac{\partial}{\partial n}(P\phi) = 0, && x \in \partial\Omega, \quad t \in (0, T-\tau), \\ &P\phi(T) = 0. && \end{aligned}$$

Moreover, there exists $\delta > 0$ such that

$$|P\mathscr{T}_{2,q}(t)w|_q \leqq e^{-\delta t}|w|_q \quad \text{for } w \in \mathscr{L}^q(\Omega), \quad t \geqq 0.$$

Arguing as for $\alpha_2 \neq 0$ but with ϕ replaced by $P\phi$ completes the proof of Lemma 3.

Our final estimate relates ϕ and θ to the solution (u, v) of (1.1):

LEMMA 4. *Let the supposition of Proposition* 1 *be satisfied, let* $0 \leqq \tau < T < T^*$, *and let* q, θ *and* ϕ *be as in Lemma* 2 *with* $\theta \geqq 0$. *Then there are constants* $E_1(\tau, T)$, $E_2(\tau, T)$ *and* $P_0(q)$ *such that*

$$\text{(i)} \quad \int_{Q_{\tau,T}} u\theta \leqq \int_{Q_{\tau,T}} \phi f(t, u, v) + \int_\Omega \phi(\cdot, \tau)u(\cdot, \tau) + E_1(\tau, T),$$

$$\text{(ii)} \quad \int_{Q_{\tau,T}} v\theta \leqq \int_{Q_{\tau,T}} \phi g(t, u, v) + \int_\Omega \phi(\cdot, \tau)v(\cdot, \tau) + E_2(\tau, T),$$

$$\text{(iii)} \quad E_1(\tau, T) + E_2(\tau, T) \leqq P_0(q)[1 + \bar{N}_1(\tau, T)](T-\tau)^{1/p}\|\theta\|_{q,\tau,T}$$

where $\bar{N}_1(\tau, T) \equiv \sup\{N_1(t): \tau \leqq t < T\}$ *and* $1/p + 1/q = 1$. *Moreover, if* $T^* < \infty$ *and* $\sup\{N_1(t): 0 \leqq t < T^*\} < \infty$, *then* (i), (ii), *and* (iii) *hold with* $T = T^*$.

Proof. Integrating ϕu_t over Ω, we obtain

$$\begin{aligned} \int_\Omega \phi u_t &= \int_\Omega [d_1\phi\Delta u + \phi f(t, u, v)] \\ &= d_1\int_\Omega u\Delta\phi + \int_\Omega \phi f(t, u, v) + I_1(t) \end{aligned} \tag{3.8}$$

where $I_1(t) = \int_{\partial\Omega}(\phi(\partial u/\partial n) - u(\partial\phi/\partial n))$.

If $\alpha_1 = 0$, then $\alpha_2 = \beta_1 = \beta_2 = 0$ (see (H1)) and so $I_1(t) \equiv 0$. If $\alpha_1 = 1$ then $\alpha_2 = 1$, and so

$$I_1(t) = -\int_{\partial\Omega} u\frac{\partial\phi}{\partial n} = -\beta_1\int_\Omega \Delta\phi \leqq \beta_1\int_\Omega |\Delta\phi|.$$

Finally, if $0 < \alpha_1 < 1$ then $0 < \alpha_2 < 1$, and so (since $\partial\phi/\partial n \leqq 0$)

$$I_1(t)=\int_{\partial\Omega}\left[\frac{(\beta_1-\alpha_1 u)(\alpha_2-1)}{(1-\alpha_1)\alpha_2}\frac{\partial\phi}{\partial n}-u\frac{\partial\phi}{\partial n}\right]$$

$$\leqq\{(\beta_1+\alpha_1\bar{N}_1(\tau,T))(1-\alpha_2)[(1-\alpha_1)\alpha_2]^{-1}+\bar{N}_1(\tau,T)\}\int_{\partial\Omega}-\frac{\partial\phi}{\partial n}$$

$$=-c_0[1+\bar{N}_1(\tau,T)]\int_\Omega\Delta\phi$$

$$\leqq c_0[1+\bar{N}_1(\tau,T)]\int_\Omega|\Delta\phi|.$$

Thus, in each case, $I_1(t)\leqq c_0[1+\bar{N}_1(\tau,T)]\int_\Omega|\Delta\phi|$ for some constant $c_0\geqq 0$.

Now integrating ϕu_t from $t=\tau$ to $t=T$ we obtain

$$\int_\tau^T\phi u_t=-\phi(\cdot,\tau)u(\cdot,\tau)-\int_\tau^T u\phi_t$$

$$=-\phi(\cdot,\tau)u(\cdot,\tau)+d_2\int_\tau^T u\,\Delta\phi+\int_\tau^T u\theta$$

using the fact that $\phi(\cdot,T)\equiv 0$. Now by integrating each side of this equation over Ω and each side of (3.8) from $t=\tau$ to $t=T$ and interchanging the order of integration, we see that (i) holds with

$$E_1=(d_1-d_2)\int_\tau^T\int_\Omega u\Delta\phi+\int_\tau^T I_1(t)\,dt$$

$$\leqq[|d_1-d_2|\bar{N}_1(\tau,T)+c_0(1+\bar{N}_1(\tau,T))]\int_\tau^T\int_\Omega|\Delta\phi|$$

$$\leqq(|d_1-d_2|+c_0)[1+\bar{N}_1(\tau,T)](T-\tau)^{1/p}|\Omega|^{1/p}\|\Delta\phi\|_{q,\tau,T}$$

where $|\Omega|$ is the measure of Ω. Therefore, by Lemma 3, there is a $c_1(q)$ such that

$$E_1\leqq c_1(q)[1+\bar{N}_1(\tau,T)](T-\tau)^{1/p}\|\theta\|_{q,\tau,T}.$$

In the same manner, one can show that (ii) holds with $E_2=\int_\tau^T I_2(t)\,dt$ where $I_2(t)=\int_{\partial\Omega}\phi\,\partial v/\partial n-v\,\partial\phi/\partial n$. Estimates similar to those for $I_1(t)$ reveal that for each boundary condition there is a constant $\bar{c}_0$ such that $I_2(t)\leqq\bar{c}_0\int_\Omega|\Delta\phi|$ for all $t\in(\tau,T)$, and hence there is by (3.3) a $c_2(q)$ such that

$$E_2\leqq c_2(q)(T-\tau)^{1/p}\|\theta\|_{q,\tau,T}.$$

Assertion (iii) now follows, and the proof is complete.

4. Proof of the theorems. Theorems 1 and 2 are proved in this section, and it is assumed throughout that (H1)-(H6) hold and that (u,v) is the noncontinuable solution to (1.1) on $\Omega\times[0,T^*)$ guaranteed by Proposition 1. A crucial estimate is the following.

LEMMA 5. *Suppose that* $0\leqq\tau<T<T^*$ *and* $1<p<\infty$. *Then* $v\in\mathscr{L}^p(Q_{\tau,T})$ *and the estimate*

$$(4.1)\qquad\int_\tau^T|v(\cdot,t)|_p^p\,dt\leqq R_p(\bar{N}_1(\tau,T),C(q,T-\tau))^p[1+|v(\cdot,\tau)|_p+(T-\tau)^{1/p}]^p$$

is valid where $R_p:[0,\infty)^2\to[0,\infty)$ *is continuous,* q *is conjugate to* p*,* C *is as in Lemma* 2, *and*

$$\bar N_1(\tau, T)=\sup\{N_1(t): \tau\leqq t<T\}.$$

Moreover, if $T^*<\infty$ *then* (4.1) *holds with* $T=T^*$.

Proof. Inequalities (i) and (ii) in Lemma 4 imply that

$$\int_{Q_{\tau,T}} u\theta+\int_{Q_{\tau,T}} v\theta\leqq\int_{Q_{\tau,T}}\phi[f(t,u,v)+g(t,u,v)]$$
$$+\int_\Omega\phi(\cdot,\tau)[u(\cdot,\tau)+v(\cdot,\tau)]+E_1(\tau,T)+E_2(\tau,T)$$

where $\theta\in\mathscr{L}^q(Q_{\tau,T})$, $\theta\geqq 0$, and ϕ satisfies (3.1). By (H6) and (1.2),

$$\int_{Q_{\tau,T}} v\theta\leqq\int_{Q_{\tau,T}}\phi\mu_0(t,\bar N_1(\tau,T))+\int_\Omega\phi(\cdot,\tau)N_1(\tau)$$
$$+\int_\Omega\phi(\cdot,\tau)v(\cdot,\tau)+E_1(\tau,T)+E_2(\tau,T).$$

Applying Hölder's inequality,

$$\int_{Q_{\tau},T} v\theta\leqq\left[\int_\tau\int_\Omega\mu_0(t,\bar N_1(\tau,T))^p\,dt\right]^{1/p}\|\phi\|_{q,\tau,T}$$
$$+N_1(\tau)|\Omega|^{1/p}|\phi(\cdot,\tau)|_q+|v(\cdot,\tau)|_p|\phi(\cdot,\tau)|_q+E_1(\tau,T)+E_2(\tau,T).$$

Now using the estimates in Lemma 2 and (iii) in Lemma 4 we have that

$$\int_{Q_{\tau,T}} v\theta\leqq\{R_p(\bar N_1(\tau,T),C(q,T-\tau))[1+|v(\cdot,\tau)|_p+(T-\tau)^{1/p}]\}\|\theta\|_{q,\tau,T}.$$

Since this holds for every $\theta\in\mathscr{L}^q(Q_{\tau,T})$, $\theta\geqq 0$, we have by duality that $v\in\mathscr{L}^p(Q_{\tau,T})$ and that the term in the braces is an estimate for $\|v\|_{p,\tau,T}$. Thus (4.1) holds and since N_1 is assumed bounded on $[0,T^*)$ if $T^*<\infty$, the final assertion is immediate from (4.1).

Combining Lemma 5 with assumption (H5) gives the following estimate:

LEMMA 6. *With the suppositions of Lemma* 5, *suppose that* $r>1$ *and* γ *is as in* (H5). *Then there is a constant* $\bar L_r(T-\tau,\bar N_1(\tau,T))$ *such that*

$$\int_\tau^T|g(t,u(\cdot,t),v(\cdot,t))|_r^r\,dt\leqq\bar L_r(T-\tau,\bar N_1(\tau,T))\left[1+\int_\tau^T|v(\cdot,t)|_{\gamma r}^{\gamma r}\,dt\right]\tag{4.2}$$

whenever $0\leqq\tau<T<T^*$. *Also, this estimate is valid for* $T=T^*$ *if* $T^*<\infty$.

Proof. By (H5),

$$|g(t,u(x,t),v(x,t))|_r^r\leqq L_0(t,\bar N_1(\tau,T))^r[1+|v(x,t)|]^{\gamma r}$$
$$\leqq 2^{\gamma r}L_0(t,\bar N_1(\tau,T))^r[1+|v(x,t)|^{\gamma r}]$$

and, integrating over Ω,

$$|g(t,u(\cdot,t),v(\cdot,t))|_r^r\leqq 2^{\gamma r}L_0(t,\bar N_1(\tau,T))^r[|\Omega|+|v(\cdot,t)|_{\gamma r}^{\gamma r}].$$

Now (4.2) follows by integrating each side of this inequality from $t=\tau$ to $t=T$.

Proof of Theorem 1. Suppose, for contradiction, that $T^*<\infty$. From (H4) and (1.3) it follows that

$$\lim_{t\uparrow T^*}|v(\cdot,t)|_\infty=\infty.\tag{4.3}$$

Let $\alpha \in (0, 1)$ and select $p > 1$ large enough so that $\alpha > n/(2p)$ (see (2.3)) and $\alpha q < 1$ where $p^{-1} + q^{-1} = 1$. Since $T^* < \infty$ and $|v_0|_r \leqq |\Omega|^{1/r} |v_0|_\infty$ for each $r > 1$, we have by (4.1) that

$$\int_0^{T^*} |v(\cdot, t)|_r^r \, dt \leqq M_1(r)^r.$$

Hence, by (4.2) there is an $M_2(p)$ such that

$$\int_0^{T^*} |g(t, u(\cdot, t), v(\cdot, t))| \, dt \leqq M_2(p)^P [1 + M_1(\gamma p)^{\gamma p}]^p. \tag{4.4}$$

Using the second equation in (2.6) and the properties of $B_{2,p}^\alpha$ in Lemma 1 we see that

$$\begin{aligned} |B_{2,p}^\alpha (v(t) - z_2)|_p &\leqq C_{\alpha,p} t^{-\alpha} \, e^{\omega t} |v_0 - z_2|_p + \int_0^t C_{\alpha,p} (t-s)^{-\alpha} |G(s, u(s), v(s))|_p \, ds \\ &\leqq C_{\alpha,p} t^{-\alpha} \, e^{\omega} \tau |v_0 - z_2|_p \\ &\quad + \left[\int_0^t C_{\alpha,p}^q (t-s)^{-\alpha q} \, ds \right]^{1/q} \left[\int_0^t |G(s, u(s), v(s))|_p^p \, ds \right]^{1/p}. \end{aligned}$$

By (4.4) and the definition of G in (2.4)

$$\begin{aligned} \int_0^t |G(s, u(s), v(s))|_p^p \, ds &\leqq \int_0^{T^*} |G(s, u(s), v(s))|_p^p \, ds \\ &\leqq M_2(p)^p [1 + M_1(\gamma p)^{\gamma p}]^p, \end{aligned}$$

and since $\alpha q < 1$ it follows that

$$\limsup_{t \uparrow T^*} |B_{2,p}^\alpha (v(t) - z_2)|_p < \infty.$$

Since $\alpha > n/(2p)$, we have by (2.3) that

$$|v(t) - z_2|_\infty \leqq M_{\alpha,p} |B_{2,p}^\alpha (v(t) - z_2)|_p,$$

which contradicts (4.3). Thus $T^* = \infty$, and the proof of Theorem 1 is complete.

Now assume that the suppositions of Theorem 2 are satisfied, and hence that (u, v) exists on $\Omega \times [0, \infty)$ by Theorem 1. If $\alpha_2 \neq 0$, by Lemma 3 one can assume that $C(q, T - \tau) \leqq \bar{C}(q)$. Since $N_1(t) \leqq \bar{N}_1$ for all $t \geqq 0$, from (4.1) we obtain

$$\int_\tau^T |v(\cdot, t)|_p^p \, dt \leqq \bar{R}_p^p [1 + |v(\cdot, \tau)|_p + (T - \tau)^{1/p}]^p \quad \text{for } T \geqq \tau \geqq 0 \tag{4.5}$$

for some $\bar{R}_p > 0$. If $\alpha_2 = 0$ and $\mu_\infty(r) \equiv 0$, then (4.5) remains valid. Indeed, from Lemma 4, we have

$$\int_{Q_{\tau,T}} v\theta \leqq \int_\Omega \phi(\cdot, \tau)[u(\cdot, \tau) + v(\cdot, \tau)] + E_1(\tau, T) + E_2(\tau, T)$$

where here $E_2 = 0$ and $E_1 \leqq |d_1 - d_2| \int_{Q_{\tau,T}} u |\Delta \phi|$. By Lemma 3,

$$E_1 \leqq |d_1 - d_2| \bar{N}_1 (T - \tau)^{1/p} |\Omega|^{1/p} \bar{C}(q) \|\theta\|_{q,\tau,T}.$$

Using again that $\mu_\infty(r) \equiv 0$ and $\alpha_2 = 0$, we have

$$\int_\Omega [u(+, \tau) + v(\cdot, \tau)] \leqq \int_\Omega u_0 + v_0.$$

Thus, if $\hat{\phi}$ and $P\phi$ are as in Lemma 3, we have

$$\int_\Omega \phi(\cdot,\tau)[u(\cdot,\tau)+v(\cdot,\tau)] = \int_\Omega [\hat{\phi}(\cdot,\tau)+P\phi(\cdot,\tau)][u(\cdot,\tau)+v(\cdot,\tau)]$$

$$\le \hat{\phi}(\cdot,\tau)\int_\Omega [u_0+v_0]+[\bar{N}_1|\Omega|^{1/p}+|v(\cdot,\tau)|_p]|P\phi(+,\tau)|_q$$

where

$$\hat{\phi}(\cdot,\tau)=\int_\tau^T \hat{\theta}(\cdot,s)\,ds \le |\Omega|^{1/p-1}(T-\tau)^{1/p}\|\theta\|_{q,\tau,T}.$$

Recalling Lemma 3 to estimate $|P\phi(\cdot,\tau)|_p$ and combining these inequalities yields (4.5).

LEMMA 7. *Let the suppositions of Theorem 2 be satisfied. For each* $p\in(1,\infty)$ *there are constants* $\Lambda_0(p)$ *and* $\Gamma_0(p)$ *and a sequence* $\{t_k\}_0^\infty$ *in* $[0,\infty)$ *such that* $t_0=0$ *and for each* $k\ge 0$,

(i) $1\le t_{k+1}-t_k\le\Lambda_0(p)$,

(ii) $|v(\cdot,t_k)|_p\le\bar{R}_p+1$,

(iii) $\int_{t_k}^{t_{k+1}}|v(\cdot,t)|_p^p\,dt\le\Gamma_0(p)$

where $\bar{R}_p$ *is as in* (4.5).

Proof. We assume without loss that $\bar{R}_p+1\ge|v_0|_p$ and that $\bar{R}_p\ge 1$. For notational convenience set $\bar{S}_p=\bar{R}_p^p(\bar{R}_p+2)^p$. Note first that

$$\text{(4.6)}\qquad \begin{array}{l}\text{if } \tau\ge 0 \text{ and } |v(\cdot,\tau)|_p\le\bar{R}_p+1, \text{ then there is a}\\ t^*\in(\tau,\tau+S_p] \text{ such that } |v(\cdot,t^*)|_p\le\bar{R}_p+1.\end{array}$$

For if this were not the case, then $|v(\cdot,t)|_p>\bar{R}_p+1$ for all $t\in(\tau,\tau+\bar{S}_p)$ and so

$$\int_\tau^{\tau+\bar{S}_p}|v(\cdot,t)|_p^p\,dt>\bar{S}_p(\bar{R}_p+1)^p.$$

However, by (4.5) with $T=\tau+\bar{S}_p$,

$$\int_\tau^{\tau+\bar{S}_p}|v(\cdot,t)|_p^p\,dt\le\bar{R}_p^p[1+\bar{R}_p+1+\bar{S}_p^{1/p}]^p$$

$$=\bar{R}_p^p[\bar{R}_p+2+\bar{R}_p(\bar{R}_p+2)]^p$$

$$=\bar{S}_p(\bar{R}_p+1)^p$$

which is impossible. Thus (4.6) is valid. Now set $\Lambda_0(p)=2\bar{S}_p$ and inductively define $\{t_k\}_0^\infty$ by $t_0=0$ and

$$t_{k+1}=\sup\{T\ge t_k\colon T-t_k\le 2\bar{S}_p \text{ and } |v(\cdot,T)|_p\le\bar{R}_p+1\}.$$

By the continuity of $t\mapsto|v(\cdot,t)|_p$ we have that $|v(\cdot,t_{k+1})|_p\le\bar{R}_p+1$ and $|v(\cdot,t_{k+1})|_p=\bar{R}_p+1$ if $t_{k+1}<t_k+2\bar{S}_p$. Moreover, $t_{k+1}-t_k\ge\bar{S}_p\ge 1$, for if $t_{k+1}-t_k<\bar{S}_p$ then (4.6) implies that there is a $t^*\in(t_{k+1},t_{k+1}+\bar{S}_p)$ such that $|v(\cdot,t^*)|_p\le\bar{R}_p+1$. But $t^*\le t_{k+1}+\bar{S}_p<t_k+2\bar{S}_p$, and this contradicts the definition of t_{k+1}. Thus $\{t_k\}_0^\infty$ is well defined and satisfies (i) and (ii). Since (4.5) implies that

$$\int_{t_k}^{t_{k+1}}|v(\cdot,t)|_p^p\,dt\le\bar{R}_p^p[1+|v(\cdot,t_k)|_p+(t_{k+1}-t_k)^{1/p}]^p$$

$$\le\bar{R}_p^p[\bar{R}_p+2+(2\bar{S}_p)^{1/p}]^p$$

we see that (iii) holds with $\Gamma_0(p)=\bar{R}_p^p[\bar{R}_p+2+(2\bar{S}_p)^{1/p}]^p$.

LEMMA 8. *Suppose that the assumptions in Theorem* 2 *are satisfied*, $p \in (1, \infty)$, γ *is as in* (H5), *and that* $\{t_k\}_0^\infty$ *is the sequence constructed in Lemma* 7 *corresponding to* γp. *Then there is a* $\Gamma_1(p, \gamma p)$ *such that*

$$\int_{t_k}^{t_{k+1}} |g(t, u(\cdot, t), v(\cdot, t))|_p^p \leqq \Gamma_1(p, \gamma p) \quad \textit{for all } k \geqq 0. \tag{4.7}$$

Proof. The boundedness assumptions on μ_0, L_0, and N_1 applied to (4.2) and Lemma 7 imply that

$$\begin{aligned}\int_{t_k}^{t_{k+1}} |g(t, u(\cdot, t), v(\cdot, t))|_p^p \, dt &\leqq M_3(p)\left[1 + \int_{t_k}^{t_{k+1}} |v(\cdot, t)|_{\gamma p}^{\gamma p} \, dt\right] \\ &\leqq M_3(p)[1 + \Gamma_0(\gamma p)] \\ &= \Gamma_1(p, \gamma p).\end{aligned}$$

$M_3(p)$ and consequently $\Gamma_1(p, \gamma p)$ are independent of k, and the proof is complete.

Proof of Theorem 2. Select $\alpha \in (0, 1)$ and $p \in (1, \infty)$ so that $\alpha > n/(2p)$ and $q < 1$, where $p^{-1} + q^{-1} = 1$. Then $\mathscr{D}(B_{2,p}^\alpha)$ is continuously embedded in $\mathscr{L}^\infty(\Omega)$ (see (2.3)); thus to establish the boundedness of $|v(\cdot, t)|_\infty$ on $[0, \infty)$ it suffices to show that

$$\sup\{|B_{2,p}^\alpha(v(t) - z_2)|_p : t \geqq 0\} < \infty. \tag{4.8}$$

So let $\{t_k\}_0^\infty$ be the sequence constructed in Lemma 7 corresponding to γp and note that for $k \geqq 2$ and $t \in [t_k, t_{k+1}]$,

$$\begin{aligned}B_{2,p}^\alpha(v(t) - z_2) = B_{2,p}^\alpha &\mathscr{T}_{2,p}(t - t_{k-1})(v(t_{k-1}) - z_2) \\ &+ \int_{t_{k-1}}^t B_{2,p}^\alpha \mathscr{T}_{2,p}(t - s) G(s, u(s), v(s)) \, ds\end{aligned}$$

(replace t by $t - t_{k-1}$ and v_0 by $v(t_{k-1})$ in (2.6)). By (ii) in Lemma 1,

$$\begin{aligned}|B_{2,p}^\alpha(v(t) - z_2)|_p \leqq\ &C_{\alpha,p}(t - t_{k-1})^{-\alpha} |v(t_{k-1}) - z_2|_p \\ &+ \int_{t_{k-1}}^t C_{\alpha,p}(t - s)^{-\alpha} |G(s, u(s), v(s))|_p \, ds.\end{aligned}$$

Since $t \geqq t_k \geqq t_{k-1} + 1$, we have from (ii) in Lemma 7 that

$$\begin{aligned}C_{\alpha,p}(t - t_{k-1})^{-\alpha} |v(t_{k-1}) - z_2|_p &\leqq C_{\alpha,p}(|v(t_{k-1})|_p + |z_2|_p) \\ &\leqq C_{\alpha,p}(|v(t_{k-1}) + 1|_{\gamma p}^\gamma + |z_2|_p) \\ &\leqq C_{\alpha,p}[(|v(t_{k-1})|_{\gamma p} + |1|_{\gamma p})^\gamma + |z_2|_p] \\ &\leqq C_{\alpha,p}[(\bar{R}_{\gamma p} + 1 + |\Omega|^{1/\gamma p})^\gamma + |z_2|_p] \\ &\equiv M_4.\end{aligned}$$

Also, by Hölder's inequality and Lemma 8 and since $\alpha q < 1$, we have

$$\begin{aligned}&\int_{t_{k-1}}^t C_{\alpha,p}(t - s)^{-\alpha} |G(s, u(s), v(s))|_p \, ds \\ &\quad\leqq C_{\alpha,p}\left[\int_{t_{k-1}}^t (t - s)^{-\alpha q} \, ds\right]^{1/q} \left[\int_{t_{k-1}}^t |G(s, u(s), v(s))|_p^p \, ds\right]^{1/p} \\ &\quad\leqq M_5\left[\int_{t_{k-1}}^{t_{k+1}} |G(s, u(s), v(s))|_p^p \, ds\right]^{1/p} \\ &\quad\leqq 2^{1/p} M_5 \Gamma_1(p, \gamma p)^{1/p}.\end{aligned}$$

Thus, for $t\in[t_k, t_{k+1}]$ with $k\geqq 2$,

$$|B^{\alpha}_{2,p}(v(t)-z_2)|_p\leqq M_4+2^{1/p}M_5\Gamma_1(p,\gamma p)^{1/p}.$$

So (4.8) holds, and the proof of Theorem 2 is complete.

5. An example and a counterexample. We begin this section by showing how the preceeding results apply to the Brusselator mentioned in the introduction:

$$(5.1)\quad \begin{array}{lll} \text{(a)} & \begin{array}{l} u_t=d_1\Delta u-uv^2+Bv, \\ v_t=d_2\Delta v+uv^2-(B+1)v+A, \end{array} & x\in\Omega,\quad t>0, \\ \text{(b)} & u(x,t)=B/A,\quad v(x,t)=A, & x\in\partial\Omega,\quad t>0, \\ \text{(c)} & u(x,0)=u_0(x),\quad v(x,0)=v_0(x), & x\in\bar{\Omega}. \end{array}$$

It is assumed that A, B, d_1, and d_2 are positive constants and that u_0 and v_0 are nonnegative, uniformly bounded, measurable functions on $\bar{\Omega}$. The following result is valid for the solution to (5.1).

PROPOSITION 2. *The system* (5.1) *has a unique solution* (u, v) *on* $\Omega\times[0,\infty)$, *and there is a constant* $M>0$ *such that*

$$0\leqq u(x,t),\quad v(x,t)\leqq M \quad \textit{for all } t\geqq 0 \textit{ and } x\in\Omega.$$

In order to establish this result we show that (5.1) satisfies the suppositions of Theorem 2 with

$$f(t,\xi,\eta)\equiv-\xi\eta^2+B\eta,\qquad g(t,\xi,\eta)\equiv\xi\eta^2-(B+1)\eta+A.$$

It is immediate that (H1)-(H3) are satisfied, and that (H5) holds with $\gamma=2$ and L_0 independent of $t\geqq 0$. Moreover, since

$$f(t,\xi,\eta)+g(t,\xi,\eta)=A-\eta\leqq A$$

for all t, ξ, $\eta\geqq 0$, we see that (H6) is valid with $\mu_0(t,r)\equiv A$. Therefore, Proposition 2 will be established once it is shown that u remains uniformly bounded on $\Omega\times[0,\infty)$.

Proof of Proposition 2. As asserted in the preceding paragraph, we need only show that $|u(\cdot,t)|_\infty$ remains uniformly bounded so long as the solution to (5.1) exists. Since the suppositions of Proposition 1 are satisfied, there is a $T^*>0$ such that (u, v) exists on $\Omega\times[0, T^*)$. So let N_1, N_2 be as in (1.2) in Proposition 1 and let $0<t_0<T^*$. Define $\delta=\min\{v(x,t_0): x\in\bar{\Omega}\}$ and note that $\delta>0$. For if $\delta=v(x^*,t_0)=0$ then $x^*\in\Omega$, and so $\Delta v(x^*,t_0)\geqq 0$. By substitution of (x^*, t_0) into the second equation in (5.1a) it follows that $v_t(x^*,t_0)\geqq A>0$, which is impossible since this implies $v(x^*,t)<0$ for $t\in[t_0-\varepsilon, t_0)$ where $\varepsilon>0$. To complete the proof we show that

$$(5.2)\quad u(x,t)\leqq\max\{|u(\cdot,t_0)|_\infty, B/\delta, B(B+1)/A\}\equiv N_1(t)\quad \text{for all } (x,t)\in\Omega\times[t_0,T^*).$$

First, however, observe that

$$(5.3)\qquad v(x,t)\geqq\min\{\delta, A/(B+1)\}\quad \text{for all } (x,t)\in\bar{\Omega}\times[t_0,T^*).$$

For otherwise, if $t_0<t_1<T^*$ and

$$\begin{aligned} v(x^*,t^*)&=\min\{v(x,t): (x,t)\in\bar{\Omega}\times[t_0,t_1]\} \\ &<\min\{\delta, A/(B+1)\}, \end{aligned}$$

then $v(x^*,t^*)<A$ and so $x^*\in\Omega$ and $\Delta v(x^*,t^*)\geqq 0$. Thus

$$\begin{aligned} v_t(x^*,t^*)&\geqq-(B+1)v(x^*,t^*)+A \\ &>-(B+1)A/(B+1)+A=0, \end{aligned}$$

and so it follows that $t^*=t_0$. But if $t^*=t_0$ then $v(x^*, t^*) \geqq \delta$ by the definition of δ, and we have a contradiction. This establishes (5.3). Now assuming for contradiction that (5.2) is not true, it follows that there is a $t_1 \in (t_0, T^*)$ such that

$$\begin{aligned} u(x^*, t^*) &= \max \{u(x, t) \colon (x, t) \in \bar{\Omega} \times [t_0, t_1]\} \\ &> \max \{|u(\cdot, t_0)|_\infty, B/\delta, B(B+1)/A\}. \end{aligned}$$

Then $t^* > t_0$ since $u(x^*, t^*) > |u(\cdot, t_0)|_\infty$, and $x^* \in \Omega$ since $u(x^*, t^*) > B/A$. Thus $\Delta u(x^*, t^*) \leqq 0$. Therefore,

$$u_t(x^*, t^*) \leqq -u(x^*, t^*)v(x^*, t^*)^2 + Bv(x^*, t^*) = v(x^*, t^*)^2[Bv(x^*, t^*)^{-1} - u(x^*, t^*)].$$

By (5.3), $\max \{B/\delta, B(B+1)/A\} \geqq Bv(x^*, t^*)^{-1}$. Thus $u(x^*, t^*) > Bv(x^*, t^*)^{-1}$, and so $u_t(x^*, t^*) < 0$. This is not possible, since $t^* > t_0$. Thus (5.2) holds, and hence Theorem 2 implies the boundedness of solutions to (5.1).

We remark here that even though $u_\infty(r) \equiv A > 0$, our techniques can be used to show that the solution to (5.1) exists and is uniformly bounded on $\Omega \times [0, \infty)$ when the boundary conditions are Neumann type rather than Dirichlet (cf. Rothe [11]). This is accomplished by incorporating the $-v$ term in the equation for v into the differential operator. The semigroups $T^{\#}_{2,p}$, $1 < p < \infty$, generated by the corresponding perturbations of the operators $A_{2,p}$ are contractive rather than nonexpansive. Hence the estimates in Lemma 3 hold for the solution σ of

$$\begin{aligned} &\sigma_t = -(d_2\Delta\sigma - \sigma) - \theta && \text{on } Q_{\tau,T}, \\ &\frac{\partial\sigma}{\partial n} = 0 && \text{on } \partial\Omega \times (\tau, T), \\ &\sigma(\cdot, T) = 0 && \text{on } \Omega \end{aligned}$$

without the aid of the operator P. Using σ in place of ϕ in Lemmas 4 and 5 yields similar results, and hence (4.5) holds. The proof then proceeds exactly as before.

Let us now consider the model

$$(5.4) \qquad \begin{aligned} &\left.\begin{aligned} &u_t = d_1\Delta u - uv^\beta, \\ &v_t = d_2\Delta v + uv^\beta, \end{aligned}\right\} && x \in \Omega, \quad t > 0, \\ &\frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} = 0, && x \in \partial\Omega, \quad t > 0, \\ &u = u_0, \quad v = v_0, && x \in \Omega, \quad t = 0 \end{aligned}$$

where $0 \leqq u_0$, $v_0 \leqq M$ and d_1, $d_2 > 0$. It is easy to see that this model (with these and other boundary conditions) fits into our result of Theorem 2, since $|u(\cdot, t)|_\infty$ is obviously a priori bounded for $t \geqq 0$. As mentioned in the introduction, global existence and uniform boundedness of solutions to (5.4) were proved by Masuda [8].

It is interesting to notice that the assumption $d_2 > 0$ is essential here. Indeed, although the situation is good when either d_1, $d_2 > 0$ or $d_1 = d_2 = 0$, one can prove that, if $d_2 = 0$ and $\beta > 1$, there is no $\mathscr{L}^\infty$-estimate of the solution of (5.4) in terms of $|u_0|_\infty$ and $|v_0|_\infty$ for t large. More precisely we have

PROPOSITION 3. *Assume $d_2 = 0$, $d_1 > 0$, and $\beta > 1$. Let $a, b > 0$ and suppose that for all u_0, v_0 satisfying*

$$0 \leqq u_0 \leqq 1, \qquad 0 \leqq v_0 \leqq b$$

there exists a solution to (5.4) *on* $[0, T)$ *such that for each* $t \in [0, T)$,

$$|v(\cdot, t)|_\infty \leqq c(T, a, b).$$

Then

$$T \leqq [(\beta-1)b^{\beta-1}a]^{-1}.$$

Proof. Let v_0 be a nonnegative and compactly supported $\mathscr{L}^\infty$ function on Ω. If (5.4) has a solution on $[0, T)$, since $d_2 = 0$, the equation in v can be explicitly solved as

$$v(x,t) = v_0(x)[1-(\beta-1)v(x)^{\beta-1}U(x,t)]^{-1/(\beta-1)} \tag{5.5}$$

where $U(x,t) \equiv \int_0^t u(x,s)\,ds$ (we use here the uniqueness of bounded solutions of (5.4)). Let us now consider (u_k, v_k) the solution of (5.4) with the initial data

$$u_k(x,0) \equiv a \quad \text{for all } x \in \Omega$$

and $v_k(x,0)$ a compactly supported $\mathscr{C}^\infty$ function on Ω satisfying

$$0 \leqq v_k(x,0) \leqq b, \tag{5.6}$$

$$v_k(x_0, 0) = b \quad \text{for some } x_0 \in \Omega \text{ independent of } k, \tag{5.7}$$

$$v_k(x,0) \to 0 \quad \text{for } x \neq x_0 \quad \text{as } k \to \infty. \tag{5.8}$$

Assume that $v_k(x,t)$ remains uniformly bounded on $\Omega \times [0, T)$. Then by (5.5) and (5.7) we have

$$(\beta-1)b^{\beta-1}U_k(x_0, T) \leqq 1. \tag{5.9}$$

Now, by (5.5) and (5.8) and the fact that $U_k(x,t)$ is uniformly bounded on $\Omega \times [0, T)$, $v_k(x,t)$ tends to 0 for all $t \in [0, T)$ and $x \neq x_0$. As u_k and v_k are uniformly bounded, $u_k v_k^\beta$ tends to 0 in any $\mathscr{L}^p(\Omega \times (0, T))$ for $1 \leqq p < \infty$. But for p large enough, the mapping $\zeta \to w$ where

$$w_t = d_1 \Delta w + \zeta,$$

$$\frac{\partial w}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

$$w(x,0) = a \quad \text{on } \Omega$$

is compact from $\mathscr{L}^p(\Omega \times (0, T))$ into $\mathscr{C}([0, T] \times \bar{\Omega})$ (see Ladyzenskaja et al. [5]). Therefore, u_k converges uniformly on $\bar{\Omega} \times [0, T]$ to the constant solution $u \equiv a$ of

$$u_t = d_1 \Delta u,$$

$$\frac{\partial u}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

$$u(x,0) = a \quad \text{on } \Omega.$$

Passing to the limit in (5.9) yields $(\beta-1)b^{\beta-1}Ta \leqq 1$.

Acknowledgment. We would like to thank Professor L. C. Evans for his helpful suggestions regarding the estimates in § 3.

ASYMPTOTICS AND AN ASYMPTOTIC GALERKIN METHOD FOR HYPERBOLIC-PARABOLIC SINGULAR PERTURBATION PROBLEMS*

BENJAMIN F. ESHAM, JR.†

Abstract. A composite asymptotic expansion including initial layer corrections is developed for treating initial boundary value problems for hyperbolic equations with a small parameter multiplying the second-order time derivative term. Proof of uniform asymptotic validity is given a Hilbert space setting. The expansion forms the basis of a continuous-time Galerkin procedure for which error analysis based on the finite element method is included. This work extends recent results of Hsiao and Weinacht in two directions, one toward greater abstraction and one toward greater utility.

Key words. asymptotics, Galerkin method, singular perturbation

AMS (MOS) subject classification. 65

1. Introduction. Let Ω be a bounded domain in R^n, a generic point of which will be denoted by $x=(x_1,\cdots,x_n)$, with smooth boundary $\partial\Omega$ and let $t_0>0$ be arbitrary. We shall be interested in approximating the solution $u(x,t)$ of the initial-boundary value problem (P_ε):

$$\varepsilon^2 u_{tt}(x,t)+u_t(x,t)+Au(x,t)=f(x,t), \qquad \Omega\times(0,t_0), \tag{1.1}$$

$$u(x,t)=0, \qquad \partial\Omega\times[0,t_0], \tag{1.2}$$

$$u(x,0)=u_0(x), \qquad x\in\bar{\Omega}, \tag{1.3}$$

$$\varepsilon u_t(x,0)=u_1(x), \qquad x\in\bar{\Omega}, \tag{1.4}$$

using a combination of asymptotic and numerical techniques.

In (1.1) and (1.4) the parameter ε is assumed to be small, $0<\varepsilon\ll 1$. Here A is the second-order uniformly strongly elliptic operator in $L^2(\Omega)$ defined on $D(A)=H^2(\Omega)\cap H_0^1(\Omega)$ by

$$Au=-\sum_{i,j=1}^{n} D_i(a_{ij}(x)D_ju)+c(x)u, \tag{1.5}$$

in which $a_{ij}=a_{ji}\varepsilon C^\infty(\bar{\Omega})$ for $i,j=1,\cdots,n$, $c(x)\varepsilon C^\infty(\bar{\Omega})$, $c(x)\geqq 0$ and D_i denotes the derivative $\partial/\partial x_i$, $i=1,\cdots,n$. We assume the ellipticity condition

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geqq \Gamma \sum_{i=1}^{n} \xi_i^2$$

holds for all $\xi=(\xi_1,\cdots,\xi_n)\varepsilon R^n$ and $x\in\bar{\Omega}$. The ε-independent data $\{f,u_0,u_1\}$ is subject to certain regularity conditions specified later (see Theorem 2.1).

Problem (P_ε) is a singular perturbation problem of hyperbolic-parabolic type that has been investigated by many authors. In [21] Zlamal has used Fourier integral methods and in [22] has used eigenfunction expansions. The method of energy integrals has been exploited by Bobisud [2] and Hsiao and Weinacht [9]. In the terminology of singular perturbation theory, there is initial layer behavior in a neighborhood of $t=0$. The solution of (P_ε) is dominated by the solution $U_0(x,t)$ of the reduced problem (P_0), an initial-boundary value problem of parabolic type, obtained by setting $\varepsilon=0$.

* Received by the editors April 8, 1985; accepted for publication (in revised form) February 19, 1986.

† Department of Mathematical Sciences, Virginia Commonwealth University, Richmond, Virginia 23284.

The solution $U_0(x, t)$ cannot generally be expected to satisfy the initial condition (1.4), so one is led to consider initial-layer correction terms, which appear in higher order expansions.

For the proof of uniform validity of the expansion, we reformulate the problem in a Hilbert space setting in § 2. The result to first order for a closely related problem was obtained by Kisynski [13] using semigroups in Hilbert space. For related results see Nur [16] and Schoene [17]. Fattorini [4], [5] has recently used cosine families in Banach space to obtain an N-term composite expansion. Our development extends the work of Hsiao and Weinacht [9] to an abstract setting relying heavily on the positive definiteness of A and the inner product induced norm on the Hilbert space.

For the numerical solution of (P_ε) one may be tempted to solve the singular perturbation problem directly by means of standard methods such as the Crank-Nicolson-Galerkin scheme since this is a linear hyperbolic problem for each $\varepsilon > 0$. However, because of the presence of ε, the usual schemes will not yield meaningful numerical results without reducing the mesh size in the initial layer. This, of course, requires considerable computational effort. Also, the discrete problems involved may become ill-posed numerically when mesh sizes get to be too small. (See [8] and [12].)

In this paper we present a continuous-in-time numerical procedure for treating singularly perturbed problems such as (P_ε), which does not require a very fine mesh. The procedure uses singular perturbation theory to construct problems for the leading terms in the formal asymptotic expansion, which are then solved numerically by the Galerkin method with finite elements as the trial functions for the space variables. This leads to an initial-value problem for a system of ordinary differential equations for which explicit solutions can be constructed. We refer to this approximation as the asymptotic Galerkin approximation. Preliminary numerical implementation of the problems show that very accurate results may be obtained in an efficient way. (For a similar approach to singular perturbation problems of parabolic-elliptic type see [8] and [12].)

In § 2 we prove the uniform validity of an N-term composite asymptotic expansion. In § 3 we formulate and describe the approximation scheme in detail. Section 4 contains error estimates for the continuous-in-time asymptotic Galerkin approximation using finite element methods. The results of some numerical experiments are given in § 5. Throughout this paper, C will denote a generic constant, not necessarily the same in any two places. Also, sums over empty index sets are zero.

2. The asymptotic expansion. In this section a procedure is developed for the construction of an N-term asymptotic expansion with initial layer corrections for the singularly perturbed Cauchy problem (P_ε^*):

$$L_\varepsilon[u] := \varepsilon^2 u''(t) + u'(t) + Au(t) = F(t), \tag{2.1}$$

$$u(0) = u_0, \qquad \varepsilon u'(0) = u_1 \tag{2.2}$$

in a Hilbert space H, with inner product $(\cdot, \cdot)$, norm $\|\cdot\|$, and zero element θ. The linear operator A is assumed to be positive-definite and self-adjoint in H. Problem (P_ε^*) is an abstract analogue of problem (P_ε) specified in (1.1)-(1.4) of § 1.

A formal asymptotic expansion may be obtained in the form of a composite expansion familiar from singular perturbation theory (see [15] and [19]), namely,

$$u_N(t; \varepsilon) = E_0^N(t; \varepsilon) + E_L^{N+1}(t/\varepsilon^2; \varepsilon). \tag{2.3}$$

Here the outer expansion,

$$E_0^N(t; \varepsilon) := \sum_{n=0}^{N} U_n(t)\varepsilon^n, \tag{2.4}$$

provides a uniformly valid $O(\varepsilon^{N+1})$ approximation to $u(t;\,\varepsilon)$ on intervals $[\delta, t_0]$, $\delta>0$, bounded away from $t=0$. The initial layer expansion

$$\text{(2.5)}\qquad E_L^{N+1}(t/\varepsilon^2;\,\varepsilon):=\sum_{n=0}^{N+1} V_n(t/\varepsilon^2;\,\varepsilon)\varepsilon^{n+1}$$

is asymptotically zero except in a neighborhood of the initial point $t=0$. We introduce the stretched variable $\tau=t/\varepsilon^2$ inside the initial layer. The expansion (2.3) contains two terms V_N and V_{N+1}, which are not useful in the final approximation, but are necessary in the proof of uniform validity. The construction of such terms of higher order is typical in singular perturbation problems.

We say that a function $z(t;\,\varepsilon)$ in $C([0, t_0], H)$ is $O(\varepsilon^k)$ as $\varepsilon\to 0^+$ uniformly in $[0, t_0]$ if there are positive constants C and ε_0 such that $\|z(t;\,\varepsilon)\|\leqq C\varepsilon^k$ holds for all t in $[0, t_0]$ and ε in $(0, \varepsilon_0]$.

A calculation shows that

$$\text{(2.6)}\qquad \begin{aligned} L_\varepsilon[u_N]=&\sum_{n=0}^{N}(U_n'(t)+AU_n(t)-U_{n-2}''(t))\varepsilon^n\\ &+\sum_{n=-1}^{N}(\ddot V_{n+1}(\tau)+\dot V_{n+1}(\tau)+AV_{n-1}(\tau))\varepsilon^n+R(t;\,\varepsilon),\end{aligned}$$

where

$$\text{(2.7)}\qquad R(t;\,\varepsilon):=U_{N-1}''(t)\varepsilon^{N+1}+U_N''(t)\varepsilon^{N+2}+AV_N(t/\varepsilon^2)\varepsilon^{N+1}+AV_{N+1}(t/\varepsilon^2)\varepsilon^{N+2}$$

and functions with negative index vanish identically. We shall consistently use primes for t-derivatives and dots for τ-derivatives.

Putting $t=0$ in (2.3) and its derivative we find

$$\text{(2.8)}\qquad u_N(0;\,\varepsilon)=U_0(0)+\sum_{n=1}^{N}(U_n(0)+V_{n-1}(0))\varepsilon^n+V_N(0)\varepsilon^{N+1}+V_{N+1}(0)\varepsilon^{N+2}$$

and

$$\text{(2.9)}\qquad \varepsilon u_N'(0;\,\varepsilon)=\dot V_0(0)+\sum_{n=0}^{N}(U_n'(0)+\dot V_{n+1}(0))\varepsilon^{n+1},$$

which serve to determine initial values for $U_n(t)$ and $\dot V_n(\tau)$, resp., when we impose (2.2).

The formal approximation u_N is now constructed by solving the following set of initial value problems. For the terms of the outer expansion, we have problems (P_n), $0\leqq n\leqq N$, given by

$$U_n'(t)+AU_n(t)=\begin{cases}F(t), & n=0,\\ \theta, & n=1,\\ -U_{n-2}''(t), & 2\leqq n\leqq N,\end{cases}$$

$$U_n(0)=\begin{cases}u_0, & n=0,\\ -V_{n-1}(0), & 1\leqq n\leqq N,\end{cases}$$

while the terms of the initial layer expansion are determined as solutions of the problems $(\tilde P_n)$, $0\leqq n\leqq N+1$,

$$\ddot V_n(\tau)+\dot V_n(\tau)=\begin{cases}\theta, & n=0, 1,\\ -AV_{n-2}(\tau), & 2\leqq n\leqq N+1,\end{cases}$$

$$\dot V_n(0)=\begin{cases}u_1, & n=0,\\ -U_{n-1}'(0), & 1\leqq n\leqq N+1,\end{cases}$$

$$V_n(\tau)\to\theta \text{ as } \tau\to\infty,\qquad 0\leqq n\leqq N+1.$$

It follows that the remainder

$$z(t;\ \varepsilon):=u(t;\ \varepsilon)-u_N(t;\ \varepsilon)$$

satisfies the second-order initial-value problem

$$\varepsilon^2 z''(t)+z'(t)+Az(t)=-R(t;\ \varepsilon), \tag{2.10}$$

$$z(0;\ \varepsilon)=z_0(\varepsilon),\ \varepsilon z'(0;\ \varepsilon)=Z_1(\varepsilon), \tag{2.11}$$

where

$$z_0(\varepsilon):=-V_N(0)\varepsilon^{N+1}-V_{N+1}(0)\varepsilon^{N+2},$$
$$z_1(\varepsilon):=\theta$$

and $R(t;\ \varepsilon)$ is given by (2.7). See [7] for proof of existence and uniqueness of a solution to this problem.

For the solution of problems (P_n), $0\leqq n\leqq N$, and $(\tilde{P}_n)$, $0\leqq n\leqq N+1$, we have the following result.

LEMMA 2.1. *Let N be any nonnegative integer and $t_0>0$. Let A be a positive-definite self-adjoint linear operator in H. Suppose $u_0\in D(A^{N+2})$ and $u_1\in D(A^{N+1})$. Then, provided*

$$F^{(l)}\in C([0,\ t_0],\ D(A^{N-2l})),\qquad 0\leqq l\leqq[N/2],$$

where [ ] denotes the greatest integer function,

(A) *The solution of problem (P_n), $0\leqq n\leqq N$, is given by*

$$U_n(t)=\begin{cases} T(t)P(tA;\ n/2)A^{n/2}u_0+T(t)\sum\limits_{l=0}^{n/2-1}P(tA;\ n/2-l-1)A^{n/2-l-1}F^{(l)}(0) \\ \quad+\displaystyle\int_0^t T(t-s)\sum_{l=0}^{n/2}P((t-s)A;\ n/2-l)A^{n/2-l}F^{(l)}(s)\,ds \quad n \text{ even}, \\ T(t)P(tA;\ (n-1)/2)A^{(n-1)/2}u_1 \quad n \text{ odd}, \end{cases}$$

where $T(t)$ is the analytic semigroup generated by $-A$, and $P(tA;\ k)$ is understood to be a generic polynomial operator in tA of degree k.

(B) *The solution of problem $(\tilde{P}_n)$, $0\leqq n\leqq N+1$, is given by*

$$V_n(\tau)=\begin{cases} e^{-\tau}P(\tau;\ n/2)A^{n/2}u_1 \quad n \text{ even}, \\ e^{-\tau}P(\tau;\ (n-1)/2)A^{(n+1)/2}u_0 \\ \quad+e^{-\tau}\sum\limits_{l=0}^{(n-1)/2}P(\tau;\ (n-1)/2-l)A^{(n-1)/2-l}F^{(l)}(0) \quad n \text{ odd}, \end{cases}$$

where $P(\tau;\ k)$ is a generic polynomial in τ of degree k.

Proof. An induction proof is based on the variation of parameters representation for $U_{n+1}(t)$ using $T(t)$, the analytic semigroup generated by $-A$,

$$U_{n+1}(t)=-T(t)V_n(0)+\int_0^t T(t-s)\{-U''_{n-1}(s)\}\,ds,$$

and a representation for $V_{N+1}(\tau)$ obtained by two Riemann integrations of $(\tilde{P}_{n+1})$, namely,

$$V_{n+1}(\tau)=e^{-\tau}U_n'(0)+\int_0^\tau e^{-(\tau-s)}AV_{n-1}(s)\,ds+\int_\tau^\infty AV_{n-1}(s)\,ds.$$

Remarks. (1) We note that in the above procedure, the zeroth order terms U_0 and V_0 are determined simultaneously from the initial data for problem (P_ε^*), but the higher order terms are determined alternately, as indicated in the diagram.

$$U_0\to V_1\to U_2\to V_3\to U_4\to\cdots,$$
$$V_0\to U_1\to V_2\to U_3\to V_4\to\cdots.$$

In particular, if $u_0=\theta$, the first chain of dependent functions vanishes, while if $u_1=\theta$, the second chain vanishes.

(2) The solution $u(t;\varepsilon)$ does not exhibit initial layer behavior since the first term U_0 of the outer expansion provides a uniformly $O(\varepsilon)$ approximation on $[0, t_0]$, i.e.,

$$u(t;\varepsilon)=U_0(t)+O(\varepsilon).$$

However, for the t-derivative

$$\varepsilon u_t(t;\varepsilon)=\dot{V}_0(\tau)+(U_0'(t)+\dot{V}_1(\tau))\varepsilon+O(\varepsilon^2),$$

so we see that $U_0'(t)$ provides a uniformly $O(\varepsilon)$ approximation in any interval $[\delta, t_0]$, $\delta>0$ where $\dot{V}_0$ and $\dot{V}_1$ are asymptotically zero, but close to the initial point the boundary layer functions V_0 and V_1 are required for a uniform approximation.

The justification of the formal expansion procedure requires that the remainder z be $O(\varepsilon^{N+1})$ on $[0, t_0]$ as $\varepsilon\to 0^+$. A crucial step is the development of an a priori bound for the solution of the second-order initial value problem

$$\varepsilon^2 z''+z'+Az=f(t;\varepsilon), \tag{2.12}$$

$$z(0)=z_0(\varepsilon),\qquad \varepsilon z'(0)=z_1(\varepsilon). \tag{2.13}$$

We formulate the result as follows.

LEMMA 2.2. *Let A be a positive-definite self-adjoint linear operator in H and suppose $z_0(\varepsilon)\in D(A)$, $z_1(\varepsilon)\in D(A^{1/2})$ and $f(\cdot;\varepsilon)\in L^2(0, t_0; H)$, where $0<\varepsilon\leqq\varepsilon_0$ for an arbitrary fixed number ε_0* in $(0, 1)$.

Then the solution $z(t;\varepsilon)$ of (2.12), (2.13) *on* $[0, t_0]$ *satisfies the inequality*

$$\begin{aligned}&\|z(t)\|+\varepsilon\|z'(t)\|+\|A^{1/2}z(t)\|\\&\leqq M\left\{\|z_0\|+\|z_1\|+\|A^{1/2}z_0\|+\left(\int_0^{t_0}\|f(s)\|^2\,ds\right)^{1/2}\right\},\end{aligned}\tag{2.14}$$

in which we have suppressed the ε-dependence of z, z_0, z_1 and f. The constant M is given explicitly by $M=[6(1-\varepsilon_0)^{-1}]^{1/2}\exp[(1-\varepsilon_0)^{-1}t_0]$.

Proof. Forming the inner product

$$(2z+2z', L_\varepsilon[z]-f)=0$$

and transferring derivatives to form perfect t-derivatives, we see that, by introduction of $A^{1/2}$ and use of the positive-definiteness of A, we obtain the differential inequality

$$\begin{aligned}&D_t\{\|z\|^2+2\varepsilon^2(z, z')+\varepsilon^2\|z'\|^2+\|A^{1/2}z\|^2\}\\&\leqq\|z\|^2+2\varepsilon^2\|z'\|^2+2\|f\|^2.\end{aligned}$$

Integrating over the interval $[0, t]$, and using the inequality

$$2\varepsilon^2(z, z')\geqq -\varepsilon\|z\|^2-\varepsilon^3\|z'\|^2$$

which holds for $0<\varepsilon<\varepsilon_0$, where ε_0 lies in $(0, 1)$, we arrive at the inequality

$$\begin{aligned}&\|z(t)\|^2+\varepsilon^2\|z'(t)\|^2+\|A^{1/2}z(t)\|^2\\ &\quad\leqq 2(1-\varepsilon_0)^{-1}\left\{(\|z_0\|^2+\|z_1\|^2+\|A^{1/2}z_0\|^2)+\int_0^{t_0}\|f(s)\|^2\,ds\right\}\\ &\qquad+2(1-\varepsilon_0)^{-1}\int_0^t(\|z(s)\|^2+\varepsilon^2\|z'(s)\|^2+\|A^{1/2}z(s)\|^2)\,ds.\end{aligned}$$

Application of Gronwall's lemma and elementary inequalities produces the result of the lemma.

We can now state the main result of this section.

THEOREM 2.1. *Let a nonnegative integer N and $t_0>0$ be given. Let A be a positive-definite self-adjoint linear operator in a Hilbert space H and suppose that $u_0\in D(A^{N+2})$ and $u_1\in D(A^{N+1})$. Assume $F=F(t)$ is such that*

$$\frac{d^lF}{dt^l}\in C([0, t_0], D(A^{N-2l})),\qquad 0\leqq l\leqq[N/2].$$

Then the solution $u(t; \varepsilon)$ of the initial-value problem (P^*_ε) has an asymptotic expansion of the form (2.3) *such that*

$$u(t;\varepsilon)=u_N(t;\varepsilon)+O(\varepsilon^{N+1}),$$
$$\varepsilon u'(t;\varepsilon)=\varepsilon u'_N(t;\varepsilon)+O(\varepsilon^{N+1}),$$

and

$$A^{1/2}u(t;\varepsilon)=A^{1/2}u_N(t;\varepsilon)+O(\varepsilon^{N+1})$$

as $\varepsilon\to 0^+$ uniformly on $[0, t_0]$.

Proof. The remainder $z(t;\varepsilon)=u(t;\varepsilon)-u_N(t;\varepsilon)$ satisfies (2.10) and (2.11). Since Lemma 2.1 implies

$$\|V_{N+1}(0)\|\leqq\begin{cases}C(\|A^{(N+2)/2}u_0\|;\ \|A^{N/2-l}F^{(l)}(0)\|, 0\leqq l\leqq N/2) & N\text{ even},\\ C(\|A^{(N+1)/2}u_1\|) & N\text{ odd},\end{cases}$$

we see that $\|z_0(\varepsilon)\|<C\varepsilon^{N+1}$. Obviously $\|z_1(\varepsilon)\|=0$.

In order to bound $\|R(t;\varepsilon)\|$, we first note that since $\varepsilon^{-\tau}P(\tau)$ is bounded on $[0,\infty)$ for any polynomial $P(\tau)$, we have from the representations in Lemma 2.1,

$$\|AV_{N+1}(\tau)\|\leqq\begin{cases}C(\|A^{(N+4)/2}u_0\|,\ \|A^{(N+2)/2-l}F^{(l)}(0)\|, 0\leqq l\leqq N/2) & N\text{ even},\\ C(\|A^{(N+3)/2}u_1\|) & N\text{ odd}.\end{cases}$$

Also, the proof of Lemma 2.1 yields an expression for $U''_n(t)$ so that for N odd,

$$\|U''_N(t)\|\leqq C(t_0;\ \|A^{N+1}u_1\|)$$

and for N even, with

$$\|G\|_\infty:=\sup_{0\leqq t\leqq t_0}\|G(t)\|,$$

$$\begin{aligned}\|U''_N(t)\|\leqq C(t_0;\ &\|A^{N+2}u_0\|;\ \|A^{N-2l}F^{(l)}(0)\|, 0\leqq l\leqq(N-2)/2\\ &\|A^{N/2-l}F^{(l+1)}(\cdot)\|_\infty,\ \|A^{N/2-l+1}F^{(l)}(\cdot)\|_\infty,\\ &\|A^{N-2l+2}F^{(l)}(\cdot)\|_\infty, 0\leqq l\leqq N/2).\end{aligned}$$

From these estimates

$$\|R(t;\varepsilon)\| \leqq C(t_0)\varepsilon^{N+1}.$$

Putting these results in the energy inequality (2.14) we obtain

$$\|z(t)\| + \varepsilon\|z'(t)\| + \|A^{1/2}z(t)\| \leqq C(t_0)\varepsilon^{N+1},$$

which establishes the theorem.

Remark. The results of this section hold for any positive-definite self-adjoint linear operator A defined on a Hilbert space H, and are not restricted to the operator defined in (1.5). In particular, if A is of arbitrary order $2m$, the plate problem is included.

3. A numerical procedure. Applying the results of § 2 to the solution $u(x, t)$ of problem (P_ε), given by (1.1) to (1.4), we have the asymptotic expansion

$$u(x,t) = U_0(x,t) + \sum_{n=1}^{N} (U_n(x,t) + V_{n-1}(x, t/\varepsilon^2))\varepsilon^n + O(\varepsilon^{N+1}).$$

Here $U_n(x, t)$ is obtained as the solution of a parabolic problem (P_n):

$$\frac{\partial U_n}{\partial t}(x,t) + AU_n(x,t) = \begin{cases} f(x,t), & n=0, \\ 0, & n=1, \\ -\partial^2 U_{n-2}/\partial t^2, & 2 \leqq n \leqq N \end{cases}$$

$$\text{for } (x,t) \in \Omega \times (0, t_0],$$

$$U_n(x,t) = 0, \quad 0 \leqq n \leqq N, \quad (x,t) \in \partial\Omega \times (0, t_0],$$

$$U_n(x,0) = \begin{cases} u_0(x), & n=0, & x \in \bar{\Omega}, \\ -V_{n-1}(x,0), & 1 \leqq n \leqq N, & x \in \bar{\Omega}, \end{cases}$$

where the elliptic operator A is given by (1.5). To determine the initial-layer correction terms we must solve $(\tilde{P}_n)$:

$$\frac{\partial^2 V_n}{\partial \tau^2}(x,\tau) + \frac{\partial V_n(x,\tau)}{\partial \tau}$$

$$= \begin{cases} 0, & n = 0, 1 \\ -AV_{n-2}(x,\tau), & 2 \leqq n \leqq N-1 \end{cases} \quad \text{for } (x,\tau) \in \Omega \times (0, \infty),$$

$$\frac{\partial V_n}{\partial \tau}(x,0) = \begin{cases} u_1(x), & n=0, & x \in \bar{\Omega}, \\ (-\partial U_{n-1}/\partial t)(x,0), & 1 \leqq n \leqq N-1, & x \in \bar{\Omega}, \end{cases}$$

$$V_n(x,\tau) \to 0 \quad \text{as } \tau \to \infty, \qquad 0 \leqq n \leqq N-1, \quad x \in \bar{\Omega}.$$

In order to develop a numerical procedure based on the Galerkin method, we introduce weak formulations of the problems (P_ε) and (P_n), $0 \leqq n \leqq N$. As usual, we denote by $H^m(\Omega)$ the real Sobolev space of integer order m on Ω equipped with the norm $\|\cdot\|_m$, and by $H_0^m(\Omega)$ the subspace of $H^m(\Omega)$ obtained by completing $C_0^\infty(\Omega)$ with respect to the norm $\|\cdot\|_m$.

By a weak solution of problem (P_ε) we mean a function $u(x, t)$, twice continuously differentiable with respect to t, such that for each fixed t in $[0, t_0]$, $u(t) := u(\cdot, t) \in H_0^1(\Omega)$ and satisfies the integral identities

$$\begin{aligned} &\varepsilon^2(u_{tt}, w) + (u_t, w) + a(u, w) = (f, w), \\ &(u(0) - u_0, w) = 0, \qquad (\varepsilon u_t(0) - u_1, w) = 0 \end{aligned} \tag{3.1}$$

for each $w \in H_0^1(\Omega)$. Here $(\cdot,\cdot)$ denotes the $L_2(\Omega)$ inner product and $a(\cdot,\cdot)$ is the bilinear form

$$a(u, w) = \int_\Omega \left\{ \sum_{i,j=1}^{n} a_{ij}(x) D_j u D_j w + c(x) uw \right\} dx$$

associated with the linear operator A defined in (1.5). Under the assumptions on the coefficients a_{ij} and c given in § 1, the bilinear form $a(\cdot,\cdot)$ is continuous as a map from $H^1(\Omega)\times H^1(\Omega)\to\mathbb{R}$, i.e., there exists a constant $\gamma > 0$ such that

$$a(u, w) \leqq \gamma \|u\|_1 \|w\|_1 \quad \text{for all } u, \quad w \in H^1(\Omega), \tag{3.2}$$

and strongly coercive, i.e., there exists a constant $\lambda > 0$ such that

$$a(u, u) \geqq \lambda \|u\|^2 \quad \text{for all } u \in H_0^1(\Omega). \tag{3.3}$$

These properties are important for the error bounds of our numerical approximation discussed in § 4.

A weak solution of problem (P_n), which we shall also denote $U_n(x, t)$, $0 \leqq n \leqq N$, is a continuously t-differentiable function $U_n(t) := U_n(\cdot, t) \in H_0^1(\Omega)$, for each t in $[0, t_0]$, which satisfies

$$\left(\frac{\partial U_n}{\partial t}, w\right) + a(U_n, w) = \begin{cases} (f, w), & n = 0, \\ 0, & n = 1, \\ (-\partial^2 U_{n-2}/\partial t^2, w), & 2 \leqq n \leqq N, \end{cases}$$

$$(U_n(0) - u_n, w) = 0, \qquad n = 0, 1,$$

$$(U_n(0) + V_{n-1}(0), w) = 0, \qquad 2 \leqq n \leqq N,$$

for each $w \in H_0^1(\Omega)$.

The existence and uniqueness of the weak solutions for (P_ε) and (P_n), $0 \leqq n \leqq N$, follow from standard results for linear hyperbolic and parabolic equations (see, for example, [14]). We note that the terms of the expansion are obtained in a recursive manner so that the problems (P_n), $0 \leqq n \leqq N$, are not solved simultaneously, but successively, together with the layer problems $(\tilde{P}_n)$, $0 \leqq n \leqq N-1$; see the remark following Lemma 2.1.

To describe the asymptotic Galerkin approximation, let us denote by S^h a one-parameter family of $M(h)$-dimensional subspaces of $H_0^1(\Omega)$ possessing a certain interpolation property to be specified later (see (4.1)). Let $\{w_k^h\}_{k=1}^M$ be a basis for S^h. The asymptotic Galerkin approximation is defined by

$$u_*^h(x, t) = U_0^h(x, t) + \sum_{n=1}^{N} (U_n^h(x, t) + V_{n-1}^h(x, t/\varepsilon^2))\varepsilon^n, \tag{3.4}$$

in which $U_n^h(\cdot, t) \in S^h$ is the continuous-in-time Galerkin approximation of the weak solution $U_n(x, t)$, which satisfies

$$\left(\frac{\partial U_n^h}{\partial t}, w^h\right) + a(U_n^h, w^h) = \begin{cases} (f(\cdot, t), w^h), & n = 0, \\ 0, & n = 1, \\ (-\partial^2 U_{n-2}^h/\partial t^2, w^h), & 2 \leqq n \leqq N, \end{cases}$$

$$(U_n^h(\cdot, 0) - u_n, w^h) = 0, \qquad n = 0, 1,$$

$$(U_n^h(\cdot, 0) + V_{n-1}^h(\cdot, 0), w^h) = 0, \qquad 2 \leqq n \leqq N,$$

for each $w^h \in S^h$.

The functions V_n^h, $0 \leqq n \leqq N-1$, are the L_2-projections of the layer functions $V_n(x, \tau)$ so that

$$(V_n(\cdot, \tau), w^h) = (V_n^h(\quad \cdot, \tau), w^h)$$

for all $w^h \in S^h$.

In terms of the basis $\{w_k^h\}_{k=1}^M$ for S^h, the outer approximations have the explicit representations

$$U_n^h(x, t) = \sum_{k=1}^M \alpha_k^n(t) w_k^h(x).$$

Here the functions $\{\alpha_k^n\}_{k=1}^M$, $n = 0, 1, \cdots, N$, are determined as solutions of an initial-value problem for a system of ordinary differential equations

$$\sum_{k=1}^M \left\{\frac{d}{dt}\alpha_k^n(t)(w_k^h, w_l^h) + \alpha_k^n(t) a(w_k^h, w_l^h)\right\}$$

$$= \begin{cases} (f(\cdot, t), w_l^h), & n = 0, \\ 0, & n = 1, \\ \displaystyle\sum_{k=1}^M \frac{d^2}{dt^2}\alpha_k^{n-2}(t)(w_k^h, w_l^h), & 2 \leqq n \leqq N, \end{cases} \tag{3.5}$$

$$\sum_{k=1}^M \alpha_k^n(0)(w_k^h, w_l^h) = \begin{cases} (u_n, w_l^h), & n = 0, 1, \\ (-V_{n-1}(0), w_l^h), & 2 \leqq n \leqq N \end{cases}$$

for $0 \leqq l \leqq M$.

The system is uniquely solvable for each $n = 0, 1, \cdots, N$, since the Gram matrix $G = [(w_k^h, w_l^h)]$ is positive definite. Let $S = [a(w_k^h, w_l^h)]$.

The solution vectors

$$\boldsymbol{\alpha}^n(t) = (\alpha_1^n, (t), \cdots, \alpha_M^n(t))^T,$$

$n = 0, 1, \cdots, N$, are given by the explicit representation

$$\boldsymbol{\alpha}^n(t) = \begin{cases} \exp\{-tG^{-1}S\}G^{-1}\mathbf{u}_0 + \displaystyle\int_0^t \exp\{-(t-t_1)G^{-1}S\}\mathbf{f}(t_1)\,dt_1, & n = 0, \\ \exp\{-tG^{-1}S\}G^{-1}\mathbf{u}_1, & n = 1, \\ \exp\{-tG^{-1}S\}G^{-1}\mathbf{V}_n(0) + \displaystyle\int_0^t \exp\{-(t-t_1)G^{-1}S\}\frac{d^2\boldsymbol{\alpha}^{n-2}(t_1)}{dt^2}\,dt_1, & 2 \leqq n \leqq N, \end{cases}$$

with

$$\mathbf{f}(t) = ((f(\cdot, t), w_1^h), \cdots, (f(\cdot, t), w_M^h))^T,$$

$$\mathbf{u}_n = ((u_n, w_1^h), \cdots, (u_n, w_M^h))^T, \qquad n = 0, 1$$

and

$$\mathbf{V}_n(0) = ((-V_{n-1}(\cdot, 0), w_1^h), \cdots, (-V_{n-1}(\cdot, 0), w_M^h))^T, \qquad 2 \leqq n \leqq N.$$

The asymptotic Galerkin approximation defined in (3.4) admits the explicit representation

$$u_*^h(x, t) = \sum_{n=0}^N \sum_{k=1}^M \beta_k^n(t) w_k^h(x) \varepsilon^n, \tag{3.6}$$

where

$$\beta_k^0(t) = \boldsymbol{\alpha}^0(t) \cdot \mathbf{e}_k \tag{3.7}$$

and

$$\beta_k^n(t) = \{\boldsymbol{\alpha}^n(t) - \mathbf{V}_{n-1}(\tau)\} \cdot \mathbf{e}_k, \qquad 1 \leqq n \leqq N,$$

in which $\mathbf{e}_k$ is the kth unit vector in $\mathbb{R}^M$, and

$$V_{n-1}(\tau) = ((V_{n-1}(\cdot, \tau), w_1^h), \cdots, (V_{n-1}(\cdot, \tau), w_M^h))^T$$

for $n = 1, \cdots, N$.

We comment that if we solve (3.1) directly by the Galerkin method and approximate the weak solution u by the Galerkin approximation

$$g^h(x, t) = \sum_{k=1}^{M} \gamma_k(t) w_k^h(x),$$

then $\boldsymbol{\gamma}(t) = (\gamma_1(t), \cdots, \gamma_M(t))^T$ satisfies the singularly perturbed second-order ordinary differential equation with initial data:

$$\varepsilon^2 G\boldsymbol{\gamma}''(t) + G\boldsymbol{\gamma}'(t) + S\boldsymbol{\gamma}(t) = \mathbf{f}(t), \qquad 0 < t \leqq t_0$$

$$\boldsymbol{\gamma}(0) = G^{-1}((u_0, w_1^h), \cdots, (u_0, w_M^h))^T,$$

$$\varepsilon\boldsymbol{\gamma}'(0) = G^{-1}((u_1, w_1^h), \cdots, (u_1, w_M^h))^T.$$

The vectors $\boldsymbol{\beta}^0$ and $\boldsymbol{\beta}^1$ defined in (3.7) are the zeroth order term and the $O(\varepsilon)$-term in the expansion of $\boldsymbol{\gamma}$. Hence the asymptotic Galerkin approximation is a combination of asymptotic and numerical approximations.

The coefficients $\beta_k^n(t)$, $1 \leqq k \leqq M$, defined by (3.7) are computable in principle. The exponential matrix is best handled in practice by difference approximations or Padé approximations. The implementation of the procedure using discrete schemes follows along well developed lines. Preliminary computations indicate that the procedure is very promising.

4. Error estimates. In this section we derive error estimates for the asymptotic Galerkin approximation u_*^h, the continuous-time Galerkin procedure developed in § 3. Since the accuracy of the procedure depends on the properties of the approximating subspaces, we follow [3] in assuming that for a fixed integer $m \geqq 2$, the finite-dimensional subspaces S^h of $H_0^1(\Omega)$ possess the following approximation property: For any $u \in H^s(\Omega) \cap H_0^1(\Omega)$, $1 \leqq s \leqq m$, there is a constant Q, independent of h and u, such that

$$\inf \{\|u - V^h\| + h\|u - V^h\|_1 \colon V^h \in S^h\} \leqq Qh^s\|u\|_s. \tag{4.1}$$

The space of piecewise linear polynomials is known to satisfy (4.1) for $s = 2$.

We introduce the elliptic projection of u onto S^h, denoted e^h, defined as the solution of the variational elliptic boundary value problem

$$a(e^h(t), w^h) = a(u(t), w^h) \tag{4.2}$$

for all $w^h \in S^h$ and for each fixed t in $[0, t_0]$, treated as a steady-state problem with parameter t. The existence of e^h is guaranteed by the Lax-Milgram theorem. The elliptic projection is the best approximation to u in S^h with respect to the H_1-norm, i.e., for some constant ν

$$\|u - e^h\|_1 \leqq \nu\|u - w^h\|_1 \quad \text{for all } w^h \in S^h.$$

Moreover, it is easily shown that if for some constant $k \geqq 0$, $u \in C^k([0, t_0]; H^s(\Omega) \cap H_0^1(\Omega))$, then for $1 \leqq s \leqq m$, and for some constant C, independent of h and u,

$$\|D_t(u - e^h)\| \leqq Ch^s \|D_t^k u\|_s. \tag{4.3}$$

We also introduce the continuous-time Galerkin solution of (3.1), $g^h \in C^2((0, t_0]; S^h)$, satisfying

$$\begin{gathered} \varepsilon^2(g_{tt}^h, w^h) + (g_t^h, w^h) + a(g^h, w^h) = (f, w^h), \\ (g^h(\cdot, 0) - u_0(\cdot), w^h) = 0, \\ (\varepsilon g_t^h(\cdot, 0) - u_1(\cdot), w^h) = 0 \end{gathered} \tag{4.4}$$

for $0 < t \leqq t_0$ and for all $w^h \in S^h$.

The elliptic projection e^h and the Galerkin solution g^h are used only to derive the desired error estimates and do not appear in the numerical procedure (see [3], [8] and [20]).

If $\underline{X}$ is a Hilbert space with norm $\|\cdot\|_{\underline{X}}$, then

$$\|u\|_{L^\infty(\underline{X})} := \sup_{t \in [0, t_0]} \|u(\cdot, t)\|_{\underline{X}}$$

and

$$\|u\|_{L^2(\underline{X})} := \left(\int_0^{t_0} \|u(\cdot, t)\|_{\underline{X}}^2 \, dt \right)^{1/2}.$$

We obtain error estimates with respect to the following norm

$$\|u\|_E := \|u\|_{L^\infty(H^1)} + \varepsilon \|u_t\|_{L^\infty(L^2)}.$$

THEOREM 4.1. *Let $\{S^h\}$, $0 < h \leqq 1$, be a family of finite-dimensional subspaces of $H_0^1(\Omega)$ satisfying the approximation property* (4.1). *Denote by*

u, *the weak solution of problem* (P_ε),

g^h, *the Galerkin approximation of u in S^h,*

e^h, *the elliptic projection of u into S^h, and*

u_*^h, *the asymptotic Galerkin approximation.*

Assume that $u_0 \in D(A^{N+2})$ and $u_1 \in D(A^{N+1})$. If $u_{tt} \in L^2(0, t_0; H^s(\Omega))$, and

$$\|e^h(\cdot, 0) - g^h(\cdot, 0)\|_1 \leqq Ch^s, \tag{4.5}$$

$$\|e_t^h(\cdot, 0) - g_t^h(\cdot, 0)\| \leqq Ch^s, \tag{4.6}$$

then the bound

$$\|u - u_*^h\|_E \leqq C\{h^{s+1} + \varepsilon^{N+1}\},$$

holds for $0 < t \leqq t_0$, where the constant C is independent of ε, h and u.

Proof. To measure $\|u - u_*^h\|_E$ we introduce the elliptic projection e^h and the Galerkin solution g^h,

$$u - u_*^h = (u - e^h) + (e^h - g^h) + (g^h - u_*^h),$$

and proceed by bounding each term on the right-hand side. The appropriate estimates are

(i) $\|u-e^h\|_E \leqq Ch^{s-1}\{\|u\|_{L^\infty(H^s)}+\varepsilon h\|u_t\|_{L^\infty(H^s)}\}$,
(ii) $\|e^h-g^h\|_E \leqq Ch^s\{1+\varepsilon+\varepsilon\|u_t\|_{L^\infty(H^s)}+\varepsilon^2\|u_{tt}\|_{L^2(H^s)}\}$,
(iii) $\|g^h-u_*^h\|_E \leqq C\varepsilon^{N+1}$.

By the best approximation property of e^h and the property of convergence of the family of subspaces S^h, we see that if $u \in H^s(\Omega) \cap H_0^1(\Omega)$, then

$$\|u-e^h\|_1 \leqq Ch^{s-1}\|u\|_s,$$

where $C=Q\nu$. Applying this argument to $u_t \in H^s(\Omega) \cap H_0^1(\Omega)$ together with Nitsche's trick (see [18]), we get

$$\|u_t-e_t^h\| \leqq Ch^s\|u_t\|_s.$$

The inequality (i) follows immediately.

For the proof of (ii), let $\psi^h := g^h - e^h$ and $\eta := u-e^h$, then we easily find, using (3.1), (4.2) and (4.4), that for each $w^h \in S^h$,

$$\varepsilon^2(\psi_{tt}^h, w^h)+(\psi_t^h, w^h)+a(\psi^h, w^h)=\varepsilon^2(\eta_{tt}, w^h)+(\eta_t, w^h).$$

We combine the first pair of terms on each side as follows

$$\varepsilon^2(e^{-t/\varepsilon^2}D_t(\psi_t^h e^{t/\varepsilon^2}), w^h)+a(\eta, w^h)=\varepsilon^2(e^{-t/\varepsilon^2}D_t(\eta_t e^{t/\varepsilon^2}), w^h).$$

For each fixed t in $(0, t_0]$ we choose the particular element of S^h given by $w^h(t)=\psi_t^h(t)e^{t/\varepsilon^2}$, so that we obtain

$$\tfrac{1}{2}\varepsilon^2 D_t\|\psi_t^h e^{t/\varepsilon^2}\|^2+\tfrac{1}{2}e^{2t/\varepsilon^2}D_t a(\psi^h, \psi^h)=\varepsilon^2(D_t(\eta_t e^{t/\varepsilon^2}), \psi_t^h e^{t/\varepsilon^2}).$$

Integration from $t=0$ to $t=\xi$ yields, after integration by parts and use of the coercivity and continuity of the bilinear form $a(\cdot\,.\,\cdot)$, specified in (3.2) and (3.3), the inequality

$$\begin{aligned}\lambda\|\psi^h(\xi)\|_1^2+\varepsilon^2\|\psi_t^h(\xi)\|^2 &\leqq e^{-2\xi/\varepsilon^2}(\gamma\|\psi^h(0)\|_1^2+\varepsilon^2\|\psi_t^h(0)\|^2)\\ &\quad+2\gamma/\varepsilon^2\int_0^\xi e^{-2(\xi-t)/\varepsilon^2}\|\psi(t)\|_1^2\,dt\\ &\quad+2\varepsilon^2\int_0^\xi e^{-(2\xi-t)/\varepsilon^2}(D_t(\eta_t e^{t/\varepsilon^2}), \psi_t^h)\,dt.\end{aligned}\tag{4.7}$$

Consider that

$$\begin{aligned}&2\varepsilon^2\int_0^\xi e^{-(2\xi-t)/\varepsilon^2}(D_t(\eta_t e^{t/\varepsilon^2}), \psi_t^h)\,dt\\ &\quad\leqq \varepsilon^4\int_0^\xi e^{-2(\xi-t)/\varepsilon^2}\|\eta_{tt}\|^2\,dt+2/\varepsilon^2\int_0^\xi e^{-2(\xi-t)/\varepsilon^2}\varepsilon^2\|\psi_t^h\|^2\,dt\\ &\quad\quad+\int_0^\xi e^{-2(\xi-t)/\varepsilon^2}\|\eta_t\|^2\,dt.\end{aligned}$$

Thus (4.7) becomes

$$\begin{aligned}&\|\psi^h(\xi)\|_1^2+\varepsilon^2\|\psi_t^h(\xi)\|^2\\ &\quad\leqq C_1\{\|\psi^h(0)\|_1^2+\varepsilon\|\psi_t^h(0)\|^2+\varepsilon^4\|\eta_{tt}\|_{L^2(L^2(\Omega))}^2+\varepsilon^2\|\eta_t\|_{L^\infty(L^2(\Omega))}^2\}\\ &\quad\quad+C_2\varepsilon^{-2}\int_0^\xi e^{-2(\xi-t)/\varepsilon^2}\{\|\psi^h(t)\|_1^2+\varepsilon^2\|\psi_t^h(t)\|^2\}\,dt.\end{aligned}$$

By Gronwall's lemma and elementary inequalities, the following is seen to hold:

$$\|\psi^h(t)\|_1+\varepsilon\|\psi_t^h(t)\|\leqq C\{\|\psi^h(0)\|_1+\varepsilon\|\psi_t^h(0)\| \\ +\varepsilon\|\eta_{tt}\|_{L^\infty(L^2(\Omega))}+\varepsilon^2\|\eta_{tt}\|_{L^2(L^2(\Omega))}\}.$$

From (4.3) and the hypotheses (4.5), (4.6),

$$\|e^h-g^h\|_E\leqq Ch^s\{1+\varepsilon+\varepsilon\|u_t\|_{L\infty(H^s)}+\varepsilon^2\|u_{tt}\|_{L^2(H^2)}\}$$

and (ii) is established.

Applying the inequality of Lemma 2.2 to $z(t)=g^h(t)-u_*^h(t)$, we find

$$\|A^{1/2}(g^h-u_*^h)\|+\varepsilon\|(g^h-u_*^h)_t\|\leq C\varepsilon^{N+1},$$

where $\|\cdot\|$ denotes the L_2-norm. From [6] we know that the norm $\|A^{1/2}\cdot\|$ is equivalent to the norm $\|\cdot\|_1$ so that

$$\|g^h(t)-u_*^h(t)\|_1+\varepsilon\|g_t^h(t)-u_*^h(t)\|\leqq C\varepsilon^{N+1}$$

and

$$\|g^h-u_*^h\|_E\leqq C\varepsilon^{N+1}.$$

Thus (iii) is seen to hold.

5. Numerical experiments. Here we present some numerical evidence that the method provides good numerical approximations to the solution of the singularly perturbed problem. We consider the following model problem (P_ε):

$$\varepsilon^2u_{tt}+u_t-u_{xx}=0, \qquad 0<x<1,\ t>0,$$

$$u(x,0)=u_0(x), \qquad \varepsilon u_t(x,0)=u_1(x), \quad 0<x<1,$$

$$u(0,t)=u(1,t)=0, \qquad t>0,$$

with $u_0(x)=u_1(x)=\sin\pi x$. The exact solution of (P_ε) can be found explicitly: when $0<\varepsilon<\frac{1}{2}\pi$, $u(x,t;\varepsilon)=\{A(\varepsilon)\,e^{r_1(\varepsilon)t}+B(\varepsilon)\,e^{r_2(\varepsilon)t}\}\sin\pi x$ where

$$r_1(\varepsilon)=\frac{-1+\sqrt{1-4\pi^2\varepsilon^2}}{2\varepsilon^2}, \qquad r_2(\varepsilon)=\frac{-1-\sqrt{1-4\pi^2\varepsilon^2}}{2\varepsilon^2},$$

$$A(\varepsilon)=\frac{2\varepsilon+1+\sqrt{1-4\pi^2\varepsilon^2}}{2\sqrt{1-4\pi^2\varepsilon^2}}, \qquad B(\varepsilon)=\frac{\sqrt{1-4\pi^2\varepsilon^2}-1-2\varepsilon}{2\sqrt{1-4\pi^2\varepsilon^2}},$$

and, when $\varepsilon>\frac{1}{2}\pi$,

$$u(x,t;\varepsilon)=e^{-t/2\varepsilon^2}\{\cos r(\varepsilon)t+C(\varepsilon)\sin r(\varepsilon)t\}\sin\pi x$$

where

$$r(\varepsilon)=\frac{\sqrt{4\pi^2\varepsilon^2-1}}{2\varepsilon^2} \quad\text{and}\quad C(\varepsilon)=\frac{1+2\varepsilon}{\sqrt{4\pi^2\varepsilon^2-1}}.$$

Attacking the hyperbolic problem directly we first write it as a system (see Baker [1]):

$$u_t = v, \qquad \varepsilon^2 v_t = -v + u_{xx}.$$

With $U^n = u(\cdot, t_n)$ and $Q^n = v(\cdot, t_n)$, we introduce the scheme

$$U^{n+1} = U^n + \tfrac{1}{2}\tau(Q^{n+1} + Q^n), \tag{5.1}$$

$$\left(\frac{\varepsilon^2}{\tau} + \frac{1}{2}\right)(Q^{n+1}, \chi) + \left(\frac{1}{2} - \frac{\varepsilon^2}{\tau}\right)(Q^n, \chi) + a(U^n, \chi) + \frac{1}{4}\tau a(Q^{n+1} + Q^n, \chi) = 0, \tag{5.2}$$

where τ is the time step and $\chi \in S^h$, the finite-dimensional subspace of piecewise linear polynomials. At each time step the new value of u_t is computed by means of (5.2) and then used to update u using (5.1). To see that this Crank-Nicolson-Galerkin scheme is well suited to the problem (P_ε) when ε is large, we set $\varepsilon = 1$, $\Delta x = \Delta t = .01$ and generated the data in Table 1 at $x = .5$. When $\varepsilon = .01$, however, the approximate time derivative oscillates wildly as shown in Table 2. Since these values are used to update u, we have a very poor approximation. In order to achieve the same accuracy as indicated in Table 1 it was necessary to reduce the time step to $\Delta t = .00001$.

TABLE 1
$\varepsilon = 1$, $\Delta x = \Delta t = .01$, $x = .5$

t	Approx Sol	Exact Sol	Rel Error
.01	1.009455	1.009455	0.0
.05	1.036466	1.036459	6.46×10^{-6}
.1	1.046283	1.046249	3.28×10^{-5}
.5	.392190	.392168	5.66×10^{-5}
1	−.594303	−.594301	3.37×10^{-6}

TABLE 2
$\varepsilon = .01$, $\Delta x = \Delta t = .01$, $x = .5$

t	Computed u_t	Exact u_t	Rel Error
.01	−114.72	−9.04	1.2×10^{1}
.02	93.32	−8.19	1.2×10^{1}
.03	−104.96	−7.42	1.3×10^{1}
.04	86.97	−6.72	1.4×10^{1}
.05	−96.11	−6.09	1.5×10^{1}

TABLE 3
$\Delta x = \Delta t = .01$, $x = .5$, $t = .01$

ε^2	Asymp Sol	Exact Sol	Rel Error
10^{-2}	.95974	1.02616	6.5×10^{-2}
10^{-3}	.93457	.94352	9.4×10^{-3}
10^{-4}	.91499	.91590	9.9×10^{-4}
10^{-5}	.90879	.90896	1.9×10^{-4}
10^{-6}	.90683	.90693	1.1×10^{-4}
10^{-7}	.90621	.90630	9.8×10^{-5}
10^{-8}	.90602	.90610	9.7×10^{-5}

The asymptotic expansion to two terms is

$$u_1(x, t) = U_0(x, t) + \varepsilon(U_1(x, t) + V_0(x_1, t/\varepsilon^2)),$$

where U_0 and U_1 both satisfy the parabolic IBVP

$$U_t - U_{xx} = 0,$$
$$U(x, 0) = \sin \pi x,$$
$$U(0, t) = U(1, t) = 0$$

and $V_0(x, t/\varepsilon^2) = -e^{-t/\varepsilon^2} \sin \pi x$. We have used a standard Crank-Nicolson-Galerkin scheme to generate the solution to the parabolic problem. Table 3 shows that the asymptotic Galerkin approximation is in close agreement with the exact solution well beyond the point at which the Crank-Nicolson-Galerkin scheme has failed. Note that this has been accomplished using the same space-time mesh sizes in both cases.

IDENTIFICATION OF THE CONDUCTIVITY COEFFICIENT IN AN ELLIPTIC EQUATION*

AVNER FRIEDMAN† AND BJÖRN GUSTAFSSON‡

Abstract. Consider an elliptic equation in a two-dimensional domain Ω with conductivity coefficient $a=1+k\chi_D$ $(k\neq 0)$ where D is a subdomain of Ω. From the measurements of a pair of Dirichlet and Neumann data one wishes to identify D. It is proved that this problem is stable in some local sense.

Key words. elliptic equations, conductivity coefficient, identification problem, electrical prospecting

AMS(MOS) subject classifications. Primary 35R30; secondary 35J25, 35R05

Introduction. Consider an elliptic equation

$$\operatorname{div}(a\nabla u)=0 \quad \text{in } \Omega \tag{0.1}$$

with Dirichlet data

$$u=f \quad \text{on } \partial\Omega, \quad f\not\equiv \text{const}, \tag{0.2}$$

and with coefficient $a=1+k\chi_D$ $(-1<k<\infty,\ k\neq 0)$, where D is an unknown subdomain of Ω. We seek to determine D by measurements of the Neumann data

$$\frac{\partial u}{\partial \nu}=g \quad \text{on } \partial\Omega. \tag{0.3}$$

This identification problem arises in electrical prospecting, whereby one wishes to discover the location of metals or fluid reservoirs inside the earth.

Let $D(t)$ be a 1-parameter monotone family of domains with $D(0)=D$ such that

$$\left.\frac{d}{dt}\chi_{D(t)}\right|_{t=0}\neq 0 \quad \text{in } \mathcal{D}', \tag{0.4}$$

and denote by $u(t)\equiv u(x,t)$ the solution of (0.1), (0.2) corresponding to $a=1+k\chi_{D(t)}$. Our main result asserts that, in case the $D(t)$ are affine transformations of D, C^1 in t, for all t with $|t|$ small enough, there holds

$$\left\|\frac{\partial}{\partial \nu}[u(t)-u(0)]\right\|_{L^2(\partial\Omega)}\geqq c|t| \tag{0.5}$$

where c is a positive constant.

If we denote by Φ the mapping from a to g (when f is fixed) then (0.5) means formally that $d\Phi/da\neq 0$; thus, if $\Phi(a_1)=g_1$, $\Phi(a_2)=g_2$ and $\|a_2-a_1\|$ is small, then

$$\|a_2-a_1\|\leqq C\|g_2-g_1\| \quad \text{where } \frac{1}{\|d\Phi/da\|}\leqq C<\infty. \tag{0.6}$$

This means that the computation of D among a monotone family of domains is stable with respect to small errors in the measurement of the Neumann data; for more details on the significance of a result of this type see [12] and § 1 below.

‡ Royal Institute of Technology, Stockholm, Sweden.

There are other versions of identification problems. In [2], [4]-[6], [11] one measures the quadratic form

$$Q_a = \int_\Omega a|\nabla u|^2$$

for *all* f and shows that this determines $a = a(x)$ in Ω, provided that either $a(x)$ is piecewise analytic [4], [6] or $\|a-1\|$ is small enough [11]. For some special domains the identification problem can be resolved by separation of variables [3], [8] or by explicit representation of u by means of Green's function [9].

In another version (0.1) is replaced by

$$\operatorname{div}(a\nabla u) = l \quad \text{in } \Omega \quad (l \text{ is given})$$

and one wishes to find a, given the knowledge of u throughout *all* of Ω; see [1], [10] and the references given there. This problem is unstable.

References to physical models and numerical computations of identification problems are given in [1], [5].

1. The main result. Let Ω be a bounded simply connected domain in $\mathbb{R}^2$ with $C^{1,\alpha}$ boundary $\partial\Omega$ $(0<\alpha<1)$ and let D be a bounded subdomain of Ω with $C^{2,\alpha}$ boundary ∂D, $\bar{D} \subset \Omega$. We shall designate points in $\mathbb{R}^2$ by $x = (x_1, x_2)$.

Denote by χ_A the characteristic function of a set A.

We assume that D is star-shaped with respect to any point x^* of some nonempty subset D^* of D.

For any $x^* \in D^*$ introduce the 1-parameter family of domains

$$D(t) = \{x^* + (1-t)(x-x^*), x \in D\} \quad (-1<t<1). \tag{1.1}$$

Then $D(t) \subset D(t')$ if $t > t'$. Also

$$\frac{\partial}{\partial t}\chi_{D(t)}\bigg|_{t=0} = \beta \otimes \delta_{\partial D} \quad \text{in } \mathscr{D}', \tag{1.2}$$

that is

$$\frac{\partial}{\partial t}\left[\iint_\Omega \chi_{D(t)}\phi\right]\bigg|_{t=0} = \int_{\partial D} \beta\phi$$

for any $\phi \in C_0^0(\Omega)$, and β is a continuous and strictly negative function on ∂D; $\beta \in C^{1,\alpha}$.

Set $D_e(t) = \Omega\backslash\overline{D(t)}$. We shall use the notation w^e (or w^i) to denote the value of a function w on $\partial D(t)$ taken as a limit from $D_e(t)$ (or $D(t)$).

Let k be a fixed number, $-1<k<0$ or $k>0$, and set

$$a(x,t) = 1 + k\chi_{D(t)}(x), \qquad a(x) = a(x,0). \tag{1.3}$$

Consider the elliptic equation

$$\operatorname{div}(a(x,t)\nabla u) = 0 \quad \text{in } \Omega \tag{1.4}$$

with the Dirichlet condition

$$u = f \quad \text{on} \quad \partial\Omega \tag{1.5}$$

where $f = f(x)$ is in $C^{1,\alpha}(\partial\Omega)$.

It is well known [7] that the solution u of this diffraction problem is in $C^{0,\beta}(\bar{\Omega}) \cap H^1(\Omega)$ for some $0 < \beta < 1$, as well as in $C^{2,\alpha}(\overline{D(t)})$ and in $C^{2,\alpha}(\overline{D_e(t)} \backslash \partial\Omega)$, and that

$$\frac{\partial u^e}{\partial \nu} = (k+1)\frac{\partial u^i}{\partial \nu} \quad \text{on } \partial D(t) \tag{1.6}$$

where ν is the outward normal to $\partial D(t)$.

Set

$$g(x, t) = \frac{\partial u(x, t)}{\partial \nu}, \qquad x \in \partial\Omega \tag{1.7}$$

where ν is the outward normal to $\partial\Omega$. Then $g \in C^\alpha$.

We would like to determine the conductivity coefficient $a(x)$ from measurements of $g(x) \equiv g(x, 0)$. Since in real terms we can only measure $g(x)$ with some error, we would like to ensure that if the measurements give us a function $g(x, t)$ "close" to $g(x)$ then the corresponding $a(x, t)$ is also "close" to the true coefficient $a(x)$. If that is the case, then by compiling a catalog of various g's corresponding to various a's we can have an effective way of determining the true conductivity: We simply correspond to a function $\tilde{g}$ that we obtained by actual measurements the coefficient a which fits to that g in our catalog that is "nearest" to $\tilde{g}$. This point of view is quite common in inverse problems [12].

If $f \equiv$ const. then $u \equiv$ const. for any choice of $a(x, t)$ and thus $g(x, t) \equiv 0$. This means that we cannot gain any information on the coefficient a. Thus we must henceforth assume that

$$f \not\equiv \text{const.} \tag{1.8}$$

THEOREM 1.1. *If* (1.8) *holds then there exists a positive constant c such that*

$$\|g(\cdot, h) - g(\cdot)\|_{L^2(\partial\Omega)} \geqq c|h| \tag{1.9}$$

if $|h|$ *is small enough.*

Theorem 1.1 extends to more general monotone families of domains $D(t)$; see § 3.

Theorem 1.1 means that we can effectively determine D by the procedure outlined in the paragraph following (1.7), provided D is known to be imbedded in a monotone family of domains.

As we shall see in § 3 (Remark 3.2), Theorem 1.1 is generally false if $D(t)$ is not a monotone family (at least in one space dimension, or for Ω an annulus).

The remainder of this paper is devoted to the proof of Theorem 1.1; some generalizations are mentioned at the end of § 3.

2. Proof of Theorem 1.1. Set $g(t) \equiv g(x, t)$. To prove the theorem it suffices to assume that

$$\left\| \frac{g(h) - g(0)}{h} \right\|_{L^2(\partial\Omega)} \to 0 \quad \text{for some sequence } h \to 0 \tag{2.1}$$

and derive a contradiction. From now on h will be restricted to this sequence.

Consider first the case where $0 < h < 1$, so that

$$D(h) \subset D, \tag{2.2}$$

and set

$$a(t)\equiv a(x,t), \qquad u(t)\equiv u(x,t),$$
$$a_h=\frac{a(h)-a(0)}{h}, \qquad v_h=\frac{u(h)-u(0)}{h}.$$

From (1.4) we get

$$\operatorname{div}(a(h)\nabla u(h)-a(0)\nabla u(0))=0, \tag{2.3}$$

which implies that there exists a function w^h in $H^1(\Omega)$ such that

$$\frac{1}{h}[a(h)\nabla u(h)-a(0)\nabla u(0)]=\operatorname{curl} w^h; \tag{2.4}$$

here curl $w=(w_{x_2},-w_{x_1})$. We normalize w^h so that

$$w^h(x^0)=0 \quad \text{at some point } x^0\in\partial\Omega. \tag{2.5}$$

Since

$$\frac{1}{h}[a(h)\nabla u(h)-a(0)\nabla u(0)]=a(0)\nabla u_h+a_h\nabla u(h) \tag{2.6}$$

we can rewrite (2.4) in the form

$$a(0)\frac{\partial}{\partial\bar z}v_h+i\frac{\partial}{\partial\bar z}w^h=-a_h\frac{\partial u(h)}{\partial\bar z}. \tag{2.7}$$

Introduce the function

$$f^h=a(0)v_h+iw^h. \tag{2.8}$$

Then

$$\frac{\partial f^h}{\partial\bar z}=\frac{\partial a(0)}{\partial\bar z}v_h+a(0)\frac{\partial v_h}{\partial\bar z}+i\frac{\partial w^h}{\partial\bar z} \quad \text{in } \mathcal{D}' \tag{2.9}$$

and, using (2.7),

$$\frac{\partial f^h}{\partial\bar z}=\frac{\partial a(0)}{\partial\bar z}v_h-a_h\frac{\partial u(h)}{\partial\bar z}: \tag{2.10}$$

the right-hand side is a measure.

It follows by Cauchy's formula that

$$\begin{aligned} f^h(\zeta)=&-\frac{1}{\pi}\iint_\Omega\left(\frac{\partial a(0)}{\partial\bar z}v_h-a_h\frac{\partial u(h)}{\partial\bar z}\right)(z)\frac{1}{z-\zeta}\,dx\,dy\\ &+\frac{1}{2\pi i}\int_{\partial\Omega}\frac{f^h(z)}{z-\zeta}\,dz, \qquad \zeta\in\Omega.\end{aligned} \tag{2.11}$$

LEMMA 2.1. *As* $h\to 0$,

$$D_x^\gamma v_h\to 0 \quad \textit{uniformly in compact subsets of } D_e, \quad 0\leqq|\gamma|\leqq 1, \tag{2.12}$$

and

$$\int_{\partial D}|v_h|\,ds\to 0. \tag{2.13}$$

Proof. Take for simplicity $x^*=0$. Define

$$\Omega_h=\left\{x\in\Omega \text{ and } \frac{x}{1-h}\in\Omega\right\}=\Omega\cap(1-h)\Omega,$$

$$u(x)=u(x,0),$$

$$U^h(x)=\frac{1}{h}\left[u\left(\frac{x}{1-h}\right)-u(x)\right] \quad \text{in } \Omega_h,$$

$$V^h(x)=\frac{1}{h}\left[u(x,h)-u\left(\frac{x}{1-h}\right)\right] \quad \text{in } \Omega_h.$$

Then

$$v_h(x)=U^h(x)+V^h(x) \quad \text{in } \Omega_h.$$

By the $C^{2,\alpha}$ regularity of u in $D_e\cup\partial D$,

$$|U^h|+|\nabla U^h|\leqq C \quad \text{in } D_e\cap\Omega_h. \tag{2.14}$$

Next,

$$\operatorname{div}(a(h)\nabla V^h)=\frac{1}{h}\left\{0-\operatorname{div}_x\left[a(h)\nabla_x u\left(\frac{x}{1-h}\right)\right]\right\}.$$

Since

$$a(h)=1+k\chi_{D(h)}(x)=1+k\chi_{(1-h)D}(x)=1+k\chi_D\left(\frac{x}{1-h}\right),$$

setting $y=x/(1-h)$, $\nabla_x=\nabla_y/(1-h)$, the expression in braces becomes

$$-\frac{1}{(1-h)^2}\operatorname{div}_y[1+k\chi_D(y)\nabla_y u(y)]=0 \quad \text{in } \Omega_h,$$

i.e.,

$$\operatorname{div}(a(h)\nabla V^h)=0 \quad \text{in } \Omega_h. \tag{2.15}$$

Further,

$$V^h(x)=\frac{u(x,h)-f(x/(1-h))}{h} \quad \text{if } x\in\partial\Omega_h\cap\partial((1-h)\Omega),$$

$$V^h(x)=\frac{f(x)-u(x/(1-h))}{h} \quad \text{if } x\in\partial\Omega_h\cap\partial\Omega;$$

since $u(x)$ and $u(x,h)$ are in $C^{1,\alpha}$ in some neighborhood of $\partial\Omega$, it follows that in both cases

$$|V^h|\leqq C,$$

i.e., $|V^h|\leqq C$ on $\partial\Omega_h$. Hence, by the maximum principle,

$$|V^h|\leqq C \quad \text{in } \Omega_h. \tag{2.16}$$

Recalling (2.14) we conclude that

$$|v_h|\leqq C \quad \text{in } D_e\backslash B_\delta(\partial\Omega)$$

for any $\delta > 0$ and h small enough, where $B_\delta(A)$ denotes a δ-neighborhood of a set A. Since v_h is harmonic in D_e and $v_h = 0$ on $\partial\Omega$, we then also have that

$$|v_h| \leqq C \quad \text{in } D_e. \tag{2.17}$$

Hence, for a subsequence,

$$v_h \to v \text{ uniformly on compact subsets of } D_e \cup \partial\Omega \tag{2.18}$$

where v is harmonic in D_e and

$$v = \frac{\partial v}{\partial \nu} = 0 \quad \text{on } \partial\Omega; \tag{2.19}$$

here (2.1) was used. It follows that the zero function is a harmonic extension of v into $\mathbb{R}^2 \backslash \Omega$ and therefore $v \equiv 0$ in D_e. Clearly (2.12) now follows from (2.18) and Harnack's theorem.

To prove (2.13) we multiply (2.15) by V^h and integrate over $\Omega' = \Omega \backslash B_\eta(\partial\Omega)$, where $0 < \eta < \operatorname{dist}(D, \partial\Omega)$. We obtain, for small h,

$$\iint_{\Omega'} a(h)|\nabla V^h|^2 \leqq \int_{\partial\Omega'} a(h)|\nabla V^h|\,|V^h|.$$

Since V^h is harmonic and bounded in $B_{\delta_0}(\partial\Omega')$ (δ_0 is independent of h) the right-hand side is uniformly bounded; hence

$$\int_{\Omega'} |\nabla V^h|^2 \leqq C.$$

Recalling (2.14) we deduce that

$$\int_{\Omega' \cap D_e} |\nabla v_h|^2 \leqq C. \tag{2.20}$$

Now, for any small $\delta > 0$,

$$\int_{\partial D} |v_h| \leqq C \int_{D_e \cap B_\delta(\partial D)} |\nabla v_h| + C \int_{(\Omega' \cap D_e) \backslash B_\delta(\partial D)} |\nabla v_h| + C \int_{\partial\Omega'} |v_h|.$$

The last two integrals on the right-hand side converge to zero as $h \to 0$, whereas the first integral is bounded by $C\delta^{1/2}$ (by (2.20)). It follows that

$$\limsup_{h \to 0} \int_{\partial D} |v_h| \leqq C\delta^{1/2},$$

and, since δ is arbitrary, (2.13) follows.

From (2.12), (2.5), (2.7) we conclude that

$$f^h \to 0, \ \nabla f^h \to 0 \text{ uniformly in closed subsets of } D_e \cup \partial\Omega. \tag{2.21}$$

Taking $h \to 0$ in (2.11) we see that if

$$I = \lim_{h \to 0} \left(-\frac{1}{\pi}\right) \iint_\Omega \frac{\partial a(0)}{\partial \bar{z}} \frac{v_h}{z - \zeta}\, dx\, dy, \tag{2.22}$$

$$J = \lim_{h \to 0} \left(-\frac{1}{\pi}\right) \iint_\Omega a_h \frac{\partial u(h)}{\partial \bar{z}} \frac{1}{z - \zeta}\, dx\, dy \tag{2.23}$$

exist for any $\zeta \in D \cup D_e$, then $f^h(\zeta) \to f^0(\zeta)$, where

$$f^0(\zeta) = I - J \quad \text{if } \zeta \in D \cup D_e; \tag{2.24}$$

from (2.21) we also have

$$f^0(\zeta)=0 \quad \text{if } \zeta \in D_e. \tag{2.25}$$

Now clearly

$$\frac{\partial a(0)}{\partial \bar{z}}=\gamma \otimes \delta_{\partial D} \quad \text{in } \mathscr{D}'$$

where γ is a $C^{1,\alpha}$ function on ∂D. Therefore

$$\lim_{h\to 0}\iint_{\Omega}\frac{\partial a(0)}{\partial \bar{z}}\,\frac{v_h}{z-\zeta}\,dx\,dy=\lim_{h\to 0}\int_{\partial D}\frac{\gamma}{z-\zeta}v_h(z)\,ds=0$$

by (2.13), i.e.,

$$I=0. \tag{2.26}$$

Next, by (1.6) and the fact that $u(t)$ is in $C^1(\overline{D(t)})$ and in $C^1(\overline{D_e(t)})$ with moduli of continuity independent of t, it follows that

$$\lim_{h\to 0}\iint_{\Omega} a_h\frac{\partial u(h)}{\partial \bar{z}}\,\frac{1}{z-\zeta}\,dx\,dy=\int_{\partial D} k\beta\left(\frac{\partial u(0)}{\partial \bar{z}}\right)^e\frac{1}{z-\zeta}\,ds;$$

here we used (1.2) and (2.2). We conclude that J exists and, by (2.24), (2.26),

$$f^0(\zeta)=\frac{k}{\pi}\int_{\partial D}\beta\left(\frac{\partial u}{\partial \bar{z}}\right)^e\frac{1}{z-\zeta}\,ds \quad \text{if } \zeta\in D\cup D_e; \tag{2.27}$$

here $u=u(x,0)$.

Let $T(z)$ be the positively oriented tangent vector to ∂D at z. Then

$$dz=T(z)\,ds \quad \text{along } \partial D.$$

Using this in (2.27) we get

$$f^0(\zeta)=\frac{k}{\pi}\int_{\partial D}\frac{\beta}{T(z)}\left(\frac{\partial u}{\partial \bar{z}}\right)^e\frac{dz}{z-\zeta} \qquad (\zeta\in D\cup D_e). \tag{2.28}$$

In view of (2.25) and the standard jump relation of the integral in (2.28) across ∂D, we then have

$$f^0(z)=2ik\frac{\beta(z)}{T(z)}\left(\frac{\partial u}{\partial \bar{z}}\right)^e \quad \text{on } \partial D \tag{2.29}$$

where $f^0(z)=(f(z))^i$ is the limit of f^0 from D. Observe also from (2.28) that

$$f^0(z) \quad \text{is holomorphic in } D. \tag{2.30}$$

LEMMA 2.2. *There holds*

$$\beta\left(\frac{\partial u}{\partial \bar{z}}\right)^e=0 \quad \textit{on } \partial D. \tag{2.31}$$

The proof is given in § 3. Assuming its validity, we shall now proceed to complete the proof of Theorem 1.1. Since $\beta\neq 0$ along ∂D,

$$\left(\frac{\partial u}{\partial \bar{z}}\right)^e=0 \quad \text{on } \partial D.$$

Recalling the jump relation (1.6) we deduce that for some constant c, the function $U = u - c$ vanishes on ∂D together with its first derivatives. By the argument following (2.19) it then follows that $U \equiv 0$ in $B_\delta(\partial D)$ and, by analytic continuation, $u \equiv c$ in D_e which contradicts (1.8).

So far we have assumed that (2.2) holds. If $-1 < h < 0$, so that

$$D(h) \supset D, \tag{2.32}$$

then we replace (2.6) by

$$\frac{1}{h}[a(h)\nabla u(h) - a(0)\nabla u(0)] = a(h)\nabla v_h + a_h \nabla u(0)$$

and proceed as above (with minor changes) to establish (2.24) with the corresponding I vanishing and with J being the same as before.

3. Proof of Lemma 2.2. Set

$$u_1 = u|_{D_e}, \qquad u_2 = u|_D.$$

Then

$$u_1 = u_2 \quad \text{on } \partial D, \tag{3.1}$$

$$\frac{\partial u_1}{\partial \nu} = (k+1)\frac{\partial u_2}{\partial \nu} \quad \text{on } \partial D. \tag{3.2}$$

Notice that the function $\partial u_2/\partial z$ is homomorphic in D. Multiplication of both sides of (2.29) by $\partial u_2/\partial z$ gives

$$F'(z)T(z) = 2ik\beta(z)\frac{\partial u_1}{\partial \bar z}\frac{\partial u_2}{\partial z} \qquad (z \in \partial D) \tag{3.3}$$

where F is a holomorphic function in D, namely, the primitive of $f^0(z)\partial u_2/\partial z$.

Along ∂D we have

$$2\frac{\partial}{\partial z} = \frac{\partial}{\partial x} - i\frac{\partial}{\partial y} = e^{i\omega}\left(\frac{\partial}{\partial \nu} - i\frac{\partial}{\partial s}\right),$$

$$2\frac{\partial}{\partial \bar z} = \frac{\partial}{\partial x} + i\frac{\partial}{\partial y} = e^{-i\omega}\left(\frac{\partial}{\partial \nu} + i\frac{\partial}{\partial s}\right)$$

where ν is the outward normal, $\partial/\partial s$ is in the tangential direction obtained from $\partial/\partial \nu$ by rotation counterclockwise by $\pi/2$ and ω is a real valued function. Therefore by (3.1), (3.2) we easily obtain

$$4\frac{\partial u_1}{\partial \bar z}\frac{\partial u_2}{\partial z} = (k+1)\left(\frac{\partial u_2}{\partial \nu}\right)^2 + \left(\frac{\partial u_2}{\partial s}\right)^2 - ik\frac{\partial u_2}{\partial \nu}\frac{\partial u_2}{\partial s}. \tag{3.4}$$

Hence, if $k > 0$,

$$4\left|\operatorname{Im}\frac{\partial u_1}{\partial \bar z}\frac{\partial u_2}{\partial z}\right| = k\left|\frac{\partial u_2}{\partial \nu}\frac{\partial u_2}{\partial s}\right| \leqq \frac{k}{2}\left[\left(\frac{\partial u_2}{\partial \nu}\right)^2 + \left(\frac{\partial u_2}{\partial s}\right)^2\right] \leqq 2k\left[\operatorname{Re}\frac{\partial u_1}{\partial \bar z}\frac{\partial u_2}{\partial z}\right].$$

Similarly, if $-1 < k < 0$,

$$4\left|\operatorname{Im}\frac{\partial u_1}{\partial \bar z}\frac{\partial u_2}{\partial z}\right| \leqq \frac{|k|}{2(k+1)}\left[(k+1)\left(\frac{\partial u_2}{\partial \nu}\right)^2 + \left(\frac{\partial u_1}{\partial s}\right)^2\right] = \frac{2|k|}{k+1}\left[\operatorname{Re}\frac{\partial u_1}{\partial \bar z}\frac{\partial u_2}{\partial z}\right].$$

Since β is real valued it follows that in both cases, for any $z \in \partial D$,

$$F'(z)T(z) \in G \equiv \{z = x_1 + ix_2;\ |x_2| \leqq C|x_1|\} \tag{3.5}$$

where

$$C=\frac{2|k|}{\min\{1,k+1\}}.$$

Writing the holomorphic function F in the form $F=V+iW$ we have

$$\frac{dF}{ds}=V_s+iW_s=V_s+iV_\nu \quad \text{along}\,\partial D.$$

Since also

$$\frac{dF}{ds}=\frac{dF}{dz}\frac{dz}{ds}=F'(z)T(z),$$

we conclude from (3.4) that

$$|V_\nu|\leqq C|V_s| \quad \text{along}\,\partial D. \tag{3.6}$$

Suppose $V\not\equiv$ const. in D. Then V must attain its maximum in $\bar{D}$ at a point $x^0\in\partial D$ and $V_\nu(x^0)>0$. Since also $V_s(x^0)=0$, we get a contradiction to (3.6). We have thus proved that $V\equiv$ const. and therefore also $F\equiv$ const. From (3.3) it then follows that

$$\beta\frac{\partial u_1}{\partial\bar{z}}\frac{\partial u_2}{\partial z}=0 \quad \text{on}\,\partial D$$

which, in view of (3.4) and (3.2), implies (2.31).

Remark 3.1. Theorem 1.1 extends (with minor changes in the proof) to the case where the domains $D(t)$ are conformal affine transformations of D varying in C^2 manner and monotonically in t, provided $\beta\not\equiv 0$ on ∂D. The theorem also extends to the case where f depends on t, say $f=f(x,t)$, provided

$$\frac{1}{h}[f(\cdot,h)-f(\cdot,0)]\to 0 \quad \text{in}\,C^{1,\alpha}(\partial D)\text{-norm}$$

as $h\to 0$. If the $D(t)$ do not vary monotonically in t, then Lemma 2.1 is still valid with (2.13) replaced by

$$\int_{\partial(D\cup D(h))}|v_h|\,ds\to 0.$$

But this is not sufficient for proving (2.26); see also next remark.

Remark 3.2. Consider the case where Ω is one-dimensional, say $\Omega=\{0<x<1\}$. The solution of (1.1) with $u(0)=\alpha$, $u(1)=\beta$, $u'(0)=\alpha'$, $u'(1)=\beta'$ is given by

$$u(x)=\alpha+u(0)\alpha'\int_0^x\frac{dy}{a(y)} \tag{3.7}$$

where

$$u(0)\alpha'=(\beta-\alpha)\Big/\int_0^1\frac{dy}{a(y)},\qquad \beta'=\frac{a(0)\alpha'}{a(1)}. \tag{3.8}$$

For any other conductivity $\tilde{a}(x)$ with

$$\tilde{a}(0)=a(0),\quad \tilde{a}(1)=a(1),\quad \int_0^1\frac{dy}{a(y)}=\int_0^1\frac{dy}{\tilde{a}(y)}, \tag{3.9}$$

the Neumann data g corresponding to the Dirchlet data f are the same as for a. Clearly (3.9) is satisfied if $\tilde{a}(t)=1+k\chi_{D(t)}$, $a=\tilde{a}(0)$ whenever $D(t)$ is a translation of D. In this example the mapping $a\rightarrow g$ is thus nonunique; furthermore, the assertion of Theorem 1.1 is not valid if $D(t)$ is a translation of D. If however $D(t)$ is monotone in t then the assertion of Theorem 1.1 is valid, as can be verified directly by means of (3.9). Similarly, if Ω is an annulus $\Omega=\{r_1<|x|<r_2\}$ and $f=c_i$ on $\{|x|=r_i\}$, c_i constants, then the assertion of Theorem 1.1 is valid for a family of annuli $D(t)=\{d_1(t)<|x|<d_2(t)\}$ provided the family is monotone in t, but it is generally false if the $D(t)$ do not vary monotonically in t (note however that Ω is not simply connected, as required in Theorem 1.1).

Remark 3.3. Let $\tilde{z}=\phi(z)$ be a conformal mapping of $\bar{\Omega}$ onto the closure of a domain $\tilde{\Omega}$ and set $\tilde{D}(t)=\phi(D(t))$, $a=\tilde{a}\circ\phi$, $f=\tilde{f}\circ\phi$, $u=\tilde{u}\circ\phi$, $\tilde{g}=|\phi'|\tilde{g}\circ\phi$. Then (1.4), (1.5) and (1.7) are equivalent to

$$\operatorname{div}(\tilde{a}\nabla\tilde{u})=0 \quad \text{in } \tilde{\Omega}, \qquad \tilde{u}=\tilde{f} \quad \text{on } \partial\tilde{\Omega},$$

$$\frac{\partial\tilde{u}}{\partial\tilde{\nu}}=\tilde{g} \quad \text{on } \partial\tilde{\Omega}.$$

Since

$$0<c\leqq\frac{\|\tilde{g}(t)-\tilde{g}(0)\|_{L^2}}{\|g(t)-g(0)\|_{L^2}}\leqq C<\infty,$$

Theorem 1.1 extends to the family $\tilde{D}(t)$ of subdomains of $\tilde{\Omega}$.

Remark 3.4. Theorem 1.1 extends to inhomogeneous equations

$$\operatorname{div}(a\nabla u)=l(x) \quad \text{in } \Omega$$

provided $l\in C^{1,\alpha}$ and $S\equiv\operatorname{supp} l$ satisfies: $S\subset D_e$ and $D_e\backslash S$ is connected; if $l\not\equiv 0$ and $l>0$, then the condition (1.8) is not needed. The function l may also be taken to depend on t.

Remark 3.5. The results of this paper extend with minor changes to the case where the Neumann data (1.7) are prescribed, whereas the Dirichlet data $f=f(t,x)$ are measured; here it is assumed that $\int_{\partial\Omega} g=0$ and u is normalized, say, by $\int_{\partial\Omega} u=0$. The assertion (1.9) is replaced by

$$\|f(\cdot,h)-f(\cdot)\|_{L^2(\partial\Omega)}\geqq c|h|$$

where c is a positive constant.

THE ELECTROPAINTING PROBLEM WITH OVERPOTENTIALS*

VIVIANA MARQUEZ† AND MEIR SHILLOR‡

Abstract. Existence, uniqueness and regularity are proved for the electropainting problem with overpotentials. The problem consists of finding a pair $\{\varphi(x, t), h(x, t)\}$ such that $\varphi(x, t)$ is a time dependent family of harmonic functions, representing the electric potential in a domain, and $h(x, t)$ is related to the paint thickness on the part of the boundary being painted. The boundary condition on this part is $\varphi_n = G(\varphi, h)$ where φ_n is the inward normal derivative. h is determined from the history of the process. The assumption on the overpotential $\sigma(x)$ implies $h \geqq \sigma(x) > 0$ and thus the boundary condition is nondegenerate. We show that the process is monotone; there is no paint dissolution. Then we consider the explicit time discretization of the problem. Letting the time step shrink to zero leads to the above mentioned results. Then the $t \to \infty$ limit is considered, existence, uniqueness and regularity are proved. Moreover it is shown that this asymptotic limit can be recast as a Signorini variational inequality with an obstacle constructed from $\varphi(x, t)$, $t < \infty$. Finally the degenerate case $\sigma(x) \equiv 0$ is considered and the existence of a weak solution is proved, in a convex geometry, using monotonicity arguments.

Key words. electropainting model, overpotentials, evolution problem for the Laplacian, Signorini problem

AMS(MOS) subject classifications. 35J65, 35R35

1. Introduction.

We consider an evolution problem associated with an electropainting process with overpotentials. The problem is to find a pair $\{\varphi(x, t), h(x, t)\}$ such that in an annular region $\Omega \subset \mathbb{R}^n$ $(n \geqq 2)$ with outer boundary S and inner boundary Γ there holds

$$(1.1) \qquad \Delta\varphi = 0 \quad \text{in } \Omega, \quad 0 \leqq t \leqq T,$$

$$(1.2) \qquad \varphi = 1 \quad \text{on S}, \quad 0 \leqq t \leqq T,$$

$$(1.3) \qquad \varphi_n = G(\varphi, h) \quad \text{on } \Gamma, \quad 0 \leqq t \leqq T,$$

$$(1.4) \qquad h(x, t) = \sigma(x) + \int_0^t g((\varphi_n(x, \tau) - \varepsilon)^+)\, d\tau, \qquad x \in \Gamma, \quad 0 \leqq t \leqq T$$

where φ_n is the inward normal derivative on Γ, $(z)^+ = \max\{0, z\}$, G, g and σ are given functions, $\varepsilon > 0$ and $T > 0$ are given constants.

Such problems were considered by Hansen and McGeough [6], Aitchison, Lacey and Shillor [1] and Caffarelli and Friedman [2]. The first two deal with the modeling aspects of the electropainting process and numerical experiments. The third deals with mathematical analysis of the model. In all these papers it was assumed that $g(s) = s$, $G(\varphi, h) = \varphi/h$ and $\sigma = 0$, thus the problem considered here is more general mathematically as well as from the practical point of view.

A problem of the type (1.1)-(1.4) can be considered (see [1] or [6]) as a model for the following process. A metal body with an outer surface Γ, to be painted, is immersed in a bath with an electrolytic solution. The solution occupies the region Ω such that $\partial\Omega = \Gamma \cup S$, where S is the inner surface of the bath. The metal part is

connected to an electric potential source, the bath itself (S) serves as the other electrode and as a result of the flow of the electric current in the solution and into Γ the process of paint deposition takes place on Γ. The existence of a cutoff current $\varepsilon > 0$, that was postulated in [1], assures that there is paint deposition only at those points of Γ where the current φ_n satisfies $\varphi_n > \varepsilon$. Indeed one of the main purposes of the construction of the model in [1] was to be able to predict which parts of Γ become painted and which remain bare. The model that was proposed in [6] is the same as in [1] but with $\varepsilon = 0$ and therefore in this case Γ becomes completely covered by paint for any $t > 0$. Thus the numerical experiments in [1] were done with the purpose of showing painted and unpainted regions in the Signorini problem that corresponds to the steady state and the evolution of the paint layer in the time dependent problem. The numerical experiments in [6] were to study the saturation and leveling effects.

Some mathematical analysis of the model in [1] was performed in [2]. First they showed that under the conditions of [1] there is no paint dissolution, i.e. the process is monotone, and therefore the boundary condition that was given in [1] for that possibility is redundant. Then they considered a time discretized version of the model and proved the existence and uniqueness of the discretized solution and its convergence to the steady state Signorini problem that was conjectured in [1].

We consider a more general problem. It is well known (see e.g. Levich [9] or McGeough [10]) that when electric current is passing in a solution some chemical reactions take place near the electrodes that lead to a nonlinear relationship between the potential and the current. This is represented above in (1.3). Moreover by taking $\sigma(x) > 0$ we allow for the existence of a resistance to current besides the paint layer. More specifically, there may exist initially on Γ a thin coating of a different material, which is a common occurrence in the industrial process; also the production of gas bubbles and a buildup of different reaction products may block the way of the paint molecules and thus form a resistance on Γ. As far as we know there exists no description of what takes place near Γ, and $\sigma(x)$ should be found experimentally. Since in cases of practical interest some or all of these phenomena are likely to be present the fact that most of our results are obtained for $\sigma(x) \geqq \sigma_* > 0$ does not restrict the applicability of these results. In the numerical experiments in [1] it was $\sigma \equiv 0$ and this did not cause any trouble, but the method of computation was not particularly sensitive to weak divergence of the normal derivative. In our case the (nondimensional) paint thickness is $h_*(x, t) = h(x, t) - \sigma(x)$ at $x \in \Gamma$, $0 \leqq t$. These two phenomena are referred to as "overpotentials" (see [9], [10] and Lacey [7]). In addition we consider a more general process of paint deposition, represented by g. Although the main practical interest is the paint thickness h_* as a function of space and time it turns out that the total resistance h is the dominant factor in the model.

We prove existence, uniqueness and asymptotic behaviour of the solution to (1.1)-(1.4) and obtain some regularity.

But first, following the ideas of [2], we too prove, in § 2, that the smooth solution to (1.1)-(1.4) with an appropriate condition for paint dissolution ($h_t < 0$) is monotone (i.e. $h_t \geqq 0$) and therefore such a condition is not needed. We stress that this is so under the given condition (1.2) on S. It is clear mathematically and from the practical point of view that under different conditions dissolution can take place. Indeed if the voltage is switched off, i.e. $\varphi = 0$ on S after some time $t \geqq t_0 > 0$, or the voltage φ on S is an oscillating function with both positive and negative values that are sufficiently large, then one should find that $h_t < 0$ on a portion of Γ. It is also shown that the process tends to an asymptotic limit, that is considered in § 5, but cannot attain it in finite time. This is in contrast to the result in [2], where such a possibility was not ruled out.

The existence and uniqueness of the weak solution are proved in § 4 where under additional assumptions on G it is shown that the weak solution is a smooth solution. The proofs are based on an explicit time discretization of the problem that is considered in § 3. Existence, uniqueness and regularity are proved for the discretized problem and then some necessary bounds, independent of the time step δ, are derived. The results of § 4 follow from the $\delta \to 0$ limit and these bounds.

In § 5 we prove that the process tends asymptotically to a unique steady state. Moreover using the fact that this steady problem is the limit of an evolution problem we are able to give a variational inequality formulation, a Signorini-like problem, where the obstacle is constructed from $\varphi(x, t)$, $t < \infty$.

It may be of interest to investigate what types of elliptic boundary value problems, like the problem of the steady state, can be given variational inequality formulations by their imbedding as asymptotic limits of evolution problems. In their analysis in [2] they used implicit time discretization and introduced $\sigma_* > 0$ as a regularizing parameter, we use an explicit one in § 3. Since they considered the limit $\sigma_* \to 0$ they were unable to consider the limit $\delta \to 0$ and hence proved the existence and uniqueness of a time discretized solution. We took the limit $\delta \to 0$ for $\sigma_* > 0$ and obtained the above mentioned results. Also the steady state in [2] is the Signorini problem but ours is more complicated.

Finally the nondegeneracy condition $\sigma(x) \geqq \sigma_* > 0$ is essential for all the proofs mentioned above. Nevertheless we are able to prove, in § 6, the existence of a weak solution to the degenerate problem with $\sigma(x) \equiv 0$ in a convex geometry as a monotone limit of solutions with $\sigma(x) \equiv \sigma > 0$, as $\sigma \to 0$. Thus in this geometry, where S is taken as the inner electrode while Γ, assumed to be convex, is the outer boundary, there exists a solution to the problem that was considered in [1] and [2].

The regularity of the free boundary, the boundary of the set in Γ where $h > \sigma$ and the regularity of the solution with $\sigma = 0$ remain open questions.

2. No paint dissolution.

The model for the electropaint process that was proposed in [1] included a condition for the case of the dissolution of the paint layer. But it was proved in [2] that any smooth solution can be modified smoothly so that the solution and the paint layer are nondecreasing in time. We give the generalization of the model in [1] to include overpotentials and nonlinear growth condition for the paint thickness and then prove that any smooth solution is monotone increasing with time. So under such conditions, $\varphi = 1$ on S, the paint dissolution does not occur and therefore the appropriate condition can be omitted from the model.

The fact that there is no paint dissolution has some importance from the mathematical point of view as well as from the practical one. Indeed it seems that if dissolution can take place then the free boundary (i.e. the boundary on Γ of the region where there is no paint deposition) is likely to be linearly unstable and so it is likely that the model will break down leading to an ill posed problem (see e.g. [3] and [4]).

We consider the process in $\Omega \subset R^n$, $n \geqq 2$, a doubly connected region with outer boundary S and inner boundary Γ. Everywhere below it is assumed that S and Γ are in $C^{1+\alpha}$ for any $\alpha \in (0, 1)$.

The modified model is to find a pair $\{\varphi(x, t), h(x, t)\}$ such that

$$\Delta\varphi = 0 \quad \text{in } \Omega, \quad 0 \leqq t, \tag{2.1}$$

$$\varphi = 1 \quad \text{on } S, \quad 0 \leqq t, \tag{2.2}$$

$$\varphi_n = G(\varphi, h) \quad \text{on } \Gamma, \quad 0 \leqq t, \tag{2.3}$$

$$h_t = g((\varphi_n - \varepsilon)^+) \quad \text{on } \Gamma, \quad 0 \leqq t \quad \text{if } h = \sigma(x), \tag{2.4$'$}$$

$$(2.4)'' \qquad h_t = g((\varphi_n - \varepsilon)) \quad \text{on } \Gamma, \quad 0 \leqq t \quad \text{if } h > \sigma(x),$$

$$(2.4)''' \qquad h(x, 0) = \sigma(x) \quad \text{on } \Gamma$$

where φ_n is the inward normal derivative on Γ and ε is a positive constant. G is prescribed and g is an odd function with $g(s) > 0$ for $s > 0$. $\sigma(x)$ is a given overpotential and the paint thickness at a point $x \in \Gamma$ at time t is given by $h(x, t) - \sigma(x)$. Condition (2.4)′ means that at $x \in \Gamma$ if there is no paint, i.e., $h = \sigma$, then paint deposition will start only if $\varphi_n > \varepsilon$. On the other hand at a point $x \in \Gamma$ where there is paint, i.e., $h > \sigma$, then by (2.4)″, if $\varphi_n > \varepsilon$ then there is paint deposition and when $\varphi_n < \varepsilon$ there is paint dissolution. It follows from (2.4)′, (2.4)″ and (2.4)‴ that

$$(2.5) \qquad h(x, t) \geqq \sigma(x), \qquad x \in \Gamma, \quad 0 \leqq t.$$

We shall need the following assumptions:

$$(2.6) \qquad \sigma(x) \in C^{0,1}(\Gamma), \qquad 0 < \sigma_* \leqq \sigma(x) \leqq \sigma^* < K_2/\varepsilon,$$

$$(2.7) \qquad g(s) \in C^1(\mathbb{R}), \quad 0 < k_* \leqq g' \leqq k, \quad g(0) = 0,$$

$$(2.8) \qquad \begin{aligned} &G(s, p) \in C^1([0, 1] \times \mathbb{R}_+), \quad G(0, p) = 0, \quad G(s, p) > 0 \quad \text{if } s > 0, \\ &G(1, p) < K_2/p, \qquad p \in \mathbb{R}_+, \end{aligned}$$

$\partial G/\partial s > 0$, $\partial G/\partial p \leqq 0$ and both bounded on compact subsets of $[0, 1] \times \mathbb{R}_+$, $\partial G/\partial p < 0$ if $s > 0$. They are used everywhere below (except in § 6).

Denote by ω_* the solution of

$$(2.9) \qquad \begin{aligned} &\Delta\omega_* = 0 \quad \text{in } \Omega, \quad \omega_* = 1 \quad \text{on } S, \\ &\omega_{*n} = G(\omega_*, \sigma) \quad \text{on } \Gamma. \end{aligned}$$

So $\omega_*(x) = \varphi(x, 0)$, where φ is a solution to (2.1)-(2.4)‴. If

$$(2.10) \qquad \omega_{*n} \leqq \varepsilon \quad \text{on } \Gamma$$

then $\varphi(x, t) \equiv \omega_*(x)$ together with $h(x, t) \equiv \sigma(x)$ form a solution of (2.1)-(2.4)‴.

In order to exclude this trivial case we shall assume that the geometry and the data are such that

$$(2.11) \qquad \omega_{*n} > \varepsilon \quad \text{for some points } x \in \Gamma.$$

DEFINITION 2.1. By a *smooth solution* of (2.1)-(2.4)‴ we mean a solution (φ, h) such that φ, φ_t, $\nabla\varphi$ are continuous in $\bar{\Omega} \times [0, \infty)$ and h, h_t are continuous on $\Gamma \times [0, \infty)$.

DEFINITION 2.2. Denote by t_0 the supremum of all s such that $h(x, t)$ is nondecreasing for all $x \in \Gamma$, $0 \leqq t < s$.

THEOREM 2.3. *Let* (φ, h) *be a smooth solution of* (2.1)-(2.4)‴ *and let* (2.11) *hold. Then* $t_0 = \infty$.

This result is stronger than the one in [2], where the authors were able to assert only that if $t_0 < \infty$ then one can join a solution continuously to the steady solution at $t = t_0$ in order to obtain a nondecreasing solution for $0 \leqq t < \infty$. This is so, as well as the uniqueness of the smooth solution, due to the fact that $0 < \sigma_* \leqq \sigma(x)$.

Proof. We follow [2] in part. By (2.3)

$$\varphi_n = G(\varphi, h) \quad \text{on } \Gamma.$$

Since $h \geqq \sigma > 0$ we can use the strong maximum principle and (2.8) to deduce that φ cannot take a positive maximum or a nonpositive minimum on Γ and therefore

$$(2.12) \qquad c_* \leqq \varphi(x, t) \leqq 1, \qquad x \in \bar{\Omega}, \quad 0 \leqq t$$

for some $c_* > 0$.

Since this holds for any function $G(s,p)$ on $\mathbb{R}\times\mathbb{R}_+$ such that $G(s,p)>0$, $s\neq 0$, $s\in\mathbb{R}$, the restriction of $s\in[0,1]$ in (2.8) leads to no loss of generality.

Thus by (2.3) and (2.8)

$$\varphi_n(x,t)>0 \quad \text{on } \Gamma. \tag{2.13}$$

LEMMA 2.4. *If $h(x,t_1)\geqq h(x,t_2)$ and $h(x,t_1)\not\equiv h(x,t_2)$ on Γ then*

$$\varphi(x,t_1)>\varphi(x,t_2) \quad \textit{in } \Omega.$$

Proof. The function $\psi(x)=\varphi(x,t_1)-\varphi(x,t_2)$ is harmonic in Ω, vanishes on S and satisfies

$$\begin{aligned}\psi_n &= G(\varphi(x,t_1),h(x,t_1))-G(\varphi(x,t_2),h(x,t_2))\\ &= G_\varphi(*)(\varphi(x,t_1)-\varphi(x,t_2))+G_h(*)(h(x,t_1)-h(x,t_2))\end{aligned}$$

where here and below, $G_\varphi(*)$ and $G_h(*)$ stand for the partial derivatives evaluated at some value by the mean value theorem, and since $\varphi>0$ then $G_h(*)<0$ by (2.8). But $h(x,t_1)\geqq h(x,t_2)$ so

$$\psi_n\leqq G_\varphi(*)\psi, \qquad G_\varphi>0$$

by (2.8). Applying the strong maximum principle we show that $\psi>0$ in Ω.

Assume that $t_0<\infty$. Then there exists a sequence (x_i,t_i) with $x_i\in\Gamma$, $t_i>t_0$ such that

$$t_i\to t_0, \qquad x_i\to x_0 \quad \text{as } i\to\infty$$

and $h_t(x_i,t_i)<0$; consequently also $h(x_i,t_i)>\sigma(x_i)$. Clearly $h_t(x_0,t_0)=0$.

LEMMA 2.5. *There holds*: $\varphi_{nt}(x_0,t_0)\leqq 0$.

Proof. If $\varphi_n(x_i,t_0)\geqq\varepsilon$ then, since $\varphi_n(x_i,t_i)<\varepsilon$,

$$\varphi_{nt}(x_i,\tilde{t}_i)<0 \quad \text{for some } t_0<\tilde{t}_i<t_i. \tag{2.14}$$

If, on the other hand, $\varphi_n(x_i,t_0)<\varepsilon$ then $h(x_i,t_0)=\sigma(x_i)$ (since $h(x_i,t_0)>\sigma(x_i)$ implies $h_t(x_i,t_0)=g(\varphi_n(x_i,t_0)-\varepsilon)<0$, a contradiction to the definition of t_0). Since further $h(x_i,t_i)>\sigma(x_i)$ we conclude that $h_t(x_i,\hat{t}_i)>0$ for some $t_0<\hat{t}_i<t_i$ and thus $\varphi_n(x_i,\hat{t}_i)>\varepsilon$, which yields (since $\varphi_n(x_i,t_i)<\varepsilon$)

$$\varphi_{nt}(x_i,\tilde{\tilde{t}}_i)<0 \quad \text{for some } \hat{t}_i<\tilde{\tilde{t}}_i<t_i. \tag{2.15}$$

The lemma now follows from (2.14), (2.15) upon taking $i\to\infty$.

From Lemma 2.4 we have

$$\varphi_t\geqq 0 \quad \text{if } 0<t\leqq t_0. \tag{2.16}$$

LEMMA 2.6. *There holds* $h_t(x,t_0)\equiv 0$.

Proof. Suppose that $h_t(x,t_0)\not\equiv 0$. For $t=t_0$

$$\varphi_{nt}=G_\varphi\varphi_t+G_h h_t \quad \text{on } \Gamma; \tag{2.17}$$

hence

$$\varphi_{nt}\leqq G_\varphi\varphi_t \qquad (G_h<0).$$

We can use the strong maximum principle to deduce that φ_t cannot take the minimum on Γ and so

$$\varphi_t>0 \quad \text{on } \Gamma. \tag{2.18}$$

At (x_0, t_0), $h_t=0$ and $\varphi_t>0$ by (2.18). Then (2.17) implies that $\varphi_{nt}(x_0, t_0)>0$, a contradiction to Lemma 2.5.

Set $\Gamma_0=\Gamma\cap\{\varphi_n(x, 0)>\varepsilon\}$ and for any $0<t_1<t_2<t_0$ let

$$\varphi^i(x)=\varphi(x, t_i) \quad \text{and} \quad h^i(x)=h(x, t_i), \quad i=1, 2.$$

Then

$$\varphi_n^2-\varphi_n^1=G_\varphi(*)(\varphi^2-\varphi^1)+G_h(*)(h^2-h^1) \tag{2.19}$$

rearranging

$$-G_h(*)(h^2-h^1)+(\varphi_n^2-\varphi_n^1)=G_\varphi(*)(\varphi^2-\varphi^1) \quad \text{on } \Gamma.$$

By Lemma 2.4, $\varphi^2\geqq\varepsilon^1$; hence

$$-G_h(*)\int_{t_1}^{t_2} h_t\,dt\geqq-(\varphi_n^2-\varphi_n^1).$$

On Γ_0, $h_t=g(\varphi_n-\varepsilon)\leqq k(\varphi_n-\varepsilon)$ if $t<t_0$; hence

$$c\int_{t_1}^{t_2}(\varphi_n-\varepsilon)\,dt\geqq-((\varphi_n^2-\varepsilon)-(\varphi_n^1-\varepsilon)), \qquad c>0 \quad \text{on } \Gamma_0. \tag{2.20}$$

Integrating (2.20) over Γ_0 we find

$$c\int_{t_1}^{t_2}\left(\int_{\Gamma_0}(\varphi_n-\varepsilon)\right)dt\geqq-\left(\int_{\Gamma_0}(\varphi_n^2-\varepsilon)-\int_{\Gamma_0}(\varphi_n^1-\varepsilon)\right),$$

and setting

$$\psi(t)=\int_{\Gamma_0}(\varphi_n(x, t)-\varepsilon),$$

we arrive at the inequality

$$c\int_{t_1}^{t_2}\psi\,dt\geqq-(\psi(t_2)-\psi(t_1))$$

or $\dot\psi+c\psi\geqq0$. So ψe^{ct} is monotone nondecreasing for $0<t<t_0$. Since $\psi(0)>0$ it follows that $\psi(t_0)>0$, which is a contradiction to Lemma 2.6, i.e., $h_t(x, t_0)\equiv0$. Hence $t_0<\infty$ is impossible and so the theorem is proved.

COROLLARY 2.7. *If $h(\bar x, s)>\sigma(\bar x)$ for some $\bar x\in\Gamma$, $s>0$, then $h_t(\bar x, t)>0$ for all $t>s$.*

Thus, once $h(\bar x, t)$ becomes greater than $\sigma(\bar x)$, i.e. once paint deposition starts at $\bar x$, it does not stop and h continues to grow at a strictly positive rate.

To prove the corollary we proceed by contradiction and consider the number t_1 such that $h_t(\bar x, t)>0$ if $\bar s\leqq t<t_1$ and $h_t(\bar x, t_1)=0$ where $\bar s\leqq s$ is such that $\varphi_n(\bar x, \bar s)>\varepsilon$. Applying the argument of Lemma 2.6, we deduce that $h_t(x, t_1)\equiv0$, which is impossible from the proof of Theorem 2.3.

Theorem 2.3 shows that, under the condition $\varphi=1$ on S, there is no paint dissolution and therefore (2.4)′-(2.4)‴ in the model can be replaced by

$$h(x, t)=\sigma(x)+\int_0^t g((\varphi_n-\varepsilon)^+)\,d\tau, \qquad x\in\Gamma, \quad 0\leqq t. \tag{2.4}$$

Finally we prove the following.

THEOREM 2.8. *The smooth solution is unique.*

Proof. Let (φ^1, h^1) and (φ^2, h^2) be two smooth solutions.

Subtracting condition (2.3) for $i=1$ from the one for $i=2$ we find (2.19), only for the same time. From (2.8) $G_\varphi>0$ and $G_h\leqq0$. Now a point of positive maximum of $\varphi^2-\varphi^1$ can be only on Γ and then $\varphi_n^2-\varphi_n^1<0$ by the strong maximum principle. Hence it follows from (2.19) that

$$G_\varphi(*)(\varphi^2-\varphi^1)\leqq -G_h(*)(h^2-h^1) \tag{2.21}$$

and since a similar argument applies to a negative minimum it follows that

$$|\varphi^2-\varphi^1|_\infty\leqq K|h^2-h^1|_\infty. \tag{2.22}$$

On the other hand

$$\begin{aligned}|h^2-h^1|&\leqq\int_0^\delta |g((\varphi_n^2-\varepsilon)^+)-g((\varphi_n^1-\varepsilon)^+)|\,dt\\&\leqq k\delta|\varphi_n^2-\varphi_n^1|_\infty.\end{aligned} \tag{2.23}$$

Combining (2.19), (2.22) and (2.23) we get

$$|\varphi_n^2-\varphi_n^1|\leqq K|h^2-h^1|_\infty\leqq K\delta|\varphi_n^2-\varphi_n^1|_\infty,$$

which implies that $\varphi_n^2\equiv\varphi_n^1$ if we take $\delta<K^{-1}$. But this implies that $\varphi^1\equiv\varphi^2$, both being harmonic functions, and also that $h^1\equiv h^2$ by (2.4).

3. The time discretized problem. We consider the time discretized version of the evolutionary process (2.1)-(2.4). We retain all the assumptions on the data and on Ω from § 2. We use explicit time discretization in order to obtain approximate solutions and then we obtain the necessary uniform bounds.

For any $T>0$ and a large integer $M>0$ let

$$\delta=\frac{T}{M}, \tag{3.1}$$

and set $t_m=m\delta$, $m=0,1,\cdots,M$. If we replace $\varphi(x,t_m)$ by $\varphi^m(x)$ in (2.1)-(2.4) we obtain the following explicit finite differences system

$$\Delta\varphi^m=0 \quad \text{in } \Omega, \tag{3.2}$$

$$\varphi^m=1 \quad \text{on } S, \tag{3.3}$$

$$\varphi_n^m=G(\varphi^m,h^m) \quad \text{on } \Gamma, \tag{3.4}$$

$$h^m=\sigma+\delta\sum_{i=0}^{m-1}g((\varphi_n^i-\varepsilon)^+) \quad \text{on } \Gamma, \tag{3.5}$$

where $m=0,1,2,\cdots,M$.

LEMMA 3.1. *There exists a unique solution* $\{\varphi^m(x),h^m(x)\}_{m=0}^M$ *of* (3.2)-(3.5) *with* $\varphi^m\in C^{1+\alpha}(\bar\Omega)$, $h^m\in C^\alpha(\Gamma)$ *any* $\alpha\in(0,1)$, $0\leqq m\leqq M$.

Proof. Proceeding by induction it is enough to prove that the elliptic problem

$$\Delta u=0 \quad \text{in } \Omega, \tag{3.6}$$

$$u=1 \quad \text{on S}, \tag{3.7}$$

$$u_n=G(u,\gamma) \quad \text{on } \Gamma \tag{3.8}$$

has a unique solution in $C^{1+\alpha}(\bar\Omega)$ any $\alpha\in(0,1)$ provided $0<\gamma$ and $\gamma\in C^\alpha(\Gamma)$. By the maximum principle and by (2.8) it is seen that a priori $0<u\leqq1$ in $\bar\Omega$. Let $\beta\in(0,1)$ and let

$$V_M=\{v\in C^\beta(\bar\Omega),\ \|v\|_{C^\beta(\bar\Omega)}\leqq M\},\qquad M>0. \tag{3.9}$$

For any $v \in V_M$ we solve (3.6) and (3.7) together with

$$u_n = G(v, \gamma) \quad \text{on } \Gamma.$$

But by (2.8) and the assumptions on v and γ, $G(v, \gamma)$ is in $C^\beta(\Gamma)$; hence $u_n \in C^\beta(\Gamma)$ and therefore $u \in C^{1+\beta}(\bar{\Omega})$ (see e.g. [5, p. 117]) and $\|u\|_{C^{\beta'}(\bar{\Omega})} \leqq M_0$ for any $\beta \leqq \beta' < 1$, where M_0 depends only on the data and β' but independent of γ. If we choose $M = M_0$ in (3.9) and define a mapping $u = Tv$ on V_M then $T: V_{M_0} \to V_{M_0}$ is continuous. Moreover $u \in C^{1+\beta}(\bar{\Omega})$; hence T has a compact range in V_{M_0} and so by Schauder's fixed point theorem T has a fixed point u such that $u = Tu$ which is the solution to (3.6)-(3.8); moreover $u \in C^{1+\beta}(\bar{\Omega})$. This argument applies to any $\beta \in (0, 1)$, hence $u \in C^{1+\alpha}(\bar{\Omega})$, any $\alpha \in (0, 1)$. Now returning to the discretized system (3.2)-(3.5) we see that if $\varphi^m \in C^{1+\alpha}(\bar{\Omega})$ then $\varphi^m_n \in C^\alpha(\Gamma)$ and so $(\varphi^m_n - \varepsilon)^+ \in C^\alpha(\Gamma)$ and therefore so is $g((\varphi^m_n - \varepsilon)^+)$ and hence, by (3.5), $h^{m+1} \in C^\alpha(\Gamma)$. Clearly this holds for any $\alpha \in (0, 1)$. To prove uniqueness we take the difference of any two solutions and apply to it the maximum principle.

We note that since $h^i \geqq h^{i-1}$ the proof of Lemma 2.4 gives

$$\varphi^i \geqq \varphi^{i-1} \quad \text{in } \Omega, \quad i \geqq 1. \tag{3.10}$$

Recall also that by the maximum principle

$$0 < \varphi^i \leqq 1 \quad \text{in } \bar{\Omega}. \tag{3.11}$$

For any $x_0 \in \Gamma$ denote by $j_0 = j(x_0)$ the first integer $j_0 \geqq 0$, if existing, such that

$$\begin{aligned} &\varphi^i_n \leqq \varepsilon \quad \text{if } i \leqq j_0 - 1, \\ &\varphi^{j_0}_n > \varepsilon. \end{aligned} \tag{3.12}$$

Notice that $h^i(x_0) = \sigma(x_0)$ if $i \leqq j_0$ and $h^{j_0+1}(x_0) > h^{j_0}(x_0)$.

Remark 3.2. We choose to work with the explicit scheme, i.e. the summation in (3.5) is $0 \leqq i \leqq m-1$. The proof of Lemma 3.1 is thus more direct and simple than in an implicit scheme where questions of the invertibility of the equation

$$\varphi_n = G(v, \gamma + \delta g((\varphi_n - \varepsilon)^+))$$

would arise. Moreover from the numerical point of view the explicit scheme is simpler to consider and to program since no iterations are needed. On the other hand the explicit scheme has an unattractive feature—we cannot assure, as was done in Corollary 2.7, that once $h^i(x_0) > \sigma(x_0)$ then $h^{j+1}(x_0) > h^j(x_0)$ holds for every $j \geqq i$; i.e., the computed h may not be strictly monotone increasing. But nevertheless the explicit scheme does introduce a correction in the cases of overshooting. Indeed let $m \geqq j_0$ be an integer such that

$$\varphi^m_n(x_0) > \varepsilon, \qquad \varphi^{m+1}_n(x_0) \leqq \varepsilon. \tag{3.13}$$

Then we find from (3.5) that

$$h^{m+1}(x_0) > h^m(x_0), \qquad h^{m+2}(x_0) = h^{m+1}(x_0). \tag{3.14}$$

Since

$$-G_h(*)(h^{m+2} - h^{m+1}) + (\varphi^{m+2}_n - \varphi^{m+1}_n) = G_\varphi(*)(\varphi^{m+2} - \varphi^{m+1})$$

and so (3.14) and (3.10) imply that $\varphi^{m+2}_n \geqq \varphi^{m+1}_n$ at x_0, i.e. the normal derivative increases in the correct way at one time step later. On the other hand it is easy to show that in an implicit scheme $h^{i+1}(x_0) > h^i(x_0)$ if $i > j_0$, i.e. the analogue of Corollary 2.7.

We proceed to obtain uniform bounds on the solution to (3.2)-(3.5).

LEMMA 3.3. *There holds*

$$\sigma(x) \leqq h^m(x) \leqq \frac{K_2}{\varepsilon} + 1 \quad \forall x \in \Gamma, \quad m \geqq 0 \tag{3.15}$$

for all $\delta < \sigma_* / kK_2$.

Proof. From (3.5) the left inequality is immediate. Now let $m \geqq 0$, $x \in \Gamma$ and suppose that there exists $l \geqq m$ such that $\varphi_n^l(x) \geqq \varepsilon$. Then by (3.4) and (2.8)

$$\varphi_n^l(x) = G(\varphi^l(x), h^l(x)) \leqq G(1, h^l(x)) \leqq \frac{K_2}{h^l(x)} \tag{3.16}$$

and so

$$h^l(x) \leqq \frac{K_2}{\varphi_n^l(x)} \leqq \frac{K_2}{\varepsilon}. \tag{3.17}$$

Since $h^m(x) \leqq h^l(x)$ for every $l \geqq m$, the other inequality holds in this case.

Now suppose that $\varphi_n^l(x) < \varepsilon$ for every $l \geqq m$. If $h^m(x) > (K_2/\varepsilon) + 1$ then by (2.6) $h^m(x) > \sigma(x)$ and so there exists $j \leqq m-1$ such that $\varphi_n^j(x) > \varepsilon$ and $\varphi_n^i(x) \leqq \varepsilon$ for every $j < i \leqq m-1$; then

$$h^m(x) = h^{j+1}(x) > h^j(x).$$

As (3.17) is true also for $l = j$ we find that $h^{j+1}(x) - h^j(x) \geqq 1$ and so

$$\delta k(\varphi_n^j - \varepsilon) \geqq \delta g(\varphi_n^j - \varepsilon) \geqq 1.$$

Hence

$$\varphi_n^j(x) \geqq \frac{1}{\delta k}. \tag{3.18}$$

Combining (3.16) with $l = j$ and (3.18) we obtain

$$h^j(x) \leqq \frac{K_2}{\varphi_n^j(x)} \leqq K_2 k \delta < \sigma_*,$$

which is impossible.

LEMMA 3.4. *For every* $\alpha \in (0, 1)$ *there exists a constant* $C > 0$ *such that for any* $0 < \sigma^* < K_2/\varepsilon$, $0 < \delta < \sigma_*/kK_2$, $m \geqq 0$

$$\|\varphi^m\|_{C^\alpha(\bar{\Omega})} \leqq C. \tag{3.19}$$

Proof. This follows from Theorem 4.2 [8, Chap. 5, p. 333].

LEMMA 3.5. *There holds*

$$0 \leqq \varphi_n^m \leqq G_* \tag{3.20}$$

where G_* *is independent of* δ *and of* T.

Proof. From (2.8), $G(s, p)$ is positive for $s > 0$ and is monotone increasing in s and monotone decreasing in p. Therefore the fact that $0 < \varphi^m \leqq 1$ and Lemma 3.3 imply that

$$\varphi_n^m = G(\varphi^m, h^m) \leqq G(1, \sigma_*) \equiv G_*, \qquad m \geqq 0. \tag{3.21}$$

LEMMA 3.6. *There exists a constant* $C > 0$, *independent of* δ *and* T, *such that*

$$\|\varphi^m\|_{H^1(\Omega)} \leqq C, \qquad m \geqq 0. \tag{3.22}$$

Proof. If we multiply (3.2) by (φ^m-1) and use Green's theorem we obtain

$$\int_\Omega |\nabla\varphi^m|^2=\int_\Gamma (1-\varphi^m)\varphi_n^m \leqq \operatorname{meas}\Gamma\cdot G_*, \qquad m\geqq 0.$$

LEMMA 3.7. *For every $\alpha\in(0,1)$ there exists a constant $C>0$, that depends on the data, on α and on T, but is independent of δ, such that*

$$\|\varphi_n^m\|_{C^\alpha(\Gamma)}, \|h^m\|_{C^\alpha(\Gamma)}\leqq C, \qquad m\geqq 0. \tag{3.23}$$

Proof. For any $x, y\in\Gamma$, $m>0$, we have as in (2.19) that

$$\varphi_n^m(x)-\varphi_n^m(y)=G_\varphi(*)(\varphi^m(x)-\varphi^m(y))+G_h(*)(h^m(x)-h^m(y)).$$

If we divide both sides by $|x-y|^\alpha$, take the supremum over all $x, y\in\Gamma$, use (2.8) and the fact that $|G_h(*)|\leqq K_3$ and $|G_\varphi(*)|<K_1$ which follows from Lemma 3.3, we find

$$H_\alpha(\varphi_n^m)\leqq K_1H_\alpha(\varphi^m)+K_3H_\alpha(h^m) \tag{3.24}$$

where $H_\alpha(f)$ stands for the Hölder constant of f. From Lemma 3.4 we have that $K_1H_\alpha(\varphi^m)\leqq K_4$ and K_4 is independent of δ and T. From (3.5) and (2.7) we see that

$$|h^m(x)-h^m(y)|\leqq|\sigma(x)-\sigma(y)|+\delta k\sum_{i=0}^{m-1}|\varphi_n^i(x)-\varphi_n^i(y)|,$$

and therefore

$$H_\alpha(h^m)\leqq H_\alpha(\sigma)+\delta k\sum_{i=0}^{m-1}H_\alpha(\varphi_n^i). \tag{3.25}$$

Inserting (3.25) in (3.24), we have

$$H_\alpha(\varphi_n^m)\leqq K_4+K_3H_\alpha(\sigma)+\delta kK_3\sum_{i=0}^{m-1}H_\alpha(\varphi_n^i).$$

In order to simplify the notation let $b_m=H_\alpha(\varphi_n^m)$, $m\geqq 0$, $D=kK_3$ and $a=K_4+K_3H_\alpha(\sigma)$. Then the last inequality can be written in the form

$$b_m\leqq a+\delta D\sum_{i=0}^{m-1}b_i, \qquad m\geqq 1. \tag{3.26}$$

Let $B=a+\delta Db_0$ then one can show by induction that

$$b_m\leqq(1+\delta D)^{m-1}B, \qquad m\geqq 1,$$

and since $\delta=T/M$ we find that

$$b_M\leqq\left(1+\frac{TD}{M}\right)^M B\leqq B\lim_{M\to\infty}\left(1+\frac{TD}{M}\right)^M=(a+Db_0)\,e^{TD}.$$

Therefore $H_\alpha(\varphi_n^m)$, for every $m\geqq 0$ is bounded for $T<\infty$ and it follows from (3.25) that $H_\alpha(h^m)$ is similarly bounded, hence (3.23) is satisfied.

LEMMA 3.8. *There exist positive constants C_1, C_2 independent of δ and of T such that*

$$\left|\frac{\varphi^{m+1}(x)-\varphi^m(x)}{\delta}\right|\leqq C_1 \quad \forall x\in\bar\Omega, \quad m\geqq 0 \tag{3.27}$$

and

$$\left|\frac{\varphi_n^{m+1}(x)-\varphi_n^m(x)}{\delta}\right|\leqq C_2 \quad \forall x\in\Gamma, \quad m\geqq 0. \tag{3.28}$$

Proof. We have that $\varphi^{m+1}-\varphi^m>0$ in Ω, (if $\varphi^{m+1}\equiv\varphi^m$ in $\bar\Omega$ then the assertion is clear), is harmonic and vanishes on S. Therefore its positive maximum is obtained on Γ, say at $x_0\in\Gamma$. Clearly at that point $\varphi_n^{m+1}-\varphi_n^m<0$. Therefore it follows from

$$\varphi_n^{m+1}-\varphi_n^m=G_\varphi(*)(\varphi^{m+1}-\varphi^m)+G_h(*)(h^{m+1}-h^m) \tag{3.29}$$

that at x_0, using (3.5) and (2.8),

$$G_\varphi(*)(\varphi^{m+1}-\varphi^m)<|G_h|\delta g((\varphi_n^m-\varepsilon)^+).$$

But $K\leqq G_\varphi$ for some $K>0$, from (2.8) and in view of Lemma 3.3 and $|G_h|<K_3$ and $g'\leqq k$; hence

$$|\varphi^{m+1}-\varphi^m|\leqq\left(\frac{K_3}{K}kG_*\right)\delta$$

where Lemma 3.5 was used, and so (3.27) is proved. Now (3.28) follows from (3.29) if we use (3.27), the necessary bounds on G_φ, G_h and $g((\varphi_n^m-\varepsilon)^+)<kG_*$.

LEMMA 3.9. *There exists a positive constant $C>0$, independent of δ and of T, such that*

$$\int_\Omega\left|\nabla\left(\frac{\varphi^{m+1}-\varphi^m}{\delta}\right)\right|^2\leqq C,\qquad m\geqq 0. \tag{3.30}$$

Proof. From

$$0=\delta^{-2}\int_\Omega(\varphi^{m+1}-\varphi^m)\Delta(\varphi^{m+1}-\varphi^m)$$

we obtain

$$\int_\Omega\left|\nabla\left(\frac{\varphi^{m+1}-\varphi^m}{\delta}\right)\right|^2\leqq\int_\Gamma\left|\frac{\varphi^{m+1}-\varphi^m}{\delta}\right|\left|\frac{\varphi_n^{m+1}-\varphi_n^m}{\delta}\right|$$

and the right-hand side is bounded by (meas Γ) $\cdot\, C_1\cdot C_2$ in view of Lemma 3.8.

4. The weak solution. In this section we use the results of the time discretized problem, take the limit $\delta\to 0$ and deduce the existence of a weak solution to (2.1)-(2.4).

DEFINITION 4.1. A *weak solution* to (2.1)-(2.4) is a pair (φ, h) of functions such that for any $0<T<\infty$:

(i)
$$\varphi\in W^{1,2}(0,T;H^1(\Omega))\cap C^\alpha(\bar\Omega\times[0,T]),$$
$$\varphi\in C^{1+\alpha}(\bar\Omega),\qquad 0\leqq t\leqq T,$$
$$h,h_t\in C^\alpha(\Gamma\times[0,T])$$

for any $\alpha\in(0,1)$;

(ii)
$$\Delta\varphi=0\quad\text{in }\Omega,\quad 0\leqq t\leqq T,$$
$$\varphi=1\quad\text{on }S\times[0,T];$$

(iii) The (inward) normal derivative on Γ, φ_n, satisfies

$$\varphi_n\in C^\alpha(\Gamma\times[0,T])\quad\text{for any }\alpha\in(0,1),$$

and

$$\varphi_n=G(\varphi,h)\quad\text{on }\Gamma\times[0,T];$$

(iv)
$$h(x,t)=\sigma(x)+\int_0^t g((\varphi_n(x,\tau)-\varepsilon)^+)\,d\tau\quad\text{on }\Gamma\times[0,T].$$

Thus (2.1)-(2.4) are satisfied but the weak solution lacks some regularity with respect to t.

THEOREM 4.2. *There exists a unique weak solution to* (2.1)-(2.4) *for any* $T>0$. *Moreover*

$$\varphi \in W^{1,\infty}(0, T; H^1(\Omega)). \tag{4.1}$$

Proof. Let φ^m be the solution of the time discretized problem (3.2)-(3.5) with $\delta = T/M$, such that $\delta < \sigma_*/kK_2$, and let $\varphi_\delta(x, t)$ denote the linear interpolation, in time, of the φ^m's, that is

$$\begin{aligned}\varphi_\delta(x, t) = [\varphi^m(x) - \varphi^{m-1}(x)][t-(m-1)\delta]\delta^{-1} + \varphi^{m-1}(x),&\\ x \in \bar{\Omega}, \qquad (m-1)\delta \leqq t \leqq m\delta.&\end{aligned} \tag{4.2}$$

By Lemma 3.1 $\varphi^m \in C^{1+\alpha}(\bar{\Omega})$ for all $m \geqq 0$ and therefore $\varphi_\delta \in C^{1+\alpha}(\bar{\Omega})$, and by Lemma 3.7

$$\|\varphi_\delta\|_{C^{1+\alpha}(\bar{\Omega})} \leqq C, \qquad 0 \leqq t \leqq T \quad \text{for any } \alpha \in (0, 1) \tag{4.3}$$

where C depends on α, and, here and below, C is a constant independent of δ.

From Lemma 3.8 we have that

$$\left|\frac{\partial \varphi_\delta}{\partial t}\right| \leqq C \quad \text{in } \bar{\Omega} \times [0, T] \tag{4.4}$$

where C is independent of T. Therefore there exists a constant C such that for any $\alpha \in (0, 1)$

$$\|\varphi_\delta\|_{C^\alpha(\bar{\Omega}\times[0, T])} \leqq C \tag{4.5}$$

and C depends on α but is independent of T. From Lemma 3.6 it follows that

$$\|\varphi_\delta\|_{H^1(\Omega)} \leqq \frac{C}{\sigma_*}, \qquad 0 \leqq t \leqq T \tag{4.6}$$

and C is independent of T. From (4.4) we find that

$$\|\varphi_\delta\|_{H^1(\Omega\times(0,T))} \leqq C. \tag{4.7}$$

Let $\delta \to 0$. For simplicity we use the same notation for subsequences. Then we have that

$$\varphi_\delta \to \varphi \begin{cases} \text{uniformly in } C^\alpha(\bar{\Omega} \times [0, T]) \quad \text{for any } \alpha \in (0, 1), \\ \text{uniformly in } C^{1+\alpha}(\bar{\Omega}), \qquad 0 \leqq t \leqq T. \end{cases} \tag{4.8}$$

Clearly the limit function satisfies $\varphi = 1$ on S. Let $\zeta \in C_0^\infty(\Omega)$; then

$$\int_\Omega \nabla\zeta \cdot \nabla\varphi_\delta = 0 \quad \forall \delta > 0,$$

so (4.8) implies that

$$\int_\Omega \nabla\zeta \cdot \nabla\varphi = 0,$$

and therefore $\Delta\varphi = 0$ in Ω, $t \in [0, T]$, so (ii) of the definition is satisfied. Now from Lemma 3.9 we have that

$$\int_\Omega \left|\nabla \frac{\partial \varphi_\delta}{\partial t}\right|^2 dx \leqq C, \qquad t \in (0, T), \tag{4.9}$$

$C>0$ independent of T; hence together with (4.4), (4.6) and (4.8) it follows that as $\delta \to 0$, $\varphi \in W^{1,\infty}(0, T; H^1(\Omega))$, i.e. (4.1) holds.

Let $\varphi_{\delta,n}$ be the linear interpolations, in time, of the φ_n^m,

$$\varphi_{\delta,n}(x,t)=[\varphi_n^{m+1}(x)-\varphi_n^m(x)][t-m\delta]\delta^{-1}+\varphi_n^m(x), \qquad x\in\Gamma, \quad m\delta\leqq t\leqq(m+1)\delta \tag{4.10}$$

then $\varphi_{\delta,n}\in C^\alpha(\Gamma)$, for any $\alpha\in(0,1)$, all $t\in[0,T]$, by Lemma 3.1. And

$$\|\varphi_{\delta,n}\|_{C^\alpha(\Gamma)}\leqq C,$$

then Lemma 3.8 implies that

$$\left|\frac{\partial\varphi_{\delta,n}}{\partial t}\right|\leqq C, \qquad 0\leqq t\leqq T$$

where $C>0$ is independent of T; therefore $\varphi_{\delta,n}$ are uniformly bounded in $C^\alpha(\Gamma\times[0,T])$ for any $\alpha\in(0,1)$.

It follows that

$$\varphi_{\delta,n}\to\psi \quad \text{uniformly in } C^\alpha(\Gamma\times[0,T]). \tag{4.11}$$

But for any $\zeta\in H^1(\Omega)$ with $\zeta=0$ on S we have

$$\int_\Omega \nabla\zeta\cdot\nabla\varphi_\delta=-\int_\Gamma \zeta\varphi_{\delta,n}, \qquad 0\leqq t\leqq T;$$

then as $\delta\to 0$, in view of (4.8), we find that

$$\int_\Omega \nabla\zeta\cdot\nabla\varphi=-\int_\Gamma \zeta\psi, \qquad 0\leqq t\leqq T.$$

It follows from (4.8) that the normal derivative φ_n satisfies

$$\varphi_n=\psi \quad \text{a.e. on } \Gamma, \quad t\in(0,T),$$

but $\varphi_n\in C^\alpha(\Gamma)$, $0\leqq t\leqq T$; hence $\varphi_n\in C^\alpha(\Gamma\times[0,T])$.

Let

$$\begin{aligned} h_\delta(x,t)&=\sigma(x)+\int_0^t g((\varphi_{\delta,n}(x,\tau)-\varepsilon)^+)\,d\tau \\ &=\sigma(x)+\delta\sum_{i=0}^{m-1} g((\varphi_{\delta,n}(*)-\varepsilon)^+)+[t-m\delta]g((\varphi_{\delta,n}(*)-\varepsilon)^+) \end{aligned} \tag{4.12}$$

for $m\delta\leqq t\leqq(m+1)\delta$. We used $\varphi(*)$ to denote the values of the function at some intermediate points $t_i<t_i^*<t_{i+1}$. So

$$\begin{aligned} h^m(x)-h_\delta(x,t)=\delta\sum_0^{m-1}\{g((\varphi_n^i-\varepsilon)^+)-g((\varphi_{\delta,n}(*)-\varepsilon)^+)\} \\ -[t-m\delta]g((\varphi_{\delta,n}(*)-\varepsilon)^+). \end{aligned}$$

But from the properties of g, (2.7), we find that

$$|g((\varphi_n^i-\varepsilon)^+)-g((\varphi_{\delta,n}(*)-\varepsilon)^+)|\leqq k|\varphi_n^i-\varphi_{\delta,n}(*)|, \qquad 0\leqq i\leqq m-1,$$

$$g((\varphi_{\delta,n}(*)-\varepsilon)^+)\leqq k\varphi_{\delta,n}(*).$$

But from (4.10) and Lemmas 3.5 and 3.8, we obtain

$$\begin{aligned} &|\varphi_n^i - \varphi_{\delta,n}(*)| \leqq |\varphi_n^{i+1} - \varphi_n^i| \leqq C\delta, && 0 \leqq i \leqq m-1, \\ &|t - m\delta| g((\varphi_{\delta,n}(*) - \varepsilon)^+) \leqq \delta k G_*, && m\delta \leqq t \leqq (m+1)\delta; \end{aligned} \tag{4.13}$$

hence

$$|h^m(x) - h_\delta(x, t)| \leqq C\delta \quad \text{on } \Gamma \times [0, T]. \tag{4.14}$$

Clearly $h_\delta(x, t) \in C^\alpha(\Gamma \times [0, T])$, since $\varphi_{\delta,n} \in C^\alpha(\Gamma \times [0, T])$. Moreover

$$h_{\delta,t} = g((\varphi_{\delta,n} - \varepsilon)^+),$$

which means that

$$h_{\delta,t} \in C^\alpha(\Gamma \times [0, T]).$$

As $\delta \to 0$

$$g((\varphi_{\delta,n} - \varepsilon)^+) \to g((\varphi_n - \varepsilon)^+) \quad \text{uniformly in } C^\alpha(\Gamma \times [0, T]) \tag{4.15}$$

and therefore

$$\left.\begin{aligned} h_\delta(x, t) &\to h(x, t) \\ h_{\delta,t}(x, t) &\to h_t(x, t) \end{aligned}\right\} \quad \text{uniformly in } C^\alpha(\Gamma \times [0, T]). \tag{4.16}$$

So, since (4.15) holds, we obtain that

$$\{h^m(x)\}_{m=0}^M \to h(x, t) \quad \text{as } \delta \to 0 \tag{4.17}$$

and clearly (4.12) implies that

$$h(x, t) = \sigma(x) + \int_0^t g((\varphi_n - \varepsilon)^+)\, d\tau \quad \text{on } \Gamma \times [0, T], \tag{4.18}$$

so (iv) is satisfied. Also it follows from (4.16) that

$$h, h_t \in C^\alpha(\Gamma \times [0, T]).$$

So (i) is satisfied and we are left with the second part of (iii), which follows from the uniform convergence in (4.8), (4.16), from (3.27) and the assumptions on G. More specifically, since

$$\varphi_n^m = G(\varphi^m, h^m) \to G(\varphi . h) \quad \text{as } \delta \to 0 \tag{4.19}$$

where the limit is uniform on $\Gamma \times [0, T]$ and in view of (4.13), $\varphi_n^m \to \varphi_n$ and therefore $\varphi_n = G(\varphi, h)$ on $\Gamma \times [0, T]$, i.e. (iii) is satisfied. The proof of the uniqueness is very similar to that of Theorem 2.8.

For later references we collect some of the facts above.

LEMMA 4.3. *The weak solution* (φ, h) *satisfies*

(i) $\varphi(x, t_1) \leqq \varphi(x, t_2)$ *in* $\bar{\Omega}$ *if* $t_1 < t_2$,

(ii) $\varphi \in C^\alpha(\bar{\Omega} \times [0, \infty))$ *any* $\alpha \in (0, 1)$,

(iii) $\|\varphi\|_{H^1(\Omega)} \leqq C, \quad 0 \leqq t \leqq T$,

C independent of T,

(iv) $\|\nabla \varphi_t\|_{L^2(\Omega)} \leqq C, \quad 0 \leqq t \leqq T$,

C independent of T,

(v) $\sigma_* \leqq h(x, t) \leqq 1 + K_2/\varepsilon$.

Proof. (i) follows from (3.10). (ii) follows from (4.5) and (4.8). (4.6) and (4.8) imply (iii). (iv) is a consequence of (4.9). (v) follows from Lemma 3.3.

In order to obtain better regularity we assume, in addition, that

(4.20) The partial derivatives $G_s(s,p)$ and $G_p(s,p)$ are C^α functions (any $\alpha\in(0,1)$) on compact subsets of $[0,1]\times\mathbb{R}_+$.

Then we can assert that under the assumptions of Theorem 4.2 and (4.20) we have for $0<T<\infty$ that the weak solution is a smooth solution (in the sense of § 2).

THEOREM 4.4. *If in addition* (4.20) *holds then the weak solution* (φ, h) *is a smooth solution,* $\nabla\varphi$ *is continuous in* $\bar\Omega\times[0,T]$ *and moreover*

$$\varphi_t(\cdot,t)\in C^{1+\alpha}(\bar\Omega),\qquad 0\leqq t\leqq T,\tag{4.21}$$
$$\varphi_t\in C^\alpha(\bar\Omega\times[0,T]),$$

$$\varphi_{nt}\in C^\alpha(\Gamma\times[0,T]).\tag{4.22}$$

Proof. Let ω be a solution of

$$\begin{aligned}&\Delta\omega=0\quad\text{in }\Omega,\\ &\omega=0\quad\text{on }S,\\ &\omega_n-G_s(\varphi,h)\omega=G_p(\varphi,h)h_t\quad\text{on }\Gamma.\end{aligned}\tag{4.23}$$

As, for $t\in[0,T]$, $G_p(\varphi,h)h_t$ and $G_s(\varphi,h)$ are in $C^\alpha(\Gamma)$ then $\omega\in C^{1+\alpha}(\bar\Omega)$. Since the solution to (4.23) is unique ($G_s\geqq 0$) we find that $\omega=\varphi_t$ and therefore $\varphi_t\in C^{1+\alpha}(\bar\Omega)$, $0\leqq t\leqq T$. To show continuity in t let $0\leqq t_1$, $t_2\leqq T$ and set

$$\varphi_t^i=\varphi_t(x,t_i),\qquad h_t^i=h_t(x,t_i),$$
$$G_s^i=G_s(\varphi(x,t_i),h(x,t_i)),\qquad G_p^i=G_p(\varphi(x,t_i),h(x,t_i)),\quad i=1,2,$$

and let $v=\varphi_t^1-\varphi_t^2$. Then v satisfies $\Delta v=0$ in Ω, $v=0$ on S and

$$v_n-(G_s^1\varphi_t^1-G_s^2\varphi_t^2)=G_p^1h_t^1-G_p^2h_t^2,\qquad x\in\Gamma.$$

The last equality can be written as

$$G_s^1v=v_n-(G_p^1h_t^1-G_p^2h_t^2)-(G_s^1-G_s^2)\varphi_t^2.\tag{4.24}$$

If $v>0$ at some point then it attains its positive maximum on Γ where, by the maximum principle, $v_n<0$. So

$$0<G_s^1v<|G_p^1h_t^1-G_p^2h_t^2|+|G_s^1-G_s^2||\varphi_t^2|\tag{4.25}$$

and a similar argument at a point of negative minimum (on Γ) gives

$$0<-G_s^1v<|G_p^1h_t^1-G_p^2h_t^2|+|G_s^1-G_s^2||\varphi_t^2|.\tag{4.26}$$

By (4.25), (4.26) and (2.8) we have

$$|v|=|\varphi_t^1-\varphi_t^2|\leqq K(\|G_p^1h_t^1-G_p^2h_t^2\|_{L^\infty(\Omega)}+\|G_s^1-G_s^2\|_{L^\infty(\Omega)}\|\varphi_t^2\|_{L^\infty(\Omega)}),\tag{4.27}$$

and the right-hand side converges to zero as $|t_2-t_1|\to 0$; hence φ_t is uniformly continuous. Now we divide (4.27) by $|t_2-t_1|^\alpha$, $\alpha\in(0,1)$, use the Hölder continuity of G_p, G_s, (4.20), and of h_t and write

$$G_p^1h_t^1-G_p^2h_t^2=(G_p^1-G_p^2)h_t^1+(h_t^1-h_t^2)G_p^2.$$

It follows that

$$\frac{|\varphi_t^1-\varphi_t^2|}{|t_1-t_2|^\alpha}\leqq K,\tag{4.28}$$

where K depends on the data and on T and is uniform in $\bar{\Omega}$. Hence $\varphi_t \in C^\alpha([0, T])$ uniformly in $\bar{\Omega}$ for any $\alpha \in (0, 1)$. In (4.20) we used the fact that $\sigma_* \leqq h \leqq 1 + K_2/\varepsilon$, (v) in Lemma 4.3. Combining this with $\varphi_t \in C^{1+\alpha}(\bar{\Omega})$ leads to the second part of (4.21).

Since $\varphi_{nt} = (\partial/\partial t)\varphi_n = G_s\varphi_t + G_p h_t$ then by the continuity we have $\varphi_{nt} = \varphi_{tn}$. Moreover the right-hand side is Hölder on Γ, $0 \leqq t \leqq T$ and in view of the second part of (4.21) it is Hölder on $[0, T]$ uniformly on Γ; hence (4.22) follows.

It remains to prove the continuity of $\nabla\varphi$ in $\bar{\Omega} \times [0, T]$. Let e be a unit vector in some (spatial) direction and denote by φ_e the derivative of φ in this direction.

By contradiction, if

$$|\varphi_e(x, t_0 + \delta t) - \varphi_e(x_0, t_0)| \geqq \gamma > 0$$

for $x - x_0 = \delta x$ small, for some $(x_0, t_0) \in \bar{\Omega} \times [0, \infty)$, then rewriting and using the fact that $\varphi_e \in C^\alpha$, it is enough to assume that

$$|\varphi_e(x_0, t_0 + \delta t) - \varphi_e(x_0, t_0)| \geqq \gamma. \tag{4.29}$$

Let $\delta t = 1/m$ then since $\varphi_m(x) = \varphi(x, t_0 + 1/m)$ is bounded uniformly in $C^{1+\alpha}$ then there exists a subsequence, also denoted by m, such that $\varphi_m(x) \to \bar{\varphi}(x)$ in $C^{1+\alpha}$ but $\varphi(x, t)$ are in $C^\alpha(\bar{\Omega} \times [0, T])$, hence $\bar{\varphi}(x) = \varphi(x, t_0)$. But clearly $\varphi_{m,e}(x) \to \bar{\varphi}_e(x)$ uniformly hence $\varphi_{m,e}(x) = \varphi_e(x, t_0 + 1/m) \to \varphi_e(x, t_0)$ which is a contradiction to (4.29), at $x = x_0$.

This holds for any direction so $\nabla\varphi$ is continuous in $\bar{\Omega} \times [0, T]$.

If (4.20) holds then the solution satisfies the following corollary.

COROLLARY 4.5. *It holds that*

$$\varphi(x, t_1) < \varphi(x, t_2), \qquad x \in \Omega \cup \Gamma \quad \textit{if } t_1 < t_2; \tag{4.30}$$

if for some $\bar{x} \in \Gamma$, $r > 0$, $h(\bar{x}, r) > \sigma(\bar{x})$ *then*

$$h_t(\bar{x}, t) > 0 \quad \forall t \geqq r. \tag{4.31}$$

Proof. Since (φ, h) is a smooth solution, it follows from Corollary 2.7. It follows from (4.31) and (2.4) that

$$\varphi_n(\bar{x}, t) > \varepsilon \quad \forall t \geqq r. \tag{4.32}$$

5. The asymptotic limit. We consider the asymptotic behavior of the solution (φ, h) of (2.1)-(2.4). For simplicity we assume (4.20) and so this is the smooth solution. It turns out that the steady state limit (as $t \to \infty$), which can be obtained formally by setting $h_t = 0$ in (2.4) (or more precisely in (2.4)′-(2.4)″), can be characterized as a Signorini problem with an obstacle that depends on $\varphi(x, t)$. Moreover the interest in the limit from the practical point of view is obvious since the thickness of the paint coat after a long time can give an indication of the areas that will not be painted at all.

The steady-state problem associated with (2.1)-(2.4) is to find a pair $\{\bar{\varphi}(x), \bar{h}(x)\}$, $\bar{\varphi} \in C^1(\bar{\Omega})$, $\bar{h} \in L^\infty(\Gamma)$ and such that

$$\Delta\bar{\varphi} = 0 \quad \text{a.e. in } \Omega, \tag{5.1}$$

$$\bar{\varphi}_n = G(\bar{\varphi}, \bar{h}) \quad \text{a.e. on } \Gamma, \qquad \bar{\varphi} = 1 \quad \text{on } S, \tag{5.2}$$

$$\left.\begin{aligned} \bar{\varphi}_n(x) &= \varepsilon \quad \text{if } \bar{h}(x) > \sigma(x), \\ \bar{\varphi}_n(x) &\leqq \varepsilon \quad \text{if } \bar{h}(x) = \sigma(x), \end{aligned}\right\} \text{a.e. on } \Gamma. \tag{5.3}$$

If we denote by $(\varphi(x, t), h(x, t))$ the smooth solution of (2.1)-(2.4) and $(\bar{\varphi}(x), \bar{h}(x))$ the solution of (5.1)-(5.3) then we have the following theorem.

THEOREM 5.1. *$\varphi(x,t) \nearrow \bar\varphi(x)$ uniformly in $C^\alpha(\bar\Omega)$, any $\alpha \in (0,1)$, and weakly in $H^1(\Omega)$ and $h(x,t) \nearrow \bar h(x)$ pointwise on Γ as $t \to \infty$. Moreover $\bar h(x) \leqq K_2/\varepsilon$.*

Proof. First suppose that $h(x,t) > \sigma(x)$ for some $x \in \Gamma$, $t > 0$. Hence $\varphi_n(x,s) > \varepsilon$ for some $0 < s \leq t$. Let $\tau = \sup\{s \leqq t;\ \varphi_n(x,s) > \varepsilon\}$. Then $\varphi_n(x,\tau) \geqq \varepsilon$, and then it follows from (2.3) and (2.8) that

$$\varepsilon \leqq \varphi_n(x,\tau) \leqq G(1,h) < \frac{K_2}{h}. \tag{5.4}$$

Therefore $h(x,\tau) < K_2/\varepsilon$ and clearly $h(x,t) < K_2/\varepsilon$ too. By Lemma 4.3(ii) $\varphi(x,t)$ is uniformly bounded in $C^\alpha(\bar\Omega \times [0,\infty))$. Let $\{t_i\}$ be a sequence such that $t_i \to \infty$ as $i \to \infty$. Consider the sequence of harmonic functions $\varphi_i(x) = \varphi(x,t_i)$. This sequence converges uniformly in $\bar\Omega$ to $\varphi_*(x)$. Clearly $\varphi_*(x) = 1$ on S. By Lemma 4.3(iii) the $\varphi_i(x)$ are uniformly bounded in $H^1(\Omega)$ and hence $\varphi_i(x) \to \varphi_*(x)$ as $i \to \infty$ (a subsequence if necessary) weakly in $H^1(\Omega)$. Hence $\varphi_*(x)$ is a harmonic function in Ω. By (2.3) and (2.8)

$$0 < \varphi_n = G(\varphi,h) < G(1,\sigma_*) = G_* \quad \text{on } \Gamma,$$

which implies that $\sup|\varphi_n(x,t)| \leqq G_* < \infty$ where the supremum is in $(x,t) \in \Gamma \times [0,\infty)$. Therefore there exists a subsequence φ_{in} that converges to ψ_* weak star in $L^\infty(\Gamma)$, i.e. for every $\zeta \in H^1(\Omega)$, $\zeta = 0$ on S,

$$\int_\Gamma \zeta\varphi_{in} \to \int_\Gamma \zeta\psi_*. \tag{5.5}$$

But since

$$\int_\Gamma \zeta\varphi_{in} = -\int_\Omega \nabla\zeta \cdot \nabla\varphi_i \to -\int_\Omega \nabla\zeta \cdot \nabla\varphi_* \tag{5.6}$$

it follows from (5.5) and (5.6) that ψ_* is a generalized (inward) normal derivative of φ_*, so we denote it by φ_{*n}. Now it is clear that $h_i(x) \equiv h(x,t_i) \geqq h_{i-1}(x)$ and since $h_i(x) < K_2/\varepsilon$ it follows that $h_i(x) \nearrow \bar h(x)$ pointwise in Γ and $\bar h(x) \leqq K_2/\varepsilon$. But then, using Lebesgue's theorem we obtain that

$$\int_\Gamma \zeta G(\varphi_i, h_i) \to \int_\Gamma \zeta G(\varphi_*, \bar h) \tag{5.7}$$

where (2.8) was used, and this in turn together with (5.6) implies that

$$\varphi_{*n} = G(\varphi_*, \bar h) \quad \text{a.e. on } \Gamma. \tag{5.8}$$

We can identify $\varphi_*(x)$ with $\bar\varphi(x)$, the unique solution of (5.1)-(5.2). Indeed if φ_1 and φ_2 satisfy (5.1), (5.2) with the same $\bar h$ then, from the monotonicity of G with φ, it follows that if we multiply $\Delta(\varphi_1 - \varphi_2) = 0$ by $(\varphi_1 - \varphi_2)$ and integrate over Ω we find

$$\begin{aligned} \int_\Omega |\nabla(\varphi_1 - \varphi_2)|^2 &= -\int_\Gamma (\varphi_{1n} - \varphi_{2n})(\varphi_1 - \varphi_2) \\ &= -\int_\Gamma (G_1 - G_2)(\varphi_1 - \varphi_2) \leqq 0, \end{aligned} \tag{5.9}$$

i.e., $\varphi_1 \equiv \varphi_2$ since $\varphi_1 = \varphi_2 = 1$ on S. It remains to show (5.3).

If $h_i(x) = \sigma(x)$ for some $x \in \Gamma$, all $i \geqq 1$, then from (2.4) it follows that $\varphi_{in}(x) \leqq \varepsilon$ all $i \geqq 1$, and by the pointwise convergence $\bar h(x) = \sigma(x)$ and $\bar\varphi_n \leqq \varepsilon$ a.e. on $\Gamma \cap \{\bar h(x) = \sigma(x)\}$. On the other hand if $h_i(x) > \sigma(x)$ for some $i > 1$ then by (4.32) $\varphi_{jn}(x) > \varepsilon$ all $j \geqq i$ but since the integral in (2.4) converges uniformly $(\bar h(x) \leqq K_2/\varepsilon)$ hence $\varphi_{in}(x) \searrow \varepsilon$ as $i \to \infty$ a.e. on $\Gamma \cap \{\bar h(x) > \sigma(x)\}$ thus (5.3) is satisfied a.e. on Γ.

We have

LEMMA 5.2. *The solution to* (5.1)-(5.3) *is unique.*

Proof. Let (φ_1, h_1) and (φ_2, h_2) be two solutions. As in (5.9) above we find that

$$\int_\Omega |\nabla(\varphi_1-\varphi_2)|^2 = -\int_\Gamma (G(\varphi_1, h_1)-G(\varphi_2, h_2))(\varphi_1-\varphi_2). \tag{5.10}$$

It is enough to show that the right-hand side of (5.10) is nonpositive. Indeed if $h_1, h_2 > \sigma(x)$ then $\varphi_{1n}(x) = \varepsilon = \varphi_{2n}(x)$.

If $h_1(x) > \sigma(x)$ and $h_2(x) = \sigma(x)$ then $\varphi_{1n}(x) = \varepsilon$ and $\varphi_{2n}(x) \leqq \varepsilon$, and this means that $G_1 \equiv G(\varphi_1, h_1) = \varepsilon \geqq G(\varphi_2, h_2) \equiv G_2$. So we want to show that $\varphi_1 \geqq \varphi_2$. Assume that $\varphi_1(x) < \varphi_2(x)$ at $x \in \Gamma$, then

$$\begin{aligned} 0 \geqq (G_1-G_2)(\varphi_1-\varphi_2) &= (G(\varphi_1, h_1)-G(\varphi_2, h_1))(\varphi_1-\varphi_2) \\ &\quad + (G(\varphi_2, h_1)-G(\varphi_2, h_2))(\varphi_1-\varphi_2) \\ &> (G(\varphi_2, h_1)-G(\varphi_2, h_2))(\varphi_1-\varphi_2), \end{aligned} \tag{5.11}$$

since G is strictly monotone increasing in φ, but G is monotone decreasing in h and $h_1 > h_2$; hence $G(\varphi_2, h_1)-G(\varphi_2, h_2) \leqq 0$ and so the assumption $(\varphi_1-\varphi_2) < 0$ leads to a contradiction in (5.11). Hence $\varphi_1 - \varphi_2 \geqq 0$ and therefore $(G_1-G_2)(\varphi_1-\varphi_2) \geqq 0$. The argument in the case when $h_1 = \sigma(x)$ and $h_2 > \sigma(x)$ is similar. Finally when $h_1 = \sigma(x) = h_2$ then $(G_1-G_2)(\varphi_1-\varphi_2) \geqq 0$ follows from the monotonicity of G in φ.

From Theorem 5.1 and Lemma 5.2 we have the following theorem.

THEOREM 5.3. *Assume that* $\partial\Omega$ *is in* $C^{1+\alpha}$, *any* $\alpha \in (0, 1)$, (2.6)-(2.8) *and* (4.20) *hold. Then there exists a unique solution* $(\bar\varphi, \bar h)$ *to the problem* (5.1)-(5.3). *Moreover*

$$\bar\varphi \in C^{1+\alpha}(\bar\Omega), \tag{5.12}$$

$$\bar h \in C^\alpha(\Gamma) \quad \textit{for any } \alpha \in (0, 1). \tag{5.13}$$

Proof. The uniqueness follows from Lemma 5.2. In addition we have that $\bar\varphi \in H^1(\Omega)$. Recall that $\sigma_* \leqq \bar h \leqq K_2/\varepsilon$ and $0 < c_* = \min_\Gamma \varphi(x, 0) \leqq \min_{\Gamma\times[0,\infty)} \varphi(x, t)$ (see (2.12)). Define

$$\Gamma^+ = \{x \in \Gamma, \bar h(x) > \sigma(x)\}, \tag{5.14}$$

then $\Gamma^+ \neq \varnothing$ by the assumption (2.11) and is open in Γ by the continuity of $h(x, t)$ and the fact that $h(x, t)$ is monotone nondecreasing in t on Γ^+. Let $x, y \in \Gamma^+$ then $G = \varepsilon$ a.e. at these points and hence

$$\begin{aligned} 0 &= G(\bar\varphi(x), \bar h(x)) - G(\bar\varphi(y), \bar h(y)) \\ &= G_\varphi(*)(\bar\varphi(x)-\bar\varphi(y)) + G_h(*)(\bar h(x)-\bar h(y)) \quad \text{a.e. on } \Gamma^+ \end{aligned} \tag{5.15}$$

where $G_\varphi(*)$ and $G_h(*)$ were evaluated by the mean value theorem. Now since $c_* > 0$ it follows from (2.8) that $0 < k' < |G_h(*)| < k''$ and therefore (5.15) can be rewritten as

$$k'|\bar h(x)-\bar h(y)| \leqq K_1|\bar\varphi(x)-\bar\varphi(y)| \quad \text{a.e. on } \Gamma^+. \tag{5.16}$$

But the right-hand side is Hölder continuous with exponent α in $\bar\Gamma^+$ hence so is the left-hand side, i.e. $\bar h(x) \in C^\alpha(\bar\Gamma^+)$. Therefore $\bar h \in C^\alpha(\Gamma)$ since on $\Gamma\backslash\Gamma^+$ we have $h(x) = \sigma(x)$. But then, since $\bar\varphi \in C^\alpha(\bar\Omega)$, we obtain by (5.2) that $\bar\varphi_n \in C^\alpha(\Gamma)$.

Let ω be a solution of

$$\begin{aligned} \Delta\omega &= 0 \quad \text{in } \Omega, \\ \omega &= 1 \quad \text{on } S, \\ \omega_n &= \bar\varphi_n \quad \text{on } \Gamma. \end{aligned} \tag{5.17}$$

Then $\omega \in C^{1+\alpha}(\bar{\Omega})$ and since the solution to (5.17) is unique we find that $\omega = \bar{\varphi}$ and therefore $\bar{\varphi} \in C^{1+\alpha}(\bar{\Omega})$, any $\alpha \in (0, 1)$.

We are able to show that the solution $(\bar{\varphi}, \bar{h})$ of (5.1)-(5.3) is also a solution of a Signorini problem (see e.g. [5, p. 111]). To this end let the obstacle be defined by

$$(5.18) \qquad Z(x) = \lim_{t \nearrow \tau(x)} \varphi(x, t), \qquad x \in \Gamma$$

where

$$(5.19) \qquad \tau(x) = \sup\{0 \leqq t;\ h(x, t) = \sigma(x)\}, \qquad x \in \Gamma.$$

Since h is monotone nondecreasing in t, $\tau(x)$ is well defined and it can have the value $+\infty$.

We have the following lemma.

LEMMA 5.4. *$\tau(x)$ is continuous from above on Γ^+.*

Proof. Clearly $\Gamma^+ = \{x \in \Gamma, \tau(x) < \infty\}$, since if $x \in \Gamma^+$ then $\bar{h}(x) > \sigma(x)$. Then for some $t < \infty$, $h(x, t) > \sigma(x)$, hence $\tau(x) < t < \infty$ and vice versa.

Now let $x_0 \in \Gamma^+$, $\tau(x_0) = M$ and by (5.19) $h(x_0, \tau(x_0)) = \sigma(x_0)$ but $h(x_0, t) > \sigma(x_0)$ for all $t > \tau(x_0)$. Consider the solution (φ, h) in $0 \leqq t \leqq 2M$ and, by Theorem 4.2 $h \in C^\alpha(\Gamma \times [0, 2M])$. Then for any x in a δ-neighbourhood $N_\delta \subset \Gamma$ of x_0, $\tau(x) < 3M/2$, $h(x, t) > \sigma(x)$ for $t > \tau(x)$, $x \in N_\delta$. Also, if $\tau(x) > \tau(x_0)$, we have

$$h(x_0, \tau(x)) - h(x, \tau(x)) = \sigma(x_0) - \sigma(x) + \int_{\tau(x_0)}^{\tau(x)} g(\varphi_n(x_0, \tau) - \varepsilon)\, d\tau$$

where we used (2.4) and the fact that $\varphi_n > \varepsilon$ for $t > \tau(x_0)$ at x_0, by (4.32). Hence

$$0 < \int_{\tau(x_0)}^{\tau(x)} g(\varphi_n(x_0, \tau) - \varepsilon)\, d\tau \leqq |\sigma(x) - \sigma(x_0)| + |h(x_0, \tau(x)) - h(x, \tau(x))|,$$

but the right-hand side converges to zero as $x \to x_0$. Hence, since $g > 0$ for $\varphi_n(x_0, t) > \varepsilon$, $t > \tau(x_0)$, it follows that $\tau(x) \searrow \tau(x_0)$.

Define

$$(5.20) \qquad \mathbb{K} = \{\zeta \in H^1(\Omega);\ \zeta = 1 \text{ on } S,\ \zeta \geqq Z \text{ on } \Gamma\},$$

then we prove the following.

THEOREM 5.5. *If (4.20) is satisfied then $(\bar{\varphi}, \bar{h})$ is a solution to (5.1)-(5.3) if and only if $\bar{\varphi}$ satisfies the variational inequality*

$$(5.21) \qquad \int_\Omega \nabla\bar{\varphi} \cdot \nabla(\zeta - \bar{\varphi}) + \varepsilon \int_\Gamma (\zeta - \bar{\varphi}) \geqq 0 \quad \forall \zeta \in \mathbb{K}, \quad \bar{\varphi} \in \mathbb{K}.$$

Remark 5.6. The fact that $(\bar{\varphi}, \bar{h})$ is a solution to a variational inequality is a result of its being the asymptotic limit of an evolutionary problem and indeed the obstacle $Z(x)$ is constructed from the time dependent solution. It may be interesting to investigate what classes of problems of the type (5.1)-(5.3) can be recast as variational inequalities via their imbedding in appropriate evolutionary problems.

Proof. It is enough to show that (5.21) is satisfied by $\varphi(x, t)$ as $t \to \infty$, where (φ, h) is the solution to (2.1)-(2.4). For any $\zeta \in \mathbb{K}$, $0 < t < \infty$, we have

$$(5.22) \quad \int_\Omega \nabla\varphi(x, t) \cdot \nabla(\zeta - \varphi) + \varepsilon \int_\Gamma (\zeta - \varphi) \geqq -\int_\Gamma (\varphi_n - \varepsilon)(\zeta - \varphi) \geqq -\int_{\Gamma_t} (\varphi_n - \varepsilon)(\zeta - \varphi)$$

where $\Gamma_t = \Gamma \cap \{x;\ \varphi_n(x, t) > \varepsilon\}$ and Lemma 4.5 was used. Clearly $\Gamma_t \nearrow \Gamma_\infty$ if $t \to \infty$ by (4.31) and so for any $\eta > 0$ small and $M > 0$ large there is a θ (depending only on η,

$\theta \to \infty$ if $\eta \to 0$) such that

$$\int_{\theta}^{\theta+M} \int_{\Gamma_t} |\varphi_n - \varepsilon| = \int_{\theta}^{\theta+M} \int_{\Gamma_t} (\varphi_n - \varepsilon)^+$$
$$\leqq \frac{1}{k_*} \int_{\theta}^{\theta+M} \int_{\Gamma_\theta} g((\varphi_n - \varepsilon)^+) + \eta M \tag{5.23}$$
$$\leqq K \int_{\Gamma_\theta} h(x, \theta + M) + \eta M \leqq \frac{K}{\varepsilon} + \eta M$$

where we used (2.7), the fact that $h \leqq K_2/\varepsilon$ and that $\Gamma_\infty \backslash \Gamma_\theta \to 0$ if $\theta \to \infty$, with an appropriate K.

We integrate (5.22) with respect to $\theta < t < \theta + M$, divide by M, use (5.23) and let $M \to \infty$, $\eta \to 0$. We find that $\bar{\varphi}(x) \overset{=}{\cdot} \lim_{t\to\infty} \varphi(x, t)$ satisfies (5.21).

The fact that $\bar{\varphi}(x) \in H^1(\Omega)$ follows from (5.12) and that $\bar{\varphi} = 1$ on S is clear. From the definition of $Z(x)$, (5.18), and from $\varphi(x, t_1) \leqq \varphi(x, t_2)$ for every $t_1 < t_2$ it follows that $\bar{\varphi} \geqq Z$ on Γ, therefore $\bar{\varphi} \in \mathbb{K}$, as was claimed above.

Remark 5.7. It follows from Theorems 5.3 and 5.5 that the solution $\bar{\varphi}$ to the Signorini problem (5.21) is in $C^{1+\alpha}(\bar{\Omega})$ for any $\alpha \in (0, 1)$.

6. A weak solution when $\sigma(x) \equiv 0$. Most of the bounds that were found in § 4 depend on the fact that $0 < \sigma_* \leqq \sigma(x)$. Nevertheless using convex geometry and a monotonicity argument we are able to prove the existence of a weak solution to the degenerate case when $\sigma(x) = 0$ on Γ; i.e. the case that was considered in [1] and [2]. To this end we invert the geometry and assume that S is the inner boundary of Ω and Γ is the outer boundary, both in $C^{1+\alpha}$, any $\alpha \in (0, 1)$ and that Γ is *convex*. For simplicity we take $g(s) = s$, $G(\varphi, h) = \varphi/h$ which satisfies (2.8) and (4.20) for $0 < \varphi \leqq 1$ and $\sigma_* \leqq h \leqq 1 + \varepsilon^{-1}$. In addition we take $\sigma(x) = \sigma$ where $\sigma \geqq 0$ is a constant. Thus we consider the problem

$$\Delta\varphi = 0 \quad \text{in } \Omega, \quad 0 \leqq t \leqq T, \tag{6.1}$$

$$\varphi = 1 \quad \text{on } S, \quad 0 \leqq t \leqq T, \tag{6.2}$$

$$h\varphi_n = \varphi \quad \text{on } \Gamma, \quad 0 \leqq t \leqq T, \tag{6.3}$$

$$h = \sigma + \int_0^t (\varphi_n - \varepsilon)^+ \, d\tau \quad \text{on } \Gamma, \quad 0 \leqq t \leqq T. \tag{6.4}$$

We refer to (6.1)-(6.4) as problem (P_σ). Our interest is in (P_0), which is the problem in the limit as $\sigma \to 0$. It follows from Theorem 4.4 that for any $\sigma > 0$ the solution to (P_σ) is smooth. On the other hand the weak solution to (P_0) is essentially weaker than in definition 4.1, as the following definition shows.

DEFINITION 6.1. A *weak solution to problem* (P_0) is a pair of functions (φ, h) such that for any $0 < T < \infty$

(i) $\varphi \in L^\infty(0, T; H^1(\Omega)) \cap C^\alpha(\bar{\Omega} \times [0, T])$,

$h \in L^\infty(\Gamma \times (0, T))$,

$h_t \in L^\infty(0, T; L^2(\Gamma))$,

for any $\alpha \in (0, 1)$;

(ii) $\Delta\varphi = 0$ in Ω, $0 \leqq t \leqq T$,

$\varphi = 1$ on S, $0 \leqq t \leqq T$;

(iii) There exists a function $\varphi_n \in L^\infty(0, T; L^2(\Gamma))$ such that

$$\int_\Omega \nabla\zeta \cdot \nabla\varphi = -\int_\Gamma \zeta\varphi_n, \qquad 0 \leqq t \leqq T$$

for any smooth function ζ such that $\zeta = 0$ in a neighborhood of S, thus φ_n can be considered as a generalized (inward) normal derivative of φ;

(iv) $\quad h\varphi_n = \varphi$ a.e. on Γ, $0 \leqq t \leqq T$;

(v) $\quad h = \int_0^t (\varphi_n - \varepsilon)^+ \, d\tau$ a.e. on Γ, $0 \leqq t \leqq T$.

We want to prove the existence of a weak solution to (P_0) as a monotone limit of (smooth) solutions to (P_σ), $\sigma > 0$. To this end we need the following a priori estimates.

LEMMA 6.2. *Let ω be the solution of*

$$(6.5) \qquad \Delta\omega = 0 \quad in\ \Omega, \qquad \omega = 1 \quad on\ S, \qquad \sigma\omega_n = \omega \quad on\ \Gamma.$$

Then there exists a constant $\theta > 0$ that depends only on the geometry but is independent of σ, such that

$$(6.6) \qquad 0 \leqq \omega_n < \theta \quad on\ \Gamma$$

for any $\sigma > 0$.

Proof. From the maximum principle $\omega > 0$ and $\omega_n > 0$ on Γ. Let $x_0 \in \Gamma$ be the point where $\max_\Gamma \omega_n$ is attained; at this point $\max_\Gamma \omega$ is attained too. Let $\Pi(x)$ be the hyperplane that passes through the point $(x_0, \omega(x_0))$, i.e. $\Pi(x_0) = \omega(x_0)$, and has a slope $\theta = 2/d_0$ in the direction of the inner normal, where $d_0 = \text{dist}(\Gamma, S)$. From the assumption on the convexity of Γ we have that $\Pi(x) \geqq \omega(x)$ on Γ and by the construction $\Pi(x) > 1$ on S. Hence $\Pi > \omega$ in Ω and therefore by the strong maximum principle, since $\Pi = \omega$ at x_0, $\theta = \Pi_n > \omega_n$ at x_0, i.e., (6.6) holds.

We use this to show the following.

LEMMA 6.3. *There holds for any $\sigma > 0$*

$$(6.7) \qquad \int_\Gamma |\varphi_n|^3 \leqq c, \qquad 0 \leqq t \leqq T$$

where $C > 0$ depends on Γ, θ and ε but is independent of σ or T.

Proof. Let (φ, h) be the solution to (P_σ). Then $\varphi_t \in C^\alpha(\bar{\Omega} \times [0, T])$ by Theorem 4.4 and satisfies

$$(6.8) \qquad \Delta\varphi_t = 0 \qquad \text{in } \Omega, \quad 0 \leqq t \leqq T,$$

$$(6.9) \qquad \varphi_t = 0 \qquad \text{on } S, \quad 0 \leqq t \leqq T,$$

$$(6.10) \qquad h\varphi_{tn} = \varphi_t - h_t\varphi_n \qquad \text{on } \Gamma, \quad 0 \leqq t \leqq T.$$

We multiply (6.8) by φ_t, integrate over Ω, integrate by parts and use (6.9) to obtain (for any $t \in [0, T]$)

$$(6.11) \qquad 0 \leqq \int_\Omega |\nabla\varphi_t|^2 = -\int_\Gamma \varphi_t\varphi_{tn}.$$

Now we multiply (6.10) by φ_{tn} and integrate over Γ. Using (6.11) and the equation $h_t = (\varphi_n - \varepsilon)^+$ we get

$$(6.12) \qquad \int_\Gamma (\varphi_n - \varepsilon)\varphi_n\varphi_{nt} \leqq \int_\Gamma (\varphi_n - \varepsilon)^+\varphi_n\varphi_{nt} \leqq \int_\Gamma \varphi_t\varphi_{tn} \leqq 0$$

where the left inequality follows from the observation that if $\varphi_n \leqq \varepsilon$ then $h_t = 0$. Hence from (6.10) it follows that $\varphi_{tn} > 0$. We rewrite (6.12) as

$$\int_\Gamma (\varphi_n - \varepsilon)^2 \varphi_{nt} + \varepsilon \int_\Gamma (\varphi_n - \varepsilon)\varphi_{nt} \leqq 0,$$

i.e.,

$$\frac{d}{dt}\int_\Gamma \left\{\frac{1}{3}(\varphi_n - \varepsilon)^3 + \frac{\varepsilon}{2}(\varphi_n - \varepsilon)^2\right\} \leqq 0$$

or

$$\begin{aligned}(6.13)\qquad &\int_\Gamma \left\{\frac{1}{3}(\varphi_n(x,t) - \varepsilon)^3 + \frac{\varepsilon}{2}(\varphi_n(x,t) - \varepsilon)^2\right\} dx \\ &\qquad \leqq \int_\Gamma \left\{\frac{1}{3}(\varphi_n(x,0) - \varepsilon)^3 + \frac{\varepsilon}{2}(\varphi_n(x,0) - \varepsilon)^2\right\} dx.\end{aligned}$$

Now clearly $\varphi(x, 0) = \omega(x)$ where ω is the solution of (6.5) and therefore $\varphi_n(x, 0) \leqq \theta$ by (6.6) and so (6.13) implies (6.7), and also

$$(6.14)\qquad \int_\Gamma \varphi_n^2 \leqq C.$$

LEMMA 6.4. *There holds for any* $\sigma > 0$

$$(6.15)\qquad \|\varphi\|_{H^1(\Omega)} \leqq C, \qquad 0 \leqq t \leqq T,$$

where C is independent of σ and of T.

Proof. We integrate $(\varphi - 1)\Delta\varphi$ over Ω and find

$$\int_\Omega |\nabla\varphi|^2 = \int_\Gamma (1-\varphi)\varphi_n \leqq \frac{1}{2}\int_\Gamma (1-\varphi)^2 + \frac{1}{2}\int_\Gamma \varphi_n^2 \leqq C$$

where we used $0 \leqq \varphi \leqq 1$ and (6.14), for any $0 \leqq t \leqq T$.

We denote by $\{\varphi_\sigma, h_\sigma\}$ the smooth solution to (P_σ), $\sigma > 0$. We have that the sequences $\{\varphi_\sigma\}$ and $\{h_\sigma\}$ are monotone increasing with $\sigma > 0$.

LEMMA 6.5. *Let $0 < \sigma_1 < \sigma_2$ and let $\varphi_{\sigma_i} \equiv \varphi_i$, $h_{\sigma_i} \equiv h_i$, $i = 1, 2$ be the smooth solutions to (P_{σ_i}). Then*

$$(6.16)\qquad \begin{aligned}&\varphi_1 \leqq \varphi_2 \quad \textit{in } \Omega \cup \Gamma, \quad 0 \leqq t \leqq T,\\ &h_1 \leqq h_2 \quad \textit{on } \Gamma, \qquad 0 \leqq t \leqq T.\end{aligned}$$

Proof. Define the set $\Sigma = \{t \in [0, T];$ (6.16) holds for $t\}$. We have that $0 \in \Sigma$. Indeed at $t = 0$ we have $h_1 = \sigma_1 < \sigma_2 = h_2$ by assumption. Let $\varphi = \varphi_2 - \varphi_1$, then $\Delta\varphi = 0$ in Ω and $\varphi = 0$ on S and

$$(6.17)\qquad \varphi = \varphi_2 - \varphi_1 = \sigma_2\varphi_{2n} - \sigma_1\varphi_{1n} \quad \text{on } \Gamma.$$

Let $x_0 \in \Gamma$ be a nonpositive minimum point of φ; then by the strong maximum principle $\varphi_n > 0$ at x_0, and so $\varphi_{2n} > \varphi_{1n}$ which is impossible by (6.17). So $\min_\Gamma \varphi > 0$ and hence

$$(6.18)\qquad \begin{aligned}&\varphi_1 < \varphi_2 \quad \text{in } \Omega \cup \Gamma, \quad t = 0,\\ &h_1 < h_2 \quad \text{on } \Gamma, \qquad t = 0.\end{aligned}$$

By continuity there exists $t_* > 0$ such that $[0, t_*) \subset \Sigma$. If $t_* < T$ then there exists $x_0 \in \Gamma$ such that $h_1(x_0, t_*) = h_2(x_0, t_*)$. Assume that $h_1 \not\equiv h_2$ at $t = t_*$. By the proof of (6.18) we have $\varphi_1(x, t_*) < \varphi_2(x, t_*)$ in $\Omega \cup \Gamma$. Then it follows from

$$0 < \varphi = \varphi_2 - \varphi_1 = h_2\varphi_{2n} - h_1\varphi_{1n}, \qquad x_0 \in \Gamma, \quad t = t_*$$

that $\varepsilon < \varphi_{1n} < \varphi_{2n}$; hence $h_{1_t} = (\varphi_{1n} - \varepsilon) < (\varphi_{2n} - \varepsilon) = h_{2t}$ at $x_0 \in \Gamma$, $t = t_*$ but this implies, by continuity, that $h_2(x_0, t) < h_1(x_0, t)$ for $t_* - \delta < t < t_*$, some $\delta > 0$, which is a contradiction to the definition of t_*. If $h_1 \equiv h_2$ at t_*, then if $\varphi_1 \not\equiv \varphi_2$ the argument is as above. If $\varphi_1 \equiv \varphi_2$ at $t = t_*$ then this holds for every $t \geqq t_*$ because of the uniqueness, and (6.16) holds trivially on $[t_*, T]$.

Now we can assert that problem (P_0) has a weak solution (as in Definition 6.1). Thus the problem that was considered in [1] and in [2] has a weak solution.

THEOREM 6.6. *There exists a weak solution* (φ, h) *to problem* (P_0). *Moreover* $0 \leqq h \leqq 1 + \varepsilon^{-1}$.

Proof. Let $\{\varphi_\sigma, h_\sigma\}$ be the solutions to (P_σ) with $\sigma > 0$. It follows from Lemma 3.4 that $\{\varphi_\sigma\}$ is bounded uniformly in $C^\alpha(\bar{\Omega} \times [0, T])$ independently of $\sigma > 0$, and Lemma 6.4 implies that the same holds true in $L^\infty(0, T; H^1(\Omega))$. For all $\sigma > 0$, $\sigma \leqq h_\sigma \leqq 1 + 1/\varepsilon$, from Lemma 4.3 (v) with $K_2 = 1$. Therefore as we let $\sigma \to 0$ we obtain

$$(6.19) \qquad \varphi_\sigma \searrow \varphi \begin{cases} \text{uniformly in } C^\alpha(\bar{\Omega} \times [0, T]), \\ \text{weakly in } H^1(\Omega), 0 \leqq t \leqq T, \\ \text{monotonically on } \bar{\Omega} \times [0, T] \end{cases}$$

and

$$(6.20) \qquad h_\sigma \searrow h \begin{cases} \text{weak* in } L^\infty(\Gamma \times (0, T)), \\ \text{monotonically on } \Gamma \times [0, T]. \end{cases}$$

From the uniform convergence $\varphi_0 \searrow \varphi$ we have $\varphi = 1$ on S, $0 \leqq t \leqq T$ and φ is harmonic in Ω, $0 \leqq t \leqq T$, thus parts of (i) and (ii) of Definition 6.1 are satisfied.

It follows from Lemma 6.3 that $\{\varphi_{\sigma,n}\}$ is bounded in $L^3(\Gamma)$, $0 \leqq t \leqq T$, independently of $\sigma > 0$. Thus $\varphi_{\sigma,n} \to \psi$ weakly in $L^3(\Gamma)$, $0 \leqq t \leqq T$ and therefore, by Sobolev's theorem (see e.g. [8]),

$$(6.21) \qquad \varphi_{\sigma,n} \to \psi \quad \text{strongly in } L^2(\Gamma), \quad 0 \leqq t \leqq T.$$

Let ζ be a smooth function such that $\zeta = 0$ on S, then

$$(6.22) \qquad \int_\Omega \nabla\zeta \cdot \nabla\varphi_\sigma = -\int_\Gamma \zeta\varphi_{\sigma,n}, \qquad 0 \leqq t \leqq T$$

for all $\sigma > 0$. Then (6.19)) and (6.21) give, as $\sigma \to 0$, that

$$(6.23) \qquad \int_\Gamma \nabla\zeta \cdot \nabla\varphi = -\int_\Gamma \zeta\psi, \qquad 0 \leqq t \leqq T.$$

Therefore, since $\Delta\varphi = 0$ in Ω, ψ can be identified with a generalized (inward) normal derivative of φ, so we write $\varphi_n = \psi$ where (6.23) is understood. Thus (iii) is satisfied. Letting $\zeta \in C_0^\infty(\mathbb{R}^n)$, we multiply (6.3) by ζ and integrate over Γ and then let $\sigma \to 0$, then (6.19)-(6.21) give

$$(6.24) \qquad \int_\Gamma \zeta h\varphi_n = \int_\Gamma \zeta\varphi, \qquad 0 \leqq t \leqq T,$$

and so (iv) is satisfied, but moreover $h\varphi_n \in C^\alpha(\Gamma \times [0, T])$. Finally we multiply (6.4) by ζ and integrate over Γ, so

$$\int_\Gamma \zeta h_\sigma = \sigma \int_\Gamma \zeta + \int_\Gamma \int_0^t \zeta(\varphi_{\sigma,n} - \varepsilon)^+ \, d\tau, \qquad 0 \leqq t \leqq T.$$

Letting $\sigma \to 0$ and using (6.20) and (6.21) we get

$$\int_\Gamma \zeta h = \int_\Gamma \int_0^t \zeta(\varphi_n - \varepsilon)^+ \, d\tau, \qquad 0 \leqq t \leqq T, \tag{6.25}$$

and so (v) is satisfied. Moreover by differentiating with respect to t in (6.25),

$$h_t = (\varphi_n - \varepsilon)^+ \quad \text{a.e. on } \Gamma, \quad 0 \leqq t \leqq T,$$

and therefore $h_t \in L^\infty(0, T; L^2(\Gamma))$. This completes (i) and therefore the proof of the theorem.

ASYMPTOTICS OF A RATHER UNUSUAL TYPE IN A FREE BOUNDARY PROBLEM*

C. M. BRAUNER†, W. ECKHAUS‡, M. GARBEY§ AND A. VAN HARTEN‡

Abstract. We consider the singular perturbation problem

$$-\varepsilon\Delta u+\frac{u}{1+u}=f \quad \text{in } \Omega\in\mathbb{R}^2$$

with $u=0$ on $\partial\Omega$. There is a region where u blows up as $\varepsilon\downarrow 0$, whose boundary S is solution of a free boundary problem. Across S there is a sharp transition layer phenomenon. We construct a uniform asymptotic expansion in $\bar{\Omega}$ which exhibits two rather unusual features: the regular expansion in the subdomain inside S has singularities as S is approached; the structure of the local expansion along S involves fractional powers of ε multiplied by powers of $\ln \varepsilon$. We prove the validity of the expansion using barrier-function techniques.

Key words. singular perturbations, free boundary, matched asymptotic expansions, nonlinear elliptic boundary value problems

AMS(MOS) subject classifications. 35B25, 35J75

1. Introduction. In this paper we take up a problem that has been studied by Brauner and Nicolaenko [5], [6], [7] and analyse it by the method of matched asymptotic expansions [1]. Let us first formulate the problem, then summarize some relevant results and show why further analysis is needed and is nontrivial.

Let the function u be a solution of

$$\begin{aligned}&-\varepsilon\Delta u+\frac{u}{1+u}=f(x) \quad \text{in } \Omega\subset\mathbb{R}^2,\\ &u=0 \quad \text{on } \partial\Omega.\end{aligned} \tag{1.1}$$

Ω is a bounded open domain without holes, the boundary $\partial\Omega$ is smooth and connected and Ω lies everywhere on one side of $\partial\Omega$. The function $f(x)$ has the following properties:

$$f\in C^\infty(\bar{\Omega}),\quad f\geqq 0,\quad \max_{x\in\bar{\Omega}} f(x)>1,\quad f<1 \quad \text{on } \partial\Omega. \tag{1.2}$$

From the theory of monotone operators and regularity theory for solutions of elliptic boundary value problems it follows that for a given $\varepsilon>0$ (1.1) with f as in (1.2) has a unique solution $u\in C^\infty(\bar{\Omega})$ (cf. [3], [4]). Furthermore, a priori bounds for this solution can be given as

$$0\leqq u\leqq\frac{K}{\varepsilon}\cdot\max_{\bar{\Omega}} f(x). \tag{1.3}$$

For the lower bound we refer to [5]. The upper bound is valid with $K=|(-\Delta)^{-1}|$. Here $(-\Delta)^{-1}$ denotes the inverse of the Laplacian with Dirichlet boundary condition considered as a bounded operator from $C(\bar{\Omega})$ into $C(\bar{\Omega})$, where $C(\bar{\Omega})$ is endowed with

§ Universite de Valenciennes, 59300 Valenciennes, France.

the maximum norm $|\ |_{\max}$ and $\|(-\Delta)^{-1}\|$ denotes its operator norm. The upper bound follows, since

$$u \leqq |u|_{\max} = \varepsilon^{-1}\left|(-\Delta)^{-1}\left(f-\frac{u}{1+u}\right)\right|_{\max} \leqq \varepsilon^{-1}\|(-\Delta)^{-1}\|\left|f-\frac{u}{1+u}\right|_{\max}$$

and, using (1.2), $|f-u/(1+u)| \leqq \max_{\bar{\Omega}} f$.

We aim to study and construct asymptotic approximations for u, valid for small positive values of ε.

From Brauner and Nicolaenko [6], [7] we have the following results. Consider the rescaled function $w=\varepsilon u$. w converges for $\varepsilon \downarrow 0$ to a function $w_0 \in W^{2,p}(\Omega) \cap C^1(\bar{\Omega})$, $p \geqq 2$, where the convergence takes place strongly in $H_0^1(\Omega)$ and weakly in $W^{2,p}(\Omega)$. Note that $w_0 \geqq 0$. We introduce

$$\begin{aligned} &\Omega_+ \underset{\text{def}}{=} \{x \in \Omega \mid w_0(x) > 0\}, \qquad S = \partial\Omega_+, \\ &\Omega_0 = \operatorname{int}\{x \in \Omega \mid w_0(x) = 0\}. \end{aligned} \tag{1.4}$$

In this paper we consider the situation where the open set Ω_+ has no holes, its boundary S is smooth and connected and Ω_+ lies everywhere on one side of S. S is called the free boundary and we suppose that S has a positive distance to $\partial\Omega$, i.e., $\bar{\Omega}_+ \subset \Omega$. We mention that regularity results on the free surface S in 2 dimensions have been established once S is a Jordan curve (cf. [8] or [20], [21]). (See Fig. 1.)

In this situation w_0 restricted to $\bar{\Omega}_+$ is in $C^\infty(\bar{\Omega}_+)$, and w_0 solves the obstacle problem

$$\begin{aligned} &-\Delta w_0 = f-1 \quad \text{in } \Omega_+, \\ &w_0 = 0 \quad \text{on } S, \\ &\frac{\partial w_0}{\partial n} = 0 \quad \text{on } S. \end{aligned} \tag{1.5}$$

Furthermore, in Ω_0 we have $f<1$ (cf. [8]) and $u(x)$ converges pointwise as $\varepsilon \downarrow 0$ to the function $U_0(x)$, which is the unique solution of the formal limit of the equation (1.1), i.e.,

$$\frac{U_0}{1+U_0} = f. \tag{1.6}$$

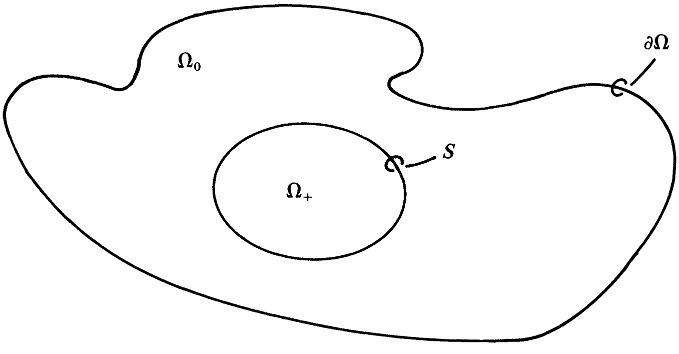

FIG. 1

Finally we can show [5], [10] that

$$\max_{x\in S} f(x) < 1. \tag{1.7}$$

Hence $U_0(x)$ is well defined in $\bar{\Omega}_0$ and $U_0 \in C^\infty(\bar{\Omega}_0)$.

From the point of view of asymptotic approximations we can summarize these results by stating that in Ω_+ the solution u is approximated by $(1/\varepsilon)w_0$, while in Ω_0 the approximation is given by U_0. A natural question arises now: can one construct asymptotic expansions in these domains and global expansion of u valid in the whole domain $\bar{\Omega}$?

Let us show that the question is highly nontrivial by attempting in an elementary way to construct an expansion in Ω_+. We write

$$w = \varepsilon u \tag{1.8}$$

and obtain for w the problem

$$-\Delta w + \frac{\varepsilon}{\varepsilon + w} = f - 1 \quad \text{in } \Omega_+. \tag{1.9}$$

This suggests an expansion

$$w = w_0 + \varepsilon w_1 + \varepsilon^2 w_2 + \cdots. \tag{1.10}$$

With w_0 as defined by (1.5) one gets for w_1 the problem

$$-\Delta w_1 = -\frac{1}{w_0} \quad \text{in } \Omega_+. \tag{1.11}$$

Clearly the right-hand side is singular on the boundary S of Ω_+. For higher terms of the expansion (1.10) one gets equations with stronger singularities.

One must realize at this stage that in a singular perturbation problem (1.1) one should expect along the "free boundary" S the occurrence of a transition layer in which the solution varies rapidly. Regular expansions of the type (1.10) can be expected to be valid only in compact subsets of Ω_+. Relations between regular expansions and expansions in the layer are established by matching. Also, one should realize that the structure of the expansions is not known a priori and that terms other than those depicted in (1.10) can (and will) occur.

In this paper we construct asymptotic expansions for the solution u of (1.1) up to an arbitrary order of accuracy and prove their validity. Our motivation in performing the analysis was not only to provide a full answer to the problem of asymptotic expansions for the specific equation (1.1). We also found that the problem at hand was a true challenge even to experienced practitioners of asymptotic analysis. We therefore hope that the techniques and reasoning that we have developed may be useful in other problems of a similar nature.

Let us now sketch the contents of the following sections: Section 2: The regular expansion in Ω_0 and the layer at $\partial\Omega$; Section 3: The principal terms in the internal layer at S and in the expansion in Ω_+; Section 4: Higher order terms near S and in Ω_+; Section 5: Matching relations of the internal layer at S and the expansions in Ω_0, Ω_+; Section 6: Composition of a global approximation Z_N and estimation of the error $u - Z_N$; Section 7: Discussion of some generalisations.

From the point of view of asymptotic expansion, § 2 will be rather straightforward. However, in the following sections the construction process contains some surprising elements. For example, the structure of the asymptotic expansions near the free surface S and in Ω_+ turns out to be unusual; not only do fractional orders of ε appear as order functions, but so do fractional orders of ε multiplied with powers of $\ln \varepsilon$. Partial results in this sense were also announced by Frank and Wendt, cf. [9]. One of the nontrivial aspects of the construction will be to determine which order functions are needed in the local expansions near S and in Ω_+. For precise information on these order functions, see §§ 3 and 4. Another interesting phenomenon in the construction is the unavoidable occurrence of singularities in the higher order terms of the expansion in Ω_+ when the variables approach the free surface. This requires a rather delicate analysis separating the singularities from the regular parts of the terms. We then show that these singularities match the layer at S and that the layer changes the singularities coming from Ω_+ into regular terms (see §§ 4 and 5). To demonstrate the validity of the constructed global approximation we use an estimation result based on barrier-function techniques (see § 6). Using the results in that section we can improve the convergence statements made earlier in this introduction. For example, if K is an ε-independent compact subset of Ω_0, then

$$\max_{x\in K} |u-U_0| = O(\varepsilon) \quad \text{for } \varepsilon \downarrow 0. \tag{1.12}$$

Instead of an estimate $\|w-w_0\|_{H_0^1(\Omega)} = O(\sqrt{\varepsilon})$ and weak convergence in $W^{2,p}(\Omega)$ we obtain here

$$\|w-w_0\|_{C^1(\bar{\Omega})} = O(\sqrt{\varepsilon}) \quad \text{for } \varepsilon \downarrow 0, \tag{1.13}$$

$$\|w-w_0\|_{W^{2,p}(\Omega)} = O(\varepsilon^q) \quad \text{for } \varepsilon \downarrow 0 \text{ with } q = 1/(2p). \tag{1.14}$$

Finally, in the discussion of generalisations in § 7 we consider the effects of domains of dimension > 2, of more general second order elliptic operators and of more general nonlinearities. To conclude this introduction we remark that the work of M. Garbey's thesis lies at the basis of this report (cf. [10]) and that some of the results can be found summarised in [11].

2. The regular expansion in Ω_0 and the layer at $\partial\Omega$. From the point of view of techniques of singular perturbations, this section is very straightforward. We simply need the results in the sequel.

In Ω_0 we construct a local formal approximation of the solution u as

$$u \simeq U^M \underset{\text{def}}{=} \sum_{k=0}^{M} \varepsilon^k U_k(x). \tag{2.1}$$

Substitution in (1.1) provides us with a recursive system of equations:

$$\frac{U_0}{(1+U_0)} = f, \quad \text{i.e. } U_0 = \frac{f}{(1-f)} \tag{2.2}$$

and

$$U_{n+1} = (1+U_0)^2 \cdot \{\Delta U_n + F_{n+1}(U_0, \cdots, U_n)\} \tag{2.3}$$

with

$$F_{n+1} = \left[\frac{\partial^{n+1}}{\partial \varepsilon^{n+1}}\left(1+U_0+\sum_{k=1}^{n} \varepsilon^k U_k\right)^{-1}\right]_{\varepsilon=0}$$

$$= \sum_{m=2}^{n} \frac{(-1)^m}{(1+U_0)^{m+1}} \sum_{\substack{\vec{k}\in\mathbb{N} \\ |\vec{k}|=n}} \prod_{i=1}^{m} U_{k_i}.$$

The system for the U_n's can be solved uniquely and each U_n is in $C^\infty(\bar{\Omega}_0)$ because of (1.2) and (1.7).

In general U_0 and also the other U_n's will not satisfy the Dirichlet boundary condition on $\partial\Omega$. As a consequence we need a layer along $\partial\Omega$ to correct this.

As usual (cf. [1], [12]) we put

$$u \simeq Z_0^M \underset{\text{def}}{=} U^M + G^M H\left(\frac{d(x)-d_0}{d_0}\right) \quad \text{with } G^M = \sum_{k=0}^{2m+1} (\sqrt{\varepsilon})^k G_k(\zeta, \omega). \tag{2.4}$$

Here ζ is the layer variable

$$\zeta = \frac{d(x)}{\sqrt{\varepsilon}} \tag{2.5}$$

where $d(x)$ denotes the distance of a point x to $\partial\Omega$.

For $x \in \Omega$ we denote by $\tilde{x}$ a point on $\partial\Omega$ such that $|x-\tilde{x}| = d(x)$. Note that $\tilde{x}$ is uniquely determined by x for $x \in \hat{D} \rightleftharpoons \{x \in \bar{\Omega} | d(x) \leqq \hat{d}\}$ with a certain $\hat{d} > 0$ depending on the curvature of $\partial\Omega$. For $x \in \hat{D}$ we define $\omega(x)$ as the distance from $\tilde{x}$ along $\partial\Omega$ to a certain reference point 0 on $\partial\Omega$ measured say in clockwise orientation, $0 \leq \omega < L$ with $L = \text{length } (\partial\Omega)$. (See Fig. 2.)

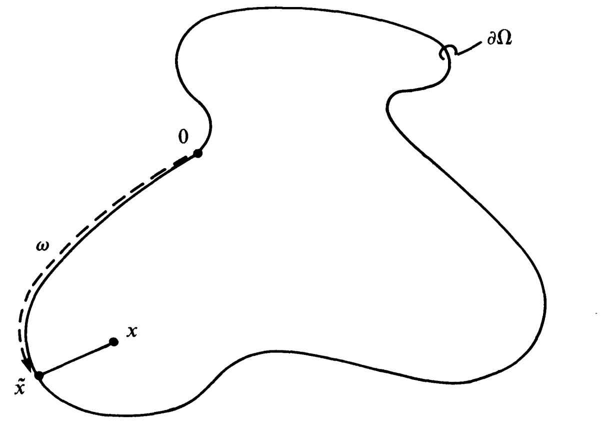

FIG. 2. $x = \tilde{x}(\omega) + d\nu(\omega)$ *with* ν *the inward normal on* $\partial\Omega$, $\langle \nu, \tilde{x}' \rangle = 0$, $\langle \tilde{x}', \tilde{x}' \rangle = \langle \nu, \nu \rangle = 1$.

The function H is introduced in order to avoid singularities in the transformation $x \to (d, \omega)$. H is a C^∞ cut-off function

$$H(s) = \begin{cases} 1 & \text{for } s \leqq \frac{1}{2} \\ 0 & \text{for } s \geqq 1 \end{cases} \quad \text{and } H'(s) \leqq 0. \tag{2.6}$$

The constant d_0 is chosen sufficiently small (say $\frac{1}{3}\hat{d}$), so that $x \to (d, e^{i2\pi\omega/L})$ is a C^∞-diffeomorphism from $\{x \in \bar{\Omega} | d(x) \leqq d_0\}$ onto $[0, d_0] \times T$ with $T = \{z \in \mathbb{C} | |z| = 1\}$.

Substitution in (1.1) leads us to:

$$\frac{\partial^2 G_0}{\partial \zeta^2} = \frac{1}{1+\gamma} - \frac{1}{1+\gamma+G_0} \tag{2.7}$$

with $\gamma(\omega) = U_0|_{\partial\Omega}(\omega) \geqq 0$. Further, we want G_0 to satisfy the following boundary conditions:

$$G_0|_{\zeta=0} = -\gamma, \qquad G_0 \to 0 \quad \text{for } \zeta \to \infty. \tag{2.8}$$

In this way G_0 is uniquely determined. As a function of ζ for a fixed ω it is given by

$$\int_{-\gamma/(1+\gamma)}^{G_0/(1+\gamma)} \frac{dg}{\sqrt{2[g-\ln(1+g)]}} = \frac{\zeta}{1+\gamma} \quad \text{if } \gamma(\omega)>0 \tag{2.9}$$

and

$$G_0 \equiv 0 \quad \text{if } \gamma(\omega)=0. \tag{2.10}$$

If $\gamma(\omega)<0$ then $G_0(\zeta,\omega)$ is strictly increasing on $[0,\infty)$. The behaviour for $\zeta\to\infty$ can be described more explicitly if we note that

$$G_0 = C\exp\left(-\frac{\zeta}{1+\gamma}\right)\cdot\exp\left(-\int_{G_0/(1+\gamma)}^{0} W(g)\,dg\right) \tag{2.11}$$

with $C=\gamma\exp(-\int_{-\gamma/(1+\gamma)}^{0} W(g)\,dg)$.

Using the implicit function theorem we see that G_0 is exponentially decreasing for $\zeta\to\infty$. Moreover, G_0 depends smoothly on ω, ζ and all derivatives $\partial^{k+l}G_0/\partial\zeta^k\partial\omega^l$ vanish exponentially for $\zeta\to\infty$.

For the higher order terms G_n we find problems of the following type:

$$\begin{gathered}\frac{\partial^2 G_{n+1}}{\partial\zeta^2}-\frac{G_{n+1}}{(1+\gamma+G_0)^2}=F_{n+1}(G_0,\cdots,G_n),\\ G_{n+1}|_{\zeta=0}=0 \text{ if } n+1 \text{ odd}, =-U_p|_{\partial\Omega} \text{ if } n+1 \text{ even, with } p=\tfrac{1}{2}(n+1)\end{gathered} \tag{2.12}$$

and

$$F_{n+1}=\frac{1}{(n+1)!}\left[\frac{\partial}{\partial\delta^{n+1}}\bar{F}^{(n)}\right]_{\delta=0},$$

$$\begin{aligned}\bar{F}^{(n)}=1-f(\delta\zeta,\omega)-\delta^2\sum_{k=0}^{M}\delta^{2k}(\Delta U_k)(\delta\zeta,\omega)\\ -\left\{1+\sum_{k=0}^{M}\delta^{2k}U_k(\delta\zeta,\omega)+\sum_{k=0}^{n}\delta^k G_k(\zeta,\omega)\right\}^{-1}\\ -\left\{\delta^2h^{-1}\frac{\partial^2}{\partial\omega^2}+\delta h^{-1}d_1\frac{\partial}{\partial\zeta}+\delta^2h^{-2}d_2\frac{\partial}{\partial\omega}\right\}\sum_{k=n}^{n}\delta^k G_k(\zeta,\omega),\end{aligned}$$

where δ is a shorthand notation for $\sqrt{\varepsilon}$.

Note that by construction of the U_k's

$$1-f-\varepsilon\Delta U^M-(1+U^M)^{-1}=O(\delta^{2M+2})=O(\varepsilon^{M+1}) \tag{2.13}$$

uniformly on $\bar{\Omega}_0$. Using this and induction with respect to n it is not difficult to show that (2.12) has a unique solution, which vanishes exponentially for $\zeta\to\infty$:

$$\begin{aligned}G_{n+1}(\zeta,\omega)=K(\zeta,\omega)\cdot\int_0^\infty K(\zeta_1,\omega)^{-2}\int_{\zeta_1}^\infty K(\zeta_2,\omega)F_{k+1}(\zeta_2)\,d\zeta_2\,d\zeta_1\\ +G_{n+1}(0,\omega)\cdot K(\zeta,\omega).\end{aligned} \tag{2.14}$$

In this expression $K(\zeta,\omega)$ is a suitably chosen solution of the homogeneous equation with $K(0,\omega)=1$:

$$K(\zeta,\omega)=\bar{C}(\omega)\frac{\partial G_0}{\partial\zeta}(\zeta,\omega),$$

$$\bar{C}(\omega)=[2(-\check{\gamma}-\ln(1-\check{\gamma}))]^{1/2} \quad \text{with } \check{\gamma}=\gamma/(1+\gamma).$$

Using (2.11) one can check that K is smoothly dependent on ω, even when $\gamma(\omega)$ has a zero. Moreover, it is not difficult to see that not only G_{n+1} but also derivatives like $\partial^{k+l}G_{n+l}/\partial\zeta^k\partial\omega^l$ vanish exponentially for $\zeta\to\infty$.

To conclude this section we remark that the approximation constructed up to now, i.e., Z_0^M as given in the right-hand side of (2.4), is such that

$$-\varepsilon\Delta Z_0^M+\frac{Z_0^M}{1+Z_0^M}=f-r \tag{2.15}$$

where the error term r is $O(\varepsilon^{M+1})$ uniformly on $\bar\Omega_0$. That is, for $d(x)\geqq\frac{1}{2}d_0$ r is given by the right-hand side of (2.13), apart from some additional exponentially small terms when $\frac{1}{2}d_0\leqq d(x)\leqq d_0$. In the region $0\leqq d(x)\leqq\frac{1}{2}\delta_0$ the error is equal to

$$\bar F^{(2M+2)}-\sum_{n=0}^{2M+1}\frac{\delta^n}{n!}\frac{\partial\bar F^{(2M+2)}}{\partial\delta^n}\bigg|_{\delta=0}.$$

Using (2.12) and the exponential decay of the G_n's we find that this expression is indeed $O(\delta^{2M+2})$.

It is now clear that this formal approximation in the subdomain Ω_0 is of the order $O(\varepsilon^{M+1})$, where M can be taken arbitrarily large. In §§ 3, 4 and 5 we shall work toward such a result in $\Omega\backslash\Omega_0$.

3. The principal terms in the internal layer at S and in the expansion in Ω_+. In this section we commence the study of the transition layer along S and the expansion in Ω_+. The main objective is to determine the set of order functions occurring in various expansions. The difficulties due to singular behaviour of the expansion in Ω_+ do not occur yet. The next term of the expansion of u in Ω_+ turns out to be $\ln\varepsilon\cdot w_1$, where w_1 is the solution of a well-defined Dirichlet problem for the Laplace's equation in Ω_+.

In order to describe the local approximation of the solution in the layer at the free surface S (see Fig. 3) we use the following coordinates. The ρ coordinate is

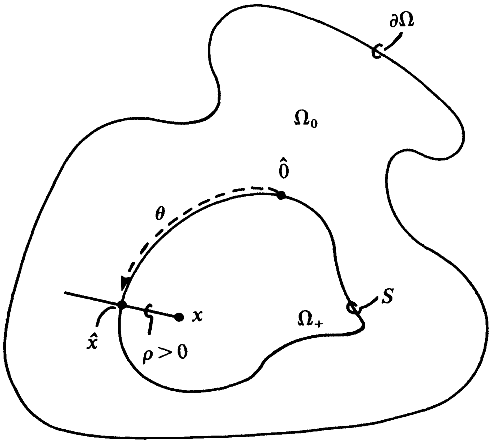

FIG. 3. $x=\hat x(\theta)+\rho n(\theta)$ *with* n *the normal on* S *in the direction of* Ω_+; $\langle n,\hat x'\rangle=0$, $\langle\hat x',\hat x'\rangle=\langle n,n\rangle=1$. *Note that* $\rho>0$ *in* Ω_+, $\rho<0$ *in* Ω_0; *for points sufficiently close to* S $|\rho|=$ *distance to* S, $0\leqq\theta<\theta_0$ *where* $\theta_0=$ *length* (S).

stretched in a significant way:

$$\xi=\rho/\sqrt{\varepsilon}. \tag{3.1}$$

In these coordinates the operator $\varepsilon\Delta$ is given by

$$\varepsilon\Delta=\frac{\partial^2}{\partial\xi^2}+\varepsilon g^{-1}\frac{\partial^2}{\partial\theta^2}+\sqrt{\varepsilon}\cdot g^{-1}e_1\frac{\partial}{\partial\xi}-\varepsilon\cdot g^{-2}\cdot e_2\frac{\partial}{\partial\theta} \tag{3.2}$$

with $g=1+2\sqrt{\varepsilon}\,\xi a+\varepsilon\xi^2 b$, $e_1=\sqrt{\varepsilon}\,\xi b+a$, $e_2=\sqrt{\varepsilon}\,\xi a'+\frac{1}{2}\varepsilon\xi^2 b'$ and $a=\{n',\hat{x}'\rangle$, $b=\langle n',n'\rangle$, where $'$ denotes differentiation with respect to θ. For the local approximation of the solution near S we put

$$u\simeq\psi_0(\xi,\theta)+\delta_1\psi_1(\xi,\theta)+\delta_2\psi_2(\xi,\theta)+\cdots. \tag{3.3}$$

In this expansion the magnitudes of the higher order terms $\delta_1(\varepsilon)$, $\delta_2(\varepsilon)$, etc., are unknown at the start of the construction. They will be determined during the construction process.

If we recall (1.5), it is clear that the local approximation in Ω_+ will be of the following type:

$$u\simeq\varepsilon^{-1}w_0+\bar{\delta}_1\bar{w}_1+\cdots. \tag{3.4}$$

Again the magnitude $\bar{\delta}_1(\varepsilon)$ has to be found during the construction. Let us now first deduce the principal term in the layer.

The equation for ψ_0 is obtained from the $O(1)$ terms in (1.1) by substituting (3.2) for $\varepsilon\Delta$. It is the following O.D.E.:

$$\frac{\partial^2\psi_0}{\partial\xi^2}=1-\hat{f}-\frac{1}{1+\psi_0}. \tag{3.5}$$

The variable θ acts only as a parameter. Here $\hat{f}$ denotes $f|_S$. This function depends only on θ, it is smooth and periodic and $0<\hat{f}<1$ (see (1.2) and (1.7)). In addition to (3.5), matching provides us with "boundary conditions" for $\xi\to-\infty$ and $\xi\to+\infty$. Expanding the regular expansion in Ω_0 in the ξ, θ variables we obtain:

$$\lim_{\xi\to-\infty}\psi_0=\hat{\gamma} \tag{3.6}$$

with $\hat{\gamma}=_{\text{def}}U_0|_S=\hat{f}/(1-\hat{f})$. From (1.5) it follows that $w_0=\frac{1}{2}(1-\hat{f})\rho^2+O(\rho^3)$ for $\rho\downarrow 0$. As a consequence, expansion of (3.4) in ξ, θ coordinate leads us to

$$\psi_0=\tfrac{1}{2}(1-\hat{f})\xi^2+o(\xi^2)\quad\text{for }\xi\to\infty. \tag{3.7}$$

The solutions of (3.5)-(3.7) can easily be found. Namely, (3.6), (3.5) imply that $\partial^2\psi_0/\partial\xi^2$ and also $\partial\psi_0/\partial\xi$ vanish for $\xi\to-\infty$. Multiplication of (3.5) with $\partial\psi_0/\partial\xi$ and integration yields

$$\begin{gathered}\psi_0=\hat{\gamma}+(1+\hat{\gamma})v\left(\frac{\xi}{1+\hat{\gamma}}\right),\\ \int_{v_0}^{v}\frac{dz}{\sqrt{2[z-\ln(1+z)]}}=\eta\quad\text{with }v_0>0.\end{gathered} \tag{3.8}$$

Here the lower endpoint $v_0(\theta)$ plays the role of a free constant, possibly depending on θ. Eventually $v_0(\theta)$ will be determined by a matching argument. The function $v(\eta,\theta)$ is strictly increasing on $(-\infty,\infty)$ from 0 to $+\infty$.

Let us have a closer look at the asymptotic behaviour of ψ_0 for both $\xi \to -\infty$ and $\xi \to +\infty$. Using a procedure as in (2.11) we find that

$$v = c\, e^{\eta}(1+O(e^{\eta})) \quad \text{for } \eta \to -\infty \tag{3.9}$$

with $c = v_0 \exp\left(\int_0^{v_0} W(g)\, dg\right) > 0$. Since

$$\frac{\partial \psi_0}{\partial \xi}(\xi, \theta) = \sqrt{2[v - \ln(1+v)]}\left(\frac{\xi}{1+\hat{\gamma}}\right), \tag{3.10}$$

it is also clear that

$$\frac{\partial \psi_0}{\partial \xi} = c\, e^{\xi/1+\hat{\gamma}}(1+O(e^{\xi/1+\hat{\gamma}})) \quad \text{for } \xi \to -\infty. \tag{3.11}$$

For the analysis of the behaviour for $\xi \to -\infty$ we introduce

$$I(z) = (2z)^{-1/2} \cdot \{(1 - z^{-1} \ln(1+z))^{-1/2} - 1\}. \tag{3.12}$$

Note that $I(z) = O(z^{-3/2} \ln z)$ for $z \to \infty$; hence, $I(z)$ is integrable at ∞.

Since

$$\frac{1}{\sqrt{2[z - \ln(1+z)]}} = \frac{1}{\sqrt{2z}} + I(z), \tag{3.13}$$

the implicit formula for v in (3.8) can be written as

$$v = \frac{1}{2}\left\{\eta + \left(\sqrt{2v_0} - \int_{v_0}^{\infty} I(z)\, dz\right) + \int_{v}^{\infty} I(z)\, dz\right\}^2, \tag{3.14}$$

i.e.,

$$v(\eta, \theta) = \frac{1}{2}\eta^2 \cdot \left\{1 + 2\eta^{-1}\left(\sqrt{2v_0} - \int_{v_0}^{\infty} I(z)\, dz\right) + o(\eta^{-1})\right\} \quad \text{for } \eta \to \infty. \tag{3.15}$$

For ψ_0 this means

$$\psi_0(\xi, \theta) = \frac{1}{2}(1 - \hat{f})\xi^2 + \left\{\sqrt{2v_0} - \int_{v_0}^{\infty} I(z)\, dz\right\}\xi + o(\xi) \quad \text{for } \xi \to \infty. \tag{3.16}$$

Next we observe that the linear term in ξ in ψ_0 gives rise to an $O(\varepsilon^{-1/2})$ term when reexpanded in the ρ, θ variables in Ω_+. Now let us take in (3.4)

$$\bar{\delta}_1 = \varepsilon^{-1/2}. \tag{3.17}$$

Then $\bar{w}_1$ has to satisfy the equation

$$\Delta \bar{w}_1 = 0. \tag{3.18}$$

Matching with the layer at the free surface, which has no $O(\varepsilon^{-1/2})$ term, makes it necessary that

$$\bar{w}_1 = 0 \quad \text{on } S. \tag{3.19}$$

The conclusion is

$$\bar{w}_1 \equiv 0 \quad \text{in } \bar{\Omega}_+. \tag{3.20}$$

Another consequence of the matching is that the linear term in ξ in (3.16) equals $\partial \bar{w}_1 / \partial n|_S$ and hence vanishes, i.e.,

$$\sqrt{2v_0} = \int_{v_0}^{\infty} I(z)\, dz. \tag{3.21}$$

Thus the value of v_0 follows indeed by a matching argument. Somewhat surprisingly $v_0 > 0$ does not depend on θ.

The leading term ψ_0 in the layer is now completely known. It will be important to have a precise description of the asymptotics of ψ_0 for $\xi \to \infty$.

LEMMA 1. *Let us denote*

$$\eta_1 = \frac{\ln \xi}{\xi^2}, \qquad \eta_2 = \frac{1}{\xi^2}. \tag{3.22}$$

Then there exists a $\xi_0 > 0$ such that for ξ sufficiently large, $\xi \geqq \xi_0$

$$\psi_0 = \frac{1}{2}(1-\hat{f})\xi^2 + \frac{2}{1-\hat{f}} \ln \xi + T(\theta, \eta_1, \eta_2) \tag{3.23}$$

where for η_1, η_2 sufficiently small: $|\eta_1| < \nu$, $|\eta_2| < \nu$ and $\theta \in [0, \theta_0)$.

(i) *T is smooth and T is periodic in θ,*

(ii) *T has a convergent power series in η_1 and η_2,*

$$T = \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} T_{kl} \eta_1^k \eta_2^l.$$

Proof of Lemma 1. The function v satisfies the equation

$$\sqrt{2v} = \eta \cdot \left\{ 1 + \eta^{-1} \int_v^{\infty} I(z)\, dz \right\}. \tag{3.24}$$

Now put

$$v = \tfrac{1}{2}\eta^2(1+\hat{v})^2. \tag{3.25}$$

After a change of the integration variable $z = \eta^2 s$ we obtain

$$\hat{v} = \int_{\frac{1}{2}(1+\hat{v})^2}^{\infty} (2s)^{-1/2}\{[1 - s^{-1}(2\hat{\eta}_1 + \hat{\eta}_2 \ln s + \hat{\eta}_2 \ln(1+\hat{\eta}_2 s^{-1}))]^{-1/2} - 1\}\, ds \tag{3.26}$$

with

$$\hat{\eta}_1 = \frac{\ln \eta}{\eta^2}, \qquad \hat{\eta}_2 = \frac{1}{\eta^2}.$$

For a moment we consider $\hat{\eta}_1$ and $\hat{\eta}_2$ as independent variables. An application of the implicit function theorem (cf. [13]) shows that for $\hat{\eta}_1$, $\hat{\eta}_2$ sufficiently small $\hat{v}$ is analytic in $\hat{\eta}_1$ and $\hat{\eta}_2$ with

$$\hat{v}(0,0) = 0, \qquad \frac{\partial \hat{v}}{\partial \hat{\eta}_1}(0,0) = 2. \tag{3.27}$$

Using (3.8), (3.25) and expressing $\hat{\eta}_1$, $\hat{\eta}_2$ in terms of η_1, η_2 and $\hat{\gamma}$, we find a transcription of this result for ψ_0:

$$\psi_0 = \hat{\gamma} + \tfrac{1}{2}(1+\hat{\gamma})^{-1}\xi^2[1 + \hat{v}((1+\hat{\gamma})^2(\eta_1 - \eta_2 \ln(1+\hat{\gamma})), (1+\hat{\gamma})^2\eta_2)]^2. \tag{3.28}$$

Herewith the growing terms for $\xi \to \infty$ in (3.23) are easily checked. Further, we deduce from (3.28) that

$$\psi_0 = \xi^2 S(\theta, \eta_1, \eta_2) \tag{3.29}$$

where S has the properties (i) and (ii) as indicated in the lemma. However, (3.29) still differs from (3.23), but a little trick is helpful.

Substitution of (3.28) in the O.D.E. (3.5) yields

$$\frac{\partial^2\psi_0}{\partial\xi^2}=1-\hat{f}-\frac{2(1+\hat{\gamma})}{\xi^2}+\frac{1}{\xi^2}\hat{S}(\theta,\eta_1,\eta_2) \tag{3.30}$$

where $\hat{S}$ has the properties (i) and (ii) and $\hat{S}(\theta,0,0)=0$. Integrating twice in (3.30), meanwhile using the fact that ψ_0 does not contain a linear term for $\xi\to\infty$, we find (3.23). □

As a consequence of the behaviour of ψ_0 for $\xi\to\infty$ we need in the expansion in Ω_+ a term of magnitude ln (ε), i.e.,

$$u=\varepsilon^{-1}w_0+\ln\varepsilon\cdot w_1+\cdots \tag{3.31}$$

where w_1 is the solution of

$$\Delta w_1=0, \tag{3.32}$$

$$w_1=2(1-\hat{f})^{-1}\quad\text{on } S. \tag{3.33}$$

But this reflects back on the layer at S. It is easy to see that matching requires that the next order term in the layer expansion correspond to

$$\delta_1=\sqrt{\varepsilon}\cdot\ln\varepsilon, \tag{3.34}$$

where ψ_1 is a solution of the homogeneous, linearized layer equation

$$\frac{\partial^2\psi_1}{\partial\xi^2}-\frac{1}{(1+\psi_0)^2}\psi_1=0, \tag{3.35}$$

which vanishes for $\xi\to-\infty$, i.e., ψ_1 is proportional to the derivative of ψ_0

$$\psi_1=K(\theta)\frac{\partial\psi_0}{\partial\xi}. \tag{3.36}$$

Now an obvious question is how the other order functions in the asymptotic sequence in the layer are generated. "Minimal" requirements for this sequence of order functions $\mathcal{S}=\{\delta_n\mid n\in\mathbb{N}\cup\{0\}\}$ are

1° $1,\sqrt{\varepsilon}\ln\varepsilon$ and $(\sqrt{\varepsilon})^k$, $k\in\mathbb{N}$ are in $\mathcal{S}$. The first magnitudes are those corresponding to ψ_0,ψ_1; the others are generated by the Taylor series of f in the ξ, θ coordinates.

2° Stability under multiplication: $\delta_n,\delta_m\in\mathcal{S}\Rightarrow\delta_n\cdot\delta_m\in\mathcal{S}$, especially $\delta_n\in\mathcal{S}\Rightarrow\delta_n\sqrt{\varepsilon}\in\mathcal{S}$. The reason is the structure of $\varepsilon\Delta$ in (3.2) and the fact that such products appear automatically in the Taylor series of the nonlinearity $u/(1+u)$.

These conditions 1° and 2° naturally lead us to (at least)

$$\mathcal{S}=\{\delta_1^k\delta_2^l\mid k\in\mathbb{N}\cup\{0\}\text{ and }l\in\mathbb{N}\cup\{0\}\} \tag{3.37}$$

with

$$\delta_1=\sqrt{\varepsilon}\ln\varepsilon,\qquad \delta_2=\sqrt{\varepsilon}.$$

In the sequel we shall demonstrate that this sequence $\mathcal{S}$ is indeed sufficient.

On the other hand, if the layer term $\delta_1^k\delta_2^l\psi_{k,l}(\xi,\theta)$ contains a constant term $\sim\delta_1^k\delta_2^l$ for $\xi\to\infty$, we expect that all these order functions $\delta_1^k\delta_2^l$ will also be present in the expansion in the region Ω_+. In combination with (3.31) this leads us to the following sequence $\mathcal{S}_+$ of order functions needed in Ω_+:

$$\mathcal{S}_+=\{\varepsilon^{-1},\ln\varepsilon\}\cup\mathcal{S}. \tag{3.38}$$

This sequence contains all the order functions generated by $\psi_0+\delta_1\psi_1$ in (ρ, θ) coordinates. It is also closed under Taylor series expansion of the nonlinearity. Below we shall show that the sequence $\mathcal{S}_+$ is sufficient to construct the expansion in Ω_+. One could have the impression that $\mathscr{S}_+$ contains superfluous order functions. It cannot be denied that $\mathscr{S}_+$ contains a few redundant order functions, for example, δ_1. However, the redundancy in $\mathscr{S}_+$ is not large, as we shall see.

4. Higher order terms near S and in Ω_+. In this section we confront the problem of the singular behaviour of the expansion in Ω_+. Our analysis is an interplay of formal construction and matching arguments. We aim to show that singularities of the expansion in Ω_+ near S are counterbalanced by corresponding terms of the layer expansion. The computational complexity comes mainly from the fact that we consider expansions to arbitrary order of accuracy. We have to do so in order to show that the construction does not break up at some stage. Let us denote the expansion in the free surface layer by

$$u \simeq \psi^N \underset{\text{def}}{=} \sum_{k=0}^{k+l\leqq N} \sum_{l=0} \delta_1^k \delta_2^l \psi_{k,l}(\xi, \theta), \tag{4.1}$$

with $\delta_1 = \sqrt{\varepsilon} \cdot \ln \varepsilon$, $\delta_2 = \sqrt{\varepsilon}$ and $\xi = \rho/\sqrt{\varepsilon}$, as before. The notation for the expansion in Ω_+ will be

$$u \cong \Phi^N \underset{\text{def}}{=} \varepsilon^{-1} w_0(x) + \ln \varepsilon \cdot w_1(x) + \sum_{k=0}^{k+l\leqq N} \sum_{l=0} \delta_1^k \delta_2^l \phi_{k,l}(x). \tag{4.2}$$

In this section we present an iterative scheme by which the $\psi_{k,l}$'s and $\phi_{k,l}$'s can be determined in a unique way. To start, we discuss in § 4.1 the construction of the $\psi_{k,l}$'s while in each $\psi_{k,l}$ an additive term $A_{kl}(\partial\psi_0/\partial\xi)$, a solution of the homogeneous equation, is still free. Furthermore, we analyze some of the properties of the $\psi_{k,l}$'s and we show that some of the A_{kl} have to be zero due to a simple matching argument.

In § 4.2 the $\phi_{k,l}$'s are constructed, while in each $\phi_{k,l}$ a linear degree of freedom, corresponding to a choice of a boundary value function $g_{k,l}$ on S, is built in. The $\phi_{k,l}$'s will contain a singular part for $\rho \downarrow 0$. The freedom of $g_{k,l}$ will arise in the boundary values on S of the regular part of $\phi_{k,l}$.

Next, in § 4.3 we describe the scheme by which all free functions $A_{k,l}$ and $g_{k,l}$ can be uniquely determined. As a matter of fact this scheme will be based on a partial matching relation. The full matching will be considered in the next section.

4.1. The $\psi_{k,l}$'s with free $A_{k,l}$'s. Let us first consider the layer along S. Collecting the $O(\sigma_1^k \delta_2^l)$ terms in (1.1) with $\varepsilon\Delta$ as in (3.2) we find the following inhomogeneous, linear O.D.E. for $\psi_{k,l}$, $k+l>0$:

$$\frac{\partial^2 \psi_{k,l}}{\partial \xi^2} - \frac{1}{(1+\psi_0)^2} \psi_{k,l} = \hat{f}_{k,l} \tag{4.1.1}$$

with

$$\hat{f}_{k,l} = (k!\,l!)^{-1} \left[\frac{\partial^{k+l}}{\partial \delta_1^k \partial \delta_2^l} f_{k,l} \right]_{\delta_1=0,\delta_2=0},$$

where

$$f_{k,l} = -f(\delta_2 \xi, \theta) - \delta_2 B \overset{v}{\sum} \delta_1^r \delta_2^s \psi_{r,s} - \left(1 + \overset{v}{\sum} \delta_1^r \delta_2^s \psi_{r,s}\right)^{-1},$$

$$\delta_2 B \underset{\text{def}}{=} \delta_2^2 g^{-1} \cdot \frac{\partial^2}{\partial \theta^2} + \delta_2 \cdot g^{-1} e_1 \frac{\partial}{\partial \xi} - \delta_2^2 g^{-2} e_2 \frac{\partial}{\partial \theta}; \qquad \text{see (3.2).}$$

$\overset{v}{\sum}$ denotes summation over all indices r, s with

$0 \leqq r \leqq k$, $\quad 0 \leqq s \leqq l$, $\quad r+s<k+l$.

In addition, matching with the expansion in Ω_0 provides the following conditions for $\xi \to -\infty$:

$$\begin{aligned} &\psi_{0,l} \text{ is bounded by a polynomial for } \xi \to -\infty, \\ &\psi_{k,l} \to 0 \text{ for } \xi \to -\infty \text{ for } k > 0. \end{aligned} \tag{4.1.2}$$

If $\hat{f}_{k,l}$ is polynomially bounded for $\xi \to -\infty$, then the solutions of (4.1.1) that do not grow exponentially for $\xi \to -\infty$ are given by:

$$\begin{aligned} \psi_{k,l}(\xi, \theta) = \frac{\partial \psi_0}{\partial \xi}(\xi, \theta) \cdot \int_{\xi_0}^{\xi} \left[\frac{\partial \psi_0}{\partial \xi}(\eta, \theta)\right]^{-2} \int_{-\infty}^{\eta} \frac{\partial \psi_0}{\partial \xi}(\zeta, \theta) \hat{f}_{k,l}(\zeta, \theta)\, d\zeta\, d\eta \\ + A_{k,l}(\theta) \cdot \frac{\partial \psi_0}{\partial \xi}(\xi, \theta). \end{aligned} \tag{4.1.3}$$

Here we shall take ξ_0 to be a fixed, sufficiently large number. The function $A_{k,l}(\theta)$ is not determined by (4.1.2) because of the exponential decay of $\partial \psi_0 / \partial \xi$ for $\xi \to -\infty$. This simply means that at the moment (4.1.3) contains an amount of freedom.

Note that, except for this freedom, (4.1.3) allows us to calculate the $\psi_{k,l}$'s recursively. This can be done in several ways, for example:

a. calculate the $\psi_{k,l}$'s with $k + l = 1$, next those with $k + l = 2$, etc., or

b. calculate all $\psi_{0,k}$ by increasing k, next all $\psi_{l,k}$ with $l = 1$, etc.

Though the $\psi_{k,l}$'s are not uniquely determined we can already derive some of their properties. When the $A_{k,l}$'s are chosen as smooth periodic functions in θ, then all $\psi_{k,l}$'s are smooth functions of ξ and θ in $\mathbb{R} \times [0, \theta_0)$, periodic in θ. As for the behaviour of $\psi_{k,l}$ for $\xi \to -\infty$ we can derive the following results:

LEMMA 2.

$$\psi_{0,l} = P_l + \textit{exponentially small terms for } \xi \to -\infty. \tag{4.1.4}$$

Here P_l is a polynomial in ξ of degree $\leqq l$ with coefficients depending smoothly and periodically on θ. Moreover P_l has the same parity as l.

Further, for $k > 0$ there is an $m \in \mathbb{N}$ such that

$$\psi_{k,l} = O\left(\xi^m \exp\left(\frac{\xi}{1+\hat{\gamma}}\right)\right) \quad \textit{for } \xi \to -\infty. \tag{4.1.5}$$

Moreover, the derivatives $\partial^{r+s}\psi_{k,l}/\partial\xi^r \partial\theta^s$ behave in an analogous way.

The derivation of (4.1.4) and (4.1.5) is an interesting, rather easy exercise in induction using recursion as in b and using (3.10)-(3.11); further details are left to the reader.

Note that the conditions in (4.1.2) are indeed fulfilled, regardless of the choice of the $A_{k,l}$'s.

Let us now consider the asymptotic behaviour of $\psi_{k,l}$ for $\xi \to \infty$. It will be convenient to introduce the following concept:

A function χ of $(\xi, \theta) \in \mathbb{R} \times [0, \theta_0)$ is said to be of <u>type p</u> with $p \in \mathbb{Z} \leftrightarrow$

(i) *χ is smooth in ξ and θ and periodic in θ,*

(ii) *for ξ sufficiently large, $\xi \geqq \xi_0$, χ can be represented in the following way:*

$$\chi = \xi^p[X(\eta_1, \theta) + \eta_2 Y(\eta_1, \eta_2, \theta)] \tag{4.1.6}$$

with

$$\eta_1 = \frac{\ln \xi}{\xi^2}, \qquad \eta_2 = \frac{1}{\xi^2}$$

and

- X is polynomial of degree $\leqq \frac{1}{2}p$ in η_1 with coefficients depending smoothly and periodically on θ. For $p<0$ this means that $X \equiv 0$.

- Y and all its derivatives with respect to θ are analytic in η_1, η_2 for $|\eta_1|<\nu$, $|\eta_2|<\nu$ with coefficients of the power series in η_1, η_2 depending smoothly and periodically on θ.

In this definition ξ_0 and ν are positive numbers which are fixed in accordance with their values in Lemma 1. It is not difficult to verify the following extension of Lemma 1:

(4.1.7) $$\psi_0 \text{ is of type } 2, \qquad \frac{\partial\psi_0}{\partial\xi} \text{ is of type } 1.$$

This demonstrates already the relevance of the type p concept. Further, the other solution of the homogeneous version of (4.1.1) is

(4.1.8) $$\Phi \underset{\text{def}}{=} \frac{\partial\psi_0}{\partial\xi} \int_\xi^\infty \left[\frac{\partial\psi_0}{\partial\xi}(\eta,\theta)\right]^{-2} d\eta.$$

Now a little calculation shows that

(4.1.9) $$\xi^2 \left[\frac{\partial\psi_0}{\partial\xi}\right]^{-2} \text{ is of type } 0$$

and

(4.1.10) $$\Phi \text{ is of type } 0.$$

The type p concept is nicely compatible with algebraic and analytic operations and notions. We mention a few useful rules, which can be checked in an elementary way.

(4.1.11) χ of type $p \Rightarrow \xi^r\chi$ is of type $p+r$ for $r \in \mathbb{N}\cup\{0\}$, $\partial\chi/\partial\theta$ is of type p, $\partial\chi/\partial\xi$ is type $p-1$, $\partial^{r+s}\chi/\partial\xi^r\partial\theta^s$ is of type $p-r$.

(4.1.12) χ_1 of type p_1 and χ_2 of type $p_2 \Rightarrow \chi_1\chi_2$ is of type p_1+p_2, χ_1 of type p_1 and χ_2 of type p_2 with $p_2 \leqq p_1$, p_1-p_2 even $\Rightarrow \chi_1+\chi_2$ is of type p_1.

(4.1.13) A polynomial in ξ of degree p of the same parity as p with smooth, periodic θ-dependent coefficients is of type p.

For a function χ of type p there exists a uniquely defined primitive $I(\chi)$ with respect to ξ-integration such that

(4.1.14) $I(\chi)$ is a function of type $p+1$ without a constant term in its expansion for $\xi \to \infty$.

Note that

(4.1.15) $$I(\chi) = \int_{\xi_0}^{\xi} \chi(\eta,\theta)\, d\eta + I_0(\chi)(\theta)$$

with a smooth, periodic function I_0, which in general is $\neq 0$.

Next we shall describe the behaviour of the $\psi_{k,l}$'s for $\xi \to \infty$ and at the same time fix some of the $A_{k,l}$'s. From now on we shall use the shorthand notation

(4.1.16) $$\chi = \text{type}(p_1) + \text{type}(p_2)$$

for $\chi = \chi_1 + \chi_2$ with χ_1 of type p_1 and χ_2 of type p_2.

LEMMA 3.

a. $k=0$:

$$\begin{aligned} &\psi_{0,0}=\text{type}\,(2), \\ &\psi_{0,l}=\text{type}\,(l+2)+\text{type}\,(l-1) \quad \textit{for } l\geqq 1. \end{aligned} \tag{4.1.17}$$

b. $k=1$:

$$\begin{aligned} &\psi_{1,0}=\text{type}\,(1), \\ &A_{1,1}\equiv 0 \quad \textit{and} \quad \psi_{1,1}=\text{type}\,(2)+\text{type}\,(-1), \\ &\psi_{1,l}=\text{type}\,(l+1)+\text{type}\,(l-2) \quad \textit{for } l\geqq 2. \end{aligned} \tag{4.1.18}$$

c. $k\geqq 2$:

$$\begin{aligned} &A_{k,0}=0, \\ &\psi_{k,l}=\text{type}\,(l)+\text{type}\,(l-1) \quad \textit{for } l\geqq 0. \end{aligned} \tag{4.1.19}$$

In order to prove this lemma it is clear that we need information about the solutions of

$$\frac{\partial^2\psi}{\partial\xi^2}-\frac{1}{(1+\psi_0)^2}\psi=F \tag{4.1.20}$$

where F is a function of type p, while on top of that, F and all its derivatives are polynomially bounded for $\xi\to-\infty$.

LEMMA 4. *Under these conditions* (4.1.20) *has a particular solution* ψ_{part}, *such that* ψ_{part} *and all its derivatives are polynomially bounded for* $\xi\to-\infty$ *and*

$$\psi_{\text{part}}=\text{type}\,(p+2)+\alpha_0\Phi \tag{4.1.21}$$

with Φ *as in* (4.1.8)-(4.1.10) *of* type 0 *and*

$$\alpha_0=\int_{-\infty}^{\xi_0}\frac{\partial\psi_0}{\partial\xi}(\eta,\theta)F(\eta,\theta)\,d\eta,$$

i.e., α_0 *is uniquely determined by* F *and in general* $\alpha_0\neq 0$. *All other nonexponentially growing solutions are of the form*

$$\psi=\psi_{\text{part}}+A(\theta)\frac{\partial\psi_0}{\partial\xi}.$$

Proof of Lemma 4. The particular solution can be given explicitly as

$$\begin{aligned} \psi_{\text{part}}&=\frac{\partial\psi_0}{\partial\xi}I\left[\left(\frac{\partial\psi_0}{\partial\xi}\right)^{-2}\int_{-\infty}^{\xi}\frac{\partial\psi_0}{\partial\xi}F\,d\zeta\right] \\ &=\frac{\partial\psi_0}{\partial\xi}I\left[\left(\frac{\partial\psi_0}{\partial\xi}\right)^{-2}I\left(\frac{\partial\psi_0}{\partial\xi}F\right)\right]+\alpha_0\Phi. \end{aligned} \tag{4.1.22}$$

It is easy to check that ψ_{part} is smooth and periodic in θ and that ψ_{part} and its derivatives are polynomially bounded for $\xi\to-\infty$. Now it remains to show that ψ_{part} has the correct structure for $\xi\geqq\xi_0$. This requires more accuracy than simply applying the rules given in (4.1.7)-(4.1.14). It is done by the following steps, the details of which are left to the reader:

$$\frac{\partial\psi_0}{\partial\xi}F=\xi\cdot\text{type}\,(p),\qquad \xi\geqq\xi_0,$$

$$I\left(\frac{\partial\psi_0}{\partial\xi}F\right)=\xi^2\,\text{type}\,(p)+C_1\xi^{p+2}\eta_1^{q+1},\qquad \xi\geqq\xi_0.$$

The smooth periodic function C_1 can only be nonzero if $p \geqq 0$ and p even. Then we denote $q = \frac{1}{2}p$.

The same remark holds for C_2, etc., here and below.

$$\left(\frac{\partial\psi_0}{\partial\xi}\right)^{-2} I\left(\frac{\partial\psi_0}{\partial\xi}F\right) = \text{type}\,(p) + C_2\xi^p\eta_1^{q+1}, \qquad \xi \geqq \xi_0,$$

$$I\left[\left(\frac{\partial\psi_0}{\partial\xi}\right)^{-2} I\left(\frac{\partial\psi_0}{\partial\xi}F\right)\right] = \text{type}\,(p+1) + C_3\xi^{p+1}\eta_1^{q+1}, \qquad \xi \geqq \xi_0,$$

$$\frac{\partial\psi_0}{\partial\xi} I\left[\left(\frac{\partial\psi_0}{\partial\xi}\right)^{-2} I\left(\frac{\partial\psi_0}{\partial\xi}F\right)\right] = \text{type}\,(p+2) + C_4\xi^{p+2}\eta_1^{q+1}, \qquad \xi \geqq \xi_0.$$

Since the $\xi^{p+2}\eta_1^{q+1}$ term can be absorbed in type $(p+2)$ our demonstration of (4.1.21) is complete. □

In addition to Lemma 4 we remark that in certain cases the constant α_0 can be calculated explicitly. For example, when $F = \psi_0^{-(1/2)p}$, then F is of type $-(p-2)$ for $p \geqq 3$ and F is bounded. Here we find $\alpha_0 = (1-\frac{1}{2}p)^{-1}\psi_0(-\infty)^{-(1/2)p+1} \neq 0$. In general, the condition $\alpha_0 = 0$ is equivalent to $\int_{-\infty}^{\infty}(\partial\psi_0/\partial\xi)F\,d\xi = 0$, when F is polynomially bounded for $\xi \to -\infty$ and F is of type $p < 0$.

Let us now give the proof of Lemma 3.

Proof of Lemma 3. The inhomogeneous term in (4.1.1) for $\psi_{k,l}$ is of the following form:

$$\hat{f}_{k,l} = \text{(i)} + \text{(ii)} + \text{(iii)} \tag{4.1.23}$$

with

$$\text{(i)} = -\frac{1}{l!} \cdot \frac{\partial^l f}{\partial\xi^l}(0, \theta) \cdot \xi^l \cdot \delta_{k,0},$$

$$\text{(ii)} = \sum_{\substack{0<r+s\leqq 2\\ 1\leqq j\leqq l\\ j\geqq 2-r}} b_j^{r,s} \cdot \xi^{j-2+r}\frac{\partial^{r+s}\psi_{k,l-j}}{\partial\xi^r\partial\theta^s},$$

$$\text{(iii)} = \sum_{2\leqq m\leqq k+l} \frac{1}{(1+\psi_0)^{m+1}} \sum_{\substack{\vec{k},\vec{l}\in(\mathbb{N}\cup\{0\})^m\\ |k|=k,|\vec{l}|=l}} C^m_{\vec{k},\vec{l}} \prod_{j=1}^m \psi_{k_j,l_j}$$

with

$\delta_{k,0} = 1$ if $k = 0$ and $\delta_{k,0} = 0$ otherwise, coefficients $b_j^{r,s}$ smooth and periodic in θ (following easily from $\delta_2 B$, for example $b_j^{2,0} = 0$, $b_2^{0,2} = 1$, etc.) and certain constants $C^m_{\vec{k},\vec{l}}$.

After these preparations the proof lies mainly in an induction argument.

a. *The case* $k = 0$. The statement holds for $l = 0$. Suppose that (4.1.17) has been verified for $0 \leqq l \leqq l_0$. Then, because of Lemma 2 and (4.1.23), $\hat{f}_{0,l_0+1}$ is smooth and $\hat{f}_{0,l_0+1}$ and all its derivatives are polynomially bounded for $\xi \to -\infty$. Moreover,

$$\hat{f}_{0,l_0+1} = \text{type}\,(l_0+1) + \text{type}\,(l_0-2). \tag{4.1.24}$$

For the first two parts of $\hat{f}_{0,l_0+1}$ (i) and (ii) the verification is straightforward. As for (iii), we note that

$$\prod_{j=1}^m \psi_{0,l_j} = \text{type}\,(|\vec{l}|+2m) + \text{type}\,(|\vec{l}|+2m-3),$$

while

$$(1+\psi_0)^{-m-1}=\text{type}\,(-2m)$$

takes care of the correct compensation. Now (4.1.17) with $l=l_0+1$ follows almost immediately when we apply Lemma 4.

b. *The case* $k=1$. For $\psi_{1,0}$ we refer to (3.36). Note that neither $\psi_{1,0}$ nor $\psi_{0,1}$ has a constant term for $\xi\to\infty$. By matching this implies that the corresponding term, $\phi_{1,0}$ in Ω_+ has to vanish on S. We obtain

$$\Delta\phi_{1,0}=0, \qquad \phi_{1,0}=0 \text{ on } S \tag{4.1.25}$$

and the conclusion is that $\phi_{1,0}\equiv 0$. In turn this implies by matching, combined with our knowledge of $\psi_{0,2}$, that $\psi_{1,1}$ cannot have a linear term in its expansion for $\xi\to\infty$. Next an easy calculation shows that

$$\hat{f}_{1,1}=\text{type}\,(0)+\text{type}\,(-3).$$

Consequently, an application of Lemma 4 leads us to (4.1.18) with $l=1$. For higher l's in (4.1.18) we proceed with induction w.r.t. l in a completely analogous fashion.

c. *The case* $k\geqq 2$.

c1. $k\geqq 2$ *and* $l=0$. We observe that $\hat{f}_{k,0}$ consists only of terms coming from (iii). Suppose that (4.1.19) holds for $k\leqq k_0$. Then we find

$$\hat{f}_{k_0+1,0}=\text{type}\,(-2)+\text{type}\,(-3).$$

Using our knowledge of $\psi_{k_0,0}$ and using the fact that there is no order $\delta_1^{k_0+1}\delta_2^{-1}$ term in the expansion in Ω_+, we find that $\psi_{k_0+1,0}$ cannot have a linear term for $\xi\to\infty$, i.e., $A_{k_0+1,0}=0$. Therefore, an application of Lemma 4 provides us with (4.1.19) for $l=0$.

c2. $k\geqq 2$ *and* $l\geqq 1$. This case is again dealt with by induction w.r.t. l with k fixed and thus the proof is complete. □

An important remark is that the contents of Lemma 3 are fully consistent with our assumption (4.2) on the structure of the expansion in Ω_+, i.e., that re-expansion in ρ, θ coordinates of $\delta_1^k\delta_2^l\psi_{k,l}$ with

$$\xi=\rho\delta_2^{-1}, \quad \eta_2=\delta_2^2\rho^{-2}, \quad \eta_1=\delta_2^2\rho^{-2}\ln\rho-\tfrac{1}{2}\delta_1\delta_2\rho^{-2} \tag{4.1.26}$$

gives rise only to order functions as in (3.38)

$$\delta_2^{-2}, \quad \delta_1\delta_2^{-1}, \quad \delta_1^k\delta_2^l, \quad k\geqq 0, \quad l\geqq 0. \tag{4.1.27}$$

However, in view of the matching with the expansion in Ω_+ it will be useful to have somewhat more precise information on the behaviour of the functions, $\psi_{k,l}$ for large values of ζ. Let us introduce the notation

(4.1.28) $E_{k,l}^{\rho,\theta}=_{\text{def}}$ the operator that gives the coefficient corresponding to the $\delta_1^k\delta_2^l$ term in an expansion written in (ρ,θ) coordinates.

The following result will be very useful later on:

LEMMA 5. *Let* k, l *be given as in* (4.1.27), *i.e.* $(k,l)\in\{(0,-2),(1,-1)\}\cup(\mathbb{N}\cup\{0\})^2$. *Set* $N'=k+l$ *and suppose* $K\geqq N'$. *Then*

$$E_{k,l}^{\rho,\theta}\Bigg(\sum_{r+s\leqq K}\delta_1^r\delta_2^s\psi_{r,s}\Bigg)=\Lambda_{k,l}^{\text{sing}}+\Lambda_{k,l}^{\text{const}}+\Lambda_{k,l}^{0,K}. \tag{4.1.29}$$

Here these parts denote the singular, the constant and the vanishing terms for $\rho\downarrow 0$, *respectively. The form of these respective parts is as follows*:

$$\Lambda_{k,l}^{\text{sing}}=\sum_{\substack{0\leqq i\leqq 1+l/2\\ 0\leqq j\leqq l\\ i+j>0}} C_{i,-j}^{k,l}(\theta)\cdot(\ln\rho)^i\rho^{-j}. \tag{4.1.30}$$

Contributions to the $(\ln\rho)^i\rho^{-j}$ *term in* $\Lambda_{k,l}^{\text{sing}}$ *can only come from values* r, s *for which* $r+s=N'-j$ *and* $0\leqq r\leqq k$.

(4.1.31) $$\Lambda_{k,l}^{\text{const}}=C_{0,0}^{k,l}(\theta).$$

Contributions to this term can only come from values r, s *with*

$$r+s=N',\, l\leqq s\leqq 2l+2, \qquad 0\leqq r\leqq k.$$

Finally

(4.1.32) $$\Lambda_{k,l}^{0,K}=\sum_{\substack{0\leqq i\leqq 1+l/2\\ 1\leqq j\leqq K-N'}} C_{i,j}^{k,l}(\theta)(\ln\rho)^i\rho^j.$$

Contributions to the $(\ln\rho)^i\rho^j$ *term in* $\Lambda_{k,l}^{0,K}$ *can only come from values* r, s *with* $r+s=N'+j$, $0\leqq r\leqq k$. *All coefficients* $C_{i,j}^{k,l}$ *are smooth and periodic in* θ.

Proof of Lemma 5. Actually, all we have to do is a little bit of "combinatorics." First, a singular term can only be produced by a term $\sim\delta_1^r\delta_2^s((\ln\xi)^m/\xi^j)$ for $\xi\to\infty$, which after re-expansion gives rise to terms $\sim\delta_1^{r+n}\delta_2^{s+j-n}((\ln\rho)^{m-n}/\rho^j)$ with $0\leqq n\leqq m$. Such a term contributes to $\Lambda_{k,l}^{\text{sing}}$ precisely if $r+n=k$, $s+j-n=l$ and $i=m-n$. Because of the structure of $\psi_{r,s}$ given in Lemma 3 we also know that $j\geqq 2m-s-2$, where equality only holds if $r=0$ and $j=0$, $m>0$. This implies $2l+2=2s+2i+2j+2-2m\geqq 2i+j+s\geqq 2i+j$ and $2i=2m-2n\leqq j+s+2-2n=l+2-n\leqq 1+2$. Thus (4.1.30) is found. A constant contribution can only come from a term for $\xi\to\infty$ proportional to $\delta_1^r\delta_2^s(\ln\xi)^q$, where because of Lemma 3, $q\leqq\frac{1}{2}(s+2)$. After re-expansion this leads to a constant term $\sim\delta_1^{r+1}\delta_2^{s-q}$, which contributes to $\Lambda_{k,l}^{\text{const}}$ if $k=r+q$, $l=s-q$. Hence the contributions to $\Lambda_{k,l}^{\text{const}}$ in (4.1.31) indeed come from pairs (r, s) with $r+s=k+l$, $s\geqq l$, $2l\geqq 2s-(s+2)=s-2$, $0\leqq r\leqq k$. The verification of (4.1.32) is left to the reader as an exercise. □

As we shall see in § 4.3, the following facts will play an important role in the actual constructions: (i) once all $\psi_{r,s}$ with $r+s\leqq k+l$ are known, the constant term $\Lambda_{k,l}^{\text{const}}$ is known; (ii) the linear term in $\Lambda_{k,l}^{0,K}$ comes precisely from those $\psi_{r,s}$ for which $0\leqq r\leqq k$, $r+s=k+l+1$. In anticipation of the full matching later on in § 5, we shall now derive a concrete estimate for the asymptotic behaviour of the $\psi_{k,l}$'s for large ξ.

(4.1.33) $$\Psi^N \underset{\text{def}}{=} \sum_{k+l\leqq N}\delta_1^k\delta_2^l\psi_{k,l},$$

as in (4.1),

(4.1.34) $$\Lambda_{k,l}^K \underset{\text{def}}{=} \Lambda_{k,l}^{\text{sing}}+\Lambda_{k,l}^{\text{const}}+\Lambda_{k,l}^{0,K},\ K\geqq N, \qquad \Lambda^{N,K} \underset{\text{def}}{=} \sum_{\substack{(k,l)=(0,-2)\text{ or}\\ (1,-1)\text{ or}\\ k\geqq 0, l\geqq 0, k+l\leqq N}} \Lambda_{k,l}^K.$$

It is important to have an estimate for the difference between Λ^N and $\Lambda_1^{N,K}$.

LEMMA 6. *There are constants* $C>0$ *such that for* $\xi\geqq\xi_0$

$$\text{(a)}\ \ |\Psi^N(\xi,\theta)-\Lambda^{N,N}(\delta_2\xi,\theta)|\leqq C\left(\delta_1+\delta_2\sqrt{\ln\xi}+\frac{\sqrt{\ln\xi}}{\xi}\right)^{N+1},$$

(4.1.35) $$\text{(b)}\ \ |\Lambda^{N,K}(\delta_2\xi,\theta)-\Lambda^{N,N}(\delta_2\xi,\theta)|\leqq C\xi^2((\delta_1+\delta_2)^{N+1}+(\delta_2\xi)^{K+1}), \qquad K>N,$$

$$\text{(c)}\ \ |\Lambda^{N_1,K}(\delta_2\xi,\theta)-\Lambda^{N,K}(\delta_2\xi,\theta)|\leqq C\ln(\rho)\cdot\left(\delta_1+\frac{\sqrt{\ln\xi}}{\xi}\right)^{N+1}(1+\delta_2\xi)^K,$$

$$k\geqq N_1>N.$$

For the derivatives of these functions r *times w.r.t.* ξ *and* s *times w.r.t.* θ, $r+s\leqq 2$ *analogous estimates hold, but with an extra factor* ξ^{-r} *in the right-hand side.*

Proof of Lemma 6. Here we shall take advantage of the fact that, because of Lemma 3, we can represent $\Psi^N - \Lambda^{N,N}$ by a convergent power series for $\xi \geqq \xi_0$

$$\psi^N - \Lambda^{N,N} = \sum_{k+l\leqq N} \delta_1^k \delta_2^l \left\{ \xi^l \sum{}' a_{rs}^{kl} \left(\frac{\ln \xi}{\xi^2}\right)^r \cdot \left(\frac{1}{\xi}\right)^s \right\}. \tag{4.1.36}$$

In $\sum'$ only these indices r and s are present, which after re-expansion in $\rho = \xi/\delta_2$ yields an order $\delta_1^p \delta_2^q$ with $p+q > N$. Since $p = k+r-m$, $q = r+m+s$ with some m in $0 \leqq m \leqq r$, then

$$k+2r+s \geqq N+1. \tag{4.1.37}$$

We can therefore estimate

$$\begin{aligned} |\Psi^N - \Lambda^{N,N}| &\leqq C \sum_{k+l\leqq N} \delta_1^k \delta_2^l \xi^l \sum_{2r+s=N+1-k} \left(\frac{1}{\xi}\right)^s \\ &\leqq C \sum_{k+l\leqq N+1} \delta_1^k \delta_2^l (\sqrt{\ln \xi})^l \left(\frac{\sqrt{\ln \xi}}{\xi}\right)^{N+1-k-l} \end{aligned} \tag{4.1.38}$$

and this leads us immediately to the first part of (4.1.35). The second part follows from the representation

$$\begin{aligned} \Lambda^{N,K} - \Lambda^{N,N} &= \sum_{N+1\leqq k+l\leqq K} \delta_1^k \delta_2^l \xi^{l+2} \sum_{\text{finite sum}}{}'' a_{rs}^{kl} \left(\frac{\ln \xi}{\xi^2}\right)^r \left(\frac{1}{\xi}\right)^s, \\ \Lambda^{N_1,K} - \Lambda^{N,K} &= \sum_{N+1\leqq k+l\leqq N_1} \delta_1^k \delta_2^l \sum_{\substack{0\leqq i\leqq 1+l/2 \\ -l\leqq j\leqq K-(k+l)}} C_{i,j}^{k,l} (\ln \rho)^i \rho^j. \end{aligned} \tag{4.1.39}$$

It is left to the reader to fill in further details. □

To conclude this section we shall derive an estimate for the error up to which Ψ^N satisfies the equation (1.1).

LEMMA 7. *There is an ε-independent constant $\rho_1 > 0$ such that for $|\xi| \leqq \rho_1/\delta_2$*

$$\left| -\varepsilon \Delta \Psi^N + \frac{\Psi^N}{1+\Psi^N} - f \right| \leqq M(\delta_1 + \delta_2 |\xi|)^{N+1} \tag{4.1.40}$$

with an ε-independent constant M.

Proof of Lemma 7. The remainder $r_N = -\delta_2^2 \Delta \Psi^N + \Psi^N/(1+\Psi^N) - f$ satisfies, by construction of the $\Psi_{k,l}$'s,

$$T_N r_N = 0, \quad \text{i.e.,}\ r_N = r_N - T_N r_N \tag{4.1.41}$$

where T_N denotes the Taylor series expansion w.r.t. δ_1 and δ_2 up to orders $\delta_1^k \delta_2^l$ with $k+l \leqq N$.

Hence

$$r_N = -(I - T_N) f(\delta_2 \xi, \theta) - (I - T_N) \delta_2^2 \Delta \Psi^N - (I - T_N)(1+\psi_N)^{-1}. \tag{4.1.42}$$

As for the first term the statement in (4.1.41) holds trivially.

For the second term we note that

$$-\delta_2^2 \Delta = \sum_{0<r+s\leqq 2} \delta_2^{2-r} B^{r,s}(\delta_2 \xi, \theta) \frac{\partial^{r+s}}{\partial \xi^r \partial \theta^s}, \tag{4.1.43}$$

where the $B^{r,s}$ can easily be identified using (3.2). Consequently,

$$(I - T_N) \delta_2^2 \Delta \Psi^N = \sum_{\substack{0<r+s\leqq 2 \\ k+l\leqq N}} \sum_{j=0}^{l-2+r} (I - T_j) B^{r,s} \cdot \delta_1^k \delta_2^{l-j} \frac{\partial^{r+s} \psi_{k,l-j-2+r}}{\partial \xi^r \partial \theta^s}. \tag{4.1.44}$$

Now

$$|(I-T_j)B^{r,s}| \leqq C(\delta_2\xi)^{j+1} \quad \text{and} \quad \left|\frac{\partial^{r+s}\psi_{k,l-j-2+r}}{\partial\xi^r\partial\theta^s}\right| \leqq C|\xi|^{l-j},$$

because of Lemmas 2 and 3, and there is an ε-independent constant $C>0$ such that

$$(4.1.45) \qquad |(I-T_N)\delta_2^2\Delta\Psi^N)| \leqq C \sum_{k+l\leqq N} \delta_1^k(\delta_2|\xi|)^{l+1}.$$

This implies that the second term is as required in (4.1.40).

For the third term we proceed as follows:

$$(4.1.46) \qquad \begin{aligned} |(I-T_N)(1+\psi_N)^{-1}| &= \left|\frac{1}{N!}\int_0^1 (1-t)^N \frac{\partial^{N+1}}{\partial t^{N+1}}\left(1+\sum_{k+l\leqq N} t^{k+l}\delta_1^k\delta_2^l\psi_{k,l}\right)^{-1} \cdot dt\right. \\ &\leqq C \sum_{k+l=N+1} \delta_1^k\delta_2^l \sum_{m=2}^{N+1}\left(1+\frac{1}{2}\psi_0\right)^{-m-1} \prod_{\substack{i=1 \\ k_i+l_i\geqq 1 \\ \Sigma k_i=k, \Sigma l_i=l}}^{m} |\psi_{k_i,l_i}| \end{aligned}$$

with some suitably chosen ε-independent constant C. Here we used Lemmas 2 and 3 to estimate $1+\psi_N \geq 1+\frac{1}{2}\psi_0$ for $|\xi| \leqq \rho_1/\delta_2$. Now, for $\xi \leqq \xi_0$ we estimate $1+\frac{1}{2}\psi_0 \geqq 1$ and $|\prod_{i=1}^m \psi_{k_i,l_i}| \leqq C(1+|\xi|^1)$ using Lemma 2. For $\xi \geqq \xi_0$ we estimate $1+\frac{1}{2}\psi_0 \geqq C\xi^2$ and $\prod_{i=1}^m |\psi_{k_i,l_i}| \leqq C\xi^{l+2m}$ and again the estimate as required for (4.1.40) is easily found. □

Note that Lemma 7 shows that we have constructed a formal approximation of arbitrary order in the layer along the free surface.

4.2. The $\phi_{k,l}$'s with free $g_{k,l}$'s. Let us now come back to the construction of a formal approximation in Ω_+. For $\phi_{k,l}$ we find by substituting (4.2) in (1.1) and collecting the terms of order $\varepsilon\delta_1^k\delta_2^l$ an equation of the following form:

$$(4.2.1) \qquad \Delta\phi_{k,l} = -\bar{F}_{k,l}$$

with

$$\bar{F}_{k,l} = (k!\,l!)^{-1}\frac{\partial^{k+l}}{\partial\delta_1^k\partial\delta_2^l}\{w_0+\delta_1\delta_2 w_1+\delta_2^2(1+\Sigma'\delta_1^r\delta_2^s\phi_{r,s})\}^{-1}$$

where $'$ denotes summation over all indices r, s such that $0 \leqq r \leqq k$, $0 \leqq s \leqq l-2$, $r+s < k+l-2$. For example, the equation for $\phi_{0,0}$ becomes

$$(4.2.2) \qquad \Delta\phi_{0,0} = -\frac{1}{w_0}.$$

Since w_0 behaves as ρ^2 for $\rho\downarrow 0$ (see (1.5)) the right-hand side of this equation is singular for $\rho\downarrow 0$. Analogously, singularities can be expected in the other $\bar{F}_{k,l}$'s. Consequently, it is logical to split $\phi_{k,l}$ into a singular part and a regular part. Now, it will be crucial to the construction that the singular part of $\phi_{k,l}$ can be determined in *a unique way* from the previous $\phi_{\bar{k},\bar{l}}$ with $\bar{k} \leqq k$, $\bar{l} \leqq l-2$, $\bar{k}+\bar{l} < k+l-2$ by an iterative procedure *using only* the equation given in (4.2.1). The regular part of $\phi_{k,l}$ will have freedom in the form of its boundary values on S. Moreover, the following lemma provides us with more information on the structure of the singularities near the free surface.

LEMMA 8. *The equations given in* (4.1.1) *have a set of solutions $\phi_{k,l}$ with the following properties*:

$$(4.2.3) \qquad \phi_{k,l} = \phi_{k,l}^{s,M}(\rho,\theta)\cdot H\left(\frac{\rho-\rho_1}{\rho_1}\right)+\phi_{k,l}^{r,M},$$

where $\phi_{k,l}^{s,M}$ will consist of certain singular terms and $\phi_{k,l}^{r,M}$ is sufficiently regular:

$$(4.2.4)\qquad \phi_{k,l}^{s,M}=\sum_{\substack{-l\leqq j\leqq M+2\\ 0\leqq i\leqq 1+l/2\\ i>0 \text{ or } j<0}} \Phi_{i,j}^{k,l}(\theta)\cdot(\ln\rho)^i\rho^j,\qquad \Phi_{i,j}^{k,l} \textit{ smooth and periodic in } \theta,$$

$$(4.2.5)\qquad \phi_{k,l}^{r,M}\in C^{M+2+\alpha}(\bar{\Omega}_+),\qquad \alpha\in(0,1).$$

In this decomposition $M\in\mathbb{N}\cup\{0\}$ is arbitrary. H is the cut-off function given in (2.6) *and $\rho_1>0$ is ε-independent, but sufficiently small. The construction of the $\phi_{k,l}$'s goes iteratively, namely, once all $\phi_{k,l}$ with $k+l\leqq N$ are known with properties as in* (4.2.3)–(4.2.5), *then for $k+l=N+1$:*

(i) *$\phi_{k,l}^{s,M}$ follows uniquely within the specified class by requiring:*

$$(4.2.6)\qquad \Delta\phi_{k,l}^{s,m}+\bar{F}_{k,l}\in C^{M+\alpha}(\{(\rho,\theta)\,|\,0\leqq\rho\leqq\rho_1\}),$$

(ii) *solution of*

$$(4.2.7)\qquad \Delta\phi_{k,l}^{r,M}=-\bar{F}_{k,l}-\Delta(\phi_{k,l}^{s,M}H),$$

$$(4.2.8)\qquad \phi_{k,l}^{r,M}=g_{k,l},$$

where $g_{k,l}\in C^\infty(S)$ is free.

Proof of Lemma 8. Working out the differentiations in the definition of $\bar{F}_{k,l}$ leads us to

$$(4.2.9)\qquad \bar{F}_{k,l}=\sum_{\substack{|\vec{s}|\leqq l-2m-2r-p\\ |\vec{r}|=k-p\\ m\geqq 1,0\leqq n\leqq m}} J_{\vec{r},\vec{s}}^{k,l,p,m,n} w_0^{-m-1} w_1^p \prod_{\substack{n\leqq m \text{ terms}\\ n=0 \text{ is allowed}}} \phi_{r_i,s_i}$$

with certain constants $J_{\vec{r},\vec{s}}^{k,l,p,m,n}$. If we assume that the lemma is true for $k+l\leqq N$, a simple calculation shows that for a pair (k,l) with $k+l=N+1$

$$(4.2.10)\qquad \bar{F}_{k,l}=\bar{F}_{k,l}^{s,M}H+\bar{F}_{k,l}^{r,m}$$

with

$$\bar{F}_{k,l}=\sum_{\substack{-(l+2)\leqq j\leqq M\\ 0\leqq i\leqq 1/2l\\ j<0 \text{ or } i>0}} \bar{J}_{i,j}^{k,l}(\ln\rho)^i\rho^j,\qquad \bar{J}_{i,j}^{k,l} \text{ smooth and periodic in } \theta,$$

and

$$\bar{F}_{k,l}^{r,M}\in C^{M+\alpha}(\bar{\Omega}_+),\qquad \alpha\in(0,1),$$

where $M\in\mathbb{N}\cup\{0\}$ is arbitrary. Using (4.2.2) we see that (4.2.10) also holds in the case $k=0$, $l=0$, where the iteration is starting.

Our next step is to solve the equation

$$(4.2.11)\qquad \Delta\phi_{k,l}^{s,M}=-\bar{F}_{k,l}^{s,M}+O((\ln\rho)^{1+\frac{1}{2}l}\cdot\rho^{M+1}).$$

This really involves no more than some linear algebra to determine the coefficients $\Phi_{i,j}^{k,l}$. In a straightforward way one can compute that these coefficients have to satisfy a system of linear equations of the following type:

$$(4.2.12)\qquad E_{ij}\Phi_{ij}^{kl}=\sum_{(i',j')>_s(i,j)}\sum_{s=0}^{2} D_{i',j'}^{k,l,s}\frac{\partial^s\Phi_{i',j'}^{k,l}}{\partial\theta^s}-\bar{J}_{i-\delta(j),j-2}^{k,l}$$

with

$$E_{ij}=\begin{cases} j(j-1) & \text{if } j<0 \text{ or } j\geqq 2,\\ (-1)^{j+1}i & \text{if } j=0 \text{ or } j=1,\end{cases}$$

$$\delta(j)=\begin{cases} 1 & \text{if } j=0 \text{ or } j=1,\\ 0 & \text{else,}\end{cases}$$

$$(i',j')\underset{s}{>}(i,j)\quad \text{if } |(\ln\rho)^i\rho^j|=o(|(\ln\rho)^{i'}\rho^{j'}|)\quad \text{for } \rho\downarrow 0,$$

i.e., if $[j'<j]$ or $[j=j'$ and $i'>i]$.

Note that $>_s$ is a linear ordering on the pairs (i,j) and that the system of equations in (4.2.12) can be solved recursively starting with $(i,j)=(1+l/2,-l)$, corresponding to the principal term w.r.t. this ordering and then going down in accordance with the ordering. In this way $\phi_{k,l}^{s,M}$ is uniquely determined and (4.2.6) holds. Next, we conclude that the right side of (4.2.7) is in $C^{M+\alpha}(\bar{\Omega}_+)$. Consequently, (4.2.5) holds (see [14], [15]). Thus the solutions of (4.2.1) defined in (4.2.3) have indeed the properties specified in Lemma 3. □

Let us now define

$$\text{(4.2.13)}\qquad \Phi^N=\varepsilon^{-1}w_0+(\ln\varepsilon)\cdot w_1+\sum_{k+l\leqq N}\delta_1^k\delta_2^l\phi_{k,l} \text{ as in (4.2).}$$

We conclude this section with the following error estimate indicating how well Φ^N satisfies (4.1.1).

LEMMA 9. *On the domain* $\{x\in\Omega_+\,|\,$*distance* $(x,S)\geqq\delta_1\}$ *we have*

$$\text{(4.2.14)}\qquad \left|-\varepsilon\Delta\Phi^N+\frac{\Phi^N}{1+\Phi^N}-f\right|\leqq K\cdot\frac{\varepsilon}{\rho^2}\cdot\left(\delta_1+\frac{\delta_2}{\rho}\right)^{N+1}$$

with an ε*-independent constant* $K>0$ *and* $\rho=d(x,S)$.

Proof of Lemma 9. We note that the error is given by

$$\left|\varepsilon\cdot\frac{1}{N!}\int_0^1(1-t)^N\cdot\frac{\partial^{N+1}}{\partial t^{N+1}}\left\{w_0+\delta_1\delta_2t^2w_1+\delta_2^2t^2\left(1+\sum_{r+s\leqq N}\delta_1^r\delta_2^s\phi_{r,s}\right)\right\}^{-1}\cdot dt\right|,$$

which for $d(x,S)\geqq\delta_1$ can be estimated as

$$\leqq K_1\varepsilon\sum_{\substack{k+l=N+1\\ |\vec{s}|\leqq l-2m-2r-p\\ |\vec{r}|=k-p}}\delta_1^k\delta_2^l\left|w_0^{-m-1}w_1^p\prod_{\substack{n\geqq m\\ \text{terms}}}\phi_{r_i,s_i}\right|$$

$$\leqq K_2\varepsilon\sum_{\substack{k+l=N+1\\ |\vec{s}|\leqq l-2m}}\delta_1^k\delta_2^l(\rho^2)^{-m-1}\cdot\left(\frac{1}{\rho}\right)^{|\vec{s}|}$$

and then (4.2.14) follows easily. □

This lemma demonstrates that the construction yields a formal approximation of arbitrary order in Ω_0.

4.3. The scheme leading to uniquely defined $\psi_{k,l}$'s and $\phi_{k,l}$'s with determined $A_{k,l}$'s and $g_{k,l}$'s. Of course we still have to determine a bunch of free "constants" in the expansion in the layer along S and in the expansion in Ω_+. This is done by a suitable matching argument. In § 5 we shall show that this leads us to a layer expansion along S and an expansion in Ω_+ with an overlapping domain of validity.

In order to fix the free $A_{k,l}$'s, we notice that matching of the layer expansion and the expansion in Ω_+ requires that

- $g_{k,l}$ is the constant term of order $\delta_1^k\delta_2^l$ found by re-expansion of the layer in (ρ, θ) coordinates,

- the linear term in $\phi_{k,l}$ near S coincides with the linear term found in the $O(\delta_1^k\delta_2^l)$ term obtained by re-expanding the layer in (ρ, θ) coordinates. Note that the term $\sim\rho$ of order $\delta_1^k\delta_2^l$ in the layer expansion has a coefficient

$$(1-\hat{f})A_{k,l+1}+B_{k,l+1}$$

where $B_{k,l+1}$ is completely determined by the functions $\psi_{r,s}$ with $0 \leqq r < k$, $r+s=k+l+1$ or with $r+s \leqq k+l$ (see (4.1.32) and Lemma 4). Hence $A_{k,l+1}$ has to satisfy the following equation:

$$A_{k,l+1}=(1+\hat{\gamma})\{\Phi_{0,1}^{k,l}-B_{k,l+1}\} \tag{4.3.1}$$

with $\Phi_{0,1}^{k,l}$ as in (4.2.4).

Consequently, the scheme that provides us with the $\psi_{k,l}$'s and $\phi_{k,l}$'s in a unique way runs as follows. We start with $N=0$ and then successively

$$\begin{tikzcd}
\boxed{\text{the } \psi_{k,l}\text{'s with } k+l=N \text{ known}} \arrow[r] & \Lambda_{k,l}^{\text{const}} \text{ is known (see (4.1.31))} \arrow[d] \\
 & g_{k,l} \underset{\text{def}}{=} \Lambda_{k,l}^{\text{const}} \arrow[d] \\
\begin{array}{l}\text{all } \Phi_{0,1}^{k,l}\text{'s with } k+l=N \\ \quad \text{are known (see (4.2.4))}\end{array} \arrow[d] & \boxed{\text{the } \phi_{k,l}\text{'s with } k+l=N \text{ known}} \arrow[l] \\
A_{0,N+1} \text{ is known (see (4.3.1))} \arrow[d] & \\
A_{1,N} \text{ is known (see (4.3.1))} & \\
\vdots \arrow[d] & \\
A_{N,1} \text{ is known (see (4.3.1))} & \\
A_{N+1,0}=0 \text{ (see Lemma 3)} \arrow[d] & \\
\boxed{\text{the } \psi_{k,l}\text{'s with } k+l=N+1 \text{ known}} \arrow[r] & \text{etc.}
\end{tikzcd}$$

This scheme leads to $g_{k,l}$ and $A_{k,l}$, which are smooth and periodic in θ. It will be clear that only a very partial matching between the layer expansion and the expansion in Ω_+ has been built into this scheme. In the next section we consider the matching relations in more detail.

5. Matching relations of the internal layer at S and the expansions in Ω_0, Ω_+.

This section is a preparation for the construction of a global uniformly valid expansion in $\bar{\Omega}$ and the demonstration of its validity. We show here that various expansions constructed in preceding sections have overlap domains in which their differences are small. First we shall show that the internal layer expansion Ψ^{N+2} and the regular expansion U^N up to terms of the order δ_2^{2N} have an overlap domain, and we shall estimate their difference there.

LEMMA 10. *There are ε-independent constants ρ_1, ξ_1, M and $\mu>0$ such that for* $-\rho_1 \leqq \rho \leqq -\delta_2\xi_1$

$$|U^N-\Psi^{N+2}| \leqq M\{(\delta_2+\rho)^{N+2}+\exp(-\mu\rho/\delta_2)\} \tag{5.1}$$

and

$$\left|\rho^r \frac{\partial^{r+s}}{\partial\rho^r\partial\theta^s}(U^N - \Psi^{N+2})\right| \leqq M\{(\delta_2+\rho)^{N+2} + \exp(-\mu\rho/\delta_2)\}, \qquad r+s \leqq 2.$$

Note that overlap up to a certain order takes place in any region $-\hat{\rho}_1(\varepsilon) \leqq \rho \leqq -\hat{\rho}_2(\varepsilon)$ with $\hat{\rho}_1 = o(1)$ and $\delta_2 = o(\hat{\rho}_2)$. The difference is almost as small as possible in a region $-\hat{A}\delta_1 \leqq \rho \leqq -\hat{B}\delta_1$ with suitably chosen ε-independent constants $\hat{A}$, $\hat{B} > 0$.

Proof of Lemma 10. This proof is not very difficult. It uses the observation that there is exactly one function $P^{\bar{N}}$, $\bar{N} =_{\text{def}} N+1$ of the form

$$(5.2) \qquad P^{\bar{N}} = \sum_{l+j \leqq N} p_{l,j}(\theta)\delta_2^l \rho^j$$

with smooth, periodic coefficients $p_{l,j}$, such that

$$(5.3) \qquad \left|-\delta_2^2 \Delta P^{\bar{N}} + \frac{P^{\bar{N}}}{1+P^{\bar{N}}} - f\right| = o(\delta_2 + |\rho|)^{\bar{N}} \quad \text{for } \delta_2 \downarrow 0, \rho \uparrow 0.$$

On the other hand, both $T_{\bar{N}} U^N$, the Taylor expansion w.r.t. δ_2 and ρ up to terms $\delta_2^l \rho^j$ with $l+j \leqq \bar{N}$ of U_N, and $Q^{\bar{N}} = \sum_{l=0}^{\bar{N}} \delta_2^l P_l(\rho/\delta_2, \theta)$ with P_l the polynomial found in the expansion of $\psi_{0,1}$ for $\xi \to -\infty$ (see Lemma 2), satisfy (5.2) and (5.3) (see (2.13) and Lemma 7). Hence $T_{\bar{N}} U^N = Q^{\bar{N}} = P^{\bar{N}}$. Further, $|U_N - T_{\bar{N}} U_N| \leqq M_1(\delta_2+\rho)^{\bar{N}+1}$, $|\Psi^{\bar{N}} - \Phi^{\bar{N}}| \leqq M_2 \exp(-\mu\rho/\delta_2)$ and $|\Psi^{N+2} - \Psi^N| \leqq M_1(\delta_2+\rho)^{\bar{N}+1}$ (see Lemma 2). Thus (5.1) has been derived. The estimates for the derivatives follow in an analogous way. □

Next we shall demonstrate that Ψ^{N+2} and Φ^N, the expansion in Ω_+, have an overlapping domain of validity. It is no surprise that in this case we have to work harder to get an appropriate estimate for the difference.

LEMMA 11. *There are ε-independent constants ρ_1, ξ_1, $M > 0$ such that for $\xi_1 \leqq \xi \leqq \rho_1/\delta_2$*

$$(5.4) \quad |\Psi^{N+2} - \Phi^N| \leqq M\left\{\left(\delta_1 + \delta_2\sqrt{\ln \xi} + \frac{\sqrt{\ln \xi}}{\xi}\right)^{N+1} \cdot \ln(\rho) + \xi^2 \cdot (\delta_1 + \delta_2 \xi)^{N+3}\right\}$$

and such an estimate also holds true for

$$\left|(\delta_2\xi)^r \frac{\partial^{r+s}}{\partial\rho^r\partial\theta^s}(\Psi^{N+2} - \Phi^N)\right|, \qquad r+s \leqq 2.$$

Proof of Lemma 11. We split the difference as

$$(5.5) \qquad \Psi^{N+2} - \Phi^N = (\Psi^{N+2} - \Lambda^{N+2,K}) + (\Lambda^{N,K} - \Phi^N) + (\Lambda^{N+2,K} - \Lambda^{N,K})$$

with $K > N$. The first and the last part have already been estimated in a way required by (5.4) (see Lemma 6).

An estimate of the second part is found by applying the following result:

for each (k, l) and for each $K_1 > 0$ there exists a $K > 0$ such that

$$(5.6) \qquad \begin{aligned} &|\Delta(\Lambda_{k,l}^K - \phi_{k,l})| = O(\rho^{K_1}) \quad \textit{for } \rho \downarrow 0, \\ &|(\Lambda_{k,l}^K - \phi_{k,l})| = O(\rho^{K_1+2}) \quad \textit{for } \rho \downarrow 0. \end{aligned}$$

Once (5.6) has been demonstrated, it is clear that the second part is such that there is an $\tilde{M} > 0$ independent of ε such that

$$(5.7) \qquad |\Lambda^{N,K} - \Phi^N| \leqq M\rho^{N+5}$$

by taking K sufficiently large. Therefore the estimate in (5.4) is complete.

Let us now derive (5.6). This is done by induction w.r.t. $N_0 =_{\text{def}} k+1$. We start with:

a. $N_0=-2$, i.e. $k=0$, $l=-2$. Using Lemma 7 and the first part of Lemma 6 (with N replaced by K) we find that

$$\Delta(\Lambda^K_{0,-2}) = 1 - f + O(\rho^{K+1}). \tag{5.8}$$

As a consequence of Lemma 5 and (4.1.17) we obtain

$$\Lambda^K_{0,-2}\Big|_{\rho=0} = 0, \frac{\partial \Lambda^K_{0,-2}}{\partial\rho}\Big|_{\rho=0} = 0. \tag{5.9}$$

Together with the problem for w_0 in (1.5), this implies that

$$\begin{gathered}\Delta(w_0 - \Lambda^K_{0,-2}) = O(\rho^{K+1}),\\ (w_0-\Lambda^K_{0,-2})|_{\rho=0}=0, \qquad \frac{\partial}{\partial\rho}(w_0-\Lambda^K_{0,-2})|_{\rho=0}=0.\end{gathered} \tag{5.10}$$

Moreover, the r.h.s. of the equation is $C^{K+1+\alpha}$ for $\rho \geqq 0$, ρ sufficiently small, because of Lemma 5 and Lemma 8. Using a Cauchy-Kowalewsky type of construction (cf. [15]) we find that

$$|w_0 - \Lambda^K_{0,-2}| = O(\rho^{K+3}) \quad \text{for } \rho \downarrow 0. \tag{5.11}$$

b. Suppose (5.6) has been proved for $k+l \leqq N_0$. Consider, then, values such that $k+l=N_0+1$, $k+l=0$ if $N_0=-2$. Given $K_1>0$, choose K so large that

$$|\Lambda^K_{r,s} - \phi_{r,s}| = O(\rho^{N_0+1+K_1})$$

for all r, s with $r+s \leqq N_0$. From the structure of $\bar{F}_{k,l}$ as given in (4.2.1) it follows that

$$\Delta\phi_{k,l} = -\bar{F}_{k,l} = -\bar{F}^*_{k,l} + O(\rho^{K_1}) \tag{5.12}$$

where $\bar{F}^*_{k,l}$ denotes $\bar{F}_{k,l}$ with w_0, w_1, $\phi_{r,s}$, $r+s \leqq N_0$ replaced by their approximation $\Lambda^K_{r,s}$, $r+s\leqq N_0$. Again using Lemma 7 and the first part of Lemma 6 with $N \to K$, we obtain

$$\Delta\Lambda^K_{k,l} = -\bar{F}^*_{k,l} + O(\rho^{K_1}). \tag{5.13}$$

Because of the uniqueness of the singular terms $(\ln\rho)^i\rho^j$ with $j<0$ or $i>0$ in the solution of $\Delta\phi = -\bar{F}^*_{k,l}$ (see (4.2.12)), we obtain

$$\begin{gathered}\phi_{k,l} - \Lambda^K_{k,l} \text{ is } C^{K_1+2+\alpha} \quad \text{for } \rho \geqq 0, \rho \text{ sufficiently small},\\ \Delta(\phi_{k,l} - \Lambda^K_{k,l}) = O(\rho^{K_1}).\end{gathered} \tag{5.14}$$

Due to the partial matching relations imposed in § 4.3 we have as boundary conditions on S

$$(\phi_{k,l} - \Lambda^K_{k,l})|_{\rho=0} = 0, \qquad \frac{\partial}{\partial\rho}(\phi_{k,l}-\Lambda^K_{k,l})|_{\rho=0} = 0. \tag{5.15}$$

Again a construction of Cauchy-Kowalewsky type shows that

$$|\phi_{k,l} - \Lambda^K_{k,l}| = O(\rho^{K_1+2}) \quad \text{for } \rho\downarrow 0. \tag{5.16}$$

The estimates on the derivatives can now also be verified in an elementary way; details are left to the reader. □

We conclude this section with the remark that for $N \geqq 0$ the overlap region is nonempty and that the difference is small in the region

$$A\sqrt{\delta_2} \leqq \rho \leqq B\sqrt{\delta_2}, \quad \text{i.e., } A\delta_2^{-1/2} \leqq \xi \leqq B\delta_2^{-1/2} \tag{5.17}$$

with suitably chosen ε-independent A and $B>0$. This region is special, since exactly in this region Ψ^{N+2} and Φ^N give rise to the same order of error in the equation;

$$\text{error} \sim (\delta_2\xi)^{N+3} = O_{\text{sharp}}\left(\frac{\delta_2}{\rho}\right)^{N+3} = O_{\text{sharp}}(\varepsilon^{(N+3)/4}) \tag{5.18}$$

in that region (see Lemma 7 and Lemma 9). In fact it is this error, which is worst in the global formal approximation, that we discuss in the next section.

6. Composition of a global approximation Z_N and estimation of the error $u-Z_N$. Now we are in a position to put all the previously constructed local approximations together into a global approximation Z_N. We define

$$Z_N = \Psi^{N+2} H\left(\frac{\rho^2}{\sqrt{\varepsilon}}\right) + (Z_0^N + \Phi^N)\cdot\left[1 - H\left(\frac{\rho^2}{\sqrt{\varepsilon}}\right)\right] \tag{6.1}$$

with

Ψ^{N+2} the expansion in the layer along with the free surface S, see (4.1.33),

Z_0^N the regular expansion in Ω_0 corrected with the layer expansion along $\partial\Omega$, see (2.4),

Φ^N the expansion in Ω_+ (see (4.2.13)),

$H\left(\frac{\rho^2}{\sqrt{\varepsilon}}\right)$ is a smooth cut-off function, which is $\equiv 1$ for $|\rho| \leqq (\frac{1}{2}\sqrt{\varepsilon})^{1/2}$ and which vanishes for $|\rho| \geqq \varepsilon^{1/4}$ (see (2.6)).

THEOREM 1. *The construction process has been successful in the sense that Z_N is a global, formal approximation*:

$$\max_{x\in\bar{\Omega}}\left|-\varepsilon\Delta Z_N + \frac{Z_N}{1+Z_N} - f\right| \leqq R\cdot\sqrt{\varepsilon^{1/2}\ln\left(\frac{1}{\varepsilon}\right)}^{(N+3)}, \tag{6.2}$$

where R is an ε-independent constant >0.

Proof of Theorem 1. The estimate in (6.2) can be derived by making a subdivision of $\bar{\Omega}$ into

$$\Omega_l = \{(\rho,\theta) \mid \rho^2 \leqq \tfrac{1}{2}\sqrt{\varepsilon}\}, \quad \Omega_{l,+} = \{(\rho,\theta) \mid \rho>0, \tfrac{1}{2}\sqrt{\varepsilon} \leqq \rho^2 \leqq \sqrt{\varepsilon}\},$$

$$\Omega_{l,0} = \{(\rho,\theta) \mid \rho<0, \tfrac{1}{2}\sqrt{\varepsilon} \leqq \rho^2 \leqq \sqrt{\varepsilon}\}, \quad \Omega_+' = \Omega_+\backslash\{\Omega_l \cup \Omega_{l,+}\}, \quad \Omega_0' = \bar{\Omega}_0\backslash\{\Omega_l \cup \Omega_{l,0}\}.$$

Partial results in the direction of (6.2) were already found. In Ω_0' we use (2.15) and obtain an $O(\varepsilon^{N+3})$ error. The larger contributions come from $\Omega_l, \Omega_{l,+}$ and Ω_+'. We apply Lemma 7 and Lemma 9 in Ω_l and $\Omega_{l,+}$ respectively. In both regions we find an $O(\varepsilon^{1/4(N+3)})$ error, because of the special choice of the cut-off at an $O(\varepsilon^{1/4})$-distance from S (compare (5.18)). In the overlap region $\Omega_{l,+}$ we have

$$Z_N = \Phi^N + H\left(\frac{\rho^2}{\sqrt{\varepsilon}}\right)(\Psi^{N+2} - \Phi^N).$$

Using Lemma 9 and the matching relations in Lemma 11, we can see that here the error is at most $(\sqrt{\delta_2|\ln\varepsilon|})^{N+3}$. Specially, the term

$$\delta_2^2\cdot\left(\partial^2 H\left(\frac{\rho^2}{\sqrt{\varepsilon}}\right)\Big/\partial\rho^2\right)\cdot(\Psi^{N+2} - \Phi^N)$$

gives rise to this order (see Lemma 11). Other terms yield contributions of a smaller order. The region $\Omega_{l,0}$ is dealt with in an analogous way using Lemma 10. □

The next step is to convert the estimate in (6.2) into an estimate for $u-Z_N$. This can be done with the following result:

LEMMA 12. *Suppose that* $Z\in C^\infty(\bar{\Omega})$, $Z\geqq 0$ *satisfies*

$$-\varepsilon\Delta Z+\frac{Z}{1+Z}-f=r,\qquad Z=0 \text{ on } \partial\Omega. \tag{6.3}$$

Then there is an ε-independent constant $\nu>0$ *such that*

$$|u-Z|_{\sup}\leqq\frac{\nu}{\varepsilon}|r|_{\sup}. \tag{6.4}$$

Proof of Lemma 12. We use a technique based on barrier functions and the maximum principle (see [17], [12] and [18]). Suppose that a positive function $v\in C^\infty(\bar{\Omega})$ can be found such that

$$\begin{aligned}&-\varepsilon\Delta(Z+v)+\frac{Z+v}{1+Z+v}-f\geqq 0\quad\text{in }\bar{\Omega},\\ &Z+v\geqq 0\quad\text{on }\partial\Omega.\end{aligned}\tag{6.5}$$

Then $Z+v$ is an upper barrier for the solution u, i.e.,

$$u\leqq Z+v\quad\text{on }\bar{\Omega}. \tag{6.6}$$

To prove (6.6) we use the fact that $Z+v-u=_{\text{def}}w$ satisfies $w\in C^\infty(\bar{\Omega})$ and

$$\begin{aligned}&-\varepsilon\Delta w+\bar{c}w\geqq 0\quad\text{in }\bar{\Omega},\\ &w\geqq 0\quad\text{on }\partial\Omega\end{aligned}$$

with

$$\bar{c}=(1+Z+v)^{-1}(1+u)^{-1},$$

i.e.,

$$\bar{c}\in C^\infty(\bar{\Omega})\quad\text{and}\quad\bar{c}\geqq 0.$$

Implicitly, we used the fact that $u\in C^\infty(\bar{\Omega})$ (cf. [4]). The maximum principle for second order elliptic Dirichlet problems (cf. [19]) implies that $w\geqq 0$.

If a negative function $v\in C^\infty(\bar{\Omega})$ can be found such that (6.5) holds with reversed signs in the region where $Z+v\geqq 0$, then $\max(0,Z+v)$ is a lower barrier for the solution u. This follows from (1.3) in combination with a maximum principle argument.

Now, we make the following choice for the function v:

$$v=b\cos\left(\frac{\pi}{2}\cdot\frac{x_1-x_1^0}{d}\right)\cdot\cos\left(\frac{\pi}{2}\cdot\frac{x_2-x_2^0}{d}\right) \tag{6.7}$$

with a value for $b\geqq 0$, which we shall specify presently. The point x^0 and the number $d>0$ are chosen in such a way that the product of the cosines is $\geqq\frac{1}{2}$ on $\bar{\Omega}$. With this function v we obtain that

$$-\varepsilon\Delta(Z+v)+\frac{Z+v}{1+Z+v}-f\geqq r-\varepsilon\Delta v\geqq r+b\cdot\frac{\varepsilon}{2}\left(\frac{\pi}{2d}\right)^2, \tag{6.8}$$

which is $\geqq 0$, when $b=(\nu/\varepsilon)\min(0,-\min_{\bar{\Omega}} r)$ with $\nu=8(d/\pi)^2$. In this way an upper bound is found. For the lower bound we proceed in an analogous way. Actually we even obtain a somewhat better estimate than we do from (6.3):

$$\max\left(0,Z-\frac{\nu}{\varepsilon}\max(0,\max_{\bar{\Omega}} r)\right)\leqq u\leqq Z+\frac{\nu}{\varepsilon}\min(0,-\min_{\bar{\Omega}} r). \tag{6.9}$$

□

An immediate consequence of Lemma 12 and Theorem 1 is

$$|u-Z_N|_{\sup}=O\left(\varepsilon^{-1}\left(\sqrt{\varepsilon^{1/2}\ln\left(\frac{1}{\varepsilon}\right)}\right)^{N+3}\right)\quad \text{if } N\geqq 0. \tag{6.10}$$

However, this estimate can be improved somewhat. It follows that

$$|Z_N-Z_{N_1}|\sup=O\left(\left(\sqrt{\varepsilon^{1/2}\ln\left(\frac{1}{\varepsilon}\right)}\right)^{N+1}\right)\quad \text{if } N_1\geqq N\geqq 0, \tag{6.11}$$

as one may verify with a straightforward calculation. Since $|u-Z_N|_{\sup}\leqq |u-Z_{N_1}|_{\sup}+|Z_N-Z_{N_1}|_{\sup}$, the following result is found from (6.10)-(6.11).

THEOREM 2. *In the sup norm it follows that the constructed global approximation Z_N differs from the solution at most by an amount*

$$|u-Z_N|_{\sup}=O\left(\sqrt{\varepsilon^{1/2}\ln\left(\frac{1}{\varepsilon}\right)}^{N+1}\right),\qquad N\geqq 0. \tag{6.12}$$

Of course the estimate given in the introduction (1.12) is contained in (6.12) for N sufficiently large. In order to prove (1.13) and (1.14) we need estimates on the derivatives $(\partial/\partial x_i)(u-Z_N)$, $(\partial^2/\partial x_i\partial x_j)(u-Z_N)$. Note that

$$\left[-\varepsilon\Delta+\frac{1}{(1+u)^2}\right]\frac{\partial}{\partial x_i}(u-Z_N)=r_{i,N}^{(1)} \tag{6.13}$$

with

$$r_{i,N}^{(1)}=\frac{\partial r}{\partial x_i}+\frac{\partial Z_N}{\partial x_i}\left\{\frac{1}{(1+Z_N)^2}-\frac{1}{(1+u)^2}\right\},$$

i.e.,

$$\|r_{i,N}^{(1)}|_{\sup}\leqq R_{i,N}^{(1)}\varepsilon^{-1}\left(\sqrt{\varepsilon^{1/2}\ln\left(\frac{1}{\varepsilon}\right)}\right)^{N+1}.$$

Using a technique shown in Lemma 12 we see that

$$\left|\frac{\partial}{\partial x_i}(u-Z_N)\right|_{\sup}=O(\varepsilon^{-1}|r_{i,N}^{(1)}|_{\sup}). \tag{6.14}$$

Now for N sufficiently large (1.13), the explicit expression for Z_N and its derivatives is contained in (6.14), (6.12). An interesting observation is that the main contribution in the estimate (1.13) comes from the layer along $\partial\Omega$. Differentiating (6.13) w.r.t. x_j and proceeding in an analogous way we obtain

$$\left|\frac{\partial^2}{\partial x_i\partial x_j}(u-Z_N)\right|_{\sup}=O(\varepsilon)\quad \text{for } N \text{ sufficiently large.} \tag{6.15}$$

Thus we are led to (1.14). Again the main contribution in (1.14) comes from the layer along $\partial\Omega$.

7. Discussion of some generalisations. Two generalisations of the problem as specified in (1.1) can be dealt with in a rather straightforward way: (i) higher dimensional domains Ω and (ii) general second order, negative, elliptic operators A with smooth coefficients, instead of the Laplacian Δ. The conditions in the Introduction have a formulation, which already applies to this situation. Of course certain minor changes have to be made in the construction. For example, in general one has to work with several local coordinate systems (ρ, θ); to describe a neighbourhood of S and expressions such as (3.2) will be more complicated. However, nothing changes in the structure of the approximation Z_N, and our methods of proving the validity of the approximation based on the maximum principle still work.

A different story arises for a generalisation to more general nonlinearities, i.e., for a problem

$$\begin{aligned} &-\varepsilon Au+\Phi(x, u)=f\geqq 0 \quad \text{on } \Omega, \\ &u=0 \quad \text{on } \partial\Omega, \end{aligned} \tag{7.1}$$

with

$$\Phi\in C^{\infty}(\bar{\Omega}\times\mathbb{R}), \quad \Phi(x, 0)=0, \quad \frac{\partial\Phi}{\partial u}>0, \quad \lim_{u\to\infty} \Phi(x, u)=1.$$

Note that a more general case with $\lim_{u\to\infty} \Phi(x, u)=\omega(x)$ on $\bar{\Omega}$, $\omega\in C^{\infty}(\bar{\Omega})$, $\omega>0$ can be reduced to the one above by dividing by ω. Now the structure of the approximation near S and Ω_+ will depend heavily on how $\Phi(x, u)$ tends to its limit as $u\to\infty$. In cases where Φ has the following asymptotics:

$$\Phi(x, u)\simeq 1-\lambda_1(x)u^{-1}+\sum_{k\geqq 2} \lambda_k(x)u^{-k} \quad \text{for } u\to\infty \tag{7.2}$$

with coefficients $\lambda_k\in C^{\infty}(\bar{\Omega})$, $\lambda_1>0$, the approximation will still have a structure as in this paper and its construction is analogous. In cases where Φ has completely different asymptotics for $u\to\infty$, the structure of the approximation will also be different. For example, for $\Phi=1-e^{-u}$ the structure of the approximation will be easier, since only order functions of the type $\varepsilon^{p/2}$, $p=-2, 0, 1, \cdots$ will then appear (see [10]).

The method of proving validity given in § 6 extends without difficulties to these more general nonlinearities.

AN ABSTRACT D'ALEMBERT FORMULA*

JEROME A. GOLDSTEIN† AND JAMES T. SANDEFUR, JR.‡

Abstract. The abstract d'Alembert formula expresses solutions of the factored linear equation $\prod_{j=1}^{n}(d/dt-A_j)u(t)=0$ as $u(t)=\sum_{j=1}^{n}u_j(t)$, where $(d/dt-A_j)u_j(t)=0$ for $j=1,\cdots,n$. Here each A_j generates a (C_0) semigroup on a Banach space X and suitable hypotheses hold. Applications are made to asymptotic theory, specifically to equipartition of energy and to scattering theory.

Key words. d'Alembert formula, wave equations, scattering theory, equipartition of energy, semigroups of operators

AMS(MOS) subject classifications. 47D05, 34G10, 35P25, 35L30

1. Introduction. Let $A_1,\cdots,A_n$ generate mutually commuting strongly continuous semigroups of bounded linear operators on a Banach space X. If A_i-A_j is invertible and has a big enough range for $i\neq j$, then any solution u of the factored nth order equation

$$\prod_{j=1}^{n}\left(\frac{d}{dt}-A_j\right)u(t)=0$$

decomposes as a sum $u(t)=\sum_{j=1}^{n}u_j(t)$ of solutions of $(d/dt-A_j)u_j(t)=0$. The motivating example for this decomposition is the classical d'Alembert formula for the one-(space-) dimensional wave equation, which expresses the solution of

$$\frac{\partial^2 u}{\partial t^2}-c^2\frac{\partial^2 u}{\partial x^2}=0 \qquad \left(=\prod_{j=1}^{2}\left(\frac{d}{dt}-(-1)^j cd/dx\right)u\right)$$

as $u(t,x)=F(x+ct)+G(x-ct)$.

The abstract d'Alembert formula is presented in § 2 and examples are given in § 3. In §§ 4, 5 and 6, we use the abstract d'Alembert formula to unify, extend and simplify equipartition of energy results. Specifically, in § 4, we improve a result of Goldstein and Rosencrans [3] by deriving equipartition of energy for the telegraph equation

$$u_{tt}+2bu_t+u_{xx}=0$$

in the sense that $\|u_t(t)\|^2/\|u_x(t)\|^2\to 1$ as $t\to\infty$. In § 5, we show for the "damped" wave equation

$$u_{tt}+2bu_{tx}+u_{xx}=0,$$

that $\lim_{t\to\infty}\|u_t(t)\|^2/\|u_x(t)\|^2$ exists, that this limit, L, satisfies

$$[(b^2+1)^{1/2}-|b|]^2\leqq L\leqq[(b^2+1)^{1/2}+|b|]^2,$$

and that L depends on the initial data. In § 6 we give equipartition of energy results for equations of higher order (in time), which unify the results of Mochizuki [11] on factored wave equations and of Goldstein and Sandefur [6] on equations of order 2^n. Applications to scattering theory are given in § 7.

2. The abstract d'Alembert formula. Let X be a Banach space. The following assumption will be made throughout this section.

Hypothesis (H1). For $j=1,\cdots,n$, A_j is the infinitesimal generator of a (C_0) semigroup $T_j=\{T_j(t)\colon t\geqq 0\}$ on X. These semigroups commute, that is,

$$T_j(t)T_k(s)=T_k(s)T_j(t)$$

holds for $j,k\in\{1,\cdots,n\}$ and all $t,s\geqq 0$.

Of concern is the nth order differential equation

$$\prod_{j=1}^{n}\left(\frac{d}{dt}-A_j\right)u(t)=0 \qquad (t\geqq 0), \tag{1}$$

to be solved for $u\colon[0,\infty)\to X$. Special cases of (1) arose naturally in our study of equipartition of energy; cf. [6]. In fact, a very special case of the abstract d'Alembert formula is buried in [6], and it was our desire to understand better the calculation in [6] that provided the initial motivation for the present paper.

Our first theorem establishes the well-posdeness of the Cauchy problem for (1). Theorems 2 and 3 give a clean statement of the d'Alembert formula. Theorem 4 gives a messier but a more useful version of the formula.

Following Sandefur [12], we say that the initial value problem for (1) is *well posed* on $\mathbb{R}^+=[0,\infty)$ if

(i) For every set of initial data $\{\phi_1,\cdots,\phi_n\}$ with $\phi_i\in D$, where D is some dense set in X, there exists a unique solution u of (1) such that $\prod_{j=1}^{k}(d/dt-A_j)u\in C^{n-k}(\mathbb{R}^+,X)$ for $k=0,1,\cdots,n-1$ and $u^{(k-1)}(0)=\phi_k$ for $k=1,\cdots,n$;

(ii) If $\{u_m\}$ is a sequence of solutions of (1) (in the sense of (i) above) and if $\prod_{j=1}^{k}(d/dt-A_j)u_m(t)|_{t=0}\to 0$ as $m\to\infty$ for $k=0,1,\cdots,n-1$, then $\prod_{j=1}^{k}(d/dt-A_j)u_m(t)\to 0$ as $m\to\infty$ for $k=0,1,\cdots,n-1$ and uniformly for t in bounded subintervals of $\mathbb{R}^+$.

THEOREM 1. *Assume Hypothesis* (H1). *Then the initial value problem for* (1) *is well posed.*

For the proof we need an extension of a classical ancient result of Gel'fand [1].

LEMMA. *Let Hypothesis* (H1) *hold. Then* $\bigcap_{j=1}^{n}C^\infty(A_j)$ *is dense in* X.

Here $C^\infty(A_j)=\bigcap_{m=1}^{\infty}\operatorname{Dom}(A_j^m)$. For $n=1$ this result is due to Gel'fand; see [7, p. 308]. We shall prove it for $n=2$, assuming it for $n=1$. Two remarks must be made in connection with this: (i) the $n=1$ case actually follows from the proof given below if we specialize A_2 to be zero, so that $T_2(t)\equiv I$; (ii) the proof of the general case is by induction and is in fact the following proof except for some inessential modifications. Thus the details of the general case may safely be omitted.

Let $f\in C^\infty(A_2)$, which by hypothesis is dense in X. Let $\phi\in C_c^\infty((0,\infty),\mathbb{R})$, the subscript c denoting "compactly supported," and set

$$g=\int_0^\infty \phi(t)T_1(t)T_2(t)f\,dt.$$

We *claim* that

$$g\in\operatorname{Dom}(A_1^m)\cap\operatorname{Dom}(A_2^m)$$

for all $m\geqq 1$. It then follows that $g\in\bigcap_{j=1}^{2}C^\infty(A_j)$. Since $g\to f$ as $\phi\to\delta_0$ (for example, take $\phi_\varepsilon\geqq 0$ supported in $[\varepsilon,2\varepsilon]$ with $\int_0^\infty\phi_\varepsilon(t)\,dt=1$ and let $\varepsilon\to 0^+$), we conclude that the lemma follows from the *claim.*

To prove the *claim*, let ϕ be supported in $[\varepsilon, 1/\varepsilon]$ and let $0<h<\varepsilon$. Then

$$T_1(h)g=\int_0^\infty \phi(t)T_1(t+h)T_2(t)f\,dt=\int_0^\infty \phi(t-h)T_1(t)T_2(t-h)f\,dt.$$

Consequently

$$\begin{aligned} h^{-1}[T_1(h)g-g]&=\int_0^\infty h^{-1}[\phi(t-h)-\phi(t)]T_1(t)T_2(t-h)f\,dt\\ &\quad+\int_0^\infty \phi(t)T_1(t)h^{-1}[T_2(t-h)f-T_2(t)]f\,dt \qquad (2)\\ &\to-\int_0^\infty \phi'(t)T_1(t)T_2(t)f\,dt-\int_0^\infty \phi(t)T_1(t)T_2(t)A_2f\,dt.\end{aligned}$$

Hence $g\in \operatorname{Dom}(A_1)$ and A_1g is given by (2). By induction the above argument shows that $g\in\operatorname{Dom}(A_1^m)$ and

$$A_1^mg=\sum_{k=0}^m(-1)^m\binom{m}{k}\int_0^\infty \phi^{(k)}(t)T_1(t)T_2(t)A_2^{m-k}f\,dt;$$

here $\binom{m}{k}=m!/(k!(m-k)!)$ is the usual binomial coefficient. Next, by the commutativity hypothesis (H1), $f\in\operatorname{Dom}(A_2)$ implies $T_1(t)f\in\operatorname{Dom}(A_2)$ and

$$A_2T_1(t)f=T_1(t)A_2f,$$

and similarly for A_2^m in place of A_2. Consequently, since A_2^m is closed and $f\in\operatorname{Dom}(A_2^m)$,

$$\int_0^\infty \phi(t)T_1(t)T_2(t)f\,dt\in\operatorname{Dom}(A_2^m)$$

and

$$A_2^m\left(\int_0^\infty \phi(t)T_1(t)T_2(t)f\,dt\right)=\int_0^\infty \phi(t)T_1(t)T_2(t)A_2^mf\,dt.$$

Since m is arbitrary, the proof is complete. □

Proof of Theorem 1. Let D be any dense subspace of $\bigcap_{j=1}^n C^\infty(A_j)$ that is left invariant by each A_j. For instance, $D=\bigcap_{j=1}^n C^\infty(A_j)$ will do. Theorem 1 now follows directly from the lemma and from a result of Sandefur [12, p. 731]. □

Consider (1) with $n=2$ and $A_1=A_2=A$, where A generates T. Then all solutions of (1) are of the form $T(t)(\phi+t\psi)$ where ϕ, ψ are in Dom (A). If we want solutions of (1) to be of the form $u(t)=\sum_{i=1}^n T_i(t)\psi_i$, then to avoid terms such as $tT_i(t)$, it is necessary that A_i-A_j be injective for $i\neq j$.

Hypothesis (H2). $0\in\rho(A_i-A_j)$ for $i\neq j$. More precisely, zero is in the resolvent set of the closure of A_i-A_j for $i\neq j$.

Write $u\in\mathcal{N}(\prod_{j=1}^k(d/dt-A_j))$ to mean that $\prod_{j=1}^k(d/dt-A_j)u(t)=0$ for $t\geqq 0$. Here $\mathcal{N}$ stands for "null space."

THEOREM 2. *Assume Hypotheses* (H1) *and* (H2). *Then* $w\in\mathcal{N}(\prod_{j=1}^n(d/dt-A_j))$ *implies* $w=\sum_{j=1}^n w_j$ *where* $w_j\in\mathcal{N}(d/dt-A_j)$.

Proof. The proof is by induction on n. (Previously we have assumed that the j's increased from right to left. For simplicity of notation we assume in this proof that the j's decrease from right to left.)

The case $n=1$ is trivially true. Assume the theorem to be true for $n-1$ with $n\geqq 2$. Let

$$\prod_{j=1}^{n}\left(\frac{d}{dt}-A_j\right)w=0$$

and define $u=(d/dt-A_n)w$. Then

$$\prod_{j=1}^{n-1}\left(\frac{d}{dt}-A_j\right)u=0.$$

By the induction hypothesis, $u=\sum_{j=1}^{n-1}u_j$ where $u_j\in\mathcal{N}(d/dt-A_j)$ for $j=1,\cdots,n-1$. Next, $w'-A_nw=u$ implies, by the variation of parameters formula (alias Duhamel's formula),

$$\begin{aligned} w(t)&=T_n(t)w(0)+\int_0^t T_n(t-s)u(s)\,ds\\ &=T_n(t)w(0)+\sum_{j=1}^{n-1}\int_0^t T_n(t-s)T_j(s)u_j(0)\,ds \qquad \text{since } u_j\in\mathcal{N}\left(\frac{d}{dt}-A_j\right)\\ &=T_n(t)w(0)+\sum_{j=1}^{n-1}\int_0^t \frac{d}{ds}[T_n(t-s)T_j(s)(A_j-A_n)^{-1}u_j(0)]\,ds\\ &\qquad\qquad \text{by Hypothesis (H2) and since } 0\in\rho(A_j-A_n)\\ &=T_n(t)\left\{w(0)-\sum_{k=1}^{n-1}(A_k-A_n)^{-1}u_k(0)\right\}\\ &\qquad+\sum_{j=1}^{n-1}T_j(t)\{(A_j-A_n)^{-1}u_j(0)\}\equiv\sum_{k=1}^{n}w_j(t), \end{aligned}$$

where $w_j\in\mathcal{N}(d/dt-A_j)$ for $j=1,\cdots,n$. □

The next theorem is a variant of Theorem 2 to the context of generalized solutions. $u=F(x+t)$ (for $x,t\in\mathbb{R}$) satisfies $u_{tt}=u_{xx}$ in some sense, even if F is not a C^2 function. This is the notion we want to generalize to an abstract context.

According to [12], (1) can be reduced to the system $dw(t)=Aw(t)$ where

$$A=\begin{bmatrix} A_1 & I & \cdots & 0\\ 0 & A_2 & & 0\\ \vdots & & \ddots & \vdots\\ & & & I\\ 0 & & & A_n \end{bmatrix}$$

acts on the product space X^n. Moreover, u is a solution of (1) if and only if u is the first component of a solution w of $w'=Aw$.

Now let A_0 generate a (C_0) semigroup T_0 on a Banach space Y. We call $T_0(\cdot)f$ a *mild solution* of $dv/dt=A_0v$ for every $f\in Y$. A mild solution need not be differentiable, but it is uniquely determined by its initial condition. By a *mild solution* of (1) we mean, using the notation of the above paragraph, the first component of a mild solution w of the first order matrix equation corresponding to (1).

Write $u\in\bar{\mathcal{N}}(\prod_{j=1}^{k}(d/dt-A_j))$ to mean that u is a mild solution of $\prod_{j=1}^{k}(d/dt-A_j)u(t)=0$ for $t\geqq 0$.

THEOREM 3. *Assume Hypotheses* (H1) *and* (H2). *Then* $w \in \bar{\mathcal{N}}(\prod_{j=1}^{n}(d/dt - A_j))$ *implies* $w = \sum_{j=1}^{n} w_j$, *where* $w_j \in \bar{\mathcal{N}}(d/dt - A_j)$.

Proof. Using the Phillips perturbation theorem, we can show (cf. [12]) that u is a mild solution to (1) if and only if

$$u(t) = T_1(t)\psi_1 + \sum_{m=1}^{n-1} \int_0^t \int_0^{t_m} \cdots \int_0^{t_2} T_1(t-t_m)T_2(t_m - t_{m-1}) \cdots T_m(t_2 - t_1)T_{m+1}(t_1)\psi_{m+1}\, dt_1 \cdots dt_m$$

where

$$\psi_m = \phi_m + \sum_{k=1}^{m-1} (-1)^k \sum_{1 \leq i_1 < \cdots < i_k \leq m-1} (A_{i_k} \cdots A_{i_1}\phi_{m-k})$$

and $\phi_m = u^{(m)}(0)$. In particular, when $n = 2$,

$$u(t) = T_1(t)\phi_1 + \int_0^t T_1(t-s)T_2(s)(\phi_2 - A_1\phi_1)\, ds.$$

The proof of the necessity is by induction. Assume the result true for $n-1$ and let u be given by the above formula with suitable $\psi_1, \cdots, \psi_n$. Note that

$$u(t) = u_0(t) + \int_0^t \int_0^{t_{n-1}} \cdots \int_0^{t_2} T_1(t - t_{n-1}) \cdots T_n(t_1)\psi_n\, dt_1 \cdots dt_{n-1}$$

where u_0 is a mild solution of an equation of form (1) but of order $n-1$. By the induction hypothesis, $u_0(t) = \sum_{j=1}^{n-1} v_j(t)$, where $v_j \in \bar{\mathcal{N}}(d/dt - A_j)$. By the argument of the proof of Theorem 2,

$$\int_0^{t_2} T_{n-1}(t_2 - t_1)T_n(t_1)\psi_n\, dt_1 = T_n(t_2)[(A_n - A_{n-1})^{-1}\psi_n] + T_{n-1}(t_2)[(A_{n-1} - A_n)^{-1}\psi_n],$$

$$\int_0^{t_3}\int_0^{t_2} T_{n-2}(t_3 - t_2)T_{n-1}(t_2 - t_1)T_n(t_1)\psi_n\, dt_1\, dt_2 = \sum_{j=n-2}^{n} T_j(t_3)\chi_j,$$

and so on (by induction), whence

$$u(t) = u_0(t) + \sum_{j=1}^{n} T_j(t)\alpha_j = \sum_{j=1}^{n} T_j(t)\beta_j$$

and thus $u = \sum_{i=1}^{n} u_i$ with $u_i \in \bar{\mathcal{N}}(d/dt - A_i)$. □

At first glance it seems "obvious" that the converse of Theorem 3 holds. It certainly seems justified calling $u(t) = \sum_{i=1}^{n} T_i(t)\beta_i$ a *weak solution* of (1), but the point is that this u is not necessarily a mild solution of (1). Let $n = 2$ and

$$\begin{aligned} u(t) &= T_1(t)[(A_1 - A_2)^{-1}\phi_2 - A_2(A_1 - A_2)^{-1}\phi_1] \\ &\quad + T_2(t)[(A_2 - A_1)^{-1}\phi_2 - A_1(A_2 - A_1)^{-1}\phi_1] \\ &\equiv T_1(t)\beta_1 + T_2(t)\beta_2. \end{aligned}$$

This u is a "weak solution" in the above sense, but u is in general not a mild solution of

$$\left(\frac{d}{dt} - A_1\right)\left(\frac{d}{dt} - A_2\right)u = 0$$

unless $\phi_1 \in \operatorname{Dom}(A_1)$. Similarly, u is a mild solution of

$$\left(\frac{d}{dt} - A_2\right)\left(\frac{d}{dt} - A_1\right)u = 0$$

if $\phi_1 \in \operatorname{Dom}(A_2)$. In particular, despite the commutativity, the order of the factors in (1) matters as far as the notion of a mild solution is concerned.

It is also of interest to note that u can formally be a solution to the Cauchy problem even if $\phi_1 \notin \operatorname{Dom}(A_1)$ and $\phi_2 \notin \operatorname{Dom}(A_2)$; but in this case u need not be a mild solution.

THEOREM 4. *Let Hypothesis* (H1) *hold. Let D be a dense subspace of $\bigcap_{j=1}^{n} C^\infty(A_j)$ such that the problem*

$$\prod_{j=1}^{n}\left(\frac{d}{dt}-A_j\right)w(t)=0 \qquad (t \geqq 0),$$

$$w^{(k)}(0)=f_k, \qquad k=0,\ 1,\cdots,n-1$$

has a unique solution whenever $f_0, f_1, \cdots, f_{n-1}$ are given in D and are such that $A_1^{i_1}\cdots A_n^{i_n} f_j \in D$ holds for $0 \leqq j \leqq n-1$ and $i_k \geqq 0$, $\sum_{k=1}^{n} i_k \leqq n-1$. Suppose further that $D \subset \operatorname{Ran}(A_i - A_j)$ for $i \neq j$. Then any $w \in \mathcal{N}(\prod_{j=1}^{n}(d/dt - A_j))$ with initial date in D satisfies $w=\sum_{j=1}^{n} w_j$ where $w_j \in \mathcal{N}(d/dt - A_j)$.

Proof. For $n=1$, this is trivial. For $n=2$, the proof of Theorem 2 gives, for $u=(d/dt-A_2)w$, $w(t)=T_2(t)\{w(0)-(A_1-A_2)^{-1}u(0)\}+T_1(t)\{(A_1-A_2)^{-1}u(0)\}$. By hypothesis,

$$u(0)=w'(0)-A_2 w(0) \in D \subset \operatorname{Ran}(A_1-A_2).$$

Thus, in the case of $n=2$, the proof of Theorem 3 does not really require the condition $0 \in \rho(A_1-A_2)$; only the assumptions of Theorem 4 are needed.

For the case of general n, the induction argument of Theorem 3 gives $w=\sum_{j=1}^{n} w_j$, where $w_j \in \mathcal{N}(d/dt - A_j)$, proved we can show that each of the vectors $(A_j-A_n)^{-1}u_j(0)$ (for $j \leqq n-1$) is in the subspace D. But this follows from the proof of Theorem 3 together with the conditions $A_1^{i_1}\cdots A_n^{i_n} w_j(0) \in D$ for $j \in \{0,\cdots,n-1\}$, $i_k \geqq 0$, and $\sum_{k=1}^{n} i_k \leqq n-1$. The details of the induction proof can be safely omitted. □

3. Four simple examples.

Example 1. Let A generate a (C_0) semigroup on X and let $0<\beta_1<\beta_2\cdots<\beta_n$. Set $A_j=\beta_j A$ for $j=1,\cdots,n$. Then Theorem 4 applies provided

$$R^\infty(A) \cap C^\infty(A)$$

is dense in X, where $R^\infty(A)=\bigcap_{n=1}^{\infty}\operatorname{Ran}(A^n)$.

Example 2. This provides an illustration of Example 1.

In Example 1 take X to be a complex Hilbert space and take $A=iH$ where H is a spectrally absolutely continuous self-adjoint operator on X. (Cf., e.g., Kato [8].) Then, by the spectral theorem (a unitarily equivalent representation of) A acts as multiplication by the identity function on $\bigoplus_{\alpha\in J} L^2(\mathbb{R}, \nu_\alpha(x)\,dx)$, where $0 \leqq \nu_\alpha \in L^1_{\text{loc}}(\mathbb{R})$ for each $\alpha \in J$, i.e.

$$A\left(\bigoplus_\alpha f_\alpha(x_\alpha)\right)=\bigoplus_\alpha x_\alpha f_\alpha(x_\alpha) \qquad (x_\alpha \in \mathbb{R},\ \alpha \in J).$$

The set

$$D=\left\{\bigoplus_\alpha f_\alpha : f_\alpha \in C_c^\infty(\mathbb{R}\backslash\{0\}) \text{ for each } \alpha \in J\right\}$$

is a subspace of $C^\infty(A) \cap R^\infty(A)$ and is dense for X. Thus by Example 1, Theorem 4 applies in this case.

A special case is the wave equation in free space: $u_{tt}=\Delta u$ where Δ acts on $L^2(\mathbb{R}^n)$. When $n=1$, we can show that Theorem 4 applies to the wave equation $u_{tt}=u_{xx}$ in $L^p(\mathbb{R})$, $1\leqq p<\infty$ and in $BUC(\mathbb{R})$, the bounded uniformly continuous functions in the supremum norm.

Example 3. The equation

$$\left(\frac{d^2}{dt^2}-\alpha^2\Delta\right)\left(\frac{d^2}{dt^2}-\beta^2\Delta\right)u(t)=0$$

in $X=L^2(\mathbb{R}^n)$ is satisfied by the shear and pressure waves in linear elasticity in free space. This is a fourth order equation covered by the analysis of Example 2, provided that α and β are distinct positive constants. The equation has the form $\prod_{j=1}^4 (d/dt-ic_jA)u(t)=0$, where $A=(-\Delta)^{1/2}$, $c_1=-c_2=\alpha$, $c_3=-c_4=\beta$.

Example 4. In the set up of Example 3 introduce a nonnegative potential $V\in L^p(\mathbb{R}^n)+L^\infty(\mathbb{R}^n)$, where $p\geqq 2$, $p\geqq n/2$. Then the fourth order equation

$$\left(\frac{d^2}{dt^2}-\alpha(\Delta-V(x))\right)\left(\frac{d^2}{dt^2}-\beta(\Delta-V(x))\right)u(t,x)=0$$

is covered by Theorem 4.

4. The abstract telegraph equation. Consider the dissipative wave equation or abstract telegraph equation

$$\frac{d^2u}{dt^2}+2b\frac{du}{dt}+H^2u=0, \tag{3}$$

where H is a spectrally absolutely continuous self-adjoint operator on a complex Hilbert space X. Define the kinetic and potential energies of a solution u at time t to be

$$K(t)=\|u'(t)\|^2, \qquad P(t)=\|Hu(t)\|^2.$$

When $b=0$, total energy is conserved $(E(t)=K(t)+P(t)=E(0))$ and energy is equipartitioned $(K(t), P(t)\to E(0)/2$ as $t\to\infty)$. When $b>0$, $E(t)$ decays to zero, but nevertheless a weak form of equipartition of energy was established by Goldstein and Rosencrans [3], who showed that $0<\liminf_{t\to\infty} K(t)/P(t)\leqq \limsup_{t\to\infty} K(t)/P(t)<\infty$, provided that $0\in\rho(H)$ and b is sufficiently small. With the aid of the abstract d'Alembert formula this result will be sharpened substantially.

THEOREM 5. *Let H be a spectrally absolutely continuous self-adjoint operator on a complex Hilbert space X and suppose $H^2\geqq\alpha^2I$. Let $0<b<\alpha$. Then every nonzero solution of* (3) *admits sharp equipartition of energy in the sense that*

$$\lim_{t\to\infty} K(t)/P(t)=1.$$

Proof. The operator $B=(H^2-b^2I)^{1/2}$ is specially absolutely continuous, and $C=iB$ generates a (C_0) unitary group which we denote by $\{T(t)=e^{tC}: t\in\mathbb{R}\}$. Equation (3) can be rewritten as

$$\left(\frac{d}{dt}-A_+\right)\left(\frac{d}{dt}-A_-\right)u=0,$$

where

$$A_\pm=-bI\pm C.$$

Thus by Theorem 2, every solution of (3) is of the form

$$u(t)=e^{-bt}(T(t)\phi+T(-t)\psi),$$

where $\phi, \psi \in \operatorname{Dom}(H)=\operatorname{Dom}(C)$. The kinetic and potential energies become

$$K(t)=e^{-2bt}\|A_+T(t)\phi+A_-T(-t)\psi\|^2,$$

$$P(t)=e^{-2bt}\|H(T(t)\phi+T(-t)\psi)\|^2.$$

Consequently, by the law of cosines, the unitarity of $T(\pm t)$ and the Riemann-Lebesgue lemma, $\lim_{t\to\infty} K(t)/P(t)$ exists and equals

$$[\|A_+\phi\|^2+\|A_-\psi\|^2][\|H\phi\|^2+\|H\psi\|^2]^{-1}.$$

We let $x=H\phi$; then $y=H\psi$ yields

$$\lim_{t\to\infty} K(t)/P(t)=[\|A_+H^{-1}x\|^2+\|A_-H^{-1}y\|^2][\|x\|^2+\|y\|^2]^{-1}.$$

But for each $z\in X$,

$$\|A_\pm H^{-1}z\|^2=\langle(-bI\pm C)H^{-1}z, (-bI\pm C)H^{-1}z\rangle$$

$$=\langle(b^2I-C^2)H^{-2}z, z\rangle$$

since $H^*=H$, $C^*=-C$, and $[H, C]=0$

$$=\langle(b^2I-(b^2I-H^2))H^{-2}z, z\rangle=\|z\|^2,$$

whence

$$\lim_{t\to\infty} K(t)/P(t)=1. \qquad \square$$

Remarks. Many cases of equipartition of energy from a finite time onward are known. By this we mean that, for $\{T(t)\colon t\in\mathbb{R}\}$ a (C_0) unitary group and for D a suitable dense subset of $X, x, y\in D$ implies that there exists a $\tau=\tau(x,y)>0$ such that $\operatorname{Re}\langle T(t)x, y\rangle=0$ for $|t|>\tau$. When $\{e^{tC}\}$ satisfies this condition we get

$$K(t)=P(t)=\tfrac{1}{2}e^{-2bt}$$

for $t>\tau=\tau_1(\phi,\psi)$ for suitable data ϕ and ψ.

Let the notation and assumptions of Theorem 5 hold. The function $v(t)=e^{bt}u(t)$ satisfies

$$v''+(H^2-b^2I)v=0.$$

If we let $K_v(t)=\|v'(t)\|^2$, $P_v(t)=\|(H^2-b^2I)^{1/2}v(t)\|^2$, then $K_v(t)/P_v(t)\to 1$ as $t\to\infty$ for each v corresponding to nonzero initial data. By combining calculations involving K_v, P_v with those involving K and P, we can conclude that (for H absolutely continuous and $H\geqq\alpha^2I$, $\alpha>b>0$)

$$\lim_{t\to\infty}\frac{\operatorname{Re}\langle u'(t), u(t)\rangle+b\|u(t)\|^2}{\|Hu(t)\|^2}=0.$$

In particular,

$$\limsup_{t\to\infty}\frac{\operatorname{Re}\langle u'(t), u(t)\rangle}{\|u'(t)\|^2}\leqq 0$$

for all nonzero solutions u of (3).

5. A "damped" wave equation. Let H be a spectrally absolutely continuous self-adjoint operator on a Hilbert space X. Of concern is the "damped" wave equation

$$\frac{d^2u}{dt^2}+2ibH\frac{du}{dt}+H^2u=0, \tag{4}$$

which differs from (3) by the presence of iH in the "friction" term. The $\sqrt{-1}$ factor makes the first order term simply a perturbation and not really a friction term. We let b be any real number and we make as initial data

$$u(0)=u_0\in \mathrm{Dom}\,(H), \qquad u'(0)=u_1\in X. \tag{5}$$

Let $c=(b^2+1)^{1/2}$.

THEOREM 6. *The limit* $L=\lim_{t\to\infty} K(t)/P(t)$ *exists and satisfies*

$$(c-|b|)^2\leqq L\leqq(c+|b|)^2.$$

Furthermore $L\to 1$ *as* $b\to 0$, *and the bounds for* L *are best possible.*

Proof. Let $A_\pm=(-b\pm c)iH$ and let $\{T_\pm(t)=\exp(tA_\pm): t\in\mathbb{R}\}$ be the corresponding (C_0) unitary groups. Then (4) factors as

$$\left(\frac{d}{dt}-A_+\right)\left(\frac{d}{dt}-A_-\right)u=0.$$

By Example 2, the solution to (4), (5) is

$$u(t)=T_+(t)\phi_++T_-(t)\phi_-,$$

where $\phi_\pm\in\mathrm{Dom}(H)$ and

$$H\phi_\pm=2^{-1}[Hu_0\pm c^{-1}(-iu_1+bHu_0)].$$

The kinetic and potential energies are

$$K(t)=\|u'(t)\|^2=\|(-b+c)T_+(t)H\phi_++(-b-c)T_-(t)H\phi_-\|^2,$$
$$P(t)=\|Hu(t)\|^2=\|T_+(t)H\phi_++T_-(t)H\phi_-\|^2.$$

As usual we expand by the law of cosines and employ the unitarity of $T_\pm(t)$ and the Riemann-Lebesgue lemma. The conclusion is that the limit L of $K(t)/P(t)$ as $t\to\infty$ exists and equals

$$L=[(c-b)^2\|H\phi_+\|^2+(b+c)^2\|H\phi_-\|^2][\|H\phi_+\|^2+\|H\phi_-\|^2]^{-1}.$$

Letting $x=\|H\phi_+\|^2$ and $y=\|H\phi_-\|^2$ it follows that L is constant on the lines $y=ax$ in the first quadrant, $0\leqq a\leqq\infty$. (Here $a=\infty$ refers to the line $x=0$.) Think of $L=L(a)$ as a function of $a\in[0,\infty]$. Then $L(a)=[(c-b)^2+(b+c)^2a^2][1+a^2]^{-1}$, $L(0)=(c-b)^2$, $L(\infty)=(b+c)^2$. Since $dL/da=8abc[1+a^2]^{-2}$ it follows that L is increasing in a (resp. decreasing in a) for $b>0$ (resp. $b<0$). Consequently L attains its maximum and minimum on the set $\{0,\infty\}$. That is,

$$(c-|b|)^2\leqq L\leqq(c+|b|)^2. \tag{6}$$

Note that $(c\pm|b|)^2\to 1$ as $b\to 0$. Taking $u_1=-iH(c+b)u_0$ we get $H\phi_+=0$ and $L=(b+c)^2$, while taking $u_1=i(c-b)Hu_0$ gives $H\phi_-=0$ and $L=(b-c)^2$. Thus (6) is sharp. □

The results of this section and the previous section can be unified by considering the equation

$$u''+2Bu'+H^2u=0,$$

where H is a spectrally absolutely continuous self-adjoint operator on a Hilbert space X and $B=b_1I+ib_2H$ where b_1, b_2 are real constants. We omit the details.

The change of variables $v(t)=e^{ibtH}u(t)$ converts (4) into

$$\frac{d^2v}{dt^2}+(1+b^2)H^2v=0$$

which admits equipartition of energy using different notions of potential and kinetic energies than those used in Theorem 6.

6. Equipartition of energy for *n*th order equations. In [6] we characterized equipartition of energy for a large class of abstract Cauchy problems of order 2^m. The theorem and methods of [6] appeared to subsume all of the literature on equipartition of energy for higher order abstract Cauchy problems that we knew of except for the interesting result of Mochizuki [11], who treated a special equation of order $2m$ and got sharp results. In this section we show how Mochizuki's result and more general results for arbitrary order equations follow from Theorem 4.

We then compare his results with ours for fourth order equations of which

$$\left(\frac{d^2}{dt^2}-\alpha^2\Delta\right)\left(\frac{d^2}{dt^2}-\beta^2\Delta\right)u=0,$$

where $\alpha\neq\beta$, is an example. This particular equation arises in the study of linear elasticity. (See Example 3 in § 3.)

Let H be a spectrally absolutely continuous self-adjoint operator acting on a complex Hilbert space X. Consider the nth order equation

$$\prod_{j=1}^{n}\left(\frac{d}{dt}-i\beta_jH\right)u(t)=0 \quad (t\in\mathbb{R}), \tag{7}$$

where $\{\beta_1,\cdots,\beta_n\}$ is a set of n distinct real numbers. Let $T_j=\{T_j(t)=\exp(it\beta_jH)\colon t\in\mathbb{R}\}$ be the (C_0) unitary group generated by $A_j=+i\beta_jH$. Then by Example 2, the initial value problem for (7) is well posed and every solution (in a dense set of solutions) of (7) has the form

$$u(t)=\sum_{j=1}^{n}T_j(t)\phi_j.$$

Assume $\phi_j\in\operatorname{Dom}(H^{n-1})$ for $j=1,\cdots,n$. Then

$$\lim_{t\to\pm\infty}\|H^{n-k-1}u^{(k)}(t)\|^2=\lim_{t\to\pm\infty}\left\|\sum_{j=1}^{n}(+i\beta_j)^kH^{n-1}T_j(t)\phi_j\right\|^2$$

$$=\sum_{j=1}^{n}\beta_j^{2k}\|H^{n-1}\phi_k\|^2$$

by the law of cosines and the Riemann-Lebesgue lemma. (Cf. the argument in [2] or [5].) If we define the jth partial energy to be

$$E_j(t)=\|H^{n-j-1}u^{(j)}(t)\|^2$$

and the total energy to be

$$E(t)=\sum_{j=0}^{n-1}E_j(t),$$

then $E_j(t)$ and $E(t)$ have limits as $t\to\pm\infty$, but $E(t)$ is not constant in general. (E is constant if $n=2$ and $\beta_2=-\beta_1$; this is the classical abstract wave equation.)

Now consider the abstract $2m$th order wave equation

$$\prod_{k=1}^{m}\left(\frac{d^2}{dt^2}+\beta_k^2H^2\right)u(t)=0 \qquad (t\in\mathbb{R}) \tag{8}$$

treated by Mochizuki [11]. Following Mochizuki we assume H is a spectrally absolutely continuous self-adjoint operator on X and that $0<\beta_1<\beta_2<\cdots<\beta_n$. Letting T_j be as above, we have (using Example 2) that every solution of (8) is of the form

$$u(t)=\sum_{j=1}^{m}(T_j(t)\phi_j+T_j(-t)\psi_j), \tag{9}$$

where $\phi_1,\cdots,\phi_m,\psi_1,\cdots,\psi_m\in\operatorname{Dom}(H^{2m-1})$. Define the $(k+1)$st partial energy of u to be

$$\begin{aligned}E_{k+1}(t)&=\|H^{2m-1-k}u^{(k)}(t)\|^2\\&=\left\|\sum_{j=1}^{m}(i\beta_j)^kH^{2m-1}(T_j(t)\phi_j+(-1)^kT_j(-t)\psi_j)\right\|^2\end{aligned}$$

for $k=0,1,\cdots,2m-1$. Then we deduce Mochizuki's asymptotic result, namely

$$\lim_{t\to\pm\infty}E_{k+1}(t)=\sum_{j=1}^{m}\beta_j^{2k}(\|H^{2m-1}\phi_j\|^2+\|H^{2m-1}\psi_j\|^2)$$

for $k=0,\cdots,2m-1$.

Remark 1. Finding ϕ_j and ψ_k in terms of the initial data is relatively easy linear algebra. In the case of (9) with $m=2$ we have, setting $u_j=u^{(j)}(0)$,

$$u_0=(\phi_1+\psi_1)+(\phi_2+\psi_2),\qquad u_1=iH[\beta_1(\phi_1-\psi_1)+\beta_2(\phi_2-\psi_2)],$$

$$u_2=-H^2[\beta_1^2(\phi_1-\psi_1)+\beta_2^2(\phi_2-\psi_2)],\qquad u_3=-iH^3[\beta_1^3(\phi_1-\psi_1)+\beta_2^3(\phi_2-\psi_2)].$$

Consequently

$$\phi_1=\chi_{1+},\quad \psi_1=\chi_{1-},\quad \phi_2=\chi_{2+},\quad \psi_2=\chi_{2-}$$

where

$$\chi_{1\pm}=\frac{[\beta_1x\pm y]}{[2\beta_1(\beta_1^2-\beta_2^2)]},\qquad \chi_{2\pm}=\frac{[\beta_2x\pm y]}{[2\beta_2(\beta_1^2-\beta_2^2)]},$$

$$x=u_0+H^{-2}u_2,\qquad y=-iH^{-1}u_1-iH^{-3}u_3.$$

By using the parallelogram law, we get the convergence of the above energies in terms of the initial data as

$$E_1(t)\to[2(\beta_2^2-\beta_1^2)]^{-1}\{(\beta_1^{-2}+\beta_2^{-2})\|H^3y\|^2+2\|H^3x\|^2\},$$

$$E_2(t)\to[2(\beta_2^2-\beta_1^2)]^{-1}\{2\|H^3y\|^2+(\beta_1^2+\beta_2^2)\|H^3x\|^2\},$$

$$E_3(t)\to[2(\beta_2^2-\beta_1^2)]^{-1}\{(\beta_1^2+\beta_2^2)\|H^3y\|^2+(\beta_1^4+\beta_2^4)\|H^3x\|^2\},$$

$$E_4(t)\to[2(\beta_2^2-\beta_1^2)]^{-1}\{(\beta_1^4+\beta_2^4)\|H^3y\|^2+(\beta_1^6+\beta_2^6)\|H^3x\|^2\}.$$

Remark 2. Let u be given by (9). Then $u(t)=\sum_{k=1}^{m}u_k(t)$, where u_k satisfies

$$\left(\frac{d^2}{dt^2}+\beta_k^2H^2\right)u_k=0.$$

Thus u is partitioned into m additive components, $u_k, k=1,\cdots,m$. We can define kinetic and potential energies as $K_k(t)=\|u_k'(t)\|^2$ and $P_k(t)=\|\beta_k H u_k(t)\|^2$; and then define partial energies as $\tilde{E}_k(t)\equiv K_k(t)+P_k(t)$. Let $\tilde{E}(t)=\sum_{k=1}^m \tilde{E}_k(t)$. Observe that we not only have conservation of energy, but that we have conservation of each partial energy since $\|u_k'(t)\|^2+\|\beta_k H u_k(t)\|^2\equiv \tilde{E}_k(t)=\tilde{E}_k(0)$. In addition, we have equipartition of the partial energies, that is,

$$\lim_{t\to\pm\infty} K_k(t)=\lim_{t\to\pm\infty} P_k(t)=2^{-1}\tilde{E}_k(0).$$

When $m=2$, an example of which is the equation of linear elasticity, this result implies that the solutions u is the sum of two waves (the shear wave and the pressure wave in the example), each of which conserves energy and is equipartitioned between kinetic energy and potential energy as $t\to\pm\infty$.

In Goldstein and Sandefur [6] we showed how (7) could be reduced to a first order system on X^n when $n=2^m$. This first order system is controlled by a unitary semigroup $\mathcal{T}(t)$. In particular, in the case of (7) with $m=2$, this first order system is

$$U'(t)=\mathcal{A}U(t), \tag{10}$$

where

$$\mathcal{A}=\begin{pmatrix} 0 & \alpha_1 & 0 & \alpha_2 \\ \alpha_1 & 0 & \alpha_2 & 0 \\ 0 & \alpha_2 & 0 & \alpha_1 \\ \alpha_2 & 0 & \alpha_1 & 0 \end{pmatrix} iH, \qquad U(t)=\begin{pmatrix} w_1(t) \\ w_2(t) \\ w_3(t) \\ w_4(t) \end{pmatrix},$$

$\alpha_1=2^{-1}(\beta_1+\beta_2)$ and $\alpha_2=2^{-1}(\beta_1-\beta_2)$.

By defining the energies as $\mathcal{E}(t)=\sum_{j=1}^n \|w_j(t)\|^2$, we showed that the total energy is conserved and that energy is equipartitioned in the sense that $\lim_{t\to\pm\infty}\|w_j(t)\|^2=2^{-n}\mathcal{E}(0)$, for $j=1,\cdots,n$.

In the case of (10), a straightforward calculation shows that

$$U(t)=\begin{pmatrix} w_1(t) \\ w_2(t) \\ w_3(t) \\ w_4(t) \end{pmatrix}=\begin{pmatrix} \alpha_2 iH[u''(t)-\beta_1\beta_2H^2u] \\ \alpha_1 iH[u''(t)-\beta_1\beta_2H^2u] \\ -2\alpha_1\alpha_2H^2u'(t) \\ u'''(t)+2^{-1}(\beta_1^2+\beta_2^2)H^2u'(t) \end{pmatrix} \tag{11}$$

is a solution to (10). By our d'Alembert formula, we know that $u=u_1+u_2$, where u_j satisfies $u_j''+\beta_j^2H^2u_j=0$, $j=1,2$. Making this substitution into (11) we get

$$U(t)=-2H^2\alpha_1\alpha_2\begin{pmatrix} i\beta_1Hu_1+i\beta_2Hu_2 \\ i\beta_1Hu_1-i\beta_2Hu_2 \\ u_1'+u_2' \\ u_1'-u_2' \end{pmatrix}.$$

Since $\|i\beta_jHu_j\|^2=P_j(t)$ and $\|u_j'\|^2=K_j(t), j=1,2$, we see, from Remark 2, polarization, and the Riemann-Lebesgue lemma, why the components, $\|w_j\|^2$, are equipartitioned for $j=1,\cdots,4$.

In addition, observe that the two waves, u_1 and u_2, are such that $\langle u_1, u_2\rangle\to 0$ as $t\to\pm\infty$.

In the general case of $n=2^m$ in (7), using d'Alembert's formula to write the solution of (7) as

$$u(t)=\sum_{j=1}^{n} T_j(t)\phi_k,$$

where the ϕ_k depend on the initial data, we can show (after tedius calculations) that each component, w_k, of the first order system is of the form

$$w_k(t) = \sum_{j=1}^{n} a_{jk} T_j(t)\psi_j,$$

where $a_{jk} = 0$ or 1, and $\{\psi_j\}$ depends on $\{\phi_j\}$ but not on k. In the case of (11), knowing that $u_j = T_j(t)\phi_j + T_j(-t)\psi_j$, $j = 1, 2$, we have that

$$U(t) = \begin{pmatrix} T_1(t)\phi_1^* + T_1(-t)\psi_1^* + T_2(t)\phi_2^* + T_2(-t)\psi_2^* \\ T_1(t)\phi_1^* + T_1(-t)\psi_1^* - T_2(t)\phi_2^* - T_2(-t)\psi_2^* \\ T_1(t)\phi_1^* - T_1(-t)\psi_1^* + T_2(t)\phi_2^* - T_2(-t)\psi_2^* \\ T_1(t)\phi_1^* - T_1(-t)\psi_1^* - T_2(t)\phi_2^* + T_2(-t)\psi_2^* \end{pmatrix},$$

where $\phi_j^* = -2i\beta_j H^3\phi_j$ and $\psi_j^* = -2i\beta_j H^3\psi_j$, $j = 1, 2$.

Using polarization and the Riemann-Lebesgue lemma, it can be seen in the general case that $\lim_{t\to\infty} \|w_k(t)\|^2 = c$, c being independent of k, $k = 1, \cdots, n = 2^m$. By conservation of energy, $c = n^{-1}\mathscr{E}(0)$, and we again see that the 2^m system exhibits equipartition of energy.

7. Applications to scattering theory. Let A_0, A_1 generate (C_0) semigroups on X. We define the *subspace of asymptotic equivalence* X_{ae} for the ordered pair (A_0, A_1) to consist of all $f \in X$ for which there is a vector $f_+ \in X$ such that $\|T_0(t)f_+ - T_1(t)f\| \to 0$ as $t \to \infty$, where T_j is the semigroup generated by A_j.

If A_0, A_1 generate (C_0) groups T_0, T_1 on X, let X_{ae}^+, X_{ae}^- denote, respectively, the subspaces of asymptotic equivalence for the pairs (A_0, A_1) and $(-A_0, -A_1)$. We say that the *scattering problem for* $(A_0\ A_1)$ *admits completeness* provided

(i) $X_{ae}^+ = X_{ae}^-$;

(ii) For each $g \in X$ there are vectors $g_\pm \in X_{ae}^\pm$ such that

$$\|T_1(t)g_+ - T_0(t)g\| + \|T_1(-t)g_- - T_0(-t)g\| \to 0 \quad \text{as } t \to \infty.$$

Suppose that A_0, A_1 are skew-adjoint operators on a Hilbert space X with iA_0 spectrally absolutely continuous. Let $H_j = iA_j$ for $j = 0, 1$. Then the scattering problem for (A_0, A_1) admits completeness if and only if the wave operators for the pair (H_0, H_1) exist and are complete (in the sense described in Kato's book [8]). In this case the scattering operator exists and is unitary, and $X_{ae}^\pm$ can be identified with the absolutely continuous subspace for H_1.

We can identify the semigroup T_j with the first order differential equation $u' = A_j u$ for X-valued functions on $\mathbb{R}$. The definitions given above extend to more general situations; we proceed rather informally. For $j = 0, 1$ let $(\mathrm{DE})_j$ be a linear ordinary differential equation for functions from $\mathbb{R}$ to X. We say that *the scattering problem for the pair* $(\mathrm{DE})_0$, $(\mathrm{DE})_1$ *admits completeness* provided the following two conditions hold:

(I) There is a space X_{ae} of continuous functions from $\mathbb{R}$ to X such that for every solution u_1 of $(\mathrm{DE})_1$ in X_{ae} there is a solution $u_\pm$ of $(\mathrm{DE})_0$ such that $\|u_1(t) - u_\pm(t)\| \to 0$ as $t \to \pm\infty$.

(II) For every solution u_0 of $(\mathrm{DE})_0$ there are solutions $u_\pm$ of $(\mathrm{DE})_1$ in X_{ae} such that

$$\|u_+(t) - u_0(t)\| + \|u_-(-t) - u_0(-t)\| \to 0 \quad \text{as } t \to \infty.$$

If we topologize the solution spaces of well-posed initial value problems by using suitable norm (or graph) topologies on the spaces of initial data, then we can extend the above definition (of completeness) to the context of a dense set of solutions.

Now suppose $(A_1^{(0)}, \cdots, A_n^{(0)})$, $(A_1^{(1)}, \cdots, A_n^{(1)})$ are two commuting families of infinitesimal generators of (C_0) groups on X, that is, let Hypothesis (H1) hold for $\{A_i^{(j)}: i=1, \cdots, n\}$ with $j=0, 1$. Assume that the scattering problem for the pair $(A_i^{(0)}, A_i^{(1)})$ admits completeness for $i=1, \cdots, n$. Finally assume $0 \in \rho(A_i^{(j)} - A_k^{(j)})$ for $i \neq k$ and $j=0, 1$. Then for $j=0, 1$, every solution of $\prod_{i=1}^n (d/dt - A_i^{(j)})u_j(t) = 0$ is of the form

$$u_j(t) = \sum_{i=1}^n \exp\{tA_i^{(j)}\}f_{ij}$$

by Theorem 2. (Similarly we could weaken the hypothesis that $0 \in \rho(A_i^{(j)} - A_k^{(j)})$ and use Theorem 4 instead.) It follows that the scattering problem for the pair of equations $\prod_{i=1}^n (d/dt - A_i^{(0)})u = 0$, $\prod_{i=1}^n (d/dt - A_i^{(1)})u = 0$ admits completeness.

Usually scattering theory for second order or higher order equations is developed by writing the equations as first order systems and using the standard results of scattering theory including the invariance principle and other tools (cf., e.g., Kato [9]). The abstract d'Alembert formula gives an alternate approach to these problems. The d'Alembert formula also enables one to extend in a natural and simple way the notions of scattering theory from the context of isometric groups and Hilbert space to the context of semigroups and Banach spaces.

We close with three simple examples of pairs of equations for which the scattering problem admits completeness. Let q be a real integrable C^∞ function on $\mathbb{R}$. Take $X = L^2(\mathbb{R})$ and

$$A_1^{(0)} = \frac{d}{dx}, \qquad A_2^{(0)} = -A_1^{(0)},$$

$$A_1^{(1)} = \frac{d}{dx} + iq(x), \qquad A_2^{(1)} = -A_1^{(1)}.$$

The corresponding differential equations are

$$(\mathrm{DE})_0 \qquad \frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2},$$

$$(\mathrm{DE})_1 \qquad \frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2} + 2iq(x)\frac{\partial u}{\partial x} + (iq'(x) - q^2(x))u.$$

For the second example take $X = L^2(\mathbb{R}^2)$,

$$A_1^{(0)} = -A_2^{(0)} = i(-\Delta)^{1/2},$$
$$A_1^{(1)} = -A_2^{(1)} = i(-\Delta + V(x))^{1/2},$$

where V is a nonnegative function in $L^p(\mathbb{R}^n) + L^\infty(\mathbb{R}^n)$ with $p \geqq 2$, $p > n/2$ and such that $V(x) = O(|x|^{-1-\varepsilon})$ for some $\varepsilon > 0$ as $|x| \to \infty$.

The final example seems not to have been treated in the literature before. Take $X = L^2(\mathbb{R}^2)$,

$$A_1^{(0)} = -A_2^{(0)} = \alpha i(-\Delta)^{1/2}, \qquad A_3^{(0)} = -A_4^{(0)} = \beta i(-\Delta)^{1/2},$$
$$A_1^{(1)} = -A_2^{(1)} = \alpha i(-\Delta + V)^{1/2}, \qquad A_3^{(1)} = -A_4^{(1)} = \beta i(-\Delta + V)^{1/2}.$$

Thus, with the aid of the Birman-Kato invariance principle, the scattering problem for the fourth order elastic wave equation with a potential term $V(x)$ (cf. Example 4 of § 3) reduces to the scattering problem for the Schrödinger equation with the same potential.

GENERATION OF ANALYTIC SEMIGROUPS BY ELLIPTIC OPERATORS WITH UNBOUNDED COEFFICIENTS*

PIERMARCO CANNARSA† AND VINCENZO VESPRI‡

Abstract. Strongly elliptic differential operators with (possibly) unbounded lower order coefficients are shown to generate analytic semigroups of linear operators on $L^2(R^N)$, $L^{2,\mu}(R^N)$, $C(R^N)$ and $C^\alpha(R^N)$. Some of these generation results are applied to parabolic initial value problems.

Key words. analytic semigroups, elliptic operators, unbounded coefficients

AMS(MOS) subject classifications. 47D05, 47505

Introduction. A number of papers has been devoted to studying the generation of analytic semigroups by elliptic operators in unbounded domains $\Omega \subset R^N$ (see, e.g. [9], [22], [21], [28], [29]). Authors, however, have usually concentrated their attention on operators with bounded coefficients.

In this paper we consider strongly elliptic operators of second order, E, with coefficients defined on R^N and allowed to grow at infinity in accordance with suitable structure conditions. Such conditions are exactly the ones we need for the applications in which we are interested.

We prove that E generates an analytic semigroup of linear operators in various Banach spaces, such as $L^2(R^N)$, $L^{2,\mu}(R^N)$, $C(R^N)$ and $C^\alpha(R^N)$ (see § 1 for a detailed description of these results). Furthermore, all these results are obtained by the same method.

It has to be noted that we have confined ourselves to the case of second order operators defined in the whole space for the sake of simplicity and also because this is what we need for the applications we have in mind. Our method may be extended to more general situations (for example, Dirichlet boundary conditions may be treated by adapting the boundary analysis of [14]). In fact, we use $\mathscr{L}^{2,\lambda}$-regularity techniques which also apply to solutions of elliptic systems of equations.

The main applications of our results concern the initial value problem for parabolic equations with unbounded coefficients. Although such equations have been studied for a long time (see, e.g. [23], [24], [3], [4], [8], [7]), interest in this topic has increased since connections with stochastic control and filtering theory were pointed out ([6], [20], [5]). While earlier treatments were mainly based on fundamental solutions, more recent ones have also developed different approaches, using dynamic programming [20], semigroup theory [18] or the Feynman-Kac formula [27].

In § 7 of this paper we obtain the existence, uniqueness and regularity of solutions to the Cauchy problem for second order parabolic operators with unbounded coefficients, as a consequence of the generation theorems proved in §§ 2-6. The results of these sections are applied to a class of stochastic partial differential equations in [16].

Part of the contents of this paper was announced by the authors in [13] and [30].

1. Notation and main results. We denote by $\|x\|$ (resp. $\|z\|$) the Euclidean norm of a point $x \in R^N$ (resp. $z \in C^N$). For any $x \in R^N$ and $r > 0$ we define

$$B_r(x) = \{y \in R^N: \|y - x\| < r\}.$$

For any $j = 1, \cdots, N$ and any multi-index $\beta = (\beta_1, \cdots, \beta_N)$ we set

$$D_j = \partial/\partial x_j, \qquad D^\beta = D_1^{\beta_1} \cdots D_N^{\beta_N}.$$

Let Ω be an open domain in R^N. We denote by $C(\Omega)$ the space of uniformly continuous and bounded complex-valued functions defined in Ω. We set $|u|_{0,\infty,\Omega} = \sup_{x \in \Omega} |u(x)|$ for any $u \in C(\Omega)$. Moreover, for any integer $m > 0$, we define $C^m(\Omega) = \{u \in C(\Omega): D^\beta u \in C(\Omega) \text{ for } |\beta| \leqq m\}$ and $|u|_{j,\infty,\Omega} = \sum_{|\beta|=j} |D^\beta u|_{0,\infty,\Omega}$ for $0 \leqq j \leqq m$.

In this paper we consider second order differential operators of the form

$$E = \sum_{i,j=1}^{N} a_{ij}(x) D_i D_j + \sum_{j=1}^{N} b_j(x) D_j - c(x) \tag{1.1}$$

where a_{ij}, b_j, c $(i, j = 1, \cdots, N)$ are complex-valued functions defined in R^N. We will always assume that E is strongly elliptic, i.e.,

$$\operatorname{Re} \sum_{i,j} a_{ij}(x) z_j \bar{z}_i \geqq \nu \|z\|^2 \quad \forall z \in C^N \tag{1.2}$$

for any $x \in R^N$ and some $\nu > 0$. The growth of the coefficients of E will be referred to a given function $V: R^N \to R$ such that for any $x \in R^N$ and any $y \in R^N$ with $\|x - y\| \leqq 1$

$$\begin{array}{ll} \text{(i)} & V(x) \geqq 1, \\ \text{(ii)} & |V(x) - V(y)| \leqq k\|x - y\|[V(x) + V(y)] \quad \text{for some } k > 0. \end{array} \tag{1.3}$$

More precisely, we will impose the following assumptions:

There exist constants $K_1, K_2, V_0 > 0$ *such that*

$$K_1 V(x) - V_0 \leqq \operatorname{Re} c(x) \leqq K_2 V(x) + V_0 \quad \forall x \in R^N. \tag{1.4}$$

There exists a constant $B \in [0, 2]$ *such that*

$$\sum |b_j(x)|^2 \leqq \nu B^2 K_1 V(x) \quad \forall x \in R^N, \tag{1.5}$$

$$a_{ij},\ b_j/V^{1/2},\ c/V \in C(R^N) \quad \text{for } i, j = 1, \cdots, N. \tag{1.6}$$

Since the top order coefficients are assumed to be bounded, this framework is roughly comprable with the one of [6, pp. 108–117]. Condition (1.4) is similar to one of the hypotheses of [23]. However, here we need no differentiability assumptions on the coefficients of E. Moreover, condition (1.5) only affects the asymptotic behavior of coefficients b_j.

Remark 1.1. From assumption (1.3)(ii) it follows that there exists a constant $k > 0$ such that

$$V(x) \leqq k V(y) \quad \text{if } \|x - y\| \leqq 1. \tag{1.7}$$

We begin by analyzing the spectral properties of operator E when realized in $L^2(R^N)$. Let Ω be an open domain in R^N and m a nonnegative integer. We denote by $H^m(\Omega)$ the space of the complex-valued functions u, defined in Ω, which belong to $L^2(\Omega)$ together with all their partial derivatives of orders $|\beta| \leqq m$. We define

$$|u|_{0,\Omega} = \left(\int_\Omega |u(x)|^2 \, dx \right)^{1/2}, \qquad |u|_{j,\Omega} = \left(\sum_{|\alpha|=j} |D^\alpha u|_{0,\Omega}^2 \right)^{1/2}$$

for $1 \leqq j \leqq m$. Moreover, we denote by $H^m_{\mathrm{loc}}(\Omega)$ the space of functions $u \in H^m(D)$ for any domain D with compact closure in Ω.

Since the coefficients of E may grow at infinity, we need weighted spaces rather than the usual Sobolev spaces $H^m(\Omega)$. For $j = 1, 2$ we denote by $H^j(\Omega, V)$ the space of functions $u \in H^j(\Omega)$ such that

$$\|u\|^2_{j,\Omega,V} = \sum_{|\beta| \leqq j} \int_\Omega V^{j-|\beta|} |D^\beta u|^2 \, dx < +\infty.$$

Extending the method [14, § 3], in § 2 of this paper we prove the following result.

THEOREM 1.2. *Assume* (1.2)-(1.6). *There exists a number* $\omega_1 \geqq V_0$ *such that, if* λ *is a complex number with* $\operatorname{Re} \lambda \geqq \omega_1$ *then the equation* $(\lambda - E)u = f \in L^2(R^N)$ *has a unique solution* $u \in H^2(R^N, V)$ *and*

$$\|u\|_{2,R^N,V} + |\lambda - \omega_1|^{1/2} \|u\|_{1,R^N,V} + |\lambda - \omega_1| \, |u|_{0,R^N} \leqq k |f|_{0,R^N} \tag{1.8}$$

where k is a constant independent of λ.

The previous result can also be extended to more general weighted spaces (see § 2 for details).

For $0 \leqq \mu \leqq N$ we denote by $L^{2,\mu}(\Omega)$ the space of functions u $L^2_{\mathrm{loc}}(\Omega)$ such that

$$|u|^2_{L^{2,\mu}(\Omega)} = \sup_{x \in \Omega, 0 < r \leqq 1} r^{-\mu} \int_{\Omega \cap B_r(x)} |u(y)|^2 \, dy < +\infty.$$

Morrey spaces $L^{2,\mu}(\Omega)$ are useful to study the regularity of solutions to elliptic problems (see e.g. [10]).

In § 4 we show that E generates an analytic semigroup on the Banach space $L^2(R^N) \cap L^{2,\mu}(R^N)$, equipped with the norm

$$\|u\|_{0,\mu,R^N} = |u|_{0,R^N} + |u|_{L^{2,\mu}(R^N)}.$$

For $j = 1, 2$ let us denote by $H^{j,\mu}(\Omega, V)$ the space of function $u \in H^j(\Omega, V)$ such that

$$|u|^2_{H^{j,\mu}(\Omega,V)} = \sum_{|\beta| \leqq j} |V^{(j-|\beta|)/2} D^\beta u|^2_{L^{2,\mu}(\Omega)} < +\infty$$

and set

$$\|u\|_{H^{j,\mu}(\Omega,V)} = \|u\|_{j,\Omega,V} + |u|_{H^{j,\mu}(\Omega,V)}.$$

THEOREM 1.3. *Assume* (1.2)-(1.6) *and let* $\lambda \in C$ *with* $\operatorname{Re} \lambda \geqq \omega_1$. *Then the equation*

$$(\lambda - E)u = f \in L^2(R^N) \cap L^{2,\mu}(R^N), \qquad 0 < \mu < N$$

has a unique solution $u \in H^{2,\mu}(R^N, V)$ *and*

$$\|u\|_{H^{2,\mu}(R^N,V)} + |\lambda - \omega_1|^{1/2} \|u\|_{H^{1,\mu}(R^N,V)} + |\lambda - \omega_1| \, \|u\|_{0,\mu,R^N} \leqq k \|f\|_{0,\mu,R^N} \tag{1.9}$$

where k is a constant independent of λ.

See [14, § 5] for a similar result in the case of bounded space domains.

In [14, § 6], generation on Morrey spaces is used to derive the uniform estimate obtained by Stewart [28], [29]. Stewart's method consists in bounding suitable localizations of solutions by classical L^p estimates [2] and applies to elliptic operators of arbitrary order with bounded coefficients. The analogue of Stewart's results for operators with unbounded coefficients is stated below and will be proved in § 5.

THEOREM 1.4. *Assume* (1.2)-(1.6). *There exists* $\omega_2 \geqq \omega_1$ *such that, if* λ *is a complex number with* $\operatorname{Re} \lambda \geqq \omega_2$, *then the equation* $(\lambda - E)u = f\, L^\infty(R^N)$ *has a unique solution* $u \in H^2_{\text{loc}}(R^N) \cap C^1(R^N)$ *satisfying* $|V^{1/2}u|_{0,\infty,R^N} < +\infty$. *Moreover*

$$|\lambda - \omega_2|^{1/2}[|u|_{1,\infty,R^N} + |V^{1/2}u|_{0,\infty,R^N}] + |\lambda - \omega_2| \cdot |u|_{0,\infty,R^N} \leqq k|f|_{0,\infty} \tag{1.10}$$

where k is a constant independent of λ.

Finally, we turn to the last topology we shall consider in this paper, namely Hölder topology. For $0 < \alpha < 1$ we denote by $C^\alpha(\Omega)$ the space of functions $u \in C(\Omega)$ such that

$$[u]_{\alpha,\Omega} = \sup_{x,y\Omega, x \neq y} \frac{|u(x) - u(y)|}{\|x - y\|^\alpha} < +\infty.$$

The Hölder norm is defined as follows:

$$\|u\|_{\alpha,\Omega} = |u|_{0,\infty,\Omega} + [u]_{\alpha,\Omega}.$$

Generation of analytic semigroups in Hölder spaces was first obtained by Campanato [12] in bounded space domains (see also [14, § 7] for the case of systems). A different procedure leading to an analogous generation theorem was developed in [25]. This procedure is based on interpolation techniques and on Stewart's result [28], [29] and applies to operators with bounded coefficients. In this paper we treat operators with unbounded coefficients by adapting the method of [12].

For $j = 1, 2$ we denote by $C^j(\Omega, V)$ the space of functions $u \in C^j(\Omega)$ such that

$$\|u\|_{Cj(\Omega,V)} = \sum_{|\beta| \leqq j} |V^{(j-|\beta|)/2} D^\beta u|_{0,\infty,\Omega} < \infty.$$

For $0 < \alpha < 1$ we set

$$C^{j,\alpha}(\Omega, V) = \{u \in C^j(\Omega, V) : |u|_{C^{j,\alpha}(\Omega,V)} = \sum_{|\beta| \leqq j} [V^{(j-|\beta|)/2} D^\beta u]_{\alpha,\Omega} < \infty\}.$$

We equip $C^{j,\alpha}(\Omega, V)$ with the norm

$$\|u\|_{C^{j\alpha}(\Omega,V)} = \|u\|_{C^j(\Omega,V)} + |u|_{C^{j,\alpha}(\alpha,V)}.$$

THEOREM 1.5. *Assume* (1.2)-(1.5) *and suppose that*

$$a_{ij}, b_j / V^{1/2}, c/V \in C^\alpha(R^N) \quad \textit{for some } \alpha \in]0, 1[. \tag{1.11}$$

There exists $\omega_2 \in R$ *such that, if* λ *is a complex number with* $\operatorname{Re} \lambda \geqq \omega_2$, *then the equation* $(\lambda - E)u = f \in C^\alpha(R^N)$ *has a unique solution* $u \in C^{2,\alpha}(R^N, V)$ *and*

$$\|u\|_{C^{2,\alpha}(R^N,V)} + |\lambda - \omega_2|^{1/2} \|u\|_{C^{1,\alpha}(R^N,V)} + |\lambda - \omega_2| \cdot \|u\|_{\alpha,R^N} \leqq k\|f\|_{\alpha,R^N} \tag{1.12}$$

where k is a constant independent of λ

Therefore, E generates an analytic semigroup on $C^\alpha(R^N)$ with domain $C^{2,\alpha}(R^N, V)$. Our semigroup fails to be strongly continuous at 0 because $C^{2,\alpha}(R^N, V)$ is not dense in $C^\alpha(R^N)$. However, the closure $C^{2,\alpha}(R^N, V)$ of the domain of E can be characterized as follows. Let us set

$$C^\alpha_V(R^N) = \{u \in C^\alpha(R^N) : Vu \in C^\alpha(R^N)\},$$

$$C^\alpha_0(R^N) = \{u \in C^\alpha(R^N) : u \to 0 \quad \text{as } \|x\| \to \infty\}.$$

Then $\overline{C^{2,\alpha}(R^N, V)}$ consists of all functions $u \in C^\alpha_V(R^N) \cup C^\alpha_0(R^N)$ such that

$$\lim_{r \to 0} \left[\sup_{0 < \|x-y\| < r} \frac{|u(x) - u(y)|}{\|x - y\|^\alpha} \right] = 0.$$

This space, which is also known as the space of "little-Hölder continuous" functions (see [25]), will be denoted by $h^\alpha(R^N, V)$.

2. Generation in the L^2 topology. In this section we prove Theorem 1.2. As in [14, § 3], the proof consists of two steps. First, we obtain an estimate for divergence form elliptic operators (Lemma 2.1 below). Then, we approximate operator E by operators in divergence form and apply the contraction mapping theorem. Therefore, we have concentrated our exposition on what is new with respect to [14, § 3]. The remainder of the proof is just sketched.

Consider the operator

$$\mathscr{E} = \sum_{i,j=1}^{N} D_j(a_{ij}(x)D_j) + \sum b_j(x)D_j - c(x)$$

with measurable complex-valued coefficients satisfying (1.2), (1.4), (1.5) and

$$a_{ij},\ b_j/V^{1/2},\ c/V \in L^\infty(R^N), \qquad i,j = 1, \cdots, N. \tag{2.1}$$

Here V is a real-valued function satisfying (1.3). For $\lambda \in C$, $u \in H^1(R^N, V)$ and $\phi \in C^\infty(R^N)$ with compact support, let us set

$$a_\lambda(u, \phi) = \lambda \int_{R^N} u\bar{\phi}\,dx + \int_{R^N} \left[\sum_{i,j} a_{ij}D_j\overline{uD_i\phi} - \sum b_jD_ju\bar{\phi} + cu\bar{\phi}\right] dx.$$

Then, a_λ can be extended to a continuous sesquilinear form on $H^1(R^N, V) \times H^1(R^N, V)$. Moreover, α_λ is coercive for $\operatorname{Re}\lambda \geqq V_0$.

$$(Re\,\lambda - V_0)|u|^2_{0,R^N} + k\|u\|^2_{1,R^N,V} \leqq \operatorname{Re} a_\lambda(u, u) \quad \forall u \in H^1(R^N, V)$$

(from now on we denote by k any positive constant independent of λ). Therefore, by standard variational arguments we conclude that for $\operatorname{Re}\lambda \geqq V_0$ and $f \in L^2(R^N)$ the equation

$$a_\lambda(u, \phi) = \int_{R^N} f\bar{\phi}\,dx \quad \forall \phi \in H^1(R^N, V) \tag{2.2}$$

has a unique solution $u \in H^1(R^N, V)$ and

$$\|u\|^2_{1,R^N,V} \leqq k|f|_{0,R^N}|u|_{0,R^N}. \tag{2.3}$$

Moreover, from (2.3) one can easily get

$$|\lambda - V_0| \cdot |u|_{0,R^N} \leqq k|f|_{0,R^N} \tag{2.4}$$

and

$$|\lambda - V_0|^{1/2} \cdot \|u\|_{1,R^N,V} \leqq k|f|_{0,R^N}. \tag{2.5}$$

Now, if the coefficients of $\mathscr{E}$ are more regular, then u solves our equation a.e. as we show below.

LEMMA 2.1. *Let the coefficients of $\mathscr{E}$ be differentiable in R^N and satisfy, in addition to* (1.2), (1.4), (1.5), (2.1), *the following condition*:

$$|D_ha_{ij}|_{0,\infty,R^N} + |D_hb_j/V^{1/2}|_{0,\infty,R^N} + |D_hc/V|_{0,\infty,R^N} = K < +\infty \tag{2.6}$$

for any $h = 1, \cdots, N$. If $\operatorname{Re}\lambda \geqq V_0$, *then the solution u of equation $(\lambda - \mathscr{E})u = f \in L^2(R^N)$ is of class $H^2(R^n, V)$ and*

$$\|u\|_{2,R^N,V} \leqq \left(k_1 + \frac{k_2}{|\lambda - V_0|^{1/2}}\right)|f|_{0,R^N} \tag{2.7}$$

where both k_1 and k_2 are independent of λ and k_1 is independent of K.

Proof. Since $u \in H^2_{\mathrm{loc}}(R^N)$ by classical regularity results, in (2.2) we can choose $\phi = D_h\psi$, where $\psi \in C^\infty(R^N)$ with compact support. A simple integration by parts yields

$$\begin{aligned} a(D_hu, \psi) = &-\int_{R^N} f\overline{D_h\psi}\, dx - \int_{R^N} \sum_{ij} D_ha_{ij}D_ju\overline{D_i\psi}\, dx \\ &-\int_{R^N} \left(D_hcu - \sum_j D_hb_jD_ju \right) \bar{\psi}\, dx. \end{aligned} \tag{2.8}$$

Clearly, (2.8) holds for any $\psi \in H^1(R^N)$ with compact support.

Let θ be a standard cutoff function, i.e. $\theta \in C^\infty(R^N)$ and

$$\begin{aligned} &0 \leqq \theta \leqq 1, \qquad \theta(y) = 1 \quad \text{if } \|y\| \leqq 1, \\ &\theta(y) = 0 \quad \text{if } \|y\| \geqq 2 \end{aligned} \tag{2.9}$$

and set $\theta_r(x) = \theta(x/r)$ for any $r > 0$. By assuming $\psi = \theta_r^2 D_hu$ in (2.8) we obtain

$$a_\lambda(\theta_rD_hu, \theta_rD_hu) = F_r + G_r$$

where

$$F_r = \int_{R^N} \theta_rfD_h\theta_R\overline{D_hu}\, dx - \int_{R^N} \theta_rf\overline{D_h(\theta_rD_hu)}\, dx$$

and the remaining term G_r contains the derivatives of a_{ij}, b_j, c. Then

$$\|\theta_rD_hu\|^2_{1,R^N,V} \leqq k(|F_r| + |G_r|). \tag{2.10}$$

Now, from (1.4), (1.5), (2.1), (2.6) we obtain, for any $\varepsilon > 0$

$$|G_r| \leqq \varepsilon \|\theta_rD_hu\|^2_{1,R^N,V} + k(\varepsilon, K)\|u\|^2_{1,R^N,V}. \tag{2.11}$$

Moreover

$$|F_r| \leqq \varepsilon \|\theta_rD_hu\|^2_{1,R^N,V} + k(\varepsilon)|f|^2_{0,R^N}. \tag{2.12}$$

By choosing ε sufficiently small and letting r go to infinity, from (2.10), (2.11), (2.12) we get

$$\sum_h \|D_hu\|^2_{1,R^N,V} \leqq k|f|^2_{0,R^N} + k(K)\|u\|^2_{1,R^N,V}. \tag{2.13}$$

Therefore, equation $(\lambda - \mathscr{E})u = f$ is satisfied a.e. and

$$(c + V_0)u = f + (V_0 - V)u + \sum_{ij} (a_{ij}D_iD_ju + D_ia_{ij}D_ju) + \sum_j b_jD_ju.$$

Consequently, $u \in H^2(R^N, V)$ and

$$|Vu|_{0,R^N} \leqq |f|_{0,R^N} + |\lambda - V_0|\, |u|_{0,R^N} + k\sum_h \|D_u\|_{1,R^N,V} + k(K)\|u\|_{1,R^N,V}.$$

The desired estimate (2.7) may thus be derived from the last inequality and from (2.13), recalling (2.4) and (2.5).

We now turn to the case of an operator E of type (1.1).

Proof of Theorem 1.2. Suppose assumptions (1.2), (1.4) hold for the coefficients of E with constants ν, K_1, K_2, V_0, B and set

$$\sum_{ij} |a_{ij}|_{0,\infty,R^N} + \sum_j |b_j/V^{1/2}|_{0,\infty,R^N} + |C/V|_{0,\infty,R^N} = M. \tag{2.14}$$

Now, if $(J_\varepsilon)_{\varepsilon>0}$ is a standard family of mollifiers (i.e. $J_\varepsilon(x)=\varepsilon^{-n}J(x/\varepsilon)$, where $J\in C^\infty(R^N)$, $J\geqq 0$, $J(x)=0$ if $\|x\|\geqq 1$ and $\int_{R^N}J(x)\,dx=1$), let us set

$$E^\varepsilon=\sum a_{ij}^\varepsilon(x)D_iD_j+\sum b_j^\varepsilon(x)D_j-c^\varepsilon(x),\qquad x\in R^N,\quad \varepsilon>0.$$

Here, $g^\varepsilon(x)=\int_{R^N}J_\varepsilon(x-y)g(y)dy$ for any $g\in L^1_{\text{loc}}(R^N)$. It is easy to check that E^ε satisfy (1.2), (1.4), (2.15) with the same constants ν, K_1, K_2, V_0, B, M as above, replacing V by V^ε in each inequality. Moreover

$$|D_ha_{ij}^\varepsilon(x)|+|D_hD_sa_{ij}^\varepsilon(x)|+|D_hb_j^\varepsilon(x)/V^\varepsilon(x)^{1/2}|+|D_hc^\varepsilon(x)/V^\varepsilon(x)|\leqq K_\varepsilon<+\infty$$

for any $x\in R^N$, $\varepsilon>0$ and $1\leqq i,j,h,s\leqq N$. Also, E^ε approximates E as $\varepsilon\to 0$ in the sense that

$$(2.15)\quad |a_{ij}-a_{ij}^\varepsilon|_{0,\infty,R^N},\ \left|\frac{b_j-b_j^\varepsilon}{V^{\varepsilon^{1/2}}}\right|_{0,\infty,R^N},\ \left|\frac{c-c^\varepsilon}{V^\varepsilon}\right|_{0,\infty,R^N},\ \left|\frac{V-V^\varepsilon}{V^\varepsilon}\right|_{0,\infty,R^N}\to 0\quad \text{as } \varepsilon\to 0.$$

Therefore, the elliptic problems

$$\begin{cases}u\in H^2(R^N,V)\\(\lambda-E)u=f\end{cases}\quad\text{and}\quad\begin{cases}u\in H^2(R^N,V^\varepsilon)\\(\lambda-E^\varepsilon)u=f+(E-E^\varepsilon)u\end{cases}$$

are equivalent if ε is sufficiently small. Let us set

$$\mathscr{E}^\varepsilon=\sum_{ij}D_i(a_{ij}^\varepsilon D_j)+\sum\left(b_j^\varepsilon-\sum_i D_ia_{ij}^\varepsilon\right)D_j-c^\varepsilon.$$

By Lemma 2.1 we conclude that there exists V_0^ε such that for $\operatorname{Re}\lambda\geqq V_\varepsilon^0$ and $u\in H^2(R^N,V^\varepsilon)$ the equation

$$(\lambda-\mathscr{E}^\varepsilon)U=f+(E-E^\varepsilon)u$$

has a unique solution $U=T_{\lambda,\varepsilon}$, $u\in H^2(R^N,V^\varepsilon)$. Also, from (2.4), (2.5), (2.7), (2.15) we get

$$\begin{aligned}&\|T_{\lambda,\varepsilon}u\|_{2,R^N,V^\varepsilon}+|\lambda-V_0^\varepsilon|^{1/2}\cdot\|T_{\lambda,\varepsilon}u\|_{1,R^NV^\varepsilon}+|\lambda-V_0^\varepsilon|\cdot|T_{\lambda,\varepsilon}u|_{0,R^N}\\(2.16)\qquad&\leqq\left(k_1+\frac{k_2(\varepsilon)}{|\lambda-V_0^\varepsilon|^{1/2}}\right)(|f|_{0,R^N}+|(E-E^\varepsilon)u|_{0,R^N})\\&\leqq\left(k_1+\frac{k_2(\varepsilon)}{|\lambda-V_0^\varepsilon|^{1/2}}\right)(|f|_{0,R^N}+k\sigma(\varepsilon)\|u\|_{2,R^N,V^\varepsilon})\end{aligned}$$

where $\sigma(\varepsilon)\to 0$ as $\varepsilon\to 0$ and k_1 is independent of ε. From (2.16) it follows that we can choose ε so small as to have $k_1k\sigma(\varepsilon)<1$ and then fix $\omega_1\geqq V_0^\varepsilon$ so large as to ensure that $T_{\lambda,\varepsilon}$ is a contraction mapping for $\operatorname{Re}\lambda\geqq\omega_1$. The remainder of the proof is standard.

Remark 2.2. A useful generalization of Theorem 2.1 can be obtained in a very straightforward way by using weighted spaces. Let π be a twice differentiable real-valued function defined on R^N and set $\Pi(x)=\exp(\pi(x)]$. Denote by $L^2_\Pi(R^N)$ resp. $H^j_\Pi(R^N,V)$, $j=1,2$) the space of functions u such that $\Pi u\in L^2(R^N)$ (resp. $\Pi u\in H^j(R^N,V)$, $j=1,2$). Then, for $f\in=L^2_\Pi(R^N)$

$$\begin{cases}u\in H^2_\Pi(R^N,V)\\(\lambda-E)u=f\end{cases}\quad\text{if and only if}\quad\begin{cases}\Pi u\in H^2(R^N,V)\\(\lambda-E_\pi)(\Pi u)=\Pi f\end{cases}$$

where

$$E_\pi=E-\sum_{ij}(a_{ij}+a_{ij})D_i\pi D_j-\sum b_jD_j\pi-\sum a_{ij}(D_iD_j\pi-D_i\pi D_j\pi).$$

As easily seen, operator E_π satisfies the assumptions of Theorem 1.2 provided that for each $\varepsilon > 0$ there exists $k(\varepsilon) \in R$ such that

$$\sum_j |D_j\pi(x)|^2 + \sum_{ij} |D_iD_j\pi(x)| \leqq \varepsilon V(x) + k(\varepsilon) \quad \forall x \in R^N. \tag{2.17}$$

Therefore, by applying Theorem 1.2 to E_π, we conclude that E generates an analytic semigroup on $L^2_{\Pi}(R^N)$.

3. Some useful lemmas. In this section we have collected some miscellaneous results that will be applied often in the sequel.

Let E be a differential operator of type (1.1), satisfying conditions (1.2)-(1.6). Let M be defined as in (2.14). If $x_0 \in R^N$, we set

$$E^0 = \sum_{ij} a_{ij}(x^0)D_iD_j + \sum_j b_j(x^0)D_j - c(x^0). \tag{3.1}$$

In the sequel, we will abbreviate $B_r = B_r(x^0)$ for any $r > 0$ and denote by k any constant depending only on ν, k_1, k_2, B and M. The result below is well known.

LEMMA 3.1. *For any $f \in L^2(B_r)$ and $\lambda \in C$ with* $\operatorname{Re} \lambda \geqq V_0$ *the Dirichlet problem*

$$(\lambda - E^0)u = f \quad \text{in } B_r, \qquad u = 0 \quad \text{on } \partial B_r$$

has a unique solution $u \in H^2(B_r)$ and

$$\|u\|_{2,B_r,V} \leqq k|f|_{0,B_r}. \tag{3.2}$$

Suppose that $u \in H^1(B_r)$ is a (weak) solution of the equation

$$(\lambda - E^0)u = \zeta \in C, \qquad \operatorname{Re} \lambda \geqq V_0. \tag{3.3}$$

Then, the following inequalities can be obtained arguing as in [12, p. 499]: denoting by u_{B_r} the integral mean value of u on B_r, for $0 < s < r$

$$|u|_{1,B_s} \leqq \frac{k}{r-s}\left(\frac{r}{s}\right)^{N/2} |u - u_{B_r}|_{0,B_r} \tag{3.4}$$

and, if $\zeta = 0$,

$$|u|_{1,B_s} \leqq \frac{k}{r-s}|u|_{0,B_r}. \tag{3.5}$$

Estimates (3.4) and (3.5) imply the result below, proved by Campanato in the case of bounded coefficients.

LEMMA 3.2. *If $u \in L^2(B_r)$ is a solution of* (3.3), *then*

$$|u - u_{B_{\tau r}}|^2_{0,B_{\tau r}} \leqq k\tau^{N+2}|u - u_{B_r}|^2_{0,B_r} \tag{3.6}$$

for any $\tau \in [0, 1]$. Moreover, if $\zeta = 0$, then

$$|u|^2_{0,B_{\tau r}} \leqq k\tau^N|u|^2_{0,B_r}. \tag{3.7}$$

We merely need to recall that (3.7) may be derived from (3.5) by the same procedure used in [12, p. 503] to show that u satisfies

$$|u|^2_{1,B_{\tau r}} \leqq k\tau^N|u|^2_{1,B_r}. \tag{3.8}$$

Estimate (3.6), which is trivial if $\frac{1}{2} \leqq \tau \leqq 1$, will then follow from (3.8) and (3.4) for $\tau \in [0, \frac{1}{2}]$. Indeed, by Poincaré's inequality we have

$$\begin{aligned} |u - u_{B_{\tau r}}|^2_{0,B_{\tau r}} &\leqq k(\tau r)^2|u|^2_{1,B_{\tau r}} \\ &\leqq k\tau^{N+2}r^2|u|^2_{1,B_{r/2}} \leqq k\tau^{N+2}|u - u_{B_r}|^2_{0,B_r}. \end{aligned}$$

Remark 3.3. Estimate (3.6) is useful to study the Hölder continuity of solutions to differential problems. Indeed, from the results of [10] it follows that

$$[u]^2_{\alpha,B_r} \leqq k(N) \sup_{xB_r,0<\rho\leqq r} \rho^{-(N+2\alpha)} \int_{B_\rho(x)} |u(y)-u_{B_\rho(x)}|^2 \, dy \tag{3.9}$$

for any function $u \in L^2_{\text{loc}}(R^N)$ and any ball $B_r \subset R^N$.

We conclude this section recalling a technical lemma proved in [11, p. 136].

LEMMA 3.4. *Let ϕ and σ be nonnegative functions on an interval $]0, d]$. Suppose that $\lim_{r\to 0} \sigma(r) = 0$ and*

$$\phi(\tau r) \leqq [K\tau^\alpha + \sigma(r)]\phi(r) + Lr^\beta$$

for any $r \in]0, d]$, any $\tau \in]0, 1]$ and some positive constants α, β, K, L with $\alpha > \beta$. Then, for any $\varepsilon \in]0, \alpha-\beta[$ there exists $r_\varepsilon \leqq d$ such that

$$\phi(\tau r) \leqq (1+K)\tau^{\alpha-\varepsilon}\phi(r) + K_\varepsilon L(\tau r)^\beta \quad \forall r \in]0, r_\varepsilon], \quad \forall \tau \in]0, 1]$$

where

$$K_\varepsilon = \frac{(1+K)^{2\alpha/\varepsilon}}{(1+K)^{(\alpha-\beta)/\varepsilon} - (1+K)}.$$

Furthermore, if $\sigma \equiv 0$, then $r_\varepsilon = d$.

4. Generation in Morrey spaces. The object of this section is the proof of Theorem 1.3, that we obtain as a consequence of Theorem 1.2 and of the local estimates recalled in the previous section. Our first step is the following lemma which adapts the idea of [11] to the present situation.

LEMMA 4.1. *Assume (1.2)-(1.6) and let $\lambda \in C$, $\operatorname{Re} \lambda \geqq V_0$. Suppose $u \in H^2_{\text{loc}}(R^N)$ is a solution of the equation $(\lambda - E)u = f\, L^{2,\mu}(R^N)$, $0 < \mu < N$. Then, for any $x^0 \in R^N$ and any $0 < r \leqq 1$,*

$$\|u\|^2_{2,B_r(x^0),V} \leqq kr^\mu[\|u\|^2_{2,B_1(x^0),V} + |f|^2_{L^{2,\mu}(R^N)}] \tag{4.1}$$

where k is a constant independent of λ, r.

Proof. Let $x^0 \in R^N$, $B_r = B_r(x^0)$, $0 < r \leqq 1$ and $w \in H^2(B_r)$ be the solution of the Dirichlet problem

$$\begin{aligned} (\lambda - E^0)w &= f + (E - E^0)u \quad &&\text{in } B_r, \\ w &= 0 &&\text{on } \partial B_r \end{aligned}$$

where E^0 is defined as in (3.1). Then, by (3.2) and (1.6) we obtain

$$\|w\|^2_{2,B_r,V} \leqq k[|f|^2_{0,B_r} + |(E-E^0)u|^2_{0,B_r}] \leqq k[\sigma(r)\|u\|^2_{2,B_r,V} + r^\mu |f|^2_{L^{2,\mu}(R^N)}] \tag{4.2}$$

where $\sigma : [0, +\infty[\to [0, +\infty[$ is increasing and $\lim_{r\to 0} \sigma(r) = 0$.

On the other hand, the difference $v = u - w$ satisfies the equation $(\lambda - E^0)v = 0$. so, applying (3.7) to every partial derivative $D^\alpha v$, $|\alpha| \leqq 2$ and using property (1.7) of V, we conclude that

$$\|v\|^2_{2,B_{\tau r},V} \leqq k\tau^N \|v\|^2_{2,B_r,V} \quad \forall \tau \in]0, 1]. \tag{4.3}$$

Therefore, (4.2) and (4.3) imply

$$\begin{aligned} \|u\|^2_{2,B_{\tau r},V} &\leqq 2[\|v\|^2_{2,B_{\tau r},V} + \|w\|^2_{2,B_{\tau r},V}] \\ &\leqq k[(\tau^N + \sigma(r))\|u\|^2_{2,B_r,V} + r^\mu |f|^2_{L^{2,\mu}(R^N)}] \end{aligned}$$

for any $0 < \tau, r \leqq 1$. We can now apply Lemma 3.4: by choosing $\varepsilon = (N-\mu)/2$ we obtain

$$\|u\|_{2,B_{\tau r_0},V} \leqq k[\tau^{(N+\mu)/2}\|u\|^2_{2,B_{r_0},V} + (\tau r_0)^{\mu}|f|^2_{L^{2,\mu}(R^N)}] \tag{4.4}$$

for any $\tau \in]0,1]$ and some $r_0 = r_0(\mu) \in]0,1]$. By assuming $\tau = r/r_0$, estimate (4.4) implies (4.1) for $0 < r \leqq r_0$ and then in general, as (4.1) is trivial if $r_0 \leqq r \leqq 1$.

Proof of Theorem 1.3. From Theorem 1.2 it follows that, if $\operatorname{Re}\lambda \geqq \omega_1$, then the equation $(\lambda - E)u = f \in L^2 \cap L^{2,\mu}(R^N)$, $0 < \mu < N$, has a unique solution $u\, H^2(R^N, V)$. Also, from (4.1) we have

$$|u|_{H^{2,\mu}(R^N,V)} \leqq k[\|u\|_{2,R^N,V} + |f|_{L^{2,\mu}(R^N)}]$$

and so, by (1.8),

$$\|u\|_{H^{2,\mu}(R^N,V)} \leqq k\|f\|_{0,\mu,R^N}. \tag{4.5}$$

Since $\lambda u = f + Eu$, from (4.5) we obtain

$$|\lambda - \omega_1| \cdot \|u\|_{0,\mu,R^N} \leqq k\|f\|_{0,\mu,R^N}. \tag{4.6}$$

The remainder of (1.9) may be derived from (4.5) and (4.6) by standard interpolation techniques (see, e.g. [26, p. 7]).

5. Generation in the topology of uniform convergence. The thesis of Theorem 1.4 will be obtained by compactness arguments once we have proved the following lemma. Here, the main idea is similar to the one contained in [28], [29], [14].

LEMMA 5.1. *Assume* (1.2)-(1.6). *There exists* $\omega_2 \geqq \omega_1$ *such that if* $\operatorname{Re}\lambda \geqq \omega_2$ *and* $u \in H^2(R^N, V) \cap C^1(R^N)$ *is a solution of the equation* $(\lambda - E)u = f \in L^\infty(R^N)$, *then* u *satisfies* (1.10).

Proof. Let $x \in R^N$, $r > 0$ and $\theta \in C^\infty(R^N)$ be such that $0 \leqq \theta \leqq 1$, $\theta \equiv 1$ on $B_{r/2} = B_{r/2}(x)$, $\theta \equiv 0$ out of $B_r = B_r(x)$, $|D^\beta\theta|_{0,\infty} \leqq kr^{-|\beta|}$, $|\beta| \leqq 2$. Then

$$\theta u \in H^2(R^N, V), \qquad (\lambda - E)(\theta u) = F,$$

where

$$F = \theta f - \sum a_{ij}[D_i u D_j\theta + D_j u D_i\theta + u D_i D_j \theta] - \sum b_j u D_j \theta. \tag{5.1}$$

In particular, $F \in L^2(R^N) \cap L^{2,\mu}(R^N)$ for any $0 \leqq \mu \leqq N$ and

$$\begin{aligned} |F|_{L^{2,\mu}(R^N)} &\leqq |f|_{L^{2,\mu}(B_r)} + \frac{k}{r^2}|u|_{L^2,\mu(B_r)} + \frac{k}{r}|u|_{H^{1,\mu}(B_r,V)} \\ &\leqq kr^{(N-\mu)/2}[|f|_{0,\infty,R^N} + r^{-2}|u|_{0,\infty,R^N} + r^{-1}(|u|_{1,\infty,R^N} + |V^{1/2}u|_{0,\infty,R^N})]. \end{aligned} \tag{5.2}$$

Now, let us fix $N-2 < \mu < N$ and apply Theorem 1.3. From (1.9) we obtain, for $\operatorname{Re}\lambda \geqq \omega_1$,

$$\|\theta u\|_{H^{2,\mu}(R^N,V)} + |\lambda - \omega_1|^{1/2}\|\theta u\|_{H^1,\mu(R^N,V)} + |\lambda - \omega_1|\ \|\theta u\|_{0,\mu,R^N} \leqq k\|F\|_{0,\mu,R^N}. \tag{5.3}$$

On the other hand, from known properties of Morrey spaces (see, e.g., [14, Lemma 6.2]) it follows that for any $\varepsilon > 0$ there exists a constant $k(\varepsilon)$, independent of r, such that

$$\begin{aligned} &r^{-2}|\theta u|_{0,\infty,B_r} + [|\theta u|_{1,\infty,B_r} + |V^{1/2}\theta u|_{0,\infty,B_r}] \\ &\quad \leqq \varepsilon r^{(\mu-N)/2}\|\theta u\|_{H^{2,\mu}(B_r,V)} \\ &\quad\quad + k(\varepsilon)r^{(\mu-N-2)/2}\|\theta u\|_{H^{1,\mu}(B_r,V)}. \end{aligned} \tag{5.4}$$

Therefore, for $0<r\leqq 1$, from (5.2), (5.3), (5.4) we conclude that for all $\varepsilon>0$

$$r^{-2}|u|_{0,\infty,B_{r/2}}+r^{-1}[|u|_{1,\infty,B_{r/2}}+|V^{1/2}u|_{0,\infty,B_{r/2}}]$$
$$\leqq k_0\left[\varepsilon+\frac{k(\varepsilon)}{r|\lambda-\omega_1|^{1/2}}\right][|f|_{0,\infty,R^N}+r^{-2}|u|_{0,\infty,R^N}+r^{-1}(|u|_{1,\infty,R^N}+|V^{1/2}u|_{0,\infty,R^N})]$$

where k_0 is independent of ε, r and λ. Now, for any $\varepsilon>0$ there exists $\omega_2(\varepsilon)\geqq\omega_1$ such that $r_\varepsilon=k(\varepsilon)\varepsilon^{-1}|\lambda-\omega_1|^{-1/2}\leqq 1$ for $\operatorname{Re}\lambda\geqq\omega_2(\varepsilon)$. Then

$$\begin{aligned}&r_\varepsilon^{-2}|u|_{0,\infty,B_{r_\varepsilon/2}}+r_\varepsilon^{-1}[|u|_{1,\infty,B_{r_\varepsilon/2}}+|V^{1/2}u|_{0,\infty,B_{r_\varepsilon/2}}]\\ &\qquad\leqq 2k_0\varepsilon[|f|_{0,\infty,R^N}+r_\varepsilon^{-2}|u|_{0,\infty,R^N}+r_\varepsilon^{-1}(|u|_{1,\infty,R^N}+|V^{1/2}u|_{0,\infty,R^N})]\end{aligned}\tag{5.5}$$

and this estimate holds for any point x R^N. But $|u|_{0,\infty,R^N}$ is actually attained at some point of R^N and the same is true for the other norms that appear in the left-hand side of (5.5). So, choosing ε sufficiently small and using (5.5) at most three times, we can easily get (1.10). □

We can now complete the proof of our theorem.

Proof of Theorem 1.4. Let us prove existence first. For each $n=1,2,\cdots$, let $\theta_n\in C^\infty(R^N)$ be such that $0\leqq\theta_n\leqq 1$, $\theta_n\equiv 1$ on $B_n(0)$, $\theta_n\equiv 0$ out of $B_{2n}(0)$ and $|D^\beta\theta_n|\leqq kn^{-|\beta|}$, $|\beta|\leqq 2$. Then $f_n=\theta_nf\in L^{2,\mu}(R^N)$ for any $0\leqq\mu\leqq B$. Fix $N-2<\mu<N$ and let u_n be the solution of the problem

$$u_n\in H^{2,\mu}(R^N,V),\qquad(\lambda-E)u_n=f_n,\operatorname{Re}\lambda\geqq\omega_2.$$

In particular, $u_n\in H^2(R^N)\cap C^1(R^N)$ and so, by Lemma 5.1, $\{u_n\}$ is bounded in $C^1(R^N)$. Therefore, there exists a subsequence $\{u_n^*\}$ which converges to a function $u\in C(R^N)$. uniformly on each compact subset of R^N.

Now, if we show that

$$u_n^*\to u\text{ in }H^2(D)\quad\text{for any }D\subset\subset R^N,\tag{5.6}$$

then standard regularity results and Lemma 5.1 will imply that u is a solution of our equation in the desired class, and that satisfies (1.10). In order to prove (5.6), let $D\subset\subset R^N$ and n_0 be such that $B_{n_0}=B_{n_0}(0)\supset D$. Let us set $u_{nm}=u_n^*-u_m^*$. Since $(\lambda-E)u_{nm}=0$ in B_{n_0+1} for each $n,m>n_0$, we can estimate u_{nm} using the Cacciopoli inequalities proved in [15, § 3]. There exists $r_0\in]0,1[$ such that

$$|u_{nm}|_{2,B_{r_0}(x)}+|u_{nm}|_{1,B_{r_0}(x)}\leqq k|u_{nm}|_{0,B_{r_0}(x)}\tag{5.7}$$

for any $x\in D$. By covering B_{n_0} with a finite number of balls of radius r_0 and adding together inequalities (5.7) we conclude that $\{u_n^*\}$ is a Cauchy sequence in $H^2(B_{n_0})$, which in turn implies (5.6).

Next, the uniqueness of solutions can be proved by similar arguments. Indeed, let $v\in H^2_{\text{loc}}(R^N)\cap C^1(R^N)$ be such that $|V^{1/2}v|_{0,\infty,R^N}<+\infty$ and $(\lambda-E)v=0$. Then $\theta_nv\in H^2(R^N)\cap C^1(R^N)$ and $(\lambda-E)(\theta_nv)=g_n$, where

$$g_n=-\sum_{ij}a_{ij}[D_ivD_j\theta_n+D_jvD_i\theta_n+vD_iD_j\theta_n]-\sum_j b_jvD_j\theta_n.$$

Clearly, $g_n\in L^\infty(R^N)$ and $\lim|g_n|_{0,\infty,R^N}=0$. But, by Lemma 5.1

$$|\lambda-\omega_2|\,|\theta_nv|_{0,\infty,R^N}\leqq k|g_n|_{0,\infty,R^N}\quad\forall n=1,2,\cdots$$

and so $v\equiv 0$.

Remark 5.2. In [28], [29], Stewart proves a generation theorem in the space

$$C_0(R^N)=\{u\in C(R^N)\colon\lim_n|u|_{0,\infty,R^N\setminus B_n(0)}=0\}.$$

The analogue of this result for operators with unbounded coefficients may be easily recovered from Theorem 1.4. Indeed, suppose $f \in C_0(R^N)$, $\operatorname{Re} \lambda \geqq \omega_2$ and let $u \in H^2_{\text{loc}}(R^N) \cap C^1(R^N)$ be the solution of equation $(\lambda - E)u = f$ with $|V^{1/2}u|_{0,\infty,R^N} < +\infty$. Define θ_n, $n = 1, 2, \cdots$, as in the proof of Theorem 1.4 and set $u_n = (1 - \theta_n)u$. Then

$$\begin{aligned}(\lambda - E)u_n &= F_n \\ &= (1-\theta_n)f + \sum_{ij} a_{ij}[D_j\theta_n D_i u + D_i\theta_n D_j u + uD_iD_j\theta_n] + \sum_j b_j u D_j\theta_n.\end{aligned}$$

Therefore, by (1.10) applied to u_n we obtain

$$|\lambda - \omega_2|^{1/2}[|u|_{0,\infty,R^N\setminus B_{2n}} + |V^{1/2}u_{0,\infty,R^N\setminus B_{2n}}] + |\lambda - \omega_2| \cdot |u|_{0,\infty,R^N\setminus B_{2n}} \leqq k|F_n|_{0,\infty,R^N\setminus B_{2n}}.$$

Since $|F_n|_{0,\infty,R^N\setminus B_{2n}} \to 0$ as $n \to \infty$, the last inequality implies that u, $V^{1/2}u$, $D_j u \in C_0(R^N)$.

Remark 5.3. Let us go back to the proof of Lemma 5.1. From (5.2), (5.3) we obtain

$$\|u\|_{H^{2,\mu}(B_{r/2},V)} \leqq kr^{(N-\mu)/2}[|f|_{0,\infty,R^N} + r^{-2}|u|_{0,\infty,R^N} + r^{-1}(|u|_{1,\infty,R^N} + |V^{1/2}u|_{0,\infty,R^N})]$$

for $0 < r < 1$. Therefore, choosing r as in the sequel of that proof, we conclude that

$$(5.8) \qquad |\lambda - \omega_2|^{(N-\mu)/4} \sup_{x \in R^N} \|u\|_{H^{2,\mu}(B_{r/2}(x),V)} \leqq k|f|_{0,\infty,R^N}.$$

See also [28], [29] for a similar estimate involving L^p norms.

6. Generation in the Hölder topology. The estimate contained in the following lemma is essential for the proof of Theorem 1.5. We will briefly sketch its proof, which uses the techniques of [12].

LEMMA 6.1. *Assume* (1.2)-(1.5), (1.11). *If* $u \in H^2_{\text{loc}}(R^N)$ *is a solution of the equation* $(\lambda - E)u = f \in C^\alpha(R^N)$, $0 < \alpha < 1$, $\operatorname{Re} \lambda \geqq V_0$, *then*

$$(6.1) \qquad \|u\|_{C^{2,\alpha}(B_1(x^0),V)} \leqq k[\|u\|_{2,B_2(x^0),V} + \|f\|_{\alpha,R^N}]$$

for any $x^0 \in R^n$ *and some constant k independent of* λ.

Proof. We note first that (6.1) will be proved provided we show that

$$(6.2) \qquad \sum_{|\beta| \leqq 2} \int_{B_r(x)} V^{2-|\beta|}|D^\beta u - (D^\beta u)_{B_r(x)}|^2 \, dy \leqq kr^{N+2\alpha}[\|u\|_{2,B_2(x^0),V)} + \|f\|_{\alpha,R^N}$$

for any $x \in B_1(x^0)$ and $0 < r \leqq 1$ (here g_{B_r} denotes the integral mean value of g on B_r). Indeed, from (1.7), (6.2) and (3.9) we obtain

$$\sum_{|\beta| \leqq 2} V^{2-|\beta|}(x^0)[D^\beta u]_{\alpha,B_1(x^0)} \leqq k[\|u\|_{2,B_2(x^0),V} + \|f\|_{\alpha,R^N}]$$

which in turn implies (6.1), recalling (1.3) and (1.7).

Also, since $f \in L^{2,\mu}(R^N)$ for any $0 \leqq \mu \leqq N$, from Lemma 4.1 and (1.11) it follows that

$$(6.3) \qquad \|u\|^2_{2,B_r(x),V} \leqq kr^{N-\alpha}[\|u\|^2_{2,B_1(x),V} + |f|^2_{0,\infty,R^N}]$$

for any $x \in R^N$ and $0 < r \leqq 1$. Here and in the sequel, k denotes a constant independent of λ.

Now, for $x \in B_1(x^0)$ and $0 < r \leqq 1$, let $B_r = B_r(x)$ and $w \in H^2(B_r)$ be the solution of the Dirichlet problem

$$\begin{aligned}(\lambda - E^0)w &= f - f_{B_r} + (E - E^0)u \quad &&\text{in } B_r, \\ w &= 0 &&\text{on } \partial B_r\end{aligned}$$

where E^0 is defined as in (3.1). From (1.3), (1.11) and (6.2) it follows that

$$|(E - E^0)u|^2_{0,B_r} \leqq kr^{2\alpha}\|u\|^2_{2,B_r,V} \leqq kr^{N+\alpha}[\|u\|^2_{2,B_1,V} + |f|^2_{0,\infty,R^N}]$$

so, by (3.2),

$$\|w\|^2_{2,B_r,V} \leqq k\{r^{N+2\alpha}[f]^2_{\alpha,R^N} + |(E-E^0)u|^2_{0,B_r}\} \\ \leqq kr^{N+\alpha}\{\|u\|^2_{2,B_1,V} + \|f\|^2_{\alpha,R^N}\}. \tag{6.4}$$

On the other hand, the difference $v=u-w$, together with the partial derivatives $D^\beta v$, $|\beta|\leqq 2$, satisfies the assumptions of Lemma 3.2. Then, by (3.6) and by the properties (1.3), (1.7) of V, we conclude that

$$\sum_{|\beta|\leqq 2}\int_{B_{\tau r}} V^{2-|\beta|}D^\beta v-(D^\beta v)_{B_{\tau r}}|^2\,dy \leqq k\tau^{N+2}\sum_{|\beta|\leqq 2}\int_{B_r} V^{2-|\beta|}|D^\beta v-(D^\beta v)_{B_r}|^2\,dy \tag{6.5}$$

for any $\tau\in[0,1]$. Since $u=v+w$, (6.4) and (6.5) yield

$$\sum_{|\beta|\le 2}\int_{B_{\tau r}} V^{2-|\beta|}|D^\beta u-(D^\beta u)_{B_{\tau r}}|^2\,dy \\ \leqq k\tau^{N+2}\sum_{|\beta|\leqq r}\int_{B_r} V^{2-|\beta|}|D^\beta u-(D^\beta u)_{B_r}|^2\,dy \\ + kr^{N+\alpha}[\|u\|^2_{2,B_1,V} + \|f\|^2_{\alpha,R^N}] \tag{6.6}$$

for any $\tau\in\,]0,1]$. So, applying Lemma 3.4, we obtain (6.2) with exponent $N+\alpha$ instead of $N+2\alpha$. Therefore, by our introductory remarks, (6.1) holds with exponent $\alpha/2$ instead of α. Now, inserting this information in the above proof, we obtain (6.3) with exponent N instead of $N-\alpha$, (6.6) with exponent $N+2\alpha$ instead of $N+\alpha$ and finally (6.2). □

Proof of Theorem 1.5. From Theorem 1.4 it follows that, for Re $\lambda\geqq\omega_2$, the equation $(\lambda-E)u=f\in C^\alpha(R^N)$ has a unique solution $u\in H^2_{\text{loc}}(R^N)\cap C^1(R^N)$ such that $|V^{1/2}u|_{0,\infty,R^N}<+\infty$. Furthermore, u satisfies (1.10). Therefore, Lemma 6.1 will allow us to conclude that $u\in C^{2,\alpha}(R^N,V)$ and

$$\|u\|_{C^{2,\alpha}(R^N,V)}\leqq k\|f\|_{\alpha,R^N} \tag{6.7}$$

provided we show that

$$\|u\|_{2,B_2(x^0),V}\leqq k\|f\|_{\alpha,R^N} \tag{6.8}$$

for any point $x^0\in R^N$.

In view of this, let us localize our equation by a cutoff function $\theta\in C^\infty(R^N)$ such that $\theta\equiv 1$ on $B_2(x^0)$ and $\theta\equiv 0$ out of $B_4(x^0)$. Then $\theta u\in H^2(R^N,V)$ and $(\lambda-E)(\theta u)=F$, where F is defined as in (5.1). Now, from (1.10) we obtain

$$|F|_{0,R^N}\leqq k|f|_{0,\infty,R^N} \tag{6.9}$$

and so (6.8) follows from (6.9) and (1.8) applied to θu.

Finally, the full estimate (1.12) may be easily recovered from (6.7). □

7. Application to parabolic equations. Let us consider the initial value problem

$$\frac{\partial u}{\partial t}(t,x)-E(t)u(t,x)=f(t,x),\ (t,x)\in[0,T]\times R^N, \\ u(0,x)=u_0(x) \tag{7.1}$$

where

$$E(t)=\sum_{ij=1}^N a_{ij}(t,x)D_iD_j+\sum_{j=1}^N b_j(t,x)D_j-c(t,x) \tag{7.2}$$

is a differential operator with unbounded coefficients. We have already recalled some of the literature on this subject. Recently, motivation for studying these problems has also been provided by nonlinear filtering for diffusion processes (see, e.g., [19]). Indeed, in the case of unbounded observations, the pathwise treatment of the Zakai equation leads to parabolic operators with unbounded lower order coefficients (see [5], [20], [18], [27], [16]).

We analyze (7.1) as an abstract Cauchy problem in a Banach space, using some of the semigroup generation theorems proved in the previous sections.

If X is a Banach space with norm $\| \|_x$, we denote by $L(X)$ the space of bounded linear operators from X into X and by $C([T_0, T_1]; X)$ the space of continuous functions $g:[T_0, T_1] \to X$. We also define, for $0<\alpha<1$,

$$C^\alpha(T_0, T_1]; X)=\left\{u\in C([T_0, T_1]; X): \sup_{\substack{T_0\leqq s,t\leqq T_1\\ s\neq t}} \frac{\|u(t)-u(s)\|_x}{|t-s|^\alpha}<+\infty\right\}.$$

The spaces $C^1([T_0, T_1]; X)$, $C^{1,\alpha}([T_0, T_1]; X)$ are defined similarly. Moreover, we set

$$C(]T_0, T_1]; X)=\bigcap_{0<\varepsilon<T_1-T_0} C([T_0+\varepsilon, T_1]; X)$$

and we give analogous definitions for the spaces $C^\alpha(]T_0, T_1]; X)$, $C^1(]T_0, T_1]; X)$ and $C^{1,\alpha}(]T_0, T_1]; X)$.

Let V be a function having properties (1.3) and suppose that $E(t)$ is an operator of type (7.2), with complex-valued coefficients satisfying the assumptions of § 1, uniformly for $t\in[0, T]$, i.e., for all $(t, x)\in[0, T]\times R^N$

$$\operatorname{Re}\sum_{ij} a_{ij}(t, x)z_j\bar{z}_i\geqq \nu\|z\|^2 \quad \forall z\in C^N, \tag{7.3}$$

$$K_1V(x)-V_0\leqq \operatorname{Re} c(t, x)\leqq K_2V(x)+V_0, \tag{7.4}$$

$$\sum |b_j(t, x)|^2\leqq \nu B^2K_1V(x) \tag{7.5}$$

for some constants $\nu, K_1, K_2, V_0>0$ and $B\in[0,2[$. Also, suppose that, for some $\alpha\in]0,1[$,

$$a_{ij}, b_j/V^{1/2}, c/V\in C^\alpha([0, T]; C(R^N)), \qquad i,j=1,\cdots, N. \tag{7.6}$$

Notice that the structure hypotheses (7.3), $\cdots$, (7.6) are similar to those of [27].

The theorem below treats the existence, uniqueness and regularity of solutions to problem (7.1) with respect to the L^2 topology.

THEOREM 7.1. *Assume* (7.3)-(7.6) *and let* $f\in C^\alpha([0, T]; L^2)(R^N))$. *Then*

(i) *For any* $u_0\in L^2(R^N)$ *problem* (7.1) *has a unique solution*

$$u\in C([0, T]; L^2(R^N))\cap C^1(]0, T]; L^2(R^N))\cap C(]0, R]; H^2(R^N, V));$$

(ii) *For any* $u_0\in H^2(R^N, V)$ *problem* (7.1) *has a unique solution*

$$u\in C^1([0, T]; L^2(R^N))\cap C([0, T]; H^2(R^N, V)).$$

Moreover, in both cases (i) *and* (ii),

$$u\in C^{1,\alpha}(]0, T]; L^2(R^N))\cap C^\alpha(]0, T]; H^2(R^N, V)). \tag{7.7}$$

Proof. Theorem 1.2 implies that $E(T)$, $t\in[0, T]$, generates an analytic semigroup on $L^2(R^N)$ with domain $H^2(R^N, V)$. Furthermore, by (1.8)

$$\|[\lambda-E(t)]^{-1}\|_{\mathscr{L}(L^2(R^N))}\leqq\frac{k}{|\lambda-\omega_1|}$$

for any $\lambda \in C$ with $\operatorname{Re} \lambda > \omega_1$. Also, from (7.6)

$$\|[E(t)-E(s)][\omega_1 - E(\tau)]^{-1}\|_{\mathscr{L}(L^2(R^N))} \leqq k|t-s|^\alpha$$

for any $\tau, s, t \in [0, T]$. Therefore, assertions (i), (ii) and (7.7) follow from classical results on nonautonomous evolution equations (see, e.g. [26]; see also [17] and [1]). □

Remark 7.2. Recalling Remark 2.2, one can easily extend the result of Theorem 7.1 to the weighted space $L^2_\pi(R^N)$, provided that $\pi = \log \Pi$ satisfies (2.17).

We will now derive the analogue of Theorem 7.1 for Hölder spaces. According to the assumptions of Theorem 1.5, we will replace (7.6) by

$$(7.8) \qquad a_{ij},\ b_j/V^{1/2},\ c/V \in C^\alpha([0, T]; C^\beta(R^N)), \qquad i, j = 1, \cdots, N$$

for some $\alpha, \beta \in]0, 1[$. Then arguing as in the proof of Theorem 7.1 we obtain the following result.

THEOREM 7.3. *Assume* (7.3), (7.4), (7.5), (7.8) *and let* $f \in C^\alpha([0, T]; C^\beta(R^N))$.

(i) *If* $u_0 \in h^\beta(R^N, V)$, *then problem* (7.1) *has a unique solution*

$$u \in C([0, T]; C^\beta(R^N)) \cap C^1(]0, T]; C^\beta(R^N)) \cap C^{2,\beta}(]0, T]; C^{2,\beta}(R^N, V)).$$

(ii) *If* $u_0 \in C^{2,\beta}(R^N, V)$ *and* $E(0)+f(\cdot, 0) \in h^\beta(R^N, V)$, *then problem* (7.1) *has a unique solution*:

$$u \in C^1([0, T]; C^\beta(R^N)) \cap C([0, T]; C^{2,\beta}(R^N, V)).$$

Moreover, in both cases (i) *and* (ii),

$$u \in C^{1,\alpha}(]0, T]; C^\beta(R^N)) \cap C^\alpha(]0, T]; C^{2,\beta}(R^N, V)).$$

Remark 7.4. Suppose that a_{ij}, b_j, c $(i, j = 1, \cdots, N)$ satisfy (7.6) and $a_{ij}, b_j, c \in C([0, T]; C^\beta(R^N))$. Then (7.8) fails to be fulfilled, in general. However, (7.8) holds under any of the following assumptions:

$$(7.9) \qquad \begin{array}{l} a_{ij},\ b_j,\ c \text{ are differentiable with respect to } x \text{ and} \\ D_h a_{ij},\ D_h b_j/V^{1/2},\ D_h c/V \in C^\alpha([0, T]; C(R^N)), \qquad i, j, h = 1, \cdots, N; \end{array}$$

$$(7.10) \qquad \begin{array}{l} a_{ij},\ b_j,\ c \text{ are differentiable with respect to } t \text{ and} \\ \dfrac{\partial a_{ij}}{\partial t}, \dfrac{\partial b_j}{\partial t}\Big/ V^{1/2}, \dfrac{\partial c}{\partial t}\Big/ V \in C([0, T]; C^\beta(R^N)), \qquad i, j = 1, \cdots, N. \end{array}$$

A DIFFERENTIAL-DIFFERENCE EQUATION*

JERRY L. FIELDS† AND WALEED A. AL-SALAM†

Abstract. Wimp showed that the hypergeometric polynomials

$$P_n(z) = {}_{p+2}F_{p+1}(-n,\ n+\lambda,\ a_{\mathrm{p}};\ b_{\mathrm{p+1}};\ z), \qquad n=0,1,\cdots,$$

satisfied a certain differential-difference equation. Here we show that all "common" solutions to the standard differential equation and the standard difference equation satisfied by the $P_n(z)$ also satisfy the above mentioned differential-difference equation.

Key words. hypergeometric functions, difference equations, difference-differential equations

AMS(MOS) subject classification. 33A35

1. Notation and introduction.

Let $\mathbf{Z}$ denote the integers, and $\mathbf{Z}^+$ the positive integers. In addition to the usual notation for hypergeometric functions and Meijer G-functions, see [1], [6], we will use the abbreviated notation

$$\Gamma_n(s+c_{\mathbf{P}}) := \prod_{k=n+1}^{p} \Gamma(s+c_k), \qquad \Gamma(s+c_{\mathbf{Q}}) := \Gamma_0(s+c_{\mathbf{Q}}),$$

$$(s)_t := \frac{\Gamma(s+t)}{\Gamma(s)}, \qquad (s+c_{\mathbf{Q}})_t := \prod_{k=1}^{q}(s+c_k)_t,$$

$${}_pF_q(z) := {}_pF_q\left(\begin{matrix} a_{\mathbf{P}} \\ b_{\mathbf{Q}} \end{matrix}\middle|\, z\right) := {}_pF_q\left(\begin{matrix} a_1, \cdots, a_p \\ b_1, \cdots, b_q \end{matrix}\middle|\, z\right)$$

$$:= \sum_{k=0}^{\infty} \frac{(a_{\mathbf{P}})_k}{(b_{\mathbf{Q}})_k}\frac{z^k}{k!},$$

$$G^{m,n}_{p,q}(w) := G^{m,n}_{p,q}\left(w\,\middle|\,\begin{matrix} a_{\mathbf{P}} \\ b_{\mathbf{Q}} \end{matrix}\right) := G^{m,n}_{p,q}\left(w\,\middle|\,\begin{matrix} a_1, \cdots, a_p \\ b_1, \cdots, b_q \end{matrix}\right)$$

$$:= \frac{1}{2\pi i}\int_L \frac{\Gamma(b_{\mathbf{M}}-t)\Gamma(1-a_{\mathbf{N}}+t)w^t}{\Gamma_m(1-b_{\mathbf{Q}}+t)\Gamma_n(a_{\mathbf{P}}-t)\,dt},$$

where L is an upward oriented contour which separates the poles of $\Gamma(b_{\mathbf{M}}-t)$ from those of $\Gamma(1-a_{\mathbf{N}}+t)$, and which runs from $-i\infty$ to $+i\infty$ ($L=L_0$), or begins and ends at $+\infty$ ($L=L_+$), or $-\infty$ ($L=L_-$). In particular, $(a_{\mathbf{Q}})_1 = a_1 \cdot a_2 \cdots a_q$. As hypergeometric functions, the polynomials

$$P_n(z) := {}_{p+2}F_{p+1}\left(\begin{matrix} -n,\ n+\lambda,\ a_{\mathbf{P}} \\ b_{\mathbf{P+1}} \end{matrix}\middle|\, z\right), \qquad n+1 \in \mathbf{Z}^+,$$

$$1-b_j \notin \mathbf{Z}^+, \qquad j=1,\cdots,p+1,$$

satisfy a standard differential equation [1], [6] of the form

$$\begin{aligned} \mathscr{L}_z\{Y_n(z)\} &= \{\delta(\delta+b_{\mathbf{P+1}}-1)_1 - z(\delta-n)(\delta+n+\lambda)(\delta+a_{\mathbf{P}})_1\}Y_n(z) \\ &= 0, \qquad \delta = z\frac{d}{dz}. \end{aligned} \tag{1}$$

* Received by the editors March 17, 1986; accepted for publication (in revised form) May 8, 1986. This work was supported in part by the Natural Sciences and Engineering Research Council of Canada under grants A7549 and A2975.

† Department of Mathematics, University of Alberta, Edmonton, Alberta, Canada T6G 2G1.

Under suitable parameter restrictions for $n \geqq p+2$, these polynomials also satisfy a standard difference equation [2], [6] of the form

$$(2) \qquad \mathcal{M}_n\{Y_n(z)\} = \sum_{m=0}^{p+2} (A_m^* + zB_m^*) Y_{n-m}(z) = 0, \quad A_0^* = 1, \quad B_0^* = B_{p+2}^* = 0,$$

where the numbers A_m^*, B_m^* are rational in n and independent of z. In [7], Wimp showed that the $P_n(z)$ also satisfy a differential-difference equation

$$(3) \qquad z(1-z)\frac{dY_n(z)}{dz} = \sum_{m=0}^{p+1} (A_m + zB_m) Y_{n-m}(z), \qquad B_{p+1} = 0,$$

where the numbers A_m, B_m are rational in n, and independent of z. When $z=1$ and $Y_n(z) = P_n(z)$, (3) gives a $p+2$ term difference equation for $P_n(1)$, which is one term less than the $p+3$ term equation given by (2). We will show that any "common" solution of (1) and (2) is also a solution of (3). We will now define what we mean by a "common" solution of (1) and (2).

In [3], it was shown that under suitable parameter restrictions, (1) and (2) have a common global basis in

$$\mathcal{D} = \{z\colon |\arg z| < \pi, |\arg(1-z)| < \pi\},$$

i.e., if n is sufficiently large, and

$$\begin{aligned} &a_k - a_r \notin \mathbf{Z}, \quad k \neq r, \\ &1 - b_j \notin \mathbf{Z}^+, \qquad\qquad k, r = 1, \cdots, p, \quad j = 1, \cdots, p+1, \\ &a_k \neq b_j, \\ &\mathcal{B} = \{G_n(z\,e^{i\pi}), G_n(z\,e^{-i\pi}), L_{n,j}(z), j = 1, \cdots, p+1\}, \end{aligned}$$

$$L_{n,j}(z) = \frac{\Gamma(n+1)}{\Gamma(n+\lambda)} G_{p+3,p+3}^{p+3,2}\left(z \,\middle|\, \begin{matrix} 1-n-\lambda, 1-a_j, 1-a_{\mathbf{P}}, n+1 \\ 0, 1-b_{\mathbf{P+1}}, 1-a_j \end{matrix}\right),$$

$$G_n(z) = \frac{\Gamma(n+1)}{\Gamma(n+\lambda)} G_{p+2,p+2}^{p+2,1}\left(z \,\middle|\, \begin{matrix} 1-n-\lambda, 1-a_{\mathbf{P}}, n+1 \\ 0, 1-b_{\mathbf{P+1}} \end{matrix}\right),$$

where $G_n(z\,e^{i\pi})$ is the analytic continuation of $G_n(z\,e^{-i\pi})$ along an arc which encloses $z=0$, but not $z=1$, then the elements of $\mathcal{B}$ are solutions of both (1) and (2) in $\mathcal{D}$, and are linearly independent both as functions of z, and of n.

Definition. The function $Y_n(z)$ is a common solution to $\mathcal{L}_z\{Y_n(z)\} = 0$ and $\mathcal{M}_n\{Y_n(z)\} = 0$ in $\mathcal{D}$, provided $Y_n(z)$ has a representation

$$Y_n(z) = D_1 G_n(z\,e^{i\pi}) + D_2 G_n(z\,e^{-i\pi}) + \sum_{j=1}^{p} C_j L_{n,j}(z),$$

where the constants $D_1, D_2, C_1, \cdots, C_p$ are independent of z and are periodic functions of n whose period is 1.

In [3] it is shown that $P_n(z)$ is such a common solution.

The following lemma is central to our analysis.

Lemma. *If $S_r(w)$ is a polynomial in w of degree r, and t is any integer $\geqq r$, then $S_r(w)$ can be represented uniquely in the form*

$$(4) \qquad S_r(w) = \sum_{m=0}^{t} Q_m (w+\gamma)_m (w+\gamma+\varepsilon)_{t-m},$$

$$
(5)\qquad
\begin{aligned}
Q_m &= \frac{(t+\varepsilon-2m)}{m!(\varepsilon)_{t+1-m}} \sum_{k=0}^{m} \frac{(-m)_k(m-\varepsilon-t)_k}{k!(1-\varepsilon)_k} S_r(-\gamma-k)\\
&= \frac{(-t-\varepsilon+2m)}{(t-m)!(-\varepsilon)_{1+m}} \sum_{k=0}^{t-m} \frac{(m-t)_k(-m+\varepsilon)_k}{k!(1+\varepsilon)_k} S_r(-\gamma-\varepsilon-k),
\end{aligned}
$$

where γ, ε are arbitrary constants, and $\varepsilon \neq 0, \pm 1, \cdots, \pm(t-1)$.

Proof. In a slightly different form, this lemma occurs in [2]. The uniqueness of the Q_m's follows immediately, as substituting the values $w=-\gamma-j, j=0, 1, \cdots, t$ into $S_r(w)$ leads one to a nonsingular, triangular system of linear equations in the Q_m's. Thus, if the Q_m's exist at all, they are unique.

For the existence of the Q_m, consider the Lagrange representation

$$
(6)\qquad S_r(w) = \sum_{k=0}^{t} \frac{(-1)^k(w+\gamma)_t(w+\gamma+t)}{k!(t-k)!(w+\gamma+k)} S_r(-\gamma-k).
$$

This follows from the fact that

$$
\frac{(w+\gamma)_t(w+\gamma+t)}{w+\gamma+k} = (w+\gamma)_k(w+\gamma+k+1)_{t-k},
$$

so that the right-hand side of (6) is a polynomial in w of degree t. When this polynomial is evaluated at the points $w=-\gamma-j, j=0, 1, \cdots, t$, it agrees with $S_r(w)$ at these points. As $t \geqq r$, this is sufficient to establish (6). By considering the partial fraction decomposition in w, one can show

$$
{}_4F_3\left(\begin{matrix} k-t,\ w+\gamma+\varepsilon,\ 1+\dfrac{\varepsilon-t}{2},\ 1 \\ 1+\varepsilon-k,\ 1-w+\gamma-t,\ \dfrac{\varepsilon-t}{2} \end{matrix}\,\middle|\, 1\right) = \frac{(\varepsilon-k)(w+\gamma+t)}{(\varepsilon-t)(w+\gamma+k)},
$$

$$
1+t-k \in \mathbf{Z}^+, \qquad (\varepsilon-t)(w+\gamma+k) \neq 0.
$$

It is worth noting that this formula also follows from a special case of a limiting form of Dougall's Theorem [1, p. 191, formula 6], i.e. set $d=1$ in

$$
{}_5F_4\left(\begin{matrix} a,\ \dfrac{a}{2}+1,\ b,\ c,\ d \\ \dfrac{a}{2},\ a+1-b,\ a+1-c,\ a+1-d \end{matrix}\,\middle|\, 1\right)
$$
$$
= \frac{\Gamma(a+1-b)\Gamma(a+1-c)\Gamma(a+1-d)\Gamma(a+1-b-c-d)}{\Gamma(a+1)\Gamma(a+1-c-d)\Gamma(a+1-b-d)\Gamma(a+1-b-c)}.
$$

Substituting this expression for $(w+\gamma+t)/(w+\gamma+k)$ into (6), expressing the ${}_4F_3$ as a sum and interchanging summation processes, one obtains the first line of (5). To obtain the second line of (5), it is sufficient to observe that

$$
S_r(w) = \sum_{m=0}^{t} Q_{t-m}(w+\gamma^*)_m(w+\gamma^*+\varepsilon^*)_{t-m},
$$

$$
\gamma^* = \gamma+\varepsilon, \qquad \varepsilon^* = -\varepsilon.
$$

Representing Q_{t-m} in the form given by the first line of (5), and then replacing m by $t-m$, we obtain the second line of (5).

Remark. Applying this lemma to the relationship

$$T(w) := \sum_{m=0}^{p+2} \{A_m^* + zB_m^*\} \frac{(w-n)_m(w+n+\lambda-p-2)_{p+2-m}}{(-n)_m(n+\lambda-p-2)_{p+2-m}}$$

$$= \frac{(n+\lambda)_n}{(n+\lambda-p-2)_n(n+b_{P+2}-1)_1}$$

$$\cdot\{(w+b_{P+2}-1)_1 - z(w-n)(w+n+\lambda-p-2)(w+a_P)_1\},$$

where $b_{p+2}=1$ and $S_r(w)$ is the right-hand side of this relation, determines the numbers A_m^*, B_m^* as convenient closed form expressions. If the A_m^* and B_m^* in (2) are the numbers determined above, and we substitute in the left-hand side of (2) the series expression for $P_n(z)$, interchange the summation processes, we get an equation of the form

$$\sum_{j=0}^{n} \frac{(a_P)_j(n+\lambda-p-2)_j(-z)^j}{(b_{P+1})_j(n+1)_{-j}} T(j).$$

Substituting in this expression the polynomial form of $T(j)$ and rearranging in powers of z, we see that the resulting expression is zero, and hence equation (2) is satisfied.

Similarly, numbers A_m, B_m are determined by

$$\sum_{m=0}^{p+1} \{A_m + zB_m\} \frac{(w-n)_m(w+n+\lambda-p-1)_{p+1-m}}{(-n)_m(n+\lambda-p-1)_{p+1-m}}$$

$$(7) \qquad = \frac{1}{(n+\lambda-p-1)_{p+1}}\{w(w+n+\lambda-p-1)_{p+1} - w(w+b_{P+1}-1)_1$$

$$+ z(-w(w+n+\lambda-p-1)_{p+1}$$

$$+ (w-n)(w+n+\lambda-p-1)(w+a_P)_1)\}.$$

In our main result, we will show that with this determination of A_m, B_m, (3) is satisfied.

2. Main result.

THEOREM. *If $Y_n(z)$ is a common solution to*

$$\mathscr{L}_z\{Y_n(z)\} = 0 \quad \textit{and} \quad \mathscr{M}_n\{Y_n(z)\} = 0$$

in $\mathscr{D}$, then $Y_n(z)$ also satisfies the differential-difference equation

$$(8) \qquad z(1-z)\frac{dY_n(z)}{dz} = \sum_{m=0}^{p+1} (A_m + zB_m) Y_{n-m}(z),$$

where the A_m, B_m are defined in (7).

Proof. In view of the linearity of the various operators and the fact that $Y_n(z)$ can be written as a linear combination of the elements in $\mathscr{B}$, it is sufficient to show that $G_n(z\,e^{\pm i\pi})$ and $L_{n,j}(z)$, $j = 1, \cdots, p+1$, satisfy (8).

For convenience, let $\sigma = p+1$. We will find use for the relationship, s general,

$$\sum_{m=0}^{\sigma} \{A_m + zB_m\} \frac{(n-m+\lambda)_s}{(n-m+1)-s}$$

$$(9) \qquad = (1-z)_s \frac{(n+\lambda)_s}{(n+1)_{-s}} - \frac{(n+\lambda)_{s-\sigma}}{(n+1)_{-s}} s(s-1+b_{P+1})_1 - z\frac{(n+\lambda)_{s+1-\sigma}}{(n+1)_{-s-1}}(s+a_P)_1.$$

To see that (9) holds, let H denote the left-hand side of (9). Using

$$\frac{(n-m+\lambda)_s}{(n-m+1)_{-s}} = \frac{(n+\lambda-\sigma)_s}{(n+1)_{-s}} \frac{(s-n)_m(s+n+\lambda-\sigma)_{\sigma-m}}{(-n)_m(n+\lambda-\sigma)_{\sigma-m}},$$

H becomes a form to which (7) is applicable, and after some algebra, the right-hand side of (9) occurs. Using the Mellin-Barnes representation

$$G_{n-m}(z\,e^{\pm i\pi})=\frac{1}{2\pi i}\int_L \Omega(s)\frac{(n-m+\lambda)_s}{(n-m+1)_{-s}}(z\,e^{\pm i\pi})^s\,ds,$$

$$\Omega(s):=\frac{\Gamma(-s)\Gamma(1-b_{\mathrm{P}+1}-s)}{\Gamma(1-a_{\mathrm{P}}-s)},$$

where the integration contour L can be chosen to be a valid contour for n fixed and $m=0,1,\cdots,\sigma$, we have

$$\begin{aligned}K&:=\sum_{m=0}^{\sigma}(A_m+zB_m)G_{n-m}(z\,e^{\pm i\pi})\\&=\frac{1}{2\pi i}\int_L \Omega(s)(z\,e^{\pm i\pi})^s\sum_{m=0}^{\sigma}(A_m+zB_m)\frac{(n-m+\lambda)_s}{(n-m+1)_{-s}}\,ds.\end{aligned}$$

After substituting (9) into this expression and doing some algebra, we get

$$\begin{aligned}K&=\frac{z(1-z)}{2\pi i}\int_L \Omega(s)\frac{(n+\lambda)_s}{(n+1)_{-s}}\frac{d}{dz}\{(z\,e^{\pm i\pi})^s\}\,ds\\&\quad+\frac{(-1)^p}{2\pi i}\left\{\int_L-\int_{L-1}\right\}\Omega^*(s)\frac{(n+\lambda)_{s+1-\sigma}}{(n+1)_{-s-1}}(z\,e^{\pm i\pi})^{s+1}\,ds\\&=z(1-z)\frac{d}{dz}G_n(z\,e^{\pm i\pi})+R,\end{aligned}$$

$$\Omega^*(s)=\frac{\Gamma(-s)\Gamma(1-b_{\mathrm{P}+1}-s)}{\Gamma(-a_{\mathrm{P}}-s)},$$

$$R=\sum_{\substack{\text{Residue}\\ s\text{ between}\\ L\text{ and }L-1}}\left\{(-1)^p\Omega^*(s)\frac{(n+\lambda)_{s+1-\sigma}}{(n+1)_{-s-1}}(z\,e^{\pm i\pi})^{s+1}\right\}.$$

By inspection, $R=0$, and $G_n(z\,e^{\pm i\pi})$ satisfies (8). Similarly one can show that the $L_{n,j}(z)$ satisfy (8), starting with the Mellin-Barnes representation

$$L_{n,j}(z)=\frac{1}{2\pi i}\int_L \Gamma(a_j+s)\Gamma(1-a_j-s)\Omega(s)\frac{(n+\lambda)_s}{(n+1)_{-s}}z^s\,ds,$$

where L separates the poles of $\Gamma(a_j+s)\Gamma(n+\lambda+s)$ from those of $\Gamma(-s)\Gamma(1-b_{\mathrm{P}+1}-s)$.

COROLLARY. *If $Y_n(z)$ is a common solution to*

$$\mathscr{L}_z\{Y_n(z)\}=0\quad\textit{and}\quad \mathscr{M}_n\{Y_n(z)\}=0$$

in $\mathscr{D}$, and the limits, taken in $\mathscr{D}$,

$$\lim_{z\to1}\frac{dY_n(z)}{dz},\quad \lim_{z\to1}Y_{n-m}(z)=Y_{n-m}(1),\quad m=0,1,\cdots,p+1,$$

as well defined finite numbers for $n\geqq p+1$, then

$$0=\sum_{m=0}^{p+1}(A_m+B_m)Y_{n-m}(1).$$

Remark. If we set $b_{p+2}=1$, and

$$\mathscr{B}_1=\{F_{n,k}(z),\ k=1,\cdots,p+2\},$$

$$F_{n,k}(z)=\frac{(n+1)_{1-b_k}}{(n+1)_{-1+b_k}}z^{1-b_k}{}_{p+3}F_{p+2}\left(\begin{matrix}1,1-b_k-n,1-b_k+n+\lambda,1-b_k+a_P\\ 1-b_k+b_{P+2}\end{matrix}\middle| z\right),$$

then under the conditions

$$b_j-b_k\notin \mathbf{Z},\qquad j\neq k,$$

$\mathscr{B}_1$ forms a basis equivalent to $\mathscr{B}$ in

$$\mathscr{D}_0=\{z\colon 0<|z|<1,\ |\arg z|<\pi\}.$$

That is, considering $\mathscr{B}$. and $\mathscr{B}_1$ as column vectors,

$$\mathscr{B}_1=M\mathscr{B}$$

where M is a nonsingular matrix whose elements are independent of z and are periodic functions of n, of period 1 (see [3]). Thus, the $F_{n,k}(z)$ are common solutions to (1) and (2) in $\mathscr{D}\cap\mathscr{D}_0$, and by analytic continuation, in $\mathscr{D}$.

Hence, the $F_{n,k}(z)$ satisfy (8). Note that $P_n(z)=F_{n,p+2}(z)$.

Similary, if we set

$$\mathscr{B}_\infty=\{H_{n,k}(z),\ k=1,\cdots,p+2\},$$

$$H_{n,k}(z)=\frac{(n+\lambda)_{-a_k}}{(n+1)_{a_k}}z^{-a_k}{}_{p+3}F_{p+2}\left(\begin{matrix}1,1+a_k-b_{P+2}\\ 1+a_k+n,1+a_k-n-\lambda,1+a_k-a_P\end{matrix}\middle|\frac{1}{z}\right),$$

$$k=1,\cdots,p,$$

$$H_{n,p+1}(z)=\frac{\Gamma(n+1)\Gamma(n+\lambda+1-b_{P+2})z^{-n-\lambda}}{\Gamma(n+\lambda)\Gamma(2n+\lambda+1)\Gamma(n+\lambda+1-a_P)}{}_{p+2}F_{p+1}\left(\begin{matrix}n+\lambda+1-b_{P+2}\\ 2n+\lambda+1,n+\lambda+1-a_P\end{matrix}\middle|\frac{1}{z}\right),$$

$$H_{n,p+2}(z)=\frac{\Gamma(n+1)\Gamma(2n+\lambda)\Gamma(n+a_P)z^n}{\Gamma(n+\lambda)\Gamma(n+b_{P+2})}\left(\begin{matrix}-n,1-b_{P+2}\\ {}_{p+2}F_{p+1}1-2n-\lambda,-n+1-a_P\end{matrix}\middle|\frac{1}{z}\right)$$

$$2n+2\lambda\notin\mathbf{Z}^+,\quad n+a_j\notin\mathbf{Z}^+,\quad j=1,\cdots,p,$$

then under the conditions

$$a_j-a_k\notin\mathbf{Z},\qquad j\neq k,$$

$\mathscr{B}_\infty$ forms a basis equivalent to $\mathscr{B}$ in

$$\mathscr{D}_\infty=\{z\colon 1<|z|,\ |\arg(z-1)|<\pi\}.$$

Remark. In [8, p. 159], Wimp observed that it was conjectured by Lewanowicz that the numbers

$$Q_n={}_{p+2}F_{p+1}\left(\begin{matrix}n+\beta_{P+2}\\ 2n+\lambda+1,n+\alpha_P\end{matrix}\middle|1\right),$$

satisfy a $p+2$ term linear recursion relationship with rational coefficients in n. When we compare Q_n with $H_{n,p+1}$ (1), it is clear that the Q_n do satisfy such a linear recursion relationship. A proof by Lewanowicz has now been given in [5].

Remark. If $Y_n(z)$ is a function such that

$$\mathscr{L}_z\{Y_n(z)\}=0 \quad \text{and} \quad \mathscr{M}_n\{Y_n(z)\}=0 \quad \text{in } \mathscr{D},$$

it is an interesting, open question whether $Y_n(z)$ is a common solution to these equations according to our definition. Also, the structure of the linear solution space for (8) is unknown.

Remark. There are q-analogues of all these results which will appear elsewhere.

Remark. Recently, Lewanowicz [4], [5] has derived other differential-difference relations for $P_n(z)$ and demonstrates relations satisfied by the coefficients A_m, B_m.

A PROOF OF THE G_2 CASE OF MACDONALD'S ROOT SYSTEM–DYSON CONJECTURE*

DORON ZEILBERGER†

Dedicated to Joe Gillis on the occasion of his 75th birthday

Key words. root systems, constant term identities, hypergeometric summation

AMS(MOS) subject classifications. 31, 05A

We will prove the following theorem.

THEOREM. *Let m and n be integers and x, y and z commuting indeterminates; then the constant term of the Laurent polynomial*

$$F(x,y,z)=\left[\left(1-\frac{x}{y}\right)\left(1-\frac{y}{z}\right)\left(1-\frac{z}{x}\right)\right]^m\left[\left(1-\frac{xy}{z^2}\right)\left(1-\frac{xz}{y^2}\right)\left(1-\frac{yz}{x^2}\right)\right]^n$$
$$\cdot\left[\left(1-\frac{y}{x}\right)\left(1-\frac{z}{y}\right)\left(1-\frac{x}{z}\right)\right]^m\left[\left(1-\frac{z^2}{xy}\right)\left(1-\frac{y^2}{xz}\right)\left(1-\frac{x^2}{yz}\right)\right]^n$$

is

$$C(m,n)=\frac{(3m+3n)!(3n)!(2m)!(2n)!}{(2m+3n)!(m+2n)!(m+n)!m!n!n!}.$$

This is the G_2 case of Macdonald's Root System–Dyson conjecture (see [6, Conjecture 2.3, and (c), p. 994]; see also Morris [7]).

Macdonald [6] showed how Selberg's integral [8] (see [1] for Aomoto's recent brilliant proof) implies his conjecture for all the so-called classical root systems. We will follow the same route and show how the G_2 case follows from a corollary of Selberg's integral that is due to Morris [7, p. 94].

After the first version of this paper was written, I was kindly informed by Dominique Foata that Laurent Habsieger [9] has independently and simultaneously obtained the results of this paper.

We only need the case $n=3$ of Morris' result that spells out to the following.

MORRIS' THEOREM ($n=3$). *Let a, b, c be integers. The constant term of the Laurent polynomial*

$$H(u,v,w;a,b,c)=[(1-u)(1-v)(1-w)]^a\quad\left[\left(1-\frac{u}{v}\right)\left(1-\frac{u}{w}\right)\left(1-\frac{v}{w}\right)\right]^c$$
$$\cdot\left[\left(1-\frac{1}{u}\right)\left(1-\frac{1}{v}\right)\left(1-\frac{1}{w}\right)\right]^b\left[\left(1-\frac{v}{u}\right)\left(1-\frac{w}{u}\right)\left(1-\frac{w}{v}\right)\right]^c$$

is

$$\frac{(a+b+2c)!(a+b+c)!(a+b)!(2c)!(3c)!}{(a+2c)!(b+2c)!(a+c)!(b+c)!a!b!c!c!}.$$

We will need the following easy corollary.

* Received by the editors May 12, 1986; accepted for publication (in revised form) June 25, 1986. This research was partly sponsored by the National Science Foundation

† Department of Mathematics, Drexel University, Philadelphia, Pennsylvania 19104.

COROLLARY. *The coefficient of $u^Av^Aw^A$ in $H(u, v, w; a, b, c)$ above is*

$$(-1)^A\frac{(a+b+2c)!(a+b+c)!(a+b)!(2c)!(3c)!}{(a-A+2c)!(b+A+2c)!(a-A+c)!(b+A+c)!(a-A)!(b+A)!c!c!}.$$

Proof. Since $(1-t)^a(1-t^{-1})^b/t^A=(-1)^A(1-t)^{a-A}(1-t^{-1})^{b+A}$, we have

$$H(u, v, w; a, b, c)/u^Av^Aw^A=(-1)^AH(u, v, w; a-A, b+A, c)$$

and taking constant terms, the corollary follows from Morris' theorem.

Finally, we need the formula shown below.

DIXON'S FORMULA (e.g. [5, 1.2.6, Ex. 62, pp. 73 and 489]). *Let M, N, K be integers; then*

$$\sum_A\frac{(-1)^A}{(M+A)!(M-A)!(N+A)!(N-A)!(K+A)!(K-A)!}$$
$$=\frac{(M+N+K)!}{M!N!K!(M+N)!(M+K)!(N+K)!}.$$

To prove the theorem we let $u=x/y$, $v=y/z$, and $w=z/x$. Then $F(x, y, x)=H(u, v, w; m, m, n)$. But $uvw=1$, so the constant term of F is the sum of all the diagonal coefficients of H. Thus by the corollary the constant term of F is

$$\sum_A(-1)^A\frac{(2m+n)!(2m+n)!(2m)!(2n)!(3n)!}{(m-A+2n)!(m+A+2n)!(m-A+n)!(m+A+n)!(m-A)!(m+A)!(n)!(n)!}$$
$$=\frac{(2m+2n)!(2m+n)!(2m)!(2n)!(3n)!}{n!n!}$$
$$\cdot\sum_A\frac{(-1)^A}{(m+2n-A)!(m+2n+A)!(m+n-A)!(m+n+A)!(m-A)!(m+A)!}.$$

Using Dixon's formula with $M=m+2n$, $N=m+n$, $K=m$, we get that this is equal to

$$\frac{(2m+2n)!(2m+n)!(2m)!(2n)!(3n)!}{n!n!}$$
$$\cdot\frac{(3m+3n)!}{(m+2n)!(m+n)!m!(2m+3n)!(2m+2n)!(2m+n)!}$$
$$=\frac{(3m+3n)!(3n)!(2m)!(2n)!}{(2m+3n)!(m+2n)!(m+n)!m!n!n!}. \qquad \text{Q.E.D.}$$

Since F of the theorem is obviously with integer coefficients, our theorem implies the not entirely obvious fact that $C(m, n)$ is an integer, thus solving Askey's problem [2].

The q-Analogue. We will show how Kadell's [4] recent q-analogue of Morris' theorem implies the q-analogue of the G_2 Macdonald-Dyson conjecture [6]. Since the ordinary case is just the special case $q=1$ of the q-analogue, we could have started with the q-analogue right away, giving the ordinary reader the option to plug in $q=1$ throughout. However we feel that this would have been very poor pedagogy. Indeed, the way mathematics is created is by slowly increasing steps of generality. Unfortunately, all too often results are presented in their overpowering full generality right from the start, thus making them very hard to read and understand, let alone use as motivation.

Let

$$(y)_a = (1-y)(1-qy)\cdots(1-q^{a-1}y)$$

and

$$[a]! = \frac{(q)_a}{(1-q)^a} = 1(1+q)(1+q+q^2)\cdots(1+q+\cdots+q^{a-1}).$$

We will prove the following theorem.

q-THEOREM. *Let m and n be integers and x, y and z commuting indeterminates; then the constant term of the Laurent polynomial*

$$F(x,y,z) = \left(\frac{x}{y}\right)_m \left(\frac{z}{y}\right)_m \left(\frac{z}{x}\right)_m \left(\frac{z^2}{xy}\right)_n \left(\frac{xz}{y^2}\right)_n \left(\frac{yz}{x^2}\right)_n$$
$$\cdot \left(q\frac{y}{x}\right)_m \left(q\frac{y}{z}\right)_m \left(q\frac{x}{z}\right)_m \left(q\frac{xy}{z^2}\right)_n \left(q\frac{y^2}{xz}\right)_n \left(q\frac{x^2}{yz}\right)_n$$

is

$$\frac{[3m+3n]![3n]![2m]![2n]!}{[2m+3n]![m+2n]![m+n]![m]![n]![n]!}.$$

We need the following theorem [4].

KADELL'S q-MORRIS THEOREM ($n=3$). *Let a, b, c be integers. The constant term of the Laurent polynomial*

$$H(u,v,w;a,b,c) = (u)_a(v)_a(w)_a \left(\frac{u}{v}\right)_c \left(\frac{u}{w}\right)_c \left(\frac{v}{w}\right)_c \left(\frac{q}{u}\right)_b \left(\frac{q}{v}\right)_b \left(\frac{q}{w}\right)_b \left(q\frac{v}{u}\right)_c \left(q\frac{w}{u}\right)_c \left(q\frac{w}{v}\right)_c$$

is

$$\frac{[a+b+2c]![a+b+c]![a+b]![2c]![3c]!}{[a+2c]![b+2c]![a+c]![b+c]![a]![b]![c]![c]!}.$$

We will need the following easy corollary.

q-COROLLARY. *The coefficient of $u^A v^A w^A$ in $H(u,v,w;a,b,c)$ above is*

$$(-1)^A q^{3A(A-1)/2}$$
$$\cdot \frac{[a+b+2c]![a+b+c]![a+b]![2c]![3c]!}{[a-A+2c]![b+A+2c]![a-A+c]![b+A+c]![a-A]![b+A]![c]![c]!}.$$

Proof. We are really looking for the constant term of $H(u,v,w;a,b,c)/u^A v^A w^A$. But since

$$\frac{(t)_a(q(1/t))_b}{t^A} = (-1)^A q^{A(A-1)/2}(q^A t)_{a-A}\left(\frac{q}{q^A t}\right)_{b+A}.$$

it follows that

$$\frac{H(u,v,w;a,b,c)}{u^A v^A w^A} = (-1)^A q^{3A(A-1)/2} H(q^A u, q^A v, q^A w; a-A, b+A, c)$$

and the corollary follows from Kadell's q-Morris Theorem.

Finally, we need the following formula.

THE q-DIXON FORMULA ([3], [5, p. 489]).

$$\sum_A \frac{(-1)^A q^{A(3A-1)/2}}{[M+A]![M-A]![N+A]![N-A]![K+A]![K-A]!} = \frac{[M+N+K]!}{[M]![N]![K]![M+N]![M+K]![N+K]!}.$$

To prove the q-Theorem we let $u=q(y/z)$, and $v=z/x$ and $w=x/y$. Then $F(x,y,z)=H(u,v,w;m,m,n)$. But $uvw=q$ so the constant term of F is the weighted sum of all the diagonal coefficients of H, where the coefficient of $u^Av^Aw^A$ gets multiplied by q^A.

Thus by the corollary the constant term of F is

$$\sum_A q^A(-1)^A q^{3A(A-1)/2} \cdot \frac{[2m+2n]![2m+n]![2m]![2n]![3n]!}{[m-A+2n]![m+A+2n]![m-A+n]![m+A+n]![m-A]![m+A]![n]![n]!}$$
$$= \frac{[2m+2n]![2m+n]![2m]![2n]![3n]!}{[n]![n]!} \cdot \sum_A \frac{(-1)^A q^{A(3A-1)/2}}{[m+2n-A]![m+2n+A]![m+n-A]![m+n+A]![m-A]![m+A]!}.$$

Using the q-Dixon formula with $M=m+2n$, $N=m+n$, $K=m$, we get that this is equal to

$$\frac{[2m+2n]![2m+n]![2m]![2n]![3n]!}{[n]![n]!} \cdot \frac{[3m+3n]!}{[m+2n]![m+n]!m![2m+3n]![2m+2n]![2m+n]!}$$
$$= \frac{[3m+3n]![3n]![2m]![2n]!}{[2m+3n]![m+2n]![m+n]![m]![n]![n]!}. \qquad \text{Q.E.D.}$$

Acknowledgment. I heartily thank Richard Askey for rekindling my interest in the Macdonald conjecture.

AN ANALYTIC CONTINUATION OF THE HYPERGEOMETRIC SERIES*

WOLFGANG BÜHRING†

Abstract. The points $z=\frac{1}{2}(1\pm i\sqrt{3})$ of the complex z-plane are on the boundary for each of the convergence domains of the various hypergeometric series which appear in the transformation or continuation formulas of the hypergeometric function ${}_2F_1(a, b; c; z)$. This paper presents a continuation formula containing series in powers of $1/(z-\frac{1}{2})$ with the convergence domain $|z-\frac{1}{2}|>\frac{1}{2}$, which contains the two points in question in its interior. The coefficients of the power series are determined by a three-term recurrence relation and are represented explicitly in terms of terminating hypergeometric series. If $2c=a+b+1$, then one term of the recurrence relation disappears and the series become hypergeometric series.

Key words. special functions, hypergeometric series, hypergeometric functions, continuation formulas, hypergeometric differential equations

AMS(MOS) subject classifications. 33A30, 34A20, 34A30, 30B40

1. Introduction. This paper is concerned with the hypergeometric differential equation

$$z(1-z)w''(z)+\{c-(a+b+1)z\}w'(z)-abw(z)=0 \tag{1}$$

and its solution

$${}_2F_1(a, b; c; z)=\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(c)_n n!}z^n. \tag{2}$$

Here z is the complex variable and a, b, c are complex parameters, with c not equal to a negative integer or zero. The notation $(a)_n$ means the Pochhammer symbol

$$(a)_n=a(a+1)\cdots(a+n-1)=\frac{\Gamma(a+n)}{\Gamma(a)}. \tag{3}$$

In addition to the gamma function $\Gamma(z)$ we shall require its logarithmic derivative $\psi(z)=\Gamma'(z)/\Gamma(z)$. Following common practice, we use the same symbol ${}_2F_1$ to denote the hypergeometric function as well as the hypergeometric series on the right-hand side of (2) which represents the function inside the unit circle.

By means of the well-known transformation or continuation formulas it is possible to express the hypergeometric function in terms of one or two other hypergeometric functions with suitably changed parameters and the variable z replaced by either $z/(z-1)$ or $1-z$ or $1/z$ or $1/(1-z)$ or $(z-1)/z$. The corresponding series have different convergence domains and so each of the formulas gives an analytic continuation of the original hypergeometric series on the right-hand side of (2). An example, which is relevant for the later discussion, is the continuation formula

$$\begin{aligned}\{\Gamma(c)\}^{-1}{}_2F_1(a, b; c; z)&=\frac{\Gamma(b-a)}{\Gamma(b)\Gamma(c-a)}(-z)^{-a}{}_2F_1\left(a, 1-c+a; 1-b+a; \frac{1}{z}\right)\\&\quad+\frac{\Gamma(a-b)}{\Gamma(a)\Gamma(c-b)}(-z)^{-b}{}_2F_1\left(b, 1-c+b; 1-a+b; \frac{1}{z}\right),\end{aligned} \tag{4}$$

$$(|\arg(-z)|<\pi, \quad b-a \text{ not an integer}).$$

* Received by the editors June 3, 1985; accepted for publication (in revised form) May 20, 1986.

† Physikalisches Institut, Universität Heidelberg, D-6900 Heidelberg, West Germany.

Following Olver [3] we consider $\{\Gamma(c)\}^{-1}{}_2F_1(a, b; c; z)$ rather than ${}_2F_1$ itself in order to avoid the restriction that c be not equal to a negative integer or zero.

There are two points of the complex z-plane which are on the boundary of the convergence domain for each of the hypergeometric series appearing in the various formulas mentioned so far. It is the purpose of this paper to communicate an appropriate continuation formula which expresses ${}_2F_1(a, b; c; z)$ in terms of power series such that the two points in question, $z=\frac{1}{2}(1\pm i\sqrt{3})=\exp(\pm i\pi/3)$, are interior points of the convergence domain. These series are not hypergeometric, but their coefficients satisfy a simple three-term recurrence relation. They also may be represented in terms of terminating hypergeometric series.

Our general results are presented in § 2; some interesting special cases are discussed in § 3. The proofs are supplied in § 4-§ 6, and the concluding remarks in § 7 deal with the computational aspects of this work.

2. General results. It would be a simple matter but of little use to consider a Taylor series solution in powers of $z-z_0$ in a neighborhood of an ordinary point z_0 of the differential equation, since then the problem remains to evaluate the two initial coefficients which are equal to ${}_2F_1(a, b; c; z_0)$ and $(ab/c)\ {}_2F_1(a+1, b+1; c+1; z_0)$, respectively. Such a problem does not occur with series in powers of $1/(z-z_0)$. For since they converge in a neighborhood of $z=\infty$, in a similar way to the hypergeometric series on the right of (4), the required initial coefficients may immediately be obtained by comparison with (4). Following this idea in detail, we can prove

THEOREM 1. *If $b-a$ is not an integer, we have for $|\arg(z_0-z)|<\pi$ the continuation formula*

$$\begin{aligned}\{\Gamma(c)\}^{-1}{}_2F_1(a, b; c; z)&=\frac{\Gamma(b-a)}{\Gamma(b)\Gamma(c-a)}(z_0-z)^{-a}\sum_{n=0}^{\infty}d_n(a, z_0)(z-z_0)^{-n}\\&\quad+\frac{\Gamma(a-b)}{\Gamma(a)\Gamma(c-b)}(z_0-z)^{-b}\sum_{n=0}^{\infty}d_n(b, z_0)(z-z_0)^{-n},\end{aligned}\tag{5}$$

where the series converge outside the circle $|z-z_0|=\max(|z_0|, |z_0-1|)$ and the coefficients $d_n(s, z_0)$ are given by the three-term recurrence relation

$$\begin{aligned}d_n(s, z_0)&=\{n(n+2s-a-b)\}^{-1}(n+s-1)\\&\quad\cdot(\{(n+s)(1-2z_0)+(a+b+1)z_0-c\}d_{n-1}(s, z_0)\\&\quad+z_0(1-z_0)(n+s-2)d_{n-2}(s, z_0))\end{aligned}\tag{6}$$

with starting values

$$d_{-1}(s, z_0)=0, \qquad d_0(s, z_0)=1.\tag{7}$$

The series in (5) may be rewritten as

$$\sum_{n=0}^{\infty}d_n(s, z_0)(z-z_0)^{-n}=\sum_{n=0}^{\infty}\frac{(s)_n}{(1+2s-a-b)_n}e_n(s, z_0)(z-z_0)^{-n},\tag{8}$$

where the coefficients $e_n(s, z_0)$ now obey the recurrence relation

$$\begin{aligned}e_n(s, z_0)&=n^{-1}(\{(n+s)(1-2z_0)+(a+b+1)z_0-c\}e_{n-1}(s, z_0)\\&\quad+z_0(1-z_0)(n-1+2s-a-b)e_{n-2}(s, z_0))\end{aligned}\tag{9}$$

with starting values

$$e_{-1}(s, z_0)=0, \qquad e_0(s, z_0)=1.\tag{10}$$

The coefficients d_n are also given by

$$d_n(s, z_0) = \frac{(s)_n(1+s-c)_n}{(1+2s-a-b)_n n!} {}_2F_1(-n, a+b-2s-n; c-s-n; z_0) \tag{11}$$

or by

$$\begin{aligned} d_n(s, z_0) = (-1)^n \frac{(s)_n(s+c-a-b)_n}{(1+2s-a-b)_n n!} \\ \cdot {}_2F_1(-n, a+b-2s-n; 1+a+b-s-c-n; 1-z_0). \end{aligned} \tag{12}$$

A formula corresponding to (5) for the case when $b-a$ is an integer can be derived from (5) by a limiting process in a similar way as described in [2]. The case $b=a$ is covered by

COROLLARY 1. *For* $|\arg(z_0-z)|<\pi$ *there holds*

$$\begin{aligned} \{\Gamma(c)\}^{-1} {}_2F_1(a, a; c; z) = \frac{1}{\Gamma(a)\Gamma(c-a)}(z_0-z)^{-a} \sum_{n=0}^{\infty} \frac{(a)_n}{n!}(e_n(a, z_0) \\ \cdot \{2\psi(1+n) - \psi(a+n) - \psi(c-a) \\ + \ln(z_0-z)\} - f_n(z_0))(z-z_0)^{-n}, \end{aligned} \tag{13}$$

where the series converges for $|z-z_0| > \max(|z_0|, |z_0-1|)$ *and the coefficients* $e_n(a, z_0)$ *are given by* (9)–(10) *with* $b=a$ *and the* $f_n(z_0)$ *by the recurrence relation*

$$\begin{aligned} f_n(z_0) = n^{-1}(\{(n+a)(1-2z_0) + (2a+1)z_0 - c\} f_{n-1}(z_0) \\ + z_0(1-z_0)(n-1) f_{n-2}(z_0) + (1-2z_0) e_{n-1}(a, z_0) \\ + 2z_0(1-z_0) e_{n-2}(a, z_0)) \end{aligned} \tag{14}$$

with starting values

$$f_{-1}(z_0) = f_0(z_0) = 0. \tag{15}$$

The case when $b-a$ is an integer different from zero is less simple and is therefore omitted.

3. Special cases. We discuss some special cases of Theorem 1.

(i) For $z_0=0$ or $z_0=1$ the recurrence relation (6) simplifies and becomes a two-term recurrence relation, the series in (5) are then hypergeometric. Consequently (5) reduces to (4) if $z_0=0$ or to another well-known continuation formula if $z_0=1$.

(ii) The case when $z_0=\frac{1}{2}$ is unique in so far as then two singular points of the differential equation are on the boundary of the convergence domain of the series. Although (6) simplifies, it remains a three-term recurrence relation. The series converge outside the circle $|z-\frac{1}{2}|=\frac{1}{2}$, which means that the convergence domain has been enlarged considerably as compared with the convergence domain $|z|>1$ of the hypergeometric series on the right of (4). As a consequence, both points in question, $z=\frac{1}{2}(1\pm i\sqrt{3})$, are now inside the convergence domain.

(iii) If $z_0=\frac{1}{2}$ and $c=\frac{1}{2}(a+b+1)$, which implies that the two singular points on the boundary of the convergence domain have the same characteristic exponents, then we have

COROLLARY 2. *If $b-a$ is not an even integer, there holds for $|\arg(\frac{1}{2}-z)|<\pi$ the continuation formula*

$$\begin{aligned}
&\{\Gamma(\tfrac{1}{2}a+\tfrac{1}{2}b+\tfrac{1}{2})\}^{-1}{}_2F_1(a, b; \tfrac{1}{2}a+\tfrac{1}{2}b+\tfrac{1}{2}; z)\\
&\quad=\frac{2^{b-a-1}\Gamma(\frac{1}{2}b-\frac{1}{2}a)}{\Gamma(b)\sqrt{\pi}}(\tfrac{1}{2}-z)^{-a}{}_2F_1(\tfrac{1}{2}a+\tfrac{1}{2}, \tfrac{1}{2}a; \tfrac{1}{2}a-\tfrac{1}{2}b+1; \{2z-1\}^{-2})\\
&\quad+\frac{2^{a-b-1}\Gamma(\frac{1}{2}a-\frac{1}{2}b)}{\Gamma(a)\sqrt{\pi}}(\tfrac{1}{2}-z)^{-b}{}_2F_1(\tfrac{1}{2}b+\tfrac{1}{2}, \tfrac{1}{2}b; \tfrac{1}{2}b-\tfrac{1}{2}a+1; \{2z-1\}^{-2}),
\end{aligned}\tag{16}$$

where the series on the right converge for $|z-\frac{1}{2}|>\frac{1}{2}$.

For $a=-\nu$ and $b=\nu+1$, if z is replaced by $\frac{1}{2}(1-z)$, this reduces to (8.1.5) of [1] with $\mu=0$.

A continuation formula valid when $b-a$ is an even integer may be obtained from (16) by a limiting process. The case $b=a$ is covered by

COROLLARY 3. *For $|\arg(\frac{1}{2}-z)|<\pi$ there holds*

$$\begin{aligned}
&\{\Gamma(a+\tfrac{1}{2})\}^{-1}{}_2F_1(a, a; a+\tfrac{1}{2}; z)\\
&\quad=\frac{1}{\Gamma(a)\sqrt{\pi}}\left(\frac{1}{2}-z\right)^{-a}\sum_{n=0}^{\infty}\frac{(\frac{1}{2}a+\frac{1}{2})_n(\frac{1}{2}a)_n}{(n!)^2}\\
&\qquad\cdot\left\{\psi(1+n)-\psi(a+2n)+2\ln(2)+\ln\left(\frac{1}{2}-z\right)\right\}(2z-1)^{-2n},
\end{aligned}\tag{17}$$

the series on the right being convergent for $|z-\frac{1}{2}|>\frac{1}{2}$.

The case $b-a=2m$ with $m=1, 2, 3\cdots$ is covered by

COROLLARY 4. *For $|\arg(\frac{1}{2}-z)|<\pi$ and for $m=1, 2, 3\cdots$ there holds*

$$\begin{aligned}
&\{\Gamma(a+m+\tfrac{1}{2})\}^{-1}{}_2F_1(a, a+2m; a+m+\tfrac{1}{2}; z)\\
&\quad=\frac{2^{a-1+2m}}{\Gamma(a+2m)\sqrt{\pi}}(1-2z)^{-a}\sum_{n=0}^{m-1}(-1)^n\frac{(\frac{1}{2}a+\frac{1}{2})_n(\frac{1}{2}a)_n(m-n-1)!}{n!}(2z-1)^{-2n}\\
&\quad+(-1)^m\frac{2^{a-1}}{\Gamma(a)\sqrt{\pi}}(1-2z)^{-a-2m}\sum_{n=0}^{\infty}\frac{(\frac{1}{2}a+\frac{1}{2}+m)_n(\frac{1}{2}a+m)_n}{(m+n)!\,n!}\\
&\quad\cdot\{\psi(1+m+n)+\psi(1+n)-\psi(\tfrac{1}{2}a+\tfrac{1}{2}+m+n)-\psi(\tfrac{1}{2}a+m+n)\\
&\qquad\qquad+2\ln(1-2z)\}(2z-1)^{-2n},
\end{aligned}\tag{18}$$

the infinite series being convergent for $|z-\frac{1}{2}|>\frac{1}{2}$.

Corollary 4 contains Corollary 3 as a special case if the empty sum is interpreted as zero. The formulas (17) and (18) can be written in various other ways by means of the duplication formulas of ψ and Γ so that $\psi(a+2m+2n)$ and $(a+2m)_{2n}$ or $(a)_{2m+2n}$ appears.

4. Proof of Theorem 1. The hypergeometric function ${}_2F_1(a, b; c; z)$ is a solution of the differential equation (1) which, when rewritten in the variable

$$x=z-z_0,\tag{19}$$

reads

$$\{-x^2+(1-2z_0)x+z_0(1-z_0)\}u''+\{c-(a+b+1)z_0-(a+b+1)x\}u'-abu(x)=0.\tag{20}$$

Relative to the regular singular point at infinity the Frobenius ansatz

$$u(x)=\sum_{n=0}^{\infty}d_n(s, z_0)x^{-s-n}\tag{21}$$

yields the recurrence relation (6) for the coefficients $d_n(s, z_0)$ with the characteristic exponents $s \in \{a, b\}$ as expected.

Next we observe that, when $|z|$ is sufficiently large, $x^{-s-n} = z^{-s-n}\{1-(z_0/z)\}^{-s-n}$ may be expanded in powers of $1/z$ for any fixed z_0. Then $u(z)$ becomes a power series in $1/z$ multiplied by z^{-s}. Since there is (apart from a constant factor) only one solution of the hypergeometric differential equation with this analytical structure, $u(x)$ must be equal to the well-known solution which corresponds to the special case when $z_0 = 0$. We therefore have, for each of the two possible values of s,

$$(22) \qquad z^{-s}{}_2F_1(s, 1+s-c; 1+2s-a-b; z^{-1}) = (z-z_0)^{-s} \sum_{n=0}^{\infty} d_n(s, z_0)(z-z_0)^{-n},$$

by means of which the continuation formula (5) follows from (4).

The explicit representation for $d_n(s, z_0)$ may be obtained from (22) by applying

$$(23) \qquad z^{-s-n} = \left\{(z-z_0)\left(1+\frac{z_0}{z-z_0}\right)\right\}^{-s-n} = (z-z_0)^{-s-n} \sum_{k=0}^{\infty} \frac{(s+n)_k}{k!}\left(\frac{-z_0}{z-z_0}\right)^k$$

to the series on the left. Collecting the terms with equal powers of $z-z_0$ we obtain

$$(24) \qquad (z-z_0)^{-s} \sum_{n=0}^{\infty} \sum_{k=0}^{n} \frac{(s)_k(1+s-c)_k}{(1+2s-a-b)_k k!} \frac{(s+k)_{n-k}(-z_0)^{n-k}}{(n-k)!}(z-z_0)^{-n},$$

which in view of

$$(25) \qquad \frac{(s+k)_{n-k}}{(n-k)!} = (-1)^k \frac{(s)_n(-n)_k}{(s)_k n!}$$

is equal to

$$(26) \qquad (z-z_0)^{-s} \sum_{n=0}^{\infty} \frac{(s)_n}{n!}(-z_0)^n(z-z_0)^{-n} \sum_{k=0}^{n} \frac{(-n)_k(1+s-c)_k}{(1+2s-a-b)_k k!}(z_0)^{-k}.$$

The sum over k is a terminating hypergeometric series, and comparison of (26) with the right-hand side of (22) then shows that

$$(27) \qquad d_n(s, z_0) = (n!)^{-1}(s)_n(-z_0)^n{}_2F_1(-n, 1+s-c; 1+2s-a-b; 1/z_0).$$

Application of the appropriate continuation formula of the hypergeometric function now yields (11) or (12), respectively.

5. Proof of Corollary 1. The starting point is (5) with the series rewritten in terms of the coefficients $e_n(s, z_0)$ according to (8). Then a is replaced by $a-\varepsilon$ and b by $a+\varepsilon$, so that the $e_n(s, z_0)$ depend on ε via s only. Introducing

$$(28) \qquad f_n(z_0) = \left\{\frac{d}{ds} e_n(s, z_0)\right\}_{s=a} = -\left\{\frac{d}{d\varepsilon} e_n(a-\varepsilon, z_0)\right\}_{\varepsilon=0}$$

and performing the limit $\varepsilon \to 0$ we obtain (13). The relation (14) follows if (9), with $a+b=2a$, is differentiated with respect to s and then s put equal to a.

6. Proof of Corollaries 2–4. When $z_0 = \frac{1}{2}$ and $c = \frac{1}{2}(a+b+1)$, the recurrence relation (6) reads

$$(29) \qquad d_n(s, \tfrac{1}{2}) = 2^{-2}\{n(n+2s-a-b)\}^{-1}(n+s-1)(n+s-2)d_{n-2}(s, \tfrac{1}{2}),$$

and the series in question becomes

$$(30) \qquad {}_2F_1(\tfrac{1}{2}s+\tfrac{1}{2}, \tfrac{1}{2}s; 1+s-\tfrac{1}{2}a-\tfrac{1}{2}b; \{2z-1\}^{-2}).$$

The factor in front of the series in (5) is

$$\frac{\Gamma(a+b-2s)}{\Gamma(a+b-s)\Gamma(c-s)}(z_0-z)^{-s}. \tag{31}$$

In the context of Corollary 2 it becomes, using the gamma duplication formula,

$$\frac{2^{a+b-2s-1}\Gamma(\frac{1}{2}a+\frac{1}{2}b-s)}{\Gamma(a+b-s)\sqrt{\pi}}(\tfrac{1}{2}-z)^{-s}. \tag{32}$$

With the two possible values of s the two connection coefficients on the right of (16) follow immediately.

Corollary 2 can also be verified in a different way by means of known transformation formulas. For if $c=\frac{1}{2}(a+b+1)$, the hypergeometric functions on the right of (4) appear with parameters such that the quadratic transformation formula (according to [1, (15.3.16)])

$$ {}_2F_1(A, B; 2B; Z)=\left\{\frac{2}{2-Z}\right\}^A {}_2F_1\left(\frac{1}{2}A+\frac{1}{2}, \frac{1}{2}A; B+\frac{1}{2}; \left\{\frac{Z}{2-Z}\right\}^2\right) \tag{33}$$

can be applied to each of them. The required result then follows in view of (32).

Corollaries 3 and 4 follow from (16) by tedious but standard calculations.

7. Concluding remarks. From a computational point of view the most efficient method for evaluating the hypergeometric function is the Miller algorithm. The relevant formulas are now easily accessible in the monograph by Wimp [4].

Nevertheless our Theorem 1 offers a method for computing the hypergeometric function at the two points in question which before were practically inaccessible by power series. If $z_0=\frac{1}{2}$ is used, the convergence ratio is $q=|\frac{1}{2}/(z-\frac{1}{2})|$, which for the two exceptional points has the value $q=1/\sqrt{3}=0.577\cdots$.

ERROR BOUNDS FOR ASYMPTOTIC EXPANSIONS OF THE RATIO OF TWO GAMMA FUNCTIONS*

C. L. FRENZEN†

Abstract. Error bounds are obtained for asymptotic expansions of the ratio of two gamma functions $\Gamma(x+a)/\Gamma(x+b)$ for the case of real, bounded a, b and large positive x. In particular an assertion of Luke about a result of Fields is rigorously justified by showing that the error made in truncating Fields' asymptotic expansion is numerically less than and has the same sign as the first neglected term. Use is made of some results for completely monotonic functions and enveloping series.

Key words. error bound, asymptotic expansion, gamma function

AMS (MOS) subject classifications. Primary 41A60; secondary 33A15

1. In 1951 Tricomi and Erdélyi [12] derived an asymptotic expansion for the ratio of two gamma functions in the form

$$\frac{\Gamma(z+a)}{\Gamma(z+b)}=\sum_{j=0}^{m-1}(-1)^j\frac{\Gamma(b-a+j)}{\Gamma(b-a)j!}B_j^{(a-b+1)}(a)z^{a-b-j}+O(z^{a-b-m}), \tag{1.1}$$

valid for all $m\geqq 1$ as $z\to\infty$ with $|\arg(z+a)|<\pi$. In (1.1) the quantities a and b are bounded complex numbers and the $B_j^{(\sigma)}(a)$ are the generalized Bernoulli polynomials defined by

$$\left(\frac{t}{e^t-1}\right)^\sigma e^{at}=\sum_{j=0}^{\infty}\frac{t^j}{j!}B_j^{(\sigma)}(a),\quad B_0^{(\sigma)}(a)=1,\quad |t|<2\pi. \tag{1.2}$$

A similar result was obtained by Fields [3], who showed that for all $m\geqq 1$

$$\frac{\Gamma(z+a)}{\Gamma(z+b)}=\sum_{j=0}^{m-1}\frac{\Gamma(1-2\rho+2j)}{\Gamma(1-2\rho)(2j)!}B_{2j}^{(2\rho)}(\rho)w^{2\rho-1-2j}+O(w^{2\rho-1-2m}), \tag{1.3}$$

as $w\to\infty$ with $|\arg(w+\rho)|<\pi$, where $2w=2z+a+b-1$ and $2\rho=a-b+1$. Furthermore, in a later paper, Fields [4] gave an improved order estimate for the remainder in (1.3). Several other authors have investigated the asymptotic expansion of the left-hand side of (1.1) for essentially the special case $a=0$, $b=\frac{1}{2}$ and $z=n$, where n is a positive integer (see [1], [6], [7] and [9]). Recently Luke [6] pointed out that when a, b and z are all real, simple adjustments using the functional equation for the gamma function can always be made so that $0<\rho<\frac{1}{2}$ $(0<a-b+1<1)$ in (1.3). In this case the generalized Bernoulli polynomials $B_{2k}^{(2\rho)}(\rho)$ are positive when k is even and negative when k is odd so that the series in (1.3) is alternating. Luke assumed, as in the case of certain alternating convergent series, that consecutive partial sums of the right-hand side of (1.3) yield upper and lower bounds for the left-hand side and his numerical calculations supported this assumption for the special case $a=\frac{1}{2}$, $b=1$ (i.e., $\rho=\frac{1}{4}$). However, while this is always the case for large enough values of real positive z in an alternating asymptotic expansion, it is not known in general at what point this occurs (see [8, p. 68] for details).

The purpose of this paper is to rigorously justify Luke's assertion about Fields' result, and consequently to establish computable error bounds for an asymptotic

* Received by the editors January 28, 1985; accepted for publication (in revised form) January 7, 1986.

† Department of Mathematics, Southern Methodist University, Dallas, Texas 75275.

expansion of the ratio of two gamma functions for the case of real bounded a, b and real z. These results make use of some of the properties of completely monotonic functions and enveloping series. Error bounds for a one parameter family of asymptotic approximations for the ratio of two gamma functions are also established which include (1.1) in a certain parameter range of a, b. Since only the real case will be considered, from now on we take $z=x$.

2. A function $f(t)$ is said to be *completely monotonic over* (t_1, t_2), where $-\infty \leqq t_1 < t_2 \leqq +\infty$, if

$$(2.1) \qquad (-1)^n f^{(n)}(t) \geqq 0, \qquad t_1 < t < t_2, \quad n = 0, 1, 2, \cdots.$$

J. Dubourdieu [2] showed that strict inequality holds in (2.1) for all nonconstant functions completely monotonic over (t_1, ∞); that is, if $f(t)$ satisfies (2.1) with $t_2 = \infty$ and is not constant, then

$$(2.2) \qquad (-1)^n f^{(n)}(t) > 0, \qquad t_1 < t < \infty, \quad n = 0, 1, 2, \cdots.$$

A function $f(t)$ is said to be *monotonic of order* N if (2.1) holds for $n = 0, 1, 2, \cdots, N$. Examples of commonly occurring completely monotonic functions are e^{-t} and $(t-t_1)^{-\gamma}$, $\gamma \geqq 0$. If $f(t)$ is also continuous at $t = t_1$, then it is called *completely monotonic over* $[t_1, t_2)$ and similar definitions exist for $(t_1, t_2]$ and $[t_1, t_2]$. In the standard case, which is the one appropriate to this paper, $t_1 = 0$ and $t_2 = \infty$. These values for t_1 and t_2 will be assumed from now on. Completely monotonic functions are often useful in asymptotic analysis because if $f(t)$ is completely monotonic over $[0, \infty)$, then

$$(2.3) \qquad |f^{(n)}(t)| \leqq |f^{(n)}(0)|, \qquad 0 \leqq t < \infty, \quad n = 0, 1, 2, \cdots.$$

A detailed study of the concept of completely monotonic functions can be found in [13, Chap. IV]. Next we discuss the notion of an enveloping series.

The series $a_0 + a_1 + a_2 + \cdots$ is said to envelop the number A if the relations

$$(2.4) \qquad |A - (a_0 + a_1 + \cdots + a_n)| < |a_{n+1}|, \qquad n = 0, 1, 2, \cdots$$

are satisfied. The enveloping series may be convergent (to A) or divergent. If A, $a_0, a_1, \cdots$ are all real and

$$(2.5) \qquad A - (a_0 + a_1 + \cdots + a_n) = \theta_n a_{n+1}, \qquad 0 < \theta_n < 1, \quad n = 0, 1, 2, \cdots,$$

then A is enveloped by the series $a_0 + a_1 + \cdots$ and in fact lies between two consecutive partial sums. Note also that (2.5) implies that the error made in approximating A by truncating the series $a_0 + a_1 + \cdots$ is numerically less than and has the same sign as the first neglected term. Following Pólya and Szegö [10, p. 33], we say that the series $a_0 + a_1 + \cdots$ envelops A in the *strict sense* if (2.5) holds. The terms of a strictly enveloping series have necessarily alternating signs.

By noting that if $f(t)$ is a nonconstant completely monotonic function over $[0, \infty)$, then $|f(t)|, |f'(t)|, |f''(t)|, \cdots$ are strictly decreasing in the interval $(0, t)$, $t > 0$, we have the following result (see Pólya and Szegö [10, Prob. 140, p. 33]):

LEMMA 1. *If $f(t)$ is a nonconstant completely monotonic function over* $[0, \infty)$, *then $f(t)$ is enveloped in the strict sense by its Maclaurin series for* $0 < t < \infty$.

These results are, for the present, all we shall need.

3. The ratio of two gamma functions can be defined by the following integral representation (see [8, p. 118]):

$$(3.1) \qquad \frac{\Gamma(x+a)}{\Gamma(x+b)} = \frac{1}{\Gamma(b-a)} \int_0^\infty e^{-xt} e^{-at} (1 - e^{-t})^{b-a-1} \, dt, \qquad x + a > 0, \quad b - a > 0.$$

The variable x will be assumed to be large and positive. The case of large negative x can be reduced to the above form by using the relationship $\Gamma(x)\Gamma(1-x)=\pi/\sin \pi x$. To consider a one parameter family of asymptotic expansions of the left-hand side of (3.1), let c be an arbitrary constant and rewrite (3.1) as

$$(3.2)\quad \frac{\Gamma(x+a)}{\Gamma(x+b)}=\frac{1}{\Gamma(b-a)}\int_0^\infty e^{-t(x+c)}t^{-(a-b+1)}G^{[c]}(t)\,dt, \qquad x+a>0,\quad b-a>0,$$

where

$$(3.3)\quad \begin{aligned} G^{[c]}(t)&=e^{t(c-b+1)}\left(\frac{t}{e^t-1}\right)^{a-b+1}\\ &=\sum_{j=0}^{\infty}\frac{t^j}{j!}B_j^{(a-b+1)}(c-b+1), \qquad |t|<2\pi, \end{aligned}$$

from (1.2). Using (3.3) and Watson's lemma in (3.2), and then employing the method of extraction of the singular part to remove the restriction on a and b (see [8, p. 119]), we obtain

$$(3.4)\quad \begin{aligned} \frac{\Gamma(x+a)}{\Gamma(x+b)}&=\sum_{j=0}^{m-1}\frac{\Gamma(b-a+j)}{\Gamma(b-a)j!}B_j^{(a-b+1)}(c-b+1)(x+c)^{a-b-j}\\ &\quad+R_m^{[c]}(a,b;x), \qquad x+\min\{a,c\}>0, \end{aligned}$$

where

$$(3.5)\quad R_m^{[c]}(a,b;x)=O((x+c)^{a-b-m}), \qquad x\to\infty,$$

for all $m\geqq 1$. With the relationship

$$(3.6)\quad B_j^{(\sigma)}(\sigma-d)=(-1)^jB_j^{(\sigma)}(d),$$

we note that (3.4) becomes a real version of the Tricomi-Erdélyi expansion (1.1) for $c=0$, and that it becomes a real version of Fields' expansion (1.3) for $c=(a+b-1)/2$.

To close this section, we mention two special cases of (3.4). If $a-b+1=m$, where m is a positive integer, then $R_m^{[c]}(a,b;x)$ is zero and (3.4) is exact. Also if $a-b=-p$, p a positive integer, and $|x+c|>|b-c+1|$, then with $m\to\infty$ the series in (3.4) is convergent and sums to $\{(x+a)(x+a+1)\cdots(x+a+p-1)\}^{-1}$.

4. In this section we obtain the main result of this paper - a proof of Luke's assertion about Fields' expansion. First assume that $|b-a|$ is not a nonnegative integer; for this case see the remarks at the end of the previous section. By using the functional relation $x\Gamma(x)=\Gamma(x+1)$ for the gamma function, as Luke noted, it is always possible to reduce consideration of $\Gamma(x+a)/\Gamma(x+b)$ to the case where $0<a-b+1<1$. Putting $c=(a+b-1)/2$ in (3.2) and (3.3) yields

$$(4.1)\quad \begin{aligned} \frac{\Gamma(x+a)}{\Gamma(x+b)}=\frac{1}{\Gamma(b-a)}\int_0^\infty e^{-t(x+(a+b-1)/2)}t^{-(a-b+1)}G^{[(a+b-1)/2]}(t)\,dt, \qquad x+a>0,\\ 0<a-b+1<1, \end{aligned}$$

where

$$(4.2)\quad \begin{aligned} G^{[(a+b-1)/2]}(t)&=e^{t((a-b+1)/2)}\left(\frac{t}{e^t-1}\right)^{a-b+1}\\ &=\left(\frac{\sinh t/2}{t/2}\right)^{-(a-b+1)}. \end{aligned}$$

Substituting the Maclaurin series of $G^{[(a+b-1)/2]}(t)$ into (4.1), requiring $x+\min\{a, (a+b-1)/2\}>0$ and using Watson's lemma then gives Fields' expansion (1.3). We now need the following result.

LEMMA 2. *The function* $h(t)=(\sinh\sqrt{t}/\sqrt{t})^{-\alpha}$ *is completely monotonic over* $[0,\infty)$ *for* $\alpha>0$.

Proof. Recall the well-known infinite product expansion of $\sin z/z$, valid for all complex z (see [11, p. 114]):

$$\frac{\sin z}{z}=\prod_{n=1}^{\infty}\left(1-\frac{z^2}{n^2\pi^2}\right). \tag{4.3}$$

Put $z=i\sqrt{t}$, $0\leqq t<\infty$, in (4.3) to obtain

$$\frac{\sinh\sqrt{t}}{\sqrt{t}}=\prod_{n=1}^{\infty}\left(1+\frac{t}{n^2\pi^2}\right). \tag{4.4}$$

Since $0\leqq t<\infty$ the product in (4.4) is strictly positive, and consequently

$$h(t)=\left(\frac{\sinh\sqrt{t}}{\sqrt{t}}\right)^{-\alpha}=\prod_{n=1}^{\infty}\left(1+\frac{t}{n^2\pi^2}\right)^{-\alpha},\qquad 0\leqq t<\infty. \tag{4.5}$$

It is easy to show that $h(t)$ may be differentiated to yield

$$h'(t)=-\alpha h(t)\sum_{n=1}^{\infty}\frac{1}{t+n^2\pi^2},\qquad 0\leqq t<\infty. \tag{4.6}$$

Now the sum in (4.6) defines a function $g(t)$ which is completely monotonic over $[0,\infty)$;

$$g(t)=\sum_{n=1}^{\infty}\frac{1}{t+n^2\pi^2}, \tag{4.7}$$

and so $(-1)^k g^{(k)}(t)\geqq 0$, $k=0,1,2,\cdots,0\leqq t<\infty$.

To prove that $h(t)$ is completely monotonic, we proceed by induction. From (4.5) and (4.6), $(-1)^k h^{(k)}\geqq 0$ for $k=0$ and $k=1$. Now suppose that $(-1)^k h^{(k)}(t)\geqq 0$ for $k=0, 1, 2, \cdots, n$. By Leibniz's rule,

$$\begin{aligned} h^{(n+1)}(t)&=(-\alpha h(t)g(t))^{(n)}\\ &=-\alpha\sum_{j=0}^{n}\binom{n}{j}h^{(j)}(t)g^{(n-j)}(t)\\ &=-\alpha(-1)^n\sum_{j=0}^{n}\binom{n}{j}|h^{(j)}(t)g^{(n-j)}(t)|,\end{aligned} \tag{4.8}$$

where we have used the inductive hypothesis and the complete monotonicity of $g(t)$. Equation (4.8) implies that $(-1)^{n+1}h^{(n+1)}(t)\geqq 0$, $0\leqq t<\infty$, thus completing the proof. □

Lemma 1 now implies that $h(t)$ is enveloped in the strict sense by its Maclaurin series for all $0<t<\infty$. Upon replacing t by t^2 and noting that $0<t^2<\infty$, we see that the even function $h(t^2)=(\sinh t/t)^{-\alpha}$ is also strictly enveloped by its Maclaurin series for $0<t<\infty$. It now follows immediately from (4.2) that $G^{[(a+b-1)/2]}(t)$ is strictly enveloped by its Maclaurin series when $0<a-b+1<1$. Consequently, (4.2), (1.2), (3.6) and (2.5) combine to give

$$\begin{gathered} G^{[\sigma]}(t)-\sum_{j=0}^{n}a_j t^{2j}=\theta_n(t)a_{n+1}t^{2n+2},\\ \sigma=\frac{a+b-1}{2},\quad \rho=\frac{a-b+1}{2},\quad a_j=\frac{B_{2j}^{(2\rho)}(\rho)}{(2j)!}\\ 0<\theta_n(t)<1,\quad n=1,2,3,\cdots,\quad 0<t<\infty,\quad 0<a-b+1<1.\end{gathered} \tag{4.9}$$

Multiplying (4.9) by $e^{-t(x+\sigma)}t^{-2p}/\Gamma(b-a)$, integrating from zero to infinity with respect to t and using (4.1) then gives

$$\begin{gathered}\frac{\Gamma(x+a)}{\Gamma(x+b)}-\sum_{j=0}^{n} b_j(x+\sigma)^{a-b-2j}=\frac{a_{n+1}}{\Gamma(b-a)}\int_0^\infty e^{-t(x+\sigma)}t^{2n+2-2p}\theta_n(t)\,dt,\\ b_j=\frac{\Gamma(b-a+2j)}{\Gamma(b-a)}a_j,\quad x+\min\{a,\sigma\}>0,\quad n=1,2,3,\cdots,\quad 0<a-b+1<1.\end{gathered}\tag{4.10}$$

Denoting the left-hand side of (4.10) by I_n, we see that

$$|I_n|<\frac{|a_{n+1}|}{\Gamma(b-a)}\int_0^\infty e^{-t(x+\sigma)}t^{2n+1+b-a}\,dt=|b_{n+1}|(x+\sigma)^{a-b-2n-2}.\tag{4.11}$$

Here we have used the fact that $\theta_n(t)$ is continuous on $(0,\infty)$. Thus, the asymptotic series $\sum_{j=0}^{\infty} b_j(x+\sigma)^{a-b-2j}$ envelops $\Gamma(x+a)/\Gamma(x+b)$. Moreover, as

$$\begin{aligned}\text{Sign}\,(I_n)&=\text{Sign}\left(\frac{a_{n+1}}{\Gamma(b-a)}\int_0^\infty e^{-t(x+\sigma)}t^{2n+1+b-a}\,dt\right)\\ &=\text{Sign}\,(b_{n+1}(x+\sigma)^{a-b-2n-2}),\end{aligned}\tag{4.12}$$

it follows from Pólya and Szegö [10, Prob. 144, p. 33] that $\Gamma(x+a)/\Gamma(x+b)$ is enveloped in the strict sense by the given asymptotic series. This proves Luke's assertion about Fields' expansion.

5. We conclude by using the notion of complete monotonicity to establish error bounds for the one parameter family of asymptotic approximations obtained from (3.2). Write $G^{[c]}(t)$, given in (3.3), as

$$G^{[c]}(t)=\left(\frac{e^{((a-c)/(a-b+1))t}-e^{((a-c)/(a-b+1)-1)t}}{t}\right)^{-(a-b+1)}.\tag{5.1}$$

We shall need the following result.

LEMMA 3. *The function* $f(t)=e^{-c_1t}-e^{-c_2t}/t$ *is completely monotonic over* $[0,\infty)$ *if* $-c_2<-c_1\leqq 0$.

Proof. By straightforward calculation one finds

$$f^{(k)}(t)=\frac{(-1)^k k!}{t^{k+1}}\{r_k(c_1t)-r_k(c_2t)\}\tag{5.2}$$

where

$$r_k(t)=e^{-t}\sum_{j=0}^{k}\frac{t^j}{j!}.\tag{5.3}$$

It is easily shown that $r_k(t)$ is strictly decreasing on $0<t<\infty$, and since $0\leqq c_1t<c_2t$ it follows from (5.2) that $(-1)^kf^{(k)}(t)\geqq 0$, $k=0,1,2,\cdots,0\leqq t<\infty$. Consequently $f(t)$ is completely monotonic over $[0,\infty)$. □

The case of interest to us is that of a completely monotonic function raised to a positive power (see (5.1)), so we assume $a-b+1<0$. To use Lemma 3 on $G^{[c]}(t)$ we must require $(a-c)/(a-b+1)\leqq 0$, or since $a-b+1<0$, $c\leqq a$. Under these assumptions (5.1) then represents a completely monotonic function raised to a positive power. If $-(a-b+1)$ is a positive integer and $c\leqq a$, then $G^{[c]}(t)$ is a completely monotonic function raised to a positive integer power and so is again completely monotonic. (The product of completely monotonic functions is completely monotonic.) In this case, by Lemma 1, $G^{[c]}(t)$ is strictly enveloped by its Maclaurin series for $0<t<\infty$, and proceeding as in § 4, we obtain

$$\frac{\Gamma(x+a)}{\Gamma(x+b)}-\sum_{j=0}^{n}\frac{\Gamma(b-a+j)}{\Gamma(b-a)j!}B_j^{(a-b+1)}(c-b+1)(x+c)^{a-b-j}$$

$$=\theta_n\frac{\Gamma(b-a+n+1)}{\Gamma(b-a)(n+1)!}B_{n+1}^{(a-b+1)}(c-b+1)(x+c)^{a-b-n-1}, \tag{5.4}$$

$$0<\theta_n<1,\quad n=0,1,2,\cdots,\quad -(a-b+1)=p,\ p \text{ a positive integer},\ c\leqq a,\ x+c>0.$$

We see from (5.4) that in this case the error made by truncating the expansion has the same sign and is numerically less than the first term neglected.

Suppose $-(a-b+1)$ is positive and not an integer. Lorch and Newman [5, p. 45] have shown that if $-(a-b+1)>1$, then $(f(t))^{-(a-b+1)}$ is monotonic of order 5 (at least) when $f(t)$ is completely monotonic. Coupling their result with (5.1) and Lemma 3 yields the following result:

$$\frac{\Gamma(x+a)}{\Gamma(x+b)}-\sum_{j=0}^{n}\frac{\Gamma(b-a+j)}{\Gamma(b-a)j!}B_j^{(a-b+1)}(c-b+1)(x+c)^{a-b-j}$$

$$=\theta_n\frac{\Gamma(b-a+n+1)}{\Gamma(b-a)(n+1)!}B_{n+1}^{(a-b+1)}(c-b+1)(x+c)^{a-b-n-1}, \tag{5.5}$$

$$0<\theta_n<1,\quad n=0,1,2,3,\quad -(a-b+1)>1,\quad c\leqq a,\quad x+c>0.$$

Equation (5.5) implies that for the first four terms of the asymptotic approximation given there, the error has the same sign and is numerically less than the first term neglected. The above results, in certain parameter ranges of a, b which can be obtained by using the functional equation for the gamma function, can be used to provide error bounds for the Tricomi-Erdélyi expansion (1.1) where $c=0$.

It is natural to ask if the function $G^{[c]}(t)$ in (5.1) is completely monotonic when $-(a-b+1)$ is positive, not an integer, and $c\leqq a$. It can be shown by using some further results on completely monotonic functions that there exist positive noninteger $-(a-b+1)>1$ such that $G^{[c]}(t)$ is not completely monotonic over $[0,\infty)$. To determine the order of monotonicity of $G^{[c]}(t)$ for general $c\leqq a$ and $-(a-b+1)$ is a difficult question which, in view of the results in § 4, will not be pursued here.

Finally we remark that the results in § 4 and this section can be used to provide some new inequalities for the ratio of two gamma functions, but we make no attempt here to compare them with previous work in this area.

Acknowledgments. I am grateful to Professor R. Wong for mentioning this problem to me, and also would like to thank the referees for pointing out the one-parameter family of asymptotic expansions given in (3.2) and (3.3) and for correcting an error in the original derivation of (4.10).

ASYNCHRONOUS EXPONENTIAL GROWTH IN TRANSITION PROBABILITY MODELS OF THE CELL CYCLE*

G. F. WEBB† AND A. GRABOSCH‡

Abstract. An analysis is given of the population dynamics of the transition probability model of the cell cycle. The model incorporates a probabilistic phase of indeterminate duration and a deterministic phase of constant duration. Individual cells increase in size according to a prescribed growth law. Sufficient conditions are established for the population to have the property of asynchronous exponential growth. The methods of proof use the theory of positive operators and semigroups of operators.

Key words. functional equation, semigroup of linear operators, positive operators, spectral bound, Banach lattice, exponential steady state

AMS(MOS) subject classifications. 92A15, 34K30

1. Introduction. During recent years an effort has been made to give a mathematical description of the cell cycle and the kinetics of proliferating cell populations. There are many unanswered questions concerning the biological processes occurring between cell birth and cell division. It is recognized that passage through the cell cycle divides into several phases. Typically there is an interphase after cell birth (G_1), a period of DNA synthesis (S), a second interphase (G_2) and a mitotic phase (M). A variety of models have been proposed to explain when and why a cell progresses from one phase into the next. Some models require cells to spend a fixed period of time in one or more phases. Others require that cell size reach a critical value. Other models concern inherited properties of cell descendants. Still others involve random transitions. Some recent mathematical treatments of such processes in cell population models have been given by Diekmann et al. [3], [4], Gyllenberg [9], Gyllenberg and Heijmans [10], Hannsgen et al. [11], Hannsgen and Tyson [12], Heijmans [13], [14], Jagers [15], Kimmel et al. [18], Lasota and Mackey [19], Lebowitz and Rubinow [20], Rotenberg [22], [23], Tyson and Hannsgen [28], [29] and Webb [32], [33].

In this paper we will give a rigorous mathematical analysis of what is known as the transition probability model of the cell cycle. This model was introduced by Smith and Martin in [26]. General discussions of this model can be found in the article of Brooks [1] and Brooks et al. [2]. The main idea of this model is the decomposition of the cell generation cycle into two kinetic states, a probabilistic A-phase and a deterministic B-phase. New cells enter the A-phase, from which they exit by random to the B-phase. The B-phase has a fixed duration normalized to 1. After passage through the B-phase a cell divides into two daughter cells of equal size, both of which enter the A-phase. The A-phase roughly corresponds to part of (G_1), and the B-phase to the rest of the cycle.

In this paper our main objective will be to determine growth laws for individual cells and transition probabilities for passage from A-phase to B-phase which are compatible with the asynchronous exponential growth of the total cell population. Roughly speaking, anynchronous or balanced exponential growth means that the density $n(x, t)$ of the total cell population at time t (with respect to some observed property x of individual cells) is asymptotic to $e^{\lambda_0 t} n_0(x)$, where λ_0 is the intrinsic

growth constant and $n_0(x)$ is the exponential steady state. The model we analyze has been discussed by Hannsgen et al. in [11]. In their paper they study the exponential steady state under general growth laws and transition probabilities. One of their conclusions is that no such exponential steady state exists if individual cells satisfy an exponential growth law. In [12] Hannsgen and Tyson show that if individual cells satisfy a linear growth law and the transition probability corresponds to a single random event, then an exponential steady state exists and the population converges to it in a weak sense. In [33] this convergence is shown to hold in a strong sense. In [6] this result is extended to a general growth law.

There are two essential elements in our model. The first is a growth function g which describes completely the growth of individual cells. The size of individual cells (or of some cell component) increases with time. In both phases of the cell cycle individual cells obey the same growth law. We suppose the following hypothesis on g:

(1.1) g is continuously differentiable on $[0,\infty)$, there exist constants $\underline{g}$ and $\bar{g}$ such that $0<\underline{g}\leqq g(x)\leqq \bar{g}$ for all $x\geqq 0$, and there exists a constant $\delta>0$ such that $2g(x)-g(2x)>\delta$ for all $x\geqq 0$.

The assumption $2g(x)-g(2x)>\delta$ was made by Heijmans in [14] for an age-size structured model of cell populations. The weaker assumption $2g(x)-g(2x)>0$ was made by Diekmann et al. in [3] and [4] for a size structured model. Both assumptions rule out the exponential growth function $g(x)=kx$. The second essential element of our model is a cumulative probability distribution function f. The cell generation time T of individual cells can be described as a random variable satisfying $\Pr\{T>t\}=\int_t^\infty f(s)\,ds$. We suppose the following hypothesis on f:

(1.2) f is a continuous function on $[0,\infty)$, $f(s)=0$ for $0\leqq s\leqq 1, f(s)>0$ for $s>1, \int_1^\infty f(s)\,ds=1$, and there exist positive constants M and p such that $|f(s)|\leqq M e^{-ps}$, $s\geqq 0$.

We define $M(t,x)$ as *the size of a cell which at t time units before had size x.* $M(t,x)$ is the solution of the initial value problem

$$\frac{\partial}{\partial t}M(t,x)=g(M(t,x)), \qquad M(0,x)=x\geqq 0. \tag{1.3}$$

$M(1,0)$ is the minimum division size (since 1 unit of time must be spent in the B-phase), $\frac{1}{2}M(1,0)$ is the minimum birth size, $\frac{1}{2}M(1,\frac{1}{2}M(1,0))$ is the minimum birth size in the second generation, and so forth. We define $T(x,y)$ as *the time required for a cell to grow from size x to size y.* In terms of g

$$T(x,y)=\int_x^y \frac{1}{g(u)}\,du, \qquad 0\leqq x\leqq y. \tag{1.4}$$

We define $m(t,x)$ as *the size of a cell which grows in t time units to size x.* For $t<T(0,x)$, $m(t,x)$ is the backward solution of (1.3), which means that

$$\frac{\partial}{\partial t}m(t,x)=-g(m(t,x)), \qquad m(0,x)=x\geqq 0. \tag{1.5}$$

We collect some basic properties of M, m and T:

(1.6) $y=M(t,x)$ iff $x=m(t,y)$ iff $t=T(x,y)$, $0\leqq x\leqq y$, $0\leqq t\leqq T(0,y)$,

$$(1.7)\qquad M_2(t,x)=\frac{M_1(t,x)}{g(x)}=\frac{g(M(t,x))}{g(x)},\qquad x\geqq 0,\quad t\geqq 0,$$

$$(1.8)\qquad m_2(t,x)=\frac{-m_1(t,x)}{g(x)}=\frac{g(m(t,x))}{g(x)},\qquad x\geqq 0,\quad 0\leqq t\leqq T(0,x),$$

$$(1.9)\qquad x-t\bar{g}\leqq m(t,x)\leqq x,\qquad x\geqq 0,\quad 0\leqq t\leqq T(0,x),$$

$$(1.10)\qquad x\leqq M(t,x)\leqq x+t\bar{g},\qquad x\geqq 0,\quad t\geqq 0.$$

Several interpretations of transition probability distribution functions f are given in [11]. Take $f(t)=f_A(t-1)$, $t\geqq 1$, $f(t)=0$, $0\leqq t\leqq 1$. The *two-transition probability model of Brooks et al.* [2] has $f_A(t)=(pq/(q-p))(e^{-pt}-e^{-qt})$, $p, q>0$, $p\neq q$. Here f_A is the convolution of two densities $f_1(t)=p\,e^{-pt}$, $f_2(t)=q\,e^{-qt}$, each corresponding to a single random transition. The *Kendall model* [17] has $f_A(t)=(p/(g-1)!)(pt)^{g-1}\,e^{-pt}$, $p>0$, $g\in\mathbb{N}$. This is the gamma distribution function. Cells divide as soon as a fixed number g events have occurred. These events can happen independently in any order and all with the same constant probability per unit time. The *Rahn model* [21] has $f_A(t)=gp\,e^{-pt}(1-e^{-pt})^{g-1}$, $p>0$, $g\in\mathbb{N}$. This is the Yule distribution function. The idea is the same as in the Kendall model except that the g events have to occur in a specified order. We mention that the *one-transition probability model of Smith and Martin* $f_A(t)=p\,e^{-pt}$, $p>0$, is not included in our development, since (1.2) requires f to be continuous. This case is treated in [6] and [33].

The derivation of our model is similar to the derivation in [11]. Let $\int_{x_1}^{x_2} n(x,t)\,dx$ be the rate at which cells divide with size between x_1 and x_2 at time t. Let $\int_{x_1}^{x_2}\tilde{n}(x,t)\,dx$ be the rate at which cells are born with size between x_1 and x_2 at time t. Fix $t>0$ and $x>M(1,0)$. We write a balance equation for the rate at which cells divide at time t with size between x and $x+\Delta x$. These cells were born σ time units ago, that is, at time $t-\sigma$, where $\sigma>0$. They must have had a birth size which leads to a size between x and $x+\Delta x$ at time t. Thus, they must have had a birth size between $m(\sigma,x)$ and $m(\sigma,x+\Delta x)$. Of those cells born between $t-\sigma-\Delta\sigma$ and $t-\sigma$ the probability that an individual cell has generation time between σ and $\sigma+\Delta\sigma$ is $f(\sigma)\Delta\sigma$. Thus, the rate of dividing cells at time t with size between x and $x+\Delta x$ is

$$\begin{aligned}\int_x^{x+\Delta x} n(y,t)\,dy&=\int_0^\infty\int_{m(\sigma,x)}^{m(\sigma,x+\Delta x)}\tilde{n}(y,t-\sigma)\,dy f(\sigma)\,d\sigma\\&=\int_0^\infty\int_x^{x+\Delta x}\tilde{n}(m(\sigma,u),t-\sigma)m_2(\sigma,u)\,du f(\sigma)\,d\sigma.\end{aligned}$$

Divide by Δx and let $\Delta x\to 0$ to obtain

$$n(x,t)=\int_0^\infty \tilde{n}(m(\sigma,x),t-\sigma)m_2(\sigma,x)f(\sigma)\,d\sigma.$$

For a cell dividing with size x at σ time units after birth σ satisfies $1=T(0,M(1,0))\leqq\sigma\leqq T(0,x)$. Consequently,

$$n(x,t)=\int_1^{T(0,x)}\tilde{n}(m(\sigma,x),t-\sigma)m_2(\sigma,x)f(\sigma)\,d\sigma.$$

We must describe $\tilde{n}$ in terms of n. The number of newborn cells at time t with size between x and $x+\Delta x$ is exactly twice the number of dividing cells at time t with size between $2x$ and $2x+2\Delta x$. Thus,

$$\int_x^{x+\Delta x}\tilde{n}(y,t)\,dy=2\int_{2x}^{2x+2\Delta x} n(y,t)\,dy=4\int_x^{x+\Delta x} n(2y,t)\,dy.$$

Divide by Δx and let $\Delta x \to 0$ to obtain $\tilde{n}(x, t) = 4n(2x, t)$. We are thus led to the following functional equation for the density $n(x, t)$:

(1.11)

$$n(x,t) = \begin{cases} 4\displaystyle\int_1^{T(0,x)} n(2m(\sigma,x), t-\sigma)m_2(\sigma,x)f(\sigma)\,d\sigma, & t \geqq 0, \quad x > M(1,0), \\ 0, & t \geqq 0, \quad 0 \leqq x \leqq M(1,0), \\ \phi(x,t), & t < 0, \quad x \geqq 0. \end{cases}$$

In (1.11) ϕ prescribes the distribution of dividing cells before time 0.

In order to state our main result we introduce some notation. Let $0 < \tau < p/2\bar{g}$. Define the Banach space $Y \equiv \{h \in C([0,\infty); \mathbf{R})\colon h(0) = 0$, and $\lim_{x\to\infty} e^{\tau x}h(x) = 0\}$ with norm $\|h\|_Y \equiv \sup_{x \geqq 0} e^{\tau x}|h(x)|$. Define the Banach space $X \equiv L^1((-\infty, 0]; Y)$.

PROPOSITION 1.1. *There exists a unique real solution λ_0 of the equation $1 = 2\int_1^\infty e^{-\lambda_0 s} f(s)\,ds$, there exists a unique solution x^* of the equation $1 = T(x^*/2, x^*)$, and there exists a unique function $h_0 \in Y$ satisfying the normalizing condition $1 = \int_{x^*}^\infty h_0(x)\,dx$ and the integral equation*

$$\text{(1.12)} \qquad h_0(x) = \begin{cases} 4\displaystyle\int_1^{T(x^*/2,x)} e^{-\lambda_0 s}h_0(2m(s,x))f(s)m_2(s,x)\,ds\,dx, & x \geqq x^*, \\ 0, & 0 \leqq x < x^*. \end{cases}$$

Let $\phi \in X$. There exists a unique solution of (1.11) *satisfying $n(\cdot, t) \in Y$ for $t \geqq 0$. Further, there exists a constant $c(\phi)$ (depending on ϕ) such that*

$$\text{(1.13)} \qquad \lim_{t\to\infty} \|e^{-\lambda_0 t}n(\cdot, t) - c(\phi)h_0\|_Y = 0.$$

The method of proof of Proposition 1.1 will employ the theory of semigroups of linear operators and the theory of positive operators. The application of these theories to the study of structured population dynamics has been developed by a number of authors. Our approach has been particularly influenced by Greiner [7], Diekmann et al. [3], [4] and Heijmans [13], [14]. We state the basic ideas we will use. Let $T(t)$, $t \geqq 0$ be a strongly continuous semigroup of bounded linear operators in a Banach space X and let A be its infinitesimal generator. The *spectral bound* of A is $s(A) \equiv \sup\{\operatorname{Re}\lambda\colon \lambda \in \sigma(A)\}$(see [7]). The *essential growth bound* of $T(t)$, $t \geqq 0$ is $\omega_1(A) \equiv \lim_{t\to\infty}(1/t)\log(\alpha[T(t)])$, where α is the Kuratowski measure of noncompactness (see [31]). Let L be a positive bounded linear operator in a Banach lattice X (see [25]). L is *nonsupporting* if and only if for each $\phi \in X_+$, $\phi \neq 0$, $F \in X_+^*$, $F \neq 0$, there is an integer n_1 such that for $n \geqq n_1$, $(F, L^n\phi) > 0$ (see [14]). The following result is proved in [7] and [33].

PROPOSITION 1.2. *Let $T(t)$, $t \geqq 0$ be a strongly continuous semigroup of positive bounded linear operators in the Banach lattice X.* (1) *If $\omega_1(A) < s(A)$, then $s(A) \in P\sigma(A)$ and there exists $\phi \in X_+$, $\phi \neq 0$, such that $A\phi = s(A)\phi$.* (2) *If $\omega_1(A) < s(A)$ and $s(A)$ is a simple eigenvalue of A (that is, $s(A)$ is a simple pole of $(\lambda I - A)^{-1}$ and $N(s(A)I - A)$ is one-dimensional), then $\lim_{t\to\infty} e^{-s(A)t}T(t) = P_0$, where P_0 is the projection of X onto $N(s(A)I - A)$ given by $(1/2\pi i)\int_\Gamma (\lambda I - A)^{-1}\,d\lambda$ (Γ is a positively oriented circle about $s(A)$ enclosing no other point of $\sigma(A)$).*

The following result is proved in [24] (see also [14]).

PROPOSITION 1.3. *Let L be a positive nonsupporting bounded linear operator in the Banach lattice X and let the spectral radius $r = r(L)$ be a pole of $(\lambda I - L)^{-1}$.* (1) *$r > 0$ and r is a simple eigenvalue of L.* (2) *There exists $\phi \in X_+$, $\phi \neq 0$, such that $L\phi = r\phi$ and*

$\langle F, \phi\rangle > 0$ *for all* $F \in X_+^*$, $F \neq 0$. (3) *There exists* $F \in X_+^*$, $F \neq 0$, *such that* $L^*F = rF$ *and* $\langle F, \phi\rangle > 0$ *for all* $\phi \in X_+$, $\phi \neq 0$.

2. The semigroup of operators. We observe that X and Y are Banach lattices with the natural ordering. Define $G: X \to Y$ as follows: for $\phi \in X$

$$(2.1)\qquad (G\phi)(x) = \begin{cases} 4\displaystyle\int_1^{T(0,x)} \phi(-s)(2m(s,x))m_2(s,x)f(s)\,ds, & x > M(1,0), \\ 0, & 0 \leqq x \leqq M(1,0). \end{cases}$$

PROPOSITION 2.1. *G is a bounded linear operator from X to Y.*

Proof. Let $\phi \in X$. Since $T(0, M(1,0)) = 1$, $(G\phi)(x)$ is a continuous function of x. Since $m(s,x) \geqq x - s\bar{g}$,

$$\begin{aligned} e^{\tau x}|(G\phi)(x)| &= e^{\tau x}4\int_1^{T(0,x)} |\phi(-s)(2m(s,x))|\, e^{2\tau m(s,x)}\, e^{-2\tau m(s,x)} m_2(s,x)f(s)\,ds \\ &\leqq 4Me^{-\tau x}(\bar{g}/g)\int_1^{T(0,x)} \|\phi(-s)\|_Y e^{(2\tau\bar{g}-p)s}\,ds \\ &\leqq 4Me^{-\tau x}(\bar{g}/g)\|\phi\|_X. \end{aligned}$$

Thus, $\lim_{x\to\infty} e^{\tau x}|(G\phi)(x)| = 0$ and $\|G_\phi\|_Y \leqq 4M(\bar{g}/g)\|\phi\|_X$. □

The problem (1.11) can be formulated as

$$(2.2)\qquad n(t) = Gn_t, \qquad t \geqq 0, \quad n_0 = \phi$$

where $n: (-\infty, \infty) \to Y$, $n_t \in X$, $n_t(\theta) = n(t+\theta)$, $\theta \leqq 0$, $\phi \in X$ and $n(x,t) = n(t)(x)$. The proof of the following proposition follows directly from the results in [30].

PROPOSITION 2.2. *For each $\phi \in X$ there exists a unique function $n: (-\infty, \infty) \to Y$ satisfying* (2.2). *If $\phi \in X_+$, then $n_t \in X_+$ for all $t \geqq 0$. The solutions of* (2.2) *define a strongly continuous semigroup of bounded linear operators in X by the formula $T(t)\phi = n_t$. The infinitesimal generator of $T(t)$, $t \geqq 0$ is $A\phi = +\phi'$, $D(A) = \{\phi \in X$: ϕ is locally absolutely continuous, $\phi'(\theta)$ exists for almost all $\theta \leqq 0$, $\phi' \in X$, and $\phi(0) = G\phi\}$.*

PROPOSITION 2.3. *The essential growth bound of $T(t)$, $t \geqq 0$ satisfies $\omega_1(A) \leqq 0$.*

Proof. By virtue of Proposition 2.4 in [33] it suffices to show that for t sufficiently large there exists a representation $T(t) = U(t) + V(t)$, where $|U(t)| \leqq C$ for some constant C independent of t and $V(t)$ is compact. Let $\phi \in X$ and define $n_j: (-\infty, \infty) \to Y$, $j = 1, 2, 3, 4$, as follows:

$$n_1(t)(x) = \begin{cases} 4\displaystyle\int_{t-T(0,x)}^0 \phi(u)(2m(t-u,x))m_2(t-u,x)f(t-u)\,du, & t \geqq 0, \quad x \geqq 0, \\ \phi(t)(x), & t < 0, \quad x \geqq 0, \end{cases}$$

$$n_2(t)(x) = \begin{cases} 4\displaystyle\int_0^{t-1} n_1(u)(2m(t-u,x))m_2(t-u,x)f(t-u)\,du, & t \geqq 1, \quad x \geqq 0, \\ 0, & t < 1, \quad x \geqq 0, \end{cases}$$

$$n_3(t)(x) = \begin{cases} 16\displaystyle\int_{-1}^0\int_0^{w+1} \phi(w)(2m(u-w), 2m(t-u,x))m_2(u-w, 2m(t-u,w)) & \\ \quad\cdot f(u-w)m_2(t-u,x)f(t-u)\,du\,dw, & t \geqq 1, \quad x \geqq 0, \\ 0, & t < 1, \quad x \geqq 0, \end{cases}$$

$$n_4(t)(x)=\begin{cases}16\displaystyle\int_0^{t-2}\int_{w+1}^{t-1} n(w)(2m(u-w),2m(t-u,x))m_2(u-w,2m(t-u,x)) & \\ \quad\cdot f(u-w)m_2(t-u,x)f(t-u)\,du\,dw, & t\geqq 2,\quad x\geqq 0,\\ 0, & t<2,\quad x\geqq 0\end{cases}$$

(all integrals are taken as 0 whenever the lower limit of integration exceeds the upper limit of integration). For $\phi\in X$, $t\geqq 0$, $x\geqq 0$,

$$\begin{aligned}n(t)(x)&=4\int_{t-T(0,x)}^{t-1} n(u)(2m(t-u,x))m_2(t-u,x)f(t-u)\,du\\ &=n_1(t)(x)+4\int_0^{t-1} n(u)(2m(t-u,x))m_2(t-u,x)f(t-u)\,du\\ &=n_1(t)(x)+n_2(t)(x)+16\int_0^{t-1}\int_0^{u-1} n(w)(2m(u-w,2m(t-u,x)))\\ &\quad\cdot m_2(u-w,2m(t-u,x))f(u-w)\,dw\,m_2(t-u,x)f(t-u)\,du\\ &=n_1(t)(x)+n_2(t)(x)+n_3(t)(x)+n_4(t)(x).\end{aligned}$$

Define$(U(t)\phi)(\theta)(x)=\sum_{j=1}^{3} n_j(t+\theta)(x)$,$(V(t)\phi)(\theta)(x)=n_4(t+\theta)(x)$.Then,$(U(t)\phi+V(t)\phi)(\theta)(x)=n(t+\theta)(x)=(T(t)\phi)(\theta)(x)$.

Since $m(t+\theta-u,x)\geqq x-(t+\theta-u)\bar{g}$, there exists a constant C independent of t, θ and x such that

$$\begin{aligned}e^{\tau x}|n_1(t+\theta)(x)|&\leqq Ce^{-\tau x}\int_{t+\theta-T(0,x)}^{0}\|\phi(u)\|_Y e^{2r(t+\theta-u)\bar{g}}\,e^{-p(t+\theta-u)}\,du\\ &\leqq C\|\phi\|_X e^{(2\tau\bar{g}-p)(t+\theta)}.\end{aligned}$$

Consequently,

$$\begin{aligned}\int_{-\infty}^{0}\sup_{x\geqq 0} e^{\tau x}|n_1(t+\theta)(x)|\,d\theta&\leqq\int_{-\infty}^{-t}\|\phi(t+\theta)\|_Y\,d\theta+C\|\phi\|_X\int_{-t}^{0} e^{(2\tau\bar{g}-p)(t+\theta)}\,d\theta\\ &\leqq(1+C)\|\phi\|_X.\end{aligned}$$

Similarly, from (2.3) we see that there exists a constant C, which is changing, but is independent of t, θ and x, such that

$$\begin{aligned}e^{\tau x}|n_2(t+\theta)(x)|&\leqq Ce^{\tau x}\int_0^{t+\theta-1}|n_1(u)(2m(t+\theta-u,x))|\,e^{-p(t+\theta-u)}\,du\\ &\leqq Ce^{\tau x}\int_0^{t+\theta-1} e^{-2\tau m(t+\theta-u,x)}\|\phi\|_X e^{(2\tau\bar{g}-p)u}\,e^{-p(t+\theta-u)}\,du\\ &\leqq C\|\phi\|_X e^{-\tau x}\,e^{(2\tau\bar{g}-p)(t+\theta)}(t+\theta-1).\end{aligned}$$

Consequently,

$$\begin{aligned}\int_{-\infty}^{0}\sup_{x\geqq 0} e^{\tau x}|n_2(t+\theta)(x)|\,d\theta&\leqq C\|\phi\|_X\int_{1-t}^{0} e^{(2\tau\bar{g}-p)(t+\theta)}(t+\theta-1)\,d\theta\\ &\leqq C\|\phi\|_X.\end{aligned}$$

Since $2m(u-w, 2m(t+\theta-u, x)) \geqq m(u-w, 2m(t+\theta-u, x)) \geqq 2x+(w+u-2(t+\theta))\bar{g}$,

$$e^{\tau x}|n_3(t+\theta)(x)| \leqq C\,e^{\tau x}\int_{-1}^{0}\int_{0}^{w+1}\|\phi(w)\|_Y\, e^{-2\tau x}\, e^{-\tau(w+u-2(t+\theta))\bar{g}}\, e^{-p(t+\theta-w)}\,du\,dw$$

$$\leqq C\,e^{-\tau x}\|\phi\|_X\, e^{(2\tau\bar{g}-p)(t+\theta)}.$$

Consequently,

$$\int_{-\infty}^{0}\sup_{x\geqq 0} e^{\tau x}|n_3(t+\theta)(x)|\,d\theta \leqq C\|\phi\|_X.$$

Thus, $|U(t)| \leqq C$, where C is a constant independent of t.

It remains to show that for $t>2$, $V(t)$ is compact from X to X. Let M be a bounded set in X. We substitute $v=2m(u-w, 2m(t-u, x))$ in the integral which defines $n_4(t)(x)$. Since $\partial v/\partial u = 2g(m(u-w, 2m(t-u, x)))[-1+2g(m(t-u, x))/g(2m(t-u, x))]$ and $2g(y)-g(2y)>\delta>0$ for all $y\geqq 0$, we have $\partial v/\partial u \geqq 2\delta\underline{g}/\bar{g}>0$. Define $u=g(v, t, x)$ if and only if $v=2m(u-w, 2m(t-u, x))$ and observe that $\partial q/\partial v \leqq \bar{g}/2\delta\underline{g}$. Thus, for $\theta \geqq 2-t$, $x\geqq 0$

$$(V(t)\phi)(\theta)(x) = 16\int_{0}^{t+\theta-2}\int_{r(x,w,t+\theta)}^{s(x,w,t+\theta)} n(w)(v)z(v, w, t+\theta, x)\,dv\,dw$$

where $s(x, w, t+\theta)=2m(t+\theta-w-1, 2m(1, x))$, $r(x, w, t+\theta)=2m(1, 2m(t-w-1, x))$ and

$$z(v, w, t+\theta, x) = m_2(q(v, t+\theta, x)-w, 2m(t+\theta-q(v, t+\theta, x), x))f(q(v, t+\theta, x)-w)$$

$$\cdot\, m_2(t+\theta-q(v, t+\theta, x), x)f(t+\theta-q(v, t+\theta, x))\partial q(v, t+\theta, x)/\partial v.$$

Since $|n(w)(v)| \leqq e^{-\tau v}\|n(w)\|_Y = e^{-\tau v}\|Gn_w\|_Y \leqq e^{-\tau v}|G|\,\|T(w)\phi\|_X$, $(V(t)\phi)(\theta)(x)$ is equicontinuous in θ for $\theta\in[2-t, 0]$ and in x for x in bounded intervals independently of $\phi\in M$. We need only show that $\lim_{x\to\infty} e^{\tau x}|(V(t)\phi)(\theta)(x)|=0$ uniformly for $\phi\in M$, $\theta\in[2-t, 0]$. Since $r(x, w, t+\theta)\geqq 4(x-(t+\theta-w-\frac{1}{2})\bar{g})$,

$$e^{\tau x}|(V(t)\phi)(\theta)(x)| \leqq C\,e^{\tau x}\int_{0}^{t+\theta-2}\int_{r(x,w,t+\theta)}^{s(x,w,t+\theta)} e^{-\tau v}\, e^{-p(t+\theta-w)}\,dv\,dw$$

$$\leqq C\,e^{\tau x}\, e^{-p(t+\theta)}\int_{0}^{t+\theta-2} e^{-\tau r(x,w,t+\theta)}\, e^{pw}\,dw$$

$$\leqq C\,e^{-3\tau x}$$

where C is independent of $\phi\in M$, $\theta\in[2-t, 0]$ and $x\geqq 0$. □

3. Spectral properties of the infinitesimal generator. Let $\lambda=\lambda_0$ be the unique real root of the equation $1=2\int_1^\infty e^{-\lambda s}f(s)\,ds$. Notice that λ_0 is positive. We will establish that $s(A)=\lambda_0$ is a simple eigenvalue of A. For $\lambda>2\tau\bar{g}-p$ and $h\in Y$ define $L_\lambda h$ by

$$(3.1)\quad (L_\lambda h)(x)=\begin{cases} 4\displaystyle\int_{1}^{T(0,x)} e^{-\lambda s}h(2m(s, x))m_2(s, x)f(s)\,ds, & x>M(1, 0),\\ 0, & 0\leqq x\leqq M(1, 0).\end{cases}$$

PROPOSITION 3.1. *Let $\lambda>2\tau\bar{g}-p$. (1) L_λ is a positive compact operator from Y to Y. (2) $\lambda\in P_\sigma(A)$ and $A\phi=\lambda\phi$, $\phi\neq 0$, if and only if there exists $h\in Y$, $h\neq 0$ such that $\phi(\theta)=e^{\lambda\theta}h$ and $L_\lambda h=h$.*

Proof. Obviously L_λ is positive. To prove L_λ is compact let M be a bounded subset of Y. The substitution $\sigma = 2m(s, x)$ in (3.1) yields

$$(3.2)\qquad (L_\lambda h)(x) = \frac{2}{g(x)} \int_0^{2m(1,x)} e^{-\lambda T(\sigma/2,x)} h(\sigma) f\left(T\left(\frac{\sigma}{2}, x\right)\right) d\sigma.$$

From (3.2) we see that $(L_\lambda h)(x)$ is equicontinuous in x for bounded intervals of x and for h in M. From (3.1),

$$\begin{aligned} e^{\tau x}|(L_\lambda h)(x)| &\leqq C e^{\tau x} \int_1^{T(0,x)} e^{-\lambda s} \|h\|_Y e^{-2\tau m(s,x)}\, e^{-ps}\, ds \\ &\leqq C e^{-\tau x} \int_1^{T(0,x)} e^{-(\lambda+p-2\tau\bar{g})s}\, ds \leqq C e^{-\tau x} \end{aligned}$$

where C is independent of $h \in M$ and $x \geqq M(1, 0)$. Thus, $\lim_{x\to\infty} e^{\tau x}(L_\lambda h)(x) = 0$ uniformly for $h \in M$. Hence, L_λ is compact and (1) is proved.

To prove (2) observe by Proposition 2.2 that $A\phi = \lambda\phi$ if and only if $\phi' = \lambda\phi$ and $\phi(0) = G\phi$ if and only if $\phi(\theta) = e^{\lambda\theta}\phi(0)$ and $\phi(0) = G(e^{\lambda\theta}\phi(0)) = L_\lambda\phi(0)$. □

PROPOSITION 3.2. *Let $\gamma(x) = \frac{1}{2}M(1, x)$, $x \geqq 0$. (1) γ has a unique fixed point y^* and $y^* > 0$. (2) Let $x \geqq 0$ and define $y_1 = \gamma(x)$, $y_{n+1} = \gamma(y_n)$, $n = 1, 2, \cdots$. If $0 \leqq x < y^*$, then $\{y_n\}$ increases to y^*, and if $y^* < x$, then $\{y_n\}$ decreases to y^*.*

Proof. Our proof follows [14, Lemma 6.5]. Observe that $\gamma'(x) = \frac{1}{2}(g(2\gamma(x))/g(x))$. Since $2g(x) - g(2x) > 0$, we have that $\gamma'(y) < 1$ for any fixed point y of γ. Hence, γ can have at most one fixed point. Since $y_{n+1} \leqq \frac{1}{2}(y_n + \bar{g})$, the sequence $\{y_n\}$ is bounded. If $0 \leqq x < \gamma(x)$, then $\{y_n\}$ is increasing to a fixed point of γ. If $x > \gamma(x)$, then $\{y_n\}$ decreases to a fixed point of γ. The claims (1) and (2) now follow immediately. □

PROPOSITION 3.3. *Let $\lambda > 2\tau\bar{g} - p$, let $x_1 = \frac{1}{2}M(1, 0)$, $x_{n+1} = \gamma(x_n)$, $n = 1, 2, \cdots$, and let $x^* \equiv \lim_{n\to\infty} 2x_n = 2y^*$. (1) If $h \in Y$, then $(L_\lambda^n h)(x) = 0$ for $0 \leqq x \leqq 2x_n$, $n = 1, 2, \cdots$. (2) If $h \in Y_+$ such that $h(x_0) > 0$ for some $x_0 > x^*$ and $y_1 = \frac{1}{2}M(1, x_0/2)$, $y_{n+1} = \gamma(y_n)$, $n = 1, 2, \cdots$, then $(L_\lambda^n(x) > 0$ for $2y_n \leqq x < \infty$, $n = 1, 2, \cdots$.*

Proof. By (3.1) $(L_\lambda h)(x) = 0$ for $0 \leqq x \leqq 2x_1$. By (3.2)

$$(3.3)\qquad (L_\lambda^2 h)(x) = \frac{2}{g(x)} \int_0^{2m(1,x)} e^{-\lambda T(\sigma/2,x)} (L_\lambda h)(\sigma) f\left(T\left(\frac{\sigma}{2}, x\right)\right) d\sigma.$$

Since $(L_\lambda h)(x) = 0$ for $0 \leqq x \leqq 2x_1$, $(L_\lambda^2 h)(x) = 0$ for $2m(1, x) \leqq 2x_1$, that is, for $x \leqq M(1, x_1) = 2x_2$. An induction argument proves (1) in the general case. By (3.2) $(L_\lambda h)$ $\cdot (x) > 0$ for $2m(1, x) \geqq x_0$, that is, for $x \geqq M(1, x_0/2) = 2y_1$. By (3.3), $(L_\lambda^2 h)(x) > 0$ for $2m(1, x) \geqq M(1, x_0/2)$, that is, for $x \geqq M(1, \frac{1}{2}M(1, x_0/2)) = 2y_2$. An induction argument proves (2) in the general case. □

Define $Z = \{h \in C([x^*, \infty); \mathbf{R})\colon h(x^*) = 0 \text{ and } \lim_{x\to\infty} e^{\tau x}h(x) = 0\}$ with norm $\|h\|_Z = \sup_{x \geqq x^*} e^{\tau x}|h(x)|$. For $\lambda > 2\tau\bar{g} - p$ and $h \in Z$ define $K_\lambda h$ by

$$(3.4)\qquad (K_\lambda h)(x) = \frac{2}{g(x)} \int_{x^*}^{2m(1,x)} e^{-\lambda T(\sigma/2,x)} h(\sigma) f\left(T\left(\frac{\sigma}{2}, x\right)\right) d\sigma, \qquad x \geqq x^*.$$

PROPOSITION 3.4. *Let $\lambda > 2\tau\bar{g} - p$. (1) If $h \in Y$ such that $h(x) = 0$ for $0 \leqq x \leqq x^*$, then $(L_\lambda h)|_{[x^*,\infty)} = K_\lambda h|_{[x^*,\infty)}$. (2) K_λ is a compact positive nonsupporting operator from Z to Z. (3) The spectral radius $r(K_\lambda)$ of K_λ is positive and is a pole of the resolvent of K_λ.*

Proof. We have (1) from (3.2), (3.4), and the fact $2m(1, x^*) = x^*$. That K_λ is a compact positive operator from Z to Z then follows from Proposition 3.1 (1). To prove (2) it remains to show that K_λ is nonsupporting. Let $h \in Z_+$, $h \neq 0$, $F \in F_+^*$, $F \neq 0$. There exists $x_0 > x^*$ such that $h(x_0) > 0$. Define $\{y_n\}$ as in (2) of Proposition 3.3 so that

$\{2y_n\}$ decreases to x^* and $(K_\lambda^n h)(x) > 0$ for $x \geqq 2y_n$. Let $0 \leqq q_n(x) \leqq 1$ such that $q_n \in Z$ and $q_n(x) = 1$ for $a_n \equiv y_n \leqq x \leqq b_n \equiv 2y_n + n$. Define $F_n \in Z_+^*$ by $\langle F_n, k\rangle = \langle F, k \cdot q_n\rangle$, $k \in Z$. For each $k \in Z$, $|\langle F_n - F, k\rangle| = |\langle F, k \cdot q_n - k\rangle| \leqq \|F\|_{Z^*} \|k \cdot q_n - k\|_Z \to 0$ as $n \to \infty$ (since $k(x^*) = \lim_{x\to\infty} k(x) = 0$). Assume there exists a subsequence such that $\langle F, K_\lambda^{m_n} h\rangle = 0$ for all n. Since $0 \leqq \langle F_{m_n}, K_\lambda^{m_n} h\rangle \leqq \langle F, K_\lambda^{m_n} h\rangle$, we have $\langle F_{m_n}, K_\lambda^{m_n} h\rangle = 0$ for all n. For each n there exists a nondecreasing function f_{m_n} on $[a_{m_n}, b_{m_n}]$ such that $\langle F_{m_n}, k\rangle = \int_{a_{m_n}}^{b_{m_n}} k(x)\, df_{m_n}(x)$ for all $k \in Z$ (see [27, § 6.1.4]). Since $(K_\lambda^{m_n} h)(x) >$ for $a_{m_n} \leqq x \leqq b_{m_n}$ and $\langle F_{m_n}, K_\lambda^{m_n} h\rangle = 0$, we must have $f_{m_n} \equiv 0$ on $[a_{m_n}, b_{m_n}]$. Then, $\langle F, k\rangle = \lim_{n\to\infty} \langle F_{m_n}, k\rangle = 0$ for all $k \in Z$, which is a contradiction. Thus, K_λ is nonsupporting and (2) is proved. To show that $r(K_\lambda) > 0$ let $h \in Z_+$ such that $h \neq 0$. From (3.4)

$$\int_{x^*}^{\infty} (K_\lambda h)(x)\, dx = \int_{x^*}^{\infty} \frac{2}{g(x)} \int_{x^*}^{2m(1,x)} e^{-\lambda T(\sigma/2,x)} h(\sigma) f\left(T\left(\frac{\sigma}{2}, x\right)\right) d\sigma\, dx$$

$$\begin{aligned} &= 4 \int_{x^*}^{\infty} \int_{1}^{T(x^*/2,x)} e^{-\lambda s} h(2m(s,x)) f(s) m_2(s,x)\, ds\, dx \\ (3.5) \qquad &= 4 \int_{1}^{\infty} \int_{M(s,x^*/2)}^{\infty} e^{-\lambda s} h(2m(s,x)) f(s) m_2(s,x)\, dx\, ds \\ &= \left(2 \int_1^{\infty} e^{-\lambda s} f(s)\, ds\right) \int_{x^*}^{\infty} h(y)\, dy. \end{aligned}$$

If $\|h\|_Z = 1$, then

$$\left(2 \int_1^{\infty} e^{-\lambda s} f(s)\, ds\right)^n \int_{x^*}^{\infty} h(y)\, dy = \int_{x^*}^{\infty} (K_\lambda h)^n(x)\, dx \leqq \frac{e^{-\tau x^*}}{\tau} |K_\lambda^n|.$$

Consequently, $\lim_{n\to\infty} |K_\lambda^n|^{1/n} = r(K_\lambda) > 0$. Since K_λ is compact, $r(K_\lambda)$ is a pole of the resolvent of K_λ (see [16, p. 185]). Thus, (3) is proved. □

PROPOSITION 3.5. *The spectral bound of* $T(t)$, $t \geqq 0$ *satisfies* $\omega_1(A) < s(A) = \lambda_0$.

Proof. By Propositions 1.3 (2) and 3.4 (2) there exists $h_0 \in Z_+$, $h_0 \neq 0$, such that $K_{\lambda_0} h_0 = r(K_{\lambda_0}) h_0$. From (3.5)

$$r(K_{\lambda_0}) \int_{x^*}^{\infty} h_0(x)\, dx = \left(2 \int_1^{\infty} e^{-\lambda_0 s} f(s)\, ds\right) \int_{x^*}^{\infty} h_0(y)\, dy.$$

Since $h_0 \in Z_+$, $h_0 \neq 0$, we have $r(K_{\lambda_0}) = 1$. Define $h \in Y$ by $h(x) = 0$, $0 \leqq x \leqq x^*$, $h(x) = h_0(x)$, $x > x^*$. By Proposition 3.4 (1), $L_{\lambda_0} h = h$. By Proposition 3.1 (2), $\lambda_0 \in P\sigma(A)$ and by Proposition 2.3 $\omega_1(A) \leqq 0 < \lambda_0 \leqq s(A)$. By Proposition 1.2 (1) there exists $\phi \in X_+$, $\phi \neq 0$, such that $A\phi = s(A)\phi$. By Proposition 3.1 (2), $L_{s(A)}\phi(0) = \phi(0)$, where $\phi(0) \in Y_+$, $\phi(0) \neq 0$. A calculation similar to (3.5) now shows that $2\int_1^{\infty} e^{-s(A)r} f(r)\, dr = 1$, which means $s(A) = \lambda_0$. □

PROPOSITION 3.6. *The spectral bound* $s(A) = \lambda_0$ *is a simple eigenvalue of* A.

Proof. By Proposition 3.1 (2), $\phi \in N(\lambda_0 I - A)$, $\phi \neq 0$, if and only if $\phi(\theta) = e^{\lambda_0 \theta} h$, $h \neq 0$, and $L_{\lambda_0} h = h$. By Proposition 3.3 $h(x) = 0$ for $0 \leqq x \leqq x^*$ and $h(x) > 0$ for $x > x^*$. By Proposition 3.4 (1) $K_{\lambda_0} h|_{[x^*,\infty)} = h|_{[x^*,\infty)}$. Since $r(K_{\lambda_0}) = 1$, Proposition 1.3 (1) yields that $N(I - K_{\lambda_0})$ is one-dimensional. Thus, $N(\lambda_0 I - A)$ is one-dimensional. To prove that λ_0 is a simple eigenvalue it suffices to show that if $\phi \in X$ such that $(\lambda_0 I - A)^2 \phi = 0$, then $(\lambda_0 I - A)\phi = 0$. Assume $\psi \equiv (\lambda_0 I - A)\phi \neq 0$ and $(\lambda_0 I - A)^2 \phi = 0$. Since $\psi \in N(\lambda_0 I - A)$, the argument above shows that $\psi(\theta) = e^{\lambda_0 \theta} h$, where $h(x) = 0$ for $0 \leqq x \leqq x^*$ and $h(x) > 0$ for $x > x^*$. Since $(\lambda_0 I - A)\phi = \psi$, we have that $\phi(\theta) = e^{\lambda_0 \theta} \phi(0) - \theta\, e^{\lambda_0 \theta} h$.

Since $\phi \in D(A)$, $\phi(0) = G\phi = G(e^{\lambda_0\theta}\phi(0)) - G(\theta\, e^{\lambda_0\theta}h) = L_{\lambda_0}\phi(0) + k$, where $k = -G(\theta\, e^{\lambda_0\theta}h)$. From (2.1)

$$k(x) = 4\int_1^{T(0,x)} s\, e^{-\lambda_0 s}h(2m(s,x))m_2(s,x)f(s)\, ds$$

$$= \frac{2}{g(x)}\int_{x^*}^{2m(1,x)} T\left(\frac{\sigma}{2}, x\right) e^{-\lambda_0 T(\sigma/2,x)}h(\sigma)f\left(T\left(\frac{\sigma}{2}, x\right)\right) d\sigma.$$

Thus, $k(x) = 0$ for $0 \leqq x \leqq x^*$, $(L_{\lambda_0}^n k)(x) = 0$ for $0 \leqq x \leqq x^*$, $n = 1, 2, \cdots$, and $k|_{[x^*,\infty)} \in Z_+$, $k|_{[x^*,\infty)} \neq 0$. Observe that $\phi(0) = L_{\lambda_0}^n\phi(0) + \sum_{j=0}^{n-1} L_{\lambda_0}^j k$, $n = 1, 2, \cdots$. By Proposition 3.3 (1), $\lim_{n\to\infty} (L_{\lambda_0}^n\phi(0))(x) = 0$ for $0 \leqq x < x^*$. Thus, $\phi(0)(x) = 0$ for $0 \leqq x \leqq x^*$. By Proposition 1.3 (3), there exists $F \in Z^*$ such that $K_{\lambda_0}^* F = F$ and $\langle F, l\rangle > 0$ for all $l \in Z_+$, $l \neq 0$. Then, $\langle F, \phi(0)|_{[x^*,\infty)}\rangle = \langle F, L_{\lambda_0}\phi(0)|_{[x^*,\infty)} + k|_{[x^*,\infty)}\rangle = \langle K_{\lambda_0}^* F, \phi(0)|_{[x^*,\infty)}\rangle + \langle F, k|_{[x^*,\infty)}\rangle = \langle F, \phi(0)|_{[x^*,\infty)}\rangle + \langle F, k|_{[x^*,\infty)}\rangle$. Consequently, $\langle F, k|_{[x^*,\infty)}\rangle = 0$, which is a contradiction. □

Proof of Proposition 1.1. The proof follows immediately from the preceding propositions. Let $h \in Z_+$ such that $K_{\lambda_0}h = h$ and $\int_{x^*}^\infty h(x)\, dx = 1$. Since $N(I - K_{\lambda_0})$ is one-dimensional, such an h is uniquely determined. Let $h_0(x) = 0$ for $0 \leqq x \leqq x^*$, $h_0(x) = h(x)$ for $x > x^*$ and h_0 is the unique solution of (1.12). For $\phi \in X$, $(P_0\phi)(\theta) = c(\phi)\, e^{\lambda_0\theta}h_0$, where $c(\phi)$ is a constant depending only on ϕ. Thus, $GP_0\phi = c(\phi)G(e^{\lambda_0\theta}h_0) = c(\phi)L_{\lambda_0}h_0 = c(\phi)h_0$. Proposition 1.2 then implies (1.13), since $\lim_{t\to\infty} \|e^{-\lambda_0 t}n(t) - c(\phi)h_0\|_Y = \lim_{t\to\infty} \|G(e^{-\lambda_0 t}T(t)\phi - P_0\phi)\|_Y = 0$. □

Remark 3.1. The value of $c(\phi)$ in (1.12) can be determined in terms of h_0. Define $N(t) = \int_0^\infty n(t)(x)\, dx$, $t \in \mathbf{R}$, and $\Phi(t) = \int_0^\infty \phi(t)(x)\, dx$, $t < 0$. Then

$$N(t) = \begin{cases} \displaystyle\int_{M(1,0)}^\infty 4\int_1^{T(0,x)} n(t-s)(2m(s,x))m_2(s,x)f(s)\, ds\, dx, & t \geqq 0, \\ \Phi(t), & t < 0. \end{cases}$$

A calculation similar to (3.5) shows that $N(t) = 2\int_1^\infty N(t-s)f(s)\, ds$, $t \geqq 0$. If we define $\mathscr{G}\colon \mathscr{X} \equiv L^1((-\infty, 0]; \mathbf{R}) \to \mathbf{R}$ by $\mathscr{G}\Phi = 2\int_1^\infty \Phi(-s)f(s)\, ds$, $\Phi \in \mathscr{X}$, then $N(t) = \mathscr{G}N_t$, $t \geqq 0$, and $N_0 = \Phi$. As in [30] this functional equation yields a semigroup of operators in $\mathscr{X}$ by the formula $\mathscr{T}(t)\Phi = N_t$. The infinitesimal generator of $\mathscr{T}(t)$, $t \geqq 0$ is $\mathscr{A}\Phi = \Phi'$, $D(\mathscr{A}) = \{\Phi \in X\colon \Phi' \in X \text{ and } \Phi(0) = \mathscr{G}\Phi\}$. For $t > 1$

$$(\mathscr{T}(t)\Phi)(\theta) = \begin{cases} 2\displaystyle\int_{-\infty}^0 \Phi(u)f(t+\theta-u)\, du + 2\int_0^{t+\theta-1} N(u)f(t+\theta-u)\, du, & 1-t \leqq \theta \leqq 0, \\ 2\displaystyle\int_{-\infty}^{t+\theta-1} \Phi(u)f(t+\theta-u)\, du, & -t \leqq \theta \leqq 0, \\ \Phi(t+\theta), & \theta < -t. \end{cases}$$

An argument similar to Proposition 2.3 shows that $\omega_1(\mathscr{A}) \leqq 0$. Further, $\lambda \in P\sigma(\mathscr{A})$, $\lambda > 0$, if and only if λ satisfies the characteristic equation $1 = 2\int_1^\infty e^{-\lambda s}f(s)\, ds$. If λ_0 is the unique real root of the characteristic equation, then $\lim_{t\to\infty} e^{-\lambda_0 t}\mathscr{T}(t)\Phi = \mathscr{P}_0\Phi$, where $\mathscr{P}_0 = (1/2\pi i)\int_\Gamma (\lambda I - \mathscr{A})^{-1}\, d\lambda$. For $\lambda > 0$, $\lambda \notin P\sigma(\mathscr{A})$, $(\lambda I - \mathscr{A})^{-1}\Phi = \Psi$ if and only if $\Psi(\theta) = e^{\lambda\theta}\Psi(0) + \chi(\theta)$, where $\chi(\theta) = \int_\theta^0 e^{\lambda(\theta - s)}\Phi(s)\, ds$ and $\Psi(0) = \mathscr{G}\Psi$. Thus,

$$((\lambda I - \mathscr{A})^{-1}\Phi)(\theta) = \frac{e^{\lambda\theta}\mathscr{G}\chi}{1 - 2\int_1^\infty e^{-\lambda s}f(s)\, ds} + \chi(\theta).$$

By the Residue Theorem

$$(\mathcal{P}_0\Phi)(\theta) = \frac{2\, e^{\lambda_0\theta} \int_1^\infty \int_{-s}^0 e^{-\lambda_0(s+r)}\Phi(r)\, dr\, f(s)\, ds}{2 \int_1^\infty s\, e^{-\lambda_0 s} f(s)\, ds}.$$

By (1.13)

$$\begin{aligned}\lim_{t\to\infty} \int_0^\infty e^{-\lambda_0 t} n(t)(x)\, dx &= c(\phi) \int_0^\infty G(e^{\lambda_0\theta} h)(x)\, dx \\ &= \lim_{t\to\infty} e^{-\lambda_0 t} N(t) \\ &= \mathcal{G} P_0 \Phi.\end{aligned}$$

Thus, $c(\phi) = \mathcal{G}\mathcal{P}_0\Phi / \int_0^\infty G(e^{\lambda_0\theta}h)(x)\, dx$. We observe that $\mathcal{G}\mathcal{P}_0\Phi$, the exponential steady state of the total population of dividing cells of all sizes, is independent of g, the growth law of individual cells.

ON DETERMINING THE PREDICTOR OF NONFULL-RANK MULTIVARIATE STATIONARY RANDOM PROCESSES*

A. G. MIAMEE†

Abstract. Algorithms for determining the generating function and the predictor for some nonfull-rank multivariate stationary stochastic processes are obtained. In fact, it is shown that the well-known algorithms given by Wiener and Masani [Acta Math., 99 (1958), pp. 93-137] for the full-rank case are valid in certain nonfull-rank cases exactly in the same form.

Key words. nonfull-rank multivariate stationary processes, generating function, best linear predictor

AMS(MOS) subject classification. Primary 60G10

1. Introduction. One of the important problems in the prediction theory of multivariate stationary stochastic processes is to obtain some algorithm for determining the best linear predictor in terms of the past observations. Wiener and Masani [9], [10] solved this problem for the full-rank case, when the spectral density f of the processes is bounded above and away from zero, in the sense that there exist positive numbers c and d such that

$$c\mathbf{I} \leqq \mathbf{f}(\theta) \leqq d\mathbf{I}. \tag{1.1}$$

Masani [2] improved their work substantially showing that the same algorithm is valid if in lieu of (1.1) one assumes that

$$\text{(1.2)}\qquad \begin{aligned} &\text{(i)} \quad \mathbf{f} \in \mathbf{L}_\infty; \\ &\text{(ii)} \quad \mathbf{f}^{-1} \in \mathbf{L}_1. \end{aligned}$$

Several other authors proved the validity of the same algorithm under more general settings, cf. for example Salehi [8], Pourahmadi [6]. However, all these results are under the severe restriction of full-rank and there has been no extension of Wiener and Masani's algorithm beyond the full-rank case.

The purpose of this note is to show that the algorithm remains valid exactly in the same manner for the nonfull-rank processes which satisfy the following conditions:

$$\text{(1.3)}\qquad \begin{aligned} &\text{(i)} \quad \text{The range of } \mathbf{f}(\theta) \text{ is constant a.e. Lebesgue measure,} \\ &\text{(ii)} \quad \mathbf{f} \in \mathbf{L}_\infty, \\ &\text{(iii)} \quad \mathbf{f}^{\#} \in \mathbf{L}_1, \end{aligned}$$

where $\mathbf{A}^{\#}$ stands for the generalized inverse (to be defined later) of the matrix $\mathbf{A}$. In the full-rank case these conditions clearly reduce to the conditions (1.2), and hence our result generalizes Masani's algorithm in [2].

Masani's assumption and approach rests on a characterization [2, Thm. 2.8], for full-rank minimal multivariate stationary stochastic processes. Our motivation and assumptions are based on a characterization of J_0-regularity (which we shall call "purely minimal") due to Makagon and Weron [1]. We will employ Wiener and Masani's algorithm to find the predictor of an associated full-rank process (to be clarified later), which is produced using the technique of Miamee and Salehi [5], and using this we will obtain our algorithm for the nonfull-rank process.

In § 2 we set down the necessary preliminaries. Section 3 is devoted to establishing our algorithm for determining the generating function and in § 4 we will show the validity of Wiener and Masani's algorithm for the best linear predictor.

2. Preliminaries. In this section we set down notation and preliminaries. Most of these are standard and can be found in [4], [9] and [10]. Let H be a complex Hilbert space and q a positive integer. H^q denotes the Cartesian product of q-copies of H, endowed with a *Gramian* structure as follows: For any two vectors $\mathbf{X}=(x^1,\cdots x^q)^T$ and $\mathbf{Y}=(y^1,\cdots,y^q)^T$, the superscript T stands for the matrix transpose, in H^q their *Gramian* matrix (X, Y) is defined by

$$(\mathbf{X},\mathbf{Y})=[(x^i,x^j)]_{i,j=1}^q.$$

It is easy to verify that it has the following properties:

$$(\mathbf{X},\mathbf{X})\geqq 0,$$

$$(\mathbf{X},\mathbf{X})=\mathbf{0}\ \Leftrightarrow\ \mathbf{X}=\mathbf{0},$$

$$\left(\sum_{i=1}^m \mathbf{A}_i\mathbf{X}_i,\ \sum_{j=1}^n \mathbf{B}_j\mathbf{X}_j\right)=\sum_{i=1}^m\sum_{j=1}^n \mathbf{A}_i(\mathbf{X}_i,\mathbf{X}_j)\mathbf{B}_j^*,$$

where $\mathbf{X}$, $\mathbf{Y}$, $\mathbf{X}_i$, $\mathbf{Y}_j$ are in H^q, $\mathbf{A}_i$, $\mathbf{B}_j$ are constant $q\times q$ matrices, and $\mathbf{A}\geqq 0$ means $\mathbf{A}$ is a *nonnegative definite* matrix. We say that $\mathbf{X}$ is *orthogonal* to $\mathbf{Y}$ if $(\mathbf{X},\mathbf{Y})=\mathbf{0}$. It is well known that H^q is a Hilbert space with the *inner product*

$$((\mathbf{X},\mathbf{Y}))=\text{trace}\,(\mathbf{X},\mathbf{Y}).$$

A subset $\mathbf{M}$ of H^q is called a *subspace* if it is closed and $\mathbf{AX}+\mathbf{BY}\in\mathbf{M}$, whenever $\mathbf{X}$ and $\mathbf{Y}$ are in $\mathbf{M}$, $\mathbf{A}$ and $\mathbf{B}$ are $q\times q$ constant matrices. It is easy to see that $\mathbf{M}$ is a subspace if and only if $\mathbf{M}=M^q$ for some subspace M of H. For any $\mathbf{X}$ in H^q, $(\mathbf{X}|\mathbf{M})$ denotes the projection of $\mathbf{X}$ onto $\mathbf{M}$, and that is the vector whose kth coordinate is $(x^k|M)$, which is the usual projection of x^k onto the subspace M.

A bisequence $\mathbf{X}_n$, $n\in Z$, in H^q is called a *q-variate stationary stochastic process* if the Gramian $(\mathbf{X}_m,\mathbf{X}_n)$ depends *only* on $m-n$.

It is well known that every q-variate stationary stochastic process X_n has a nonnegative matrix valued measure $\mathbf{F}$ on $[0,2\pi]$, called its *spectral measure* such that

$$(\mathbf{X}_m,\mathbf{X}_n)=\frac{1}{2\pi}\int_0^{2\pi} e^{-i(m-n)\theta}\,d\mathbf{F}(\theta).$$

$\mathbf{f}$ stands for the Radon-Nikodym derivative of the absolutely continuous (a.c.) part of $\mathbf{F}$ with respect to the normalized Lebesgue measure $d\theta$, and it is called the *spectral density* of the process.

To every stationary stochastic process $\mathbf{X}_n$, $n\in Z$ the following subspaces are attached:

$\mathbf{M}(+\infty)=\overline{\text{sp}}\,(\mathbf{X}_n,\ -\infty<n<\infty)$, i.e., the subspace of H^q generated by all $\mathbf{X}_n$, $n\in Z$,

$$\mathbf{M}(n)=\overline{\text{sp}}\,(\mathbf{X}_k,\ -\infty<k\leqq n),$$

$$\mathbf{M}(-\infty)=\bigcap_n \mathbf{M}(n),$$

$$\mathbf{M}'(n)=\overline{\text{sp}}\,(\mathbf{X}_k,\ k\neq n).$$

A q-variate stationary stochastic process is called

(a) *Nondeterministic* if $\mathbf{M}(+\infty)\neq\mathbf{M}(n)$ for some and hence all n in Z;

(b) *Purely nondeterministic* if $\mathbf{M}(-\infty)=\mathbf{0}$;

(c) *Minimal* if $\mathbf{M}'(n)\neq\mathbf{M}(+\infty)$ for some and hence all $n\in Z$;

(d) *Purely minimal* if $\bigcap_n \mathbf{M}'(n)=\mathbf{0}$.

If $\mathbf{X}_n$ is nondeterministic then $\mathbf{X}_n \notin \mathbf{M}(n-1)$ for all n, and hence it has a nonzero *one-sided innovation process*

$$\mathbf{g}_n = \mathbf{X}_n - (\mathbf{X}_n|\mathbf{M}(n-1)).$$

If $\mathbf{X}_n$ is minimal then $\mathbf{X}_n \notin \mathbf{M}'(n)$ for all n, and hence it has a nonzero *two-sided innovation process*

$$\boldsymbol{\phi}_n = \mathbf{X}_n - (\mathbf{X}_n|\mathbf{M}'(n)).$$

The corresponding *one-sided and two-sided predictor error matrices* are defined by

$$\mathbf{G} = (\mathbf{g}_0, \mathbf{g}_0) \quad \text{and} \quad \boldsymbol{\Sigma} = (\boldsymbol{\phi}_0, \boldsymbol{\phi}_0),$$

respectively. $\hat{\mathbf{X}}_\nu = (\mathbf{X}_\nu|\mathbf{M}(0))$ is called the *best linear predictor of lag* ν. Clearly $\mathbf{X}_n$ is nondeterministic if and only if $\mathbf{G} \neq \mathbf{0}$ and minimal if and only if $\boldsymbol{\Sigma} \neq \mathbf{0}$. A nondeterministic (purely nondeterministic) process $\mathbf{X}_n$ is said to be *nondeterministic* (*purely nondeterministic*), *of full-rank* if $\mathbf{G}$ is invertible. The process is called *full-rank minimal* if it is minimal and its two-sided predictor error matrix $\boldsymbol{\Sigma}$ is invertible.

It is useful to note that we have the following inclusions between these various classes of processes.

PROPOSITION. *The following inclusions are valid*:

(a) *Purely nondeterministic processes* $\subseteq$ *nondeterministic processes*;

(b) *Purely minimal processes* $\subseteq$ *minimal processes* $\subseteq$ *nondeterministic processes*;

(c) *Purely minimal processes* $\subseteq$ *purely nondeterministic processes.*

Proof. (a) This is clear and well known. (b) If a process is purely minimal, then $\bigcap_n \mathbf{M}'(n) = \mathbf{0}$ which clearly implies that $\mathbf{M}'(n) \neq \mathbf{M}(-\infty)$ for some n, and hence the process must be minimal. This proves the first inclusion in (b). Now if a process is minimal then $\mathbf{M}'(n) \neq \mathbf{M}(+\infty)$ for some n. Since $\mathbf{M}(n-1) \subseteq \mathbf{M}'(n)$ we have $\mathbf{M}(n-1) \neq \mathbf{M}(+\infty)$. That is, the process must be nondeterministic.(c) Since $\mathbf{M}(n-1) \subseteq \mathbf{M}'(n)$ we have $\bigcap_n \mathbf{M}(n) \subseteq \bigcap_n \mathbf{M}'(n)$, which then shows that purely minimality is stronger than being purely nondeterministic.

Remarks. (a) Considering the well-known characterization for minimal and that of purely nondeterministic univariate processes, one can see that neither of these two classes is a subset of the other one.

(b) All the inclusions stated in the above proposition are proper. This for the first inclusion in (b) is shown via the next example, and for the rest of them it is either well-known or can be easily verified.

Example. Let Y_n be orthonormal and Z any vector orthogonal to all Y_n's, and let $X_n = Y_n + Z$. Then

(i) X_n is *stationary*, because $(X_m, X_n) = \delta_{m-n,0} + (Z, Z)$ depends only on $m-n$.

(ii) X_n is *minimal*, because otherwise X_0 must belong to $\overline{\text{sp}}\,\{X_k\colon k \neq 0\} = M'(0)$ and hence there exists a sequence p_n of finite sums of the form

$$p_n = \sum_{k\neq 0} a_k^n X_k = \sum_{k\neq 0} a_k^n (Y_k + Z)$$

such that $X_0 = \lim_{n\to\infty} p_n$. Now since

$$p_n = \sum_{k\neq 0} a_k^n Y_k + \left(\sum_{k\neq 0} a_k^n\right) Z = Q_n + r_n Z \quad \text{and} \quad Q_n \perp r_n Z$$

the convergence of p_n implies the convergence of both sequences Q_n and r_n to some Q and r, respectively. Taking limit on both sides of the last equation, we get

$$X_0 = Q + rZ$$

which gives

$$Y_0 - Q = (r-1)Z, \qquad Y_0 - Q \perp (r-1)Z.$$

We see that $Y_0 - Q = 0$ or $Y_0 = Q$. But since each Q_n is in $\overline{\mathrm{sp}}\{Y_k: k \neq 0\}$, we get $Y_0 \in \overline{\mathrm{sp}}\{Y_k: k \neq 0\}$ which is impossible, because Y_n is an orthonormal sequence.

(iii) X_n is *not purely minimal.* In fact, its spectral distribution $F(\theta) = \theta + \delta_0$, where δ_0 is the unit mass concentrated at 0, is not a.c. A purely time domain proof of this fact may also be given. Q.E.D.

It is known that

$$\mathbf{M}(n) = \sum_{k=0}^{\infty} \overline{\mathrm{sp}}\,(\mathbf{g}_{n-k}) + \mathbf{M}(-\infty).$$

Consider $\mathbf{G}$ as a linear operator on C^q to C^q, C being the complex plane. Let $\mathbf{J}$ be the matrix of the projection on C^q onto the range of $\mathbf{G}$, and we put $(\sqrt{\mathbf{G}} + \mathbf{J}^{\perp})^{-1} = \mathbf{H}$. The *normalized one-sided innovations* are defined by $\mathbf{h}_n = \mathbf{H}\mathbf{g}_n$. One can show that [4]

$$\mathbf{X}_n = \sum_{k=0}^{\infty} \mathbf{A}_k \sqrt{\mathbf{G}}\,\mathbf{h}_{n-k} + (\mathbf{X}_n | \mathbf{M}(-\infty)).$$

Although $\mathbf{A}_k$'s in this decomposition *are not unique*, the coefficients $\mathbf{A}_k\sqrt{\mathbf{G}}$ are in fact *unique* and this enables us to associate the following function to our process

$$\mathbf{\Phi}(e^{i\theta}) = \sum_{k=0}^{\infty} \mathbf{A}_k \sqrt{\mathbf{G}}\, e^{ik\theta};$$

this is called the *generating function* of the process.

We shall be concerned with the class $\mathbf{L}_p (1 \leqq p \leqq \infty)$ of all $q \times q$ matrix valued functions $\mathbf{g}$ on $[0, 2\pi]$ whose entries are in the usual Lebesgue space L_p. $\mathbf{L}_2^{0+}$ will denote the subspace of $\mathbf{L}_2$ consisting of those matrix valued functions whose nth Fourier coefficient vanishes for $n < 0$, i.e.,

$$\int e^{-in\theta} \mathbf{g}(\theta)\, d\theta = \mathbf{0} \quad \text{for all } n < 0.$$

For any $q \times q$ matrix $\mathbf{A}$ its *generalized inverse* $\mathbf{A}^{\#}$ is defined to be

$$\mathbf{A}^{\#} = p_{N(\mathbf{A})^{\perp}} \mathbf{A}^{-1} p_{R(\mathbf{A})},$$

where $N(\mathbf{A})$ denotes the null space of $\mathbf{A}$, $\mathbf{A}^{-1}$ denotes the (many valued) inverse of $\mathbf{A}$, and $R(\mathbf{A})$ stands for the range of $\mathbf{A}$. One can see that $\mathbf{A}^{\#}$ has the following properties [7]:

$$\mathbf{A}\mathbf{A}^{\#}\mathbf{A} = \mathbf{A}, \qquad \mathbf{A}^{\#}\mathbf{A}\mathbf{A}^{\#} = \mathbf{A}^{\#},$$
$$(\mathbf{A}^{\#}\mathbf{A})^* = \mathbf{A}^{\#}\mathbf{A}, \qquad (\mathbf{A}\mathbf{A}^{\#})^* = \mathbf{A}\mathbf{A}^{\#},$$
$$N(\mathbf{A})^{\perp} = R(\mathbf{A}^{\#}), \qquad R(\mathbf{A})^{\perp} = N(\mathbf{A}^{\#}).$$

For the ease of reference we state the following two theorems which are due to Masani [2, Thm. 2.8] and to Makagon and Weron [1], respectively.

THEOREM 1. *Let* $\mathbf{X}_n$, $n \in Z$, *be a q-variate stationary stochastic process with spectral distribution* $\mathbf{F}$. $\mathbf{X}_n$ *is full-rank minimal if and only if* $\mathbf{f} = \mathbf{F}'$ *is invertible and* $\mathbf{f}^{-1} \in \mathbf{L}_1$.

THEOREM 2. *Let* $\mathbf{X}_n$, $n \in Z$ *be a q-variate stationary stochastic process with spectral measure* $\mathbf{F}$. *The process* $\mathbf{X}_n$ *is purely minimal if and only if*

(i) $\mathbf{F}$ *is a.c. with respect to Lebesque measure*; *with spectral density* $\mathbf{f}$,

(ii) $R(\mathbf{f}(\theta))$ *is constant a.e. Lebesque measure,*

(iii) $\mathbf{f}^{\#} \in \mathbf{L}_1$.

3. Determination of the generating function. In this section we give an algorithm for determining the generating function of a (not necessarily full-rank) stationary stochastic process. The result of this section extends Masani's algorithm developed in [2] to the nonfull-rank case. Our technique is essentially that used by Miamee and Salehi in [5], where the following formula for the two-sided prediction error matrix $\mathbf{\Sigma}$ of a purely minimal process was obtained:

$$\mathbf{\Sigma}=\left[\frac{1}{2\pi}\int_0^{2\pi}\mathbf{f}^{\#}(\theta)\,d\theta\right]^{\#}.$$

We will continue this work under the assumption that our process is purely minimal or equivalently assuming that conditions (i), (ii) and (iii) of Theorem 2 are valid. Let $\mathbf{h}_1, \mathbf{h}_2, \cdots, \mathbf{h}_p, \mathbf{h}_{p+1}, \cdots, \mathbf{h}_q$ be an orthonormal basis for the q-dimensional complex Euclidean space C^q such that

$$R=R(\mathbf{f}(\theta))=\overline{\mathrm{sp}}\,(\mathbf{h}_i, 1\leqq i\leqq p)\quad \text{a.e.}\,(d\theta),$$

and

$$N=R^{\perp}=N(\mathbf{f}(\theta))=\overline{\mathrm{sp}}\,(\mathbf{h}_i, p+1\leqq i\leqq q).$$

Let $\mathbf{e}_1, \mathbf{e}_2, \cdots, \mathbf{e}_q$ be the standard basis of C^q. Define the unitary operator $\mathbf{U}$ on C^q by $\mathbf{U}\mathbf{h}_i=\mathbf{e}_i$, $1\leqq i\leqq q$. Letting $R_1=\overline{\mathrm{sp}}\,(\mathbf{e}_i, 1\leqq i\leqq p)$ then $R_1^{\perp}=\overline{\mathrm{sp}}\,(\mathbf{e}_i, p+1\leqq i\leqq q)$. Clearly $\mathbf{U}$ maps R onto R_1 and $R^{\perp}$ onto $R_1^{\perp}$ and $\mathbf{U}^*$ maps R_1 onto R and $R_1^{\perp}$ onto $R^{\perp}$. As usual we will identify any linear operator on C^q with its matrix with respect to the standard basis of C^q. By our choice of $\mathbf{U}$ we have

$$\mathbf{U}\mathbf{f}(\theta)\mathbf{U}^*=\begin{bmatrix}\mathbf{g}(\theta) & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{bmatrix}\tag{3.1}$$

where $\mathbf{g}(\theta)$ is a $p\times p$ nonnegative matrix valued function whose rank is a.e. equal to p. Let

$$\mathbf{Y}_n=\mathbf{U}\mathbf{X}_n,\qquad n\in Z$$

be a new stationary stochastic process, then we have

$$\begin{aligned}(\mathbf{Y}_m, \mathbf{Y}_n)=(\mathbf{U}\mathbf{X}_m, \mathbf{U}\mathbf{X}_n)&=\mathbf{U}\left(\frac{1}{2\pi}\int_0^{2\pi}e^{-i(m-n)\theta}\mathbf{f}(\theta)\,d\theta\right)\mathbf{U}^*\\ &=\frac{1}{2\pi}\int_0^{2\pi}e^{-i(m-n)\theta}\mathbf{U}\mathbf{f}(\theta)\mathbf{U}^*\,d\theta\\ &=\frac{1}{2\pi}\int_0^{2\pi}e^{-i(m-n)\theta}\begin{bmatrix}\mathbf{g}(\theta) & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{bmatrix}d\theta.\end{aligned}\tag{3.2}$$

This shows that, for $p+1\leqq k\leqq q$, the kth component Y_n^k of $\mathbf{Y}_n$ is zero for all $n\in Z$. The p-variate stationary stochastic process $\mathbf{Z}_n=(Y_n^1, \cdots, Y_n^p)^T$ has spectral density $\mathbf{g}$. Since $\mathbf{U}$ takes R onto R_1 and $R^{\perp}$ onto $R_1^{\perp}$, one can see that

$$\begin{bmatrix}\mathbf{g}^{-1} & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{bmatrix}=\begin{bmatrix}\mathbf{g} & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{bmatrix}^{\#}=(\mathbf{U}\mathbf{f}\mathbf{U}^*)^{\#}=\mathbf{U}^*\mathbf{f}^{\#}\mathbf{U}.\tag{3.3}$$

Now since $\mathbf{X}_n$ is assumed to be purely minimal, Theorem 2 implies that $\mathbf{f}^{\#}(\theta)$ is integrable. Thus (3.2) implies that $\mathbf{g}^{-1}$ is integrable and hence by Theorem 1, $\mathbf{Z}_n$ is full-rank minimal.

We are going to utilize Masani's algorithm to obtain the generating function $\mathbf{\Psi}$ and predictor $\hat{\mathbf{Z}}_\nu$ of this full-rank minimal process $\mathbf{Z}_n$, and then use this to get the generating function $\mathbf{\Phi}$ and predictor $\hat{\mathbf{X}}_\nu$ of our process $\mathbf{X}_n$. The following lemma, which reveals the close tie between $\mathbf{\Psi}$ and $\mathbf{\Phi}$, is crucial in the development of our algorithm.

LEMMA. *Let $\mathbf{X}_n$, $n \in Z$ be a purely minimal stationary stochastic process with spectral density* $\mathbf{f}$. *Let* $\mathbf{g}$ *be the spectral density of the corresponding full-rank minimal process* $\mathbf{Z}_n$ *discussed above. If* $\mathbf{\Phi}$ *and* $\mathbf{\Psi}$ *are the generating functions of* $\mathbf{X}_n$ *and* $\mathbf{Z}_n$, *respectively, then*

$$\mathbf{\Phi} = \mathbf{U}^* \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U},$$

where $\mathbf{U}$ *is the unitary matrix obtained above.*

Proof. We first note that, since $\mathbf{\Phi}$ and $\mathbf{\Psi}$ as generating functions are optimal (cf. Lemma 3.7 and Definition 4.1 in [3]). Now from (3.1) we get

$$\mathbf{f} = \mathbf{U}^* \begin{bmatrix} \mathbf{g} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U} = \left(\mathbf{U}^* \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U} \right) \left(\mathbf{U}^* \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U} \right)^* \tag{3.4}$$

so $\mathbf{f}$ has two factorization, namely the one in (3.4) and

$$\mathbf{f} = \mathbf{\Phi}\mathbf{\Phi}^*,$$

where both $\mathbf{\Phi}$ and

$$\mathbf{\delta} = \mathbf{U}^* \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}$$

belong to $\mathbf{L}_2^{0+}$; to complete the proof it suffices to show that the factor $\mathbf{\delta}$ is also optimal (cf. uniqueness Theorem 4.4 of [3]). To prove this, we first note that since the zeroth coefficient $\mathbf{\Psi}_+(0)$ of $\mathbf{\Psi}$ is nonnegative definite and

$$\mathbf{\delta}_+(0) = \mathbf{U}^* \begin{bmatrix} \mathbf{\Psi}_+(0) & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}$$

we have

$$\mathbf{\delta}_+(0) \geqq \mathbf{0}. \tag{3.5}$$

On the other hand, if

$$\mathbf{f} = \mathbf{\gamma}\mathbf{\gamma}^*, \qquad \mathbf{\gamma} \in \mathbf{L}_2^{0+} \tag{3.6}$$

is another factorization of $\mathbf{f}$, then

$$\begin{bmatrix} \mathbf{g} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \mathbf{U}\mathbf{f}\mathbf{U}^* = (\mathbf{U}\mathbf{\gamma}\mathbf{U}^*)(\mathbf{U}\mathbf{\gamma}\mathbf{U}^*)^* \tag{3.7}$$

but $\mathbf{g} = \mathbf{\Psi}\mathbf{\Psi}^*$ implies that

$$\begin{bmatrix} \mathbf{g} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}^*. \tag{3.8}$$

Since $\mathbf{\Psi}$ is the generating function of $\mathbf{Z}_n$ one can prove that the function

$$\begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

is the generating function of $\mathbf{Y}_n$. In fact we know that the generating function $\mathbf{\Phi}$ of a q-variate stationary stochastic process $\mathbf{X}_n$ is given by

$$\mathbf{\Phi} = \sum_{n=0}^{\infty} \mathbf{A}_n \sqrt{\mathbf{G}} e^{in\theta},$$

where $\mathbf{A}_n$'s are the coefficients in the representation

$$\mathbf{X}_0 = \sum_{n=0}^{\infty} \mathbf{A}_n \mathbf{g}_{-n} + (\mathbf{X}_0 | \mathbf{M}(-\infty))$$

of $\mathbf{X}_n$ in terms of its innovation process

$$\mathbf{g}_n = \mathbf{X}_n - (\mathbf{X}_n | \mathbf{M}(n-1))$$

and $\mathbf{G} = (\mathbf{g}_0, \mathbf{g}_0)$ is the predictor error matrix. Comparing $\mathbf{Z}_n$ with $\mathbf{Y}_n = [\mathbf{Z}_n | \mathbf{0}]^T$, we note that

$$\mathbf{g}_n^{\mathbf{Y}} = \begin{bmatrix} \mathbf{g}_n^{\mathbf{Z}} \\ \mathbf{0} \end{bmatrix}, \quad \mathbf{G}^{\mathbf{Y}} = \begin{bmatrix} \mathbf{G}^{\leqq} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}, \quad \sqrt{\mathbf{G}^{\mathbf{Y}}} = \begin{bmatrix} \sqrt{\mathbf{G}^{\mathbf{Y}}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix},$$

$$\mathbf{Y}_0 = \begin{bmatrix} \mathbf{Z}_0 \\ \mathbf{0} \end{bmatrix} = \begin{bmatrix} \sum_{n=0}^{\infty} \mathbf{A}_n^{\mathbf{Z}} \mathbf{g}_n^{\mathbf{Z}} + (\mathbf{Z}_0 | \mathbf{M}^{\mathbf{Z}}(-\infty)) \\ \mathbf{0} \end{bmatrix}$$

$$= \sum_{n=0}^{\infty} \begin{bmatrix} \mathbf{A}_n^{\mathbf{Z}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{g}_n^{\mathbf{Z}} \\ \mathbf{0} \end{bmatrix} + (\mathbf{Y}_0 | \mathbf{M}^{\mathbf{Y}}(-\infty)).$$

Although the coefficients arising in this sum are not unique, they will give us the generating function uniquely, and we have

$$\mathbf{\Phi}^{\mathbf{Y}} = \sum_{n=0}^{\infty} \left(\begin{bmatrix} \mathbf{A}_n^{\mathbf{Z}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \sqrt{\mathbf{G}^{\mathbf{Y}}} \right) e^{-in\theta}$$

$$= \sum_{n=0}^{\infty} \begin{bmatrix} \mathbf{A}_n^{\mathbf{Z}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \sqrt{\mathbf{G}^{\mathbf{Y}}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} e^{-in\theta} = \sum_{n=0}^{\infty} \begin{bmatrix} \mathbf{A}_n^{\mathbf{Z}} \sqrt{\mathbf{G}^{\mathbf{Y}}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} e^{-in\theta}$$

$$= \begin{bmatrix} \sum_{n=0}^{\infty} \mathbf{A}_n^{\mathbf{Z}} \sqrt{\mathbf{G}^{\mathbf{Z}}}\, e^{in\theta} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \begin{bmatrix} \mathbf{\Phi}^{\mathbf{Z}} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}.$$

Thus

$$\begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

is the optimal factor of

$$\begin{bmatrix} \mathbf{g} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}.$$

(3.7) and (3.8) together with the optimality of

$$\begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

imply that

$$\begin{bmatrix} \mathbf{\Psi}_+(0) & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{\Psi}_+(0) & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \geqq (\mathbf{U}\boldsymbol{\gamma}_+(0)\mathbf{U}^*)(\mathbf{U}\boldsymbol{\gamma}_+(0)\mathbf{U}^*)^*.$$

This in turn implies that

$$(\boldsymbol{\delta}_+(0))^2 = \left(\mathbf{U}^* \begin{bmatrix} \mathbf{\Psi}_+(0) & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U} \right) \left(\mathbf{U}^* \begin{bmatrix} \mathbf{\Psi}_+(0) & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U} \right) \geqq \boldsymbol{\gamma}_+(0)\boldsymbol{\gamma}_+(0)^*.$$

This together with (3.5) shows that $\boldsymbol{\delta}$ is the optimal factor of $\mathbf{f}$. Thus by the uniqueness theorem mentioned above

$$\mathbf{\Phi} = \boldsymbol{\delta} = \mathbf{U}^* \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}. \tag{3.9}$$

Q.E.D

Now we are ready to give the algorithm determining the generating function of our purely minimal q-variate stationary stochastic process $\mathbf{X}_n$:

Step 1. Since $\mathbf{f}$ satisfies condition (i) in (1.3) and its range is constant with dimension p, one can easily see that the rank of the covariance matrix $\mathbf{\Gamma}_0 = \int_0^{2\pi} \mathbf{f}(\theta)\, d\theta$ is also p. In fact, it can be shown that a unitary matrix $\mathbf{U}$ has the property (3.1) if and only if it can reduce $\mathbf{\Gamma}_0$ to the form

$$\mathbf{U\Gamma}_0\mathbf{U}^* = \begin{bmatrix} \mathbf{\Sigma}_0 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}, \tag{3.10}$$

with $\mathbf{\Sigma}_0$ being a $p \times p$ nonsingular matrix. Using this fact, we can find our unitary matrix $\mathbf{U}$ of this section by finding a $\mathbf{U}$ as in (3.10).

Step 2. Taking the unitary matrix $\mathbf{U}$ obtained in Step 1, we can form the full-rank density $\mathbf{g}$ as in (3.1). Because $\mathbf{f}$ satisfies conditions (ii) and (iii) of (1.3), as we saw before, $\mathbf{g}$ has the properties (i) and (ii) of (1.2). Thus we can use Masani's algorithm developed in § 4 of [2] to find the generating function $\mathbf{\Psi}$, of the process with density $\mathbf{g}$.

Step 3. We can find the generating function $\mathbf{\Phi}$ of our original process with density $\mathbf{f}$, via the formula (3.9) above.

Remark. One can similarly extend the other available extension of Masani's algorithm (such as that in [8]) for the full-rank case to obtain corresponding algorithms for the nonfull-rank case.

4. Determination of the predictor. In this section we show that the unique autoregressive series, of [2], giving the linear predictor in the full-rank case, can be used to obtain the predictor in our nonfull-rank case. In fact as we will see, exactly the same formula works in this case as well. We continue to assume that $\mathbf{F}$ is a.c. and the density $\mathbf{f}$ of our stationary stochastic process $\mathbf{X}_n$ satisfies conditions (1.3). Using the notations and results of § 3, we know that

$$\mathbf{f} = \mathbf{U} \begin{bmatrix} \mathbf{g} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}^*$$

and the density $\mathbf{g}$ satisfies conditions (i) and (ii) of (1.2). Thus, using the technique developed in [2] one can show that

$$\hat{\mathbf{Z}}_\nu = \sum_{k=0}^{\infty} \mathbf{E}_{\nu k} \mathbf{Z}_{-k} \quad \text{in } H^p,$$

where

$$\mathbf{E}_{\nu k} = \sum_{n=0}^{k} \mathbf{C}_{\nu+n} \mathbf{D}_{k-n}$$

with $\mathbf{C}_k$ and $\mathbf{D}_k$ being the kth Fourier coefficients of $\mathbf{\Psi}$ and $\mathbf{\Psi}^{-1}$, respectively. Now one can easily verify that

$$\hat{\mathbf{Y}}_\nu = \begin{bmatrix} \hat{\mathbf{Z}}_\nu \\ \mathbf{0} \end{bmatrix} = \sum_{k=0}^{\infty} \begin{bmatrix} \mathbf{E}_{\nu k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{Y}_{-k} \quad \text{in } H^q,$$

and

$$\begin{bmatrix} \mathbf{E}_{\nu k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \sum_{n=0}^{k} \begin{bmatrix} \mathbf{C}_{\nu+n} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{D}_{k-n} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}. \tag{4.1}$$

Since $\mathbf{Y}_n = \mathbf{U}\mathbf{X}_n$, one can also verify that

$$\hat{\mathbf{X}}_n = \widehat{\mathbf{U}^*\mathbf{Y}}_n = \mathbf{U}^*\hat{\mathbf{Y}}_n.$$

Hence we have

$$\begin{aligned} \hat{\mathbf{X}}_n &= \mathbf{U}^*\left(\sum_{k=0}^{\infty} \begin{vmatrix} \mathbf{E}_{\nu k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{vmatrix} \mathbf{Y}_{-k}\right) \\ &= \sum_{k=0}^{\infty} \left(\mathbf{U}^* \begin{bmatrix} \mathbf{E}_{\nu k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}\right) \mathbf{U}^*\mathbf{Y}_{-k} \quad \text{in } H^q. \end{aligned} \tag{4.2}$$

Letting

$$\mathbf{F}_{\nu k} = \mathbf{U}^* \begin{bmatrix} \mathbf{E}_{\nu k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}, \tag{4.3}$$

we get the following autoregressive series representation for the best linear predictor $\hat{\mathbf{X}}_\nu$:

$$\hat{\mathbf{X}}_\nu = \sum_{k=0}^{\infty} \mathbf{F}_{\nu k}\mathbf{X}_{-k}.$$

Now let us examine the coefficients $\mathbf{F}_{\nu k}$ in (4.3) more carefully. Doing this, we will be able to write $\mathbf{F}_{\nu k}$ in terms of the Fourier coefficients of the generating function $\mathbf{\Phi}$ of our original process $\mathbf{X}_n$ rather than that of the auxiliary process $\mathbf{Z}_n$. From (4.2) we can write

$$\mathbf{F}_{\nu k} = \mathbf{U}^* \begin{bmatrix} \mathbf{E}_{\nu k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}.$$

Now using (4.1), we have

$$\begin{aligned} \mathbf{F}_{\nu k} &= \mathbf{U}^*\left(\sum_{n=0}^{k} \begin{bmatrix} \mathbf{C}_{\nu+n} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{D}_{k-n} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}\right)\mathbf{U} \\ &= \sum_{n=0}^{k} \left(\mathbf{U}^* \begin{bmatrix} \mathbf{C}_{\nu+n} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}\right)\left(\mathbf{U}^* \begin{bmatrix} \mathbf{D}_{k-n} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}\right). \end{aligned}$$

Thus

$$\mathbf{F}_{\nu k} = \sum_{n=0}^{k} \mathbf{M}_{\nu+n}\mathbf{N}_{k-n},$$

with

$$\mathbf{M}_n = \mathbf{U}^* \begin{bmatrix} \mathbf{C}_n & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}, \qquad \mathbf{N}_n = \mathbf{U}^* \begin{bmatrix} \mathbf{D}_n & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}.$$

But by the lemma we have

$$\mathbf{\Phi} = \mathbf{U}^* \begin{bmatrix} \mathbf{\Psi} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}, \qquad \mathbf{\Phi}^{\#} = \mathbf{U}^* \begin{bmatrix} \mathbf{\Psi}^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \mathbf{U}. \tag{4.4}$$

Thus we observe that $\mathbf{M}_n$ and $\mathbf{N}_n$ are exactly the nth Fourier coefficients of $\mathbf{\Phi}$ and $\mathbf{\Phi}^{\#}$, respectively.

Summarizing, we have shown that the best linear predictor $\hat{\mathbf{X}}_\nu$ can be written exactly in the same form obtained in [2] for the full-rank processes, i.e., we have

$$\hat{\mathbf{X}}_\nu = \sum_{k=0}^{\infty} \left(\sum_{n=0}^{k} \mathbf{M}_{\nu+n}\mathbf{D}_{k-n}\right)\mathbf{X}_{-k} \quad \text{in } H^q$$

where $\mathbf{M}_n$ and $\mathbf{N}_n$ are the nth Fourier coefficients of $\mathbf{\Phi}$ and its generalized inverse $\mathbf{\Phi}^{\#}$ (instead of $\mathbf{\Phi}$ and its inverse $\mathbf{\Phi}^{-1}$ in the full-rank case).

A STOCHASTIC INTEGRATION FORMULA FOR TWO-PARAMETER WIENER×TWO-PARAMETER WIENER SPACE*

G. W. JOHNSON† AND D. L. SKOUG†

Abstract. We establish a stochastic integration by parts formula in which both the integrator and the integrand are elements of two-parameter Wiener (or Yeh-Wiener) space. We also establish the continuity of the stochastic integral with respect to binary quadratic approximation.

Key words. stochastic integration by parts, Wiener process, two-parameter (or Yeh-Wiener) process

AMS(MOS) subject classifications. Primary 60H05; secondary 28C20

1. Introduction. We prove an integration by parts formula where the integrator and the integrand are independent random functions from two-parameter Wiener (or Yeh-Wiener) space. In light of the recent great interest in Markov random fields among probabilists [15], [26] and mathematical physicists [8], [18], [19], [27], [29], it seems likely that this result and extensions of it will be useful. There are parts formulas in the literature involving two independent one-parameter processes [7, p. 268], but, as far as we can tell, the present result is new.

Our interest in this topic came out of our joint work on the Feynman integral [4] with Kun Chang. In proving that a certain class of functions on one-parameter Wiener space is in a Banach algebra of Feynman integrable functions, we found it necessary to move a Wiener variable from the integrand to the integrator. Ultimately we justified this by proving a parts formula involving two independent Wiener processes, one a one-parameter and the other a two-parameter process [4, Thm. 3.1]. An additional nonstochastic function was also involved. The present result was essentially discovered while we were finishing the earlier paper.

Our proofs here and in [4] are, in some respects, analysis proofs. It is quite likely that alternate proofs making more use of the machinery of stochastic processes can be found which will shed further light on these formulas. The second author is pursuing extensions of these parts formulas in various directions.

Let $C_1[0,1]$ denote Wiener space; that is, the space of continuous functions x on $[0,1]$ such that $x(0)=0$. Let $Q=[0,1]^2$ and let $C_2=C_2(Q)$ denote two-parameter Wiener (or Yeh-Wiener) space; that is, the space of continuous functions f on Q such that $f(0,t)=f(s,0)=0$ for all $(s,t)\in Q$. Let m_1 denote Wiener measure and m_2 denote Yeh-Wiener measure.

We now briefly describe our results, delaying further precise definitions until later. In our main result, Theorem 4.1, we obtain an integration by parts formula relating the stochastic integrals $\int_Q f\,\tilde{d}_2 g$ and $\int_Q g\,\tilde{d}_2 f$, where both f and g are elements of $C_2(Q)$. One version of the corresponding well-known result for stochastic integrals of functions of one variable is given in [7, p. 268].

The key to our parts formula is Theorem 3.1 in which we obtain the continuity with respect to "binary quadratic approximation" (to be defined below) of the stochastic

integral

$$F(f) := \int_Q g\, \tilde{d}_2 f$$

for each g in $L_2(Q)$. This is an extension of a recent result of Cameron and Storvick [1, Lemma 2.3] in which they obtain the continuity with respect to "binary polygonal approximation" of the stochastic integral $\int_0^1 V(s)\, \tilde{d}x(s)$ for each V in $L_2[0, 1]$.

2. Preliminaries. The concept of bounded variation for a function of two variables is surprisingly complex. Several nonequivalent definitions have appeared in the literature; see for example [5], [6], [9], [10], [17]. (We would like to thank our colleague Professor Gary Meisters for bringing some of these references to our attention.) The paper [5] by Clarkson and Adams is old but still useful in sorting out many of the relationships between the various definitions. Throughout this paper we will use the definition used by Hardy and by Krause (see [5, p. 825] and [9, p. 345]) which we now briefly review.

Let Δ denote the rectangular partition of Q determined by $0 = s_0 < s_1 < \cdots < s_n = 1$ and $0 = t_0 < t_1 < \cdots < t_m = 1$. A function $f(s, t)$ is said to be of bounded variation on Q in the sense of Hardy and Krause provided the following three conditions hold:

(i) There exists a constant K such that for any partition Δ

$$\sum_{i=1}^{n} \sum_{j=1}^{m} |f(s_i, t_j) - f(s_{i-1}, t_j) - f(s_i, t_{j-1}) + f(s_{i-1}, t_{j-1})| \leqq K, \tag{2.1}$$

(ii) $f(s, t)$ is a function of bounded variation in s for each $t \in [0, 1]$,

(iii) $f(s, t)$ is a function of bounded variation in t for each $s \in [0, 1]$.

The total variation of f over Q, Var (f, Q), is defined to be the supremum of the sums in (2.1) over all partitions Δ. It is easy to see [9, p. 345] that conditions (ii) and (iii) can be relaxed to the requirements that $f(s, t)$ is of bounded variation in s for one fixed value of t and is of bounded variation in t for one fixed value of s. It is also easy to see that if f is of bounded variation on Q then the set of discontinuities of f lie on a countable number of vertical and horizontal lines.

For later reference we mention that if a function f satisfies condition (i) above, but not necessarily conditions (ii) and (iii), then f is said to be of bounded variation on Q in the sense of Vitali [5, pp. 824-825].

Next we give a brief discussion of the Riemann-Stieltjes integral $\int_Q g\, df$. Let $f(s, t)$ and $g(s, t)$ be defined and bounded on Q. Let Δ be the rectangular partition of Q given above and let $|\Delta|$, the norm of Δ, be given by

$$|\Delta| = \sup_{i,j} \{[(s_i - s_{i-1})^2 + (t_j - t_{j-1})^2]^{1/2}\}.$$

Then $g(s, t)$ is said to be Riemann-Stieltjes integrable with respect to $f(s, t)$ on Q with Riemann-Stieltjes integral I, if and only if corresponding to any $\varepsilon > 0$ there exists a $\delta > 0$ such that, for any rectangular partition Δ of Q with $|\Delta| < \delta$ and any choice of points (ξ_i, η_j) with $s_{i-1} \leqq \xi_i \leqq s_i$ and $t_{j-1} \leqq \eta_j \leqq t_j$, we have

$$\left| \sum_{i=1}^{n} \sum_{j=1}^{m} g(\xi_i, \eta_j)[f(s_i, t_j) - f(s_{i-1}, t_j) - f(s_i, t_{j-1}) + f(s_{i-1}, t_{j-1})] - I \right| < \varepsilon.$$

The following well-known theorem [9, p. 561] gives a necessary and sufficient condition for the existence of the Riemann-Stieltjes integral $\int_Q g\, df$.

THEOREM. *Let f be of bounded variation (Hardy and Krause) on Q and let g be a bounded function defined on Q. Then a necessary and sufficient condition that g be Riemann-Stieltjes integrable with respect to f on Q is that the set of discontinuities of g have total variation measure zero with respect to f.*

COROLLARY. *If g is continuous on Q and f is of bounded variation (Hardy and Krause) on Q then $\int_Q g\,df$ exists.*

The definition of bounded variation used by Hardy and Krause has the important property that if g is continuous on Q and f is of bounded variation on Q then the Riemann-Stieltjes integrals $\int_Q g\,df$ and $\int_Q f\,dg$ both exist and are related by the usual integration by parts formula. The definition of bounded variation given by Vitali fails to have this property since $f(s, t)$ may be of bounded variation on Q while $f(s, 1)$ is not of bounded variation on $[0, 1]$; for example $f(s, t) = s \sin(1/s)$.

A paper of Yeh [31] has a nice discussion of the n-dimensional Riemann-Stieltjes integral and some of its properties. However his definition is based on the Vitali concept of bounded variation. Of course all of the results he obtains concerning the Riemann-Stieltjes integral are true in our more restrictive setting. In theorems involving Yeh-Wiener space $C_2(Q)$, Yeh then adds conditions (ii) and (iii) as hypotheses; so in the final analysis the setting is essentially the same.

Next we give the definition of the Paley-Wiener-Zygmund (P.W.Z.) integral, a simple type of stochastic integral, for functions of one and two variables.

Let $\{\phi_j\}$ be a complete orthonormal set of functions of bounded variation on $[0, 1]$. For V in $L_2[0, 1]$ let

$$V_n(s) = \sum_{j=1}^{n} (V, \phi_j)\phi_j(s).$$

The P.W.Z. integral for functions of one variable is defined by the formula

$$\int_0^1 V(s)\,\tilde{d}x(s) := \lim_{n\to\infty} \int_0^1 V_n(s)\,dx(s)$$

for all x in $C_1[0, 1]$ for which the limit exists.

Let $\{\phi_j\}$ be a complete orthonormal set of functions of bounded variation on Q. For g in $L_2(Q)$ let

$$g_n(s, t) = \sum_{j=1}^{n} (g, \phi_j)\phi_j(s, t).$$

Then the P.W.Z. integral for functions of two variables is defined by the formula

$$\int_Q g(s, t)\tilde{d}_2 f(s, t) := \lim_{n\to\infty} \int_Q g_n(s, t)\,df(s, t)$$

for all f in $C_2(Q)$ for which the limit exists.

In order to state various properties of the P.W.Z. integral we need the notion of scale-invariant measurability. A subset A of $C_2(Q)$ is said to be scale-invariant measurable provided ρA is Yeh-Wiener measurable for every $\rho > 0$, and a scale-invariant measurable set N is said to be scale-invariant null provided $m_2(\rho N) = 0$ for every $\rho > 0$ [3], [11]. A property that holds except on a scale-invariant null set is said to hold scale-invariant almost everywhere (s-a.e.).

Following are some useful facts about the P.W.Z. integral (we will state them in terms of functions of two variables; similar properties of course hold in the one variable setting):

(2.2) For each g in $L_2(Q)$ the P.W.Z. integral $\int_Q g\,\tilde{d}_2 f$ exists for s-a.e. f in $C_2(Q)$.

(2.3) The P.W.Z. integral $\int_Q g\,\tilde{d}_2 f$ is essentially independent of the complete orthonormal set $\{\phi_j\}$. (For us it will often be convenient to let $\{\phi_j\}$ be the Haar functions on Q.)

(2.4) If g is of bounded variation on Q, then the P.W.Z. integral $\int_Q g\,\tilde{d}_2 f$ is s-a.e. equal to the Riemann-Stieltjes integral $\int_Q g\,df$.

(2.5) The P.W.Z. integral has the usual linearity properties when interpreted properly.

(2.6) The map sending g in $L_2(Q)$ to the function F_g on $C_2(Q)$ given by $F_g(f) := \int_Q g\,\tilde{d}_2 f$ is an isometric isomorphism of $L_2(Q)$ into $L_2(C_2(Q), m_2)$.

(2.7) The sequence $\{\int_Q g_n df\}$, considered as a function of f converges in $L_2(C_2(Q))$ mean to $\int_Q g\,\tilde{d}_2 f$.

Remark. W. J. Park [24] defines the stochastic integral with respect to the two-parameter (actually p-parameter) Wiener process in two ways: (i) as above except using the two variable Haar functions for the complete orthonormal set $\{\phi_j\}$; (ii) following the usual approach of the Itô theory. Park shows that these two approaches are equivalent in the sense that for every g in $L_2(Q)$ they are equal for m_2-a.e. f in $C_2(Q)$. It is easy to see that they are in fact equal for s-a.e. f in $C_2(Q)$. When these facts are combined with (2.3) above, we see that in our setting the P.W.Z. integral essentially agrees with the usual Itô stochastic integral. However, these integrals do not necessarily agree when the integrand contains a random function. For example, in the one variable setting, the Itô integral $\int_0^1 x(t)\,dx(t)$ equals $(x^2(1)-1)/2$ for a.e. $x \in C_1[0,1]$, while the P.W.Z. integral $\int_0^1 x(t)\,\tilde{d}x(t)$ equals $x^2(1)/2$ for a.e. $x \in C_1[0,1]$.

3. Continuity of the P.W.Z. integral with respect to binary quadratic approximation. As mentioned in the introduction, one of the keys to our proof of the parts formula is an extension to the two-parameter P.W.Z. integral of a recent result of Cameron and Storvick [1, Lemma 2.3] concerning the one-parameter P.W.Z. integral. Their result says that for every V in $L_2[0,1]$, $\int_0^1 V(s)\,\tilde{d}x(s)$ is continuous with respect to "binary polygonal approximation" for s-a.e. x in $C_1[0,1]$. The binary polygonal approximators for x are piecewise linear functions which agree with x on a certain set of binary rationals which form a partition of $[0,1]$. In trying to extend this result, it seemed natural to use piecewise linear functions of two variables as approximators for f in $C_2(Q)$. There are technical problems with this and we could not see how to make it work. We have instead used functions which are binary polygonal approximations in each variable when the other variable is fixed but which are quadratic functions of two variables. We will refer to these approximators $[f]_m$ for f as "binary quadratic approximations." We begin this section by defining $[f]_m$ precisely and noting several of its properties.

Let m be a nonnegative integer and consider the division of Q into 2^{2m} squares by means of the partition $0 = s_0 < s_1 = 1/2^m < \cdots < s_i = i/2^m < \cdots < s_{2^m} = 1$ and $0 = t_0 < t_1 = 1/2^m < \cdots < t_j = j/2^m < \cdots < t_{2^m} = 1$. For each f in $C_2(Q)$ we define the mth binary quadratic approximation $[f]_m$ by the formula

$$[f]_m(s,t) := \frac{f(s_i,t_j) - f(s_{i-1},t_j) - f(s_i,t_{j-1}) + f(s_{i-1},t_{j-1})}{(s_i - s_{i-1})(t_j - t_{j-1})}(s - s_{i-1})(t - t_{j-1})$$

$$+\frac{f(s_i,t_{j-1}) - f(s_{i-1},t_{j-1})}{(s_i - s_{i-1})}(s - s_{i-1}) \tag{3.1}$$

$$+\frac{f(s_{i-1}, t_j)-f(s_{i-1}, t_{j-1})}{(t_j - t_{j-1})}(t-t_{j-1})+f(s_{i-1}, t_{j-1})$$

for $(s, t) \in [s_{i-1}, s_i] \times [t_{j-1}, t_j]$, $i, j = 1, 2, \cdots, 2^m$.

We first note the following properties of $[f]_m$:

(3.2) $[f]_0(s, t) = stf(1, 1)$,

(3.3) $[f]_m(s_i, t_j) = f(s_i, t_j)$ at all binary partition points (s_i, t_j),

(3.4) $[f]_m \in C_2(Q)$ for each m and all $f \in C_2(Q)$,

(3.5) $\|[f]_m\|_\infty \leqq \|f\|_\infty$ for each m and all $f \in C_2(Q)$,

(3.6) For each f in $C_2(Q)$, $\|f-[f]_m\|_\infty \to 0$ as $m \to +\infty$.

(3.7) A direct caclulation shows that

$$\operatorname{Var}([f]_m, [s_{i-1}, s_i] \times [t_{j-1}, t_j]) = \int_{t_{j-1}}^{t_j} \int_{s_{i-1}}^{s_i} \left| \frac{\partial^2 [f]_m(s, t)}{\partial s \partial t} \right| ds\, dt$$
$$= |f(s_i, t_j) - f(s_{i-1}, t_j) - f(s_i, t_{j-1}) + f(s_{i-1}, t_{j-1})|$$

for each i, $j = 1, 2, \cdots, 2^m$ (also see [31, p. 413]). Hence for each f in $C_2(Q)$ and $m = 0, 1, 2, \cdots, [f]_m$ is of bounded variation on Q and we have the formula

$$\operatorname{Var}([f]_m, Q) = \int_0^1 \int_0^1 \left| \frac{\partial^2 [f]_m(s, t)}{\partial s\, \partial t} \right| ds\, dt$$
$$= \sum_{i=1}^{2^m} \sum_{j=1}^{2^m} |f(s_i, t_j) - f(s_{i-1}, t_j) - f(s_i, t_{j-1}) + f(s_{i-1}, t_{j-1})|.$$

(3.8) For each $s \in [0, 1]$, $[f]_m$ is a binary polygonal function of t in $C_1[0, 1]$ while, for each $t \in [0, 1]$, $[f]_m$ is a binary polygonal function of s in $C_1[0, 1]$, i.e., it is linear on each interval $[s_{i-1}, s_i]$.

Remark. After reading a preliminary handwritten version of this paper, Chull Park has kindly pointed out to us that he made use of these "binary quadratic approximators" in his paper [22].

Now using our binary quadratic approximators, we make a definition which parallels Cameron and Storvick's definition [1, p. 6] of continuity with respect to binary polygonal approximation.

DEFINITION. A function $F: C_2(Q) \to C$ will be called continuous at $f \in C_2(Q)$ with respect to binary quadratic approximation if $\lim_{m\to\infty} F([f]_m) = F(f)$.

We note that if F is continuous on $C_2(Q)$ then it is certainly continuous with respect to binary quadratic approximation at every f in $C_2(Q)$.

The Haar functions

$$H_0^{(0)}(s) \equiv 1 \quad \text{on } [0, 1]$$

and

$$H_n^{(k)}(s) = \begin{cases} 2^{n/2}, & \dfrac{2k-2}{2^{n+1}} \leqq s < \dfrac{2k-1}{2^{n+1}}, \\ -2^{n/2}, & \dfrac{2k-1}{2^{n+1}} < s \leqq \dfrac{2k}{2^{n+1}}, \\ 0 & \text{elsewhere}, \end{cases}$$

for $n=0,1,2,\cdots$ and $k=1,2,\cdots,2^n$ are a complete orthonormal set on $[0,1]$. Denote this collection by $\mathscr{H}$ and let

$$\mathscr{G}:=\{H_n^{(k)}(s)H_l^{(q)}(t)\colon H_n^{(k)} \text{ and } H_l^{(q)} \text{ are in } \mathscr{H}\}.$$

Then $\mathscr{G}$, the set of Haar functions on Q, is a complete orthonormal set. Furthermore the elements of $\mathscr{G}$ are defined everywhere on Q, are step-functions, and are of bounded variation on Q.

Remark. Let m be a positive integer and let $h(s,t)$ be a step-function on Q with partition points at the binary points (s_i,t_j), $i,j=0,1,\cdots,2^m$. Then $h(s,t)$ is *orthogonal* to the Haar function $H_n^{(k)}(s)H_l^{(q)}(t)\in\mathscr{G}$ whenever $\max\{n,l\}\geqq m$. Hence the orthogonal development of $h(s,t)$ in terms of the Haar functions, namely

$$h(s,t)=\sum_{g\in\mathscr{G}}(h,g)g(s,t)$$

will only involve terms $g(s,t)=H_n^{(k)}(s)H_l^{(q)}(t)$ with $n\leqq m-1$ and $l\leqq m-1$.

Next we give two lemmas which will be used in proving our continuity result.

LEMMA 3.1. *Let $g(s,t)=H_n^{(k)}(s)H_l^{(q)}(t)$ be any element of $\mathscr{G}$ (here of course n, l, k and q are nonnegative integers such that $0\leqq k\leqq 2^n$ and $0\leqq q\leqq 2^l$). Then for each $m>\max\{n,l\}$ and each $f\in C_2(Q)$ we have that*

$$\int_Q g(s,t)\,df(s,t)=\int_Q g(s,t)d[f]_m(s,t). \tag{3.9}$$

Proof. Since $m\geqq n+1$ and $m\geqq l+1$ we can interpret $g(s,t)$ as a step-function on Q with partition points at the binary points (s_i,t_j), $i,j=0,1,2,\cdots,2^m$. Since g is of bounded variation on Q we can apply the ordinary integration by parts formula for two-dimensional Riemann-Stieltjes integrals [9, p. 666] or [31, p. 415] and obtain the formula

$$\begin{aligned}\int_Q g(s,t)d(f(s,t)-[f]_m(s,t))&=g(1,1)(f(1,1)-[f]_m(1,1))\\&\quad-\int_0^1\{f(s,1)-[f]_m(s,1)\}\,dg(s,1)\\&\quad-\int_0^1\{f(1,t)-[f]_m(1,t)\}\,dg(1,t)\\&\quad+\int_Q\{f(s,t)-[f]_m(s,t)\}\,dg(s,t).\end{aligned}\tag{3.10}$$

First we note that each of the first three terms on the right-hand side of (3.10) equals zero since f and $[f]_m$ agree at the partition points (s_i,t_j) and the jumps of the functions $g(s,1)$ and $g(1,t)$ occur only at the partition points $(s_i,1)$ and $(1,t_j)$ respectively.

Next we see that $\int_Q\{f(s,t)-[f]_m(s,t)\}\,dg(s,t)=0$. This follows from the definition of the integral since, for any rectangle $R=[a,b]\times[\alpha,\beta]\subseteq Q$, if R contains no binary partition points (s_i,t_j), then g is constant in either its first or second variable and so

$$g(b,\beta)-g(b,\alpha)-g(a,\beta)+g(a,\alpha)=0.$$

Thus Lemma 3.1 is established.

LEMMA 3.2. *Let $V(s, t) \in L_2(Q)$. Then for $m = 0, 1, 2, \cdots$, the left member below exists for every $f \in C_2(Q)$ and we have*

$$\int_Q V(s, t)\tilde{d}_2[f]_m(s, t) = \int_0^1 \int_0^1 V(s, t)\frac{\partial^2[f]_m(s, t)}{\partial s \partial t}\, ds\, dt. \tag{3.11}$$

In the special case $V(s, t) = H_n^{(k)}(s)H_l^{(q)}(t) \in \mathscr{G}$, both sides of equation (3.11) vanish whenever $m \leqq \max\{n, l\}$.

Proof. Equation (3.11) follows from [21, Thm. 4] since $[f]_m(s, t)$ is absolutely continuous on Q. Next assume that $m \leqq \max\{n, l\}$ and consider the partition of Q with binary partition points (s_i, t_j), $i, j = 0, 1, \cdots, 2^m$. Without loss of generality assume that $n \geqq m$. Then for all k, $\int_{s_{i-1}}^{s_i} H_n^{(k)}(s)\, ds = 0$, and so, on each square $(s_{i-1}, s_i) \times (t_{j-1}, t_j)$, we see that

$$\begin{aligned}\int_{s_{i-1}}^{s_i} \int_{t_{j-1}}^{t_j} & H_l^{(q)}(t)H_n^{(k)}(s)\frac{\partial^2[f]_m(s, t)}{\partial s \partial t}\, dt\, ds \\ &= \frac{f(s_i, t_j) - f(s_{i-1}, t_j) - f(s_i, t_{j-1}) + f(s_{i-1}, t_{j-1})}{(s_i - s_{i-1})(t_j - t_{j-1})} \int_{t_{j-1}}^{t_j} H_l^{(q)}(t)\, dt \int_{s_{i-1}}^{s_i} H_n^{(k)}(s)\, ds \\ &= 0\end{aligned}$$

from which it easily follows that the right-hand side of (3.11) equals zero. Thus Lemma 3.2 is established.

We are now ready to establish the main result in this section.

THEOREM 3.1. *Let $V \in L_2(Q)$ and let*

$$F(f) := \int_Q V(s, t)\tilde{d}_2 f(s, t). \tag{3.12}$$

Then for s-a.e. *$f \in C_2(Q)$, $F(f)$ is continuous with respect to binary quadratic approximation.*

Proof. Assume that the P.W.Z. integral in (3.12) is given in terms of the Haar functions $\mathscr{G}$. Let

$$V_0(s, t) := (H_0^{(0)}H_0^{(0)}, V)H_0^{(0)}(s)H_0^{(0)}(t) = \int_0^1 \int_0^1 V(u, v)\, du\, dv$$

and for $m = 1, 2, 3, \cdots$. Let

$$V_m(s, t) := \sum_{\substack{g \in \mathscr{G} \\ \max\{n, l\} < m}} (g, V)g(s, t), \tag{3.13}$$

where as usual $g(s, t) = H_n^{(k)}(s)H_l^{(q)}(t)$. Next for each $f \in C_2(Q)$ let

$$f_0(s, t) := \int_Q H_0^{(0)}(s)H_0^{(0)}(t)\, df(s, t) = f(1, 1)$$

and for $m = 1, 2, \cdots$, let

$$f_m(s, t) := \sum_{\substack{g \in \mathscr{G} \\ \max\{n,l\} < m}} g(s, t) \int_Q g(u, v)\, df(u, v). \tag{3.14}$$

Note that the sequences $\{V_m\}_{m=0}^{\infty}$ and $\{f_m\}_{m=0}^{\infty}$ are "expansions" in terms of the Haar functions $\mathscr{G}$. It is quite easy to see that the functions V_m and f_m are related by the equation

$$\int_Q V_m(s,t)\,df(s,t)=\int_0^1\int_0^1 V(s,t)f_m(s,t)\,ds\,dt \tag{3.15}$$

for all m.

Next we claim that for each $m=0,1,2,\cdots$

$$\frac{\partial^2[f]_m(s,t)}{\partial s\partial t}=f_m(s,t) \tag{3.16}$$

for almost all $(s,t)\in Q$. This is clear in the case $m=0$ since in that case each side of (3.16) equals $f(1,1)$. We will establish (3.16) by showing that both sides of (3.16) have the same orthogonal expansion in terms of the Haar functions $\mathscr{G}$. First, using (3.14), Lemma 3.1, and Lemma 3.2, it follows that

$$\begin{aligned} f_m(s,t)&=\sum_{\substack{g\in\mathscr{G}\\ \max\{n,l\}<m}} g(s,t)\int_Q g(u,v)\,df(u,v)\\ &=\sum_{\substack{g\in\mathscr{G}\\ \max\{n,l\}<m}} g(s,t)\int_Q g(u,v)d[f]_m(u,v)\\ &=\sum_{\substack{g\in\mathscr{G}\\ \max\{n,l\}<m}} g(s,t)\int_0^1\int_0^1 g(u,v)\frac{\partial^2[f]_m(u,v)}{\partial u\partial v}\,du\,dv\\ &=\int_0^1\int_0^1\frac{\partial^2[f]_m(u,v)}{\partial u\partial v}\Bigg(\sum_{\substack{g\in\mathscr{G}\\ \max\{n,l\}<m}} g(u,v)g(s,t)\Bigg)\,du\,dv. \end{aligned} \tag{3.17}$$

Using (3.17) and the fact that $\mathscr{G}$ is a complete orthonormal set of functions on Q we obtain that

$$\int_0^1\int_0^1 f_m(s,t)h(s,t)\,ds\,dt=\int_0^1\int_0^1\frac{\partial^2[f]_m(u,v)}{\partial u\partial v}h(u,v)\,du\,dv \tag{3.18}$$

for all elements $h(s,t)=H_n^{(k)}(s)H_l^{(q)}(t)$ in $\mathscr{G}$ with $\max\{n,l\}<m$. (Simply multiply both sides of (3.17) by $h(s,t)$ and then integrate with respect to s and t over Q.) Next, using (3.17) we see that

$$\int_0^1\int_0^1 f_m(s,t)h(s,t)\,ds\,dt=0$$

for all elements $h(s,t)=H_n^{(k)}(s)H_l^{(q)}(t)$ in $\mathscr{G}$ with $m\leqq\max\{n,l\}$. Also for all such h, using Lemma 3.2 we see that

$$\int_0^1\int_0^1 h(s,t)\frac{\partial^2[f]_m(s,t)}{\partial s\partial t}\,ds\,dt=0.$$

Thus (3.18) holds for all $h\in\mathscr{G}$ and so both sides of (3.16) have the same orthogonal expansion in terms of the Haar functions on Q and so they are equal almost everywhere on Q.

Finally, using the definition of the P.W.Z. integral, (3.15), (3.16), and Lemma 3.2, we see that for s-a.e. $f\in C_2(Q)$

$$\begin{aligned}F(f)&:=\int_Q V(s,t)\tilde{d}_2f(s,t)\\&=\lim_{m\to\infty}\int_Q V_m(s,t)\,df(s,t)\\&=\lim_{m\to\infty}\int_0^1\int_0^1 V(s,t)f_m(s,t)\,ds\,dt\\&=\lim_{m\to\infty}\int_0^1\int_0^1 V(s,t)\frac{\partial^2[f]_m(s,t)}{\partial s\partial t}\,ds\,dt\\&=\lim_{m\to\infty}\int_Q V(s,t)\,\tilde{d}_2[f]_m(s,t)\\&=\lim_{m\to\infty}F([f]_m),\end{aligned}$$

which establishes Theorem 3.1.

COROLLARY 3.1. *Let $R=[a,b]\times[\alpha,\beta]\subseteq Q$. Let $U(s,t)\in L_2(R)$ and let*

$$H(f):=\int_R U(s,t)\,\tilde{d}_2f(s,t).$$

Then for s-a.e. $f\in C_2(Q)$, $H(f)$ is continuous with respect to binary quadratic approximation.

Proof. Let $V(s,t)=U(s,t)\chi_R(s,t)$. Then $V\in L_2(Q)$ and

$$\begin{aligned}H(f)&:=\int_R U(s,t)\,\tilde{d}_2f(s,t)\\&=\int_Q V(s,t)\,\tilde{d}_2f(s,t)\\&=\lim_{m\to\infty}\int_Q V(s,t)\,\tilde{d}_2[f]_m(s,t)\\&=\lim_{m\to\infty}\int_R U(s,t)\,\tilde{d}_2[f]_m(s,t)\\&=\lim_{m\to\infty}H([f]_m).\end{aligned}$$

4. A stochastic integration by parts formula for Yeh–Wiener × Yeh–Wiener space. To obtain our main result we will use the fact that the function $\|f\|_\infty^2$ is in $L_1(C_1,m_2)$. For the sake of completeness we include an elementary proof of a result somewhat stronger than this (see [16, pp. 159-164] for a related discussion).

LEMMA 4.1. *For $\alpha<\frac{1}{2}$, $\exp\{\alpha\|f\|_\infty^2\}\in L_1(C_2,m_2)$.*

Proof. Let $G(f)=\exp\{\alpha\|f\|_\infty^2\}$, where $\|f\|_\infty=\sup_Q|f(s,t)|$. By [25, p. 30] we know that G is in $L_1(C_2,m_2)$ if and only if

$$\int_0^\infty m_2\{f\in C_2(Q):|Gf)|>\lambda\}\,d\lambda<\infty.$$

Since m_2 is a probability measure it suffices to show that

$$\int_2^\infty m_2\{f \in C_2(Q): |G(f)| > \lambda\}\, d\lambda < \infty.$$

Let $N(\cdot)$ denote the standard normal distribution function. Kiefer has shown [23, p. 455] that $m_2\{f: \sup_Q f(s,t) > \lambda\} \leqq 4N(-\lambda)$. Thus for $\lambda \geqq 2$, letting $\rho \equiv (\ln \lambda/\alpha)^{1/2}$ we see that

$$\begin{aligned}
m_2\{f: |G(f)| > \lambda\} &= m_2\{f: \exp\{\alpha\|f\|_\infty^2\} > \lambda\} \\
&= m_2\{f: \|f\|_\infty > \rho\} \\
&= m_2[\{f: \sup_Q f(s,t) > \rho\} \cup \{f: \inf_Q f(s,t) < -\rho\}] \\
&\leqq m_2\{f: \sup_Q f(s,t) > \rho\} + m_2\{f: \inf_Q f(s,t) < -\rho\} \\
&= 2m_2\{f: \sup_Q f(s,t) > \rho\} \\
&\leqq 8N(-\rho) \\
&= \frac{8}{\sqrt{2\pi}} \int_{-\infty}^{-\rho} \exp\left[\frac{-u^2}{2}\right] du \\
&= \frac{8}{\sqrt{2\pi}} \int_{\rho}^{\infty} \exp\left[\frac{-u^2}{2}\right] du \\
&\leqq \frac{8}{\rho\sqrt{2\pi}} \int_{\rho}^{\infty} u \exp\left[\frac{-u^2}{2}\right] du \\
&= \frac{8}{\rho\sqrt{2\pi}} \exp\left(\frac{-\rho^2}{2}\right) \\
&= 8\left(\frac{\alpha}{2\pi \ln \lambda}\right)^{1/2} \exp\left(-\frac{\ln \lambda}{2\alpha}\right) \\
&= 8\left(\frac{\alpha}{2\pi \ln \lambda}\right)^{1/2} \left(\frac{1}{\lambda}\right)^{1/2\alpha}
\end{aligned}$$

which is in $L_1([2,\infty))$ as a function of λ if and only if $\alpha < \frac{1}{2}$.

COROLLARY 4.1. $\|f\|_\infty^2 \in L_1(C_2, m_2)$.

In our next lemma we establish the convergence of the P.W.Z. integral in the L_2-norm on $C_2(Q) \times C_2(Q)$ with respect to binary quadratic approximation in the first variable.

LEMMA 4.2. *Let* $L: C_2(Q) \times C_2(Q) \to \mathbb{R}$ *be given by*

$$L(f,g) := \int_Q f(s,t)\, \tilde{d}_2 g(s,t). \tag{4.1}$$

Then $L([f]_m, g) \to L(f,g)$ *in* L_2*-norm as* $m \to \infty$, *i.e.,*

$$\lim_{m\to\infty} \int_{C_2 \times C_2} |L(f,g) - L([f]_m, g)|^2 d(m_2 \times m_2)(f,g) = 0. \tag{4.2}$$

Proof. Using (2.6) we see that for $f \in C_2(Q)$ and each $m = 0, 1, 2, \cdots$

$$\left\{\int_{C_2} |L(f,g) - L([f]_m, g)|^2\, dm_2(g)\right\}^{1/2} = \|f - [f]_m\|_2. \tag{4.3}$$

It follows from (4.3) that

$$(4.4)\qquad \int_{C_2} |L(f,g)-L([f]_m,g)|^2\,dm_2(g)=\|f-[f]_m\|_2^2\to 0\quad \text{as } m\to\infty.$$

Also from (4.3) and the Minkowski inequality we get

$$(4.5)\qquad \begin{aligned} \int_{C_2} |L(f,g)-L([f]_m,g)|^2\,dm_2(g) &\leqq [\|f\|_2+\|[f]_m\|_2]^2 \\ &\leqq [\|f\|_\infty+\|[f]_m\|_\infty]^2 \\ &\leqq [\|f\|_\infty+\|f\|_\infty]^2 \\ &=4\|f\|_\infty^2. \end{aligned}$$

Now using (4.4), (4.5), the Fubini Theorem, Corollary 4.1 and the Dominated Convergence Theorem we obtain (4.2).

The following corollary to the proof of Lemma 4.2 gives the L_2-norm convergence on subrectangles of Q.

COROLLARY 4.2. *Let $R=[a,b]\times[\alpha,\beta]\subseteq Q$ and let $L\colon C_2(Q)\times C_2(Q)\to\mathbb{R}$ be given by*

$$(4.6)\qquad L(f,g):=\int_Q \chi_R(s,t)f(s,t)\,\tilde{d}_2 g(s,t).$$

Then

$$\lim_{m\to\infty}\int_{C_2\times C_2} |L(f,g)-L([f]_m,g)|^2 d(m_2\times m_2)(f,g)=0.$$

THEOREM 4.1. *For any rectangle $R=[a,b]\times[\alpha,\beta]\subseteq Q$ and for $m_2\times m_2$-a.e. $(f,g)\in C_2\times C_2$*

$$(4.7)\qquad \begin{aligned} \int_R f(s,t)\,\tilde{d}_2 g(s,t) &= f(b,\beta)g(b,\beta)-f(b,\alpha)g(b,\alpha) \\ &\quad -f(a,\beta)g(a,\beta)+f(a,\alpha)g(a,\alpha) \\ &\quad -\int_a^b [g(s,\beta)\,\tilde{d}f(s,\beta)-g(s,\alpha)\,\tilde{d}f(s,\alpha)] \\ &\quad -\int_\alpha^\beta [g(b,t)\,\tilde{d}f(b,t)-g(a,t)\,\tilde{d}f(a,t)] \\ &\quad +\int_R g(s,t)\,\tilde{d}_2 f(s,t). \end{aligned}$$

In fact, given any (f,g) for which (4.7) *holds and any ρ_1, $\rho_2>0$,* (4.7) *also holds for $(\rho_1 f,\rho_2 g)$. In fact for m_2-a.e.f,* (4.7) *holds for s-a.e.g and for m_2-a.e.g,* (4.7) *holds for s-a.e.f.*

Proof. Let $L\colon C_2\times C_2\to\mathbb{R}$ be defined by the left-hand side of (4.7) (i.e. L is given by (4.6)) for all (f,g) for which the P.W.Z. integral exists, and let $M\colon C_2\times C_2\to\mathbb{R}$ be defined by the right-hand side of (4.7) for all (f,g) for which all the P.W.Z. integrals exist. We first note that for each $f\in C_2(Q)$, $L(f,g)$ exists for s-a.e.$g\in C_2(Q)$ while for each $g \in C_2(Q)$, $M(f, g)$ exists for s-a.e.$f \in C_2(Q)$. To establish Theorem 4.1 it clearly suffices to establish (i), (ii), and (iii) below.

(i) For each $f \in C_2(Q)$ and each $m = 0, 1, 2, \cdots$, $L([f]_m, g) = M([f]_m, g)$ for s-a.e.$g \in C_2(Q)$.

(ii) $L([f]_m, g) \to L(f, g)$ in L_2-norm as $m \to \infty$ (this is simply Corollary 4.2 above).

(iii) For each $g \in C_2(Q)$, $M([f]_m, g) \to M(f, g)$ as $m \to \infty$ for s-a.e.$f \in C_2(Q)$.

Proof of (i). Let $f \in C_2(Q)$ and m be given. Then for s-a.e.$g \in C_2(Q)$, $L([f_m], g)$ exists and satisfies the equation

$$\begin{aligned} L([f]_m, g) &:= \int_R [f]_m(s, t)\, \tilde{d}_2 g(s, t) \\ &= \int_R [f]_m(s, t)\, dg(s, t). \end{aligned} \tag{4.8}$$

But, by the nonstochastic integration by parts formula [31, Thm. 4], we know that for *all* $(f, g) \in C_2 \times C_2$ and all m

$$\begin{aligned} \int_R [f]_m(s, t)\, dg(s, t) = {} & [f]_m(b, \beta) g(b, \beta) - [f]_m(b, \alpha) g(b, \alpha) \\ & - [f]_m(a, \beta) g(a, \beta) + [f]_m(a, \alpha) g(a, \alpha) \\ & - \int_a^b [g(s, \beta) d[f]_m(s, \beta) - g(s, \alpha) d[f]_m(s, \alpha)] \\ & - \int_\alpha^\beta [g(b, t) d[f]_m(b, t) - g(a, t) d[f]_m(a, t)] \\ & + \int_R g(s, t) d[f]_m(s, t). \end{aligned} \tag{4.9}$$

Next by Lemma 3.2 and the corresponding result for P.W.Z. integrals of functions of one variable we see that for *all* $(f, g) \in C_2 \times C_2$ and all m, $M([f]_m, g)$ exists and equals the right-hand side of (4.9) above. Thus, using (4.8) and (4.9), we see that for fixed f and m, $L([f]_m, g) = M([f]_m, g)$ for s-a.e.$g \in C_2(Q)$ and so (i) is established.

Proof of (iii). To establish (iii) it suffices to show that for each $g \in C_2(Q)$, each of the seven terms involved in the definition of $M([f]_m, g)$ converges to the corresponding term in the definition of $M(f, g)$ for s-a.e.$f \in C_2(Q)$. This is easy to see for the first 4 terms. Corollary 3.1 assures that this is true for the 7th term also, i.e.,

$$\lim_{m \to \infty} \int_R g(s, t)\, \tilde{d}_2 [f]_m(s, t) = \int_R g(s, t)\, \tilde{d}_2 f(s, t)$$

for s-a.e.$f \in C_2(Q)$. Next, using a result of Cameron and Storvick [1, Lemma 2.3] together with [28, p. 306], it is quite easy to see that, for example,

$$\lim_{m \to \infty} \int_a^b g(s, \beta) d[f]_m(s, \beta) = \int_a^b g(s, \beta)\, \tilde{d} f(s, \beta)$$

for s-a.e.$f \in C_2(Q)$. Similarly we get the desired convergence for the other integrals involved in the 5th and 6th terms of $M([f]_m, g)$ and $M(f, g)$. Thus (iii) is established, which concludes the proof of Theorem 4.1.

Choosing $R = Q = [0, 1]^2$ in Theorem 4.1 and keeping in mind that f and g vanish on the left-hand and lower edges of Q, we get the following corollary.

COROLLARY 4.3. *For $m_2 \times m_2$-a.e.$(f, g) \in C_2 \times C_2$*

$$\int_{[0,1]^2} f(s,t)\,\tilde{d}_2 g(s,t) = f(1,1)g(1,1) - \int_0^1 g(s,1)\,\tilde{d}f(s,1) - \int_0^1 g(1,t)\,\tilde{d}f(1,t) + \int_{[0,1]^2} g(s,t)\,\tilde{d}_2 f(s,t). \tag{4.10}$$

In addition, given any (f, g) for which (4.10) *holds and any $\rho_1, \rho_2 > 0$,* (4.10) *also holds for $(\rho_1 f, \rho_2 g)$. In fact for m_2-a.e.f,* (4.10) *holds for s-a.e.g and for m_2-a.e.g,* (4.10) *holds for s-a.e.f.*

Next, using Theorem 3.1 and Theorem 4.1, we obtain the following interesting corollary.

COROLLARY 4.4. *For m_2-a.e.$g \in C_2(Q)$, the function $\int_Q f(s,t)\,\tilde{d}_2 g(s,t)$ is continuous with respect to binary quadratic approximation for s-a.e.f in $C_2(Q)$. That is to say, for almost all $g \in C_2(Q)$,*

$$\lim_{m\to\infty} \int_Q [f]_m(s,t)\,\tilde{d}_2 g(s,t) = \int_Q f(s,t)\,\tilde{d}_2 g(s,t)$$

for s-a.e.f in $C_2(Q)$.

Concluding remarks. Using the techniques of § 4 together with Lemma 2.3 of [1, p. 7], one can quite easily obtain an alternate proof of the parts formula for the stochastic integral of functions of one variable [7, p. 268] which follows.

THEOREM 4.1(a). *For $0 \leqq a < b \leqq 1$ and $m_1 \times m_1$-a.e.(x, w) in $C_1[0,1] \times C_1[0,1]$*

$$\int_a^b x(s)\,\tilde{d}w(s) = x(b)w(b) - x(a)w(a) - \int_a^b w(s)\,\tilde{d}x(s). \tag{4.11}$$

In fact for m_1-a.e.x, (4.11) *holds for s-a.e.w and for m_1-a.e.w,* (4.11) *holds for s-a.e.x.*

COROLLARY 4.4(a). *For m_1-a.e.$w \in C_1[0,1]$, the function $H(x) := \int_0^1 x(s)\,\tilde{d}w(s)$ is continuous with respect to binary polygonal approximation for s-a.e.$x \in C_1[0,1]$.*

Proof. Theorem 4.1(a) and Lemma 2.3 of [1, p. 7].

SOME APPROXIMATION FORMULA FOR STOCHASTIC EIGENVALUES*

DAVID C. BARNES†

Abstract. We consider some random eigenvalue problems of the form $L(\cdot)=\lambda M(\cdot)$, where $L(\cdot)$ and $M(\cdot)$ may be ordinary or partial differential operators which depend on a (perhaps multi-dimensional) random variable ω. We generalize some formulas due to Boyce [*Probabilistic Methods in Applied Mathematics*, Academic Press, New York, 1968, pp. 1-73] which give estimates for the eigenvalues of the form $\lambda(\omega)=\lambda^*+K(\omega)+O(\|\omega\|^2)$. Here $\lambda(\omega)$ is an eigenvalue corresponding to the random variable ω while λ^* is an eigenvalue corresponding to some approximating deterministic problem. The term $K(\omega)$ will be $O(\|\omega\|)$, although it may not be linear in ω. These formulas may be used with very general boundary conditions, including those which contain random coefficients and those which may be nonlinear and nonhomogeneous. The boundary conditions also may contain the eigenvalue parameter λ and they need not be self-adjoint. We will first give the theory for ordinary equations, then generalize to partial differential equations, first in a deterministic domain, then in a random domain.

Key words. stochastic eigenvalues, approximation

1. Introduction.

Consider the eigenvalue problem

$$L(y)=\lambda g y, \quad L(y)=-(fy')'-qy, \quad 0<x<l. \tag{1}$$

We assume the coefficients f, g and q depend on x as well as a random variable $\omega=(\omega_1, \omega_2, \cdots, \omega_N)$, taken from a sample space $\Omega=\Omega_1\times\Omega_2\times\cdots\times\Omega_N$ where, for each $x\in[0, l]$, probability measures $\mu_i(\cdot)$ are defined on Ω_i. The ω_i may or may not be independent. When appropriate boundary conditions are given, and with some mild restrictions on the coefficients, the problem will have eigenvalues $\lambda(\omega)$ which will then be random variables defined on Ω. In this work, we will be concerned with finding approximations of the form $\lambda(\omega)=\lambda^*+K(\omega)+O(\|\omega\|^2)$. Here, λ^* is an eigenvalue of an approximating deterministic problem

$$L^*(y^*)=\lambda^* g^* y^*, \qquad L^*(y^*)=-(f^*y^{*\prime})'-q^*y^*. \tag{2}$$

We will first develop the theory for (1), then generalize it to problems of the form $L(y)=\lambda M(y)$, where $L(\cdot)$ and $M(\cdot)$ are (possibly partial) differential operators having random coefficients. Finally, we will give a modest treatment of the simple equation $\nabla^2 u+\lambda u=0$ with $u=0$ on $\partial\mathcal{R}$, where $\mathcal{R}$ is a random domain. Throughout we will use the notation $\Delta(\cdot)=(\cdot)-(\cdot)^*$, and *-ed quantities will all be deterministic; so, for example, $\Delta L=L-L^*$, $\Delta\lambda=\lambda-\lambda^*$ and so on. We denote the mean of a random variable by $\langle\cdot\rangle$ and also use the notations

$$\|\omega\|^2=\max_{i,j}\{|\omega_i\omega_j|\}, \qquad (u, v)=\int_0^l u(x)v(x)\,dx.$$

2. The second order equation.

Methods used by D. C. Barnes [3] can be used to prove the following theorem.

THEOREM 1. *Let y, λ and y^*, λ^* be eigenpairs for* (1), (2). *Define a random variable $J(\omega)$ by*

$$J(\omega)=\int_0^l [\lambda^* g y^{*2}+q y^{*2}-f(y^{*\prime 2})]\,dx. \tag{3}$$

* Received by the editors March 28, 1985; accepted for publication April 7, 1986.

† Mathematics Department, Washington State University, Pullman, Washington 99164-2930.

Define also a boundary term BT and a random variable $K(\omega)$ by

$$BT = f^*y^{*\prime}y - fy'y^* - f^*y^{*\prime}y^*|_{x=0}^{x=l}, \qquad K(\omega) = \lambda^* + BT - J(\omega). \tag{4}$$

Suppose that y^* is normalized so that

$$\int_0^l g^*y^{*2}\,dx = 1. \tag{5}$$

Then

$$\lambda(\omega) = K(\omega) + O_2 = \lambda^* + BT - J(\omega) + O_2 \tag{6}$$

where the term O_2 is defined by

$$O_2 = \int_0^l [\Delta\lambda\,\Delta y g^* y^* + \lambda^*\Delta g\Delta y y^* + \Delta q \Delta y y^* - \Delta f \Delta y' y^{*\prime}]\,dx. \tag{7}$$

In the context of [3], ω was simply a real parameter and (6) was used to develop some variational properties of the eigenvalues λ. However, (6) shows that the functional $K(\omega)$ is tangent to $\lambda(\omega)$ at $\omega = 0$ and thus will provide a good approximation formula when $\|\omega\|$ is small. Now we need to make O_2 small by selecting the base problem (2). One good way to do this is to take

$$f^* = \langle f \rangle, \qquad g^* = \langle g \rangle, \qquad q^* = \langle q \rangle. \tag{8}$$

As an example, we will take the simple boundary conditions, $y(0) = y(l) = 0$, and use (6) to approximate $\langle \lambda \rangle$. We see that

$$\langle \lambda(\omega) \rangle = \lambda^* - \int_0^l [\lambda^*\langle g \rangle y^{*2} + \langle q \rangle y^{*2} - \langle f \rangle (y^{*\prime 2})]\,dx + O_2. \tag{9}$$

Now multiply (2) by y^* and integrate. This shows that the integral term in (9) vanishes, so $\langle \lambda(\omega) \rangle = \lambda^* + \langle O_2 \rangle$. This estimate has been given by Boyce [4]. Generally, in the case of homogeneous, linear, self-adjoint, and deterministic boundary conditions, and in the choice of base problem (8), the result (9) is well known.

It is, however, not at all necessary that the boundary conditions be homogeneous, linear, self-adjoint or deterministic. Equation (6) holds in any case. The boundary conditions might even involve the eigenvalue parameter λ.

There are only two conditions which are necessary in order to use the approximation (6) effectively. First of all BT will, in general, involve the values of y at $x = 0$ and at $x = l$. So we must be able to use the boundary conditions to eliminate, or at least approximate, the terms in BT which involve y. The second requirement is that the eigenvalue problem must be well posed when considered as a function of ω. That is, the eigenvalues, the eigenfunctions and their derivatives must depend continuously on ω. This will insure that the error term O_2 is small. Other than these requirements, the boundary conditions are quite arbitrary.

Suppose we are given constants a, b and random variables ω_i taken from sample spaces (Ω_i, μ_i) with $\omega = (\omega_1, \omega_2, \omega_3) \in \Omega_1 \times \Omega_2 \times \Omega_3$. Consider the boundary conditions

$$y(0) + (a + \omega_2) f(0, \omega_1) y'(0) = 0, \qquad (b + \omega_3) y(l) + f(l, \omega_1) y'(l) = 0. \tag{10}$$

We select the base problem by letting $\omega = 0$, so that

$$\begin{gathered} f^*(x) = f(x, 0), \qquad g^*(x) = g(x, 0), \qquad q^*(x) = q(x, 0), \\ y^*(0) + af^*(0) y^{*\prime}(0) = 0, \qquad by^*(l) + f^*(l) y^{*\prime}(l) = 0. \end{gathered} \tag{11}$$

Using (10) and (11) in (4), it follows that

$$BT=(by^{*2}+\omega_3 yy^*)|_{x=l}-(af^{*2}y^{*\prime 2}-\omega_2 ff^*y^{*\prime}y')|_{x=0}.$$

We now use the approximations $y=y^*+O(\omega)$ and $y'=y^{*\prime}+O(\omega)$ to eliminate the terms involving y and obtain the first order approximation

$$BT=y^{*2}(b+\omega_3)|_{x=l}-(a-\omega_2)f^{*2}y^{*\prime 2}|_{x=0}+O_2.$$

Since we have eliminated the terms in BT which involve y, we may substitute this formula in (6) to obtain first order approximation to $\lambda(\omega)$ which can be easily computed.

As a second example, consider a slender column subject to a compressive load λ which may cause it to buckle. The critical buckling load is determined by the smallest nonzero eigenvalue of an equation of the form (1). The eigenfunction $y(x)$ represents the bending moment of the column in the buckled state. If the load λ is applied exactly on the center line of the column, then the boundary conditions will be $y^*(0)=y^*(l)=0$. Suppose, however, that the load at $x=l$ is applied at a small, random distance ω away from the center line. If the column is pinned at both ends, then the boundary conditions are [2], [6]

$$y(0)=0,\quad y(l)=\lambda\omega,\qquad y^*(0)=0,\quad y^*(l)=0. \tag{12}$$

We suppose that the shape of the column is deterministic, so that the coefficients f, g, q do not depend on ω. The eigenfunction y^* is uniquely determined by (2) and (5) up to a factor of ± 1. Suppose first that $\omega>0$. We then take y^* to be the eigenfunction satisfying $y^*>0$ for $0<x<l$ so that $y^{*\prime}(l)<0$. However, if $\omega<0$, then we will take y^* to satisfy $y^*<0$ so that $y^{*\prime}(l)>0$. This will insure, at least for small ω, that y and y^* will have no zeros on $0<x<l$ so that Δy and $\Delta y'$ will be small. It also insures that the approximation formulas will be symmetric about $\omega=0$, as is the eigenvalue itself, $\lambda(-\omega)=\lambda(\omega)$.

Since the problem (12) is not homogeneous, the eigenfunction y cannot be normalized at will. We still, however, use the relation

$$\int_0^l gy^2\,dx=1, \tag{13}$$

in order to force the approximations of y to y^*. The three conditions (12), (13) will serve to determine the two constants in the general solution of (1) as well as λ. These conditions, together with the above sign conventions, will determine the eigenfunction y uniquely.

Using (4), we find $BT\approx\lambda(\omega)f^*(l)y^{*\prime}(l)\omega$. Since the choice of y^* depends on sign(ω), we recast BT into the general form (which works for either y^*) $BT\approx -\lambda(\omega)f^*(l)|y^{*\prime}(l)\omega|$. Putting this into (6) and solving the resulting equation for $\lambda(\omega)$ yields the first order approximation

$$\lambda(\omega)=\frac{\lambda^*-J(\omega)+O_2}{1+f^*(l)|y^{*\prime}(l)\omega|}=\frac{\lambda^*-J(\omega)}{1+f^*(l)|y^{*\prime}(l)\omega|}+O_2. \tag{14}$$

The form of this equation, and physical intuition, suggests that $\lambda(\omega)\leqq\lambda^*$ but this has not been proved.

Consider an example of (14). Suppose that the column is uniform. That is, $f=g=1$, $q=0$, and use nondimensional coordinates, so that

$$y''+\lambda y=0,\quad y(0)=0,\quad y(1)=\lambda\omega,\quad\text{and}\quad y^*=\pm\sqrt{2}\sin\pi x,\quad \lambda^*=\pi^2.$$

Solving for y and $\lambda(\omega)$, we find, for given ω, that $\lambda(\omega)$ is the smallest positive root of the equation

$$(15)\qquad t^3\omega^2(2t-\sin t)=4\sin^2 t,\quad t=\sqrt{\lambda}\quad\text{and}\quad y=2\sqrt{\frac{t}{(2t-\sin 2t)}}\sin tx.$$

Using (14) we find that

$$(16)\qquad \lambda(\omega)=\frac{\lambda^*}{1+\sqrt{2}\pi|\omega|}+O_2.$$

We will now check the accuracy of this approximation. Rather than attempt to solve (15) for $\lambda(\omega)$, it is more convenient to use the inverse functions for $|\omega|$ as a function of $t=\sqrt{\lambda}$. Solving for $|\omega|$, using both (15) and (16) we find

$$|\omega|=\frac{2\sin t}{\sqrt{t^3(2t-\sin 2t)}},\qquad |\omega|=\frac{\pi^2-t^2}{\sqrt{2}\pi t^2}+O_2.$$

Now one can easily verify that the two right-hand sides are tangent to each other at the point $t=\pi$, $\omega=0$. Thus the approximation (16) will be good for small ω.

The sign conventions used in this example essentially amounted to decomposing the sample space Ω into its positive and negative parts, Ω^+ and Ω^-, and then using two distinct approximation formulas on each part. Such decompositions can be useful in other situations as well.

Suppose that either the coefficient functions f, g, q, or the boundary conditions are not continuous in ω. In such an event, the eigenvalue problem may not be well posed and the methods used here would not apply. Suppose, however, that we can decompose Ω into a disjoint union,

$$(17)\qquad \Omega=\bigcup_{i=1}^{N}\Omega_i,\qquad \Omega_i\cap\Omega_j=\varnothing\quad\text{for } i\neq j$$

in such a way that the problem is well posed on each Ω_i. We then select approximating base problems for each Ω_i,

$$(18)\qquad (f_i^*y_i^{*\prime})'+(\lambda_i^*g_i^*+q_i^*)y_i^*=0,\qquad U_1^{(i)}(y_i^*)=U_2^{(i)}(y_i^*)=0$$

where, for each i, we might select a fixed value of $\omega_i\in\Omega_i$ and define the approximating problems by

$$f_i^*(x)=f(x,\omega_i),\qquad g_i^*(x)=g(x,\omega_i),\qquad q_i^*(x)=q(x,\omega_i).$$

Now construct the piecewise O_2 approximation to $\lambda(\omega)$ using

$$(19)\quad \lambda(\omega)=\lambda_i^*+BT_i-J_i(\omega)+O_{2,i},\quad \omega\in\Omega_j,\qquad J_i(\omega)=\int_0^l \lambda_i^*gy_i^*+qy_i^*-fy_i^{*\prime 2}\,dx.$$

The error terms $O_{2,i}$ will be $O((\omega-\omega_i)^2)$ on Ω_i. Even though such a piecewise approximation may not be continuous on all Ω, it will still be a global first order approximation to $\lambda(\omega)$.

This also suggests numerical procedures for high accuracy computations. Suppose, for example, that we need to compute $\langle\lambda\rangle$. We could then decompose Ω as in (17) so that $\mu(\Omega_i)=1/N$. Then solve the N base problems (18) for y_i^* and take the mean in (19) to obtain

$$(20)\qquad \langle\lambda\rangle=\sum_{i=1}^{N}\int_{\Omega_i}\langle\lambda_i^*+BT_i-J_i(\omega)\rangle\,d\mu+O\left(\frac{1}{N}\right).$$

Since each error term in (19) is $O(1/N^2)$, the error term in (20) will be $O(1/N)$. The obvious thing to do at this point, is to use (20) together with a Romberg style extrapolation scheme to compute more accurate values for $\langle\lambda\rangle$.

3. More general problems. These methods will also work on more general problems of the form

$$L(y)=\lambda M(y), \qquad U_p(y,\omega,\lambda)=0, \quad p=1,2,\cdots,2m, \tag{21}$$
$$L(y)=\sum_{i=0}^{m}(-1)^i(f_iy^{(i)})^{(i)}, \qquad M(y)=\sum_{j=0}^{m'}(-1)^j(g_jy^{(j)})^{(j)}.$$

Here, f_i and g_j are random functions, and we will assume that $m>m'\geqq 0$. The boundary conditions may be quite arbitrary, being subject to the same conditions outlined in the second order case.

Consider any deterministic problem which approximates (21),

$$L^*(y^*)=\lambda^*M^*(y^*), \qquad U_p^*(y^*,\lambda^*)=0, \quad p=1,2,\cdots,2m, \tag{22}$$
$$L^*(y^*)=\sum_{i=0}^{m}(-1)^i(f_i^*y^{*(i)})^{(i)}, \qquad M^*(y^*)=\sum_{i=0}^{m'}(-1)^j(g_j^*y^{*(j)})^{(j)}.$$

We have the following theorem.

THEOREM 2. *Let y, λ and y^*, λ^* be eigenpairs for* (21) *and* (22). *Define a random variable $J(\omega)$ by*

$$J(\omega)=\int_0^l \sum_{j=0}^{m'} g_j(y^{*(j)})^2-\sum_{i=0}^{m} f_i(y^{*(i)})^2\,dx. \tag{23}$$

Define boundary terms $BT1$, $BT2$ and $BT3$ by the following equations:

$$(L^*(y),y^*)=BT1+(y,L^*(y^*)), \tag{24}$$

$$(M^*(y),y^*)=BT2+(y,M^*(y^*)), \tag{25}$$

$$(L(y^*),y^*)-\lambda^*(M(y^*),y^*)=BT3-J(\omega). \tag{26}$$

Suppose that y^* is normalized so that

$$(M^*(y^*),y^*)=1, \qquad (L^*(y^*),y^*)=\lambda^*. \tag{27}$$

Then

$$\lambda(\omega)=\lambda^*+BT1-\lambda^*BT2+(L(y^*),y^*)-\lambda^*(M(y^*),y^*)+O_2, \tag{28}$$

$$\lambda(\omega)=\lambda^*+BT1-\lambda^*BT2+BT3-J(\omega)+O_2. \tag{29}$$

The error term O_2 is given by

$$O_2=(\Delta L(\Delta y)-\Delta\lambda M^*(\Delta y)-\Delta\lambda\,\Delta M(y^*)-\lambda\,\Delta M(\Delta y),y^*) \tag{30}$$

where $\Delta(\cdot)=(\cdot)-(\cdot)^*$.

The proof consists of a rather straightforward, but lengthy, computation. First multiply (22) by y and (21) by y^*. Then subtract the equations and integrate to find

$$(L(y),y^*)-(L^*(y^*),y)=\lambda(M(y),y^*)-\lambda^*(M^*(y^*),y).$$

We now substitute the Δ notation into this equation, giving

$$((L^*+\Delta L)(y^*+\Delta y),y^*)-(L^*(y^*),y^*+\Delta y)$$
$$=(\lambda^*+\Delta\lambda)((M^*+\Delta M)(y^*+\Delta y),y^*)-\lambda^*(M^*(y^*),y^*+\Delta y).$$

Now multiply out these expressions, collecting all terms of second order into O_2 as given by (30). Next, use the relations $\Delta(\cdot) = (\cdot) - (\cdot)^*$ to eliminate all of the remaining terms which involve Δ. Finally, use (24), (25) and (27) to simplify the formula. After some manipulation, (28) follows. Finally, (26) implies (29).

In the important special case $m = 2$ and $m' = 1$, we find that

$$BT1 = (f_2^* y'')' y^* - (f_2^* y^{*''})' y + f_2^* y^{*''} y' - f_2^* y'' y^{*'} + f_1^* y y^{*'} - f_1^* y' y^* \Big|_{x=0}^{x=l}, \tag{31}$$

$$BT2 = g_1^* y^{*'} y - g_1^* y^* y' \Big|_{x=0}^{x=l}, \tag{32}$$

$$BT3 = (f_2 y^{*''})' y^* - f_2 y^{*'} y^{*''} - f_1 y^{*'} y^* + \lambda^* g_1 y^{*'} y^* \Big|_{x=0}^{x=l}. \tag{33}$$

As an example, consider a uniform slender column subject to an axial compressive load λ which may cause it to buckle. Suppose that it is pinned at each end and that it is supported on an elastic foundation which provides, at each point x, a random restoring force $F(x, \omega_1)y$, which is directly proportional to the displacement y. The critical buckling load is determined [6] by the first eigenvalue of the system:

$$y'''' + F(x, \omega_1) y = \lambda(-y''), \qquad y(0) = y''(0) = y(l) = y''(l) = 0.$$

Take the base problem to correspond to $\omega_1 = 0$, so that

$$y^{*''''} + F^*(x) y^* = \lambda^*[-y^{*''}], \qquad F^*(x) = F(x, 0). \tag{34}$$

Using (29) we see that

$$\lambda(\omega) = \lambda^* - \int_0^l \lambda^* (y^{*'})^2 - F(x, \omega_1) y^{*2} + (y^{*''})^2 \, dx + O_2.$$

Multiplying (34) by y^* and integrating shows that

$$\lambda(\omega) = \lambda^* - \int_0^l (F(x, \omega_1) - F^*(x)) y^{*2} \, dx + O_2.$$

We can also deal with random boundary conditions. Suppose, for example, that

$$y'(0) + (a + \omega_2) y''(0) = 0, \qquad (b + \omega_3) y'(l) + y''(l) = 0, \qquad y(0) = 0, \quad y(l) = 0.$$

Using (24)-(26) and the approximations $y = y^* + O(\|\omega\|)$, we soon find that

$$BT1 - \lambda^* BT2 + BT3 = (b + \omega_3) y^{*'2}(l) - (a + \omega_2) y^{*''2}(0) + O_2.$$

This approximation can now be used in (29) to obtain an approximation for $\lambda(\omega)$.

A second example, which has been used to study vibrations of a helicopter roter (see [1] and the references listed there) is given by

$$\begin{gathered} y'''' - ((\tfrac{1}{2})\alpha^2(1 - x^2 + \gamma^2) y')' = \lambda y, \qquad 0 < x < 1, \\ y(0) = y'(0) - a y''(0) = y''(1) = 0, \qquad y'''(1) = (\tfrac{1}{2})\gamma^2 \alpha^2 y'(1) - (\tfrac{1}{2})\lambda \gamma^2 y(1). \end{gathered} \tag{35}$$

We suppose that α and γ are fixed but that a is a random variable, $a = a^* + \omega$, with $\omega \in \Omega$. Letting $\omega = 0$ correspond to the base problem, we use (31)-(33) to find that $BT2 = 0$ and that

$$BT1 = (\lambda^* - \lambda)(\tfrac{1}{2})\gamma^2 y^{*2}(1) - \omega y^{*''2}(0) + O_2, \qquad BT3 = -(\tfrac{1}{2})\lambda^* \gamma^2 y^{*2}(1).$$

Substituting this into (29) and solving the resulting equation for λ yields the first order approximation

$$\lambda(\omega) = \frac{\lambda^* - \omega y^{*''2}(0) - J(\omega) + O_2}{1 + \frac{1}{2}\gamma^2 y^{*2}(1)}. \tag{36}$$

Now $J(\omega)$ is actually independent of ω so that $J(\omega)=J(0)$. Letting $\omega=0$ in (26) shows that $J(\omega)=BT3=-\frac{1}{2}\lambda^*\gamma^2y^{*2}(1)$. Substituting into (36) we obtain

$$(37) \qquad \lambda(\omega)=\lambda^*-\omega\frac{y^{*\prime 2}(0)}{1+\frac{1}{2}\gamma^2y^{*2}(1)}+O(\omega^2).$$

It follows from this equation that, at $\omega=0$, $d\lambda(\omega)/d\omega<0$. Therefore, $\lambda(\omega)$ is a decreasing function of ω. Thus, we see that λ^* is a decreasing function of a^*.

With more involved calculations, we could allow the coefficients in (35) to be random also. We will not pursue that idea here.

It is interesting to note that Theorem 1 is not, exactly, a special case of Theorem 2. To see this, let $m=1$, $m'=0$ in Theorem 2, and take

$$L(y)=-(fy')'-qy, \qquad M(y)=gy,$$

$$L^*(y^*)=-(f^*y^{*\prime})-q^*y^*, \qquad M^*(y^*)=g^*y^*.$$

Computing the boundary term given in Theorem 2 we find

$$(38) \qquad BT1-\lambda^*BT2+BT3=f^*y^{*\prime}y-f^*y'y^*-fy^{*\prime}y^*\Big|_{x=0}^{x=l}.$$

However, computing the boundary term BT given in Theorem 1 yields a different result. But taking the difference between the two boundary terms and doing a direct computation shows that the difference $=y^*\Delta f\Delta y'|_0^l$. Since this term is of second order, we see that either boundary term could be used to get a first order approximation to $\lambda(\omega)$. This discrepancy arises from the fact that in the work [3] the O_2 terms were collected after the integration by parts whereas in Theorem 2 the O_2 terms were collected before the integration by parts. It seems difficult, at this point, to decide which method should give a better result. Such questions would have to be dealt with by a more careful analysis of the O_2 terms.

4. Partial differential equations. These methods generalize easily to partial differential equations in a deterministic domain $\mathcal{R}$. Using Green's Theorem in place of integration by parts shows that Theorem 2 can be used when $L(\cdot)$ and $M(\cdot)$ are partial differential operators. Consider the special case of the two-dimensional equation

$$(fu_x)_x+(fu_y)_y+(\lambda g+q)u=0, \quad \text{in } \mathcal{R} \text{ with } u+(a+\omega)u_{\vec{\eta}}=0 \text{ on } \partial\mathcal{R}.$$

Here, f, g, q, and ω are random but a is a deterministic function of s, arc length on $\partial\mathcal{R}$. For now, $\mathcal{R}$ is a deterministic domain. Using (29), we see that

$$\lambda=\lambda^*+\int_{\partial\mathcal{R}}(a+\omega)\left(\frac{\partial u^*}{\partial\vec{\eta}}\right)^2 ds+\iint_{\mathcal{R}}\lambda^*gu^{*2}+qu^{*2}-f(u_x^{*2}+u_y^{*2})\,dA+O_2$$

where

$$\iint_{\mathcal{R}} g^*u^{*2}\,dA=1.$$

If l, the length of the interval in a one-dimensional problem, was a random function of some $\omega\in\Omega$, then a simple change of variable $s=x/l$ would give a new problem on the fixed domain $0\leqq s\leqq 1$ with random coefficients. Theorem 2 would then apply. In the case of partial differential equations, such a change of variables is much more difficult. One can, however, appeal to the Hadamard variational formula to accomplish much the same kind of manipulation.

Following Garabedian [5, Chap. 15], we consider a fixed two-dimensional domain $\mathcal{R}^*$ and let $\mathcal{R}(\omega)$ be the region whose boundary, $\partial\mathcal{R}(\omega)$, is obtained by shifting $\partial\mathcal{R}^*$ an "infinitesimal" distance $\delta\vec{\eta}=\rho(s,\omega)\vec{\eta}$ along its inner normal $\vec{\eta}$, so that $\mathcal{R}(0)=\mathcal{R}^*$. Here, s is arc length on $\partial\mathcal{R}$ and ω is a random variable. We assume that $\partial\rho/\partial\omega$ exists near $\omega=0$.

Let $\lambda_1(\mathcal{R}(\omega))$ denote the first eigenvalue of $\nabla^2u+\lambda u=0$, with $u=0$ on $\partial\mathcal{R}(\omega)$, and let u_1 and u_1^* be the eigenfunctions corresponding to $\mathcal{R}$ and $\mathcal{R}^*$. It follows from the Hadamard variational formula [5, Chap. 15] that

$$\Delta\lambda_1=\lambda_1(\mathcal{R}(\omega))-\lambda_1(\mathcal{R}^*)=\delta\lambda_1+O(\omega^2),\qquad \delta\lambda_1=\int_{\partial\mathcal{R}^*}\rho(s,\omega)\left(\frac{\partial u_1^*}{\partial\vec{\eta}}\right)^2ds.$$

Thus we obtain the first order approximation formula

$$\lambda_1(\mathcal{R}(\omega))=\lambda_1(\mathcal{R}^*)+\int_{\partial\mathcal{R}^*}\rho(s,\omega)\left(\frac{\partial u_1^*}{\partial\vec{\eta}}\right)^2ds+O(\omega^2). \tag{39}$$

As an example of this, consider a triangular domain $\mathcal{R}^*$ bounded by $x=0$, $y=0$, and $x+y=\pi$. Suppose the sides $x=0$, $y=0$ are fixed but that the diagonal side has a random variation ω. Thus $\rho(s,\omega)$ is zero on $x=0$, $y=0$ but $\rho(s,\omega)=\omega$ on $x+y=\pi$, and $\mathcal{R}(\omega)$ is the domain bounded by the lines $x=0$, $y=0$, and $x+y=\pi-\sqrt{2}\omega$. The minus sign is due to the inward directed normal. There is a problem at the corner points since $\partial\mathcal{R}^*$ is not smooth there and ρ is not continuous. However, there do exist analytic approximations to $\partial\mathcal{R}^*$, $\partial\mathcal{R}(\omega)$ and ρ, and the error introduced using them will be $O(\omega^2)$.

Solving for u_1^*, λ_1^*, we find that $u_1^*=2(\sin x\sin 2y+\sin y\sin 2x)$ and that $\lambda_1^*=5$. Now the change of variables $x=\bar{x}(1-\pi\omega/\sqrt{2})$, $y=\bar{y}(1-\pi\omega/\sqrt{2})$ shows that

$$\lambda_1(\mathcal{R}(\omega))=\frac{\lambda_1^*}{(1-\pi\omega/\sqrt{2})^2}. \tag{40}$$

Using u_1^* in (39), we find, after some calculation, that

$$\lambda_1(\mathcal{R}(\omega))=\lambda_1^*+\omega\lambda_1^*2^{3/2}/\pi+O(\omega^2). \tag{41}$$

One can now easily verify that (40) and (41) agree up to second order terms.

EIGENVALUES ON A DOMAIN WITH DISCRETE ROTATIONAL SYMMETRY*

BONITA HART DRISCOLL†

Abstract. The spectrum of the Laplace operator on a bounded domain or manifold consists of only isolated eigenvalues of finite multiplicity. In problems with a high degree of symmetry it is necessary that these multiplicities are large. The generic structure of the eigenspaces of the Laplace operator with no symmetry constraints is that the eigenvalues are simple.

We consider the structure of the eigenfunctions of the Laplace operator in a planar domain under deformations that preserve symmetry under a discrete rotation. There are two types of eigenfunctions: symmetric and asymmetric.

The main theorem shows that generically, symmetric eigenfunctions are simple and asymmetric eigenfunctions are of multiplicity two. This is a partial proof of the conjecture of V. I. Arnol'd concerning the codimension of large multiplicity eigenspaces in the space of domains preserving symmetry.

Key words. symmetric eigenfunctions, asymmetric eigenfunctions, generic

Introduction. The spectrum of the Laplace operator on a bounded domain or manifold consists of only isolated eigenvalues of finite multiplicity. If the domain has symmetry, for example, and is invariant under the action of a cyclic group, the fact that the Laplace operator commutes with the group action forces multiplicities in the eigenvalues. The minimal polynomial for the group generator splits the space into subspaces. The subspaces determine different types of eigenfunctions and determine the multiplicities of the eigenvalues.

Let D be the unit disk in R^2 and $\Delta=(\partial/\partial x)^2+(\partial/\partial y)^2$; then what follows is the main result of this paper.

MAIN THEOREM. *Let $\Delta U+\lambda\rho U=0$ with $U=0$ on the boundary and ρ invariant under the Z_p action $\alpha z=e^{2\pi i/p}z$; then the set of $\rho\in C^k$, $k>2$ such that the following*:

(a) *Symmetric eigenspaces (those corresponding to rotation invariant eigenfunctions) are one-dimensional*;

(b) *Asymmetric eigenspaces (those corresponding to irreducible quadratic factors of the minimal polynomial for the group) are two-dimensional*;

(c) *No symmetric eigenvalue equals an asymmetric eigenvalue*;

is residual in C^k, i.e., is a countable intersection of open dense sets in a Banach space.

As a corollary we obtain: For a residual set of surfaces of the conformal type of the disk having Z_3 symmetry, the eigenspaces algebraically have minimal dimension. Note that by "residual" we mean that the measure in the conformal factor ρ is residual.

The main theorem is actually Theorem 2.8, which establishes for $p=2$, 3, 4 that the eigenspaces generically have the lowest possible dimension. We have not included the details of the case for p even corresponding to $f(\alpha z)=-f(z)$, since it is virtually identical to the symmetric case, $f(\alpha z)=f(z)$. For $p\geqq 5$ we have only partial results. In addition to the results in the main theorem, we need to show that eigenspaces corresponding to different conjugate pairs of complex roots generically have different eigenvalues. This poses interesting algebraic questions. The computations reduce to algebraic identities between eigenfunctions. For $p<5$, these identities cannot be

† Department of Mathematical Sciences, Loyola University of Chicago, Chicago, Illinois 60626.

satisfied by orthogonal eigenfunctions, hence assuming that they are leads to a contradiction. However, for $p \geqq 5$, it is possible that there are some rational relations between eigenfunctions, i.e., these identities may be satisfied in some cases. Results in Eskin, Ralston and Trubowitz [9] suggest that problems will arise for certain algebraic manifolds.

The results in this paper originate in a conjecture by Arnol'd [6]. He has conjectured that the map from membranes into bilinear forms is transverse to the various strata of the varieties of bilinear forms with multiple eigenvalues.

From this hypothesis, the results of this paper would follow. One would also be able to determine the codimension of the degeneracies, i.e., the codimension of the submanifolds in the space of membranes which correspond to higher than necessary eigenvalue multiplicities. K. Uhlenbeck has used transversality in the problem on a domain without symmetry [20], [21]. Clearly her technique could be used in the problem with symmetry on the space of symmetric eigenfunctions, but there are inherent difficulties on the space of asymmetric eigenfunctions. We use a perturbation argument similar to that used by Albert [2], [3]. The results are easily extended to a larger class of elliptic operators on an n-dimensional manifold: in particular to the Schrödinger operator. We have chosen to restrict the argument to R^2 since this case seems to contain the basic phenomena. In particular the extension to noncommutative or continuous groups appears to present serious problems.

1. Preliminary results. In what follows Ω will be a bounded simply connected nonempty set in the plane, bounded by a curve of class $C^{k+\beta}$, $k \geqq 3$, and invariant under rotation by $\alpha = 2\pi/p$ where p is an integer. Recall that $C^{k+\beta}$ functions are continuous with continuous derivatives and kth derivative that is Lipschitz with Lipschitz constant β, $0 < \beta < 1$. $D = \{x \mid x \in R^2, \|x\| \leqq 1\}$. The Sobolev space of functions on the unit disk with distributional derivatives through order k that are p integrable is denoted $H_k^p(D)$ and, for $p = 2$, $H_k(D)$. $H_{k,0}^p(D) \subset H_k^p(D)$ is the closure of smooth functions with compact support in the interior of D. We will use generic to mean residual, i.e., a countable intersection of open dense sets.

The first topic we consider is reducing the eigenvalue problem for the Laplace operator on a domain of the kind considered to one on a simpler set, namely, the unit disk, D. To do this we use an equivariant form of the Riemann mapping theorem. Consider a domain $\Omega \subset R^2$ to be a subset of the complex plane by $x = (x, y) \to (x + iy) = z$.

LEMMA 1.1. *For a domain Ω as described, Ω invariant under rotation by α, $0 < \alpha \leqq 2\pi$ and $p\alpha = 2\pi$ for p an integer, there is a conformal map $g: D \to \Omega$ such that $g \in C^{k+\beta}(D)$ and g commutes with rotation by α.*

Proof. Pick a point w_0 on the boundary of Ω and z_0 on the boundary of the unit disk. Choose the unique conformal map g^{-1} which takes Ω to D with

$$g^{-1}(e^{k\alpha i} w_0) = e^{k\alpha i} z_0, \qquad k = 0, 1, 2.$$

Let $h(z) = e^{\alpha i} z$ and $h^{-1}(w) = e^{-\alpha i} w$; then

$$h^{-1} \circ g \circ h(e^{k\alpha i} z_0) = e^{k\alpha i} w_0, \qquad k = 0, 1, 2.$$

Therefore, by uniqueness, since $h^{-1} \circ g \circ h$ maps $D \to \Omega$ and fixes the same points as g, $h^{-1} \circ g \circ h = g$ hence $g(e^{\alpha i} z) = e^{\alpha i} g(z)$.

In the coordinates of the disk used as conformal coordinates for Ω, we have

$$\Delta_\Omega = \rho^{-1} \left[\left(\frac{\partial}{\partial x} \right)^2 + \left(\frac{\partial}{\partial y} \right)^2 \right]$$

where $\rho=|g'(z)|^2$. Because g commutes with the rotation α,

$$\rho(e^{\alpha i}z)=|g'(e^{\alpha i}z)\,e^{\alpha i}|^2=|g'(z)|^2.$$

THEOREM 1.2. *The problem $\Delta_\Omega U+\lambda U=0$, for Ω invariant under rotation by $\alpha=2\pi/p$, is equivalent to $\Delta_D U+\lambda\rho U=0$ for $\rho=|g'(z)|^2$ and ρ invariant under rotation by α.*

Rather than consider only ρ's that arise from the conformal maps described, we consider all $\rho\in C^k(D)$, $k>2$, $\rho(x)\neq 0$ for all x, and ρ invariant under rotation by α. The problem we consider is the problem of the Laplace-Beltrami operator on C^k surfaces of the conformal type of the disk.

THEOREM 1.3. *Let $\rho: D\to R^+$, and a metric on D be given by $g_{ij}=\rho\delta_{ij}$. This puts the set of $\rho>0$, $\rho\in C^k(D)$, $k>2$ in one-to-one correspondence with the diffeomorphism classes of C^k surfaces of the conformal type of the disk. The Laplace-Beltrami operator in this parameterization appears as $\rho^{-1}\Delta$.*

Proof. See [13, pp. 366-367] and [10, pp. 88-101].

The rotational symmetry of the domain Ω under α induces well-known properties on the Hilbert space $H_{1,0}=H$ and the eigenvalues of $\rho^{-1}\Delta$. Let O be the rotation matrix

$$O=\begin{bmatrix}\cos\alpha & -\sin\alpha\\ \sin\alpha & \cos\alpha\end{bmatrix},\qquad \alpha=2\pi/p.$$

For $f\in H$, define $O^*(f(x))=f(O(x))$. Note that $O^{*p}=I$ so we have an irreducible representation of the Z_p action on H,

$$Z_p=\{I, O^*, O^{*2}\cdots O^{*p-1}\}.$$

Clearly O^* is orthogonal on $H_{1,0}(D)$ and $H_0(D)$. The minimal polynomial for O^* is t^p-1 which has as possible factors $t-1$, $t+1$ and $t^2+c(k)t+1$. Let

$$\begin{aligned}&H_1=\{f\colon (O^*-1)f=0\},\\ &H_{-1}=\{f\colon (O^*+1)f=0\},\\ &H_{c(k)}=\{f\colon ((O^*)^2+c(k)O^*+1)f=0,\ k\in\mathcal{I}\}\end{aligned}$$

where $\mathcal{I}=\{k\colon k=1,\cdots,l,\ l=(p-1)/2$ when p is odd or $l=(p-2)/2$ when p is even$\}$. We call elements of H_1 symmetric functions and elements of $H_{c(k)}$ asymmetric functions.

The following are well-known facts commonly used in mathematics and physics.

PROPOSITION 1.4. *The equation $\Delta U+\lambda\rho U=0$ has countably many real eigenvalues that are bounded from below by 0 and have no finite accumulation point. The eigenvectors for $\rho^{-1}\Delta$ form a complete ρ-orthonormal basis for H, and the eigenspaces are all finite dimensional.*

The Hilbert space H is split into invariant subspaces by the irreducible actions of Z_p, namely

$$H=H_1\oplus H_{-1}\oplus\sum_{c(k)\in\mathcal{I}}H_{c(k)}.$$

Since O^* and $\rho^{-1}\Delta$ commute, it follows that there is a ρ-orthonormal basis of eigenvectors for $\rho^{-1}\Delta$ that splits into a basis for H_1, H_{-1} and $H_{c(k)}$.

We will proceed with some technical lemmas. The main result is the reduction of the perturbation problem to a computation on the finite dimensional eigenspace. The technique used relies heavily on Rellich's lemma which says that $H_{1,0}(D)$ is relatively compact in $H_0(D)$ [11, p. 31]. In what follows we use $\int_D f$ to mean $\int_D\int f(x)\,dx$ with respect to Lebesgue measure in R^2. We include the first lemma, although it is well known, because the method of proof is typical of the technique used.

LEMMA 1.5. (Upper semi-continuity of the dimension of the eigenspaces). *Let $\rho(t_i, x) = \rho_i$ for $t_i \in [0, 1]$ where ρ_i converges to $\rho = \rho(0, x)$ in C^0. Let $E_i = \{U \mid U \in H_{1,0}, \Delta U + \lambda_i \rho_i U = 0, \lambda_i$ is the mth eigenvalue$\}$, where m is fixed and $E = \{U \mid U \in H_{1,0}, \Delta U + \lambda \rho U = 0$ and λ is the mth eigenvalue$\}$. If E_i is l-dimensional for all i and $\{\lambda_i\}$ is bounded, then dimension $(E) \geqq l$.*

This is a well-known result. However we need a construction which occurs in the proof. We will construct a sequence of eigenspaces E_{ik}, which converges to a subspace of the eigenspace E in the sense that the orthonormal basis we chose for $E_{i,k}$ converges to a subbasis of E in $H = H_{1,0}(D)$.

Proof. For U in eigenfunction, by Green's formula we have:

$$\|U\|_{H_1}^2 = \int_D (U_x^2 + U_y^2 + U^2) = \int_D [(-\Delta U)U + U^2] = \int (\rho\lambda U^2 + U^2).$$

Hence,

$$\|U_i\|_{H_1}^2 = \int_D (\rho_i\lambda_i + 1) U_i^2.$$

Since $\rho_i \to \rho$ in C^0 and $\{\lambda_i\}$ is bounded, there is a constant K such that

$$\|\rho_i\lambda_i\|_\infty \leqq K.$$

Therefore

$$\|U_i\|_{H_1}^2 \leqq \int_D (K+1)U_i^2 = (K+1)\|U_i\|_{H_0}^2.$$

In addition we have,

$$\Delta U_i + \lambda_i\rho_i U_i = 0 \Rightarrow \Delta U_i = -\lambda_i\rho_i U_i.$$

So by regularity theory [11, p. 68],

$$\|U_i\|_{H_2}^2 \leqq C(\|\lambda_i\rho_i U_i\|_{H_0}^2 + \|U_i\|_{H_1}^2)$$
$$\leqq K'\|U_i\|_{H_0}^2, \qquad K' = C(2K+1).$$

Since $\{\lambda_i\}$ is a bounded sequence in R, there is a convergent subsequence. Call it $\{\lambda_i\}$, and let $\{E_i\}$ be the corresponding sequence of eigenspaces. Choose a ρ_i-orthonormal basis $\{U_{ik}\}$, $1 \leqq k \leqq l$ for E_i. Consider the sequence $\{U_{i1}\}$.

$$\|U_{i1}\|_{H_2}^2 \leqq K'\|U_{i1}\|_{H_0}^2 = K'$$

from the estimate above. By Rellich's lemma, there is a convergent subsequence, call it $\{U_{i1}\}$, such that $\{U_{i1}\} \to U_1$ in $H = H_{1,0}$. Let $\{E_{i1}\}$ be the subsequence of $\{E_i\}$ associated with the subsequence $\{U_{i1}\}$; i.e., U_{i1} is the first basis vector of E_{i1}.

We proceed by induction. Let $r \leqq l$ and assume we have sequence $\{U_{ik}\} \to U_k$ in H, $1 \leqq k \leqq r-1$ and a sequence of eigenspaces $\{E_{ir-1}\}$ where

$$\{U_{ik} \mid 1 \leqq k \leqq r-1\} \subset E_{ir-1} \quad \text{for all } i.$$

Consider the sequence $\{U_{ir}\}$ where $U_{ir} \in E_{ir-1}$. Since each E_{ir-1} is l-dimensional and $r \leqq l$, this sequence is nonempty.

From the earlier estimate,

$$\|U_{ir}\|_{H_2}^2 \leqq K'\|U_{ir}\|_{H_0}^2 = K'.$$

So by Rellich's Lemma, there is a convergent subsequence $U_{ir} \to U_r$ in H. Let $\{E_{ir}\}$ be the subsequence of $\{E_{ir-1}\}$ associated with the subsequence U_{ir}, i.e., $U_{ir} \in E_{ir}$. Choose subsequences of $\{U_{ik}\}$, $1 \leqq k \leqq r-1$ by requiring that elements of $\{U_{ik}\}$ $1 \leqq k \leqq r-1$ be elements of E_{ir}. Call the subsequences $\{U_{ik}\}$ $1 \leqq k \leqq r-1$. We now have that $\{U_{ik}\} \to U_k$ $1 \leqq k \leqq r$ and $U_{ik} \in E_{i,r}$ to complete the induction.

We must show that $\{U_k \mid 1 \leqq k \leqq l\} \subset E$, and is orthogonal in E.

(i) Show $\Delta U_k + \lambda \rho U_k = 0$, i.e., $U_k \in E$. Recall that $\{U_{ik}\} \to U_k$ in H and $\rho_i \to \rho$ uniformly in x, where $\rho \in C^k(D)$, $k \geqq 2$ and $\lambda_i \to \lambda$. By a regularity theorem, a weak solution in H is a classical solution [11, p. 67].

$$\Delta U_{ik} + \lambda_i \rho_i U_{ik} = 0,$$

so

$$\int_D (\Delta U_{ik} + \lambda_i \rho_i U_{ik}) \phi = 0$$

and

$$\int_D \Delta U_{ik} \phi = -\int_D \lambda_i \rho_i U_{ik} \phi \quad \text{for all } \phi \in C_0^\infty(D).$$

Clearly

$$\int_D \lambda_i \rho_i U_{ik} \phi \to \int_D \lambda \rho U_k \phi$$

and

$$\int_D U_{ik} \Delta \phi \to \int_D U_k \Delta \phi;$$

then

$$\int_D (\Delta \phi + \lambda \rho \phi) U_k = 0 \quad \text{for all } \phi \in C^\infty(D)$$

and U_k is a weak solution and hence a classical solution of $\Delta U_k + \lambda \rho U_k = 0$; i.e., $U_k \in E$.

(ii) Show $(U_k \mid U_j)_\rho = 0$ for $k \neq j$.

$$U_{ik} \to U_k, \qquad U_{ij} \to U_j,$$
$$(U_{ik} \mid U_{ij})_{\rho_i} = 0 \quad \text{for all } i \text{ and } k \neq j.$$

Therefore if $k \neq j$,

$$\lim_{i \to \infty} (U_{ik} \mid U_{ij})_{\rho_i} = (U_k \mid U_j)_\rho = 0.$$

By the same reasoning

$$\lim_{i \to \infty} (U_{ik} \mid U_{ik})_{\rho_i} = (U_k \mid U_k)_\rho = 1.$$

Hence $\dim E \geqq l$ since E contains l orthogonal vectors.

THEOREM 1.6. *Let* $\rho_i = \rho(t_i, x)$, $\lambda_i = \lambda(t_i)$ *where* $\lim_{t_i \to 0} \rho_i = \rho(0, x)$. *Let* $\partial \rho / \partial t(0, x) \in C^0(D)$ *and* E_i (*the mth eigenspace*) *be l-dimensional for all i and l fixed. Then* $\dim E \geqq l$ *and equality implies that there exists a number* $d\lambda/dt$ *such that for all* $U, V \in E_{\lambda\rho}$

$$\lambda \int_D \frac{\partial \rho}{\partial t}(0, x) UV = -\frac{d\lambda}{dt} \int_D \rho VU.$$

Proof. Let $U_1, \cdots, U_l$ be the orthonormal basis for $E_{\lambda,\rho}$ constructed in Lemma 1.5. There are sequences $\{U_{ik}\} \to^H U_k$, $k=1, \cdots, l$ where $U_{ik} \in E_i$ and $H = H_{1,0}(D)$. Let $V_i = \sum_{k=1}^l a_k U_{ik}$. Then $V_i \in E_i$ and $V_i \to_H \sum_{k=1}^l a_k U_k = V \in E$;

$$\Delta U + \lambda \rho U = 0$$

so

$$\Delta U + \lambda_i \rho_i U + \lambda_i(\rho - \rho_i)U + \rho(\lambda - \lambda_i)U = 0.$$

The image is ρ_i orthogonal to the eigenspace E_i so $(\Delta U + \lambda_i \rho_i U \mid U_i) = 0$;

$$(\Delta U + \lambda_i \rho_i U + \lambda_i(\rho - \rho_i)U + \rho(\lambda - \lambda_i)U \mid U_i) = 0$$

so

$$\lambda_i\left(\left(\frac{\rho - \rho_i}{t_i}\right)U \mid U_i\right) + \left(\frac{\lambda - \lambda_i}{t_i}\right)(\rho U \mid U_i) = 0.$$

For $V_i \in E_i$,

$$V_i = \sum_{k=1}^{l} a_k U_{ik},$$

$$\lambda_i\left(\left(\frac{\rho - \rho_i}{t_i}\right)U \mid V_i\right) + \left(\frac{\lambda - \lambda_i}{t_i}\right)(\rho U \mid V_i) = 0. \tag{1.6}$$

Look at

$$\lim_{i\to\infty} \lambda_i\left(\left(\frac{\rho - \rho_i}{t_i}\right)U \mid V_i\right) = \lim_{i=\infty} \sum_{k=1}^{l} a_k \lambda_i\left(\left(\frac{\rho - \rho_i}{t_i}\right)U \mid U_{ik}\right).$$

Since $\lambda_i \to \lambda$, $(\rho - \rho_i)/t_i \to d\rho/dt(0)$ uniformly in x, and $U_{ik} \to^H U_k$;

$$\lim_{i\to\infty} \sum_{k=1}^{l} a_k \lambda_i\left(\left(\frac{\rho - \rho_i}{t_i}\right)U \mid U_{ik}\right) = \sum_{k=1}^{l} a_k \lambda\left(\frac{\partial \rho}{\partial t}(0)U \mid U_k\right)$$

$$= \lambda\left(\frac{\partial \rho}{\partial t}(0)U \mid V\right).$$

Also

$$\lim_{i\to\infty} (\rho U \mid V_i) = (\rho U \mid V)$$

since $V_i \to^H V$.

From (1.6), with $U = V \neq 0$, $\lim_{i\to\infty} (\lambda - \lambda_i)/t_i$ exists, since

$$\lim_{i\to\infty} \frac{\lambda - \lambda_i}{t_i} = \frac{-\lambda(\partial\rho/\partial t(0)U \mid U)}{(U \mid U)_\rho} = \frac{d\lambda}{dt}.$$

We have

$$\lambda\left(\frac{\partial \rho}{\partial t}(0)U \mid V\right) = -\frac{d\lambda}{dt}(\rho U \mid V)$$

for all $U, V \in E$.

COROLLARY 1.7. *Let $\rho(t,\ ) \in C^k(D)$, $k \geqq 2$ and assume $\partial\rho/\partial t(t,\ ) \in C^k(D)$. Let $q = \partial\rho/\partial t(0,\ ) \in C^k(D)$. If there exists a U, $V \in E$ and an eigenspace for $\Delta U + \lambda \rho U = 0$ of dimension l, such that $(U \mid V)_\rho = 0$ and $(U \mid V)_q \neq 0$, then there exists an $\varepsilon > 0$ such that* dim $E_t < l$ *for $0 < t < \varepsilon$, where E_t is the eigenspace corresponding to $\Delta U + \lambda \rho(t,\ )U = 0$, $\lambda_i \to \lambda$.*

Proof. Suppose not. Apply the theorem to $E_{t_i} = E_i$ for $t_i \to 0$ and E_i of dimension l. Then $\lambda(U|V)_q = -d\lambda/dt(U|V)_\rho = 0$, which is a contradiction.

2. Main theorem. In this section we prove the main theorem. The technique used is similar to that of Albert [2], [3]. We define sequences of nested sets. Let

$$P = \{\rho \in C^k(D) \mid O^*\rho = \rho \text{ and } \rho > 0\},$$

$$S_n = \{\rho \in P \mid \text{the first } n \text{ symmetric eigenvalues of } \rho^{-1}\Delta \text{ are of multiplicity } 1\},$$

$$A_n(k) = \{\rho \in P \mid \text{the first } 2n \text{ asymmetric eigenvalues corresponding to eigenfunctions which satisfy } O^{*2} + C(k)O^* + 1 = 0 \text{ have multiplicity } 2\},$$

$$T_n = \{\rho = P \mid \rho \in S_n \cap A_n(k) \text{ and none of the first } n \text{ symmetric eigenvalues is equal to any of the first } 2n \text{ asymmetric eigenvalues}\},$$

$$S_0 = A_0(k) = T_0 = P.$$

Then

$$S_0 \supset S_1 \supset S_2 \supset \cdots, \qquad S = \bigcap_{n=1}^{\infty} S_n,$$

$$A_0(k) \supset A_1(k) \supset A_2(k) \supset \cdots, \qquad A(k) = \bigcap_{n=1}^{\infty} A_n(k),$$

$$T_0 \supset T_1 \supset T_2 \supset \cdots, \qquad T = \bigcap_{n=1}^{\infty} T_n.$$

We show that S_n is open in P and $A_n(k)$ is open in P, and T_n is open in P. The proof of openness is an easy consequence of Lemma 1.5. The proof of density is more complicated and constitutes the rest of the section. We apply the criterion we have developed in Corollary 1.7 to show that S_n is dense in S_{n-1}, $A_n(k)$ is dense in $A_{n-1}(k)$ and T_n is dense in T_{n-1}. The proof consists in showing that the multiplicity of the eigenspaces can be reduced by at least one (two in the asymmetric case), and of using a series of perturbations as required. The proof for eigenvalues corresponding to eigenfunctions satisfying $O^*f = -f$ is identical to the symmetric case, so for simplicity it is not included.

We will first prove openness. In what follows, we define simple eigenvalue to mean: for symmetric eigenvalues the multiplicity is 1 and for asymmetric eigenvalues the multiplicity is 2.

THEOREM 2.1. *S_n, $A_n(k)$ and T_n are open in P in the C^k topology.*

Proof. We shall first consider T_n.

For $\rho \in T_n$, we must show that there is an ε-neighborhood of ρ such that for all q with $\|\rho - q\|_k < \varepsilon$, the first n eigenspaces of q are simple. We proceed by contradiction.

Assume that for every $t > 0$ there is a q_t such that $\|\rho - q_t\|_k < t$ and the dimension of at least one of the first n eigenspaces of q_t is not simple. Since n is finite, we may assume that the mth eigenspace is not simple for each t. Let λ be the mth eigenvalue for ρ and λ_t the mth eigenvalue for q_t. There is a sequence of $q_t \to \rho$, with dimension of the mth eigenspace $\geqq 2$ if λ is a symmetric eigenvalue or $\geqq 3$ if λ is a asymmetric eigenvalue. Since $q_t \to \rho$ and D is compact, it is easily shown that $\{\lambda_t\}$ is bounded. Hence by the proof of Lemma 1.5, we have that the dimension of the mth eigenspace of ρ is not simple, which is a contradiction. Restriction to H_1 and H_{c_k} gives the lemma for S_n and $A_n(k)$.

We will now prove the perturbation lemmas, which easily imply density.

LEMMA 2.2. *Let E_0, the nth eigenspace for ρ_0, be l-dimensional where $l>1$ and $E_0 \subset H_1$. Then there is a ρ, C^k close to ρ_0, such that the nth eigenspace of ρ has dimension $<l$.*

Proof. The proof is by contradiction. If false by Theorem 1.6 and Corollary 1.7,

$$\lambda \int_D \frac{\partial \rho}{\partial t}(0,\ )UV + \frac{d\lambda}{dt}\int_D \rho UV = 0$$

for all U, $V \in E$ and all $\rho \in P$. Then for U, V such that $(U \mid V)_\rho = 0$ we have $\int_D \rho UV = 0$ and so

$$\lambda \int_D \frac{\partial \rho}{\partial t}(0,\ )UV = 0, \qquad \lambda \neq 0.$$

Choose $\rho(t,\ ) = \rho_0 + t\cdot S$ where $S \in P$. Then $\partial\rho/\partial t(0,\ ) = S$, and S is invariant under O^*. Since U and V are symmetric eigenfunctions, U and V are invariant, under O^*, so by change of variable,

$$\int_D S\cdot U\cdot V = p\int_{D/p} SUV = 0.$$

But S is arbitrary on D/p, so by the Fundamental Lemma of the Calculus of Variations, $UV=0$. Notice that $L(U) = \Delta U + \lambda\rho_0 U$ has the weak continuation property [12]. This means that if U is a solution of $L(U)=0$ and U vanishes on an open set, U is identically zero. Since U and V are C^2 and $UV=0$, either U or V must vanish on an open set which, as we just showed, implies U or V is identically zero. This is a contradiction.

LEMMA 2.3. *Let E_0, the nth eigenspace for ρ_0, be 2l-dimensional where $l>1$ and $E_0 \subset H_{c(k)}$. Then there is a ρ, C^k close to ρ_0, such that the nth eigenspace of ρ has dimension $<2l$.*

Proof. The proof is by contradiction. As in Lemma 2.2, if the theorem is false, then for $(u \mid v)_\rho = 0$ and $\rho(t,\ ) = \rho_0 + tS$, $S \in P$, we have $\lambda \int_D Suv = 0$, $\lambda \neq 0$.

By change of variable, recalling S is invariant under O^*, we have

$$\int_D Suv = \sum_{i=0}^{p-1}\int_{D/p} SO^{*i}(uv) = 0.$$

But S is arbitrary on D/p, so

$$\sum_{i=0}^{p-1} O^{*i}(uv) = 0. \tag{2.3}$$

Let E_u = space spanned by $\{u, O^*u\}$ where $u \in E \subset H_{c(k)}$. Notice that E_u is two-dimensional over the reals since $O^*u \neq ku$ for all $k \in R$. For $u \in E$, choose $v \in E$ so that $(u \mid v)_\rho = 0$ and $(O^*u \mid v)_\rho = 0$. This is possible since $\dim E \geqq 4$. We notice that $(u \mid O^*v)_\rho = 0$. This is true since $(O^*)^T = (O^*)^{-1}$, $(U + O^*u \mid v)_\rho = 0$, and $-O^{*-1}u = O^*u + u$. Therefore $-(O^{*-1}u \mid v)_\rho = 0 = (u \mid O^*v)$. We will show $uv=0$ for u, v as above by looking at the problem in the complex plane. Let $(x,y) \to z \in C$ by $(x,y) \to (x+iy)$, and let $v \notin E_u$ as above.

$$u, v \in H_{c(k)} \Rightarrow [(O^*)^2 + c(k)O^* + 1]u = 0 \quad \text{and}$$

$$[(O^*)^2 + c(k)O^* + 1]v = 0.$$

Then

$$(O^*-\lambda)(O^*-\bar{\lambda})u=0, \quad \lambda=e^{2\pi ki/p}, \quad k\neq p \text{ and } k\neq p/2 \text{ if } p \text{ is even}$$

and

$$(O^*-\lambda)(O^*-\bar{\lambda})v=0.$$

Define $U(z)=O^*u(z)-\bar{\lambda}u(z)$, and $V(z)=O^*v(z)-\bar{\lambda}v(z)$. Then $(O^*-\lambda)V(z)=(O^*-\lambda)(O^*-\bar{\lambda})v(z)=0$, so $(O^*-\lambda)V(z)=0$ or $O^*V(z)=\lambda V(z)$. Also, $O^*U(z)=\lambda U(z)$, so $O^*(U\bar{V})=\lambda\bar{\lambda}U\bar{V}=U\bar{V}$, and hence

$$(O^*)^k(U\bar{V})=O^*(U\bar{V})=U\bar{V}, \qquad k=1,\cdots,p.$$

Therefore

$$\begin{aligned} U\bar{V}=\frac{1}{p}\sum_{k=0}^{p-1}(O^*)^k(U\bar{V})&=\frac{1}{p}\sum_{k=0}^{p-1}[O^{*^{k+1}}u(z)-\bar{\lambda}O^{*^k}u(z)][(O^*)^{k+1}v(z)-\lambda O^{*^k}v(z)]\\ &=\frac{1}{p}\sum_{k=0}^{p-1}[O^{*^{k+1}}u(z)O^{*^{k+1}}v(z)+O^{*^k}u(z)O^{*^k}v(z)\\ &\qquad -\bar{\lambda}O^{*^k}u(z)O^{*^{k+1}}v(z)-\lambda O^{*^k}v(z)O^{*^{k+1}}u(z)]. \end{aligned}$$

By (2.3)

$$\sum_{k=0}^{p-1}O^{*^k}(uv)=0.$$

Since O^* is linear,

$$O^*\sum_{k=0}^{p-1}O^{*^k}(uv)=\sum_{k=0}^{p-1}O^{*^{k+1}}(uv)=0$$

if $(u|v)_\rho=0$. Recall that $(u|O^*v)_\rho=0$ and $(O^*u|v)_\rho=0$. Therefore

$$\sum_{k=0}^{p-1}O^{*^{k+1}}u(z)O^{*^{k+1}}v(z)=\sum_{k=0}^{p-1}O^{*^{k+1}}[u(z)v(z)]=0,$$

$$\sum_{k=0}^{p-1}O^{*^k}u(z)O^{*^k}v(z)=\sum_{k=0}^{p-1}O^{*^k}(u(z)v(z))=0$$

and

$$\sum_{k=0}^{p-1}O^{*^k}u(z)O^{*^{k+1}}v(z)=\sum_{k=0}^{p-1}O^{*^k}(u(z)O^*v(z))=0,$$

by (2.3) with O^*v replacing v. Similarly,

$$\sum_{k=0}^{p-1}O^{*^k}v(z)O^{*^{k+1}}u(z)=0.$$

Therefore $U\bar{V}=0$ so either U or $\bar{V}$ is zero on an open set. Hence Im $U=\sin(2\pi k/p)u$ and Im $V=\sin(2\pi k/p)v$ are zero on an open set, so by the weak continuation property u and v are identically zero.

LEMMA 2.4. *Let E_0, the nth eigenspace for ρ_0, be l-dimensional $l\geqq 3$, where $E_0\cap H_{c(k)}\neq\emptyset$ and $E_0\cap H_1\neq\emptyset$. Then there is a ρ, arbitrarily C^k close to ρ_0, such that the nth eigenspace of ρ has dimension less than l.*

Proof. As in Lemmas 2.2 and 2.3, we will use proof by contradiction. We will assume the theorem is false for $U \in E_0 \cap H_{c(k)}$ and $V \in E_0 \cap H_1$. Let $(U|U)_\rho = 1$ and $(V|V)_\rho = 1$. Notice that $H_1 \perp H_{c(k)}$, for all ρ, so we will consider $U+V$, $U-V$.

$$(U+V|U-V)_\rho = (U|U)_\rho - (V|V)_\rho = 0.$$

As before, assume the lemma is false, and by Theorem 1.6 and Corollary 1.7, we have for all ρ and for $(U+V|U-V)_\rho = 0$ where $U \in H_{c(k)}$ and $V \in H_1$,

$$\int_D \frac{\partial \rho}{\partial t}(0, \ )(U^2 - V^2) = 0.$$

For $\rho(t, \ ) = \rho + ts$, $s \in P$. Since $O^*s = s$ and $O^*V = V$, by change of variable,

$$0 = \int_D s(U^2 - V^2) = \int_{D/p} s \sum_{k=0}^{p-1} O^{*k}(U^2 - V^2).$$

So since s is arbitrary,

$$\sum_{k=0}^{p-1} O^{*k}U^2 - pV^2 = 0.$$

Therefore,

$$V^2 = \frac{1}{p} \sum_{k=0}^{p-1} O^{*k}U^2.$$

Since V is an eigenfunction for $\rho^{-1}\Delta$, there is a connected component G of the set in D on which V is positive bounded by nodal curves of V [8, p. 451]. Consider $\Delta V + \lambda \rho V = 0$ on G, $V = 0$ on ∂G. V is an eigenfunction for this domain G, and since $V > 0$ on G, λ must be the first eigenvalue [8, p. 451]. The first eigenvalue is simple. Notice that $V = 0$ on the boundary of G, gives $V^2 = 0$, so

$$0 = \frac{1}{p} \sum_{k=0}^{p-1} O^{*k}U^2 \quad \text{on } \partial G.$$

Each summand is positive, so $U^2 = 0$ on ∂G which says $U = 0$ on ∂G. Therefore U is an eigenfunction for $\Delta V + \lambda \rho V = 0$ on G and since λ is simple this says $U = V$ which is a contradiction since $(U|V)_\rho = 0$.

We shall now prove that S_n is dense in S_{n-1}, $A_n(k)$ is dense in $A_{n-1}(k)$ and T_n is dense in T_{n-1}. We have shown in Lemmas 2.2-2.4 that if the multiplicities are not minimal we can reduce the multiplicity of the eigenspaces at least one in the symmetric case, at least two in the asymmetric case and at least one if asymmetric and symmetric coincide. We shall show the density, by using a sequence of perturbations to lower the multiplicity of the nth eigenspace one step at a time. By the openness one can make small enough perturbations so none of the multiplicities of any other eigenspace is increased.

THEOREM 2.5. *S_n is dense in S_{n-1} in the C^k topology.*

Proof. Let $\rho \in S_{n-1}$ and let E_0, the nth eigenspace of ρ, have dimension $l > 1$. Since S_{n-1} is open in P in the C_k topology (Theorem 2.1), There is a δ so that if $\|\rho - q\|_k < \delta$ then $q \in S_{n-1}$. By Lemma 2.2, there is an ε_1, $\varepsilon_1 < \delta$ and a ρ_1 with $\|\rho - \rho_1\|_k < \varepsilon_1/l$, where the nth eigenspace E_1 of ρ_1 has dimension less than or equal to $l-1$. Notice that $\rho_1 \in S_{n-1}$ by construction. We proceed by induction. In what follows $l > 2$. For $r \leqq l$ assume that we have ρ_{r-1} with $\|\rho_{r-2} - \rho_{r-1}\|_k < \varepsilon_{r-1}/l$ where $\rho_{r-1} \in S_{n-1}$ and the dimension of the nth eigenspace E_{r-1} of ρ_{r-1} is less than or equal to $l-(r-1)$.

By Lemma 2.2, there is an ε_r, $\varepsilon_r < \delta$ and a ρ_r so that $\|\rho_{r-1} - \rho_r\|_k < \varepsilon_r / l$ and the dimension of the nth eigenspace E_r of ρ_r is less than or equal to $[l-(r-1)]-1 = l-r$.

We must show $\|\rho - \rho_r\|_k < \delta$. Let $\rho = \rho_0$ and look at

$$\|\rho - \rho_r\|_k = \left\| \sum_{j=0}^{r-1} (\rho_j - \rho_{j+1}) \right\|_k \leqq \sum_{j=0}^{r-1} \|\rho_j - \rho_{j+1}\|_k,$$

$$\|\rho - \rho_r\|_k \leqq \sum_{j=0}^{r-1} \frac{1}{l} \varepsilon_{j+1} \leqq \sum_{j=0}^{r-1} \frac{1}{l} \delta \leqq \delta,$$

since $r \leqq l$.

Therefore $\rho_r \in S_{n-1}$ and the dimension of E_r is less than $l-r$. Clearly this process will terminate only if $\dim(E_j) = 1$ and that must happen before $j = l$.

THEOREM 2.6. *$A_n(k)$ is dense in $A_{n-1}(k)$ in the C^k topology.*

Proof. Use Lemma 2.3 and the same construction as Theorem 2.5.

THEOREM 2.7. *T_n is dense in T_{n-1}.*

Proof. Recall that

$$T_{n-1} = \{\rho \mid \rho \in S_{n-1} \cap A_{n-1}(k) \text{ such that the first } (n-1) \text{ symmetric eigenvalues are all different from the first } 2(n-1) \text{ asymmetric eigenvalues}\}.$$

For $\rho \in T_{n-1}$, the nth eigenspace E_n is at most 3-dimensional since $\rho \in S_{n-1} \cap A_{n-1}(k)$. Since T_{n-1} is open in P, by Theorem 2.1 there is a neighborhood of ρ in C^k so that for q in that neighborhood, $q \in T_{n-1}$. Using Lemma 2.4, pick ρ_ε so that $\rho_\varepsilon \in T_{n-1}$ and the dimension of the nth eigenspace of $\rho_\varepsilon < 3$. This completes the proof, since for ρ_ε the nth asymmetric eigenvalue must be different from the nth symmetric one.

THEOREM 2.8. *T_n is dense and open in P and $T = \bigcap_{n=1}^{\infty} T_n$ is residual in P.*

Proof. T_n is open in P from Theorem 2.1. T_n is dense in P from Lemma 2.4.

3. Some examples.

Example 1. The simplest example of a domain with Z_3 symmetry is an equilateral triangle. Let D be an equilateral triangle of side 1, and consider the problem $\Delta u + \lambda u = 0$ in D with $u = 0$ on the boundary of D. The eigenvalues of Δ on

$$D = \{(x, y) : 0 < y < x\sqrt{3}, y < \sqrt{3}(1-x)\} \tag{3.1}$$

are the numbers

$$\lambda_{mn} = \left(\frac{16\pi^2}{27}\right)(m^2 + n^2 - mn), \qquad m, n = 0, \pm 1, \tag{3.2}$$

with the following conditions:

$$\begin{aligned} &\text{(A)} \quad m+n \text{ is a multiple of } 3,\\ &\text{(B)} \quad m \neq 2n,\\ &\text{(C)} \quad n \neq 2m. \end{aligned} \tag{3.3}$$

The multiplicity of λ_{mn} is $(1/6) \times$ the number of times it appears in the lattice (3.2). The eigenfunctions are of the form

$$f(x, y) = \sum_{(m,n)} \pm \exp\left(\frac{2\pi i}{3}\right)\left(nx + \frac{(2n-m)y}{\sqrt{3}}\right). \tag{3.4}$$

In this sum (m, n) range over $\mathscr{L} \subseteq Z^2$, where $|\mathscr{L}| = 6$ and ± is determined by the following

$$\begin{tikzcd}
 & (m, n) \arrow[dr] & \\
(n-m, n) \arrow[ur] & & (m, m-n) \\
(n-m, -m) \arrow[u] & & (-n, m-n) \arrow[dl] \\
 & (-n, -m) \arrow[ul] &
\end{tikzcd} \tag{3.5}$$

Each transition induces a change of sign in the (m, n) entry of (3.4). Each pair (m, n) that appear in (3.5) must satisfy (B) and (C).

These results were obtained by M. Pinsky [15]. He also shows that a given eigenvalue is either symmetric or asymmetric, i.e., either all of its eigenfunctions are symmetric or all of them are asymmetric. He includes a formula for the multiplicity of the eigenvalues which shows that the dimensions of the eigenspaces become arbitrarily large for both symmetric and asymmetric eigenvalues. Hence this example does not exhibit generic behavior.

Example 2. Domains with Z_5 symmetry illustrate what is necessary to complete the proof for Z_p. The minimal polynomial for Z_5 is

$$\begin{aligned} t^5 - 1 &= (t-1)\left(t^2 - 2t\left(\frac{\sqrt{5}-1}{4}\right) + 1\right)\left(t^2 + 2t\left(\frac{\sqrt{5}+1}{4}\right) + 1\right) \\ &= (t-1)P_1(t)P_2(t). \end{aligned}$$

Rotation through $\alpha = 2\pi/5$ gives an irreducible representation for the group Z_5.

Since $\rho^{-1}\Delta$ commutes with rotation, the 3 invariant subspaces for Z_5 are invariant subspaces for $\rho^{-1}\Delta$. Hence the eigenfunction for $\rho^{-1}\Delta$ must satisfy one of these three equations:

(i) $(O^* - 1)f = 0,$

(ii) $P_1(O^*)f = 0,$

(iii) $P_2(O^*)f = 0.$

It remains to be shown that if an eigenvalue has some eigenfunctions satisfying (ii) and others satisfying (iii) (hence the eigenspace has dimension $\geqq 4$), one can perturb ρ so as to lower the dimension of the eigenspaces. This is the analogue of Lemma 2.4. From this it would follow that generically a given eigenvalue has eigenfunctions that satisfy exactly 1 of the equations (i), (ii) or (iii). This would complete the proof that the eigenspaces for a domain with Z_5 symmetry (in fact Z_p symmetry) have algebraically minimal dimension.

Example 3. Consider the Dirichlet problem for the Laplace operator on the unit disk in R^2, that is, $\Delta U + \lambda U = 0$ where $U(1, \theta) = 0$. It can be shown that the eigenvalues are squares of the zeros of the Bessel functions J_n. Let $k_{n,m}$ be the mth zero of the nth Bessel function J_n. Then

$$J_n(k_{n,m}r) = \frac{(k_{n,m}r)^n}{2^n n!}\left\{1 - \frac{(k_{n,m}r)^2}{2(2n+2)} + \frac{(k_{n,m}r)^4}{2 \cdot 4(2n+2)(2n+4)} \cdots\right\}.$$

The eigenfunctions are of the form $J_n(k_{n,m}r)(\alpha \cos n\theta + \beta \cos n\theta)$ where α and β are arbitrary [8, pp. 302-305]. For n and k positive integers, the functions $J_n(z)$ and $J_{n+k}(z)$ have no common zeros other than the origin [22, pp. 484-485]. Therefore except for

$n=0$, all of the eigenvalues have multiplicity 2, since $J_n(k_{n,m}r)\cos n\theta$ and $J_n(k_{n,m}r)\sin n\theta$ are independent eigenfunctions.

The symmetric eigenfunctions occur for $n\equiv 0 \pmod 3$ and the asymmetric eigenfunctions for $n\equiv S \pmod 3$, $S=1$ or 2. It is clear that approximately $\frac{1}{3}$ of the eigenfunctions are symmetric. Notice that a given eigenvalue is either symmetric or asymmetric.

We do not see generic behavior in this example for a Z_3 action since the symmetric eigenvalues have multiplicity two. However, the disk is invariant under S^1 and for this group the example is generic.

THE EXACT NUMBER OF SOLUTIONS OF FINITE DIFFERENCE APPROXIMATIONS OF SOME NONLINEAR ELLIPTIC BOUNDARY VALUE PROBLEMS*

HENNING WIEBERS†

Abstract. We consider finite dimensional nonlinear eigenvalue problems of the type $Az=\lambda F(z)$ where A is a matrix, $(F(z))_j=f(z_j), j=1,\cdots,n$. Such systems arise as discretizations of a corresponding boundary value problem. The number of solutions of both equations at a fixed $\lambda\in\mathbb{R}_+$ may differ significantly, i.e., spurious solutions occur. We give an upper bound on the number of solutions at a fixed λ in case of the nonlinearities $f(z)=\exp(z), f(z)=\sin z$, for polynomial and related nonlinearities. To this end we extend the equation into $\mathbb{C}^n$ and use the Brouwer degree for complex analytic mappings. A homotopy argument yields that, roughly speaking, the number of solutions of the finite system is limited by the number of the solutions of the uncoupled system $z=\lambda F(z)$.

Key words. discretizations, nonlinear eigenvalue problems, spurious solutions

0. Introduction. We consider finite dimensional nonlinear eigenvalue problems of the type

$$(0.1)_\lambda \qquad Az=\lambda F(z),$$

where $\lambda\in\mathbb{R}_+$, $A=(a_{jk})$ is an (n,n) matrix which satisfies

$$a_{jk}\in\mathbb{R},\quad a_{jj}>0,\quad a_{jk}\leqq 0\quad \text{if } j\neq k,$$

$$(0.2)\qquad a_{jj}\geqq\sum_{\substack{k=1\\k\neq j}}^{n}|a_{jk}|\quad\text{with strict inequality for at least one } j\in\{1,\cdots,n\},$$

A is irreducible.

$F:\mathbb{R}^n\to\mathbb{R}^n$ is assumed to be diagonally nonlinear, i.e.,

$$(0.3)\qquad F(z)=(f(z_1),\cdots,f(z_n))^t\quad\text{with } f:\mathbb{R}\to\mathbb{R}.$$

The properties typically arise in the discretization of nonlinear boundary value problems (bvp). Various authors [3], [4], [12] have observed that the solution sets of $(0.1)_\lambda$ and the bvp may differ significantly, i.e., the number of the solution branches of $(0.1)_\lambda$ increases with the number n of meshpoints and $(0.1)_\lambda$ admits extra (spurious) solutions which do not converge to solutions of the bvp as $n\to\infty$.

In this paper we give an upper bound of the number of solutions of $(0.1)_\lambda$ for the examples $f(z)=\exp(z), f(z)=\sin z$, for polynomial and related nonlinearities, which have also been studied in [3], [4], [9], [12].

Let us consider the bvp

$$(0.4)_\lambda\qquad -u''=\lambda f(u)\quad\text{in }(0,1),\qquad u(0)=u(1)=0$$

with $f(z)=\exp(z)$. It is well known [10] that the solution set of $(0.4)_\lambda$ is given by the solid branch in Fig. 1, whereas $(0.1)_\lambda$ with a simple discretization matrix A admits extra solutions (the dotted branches). It is shown in [3] that $(0.1)_\lambda$ admits at least $2n$ solutions if λ is small enough. We will show that there are at most 2^n solutions of $(0.1)_\lambda$ for each $\lambda>0$.

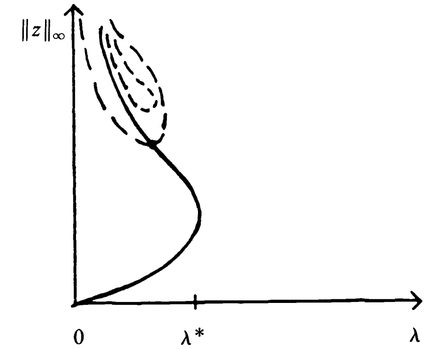

FIG. 1

Another type of spurious solution is obtained by the discretization of $(0.4)_\lambda$ with $f(z) = \sin z$. Equation $(0.4)_\lambda$ admits at most one positive solution, the solid branch in Fig. 2, whereas $(0.1)_\lambda$ possesses an increasing number of solutions as $\lambda \to \infty$ [12], the dotted branches. It is shown in [12] that there are at least $(2 \cdot 3 + 1)^n$ solutions of $(0.1)_\lambda$ with a maximum norm less than 3π, if λ is sufficiently large. We state that there are at most 7^n such solutions for each λ.

A third type of spurious solution occurs in the case $f(z) = (p-z)/1+(p-z)+(p-z)^2$ with $p > 0$ arbitrary which has been considered in [9].

The solution set of $(0.4)_\lambda$ has to be a one-dimensional manifold (cf. [10]), the S-curve in Fig. 3, whereas numerical calculations in [9] show that $(0.1)_\lambda$ with $n = 2$

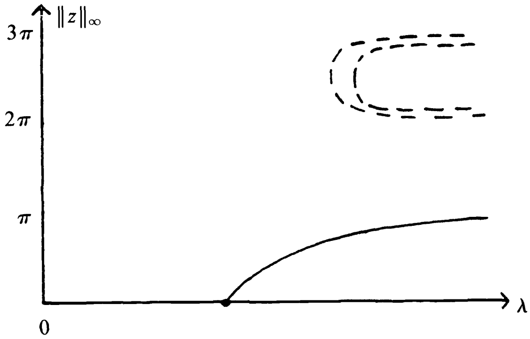

FIG. 2

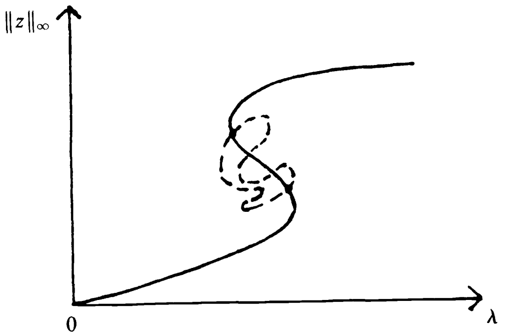

FIG. 3

meshpoints admits 3^2 solutions for specific values of λ and p, the dotted branch. The number of solutions increases with n. Our consideration yields that there are at most 3^n solutions of $(0.1)_\lambda$ for a fixed λ. In the last example the system $(0.1)_\lambda$ is more important than the bvp, because $(0.1)_\lambda$ describes a chemical reaction in an assemblage of n biological cells (cf. [9]). z_j denotes the concentration of a substrate S in the cell C_j which is coupled with its neighbors by diffusion through a membrane. From this point of view all solutions of $(0.1)_\lambda$ are physically relevant.

To obtain our results, two ideas are used. First: relax the coupling between the cells, i.e., we consider the homotopy

$$(0.5)_\lambda \qquad H_\lambda(t,z) := ((1-t)I + tA)z - \lambda F(z) = 0,$$

where $t \in [0, 1]$ and I denotes the identity. If $t=1$ we obtain $(0.1)_\lambda$, the fully coupled state, whereas $t=0$ is the uncoupled state, i.e., a system of n independent equations. In the latter case the number of solutions of $(0.5)_\lambda$ is given by $r(\lambda)^n$, where $r(\lambda)$ denotes the number of solutions of the scalar equation

$$(0.6)_\lambda \qquad \lambda f(z) = z, \qquad z \in \mathbb{R}.$$

Now we choose a solution z_0 of $H_\lambda(0, z)=0$ at a fixed λ and follow the solution curve $(t, z(t))$ of $H_\lambda(t, z)=0$ with $z(0)=z_0$ in the direction of $t \geqq 0$. In § 1 this is examined numerically in the case $f(z)=\exp(z)$.

In the above examples we are able to show that all solutions of $H_\lambda(1, z)=0$ are induced by the solutions of $H_\lambda(0, z)=0$, i.e., the number is limited by $r(\lambda)^n$.

This will be done in §§ 3, 4 and 5. To this end we use a second idea: extend $(0.5)_\lambda$ to a complex analytic mapping in $\mathbb{C}^n$ for each (t, λ). Now degree arguments for complex analytic mappings are used to examine the number of solutions of $(0.1)_\lambda$ in $\mathbb{C}^n$. The special properties of the Brouwer degree for those mappings are listed in § 3.

1. Numerical results for $f(z)=\exp(z)$.

Here we examine a slight modification of the homotopy $(0.5)_\lambda$ with $f(z)=\exp(z)$ and the simplest discretization matrix A of $-u''$. We consider

$$(1.1)_\lambda \qquad \tilde{H}_\lambda(t,z) = ((1-t)\mu I + tA)z - \lambda F(z) = 0,$$

with the lowest eigenvalue μ of A. This seems to be more promising, since the solution sets of $(0.1)_\lambda$ and of $\lambda f(z)=\mu z$ are strongly related. Define $\lambda^* := \sup\{\lambda | (0.1)_\lambda \text{ is solvable}\}$, then the results of [15] yield

$$(1.2) \qquad \lambda_0^*/\mu \|A^{-1}\|_\infty \leqq \lambda^* \leqq \lambda_0^*,$$

where $\lambda_0^* = \mu \exp(1)^{-1}$. Observe that there is no solution of $\tilde{H}_\lambda(0, z)=0$, if $\lambda > \lambda_0^*$. If $\lambda < \lambda_0^*$ there are two solutions of $\lambda f(z)=\mu z$; we denote the minimal one by $+$ and the maximal one by $*$.

We have examined $(1.1)_\lambda$ numerically for $n=3$ and $n=4$ at fixed values of λ. If $n=3$, there are 2^3 solutions of $\tilde{H}_\lambda(0, z)=0$ which we denote in form $z_1 = (+,+,+)$, $z_2(+,*,+), \cdots, z_8=(*,*,*)$. Now we used a path following method as described in [11] to follow the solution curve of $(1.1)_\lambda$ through $(0, z_j)$ in direction of $t>0$.

If $\lambda \in (\lambda^*, \lambda_0^*)$, we cannot reach $t=1$ because of (1.2). Results for various values of λ are shown schematically in Fig. 4. If λ is decreased further, the branch in Fig. 4 connecting $(*,*,*)$ with $(*,+,*)$ will reach $t=1$. Thus there are at least 2^3 solutions of $(1.1)_\lambda$ at $t=1$ if λ is chosen sufficiently small. Fig. 5 shows the case $n=4$, where the 2^4 solutions of $\tilde{H}(0, z)=0$ are denoted in the same manner.

Quite the same results are obtained in the simple case $n=2$. Observe that there is a significant difference between $n=4$ and $n=3$. In the first case bifurcation occurs,

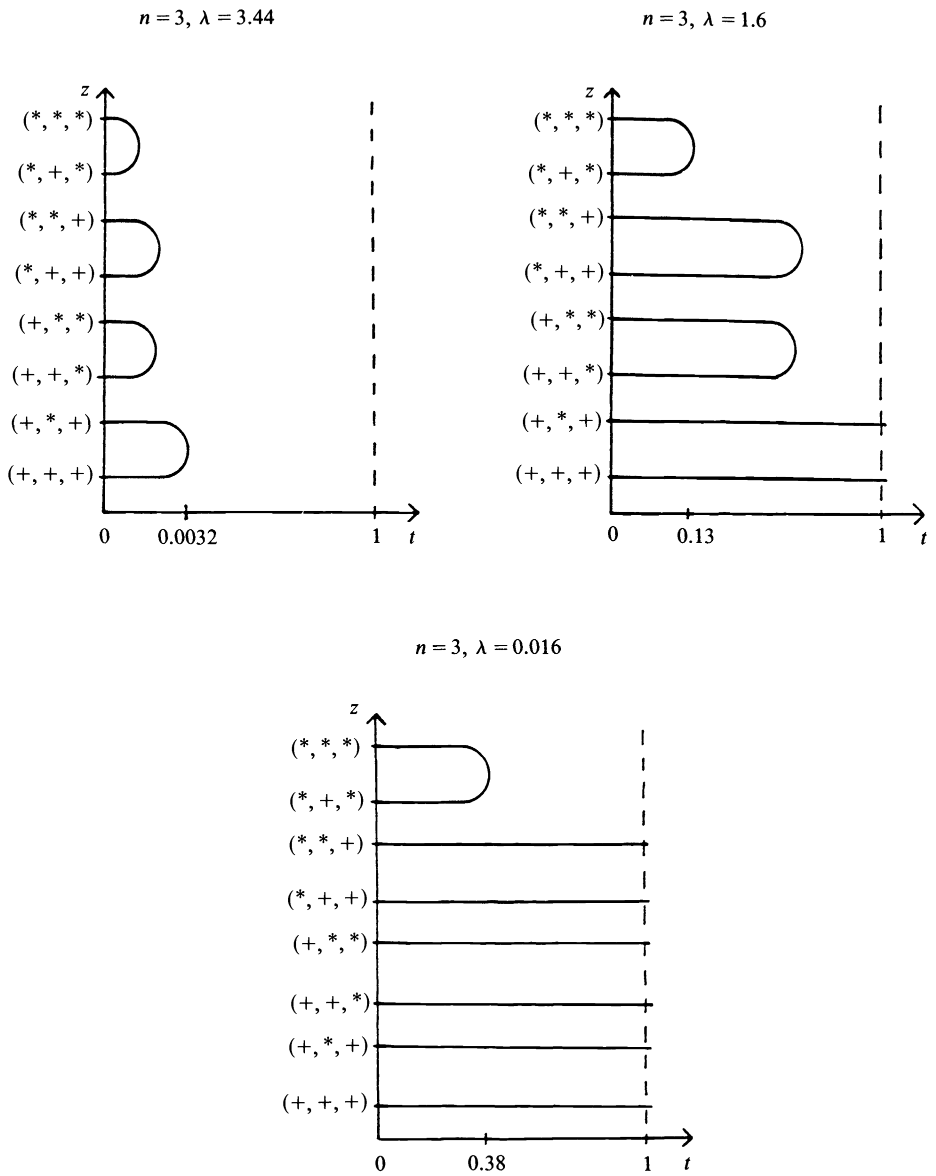

FIG. 4

but not in the latter. We expect diagrams analogous to Figs. 4 and 5 and for the example $f(z) = \sin z$. In this case all branches should reach $t = 1$, if λ is chosen sufficiently large.

With the above computational results the question arises whether all solutions of $(0.1)_\lambda$ are induced by the solutions of the uncoupled system. To answer this question we rewrite $(0.1)_\lambda$ as an equation in $\mathbb{C}^n$ for each $\lambda \in \mathbb{R}_+$, where $F: \mathbb{C}^n \to \mathbb{C}^n$ is an extension of $F: \mathbb{R}^n \to \mathbb{R}^n$. If $f(z) = \exp(z)$ or $f(z) = \sin z$ there is a well-defined extension such that F is a complex analytic mapping. In order to examine $(0.1)_\lambda$ in $\mathbb{C}^n$, we have to deal with the Brouwer degree for complex analytic mappings. In the next section we develop its properties for the reader's convenience.

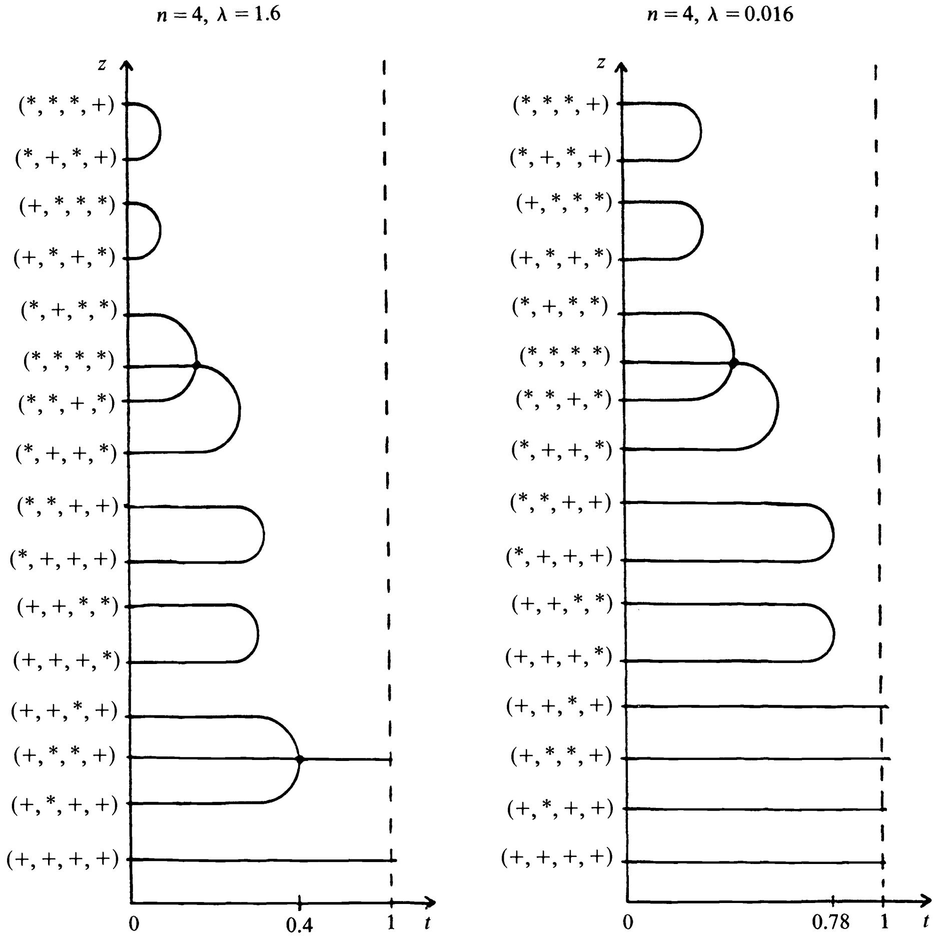

FIG. 5

2. The Brouwer degree of complex analytic mappings. Let G be a complex analytic mapping of an open subset V of $\mathbb{C}^n$ into $\mathbb{C}^n$ and let U be a bounded open subset of V with $\bar{U} \subset V$. By ignoring the complex structure, $G = (g_1 + ih_1, \cdots, g_n + ih_n)$, $g_j, h_j : \mathbb{C}^n \to \mathbb{R}$ can be interpreted as a mapping $(g_1, \cdots, g_n, h_1, \cdots, h_n)$ from $V \subset \mathbb{R}^{2n}$ into $\mathbb{R}^{2n}$. Let w be a point of $\mathbb{R}^{2n} \backslash G(\partial U)$, then the Brouwer degree $\deg(G, U, w)$ is well defined and the usual properties hold (cf. [8] for a detailed discussion).

If the analyticity of G is taken into account these properties can be strengthened. A detailed description of the following considerations can be found in [5], [7], [14].

Denote by $G'(z)$ the complex Jacobian matrix of G at $z = (z_1, \cdots, z_n) = (x_1 + iy_1, \cdots, x_n + iy_n) \in \mathbb{C}^n$ and by $J(G)(z)$ the real Jacobian of $G: V \to \mathbb{R}^{2n}$ at $\tilde{z} = (x_1, \cdots, x_n, y_1, \cdots, y_n)$, then we have

$$\text{Det}\,(J(G)(\tilde{z})) = |\text{Det}\,(G'(z))|^2, \tag{2.1}$$

i.e., the determinant of the real Jacobian is always nonnegative (cf. [5]). Using the identity theorem, it is shown in [5] that for each connected open subset V_1 of V the set

$$S_\varepsilon := \{\tilde{z} \in V_1 \,|\, \text{Det}\,(J(G_\varepsilon)(\tilde{z})) = 0\}$$

of singular points of $G_\varepsilon(z) := G(z) + \varepsilon z$ is nowhere dense in V_1, if $\varepsilon \geqq 0$ is chosen sufficiently small. A theorem of Remmert and Stein [13] yields that the number of solutions of $G(z) = w$ with $z \in U$ is finite. These three properties are responsible for the fact that the following statements hold (cf. [5], [14]).

PROPOSITION 2.1. *Let G, V, U, w be as above. Then*

(2.2) $\deg(G, U, w) \geqq 0$,

(2.3) $\deg(G, U, w) > 0$ *if and only if w lies in $G(U)$,*

(2.4) $\deg(G, U, w) = 1$ *if and only if for the component C of $\mathbb{C}^n \backslash G(\partial U)$ which contains w, G is a one-to-one bicontinuous map of $G^{-1}(C) \cap U$ onto C,*

(2.5) $\deg(G, U, w) \geqq 2$ *if and only if either there is more than one solution in U of $G(z) = w$, or the unique solution is a singular point of G.*

In the following we choose $w = 0$ for convenience. Since there are only finitely many solutions $z_1, \cdots, z_m$ of $G(z) = 0$ in U, the local degree $\deg(G, z_j)$ is well defined for each solution z_j. By the additivity of the degree and (2.3) we have

$$\deg(G, U, 0) = \sum_{j=1}^{m} \deg(G, z_j) \geqq m. \tag{2.6}$$

Thus the degree is an upper bound for the number of solutions.

If G is a function of $U \subset \mathbb{C}$ into $\mathbb{C}$, the degree equals the winding number of $G(\partial U)$ with respect to zero (cf. [8]). In this case it is well known that the local degree $\deg(G, z_j)$ equals the multiplicity of the solution z_j, i.e., the lowest number k at which $G^{(k)}(z_j) \neq 0$. An analogous characterisation of the local degree is valid in general. Since G is analytic, we expand G into the Taylor series at a solution z_j. Without loss of generality we assume that $z_j = 0$.

$$G_j(z) = \sum_{k=1}^{\infty} P_j^{(k)}(z_1, \cdots, z_n), \qquad j = 1, \cdots, n,$$

where $P_j^{(k)}$ is a polynomial in $z_1, \cdots, z_n$ and homogeneous of degree k. Suppose $P_j^{(k_j)}$ is the polynomial of lowest degree in the jth series which is not identically zero. Then it is shown in [6] that

$$\deg(G, 0) = \prod_{j=1}^{n} k_j,$$

if the local degree of the map $(P_1^{(k_1)}, P_2^{(k_2)}, \cdots, P_n^{(k_n)}): \mathbb{C}^n \to \mathbb{C}^n$ is well defined, i.e., $z = 0$ is an isolated zero of this map. Otherwise $\deg(G, 0) \geqq \prod_{j=1}^{n} k_j$ (cf. [6]). Thus it is appropriate to define the multiplicity of a solution of $G(z) = 0$ by its local degree. In this respect (2.6) means that the degree $\deg(G, U, 0)$ equals the number of solutions of $G(z) = 0$, each counted according to its multiplicity.

The considerations above and the homotopy invariance of the degree yield Proposition 2.2 which is basic for our considerations.

PROPOSITION 2.2. *Let V and U be as above. Suppose $H(t, \cdot): V \to \mathbb{C}^n$ is complex analytic for each $t \in [0, 1]$ and continuous in t. Suppose $0 \notin H(t, \cdot)(\partial U)$ for each $t \in [0, 1]$. Then $\deg(H(t, \cdot), U, 0)$ is independent of t, i.e., the number of solutions (counted according to their multiplicities) of $H(t, z) = 0$ in U is finite and independent of t.*

The situation is illustrated in Fig. 6. It is shown in [1], where different methods are used to examine the solution set of $H(t, z) = 0$, that there are indeed solution curves connecting $t = 0$ and $t = 1$.

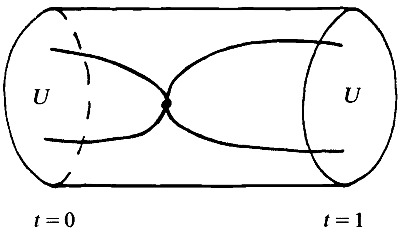

FIG. 6

Now we suppose that the domain U satisfies $U=U^*:=\{z\in\mathbb{C}^n \mid z^*\in U\}$, where z^* denotes the conjugate of z. The mappings we consider fulfill the additional property

$$(2.7)\qquad G(z^*)=(G(z))^*$$

for all $z\in U$. Especially we have $G|_{U\cap\mathbb{R}^n}\subset\mathbb{R}^n$, i.e., G is an extension of a real mapping. Suppose $0\notin G(\partial U)$. Let $\{z_1,\cdots,z_k\}\subset\mathbb{R}^n$ be the set of real solutions of $G(z)=0$. There exists an open subset $W\subset U$ such that

$$(2.8)\qquad W\cap(G^{-1}(0)\cap U)=\{z_1,\cdots,z_k\},\qquad 0\notin G(\partial W).$$

$U\setminus\bar{W}$ is an open set such that $0\notin G(\partial(U\setminus\bar{W}))$. By the additivity of degree we have

$$(2.9)\qquad \deg(G,U,0)=\deg(G,W,0)+\deg(G,U\setminus\bar{W},0).$$

PROPOSITION 2.3. $\deg(G,U\setminus\bar{W},0)$ *is a nonnegative even number.*

Proof. If $G(z)=0$, it follows from (2.7) that $G(z^*)=0$. Denote by $z_1,\cdots,z_l,z_1^*,\cdots,z_l^*$ the solutions of $G(z)=0$ in $U\setminus\bar{W}$, then we have

$$\deg(G,U\setminus\bar{W},0)=\sum_{j=1}^{l}\deg(G,z_j)+\sum_{j=1}^{l}\deg(G,z_j^*).$$

It remains to show that $\deg(G,z_j)=\deg(G,z_j^*)$. This has been done in [7, Proof of Lemma 2]. □

If G satisfies (2.7), it follows from (2.9) and Proposition 2.3 that the number of real zeros of G is even if and only if $\deg(G,U,0)$ is even.

3. The case $f(z)=\exp(z)$.

We choose $F(z):=(\exp(z_1),\cdots,\exp(z_n))$ and examine $(0.1)_\lambda$ in $\mathbb{C}^n$, i.e.,

$$(3.1)_\lambda\qquad Az=\lambda F(z),\qquad \lambda\in\mathbb{R}_+,\quad z\in\mathbb{C}^n.$$

We will apply Proposition 2.2 to the homotopy $(0.5)_\lambda$. Clearly $H_\lambda(t,\cdot):\mathbb{C}^n\to\mathbb{C}^n$ is complex analytic for each (λ,t). To compute $\deg(H_\lambda(0,\cdot),U,0)$ on an appropriate domain U, we deal with the one-dimensional equation

$$(3.2)_\lambda\qquad g_\lambda(z):=z-\lambda\exp(z)=0,\qquad z\in\mathbb{C},\quad \lambda\in\mathbb{R}_+$$

on the domain $U_r:=\{z=x+iy\in\mathbb{C} \mid |x|<r, y\in(-\pi,+\pi)\}$.

PROPOSITION 3.1. *Let* $\lambda>0$ *be arbitrary. Then* $\deg(g_\lambda,U_r,0)=2$, *if* r *is sufficiently large.*

Proof. Observe that $\exp(z)\in\mathbb{R}$, if $z=(x\pm i\pi)$ and that the solution set of $(3.2)_\lambda$ is equibounded with respect to $\lambda\in[\tilde{\lambda},\hat{\lambda}]$ with $\tilde{\lambda},\hat{\lambda}>0$ arbitrary. Thus $\deg(g_\lambda,U_r,0)$ is well defined and independent of $\lambda>0$, if r is chosen sufficiently large. An elementary calculation shows that each solution $z\in U_r$ of $(3.2)_\lambda$ is real and nonsingular, if

$\lambda < \exp(1)^{-1}$. Since there are exactly two solutions of $(3.2)_\lambda$, if $\lambda < \exp(1)^{-1}$ we conclude $\deg(g_\lambda, U_r, 0) = 2$ for those λ. □

Fig. 7 exhibits the real and the imaginary part of the solution set of $(3.2)_\lambda$ in U_r.

Remark 3.2. There exists an infinite number of solutions of $(3.2)_\lambda$ in $\mathbb{C}$ for each λ. Elementary calculations yield that there are exactly two solutions $z = x \pm iy$ with $y \in (k\pi, (k+2)\pi)$ for each number $k = 1, 3, 5, \cdots$.

Now we define $U := U_r^n \subset \mathbb{C}^n$. Choose r sufficiently large, then, for a fixed λ, all solutions of $H_\lambda(0, z) = 0$ are within U. Thus

$$\deg(H_\lambda(0, \cdot), U, 0) = 2^n \tag{3.3}$$

by Proposition 3.1 and the Cartesian product formula for the degree. In the following we denote by $\operatorname{Re}(z) := (x_1, \cdots, x_n)$, $\operatorname{Im}(z) := (y_1, \cdots, y_n)$ the real and the imaginary part of $z = (y_1 + iy_1, \cdots, x_n + iy_n) \in \mathbb{C}^n$.

THEOREM 3.3. *Let $\lambda > 0$ be fixed. Equation $(3.1)_\lambda$ has exactly 2^n solutions (counted according to their multiplicities) with $\operatorname{Im}(z) \in (-\pi, \pi)^n$. Thus, with λ^* defined as in* § 1 *there are at most 2^n distinct real solutions of $(3.1)_\lambda$ for each $\lambda < \lambda^*$. At $\lambda = \lambda^*$ there is exactly one real solution.*

Proof. The assertion follows from Proposition 2.2 and (3.3), if we show that for each $t \in [0, 1]$ there are no solutions of $H_\lambda(t, z) = 0$ on ∂U, if r is sufficiently large. The last assertion can be deduced from the results in [2, Chap. 5].

Suppose there exists $(t, z) \in [0, 1] \times \partial U$ with $H_\lambda(t, z) = 0$ such that $z_j = x_j + i\pi$ for one $j \in \{1, \cdots, n\}$. Then $(\lambda F(z))_j \in \mathbb{R}$ and therefore

$$((1-t) + ta_{jj})\pi + t \sum_{\substack{k=1 \\ k \neq j}}^{n} a_{jk} y_k = 0. \tag{3.4}$$

Since $y_k \in [-\pi, \pi]$ and since A satisfies (0.2), it follows that $y_k = \pi$ in (3.4) for each k with $a_{jk} \neq 0$. Since A is irreducible, (3.4) must hold for each $j \in \{1, \cdots, n\}$ with $y_k = \pi$. But this contradicts the second property of A in (0.2). Using the same arguments we show that there could be no solution of $H_\lambda(t, z) = 0$ with $z_j = x_j - i\pi$ for $j \in \{1, \cdots, n\}$.

Suppose there is a sequence $(t, z(t))$ with $H_\lambda(t, z(t)) = 0$ and $\operatorname{Im}(z(t)) \in [-\pi, \pi]^n$ such that $\|z(t)\|_\infty := \max |z_j(t)|$ becomes unbounded. Then there is a $j_0 \in \{1, \cdots, n\}$

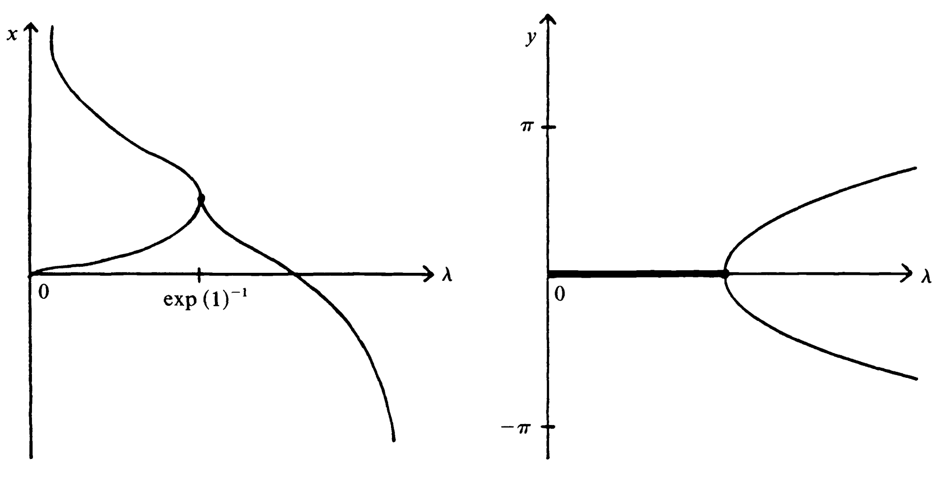

FIG. 7

such that $|x_{j_0}(t)|\to\infty$. Suppose $x_{j_0}(t)\to\infty$. Then we have

$$\lambda=\frac{\|((1-t)I+tA)z(t)\|_\infty}{\|F(z(t))\|_\infty}\leqq\frac{\|(1-t)I+tA\|_\infty(x_{j_0}^2+\pi^2)^{1/2}}{\exp(x_{j_0}(t))}\to 0.$$

This is a contradiction, since λ is fixed.

Suppose $x_{j_0}(t)\to-\infty$. $(1-t)I+tA$ satisfies (0.2), thus the inverse exists and is equibounded with respect to t, i.e., $\|((1-t)I+tA)^{-1}\|_\infty\leqq c$ for all $t\in[0,1]$. Therefore

$$\lambda\geqq\frac{\|z(t)\|_\infty}{c\|F(z(t))\|_\infty}\to\infty, \tag{3.5}$$

since $\|F(z(t))\|_\infty$ is bounded. Formula (3.5) contradicts the choice of λ. □

COROLLARY 3.4. *Suppose $\lambda\leqq\lambda^*$. The number m of real solutions* (*counted according to their multiplicities*) $z\in\mathbb{R}^n$ *of* $(3.1)_\lambda$ *is even.*

Proof. Choose $U\subset\mathbb{C}^n$ as above and an open subset $W\subset U$ as in (2.8) which only contains the real solutions of $H_\lambda(1,z)=0$. Then we deduce

$$2^n=m+\deg(H_\lambda(1,\cdot),U\backslash\bar{W},0)$$

as in (2.9) and m must be even by Proposition 2.3. □

If we change λ in $(3.1)_\lambda$, then we know from Corollary 3.4 that the real solutions appear and disappear pairwise, as is shown in Figs. 1–3.

Remark 3.5. Using Remark 3.2 and the same arguments as in the proof of Theorem 3.3, we conclude that there are exactly $(2k)^n$ solutions of $(3.1)_\lambda$ in the domain $\{z\in\mathbb{C}^n\,|\,\mathrm{Im}(z)\in[-k\pi,k\pi]^n\}$ for each odd number k.

If $(3.1)_\lambda$ is the discretization of the differential equation $(0.4)_\lambda$, one asks for the number of symmetric solutions of $(3.1)_\lambda$, since all solutions of $(0.4)_\lambda$ are symmetric with respect to $\frac{1}{2}$ (cf. [10]). Suppose that the meshpoints are chosen equidistant. Then $(3.1)_\lambda$ reduces to an equation in $\mathbb{R}^{n/2}(\mathbb{C}^{n/2})$, if n is even and to an equation in $\mathbb{R}^{(n+1)/2}(\mathbb{C}^{(n+1)/2})$, if n is odd. Using the same arguments as above, we conclude that $(3.1)_\lambda$ has exactly $2^{n/2}$ symmetric solutions (counted according to their multiplicities) in the former case and $2^{(n+1)/2}$ in the latter. More generally, let L be an (n,n) permutation matrix which commutes with A, i.e., $A\circ L=L\circ A$. Denote by $S\subset\mathbb{R}^n$ the subspace which satisfies $L|_S=I$, by $\tilde{S}$ its complexification, and by $m:=\dim(S)$.

THEOREM 3.6. *Let $\lambda>0$ be fixed. Then there are exactly 2^m solutions of* $(3.1)_\lambda$ (*counted according to their multiplicities*) *in $\tilde{S}$ with* $\mathrm{Im}(z)\in(-\pi,\pi)^n$. *Thus there are at most 2^m* (*real*) *solutions of* $(3.1)_\lambda$ *in S for each $\lambda<\lambda^*$. At $\lambda=\lambda^*$ there is exactly one solution in S.*

Proof. By definition of $F(\cdot)$, L commutes with $F(\cdot)$ and therefore with $H_\lambda(t,\cdot)$ for each $\lambda>0$ and $t\in[0,1]$. Thus $H_\lambda(t,\tilde{S})\subset\tilde{S}$. There exist 2^m zeros of $H_\lambda(0,\cdot)$ in $\tilde{S}\cap U$ with U as above. Since there are no solutions of $H_\lambda(t,z)=0$ on ∂U for each $t\in[0,1]$, the first assertion follows from Proposition 2.2 as in the proof of Theorem 3.3. The last assertion follows again from the results in [2, Chap. 5]. □

With an appropriate modification, Corollary 3.4 is also valid in the above case. All results of this section remain valid, if we consider $F(z)=(c_1\exp(z_1)\cdots c_n\exp(z_n))$ with positive constants c_j.

4. The case $f(z)=\sin z$. We now study $(0.1)_\lambda$ with $F(z)=(\sin z_1,\cdots,\sin z_2)$ in $\mathbb{C}^n$. Analogously to § 3 we use the homotopy $(0.5)_\lambda$ and Proposition 2.2. To this end we have to examine the scalar equation

$$g_\lambda(z):=z-\lambda\sin z=0,\qquad z\in\mathbb{C},\quad\lambda\in\mathbb{R}_+. \tag*{$(4.1)_\lambda$}$$

Since $\sin z = \sin x \cosh y + i \cos x \sinh y$, there are no solutions of $(4.1)_\lambda$ with $z = \pm k\pi + iy$, $y \in \mathbb{R}$, $k \in \mathbb{N}$. For a fixed k we define $U_r := \{z \in \mathbb{C} | x \in (-k\pi, k\pi), |y| < r\}$. Let $\tilde{\lambda} > 0$ be arbitrary then we can choose $r > 0$ such that for each $\lambda \in [\tilde{\lambda}, \infty)$ all solutions of $(4.1)_\lambda$ with real part in $[-k\pi, k\pi]$, are contained in U_r. If λ is sufficiently large, all solutions in U_r become real and nonsingular. Thus for those λ we have

$$(4.2) \qquad \deg(g_\lambda, U_r, 0) = \begin{cases} 2k-1 & \text{if } k \text{ is even,} \\ 2k+1 & \text{if } k \text{ is odd.} \end{cases}$$

By the homotopy invariance of the degree, (4.2) holds for each $\lambda > 0$, if r is sufficiently large.

Now we consider the homotopy $(0.5)_\lambda$ for a fixed $\lambda > 0$. Clearly $H_\lambda(t, \cdot)$ is complex analytic for each (λ, t). Define $U := U_r^n \subset \mathbb{C}^n$. If r is sufficiently large, we obtain

$$(4.3) \qquad \deg(H_\lambda(0, \cdot), U, 0) = \begin{cases} (2k-1)^n & \text{if } k \text{ is even,} \\ (2k+1)^n & \text{if } k \text{ is odd,} \end{cases}$$

by (4.2). Now we can prove the following theorem.

THEOREM 4.1. *Let $\lambda > 0$ be fixed. The nonlinear system*

$$(4.4)_\lambda \qquad Az = \lambda F(z), \qquad z \in \mathbb{C}^n$$

with $F(z) = (\sin z_1, \cdots, \sin z_n)$ has exactly $(2k+1)^n$ solutions (counted according to their multiplicities) with $\operatorname{Re}(z) \in [-k\pi, k\pi]^n$, if $k \in \mathbb{N}$ is odd and exactly $(2k-1)^n$ solutions, if k is even.

Proof. Using (4.3) the assertion follows from Proposition 2.2 if we show that for each $t \in [0, 1]$, there are no solutions of $H_\lambda(t, z) = 0$ on ∂U, if r is sufficiently large. Using the definition of $\sin z$ and the property (0.2) of the matrix A we can deduce this as in the proof of Theorem 3.3. □

Remark 4.2. With slight reformulations the considerations in § 3 concerning the number of symmetric solutions and the appearance of real solutions remain valid in case of the above nonlinearity.

Using an argument given in [12], we can show that all solutions of $(4.4)_\lambda$ become real if λ increases. Let $\tilde{z} \in \mathbb{C}^n$ be a zero of $F(\cdot)$, i.e., $\tilde{z} = (k_1\pi, \cdots, k_n\pi)$, $k_j \in \mathbb{N}$. Consider $F(\cdot)$ as a mapping from $\mathbb{R}^n$ into itself. Dividing $(4.4)_\lambda$ by λ and using the homotopy invariance property, we compute the local degree

$$\deg(A/\lambda - F, \tilde{z}) = \deg(F, \tilde{z}) = \pm 1$$

if λ is sufficiently large. Thus for those λ there exists a solution $z \in \mathbb{R}^n$ of $(4.4)_\lambda$ in a small neighborhood of $\tilde{z}$. This consideration together with Theorem 4.1 yields the following corollary.

COROLLARY 4.3. *For each $k \in \mathbb{N}$ there exists a value $\lambda(k)$ such that for each $\lambda > \lambda(k)$ the system $(4.4)_\lambda$ admits exactly $(2k+1)^n$ different (real) solutions in $[-k\pi, k\pi]^n$ if k is odd and exactly $(2k-1)^n$ solutions if k is even.*

5. Polynomial and related nonlinearities. First we consider $(0.1)_\lambda$ with $F(z) = (p_1(z_1), \cdots, p_n(z_n))$, where $p_j: \mathbb{C} \to \mathbb{C}, j \in \{1, \cdots, n\}$ are polynomials of degree $m_j > 1$. We use the ideas of the preceding sections to prove the following theorem.

THEOREM 5.1. *Let $\lambda > 0$ be fixed and let $F(\cdot)$ be as above. Then there are exactly $\prod_{j=1}^n m_j$ solutions (counted according to their multiplicities) of $(0.1)_\lambda$ in $\mathbb{C}^n$.*

Proof. We use the homotopy $(0.5)_\lambda$. Each component of $H_\lambda(t, \cdot)$ is a polynomial $P_j: \mathbb{C}^n \to \mathbb{C}$ of the form $P_j(z) = p_j(z_j) + q_j(z)$, where q_j is a polynomial of degree one. Therefore it is easy to see that there exists a ball $B_r \subset \mathbb{C}$ with center 0 and radius r

such that for all $t \in [0,1]$ the solutions of $H_\lambda(t,z)=0$ are contained in B_r^n. Since $\deg(p, B_r, 0)$ of a polynomial $p:\mathbb{C}\to\mathbb{C}$ equals the degree of the polynomial we obtain

$$\deg(H_\lambda(0,\cdot), B_r^n, 0) = \prod_{j=1}^{n} m_j.$$

Now the assertion follows from Proposition 2.2. □

Now we consider the third example of § 0, i.e., $(0.1)_\lambda$ with $F(z) = (f(z_1), \cdots, f(z_n))$, where

$$f(z) = \frac{(p-z)}{1+(p-z)+(p-z)^2}, \qquad z \in \mathbb{R}, \quad p > 0.$$

If $n=2$, at most 3^2 solutions occur (cf. (Fig. 3). The following theorem shows that this is true in general.

THEOREM 5.2. *Let $\lambda > 0, p > 0$ be fixed and $F(\cdot)$ be as above. Then there are 3^n solutions (counted according to their multiplicities) of $(0.1)_\lambda$ in $\mathbb{C}^n$.*

Proof. We consider the homotopy $(0.5)_\lambda$ in $\mathbb{C}^n$. But $H_\lambda(t,\cdot)$ is not complex analytic on $\mathbb{C}^n$. Thus for each $j \in \{1, \cdots, n\}$ we multiply the jth row of $(0.1)_\lambda$ by $(1+(p-z_j)+(p-z_j)^2)$ and obtain a mapping $\tilde{H}_\lambda(t,\cdot):\mathbb{C}^n \to \mathbb{C}^n$ which is complex analytic for each (λ, t). The solution sets of $H_\lambda(t,z)=0$ and $\tilde{H}_\lambda(t,z)=0$ coincide. There exists a ball $B_r \subset \mathbb{C}$ with center 0 and radius r such that for each $t \in [0,1]$ all solutions of $\tilde{H}_\lambda(t,z)=0$ are contained in $B_r^n \subset \mathbb{C}^n$. Otherwise there would exist a sequence $(t, z(t)) \subset \mathbb{C}^n$ of solutions of $\tilde{H}_\lambda(t,z)=0$ with $|z_{j_0}(t)| \to \infty$ for a $j_0 \in \{1, \cdots, n\}$ and $|z_{j_0}(t)| \geqq |z_j(t)|$ for all $j \in \{1, \cdots, n\}$. Consider the j_0th row of $\tilde{H}_\lambda(t,z)=0$,

$$\begin{aligned}|((1-t)+ta_{j_0j_0})z_{j_0}(1+(p-z_{j_0})+(p-z_{j_0})^2)\\ +t\sum_{\substack{k=1\\k\neq j_0}}^{n} a_{j_0k}z_k(1+(p-z_{j_0})+(p-z_{j_0})^2)-\lambda(p-z_{j_0})|=0.\end{aligned}$$

Since the matrix A satisfies (0.2), the expression on the left converges to infinity, a contradiction.

Denote by $\tilde{H}_\lambda^j(\cdot)$ the jth row of $\tilde{H}_\lambda(0,\cdot)$. $\tilde{H}_\lambda^j:\mathbb{C}\to\mathbb{C}$ is a polynomial of degree three. Thus by Proposition 2.2 and the Cartesian product formula we obtain

$$\deg(\tilde{H}_\lambda(1,\cdot), B_r^n, 0) = \prod_{j=1}^{n} \deg(\tilde{H}_\lambda^j, B_r, 0) = 3^n.$$

This proves the assertion. □

Observe that $\tilde{H}_\lambda^j(z)=0$, $z \in \mathbb{C}$ is equivalent to $\lambda f(z)=0$ with $f(\cdot)$ as above. Thus also in this example the number of solutions of $(0.1)_\lambda$ is limited by the number of solutions of the uncoupled state. The considerations in § 3 about the number of symmetric solutions also holds in this case.

A FAST, ACCURATE ALGORITHM FOR THE ISOMETRIC MAPPING OF A DEVELOPABLE SURFACE*

JOHN C. CLEMENTS† AND L. J. LEON†‡

Abstract. This work is concerned with the derivation of a fast, accurate algorithm for the isometric mapping of a developable surface onto the plane $\mathcal{M}: \vec{r} \rightarrow \vec{R}$. The algorithm is based on the relationship between the ruling lines $\vec{r}$ generating the developable surface $\vec{S}(s, t)$ and one additional geodesic $\vec{g}(s)$ constructed within the surface as the solution of the geodesic curvature equation $\det(\vec{g}'\vec{g}''\vec{n}) = 0$, where $\vec{n}$ is the unit normal to the surface $\vec{S}$ at $\vec{g}$ and $\vec{R}$ is the image of $\vec{r}$ in the plane. Since $\vec{g}$ as well as the ruling lines reduce to straight lines in the plane, the isometric mapping procedure is defined in terms of the ruling line lengths, the arclength along $\vec{g}$ and the angles of intersection of $\vec{r}$ and $\vec{g}$.

Key words. developable surface, isometric mapping

AMS(MOS) subject classifications. 65, 53

1. Introduction. A surface $\vec{S}$ in $\mathbb{R}^3$ is called a ruled surface if it contains a one-parameter family of straight lines called generators or ruling lines $\vec{r}$, which can be chosen as coordinate curves on the surface. A developable surface is a ruled surface defined by nonintersecting generators which has the same tangent plane at all points of each generator. We shall be concerned here with developable surfaces which can be represented in the form (Fig. 1)

$$\vec{S}(s, t) = \vec{f}(s) + t\vec{r}(s), \qquad \vec{f}'(s) \times \vec{r}(s) \neq 0, \quad s \in [a, b], \quad t \in [0, 1] \tag{1.1}$$

where $\vec{f}$ and $\vec{r}$ are twice continuously differentiable vector functions on $[a, b]$.

The term "developable" refers to the property that by a succession of small rotations about each of the generating lines the surface can be laid flat or developed onto a plane without stretching or tearing. That is, it can be mapped isometrically onto a subset of $\mathbb{R}^2$. Conversely, a plane surface material can be shaped into a developable surface with only simple unidirectional bending along the generating lines.

Currently, an important mathematical problem in computer-aided design and manufacture involves determining whether a given design surface is developable and if so, the precise dimensions of a plane surface material which will produce that surface ([3], [5], [8]-[10]). The use of developable hull forms in shipbuilding offers significant advantages in terms of lower cost and faster and simpler construction techniques ([3], [10]). Developable surfaces are also involved in many other industries such as aircraft manufacture, where they are utilized in the fabrication of airfoil and fuselage sections. The motivation for this work is based on an industry requirement ([3]) for a procedure which would permit the very accurate pre-cutting of steel plate sections greater than 50 feet in length to be used in the construction of developable hull steel ships. Previous approaches to hull plate expansion have involved the use of circular arcs generated from offset data ([2]) or the calculation of very fine surface envelope

‡ The research of this author was supported in part by the Natural Sciences and Engineering Research Council of Canada under grant A5338.

plane sections ([3]) to define the mapping. The first of these approaches makes no use of the geodesic structure of developable surfaces and is a rough approximation at best. The second is computationally complex with the potential for serious error propagation problems. Neither has the capability for error control.

In what follows, a fast, accurate algorithm is derived for the isometric mapping of developable surfaces onto the plane. This simple algorithm is based on the relationship between the ruling lines $\vec{r}$ generating the developable surface $\vec{S}$ and one additional geodesic $\vec{g}(s)$ constructed within the surface. The algorithm defines a numerical procedure $\mathcal{M}$ for mapping the ruling lines $\vec{r}$ of $\vec{S}$ onto the corresponding plane coordinate lines $\vec{R}$ of the surface developed onto the plane $\mathcal{M}: \vec{r} \to \vec{R}$. Accuracy control is achieved through the application of a variable stepsize differential equation solving routine.

2. Preliminary definitions and results. Let $\mathcal{C}^k[a, b]$ denote the linear space

$$\mathcal{C}^k[a, b] \equiv \{f(s) \,|\, f \text{ is } k \text{ times continuously differentiable for all } s \in [a, b]\}.$$

C will denote a curve in $\mathbb{R}^3$:

$$\begin{aligned} C: \vec{f}(s) &= f_1(s)\vec{i} + f_2(s)\vec{j} + f_3(s)\vec{k} \\ &= (f_1(s), f_2(s), f_3(s))^T, \qquad s \in [a, b], \end{aligned}$$

with components $f_i(s)$, $i = 1, 2, 3$, and Euclidean norm $|\vec{f}(s)| \equiv (f_1^2(s) + f_2^2(s) + f_3^2(s))^{1/2}$. Here T denotes the usual vector transpose and $\circ$ and $\times$ the scalar and vector products respectively.

A ruled surface can be thought of as the surface $\vec{S}$ generated by the continuous motion of a straight line along a curve C (Fig. 1). It will be assumed here ([7]) that $\vec{S}$ has the representation (1.1), where:

(2.1)
- (i) $f_i(s) \in \mathcal{C}^2[a, b]$, $i = 1, 2, 3$,
- (ii) $\vec{r}(s) = (r_1(s), r_2(s), r_3(s))^T$ with $r_i(s) \in \mathcal{C}^2[a, b]$, $i = 1, 2, 3$,
- (iii) each point of $\vec{S}$ corresponds to only one ordered pair (s, t),
- (iv) $t \in [0, 1]$ is the directed distance along $\vec{r}(s)$ from $\vec{f}(s)$.

The ruled surface (1.1) is developable if and only if ([7])

$$\det(\vec{f}'\vec{r}\vec{r}') = 0 \quad \text{for all } s \in [a, b] \tag{2.2}$$

where $' \equiv d/ds$. This is equivalent to the requirement that the tangent planes at every point on a given ruling line must coincide or that the normals must be parallel (Fig. 1).

Let $g(s) = (g_1(s), g_2(s), g_3(s))^T$ be a curve in R^3 with $g_i(s) \in \mathcal{C}^2[a, b]$, $i = 1, 2, 3$. The curvature κ at $\vec{g}(s_0)$ on C: $\vec{g}(s)$, $a \leqq s \leqq b$ is given by

$$\kappa(s_0) = |\vec{K}(s_0)| = |\dot{\vec{T}}(s_0)| = |\vec{T}'(s_0)|/|\vec{g}'(s_0)|$$

where $\vec{T}(s_0) = \vec{g}'(s_0)/|\vec{g}'(s_0)|$. Thus the curvature vector $\vec{K}$ has the same or opposite direction as the principal unit normal $\vec{N}(s_0) = \vec{T}'(s_0)/|\vec{T}'(s_0)|$ to C at $\vec{g}(s_0)$ when $|\vec{T}'(s_0)| > 0$. Here $\cdot \equiv d/d\sigma$ denotes differentiation with respect to the arclength parameter σ. The geodesic curvature $\kappa_{\vec{g}}$ of a curve C: $\vec{g}(s)$ in a surface $\vec{S}$ is given by

$$\kappa_{\vec{g}}(s_0) = \det(\dot{\vec{g}}\ddot{\vec{g}}\vec{n})$$

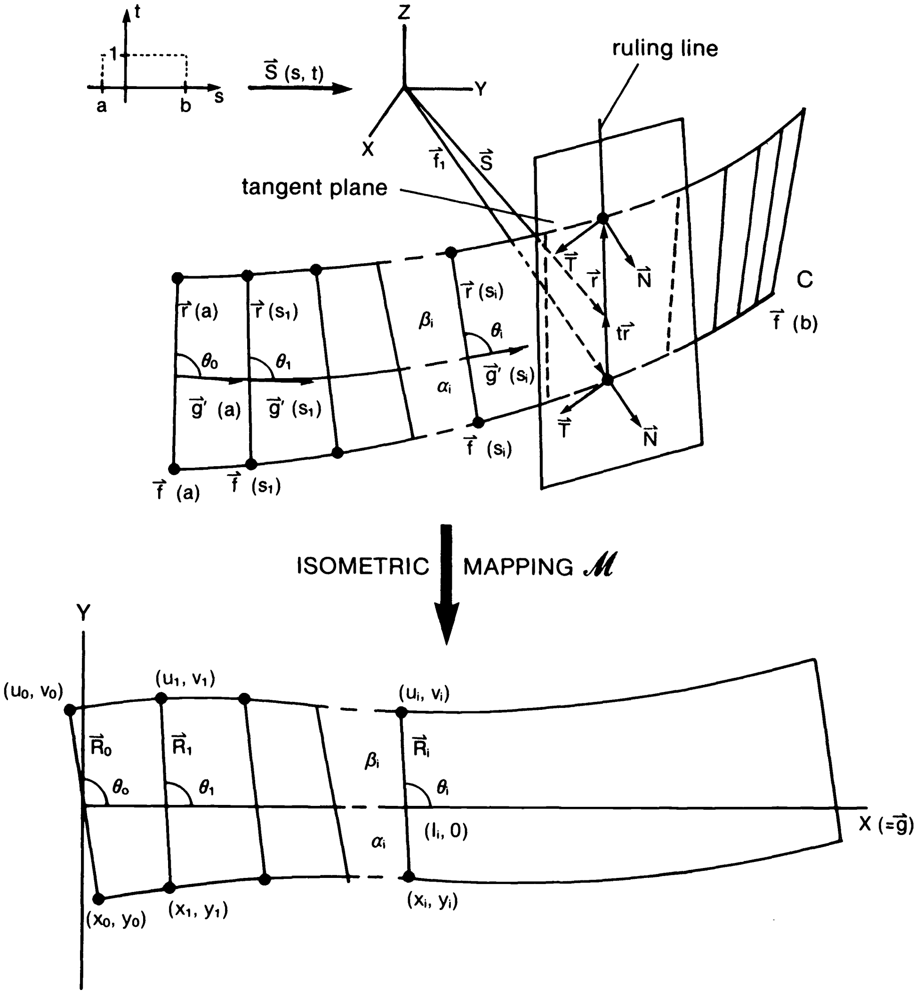

FIG. 1. $\mathcal{M}: \vec{r} \to \vec{R}$.

where $\vec{n}$ is the unit normal to the surface $\vec{S}$ at $\vec{g}(s_0)$. Two important properties of geodesics $\vec{r}$ in a surface $\vec{S}$ are ([8]):

(i) $\vec{g}$ on $\vec{S}$ is a geodesic if and only if

$$\det(\vec{g}'\vec{g}''\vec{n}) = \vec{g}'' \circ (\vec{g}' \times \vec{n}) = 0; \tag{2.3}$$

(ii) If $\vec{S}$ is the developable surface given by (1.1), a geodesic $\vec{g}$ in $\vec{S}$ joining any two points of $\vec{S}$ not on the same generator can be represented in the form

$$\vec{g}(s) = \vec{f}(s) + t^*(s)\vec{r}(s), \qquad t^*(s) \in \mathscr{C}^2[a, b]. \tag{2.4}$$

Equation (2.3) is equivalent to the requirement that the plane of curvature of $\vec{g}$ (provided $\vec{N} \neq 0$) is orthogonal to the tangent plane to $\vec{S}$ (i.e. coincides with $\vec{N}$) at every point of $\vec{g}$ in $\vec{S}$. Equations (2.3) and (2.4) also ensure that $\vec{r} \circ (\vec{g}' \times \vec{n}) \neq 0$ everywhere on $\vec{g}$ in $\vec{S}$.

3. The mapping $\mathscr{M}$: $\vec{r}\to\vec{R}$. Equation (2.3) gives

$$\vec{g}'(s)=\vec{f}'(s)+t^{*\prime}(s)\vec{r}(s)+t^*(s)\vec{r}'(s),$$
$$g''(s)=\vec{f}''(s)+t^{*\prime\prime}(s)\vec{r}(s)+2t^{*\prime}(s)\vec{r}'(s)+t^*(s)\vec{r}''(s)$$

for $s\in[a,b]$. Since $\vec{g}(s)$ must have geodesic curvature zero, it follows from (2.3) that $t^*(s)$ must satisfy the second order nonlinear ordinary differential equation

$$\begin{aligned}t^{*\prime\prime}(s)&=-[\vec{f}''\circ(\vec{g}'\times\vec{n})+t^*\vec{r}''\circ(\vec{g}'\times\vec{n})+2t^{*\prime}\vec{r}'\circ(\vec{g}'\times\vec{n})]/\vec{r}\circ(\vec{g}'\times\vec{n})\\&=F(t^*(s),t^{*\prime}(s))\end{aligned}\tag{3.1}$$

at each s in $[a,b]$, where $\vec{n}(s)=\vec{r}(s)\times\vec{T}(s)$ is the normal to the developable surface $\vec{S}$ at $\vec{g}(s)$ and $\vec{T}(s)=\vec{f}'(s)/|\vec{f}'(s)|$. The equivalent first order system is given by

$$\begin{aligned}u_1'(s)&=u_2(s),\\u_2'(s)&=F(u_1(s),u_2(s)),\end{aligned}\qquad a\leqq s\leqq b,\tag{3.2}$$

for u_1 and u_2 on $[a,b]$, where $u_1(s)=t^*(s)$ and $u_2(s)=t^{*\prime}(s)$. The numerical solution of system (3.2) requires some starting values at $s=a$ and involves the computation of $\vec{f}$, $\vec{f}'$, $\vec{f}''$, $\vec{r}$, $\vec{r}'$ and $\vec{r}''$. For simplicity, the starting values employed here will be $u_1(0)=t^*(a)=.5$ and $u_2(a)=t^{*\prime}(a)=0$. Since the denominator of $\partial F/\partial u_1$ and $\partial F/\partial u_2$ is $[\vec{r}\circ(\vec{g}'\times\vec{n})]^2$, these terms are bounded away from zero except near an edge of regression and F satisfies a Lipschitz condition [4]. If $\vec{r}\circ(\vec{g}'\times\vec{n})$ becomes small, it is only necessary to restart the solution of (3.2) with a new set of initial conditions. Thus, $t^*(s)$ and $t^{*\prime}(s)$ can be solved numerically to within a given specified accuracy ε_{t^*} using a standard variable stepsize differential equation solving routine.

Let $P_N=\{a=s_0<s_1<s_2<\cdots<s_N=b\}$ be any partition of the parameter interval $[a,b]$ and let $\vec{h}(s)$ be defined by $\vec{h}(s)=\vec{S}(s,1)=\vec{f}(s)+\vec{r}(s)$, $s\in[a,b]$. The isometric mapping of the surface $\vec{S}(s,t)$ in (1.1), or more precisely the isometric mapping of the geodesics in $\vec{S}$, is accomplished as follows (Fig. 1). $\vec{g}(a)=\vec{f}(a)+(\frac{1}{2})\vec{r}(a)$ is mapped to the origin of the xy-plane, and computing

$$\begin{aligned}&\vec{r}(a)=\vec{h}(a)-\vec{f}(a),\\&\alpha_0=\beta_0=|\vec{r}(a)|/2,\\&\vec{g}'(a)=\vec{f}'(a)+t^{*\prime}(a)\vec{r}(a)+t^*(a)\vec{r}'(a),\\&\theta_0=\cos^{-1}((\vec{g}'(a)\circ\vec{r}(a))/(|\vec{g}'(a)||\vec{r}(a)|))\end{aligned}\tag{3.3}$$

gives

$$(x_0,y_0)=(-\alpha_0\cos\theta_0,-\alpha_0\sin\theta_0),\qquad(u_0,v_0)=(\beta_0\cos\theta_0,\beta_0\sin\theta_0),$$

and $\vec{R}_0=(u_0-x_0,v_0-y_0)$ is the isometric image of $\vec{r}_0=\vec{r}(a)$. More important, since $\vec{g}(s)$ is a geodesic in the developable surface $\vec{S}$, its image under the mapping must be a straight line in the plane and, by our choice of θ_0, it must be that subinterval of the positive x-axis from zero to the point

$$I_N=\int_{s_0}^{s_N}|\vec{g}'(s)|\,ds.$$

That is, the coordinate in the xy-plane of the intercept $\vec{g}(s_i)$ of the ruling line $\vec{r}(s_i)$

and the geodesic $\vec{g}(s)$ is always given by $(I_i, 0)$, where

$$
\begin{aligned}
I_i &= \int_{s_0}^{s_i} |\vec{g}\,'(s)|\, ds \\
&= \int_{s_0}^{s_i} \sqrt{(f_1' + t^* r_1' + t^{*\prime} r_1)^2 + (f_2' + t^* r_2' + t^{*\prime} r_2)^2 + (f_3' + t^* r_3' + t^{*\prime} r_3)^2}\, ds
\end{aligned}
\tag{3.4}
$$

for every $i = 1, \cdots, N$. To determine the image of $\vec{r}(s_1)$, we compute I_1 and

$$
\begin{aligned}
&\alpha_1 = |\vec{g}(s_1) - \vec{f}(s_1)| = t^*(s_1)|\vec{r}(s_1)|, \\
&\beta_1 = |\vec{g}(s_1) - \vec{h}(s_1)|, \\
&\theta_1 = \cos^{-1}((\vec{g}\,'(s_1) \circ \vec{r}(s_1))/(|\vec{g}\,'(s_1)|\,|\vec{r}(s_1)|))
\end{aligned}
\tag{3.5}
$$

where for simplicity it is assumed that $\vec{g}$ always stays within the surface $\vec{S}$ (that is, that $0 \leqq t^*(s) \leqq 1$ for all s in $[a, b]$). Then

$$
\begin{aligned}
&(x_1, y_1) = (I_1 - \alpha_1 \cos\theta_1, -\alpha_1 \sin\theta_1), \\
&(u_1, v_1) = (I_1 + \beta_1 \cos\theta_1, \beta_1 \sin\theta_1), \\
&\vec{R}_1 = (u_1 - x_1, v_1 - y_1)
\end{aligned}
\tag{3.6}
$$

and that portion of $\vec{S}$ bounded by $\vec{r}(a)$ and $\vec{r}(s_1)$ has been mapped isometrically onto the portion bounded by $\vec{R}_0$ and $\vec{R}_1$ in the plane. Replacing the subscript 1 by 2 in (3.5) and (3.6) and repeating the operation successively for $i = 2, \cdots, N$ completes the isometric mapping of the surface.

The important calculation in this mapping procedure is the numerical evaluation of I_i in (3.4). Consequently, it will be assumed here that a standard quadrature rule is to be used which is to satisfy a user-specified maximum error tolerance ε_I. This in turn induces a refinement $P_{\tilde{N}} = \{a = s_0 = \tau_0 < \tau_1 < \cdots < \tau_{M_1} = s_1 < \cdots < \tau_{M_N} = s_N = b\}$ of P_N and imposes a maximum error tolerance ε_{t^*} on the evaluation of t^* and $t^{*\prime}$ at each point of $P_{\tilde{N}}$.

4. The algorithm. The following algorithm assumes that the geodesic $\vec{g}(s)$ does not encounter an edge of regression of the developable surface and hence that the system of differential equations (3.2) is solvable everywhere on $[a, b]$. One method for ensuring this is to restart the mapping procedure with new initial values at that point on $\vec{g}(s)$ where it crosses one of the boundary curves $\vec{f}$ and $\vec{h}$—that is, whenever $t^*(\tau_j) > 1$ or $t^*(\tau_j) < 0$ for some j.

ALGORITHM. ($\mathcal{M} : \vec{r} \to \vec{R}$). Given a developable surface $\vec{S}$ satisfying (1.1) and (2.1):

(i) specify the error tolerance ε_I and a partition $P_N = \{a = s_0 < s_1 < \cdots < s_N = b\}$ of $[a, b]$,

(ii) choose a quadrature method for evaluating I_i in (3.4) and a refinement $P_{\tilde{N}} = \{a = \tau_0 < \tau_1 < \cdots < \tau_{M_N} = b\}$ of P_N so that I_i is computed accurately to ε_I for each $i = 1, \cdots, N$, provided t^* and $t^{*\prime}$ are computed accurately to within ε_{t^*},

(iii) solve the system of differential equations (3.2) for t^* and $t^{*\prime}$ accurate to ε_{t^*} on $P_{\tilde{N}}$,

(iv) compute $\alpha_0 = \beta_0$ and θ_0 in (3.3) to obtain

$$
\begin{aligned}
&(x_0, y_0) = (-\alpha_0 \cos\theta_0, -\alpha_0 \sin\theta), \\
&(u_0, v_0) = (\beta_0 \cos\theta_0, \beta_0 \sin\theta_0);
\end{aligned}
$$

and

(v) for each $i=1, \cdots, N$ compute I_i, α_i, β_i and θ_i as in (3.5) and (3.6) to obtain the coordinates of the ruling-line endpoints of $\vec{S}$ mapped isometrically,

$$(x_i, y_i)=(I_i-\alpha_i \cos \theta_i, -\alpha_i \sin \theta_i),$$

$$(u_i, v_i)=(I_i+\beta_i \cos \theta_i, \beta_i \sin \theta_i),$$

onto the plane.

5. Discussion. The algorithm developed here has been applied successfully in the design and construction of developable hull steel ships and several improvements have already been proposed. Perhaps the most interesting suggestion has been to compute two geodesics $\vec{g}_1(s)$ and $\vec{g}_2(s)$ simultaneously. This would simplify the remaining calculations and provide an error check on the calculation of θ_i, $i=1, \cdots, N$, which could be sensitive to error propagation. The restriction of t^* to $[0, 1]$ is imposed here for simplicity only. What is required in practice is a check on the stepsize calculation in the differential equation solver for (3.2) or on the magnitude of $|\vec{r} \circ (\vec{g}' \times \vec{n})|$ at each step. A detailed error analysis for the coupled integral-differential equations (3.4) and (3.2) is currently in progress.

ON THE DYNAMIC SHEAR FLOW PROBLEM FOR VISCOELASTIC LIQUIDS*

HANS ENGLER†

Abstract. Initial-boundary value problems for a third order nonlinear integro-differential equation describing dynamic simple shear flow for viscoelastic liquids are studied on bounded one-dimensional spatial domains. Local and global existence results for arbitrary forces and initial data are given under suitable assumptions on the constitutive relations. Conditions on the forces and on the constitutive equations are formulated that imply that solutions of the equations tend to a rest state, and the convergence rates are estimated in terms of the force decay and of dissipation rates that can be derived from the constitutive equations.

Key words. parabolic integro-differential equations, non-Newtonian liquids, simple shear flow, energy estimates, asymptotic behavior

AMS(MOS) subject classifications. Primary 45K05, 45G10, 76A10; secondary 35B40, 35K55

Introduction. The purpose of this note is a study of unsteady simple shear flow for a class of non-Newtonian (viscoelastic) liquids. Using a general class of constitutive equations, the equations of motion reduce to a single third order partial integro-differential equation for the displacement u:

$$(0.1)\qquad u_{tt}(x,t)-\eta\cdot u_{xxt}(x,t)=\int_0^\infty (g(s,u_x(x,t)-u_x(x,t-s))_x\,ds+f(x,t)).$$

Here, $0\leqq x\leqq 1$, $t>0$, $\eta>0$, and g is function characterizing certain properties of the liquid. Details of the derivation of this equation are given in § 5.

To solve (0.1), one has to prescribe the initial history of the flow (i.e. u for $t\leqq 0$) and the initial velocity (i.e. $u_t(x,0)$). At the boundary, the displacement is prescribed ($u(j,t)=f_j(t)$), or traction forces act on the liquid ($\eta\cdot u_{xt}(j,t)+\int_0^\infty g(s,u_x(j,t)-u_x(j,t-s))\,ds=h_j(t)$) for $j=0,1$.

The plan and contents of this paper are as follows: in § 1, we give conditions under which (0.1), together with displacement or traction type boundary conditions, has local (in time) unique solutions in various regularity classes. We show that certain a priori estimates on the solution will guarantee that it can be continued for all times and comment on the relations between regularity properties of the solution and of the data.

In § 2, conditions on the constitutive function g are given under which the boundary displacement problem has a global classical solution for any choice of smooth data. If, e.g., $g(s,u)=a(s)\cdot g_0(u)$, then global existence will follow if $a(\cdot)$ is integrable over $\mathbb{R}^+$ and nonincreasing, and if g_0 is nondecreasing (up to an affine function in u). These conditions reflect a "fading memory" assumption and imply that a certain natural functional for the potential energy has suitable positivity properties and satisfies a dissipation inequality. We then use a transformation introduced in [1] to apply pointwise comparison arguments for scalar integro-differential equations and deduce a priori estimates that imply global existence of solutions. In § 3, the same argument is carried out for the boundary traction problem. In this case, global existence can be shown under slightly weaker conditions.

* Received by the editors August 19, 1985; accepted for publication (in revised form) May 13, 1986.

† Department of Mathematics, Georgetown University, Washington, D.C. 20057.

In § 4, we use a "weighted" energy estimate, similar to an argument used in [8], to show that first time derivatives of the solution decay at essentially the same rate as the forces, provided this rate does not exceed the natural decay rate for Newtonian liquids with the same dynamic viscosity η in shear flow or the decay rate of the kernel $a(\cdot)$.

In the last section, we show in some more detail how an equation of type (0.1) can be derived from rheological models and interpret the results. For the rheological background of this paper, we refer to the monographs [3] and [15]. A general local existence result for unsteady flows of weakly non-Newtonian liquids is given in [18]. Global solutions for extensional flows and small forces are studied in [20] in the case of a special constitutive equation. There is also a relation between the equations studied here and those describing longitudinal motions of one-dimensional viscoelastic bars (cf. [1], [10], [21]). Abstract parabolic integro-differential equations related to those discussed below have been studied by various authors; see, e.g., [12] and its bibliography. Finally, model equations for other one-dimensional motions of visco-elastic materials have been studied in [6], [13], [16].

Throughout this paper, we use the usual notation for Sobolev and Hölder spaces. Single bars $|\cdot|$ denote absolute values or matrix norms; double bars $\|\cdot\|$ indicate function norms. In the proofs, we shall sometimes use the same letter C for various constants that may change from line to line.

1. Local existence of solutions. In this section, we want to give conditions under which the integro-differential equation

$$(1.1)\qquad u_{tt}(x,t)-u_{xxt}(x,t)=\int_0^\infty g(s,u_x(x,t)-u_x(x,t-s))_x\,ds+f(x,t)$$

with initial conditions

$$(1.2)\qquad u_t(x,0)=u_1(x),\ u(x,t)=u_0(x,t)\quad\text{for } t\leqq 0$$

and boundary conditions

$$(1.3)\qquad u(j,t)=f_j(t),\quad\text{or}$$

$$(1.4)\qquad u_{xt}(j,t)+\int_0^\infty g(s,u_x(j,t)-u_x(j,t-s))\,ds=h_j(t)$$

has a unique local (in time) smooth solution. Here, $x\in I=[0,1]$ and $j\in\{0,1\}$. We write (1.1) resp. (1.4) in the abstract forms

$$(1.5)\qquad u_{tt}(x,t)-u_{xxt}(x,t)=\mathbf{F}(u)(x,t),\quad\text{respectively,}$$

$$(1.6)\qquad u_{xt}(j,t)=\mathbf{G}_j(u)(x,t),$$

assuming that $\mathbf{F}$ and $\mathbf{G}_j$ are defined for smooth functions $u: I\times(-\infty,T]\to\mathbb{R}$ for any $T<\infty$ and are of "Volterra-type," that is, for any $0\leqq t\leqq T$

$$(1.7)\quad u=v \text{ on } I\times(-\infty,t]\Rightarrow \mathbf{F}(u)=\mathbf{F}(v)\text{ on } I\times[0,t],\ \mathbf{G}_j(u)=\mathbf{G}_j(v)\text{ on }[0,t].$$

Also, since the unknown function u is given on $I\times(-\infty,0]$ and since it should be continuous across $t=0$, one can incorporate u_0 into the definition of $\mathbf{F}$ and $\mathbf{G}_j$ and assume that these operators are actually defined on a suitable subspace of $C(I\times[0,T],\mathbb{R})$. The modified initial conditions for the problems (1.3), (1.5) resp. (1.5), (1.6) will then be

$$(1.8)\qquad u_t(x,0)=u_1(x),\qquad u(x,0)=u_0(x)\quad\text{for } x\in I.$$

One has corresponding linear boundary value problems which have the form (after integrating once with respect to t)

$$\begin{aligned} &w_t - w_{xx} = \varphi \quad \text{on } I \times [0, T], \\ &w(j, t) = \psi_j(t) \quad (j = 0, 1), \quad w(x, 0) = w_0(x), \end{aligned} \tag{1.9}$$

$$\begin{aligned} &w_t - w_{xx} = \varphi \quad \text{on } I \times [0, T], \\ &w_x(j, t) = \eta_j(t) \quad (j = 0, 1), \quad w(x, 0) = w_0(x). \end{aligned} \tag{1.10}$$

As is well known, these problems have unique solutions $w = \mathbf{L}_1(\varphi, \psi_j, w_0)$ (for (1.9)) and $w = \mathbf{L}_2(\varphi, \eta_j, w_0)$ (for (1.10)) in various classes of differentiable or integrable functions; $\mathbf{L}_1$ and $\mathbf{L}_2$ are in fact Volterra integral operators with weakly singular kernels (see [9], [14]). Therefore, (1.3), (1.5), (1.8), resp. (1.5), (1.6), (1.8), can be rewritten as integral equations. We shall first look for solutions of these integral equations and then show that in the situation studied here these "mild" solutions are in fact smooth functions, satisfying the original integro-differential equations (1.1)-(1.4). We abbreviate $C^{i,j}(T) = C^i([0, T], C^j(I, \mathbb{R}))$ and $C^i(T) = C^i([0, T], \mathbb{R})$ for various integer and noninteger values of i and j and write $\|u\|_{C^{i,j}(T)}$ etc. for the corresponding norms.

The main assumptions on $\mathbf{F}$ and $\mathbf{G}_j$ are

(1.11) $\mathbf{F} : C^{0,2}(T) \to C^{0,0}(T)$ is uniformly Lipschitz-continuous on any bounded set in $C^{0,2}(T)$,

(1.12) $\mathbf{G}_j : C^{0,2}(T) \to C^0(T)$ is uniformly Lipschitz-continuous on any bounded set in $C^{0,2}(T)$.

THEOREM 1.1. *Let $\mathbf{F}$, $\mathbf{G}_0$, $\mathbf{G}_1$ be Volterra-type operators with the Lipschitz properties* (1.11), (1.12), *and let u_0, $u_1 : I \to \mathbb{R}$, $f_0, f_1 : [0, T] \to \mathbb{R}$ be given functions.*

(a) *If $u_0 \in C^2(I)$, $u_1 \in C(I)$, $f_j' \in C^\alpha(T)$ for some $0 < \alpha < 1$, and*

$$u_0(j) = f_j(0), \qquad u_1(j) = f_j'(0) \quad \text{for } j = 0, 1, \tag{1.13}$$

then there exists a number $t_0 > 0$ and a unique solution u of

$$u_t(x, t) - u_{xx}(x, t) = \int_0^t \mathbf{F}(u)(x, s)\, ds + u_1(x) - u_0''(x) \tag{1.14}$$

on $I \times [0, t_0]$ that attains the initial and boundary values (1.3), (1.8) *and for which u_t and u_{xx} are still continuous on $I \times [0, t_0]$.*

(b) *If $u_0 \in C^2(I)$, $u_1 \in C(I)$, then there exists a unique solution u of* (1.14) *on some $I \times [0, t_0]$, satisfying* (1.8) *and the boundary conditions*

$$u_x(j, t) = u_0'(j) + \int_0^t \mathbf{G}_j(u)(s)\, ds, \qquad j = 0, 1 \tag{1.15}$$

and for which u_t and u_{xx} are continuous on $I \times [0, t_0]$.

The proof will be given by means of a standard fixed point argument. We first prepare a few well-known results concerning the solvability of the corresponding linear problems.

LEMMA 1.2. *Let $\mathbf{L}_1$ resp. $\mathbf{L}_2$ be the solution operators of the linear initial boundary value problems* (1.9) *resp.* (1.10).

(a) *If $\varphi \in C^{\alpha,0}(T)$, $0 < \alpha < 1$, $\varphi(j, 0) = 0$, then $\|\mathbf{L}_1(\varphi, 0, 0)\|_{C^{0,2}(T)} \leqq C_1 \cdot \|\varphi\|_{C^{\alpha,0}(T)}$ and $[\mathbf{L}_1(\varphi, 0, 0)]_{xx} \in C^{\beta,0}(T)$ for any $\beta < \alpha$.*

(b) *If $\psi_j' \in C^\alpha(T)$, $\psi_j(0) = \psi_j'(0) = 0$, then for $w = \mathbf{L}_1(0, \psi_j, 0)$, w_t and w_{xx} are Hölder-continuous in $I \times [0, T]$ (with exponents α with respect to t,* min $(2\alpha, 1)$ *with respect to x).*

(c) *If* $w_0\in C^2(I)$, $w_0(j)=w_0''(j)=0$, *then for* $w=\mathbf{L}_1(0,0,w_0)$, w_t *and* w_{xx} *are continuous on* $I\times[0,T]$ (*and analytic for* $t>0$).

(d) *If for some* $\alpha>0$, $\varphi\in C^{\alpha,0}(T)$, $\varphi(j,0)=0$, *then* $[\mathbf{L}_2(\varphi,0,0)]_{xx}\in C^{\gamma,0}(T)$ *for any* $\gamma<\alpha$, *and* $\|\mathbf{L}_2(\varphi,0,0)\|_{C^{0,2}(T)}\leqq C_2\cdot\|\varphi\|_{C^{\alpha,0}(T)}$.

(e) *If for some* $\beta>\frac{1}{2}, \eta_j\in C^{\beta}(T)$ *and* $\eta_j(0)=0$, *then* $[\mathbf{L}_2(0,\eta_j,0)]_{xx}\in C^{\gamma,0}(T)$ *for* $\gamma=2\beta-1$ *and* $\|\mathbf{L}_2(0,\eta_j,0)\|_{C^{0,2}(T)}\leqq C_3\cdot(\|\eta_0\|_{C^{\beta}(T)}+\|\eta_1\|_{C^{\beta}(T)})$.

(f) *If* $w_0\in C^2(I)$, $w_0'(j)=0$, *then for* $w=\mathbf{L}_2(0,0,w_0)$, w_t *and* w_{xx} *are continuous on* $I\times[0,T]$ (*and analytic for* $t>0$).

Here, the C_i depend only on T, α, and β.

These regularity results are neither optimal nor exhaustive, but they suffice for our purposes. Parts (a) and (d) follow from the representation formulae for inhomogeneous heat equations,

$$\mathbf{L}_j(\varphi,0,0)(x,t)=\int_0^t\int_0^1 H_j(x,y,t-s)\varphi(y,s)\,dy\,ds \quad \text{with}$$

$$H_1(x,y,t)=(4\pi t)^{-1/2}\sum_{-\infty}^{\infty}(\exp(-(x-y+2k)^2/4t)-\exp(-(x+y+2k)^2/4t))$$

and $H_2(x,y,t)=\int_x^1 H_{1y}(\zeta,y,t)\,d\zeta+1$ (see [9]), and from the facts that the solution semigroups $v\to S_i(t)(v)$, $S_i(t)(v)(x)=\int_0^1 H_i(x,y,t)v(y)\,dy$, map $C(I)$ into $C^2(I)$ with norms that can be estimated by $C\cdot t^{-1}$, as can be checked directly (see [1]).

The estimates in (a) and (d) then follow in a standard fashion, first for smooth φ and then by approximation in the general case (this is where the compatibility condition in (a) is needed). Parts (b) and (e) are special cases of the general regularity theory for parabolic equations ([9], [14]). Part (c) and (f) again follow from the facts that $\mathbf{L}_i(0,0,w_0)(x,t)=S_i(t)(w_0)(x)$ and that the S_i are suitable analytic semigroups.

Proof of Theorem 1.1. We abbreviate $\mathbf{JF}(u)(x,t)=\int_0^t \mathbf{F}(u)(x,s)\,ds$. To prove part (a), we look for a solution of (1.14) with the corresponding boundary conditions, i.e., for a solution u of

$$\begin{aligned}u&=\mathbf{L}_1(u_1-u_0''+\mathbf{JF}(u),f_j,u_0)\\&=\mathbf{L}_1(u_1-u_0'',f_j,u_0)+\mathbf{L}_1(\mathbf{JF}(u),0,0)=v_1+\mathbf{L}_1(\mathbf{JF}(u),0,0).\end{aligned}\tag{1.16}$$

Since $v_1(x,t)=u_0(x)+t\cdot u_2(x)+\mathbf{L}_1(u_1-u_2,0,0)+\mathbf{L}_1(0,g_j,0)$, with $u_2(x)=(1-x)u_1(0)+xu_1(1)$, $g_j(t)=f_j(t)-u_0(j)-t\cdot u_1(j)$, Lemma 1.2 shows that $v_1\in C^{0,2}(T)$, and we rewrite (1.16) with $v=u-v_1$ as

$$v=\mathbf{L}_1(\mathbf{JF}(v+v_1),0,0).\tag{1.17}$$

Fix $\gamma\in(0,1)$, let $M=\|v_1\|_{C^{0,2}(T)}$ and let K be the Lipschitz constant for $\mathbf{F}$ on the set $B_0=\{w\in C^{0,2}(T)\,|\,\|w\|_{C^{0,2}(T)}\leqq 2M\}$. Let $t_0>0$ be so small that

$$C_1\cdot t_0^{1-\gamma}(\|\mathbf{L}_1(\mathbf{F}(v_1),0,0)\|_{C^{0,0}(T)}+2M)\leqq M,\tag{1.18}$$

and

$$C_1\cdot t_0^{1-\gamma}K\leqq\tfrac{1}{2},\tag{1.19}$$

where $C_1=C_1(\gamma,T)$ is as in Lemma 1.2(a). Then for $w_1,w_2\in B_0$

$$\begin{aligned}\|\mathbf{L}_1(\mathbf{JF}(w_1),0,0)-\mathbf{L}_1(\mathbf{JF}(w_2),0,0)\|_{C^{0,2}(t_0)}&\leqq C_1\cdot\|J(\mathbf{F}(w_1)-\mathbf{F}(w_2))\|_{C^{\beta,0}(t_0)}\\&\leqq C_1\cdot t_0^{1-\gamma}\|\mathbf{F}(w_1)-\mathbf{F}(w_2)\|_{C^{0,0}(t_0)}\\&\leqq C_1\cdot t_0^{1-\gamma}\cdot K\cdot\|w_1-w_2\|_{C^{0,2}(t_0)}.\end{aligned}\tag{1.20}$$

Using (1.18) and (1.19), it follows that the operator $v \to \mathbf{L}_1(\mathbf{JF}(v_1+v), 0, 0)$ is a contraction from the complete metric space $B_1 = \{v \in C^{0,2}(t_0) \mid \|v\|_{C^{0,2}(t_0)} \leqq 2M\}$ into itself. Therefore it has a unique fixed point v. By Lemma 1.2(a), v_t and v_{xx} are also continuous; therefore $u = v + v_1$ is the desired solution of (1.14) with the corresponding boundary conditions. To prove part (b), we look for a solution of

$$u = \mathbf{L}_2(u_1 - u_0'' + \mathbf{JF}(u), u_0'(j) + \mathbf{JG}_j(u), u_0)$$
$$= \mathbf{L}_2(u_1 - u_0'', u_0'(j), u_0) + \mathbf{L}_2(\mathbf{JF}(u), 0, 0) + \mathbf{L}_2(0, \mathbf{JG}_j(u), 0)$$

and apply a similar argument, noting that $\mathbf{L}_2(u_1 - u_0'', u_0'(j), u_0)$ will again have continuous first time and second space derivatives in $I \times [0, T]$ by Lemma 1.2(d)-(f). □

It follows from the proofs that the solutions of both problems will exist on all $I \times [0, T]$ as soon as an a priori estimate in $C^{0,2}(T)$ is known, since the existence interval $[0, t_0]$ can then be fixed a priori and the solutions can successively be continued on $[t_0, 2t_0]$, $[2t_0, 3t_0]$, etc.

As a consequence, we obtain an existence-uniqueness theorem for the original integro-differential equations. Here, the general assumptions will be

(1.21) $g: (0, \infty) \times \mathbb{R} \to \mathbb{R}$, g_t and g_u are jointly continuous on $(0, \infty) \times \mathbb{R}$,

(1.22) $g_u(\cdot, 0) \in L^1(0, \infty; \mathbb{R})$; if $|v|, |w| \leqq R$, then,

$|g_u(t, v) - g_u(t, w)| \leqq a_R(t) \cdot |v - w|$ with some $a_R(\cdot) \in L^1(0, \infty; \mathbb{R})$,

(1.23) u_0 and $u_{0,xx}$ are bounded and continuous on $I \times (-\infty, 0]$.

THEOREM 1.3. (a) *If $u_1 \in C(I)$, $f_j' \in C^\alpha(T)$ for some $0 < \alpha < 1$, $f \in C^{0,0}(T)$, and if* (1.13) *holds, then there are a $t_0 > 0$ and a unique classical solution u on $I \times [0, t_0]$ of*

$$u_t(x, t) - u_{xx}(x, t) = u_1(x) - u_0''(x)$$
$$(1.24) \qquad + \int_0^t \left\{ \int_0^\infty g(s - \tau, u_x(x, s) - u_x(x, s - \tau))_x \, d\tau + f(x, s) \right\} ds$$

that satisfies the initial and boundary conditions (1.2), (1.3).

(b) *If $u_1 \in C(I)$, $h_j \in C^0(T)$, then there are $t_0 > 0$ and a unique classical solution u of* (1.24) *on $I \times [0, t_0]$ that satisfies the initial condition* (1.3) *and the boundary condition*

$$(1.25) \qquad u_x(j, t) + \int_0^t \int_0^\infty g(s - \tau, u_x(j, s) - u_x(j, s - \tau)) \, d\tau \, ds = u_0'(j) + \int_0^t h_j(s) \, ds.$$

Proof. For $v \in C^{0,2}(T)$, define $\mathbf{F}(v)(x, t) = \int_0^\infty g(s - \tau, v_x(x, t) - v_x(x, t - \tau))_x \, d\tau + f(x, t)$, and $v(x, t) = u_0(x, t)$ for $t < 0$; $v(x, t) = v(x, t) - v(x, 0) + u_0(x, 0)$ for $t \geqq 0$. One easily checks that all conditions in Theorem 1.1(a) are met, and part (a) follows. Part (b) is proved similarly by defining suitable operators $\mathbf{G}_j$. □

One can use the quasilinear structure of (1.1) to deduce a $C^{0,2}(T)$-bound for the solution from a $C^{0,1}(T)$-bound.

COROLLARY 1.4. *If in* (1.22) *$a_R(\cdot)$ can be chosen independently from R, then the solution found in Theorem* 1.3 *can be continued on all $I \times [0, T]$. In particular, if the derivative of a solution u_x can be a priori bounded uniformly on any existence set $I \times [0, t_0]$, then u exists as a solution on $I \times [0, T]$.*

Proof. Carrying out the differentiation, one sees that (1.24) can be written as

$$(1.26) \qquad u_t(x, t) - u_{xx}(x, t) = \int_0^t b(x, t, s) \cdot u_{xx}(x, s) \, ds + f_2(x, t)$$

with a suitable $f_2 \in C^{1,0}(T^*)$ and certain continuous coefficients b, both depending on the data u_0 and on the solution, where $I \times [0, T^*]$ is any existence set. Under the assumptions given above, both b and f_2 will be uniformly bounded, with bounds depending only on the data. Abbreviating the integro-differential operator on the right-hand side of (1.24) by **K**, we then have for all $1 < p < \infty$ and all $t > 0$ with $\|u\|_{L^p(t)} = \|u\|_{L^p(I \times [0,t])}$

$$\|\mathbf{K}(u)\|_{L^p(t)} \leqq C(p) \cdot \int_0^t \|u_{xx}\|_{L^p(s)}\, ds. \tag{1.27}$$

By standard regularity results for parabolic equations in L^p-spaces [14], it follows that for the solution of (1.2), (1.3), (1.24)

$$\|u_{xx}\|_{L^p(t)} + \|u_t\|_{L^p(t)} \leqq C \cdot \left(1 + \int_0^t \|u_{xx}\|_{L^p(s)}\, ds\right).$$

Gronwall's lemma implies bounds $\|u_{xx}\|_{L^p(T^*)} + \|u_t\|_{L^p(T^*)} \leqq C(p)$ on $I \times [0, T^*]$ and by standard imbedding theorems [14], u_x is a priori bounded in $C^{\beta,0}(T^*) \cap C^{0,2\beta}(T^*)$ for any $0 < \beta < \frac{1}{2}$. This implies that in (1.26) the derivatives b_t are also uniformly Hölder-continuous in x and t and that f_2 is Hölder-continuous in t, with exponents and bounds depending only on the data. Therefore, we have estimates

$$\|\mathbf{K}(u)\|_{C^{1,0}(t)} \leqq C \cdot \|u_{xx}\|_{C^{0,0}(t)}, \tag{1.28}$$

$$\|\mathbf{K}(u)\|_{C^{0,0}(t)} \leqq C \cdot \int_0^t \|u_{xx}\|_{C^{0,0}(s)}\, ds. \tag{1.29}$$

Hence by interpolation

$$\|\mathbf{K}(u)\|_{C^{\alpha,0}(t)} \leqq \varepsilon \cdot \|u_{xx}\|_{C^{0,0}(t)} + C(\varepsilon) \cdot \int_0^t \|u_{xx}\|_{C^{0,0}(s)}\, ds \tag{1.30}$$

for any $\varepsilon > 0$, $0 < \alpha < 1$, with some $C(\varepsilon) > 0$. Thus by Lemma 1.2(a)-(c)

$$\|u_{xx}\|_{C^{0,0}(t)} \leqq C^* \cdot \left(\varepsilon \cdot \|u_{xx}\|_{C^{0,0}(t)} + C(\varepsilon) \cdot \int_0^t \|u_{xx}\|_{C^{0,0}(s)}\, ds + 1\right) \tag{1.31}$$

with C^* a universal constant. Choosing $C^* \cdot \varepsilon < \frac{1}{2}$ and using Gronwall's lemma, an a priori estimate for u in $C^{0,2}(T^*)$ follows, which implies that the solution exists on $I \times [0, T]$.

A similar argument applies in case (b). In addition to (1.27), we use here that the boundary operators $J\mathbf{G}_j$ satisfy sublinear estimates as mappings from $L^p(0, T; W^{2,p}(I)) \cap W^{1,p}([0, T], L^p(I))$ into $C^0(T)$, if $p > 3$ (cf. [14]), using first L^p-theory and then the regularity estimates of Lemma 1.2(d)-(f).

Finally, if u_x is a priori uniformly bounded on any existence interval by, say, $R > 0$, then $g(t, v)$ can be made constant for $|v| > R + 1$ without changing the equation satisfied by u. Therefore, we can choose $a(\cdot) = a_{R+1}(\cdot)$ in (1.22) and the previous arguments imply a $C^{0,2}$-bound and the continuability for the solution. □

We conclude this section with some remarks concerning the question under which additional assumptions the solutions found in Theorem 1.3 will actually satisfy (1.1) and (1.4).

First, since the right-hand side of (1.1) is always bounded for the solutions found above, (1.1) will hold a.e. (in fact, in any $L^p_{\text{loc}}((0, 1) \times (\varepsilon, t_0))$, $p < \infty$, $\varepsilon > 0$). Also, if in case (a) the f_j are in $C^2(T)$, then u_{tt} and u_{xxt} will still be in any $L^p((0, 1) \times (\varepsilon, t_0))$, $\varepsilon > 0$. For such a result to be true in case (b), one will need that $h_j' \in C^1(T)$, and one can either assume more regularity for the data u_0 (e.g., $u_{0x}(j,\cdot)\in C^{1/2}((-\infty,0])$ will suffice), or more t-regularity for g, e.g.,

$$\int_0^h |g(s,v)|\,ds \leqq C_R\cdot h^\gamma, \tag{1.32}$$

$$|g(t+h,v)-g(t,v)|\leqq b_R(t)\cdot h^\gamma \quad \text{if } |v|\leqq R, \tag{1.33}$$

for any small h, with some $\gamma\geqq\frac{1}{2}$.

To obtain classical solutions of (1.1) on all $I\times[0,t_0]$ in case (a), it will be sufficient to assume that also $u_1''\in C(I)$, $f\in C^{\alpha,0}(T)$, $f_j''\in C^\alpha(T)$, and that either $u_{0,xx}\in C^\alpha((-\infty,0],C(I))$ or that (1.33) and (1.32) hold also for g_u instead of g with some $\gamma>0$. Also, the natural compatibility condition $f_j''(0)-u_1''(j)=\int_0^\infty g(s,u_{0x}(j,0)-u_{0x}(j,-s))_x\,ds+f(j,0)$ will be needed for $j=0,1$. Similarly, in case (b) we will have a classical solution of (1.1), (1.4), if $u_1''\in C(I)$, $f\in C^{\alpha,0}(T)$, $h_j\in C^\gamma(T)$ with $\gamma>\frac{1}{2}$, and if corresponding conditions hold that guarantee that the right-hand side of (1.1) is in $C^{\alpha,0}(T)$ and the right-hand side of (1.4) is in $C^\gamma(T)$ with some $\gamma>\frac{1}{2}$. We omit the details, which are similar to the conditions in case (a). All arguments leading to these conditions are straightforward applications of the regularity theory for parabolic equations.

2. Global existence for the boundary displacement problem. In this section conditions are given under which problem (1.1)–(1.3) has global solutions for arbitrary forces f, initial histories u_0 and boundary displacements f_j. We assume without loss of generality that $g(t,0)=0$ and define

$$G(t,u)=\int_0^u g(t,v)\,dv \quad \text{for } t>0, \qquad u\in\mathbb{R}. \tag{2.1}$$

We shall obtain pointwise a priori estimates on the displacement gradient u_x, based on

(i) a natural energy estimate, using the variational structure of the integral operator in (1.1);

(ii) a comparison argument for scalar integro-differential equations, using a technique from [1].

We always assume in this and the following sections that $t\cdot G_t(t,u)$ is still integrable for $0<t\leqq 1$; more precisely, it will be assumed that for all $t>0$, $|u|\leqq R$, $|G_t(t,u)\cdot\min(1,t)|\leqq d_R(t)$, with $d_R(\cdot)\in L^1(0,\infty)$. Also, the L^2-norm on the interval I will be abbreviated by $\|\cdot\|$, and we write $\langle\cdot,\cdot\rangle$ for the inner product on $L^2(I)$.

To carry out the first step, the key assumption on the integral operator is the following.

(H1) There exist $C_0\geqq 0$, $C_1\in L^1(0,\infty;\mathbb{R}^+)$ such that for all $t>0$, $u\in\mathbb{R}$,

$$G(t,u)\geqq -C_1(t)\cdot(u^2+1), \qquad G_t(t,u)\leqq C_0\cdot(G(t,u)+C_1(t)\cdot(u^2+1)), \tag{2.2}$$

$$|g(t,u)|\leqq C_0\cdot(G(t,u)+C_1(t)\cdot(u^2+1)). \tag{2.3}$$

LEMMA 2.1. *Let g satisfy* (H1) *and the assumptions from Theorem* 1.3, *let u_0, u_1 and f be as in Theorem* 1.3 *and let $f_1,f_2\in C^2(T)$. Then there exists a constant $C^*>0$, depending only on the data, T, C_0, and C_1, such that for any solution u of the integrated equations* (1.2), (1.3), (1.24) *on $I\times[0,T_0]$ and for any $0\leqq t\leqq T_0$*

$$\|u_t(\cdot,t)\|^2+\int_0^\infty\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds+\int_0^t \|u_{xt}(\cdot,s)\|^2\,ds\leqq C^*. \tag{2.4}$$

Proof. We can assume that $f_j(t)=w(j,t)$ and w_x is x-independent. Define

$$E(t)=\|u_t(\cdot,t)-w_t(\cdot,t)\|^2/2+\int_0^\infty\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds, \tag{2.5}$$

$$E_1(t)=E(t)+\int_0^\infty C_1(s)\{\|u_x(\cdot,t)-u_x(\cdot,t-s)\|^2+1\}\,ds \tag{2.6}$$

for $0\leqq t\leqq T_0$. Note that $E_1(t)\geqq 0$ by (2.2).

The remarks following Corollary 1.4 show that (1.1) will hold in any $L^p(I\times(\varepsilon,T_0))$, $\varepsilon>0$, p finite. Consequently, u_{xt} is still continuous in any $I\times(\varepsilon,T_0]$, and by the integrability assumption for $t\cdot G_t(t,u)$, $E(\cdot)$ is absolutely continuous on any $(\varepsilon,T_0]$. Differentiating (2.5) then gives, for a.e. t

$$\begin{aligned} d/dt\,E(t)&=\langle u_t(\cdot,t)-w_t(\cdot,t),u_{tt}(\cdot,t)-w_{tt}(\cdot,t)\rangle\\ &\quad+\int_0^\infty\int_I G_s(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds\\ &\quad+\int_0^\infty\langle g(s,u_x(\cdot,t)-u_x(\cdot,t-s)),u_{xt}(\cdot,t)\rangle\,ds\\ &\leqq\langle u_t(\cdot,t)-w_t(\cdot,t),u_{tt}(\cdot,t)\rangle+C\cdot(E_1(t)+1) \qquad (2.7)\\ &\quad+\int_0^\infty\langle g(s,u_x(\cdot,t)-u_x(\cdot,t-s)),u_{xt}(\cdot,t)-w_{xt}(\cdot,t)\rangle\,ds\\ &=\left\langle u_t(\cdot,t)-w_t(\cdot,t),u_{tt}(\cdot,t)-\int_0^\infty g(s,u_x(\cdot,t)-u_x(\cdot,t-s))_x\,ds\right\rangle\\ &\quad+C\cdot(E_1(t)+1), \end{aligned}$$

using an integration by parts. Inserting (1.1) into the last estimate, integrating the product $\langle u_t-w_t,u_{xxt}\rangle$ by parts and estimating further we obtain

$$\begin{aligned} d/dt\,E(t)&\leqq-\langle u_{xt}(\cdot,t)-w_{xt}(\cdot,t),u_{xt}(\cdot,t)\rangle+C\cdot(E_1(t)+1)\\ &\leqq-\tfrac{1}{2}\|u_{xt}(\cdot,t)\|^2+C\cdot(E_1(t)+1). \end{aligned} \tag{2.8}$$

Integrating (2.8) from ε to t and sending ε to 0, we obtain

$$\begin{aligned} &E_1(t)+\frac{1}{2}\int_0^t\|u_{xt}(\cdot,s)\|^2\,ds\\ &\leqq C\cdot\left(\int_0^t E_1(s)\,ds+1\right)+\int_0^\infty C_1(s)\{\|u_x(\cdot,t)-u_x(\cdot,t-s)\|^2+1\}\,ds \qquad (2.9)\\ &\leqq K\cdot\left(\int_0^t E_1(s)\,ds+\|u_x(x,t)\|^2+1\right)+2\int_0^t C_1(t-s)\cdot\|u_x(\cdot,s)\|^2\,ds \end{aligned}$$

with $K>0$. Now, for any δ and some constant C_δ (depending also on u_0)

$$\|u_x(\cdot,t)\|^2\leqq\delta\cdot\int_0^t\|u_{xs}(\cdot,s)\|^2\,ds+C_\delta\cdot\left(\int_0^t\int_0^s\|u_{xs}(\cdot,\tau)\|^2\,d\tau\,ds+1\right).$$

Pick δ such that $K\cdot\delta=\frac{1}{4}$; then (2.9) implies an estimate of the form

$$\begin{aligned}&E_1(t)+\frac{1}{4}\int_0^t \|u_{xt}(\cdot,s)\|^2\,ds\\ &\quad\leqq C\cdot\left(1+\int_0^t(1+C_1(t-s))\cdot\left(E_1(s)+\int_0^s\|u_{xt}(\cdot,\tau)\|^2\,d\tau\right)ds\right).\end{aligned}\tag{2.10}$$

This implies a bound for $E_1(t)$, and (2.4) follows. □

We now deduce a uniform a priori estimate for u_x, if additionally

(H2) $g(t,u)=g_0(t,u)+L(t)u$, with $L(\cdot)\in L^1(0,\infty;\mathbb{R})$ and g_0 nondecreasing.

THEOREM 2.2. *Assume that* u_0, u_1, *and* f *are as in Theorem* 1.3, *that* $f_0,f_1\in C^2(T)$, *and that* g *satisfies the assumptions of Theorem* 1.3 *as well as* (H1) *and* (H2). *Let* u *be a solution of* (1.2), (1.3), (1.24) *on some set* $I\times[0,T_0]$. *Then there exists a constant* C^*, *depending only on the data and on* T, *but not on* T_0, *such that*

$$|u_x(x,t)|\leqq C^*\quad\text{on } I\times[0,T_0],\tag{2.11}$$

and thus u *can be extended as a solution on* $I\times[0,T]$.

Proof. We use a version of a technique introduced in [1]. For fixed (x,t), integrate (1.1) (which holds a.e.) from $y\in[0,1]$ to x and then from 0 to 1 with respect to y. Using the abbreviation

$$p(x,t)=\int_0^1\int_y^x u_t(\zeta,t)\,d\zeta\,dy,\tag{2.12}$$

we get the identity (valid for all (x,t) due to the regularity of u)

$$\begin{aligned}&(u_x(x,t)-p(x,t))_t+\int_0^\infty g(s,u_x(x,t)-u_x(x,t-s))\,ds\\ &\quad=\int_0^\infty\int_I g(s,u_x(y,t)-u_x(y,t-s))\,dy\,ds+f_1(t)-f_0(t)\\ &\qquad-\int_0^1\int_y^x f(\zeta,t)\,d\zeta\,dy=:k(x,t).\end{aligned}\tag{2.13}$$

Now from Lemma 2.1 $|p(x,t)|$ is bounded independently of x and t, and (2.3) and (2.4) imply that also $|k(x,t)|$ is uniformly bounded. Dropping the x-dependence and using (H2), we obtain

$$\begin{aligned}&w'(t)+\int_0^t g_0(t-s,w(t)-w(s)+p(t)-p(s))\,ds+L_0\cdot w(t)\\ &\quad+\int_0^\infty g_0(t+s,w(t)+p(t)-k_0(s))\,ds=k_1(t)+\int_0^\infty L(t-s)w(s)\,ds\end{aligned}\tag{2.14}$$

with $w(t)=u_x(x,t)-p(x,t)$, $L_0=\int_0^\infty L(s)\,ds$, and suitable functions k_0, k_1 that are a priori bounded. Also, $|w(0)|\leqq\|u_{0,x}\|_{C(I)}+\|u_1\|_{C(I)}=M_0$. Assume now that for some minimal $t>0$ and all $0\leqq s<t$, $|w(t)|=(1+M_0)\cdot e^{Mt}$, $|w(s)|<(1+M_0)\cdot e^{Ms}$, where M is some arbitrary constant. If, e.g., $w(t)>0$, then consequently $w'(t)\geqq(1+M_0)\cdot M\cdot e^{Mt}=M\cdot w(t)$, and for $0\leqq s<t$, $w(s)\leqq|w(s)|\leqq e^{M(t-s)}w(t)$. Then (2.14)

implies

$$
\begin{aligned}
(1+M_0)\cdot M\cdot e^{Mt} &\leqq |L_0|\cdot(1+M_0)\cdot e^{Mt}+\int_0^t |L(s)|\,e^{-Ms}\,ds\cdot(1+M_0)\cdot e^{Mt}\\
&\quad+|k_1(t)|+\left|\int_0^t g_0(t-s,p(t)-p(s))\,ds\right|\\
&\quad+\left|\int_0^\infty g_0(t+s,p(t)-k_0(s))\,ds\right|\\
&\leqq C+(1+M_0)\cdot e^{Mt}\cdot\left(|L_0|+\int_0^\infty |L(s)|\cdot e^{-Ms}\,ds\right)
\end{aligned}
\tag{2.15}
$$

with some fixed constant C. It is clear that (2.15) can never hold if $M>(C+|L_0|+\int_0^\infty |L(s)|\cdot e^{-Ms}\,ds)$. A similar contradiction can be derived if $w(t)=-(1+M_0)\cdot e^{Mt}$ and M is sufficiently large. Therefore, $|w(t)|\leqq(1+M_0)\cdot e^{Mt}$ for all t, which gives the desired a priori bound for u_x. Corollary 1.4 then implies that the solution u exists on all $I\times[0,T]$. □

In [1] the second order equation $u_{tt}=u_{xxt}+\sigma(u_x)_x$ is treated, and a differential equation (instead of an integro-differential equation) is derived for w, which allows us to find a t-independent a priori bound. It is not clear how to do this in our situation. However, under suitable assumptions (that are satisfied in the setting of § 4), an a priori bound for $|u_x(x,t)|$ can be deduced that grows linearly in t.

COROLLARY 2.3. *Assume that in* (2.4) C^* *does not depend on* T, *that* f, f_0' *and* f_1' *are uniformly bounded, that in* (H2) $L=0$, *and that also* $\|u_x(\cdot,t)\|\leqq C^*$, *independent of* t. *Then there exists a constant* $K>0$, *dependent only on the data, such that for all* $(x,t)\in I\times[0,\infty)$

$$|u_x(x,t)|\leqq K\cdot(1+t).$$

Proof. Using the same arguments as in the proof above, one deduces (2.13) and observes that the assumptions imply that the right-hand side of (2.13) is bounded, independent of x and t. Thus (2.14) follows with $L_0=0=L(\cdot)$ and with uniformly bounded functions k_0, k_1 and p. Denote again by M_0 a common bound for $|w(0)|$; for arbitrary $M>0$, we then assume that for some $t>0$, $|w(t)|=(1+M_0)\cdot(1+M\cdot t)$ and $|w(s)|<(1+M_0)\cdot(1+M\cdot s)$ for $s<t$. An inequality similar to (2.15) follows which leads to a contradiction, if M is too big. This proves the corollary. □

3. Global solutions for the boundary traction problem. In this section, conditions are given under which the problem (1.1), (1.2), (1.4) has global solutions for arbitrary forces f, h_j and for arbitrary initial histories u_0. Again, we assume that $g(t,0)=0$ and define $G(t,u)$ as in (2.1). Instead of (H1), we shall use the weaker assumption

(H1′) There exist $C_0\geqq 0$, $C_1\in L^1(0,\infty;\mathbb{R}^+)$ such that for all $t>0$, $u\in\mathbb{R}$,

$$G(t,u)\geqq -C_1(t)\cdot(u^2+1),\tag{3.1}$$

$$G_t(t,u)\leqq C_0\cdot(G(t,u)+C_1(t)\cdot(u^2+1)).\tag{3.2}$$

We also assume the same integrability properties for $G_t(t,u)$ and the same abbreviations as in the previous section.

THEOREM 3.1. *Let* g *satisfy the assumptions of Theorem* 1.3, (H1′) *and* (H2). *Let* u_0, u_1, f *and* h_j *be as in Theorem* 1.3, $h_j\in C^1(T)$, *and assume that* $u_{0,x}(j,\cdot)\in C^{1/2}((-\infty,0],\mathbb{R})$ *for* $j=0,1$. *Then there exists a solution* u *of the integrated equations* (1.24), (1.25), (1.3) *on all* $I\times[0,T]$.

Proof. We use an energy estimate as in Lemma 2.1 and a comparison argument as in the proof of Theorem 2.2. Define

$$E(t)=\|u_t(\cdot,t)\|^2/2+\int_0^\infty\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds, \tag{3.3}$$

$$E_1(t)=E(t)+\int_0^\infty C_1(s)\cdot(\|u_x(\cdot,t)-u_x(\cdot,t-s)\|^2+1)\,ds. \tag{3.4}$$

By the same arguments as in the proof of Lemma 2.1, $E(\cdot)$ is absolutely continuous on any interval $[\varepsilon, T_0]$, and by differentiating we obtain (cf. (2.7))

$$\begin{aligned} d/dt\,E(t)&\leqq\langle u_t(\cdot,t),u_{tt}(\cdot,t)\rangle+C_0\cdot E_1(t)\\ &\quad+\left\langle u_{xt}(\cdot,t),\int_0^\infty g(s,u_x(\cdot,t)-u_x(\cdot,t-s))\,ds\right\rangle. \end{aligned}$$

Note that the assumptions imply that u_{tt} and u_{xxt} exist in $L^p(I\times(\varepsilon,T_0))$. Integrating the last integral on the right-hand side by parts with respect to x, inserting the equation and integrating by parts again gives

$$\begin{aligned} d/dt\,E(t)&\leqq-\|u_{xt}(\cdot,t)\|^2+\langle u_t(\cdot,t),f(\cdot,t)\rangle\\ &\quad+u_t(1,t)\cdot h_1(t)-u_t(0,t)\cdot h_0(t)+C_0\cdot E_1(t). \end{aligned}$$

Since the boundary power terms can be estimated by, e.g.,

$$|u_t(1,t)\cdot h_1(t)|\leqq\tfrac14\|u_{xt}(\cdot,t)\|^2+C\cdot(1+\|u_t(\cdot,t)\|^2),$$

we obtain an estimate

$$d/dt\,E(t)\leqq-\|u_{xt}(\cdot,t)\|^2/2+C\cdot(E_1(t)+1).$$

The rest of the argument is as in the proof of Lemma 2.1, and therefore

$$\|u_t(\cdot,t)\|^2\leqq C^*(t), \tag{3.5}$$

where the locally bounded function $C^*(\cdot)$ depends only on the data. Integrating now (1.1) (which holds locally in the L^p-sense) from $y=0$ to $y=x$ and abbreviating $q(x,t)=\int_0^x u_t(y,t)\,dy$, we obtain (for all (x,t))

$$\begin{aligned} (u_x(x,t)-q(x,t))_t&+\int_0^\infty g(s,u_x(x,t)-u_x(x,t-s))\,ds\\ &=h_0(t)-\int_0^x f(y,t)\,dy=k(x,t). \end{aligned} \tag{3.6}$$

Since (3.5) implies that q is uniformly bounded, we can use the same argument as in the proof of Theorem 2.2 to infer that $w=u_x-q$ is a priori bounded, which implies the theorem. □

We note that the argument given here still applies in the case where one of the boundary conditions is of traction type and the displacement is prescribed on the other boundary. Obviously a local existence result and the same continuability properties as in § 1 will hold for such a problem. If, e.g., $u(1,t)=f_1(t)$ is prescribed (with traction forces h_0 acting at $x=0$), then one defines the energy

$$E(t)=\|u_t(\cdot,t)-f_1'(t)\|^2/2+\int_0^\infty\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds$$

and uses the same arguments as above to arrive at the estimate (3.5). The comparison argument remains unchanged.

Also, $|u_x(x,t)|$ can be shown to grow linearly in t (uniformly in x) by using an argument that is similar to the one in Corollary 2.3 under the weaker assumptions that in (H2) $L(\cdot)=0$, that h_0 and f are uniformly bounded, and that in (3.5) $C^*(\cdot)$ does not depend on t (cf. the following section). Finally, by examining the proof of Theorem 3.1, one notices that both the estimates (3.5) and the bound on w depend only on the supremum norms of the h_j and of u_0 and $u_{0,x}$. Therefore, we can approximate any smooth h_j and any u_0 which is only continuous together with its second space derivatives by Hölder-continuous data and still obtain uniformly bounded solutions on all $I\times[0,T]$ which will approximate the solution of the original problem (by uniqueness). Consequently, we have the following corollary.

COROLLARY 3.2. *The statement of Theorem* 3.1 *remains true if only* $h_j\in C^0(T)$ *and* u_0 *and* $u_{0,xx}$ *are bounded and continuous on* $I\times(-\infty,0]$.

4. Asymptotic behavior of solutions. In this section we show decay estimates for the derivatives of the solutions of (1.1)-(1.4) which imply their convergence to a steady state u_∞. Instead of (1.1), the equation

$$u_{tt}(x,t)-\eta\cdot u_{xxt}(x,t)=\int_0^\infty g(s,u_x(x,t)-u_x(x,t-s))_x\,ds+f(x,t) \tag{4.1}$$

will be studied with $\eta>0$, and (1.4) will be replaced by

$$\eta\cdot u_{xt}(j,t)+\int_0^\infty g(s,u_x(j,t)-u_x(j,t-s))\,ds=h_j(t). \tag{4.2}$$

Of course, (4.1) and (4.2) are equivalent to (1.1) and (1.4) by rescaling; here we want to display the dependence of the estimates on the "viscosity" η.

The key hypothesis for g in addition to (H1), (H1′), (H2) for both the boundary displacement and the boundary traction problems will be

(H3) $0=G(t,0)\leqq G(t,u)$ for all $u\in\mathbb{R}$, $t>0$;

there is a constant $\delta>0$ such that for all $u\in\mathbb{R}$, $t>0$

$$G_t(t,u)+\delta\cdot G(t,u)\leqq 0. \tag{4.3}$$

THEOREM 4.1. *Let g satisfy the general assumptions of* § 1 *as well as* (H1), (H2), (H3). *Let* u_0, u_1 *and* f *be as in Theorem* 1.3(a) *and assume that* f_0 *and* f_1 *are t-independent. Let* $b:[0,\infty)\to[0,\infty)$ *be continuously differentiable,* $b(0)=1$, *and assume that* $0\leqq b'(t)\leqq\kappa\cdot b(t)$ *for some* $\kappa\leqq\delta$, $\kappa<2\eta\pi^2$. *Then for all* $t>0$ *and for any solution of* (1.2), (1.3), (4.1)

$$\|u_t(\cdot,t)\|\cdot b^{1/2}(t)\leqq C(u_0,u_1)^{1/2}+\int_0^t\|f(\cdot,s)\|\cdot b^{1/2}(s)\,ds, \tag{4.4}$$

$$\begin{aligned}\int_0^t b(s)\cdot\|u_{xt}(\cdot,s)\|^2\,ds&\leqq 2\pi^2(2\eta\pi^2-\kappa)^{-1}\\&\quad\cdot\left\{C(u_0,u_1)+\left(\int_0^t\|f(\cdot,s)\|\cdot b^{1/2}(s)\,ds\right)^2\right\},\end{aligned} \tag{4.5}$$

where $C(u_0,u_1)=\|u_1(\cdot)\|^2+2\cdot\int_0^\infty\int_I G(s,u_{0,x}(x,0)-u_{0,x}(x,-s))\,dx\,ds$.

COROLLARY 4.2. *Under the assumptions of Theorem* 4.1, *and if*

$$\int_0^\infty \|f(\cdot,s)\|\cdot b^{1/2}(s)\,ds<\infty, \tag{4.6}$$

$$\int_0^\infty b^{-1}(s)\,ds<\infty, \tag{4.7}$$

then there exists $u_\infty \in W^{1,2}(I,\mathbb{R})$ *with* $u_\infty(j)=f_j$ $(j=0,1)$ *such that*

$$\|u_x(\cdot,t)-u_{\infty x}(\cdot)\|^2=O\left(\int_t^\infty b^{-1}(s)\,ds\right)\quad \textit{as } t\to\infty. \tag{4.8}$$

Proof of the corollary. For $0<t<s$ we have

$$\begin{aligned}\|u_x(\cdot,t)-u_x(\cdot,s)\|^2&\leqq\left\|\int_t^s u_{xt}(\cdot,\tau)\,d\tau\right\|^2\\ &\leqq\int_t^s \|u_{xt}(\cdot,\tau)\|^2\cdot b(\tau)\,d\tau\cdot\int_t^s b^{-1}(\tau)\,d\tau\leqq C\cdot\int_t^s b^{-1}(\tau)\,d\tau.\end{aligned} \tag{4.9}$$

Then (4.5) and (4.7) imply that $t\to u(\cdot,t)$ has a limit in $W^{1,2}(I,\mathbb{R})$, as $t\to\infty$. Sending $s\to\infty$ in (4.9), the convergence estimate (4.8) follows. □

In the case $g=0$ (where (4.1) reduces to the heat equation), the existence of u_∞ already follows if (4.6) holds with $b(t)=1$; thus the convergence result certainly is not optimal. Also, we do not quite recover the "optimal" convergence rate $\|u(\cdot,t)-u_\infty\|\sim\exp(-\eta\pi^2 t)$ for $g=0$ and $f=0$.

For the case of the boundary traction problem (4.1), (4.2), (1.2) we introduce some additional notation: Let u be a solution. Define the mean displacement $U(t)=\int_I u(x,t)\,dx$ and $u^*(x,t)=u(x,t)-U(t)$. Then U can be computed from the equation; we have

$$U(t)=\int_I u_0(x)\,dx+t\cdot\int_I u_1(x)\,dx+\int_0^t (t-s)(F(s)+h_1(s)-h_0(s))\,ds, \tag{4.10}$$

where $F(t)=\int_I f(x,t)\,dx$ is the mean body force. Also, define $f^*(x,t)=f(x,t)-F(t)$. Then u^* will again satisfy (4.1) and (4.2), with f replaced by f^*, and additionally, $\int_I u^*(x,t)\,dx=0$ for all t.

THEOREM 4.3. *Let g satisfy the assumptions of* § 1, *as well as* (H1′), (H2) *and* (H3). *Let u_0, u_1, f and h_j be as in Theorem* 1.3(b), *and let b be as in Theorem* 4.1. *Then there is a constant $C_1>0$ such that for all $t>0$ and any solution u of* (1.2), (4.1), (4.2)

$$\begin{aligned}&b(t)\cdot\|u_t^*(\cdot,t)\|^2+\int_0^t b(s)\cdot\|u_{xt}(\cdot,s)\|^2\,ds\\ &\leqq C_1\left\{\left(\left(\int_0^t \|f(\cdot,s)\|+|h_0(s)|+|h_1(s)|\right)\cdot b^{1/2}(s)\,ds\right)^2\right.\\ &\qquad\left.+\int_0^t b(s)\cdot(h_0^2(s)+h_1^2(s))\,ds+C(u_0,u_1)\right\}\end{aligned} \tag{4.11}$$

where $C(u_0,u_1)$ is as in Theorem 4.1.

COROLLARY 4.4. *If*

$$\|f(x,\cdot)\|\cdot b^{1/2}(\cdot)\in L^1(0,\infty;\mathbb{R})\quad\textit{and}\quad h_j(\cdot)\cdot b^{1/2}(\cdot)\in L^1\cap L^2(0,\infty;\mathbb{R}), \tag{4.12}$$

and if (4.7) *holds, then there is a* $u_\infty \in W^{1,2}(I, \mathbb{R})$, $\int_I u_\infty(x)\,dx = 0$, *so that*

$$\|u(\cdot, t) - U(t) - u_\infty\|_{W^{1,2}} = O\left(\int_t^\infty b^{-1}(s)\,ds\right) \quad \text{as } t \to \infty. \tag{4.13}$$

The proof is similar to the one of Corollary 4.2.

In both convergence results, we are not able to deduce equations for the rest state u_∞. This reflects the fact that any t-independent function satisfies the equation (4.1), if $f = 0$. The only exception seems to be the case of a linear g, in which (4.1) is equivalent to a convolution equation (with a first time derivative), for which an equation for the rest state can be deduced: If $g(s, v) = a(s) \cdot v$ with $a(t) \geqq 0 \geqq a'(t) + \delta \cdot a(t)$ and $a(\cdot) \in L^1(0, \infty)$ (reflecting (H1) and (H3)), then (4.1) is equivalent to

$$u_t(x, t) - \eta \cdot u_{xx}(x, t) = \int_0^\infty a_0(s) \cdot u_{xx}(x, t - s)\,ds + f_0(x, t) \tag{4.14}$$

with $a_0(t) = \int_t^\infty a(s)\,ds$ and $f_0(\cdot, t) = u_1(\cdot) - \eta \cdot u_{0,xx}(\cdot, 0) - \int_0^\infty a_0(s) u_{0,xx}(\cdot, -s)\,ds + \int_0^t f(\cdot, s)\,ds$. Since (H1) and (H3) imply that $0 \leqq a_{00} = \int_0^\infty a_0(s)\,ds < \infty$, the limit u_∞ then satisfies

$$(\eta + a_{00}) \cdot u_{\infty,xx} + u_1 + \int_0^\infty f(\cdot, s)\,ds = \eta u_{0,xx}(\cdot, 0) + \int_0^\infty a_0(s) u_{0,xx}(\cdot, -s)\,ds. \tag{4.15}$$

This shows that $u_\infty \in W^{2,2}(I)$ in the case of a linear equation and suggests that the same should also be true for solutions of general nonlinear equations; however, it is not clear how to show this. A certain improvement is possible if a sublinear growth bound for $|u_x(x, t)|$ is known.

COROLLARY 4.5. *Under the assumptions of Corollary* 4.2, *and if in* (H2) $L(\cdot) = 0$, *then* $b^{-1}(t) = O(t^{-\alpha})$ *for some* $\alpha > 1$ *implies that*

$$\|u(\cdot, t) - u_\infty(\cdot)\|_{W^{1,p}} = O(t^{-\beta}) \tag{4.16}$$

for any $2 < p < \alpha + 1$, *with* $\beta = (\alpha + 1 - p)/p$. *Similarly,* $b^{-1}(t) = O(e^{-\gamma t})$ *implies*

$$\|u(\cdot, t) - u_\infty(\cdot)\|_{W^{1,p}} = O(e^{-\beta t}) \tag{4.17}$$

for any $2 < p < \infty$ *and any* $\beta < \gamma/p$.

Proof. The assumptions and conclusions of Corollary 4.2 together with the additional assumption $L(\cdot) = 0$ allow us to use Corollary 2.3 to conclude that $|u_x(x, t)| \leqq K \cdot (1 + t)$ for all (x, t), with $K > 0$ depending on the data. Now let $0 < t < s < \infty$, and let $k \geqq 0$ be such that $2^k t \leqq s < 2^{k+1} t$. Then for $2 < p$, writing $\|\cdot\|_p$ for the $L^p(I)$-norm and abbreviating $v = u_x$, we have

$$\begin{aligned}
\|v(\cdot, t) - v(\cdot, s)\|_p &\leqq \sum_{1 \leqq j \leqq k} \|v(\cdot, 2^{j-1}t) - v(\cdot, 2^j t)\|_p + \|v(\cdot, 2^k t) - v(\cdot, s)\|_p \\
&\leqq \sum_{1 \leqq j \leqq k} (\|v(\cdot, 2^{j-1}t) - v(\cdot, 2^j t)\|_\infty)^{1-2/p} (\|v(\cdot, 2^{j-1}t) - v(\cdot, 2^j t)\|_2)^{2/p} \\
&\quad + (\|v(\cdot, 2^k t) - v(\cdot, s)\|_\infty)^{1-2/p} (\|v(\cdot, 2^k t) - v(\cdot, s)\|_2)^{2/p} \\
&\leqq C \cdot \sum_{1 \leqq j \leqq k+1} (2^j t)^{1-2/p} \left(\int_{2^{j-1}t}^{2^j t} b^{-1}(s)\,ds\right)^{1/p},
\end{aligned} \tag{4.18}$$

using Hölder's inequality, the L^∞-estimate for u_x and (4.9). A direct calculation then shows that $u_x(\cdot, t)$ has a limit in $L^p(I)$ with the convergence rates given in (4.16) and (4.17). □

Proof of Theorem 4.1. Recall that under our assumptions, (4.1) still holds in any $L^p(I\times(T_0, T_1))$ for any finite p, T_0, T_1, and that u_{tt} and u_{xxt} are in these L^p-spaces. Also, by Theorem 2.2, u_x is uniformly bounded on any $I\times[0, T]$. Multiply (4.1) by $b(t)\cdot u_t(x, t)$, and integrate over $I\times[0, T]$. After an integration by parts with respect to x, this gives the identity

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}(b(t)\cdot\|u_t(\cdot,t)\|^2)-\frac{1}{2}b'(t)\cdot\|u_t(\cdot,t)\|^2\\ \text{(4.19)}\qquad &+\eta b(t)\cdot\|u_{xt}(\cdot,t)\|^2+\int_0^\infty b(t)\cdot\langle g(s,u_x(\cdot,t)-u_x(\cdot,t-s)),u_{xt}(\cdot,t)\rangle ds\\ &=b(t)\cdot\langle f(\cdot,t),u_t(\cdot,t)\rangle.\end{aligned}$$

We now note that for $t>0$, $t\to\int_0^\infty b(t)\cdot\int_I G(s, u_x(x,t)-u_x(x,t-s))\,dx\,ds$ is absolutely continuous in t (since u_{xt} is still bounded on any $I\times[T_0, T_1]$, $0<T_0<T_1$) and that for a.e. t

$$\begin{aligned}&\frac{d}{dt}\int_0^\infty b(t)\cdot\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds\\ \text{(4.20)}\qquad &\leqq\int_0^\infty b(t)\cdot\langle g(s,u_x(\cdot,t)-u_x(\cdot,t-s)),u_{xt}(\cdot,t)\rangle\,ds\end{aligned}$$

due to (H3), the assumptions on b' and the behavior of G_t near $t=0$. Also, since u_t vanishes at the endpoints of I, by Poincaré's inequality

$$\begin{aligned}&-\tfrac{1}{2}b'(t)\cdot\|u_t(\cdot,t)\|^2+\eta\cdot b(t)\cdot\|u_{xt}(\cdot,t)\|^2\\ \text{(4.21)}\qquad &\geqq b(t)\cdot(\eta\cdot\|u_{xt}(\cdot,t)\|^2-\tfrac{1}{2}\kappa\cdot\|u_t(\cdot,t)\|^2)\\ &\geqq b(t)\cdot(2\pi^2\eta-\kappa)(2\pi^2)^{-1}\cdot\|u_{xt}(\cdot,t)\|^2.\end{aligned}$$

Substituting (4.20) and (4.21) into (4.19), integrating over $[\varepsilon, t]$ and sending ε to 0, we obtain with $c=(2\pi^2\eta-\kappa)(2\pi^2)^{-1}$

$$\begin{aligned}&\frac{1}{2}b(t)\cdot\|u_t(\cdot,t)\|^2+c\cdot\int_0^t b(s)\cdot\|u_{xt}(\cdot,s)\|^2\,ds\\ \text{(4.22)}\qquad &+\int_0^\infty b(t)\cdot\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds\\ &\leqq\frac{1}{2}C(u_0,u_1)+\int_0^t\|f(x,s)\|\cdot b^{1/2}(s)\cdot\|u_t(\cdot,s)\|\cdot b^{1/2}(s)\,ds.\end{aligned}$$

We now drop the second integral on the left-hand side of (4.22) and apply Bihari's inequality [4]; then (4.4) follows. Inserting this estimate into the right-hand side of (4.22) and dropping the first and third integral on the left-hand side gives (4.5). □

Proof of Theorem 4.3. By an approximation argument similar to the one leading to Corollary 3.2, we can assume that the h_j and the data u_0 are so regular that (4.1) holds in any L^p_{loc}, that u_t and u_{xxt} are locally in L^p and that (4.2) holds pointwise for $t>0$. Recall that (4.1) and (4.2) also hold for u^*, with f^* instead of f. Multiply the equation for u^* with $b(t)\cdot u_t^*$, integrate with respect to x and use (4.20) to obtain

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}(b(t)\cdot\|u_t^*(\cdot,t)\|^2)-\frac{1}{2}b'(t)\cdot\|u_t^*(\cdot,t)\|^2\\ &\quad+\eta b(t)\cdot\|u_{xt}(\cdot,t)\|^2+d/dt\int_0^\infty b(t)\cdot\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds\\ &\leqq b(t)\cdot(\langle f^*(\cdot,t),u_t^*(\cdot,t)\rangle+(h_0(t)\cdot u^*(0,t)-h_1(t)\cdot u^*(1,t))).\end{aligned}\tag{4.23}$$

Since $\int_I u^*(x,t)\,dx=0$, Poincaré's inequality implies again

$$-\tfrac{1}{2}b'(t)\cdot\|u_t^*(\cdot,t)\|^2+\eta\cdot b(t)\cdot\|u_{xt}(\cdot,t)\|^2\geqq b(t)\cdot c\cdot\|u_{xt}(\cdot,t)\|^2\tag{4.24}$$

with $c=(2\pi^2\eta-\kappa)(2\pi^2)^{-1}$. Also, for any $\gamma>0$ there exists $C_\gamma>0$ such that

$$\begin{aligned}|h_j(t)\cdot u_t^*(j,t)\cdot b(t)|&\leqq\gamma\cdot b(t)\cdot\|u_{xt}(\cdot,t)\|^2+b(t)\cdot h_j^2(t)\\ &\quad+C_\gamma\cdot b(t)\cdot|h_j(t)|\cdot\|u_t^*(\cdot,t)\|,\end{aligned}\tag{4.25}$$

due to the compactness of the imbedding $\{u^*\in W^{1,2}|\int_I u^*\,dx=0\}$ into $C(I)$. Picking $\gamma=C/4$, inserting (4.24) and (4.25) into (4.23), and integrating with respect to t then gives again (4.11) as before. □

Finally, it should be noted that the arguments above also give estimates

$$b(t)\cdot\int_0^\infty\int_I G(s,u_x(x,t)-u_x(x,t-s))\,dx\,ds\leqq C(t),\tag{4.26}$$

where $C(t)$ is the right-hand side in (4.4) resp. in (4.11). If, e.g., (2.3) is satisfied with $C_1(t)=0$, then (4.26) implies that the right-hand side of (1.1) still decays in a certain sense in $W^{-1,2}(I)$. This, together with suitable asymptotic results for weak solutions of inhomogeneous heat equations, can be used to show that $u_{xxt}(\cdot,t)$ and $u_{tt}(\cdot,t)$ decay to zero in $W^{-1,2}(I)$, as $t\to\infty$.

5. Simple shear flow for viscoelastic liquids. In this section, we apply the previous results to a class of equations that model a certain unsteady flow for certain non-Newtonian liquids. Typical examples for such liquids are polymer solutions, such as glues, paints, engine fuels with polymer additives or protein mixtures. The liquid is assumed to occupy a reference configuration at time $t=-\infty$ with a Lagrangian coordinate system $\boldsymbol{\xi}=(\xi^1,\xi^2,\xi^3)$. Let $\mathbf{y}(\boldsymbol{\xi},t)$ denote the position of the fluid particle $\boldsymbol{\xi}$ at time $t>-\infty$, let $\mathbf{T}(\boldsymbol{\xi},t)$ denote the Cauchy stress at $\boldsymbol{\xi}$ and t (i.e. the stress measured with respect to the deformed configuration), and let

$$\mathbf{F}(\boldsymbol{\xi},t)=\mathbf{F}=\left(\frac{\partial y^i}{\partial\xi^j}\right)_{ij}$$

be the deformation gradient. Assuming that the material is incompressible (i.e. det $\mathbf{F}=1$) and has density ρ, the equations of motion are

$$\rho\cdot\mathbf{y}_{tt}=\operatorname{div}_{\boldsymbol{\xi}}(\mathbf{T}\cdot\mathbf{F}^{-T})+\mathbf{f},\tag{5.1}$$

where $\mathbf{f}$ denotes body forces and the superscript $^{-T}$ indicates the operation of taking the inverse of the transpose of a matrix (see [11]). It is customary to write constitutive equations for elastic liquids in terms of the "upper convected stress" $\pi=\mathbf{F}^{-1}\cdot\mathbf{T}\cdot\mathbf{F}^{-T}$ and the Cauchy strains $\boldsymbol{\gamma}(\boldsymbol{\xi},t)=\mathbf{F}^T(\boldsymbol{\xi},t)\cdot\mathbf{F}(\boldsymbol{\xi},t)$. Using the relative strain invariants

$$I_1(\xi, t, s) = \operatorname{tr}(\gamma(\xi, t) \cdot \gamma^{-1}(\xi, s)), \qquad I_2(\xi, t, s) = \operatorname{tr}(\gamma^{-1}(\xi, t) \cdot \gamma(\xi, s)), \tag{5.2}$$

a wide class of constitutive equations can then be written as

$$\begin{aligned} \pi(t) &= -p(t)\gamma^{-1}(t) - \eta \cdot \partial_t \gamma^{-1}(t) \\ &\quad + \int_0^\infty W_1(s, I_1(t, t-s), I_2(t, t-s)) \cdot \gamma^{-1}(t-s)\, ds \\ &\quad - \int_0^\infty W_2(s, I_1(t, t-s), I_2(t, t-s)) \cdot \gamma^{-1}(t) \cdot \gamma(t-s) \cdot \gamma^{-1}(t)\, ds, \end{aligned} \tag{5.3}$$

where $W_i : \mathbb{R}^+ \times [3, \infty)^2 \to \mathbb{R}$ are suitable functions, $p(t)$ is an undetermined (reactive) pressure and $\eta \geqq 0$ is (Newtonian) dynamic viscosity. The dependence on the particle ξ has been suppressed. Special cases include viscous ($\eta > 0$) and inviscid ($\eta = 0$) Newtonian fluids ($W_i = 0$); various "rubberlike liquid" models, in which typically $W_i(t, I_1, I_2) = a_i(t)$ (cf. [3], [15] and the literature given there); the "K-BKZ-model" [2] in which $W_j = \partial_{I_j} W(t, I_1, I_2)$ for some scalar function W; in particular the "Doi-Edwards" model [7], which is a K-BKZ-model [5], derived from molecular considerations, with the separable structure $W(t, I_1, I_2) = a(t) \cdot W_0(I_1, I_2)$; and various empirical models, in which one often assumes a semi-separable structure

$$W_j(t, I_1, I_2) = \sum_{k \leqq N} a_{kj}(t) \cdot g_{kj}(I_1, I_2) \tag{5.4}$$

(see, e.g., [17]). Some of these models have originally been proposed for the case of vanishing dynamic viscosity η (corresponding to, e.g., concentrated polymer solutions or polymer melts); we shall, however, always assume that $\eta > 0$.

We want to study simple shear flow between two parallel infinite plates (parallel to the y^1-y^2-plane) of unit separation (in the y^3-direction). Using Lagrangian coordinates ξ that agree with the spatial coordinates $\mathbf{y}$, we are thus looking for a motion of the special form $y^1(\xi, t) = \xi^1 + u(\xi^3, t)$, $y^i(\xi, t) = \xi^i$ for $i = 2, 3$, with volume forces acting only in the y^1-direction and depending only on t and ξ^3. It turns out that such an *ansatz* is consistent with the equations of motion and with the constitutive assumption (5.3). One finds that in this situation $I_1(\xi, t, s) = I_2(\xi, t, s) = 3 + |u_x(x, t) - u_x(x, s)|^2$ (writing x for ξ^3), and (5.1) becomes, assuming constant density $\rho = 1$,

$$u_{tt}(x, t) = \eta \cdot u_{xxt}(x, t) + \int_0^\infty g(s, u_x(x, t) - u_x(x, t-s))_x\, ds + f(x, t), \tag{5.5}$$

where $g(s, v) = (W_1(s, 3 + v^2, 3 + v^2) + W_2(s, 3 + v^2, 3 + v^2)) \cdot v$ and f is the sum of the force component f^1 and a contribution from the pressure gradient in the flow direction.

If the liquid adheres to the plates which move parallel to the flow direction, one obtains the boundary conditions (1.2); if traction forces of magnitude $h_1(t)$ and $-h_0(t)$ in the y^1-direction act on the liquid at the plates, boundary conditions (1.4) arise. In applications, one frequently has $h_j = 0$, which means that there is a lubricant between the plates and the liquid. We do not discuss friction type boundary conditions, although similar results could be shown with the methods employed above. The flow history for $t \leqq 0$ is given by u_0; u_1 is the flow velocity at $t = 0$ (which is allowed to have a jump across $t = 0$). The results obtained in the previous section then have the following interpretations:

(i) For smooth flow histories and smooth forces and displacements, (5.1) with the corresponding boundary conditions has a unique local (in time) solution. This holds in fact for completely general flows and for a much wider class of constitutive equations, as was shown in [18].

(ii) One has global existence for arbitrary forces and initial histories, if, e.g., in (5.4) the a_{ki} are nonincreasing, C^1-smooth for $t>0$ and integrable on $(0,\infty)$ and if the g_{ki} satisfy $\partial/\partial v(g_{ki}(3+v^2, 3+v^2)\cdot v) \geqq -M$ for all $v \in \mathbb{R}$ and some constant M. This class of functions includes polynomially growing functions and the case in which the g_{ki} are rational functions of their arguments that vanish at ∞ (see [17]) or, as in the Doi-Edwards model, derivatives of certain elliptic integrals (see [5]). The first assumption would describe a "shear-thickening" liquid, the last two correspond to liquids that show a "shear-thinning" behavior (which is commonly observed). We note that in this latter case, the integral operator in (5.5) satisfies a global Lipschitz condition, such that the arguments of §§ 2 and 3 will in fact not be needed. Also, our assumptions allow weakly singular kernels a_{kj}, which are predicted by some molecular theories (see [7]).

(iii) If, e.g., in (5.4) for some $\delta>0$

$$a'_{ki}(t)+\delta\cdot a_{ki}(t)\leqq 0, \tag{5.6}$$

and

$$\int_0^v g_{ki}(3+r^2, 3+r^2)\cdot r\,dr \geqq 0 \quad \text{for all } v\in\mathbb{R}, \tag{5.7}$$

then forces that decay like $e^{-\gamma t}$ with $\gamma<\min(\delta, 2\eta\pi^2)$ give a displacement u in a boundary traction experiment that reaches a steady state at the same rate. This will also hold for flows with prescribed boundary displacement, if the plates are kept fixed after a certain finite time. If the forces decay at a weaker (e.g. algebraic) rate, the flow velocity will again decay at a comparable rate. It is not claimed that these rates are optimal, but they show the interplay between the force decay (measured by γ), the Newtonian dissipation mechanism (given by η) and the dissipation due to the history dependence in the constitutive law (expressed by δ). Also, no ellipticity conditions are needed for the differential operators under the integrals in (5.5); such conditions will rather play a role in the case of vanishing Newtonian viscosity η (see [19]) or for the study of steady flows. Assumptions (5.6) and (5.7) are always true for various "rubber-like liquid" models as well as for the Doi-Edwards model with additional Newtonian viscosity. Finally, using (4.22), one can also show that for decaying volume forces, space averages of shear stresses and of normal stress differences will decay at the same rate.

Acknowledgment. The author wishes to thank the referee of an earlier version of this paper for several helpful hints.

SOLUTIONS TO THE KORTEWEG–DE VRIES EQUATION WITH INITIAL PROFILE IN $L_1^1(\mathbb{R}) \cap L_N^1(\mathbb{R}^+)$*

AMY COHEN† AND THOMAS KAPPELER‡

Abstract. The Cauchy problem for the Korteweg-deVries equation is considered with initial profile integrable against $(1+|x|)\,dx$ on $\mathbb{R}$ and against $(1+|x|)^N\,dx$ on $\mathbb{R}^+$. Classical solutions are constructed for $N \geqq 11/4$. Under mild additional hypotheses the solution evolves in $L^2(\mathbb{R})$.

Key words. Korteweg-de Vries equation, inverse scattering method

AMS(MOS) subject classification. 35Q20

1. Introduction and summary of results. This paper considers the initial value problem for the Korteweg-deVries equation (KdV),

$$u_t - 6uu_x + u_{xxx} = 0, \tag{1.1}$$

$$u(x,0) = U(x), \tag{1.2}$$

under the hypothesis that

$$\int_{-\infty}^{\infty} |U(x)|(1+|x|)\,dx < \infty, \tag{1.3a}$$

$$\int_{0}^{\infty} |U(x)|(1+|x|)^N\,dx < \infty. \tag{1.3b}$$

No differentiability is assumed at all. The goal is to find the range of N such that the problem (1.1), (1.2) has a solution. Our existence theorem is based on a construction suggested by the inverse scattering method. We show that if $N \geqq 11/4$, then a classical solution exists in $t > 0$ which approaches its initial profile in an appropriate distribution sense as $t \to 0^+$.

These results improve considerably on earlier work of the first author [3], which required that U be at least piecewise C^1 as well as that U be integrable against $(1+|x|)^N\,dx$ on $\mathbb{R}$ for large enough N. By using Kappeler's new L^2 inverse scattering result [8], we are also able to get control over our solution as $x \to -\infty$, at least for U satisfying a rather mild additional hypothesis. These results also improve on work of Sachs [14], who requires that $U(x)$ be integrable against $(1+|x|)^N\,dx$ on all of $\mathbb{R}$ with $N > 11/4$ rather than only on $\mathbb{R}^+$ with $N \geqq 11/4$. Sachs claims convergence to initial profile in a weighted L^1 norm on each halfline $[a, +\infty)$; it appears that his proof of this point is flawed.

There is no direct comparison between our results and the very interesting paper of Kruzhkov and Faminskii [11], in which they prove the existence of a weak solution to KdV with arbitrary L^2 initial data, and show that the solution is classical if the datum is not only L^2 on $\mathbb{R}$ but also L^2 with respect to $(1+|x|)^3\,dx$ on $\mathbb{R}^+$. While Sachs' paper uses a different inverse scattering construction from ours (Deift and Trubowitz [5] rather than Faddeev [6]), Kruzhkov and Faminskii use a different approach altogether: they cut off and mollify their initial profile, apply results of Yakupov [19] and Shabat [16] solving KdV with data in $C_0^\infty(\mathbb{R})$, and then take limits.

In their pioneering paper [7], Gardner, Greene, Kruskal and Miura showed that if $u(x, t)$ solved KdV and evolved in the Schwartz class $\mathcal{S}$, then the scattering data of the Schrödinger equation

$$-y''+u(x,t)y=k^2y \tag{1.4}$$

evolved according to simple first order linear o.d.e.'s in the variable t. By appealing to Faddeev's inverse scattering theory [6], they showed that $u(x, t)$ for $t>0$ could be recovered from $u(x, 0)$. This idea has been the basis for a succession of existence theorems [17], [3], [13], [14] employing progressively weaker hypotheses on the initial profile U.

Rather than give a detailed exposition of the forward scattering theory of (1.4) we refer the reader to Cohen's paper [4].

In § 2 we analyze the scattering data associated to (1.4) under the hypothesis $U\in L^1_N(\mathbb{R})$, i.e., U is integrable with respect to $(1+|x|^N)\,dx$, with $N\geqq 1$. The main result is Proposition 2.5 which says that generically the reflection coefficient R_+ is in $C^{N-1}(\mathbb{R})\cap C^N(\mathbb{R}\sim\{0\})$ and $\lim_{k\to 0} kR_+{}^{(N)}(k)$ exists—but that if U is exceptional, then R_+ is only in $C^{N-2}(\mathbb{R})\cap C^{N-1}(\mathbb{R}\sim\{0\})$ and $\lim_{k\to 0} kR_+{}^{(N-1)}(k)$ exists.

In § 3 we analyze the kernels $\Omega_+(x, t)$ and $\Omega_-(x, t)$ used in the Marchenko equations

$$B_+(x,y,t)+\Omega_+(x+y,t)+\int_0^\infty B_+(x,z,t)\Omega_+(x+y+z,t)\,dz=0, \tag{M+}$$

$$B_-(x,y,t)+\Omega_-(x+y,t)+\int_{-\infty}^0 B_-(x,z,t)\Omega_-(x+y+z,t)\,dz=0. \tag{M−}$$

What Gardner, Green, Kruskal and Miura showed was that if $u(x, t)$ solves KdV, and $\Omega_\pm$ are as defined below, then

$$u(x,t)=-\partial_x B_+(x,0,t)=+\partial_x B_-(x,0,t).$$

The kernels are defined as follows:

$$\Omega_+(x,t)=F_+(x,t)+2\sum c_{+j}\exp(-2\kappa_j x+8\kappa_j^3 t)$$

where

$$F_+(x,t)=\pi^{-1}\int_{-\infty}^\infty R_+(k)\exp(2ikx+8ik^3t)\,dk$$

and

$$\Omega_-(x,t)=F_-(x,t)+2\sum c_{-j}\exp(2\kappa_j x-8\kappa_j^3 t)$$

where

$$F_-(x,t)=\pi^{-1}\int_{-\infty}^\infty R_-(k)\exp(-2ikx-8ik^3t)\,dk.$$

Clearly the existence, regularity and decay of the $B_\pm(x, y, t)$ depend on the regularity and decay of the $\Omega_\pm$. In § 3, we show that for each fixed $t>0$, $\partial_x^\nu\Omega_+(x, t)$ is continuous for $0\leqq\nu\leqq 2N+3/2$ and establish algebraic decay rates as $x\to+\infty$ for these derivatives. We also analyze the decay and regularity of $\Omega_+(x, t)$ using the properties of R_+ proved in Proposition 2.5. To study F_-, we note just that R_- is quite similar to R_+ in its regularity and decay. Then we see that the decay of Ω_- is controlled by that of F_- and that the integral for F_- has stationary points when $x<0$. Nonetheless we find that if $U \in L^1_N$, $N \geqq 5$, and $R_-^{(n)}(k) = O(k^{-\lambda})$ for $\lambda \geqq 5/2$, then $\partial_x \Omega_-(x, t) = O(|x|^{-\lambda/2+1/4})$ as $x \to -\infty$.

In § 5 we prove sharper versions of the following results.

Result 1. Suppose U satisfies (1.3a) and (1.3b) with $N \geqq 11/4$. Then there is a classical solution $u(x, t)$ of KdV in $t > 0$ such that

$$u(x, t) \to U(x) \quad \text{in } H^{-1}(+\infty).$$

Result 2. Suppose that $U \in L^1_5(\mathbb{R}) \cap L^2(\mathbb{R})$ and that $R_+^{(n)}(k) = O(|k|^{-\lambda})$ as $k \to \pm\infty$ for some $\lambda > 5/2$, and $n = 0, 1, 2$. Then the solution given by Result 1 evolves in $L^2(\mathbb{R})$ for $t > 0$.

Result 3. Suppose that $N \geqq 3$ and that $U \in L^1_N(\mathbb{R})$ if U is generic but that $U \in L^1_{N+1}(\mathbb{R})$ if U is nongeneric. Suppose further that $(1+|x|)^{N-1}U(x)$ is in $L^2(\mathbb{R})$. If $u(x, t)$ is the solution to KdV given by Result 1, then $x^\alpha u(x, t) \to x^\alpha U(x)$ in $L^2(+\infty)$ as $t \to 0$ for $\alpha = 0$ and $\alpha = N - 1$.

We should also remark that the question of uniqueness is still largely open. Uniqueness is known for the initial value problem for KdV if the initial profile is in H^s with $s \geqq 3/2$ [2], [10], [15]. Uniqueness is also known within the class of solutions $u(x, t)$ such that $u(x, t)$ and $u_x(x, t)$ go to 0 as $x \to \pm\infty$ and $u_{xx}(x, t)$ is bounded as $x \to \pm\infty$ [12]. Kruzhkov and Faminskii [11] have shown that the problem (1.1), (1.2) is well posed in the class of functions U which are L^2 on $\mathbb{R}$ and L^2 with respect to a weight on $\mathbb{R}^+$. Unless we add to our minimal hypotheses we cannot show that our solution $u(x, t)$ evolves in a class where either of these uniqueness theorems applies.

Notational conventions. The operator ∂_x denotes the partial derivative with respect to the subscript variable.

$$f^*(x, k) = \text{the complex conjugate of } f(x, k).$$

In dealing with functions of x and k, prime (′) always denotes the x-derivative and dot (·) always denotes the k-derivative; thus

$$f'(x, k) = \partial_x f(x, k), \qquad \dot{f}(x, k) = \partial_k f(x, k).$$

The space $L^1_N(+\infty)$ consists of functions $g(x)$ such that

$$\int_X^\infty |g(x)|(1+|x|)^N \, dx < \infty \quad \text{for all finite } X.$$

The space $L^2(+\infty)$ consists of functions $g(x)$ such that

$$\int_X^\infty |g(x)|^2 \, dx < \infty \quad \text{for all finite } X.$$

We use aVb to denote $\max\{a, b\}$.

2. Analysis of the initial scattering data.

2.1. The Jost functions. Suppose that $U(x)$ belongs to $L^1_N(\mathbb{R})$ with $N \geqq 1$. Then the Jost functions for

$$-y'' + U(x)y = k^2 y \tag{2.1}$$

are the solutions $f_+(x, k)$ and $f_-(x, k)$ with the asymptotic behavior

$$f_+(x, k) \sim e^{+ikx} \quad \text{as } x \to +\infty, \qquad f_-(x, k) \sim e^{-ikx} \quad \text{as } x \to -\infty. \tag{2.2}$$

These exist for $\operatorname{Im} k \geqq 0$ and can be represented as

$$f_+(x, k) = e^{ikx} h_+(x, k), \qquad f_-(x, k) = e^{-ikx} h_-(x, k) \tag{2.3}$$

where

$$(2.4)\qquad h_+(x,k)=1+\int_0^\infty B_+(x,y)\,e^{2iky}\,dy,\qquad h_-(x,k)=1+\int_{-\infty}^0 B_-(x,y)\,e^{-2iky}\,dy$$

where, in turn,

$$B_\pm(x,\cdot)\in L^1(\mathbb{R}^\pm)\cap L^\infty(\mathbb{R}^\pm)\subset L^2(\mathbb{R}^\pm),$$

$$B_\pm(x,y)\quad\text{is continuous on }\mathbb{R}\times\mathbb{R}^\pm.$$

Here $\mathbb{R}^+=[0,\infty)$ and $\mathbb{R}^-=(-\infty,0]$. Moreover, the maps $x\to B_\pm(x,\cdot)$ are absolutely continuous and Fréchet differentiable from $\mathbb{R}$ to $L^1(\mathbb{R}^\pm)$. The following estimates are valid since $U\in L^1_1(\mathbb{R})$:

$$(2.5+)\qquad |B_\pm(x,y)|\leqq\left[\exp\left\{\int_x^\infty (t-x)|U(t)|\,dt\right\}\right]\int_{x+y}^\infty |U(t)|\,dt,$$

$$(2.6+)\qquad \begin{aligned}&|\partial_x B_+(x,y)+U(x+y)|\\&\leqq\left[\exp\left\{\int_x^\infty (t-x)|U(t)|\,dt\right\}\right]\int_x^\infty |U(t)|\,dt\int_{x+y}^\infty |U(s)|\,ds,\end{aligned}$$

$$(2.7+)\qquad \begin{aligned}&|\partial_y B_+(x,y)+U(x+y)|\\&\leqq 2\left[\exp\left\{\int_x^\infty (t-x)|U(t)|\,dt\right\}\right]\int_x^\infty |U(t)|\,dt\int_{x+y}^\infty |U(s)|\,ds.\end{aligned}$$

Analogous bounds (2.5−), (2.6−) and (2.7−) hold for $B_-(x,y)$, $\partial_x B_-(x,y)-U(x+y)$ and $\partial_y B_-(x,y)-U(x+y)$ in terms of integrals over left-half-lines. See [1], [3]-[6] for details. Applying these bounds to the forms (2.3), (2.4), one obtains the following.

PROPOSITION 2.1. *For any fixed* x, *the functions* $y^nB_+(x,y)$, $y^n\partial_xB_+(x,y)$, *and* $y^n\partial_yB_+(x,y)$ *are integrable over* $0<y<\infty$ *for* $0\leqq n\leqq N-1$. *Similar results hold for* B_- *with integrability over* $-\infty<y<0$.

It follows that $h_+(x,k)$ and $\partial_xh_+(x,k)$ are $(N-1)$ times continuously differentiable with respect to k. Indeed, if $1\leqq n\leqq N-1$ and $\operatorname{Im}k\geqq0$, then

$$(2.8)\qquad \partial_k^n[h_+(x,k)]=\int_0^\infty (2iy)^nB_+(x,y)\,e^{2iky}\,dy.$$

If in addition $k\neq0$, then an integration by parts yields

$$\partial_k^n[h_+(x,k)]\frac{-1}{2ik}\int_0^\infty [n(2iy)^{n-1}B_+(x,y)+(2iy)^n\partial_yB_+(x,y)]\,e^{2iky}\,dy.$$

Further

$$(2.9)\qquad \partial_k^n\partial_x^1[h_+(x,k)]=\int_0^\infty (2iy)^n\partial_xB_+(x,y)\,e^{2iky}\,dy.$$

Thus for $1\leqq n\leqq N-1$ and for each finite X, $k\partial_k^nh_+(x,k)$ and $\partial_k^n\partial_x^1h_+(x,k)$ are uniformly bounded on $\{(x,k)\colon x\geqq X \text{ and } \operatorname{Im}k\geqq0\}$.

It is possible to get better information about the regularity of $h_+(x,k)$ by using the approach of Deift and Trubowitz [5, p. 130]. Let

$$(2.10)\qquad D_k(y)=\int_0^y e^{2ikt}\,dt=(e^{2iky}-1)/2ik.$$

Deift and Trubowitz show that $h_+(x, k) = 1 + \int_x^\infty D_k(t-y)U(t)h_+(t, k)\,dt$. The next several propositions are similar to results in [4]-[6].

PROPOSITION 2.2. *Assume that $U \in L_N^1(\mathbb{R})$ with $N \geqq 1$. As functions of k with x fixed in $\mathbb{R}$, $h_+(x, k)$ and $\partial_x h_+(x, k)$ are C^{N-1} on $\{k\colon \operatorname{Im} k \geqq 0\}$ and C^N on $\{k\colon \operatorname{Im} k \geqq 0, k \neq 0\}$. Further $k\partial_k^N h_+(x, k)$ and $k\partial_k^N \partial_x h_+(x, k)$ extend continuously to $k = 0$. Moreover there are nonincreasing functions $K(x)$ such that for $0 \leqq n \leqq N$, $\operatorname{Im} k \geqq 0$, and $x \leqq t < \infty$*

(i) $|k\,\partial_k^n h_+(t, k)| \leqq K(x)$,

(ii) $\dfrac{|k|}{|k|+1}|\partial_k^n \partial_t^1 h_+(t, k)| \leqq K(x)$, *and*

(iii) $k\,\partial_k^n[h_+(x, k)] \to 0$ *and* $\partial_k^n \partial_x^1[h_+(x, k)] \to 0$ *as* $|k| \to \infty$, *uniformly in* $\operatorname{Im} k \geqq 0$.

Proof. We have already noted the claimed regularity on $\{k\colon \operatorname{Im} k \geqq 0\}$. To get the Nth derivative away from $k = 0$, we differentiate (2.10) N times formally and multiply by k. Thus if $\partial_k^N h_+(x, k)$ exists then $w \equiv k\,\partial_k^N h_+(x, k)$ satisfies the integral equation

$$(\mathbf{I} - \mathbf{T})w = r \tag{2.11}$$

where

$$\mathbf{T}[g](x) \equiv \int_x^\infty D_k(t-x)U(t)g(t)\,dt$$

and

$$r(x) \equiv \sum_{\nu=1}^N C_\nu \int_x^\infty k\,\partial_k^\nu[D_k(t-x)]U(t)\partial_k^{N-\nu} h_+(t, k)\,dt$$

for easily computable C_ν. For any finite X, $\mathbf{T}$ is a bounded operator on $L^\infty(X, \infty)$; indeed for $m \in \mathbb{N}$

$$\|\mathbf{T}^m g\| \leqq \|g\| \left(\int_X^\infty |U(t)|\,dt/|k| \right)^m.$$

Since $|k\partial_k^\nu[D_k(y)]| \leqq |2y|^\nu$ for all $\nu \geqq 0$, it follows that

$$\|r\| \leqq \sum_{\nu=1}^N C_\nu \int_x^\infty |2(t-x)|^\nu |U(t)| A(x)\,dt$$

where

$$A(x) = \sup\{|\partial_k^\mu h_+(t, k)|\colon \operatorname{Im} k \geqq 0, 0 \leqq \mu \leqq N-1, x \leqq t \leqq \infty\}.$$

Note that $A(x)$ is finite and nonincreasing. One can also verify that

$$\int_x^\infty |2(t-x)|^\nu |U(t)|\,dt \leqq K_\nu(x) \quad \text{for } 1 \leqq \nu \leqq N$$

where K_ν is the nonincreasing function

$$K_\nu(x) = \begin{cases} \displaystyle\int_{-\infty}^\infty |2t|^\nu |U(t)|\,dt + |2x|^\nu \int_x^\infty |U(t)|\,dt & \text{if } x < 0, \\ \displaystyle\int_{-\infty}^\infty |2t|^\nu |U(t)|\,dt & \text{if } x \geqq 0. \end{cases}$$

So $\|r\|$ in $L^\infty(X, \infty)$ is bounded by a nonincreasing function $B(X) = K(X)\sum_1^N C_\nu K_\nu$. It follows that the solution of (2.11) is given by

$$w = \sum_{m=0}^\infty \mathbf{T}^m r$$

and that w is continuous in x and k in $\mathbb{R}\times\{\operatorname{Im} k\geqq 0\}$. Further analysis reveals that $w(x,k)/k$ is indeed $\partial_k^N h_+(x,k)$ and that

$$|k\partial_k^N h_+(x,k)|\leqq \exp\left(\int_x^\infty |U(t)|\,dt/|k|\right)B(x).$$

Continuing in this vein one finds that $k\partial_k^N h_+(x,k)$ has a derivative with respect to x in distribution sense, and then that $\partial_x^1[k\partial_k^N h_+(x,k)]$ is a classical derivative as well, and satisfies (ii) and (iii). □

Remark. The factor $(1+|k|)^{-1}$ in (ii) is necessary because the term with $n=N$ in the sum for $r(x)$ involves $kh_+(x,k)$, which grows like $|k|$ as $|k|\to\infty$.

2.2. Regularity and decay of $W[f_-,f_+]$ and $W[f_+^*,f_-]$. Let $W(k)$ and $V(k)$ be defined on $\operatorname{Im} k\geqq 0$ by $W(k)=W[f_-,f_+]$ and $V(k)=W[f_+^*,f_-]$. Since f_-, f_+, and f_+^* solve (2.1), these Wronskians are independent of x. Evaluating at $x=0$, we get

$$W(k)=h_-(0,k)h_+'(0,k)-h_-'(0,k)h_+(0,k)+2ikh_-(0,k)h_+(0,k) \tag{2.12}$$

and

$$V(k)=h_+^*(0,k)h_-'(0,k)-h_-(0,k)h_+^{*\prime}(0,k). \tag{2.13}$$

Where ambiguity is possible we reserve prime (′) for $\partial/\partial x$ and dot ($\cdot$) for $\partial/\partial k$.

The following propositions follow immediately from the results of § 2.1.

PROPOSITION 2.3. *Assume* $U\in L_N^1(\mathbb{R})$ *with* $N\geqq 1$. *Then* $W\in C^{N-1}(\mathbb{R})\cap C^N(\mathbb{R}\sim\{0\})$. *Moreover* $k\partial_k^N[W(k)]$ *extends continuously to* $k=0$. *For all* n with $0\leqq n\leqq N$, $\lim_{|k|\to\infty}\partial_k^n[W(k)-2ik]=0$.

PROPOSITION 2.4. *Assume* $U\in L_N^1(\mathbb{R})$ *with* $N\geqq 1$. *Then* $V\in C^{N-1}(\mathbb{R})\cap C^N(\mathbb{R}\sim\{0\})$; $k\partial_k^N[V(k)]$ *extends continuously to* $k=0$; *and* $\lim_{|k|\to\infty}\partial_k^n[V(k)]=0$ *for* $0\leqq n\leqq N$.

2.3. Regularity and decay of $R_+(k)$, $R_-(k)$. Recall that the reflection coefficients R_+ and R_- are defined for $k\neq 0$ by

$$R_+(k)=\frac{V(k)}{W(k)},\qquad R_-(k)=\frac{V^*(k)}{W(k)}.$$

We concentrate on $R_+(k)$; $R_-(k)$ can be analyzed by the same methods. Note that

$$W(k)R_+(k)=V(k)$$

so that formally

$$W(k)R_+^{(n)}(k)=V^{(n)}(k)-\sum_{\nu=0}^{n-1}\binom{n}{\nu}R_+^{(\nu)}(k)W^{(n-\nu)}(k). \tag{2.14}$$

PROPOSITION 2.5. *Assume that* $U\in L_N^1(\mathbb{R})$ *with* $N\geqq 1$. *Then* $R_+\in C^N(\mathbb{R}\sim\{0\})$ *and* $\lim_{|k|\to\infty}kR_+^{(n)}(k)=0$ *for* $0\leqq n\leqq N$.

Furthermore

(A) *If U is of generic type, then* $R_+\in C^{N-1}(\mathbb{R})$ *and* $kR_+^{(N)}(k)$ *extends continuously to* $k=0$.

(B) *If U is of exceptional type and* $N\geqq 2$, *then* $R_+\in C^{N-2}(\mathbb{R})$ *and both* $kR_+^{(N-1)}(k)$ *and* $k^2R_+^{(N)}(k)$ *extend continuously to* $k=0$.

Proof. The regularity away from $k=0$ and the decay as $k\to\pm\infty$ follow from Propositions 2.3 and 2.4.

If U is generic then $W(k)$ is nonzero on $\mathbb{R}$ and (A) follows by an induction using (2.14). Suppose next that U is exceptional and that $N\geqq 2$. Then instead of treating R_+ as the ratio V/W we treat R_+ as the quotient of V/k and W/k. In this case it is known that W/k is continuous on $\mathbb{R}$ and never zero. Since V/k and W/k are C^{N-2} on $\mathbb{R}$, so is R_+. Using (2.14) it is easy to complete the proof of (B). □

We now turn to results involving L^2 hypotheses as well as L^1 assumptions on U.

LEMMA 2.6. *Suppose that $y^\nu U(y) \in L^2(\mathbb{R})$ and $U(y) \in L^1_{\nu+1}(\mathbb{R})$ for $0 \leqq \nu \leqq n$. Then $V^{(\nu)} \in L^2$ for $0 \leqq \nu \leqq n$.*

Proof. Deift and Trubowitz [5, p. 159] have proved that

$$V(k) = \int_{-\infty}^{\infty} \Pi_1(y)\, e^{-2iky}\, dy$$

where there is a constant K such that

$$|\Pi_1(y)| \leqq |U(y)| + KL(y)$$

for

$$L(y) = \int_y^\infty |U(t)|\, dt \quad \text{if } y \geqq 0, \qquad L(y) = \int_{-\infty}^y |U(t)|\, dt \quad \text{for } y < 0.$$

To show that $V^{(\nu)} \in L^2$, it suffices to show that $y^\nu \Pi_1(y) \in L^2$. Since

$$|\Pi_1(y)|^2 \leqq (1+K^2)(|U(y)|^2 + L(y)^2)$$

it follows that

$$\int_0^\infty |y^\nu \Pi_1(y)|^2\, dy \leqq (1+K^2) \int_0^\infty |y^\nu U(y)|^2\, dy + (1+K^2) \int_0^\infty y^{2\nu} L(y)^2\, dy.$$

The first term is finite since $y^\nu U(y) \in L^2$. Further

$$\begin{aligned}\int_0^\infty y^{2\nu} L(y)^2\, dy &= \int_{y=0}^\infty \left(y^\nu \int_{s=y}^\infty |U(s)|\, ds \right)\left(y^\nu \int_{t=y}^\infty |U(t)|\, dt \right) dy \\ &\leqq \int_{y=0}^\infty \left(\int_{s=0}^\infty s^\nu |U(s)|\, ds \right)\left(y^\nu \int_{t=y}^\infty |U(t)|\, dt \right) dy \\ &= \int_{s=0}^\infty s^\nu |U(s)|\, ds \int_{t=0}^\infty \frac{t^{\nu+1}}{\nu+1} |U(t)|\, dt < \infty.\end{aligned}$$

Thus $y^\nu \Pi_1(y)$ is in L^2 on $\mathbb{R}^+$; the proof that it is in L^2 on $\mathbb{R}^-$ is similar. □

PROPOSITION 2.7. *Suppose that $U \in L^1_N(\mathbb{R})$ and that $y^n U(y) \in L^2(\mathbb{R})$ for $0 \leqq n \leqq M$.*

(A) *If U is of generic type, then $R_+^{(n)} \in L^1(\mathbb{R})$ and $kR_+^{(n)}(k) \in L^2(\mathbb{R})$ for $0 \leqq n \leqq \min\{M, N-1\}$.*

(B) *If U is of exceptional type, then $R_+^{(n)} \in L^1(\mathbb{R})$ and $kR_+^{(n)}(k) \in L^2(\mathbb{R})$ for $0 \leqq n \leqq \min\{M, N-2\}$.*

Proof. The proof is an induction based on the formula

$$R_+^{(n)}(k) = \left[V^{(n)}(k) - \sum_{\nu=1}^n \binom{n}{\nu} R_+^{(n-\nu)}(k)\, W^{(\nu)}(k) \right] \Big/ W(k).$$

We discuss (A) first. Since $W(k)$ is continuous, never zero, and grows like $|k|$ at $\pm\infty$ it follows that $1/W$ is in L^2 and that $k/W \in L^\infty$. Since $V \in L^2$, it follows that $R_+ = V/W$ is both L^1 and L^2, and that $kR_+ \in L^2$.

Keep $0 \leqq n \leqq \min\{M, N-1\}$. We then know that $V^{(n)} \in L^2$ and that $W^{(\nu)} \in L^\infty$ for $1 \leqq \nu \leqq n$, then $R_+^{(n)} \in L^1 \cap L^2$ and $kR_+^{(n)} \in L^2$. Result (A) now follows by induction.

The induction for result (B) is similar, except that in the exceptional case we have only $R_+ \in C^{N-2}$. □

3. Regularity and decay of $\Omega_+(x, t)$ and $\Omega_-(x, t)$ for $t>0$.

3.1. Properties of $F_+(x, t)$. Recall from the introduction that the kernel of the Marchenko equation $(M+)$ is

$$\Omega_+(x, t) = F_+(x, t) + G_+(x, t)$$

where

$$F_+(x, t) = \pi^{-1} \int_{-\infty}^{\infty} R_+(k) \exp(2ikx + 8ik^3 t)\, dk$$

and

$$G_+(x, t) = 2 \sum_{j \in J} c_{+j} \exp(-2\kappa_j x + 8\kappa_j^3 t).$$

Since $G_+(x, t)$ is C^∞ and decays exponentially as $x \to +\infty$ for fixed $t>0$, we need to concentrate on the properties of F_+. In the first part of this subsection we use a representation of $F_+(x, t)$ in terms of $F_+(x)$ and the Airy function to find out as much as possible about $F_+(x, t)$ without using differentiability of $R_+(k)$. Later we report on what can be said of $F_+(x, t)$ using derivatives of $R_+(k)$ by a careful extension of the methods of Cohen in [3]. For convenience, we set

$$F_+(x) := F_+(x, 0) = \pi^{-1} \int_{-\infty}^{\infty} R_+(k)\, e^{2ikx}\, dk.$$

LEMMA 3.1. *If $U(x) \in L_1^1(\mathbb{R})$, then $R_+(k) \in L^2(\mathbb{R})$ and $F_+(x) \in L^2(\mathbb{R})$.*

Proof. These results are well known; see [5].

LEMMA 3.2. *Suppose* $U(x) \in L_1^1(\mathbb{R}) \cap L_N^1(\mathbb{R}^+)$ *for some N with $N \geqq 11/4$. Then*

(a) $$\int_0^\infty |F_+(x)|(1+x)^{N-1}\, dx < \infty,$$

(b) $$\int_0^\infty |\partial_+ F_+(x)|(1+x)^N\, dx < \infty.$$

Proof. Because of the exponential decay of $G_+(x, 0)$ as $x \to +\infty$, it is enough to prove the analogues of (a) and (b) for Ω_+. By Faddeev [6, p. 155], we know that

$$|\Omega_+(x)| \leqq C(x) \int_x^\infty |U(z)|\, dz \tag{3.1}$$

and

$$|\partial_x \Omega_+(x) - U(x)| \leqq C(x) \left[\int_x^\infty |U(z)|\, dz \right]^2 \tag{3.2}$$

where each $C(x)$ is a nonincreasing function of x. Now by (3.1)

$$\begin{aligned}
\int_0^\infty |\Omega_+(x)| x^{N-1}\, dx &\leqq \int_{x=0}^\infty C(0) \int_x^\infty |U(z)|\, dz\, x^{N-1}\, dx \\
&= C(0) \int_{z=0}^\infty |U(z)| \int_{x=0}^z x^{N-1}\, dx\, dz \\
&= C(0) N^{-1} \int_{z=0}^\infty |U(z)| z^N\, dz < \infty.
\end{aligned}$$

Thus (a) follows. For (b), use (3.2):

$$\int_0^\infty |\partial_+\Omega_+(x)|x^N\,dx \leqq \int_0^\infty |U(z)|x^N\,dx + \int_0^\infty C(x)\left[\int_x^\infty |U(z)|\,dz\right]^2 x^N\,dx.$$

The first term is finite by hypothesis. For the second,

$$\begin{aligned}\int_{x=0}^\infty \left[\int_x^\infty |U(z)|\,dz\right]^2 x^N\,dx &\leqq \int_{x=0}^\infty \left[x\int_x^\infty |U(z)|dz\right]\left[x^{N-1}\int_x^\infty |U(z)|\,dz\right]dx\\ &\leqq \int_{x=0}^\infty \left[\int_x^\infty z|U(z)|\,dz\right]\left[x^{N-1}\int_{z=x}^\infty |U(z)|\,dz\right]dx\\ &\leqq \int_0^\infty |U(z)|z\,dz\int_{x=0}^\infty x^{N-1}\left[\int_{z=x}^\infty |U(z)|\,dz\right]dx\\ &\leqq \int_0^\infty |U(z)|z\,dz\left[\int_{z=0}^\infty |U(z)|\int_{z=0}^\infty x^{N-1}\,dx\,dz\right]\\ &\leqq \left[\int_0^\infty |U(z)|z\,dz\right]N^{-1}\left[\int_{z=0}^\infty |U(z)|z^N\,dz\right]\\ &< \infty\end{aligned}$$

since each factor is finite. □

By Lemmas 3.1 and 3.2 we know that $F_+(x)$ is a real valued function such that

$$F_+(x)\in L^2(\mathbb{R})\cap L^1_{N-1}(\mathbb{R}^+),\qquad \partial_x F_+(x)\in L^1_{\text{loc}}(\mathbb{R})\cap L^1_N(\mathbb{R}^+).$$

To analyze $F_+(x, t)$ with $t>0$, we use the observation [13] that $F_+(x, t)$ is essentially a convolution of $F_+(x)$ with an Airy function:

$$F_+(x,t)=(3t)^{-1/3}\int_{-\infty}^\infty F_+(y)\,\mathrm{Ai}\left(\frac{x-y}{(3t)^{1/3}}\right)dy. \tag{3.3}$$

We use the following properties of the Airy function [13]:

$$|\mathrm{Ai}\,(z)|<1\quad \forall z \text{ in } \mathbb{R}, \tag{3.4}$$

$$\mathrm{Ai}\,(z)\in C^\infty(\mathbb{R})\quad\text{and}\quad \mathrm{Ai}''\,(z)=z\,\mathrm{Ai}\,(z), \tag{3.5}$$

$$\begin{aligned}&|\mathrm{Ai}^{(n)}\,(z)|\leqq C_n^-(1+|z|)^{n/2-1/4}\quad \text{as } z\to-\infty,\\ &|\mathrm{Ai}^{(n)}\,(z)|\leqq C_n^+(1+|z|)^{n/2-1/4}\exp\,(-2|z|^{3/2}/3)\quad \text{as } z\to+\infty.\end{aligned} \tag{3.6}$$

Because of the different behavior at $+\infty$ and $-\infty$, it is convenient to divide the integral in (3.3) into pieces. To this end let $\zeta_1(x)$ denote a nonincreasing C^∞ function such that

$$\zeta_1(x)=1\quad \text{on } -\infty<x\leqq\tfrac{1}{3},\qquad \zeta_1(x)=0\quad \text{on } \tfrac{2}{3}\leqq x<\infty.$$

Let $\zeta_2(x):=1-\zeta_1(x)$. Next set $F_i(x)=F_+(x)\zeta_i(x)$ for $i=1,2$. Next set

$$F_i(x,t)=\begin{cases}(3t)^{-1/3}\displaystyle\int_{-\infty}^\infty F_i(y)\,\mathrm{Ai}\left(\frac{x-y}{(3t)^{1/3}}\right)dy & \text{if } t>0,\\ F_i(x) & \text{if } t=0.\end{cases} \tag{3.7}$$

Note that $F_+(x,t)=F_1(x,t)+F_2(x,t)$.

LEMMA 3.3.

(a) $F_1(x,t)$ *is* C^∞ *in* $\mathbb{R}\times\mathbb{R}^+$;

(b) $\lim_{x\to+\infty} x^n\,\partial_x^j F_1(x,t)=0$ *for nonnegative integers* n, j;

(c) $\int_0^\infty |\partial_x^j F_1(x,t)|x^m\,dx<\infty$ *for all* j, m.

Proof. Part (c) follows immediately from (a) and (b). The regularity (a) follows from (3.7), the rapid decay of all $\mathrm{Ai}^{(j)}(z)$ as $z \to +\infty$, and the fact that supp $F_1 \subseteq (-\infty, 1]$. Now

$$\partial_x^j F_1(x,t) = (3t)^{-1/3} \int_{-\infty}^{\infty} F_1(y)\, \mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)(3t)^{-j/3}\, dy$$

and

$$|\partial_x^j F_1(x,t)| \leqq (3t)^{-(j+1)/3}\left[\int_{-\infty}^{1} |F_1(y)|^2\, dy\right]^{1/2}\left[\int_{-\infty}^{1} \left|\mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)\right|^2 dy\right]^{1/2}.$$

Setting $\xi = (x-y)/(3t)^{1/3}$ we see that the second integral is

$$I(x,t) = \int_{(x-1)(3t)^{-1/3}}^{\infty} |\mathrm{Ai}^{(j)}(\xi)|^2 (3t)^{1/3}\, d\xi.$$

Since $\mathrm{Ai}^{(j)}(\xi)$ decays faster than exponentially as $\xi \to +\infty$, it follows that $I(x,t)$ decays at least exponentially fast as $x \to +\infty$, and (b) follows. □

We next analyze $F_2(x,t)$. Note that supp $F_2 \subseteq [0, +\infty]$ and that $\mathrm{Ai}\,((x-y)/(3t)^{1/3})$ is less well behaved as $y \to +\infty$. A technical remark precedes the analysis.

LEMMA 3.4. *There is a constant C such that*

$$|\mathrm{Ai}\,(-\xi)| \leqq C(1 \vee \xi)^{-1/4} \quad \textit{for all real } \xi.$$

Proof. We know that $|\mathrm{Ai}\,(z)| < 1$ for all z, and that there is a K such that

$$|\mathrm{Ai}\,(z)| \leqq K(1+|z|)^{-1/4} \quad \text{for all } z \leqq 0.$$

Choose $C = \max\{1, K\}$. If $\xi \leqq 1$, then $(1 \vee \xi) = 1$ and

$$|\mathrm{Ai}\,(-\xi)| \leqq 1 = (1 \vee \xi)^{-1/4} \leqq C(1 \vee \xi)^{-1/4}.$$

If $\xi > 1$, then $(1 \vee \xi) = \xi$ and

$$|\mathrm{Ai}\,(-\xi)| \leqq K(1+\xi)^{-1/4} \leqq C(1 \vee \xi)^{-1/4}$$

since $(1 \vee \xi)/(1+\xi) \leqq 1$ for $\xi > 1$. □

LEMMA 3.5. (a) *$F_2(x,t)$ is continuous in $\mathbb{R} \times (0, \infty)$.*

(b) *If $0 \leqq n \leqq N-1$, then $F_2(x,t) = o(x^{-n})$ as $x \to +\infty$.*

(c) *If $0 \leqq n \leqq N - 7/4$, then $\int_0^\infty x^n |F_2(x,t)|\, dx < \infty$.*

Proof. Because of the support of $F_2(x)$ we have

$$F_2(x,t) = (3t)^{-1/3} \int_0^\infty F_2(y)\, \mathrm{Ai}\left(\frac{x-y}{(3t)^{1/3}}\right) dy. \tag{3.8}$$

The integrand is continuous in $(x,t) \in \mathbb{R} \times \mathbb{R}^+$ for each y. By its definition, $F_2(y) \in L^1(\mathbb{R})$. By (3.4) the integrand is bounded by $|F_2(y)|$. Thus (a) follows by Lebesgue's dominated convergence theorem.

For (b) we assume $0 \leqq n \leqq N-1$, keep $x \geqq 2$, and fix $t > 0$. Let $A(x,t)$ denote the part of the integral in (3.8) over $[0, x/2]$, and $B(x,t)$, the part over $[x/2, \infty)$. We need to show that $x^n A(x,t)$ and $x^n B(x,t)$ go to 0 as $x \to +\infty$. Now

$$\begin{aligned} x^n A(x,t) &= x^n \int_0^{x/2} F_2(y)\, \mathrm{Ai}\left(\frac{x-y}{(3t)^{1/3}}\right) dy \\ &= x^n \int_{x/2(3t)^{1/3}}^{x/(3t)^{1/3}} \mathrm{Ai}\,(\xi) F_2(x-(3t)^{1/3}\xi)(3t)^{1/3}\, d\xi. \end{aligned}$$

Note $\xi > x/2(3t)^{1/3}$ implies $x \leqq 2(3t)^{1/3}\xi$. So

$$|x^n A(x,t)| \leqq 2^n (3t)^{(n+1)/3} \int_{x/2(3t)^{1/3}}^{x/(3t)^{1/3}} \xi^n |\mathrm{Ai}\,(\xi) F_2(x-(3t)^{1/3}\xi)|\,d\xi$$

$$\leqq 2^n (3t)^{(n+1)/3} \left[\int_{-\infty}^{\infty} |F(s)|^2\,ds\right]^{1/2} \left[\int_{x/2(3t)^{1/3}}^{x/(3t)^{1/3}} \xi^{2n} |\mathrm{Ai}\,(\xi)|^2\,d\xi\right]^{1/2}.$$

The decay rate (3.6) of Ai at $+\infty$ is such that $\xi^{2n}|\mathrm{Ai}\,(\xi)|^2$ is integrable on $\mathbb{R}^+$. Thus $x^n A(x,t) \to 0$ as $x \to +\infty$.

Next, since $|\mathrm{Ai}\,(s)| \leqq 1$ for all s,

$$|x^n B(x,t)| = \left| x^n \int_{x/2}^{\infty} F_2(y) \mathrm{Ai}\left(\frac{x-y}{(3t)^{1/3}}\right) dy \right| \leqq 2^n \int_{x/2}^{\infty} y^n |F_2(y)|\,dy.$$

Since $F \in L^1_{N-1}(\mathbb{R}^+)$ and $n \leqq N-1$, $x^n B(x,t) \to 0$ as $x \to +\infty$. Thus (b) is proved. For (c) note that

$$\int_0^{\infty} x^n |F_2(x,t)|\,dx = \int_0^{\infty} x^n \left| (3t)^{-1/3} \int_{y=0}^{\infty} F_2(y)\,\mathrm{Ai}\left(\frac{y-x}{(3t)^{1/3}}\right) dy \right| dx$$

$$\leqq (3t)^{-1/3} \int_{x=0}^{\infty} x^n \int_{y=x}^{\infty} |F_2(y)| \left|\mathrm{Ai}\left(\frac{y-x}{(3t)^{1/3}}\right)\right| dy\,dx$$

$$+ (3t)^{-1/3} \int_{x=0}^{\infty} x^n \int_{y=0}^{x} |F_2(y)| \left|\mathrm{Ai}\left(\frac{y-x}{(3t)^{1/3}}\right)\right| dy\,dx.$$

Call these terms T_1 and T_2. It suffices to show T_1 and T_2 are finite. Now by Lemma 3.4

$$T_1 \leqq (3t)^{-1/3} \int_{x=0}^{\infty} x^n \int_{y=x}^{\infty} |F_2(y)| C\left(1 \vee \left\{\frac{y-x}{(3t)^{1/3}}\right\}\right)^{-1/4} dy\,dx$$

$$= C(3t)^{-1/3} \int_{y=0}^{\infty} |F_2(y)| \int_{x=0}^{y} x^n \left(1 \vee \frac{y-x}{(3t)^{1/3}}\right)^{-1/4} dx\,dy$$

$$\leqq C(3t)^{-1/3} \int_{y=0}^{\infty} |F_2(y)| \int_0^{y} x^n \left(\frac{y-x}{(3t)^{1/3}}\right)^{-1/4} dx\,dy.$$

It is easy to prove by induction on n that

$$\int_0^{y} x^n \left(\frac{y-x}{(3t)^{1/3}}\right)^{-1/4} dx \leqq (3t)^{-1/12} K_n y^{n+3/4}.$$

Thus there is a function $C = C(t)$ such that

$$T_1 \leqq C(t) \int_{y=0}^{\infty} |F_2(y)| y^{n+3/4}\,dy.$$

Since $n + \frac{3}{4} \leqq N-1$ and $F_2 \in L^1_{N-1}(\mathbb{R}^+)$, $T_1 < \infty$. Next

$$T_2 = (3t)^{-1/3} \int_{y=0}^{\infty} |F_2(y)| \int_{x=y}^{\infty} x^n \left|\mathrm{Ai}\left(\frac{y-x}{(3t)^{1/3}}\right)\right| dx\,dy.$$

Consider the inside integral $I(y)$ and let $\xi = (x-y)/(3t)^{1/3}$. Thus

$$I(y) = \int_{\xi=0}^{\infty} (y + (3t)^{1/3}\xi)^n |\mathrm{Ai}\,(\xi)| (3t)^{1/3}\,d\xi$$

$$\leqq 2^n (3t)^{1/3} \int_{\xi=0}^{\infty} (y^n + (3t)^{n/3}\xi^n) |\mathrm{Ai}\,(\xi)|\,d\xi \leqq C_1(t) y^n + C_2(t)$$

for positive functions $C_1(t)$, $C_2(t)$, since $\xi^j|\mathrm{Ai}\,(\xi)|\in L^1(\mathbb{R}^+)$ for all $j\geqq 0$. Now

$$T_2\leqq (3t)^{-1/3}\int_{y=0}^{\infty}|F_2(y)|(C_2(t)+y^nC_1(t))\,dy<\infty$$

because $n\leqq N-7/4<N-1$ and $F_2\in L^1_{N-1}(\mathbb{R}^+)$. □

Lemma 3.6. *Suppose* $0\leqq j\leqq 2N+1/2$. *Then*

(a) $\partial^j_x\partial_xF_2(x,t)$ *is continuous in* $\mathbb{R}\times(0,\infty)$,

(b) $\partial_xF_2(x,t)=o(x^{-n})$ *as* $x\to+\infty$ *for* $0\leqq n\leqq N$. *If* $j\geqq 1$, *then* $\partial^j_x\partial_xF_2(x,t)=o(x^{-n})$ *as* $x\to+\infty$ *for* $0\leqq n\leqq N+\frac{1}{4}-j/2$,

(c) $\int_0^\infty x^n|\partial^j_x\partial_xF_2(x,t)|\,dx<\infty$ *for* $0\leqq n\leqq N-\frac{3}{4}-j/2$.

Proof. From (3.3) we see

$$\partial_xF_2(x,t)=(3t)^{-2/3}\int_0^\infty F_2(y)\,\mathrm{Ai}'\left(\frac{y-x}{(3t)^{1/3}}\right)dy. \tag{3.9}$$

The continuity of $\partial_xF_2(x,t)$ follows from the Lebesgue dominated convergence theorem and the facts $F_2(y)\in L^1_{N-1}$ with $N\geqq 11/4$ and $\mathrm{Ai}'\,(\xi)=O(|\xi|^{+1/4})$ as $\xi\to-\infty$. To show continuity of $\partial^j_x\partial_xF_2$ with $j\geqq 1$, we integrate by parts in (3.9) getting

$$\partial_xF_2(x,t)=+(3t)^{-1/3}\int_0^\infty F_2'(y)\,\mathrm{Ai}\left(\frac{x-y}{(3t)^{1/3}}\right)dy. \tag{3.10}$$

Now fix $j\geqq 1$

$$\partial^j_xF_2(x,t)=(3t)^{-(j+1)/3}\int_0^\infty F_2'(y)\,\mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)dy. \tag{3.11}$$

We need to show the continuity of $\partial^j_x\partial_xF_2$ at $x_0\in\mathbb{R}$, $t_0>0$. We keep $x\geqq x_0-1$, $t\geqq t_0/3$. The integrand is continuous in (x,t) for almost all y. Further it is uniformly bounded for $x\geqq x_0-1$:

$$\begin{aligned}\left|F_2'(y)\,\mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)\right|&\leqq C|F_2'(y)|\left(1\vee\left\{\frac{y-x}{(3t)^{1/3}}\right\}\right)^{j/2-1/4}\\&\leqq C|F_2'(y)|\left(1\vee\left\{\frac{y+1-x_0}{t_0^{1/3}}\right\}\right)^{j/2-1/4}\end{aligned}$$

since $j/2-\frac{1}{4}>0$ when $j\geqq 1$. Further this bound is integrable on $\mathbb{R}^+$ since $F_2'\in L^1_N$ and the hypothesis on j implies $j/2-\frac{1}{4}\leqq N$. This completes (a).

For the remainder of the proof fix j so $0\leqq j\leqq 2N+\frac{1}{2}$. For part (b) we pick n so $0\leqq n\leqq N+\frac{1}{4}-j/2$ and keep $x\geqq 2$. From (3.11) we get

$$|x^n\partial^j_x\partial_xF_2(x,t)|\leqq(3t)^{-(j+1)/3}x^n\int_0^\infty\left|F_2'(y)\,\mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)\right|dy.$$

Let J_1 and J_2 be the two terms obtained by splitting the integral at $y=x/2$. Note that $y>x/2$ implies $x^n\leqq 2^ny^n$.

$$\begin{aligned}J_1&=(3t)^{-(j+1)/3}x^n\int_0^{x/2}\left|F_2'(y)\,\mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)\right|dy\\&=(3t)^{-j/3}x^n\int_{\xi=x/2(3t)^{1/3}}^{x/(3t)^{1/3}}|F_2'(x-(3t)^{1/3}\xi)\,\mathrm{Ai}^{(j)}\,(\xi)|\,d\xi\end{aligned}$$

after setting $\xi=(x-y)/(3t)^{1/3}$. Note $0\leqq y\leqq x/2$ implies $x^n\leqq 2^n(3t)^{n/3}\xi^n$. Thus

$$J_1\leqq(3t)^{-(n-j)/3}2^n\int_{x/2(3t)^{1/3}}^{x/(3t)^{1/3}}\xi^n|F_2'(x-(3t)^{1/3}\xi)\,\mathrm{Ai}^{(j)}\,(\xi)|\,d\xi.$$

By (3.6) we can find a constant K such that $|\xi^n \operatorname{Ai}^{(j)}(\xi)| \leqq K \mathrm{e}^{-\xi}$ for $\xi \geqq 0$ and in particular $|\xi^n \operatorname{Ai}^{(j)}(\xi)| \leqq K \exp(-x/2(3t)^{1/3})$ for $\xi \geqq x/2(3t)^{-1/3}$. Thus

$$J_1 \leqq (3t)^{(j-n)/2} 2^n K \, \mathrm{e}^{-x/2(3t)^{1/3}} \int_0^{x/2} |F_2'(y)| \, dy.$$

Since $F_2' \in L^1(\mathbb{R}^+)$, $J_1 \to 0$ as $x \to +\infty$.

It remains to deal with

$$J_2 = J_{2,j}(x) = (3t)^{-(j+1)/3} x^n \int_{x/2}^{\infty} \left| F_2'(y) \operatorname{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right) \right| dy.$$

If $j=0$ and $0 \leqq n \leqq N$, then

$$J_{2,0}(x) \leqq (3t)^{-1/3} 2^n \int_{y/2}^{\infty} y^n |F_2'(y)| \, dy,$$

which goes to 0 as $x \to +\infty$ because $F_2' \in L_N^1$.

Note that (3.6) implies that there is a constant A_j such that

$$|\operatorname{Ai}^{(j)}(-\xi)| \leqq A_j (1 \vee \xi)^{j/2-1/4}$$

for real ξ. Thus when $j \geqq 1$ we get

$$\begin{aligned} J_{2,j}(x) &\leqq (3t)^{-(j+1)/3} 2^n \int_{x/2}^{\infty} y^n |F_2'(y)| A_j \left(1 \vee \frac{y-x}{(3t)^{1/3}}\right)^{j/2-1/4} dy \\ &\leqq C_1(t) \int_{x/2}^{x+(3t)^{1/3}} y^n |F_2'(y)| \, dy + C_2(t) \int_{x+(3t)^{1/3}}^{\infty} y^n |F_2'(y)| (y-x)^{j/2-1/4} \, dy \end{aligned}$$

where $C_1(t)$ and $C_2(t)$ are positive functions of t. The first integral goes to 0 as $x \to +\infty$ because $n \leqq N - \frac{1}{4} < N$. In the second integral note $(y-x)^{j/2-1/4}$ is a decreasing function of x since $j \geqq 1$. Keeping $x \geqq 1$, the second integral is bounded by

$$\int_{x+(3t)^{1/3}}^{\infty} y^n |F_2'(y)| (y-1)^{j/2-1/4} \, dy,$$

which goes to zero as $x \to +\infty$ since we assume $n + j/2 - \frac{1}{4} \leqq N$ and know $F_2' \in L_N^1$. This finishes (b).

We finally turn to part (c). Keep $0 \leqq n \leqq N - \frac{3}{4} - j/2$ and note $n < N$ for all $j \geqq 0$. Now

$$\int_0^{\infty} x^n |\partial_x^j \partial_x F_2(x,t)| \, dx \leqq \int_{x=0}^{\infty} x^n \left(\int_{y=0}^{x} + \int_{y=x}^{\infty} \right) (3t)^{-(j+1)/3} \left| \operatorname{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right) F_2'(y) \right| dy \, dx.$$

Let K_1 denote the integral $\int_{x=0}^{\infty} \int_{y=0}^{x} \cdots dy \, dx$, and let K_2 denote the other. Set $\xi = (x-y)/(3t)^{1/3}$ in K_1. We get

$$\begin{aligned} K_1 &= (3t)^{-j/3} \int_{x=0}^{\infty} x^n \left(\int_{\xi=0}^{x/(3t)^{1/3}} |\operatorname{Ai}^{(j)}(\xi) F_2'(x-(3t)^{1/3}\xi)| \, d\xi \right) dx \\ &= (3t)^{-j/3} \int_{\xi=0}^{\infty} |\operatorname{Ai}^{(j)}(\xi)| \int_{x=(3t)^{1/3}\xi}^{\infty} x^n |F_2'(x-(3t)^{1/3}\xi)| \, dx \, d\xi \\ &= (3t)^{-j/3} \int_{\xi=0}^{\infty} |\operatorname{Ai}^{(j)}(\xi)| \int_{y=0}^{\infty} |F_2'(y)| (y+(3t)^{1/3}\xi)^n \, dy \, d\xi \\ &\leqq (3t)^{-j/3} 2^n \left[\int_{\xi=0}^{\infty} |\operatorname{Ai}^{(j)}(\xi)| \int_{y=0}^{\infty} y^n |F_2'(y)| \, dy \, d\xi \right. \\ &\qquad \left. + (3t)^{n/3} \int_{\xi=0}^{\infty} |\operatorname{Ai}^{(j)}(\xi)| \xi^n \int_{y=0}^{\infty} |F_2'(y)| \, dy \right] < \infty \end{aligned}$$

since $F_2' \in L^1_N$ with $N \geqq 11/4$ and $\mathrm{Ai}^{(j)}(\xi)$ has faster than exponential decay as $\xi \to +\infty$, and $|y+(3t)^{1/3}\xi|^n \leqq 2^n(y^n+(3t)^{n/3}\xi^n)$.

$$K_2=(3t)^{-(j+1)/3}\int_{x=0}^{\infty} x^n \int_{y=x}^{\infty} \left| F_2'(y)\,\mathrm{Ai}^{(j)}\left(\frac{x-y}{(3t)^{1/3}}\right)\right| \,dy\,dx.$$

By (3.6)

$$\begin{aligned} K_2 &\leqq (3t)^{-(j+1)/3}\int_{x=0}^{\infty} x^n \int_{y=x}^{\infty} |F_2'(y)| C_j^+ \left(1+\frac{y-x}{(3t)^{1/3}}\right)^{-j/2-1/4} dy\,dx \\ &\leqq C_j^+(3t)^{-(j+1)/3}\int_{y=0}^{\infty} |F_2'(y)| \int_{x=0}^{y} x^n \left(1+\frac{y-x}{(3t)^{1/3}}\right)^{j/2-1/4} dx\,dy. \end{aligned}$$

In case $j \geqq 1$ we have $j/2-\frac{1}{4}>0$. So for $x \geqq 1$

$$\begin{aligned} K_2 &\leqq C_j^+(3t)^{-(j+1)/3}\int_{y=0}^{\infty} |F_2'(y)| \int_{x=0}^{y} x^n \left(1+\frac{y-1}{(3t)^{1/3}}\right)^{j/2-1/4} dx\,dy \\ &\leqq C(3t)^{-(j+1)/3}\int_{y=0}^{\infty} |F_2'(y)|(1+y)^{n+1+j/2-1/4}\,dy<\infty \end{aligned}$$

since $n+\frac{3}{4}-j/2 \leqq N$. If $j=0$, then $j/2-\frac{1}{4}<0$ and this argument fails. However, if $j=0$ we get

$$K_2 \leqq C_j^+(3t)^{-1/3}\int_{y=0}^{\infty} |F_2'(y)| \int_{x=0}^{y} x^n \left(1+\frac{y-x}{(3t)^{1/3}}\right)^{-1/4} dx\,dy.$$

By induction one shows that the inner integral is $O(y^{n+(3/4)})$. Thus

$$K_2 \leqq C(3t)^{-1/3}\int_{y=0}^{\infty} |F_2'(y)|(1+y)^{n+3/4}\,dy<\infty$$

since we are assuming $n \leqq N-\frac{3}{4}$ when $j=0$. □

The results of Lemmas 3.5 and 3.6 rely on the fact that $\partial_x F_+(x,0)$ is in $L^1(+\infty)$. By contrast our next result does not use estimates on $\partial_x F_+(x,0)$. The next result is used by Kappeler in [9] where he considers KdV with certain measures as initial data. Up to this point we have used the Airy function strenuously; the rest of our results in this section rely on the type of analysis found in Cohen's paper [3]. Also by way of contrast, note that the distinction between generic and nongeneric data does not arise in the Airy function approach, whereas it does arise using the method of [3].

PROPOSITION 3.7. *Suppose that $U \in L^1_M(\mathbb{R})$ with $M \geqq 3$. If U is generic, set $N=M$; otherwise, set $N=M-1$. Let R_+ be the reflection coefficient of $U(x)$. Then a function*

$$F_+(x,t)=\pi^{-1}\int_{-\infty}^{\infty} R_+(k)\exp(2ikx+8ik^3t)\,dk$$

may be well defined on $\mathbb{R}\times(0,\infty)$ as an improper Riemann integral. Further for each fixed $t>0$, $F_+(x,t)$ is $(2N-1)$-times continuously differentiable with respect to x. Moreover for arbitrarily small $\varepsilon(0<\varepsilon \ll 1/2)$ there are functions $K_{0,N}(t)$ and $K_{1,N}(t)$ such that

$$\begin{aligned} &|F_+(x,t)| \leqq K_{0,N}(t)x^{-N+1+\varepsilon}, \\ &|\partial_x^j F_+(x,t)| \leqq K_{j,N}(t)x^{-N+j/2+\varepsilon} \quad \textit{for } 1 \leqq j \leqq 2N-1 \end{aligned}$$

whenever $x>12t>0$. $K_{j,N}(t)$ can be chosen nonincreasing, bounded as $t\uparrow+\infty$, and $O(t^{-j/2-\varepsilon})$ as $t\downarrow 0$.

Proof. Use Proposition 2.7 and a careful adaptation of the methods of [3]. □

3.2. Properties of $F_-(x, t)$. Recall that the crucial term in the kernel of the left-side Marchenko equation is

$$F_-(x,t)=\pi^{-1}\int_{-\infty}^{\infty} R_-(k)\exp(-2ikx-8ik^3t)\,dk.$$

Since $R_-(-k)=R_-^*(k)$, this may be rewritten as

$$F_-(x,t)=\pi^{-1}\int_{-\infty}^{\infty} R_-^*(k)\exp(2ikx+8ik^3t)\,dk.$$

Because $R_-^*(k)=V^*(k)/W(k)$, the analysis of R_+ is easily adapted to R_- and the regularity of F_- is the same as that of F_+. The decay of F_- and its derivatives as $x\to-\infty$ requires different treatment because there will be stationary points when $x<0$, namely $k=\pm(|x|/12t)^{1/2}$.

The purpose of this subsection is to identify conditions on $R_-(k)$ sufficient to verify the hypotheses on F_- in Kappeler's L^2 inverse scattering theorem [8]. The crucial point is to see when $\partial_x^j F_-(x,t)$ and $|x|^{1/2}\partial_x^j F_-(x,t)$ are in $L^2(-\infty, X)$ for finite X and $j=0,1,\cdots,4$. We formulate the results in two ways to allow some flexibility as to whether we ask R_- to have many derivatives of slower decay or fewer derivatives of faster decay.

This subsection will not be used until late in § 5.

LEMMA 3.8. *Suppose the function g has property $A(\lambda, N)$, namely*

$$g\in C^N(\mathbb{R}) \quad \textit{for } N\geqq 2,$$
$$g^{(n)}(k)=O(|k|^{-\lambda}) \quad \textit{as } |k|\to\infty \textit{ for } n=0,1,2,$$
$$g^{(n)}(k)=O(|k|^{-\lambda(n)}) \quad \textit{as } |k|\to\infty \textit{ for } 3\leqq n\leqq N$$

where

$$\lambda\geqq 1,\quad \lambda(n)\geqq\max\{1,\lambda-n\}\quad \textit{and}\quad \lambda\geqq\lambda(3)\geqq\cdots\geqq\lambda(N).$$

Let $G(x,t)$ be defined by

$$G(x,t)=\int_{-\infty}^{\infty} g(k)\,e^{8ik^3t+2ikx}\,dk.$$

If $N\geqq\lambda+3/2$, then for $t>0$

(i) $\partial_x^j G(x,t)=O(|x|^{-(\lambda-j)/2-1/4})$ *as $x\to-\infty$ for $j=0,1,2$.*

If $N>(\lambda+1)/2$, then for $t>0$ there is a δ such that $0<\delta\ll 1$ and

(ii) $\partial_x^j G(x,t)=O(|x|^{-1/2(\lambda-j)-\delta})$ *as $x\to-\infty$, $j=0,1,2$.*

Proof. This proof requires the careful extension and correction of the Appendix B of [13], i.e., a careful analysis by the method of stationary phase. □

Remark. Result (ii) gets a weaker result but requires less regularity in g for fixed λ. The following applications will be used in discussion of the L^2 inverse scattering problem in § 5.

Application 1(i). Suppose g satisfies $A(\lambda, N)$ with $5/2<\lambda\leqq 7/2$, $N=5$, and $\lambda(n)=1$ for $3\leqq n\leqq 5$. Then $N\geqq\lambda+3/2$. Part (i) of Lemma 3.8 tells us that for $t>0$

$$\partial_x G(x,t)=O(|x|^{-(\lambda-1)/2-1/4})=O(|x|^{-\lambda/2+1/4})\quad\text{as } x\to-\infty.$$

Since $-\lambda/2+\frac{1}{4}<-1$, it follows that both $\partial_x G(x,t)$ and $|x|^{1/2}\,\partial_x G(x,t)$ are in $L^2(-\infty)$.

Application 1(ii). Suppose g satisfies $A(\lambda, N)$ with $\lambda=3, N=3, \lambda(3)=1$. This requires more decay but fewer derivatives than the previous application. Note that $N>(\lambda+1)/2$. By part (ii) of Lemma 3.8, if $t>0$, then

$$\partial_x G(x, t)=O(|x|^{-(\lambda-1)/2-\delta})=O(|x|^{-1-\delta})$$

for some very small positive δ. Thus, in this case also, both $\partial_x G(x, t)$ and $|x|^{1/2}\,\partial_x G(x, t)$ are in $L^2(-\infty)$.

Application 2(i). Suppose that $g \in C^8(\mathbb{R})$ and that

$$g^{(n)}(k)=O(|k|^{-\lambda_0}) \quad \text{as } |k| \to \infty \text{ for } n=0,1,2,$$
$$g^{(n)}(k)=O(|k|^{-\lambda_0(n)}) \quad \text{as } |k| \to \infty \text{ for } 3 \leqq n \leqq 8$$

where

$$\lambda_0=\tfrac{11}{2}+\varepsilon, \qquad 0<\varepsilon<\tfrac{1}{2},$$
$$\lambda_0(n) \geqq \max\{1, \lambda_0-n\} \quad \text{for } 3 \leqq n \leqq 8,$$
$$4=\lambda_0(3) \geqq \lambda_0(4) \geqq \cdots \geqq \lambda_0(8).$$

Let $g_0=g$ and $g_1=g'$. Then it is easy to see that g_0 satisfies $A(\lambda, N)$ with $\lambda=\lambda_0$ and $N=8$. One can also verify that g_1 satisfies $A(\lambda, N)$ with $\lambda=\lambda_1=4$ and $N=7$. Since $8>\lambda_0+3/2$ we can apply Lemma 3.8(i) to get

$$\partial_x^j G_0(x, t)=O(|x|^{-(\lambda_0-j)/2-1/4}) \quad \text{as } x \to -\infty, \qquad j=0,1,2.$$

Since $7>\lambda_1+3/2$, we can also obtain

$$\partial_x^j G_1(x, t)=O(|x|^{-(\lambda_1-j)/2-1/4}) \quad \text{as } x \to -\infty, \qquad j=0,1,2.$$

Recall that

$$\partial_x^2 G_0(x, t)=\frac{1}{6it}\,G_1(x, t)+\frac{x}{3t}\,G_0(x, t),$$

$$\partial_x^3 G_0(x, t)=\frac{1}{6it}\,\partial_x^1 G_1(x, t)+\frac{1}{3t}\,G_0(x, t)+\frac{x}{3t}\,\partial_x G_0(x, t),$$

$$\partial_x^4 G_0(x, t)=\frac{1}{6it}\,\partial_x^2 G_1(x, t)+\frac{2}{3t}\,G_0(x, t)+\frac{x}{3t}\,\partial_x^2 G_0(x, t).$$

It follows that

$$\partial_x^3 G_0(x, t)=O(|x|^{-1-(3/4)}) \quad \text{as } x \to -\infty$$

and

$$\partial_x^4 G_0(x, t)=O(|x|^{-1-\varepsilon/2}) \quad \text{as } x \to -\infty.$$

We can conclude that for $j=0,1,\cdots,4$ both $\partial_x^j G(x, t)$ and $|x|^{1/2}\partial_x^j G(x, t)$ belong to $L^2(-\infty)$.

Application 2(ii). Suppose that g satisfies $A(\lambda, N)$ with $\lambda=6$, $N=4$, $\lambda(3)=4$, and $\lambda(4)=2$. Then since $4>(6+1)/2$, Lemma 3.8(ii) gives us

$$\partial_x^j G_1(x, t)=O(|x|^{-(6-j)/2-\delta}) \quad \text{as } x \to -\infty, \quad j=0,1,2$$

for some small positive δ. Also g' satisfies $A(\lambda, N)$ with $\lambda=4$ and $N=3$. Since $3>(4+1)/2$, Lemma 3.8(i) gives us

$$\partial_x^j G_1(x, t)=O(|x|^{-(4-j)/2-1/4}) \quad \text{as } x \to -\infty, \quad j=0,1,2.$$

Thus

$$\partial_x^j G(x,t) = O(|x|^{-3+j/2-\delta}) \quad \text{as } x \to -\infty, \quad j = 0, 1, 2,$$
$$\partial_x^3 G(x,t) = O(|x|^{-3/2-\delta}) \quad \text{as } x \to -\infty,$$
$$\partial_x^4 G(x,t) = O(|x|^{-1-\delta}) \quad \text{as } x \to -\infty.$$

It follows that for $j = 0, 1, \cdots, 4$ both $\partial_x^j G(x,t)$ and $|x|^{1/2}\,\partial_x^j G(x,t)$ are in $L^2(-\infty)$.

4. The regularity of the solutions of the Marchenko equation. The right-hand side Marchenko equation is

$$B_+(x,y) + \Omega_+(x+y) + \int_0^\infty B_+(x,z)\Omega_+(x+y+z)\,dz = 0. \tag{4.1}$$

It is well known [1], [6] that if $\Omega_+ \in L^1(+\infty) \cap L^\infty(+\infty)$ and if $\Omega_+' \in L_1^1(+\infty)$, then Ω_+ generates a compact operator from $L^1(\mathbb{R}^+)$ to $L^1(\mathbb{R}^+)$ and from $L^2(\mathbb{R}^+)$ to $L^2(\mathbb{R}^+)$ for each x by

$$\mathbf{\Omega}_{+x}[f](y) = \int_0^\infty f(z)\Omega_+(x+y+z)\,dz.$$

Theorems 4.1 and 4.2 are similar to results in [4]-[6]. They are stated here in the form used later.

THEOREM 4.1. *Suppose $n \geqq 1$. Suppose that $\Omega_+ \in C^{n+1}(\mathbb{R})$ and that for all finite X*

(i) $\int_X^\infty |\Omega_+'(s)|(1+|s|)\,ds < \infty$;

(ii) *If $0 \leqq k \leqq n$, then* $\int_X^\infty |\Omega_+^{(k)}(s)|\,ds < \infty$;

(iii) *If $0 \leqq k \leqq n+1$, then* $\sup\{|\Omega_+^{(k)}(X+s)|: s \geqq 0\} < \infty$;

(iv) $\int_X^\infty |\Omega_+^{(n+1)}(s)|^2\,ds < \infty$.

Then (4.1) *has a unique solution $B_+(x,\cdot)$ in $L^1(\mathbb{R}^+) \cap L^2(\mathbb{R}^+)$. Further $x \mapsto B_+(x,\cdot)$ is $(n+1)$-times Frechet-differentiable as a function from $\mathbb{R}$ to $L^2(\mathbb{R}^+)$. Moreover $\partial_x^k B_+(x,y)$ is continuous in $\mathbb{R} \times [0,\infty)$ for $k \leqq n+1$. Finally if $k \leqq n$, then $\partial_x^k B_+(x,\cdot) \in L^1(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$.*

Proof. Consider first the case $n = 1$:

The existence of $B_+(x,\cdot)$ in $L^1(\mathbb{R}^+)$ is well known [1], [6]. We need to show (a) that $x \mapsto B_x(x,\cdot)$ is twice differentiable as a function from $\mathbb{R}$ to $L^2(\mathbb{R}^+)$, (b) that $\partial_x^k B_+(x,y)$ is continuous on $\mathbb{R} \times \mathbb{R}^+$ for $k = 0, 1, 2$, and (c) that $\partial_x^k B_+(x,\cdot) \in L^1(\mathbb{R}^+)$ for $k = 0, 1$.

Since $\Omega_+ \in L^1(+\infty)$ it is easy to check that $x \mapsto \mathbf{\Omega}_{+x}$ is continuous in the uniform operator norm on both $L^1(\mathbb{R}^+)$ and $L^\infty(\mathbb{R}^+)$. Thus $(\mathbf{I} + \mathbf{\Omega}_{+x})^{-1}$ also depends continuously on x in the uniform norm in $\mathscr{L}(L^1(\mathbb{R}^+))$. It is also easy to see that $\mathbf{\Omega}_{+x}$ maps $L^1(\mathbb{R}^+)$ into $L^\infty(\mathbb{R}^+)$:

$$\sup_{y \geqq 0} |\mathbf{\Omega}_{+x}[g](y)| \leqq \sup_{y \geqq 0} \int_0^\infty |g(z)|\,|\Omega_+(x+y+z)|\,dz \leqq \sup_{s > x} |\Omega_+(s)| \cdot \int_{z=0}^\infty |g(z)|\,dz.$$

It now follows from (4.1) that $B_+(x,\cdot)$ is in $L^\infty(\mathbb{R}^+)$ as well as in $L^1(\mathbb{R}^+)$. To see the continuity of $B_+(x,y)$ we note

$$\begin{aligned} B_+(x_1,y_1) - B_+(x_2,y_2) = {} & -\Omega_+(x_1,y_1) + \Omega_+(x_2,y_2) \\ & - \int_0^\infty B_+(x_1,z)\{\Omega_+(x_1+y_1+z) - \Omega_+(x_2+y_2+z)\}\,dz \\ & - \int_0^\infty \{B_+(x_1,z) - B_+(x_2,z)\}\Omega_+(x_2+y_2+z)\,dz. \end{aligned}$$

Thus

$$
\begin{aligned}
|B_+(x_1, y_1) - B_+(x_2, y_2)| \leqq |\Omega_+(x_1+y_1) - \Omega_+(x_2+y_2)| \\
+ \sup_{s \geqq s_0} |\Omega'_+(s)|\,|x_1+y_1-x_2-y_2|\, \|B_+(x_1, \cdot)\|_{L^1} \\
+ \sup_{s \geqq s_0} |\Omega_+(s)| \cdot \|B_+(x_1, \cdot) - B_+(x_2, \cdot)\|_{L^1}
\end{aligned}
$$

where $s_0 \leqq \min\{x_1+y_1, x_2+y_2\}$. The continuity of $B_+(x, y)$ as a map $\mathbb{R} \times \mathbb{R}^+ \to R$ now follows easily.

For the rest of this section we will omit the subscripts "+" from B_+, Ω_+, and $\mathbf{\Omega}_+$. Where we intend B_- and Ω_-, the subscript "−" will appear.

Next we ask whether $x \mapsto B(x, \cdot)$ is differentiable as a map $\mathbb{R} \mapsto L^1(\mathbb{R}^+)$.

For $h \neq 0$, set

$$
\Phi_h(x, y) = \frac{\Omega(x+y+h) - \Omega(x+y)}{h} + \int_{z=0}^{\infty} B(x, z) \frac{\Omega(x+y+z+h) - \Omega(x+y+z)}{h}\, dz
$$

and for $h = 0$, set

$$
\Phi_0(x, y) = \Omega'(x+y) + \int_0^{\infty} B(x, z)\Omega'(x+y+z)\, dz.
$$

Note that

$$
\frac{B(x+h, y) - B(x, y)}{h} = -(\mathbf{I} + \mathbf{\Omega}_{(x+h)})^{-1}[\Phi_h(x, \cdot)](y).
$$

Clearly $\Phi_h(x, \cdot) \in L^1(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ for all h. Further $\Phi_h(x, \cdot) \mapsto \Phi_0(x, \cdot)$ in both $L^1(\mathbb{R}^+)$ and $L^\infty(\mathbb{R}^+)$ as $h \to 0$. Thus

$$
\lim_{h \to \infty} \frac{B(x+h, \cdot) - B(x, \cdot)}{h} = -(\mathbf{I} + \mathbf{\Omega}_x)^{-1}[\Phi_0(x, \cdot)] \quad \text{in } L^1(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+).
$$

Thus

$$
\begin{aligned}
\partial_x^1 B(x, y) + \int_{z=0}^{\infty} \partial_x^1 B(x, z)\Omega(x+y+z)\, dz &= -\Phi_0(x, y) \\
&= -\Omega'(x+y) - \int_0^{\infty} B(x, z)\Omega'(x+y+z)\, dz.
\end{aligned}
$$

It now follows that $\partial_x^1 B(x, y)$ depends continuously on x and y.

Finally consider the map $x \mapsto \partial_x^1 B(x, \cdot)$ as going from $\mathbb{R}$ to $L^2(\mathbb{R}^+)$. We must show that it is differentiable. Write $B^{(1,0)}(x, y)$ for $\partial_x^1 B(x, y)$. For $h \neq 0$, set

$$
\psi_h(x, \cdot) = -(\mathbf{I} + \mathbf{\Omega}_{(x+h)}) \left[\frac{B^{(1,0)}(x+h, \cdot) - B^{(1,0)}(x, \cdot)}{h} \right].
$$

Since all $B^{(1,0)}(x, \cdot)$ are in $L^1(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ it follows that $\psi_h(x, \cdot)$ is in $L^1(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$. Computation shows that

$$
\begin{aligned}
\psi_h(x, y) = {} & \frac{\Omega'(x+y+h) - \Omega'(x+y)}{h} + \int_0^{\infty} \frac{B(x+h, z) - B(x, z)}{h} \Omega'(x+y+h+z)\, dz \\
& + \int_0^{\infty} B^{(1,0)}(x, z) \frac{\Omega(x+y+h+z) - \Omega(x+y+z)}{h}\, dz \\
& + \int_0^{\infty} B(x, z) \frac{\Omega'(x+y+h+z) - \Omega'(x+y+z)}{h}\, dz.
\end{aligned}
$$

For $h=0$ set

$$\psi_0(x, y)=\Omega''(x+y)+2\int_0^\infty B^{(1,0)}(x, z)\Omega'(x+y+z)\,dz+\int_0^\infty B(x, z)\Omega''(x+y+z)\,dz.$$

Our hypotheses and earlier results tell us that

$$\psi_0(x,\cdot)\in L^2(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+).$$

Now we verify that $\psi_h(x,\cdot)\to\psi_0(x,\cdot)$ in $L^2(\mathbb{R}^+)$. As a function of y in $\mathbb{R}^+$, $\{\Omega'(x+y+h)-\Omega'(x+y)\}/h$ converges to $\Omega''(x+y)$ in $L^2(\mathbb{R}^+)$ as $h\to 0$. The remaining three terms in $\psi_h(x, y)$ are essentially convolutions. It is straightforward to verify the convergence of the factors in these convolutions in $L^2(\mathbb{R}^+)$. Thus, still in $L^2(\mathbb{R}^+)$, $\psi_h(x,\cdot)\to\psi_0(x,\cdot)$ as $h\to 0$. Thus

$$\begin{aligned}\lim_{h\to 0}\frac{B^{(1,0)}(x+h,\cdot)-B^{(1,0)}(x,\cdot)}{h}&=-\lim_{h\to 0}(\mathbf{I}+\mathbf{\Omega}_{(x+h)})^{-1}\Psi_h(x,\cdot)\\&=-(\mathbf{I}+\mathbf{\Omega}_x)^{-1}\psi_0(x,\cdot).\end{aligned}$$

So $\partial_x^2B(x,\cdot)$ exists in $L^2(\mathbb{R}^+)$ and satisfies

$$\begin{aligned}\partial_x^2B(x, y)+\int_0^\infty\partial_x^2B(x, z)\Omega(x+y+z)\,dz=-\Omega''(x+y)-2\int_0^\infty B^{(1,0)}(x, z)\Omega'(x+y+z)\,dz\\-\int_0^\infty B(x, z)\Omega''(x+y+z)\,dz.\end{aligned}$$

The continuity of $\partial_x^2B(x, y)$ follows from analysis of this equation.

This proves the theorem for $n=1$. The method extends in the obvious way to cases where $n>1$. □

THEOREM 4.2. *Suppose that $\Omega(x, t)$ has the following properties*:

(i) *For fixed $t>0$, $\Omega(x, t)$ is a C^1 function of x, and*

$$\int_X^\infty|\partial_x\Omega(x, t)|(1+|x|)\,dx<\infty\quad\textit{for all finite } X.$$

(ii) *The mapping $t\mapsto\Omega(\cdot, t)$ is differentiable both as a map from $(0,\infty)$ to $L^1(+\infty)$ and from $(0,\infty)$ to $L^\infty(+\infty)$; $\int_X^\infty|\partial_t\Omega(x, t)|\,dx<\infty$, for finite X.*

(iii) *The mapping $t\mapsto\Omega(\cdot, t)$ is differentiable as a map from $(0,\infty)$ to $L^2(+\infty)$, $\int_X^\infty|\partial_t\partial_x\Omega(x, t)|^2\,dx<\infty$ for finite X.*

(iv) *For fixed $t>0$, the functions $\Omega(x, t)$, $\partial_x\Omega(x, t)$, $\partial_t\Omega(x, t)$, and $\partial_t\partial_x\Omega(x, t)$ are in $L^\infty(+\infty)$.*

(v) *The functions mentioned in* (iv) *are continuous on $\mathbb{R}\times(0,\infty)$. For each $t>0$, let $B(x,\cdot, t)$ denote the solution of*

$$B(x, y, t)+\Omega(x+y, t)+\int_0^\infty B(x, z, t)\Omega(x+y+z, t)\,dz=0,$$

which is the Marchenko equation with $\Omega=\Omega(x, t)$. Then

(a) *The map $t\mapsto B(x,\cdot, t)$ is differentiable both as a map $(0,\infty)\to L^1(\mathbb{R}^+)$ and as a map $(0,\infty)\to L^2(\mathbb{R}^+)$. Further both $B(x, y, t)$ and $\partial_tB(x, y, t)$ are continuous in $\mathbb{R}\times[0,\infty)\times(0,\infty)$.*

(b) *The map $t\mapsto\partial_xB(x,\cdot, t)$ is differentiable as a map $(0,\infty)\to L^2(\mathbb{R}^+)$, and $\partial_t\partial_xB(x, y, t)$ is continuous in $\mathbb{R}\times[0,\infty)\times(0,\infty)$.*

Proof. By hypotheses we have $\Omega(x, t) \in L^1(+\infty)$ and $\partial_x \Omega(x, t) \in L_1^1(+\infty)$ for each fixed $t > 0$. Therefore the solutions $B(x, \cdot, t)$ exist in $L^1(\mathbb{R}^+)$. The continuity of $B(x, y, t)$ follows immediately, as does the existence and continuity of $\partial_x B(x, y, t)$.

Let $\mathbf{\Omega}_x^t$ denote the operator $\mathbf{\Omega}_x^t[g](y) = \int_0^\infty \Omega_+(x+y+z, t) g(z)\, dz$.

We use again the methods of the previous theorem. For $h \neq 0$, one gets

$$\frac{B(x, y, t+h) - B(x, y, t)}{h} + \int_{z=0}^\infty \frac{B(x, z, t+h) - B(x, z, t)}{h} \Omega(x+y+z, t+h)\, dz$$
$$= -\Phi_h(x, y, t)$$

where

$$\Phi_h(x, y, t) \equiv \frac{\Omega(x+y, t+h) - \Omega(x+y, t)}{h}$$
$$+ \int_0^\infty B(x, z, t) \left\{ \frac{\Omega(x+y+z, t+h) - \Omega(x+y+z, t)}{h} \right\} dz.$$

We have assumed that the map $t \mapsto \Omega(\cdot, t)$ is differentiable in $L^1(+\infty)$. Therefore as $h \to 0$, $\Phi_h(x, \cdot, t)$ converges in $L^1(\mathbb{R}^+)$ to

$$\Phi_0(x, y, t) \equiv \partial_t \Omega(x+y, t) + \int_0^\infty B(x, z, t) \partial_t \Omega(x+y+z, t)\, dz.$$

It is easy to see that $\Phi_h(x, \cdot, t) \to \Phi_0(x, \cdot, t)$ also in $L^\infty(\mathbb{R}^+)$, whence in $L^2(\mathbb{R}^+)$ as well. Now we have

$$\frac{B(x, \cdot, t+h) - B(x, \cdot, t)}{h} = (\mathbf{I} + \mathbf{\Omega}_x^{t+h})^{-1}[-\Phi_h(x, \cdot, t)].$$

The operator $(\mathbf{I} + \mathbf{\Omega}_x^{t+h})^{-1}$ depends continuously on h in the operator norms on both $L^1(\mathbb{R}^+)$ and $L^2(\mathbb{R}^+)$. So

$$\lim_{h \to 0} \frac{B(x, \cdot, t+h) - B(x, \cdot, t)}{h} = (\mathbf{I} + \mathbf{\Omega}_x^t)^{-1}[-\Phi_0(x, \cdot, t)]$$

in both spaces; equivalently $\partial_t B(x, \cdot, t)$ exists in $L^1(\mathbb{R}^+) \cap L^2(\mathbb{R}^+)$ and satisfies

$$\partial_t B(x, y, t) = -\Omega_t(x+y, t) - \int_0^\infty B_t(x, z, t) \Omega(x+y+z, t)\, dz$$
$$- \int_0^\infty B(x, z, t) \Omega_t(x+y+z, t)\, dz.$$

From this it follows that $\partial_t B(x, \cdot, t)$ is in $L^\infty(\mathbb{R}^+)$ and that $\partial_t B(x, y, t)$ is continuous in $\mathbb{R} \times [0, \infty) \times (0, \infty)$.

Next we study the map $t \mapsto \partial_x B(x, \cdot, t)$. Set

$$-\Psi_h(x, \cdot, t) = (\mathbf{I} + \mathbf{\Omega}_x^{t+h})^{-1} \left[\frac{B(x, \cdot, t+h) - B(x, \cdot, t)}{h} \right].$$

Computation shows that

$$\Psi_h(x, y, t) = \{\Omega^{(1,0)}(x+y, t+h) - \Omega^{(1,0)}(x+y, t)\}/h$$
$$+ \int_0^\infty B_x(x, z, t)\{\Omega(x+y+z, t+h) - \Omega(x+y+z, t)\} h^{-1}\, dz$$
$$+ \int_0^\infty B(x, z, t)\{\Omega^{(1,0)}(x+y+z, t+h) - \Omega^{(1,0)}(x+y+z, t)\} h^{-1}\, dz$$

$$+\int_0^\infty \{B(x,z,t+h)-B(x,z,t)\}h^{-1}\Omega^{(1,0)}(x+y+z,t+h)\,dz.$$

Clearly as $h\to 0$, we get the convergence $\Psi_h(x,\cdot,t)\to\Psi_0(x,\cdot,t)$ in $L^2(\mathbb{R}^+)$, where

$$\begin{aligned}\Psi_0(x,y,t)=\partial_t\partial_x\Omega(x+y,t)&+\int_0^\infty B_x(x,z,t)\Omega(x+y+z,t)\,dz\\&+\int_0^\infty B(x,z,t)\Omega_{x,t}(x+y+z,t)\,dz\\&+\int_0^\infty B_t(x,z,t)\Omega_x(x+y+z,t)\,dz.\end{aligned}$$

Thus $t\mapsto B_x(x,\cdot,t)$ is differentiable in $L^2(\mathbb{R}^+)$ and

$$\partial_t\partial_x B(x,y,t)+\int_0^\infty \partial_t\partial_x B(x,z,t)\Omega(x+y+z,t)\,dz=-\psi_0(x,y,t)$$

whence $\partial_t\partial_x B(x,y,t)$ is continuous and belongs to $L^\infty(\mathbb{R}^+)$ as a function of y. □

We next investigate the consequences of a stronger decay assumption on $\Omega'(x)$, namely that there is an $\alpha\geqq 1$ such that

$$\int_X^\infty |\Omega'(x)|(1+|x|^\alpha)\,dx<\infty \quad \text{for all } X \text{ in } \mathbb{R}.$$

We make use of an inequality of Faddeev's [6, p. 160]

$$|\Omega(x)+\partial_x B(x,0)|\leqq C(x)\left[\int_x^\infty |\Omega'(t)|\,dt\right]^2 \tag{4.2}$$

where $C(x)$ is a nonincreasing function of x.

LEMMA 4.3. *Suppose that $\Omega\in L^1(+\infty)$ and $\Omega'\in L^1_\alpha(+\infty)$ with $\alpha\geqq 1$. Let $B(x,y)$ be the solution of* (4.1) *and set $u(x)=-\partial_x B(x,0)$. Then $u\in L^1_\alpha(+\infty)$.*

Proof. Because of (4.2) it suffices to prove that

$$Q\equiv\int_{y=x}^\infty y^\alpha\left(\int_{t=y}^\infty |\Omega'(t)|\,dt\right)^2 dy<\infty$$

for $x\geqq 0$.

Now

$$\begin{aligned}Q&=\int_{y=x}^\infty y^\alpha\left(\int_{t=y}^\infty |\Omega'(t)|\,dt\right)\left(\int_{s=y}^\infty |\Omega'(s)|\,ds\right)dy\\&=\int_{t=x}^\infty |\Omega'(t)|\int_{s=x}^t |\Omega'(s)|\int_{y=x}^s y^\alpha\,dy\,ds\,dt+\int_{t=x}^\infty |\Omega'(t)|\int_{s=t}^\infty |\Omega'(s)|\int_{y=x}^t y^\alpha\,dy\,ds\,dt\\&\leqq\frac{1}{\alpha+1}\int_{t=x}^\infty |\Omega'(t)|t^{(\alpha+1)/2}\int_{s=x}^\infty \Omega'(s)|s^{(\alpha+1)/2}\,ds\,dt\\&<\infty\end{aligned}$$

since $(\alpha+1)/2\leqq\alpha$. □

5. The existence theorem for KdV; properties of the solution. In this section we describe the properties of the function $u(x,t)$ constructed by the inverse scattering method and establish the sense in which it solves the problem (1.1), (1.2).

THEOREM 5.1. *Suppose that $U\in L_1^1(\mathbb{R})$ and that $U\in L_N^1(\mathbb{R}^+)$ for some $N\geqq 11/4$. Then there is a classical solution $u(x,t)$ of* KdV *in $t>0$ such that*

(i) *$\partial_x^j\partial_t^k u(x,t)$ is continuous in x for each positive t when $0\leqq j+3k\leqq 2N-3$;*

(ii) *$u(\cdot,t)\to U$ in $H^{-1}(+\infty)$ as $t\to 0$.*

(iii) *$x^n\partial_x^j u(x,t)\to 0$ as $x\to+\infty$ for $0\leqq n\leqq N+\frac{1}{4}-(j+1)/2$.*

Proof. For each fixed positive t we consider the Marchenko equation

$$B_+(x,y,t)+\Omega_+(x+y,t)+\int_{z=0}^{\infty}\Omega_+(x+y+z,t)B_+(x,z,t)\,dz=0 \tag{5.1}$$

where

$$\Omega_+(x,t)=F_+(x,t)+2\sum_{j\in J}c_{+j}\,e^{-2\kappa_j x+8\kappa_j^3 t}$$

and

$$F_+(x,t)=\pi^{-1}\int_{-\infty}^{\infty}R_+(k)\,e^{8ik^3t+2ikx}\,dk.$$

This $F_+(x,t)=F_1(x,t)+F_2(x,t)$ as in § 3. By appealing to Lemmas 3.3, 3.4, 3.5 and to the hypothesis $N\geqq 11/4$ we conclude that

(a) $\partial_x\Omega_+(x,t)\in L_1^1(+\infty)$,

(b) $\partial_x^\nu\Omega_+(x,t)\in L^1(+\infty)$ for $0\leqq\nu\leqq 2N-\frac{1}{2}$,

(c) $\partial_x^\nu\Omega_+(x,t)\in L^\infty(+\infty)$ for $0\leqq\nu\leqq 2N+\frac{1}{2}$, and

(d) $\partial_x^{\nu+1}\Omega_+(x,t)\in L^2(+\infty)$ for $0\leqq\nu\leqq 2N-3/2$.

Note that $N\geqq 11/4$ implies that $2N-3/2\geqq 4$. Thus our kernel $\Omega_+(x,t)$ satisfies the hypotheses of Theorem 4.1 with $1\leqq n\leqq 2N-\frac{3}{4}$. So we obtain a solution $B_+(x,y,t)$ to (5.1) such that

$$B_+(x,\cdot,t)\in L^1(\mathbb{R}^+)\cap L^2(\mathbb{R}^+).$$

$$\partial_x^\nu B_+(x,y,t)\text{ is continuous for }(x,y)\text{ in }\mathbb{R}\times(0,\infty)\text{ if }\nu\leqq n+1.$$

$$\partial_x^\nu B_+(x,\cdot,t)\in L^1(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+)\quad\text{if } 0\leqq\nu\leqq n.$$

Let $u(x,t)=-\partial_x B_+(x,0,t)$. We must now show that $u(x,t)$ is the desired solution of KdV.

In addition to properties (a)-(d) of Ω_+ we know that in the distribution sense

$$\partial_t\Omega_+(x,t)+\partial_x^3\Omega_+(x,t)=0\quad\text{for } t>0,\quad x\in\mathbb{R}.$$

Since $N\geqq 11/4$, and thus $2N-1\geqq 4$ we conclude that $\Omega_+(x,t)$ and $\partial_x\Omega_+(x,t)$ are continuously differentiable with respect to t, and that

$$\partial_t\Omega_+(\cdot,t)=-\partial_x^3\Omega_+(\cdot,t)\in L^1(+\infty)\cap L^\infty(+\infty),$$

$$\partial_t\partial_x\Omega_+(\cdot,t)=-\partial_x^4\Omega_+(\cdot,t)\in L^2(+\infty)\cap L^\infty(+\infty).$$

In order to apply Theorem 4.2 we need finally to check that $t\mapsto\Omega_+(\cdot,t)$ is differentiable in $L^\infty(+\infty)$ for $t>0$; but this follows from the continuity and decay rate of $\Omega_t=-\Omega_{xxx}$.

By applying Theorem 4.2 we now learn that

$$\partial_t B_+(x,\cdot,t)\in L^1(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+),$$

$$\partial_t\partial_x B_+(x,\cdot,t)\in L^2(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+),$$

and further that all $\partial_x^j\partial_t^k B_+(x,y,t)$ are continuous in $\mathbb{R}\times[0,\infty)\times(0,\infty)$ for $j+3k\leqq 2N-2$.

For fixed positive t, it is clear that u has the regularity (i) and the decay rate (iii). The proof that this function $u(x, t)$ satisfies the KdV equation (1.1) in $t>0$ follows Tanaka's argument in [17]. The condition $N \geqq 11/4$ gives enough regularity to justify the formal argument.

To prove (ii) we show that $u(x, t) \to U(x)$ in $H^{-1}([X, \infty))$ as $t \to 0$ for each finite X. Since $B_+(x, 0, t) = \int_x^\infty u(s, t)\, ds$ for $t \geqq 0$ we must show that $B_+(x, 0, t) \to B_+(x, 0, 0)$ in $L^2([X, \infty))$ as $t \to 0$. From the Marchenko equation (4.1) we obtain

$$B_+(x, 0, t) - B_+(x, 0, 0) = -Q_1(x, t) - Q_2(x, t) - Q_3(x, t)$$

where

$$Q_1(x, t) = \Omega_+(x, t) - \Omega_+(x, 0),$$

$$Q_2(x, t) = \int_0^\infty \{B_+(x, z, t) - B_+(x, z, 0)\}\Omega_+(x+z, t)\, dz,$$

$$Q_3(x, t) = \int_0^\infty B_+(x, z, 0)\{\Omega_+(x+z, t) - \Omega_+(x+z, 0)\}\, dz.$$

One easily sees that $Q_1(x, t) \to 0$ in $L^2([X, \infty))$ as $t \to 0$.

Next we show $Q_3(x, t) \to 0$ in $L^2([X, \infty))$ as $t \to 0$ by showing that

$$\|Q_3(\cdot, t)\|_{L^2([X,\infty))} \leqq C\|\Omega_+(\cdot, t) - \Omega_+(\cdot, 0)\|_{L^2([X,\infty))}. \tag{5.2}$$

For any $h \in L^2([X, \infty))$

$$\begin{aligned}\left|\int_X^\infty h(x) Q_3(x, t)\, dx\right| &= \left|\int_{x=X}^\infty h(x) \int_{s=x}^\infty B_+(x, s-x, 0)\{\Omega_+(s, t) - \Omega_+(s, 0)\}\, ds\, dx\right| \\ &\leqq \int_{s=X}^\infty |\Omega_+(s, t) - \Omega_+(s, 0)| \left\{\int_{x=X}^s |h(x) B_+(x, s-x, 0)| dx\right\} ds \\ &\leqq \|\Omega_+(\cdot, t) - \Omega_+(\cdot, 0)\|_{L^2([X,\infty))} \\ &\quad \cdot \left\{\int_{s=X}^\infty \left(\int_{x=X}^s |h(x) B_+(x, s-x, 0)|\, dx\right)^2 ds\right\}^{1/2}.\end{aligned}$$

Letting Φ denote the second factor, we have

$$\begin{aligned}\Phi &\leqq \left\{\int_{s=X}^\infty \left(\int_{x=X}^s |h(x)|^2\, dx\right)\left(\int_{x=X}^s |B_+(x, s-x, 0)|^2\, dx\right) ds\right\}^{1/2} \\ &\leqq \|h\|_{L^2([X,\infty))} \left\{\int_{s=X}^\infty \int_{x=X}^s |B_+(x, s-x, 0)|^2\, dx\, ds\right\}^{1/2}.\end{aligned}$$

From Tanaka's paper [17, § 1] we have

$$|B_+(x, y, 0)| \leqq K \int_{x+y}^\infty |U(z)|\, dz \quad \text{for all } x \geqq X, \quad y \geqq 0,$$

whence

$$|B_+(x, s-x, 0)| \leqq K \int_x^\infty |U(z)|\, dz \quad \text{for all } x \geqq X, \quad s \geqq x.$$

Thus

$$\Phi \leqq \|h\|_{L^2([X,\infty))} \left\{\int_{s=X}^\infty \int_{x=X}^s \left(K \int_{z=s}^\infty |U(z)|\, dz\right)^2 dx\, ds\right\}^{1/2}$$

whence $\Phi \leqq C\|h\|_{L^2([X,\infty))}$ where

$$C=\frac{1}{2}K\left\{\int_X^\infty |U(w)|\,dw \int_{z=X}^\infty (z-X)^2|U(z)|\,dz\right\}^{1/2}<\infty.$$

Now (5.2) follows since h was arbitrary.

Finally we look at $Q_2(x,t)$: One finds

$$\|Q_2(x,t)\|^2_{L^2([X,\infty))} \leqq \left\{\int_{x=X}^\infty \int_{z=0}^\infty |B_+(x,z,t)-B_+(x,z,0)|^2\,dz\,dx\|Q_1(\cdot,t)\|^2_{L^2([X,\infty))}.\right.$$

The second factor is bounded as $t\to 0$, so we look at the first factor, $\Psi(t)$.

$$B_+(x,z,t)-B_+(x,z,0)=-Q_4(x,z,t)-Q_5(x,z,t)$$

where

$$Q_4(x,\cdot,t)=(\mathbf{I}+\mathbf{\Omega}_x^t)^{-1}[\Omega_+(x+[\cdot],t)-\Omega_+(x+[\cdot],0)]$$

and

$$Q_5(x,\cdot,t)=[(\mathbf{I}+\mathbf{\Omega}_x^t)^{-1}-(\mathbf{I}+\mathbf{\Omega}_x^0)^{-1}]\Omega_+(x+[\cdot],0).$$

Thus

$$\psi(t)=\int_X^\infty \|Q_4(x,\cdot,t)+Q_5(x,\cdot,0)\|^2_{L^2(\mathbb{R}^+)}\,dx \leqq 2\int_X^\infty (\|Q_4(x,\cdot,t)\|^2+\|Q_5(x,\cdot,t\|^2)\,dx.$$

There is a bound M such that

$$\|(\mathbf{I}+\mathbf{\Omega}_x^t)^{-1}\|_{op,L^2(\mathbb{R}^+)} \leqq M \quad \text{for } X\leqq x\leqq\infty, \quad 0\leqq t\leqq 1$$

because the operator depends continuously on (x,t) and the kernel decays fast enough as $x\to+\infty$. Thus

$$\|Q_4(x,\cdot,t)\|^2_{L^2(\mathbb{R}^+)} \leqq M\int_x^\infty |\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds$$

and

$$\int_X^\infty \|Q_4(x,\cdot,t)\|^2\,dx \leqq M\int_X^\infty (s-X)|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds.$$

By the form of $\Omega_+, \Omega_+=F_++G_+$ in §3.1, we need only show

$$\int_X^\infty (s-X)|F_+(s,t)-F_+(s,0)|^2\,ds\to 0 \quad \text{as } t\to 0.$$

We already know $F_+(s,t)\to F_+(s,0)$ in $L^2(\mathbb{R})$ so it suffices to show $\int_{X+1}^\infty s^2|F_+(s,t)-F_+(s,0)|^2\,ds\to 0$. By Proposition 2.5 we know $R_+\in C^1(\mathbb{R})$ and $R_+(k)=O(k^{-1})$ as $k\to\pm\infty$. We may therefore follow Kappeler's proof of Theorem 3.1(iv) in [9] to conclude that $sF_+(s,t)\to sF_+(s,0)$ in $L^2(+\infty)$ as $t\to 0$. It remains to make $\int_X^\infty \|Q_5(x,\cdot,t)\|^2\,dx\to 0$ as $t\to 0$. But, using L^2 norms on $\mathbb{R}^+$,

$$\begin{aligned}\|Q_5(x,\cdot,t)\| &\leqq \|(\mathbf{I}+\mathbf{\Omega}_x^t)^{-1}(\mathbf{\Omega}_x^0-\mathbf{\Omega}_x^t)(\mathbf{I}+\mathbf{\Omega}_x^0)^{-1}\|_{op}\|\Omega_+(x+[\cdot],t)\| \\ &\leqq M^2\|\mathbf{\Omega}_x^0-\mathbf{\Omega}_x^t\|_{op}\|\Omega_+(x+[\cdot],t)\|.\end{aligned}$$

The last factor is bounded as $t \to 0$ so

$$\begin{aligned}\int_X^\infty \|Q_5(x,\cdot,t)\|^2\,dx &\leqq C\int_X^\infty \|\Omega_x^0-\Omega_x^t\|_{op}^2\,dx\\ &\leqq C\int_X^\infty\int_x^\infty |\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\,dx\\ &\leqq C\int_X^\infty (s-X)|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds,\end{aligned}$$

which we have already seen goes to 0 with t.

This completes the proof of Theorem 5.1. □

Under certain additional hypotheses we can also study $u(x,t)$ as $x \to -\infty$.

THEOREM 5.2. (i) *Assume that $U \in L_N^1(\mathbb{R})$, that $N \geqq 5$, and that $R_-^{(n)}(k) = O(|k|^{-\lambda})$ as $k \to \pm\infty$ for $n = 0, 1, 2$ and some $\lambda > 5/2$. Let $u(x,t)$ be the solution to* KdV *with initial profile U in the sense of Theorem* 5.1. *Then $u(\cdot,t)$ evolves in $L^2(\mathbb{R})$ for $t > 0$. If $N \geqq \lambda + 2$, then $\int_{-\infty}^\infty |u(x,t)|^2|x|^{2\alpha}\,dx < \infty$ for any α with $\lambda - 3/2 > 2\alpha \geqq 1$.*

(ii) *Suppose that U satisfies the hypothesis of Theorem* 5.1, *that $R_-^{(n)}(k) = O(k^{-3})$ for $n = 0, 1, 2$, and that $R_-^{(3)}(k) = O(k^{-1})$. Let $u(x,t)$ be the solution of* KdV *given by Theorem* 5.1. *Then $u(x,t)$ evolves in $L^2(\mathbb{R})$ for $t > 0$.*

Remark 1. The purpose of the extra hypothesis is to allow use of the left-side Marchenko equation as well as the right-side one, and thereby to study $u(x,t)$ as $x \to -\infty$. Sachs did not treat this point. Kruzhkov and Faminskii also show evolution in $L^2(\mathbb{R})$, but they consider weighted L^2 norms only on $\mathbb{R}^+$, and their construction is not conducive to analysis of the long time asymptotics of their solution.

Remark 2. For U in $L_N^1(\mathbb{R})$ it is known that additional regularity of U is a sufficient condition for additional decay of $R_-(k)$. For example, from [4] one learns that if $U(x)$ is absolutely continuous, $U'(x)$ is piecewise absolutely continuous, $U \in L_5^1(\mathbb{R})$, $U' \in L_5^1(\mathbb{R})$, and $U'' \in L_4^1(\mathbb{R})$, then the hypothesis of (ii) is satisfied. Another example [20] shows that if $x^m \partial_x^j U(x)$ is in $L^2(\mathbb{R})$ for $0 \leqq m \leqq 4$ and $0 \leqq j \leqq 4$, then the hypothesis of (ii) is also satisfied.

Proof. (i) We consider the solution $u(x,t)$ provided by Theorem 5.1. We know from § 3 that for $t > 0$

$$\begin{aligned}\partial_x F_+(x,t) &= O(|x|^{-N+1/2+\varepsilon}) \quad \text{as } x \to +\infty,\\ \partial_x F_-(x,t) &= O(|x|^{-\lambda/2+1/4}) \quad \text{as } x \to -\infty.\end{aligned}$$

The same decay rates hold for $\partial_x\Omega_+, \partial_x\Omega_-$. By the forward scattering theory [5], [6] all hypotheses of Theorem 3.3 in [8] are satisfied at each $t > 0$. Thus we conclude by Theorem 3.9 of [8] that

$$u(\cdot,t) = -\partial_x B_+(\cdot,0,t) = \partial_x B_-(\cdot,0,t)$$

in $L_{\text{loc}}^1(\mathbb{R})$ for each fixed positive t, where B_+ and B_- are the solutions of the Marchenko equations

$$\begin{aligned}B_+(x,y,t) + \Omega_+(x+y,t) + \int_{z=0}^\infty B_+(x,z,t)\Omega_+(x+y+z,t) &= 0,\\ B_-(x,y,t) + \Omega_-(x+y,t) + \int_{z=-\infty}^0 B_-(x,z,t)\Omega_-(x+y+z,t) &= 0\end{aligned}$$

in $L^1(\mathbb{R}^+)$ and $L^1(\mathbb{R}^-)$, respectively.

In the generic case $u(x, t) = O(|x|^{-N+1+\varepsilon})$ as $x \to \infty$ for $0 < \varepsilon \ll 1/2$. In the exceptional case $u(x, t) = O(x^{-N+2+\varepsilon})$ as $x \to \infty$ for $0 < \varepsilon \ll 1/2$. Since $N \geqq 5$, $u(\cdot, t) \in L^2(\mathbb{R}^+)$. If we know that both $\lambda > 5/2$ and $N \geqq \lambda + 2$, then we can pick α so $\lambda - 3/2 > 2\alpha \geqq 1$ and conclude that

$$\int_0^\infty |s|^{2\alpha} |u(s, t)|^2 \, ds < \infty$$

since $2\alpha + 2(-N + 2\varepsilon) < -1$.

If we take α so $\lambda - 3/2 > 2\alpha \geqq 1$, then by Kappeler's Theorem 3.9 [8] we get

$$\int_{-\infty}^0 |s|^{2\alpha} |u(s, t)|^2 \, ds < \infty \quad \text{for } t > 0.$$

Since $2\alpha \geqq 1$ we get $\int_{-\infty}^{-1} |u(s, t)|^2 \, ds < \infty$ also. But since $u(x, t)$ is in $L^1(+\infty) \cap L^\infty(+\infty)$ we can conclude that $\int_{-1}^0 |u(s, t)|^2 \, ds < \infty$, and further that $u(\cdot, t) \in L^2(\mathbb{R}^-)$.

The proof of (i) is completed by combining results on $\mathbb{R}^+, \mathbb{R}^-$; the proof of (ii) is similar. □

THEOREM 5.3. *For $N \geqq 3$, assume that $U \in L^1_N(\mathbb{R})$ if U is generic, but that $U \in L^1_{N+1}(\mathbb{R})$ if U is nongeneric. Let $u(x, t)$ be the solution of* KdV *provided by Theorem* 5.1. *Recall $B_+(x, 0, t) = \int_x^\infty u(z, t) \, dz$. Then*

(i) *For $0 \leqq n \leqq N - 1$, $x^n B_+(x, 0, t) \to x^n B_+(x, 0, 0)$ in $L^2(+\infty)$ as $t \to 0$;*

(ii) *For each n with $1 \leqq n \leqq N - 1$, if $(1 + x^n) U(x)$ is in $L^2(\mathbb{R})$, then $x^\alpha u(x, t) \to x^\alpha U(x)$ in $L^2(+\infty)$ as $t \to 0$ for all α with $0 \leqq \alpha \leqq n$;*

(iii) *For each n with $1 \leqq n \leqq N - 1$, if both $(1 + x^n) U(x)$ and $(1 + x^n) U'(x)$ are in $L^2(+\infty)$, then also $x^\alpha \partial_x u(x, t) \to x^\alpha U'(x)$ in $L^2(+\infty)$ as $t \to 0$ for all α with $0 \leqq \alpha \leqq n$.*

Proof. Because $R_+(k)$ is at least C^1 and $R_+'(k)$ is $O(k^{-1})$ as $k \to \pm\infty$, the proof of (i) may be taken over from the proof of Kappeler's [9, Thm. 3.1]. We prove (ii) below; the proof of (iii) is similar.

Start with the representation

$$\begin{aligned} u(x, t) - U(x) = {} & \partial_x \Omega_+(x, t) - \partial_x \Omega_+(x, 0) \\ & + \int_0^\infty \{B_+(x, z, t) - B_+(x, z, 0)\} \partial_x \Omega_+(x + z, t) \, dz \\ & + \int_0^\infty B_+(x, z, 0) \{\partial_x \Omega_+(x + z, t) - \partial_x \Omega + (x + z, 0)\} \, dz \\ & + \int_0^\infty \{\partial_x B_+(x, z, t) - \partial_x B_+(x, z, 0)\} \Omega_+(x + z, t) \, dz \\ & + \int_0^\infty \partial_x B_+(x, z, 0) \{\Omega_+(x + z, t) - \Omega_+(x + z, 0)\} \, dz, \end{aligned}$$

which is based on the Marchenko equation. Call the five terms on the right $T_\nu(x, t)$ for $\nu = 1, \cdots, 5$. We must show that $x^\alpha T_\nu(x, t) \to 0$ in $L^2([X, \infty))$ as $t \to 0$ for arbitrary X and $\nu = 1, \cdots, 5$. We do this by assuming three technical points which will be stated when first used but not proved until the end.

Since $x^\alpha U(x) \in L^2(\mathbb{R})$ for $0 \leqq \alpha \leqq n$, Proposition 2.7 tells us that $k R_+^{(\alpha)}(k)$ is in $L^2(\mathbb{R})$ for $0 \leqq \alpha \leqq n$, and that $R_+^{(\alpha)}(k)$ is in $L^2(\mathbb{R})$ for $0 \leqq \alpha \leqq N$. Thus

$$x^\alpha F_+(x) \in L^2(\mathbb{R}) \quad \text{for } 0 \leqq \alpha \leqq N,$$

and

$$x^\alpha \partial_x F_+(x) \in L^2(\mathbb{R}) \quad \text{for } 0 \leqq \alpha \leqq n.$$

By Kappeler's method of proof [9, Thm. 3.1] one may show that if $0 \leqq \beta \leqq n$, then

$$x^\beta \Omega_+(x,t) \to x^\beta \Omega_+(x,0) \quad \text{in } L^2(+\infty) \text{ as } t \to 0 \tag{5.3a}$$

and that

$$\partial_x \Omega_+(x,t) \to \partial_x \Omega_+(x,0) \quad \text{in } L^2(+\infty) \text{ as } t \to 0. \tag{5.3b}$$

The convergence of $x^\alpha T_1(x,t)$ to 0 in $L^2([X,\infty))$ as $t \to 0$ is one part of our first technical result:

Point 1. If $0 \leqq \alpha \leqq n$ and X is fixed, then

$$x^\alpha \partial_x \Omega_+(x,t) \to x^\alpha \partial_x \Omega_+(x,0) \quad \text{in } L^2([X,\infty)) \quad \text{as } t \to 0, \tag{5.4}$$

$$\int_X^\infty |x|^{2\alpha} \left(\int_x^\infty |\partial_s \Omega_+(s,t) - \partial_s \Omega_+(s,0)| \right)^2 dx \to 0 \quad \text{as } t \to 0. \tag{5.5}$$

Looking at $T_2(x,t)$ we see

$$\begin{aligned}\int_X^\infty |x^\alpha T_2(x,t)|^2 \, dx &\leqq \int_X^\infty \left\{ |x|^\alpha \int_0^\infty |B_+(x,z,t) - B_+(x,z,0)|^2 \, dz \right\} \\ &\quad \cdot \left\{ |x|^\alpha \int_0^\infty |\partial_x \Omega_+(x+z,t)|^2 \, dz \right\} dx \\ &\leqq \left\{ \int_X^\infty |x|^{2\alpha} \left(\int_0^\infty |B_+(x,z,t) - B_+(x,z,0)|^2 \, dz \right)^2 dx \right\}^{1/2} \\ &\quad \cdot \left\{ \int_X^\infty |x|^{2\alpha} \left(\int_0^\infty |\partial_x \Omega_+(x+z,t)|^2 \, dz \right)^2 dx \right\}^{1/2}.\end{aligned}$$

The second factor is bounded as $t \to 0$ by (5.4). Part of our next technical point tells us that the first factor vanishes as $t \to 0$:

Point 2. Fix X. Then, as $t \to 0$,

$$B_+(x,\cdot,t) \to B_+(x,\cdot,0) \quad \text{in } L^2(\mathbb{R}^+) \text{ uniformly for } x \geqq X, \tag{5.6}$$

$$\int_X^\infty |x|^{2\alpha} \left(\int_0^\infty |B_+(x,z,t) - B_+(x,z,0)|^2 \, dz \right)^2 dx \to 0 \quad \text{for } 0 \leqq \alpha \leqq n. \tag{5.7}$$

Looking at the third term we see

$$\begin{aligned}\int_X^\infty |x^\alpha T_3(x,t)|^2 \, dx &\leqq \int_X^\infty \left\{ |x|^\alpha \int_0^\infty |B_+(x,z,0)|^2 dz \right\} \\ &\quad \cdot \left\{ |x|^\alpha \int_0^\infty |\partial_x \Omega_+(x+z,t) - \partial_x \Omega_+(x+z,0)|^2 \, dz \right\} dx \\ &\leqq \left\{ \int_X^\infty |x|^{2\alpha} \left(\int_0^\infty |B_+(x,z,0)|^2 \, dz \right)^2 dx \right\}^{1/2} \\ &\quad \cdot \left\{ \int_X^\infty |x|^{2\alpha} \left(\int_0^\infty |\partial_x \Omega_+(x+z,t) - \partial_x \Omega_+(x+z,0)|^2 \, dz \right)^2 dx \right\}^{1/2}.\end{aligned}$$

The first factor is finite by (5.6). The second factor vanishes because of the form of Ω_+ and result (5.5).

For the fourth term, we see

$$\int_X^\infty |x^\alpha T_4(x,t)|^2\,dx \leqq \int_X^\infty \left\{|x|^\alpha \int_0^\infty |\partial_x B_+(x,z,t)-\partial_x B_+(x,z,0)|^2\,dz\right\} \cdot \left\{|x|^\alpha \int_0^\infty |\Omega_+(x+z,t)|^2\,dz\right\}dx$$

$$\leqq \left\{\int_X^\infty |x|^{2\alpha}\left(\int_0^\infty |\partial_x B_+(x,z,t)-\partial_x B_+(x,z,0)|^2\,dz\right)^2 dx\right\}^{1/2} \cdot \left\{\int_X^\infty |x|^{2\alpha}\left(\int_0^\infty |\Omega_+(x+,z,t)|^2\,dz\right)^2 dx\right\}^{1/2}.$$

The second factor is bounded as $t\to 0$ by Point 1. The first factor vanishes by the final technical result:

Point 3. As $t\to 0$

(5.8) $$\partial_x B_+(x,z,t)\to\partial_x B_+(x,z,0)\quad \text{in } L^2(\mathbb{R}^+) \text{ uniformly for } x\geqq X,$$

(5.9) $$\int_X^\infty |x|^{2\alpha}\left(\int_0^\infty |\partial_x B_+(x,z,t)-\partial_x B_+(x,z,0)|^2\,dz\right)^2 dx\to 0\quad \text{for } 0\leqq\alpha\leqq n.$$

Finally,

$$\int_X^\infty |x^\alpha T_5(x,t)|^2\,dx \leqq \int_X^\infty \left\{|x|^\alpha \int_0^\infty |\partial_x B_+(x,z,0)|^2\,dz\right\} \cdot \left\{|x|^\alpha \int_0^\infty |\Omega_+(x+z,t)-\Omega_+(x+z,0)|^2\,dz\right\}dx$$

$$\leqq \left\{\int_X^\infty |x|^{2\alpha}\left(\int_0^\infty |\partial_x B_+(x,z,0)|^2\,dz\right)^2 dx\right\}^{1/2} \cdot \left\{\int_X^\infty |x|^{2\alpha}\left(\int_0^\infty |\Omega_+(x+z,t)-\Omega_+(x+z,0)|^2\,dz\right)^2 dx\right\}^{1/2}.$$

Point 3 says the first factor is finite; the second factor vanishes by (5.3a).

To complete the proof of Theorem 5.3 we must now prove three technical points. Recall that

$$\Omega_+(x,t)=F_+(x,t)+2\sum c_{+j}\exp(8\kappa_j^3 t-2\kappa_j x).$$

Thus for Point 1 it suffices to prove

Point 1′. If $0\leqq\alpha\leqq n$, $1\leqq n\leqq N-1$ and $X\in\mathbb{R}$, then as $t\to 0$

(5.4′) $$x^\alpha\partial_x F_+(x,t)\to x^\alpha\partial_x F_+(x,0)\quad \text{in } L^2([X,\infty)),$$

(5.5′) $$\int_X^\infty |x|^{2\alpha}\left(\int_x^\infty |\partial_s F_+(s,t)-\partial_s F_+(s,0)|^2\,ds\right)^2 dx\to 0.$$

Proof of (5.4′). It suffices to treat $\alpha=0$ and $\alpha=n$. Recall that

(5.10) $$\partial_x F_+(x,t)=\pi^{-1}\int_{-\infty}^\infty 2ikR_+(k)\,e^{8ik^3t+2ikx}\,dk.$$

By Proposition 2.7 we know $2ikR_+(k)$ is in $L^2(\mathbb{R})$. It follows that $\partial_x F_+(x, t) \to \partial_x F_+(x, 0)$ in $L^2(\mathbb{R})$ as $t \to 0$. It is the exponential terms in $\partial_x \Omega_+(x, t)$ that restrict the convergence (5.4) to halflines. This takes care of the case $\alpha = 0$. Next we take $1 \leqq \alpha = n \leqq N-1$. By the case $\alpha = 0$ we know

$$x^\alpha \partial_x F_+(x, t) \to x^\alpha \partial_x F_+(x, 0) \quad \text{in } L^2_{\text{loc}}.$$

Thus it suffices to prove

$$x^\alpha \partial_x F_+(x, t) \to x^\alpha \partial_x F_+(x, 0) \quad \text{in } L^2([2, \infty)).$$

Set $\mathcal{R}(k) = 2ikR_+(k)$ in (5.10). Note that

$$\partial_x F_+(x, t) = \pi^{-1} \int_{-\infty}^{\infty} \mathcal{R}(k) \frac{1}{2i(12k^2t + x)} \frac{\partial[e^{8ik^3t + 2ikx}]}{\partial k}\, dk$$

$$= (-1)\pi^{-1} \int_{-\infty}^{\infty} \frac{\partial}{\partial k}\left[\frac{\mathcal{R}(k)}{2i(12k^2t + x)}\right][e^{8ik^3t + 2ikx}]\, dk.$$

Repeating this procedure one finds

$$\partial_x F_+(x, t) = (-1)^\alpha \pi^{-1} \int_{-\infty}^{\infty} \mathcal{T}^\alpha[\mathcal{R}]\, e^{8ik^3t + 2ikx}\, dk$$

where $\mathcal{T}[g] \equiv \partial_k[g/12i(12k^2t + x)]$. Now $\mathcal{T}^\alpha[\mathcal{R}]$ is a linear combination of terms of the form

$$\frac{\mathcal{R}^{(\lambda)}(k) k^\mu t^\nu}{(12k^2t + x)^{\alpha+\nu}} \quad \text{where } 0 \leqq \lambda \leqq \alpha,\ 0 \leqq \mu \leqq \nu,\ 0 \leqq \lambda + \nu \leqq \alpha.$$

Since $x^\alpha \partial_x F_+(x, t)$ is a linear combination of the terms

$$I_{\lambda,\mu,\nu}(x, t) = t^\nu \pi^{-1} \int_{-\infty}^{\infty} \mathcal{R}^{(\lambda)}(k) \frac{k^\mu x^\alpha}{(12k^2t + x)^{\alpha+\nu}} e^{8ik^3t + 2ikx}\, dk,$$

it will suffice to show that as $t \to 0$

$$I_{\lambda,\mu,\nu}(x, t) \to I_{\lambda,\mu,\nu}(x, 0) \quad \text{in } L^2([2, \infty)).$$

Case $\nu > 0$. Here we need $I_{\lambda,\mu,\nu}(x, t) \to 0$ in $L^2([2, \infty))$. Since $\lambda \leqq \alpha = n \leqq N-1$ we know $\mathcal{R}^{(\lambda)} \in L^2(\mathbb{R})$. For each t let $W_\lambda(x, t)$ denote the inverse Fourier transform of $\mathcal{R}^{(\lambda)}(k) \exp(8ik^3t)$. Now we can see $I_{\lambda,\mu,\nu}$ as the result of a pseudo-differential operator acting on W_λ. The symbol

$$p_{\mu,\nu}(x, k) = \frac{k^\mu x^\alpha}{(12k^2t + x)^{\alpha+\nu}}$$

has the property that there is a C such that

$$|\partial_k^i \partial_x^j p_{\mu,\nu}(x, k)| \leqq C \quad \text{for } x \geqq 1, \qquad 0 \leqq t \leqq 1.$$

Choose a nonnegative C^∞ cutoff function $\zeta(x)$ such that $\zeta(x) = 0$ for $x \leqq 0$, $\zeta(x) = 1$ for $x \geqq 2$, and $|\partial_x^m \zeta(x)| \leqq M_0$ for all $m \in \mathbb{N}$. Now for $x \geqq 2$

$$I_{\lambda,\mu,\nu}(x, t) = t^\nu \mathcal{F}^{-1}[\zeta(x) p_{\mu,\nu}(x, t) \mathcal{F}[W_\lambda(x, t)]].$$

By a result of Calderon and Vaillancourt (as present in [18, Thm. 3.1, p. 347]) we see there is a constant M_1 independent of t for $0 \leqq t \leqq 1$ such that

$$\|t^\nu \mathcal{F}^{-1}[\zeta(x)p_{\mu,\nu}(x, t)\mathcal{F}[W_\lambda(x, t)]]\|_{L^2(-\infty<x<\infty)}$$
$$\leqq t^\nu M_1 \|\mathcal{F}[W_\lambda(x, t)]\|_{L^2(-\infty<x<\infty)} = t^\nu M_1 \|\mathcal{R}^{(\lambda)}\|_{L^2(-\infty<k<\infty)}.$$

Thus, as required, $I_{\lambda,\mu,\nu}(x, t) \to 0$ in $L^2([2, \infty))$ as $t \to 0$.

Case $\nu = 0$. Since $0 \leqq \mu \leqq \nu$, we must show

$$I_{\lambda,0,0,}(x, t) \to I_{\lambda,0,0,}(x, 0) \quad \text{in } L^2([2, \infty)) \text{ as } t \to 0.$$

Now

$$I_{\lambda,0,0,}(x, t) - I_{\lambda,0,0,}(x, 0) = \pi^{-1} \int_{-\infty}^{\infty} \mathcal{R}^{(\lambda)}(k) \frac{x^\alpha}{(12k^2t + x)^\alpha} [e^{8ik^3t} - 1]\, e^{2ikx}\, dk$$
$$+ \pi^{-1} \int_{-\infty}^{\infty} \mathcal{R}^{(\lambda)}(k) \left\{ \frac{x^\alpha}{(12k^2t + x)^\alpha} - 1 \right\} e^{2ikx}\, dk$$

and $\mathcal{R}^{(\lambda)}(k)[e^{8ik^3t} - 1]$ is in $L^2(\mathbb{R})$. Apply the same result of Calderon and Vaillancourt to obtain

$$\left\| \pi^{-1} \int_{-\infty}^{\infty} \mathcal{R}^{(\lambda)}(k)[e^{8ik^3t} - 1]\zeta(x) \left(\frac{x}{12k^2t + x} \right)^\alpha e^{2ikx}\, dk \right\|_{L^2(-\infty<x<\infty)}$$
$$\leqq M_1 \|\mathcal{R}^{(\lambda)}(k)[e^{8ik^3t} - 1]\|_{L^2(-\infty<k<\infty)},$$

the right side of which clearly goes to 0 as $t \to 0$. The second term in the difference $I_{\lambda,0,0}(x, t) - I_{\lambda,0,0}(x, 0)$ is treated similarly to complete the proof of (5.4′).

In proving (5.5′) we may assume $X \leqq 1$. Let $E(x, t)$ denote $\int_x^\infty |\partial_s F_+(s, t) - \partial_s F_+(s, 0)|^2\, ds$. We must show

$$\int_X^\infty |x|^{2\alpha} E(x, t)^2\, dx \to 0 \quad \text{as } t \to 0.$$

Divide the integral at $x = 1$. Clearly

$$\int_X^1 \cdots dx \leqq \max\{1, |x|^{2\alpha}\} \int_X^\infty E(x, t)^2\, dx$$
$$\leqq \max\{1, |x|^{2\alpha}\} E(X) \int_X^\infty E(x, t)\, dx$$
$$\leqq KE(X) \int_X^\infty \int_x^\infty |\partial_s F_+(s, t) - \partial_s F_+(s, 0)|^2\, ds\, dx$$
$$\leqq KE(X) \int_{s=X}^\infty (s - X)|\partial_s F_+(s, t) - \partial_s F_+(s, 0)|^2\, ds,$$

which goes to zero by (5.4′). Next

$$\int_1^\infty \cdots dx = \int_1^\infty \{x^{2\alpha} E(x, t)\} E(x, t)\, dx$$
$$\leqq \int_1^\infty \left\{ \int_x^\infty s^{2\alpha} |\partial_s F_+(s, t) - \partial_s F_+(s, 0)|^2\, ds \right\} E(x, t)\, dx$$
$$\leqq \left\{ \int_1^\infty s^{2\alpha} |\partial_s F_+(s, t) - \partial_s F_+(s, 0)|^2\, ds \right\} \int_1^\infty E(x, t)\, dx.$$

The first factor goes to zero by (5.4′). The second also does since

$$\int_1^\infty E(x,t)\,dx=\int_1^\infty (s-1)|\partial_s F_+(s,t)-\partial_s F_+(s,0)|^2\,ds.$$

This completes the proof of Point 1. □

Point 2.

(i) $B_+(x,\cdot,t)\to B_+(x,\cdot,0)$ in $L^2(\mathbb{R}^+)$ as $t\to 0$ uniformly in $x\geqq X$;

(ii) $\int_1^\infty |x|^{2\alpha}\|B_+(x,\cdot,t)\to B_+(x,\cdot,0)\|^4_{L^2(\mathbb{R}^+)}\,dx\to 0$ as $t\to 0$ for $0\leqq \alpha\leqq n$.

Proof. We have

$$\begin{aligned}&\|B_+(x,\cdot,t)-B_+(x,\cdot,0)\|_{L^2(\mathbb{R}+)}\\ &\quad\leqq C_0(x)\|\Omega_+(x+[\cdot],t)-\Omega_+(x+[\cdot],0)\|_{L^2(\mathbb{R}+)}\\ &\qquad+\|(\mathbf{I}+\mathbf{\Omega}^t_x)^{-1}-(\mathbf{I}+\mathbf{\Omega}^0_x)^{-1}\|_{op}\|\Omega_+(x+[\cdot],0)\|_{L^2(\mathbb{R}^+)}\end{aligned}\tag{5.11}$$

where $C_0(x)=\sup\{\|(\mathbf{I}+\mathbf{\Omega}^t_w)^{-1}\|_{op}: x\leqq w, 0\leqq t\leqq 1\}$. $C_0(x)$ is finite and nonincreasing. We show that each term on the right of (5.11) vanishes as $t\to 0$. First

$$\sup\{\|\Omega_+(x+[\cdot],t)-\Omega_+(x+[\cdot],0)\|^2_{L^2(\mathbb{R}^+)}: x\geqq X\}\leqq\int_X^\infty |\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds,$$

which, as we have already seen, vanishes as $t\to 0$. Second,

$$\begin{aligned}\|(\mathbf{I}+\mathbf{\Omega}^t_x)^{-1}-(\mathbf{I}+\mathbf{\Omega}^0_x)^{-1}\|_{op}&\leqq C_0(x)^2\|(\mathbf{I}+\mathbf{\Omega}^t_x)^{-1}\|_{op}\\ &\leqq C_0(x)^2\left(\int_{y=x}^\infty (y-x)|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy\right)^{1/2}.\end{aligned}$$

Thus

$$\begin{aligned}&\sup\{\|(\mathbf{I}+\mathbf{\Omega}^t_x)^{-1}-(\mathbf{I}+\mathbf{\Omega}^0_x)^{-1}\|_{op}: x\geqq X\}\\ &\qquad\leqq C_0(X)\left(\int_{y=x}^\infty (y-X)|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy\right)^{1/2}\end{aligned}$$

which vanishes as $t\to 0$ by Point 1. This completes (i). Because of (i) it suffices to prove (ii) for $X=0$. Now by (5.11)

$$\begin{aligned}&\|B_+(x,\cdot,t)-B_+(x,\cdot,0)\|^4\\ &\quad\leqq C_1(x)\left(\int_x^\infty|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\right)^2\\ &\qquad+C_0(x)\left(\int_x^\infty (y-x)|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy\right)^2\left(\int_x^\infty|\Omega_+(s,0)|^2\,ds\right)^2\end{aligned}$$

where $C_1(x)$ and $C_2(x)$ are nonincreasing. Now first

$$\begin{aligned}\int_0^\infty |x|^{2\alpha}\left(\int_x^\infty|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\right)^2dx&\leqq\int_0^\infty\left(\int_x^\infty s^\alpha|\Omega_+(s,t)-\Omega_+(s,0)|\,ds\right)^2dx\\ &=\int_0^\infty\int_x^\infty s^\alpha|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\,dx\cdot\int_x^\infty s^\alpha|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\end{aligned}$$

$$= \int_0^\infty s^{\alpha+1}|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds \cdot \int_0^\infty s^\alpha|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds,$$

which goes to 0 as $t \to 0$ by (5.3a) since $\alpha \leqq N-1$. Next, we see

$$\int_0^\infty |x|^{2\alpha}\left(\int_x^\infty (y-x)|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy\right)^2\left(\int_x^\infty |\Omega_+(s,0)|^2\,ds\right)^2 dx$$

$$\leqq \int_0^\infty \left(\int_x^\infty (y-x)|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy\right)^2\left(\int_x^\infty s^\alpha|\Omega_+(s,0)|^2\,ds\right)^2 dx$$

$$\leqq K^2\int_0^\infty y|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy \int_0^\infty\int_x^\infty y|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy\,dx$$

$$= K^2\int_{y=0}^\infty y|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy \int_{y=0}^\infty y^2|\Omega_+(y,t)-\Omega_+(y,0)|^2\,dy.$$

Both of the last two factors go to 0 with t by (5.3a). This completes part (ii).

Point 3.

(i) $\partial_x B_+(x,\cdot,t) \to \partial_x B_+(x,\cdot,0)$ in $L^2(\mathbb{R}^+)$ as $t \to 0$ uniformly in $x \geqq X$;

(ii) $\int_X^\infty |x|^{2\alpha}\|\partial_x B_+(x,\cdot,t)-\partial_x B_+(x,\cdot,0)\|^4_{L^2(\mathbb{R}^+)}\,dx \to 0$ as $t \to 0$ for $0 \leqq \alpha \leqq n$.

Proof. One may verify that

$$(\mathbf{I}+\mathbf{\Omega}_x^t)[\partial_x B_+(x,\cdot,t)-\partial_x B_+(x,\cdot,0)] = -\sum_{\nu=1}^4 Q_\nu(x,\cdot,t)$$

where

$$Q_1(x,\cdot,t) = [(\mathbf{I}+\mathbf{\Omega}_x^t)-(\mathbf{I}+\mathbf{\Omega}_x^0)]\partial_x B_+(x,\cdot,0),$$

$$Q_2(x,y,t) = \partial_x\Omega_+(x+y,t)-\partial_x\Omega_+(x+y,0),$$

$$Q_3(x,y,t) = \int_0^\infty \{B_+(x,z,t)-B_+(x,z,0)\}\partial_x\Omega_+(x+y+z,t)\,dz,$$

$$Q_4(x,y,t) = \int_0^\infty B_+(x,z,0)\{\partial_x\Omega_+(x+y+z,t)-\partial_x\Omega_+(x+y+z,0)\}\,dz.$$

Since $\|(\mathbf{I}+\mathbf{\Omega}_x^t)^{-1}\|_{op} \leqq C_0(X)$ for all $x \geqq X$, $0 \leqq t \leqq 1$, it suffices to prove for each ν that as $t \to 0$

(i) $Q_\nu(x,\cdot,t) \to 0$ in $L^2(\mathbb{R}^+)$ uniformly for $x \geqq X$, and

(ii) $\int_X^\infty |x|^{2\alpha}\|Q_\nu(x,\cdot,t)\|^4_{L^2(\mathbb{R}^+)}\,dx \to 0$.

Case $\nu = 1$.

$$\|Q_1(x,\cdot,t)\|^2_{L^2(\mathbb{R}^+)} = \|\mathbf{\Omega}_x^t-\mathbf{\Omega}_x^0\|^2_{op}\|\partial_x B_+(x,\cdot,0)\|^2_{L^2(\mathbb{R}^+)}.$$

So

$$\sup\{\|Q_1(x,\cdot,t)\|^2_{L^2(\mathbb{R}^+)}: x \geqq X\} \leqq K\int_{s=x}^\infty (s-X)|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds,$$

which goes to 0 with t by (5.3). Thus (i) holds.

$$\begin{aligned}
\int_0^\infty |x|^{2\alpha}\|Q_1(x,\cdot,t)\|^4\,dx &\leqq K\int_0^\infty x^{2\alpha}\left(\int_{s=x}^\infty s|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\right)^2 dx\\
&\leqq K\int_0^\infty\left\{x^2\int_{s=x}^\infty s|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\right\}\\
&\qquad\cdot\left\{x^{2\alpha-2}\int_x^\infty s|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\right\}dx\\
&\leqq K\int_{s=0}^\infty s^3|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\\
&\qquad\cdot\int_0^\infty\int_x^\infty s^{2\alpha-1}|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\,dx\\
&\leqq K\int_0^\infty s^3|\Omega_+(s,t)-\Omega_+(s,0)|^2\,ds\int_0^\infty s^{2\alpha}|\Omega_+(s,t)-(s,0)|^2\,ds,
\end{aligned}$$

which goes to zero with t by (5.3) since $N\geqq 3$ says $3/2\leqq n\leqq N-1$. This finishes (ii).

Case $\nu=2$. This follows directly from Point 1.

Case $\nu=3$.

$$\begin{aligned}
\|Q_3(x,\cdot,t)\|^2_{L^2(\mathbb{R}^+)} &= \int_{y=0}^\infty\left|\int_{z=0}^\infty\{B_+(x,z,t)-B_+(x,z,0)\}\partial_x\Omega_+(x+y+z,t)\,dz\right|^2 dy\\
&\leqq\int_{z=0}^\infty\|B_+(x,\cdot,t)-B_+(x,\cdot,0)\|^2_{L^2(\mathbb{R}^+)}\int_{s-x+y}^\infty|\partial_x\Omega_+(s,t)|^2\,ds\,dy\\
&\leqq\|B_+(x,\cdot,t)-B_+(x,\cdot,0)\|^2\int_{s=x}^\infty(s-x)|\partial_x\Omega_+(s,t)|^2\,ds.
\end{aligned}$$

Convergence (i) follows by Point 1 and Point 2. For (ii) note

$$\begin{aligned}
&\int_0^\infty |x|^{2\alpha}\|Q_3(x,\cdot,t)\|^4\,dx\\
&\qquad\leqq\int_0^\infty |x|^{2\alpha}\|B_+(x,\cdot,t)-B_+(x,\cdot,0)\|^4\left(\int_{s=x}^\infty(s-x)|\partial_s\Omega_+(s,t)|^2\,ds\right)^2 dx.
\end{aligned}$$

Since $B_+(x,\cdot,t)\to B_+(x,\cdot,0)$ in $L^2(\mathbb{R}^+)$ uniformly in $x\geqq 0$ we check the boundedness of the rest:

$$\begin{aligned}
&\int_0^\infty |x|^{2\alpha}\left(\int_{s=x}^\infty(s-x)|\partial_s\Omega_+(s,t)|^2\,ds\right)^2 dx\\
&\qquad\leqq\int_0^\infty\left\{x^2\int_x^\infty s|\partial_s\Omega_+(s,t)|^2\,ds\right\}^2\left\{x^{2\alpha-2}\int_{s=x}^\infty s|\partial_x\Omega_+(s,t)|^2\,ds\right\}^2 dx\\
&\qquad\leqq\int_0^\infty s^3|\partial_s\Omega_+(s,t)|^2\,ds\int_0^\infty s^{2\alpha}|\partial_x\Omega_+(s,t)|^2\,ds.
\end{aligned}$$

Both factors are bounded for $0\leqq t\leqq 1$ by Point 1.

Case $\nu = 4$.

$$\|Q_4(x,\cdot,t)\|^2 = \int_{y=0}^{\infty}\left|\int_0^\infty B_+(x,z,0)\{\partial_x\Omega_+(x+y+z,t)-\partial_x\Omega_+(x+y+z,0)\}\,dz\right|^2 dy$$

$$\leqq \int_0^\infty\left(\int_0^\infty |B_+(x,z,0)|^2\,dz\right)$$

$$\cdot\left(\int_0^\infty |\partial_x\Omega_+(x+y+z,t)-\partial_x\Omega_+(x+y+z,0)|^2\,dz\right)dy$$

$$\leqq \int_0^\infty |B_+(x,z,0)|^2\,dz \int_{y=0}^\infty \int_{s=x+y}^\infty |\partial_s\Omega_+(s,t)-\partial_s\Omega_+(s,0)|^2\,ds\,dy$$

$$\leqq \int_0^\infty |B_+(x,z,0)|^2\,dz \int_{s=x}^\infty (s-x)|\partial_s\Omega_+(s,t)-\partial_s\Omega_+(s,0)|^2\,ds.$$

Now

$$\sup\{\|Q_4(x,\cdot,t)\|^2 : x \geqq X\} \leqq \sup\{\|B_+(x,\cdot,0)\|^2 : x \geqq X\}$$

$$\cdot \int_{x=X}^\infty (s-X)|\partial_s\Omega_+(s,t)-\partial_s\Omega_+(s,0)|^2\,ds$$

which goes to 0 by Point 1. Further

$$\int_0^\infty |x|^{2\alpha}\|Q_4(x,\cdot,t)\|^4\,dx$$

$$\leqq \int_0^\infty |x|^{2\alpha}\left(\int_0^\infty |B_+(x,z,0)|^2\,dz\right)\left(\int_{s=x}^\infty (s-x)|\partial_s\Omega_+(s,t)-\partial_s\Omega_+(s,0)|^2\,ds\right)dx$$

$$\leqq \int_{s=x}^\infty s|\partial_s\Omega_+(s,t)-\partial_s\Omega_+(s,0)|^2\,ds \int_0^\infty x^{2\alpha}\int_0^\infty |B_+(x,z,0)|^2\,dz\,dx.$$

The second factor is finite and the first goes to 0 by Point 1.

This finishes the proof of the last of the three technical points needed to complete the proof of Theorem 5.3. □

ON A COUPLED REACTION DIFFUSION SYSTEM WITH TIME DELAYS*

C. V. PAO†

Abstract. In a two-compartment model for cellular control by repression there arises a coupled system of reaction diffusion equations which governs the densities of the chemical species in the compartments. The reaction mechanism in this model is affected by time delays and the coupling of the equations is through the interface of the two compartments. The purpose of this paper is to give a qualitative analysis of this unusual coupled reaction diffusion system with time delays. This analysis includes the existence and uniqueness of a global time-dependent solution and the corresponding steady state solution, iterative methods for the construction of the solution, and local and global stability of the steady-state solution. Also included is the uniform boundedness of the solution.

Key words. reaction-diffusion equations, upper-lower solutions, time-delayed equations, existence-uniqueness, stability

AMS(MOS) subject classifications. 35K60, 35R10, 35K20

1. Introduction. In the compartment analysis of certain biochemical reactions there arise some mathematical models which are governed by a coupled system of differential equations with time delays. A well-known model for biochemical control of genes was first proposed by Goodwin [3], [4] and later analyzed by many authors (e.g. [1], [5], [7]). Goodwin's model was recently extended to a two-compartment and a three-compartment model where the spatial effect of diffusion is taken into consideration (cf. [6]). This extension leads to a coupled system of parabolic partial differential equations with time-delays. A mathematical analysis for the three-compartment model has been given in [8] where the time-delays only appear in the ordinary differential equations. However, in the two-compartment model the time-delays also occur in the parabolic equation which is coupled with an ordinary differential equation through the interface of the two compartments. This yields an unusual coupling system of reaction diffusion equations. To include possible spherical or cylindrical interface between the two compartments, we consider a multi-dimensional diffusion medium Ω in $\mathbb{R}^m (m=1,2,\cdots,)$ for the second compartment. In this situation the system of reaction diffusion equations is given by

$$\text{(1.1a)}\quad \begin{aligned} L_1[u_1] &\equiv (u_1)_t + (a_1+b_1)u_1 = a_1u_2 + f(v_1(x, t-r_1)) \\ \mathcal{L}_1[v_1] &\equiv (v_1)_t + (a_2+b_2)v_1 = a_2v_2 \end{aligned} \qquad (x \in \Gamma_1,\ t>0),$$

$$\text{(1.1b)}\quad \begin{aligned} L_2[u_2] &\equiv (u_2)_t - D_1\nabla^2 u_2 + b_1u_2 = 0 \\ \mathcal{L}_2[v_2] &\equiv (v_2)_t - D_2\nabla^2 v_2 + b_2v_2 = g(u_2(x, t-r_2)) \end{aligned} \qquad (x \in \Omega,\ t>0)$$

where ∇^2 is the Laplace operator and Γ_1 is the interface between the two compartments (see [6] for a derivation). In the above equations, (u_1, v_1) and (u_2, v_2) represent the densities of the chemical species in the first and second compartment, respectively, a_i and b_i $(i=1,2)$ are the various reaction rates, D_i is the diffusion coefficient, r_i is the time-delay, and f and g are, in general, nonlinear reaction functions with time-delays. On the interface Γ_1, the concentrations (u_1, v_1) and (u_2, v_2) are related through the

boundary condition

$$B(u_2) \equiv \frac{\partial u_2}{\partial \nu} + \beta_1 u_2 = \beta_1 u_1 \qquad\qquad (x \in \Gamma_1, t > 0), \tag{1.2a}$$
$$\mathscr{B}(v_2) \equiv \frac{\partial v_2}{\partial \nu} + \beta_2 v_2 = \beta_2 v_1$$

where β_1 and β_2 are positive constants and $\partial/\partial\nu$ is the outward normal derivative on $\partial\Omega$. On the nonintersecting boundary surface Γ_2 the concentration (u_2, v_2) is required to satisfy the no-flex boundary condition

$$\frac{\partial u_2}{\partial \nu} = 0, \quad \frac{\partial v_2}{\partial \nu} = 0 \quad (x \in \Gamma_2, t > 0). \tag{1.2b}$$

In view of the time-delay the initial condition is given in the form

$$\begin{aligned} &u_1(x, 0) = \xi_1(x), \qquad v_1(x, t) = \eta_1(x, t) \qquad (x \in \Gamma_1, -\gamma_1 \leqq t \leqq 0),\\ &u_2(x, t) = \xi_2(x, t), \qquad v_2(x, 0) = \eta_2(x) \qquad (x \in \Omega, -\gamma_2 \leqq t \leqq 0). \end{aligned} \tag{1.3}$$

Throughout the paper we assume that Ω is a smooth bounded domain in $\mathbb{R}^m$, the initial functions ξ_i, η_i are continuous nonnegative in their respective domain, and f and g are C^1-functions on $\mathbb{R}^+ \equiv [0, \infty)$. Of special interest are the reaction functions

$$f_0(v_1) = \sigma_0(1 + k_0 v_1^\rho)^{-1}, \qquad g_0(u_2) = c_0 u_2, \tag{1.4}$$

where σ_0, k_0, ρ and c_0 are positive constants (cf. [6]). Notice that when Ω is the one-dimensional interval $(0, l)$ and f and g are given by (1.4), problem (1.1)-(1.3) is reduced to the model given in [6].

The purpose of this paper is to study the existence and stability problem of the system (1.1)-(1.3) and its corresponding steady-state system. Our discussion includes the existence and uniqueness of global time-dependent solution and steady-state solution, method of construction of these solutions and the stability property of steady-state solutions. Also included is the uniform boundedness of the time-dependent solution. In § 2 we use the method of upper-lower solutions to establish an existence-comparison theorem for the problem (1.1)-(1.3) and to construct some explicit upper and lower bounds of the solution. Through suitable construction of upper-lower solutions in § 3 we give some sufficient conditions which ensure the local stability and global stability of a steady-state solution. The existence and uniqueness of a steady-state solution is discussed in § 4 where similar upper and lower bounds of the solution are also given.

2. The existence–comparison theorem. In this section we investigate the existence and uniqueness of a global solution to the time-dependent system (1.1)-(1.3). The basic tool for the existence problem is the monotone method and the associated upper-lower solutions for coupled reaction diffusion systems (cf. [9]). The construction of the monotone sequences and the definition of upper-lower solutions depend on the quasi-monotone property of the reaction functions. Motivated by the reaction functions given by (1.4), we make the following basic assumptions.

$$\text{(H)} \qquad f(\eta) \geqq 0, \quad g(\eta) \geqq 0, \quad f'(\eta) \leqq 0, \quad g'(\eta) \geqq 0 \quad \text{for } \eta \geqq 0.$$

The main hypothesis in (H) is that $f(v_1)$ is monotone nonincreasing and $g(u_2)$ is monotone nondecreasing on $[0, \infty)$. With this monotone property of f, g we have the following definition of upper-lower solutions. For notational convenience, we write (u_i, v_i) to represent the function $(u_1, v_1; u_2, v_2)$.

DEFINITION 2.1. A pair of smooth functions $(\tilde{u}_i, \tilde{v}_i)$, $(\underset{\sim}{u}_i, \underset{\sim}{v}_i)$ are called upper and lower solutions of (1.1)-(1.3), respectively, if they satisfy

(i) The differential inequalities:

$$\begin{aligned} &L_1[\tilde{u}_1]-[a_1\tilde{u}_2+f(\underset{\sim}{v}_1(x,t-r_1))]\geqq 0\geqq L_1[\underset{\sim}{u}_1]-[a_1\underset{\sim}{u}_2+f(\tilde{v}_1(x,t-r_1))],\\ &\mathscr{L}_1[\tilde{v}_1]-a_2\tilde{v}_2\geqq 0\geqq \mathscr{L}_1[\underset{\sim}{v}_1]-a_2\underset{\sim}{v}_2,\\ &L_2[\tilde{u}_2]\geqq 0\geqq L_2[\underset{\sim}{u}_2],\\ &\mathscr{L}_2[\tilde{v}_2]-g(\tilde{u}_2(x,t-r_2))\geqq 0\geqq \mathscr{L}_2[\underset{\sim}{v}_2]-g(\underset{\sim}{u}_2(x,t-r_2)); \end{aligned}\tag{2.1}$$

(ii) The boundary inequalities:

$$\begin{aligned} &\left.\begin{aligned} &B[\tilde{u}_2]-\beta_1\tilde{u}_1\geqq 0\geqq B[\underset{\sim}{u}_2]-\beta_1\underset{\sim}{u}_1\\ &\mathscr{B}[\tilde{v}_2]-\beta_2\tilde{v}_1\geqq 0\geqq \mathscr{B}[\underset{\sim}{v}_2]-\beta_2\underset{\sim}{v}_1 \end{aligned}\right. &&(t>0,\ x\in\Gamma_1),\\ &\left.\begin{aligned} &\frac{\partial\tilde{u}_2}{\partial\nu}\geqq 0\geqq\frac{\partial\underset{\sim}{u}_2}{\partial\nu}\\ &\frac{\partial\tilde{v}_2}{\partial\nu}\geqq 0\geqq\frac{\partial\underset{\sim}{v}_2}{\partial\nu} \end{aligned}\right. &&(t>0,\ x\in\Gamma_2); \end{aligned}\tag{2.2}$$

(iii) The initial inequalities:

$$\begin{aligned} &\left.\begin{aligned} &\tilde{u}_1(x,0)-\xi_1(x)\geqq 0\geqq\underset{\sim}{u}_1(x,0)-\xi_1(x)\\ &\tilde{v}_1(x,t)-\eta_1(x,t)\geqq 0\geqq\underset{\sim}{v}_1(x,t)-\eta_1(x,t) \end{aligned}\right. &&(x\in\Gamma_1,\ t\in[-r_1,0]),\\ &\left.\begin{aligned} &\tilde{u}_2(x,t)-\xi_2(x,t)\geqq 0\geqq\underset{\sim}{u}_2(x,t)-\xi_2(x,t)\\ &\tilde{v}_2(x,0)-\eta_2(x)\geqq 0\geqq\underset{\sim}{v}_2(x,0)-\eta_2(x) \end{aligned}\right. &&(x\in\Omega,\ t\in[-r_2,0]). \end{aligned}\tag{2.3}$$

Here by a pair of smooth functions we mean $(\tilde{u}_i, \tilde{v}_i)$ and $(\underset{\sim}{u}_i, \underset{\sim}{v}_i)$ are continuous in their respective domains and are once continuously differentiable in t and twice continuously differentiable in x for $t>0, x\in\Omega$; in addition, $(\tilde{u}_2, \tilde{v}_2)$ and $(\underset{\sim}{u}_2, \underset{\sim}{v}_2)$ are differentiable in the outward normal direction on $\partial\Omega$. Notice that in the above definition, upper and lower solutions are interrelated through the first inequality in (2.1).

Let $D_T=\Omega\times(0,T]$, $S_1=\Gamma_1\times(0,T]$, $S_2=\Gamma_2\times(0,T]$ and let $\bar{D}_T$ be the closure of D_T. Assume there exist upper and lower solutions such that $(\tilde{u}_i, \tilde{v}_i)\geqq(\underset{\sim}{u}_i, \underset{\sim}{v}_i)\geqq(0,0)$ on $\bar{D}_T$ (i.e., $\tilde{u}_i\geqq\underset{\sim}{u}_i\geqq 0$, $\tilde{v}_i\geqq\underset{\sim}{v}_i\geqq 0$ on $\bar{D}_T$, $i=1,2$). By using $(\bar{u}_i^{(0)}, \bar{v}_i^{(0)})=(\tilde{u}_i, \tilde{v}_i)$ and $(\underline{u}_i^{(0)}, \underline{v}_i^{(0)})=(\underset{\sim}{u}_i, \underset{\sim}{v}_i)$ as two initial iterations we construct two sequences $\{\bar{u}_i^{(k)}, \bar{v}_i^{(k)}\}$, $\{\underline{u}_i^{(k)}, \underline{v}_i^{(k)}\}$ from the following iterative process:

$$\begin{aligned} &\left.\begin{aligned} &L_1[\bar{u}_1^{(k)}]=a_1\bar{u}_2^{(k-1)}+f(\underline{v}_1^{(k-1)}(x,t-r_1))\\ &\mathscr{L}_1[\bar{v}_1^{(k)}]=a_2\bar{v}_2^{(k-1)} \end{aligned}\right. &&((x,t)\in S_1),\\ &\left.\begin{aligned} &L_2[\bar{u}_2^{(k)}]=0\\ &\mathscr{L}_2[\bar{v}_2^{(k)}]=g(\bar{u}_2^{(k-1)}(x,t-r_2)) \end{aligned}\right. &&((x,t)\in D_T), \end{aligned}\tag{2.4}$$

$$
(2.5)\qquad
\begin{aligned}
&L_1[\underline{u}_1^{(k)}]=a_1\underline{u}_2^{(k-1)}+f(\bar{v}_1^{(k-1)}(x,t-r_1))\\
&\mathscr{L}_1[\underline{v}_1^{(k)}]=a_2\underline{v}_2^{(k-1)}
\end{aligned}
\qquad ((x,t)\in S_1),
$$
$$
\begin{aligned}
&L_2[\underline{u}_2^{(k)}]=0\\
&\mathscr{L}_2[\underline{v}_2^{(k)}]=g(\underline{u}_2^{(k-1)}(x,t-r_2))
\end{aligned}
\qquad ((x,t)\in D_T).
$$

The boundary and initial conditions for both systems (2.4) and (2.5) are given in the form

$$
(2.6)\qquad
\begin{aligned}
&B[u_2^{(k)}]=\beta_1 u_1^{(k-1)}, \qquad \mathscr{B}[v_2^{(k)}]=\beta_2 v_1^{(k-1)} &&((x,t)\in S_1),\\
&\frac{\partial u_2^{(k)}}{\partial \nu}=\frac{\partial v_2^{(k)}}{\partial \nu}=0 &&((x,t)\in S_2),
\end{aligned}
$$

$$
(2.7)\qquad
\begin{aligned}
&u_1^{(k)}(x,0)=\xi_1(x), \qquad v_1^{(k)}(x,t)=\eta_1(x,t) &&(x\in\Gamma_1,\ t\in[-r_1,0]),\\
&u_2^{(k)}(x,t)=\xi_2(x,t), \qquad v_2^{(k)}(x,0)=\eta_2(x) &&(x\in\Omega,\ t\in[-r_2,0)).
\end{aligned}
$$

Notice that the two sequences $\{\bar{u}_i^{(k)},\bar{v}_i^{(k)}\}$, $\{\underline{u}_i^{(k)},\underline{v}_i^{(k)}\}$ are interrelated through the first equation in (2.4) and (2.5). Our aim is to show that these two sequences, called maximal and minimal sequence respectively, are monotone and both converge to a unique solution of the system (1.1)-(1.3). We first establish the monotone property of the sequences.

LEMMA 2.1. *Let* $(\tilde{u}_i,\tilde{v}_i)$, $(\underset{\sim}{u}_i,\underset{\sim}{v}_i)$ *be upper and lower solutions such that* $(\tilde{u}_i,\tilde{v}_i)\geqq(\underset{\sim}{u}_i,\underset{\sim}{v}_i)\geqq(0,0)$ *and let hypothesis* (H) *hold. Then the sequences* $\{\bar{u}_i^{(k)},\bar{v}_i^{(k)}\}$, $\{\underline{u}_i^{(k)},\underline{v}_i^{(k)}\}$ *obtained from* (2.4)-(2.7) *possess the monotone property*

$$
(2.8)\qquad (\underline{u}_i^{(k)},\underline{v}_i^{(k)})\leqq(\underline{u}_i^{(k+1)},\underline{v}_i^{(k+1)})\leqq(\bar{u}_i^{(k+1)},\bar{v}_i^{(k+1)})\leqq(\bar{u}_i^{(k)},\bar{v}_i^{(k)}),\qquad k=0,1,2,\cdots.
$$

Moreover, for each fixed k, the pair $(\bar{u}_i^{(k)},\bar{v}_i^{(k)})$ *and* $(\underline{u}_i^{(k)},\underline{v}_i^{(k)})$ *are also upper and lower solutions of* (1.1)-(1.3).

Proof. The proof of the monotone property follows along the same line as in [8] and we give a sketch as follows: Let $\bar{w}_i=\bar{u}_i^{(0)}-\bar{u}_i^{(1)}=\tilde{u}_i-\bar{u}_i^{(1)}$, $\bar{z}_i=\bar{v}_i^{(0)}-\bar{v}_i^{(1)}=\tilde{v}_i-\bar{v}_i^{(1)}$. Then by (2.4) and (2.1), $(\bar{w}_i,\bar{z}_i)$ satisfies the relation

$$
(2.9)\qquad
\begin{aligned}
&L_1[\bar{w}_1]=L_1[\tilde{u}_1]-(a_1\tilde{u}_2+f(\underset{\sim}{v}_1(x,t-r_1))\geqq 0,\\
&\mathscr{L}_1[\bar{z}_1]=\mathscr{L}_1[\tilde{v}_1]-a_2\tilde{v}_2\geqq 0,\\
&L_2[\bar{w}_2]=L_2[\tilde{u}_2]-L_2[\bar{u}_2^{(1)}]\geqq 0,\\
&\mathscr{L}_2[\bar{z}_2]=\mathscr{L}_2[\tilde{v}_2]-g(\tilde{u}_2(x,t-r_2))\geqq 0.
\end{aligned}
$$

It is easily seen from the boundary and initial requirement on $(\tilde{u}_i,\tilde{v}_i)$ and (2.6) that

$$
(2.10)\qquad
\begin{aligned}
&B[\bar{w}_2]=B[\tilde{u}_2]-\beta_1\tilde{u}_1\geqq 0, \qquad \mathscr{B}[\bar{z}_2]=\mathscr{B}(\tilde{v}_2]-\beta_2\tilde{v}_1\geqq 0,\\
&\frac{\partial \bar{w}_2}{\partial \nu}=\frac{\partial \tilde{u}_2}{\partial \nu}\geqq 0, \qquad \frac{\partial \bar{z}_2}{\partial z}=\frac{\partial \tilde{v}_2}{\partial \nu}\geqq 0
\end{aligned}
$$

and

$$
(2.11)\qquad
\begin{aligned}
&\bar{w}_1(x,0)=\tilde{u}_1(x,0)-\xi_1(x)\geqq 0, \qquad \bar{z}_1(x,t)=\tilde{v}_1(x,t)-\eta_1(x,t)\geqq 0,\\
&\bar{w}_2(x,t)=\tilde{u}(x,t)-\xi_2(x,t)\geqq 0 \qquad \bar{z}_2(x,0)=\tilde{v}_2(x,0)-\eta_2(x)\geqq 0.
\end{aligned}
$$

The relations (2.9)-(2.11) and the maximum principle ensure that $\bar{w}_i\geqq 0$, $\bar{z}_i\geqq 0$. This proves $(\bar{u}_i^{(1)},\bar{v}_i^{(1)})\leqq(\bar{u}_i^{(0)},\bar{v}_i^{(0)})$. By the property of a lower solution and the monotone property of f and g the same argument shows that

$$(\underline{u}_i^{(0)}, \underline{v}_i^{(0)}) \leqq (\underline{u}_i^{(1)}, \underline{v}_i^{(1)}) \leqq (\bar{u}_i^{(1)}, \bar{v}_i^{(1)}) \leqq (\bar{u}_i^{(0)}, \bar{v}_i^{(0)}).$$

Finally, the conclusion in (2.8) follows by induction.

To show that $(\bar{u}_i^{(k)}, \bar{v}_i^{(k)})$ and $(\underline{u}_i^{(k)}, \underline{v}_i^{(k)})$ are upper-lower solutions for each k, we observe from hypothesis (H) and (2.8) that

$$\begin{aligned} &f(\underline{v}_1^{(k-1)}) \geqq f(\underline{v}_1^{(k)}), \quad f(\bar{v}_1^{(k-1)}) \leqq f(\bar{v}_1^{(k)}), \\ &g(\underline{u}_2^{(k-1)}) \leqq g(\underline{u}_2^{(k)}), \quad g(\bar{u}_2^{(k-1)}) \geqq g(\bar{u}_2^{(k)}), \end{aligned} \qquad k = 1, 2, \cdots. \tag{2.12}$$

This relation and (2.4), (2.8) imply that

$$\begin{aligned} &L_1[\bar{u}_1^{(k)}] = a_1 \bar{u}_2^{(k-1)} + f(\underline{v}_1^{(k-1)}(x, t-r_1)) \geqq a_1 \bar{u}_2^{(k)} + f(\underline{v}_1^{(k)}(x, t-r_1)), \\ &\mathscr{L}_1[\bar{v}_1^{(k)}] = a_2 \bar{v}_2^{(k-1)} \geqq a_2 \bar{v}_2^{(k)}, \\ &L_2[\bar{u}_2^{(k)}] = 0, \\ &\mathscr{L}_2[\bar{v}_2^{(k)}] = g(\bar{u}_2^{(k-1)}(x, t-r_2)) \geqq g(\bar{u}_2^{(k)}(x, t-r_2)). \end{aligned} \tag{2.13}$$

By the same reasoning, a similar set of reversed inequalities hold for $(\underline{u}_i^{(k)}, \underline{v}_i^{(k)})$. Since the boundary and initial requirements in (2.2), (2.3) are trivially satisfied, we conclude that $(\bar{u}_i^{(k)}, \bar{v}_i^{(k)})$ and $(\underline{u}_i^{(k)}, \underline{v}_i^{(k)})$ are upper-lower solutions. This proves the lemma.

In view of the relation (2.8) the pointwise limits

$$\lim_{k\to\infty} (\bar{u}_i^{(k)}, \bar{v}_i^{(k)}) = (\bar{u}_i, \bar{v}_i), \qquad \lim_{k\to\infty} (\underline{u}_i^{(k)}, \underline{v}_i^{(k)}) = (\underline{u}_i, \underline{v}_i) \tag{2.14}$$

exist and satisfy the relation

$$(\underline{u}_i^{(k)}, \underline{v}_i^{(k)}) \leqq (\underline{u}_i, \underline{v}_i) \leqq (\bar{u}_i, \bar{v}_i) \leqq (\bar{u}_i^{(k)}, \bar{v}_i^{(k)}), \qquad k = 1, 2, \cdots. \tag{2.15}$$

By letting $k \to \infty$ in (2.4)-(2.7) a standard regularity argument shows that both $(\bar{u}_i, \bar{v}_i)$ and $(\underline{u}_i, \underline{v}_i)$ satisfy all the equations in (1.1)-(1.3) except with the first equation in (1.1) replaced by

$$\begin{aligned} &L_1[\bar{u}_1] = a_1 \bar{u}_2 + f(\underline{v}_1(x, t-r_1)) \quad \text{for } (\bar{u}_i, \bar{v}_i), \\ &L_1[\underline{u}_1] = a_1 \underline{u}_2 + f(\bar{v}_1(x, t-r_1)) \quad \text{for } (\underline{u}_i, \underline{v}_i) \end{aligned} \tag{2.16}$$

(cf. [2], [9]). In order to ensure that $(\bar{u}_i, \bar{v}_i)$ and $(\underline{u}_i, \underline{v}_i)$ are solutions of (1.1)-(1.3), we need to show $(\bar{u}_i, \bar{v}_i) = (\underline{u}_i, \underline{v}_i)$. This is given in the following existence-comparison theorem.

THEOREM 2.1. *Let $(\tilde{u}_i, \tilde{v}_i)$, $(\underset{\sim}{u}_i, \underset{\sim}{v}_i)$ be upper and lower solutions such that $(\tilde{u}_i, \tilde{v}_i) \geqq (\underset{\sim}{u}_i, \underset{\sim}{v}_i) \geqq (0, 0)$ and let hypothesis* (H) *hold. Then there exists a unique global solution (u_i, v_i) to the problem* (1.1)-(1.3). *Moreover, the maximum and minimum sequences $\{\bar{u}_i^{(k)}, \bar{v}_i^{(k)}\}$, $\{\underline{u}_i^{(k)}, \underline{v}_i^{(k)}\}$ converge monotonically to the solution (u_i, v_i) and*

$$(\underset{\sim}{u}_i, \underset{\sim}{v}_i) \leqq (\underline{u}_i^{(k)}, \underline{v}_i^{(k)}) \leqq (u_i, v_i) \leqq (\bar{u}_i^{(k)}, \bar{v}_i^{(k)}) \leqq (\tilde{u}_i, \tilde{v}_i), \qquad k = 1, 2, \cdots. \tag{2.17}$$

Proof. Let $w_i = \bar{u}_i - \underline{u}_i$, $z_i = \bar{v}_i - \underline{v}_i$. Then (w_i, z_i) satisfies the differential equation

$$(2.18)\qquad \begin{aligned} &L_1[w_1] = a_1 w_2 + f(\underline{v}_1(x, t-r_1)) - f(\bar{v}_1(x, t-r_1)) \\ &\mathscr{L}_1[z_1] = a_2 z_2 \end{aligned} \qquad ((x,t)\in S_1),$$
$$\begin{aligned} &L_2[w_2] = 0 \\ &\mathscr{L}_2[z_2] = g(\bar{u}_2(x, t-r_2)) - g(\underline{u}_2(x, t-r_2)) \end{aligned} \qquad ((x,t)\in D_T)$$

the boundary condition

$$(2.19)\qquad \begin{aligned} &B[w_2] = \beta_1 w_1, \qquad \mathscr{B}[z_2] = \beta_2 z_1 \qquad ((x,t)\in S_1), \\ &\frac{\partial w_2}{\partial \nu} = \frac{\partial z_2}{\partial \nu} = 0 \qquad ((x,t)\in S_2) \end{aligned}$$

and the initial condition

$$(2.20)\qquad \begin{aligned} &w_1(x,0) = z_1(x,t) = 0 \qquad (x\in\Gamma_i,\ t\in[-r_1, 0]), \\ &w_2(x,t) = z_2(x,0) = 0 \qquad (x\in\Omega,\ t\in[-r_2, 0]). \end{aligned}$$

In view of Lemma 2.1 and (2.14) it suffices to show that $(w_i, z_i) = (0, 0)$ on $\bar{D}_T$. Clearly the equations for w_1 and z_1 are equivalent to the integral equation

$$(2.21)\qquad \begin{aligned} &w_1(x,t) = \int_0^t e^{-\alpha_1(t-\tau)}[a_1 w_2(x,\tau) + f(\underline{v}_1(x, \tau-r_1)) - f(\bar{v}_1(x,\tau-r_1))]\,d\tau, \\ &z_1(x,t) = a_2\int_0^t e^{-\alpha_2(t+\tau)} z_2(x,\tau)\,d\tau \end{aligned}$$

where $\alpha_i = a_i + b_i$, $i = 1, 2$. To obtain an integral representation for (w_2, z_2), we make use of the Green's function $\hat{G} \equiv \hat{G}(x, t|\xi, \tau)$ which is governed by the equations

$$(2.22)\qquad \begin{aligned} &\hat{L}[G] \equiv G_t - D\nabla^2 G + bG = \delta(x-\xi)\delta(t-\tau) \qquad ((x,t)\in D_T), \\ &\hat{B}[G] \equiv \frac{\partial G}{\partial \nu} + \beta G = 0 \qquad ((x,t)\in S_1), \\ &\frac{\partial G}{\partial \nu} = 0 \qquad ((x,t)\in S_2), \\ &G(x, t|\xi,\tau) = 0 \qquad (x\in\bar{\Omega},\ t<\tau), \end{aligned}$$

where D, b, and β are positive constants, δ is the Dirac δ-function and (ξ, τ) is a fixed point in D_T. This Green's function can be expressed in the form

$$\hat{G}(x, t|\xi,\tau) = \Gamma^*(x, t|\xi,\tau) + V(x, t|\xi, \tau)$$

where Γ^* is the fundamental solution of $\hat{L}$ given by (cf. [2, 10])

$$\Gamma^*(x, t|\xi,\tau) = (4\pi D(t-\tau))^{-n/2}\exp\,[-(bt + |x-\xi|^2/4D|t-\tau|)] \qquad (t>\tau)$$

and V is the solution of the problem

$$(2.23)\qquad \begin{aligned} &\hat{L}[V] = 0 \qquad ((x,t)\in D_T), \\ &\hat{B}[V] = -\hat{B}[\Gamma^*] \quad ((x,t)\in S_1), \quad \frac{\partial V}{\partial \nu} = -\frac{\partial \Gamma^*}{\partial \nu} \quad ((x,t)\in S_2), \\ &V(x, t|\xi,\tau) \equiv 0 \qquad (x\in\Omega,\ t\leqq\tau). \end{aligned}$$

The function Γ^* has a weak singular point at $(x, t) = (\xi, \tau)$ while V is a bounded smooth function in D_T. It is easily seen that by writing Γ^* in the form

$$\Gamma^*(x, t|\xi,\tau) = (\pi^{-n/2}e^{-bt})\frac{(4D(t-\tau)^{-\mu})}{|x-\xi|^{n-2\mu}}\left[\left(\frac{|x-\xi|^2}{4D(t-\tau)}\right)^{(n-2\mu)/2}\exp\left(-\frac{|x-\xi|^2}{4D(t-\tau)}\right)\right],$$

where $\mu \in (0, 1)$ is a fixed constant, there exists a constant K, independent of (x, t), such that

$$\Gamma^*(x, t|\xi, \tau) \leqq K(t-\tau)^{-\mu}|x-\xi|^{-(n-2\mu)}. \tag{2.24}$$

Let G_1, G_2 be the Green's function corresponding to $(\hat{L}, \hat{B}) = (L, B)$ and $(\hat{L}, \hat{B}) = (\mathscr{L}, \mathscr{B})$, respectively. Then the integral representation for (w_2, z_2) is given by

$$\begin{aligned} w_2(x, t) &= \beta_1 D_1 \int_0^t \int_{\Gamma_1} G_1(x, t|\xi, \tau) w_1(\xi, \tau)\, d\xi\, d\tau, \\ z_2(x, t) &= \int_0^t \int_\Omega G_2(x, t|\xi, \tau)[g(\bar{u}_2(\xi, \tau - r_2)) - g(\underline{u}_2(\xi, \tau - r_2))]\, d\xi\, d\tau \\ &\quad + \beta_2 D_2 \int_0^t \int_{\Gamma_1} G_2(x, t|\xi, \tau) z_1(\xi, \tau)\, d\xi\, d\tau. \end{aligned} \tag{2.25}$$

Hence the system (2.18)-(2.20) is reduced to the integral system (2.21) and (2.25). Our aim is to show that the only solution to this integral system is the trivial solution $(w_i, z_i) = (0, 0)$.

Let M_0 be a common upper bound of $f'(v_1)$ and $g'(u_2)$ on $[\underline{v}_1, \bar{v}_1]$ and $[\underline{u}_2, \bar{u}_2]$, respectively. For each fixed $t > 0$ let $\|w\|_t$, $\|z\|_t$ be the respective sup-norm of w and z on $\Omega \times [0, t]$ and $\Gamma_1 \times [0, t]$. In view of $\bar{v}_1(x, t) = \underline{v}_1(x, t)$ on $\Gamma_1 \times [-r_1, 0]$ and $\bar{u}_2(x, t) = \underline{u}_2(x, t)$ on $\bar{\Omega} \times [-r_2, 0]$, f and g satisfy the estimate

$$\begin{aligned} |f(\underline{v}(x, t - r_1)) - f(\bar{v}_1(x, t - r_1))| &\leqq M_0 \|\bar{v}_1 - \underline{v}_1\|_t = M_0 \|z_1\|_t, \\ |g(\bar{u}_2(x, t - r_2)) - g(\underline{u}_2(x, t - r_2))| &\leqq M_0 \|\bar{u}_2 - \underline{u}_2\|_t = M_0 \|w_2\|_t. \end{aligned} \tag{2.26}$$

Since by (2.24)

$$\begin{aligned} |G_i(x, t|\xi, \tau)| &\leqq |\Gamma_i^*(x, t|\xi, \tau)| + |V_i(x, t|\xi, \tau)| \\ &\leqq K_i(t-\tau)^{-\mu}|x-\xi|^{-n+2\mu} + M_i \qquad (i = 1, 2), \end{aligned}$$

where M_i is an upper bound of V_i, an elementary calculation shows that for some constant M_3, independent of $(x, t; \xi, \tau)$,

$$\begin{aligned} &\int_0^t \int_{\Gamma_1} |G_i(x, t|\xi, \tau)|\, d\xi\, d\tau \leqq M_3(t^{1-\mu} + t) \qquad (i = 1, 2), \\ &\int_0^t \int_\Omega |G_2(x, t|\xi, \tau)|\, d\xi\, d\tau \leqq M_3(t^{1-\mu} + t). \end{aligned} \tag{2.27}$$

Using the estimates (2.26), (2.27) in (2.21), (2.25), we obtain

$$\begin{aligned} |w_1(x, t)| &\leqq \alpha_1^{-1}(1 - e^{-\alpha_1 t})[a_1 \|w_2\|_t + M_0 \|z_1\|_t] \\ &\leqq M(1 - e^{-\alpha_1 t})(\|w_2\|_t + \|z_1\|_t), \\ |z_1(x, t)| &\leqq M(1 - e^{-\alpha_2 t}) \|z_2\|_t, \\ |w_2(x, t)| &\leqq M(t^{1-\mu} + t) \|w_1\|_t, \\ |z_2(x, t)| &\leqq M(t^{1-\mu} + t)(\|w_2\|_t + \|z_1\|_t), \end{aligned} \tag{2.28}$$

where M is a constant independent of (x, t). Define

$$\|W\|_t = \|w_1\|_t + \|z_1\|_t + \|w_2\|_t + \|z_2\|_t.$$

Then the relation (2.28) implies that

$$\|W\|_t \leqq M^*(1 - e^{-\alpha t} + t^{1-\mu} + t) \|W\|_t \tag{2.29}$$

for some constants M^*, α. Let $t_1>0$ be any constant such that $M^*(1-e^{-\alpha t_1}+t_1^{1-\mu}+t_1)<1$. Then by (2.29), $\|W\|_{t_1}=0$. But since $\|W\|_t$ is a nondecreasing function of t we conclude that $\|W\|_t=0$ for all $t\in[0,t_1]$. This proves $(\tilde{u}_i,\tilde{v}_i)=(\underline{u}_i,\underline{v}_i)$ on $\bar{\Omega}\times[0,t_1]$. Using $(w_i(t_1),z_i(t_1))=(0,0)$ as the initial condition, a continuation of the above argument leads to the conclusion $(\tilde{u}_i,\tilde{v}_i)=(\underline{u}_i,\underline{v}_i)$ on $\bar{D}_T$. The above argument also shows that $(\tilde{u}_i,\tilde{v}_i)=(\underline{u}_i,\underline{v}_i)$ on $\bar{D}_T$ is the unique solution of (1.1)-(1.3). This completes the proof of the theorem.

It is seen from Theorem 2.1 that the existence of a global solution is ensured if there exists an ordered pair of upper and lower solutions. Such a pair of functions can be obtained in the form $(\tilde{u}_i,\tilde{v}_i)=(\rho,\rho^*)$ and $(\underline{u}_i,\underline{v}_i)=(0,0)$, where ρ and ρ^* are some positive constants. Indeed, these constant functions fulfill all the requirements in Definition 2.1 if ρ and ρ^* satisfy the inequalities

$$
\begin{aligned}
&(a_1+b_1)\rho-(a_1\rho+f(0))\geqq 0\geqq -f(\rho^*),\\
&b_2\rho^*-g(\rho)\geqq 0\geqq -g(0),\\
&\rho-\xi_1\geqq 0,\qquad \rho^*-\eta_1(x,t)\geqq 0\qquad (t\in[-r_1,0]),\\
&\rho-\xi_2(x,t)\geqq 0,\qquad \rho^*\geqq \eta_2(x)\qquad (x\in\Omega,\ t\in[-r_2,0])
\end{aligned}
\tag{2.30}
$$

since all the other inequalities in (2.1)-(2.3) are trivially satisfied. By hypothesis (H), the relations in (2.30) hold if ρ and ρ^* are chosen such that

$$
\rho\geqq\max\left\{\bar{\xi}_1,\bar{\xi}_2,\frac{f(0)}{b_1}\right\},\qquad \rho^*\geqq\max\left\{\bar{\eta}_1,\bar{\eta}_2,\frac{g(\rho)}{b_2}\right\}
\tag{2.31}
$$

where $\bar{\xi}_i$ and $\bar{\eta}_i$ are the least upper bounds of ξ_i, η_i in their respective domains. With this choice of ρ, ρ^*, $(\tilde{u}_i,\tilde{v}_i)=(\rho,\rho^*)$ and $(\underline{u}_i,\underline{v}_i)=(0,0)$ are upper-lower solutions. As an application of Theorem 2.1 we have the following conclusion.

THEOREM 2.2. *Let f, g satisfy hypothesis* (H). *Then the problem* (1.1)-(1.3) *has a unique nonnegative global solution (u_i,v_i). Moreover this solution is uniformly bounded by (ρ,ρ^*), where ρ and ρ^* are any constants satisfying* (2.31).

3. Asymptotic stability. The construction of constant upper-lower solutions in § 2 ensures the existence of a unique bounded solution to (1.1)-(1.3). In order to investigate the asymptotic behavior of the solution for large values of t, we need to find a different pair of upper-lower solutions. In this section we study the stability problem of the system (1.1)-(1.3) for a given steady-state solution. The existence of steady-state solutions will be discussed in the following section. Here by a steady-state solution we mean a time-independent function $(u_i^s,v_i^s)\equiv(u_1^s,v_1^s;u_2^s,v_2^s)$ which satisfies (1.1), (1.2) without the time-derivative term.

THEOREM 3.1. *Let $(u_i^s(x),v_i^s(x))$ be a nonnegative steady-state solution of* (1.1), (1.2) *and let hypothesis (H) hold. If*

$$
-f'(v_1^s)g'(u_2^s)<b_1b_2\qquad (x\in\bar{\Omega})
\tag{3.1}
$$

then (u_i^s,v_i^s) is asymptotically stable. If, in addition,

$$
\sup_{n\geqq 0}[-f'(\eta)]\sup_{\eta\geqq 0}[g'(\eta)]<b_1b_2
\tag{3.2}
$$

then (u_i^s,v_i^s) is globally asymptotically stable.

Proof. Let $p(t)$, $q(t)$ be some positive functions defined in $\mathbb{R}^1$ and let

$$
(\tilde{u}_i,\tilde{v}_i)=(u_i^s+p,\ v_i^s+q),\qquad (\underline{u}_i,\underline{v}_i)=(u_i^s-p,\ v_i^s-q).
\tag{3.3}
$$

Our aim is to find p, q such that $(p(t), q(t)) \to (0,0)$ and the pair given by (3.3) are upper-lower solutions. To achieve this, we observe that (u_i^s+p, v_i^s+q) is an upper solution if (p, q) satisfies the differential inequalities

$$\begin{aligned}
&L_1[u_1^s]+p'+(a_1+b_1)p-a_1(u_2^s+p)-f(v_1^s-q(t-r_1)) \geqq 0,\\
&\mathscr{L}_1[v_1^s]+q'+(a_2+b_2)q-a_2(v_2^s+q) \geqq 0,\\
&L_2[u_2^s]+p'+b_1p \geqq 0,\\
&\mathscr{L}_2[v_2^s]+q'+b_2q \geqq g(u_2^s+p(t-r_2))
\end{aligned}\tag{3.4}$$

and the initial inequalities

$$\begin{aligned}
&u_1^s(x)+p(0) \geqq \xi_1(x), \qquad v_1^s(x)+q(t) \geqq \eta_1(x,t) \qquad (x \in \Gamma_1, t \in [-r_1, 0]),\\
&u_2^s(x)+p(t) \geqq \xi_2(x,t), \qquad v_2^s(x)+q(0) \geqq \eta_2(x) \qquad (x \in \Omega, t \in [-r_2, 0]).
\end{aligned}\tag{3.5}$$

The boundary inequalities are trivially fulfilled since (u_i^s, v_i^s) satisfies the boundary condition (1.2). Using the property of a steady-state solution, relation (3.4) is equivalent to

$$\begin{aligned}
&p'+b_1p \geqq f(v_1^s-q(t-r_1))-f(v_1^s),\\
&q'+b_2q \geqq 0,\\
&p'+b_1p \geqq 0,\\
&q'+b_2q \geqq g(u_2^s+p(t-r_2))-g(u_2^s).
\end{aligned}\tag{3.6}$$

By the same reasoning, (u_i^s-p, v_i^s-q) is a lower solution if all the reversed inequalities in (3.4), (3.5) are satisfied when p, q are replaced by $-p$ and $-q$, respectively. This implies that p and q must satisfy the additional requirements

$$\begin{aligned}
&p'+b_1p \geqq f(v_1^s)-f(v_1^s+q(t-r_1)),\\
&q'+b_2q \geqq g(u_2^s)-g(u_2^s-p(t-r_2)),
\end{aligned}\tag{3.7}$$

$$\begin{aligned}
&u_1^s(x)-p(0) \leqq \xi_1(x), \quad v_1^s(x)-q(t) \leqq \eta_1(x,t) \quad (x \in \Gamma_1, t \in [-r_1, 0]),\\
&u_2^s(x)-p(t) \leqq \xi_2(x,t), \quad v_2^s(x)-q(0) \leqq \eta_2(x) \quad (x \in \Omega, t \in [-r_2, 0]).
\end{aligned}\tag{3.8}$$

For any positive constants ρ_1, ρ_2, define $M_1 = M_1(\rho_1)$, $M_2 = M_2(\rho_2)$ by

$$\begin{aligned}
&M_1 \equiv \max\{-f'(v_1^s+\eta);\ |\eta| \leqq \rho_1,\ v_1^s+\eta \geqq 0,\ x \in \Gamma_1\},\\
&M_2 \equiv \max\{g'(u_2^s+\eta);\ |\eta| \leqq \rho_2,\ u_2^s+\eta \geqq 0,\ x \in \bar{\Omega}\}.
\end{aligned}\tag{3.9}$$

Then all the inequalities in (3.6) and (3.7) are fulfilled if

$$\left.\begin{aligned}
&p'+b_1p \geqq M_1q(t-r_1), \quad q(t-r_1) \leqq \rho_1\\
&q'+b_2q \geqq M_2p(t-r_2), \quad p(t-r_2) \leqq \rho_2
\end{aligned}\right. \quad (t>0).\tag{3.10}$$

We choose ρ_1, ρ_2 such that $M_1M_2 < b_1b_2$. This is possible by virtue of condition (3.1). To satisfy the relation (3.10) we let p, q in the form

$$p(t) = p_0\, e^{-\varepsilon t}, \qquad q(t) = q_0\, e^{-\varepsilon t}$$

for some $\varepsilon > 0$. Then the inequalities in (3.10) hold if

$$\left.\begin{aligned}
&(b_1-\varepsilon)p_0 \geqq M_1q_0\, e^{\varepsilon r_1}, \quad q(t-r_1) \leqq \rho_1\\
&(b_2-\varepsilon)q_0 \geqq M_2p_0\, e^{\varepsilon r_2}, \quad p(t-r_2) \leqq \rho_2
\end{aligned}\right. \quad (t>0).$$

Let $p_0 = \rho_1\, e^{-\varepsilon r_1}$, $q_0 = \rho_2\, e^{-\varepsilon r_2}$ so that $p(t-r_1) \leqq \rho_1$, $q(t-r_2) \leqq \rho_2$ for $t>0$. Then it suffices to find ρ_1, ρ_2 such that

$$\frac{M_1\, e^{\varepsilon(2r_1-r_2)}}{b_1-\varepsilon} \leqq \frac{\rho_1}{\rho_2} \leqq \frac{b_2-\varepsilon}{M_2\, e^{\varepsilon(2r_2-r_1)}}.\tag{3.11}$$

This is clearly possible for a sufficiently small $\varepsilon>0$ since $M_1M_2<b_1b_2$. The above construction shows that the functions given by (3.3) with $p(t)=\rho_1 e^{-\varepsilon(t+r_1)}$, $q(t)=\rho_2 e^{-\varepsilon(t+r_2)}$ are upper and lower solutions whenever the initial functions satisfy the relation

$$\begin{aligned} &|u_1^s-\xi_1|\leqq \rho_1 e^{-\varepsilon r_1}, && |v_1^s-\eta_1|\leqq \rho_2 e^{-\varepsilon(t+r_2)} && (x\in\Gamma_1,\ t\in[-r,0]),\\ &|u_2^s-\xi_2|\leqq \rho_1 e^{-\varepsilon(t+r_1)}, && |v_2^s-\eta_2|\leqq \rho_2 e^{-\varepsilon r_2} && (x\in\Omega,\ t\in[-r_2,0]). \end{aligned}\tag{3.12}$$

It follows from Theorem 2.1 that the time-dependent solution (u_i, v_i) satisfies the relation

$$\begin{aligned} u_i^s(x)-\rho_1 e^{-\varepsilon(t+r_1)}\leqq u_i(t,x)\leqq u_i^s(x)+\rho_1 e^{-\varepsilon(t+r_1)}\\ v_i^s(x)-\rho_2 e^{-\varepsilon(t+r_1)}\leqq v_i(t,x)\leqq v_i^s(x)+\rho_2 e^{-\varepsilon(t+r_2)} \end{aligned}\qquad (t>0,\ x\in\bar{\Omega})\tag{3.13}$$

for a sufficiently small $\varepsilon>0$. The above relation ensures that (u_i^s, v_i^s) is asymptotically stable. Now if condition (3.2) holds then $M_1M_2<b_1b_2$ for all positive constants ρ_1, ρ_2. In this situation the relations (3.11) and (3.12) can be satisfied by choosing ρ_1, ρ_2 sufficiently large. This implies that (u_i^s, v_i^s) is globally asymptotically stable. The proof of the theorem is completed.

Remark 3.1. When ρ_1, ρ_2 are large it is possible that the lower solution (u_i^s-p, v_i^s-q) takes negative values. In this situation we need to define some modified functions $\hat{f}, \hat{g}$ in place of f, g and using the same argument as in [8] to show that all the conclusions in Theorem 3.1 remain true.

4. The steady-state problem. The monotone method for the time-dependent problem (1.1)–(1.3) can be used to construct similar maximal and minimal sequences for the corresponding steady-state problem

$$\begin{aligned} &(a_1+b_1)u_1=a_1u_2+f(v_1)\\ &(a_2+b_2)v_1=a_2v_2 && (x\in\Gamma_1),\\ &-D_1\nabla^2u_2+b_1u_2=0\\ &-D_2\nabla^2v_2+b_2v_2=g(u_2) && (x\in\Omega). \end{aligned}\tag{4.1}$$

By solving the first two equations in (4.1) for (u_1, v_1) and substituting into the boundary condition (1.2), the steady-state solution must satisfy the boundary condition

$$\begin{aligned} &\frac{\partial u_2}{\partial \nu}+(\beta_1b_1/(a_1+b_1))u_2=(\beta_1/(a_1+b_1))f(a_2v_2/(a_2+b_2)),\\ &\frac{\partial v_2}{\partial \nu}+(\beta_2b_2/(a_2+b_2))v_2=0 \qquad (x\in\Gamma_1),\\ &\frac{\partial u_2}{\partial \nu}=\frac{\partial v_2}{\partial \nu}=0 \qquad (x\in\Gamma_2). \end{aligned}\tag{4.2}$$

Let $u=u_2$, $v=v_2$ and define

$$\begin{aligned} &F(v)=(\beta_1/(a_1+b_1))f(a_2v/(a_2+b_2)), \qquad G(u)=\frac{g(u)}{D_2},\\ &c_i=\frac{b_i}{D_i}, \qquad \gamma_i=\frac{\beta_ib_i}{a_i+b_i} \qquad (i=1,2). \end{aligned}\tag{4.3}$$

Then the steady-state problem is reduced to the coupled system

$$-\nabla^2u+c_1u=0, \quad -\nabla^2v+c_2v=G(u) \quad (x\in\Omega),\tag{4.4}$$

$$\begin{aligned}&B_1[u]\equiv\frac{\partial u}{\partial\nu}+\gamma_1 u=F(v),\quad B_2[v]\equiv\frac{\partial v}{\partial\nu}+\gamma_2 v=0\quad(x\in\Gamma_1),\\ &\frac{\partial u}{\partial\nu}=\frac{\partial v}{\partial\nu}=0\qquad(x\in\Gamma_2).\end{aligned}\tag{4.5}$$

It is clear from (4.3) that $F(v)$ and $G(u)$ possess the same monotone property as $f(u)$, $g(v)$ in the hypothesis (H). In view of the quasi-monotone property of F and G we define upper and lower solutions for the problem (4.4)-(4.5) as follows:

DEFINITION 4.1. A pair of smooth functions $(\tilde{u},\tilde{v})$, $(\underset{\sim}{u},\underset{\sim}{v})$ are called upper and lower solutions of (4.4), (4.5) if they satisfy the relations

$$\left.\begin{aligned}&-\nabla^2\tilde{u}+c_1\tilde{u}\geqq 0\geqq-\nabla^2\underset{\sim}{u}+c_1\underset{\sim}{u}\\ &-\nabla^2\tilde{v}+c_2\tilde{v}-G(\tilde{u})\geqq 0\geqq-\nabla^2\underset{\sim}{v}+c_2\underset{\sim}{v}-G(\underset{\sim}{u})\end{aligned}\right.\qquad(x\in\Omega),\tag{4.6}$$

$$\begin{aligned}&B_1[\tilde{u}]-F(\underset{\sim}{v})\geqq 0\geqq B_1[\underset{\sim}{u}]-F(\tilde{v}),\qquad B_2[\tilde{v}]\geqq 0\geqq B_2[\underset{\sim}{v}]\qquad(x\in\Gamma_1).\\ &\frac{\partial\tilde{u}}{\partial\nu}\geqq 0\geqq\frac{\partial\underset{\sim}{u}}{\partial\nu},\quad\frac{\partial\tilde{v}}{\partial\nu}\geqq 0\geqq\frac{\partial\underset{\sim}{v}}{\partial\nu}\qquad(x\in\Gamma_2).\end{aligned}\tag{4.7}$$

In the above definition a smooth function is referred to as a continuous function in $\bar{\Omega}$ which is twice continuously differentiable in Ω and has outward normal derivative on $\partial\Omega$. Notice that upper and lower solutions for the boundary value problem are interrelated through the boundary condition.

Let $(\bar{u}^{(0)},\bar{v}^{(0)})=(\tilde{u},\tilde{v})$, $(\underline{u}^{(0)},\underline{v}^{(0)})=(\underset{\sim}{u},\underset{\sim}{v})$ be initial iterations and construct two sequences $\{\bar{u}^{(k)},\bar{v}^{(k)}\}$, $\{\underline{u}^{(k)},\underline{v}^{(k)}\}$ from the iteration process

$$\begin{aligned}&-\nabla^2\bar{u}^{(k)}+c_1\bar{u}^{(k)}=0,\qquad -\nabla^2\bar{v}^{(k)}+c_2\bar{v}^{(k)}=G(\bar{u}^{(k-1)})\qquad(x\in\Omega),\\ &B_1[\bar{u}^{(k)}]=F(\underline{v}^{(k-1)}),\qquad B_2[\bar{v}^{(k)}]=0\qquad(x\in\Gamma_1)\\ &\frac{\partial\bar{u}^{(k)}}{\partial\nu}=\frac{\partial\bar{v}^{(k)}}{\partial\nu}=0\qquad(x\in\Gamma_2)\end{aligned}\tag{4.8}$$

and

$$\begin{aligned}&-\nabla^2\underline{u}^{(k)}+c_1\underline{u}^{(k)}=0,\qquad -\nabla^2\underline{v}^{(k)}+c_2\underline{v}^{(k)}=G(\underline{u}^{(k-1)})\qquad(x\in\Omega),\\ &B_1[\underline{u}^{(k)}]=F(\bar{v}^{(k-1)}),\qquad B_2[\underline{v}^{(k)}]=0\qquad(x\in\Gamma_1),\\ &\frac{\partial\underline{u}^{(k)}}{\partial\nu}=\frac{\partial\underline{v}^{(k)}}{\partial\nu}=0\qquad(x\in\Gamma_2).\end{aligned}\tag{4.9}$$

We again refer to these two sequences as maximal and minimal sequence, respectively. Just as in the time-dependent problem the maximal and minimal sequences possess the following monotone properties.

LEMMA 4.1. *Let* $(\tilde{u},\tilde{v})$, $(\underset{\sim}{u},\underset{\sim}{v})$ *be upper-lower solutions of* (4.4), (4.5) *such that* $(\tilde{u},\tilde{v})\geqq(\underset{\sim}{u},\underset{\sim}{v})\geqq(0,0)$ *and let hypothesis* (H) *hold. Then the sequences* $\{\bar{u}^{(k)},\bar{v}^{(k)}\}$, $\{\underline{u}^{(k)},\underline{v}^{(k)}\}$ *given by* (4.8), (4.9) *possess the monotone property*

$$\begin{aligned}(\underline{u}^{(k)},\underline{v}^{(k)})&\leqq(\underline{u}^{(k+1)},\underline{v}^{(k+1)})\leqq(\bar{u}^{(k+1)},\bar{v}^{(k+1)})\\ &\leqq(\bar{u}^{(k)},\bar{v}^{(k)}),\qquad k=0,1,2,\cdots.\end{aligned}\tag{4.10}$$

Moreover, for each fixed k, the pair $(\bar{u}^{(k)},\bar{v}^{(k)})$ *and* $(\underline{u}^{(k)},\underline{v}^{(k)})$ *are upper-lower solutions.*

Proof. Since the proof of the lemma follows from the same argument as for Lemma 2.1 we omit the details.

In view of the monotone property (4.10) the pointwise limits

$$\lim_{k\to\infty} (\bar{u}^{(k)}, \bar{v}^{(k)}) = (\bar{u}, \bar{v}), \qquad \lim_{k\to\infty} (\underline{u}^{(k)}, \underline{v}^{(k)}) = (\underline{u}, \underline{v}) \tag{4.11}$$

exist and satisfy the relation

$$(\underline{u}^{(k)}, \underline{v}^{(k)}) \leqq (\underline{u}, \underline{v}) \leqq (\bar{u}, \bar{v}) \leqq (\bar{u}^{(k)}, \bar{v}^{(k)}), \qquad k = 0, 1, 2, \cdots. \tag{4.12}$$

By letting $k \to \infty$ in (4.8), (4.9) the usual regularity argument shows that $(\bar{u}, \bar{v})$ and $(\underline{u}, \underline{v})$ satisfy the equations

$$\begin{aligned}
&-\nabla^2 \bar{u} + c_1 \bar{u} = 0, && B_1[\bar{u}] = f(\underline{v}), && \frac{\partial \bar{u}}{\partial \nu} = 0,\\
&-\nabla^2 \bar{v} + c_2 \bar{v} = G(\bar{u}), && B_2[\bar{v}] = 0, && \frac{\partial \bar{v}}{\partial \nu} = 0,\\
&-\nabla^2 \underline{u} + c_1 \underline{u} = 0, && B_1[\underline{u}] = F(\bar{v}), && \frac{\partial \underline{u}}{\partial \nu} = 0,\\
&-\nabla^2 \underline{v} + c_2 \underline{v} = G(\underline{u}), && B_2[\underline{v}] = 0, && \frac{\partial \underline{v}}{\partial \nu} = 0.
\end{aligned} \tag{4.13}$$

In order to ensure that $(\bar{u}, \bar{v})$ and $(\underline{u}, \underline{v})$ are solutions of (4.4), (4.5), we must show that $(\bar{u}, \bar{v}) = (\underline{u}, \underline{v})$. For this purpose we need to impose some additional conditions on F and G. Specifically, by defining

$$M_f \equiv \max\{-F'(v); \utilde{v} \leqq v \leqq \tilde{v}\}, \qquad M_g \equiv \max\{G'(u); \utilde{u} \leqq u \leqq \tilde{u}\} \tag{4.14}$$

we have the following existence-uniqueness result.

THEOREM 4.1. *Let* $(\tilde{u}, \tilde{v}), (\utilde{u}, \utilde{v})$ *be upper-lower solutions of* (4.4), (4.5) *such that* $(\tilde{u}, \tilde{v}) \geqq (\utilde{u}, \utilde{v}) \geqq (0, 0)$ *and let hypothesis* (H) *hold. If*

$$M_f M_g \leqq c_1 \gamma_2 \tag{4.15}$$

then the steady-state problem (4.4), (4.5) *has a unique solution* (u, v) *such that*

$$(\utilde{u}, \utilde{v}) \leqq (u, v) \leqq (\tilde{u}, \tilde{v}) \qquad (x \in \bar{\Omega}). \tag{4.16}$$

Moreover the maximal and minimal sequences $\{\bar{u}^{(k)}, \bar{v}^{(k)}\}, \{\underline{u}^{(k)}, \underline{v}^{(k)}\}$ *converge monotonically to* (u, v).

Proof. Let $U = \bar{u} - \underline{u} \geqq 0$, $V = \bar{v} - \underline{v} \geqq 0$. Since by the mean value theorem

$$\begin{aligned}
F(\underline{v}) - F(\bar{v}) &= -F'(\hat{v}) V \equiv \sigma_1(x) V\\
G(\bar{u}) - G(\underline{u}) &= G'(\hat{u}) U \equiv \sigma_2(x) U
\end{aligned} \qquad (x \in \Omega), \tag{4.17}$$

where $\hat{u}$ and $\hat{v}$ are some intermediate values in $[\utilde{u}, \tilde{u}]$ and $[\utilde{v}, \tilde{v}]$ respectively, relation (4.13) implies that

$$-\nabla^2 U + c_1 U = 0, \qquad -\nabla^2 V + c_2 V = \sigma_2 U \qquad (x \in \Omega), \tag{4.18}$$

$$\begin{aligned}
&\frac{\partial U}{\partial \nu} + \gamma_1 U = \sigma_1 V, \qquad \frac{\partial V}{\partial \nu} + \gamma_2 V = 0 && (x \in \Gamma_1),\\
&\frac{\partial U}{\partial \nu} = \frac{\partial V}{\partial \nu} = 0 && (x \in \Gamma_2).
\end{aligned} \tag{4.19}$$

Let ρ_1, ρ_2 be any positive constants such that $M_g/c_1 \leqq \rho_1/\rho_2 \leqq \gamma_2/M_f$ and let $W = \rho_1 U + \rho_2 V$. The existence of ρ_1, ρ_2 is ensured by condition (4.15). In view of (4.18) and (4.19), W satisfies the relation

$$\begin{aligned} &-\nabla^2 W+(\rho_1 c_1-\rho_2\sigma_2)U+c_2\rho_2 V=0 && (x\in\Omega),\\ (4.20)\qquad &\frac{\partial W}{\partial \nu}+\rho_1\gamma_1 U+(\rho_2\gamma_2-\rho_1\sigma_1)V=0 && (x\in\Gamma_1),\\ &\frac{\partial W}{\partial \nu}=0 && (x\in\Gamma_2). \end{aligned}$$

Since by the choice of ρ_1, ρ_2,

$$\rho_1 c_1-\rho_2\sigma_2\geqq \rho_1 c_1-\rho_2 M_g\geqq 0, \qquad \rho_2\gamma_2-\rho_1\sigma_1\geqq\rho_2\gamma_2-\rho_1 M_f\geqq 0,$$

the nonnegative property of (U, V) implies that

$$(4.21)\qquad -\nabla^2 W\leqq 0\quad (x\in\Omega), \qquad \frac{\partial W}{\partial \nu}\leqq 0\quad (x\in\partial\Omega).$$

By the maximum principle and the nonnegative property of W we must have $W=0$ on $\bar{\Omega}$. This shows that $(\bar{u}, \bar{v})=(\underline{u}, \underline{v})$. The monotone convergence of the maximal and minimal sequences follows from Lemma 4.1.

To show the uniqueness of the solution, we let (u^*, v^*) be any solution of (4.4), (4.5) such that $(\underset{\sim}{u}, \underset{\sim}{v})\leqq(u^*, v^*)\leqq(\tilde{u}, \tilde{v})$. Then by the iteration process (4.8), (4.9) and hypothesis (H) the functions $(\bar{w}_1, \bar{w}_2)\equiv(\bar{u}^{(1)}-u^*, \bar{v}^{(1)}-v^*)$ and $(\underline{w}_1, \underline{w}_2)\equiv(u^*-\underline{u}_1, v^*-\underline{v}_1)$ satisfy the relations

$$\begin{aligned} &-\nabla^2\bar{w}_1+c_1\bar{w}_1=0, && B_1[\bar{w}_1]=F(\underline{v}^{(0)})-F(v^*)\geqq 0,\\ &-\nabla^2\bar{w}_2+c_2\bar{w}_2=G(\bar{u}^{(0)})-G(u^*)\geqq 0, && B_2[w_2]=0,\\ &-\nabla^2\underline{w}_1+c_1\underline{w}_1=0, && B_1[\underline{w}_1]=F(v^*)-F(\bar{v}^{(0)})\geqq 0,\\ &-\nabla^2\underline{w}_2+c_2\underline{w}_2=G(u^*)-G(\underline{u}^{(0)})\geqq 0, && B_2[\underline{w}_2]=0 \end{aligned}$$

and $\partial\bar{w}_i/\partial\nu=\partial\underline{w}_i/\partial\nu=0$ on Γ_2, $i=1,2$. These inequalities imply that $(\underline{u}^{(1)}, \underline{v}^{(1)})\leqq(u^*, v^*)\leqq(\bar{u}^{(1)}, \bar{v}^{(1)})$. An induction argument shows that

$$(4.22)\qquad (\underline{u}^{(k)}, \underline{v}^{(k)})\leqq(u^*, v^*)\leqq(\bar{u}^{(k)}, \bar{v}^{(k)}), \qquad k=1,2,\cdots.$$

Since the sequences $\{\bar{u}^{(k)}, \bar{v}^{(k)}\}$ and $\{\underline{u}^{(k)}, \underline{v}^{(k)}\}$ both converge to the solution (u, v) we conclude that $(u^*, v^*)=(u, v)$. This completes the proof of the theorem.

Remark 4.1. Unlike systems with both quasi-monotone increasing or quasi-monotone decreasing functions, the pair $(\tilde{u}, \tilde{v})$ and (u^*, v^*) (or (u^*, v^*) and $(\underset{\sim}{u}, \underset{\sim}{v})$) are not upper-lower solutions as defined in Definition 4.1. In fact, if $(\tilde{u}, \tilde{v})$ and (u^*, v^*) are used as the initial iterations in the process (4.8) and (4.9) the corresponding sequences are no longer monotone. Nevertheless each sequence contains a subsequence which consists of the same function (u^*, v^*).

In analogy to the time-dependent problem, the constant functions $(\tilde{u}, \tilde{v})=(\rho, \rho^*)$ and $(\underset{\sim}{u}, \underset{\sim}{v})=(0,0)$ are upper-lower solutions of (4.4), (4.5) if

$$(4.23)\qquad c_2\rho^*-G(\rho)\geqq 0\geqq -G(0), \qquad \gamma_1\rho-F(0)\geqq 0\geqq -F(\rho)$$

because all the other requirements in (4.6) and (4.7) are fulfilled. By hypothesis (H), it suffices to choose ρ, ρ^* such that

$$(4.24)\qquad \rho\geqq\frac{F(0)}{\gamma_1}, \qquad \rho^*\geqq\frac{G(\rho)}{c_2}.$$

This choice of (ρ, ρ^*) and Theorem 4.1 lead to the following.

THEOREM 4.2. *Let hypothesis* (H) *and condition* (4.15) *hold and let* ρ, ρ^* *be any constants satisfying* (4.24). *Then the sequences* $\{\bar{u}^{(k)}, \bar{v}^{(k)}\}$ *and* $\{\underline{u}^{(k)}, \underline{v}^{(k)}\}$ *with* $(\bar{u}^{(0)}, \bar{v}^{(0)}) = (\rho, \rho^*)$, $(\underline{u}^{(0)}, \underline{v}^{(0)}) = (0, 0)$ *converge to a unique solution* (u, v) *and*

$$(0, 0) \leqq (u, v) \leqq (\rho, \rho^*). \tag{4.25}$$

CHAOTIC SOLUTIONS OF SYSTEMS OF FIRST ORDER PARTIAL DIFFERENTIAL EQUATIONS*

ROBERT WOLFE† AND HEDLEY C. MORRIS‡

Abstract. We consider the system of partial differential equations

$$\frac{\partial \mathbf{u}}{\partial t}+(\mathbf{c}(\mathbf{x})\cdot\nabla)\mathbf{u}=\mathbf{f}(\mathbf{x},\mathbf{u}),$$

$$\mathbf{u}(t=0,\mathbf{x})=\mathbf{v}(\mathbf{x})$$

where $\mathbf{x}\in\Delta$, a compact connected subset of R^m, $\mathbf{u}\in R^n$, and $t\geqq 0$. This is a generalization of a problem investigated by Lasota [6] and Brunovsky [2], and the methods used are similar to those used by these authors.

Imposing certain conditions on $\mathbf{c}$ and $\mathbf{f}$, we show that for $\mathbf{v}$ in a certain subset of the phase space the solution uniformly approaches a limit set of dimension $n-1$. We also show that in another subset of the phase space there are both (a) dense orbits and (b) periodic orbits of all periods. Each of (a) and (b) leads to a proof of the existence of a type of chaos in this subset.

Key words. first order partial differential equations, semiflow, chaos

AMS(MOS) subject classification. 35B

1. Introduction. This paper is concerned with a particular type of chaotic behaviour that can occur in a function space. In order that the nature of this particular type of stochastic behaviour can be appreciated, it is necessary to present some background information concerning chaos in other types of dynamical systems. There are essentially three types of situation in which chaotic phenomena have been investigated by mathematicians. These are chaos in one dimension involving maps of the interval or the circle, mappings of R^n into itself and chaos in function spaces such as those associated with the equations of fluid mechanics. We consider each in turn.

Chaos in one dimension. "Chaos" is taken loosely to mean a state where nonperiodic motion is observed as a nontransient phenomena. We will give various definitions of chaos, and show how the concept has been developed and generalized in different ways. One of those ways leads to the particular form of chaotic motion considered in this paper.

The first rigorous definition of chaos was that used by Li and Yorke [7] for iterations of an interval map.

THEOREM (Li and Yorke). *Let J be an interval and $F: J\to J$ be continuous. Suppose there is a point $a\in J$ that satisfies either*

$$F^3(a)\leqq a<F(a)<F^2(a) \tag{1.1}$$

or

$$F^3(a)\geqq a>F(a)>F^2(a).$$

Then

1) *For every integer $k>0$ there is a point in J having period k.*

* Received by the editors September 28, 1984; accepted for publication February 25, 1986.

2) *J has an uncountable subset S (called the scrambled set) that contains no periodic points and satisfies the following conditions:*

For each p, q distinct in S we have

$$\limsup_{n\to\infty} |F^n(p) - F^n(q)| > 0 \tag{1.2}$$

and

$$\liminf_{n\to\infty} |F^n(p) - F^n(q)| = 0. \tag{1.3}$$

For each $p \in S$ and each periodic $q \in J$ we have

$$\limsup_{n\to\infty} |F^n(p) - F^n(q)| > 0. \tag{1.4}$$

This "period three implies chaos" theorem makes the definition attractive, and it has been widely used. Li and Yorke's work is partly a special case of a theorem of Sharkovskii [10].

Kloeden et al. [5] have proposed that the existence of orbits of any given period should not be a necessary condition in the definition of chaos. Ott [9] uses a definition of chaos for sequences based on sensitivity to initial conditions and on average correlation functions.

Chaos in R^n. How to characterise the n-dimensional analogue of the chaotic behaviour of one-dimensional systems is not immediately apparent. Marotto [8] has extended the Li-Yorke theorem to R^n by introducing the idea of "snap-back-repellers." If F is a C^1 mapping from R^n to R^n, then $\mathbf{z} \in R^n$ is defined to be a snap-back-repeller if (a) $F(\mathbf{z}) = \mathbf{z}$; (b) there is some $r > 0$ such that all the eigenvalues of $DF(\mathbf{x})$ have norm greater than one; (c) there is some point $\mathbf{x}_0$ with $0 < |\mathbf{z} - \mathbf{x}_0| < r$ such that $F^M(\mathbf{x}_0) = \mathbf{z}$ and $|DF^M(\mathbf{x}_0)| \neq 0$ for some $M > 0$.

Marotto has shown that if a mapping F has a "snap-back-repeller," then it has a scrambled set of the type defined in the Li-Yorke theorem. Marotto's theorem has been further extended by Shiraiwa and Kurata [11].

Chaos in abstract spaces. Auslander and Yorke [1] put forward the following definition, again for discrete dynamical systems.

> If X is a compact metric space and τ a continuous surjection from X to itself then (X, τ) is defined to be a compact system. The point $x \in X$ is said to be stable if for each $\varepsilon > 0$ there is a $\delta > 0$ such that $d(\tau^n(x), \tau^n(y)) < \varepsilon$ for each y with $d(x, y) < \delta$ and each $n \in N$. The compact system (X, τ) is defined to be chaotic if no point $x \in X$ is stable and if there is some $y \in X$ whose orbit is dense in X.

Chaos may also be observed in function spaces. Lasota [6] has proved the existence of chaos, in a sense analogous to that of Auslander and Yorke [1], for the first order partial differential equation

$$\begin{aligned} &\frac{\partial u}{\partial t} + c(x)\frac{\partial u}{\partial x} = f(u, x), \\ &u(x, 0) = v(x) \end{aligned} \tag{1.5}$$

where $x \in [0, 1]$, $t \geqq 0$, and $c, f,$ and v obey certain specified conditions. Here the phase space is the space of functions $v : [0, 1] \to [0, \infty)$. Lasota's extension of Auslander and Yorke's definition is natural, but, as a result of this extension, the set in which he proves chaos to exist is not compact.

Walther [12], and an der Haiden and Walther [4], examine delay-differential equations. Here the phase space is a function space, $C([0,1], R)$. A Poincaré section is used, and the existence of chaos is proved (in the sense of Li and Yorke) for the first-return map on this section.

In this paper we extend the recent results of Lasota [6] to a higher-dimensional situation. In § 2 we prove a series of preliminary theorems that generalize those of Lasota. In order to produce these results we attempt to extend the conditions that Lasota imposes on scalar valued functions to the vector case. In so doing we also introduce minor modifications in his results in the one-dimensional situation. The main result, confirming a generalized form of chaos for the semiflow defined by (2.1) and (2.2), is proved in § 3. Brunovsky [2] has proved some of Lasota's results by an alternative means. In our final § 4 we generalize this technique to our more general situation. So that this paper can be read independently of Lasota's and so that the differences and extensions we have made can be readily identified it is necessary for us to review the existing results of [6].

Lasota's results. We now review the results of Lasota [6].

If D is some topological space, denote the space of continuous functions from D to the real line by $C(D)$. Denote the space of continuously differentiable functions by $C^1(D)$, and the corresponding spaces of nonnegative functions by $C_+(D)$ and $C^1_+(D)$.

If D is a compact subset of R^n, define the distance between two functions F_1 and F_2 in $C(D)$ to be $\max_{\mathbf{x}\in D} |F_1(\mathbf{x}) - F_2(\mathbf{x})|$.

Consider the partial differential equation (1.5)

$$\frac{\partial u}{\partial t} + c(x)\frac{\partial u}{\partial x} = f(x, u),$$

$$u(0, x) = v(x),$$

where $t \geqq 0$ and $x \in \Delta = [0, 1]$.

This equation can be used to model a variety of phenomena, in particular the growth of populations of certain types of cells, including red blood cells.

Assume the following:

1) The functions c and f are both C^1;

2) $c(0) = 0$ and $c(x) > 0$ for all $x > 0$;

3) There is some $u_0 \in (0, 1]$ such that

(a) $f(0, u)(u - u_0) < 0$ for all $u > 0$, $u \neq u_0$, and

(b) $f_u(0, u_0) < 0$;

4) There exist $k_1 \geqq 0$, $k_2 \geqq 0$ such that $f(x, u) \leqq k_1 u + k_2$ for all $x \in \Delta$, $u \geqq 0$.

5) $f(x, 0) \geqq 0$ for all $x \in \Delta$, and $f(0, 0) = 0$.

Under these assumptions the following results are proved:

1) For every $v \in C_+(\Delta)$ there is a unique solution to (1.5). Let $\phi(t; t_0, x_0)$ be the unique solution of

$$\frac{dx}{dt} = c(x) \tag{1.6}$$

with $x(t_0) = x_0$; and $\phi(t; x_0, r)$ be the unique solution of

$$\frac{dy}{dt} = f(\phi_{x_0}(t), y) \tag{1.7}$$

with $y(0)=r$, where $\phi_x(t)$ is defined as $\phi(t; 0, x)$. Then the solution $u(t, x)$ of (1.5) can be written as

$$u(t, x)=\psi(t; \phi(0, t, x), v(\phi(0; t, x))). \tag{1.8}$$

2) There is a unique solution $w_0(x)$ to the equation

$$c(x)\frac{du}{dx}=f(x, u) \tag{1.9}$$

for $x \in \Delta$, with $w_0(x)=u_0$. If $v \in C_+(\Delta)$ with $v(0)>0$, then $(S_t v)(x) \to w_0(x)$ as $t \to \infty$, uniformly for $x \in \Delta$.

3) Let

$$V_0=\{v \in C_+(\Delta) \colon v(0)=0\}$$

and

$$V_w=\{v \in C_+(\Delta) \colon v(x)<w_0(x)\ \forall x \in \Delta\}.$$

Define the semidynamical system $\{S_t v\}_{t \geqq 0}$ by

$$(S_t v)(x)=u(t, x) \tag{1.10}$$

where $u(t, x)$ is a solution of (1.5).

Then the sets V_0 and V_w are invariant under S_t; also for each $v \in V_0$ there is a $T_0 \geqq 0$ such that $S_t v \in V_w$ for all $t \geqq T_0$.

If condition 5 is replaced by the stronger condition

5′) $f(x, 0)=0$ for all $x \in \Delta$

(see [2]), then one can show that the semidynamical system $\{S_t\}_{t \geqq 0}$ is chaotic in the set V_w, that is,

(a) no point of V_w is stable;

(b) there is some $v \in V_w$ such that the orbit $\{S_t v \colon t \geqq 0\}$ of v is dense in V_w.

Brunovsky [2] shows that there cannot be chaos in all of V_w if the stronger condition 5′ is not satisfied.

Define a generalized solution of (1.5) to be a function in $C_+(\Delta)$ which is the uniform limit on compact subsets of Δ of solutions of (1.5). We will normally use the word "solution" loosely to refer to a generalized solution.

For consistency we will use notation derived from that of Lasota and Brunovsky where possible.

2. Preliminary theorems. In this section and the next we will generalize the results of Lasota [6], by proving theorems for an initial value problem involving n simultaneous equations in one time variable and m spatial variables.

Lasota deals with the nonlinear initial value problem

$$\begin{gathered}\frac{\partial u}{\partial t}+c(x)\frac{\partial u}{\partial x}=f(x, u),\\ u(t=0, x)=v(x)\end{gathered} \tag{2.1}$$

and the associated semidynamical system

$$(S_t v)(x)=u(t, x). \tag{2.2}$$

Here the results of [6] are extended to the initial value problem for a system of n partial differential of the form

$$\frac{\partial \mathbf{u}}{\partial t}+(\mathbf{c}(\mathbf{x})\cdot\nabla_{\mathbf{x}})\mathbf{u}=\mathbf{f}(\mathbf{x},\mathbf{u}), \qquad \mathbf{u}(t=0,\mathbf{x})=\mathbf{v}(\mathbf{x}) \tag{2.3}$$

where x is now replaced by m independent spatial variables.

Let Δ be a compact simply-connected m-dimensional region in R^m and let Δ have a piecewise C^1 boundary $\partial\Delta$.

Let $\mathbf{c}$ be a function from Δ to R^n satisfying the following conditions:

(C1) $\mathbf{c}$ is a C^1 function of $\mathbf{x}$;

(C2) if the outward unit normal $\hat{\mathbf{n}}(\mathbf{x})$ exists at $\mathbf{x}\in\partial\Delta$ then

$$\hat{\mathbf{n}}(\mathbf{x})\cdot\mathbf{c}(\mathbf{x})>0. \tag{2.4}$$

Thus at all points on Δ the vector field $\mathbf{c}$ points outwards. This is true for the "corners" by continuity of $\mathbf{c}$.

Let $\mathbf{f}$ be a function from $\Delta\times R^m$ to R^n satisfying

(F1) $\mathbf{f}$ is a C^1 function of $\mathbf{x}$ and $\mathbf{u}$.

(F2) We have

$$|\mathbf{f}(\mathbf{x},\mathbf{u})|<k_1|\mathbf{u}|+k_2 \tag{2.5}$$

for all $(\mathbf{x},\mathbf{u})$ in $\Delta\times R^n$ where k_1, k_2 are real numbers, and $|\cdot|$ denotes the usual Euclidean norm.

As in Lasota's original paper the method of characteristics is extensively used. Let $\boldsymbol{\phi}(t;\, t_0,\mathbf{p})$ be the unique solution of

$$\frac{d\mathbf{x}}{dt}=\mathbf{c}(\mathbf{x}), \qquad \mathbf{x}(t_0)=\mathbf{p}. \tag{2.6}$$

Let $\boldsymbol{\phi}_{\mathbf{p}}(t)=\boldsymbol{\phi}(t;\,0,\mathbf{p})$.

Let $\boldsymbol{\psi}(t;\,\mathbf{p},\mathbf{r})$ be the unique solution of

$$\frac{d\mathbf{u}}{dt}=\mathbf{f}(\boldsymbol{\phi}_{\mathbf{p}}(t),\mathbf{u}), \qquad \mathbf{u}(0)=\mathbf{r}. \tag{2.7}$$

Define $T(\mathbf{p})$ to be the value of t at which the curve $\boldsymbol{\phi}_{\mathbf{p}}(t)$ intersects $\partial\Delta$, if this intersection occurs. Let $T(\mathbf{p})=\infty$ if the curve does not intersect the boundary.

Define Δ_0 to be the set $\{p\in\Delta\colon T(\mathbf{p})=\infty\}$.

Define $\partial\Delta_0$ to be $\Delta_0-\operatorname{int}\Delta_0$. Thus, for example, if Δ_0 consists of a single point then $\partial\Delta_0=\Delta_0$.

LEMMA 2.1. *If* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F2), *then the* PDE (2.3) *has a unique solution for all* $\mathbf{x}\in\Delta$, $\mathbf{u}\in R^n$.

Proof. The function $\boldsymbol{\phi}$ is well defined in Δ because Δ is compact and $\mathbf{c}(\mathbf{x})$ is Lipschitz for all $\mathbf{x}$ in Δ. The curves $\boldsymbol{\phi}_{\mathbf{p}}(t)$ are characteristic curves which originate in Δ and cross the boundary $\partial\Delta$ at most once. (The condition $\hat{\mathbf{n}}(\bar{\mathbf{x}})\cdot\mathbf{c}(\bar{\mathbf{x}})>0$ for $\bar{\mathbf{x}}\in\partial\Delta$ ensures that no characteristic curves enter Δ from outside.)

Therefore $\boldsymbol{\phi}_{\mathbf{p}}(t)$ is defined for all $t \leqq T(\mathbf{p})$. Condition (F1) on $\mathbf{f}$ ensures that $\boldsymbol{\psi}(t; \mathbf{p}, \mathbf{r})$ is defined for all t in this range. So letting

$$\text{(2.8)} \qquad \mathbf{u}(t; \mathbf{x}) = \boldsymbol{\psi}(t; \boldsymbol{\phi}(0; t, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t, \mathbf{x})))$$

we have a unique solution to the PDE (2.3).

We will consider, as in Lasota's paper, generalized solutions, which are limits of solutions of (2.3); that is, if $\{\mathbf{u}_n\}_{n=1}^{\infty}$ are solutions of (2.3) and

$$\lim_{n\to\infty} \sup_{\mathbf{x}\in\Delta} |\mathbf{u}_n(\mathbf{x}) - \mathbf{u}(\mathbf{x})| = 0,$$

then $\mathbf{u}$ is said to be a generalized solution of (2.3).

LEMMA 2.2. *T is a continuous function of* $\mathbf{x}$.

Proof. Let $\mathbf{x}_1$ be a point in $\Delta - \Delta_0$. We want to show that for any $\varepsilon > 0$ there is an open set $\mathcal{O}$ in $\Delta - \Delta_0$ containing $\mathbf{x}_1$ such that $|T(\mathbf{x}_1) - T(\mathbf{x})| < \varepsilon$ for all $\mathbf{x}$ in $\mathcal{O}$.

Now $\boldsymbol{\phi}(t_1; t_2, \mathbf{x})$ is a continuous function of $\mathbf{x}$, since the solution of a system of ordinary differential equations is a continuous function of the initial values.

Thus if $t \geqq 0$ then $\phi(0; t, \cdot)$ defines a homeomorphism from $\partial\Delta$ to a subset of $\Delta - \Delta_0$. The sets $\boldsymbol{\phi}(0; T(\mathbf{x}_1) + \varepsilon, \partial\Delta)$ and $\boldsymbol{\phi}(0; T(\mathbf{x}_1) - \varepsilon, \partial\Delta)$ are thus homeomorphic to $\partial\Delta$, and to S^{m-1}. The open region enclosed by these surfaces contains $\mathbf{x}_1$, since the integral curve $\boldsymbol{\phi}(t; 0, \mathbf{x}_1)$ intersects each surface exactly once, and $\mathbf{x}_1$ lies between these intersections. Similarly any point $\mathbf{x}$ in this region satisfies $|T(\mathbf{x}_1) - T(\mathbf{x})| < \varepsilon$. $\mathcal{O}$ can then be chosen to be any open subset of this region that contains $\mathbf{x}_1$.

So T is a continuous function of $\mathbf{x} \in \Delta - \Delta_0$.

LEMMA 2.3. *Δ_0 is nonempty, closed and connected.*

Proof. To show that Δ_0 is not empty, it is sufficient to show that there is some $\mathbf{x}$ in Δ for which $\mathbf{c}(\mathbf{x}) = \mathbf{0}$. For $m = 1$ this follows immediately from the intermediate value theorem. For $m > 1$ Δ can be continuously deformed into B^m, the unit closed ball in m-space, with $\partial\Delta$ becoming S^{m-1}. But any continuous nonvanishing vector field on B^m must contain at least one inward-pointing and at least one outward-pointing normal to S^{m-1}. (See, for example, Dugundji [3].) Here there are no inward-pointing normals, and so it follows that $\mathbf{c}$ vanishes at some point $\mathbf{x}$ in Δ. Note that (2.4) implies that Δ_0 is contained in int Δ.

From every point $\bar{\mathbf{x}}$ of $\partial\Delta$ we can trace back the integral curve by looking at $\boldsymbol{\phi}(0; t, \bar{\mathbf{x}})$ for $t > 0$. We can find in this way points in $\Delta - \Delta_0$ corresponding to any finite nonnegative value of T. Also we have seen that $\boldsymbol{\phi}(0; t, \cdot)$ defines a homeomorphism from $\partial\Delta$ to $T^{-1}(t)$ for any finite $t > 0$.

The complement of Δ_0 is $\bigcup_{n=1}^{\infty} \{\mathbf{x} \in \Delta\colon T(\mathbf{x}) < n\}$. But T is continuous (Lemma 2.2), and $\{\mathbf{x} \in \Delta\colon T(\mathbf{x}) < n\}$ is the inverse image in Δ of an open set in R, and hence is open in Δ. Thus the complement of Δ_0 is a union of sets open in Δ, and so Δ_0 is a closed subset of Δ.

Next suppose that Δ_0 is not connected. Since R^m is normal we can find disjoint open sets U_1 and U_2 such that Δ_0 has nonempty intersection with both U_1 and U_2, and Δ_0 is contained in $U_1 \cup U_2$. Therefore $\Delta - (U_1 \cup U_2)$ is a closed set which does not intersect Δ_0. So there exists

$$T_m = \max_{\mathbf{x}\in\Delta-(U_1\cup U_2)} T(\mathbf{x}) < \infty.$$

Consider the set $T^{-1}(t_0)$ for $t_0 > T_m$. This set $T^{-1}(t_0)$ is contained in $U_1 \cup U_2$ since $t_0 > T_m$. Now since $\boldsymbol{\phi}(0; t_0, \cdot)$ defines a homeomorphism from $\partial\Delta$ to $T^{-1}(t_0)$, it follows that $T^{-1}(t_0)$ is connected. Therefore, $T^{-1}(t_0)$ cannot intersect both U_1 and U_2. Suppose without loss of generality that $T^{-1}(t_0)$ is a subset of U_1, and so $T^{-1}(t_0)$ does not intersect U_2.

Choose ε less than the distance from Δ_0 to $\Delta-(U_1\cup U_2)$. Thus because $\boldsymbol{\phi}(t_0;0,\cdot)$ is continuous we can find $\mathbf{x}_1$ in the intersection of Δ_0 and U_2, and $\mathbf{x}_2\in U_2-\Delta_0$ such that

$$|\boldsymbol{\phi}_{\mathbf{x}_1}(t)-\boldsymbol{\phi}_{\mathbf{x}_2}(t)|<\varepsilon$$

for $0\leqq t\leqq t_0$. Since $\boldsymbol{\phi}_{\mathbf{x}_1}(t_0)\in\Delta_0$ it follows that $\boldsymbol{\phi}_{\mathbf{x}_2}(t_0)\in U_2$. Therefore, $t_0<T(\mathbf{x}_2)<\infty$.

Now consider the curve $\boldsymbol{\phi}_{\mathbf{x}_2}(t)$. We have

$$T(\boldsymbol{\phi}_{\mathbf{x}_2}(0))=T(\mathbf{x}_2)>0,$$

and since $\boldsymbol{\phi}_{\mathbf{x}_2}(T(\mathbf{x}_2))$ lies on $\partial\Delta_0$ we have

$$T(\boldsymbol{\phi}_{\mathbf{x}_2}(T(\mathbf{x}_2)))=0.$$

Therefore there is some point $\mathbf{x}$ on the curve for which $T(\mathbf{x})=t_0$. This point is in U_2, since $t_0>T_m$. But this is a contradiction, since $T^{-1}(t_0)$ does not intersect U_2.

Therefore Δ_0 must be connected.

LEMMA 2.4. *If* $\mathbf{x}_0\in\partial\Delta_0$, *then* $\boldsymbol{\phi}_{\mathbf{x}_0}(t)\in\partial\Delta_0$ *for all* $t\geqq 0$.

Proof. First, suppose that $\boldsymbol{\phi}_{\mathbf{x}_0}(t)\in\Delta-\Delta_0$ for some $t>0$. Then $T(\boldsymbol{\phi}_{\mathbf{x}_0}(t))<\infty$, say $T(\boldsymbol{\phi}_{\mathbf{x}_0}(t))=T_0$. But this implies that $\boldsymbol{\phi}_{\mathbf{x}_0}(t+T_0)\in\Delta_0$, and so $T(\mathbf{x}_0)<\infty$, which contradicts the assumption that $\mathbf{x}_0\in\Delta_0$.

Suppose $\mathbf{x}_0\in\partial\Delta_0$ with $\boldsymbol{\phi}_{\mathbf{x}_0}(t_0)\in\operatorname{int}\Delta_0$ for some $t_0>0$. Choose ε with $0<\varepsilon<d(\boldsymbol{\phi}_{\mathbf{x}_0}(t_0),\partial\Delta_0)$. Let $\delta>0$ be such that for all $\mathbf{x}\in\Delta$ with $|\mathbf{x}-\mathbf{x}_0|<\delta$ we have $|\boldsymbol{\phi}_{\mathbf{x}}(t)-\boldsymbol{\phi}_{\mathbf{x}_0}(t)|<\varepsilon$ for all $t<t_0$. But since $\mathbf{x}_0\in\partial\Delta_0$ we can find $\mathbf{x}\in\Delta-\Delta_0$ with $|\mathbf{x}-\mathbf{x}_0|<\delta$. Thus $|\boldsymbol{\phi}_{\mathbf{x}}(t_0)-\boldsymbol{\phi}_{\mathbf{x}_0}(t_0)|<\varepsilon$, which implies that $\boldsymbol{\phi}_{\mathbf{x}}(t_0)\in\operatorname{int}\Delta_0$. But this is impossible since $T(\mathbf{x})<\infty$.

Therefore $\boldsymbol{\phi}_{\mathbf{x}_0}(t)\in\partial\Delta_0$.

In [6] the function $f(x,u)$ is required to satisfy

$$(u-u_0)f(0,u)<0 \quad \text{for } u>0, u\neq u_0,$$

$$f_u(0,u_0)<0 \quad \text{for some } u_0>0.$$

Thus u_0 is an attracting stationary point for the trajectory $u(0,t)$.

Here this is generalized to an invariant surface of dimension $n-1$, where $n>1$, or two points if $n=1$. This surface is to be attracting in the sense that at least locally $\mathbf{f}(\mathbf{x},\mathbf{u})$ points towards this surface, for each $\mathbf{x}$ in Δ_0. Here, however the point $0\in R$ has been generalized to the set Δ_0. Thus the question arises as to whether the invariant surface can depend on the element $\mathbf{x}$ of Δ_0, or whether it must be independent of $\mathbf{x}$. We find results for the more general case, that is, where the surface depends on $\mathbf{x}\in\Delta_0$.

We require $\mathbf{f}$ to satisfy the following further conditions:

(F3) There is a compact simply-connected n-dimensional subset $W(\mathbf{x})$ of R^n associated (continuously) with each point $\mathbf{x}$ in Δ_0 with $\partial W(\mathbf{x})$ piecewise C^1.

(F4) For each $\mathbf{x}$ in Δ_0 there is an open set $R(\mathbf{x})$ in R^n, such that $\partial W(\mathbf{x})$ is contained in $R(\mathbf{x})$. If $\mathbf{x}\in\Delta_0$, $\mathbf{u}\in R(\mathbf{x})$ and $\mathbf{u}_1\in\partial W(\mathbf{x})$ is the nearest point (in the Euclidean sense) in $\partial W(\mathbf{x})$ to $\mathbf{u}$ (if this is well defined) then

$$(\mathbf{u}-\mathbf{u}_1)\cdot\mathbf{f}(\mathbf{x},\mathbf{u})<0. \tag{2.9}$$

(F5) If $\mathbf{x}_0\in\partial\Delta_0$, $\mathbf{u}_1\in\partial W(\mathbf{x}_0)$, then

$$\mathbf{N}\cdot(Jf(\mathbf{x},\mathbf{u}_1)\mathbf{N})<0 \tag{2.10}$$

where $\mathbf{N}$ is normal to $\partial W(\mathbf{x})$ at $\mathbf{u}_1$ and where Jf denotes the Jacobian of f.

Note that $\mathbf{u}_1(\mathbf{x},\mathbf{u})$ is well defined for almost all $\mathbf{u}\in R^n$. If $\mathbf{u}_1$ is not uniquely defined then $\mathbf{f}(\mathbf{x},\mathbf{u})$ may still satisfy (2.9) for each of the several nearest $\mathbf{u}_1$ to $\mathbf{u}$. However, by an argument similar to that of Lemma 2.3 we see that the vector fields $\mathbf{u}-\mathbf{u}_1$ and $\mathbf{f}$ on

$W(\mathbf{x})$ cannot be well defined, continuous and nonzero everywhere on int $W(\mathbf{x})$. So there is some point $\mathbf{u} \in \operatorname{int} W(\mathbf{x})$ where $\mathbf{u}-\mathbf{u}_1$ is undefined because $\mathbf{u}_1$ is undefined, and at this point it is not possible to define $\mathbf{f}(\mathbf{x}, \mathbf{u})$ such that (2.9) holds for each of the nearest points of $\partial W(\mathbf{x})$. There may be more than one such point, for if the distance $|\mathbf{u}-\mathbf{u}_1|$ has a local maximum at $\mathbf{u}$, then $\mathbf{f}$ is necessarily zero at this point.

Let

$$m = \min_{\mathbf{x}_0 \in \Delta_0} d(\partial R(\mathbf{x}_0), \partial W(\mathbf{x}_0)),$$

and for each $\mathbf{x}_0 \in \Delta_0$ let

$$R'(\mathbf{x}_0) = \{\mathbf{u} \in R^n \colon d(\mathbf{u}, \partial W(\mathbf{x}_0)) \leqq m/2\}.$$

Let $R_0(\mathbf{x}_0)$ be the open subset of R^n defined by

$$R_0(\mathbf{x}_0) = \{\mathbf{u} \in R^n \colon \boldsymbol{\psi}(t; \mathbf{x}_0, \mathbf{u}) \in R'(\boldsymbol{\phi}_{\mathbf{x}_0}(t)) \text{ for some } t \geqq 0\}.$$

$R_0(\mathbf{x}_0)$ is nonempty, as it contains at least $R'(\mathbf{x}_0)$. Also, by an argument similar to that of Lemma 2.3, we see that there is at least one point in int $W(\mathbf{x}_0)$ that is not in $R_0(\mathbf{x}_0)$.

Let $S_0(\mathbf{x}_0) = W(\mathbf{x}_0) - R_0(\mathbf{x}_0)$. Clearly, if $\mathbf{v}(\mathbf{x}_0) \in S_0(\mathbf{x}_0)$ for all $\mathbf{x}_0 \in \Delta_0$, then $(S_t\mathbf{v})(\mathbf{x}_0) \in S_0(\mathbf{x}_0)$ for all $\mathbf{x}_0 \in \Delta_0$ and all $t \geqq 0$.

Let θ be a continuous function from Δ to R with

$$\theta(\mathbf{x}) = 0 \quad \forall \mathbf{x} \in \Delta_0,$$
$$\theta(\mathbf{x}) \geqq d(\mathbf{x}, \Delta_0) \quad \forall \mathbf{x} \in \Delta - \Delta_0,$$

such that θ has no stationary points in $\Delta - \operatorname{int} \Delta_0$. Thus if $0 < h \leqq \min_{\mathbf{x} \in \partial\Delta} d(\mathbf{x}, \Delta_0)$ then $\theta^{-1}(h)$ is homeomorphic to S^{m-1}. For each $h > 0$ let

$$A_h = \{\mathbf{x} \in \Delta \colon \theta(\mathbf{x}) \leqq h\}.$$

Then A_h is a closed subset of Δ, containing Δ_0 in its interior with $d(\mathbf{x}, \Delta_0) \leqq h$ for all $\mathbf{x}$ in A_h, and A_{h_1} a subset of A_{h_2} if $0 < h_1 \leqq h_2$. Now let $t_h = \max_{\mathbf{x} \in \partial A_h} T(\mathbf{x})$, and let $\Delta_h = \{\mathbf{x} \in \Delta \colon T(\mathbf{x}) \geqq t_h\}$. Clearly Δ_h is a subset of A_h, containing Δ_0 in its interior. If $0 < h_1 \leqq h_2$, then $t_{h_1} \geqq t_{h_2}$ and Δ_{h_1} is a subset of Δ_{h_2}. Also if $\mathbf{x} \in \Delta_h$ for some $h > 0$ then the characteristic curve $\boldsymbol{\phi}_{\mathbf{x}}(t)$ intersects $\partial\Delta_h$ exactly once.

LEMMA 2.5. *If* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F5), *then there is a unique* C^1 *function* $\mathbf{w}_h : \Delta - \operatorname{int} \Delta_h \to R^n$ *satisfying*

$$(2.11) \qquad \begin{aligned} (\mathbf{c}(\mathbf{x}) \cdot \nabla)\mathbf{w}_h &= \mathbf{f}(\mathbf{x}, \mathbf{w}_h) \quad \forall \mathbf{x} \in \Delta - \operatorname{int} \Delta_h, \\ \mathbf{w}_h(\mathbf{x}) &= \mathbf{v}_h(\mathbf{x}) \quad \forall \mathbf{x} \in \partial\Delta_h. \end{aligned}$$

Proof. The intersection of $\boldsymbol{\phi}_{\mathbf{x}}$ with $\partial\Delta_h$ is unique for all $\mathbf{x} \in \Delta - \operatorname{int} \Delta_h$. Suppose this intersection takes place at $t = \tau(\mathbf{x}, h) \leqq 0$, and let $\mathbf{x}_h = \boldsymbol{\phi}_{\mathbf{x}}(\tau(\mathbf{x}, h))$. Let $\boldsymbol{\psi}$ satisfy

$$(2.12) \qquad \begin{aligned} &\frac{d\boldsymbol{\psi}}{dt} = \mathbf{f}(\mathbf{x}, \mathbf{u}), \\ &\boldsymbol{\psi}(\tau(\mathbf{x}, h)) = \mathbf{v}_h(\mathbf{x}_h). \end{aligned}$$

Now $\boldsymbol{\psi}$ is unique for $\tau(\mathbf{x}, h) \leqq t \leqq T(\mathbf{x})$. So $\mathbf{w}_h(\mathbf{x}) = \boldsymbol{\psi}(\mathbf{0})$, giving a unique solution to (2.11).

THEOREM 2.1. *Suppose* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F5). *Then we can define* $W(\mathbf{x})$ *for all* $\mathbf{x}$ *in* $\Delta - \text{int}\,\Delta_0$; *that is, to each* $\mathbf{x} \in \Delta - \text{int}\,\Delta_0$ *there corresponds a unique compact simply connected subset* $W(\mathbf{x})$ *of* R^n (*where for* $\mathbf{x}_0 \in \partial\Delta_0$, $W(\mathbf{x}_0)$ *is as previously defined*), *such that if* $\mathbf{w}(\mathbf{x})$ *satisfies*

$$(\mathbf{c}(\mathbf{x}) \cdot \nabla)\mathbf{w} = \mathbf{f}(\mathbf{x}, \mathbf{w}) \tag{2.13}$$

and $\mathbf{w}(\mathbf{x}) \in \partial W(\mathbf{x})$ *for some* $\mathbf{x}$ *in* $\Delta - \Delta_0$, *then* $\mathbf{w}(\mathbf{x}) \in \partial W(\mathbf{x})$ *for all* $\mathbf{x}$ *in* $\Delta - \Delta_0$.

Proof. Let $\mathbf{x} \in \Delta - \Delta_0$. If h is sufficiently small, so that $\mathbf{x} \in \Delta - \Delta_h$, then we can consider the set of points $\{\mathbf{w}_h(\mathbf{x})\}$ arising from different values of $\mathbf{v}_h$ at the point $\mathbf{x}_h$ where the characteristic curve through $\mathbf{x}$ crosses $\partial\Delta_h$. Let $\mathbf{x}_0$ be a point on $\partial\Delta_0$ within a distance h of $\mathbf{x}_h$. Let $\mathbf{v}_h(\mathbf{x}_h)$ range over $\partial W(\mathbf{x}_0)$. Uniqueness of solutions (Lemma 2.5) ensures that the resulting set of points $\{\mathbf{w}_h(\mathbf{x})\}$ is homeomorphic to $\partial W(\mathbf{x}_0)$, that is, homeomorphic to S^{n-1}. Denote by $W_h(\mathbf{x})$ the region bounded by this set, and the set itself by $\partial W(\mathbf{x})$.

We wish to show that as $h \to 0$, $W_h(\mathbf{x})$ approaches a limit.

Let $\mathbf{u}_1 \in \partial W(\mathbf{x}_0)$ and let $\mathbf{N}$ be normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$ with $\hat{\mathbf{N}}$ the corresponding unit normal.

Then (2.9) implies

$$\hat{\mathbf{N}} \cdot \mathbf{f}(\mathbf{x}, \mathbf{u}_1 + \alpha\hat{\mathbf{N}}) < 0 \tag{2.14}$$

for $\alpha > 0$ sufficiently small and for all $\mathbf{x}$ in $\partial\Delta_0$. Inequality (2.10) gives

$$\hat{\mathbf{N}} \cdot (Jf(\mathbf{x}, \mathbf{u}_1)\hat{\mathbf{N}}) < 0 \quad \forall \mathbf{x} \text{ in } \partial\Delta_0. \tag{2.15}$$

Choose $h > 0$, $k > 0$ such that if $\mathbf{u}_1 \in \partial W(\mathbf{x}_0)$ and $\mathbf{N}$ is normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$, then the following conditions hold:

(a) If $\mathbf{x} \in \Delta_h$, $|\mathbf{N}| = k$, then

$$\hat{\mathbf{N}} \cdot \mathbf{f}(\mathbf{x}, \mathbf{u}_1 + \mathbf{N}) < 0; \tag{2.16}$$

(b) If $\mathbf{x} \in \Delta_h$, $|\mathbf{N}| < k$, then

$$\hat{\mathbf{N}} \cdot (Jf(\mathbf{x}, \mathbf{u}_1 + \mathbf{N})\hat{\mathbf{N}}) < 0; \tag{2.17}$$

(c) If $|\mathbf{N}| \leqq k$ then $\mathbf{u}_1$ is the nearest point on $\partial W(\mathbf{x}_0)$ to $\mathbf{u}_1 + \mathbf{N}$.

Denote by W_h the set of points $\{w_h(\mathbf{x})\colon \mathbf{x} \in \Delta - \text{int}\,\Delta_0\}$, and consider W_{h_1} and W_{h_2} where $h_1 < h_2 < h$. We want to show that W_h approaches a limit as $h \to 0$, and in order to do this we use Cauchy convergence.

Let $\mathbf{x} \in \Delta_h - \Delta_{h_2}$. If $\mathbf{x}_1 \in \partial\Delta_{h_1}$ and $\mathbf{x}_2 \in \partial\Delta_{h_2}$, we have $\mathbf{w}_{h_1}(\mathbf{x}_{h_1}) \in \partial W(\mathbf{x}_0)$ and $\mathbf{w}_{h_1}(\mathbf{x}_{h_1}) \in \partial W(\mathbf{x}_0)$. So $d(\mathbf{w}_{h_i}, W(\mathbf{x}_0)) < k$ because $\mathbf{N} \cdot \mathbf{f}(\mathbf{x}, \mathbf{u}_1 + \mathbf{N}) < 0$ for all $\mathbf{u}_1 \in \partial W(\mathbf{x}_0)$, $\mathbf{x} \in \Delta_h$, $|\mathbf{N}| = k$.

Let $z(\mathbf{x}, \mathbf{u}_1)$ be the distance along the normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$ from the intersection with $W_{h_1}(\mathbf{x})$ to the intersection with $W_{h_2}(\mathbf{x})$. (If there is more than one possible value of $z(\mathbf{x}, \mathbf{u}_1)$ due to multiple intersections, take the largest such value.)

So $z(\mathbf{x}, \mathbf{u}_1) < 2k$ if $\mathbf{x} \in \Delta_h$. Let $\mathbf{w}_{h_1}(\mathbf{x}, \mathbf{u}_1)$ and $\mathbf{w}_{h_2}(\mathbf{x}, \mathbf{u}_1)$ be these points of intersection and so

$$\mathbf{z}(\mathbf{x}, \mathbf{u}_1) = \mathbf{w}_{h_1}(\mathbf{x}, \mathbf{u}_1) - \mathbf{w}_{h_2}(\mathbf{x}, \mathbf{u}_1).$$

Therefore $z(\mathbf{x}, \mathbf{u}_1) = \hat{\mathbf{N}} \cdot \mathbf{z}(\mathbf{x}, \mathbf{u}_1)$, where $\hat{\mathbf{N}}$ is the unit normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$ in the direction of $\mathbf{z}(\mathbf{x}, \mathbf{u}_1)$.

Then if s represents the arc-length of the characteristic $\phi_{\mathbf{x}_h}(t)$ we have

$$\begin{aligned}\frac{d}{ds}z(\mathbf{x},\mathbf{u}_1)&=\frac{d}{dt}z(\mathbf{x},\mathbf{u}_1)\Big/\frac{ds}{dt}\\&=\hat{\mathbf{N}}\cdot(\mathbf{f}(\mathbf{x},\mathbf{w}_{h_1})-\mathbf{f}(\mathbf{x},\mathbf{w}_{h_2}))/(|\mathbf{c}(\mathbf{x})|)\\&=\hat{\mathbf{N}}\cdot(Jf(\mathbf{x},\mathbf{w}_{s_2}+\gamma\mathbf{z})\mathbf{z})/(|\mathbf{c}(\mathbf{x})|),\end{aligned}$$

where γ is in $(0,1)$.

So $(d/ds)z(\mathbf{x},\mathbf{u}_1)<0$ because $\mathbf{z}$ is a positive multiple of $\hat{\mathbf{N}}$ and (2.17) holds. So $z(\mathbf{x},\mathbf{u}_1)$ decreases with s for all $\mathbf{u}_1$ in $\partial W(\mathbf{x}_0)$, $\mathbf{x}$ in Δ_h.

Existence of $\lim_{h\to 0} W_h$. Choose $\varepsilon>0$ $(\varepsilon<2k)$. Now there is some $h_0\in(0,h)$ such that

$$\mathbf{N}\cdot\mathbf{f}(\mathbf{x},\mathbf{u}_1+\mathbf{N})<0 \tag{2.18}$$

for $\mathbf{N}=\varepsilon/2$, $\mathbf{x}\in\Delta_{h_0}$ (using (2.7) and (2.15)).

Suppose $h_1, h_2<h_0$. Then $d(\mathbf{w}_{h_i}, W(\mathbf{x}_0))<\varepsilon/2$ for $\mathbf{x}\in\Delta_{h_0}$. Hence if $\mathbf{w}_{h_1}$, $\mathbf{w}_{h_2}$ are on the normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1\in\partial \mathrm{W}(\mathbf{x}_0)$ and

$$\mathbf{z}(\mathbf{x},\mathbf{u}_1)=\mathbf{w}_{h_1}(\mathbf{x},\mathbf{u}_1)-\mathbf{w}_{h_2}(\mathbf{x},\mathbf{u}_1)$$

then $z(\mathbf{x},\mathbf{u}_1)<\varepsilon$ for $\mathbf{x}\in\Delta_{h_0}$. We have just shown that $z(\mathbf{x},\mathbf{u}_1)$ decreases with s if $\mathbf{x}\in\Delta_h$. So $z(\mathbf{x},\mathbf{u}_1)\leqq z(\mathbf{x}_{h_0},\mathbf{u}_1)<\varepsilon$ if $\mathbf{x}_{h_0}\in\Delta_{h_0}$, $\mathbf{x}\in\Delta_h-\Delta_{h_0}$. Therefore $\{W_h(\mathbf{x})\}$ satisfies a Cauchy condition for $\mathbf{x}\in\Delta_h-\Delta_0$. Hence if $\mathbf{x}\in\Delta_h-\Delta_0$ there is a limit subset $W_0(\mathbf{x})$ in R^n satisfying $W_0(\mathbf{x})=\lim_{h\to 0}W_h(\mathbf{x})$. Clearly $W_0(\mathbf{x}_0)=W(\mathbf{x}_0)$ for all $\mathbf{x}_0\in\partial\Delta_0$ for continuity.

By Lemma 2.5 it can be seen that $W_0(\mathbf{x})$ is well defined for all $\mathbf{x}$ in $\Delta-\operatorname{int}\Delta_0$ since elements of $\partial W_0(\mathbf{x})$ clearly lie on integral curves of (2.11) and these curves can be extended until $\partial\Delta$ is reached.

Uniqueness. Suppose there are two limit subsets $W_{01}(\mathbf{x})$ and $W_{02}(x)$ of $W_h(\mathbf{x})$ satisfying $\lim_{h\to 0}W_{0i}(\mathbf{x}_h)=W(\mathbf{x}_0)$. Let $z(\mathbf{x},\mathbf{u}_1)$ be the distance between $W_{01}(\mathbf{x})$ and $W_{02}(\mathbf{x})$ along the normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$. But $z(\mathbf{x},\mathbf{u}_1)$ decreases with s, since both $\mathbf{w}_{01}(\mathbf{x})$ and $\mathbf{w}_{02}(\mathbf{x})$ are generalized solutions of (2.11). $W_{0i}(\mathbf{x})$ is fixed for $\mathbf{x}\in\partial\Delta_0$, giving $\lim_{h\to 0}z(\mathbf{x}_h,\mathbf{u}_1)=0$ for all $\mathbf{u}_1\in W(\mathbf{x}_0)$. So $z(\mathbf{x},\mathbf{u}_1)=0$ for all $\mathbf{x}\in\Delta-\operatorname{int}\Delta_0$, $\mathbf{u}_1\in\partial\mathrm{W}(\mathbf{x}_0)$. Hence $W_0(\mathbf{x})$ is well defined for all $\mathbf{x}\in\Delta-\operatorname{int}\Delta_0$.

THEOREM 2.2. *Suppose* (C1)-(C2) *and* (F1)-(F5) *hold for* $\mathbf{c}$ *and* $\mathbf{f}$ *and that* $\mathbf{v}(\mathbf{x}_0)$ *lies in* $R_0(\mathbf{x}_0)$ *for all* $\mathbf{x}_0$ *in* Δ_0. *Then the solution* $\mathbf{u}(t,\mathbf{x})$ *of* (2.3) *has the property that as* $t\to\infty$ *the distance between the point* $\mathbf{u}(t,\mathbf{x})$ *and the surface* $\partial W(\mathbf{x})$ *tends to zero uniformly for* $\mathbf{x}$ *in* Δ.

First we give three lemmas which will enable us to prove this theorem.

Let $\mathbf{u}(t,\mathbf{x})$ be the solution to

$$\frac{\partial\mathbf{u}}{\partial t}+(\mathbf{c}\cdot\nabla)\mathbf{u}=\mathbf{f}(\mathbf{x},\mathbf{u})$$

with

$$\mathbf{u}(t=0,\mathbf{x})=\mathbf{v}(\mathbf{x})$$

where $\mathbf{c}$ and $\mathbf{f}$ satisfy (C1)-(C2) and (F1)-(F5). Define $w(\mathbf{u}(t,\mathbf{x}))\equiv w(t,\mathbf{x})$ to be the distance from $\mathbf{u}(t,\mathbf{x})$ to the nearest point on $\partial W(\mathbf{x})$. The function $w(\mathbf{u})$ is defined and continuous everywhere. If this nearest point is unique denote it by $\mathbf{u}_1(t,\mathbf{x})$. Now if $\mathbf{u}$ and $\mathbf{u}_1$ are distinct, then $\mathbf{u}-\mathbf{u}_1$ is normal to $\partial W(\mathbf{x})$. Denote $\mathbf{u}-\mathbf{u}_1$ by N, and the corresponding unit vector by $\hat{\mathrm{N}}$.

Let

$$\bar{u}(t,\mathbf{x})=[(w(t,\mathbf{x}))^2+1]^{-1}. \tag{2.19}$$

Note that $0<\bar{u}\leqq 1$. Suppose

$$\frac{\partial \bar{u}}{\partial t}+(\mathbf{c}\cdot\nabla)\bar{u}=\bar{f}(t,\mathbf{x},\mathbf{u}) \tag{2.20}$$

and define

$$f_0(t,\mathbf{x},\mathbf{u})=\frac{\bar{f}(t,x,u)}{\bar{u}-1}. \tag{2.21}$$

LEMMA 2.6. *$\bar{f}$ and f_0 are independent of t.*

Proof. Now

$$\frac{\partial \mathbf{u}}{\partial t}+(\mathbf{c}\cdot\nabla)\mathbf{u}=\mathbf{f}(\mathbf{x},\mathbf{u}),$$

and so

$$\frac{\partial \bar{u}}{\partial t}+(\mathbf{c}\cdot\nabla)\bar{u}=-\frac{2(\mathbf{u}-\mathbf{u}_1)\cdot(\mathbf{f}(\mathbf{x},\mathbf{u})-\partial\mathbf{u}_1/\partial t-(\mathbf{c},\nabla)\mathbf{u}_1)}{(w^2+1)^2}.$$

Now $\mathbf{u}-\mathbf{u}_1$ is normal to the surface $\partial W(\mathbf{x})$, and since $\mathbf{u}_1$ remains on $\partial W(\mathbf{x})$ we have $\partial\mathbf{u}_1/\partial t$ tangential to $\partial W(\mathbf{x})$, giving

$$(\mathbf{u}-\mathbf{u}_1)\cdot\frac{\partial \mathbf{u}_1}{\partial t}=0.$$

Theorem 2.1 states that if $\mathbf{w}(\mathbf{x})$ satisfies $(\mathbf{c}\cdot\nabla)\mathbf{w}=\mathbf{f}(\mathbf{x},\mathbf{w})$, and $\mathbf{w}(\mathbf{x})\in\partial W(\mathbf{x})$ for some $\mathbf{x}\in\Delta-\Delta_0$, then $\mathbf{w}(\mathbf{x})\in W(\mathbf{x})$ for all $\mathbf{x}\in\Delta-\Delta_0$. Suppose that for some $\mathbf{x}\in\Delta-\Delta_0$ and some $t\geqq 0$, $\mathbf{w}(\mathbf{x})=\mathbf{u}_1(t,\mathbf{x})\in\partial W(\mathbf{x})$.

Consider $(\mathbf{c}\cdot\nabla)\mathbf{u}_1$. The function $\mathbf{u}_1(\mathbf{x},\cdot)$ takes values on $\partial W(\mathbf{x})$. Then $(\mathbf{c}\cdot\nabla)(\mathbf{u}_1-\mathbf{w})$ is tangential to $\partial W(\mathbf{x})$, since both $\mathbf{u}_1(\mathrm{t},\mathbf{x})$ and $\mathbf{w}(\mathbf{x})$ remain on $\partial W(\mathbf{x})$. Therefore the components of $(\mathbf{c}\cdot\nabla)\mathbf{u}_1$ and $(\mathbf{c},\nabla)\mathbf{w}$ normal to $\partial W(\mathbf{x})$ must be equal. Therefore

$$(\mathbf{u}-\mathbf{u}_1)\cdot((\mathbf{c}\cdot\nabla)\mathbf{u}_1)=(\mathbf{u}-\mathbf{u}_1)\cdot\mathbf{f}(\mathbf{x},\mathbf{u}_1).$$

In other words $\hat{\mathbf{N}}\cdot\mathbf{f}(\mathbf{x},\mathbf{u}_1)$ is the component of $(\mathbf{c}\cdot\nabla)\mathbf{u}_1$ normal to $\partial W(\mathbf{x})$ at $\mathbf{u}_1$, representing the change in $\mathbf{u}_1$ necessary to keep $\mathbf{u}_1$ on $\partial W(\mathbf{x})$ as $\mathbf{x}$ changes.

Also, if $\mathbf{x}_0\in\Delta_0$, $\mathbf{u}_1\in\partial W(\mathbf{x})$, then $\psi(t;\mathbf{x}_0,\mathbf{u}_1)$ lies on $\partial W(\mathbf{f}_{\mathbf{x}_0}(t))$ for all $t\geqq 0$. So if $\mathbf{u}(t,\mathbf{x})$ satisfies

$$\frac{\partial \mathbf{u}}{\partial t}+(\mathbf{c}\cdot\nabla)\mathbf{u}=\mathbf{f}(\mathbf{x},\mathbf{u}),$$

$$\mathbf{u}(t=0,\mathbf{x})=\mathbf{v}(\mathbf{x}),$$

and $\mathbf{v}(\mathbf{x}_0)\in\partial W(\mathbf{x}_0)$ for each $\mathbf{x}_0\in\Delta_0$, then $\mathbf{u}(t,\mathbf{x}_0)\in\partial W(\mathbf{x}_0)$ for all $\mathbf{x}_0\in\Delta_0$, $t\geqq 0$. Suppose that $\mathbf{v}(\mathbf{x}_0)=\mathbf{u}_1$. Then $\mathbf{N}\cdot(\partial\mathbf{u}/\partial t)=0$ if $\mathbf{N}$ is normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$. So, as before, we have

$$(\mathbf{u}-\mathbf{u}_1)\cdot((\mathbf{c}\cdot\nabla)\mathbf{u}_1)=(\mathbf{u}-\mathbf{u}_1)\cdot\mathbf{f}(\mathbf{x},\mathbf{u}_1).$$

So if $\mathbf{x}$ is in Δ, $\mathbf{u}\in R^n$, then

$$\bar{f}(t,\mathbf{x},\mathbf{u})=\frac{2[(\mathbf{u}-\mathbf{u}_1)\cdot(\mathbf{f}(\mathbf{x},\mathbf{u})-\mathbf{f}(\mathbf{x},\mathbf{u}_1))]}{(w^2+1)^2},$$

which is independent of t for $\mathbf{x}\in\Delta$, $\mathbf{u}\in R^n$. Hence f_0 is also independent of t.

LEMMA 2.7. *If* $\mathbf{x}_0 \in \partial\Delta_0$ *then* $f_0(\mathbf{x}_0, \mathbf{u}_0) < 0$ *for all* $\mathbf{u} \in R_0(\mathbf{x}_0)$.

Proof. Let $\mathbf{x}_0 \in \partial\Delta_0$. Now

$$\frac{1}{(\bar{u}-1)} = \frac{1}{(w^2+1)^{-1}-1} = -\frac{w^2+1}{w^2}.$$

Therefore, if $\mathbf{u}$ is not on $\partial W(\mathbf{x}_0)$

$$\begin{aligned} f_0(\mathbf{x}_0, \mathbf{u}) &= \frac{2[(\mathbf{u}-\mathbf{u}_1)\cdot(\mathbf{f}(\mathbf{x}_0,\mathbf{u})-\mathbf{f}(\mathbf{x}_0,\mathbf{u}_1))]}{w^2(w^2+1)} \\ &= \frac{2[\mathbf{N}\cdot(\mathbf{f}(\mathbf{x}_0,\mathbf{u}_1+\mathbf{N})-\mathbf{f}(\mathbf{x}_0,\mathbf{u}_1))]}{|\mathbf{N}|^2(|\mathbf{N}|^2+1)}. \end{aligned} \tag{2.22}$$

But, since $\mathbf{N}$ is normal to $\partial W(\mathbf{x}_0)$ at $\mathbf{u}_1$, we have $\mathbf{N}\cdot\mathbf{f}(\mathbf{x}_0,\mathbf{u}_1)=0$, and $\mathbf{N}\cdot\mathbf{f}(\mathbf{x}_0,\mathbf{u})<0$, giving

$$f_0(\mathbf{x}_0, \mathbf{u}) < 0. \tag{2.23}$$

For $\mathbf{u}$ close to $\partial W(\mathbf{x}_0)$, we have

$$\begin{aligned} f_0(\mathbf{x}_0, \mathbf{u}) &= \frac{2[\mathbf{N}\cdot((Jf(\mathbf{x}_0,\mathbf{u}_1)\mathbf{N})+O(|\mathbf{N}|)^2)]}{|\mathbf{N}|^2(|\mathbf{N}|^2+1)} \\ &= \frac{[\hat{\mathbf{N}}\cdot(Jf(\mathbf{x}_0,\mathbf{u}_1)\hat{\mathbf{N}})+O(|\mathbf{N}|)]}{|\mathbf{N}|^2+1}. \end{aligned}$$

But condition (F5) implies that $\hat{\mathbf{N}}\cdot(Jf(\mathbf{x}_0,\mathbf{u}_1)\hat{\mathbf{N}})<0$. Also, $f_0(\mathbf{x}_0,\mathbf{u})$ is bounded as $\mathbf{u}$ approaches $\partial W(\mathbf{x}_0)$. So $f_0(\mathbf{x}_0,\mathbf{u})$ is continuous and negative for $\mathbf{u}$ in $R_0(\mathbf{x}_0)$.

LEMMA 2.8. $|f_0(\mathbf{x},\mathbf{u})|$ *is bounded for* $\mathbf{x}\in\Delta-\operatorname{int}\Delta_0$ *and* $\mathbf{u}\in R^n$.

Proof. For any $\mathbf{x}\in\Delta-\operatorname{int}\Delta_0$, $\mathbf{u}$ close to $\partial W(\mathbf{x})$, $\mathbf{N}=\mathbf{u}_1(\mathbf{u})-\mathbf{u}$, we have, similarly to before,

$$f_0(\mathbf{x},\mathbf{u}) = \frac{[\hat{\mathbf{N}}\cdot(Jf(\mathbf{x},\mathbf{u}_1)\hat{\mathbf{N}})+O(|\mathbf{N}|)]}{|\mathbf{N}|^2+1}, \tag{2.24}$$

which is clearly bounded as $|\mathbf{N}|\to 0$.

Also,

$$f_0(\mathbf{x},\mathbf{u}) = 2|\mathbf{N}|^{-2}(|\mathbf{N}|^2+1)^{-1}[\mathbf{N}\cdot(\mathbf{f}(\mathbf{x},\mathbf{u})-\mathbf{f}(\mathbf{x},\mathbf{u}_1))].$$

We know that $|\mathbf{f}(\mathbf{x},\mathbf{u})|<k_1|\mathbf{u}|+k_2$. Let

$$F = \max_{\substack{\mathbf{x}\in\Delta-\operatorname{int}\Delta_0 \\ \mathbf{u}\in\partial W(\mathbf{x})}} |\mathbf{f}(\mathbf{x},\mathbf{u})|. \tag{2.25}$$

Then

$$|f_0(\mathbf{x},\mathbf{u})| < 2|\mathbf{N}|^{-1}(|\mathbf{N}|^2+1)^{-1}[k_1|\mathbf{u}|+k_2+F].$$

Now assume that

$$U = \max_{\substack{\mathbf{x}\in\Delta-\operatorname{int}\Delta_0 \\ \mathbf{u}_1\in\partial W(\mathbf{x})}} |\mathbf{u}_1|. \tag{2.26}$$

If $|\mathbf{u}|>2U$ then $|\mathbf{u}-\mathbf{u}_1|>|\mathbf{u}|/2$. Therefore

$$\begin{aligned} |f_0(\mathbf{x},\mathbf{u})| &< 4|\mathbf{u}|^{-1}(\tfrac{1}{2}|\mathbf{u}|^2+1)^{-1}[k_1|\mathbf{u}|+k_2+F] \\ &< 8|\mathbf{u}|^{-2}[k_1+|\mathbf{u}|^{-1}(k_2+F)], \end{aligned} \tag{2.27}$$

which approaches zero as $|\mathbf{u}|\to\infty$.

So $|f_0(\mathbf{x},\mathbf{u})|$ is bounded in the compact region $\mathbf{x}\in\Delta-\operatorname{int}\Delta_0$, $|\mathbf{u}|<2U$ and $f_0\to 0$ as $|\mathbf{u}|\to\infty$. This implies that f_0 is bounded everywhere.

Proof of Theorem 2.2. First, show that for each $\varepsilon > 0$ there exists $\delta > 0$ such that for any $t_1 > 0$, $\mathbf{p} \in \Delta$, $\mathbf{r} \in R^n$ if

$$1 - \frac{1}{1 + |\boldsymbol{\psi}(t_1; \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2} \leqq \delta$$

then

$$1 - \frac{1}{1 + |\boldsymbol{\psi}(t; \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2} \leqq \varepsilon$$

for $t_1 \leqq t \leqq T(\mathbf{p})$.

If $\mathbf{p} \in \Delta - \Delta_0$ and $s(t) \geqq 0$ is the arc-length along the characteristic $\boldsymbol{\phi}_{\mathbf{p}}(t)$ from $\mathbf{p}$, then we can define t as $t \equiv t(s)$ because we know that s is strictly increasing with t. Define

$$z(s) = [1 + |\boldsymbol{\psi}(t(s); \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2]^{-1}$$

for $s \geqq 0$.

Then

$$\begin{aligned}\frac{d}{dt} \ln (1 - z) &= \frac{1}{1 - z} \bar{f}(\mathbf{x}, \boldsymbol{\psi}) \\ &= f_0(\mathbf{x}, \boldsymbol{\psi})\end{aligned}$$

and

$$\begin{aligned}\frac{d}{dx} \ln (1 - z) &= f_0(\mathbf{x}, \boldsymbol{\psi}) / |\mathbf{c}(\mathbf{x})| \\ &= g(\mathbf{x}, \boldsymbol{\psi}), \quad \text{say.}\end{aligned} \tag{2.28}$$

Now there are $h > 0$, $k > 0$ such that $g(\mathbf{x}, \mathbf{u}) < 0$ for $\mathbf{x} \in \Delta_h - \operatorname{int} \Delta_0$, $|\mathbf{u} - \mathbf{u}_1(\mathbf{u})| < k$.

So if $1 - z < k$ for $\mathbf{p}$ in $\partial \Delta_0$ then $1 - z$ remains less than k while $\boldsymbol{\phi}_{\mathbf{p}}(t) \in \Delta_h$.

$\Delta - \operatorname{int} \Delta_h$ is a compact set and so there is an $M = \max_{\mathbf{x} \in \Delta - \operatorname{int} \Delta_n} g(\mathbf{x}, \mathbf{u})$ (because $g = f_0 / |\mathbf{c}|$ and $f_0(\mathbf{x}, \mathbf{u})$ is bounded). Therefore $(d/ds) \ln (1 - z) \leqq M$.

Let $m = \max_{\mathbf{x} \in \Delta - \operatorname{int} \Delta_h} s(\mathbf{x})$. Now $1 - z \leqq k$ for $\mathbf{x} \in \Delta_h$, and so

$$\ln (1 - z(s)) \leqq Mm + \ln (1 - z(s_1))$$

for $0 < s_1 \leqq s$. Therefore

$$1 - z(s) \leqq \exp (Mm)(1 - z(s_1)).$$

Putting $\delta = \exp (-Mm) \min (\varepsilon, k)$ we finally obtain $1 - z(s) \leqq \varepsilon$ for $0 < s_1 \leqq s$, giving

$$1 - [1 + |\boldsymbol{\psi}(t; \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2]^{-1} \leqq \varepsilon \tag{2.29}$$

if $t_1 \leqq t \leqq T(\mathbf{p})$, and

$$1 - [1 + |\boldsymbol{\psi}(t_1; \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2]^{-1} \leqq \delta.$$

Now we must show that this gives $\lim_{t \to \infty} \bar{u}(t, \mathbf{x}) = 1$ uniformly for $\mathbf{x} \in \Delta - \operatorname{int} \Delta_0$. Choose $\varepsilon \in (0, 1)$. Choose δ such that if

$$1 - [1 + |\boldsymbol{\psi}(t_1; \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2]^{-1} \leqq \delta$$

then

$$1 - [1 + |\boldsymbol{\psi}(t; \mathbf{p}, \mathbf{r}) - \mathbf{u}_1|^2]^{-1} \leqq \varepsilon/2 \tag{2.30}$$

for all t in the range $[t_1, T(\mathbf{p})]$. Now Lemma 2.4 implies that $\boldsymbol{\phi}_{\mathbf{p}}(t)$ is in $\partial\Delta_0$ for all t if $\mathbf{p}$ is in $\partial\Delta_0$. In other words this characteristic curve lies entirely on $\partial\Delta_0$.

If $\mathbf{x}_0$ is on $\partial\Delta_0$, $\mathbf{r}\in R_0(\mathbf{x}_0)$ and

$$y(t)=[1+|\boldsymbol{\psi}(t;\mathbf{x}_0,\mathbf{r})-\mathbf{u}_1(\boldsymbol{\psi})|^2]^{-1} \tag{2.31}$$

then

$$\frac{dy}{dt}=\bar{f}(\boldsymbol{\phi}_{\mathbf{x}_0}(t),\boldsymbol{\psi}),$$

which, from Lemma 2.7, is positive if $\boldsymbol{\psi}$ is not on $\partial W(\boldsymbol{\phi}_{\mathbf{x}_0}(t))$.

Recall that $R'(\mathbf{x}_0)$ is a closed subset of R^n containing $\partial W(\mathbf{x}_0)$, and if $\mathbf{u}\in R_0(\mathbf{x}_0)$ then there is some $t_0\geqq 0$ such that $\boldsymbol{\psi}(t;\mathbf{x}_0,\mathbf{u})\in R'(\mathbf{x}_0)$ for all $t\geqq t_0$. Let

$$\alpha=\max\{f_0(\mathbf{x}_0,\mathbf{u}):\mathbf{x}_0\in\partial\Delta_0,\mathbf{u}\in R'(\mathbf{x}_0)\}. \tag{2.32}$$

Thus $\alpha<0$. Now $\boldsymbol{\psi}(t;\mathbf{x}_0,\mathbf{r})\in R'$ for all t greater than some $t_0\geqq 0$. So for $t\geqq t_0$

$$\begin{aligned}\frac{d}{dt}\ln(1-y)&=-\frac{1}{(1-y)}\bar{f}(\boldsymbol{\phi}_{\mathbf{x}_0}(t),\boldsymbol{\psi})\\&=f_0(\boldsymbol{\phi}_{\mathbf{x}_0}(t),\boldsymbol{\psi})\\&<\alpha\end{aligned}$$

because $\boldsymbol{\psi}$ approaches $\partial W(\boldsymbol{\phi}_{\mathbf{x}_0}(t))$ and never leaves $R'(\boldsymbol{\phi}_{\mathbf{x}_0}(t))$. So

$$1-y(t)\leqq(1-y(t_0))\,e^{\alpha(t-t_0)}. \tag{2.33}$$

So there exists $t_1>0$ such that $1-y(t)<\delta/2$ for $t\geqq t_1$, $\mathbf{r}\in R_0(\mathbf{x}_0)$. Also, since $\mathbf{v}$ is continuous, there is $h_0>0$ such that

$$1-[1+|\boldsymbol{\psi}(t_1;\mathbf{x},\mathbf{v}(\mathbf{x}))-\mathbf{u}_1|^2]^{-1}<\delta$$

for $\mathbf{x}\in\Delta_{h_0}$, such that $\min_{\mathbf{x}\in\partial\Delta_{h_0}}T(\mathbf{x})\geqq t_1$. Now the conditions for the first part are satisfied, giving

$$1-[1+|\boldsymbol{\psi}(t;\mathbf{x},\mathbf{v}(\mathbf{x}))-\mathbf{u}_1|^2]^{-1}<\varepsilon/2$$

for all $t\geqq t_1$. So

$$|\boldsymbol{\psi}-\mathbf{u}_1|^2<\frac{\varepsilon/2}{1-\varepsilon/2}<\varepsilon,$$

since $\varepsilon<1$.

So if $t\geqq t_1$ we have $\boldsymbol{\phi}(0;t,\mathbf{x})\in\Delta_{h_0}$, and hence

$$|\boldsymbol{\psi}(t;\boldsymbol{\phi}(0;t,\mathbf{x}),\mathbf{v}(\boldsymbol{\phi}(0;t,\mathbf{x})))-\mathbf{u}_1|^2<\varepsilon. \tag{2.34}$$

So $\lim_{t\to\infty}|\mathbf{u}(t,\mathbf{x})-\mathbf{u}_1|=0$.

3. Chaos. Recall that for $\mathbf{x}\in\Delta_0$, $S_0(\mathbf{x})$ was defined as $S_0(\mathbf{x})=W(\mathbf{x})-R_0(\mathbf{x})$. From now on we will assume that for each $\mathbf{x}$ in Δ_0, $S_0(\mathbf{x})$ consists of just one point $\mathbf{u}_0(\mathbf{x})$.

Now we show that chaos exists if $\mathbf{v}(\mathbf{x})=\mathbf{u}_0(\mathbf{x})$ for each $\mathbf{x}\in\Delta_0$.

Let

$$V_+=\{\mathbf{v}\in C(\Delta):\mathbf{v}(\mathbf{x})\in R_0(\mathbf{x})\ \forall\mathbf{x}\in\Delta_0\} \tag{3.1}$$

and

$$V_0=\{\mathbf{v}\in C(\Delta):\mathbf{v}(\mathbf{x})=\mathbf{u}_0(\mathbf{x})\ \forall\mathbf{x}\in\Delta_0\}. \tag{3.2}$$

LEMMA 3.1. *Both V_+ and V_0 are invariant under S_t where S_t is an element of the semidynamical system $\{S_t\}_{t\geqq 0}$ which maps $\mathbf{u}(t_0,\cdot)$ to $\mathbf{u}(t_0+t,\cdot)$.*

Proof. Recall that

$$\begin{aligned}(S_t\mathbf{v})(\mathbf{x})&=\mathbf{u}(t,\mathbf{x})\\&=\boldsymbol{\psi}(t;\mathbf{x}_0,\mathbf{v}(\mathbf{x}_0))\end{aligned}$$

where $\mathbf{x}_0=\boldsymbol{\phi}(0;t,\mathbf{x})$; also $\boldsymbol{\psi}$ satisfies

$$\frac{d\psi}{dt}=\mathbf{f}(\mathbf{x},\boldsymbol{\psi}).$$

Now if $\mathbf{x}\in\Delta_0$ we have $\boldsymbol{\phi}(0;t,\mathbf{x})\in\Delta_0$ for all $t\geqq 0$. Hence

$$\mathbf{v}(\boldsymbol{\phi}(0;t,\mathbf{x}))=\mathbf{u}_0(\boldsymbol{\phi}(0;t,\mathbf{x})),$$

which is in $S_0(\boldsymbol{\phi}(0;t,\mathbf{x}))$. But $S_0(\mathbf{x})$ is defined as the subset of $W(\mathbf{x})$ for which $\boldsymbol{\psi}(t;\mathbf{x},\mathbf{u})$ does not approach $\partial W(\boldsymbol{\phi}_{\mathbf{x}}(t))$ as $t\to\infty$. Therefore if $\mathbf{u}\in S_0(\mathbf{x})$ it follows that $\boldsymbol{\psi}(t;\mathbf{x},\mathbf{u})$ lies in $S_0(\boldsymbol{\phi}_{\mathbf{x}}(t))$ for all $t\geqq 0$. Thus for each $\mathbf{x}\in\Delta_0$ we have $(S_t\mathbf{v})(\mathbf{x})\in S_0(\mathbf{x})$, giving $(S_t\mathbf{v})(\mathbf{x})=\mathbf{u}_0(\mathbf{x})$ for all t. So V_0 is invariant under S_t.

Similarly if $\mathbf{v}(\mathbf{x})\in R_0(\mathbf{x})$ for all $\mathbf{x}$ in Δ_0 then $(S_t\mathbf{v})(\mathbf{x})$ is also in $R_0(\mathbf{x})$ for all $\mathbf{x}$ in Δ_0. So V_+ is invariant under S_t. We have shown that if $\mathbf{v}\in V_+$ then $(S_t\mathbf{v})(\mathbf{x})$ approaches $\partial W(\mathbf{x})$ as $t\to\infty$.

Let

$$V_W=\{\mathbf{v}\in V_0\colon \mathbf{v}(\mathbf{x})\in\operatorname{int} W(\mathbf{x})\ \forall\mathbf{x}\in\Delta\}. \tag{3.3}$$

We demonstrate that this is a global attractor.

LEMMA 3.2. *If* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F5), *then V_W is invariant under S_t, and for each $\mathbf{v}\in V_0$ there is some $T_0\geqq 0$ such that $S_t\mathbf{v}\in V_W$ for all $t\geqq T_0$.*

Proof. Now $\partial W(\mathbf{x})$ is invariant under S_t since if $\mathbf{u}(t_0,\mathbf{x})$ lies on $W(\mathbf{x})$ for some $t_0\geqq 0$ and all $\mathbf{x}\in\Delta$ then $\mathbf{u}(t,\mathbf{x})$ lies on $\partial W(\mathbf{x})$ for all $\mathbf{x}$ and all $t\geqq t_0$. Now

$$(S_t\mathbf{v})(\mathbf{x})=\boldsymbol{\psi}(t;\boldsymbol{\phi}(0;t,\mathbf{x}),\mathbf{v}(\boldsymbol{\phi}(0;t,\mathbf{x}))). \tag{3.4}$$

If $\mathbf{v}(\mathbf{x})$ lies in $\partial W(\mathbf{x})$ for all $\mathbf{x}$ in Δ, then $(S_t\mathbf{v})(\mathbf{x})$ remains in $\partial W(\mathbf{x})$ for all $\mathbf{x}\in\Delta$ and all $t\geqq 0$.

The property of uniqueness of solutions ensures that if $\mathbf{v}(\boldsymbol{\phi}(0;t,\mathbf{x}))$ is in $\operatorname{int} W(\boldsymbol{\phi}(0;t,\mathbf{x}))$ then $(S_t\mathbf{v})(\mathbf{x})\in\operatorname{int} W(\mathbf{x})$ for all $t\geqq 0$. Similarly if $\mathbf{v}(\boldsymbol{\phi}(0;t,\mathbf{x}))$ is in $R^n-W(\boldsymbol{\phi}(0;t,\mathbf{x}))$ then $(S_t\mathbf{v})(\mathbf{x})\in R^n-W(\mathbf{x})$ for all $t\geqq 0$. This, together with the invariance of V_0, gives invariance of V_W.

Also if $\mathbf{v}\in V_0$ we know that $\mathbf{v}(\mathbf{x})=\mathbf{u}_0(\mathbf{x})$ for all $\mathbf{x}$ in Δ_0. Since $\partial W(\mathbf{x})$ is contained in $R_0(\mathbf{x})$ for all $\mathbf{x}\in\Delta_0$, it follows that in this case $\mathbf{v}(\mathbf{x})\in\operatorname{int} W(\mathbf{x})$.

So there is some $h_0>0$ such that $\mathbf{v}(\mathbf{x})\in\operatorname{int} W(\mathbf{x})$ for all $\mathbf{x}$ in $\Delta_{h_0}-\operatorname{int}\Delta_0$. So if $T_0=\max_{\mathbf{x}\in\partial\Delta_{h_0}} T(\mathbf{x})$, $\mathbf{x}\in\Delta-\Delta_0$ and $t_0\geqq T_0$, we have $\boldsymbol{\phi}(0;t,\mathbf{x})\in\Delta_{h_0}$ giving $(S_{t_0}\mathbf{v})(\mathbf{x})\in\operatorname{int} W(\mathbf{x})$, because $\mathbf{v}(\boldsymbol{\phi}(0;t_0,\mathbf{x}))$ is in $\operatorname{int} W(\boldsymbol{\phi}(0;t_0,\mathbf{x}))$.

Now extend $\mathbf{u}_0$ to be a continuous function from Δ to R^n with $\mathbf{u}_0(\mathbf{x})\in\operatorname{int} W(\mathbf{x})$ for each $\mathbf{x}\in\Delta$.

LEMMA 3.3. *Suppose* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F5), *and that for each $\mathbf{x}$ in Δ_0, $S_0(\mathbf{x})$ consists of the single point $\mathbf{u}_0(\mathbf{x})$. Let $\mathbf{v}_0\in V_W$. Let $\delta<\max_{\mathbf{x}\in\Delta_0} d(\mathbf{u}_0(\mathbf{x}),\partial W(\mathbf{x}))$, and let*

$$V_\delta=\{\mathbf{v}_0+\delta\hat{\mathbf{n}}\colon |\hat{\mathbf{n}}|=1\}, \tag{3.5}$$

with

$$S_tV_\delta=\{S_t\mathbf{v}\colon \mathbf{v}\in V_\delta\}.$$

For $\varepsilon > 0$ denote by $W_\varepsilon(\mathbf{x})$ the subset of $W(\mathbf{x})$ consisting of points $\mathbf{x}$ such that the open ball centered at $\mathbf{x}$ with radius ε lies in $W(\mathbf{x})$. Let $\varepsilon > 0$ be sufficiently small so that for each $\mathbf{x}$ in Δ, $W_\varepsilon(\mathbf{x})$ is nonempty and simply connected.

Then there is some $t_0 > 0$ such that for all $t \geqq t_0$ and all $\mathbf{x} \in \Delta$, $(S_t V_\delta)(\mathbf{x})$ lies in $W(\mathbf{x})$ and encloses $W_\varepsilon(\mathbf{x})$.

Proof. From Theorem 2.2 and Lemma 3.2 it is clear that there is some $t_0 > 0$ such that if $t > t_0$, $\mathbf{x} \in \Delta$ and $\mathbf{v} \in V_\delta$, then $(S_t \mathbf{v})(\mathbf{x}) \in W(\mathbf{x})$ and lies within distance ε of $\partial W(\mathbf{x})$. It remains to show that $(S_t V_\delta)(\mathbf{x})$ encloses all of $W_\varepsilon(\mathbf{x})$.

Consider $\mathbf{x}_0 \in \Delta_0$. Now $\mathbf{v}_0(\mathbf{x}_0)$ is inside $V_\delta(\mathbf{x}_0)$, and so $(S_{t_0}\mathbf{v}_0)(\mathbf{x}_0)$ lies inside $(S_{t_0} V_\delta)(\mathbf{x}_0)$. But $(S_{t_0}\mathbf{v}_0)(\mathbf{x}_0) = \mathbf{u}_0(\mathbf{x}_0)$, whose distance from $\partial W(\mathbf{x}_0)$ is greater than ε. Hence $(S_{t_0} V_\delta)(\mathbf{x}_0)$ encloses at least one point of $W_\varepsilon(\mathbf{x}_0)$. Therefore $(S_{t_0} V_\delta)(\mathbf{x}_0)$ must enclose all of $W_\varepsilon(\mathbf{x}_0)$, since all points of $(S_{t_0} V_\delta)(\mathbf{x}_0)$ lie outside $W_\varepsilon(\mathbf{x}_0)$.

Now $(S_{t_0} V_\delta)(\mathbf{x})$ and $W(\mathbf{x})$ both vary continuously with $\mathbf{x}$. Also, $W_\varepsilon(\mathbf{x})$ is nonempty and connected for each $\mathbf{x} \in \Delta$. So it follows that for each $\mathbf{x} \in \Delta$, $(S_{t_0} V_\delta)(\mathbf{x})$ encloses $W_\varepsilon(\mathbf{x})$.

LEMMA 3.4. *Suppose* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F5). *Let* $\mathbf{q}$ *be an element of* V_W. *Let* $\delta > 0$, $\tau \geqq 0$ *and* $h_0 > 0$. *Then there is some* $t_0 > \tau$, *numbers* $\beta \geqq \alpha > 0$ *with* $\beta \leqq h_0$ *and a continuous mapping* $\mathbf{p}$ *from* $\mathbf{x}$ *in* $\Delta_\beta - \operatorname{int} \Delta_\alpha$ *to* $\mathbf{p}(\mathbf{x}) \in R^n$ *with the following properties*:

1) *For all* $\mathbf{x}$ *in* $\Delta_\beta - \operatorname{int} \Delta_\alpha$ *we have* $|\mathbf{p}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \delta$;

2) *For each* $\mathbf{v} \in V_W$ *with*

$$|\mathbf{v}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \max_{\mathbf{x} \in \partial\Delta_\alpha} |\mathbf{p}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x} \in \Delta_\alpha - \operatorname{int} \Delta_0 \tag{3.6}$$

and

$$\mathbf{v}(\mathbf{x}) = \mathbf{p}(\mathbf{x}) \quad \forall \mathbf{x} \in \Delta_\alpha - \operatorname{int} \Delta_\beta$$

we have

$$|(S_{t_0}\mathbf{v})(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \max_{\mathbf{x} \in \partial\Delta_{h_0}} |\mathbf{q}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x} \in \Delta_{h_0} - \operatorname{int} \Delta_0 \tag{3.7}$$

and

$$(S_{t_0}\mathbf{v})(\mathbf{x}) = \mathbf{q}(\mathbf{x}) \quad \forall \mathbf{x} \in \Delta - \operatorname{int} \Delta_{h_0}.$$

Proof. Let

$$q_{h_0} = \max_{\mathbf{x} \in \partial\Delta_{h_0}} |\mathbf{q}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})|. \tag{3.8}$$

Without loss of generality assume that $|\mathbf{q}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq q_{h_0}$ if $\mathbf{x} \in \Delta_{h_0}$.

Let θ be a continuous function from Δ to $[0, 1]$ such that $\theta(\mathbf{x}) = 1$ for all $\mathbf{x} \in \Delta_0$, $0 < \theta(\mathbf{x}) < 1$ for all $\mathbf{x}$ in $\operatorname{int} \Delta_{h_0} - \Delta_0$ and $\theta(\mathbf{x}) = 0$ for all $\mathbf{x}$ outside Δ_{h_0}. Let V_δ be the subset of V_+ consisting of functions $\bar{\mathbf{v}}$ that satisfy

$$\bar{\mathbf{v}}(\mathbf{x}) = \tfrac{1}{2}\delta\theta(\mathbf{x})\mathbf{n} + u_0(\mathbf{x}) \tag{3.9}$$

for all $\mathbf{x}$ in $\Delta - \operatorname{int} \Delta_0$, where $\mathbf{n}$ is some unit vector in R^n. Denote by $V_\delta(\mathbf{x})$ the set of points $\{\bar{\mathbf{v}}(\mathbf{x}) \colon \bar{\mathbf{v}} \in V_\delta\}$. For each $\mathbf{x} \in \operatorname{int} \Delta_{h_0}$, $V_\delta(\mathbf{x})$ forms a surface homeomorphic to S^{n-1}, and $u_0(\mathbf{x})$ lies inside this surface. Denote by $(S_t V_\delta)(\mathbf{x})$ the set of points $\{(S_t\bar{\mathbf{v}})(\mathbf{x}) \colon \bar{\mathbf{v}} \in V_\delta\}$. This is a surface homeomorphic to $V_\delta(\mathbf{x})$.

From Theorem 2.2 we know that for each element $\bar{\mathbf{v}}$ of V_δ, $(S_t\bar{\mathbf{v}})(\mathbf{x})$ approaches $\partial W(\mathbf{x})$ uniformly for $\mathbf{x}$ in Δ. Also since $u_0(\mathbf{x})$ lies inside $V_\delta(\mathbf{x})$ for each $\mathbf{x}$ in $\operatorname{int} \Delta_{h_0}$, and $\mathbf{q} \in V_W$ it follows, as in Lemma 3.3, that there exists $t_0 > \max_{\mathbf{x} \in \partial\Delta_{h_0}} T(\mathbf{x})$ such that $\mathbf{q}(\mathbf{x})$ is inside the surface $(S_{t_0})(\mathbf{x})$ for all $\mathbf{x}$ in Δ. So $\boldsymbol{\phi}(0; t, \mathbf{x}) \in \Delta_{h_0}$ for all $t \geqq t_0$, and for all $\mathbf{x}$ in Δ.

Let $\psi_0(t; \mathbf{x})$ be the solution of

$$\frac{d\mathbf{u}}{dt} = \mathbf{f}(\boldsymbol{\phi}(t;\, t_0, \mathbf{x}), \mathbf{u}) \tag{3.10}$$

with $\psi_0(t_0, \mathbf{x}) = \mathbf{q}(\mathbf{x})$. Now $\psi_0(t_0, \mathbf{x})$ lies inside $(S_{t_0} V_\delta)(\mathbf{x})$. So $\psi_0(t; \mathbf{x})$ lies inside $(S_t V_\delta)(\mathbf{x})$ for all $t \geqq 0$. Putting $t = 0$ we find that $\psi_0(0; \mathbf{x})$ is inside $V_\delta(\boldsymbol{\phi}(0;\, t_0, \mathbf{x}))$.

So $|\psi_0(0; \mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta$ for all $\mathbf{x}$ in $\Delta - \Delta_0$ since $|\bar{\mathbf{v}}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta$ for all $\mathbf{x}$ in $\Delta - \Delta_0$.

Now if $\mathbf{x} \in \partial\Delta_0$, then $\psi(t_0; \mathbf{x}, \mathbf{u}_0(\mathbf{x})) = \mathbf{u}_0(\mathbf{x})$. So there exist numbers $r_0 > 0$ and $h > 0$ such that if $\mathbf{x} \in \Delta_h - \operatorname{int} \Delta_0$ and $\mathbf{u} \in R^n$ with $|\mathbf{u} - \mathbf{u}_0(\mathbf{x})| < r_0$ then we have $|\psi(t_0; \mathbf{x}, \mathbf{u}) - \mathbf{u}_0(\mathbf{x})| < q_{h_0}$.

Now by the definition of t_0 we have $\boldsymbol{\phi}(0;\, t_0, \mathbf{x}) \in \operatorname{int} \Delta_{h_0}$ for all $\mathbf{x}$ in Δ. Let $\beta < h_0$ such that $\boldsymbol{\phi}(0;\, t_0, \mathbf{x}) \in \Delta_\beta$ for all $\mathbf{x}$ in Δ and choose α such that

1) $0 < \alpha < \beta$,
2) $\boldsymbol{\phi}(0;\, t_0, \mathbf{x}) \in \Delta_\beta - \operatorname{int} \Delta_\alpha$ for all $\mathbf{x}$ in $\Delta - \operatorname{int} \Delta_{h_0}$,
3) $|\psi(0; \boldsymbol{\phi}_{\mathbf{x}}(t_0)) - \mathbf{u}_0(\mathbf{x})| < r_0$ for all $\mathbf{x}$ in Δ_α.

Define

$$\mathbf{p}(\mathbf{x}) = \psi(0; \boldsymbol{\phi}_{\mathbf{x}}(t_0)) \tag{3.11}$$

for all $\mathbf{x}$ in $\Delta_\beta - \operatorname{int} \Delta_\alpha$. Now

$$\psi(t_0; \boldsymbol{\phi}_{\mathbf{x}}(t_0)) = \mathbf{q}(\boldsymbol{\phi}_{\mathbf{x}}(t_0)).$$

We have shown that $|\psi(0; \mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta$, which implies that $|\mathbf{p}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta$ for all $\mathbf{x}$ in $\Delta_\beta - \operatorname{int} \Delta_\alpha$.

Define

$$p_\alpha = \max_{\mathbf{x} \in \partial\Delta_\alpha} |\mathbf{p}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})|. \tag{3.12}$$

Choose $\mathbf{v} \in V_W$ such that

$$|\mathbf{v}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq p_\alpha \quad \forall \mathbf{x} \text{ in } \Delta_\alpha,$$

$$\mathbf{v}(\mathbf{x}) = \mathbf{p}(\mathbf{x}) \quad \forall \mathbf{x} \text{ in } \Delta_\beta - \operatorname{int} \Delta_\alpha.$$

Now $\boldsymbol{\phi}(0;\, t_0, \mathbf{x}) \in \Delta_\beta - \operatorname{int} \Delta_\alpha$ for all $\mathbf{x}$ in $\Delta - \operatorname{int} \Delta_{h_0}$, and so

$$\mathbf{p}(\boldsymbol{\phi}(0;\, t_0, \mathbf{x})) = \mathbf{v}(\boldsymbol{\phi}0;\, t_0, \mathbf{x}))$$

for all $\mathbf{x}$ in $\Delta - \operatorname{int} \Delta_{h_0}$. Therefore

$$\begin{aligned} (S_{t_0}\mathbf{v})(\mathbf{x}) &= \psi(t_0; \boldsymbol{\phi}(0;\, t_0, \mathbf{x}), \mathbf{p}(\boldsymbol{\phi}(0;\, t_0, \mathbf{x}))) \\ &= \psi(t_0; \boldsymbol{\phi}(0;\, \mathrm{t}_0, \mathbf{x}), \psi_0(0; \mathbf{x})) \\ &= \psi_0(t_0; \mathbf{x}) \\ &= \mathbf{q}(\mathbf{x}) \end{aligned} \tag{3.13}$$

if $\mathbf{x}$ is outside Δ_{h_0}.

If $\mathbf{x} \in \Delta_{h_0}$ and $\boldsymbol{\phi}(0;\, t_0, \mathbf{x})$ is not in Δ_α, then

$$(S_{t_0}\mathbf{v})(\mathbf{x}) = \mathbf{q}(\mathbf{x})$$

as before, giving $|(S_{t_0}\mathbf{v})(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < q_{h_0}$.

If $\mathbf{x} \in \Delta_{h_0} - \operatorname{int} \Delta_0$ and $\boldsymbol{\phi}(0;\, t_0, \mathbf{x}) \in \Delta_\alpha$, then

$$|\mathbf{v}(\boldsymbol{\phi}(0;\, t_0, \mathbf{x})) - \mathbf{u}_0(\mathbf{x})| \leqq p_\alpha = \max_{\mathbf{x} \in \partial\Delta_\alpha} |\mathbf{p}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})|.$$

So if $\mathbf{x}_\alpha$ is on $\partial\Delta_\alpha$ we have

$$\begin{aligned}|\mathbf{v}(\boldsymbol{\phi}(0;\, t_0, \mathbf{x})) - \mathbf{u}_0(\mathbf{x})| &\leqq |\mathbf{p}(\mathbf{x}_\alpha) - \mathbf{u}_0(\mathbf{x})| \\ &\leqq |\boldsymbol{\psi}_0(0;\, \boldsymbol{\phi}_{\mathbf{x}_\alpha}(t_0)) - \mathbf{u}_0(\mathbf{x})| \\ &\leqq r_0.\end{aligned}$$

Now

$$(S_{t_0}\mathbf{v})(\mathbf{x}) = \boldsymbol{\psi}(t_0;\, \boldsymbol{\phi}(0;\, t_0, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0;\, t_0, \mathbf{x}))),$$

and therefore

$$\begin{aligned}|(S_{t_0}\mathbf{v})(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| &= |\boldsymbol{\psi}(t_0;\, \boldsymbol{\phi}(0;\, t_0, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0;\, t_0, \mathbf{x}))) - \mathbf{u}_0(\mathbf{x})| \\ &\leqq \sup_{\substack{\mathbf{x}\in\Delta_{h_0} \\ |\mathbf{r}-\mathbf{u}_0(\mathbf{x})|<r_0}} |\boldsymbol{\psi}(t_0;\, \mathbf{p}, \mathbf{r}) - \mathbf{u}_0(\mathbf{x})| \\ &< q_{h_0} \quad \text{as required.}\end{aligned}$$

THEOREM 3.1. *If* **c** *and* **f** *satisfy* (C1)-(C2) *and* (F1)-(F5) *and* $S_0(\mathbf{x}) = \{\mathbf{u}_0(\mathbf{x})\}$ *for each* $\mathbf{x} \in \Delta_0$, *then the semidynamical system* $\{S_t\}_{t\geqq 0}$ *is chaotic in* V_W.

Proof. First, we show instability of each element of V_W. Let

$$\varepsilon = \tfrac{1}{4} \min_{\substack{\mathbf{x}\in\partial\Delta \\ \mathbf{u}\in\partial W(\mathbf{x})}} |\mathbf{u} - \mathbf{u}_0(\mathbf{x})|. \tag{3.14}$$

Choose $\delta > 0$ with

$$\delta < \min_{\substack{\mathbf{x}\in\Delta-\text{int}\,\Delta_0 \\ \mathbf{u}\in\partial W(\mathbf{x})}} |\mathbf{u} - \mathbf{u}_0(\mathbf{x})|. \tag{3.15}$$

Let $\mathbf{v}_0$ be an element of V_W; that is, $\mathbf{v}_0$ is a continuous function from Δ to R^n with $\mathbf{v}_0(\mathbf{x}) = \mathbf{u}_0(\mathbf{x})$ if $\mathbf{x}$ is in $\partial\Delta_0$, and $\mathbf{v}_0(\mathbf{x})$ is in the interior of $W(\mathbf{x})$ for each $\mathbf{x}$ in $\Delta - \Delta_0$. Let

$$V_\delta = \{\mathbf{v} \in V_W \colon \max_{\mathbf{x}\in\Delta} |\mathbf{v}(\mathbf{x}) - \mathbf{v}_0(\mathbf{x})| < \delta\}. \tag{3.16}$$

Now there exists $h_0 > 0$ such that

$$|\mathbf{v}_0(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta/2 \tag{3.17}$$

for all $\mathbf{x}$ in Δ_{h_0}, since $\mathbf{v}_0(\mathbf{x}) = \mathbf{u}_0(\mathbf{x})$ for all $\mathbf{x}$ in Δ_0.

Choose $\mathbf{q}_1$, $\mathbf{q}_2$ in V_W such that $|\mathbf{q}_1(\mathbf{x}) - \mathbf{q}_2(\mathbf{x})| > 2\varepsilon$ for some $\mathbf{x}$ in Δ.

Applying Lemma 3.4 with $\tau = 0$, we can choose $t_0 > 0$ and $\mathbf{p}_1$, $\mathbf{p}_2$ defined on $\Delta_{\beta_1} - \text{int}\,\Delta_{\alpha_1}$ and $\Delta_{\beta_2} - \text{int}\,\Delta_{\alpha_2}$ respectively, with the following properties:

1) $|\mathbf{p}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta/2$ in the range of definition of $\mathbf{p}_i$;

2) For each $\mathbf{v}_i$ in V_W with

$$|\mathbf{v}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \max_{\mathbf{x}\in\partial\Delta_{\alpha_i}} |\mathbf{p}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x} \in \Delta_{\alpha_i},$$

$$\mathbf{v}_i(\mathbf{x}) = \mathbf{p}_i(\mathbf{x}) \quad \forall \mathbf{x} \in \Delta_{\beta_i} - \text{int}\,\Delta_{\alpha_i}$$

we have

$$|(S_{t_0}\mathbf{v}_i)(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \max_{\mathbf{x}\in\partial\Delta_{h_0}} |\mathbf{q}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x} \in \Delta_{h_0},$$

$$(S_{t_0}\mathbf{v}_i)(\mathbf{x}) = \mathbf{q}_i(\mathbf{x}) \quad \forall \mathbf{x} \in \Delta - \text{int}\,\Delta_{h_0}.$$

Let $\mathbf{v}_i(\mathbf{x})$ be a continuous function from Δ to R^n, with

$$\mathbf{v}_i(\mathbf{x}) = \begin{cases} \mathbf{u}_0(\mathbf{x}) & \forall \mathbf{x} \in \Delta_0, \\ \mathbf{p}_i(\mathbf{x}) & \forall \mathbf{x} \in \Delta_{\beta_i} - \operatorname{int} \Delta_{\alpha_i}, \\ \mathbf{v}_0(\mathbf{x}) & \forall \mathbf{x} \in \Delta - \operatorname{int} \Delta_{h_0}, \end{cases} \tag{3.18}$$

$$|\mathbf{v}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \delta/2 \quad \forall \mathbf{x} \in \Delta_{h_0}$$

and

$$|\mathbf{v}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \max_{\mathbf{x} \in \partial\Delta_{\alpha_i}} |\mathbf{p}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x} \in \Delta_{\alpha_i}.$$

Now for $\mathbf{x}$ outside Δ_{h_0} we have

$$|\mathbf{v}_i(\mathbf{x}) - \mathbf{v}_0(\mathbf{x})| = 0.$$

For $\mathbf{x}$ in $\Delta_{h_0} - \operatorname{int} \Delta_0$, (3.17) implies that $|\mathbf{v}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \delta/2$; and (3.18) implies that $|\mathbf{v}_0(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \delta/2$, which gives

$$|\mathbf{v}_i(\mathbf{x}) - \mathbf{v}_0(\mathbf{x})| \leqq \delta.$$

Also, for $\mathbf{x} \in \Delta_0$ we have

$$\mathbf{v}_i(\mathbf{x}) = \mathbf{v}_0(\mathbf{x}) = \mathbf{u}_0(\mathbf{x}).$$

Hence $|\mathbf{v}_i(\mathbf{x}) - \mathbf{v}_0(\mathbf{x})| \leqq \delta$ for all $\mathbf{x}$ in Δ, and so $\mathbf{v}_i \in V_\delta$.

So

$$\begin{aligned} \mathbf{v}_i(\mathbf{x}) &= \mathbf{p}_i(\mathbf{x}) && \forall \mathbf{x} \in \Delta_{\beta_i} - \operatorname{int} \Delta_{\alpha_i}, \\ |\mathbf{v}_i(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| &\leqq \mathbf{p}_\alpha && \forall \mathbf{x} \in \Delta_{\alpha_i}. \end{aligned}$$

Therefore

$$(S_{t_0}\mathbf{v}_i)(\mathbf{x}) = \mathbf{q}_i(\mathbf{x}) \quad \text{for } \mathbf{x} \text{ in } \Delta - \operatorname{int} \Delta_{h_0},$$

and so

$$\begin{aligned} |(S_{t_0}\boldsymbol{v}_2)(\mathbf{x}) - (S_{t_0}\mathbf{v}_1)(\mathbf{x})| &= |\mathbf{q}_2(\mathbf{x}) - \mathbf{q}_1(\mathbf{x})| \\ &> \varepsilon \end{aligned} \tag{3.19}$$

at some point $\mathbf{x}$ in $\partial\Delta$. This holds for all $\delta > 0$. So there is no uniform convergence, and each element of V_W is unstable under $\{S_t\}_{t \geqq 0}$.

For the second part of the proof it remains to show that some element of V_W has a dense orbit.

Let $\{\mathbf{q}_n\}_{n=1}^{\infty}$ be a dense set in V_W and suppose that $\mathbf{q}_n(\mathbf{x}) \neq \mathbf{u}_0(\mathbf{x})$ for all $\mathbf{x}$ in $\Delta - \Delta_0$. Let

$$b = \min_{\substack{\mathbf{x} \in \Delta \\ \mathbf{u} \in W(\mathbf{x})}} |\mathbf{u} - \mathbf{u}_0(\mathbf{x})| \tag{3.20}$$

and let $\delta = b/2$. Choose $h_1 \in (0, \frac{1}{2})$ such that $|\mathbf{q}_1(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq b/2$ for all $\mathbf{x}$ in Δ_{h_1}. Let $\tau_1 = 0$.

Apply Lemma 3.4 to get a function $\mathbf{p}_1$ defined on $\Delta_{\beta_1} - \operatorname{int} \Delta_{\alpha_1}$ and a number t_{01} such that

1) $|\mathbf{p}_1(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| < \delta_1/2$ in the range of definition of $\mathbf{p}_1$;
2) For each $\mathbf{v}$ in V_W with

$$|\mathbf{v}(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \leqq \max_{\mathbf{x} \in \partial\Delta_{\alpha_1}} |\mathbf{p}_1(\mathbf{x}) - \mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x} \in \Delta_{\alpha_1},$$

$$\mathbf{v}(\mathbf{x}) = \mathbf{p}_1(\mathbf{x}) \quad \forall \mathbf{x} \in \Delta_{\beta_1} - \operatorname{int} \Delta_{\alpha_1}$$

we have

$$|(S_{t_0}\mathbf{v})(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\leqq \max_{\mathbf{x}\in\partial\Delta_{h_0}} |\mathbf{q}_1(\mathbf{x})-\mathbf{u}_0(\mathbf{x})| \quad \forall \mathbf{x}\in\Delta_{h_0},$$

$$(S_{t_0}\mathbf{v})(\mathbf{x})=\mathbf{q}_1(\mathbf{x}) \quad \forall \mathbf{x}\in\Delta-\operatorname{int}\Delta_{h_0}.$$

For each integer $n>1$ let

$$\delta_n=\min\left(\frac{b}{2^n}, \max_{\mathbf{x}\in\Delta_{\alpha_{n-1}}} |\mathbf{p}_{n-1}(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\right)$$

and choose $h_n>0$ with $h_n<\min(2^{-n}, \alpha_{n-1})$ such that $|\mathbf{q}_n(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\leqq(b/2^n)$ for all $\mathbf{x}$ in Δ_{h_n}. Let $\tau_n=t_{0,n-1}$. Again apply Lemma 3.4 to get $\mathbf{p}_n$ defined on $\Delta_{\beta_n}-\operatorname{int}\Delta_{\alpha_n}$ and $t_{0n}\geqq t_{0,n-1}$.

Now

$$0<\cdots<\alpha_n<\beta_n<h_n<\alpha_{n-1}<\cdots.$$

Also, $\lim_{n\to\infty}\delta_n=0$, and $\lim_{n\to\infty}d_n=0$. Let $\mathbf{v}$ be a continuous function from Δ to R^n satisfying

$$\begin{aligned} &\mathbf{v}(\mathbf{x})=\mathbf{u}_0(\mathbf{x}) \quad \forall\mathbf{x}\in\Delta_0,\\ &\mathbf{v}(\mathbf{x})=\mathbf{p}_n(\mathbf{x}) \quad \forall\mathbf{x}\in\Delta_{\beta_n}-\operatorname{int}\Delta_{\alpha_n},\\ &|\mathbf{v}(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\leqq\max_{\mathbf{x}\in\Delta_{\alpha_n}}|\mathbf{p}_n(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|.\end{aligned} \tag{3.21}$$

Now $\mathbf{v}$ is continuous on $\partial\Delta_0$ because $|\mathbf{p}_n(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\leqq\delta_n$ in the area of definition of $\mathbf{p}_n$. Clearly $\mathbf{v}\in V_W$.

Also

$$\begin{aligned}|(S_{t_{0n}}\mathbf{v})(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|&\leqq\max_{\mathbf{x}\in\partial\Delta_{h_n}}|\mathbf{q}_n(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\\ &\leqq\frac{b}{2^n}\end{aligned}$$

for $\mathbf{x}\in\Delta_{h_n}$, and

$$(S_{t_{0n}}\mathbf{v})(\mathbf{x})=\mathbf{q}_n(\mathbf{x})$$

if $\mathbf{x}\in\Delta-\operatorname{int}\Delta_{h_n}$, giving

$$|(S_{t_{0n}}\mathbf{v})(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\leqq\frac{b}{2^n}.$$

So

$$|(S_{t_{0n}}\mathbf{v})(\mathbf{x})-\mathbf{u}_0(\mathbf{x})|\leqq\frac{b}{2^n} \quad \forall\mathbf{x}\in\Delta. \tag{3.22}$$

Therefore

$$\sup_{\mathbf{x}\in\Delta}|(S_{t_{0n}}\mathbf{v})(\mathbf{x})-\mathbf{q}_n(\mathbf{x})|\leqq\frac{2b}{2^n},$$

which implies that $\{S_{t_{0n}}\mathbf{v}\}_{n=1}^{\infty}$ is dense in V_W.

4. Periodic orbits. P. Brunovsky [2] proves the following.

THEOREM (Brunovsky). *Let* $\Delta = [0, 1]$. *Assume that*

1) *The function* c *maps* Δ *to* $[0, \infty)$, *the function* f *maps* $\Delta \times [0, \infty)$ *to* R, *and both* c *and* f *are* C^1;

2) $c(0) = 0$ *and* $c(x) > 0$ *for all* $x > 0$;

3) *There is some* $u_0 \in (0, 1]$ *such that* (a) $f(0, u)(u - u_0) < 0$ *for all* $u > 0$, $u \neq u_0$, *and* (b) $f_u(0, u_0) < 0$;

4) *There exist* $k_1 \geqq 0$, $k_2 \geqq 0$ *such that* $f(x, u) \leqq k_1 u + k_2$ *for all* $x \in \Delta$, $u \geqq 0$;

5) $f(x, 0) = 0$ *for all* $x \in \Delta$.

Then we have

(a) *For each* $\tau > 0$ *there is a continuum of functions* v *in* V_W (*defined as before*) *satisfying* $S_\tau v = v$, *that is, functions* v *that give rise to* τ*-periodic behaviour*;

(b) *The set of all periodic points of* S_t *is dense in* V_W.

We now wish to prove an analogous result for the more general case. In fact this theorem generalizes to an almost identical statement.

THEOREM 4.1. *Suppose* $\mathbf{c}$ *and* $\mathbf{f}$ *satisfy* (C1)-(C2) *and* (F1)-(F5), *and for each* $\mathbf{x}$ *in* Δ_0, $S_0(\mathbf{x})$ *consists of just the one point* $\{\mathbf{u}_0(\mathbf{x})\}$. *Then*

(a) *For each* $\tau > 0$ *there is a continuum of functions* $\mathbf{v}$ *in* V_W (*defined as before*) *satisfying* $S_\tau \mathbf{v} = \mathbf{v}$, *that is, functions* $\mathbf{v}$ *that give rise to* τ*-periodic behaviour*;

(b) *The set of all periodic points of* S_t *is dense in* V_W.

Recall that if $\mathbf{x} \in \Delta - \Delta_0$, then $\boldsymbol{\phi}_{\mathbf{x}}(t)$ is the characteristic curve satisfying

$$\frac{\partial \boldsymbol{\phi}}{\partial t} = \mathbf{c}(\boldsymbol{\phi})$$

and $T(\mathbf{x})$ is the (unique) value of t for which $\boldsymbol{\phi}_{\mathbf{x}}(t)$ intersects $\partial\Delta$. Thus $\boldsymbol{\phi}_{\mathbf{x}}(T(\mathbf{x}))$ is the point of $\partial\Delta$ at which this intersection takes place.

We now consider a one-to-one correspondence between functions $\mathbf{v}\colon \Delta - \Delta_0 \to R^n$ and functions $\mathbf{g}\colon \partial\Delta \times [0, \infty) \to R^n$.

Let $\bar{\mathbf{x}} \in \partial\Delta$. Let $\boldsymbol{\Phi}$ be the mapping from the function space $(C(\Delta - \Delta_0))^n$ to the function space $(C(\partial\Delta \times [0, \infty)))^n$ defined by

$$\begin{aligned} \boldsymbol{\Phi}(\mathbf{v})(\bar{\mathbf{x}}, t) &= \boldsymbol{\psi}(t; \boldsymbol{\phi}(0; t, \bar{\mathbf{x}}), \mathbf{v}(\boldsymbol{\phi}(0; t, \bar{\mathbf{x}}))) \\ &= \mathbf{u}(t, \bar{\mathbf{x}}) \end{aligned} \tag{4.1}$$

if $\mathbf{u}(0, \mathbf{x}) = \mathbf{v}(\mathbf{x})$ for all $\mathbf{x} \in \Delta - \Delta_0$. Thus if $\mathbf{g}$ is a function from $\partial\Delta \times [0, \infty)$ to R^n, we have $\mathbf{g} = \boldsymbol{\Phi}(\mathbf{v})$ iff

$$\mathbf{v}(\mathbf{x}) = \boldsymbol{\psi}(-T(\mathbf{x}); \boldsymbol{\phi}_{\mathbf{x}}(T(\mathbf{x})), \mathbf{g}(\boldsymbol{\phi}_{\mathbf{x}}(T(\mathbf{x})), T(\mathbf{x}))) \tag{4.2}$$

for all $\mathbf{x}$ in $\Delta - \Delta_0$.

Therefore we can state the following.

LEMMA 4.1. *The map* $\boldsymbol{\Phi}$ *defined by* (4.1) *is invertible, with inverse given by* (4.2).

Note that here one is not necessarily able to extend $\mathbf{v}$ to a function from Δ to R^n, as $\mathbf{v}(\mathbf{x})$ need not have a limit as $\mathbf{x}$ approaches $\partial\Delta_0$.

LEMMA 4.2. *Let* $\mathbf{g}$ *be a continuous function from* $\partial\Delta \times [0, \infty)$ *to* R^n, *with* $\mathbf{g}(\bar{\mathbf{x}}, t) \in W(\bar{\mathbf{x}})$ *and*

$$d(\mathbf{g}(\bar{\mathbf{x}}, t), \partial W(\bar{\mathbf{x}})) \geqq \eta \tag{4.3}$$

for some $\eta > 0$ *and all* $t \geqq 0$, *all* $\bar{\mathbf{x}} \in \partial\Delta$. *Then* $\mathbf{g} \in \boldsymbol{\phi}(V_W)$.

Proof. We must show that if $\mathbf{x} \in \Delta - \Delta_0$ approaches $\mathbf{x}_0 \in \partial\Delta_0$, then $\lim_{\mathbf{x} \to \mathbf{x}_0} \boldsymbol{\Phi}^{-1}(\mathbf{g})(\mathbf{x}) = \mathbf{u}_0(\mathbf{x}_0)$. This is sufficient, because then we can define

$$\begin{aligned} \mathbf{v}(\mathbf{x}) &= \boldsymbol{\Phi}^{-1}(\mathbf{g})(\mathbf{x}) \qquad \forall \mathbf{x} \in \Delta - \Delta_0, \\ \mathbf{v}(\mathbf{x}_0) &= \lim_{\mathbf{x} \to \mathbf{x}_0} \boldsymbol{\Phi}^{-1}(\mathbf{g})(\mathbf{x}) \quad \forall \mathbf{x}_0 \in \partial\Delta_0. \end{aligned} \tag{4.4}$$

Let $\bar{\mathbf{x}}$ be a point on $\partial\Delta$. Let $\delta > 0$, $0 < h_0 \leqq \frac{1}{2}$ and define V_δ as in (3.9), that is,

$$V_\delta = \{\mathbf{u}_0 + \tfrac{1}{2}\delta\theta\mathbf{n}: |\mathbf{n}| = 1\}$$

where θ is a continuous function from Δ to R, with $\theta(\mathbf{x}) = 1$ if $\mathbf{x} \in \Delta_0$, $\theta(\mathbf{x}) = 0$ if $\mathbf{x}$ is outside Δ_{h_0}, and $0 < \theta(\mathbf{x}) < 1$ otherwise. Define $S_t V_\delta$ as $\{S_t\mathbf{v}: \mathbf{v} \in V_\delta\}$.

Because $\mathbf{v}(\mathbf{x}_0) \in R_0(\mathbf{x}_0)$ for all $\mathbf{x} \in \Delta_0$, we know from Theorem 2.2 that for each $\mathbf{v}$ in V_δ, $\mathbf{\Phi}(\mathbf{v})(\bar{\mathbf{x}}, t)$ approaches $\partial \mathrm{W}(\bar{\mathbf{x}})$ as $t \to \infty$. Therefore there is some time $t_\delta > 0$ such that for each $t \geqq t_\delta$ and each $\mathbf{v} \in V_\delta$ we have $d(\mathbf{\Phi}(\mathbf{v})(\bar{\mathbf{x}}, t), \partial W(\bar{\mathbf{x}})) < \eta$.

Now $\mathbf{\Phi}(V_\delta)(\bar{\mathbf{x}}, t)$ is homeomorphic to $\partial W(\mathbf{x})$. Also for each $\mathbf{x}_0 \in \partial\Delta_0$, $V_\delta(\mathbf{x}_0)$ encloses $\mathbf{u}_0(\mathbf{x}_0)$. So, by an argument similar to that of Lemma 3.1, if $t \geqq t_\delta$, then $\mathbf{\Phi}(V_\delta)(\bar{\mathbf{x}}, t)$ encloses the subset of $W(\bar{\mathbf{x}})$ which lies at distance greater than η from the boundary. Thus $\mathbf{g}(\bar{\mathbf{x}}, t)$ lies inside $\mathbf{\Phi}(V_\delta)(\bar{\mathbf{x}}, t)$. This implies that $\mathbf{\Phi}^{-1}(\mathbf{g})(\mathbf{x})$ lies inside $V_\delta(\mathbf{x})$ for all $\mathbf{x}$ with $T(\mathbf{x}) \geqq t_\delta$. So there is some $h > 0$ such that $V_\delta(\mathbf{x})$ encloses $\mathbf{\Phi}^{-1}(\mathbf{g})(\mathbf{x})$ for all $\mathbf{x}$ in $\Delta_h - \Delta_0$.

However δ was arbitrary, and for each $\mathbf{x}_0 \in \partial\Delta_0$ the surface $V_\delta(\mathbf{x}_0)$ encloses $\mathbf{u}_0(\mathbf{x}_0)$. Therefore $\lim_{\mathbf{x}\to\mathbf{x}_0} \mathbf{\Phi}^{-1}(\mathbf{g})(\mathbf{x}) = \mathbf{u}_0(\mathbf{x}_0)$, and so $\mathbf{g} \in \mathbf{\Phi}(V_W)$.

LEMMA 4.3. *If $\mathbf{\Phi}(\mathbf{v})(\bar{\mathbf{x}}, t)$ is periodic in t with period τ independent of $\bar{\mathbf{x}}$, then the solution $\mathbf{u}(\mathbf{x}, t)$ is periodic with period τ for all $\mathbf{x} \in \Delta - \Delta_0$.*

Proof. Suppose $(S_t\mathbf{v})(\mathbf{x}) \neq (S_{t+\tau}\mathbf{v})(\mathbf{x})$ for some $\mathbf{x} \in \Delta - \Delta_0$ and some $t \geqq 0$. Therefore

$$\boldsymbol{\psi}(t; \boldsymbol{\phi}(0; t, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t, \mathbf{x}))) \neq \boldsymbol{\psi}(t+\tau; \boldsymbol{\phi}(0; t+\tau, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t+\tau, \mathbf{x}))).$$

Consider the situation after time $T(\mathbf{x})$. Then

$$\boldsymbol{\psi}(t+T(\mathbf{x}); \boldsymbol{\phi}(0; t, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t, \mathbf{x}))) \neq \boldsymbol{\psi}(t+T(\mathbf{x})+\tau; \boldsymbol{\phi}(0; t+\tau, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t+\tau, \mathbf{x}))).$$

But after time $T(\mathbf{x})$ we also have $\boldsymbol{\phi}_{\mathbf{x}}(T(\mathbf{x})) \in \partial\Delta$. Thus

$$\boldsymbol{\psi}(t+T(\mathbf{x}); \boldsymbol{\phi}(0; t, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t, \mathbf{x}))) = \mathbf{\Phi}(\mathbf{v})(\boldsymbol{\phi}(t+T(\mathbf{x}); t, \mathbf{x}), t+T(\mathbf{x}))$$

and

$$\begin{aligned}\boldsymbol{\psi}(t+T(\mathbf{x})+\tau;\ & \boldsymbol{\phi}(0; t+\tau, \mathbf{x}), \mathbf{v}(\boldsymbol{\phi}(0; t+\tau, \mathbf{x}))) \\ &= \mathbf{\Phi}(\mathbf{v})(\boldsymbol{\phi}(t+T(\mathbf{x})+\tau; t+\tau, \mathbf{x}), t+T(\mathbf{x})+\tau).\end{aligned}$$

But since $\mathbf{c}$ is independent of t, we have

$$\boldsymbol{\phi}(t+T(\mathbf{x}); t, \mathbf{x}) = \boldsymbol{\phi}(t+T(\mathbf{x})+\tau; t+\tau, \mathbf{x}),$$

and thus

$$\mathbf{\Phi}(\mathbf{v})(\boldsymbol{\phi}(t+T(\mathbf{x}); t, \mathbf{x}), t+T(\mathbf{x})) \neq \mathbf{\Phi}(\mathbf{v})(\boldsymbol{\phi}(t+T(\mathbf{x}); t, \mathbf{x}), t+T(\mathbf{x})+\tau).$$

But this contradicts the hypothesis that $\mathbf{\Phi}(\mathbf{v})(\bar{\mathbf{x}}, t)$ is periodic in t with period τ. Therefore we must have

$$(S_t\mathbf{v})(\mathbf{x}) = (S_{t+\tau}\mathbf{v})(\mathbf{x})$$

for all $\mathbf{x} \in \Delta - \Delta_0$ and all $t \geqq 0$.

If $\mathbf{v}_0 \in V_W$ and

$$\varepsilon < \tfrac{1}{2} \min_{\mathbf{x}\in\Delta - \mathrm{int}\,\Delta_0} d(\mathbf{v}_0(\mathbf{x}), \partial W(\mathbf{x})), \tag{4.5}$$

denote by $V_\varepsilon(\mathbf{v}_0)$ the set of functions $V_\varepsilon = \{\mathbf{v}_0 + \hat{\mathbf{u}}: |\hat{\mathbf{u}}| = 1\}$, and denote by $S_t V_\varepsilon(\mathbf{v}_0)$ the set of functions $\{S_t\mathbf{v}: \mathbf{v} \in V_\varepsilon(\mathbf{v}_0)\}$.

LEMMA 4.4. *For each $\mathbf{v}_0 \in V_W$ and ε as in* (4.5), *there is some $t_0 > 0$ such that $(S_s V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ lies strictly inside $(S_{s+t}V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ for all $s \geqq 0$, $t \geqq t_0$, $\mathbf{x} \in \Delta$.*

Proof. Each element $\mathbf{v}$ of $V_\varepsilon(\mathbf{v}_0)$ is in V_+, since $\mathbf{v}(\mathbf{x}) \neq \mathbf{u}_0(\mathbf{x})$ for $\mathbf{x}$ in Δ_0. Hence, by Theorem 2.2, $(S_t\mathbf{v})(\mathbf{x})$ approaches $\partial W(\mathbf{x})$ as $t \to \infty$ uniformly for $\mathbf{x} \in \Delta$. Thus there is some $t_0 > 0$ such that $d((S_t\mathbf{v})(\mathbf{x}), \partial W(\mathbf{x})) < \varepsilon$ for each $\mathbf{v} \in V_\varepsilon(\mathbf{v}_0)$, $\mathbf{x} \in \Delta$ and $t \geqq t_0$.

Now, by Lemma 3.3, if $t \geqq t_0$, $\mathbf{x} \in \Delta$, then $(S_t V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ encloses $\{\mathbf{u} \in W(\mathbf{x}) : d(\mathbf{u}, \partial W(\mathbf{x})) > \varepsilon\}$, which in turn contains $V_\varepsilon(\mathbf{v}_0)(\mathbf{x})$. So $V_\varepsilon(\mathbf{v}_0)(\mathbf{x})$ is enclosed by $(S_t V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ for all $\mathbf{x} \in \Delta$ and all $t \geqq t_0$. Hence, using the uniqueness of solutions (Lemma 2.1), it follows that $(S_s V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ is enclosed by $(S_{s+t} V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ for $s \geqq 0$.

Proof of Theorem 4.1. (a) There is a continuum of functions $\mathbf{g}: \partial\Delta \times [0, \infty) \to R^n$ periodic in t with period τ, such that $\mathbf{g}(\bar{\mathbf{x}}, t) \in \operatorname{int} W(\bar{\mathbf{x}})$. Now Lemmas 4.1 and 4.2 imply that each $\mathbf{g}$ is in $\Phi(V_W)$, and from Lemma 4.3 it follows that for each such $\mathbf{g}$ the associated function $\mathbf{u}(t, \mathbf{x})$ is periodic in t with period τ for $\mathbf{x} \in \Delta - \Delta_0$. For $\mathbf{x}_0 \in \Delta_0$, $\mathbf{v} \in V_W$, it follows, by the definition of $S_0(\mathbf{x}_0)$, that $(S_t\mathbf{v})(\mathbf{x}_0) = \mathbf{u}_0(\mathbf{x}_0)$ for all $t \geqq 0$. Hence there is a continuum of initial functions $\mathbf{v} \in V_W$ that give rise to τ-periodic solutions $\mathbf{u}(t, \mathbf{x})$.

(b) Choose $\mathbf{v}_0 \in V_W$, and let

$$\varepsilon < \tfrac{1}{2} \min_{\mathbf{x} \in \Delta - \operatorname{int} \Delta_0} d(\mathbf{v}_0(\mathbf{x}), \partial W(\mathbf{x})).$$

Define $V_\varepsilon(\mathbf{v}_0)$ and $S_t V_\varepsilon(\mathbf{v}_0)$ as before. Let $\mathbf{g} = \Phi(\mathbf{v}_0)$.

By Lemma 4.4 we can choose t_p such that if $t \geqq 0$ and $\mathbf{x} \in \Delta$, then $(S_{t_p+t} V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$ encloses $(S_t V_\varepsilon(\mathbf{v}_0))(\mathbf{x})$.

Now choose $\bar{\mathbf{g}}$ to be a continuous function from $\partial\Delta \times [0, \infty)$ to R^n subject to the following conditions:

1) For all $\bar{\mathbf{x}} \in \partial\Delta$ and $0 \leqq t < t_p$ let $\bar{\mathbf{g}}(\bar{\mathbf{x}}, t)$ be in the open region bounded by $(S_t V_\varepsilon(\mathbf{v}_0))(\bar{\mathbf{x}})$.

2) For all $\bar{\mathbf{x}} \in \partial\Delta$ and all $t \geqq t_p$ let $\bar{\mathbf{g}}(\bar{\mathbf{x}}, t) = \bar{\mathbf{g}}(\bar{\mathbf{x}}, t - nt_p)$, where n is a positive integer, and $0 \leqq t - nt_p < t_p$.

This is possible, since t_p was chosen such that $(S_{t_p} V_\varepsilon(\mathbf{v}_0))(\bar{\mathbf{x}})$ encloses $(S_0 V_\varepsilon(\mathbf{v}_0))(\bar{\mathbf{x}})$, which in turn encloses $\bar{\mathbf{g}}(\bar{\mathbf{x}}, 0)$. Thus $\bar{\mathbf{g}}$ is periodic in t with period t_p.

By Lemma 4.1 we have $\mathbf{g} \in \Phi(\bar{\mathbf{v}})$ for some $\bar{\mathbf{v}}$ which maps Δ to R^n. Also, since $\bar{\mathbf{g}}$ is periodic in t, and $\bar{\mathbf{g}}(\bar{\mathbf{x}}, t) \in \operatorname{int} W(\bar{\mathbf{x}})$ for all $t \geqq 0$ and all $\bar{\mathbf{x}} \in \partial\Delta$, $\bar{\mathbf{g}}$ satisfies the conditions of Lemma 4.2. Therefore $\bar{\mathbf{v}} \in V_W$.

Now $\bar{\mathbf{g}}(\bar{\mathbf{x}}, t)$ lies inside $(S_t V_\varepsilon(\mathbf{v}_0))(\bar{\mathbf{x}})$ for all $t \geqq 0$ and all $\bar{\mathbf{x}} \in \partial\Delta$. Therefore $\bar{\mathbf{v}}(\mathbf{x})$ lies inside $V_\varepsilon(\mathbf{v}_0)(\mathbf{x})$ for all $\mathbf{x}$ in $\Delta - \operatorname{int} \Delta_0$. Also, since $\mathbf{v} \in V_W$, we have

$$\bar{\mathbf{v}}(\mathbf{x}) = \mathbf{v}_0(\mathbf{x}) = \mathbf{u}_0(\mathbf{x})$$

for all $\mathbf{x} \in \Delta_0$. Hence for each $\mathbf{x} \in \Delta$ we have

$$|\bar{\mathbf{v}}(\mathbf{x}) - \mathbf{v}_0(\mathbf{x})| < \varepsilon.$$

Thus for any $\mathbf{v}_0$ in V_W there is some $\bar{\mathbf{v}}$ arbitrarily close to $\mathbf{v}_0$, such that $\{S_t\bar{\mathbf{v}}\}_{t \geqq 0}$ is periodic in t. Therefore the set of periodic points of S_t is dense in V_W.

Hence chaos of a type analogous to that of Li and Yorke [7] is present in V_W.

ON THREE-BODY SCATTERING NEAR THRESHOLDS*

F. GESZTESY† AND G. KARNER‡

Abstract. Using exponential decay of the two-body interactions at infinity we discuss analytic expansions of two-cluster scattering operators and scattering amplitudes with respect to channel momenta around (negative) thresholds. An explicit formula for elastic scattering amplitudes in terms of the three-body resolvent is derived.

Key words. three-body scattering, scattering thresholds

AMS(MOS) subject classifications. 46, 47, 81

1. Introduction. This paper continues previous studies of threshold scattering in nonrelativistic two-body systems (cf. [1], [2]) to the three-body problem. We are especially concerned with analytic expansions of two-cluster scattering operators and scattering amplitudes with respect to channel momenta around (negative) thresholds assuming exponential falloff of the two-body interactions at infinity.

In § 2 we introduce our basic assumptions on the two-body interactions, establish the terminology used throughout this paper, and recall the direct integral decomposition of channel Hamiltonians. Faddeev's theory [14] in the Hilbert space version of Ginibre and Moulin [16] is discussed in § 3. Here our presentation essentially follows Amrein, Jauch and Sinha [3] and Amrein and Sinha [5]. Since we are particularly interested in the behaviour of the three-particle resolvent near thresholds, we use stronger decay assumptions on the two-body potentials (of the type $|x|^{-4-\varepsilon}$, $\varepsilon>0$ as $|x|\to\infty$) than in [5]. Section 4, which describes continuity and the threshold behaviour of averaged total cross sections, merely supplements the treatment in [5] (cf. their Remark 3). For two-body potentials decaying like $|x|^{-5-\varepsilon}$, $\varepsilon>0$ at infinity we represent the two-cluster scattering amplitudes as scalar products in $L^2(\mathscr{R}^6)$ (in analogy to the two-body problem) and discuss their continuity properties with respect to energy and angle variables in § 5. As a special case of our threshold considerations of two-cluster scattering amplitudes we mention the definition of elastic scattering lengths and their explicit formulas in terms of the three-body resolvent (cf. also [15]). Finally, using an exponential decay of the two-body potentials in § 6, we derive analytic expansions of two-cluster scattering operators and amplitudes with respect to channel momenta around (negative) thresholds.

2. Notations and basic facts. Greek indices α, β, γ, δ denote pairs of particles, or the corresponding third particle, i.e., (1, 2) or 3 (resp. (2, 3), or 1 and (3, 1) or 2). If all particles are considered simultaneously we denote the triple (1, 2, 3) by $\alpha=0$ ($\beta=0$, etc.). If μ_j, $j=1,2,3$ denote the masses of the spinless and distinguishable particles in $\mathscr{R}^3$, m_α denotes the reduced mass of the pair $\alpha=(j,l)$, i.e.,

$$m_\alpha^{-1}=\mu_j^{-1}+\mu_l^{-1},\qquad \alpha=(j,l) \tag{2.1}$$

and n_α denotes the reduced mass of the pair $\alpha=(j,l)$ and the corresponding third particle, i.e.,

$$n_\alpha^{-1}=(\mu_j+\mu_l)^{-1}+\mu_p^{-1},\qquad \alpha=(j,l)=p. \tag{2.2}$$

Finally $M=\sum_{j=1}^{3}\mu_j$ abbreviates the total mass. If $\xi_j, j=1,2,3$ denote the coordinates of the particles in configuration space the center of mass and Jacobi coordinates are defined by

$$\begin{aligned} x_s &= M^{-1}\sum_{j=1}^{3}\mu_j\xi_j,\\ x_\alpha &= \xi_j-\xi_l,\\ y_\alpha &= x_p-(\mu_j+\mu_l)^{-1}(\mu_j\xi_j+\mu_l\xi_l), \qquad \alpha=(j,l)=p. \end{aligned}\tag{2.3}$$

The associated conjugate momenta are denoted by

$$\begin{aligned} k_s &= \sum_{j=1}^{3}\eta_j,\\ k_\alpha &= (\mu_j+\mu_l)^{-1}(\mu_l\eta_j-\mu_j\eta_l),\\ q_\alpha &= M^{-1}(\mu_j+\mu_l)\eta_p-M^{-1}\mu_p(\eta_j+\eta_l), \qquad \alpha=(j,l)=p \end{aligned}\tag{2.4}$$

where η_j are conjugate momenta of $\xi_j, j=1,2,3$. For later purposes we note that

$$\begin{aligned} x_\alpha &= -x_\beta-x_\gamma,\\ y_\alpha &= -(\mu_\alpha+\mu_\gamma)\mu_\alpha^{-1}y_\beta+\varepsilon(\alpha,\beta,\gamma)(\mu_\beta+\mu_\gamma)^{-1}M(\mu_\gamma/\mu_\alpha)x_\alpha,\\ x_\alpha &= \varepsilon(\alpha,\beta,\gamma)y_\beta-(\mu_\alpha+\mu_\gamma)^{-1}\mu_\alpha x_\beta,\\ y_\alpha &= -(\mu_\beta+\mu_\gamma)^{-1}\mu_\beta y_\beta-\varepsilon(\alpha,\beta,\gamma)[(\mu_\alpha+\mu_\gamma)(\mu_\beta+\mu_\gamma)]^{-1}M\mu_\gamma x_\beta,\\ y_\alpha &= -\varepsilon(\alpha,\beta,\gamma)x_\beta-\varepsilon(\alpha,\beta,\gamma)(\mu_\beta+\mu_\gamma)^{-1}\mu_\beta x_\alpha,\\ y_\alpha &= -\varepsilon(\alpha,\beta,\gamma)(\mu_\beta+\mu_\gamma)^{-1}\mu_\gamma x_\beta+\varepsilon(\alpha,\beta,\gamma)(\mu_\beta+\mu_\gamma)^{-1}\mu_\beta x_\gamma, \end{aligned}\tag{2.5}$$

$$\alpha\neq\beta,\quad \alpha\neq\gamma,\quad \beta\neq\gamma,\quad \varepsilon(\alpha,\beta,\gamma)=\begin{cases}+1 & (\alpha,\beta,\gamma) \text{ an even permutation of } (1,2,3),\\ -1 & (\alpha,\beta,\gamma) \text{ an odd permutation of } (1,2,3).\end{cases}$$

The total kinetic energy (of the relative motion) is given by

$$(2m_\alpha)^{-1}k_\alpha^2+(2n_\alpha)^{-1}q_\alpha^2, \qquad \alpha=1,2,3.\tag{2.6}$$

The self-adjoint free Hamiltonian H_0 in $\mathscr{H}=L^2(\mathscr{R}^6)$ then reads

$$H_0=-(2m_\alpha)^{-1}\Delta_{x_\alpha}\otimes 1-1\otimes(2n_\alpha)^{-1}\Delta_{y_\alpha}, \qquad \alpha=1,2,3.\tag{2.7}$$

We assume that the particles interact via real, local translationally invariant potentials v_α obeying the following hypothesis.

Hypothesis (I). Let $\nu>0$, $u_\alpha\in L^p(\mathscr{R}^3)$ for some $p>3/2$ be real-valued, $\alpha=1,2,3$. Then v_α is defined as

$$v_\alpha(x_\alpha)=(1+|x_\alpha|)^{-2-\nu}u_\alpha(x_\alpha), \qquad \alpha=1,2,3.\tag{2.8}$$

The total Hamiltonian H in $\mathscr{H}$ is then defined as the form sum (cf. [36])

$$H=H_0\dot{+}\sum_{\alpha=1}^{3}v_\alpha\tag{2.9}$$

and the α-cluster Hamiltonian H_α in $\mathscr{H}$ reads

$$H_\alpha=h_\alpha\otimes 1-1\otimes(2n_\alpha)^{-1}\Delta_{y_\alpha}, \qquad \alpha=1,2,3\tag{2.10}$$

where h_α denotes the two-particle Hamiltonian of the subsystem α given by the form sum in $L^2(\mathscr{R}^3)$

$$(2.11)\qquad h_\alpha = h_{0,\alpha} \dotplus v_\alpha, \qquad h_{0,\alpha} = -(2m_\alpha)^{-1}\Delta_{x_\alpha}, \qquad \alpha = 1, 2, 3.$$

The corresponding resolvents are denoted by

$$(2.12)\qquad \begin{aligned} &G_0(z) = (H_0 - z)^{-1}, && z \in \mathscr{C}\backslash[0, \infty), \\ &G(z) = (H - z)^{-1}, && z \in \rho(H), \\ &G_\alpha(z) = (H_\alpha - z)^{-1}, && z \in \rho(H_\alpha), \\ &g_\alpha(z) = (h_\alpha - z)^{-1}, && z \in \rho(h_\alpha), \\ &g_{0,\alpha}(z) = (h_{0,\alpha} - z), && z \in \mathscr{C}\backslash[0, \infty), \qquad \alpha = 1, 2, 3 \end{aligned}$$

where $\rho(\cdot)$ denotes the corresponding resolvent set. Concerning the spectra of the operators involved, we remark that

$$(2.13)\qquad \begin{aligned} &\sigma_{\text{ess}}(h_\alpha) = \sigma_{\text{ess}}(h_{0,\alpha}) = \sigma_{\text{ess}}(H_0) = [0, \infty), \\ &\sigma_{\text{ess}}(H_\alpha) = [E_{0,\alpha}^{(2)}, \infty), \qquad E_{0,\alpha}^{(2)} = \inf \sigma(h_\alpha) > -\infty, \\ &\sigma_{\text{ess}}(H) = [E_0^{(2)}, \infty), \qquad E_0^{(2)} = \inf_{\alpha=1,2,3} \sigma(h_\alpha), \\ &\sigma_d(h_\alpha) \subset [E_{0,\alpha}^{(2)}, 0) \text{ (if } E_{0,\alpha}^{(2)} < 0\text{, otherwise empty) is finite,} \\ &E_0^{(3)} = \inf \sigma(H) > -\infty, \\ &\sigma_d(H) \subset [E_0^{(3)}, E_0^{(2)}) \text{ (if } E_0^{(3)} < E_0^{(2)}\text{, otherwise empty) is finite,} \qquad \alpha = 1, 2, 3 \end{aligned}$$

where $\sigma_{\text{ess}}(\cdot)$, $\sigma_d(\cdot)$ denote the corresponding essential and discrete spectra (for proofs cf. e.g. [11], [31], [39]). For additional results on the point spectrum $\sigma_p(H)$ of H see Lemma 3.8.

Next we introduce the channel structure. Let $E_{(-\infty,0)}(h_\alpha)L^2(\mathscr{R}^3) =$ lin span $\{\psi_\alpha^j | h_\alpha \psi_\alpha^j = e_\alpha^j \psi_\alpha^j, (\psi_\alpha^j, \psi_\alpha^{j'}) = \delta_{jj'}, j, j' = 1, \cdots, N_\alpha\}$, $\alpha = 1, 2, 3$ denote the negative point spectral subspace associated with h_α, where $N_\alpha < \infty$ denotes the number of negative bound states (counting multiplicity) and $e_\alpha^j < 0$ denote the corresponding eigenvalues of h_α, $e_\alpha^1 \leqq e_\alpha^2 \leqq \cdots \leqq e_\alpha^{N_\alpha} < 0$ (not necessarily distinct). The channel subspace $\mathscr{M}_\alpha^j \subset \mathscr{H}$ is then given by

$$(2.14)\qquad \mathscr{M}_\alpha^j = \{\psi_\alpha^j\} \otimes L^2(\mathscr{R}^3; d^3y_\alpha), \qquad j = 1, \cdots, N_\alpha, \qquad \alpha = 1, 2, 3$$

($\psi_\alpha^j = \psi_\alpha^j(x_\alpha)$) and the cluster subspace $\mathscr{M}_\alpha \subset \mathscr{H}$ reads

$$(2.15)\qquad \mathscr{M}_\alpha = \bigoplus_{j=1}^{N_\alpha} \mathscr{M}_\alpha^j = E_{(-\infty,0)}(h_\alpha)L^2(\mathscr{R}^3, d^3x_\alpha) \otimes L^2(\mathscr{R}^3, d^3y_\alpha), \qquad \alpha = 1, 2, 3.$$

The corresponding orthogonal projections onto $\mathscr{M}_\alpha^j$ and $\mathscr{M}_\alpha$ are denoted by E_α^j and E_α:

$$(2.16)\qquad \begin{aligned} &E_\alpha^j = (\psi_\alpha^j, \cdot)\psi_\alpha^j \otimes 1, \qquad E_\alpha = \bigoplus_{j=1}^{N_\alpha} E_\alpha^j, \\ &E_\alpha^j E_\alpha^l = \delta_{jl} E_\alpha^j, \qquad j = 1, \cdots, N_\alpha, \qquad \alpha = 1, 2, 3. \end{aligned}$$

The (α, j)-channel Hamiltonian H_α^j in $\mathscr{H}$ is then defined by

$$(2.17)\qquad H_\alpha^j = H_\alpha E_\alpha^j = \psi_\alpha^j, \cdot)\psi_\alpha^j \otimes [-(2n_\alpha)^{-1}\Delta_{y_\alpha} + e_\alpha^j], \quad j = 1, \cdots, N_\alpha, \quad \alpha = 1, 2, 3.$$

Clearly

$$\sigma_p(H_\alpha^j)=\varnothing, \qquad \sigma_{\text{ess}}(H_\alpha^j)=\sigma_{ac}(H_\alpha^j)=[e_\alpha^j,\infty), \qquad j=1,\cdots,N_\alpha, \quad \alpha=1,2,3. \tag{2.18}$$

($\sigma_{ac}(\cdot)$ denotes the absolutely continuous spectrum.) Finally we introduce the zeroth channel $(0,0)$. Define

$$e_0^0=0, \qquad \mathscr{M}_0^0=\mathscr{H}, \qquad E_0^0=1; \tag{2.19}$$

then $H_0^0=H_0$ is the corresponding cluster (channel) Hamiltonian.

In order to discuss scattering theory, we introduce

Hypothesis (II). Suppose H(I) holds and define

$$\varepsilon_\alpha^\pm=\{z\in\mathscr{C}\,|\,v_\alpha^{1/2}g_{0,\alpha}(z\pm i0)|v_\alpha|^{1/2}\Phi=-\Phi \text{ for some } \Phi\in L^2(\mathscr{R}^3),\ \Phi\neq 0\} \tag{2.20}$$

where

$$v_\alpha^{1/2}(x_\alpha)=\operatorname{sgn}(v_\alpha(x_\alpha))|v_\alpha(x_\alpha)|^{1/2}, \qquad \alpha=1,2,3. \tag{2.21}$$

Then we assume that

$$\varepsilon_\alpha=\{\varepsilon_\alpha^+\cup\varepsilon_\alpha^-\}\cap[0,\infty)=\varnothing, \qquad \alpha=1,2,3. \tag{2.22}$$

Obviously (2.22) implies the absence of zero-energy resonances and nonnegative (embedded) eigenvalues as well as

$$\sigma_{\text{ess}}(h_\alpha)=\sigma_{ac}(h_\alpha)=[0,\infty), \qquad \alpha=1,2,3 \tag{2.23}$$

(cf. [31], [36]). H(II) implies the existence (cf. [30], [37]) and completeness (cf. [12], [16], [17], [20], [21], [25], [26], [30], [34], [35], [38], [40] and [41]) of the wave operators $\Omega_\pm^{\alpha j}$ in $\mathscr{H}$ defined by

$$\Omega_\pm^{\alpha j}=s-\lim_{t\to\pm\infty} e^{itH}e^{-itH_\alpha^j}E_\alpha^j, \qquad \alpha=0,1,2,3. \tag{2.24}$$

More precisely we have

$$\begin{gathered}\operatorname{Ran}\Omega_\pm^{00}\oplus\bigoplus_{\alpha=1}^{3}\bigoplus_{j=1}^{N_\alpha}\operatorname{Ran}\Omega_\pm^{\alpha j}=\mathscr{H}_{ac}(H),\\ (\Omega_\pm^{\beta l})^*\Omega_\pm^{\alpha j}=\delta_{\beta\alpha}^{lj}E_\alpha^j, \qquad \alpha=0,1,2,3.\end{gathered} \tag{2.25}$$

Here and in the following sections we always assume that in a two-cluster channel (α,j), $\alpha\neq 0$, j runs from 1 to N_α whereas for a three-cluster channel (β,l), $\beta=0$, l equals zero. For weaker two-body spectral assumptions cf. [12], [24], [34], [38]. The absence of the singular continuous spectrum of H follows from [26], [29]. The corresponding scattering operator $S_{\beta\alpha}^{lj}$ in $\mathscr{H}$, defined by

$$S_{\beta\alpha}^{lj}=(\Omega_+^{\beta l})^*\Omega_-^{\alpha j}, \qquad \alpha,\beta=0,1,2,3, \tag{2.26}$$

describes scattering from channel (α,j) into channel (β,l): $S_{\alpha\alpha}^{jj}$ describes elastic scattering, $S_{\alpha\alpha}^{lj}$, $l\neq j$ (i.e. $\psi_\alpha^j\neq$ const. ψ_α^l) inelastic scattering, $S_{\beta\alpha}^{lj}$, $\alpha\neq\beta$ rearrangement scattering, $S_{0\alpha}^{0j}$ breakup scattering, S_{00}^{00} the scattering of three free particles. We recall that

$$H_\beta^l S_{\beta\alpha}^{lj}=S_{\beta\alpha}^{lj}H_\alpha^j, \qquad \alpha,\beta=0,1,2,3. \tag{2.27}$$

Clearly $S_{\beta\alpha}^{lj}$ maps $\mathscr{M}_\alpha^j$ onto $\mathscr{M}_\beta^l$ and unitary of the scattering operator is equivalent to

$$S_{\beta 0}^{l0}(S_{\beta' 0}^{l'0})^*+\sum_{\alpha=1}^{3}\sum_{j=1}^{N_\alpha}S_{\beta\alpha}^{lj}(S_{\beta'\alpha}^{l'j})^*=\delta_{\beta\beta'}^{ll'}E_\beta^l, \qquad \beta,\beta'=0,1,2,3. \tag{2.28}$$

Each eigenvalue $e^j_\alpha < 0$ of h_α together with $e^0_0 = 0$ defines a threshold for the three-body system. We introduce

$$(2.29)\qquad \theta_\alpha = \{e^j_\alpha < 0, j = 1, \cdots, N_\alpha\}, \qquad \alpha = 1, 2, 3, \qquad \theta = \{0\} \cup \bigcup_{\alpha=1}^{3} \theta_\alpha.$$

Finally we turn to spectral representations associated with H^j_α, H_0. Define

$$(2.30)\qquad \lambda = (2n_\alpha)^{-1}(q^j_\alpha)^2 + e^j_\alpha, \qquad \omega^j_\alpha = |q^j_\alpha|^{-1} q^j_\alpha \in S^2, \qquad \alpha = 1, 2, 3,$$

S^2 the unit sphere in $\mathscr{R}^3$. The spectral representation (cf. [3]) of H^j_α then reads

$$(2.31)\qquad \mathscr{G}^j_\alpha = L^2((e^j_\alpha, \infty); L^2(S^2))$$

and the corresponding spectral transformation $\mathscr{U}^j_\alpha$ is given by

$$\mathscr{U}^j_\alpha : \mathscr{M}^j_\alpha \to \mathscr{G}^j_\alpha,$$

$$(2.32)\qquad \begin{aligned} \mathscr{U}^j_\alpha(\psi^j_\alpha \otimes \phi)(\lambda, \omega^j_\alpha) &= (2\pi)^{-3/2} n_\alpha^{1/2} [2n_\alpha(\lambda - e^j_\alpha)]^{1/4} \\ &\quad \cdot \operatorname*{l.i.m.}_{R\to\infty} \int_{|y_\alpha| \leqq R} d^3 y_\alpha \exp(-i[2n_\alpha(\lambda - e^j_\alpha)]^{1/2} \omega^j_\alpha y_\alpha) \phi(y_\alpha), \\ &\qquad \phi \in L^2(\mathscr{R}^3), \qquad \alpha = 1, 2, 3. \end{aligned}$$

As a consequence

$$(2.33)\qquad \mathscr{U}^j_\alpha H^j_\alpha \mathscr{U}^{j*}_\alpha = \int^{\oplus}_{(e^j_\alpha, \infty)} d\lambda \lambda 1_{L^2(S^2)}, \qquad \alpha = 1, 2, 3.$$

In addition we define

$$(2.34)\qquad U^j_\alpha = \mathscr{U}^j_\alpha E^j_\alpha, \qquad \alpha = 1, 2, 3$$

and (cf. [3], [5]) $M^j_\alpha(A, \lambda): \mathscr{D}(A) \to L^2(S^2)$,

$$(2.35)\qquad (M^j_\alpha(A, \lambda) g)(\omega^j_\alpha) = (U^j_\alpha E^j_\alpha A g)(\lambda, \omega^j_\alpha), \qquad g \in \mathscr{D}(A), \quad \alpha = 1, 2, 3.$$

Here A denotes a multiplication operator in $\mathscr{H}$ with one of the following functions (cf. (3.4) and (3.5)): $|v_\beta(x_\beta)|^{1/2}$, $v_\beta^{1/2}(x_\beta)$, ${}^{(\hat{}\,)}\rho^j_\alpha(y_\alpha)$, $v_\beta(x_\beta)|{}^{(\hat{}\,)}\rho^j_\beta(y_\beta)|^{-1}$, $v_\beta^{1/2}(x_\beta)|{}^{(\hat{}\,)}\rho^j_\beta(y_\beta)|^{-1}$, $g_\kappa(x_\alpha, x_\beta)$ where $|g_\kappa(x_\alpha, x_\beta)| \leqq \exp[\kappa|x_\alpha|]\phi(x_\beta)$ for some $\kappa < (-2m_\alpha e^j_\alpha)^{1/2}$, $\phi \in L^2(\mathscr{R}^3)$, $\beta = 1, 2, 3$, $\beta \neq \alpha$.

It remains to discuss H_0. Let

$$(2.36)\qquad \begin{aligned} &\lambda = (2m_\gamma)^{-1}|k_\gamma|^2 + (2n_\gamma)^{-1}|q_\gamma|^2, \\ &\omega = |k_\gamma|^{-1} k_\gamma \in S^2, \qquad q = [m_\gamma^{-1} n_\gamma |k_\gamma|^2 + |q_\gamma|^2]^{-1/2} q_\gamma, \qquad \gamma = 1, 2, 3. \end{aligned}$$

Then $\omega^0_0 = (\omega, q)$ parametrizes the ellipsoid E^5

$$(2.37)\qquad E^5 = \{k_\gamma, q_\gamma | (2m_\gamma)^{-1}|k_\gamma|^2 + (2n_\gamma)^{-1}|q_\gamma|^2 = 1\}, \qquad \gamma = 1, 2, 3.$$

The spectral representation of H_0 is

$$(2.38)\qquad \mathscr{G}^0_0 = L^2((0, \infty); L^2(E^5))$$

and the corresponding spectral transformation U_0^0 reads

$$U_0^0: \mathscr{H} \to \mathscr{G}_0^0,$$

$$(U_0^0\phi)(\lambda, \omega, q) = (2\pi)^{-3}[4(n_\gamma m_\gamma)^{3/2}(1-|q|^2)^{1/2}\lambda^2]^{1/2}$$

$$\cdot \operatorname*{l.i.m.}_{R\to\infty} \int_{|x_\gamma|\le R, |y_\gamma|\le R} d^3x_\gamma\, d^3y_\gamma \tag{2.39}$$

$$\cdot \exp(-i[2m_\gamma\lambda(1-|q|^2)]^{1/2}\omega x_\gamma - i(2n_\gamma\lambda)^{1/2}qy_\gamma)\phi(x_\gamma, y_\gamma),$$

$$\phi \in \mathscr{H}, \quad \gamma = 1, 2, 3.$$

Consequently

$$U_0^0 H_0(U_0^0)^* = \int_{(0,\infty)}^{\oplus} d\lambda\, \lambda 1_{L^2(E^5)}. \tag{2.40}$$

Similarly to (2.35) we also define $M_0^0(A, \lambda): \mathscr{D}(A) \to L^2(E^5)$:

$$(M_0^0(A, \lambda)g)(\omega, q) = (U_0^0 Ag)(\lambda, \omega, q), \qquad g \in \mathscr{D}(A) \tag{2.41}$$

where now A denotes a multiplication operator in $\mathscr{H}$ with one of the following functions: $|v_\beta(x_\beta)|^{1/2}$, $\phi(x_\beta)$, where $\phi \in L^p(\mathscr{R}^3)$ for $p=2$ or $p=3$, $\beta = 1, 2, 3$.

3. The three-particle resolvent $G(z)$. In this section we shall discuss the three-particle resolvent $G(z)$. We closely follow [5] (see also [3], [1]). Due to the stronger decay assumptions in H(II) (and in H(III) defined below) when compared to [5] we extend their results to be valid near thresholds contained in θ (cf. (2.29)).

We alternatively use H(II) and the following hypothesis.

Hypothesis (III). Let $b>0$ and $u_\alpha \in L^p(\mathscr{R}^3) + L^\infty(\mathscr{R}^3)$ for some $p > 3/2$ be real-valued, $\alpha = 1, 2, 3$. Then v_α is defined by

$$v_\alpha(x_\alpha) = e^{-b|x_\alpha|}u_\alpha(x_\alpha), \qquad \alpha = 1, 2, 3. \tag{3.1}$$

In addition we assume that

$$\varepsilon_\alpha = \{\varepsilon_\alpha^+ \cup \varepsilon_\alpha^-\} \cap [0, \infty) = \varnothing, \qquad \alpha = 1, 2, 3 \tag{3.2}$$

(cf. (2.20)).

Obviously H(III) implies H(II) and both H(II) and H(III) imply $v_\alpha \in L^1(\mathscr{R}^3) \cap L^{3/2}(\mathscr{R}^3)$, $\alpha = 1, 2, 3$. The exponential decreases of v_α at infinity assumed in H(III) will be used in § 6 to derive analytic expansions of scattering operators and amplitudes with respect to channel momenta near thresholds in $\theta\backslash\{0\}$.

LEMMA 3.1. *Assume* H(II) *and* $h_\alpha\psi_\alpha^j = e_\alpha^j\psi_\alpha^j$, $e_\alpha^j < 0$, $\psi_\alpha^j \in L^2(\mathscr{R}^3)$ *for some* $j = 1, \cdots, N_\alpha$, $\alpha = 1, 2, 3$. *Then* $e^{\kappa|\cdot|}\psi_\alpha^j \in L^2(\mathscr{R}^3)$ *for all* $\kappa < (-2m_\alpha e_\alpha^j)^{1/2}$ *and* $(1+|\cdot|^\beta)\psi_\alpha^j \in H^{2,1}(\mathscr{R}^3)$, $\beta \in [0, 2+\nu)$. *If in addition* H(III) *holds then* $e^{\kappa|\cdot|}\psi_\alpha^j \in H^{2,1}(\mathscr{R}^3)$ *for all* $\kappa < (-2m_\alpha e_\alpha^j)^{1/2}$.

Proof. Using H(II) the result is due to [36] and [5]. Suppose H(III) then $e^{\kappa|\cdot|}\psi_\alpha^j$, $|v_\alpha|^{1/2}e^{\kappa|\cdot|}\psi_\alpha^j \in L^2(\mathscr{R}^3)$ for all $\kappa < \kappa_0 \equiv (-2m_\alpha e_\alpha^j)^{1/2}$ by Theorems VI.6 and VI.7 of [36]. From

$$\psi_\alpha^j(x) = -(4\pi)^{-1}\int_{\mathscr{R}^3} d^3y\, e^{-\kappa_0|x-y|}|x-y|^{-1}v_\alpha(y)\psi_\alpha^j(y)$$

we infer

$$\begin{aligned}|(\nabla\psi_\alpha^j)(x)| &\leqq (4\pi)^{-1}\kappa_0\int_{\mathscr{R}^3} d^3y\, e^{-\kappa_0|x-y|}|x-y|^{-1}|v_\alpha(y)||\psi_\alpha^j(y)| \\ &\quad +(4\pi)^{-1}\int_{\mathscr{R}^3} d^3y\, e^{-\kappa_0|x-y|}|x-y|^{-2}|v_\alpha(y)||\psi_\alpha^j(y)| \\ &\equiv |(\nabla\psi_\alpha^j)_1(x)|+|(\nabla\psi_\alpha^j)_2(x)|.\end{aligned}$$

Clearly $e^{\kappa|\cdot|}|(\nabla\psi_\alpha^j)_1|\in L^2(\mathscr{R}^3)$ for all $\kappa<\kappa_0$ by the above remarks. Next we get

$$\begin{aligned}\|e^{\kappa|\cdot|}|(\nabla\psi_\alpha^j)_2|\,\|_2^2 &\leqq (4\pi)^{-2}\int_{\mathscr{R}^6} d^3y\, d^3z\, e^{(\kappa_0-\kappa)|y|}|v_\alpha(y)|\, e^{(\kappa_0-\kappa)|z|}|v_\alpha(z)| \\ &\quad \cdot e^{\kappa|y|}|\psi_\alpha^j(y)|e^{\kappa|z|}|\psi_\alpha^j(z)| \\ &\quad \cdot\int_{\mathscr{R}^3} d^3x|x-y|^{-2}|x-z|^{-2}\, e^{\kappa|x|}\, e^{-\kappa_0|x-y|}\, e^{-\kappa_0|y|}\, e^{\kappa|x|}\, e^{-\kappa_0|x-z|}\, e^{-\kappa_0|z|} \\ &\leqq \text{const.}\, \|e^{(\kappa_0-\kappa)|\cdot|}v_\alpha\|_R\|\,|v_\alpha|^{1/2}\, e^{\kappa|\cdot|}\psi_\alpha^j\|_2^2<\infty \quad \text{for } 0<\kappa_0-\kappa<b\end{aligned}$$

($\|\cdot\|_R$ the Rollnik norm [36]) using Fubini's Theorem,

$$\int_{\mathscr{R}^3} d^3x|x-y|^{-2}|x-z|^{-2}\leqq \text{const.}\,|y-z|^{-1}, \tag{3.3}$$

and the Schwarz' inequality. Thus $e^{\kappa|\cdot|}|(\nabla\psi_\alpha^j)_2|\in L^2(\mathscr{R}^3)$ for all $\kappa<\kappa_0$ and we only need to note

$$\nabla(e^{\kappa|\cdot|}\psi_\alpha^j)(x)=\kappa\, e^{\kappa|x|}(|x|^{-1}x)\psi_\alpha^j(x)+e^{\kappa|x|}(\nabla\psi_\alpha^j)(x). \qquad \square$$

Next we introduce

$$\begin{aligned}&\rho_\alpha(y_\alpha)=\begin{cases}(1+|y_\alpha|)^{-1-\nu/2} & \text{if H(II) holds,}\\ e^{-a_\alpha|y_\alpha|} & \text{if H(III) holds,}\end{cases} \\ &\qquad 0<a_\alpha<\inf\left\{\frac{b}{2},\left(\frac{\mu_\alpha}{M}\right)\inf_{\beta=1,2,3}[-2m_\beta e_\beta^{N_\beta}]^{1/2}\right\},\end{aligned} \tag{3.4}$$

$$\begin{aligned}&\hat\rho_\alpha(y_\alpha)=\begin{cases}(1+|y_\alpha|)^{-1-\nu/2} & \text{if H(II) holds,}\\ e^{-\hat a|y_\alpha|} & \text{if H(III) holds,}\end{cases} \\ &\qquad 0<\hat a<\inf_{\alpha=1,2,3}\left(\frac{\mu_\alpha}{M}\right)\inf_{\beta=1,2,3}(a_\beta),\end{aligned} \tag{3.5}$$

$$\sigma_\alpha(x_\alpha)=\begin{cases}(1+|x_\alpha|)^{-1-\nu/2} & \text{if H(II) holds,}\\ e^{-a_\alpha|x_\alpha|} & \text{if H(III) holds,}\end{cases} \tag{3.6}$$

$$\hat\sigma_\alpha(x_\alpha)=\begin{cases}(1+|x_\alpha|)^{-1-\nu/2} & \text{if H(II) holds,}\\ e^{-\hat a|x_\alpha|} & \text{if H(III) holds;} \quad \alpha=1,2,3\end{cases} \tag{3.7}$$

and denote by $\rho_\alpha(\hat\rho_\alpha)$ resp. $\sigma_\alpha(\hat\sigma_\alpha)$ the multiplication operators in $\mathscr{H}$

$$(\overset{(\wedge)}{\rho}_\alpha\psi)(x_\alpha,y_\alpha)=\overset{(\wedge)}{\rho}_\alpha(y_\alpha)\psi(x_\alpha,y_\alpha), \qquad (\overset{(\wedge)}{\sigma}_\alpha\psi)(x_\alpha,y_\alpha)=\overset{(\wedge)}{\sigma}_\alpha(x_\alpha)\psi(x_\alpha,y_\alpha),$$

$$\psi\in\mathscr{H}, \quad \alpha=1,2,3.$$

LEMMA 3.2. *Assume* H(II) *or* H(III). *Then the following operators are in* $\mathscr{B}(\mathscr{H})$:

(i) $|u_\alpha|^{1/2}(|\nabla_{x_\beta}|+1)^{-1}, |v_\alpha|^{1/2}(|\nabla_{x_\beta}|+1)^{-1}, |v_\alpha|^{1/2}(H_0+1)^{-1/2},$
$|u_\alpha|^{1/2}E_\beta, |v_\alpha|^{1/2}E_\beta, \quad \alpha, \beta = 1, 2, 3.$

(ii) $\rho_\alpha^{-1}\rho_\beta^{-1}\, e^{-b|x_\delta|}|u_\delta|^{1/2}E_\gamma, \quad \gamma \neq \delta, \quad \rho_\gamma^{-2}E_\gamma\, e^{-b|x_\delta|}|u_\delta|^{1/2}, \quad \gamma \neq \delta,$
$\rho_\gamma^{-1}E_\gamma\, e^{-b|x_\delta|}|u_\delta|^{1/2}\rho_\delta^{-1}, \quad \gamma \neq \delta, \qquad \alpha, \beta, \gamma, \delta = 1, 2, 3$ *if* H(III) *holds.*

If only H(II) *holds replace* $e^{-b|x_\delta|}$ *by* $(1+|x_\delta|)^{-2-\nu}$.

(iii) $|v_\gamma|^{1/2}E_\delta\rho_\delta^{-1}, \quad \gamma \neq \delta, \quad \hat{\rho}_\alpha^{-1}E_\alpha\rho_\beta, \qquad \alpha, \beta, \gamma, \delta = 1, 2, 3.$

(iv) $\sigma_\alpha^{-1}E_\alpha, |v_\alpha|^{1/2}E_\alpha\sigma_\alpha^{-1}, \qquad \alpha = 1, 2, 3.$

(v) $\hat{\sigma}_\beta^{-1}\hat{\rho}_\alpha E_\alpha, \qquad \alpha, \beta = 1, 2, 3.$

Proof. See [5] for the proof under H(II). If H(III) holds one can follow their methods using the second part in Lemma 3.1. □

Introducing for $z \in \mathscr{C}\backslash\mathscr{R}$,

$$
\begin{aligned}
&W_{\gamma\delta}(z) = v_\gamma^{1/2}G_0(z)|v_\delta|^{1/2}, \qquad Z_{\gamma\delta}(z) = v_\gamma^{1/2}G(z)|v_\delta|^{1/2},\\
&X_{\gamma\delta}(z) = v_\gamma^{1/2}G_\gamma(z)|v_\delta|^{1/2}, \qquad \mathbf{X}_{\gamma\delta}(z) = X_{\gamma\gamma}(z)\delta_{\gamma\delta},\\
&V_{\gamma\delta}(z) = v_\gamma^{1/2}G_\gamma(z)\rho_\delta, \qquad Y_{\gamma\delta}(z) = v_\gamma^{1/2}G(z)\rho_\delta,\\
&K_{0,\gamma\delta}(z) = v_\gamma^{1/2}(1-E_\gamma)G_\gamma(z)\rho_\delta, \qquad K_{1,\gamma\delta} = \hat{\rho}_\gamma^{-1}E_\gamma\rho_\delta,\\
&L_{\gamma\delta}(z) = v_\gamma^{1/2}E_\gamma G_\gamma(z)\hat{\rho}_\gamma\delta_{\gamma\delta},\\
&D_{00,\gamma\delta}(z) = v_\gamma^{1/2}(1-E_\gamma)G_\gamma(z)|v_\delta|^{1/2}(1-\delta_{\gamma\delta}),\\
&D_{01,\gamma\delta}(z) = \sum_{\alpha=1}^{3} D_{00,\gamma\alpha}(z)L_{\alpha\delta}(z)\\
&\qquad = v_\gamma^{1/2}(1-E_\gamma)G_\gamma(z)|v_\delta|^{1/2}(1-\delta_{\gamma\delta})v_\delta^{1/2}E_\delta G_\delta(z)\hat{\rho}_\delta,\\
&D_{10,\gamma\delta} = \hat{\rho}_\gamma^{-1}E_\gamma|v_\delta|^{1/2}(1-\delta_{\gamma\delta}),\\
&D_{11,\gamma\delta}(z) = \sum_{\alpha=1}^{3} D_{10,\gamma\alpha}L_{\alpha\delta}(z)\\
&\qquad = \hat{\rho}_\gamma^{-1}E_\gamma|v_\delta|^{1/2}(1-\delta_{\gamma\delta})v_\delta^{1/2}E_\delta G_\delta(z)\hat{\rho}_\delta, \qquad \gamma, \delta = 1, 2, 3.
\end{aligned}
\tag{3.8}
$$

We recall the following lemma ([5]).

LEMMA 3.3. *Assume* H(II) *and* $z \in \mathscr{C}\backslash\mathscr{R}$. *Then all operators defined in* (3.8) *are in* $\mathscr{B}(\mathscr{H})$.

LEMMA 3.4. *Assume* H(II). *Then*

(i) $W_{\gamma\delta}(z)$, $\gamma, \delta = 1, 2, 3$ *converges in norm as* $z \to \lambda \pm i0$, *uniformly in* $\lambda \in \mathscr{R}$. *For* $\gamma \neq \delta$, $W_{\gamma\delta}(z) \in \mathscr{B}_\infty(\mathscr{H})$ *for all* $z \in \mathscr{C}$, $W_{\gamma\gamma}(z) \notin \mathscr{B}_\infty(\mathscr{H})$, $z \in \mathscr{C}$.

(ii) $\rho_\alpha E_\alpha G_\alpha(z)\rho_\alpha$ *converges in norm as* $z \to \lambda \pm i0$, *uniformly in* $\lambda \in \mathscr{R}$, $\rho_\alpha E_\alpha G_\alpha(z)\rho_\alpha \in \mathscr{B}_\infty(\mathscr{H})$ *for all* $z \in \mathscr{C}$, $\alpha = 1, 2, 3$.

(iii) $v_\alpha^{1/2}(1-E_\alpha)G_\alpha(z)|v_\alpha|^{1/2}$ *converges in norm as* $z \to \lambda \pm i0$, *uniformly in* $\lambda \in \mathscr{R}$, $\alpha = 1, 2, 3$.

(iv) $v_\gamma^{1/2}G_\gamma(z)|v_\delta|^{1/2} \in \mathscr{B}_\infty(\mathscr{H})$ *for* $\gamma \neq \delta$, $\operatorname{Im} z \neq 0$, $\gamma, \delta = 1, 2, 3$.

Proof. (i), (iii) and (iv) are due to [5] and based on [22]. Due to our stronger decay properties in ρ_α we infer (ii) for all $\lambda \in \mathscr{R}$ from

$$
\rho_\alpha E_\alpha G_\alpha(z)\rho_\alpha = \bigoplus_{j=1}^{N_\alpha} E_\alpha^j \otimes \rho_\alpha[-(2n_\alpha)^{-1}\Delta_{y_\alpha} - (z - e_\alpha^j)]^{-1}\rho_\alpha
\tag{3.9}
$$

since $N_\alpha < \infty$ and $\rho_\alpha \in L^{3/2}(\mathcal{R}^3)$. We also note that (iii) immediately follows from

$$v_\alpha^{1/2}(1-E_\alpha)G_\alpha(z)|v_\alpha|^{1/2} = i\int_0^\infty d\tau\, e^{iz\tau} v_\alpha^{1/2} E_{ac}(h_\alpha)\, e^{-i\tau h_\alpha}|v_\alpha|^{1/2}$$
$$\otimes \exp(-i\tau(-2n_\alpha)^{-1}\Delta_{y_\alpha}), \qquad \operatorname{Im} z > 0$$

(similar for $\operatorname{Im} z < 0$) and from ([20])

$$\|v_\alpha^{1/2} E_{ac}(h_\alpha)\, e^{-i\tau h_\alpha}|v_\alpha|^{1/2}\| \in L^1(\mathcal{R}, d\tau). \qquad \square$$

For the following it is convenient to define

$$\bar{\mathcal{H}} = \mathcal{H} \oplus \mathcal{H} \oplus \mathcal{H} \tag{3.10}$$

and to represent linear operators $\bar{T}: \bar{\mathcal{H}} \to \bar{\mathcal{H}}$ by $\bar{T} = \{T_{\alpha\beta}\}_{\alpha,\beta=1,2,3}$. Then we have

$$\begin{aligned} \bar{Z}(z) &= \bar{W}(z) - \bar{W}(z)\bar{Z}(z), \\ \bar{Z}(z) &= \bar{X}(z') - [\bar{X}(z) - \bar{\mathbf{X}}(z)]\bar{Z}(z), \\ \bar{Y}(z) &= \bar{V}(z) - [\bar{X}(z) - \bar{\mathbf{X}}(z)]\bar{Y}(z), \qquad \operatorname{Im} z \neq 0. \end{aligned} \tag{3.11}$$

In addition we define

$$\overset{\Delta}{\mathcal{H}} = \bar{\mathcal{H}} \oplus \bar{\mathcal{H}} \tag{3.12}$$

and represent linear operators $\overset{\Delta}{U}: \overset{\Delta}{\mathcal{H}} \to \overset{\Delta}{\mathcal{H}}$ by $\overset{\Delta}{U} = \{\bar{U}_{st}\}_{s,t=0,1}$ such that

$$\overset{\Delta}{U}g = \begin{pmatrix} \bar{U}_{00} & \bar{U}_{01} \\ \bar{U}_{10} & \bar{U}_{11} \end{pmatrix}\begin{pmatrix} g_0 \\ g_1 \end{pmatrix} = \begin{pmatrix} \bar{U}_{00}g_0 + \bar{U}_{01}g_1 \\ \bar{U}_{10}g_0 + \bar{U}_{11}g_1 \end{pmatrix},$$
$$g = \begin{pmatrix} g_0 \\ g_1 \end{pmatrix} \in \mathcal{D}(\overset{\Delta}{U}), \qquad g_0, g_1 \in \bar{\mathcal{H}}.$$

For $\operatorname{Im} z \neq 0$ we introduce

$$\begin{aligned} &K(z): \begin{cases} \bar{\mathcal{H}} \to \overset{\Delta}{\mathcal{H}}, \\ g \to K(z)g = \begin{pmatrix} \bar{K}_0(z)g \\ \bar{K}_1 g \end{pmatrix}, \end{cases} \\ &J(z): \begin{cases} \overset{\Delta}{\mathcal{H}} \to \bar{\mathcal{H}}, \\ \begin{pmatrix} g_0 \\ g_1 \end{pmatrix} \to g_0 + \bar{L}(z)g_1, \end{cases} \end{aligned} \tag{3.13}$$

with $K_{0,\gamma\delta}(z)$, $K_{1,\gamma\delta}$, $L_{\gamma\delta}(z)$ given by (3.8) and

$$\overset{\Delta}{D}(z) = \{\bar{D}_{st}(z)\}_{s,t=0,1} \tag{3.14}$$

with $D_{st,\gamma\delta}(z)$ defined in (3.8).

Then we have the following lemma ([5]).

LEMMA 3.5. *Assume* H(II) *or* H(III) *and* $\operatorname{Im} z \neq 0$. *Then*

(i) $J(z)K(z) = \bar{V}(z)$,

(ii) $J(z)\overset{\Delta}{D}(z) = [\bar{X}(z) - \bar{\mathbf{X}}(z)]J(z)$,

(iii) $[1 + \bar{W}(z)][1 - \bar{Z}(z)] = [1 - \bar{Z}(z)][1 + \bar{W}(z)] = 1$,
i.e., $[1 + \bar{W}(z)]^{-1} \in \mathcal{B}(\bar{H})$,

(iv) $[1+\bar{X}(z)-\bar{\mathbf{X}}(z)]^{-1}\in\mathcal{B}(\bar{\mathcal{H}})$,

(v) $[1+\overset{\Delta}{D}(z)]^{-1}$ *exists*,

$$\bar{Y}(z)=[1+\bar{X}(z)-\bar{\mathbf{X}}(z)]^{-1}J(z)K(z)=J(z)[1+\overset{\Delta}{D}(z)]^{-1}K(z). \tag{3.15)(vi}$$

Since $\bar{D}_{10}\in\mathcal{B}(\bar{\mathcal{H}})$ but $\bar{D}_{10}\notin\mathcal{B}_\infty(\bar{\mathcal{H}})$ we define in $\overset{\Delta}{\mathcal{H}}$ (cf. [3], [5])

$$\overset{\Delta}{N}=\begin{pmatrix}0 & 0\\ \bar{D}_{10} & 0\end{pmatrix},\qquad \overset{\Delta}{A}(z)=(1-\overset{\Delta}{N})[\overset{\Delta}{D}(z)-\overset{\Delta}{N}],\qquad \operatorname{Im} z\neq 0. \tag{3.16}$$

We recall the following lemma ([3], [5]).

LEMMA 3.6. *Assume* H(II) *or* H(III) *and* $\operatorname{Im} z\neq 0$. *Then*

(i) $\overset{\Delta}{N}$ *is nilpotent*, $\overset{\Delta}{N}{}^2=0$, $(1+\overset{\Delta}{N})^{-1}=1-\overset{\Delta}{N}$.

(ii) $1+\overset{\Delta}{A}(z)$ *is invertible if and only if* $1+\overset{\Delta}{D}(z)$ *is since*

$$[1+\overset{\Delta}{A}(z)]^{-1}=[1+\overset{\Delta}{D}(z)]^{-1}(1+\overset{\Delta}{N}),\qquad [1+\overset{\Delta}{D}(z)]^{-1}=[1+\overset{\Delta}{A}(z)]^{-1}(1-\overset{\Delta}{N}).$$

LEMMA 3.7. *Assume* H(II) *or* H(III). *Then*

(i) $\overset{\Delta}{A}(z)\in\mathcal{B}_\infty(\overset{\Delta}{\mathcal{H}})$ *for all* $z\in\mathcal{C}$;

(ii) $\overset{\Delta}{A}(z)$ *converges in norm as* $z\to\lambda\pm i0$, *uniformly in* $\lambda\in\mathcal{R}$ *and*

$$\lim_{|z|\to\infty}\|\overset{\Delta}{A}(z)\|=0,\qquad z\in\mathcal{C}.$$

(iii) $\overset{\Delta}{A}(z)$ *is analytic in* $z\in\mathcal{C}\backslash[E_0^{(2)},\infty)$, $E_0^{(2)}=\inf_{\alpha=1,2,3}\sigma(h_\alpha)$.

Proof. Following [5], we treat $\bar{D}_{00}(z)$, $\bar{D}_{01}(z)$, $\bar{D}_{11}(z)$ in some detail for later purposes (cf., e.g., Lemma 6.2).

$$\begin{aligned}\text{(a)}\quad D_{00,\gamma\delta}(z)&=v_\gamma^{1/2}(1-E_\gamma)[G_0(z)-G_\gamma(z)v_\gamma G_0(z)]|v_\delta|^{1/2}\\ &=[1-v_\gamma^{1/2}(1-E_\gamma)G_\gamma(z)|v_\gamma|^{1/2}]v_\gamma^{1/2}G_0(z)|v_\delta|^{1/2}\\ &\quad-[v_\gamma^{1/2}E_\gamma\sigma_\gamma^{-1}]\sigma_\gamma G_0(z)|v_\delta|^{1/2},\qquad \gamma\neq\delta.\end{aligned} \tag{3.17}$$

Lemma 3.4(iii), respectively, Lemma 3.2(iv) apply for the terms $[\cdots]$ in (3.17). Lemma 3.4(i) applies for $v_\gamma^{1/2}G_0(z)|v_\delta|^{1/2}$ and $\sigma_\gamma G_0(z)|v_\delta|^{1/2}$. Clearly $D_{00,\gamma\delta}(z)$ is analytic in $z\in\mathcal{C}\backslash[0,\infty)$.

$$\begin{aligned}\text{(b)}\quad D_{01,\gamma\delta}(z)&=[1-v_\gamma^{1/2}(1-E_\gamma)G_\gamma(z)|v_\gamma|^{1/2}]v_\gamma^{1/2}G_0(z)v_\delta E_\delta G_\delta(z)\hat{\rho}_\delta\\ &\quad-[v_\gamma^{1/2}E_\gamma\sigma_\gamma^{-1}]\sigma_\gamma G_0(z)v_\delta E_\delta G_\delta(z)\hat{\rho}_\delta,\qquad \gamma\neq\delta.\end{aligned} \tag{3.18}$$

The terms $[\cdots]$ in (3.18) have already been discussed in (3.17).

$$v_\gamma^{1/2}G_0(z)v_\delta E_\delta G_\delta(z)\hat{\rho}_\delta=[v_\gamma^{1/2}G_0(z)\hat{\sigma}_\delta]\hat{\sigma}_\delta^{-1}E_\delta\hat{\rho}_\delta-[v_\gamma^{1/2}E_\delta\hat{\rho}_\delta^{-1}]\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta. \tag{3.19}$$

Lemma 3.2(iii) and (v) apply for $v_\gamma^{1/2}E_\delta\hat{\rho}_\delta^{-1}$ and $\hat{\sigma}_\delta^{-1}E_\delta\hat{\rho}_\delta$. Lemma 3.4(i) applies for $v_\gamma^{1/2}G_0(z)\hat{\sigma}_\delta$. The operator $\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$ is treated in Lemma 3.4(ii). In particular (3.9) shows its analyticity in $z\in\mathcal{C}\backslash[e_\delta^1,\infty)$ (and hence analyticity of $\bar{D}_{01}(z)$ in $z\in\mathcal{C}\backslash[E_0^{(2)},\infty)$). The operator $\sigma_\gamma G_0(z)v_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$ can be discussed identically to (3.19) after replacing $v_\gamma^{1/2}$ by σ_γ.

$$\text{(c)}\quad D_{11,\gamma\delta}(z)=[\hat{\rho}_\gamma^{-1}E_\gamma e^{-b|x_\delta|}|u_\delta|^{1/2}\hat{\rho}_\delta^{-1}][u_\delta^{1/2}E_\delta]\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta,\qquad \gamma\neq\delta \tag{3.20}$$

if H(III) holds (if only H(II) holds replace $e^{-b|x_\delta|}$ by $(1+|x_\delta|)^{-2-\nu}$) and Lemma 3.2(i), (ii) and Lemma 3.4(ii) apply. Again $\tilde{D}_{11}(z)$ is analytic in $z \in \mathscr{C}\backslash[E_0^{(2)}, \infty)$.

(d) $\lim_{|z|\to\infty} \|\overset{\Delta}{A}(z)\| = 0$, $z \in \mathscr{C}$ is proved in [16] (for $z \in \mathscr{C}\backslash[0,\infty)$) and in [19]. □

Next we define

$$\overset{\Delta}{\mathscr{E}}{}^{\pm} = \{z \in \mathscr{C} \mid \overset{\Delta}{A}(z \pm i0)\Phi = -\Phi, \Phi \in \overset{\Delta}{\mathscr{H}}, \Phi \neq 0\}, \qquad \overset{\Delta}{\mathscr{E}} = \overset{\Delta}{\mathscr{E}}{}^{+} \cup \overset{\Delta}{\mathscr{E}}{}^{-} \tag{3.21}$$

and note the following lemma.

LEMMA 3.8. *Assume* H(II). *Then*

(i) $\overset{\Delta}{\mathscr{E}}$ *is a compact subset of* $\mathscr{R}$ *of Lebesgue measure zero*;

(ii) $\sigma_d(H) = \overset{\Delta}{\mathscr{E}} \cap (-\infty, E_0^{(2)})$ *is finite,* $\sigma_p(H) \subset \overset{\Delta}{\mathscr{E}}$, $\sigma_p(H) \cap (-\infty, 0) = \overset{\Delta}{\mathscr{E}} \cap (-\infty, 0)$ *consists of eigenvalues of H with finite multiplicity accumulating at most at zero.*

Proof. For (i) cf. [16], [19], [23]; for (ii) see [11], [16], [19].

Lemma 3.7 implies Lemma 3.9 as follows.

LEMMA 3.9. *Assume* H(II) *or* H(III). *Then*

$$[1+\overset{\Delta}{D}(z)]^{-1} \in \mathscr{B}(\overset{\Delta}{\mathscr{H}}) \quad \textit{for all } z \in \mathscr{C}\backslash\overset{\Delta}{\mathscr{E}}.$$

Moreover $\overset{\Delta}{D}(z)$ *converges in norm as* $z \to \lambda \pm i0$, *uniformly in* $\lambda \in \mathscr{R}$ *and* $[1+\overset{\Delta}{D}(z)]^{-1}$ *converges in norm as* $z \to \lambda \pm i0$, $\lambda \notin \overset{\Delta}{\mathscr{E}}$, *uniformly in* $\lambda \in \Delta$, $\Delta \subset \mathscr{R}\backslash\overset{\Delta}{\mathscr{E}}$ *compact if z varies in* $\Delta_\pm = \{z \in \mathscr{C} \mid \operatorname{Re} z \in \Delta, \operatorname{Im} z \in [0, \pm 1]\}$.

Finally we get for the three-particle resolvent $G(z)$

LEMMA 3.10. *Assume* H(II) *or* H(III). *Then*

$$\hat{\rho}_\gamma v_\gamma^{1/2} G(z) |v_\delta|^{1/2} = \hat{\rho}_\gamma \{J(z)[1+\overset{\Delta}{D}(z)]^{-1} K(z)\}_{\gamma\delta} \rho_\delta^{-1} |v_\delta|^{1/2}, \qquad \gamma, \delta = 1, 2, 3$$

is norm continuous in z as $z \to \lambda \pm i0$, $\lambda \notin \overset{\Delta}{\mathscr{E}}$, *uniformly continuous in* $\lambda \in \Delta$, $\Delta \in \mathscr{R}\backslash\overset{\Delta}{\mathscr{E}}$ *compact if z varies in* $\Delta_\pm$ (*cf. Lemma* 3.9).

Proof. The proof follows from

$$\hat{\rho}_\gamma \left\{ J(z) \begin{pmatrix} g_0 \\ g_1 \end{pmatrix} \right\}_\gamma = \hat{\rho}_\gamma g_{0,\gamma} + [v_\gamma^{1/2} E_\gamma] \hat{\rho}_\gamma E_\gamma G_\gamma(z) \hat{\rho}_\gamma g_{1,\gamma}$$

and Lemma 3.2(i), Lemma 3.4(ii), from Lemma 3.9, from

$$K_{0,\gamma\delta}(z) \rho_\delta^{-1} |v_\delta|^{1/2} = v_\gamma^{1/2} (1 - E_\gamma) G_\gamma(z) |v_\delta|^{1/2}$$

which is discussed for $\gamma = \delta$ in Lemma 3.4(iii) and for $\gamma \neq \delta$ in Lemma 3.7 (cf. $D_{00,\gamma\delta}(z)$), and from

$$K_{1,\gamma\delta} \rho_\delta^{-1} |v_\delta|^{1/2} = \hat{\rho}_\gamma^{-1} E_\gamma |v_\delta|^{1/2} \in \mathscr{B}(\mathscr{H})$$

by Lemma 3.2(iii). □

Using the above methods, one can easily prove that $G(z) \in \mathscr{B}_\infty(L^2_{1+\nu/2}(\mathscr{R}^6), L^2_{-1-\nu/2}(\mathscr{R}^6))$, $z \in \mathscr{C}\backslash\overset{\Delta}{\mathscr{E}}$ and converges in $\mathscr{B}(L^2_{1+\nu/2}(\mathscr{R}^6), L^2_{-1-\nu/2}(\mathscr{R}^6))$-norm as $z \to \lambda \pm i0$, $\lambda \in \mathscr{R}\backslash\overset{\Delta}{\mathscr{E}}$, uniformly in $\lambda \in \Delta$, $\Delta \subset \mathscr{R}\backslash\overset{\Delta}{\mathscr{E}}$ compact, if z varies in $\Delta_\pm$, where $L^2_\mu(\mathscr{R}^6) = L^2(\mathscr{R}^6; (1+|x_\alpha|^2+|y_\alpha|^2)^\mu \, d^3x_\alpha \, d^3y_\alpha)$. In fact one can prove Hölder continuity of $G(z)$ for z in compacts not intersecting $\overset{\Delta}{\mathscr{E}}$ (cf. [16]).

4. Continuity of averaged total cross sections. Given the results of § 3 we rederive the continuity results for averaged total cross sections in [5]. Because of our stronger decay assumptions in H(II) when compared to [5] we are particularly able to discuss the threshold behaviour of the scattering operator, resp., the cross section for two-cluster initial channels.

In the following the operator $M_\alpha^j(A, \lambda)$ introduced at the end of § 2 plays a central role. From the definitions (2.35) and (2.41) one infers

$$\begin{aligned} &M_\alpha^j(AB, \lambda) = M_\alpha^j(A, \lambda)B, \qquad \operatorname{Ran}(B) \subset \mathscr{D}(A), \\ (4.1)\quad &M_\alpha^j(A, \lambda) = M_\alpha^j(E_\alpha^j A, \lambda), \qquad \alpha = 0, 1, 2, 3, \\ &M_0^0(A, \lambda) = M_0^0(E_\Lambda(H_0)A, \lambda) = \chi_\Lambda(\lambda) M_0^0(A, \lambda), \qquad \lambda \in \Lambda \subset \mathscr{R} \text{ a Borel set} \end{aligned}$$

where $E_\Lambda(H_0)$ denotes the spectral projection associated with H_0. We recall ([5])

LEMMA 4.1. *Assume* H(II). *Then*

(i) *For $\alpha \neq 0$, $\alpha \neq \beta$ and $|g_\kappa(x_\alpha, x_\beta)| \leqq e^{\kappa |x_\alpha|} \phi(x_\beta)$, $\phi \in L^2(\mathscr{R}^3)$, $\kappa < (-2m_\alpha e_\alpha^j)^{1/2}$, we get $M_\alpha^j(g_\kappa, \lambda) \in \mathscr{B}_2(\mathscr{H}, L^2(S^2))$, $\lambda \geqq e_\alpha^j$ and $M_\alpha^j(g_\kappa, \lambda)$ is continuous in $\mathscr{B}_2$-norm for $\lambda \geqq e_\alpha^j$, $\alpha = 1, 2, 3$.*

(ii) *Let $\alpha \neq 0$, $\alpha \neq \beta$; then $M_\alpha^j(|v_\beta|^{1/2}, \lambda)$, $M_\alpha^j(\rho_\alpha, \lambda) \in \mathscr{B}_4(\mathscr{H}, L^2(S^2))$, $\lambda \geqq e_\alpha^j$ and both operators are continuous in $\mathscr{B}_4$-norm for $\lambda \geqq e_\alpha^j$, $\alpha = 1, 2, 3$.*

(iii) *Assume $\phi \in L^p(\mathscr{R}^3)$, where $p = 2$ or 3 and denote by ϕ_γ the operator of multiplication by $\phi(x_\gamma)$. Then $M_0^0(\phi_\gamma, \lambda) \in \mathscr{B}(\mathscr{H}, L^2(E^5))$, $\lambda \geqq 0$ and $M_0^0(\phi_\gamma, \lambda)$ is strongly continuous in $\lambda \geqq 0$. Moreover $M_0^0(\phi_\gamma, \lambda) \notin \mathscr{B}_\infty(\mathscr{H}, L^2(E^5))$ as long as $\phi_\gamma \not\equiv 0$.*

Introducing the decomposed operators ([3])

$$(4.2)\qquad R_{\beta\alpha}^{lj}(\lambda) = S_{\beta\alpha}^{lj}(\lambda) - \delta_{\beta\alpha}^{lj} 1, \quad \lambda \in [\sup(e_\alpha^j, e_\beta^l), \infty), \quad \alpha \neq 0, \quad \beta = 0, 1, 2, 3,$$

we obtain the splitting ([5])

$$(4.3)\quad R_{\beta\alpha}^{lj}(\lambda) = {}^{(1)}R_{\beta\alpha}^{lj}(\lambda) + {}^{(2)}R_{\beta\alpha}^{lj}(\lambda), \quad \alpha \neq 0, \quad \beta = 0, 1, 2, 3, \quad \lambda \in [\sup(e_\alpha^j, e_\beta^l), \infty) \backslash \overset{\Delta}{\mathscr{E}}$$

where

$$(4.4)\qquad {}^{(1)}R_{\beta\alpha}^{lj}(\lambda) = -2\pi i \sum_{\substack{\gamma=1 \\ \gamma \neq \alpha}}^{3} M_\beta^l(|v_\gamma|^{1/2}, \lambda) M_\alpha^j(v_\gamma^{1/2}, \lambda)^*, \qquad \lambda \in [\sup(e_\alpha^j, e_\beta^l), \infty)$$

represents the Born-term (for $\beta = \gamma$ cf. (6.4)) and

$$\begin{aligned} &{}^{(2)}R_{\beta\alpha}^{lj}(\lambda) = 2\pi i \sum_{\gamma=1}^{3} [1 + \delta_{\beta 0}\delta_{\beta\gamma} - \delta_{\beta\gamma}] \sum_{\substack{\delta=1 \\ \delta \neq \alpha}}^{3} M_\beta^l(|v_\gamma|^{1/2}, \lambda) \\ (4.5)\qquad &\cdot \{J[1 + \overset{\Delta}{D}]^{-1} K\}_{\gamma\delta}(\lambda + i0) M_\alpha^j(v_\delta \rho_\delta^{-1}, \lambda)^*, \qquad \lambda \in [\sup(e_\alpha^j, e_\beta^l), \infty) \backslash \overset{\Delta}{\mathscr{E}}. \end{aligned}$$

For extensive discussions of analyticity properties of $S_{\beta\alpha}^{lj}(\lambda)$ using dilation analytic two-body potentials v_α we refer to [6], [10], [18] and [33]. Trace relations in connection with three-particle systems appeared in [8], [9]. The corresponding Riemann surface and resonances in case of exponentially decaying two-body interactions are studied in great detail in [7].

Going back to Lemma 4.1, we obtain the following.

LEMMA 4.2. *Assume* H(II) *and $\alpha \neq 0$. Then $R_{\beta\alpha}^{lj}(\lambda) \in \mathscr{B}_2(L^2(S^2))$, $\beta \neq 0$, $R_{0\alpha}^{0j}(\lambda) \in \mathscr{B}_2(L^2(S^2), L^2(E^5))$ and $R_{\beta\alpha}^{lj}(\lambda)$ is continuous in $\mathscr{B}_2$-norm for $\lambda \in [\sup(e_\alpha^j, e_\beta^l), \infty) \backslash \overset{\Delta}{\mathscr{E}}$, $\beta = 0, 1, 2, 3$.*

Proof. The only difference to [5] concerns the fact that H(II) allows to include threshold points $\sup(e_\alpha^j, e_\beta^l) \in \theta$. In fact, one can follow [5] step by step, replacing its Proposition 1 (which excludes thresholds) by our Lemma 3.9. □

By (4.2) one obtains analogous results for the decomposed scattering operator $S^{lj}_{\beta\alpha}(\lambda)$.

Next we turn to the concept of averaged total cross sections for initial two-cluster channels as defined, e.g., in [3]-[5]:

$$\bar{\sigma}^{lj}_{\beta\alpha}(\lambda)=\pi[2n_\alpha(\lambda-e^j_\alpha)]^{-1}\|R^{lj}_{\beta\alpha}(\lambda)\|^2_2, \qquad \alpha\neq 0, \quad \beta=0,1,2,3. \tag{4.6}$$

Hence we get the next theorem.

THEOREM 4.3. *Assume* H(II), $\alpha\neq 0$ *and* $\beta=0,1,2,3$. *If* $\sup(e^j_\alpha, e^l_\beta)\notin\overset{\Delta}{\mathscr{E}}$ *then* $\bar{\sigma}^{lj}_{\beta\alpha}(\lambda)$ *is continuous in* $\lambda\in(\sup(e^j_\alpha,e^l_\beta),\infty)\backslash\overset{\Delta}{\mathscr{E}}$. *In addition we obtain the threshold behaviour*

Elastic case: $\alpha=\beta$, $j=l$.

$$\bar{\sigma}^{jj}_{\alpha\alpha}(\lambda)\underset{\lambda\downarrow e^j_\alpha}{=}O(1). \tag{4.7}$$

Inelastic case: $\alpha=\beta$, $j\neq l$ (*i.e.* $\psi^j_\alpha\neq$ const. ψ^l_α).

$$\bar{\sigma}^{lj}_{\alpha\alpha}(\lambda)\underset{\lambda\downarrow\sup(e^j_\alpha,e^l_\alpha)}{=}\begin{cases}O((\lambda-e^j_\alpha)^{-1/2}), & e^j_\alpha>e^l_\alpha,\\ O((\lambda-e^l_\alpha)^{1/2}), & e^j_\alpha<e^l_\alpha,\\ O(1), & e^j_\alpha=e^l_\alpha.\end{cases} \tag{4.8}$$

Rearrangement case: $\alpha\neq\beta$, $\beta\neq 0$.

$$\bar{\sigma}^{lj}_{\beta\alpha}(\lambda)\underset{\lambda\downarrow\sup(e^j_\alpha,e^l_\beta)}{=}\begin{cases}O((\lambda-e^j_\alpha))^{-1/2}, & e^j_\alpha>e^l_\beta,\\ O((\lambda-e^l_\beta))^{1/2}, & e^j_\alpha<e^l_\beta,\\ O(1), & e^j_\alpha=e^l_\beta.\end{cases} \tag{4.9}$$

Breakup case: $\beta=0$.

$$\bar{\sigma}^{0j}_{0\alpha}(\lambda)\underset{\lambda\downarrow 0}{=}O(\lambda^{1/2}). \tag{4.10}$$

Proof. The continuity statement is due to Lemma 4.2 of [5]. The threshold behaviour (4.7)-(4.9) can be read off from

$$\begin{aligned}M^j_\alpha(f_\gamma,\lambda)(\omega^j_\alpha,x_\alpha,y_\alpha)&=(2\pi)^{-3/2}n^{1/2}_\alpha[2n_\alpha(\lambda-e^j_\alpha)]^{1/4}f_\gamma(x_\gamma(x_\alpha,y_\alpha),y_\gamma(x_\alpha,y_\alpha))\\ &\quad\cdot\exp(-i[2n_\alpha(\lambda-e^j_\alpha)]^{1/2}\omega^j_\alpha y_\alpha)\overline{\psi^j_\alpha(x_\alpha)}, \qquad \alpha\neq 0\end{aligned} \tag{4.11}$$

where f_γ denotes the operator of multiplication by $f_\gamma(x_\gamma,y_\gamma)$ (i.e. $f_\gamma=|v_\gamma|^{1/2}$, $v^{1/2}_\gamma$, $v_\gamma\rho^{-1}_\gamma$ according to (4.4) and (4.5)). The estimate (4.10) follows from

$$\begin{aligned}\|M^0_0(|v_\gamma|^{1/2},\lambda)g\|^2_2&=\int_{|q|\leqq 1}d^3q\int_{S^2}d\omega|(U^0_0|v_\gamma|^{1/2}g)(\lambda,\omega,q)|^2\\ &=2m_\gamma(2n_\gamma)^{3/2}\int_{|q|\leqq 1}d^3q\,\lambda^{3/2}\|M(|v_\gamma|^{1/2},2m_\gamma\lambda(1-|q|^2))\\ &\qquad\qquad \hat{g}(\cdot,(2n_\gamma\lambda)^{1/2}q)\|^2_2,\\ &\qquad\qquad\qquad g\in\mathscr{S}(\mathscr{R}^6)\end{aligned}$$

where

$$M(|v_\gamma|^{1/2},\mu):\begin{cases}L^2(\mathscr{R}^3)\to L^2(S^2)\\ f\to(M(|v_\gamma|^{1/2},\mu)f)(\omega)=2^{-1/2}\mu^{1/4}(\overline{|v_\gamma|^{1/2}}f)(\mu^{1/2}\omega), \qquad \omega\in S^2\end{cases}$$

is a "two-particle" operator and

$$\hat{g}(\cdot,p)=(2\pi)^{-3/2}\int_{\mathscr{R}^3}d^3y\,e^{-ipy}g(\cdot,y), \qquad p\in\mathscr{R}^3$$

denotes the partial Fourier transform. Observing

$$\|M(|v_\gamma|^{1/2},\mu)\|_2^2=(2\pi)^{-2}\mu^{1/2}\|v_\gamma\|_1<\infty,$$

we infer

$$\begin{aligned}\|M_0^0(|v_\gamma|^{1/2},\lambda)g\|_2^2&\leqq \text{const. }\|v_\gamma\|_1\int_{|q|\leqq 1}d^3q(1-|q|^2)^{1/2}\lambda^2\|\hat{g}(\cdot,(2n_\gamma\lambda)^{1/2}q)\|_2^2\\&\leqq\text{const. }\|v_\gamma\|_1\lambda^{1/2}\int_{\mathscr{R}^3}d^3p\|\hat{g}(\cdot,p)\|_2^2\\&=\text{const. }\|v_\gamma\|_1\|g\|_2^2\lambda^{1/2}.\end{aligned}\qquad\square$$

5. Continuity of two-cluster scattering amplitudes. In this section we consider two-cluster scattering amplitudes and prove their continuity with respect to energy- and angle variables. Again we discuss their threshold behaviour, in particular we define the concept of elastic scattering lengths and derive an explicit formula in terms of the three-body resolvent.

In order to obtain an expression for the scattering amplitudes as a scalar product in $\mathscr{H}$ (in analogy to the two-body case, cf. e.g. [1], [2]) we introduce

Hypothesis (IV). In addition to H(II) we assume that $u_\alpha\in L^1(\mathscr{R}^3)$, $\alpha=1,2,3$.

According to [3] the scattering amplitude for two-cluster initial channels are proportional to the integral kernel of $R_{\beta\alpha}^{lj}(\lambda)$, more precisely one defines

$$f_{\beta\alpha}^{lj}(\lambda,\omega_\alpha^j\to\omega_\beta^l)=-2\pi i[2n_\alpha(\lambda-e_\alpha^j)]^{-1/2}R_{\beta\alpha}^{lj}(\lambda,\omega_\beta^l,\omega_\alpha^j),\tag{5.1}$$
$$\alpha\neq 0,\quad \beta=0,1,2,3.$$

Thus $f_{\beta\alpha}^{lj}$ splits up into a Born-term and a remainder as can be seen from (4.3)

$$\begin{aligned}&f_{\beta\alpha}^{lj}(\lambda,\omega_\alpha^j\to\omega_\beta^l)={}^{(1)}f_{\beta\alpha}^{lj}(\lambda,\omega_\alpha^j\to\omega_\beta^l)+{}^{(2)}f_{\beta\alpha}^{lj}(\lambda,\omega_\alpha^j\to\omega_\beta^l),\\&\qquad\alpha\neq 0,\quad\beta=0,1,2,3,\quad\lambda\in[\sup(e_\alpha^j,e_\beta^l),\infty)\backslash\overset{\Delta}{\mathscr{E}}.\end{aligned}\tag{5.2}$$

We start with the elastic case $\alpha=\beta\neq 0$, $j=l$.

THEOREM 5.1. *Assume* H(IV), $\alpha\neq 0$ *and* $e_\alpha^j\notin\overset{\Delta}{\mathscr{E}}$. *Then* $f_{\alpha\alpha}^{jj}(\lambda,\omega_\alpha^j\to\hat{\omega}_\alpha^j)$ *is continuous with respect to* $(\lambda,\omega_\alpha^j,\hat{\omega}_\alpha^j)\in\{[e_\alpha^j,\infty)\backslash\overset{\Delta}{\mathscr{E}})\}\times S^2\times S^2$. *In particular*

$$\begin{aligned}&{}^{(1)}f_{\alpha\alpha}^{jj}(\lambda,\omega_\alpha^j\to\hat{\omega}_\alpha^j)\\&\quad=-(2\pi)^{-1}n_\alpha\sum_{\substack{\gamma=1\\\gamma\neq\alpha}}^{3}(|v_\gamma|^{1/2}\exp(i[2n_\alpha(\lambda-e_\alpha^j)]^{1/2}\hat{\omega}_\alpha^jy_\alpha)\psi_\alpha^j,v_\gamma^{1/2}\\&\qquad\cdot\exp(i[2n_\alpha(\lambda-e_\alpha^j)]^{1/2}\omega_\alpha^jy_\alpha)\psi_\alpha^j),\\&\qquad(\lambda,\omega_\alpha^j,\hat{\omega}_\alpha^j)\in[e_\alpha^j,\infty)\times S^2\times S^2,\end{aligned}\tag{5.3}$$

$$\begin{aligned}&{}^{(2)}f_{\alpha\alpha}^{jj}(\lambda,\omega_\alpha^j\to\hat{\omega}_\alpha^j)=(2\pi)^{-1}n_\alpha\sum_{\substack{\gamma=1\\\gamma\neq\alpha}}^{3}\sum_{\substack{\delta=1\\\delta\neq\alpha}}^{3}(\rho_\gamma^{-1}|v_\gamma|^{1/2}\exp(i[2n_\alpha(\lambda-e_\alpha^j)]^{1/2}\hat{\omega}_\alpha^jy_\alpha)\psi_\alpha^j,\\&\quad\rho_\gamma\{J[1+\overset{\Delta}{D}]^{-1}K\}_{\gamma\delta}(\lambda+i0)\rho_\delta^{-1}|v_\delta|^{1/2}v_\delta^{1/2}\exp(i[2n_\alpha(\lambda-e_\alpha^j)]^{1/2}\omega_\alpha^jy_\alpha)\psi_\alpha^j),\\&\qquad(\lambda,\omega_\alpha^j,\hat{\omega}_\alpha^j)\in\{[e_\alpha^j,\infty)\backslash\overset{\Delta}{\mathscr{E}}\}\times S^2\times S^2.\end{aligned}\tag{5.4}$$

Here $(\cdot,\cdot)$ *means the scalar product in* $\mathscr{H}=L^2(\mathscr{R}^6;d^3x_\alpha\,d^3y_\alpha)$, $\psi_\alpha^j=\psi_\alpha^j(x_\alpha)$ *and in obvious notation the plane waves in* (5.3) *and* (5.4) *depend on the variable* y_α. *The* *threshold behaviour reads*

$$f^{jj}_{\alpha\alpha}(\lambda, \omega^j_\alpha \to \hat{\omega}^j_\alpha) \underset{\lambda \downarrow e^j_\alpha}{=} O(1). \tag{5.5}$$

Proof. Clearly

$$|v_\gamma|^{1/2}\, e^{\hat{q}^j_\alpha y_\alpha} \psi^j_\alpha, \quad \gamma \neq \alpha \quad (\hat{q}^j_\alpha = [2n_\alpha(\lambda - e^j_\alpha)]^{1/2} \hat{\omega}^j_\alpha)$$

is strongly continuous in $(\lambda, \hat{\omega}^j_\alpha) \in [e^j_\alpha, \infty) \times S^2$ by dominated convergence since

$$\| |v_\gamma|^{1/2}\, e^{i\hat{q}^j_\alpha y_\alpha} \psi^j_\alpha \|_2^2 = \text{const. } \|v_\gamma\|_1 \|\psi^j_\alpha\|_2^2 < \infty, \qquad \gamma \neq \alpha.$$

Similarly $\rho_\gamma^{-1}|v_\gamma|^{1/2}\, e^{i\hat{q}^j_\alpha y_\alpha}\psi^j_\alpha$, $\gamma \neq \alpha$ is strongly continuous in $(\lambda, \hat{\omega}^j_\alpha) \in [e^j_\alpha, \infty) \times S^2$ since

$$\begin{aligned} \|\rho_\gamma^{-1}|v_\gamma|^{1/2}\, e^{i\hat{q}^j_\alpha y_\alpha}\psi^j_\alpha\|_2^2 &\leqq \text{const.} \int_{\mathscr{R}^6} d^3x_\alpha\, d^3z_\alpha [1+|x_\alpha|]^{2+\nu} |\psi^j_\alpha(x_\alpha)|^2 [1+|z_\alpha|]^{2+\nu} |v_\gamma(z_\alpha)| \\ &\leqq \text{const. } \|(1+|\cdot|)^{1+\nu/2}\psi^j_\alpha\|_2^2 \|u_\gamma\|_1 < \infty, \qquad \gamma \neq \alpha \end{aligned}$$

by H(IV), Lemma 3.1 and

$$\begin{aligned} &|y_\gamma| \leqq |y_\alpha| + |x_\alpha| \quad (\text{cf. } (2.5)), \\ &\rho_\gamma^{-2}(y_\gamma) = [1+|y_\gamma|]^{2+\nu} \leqq [1+|x_\alpha|]^{2+\nu}[1+|y_\alpha|]^{2+\nu}. \end{aligned}$$

By Lemma 3.10, $\rho_\gamma\{(J[1+\overset{\Delta}{D}]^{-1}K)\}_{\gamma\delta}(\lambda + i0)\rho_\delta^{-1}|v_\delta|^{1/2}$ is norm continuous in $\lambda \in [e^j_\alpha, \infty) \backslash \overset{\Delta}{\mathscr{E}}$ completing the proof. □

The inelastic case $\alpha = \beta \neq 0$, $j \neq l$ is contained in the following theorem.

THEOREM 5.2. *Assume* H(IV), $\alpha \neq 0, j \neq l$ (*i.e.* $\psi^j_\alpha \neq$ const. ψ^l_α) *and* $\sup(e^j_\alpha, e^l_\alpha) \notin \overset{\Delta}{\mathscr{E}}$. *Then* $f^{lj}_{\alpha\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\alpha)$ *is continuous with respect to* $(\lambda, \omega^j_\alpha, \omega^l_\alpha) \in \{(\sup(e^j_\alpha, e^l_\alpha), \infty) \backslash \overset{\Delta}{\mathscr{E}}\} \times S^2 \times S^2$. *In particular*

$$\begin{aligned} {}^{(1)}f^{lj}_{\alpha\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\alpha) &= -(2\pi)^{-1} n_\alpha (\lambda - e^j_\alpha)^{-1/4} (\lambda - e^l_\beta)^{1/4} \\ &\quad \cdot \sum_{\substack{\gamma=1 \\ \gamma \neq \alpha}}^{3} (|v_\gamma|^{1/2} \exp(i[2n_\alpha(\lambda - e^l_\alpha)]^{1/2} \omega^l_\alpha y_\alpha)\psi^l_\alpha, v_\gamma^{1/2} \\ &\quad \cdot \exp(i[2n_\alpha(\lambda - e^j_\alpha)]^{1/2}\omega^j_\alpha y_\alpha)\psi^j_\alpha), \\ &\quad (\lambda, \omega^j_\alpha, \omega^l_\alpha) \in (\sup(e^j_\alpha, e^l_\alpha), \infty) \times S^2 \times S^2, \end{aligned} \tag{5.6}$$

$$\begin{aligned} {}^{(2)}f^{lj}_{\alpha\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\alpha) &= (2\pi)^{-1} n_\alpha (\lambda - e^j_\alpha)^{-1/4} (\lambda - e^l_\alpha)^{1/4} \sum_{\substack{\gamma=1 \\ \gamma \neq \alpha}}^{3} \sum_{\substack{\delta=1 \\ \delta \neq \alpha}}^{3} \\ &\quad \cdot (\rho_\gamma^{-1}|v_\gamma|^{1/2} \exp(i[2m_\alpha(\lambda - e^l_\alpha)]^{1/2}\omega^l_\alpha y_\alpha)\psi^l_\alpha, \rho_\gamma \\ &\quad \cdot \{J[1+\overset{\Delta}{D}]^{-1}K\}_{\gamma\delta}(\lambda + i0)\rho_\delta^{-1}|v_\delta|^{1/2} \\ &\quad \cdot v_\delta^{1/2} \exp(i[2n_\alpha(\lambda - e^j_\alpha)]^{1/2}\omega^j_\alpha y_\alpha)\psi^j_\alpha), \\ &\quad (\lambda, \omega^j_\alpha, \omega^l_\alpha) \in \{(\sup(e^j_\alpha, e^l_\alpha), \infty) \backslash \overset{\Delta}{\mathscr{E}}\} \times S^2 \times S^2. \end{aligned} \tag{5.7}$$

The threshold behaviour reads

$$(5.8)\qquad f^{lj}_{\alpha\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\alpha) \underset{\lambda \downarrow \sup(e^j_\alpha, e^l_\alpha)}{=} \begin{cases} O((\lambda - e^j_\alpha)^{-1/4}), & e^j_\alpha > e^l_\alpha, \\ O((\lambda - e^l_\alpha)^{1/4}), & e^j_\alpha < e^l_\alpha, \\ O(1), & e^j_\alpha = e^l_\alpha. \end{cases}$$

Proof. The proof is identical to that of Theorem 5.1.

Finally we discuss the rearrangement case $\alpha \neq \beta$, $\alpha \neq 0$, $\beta \neq 0$.

THEOREM 5.3. *Assume* H(IV), $\alpha \neq 0$, $\beta \neq 0$, $\alpha \neq \beta$ *and* $\sup(e^j_\alpha, e^l_\beta) \notin \overset{\Delta}{\mathscr{E}}$. *Then* $f^{lj}_{\beta\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\beta)$ *is continuous with respect to* $(\lambda, \omega^j_\alpha, \omega^l_\beta) \in \{(\sup(e^j_\alpha, e^l_\beta), \infty) \backslash \overset{\Delta}{\mathscr{E}}\} \times S^2 \times S^2$. *In particular*

$$\begin{aligned} {}^{(1)}f^{lj}_{\beta\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\beta) &= -(2\pi)^{-1}\, n_\alpha^{1/4} n_\beta^{3/4} (\lambda - e^j_\alpha)^{-1/4} (\lambda - e^l_\beta)^{1/4} \\ &\quad \cdot \sum_{\substack{\gamma=1 \\ \gamma \neq \alpha}}^{3} (|v_\gamma|^{1/2} \sigma_\alpha^{3\delta_{\gamma\beta}/2} \exp(i[2n_\beta(\lambda - e^l_\beta)]^{1/2} \omega^l_\beta y_\beta) \\ (5.9)\qquad &\quad \cdot \psi^l_\beta,\, v_\gamma^{1/2} \sigma_\alpha^{-3\delta_{\gamma\beta}/2} \\ &\quad \cdot \exp(i[2n_\alpha(\lambda - e^j_\alpha)]^{1/2} \omega^j_\alpha y_\alpha) \psi^j_\alpha), \\ &\qquad (\lambda, \omega^j_\alpha, \omega^l_\beta) \in (\sup(e^j_\alpha, e^l_\beta), \infty) \times S^2 \times S^2, \end{aligned}$$

$$\begin{aligned} {}^{(2)}f^{lj}_{\beta_\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\beta) &= (2\pi)^{-1} n_\alpha^{1/4} n_\beta^{3/4} (\lambda - e^j_\alpha)^{-1/4} (\lambda - e^l_\beta)^{1/4} \\ &\quad \cdot \sum_{\substack{\gamma=1 \\ \gamma \neq \beta}}^{3} \sum_{\substack{\delta=1 \\ \delta \neq \alpha}}^{3} (\rho_\gamma^{-1} |v_\gamma|^{1/2} \exp(i[2n_\beta(\lambda - e^l_\beta)]^{1/2} \omega^l_\beta y_\beta) \\ (5.10)\qquad &\quad \cdot \psi^l_\beta,\, \rho_\gamma \{J[1 + \overset{\Delta}{D}]^{-1} K\}_{\gamma\delta}(\lambda + i0) \rho_\delta^{-1} |v_\delta|^{1/2} \\ &\quad \cdot v_\delta^{1/2} \exp(i[2n_\alpha(\lambda - e^j_\alpha)]^{1/2} \omega^j_\alpha y_\alpha) \psi^j_\alpha), \\ &\qquad (\lambda, \omega^j_\alpha, \omega^l_\beta) \in \{(\sup(e^j_\alpha, e^l_\beta), \infty) \backslash \overset{\Delta}{\mathscr{E}}\} \times S^2 \times S^2. \end{aligned}$$

The threshold behaviour reads

$$(5.11)\qquad f^{lj}_{\beta\alpha}(\lambda, \omega^j_\alpha \to \omega^l_\beta) \underset{\lambda \downarrow \sup(e^j_\alpha, e^l_\beta)}{=} \begin{cases} O((\lambda - e^j_\alpha)^{-1/4}), & e^j_\alpha > e^l_\beta, \\ O((\lambda - e^l_\beta)^{1/4}, & e^j_\alpha < e^l_\beta, \\ O(1), & e^j_\alpha = e^l_\beta. \end{cases}$$

Proof. Since the discussion of ${}^{(2)}f^{lj}_{\beta\alpha}$ is identical to that of Theorem 5.1 we only consider ${}^{(1)}f^{lj}_{\beta\alpha}$. For $\gamma \neq \beta$ $(\gamma \neq \alpha)$ the corresponding proof of Theorem 5.1 applies. For $\gamma = \beta$ $(\gamma \neq \alpha)$ $e^{iq^j_\alpha \omega^j_\alpha y_\alpha} \sigma_\alpha^{-3/2} \psi^j_\alpha$ is strongly continuous in $(\lambda, \omega^j_\alpha) \in [e^j_\alpha, \infty) \times S^2$ since $e^{\kappa|\cdot|} \psi^j_\alpha \in L^2(\mathscr{R}^3)$ for all $\kappa < (-2m_\alpha e^j_\alpha)^{1/2}$ by Lemma 3.1. In addition $|v_\beta|^{1/2} \sigma_\alpha^{3/2}\, e^{iq^l_\beta \omega^l_\beta y_\beta} \psi^l_\beta$ is strongly continuous in $(\lambda, \omega^l_\beta) \in [e^l_\beta, \infty) \times S^2$ since

$$\begin{aligned} \| |v_\beta|^{1/2} \sigma_\alpha^{3/2}\, e^{iq^l_\beta \omega^l_\beta y_\beta} \psi^l_\beta \|_2^2 &= \text{const.} \int_{\mathscr{R}^6} d^3x_\alpha\, d^3z_\alpha [1 + |x_\alpha|]^{-3-3\nu/2} |v_\beta(z_\alpha)|\, |\psi^l_\beta(z_\alpha)|^2 \\ &= \text{const.}\, \|(1 + |\cdot|)^{-3-3\nu/2}\|_1 \|\, |v_\beta|^{1/2} \psi^l_\beta \|_2^2 < \infty, \qquad \beta \neq \alpha. \qquad \square \end{aligned}$$

Scattering amplitudes have also been discussed in [27] on the basis of Faddeev's original treatment ([14]) (cf. also [32]). Analyticity properties of scattering amplitudes in the case of dilation analytic two-body potentials are studied in [10], [18], [19]. For exponentially decaying two-body interactions their analytic continuation to the corresponding Riemann surface is considered in [7].

Finally we turn to a discussion of elastic scattering lengths.

DEFINITION 5.4. Assume H(IV), $\alpha \neq 0$ and $e_\alpha^j \notin \overset{\Delta}{\mathscr{E}}$. Then the elastic scattering length $A_{\alpha\alpha}^{jj}$ is defined by

$$A_{\alpha\alpha}^{jj} = -\lim_{\lambda \downarrow e_\alpha^j} f_{\alpha\alpha}^{jj}(\lambda, \omega_\alpha^j \to \hat{\omega}_\alpha^j). \tag{5.12}$$

An explicit expression for $A_{\alpha\alpha}^{jj}$ in terms of the three-body resolvent $G(z)$ (in analogy to the two-body situation [1], [2]) reads as follows.

THEOREM 5.5. *Assume* H(IV), $\alpha \neq 0$, $e_\alpha^j \notin \overset{\Delta}{\mathscr{E}}$. *Then*

$$\begin{aligned}A_{\alpha\alpha}^{jj} &= (2\pi)^{-1} n_\alpha \sum_{\substack{\gamma=1\\ \gamma\neq\alpha}}^{3} (|v_\gamma|^{1/2}\psi_\alpha^j, v_\gamma^{1/2}\psi_\alpha^j)\\ &\quad - (2\pi)^{-1} n_\alpha \sum_{\substack{\gamma=1\\ \gamma\neq\alpha}}^{3} \sum_{\substack{\delta=1\\ \delta\neq\alpha}}^{3} (\rho_\gamma^{-1}|v_\gamma|^{1/2}\psi_\alpha^j, \rho_\gamma\{J[1+\overset{\Delta}{D}]^{-1}K\}_{\gamma\delta}\\ &\qquad\qquad (e_\alpha^j + i0)\rho_\delta^{-1}|v_\delta|^{1/2}v_\delta^{1/2}\psi_\alpha^j)\\ &= (2\pi)^{-1} n_\alpha \sum_{\substack{\gamma=1\\ \gamma\neq\alpha}}^{3} (|v_\gamma|^{1/2}\psi_\alpha^j, v_\gamma^{1/2}\psi_\alpha^j)\\ &\quad - (2\pi)^{-1} n_\alpha \sum_{\substack{\gamma=1\\ \gamma\neq\alpha}}^{3} \sum_{\substack{\delta=1\\ \delta\neq\alpha}}^{3} (\rho_\gamma^{-1}|v_\gamma|^{1/2}\psi_\alpha^j, \rho_\gamma v_\gamma^{1/2}\\ &\qquad\qquad \cdot (H - e_\alpha^j - i0)^{-1}|v_\delta|^{1/2}\rho_\delta\rho_\delta^{-1}v_\delta^{1/2}\psi_\alpha^j).\end{aligned} \tag{5.13}$$

Proof. This is obvious by the proof of Theorem 5.1.

Remark 5.6. For $e_{\alpha_0}^{j_0} = E_0^{(2)}$, $E_0^{(2)} \notin \overset{\Delta}{\mathscr{E}}$, $A_{\alpha_0\alpha_0}^{j_0j_0}$ is real.

Proof. It suffices to note that by Lemma 3.10

$$\rho_\gamma|v_\gamma|^{1/2}(H - E_0^{(2)} - i0)^{-1}|v_\delta|^{1/2}\rho_\delta = \rho_\gamma|v_\gamma|^{1/2}(H - E_0^{(2)} + i0)^{-1}|v_\delta|^{1/2}\rho_\delta, \qquad \gamma, \delta = 1, 2, 3.$$

□

Remark 5.7. The analogue of (5.13) in the two-body case reads for h_α (cf. [1], [2])

$$\begin{aligned}a_\alpha &= (2\pi)^{-1} m_\alpha(|v_\alpha|^{1/2}, v_\alpha^{1/2}) - (2\pi)^{-1} m_\alpha(|v_\alpha|^{1/2}, v_\alpha^{1/2}(h_\alpha - i0)^{-1}|v_\alpha|^{1/2}v_\alpha^{1/2})\\ &= (2\pi)^{-1} m_\alpha(|v_\alpha|^{1/2}, [1 + v_\alpha^{1/2}(h_{0,\alpha} - i0)^{-1}|v_\alpha|^{1/2}]^{-1}v_\alpha^{1/2}), \qquad \alpha = 1, 2, 3.\end{aligned} \tag{5.14}$$

For the physical relevance of scattering lengths in three-body systems see, e.g., [28] and the references cited therein.

6. Analytic expansions around thresholds in $\boldsymbol{\theta}\backslash\{0\}$. Finally we use the exponential decay of v_α in H(III) to extend our previous threshold considerations by deriving analytic expansions of two-cluster scattering operators and amplitudes with respect to channel momenta near points in $\theta\backslash\{0\}$.

We start with ($^{(}\hat{\rho}^{)}_\beta$ denotes ρ_β or $\hat{\rho}_\beta$)

LEMMA 6.1. *Assume* H(III) *and* $\alpha \neq 0$. *If* $M_\alpha^j(\lambda)$, $\lambda \geqq e_\alpha^j$ *denotes one of the operators* $M_\alpha^j(|v_\gamma|^{1/2}, \lambda)$, $\gamma \neq \alpha$, $M_\alpha^j(^{(}\hat{\rho}^{)}_\alpha, \lambda)$, $M_\alpha^j(^{(}\hat{\rho}^{)-1}_\gamma|v_\gamma|^{1/2}, \lambda)$, $\gamma \neq \alpha$ *then* $(\lambda - e_\alpha^j)^{-1/4}M_\alpha^j(\lambda)$

is analytic in $(\lambda - e_\alpha^j)^{1/2}$ *near zero in* $\mathcal{B}_2(\mathcal{H}, L^2(S^2))$*-norm. Moreover* $M_\alpha^j(\lambda)$ *is analytic in* $(\lambda - \lambda_0)$ *near zero in* $\mathcal{B}_2(\mathcal{H}, L^2(S^2))$*-norm for all* $\lambda_0 > e_\alpha^j$.

Proof. (a) Taking $f_\gamma = |v_\gamma|^{1/2}$ in (4.11) and observing $(\gamma \neq \alpha)$

$$\int_{\mathcal{R}^6} d^3x_\alpha\, d^3y_\alpha |v_\gamma(cx_\alpha + dy_\alpha)| \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}|y_\alpha|)|\psi_\alpha^j(x_\alpha)|^2$$

$$= d^{-3}\int_{\mathcal{R}^6} d^3x_\alpha\, d^3z_\alpha \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}|z_\alpha|/d)|v_\gamma(z)|$$

$$\cdot \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}c|x_\alpha|/d)|\psi_\alpha^j(x_\alpha)|^2 < \infty$$

for $|\lambda - e_\alpha^j|$ sufficiently small the assertions follow for $M_\alpha^j(|v_\gamma|^{1/2}, \lambda)$, $\gamma \neq \alpha$ concerning the expansion near e_α^j. Similar for the expansion near $\lambda_0 > e_\alpha^j$. (Note that $e^{\varepsilon|\cdot|}v_\gamma = e^{-(b-\varepsilon)|\cdot|}u_\gamma \in L^1(\mathcal{R}^3)$ for $\varepsilon > 0$ small enough.)

(b) Taking $f_\gamma = {}^{(}\hat{\rho}^{)}_\alpha$ in (4.11), we infer the assertions for $M_\alpha^j({}^{(}\hat{\rho}^{)}, \lambda)$ from

$$\int_{\mathcal{R}^6} d^3x_\alpha\, d^3y_\alpha |{}^{(}\hat{\rho}^{)}_\alpha(y_\alpha)|^2 \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}|y_\alpha|)|\psi_\alpha^j(x_\alpha)|^2 < \infty$$

for $|\lambda - e_\alpha^j|$ small enough.

(c) Choosing $f_\gamma = {}^{(}\hat{\rho}^{)-1}_\gamma |v_\gamma|^{1/2}$ in (4.11) we prove the assertions for $M_\alpha^j({}^{(}\hat{\rho}^{)-1}_\gamma |v_\gamma|^{1/2}, \lambda)$ as follows: Noting

$$x_\gamma = cx_\alpha + dy_\alpha, \qquad y_\gamma = c'x_\alpha + d'y_\alpha, \qquad \gamma \neq \alpha,$$

$$|d'/d| \leqq 1, \qquad |c' - d^{-1}\, d'c| = 1$$

(cf. (2.5)) we obtain

$$\int_{\mathcal{R}^6} d^3x_\alpha\, d^3y_\alpha {}^{(}\hat{\rho}^{)-2}_\gamma(c'x_\alpha + d'y_\alpha) \exp(-b|cx_\alpha + dy_\alpha|)|u_\gamma(cx_\alpha + dy_\alpha)|$$

$$\cdot \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}|y_\alpha|)|\psi_\alpha^j(x_\alpha)|^2$$

$$\leqq d^{-3}\int_{\mathcal{R}^6} d^3x_\alpha\, d^3z_\alpha {}^{(}\hat{\rho}^{)-2}_\gamma([c' - d^{-1}\, d'c]x_\alpha + d^{-1}\, d'z_\alpha)\, e^{-b|z_\alpha|}|u_\gamma(z_\alpha)|$$

$$\cdot \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}|z_\alpha|/d)$$

$$\cdot \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}c|x_\alpha|/d)|\psi_\alpha^j(x_\alpha)|^2$$

$$\leqq d^{-3}\int_{\mathcal{R}^6} d^3x_\alpha\, d^3z_\alpha \exp(2a_\gamma|x_\alpha|) \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}c|x_\alpha|/d)|\psi_\alpha^j(x)|^2$$

$$\cdot \exp(2a_\gamma|z_\alpha|) \exp(2[2n_\alpha|\lambda - e_\alpha^j|]^{1/2}|z_\alpha|/d)\, e^{-b|z_\alpha|}|u_\gamma(z_\alpha)| < \infty$$

for $|\lambda - e_\alpha^j|$ small enough since

$$a_\gamma < \inf_{\beta=1,2,3}[-2m_\beta\, e_\beta^{N_\beta}]^{1/2}, \qquad 2a_\gamma < b. \qquad \square$$

LEMMA 6.2. *Assume* H(III). *Then* $\overset{\Delta}{D}(\lambda+i0)$ *is norm analytic in* $(\lambda-\lambda_0)^{1/2}$ *near zero for all* $\lambda_0<0$. *Thus* $[1+\overset{\Delta}{D}(\lambda+i0)]^{-1}$ *is norm analytic in* $(\lambda-\lambda_0)^{1/2}$ *near zero for all* $\lambda_0<0$, $\lambda_0\notin\overset{\Delta}{\mathscr{E}}$.

Proof. Cf. Lemma 3.7. (a) $D_{00,\gamma\delta}(z)$ is analytic in $z\in\mathscr{C}\backslash[0,\infty)$ and hence in $(\lambda-\lambda_0)$.

(b) $D_{01,\gamma\delta}(z)$ is analytic in $z\in\mathscr{C}\backslash[E_0^{(2)},\infty)$ because of the term $\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$, the rest is analytic in $z\in\mathscr{C}\backslash[0,\infty)$.

$\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta=\bigoplus_{m=1}^{N_\delta}(\psi_\delta^m,\cdot)\psi_\delta^m\otimes e^{-\hat{a}|y_\delta|}[-(2n_\delta)^{-1}\Delta_{y_\delta}-(z-e_\delta^m)]^{-1}e^{-\hat{a}|y'_\delta|}$.

$\lambda_0<e_\delta^1:\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$ is norm analytic in $(z-\lambda_0)$ near zero.

$\lambda_0>e_\delta^1$, $\lambda_0\neq e_\delta^m$, $m=2,\cdots,N_\delta:\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$ is norm analytic in $(z-\lambda_0)$ near zero.

$\lambda_0\geqq e_\delta^1$, $\lambda_0=e_\delta^m$ for some $m=1,\cdots,N_\delta:\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$ is norm analytic in $(z-\lambda_0)^{1/2}$ near zero.

(c) $D_{10,\gamma\delta}$ is independent of z.

(d) $D_{11,\gamma\delta}(z)=[\hat{\rho}_\gamma^{-1}E_\gamma e^{-b|x_\delta|}|u_\delta|^{1/2}\hat{\rho}_\delta^{-1}][u_\delta^{1/2}E_\delta]\hat{\rho}_\delta E_\delta G_\delta(z)\hat{\rho}_\delta$ and hence (b) applies again.

Altogether $\overset{\Delta}{D}(\lambda+i0)$ is norm analytic in $(\lambda-\lambda_0)^{1/2}$ near zero for all $\lambda_0<0$. □

LEMMA 6.3. *Assume* H(III), $\alpha\neq0$, $\beta\neq0$ *and* $\sup(e_\alpha^j,e_\beta^l)\notin\overset{\Delta}{\mathscr{E}}$. *Then* $R_{\beta\alpha}^{lj}(\lambda)\in\mathscr{B}_1(L^2(S^2))$ *and* $R_{\beta\alpha}^{lj}(\lambda)$ *is continuous in* $\mathscr{B}_1$*-norm for* $\lambda\in[\sup(e_\alpha^j,e_\beta^l),\infty)\backslash\overset{\Delta}{\mathscr{E}}$. *Moreover* $R_{\beta\alpha}^{lj}(\lambda)$ *has the following threshold expansions valid in* $\mathscr{B}_1(L^2(S^2))$*-norm when* $|\lambda-\sup(e_\alpha^j,e_\beta^l)|$ *is small enough*:

Elastic case: $\alpha=\beta, j=l$.

$$R_{\alpha\alpha}^{jj}(\lambda)=\sum_{n=1}^{\infty}R_{\alpha\alpha,n}^{jj}(\lambda-e_\alpha^j)^{n/2}. \tag{6.1}$$

Inelastic case: $\alpha=\beta$, $j\neq l$ (*i.e.* $\psi_\alpha^j\neq$ const. ψ_α^l).

$$\begin{aligned}R_{\alpha\alpha}^{lj}(\lambda)&=[\lambda-\sup(e_\alpha^j,e_\alpha^l)]^{1/4}\sum_{n=0}^{\infty}R_{\alpha\alpha,n}^{lj}[\lambda-\sup(e_\alpha^j,e_\alpha^l)]^{n/2}, \qquad e_\alpha^j\neq e_\alpha^l,\\ R_{\alpha\alpha}^{lj}(\lambda)&=\sum_{n=1}^{\infty}\tilde{R}_{\alpha\alpha,n}^{lj}(\lambda-e_\alpha^j)^{n/2}, \qquad e_\alpha^j=e_\alpha^l.\end{aligned} \tag{6.2}$$

Rearrangement case: $\alpha\neq\beta$.

$$\begin{aligned}R_{\beta\alpha}^{lj}(\lambda)&=[\lambda-\sup(e_\alpha^j,e_\beta^l)]^{1/4}\sum_{n=0}^{\infty}R_{\beta\alpha,n}^{lj}[\lambda-\sup(e_\alpha^j,e_\alpha^l)]^{n/2}, \qquad e_\alpha^j\neq e_\beta^l,\\ R_{\beta\alpha}^{lj}(\lambda)&=\sum_{n=1}^{\infty}\tilde{R}_{\beta\alpha,n}^{lj}(\lambda-e_\alpha^j)^{n/2}, \qquad e_\alpha^j=e_\beta^l.\end{aligned} \tag{6.3}$$

Proof. (a) ${}^{(1)}R_{\beta\alpha}^{lj}(\lambda)$: The elastic and inelastic cases directly follow from Lemma 6.1. The rearrangement case is treated as follows:

$${}^{(1)}R_{\beta\alpha}^{lj}(\lambda)=-2\pi i\sum_{\substack{\gamma=1\\ \gamma\neq\alpha}}^{3}M_\beta^l(|v_\gamma|^{1/2},\lambda)M_\alpha^j(v_\gamma^{1/2},\lambda)^*$$

and hence the summand $\gamma\neq\beta$ is treated identical to the (in)-elastic case. For $\gamma=\beta$ $(\gamma\neq\alpha)$ we use

$$M_\gamma^l(|v_\gamma|^{1/2},\lambda)M_\alpha^j(v_\gamma^{1/2},\lambda)^*=M_\gamma^l(\hat{\rho}_\gamma,\lambda)[E_\gamma^l|v_\gamma|^{1/2}]M_\alpha^j(\hat{\rho}_\gamma^{-1}v_\gamma^{1/2},\lambda)^* \tag{6.4}$$

and again Lemma 6.1.

(b) ${}^{(2)}R^{lj}_{\beta\alpha}(\lambda)$: Since $[1+\overset{\Delta}{D}(z)]^{-1}$ has been considered in Lemma 6.2 we concentrate on the "*MJ*" and "*KM*"-terms:

"*MJ*":

$$\sum_{\substack{\gamma=1\\ \gamma\neq\beta}}^{3} M^l_\beta(\hat\rho_\gamma^{-1}|v_\gamma|^{1/2},\lambda)\{\hat\rho_\gamma g_{0,\gamma}+[v_\gamma^{1/2}E_\gamma]\hat\rho_\gamma E_\gamma G_\gamma(\lambda+i0)\hat\rho_\gamma g_{1,\gamma}\},\qquad g=\begin{pmatrix}g_0\\ g_1\end{pmatrix}\in\overset{\Delta}{\mathscr{H}}$$

and we need only to apply Lemma 6.1 and the proof of Lemma 6.2 to obtain the corresponding $\mathscr{B}_2$-expansions.

"*KM*": $\delta\neq\alpha$.

$$K_{1,\gamma\delta}M^j_\alpha(v_\delta\rho_\delta^{-1},\lambda)^*=[\hat\rho_\gamma^{-1}E_\gamma\rho_\delta][E_\gamma|v_\delta|^{1/2}]M^j_\alpha(\rho_\delta^{-1}v_\delta^{1/2},\lambda)^*,$$

$$(K_{0,\gamma\delta}\rho_\delta^{-1}|v_\delta|^{1/2})(\lambda+i0)M^j_\alpha(v_\delta^{1/2},\lambda)^*=v_\gamma^{1/2}(1-E_\gamma)G_\gamma(\lambda+i0)|v_\delta|^{1/2}M^j_\alpha(v_\delta^{1/2},\lambda)^*$$

and we apply again Lemma 6.1 since $v_\gamma^{1/2}(1-E_\gamma)G_\gamma(z)|v_\delta|^{1/2}$ is analytic in $z\in\mathscr{C}\backslash[0,\infty)$. □

Given Lemmas 6.1-6.3, we are able to formulate the following.

THEOREM 6.4. *Assume* H(III), $\alpha\neq 0$, $\beta\neq 0$ *and* $\sup(e^j_\alpha,e^l_\beta)\notin\overset{\Delta}{\mathscr{E}}$. *Then the averaged total cross section* $\bar\sigma^{lj}_{\beta\alpha}(\lambda)$ *is continuous in* $\lambda\in(\sup(e^j_\alpha,e^l_\beta),\infty)\backslash\overset{\Delta}{\mathscr{E}}$ *and has the following Taylor* (*resp. Laurent*) *expansions near the threshold* $\sup(e^j_\alpha,e^l_\beta)$:

Elastic case: $\alpha=\beta, j=l$.

$$\bar\sigma^{jj}_{\alpha\alpha}(\lambda)=\sum_{n=0}^{\infty}\bar\sigma^{jj}_{\alpha\alpha,n}(\lambda-e^j_\alpha)^{n/2},\ \bar\sigma^{jj}_{\alpha\alpha,0}=4\pi|A^{jj}_{\alpha\alpha}|^2.\tag{6.5}$$

Inelastic case: $\alpha=\beta$, $j\neq l$ (*i.e.* $\psi^j_\alpha\neq$ const. ψ^l_α).

$$\begin{aligned}\bar\sigma^{lj}_{\alpha\alpha}(\lambda)&=\sum_{n=-1}^{\infty}\bar\sigma^{lj}_{\alpha\alpha,n}(\lambda-e^j_\alpha)^{n/2}, && e^j_\alpha>e^l_\alpha,\\ \bar\sigma^{lj}_{\alpha\alpha}(\lambda)&=\sum_{n=1}^{\infty}\hat{\bar\sigma}^{lj}_{\alpha\alpha,n}(\lambda-e^l_\alpha)^{n/2}, && e^j_\alpha<e^l_\alpha,\\ \bar\sigma^{lj}_{\alpha\alpha}(\lambda)&=\sum_{n=0}^{\infty}\tilde{\bar\sigma}^{lj}_{\alpha\alpha,n}(\lambda-e^j_\alpha)^{n/2}, && e^j_\alpha=e^l_\alpha.\end{aligned}\tag{6.6}$$

Rearrangement case: $\alpha\neq\beta$.

$$\begin{aligned}\bar\sigma^{lj}_{\beta\alpha}(\lambda)&=\sum_{n=-1}^{\infty}\bar\sigma^{lj}_{\beta\alpha,n}(\lambda-e^j_\alpha)^{n/2}, && e^j_\alpha>e^l_\beta,\\ \bar\sigma^{lj}_{\beta\alpha}(\lambda)&=\sum_{n=1}^{\infty}\hat{\bar\sigma}^{lj}_{\beta\alpha,n}(\lambda-e^l_\beta)^{n/2}, && e^j_\alpha<e^l_\beta,\\ \bar\sigma^{lj}_{\beta\alpha}(\lambda)&=\sum_{n=0}^{\infty}\tilde{\bar\sigma}^{lj}_{\beta\alpha,n}(\lambda-e^j_\alpha)^{n/2}, && e^j_\alpha=e^l_\beta.\end{aligned}\tag{6.7}$$

Proof. All expansions directly follow from Lemma 6.3. Since without loss of generality we may assume $u_\alpha\in L^1(\mathscr{R}^3)$, $\alpha=1,2,3$ (otherwise $v_\alpha(x_\alpha)=e^{-b'|x_\alpha|}e^{-(b-b')|x_\alpha|}u_\alpha(x_\alpha)\equiv e^{-b'|x_\alpha|}u'_\alpha(x_\alpha)$, $0<b'<b$, $u'_\alpha\in L^1(\mathscr{R}^3)\cap L^p(\mathscr{R}^3)$ for some $p>3/2$ and we need only to replace (b,u_α) by (b',u'_α), $\alpha=1,2,3$) Definition 5.4 applies and yields the assertion for $\bar\sigma^{jj}_{\alpha\alpha,0}$ in terms of $A^{jj}_{\alpha\alpha}$. □

Our final result reads

THEOREM 6.5. *Assume* H(III), $\alpha \neq 0$, $\beta \neq 0$ *and* $\sup(e_\alpha^j, e_\beta^l) \notin \overset{\Delta}{\mathscr{E}}$. *Then the scattering amplitude* $f_{\beta\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\beta^l)$ *is continuous in* $(\lambda, \omega_\alpha^j, \omega_\beta^l) \in \{(\sup(e_\alpha^j, e_\beta^l), \infty) \backslash \overset{\Delta}{\mathscr{E}}\} \times S^2 \times S^2$ *and has the following Taylor* (*resp. Laurent*) *expansion near the threshold* $\sup(e_\alpha^j, e_\beta^l)$:

Elastic case: $\alpha = \beta, j = l$.

$$(6.8)\quad f_{\alpha\alpha}^{jj}(\lambda, \omega_\alpha^j \to \hat{\omega}_\alpha^j) = \sum_{n=0}^{\infty} f_{\alpha\alpha,n}^{jj}(\omega_\alpha^j \to \hat{\omega}_\alpha^j)(\lambda - e_\alpha^j)^{n/2}, \qquad f_{\alpha\alpha,0}^{jj}(\omega_\alpha^j \to \hat{\omega}_\alpha^j) = -A_{\alpha\alpha}^{jj}.$$

Inelastic case: $\alpha = \beta$, $j \neq l$ (*i.e.* $\psi_\alpha^j \neq \text{const.}\ \psi_\alpha^l$).

$$f_{\alpha\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\alpha^l) = (\lambda - e_\alpha^j)^{-1/4} \sum_{n=0}^{\infty} f_{\alpha\alpha,n}^{lj}(\omega_\alpha^j \to \omega_\alpha^l)(\lambda - e_\alpha^j)^{n/2}, \qquad e_\alpha^j > e_\alpha^l,$$

$$(6.9)\quad f_{\alpha\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\alpha^l) = (\lambda - e_\alpha^l)^{1/4} \sum_{n=0}^{\infty} \hat{f}_{\alpha\alpha,n}^{lj}(\omega_\alpha^j \to \omega_\alpha^l)(\lambda - e_\alpha^l)^{n/2}, \qquad e_\alpha^j < e_\alpha^l,$$

$$f_{\alpha\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\alpha^l) = \sum_{n=0}^{\infty} \tilde{f}_{\alpha\alpha,n}^{lj}(\omega_\alpha^j \to \omega_\alpha^l)(\lambda - e_\alpha^j)^{n/2}, \qquad e_\alpha^j = e_\alpha^l.$$

Rearrangement case: $\alpha \neq \beta$.

$$f_{\beta\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\beta^l) = (\lambda - e_\alpha^j)^{-1/4} \sum_{n=0}^{\infty} f_{\beta\alpha,n}^{lj}(\omega_\alpha^j \to \omega_\beta^l)(\lambda - e_\alpha^j)^{n/2}, \qquad e_\alpha^j > e_\beta^l,$$

$$(6.10)\quad f_{\beta\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\beta^l) = (\lambda - e_\beta^l)^{1/4} \sum_{n=0}^{\infty} \hat{f}_{\beta\alpha,n}^{lj}(\omega_\alpha^j \to \omega_\beta^l)(\lambda - e_\beta^l)^{n/2}, \qquad e_\alpha^j < e_\beta^l,$$

$$f_{\beta\alpha}^{lj}(\lambda, \omega_\alpha^j \to \omega_\beta^l) = \sum_{n=0}^{\infty} \tilde{f}_{\beta\alpha,n}^{lj}(\omega_\alpha^j \to \omega_\beta^l)(\lambda - e_\alpha^j)^{n/2}, \qquad e_\alpha^j = e_\beta^l.$$

Proof. The proof is a direct consequence of Theorems 5.1-5.3 and Lemmas 6.1-6.3.

Given the expansion (6.8) one can define higher-order low energy parameters such as the elastic effective range parameter similar to the two-body case (cf. [1]). We omit the details.

LIE THEORY OF SOLUTIONS OF CERTAIN DIFFERINTEGRAL EQUATIONS*

M. A. AL-BASSAM† AND H. L. MANOCHA‡

Abstract. A new Lie algebraic technique based on the idea of fractional differentiation is evolved for constructing new models of representations of the Lie algebra $sl(2, C)$. Some of the Lie algebra elements in the new models are differintegral (integral-differential) operators while the basis vectors turn out to be solutions of differintegral equations

Key words. Lie algebra $sl(2, C)$, multiplier representation, generating functions, fractional derivative, Lie group $SL(2, C)$

AMS(MOS) subject classification. 33A75

1. Introduction. In [7], irreducible representations of the Lie algebras $sl(2, C)$, the oscillator algebra and the algebra of the Euclidean group in the plane have been determined, and models of these representations have been constructed in terms of first order differential operators (the operator types A, B, C', C'', D') acting on spaces of functions of two complex variables z, t. The basis vectors $f_m(z, t) = Z_m(z)t^m$ of such irreducible representations have turned out to be such that $Z_m(z)$ are functions of hypergeometric type. This connection between Lie algebras and special functions has led to recurrence relations, differential equations, generating functions and addition theorems for the functions of hypergeometric type. Later, in [8], the type A, $\cdots$, D$'$ operators have been used as building blocks to construct more complicated models of irreducible representations of these Lie algebras. Some of the Lie algebra elements in these models are second order differential operators. Furthermore, the models have been constructed in such a way that the basis vectors turn out to be special functions satisfying second order nonhomogeneous differential equations.

In this paper we propose to use type A and type B operators as building blocks for constructing new models of irreducible representations of the Lie algebras $sl(2, C)$. The method that we employ for this construction will be based on the idea of fractional differentiation. These new models will be such that somc of the Lie algebra elements in them are differintegral operators, while the basis vectors turn out to be solutions of differintegral equations.

In § 2, we define the fractional (or generalized) derivative of order α of an analytic function $f(z)$, written as $D_z^\alpha f(z)$, and then make use of this to express fractional derivative representations of some special functions which we need in our discussion.

In § 3, we discuss the generalized Leibnitz rule for the fractional derivative of the product of two analytic functions. We introduce a new operator $\mathscr{D}$, defined as $\mathscr{D}f(z) = z^{1-\lambda}D_z^{\mu-\lambda}f(z)$, and thereafter make use of the rule for obtaining operator expressions for $\mathscr{D}^{-1}L\mathscr{D}$, $L = z$, $z(d/dz)$, $z^2(d/dz)$. The new expressions turn out to be differintegral operators.

In §§ 4-6, we consider the type A and type B representations of $sl(2, C)$ [7, Chap. 5]. The basis functions corresponding to these representations are in terms of ${}_2F_1$ and ${}_1F_1$, respectively. Through $\mathscr{D}^{-1}L\mathscr{D}$, the type A,B operators induce new sets of Lie algebra operators, the corresponding basis vectors turning out in terms of ${}_3F_2$ and ${}_2F_2$, respectively. This leads to the construction of new models of representations of $sl(2, C)$.

2. Fractional derivative representation. In 1731, L. E. Euler considered the concept of fractional differentiation when he extended the familiar formula

$$\frac{d^n z^p}{dz^n} = p(p-1)(p-2)\cdots(p-n+1)z^{p-n} = \frac{p!}{(p-n)!}z^{p-n}$$

to $n=\alpha$, where α is as usual arbitrary, by writing

$$D_z^\alpha z^p = \frac{\Gamma(p+1)}{\Gamma(p-\alpha+1)} z^{p-\alpha}. \tag{2.1}$$

In fact, it was this formula which led Euler to invent the gamma function for fractional values of the factorial: $\Gamma(p+1)=p!$.

It immediately follows that if

$$g(z) = \sum_{n=0}^{\infty} a_n z^n, \qquad |z|<R, \tag{2.2}$$

then, for $0<|z|<R$,

$$\begin{aligned} D_z^\alpha(z^p g(z)) &= \sum_{n=0}^{\infty} a_n D_z^\alpha z^{p+n} \\ &= \sum_{n=0}^{\infty} a_n \frac{\Gamma(p+n+1)}{\Gamma(p+n-\alpha+1)} z^{p+n-\alpha}. \end{aligned} \tag{2.3}$$

Relation (2.3) fails to have meaning when p is a negative integer. Using (2.3), we list the following results:

$$D_z^{\lambda-\mu}\left\{z^{\lambda-1}\,{}_1F_1\left[\begin{matrix}\alpha; \\ \beta;\end{matrix}\; z\right]\right\} = \frac{\Gamma(\lambda)}{\Gamma(\mu)} z^{\mu-1}\,{}_2F_2\left[\begin{matrix}\alpha, & \lambda; \\ \beta, & \mu;\end{matrix}\; z\right], \qquad 0<|z|<\infty, \tag{2.4}$$

$$D_z^{\lambda-\mu}\left\{z^{\lambda-1}\,{}_2F_1\left[\begin{matrix}\alpha, \beta; \\ \gamma;\end{matrix}\; z\right]\right\} = \frac{\Gamma(\lambda)}{\Gamma(\mu)} z^{\mu-1}\,{}_3F_2\left[\begin{matrix}\alpha, \beta, \lambda; \\ \gamma, \mu;\end{matrix}\; z\right], \qquad 0<|z|<1, \tag{2.5}$$

$$\begin{aligned} D_z^{\lambda-\mu}\left\{z^{\lambda-1}e^{az}\,{}_1F_1\left[\begin{matrix}\alpha; \\ \beta;\end{matrix}\; bz\right]\right\} &= \frac{\Gamma(\lambda)}{\Gamma(\mu)} z^{\mu-1} F^{1:1;0}_{1:1;0}\left(\begin{matrix}\lambda: \alpha; -; \\ \mu: \beta; -;\end{matrix}\; az, bz\right), \\ &\qquad 0<|az|, \qquad |bz|<\infty, \end{aligned} \tag{2.6}$$

$$\begin{aligned} &D_z^{\lambda-\mu}\left\{z^{\lambda-1}(1-bz)^{-\alpha}2F_1\left[\begin{matrix}\alpha, \beta; \\ \gamma;\end{matrix}\; \frac{az}{1-bz}\right]\right\} \\ &= \frac{\Gamma(\lambda)}{\Gamma(\mu)} z^{\mu-1} F^{2:1;0}_{1:1;0}\left(\begin{matrix}\alpha, \lambda: \beta; —; \\ \mu: \gamma; —;\end{matrix}\; az, bz\right), \\ &\qquad\qquad 0<(|a|+|b|)|z|<1, \end{aligned} \tag{2.7}$$

$$\begin{aligned} D_z^{\lambda-\mu}\left\{z^{\lambda-1}F_2(\alpha; \beta, \beta'; \gamma, \gamma'; z, t)\right\} &= \frac{\Gamma(\lambda)}{\Gamma(\mu)} z^{\mu-1} F^{1:2;1}_{0:2;1}\left(\begin{matrix}\alpha: \beta, \lambda; \beta'; \\ -: \gamma, \mu; \gamma';\end{matrix}\; z, t\right), \\ &\qquad 0<|z|+|t|<1, \end{aligned} \tag{2.8}$$

$$\begin{aligned} &D_z^{\lambda-\mu}\left\{z^{\lambda-1}e^z\psi_2[\alpha; \gamma, \gamma'; -z, t]\right\} \\ &= \frac{\Gamma(\lambda)}{\Gamma(\mu)} z^{\mu-1} G^{1:1;2}_{0:2;1}\left(\begin{matrix}\gamma-\alpha: \lambda; \alpha, 1+\alpha-\gamma; \\ -: \mu, \gamma; \gamma';\end{matrix}\; z, -t\right), \\ &\qquad\qquad 0<|z|<\infty, \quad |t|<\infty, \end{aligned} \tag{2.9}$$

$$D_z^{\lambda-\mu}\left\{z^{\lambda-1}e^z\psi_2[\alpha;\alpha,\beta;-z,t]\right\}=\frac{\Gamma(\lambda)}{\Gamma(\mu)}z^{\mu-1}F^{1:1;0}_{1:2;0}\left(\begin{matrix}\alpha:\lambda;—;\\ \beta:\alpha,\mu;—;\end{matrix}\quad -zt,t\right),\tag{2.10}$$

$$0<|z|<\infty,\quad |t|<\infty,$$

$$\begin{aligned}&D_z^{\lambda-\mu}\left\{z^{\lambda-1}(1-z)^{-\beta}F_2\left[\alpha;\beta,\beta';\alpha,\gamma;\frac{-z}{1-z},t\right]\right\}\\&=\frac{\Gamma(\lambda)}{\Gamma(\mu)}z^{\mu-1}F^{2:2;0}_{1:2;0}\left(\begin{matrix}\alpha,\alpha':\beta,\lambda;—;\\ \beta':\alpha,\mu;—;\end{matrix}\quad -zt,t\right),\end{aligned}\tag{2.11}$$

$$0<|z|<1,\quad |zt|+|t|<1,$$

where [10],

$${}_pF_q\left[\begin{matrix}\alpha_1,\cdots,\alpha_p;\\ \beta_1,\cdots,\beta_q;\end{matrix}\quad z\right]=\sum_{n=0}^{\infty}\frac{(\alpha_1)_n\cdots(\alpha_p)_n}{(\beta_1)_n\cdots(\beta_q)_n}\frac{z^n}{n!},\tag{2.12}$$

$$|z|<\infty\quad \text{if } p\leqq q;\quad |z|<1\quad \text{if } p=q+1,$$

$$\psi_2(\alpha;\beta,\gamma;z,t)=\sum_{m,n=0}^{\infty}\frac{(\alpha)_{m+n}}{(\beta)_m(\gamma)_n}\frac{z^mt^n}{m!n!},\qquad 0\leqq|z|<\infty,\quad 0\leqq|t|<\infty,\tag{2.13}$$

$$F_2[\alpha;\beta,\beta';\gamma,\gamma';z,t]=\sum_{m,n=0}^{\infty}\frac{(\alpha)_{m+n}(\beta)_m(\beta')_n}{(\gamma)_m(\gamma')_n}\frac{z^mt^n}{m!n!},\qquad |z|+|t|<1,\tag{2.14}$$

$$\begin{aligned}&F^{A:B;B'}_{C:E;E'}\left(\begin{matrix}(a):(b);(b');\\ (c):(e);(e');\end{matrix}\quad z,t\right)\\&=\sum_{m,n=0}^{\infty}\frac{\prod_{j=1}^{A}(a_j)_{m+n}\prod_{j=1}^{B}(b_j)_m\prod_{j=1}^{B'}(b_j')_n}{\prod_{j=1}^{C}(c_j)_{m+n}\prod_{j=1}^{E}(e_j)_m\prod_{j=1}^{E'}(e_j')_n}\frac{z^mt^n}{m!n!},\end{aligned}\tag{2.15}$$

$$\begin{aligned}&G^{A:B;B'}_{C:E;E'}\left(\begin{matrix}(a):(b);(b');\\ (c):(e);(e');\end{matrix}\quad z,t\right)\\&=\sum_{m,n=0}^{\infty}\frac{\prod_{j=1}^{A}(a_j)_{m-n}\prod_{j=1}^{B}(b_j)_m\prod_{j=1}^{B'}(b_j')_n}{\prod_{j=1}^{C}(c_j)_{m-n}\prod_{j=1}^{E}(e_j)_m\prod_{j=1}^{E'}(e_j')_n}\frac{z^mt^n}{m!n!}.\end{aligned}\tag{2.16}$$

3. Generalized Leibnitz rule. Consider the Leibnitz rule from elementary calculus for the derivative of the product of two functions $u(z)$ and $v(z)$:

$$D_z^Nuv=\sum_{n=0}^{N}\binom{N}{n}D_z^{N-n}uD_z^nv.$$

A reasonable guess for the generalization of this result to fractional derivatives is

$$D_z^\alpha uv=\sum_{n=0}^{\infty}\binom{\alpha}{n}D_z^{\alpha-n}uD_z^nv.\tag{3.1}$$

This guess is indeed correct and it was given as early as 1867 by A. K. Grunwald [2]. It has been proved by Al-Bassam [1] and Osler [9] in a manner different from that of Grunwald.

In order to construct new models of representations, we introduce, for convenience's sake, operators $\mathcal{D}$ and $\mathcal{D}^{-1}$ defined as

$$\mathcal{D}f(z)=z^{1-\lambda}D_z^{\mu-\lambda}f(z),\tag{3.2}$$

$$\mathcal{D}^{-1}f(z)=D_z^{\lambda-\mu}z^{\lambda-1}f(z).\tag{3.3}$$

Indeed

$$\mathscr{D}\mathscr{D}^{-1}f(z)=\mathscr{D}^{-1}\mathscr{D}f(z)=f(z). \tag{3.4}$$

Using (3.1), one arrives at the following:

$$\mathscr{D}^{-1}z\mathscr{D}=z+(\lambda-\mu)\frac{d^{-1}}{dz^{-1}}, \tag{3.5}$$

$$\mathscr{D}^{-1}\left(z\frac{d}{dz}\right)\mathscr{D}=z\frac{d}{dz}+1-\mu, \tag{3.6}$$

$$\mathscr{D}^{-1}\left(z^2\frac{d}{dz}\right)\mathscr{D}=z^2\frac{d}{dz}+(1+\lambda-2\mu)z-\mu(\lambda-\mu)\frac{d^{-1}}{dz^{-1}}. \tag{3.7}$$

Note that d^{-1}/dz^{-1} is an indefinite integral in disguise.

4. Representation $D(u, m_0)$. Consider the representation $D(u, m_0)$ defined for u, $m_0\in C$ such that $0\leqq \operatorname{Re} m_0<1$ and $u\pm m_0$ are not integers [7, Chap. 5]. The representation space W has a basis $\{f_m\}$, $m\in S=\{m_0+n\colon n=0,\pm1,\cdots\}$, such that the action of $sl(2, C)$ on W is given by

$$\begin{gathered} J^+f_m=(m-u)f_{m+1},\quad J^-f_m=-(m+u)f_{m-1},\quad J^3f_m=mf_m,\\ (J^+J^-+J^3J^3-J^3)f_m=u(u+1)f_m. \end{gathered} \tag{4.1}$$

The operators $\{J^+, J^-, J^3\}$ satisfy the commutation relations

$$[J^3, J^\pm]=\pm J^\pm,\qquad [J^+, J^-]=2J^3, \tag{4.2}$$

and as such generate a Lie algebra which is an isomorphic image of the complex Lie algebra $sl(2, C)$ [7, p. 7].

4.1. Type A operators. The type A operators $\{J^+, J^-, J^3\}$ satisfying (4.1), and indeed (4.2), are

$$\begin{aligned} J^+&=t\left(z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}-u\right),\\ J^-&=t^{-1}\left[z(1-z)\frac{\partial}{\partial z}-t\frac{\partial}{\partial t}+z(q+u)-u\right],\\ J^3&=t\frac{\partial}{\partial t}, \end{aligned} \tag{4.3}$$

and

$$f_m(z,t)={}_2F_1\left[\begin{matrix} m-u, -q-u;\\ -2u;\end{matrix}\ z\right]t^m. \tag{4.4}$$

The multiplier representation T induced by the operators (4.3) on $\mathscr{F}$, the space of all analytic functions in a neighbourhood of (z_0, t_0), is

$$\begin{aligned}{}[T(g)f](z,t)&=(d+bt)^u\left(a+\frac{c}{t}\right)^{-q}\left(a-\frac{c(z-1)}{t}\right)^{q+u}\\ &\quad\times f\left(\frac{zt}{(d+bt)(at-c(z-1))},\frac{c+at}{d+bt}\right),\end{aligned} \tag{4.5}$$

$|bt/d|<1$, $|c/at|<1$, $|c(z-1)/at|<1$, $-\pi<\arg a$, $\arg d<\pi$, and

$$g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \qquad ad\text{-}bc=1,$$

lies in a sufficiently small neighbourhood of the identity element

$$e=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \varepsilon SL(2, C).$$

Now we use the type A operators as building blocks for constructing a new model of irreducible representations of $sl(2, C)$.

To illustrate the method, we rewrite, with the help of (2.3),

$$J^+f_m=t\left(z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}-u\right)f_m=(m-u)f_{m+1},$$

$$f_m(z, t)={}_2F_1\left[\begin{matrix} m-u, -q-u; \\ -2u; \end{matrix}\ z\right]t^m,$$

as

$$J^+\left\{z^{1-\lambda}\frac{\partial^{\mu-\lambda}}{\partial z^{\mu-\lambda}}\left(z^{\mu-1}{}_3F_2\left[\begin{matrix} m-u, -q-u, \lambda; \\ -2u, \mu; \end{matrix}\ z\right]t^m\right)\right\}$$

$$=(m-u)z^{1-\lambda}\frac{\partial^{\mu-\lambda}}{\partial z^{\mu-\lambda}}\left(z^{\mu-1}{}_3F_2\left[\begin{matrix} 1+m-u, -q-u, \lambda; \\ -2u, \mu; \end{matrix}\ z\right]t^m\right).$$

It follows that

(4.6) $$K^+h_m=(m-u)h_{m+1},$$

where, by (3.6),

(4.7) $$K^+=\mathscr{D}^{-1}J^+\mathscr{D}=t\left(z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}+1-\mu-u\right),$$

and

(4.8) $$h_m(z, t)=z^{\mu-1}{}_3F_2\left[\begin{matrix} m-u, -q-u, \lambda; \\ -2u, \mu; \end{matrix}\ z\right]t^m,$$

$$m=m_0+n, \quad n=0, \pm1, \pm2, \cdots.$$

Similarly,

(4.9) $$K^-h_m=-(m+u)h_{m-1}, \qquad K^3h_m=mh_m$$

where

(4.10) $$K^-=\mathscr{D}^{-1}J^-\mathscr{D}=t^{-1}\left[z(1-z)\frac{\partial}{\partial z}-t\frac{\partial}{\partial t}+(q+u+2\mu-1-\lambda)z\right.$$
$$\left.+1-\mu-u+(\lambda-\mu)(q+u+\mu)\frac{\partial^{-1}}{\partial z^{-1}}\right],$$

(4.11) $$K^3=\mathscr{D}^{-1}J^3\mathscr{D}=t\frac{\partial}{\partial t}.$$

Indeed,

$$\begin{aligned}&[K^3, K^\pm]=\pm K^\pm, \qquad [K^+, K^-]=2K^3,\\ &(K^+K^-+K^3K^3-K^3)h_m=u(u+1)h_m.\end{aligned}\tag{4.12}$$

We have thus constructed a new model of irreducible representation $D(u, m_0)$ in terms of differintegral operators $\{K^+, K^-, K^3\}$ such that the vectors $h_m(z, t)$ defined by (4.8) form a basis of the representation space. Writing $h_m(z, t)=Z_m(z)t^m$, in terms of the functions $Z_m(z)$ the above relations take the form

$$\begin{aligned}&\left(z\frac{d}{dz}+1+m-\mu-u\right)Z_m(z)=(m-u)Z_{m+1}(z),\\ &\left[z(1-z)\frac{d}{dz}+(\lambda-\mu)(q+u+\mu)\frac{d^{-1}}{dz^{-1}}+(q+u+2\mu-\lambda-1)z+1-u-\mu-m\right]\\ &\quad\cdot Z_m(z)=-(m+u)Z_{m-1}(z),\\ &\left[z^2(1-z)\frac{d^2}{dz^2}+z\{(q+2u+3\mu-3-\lambda-m)z+2(1-\mu-u)\}\frac{d}{dz}\right.\\ &\qquad+(\lambda-\mu)(q+u+\mu)\frac{d^{-1}}{dz^{-1}}+z\\ &\qquad\left.\cdot\{(\lambda-\mu)(q+u+\mu)+(q+u+2\mu-\lambda-1)(1+m-u-\mu)\}\right]Z_m(z)\\ &\quad=(1-\mu)(\mu+2u)Z_m(z).\end{aligned}\tag{4.13}$$

The multiplier representation T' induced by the K-operators on $\mathcal{F}$ is

$$\begin{aligned}[T'(g)h](z, t)&=\mathcal{D}^{-1}\left[\exp\left(-\frac{b}{d}J^+\right)\exp(-cdJ^-)\exp(\tau J^3)(\mathcal{D}h)(z, t)\right.\\ &=\mathcal{D}^{-1}[T(g)(\mathcal{D}h)](z, t), \qquad e^{\tau/2}=d^{-1}.\end{aligned}\tag{4.14}$$

By (4.5) it follows that

$$\begin{aligned}[T'(g)h](z, t)=\mathcal{D}^{-1}\Bigg[&(d+bt)^u\left(a+\frac{c}{t}\right)^{-q}\left(a-\frac{c(z-1)}{t}\right)^{q+u}\\ &\times(\mathcal{D}h)\left(\frac{zt}{(d+bt)(at-c(z-1))}, \frac{c+at}{d+bt}\right)\Bigg],\end{aligned}\tag{4.15}$$

$|bt/d|<1$, $|c/at|<1$, $|c(z-1)/at|<1$ and $g\in SL(2, C)$ lies in small enough neighbourhood of e so that the above expression is uniquely defined.

In [5, § 2] it has been shown that 16 of the Horn functions of two variables [3] can be realized in terms of type A operators. In particular, the function

$$F=F_2[m_0-u; -q-u, \beta'; -2u, \gamma'; z, t]t^{m_0}\tag{4.16}$$

satisfies the Casimir eigenvalue equation

$$(J^+J^-+J^3J^3-J^3)F=u(u+1)F\tag{4.17}$$

as well as

$$[J^3J^3-J^+J^3+(m_0-\beta')J^+-(2m_0-\gamma'+1)J^3]F=m_0(\gamma'-m_0-1)F.\tag{4.18}$$

Likewise, it can be shown that

$$G = t^{m_0}(1-t)^{u-m_0}\,{}_2F_1\left[\begin{matrix} m_0-u, -q-u; & \dfrac{z}{1-t} \\ -2u; & \end{matrix}\right] \tag{4.19}$$

is a simultaneous solution of

$$(J^+J^- + J^3J^3 - J^3)G = u(u+1)G \tag{4.20}$$

and

$$[J^3J^3 - J^+J^3 + m_0J^+ - (2m_0+1)J^3]G = -m_0(1+m_0)G. \tag{4.21}$$

Thus, by (2.5) and (2.8), it follows that

$$\mathscr{H}_1 = t^{m_0}z^{\mu-1}F^{1:2;1}_{0:2;1}\left(\begin{matrix} m_0-u: -q-u, \lambda; \beta'; \\ —: -2u, \mu; \gamma'; \end{matrix}\ z, t\right) \tag{4.22}$$

satisfies the differintegral equation

$$(K^+K^- + K^3K^3 - K^3)\mathscr{H}_1 = u(u+1)\mathscr{H}_1 \tag{4.23}$$

as well as

$$[K^3K^3 - K^+K^3 + (m_0-\beta')K^+ - (2m_0-\gamma'+1)K^3]\mathscr{H}_1 = m_0(\gamma'-m_0-1)\mathscr{H}_1, \tag{4.24}$$

while

$$\mathscr{H}_2 = t^{m_0}z^{\mu-1}(1-t)^{u-m_0}\,{}_3F_2\left[\begin{matrix} m_0-u, -q-u, \lambda; & \dfrac{z}{1-t} \\ -2u, \mu; & \end{matrix}\right] \tag{4.25}$$

is a common solution of both

$$(K^+K^- + K^3K^3 - K^3)\mathscr{H}_2 = u(u+1)\mathscr{H}_2 \tag{4.26}$$

and

$$[K^3K^3 - K^+K^3 + m_0K^+ - (2m_0+1)K^3]\mathscr{H}_0 = -m_0(1+m_0)\mathscr{H}_2. \tag{4.27}$$

Now, we have the expansions [6], [11],

$$T'(g)\mathscr{H}_i = \sum_{n=-\infty}^{\infty} k_{in}(g)h_{m_0+n}, \qquad i = 1, 2, \tag{4.28}$$

each valid in a region determined by the inequalities (4.15).

The identities which follow as special cases from (4.28), are as under:

$$\begin{aligned}(1-t)^{-\alpha}&F^{1:2;1}_{0:2;1}\left(\begin{matrix} \alpha: \beta, \lambda; \beta'; \\ —: \gamma, \mu; \gamma'; \end{matrix}\ \frac{z}{1-t}, \frac{-\omega t}{1-t}\right) \\ &= \sum_{n=0}^{\infty} \frac{(\alpha)_n}{n!}\,{}_3F_2\left[\begin{matrix} \alpha+n, \beta, \lambda; & z \\ \gamma, \mu; & \end{matrix}\right]{}_2F_1\left[\begin{matrix} -n, \beta'; & \omega \\ \gamma'; & \end{matrix}\right]t^n, \\ &\qquad |t|<1, \qquad \left|\frac{z}{1-t}\right| + \left|\frac{\omega t}{1-t}\right| < 1,\end{aligned} \tag{4.29}$$

$$\begin{aligned}\left(1+\frac{c}{t}\right)^{\alpha-\gamma}&(1-c-t)^{-\alpha}F^{2:1;0}_{1:1;0}\left(\begin{matrix} \beta, \lambda: \alpha; —; \\ \mu: \gamma; —; \end{matrix}\ \frac{zt}{(c+t)(1-c-t)}, \frac{cz}{c+t}\right) \\ &= \sum_{n=-\infty}^{\infty} \frac{\Gamma(\alpha+n)}{\Gamma(\alpha)}\,{}_3F_2\left[\begin{matrix} \alpha+n, \beta, \lambda; & z \\ \gamma, \mu; & \end{matrix}\right]\frac{{}_2F_1(\alpha+n, 1+\alpha-\gamma-n; n+1; c)}{\Gamma(n+1)}t^n, \\ &\qquad \left|\frac{c}{t}\right| < 1, \quad |c+t| < 1, \quad \left|\frac{zt}{(c+t)(1-c-t)}\right| + \left|\frac{cz}{c+t}\right| < 1,\end{aligned} \tag{4.30}$$

$$(4.31)\qquad (1-t)^{-\alpha}{}_3F_2\left[\begin{matrix}\alpha,\beta,\lambda; & \dfrac{z}{1-t}\\ \gamma,\mu; & \end{matrix}\right]=\sum_{n=0}^{\infty}\frac{(\alpha)_n}{n!}{}_3F_2\left[\begin{matrix}\alpha+n,\beta,\lambda; & z\\ \gamma,\mu; & \end{matrix}\right]t^n,\quad |z|+|t|<1.$$

In (4.30), the terms corresponding to $n=-1,-2,-3,\cdots$ are well defined in view of the relation

$$(4.32)\qquad \begin{aligned}&\lim_{s\to-k}\frac{1}{\Gamma(1+s)}{}_2F_1\left[\begin{matrix}\alpha+s,1+\alpha-\gamma+s; & c\\ 1+s; & \end{matrix}\right]\\ &=\frac{(\alpha-k)_k(1+\alpha-\gamma-k)_k}{k!}c^k{}_2F_1\left[\begin{matrix}\alpha,1+\alpha-\gamma; & c\\ 1+k; & \end{matrix}\right].\end{aligned}$$

The above identities are valid for all α, β, β', γ, γ', λ, $\mu\in C$ such that α, $\alpha-\gamma$ are not integers and γ, γ', $\mu\neq 0,-1,-2,\cdots$.

4.2. Type B operators. The type B operators $\{J^+, J^-, J^3\}$ and the corresponding basis vectors $\{f_m\}$ satisfying (4.1) as well as (4.2) are

$$(4.33)\qquad \begin{aligned}J^+&=t\left(z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}-z+u+1\right),\\ J^-&=t^{-1}\left(z\frac{\partial}{\partial z}-t\frac{\partial}{\partial t}+u+1\right),\\ J^3&=t\frac{\partial}{\partial t},\end{aligned}$$

and

$$(4.34)\qquad f_m(z,t)=L^{(2u+1)}_{m-u-1}(z)t^m.$$

$L^{(2u+1)}_{m-u-1}(z)$ are generalized Laguerre functions defined as [10]

$$(4.35)\qquad L^{(\alpha)}_n(z)=\frac{\Gamma(1+\alpha+n)}{\Gamma(1+\alpha)\Gamma(1+n)}{}_1F_1\left[\begin{matrix}-n; & z\\ 1+\alpha; & \end{matrix}\right].$$

The multiplier representation induced by the J-operators on the space $\mathcal{F}$ is

$$(4.36)\qquad \begin{aligned}[T(g)f](z,t)&=(d+bt)^{-u-1}\left(a+\frac{c}{t}\right)^{-u-1}\exp\left(\frac{bzt}{d+bt}\right)\\ &\quad\cdot f\left(\frac{zt}{(at+c)(d+bt)},\frac{at+c}{d+bt}\right),\end{aligned}$$

$|c/at|<1$, $|bt/d|<1$, $-\pi<\arg a$, $\arg d<\pi$, $ad-bc=1$, and g lies in a sufficiently small neighbourhood of the identity element $e\in SL(2,C)$.

As in *I*, the operators J^+, J^-, J^3 give rise to the operators K^+, K^-, K^3:

$$(4.37)\qquad \begin{aligned}K^+&=\mathcal{D}^{-1}J^+\mathcal{D}=t\left[z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}-z+u-\mu+(\mu-\lambda)\frac{\partial^{-1}}{\partial z^{-1}}+2\right],\\ K^-&=\mathcal{D}^{-1}J^-\mathcal{D}=t^{-1}\left(z\frac{\partial}{\partial z}-t\frac{\partial}{\partial t}+u-\mu+2\right),\\ K^3&=\mathcal{D}^{-1}J^3\mathcal{D}=t\frac{\partial}{\partial t}\end{aligned}$$

such that

$$K^+h_m=(m-u)h_{m+1},\quad K^-h_m=-(m+u)h_{m-1},\quad K^3h_m=mh_m, \tag{4.38}$$

$$h_m(z,t)=\frac{\Gamma(u+m+1)}{\Gamma(2u+2)\Gamma(m-u)}z^{\mu-1}{}_2F_2\left[\begin{matrix}1+u-m,\lambda; \\ 2+2u,\mu;\end{matrix}\ z\right]t^m. \tag{4.39}$$

Again

$$\begin{gathered}[K^3,K^\pm]=\pm K^\pm,\qquad [K^+,K^-]=2K^3,\\ (K^+K^-+K^3K^3-K^3)h_m=u(u+1)h_m.\end{gathered} \tag{4.40}$$

If we write $h_m(z,t)=Z_m(z)t^m$, in terms of the functions $Z_m(z)$ the above relations become

$$\begin{gathered}\left[z\frac{d}{dz}+(\mu-\lambda)\frac{d^{-1}}{dz^{-1}}+m+u-\mu-z+2\right]Z_m(z)=(m-u)Z_{m+1}(z),\\ \left(z\frac{d}{dz}+u-\mu+2-z\right)Z_m(z)=-(m+u)Z_{m-1}(z),\\ \left[z^2\frac{d^2}{dz^2}+(2u-2\mu-z)z\frac{d}{dz}+(\mu-\lambda)(u-\mu-m-1)\frac{d^{-1}}{dz^{-1}}\right.\\ \left.+(2\mu+m-u-\lambda)z+(m-2u)(\mu+1)\right]Z_m(z)=0.\end{gathered} \tag{4.41}$$

The multiplier representation T' induced by the K-operators on $\mathcal{F}$ is

$$\begin{aligned}[T'(g)h](z,t)=\mathcal{D}^{-1}\Bigg[&(b+dt)^{-u-1}\left(a+\frac{c}{t}\right)^{-u-1}\exp\left(\frac{bzt}{d+bt}\right)\\ &\cdot(\mathcal{D}h)\left(\frac{zt}{(at+c)(d+bt)},\frac{at+c}{d+bt}\right)\Bigg],\end{aligned} \tag{4.42}$$

$|c/at|<1$, $|bt/d|<1$ and $g\in SL(2,C)$ lies in a sufficiently small neighbourhood of the identity element so that the above expression is uniquely defined.

It has been shown in [4] that

$$F=t^{m_0}e^z\psi_2[1+u+m_0;\,2+2u,\gamma';\,-z,t] \tag{4.43}$$

satisfies both

$$(J^+J^-+J^3J^3-J^3)F=u(u+1)F \tag{4.44}$$

and

$$[J^3J^3+(\gamma'-2m_0-1)J^3-J^+]F=m_0(\gamma'-m_0)F, \tag{4.45}$$

while it can be shown that

$$G=t^{m_0}(1-t)^{-1-u-m_0}e^z{}_1F_1\left[\begin{matrix}1+u+m_0; \\ 2+2u;\end{matrix}\ -\frac{z}{1-t}\right] \tag{4.46}$$

is a common solution of

$$(J^+J^-+J^3J^3-J^3)G=u(u+1)G \tag{4.47}$$

and

$$[J^3J^3-J^-J^3+m_0J^--(1+2m_0)J^3]G=-m_0(m_0+1)G. \tag{4.48}$$

Therefore, by (2.6) and (2.9), it follows that

$$\mathscr{H}_1 = z^{\mu-1} t^{m_0} G^{1:1;2}_{0:2;1}\left(\begin{matrix} 1+u-m_0\colon \lambda;\ 1+u+m_0,\ m_0-u; \\ \text{—}\colon 2+2u,\ \mu;\ \gamma'; \end{matrix}\quad z, -t\right) \tag{4.49}$$

satisfies

$$(K^+K^- + K^3K^3 - K^3)\mathscr{H}_1 = u(u+1)\mathscr{H}_1 \tag{4.50}$$

as well as

$$[K^3K^3 + (\gamma' - 2m_0 - 1)K^3 - K^+]\mathscr{H}_1 = m_0(\gamma' - m_0)H_1, \tag{4.51}$$

while

$$\mathscr{H}_2 = z^{\mu-1} t^{m_0}(1-t)^{-1-u-m_0} F^{1:1;0}_{1:1;0}\left(\begin{matrix} \lambda\colon 1+u+m_0;\ \text{—}; \\ \mu\colon 2+2u;\ \text{—}; \end{matrix}\quad -\frac{z}{1-t}, z\right) \tag{4.52}$$

satisfies

$$(K^+K^- + K^3K^3 - K^3)\mathscr{H}_2 = u(u+1)\mathscr{H}_2 \tag{4.53}$$

as well as

$$[K^3K^3 - K^-K^3 + m_0K^- - (1+2m_0)K^3]\mathscr{H}_2 = -m_0(m_0+1)\mathscr{H}_2. \tag{4.54}$$

From the expansions

$$T(g)\mathscr{H}_i = \sum_{n=-\infty}^{\infty} j_{in} h_{m_0+n}, \qquad i = 1, 2, \tag{4.55}$$

we obtain the following identities:

$$\begin{aligned} &(1-t)^{-\alpha} F^{1:1;0}_{0:2;1}\left(\begin{matrix} \alpha\colon \lambda;\ \text{—}; \\ \text{—}\colon \mu,\ \gamma;\ \gamma'; \end{matrix}\quad \frac{z}{1-t}, \frac{-\omega t}{1-t}\right) \\ &\quad = \sum_{n=0}^{\infty} \frac{(\alpha)_n}{n!}\, {}_2F_2\left[\begin{matrix} \alpha+n,\ \lambda; \\ \gamma,\ \mu; \end{matrix}\quad z\right] {}_1F_1\left[\begin{matrix} -n; \\ \gamma'; \end{matrix}\quad \omega\right] t^n, \qquad |t| < 1, \end{aligned} \tag{4.56}$$

$$\begin{aligned} &\left(1+\frac{c}{t}\right)^{-\alpha} (1-c-t)^{\alpha-\gamma} F^{1:1;0}_{1:1;0}\left(\begin{matrix} \lambda\colon \gamma-\alpha;\ \text{—}; \\ \mu\colon \gamma;\ \text{—}; \end{matrix}\quad \frac{-zt}{(c+t)(1-c-t)}, \frac{zt}{c+t}\right), \\ &\quad = \sum_{n=-\infty}^{\infty} \frac{\Gamma(\gamma-\alpha+n)}{\Gamma(\gamma-\alpha)}\, {}_2F_2\left[\begin{matrix} \alpha-n,\ \lambda; \\ \gamma,\ \mu; \end{matrix}\quad z\right] \\ &\qquad \cdot \frac{{}_2F_1(\gamma-\alpha+n, 1-\alpha+n; 1+n; c)}{\Gamma(1+n)} t^n, \qquad \left|\frac{c}{t}\right| < 1, \quad |c+t| < 1, \end{aligned} \tag{4.57}$$

where the terms corresponding to $n = -1, -2, -3, \cdots$ are well defined because of the relation of the type (4.32).

The above identities are valid for all α, γ, γ', λ, $\mu \in C$ such that α and $\gamma - \alpha$ are not integers and γ, γ', $\mu \neq 0, -1, -2, \cdots$.

5. Type B representation $\uparrow u$. Consider the representation $\uparrow u$ of $sl(2, C)$, $2u$ not a nonnegative integer. The representation space W has a basis $\{f_m\}$, $m \in S = \{-u+n\colon n \geqq 0\}$, such that the action of $sl(2, C)$ on W is given by

$$\begin{aligned} &J^+ f_m = (m-u) f_{m+1}, \quad J^- f_m = -(m+u) f_{m-1}, \quad J^3 f_m = m f_m, \\ &(J^+J^- + J^3J^3 - J^3) f_m = u(u+1) f_m. \end{aligned} \tag{5.1}$$

The type B operators $\{J^+, J^-, J^3\}$ and the basis functions $\{f_m\}$ satisfying (5.1) are [7, p. 188]

$$(5.2)\qquad \begin{aligned} J^+ &= t\left(z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}-z-u\right),\\ J^- &= t^{-1}\left(z\frac{\partial}{\partial z}-t\frac{\partial}{\partial t}-u\right),\\ J^3 &= t\frac{\partial}{\partial t} \end{aligned}$$

and

$$(5.3)\qquad f_m(z,t)=\frac{\Gamma(-2u)n!}{\Gamma(n-2u)}L_n^{(-2u-1)}(z)t^m,\qquad m=-u+n\in S.$$

The representation $\uparrow u$ can be extended to a local multiplier representation T of $SL(2,C)$ on the space $\mathcal{F}$ of all functions analytic in a neighbourhood of the point $(z^0,t^0)=(1,1)$.

Thus

$$(5.4)\qquad [T(g)f](z,t)=(d+bt)^u\left(a+\frac{c}{t}\right)^u e^{bzt/(d+bt)}f\left(\frac{zt}{(at+c)(d+bt)},\frac{at+c}{d+bt}\right),$$

$|c/at|<1, |bt/d|<1, f\in\mathcal{F}$ and g lies in a small enough neighbourhood of $e\in SL(2,C)$ such that the right-hand side of the expression is uniquely defined.

As in § 4, the operators J^+, J^-, J^3 induce operators K^+, K^-, K^3

$$(5.5)\qquad \begin{aligned} K^+ &= \mathcal{D}^{-1}J^+\mathcal{D}=t\left[z\frac{\partial}{\partial z}+t\frac{\partial}{\partial t}-z-u-\mu+1+(\mu-\lambda)\frac{\partial^{-1}}{\partial z^{-1}}\right],\\ K^- &= \mathcal{D}^{-1}J^-\mathcal{D}=t^{-1}\left(z\frac{\partial}{\partial z}-t\frac{\partial}{\partial t}-u-\mu+1\right),\\ K^3 &= \mathcal{D}^{-1}J^3\mathcal{D}=t\frac{\partial}{\partial t}, \end{aligned}$$

$$(5.6)\qquad \begin{aligned} &K^+h_m=(m-u)h_{m+1},\quad K^-h_m=-(m+u)h_{m-1},\quad K^3h_m=mh_m,\\ &(K^+K^-+K^3K^3-K^3)h_m=u(u+1)h_m, \end{aligned}$$

where

$$(5.7)\qquad h_m(z,t)={}_2F_2\left[\begin{matrix}-n,\lambda;\\ -2u,\mu;\end{matrix}\; z\right]t^m,\qquad m=-u+n\in S.$$

In view of the fact that

$$(5.8)\qquad [K^3,K^\pm]=\pm K^\pm,\qquad [K^+,K^-]=2K^3,$$

we have constructed a new model of irreducible representation $\uparrow u$ of $sl(2,C)$ in terms of differintegral operators $\{K^+, K^-, K^3\}$ such that the functions $h_m(z,t)$ defined by (5.7) are basis vectors.

The multiplier representation T' induced by the K-operators is

$$(5.9)\qquad \begin{aligned} [T'(g)h](z,t)=\mathcal{D}^{-1}\bigg[&(d+bt)^u\left(a+\frac{c}{t}\right)^u\exp\left(\frac{bzt}{d+bt}\right)\\ &\cdot(\mathcal{D}h)\left(\frac{zt}{(at+c)(d+bt)},\frac{at+c}{d+bt}\right)\bigg], \end{aligned}$$

$|c/at|<1$, $|bt/d|<1$, $ad-bc=1$, and g lies in a sufficiently small neighbourhood of $e\in SL(2, C)$.

It can be easily shown that

$$F=\psi_2[-2u;\ -2u,\ \gamma';\ -z,\ t]e^z t^{-u} \tag{5.10}$$

satisfies

$$(J^+J^-+J^3J^3-J^3)F=u(u+1)F \tag{5.11}$$

as well as

$$[J^3J^3+(2u+\gamma'-1)J^3-J^+]F=-u(u+\gamma')F. \tag{5.12}$$

It therefore follows that

$$\mathscr{H}=z^{\mu-1}t^{-u}F^{1:1;0}_{1:2;0}\left(\begin{matrix}-2u\colon \lambda;\text{—};\\ \gamma'\colon -2u,\ \mu;\text{—};\end{matrix}\quad -zt,\ t\right) \tag{5.13}$$

satisfies the differintegral equation

$$(K^+K^-+K^3K^3-K^3)\mathscr{H}=u(u+1)\mathscr{H} \tag{5.14}$$

as well as

$$[K^3K^3+(2u+\gamma'-1)K^3-K^+]\mathscr{H}=-u(u+\gamma')\mathscr{H}. \tag{5.15}$$

The expansion

$$T'(g)\mathscr{H}=\sum_{n=0}^{\infty} p_n(g)h_{-u+n} \tag{5.16}$$

leads us to an identity

$$\begin{aligned} &F^{1:1;0}_{1:2;0}\left(\begin{matrix}\gamma\colon \lambda;\text{—};\\ \gamma'\colon \mu,\ \gamma;\text{—};\end{matrix}\quad zt,\ t+c\right)\\ &=\sum_{n=0}^{\infty}\frac{(\gamma)_n}{n!(\gamma')_n}\,{}_2F_2\left[\begin{matrix}-n,\ \lambda;\\ \gamma,\ \mu;\end{matrix}\quad z\right]{}_1F_1\left[\begin{matrix}\gamma+n;\\ \gamma'+n;\end{matrix}\quad c\right]t^n.\end{aligned} \tag{5.17}$$

We are not discussing type A representation $\uparrow u$ since the operators defining it do not fit into the fractional derivative approach.

6. Type A representation $\downarrow u$. consider the representation $\downarrow u$ of $sl(2, C)$, $2u$ not a nonnegative integer [7, p. 205]. The representation space W has a basis $\{f_m\}$, $m\in S=\{u-n\colon n=0, 1, 2, \cdots\}$ such that the action of $sl(2, C)$ on W is given by

$$\begin{gathered} J^+f_m=(m-u)_{m+1},\quad J^-f_m=-(m+u)f_{m-1},\quad J^3f_m=mf_m,\\ (J^+J^-+J^3J^3-J^3)f_m=u(u+1)f_m.\end{gathered} \tag{6.1}$$

The type A operators $\{J^+, J^-, J^3\}$ here are (4.3) while

$$f_m(z, t)={}_2F_1(-n, -q-u;\ -2u;\ z)t^m,\qquad m=u-n,\quad n=0, 1, 2, \cdots. \tag{6.2}$$

Accordingly, K-operators induced by the J-operators are (4.7) and (4.9), while the corresponding basis functions $h_m(z, t)$ are

$$h_m(z, t)=z^{\mu-1}\,{}_3F_2\left[\begin{matrix}-n,\ -q-u,\ \lambda;\\ -2u,\ \mu;\end{matrix}\quad z\right]t^m,\qquad m=u-n,\quad n=0, 1, 2, \cdots, \tag{6.3}$$

where

$$\begin{gathered} K^+h_m=(m-u)h_{m+1}, \quad K^-h_m=-(m+u)h_{m-1}, \quad K^3h_m=mh_m, \\ (K^+K^-+K^3K^3-K^3)h_m=u(u+1)h_m, \\ [K^3, K^\pm]=\pm K^\pm, \quad [K^+, K^-]=2K^3. \end{gathered} \tag{6.4}$$

The multiplier representation T' of $SL(2, C)$ in consequence of the K-operators is (4.15). That is,

$$\begin{aligned} [T'(g)h](z, t)=\mathscr{D}^{-1}\Bigg[&(d+bt)^u\left(a+\frac{c}{t}\right)^{-q}\left(a-\frac{c(z-1)}{t}\right)^{q+u} \\ &\cdot(\mathscr{D}h)\left(\frac{zt}{(d+bt)(at-c(z-1))}, \frac{c+at}{d+bt}\right)\Bigg], \end{aligned} \tag{6.5}$$

$|bt/d|<1$, $|c/at|<1$, $|(c(z-1))/at|<1$, and g lies in a sufficiently small neighbourhood of $e\in SL(2, C)$.

It can be shown that

$$F=F_2\left[-2u; -q-u, \alpha'; -2u, \beta'; \frac{-z}{1-z}, \frac{1}{t}\right](1-z)^{q+u}t^u \tag{6.6}$$

is a solution of both

$$(J^+J^-+J^3J^3-J^3)F=u(u+1)F \tag{6.7}$$

and

$$[J^3J^3+J^-J^3-(u+\alpha')J^-+(1-2u-\beta')J^3]F=u(1-u-\beta')F. \tag{6.8}$$

Therefore, it follows that

$$\mathscr{H}=z^{\mu-1}t^uF^{2:2;0}_{1:2;0}\left(\begin{matrix}-2u, \alpha'\colon -q-u, \lambda; —; \\ \beta'\colon -2u, \mu; —;\end{matrix}\quad -\frac{z}{t}, \frac{1}{t}\right) \tag{6.9}$$

satisfies

$$(K^+K^-+K^3K^3-K^3)\mathscr{H}=u(u+1)\mathscr{H} \tag{6.10}$$

as well as

$$[K^3K^3+K^-K^3-(u+\alpha')K^-+(1-2u-\beta')K^3]\mathscr{H}=u(1-u-\beta')\mathscr{H}. \tag{6.11}$$

From the expansion

$$T'(g)\mathscr{H}=\sum_{n=0}^{\infty} q_n(g)h_{u-n}, \tag{6.12}$$

valid in a region to be determined by the inequalities (6.5), we obtain the following identity as a special case:

$$\begin{aligned} &F^{2:2;0}_{1:2;0}\left(\begin{matrix}\beta, \alpha'\colon \alpha, \lambda; —; \\ \beta'\colon \beta, \mu; —;\end{matrix}\quad \frac{z}{t}, \frac{1+bt}{t}\right) \\ &\quad=\sum_{n=0}^{\infty}\frac{(\alpha')_n(\beta)_n}{n!(\beta')_n}\,{}_3F_2\left[\begin{matrix}-n, \alpha, \lambda; \\ \beta, \mu;\end{matrix}\quad z\right]{}_2F_1\left[\begin{matrix}\alpha'+n, \beta+n; \\ \beta'+n;\end{matrix}\quad b\right]\frac{1}{t^n}, \\ &\qquad\qquad\left|\frac{z}{t}\right|+\left|\frac{1+bt}{t}\right|<1. \end{aligned} \tag{6.13}$$

We are not discussing type B representation $\downarrow u$ since it would lead to the identity (5.17) again and as such give no new results.

7. Conclusion. As we have seen, the operator $\mathscr{D}$ has been highly instrumental in constructing new models of irreducible representation of $sl(2, C)$, induced by type A and type B operators. For $\lambda = \mu$ all the new models reduce to the known ones.

We have not included the discussion on representations of the oscillator algebra or the Lie algebra of the Euclidean group, based on type C′, C″, · · · , operators, since, to deal with these, we need to define the operator $\mathscr{D}$ in a different way. However, we propose to discuss this in a separate article.

Acknowledgment. The authors record their thanks to the referee for suggestions which have led to a better presentation of the paper.

A GENERAL FORM FOR SOLVABLE LINEAR TIME VARYING SINGULAR SYSTEMS OF DIFFERENTIAL EQUATIONS*

STEPHEN L. CAMPBELL†

Abstract. A canonical form is derived for all linear solvable systems $E(t)x'(t)+F(t)x(t)=f(t)$ with sufficiently smooth coefficients E, F. Using this form it is shown that for all smooth enough solvable systems a class of recently defined numerical imbedding methods and an algorithm to compute the manifold of consistent initial conditions always work. In addition, necessary and sufficient conditions are given on $E(t)$, $F(t)$ to insure solvability in the case when $E(t)$, $F(t)$ are infinitely differentiable.

Key words. linear time varying system, implicit, descriptor, singular, solvability, numerical imbedding, consistent initial conditions, approximation

1. Introduction.

The theory for linear time invariant singular systems (also called differential-algebraic, descriptor, implicit or constrained) has become well developed over the last decade (see [3], [4]). However, progress on the linear time varying problem

$$E(t)x'(t)+F(t)x(t)=f(t) \tag{1.1}$$

is more recent and has been less complete. Work on (1.1) initially took either the form of algorithms utilizing repeated coordinate changes and differentiations to reduce (1.1) to some type of canonical or explicit form [18], [21], or of traditional numerical methods such as backward differences [12].

The canonical form approach was continued in [6], [10], [19]. However, examples in [6], [10] showed that there were solvable systems (to be defined shortly) which could not be put into these canonical forms. It was also observed in [19] that backward difference methods do not converge for all solvable systems although they do work for certain important classes of problems [2], [14], [15], [19]. (Note also [13].) In an attempt to rectify this difficulty, a different numerical approach was introduced in [7] and further developed in [8], [9]. This method was shown to work for many of the standard classes of singular systems (1.1) including some for which backward differences failed and the approach of [18], [21] was numerically impractical. This paper will bring together some of this previous work.

First, we shall give a result which exhibits for the first time the structure of all sufficiently smooth solvable systems. In particular, we will show that the counterexamples in [10] are, in a sense, "generic". Using this structure result, which is similar to, but different from, that of [10], [19], we show that the method [7] works for all sufficiently smooth solvable systems and that [7] also provides a tool for the theoretical analysis of (1.1). Also, under the added assumption that E, F, f are infinitely differentiable we develop a test for solvability that can be verified directly from E, F and their derivatives without any time varying coordinate changes.

2. Terminology and the canonical form.

Let $\mathcal{I}=[t_0, t_1]$ be a finite subinterval of the real line. We assume that E, F are $n\times n$ (possible complex) matrix valued functions, $n\geqq 2$, and E is singular for all $t\in\mathcal{I}$. We do not assume E has constant rank. To avoid

technical difficulties we assume E, F, are $2n$-times differentiable and f is at least n-times differentiable where differentiable is taken throughout this paper to mean continuously differentiable.

The system (1.1) is *solvable* on $\mathcal{I}$ if for every such f there exists at least one continuously differentiable solution x. (This is a form of target path controllability [24].) Also, all solutions for this f are defined on all of $\mathcal{I}$, are at least differentiable, and are uniquely determined by their value at any $t \in \mathcal{I}$. Finally, all solutions of the homogeneous equation $Ex'+Fx=0$ are at least $(2n+1)$-times differentiable and if f is m-times differentiable with $n \leqq m \leqq 2n$, then the solution x is $(m-n+1)$-times differentiable.

This definition may appear somewhat cumbersome, but when E, F are constant it is equivalent to the usual definition of solvability [3], [4] and allows us to concentrate on structural questions without worrying if we have lost differentiability during coordinate changes.

Those x^o for which (1.1) has a differentiable solution such that $x(t_0)=x^o$ are called *consistent initial conditions* at t_0.

Two singular systems $Ex'+Fx=f$ and $\tilde{E}\tilde{x}'+\tilde{F}\tilde{x}=\tilde{f}$ are said to be *equivalent* if there exists $2n$-times differentiable nonsingular $H(t)$, and $(2n+1)$-times differentiable nonsingular $K(t)$ such that letting $x=K\tilde{x}$ and multiplying by H changes $Ex'+Fx=f$ into $\tilde{E}\tilde{x}'+\tilde{F}\tilde{x}=\tilde{f}$. That is,

$$HEK=\tilde{E},\quad HEK'+HFK=\tilde{F},\quad Hf=\tilde{f}. \tag{2.1}$$

Finally, from [6], a system is in standard canonical form (SCF) if it takes the form

$$y'+C(t)y=g(t), \tag{2.2}$$

$$N(t)z'+z=h(t) \tag{2.3}$$

where N is strictly lower triangular independent of t and (2.2) may be absent. Note that (2.3) has only one solution for each h [6]. By an additional coordinate change on y, one could rewrite (2.2) as $y'(t)=g(t)$. Systems equivalent to one in SCF are clearly solvable.

If E, F are real analytic, then (1.1) is solvable if and only if it can be put into SCF [10]. However, not all solvable systems can be put into SCF. In [19], Petzold and Gear show that if (1.1) is solvable, then there is a collection of open intervals $\mathcal{I}_i$ such that $\bigcup \mathcal{I}_i$ is dense in $\mathcal{I}$ and on each $\mathcal{I}_i$, (1.1) can be put into SCF. However, the coordinate changes and canonical form need not be continuous on $\mathcal{I}$ [10].

Example 2.1. Let N_-, N_+ be any two $n\times n$ nilpotent matrices. Let $\phi(t)$ be a $(2n+1)$-times differentiable function on $[-1,1]$ such that $\phi^{(i)}(0)=0$ for $0\leqq i \leqq 2n+1$. Let $F(t)=I$, $E(t)=\phi(t)N_-$ if $t\leqq 0$ and $E(t)=\phi(t)N_+$ if $t>0$. Then it is not hard to show by the next lemma that

$$Ex'+x=f \tag{2.4}$$

is solvable on $[-1,1]$. If, for example, the nullspaces of N_+, N_- do not intersect, then (2.4) cannot be put into SCF.

LEMMA 2.1. *If N is an $n\times n$ $2n$-times differentiable function such that any n-product of N and its derivatives is zero, then $Nx'+x=f$ is solvable on $\mathcal{I}$ and the unique solution is*

$$x=(I+\bar{N}D)^{-1}f=(I-\bar{N}D+(\bar{N}D)^2+\cdots(-1)^{n-1}(\bar{N}D)^{n-1})f \tag{2.5}$$

where $\bar{N}$ is the operator of multiplication by N and D is the operator of differentiation.

Proof. By assumption, $(\bar{N}D)^n = 0$. □

In Example 2.1, a projection onto the nullspace of $E(t)$ could exhibit a jump discontinuity at zero. An example where the projection is not even piecewise continuous is given in [10]. The next result gives the first general structure theorem for solvable systems and show that the previous examples are typical of how a solvable system can fail to be equivalent to a system in SCF.

THEOREM 2.1. *Suppose that* (1.1) *is solvable on* $\mathcal{I}$. *Then* (1.1) *is equivalent to a system in the form*

$$y' + C(t)z' = g(t), \tag{2.6a}$$

$$N(t)z' + z = h(t) \tag{2.6b}$$

where (2.6a) *may be absent and* (2.6b) *has only one solution for each sufficiently smooth* $h(t)$. *Furthermore, there exists a family of disjoint open intervals* $\mathcal{I}_i$ *such that* $\bigcup \mathcal{I}_i$ *is dense in* $\mathcal{I}$ *and on each* $\mathcal{I}_i$ *the system* (2.6b) *may be transformed by H, K as in* (2.1) *so that* (2.6b) *is in* SCF. *In particular, on* $\mathcal{I}_i$ *the equivalent system will have the form* (2.6) *with* $N(t)$ *at least* $2n$*-times differentiable and strictly lower triangular independent of t.*

Before proceeding to prove Theorem 2.1 we point out that the key differences between Theorem 2.1 and those of [10], [18], [19], [21] are that, while the structure is less detailed and the systems (2.6a), (2.6b) are not completely decoupled, the coordinate changes and matrices in (2.6b) are defined and sufficiently differentiable on *all* of $\mathcal{I}$ and not just on $\bigcup \mathcal{I}_i$. Also, we do not make assumptions of analyticity or constant rank so that Theorem 2.1 applies to all solvable systems which have smooth enough coefficients.

Proof. Suppose that (1.1) is solvable. First we wish to get (1.1) in the form

$$x' + A_1 y' + Cx = f_1, \tag{2.7a}$$

$$A_2 y' + By = f_2 \tag{2.7b}$$

with the bottom equation having only one solution for sufficiently smooth f. If the associated homogeneous equation of (1.1) has only $x = 0$ as a solution, (1.1) is already in the form (2.7b) with (2.7a) absent and this step is complete. So suppose there are nontrivial solutions of (1.1) with $f = 0$. Let $\{\phi_1, \cdots, \phi_r\}$ be a basis for these homogeneous solutions. By the assumption of solvability $\{\phi_1, \cdots, \phi_r\}$ are linearly independent for each t and $(2n+1)$-times differentiable on all of $\mathcal{I}$. Then there exists $\{\phi_{r+1}, \cdots, \phi_n\}$ equally smooth such that $\Phi = [\phi_1, \cdots, \phi_n]$ is invertible on $\mathcal{I}$ (see [22] for example). Let $x = \Phi \tilde{x}$. Then (1.1) becomes

$$E\Phi\tilde{x}' + (E\Phi' + F\Phi)\tilde{x} = f$$

or

$$\begin{bmatrix} E_{11} & E_{12} \\ E_{21} & E_{22} \end{bmatrix} \begin{bmatrix} \tilde{x}_1' \\ \tilde{x}_2' \end{bmatrix} + \begin{bmatrix} 0 & F_{21} \\ 0 & F_{22} \end{bmatrix} \begin{bmatrix} \tilde{x}_1 \\ \tilde{x}_2 \end{bmatrix} = \begin{bmatrix} \tilde{f}_1 \\ \tilde{f}_2 \end{bmatrix} \tag{2.8}$$

where $E\Phi = [E_{ij}]$, $E\Phi' + F\Phi = [F_{ij}]$. We omit the tilde and use x_1, x_2 to denote our new variables. We shall now show $[\begin{smallmatrix} E_{11} \\ E_{21} \end{smallmatrix}]$ has full (column) rank. Suppose that $\hat{t} \in \mathcal{I}$ such that $[\begin{smallmatrix} E_{11} \\ E_{21} \end{smallmatrix}]$ is not full rank. Let ϕ be a nonzero constant vector such that

$$\begin{bmatrix} E_{11}(\hat{t}) \\ E_{21}(\hat{t}) \end{bmatrix} \phi = 0.$$

Define

$$f(t)=\begin{cases}\dfrac{1}{t-\hat{t}}\begin{bmatrix}E_{11}(t)\\ E_{21}(t)\end{bmatrix}\phi & \text{if } t\neq\hat{t},\\[2ex] \begin{bmatrix}E_{11}'(\hat{t})\\ E_{21}'(\hat{t})\end{bmatrix}\phi & \text{if } t=\hat{t}.\end{cases}$$

Then f is $2n-1$ times differentiable on $\mathscr{I}$. However $x_1=\ln|t-\hat{t}|\phi$, $x_2=0$ defines an unbounded solution on $\mathscr{I}\backslash\{\hat{t}\}$ wnich contradicts solvability. Hence $[{E_{11} \atop E_{21}}]$ has full (column) rank on $\mathscr{I}$.

Thus there exists a $2n$-times differentiable nonsingular matrix P such that

$$P\begin{bmatrix}E_{11}\\ E_{21}\end{bmatrix}=\begin{bmatrix}I\\ 0\end{bmatrix}.$$

Multiplying (2.8) by P gives that our system is now

$$\begin{bmatrix}I & E_1\\ 0 & E_2\end{bmatrix}\begin{bmatrix}x_1'\\ x_2'\end{bmatrix}+\begin{bmatrix}0 & F_1\\ 0 & F_2\end{bmatrix}\begin{bmatrix}x_1\\ x_2\end{bmatrix}=\begin{bmatrix}f_1\\ f_2\end{bmatrix}\tag{2.9}$$

and by the construction of Φ, $E_2x_2'+F_2x_2=f_2$ has only one solution for each f_2. Let $x_2=S\bar{x}_2$. Then (2.9) becomes

$$\begin{bmatrix}I & E_1S\\ 0 & E_2S\end{bmatrix}\begin{bmatrix}x_1'\\ \bar{x}_2'\end{bmatrix}+\begin{bmatrix}0 & F_1S+E_1S'\\ 0 & F_2S+E_2S'\end{bmatrix}\begin{bmatrix}x_1\\ \bar{x}_2\end{bmatrix}=\begin{bmatrix}f_1\\ f_2\end{bmatrix}.\tag{2.10}$$

Suppose for the moment that it is possible to choose $2n+1$-times differentiable S such that S and $E_2S'+F_2S$ are both invertible for every $t\in\mathscr{I}$. Then we have (2.9) with F_2 now nonsingular. Multiplying (2.9) by

$$\begin{bmatrix}I & -F_1F_2^{-1}\\ 0 & F_2^{-1}\end{bmatrix}$$

yields the equivalent system

$$\begin{bmatrix}I & C\\ 0 & N\end{bmatrix}\begin{bmatrix}z'\\ w'\end{bmatrix}+\begin{bmatrix}0 & 0\\ 0 & I\end{bmatrix}\begin{bmatrix}z\\ w\end{bmatrix}=\begin{bmatrix}f_1\\ f_2\end{bmatrix}\tag{2.11}$$

which is (2.6). To complete the proof, we need to verify that one can define S as indicated. Suppose that $p=$ dimension of the w space in (2.11). Let $\mathscr{C}_m$ be the Banach space of m-times continuously differentiable $p\times p$ complex valued matrix functions defined on $\mathscr{I}$ with $\|X\|_m=\sum_{i=0}^m\|X^{(i)}\|_\infty$, where $\|\cdot\|_\infty$ is the sup norm on $\mathscr{C}_0$. Let $\mathscr{L}(x)=E_2x'+F_2x$ with E_2, F_2 from (2.9). Let Ω_m be those $X\in\mathscr{C}_m$ which are nonsingular for every $t\in\mathscr{I}$. We need the technical fact that

(2.12) For $m\geqq 0$, Ω_m is an open dense subset of $\mathscr{C}_m$.

Lacking a reference for (2.12), we include a proof. Clearly Ω_m is open in $\mathscr{C}_m$ so we need only show Ω_m is dense. Suppose $T\in\mathscr{C}_m\backslash\Omega_m$. Take $\varepsilon>0$. Then there exists $P\in\mathscr{C}_m$ such that $\|P-T\|_m<\varepsilon/2$ and P has polynomial entries. Let Σ be the set of all eigenvalues of $P(t)$ for all $t\in\mathscr{I}$. Then Σ has no interior as a subset of the complex plane. This follows from the fact that $P(t)$ is real analytic in t and hence the eigenvalues are continuous functions of t which are analytic except at a finite number of t values [16]. Hence there exists a number $\varepsilon_1>0$ such that $\varepsilon_1<\varepsilon/2$ and $\varepsilon_1\notin\Sigma$. Let $H=P-\varepsilon_1$. Then $H\in\Omega_m$ and $\|H-T\|_m<\varepsilon$ as desired. This completes the proof of (2.12). Now take $\Psi\in\Omega_n$. By assumption on $\mathscr{L}$ (solvability) there exists a $\Phi\in\mathscr{C}_1$ such that $\mathscr{L}(\Phi)=\Psi$. Let ε be such that the ε neighborhood of $\Psi\in\mathscr{C}_0$ is in Ω_0. By (2.12) there exists $\{\Phi_j\}\subset\Omega_{2n+1}$ such that $\Phi_j\to\Phi$ in $\mathscr{C}_1$. But then $\mathscr{L}(\Phi_j)\to\mathscr{L}(\Phi)=\Psi$ in $\mathscr{C}_0$. Let $\hat{j}$ be such that $\|\mathscr{L}(\Phi_{\hat{j}})-\mathscr{L}(\Phi)\|<\varepsilon$. Then $\Phi_{\hat{j}}\in\Omega_{2n+1}$ and $\mathscr{L}(\Phi_{\hat{j}})\in\mathscr{C}_{2n}\cap\Omega_0=\Omega_{2n}$ so that $\Phi_{\hat{j}}$ is the required S. This completes the proof of (2.11). To get the structure of N we use the fact that if $X(t)$ is any continuous matrix function on $\mathscr{I}$, then there exists a countable collection of disjoint open intervals $\mathscr{I}_i$ such that $\cup\mathscr{I}_i$ is dense in $\mathscr{I}$ and rank X is constant on each $\mathscr{I}_i$. One can then do the reduction process of [19] (or Silverman [21]) where on each step it may be necessary to break each $\mathscr{I}_i$ into another countable family. □

It would be nice if the matrix C could be eliminated in (2.6a) so that (2.6a) and (2.6b) were completely decoupled. We are not sure if this is always possible. However, note that if we let $z=u+Tw$ in (2.11) and then add $-T'$ times the second equation to the first, then (2.11) becomes

$$\begin{bmatrix} I & T+C-T'N \\ 0 & N \end{bmatrix}\begin{bmatrix} u' \\ w' \end{bmatrix}+\begin{bmatrix} 0 & 0 \\ 0 & I \end{bmatrix}\begin{bmatrix} u \\ w \end{bmatrix}=\begin{bmatrix} \tilde{f}_1 \\ f_2 \end{bmatrix}. \tag{2.13}$$

If $T'N-T=C$ has a smooth solution on $\mathscr{I}$, then (2.13) is in the form (2.11) with $C=0$. There are several sufficient conditions for this including the solvability of $N^*X'-X=C^*$ where $*$ denotes the pointwise conjugate transpose and $X=T^*$.

The next section applies Theorem 2.1 to the numerical methods of [7]-[9].

3. Application to the imbedding method. Theorem 2.1 should not be considered a method of solution but rather a very useful theoretical fact.

In [5] and Lemma 2.1 it was shown that the solutions of (1.1) will generally involve not only f and its derivatives but also derivatives of E, F. For simple small scale problems it may be possible to differentiate and solve for variables [20]. This may not be practical on larger or more complicated problems. One of our goals then is to develop a theory as directly in terms of the derivatives of E, F, f as possible. While the proofs involve time varying coordinate changes the results do not.

Suppose that (1.1) is solvable and that $\hat{t}\in\mathscr{I}$. Let

$$c_i(\hat{t})=\frac{c^{(i)}(\hat{t})}{i!}\quad\text{for } c=E, F, f, x,\quad \hat{t}\in\mathscr{I} \tag{3.1}$$

so that

$$c(t)=\sum_i c_i\delta^i,\qquad \delta=t-\hat{t} \tag{3.2}$$

(where (3.1) is a Taylor approximation with a remainder if c is not analytic). Substituting these expansions into (1.1) gives that for any $j>0$ (j less than the smoothness of E, F, x, f), $t\in\mathscr{I}$,

$$\begin{bmatrix} E_0 & 0 & \cdot & \cdot & \cdot & 0 \\ E_1+F_0 & 2E_0 & \cdot & \cdot & \cdot & \cdot \\ E_2+F_1 & 2E_1+F_0 & 3E_0 & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ E_{j-1}+F_{j-2} & 2E_{j-2}+F_{j-3} & \cdot & \cdot & \cdot & jE_0 \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \\ \cdot \\ \cdot \\ \cdot \\ x_j \end{bmatrix}=\begin{bmatrix} f_0 \\ f_1 \\ \cdot \\ \cdot \\ \cdot \\ f_{j-1} \end{bmatrix}-\begin{bmatrix} F_0 \\ F_1 \\ \cdot \\ \cdot \\ \cdot \\ F_{j-1} \end{bmatrix}x_0 \tag{3.3}$$

or

$$\mathscr{E}_j\mathbf{x}_j=\not{f}_j-\mathscr{F}_jx_0=\mathbf{f}_j \tag{3.4}$$

where all the terms in (3.3) depend on t. Note that $\mathscr{E}_j$ is singular since E_0 is. The system (3.4) (or (3.3)) is said to be *smoothly* 1-*full* on $\mathscr{I}$ if there exists continuously differentiable nonsingular $R(t)$ on $\mathscr{I}$ such that

$$R(t)\mathscr{E}_j(t)=\begin{bmatrix} I & 0 \\ 0 & L(t) \end{bmatrix}$$

where I is $n\times n$. In this case, if $[R_0,\cdots,R_{j-1}]$ is the top n rows of $R(t)$ we have that

$$x_1=-\sum_{i=0}^{j-1} R_iF_ix_0+\sum_{i=0}^{j-1} R_if_i$$

or

$$x'(t)=Q(t)x(t)+q(t). \tag{3.5}$$

Thus the solutions of the original descriptor system (1.1) corresponding to consistent initial conditions are also solutions of the nonsingular system (3.5) provided (3.4) is smoothly 1-full. But solving (3.4) for x_1, given x_0, is the same as evaluating $Q(t)x(t)+q(t)$ in (3.5) given $x(t)$, t. This makes it possible to numerically solve (1.1) by numerically solving (3.5). This is discussed in more detail in [7], [8]. The key then in utilizing the approach of [7], [8] is that $\mathscr{E}_j$ be smoothly 1-full. Notice that (3.3), (3.5) only require that E, F, f, are $(j-1)$-times differentiable, and as we shall see one may usually assume $j\leqq n+1$. However, forming $\mathbf{x}_j$ requires x to be j-times differentiable which usually requires extra smoothness from E, F, f.

An example in [7] shows that 1-full for each $t\in\mathscr{I}$ does not imply smoothly 1-full.

LEMMA 3.1. *Let*

$$M(t)=\begin{bmatrix} M_1 & M_2 \\ M_3 & M_4 \end{bmatrix} \tag{3.6}$$

where M_1 is $n\times n$ and suppose that M is smooth on $\mathscr{I}$ and has constant rank. Then M is smoothly 1-*full on $\mathscr{I}$ if and only if it is* 1-*full for each $t\in\mathscr{I}$.*

Proof. Sufficiency is obvious. Suppose M is 1-full for each $t\in\mathscr{I}$ and has constant rank. From the 1-fullness assumption the submatrix $\left[\begin{smallmatrix} M_1 \\ M_3 \end{smallmatrix}\right]$ has full column rank for all t. Thus there exists a smooth invertible $R_1(t)$ such that

$$R_1(t)M(t)=\begin{bmatrix} I & \tilde{M}_2 \\ 0 & \tilde{M}_4 \end{bmatrix}.$$

But $\tilde{M}_4$ has constant rank by assumption since M does. Thus there exist smooth $R_2(t)$, $R_3(t)$ such that

$$R_2\tilde{M}_4R_3=\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}.$$

Hence

$$\begin{bmatrix} I & 0 \\ 0 & R_2 \end{bmatrix} R_1M=\left[\begin{array}{c|c} I & \tilde{M}_2 \\ \hline \begin{matrix} 0 \\ 0 \end{matrix} & \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} R_3^{-1} \end{array}\right]=\left[\begin{array}{c|ccc} I & [\hat{M}_{21} & \hat{M}_{22}] & R_3^{-1} \\ \hline 0 & [I & 0] & R_3^{-1} \\ 0 & 0 & 0 & \end{array}\right]. \tag{3.7}$$

Now multiply both sides of (3.7) on the left by

$$\begin{bmatrix} I & -\hat{M}_{21} & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} \quad \text{to get} \quad \left[\begin{array}{c|ccc} I & [0 & \hat{M}_{22}] & R_3^{-1} \\ \hline 0 & [I & 0] & R_3^{-1} \\ 0 & 0 & 0 & \end{array}\right]. \tag{3.8}$$

But M is 1-full for each t. Thus $\hat{M}_{22}=0$. Since all the row operations given by R_2, $\hat{M}_{21}$, R_1, were smooth, we have the proof of Lemma 3.1. □

Note that in Lemma 3.1 we may take smooth to mean m-times continuously differentiable or real analytic so that r is as smooth as M. Thus if E, F, f are $2n$-times differentiable, then Q, q, in (3.5) will be at least $2n-j+1$ times differentiable and (3.5) will imply the solutions are $(2n-j+2)$-times differentiable.

In [7] it was shown that for some $j\leqq n+1$ one has $\mathscr{E}_j$ is 1-full and constant rank for many known classes of solvable systems. Using Theorem 2.1, we now show that in fact this holds for all solvable systems with smooth enough coefficients. Let $\mathscr{R}(X)$ denote the range (column space) of a matrix X.

THEOREM 3.1. *Suppose that* (1.1) *is solvable on* $\mathscr{I}$ *and* E, F *are* $2n$*-times differentiable. Then*

(3.9) $\mathscr{E}_j$ *has constant rank on* $\mathscr{I}$ *for* $j=n+1$,

(3.10) $\mathscr{E}_j$ *is smoothly one-full on* $\mathscr{I}$ *for* $j=n+1$,

(3.11) $\mathscr{R}(\mathscr{E}_j)+\mathscr{R}(\mathscr{F}_j)=C^{jn}$ *for every* $t\in\mathscr{I}$ *for* $1\leqq j\leqq n+1$.

Proof. Suppose (1.1) is solvable. As shown in [7], performing smooth coordinate changes amounts to doing block row operations and right to left block column operations on $\mathscr{E}_j$, $\mathscr{F}_j$ where the blocks have size $n\times n$. Thus (3.9)-(3.11) are not altered by such changes of coordinates. By Theorem 2.1 we may assume that (1.1) is in the form (2.6). Thus

(3.12)
$$\mathscr{E}_j=\begin{bmatrix} I & C_0 & & & & & & \\ 0 & N_0 & & & & & & \\ 0 & C_1 & 2I & 2C_0 & & & & \\ 0 & N_1+I & 0 & 2N_0 & & & & \\ 0 & C_2 & 0 & 2C_1 & 3I & 3C_0 & & \\ 0 & N_2 & 0 & 2N_1+1 & 0 & 3N_0 & & \\ 0 & & & & & \ddots & jI & jC_0 \\ 0 & & & & & & 0 & jN_0 \end{bmatrix},\quad F_j=\begin{bmatrix} 0 & 0 \\ 0 & I \\ 0 & 0 \\ 0 & 0 \\ \vdots & \vdots \\ 0 & 0 \end{bmatrix}.$$

If we perform column operations to eliminate the C_i we see that (3.9), (3.11) hold for (3.12) if and only if they hold for

$$\hat{\mathscr{E}}_j=\begin{bmatrix} N_0 & & & \\ N_1+I & 2N_0 & & \\ N_2 & 2N_1+I & 3N_0 & \\ \vdots & & \ddots & \\ N_j & 2N_{j-1} & \cdots & jN_0 \end{bmatrix},\quad \hat{\mathscr{F}}_j=\begin{bmatrix} I \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \tag{3.13}$$

Note that because of the block lower triangularity of $\mathscr{E}_j$ that $\mathscr{R}(\mathscr{E}_{j_0})+\mathscr{R}(\mathscr{F}_{j_0})=C^{nj_0}$ implies $\mathscr{R}(\mathscr{E}_j)+\mathscr{R}(\mathscr{F}_j)=C^{nj}$ for $1\leqq j\leqq j_0$. Also if $\hat{\mathscr{E}}_j$ in (3.13) is 1-full, then so is $\mathscr{E}_j$ in (3.12). Thus it suffices to prove Theorem 3.1 for (3.11), that is, the subsystem $Nx'+x=f$. Suppose that N is $n\times n$. Now since (1.1) is solvable, at a given t one may take $\mathscr{f}_j$ arbitrary. Thus (3.11) holds for (3.13). Hence rank $(\hat{\mathscr{E}}_j)\geqq(n-1)j$ for all t, $1\leqq j\leqq 2n$, since rank $(\hat{\mathscr{F}}_j)=n$. Now by Theorem 2.1 there exists disjoint open intervals $\mathscr{I}_i$ such that $\bigcup\mathscr{I}_i$ is dense in $\mathscr{I}$ and $Nx'+x=f$ can be put into SCF on each $\mathscr{I}_i$. But then on $\mathscr{I}_i$ the new coefficient matrices in $\mathscr{E}_j$ are all strictly lower triangular independent of t. Then since any n products of the N_i are zero, we can use a variation of a row operation argument used in [7, Thm. 4.3] to show that $\hat{\mathscr{E}}_j$ is 1-full and has rank $(j-1)n$ on $\mathscr{I}_i$, if $j>n$. But $\hat{\mathscr{E}}_j$ is a continuous function of t and thus the rank can only drop at a discontinuity of the rank. Hence rank $(\hat{\mathscr{E}}_j) \leqq (j-1)n$ on the closure $\overline{\cup \mathscr{I}_i}$ for $j=n+1$. But we already have rank $(\hat{\mathscr{E}}_j) \geqq (j-1)n$ on $\mathscr{I} = \overline{\cup \mathscr{I}_i}$ so that rank $(\hat{\mathscr{E}}_j) = (j-1)n$ on $\mathscr{I}$ and $\hat{\mathscr{E}}_j$ has constant rank if $j=n+1$. Now we can show that $\hat{\mathscr{E}}_j$ is also 1-full. Let $\mathscr{M}$ be the span of the first n standard basis vectors $\{e_1, \cdots, e_n\}$ in C^{jn}. Notice that

(3.14) $\hat{\mathscr{E}}_j$ is 1-full if and only if $\mathscr{M} \perp \mathscr{N}(\hat{\mathscr{E}}_j)$, where $\mathscr{N}$ denotes nullspace

and $\perp$ is determined by the usual inner product on C^{jn}. Suppose $j=n+1$. Since $\hat{\mathscr{E}}_j$ has constant rank there exists a continuous basis $\psi_1, \cdots, \psi_s$ for its nullspace. But then $e_k^* \psi_r = 0$ on $\cup \mathscr{I}_i$ for $1 \leqq k \leqq n$, $1 \leqq r \leqq s$ implies, by continuity, that $e_k^* \psi_j = 0$ on $\overline{\cup \mathscr{I}_i}$ which is $\mathscr{I}$. Thus by Lemma 3.1 and (3.14), we have that (3.10) holds. □

Theorem 3.1 has several important consequences.

COROLLARY 3.1. *If* (1.1) *is a sufficiently smooth solvable system, then the numerical methods of* [7], [8] *can be used, in principle, to integrate it.*

Thus the method of [7], [8] is in fact a general method for (1.1).

COROLLARY 3.2. *Suppose E, F are n-times differentiable where $m \geqq 2n$ and* (1.1) *is a solvable system. If $m+1-n \geqq j \geqq n+1$, then $\eta = \dim (\mathscr{N}(\mathscr{E}_j(t)))$ is independent of t and j. Furthermore, for any given n-times differentiable f, the solutions to* (1.1) *form an $(n-\eta)$-dimensional manifold.*

From [9] we now have the following theorem.

THEOREM 3.2. *Suppose that* (1.1) *is solvable, E, F are $2n$-times differentiable and $n+1 \geqq j \geqq 1+($size of N in* (2.6b)). (*In particular, $j=1+n$ suffices.*) *Then the linear manifold of consistent initial conditions is precisely the set of all x_0 such that $\mathscr{E}_j(t_0)\mathbf{x} = f_j(t_0) - \mathscr{F}_j(t_0)x_0$ is consistent. Equivalently, $f_j(t_0) - \mathscr{F}_j(t_0)x_0$ is in the range of $\mathscr{E}_j(t_0)$. Thus one may determine the manifold of consistent initial conditions by*

> *Computing W such that $\mathscr{E}_j^* W = 0$ and rank $W =$ nullity of $\mathscr{E}_j^*$;*
> *Solving $W^* \mathscr{F}_j x_0 = W^* f_j$ for x_0.*

We have then that if (1.1) is solvable it is straightforward, if time consuming, to compute the initial conditions and integrate the equations.

However, none of the development so far, other than Theorem 2.1, tells us whether (1.1) is solvable on $\mathscr{I}$ and the actual implementation of (2.6) is difficult. We now address this problem by deriving algebraic criteria on $\mathscr{E}_j$, $\mathscr{F}_j$ to ensure solvability. The criteria are to be numerically verifiable. The next result is a partial converse to Theorem 3.2.

THEOREM 3.3. *The system* (1.1) *with E, F, $n \times n$ and real analytic is solvable if and only if there is an integer $j_0 \in [1, n+1]$ such that*

(3.15) Rank $(\mathscr{E}_{j_0})$ *is constant on* $\mathscr{I}$,

(3.16) $\mathscr{E}_{j_0}$ *is* 1-*full at each* $t \in \mathscr{I}$,

(3.17) $\mathscr{R}(\mathscr{E}_{j_0}(t)) + \mathscr{R}(\mathscr{F}_{j_0}(t)) = C^{nj}$ *on* $\mathscr{I}$.

Proof [Only if]. The only if part follows from Theorem 3.1 and the observations that all transformations may be replaced by analytic ones. In particular the Q, R of (3.5) will be analytic so that we get that if f is analytic, then so is the solution x.

Lemma 3.1 goes through for any level of smoothness. The next lemma uses real analyticity in an essential way and will be used to prove the sufficiency of (3.15)–(3.17).

LEMMA 3.2. *Suppose that E, F, f are real analytic and $\mathscr{E}_j$ has constant rank on $\mathscr{I}$. If $\mathscr{E}_j$ is* 1-*full for every $t \in \mathscr{I}$ and if* (1.1) *is solvable on any subinterval $\tilde{\mathscr{I}}$ of $\mathscr{I}$, then* (1.1) *is solvable on* $\mathscr{I}$.

Proof. Assume that $\mathscr{C}_j$ is 1-full for every $t \in \mathscr{I}$ and has constant rank. Then by Lemma 2.1 it is smoothly 1-full. Suppose that (1.1) is solvable on $\tilde{\mathscr{I}} \subset \mathscr{I}$. Let x be a solution of (1.1) on $\tilde{\mathscr{I}}$. Pick $t_0 \in \tilde{\mathscr{I}}$. Let $\bar{x}$ be the solution of $x' = Qx + q$ for $t \in \mathscr{I}$ such that $\bar{x}(t_0) = \tilde{x}(t_0)$. Then $\bar{x}$ is analytic on $\mathscr{I}$ and $\bar{x} = x$ for $t \in \tilde{\mathscr{I}}$ since $x' = Qx + q$ for $t \in \tilde{\mathscr{I}}$. Thus $E\bar{x}' + F\bar{x} = f$ for $t \in \tilde{\mathscr{I}}$. Since E, $\bar{x}$, F, f are all analytic on $\mathscr{I}$, this relationship must hold for all t by analytic continuation and $\bar{x}$ is a solution of (1.1) on $\mathscr{I}$. This shows that solutions of (1.1) exist for any analytic f. The uniqueness follows from the fact they are also solutions of (3.5). Thus (1.1) is solvable on $\mathscr{I}$ for real analytic f. Then using the existence of the SCF on $\mathscr{I}$ gives solvable for $f \in \mathscr{C}_{2n}$. □

We can now complete the proof of Theorem 3.3.

Proof of Theorem 3.3 [If part]. If the system (1.1) is one-dimensional then the theorem is true. Suppose then that (1.1) is a minimal-dimensional counterexample to Theorem 3.3. That is, (1.1) satisfies (3.15)-(3.17), but is not solvable on an interval $\mathscr{I}$. By Lemmas 3.1, 3.2, it is also a counterexample on any nontrivial subinterval $\tilde{\mathscr{I}} \subset \mathscr{I}$. Note that E, F are $n \times n$ matrices with $n \geqq 2$. Since (1.1) is assumed not solvable, E must be singular for some $t \in \mathscr{I}$. But (3.15) then implies E is singular for all $t \in \mathscr{I}$. Let p be a positive integer such that rank $E \leqq p < n$ for all $t \in \mathscr{I}$. Then there exists analytic nonsingular H such that

$$HE = \begin{bmatrix} E_{11} & E_{12} \\ 0 & 0 \end{bmatrix}$$

where E_{11} is $p \times p$. We now use the fact that (3.15)-(3.17) are unaffected by changes of coordinates. Multiplying (1.1) by H gives the equivalent system

$$\begin{bmatrix} E_{11} & E_{12} \\ 0 & 0 \end{bmatrix}\begin{bmatrix} z' \\ w' \end{bmatrix} + \begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix}\begin{bmatrix} z \\ w \end{bmatrix} = \begin{bmatrix} g \\ h \end{bmatrix} \tag{3.18}$$

where (3.15)-(3.17) still hold. But if (3.17) holds, then it must be that $\mathscr{R}(E) + \mathscr{R}(F) = \mathrm{C}^n$ and similarly for (3.18). Thus

$$\mathscr{R}\left(\begin{bmatrix} E_{11} & E_{12} \\ 0 & 0 \end{bmatrix}\right) + \mathscr{R}\left(\begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix}\right) = \mathrm{C}^n$$

and $[F_{21} \quad F_{22}]$ must be identically full row rank. Hence there exists a nonsingular real analytic $Q(t)$ such that $[F_{21} \quad F_{22}]\ Q = [0 \quad \tilde{F}_{22}]$ with $\tilde{F}_{22}$ invertible. Letting

$$\begin{bmatrix} z \\ w \end{bmatrix} = Q\begin{bmatrix} u \\ v \end{bmatrix}$$

changes (3.18) to the equivalent system

$$\begin{bmatrix} \tilde{E}_{11} & \tilde{E}_{12} \\ 0 & 0 \end{bmatrix}\begin{bmatrix} u' \\ v' \end{bmatrix} + \begin{bmatrix} \tilde{F}_{11} & \tilde{F}_{12} \\ 0 & \tilde{F}_{22} \end{bmatrix}\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} g \\ h \end{bmatrix}. \tag{3.19}$$

But by (3.17) $\tilde{F}_{22}$ must be nonsingular. Multiply (3.19) by

$$\begin{bmatrix} I & -\tilde{F}_{12}\tilde{F}_{22}^{-1} \\ 0 & \tilde{F}_{22}^{-1} \end{bmatrix}$$

to give

$$\begin{bmatrix} \tilde{E}_{11} & \tilde{E}_{12} \\ 0 & 0 \end{bmatrix}\begin{bmatrix} u' \\ v' \end{bmatrix} + \begin{bmatrix} \tilde{F}_{11} & 0 \\ 0 & I \end{bmatrix}\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} \tilde{g} \\ \tilde{h} \end{bmatrix}. \tag{3.20}$$

Take j to be the j_0 of (3.15)-(3.17). Then for (3.20) the $\mathscr{E}_j$, $\mathscr{F}_j$ take the form

$$(3.21)\qquad \mathscr{E}_j=\begin{bmatrix} \tilde{E}_{110} & \tilde{E}_{120} & & & & & \\ 0 & 0 & & & & & \\ \tilde{E}_{111}+\tilde{F}_{110} & \tilde{E}_{120} & 2\tilde{E}_{110} & 2\tilde{E}_{120} & & & \\ 0 & I & 0 & 0 & & & \\ \vdots & & & & \ddots & & \\ \tilde{E}_{11j-1}+\tilde{F}_{11j-2} & \tilde{E}_{12j-1} & & & & j\tilde{E}_{110} & j\tilde{E}_{120} \\ 0 & 0 & \cdots & & I & 0 & 0 \end{bmatrix}$$

and

$$(3.22)\qquad \mathscr{F}_j=\begin{bmatrix} \tilde{F}_{110} & 0 \\ 0 & I \\ \tilde{F}_{111} & 0 \\ 0 & 0 \\ \vdots & \vdots \\ \tilde{F}_{11j-1} & 0 \\ 0 & 0 \end{bmatrix}.$$

By assumption $\mathscr{R}(\mathscr{E}_j)+\mathscr{R}(\mathscr{F}_j)=C^{jn}$. Let u, v be any two vectors such that $\mathscr{E}_j u+\mathscr{F}_j v\in C^p\oplus 0^{jn-p}\subseteq C^{jn}$ where $C^n\oplus 0^s$ means n arbitrary entries followed by s zero entries. The fourth row of $\mathscr{E}_j$ in (3.21) shows that the $p+1$ through n entries of u are zero and thus $\mathscr{R}(\tilde{\mathscr{E}}_{110})+\mathscr{R}(\tilde{\mathscr{F}}_{110})=C^p$. Pick a point $t_0\in\mathscr{I}$. Then there is an analytic matrix $Q(t)$ such that $\tilde{E}_{110}Q(t)+\tilde{F}_{110}$ is invertible on a neighborhood of t_0. Let U be the solution of $U'=QU$, $U(t_0)=I$, let $u=U\tilde{u}$, and restrict (3.20) to the subinterval $\tilde{\mathscr{I}}$. We still have a counterexample to Theorem 3.3 except now $\tilde{F}_{11}$ in (3.20) is nonsingular. Multiplying by $\tilde{F}_{11}^{-1}$ we finally get that our counterexample is

$$(3.23)\qquad \begin{bmatrix} E_1 & E_2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} u' \\ v' \end{bmatrix}+\begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}\begin{bmatrix} u \\ v \end{bmatrix}=\begin{bmatrix} g \\ h \end{bmatrix}$$

(with new E_1, E_2, u, v, g). Also now

$$(3.24)\qquad \mathscr{E}_j=\begin{bmatrix} E_{10} & E_{20} & & & & & \\ 0 & 0 & & & & & \\ E_{11}+I & E_{21} & 2E_{10} & 2E_{20} & & & \\ 0 & I & 0 & 0 & \ddots & & \\ \vdots & & & & & & \\ E_{1j-1} & E_{2j-1} & \cdots & (j-1)E_{11}+I & (j-1)E_{21} & jE_{10} & jE_{20} \\ 0 & 0 & \cdots & 0 & I & 0 & 0 \end{bmatrix},$$

$$\mathscr{F}_j=\begin{bmatrix} I & 0 \\ 0 & I \\ 0 & 0 \\ \vdots & \vdots \\ 0 & 0 \end{bmatrix}.$$

Notice that if

$$(3.25)\qquad E_1u'+u=g$$

is solvable, then so is (3.18), which is a contradiction. Since E_1 has smaller dimensions than E it suffices to show (3.15)-(3.17) hold for (3.25) to obtain a contradiction. Using the I blocks in (3.24) and doing row operations on $\mathscr{E}_j$ to zero the remaining entries in those columns we see that

$$\tilde{\mathscr{E}}_j = \begin{bmatrix} E_{10} & & & & 0 \\ E_{11}+I & 2E_{10} & & & 0 \\ \vdots & & \ddots & & \vdots \\ E_{1j-1} & & & jE_{10} & jE_{20} \end{bmatrix} = [\Sigma_j|\phi],$$

$$\tilde{\mathscr{F}}_j = \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} \tag{3.26}$$

is 1-full iff (3.24) is. But $\tilde{\mathscr{E}}_j$ 1-full implies Σ_j is 1-full and Σ_j is the $\mathscr{E}_j$ matrix for (3.25). Thus (3.16) holds for (3.25). Since Σ_j is real analytic we may take a subinterval on which it has constant rank so that (3.15) holds for (3.25). There remains only to verify (3.17) for (3.25) to complete the proof. We may assume $j \geqq 2$. Then by assumption on (3.24), (3.17) holds. Observe that then one can find u, v so that $\mathscr{E}_j u + \mathscr{F}_j v$ gives any vector in $\sum_{i=1}^{j} \oplus (\mathrm{C}^p \oplus o^{n-p})$. The last row implies that the $jn-2$ block entry of u is zero. Let $\hat{\mathscr{E}}_j$ be $\tilde{\mathscr{E}}_j$ with the $(j-1)E_{20}$ entry zero. Then this says $\mathscr{R}(\hat{\mathscr{E}}_j) + \mathscr{R}(\tilde{\mathscr{F}}_j) = \mathrm{C}^{jp}$. But $\mathscr{R}(\Sigma_{j-1}) + \mathscr{R}(\mathscr{F}_{j-1}) = \mathrm{C}^{(j-1)p}$ since Σ_{j-1} is the $n(j-1) \times n(j-1)$ principal submatrix of $\hat{E}_j$. As noted Σ_j is the $\mathscr{E}_j$ matrix for (3.24). Thus $\mathscr{R}(\mathscr{E}_i) + \mathscr{R}(\mathscr{F}_i) = \mathrm{C}^{ni}$ for (3.25) for $i = j_0 - 1 = n$. Since E_1 has dimension less than or equal to $n-1$, we have (3.25) satisfies (3.15), (3.16), (3.17) which is a contradiction. □

COROLLARY 3.3. *Suppose that E, F, f are real analytic on $\mathscr{I}$. Then* (1.1) *is solvable on $\mathscr{I}$ if and only if* (3.15) *holds on $\mathscr{I}$,* (3.17) *holds at t_0, and* (3.16) *holds on a dense subset of $\mathscr{I}$.*

Proof. If (3.17) holds at t_0, it will hold in some subinterval $[t_0, t_0+\varepsilon]$. Now use Lemma 3.2, Theorem 3.3, and (3.15). □

We can extend the proof of Theorem 3.2 to cover infinitely differentiable functions. To do this, observe first that if E, F are infinitely differentiable and (1.1) is solvable on $\mathscr{I}$, then by considering only infinitely differentiable solutions one may get (2.11) where $Nw' + w = f_2$ has only one infinitely differentiable solution for each infinitely differentiable f_2. However, if $Nw' + w = 0$ and w is not infinitely differentiable it follows that $w = 0$ on $\bigcup \mathscr{I}_i$ and hence $w = 0$ on $\mathscr{I}$. Also, as noted earlier if E, F, f are infinitely differentiable, then so are Q, q and hence x. Thus for E, F infinitely differentiable, we may consider solvability to mean that x, f are also infinitely differentiable. This version of Theorem 2.1 is actually slightly weaker, since solvability is taken to mean for every infinitely differentiable f, (1.1) has a solution. This does not immediately imply that for every n-times differentiable f, (1.1) will have a smooth solution. If we call this weaker form of solvability $\mathscr{C}^\infty$-solvability, then Theorem 2.1 becomes the following.

THEOREM 3.4. *If* (1.1) *is $\mathscr{C}^\infty$-solvable, then* (1.1) *is equivalent to* (2.6) *where all of the functions including g, h are infinitely differentiable.*

Using Theorem 3.4, we may generalize Theorem 3.3 as follows.

THEOREM 3.5. *The system* (1.1) *with E, F infinitely differentiable is $\mathscr{C}^\infty$-solvable if and only if there exists a $j_0 \geqq n+1$ such that* (3.15)-(3.17) *hold.*

Proof. The "only if" part follows from Theorem 3.1. To prove the "if" part, suppose that E, F, f are infinitely differentiable on $\mathscr{I}$ and that (3.15)-(3.17) hold for

$j_0 \geqq n+1$. There are a countable number of open intervals $\mathcal{I}_i$ such that $\bigcup \mathcal{I}_i$ is dense in $\mathcal{I}$ and rank E is constant on each $\mathcal{I}_i$. Premultiplication (on each $\mathcal{I}_i$) gives

$$\begin{bmatrix} E_1 & E_2 \\ 0 & 0 \end{bmatrix} x' + \begin{bmatrix} F_1 & F_2 \\ F_3 & F_4 \end{bmatrix} x = f.$$

By (3.17), the matrix $[F_3, F_4]$ has full row rank and we may do a change of coordinates $x = Vy$ to give

$$\begin{bmatrix} E_1 & E_2 \\ 0 & 0 \end{bmatrix} y' + \begin{bmatrix} F_1 & F_2 \\ 0 & I \end{bmatrix} y = f$$

with new E_i, F_i. A premultiplication gives finally that

$$\begin{bmatrix} E_1 & E_2 \\ 0 & 0 \end{bmatrix} y' + \begin{bmatrix} F_1 & 0 \\ 0 & I \end{bmatrix} y = \tilde{f}.$$

As shown in [7] these coordinate changes do not affect (3.15)-(3.17). Thus $E_1 y_1' + F_1 y_1 = g$ satisfies (3.17) with $\mathrm{j}_0 \leqq n$. Continuing in this manner we get that there exists a countable family of disjoint open intervals $\mathcal{I}_i$ such that $\bigcup \mathcal{I}_i$ is dense in $\mathcal{I}$ and on each $\mathcal{I}_i$ there exists P_i, V_i so that premultiplication by P_i and letting $x = V_i y$ transfers (1.1) to standard canonical form [6] so that (1.1) is solvable on each $\mathcal{I}_i$. The P_i, V_i are defined only on $\mathcal{I}_i$.

By assumption on $\mathscr{E}_j$, $\mathscr{F}_j$ there exists smooth nonsingular $\mathscr{R}$ on all of $\mathcal{I}$ so that

$$R[\mathscr{E}_j \mid \mathscr{F}_j] = \left[\begin{array}{c|c} X & Y \\ \hline 0 & \theta \end{array}\right]$$

with X of full row rank. Now (1.1) is solvable on each $\mathcal{I}_i$ and from [2], [8] we have the solutions are given by (3.5) and the constraint matrix $\theta(t)$:

$$\dot{x} = Q(t)x(t) + q(t), \tag{3.27}$$

$$0 = \theta(t)x(t) + h(t) \tag{3.28}$$

and g, h are differential operators applied to f,

$$g(t) = \sum_{i=0}^{n} \phi_i(t) f^{(i)}(t), \qquad h(t) = \sum_{i=0}^{n} \psi_i(t) f^{(i)}(t).$$

By assumption on $\mathscr{E}_j$, $\mathscr{F}_j$, the coefficients $Q(t)$, $\theta(t)$, $\phi_i(t)$, $\psi_i(t)$ are in $\mathscr{C}^\infty[\mathcal{I}]$. Also since $\theta(t)$ has full row rank on $\mathcal{I}$ by (3.15), (3.16), (3.17), there exists a change of coordinates W defined on $\mathcal{I}$ so that $\theta(t)W(t) = [0 \ \ I]$. Then (3.27), (3.28) becomes

$$x_1' = Q_{11}x_1 + Q_{12}x_2 + q_1, \tag{3.29}$$

$$x_2' = Q_{21}x_1 + Q_{22}x_2 + q_2, \tag{3.30}$$

$$0 = x_2 + h \tag{3.31}$$

where $[Q_{ij}] = Q^{-1}(QW - W')$, $[q_i] = W^{-1}q$. But (3.29)-(3.31) characterize the solutions of (1.1) on $\mathcal{I}_i$. Letting $f = 0$ in (3.29), (3.30), (3.31) gives, on each $\mathcal{I}_i$,

$$x_1' = Q_{11}x_1, \qquad 0 = Q_{21}x_1.$$

However, $\dim x_1$ is the dimension of the solution manifold on $\mathcal{I}_i$ so $Q_{21} = 0$ on $\bigcup \mathcal{I}_i$. By continuity $Q_{21} \equiv 0$ on $\mathcal{I}$. Returning to (3.29)-(3.31) we now have

$$x_1' = Q_{11}x_1 - Q_{12}h + q_1, \tag{3.32}$$

$$0 = -Q_{22}h + q_2 - h'. \tag{3.33}$$

Given an $f \in \mathscr{C}^\infty[\mathscr{I}]$, by solvability of (3.23) on $\mathscr{I}_i$, we have (3.33) trivially holds on $\bigcup \mathscr{I}_i$. But then (3.33) holds on $\mathscr{I}$ by continuity. Thus (3.32), (3.33), and hence (3.19)-(3.21) have dim x_2 linearly independent solutions defined on all of $\mathscr{I}$. But by construction these solutions satisfy (1.1) on $\bigcup \mathscr{I}_i$. By continuity they satisfy (1.1) on $\mathscr{I}$. □

Observe that if we let

$$\mathscr{L}x = Ex' + Fx, \quad \mathscr{H}x = x' - Qx, \quad \mathscr{R}x = \sum_i R_{1i}x^{(i)}$$

then we can write

$$\mathscr{R}\mathscr{L} = \mathscr{H}. \tag{3.34}$$

Also this proof does not actually require infinite differentiability. Being $3n$-times differentiable would suffice.

4. Comments. This paper provides a fairly complete theory for (1.1) based on the ideas of [7]. In particular, the numerical approach of [7], [8] works on all smooth solvable systems. For infinitely differentiable coefficients, it works if and only if the system is solvable. The conclusion (3.34) implies that the operator L is what Emre calls left-admissable [11]. Examining this connection with [11] would be a major digression and will be done elsewhere.

One difficulty in working with (1.1) is that a system $Ex' + Fx = f$ with E, F close in the $\|\cdot\|_m$ norm to E, F need not be solvable, and if solvable, need not have solutions close to those of (1.1). However, using the differential equation (3.5), Theorem 3.1 and Corollary 3.2, we can now make the following statement (Theorem 4.1). While an immediate consequence of § 3, this is the first result of its kind we are familiar with.

THEOREM 4.1. *Suppose that E^τ, F^τ, E, F are in $\mathscr{C}_{2n}$ where τ is a parameter. Suppose that $E^\tau \to E$, $F^\tau \to F$ in $\mathscr{C}_{2n}$ as $\tau \to \tau_0$. Suppose that $E^\tau x' + F^\tau x = f$ is solvable for each t and that for $j = n+1$*, rank $(\mathscr{C}_j^\tau) =$ rank $(\mathscr{C}_j)$ *for all $t \in \mathscr{I}$. Then $Ex' + Fx = f$ is solvable. Furthermore, the manifolds of initial conditions and solutions are also continuous in τ at τ_0.*

Proof. The only part that needs proof is that $\mathscr{C}_j$ is 1-full. But this follows in the same way we extended 1-fullness to the closure of $\bigcup \mathscr{I}_i$ in Theorem 2.1. □

COROLLARY 4.1. *Suppose* (1.1) *is equivalent to a system in* SCF. *Then there exist polynomial matrices (in t) E^τ, F^τ such that $E^\tau \to E$, $F^\tau \to F$ in $\mathscr{C}_{2n}$ as $\tau \to \tau_0$. $E^\tau x' + F^\tau x = f$ is a solvable system for every τ, and the solution manifold is continuous in τ at τ_0.*

Proof. Take $\mathscr{C}_{2n}$ polynomial approximations of both the SCF and the coordinate changes that put it into SCF. □

This argument does not work if (1.1) is not equivalent to a system in SCF. We do not know if the polynomial solvable systems are dense (in the sense of Corollary 4.1) in all solvable systems.

Theorem 3.3 (or Corollary 3.3), to our knowledge, supplies the first explicit characterization of solvability. However, it appears to involve a great deal of computation. We shall now show how this may usually be done simultaneously with the solution at little additional overhead.

Suppose then that we have (1.1) on $[t_0, t_1]$ with E, F, f real analytic or infinitely differentiable. At t_0, rank $(\mathscr{C}_j(t_0)) = r_0$ is determined, possibly by a singular value decomposition (SVD) and (3.16), (3.17) are also verified. This SVD may also be used to estimate the conditioning of (3.4). Suppose that we now proceed to numerically solve (1.1) by integrating (3.5) as described in [8]. First a QR factorization is performed on the first n columns of $\mathscr{E}_j$ to yield

$$Q^T\mathscr{E}_j=\begin{bmatrix} R_{11} & H_{12} \\ 0 & H_{22}\end{bmatrix}, \qquad Q^T\mathbf{f}_j=\begin{bmatrix} f_1 \\ f_2\end{bmatrix} \tag{4.1}$$

and R_{11} is nonsingular and upper triangular. If this cannot be done, then we could use an SVD. If this still fails to produce a nonsingular R_{11}, then either the problem is not 1-full or is too numerically ill conditioned. Suppose then we have that (3.4) is now (4.1). Now perform a QR on H_{22} using column pivoting so that (3.4) is now

$$\begin{bmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \\ 0 & 0 & \varepsilon_1 \end{bmatrix}\begin{bmatrix} \tilde{x}_1 \\ z_1 \\ z_2 \end{bmatrix}=\begin{bmatrix} \hat{f}_1 \\ \hat{f}_2 \\ \varepsilon_2 \end{bmatrix} \tag{4.2}$$

where R_{22} is nonsingular, upper triangular, and $(r_0-n)\times(r_0-n)$. If R_{22} is not that size, then use an SVD instead of a QR. If R_{22} is still not the correct size, either we are near a place where (3.15) is violated or the problem is too ill conditioned to proceed directly (note [23]). Similarly, if ε_1, ε_2 are not negligible, then (3.17) is being violated numerically. It is probably not necessary to check 1-fullness at every time step and one can often use the basic solution in (4.2) by setting $z_2=0$ and backsolving for x_1. However, there are a couple of ways to check 1-fullness. One is to use elementary row operations to use R_{22} to zero R_{12}. Then E_j is 1-full if and only if R_{13} is also zeroed out. An alternative is to perform Householder transformations (which need not be saved) on the right of the coefficient matrix in (4.2) to get

$$\begin{bmatrix} R_{11} & \tilde{R}_{12} & \varepsilon_3 \\ 0 & \tilde{R}_{22} & 0 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} x_1 \\ z_1 \\ z_2 \end{bmatrix}=\begin{bmatrix} \hat{f}_1 \\ \hat{f}_2 \\ 0 \end{bmatrix} \tag{4.3}$$

where $\tilde{R}_{22}$ is again upper triangular. If ε_3 is not negligible, we consider the system to not be 1-full, (3.16) is violated and we stop. If $\varepsilon_3=0$, then we solve (4.3) for z_1 and then x_1 by back substitution to get

$$\tilde{x}_1=-R_{11}^{-1}\tilde{R}_{12}\tilde{R}_{22}^{-1}\hat{f}_2 \tag{4.4}$$

and proceed with our integration scheme.

The decisions require, as is often the case with numerical procedures, making decisions on numerical rank [15], [23]. However, if (1.1) is solvable on $\mathscr{I}$, with smooth enough coefficients, then there exists a precision and step size (depending on the conditioning of the algebraic equations) and the system (3.5) which will permit us to integrate (1.1) (equivalently (3.5)). Conversely, if (1.1) is not solvable on all of $\mathscr{I}$, then there is a stepsize h such that using any stepsize smaller than this will lead to the determination that (3.15) or (3.16) are violated and the problem is not solvable. In any event, the conditioning of the required algebra in (3.4) over $\mathscr{I}$ is independent of the stepsize, whereas the conditioning of the algebraic problems in a backward difference scheme increases as h decreases.

Finally, note that showing the solution x of (1.1) satisfied (3.5) required f to be in $\mathscr{C}_{2n}$ (or $\mathscr{C}_{2r}$ if there was a SCF) since we need $\mathbf{x}_{n+1}$ to exist. However, by taking limits in $\mathscr{C}_1$ one may show that if $f\in\mathscr{C}_n$, then x satisfies (3.5) for some q with the same Q.

A SYNTHETIC STUDY OF ONE-PARAMETER NONLINEAR PROBLEMS*

PATRICK RABIER†

Abstract. We present a study on the local structure of the set of solutions of one-parameter nonlinear problems, based on a recent generalization of the Implicit function theorem. We show how the combination of some nondegeneracy condition together with a priori requirements allows one to treat both cases without or with change of scale. The approach we develop is self-contained and provides most of the classical results on "nondegenerate" bifurcation with various improvements and extensions. Also, the suitable change of scale, if any, is shown to be as predicted by Newton's diagrams. Applications to standard model problems in nonlinear P.D.E.'s are given.

Key words. nondegeneracy condition, one-parameter problems, Newton's diagrams

AMS(MOS) subject classification. 58E07

1. Introduction and preliminaries. Let X and Y be two real Banach spaces and $G(=G(\mu, x))$ a mapping of the variables $\mu \in \mathbb{R}$ and $x \in X$ with values in Y such that $G(0)=0$. We intend to show how a generalization of the Implicit function theorem (Theorem 1.1) can be used for finding the zero set of G around the origin. The first step of our method is classical insofar as it makes use of the Lyapunov-Schmidt reduction so that the problem becomes equivalent to a finite-dimensional one, the mapping G being replaced by the so-called reduced mapping. Unfortunately, the assumptions on the reduced mapping involve higher-order derivatives whose expression in terms of G rapidly becomes very intricate. This fact is even more pronounced when a preliminary change of the parameter μ into $\pm\eta^p$ for some suitable integer $p \geqq 2$ is necessary.

Our first aim has been to give a sharp criterion for the generalization of the Implicit function theorem mentioned above to be available under "simple" assumptions on the mapping G, whether the parameter μ is changed or not. What we mean by "simple" will be made precise later in this section and makes explicit a condition already considered desirable by most authors, who have formulated appropriate particular hypotheses in this aim. Of course, this does not mean that there is no problem of interest which does not fulfill our conditions: for instance, bifurcation near a degenerated eigenray does not fit into our framework in general.

The basic form of the criterion we use is established in § 2, but its most useful versions are derived in § 4. The effect of its combination with Theorem 1.1 are briefly examined in § 3 (no change of parameter) and in more detail in § 4 ($\mu = \pm\eta^p$). In both cases, we obtain results of regularity of the curves that are better than the existing ones (when any exist at all) and our study applies beyond the classical framework.

The analysis of § 4 naturally leads to the observation that the value of p in the change of scale not only cannot be arbitrary but is uniquely determined as a rational number (or $-\infty$) that becomes available for our purposes as soon as its value is an integer. Integer or not, an a posteriori verification shows that it is exactly as provided by using Newton's diagrams. Besides, it is related to another integer κ whose meaning in the problem is evident by showing that p must divide κ or $\kappa-1$. Hence, the two cases $p=\kappa$ and $p=\kappa-1$ only bear a general discussion. Heuristically, this explains

* Received by the editors October 8, 1984; accepted for publication (in revised form) June 17, 1986.

† Université Pierre et Marie Curie, Laboratoire d'Analyse Numérique, 4 Place Jussieu, 75230 Paris Cedex 05, France. Present address, Southern Methodist University, Department of Mathematics, Dallas, Texas 75275.

why they have already attracted attention in general problems (especially $p=\kappa-1$ in the study of problems of bifurcation from the trivial branch). Note however that noninteger values of p have sometimes been successfully used; for instance in problems of bifurcation from the trivial branch when the linearized operator has a nontrivial generalized null-space (see Landman and Rosenblat [10]).

The location of the curves of solutions of the equation $G(\mu, x)=0$ with respect to the hyperplane $\mu=0$ in $\mathbb{R}\times X$ is fully discussed from the parity of p. Our conclusions cover the concepts of "regular," "turning" or "hysteresis" point as well as "supercritical," "subcritical" or "transcritical" bifurcation point.

This paper contains conclusions related to those of Crandall and Rabinowitz [4], McLeod and Sattinger [11], Magnus [12], Szulkin [19] and Buchner, Marsden and Schecter [3], which follow with various complements and extensions. Problems beyond their domain of validity (including standard ones) can also be treated. The results we present are then fairly general though accurate. It is noteworthy that they all derive from the criterion of § 2 in conjunction with the nondegeneracy condition of Theorem 1.1: the whole theory thus reduces to these two basic aspects after technical manipulations which are precisely the purpose of §§ 3 and 4. Related computational algorithms are described in [15], [16].

Due to the abundant literature devoted to the subject, special attention has been given to problems of bifurcation from the trivial branch, although existence of a known branch plays no role in this approach. In particular, nonexistence of a nontrivial generalized null-space (i.e., direct sum of the null-space and the range) for the linearized operator is shown to be a necessity imposed by the standing nondegeneracy condition.

Examples of application to nonlinear partial differential equations are given in § 5. Other examples of interest in which the usual properties of the mapping G may significantly differ are, for instance, concerned with the determination of steady solutions to systems of ordinary differential equations.

We shall now develop a few preliminaries. Throughout this paper, the mapping G is supposed to be of class $\mathscr{C}^m$, $m\geqq 1$, on a neighbourhood of the origin in $\mathbb{R}\times X$. We also assume that the partial derivative $D_xG(0)$ is a Fredholm operator with index 0, namely, that the space

$$X_1=\operatorname{Ker} D_xG(0) \tag{1.1}$$

is finite dimensional, and that the space

$$Z_2=\operatorname{Range} D_xG(0) \tag{1.2}$$

(is closed and) has finite codimension with

$$\dim X_1=\operatorname{codim} Z_2=N\geqq 0. \tag{1.3}$$

Let X_2 and Z_1 be two topological complements of X_1 and Z_2, respectively,

$$X=X_1\oplus X_2, \qquad Y=Z_1\oplus Z_2, \tag{1.4}$$

so that $\dim Z_1=\operatorname{codim} Z_2=N$ and

$$D_xG(0)|_{X_2}\in \operatorname{Isom}(X_2, Z_2). \tag{1.5}$$

Note. A previous version of this work, announced in [14], required $X=Y$ and made use of generalized null-spaces. These restrictions have disappeared in the present exposition.

Here is the basic tool we use in §§ 3 and 4 for determining the local zero set of the mapping G. A slightly more general statement can be found in [14, Thm. 3.2] and, with a loss of one degree of regularity at the origin, is also proved in Buchner et al. [3].

THEOREM 1.1. *Let $n \geqq 0$ be a given integer and $\tilde{X}_1$ and Y_1 two real vector spaces with dimension $n+1$ and n, respectively. On the other hand, let f be a mapping of class $\mathscr{C}^m$, $m \geqq 1$, defined on a neighbourhood of the origin in $\tilde{X}_1$ with values in Y_1. Assume that*

$$(1.6) \qquad D^j f(0) = 0, \qquad 0 \leqq j \leqq k-1,$$

for some $1 \leqq k \leqq m$. Denoting by q the polynomial mapping

$$(1.7) \qquad q : \tilde{x}_1 \in \tilde{X}_1 \to q(\tilde{x}_1) = D^k f(0) \cdot (\tilde{x}_1)^k \in Y_1,$$

assume further that for every nonzero solution $\tilde{x}_1 \in \tilde{X}_1$ of the equation $q(\tilde{x}_1) = 0$ the derivative $Dq(\tilde{x}_1) \in \mathscr{L}(\tilde{X}_1, Y_1)$ is onto.

Then, the zero set of the mapping q in the whole space $\tilde{X}_1$ is the union of a finite number $0^n \leqq j \leqq k^n$[1] of lines through the origin and the zero set of the mapping f around the origin of $\tilde{X}_1$ consists of exactly ν curves of class $\mathscr{C}^m$ away from the origin and $\mathscr{C}^{m-k+1}$ at the origin, where each of them is tangent to a different one of the lines in the zero set of the mapping q (1.7).

Remark 1.1. (i) When $n=0$, Theorem 1.1 applies with any $1 \leqq k \leqq m$ but the best result is obtained with $k=1$: Theorem 1.1 is then nothing but the Implicit function theorem, a fact somewhat hidden by the obviousness of the situation. Conversely, if $k=1$, Theorem 1.1 applies with $n=0$ only since the mapping q (1.7) is the trivial one $q=0$. Thus, assuming $n>1$ implicitly requires $k \geqq 2$.

(ii) When $n=1$ and $k=2$, Theorem 1.1 gives a result which is better than when using the classical Morse lemma (providing $\mathscr{C}^{m-2}$ regularity at the origin instead of $\mathscr{C}^{m-1}$). However, in this case, Theorem 1.1 follows from an improved version of the Morse lemma that can be found in Kuiper [9].

Remark 1.2. The assumption we make on the mapping q (1.7) in Theorem 1.1 will be referred to as "condition of $\mathbb{R}$-nondegeneracy" and abbreviated as ($\mathbb{R}$-N.D.) according to the denomination used in [14]. Some comments on how it can be checked in practice are given in [3], [15].

Remark 1.3. As an odd continuous mapping from $\mathbb{R}^m$ into $\mathbb{R}^n$ always vanishes on the unit sphere of $\mathbb{R}^m$ when $m>n$, we find that $\nu \geqq 1$ when k is odd. When k is even, Buchner et al. have proved that ν is even too [3, Thm. 2.7].

We shall use Theorem 1.1 in the following way: Let $\tilde{X}$ be another real Banach space (in practice, $\tilde{X}$ will be $\mathbb{R} \times X$ but the real variable will not always be μ) and H a mapping of class $\mathscr{C}^m$, $m \geqq 1$, on a neighbourhood of the origin in $\tilde{X}$ with values in Y such that $H(0)=0$. Assume that $DH(0)$ is a Fredholm operator with index 1, namely that

$$(1.8) \qquad \tilde{X}_1 = \operatorname{Ker} DH(0)$$

is finite dimensional, and

$$(1.9) \qquad Y_2 = \operatorname{Range} DH(0),$$

(is closed and) has finite codimension with

$$(1.10) \qquad \operatorname{codim} Y_2 = n \geqq 0, \qquad \dim \tilde{X}_1 = n+1.$$

[1] With $0^0 = 1$ as an understanding.

Let $\tilde{X}_2$ and Y_1 be two topological complements of $\tilde{X}_1$ and Y_2, respectively. Denoting by P_1 and P_2 the (continuous) projection operators onto Y_1 and Y_2, respectively, and after Lyapunov-Schmidt reduction, finding the local zero set of H near the origin amounts to finding the local zero set of the reduced mapping

$$\tilde{x}_1 \in \tilde{X}_1 \to f(\tilde{x}_1) = P_1 H(\tilde{x}_1 + \tilde{\phi}(\tilde{x}_1)) \in Y_1, \tag{1.11}$$

where the function $\tilde{\phi}$ with values in $\tilde{X}_2$ and of class $\mathscr{C}^m$ around the origin is characterized through the Implicit function theorem as solving the equation

$$P_2 H(\tilde{x}_1 + \tilde{\phi}(\tilde{x}_1)) = 0. \tag{1.12}$$

The local zero set of f can be determined by using Theorem 1.1. Nevertheless, in proportion as the index j grows, the derivative $D^j f(0)$ becomes more and more complicated in terms of H because of the increasing number of derivatives of $\tilde{\phi}$ involved in its expression. As a result, writing down the corresponding assumptions on H and checking that they are satisfied seems to be impossible even for relatively small values of k.

However, there is no difficulty if $k = 2$: indeed, implicit differentiation of (1.12) shows that $D\tilde{\phi}(0) = 0$ and it follows that the first two derivatives of the mappings f and $P_1 H(\tilde{x}_1)$ at the origin coincide. This raises the question of whether a simple criterion can be found ensuring that the assumptions of Theorem 1.1 can be checked with the mapping $P_1 H(\tilde{x}_1)$ instead of the reduced mapping. In this case, $D^j f(0) = P_1 D^j H(0)|_{(\tilde{X}_1)^j}$, $0 \leqq j \leqq k$, a particularly simple expression in terms of H. Such a criterion will be established in § 2. In § 3, we take $\tilde{X} = \mathbb{R} \times X$ with generic element (μ, x) and $H = G$. Next, observe that if p is an odd integer, the solutions of the equation $G(\eta^p, x) = 0$ are in one-to-one onto correspondence with the solutions of the equation $G(\mu, x) = 0$ since the mapping $\eta \to \eta^p$ is a $\mathscr{C}^\infty$ homeomorphism. If p is even, the solutions of the equation $G(\eta^p, x) = 0$ provide those of $G(\mu, x) = 0$ with $\mu \geqq 0$ only. In order to get the solutions with $\mu \leqq 0$, we must consider the equation $G(-\eta^p, x) = 0$ as well. That is why, in § 4, setting $\sigma = \pm 1$ we take $\tilde{X} = \mathbb{R} \times X$ with generic element (η, x) and $H(\eta, x) = G(\sigma\eta^p, x)$. It is shown that the integer p must have specific values and that the criterion of § 2 keeps a simple form in terms of G, providing other assumptions made in the literature as particular cases. The usefulness of our generalization is exemplified in § 5 on a model problem. Also, it will be obvious that both choices $\sigma = 1$ and $\sigma = -1$ are equivalent when p is odd ($\geqq 3$). For this reason the case when the parameter p is unchanged will be referred to as the "case $p = 1$" for the sake of convenience.

2. A criterion for the first nonzero derivative. Let the mapping H be as in § 1. Assuming $n = \operatorname{codim} Y_2 = \dim Y_1 \geqq 1$, we shall give a criterion for the first nonzero derivative at the origin of the reduced mapping f (1.11) to coincide with the first nonzero derivative at the origin of the mapping $P_1 H(\tilde{x}_1)$.

Given any integer $0 \leqq l \leqq m$ we define the quantities

$$k_1(l) = \min\{0 \leqq j \leqq l,\ P_1 D^j H(0) \neq 0\}, \tag{2.1}$$

$$k^1(l) = \min\{0 \leqq j \leqq l,\ D^j H(0)|_{(\tilde{X}_1)^j} \neq 0\}. \tag{2.2}$$

In a moment, we shall also need to consider

$$k_2^1(l) = \min\{0 \leqq j \leqq l,\ P_2 D^j H(0)|_{(\tilde{X}_1)^j} \neq 0\}. \tag{2.3}$$

In the definitions (2.1)-(2.3), it is understood that $\min(\varnothing) = +\infty$ and it is then immediate that $k_1(l)$ (resp., $k^1(l)$, $k_2^1(l)$) $= +\infty$ if the derivatives of the mapping $P_1 H$ (resp., $H|_{\tilde{X}_1}$, $P_2 H|_{\tilde{X}_1}$) vanish up to order l, whereas $k_1(l)$ (resp., $k^1(l)$, $k_2^1(l)$) $\leqq l$ otherwise.

As a first step, we establish a simple estimate on the mapping $\tilde{\phi}$.

LEMMA 2.1. *Around the origin in the space $\tilde{X}_1$, one has*

$$\|\tilde{\phi}(\tilde{x}_1)\| = O(\|P_2H(\tilde{x}_1)\|), \tag{2.4}$$

and

$$\|P_2H(\tilde{x}_1)\| = O(\|\tilde{\phi}(\tilde{x}_1)\|), \tag{2.5}$$

so that the derivatives at the origin of order $\leqq m$ of the mappings $\tilde{\phi}$ and $P_2H|_{\tilde{X}_1}$ vanish up to the same order.

Proof. The mapping $\tilde{\phi}$ is characterized by the condition (cf. (1.12))

$$P_2H(\tilde{x}_1 + \tilde{\phi}(\tilde{x}_1)) = 0.$$

Hence, from Taylor's formula

$$0 = P_2H(\tilde{x}_1) + \int_0^1 P_2DH(\tilde{x}_1 + t\tilde{\phi}(\tilde{x}_1)) \cdot \tilde{\phi}(\tilde{x}_1)\,dt. \tag{2.6}$$

Since the mapping H is of class $\mathscr{C}^1$ at least, the mapping

$$\Lambda(\tilde{x}_1) = \int_0^1 P_2DH(\tilde{x}_1 + t\tilde{\phi}(\tilde{x}_1))\,dt \in \mathscr{L}(X, Y_2)$$

is continuous w.r.t. $\tilde{x}_1$ around the origin of $\tilde{X}_1$. As $\Lambda(0) = P_2DH(0)$ is an isomorphism of $\tilde{X}_2$ to Y_2 from the assumptions made in § 1, one has

$$\Lambda(\tilde{x}_1) \in \operatorname{Isom}(\tilde{X}_2, Y_2)$$

for $\tilde{x}_1$ close enough to the origin. Thus, (2.6) becomes

$$P_2H(\tilde{x}_1) = -\Lambda(\tilde{x}_1) \cdot \tilde{\phi}(\tilde{x}_1),$$

or equivalently

$$\tilde{\phi}(\tilde{x}_1) = -\Lambda^{-1}(\tilde{x}_1) \cdot P_2H(\tilde{x}_1).$$

This yields the relations (2.4) and (2.5) since the norms of $\Lambda(\tilde{x}_1)$ and $\Lambda^{-1}(\tilde{x}_1)$ are bounded around the origin. Our last assertion follows from elementary arguments. □

Given an integer $0 \leqq l \leqq m$, it is immediate on (2.1)-(2.3) and the definition of the spaces $\tilde{X}_1$, Y_1 and Y_2 that

$$k_1(l) \geqq 2, \tag{2.7}$$

$$k_2^1(l) \geqq k^1(l) \geqq 2. \tag{2.8}$$

Let us now specify the value of l by setting

$$k = \min\{0 \leqq j \leqq m,\ P_1D^jH(0)|_{(\tilde{X}_1)^j} \neq 0\}. \tag{2.9}$$

Clearly, from (2.7),

$$k \geqq \max(k_1(k), k^1(k)) \geqq 2. \tag{2.10}$$

THEOREM 2.1. *Assume $n \geqq 1$ and k defined by* (2.9) *is finite* (*i.e.* $2 \leqq k \leqq m$). *If*

$$k \leqq k_1(k) + k^1(k) - 2, \tag{2.11}$$

the reduced mapping (1.11) *verifies*

$$D^jf(0) = 0, \qquad 0 \leqq j \leqq k-1, \tag{2.12}$$

$$D^kf(0) = P_1D^kH(0)|_{(\tilde{X}_1)^k} \neq 0. \tag{2.13}$$

Proof. First, observe that

$$k^1(k)=\min(k, k_2^1(k)). \tag{2.14}$$

With (2.10) and since $k \leqq m$ we find $k_1(k) \leqq k \leqq m$. Expanding the mapping P_1H about the origin, we get

$$P_1H(\tilde{x}) = \sum_{j=k_1(k)}^{k} \frac{1}{j!} P_1 D^j H(0) \cdot (\tilde{x})^j + o(\|\tilde{x}\|^k).$$

For $\tilde{x} = \tilde{x}_1 + \tilde{\phi}(\tilde{x}_1)$ we obtain

$$f(\tilde{x}_1) = \sum_{j=k_1(k)}^{k} \frac{1}{j!} P_1 D^j H(0) \cdot (\tilde{x}_1 + \tilde{\phi}(\tilde{x}_1))^j + o(\|\tilde{x}_1 + \tilde{\phi}(\tilde{x}_1)\|^k).$$

As $\tilde{\phi}(0)=0$ and $\tilde{\phi}$ is of class $\mathscr{C}^m$, one has $\tilde{\phi}(\tilde{x}_1) = O(\|\tilde{x}_1\|)$ and the remainder in the above formula can be replaced by $o(\|\tilde{x}_1\|^k)$. Thus

$$f(\tilde{x}_1) = \sum_{j=k_1(k)}^{k} \frac{1}{j!} \sum_{i=0}^{j} \binom{j}{i} P_1 D^j H(0) \cdot ((\tilde{x}_1)^{j-i}, (\tilde{\phi}(\tilde{x}_1))^i) + o(\|\tilde{x}_1\|^k). \tag{2.15}$$

Due to Lemma 2.1 and the definition of $k_2^1(k)$, the derivatives at the origin of the mapping $\tilde{\phi}$ vanish up to order $k_2^1(k)-1$ when $k_2^1(k) < +\infty$ and up to order k when $k_2^1(k) = +\infty$. In any case, (2.14) shows that they vanish up to order $k^1(k)-1$. Hence

$$\|\tilde{\phi}(\tilde{x}_1)\| = O(\|\tilde{x}_1\|^{k^1(k)}).$$

Each term in the sum (2.15) is then of order

$$O(\|\tilde{x}_1\|^{j-i} \|\tilde{\phi}(\tilde{x}_1)\|^i) = O(\|\tilde{x}_1\|^{j-i+(k^1(k)-1)i}).$$

For $1 \leqq i \leqq j$, this term is actually in the remainder of order k. Indeed, $j+(k^1(k)-1)i$ is an increasing function of i so that

$$j+(k^1(k)-1)i \geqq j + k^1(k) - 1 \quad \text{when } 1 \leqq i \leqq j.$$

As j runs over the integers $k_1(k), \cdots, k$

$$j + k^1(k) - 1 \geqq k_1(k) + k^1(k) - 1 > k,$$

from condition (2.11). To sum up, (2.15) simplifies in the form

$$f(\tilde{x}_1) = \sum_{j=k_1(k)}^{k} \frac{1}{j!} P_1 D^j H(0) \cdot (\tilde{x}_1)^j + o(\|\tilde{x}_1\|^k).$$

But, by definition of k and since $\tilde{x}_1 \in \tilde{X}_1$, the expressions $P_1 D^j H(0) \cdot (\tilde{x}_1)^j$ vanish for $k_1(k) \leqq j < k$ and we are left with

$$f(\tilde{x}_1) = \frac{1}{k!} P_1 D^k H(0) \cdot (\tilde{x}_1)^k + o(\|\tilde{x}_1\|^k).$$

Since f is of class $\mathscr{C}^m$, $m \geqq k$, the above relation shows that the first nonzero derivative of f at the origin is of order k with

$$D^k f(0) = P_1 D^k H(0)|_{(\tilde{X}_1)^k},$$

and the proof is complete. □

Note that criterion (2.11) is always satisfied if $k=2$ since $k_1(2) = k^1(2) = 2$ as it follows from (2.7), (2.8) and (2.10). More generally, condition (2.11) is vacuous if

$k=k_1(k)$ or if $k=k^1(k)$ since $k_1(k)\geqq 2$ and $k^1(k)\geqq 2$. The case when $k=k^1(k)<+\infty$ amounts to assuming

$$D^jH(0)|_{(\tilde{X}_1)^j}=0, \qquad 0\leqq j\leqq k-1 \quad \text{(vacuous if } k=2), \tag{2.16}$$

whereas $k=k_1(k)<+\infty$ if and only if

$$P_1D^jH(0)=0, \qquad 0\leqq j\leqq k-1 \quad \text{(vacuous if } k=2). \tag{2.17}$$

A more restrictive version of (2.16) and (2.17) which is also more frequently encountered in the literature (often implicitly) is

$$D^jH(0)=0, \qquad 0\leqq j\leqq k-1. \tag{2.18}$$

Combining Theorems 1.1 and 2.1, we find the following.

THEOREM 2.2. *Let H be a mapping of class $\mathscr{C}^m$, $m\geqq 1$, on a neighbourhood of the origin in $\tilde{X}$ with values in Y such that $H(0)=0$. Assume that $DH(0)$ is a Fredholm operator with index* 1 *and set $\tilde{X}_1=\operatorname{Ker} DH(0)$, $Y_2=\operatorname{Range} DH(0)$. Let $\tilde{X}_2$ and Y_1 be two topological complements of the spaces $\tilde{X}_1$ and Y_2, respectively. Then,* $\dim Y_1=n$ *and* $\dim \tilde{X}_1=n+1$. *Let P_1 denote the projection operator associated with the decomposition $Y=Y_1\oplus Y_2$. Define*

$$k=\begin{cases}1 & \text{if } n=0,\\ \min\{0\leqq j\leqq m, P_1D^jH(0)|_{(\tilde{X}_1)^j}\neq 0\}\geqq 2 & \text{if } n\geqq 1.\end{cases} \tag{2.19}$$

When $n\geqq 1$, and in this case only, set

$$k_1(k)=\min\{0\leqq j\leqq k, P_1D^jH(0)\neq 0\}\geqq 2, \tag{2.20}$$

$$k^1(k)=\min\{0\leqq j\leqq k, D^jH(0)|_{(\tilde{X}_1)^j}\neq 0\}\geqq 2 \tag{2.21}$$

and assume

(i) $k<+\infty$,
(ii) $k\leqq k_1(k)+k^1(k)-2$ (*vacuous for* $k=2$),
(iii) *the mapping*

$$\tilde{x}_1\in\tilde{X}_1\to P_1D^kH(0)\cdot(\tilde{x}_1)^k\in Y_1, \tag{2.22}$$

verifies the condition ($\mathbb{R}$-N.D.).[2]

Then, the zero set of the mapping (2.22) *consists of* $0^n\leqq \nu\leqq k^n$[3] *lines through the origin in the space $\tilde{X}_1$ and the zero set of the mapping H around the origin of $\tilde{X}$ consists of exactly ν curves of class $\mathscr{C}^m$ away from the origin and of class $\mathscr{C}^{m-k+1}$ at the origin where each of them is tangent to a different one of the lines in the zero set of the mapping* (2.22).

Remark 2.1. It is easily seen that k, $k_1(k)$ and $k^1(k)$ are independent of the choice of the spaces $\tilde{X}_2$ and Y_1. The same is true as concerns the fact that the mapping (2.22) verifies the condition ($\mathbb{R}$-N.D.): Indeed, let Y_1' be a second space such that $Y=Y_1'\oplus Y_2$ and call P_1' the associated projection onto Y_1'. As $P_1'P_2=0$ one has $P_1'=P_1'P_1$. Also, $\operatorname{Ker} P_1'=Y_2$ and hence $P'_{1|Y_1}\in\operatorname{Isom}(Y_1, Y_1')$. The assertion is now immediate from this observation. As a result, Theorem 2.2 is independent of the choice of the Lyapunov-Schmidt reduction. Actually, from a result of Beyn [1] showing the equivalence (in some precise sense) of any two Lyapunov-Schmidt reductions, it can be shown that the order of the first nonzero derivative of the reduced mapping (1.11) at the origin

[2] Recall that the condition ($\mathbb{R}$-N.D.) was defined in Remark 1.2.

[3] With $0^0=1$ as an understanding.

and the fact that it verifies the condition ($\mathbb{R}$-N.D.) are *always* independent of the choice of the Lyapunov–Schmidt reduction.

3. Applications to one-parameter nonlinear problems: the case $p=1$. In this section, we come back to the situation described in § 1: given two real Banach spaces X and Y and a mapping $G(=G(\mu, x))$ defined and of class $\mathscr{C}^m$, $m \geqq 1$, on a neighbourhood of the origin in $\mathbb{R}\times X$ with values in Y such that $G(0)=0$, we consider the problem of finding the local zero set of G near the origin. As this paper is intended to emphasize the role of the change of parameter in this problem, we shall especially bring prominence to situations in which a direct approach (i.e. without changing the parameter μ) fails or does not provide all the desirable information.

As in § 1, we shall assume that $D_xG(0)$ is a Fredholm operator with index 0 and set

$$X_1 = \text{Ker } D_xG(0), \tag{3.1}$$

$$Z_2 = \text{Range } D_xG(0). \tag{3.2}$$

Given two topological complements X_2 and Z_1 of X_1 and Z_2, respectively, we shall denote by Q_1 and Q_2 the (continuous) projection operators from Y onto Z_1 and Z_2 and, whenever necessary, write the generic element $x \in X$ in the form $x = x_1 + x_2$, $x_1 \in X_1$, $x_2 \in X_2$. Since $D_xG(0)$ has index 0

$$N = \dim X_1 = \dim Z_1 \geqq 0. \tag{3.3}$$

Setting $\tilde{X} = \mathbb{R}\times X$ with generic element $\tilde{x} = (\mu, x)$ we shall see how the general results of § 2 apply when $H = G$. First, one has

$$DG(0)\cdot(\mu, x) = \mu D_\mu G(0) + D_xG(0)\cdot x, \tag{3.4}$$

so the null-space and the range of $DG(0)$ depend on the alternative $D_\mu G(0) \in Z_2$ or $D_\mu G(0) \notin Z_2$.

First case. $D_\mu G(0) \notin Z_2$. In the notation of § 2 and from (3.4)

$$\tilde{X}_1 = \text{Ker } DG(0) = \{0\}\times X_1 \simeq X_1, \tag{3.5}$$

$$Y_2 = \text{Range } DG(0) = \mathbb{R} D_\mu G(0) \oplus Z_2. \tag{3.6}$$

From the above and our assumptions on G, the space Y_2 is closed. Besides, due to (3.3), $\dim \tilde{X}_1 = \text{codim } Y_2 + 1 = N$. Thus, the codimension n of Y_2 is

$$n = N - 1. \tag{3.7}$$

When $N = 1$ (i.e. $n = 0$), Theorem 2.2 applies without any further assumption and the zero set of G is made of exactly one curve of class $\mathscr{C}^m$. This curve is tangent to the one-dimensional space $\tilde{X}_1 = \{0\}\times X_1$ at the origin ("vertical" tangent). Note that no information is provided as concerns its location in $\mathbb{R}\times X$ relative to the hyperplane $\mu = 0$. This will be complemented in § 4 (case "$p = \kappa$").

When $N \geqq 2$ (i.e. $n \geqq 1$), k is defined by (cf. § 2 and (3.5)–(3.6))

$$k = \min\{0 \leqq j \leqq m, P_1 D_x^j G(0)|_{(X_1)^j}\} \neq 0. \tag{3.8}$$

Assuming $k < +\infty$ (i.e. $2 \leqq k \leqq m$) one has

$$k^1(k) = \min\{0 \leqq j \leqq k, D_x^j G(0)|_{(X_1)^j} \neq 0\}. \tag{3.9}$$

In contrast, $k_1(k)$ involves derivatives of G in all directions

$$k_1(k) = \min\{0 \leqq j \leqq k, P_1 D^j G(0) \neq 0\}. \tag{3.10}$$

Theorem 2.2 will apply if $k<+\infty$ and

$$k \leqq k_1(k)+k^1(k)-2 \quad \text{(vacuous for } k=2) \tag{3.11}$$

and the mapping

$$x_1 \in X_1 \rightarrow P_1 D_x^k G(0) \cdot (x_1)^k \in Y_1, \tag{3.12}$$

verifies the condition ($\mathbb{R}$-N.D.). If so, the largest number of curves in the zero set of G is k^{N-1} and the curves are of class $\mathscr{C}^{m-k+1}$ at the origin and $\mathscr{C}^m$ away from it. Here, the two particular cases when $k=k^1(k)$ or $k=k_1(k)$ (ensuring that (3.11) holds) are, respectively,

$$D_x^j G(0)|_{(X_1)^j}=0, \qquad 0 \leqq j \leqq k-1 \quad \text{(vacuous for } k=2), \tag{3.13}$$

$$P_1 DG(0)=0, \qquad 0 \leqq j \leqq k-1 \quad \text{(vacuous for } k=2). \tag{3.14}$$

In the next section, we shall consider the quantity

$$\kappa=\min\{0 \leqq j \leqq m, \, Q_1 D_x^j G(0)|_{(X_1)^j} \neq 0\} \geqq 2. \tag{3.15}$$

When $N=1$ (i.e., $n=0$), one has $k=1$ in Theorem 2.2 and, in particular, $k<\kappa$. On the contrary, when $N \geqq 2$ (i.e., $n \geqq 1$) the inequality $k \geqq \kappa$ holds. Indeed, since Ker $P_1 = Y_2 \supset Z_2$, one has $P_1 Q_2=0$ and hence $P_1=P_1 Q_1$ so that $k \geqq \kappa$ from the definitions. Anticipating some of the results of the next section, it is not without interest to notice that the equality $k=\kappa$ holds in most cases (when $N \geqq 2$). Indeed, $k=\kappa$ unless $\kappa<+\infty$ and the κ-linear mapping $Q_1 D_x^\kappa G(0)|_{(X_1)^\kappa}$ has one-dimensional range $\mathbb{R} Q_1 D_\mu G(0)$. In the applications, a consequence of this observation is that the necessary assumptions in the study of the same problem, after we change the parameter μ in the next section, will not differ too much from those we make here. The main advantage in considering the approach of § 4 will be that it provides the information on the location of the branches relatively to the hyperplane $\mu=0$ in $\mathbb{R} \times X$, which is not available here.

Remark 3.1. For $N \geqq 2$, a simple case when $k=\kappa$ is when κ is odd and

$$Q_1 D_x^\kappa G(0) \cdot (x_1)^\kappa \neq 0 \quad \text{for every } x_1 \in X_1-\{0\}. \tag{3.16}$$

Indeed, the unit sphere in the space X_1 is connected when $N \geqq 2$ and the polynomial mapping $Q_1 D_x^\kappa G(0) \cdot (x_1)^\kappa$ is odd if κ is odd. Assuming that it takes its values in a one-dimensional subspace of Z_1, we deduce that there is a point on the unit sphere in X_1 at which it vanishes, contradicting (3.16). Condition (3.16) will appear again in § 4 regardless of the parity of κ for other reasons. Note that it is not very restrictive since the spaces X_1 and Y_1 have the same dimension (generically, a homogeneous polynomial mapping between two spaces with the same dimension is known not to vanish away from the origin according to a classical result in elementary algebraic geometry; see e.g. [6]).

Second case. $D_\mu G(0) \in Z_2$. As $D_\mu G(0) \in Z_2$, there exists $\xi \in X$ such that

$$D_x G(0) \cdot \xi = D_\mu G(0). \tag{3.17}$$

From (3.4) one has

$$\tilde{X}_1^\xi \equiv \text{Ker } DG(0)=\{(\mu, x_1-\mu\xi), (\mu, x_1) \in \mathbb{R} \times X_1\} \simeq \mathbb{R} \times X_1, \tag{3.18}$$

$$Y_2=\text{Range } DG(0)=Z_2. \tag{3.19}$$

Thus, Range $DG(0)$ is closed and dim $\tilde{X}_1^\xi = \text{codim } Y_2+1$. The codimension n of Y_2 is

$$n=N. \tag{3.20}$$

When $N=0$ (i.e. $n=0$), Theorem 2.2 applies and the zero set of G is made of exactly one curve of class $\mathscr{C}^m$. This curve is tangent to the one-dimensional space $\tilde{X}_1^\xi \subset \mathbb{R} \times X$ ("oblique" tangent). This is the case when the origin is referred to as a "regular point."

When $N \geqq 1$ (i.e. $n \geqq 1$), a complement of the space Y_2 (3.19) is nothing but a complement of Z_2. In other words, $Y_1 = Z_1$ and k is defined by

$$k = \min\{0 \leqq j \leqq m, \; Q_1 D^j G(0)|_{(\tilde{X}_1^\xi)^j} \neq 0\}. \tag{3.21}$$

Assuming $k < +\infty$ (i.e. $2 \leqq k \leqq m$) one has

$$k^1(k) = \min\{0 \leqq j \leqq m, \; D^j G(0)|_{(\tilde{X}_1^\xi)^j} \neq 0\}, \tag{3.22}$$

$$k_1(k) = \min\{0 \leqq j \leqq m, \; Q_1 D^j G(0) \neq 0\}. \tag{3.23}$$

Theorem 2.2 applies if

$$k \leqq k_1(k) + k^1(k) - 2 \quad \text{(vacuous for } k=2) \tag{3.24}$$

and the mapping

$$(\mu, x) \in \tilde{X}_1^\xi \to Q_1 D^k G(0) \cdot (\mu, x)^k \in Z_1 \quad (= Y_1) \tag{3.25}$$

verifies the condition ($\mathbb{R}$-N.D.). If so, the largest number of curves in the zero set of G is k^N and the curves are of class $\mathscr{C}^{m-k+1}$ at the origin and $\mathscr{C}^m$ away from it. The cases $k = k_1(k)$ or $k = k^1(k)$ (ensuring that (3.24) holds) are, respectively

$$Q_1 D^j G(0) = 0, \qquad 0 \leqq j \leqq k-1 \quad \text{(vacuous for } k=2), \tag{3.26}$$

$$D^j G(0)|_{(\tilde{X}_1^\xi)^j} = 0, \qquad 0 \leqq j \leqq k-1 \quad \text{(vacuous for } k=2). \tag{3.27}$$

As in the previous case when $D_\mu G(0) \notin Z_2$ and assuming $N \geqq 1$, define

$$\kappa = \min\{0 \leqq j \leqq m, \; Q_1 D_x^j G(0)|_{(X_1)^j} \neq 0\} \geqq 2. \tag{3.28}$$

As $\{0\} \times X_1 \subset \tilde{X}_1^\xi$, it follows from (3.21) that

$$k \leqq \kappa. \tag{3.29}$$

Recall when $D_\mu G(0) \notin Z_2$ and $N \geqq 2$ that the opposite inequality $k \geqq \kappa$ holds and we observed that the equality is true in most cases. The latter conclusion is no longer appropriate here. Nevertheless, the condition $k = \kappa$ is *necessary* for the mapping (3.25) to verify the condition ($\mathbb{R}$-N.D.) when $N \geqq 2$. Indeed, if $k < \kappa$, the derivative $Q_1 D_x^k G(0)|_{(X_1)^k}$ vanishes and the N-dimensional space $\{0\} \times X_1$ is readily seen to be in the zero set of the mapping (3.25). Thus, it does not consist of a finite number of lines when $N \geqq 2$ and the mapping (3.25) cannot verify the condition ($\mathbb{R}$-N.D.). As it will be seen on the example of problems of bifurcation from the trivial branch, this may be a serious reason for the failure of the approach developed in this section. Thus, when $D_\mu G(0) \in Z_2$, performing a change of the parameter μ may be a necessity, not merely for locating the curves but for proving their existence (or nonexistence) as well. When $N=1$, k need not equal κ as we shall now see.

Assume then $N=1$. Denoting by $\langle \cdot, \cdot \rangle$ the pairing between the space Y and its dual Y', one has

$$Q_1 y = \langle y^*, y \rangle y_1^0, \tag{3.30}$$

for every $y \in Y$ where y_1^0 is a given nonzero element of the one-dimensional space $Z_1 = Y_1$ and $y^* \in Y'$ is characterized by

$$(3.31) \qquad \langle y^*, y_1^0 \rangle = 1, \qquad \langle y^*, y \rangle = 0 \quad \text{for every } y \in Z_2.$$

As the space X_1 is one-dimensional too, we may set $X_1 = \mathbb{R}x_1^0$, where x_1^0 is a given nonzero element. In the discussion below, we shall limit ourselves to considering the case $D_\mu G(0) = 0$, to which the general situation $D_\mu G(0) \in Z_2$ reduces by changing $G(\mu, x)$ into $\hat{G}(\mu, x) = G(\mu, x - \mu\xi)$. If $D_\mu G(0) = 0$, we may take $\xi = 0$ so $\tilde{X}_1^0 = \mathbb{R} \times X_1$ and the mapping (3.25) is

$$(3.32) \qquad (\mu, x_1) \in \mathbb{R} \times X_1 \rightarrow Q_1 D^k G(0) \cdot (\mu, x_1)^k \in Z_1.$$

From (3.30)-(3.31), the above mapping verifies the condition ($\mathbb{R}$-N.D.) if and only if the mapping

$$(3.33) \qquad (\mu, t) \in \mathbb{R}^2 \rightarrow \langle y^*, D^k G(0) \cdot (\mu, t x_1^0)^k \rangle \in \mathbb{R},$$

does the same. It can be shown (cf. [15] for details) that a sufficient condition for this is that a certain determinant does not vanish. For $k = 2$, this determinant is that of the quadratic form (3.33) (Morse condition) and the condition is also necessary (this remains true for $k = 3$ but not for $k \geqq 4$). When $k = 2$ the result is well known but it does not seem to be widely reported for a general k.

We shall now examine in some detail the example of problems of bifurcation from the trivial branch. With $X = Y$ the mapping G is of the form

$$(3.34) \qquad G(\mu, x) = x - (\lambda_0 + \mu) L x + \Gamma(\mu, x),$$

where $L \in \mathscr{L}(X)$ is a compact operator and $\lambda_0 \in \mathbb{R} - \{0\}$ a given real number. The mapping Γ is of class $\mathscr{C}^m$, $m \geqq 1$ (with values in X) and $\Gamma(\mu, 0) = 0$ for μ around $0 \in \mathbb{R}$. In particular

$$(3.35) \qquad D_\mu^j \Gamma(0) = 0, \qquad 0 \leqq j \leqq m.$$

We shall also assume

$$(3.36) \qquad D_\mu D_x \Gamma(0) = 0,$$

$$(3.37) \qquad D_x \Gamma(0) = 0.$$

The case when λ_0 is not a characteristic value of L (i.e. $N = 0$) is obvious and well known. When λ_0 is a characteristic value of L (i.e. $N \geqq 1$), the integer k is defined by

$$(3.38) \qquad k = \min \{0 \leqq j \leqq m, \; Q_1 D^j G(0)|_{(\mathbb{R} \times X_1)^j} \neq 0\}.$$

PROPOSITION 3.1. *Assume that λ_0 is a characteristic value of L. Then, a necessary condition for our conclusions to hold is*

$$(3.39) \qquad X = \operatorname{Ker}(I - \lambda_0 L) \oplus \operatorname{Range}(I - \lambda_0 L).$$

If so, $k = 2$ and we can take $Z_1 (= Y_1) = X_1 (= \operatorname{Ker}(I - \lambda_0 L))$ without loss of generality. The criterion (3.24) *is then vacuous and it suffices to assume that the mapping*

$$(3.40) \quad (\mu, x_1) \in \mathbb{R} \times \operatorname{Ker}(I - \lambda_0 L) \rightarrow -\frac{2}{\lambda_0} \mu x_1 + Q_1 D_x^2 \Gamma(0) \cdot (x_1)^2 \in \operatorname{Ker}(I - \lambda_0 L),$$

verifies the condition ($\mathbb{R}$-N.D.).

Proof. Due to (3.36) one has $D_\mu D_x G(0) = -L$. Next, by definition of $X_1 = \operatorname{Ker}(I - \lambda_0 L)$,

$$Q_1 D_\mu D_x G(0) \cdot x_1 = -\frac{1}{\lambda_0} Q_1 x_1$$

for every $x_1 \in X_1$. Hence,

$$Q_1 D_\mu D_x G(0)|_{X_1} \neq 0 \Leftrightarrow X_1 \not\subset Z_2 (= Y_2). \tag{3.41}$$

Let us first assume $X_1 \subset Z_2$. From (3.35), (3.36) and (3.41) the value of k is $k = 2$ if and only if $Q_1 D_x^2 \Gamma(0)|_{(X_1)^2} \neq 0$. The criterion (3.24) is satisfied and the mapping (3.25) reduces to

$$(\mu, x_1) \in \mathbb{R} \times X_1 \to Q_1 D_x^2 \Gamma(0) \cdot (x_1)^2 \in Z_1 (= Y_1).$$

But the above mapping does not verify the condition ($\mathbb{R}$-N.D.) because of the elements of the form $(\mu, 0)$ in its zero set at which its derivative vanishes. Therefore, when $X_1 \subset Z_2$, the analysis of this section may be available with $k \geqq 3$ only. In this case, however, the criterion (3.24) is not satisfied. To see this, it suffices to prove that $k^1(k) = k_1(k) = 2$, that is to say that the derivatives $D^2 G(0)|_{(\mathbb{R} \times X_1)^2}$ and $Q_1 D^2 G(0)$ do not vanish. This will follow from the relations

$$D_\mu D_x G(0)|_{X_1} \neq 0, \qquad Q_1 D_\mu D_x G(0) \neq 0.$$

Indeed, assume by contradiction that $D_\mu D_x G(0)|_{X_1} = 0$, namely $Lx_1 = 0$ for every $x_1 \in \operatorname{Ker}(I - \lambda_0 L)$. Thus, $\operatorname{Ker}(I - \lambda_0 L) = \{0\}$ and we reach a contradiction with the fact that λ_0 is a characteristic value of L. Now, assume by contradiction that $Q_1 D_\mu D_x G(0) = 0$. This means $Q_1 L = 0$ and, as $Q_1(I - \lambda_0 L) = 0$ by definition of Q_1, we find $Q_1 = 0$, namely $Z_2 = X$, again a contradiction.

To sum up, we must assume $X_1 \not\subset Z_2$. From (3.41) it follows that $k = 2$ and the criterion (3.24) is satisfied. The mapping (3.25) becomes

$$(\mu, x_1) \in \mathbb{R} \times X_1 \to -\frac{2}{\lambda_0} \mu Q_1 x_1 + Q_1 D_x^2 \Gamma(0) \cdot (x_1)^2 \in Z_1.$$

Its zero set contains the pairs $(\mu, 0)$, $\mu \in \mathbb{R}$ and its derivative at such a point with $\mu \neq 0$ is the linear mapping $-(2/\lambda_0)\mu Q_1|_{X_1} \in \mathcal{L}(X_1, Z_1)$. The nondegeneracy condition requires it to be onto, or, equivalently, one-to-one since $\dim X_1 = \dim Z_1 = N$. This means $Q_1 x_1 \neq 0$ for every $x_1 \in X_1$. In other words, $X_1 \cap Z_2 = \{0\}$ which amounts to saying that $X = X_1 \oplus Z_2$. As $Z_2 = Y_2$ and we observed in § 2 that Theorem 2.2 was independent of the choice of the complement $Y_1 (= Z_1)$ of Y_2, we may choose $Z_1 = X_1$ and the proof is complete. □

When $N = 1$, condition (3.39) is often referred to as "Crandall and Rabinowitz nondegeneracy condition." For $N \geqq 2$ it also appears in McLeod and Sattinger [11]. Assuming that (3.39) holds, it is easily checked that the assumptions we make and the conclusions we draw by using Theorem 2.2 are indeed the same as in Crandall and Rabinowitz [4] when $N = 1$ (including the regularity of the curves at the origin). When $N \geqq 2$, our conclusions are as in McLeod and Sattinger [11] under somewhat weaker assumptions. Besides ours, they also require that

$$Q_1 D_x^2 \Gamma(0) \cdot (x_1)^2 \neq 0 \quad \text{for every } x_1 \in X_1 - \{0\} \tag{3.42}$$

(replacing λL by $L(\lambda)$ as in [11] does not affect this remark). Although very little restrictive in the applications, condition (3.42) merely ensures that bifurcation occurs transcritically, as in the case $N = 1$ for a quadratic nonlinearity. The largest number of bifurcated branches is 2^N-1 and the curves are of class $\mathscr{C}^{m-1}$ at the origin, $\mathscr{C}^m$ away from it. Apparently, the result of regularity at the origin is new when $N\geqq 2$. Bifurcation is ensured since $k=2$ is even (cf. Remark 1.3).

4. Applications to one parameter nonlinear problems: the case $p\geqq 2$. Let the mapping G satisfy the general hypotheses of §§ 1 and 3. Given an integer $p\geqq 2$ and with $\sigma=\pm 1$, let $\tilde{X}$ denote the space $\mathbb{R}\times X$ with generic point (η, x). We intend to use Theorem 2.2 with the mapping $H=H_\sigma$, where

$$H_\sigma(\eta,x)=G(\sigma\eta^p,x). \tag{4.1}$$

As $p\geqq 2$ and by differentiating

$$DH_\sigma(0)\cdot(\eta,x)=D_xG(0)\cdot x \tag{4.2}$$

so that the spaces $\tilde{X}_1=\operatorname{Ker} DH_\sigma(0)$ and $Y_2=\operatorname{Range} DH_\sigma(0)$ are independent of σ and p. More precisely

$$\tilde{X}_1=\operatorname{Ker} DH_\sigma(0)=\mathbb{R}\times\operatorname{Ker} D_xG(0)=\mathbb{R}\times X_1, \tag{4.3}$$

$$Y_2=\operatorname{Range} DH_\sigma(0)=\operatorname{Range} D_xG(0)=Z_2. \tag{4.4}$$

As $\dim X_1=\operatorname{codim} Z_2=N$, the operator $DH_\sigma(0)$ is a Fredholm operator with index 1. Here, the codimension n of $Y_2(=Z_2)$ is

$$n=N. \tag{4.5}$$

A complement Y_1 of Y_2 in Y is of course any complement Z_1 of Z_2 with associated projection operator $P_1=Q_1$. When $N=0$ (i.e. $n=0$) Theorem 2.2 applies. As in the previous section, this situation is essentially obvious and no further information is provided here. We shall henceforth assume $N\geqq 1$. When finite, the value k defined by (2.9) with $H=H_\sigma$ is the order of the first nonzero derivative of the mapping $Q_1H_\sigma|_{\mathbb{R}\times X_1}$ at the origin (that k does not depend on σ will be shown in Proposition 4.1 below). We shall characterize it in terms of G: for every integer $0\leqq l\leqq m$, define the set

$$I_1^1(l)=\{(i,j)\in\mathbb{N}\times\mathbb{N},\ 0\leqq i\leqq j\leqq l,\ Q_1D_\mu^{j-i}D_x^iG(0)|_{(X_1)^i}\neq 0\}. \tag{4.6}$$

Now, for $0\leqq l\leqq m$ and $p\geqq 2$ we introduce the mapping

$$\chi_1^1(l,p)=\min\{pj+(1-p)i,\ (i,j)\in I_1^1(l)\}. \tag{4.7}$$

Clearly,

$$\chi_1^1(l,p)=+\infty\Leftrightarrow I_1^1(l)=\varnothing, \tag{4.8}$$

while there is at least one pair $(i,j)\in I_1^1(l)$ such that $pj+(1-p)i=\chi_1^1(l,p)$ when $I_1^1(l)\neq\varnothing$ since $I_1^1(l)$ is finite in any case.

PROPOSITION 4.1. *Let $0\leqq l\leqq m$ be given. If $\chi_1^1(l,p)>l$, the derivatives of the mapping $Q_1H_\sigma|_{\mathbb{R}\times X_1}$ vanish up to order l at the origin. In contrast, if $\chi_1^1(l,p)\leqq l$, one has*

$$k=\chi_1^1(l,p) \tag{4.9}$$

(*so that k is independent of σ*) *and*

(4.10)$_\sigma$

$$Q_1D^kH_\sigma(0)\cdot(\eta,x_1)^k=\sum_{\substack{0\leqq i\leqq j\leqq l,\\ pj+(1-p)i=k}}\frac{k!}{(j-i)!\,i!}(\sigma\eta^p)^{j-i}Q_1D_\mu^{j-i}D_x^iG(0)\cdot(x_1)^i\in Z_1.$$

Proof. For every pair (h,i) of integers and provided that the derivative of order $h+i$ if H_σ is defined, one has

$$Q_1D_\eta^hD_{x_1}^iH_\sigma(0)=Q_1D_{x_1}^i[D_\eta^hH_\sigma(0,x_1)]|_{x_1=0}.$$

As $H_\sigma(\eta, x_1)$ depends only on η^p (cf. (4.1)) it is easily checked that $D^h_\eta H_\sigma(0, x_1)=0$ unless h is a multiple of p, namely $h=p(j-i)$ for some index $j \geqq i$. Besides, a simple calculation based on Taylor's formula yields

$$D^{p(j-i)}_\eta H_\sigma(0, x_1)=\frac{[p(j-i)]!}{(j-i)!} D^{j-i}_\mu G(0, x_1).$$

Hence,

$$Q_1 D^{p(j-i)}_\eta D^i_{x_1} H_\sigma(0)=\frac{[p(j-i)]!}{(j-i)!} Q_1 D^{j-i}_\mu D^i_{x_1} G(0), \tag{4.11}$$

while all the expressions $Q_1 D^h_\eta D^i_{x_1} H_\sigma(0)$ vanish if h is not of the form $p(j-i)$. Any nonzero derivative of the mapping $Q_1 H_\sigma|_{\mathbb{R}\times X_1}$ at the origin is then of order $p(j-i)+i$ for some pairs (i, j) with $i \leqq j$. This order is less than or equal to a given integer $0 \leqq l \leqq m$ if and only if $p(j-i)+i=pj+(1-p)i \leqq l$ and the derivative involves indices $(i, j) \in I^1_1(l)$ only. Our assertions follow at once from this observation. □

For $0 \leqq l \leqq m$ again, let us now introduce the sets

$$I_1(l)=\{0 \leqq i \leqq j \leqq l,\ Q_1 D^{j-i}_\mu D^i_x G(0) \neq 0\}, \tag{4.12}$$

$$I^1(l)=\{0 \leqq i \leqq j \leqq l,\ D^{j-i}_\mu D^i_x G(0)|_{(X_1)^i} \neq 0\}. \tag{4.13}$$

To these sets, we associate the mappings

$$\chi_1(l, p)=\min\{pj+(1-p)i, (i, j) \in I_1(l)\}, \tag{4.14}$$

$$\chi^1(l, p)=\min\{pj+(1-p)i, (i, j) \in I^1(l)\}. \tag{4.15}$$

Arguing as in Proposition 4.1 we see that the derivatives of the mapping $Q_1 H_\sigma$ (resp., $H_\sigma|_{\mathbb{R}\times X_1}$) vanish up to order l at the origin if $\chi_1(l, p)>l$ (resp., $\chi^1(l, p)>l$) and $\chi_1(l, p)$ (resp., $\chi^1(l, p)$) is the order of the first nonzero derivative of the mapping $Q_1 H_\sigma$ (resp., $H_\sigma|_{\mathbb{R}\times X_1}$) at the origin if $\chi_1(l, p) \leqq l$ (resp., $\chi^1(l, p) \leqq l$). In the notation of § 2 (cf. (2.1) and (2.2)) this means that

$$\chi_1(l, p) \leqq l \Rightarrow \chi_1(l, p)=k_1(l), \qquad \chi^1(l, p) \leqq l \Rightarrow \chi^1(l, p)=k^1(l), \tag{4.16}$$

where $k_1(\cdot)$ and $k^1(\cdot)$ are defined through the mapping $H=H_\sigma$. Since $k_1(l)=k_1(l')$ (resp., $k^1(l)=k^1(l')$) when both sides are finite as it is obvious from the definitions, we obtain

$$\begin{gathered}\{\chi_1(l, p) \leqq l \text{ and } \chi_1(l', p) \leqq l'\} \Rightarrow \chi_1(l, p)=\chi_1(l', p), \\ \{\chi^1(l, p) \leqq l \text{ and } \chi^1(l', p) \leqq l'\} \Rightarrow \chi^1(l, p)=\chi^1(l', p).\end{gathered} \tag{4.17}$$

Finally, as $I^1_1(l)$ is contained in both sets $I_1(l)$ and $I^1(l)$ for every $0 \leqq l \leqq m$, it is clear that

$$\chi^1_1(l, p) \geqq \max(\chi_1(l, p), \chi^1(l, p)). \tag{4.18}$$

When we combine the above observations, and according to the definitions, it is easily seen that

PROPOSITION 4.2. *Let $0 \leqq l \leqq m$ be such that $\chi^1_1(l, p) \leqq l$. Then*

$$k_1(\chi^1_1(l, p))=\chi_1(l, p), \qquad k^1(\chi^1_1(l, p))=\chi^1(l, p). \qquad \square$$

We shall now see that Theorem 2.2 cannot be used with the mapping H_σ unless k and p have specific values. The quantity

$$\kappa=\min\{0 \leqq j \leqq m,\ Q_1 D^j_x G(0)|_{(X_1)^j} \neq 0\} \geqq 2, \tag{4.19}$$

we have already encountered in § 3, will play a key role.

THEOREM 4.1. *Assume that Theorem* 2.2 *applies with* $H = H_\sigma$. *Then*

$$k = \chi_1^1(\kappa, p) = \kappa < +\infty \tag{4.20}$$

and the mapping

(4.21)$_\sigma$

$$Q_1 D^\kappa H_\sigma(0) \cdot (\eta, x_1)^\kappa = \sum_{\substack{0 \leqq i \leqq j \leqq \kappa, \\ pj+(1-p)i=\kappa}} \frac{1}{(j-i)!\,i!} (\sigma\eta^p)^{j-i} Q_1 D_\mu^{j-i} D_x^i G(0) \cdot (x_1)^i \in Z_1$$

verifies the condition ($\mathbb{R}$-N.D.). *In addition*

$$\kappa \leqq \chi_1(\kappa, p) + \chi^1(\kappa, p) - 2 \tag{4.22}$$

and the integer p is characterized by

$$p = \max\left\{\frac{\kappa - i}{j - i}, (i, j) \in I_1^1(\kappa), j < \kappa\right\} \tag{4.23}$$

(*in particular, p is independent of* σ).

Proof. Since k is finite by hypothesis, it coincides with the order of the first nonzero derivative of the mapping $Q_1 H_\sigma|_{\mathbb{R}\times X_1}$ at the origin. From the first part of Proposition 4.1 it follows that there is an integer $0 \leqq l \leqq m$ such that $\chi_1^1(l, p) \leqq l$ and hence $k = \chi_1^1(l, p)$ from the second part of Proposition 4.1. By hypothesis, the mapping (4.10)$_\sigma$ verifies the condition ($\mathbb{R}$-N.D.). If the pair (k, k) is not in the set $I_1^1(l)$, η^p is in factor in (4.10)$_\sigma$ since $pj + (1-p)j = j \neq k$ for each pair $(j, j) \in I_1^1(l)$. But this is impossible. Indeed, as $p \geqq 2$, the mapping (4.10)$_\sigma$ and its derivative vanish on the N-dimensional space $\{0\} \times X_1$, contradicting the condition ($\mathbb{R}$-N.D.) since $N \geqq 1$. Thus

$$Q_1 D_x^k G(0)|_{(X_1)^k} \neq 0. \tag{4.24}$$

On the contrary

$$Q_1 D_x^j G(0)|_{(X_1)^j} = 0, \qquad 0 \leqq j \leqq k-1, \tag{4.25}$$

for there is no pair $(j, j) \in I_1^1(l)$ with $j < k$ since this would contradict the relation $k = \chi_1^1(l, p)$. The relations (4.24) and (4.25) characterize k as being κ (cf. (4.19)). In particular, $\kappa < +\infty$; hence the pair (κ, κ) is in the set $I_1^1(\kappa)$. Thus, $\chi_1^1(\kappa, p) \leqq p\kappa + (1-p)\kappa = \kappa$ and Proposition 4.1 show that $k = \chi_1^1(\kappa, p)$, which proves (4.20). Besides, the mapping (4.10)$_\sigma$ with $k = \kappa$ and $l = \kappa$ is nothing but (4.21)$_\sigma$ (and verifies the condition ($\mathbb{R}$-N.D.)).

Next, from (4.20), (4.16) and (4.18),we find $k_1(k) = \chi_1(\kappa, p)$, $k^1(k) = \chi^1(\kappa, p)$ and the criterion $k \leqq k_1(k) + k^1(k) - 2$ reads as (4.22).

Let us finally show that p is characterized by (4.23): from (4.20) and for every pair $(i, j) \in I_1^1(\kappa)$, one has $pj + (1-p)i \geqq \chi_1^1(\kappa, p) = \kappa$ or, equivalently, $p \geqq (\kappa - i)/(j-i)$. It suffices to prove that there is a pair $(i, j) \in I_1^1(\kappa)$ with $j < \kappa$ for which $pj + (1-p)i = \kappa$. If there is none, the mapping (4.21)$_\sigma$ reduces to

$$(\eta, x_1) \in \mathbb{R} \times X_1 \to Q_1 D_x^\kappa G(0) \cdot (x_1)^\kappa \in Z_1 \tag{4.26}$$

because there is no pair $(i, j) \in I_1^1(\kappa)$ with $j < \kappa$ such that $pj + (1-p)i = \kappa$ by hypothesis and there is no such pair with $j = \kappa > i$ either since $p \geqq 2$ and hence $p\kappa + (1-p)i > \kappa$.

But the mapping (4.26) as well as its derivative vanishes on the line $\mathbb{R} \times \{0\}$ since $\kappa \geqq 2$, so that it does not verify the condition ($\mathbb{R}$-N.D.). □

Remark 4.1. It is easy to check that the value of p given by (4.23) is exactly as provided by using Newton's diagram (see e.g. Sattinger [18]).

The proof of the converse of Theorem 4.1, which is the useful version in practical applications, is based on the same arguments and is omitted. The result is stated in Theorem 4.2 below.

THEOREM 4.2. *Assume* $\kappa<+\infty$ (*i.e.* $2\leqq\kappa\leqq m$) *and suppose that formula* (4.23) *defines p as an integer. Then,*

$$2\leqq p\leqq\kappa \tag{4.27}$$

and the order of the first nonzero derivative of the mapping $Q_1H_\sigma|_{\mathbb{R}\times X_1}$ *at the origin is*

$$k=\chi_1^1(\kappa,p)=\kappa. \tag{4.28}$$

Also, the expression of this derivative is given by $(4.21)_\sigma$ *and*

$$k_1(k)=\chi_1(\kappa,p),\qquad k^1(k)=\chi^1(\kappa,p), \tag{4.29}$$

so that the criterion $k\leqq k_1(k)+k^1(k)-2$ *takes the form*

$$\kappa\leqq\chi_1(\kappa,p)+\chi^1(\kappa,p)-2. \tag{4.30}$$

Finally, if (4.30) *holds and the mapping* $(4.21)_\sigma$ *verifies the condition* ($\mathbb{R}$-N.D.), *Theorem* 2.2 *applies with* $H=H_\sigma$.

Remark 4.2. Observe that κ and the sets $I_1^1(\kappa)$, $I^1(\kappa)$ and $I_1(\kappa)$ are independent of the choice of the space $Z_1(=Y_1)$ and of the complement $\tilde{X}_2$ of $\tilde{X}_1$ $(=\mathbb{R}\times X_1)$. Thus, Theorem 4.2 is independent of the choice of the Lyapunov-Schmidt reduction (in particular, p is independent of it).

According to Proposition 4.2 one has $\chi_1(\kappa,p)\geqq2$, $\chi^1(\kappa,p)\geqq2$. Hence, the criterion (4.30) will be satisfied in particular when $\kappa=\chi_1(\kappa,p)$ or $\kappa=\chi^1(\kappa,p)$, for instance, if the set $I_1^1(\kappa)$ coincides with either set $I_1(\kappa)$ or $I^1(\kappa)$. In such a case, the value of p is without importance, but we shall find that weaker and simpler assumptions can be made to ensure one of the relations $\kappa=\chi_1(\kappa,p)$ or $\kappa=\chi^1(\kappa,p)$ by taking the value of p (given by (4.23)) into account. Besides, we shall see in § 5 that there are standard problems in which the full criterion (4.30) cannot be limited to any of these simple two forms.

We now give prominence to two necessary conditions for Theorem 4.2 to be available. The first one is important because it will allow us to derive precise information on the structure of the zero set of the mapping H_σ and is a common hypothesis in these problems. The second one is not usual and shows that there are only *two* values of p for which a general discussion is possible.

PROPOSITION 4.3. *A first necessary condition for Theorem* 4.2 *to apply in full is*

$$Q_1D_x^\kappa G(0)\cdot(x_1)^\kappa\neq0\quad\textit{for every } x_1\in X_1-\{0\}. \tag{4.31}$$

A second necessary condition is that p is a divisor of κ *and* $(0,\kappa/p)\in I_1^1(\kappa)$ *or p is a divisor of* $\kappa-1$ *and* $(1,[(\kappa-1)/p]+1)\in I_1^1(\kappa)$.

Proof. To show (4.31), we parallel the beginning of the proof of Theorem 4.1: if there is an element $x_1\in X_1-\{0\}$ such that $Q_1D_x^\kappa G(0)\cdot(x_1)^\kappa=0$, η^p factors out in the expression $(4.21)_\sigma$ for this specific value x_1. As $p\geqq2$, the derivative of $(4.21)_\sigma$ at $(0,x_1)$ has rank deficiency $\geqq1$, contradicting the condition ($\mathbb{R}$-N.D.).

The second assertion follows from the observation that the mapping $(4.21)_\sigma$ cannot verify the condition ($\mathbb{R}$-N.D.) if there is no pair $(i,j)\in I_1^1(\kappa)$ such that $pj+(1-p)i=\kappa$ and $i=0$ or $i=1$. Indeed, in this case, the expression $(4.21)_\sigma$ involves pairs with $i\geqq2$ only and vanishes together with its derivative at the points of the line $\mathbb{R}\times\{0\}$. Therefore, there must be a pair $(i_0,j_0)\in I_1^1(\kappa)$ for which $i_0=0$ and $pj_0=\kappa$ so that p divides κ and $(0,\kappa/p)\in I_1^1(\kappa)$ or $i_0=1$ and $pj_0+(1-p)=\kappa$ so that p divides $\kappa-1$ and $(1,[(\kappa-1)/p]+1)\in I_1^1(\kappa)$. □

Remark 4.3. As the sole pair (j, j) such that $pj+(1-p)j(=j)=\kappa$ is obviously the pair (κ, κ), (4.31) means that there is no element of the form $(0, x_1)$, $x_1 \in X_1-\{0\}$ in the zero set of $(4.21)_\sigma$. When $N=1$, (4.31) is not an additional assumption.

A classification of the mappings G to which Theorem 4.2 may apply is then based on the divisors of κ or $\kappa-1$ (observe in passing that κ and $\kappa-1$ are always prime to each other). A general discussion is then impossible unless $p=\kappa$ or $p=\kappa-1$. These cases will be considered later on.

To complete these general considerations, we now show how the structure of the local zero set of G can be derived from the structure of the local zero set of the mappings H_σ. Of course, we suppose that the assumptions of Theorem 4.2 are fulfilled so that the latter consists of a finite number $\nu_\sigma \leqq \kappa^N$ (possibly 0) of curves of class $\mathscr{C}^m$ away from the origin and $\mathscr{C}^{m-\kappa+1}$ at the origin, where each of them is tangent to a different one of the lines in the zero set of the mapping $(4.21)_\sigma$. Let

$$t \to (\eta(t), x(t)) \in \mathbb{R} \times X, \quad \eta(0)=0, \quad x(0)=0 \tag{4.32}$$

be such a curve. From the above, the parameterization can be chosen so that $((d\eta/dt)(0), (dx/dt)(0))$ is a *nonzero* element of the zero set of the mapping $(4.21)_\sigma$ (this can be directly established by looking at the proof of Theorem 1.1 and examining how Theorem 2.2 is derived from it). In particular, $(dx/dt)(0) \in X_1$ and, using Remark 4.3, we deduce

$$(d\eta/dt)(0) \neq 0. \tag{4.33}$$

Also, for each curve (4.32) except that one tangent to the line $\mathbb{R} \times \{0\}$ at the origin (when it is in the zero set of $(4.21)_\sigma$), one has

$$\frac{dx}{dt}(0) \neq 0. \tag{4.34}$$

Remark 4.4. From Proposition 4.3, the line $\mathbb{R} \times \{0\}$ is not in the zero set of $(4.21)_\sigma$ when p is a divisor of κ since the pair $(0, \kappa/p)$ belongs to the set $I_1^1(\kappa)$. On the contrary, it is in the zero set of $(4.21)_\sigma$ when p divides $\kappa-1$ because there is no pair $(0, j) \in I_1^1(\kappa)$ such that $pj=\kappa$ for p would also be a divisor of κ. These remarks are independent of the choice $\sigma=1$ or $\sigma=-1$.

Assume first that $p(\geqq 3)$ is odd. The zero sets of the mappings G and H_σ are homeomorphic and Theorem 2.2 applies with H_1 or H_{-1} equivalently (the verification of this fact is obvious). Thus, the zero set of G consists of the $\nu_1(=\nu_{-1})$ distinct curves

$$t \to \gamma(t)=(\eta^p(t), x(t)) \in \mathbb{R} \times X, \tag{4.35}$$

where (4.32) is one of the ν_1 curves in the local zero set of H_1. As $p \geqq 3$, $(d\gamma/dt)(0)=(0, (dx/dt)(0))$: if p is a divisor of κ, one has $(d\gamma/dt)(0) \neq 0$ (cf. (4.34) and Remark 4.4) and the ν_1 curves (4.35) are of class $\mathscr{C}^{m-\kappa+1}$ at the origin, $\mathscr{C}^m$ away from it. If p is a divisor of $\kappa-1$, $(d\gamma/dt)(0) \neq 0$ except when γ corresponds with that curve (4.32) which is tangent to the line $\mathbb{R} \times \{0\}$ at the origin. As a result, all the ν_1 curves in the zero set of G except possibly one are found to be of class $\mathscr{C}^{m-\kappa+1}$ at the origin and $\mathscr{C}^m$ away from it. The remaining curve is easily seen to be $\mathscr{C}^m$ away from the origin but we can only conclude to its continuity at the origin. Observe finally from (4.33) that $\eta(t)$, and hence $\eta^p(t)$, takes positive and negative values as t is varied around the origin: all the ν_1 curves (4.35) cross the hyperplane $\mu=0$ at the origin.

Next, assume that $p(\geqq 2)$ is even. Taking $\sigma=1$, the solutions of the equation $H_1(\eta, x)=0$ provide the solutions of the equation $G(\mu, x)=0$ with $\mu \geqq 0$. These solutions are then obtained through the ν_1 curves

$$t \to \gamma_+(t)=(\eta^p(t), x(t)) \in \mathbb{R} \times X, \tag{4.36}$$

where (4.32) denotes any of the ν_1 curves in the local zero set of H_1. Contrary to what happens when p is odd, the ν_1 curves (4.36) are not distinct here because $H_1(-\eta, x) = H_1(\eta, x)$, so that the curve $(-\eta(t), x(t))$ is in the zero set of H_1 as soon as $(\eta(t), x(t))$ is in it. Clearly, they provide the same curve γ_+ (4.36) and, except in one case, are distinct. To see this, notice from (4.33) that the vectors $((d\eta/dt)(0), (dx/dt)(0))$ and $(-(d\eta/dt)(0), (dx/dt)(0))$ are not collinear unless $(dx/dt)(0) = 0$, which happens, for one curve only, when p divides $\kappa - 1$. Thus, when p is a divisor of κ, each curve (4.36) is provided by two distinct curves in the local zero set of H_1 and the exact number of distinct curves (4.36) is $\nu_1/2$ (hence, ν_1 is even; this can be found a priori since p is even and divides κ, so that κ is even and it suffices to apply [3, Thm. 2.7]). The regularity of the curves is the same as when p is odd. When p is a divisor of $\kappa - 1$, the two curves $(\eta(t), x(t))$ and $(-\eta(t), x(t))$ with $(dx/dt)(0) = 0$ are both tangent to the line $\mathbb{R} \times \{0\}$ at the origin and hence coincide (which merely means that the curve is symmetric with respect to the hyperplane $\eta = 0$, but of course not that $\eta(t) = 0$). The corresponding curve γ_+ (4.36) is then a half-branch emerging from the origin into the half-space $\mu \geqq 0$ in $\mathbb{R} \times X$. The exact number of curves γ_+, including the half-branch, is $(\nu_1 + 1)/2$ (hence, ν_1 is odd, as κ is since p is even and divides $\kappa - 1$) and, except for the half-branch, their regularity is the same as when p is odd.

Taking $\sigma = -1$ and by the same arguments, we find that the solutions of the equation $G(\mu, x) = 0$ with $\mu \leqq 0$ are provided by the ν_{-1} curves

$$t \to \gamma_-(t) = (-\eta^p(t), x(t)) \in \mathbb{R} \times X, \tag{4.37}$$

where (4.32) is one of the ν_{-1} curves in the local zero set of H_{-1}. There are $\nu_{-1}/2$ distinct curves γ_- when p is a divisor of κ and $(\nu_{-1} + 1)/2$ when p divides $\kappa - 1$ (including a half-branch emerging from the origin into the half-space $\mu \leqq 0$ in $\mathbb{R} \times X$). The regularity results are identical to those when $\sigma = 1$.

Observe that the exact number of curves in the zero set of G is always $(\nu_1 + \nu_{-1})/2$. This is obvious when p is a divisor of κ. When p is a divisor of $\kappa - 1$, a first estimate is $[(\nu_1 + \nu_{-1})/2] + 1$. But if we do so, the two half-branches emerging from the origin into the half-spaces $\mu \geqq 0$ and $\mu \leqq 0$ are counted separately while they extend each other as a single branch.

To complete this section, we shall examine in some detail the two particular cases $p = \kappa$ and $p = \kappa - 1$, as motivated by Proposition 4.3.

The case $p = \kappa$. From Proposition 4.3, the pair $(0, 1)$ is in the set $I_1^1(\kappa)$. Conversely, it is immediately checked that $p = \kappa$ if $(0, 1) \in I_1^1(\kappa)$. By definition of the operator Q_1, we deduce

$$p = \kappa \Leftrightarrow D_\mu G(0) \notin Z_2. \tag{4.38}$$

Surprisingly enough, we find again the first case of the classification of § 3. The criterion (4.30) becomes

$$\kappa \leqq \chi_1(\kappa, \kappa) + \chi^1(\kappa, \kappa) - 2, \tag{4.39}$$

where the quantities $\chi^1(\kappa, \kappa)$ and $\chi_1(\kappa, \kappa)$ are easily found to be

$$\chi^1(\kappa, \kappa) = \min\{0 \leqq j \leqq \kappa, D_x^j G(0)|_{(X_1)^j} \neq 0\}, \tag{4.40}$$

$$\chi_1(\kappa, \kappa) = \min\{0 \leqq j \leqq \kappa, Q_1 D_x^j G(0) \neq 0\}. \tag{4.41}$$

The only pairs (i, j) such that $0 \leqq i \leqq j \leqq \kappa$ and $\kappa j + (1 - \kappa) i = \kappa$ are $(0, 1)$ and (κ, κ). Therefore, the mapping $(4.21)_\sigma$ (with $p = \kappa$) reads

$$(\eta, x_1) \in \mathbb{R} \times X_1 \to \sigma\kappa!\, \eta^\kappa Q_1 D_\mu G(0) + Q_1 D_x^\kappa G(0) \cdot (x_1)^\kappa \in Z_1. \tag{4.42$_\sigma$}$$

In § 3, the analysis of the same problem led us to consider an arbitrary complement Y_1 of $\mathbb{R}D_\mu G(0)\oplus Z_2$ in Y with associated projection operator P_1. Proposition 4.4 applies to this notation.

PROPOSITION 4.4. *Both mappings* $(4.42)_1$ *and* $(4.42)_{-1}$ *verify the condition* ($\mathbb{R}$-N.D.) *if and only if*

$$(4.43)\qquad Q_1 D_x^\kappa G(0)\cdot(x_1)^\kappa \neq 0 \quad \textit{for every } x_1\in X_1-\{0\}$$

and the mapping

$$(4.44)\qquad x_1\in X_1 \to P_1 D_x^\kappa G(0)\cdot (x_1)^\kappa \in Y_1$$

verifies the condition ($\mathbb{R}$-N.D.).

Proof. We already know that whether or not the mapping $(4.42)_\sigma$ verifies the condition ($\mathbb{R}$-N.D.) is independent of the choice of the space Z_1 (cf. Remark 4.2) and that the condition (4.43) is necessary (Proposition 4.3). For the sake of convenience, we may then suppose

$$(4.45)\qquad Z_1=\mathbb{R}D_\mu G(0)\oplus Y_1.$$

If so, $Q_1D_\mu G(0)=D_\mu G(0)$, $P_1Q_1=Q_1P_1=P_1$ and the operator (Q_1-P_1) is the projection onto the space $\mathbb{R}D_\mu G(0)$ associated with the decomposition $Y=\mathbb{R}D_\mu G(0)\oplus(Y_1\oplus Z_2)$. Thus, the mapping $(4.42)_\sigma$ is

$$(4.46)_\sigma\qquad (\eta, x_1)\in\mathbb{R}\times X_1\to \sigma\kappa!\,\eta^\kappa D_\mu G(0)+Q_1D_x^\kappa G(0)\cdot(x_1)^\kappa\in Z_1.$$

Assume first that $(4.46)_1$ and $(4.46)_{-1}$ verify the condition ($\mathbb{R}$-N.D.). Let $x_1\in X_1$ be a nonzero element of the zero set of the mapping (4.44). One has

$$Q_1D_x^\kappa G(0)\cdot(x_1)^\kappa=(Q_1-P_1)D_x^\kappa G(0)\cdot(x_1)^\kappa.$$

From the above, the right-hand side is collinear with $D_\mu G(0)$. As a result, $Q_1D_x^\kappa G(0)\cdot(x_1)^\kappa=\lambda D_\mu G(0)$ for some real number λ. For either $\sigma=1$ or $\sigma=-1$ (and for both if κ is odd) there is $\eta\in\mathbb{R}$ such that $\sigma\kappa!\,\eta^\kappa=-\lambda$ so that the pair (η,x_1) is in the zero set of the mapping $(4.46)_\sigma$. Let $y_1\in Y_1$ be given. In particular, $y_1\in Z_1$ and there is a pair $(\tau,\xi_1)\in\mathbb{R}\times X_1$ such that

$$\sigma\kappa(\kappa!)\eta^{\kappa-1}\tau D_\mu G(0)+\kappa Q_1D_x^\kappa G(0)\cdot((x_1)^{\kappa-1},\xi_1)=y_1.$$

Projecting onto Y_1, we find $\kappa P_1D_x^\kappa G(0)\cdot((x_1)^{\kappa-1},\xi_1)=y_1$, which proves that the mapping (4.44) verifies the condition ($\mathbb{R}$-N.D.).

Conversely, let $(\eta,x_1)\in\mathbb{R}\times X_1$ be a nonzero element of the zero set of the mapping $(4.46)_\sigma$. Observe that $\eta\neq 0$ from (4.43) and it is obvious that $x_1\neq 0$. Projecting onto Y_1, we see that x_1 is a nonzero element of the zero set of the mapping (4.44). Let $z_1\in Z_1$ be given and set $y_1=P_1z_1$. From ($\mathbb{R}$-N.D.), there is $\xi_1\in X_1$ such that $\kappa D_x^\kappa G(0)\cdot((x_1)^{\kappa-1},\xi_1)=y_1$. As (Q_1-P_1) is the projection onto $\mathbb{R}D_\mu G(0)$ and by definition of y_1, one has $\kappa Q_1D_x^\kappa G(0)\cdot((x_1)^{\kappa-1},\xi_1)=z_1+\lambda D_\mu G(0)$ for some real number λ. Setting $\tau=-\lambda/(\sigma\kappa(\kappa!)\eta^{\kappa-1})$ it is clear that

$$\sigma\kappa(\kappa!)\eta^{\kappa-1}\tau D_\mu G(0)+\kappa Q_1D_x^\kappa G(0)\cdot((x_1)^{\kappa-1},\xi_1)=z_1,$$

so that the mapping $(4.46)_\sigma$ verifies the condition ($\mathbb{R}$-N.D.). □

As $p=\kappa$ divides κ, all the curves are of class $\mathscr{C}^{m-\kappa+1}$ at the origin and $\mathscr{C}^m$ away from it. Note when $N=1$ that the assumptions we make in § 3 in the analysis of the same problem are weaker and the results we obtain there are better: for instance, it is known from § 3 that the local zero set of G is made of exactly one curve. Here, the information is only "at most κ" but existence and uniqueness can also be derived from the special form of the mapping $(4.42)_\sigma$. More generally, by arguments similar to those we used in Proposition 4.4, the maximum number of lines in the zero set of either mapping $(4.42)_\sigma$ (hence the maximum number of curves in the zero set of G) can be shown to be κ^{N-1}, an improvement over the general estimate κ^N that is due to the fact that $p=\kappa$. Also, when $N=1$ in § 3, the curve in the zero set of G is found to be of class $\mathscr{C}^m$ around the origin instead of $\mathscr{C}^{m-\kappa+1}$ here. However, its location with respect to the hyperplane $\mu=0$ in $\mathbb{R}\times X$ cannot be specified under the assumptions of § 3. The hypotheses of this section are trivially satisfied as soon as the criterion (4.39) is fulfilled (in particular, note that $Y_1=\{0\}$) and the origin is a turning point if κ is even, a hysteresis point if κ is odd, which agrees with well-known results.

When $N\geqq 2$, the assumptions of § 3 are no longer weaker in general: the analysis involves the order of the first nonzero derivative of the mapping $P_1G(0,\cdot)|_{X_1}$ at the origin, denoted by k, and we observed that $k\geqq\kappa$. Here, the equality $k=\kappa$ is a necessity from Proposition 4.4. However, this is not really restrictive since it was already mentioned in § 3 that the equality $k=\kappa$ holds with most of the values $D_\mu G(0)\notin Z_2$. If so, the result of regularity and the estimate on the number of curves is the same. Condition (4.43) is not required in § 3 but it is also little restrictive in practice (see Remark 3.1). A more significant difference is observed between the criterion (4.39) and its analogue of § 3, which, when $k=\kappa$, is $\kappa\leqq k_1(\kappa)+k^1(\kappa)-2$, where

$$k^1(\kappa)=\min\{0\leqq j\leqq\kappa,\ D_x^jG(0)|_{(X_1)^j}\neq 0\},$$
$$k_1(\kappa)=\min\{0\leqq j\leqq\kappa,\ P_1D^jG(0)\neq 0\}.$$

On comparison with (4.40) and (4.41) we see that $k^1(\kappa)=\chi^1(\kappa,\kappa)$ but there is no relation between $k_1(\kappa)$ and $\chi_1(\kappa,\kappa)$ in general so that either criterion may be satisfied while the other one is not. This is not surprising since a simple examination shows that there is no explicit relation between the two reduced mappings when $D_\mu G(0)\notin Z_2$.

The case $p=\kappa-1$. Of course, this case requires the a priori assumption $\kappa\geqq 3$. From Proposition 4.3, the pair $(1,2)$ belongs to $I_1^1(\kappa)$, namely

$$Q_1D_\mu D_xG(0)\neq 0. \tag{4.47}$$

Also, from the equivalence (4.38) we must assume that

$$D_\mu G(0)\in Z_2. \tag{4.48}$$

Conversely, it is easily checked when (4.47) and (4.48) hold that $p=\kappa-1$. The criterion (4.30) is then

$$\kappa\leqq\chi_1(\kappa,\kappa-1)+\chi^1(\kappa,\kappa-1)-2. \tag{4.49}$$

Elementary considerations lead to

$$\chi^1(\kappa,\kappa-1)=\min\{0\leqq j\leqq\kappa,\ D_x^jG(0)|_{(X_1)^j}\neq 0\}, \tag{4.50}$$

unless $D_\mu G(0)=0$ and $D_x^jG(0)|_{(X_1)^j}=0$, $0\leqq j\leqq\kappa-1$, and, if so

$$\chi^1(\kappa,\kappa-1)=\kappa-1.$$

Next, in any case, $\chi_1(\kappa,\kappa-1)$ is computed to be

$$\chi_1(\kappa,\kappa-1)=\min\{0\leqq j\leqq\kappa,\ Q_1D_x^jG(0)\neq 0\}. \tag{4.51}$$

It is easy to check that the only pairs (i,j) such that $0\leqq i\leqq j\leqq\kappa$ and $(\kappa-1)j+(2-\kappa)i=\kappa$ are $(1,2)$ and (κ,κ). Thus, the mapping $(4.21)_\sigma$ (with $p=\kappa-1$) becomes

$$(\eta,x_1)\in\mathbb{R}\times X_1\to\sigma\kappa!\,\eta^{\kappa-1}Q_1D_\mu D_xG(0)\cdot x_1+Q_1D_x^\kappa G(0)\cdot(x_1)^\kappa\in Z_1. \tag*{$(4.52)_\sigma$}$$

As stated by Proposition 4.3, a necessary condition for this mapping to verify the nondegeneracy condition of this paper is

$$Q_1 D_x^\kappa G(0) \cdot (x_1)^\kappa \neq 0 \quad \text{for every } x_1 \in X_1 - \{0\}. \tag{4.53}$$

As an example, we shall consider the problems of bifurcation from the trivial branch as they were already encountered in § 3: with $X = Y$, the mapping G is of the form

$$G(\mu, x) = x - (\lambda_0 + \mu)Lx + \Gamma(\mu, x), \tag{4.54}$$

where $L \in \mathscr{L}(X)$ is compact, λ_0 is a characteristic value of L and the mapping Γ is of class $\mathscr{C}^m$, $m \geqq 2$, around the origin of $\mathbb{R} \times X$ with values in X and verifies $\Gamma(\mu, 0) = 0$ for μ around $0 \in \mathbb{R}$. In particular

$$D_\mu^j \Gamma(0) = 0, \qquad 0 \leqq j \leqq m, \tag{4.55}$$

and we further require that

$$D_\mu D_x \Gamma(0) = 0, \tag{4.56}$$

$$D_x \Gamma(0) = 0. \tag{4.57}$$

Under these assumptions, the zero set of G was determined in § 3 when the decomposition

$$X = \operatorname{Ker}(I - \lambda_0 L) \oplus \operatorname{Range}(I - \lambda_0 L) \tag{4.58}$$

holds. If so, we can make the choice $Z_1 = X_1$ $(= \operatorname{Ker}(I - \lambda_0 L))$ without loss of generality. We were able to settle the two cases when $\dim \operatorname{Ker}(I - \lambda_0 L) = 1$ or when $\dim \operatorname{Ker}(I - \lambda_0 L) \geqq 2$, $Q_1 D_x^2 \Gamma(0)|_{(X_1)^2} \neq 0$ and the mapping

$$(\mu, x_1) \in \mathbb{R} \times \operatorname{Ker}(I - \lambda_0 L) \to -\frac{2}{\lambda_0} \mu x_1 + Q_1 D_x^2 \Gamma(0) \cdot (x_1)^2 \in \operatorname{Ker}(I - \lambda_0 L),$$

verifies the condition ($\mathbb{R}$-N.D.).

We shall now assume that $Q_1 D_x^2 \Gamma(0)|_{(X_1)^2} = 0$. Clearly, κ is defined by

$$\kappa = \min\{0 \leqq j \leqq m, \; Q_1 D_x^j \Gamma(0)|_{(X_1)^j} \neq 0\}, \tag{4.59}$$

so that $\kappa \geqq 3$. As $D_\mu G(0) = 0$ and $Q_1 D_\mu D_x G(0) = (-1/\lambda_0) Q_1|_{X_1}$, conditions (4.47) and (4.48) are satisfied if and only if $Q_1|_{X_1} \neq 0$ (i.e. $\operatorname{Ker}(I - \lambda_0 L) \not\subset \operatorname{Range}(I - \lambda_0 L)$) so that $p = \kappa - 1$. From (4.50) and (4.51) the quantities $\chi^1(\kappa, \kappa - 1)$ and $\chi_1(\kappa, \kappa - 1)$ are given by

$$\chi^1(\kappa, \kappa - 1) = \min\{0 \leqq j \leqq \kappa, \; D_x^j \Gamma(0)|_{(X_1)^j} \neq 0\}, \tag{4.60}$$

$$\chi_1(\kappa, \kappa - 1) = \min\{0 \leqq j \leqq \kappa, \; Q_1 D_x^j \Gamma(0) \neq 0\}. \tag{4.61}$$

The mapping $(4.52)_\sigma$ is then

$$(\eta, x_1) \in \mathbb{R} \times \operatorname{Ker}(I - \lambda_0 L) \to -\frac{\sigma\kappa!}{\lambda_0} \eta^{\kappa - 1} Q_1 x_1 + Q_1 D_x^\kappa \Gamma(0) \cdot (x_1)^\kappa \in Z_1.$$

Because of the elements of the trivial branch in the zero set, it is easily seen that the condition (4.58) is still necessary for the above mapping to verify the condition ($\mathbb{R}$-N.D.). Again, we may then take $Z_1 = X_1 (= \operatorname{Ker}(I - \lambda_0 L))$ and, with this choice, $(4.52)_\sigma$ reads

$$(\eta, x_1) \in \mathbb{R} \times \operatorname{Ker}(I - \lambda_0 L) \to -\frac{\sigma\kappa!}{\lambda_0} \eta^{\kappa - 1} x_1 + Q_1 D_x^\kappa \Gamma(0) \cdot (x_1)^\kappa \in \operatorname{Ker}(I - \lambda_0 L). \tag*{$(4.62)_\sigma$}$$

The condition (4.53), necessary for it to verify the condition ($\mathbb{R}$-N.D.), is equivalent to

$$Q_1 D_x^\kappa \Gamma(0) \cdot (x_1)^\kappa \neq 0 \quad \text{for every } x_1 \in \operatorname{Ker}(I - \lambda_0 L) - \{0\}. \tag{4.63}$$

As $p = \kappa - 1$ divides $\kappa - 1$, the only curve in the local zero set of G for which continuity at the origin only can be proved in general is the curve tangent to the line $\mathbb{R} \times \{0\}$ at the origin. Here, it is then the trivial branch itself so that the bifurcated branches are of class $\mathscr{C}^{m-\kappa+1}$ at the origin (and $\mathscr{C}^m$ away from it). The location of these curves with respect to the hyperplane $\mu = 0$ is as described before in the general comments and their number cannot exceed $\kappa^N - 1$. When $N = 1$, $\kappa - 1$ is always an overestimate since $\kappa \geqq 3$ and we know that there is exactly one bifurcated branch. When $N = 2$, it is possible to show that a more accurate and optimal estimate is $\kappa + 1$ but we are not aware of a general improvement. When $N = 1$, all the assumptions of this section are satisfied provided the criterion (4.49) is fulfilled and bifurcation is transcritical if κ is even, supercritical if κ is odd. This agrees with well-known results.

When $N \geqq 2$, our assumptions coincide with those of McLeod and Sattinger [11] except for the criterion (4.49) which, in [11], is replaced by

$$D_x^j\Gamma(0) = 0, \qquad 0 \leqq j \leqq \kappa - 1, \tag{4.64}$$

an assumption that makes (4.49) trivially fulfilled. The result on the location of the curves is identical but, beyond continuity, no regularity of the curves at the origin is proved in [11].

Remark 4.5. Assumption (4.64) can be found in a number of publications (see e.g. [5], [11], [17], [18]). Two somewhat more general forms of (4.64), corresponding to the cases $\kappa = \chi^1(\kappa, \kappa - 1)$ and $\kappa = \chi^1(\kappa, \kappa - 1)$ respectively, are

$$Q_1 D_x^j\Gamma(0) = 0, \qquad 0 \leqq j \leqq \kappa - 1, \tag{4.65}$$

or

$$D_x^j\Gamma(0)\big|_{(x_1)^j} = 0, \qquad 0 \leqq j \leqq \kappa - 1. \tag{4.66}$$

Both assumptions are mentioned in [3] and, again, both make the criterion (4.49) trivially fulfilled. Nevertheless, as already mentioned, there are quite standard problems in which (4.49) cannot be reduced to any of these simplified versions (see § 5).

5. Examples. In this section we shall briefly examine the usefulness of some aspects of our approach. We begin with the problem

$$-\Delta u - \lambda u + u^4 + u^5(+\text{higher-order terms}) = 0, \qquad u \in H_0^1(\Omega), \tag{5.1}$$

where $\Omega \subset \mathbb{R}^2$ denotes the square $(0, \pi) \times (0, \pi)$. Problem (5.1) is a typical model of bifurcation from the trivial branch. Denoting by $L \in (H^{-1}(\Omega), H_0^1(\Omega))$ the inverse of $-\Delta$, an equivalent form of (5.1) is

$$u - \lambda L u + L(u^4 + u^5 + \cdots) = 0, \qquad u \in H_0^1(\Omega). \tag{5.2}$$

The characteristic values of L are of the form $\lambda_0 = a^2 + b^2$ where a and b are positive integers and the multiplicity of λ_0 equals the number of such distinct pairs (a, b). Assume first that λ_0 is simple, hence $\lambda_0 = 2a^2$. Then, it is known that there is exactly one bifurcated branch passing through $(\lambda_0, 0)$. If a is odd, it can be shown by classical arguments that bifurcation occurs transcritically. This situation corresponds to the case $\kappa = 4$ in § 4 and the criterion (4.49) holds trivially. On the contrary, if a is even, determining whether bifurcation occurs transcritically or supercritically requires the examination of derivatives of the reduced mapping of order >4. This is precisely when the criterion (4.49) is useful: one can easily check that $\kappa = 5$ and (with the choice $p = \kappa - 1$ as obtained in § 4) $\chi^1(5, 4) = \chi_1(5, 4) = 4$ so that (4.49) is fulfilled and it follows at once that bifurcation occurs supercritically, as if the term u^4 were not present and the problem were

$$-\Delta u - \lambda u + u^5(+\text{higher-order terms}) = 0. \tag{5.3}$$

A similar observation remains true when we study bifurcation at a multiple characteristic value. For instance, bifurcation near the point (10, 0) in the problem (5.1) can be equally studied by the method of McLeod and Sattinger [11] or that of § 4: bifurcation occurs transcritically and there are three bifurcated branches. But bifurcation near the point $(5,0)$ $(\lambda_0=5$ is double) cannot be analyzed under the assumptions of [11] nor those of [3]. Note that the situation is worse than when λ_0 is simple since not merely the location but the very structure of the solutions is unknown. Again, it can easily be shown that $\kappa=5$ while $\chi^1(5,4)=\chi_1(5,4)=4$: due to the criterion (4.49) we see that bifurcation near $(5,0)$ occurs as in the problem (5.3). Further investigation shows that there are exactly four bifurcated branches, located supercritically. This example can be embedded into a general problem, namely

$$(5.4)\qquad -\Delta u-\lambda u+P(u)+\varepsilon u^\kappa(+\text{higher-order terms})=0,\qquad u\in H_0^1(\Omega),$$

where $\Omega=(0,\pi)\times(0,\pi)$, $\kappa\geqq 3$ is odd, $\varepsilon=\pm 1$ and P is an even polynomial with degree $\leqq\kappa-1$ and valuation $k\geqq 2$. Bifurcation is studied near the point $(\lambda_0,0)$ where λ_0 is a double characteristic value of $L=(-\Delta)^{-1}$ of the form $\lambda_0=5a^2(a\in\mathbb{N}-\{0\})$. In any case, κ is then defined as in § 4. If $P=0$, one has $\chi_1(\kappa,\kappa-1)=\chi^1(\kappa,\kappa-1)=\kappa$ and the criterion (4.49) is trivially fulfilled. If $P\neq 0$, it is easy to check that $\chi_1(\kappa,\kappa-1)=\chi^1(\kappa,\kappa-1)=k$ so that (4.49) reduces to the assumption $\kappa\leqq 2k-3$ (which requires $k\geqq 4$ and $\kappa\geqq 5$). After rescaling η, the mapping $(4.62)_\sigma$ identifies with

$$(\eta,\alpha,\beta)\in\mathbb{R}^3\to\begin{pmatrix}\sigma\eta^{\kappa-1}\alpha-\varepsilon\displaystyle\sum_{j=0}^{(\kappa-1)/2}a_{2j+1}\alpha^{2j+1}\beta^{\kappa-2j-1}\\ \sigma\eta^{\kappa-1}\beta-\varepsilon\displaystyle\sum_{j=0}^{(\kappa-1)/2}a_{2j+1}\alpha^{\kappa-2j-1}\beta^{2j+1}\end{pmatrix}\in\mathbb{R}^2,$$

where the coefficients $a_{2j+1}>0$ are explicitly given through the Eulerian function Γ. Arguing as in Bolley [2] it can be shown that the above equation has nontrivial solutions (α,β) for $\sigma=\varepsilon$ only, and in this case its zero set is made of the nine lines generated by $(1,0,0)$, $(1,1,0)$, $(-1,1,0)$, $(1,0,1)$, $(-1,0,1)$, $(\eta_0,1,1)$, $(-\eta_0,1,1)$, $(\eta_0,1,-1)$ and $(-\eta_0,1,-1)$ with

$$\eta_0=\left(\sum_{j=0}^{(\kappa-1)/2}a_{2j+1}\right)^{1/(\kappa-1)}.$$

The nondegeneracy condition is satisfied (such a verification is often straightforward, although sometimes lengthy, when the zero set is known explicitly) and we conclude that problem (5.4) exhibits exactly four bifurcated branches emerging from the point $(\lambda_0,0)$, located supercritically if $\varepsilon=1$ and subcritically for $\varepsilon=-1$. By comparison, the same statement is made in [2] for the problem with $P=0$, $\varepsilon=1$ and no higher-order term

$$-\Delta u-\lambda u+u^\kappa=0$$

only (the equation $-\Delta u-\lambda u-u^\kappa$ cannot be considered in [2] due to growth conditions imposed on the nonlinearity). If $P\neq 0$, our conclusions do not follow from [11] either.

These examples show what criterion (4.49) (or its analogues in other problems) can be good for. They clearly establish that the exponent governing the structure of the bifurcation set in problems like (5.4) depends on the characteristic value λ_0 and, to some extent, allow to determine this "leading" exponent as λ_0 is varied. Other nonlinearities in which the Nemytskii's operator does not only depend on u but also on the generic point $x\in\Omega$ (and also possibly on λ) induce similar phenomena. Problems with nonlocal nonlinearities, such as von Kármán equations, can be considered as well. In this last example, the criterion (4.49) is trivially fulfilled and the nondegeneracy condition alone has to be examined (see Hölder and Schaeffer [7]).

Showing that the condition ($\mathbb{R}$-N.D.) remains appropriate in the study of problems in which no branch of solution is known a priori is our next purpose. For simplicity of calculations and since we do not intend here to discuss the usefulness of some version of the criterion of § 2, we shall consider the problem

$$(5.5)\qquad -\Delta u-\lambda_0 u+u^2=\mu f,\qquad u\in H_0^1(\Omega),$$

where $\Omega\subset\mathbb{R}^2$ is again the square $(0,\pi)\times(0,\pi)$, f is a given element of the space $H^{-1}(\Omega)$ and λ_0 is some eigenvalue of $-\Delta$. With $L=(-\Delta)^{-1}\in\mathscr{L}(H^{-1}(\Omega), H_0^1(\Omega))$ the problem becomes

$$(5.6)\qquad u-\lambda Lu+L(u^2)=\mu F,\qquad u\in H_0^1(\Omega),$$

where we have set $F=Lf$. We shall assume

$$(5.7)\qquad F\notin \text{Range}\,(I-\lambda_0 L),$$

so that the problem falls into the case $D_\mu G(0)\notin Z_2$ of §§ 3 and 4. When λ_0 is simple, hence of the form $\lambda_0=2a^2$, the solutions are given by a single curve. Further, if a is odd, it is easy to check that $\kappa=2$ so that the origin is a turning point (if a is even, higher order derivatives of the reduced mapping are needed to conclude). We shall apply our method to the study of the case when λ_0 is double. More precisely, we shall assume that $\lambda_0=a^2+b^2$ with $a>0$ and $b>0$ odd (and distinct). We leave it to the reader to check that the analysis can be made without changing the parameter μ by the method of § 3 and we shall focus on the method of § 4 since it provides additional information on the location of the curves. The null space Ker $(I-\lambda_0 L)=X_1$ is generated by the two normalized eigenvectors ϕ_{ab} and ϕ_{ba} (the inner product on $H_0^1(\Omega)$ being the usual one $(u,v)=\int_\Omega \nabla u\nabla v$) with

$$\phi_{ab}(t,s)=\frac{2}{\pi\sqrt{\lambda_0}}\sin at\sin bs$$

and $\phi_{ba}(t,s)=\phi_{ab}(s,t)$. With the choice $Z_1=X_1$ one has

$$Q_1F=y_{ab}\phi_{ab}+y_{ba}\phi_{ba},$$

with $y_{ab}, y_{ba}\in\mathbb{R}$ and $y_{ab}^2+y_{ba}^2\neq 0$ from (5.7). After renorming F (i.e. rescaling μ) it is not restrictive to assume

$$y_{ab}^2+y_{ba}^2=1.$$

It is easy to check that $\kappa=2$ and, after rescaling η for ease of calculations, the mapping $(4.42)_\sigma$ identifies with

$$(5.8)_\sigma\qquad (\eta,\alpha,\beta)\in\mathbb{R}^3\to\begin{pmatrix}-\sigma y_{ab}\eta^2+A\alpha^2+2B\alpha\beta+B\beta^2\\ -\sigma y_{ba}\eta^2+B\alpha^2+2B\alpha\beta+A\beta^2\end{pmatrix}\in\mathbb{R}^2,$$

where

$$A=\frac{16}{9ab},\qquad B=\frac{16ab}{(b^2-4a^2)(a^2-4b^2)}.$$

Applying Proposition 4.4 we can see that the condition (4.43) is automatically satisfied from the relations $A\neq B$ and $A+3B\neq 0$ (the former follows from $A/B<1$ and the latter holds because a^2/b^2 could not be rational otherwise). Taking $Y_1=\mathbb{R}(y_{ba}, -y_{ab})$ in Proposition 4.4, it suffices to prove that the mapping

$$(\alpha, \beta)\in\mathbb{R}^2\to(Ay_{ba}-By_{ab})\alpha^2+2B(y_{ba}-y_{ab})\alpha\beta+(By_{ba}-Ay_{ab})\beta^2\in\mathbb{R}$$

verifies the condition ($\mathbb{R}$-N.D.). As the above mapping is quadratic, it is equivalent to check that the discriminant

$$\Delta(F)=y_{ba}^2-\left(\frac{A}{B}+1\right)y_{ab}y_{ba}+y_{ab}^2$$

is nonzero (which will happen for most choices of F). Note that $\Delta(F)>0$ regardless of F when $(A/B)+3>0$ but the sign of $\Delta(F)$ will be negative for some choices of F if $(A/B)+3<0$. If $\Delta(F)<0$, the zero set of $(5.8)_\sigma$ reduces to the origin for both $\sigma=1$ and $\sigma=-1$. In other words, the origin is an *isolated solution* of the problem (5.4) for those F with $\Delta(F)<0$. Note that the condition $(A/B)+3<0$ is satisfied with $\lambda_0=26$ so that this situation does happen. If $\Delta(F)>0$, the zero set of $(5.8)_\sigma$ depends on σ and F. More precisely, define K_i, $i=1, 2$, to be the two distinct roots of the polynomial[4]

$$(By_{ba}-Ay_{ab})K^2+2B(y_{ba}-y_{ab})K+(Ay_{ba}-By_{ab})=0$$

and set

$$\theta_i=(By_{ab}+Ay_{ba})K_i^2+2B(y_{ab}+y_{ba})K_i+(Ay_{ab}+By_{ba}).$$

It can be shown that $\theta_i\neq 0$, $i=1, 2$ (an easy way is to observe that either relation $\theta_1=0$ or $\theta_2=0$ would contradict the fact that condition (4.43) is satisfied) and the discussion is as follows: if θ_1 and θ_2 have the same sign, the solutions of problem (5.4) near the origin consist of two curves located on the same half-space $\mu\geqq 0$ or $\mu\leqq 0$ (depending on the sign of θ_1 and θ_2). If θ_1 and θ_2 have opposite signs, the solutions of problem (5.4) near the origin still consist of two curves, but one of them is located on the half-space $\mu\leqq 0$ and the other is located on the half-space $\mu\geqq 0$. That both situations do occur depending on λ_0 (with the same F) is easily seen: take for instance

$$F=\frac{\sqrt{2}}{2}(\phi_{13}+\phi_{31}+\phi_{15}+\phi_{51}).$$

Then, if $\lambda_0=10$, one has $\theta_1>0$ and $\theta_2<0$ while, if $\lambda_0=26$, one has $\theta_1>0$ and $\theta_2>0$.

Acknowledgments. I wish to thank Prof. F. Weissler for stimulating discussions while I was visiting the University of Texas at Austin. I am also grateful to one of the referees for numerous helpful comments on the presentation of this paper.

THE SADDLE-NODE SEPARATRIX-LOOP BIFURCATION*

STEPHEN SCHECTER†

Abstract. We study vector fieldx $\dot{x}=f(x)$, $x\in\mathbb{R}^2$, having at some point an equilibrium of saddle-node type with a separatrix loop. Such vector fields fill a codimension two submanifold Σ of an appropriate Banach space. We give analytic conditions that determine whether a two-parameter perturbation of $\dot{x}=f(x)$ is transverse to Σ. The new condition is a version of Melnikov's integral around the separatrix loop. If it is nonzero, then as one perturbs away from $\dot{x}=f(x)$ in the direction in which an equilibrium of saddle-node type persists, the separatrix loop breaks in a nondegenerate manner. This integral is shown to be nonzero for the two-parameter pendulum equation $\beta\ddot{\phi}+\dot{\phi}+\sin\phi=\rho$ at its organizing center.

Key words. saddle-node separatrix-loop bifurcation, Melnikov integral, pendulum, Josephson junction

AMS(MOS) subject classification. 58F14

1. Introduction. We shall be concerned with vector fields

$$\dot{x}=f(x),\qquad x\in\mathbb{R}^2 \tag{1}$$

having at some $p\in\mathbb{R}^2$ an equilibrium of saddle-node type with a separatrix loop Γ (see Fig. 1). We assume that the saddle-node has one negative eigenvalue and, of course, one zero eigenvalue. Such vector fields fill a codimension two submanifold Σ of an appropriate Banach space of planar vector fields. Consider a two-parameter unfolding of (1),

$$\dot{x}=\tilde{f}(x,\nu_1,\nu_2),\qquad x\in\mathbb{R}^2,\quad \nu_1,\nu_2\in\mathbb{R} \tag{2}$$

where $\tilde{f}(x,0,0)=f(x)$. We shall give a computable condition that determines whether the family (2) is transverse to Σ at $(\nu_1,\nu_2)=(0,0)$.

If the transversality condition is satisfied, there is a smooth nonsingular change of coordinates in parameter space,

$$(\nu_1,\nu_2)\leftrightarrow(\mu_1,\mu_2),\qquad (0,0)\leftrightarrow(0,0),$$

such that

$$\dot{x}=\tilde{f}(x,\nu_1(\mu_1,\mu_2),\nu_2(\mu_1,\mu_2))\underset{\text{def}}{=}f(x,\mu_1,\mu_2)$$

has the bifurcation diagram of Fig. 2 in a neighborhood of $(\mu_1,\mu_2)=(0,0)$. The curve C lies in $\{(\mu_1,\mu_2)\colon \mu_1\leqq 0,\ \mu_2\geqq 0\}$. It has a quadratic tangency with the μ_2-axis at

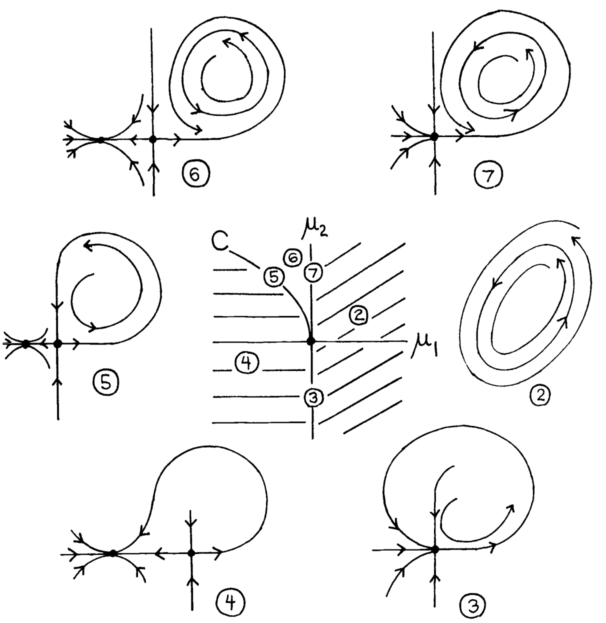

FIG. 2

(0, 0). The phase portrait of $\dot{x}=f(x, \mu_1, \mu_2)$ in a fixed neighborhood of Γ that is positively invariant for each vector field $\dot{x}=f(x, \mu_1, \mu_2)$ is as follows (see Fig. 2):

1) $\mu_1=0$, $\mu_2=0$; a saddle-node and a separatrix loop.

2) $\mu_1>0$; no equilibria, a unique stable closed orbit near Γ.

3) $\mu_1=0$, $\mu_2<0$; a saddle-node.

4) $\mu_1<0$, (μ_1, μ_2) below C; a saddle and a node.

5) $\mu_1<0$, (μ_1, μ_2) on C; a saddle and a node; the saddle has a separatrix loop.

6) $\mu_1<0$, (μ_1, μ_2) above C; a saddle and a node; there is a unique stable closed orbit near Γ.

7) $\mu_1=0$, $\mu_2>0$; a saddle-node and a unique stable closed orbit near Γ.

This bifurcation diagram is developed in [4], except that it is mistakenly stated there that the curve C is transverse to the μ_2-axis.

Perhaps the best known example of this bifurcation diagram occurs in the study of the differential equation for a pendulum with linear damping and constant applied torque, which are the two parameters (see [3], in which the same equation arises in the study of the DC current-driven point Josephson junction). In § 5 we show that the pendulum equation satisfies our transversality condition at its organizing center. Thus the pendulum equation is a generic two-parameter unfolding of the saddle-node separatrix-loop bifurcation.

The heart of this paper is the study, in § 3, of Melnikov's integral (see [2]) around a saddle-node separatrix loop. The same method allows one to study time-periodic perturbations of a saddle-node separatrix loop. This subject is treated in the companion paper [6]. There the motivating example is the pendulum equation with, in addition, sinusoidal applied torque (or, equivalently, the AC–DC current-driven point Josephson junction).

2. Statement of results.

We shall consider vector fields $\dot{x}=f(x)$, $x\in\mathbb{R}^2$, satisfying the following conditions at some $p\in\mathbb{R}^2$:

(i) $f(p)=0$.

(ii) $Df(p)$ has eigenvalues 0 and $-\lambda$, where $\lambda > 0$.

Let u be a right eigenvector and w a left eigenvector of the eigenvalue 0, with w chosen so that $wu > 0$.

(iii) $wD^2f(p)(u, u) > 0$.

(iv) $\dot{x} = f(x)$ has a separatrix loop Γ at p.

Assumptions (i)-(iii) say that $\dot{x} = f(x)$ has a saddle-node at p with one negative eigenvalue (see [7]). Moreover, the assumptions imply that u (not $-u$) is one tangent vector to Γ at p (see Fig. 1). Let v be a right eigenvector of $Df(p)$ for the eigenvalue $-\lambda$, chosen so that v is also tangent to Γ at p as in Fig. 1.

Let $\dot{x} = \tilde{f}(x, \nu_1, \nu_2)$ be a two-parameter family of vector fields on $\mathbb{R}^2$ such that $\dot{x} = \tilde{f}(x, 0, 0)$ satisfies (i)-(iv), and

(v) $\tilde{f}(x, \nu_1, \nu_2)$ is C^{k+1}, $k \geqq 5$.

(vi) $wD_{\nu_1}\tilde{f}(p, 0, 0) > 0$.

Assumptions (iii) and (vi) imply that perturbation in the positive ν_1 direction eliminates the equilibrium p, while perturbation in the negative ν_1 direction splits the equilibrium in two (see [7]).

According to [7] there is a C^k function $\alpha(\nu_2)$, with $\alpha(0) = 0$, such that $\dot{x} = \tilde{f}(x, \nu_1, \nu_2)$ has an equilibrium of saddle-node type near p if and only if $\nu_1 = \alpha(\nu_2)$. Let $f(x, \mu_1, \mu_2) = \tilde{f}(x, \nu_1, \nu_2)$, where (μ_1, μ_2) and (ν_1, ν_2) are related by

$$\mu_1 = \nu_1 - \alpha(\nu_2), \qquad \mu_2 = \nu_2.$$

Then

$$\dot{x} = f(x, \mu_1, \mu_2) \tag{3}$$

is C^k, and has an equilibrium of saddle-node type near p if and only if $\mu_1 = 0$. Let $p(\mu_2)$ denote the saddle-node equilibrium near p of $\dot{x} = f(x, 0, \mu_2)$; $p(\mu_2)$ is C^k. If $\mu_1 < 0$, there are a saddle and a sink of (3) near p; if $\mu_1 > 0$, there are no equilibria of (3) near p.

If w and z are vectors in $\mathbb{R}^2$, let $w \wedge z = w_1 z_2 - w_2 z_1$. Let $q(t)$ be a solution of $\dot{x} = f(x, 0, 0)$ with $q(0) \in \Gamma$. Consider the expression

$$\begin{aligned} I = {} & \frac{dp}{d\mu_2}(0) \wedge \lim_{t_1 \to \infty} f(q(t_1), 0, 0) \exp\left[-\int_0^{t_1} \operatorname{div} f(q(s), 0, 0)\, ds\right] \\ & + \int_{-\infty}^{\infty} \exp\left[-\int_0^{t} \operatorname{div} f(q(s), 0, 0)\, ds\right] f(q(t), 0, 0) \wedge \frac{\partial f}{\partial \mu_2}(q(t), 0, 0)\, dt. \end{aligned} \tag{4}$$

THEOREM 1. *The limit in* (4) *exists and is a negative multiple of v. The improper integral in* (4) *converges. If $I \neq 0$, then there is a C^{k-2} curve $\mu_1 = \psi(\mu_2) = -\ell^2\mu_2^2 + o(\mu_2^2)$, $\ell \neq 0$, such that for (μ_1, μ_2) sufficiently small,* (3) *has a separatrix loop near Γ if and only if $\mu_1 = \psi(\mu_2)$ and $I \cdot (u \wedge v) \cdot \mu_2 \geqq 0$.*

The integral in (4) is just the usual Melnikov integral used to study perturbations of a separatrix loop at a hyperbolic saddle (see [2], [5]). The limit in (4) is zero in the case of a hyperbolic saddle, but must be retained in the case of a saddle-node.

The bifurcation diagram presented in § 1 holds if $I \cdot (u \wedge v) > 0$, in which case separatrix loops occur for $\mu_1 = \psi(\mu_2)$ and $\mu_2 \geqq 0$. If $I \cdot (u \wedge v) < 0$, this bifurcation diagram holds after the further change of parameter $\mu_2 \to -\mu_2$.

We remark that in order to compute I in applications, the only knowledge of the function $\alpha(\nu_2)$ that is needed is $\alpha'(0)$.

We shall now give a precise interpretation of the condition $I \neq 0$ as a transversality condition. Let E denote the space of C^{k+1} vector fields, $k \geqq 5$, on a closed disk $D \subset \mathbb{R}^2$, with the C^{k+1} topology. Let $\Sigma' = \{f \in E : f$ satisfies, at a unique $p \in \operatorname{Int} D$, conditions (i)-(iii); and all other equilibria of f in D are hyperbolic$\}$. Σ' is a C^k codimension one submanifold of E [7]. Let $\Sigma = \{f \in \Sigma' : f$ satisfies condition (iv), and $\Gamma \subset \operatorname{Int} D\}$. We shall show in § 3 that Σ is a C^k codimension two submanifold of E, in fact a codimension one submanifold of Σ'. Let $\dot{x} = \tilde{f}(x, \nu_1, \nu_2)$ be a two-parameter family of vector fields in E with $\dot{x} = \tilde{f}(x, 0, 0) \in \Sigma$. Assume in addition that $\dot{x} = \tilde{f}(x, \nu_1, \nu_2)$ satisfies conditions (v) and (vi). Make the change of parameters $\mu_1 = \nu_1 - \alpha(\nu_2)$, $\mu_2 = \nu_2$ described earlier.

THEOREM 2. *The family $\dot{x} = \tilde{f}(x, \nu_1, \nu_2)$ is transverse to Σ at $(\nu_1, \nu_2) = (0, 0)$ if and only if $I \neq 0$.*

3. Proof of Theorem 1. The equilibrium $(p, 0, 0)$ of

$$\dot{x} = f(x, \mu_1, \mu_2), \quad \dot{\mu}_1 = 0, \quad \dot{\mu}_2 = 0 \tag{5}$$

has a 3-dimensional neutral subspace. The center manifold theorem [1, § 9.2] yields a 3-dimensional C^k local center manifold N_{loc} of (5), tangent at $(p, 0, 0)$ to this subspace. N_{loc} meets each plane $\mathbb{R}^2 \times \{(\mu_1, \mu_2)\}$, (μ_1, μ_2) small, in a curve. $N_{\text{loc}} \cap \mathbb{R}^2 \times \{(0, 0)\}$ contains a portion of $\Gamma \times \{(0, 0)\}$ that is tangent at $(p, 0, 0)$ to $(u, 0, 0)$.

Let N denote the global center manifold that contains N_{loc}, i.e., the union of all integral curves of (5) that meet N_{loc}. N meets each plane $\mathbb{R}^2 \times \{(\mu_1, \mu_2)\}$ in a curve, which we denote $N(\mu_1, \mu_2) \times \{(\mu_1, \mu_2)\}$. Thus $N(\mu_1, \mu_2)$ is a curve in $\mathbb{R}^2$. Let L be a line segment in $\mathbb{R}^2$ perpendicular to Γ at $q(0)$. Then for (μ_1, μ_2) small, $N(\mu_1, \mu_2)$ meets L transversally near $q(0)$. Therefore for (μ_1, μ_2) small there is a C^k function $x(\mu_1, \mu_2)$ such that $x(0, 0) = q(0)$ and $x(\mu_1, \mu_2) \in N(\mu_1, \mu_2) \cap L$. Since a C^k vector field has a C^k flow, there is a C^k family of solutions of (3)

$$q^c(\mu_1, \mu_2, t), \qquad (\mu_1, \mu_2) \text{ small},$$

such that $q^c(\mu_1, \mu_2, 0) = x(\mu_1, \mu_2)$. Then $q^c(0, 0, t) = q(t)$, and each curve $q^c(\mu_1, \mu_2, t)$ lies in $N(\mu_1, \mu_2)$. For $\mu_1 < 0$, $q^c(\mu_1, \mu_2, t)$ is a branch of the unstable manifold of the saddle of (3) near p. Similarly, $q^c(0, \mu_2, t)$ is the unstable separatrix of the saddle-node of $\dot{x} = f(x, 0, \mu_2)$ near p (see Fig. 3).

We shall now define a μ-dependent change of coordinates on $\mathbb{R}^2$ that will make possible our computations. According to [1, § 9.2] there is a C^k change of coordinates

$$y(x, \mu_1, \mu_2) = (y_1(x, \mu_1, \mu_2), y_2(x, \mu_1, \mu_2)), \tag{6}$$

defined for (x, μ_1, μ_2) near $(p, 0, 0)$, such that (1) $y(p, 0, 0) = 0$; (2) $N_{\text{loc}} \cap \mathbb{R}^2 \times \{(\mu_1, \mu_2)\}$ is transformed into the line $y_2 = 0$, which is therefore invariant; (3) the lines $y_1 = \text{constant}$ are mapped into each other by the flow. In other words, in the new coordinates we have a C^k differential equation of the form

$$\dot{y}_1 = a(y_1, \mu_1, \mu_2), \qquad \dot{y}_2 = y_2 b(y_1, y_2, \mu_1, \mu_2).$$

Since $p(\mu_2)$, defined in § 2, is C^k, we may assume that $p(\mu_2)$ is transformed to $(0, 0)$ for all μ_2. In other words, $a(0, 0, \mu_2) \equiv 0$. Since the stable manifold of $\dot{x} = f(x, 0, 0)$ at p is necessarily transformed into the line $y_1 = 0$, it is easy to arrange that

$$D_x y(p, 0, 0)u = (1, 0), \qquad D_x y(p, 0, 0)v = (0, 1). \tag{7}$$

Taking into account assumptions (i)-(iii) and (vi), we have

$$\begin{aligned} \dot{y}_1 &= \eta(\mu_2) y_1^2 (1 + y_1 g(y_1, \mu_2)) + \mu_1 h(y_1, \mu_1, \mu_2), \\ \dot{y}_2 &= -\lambda(y_1, \mu_1, \mu_2) y_2 (1 + y_2 k(y_1, y_2, \mu_1, \mu_2)), \end{aligned} \tag{8}$$

with $\eta > 0$, $h(0, 0, 0) > 0$, $\lambda(0, 0, 0) = \lambda$.

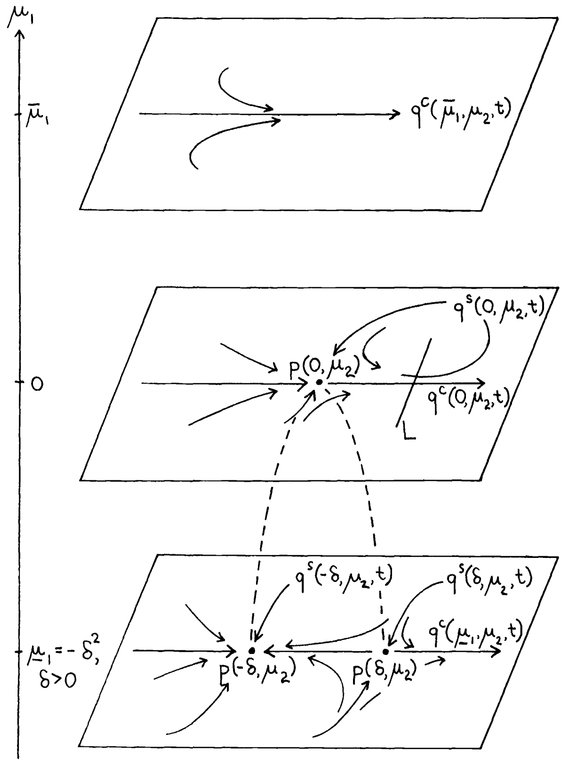

FIG. 3

LEMMA 1. *There is a C^{k-2} mapping $p(\delta, \mu_2)$, defined for (δ, μ_2) near $(0, 0)$, with values in $\mathbb{R}^2$, such that $p(0, 0) = p$, and*

$$p(\delta, \mu_2) \text{ is} \begin{cases} \text{a saddle-node of } \dot{x} = f(x, 0, \mu_2) & \text{if } \delta = 0, \\ \text{a saddle of } \dot{x} = f(x, -\delta^2, \mu_2) & \text{if } \delta > 0, \\ \text{a sink of } \dot{x} = f(x, -\delta^2, \mu_2) & \text{if } \delta < 0. \end{cases}$$

Moreover, the mapping $(\delta, \mu_2) \to (p(\delta, \mu_2), -\delta^2, \mu_2)$ is a C^{k-2} diffeomorphism of a neighborhood of $(0, 0)$ in $\mathbb{R}^2$ onto a neighborhood of $(p, 0, 0)$ in the set of equilibria of (5) *near* $(0, 0, 0)$ (see Fig. 3).

We remark that $p(0, \mu_2)$ equals $p(\mu_2)$ defined in § 2.

Proof. The equilibria of the system

$$\begin{aligned} \dot{y}_1 &= \eta(\mu_2) y_1^2 (1 + y_1 g(y_1, \mu_2)) + \mu_1 h(y_1, \mu_1, \mu_2), \\ \dot{y}_2 &= -\lambda(y_1, \mu_1, \mu_2) y_2 (1 + y_2 k(y_1, y_2, \mu_1, \mu_2)), \\ \dot{\mu}_1 &= 0, \\ \dot{\mu}_2 &= 0 \end{aligned}$$

near $(0, 0, 0, 0)$ comprise a set of the form

$$\{(y_1, 0, \mu_1, \mu_2) \colon \mu_1 = \mu_1(y_1, \mu_2)\},$$

where

$$\mu_1(0, \mu_2) = \frac{\partial \mu_1}{\partial y_1}(0, \mu_2) = 0 \quad \text{and} \quad \frac{\partial^2 \mu_1}{\partial y_1^2}(0, \mu_2) < 0.$$

Therefore,

$$\mu_1 = -y_1^2(A(\mu_2)+y_1B(y_1,\mu_2)),$$

where $A(\mu_2)>0$ and $A(\mu_2)+y_1B(y_1,\mu_2)$ is C^{k-2}. For $\mu_1 \leqq 0$, let $\mu_1 = -\delta^2$. Then

$$\delta = y_1(A(\mu_2)+y_1B(y_1,\mu_2))^{1/2}. \tag{9}$$

(Taking into account the negative square root gives no additional information.) By the implicit function theorem, we can solve (9) for y_1 near $y_1=0$, $\delta=0$, $\mu_2=0$. We obtain

$$y_1=\hat{p}(\delta,\mu_2) \quad \text{with } \hat{p}(0,\mu_2)=0, \qquad \frac{\partial \hat{p}}{\partial \delta}(0,\mu_2)>0. \tag{10}$$

Then $\eta>0$ and (10) imply that the equilibrium $(\hat{p}(\delta,\mu_2),0)$ of (8) with $\mu_1=-\delta^2$ is a saddle-node if $\delta=0$, a saddle if $\delta>0$, and a sink if $\delta<0$.

Let

$$x=x(y,\mu_1,\mu_2) \tag{11}$$

be the change of coordinates inverse to (6). Define

$$p(\delta,\mu_2)=x((\hat{p}(\delta,\mu_2),0),-\delta^2,\mu_2). \tag{12}$$

Then $p(\delta,\mu_2)$ satisfies the assertions of the lemma. □

For future use, we note that

$$\frac{\partial p}{\partial \delta}(0,0) \text{ is a positive multiple of } u. \tag{13}$$

To see this, we compute from (12)

$$\frac{\partial p}{\partial \delta}(0,0)=D_yx((0,0),0,0)\left(\frac{\partial \hat{p}}{\partial \delta}(0,0),0\right). \tag{14}$$

Since $(\partial\hat{p}/\partial\delta)(0,0)>0$ by (10), (14) is a positive multiple of u by (7).

System (8) with $\mu_1=-\delta^2$ has at the equilibrium $(\hat{p}(\delta,\mu_2),0)$ the invariant manifold $\{(y_1,y_2)\colon y_1=\hat{p}(\delta,\mu_2)\}$, a line. For $\delta=0$ this line is the stable manifold of the saddle-node $(0,0)$; for $\delta>0$ it is the stable manifold of the saddle $(\hat{p}(\delta,\mu_2),0)$; and for $\delta<0$ it is the strong stable manifold of the sink $(\hat{p}(\delta,\mu_2),0)$. These lines correspond to invariant manifolds of $\dot{x}=f(x,-\delta^2,\mu_2)$ at $p(\delta,\mu_2)$. Let $v(\delta,\mu_2)=D_yx((\hat{p}(\delta,\mu_2),0),-\delta^2,\mu_2)(0,1)$. Then $\dot{x}=f(x,-\delta^2,\mu_2)$ has at $p(\delta,\mu_2)$ an invariant curve tangent to $v(\delta,\mu_2)$ and these invariant curves vary in a C^{k-2} manner with (δ,μ_2). For $(\delta,\mu_2)=(0,0)$, this invariant curve contains Γ. Now a construction similar to that of $q^c(\mu_1,\mu_2,t)$ yields a C^{k-2} family

$$q^s(\delta,\mu_2,t), \qquad (\delta,\mu_2) \text{ small},$$

each a solution of $\dot{x}=f(x,-\delta^2,\mu_2)$, such that $q^s(\delta,\mu_2,t)\to p(\delta,\mu_2)$ as $t\to\infty$ along the negative $v(\delta,\mu_2)$ direction. Again we require $q^s(\delta,\mu_2,0)\in L$; thus $q^s(0,0,t)=q(t)$. Note that $q^s(0,\mu_2,t)$ is a branch of the stable manifold of the saddle-node $p(0,\mu_2)$ of $\dot{x}=f(x,0,\mu_2)$; and if $\delta>0$, $q^s(\delta,\mu_2,t)$ is a branch of the stable manifold of the saddle $p(\delta,\mu_2)$ of $\dot{x}=f(x,-\delta^2,\mu_2)$ (see Fig. 3).

For any vector $w=(w_1,w_2)\in\mathbb{R}^2$, let $w^\perp=(-w_2,w_1)$. Define $d^c(\mu_1,\mu_2)$ and $d^s(\delta,\mu_2)$ by

$$q^c(\mu_1,\mu_2,0)=q(0)+[d^c(\mu_1,\mu_2)/\|f(q(0),0,0)\|^2]f^\perp(q(0),0,0),$$

$$q^s(\delta,\mu_2,0)=q(0)+[d^s(\delta,\mu_2)/\|f(q(0),0,0)\|^2]f^\perp(q(0),0,0).$$

Then d^c is C^k and d^s is C^{k-2}. The number $d^c(\mu_1, \mu_2)$ (resp. $d^s(\delta, \mu_2)$) determines where on L the curve $q^c(\mu_1, \mu_2, t)$ (resp. $q^s(\delta, \mu_2, t)$) starts. We have

$$\begin{aligned} d^c(\mu_1, \mu_2) &= f^{\perp}(q(0), 0, 0) \cdot [q^c(\mu_1, \mu_2, 0) - q(0)] \\ &= f(q(0), 0, 0) \wedge [q^c(\mu_1, \mu_2, 0) - q(0)]. \end{aligned}$$

Similarly,

$$d^s(\delta, \mu_2) = f(q(0), 0, 0) \wedge [q^s(\delta, \mu_2, 0) - q(0)].$$

There is a separatrix loop of $\dot{x} = f(x, -\delta^2, \mu_2)$ through $p(\delta, \mu_2)$ if and only if $\delta \geqq 0$ and

$$d(\delta, \mu_2) \underset{\text{def}}{=} d^c(-\delta^2, \mu_2) - d^s(\delta, \mu_2) = 0. \tag{15}$$

Here $d(\delta, \mu_2)$ is C^{k-2}.

We shall show that $(\partial d/\partial \delta)(0, 0)$ is a negative multiple of $u \wedge v$ (hence is nonzero), and $(\partial d/\partial \mu_2)(0, 0) = I$. Given these facts, the proof of Theorem 1 is completed as follows: if $I \neq 0$, then $\{(\delta, \mu_2)\colon d(\delta, \mu_2) = 0\}$ is a C^{k-2} curve through $(0, 0)$ of the form

$$\delta = \ell \mu_2 + o(\mu_2), \qquad \ell = -I \Big/ \frac{\partial d}{\partial \delta}(0, 0). \tag{16}$$

Squaring both sides of (16) yields

$$\mu_1 = -\ell^2 \mu_2^2 + o(\mu_2^2).$$

The condition $\delta \geqq 0$, applied to (16), shows that $\mu_2 = 0$ or ℓ and μ_2 have the same sign. But ℓ has the sign of $I \cdot (u \wedge v)$.

We now turn to the computation of $(\partial d/\partial \delta)(0, 0)$ and $(\partial d/\partial \mu_2)(0, 0)$. We shall need the following variational equations for $q^c(-\delta^2, \mu_2, t)$ and $q^s(\delta, \mu_2, t)$:

$$\begin{aligned} &\frac{d}{dt} \frac{\partial q^c}{\partial \mu_2}(0, 0, t) = D_x f(q(t), 0, 0) \frac{\partial q^c}{\partial \mu_2}(0, 0, t) + \frac{\partial f}{\partial \mu_2}(q(t), 0, 0), \\ &\frac{d}{dt} \frac{\partial q^s}{\partial \delta}(0, 0, t) = D_x f(q(t), 0, 0) \frac{\partial q^s}{\partial \delta}(0, 0, t), \\ &\frac{d}{dt} \frac{\partial q^s}{\partial \mu_2}(0, 0, t) = D_x f(q(t), 0, 0) \frac{\partial q^s}{\partial \mu_2}(0, 0, t) + \frac{\partial f}{\partial \mu_2}(q(t), 0, 0). \end{aligned}$$

As in [2], we define

$$\Delta^c_{\mu_2}(t) = f(q(t), 0, 0) \wedge \frac{\partial q^c}{\partial \mu_2}(0, 0, t)$$

and define $\Delta^s_\delta(t)$ and $\Delta^s_{\mu_2}(t)$ analogously.

For $d^c(-\delta^2, \mu_2)$ and $d^s(\delta, \mu_2)$ we have the derivative formulas

$$\begin{aligned} &\frac{\partial d^c}{\partial \delta}(0, 0) = \frac{\partial d^c}{\partial \mu_1}(0, 0) \cdot \frac{d\mu_1}{d\delta}(0) = 0, \qquad \frac{\partial d^c}{\partial \mu_2}(0, 0) = \Delta^c_{\mu_2}(0), \\ &\frac{\partial d^s}{\partial \delta}(0, 0) = \Delta^s_\delta(0), \qquad \frac{\partial d^s}{\partial \mu_2}(0, 0) = \Delta^s_{\mu_2}(0). \end{aligned} \tag{17}$$

Using the variational equations for q^c and q^s, we compute as in [2]:

$$\frac{d}{dt} \Delta^c_{\mu_2}(t) = \operatorname{div} f(q(t), 0, 0) \Delta^c_{\mu_2}(t) + f(q(t), 0, 0) \wedge \frac{\partial f}{\partial \mu_2}(q(t), 0, 0), \tag{18}$$

$$\frac{d}{dt}\Delta^s_\delta(t)=\operatorname{div} f(q(t),0,0)\Delta^s_\delta(t), \tag{19}$$

$$\frac{d}{dt}\Delta^s_{\mu_2}(t)=\operatorname{div} f(q(t),0,0)\Delta^s_{\mu_2}(t)+f(q(t),0,0)\wedge\frac{\partial f}{\partial\mu_2}(q(t),0,0). \tag{20}$$

Solving these linear differential equations, we obtain, for any t_1,

$$\begin{aligned}\Delta^c_{\mu_2}(0)=\Delta^c_{\mu_2}(t_1)\exp\int_{t_1}^0 \operatorname{div} f(q(t),0,0)\,dt\\ +\int_{t_1}^0\exp\left[-\int_0^t \operatorname{div} f(q(s),0,0)\,ds\right]\\ \cdot f(q(t),0,0)\wedge\frac{\partial f}{\partial\mu_2}(q(t),0,0)\,dt,\end{aligned} \tag{21}$$

$$-\Delta^s_\delta(0)=-\Delta^s_\delta(t_1)\exp\left[-\int_0^{t_1}\operatorname{div} f(q(t),0,0)\,dt\right], \tag{22}$$

$$\begin{aligned}-\Delta^s_{\mu_2}(0)=-\Delta^s_{\mu_2}(t_1)\exp\left[-\int_0^{t_1}\operatorname{div} f(q(t),0,0)\,dt\right]\\ +\int_0^{t_1}\exp\left[-\int_0^t \operatorname{div} f(q(s),0,0)\,ds\right]\\ \cdot f(q(t),0,0)\wedge\frac{\partial f}{\partial\mu_2}(q(t),0,0)\,dt.\end{aligned} \tag{23}$$

We shall first evaluate (22) in the limit $t_1\to\infty$. Using the definition of Δ^s_δ, we write

$$-\Delta^s_\delta(0)=\frac{\partial q^s}{\partial\delta}(0,0,t_1)\wedge f(q(t_1),0,0)\exp\left[-\int_0^{t_1}\operatorname{div} f(q(s),0,0)\,ds\right]. \tag{24}$$

LEMMA 2.

$$\lim_{t\to\infty}\frac{\partial q^s}{\partial\delta}(0,0,t)=\frac{\partial p}{\partial\delta}(0,0),\qquad \lim_{t\to\infty}\frac{\partial q^s}{\partial\mu_2}(0,0,t)=\frac{\partial p}{\partial\mu_2}(0,0).$$

Proof. We shall use the coordinates (6). Define

$$\begin{aligned}\tilde q^s(\delta,\mu_2,t)&=y(q^s(\delta,\mu_2,t),-\delta^2,\mu_2)\\ &=(\hat p(\delta,\mu_2),y_2(\delta,\mu_2,t)),\end{aligned} \tag{25}$$

where $\hat p(\delta,\mu_2)$ is given by (10) and $y_2(\delta,\mu_2,t)$ is defined by (25). Since $q^s(\delta,\mu_2,t)\to p(\delta,\mu_2)$ as $t\to\infty$, for each (δ,μ_2) near $(0,0)$, $\tilde q^s(\delta,\mu_2,t)$ and hence $y_2(\delta,\mu_2,t)$ are defined for sufficiently large t. It follows from (7) that $y_2(\delta,\mu_2,t)>0$ for large t. From (8), $y_2(\delta,\mu_2,t)$ satisfies a differential equation of the form

$$\frac{dz}{dt}=-\lambda(\delta,\mu_2)z(1+zG(z,\delta,\mu_2)), \tag{26}$$

where $\lambda(0,0)=\lambda$. Here λ and zG are C^{k-3}.

In order to prove the lemma, we shall study the asymptotic behavior of solutions of (26) as $t\to\infty$ by solving (26) by separation of variables. Let

$$z^{-1}[1+zG(z,\delta,\mu_2)]^{-1}=z^{-1}+H(z,\delta,\mu_2). \tag{27}$$

Then H is C^{k-4}. Fix $z_0>0$. Let

$$J(z, \delta, \mu_2)=\int_{z_0}^{z} H(s, \delta, \mu_2)\, ds.$$

Then J is C^{k-4}. Solving (26) by separation of variables using (27) yields

$$\ln z+J(z, \delta, \mu_2)=-\lambda(\delta, \mu_2)t+A(\delta, \mu_2),$$

or

$$z \exp J(z, \delta, \mu_2)=B(\delta, \mu_2) \exp(-\lambda(\delta, \mu_2)t).$$

Here $B(\delta, \mu_2)$ is determined by the value of $y_2(\delta, \mu_2, t)$ at some $t=t_0$. Hence B is C^{k-4} and $B>0$. Since

$$\frac{\partial}{\partial z}[z \exp J(z, \delta, \mu_2)](0, \delta, \mu_2)\neq 0,$$

by the implicit function theorem we can solve the equation

$$z \exp J(z, \delta, \mu_2)=v$$

for z when z and v are near 0. We obtain

$$z=K(v, \delta, \mu_2),$$

where K is C^{k-4} and

$$K(0, \delta, \mu_2)\equiv 0. \tag{28}$$

Putting $z=y_2$ and $v=B(\delta, \mu_2)\exp(-\lambda(\delta, \mu_2)t)$, we obtain

$$y_2=K(B(\delta, \mu_2) \exp(-\lambda(\delta, \mu_2)t), \delta, \mu_2). \tag{29}$$

From (29) and (28) it follows that $(\partial y_2/\partial\delta)(\delta, \mu_2, t)$ and $(\partial y_2/\partial\mu_2)(\delta, \mu_2, t)$ approach 0 as $t\to\infty$. Therefore (25) implies that as $t\to\infty$,

$$\frac{\partial\tilde{q}^s}{\partial\delta}(\delta, \mu_2, t)\to\left(\frac{\partial\hat{p}}{\partial\delta}(\delta, \mu_2), 0\right), \qquad \frac{\partial\tilde{q}^s}{\partial\mu_2}(\delta, \mu_2, t)\to\left(\frac{\partial\hat{p}}{\partial\mu_2}(\delta, \mu_2), 0\right). \tag{30}$$

Now

$$\frac{\partial q^s}{\partial\delta}(\delta, \mu_2, t)=\frac{\partial}{\partial\delta}x(\tilde{q}^s(\delta, \mu_2, t), -\delta^2, \mu_2),$$

where $x(y, \mu_1, \mu_2)$ is given by (11). Therefore

$$\frac{\partial q^s}{\partial\delta}(0, 0, t)=D_yx(\tilde{q}^s(0, 0, t), 0, 0)\frac{\partial\tilde{q}^s}{\partial\delta}(0, 0, t).$$

By (30) and (14),

$$\lim_{t\to\infty}\frac{\partial q^s}{\partial\delta}(0, 0, t)=D_yx((0, 0), 0, 0)\left(\frac{\partial\hat{p}}{\partial\delta}(0, 0), 0\right)$$

$$=\frac{\partial p}{\partial\delta}(0, 0).$$

Similarly, the second formula of the lemma follows from (30) and the following formula derived from (12):

$$\frac{\partial p}{\partial\mu_2}(0, 0)=D_yx((0, 0), 0, 0)\left(\frac{\partial\hat{p}}{\partial\mu_2}(0, 0), 0\right)+\frac{\partial x}{\partial\mu_2}((0, 0), 0, 0). \qquad \square$$

We shall now use the computations we have done in proving Lemma 2 to study the other terms of (24). By (25),

$$\overset{*}{q}^s(\delta, \mu_2, t) = D_xy(q^s(\delta, \mu_2, t), -\delta^2, \mu_2)\dot{q}^s(\delta, \mu_2, t). \tag{31}$$

Let $\delta = \mu_2 = 0$ in (31). Since $\dot{q}^s(0, 0, t) = \dot{q}(t) = f(q(t), 0, 0)$, we obtain

$$f(q(t), 0, 0) = [D_xy(q(t), 0, 0)]^{-1}\overset{*}{q}^s(0, 0, t).$$

It follows easily from (25), (28) and (29) that

$$\begin{aligned} q(t) &= p + \mathcal{O}(\exp(-\lambda t)), \\ \overset{*}{q}^s(t) &= (0, -C\exp(-\lambda t) + o(\exp(-\lambda t))), \end{aligned} \tag{32}$$

where $C > 0$. Therefore, setting $t = t_1$,

$$\begin{aligned} f(q(t_1), 0, 0) = \{[D_xy(p, 0, 0)]^{-1} + \mathcal{O}(\exp(-\lambda t_1))\} \\ \cdot (0, -C\exp(-\lambda t_1) + o(\exp(-\lambda t_1))). \end{aligned} \tag{33}$$

From (32) we also have

$$\operatorname{div} f(q(t), 0, 0) = -\lambda + \mathcal{O}(\exp(-\lambda t)).$$

Therefore

$$\exp\left[-\int_0^{t_1} \operatorname{div} f(q(s), 0, 0)\, ds\right] = \exp(\lambda t_1) \cdot \exp\int_0^{t_1} \mathcal{O}(\exp(-\lambda s))\, ds. \tag{34}$$

Then (33) and (34) give

$$\begin{aligned} &\lim_{t_1\to\infty} f(q(t_1), 0, 0)\exp\left[-\int_0^{t_1} \operatorname{div} f(q(s), 0, 0)\, ds\right] \\ &\quad = [D_xy(p, 0, 0)]^{-1} \cdot \left(0, -C\exp\int_0^{\infty} \mathcal{O}(\exp(-\lambda s))\, ds\right), \end{aligned} \tag{35}$$

where the integral clearly converges.

Now (24), Lemma 2 and (35) imply that

$$-\Delta_\delta^s(0) = \frac{\partial p}{\partial\delta}(0, 0) \wedge \lim_{t_1\to\infty} f(q(t_1), 0, 0)\exp\left[-\int_0^{t_1} \operatorname{div} f(q(s), 0, 0)\, ds\right], \tag{36}$$

where the limit exists.

Notice that (7) implies that (35) is a negative multiple of v. Then (13) implies that $-\Delta_\delta^s(0)$ is a negative multiple of $u \wedge v$. By (15) and (17), $(\partial d/\partial\delta)(0, 0)$ is also a negative multiple of $u \wedge v$.

We now turn to (23). We claim that

$$\begin{aligned} -\Delta_{\mu_2}^s(0) = \frac{\partial p}{\partial\mu_2}(0, 0) \wedge \lim_{t_1\to\infty} f(q(t_1), 0, 0)\exp\left[-\int_0^{t_1} \operatorname{div} f(q(s), 0, 0)\, ds\right] \\ + \int_0^{\infty} \exp\left[-\int_0^{t} \operatorname{div} f(q(s), 0, 0)\, ds\right] f(q(t), 0, 0) \\ \wedge \frac{\partial f}{\partial\mu_2}(q(t), 0, 0)\, dt. \end{aligned} \tag{37}$$

The proof is modeled on that of (36). Using Lemma 2, we first show that the first summand of (23) approaches, as $t_1 \to \infty$, the first summand of (37), where the limit exists. Then, since $-\Delta^s_{\mu_2}(0)$ is finite, the second summand of (23), the integral, must approach a limit as $t_1 \to \infty$.

Finally we turn to (21).

LEMMA 3.

$$\lim_{t\to-\infty} \frac{\partial q^c}{\partial \mu_2}(0, 0, t) = 0.$$

Proof. Again we shall use the coordinates (6). Define

$$\tilde{q}^c(\mu_2, t) = y(q^c(0, \mu_2, t), 0, \mu_2) = (y_1(\mu_2, t), 0).$$

Since $q^c(0, \mu_2, t) \to p(0, \mu_2)$ as $t \to -\infty$, for each μ_2 near 0, $\tilde{q}^c(\mu_2, t)$, and hence $y_1(\mu_2, t)$, is defined for sufficiently negative t. From (7), $y_1(\mu_2, t) > 0$ for sufficiently negative t. From its definition, $y_1(\mu_2, t)$ satisfies a differential equation of the form

$$\frac{dz}{dt} = \eta(\mu_2) z^2(1 + zG(z, \mu_2)). \tag{38}$$

Here η and zG are C^{k-2}.

Let

$$z^{-2}(1 + zG(z, \mu_2))^{-1} = z^{-2} + A(\mu_2) z^{-1} + H(z, \mu_2). \tag{39}$$

Here A is C^{k-3} and H is C^{k-4}. Fix $z_0 > 0$. Let

$$J(z, \mu_2) = \int_{z_0}^{z} H(s, \mu_2)\, ds.$$

J is C^{k-4}. Then solving (38) by separation of variables using (39) yields

$$-z^{-1} + A(\mu_2) \ln z + J(z, \mu_2) = \eta(\mu_2) t + B(\mu_2).$$

Here $B(\mu_2)$ is determined by the value of $y_1(\mu_2, t)$ at some $t = t_0$. Hence B is C^{k-4}. Rearranging yields

$$z[1 - A(\mu_2) z \ln z - zJ(z, \mu_2)]^{-1} = -[\eta(\mu_2) t + B(\mu_2)]^{-1}. \tag{40}$$

Let $\Phi(z, \mu_2)$ equal the left-hand side of (40). $\Phi(z, \mu_2)$ is a C^1 function of z and μ_2 on a neighborhood of $(0, 0)$ in $\{(z, \mu_2): z \geqq 0\}$; $\Phi(0, \mu_2) \equiv 0$, and $(\partial/\partial z)\Phi(0, \mu_2) \equiv 1$. By the implicit function theorem, we can solve the equation $\Phi(z, \mu_2) = v$ for z when z and v are near 0, $v \geqq 0$ (in which case $z \geqq 0$). We obtain

$$z = v + R(v, \mu_2),$$

where R is C^1, $R(0, \mu_2) \equiv 0$ and R is $o(v)$. Putting $z = y_1$ and $v = -[\eta(\mu_2) t + B(\mu_2)]^{-1}$, t large negative, we obtain

$$y_1 = -[\eta(\mu_2) t + B(\mu_2)]^{-1} + R(-[\eta(\mu_2) t + B(\mu_2)]^{-1}, \mu_2).$$

It follows that $(\partial y_1/\partial \mu_2)(\mu_2, t) \to 0$ as $t \to -\infty$, so

$$\frac{\partial \tilde{q}^c}{\partial \mu_2}(\mu_2, t) \to 0 \quad \text{as } t \to -\infty. \tag{41}$$

Lemma 3 follows from (41) the way Lemma 2 follows from (30). □

To evaluate (21) in the limit $t_1 \to -\infty$, we use the definition of $\Delta^c_{\mu_2}$ to write (21) as

$$\begin{aligned}\Delta^c_{\mu_2}(0) &= -\frac{\partial q^c}{\partial \mu_2}(0,0,t_1) \wedge f(q(t),0,0) \exp \int_{t_1}^0 \operatorname{div} f(q(s),0,0)\,ds \\ &\quad + \int_{t_1}^0 \exp\left[-\int_0^t \operatorname{div} f(q(s),0,0)\,ds\right] f(q(t),0,0) \wedge \frac{\partial f}{\partial \mu_2}(q(t),0,0)\,dt.\end{aligned} \tag{42}$$

Of course

$$f(q(t),0,0) \to 0 \quad \text{as } t_1 \to -\infty. \tag{43}$$

Moreover,

$$\operatorname{div} f(q(t),0,0) = -\lambda + \mathcal{O}([\eta(0)t + c(0)]^{-1}) \quad \text{as } t \to -\infty. \tag{44}$$

By Lemma 3, (43) and (44), we have

$$\lim_{t_1 \to -\infty} -\frac{\partial q^c}{\partial \mu_2}(0,0,t_1) \wedge f(q(t_1),0,0) \exp \int_{t_1}^0 \operatorname{div} f(q(s),0,0)\,ds = 0.$$

Therefore the second summand of (42), the integral, approaches a limit as $t_1 \to -\infty$, so

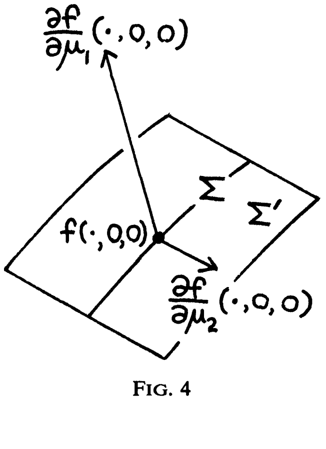
$$\Delta^c_{\mu_2}(0) = \int_{-\infty}^0 \exp\left[-\int_0^t \operatorname{div} f(q(s),0,0)\,ds\right] f(q(t),0,0) \wedge \frac{\partial f}{\partial \mu_2}(q(t),0,0)\,dt. \tag{45}$$

Finally, we complete the proof of Theorem 1 by calculating

$$\frac{\partial d}{\partial \mu_2}(0,0) = \frac{\partial d^c}{\partial \mu_2}(0,0) - \frac{\partial d^s}{\partial \mu_2}(0,0) = \Delta^c_{\mu_2}(0) - \Delta^s_{\mu_2}(0) = (45) + (37) = I.$$

4. Proof of Theorem 2. First we show that Σ is a C^k codimension one submanifold of Σ'. Let $f \in \Sigma$ with saddle-node p and let L be a line segment perpendicular to the separatrix loop Γ as in § 3. For g near f in Σ', there is a unique saddle-node p_g near p; p_g is a C^k function of $g \in \Sigma'$. The stable and center manifolds of p_g also depend C^k on g [1, § 9.2]. Thus their intersections with L are C^k functions of g. Therefore the function $d(0,\mu_2)$ from § 2 extends to a C^k function $d(g)$ defined for $g \in \Sigma'$ near f; $d(g)$ measures the separation of these points of intersection. (We remark that $d(0,\mu_2)$ is C^k although $d(\delta,\mu_2)$ is only C^{k-2}.) Then $d(g)=0$ if and only if $g \in \Sigma$. Since it is easy to find a perturbation $f+\varepsilon h$ in Σ' such that $d/d\varepsilon|_{\varepsilon=0} d(f+\varepsilon h) \neq 0$, Σ is a C^k codimension one submanifold of Σ'.

To prove Theorem 2, it suffices to show that $f(\cdot,\mu_1,\mu_2)$ is transverse to Σ at $(\mu_1,\mu_2)=(0,0)$ if and only if $I \neq 0$. Since $f(\cdot,0,\mu_2) \in \Sigma'$ for all small μ_2, $(\partial f/\partial \mu_2)(\cdot,0,0)$ is tangent to Σ' (see Fig. 4). But $(\partial \tilde{f}/\partial \nu_1)(\cdot,0,0) = (\partial f/\partial \mu_1)(\cdot,0,0) - (\partial f/\partial \mu_2)(\cdot,0,0)\alpha'(0)$. Since $(\partial \tilde{f}/\partial \nu_1)(\cdot,0,0)$ is transverse to Σ' by



$\frac{\partial f}{\partial \mu_1}(\cdot,0,0)$
Σ
Σ'
$f(\cdot,0,0)$
$\frac{\partial f}{\partial \mu_2}(\cdot,0,0)$

FIG. 4

assumption (vi) (see [7]), and $(\partial f/\partial\mu_2)(\cdot,0,0)$ is tangent to Σ', $(\partial f/\partial\mu_1)(\cdot,0,0)$ is transverse to Σ'. Thus we need to show that $(\partial f/\partial\mu_2)(\cdot,0,0)$ is transverse to Σ if and only if $I\neq 0$. But this follows from the formula $(\partial d/\partial\mu_2)(0,0)=I$.

5. The pendulum equation. We consider the differential equation for the damped pendulum with constant applied torque, in the dimensionless form studied in [5]:

$$\beta\ddot{\phi}+\dot{\phi}+\sin\phi=\rho.$$

Putting $y=\dot{\phi}$, we have

$$\dot{\phi}=y,\qquad \dot{y}=\frac{1}{\beta}(-y-\sin\phi+\rho). \tag{46}$$

We identitify ϕ and $\phi+2\pi$, so that (46) defines a vector field on a cylinder; ρ and β are parameters, which we shall assume positive. We remark that Theorem 1 applies equally well to vector fields on the compact set $\{(\phi,y)\colon |y|\leqq d\}$.

Let $x=(\phi,y)$,

$$f(x,\beta,\rho)=(f_1((\phi,y),\beta,\rho),f_2((\phi,y),\beta,\rho))=\left(y,\frac{1}{\beta}(-y-\sin\phi+\rho)\right).$$

If $\rho<1$, $\dot{x}=f(x,\rho,\beta)$ has two equilibria, one a saddle and one a sink; $\dot{x}=f(x,1,\beta)$ has one equilibrium, at $(\pi/2,0)$ independent of β; if $\rho>1$, $\dot{x}=f(x,\rho,\beta)$ has no equilibria. We note that

$$D_xf\left(\left(\frac{\pi}{2},0\right),1,\beta\right)=\begin{bmatrix}0 & 1\\ 0 & -1/\beta\end{bmatrix},$$

which has eigenvalues $0,-1/\beta$. Corresponding right eigenvectors are $u=(1,0)$ and $v=(-\beta,1)$; a left eigenvector for the eigenvalue 0 is $(1,\beta)$.

To show that $\dot{x}=f(x,1,\beta)$ has a saddle-node at $(\pi/2,0)$, we compute (assumption (iii)):

$$\begin{aligned}(1,\beta)\cdot D_x^2f\left(\left(\frac{\pi}{2},0\right),1,\beta\right)\cdot((1,0),(1,0))&=(1,\beta)\cdot\left(0,\frac{\partial^2 f}{\partial\phi^2}\left(\left(\frac{\pi}{2},0\right),1,\beta\right)\right)\\&=(1,\beta)\cdot\left(0,\frac{1}{\beta}\right)=1.\end{aligned}$$

We also note (assumption (iv)):

$$(1,\beta)\cdot D_\rho f\left(\left(\frac{\pi}{2},0\right),1,\beta\right)=(1,\beta)\cdot\left(0,\frac{1}{\beta}\right)=1.$$

It is shown in [3] that there is a unique positive β_0 such that $\dot{x}=f(x,1,\beta_0)$ has a separatrix loop at the saddle-node $(\pi/2,0)$. The separatrix loop, considered as a curve in ϕy-space with ϕ and $\phi+2\pi$ not yet identified, can be expressed as $y=y(\phi)$, $\pi/2<\phi<5\pi/2$; $y(\phi)>0$ for all ϕ. As $\phi\to\pi/2$, $y\to 0$ and $y/(\phi-\pi/2)\to 0$; as $\phi\to 5\pi/2$, $y\to 0$ and $y/(\phi-5\pi/2)\to -1/\beta)$ (see Fig. 5).

Thus assumptions (i)-(vi) are verified if we put $\tilde{f}=f$, $\nu_1=\rho-1$, $\nu_2=\beta-\beta_0$. The change of variables from ν to μ is not necessary here, i.e., we may put $\mu_1=\nu_1$, $\mu_2=\nu_2$. For simplicity we shall continue to use the parameters ρ and β.

To compute I, we first note that the saddle-node $p(\beta)$ of $\dot{x}=f(x,1,\beta)$ is identically $(\pi/2,0)$, so that the first summand of I is 0. Now $\operatorname{div} f(x,\rho,\beta)=-1/\beta$, and

$$f((\phi,y),\rho,\beta)\wedge\frac{\partial f}{\partial\beta}((\phi,y),\rho,\beta)=-\frac{1}{\beta^2}y(-y-\sin\phi+\beta)=-\frac{1}{\beta}y\dot{y}.$$

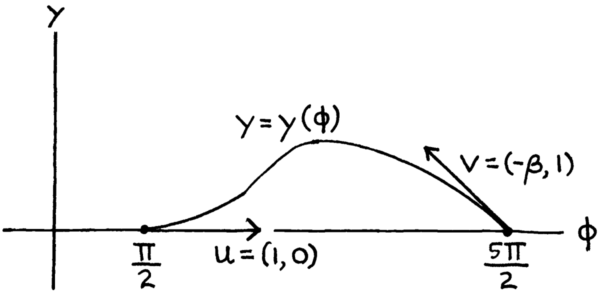


FIG. 5

Therefore,

$$I=-\frac{1}{\beta_0}\int_{-\infty}^{\infty} e^{t/\beta_0}y\dot{y}\,dt$$

$$=\lim_{S,T\to\infty}\left\{-\frac{1}{\beta_0}e^{t/\beta_0}\cdot\frac{y^2}{2}\bigg|_{-S}^{T}+\frac{1}{\beta_0^2}\int_{-S}^{T}e^{t/\beta_0}\cdot\frac{y^2}{2}\,dt\right\}.$$

From (29), as $t\to\infty$, $(\phi(t)-(5\pi/2), y(t))=c\,e^{-t/\beta_0}(-\beta_0, 1)+o(e^{-t/\beta_0})$ for some positive constant c. Therefore $[y(t)]^2=c^2\,e^{-2t/\beta_0}+o(e^{-2t/\beta_0})$ as $t\to\infty$. Hence

$$\lim_{T\to\infty}-\frac{1}{\beta_0}e^{T/\beta_0}\cdot\frac{[y(T)]^2}{2}=0.$$

Of course,

$$\lim_{S\to\infty}-\frac{1}{\beta_0}e^{-S/\beta_0}\cdot\frac{[y(-S)]^2}{2}=0,$$

since $y(t)\to 0$ as $t\to-\infty$. Therefore

$$I=\frac{1}{\beta_0^2}\int_{-\infty}^{\infty}e^{t/\beta_0}\cdot\frac{y^2}{2}\,dt>0.$$

Since $u\wedge v>0$, Theorem 1 implies that for (ρ,β) near $(1,\beta_0)$, $\dot{x}=f(x,\rho,\beta)$ has a separatrix loop if and only if $\rho=1-\ell^2(\beta-\beta_0)^2+\cdots$, with $\ell\neq 0$, and $\beta-\beta_0\geqq 0$ (see Fig. 6). This result is in agreement with statements in [5].

NONEXISTENCE FOR THE KASSOY PROBLEM*

J. BEBERNES† AND W. TROY‡

Abstract. We prove that the Kassoy problem

$$y''-\frac{x}{2}y'+e^y-1=0, \quad y(0)=\alpha, \quad y'(0)=0, \quad \alpha\in\mathbb{R} \tag{1}$$

has no solution which has the asymptotic property

$$y(x)\sim -2\ln x+K \quad \text{as } x\to\infty. \tag{2}$$

Key words. combustion, supercritical, final time asymptotic analysis, nonexistence

AMS(MOS) subject classification. 34A34

1. Introduction. The purpose of this paper is to rigorously prove that a solution to the initial value problem

$$\begin{gathered} y''-\frac{x}{2}y'+e^y-1=0, \\ y(0)=\alpha, \quad y'(0)=0, \quad \alpha\in\mathbb{R} \end{gathered} \tag{1}$$

cannot have the asymptotic property

$$y(x)\sim -2\ln x+K \quad \text{as } x\to\infty. \tag{2}$$

This problem, hereafter referred to as the Kassoy problem, has an interesting history.

The nondimensional induction period equation for a high activation energy thermal explosion in a bounded container Ω can be written in the form

$$\theta_t-\Delta\theta=\delta\, e^{\theta} \tag{3}$$

where $\theta(x, t)$ must satisfy the initial-boundary conditions

$$\begin{gathered} \theta(x,0)=\psi(x), \qquad x\in\Omega, \\ \theta(x,t)=0, \qquad x\in\partial\Omega, \quad t>0. \end{gathered} \tag{4}$$

The dependent variable $\theta(x, t)$ can be interpreted as a perturbation temperature, describing deviations from a prescribed initial state. The temperature variation is driven by the heat release term $\delta\, e^{\theta}$, where $\delta>0$ is the Frank-Kamenetski parameter.

For Ω a radially symmetric container centered at $x=0$ and $\psi(x)\equiv 0$, Bebernes and Kassoy [1] and Lacey [8] proved that there exists a critical value $\delta_{\mathrm{CR}}>0$, which depends on the geometry of the system such that for $\delta>\delta_{\mathrm{CR}}$ the solution $\theta(x, t)$ becomes unbounded at some $x\in\Omega$ as t approaches a finite time $t_e(\delta)$, and blowup occurs. Recently, Friedman and McLeod [4] proved that this blowup occurs at a single point $x_0=0\in\Omega$ as $t\to t_e$.

These supercritical processes, which are characterized by the appearance of a singularity somewhere in the spatial domain Ω at a finite time t_e, were considered earlier by Kassoy and Poland [6], [7] and Kapila [5]. Using computational methods for symmetric slab, cylindrical, and spherical geometries, they predicted that $\theta(x, t)$ becomes unbounded at the symmetry point $x = 0$ at a time t_e. Elsewhere $\theta(x, t) \to \theta_e(x)$, $x \neq 0$, $x \in \Omega$ as $t \to t_e$. By applying a final-value asymptotic analysis at t_e, they also studied the character of the singularity function $\theta_e(x)$. In their analysis of this singularity function $\theta_e(x)$ in the case of a slab, they numerically predicted the existence of a solution $y(x)$ of the Kassoy problem.

Lacey [9] and Dold [3] have questioned the existence of a solution to the Kassoy problem. In fact, Dold rejects the formulation given in [6] and [5] on numerical grounds and generates a new final value theory which leads to a different description of the singular solution. In this paper we resolve the issue by proving the following theorem.

THEOREM. *There is no solution of problem* (1) *which satisfies condition* (2).

The proof of nonexistence is given in the next three sections. In § 2, for $\alpha < 0$ we prove the existence of a special solution to the IVP(1) assuming the Kassoy problem has a solution. This special solution has several precisely describable properties. In § 3, we prove that our special solution cannot have one of these properties. This contradiction leads us to the conclusion that no solution to the Kassoy problem can exist for $\alpha > 0$. In § 4, we prove that the Kassoy problem has no solution for $\alpha < 0$.

2. A special solution for $\alpha > 0$.

We begin this section by showing some needed properties of solutions of IVP(1). In particular, we first show that for α sufficiently large, the solution $y(x, \alpha)$ of IVP(1) is strictly concave down for $x \geqq 0$.

LEMMA 1. *If* $\alpha \geqq 1$, *then* $y''(x, \alpha) < 0$ *for all* $x \geqq 0$.

Proof. A solution $y(x) = y(x, \alpha)$ of (1) satisfies $y(0) = \alpha$, $y'(0) = 0$, $y''(0) < 0$. From this and (1), it follows that $y''(x) < 0$ as long as $y(x) \geqq 0$. Hence $y(x)$ has a first zero $a > 0$ with $y'(a) < 0$ and $y''(a) < 0$.

If $y''(x_1) = 0$ for some first $x_1 > a$, then $y(x_1) < 0$ and $y'''(x_1) \geqq 0$. Let $g(x) = xy'(x) + 1$. Then $g(0) = 1$ and $g' < y'$ on $(0, x_1)$. By integrating, we have $g(x) < 1 + y(x) - \alpha$ on $(0, x_1)$. Thus $g(x_1) \leqq y(x_1) < 0$; hence $y'(x_1) < -1/x_1$. From this and (1) we conclude that

$$0 = y''(x_1) = \frac{x_1}{2} y'(x_1) + 1 - e^{y(x_1)}$$

$$< \frac{1}{2} - e^{y(x_1)}.$$

Finally, a differentiation of (1) leads to $y'''(x_1) = (\frac{1}{2} - e^{y(x_1)}) y'(x_1) < 0$, a contradiction. Hence, $y''(x) < 0$ for all $x > 0$.

COROLLARY. *If a solution* $y(x, \alpha)$ *of* (1), (2) *exists for* $\alpha > 0$, *then* $0 < \alpha < 1$.

LEMMA 2. *If a solution* $y(x, \alpha)$ *of* (1), (2) *exists, then there exists a first* x_1 *such that*

$$y''(x, \alpha) < 0 \quad \text{on } (0, x_1), \quad y''(x_1, \alpha) = 0, \quad y'''(x_1, \alpha) \geqq 0, \quad y(x_1, \alpha) \geqq -\ln 2.$$

Proof. The solution $y(x) = y(x, \alpha)$ of (1), (2) satisfies $y(0) = \alpha$, $y'(0) = 0$, and $y''(0) = 1 - e^{\alpha} < 0$. This implies $y'(x)$ is negative in a right neighborhood of 0, and, because $y(x)$ satisfies (2), $y'(x) \to 0$ as $x \to \infty$. Hence there exists a first x_1 such that $y''(x) < 0$ on $(0, x_1)$, $y'(x_1) < 0$, $y''(x_1) = 0$, $y'''(x_1) \geqq 0$. Since $y'''(x_1) = (\frac{1}{2} - e^{y(x_1)}) y'(x_1) \geqq 0$ and $y'(x_1) < 0$, we have $y(x_1) \geqq -\ln 2$.

LEMMA 3. *If $y(x, \alpha)$ is a solution of* (1) *with $y''(x, \alpha) < 0$ on $[0, x_2]$ and $y(x_2, \alpha) \leqq -\ln 2$. Then $y''(x) < 0$ for all $x \geqq 0$.*

Proof. At x_2, $y'(x_2, \alpha) < 0$ and $y''(x_2, \alpha) < 0$. If there is a first $x_3 > x_2$ for which $y''(x_3, \alpha) = 0$, then $y'''(x, \alpha) \geqq 0$. However, differentiating (1), we find that $y'''(x_3) = y'(x_3)(\frac{1}{2} - e^{y(x_3)}) < 0$, a contradiction. From this we conclude that $y'' < 0$ for all $x \geqq 0$.

We are now in a position to define our special solution under the following assumption.

Assumption. There exists $\beta \in (0, 1)$ such that $y(x, \beta)$ is a solution of (1), (2).

In order to make use of this assumption we define the set

$$A = \{\hat{\alpha} > 0 \,|\, \text{if } \alpha > \hat{\alpha}, \text{then } y''(x, \alpha) < 0 \text{ for all } x \geqq 0\}.$$

From Lemma 1 we observe that $[1, \infty) \subseteq A$. Furthermore, continuity of solutions with respect to initial conditions, together with Lemma 3, shows that A is open. Finally, it is clear that A is bounded below by β. Thus the value

$$\bar{y} \equiv \inf A$$

is well defined.

Hereafter we let $y(x) = y(x, \bar{y})$. In the next lemma we list four properties which $y(x)$ must satisfy. Our goal in the remainder of the paper is to show that $y(x)$ cannot satisfy property (iv) of Lemma 4. From this contradiction we conclude that $y(x)$ cannot exist, which in turn implies that the original problem (1), (2) has no solution.

LEMMA 4. *There is a first $\bar{x} > 0$ such that*

(i) $y(\bar{x}) = -\ln(2)$,

(ii) $y''(x) < 0$ *for* $0 < x < \bar{x}$,

(iii) $y''(\bar{x}) = y'''(\bar{x}) = 0$,

(iv) $y'(\bar{x}) = -\bar{x}^{-1}$.

Proof. It follows from (1) that $y'' < 0$ for $x > 0$ as long as $y \geqq 0$. As shown in the proof of Lemma 1 there is a first value, $x = a$, for which $y(a) = 0$ with $y'(a) < 0$ and $y''(a) < 0$. Suppose that $y'' < 0$ for all $x > a$. Then $\bar{y} \in A$. It follows from continuity and Lemma 3 that $\alpha \in A$ if $\bar{y} - \alpha > 0$ is sufficiently small, contradicting the definition of $\bar{y}$. Thus, there exists a first $\bar{x} > a$ such that $y''(\bar{x}) = 0$, and $y'''(\bar{x}) \geqq 0$. If $y(\bar{x}) < -\ln(2)$, then $y'''(\bar{x}) = (\frac{1}{2} - e^{y(\bar{x})})y'(\bar{x}) < 0$, a contradiction. If $y(\bar{x}) > -\ln 2$, then $y'''(\bar{x}) > 0$.

It then follows from continuity that $\alpha \notin A$ if $\alpha - \bar{y} > 0$ is sufficiently small, again contradicting the definition of $\bar{y}$. Therefore, it must be the case that $y(\bar{x}) = -\ln(2)$ and $y'''(\bar{x}) = 0$. Finally, from these observations and (1) we conclude that $y'(\bar{x}) = -\bar{x}^{-1}$, and the lemma is proved.

Further technical properties of the solution $y(x, \bar{y}) = y(x)$ are given in the following lemma.

LEMMA 5. *The solution $y(x)$ has initial value $\bar{y} \leqq 1 - \ln 2$. Furthermore, $y''' \geqq 0$ for all $x \in [0, \bar{x}]$.*

Proof. Suppose that $\bar{y} > 1 - \ln(2)$ and recall the function $g(x) = xy'(x) + 1$. Then $g(0) = 1$ and $g'(x) < y'(x)$ on $(0, \bar{x})$, where $\bar{x}$ is the $\bar{x}$ of Lemma 4. An integration leads to $g(\bar{x}) < \ln(2) + y(\bar{x}) < 0$. Thus $\bar{x}y'(\bar{x}) + 1 < 0$, contradicting (iv) of Lemma 4. We conclude that $\bar{y} \leqq 1 - \ln(2)$.

Next, recall that $y(a) = 0$. If $a \geqq \sqrt{2}$, then $y'''(a) \leqq 0$. Also, from (1) we obtain

$$y^{(4)} = \frac{x}{2} y''' + (1 - e^y)y'' - e^y(y')^2 \tag{5}$$

and it follows that $y''' < 0$ for all $x > a$, contradicting Lemma 4. Thus $a \in (0, \sqrt{2})$ and $y'''(a) = ((a^2/4) - \frac{1}{2})y'(a) > 0$. Furthermore, Lemma 4 shows that $y'''(\bar{x}) = 0$. We need to show that y''' is nonnegative on each of the intervals $(0, a)$ and $(a, \bar{x})$. Suppose, first of all, that $y''' < 0$ at some point in $(a, \bar{x})$. Thus, since $y'''(\bar{x}) = 0$ there must be a value $x^* \in (a, \bar{x}]$ such that $y'''(x^*) = 0$ and $y^{(4)}(x^*) \geqq 0$. However, from (5) it follows that $y^{(4)}(x^*) < 0$, a contradiction. Therefore $y''' \geqq 0$ for all $x \in (a, \bar{x}]$. Next, suppose that $y''' < 0$ at some point in $(0, a)$. From (1) and (5) it follows that $y'''(0) = 0$ and $y^{(4)}(0) > 0$. Thus y''' must reach a negative minimum at some value $\hat{x} \in (0, a)$. That is, $y'''(\hat{x}) < 0$, $y^{(4)}(\hat{x}) = 0$ and $y^{(5)}(\hat{x}) \geqq 0$. A differentiation of (5) leads to

$$y^{(5)} = \frac{x}{2} y^{(4)} + y'''\left(\frac{3}{2} - e^y\right) - 3y'y''\,e^y - (y')^3\,e^y. \tag{6}$$

At $\hat{x}$, since $y^{(4)}(\hat{x}) = 0$, we have

$$0 = \frac{\hat{x}}{2} y''' + y''(1 - e^y) - e^y (y')^2.$$

Thus $-e^y(y')^3 = y'y''(e^y - 1) - (\hat{x}/2)y'y'''$. Substituting this into (6), and noting that $3/2 - e^y > 0$ for $y(\hat{x}) < \bar{y} \leqq 1 - \ln(2)$, we obtain, at $x = \hat{x}$, $y^{(5)}(\hat{x}) = y'''(3/2 - e^y) - 2y'y''e^y - y'y'' - (\hat{x}/2)y'y''' < 0$, a contradiction. We conclude that $y''' \geqq 0$ on $(0, a]$ which completes the proof of the lemma.

COROLLARY. *On* $(0, \bar{x})$, $y(x) \geqq p(x) \equiv y''(0)(x^2/2) + \bar{y}$.

Define $\tilde{x}(\bar{y})$ by $p(\tilde{x}(\bar{y})) = -\ln 2$; then $\tilde{x}(\bar{y}) = [2(\ln 2 + \bar{y})/(e^{\bar{y}} - 1)]^{1/2} < \bar{x}$.

3. Nonexistence for $\alpha > 0$. To prove our theorem for the case $\alpha > 0$ it suffices to eliminate the existence of the solution satisfying Lemma 4 (recall that such a solution must exist if the Kassoy problem (1), (2) has a solution). In particular we show that the solution described in Lemma 4 satisfies

$$y'(\tilde{x}) < -\tilde{x}^{-1} \tag{7}$$

where $\tilde{x} = \tilde{x}(\bar{y}) \equiv [2(\ln(2) + \bar{y})/(e^{\bar{y}} - 1)]^{1/2}$. Since $\tilde{x} < \bar{x}$ and $y'' < 0$ on $[0, \bar{x}]$, then (7) implies that $y'(\bar{x}) < y'(\tilde{x}) < -1/\tilde{x} < -1/\bar{x}$. Hence, property (iv) of Lemma 4 is violated and a contradiction is reached. The next three technical lemmas are necessary to show that (7) holds. We introduce the comparison function

$$G(x, \bar{y}) \equiv x\,e^{x^2/4} \int_0^x \left(1 - e^{\bar{y}}\,e^{(1 - e^{\bar{y}})s^2/2}\right) e^{-s^2/4}\,ds + 1. \tag{8}$$

In the next lemma we show that $g(x) \leqq G(x, \bar{y})$ for $0 \leqq x \leqq \bar{x}$. Subsequently, we prove that $G(\tilde{x}(\bar{y}), \bar{y}) < 0$ for all $\bar{y} \in (0, 1 - \ln(2)]$. Thus it follows that $g(\tilde{x}(\bar{y})) < 0$ for all $\bar{y} \in (0, 1 - \ln(2)]$ and (7) is proved.

LEMMA 6. $g(x) \leqq G(x, \bar{y})$ *for* $0 \leqq x \leqq \bar{x}$.

Proof. From Lemma 5, $y''' \geqq 0$ on $[0, \bar{x}]$, which in turn implies that $y(x) \geqq y''(0)(x^2/2) + \bar{y} = \bar{y} + ((1 - e^{\bar{y}})/2)x^2$. Thus $e^{y(x)} \geqq e^{\bar{y}}\,e^{(1 - e^{\bar{y}})x^2/2}$ on $[0, \bar{x}]$. Since $g(x) = xy'(x) + 1 = x\,e^{x^2/4} \int_0^x (1 - e^{y(s)})\,e^{-s^2/4}\,ds + 1$ it follows immediately that $g(x) \leqq G(x, \bar{y})$ on $[0, \bar{x}]$.

LEMMA 7. $\lim_{\bar{y} \to 0^+} G(\tilde{x}(\bar{y}), \bar{y}) = -\infty$.

Proof. We observe that

$$\begin{aligned} G(\tilde{x}(\bar{y}), \bar{y}) &= \tilde{x}\,e^{\tilde{x}^2/4} \int_0^{\tilde{x}} e^{-s^2/4}\,ds - \tilde{x}\,e^{\tilde{x}^2/4} \int_0^{\tilde{x}} e^{\bar{y}}\,e^{(1 - 2e^{\bar{y}})s^2/4}\,ds + 1 \\ &= \tilde{x}\,e^{\tilde{x}^2/4} \int_0^{\tilde{x}} e^{-s^2/4}\,ds - \frac{\tilde{x}\,e^{\tilde{x}^2/4}\,e^{\bar{y}}}{(2\,e^{\bar{y}} - 1)^{1/2}} \int_0^{\tilde{x}(2e^{\bar{y}} - 1)^{1/2}} e^{-s^2/4}\,ds + 1 \\ &= \tilde{x}\,e^{\tilde{x}^2/4}\left(1 - \frac{e^{\bar{y}}}{(2\,e^{\bar{y}} - 1)^{1/2}}\right) \int_0^{\tilde{x}} e^{-s^2/4}\,ds + 1. \end{aligned}$$

Since $\lim_{\bar{y}\to 0}\int_0^{\tilde{x}(y)} e^{-s^2/4}\,ds = \pi^{1/2}$, it suffices to consider

$$H(\bar{y}) \equiv \frac{((2e^{\bar{y}}-1)^{1/2}-e^{\bar{y}})}{\tilde{x}^{-1}\,e^{-\tilde{x}^2/4}}\cdot\frac{1}{(2\,e^{\bar{y}}-1)^{1/2}}$$

$$=\frac{-(e^{\bar{y}}-1)^2}{\tilde{x}^{-1}\,e^{-\tilde{x}^2/4}}\cdot\frac{1}{((2\,e^{\bar{y}}-1)^{1/2}+e^{\bar{y}})}\cdot\frac{1}{(2\,e^{\bar{y}}-1)^{1/2}}.$$

We set $h(\bar{y}) = -(e^{\bar{y}} = 1)^2/(\tilde{x}^{-1}\,e^{-\tilde{x}^2/4})$ and use the definition of $\tilde{x}(\bar{y})$ to obtain

$$h(\bar{y}) = -4\,e^{\tilde{x}^2/4}(\ln(2)+\bar{y})^2/\tilde{x}^3.$$

Since $\tilde{x}(\bar{y})\to\infty$ as $\bar{y}\to 0^+$ it follows that $\lim_{\bar{y}\to 0^+} h(\bar{y}) = -\infty$. Therefore we conclude that

$$\lim_{\bar{y}\to 0^+} H(\bar{y}) = \lim_{\bar{y}\to 0^+} G(\tilde{x}(\bar{y}),\bar{y}) = -\infty$$

and the lemma is proved.

LEMMA 8. *$G(\tilde{x}(\bar{y}),\bar{y})<0$ for all $\bar{y}\in(0, 1-\ln(2)]$.*

Proof. An integration by parts shows that

$$x = e^{x^2/4}\int_0^x e^{-s^2/4}(1-s^2/2)\,ds \quad \text{for all } x>0. \tag{9}$$

If there is a first $\hat{y}\in(0, 1-\ln(2))$ for which $G(\tilde{x}(\hat{y}),\hat{y}) = 0$, then

$$\frac{dG}{d\bar{y}}(\tilde{x}(\bar{y}),\bar{y})|_{\bar{y}=\hat{y}} \geqq 0. \tag{10}$$

Our goal is to obtain a contradiction of (10). First, from the definition of $\tilde{x}$ and the assumption that $G(\tilde{x}(\hat{y}),\hat{y}) = 0$ we obtain

$$\frac{dG}{d\bar{y}}(\tilde{x}(\bar{y}),\bar{y})|_{\bar{y}=\hat{y}} = \left(-\frac{\tilde{x}'}{\tilde{x}} - \tilde{x}\,e^{\tilde{x}^2/4}\int_0^{\tilde{x}} e^{\bar{y}}\,e^{(1-2e^{\bar{y}})s^2/4}\left(1-\frac{e^{\bar{y}}s^2}{2}\right)^2 ds\right)\Bigg|_{\bar{y}=\hat{y}}. \tag{11}$$

Next, substitute $u = s(2\,e^{\bar{y}}-1)^{1/2}$ into (11) and use (9) to conclude that

$$\frac{dG}{d\bar{y}}(\tilde{x}(\bar{y}),\bar{y})\Bigg|_{\bar{y}=\hat{y}} = -\frac{\tilde{x}'}{\tilde{x}} - \frac{\tilde{x}^2}{2} - \frac{\tilde{x}\,e^{\tilde{x}^2/4}(e^{\bar{y}}-1)}{2(2\,e^{\bar{y}}-1)^{3/2}}\int_0^{\tilde{x}(2e^{\bar{y}}-1)^{1/2}/2} u^2\,e^{-u^2/4}\,du. \tag{12}$$

A straightforward calculation shows that

$$-\frac{\tilde{x}'}{\tilde{x}} - \frac{\tilde{x}^2}{2} = \frac{\tilde{x}^2(e^{\bar{y}}-2\ln(2)-2\bar{y})-2}{2\tilde{x}^2(e^{\bar{y}}-1)} < 0 \tag{13}$$

for $0<\bar{y}\leqq 1-\ln(2)$. Thus, from (12), (13) and the assumption that $\hat{y}\in(0, 1-\ln(2)]$, it follows that $dG/d\bar{y}(\tilde{x}(\bar{y}),\bar{y})|_{\bar{y}=\hat{y}}<0$, contradicting (10).

This completes the proof of the first part of our theorem, that (1), (2) has no solution for $\alpha>0$.

4. Nonexistence for $\alpha<0$.

We now show that the Kassoy problem has no solution for $\alpha<0$. This completes the proof of the theorem.

LEMMA 9. *For $\alpha<0$, the solution $y(x,\alpha)$ of (1) cannot satisfy (2).*

Proof. If $y(x) = y(x,\alpha)$ satisfies (2), then y attains a relative maximum at some $\hat{x}>0$. It follows from (1) and uniqueness of solutions that $y(\hat{x})>0$ and $y''(\hat{x})<0$. Thus there exist $x_1\in(0,\hat{x})$ and $x_2>\hat{x}$ such that $y(x_1) = 0 = y(x_2)$ and $y(x)>0$ on (x_1, x_2).

Since $e^z - 1 > z$ for $z \neq 0$, we have that $y(x)$ satisfies $y'' - (x/2)y' + y < 0$ on $[0, x_1]$. Thus, $y(x)$ is an upper solution of

$$z'' - \frac{x}{2}z' + z = 0 \tag{14}$$

and if $u(x)$ is the solution of (14) with $u(0) = \alpha$, $u'(0) = 0$, then $y(x) < u(x)$ on $(0, \sqrt{2}]$, where $\sqrt{2}$ is the only zero of $u(x)$. We conclude that $x_2 > x_1 > \sqrt{2}$.

At x_2, $y'(x_2) < 0$, $y''(x_2) < 0$, $y'''(x_2) \leqq 0$ and $y^{(4)}(x_2) < 0$. It follows from (5) that $y'''(x) < 0$ for all $x > x_2$ and hence $y''(x) < 0$ for all $x > x_2$. This contradicts our assumption that $y(x)$ satisfies (2).

ORTHOGONAL POLYNOMIALS AND THEIR DERIVATIVES, II*

S. BONAN†, D. S. LUBINSKY‡ AND P. NEVAI§

Abstract. Let $d\alpha$ and $d\beta$ be nonnegative mass distributions on the real line, with all moments finite, and with infinitely many points of increase. Let $\{p_n\}$ and $\{q_n\}$ be the orthonormal polynomials associated with $d\alpha$ and $d\beta$ respectively. We characterize $d\alpha$ and $d\beta$ in the case when there exists a fixed rational function R, a positive integer j and nonnegative integers s and t such that, for $n=0, 1, 2, 3, \cdots$, $Rp_n^{(j)}$ may be expressed as a linear combination of $q_{n-j-t}, q_{n-j-t+1}, \cdots, q_{n-j+s}$.

Key words. orthogonal polynomials, derivatives of orthogonal polynomials, generalised Jacobi weights, exponential weights

AMS(MOS) subject classification. 42C05

1. Introduction. Let $d\alpha$ and $d\beta$ be finite positive measures on the real line with infinitely many points of increase and all moments finite. We shall call $d\alpha$ and $d\beta$ distributions, and shall denote the corresponding sequences of orthonormal polynomials by $\{p_n\}$ and $\{q_n\}$.

The purpose of this paper is to solve the following problem: Characterize $d\alpha$ and $d\beta$ for which there exist a rational function $R=S/T$, a positive integer j, and nonnegative integers s and t such that

$$Rp_n^{(j)} = \sum_{k=n-j-t}^{n-j+s} c_{nk}q_k, \qquad n=0,1,2,\cdots, \tag{1.1}$$

where the coefficients $\{c_{nk}\}$ are real numbers and $c_{nk}=0$ if $k<0$. It turns out that, at least in a description of $d\alpha$ and $d\beta$, the integer j and the denominator polynomial T are unimportant, while S plays an important role.

In solving (1.1), our results largely resolve a problem raised by Askey (see Al-Salam and Chihara [1, p. 69]) to characterize sequences of polynomials $\{p_n\}$ satisfying (1.1) with $R=S, j=1$ and $\{p_n\}=\{q_n\}$. An algebraic solution to Askey's problem has recently been provided by Maroni [13], [14], involving quasi-orthogonality and linear forms defined on the space of all polynomials. Earlier work along this line is due to Ronveaux [20] and Hendriksen and van Rossum [8]. By contrast, our characterization of polynomials satisfying (1.1) is analytic, and provides a complete description of the distributions $d\alpha$ and $d\beta$ associated with $\{p_n\}$ and $\{q_n\}$.

Relationships such as (1.1) are useful in studying analytic aspects of orthonormal polynomials. For example, Bonan [3] recently established a relationship similar to (1.1) with $R=1, j=1$ and $d\alpha=d\beta$, for the weights $d\alpha(x)=\exp(-x^m)\,dx$, where m is a positive even integer. He used this identity to prove part of a conjecture of Nevai [16] concerning bounds on orthonormal polynomials. (See also [10], [18].)

Further, (1.1) is a unifying feature of the most important families of orthogonal polynomials. It is well known that the classical orthogonal polynomials are the only orthogonal polynomials that satisfy (1.1) with $R=1, j=1$ and $s=t=0$ (Freud [5, p.

52])—this special case has been called the problem of W. Hahn [22]. It turns out that the generalised Jacobi weights (GJ) studied by Badkov [2], Geronimus [7], Nevai [15], [17], [19] satisfy several relationships such as (1.1), as do exponential weights on $[0, \infty)$ of the form $\exp(-P(x))$, $P(x)$ a polynomial of positive degree with positive leading coefficient. In this context, the latter have been studied by Ronveaux [20]. For further historical remarks and references, see Bonan and Nevai [4], Hendriksen and van Rossum [8], and Maroni [13], [14]. We note that our main result, Theorem 1.1, essentially contains [8, Thms. 3.1 and 3.2]. The latter two theorems in [8] largely characterize "semiclassical orthogonal polynomial systems" in terms of a differentiation property that is a special case of (1.1).

Given an interval I, we let χ_I denote the characteristic function of I, while δ_x denotes a (unit) point mass at a real number x.

THEOREM 1.1. *Let $d\alpha$ and $d\beta$ be distributions, with corresponding sequences of orthonormal polynomials $\{p_n\}$ and $\{q_n\}$. The following are equivalent:*

I. *There exist a real rational function $R = S/T$ (not identically zero), a positive integer j and nonnegative integers s' and t' such that*

$$Rp_n^{(j)} = \sum_{k=n-j-t'}^{n-j+s'} c'_{nk} q_k, \qquad n = 0, 1, 2, \cdots, \tag{1.2}$$

where the $\{c'_{nk}\}$ are real numbers with $c'_{nk} = 0$, $k < 0$.

II. *There exist a real polynomial S (not identically zero) and nonnegative integers s and t such that*

$$Sp'_n = \sum_{k=n-1-t}^{n-1+s} c_{nk} q_k, \qquad n = 0, 1, 2, \cdots, \tag{1.3}$$

where the $\{c_{nk}\}$ are real numbers with $c_{nk} = 0$, $k < 0$.

III. *There exist nonnegative integers s and t, and real polynomials S, U and V, not identically zero, and with degrees at most s, $t+1$ and $t+2$ respectively. Further, there exist nonnegative integers N and N', and nonnegative numbers A_0, $A_1 \cdots A_N$ (not all zero), $\lambda_1, \lambda_2 \cdots \lambda_N$, and $\mu_1, \mu_2 \cdots \mu_{N'}$, with the following properties: V has N real zeros*

$$-\infty < v_1 < v_2 < \cdots < v_N < \infty$$

and S has N' real zeros

$$-\infty < s_1 < s_2 \cdots < s_{N'} < \infty.$$

Let $v_0 = -\infty$, $v_{N+1} = \infty$ and

$$I_K = (v_k, v_{k+1}), \qquad k = 0, 1, 2, \cdots, N. \tag{1.4}$$

Then

$$d\alpha(x) = \frac{H(x)}{|V(x)|} \exp\left(-\int^x \frac{U(u)}{V(u)}\,du\right) dx + \sum_{k=1}^{N} \lambda_k \delta_{v_k}(x) \tag{1.5}$$

and

$$d\beta(x) = \frac{H(x)}{|S(x)|} \exp\left(-\int^x \frac{U(u)}{V(u)}\,du\right) dx + \sum_{k=1}^{N'} \mu_k \delta_{s_k}(x), \tag{1.6}$$

where

$$H(x) = \sum_{k=0}^{N} A_k \chi_{I_k}(x), \qquad x \in \mathbb{R}, \tag{1.7}$$

$$\lambda_k > 0 \Rightarrow U(v_k) = 0, \tag{1.8}$$

and S and V have the same (nonzero) sign in any interval I_k in which $\alpha' \neq 0$.

If any of the assertions of Theorem 1.1, I, II, III, hold, we may choose the polynomial S to be the same in all of I, II and III. Further, we may relate s, s', t and t' by

$$s-s'=\text{degree}\,(T) \quad\text{and}\quad t-t'=\text{degree}\,(T)+2j-1. \tag{1.9}$$

The degree of S is s, while U and V admit the representation

$$U(x)=\int_{-\infty}^{\infty}\sum_{k=0}^{t+1} p_k(x)p_k'(u)S(u)\,d\beta(u), \tag{1.10}$$

$$V(x)=\int_{-\infty}^{\infty}\sum_{k=0}^{t+2} p_k(x)p_k(u)S(u)\,d\beta(u). \tag{1.11}$$

The following result gives more information on $d\alpha$ and $d\beta$, but is an immediate consequence of Theorem 1.1 and the partial fraction decomposition of U/V.

THEOREM 1.2. *Let $d\alpha$ and $d\beta$ be distributions, with corresponding sequences of orthonormal polynomials $\{p_n\}$ and $\{q_n\}$. Then assertions* I, II *and* III *of Theorem* 1.1 *hold if and only if $d\alpha$ and $d\beta$ are given by* (1.4)-(1.8). *Further,*

$$\phi(x)=\exp\left(-\int^{x} U(u)/V(u)\,du\right) \tag{1.12}$$

satisfies

$$\begin{aligned}\phi(x)&=\exp(-P(x))\prod_{k=1}^{N}|x-v_k|^{\Gamma_k}\\&\quad\cdot\exp\left(-\sum a_{ik}(x-v_i)^{-k}-\int^{x}U^*(u)/V^*(u)\,du\right),\end{aligned} \tag{1.13}$$

where $P(x)$ is a polynomial and $\Gamma_1, \Gamma_2\cdots\Gamma_N$ are positive. In addition, U^* and V^* are polynomials with degree $(U^*)<$ degree (V^*) *and V^* is a product of positive quadratic factors of V so that $V^*(x)>0$, $x\in(-\infty,\infty)$. Consider a term $a_{ik}(x-v_i)^{-k}$ in the finite sum $\sum a_{ik}(x-v_i)^{-k}$.*

If $A_{i-1}=A_i=0$, so that $\alpha'\equiv 0$ in $I_{i-1}\cup I_i$, then the sign of a_{ik} is arbitrary, and k may be any positive integer.

If $A_{i-1}=0$ but $A_i\neq 0$, so that $\alpha'\equiv 0$ in I_{i-1}, but $\alpha'\neq 0$ in I_i, then $a_{ik}\geqq 0$, while k may be any positive integer.

If $A_{i-1}\neq 0$ but $A_i=0$, so that $\alpha'\neq 0$ in I_{i-1}, but $\alpha'\equiv 0$ in I_i then $a_{ik}\geqq 0$ if k is even, while $a_{ik}\leqq 0$ if k is odd.

If $A_{i-1}\neq 0$ and $A_i\neq 0$, so that $\alpha'\neq 0$ in $I_{i-1}\cup I_i$, then $a_{ik}=0$ if k is odd, while $a_{ik}\geqq 0$ if k is even.

Finally, if $A_0\neq 0$ and $A_N\neq 0$ so that $\alpha'(x)\neq 0$ for large enough $|x|$, then $P(x)$ must be a polynomial of positive even degree with positive leading coefficient. If $A_0=0$ but $A_N\neq 0$, so that $\alpha'(x)\neq 0$ for large positive x, but $\alpha'(x)=0$ for large negative x, then $P(x)$ must be a polynomial of positive degree with positive leading coefficient.

Using the partial fraction decomposition of U^*/V^*, we may express $\exp(-\int^x U^*(u)/V^*(u)\,du)$ as a product of powers $(x^2+Bx+C)^D$ of positive quadratic factors of V, and of terms of the form $\exp(-E\arctan(Fx+g))$ and $\exp(-Y(x)/(x^2+Bx+C)^J)$, where J is a positive integer and Y is a polynomial of degree less than $2J$. At this stage, it is pertinent to illustrate the above theorems with some examples.

Example 1.3: GJ. The generalized Jacobi weights GJ [15] take the form

$$w(x)=\begin{cases}\prod_{j=1}^{N}|x-v_j|^{\Gamma_j}, & x\in[-1,1],\\ 0\end{cases}\tag{1.14}$$

where $N\geqq 2$, $\Gamma_j>-1$, $j=1,2,\cdots,N$, and

$$-1=v_1<v_2<\cdots<v_N=1.$$

Let us set

$$d\alpha(x)=w(x)\,dx.$$

The choice of V, U and $d\beta$ in (1.5) to (1.11) depend on S. In particular V and S must have the same sign in $(-1,1)$. We consider two choices for S.

CASE 1: $S=1$. Since V must be nonnegative in $(-1,1)$ and vanish at $v_1, v_2\cdots v_N$, we set

$$V(x)=(1-x^2)\prod_{j=2}^{N-1}(x-v_j)^2$$

and

$$U(x)=-V(x)\left\{\frac{\Gamma_1+1}{x+1}+\frac{\Gamma_{N+1}+1}{x-1}+\sum_{j=2}^{N-1}\frac{\Gamma_j+2}{x-v_j}\right\},$$

so that V has degree $2N-2$, and U has degree $2N-3$, as each $\Gamma_j+1>0$. It is clear that (1.5) holds with the obvious choice for H, and from (1.6), we see that

$$d\beta(x)=w_1(x)\,dx$$

where

$$w_1(x)=\begin{cases}(1+x)^{\Gamma_1+1}(1-x)^{\Gamma_N+1}\prod_{j=2}^{N-1}|x-v_j|^{\Gamma_j+2}, & x\in[-1,1],\\ 0 & \text{otherwise.}\end{cases}$$

From (1.10) and (1.11), we see that we may choose $t=2N-4$. Thus, by (1.3), the orthonormal polynomials $\{p_n\}$ and $\{q_n\}$ associated with w and w_1 satisfy

$$p_n'(x)=\sum_{k=n-2N+3}^{n-1}c_{nk}q_k(x),\qquad n=0,1,2,\cdots.$$

In the case $N=2$, this is precisely the classical result that the derivative of an orthonormal polynomial associated with a Jacobi weight $w(x)$ is an orthogonal polynomial associated with the Jacobi weight $w_1(x)=(1-x^2)w(x)$.

CASE 2: $S(x)=\prod_{j=1}^{N}(x-v_j)$. In this case we may choose $V(x)=S(x)$ and

$$U(x)=-V(x)\sum_{j=1}^{N}(\Gamma_j+1)/(x-v_j),$$

so that U and V have degree $N-1$ and N, respectively. It is clear that (1.5) is valid, while from (1.6), we may set $d\beta(x)=d\alpha(x)$. Finally from (1.10) and (1.11), we may choose $t=N-2$. Thus, by (1.3),

$$S(x)p_n'(x)=\sum_{k=n+1-N}^{n-1+N}c_{nk}p_k(x),\qquad n=0,1,2,\cdots.$$

Example 1.4: GJ and point masses. Let

$$d\alpha(x)=w(x)\,dx+\sum_{j=1}^{N}\lambda_j\delta_{v_j}(x),$$

where $w(x)$ is the generalised Jacobi weight (1.14), and λ_1 and λ_N are positive, while $\lambda_2, \lambda_3\cdots\lambda_N$ are nonnegative. In the case $N=2$, this weight has been considered by Koornwinder [9].

Let $S=1$, and let us determine what U, V and $d\beta$ should be. From (1.8), $U(\pm1)=0$, while V must be nonnegative throughout $(-1,1)$. We may set

$$V(x)=\prod_{j=1}^{N}(x-v_j)^2$$

and

$$U(x)=-V(x)\sum_{j=1}^{N}(\Gamma_j+2)/(x-v_j),$$

so that V and U have degree $2N$ and $2N-1$, respectively. From (1.6), we see that we must choose

$$d\beta(x)=w_1(x)\,dx,$$

where

$$w_1(x)=\begin{cases}\prod_{j=1}^{N}|x-v_j|^{\Gamma_j+2}, & x\in[-1,1],\\ 0 & \text{otherwise.}\end{cases}$$

From (1.10) and (1.11), we may choose $t=2N-2$. Thus

$$p_n'(x)=\sum_{k=n-2N+1}^{n-1}c_{nk}q_k(x),\qquad n=0,1,2,\cdots.$$

Example 1.5: exponential weights. Let

$$d\alpha(x)=\exp\left(-P(x)\right)dx,\qquad x\in\mathbb{R},$$

where $P(x)$ is a polynomial of even positive degree m with positive leading coefficient. In this case, we may set $V=1$ and $U=P'$, so that V and U have degree 0 and $m-1$, respectively. If we set $S=1$, then $d\beta(x)=d\alpha(x)$, and from (1.10) and (1.11), we may choose $t=m-2$. Thus

$$p_n'(x)=\sum_{k=n-m+1}^{n-1}c_{nk}p_k(x),\qquad n=0,1,2,\cdots.$$

Using the results and methods of [3], [6], [11] this may be used to establish bounds on $p_n(x)$. Magnus [12] recently proved Freud's Conjecture for the above weights.

2. Proof of Theorems 1.1 and 1.2. To prove Theorem 1.1, we shall show I⇔II⇔III. First however, we need to introduce notation: The orthonormal polynomial sequences $\{p_n\}$ and $\{q_n\}$ satisfy three term recurrence relations

$$xp_n=a_{n+1}p_{n+1}+a_np_{n-1}+b_np_n,\qquad n=1,2,3,\cdots,\tag{2.1}$$

$$xq_n=e_{n+1}q_{n+1}+e_nq_{n-1}+f_nq_n,\qquad n=1,2,3,\cdots,\tag{2.2}$$

where

$$a_0=e_0=0,\quad a_n>0,\quad e_n>0,\quad n=1,2,3,\cdots,$$

while b_n and f_n are real, $n=1, 2, 3, \cdots$. Further, if $\gamma_n(d\alpha)$ and $\gamma_n(d\beta)$ denote the leading coefficients of p_n, $n=0, 1, 2, \cdots$, it is well known that

$$a_n=\gamma_{n-1}(d\alpha)/\gamma_n(d\alpha), \quad e_n=\gamma_{n-1}(d\beta)/\gamma_n(d\beta), \quad n=1,2,3,\cdots.$$

Proof of I⇔II. The implication II⇒I is trivial, so we must show I⇒II. By hypothesis, we have $R=S/T$ satisfying

$$Sp_n^{(j)}=T\sum_{k=n-j-t'}^{n-j+s'} c'_{nk}q_k, \qquad n=0,1,2,\cdots. \tag{2.3}$$

We shall first show that for some real $\{c''_{nk}\}$,

$$Sp_n^{(j)}=\sum_{k=n-j-t''}^{n-j+s''} c''_{nk}q_k, \qquad n=0,1,2,\cdots \tag{2.4}$$

where $t''-t'=s''-s'=\text{degree}\,(T)$. It clearly suffices to show that there exist real numbers a_{jkl} with $a_{jkl}=0$ for $l<0$, such that

$$x^jq_k(x)=\sum_{l=k-j}^{k+j} a_{jkl}q_l(x), \qquad j, k=0,1,2,\cdots. \tag{2.5}$$

But this is trivial for $j=0$ and $k=0, 1, 2, \cdots$, while for $j=1$ and $k=0, 1, 2, \cdots$, it follows from the recurrence relation. An easy induction on j establishes (2.5) for all $j, k=0, 1, 2, \cdots$. Thus, (2.4) follows from (2.3) and (2.5).

Next, applying Leibniz's formula for the jth derivative of a product of two functions to (2.1), we see that

$$xp_n^{(j)}+jp_n^{(j-1)}=a_{n+1}p_{n+1}^{(j)}+a_np_{n-1}^{(j)}+b_np_n^{(j)}, \qquad n=0,1,2,\cdots,$$

so that

$$\begin{aligned} Sp_n^{(j-1)}&=j^{-1}\{a_{n+1}Sp_{n+1}^{(j)}+a_nSp_{n-1}^{(j)}+b_nSp_n^{(j)}-xSp_n^{(j)}\}\\ &=\sum_{k=n-j-1-t''}^{n-j+1+s''} c_{nk}^{\#}q_k, \end{aligned}$$

for some real numbers $\{c_{nk}^{\#}\}$. Here we have used (2.4) and the recurrence relation (2.2) for xq_k. Proceeding in the same way, we obtain after altogether $j-1$ such steps that (1.3) holds, where s, s', t and t' are related by (1.9). □

The proof of II⇒III will be split into several steps.

LEMMA 2.1. *Assume that assertion* II *of Theorem* 1.1 *holds.*

(i) *Then there exist real numbers* $\{c_{nk}^*\}$ *such that* $c_{nk}^*=0$ *for* $k<0$, *and*

$$Sp_n=\sum_{k=n-2-t}^{n+s} c_{nk}^*q_k, \qquad n=0,1,2,\cdots. \tag{2.6}$$

(ii) *Define polymials* U *and* V *of degree at most* $t+1$ *and* $t+2$ *respectively by* (1.10) *and* (1.11). *Then for every polynomial* P,

$$\int_{-\infty}^{\infty} P(x)V(x)\,d\alpha(x)=\int_{-\infty}^{\infty} P(x)S(x)\,d\beta(x) \tag{2.7}$$

and

$$\int_{-\infty}^{\infty} P(x)U(x)\,d\alpha(x)=\int_{-\infty}^{\infty} P'(x)S(x)\,d\beta(x). \tag{2.8}$$

Proof. (i) From the recurrence relation (2.1)

$$xp_n'(x)+p_n(x)=a_{n+1}p_{n+1}'(x)+a_np_{n-1}'(x)+b_np_n'(x),$$

so that

$$S(x)p_n(x)=a_{n+1}S(x)p_{n+1}'(x)+a_nS(x)p_{n-1}'(x)+b_nS(x)p_n'(x)-xS(x)p_n'(x).$$

Then (2.6) follows easily from (1.3) and the recurrence relation (2.2) for xq_k.

(ii) It suffices to show that (2.7) and (2.8) hold for $P=p_n$, $n=0, 1, 2, \cdots$. Now if V is given by (1.11), so that V has degree at most $t+2$,

$$\int_{-\infty}^{\infty} p_n(x)V(x)\,d\alpha(x)=\begin{cases}0, & n>t+2,\\ \displaystyle\int_{-\infty}^{\infty} p_n(u)S(u)\,d\beta(u), & n\leqq t+2.\end{cases}$$

But (2.6) and orthonormality of $\{q_k\}$ with respect to $d\beta$, show that

$$\int_{-\infty}^{\infty} p_n(u)S(u)\,d\beta(u)=0, \qquad n>t+2.$$

Thus (2.7) holds for $P=p_n$, $n=0, 1, 2, \cdots$. Next, if U is given by (1.10)

$$\int_{-\infty}^{\infty} p_n(x)U(x)\,d\alpha(x)=\begin{cases}0, & n>t+1,\\ \displaystyle\int_{-\infty}^{\infty} p_n'(u)S(u)\,d\beta(u), & n\leqq t+1.\end{cases}$$

But (1.3) and orthonormality of $\{q_k\}$ with respect to $d\beta$ show that

$$\int_{-\infty}^{\infty} p_n'(u)S(u)\,d\beta(u)=0, \qquad n>t+1.$$

Thus (2.8) holds for $P=p_n$, $n=0, 1, 2, \cdots$. □

Next, we estimate some modified moments.

LEMMA 2.2. *Assume that assertion* II *of Theorem* 1.1 *holds. Let*

$$L_n=\int_{-\infty}^{\infty}|x|^n\,d\alpha(x), \qquad n=0,1,2,\cdots, \tag{2.9}$$

and

$$M_n=\int_{-\infty}^{\infty}|x|^n\,d\beta(x), \qquad n=0,1,2,\cdots. \tag{2.10}$$

Then

$$\limsup_{n\to\infty} L_n^{1/n}/n<\infty \tag{2.11}$$

and

$$\limsup_{n\to\infty} M_n^{1/n}/n<\infty. \tag{2.12}$$

Proof. First note that as $S\equiv 0$, (2.7) and (2.8) show that $U\equiv 0$ and $V\equiv 0$. Now from (2.8) with $P(x)=x^{n+1}$,

$$\begin{aligned}\int_{-\infty}^{\infty} x^{n+1}U(x)\,d\alpha(x)&=(n+1)\int_{-\infty}^{\infty} x^nS(x)\,d\beta(x)\\ &=(n+1)\int_{-\infty}^{\infty} x^nV(x)\,d\alpha(x),\end{aligned}$$

by (2.7). Thus

$$\int_{-\infty}^{\infty} x^n[xU(x)-(n+1)V(x)]\,d\alpha(x)=0, \qquad n=0,1,2,\cdots. \tag{2.13}$$

Next, there exist nonzero constants C_1 and C_2 and nonnegative integers p and q such that

$$xU(x)=C_1x^p(1+o(1)), \qquad |x|\to\infty$$

and

$$V(x)=C_2x^q(1+o(1)), \qquad |x|\to\infty.$$

We distinguish between the cases where $xU(x)$ or $(n+1)V(x)$ dominates in (2.13).

CASE 1: $p\leqq q$. As usual, for any real x, we let sign (x) denote the sign of x if $x\neq 0$, while sign $(0)=0$. Now there exist $C>0$ and n_0 such that

$$\operatorname{sign}(-C_2x^q)\{xU(x)-(n+1)V(x)\}\geqq 1, \qquad |x|\geqq C, \quad n\geqq n_0.$$

Then for $n\geqq n_0$ and $n+q$ even, so that sign $(x^n)=$ sign (x^q),

$$\int_{|x|\geqq C}|x|^n\,d\alpha(x)\leqq \operatorname{sign}(-C_2)\int_{|x|\geqq C}x^n\{xU(x)-(n+1)V(x)\}\,d\alpha(x)$$
$$=-\operatorname{sign}(-C_2)\int_{|x|\leqq C}x^n\{xU(x)-(n+1)V(x)\}\,d\alpha(x)=O(nC^n),$$

by (2.13). Since

$$\int_{|x|\leqq C}|x|^n\,d\alpha(x)=O(C^n),$$

we obtain, for $n\geqq n_0$ and $n+q$ even,

$$L_n=O(nC^n).$$

However for $n+q$ odd,

$$L_n\leqq\int_{-1}^{1}d\alpha(x)+\int_{|x|\geqq 1}|x|^{n+1}\,d\alpha(x)\leqq L_0+L_{n+1} \tag{2.14}$$

and then (2.11) follows.

CASE 2: $p>q$. Let $X(n)=16|C_2/C_1|n$, $n=1,2,3,\cdots$. Then for $|x|\geqq X(n)$, and n large enough,

$$\operatorname{sign}(C_1x^p)\{xU(x)-(n+1)V(x)\}\geqq\{|C_1x^p|/2-2(n+1)|C_2x^q|\}$$
$$\geqq|C_1x^p|/2\{1-8n|C_2/C_1|\,|x|^{q-p}\}\geqq 1$$

as $q-p\leqq -1$. Hence if $n+p$ is even and n is large enough, so that sign $(x^n)=$ sign (x^p),

$$\int_{|x|\geqq X(n)}|x|^n\,d\alpha(x)\leqq\operatorname{sign}(C_1)\int_{|x|\geqq X(n)}x^n\{xU(x)-(n+1)V(x)\}\,d\alpha(x)$$
$$=-\operatorname{sign}(C_1)\int_{|x|\leqq X(n)}x^n\{xU(x)-(n+1)V(x)\}\,d\alpha(x)\quad \text{by (2.13))}$$
$$=O(nX(n)^{n+p}).$$

Further,

$$\int_{|x|\le X(n)} |x|^n \, d\alpha(x) = O(X(n)^n),$$

and thus if $n+p$ is even,

$$L_n = O(nX(n)^{n+p}) = O((C_3 n)^{n+p}),$$

for some $C_3 > 0$. This establishes (2.11) if we restrict n to those integers for which $n+p$ is even. As before, (2.14) yields (2.11) in the general case. Finally, (2.12) follows easily from (2.7) and (2.11). □

Finally, we need two Fourier transform identities.

LEMMA 2.3. *Assume that assertion* II *of Theorem* 1.1 *holds. Then for all real u,*

$$\int_{-\infty}^{\infty} e^{iux} V(x) \, d\alpha(x) = \int_{-\infty}^{\infty} e^{iux} S(x) \, d\beta(x) \tag{2.15}$$

and

$$\int_{-\infty}^{\infty} e^{iux} U(x) \, d\alpha(x) = iu \int_{-\infty}^{\infty} e^{iux} S(x) \, d\beta(x). \tag{2.16}$$

Proof. Our proof will be similar to that of the uniqueness criterion of M. Riesz for the moment problem [5, pp. 79-80]. Let

$$\varphi_1(u) = \int_{-\infty}^{\infty} e^{iux} V(x) \, d\alpha(x)$$

and

$$\varphi_2(u) = \int_{-\infty}^{\infty} e^{iux} S(x) \, d\beta(x) \tag{2.17}$$

for all real u. We shall show that there exists $r > 0$ such that both $\varphi_1(u)$ and $\varphi_2(u)$ are analytic in the strip $\{u \in \mathbb{C}: |\text{Im } u| < r\}$. To this end, we first note that by Lemma 2.2, there exists $r > 0$ such that the series $\sum_{k=0}^{\infty} L_{k+t+2} z^k / k!$ and $\sum_{k=0}^{\infty} M_{k+t+2} z^k / k!$ converge absolutely and uniformly in compact subsets of $|z| < r$. Then given real u and $|z| < r$, we have formally

$$\begin{aligned}\varphi_1(u+z) &= \int_{-\infty}^{\infty} e^{ix(u+z)} V(x) \, d\alpha(x) \\ &= \int_{-\infty}^{\infty} e^{ixu} \sum_{k=0}^{\infty} (ixz)^k / k! \, V(x) \, d\alpha(x) \\ &= \sum_{k=0}^{\infty} (iz)^k \int_{-\infty}^{\infty} e^{ixu} x^k V(x) \, d\alpha(x) / k!.\end{aligned}$$

As V has degree at most $t+2$, it is not difficult to see that the coefficient of z^k in this last series is bounded by $C \ (L_{k+t+2} + L_k)/k!$, where C is a positive constant independent of k. Thus the power series converges uniformly for z in compact subsets of $|z| < r$, where $r > 0$ is independent of u. We deduce that the formal interchanges above are analytically valid and that $\varphi_1(u)$ is analytic in the strip $\{u : |\text{Im } u| < r\}$. Similarly φ_2 is analytic in this strip.

If we can show that for some $\varepsilon > 0$,

$$\varphi_1(u) = \varphi_2(u), \qquad u \in (-\varepsilon, \varepsilon),$$

so that (2.15) is valid for $u \in (-\varepsilon, \varepsilon)$, then analytic continuation will show that (2.15) is valid for all real u. Now from (2.7), we have that (2.15) is valid for real u, provided we replace e^{iux} by its $(n+1)$th partial sum,

$$P_n(xu) = \sum_{k=0}^{n} (iux)^k/k!,$$

that is,

$$\int_{-\infty}^{\infty} P_n(xu) V(x)\, d\alpha(x) = \int_{-\infty}^{\infty} P_n(xu) S(x)\, d\beta(x). \tag{2.18}$$

Next, applying Taylor's formula to the real and imaginary parts of e^{iy}, y real, we see (cf. [5, p. 79]) that

$$|e^{iy} - P_n(y)| \leqq 2|y|^n/n!, \qquad y \text{ real}.$$

Then, using (2.18), we see that

$$\begin{aligned}\left|\int_{-\infty}^{\infty} e^{iux} V(x)\, d\alpha(x) - \int_{-\infty}^{\infty} e^{iux} S(x)\, d\beta(x)\right| \\ &= \left|\int_{-\infty}^{\infty} \{e^{iux} - P_n(xu)\}(V(x)\, d\alpha(x) - S(x)\, d\beta(x))\right| \\ &\leqq 2|u|^n \int_{-\infty}^{\infty} |x|^n \{|V(x)|\, d\alpha(x) + |S(x)|\, d\beta(x)\}/n! \\ &\to 0 \quad \text{as } n \to \infty,\end{aligned}$$

if $|u|$ is small enough, by Lemma 2.2, and as S and V are polynomials. Thus (2.15) is valid.

The proof of (2.16) is rather similar. One shows that the left and right members of (2.16) are analytic functions of u in a strip containing the real line. Further, one uses (2.8) to show that

$$\int_{-\infty}^{\infty} P_n(ux) U(x)\, d\alpha(x) = iu \int_{-\infty}^{\infty} P_{n-1}(ux) S(x)\, d\beta(x)$$

and proceeds much as above. □

Recall that we can write

$$d\alpha\ (x) = \alpha'(x)\, dx + d\alpha_j(x) + d\alpha_s(x),$$

where $\alpha'(x)\, dx$ is the absolutely continuous part of $d\alpha$, while $d\alpha_j$ is a series of point masses, and $d\alpha_s$ is the singularly continuous part of $d\alpha$. Similar remarks apply to $d\beta$.

Proof of II⇒III. Let U and V be given by (1.10) and (1.11), and let ϕ_2 be given by (2.17). From (2.16), we see that

$$\varphi_2(u) = O(u^{-1}), \qquad |u| \to \infty,$$

and hence

$$\int_{-x}^{x} |\varphi_2(u)|\, du = o(x), \qquad x \to \infty.$$

It then follows from Wiener's Theorem (Zygmund [21, p. 261]) that

$$F(u) = \int_{-\infty}^{u} S(x)\, d\beta(x) \tag{2.19}$$

is continuous in $(-\infty, \infty)$. Next, integrating the left member of (2.16) by parts, and using

$$\int_{-\infty}^{\infty} U(x)\, d\alpha(x) = 0 \tag{2.20}$$

(which follows from (2.16) with $u = 0$), we obtain

$$-\int_{-\infty}^{\infty} iu\, e^{iux}\left\{\int_{-\infty}^{x} U(y)\, d\alpha(y)\right\} dx = iu\int_{-\infty}^{\infty} e^{iux} S(x)\, d\beta(x)$$

and hence that

$$-\int_{-\infty}^{\infty} e^{iux}\left\{\int_{-\infty}^{x} U(y)\, d\alpha(y)\right\} dx = \int_{-\infty}^{\infty} e^{iux} S(x)\, d\beta(x), \tag{2.21}$$

$u \neq 0$. We can let $u \to 0$ to deduce that (2.21) holds even for $u = 0$. To see this it suffices to prove

$$\int_{-\infty}^{\infty}\left|\int_{-\infty}^{x} U(y)\, d\alpha(y)\right| dx < \infty, \tag{2.22}$$

and then to apply Lebesgue's Dominated Convergence Theorem. Now, since all moments of $d\alpha$ are finite, and since (2.20) holds, we see that as $x \to \infty$,

$$\int_{-\infty}^{x} U(y)\, d\alpha(y) = -\int_{x}^{\infty} U(y)\, d\alpha(y) = O(x^{-j}),$$

for each positive integer j. Further as $x \to -\infty$,

$$\int_{-\infty}^{x} U(y)\, d\alpha(y) = O(x^{-j})$$

for each positive integer j. Thus (2.22) holds and hence (2.21) is valid for all real u.

We may now use the uniqueness of Fourier transforms and the continuity of $F(u)$ in (2.19) (see Zygmund [21, p. 293, Thm. 10.15]) to deduce for all real u.

$$-\int_{-\infty}^{u}\left\{\int_{-\infty}^{x} U(y)\, d\alpha(y)\right\} dx = \int_{-\infty}^{u} S(x)\, d\beta(x). \tag{2.23}$$

It now follows that $S(x)\, d\beta(x)$ is absolutely continuous in $(-\infty, \infty)$. Thus $d\beta_s \equiv 0$ and $d\beta_j$ can have point masses only at zeros of S, so that with the notation of Theorem 1.1,

$$d\beta(x) = \beta'(x)\, dx + \sum_{k=1}^{N'} \mu_k \delta_{s_k}(x). \tag{2.24}$$

Further, from (2.23)

$$-\int_{-\infty}^{u} U(y)\, d\alpha(y) = S(u)\beta'(u), \qquad u \in (-\infty, \infty). \tag{2.25}$$

Next, using (2.15), in the same way as we used (2.21), we deduce that for all real u,

$$\begin{aligned}\int_{-\infty}^{u} V(x)\, d\alpha(x) &= \int_{-\infty}^{u} S(x)\, d\beta(x)\\ &= \int_{-\infty}^{u} S(x)\beta'(x)\, dx,\end{aligned} \tag{2.26}$$

by absolute continuity of $S\,d\beta$. We deduce that $V(x)\,d\alpha(x)$ is absolutely continuous in $(-\infty, \infty)$. Thus $d\alpha_s \equiv 0$ and $d\alpha_j$ can have point masses only at zeros of V, so that

$$d\alpha(x) = \alpha'(x)\,dx + \sum_{k=1}^{N} \lambda_k \delta_{v_k}(x), \tag{2.27}$$

with the notation of Theorem 1.1. Then (2.26) and (2.27) show that

$$V(x)\alpha'(x) = S(x)\beta'(x), \qquad x \in (-\infty, \infty). \tag{2.28}$$

Further, substituting (2.27) and (2.28) into (2.25), we obtain for all real $u \notin \{v_1, v_2 \cdots v_N\}$,

$$-\int_{-\infty}^{u} U(y)\alpha'(y)\,dy - \sum_{v_k \leqq u} \lambda_k U(v_k) = V(u)\alpha'(u). \tag{2.29}$$

We deduce that $V\alpha'$ is absolutely continuous in any interval $I_k = (v_k, v_{k+1})$, and

$$-U(u)\alpha'(u) = (V(u)\alpha'(u))', \qquad u \in I_k.$$

Hence in I_k,

$$(V\alpha')'/(V\alpha') = -U/V,$$

and integrating, we obtain

$$\alpha'(x) = (A_k/|V(x)|)\exp\left(-\int^{x} U(u)/V(u)\,du\right), \qquad x \in I_k,$$

where A_k is a nonnegative constant. Together with (2.27), this establishes (1.5) and (1.7). It is obvious that at least one A_k must be positive, since $\alpha(x)$ has infinitely many points of increase. Now consider an interval I_k in which α' is not identically zero. Then $A_k > 0$ and α' and V do not vanish in I_k. Hence the left member of (2.28) is of one sign and nonzero in I_k, so that S must have the same sign as V in I_k and does not vanish in I_k. Now (1.6) follows easily from (1.5), (2.24) and (2.28).

It remains to prove (1.8). Since the integral in (2.29) is continuous in $\mathbb{R}$, it suffices to show that $\alpha'(x)V(x)$ is continuous in $\mathbb{R}$. As $\alpha'V$ is continuous in each I_k, it suffices to show that

$$\lim_{x \to v_k} \alpha'(x)V(x) = 0, \qquad k = 1, 2, \cdots, N. \tag{2.30}$$

Fix k. If as $x \to v_k$, $\exp(-\int^x U(u)/V(u)\,du) \nrightarrow 0$, it will be bounded below by a positive number in either some left or right neighbourhood of v_k. Then if $\alpha'(x)$ is not identically zero in that neighbourhood, it follows from (1.5) that in that neighbourhood

$$\alpha'(x) \geqq C/|x - v_k|^l,$$

where l is a positive integer and $C > 0$. This contradicts the integrability of $d\alpha$. Thus either $\alpha' \equiv 0$ near v_k (in which case (2.30) is trivial), or $\exp(-\int^x U(u)/V(u)\,du) \to 0$ as $x \to v_k$ and then (1.5) yields (2.30). □

Proof of III⇒II. From (1.5) and (1.7) we see that in any interval I_k (given by (1.4)), α' is absoutely continuous and

$$(V(x)\alpha'(x))' = -U(x)\alpha'(x), \qquad x \in I_k. \tag{2.31}$$

Further, using the integrability of $d\alpha$ as in the proof of II⇒III, we see that (2.30) is true. Finally, from (1.5) and (1.6), we deduce that for all real $x \notin \{v_1, v_2, \cdots, v_N\}$,

$$V(x)\alpha'(x) = S(x)\beta'(x). \tag{2.32}$$

Let n be a nonnegative integer. As $d\beta$ has jumps only at zeros of S,

$$\begin{aligned}\int_{-\infty}^{\infty} Sp_n' q_k \, d\beta(x) &= \int_{-\infty}^{\infty} Sp_n' q_k \beta' \, dx \\ &= \int_{-\infty}^{\infty} p_n' q_k V\alpha' \, dx \quad (\text{by } (2.32)) \\ &= \sum_{k=0}^{N} \int_{I_k} p_n' q_k V\alpha' \, dx \\ &= -\sum_{k=0}^{N} \left\{ p_n q_k V\alpha' \Big|_{v_k}^{v_{k+1}} - \int_{I_k} p_n (q_k V\alpha')' \, dx \right\} \\ &= -\int_{-\infty}^{\infty} p_n \{ q_k' V\alpha' + q_k (V\alpha')' \} \, dx \quad (\text{by } (2.30)) \\ &= -\int_{-\infty}^{\infty} p_n \{ q_k' V - q_k U \} \alpha' \, dx \quad (\text{by } (2.31)) \\ &= -\int_{-\infty}^{\infty} p_n \{ q_k' V - q_k U \} \, d\alpha(x) + \sum_{k=1}^{N} \lambda_k p_n(v_k) \{ q_k' V - q_k U \}(v_k), \end{aligned} \tag{2.33}$$

by (1.5). Since $q_k' V - q_k U$ has degree at most $k+t+1$, the integral in the right member of (2.33) will vanish if $n > k+t+1$, that is if $k < n-1-t$. In view of (1.8), and as $v_1, v_2, \cdots, v_N$ are zeros of V, the sum in (2.33) is zero. Thus, expanding Sp_n' in terms of $q_0, q_1, \cdots, q_n$, we obtain (1.3). □

Thus the proof of Theorem 1.1 is complete. We turn to proving Theorem 1.2.

Proof of Theorem 1.2. Suppose that any of the assertions I, II or III of Theorem 1.1 hold, so that, in particular, (1.5) and (1.6) are valid. The partial fraction decomposition of U/V has the form

$$U(u)/V(u) = P'(u) - \sum_{k=1}^{N} \Gamma_k/(u - v_k) + \sum b_{ik}(u - v_i)^{-k-1} + U^*(u)/V^*(u), \tag{2.34}$$

where P is a polynomial, U^* and V^* are as in Theorem 1.2, and in the finite sum $\sum b_{ik}(u-v_i)^{-k-1}$, all the integers k are positive. Integrating (2.34), we obtain (1.13). The stated restrictions on $\{a_{ik}\}$ and P depending on the support of $d\alpha$, follow immediately from the integrability of $d\alpha$. □

ON SIEVED ORTHOGONAL POLYNOMIALS. V: SIEVED POLLACZEK POLYNOMIALS*

JAIRO A. CHARRIS† AND MOURAD E. H. ISMAIL‡

This paper is dedicated to the memory of Jerry Fields, our teacher and our friend.

Abstract. The general Pollaczek polynomials and their sieved analogues are studied in detail. Basic analogues of the Pollaczek polynomials are introduced. The measures that these polynomials are orthogonal with respect to are obtained by applying Darboux's Method and Markov's Theorem.

1. Introduction. A distribution function $\psi(x)$ is a nondecreasing function defined on $(-\infty, \infty)$ and having infinitely many points of increase and finite moments of all orders. A sequence of polynomials $\{p_n(x)\}$ is orthogonal if $p_n(x)$ has precise degree n and there exists a distribution function $\psi(x)$ such that

$$\int_{-\infty}^{\infty} p_n(x)p_m(x)\,d\psi(x) = \lambda_n\delta_{mn}. \tag{1.1}$$

The support of $d\psi(x)$ is the spectrum of ψ and will be denoted by $\sigma(\psi)$. Let

$$p_0(x) = 1, \qquad p_1(x) = A_0x + B_0. \tag{1.2}$$

A set of polynomials $\{p_n(x)\}$ satisfying (1.2) is orthogonal if and only if it satisfies a three term recurrence relation

$$p_{n+1}(x) = (A_nx + B_n)p_n(x) - C_np_{n-1}(x), \qquad n > 0, \tag{1.3}$$

and a positivity condition

$$A_nA_{n-1}C_n > 0, \qquad n = 1, 2, \cdots. \tag{1.4}$$

This is known as Favard's Theorem [9], [30]. We shall normalize $\psi(x)$ by

$$\int_{-\infty}^{\infty} d\psi(x) = 1, \tag{1.5}$$

$$\psi(-\infty) = 0, \qquad \psi(x) = \lfloor \psi(x+0) + \psi(x-0) \rfloor /2. \tag{1.6}$$

It is easy to obtain

$$\lambda_0 = 1, \quad \lambda_n = A_0C_1 \cdots C_n/A_n, \quad n = 1, 2, \cdots. \tag{1.7}$$

A central problem in the theory of orthogonal polynomials is to determine the qualitative behavior of a distribution function from the qualitative behavior of the coefficients in the three term recurrence relation [10], [18]-[21]. These qualitative results are usually motivated by specific examples, or models, where both the polynomials and the distribution function are known explicitly. These models are usually hard to come by so new models that exhibit distinctly different qualitative behavior are of some interest and importance. The Szegö theory of orthogonal polynomials is modeled after the Chebyshev polynomials [10]-[12], [30]. Recently several good candidates of models for new theories have been discovered [4], [15].

The second order difference equation (1.3) has two linearly independent solutions $\{p_n(x)\}$ and $\{p_n^*(x)\}$. The denominator polynomials $\{p_n(x)\}$ satisfy the initial conditions (1.2) while the numerator polynomials $\{p_n^*(x)\}$ are given initially by

$$p_0^*(x)=0, \qquad p_1^*(x)=A_0. \tag{1.8}$$

It can be proved that the boundedness conditions

$$|B_n/A_n|\leqq M \quad \text{and} \quad C_n/(A_nA_{n-1})<M, \quad n=1,2,\cdots, \tag{1.9}$$

imply the boundedness of $\sigma(\psi)$ (Chihara [9, pp. 67, 109]). When $\sigma(\psi)$ is bounded, the Stieltjes transform of the distribution function can be recovered from the asymptotic behavior of $p_n(x)$ and $p_n^*(x)$.

THEOREM 1.1 (Markov). *If $\sigma(\psi)$ is compact then*

$$\lim_{n\to\infty} p_n^*(z)/p_n(z)=\int_{-\infty}^{\infty}\frac{d\psi(t)}{z-t}, \qquad z\notin\sigma(\psi), \tag{1.10}$$

and the limit is uniform on compact subsets of $\mathbb{C}-\sigma(\psi)$.

The Perron-Stieltjes Inversion Formula is

$$F(z)=\int_{-\infty}^{\infty}\frac{d\psi(t)}{z-t} \quad \text{iff } \psi(t_2)-\psi(t_1)=\lim_{\varepsilon\to 0+}\int_{t_1}^{t_2}\frac{F(t-i\varepsilon)-F(t+i\varepsilon)}{2\pi i}\,dt. \tag{1.11}$$

In (1.11) it is assumed that $\sigma(\psi)$ is contained in a half line. The asymptotic behavior of $p_n(z)$ and $p_n^*(z)$ may be computed by applying Darboux's Method (Olver [23, § 8.9]).

THEOREM 1.2 (Darboux's Method). *Let $f(z)$ be analytic in $|z|<r$, $0<r<\infty$, and have a finite number of singularities on $|z|=r$. Assume that $g(z)$ is also analytic in $|z|<r$ and $f-g$ is continuous in $|z|=r$. If $f(z)=\sum_0^\infty f_nz^n$, $g(z)=\sum_0^\infty g_nz^n$, then $f_n=g_n+o(r^{-n})$.*

The function $g(z)$ is called a comparison function. The origin of the terminology "numerator" and "denominator" is that the continued fraction

$$\chi(z):=\frac{A_0|}{|A_0z+B_0}-\frac{C_1|}{|A_1z+B_1}-\cdots-\frac{C_n|}{|A_nz+B_n}-\cdots$$

is given by

$$\chi(z)=\lim_{n\to\infty}p_n^*(z)/p_n(z), \qquad z\notin\sigma(\psi).$$

Pollaczek's investigations of a stochastic model of the French telephones led him to a generalization of the Legendre polynomials [24]. The ultraspherical polynomials are generated by

$$C_0^\lambda(x)=1, \qquad C_1^\lambda(x)=2\lambda x, \tag{1.12}$$

$$(n+1)C_{n+1}^\lambda(x)=2x(n+\lambda)C_n^\lambda(x)-(n+2\lambda-1)C_{n-1}^\lambda(x), \qquad n>0. \tag{1.13}$$

The case $\lambda=\frac{1}{2}$ is the Legendre polynomials. Later, Szegö [29] extended Pollaczek's work by generalizing the ultraspherical polynomials in the way Pollaczek generalized the Legendre polynomials. Szegö considered the polynomials

$$(n+1)P_{n+1}^\lambda(x;a,b)=2[x(n+\lambda+a)+b]P_n^\lambda(x;a,b)-(n+2\lambda-1)P_{n-1}^\lambda(x;a,b) \tag{1.14}$$

with

$$P_0^\lambda(x;a,b)=1, \qquad P_1^\lambda(x;a,b)=2x(\lambda+a)+2b. \tag{1.15}$$

Clearly $P_n^\lambda(x; 0, 0) = C_n^\lambda(x)$. Szegö referred to $\{P_n^\lambda(x; a, b)\}$ as the Pollaczek polynomials. They do not belong to the Szegö class and the limiting distribution of their zeros is very different from the classical polynomials (Novikoff [22]). Both Pollaczek and Szegö only handled the case $\lambda > 0$, $a > |b|$, when ψ is absolutely continuous and $\sigma(\psi)$ is $[-1, 1]$. Askey and Ismail [4] treated the case $b = 0$ of the polynomials in (1.15) and (1.14). The case $b = 0$ contains subcases when the distribution function has infinitely many jumps. The jumps and the polynomials have been computed explicitly. This provides a model very different from the case $\lambda > 0$, $a > |b|$ of Pollaczek and Szegö. This raises the question of determining the distribution function of the general Pollaczek polynomials. This will follow as a corollary of some of the results of this work, see § 6. The special cases $b = \pm a$ were treated in Bank and Ismail [7]. This is equivalent to determining the spectral measure of the differential operator

$$-\frac{1}{2}\frac{d^2}{dr^2} + \frac{l(l+1)}{2r^2} + \frac{Z}{r},$$

which is the radial part of a Schrödinger wave equation with a Coulomb potential.

L. J. Rogers introduced continuous q-ultraspherical polynomials $\{C_n(x; \beta \mid q)\}$ and used them to prove the celebrated Rogers-Ramanujan identities. They satisfy

$$(1.16) \qquad (1 - q^{n+1})C_{n+1}(x; \beta \mid q) = 2x(1 - \beta q^n)C_n(x; \beta \mid q) - (1 - \beta^2 q^{n-1})C_{n-1}(x; \beta \mid q),$$

for $n > 0$ and

$$(1.17) \qquad C_0(x; \beta \mid q) = 1, \qquad C_1(x; \beta \mid q) = 2x(1 - \beta)/(1 - q),$$

where $-1 < q < 1$. The distribution function of these polynomials was computed in [2], [3], [6]. These polynomials generalize the ultraspherical polynomials in a direction different from Szegö's generalization. It is clear that $C_n(x; q^\lambda \mid q) \to C_n^\lambda(x)$ as $q \to 1$.

Al-Salam, Allaway and Askey [1] observed that other interesting polynomials arise as limiting cases of the continuous q-ultraspherical polynomials. They showed that

$$(1.18) \qquad B_n^\lambda(x; k) = \lim_{s \to 1} C_n(x; s^{\lambda k + 1}\omega \mid s\omega), \qquad \omega = \exp(2\pi i/k)$$

exists and satisfies

$$(1.19) \qquad \begin{cases} B_{n+1}^\lambda(x; k) = 2xB_n^\lambda(x; k) - B_{n-1}^\lambda(x; k), & k \nmid n+1, \\ mB_{mk}^\lambda(x; k) = 2x(m + \lambda)B_{mk-1}^\lambda(x; k) - (m + 2\lambda)B_{mk-2}^\lambda(x; k), & m > 0, \end{cases}$$

$$(1.20) \qquad B_0^\lambda(x; k) = 1, \quad B_1^\lambda(x; k) = 2x, \quad k > 1.$$

Al-Salam, Allaway and Askey named these polynomials "sieved ultraspherical polynomials of the second kind." They also showed that the sieved ultraspherical polynomials of the first kind

$$(1.21) \qquad c_n^\lambda(x; k) = \lim_{s \to 1} (\omega s; \omega s)_n C_n(x; s^{\lambda k} \mid \omega s)/(s^{2\lambda k}; s\omega)_n$$

satisfy

$$(1.22) \qquad \begin{cases} c_{n+1}^\lambda(x; k) = 2xc_n^\lambda(x; k) - c_{n-1}^\lambda(x; k), & k \nmid n, \\ (m + 2\lambda)c_{mk+1}^\lambda(x; k) = 2x(m + \lambda)c_{m_k}^\lambda(x; k) - mc_{mk-1}^\lambda(x; k), & m > 0, \end{cases}$$

$$(1.23) \qquad c_0^\lambda(x; k) = 1, \qquad c_1^\lambda(x; k) = x, \quad k > 1$$

where ω is as in (1.18). In (1.21) we used the notation

$$(1.24) \qquad (a; q)_0 = 1, \qquad (a; q)_n = \prod_{j=1}^{n} (1 - aq^{j-1}).$$

Al-Salam, Allaway and Askey let $q=\omega s$ and let $s\to 1$ formally in the orthogonality relation of the continuous q-ultraspherical polynomials after choosing β as in (1.18) and (1.21). They mentioned the orthogonality relations

$$\int_{-1}^{1} c_n^\lambda(x;k)c_m^\lambda(x;k)w_1(x)\,dx=\Gamma\left(\frac{1}{2}\right)\Gamma\left(\lambda+\frac{1}{2}\right)h_{n,1}\delta_{m,n}/\Gamma(\lambda+1), \tag{1.25}$$

and

$$\int_{-1}^{1} B_m^\lambda(x;k)B_n^\lambda(x;k)w_2(x)\,dx=\Gamma\left(\frac{1}{2}\right)\Gamma\left(\lambda+\frac{1}{2}\right)h_{n,2}\delta_{m,n}/\Gamma(\lambda+1), \tag{1.26}$$

where

$$w_1(x)=(1-x^2)^{\lambda-1/2}|U_{k-1}(x)|^{2\lambda},\qquad h_{n,1}=\frac{(\lambda)_{\lceil n/k\rceil}(1)_{\lfloor n/k\rfloor}}{(2\lambda)_{\lceil n/k\rceil}(\lambda+1)_{\lfloor n/k\rfloor}}, \tag{1.27}$$

and

$$w_2(x)=(1-x^2)^{\lambda+1/2}|U_{k-1}(x)|^{2\lambda},\qquad h_{n,2}=\frac{(\lambda+1)_{\lfloor n/k\rfloor}(2\lambda+1)_{\lfloor (n+1)/k\rfloor}}{2(1)_{\lfloor n/k\rfloor}(\lambda+1)_{\lfloor (n+1)/k\rfloor}}. \tag{1.28}$$

For proofs, see Askey and Shukla [5], Charris and Ismail [8] and Ismail [14].

This paper is part of a series of papers on sieved orthogonal polynomials, [8], [14]-[16]. In this part, we thoroughly investigate a sieved analogue of the Pollaczek polynomials. We start with an analogue of the continuous q-ultraspherical polynomials. The appropriate analogue is

$$\begin{cases} F_0(x)=1, \quad F_1(x)=2[(1-\Delta U)x+V]/(1-q),\\ (1-q^{n+1})F_{n+1}(x)=2[(1-U\Delta q^n)x+Vq^n]F_n(x)-(1-\Delta^2q^{n-1})F_{n-1}(x), \end{cases} \tag{1.29}$$

$$n>0.$$

We shall also use $F_n(x;U,V,\Delta;q)$ instead of $F_n(x)$ if we need to exhibit the dependence on the parameters U, V, Δ and q. In § 3 we obtain generating functions for $\{F_n(x)\}$ and $\{F_n^*(x)\}$. We then take

$$U=s^{ka},\quad V=\omega s^k(1-s^{kb}),\quad \Delta=\omega s^{k\lambda+1},\quad q=s\omega, \tag{1.30}$$

and let $s\to 1$. Set

$$B_n^\lambda(x;a,b;k)=\lim_{s\to 1}F_n(x;s^{ka},\omega s^k(1-s^{kb}),\omega s^{k\lambda+1};s\omega). \tag{1.31}$$

Writing $B_n^\lambda(x)$ for $B_n^\lambda(x;a,b;k)$ we get

$$B_0^\lambda(x)=1,\qquad B_1^\lambda(x)=2x, \tag{1.32}$$

and

$$\begin{cases} B_{n+1}^\lambda(x)=2xB_n^\lambda(x)-B_{n-1}^\lambda(x), \qquad k\nmid n+1,\\ mB_{mk}^\lambda(x)=2[(m+\lambda+a)x+b]B_{mk-1}^\lambda(x)-(2\lambda+m)B_{mk-2}^\lambda(x), \qquad m>0. \end{cases} \tag{1.33}$$

These are the sieved Pollaczek polynomials of the second kind. The case $b=0$ is in [14] when $\lambda>0$. Generating functions for the B_n^λ's and their numerators follow from the generating functions for the F_n's and F_n^*'s. This is also done in § 3. The q-binomial theorem

$$\frac{(az;q)_\infty}{(z;q)_\infty}=\sum_{n=0}^{\infty}\frac{(a;q)_n}{(q;q)_n}z^n \tag{1.34}$$

(Slater [28, p. 248]) will be used. The asymptotic behavior of $B_n^\lambda(x)$ and $B_n^{*\lambda}(x)$ are determined and the continued fraction whose numerators are $\{B_n^{*\lambda}(x)\}$ and denominators are $\{B_n^\lambda(x)\}$ is computed. Also, in § 4 analogous results are obtained for the sieved Pollaczek polynomials of the first kind which arise as follows. Let $\{G_n(x; U, V, \Delta; q)\}$ or simply $\{G_n(x)\}$ be

$$G_n(x)=\frac{(q;q)_nF_n(x)}{(\Delta^2;q)_n}. \tag{1.35}$$

The G_n's satisfy $G_0(x)=1$, $G_1(x)=2[(1-\Delta U)x+V]/(1-\Delta^2)$ and

$$(1-\Delta^2q^n)G_{n+1}(x)=2[(1-\Delta Uq^n)x+Vq^n]G_n(x)-(1-q^n)G_{n-1}(x), \qquad n>0. \tag{1.36}$$

Now let

$$U=s^{ka}, \quad V=s^k(1-s^{kb}), \quad \Delta=s^{k\lambda}, \quad q=s\omega, \tag{1.37}$$

and define the sieved Pollaczek polynomials of the first kind by

$$c_n^\lambda(x; a, b; k)=\lim_{s\to1} G_n(x; s^{ka}, s^k(1-s^{kb}), s^{k\lambda}; \omega s).$$

They satisfy

$$c_0^\lambda(x; a, b; k)=1, \qquad c_1^\lambda(x; a, b; k)=x, \tag{1.38}$$

and

$$\begin{cases} c_{n+1}^\lambda(x; a, b; k)=2xc_n^\lambda(x; a, b; k)-c_{n-1}^\lambda(x; a, b; k), & k\nmid n \\ (m+2\lambda)c_{mk+1}^\lambda(x; a, b; k)=2[x(m+a+\lambda)+b]c_{mk}^\lambda(x; a, b; k) \\ \qquad\qquad -mc_{mk-1}^\lambda(x; a, b; k), \end{cases} \tag{1.39}$$

for $m>0$. The distribution functions of both polynomials are determined in §§ 4 and 5. It turns out that the discrete spectrum (the closure of the isolated points of discontinuity of $\psi(x)$) is very hard to determine in this generality. The orthogonality relations are stated explicitly at the end of § 5. Section 2 contains a brief survey of the Hadamard integral, a very important technique in determining the leading term in the singular part of a complex valued function defined as a definite integral. This technique is used in §§ 4 and 5. In § 6, we treat the general Pollaczek polynomials. This is achieved by letting $k=1$ in our results on the sieved Pollaczek polynomials of the first kind. The measure that the q-Pollaczek polynomials $\{F_n(x)\}$ are orthogonal with respect to is also found in § 6.

The asymptotic formula

$$\frac{\Gamma(a+n)}{\Gamma(b+n)}\sim n^{a-b} \quad \text{as } n\to\infty \tag{1.40}$$

and the Chu-Vandermonde sum (Rainville [26, p. 69])

$${}_2F_1\left(\left.\begin{matrix}-n, b\\ c\end{matrix}\right|1\right)=\frac{(c-b)_n}{(c)_n} \tag{1.41}$$

will be used in the sequel. In § 5 we shall need the following lemma (Shohat and Tamarkin [27, pp. 45-46]).

LEMMA 1.3. *Let $\{P_n(x)\}$ be an orthonormal polynomial set and assume that the associated moment problem is determined. The corresponding distribution function has a jump at $x=\xi$ if and only if*

$$\sum_0^\infty |P_n(\xi)|^2<\infty. \tag{1.42}$$

2. The Hadamard integral. In this section we study some basic properties of the (simple) Hadamard integral (Hadamard [13]).

We say that an open subset Ω of the complex plane is a branched neighborhood of b if Ω contains a set of the form $D-R_b$, where D is an open disc such that $b\in\bar{D}$ and R_b is a half-line emanating at b and not bisecting D. We will usually assume that Ω is simply connected. Clearly, any open disc is a branched neighborhood of its boundary points. If D is the unit disc, $D-[0,\infty)$ is a branched neighborhood of 0.

Let Ω be a simply connected branched neighborhood of b and assume that ρ is a complex number which is not a negative integer, that $(t-b)^\rho$ is defined in Ω and that $g(t)$ is an analytic function having a power series development $\sum_{n=0}^\infty a_n(b-t)^n$ around b which holds in a neighborhood of $\Omega\cup\{b\}$. We define the Hadamard integral

$$\int_z^{\overline{b|}} (b-t)^\rho g(t)\,dt, \qquad z\in\Omega,$$

by the formula

$$\int_z^{\overline{b|}} (b-t)^\rho g(t)\,dt=\sum_{n=0}^\infty \frac{a_n}{\rho+n+1}(b-z)^{\rho+n+1}. \tag{2.1}$$

It is clear that when $\operatorname{Re}(\rho)>-1$, then

$$\int_z^{\overline{b|}} (b-t)^\rho g(t)\,dt=\int_z^b (b-t)^\rho g(t)\,dt, \tag{2.2}$$

where the integral on the right side is over any curve in Ω joining z and b.

More generally, if Ω' is a simply connected open set containing Ω, and g is analytic in Ω' and has a power series expansion around b which holds in a neighborhood of $\Omega\cup\{b\}$, we define

$$\int_a^{\overline{b|}} (b-t)^\rho g(t)\,dt=\int_a^z (b-t)^\rho g(t)\,dt+\int_z^{\overline{b|}} (b-t)^\rho g(t)\,dt, \qquad a\in\Omega', \tag{2.3}$$

where $z\in\Omega$. Furthermore

$$\int_{\underline{|b}}^a (b-t)^\rho g(t)\,dt=-\int_a^{\overline{b|}} (b-t)^\rho g(t)\,dt. \tag{2.4}$$

If Ω is also a branched neighborhood of a and Ω' is a neighborhood of $\Omega\cup\{a\}$, we define, for $g(t)$ analytic in Ω' and $\rho,\sigma\neq-1,-2,\cdots$,

$$\begin{aligned}\int_{\underline{|a}}^{\overline{b|}} (t-a)^\sigma(b-t)^\rho g(t)\,dt&=\int_{\underline{|a}}^z (t-a)^\sigma(b-t)^\rho g(t)\,dt\\&\quad+\int_z^{\overline{b|}} (t-a)^\sigma(b-t)^\rho g(t)\,dt,\end{aligned} \tag{2.5}$$

where z is any point in Ω'.

The integral $\int_{\underline{|a}}^{\overline{b|}} (t-a)^\sigma(b-t)^\rho g(t)\,dt$ is an extension of the integral $\int_a^b (t-a)^\sigma(b-t)^\rho g(t)\,dt$ from the proper cases $\operatorname{Re}(\sigma)>-1$, $\operatorname{Re}(\rho)>-1$ to the case $\sigma,\rho\neq-1,-2,-3,\cdots$.

The definition of the Hadamard integral can be extended to a function $f(t)$ of the form

$$f(t)=\sum_{n=0}^{\infty} C_n(b-t)^{\rho+n}, \qquad t\in\Omega. \tag{2.6}$$

Let g satisfy the same assumptions as in (2.3). We now define the extended Hadamard integral by

$$\int_a^{\overline{b|}} f(t)g(t)\,dt=\sum_{n=0}^{N} C_n\int_a^{\overline{b|}}(b-t)^{\rho+n}g(t)\,dt+\int_a^b h(t)g(t)\,dt, \tag{2.7}$$

where

$$h(t)=\sum_{n=N+1}^{\infty} C_n(b-t)^{\rho+n}$$

and $\operatorname{Re}(\rho+n)>-1$ for $n>N$. Functions defined by (2.6) are said to have an algebraic branch singularity at $t=b$. When f is given by (2.6), Ω is a branched neighborhood of a, and

$$g(t)=\sum_{n=0}^{\infty} a_n(t-a)^{\sigma+n} \tag{2.8}$$

with $\operatorname{Re}(\sigma)\neq -1,-2,\cdots$, we define

$$\int_{\underline{|a}}^{\overline{b|}} f(t)g(t)\,dt=\int_{\underline{|a}}^{z} f(t)g(t)\,dt+\int_z^{\overline{b|}} f(t)g(t)\,dt, \qquad z\in\Omega'. \tag{2.9}$$

It is not difficult to prove the following.

THEOREM 2.1. *Let f be an analytic function in the simply connected branched neighborhood Ω of the point b, and assume that f has an algebraic branch singularity at b. Let $\{g_n\}$ be a sequence of analytic functions in a neighborhood Ω' of $\Omega\cup\{b\}$ converging uniformly to zero on compact subsets of Ω'. Then, for all $a\in\Omega'$ we have*

$$\lim_{n\to\infty}\int_a^{\overline{b|}} f(t)g_n(t)\,dt=0.$$

COROLLARY 2.2. *Let f, Ω, $\{g_n\}$ and Ω' be as in Theorem 2.1 but assume that $\{g_n\}$ converges to g on compact sets. Then*

$$\lim_{n\to\infty}\int_a^{\overline{b|}} f(t)g_n(t)\,dt=\int_a^{\overline{b|}} f(t)g(t)\,dt. \tag{2.10}$$

COROLLARY 2.3. *Let f, Ω, Ω' be as in the theorem, and assume that*

$$g(t)=\sum_{n=0}^{\infty} a_n(t-a)^n \tag{2.11}$$

holds for $a\in\Omega$ and all $t\in\Omega'$. Then

$$\int_a^{\overline{b|}} f(t)g(t)\,dt=\sum_{n=0}^{\infty} a_n\int_a^{\overline{b|}} f(t)(t-a)^n\,dt. \tag{2.12}$$

Since uniform convergence on compact subsets is sometimes difficult to check, the following corollary is often useful.

COROLLARY 2.4. *Let f, Ω, Ω', $\{g_n\}$ and g be as in Theorem* 2.1, *but assume only that $\{g_n\}$ is uniformly bounded on compact subsets of Ω' and that $\{g_n(t)\}$ converges to $g(t)$ for each t in a subset S of Ω' having a limit point in Ω'. Then*

$$\lim_{n\to\infty}\int_a^{\overline{b}\rceil} f(t)g_n(t)\,dt=\int_a^{\overline{b}\rceil} f(t)g(t)\,dt. \tag{2.13}$$

We now study Hadamard integrals of functions that will arise in this work. These integrals are related to certain analytic functions in the cut plane $\mathbb{C}-[-1,1]$ that we will now introduce.

Let $\sqrt{z+1}$ be the branch of the square root of $z+1$ in $\mathbb{C}-(-\infty,-1]$ that makes $\sqrt{z+1}>0$ if $z>-1$, and $\sqrt{z-1}$ be the branch of the square root of $z-1$ in $\mathbb{C}-(-\infty,1]$ with $\sqrt{z-1}>0$ for $z>1$. Both $\sqrt{z+1}$ and $\sqrt{z-1}$ are single valued in the cut plane $\mathbb{C}-(-\infty,1]$. Let

$$\tau(z)=\sqrt{z+1}\sqrt{z-1},\qquad z\in\mathbb{C}-(-\infty,1]. \tag{2.14}$$

Observe that when $x<-1$ we have

$$\lim_{\substack{y\to0\\ y>0}}\sqrt{x+iy+1}\,\sqrt{x+iy-1}=i\sqrt{-x-1}\cdot i\sqrt{-x+1}=-\sqrt{x^2-1} \tag{2.15}$$

and

$$\lim_{\substack{y\to0\\ y<0}}\sqrt{x+iy+1}\,\sqrt{x+iy-1}=(-i\sqrt{-x-1})\cdot(-i\sqrt{-x+1})=-\sqrt{x^2-1}. \tag{2.16}$$

We now extend τ, by continuity, to the cut plane $\mathbb{C}-[-1,1]$. In order to do so we define

$$\tau(z)=-\sqrt{z^2-1},\qquad z<-1. \tag{2.17}$$

Clearly, $\tau(z)$ is analytic in $\mathbb{C}-[-1,1]$. In what follows we shall simply write

$$\tau(z)=\sqrt{z^2-1}. \tag{2.18}$$

We now define the following analytic functions in $\mathbb{C}-[-1,1]$

$$\alpha(z)=z+\tau(z)=z+\sqrt{z^2-1},\qquad \beta(z)=z-\tau(z)=z-\sqrt{z^2-1} \tag{2.19}$$

and

$$A(z)=-\lambda+\frac{az+b}{\tau(z)}=-\lambda+\frac{az+b}{\sqrt{z^2-1}},\qquad B(z)=-\lambda-\frac{az+b}{\tau(z)}=-\lambda-\frac{az+b}{\sqrt{z^2-1}}. \tag{2.20}$$

Here, a, b, λ are real numbers and

$$\lambda>-\tfrac{1}{2}, \tag{2.21}$$

$$a-\lambda\neq0,1,2,\cdots. \tag{2.22}$$

We note that

$$\alpha(x)=x+\sqrt{x^2-1},\qquad \beta(x)=x-\sqrt{x^2-1}\quad \text{if } x>1, \tag{2.23}$$

$$\alpha(x)=x-\sqrt{x^2-1},\qquad \beta(x)=x+\sqrt{x^2+1}\quad \text{if } x<-1, \tag{2.24}$$

$$A(x)=-\lambda\pm\frac{ax+b}{\sqrt{x^2-1}},\qquad B(x)=-\lambda\mp\frac{ax+b}{\sqrt{x^2-1}},\qquad \pm x>1, \tag{2.25}$$

$$\lim_{y\to0\pm}\tau(x+iy)=\pm i\sqrt{1-x^2},\qquad -1\leqq x\leqq1. \tag{2.26}$$

The following functions are continuous on their domain of definition

$$\tau_+(x+iy)=\begin{cases}\tau(x+iy), & y>0, \quad \tau(x), \quad |x|>1, \quad y=0,\\ i\sqrt{1-x^2}, & |x|\leqq 1, \quad y=0,\end{cases} \tag{2.27}$$

$$\tau_-(x+iy)=\begin{cases}\tau(x+iy), & y<0, \quad \tau(x), \quad |x|>1, \quad y=0,\\ -i\sqrt{1-x^2}, & |x|\leqq 1, \quad y=0,\end{cases} \tag{2.28}$$

$$\alpha_\pm(z)=z+\tau_\pm(z), \qquad \beta_\pm(z)=z-\tau_\pm(z), \tag{2.29}$$

$$A_\pm(z)=-\lambda+\frac{az+b}{\tau_\pm(z)}, \qquad \beta_\pm(z)=-\lambda-\frac{az+b}{\tau_\pm(z)}. \tag{2.30}$$

Observe that for $-1\leqq x\leqq 1$ we have

$$\alpha_-(x)=\overline{\beta_+(x)}, \qquad \overline{\beta_-(x)}=\alpha_+(x), \tag{2.31}$$

and

$$A_-(x)=\overline{B_+(x)}, \qquad \overline{B_-(x)}=A_+(x). \tag{2.32}$$

To simplify the notation we will write when $-1<x<1$

$$\alpha_+(x)=\alpha(x), \quad \beta_+(x)=\beta(x); \quad A_+(x)=A(x), \quad B_+(x)=B(x). \tag{2.33}$$

The following elementary result will be very useful.

LEMMA 2.5. *For each z in $\mathbb{C}$, $\alpha(z)$ and $\beta(z)$ are the solutions of the equation*

$$t^2-2zt+1=0 \tag{2.34}$$

that satisfy

$$\alpha(z)+\beta(z)=2z, \quad \alpha(z)-\beta(z)=2\tau(z)=2\sqrt{z^2-1}, \quad \alpha(z)\beta(z)=1. \tag{2.35}$$

Furthermore, $|\beta(z)|\leqq|\alpha(z)|$, with $|\alpha(z)|=|\beta(z)|$ if and only if $-1\leqq z\leqq 1$.

Now let

$$\Omega=\{z\notin[-1,1]\colon B(z)\neq 1,2,\cdots\}, \qquad \Omega^*=\{z\notin[-1,1]\colon B(z)\neq 0,1,\cdots\}. \tag{2.36}$$

LEMMA 2.6. *For $z\in\Omega$ (respectively $z\in\Omega^*$) and all integers $n\geqq 0$,*

$$\int_0^1(1-u)^{-B(z)}u^n\,du=\frac{n!}{(-B+1)_{n+1}}, \qquad z\in\Omega, \tag{2.37}$$

$$\int_0^1(1-u)^{-B(z)-1}u^n\,du=\frac{n!}{(-B)_{n+1}}, \qquad z\in\Omega^*. \tag{2.38}$$

The next theorem gives a series expansion for a Hadamard integral.

THEOREM 2.7. *For every $z\in\Omega$, define $F(z)$ by*

$$F(z)=\int_0^1\left(1-\frac{\beta^k}{\alpha^k}u\right)^{-A(z)-1}(1-u)^{-B(z)}\,du. \tag{2.39}$$

Then

$$F(z)=\sum_{n=0}^{\infty}\frac{(A+1)_n}{(-B+1)_{n+1}}\left(\frac{\beta^k}{\alpha^k}\right)^n \tag{2.40}$$

and is analytic in Ω.

We observe that

$$F(z)=\frac{-1}{B-1}{}_2F_1\left(\begin{matrix}A+1,1\\-B+2\end{matrix}\,\middle|\,\frac{\beta^k}{\alpha^k}\right). \tag{2.41}$$

For points in Ω^* Theorem 2.7 takes the following form.

THEOREM 2.8. *For each $z\in\Omega^*$, let*

$$G(z)=\int_0^{\rceil 1}\left(1-\frac{\beta^k}{\alpha^k}u\right)^{-A-1}(1-u)^{-B-1}\,du. \tag{2.42}$$

Then the function $G(z)$ is analytic in Ω^* and is given by

$$G(z)=-\frac{1}{B}\sum_{n=0}^{\infty}\frac{(A+1)_n}{(-B+1)_n}\left(\frac{\beta^k}{\alpha^k}\right)^n=-\frac{1}{B}{}_2F_1\left(\begin{matrix}A+1,1\\-B+1\end{matrix}\,\middle|\,\frac{\beta^k}{\alpha^k}\right). \tag{2.43}$$

The next theorem relates a Hadamard beta integral to an ordinary beta integral.

THEOREM 2.9. *For $-1<x<1$, we have*

$$\int_{\lfloor 0}^{\rceil 1}(1-u)^{-B(x)-1}u^{-A(x)-1}\,du=\frac{\Gamma(-A(x))\Gamma(-B(x))}{\Gamma(2\lambda)},\qquad \lambda\neq 0, \tag{2.44}$$

and

$$\int_{\lfloor 0}^{\rceil 1}(1-u)^{-B(x)}u^{-A(x)-1}\,du=\frac{\Gamma(-B(x)+1)\Gamma(-A(x))}{\Gamma(2\lambda+1)}. \tag{2.45}$$

Proof. Note in the first place that $-A-B=2\lambda$. We shall only give a proof of (2.44) because (2.45) can be proved similarly. When $-1<x<1$, we have

$$A(x)=-\lambda-i\frac{ax+b}{\sqrt{1-x^2}},\qquad B(x)=-\lambda+i\frac{ax+b}{\sqrt{1-x^2}}, \tag{2.46}$$

so that $\operatorname{Re}(A(x))=\operatorname{Re}(B(x))=-\lambda$. If $\lambda>0$, (2.44) and (2.45) are just the beta integral. Now, assume $-\frac{1}{2}<\lambda<0$ and $0<z<1$. Clearly

$$\int_{\lfloor 0}^{\rceil 1}(1-u)^{-B-1}u^{-A-1}\,du=\int_{\lfloor 0}^{z}(1-u)^{-B-1}u^{-A-1}\,du+\int_{z}^{\rceil 1}(1-u)^{-B-1}u^{-A-1}\,du. \tag{2.47}$$

By the definition of the Hadamard integral,

$$\int_{\lfloor 0}^{z}(1-u)^{-B-1}u^{-A-1}\,du=z^{-A}\sum_{n=0}^{\infty}\frac{(B+1)_n}{n!}\cdot\frac{z^n}{n-A}. \tag{2.48}$$

For the time being we let λ be a complex number in the domain U given by $\operatorname{Re}(\lambda)>-\frac{1}{2}$, $\lambda\neq 0$. Then, the right side of (2.44) is an analytic function of λ in this domain, and an argument based on (2.48) shows that

$$f(\lambda)=\int_0^z(1-u)^{-B-1}u^{-A-1}\,du$$

is analytic in U. On the other hand,

$$g(\lambda)=\int_z^{\rceil 1}(1-u)^{-B-1}u^{-A-1}\,du=\int_{\lfloor 0}^{1-z}u^{-B-1}(1-u)^{-A-1}\,du$$

is also analytic in U. Since, from (2.47),

$$f(\lambda)+g(\lambda)=\frac{\Gamma(-A)\Gamma(-B)}{\Gamma(2\lambda)}$$

for $\operatorname{Re}(\lambda) > 0$, the above equality also holds in U and, in particular, for $-\frac{1}{2} < \lambda < 0$. This completes the proof of the theorem.

3. Generating functions and asymptotics. We first evaluate the generating function

$$F(x, t) = \sum_{n=0}^{\infty} F_n(x; U, V, \Delta; q) t^n. \tag{3.1}$$

Multiply (1.29) by t^{n+1}, $n = 1, 2, \cdots$, and add the resulting equations to obtain the q-difference equation

$$(t^2 - 2tx + 1) F(x, t) = [\Delta^2 t^2 - 2(U\Delta x - V)t + 1] F(x, qt). \tag{3.2}$$

Now, $\alpha(x)$, $\beta(x)$, as given by (2.19) are roots of

$$t^2 - 2xt + 1 = (1 - t/\alpha)(1 - t/\beta). \tag{3.3}$$

The roots of $\Delta^2 t^2 - 2(U\Delta x - V)t + 1 = 0$ are

$$\xi(x) = \frac{(U\Delta x - V) + \sqrt{(U\Delta x - V)^2 - \Delta^2}}{\Delta^2}, \quad \zeta(x) = \frac{(U\Delta x - V) - \sqrt{(U\Delta x - V)^2 - \Delta^2}}{\Delta^2}. \tag{3.4}$$

Clearly

$$\xi(x)\zeta(x) = \frac{1}{\Delta^2}, \qquad \Delta^2 t^2 - 2(U\Delta x - V)t + 1 = (1 - t/\xi)(1 - t/\xi). \tag{3.5}$$

Iteration of (3.2) gives the functional equation

$$F(x, t) = \frac{(t/\xi; q)_n (t/\zeta; q)_n}{(t/\alpha; q)_n (t/\beta; q)_n} F(x, q^n t), \tag{3.6}$$

whose solution, since $F(x, tq^n) \to F(x, 0) = 1$ as $n \to \infty$, is

$$F(x, t) = \frac{(t/\xi; q)_\infty (t/\zeta; q)_\infty}{(t/\alpha; q)_\infty (t/\beta; q)_\infty}. \tag{3.7}$$

We now determine the generating function of $\{F_n^*(x)\}$, namely

$$F^*(x, t) = \sum_{n=0} F_n^*(x) t^n.$$

In this case, $F^*(x; q^n t^n) \to 0$ as $n \to \infty$, since $F_0^*(x) = 0$.

Replace the F_n's in (1.29) by F_n^*'s then multiply by t^{n+1}, $n = 1, 2, \cdots$ and add to get

$$F^*(x, t) = \frac{2(1 - U\Delta)t}{(1 - t/\alpha)(1 - t/\beta)} + \frac{(1 - t/\xi)(1 - t/\zeta)}{(1 - t/\alpha)(1 - t/\beta)} F^*(x, qt), \tag{3.8}$$

where α, β are as in (3.3) and ξ, ζ as in (3.4). Iterating (3.8) gives

$$F^*(x, t) = 2t(1 - U\Delta) \sum_{n=0}^{\infty} \frac{(t/\xi; q)_n (t/\zeta; q)_n}{(t/\alpha; q)_{n+1} (t/\beta; q)_{n+1}} q^n. \tag{3.9}$$

The generating function (3.9) can be written in the form

$$F^*(x, t) = 2t(1 - U\Delta) F(x, t) \sum_{n=0}^{\infty} \frac{(q^{n+1} t/\alpha; q)_\infty (q^{n+1} t/\beta; q)_\infty}{(q^n t/\xi; q)_\infty (q^n t/\zeta; q)_\infty} q^n.$$

The q-binomial theorem (1.34) implies

$$F^*(x,t)=2t(1-u\Delta)F(x,t)\sum_{m,j=0}^{\infty}\frac{(q\xi/\alpha;q)_j(q\zeta/\beta;q)_m}{(q;q)_j(q;q)_m}\left(\frac{t}{\xi}\right)^j\left(\frac{t}{\zeta}\right)^m\sum_{n=0}^{\infty}q^{(m+j+1)n}.$$

Therefore,

$$\begin{aligned}F^*(x,t)=2tF(x,t)&\sum_{m,j=0}^{\infty}\frac{(q^2\xi/\alpha;q)_j(q^2\zeta/\beta;q)_m}{(q;q)_j(q;q)_m}\left(\frac{t}{\xi}\right)^j\left(\frac{t}{\zeta}\right)^m\\&\cdot\frac{(1-\xi q/\alpha)}{(1-\xi q^{j+1}/\alpha)}\frac{(1-\zeta q/\beta)}{(1-\zeta q^{j+1}/\beta)}\frac{1-U\Delta}{(1-q^{m+j+1})}.\end{aligned}\tag{3.10}$$

We obtain a generating function for the B_n^λ's by taking

$$U=s^{ka},\quad V=\omega s^k(1-s^{kb}),\quad \Delta=\omega s^{k\lambda+1},\quad q=s\omega,\tag{3.11}$$

and letting $s\to 1$ in (3.7). Let

$$B^\lambda(x,t)=\sum_{n=0}^{\infty}B_n^\lambda(x)t^n=\lim_{s\to 1}F(x,t),\tag{3.12}$$

where U, V, Δ, q are given as in (3.11).

The q-binomial theorem (1.34) yields

$$\frac{(t/\xi;q)_\infty}{(t/\alpha;q)_\infty}=\sum_{n=0}^{\infty}\frac{(\alpha/\xi;q)_n}{(q;q)_n}\left(\frac{t}{\alpha}\right)^n.$$

We write

$$\frac{(\alpha/\xi;q)_n}{(q;q)_n}=\prod_{j=0}^{n-1}\frac{1-q^j\alpha/\xi}{1-q^{j+1}},$$

and examine the behavior as $s\to 1$ of each factor in the above product. Set

$$\eta(s):=\omega(xs^{k\lambda+ka+1}-s^k(1-s^{kb})).\tag{3.13}$$

It is easy to see that when Δ is given by (3.11)

$$\xi=\frac{\eta(s)+\sqrt{\eta^2(s)-\Delta^2}}{\Delta^2},\qquad \zeta=\frac{\eta(s)-\sqrt{\eta^2(s)-\Delta^2}}{\Delta^2}.\tag{3.14}$$

When $s\to 1$, $\eta(s)\to\eta(1)=\omega x$ and $\alpha/\xi\to\omega$. Hence, if $k\nmid j+1$, we obtain

$$\lim_{s\to 1}\frac{1-q^j\alpha/\xi}{1-q^{j+1}}=\frac{1-\omega^{j+1}}{1-\omega^{j+1}}=1.\tag{3.15}$$

We now consider the case $k|j+1$. Let

$$f_j(s):=q^j\alpha/\xi,\qquad j=0,\pm1,\pm2,\cdots,\tag{3.16}$$

i.e.,

$$f_j(s)=\alpha q^j\Delta^2\zeta=\alpha\omega^js^j[\eta(s)-\sqrt{\eta(s)^2-\Delta^2}],\qquad f_j(1)=1.$$

Then

$$f_j'(s)=\alpha j\omega^js^{j-1}[\eta(s)-\sqrt{\eta(s)^2-\Delta^2}]+\alpha\omega^js^j\left[\eta'(s)-\frac{\eta(s)\eta'(s)-\Delta\Delta'}{\sqrt{\eta(s)^2-\Delta^2}}\right],$$

so that

$$f_j'(1)=j+\alpha\omega^j\left[\eta'(1)-\frac{\eta(1)\eta'(1)-\Delta(1)\Delta'(1)}{\sqrt{\eta(1)^2-\Delta(1)^2}}\right].$$

Since $\eta(1)=\omega x$, $\Delta(1)=\omega$ and $\Delta'(1)=\omega(k\lambda+1)$, we have

$$f_j'(1)=j+\alpha\omega^j\frac{\eta'(1)(-\beta)+(k\lambda+1)\omega}{\sqrt{x^2-1}}$$

$$=j-\frac{\omega^j[\eta'(1)-(k\lambda+1)\alpha\omega]}{\sqrt{x^2-1}}.$$

It is easy to see that $\eta'(1)=\omega[(k\lambda+ka+1)x+bk]$ and

(3.17) $$f_j'(1)=k\lambda+j+1-k\frac{ax+b}{\sqrt{x^2-1}},\qquad k|j+1.$$

If $g_j(s)=\omega^{j+1}s^{j+1}$, $j=0,\pm1,\pm2,\cdots$,

$$g_j'(s)=(j+1)\omega^{j+1}s^j,\qquad g_j'(1)=(j+1)\omega^{j+1}.$$

When $k|j+1$, this yields

$$\lim_{s\to1}\frac{1-q^j\alpha/\xi}{1-q^{j+1}}=\frac{f_j'(1)}{g_j'(1)}=\frac{-A(x)+m}{m},\qquad j+1=km,$$

where $A(x)$ is given by (2.20). Similarly

(3.18) $$\lim_{s\to1}\frac{1-q^j\beta/\zeta}{1-q^{j+1}}=\frac{-B(x)+m}{m},\qquad j+1=km,$$

with $B(x)$ given by (2.20). Hence, using the q-binomial theorem, we get

$$\lim_{s\to1}(t/\xi;q)_\infty/(t/\alpha;q)_\infty=\lim_{s\to1}\sum_{\substack{0\le l<k\\ m\ge0}}\frac{(\alpha/\xi;q)_{mk+l}}{(q;q)_{mk+l}}\left(\frac{t}{\alpha}\right)^{mk+l}$$

$$=\sum_{m=0}^{\infty}\frac{(-A+1)_m}{m!}\left(\frac{t}{\alpha}\right)^{mk}\sum_{l=0}^{k-1}\left(\frac{t}{\alpha}\right)^l$$

$$=\sum_{m=0}^{\infty}\frac{(-A+1)_m}{m!}\left(\frac{t}{\alpha}\right)^{mk}\frac{1-(t/\alpha)^k}{1-t/\alpha},$$

so that

$$\lim_{s\to1}(t/\xi;q)_\infty/(t/\alpha;q)_\infty=(1-t/\alpha)^{-1}(1-t^k/\alpha^k)^A.$$

Similarly

$$\lim_{s\to1}(t/\zeta;q)_\infty/(t/\beta;q)_\infty=(1-t/\beta)^{-1}(1-t^k/\beta^k)^B;$$

hence for $x\in C$ and $|t|<|\beta(x)|$ we have

(3.19) $$B^\lambda(x,t)=(1-2xt+t^2)^{-1}(1-t^k/\alpha^k)^A(1-t^k/\beta^k)^B.$$

We now proceed to similarly evaluate the generating function

(3.20) $$B^{*\lambda}(x,t)=\sum_{n=0}^{\infty}B_n^{*\lambda}(x)t^n=\lim_{s\to1}F^*(x,t),$$

with U, V, Δ, q as given by (3.11) and $F^{\lambda}(x, t)$ is as in (3.10). Clearly

$$\lim_{s\to 1}\frac{1-q^{r+1}\xi/\alpha}{1-q^{r}}=\lim_{s\to 1} q\xi/\alpha\,\frac{1-q^{-r-1}\alpha/\xi}{1-q^{-r}}=\lim_{s\to 1}\frac{1-q^{-r-1}\alpha/\xi}{1-q^{-r}}$$

$$=1 \text{ or } \frac{f'_{-r-1}(1)}{g'_{-r-1}(1)}, \quad \text{accordingly as } k\nmid r \text{ or } k\mid r.$$

Here, f_j, g_j are as before. Hence

$$\lim_{s\to 1}\frac{1-q^{r+1}\xi/\alpha}{1-q^{r}}=\frac{A+r/k}{r/k} \text{ or } 1 \quad \text{if } k\mid r \text{ or } k\nmid r. \tag{3.21}$$

Similarly

$$\lim_{s\to 1}\frac{1-q^{r+1}\xi/\beta}{1-q^{r}}=\frac{B+r/k}{r/k} \text{ or } 1 \quad \text{if } k\mid r \text{ or } k\nmid r. \tag{3.22}$$

On the other hand,

$$\lim_{s\to 1}(1-q\xi/\alpha)/(1-q^{1+kr}\xi/\alpha)=\lim_{s\to 1}(1-q^{-1}\alpha/\xi)/(1-q^{-1-kr}\alpha/\xi)$$

and (3.16) imply

$$\lim_{s\to 1}\frac{1-q\xi/\alpha}{1-q^{1+kr}\xi/\alpha}=\frac{f'_{-1}(1)}{f'_{-1-kr}(1)}=\frac{A}{A+r}, \tag{3.23}$$

and similarly

$$\lim_{s\to 1}\frac{1-q\zeta/\beta}{1-q^{1+kr}\zeta/\beta}=\frac{B}{B+r}. \tag{3.24}$$

Clearly

$$\lim_{s\to 1}\frac{1-\xi q/\alpha}{1-q^{m+j+1}}=0 \text{ or } \frac{1}{m+j+1} \quad \text{if } k\nmid m+j+1 \text{ or } k\mid m+j+1,$$

$$\lim_{s\to 1}\frac{1-U\Delta}{1-\xi/\alpha q^{j+1}}=\frac{1-\omega}{1-\omega^{l}} \quad \text{if } j=ks+l, \quad 0<l<k,$$

and

$$\lim_{s\to 1}\frac{1-U\Delta}{1-\zeta/\beta q^{m+1}}=\frac{1-\omega}{1-\omega^{l}} \quad \text{if } m=kr+l, \quad 0<l<k,$$

imply that the summands in (3.10) vanish except in three cases:

(I) $k\mid j$ and $k\mid m$,
(II) $k\mid j$ and $k\mid j+m+1$,
(III) $k\mid m$ and $k\mid j+m+1$.

Since in case (I) $(1-U\Delta)/(1-q^{m+j+1})\to 1$ as $s\to 1$ we get

$$\lim_{s\to 1}\frac{F^{*}}{F}=\Sigma_1(x)+\Sigma_2(x)+\Sigma_3(x), \tag{3.25}$$

where k, j belong to case (I), (II), (III), respectively, in $\Sigma_1, \Sigma_2, \Sigma_3$. Using (3.21), (3.22), (3.23) and (3.24), we obtain

$$(3.26)\qquad \begin{cases} \Sigma_1(x)=2t(1-t^k/\alpha^k)^{-A}(1-t^k/\beta^k)^{-B}, \\ \Sigma_2(x)=-2t^k\alpha^{k-1}B\displaystyle\sum_{j,m}\frac{(A)_j}{j!}\frac{(B+1)_m}{m!}\left(\frac{t}{\alpha}\right)^{kj}\left(\frac{t}{\beta}\right)^{km}\frac{1}{j+m+1}, \\ \Sigma_3(x)=-2t^k\beta^{k-1}A\displaystyle\sum_{j,m}\frac{(A+1)_j}{j!}\frac{(B)_m}{m!}\left(\frac{t}{\alpha}\right)^{kj}\left(\frac{t}{\beta}\right)^{km}\frac{1}{j+m+1}. \end{cases}$$

Therefore

$$\begin{aligned} B^{*\lambda}(x,t)&=\frac{2t}{1-2xt+t^2}+2B^\lambda(x,t) \\ &\cdot\left\{(-B)\alpha^{k-1}\int_0^{t^k}\left(1-\frac{u}{\alpha^k}\right)^{-A}\left(1-\frac{u}{\beta^k}\right)^{-B-1}du\right. \\ &\left.+(-A)\beta^{k-1}\int_0^{t^k}\left(1-\frac{u}{\alpha^k}\right)^{-A-1}\left(1-\frac{u}{\beta^k}\right)^{-B}du\right\}. \end{aligned}$$

Integration by parts gives

$$\begin{aligned} B^{*\lambda}(x,t)&=\frac{2}{t-\alpha}+2B^\lambda(x,t) \\ &\cdot\left\{\beta+A\beta^k(\beta-\alpha)\int_0^{t^k}\left(1-\frac{u}{\alpha^k}\right)^{-A-1}\left(1-\frac{u}{\beta^k}\right)^{-B}du\right\}, \end{aligned}$$

which, after the change of variables $u=vt^k$, becomes

$$\begin{aligned} (3.27)\qquad B^{*\lambda}(x,t)&=\frac{2}{t-\alpha}+2B^\lambda(x,t) \\ &\cdot\left\{\beta+A(\beta-\alpha)\left(\frac{t}{\alpha}\right)^k\int_0^1\left(1-v\frac{t^k}{\alpha^k}\right)^{-A-1}\left(1-v\frac{t^k}{\beta^k}\right)^{-B}dv\right\}. \end{aligned}$$

This is an analytic function of x, t for all x in the cut plane $\mathbb{C}-[-1,1]$ and $|t|<|\beta(x)|$.

We now study the asymptotic behavior of $\{B_n^\lambda(x)\}$ and $\{B_n^{*\lambda}(x)\}$ for large n. We use Darboux's Method, Theorem 1.2. Let $x\in\mathbb{C}-[-1,1]$ be fixed. The generating function $B^\lambda(x,t)$, as given by (3.19), is an analytic function of t, for $|t|<|\beta(x)|$, and has an algebraic branch singularity of order $-B(x)+1$ at $\beta(x)$. The leading term in a comparison function is

$$\begin{aligned} \left(1-\frac{t}{\beta}\right)^{B-1}\lim_{t\to\beta}\frac{B^\lambda(x,t)}{(1-t/\beta)^{B-1}}&=\left(1-\frac{t}{\beta}\right)^{B-1}\left(1-\frac{\beta}{\alpha}\right)^{-1}\left(1-\left(\frac{\beta}{\alpha}\right)^k\right)^A\lim_{t\to\beta}\frac{(1-(t/\beta)^k)^B}{(1-t/\beta)^B} \\ &=k^B\left(1-\frac{\beta}{\alpha}\right)^{-1}\left(1-\frac{\beta^k}{\alpha^k}\right)^A\sum_{n=0}^{\infty}\frac{(-B+1)_n}{n!}\left(\frac{t}{\beta}\right)^n. \end{aligned}$$

Using (1.40) we obtain

$$(3.28)\qquad B_n^\lambda(x)\sim k^B\frac{\alpha}{\alpha-\beta}\left(1-\frac{\beta^k}{\alpha^k}\right)^A\frac{\beta^{-n}}{\Gamma(-B+1)}n^{-B},\qquad n\to\infty.$$

This formula gives the asymptotic behavior of the $B_n^\lambda(x)$'s for $x \in \mathbb{C}-[-1,1]$. For $-1 \leqq x \leqq 1$ then $|\alpha(x)|=|\beta(x)|$, and $\alpha(x), \beta(x)$ are both branched singularities of $B^\lambda(x,t)$. There is an additional difficulty. If $\operatorname{Re}(A)<0$ and $x=\xi_j$, where

$$\xi_j=\cos\left(\frac{j\pi}{k}\right), \qquad 0 \leqq j \leqq k, \tag{3.29}$$

then $(\beta/\alpha)^k=1$ (and also $\beta/\alpha=1$ if $j=0,k$), so that $(1-(\beta/\alpha)^k)^A$ is meaningless (also $(1-\beta/\alpha)^{-1}$ is meaningless if $j=0,k$). This makes it difficult to establish the asymptotic behavior of the $B_n^\lambda(x)$ at $x=\xi_j$. For the sake of completeness, we state the asymptotic behavior of $B_n^\lambda(x)$ for $x \neq \xi_j$, although we will not make any use of it. In § 6 we will study the asymptotic behavior at the points ξ_j.

Assume $x \neq \xi_j$, $j=0,1,2,\cdots,k$. Clearly

$$\begin{aligned} B_n^\lambda(x) &\sim k^B\frac{\alpha}{\alpha-\beta}\left(1-\left(\frac{\beta}{\alpha}\right)^k\right)^A\frac{\beta^{-n}}{\Gamma(-B+1)}n^{-B} \\ &+k^A\frac{\beta}{\beta-\alpha}\left(1-\left(\frac{\alpha}{\beta}\right)^k\right)^B\frac{\alpha^{-n}}{\Gamma(-A+1)}n^{-A} \qquad \text{as } n\to\infty. \end{aligned} \tag{3.30}$$

Recalling that $\overline{\alpha(x)}=\beta(x)$ and $\overline{A(x)}=B(x)$ when $-1\leqq x\leqq 1$, we have that

$$B_n^\lambda(x)\sim 2\operatorname{Re}\left\{k^B\frac{\alpha}{\alpha-\beta}\left(1-\left(\frac{\beta}{\alpha}\right)^k\right)^A\frac{\beta^{-n}n^{-B}}{\Gamma(-B+1)}\right\}. \tag{3.31}$$

This can be put in the form

$$\begin{aligned} B_n^\lambda(x) &\sim \frac{(2k)^{-\lambda}n^\lambda}{\Gamma(-B+1)|(\alpha-\beta)/2i||(\alpha^k-\beta^k)/2i|\lambda} \\ &\times\exp\left(\Phi(x)\arg i\alpha^{-k}\left(\frac{\alpha^k-\beta^k}{2i}\right)\right)\cos\varepsilon_n(x), \end{aligned} \tag{3.32}$$

where $-\pi<\arg z\leqq\pi$,

$$\Phi(x)=\frac{ax+b}{\sqrt{1-x^2}}$$

and

$$\begin{aligned} \varepsilon_n(x)&=n(\arg\alpha)-\Phi(x)\left[\ln\left(\frac{n}{k}\right)+\ln|2\sin(k(\arg\alpha))|\right]-\lambda\arg(i\alpha^{-k}\sin(k\arg\alpha)) \\ &-\arg(\Gamma(-B+1))-\arg(i\alpha^{-1}\sin(\arg\alpha)). \end{aligned}$$

If $x=\cos\Theta$, $(j-1)/k\pi<\Theta<j\pi/k$, $j=1,2,\cdots,k$, we can write (3.32) in the form

$$B_n^\lambda(\cos\Theta)\sim\frac{(2k)^{-\lambda}n^\lambda\cos\varepsilon_n(\Theta)}{|\Gamma(-B+1)|\sin\Theta|\sin k\Theta|^\lambda}\exp\left[\left(j\pi-k\Theta-\frac{\pi}{2}\right)\Phi(\cos\Theta)\right], \tag{3.33}$$

where

$$\Phi(\cos\Theta)=a\cot\Theta+b\csc\Theta,$$

and

$$\varepsilon_n(\Theta)=(n+k\lambda+1)\Theta+\frac{\pi}{2}(\lambda(1-2j)-1)-\Phi(\cos\Theta)\left[\ln\left(\frac{n}{k}\right)+\ln|2\sin k\Theta|\right].$$

We now determine the asymptotic behavior of $B_n^{*\lambda}(x)$ for $x \notin [-1, 1]$. Note that

$$B(x) = B_+(x) = -\lambda + i\Phi(x) = -\lambda + i\frac{ax+b}{\sqrt{1-x^2}}, \qquad -1 \leqq x \leqq 1,$$

implies $\operatorname{Re}(B(x)) = -\lambda < -\frac{1}{2}$ for $-1 \leqq x \leqq 1$. Let $\delta > 0$ be such that $\operatorname{Re}(B(z)) < 1$ for $z \in (x-\delta, x+\delta) \times (0, \delta)$, and call this last set K. For $z \in K$, $\operatorname{Re}(B) > 0$,

$$(3.34) \qquad \left|\left(1-\frac{t^k}{\alpha^k}u\right)^{-A-1}\left(1-\frac{t^k}{\beta^k}u\right)^{-B}\right| \leqq C(1-u)^{-\operatorname{Re}(B)}, \qquad 1 \leqq u < 1,$$

where C depends only on z. Since $\operatorname{Re}(B) < 1$, the function $(1-u)^{-\operatorname{Re}(B)}$ is integrable in $[0, 1]$. The Lebesgue Dominated Convergence Theorem implies

$$(3.35) \qquad \lim_{t \to \beta(z)} \int_0^1 \left(1-\frac{t^k}{\alpha^k}u\right)^{-A-1}\left(1-\frac{t^k}{\beta^k}u\right)^{-B} du = \int_0^1 \left(1-\frac{\beta^k}{\alpha^k}u\right)^{-A-1}(1-u)^{-B}\,du.$$

The relationship (3.35) trivially holds if $\operatorname{Re}(B) \leqq 0$. Hence, the leading term in a comparison function for $B^{*\lambda}(z, t)$ is

$$(3.36) \quad 2\tilde{B}^\lambda(z,t)\left\{\beta + A(\beta-\alpha)\left(\frac{\beta}{\alpha}\right)^k \int_0^1 \left(1-u\frac{\beta^k}{\alpha^k}\right)^{-A-1}(1-u)^{-B}\,du\right\}, \qquad z \in K$$

where $\tilde{B}^\lambda(z, t)$ is the dominant term in a comparison function for $B^\lambda(z, t)$. Thus

$$(3.37) \quad B_n^{*\lambda}(z) - 2B_n^\lambda(z)\left\{\beta + A(\beta-\alpha)\left(\frac{\beta}{\alpha}\right)^k \int_0^1 \left(1-u\frac{\beta^k}{\alpha^k}\right)^{-A-1}(1-u)^{-B}\,du\right\},$$

as $n \to \infty$ and the associated continued fraction is

$$(3.38) \quad \chi(z) = 2\left\{\beta + A(\beta-\alpha)\beta^{2k}\int_0^1 \left(1-\frac{\beta^k}{\alpha^k}u\right)^{-A-1}(1-u)^{-B}\,du\right\}, \qquad z \in K.$$

The right-hand side of (3.38) is analytic on K. The left-hand side of (3.38) fails to be analytic only on the support of $d\phi$, ϕ being the normalized distribution function for $\{B_n^\lambda(x)\}$. From the properties of the Hadamard Integral of § 2

$$\int_0^{\overline{1}\rceil} \left(1-\frac{\beta^k}{\alpha^k}u\right)^{-A-1}(1-u)^{-B}\,du$$

is an analytic continuation of $\int_0^1 (1-(\beta^k/\alpha^k)u)^{-A-1}(1-u)^{-B}\,du$ to the set Ω of (2.36). Thus, we proved that $\Omega \subseteq \mathbb{C} - \sigma(\phi)$ and

$$(3.39) \quad \chi(z) = 2\left\{\beta + A(\beta-\alpha)\beta^{2k}\int_0^{\overline{1}\rceil} \left(1-u\frac{\beta^k}{\alpha^k}\right)^{-A-1}(1-u)^{-B}\,du\right\}, \qquad z \in \Omega.$$

In the next section, we study the behavior of $\chi(z)$ on the set $D = \{z\colon B(z) = 1, 2, \cdots\}$ in order to determine the conditions under which it is part of $\sigma(\phi)$.

We now establish a generating function for the polynomials of the first kind $\{c_n^\lambda(x; a, b; k)\}$. For brevity, we will write $c_n^\lambda(x)$ for $c_n^\lambda(x; a, b; k)$. Recall

$$(3.40) \qquad c_n^\lambda(x) = \lim_{s \to 1} G_n(x; U, V, \Delta; q)$$

where

$$(3.41) \qquad U = s^{ka}, \quad V = s^k(1-s^{kb}), \quad \Delta = s^{k\lambda}, \quad q = s\omega.$$

Now (3.3), (3.4) and (3.7) give

$$G(x, t) := \sum_{n=0}^{\infty} \frac{1-U\Delta q^n}{1-U\Delta} F_n(x) = h(s, t) \frac{(qt/\xi; q)_\infty (qt/\zeta; q)_\infty}{(t/\alpha; q)_\infty (t/\beta; q)_\infty} \tag{3.42}$$

where

$$g(s, t) := 1-\Delta U + (\Delta - U)\Delta t^2 + 2Vt, \qquad h(s, t) := g(s, t)/(1-\Delta U). \tag{3.43}$$

As $s \to 1$, $h(s, t) \to 1 + \lfloor 2bt - (\lambda - a)t^2 \rfloor / (\lambda + a)$. Furthermore,

$$\lim_{s\to 1} \frac{(1-q^j\alpha/\xi)}{1-q^j} = \frac{A+m}{m} \text{ or } 1 \quad \text{if } j = km \text{ or } k \nmid j. \tag{3.44}$$

A calculation similar to what we used to prove (3.9) yields

$$C^\lambda(x, t) = \frac{[\lambda + a + 2bt - (\lambda - a)t^2]}{(1-2xt+t^2)(\lambda + a)} (1-t^k\beta^k)^A (1-t^k\alpha^k)^B, \tag{3.45}$$

where $C^\lambda(x, t)$ is the limit of $G(x, t)$ as $s \to 1$. In fact

$$C^\lambda(x, t) = \sum_{n=0}^{\infty} b_n c_n^\lambda(x) t^n, \tag{3.46}$$

where b_n is the limit of $(1-U\Delta q^n)(\Delta^2; q)_n / [(1-\Delta U)(q; q)_n]$. Thus

$$b_n = \frac{(\lambda + a + 1)_{\lfloor n/k \rfloor} (2\lambda)_{\lceil n/k \rceil}}{\lfloor n/k \rfloor ! (\lambda + a)_{\lceil n/k \rceil}}, \tag{3.47}$$

where $\lfloor x \rfloor$ and $\lceil x \rceil$ denote, respectively, the largest integer $<x$ and the smallest integer $>x$.

From (3.45) and Darboux's Method we readily obtain

$$b_n c_n^\lambda(x) \sim -k^B \frac{B}{\lambda + a} (1-\beta^{2k})^A \frac{\beta^{-n}}{\Gamma(-B+1)} n^{-B}, \qquad n \to \infty, \tag{3.48}$$

holding in the complex plane outside the interval $[-1, 1]$.

We wish to determine the asymptotic behavior of $c_n^{*\lambda}(x)$ in order to find the continued fraction whose denominators are $\{c_n^\lambda(x)\}$. The first step is to derive a generating function for $\{c_n^{*\lambda}(x)\}$. Let

$$f(s, t) := 1 + \Delta^2 t^2 + 2(V - xU\Delta)t, \tag{3.49}$$

$$G^*(x, t) := \sum_{n=0}^{\infty} \frac{1-U\Delta q^n}{1-U\Delta} F_n^*(x) t^n. \tag{3.50}$$

Formulas (3.9), (3.42), (3.43), (3.49) and (3.50) lead to

$$G^*(x, t) = \frac{2t}{f(s, t)} + G(x, t) \frac{F^*(x, t)}{F(x, t)}. \tag{3.51}$$

Letting $s \to 1$ in (3.51) and taking (3.41) into account we obtain

$$\sum_{n=0}^{\infty} b_n c_n^{*\lambda}(x) t^n = \frac{2t}{1-2xt+t^2} + C^\lambda(x, t) \lim_{s\to 1} \frac{F^*(x, t)}{F(x, t)}, \tag{3.52}$$

and $C^\lambda(x, t)$ and b_n are given by (3.45) and (3.47), respectively. The following lemma generalizes results of [1] and [14].

LEMMA 3.1. *With $F(x, t)$ given by* (3.7) *and $F^*(x, t)$ by* (3.9), *we have*

$$\lim_{s\to 1}\frac{F^*(x,t)}{F(x,t)}=2(\lambda+a)\frac{\alpha^k-\beta^k}{\alpha-\beta}\int_0^{t^k}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B-1}\,du. \tag{3.53}$$

Proof. Using

$$F^*(x,t)=2tF(x,t)\sum_{m,j=0}^{\infty}\frac{(q\xi/\alpha;q)_j(q\zeta/\beta;q)_m}{(q;q)_j(q;q)_m}\left(\frac{t}{\xi}\right)^j\left(\frac{t}{\zeta}\right)^m\frac{1-U\Delta}{1-q^{m+j+1}},$$

we easily see that

$$\lim_{s\to 1}\frac{1-q^j\xi/\alpha}{1-q^j}=1\left(\text{or }\frac{A+r}{r}\right)\text{ if } k\nmid j \text{ (or } j=kr),$$

$$\lim_{s\to 1}\frac{1-q^m\zeta/\beta}{1-q^m}=1\left(\text{or }\frac{B+r}{r}\right)\text{ accordingly as } k\nmid m \text{ or } m=kr.$$

Furthermore,

$$\lim_{s\to 1}\frac{1-U\Delta}{1-q^{m+j+1}}\text{ is 0 if } k\nmid j+m+1 \text{ and is } \frac{\lambda+a}{r} \text{ if } j+m+1=kr.$$

Using the above limiting relationships we see that

$$\lim_{s\to 1}\frac{F^*(x,t)}{F(x,t)}=2k(\lambda+a)\sum_{\substack{j,m=0\\ k|j+m+1}}^{\infty}\frac{(A+1)_{\lfloor j/k\rfloor}(B+1)_{\lfloor m/k\rfloor}}{\lfloor j/k\rfloor!\,\lfloor m/k\rfloor!\,(m+j+1)}t^{j+m+1}\alpha^{m-j}.$$

Let $j=kj_1+l$, $m=km_1+k-l-1$, where $0\leqq l<k$, $j_1\geqq 0$, $m_1\geqq 0$. Then

$$\lim_{s\to 1}\frac{F^*(x,t)}{F(x,t)}=2(\lambda+a)\sum_{j_1,m_1=0}^{\infty}\frac{(A+1)_{j_1}(B+1)_{m_1}}{j_1!\,m_1!\,(j_1+m_1+1)k}t^{(m_1+j_1+1)k}$$
$$\cdot\,\beta\alpha^{(m_1-j_1+1)k}\sum_{l=0}^{k-1}\beta^{2l}.$$

Therefore

$$\lim_{s\to 1}\frac{F^*(x,t)}{F(x,t)}=2(\lambda+a)\frac{\alpha^k-\beta^k}{\alpha-\beta}\int_0^{t^k}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B-1}\,du.$$

This proves the lemma.

This shows that a generating function of the numerator polynomials is

$$\begin{aligned}\sum_{n=0}^{\infty}b_nc_n^{*\lambda}(x)t^n={}&\frac{2t}{t^2-2xt+1}+2(\lambda+a)\frac{\alpha^k-\beta^k}{\alpha-\beta}\left\{1+\frac{2b}{\lambda+a}t-\frac{\lambda-a}{\lambda+a}t^2\right\}\\ &\cdot\frac{(1-t^k\beta^k)^A(1-t^k\alpha^k)^B}{t^2-2xt+1}\int_0^{t^k}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B-1}\,du.\end{aligned}\tag{3.54}$$

Integration by part gives

$$\begin{aligned}\int_0^{t^k}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B-1}\,du={}&\frac{\beta^k}{B}(1-t^k\beta^k)^{-A-1}(1-t^k\alpha^k)^{-B}-\frac{\beta^k}{B}\\ &-\beta^{2k}\frac{A+1}{B}\int_0^{t^k}(1-u\beta^k)^{-A-2}(1-u\alpha^k)^{-B}\,du.\end{aligned}$$

An argument similar to the one used to prove (3.38) gives

$$\lim_{t\to\beta}\int_0^{t^k}(1-u\beta^k)^{-A-2}(1-u\alpha^k)^{-B}\,du=\int_0^{\overline{\beta^k}\rceil}(1-u\beta^k)^{-A-2}(1-u\alpha^k)^{-B}\,du.$$

The above calculations, (3.54) and Darboux's Method establish

$$b_nc_n^{*\lambda}(x)\sim 2(\lambda+a)\frac{(\beta^k-\alpha^k)}{(\beta-\alpha)}\frac{\beta^k}{B}\left\{1+\frac{A+1}{\alpha^k}\int_0^{\overline{\beta^k}\rceil}(1-u\beta^k)^{-A-2}(1-u\alpha^k)^{-B}\,du\right\}b_nc_n^{\lambda}(x),$$

as $n\to\infty$, when $x\in\mathbb{C}-[a,b]$. This proves that the continued fraction is

$$\chi^*(z)=-2\frac{\lambda+a}{\alpha-\beta}\left(1-\frac{\beta^k}{\alpha^k}\right)\frac{1}{B}\left\{1+\frac{(A+1)}{\alpha^k}\int_0^{\overline{\beta^k}\rceil}(1-u\beta^k)^{-A-2}(1-u\alpha^k)^{-B}\,du\right\},\tag{3.55}$$

$x\in\mathbb{C}-[a,b]$, which can also be written

$$\chi^*(z)=-2\frac{(\lambda+a)}{\alpha-\beta}\left(1-\frac{\beta^k}{\alpha^k}\right)\frac{1}{B}\left\{1+(A+1)\frac{\beta^k}{\alpha^k}\int_0^{\overline{1}\rceil}\left(1-u\frac{\beta^k}{\alpha^k}\right)^{-A-2}(1-u)^{-B}\,du\right\}.\tag{3.56}$$

This is the form of the continued fraction for the polynomials $c_n^\lambda(x)$ that we will use henceforth. It is an analytic function of z in the subset Ω^* of $\mathbb{C}-[-1,1]$ where $B(z)\neq 0,1,2,\cdots$, i.e., its only possible singularities outside $[-1,1]$ are on the set $D^*=\{z\colon B(z)=0,1,2,\cdots\}$.

4. The continued fractions $\chi(z)$ and $\chi^*(z)$. The continued fractions $\chi(z)$ and $\chi^*(z)$ are analytic function of z in the cut plane $\mathbb{C}-[-1,1]$, except possibly on the sets D and D^* where $B(z)$ is, respectively, a positive and a nonnegative integer. We now identify these sets and the type of singularities $\chi(z)$ and $\chi^*(z)$ have on such sets.

Let Ω be, as in (2.36), the set of points in $\mathbb{C}-[-1,1]$ where $B(z)\neq 1,2,\cdots$, and Ω^* be the subset of Ω where $B(z)\neq 0$. The function $\chi(z)$ is analytic in Ω and

$$\begin{aligned}\int_0^{\overline{1}\rceil}(1-u\beta^{2k})^{-A-1}(1-u)^{-B}\,du&=(1-\beta^{2k})^{-A-1}\sum_{n=1}^{\infty}\frac{(A+1)_n}{n!}\left(\frac{\beta^k}{\beta^k-\alpha^k}\right)^n\cdot\frac{1}{n+1-B}\\&=-\frac{\alpha^k}{A\beta^k}(1-\beta^{2k})^{-A}\sum_{n=1}^{\infty}\frac{(A)_n}{n!}\left(\frac{\beta^k}{\beta^k-\alpha^k}\right)^n\frac{n}{n-B}\end{aligned}$$

for $z\in\Omega$. Therefore

$$\chi(z)=2\left\{\beta+(\alpha-\beta)(1-\beta^{2k})^{-A}\sum_{n=1}^{\infty}\frac{(A)_n}{n!}\left(\frac{\beta^k}{\beta^k-\alpha^k}\right)^n\frac{n}{n-B}\right\}.\tag{4.1}$$

This series representation of $\chi(z)$ will be used to determine the type of the singularities of $\chi(z)$ in D. For $z\in\Omega^*$ we have

$$\begin{aligned}&(A+1)\int_0^{\overline{1}\rceil}(1-u\beta^{2k})^{-A-2}(1-u)^{-B}\,du\\&=(1-\beta^{2k})^{-A-2}\sum_{n=1}^{\infty}\frac{(A+1)_n}{n!}\left(\frac{\beta^k}{\beta^k-\alpha^k}\right)^{n-1}\cdot\left(\frac{n}{n-B}\right),\end{aligned}$$

which leads to the series representation

$$\begin{aligned}\chi^*(z)=&-\frac{2(\lambda+a)}{(\alpha-\beta)B}\left(1-\frac{\beta^k}{\alpha^k}\right)\\&\cdot\left\{1-\left(1-\frac{\beta^k}{\alpha^k}\right)^{-A-1}\sum_{n=1}^{\infty}\frac{(A+1)_n}{n!}\left(\frac{\beta^k}{\beta^k-\alpha^k}\right)^n\frac{n}{n-B}\right\}.\end{aligned}\tag{4.2}$$

We now analyze the singularities of $\chi(z)$ and $\chi^*(z)$. Markov's Theorem gives

$$(4.3) \qquad \chi(z)=\int_{-\infty}^{+\infty}\frac{d\phi(t)}{z-t}\,dt, \qquad \chi^*(z)=\int_{-\infty}^{+\infty}\frac{d\psi(t)}{z-t},$$

where $\phi(t)$, $\psi(t)$ are, respectively, the normalized distribution functions of $\{B_n^\lambda(x)\}$ and $\{c_n^\lambda(x)\}$. From Markov's Theorem it also follows that the set of singularities of $\chi(z)$ (respectively, $\chi^*(z)$) coincides with the support $\sigma(\phi)$ of $d\phi$ (respectively, $\sigma(\psi)$ of $d\psi$). Hence, the singularities of both $\chi(z)$ and $\chi^*(z)$ are real numbers. The singularities of $\chi(z)$ are located on $[-1,1]$ and on the set $D=\{z\in\mathbb{C}-[-1,1]\colon B(z)=1,2,\cdots\}$, and those of $\chi^*(z)$, on $[-1,1]$ and on the set $D^*=\{z\in\mathbb{C}-[-1,1]\colon B(z)=0,1,2,\cdots\}$. It follows that both D and D^* are subsets of $\mathbb{R}$. In fact $D\subseteq D^*\subseteq(-\infty,-1)U(1,+\infty)$. Furthermore $\sigma(\phi)\subseteq DU[-1,1]$ and $\sigma(\psi)\subseteq D^*U[-1,1]$ hold. To determine if $D\subseteq\sigma(\phi)$, or if $D^*\subseteq\sigma(\psi)$, we have to determine the sets of D and D^* and the nature of the singularities $\chi(z)$, and $\chi^*(z)$ have on these sets. We will do this in this part of the paper, leaving for § 5 the study of the singularities of $\chi(z)$ and $\chi^*(z)$ in $[-1,1]$.

Recall that $B(x)$ is defined in (2.20) and (2.25). To determine D and D^* we solve the equations $B(x)=n$. In doing so, we will first consider the case $n+\lambda>0$; i.e., we will assume $n\geqq 1$ in the general case $\lambda>-\frac{1}{2}$ (this determines D) and also allow $n=0$ if $\lambda>0$. The solutions of $B(x)=n$ satisfy

$$(4.4) \qquad (a^2-(n+\lambda)^2)x^2+2abx+b^2+(n+\lambda)^2=0, \qquad x\neq\pm1.$$

Let

$$(4.5)\quad \Delta_n=(n+\lambda)^2+b^2-a^2,\quad x_n=\frac{-ab+(n+\lambda)\sqrt{\Delta_n}}{a^2-(n+\lambda)^2},\quad y_n=\frac{-ab-(n+\lambda)\sqrt{\Delta_n}}{a^2-(n+\lambda)^2}.$$

The solutions of the quadratic equation in (4.4) are $x=x_n$, $x=y_n$. Those solutions contain the solutions of $B(x)=n$.

In order to obtain a sufficient condition for x_n, y_n to belong to D^*, observe that

$$(4.6)\quad ax_n+b=(n+\lambda)\frac{a\sqrt{\Delta_n}-b(n+\lambda)}{a^2-(n+\lambda)^2},\qquad ay_n+b=-(n+\lambda)\frac{a\sqrt{\Delta_n}+b(n+\lambda)}{a^2-(n+\lambda)^2},$$

$$(4.7)\qquad \sqrt{x_n^2-1}=\pm\frac{a\sqrt{\Delta_n}-b(n+\lambda)}{a^2-(n+\lambda)^2},\qquad \sqrt{y_n^2-1}=\pm\frac{a\sqrt{\Delta_n}+b(n+\lambda)}{a^2-(n+\lambda)^2}.$$

The fact that the numbers in (4.7) are positive numbers when x_n, $y_n\in D^*$ will be important in our considerations. Now, if $B(x_n)=n$ and $x_n<-1$, then $ax_n+b=(n+\lambda)\sqrt{x_n^2-1}$ and (4.6) yields

$$(4.8)\qquad \sqrt{x_n^2-1}=\frac{[a\sqrt{\Delta_n}-b(n+\lambda)]}{[a^2-(\lambda+n)^2]}.$$

Similarly, when $B(x_n)=n$ but $x_n>1$, then

$$(4.9)\qquad \sqrt{x_n^2-1}=\frac{[-a\sqrt{\Delta_n}+b(n+\lambda)]}{\lfloor a^2-(n+\lambda)^2\rfloor}.$$

We prove in the same manner that if $B(y_n)=n$ then

$$(4.10)\qquad \frac{ay_n+b}{\sqrt{y_n^2-1}}=n+\lambda,\qquad \sqrt{y_n^2-1}=-\frac{a\sqrt{\Delta_n}+b(n+\lambda)}{a^2-(n+\lambda)^2}\quad \text{if } y_n<-1,$$

$$(4.11)\qquad -\frac{ay_n+b}{\sqrt{y_n^2-1}}=n+\lambda,\qquad \sqrt{y_n^2-1}=\frac{a\sqrt{\Delta_n}+b(n+\lambda)}{a^2-(n+\lambda)^2}\quad \text{if } y_n>1.$$

Now we give a condition guaranteeing that $x_n < -1$ and $y_n > 1$. An obvious necessary condition is that $\Delta_n \geqq 0$.

LEMMA 4.1. *Assume $n+\lambda > 0$, $a < n+\lambda$. Then $x_n < -1$ for all $b \neq a$ and $y_n > 1$ for all $b \neq -a$.*

Proof. The above conditions make $(n+\lambda)^2 - a^2 > 0$. In fact $a+n+\lambda > 0$ follows from the positivity condition and $n+\lambda-a > 0$ by assumption. Thus $\Delta_n > 0$ for all $b \in \mathbb{R}$. Consider x_n, y_n as functions of the parameter b. Both $x_n(b)$ and $y_n(b)$ are continuous functions of b for all $b \in \mathbb{R}$ and $x_n(b) = -1$ if and only if $b = a$, $x_n(b) = 1$ if and only if $b = -a$. Since $x_n(a) = 1$ and $x_n(b)$ cannot take values in $(-1, 1)$, it follows that $x_n(b) < -1$ for all $b \in \mathbb{R}$, $b \neq a$. From $y_n(-a) = 1$ we conclude that $y_n(b) > 1$ for all $b \in \mathbb{R}$, $b \neq -a$. This proves the lemma.

Remark 4.2. The assumptions of the lemma are automatically satisfied if $a < 0$.

The next theorem characterizes the solutions of $B(x) = n$ among $\{x_n, y_n\}$.

THEOREM 4.3. *Assume $n+\lambda > 0$, $a < n+\lambda$. Then, $x_n \in D^*$ if and only if $b \neq a$ and*

$$a\sqrt{\Delta_n} - b(n+\lambda) < 0,$$

and, under these conditions $x_n < -1$. Furthermore, $y_n \in D^*$ if and only if $b \neq -a$, and

$$a\sqrt{\Delta_n} + b(n+\lambda) < 0,$$

in which case $y_n > 1$.

Proof. If $n+\lambda > 0$, $a < n+\lambda$ we have, by Lemma 4.1, $x_n \leqq -1$ with $x_n = -1$ if and only if $b = a$. Similarly $y_n \geqq 1$, with $y_n = 1$ if and only if $b = -a$. Hence, if $x_n \in D^*$ we must have $b \neq a$ and, since

$$\sqrt{x_n^2 - 1} = \frac{a\sqrt{\Delta_n} - b(n+\lambda)}{a^2 - (n+\lambda)^2}, \qquad a^2 - (n+\lambda)^2 < 0,$$

we must have $a\sqrt{\Delta_n} - b(n+\lambda) < 0$. In the same manner we see that if $y_n \in D^*$ then $b \neq -a$ and

$$\sqrt{y_n^2 - 1} = \frac{a\sqrt{\Delta_n} + b(n+\lambda)}{a^2 - (b+\lambda)^2},$$

then $a\sqrt{\Delta_n} + b(n+\lambda) < 0$. Conversely, if $b \neq a$ we have $x_n < -1$; and if $a\sqrt{\Delta_n} - b(n+\lambda) < 0$, $\sqrt{x_n^2 - 1}$ is given by (4.7). Then we immediately obtain that $B(x_n) = n$, and thus $x_n \in D^*$. In the same way we prove that if $b \neq -a$ then $y_n > 1$, and if $a\sqrt{\Delta_n} + b(n+\lambda) < 0$ then $\sqrt{y_n^2 - 1}$ is given by (4.11). Thus $B(y_n) = n$ and $y_n \in D^*$. This completes the proof.

Remark 4.4. Even under the conditions of Theorem 4.3, $x = -1$ (respectively, $y = 1$) is not in D^* if $a = b$ (respectively, if $b = -a$). They are not even solutions of $B(x) = n$. However, $x_n(-a)$ and $y_n(a)$ are in D^*.

Now let

$$X_n(b) = a\sqrt{\Delta_n} - b(n+\lambda), \qquad Y_n(b) = a\sqrt{\Delta_n} + b(n+\lambda). \tag{4.12}$$

Theorem 4.3 points out the importance of knowing the signs of $X_n(b)$ and $Y_n(b)$. The sign of $X_n(b)$ and $Y_n(b)$ can often be determined from their asymptotic behavior as $b \to \pm\infty$, which is, in general, easier than struggling with the inequalities. This is so because $X_n(b) = 0$ if and only if $b = a$, while $Y_n(b) = 0$ if and only if $b = -a$. We can say a little more. In fact, in any interval I in which $\Delta_n > 0$, we have

$$X_n'(b) = \frac{ab}{\sqrt{\Delta_n}} - n + \lambda, \qquad Y_n'(b) = \frac{ab}{\sqrt{\Delta_n}} + (n+\lambda),$$

so $X_n'(b)\neq 0$, $Y_n'(b)\neq 0$ for all $b\in I$. It follows that X_n and Y_n are strictly monotonic in I. For example, if $I=(a,+\infty)$ and $\Delta_n\geqq 0$ for all $b\in I$, we can deduce that the sign of $X_n(b)$ will be that of $a-n-\lambda$ for all $b\in I$. In fact

$$X_n(b)\sim b(a-b-\lambda)\quad \text{as } b\to+\infty$$

and $X_n(b)$ does not change sign in $(a,+\infty)$. Similarly we conclude that the sign of $Y_n(b)$ in $(-\infty,-\mathrm{a})$, agrees with the sign of $a-n-\lambda$ (provided that $\Delta_n\geqq 0$ in $(-\infty,-a)$).

We now establish two corollaries to Theorem 4.3.

COROLLARY 4.5. *Assume* $0\leqq a<n+\lambda$. *If* $b>a$, *then* $x_n<-1$ *and is in* D^* *but* y_n *is not a solution of* $B(x)=n$.

Proof. Clearly $a\sqrt{\Delta_n}-b(n+\lambda)\sim b(a-n-\lambda)$ as $b\to+\infty$ and does not change sign in $(a,+\infty)$. Thus $a\sqrt{\Delta_n}-b(n+\lambda)<0$. On the other hand, $a\sqrt{\Delta_n}+b(n+\lambda)>0$. By Theorem 4.3, $x_n\in D^*$ and y_n is not a solution of $B(x)=n$.

COROLLARY 4.6. *Let* $n+\lambda>0$, $a<0$, $b\geqq 0$. *Then*

(i) *if* $-b\leqq a$, $x_n<-1$ *and belongs to* D^* *but* y_n *is not a solution of* $B(x)=n$;

(ii) *if* $a<-b$, *both* x_n *and* y_n *are in* D^*, $x_n<-1$ *and* $y_n>1$.

Proof. (i) If $-b<a$, we have $a<n+\lambda$, $a\sqrt{\Delta_n}-b(n+\lambda)<0$, $a\sqrt{\Delta_n}+b(n+\lambda)>0$. By Theorem 4.3, $x_n\in D^*$ and y_n does not satisfy $B(x)=n$. If $a=-b$ we still have $a\sqrt{\Delta_n}-b(n+\lambda)=2a(n+\lambda)<0$, and $x_n\in D^*$. On the other hand, $y_n=1\notin D^*$.

(ii) In this case $a<n+\lambda$, $a\sqrt{\Delta_n}-b(n+\lambda)<0$, $a\sqrt{\Delta_n}+b(n+\lambda)<0$. By Theorem 4.3, x_n, $y_n\in D^*$. This completes the proof.

THEOREM 4.7. *Assume* $0<n+\lambda<a$. *Then, for all* $b>a$, $x_n<-1$ *and is in* D^* *but* y_n *is not a solution of* $B(x)=n$.

Proof. In this case $b^2>a^2$, hence $\Delta_n>0$ for $b\in[a,\infty)$. Since $x_n(a)=-1$, the continuity of $x_n(b)$ in the interval $[a,\infty)$ forces $x_n(b)<-1$ for all $b\in(a,\infty)$. Since $a^2-(n+\lambda)^2>0$, $x_n(b)$ will be in D^* if and only if $X_n(b)>0$. But this is the case, as

$$X_n(b)-b(a-(n+\lambda))>0,\qquad b\to\infty.$$

Now, $y_n(a)=-(a^2+(n+\lambda)^2)/(a^2-(n+\lambda)^2)<-1$, and the continuity of $y_n(b)$ in the interval $[a,\infty)$ implies $y_n(b)<-1$ for all $b>a$. If $y_n(b)$ were a solution of $B(x)=n$ we would have

$$\sqrt{y_n^2(b)-1}=-\frac{Y_n(b)}{a^2-(n+\lambda)^2}=\frac{Y_n(b)}{(n+\lambda)^2-a^2},$$

so that $Y_n(b)<0$. But obviously $Y_n(b)>0$ under the assumptions. Hence, $y_n(b)$ is not a solution of $B(x)=n$. This proves the theorem.

The results contained in Theorems 4.3 and 4.7 and their corollaries provide the information needed to characterize the set D. To determine D^* we need to consider the additional case $n=0$, $\lambda<0$. So, assume $\lambda<0=n$, and consider x_0, y_0 as function of the parameter b (for fixed a). Therefore

$$x_0(b)=\frac{-ab+\lambda\sqrt{\Delta_0}}{a^2-\lambda^2},\qquad y_0(b)=-\frac{ab+\lambda\sqrt{\Delta_0}}{a^2-\lambda^2}. \tag{4.13}$$

Observe that $\sqrt{\lambda^2}=-\lambda$, and now $x_0(b)=1$ if and only if $b=-a$, $y_0(b)=-1$ if and only if $b=a$. Again, $x_0(b)$ and $y_0(b)$ cannot take values in the interval $(-1,1)$.

Let

$$X_0(b)=a\sqrt{\Delta_0}-b\lambda,\qquad Y_0(b)=a\sqrt{\Delta_0}+b\lambda. \tag{4.14}$$

If x_0, y_0 are solutions of $B(x)=0$ then,

$$\sqrt{x_0^2-1}=\pm\frac{X_0(b)}{a^2-\lambda^2}, \qquad \sqrt{y_n^2-1}=\pm\frac{Y_0(b)}{a^2-\lambda^2}.$$

Therefore,

$$\sqrt{x_0^2-1}=\frac{X_0(b)}{a^2-\lambda^2},\quad x_0<-1, \qquad \sqrt{x_0^2-1}=-\frac{X_0(b)}{a^2-\lambda^2},\quad x_0>1, \tag{4.15}$$

while

$$\sqrt{y_0^2-1}=-\frac{Y_0(b)}{a^2-\lambda^2},\quad y_0<-1, \qquad \sqrt{y_0^2-1}=\frac{Y_0(b)}{a^2-\lambda^2},\quad y_0>1. \tag{4.16}$$

We now have that $X_0(b)=0$ if and only if $b=-a$, $Y_0(b)=0$ if and only if $b=a$. As before, it is easy to check that $X_0'(b)$, $Y_0'(b)$ never vanish, so that $X_0(b)$, $Y_0(b)$ are strictly monotonic in any interval I where $\Delta_0>0$; therefore, $X_0(b)$ never changes sign in such an interval if $-a\notin I$ and the same is true of $Y_0(b)$ if $a\notin I$. The signs of $X_0(b)$, $Y_0(b)$ can then be obtained, as before, from their asymptotic behavior.

Remark 4.8. Observe that the behavior of $X_0(b)$, $Y_0(b)$ when $\lambda>0$ is included in the case $n+\lambda>0$.

LEMMA 4.9. *If $a>\lambda$, $\lambda<0$, then $x_0>1$ for $b\neq -a$ and $y_0<-1$ when $b\neq a$.*

Proof. The proof is similar to that of Lemma 4.1. Observe that $\lambda^2-a^2=(\lambda+a)(\lambda-a)>0$ (since $a+\lambda<0$ if $\lambda<0$), so that $\Delta_0>0$ for all $b\in\mathbb{R}$. Considering again x_0 as a function of b we see that $x_0(-a)=1$, and therefore $x_0(b)>1$ if $b\neq -a$. The same type of argument proves the assertions concerning y_0.

THEOREM 4.10. *If $a>\lambda$, $\lambda<0$, then $x_0\in D^*$ if and only if $b\neq -a$ and $a\sqrt{\Delta_0}-b\lambda>0$. In this case $x_0>1$. Furthermore $y_0\in D^*$ if and only if $b\neq a$ and $a\sqrt{\Delta_0}+b\lambda>0$, in which case $y_0<-1$.*

Proof. The proof is essentially the same as that of Theorem 4.3.

Remark 4.11. Observe that $x_0(-a)$, $y_0(a)$ are not solutions of $B(x)=0$. However, both $x_0(a)$ and $y_0(-a)$ are in D^*.

COROLLARY 4.12. *Assume $a>b>0$, $\lambda<0$. Then x_0 and y_0 are solutions of $B(x)=0$ in D^*. Furthermore, $x_0>1$ and $y_0<-1$.*

Proof. We have $a>\lambda$ and obviously $a\sqrt{\Delta_0}-b\lambda>0$. Theorem 4.10 shows that $x_0\in D^*$ and $x_0>1$. If $b=0$, we trivially have $a\sqrt{\Delta_0}+b\lambda>0$. Therefore, we also have $a\sqrt{\Delta_0}+b\lambda>0$ if $b>0$. Thus, $y_0<-1$ and is in D^*.

THEOREM 4.13. *Assume $a<\lambda<0$. Then*

(i) *if $-b<a$, $x_0>1$ and is in D^* but y_0 does not make $B(x)=0$;*

(ii) *if $a\leqq -b$, $b>0$, neither x_0 nor y_0 is a solution of $B(x)=0$.*

Proof. (i) In this case $\Delta_0\geqq b^2-a^2>0$ and $b>-a$. Moreover $x_0(b)>1$ for $b>-a$, because $x_0=1$ when $b=-a$. Since $a\sqrt{\Delta_0}-b\lambda\sim b(a-\lambda)$ when $b\to+\infty$, we have $a\sqrt{\Delta_0}-b\lambda<0$. Thus $\sqrt{x_0^2-1}=[b\lambda-a\sqrt{\Delta_0}]/[a^2-\lambda^2]$ and $x_0(b)$ is in fact a solution of $B(x)=0$. On the other hand, $a\sqrt{\Delta_0}+b\lambda<0$ and $y_0(b)=-[ab+\lambda\sqrt{\Delta_0}]/[a^2-\lambda^2]$ contradict each other, as it is impossible to have $(a^2-\lambda^2)\sqrt{y_0^2-1}=a\sqrt{\Delta_0}+b\lambda$. Therefore, y_0 is not a solution of $B(x)=0$.

(ii) The conclusion is obviously true if $\Delta_0<0$. So, assume $\Delta_0>0$. We have $b<-a$ and from $a\sqrt{\Delta_0}-b'\lambda\sim b'(a-\lambda)<0$, as $b'\to+\infty$, we conclude that $a\sqrt{\Delta_0}-b\lambda>0$. Also, $x_0=1$ when $b=-a$, so that $x_0(b)>1$. This leads to the contradiction $\sqrt{x_0^2-1}=(b\lambda-a\sqrt{\Delta_0})/(a^2-\lambda^2)<0$. Hence, x_0 is not a solution of $B(x)=0$. Since $a\sqrt{\Delta_0}+b\lambda<0$ and $y_0(b)>1$ are contradictory, the proof is complete.

The proof of the following theorem requires only a slight modification of the proof of Theorem 4.13.

THEOREM 4.14. *Assume $\lambda < a < 0$. Then*

(i) *if $-b < a$, $x_0 > 1$ and is in D^* but y_0 is not a solution of $B(x) = 0$;*

(ii) *if $a < -b$, $b > 0$, neither x_0 nor y_0 is a solution of $B(x) = 0$.*

We shall now study the structure of D and the types of singularities of $\chi(z)$ on this set. We recall that D and D^* are subsets of $\mathbb{R} - [-1, 1]$ defined by

$$D = \{z \in \mathbb{C} - [-1, 1]: B(z) = 1, 2, \cdots\}, \qquad D^* = DU\{z: B(z) = 0\}. \tag{4.17}$$

THEOREM 4.15. *If $a \geqq |b|$, the set D is empty.*

Proof. When $x < -1$, $B(x)$ equals n iff $(n+\lambda)\sqrt{x^2-1} = ax + b$. When $n \geqq 1$, $\lambda > -\frac{1}{2}$ in order for the above inequality to hold $ax + b$ must be positive. But $ax + b < b - a < 0$ when $x < -1$ and we conclude that D has no elements less than -1. Similarly, when $x > 1$, $ax + b$ is positive and $B(x) = n$ iff $(n+\lambda)\sqrt{x^2-1} = -(ax+b)$, which cannot hold since $a \geqq |b|$.

We now consider the cases $a \leqq |b|$. Figure 4.1 shows a subdivision of the (λ, a) plane into five regions by the line $\lambda = -\frac{1}{2}$, the half line $a + \lambda + 1 = 0$, $\lambda > -\frac{1}{2}$ and the λ-axis $a = 0$. The first two lines do not belong to any region while the last one is assumed to be part of Region I for $\lambda > -\frac{1}{2}$. Notice that $\lambda = 0$ is not a division line. The positivity conditions $\lambda + a + 1 > 0$, $\lambda > -\frac{1}{2}$ restrict us to Regions I and II of the (λ, a) plane. We now characterize the set D when λ and a belong to either region. Consider first the case $b \geqq 0$.

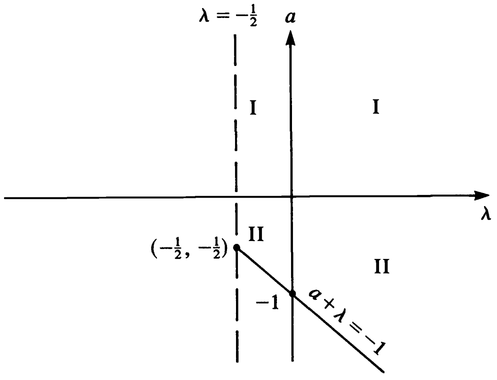

FIG. 4.1

THEOREM 4.16. *Let $a \leqq b$, $b \geqq 0$. Then, the set D is given, in each one of the two possible regions, as follows.*

Region I (i) *$a < b$. Then $D = \{x_n: n \geqq 1\}$.*
(ii) *$a = b$. Then $D = \varnothing$.*

Region II (i) *$-b \leqq a < b$. Then $D = \{x_n: n \geqq 1\}$.*
(ii) *$a < -b$. Then $D = \{x_n: n \geqq 1\} \cup \{y_n: n \geqq 1\}$.*

In the two regions x_n, y_n are given by (4.5) and we have $x_n < -1$ and $y_n > 1$ for all $n \geqq 1$.

Proof. I. Part (i) follows from Corollary 4.5 and Theorem 4.7. Part (ii) has been treated in Theorem 4.15.

II. Part (i) follows immediately from part (i) of Corollary 4.6. Part (ii) follows at once from Corollary 4.6 (ii).

Remark 4.17. The case $b=0$ was studied in Ismail [14]. It corresponds to the symmetric sieved Pollaczek polynomials of the second kind. Notice that in this case we are restricted to Region II with the constraint $a<-b$. By Theorem 4.16, D is $\{x\colon x=x_n \text{ or } y_n,\ n>0\}$.

We now come to the case $b<0$, $a\leqq -b$. Note that

$$B_n^\lambda(x;\, a, b;\, k)=(-1)^n B_n^\lambda(-x;\, a, -b;\, k) \tag{4.18}$$

follows from the three term recurrence relation. Thus we have the following.

THEOREM 4.18 *If $a\leqq -b$, $b<0$, the set D is given, in each one of the Regions* I, II *in the following manner.*

Region I (i) $a<-b$. *Then,* $D=\{y_n\colon n\geqq 1\}$.
(ii) $a=-b$. *Then,* $D=\varnothing$.
Region II (i) $b\leqq a<-b$. *Then,* $D=\{y_n\colon n\geqq 1\}$.
(ii) $a<b$. *Then,* $D=\{x_n\colon n\geqq 1\}\cup\{y_n\colon n\geqq 1\}$.

Here, x_n, y_n are also given by (4.7) *and $x_n<-1$, $y_n>1$ for all $n\geqq 1$.*

Now we study the nature of singularities of $\chi(z)$ on the set D. Recall that

$$\chi(z)=2\left\{\beta+(\alpha-\beta)(1-\beta^{2k})^{-A}\sum_{n=1}^{\infty}\frac{(A)_n}{n!}\left(\frac{\beta^k}{\beta^k-\alpha^k}\right)^n\frac{n}{n-B}\right\}.$$

Let $x_n\in D$ with $x_n<-1$ and $B(x_n)=n$. A simple calculation gives

$$\lim_{z\to x_n}(z-x_n)\chi(z)=2(-1)^{n+1}(\alpha-\beta)\beta^{2kn}(1-\beta^{2k})^{2\lambda}\frac{B(x_n)}{B'(x_n)}.$$

We used $B(x_n)=n$, $-A-B=2\lambda$, $\alpha\beta=1$ and $B'(x_n)=\lim_{z\to x_n}(B-n)/(z-x_n)$. Hence, if $B'(x_n)\neq 0$, x_n will be a simple pole of $\chi(z)$. We now have

$$B'(x_n)=\frac{d}{dx}\left[-\lambda+\frac{ax+b}{\sqrt{x^2-1}}\right]\Bigg|_{x=x_n}=\frac{a\sqrt{x_n^2-1}-(n+\lambda)x_n}{x_n^2-1}.$$

Using (4.5) one can derive

$$B'(x_n)=\frac{\sqrt{\Delta_n}[\alpha^2-(n+\lambda)^2]^2}{[a\sqrt{\Delta_n}-b(n+\lambda)]^2}. \tag{4.19}$$

In the same way when $y_n>1$ and $B(y_n)=n$, we obtain

$$B'(y_n)=-\frac{\sqrt{\Delta_n}[a^2-(n+\lambda)^2]^2}{[a\sqrt{\Delta_n}+b(n+\lambda)]^2}. \tag{4.20}$$

Therefore $B'(x)\neq 0$ in all cases.

Remark 4.19. Note that the denominator of (4.19) vanishes when $a=b$. This does not affect our results, because in this case $D=\varnothing$ in Region I, while $D\subseteq(1,+\infty)$ in Region II. The denominator of (4.20) is zero when $b=-a$, but in this case D is either empty or contained in $(-\infty,-1)$.

We now record the residues of $\chi(z)$ on D. Recall that $(-1)^n(A)_n=(-A-n+1)_n$, $-A-B=2\lambda$ and $\alpha-\beta=-2\sqrt{x_n^2-1}$ when $x_n<-1$, $\alpha-\beta=2\sqrt{y_n^2-1}$ when $y_n>1$. The use of (4.8), (4.19) and (4.20) lead to

$$\operatorname{Res}(\chi(z), x_n)=4\beta^{2kn}\frac{(2\lambda+1)_n}{(n-1)!\sqrt{\Delta_n}}(1-\beta^{2k})^{2\lambda}\left[\frac{a\sqrt{\Delta_n}-b(n+\lambda)}{a^2-(n+\lambda)^2}\right]^3,\qquad x_n<-1, \tag{4.21}$$

$$(4.22)\quad \operatorname{Res}(\chi(z), y_n) = 4\beta^{2kn}\frac{(2\lambda+1)_n}{(n-1)!\sqrt{\Delta_n}}(1-\beta^{2k})^{2\lambda}\left[\frac{a\sqrt{\Delta_n}+b(n+\lambda)}{a^2-(n+\lambda)^2}\right]^3, \qquad y_n > 1.$$

The last two equations could be written somewhat more explicitly by noticing that

$$(4.23)\qquad \beta(x_n) = \frac{\sqrt{\Delta_n}-b}{a-\lambda-n}, \qquad \alpha(x_n) = -\frac{\sqrt{\Delta_n}+b}{a+\lambda+n}, \quad x_n < -1,$$

$$(4.24)\qquad \beta(y_n) = -\frac{\sqrt{\Delta_n}+b}{a-n-\lambda}, \qquad \alpha(y_n) = \frac{\sqrt{\Delta_n}-b}{a+\lambda+n}, \qquad y_n > 1.$$

In view of Markov's Theorem we have the following.

THEOREM 4.20. *The function $\chi(z)$ has a simple pole at every point of D and $D \subseteq \sigma(\phi)$.*

Remark 4.21. Note that since

$$\lim_{n\to\infty} x_n = -1 \quad \text{and} \quad \lim_{n\to\infty} y_n = 1,$$

$-1, 1$ are the only possible limit points of D in $\mathbb{C}$ (or in $\mathbb{R}$).

In § 6 we shall characterize the singularities of $\chi(z)$ in $[-1, 1]$.

We next determine the structure of D^* as a function of a, b, λ. First we treat the case $b \geqq 0$.

THEOREM 4.22. *Let $a > b$, $b \geqq 0$. Then*

(i) *if $\lambda > 0$, $D^* = \emptyset$;*

(ii) *if $\lambda < 0$, $D^* = \{x_0, y_0\}$. Here $x_0 > 1$, $y_0 < -1$.*

Proof. The proof of (i) is similar to the proof of Theorem 4.15 and will be omitted. Part (ii) follows from Corollary 4.12.

Remark 4.23. The case $b = 0$ is also in Ismail [14]. If $a = b > 0$ we still have $x_0 \in D^*$, but $y_0 = -1 \in D^*$. The identity

$$(4.25)\qquad c_n^\lambda(x; a, b; k) = (-1)^n c_n^\lambda(-x; a, -b; k)$$

can be easily proved from the three term recurrence relation. Thus (4.25) and Theorem 4.22 give the following.

THEOREM 4.24. *If $a > -b$, $b < 0$, then $D^* = \emptyset$ when $\lambda > 0$ and $D^* = \{x_0, y_0\}$ when $\lambda < 0$. Here, $x_0 > 1$ and $y_0 < -1$.*

We now consider the case $a \leqq |b|$. In doing so it is convenient to divide the (λ, a)-plane into the ten regions shown in Fig. 4.2. The divisions are determined by the lines $\lambda = \frac{1}{2}$ and $\lambda = 0$; the half lines $\lambda + a = 0$, $\lambda > -\frac{1}{2}$ and $\lambda + a + 1 = 0$, $\lambda > -\frac{1}{2}$, as well as by the λ-axis, $a = 0$, for $\lambda < -\frac{1}{2}$ and $\lambda > 0$. The division between Regions III* and IV* is determined by the line segment $\lambda - a = 0$, $-\frac{1}{2} < \lambda < 0$. The positivity conditions

$$\lambda + a + 1 > 0, \quad \lambda(\lambda + a) > 0, \quad \lambda > -\tfrac{1}{2},$$

restrict cases of orthogonality to Regions I*–IV*. We assume that the λ-axis belong to Region I for $\lambda > 0$. None of the other division lines is part of any region. Note that $\lambda = 0$ is now a dividing line.

THEOREM 4.25. *The set D^* can be described as follows when $a \leqq b$, $b \geqq 0$.*

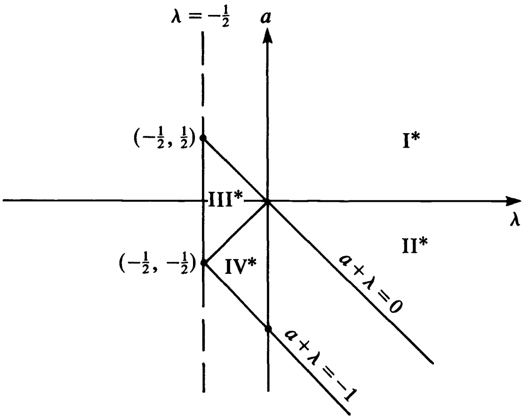

FIG. 4.2

Region I* (i) *$a<b$. Then, $D^*=\{x_n\colon n\geqq 0\}$.*
(ii) *$a=b$. Then, $D^*=\varnothing$.*
Region II* (i) *$-b\leqq a<b$. Then, $D^*=\{x_n\colon n\geqq 0\}$.*
(ii) *$a<-b$. Then, $D^*=\{x_n\colon n\geqq 0\}\cup\{y_n\colon n\geqq 0\}$.*
Region III* (i) *$-b<a$. Then, $D^*=\{x_n\colon n\geqq 0\}$, $x_0>1$.*
(ii) *$-b=a\neq 0$. Then, $D^*=\{x_n\colon n\geqq 1\}$.*
(iii) *$a<-b$. Then, $D^*=\{x_n\colon n\geqq 1\}\cup\{y_n\colon n\geqq 1\}$.*
(iv) *$a=b>0$ $(=0)$. Then, $D^*=\{x_0\}$ $(=\varnothing)$, $x_0>1$.*
Region IV* (i) *$-b<a$. Then, $D^*=\{x_n\colon n\geqq 0\}$, $x_0>1$.*
(ii) *$b=-a$. Then, $D^*=\{x_n\colon n\geqq 1\}$.*
(iii) *$a<-b$. Then, $D^*=\{x_n\colon n\geqq 1\}\cup\{y_n\colon n\geqq 1\}$.*

In all regions, $x_n<-1$ and $y_n>1$ for $n\geqq 1$. Also, $x_0<-1$, $y_0>1$ if $\lambda>0$.

Proof. Regions I*, II*. The proof in these cases is as the proof of I, II in Theorem 4.16, because Theorems 4.3, 4.7 and their corollaries hold for $n=0$ when $\lambda>0$.

III* (i) follows immediately from Theorem 4.16 for $n\geqq 1$, and from Theorem 4.14, (i), for $n=0$.
(ii) follows from Theorem 4.16 for $n\geqq 1$ and from Theorem 4.14, (ii), for $n=0$.
(iii) follows from Theorem 4.16 for $n\geqq 1$ and from Theorem 4.14, (ii), for $n=0$.
(iv) If $b=0$, it is impossible to have $-\lambda=n$, $n\geqq 0$, since $0>2\lambda>-1$. If $b>0$, use Theorem 4.16 and Remark 4.23.

IV* (i) follows from Theorem 4.16 for $n\geqq 1$ and from Theorem 4.13, (i), for $n=0$.
(ii) follows from Theorem 4.16 for $n\geqq 1$ and from Theorem 4.13, (ii), for $n=0$.
(iii) follows from Theorem 4.16 for $n\geqq 1$ and from Theorem 4.13, (ii), for $n=0$.

The proof of the theorem is now complete.

Now consider the case $b<0$. In view of (4.25) we easily obtain the following.

THEOREM 4.26. *If $a\leqq -b$, $b<0$, the composition of D^* in different regions of the a, b, λ parameter space is as follows.*

Region I* (i) *$a<-b$. Then, $D^*=\{y_n\colon n\geqq 0\}$.*
(ii) *$a=-b$. Then, $D^*=\varnothing$.*

Region II* (i) $b \leqq a < -b$. *Then*, $D^* = \{y_n \colon n \geqq 0\}$.
(ii) $a < b$. *Then*, $D^* = \{x_n \colon n \geqq 0\} \cup \{y_n \colon n \geqq 0\}$.
Region III* (i) $b < a < -b$. *Then*, $D^* = \{y_n \colon n \geqq 0\}$, $y_0 > 1$.
(ii) $a = b$. *Then*, $D^* = \{y_n \colon n \geqq 1\}$.
(iii) $a < b$. *Then*, $D^* = \{x_n \colon n \geqq 1\} \cup \{y_n \colon n \geqq 1\}$.
(iv) $a = -b > 0\ (=0)$. *Then*, $D^*\{y_0\}$ $(D^* = \varnothing)$.
Region IV* (i) $b < a$. *Then*, $D^* = \{y_n \colon n \geqq 0\}$, $y_0 < -1$.
(ii) $a = b$. *Then*, $D^* = \{y_n \colon n \geqq 1\}$.
(iii) $a < b$. *Then*, $D^* = \{x_n \colon n \geqq 1\} \cup \{y_n \colon n \geqq 1\}$.

In all regions we always have $x_n < -1$ *and* $y_n > 1$ *for* $n \geqq 1$. *Furthermore*, $x_0 < -1$, $y_0 > 1$, *if* $\lambda > 0$.

Remark 4.27. Note that $-1, 1$ are the only possible limit points of D^* in $\mathbb{C}$ (or in $\mathbb{R}$).

Now we study the nature of the singularities of $\chi^*(z)$ in D^*. If $x \in D^*$ and $B(x) = n > 1$, we have, from (4.2),

$$\lim_{z \to x} (z-x)\chi^*(z) = -2\frac{\lambda + a}{\alpha - \beta}\beta^{2kn}(1-\beta^2)^{2\lambda}\frac{(2\lambda)_n}{n!}\frac{n}{B'(x)}. \tag{4.26}$$

Here we used $B = n$, $-A - B = 2\lambda$ and $\alpha\beta = 1$. If $B(x) = 0$ then

$$\lim_{z \to x} (z-x)\chi^*(z) = -2\frac{(\lambda + a)}{\alpha - \beta}(1-\beta^{2k})^{2\lambda}\frac{1}{B'(x)}. \tag{4.27}$$

Now, a calculation similar to that used to obtain (4.19) and (4.20) shows that

$$B'(x_0) = \pm\frac{\sqrt{\Delta_0}(a^2 - \lambda^2)^2}{(a\sqrt{\Delta_0} - b\lambda)^2}. \tag{4.28}$$

The sign is according to whether $\lambda > 0$ or $\lambda < 0$ (i.e., according to whether $x_0 < -1$ or $x_0 > 1$). Furthermore

$$B'(y_0) = \mp\frac{\sqrt{\Delta_0}(a^2 - \lambda^2)^2}{(a\sqrt{\Delta_0} - b\lambda)^2} \tag{4.29}$$

with the same determination of the sign. Hence, all the singularities of $\chi^*(z)$ in D^* are simple poles.

Recall that $\alpha(x_n) - \beta(x_n) = -2\sqrt{x_n^2 - 1}$, $\alpha(y_n) - \beta(y_n) = 2\sqrt{y_n^2 - 1}$ for $n \geqq 1$, and also for $n = 0$ if $\lambda > 0$. If $\lambda < 0$ then $\alpha(x_0) - \beta(x_0) = 2\sqrt{x_0^2 - 1}$, $\alpha(y_0) - \beta(y_0) = -2\sqrt{y_0^2 - 1}$. This information coupled with (4.19), (4.20), (4.27), (4.28) and (4.29) establish

$$\operatorname{Res}(\chi(z), x_n) = (\lambda + a)\beta^{2kn}(1 - \beta^{2k})^{2\lambda}\frac{(2\lambda)_n}{n!\sqrt{\Delta_n}}\left[\frac{a\sqrt{\Delta_n} - b(n+\lambda)}{a^2 - (n+\lambda)^2}\right], \tag{4.30}$$

$$\operatorname{Res}(\chi(z), y_n) = (\lambda + a)\beta^{2kn}(1 - \beta^{2k})^{2\lambda}\frac{(2\lambda)_n}{n!\sqrt{\Delta_n}}\left[\frac{a\sqrt{\Delta_n} + b(n+\lambda)}{a^2 - (n+\lambda)^2}\right], \tag{4.31}$$

for $n > 1$, and also, according to $\lambda \lessgtr 0$,

$$\operatorname{Res}(\chi(z), x_0) = \pm\frac{(a + \lambda)}{\sqrt{\Delta_0}}(1 - \beta^{2k})\left[\frac{a\sqrt{\Delta_0} - b\lambda}{a^2 - \lambda^2}\right], \tag{4.32}$$

$$\operatorname{Res}(\chi(z), y_0) = \mp\frac{a + \lambda}{\sqrt{\Delta_0}}(1 - \beta^{2k})\left[\frac{a\sqrt{\Delta_0} + b\lambda}{a^2 - \lambda^2}\right]. \tag{4.33}$$

The quantities α and β are given by (4.23) and (4.24) when $n>1$ or $n=1$ and $\lambda>0$. Furthermore

$$\beta(x_0)=-\frac{\sqrt{\Delta_0}+b}{a-\lambda},\qquad \alpha(x_0)=\frac{\sqrt{\Delta_0}-b}{a+\lambda},\qquad \lambda<0, \tag{4.34}$$

$$\beta(y_0)=\frac{\sqrt{\Delta_0}-b}{a-\lambda},\qquad \alpha(y_0)=-\frac{\sqrt{\Delta_0}+b}{a+\lambda},\qquad \lambda<0. \tag{4.35}$$

In view of Markov's Theorem we have shown the following.

THEOREM 4.28. *The function* $\chi^*(z)$ *has a simple pole at each point of* D^* *and* $D^*\subseteq\sigma(x)$.

Note, again, that the only possible limit points of D^* in $\mathbb{R}$ are $-1, 1$.

5. Orthogonality relations. We saw in § 4 that

$$D\subseteq\sigma(\phi)\subseteq[-1,1]\cup D,\qquad D^*\subseteq\sigma(\psi)\subseteq[-1,1]\cup D^*.$$

The purpose of the present section is to compute the orthogonality relation for our polynomials. This will follow from analyzing the singularities of $\chi(z)$ and $\chi^*(z)$ in $[-1,1]$. Observe that both $\sigma(\phi)$ and $\sigma(\psi)$ are compact subset of $\mathbb{R}$.

We start by determining the measure $d\phi$.

Remark 5.1. Observe that when $\lambda>0$, (3.38) implies the more symmetric form

$$\begin{aligned}\chi(z)=-2\Big\{A\beta^{k-1}&\int_0^{\overline{\beta^k}|}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B}\,du\\ &+B\alpha^{k-1}\int_0^{\overline{\beta^k}|}(1-u\beta^k)^{-A}(1-u\alpha^k)^{-B-1}\,du\Big\}.\end{aligned} \tag{5.1}$$

In fact,

$$A\beta^k\int_0^{\overline{\beta^k}|}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B}\,du=-1-B\alpha^k\int_0^{\overline{\beta^k}|}(1-u\beta^k)^{-A}(1-u\alpha^k)^{-B-1}\,du$$

for z in a neighborhood of $[-1,1]$, where $\operatorname{Re}(B(z))>0$ and, hence for all z, by analytic continuation.

Now, the restriction of the function $\beta(x)/\alpha(x)=\beta_+(x)/\alpha_+(x)$, to $[-1,1]$ is continuous. Let

$$\xi_j=\cos(\pi j/k),\qquad j=1,2,\cdots,k-1. \tag{5.2}$$

Clearly the points $x\in[-1,1]$, $x\neq\xi_j$, for any j, make $|\beta(x)/\alpha(x)|=1$ and $\operatorname{Im}\{\beta(x)/\alpha(x)\}^k\neq 0$, thus $\operatorname{Re}\{\beta(x)/\alpha(x)\}^k<1$ and

$$1-\operatorname{Re}\left\{u\left(\frac{\beta(x)}{\alpha(x)}\right)^k\right\}>0,\qquad 0\leqq u\leqq 1.$$

Hence, there are $\gamma,\delta>0$ such that

$$1-\operatorname{Re}\left(u\left(\frac{\beta(z)}{\alpha(z)}\right)^k\right)\geqq\gamma,\qquad 0\leqq u\leqq 1+\delta,$$

for all z in a compact set $K_x=[x-\delta,x+\delta]\times[0,\delta]$. It follows that if $0<\varepsilon_n<\delta$ and $\varepsilon_n\to 0$ as $n\to\infty$, then

$$\lim_{n\to\infty}\left[1-u\left\{\frac{\beta(t+i\varepsilon_n)}{\alpha(t+i\varepsilon_n)}\right\}^k\right]^{-A(t+i\varepsilon_n)-1}=\left[1-u\left\{\frac{\beta(t)}{\alpha(t)}\right\}^k\right]^{-A(t)-1}$$

holds uniformly for all $t\in[x-\delta,x+\delta]$ and all $u\in[0,1+\delta]$. As in § 2, we let

$$F(z)=\int_0^{1\rceil}\left[1-u\left\{\frac{\beta(z)}{\alpha(z)}\right\}^k\right]^{-A(z)-1}(1-u)^{-B(z)}\,du,\qquad z\in\Omega.$$

From the above argument

$$F_+(t):=\lim_{n\to\infty}F(t+i\varepsilon_n)=\int_0^{1\rceil}\left[1-u\left\{\frac{\beta(t)}{\alpha(t)}\right\}^k\right]^{-A(t)-1}(1-u)^{-B(t)}\,du,\tag{5.3}$$

the limit being uniform for $t\in[x-\delta,x+\delta]$.

Recall that $\overline{\beta_-(x)}=\alpha(x)$, $\overline{\alpha_-(x)}=\beta(x)$, $\overline{B_-(x)}=A(x)$ and $\overline{A_-(x)}=B(x)$. It is now easy to get, uniformly on $[x-\delta,x+\delta]$

$$F_-(t):=\lim_{n\to\infty}F(t-i\varepsilon_n)=\int_0^{1\rceil}\left[1-u\left\{\frac{\alpha(t)}{\beta(t)}\right\}^k\right]^{-B(t)-1}(1-u)^{-A(t)}\,du.\tag{5.4}$$

This shows that both $F_+(x)$ and $F_-(x)$ are continuous functions of x, $-1\leqq x\leqq 1$, $x\neq\xi_j$. Now

$$\chi_\pm(t):=\lim_{\varepsilon\to 0+}\chi(t+i\varepsilon)=2\{\beta+A(\beta-\alpha)\beta^{2k}F_\pm(t)\}\tag{5.5}$$

uniformly in $[x-\delta,x+\delta]$. This shows that the limit

$$\tilde{\chi}(t)=\lim_{\varepsilon\to 0+}(\chi(t-i\varepsilon)-\chi(t+i\varepsilon))\tag{5.6}$$

is uniform in $[x-\delta,x+\delta]$. This and (5.5) prove that $\tilde{\chi}(x)$

$$\begin{aligned}\tilde{\chi}(x)=2(\alpha-\beta)\biggl\{1+A\beta^k&\int_0^{\beta^k\rceil}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B}\,du\\&+B\alpha^k\int_0^{\alpha^k\rceil}(1-u\beta^k)^{-A}(1-u\alpha^k)^{-B-1}\,du\biggr\}\end{aligned}\tag{5.7}$$

is a continuous function of x, for $-1<x<1$, $x\neq\xi_j$, $j=1,2,\cdots,k-1$. The uniform convergence in (5.6) and the Perron-Stieltjes Inversion Formula imply

$$\phi(x)-\phi(x')=\frac{1}{2\pi i}\int_{x'}^{x}\tilde{\chi}(t)\,dt,\qquad x'\in[x-\delta,x+\delta],$$

so that the measure $d\phi$ is absolutely continuous in each one of the subintervals (ξ_j,ξ_{j-1}), and is given on such an interval by

$$d\phi=\phi'(x)\,dx=\frac{1}{2\pi i}\tilde{\chi}(x)\,dx.\tag{5.8}$$

Now, the right-hand side of (5.7) is an analytic function of λ for $\operatorname{Re}(\lambda)>-\frac{1}{2}$. If $\lambda\geqq 0$, we can use integration by parts because the first integral is a proper integral. Thus

$$\int_0^{\beta^k\rceil}(1-u\beta^k)^{-A-1}(1-u\alpha^k)^{-B}\,du=-\frac{1}{A\beta^k}-\frac{B\alpha^k}{A\beta^k}\int_0^{\beta^k\rceil}(1-u\beta^k)^{-A}(1-u\alpha^k)^{-B-1}\,du.$$

Therefore

$$\tilde{\chi}(x)=-2(\alpha-\beta)\alpha^kB\int_{\lfloor\alpha^k}^{\beta^k\rceil}(1-u\beta^k)^{-A}(1-u\alpha^k)^{-B-1}\,du,\qquad\lambda\geqq 0,$$

which is equivalent to

$$\tilde{\chi}(x)=-2(\alpha-\beta)B\left(1-\frac{\beta^k}{\alpha^k}\right)^{-A}\left(1-\frac{\alpha^k}{\beta^k}\right)^{-B}\int_{\lfloor 0}^{1\rceil}(1-v)^{-B-1}v^{-A}\,dv.\tag{5.9}$$

The integral on the right-hand side is, in fact, proper. Therefore

$$\tilde{\chi}(x)=2(\alpha-\beta)\left(1-\frac{\beta^k}{\alpha^k}\right)^{-A}\left(1-\frac{\alpha^k}{\beta^k}\right)^{-B}\frac{\Gamma(-B+1)\Gamma(-A+1)}{\Gamma(2\lambda+1)},\tag{5.10}$$

since $A+B=-2\lambda$. Since the right-hand side is also an analytic function of λ for $\operatorname{Re}(\lambda)>-\frac{1}{2}$, the identity (5.10) holds for all $\lambda>-\frac{1}{2}$. From (5.8) and (5.10) we obtain

$$\phi'(x)=\frac{\alpha-\beta}{\pi i}\left(1-\frac{\beta^k}{\alpha^k}\right)^{-A}\left(1-\frac{\alpha^k}{\beta^k}\right)^{-B}\frac{\Gamma(-B+1)\Gamma(-A+1)}{\Gamma(2\lambda+1)}\tag{5.11}$$

holding for $x\neq\xi_j$. Clearly (5.11) determines $d\phi$ as an absolutely continuous measure in each one of the intervals (ξ_j,ξ_{j-1}), $j=1,2,\cdots,k$.

Now write $x=\cos\theta$, $(j-1)\pi/k<\theta<j\pi/k$, $j=1,2,\cdots,k$, and recall that $\alpha(x)$, $\beta(x)$ are complex conjugate and so are $A(x)$, $B(x)$. Since $\alpha(\cos\theta)=e^{i\theta}$, $\beta(\cos\theta)=e^{-i\theta}$, $A=-\lambda-i\Phi(x)$ and $B=-\lambda+i\Phi(x)$, where $\Phi(\cos\theta)=a\cot\theta+b\csc\theta$. We thus obtain

$$\left(1-\frac{\beta^k}{\alpha^k}\right)^{-A}\left(1-\frac{\alpha^k}{\beta^k}\right)^{-B}=2^{2\lambda}|\sin k\theta|^{2\lambda}\exp\{\Phi(\cos\theta)(2k-2j\pi+\pi]\},$$

where we used the identities

$$\arg(i\alpha^{-k}\sin k\theta)=\pi j-k\theta-\frac{\pi}{2},\qquad \arg(-i\alpha^k\sin k\theta)=k\theta-j\pi+\frac{\pi}{2}.\tag{5.12}$$

For $(j-1)\pi<k\theta<j\pi$, $j=1,2,\cdots,k$, (5.11) is

$$\begin{aligned}\phi'(\cos\theta)=2\frac{2\lambda+1\sin\theta}{\pi\Gamma(2\lambda+1)}&|\sin(k\theta)|^{2\lambda}|\Gamma(\lambda+1+i\Phi(\cos\theta))|^2\\ &\cdot\exp\{2\Phi(\cos\theta)[k\theta-j\pi+\pi/2]\}.\end{aligned}\tag{5.13}$$

Note that if $\lambda\geqq 0$, ϕ' is continuous in $(-1,1)$, and $d\phi$ is absolutely continuous in $(-1,1)$. Clearly ϕ' vanishes at $t=\xi$ if $\lambda>0$.

We now apply Lemma 1.3 to show that the points $-1, 1, \xi_j$, $0<j<k$ do not support discrete masses. In the present case the coefficients A_n and C_n of (1.2) and (1.3) are

$$A=\begin{cases}2 & \text{if } k\nmid n+1,\\ \dfrac{2(\lambda+a+m)}{m} & \text{if } n+1=km,\end{cases}\qquad C_n=\begin{cases}1 & \text{if } k\nmid n+1,\\ \dfrac{2\lambda+m}{m} & \text{if } n+1=mk.\end{cases}\tag{5.14}$$

Therefore, from (1.1) and (1.6),

$$\lambda_n=\begin{cases}\dfrac{m}{\lambda+a+m}\cdot\dfrac{(2\lambda+1)_m}{m!} & \text{if } n+1=km,\\ \dfrac{(2\lambda+1)_p}{p!}, & p=[(n+1)/k]\quad\text{if } k\nmid n+1.\end{cases}\tag{5.15}$$

This and (1.40) show that $\Gamma(2\lambda+1)\lambda_{mk}\sim m^{2\lambda}$ as $m\to\infty$. Now we determine the asymptotic behavior of the polynomials $\{B_n^\lambda(x)\}$ at $x=\pm1$, ξ_j, $0<j<k$. Clearly $A(\xi_j)$, $B(\xi_j)$ are well defined. At $\alpha=\alpha(\xi_j)$ and $\beta=\beta(\xi_j)$, $B^\lambda(x,t)$ has an algebraic branch singularity of order $-A-B+1=2\lambda+1$. The dominant term in a comparison function is

$$\tilde{B}^\lambda(\xi_j,t)=k^{-2\lambda}\frac{\alpha}{\alpha-\beta}(1-t/\beta)^{-2\lambda-1}+k^{-2\lambda}\frac{\beta}{\beta-\alpha}(1-t/\alpha)^{-2\lambda-1}.\tag{5.16}$$

Darboux's Method readily gives

$$B_n^\lambda(\xi_j) \sim k^{-2\lambda} \frac{(\alpha^{n+1}-\beta^{n+1})(2\lambda+1)_n}{(\alpha-\beta)n!}.$$

Using (1.40) and $U_n(\varepsilon_j) = (\alpha^{n+1}-\beta^{n+1})/(\alpha-\beta) = \pm 1$, we obtain $[\Gamma(2\lambda+1)B_{mk}^\lambda(\xi_j)]^2 \sim m^{4\lambda}$, which implies

$$\frac{[B_{mk}^\lambda(\xi_j)]^2}{\lambda_{mk}} \sim \frac{m^{2\lambda}}{\Gamma(2\lambda+1)}. \tag{5.17}$$

Therefore the series $\sum_{n=0}^\infty [B_n^\lambda(\xi_j)]^2/\lambda_n$ is divergent, and $d\phi$ has no masses at the points $\xi_j, j=1, 2, \cdots, k-1$.

Now we consider the points $x=\pm 1$. In this case A and B are undefined, and we have to evaluate $B^\lambda(\pm 1, t)$ by a limiting process. In view of (2.25) and (3.31) the generating function (3.19) can be expressed in the form

$$B^\lambda(z, t) = \frac{(1-t^k\alpha^k)^{-\lambda}(1-t^k\beta^k)^{-\lambda}}{(1-t\alpha)(1-t\beta)} \exp\left\{ i\Phi(z) \log \frac{1-t^k\beta^k}{1-t^k\alpha^k} \right\}.$$

As $z \to \pm 1$, $a(z)$, $\beta(z) \to \pm 1$, and we apply L'Hôpital's rule to determine the limit under the exponential. Now (2.19) yields

$$\alpha'(z) = 2\alpha(z)/[\alpha(z)-\beta(z)], \qquad \beta'(z) = -2\beta(z)/[\alpha(z)-\beta(z)],$$

and an elementary calculation establishes the representation

$$B^\lambda(1, t) = \left(\frac{1-t^k}{1-t}\right)^2 (1-t^k)^{-2\lambda-2} \exp\left\{ 2(a+b)k \frac{t^k}{1-t^k} \right\}, \tag{5.18}$$

or, equivalently,

$$B^\lambda(1, t) = \left(\frac{1-t^k}{1-t}\right)^2 L^{(2\lambda+1)}(-2k(a+b), t^k), \tag{5.19}$$

where

$$L^{(2\lambda+1)}(x, t) := \sum_{n=0}^\infty L_n^{(2\lambda+1)}(x) t^n$$

is a generating function for the Laguerre polynomials of order $2\lambda+1$. Similarly

$$B^\lambda(-1, t) = \left(\frac{1 \pm t^k}{1+t}\right)^2 L^{(2\lambda+1)}(-2k(a-b), \pm t^k), \quad k = \text{odd or even}. \tag{5.20}$$

This and Darboux's Method establish

$$(\pm 1)^{km} B_{km}^\lambda(\pm 1) \sim k^2 L_m^{(2\lambda+1)}(-2k(a \pm b)). \tag{5.21}$$

Now, if $a=-b$, then $B_{km}^\lambda(1) \sim k^2 L_m^{(2\lambda+1)}(0) = k^2\Gamma(m+2\lambda+2)/[m!\Gamma(2\lambda+2)]$ (Lebedev [17, p. 85]) and $[B_{km}^\lambda(1)]^2/\lambda_{km} \sim m^{2\lambda+2}/(2\lambda+1)$. This argument shows that the series $\sum_{m=0}^\infty [B_{km}^\lambda(1)]^2/\lambda_{km}$ diverges and we conclude that $d\phi$ has no mass at 1 if $a+b=0$. If $a+b>0$, then Fejér's Formula for the Laguerre polynomials (Szegö [29, p. 198]) gives

$$B_{km}^\lambda(1) \sim \sqrt{\frac{e^{-2k(a+b)}}{\pi}}\, m^{\lambda+1/4}[-2k(a+b)]^{-\lambda-3/4} \cos\left(2\sqrt{-2km(a+b)} - \left(\lambda+\frac{3}{4}\right)\pi\right),$$

so that

$$\frac{[B_{km}^{\lambda}(1)]^2}{\lambda_{km}} \sim \frac{\sqrt{m}}{\pi} e^{-2k(a+b)}(-2k(a+b))^{-2\lambda-3/2}\Gamma(2\lambda+1)$$
$$\cdot \cos^2\left(2\sqrt{-2km(a+b)}-\left(\lambda+\frac{3}{4}\right)\pi\right).$$

Since the mth terms of the series $\sum_{m=0}^{\infty}[B_{km}^{\lambda}(1)]^2/\lambda_{km}$ does not tend to zero as $m\to\infty$, the series is divergent and 1 does not support any mass of $d\phi$. In case $a+b<0$, there is a positive constant C such that

$$B_{km}^{\lambda}(1)\sim C\sqrt{\frac{e^{-2k(a+b)}}{\pi}}(2k(a+b))^{-\lambda-3/4}m^{\lambda+1/2}\, e^{2\sqrt{2km(a+b)}}.$$

This is Perron's Formula for the Laguerre polynomials (Szegö [30, p. 199]). As before

$$\frac{[B_{km}^{\lambda}(1)]^2}{\lambda_{km}} \sim C\frac{e^{-2k(a+b)}(2k(a+b))^{-2\lambda-3/2}}{\pi}\Gamma(2\lambda+1)\sqrt{m}\, e^{4\sqrt{2km(a+b)}},$$

and the series $\sum_{n=0}^{\infty}[B_n^{\lambda}(1)]^2/\lambda_n$ also diverges.

A similar argument based on (5.21) shows that -1 supports no masses of $d\phi$. Thus we have proved the following.

THEOREM 5.2. *The measure $d\phi$ is absolutely continuous in the interval* $[-1,1]$ *and has masses only at the points of the discrete set D where B is a positive integer. In the interval* $[-1,1]$, *$d\phi=\phi'\,dx$, where ϕ' is given by*

$$\phi'(\cos\theta)=2^{2\lambda+1}\frac{(\sin\theta)^{2\lambda+1}}{\pi\Gamma(2\lambda+1)}|U_{k-1}(\cos\theta)|^{2\lambda}|\Gamma(\lambda+1+i\Phi(\cos\theta))|^2$$
$$\cdot\exp\left[2(k\theta-j\pi+\pi/2)\Phi(\cos\theta)\right] \tag{5.22}$$

and $\Phi(\cos\theta)=a\cot\theta+b\csc\theta$, $(j-1)\pi/k<\theta<j\pi/k$. *Furthermore, the support of $d\phi$ is the set*

$$\sigma(\phi)=DU[-1,1], \tag{5.23}$$

and $-1, 1$ are the only possible limit points of D in R. With the weight function

$$w(x)=\frac{\pi\Gamma(2\lambda+1)}{2^{2\lambda+1}}\phi'(x), \tag{5.24}$$

we have the orthogonality relation

$$\int_{-\infty}^{+\infty}B_n^{\lambda}(x)B_m^{\lambda}(x)w(x)\,dx+\sum_{\xi\in D}J_{\xi}B_n^{\lambda}(\xi)\beta_m^{\lambda}(\xi)=\frac{\pi\Gamma(2\lambda+1)}{2^{2\lambda+1}}\lambda_n\delta_{mn} \tag{5.25}$$

where

$$J_{\xi}=\frac{\pi\Gamma(2\lambda+1)}{2^{2\lambda+1}}\operatorname{Res}(\chi(z),\xi) \tag{5.26}$$

and Res $(\chi(z),\xi)$ *is as in* (4.21) *or* (4.22).

Finally, the set D is empty if and only if $a\geqq|b|$, and is an infinite countable set if $a<|b|$. Every point of $[-1,1]$ *is a continuous singularity of $\chi(z)$.*

We now wish to determine ψ' and show that the measure $d\psi$ has no discrete masses in $[-1, 1]$. The argument is similar to what we used to analyze $\chi(z)$. When $\lambda = 0$, (3.55) and integration by parts give

$$\chi^*(z) = 2(\lambda + a)\frac{\alpha^k - \beta^k}{\alpha - \beta}\int_0^{\overline{\beta^k}\rceil}(1 - u\beta^k)^{-A-1}(1 - u\alpha^k)^{-B-1}\,du. \tag{5.27}$$

Let $G(z) := \int_0^{\overline{1}\rceil}(1 - u\beta^{2k})^{-A-2}(1-u)^{-B}\,du$. Therefore

$$G_+(x) := \lim_{y\to 0+} G(x+iy) = \int_0^{\overline{1}\rceil}(1 - u\beta^{2k})^{-A-2}(1-u)^{-B}\,du,$$

$$G_-(x) := \lim_{y\to 0+} G(x-iy) = \int_0^{\overline{1}\rceil}(1 - u\beta^{2k})^{-B-2}(1-u)^{-A}\,du,$$

the limits being uniform in any closed subinterval of (ξ_j, ξ_{j-1}), $0 < j < k$. This implies, as before, that the limits

$$\chi^*_+(x) = \lim_{\varepsilon\to 0+}\chi^*(x + i\varepsilon), \qquad \chi^*_-(x) = \lim_{\varepsilon\to 0+}\chi^*(x - i\varepsilon)$$

hold uniformly on compact subintervals of (ξ_j, ξ_{j-1}). The function

$$\tilde{\chi}^*(x) = \chi^*_-(x) - \chi^*_+(x) = \lim_{\varepsilon\to 0+}(\chi^*(x - i\varepsilon) - \chi^*(x + i\varepsilon))$$

satisfies

$$\tilde{\chi}^*(x) = 2(\lambda + a)\frac{\alpha^k - \beta^k}{\alpha - \beta}\int_{\underline{\lfloor\alpha^k}}^{\overline{\beta^k}\rceil}(1 - u\beta^k)^{-A-1}(1 - u\alpha^k)^{-B-1}\,du, \tag{5.28}$$

from which we conclude that $\tilde{\chi}^*(x)$ is continuous in each one of the intervals (ξ_j, ξ_{j-1}). Furthermore, in (ξ_j, ξ_{j-1}), $d\psi$ is absolutely continuous with $2\pi i\,dx = \tilde{\chi}^*(x)\,dx$. This shows that

$$\pi i\psi'(x) = (\lambda + a)\frac{\alpha^k - \beta^k}{\alpha - \beta}\int_{\underline{\lfloor\alpha^k}}^{\overline{\beta^k}\rceil}(1 - u\beta^k)^{-A-1}(1 - u\alpha^k)^{-B-1}\,du,$$

that is

$$\pi i\psi'(x) = \frac{\lambda + a}{\alpha - \beta}\left(1 - \frac{\beta^k}{\alpha^k}\right)^{-A}\left(1 - \frac{\alpha^k}{\beta^k}\right)^{-B}\int_{\underline{\lfloor 0}}^{\overline{1}\rceil}(1 - \nu)^{-B-1}\nu^{-A-1}\,d\nu.$$

This establishes the explicit formula

$$\pi i\psi'(x) = \frac{\lambda + a}{\alpha - \beta}(1 - \beta^{2k})^{-A}(1 - \alpha^{2k})^{-B}\frac{\Gamma(-A)\Gamma(-B)}{\Gamma(2\lambda)}, \tag{5.29}$$

holding for $x \neq \xi_j$. Set $x = \cos\theta$, $(j-1)\pi < k\theta < j\pi$. The observations $\alpha(\cos\theta) = e^{i\theta}$, $\beta(\cos\theta) = e^{-i\theta}$ and $A = -\lambda - i\Phi(x)$, $B = -\lambda + i\Phi(x)$, where $\Phi(x)$ is as in (3.32), lead to

$$\begin{aligned}\psi'(\cos\theta) &= 2^{2\lambda-1}(\lambda + a)\frac{(\sin\theta)^{2\lambda-1}}{\pi\Gamma(2\lambda)}|U_{k-1}(\cos\theta)|^{2\lambda}\\ &\quad\cdot|\Gamma(\lambda + i\Phi(\cos\theta))|^2\exp(2\Phi(\cos\theta)(k\theta - j\pi + \pi/2)).\end{aligned} \tag{5.30}$$

Again, $\psi'(x)$ is continuous in $(-1, 1)$ if $\lambda > 0$, and vanishes at $x = \xi_j$, $j = 1, 2, \cdots, k-1$.

We now examine the possibility of $d\psi$ having discrete masses at the points $x = \pm 1$, ξ_j. We recall from formulas (3.19) and (3.45) that

$$C^\lambda(x, t) = \left(1 + \frac{2b}{\lambda + a}t - \frac{\lambda - a}{\lambda + a}t^2\right)B^\lambda(x, t). \tag{5.31}$$

If $x=\xi_j$ we have, from (2.19) and (2.20)

$$\lim_{t\to\beta}\left(1+\frac{2b}{\lambda+a}t-\frac{\lambda-a}{\lambda+a}t^2\right)=\frac{(\beta-\alpha)B}{\alpha(\lambda+a)},\qquad \lim_{t\to\alpha}\left(1+\frac{2b}{\lambda+a}t-\frac{\lambda-a}{\lambda+a}t^2\right)=\frac{(\alpha-\beta)A}{(\lambda+a)\beta}.$$

Hence, from (5.16)

$$\begin{aligned}\frac{1}{2}b_nc_n^\lambda(x)&\sim-\frac{(A+B)(n/k)^{2\lambda}}{\Gamma(2\lambda+1)(\lambda+a)}\cos(jn\pi/k)\\&=\frac{(n/k)^{2\lambda}}{\Gamma(2\lambda)(\lambda+a)}\cos(jn\pi/k).\end{aligned}$$

From (3.47), we have

$$b_{mk}=\frac{(\lambda+a+1)_m(2\lambda)_m}{m!(\lambda+a)_m}\sim\frac{m^{2\lambda}}{(\lambda+a)\Gamma(2\lambda)}. \tag{5.32}$$

This shows that

$$c_{mk}^\lambda(\xi_j)\sim 2(-1)^m,\qquad j=1,2,\cdots,k-1, \tag{5.33}$$

as can also be checked from the recurrence relation.

On the other hand $A_0=1$,

$$A_n=\begin{cases}2 & \text{if } k\nmid n,\\ \dfrac{2(\lambda+a+m)}{2\lambda+m} & \text{if } n=mk,\end{cases}\qquad C_n=\begin{cases}1 & \text{if } k\nmid n,\\ \dfrac{m}{2\lambda+m} & \text{if } n=mk,\end{cases}$$

so that

$$\lambda_{mk+l}=\frac{\lambda(m!)}{(2\lambda)_{m+1}},\quad 0<l<k;\qquad \lambda_{mk}=\frac{\lambda(m!)}{(\lambda+a+m)(2\lambda)_{m+1}}. \tag{5.34}$$

Clearly (5.34) gives

$$\lambda_{mk}\sim\lambda\Gamma(2\lambda)m^{-2\lambda}, \tag{5.35}$$

which when combined with (5.33) and the fact $2\lambda>-1$ will prove the divergence of the series $\sum_{n=0}^\infty[c_n^\lambda(\xi_j)]^2/\lambda_n$. Hence ξ_j, $0<j<k$ is not a discrete mass point.

Now we consider the cases $x=\pm1$. Note that the function

$$h(t):=1-\frac{\lambda-a}{\lambda+a}t^2+\frac{2b}{\lambda+a}t=1-t^2+2t\frac{at+b}{\lambda+a}$$

vanishes at $t=1$ when $a+b=0$ and at $t=-1$ if $a-b=0$. The functions $C^\lambda(\pm1,t)$ behave differently according to whether $a=\pm b$ or $|a|\neq|b|$. The reason is that $\lim_{t\to\pm1}h(t)=2(a\pm b)/(\lambda+a)$. Using the asymptotic properties of Laguerre polynomials, one can show that $x=\pm1$ are not discrete mass points of $d\psi$ if $|a|\neq|b|$. The proof is similar to the way we handled the same points in relation to the measure $d\phi$. The same conclusion holds for $x=1$ if $a=b$ and for $x=-1$ if $a=-b$. Now, assume $a=-b$. Clearly

$$C^\lambda(1,t)=\frac{h(t)}{1-t}\frac{1-t^k}{1-t}L^{(2\lambda)}(0,t^k) \tag{5.36}$$

implies $(l+a)b_{mk}c_{mk}^\lambda(1)\sim 2k\lambda L_m^{(2\lambda)}(0)$. This, (5.32) and (5.33) ensure the divergence of the series $\sum_{n=0}^\infty[c_n^\lambda(1)]/\lambda_n$. The case $a=b$ and $x=-1$ can be handled in a similar way. This shows that neither $x=1$ nor $x=-1$ support discrete masses for dx. We summarize these results in the next theorem.

THEOREM 5.3. *The measure $d\psi$ is absolutely continuous in $[-1, 1]$ and its only masses are located on the discrete set D^* where $B(z)=0, 1, 2, \cdots$. On $[-1, 1]$, $d\psi=\psi'\,dx$, where $\psi'(x)$ is given by* (5.29) *or* (5.30). *The support of the measure $d\psi$ is*

$$\sigma(\psi)=[-1, 1]UD^*, \tag{5.37}$$

and the set D^* is empty if and only if $a \geqq |b|$ and $\lambda>0$, and a countable subset of $\mathbb{R}-[-1, 1]$, having at most 1 or -1 as limit points, in any case. With the weight function

$$W^*(x)=\pi\frac{\Gamma(2\lambda)}{\lambda+a}2^{-2\lambda+1}\psi'(x) \tag{5.38}$$

we obtain the orthogonality relation

$$\int_{-\infty}^{+\infty} c_n^\lambda(x)c_m^\lambda(x)W^*(x)\,dx+\sum_{\xi\in D^*} J_\xi c_n^\lambda(\xi)c_m^\lambda(\xi)=\lambda_n\delta_{mn}, \tag{5.39}$$

where λ_n is given by (5.34), *and*

$$J_\xi=\pi\frac{\Gamma(2\lambda)}{\lambda+a}2^{-2\lambda+1}\,\mathrm{Re}\, s(\chi^*(z), \xi), \tag{5.40}$$

and Res $(\chi(z), \xi)$ *is as in* (4.30), (4.31), (4.32) *and* (4.33).

6. The Pollaczek polynomials and their q-analogues. The recurrence relation (1.14) and the initial conditions (1.15) define the general Pollaczek polynomials $\{P_n^\lambda(x, a, b)\}$, or $\{P_n^\lambda(x)\}$ for short. The case $\lambda=\frac{1}{2}$ was studied in Pollaczek [24]. Szegö [29] studied the general nonsingular case $a \geqq |b|$, $\lambda>0$, and showed that the polynomials are orthogonal with respect to an absolutely continuous measure. He also found the measure. Special instances of the singular case have been studied by Bank and Ismail [7]. They covered the cases $a=\pm b$. In this section, we first study the general case, and especially the singular cases among $a<|b|$. It turns out that this is essentially the case $k=1$ of the sieved Pollaczek polynomials of the first kind previously studied. We also compute the continued fraction whose denominators are the q-Pollaczek polynomials $\{F_n(x)\}$, then determine the corresponding distribution function when it is continuous. The results of § 2 may be used to completely analyze the singular cases, if needed, but we will spare the reader the details. The q-Pollaczek polynomials arose recently in Al-Salam and Chihara's solution of a characterization problem of Andrews and Askey.

We denote by $P_n^{*\lambda}(x; a, b)$, or simply by $P_n^{*\lambda}(x)$, the Pollaczek numerator polynomials, and by $\chi_0(z)$ the continued fraction

$$\chi_0(z)=\lim_{n\to\infty} P_n^{*\lambda}(x)/P_n^\lambda(x). \tag{6.1}$$

The numerator polynomials satisfy (1.14) and the initial conditions

$$P_0^{*\lambda}(x)=0, \qquad P_1^{*\lambda}(x)=2(\lambda+a). \tag{6.2}$$

The positivity conditions are

$$(a+\lambda+n-1)(a+\lambda+n)(2\lambda+n-1)>0, \qquad n=1, 2, \cdots, \tag{6.3}$$

which evidently reduce to

$$\lambda>0 \text{ and } \lambda+a>0 \text{ or } -\tfrac{1}{2}<\lambda<0 \text{ and } 0<\lambda+a+1<1. \tag{6.4}$$

We will use the generating functions

$$P(x,t)=\sum_{n=0}^{\infty}P_n^{\lambda}(x)t^n,\qquad P^*(x,t)=\sum_{n=0}^{\infty}P_n^{*\lambda}(x)t^n. \tag{6.5}$$

They are solutions of the initial value problems

$$(t^2-2xt+1)\frac{\partial P}{\partial t}-2[(a+\lambda)x-\lambda t+b]P=0,\qquad P(x,0)=1, \tag{6.6}$$

$$(t^2-2xt+1)\frac{\partial P^*}{\partial t}-2[(a+\lambda)x-\lambda t+b]P^*=2(\lambda+a),\qquad P^*(x,0)=0. \tag{6.7}$$

From the partial fraction decomposition

$$\frac{2[(a+\lambda)x-\lambda t+b]}{t^2-2xt+1}=\frac{A(x)}{t-\alpha(x)}+\frac{B(x)}{t-\beta(x)} \tag{6.8}$$

where $\alpha(x)$, $\beta(x)$ are given by (2.19) and $A(x)$, $B(x)$ by (2.20), we readily obtain

$$P(x,t)=(1-t/\alpha)^A(1-t/\beta)^B \tag{6.9}$$

and

$$\begin{aligned} P^*(x,t)&=2(\lambda+a)(1-t/\alpha)^A(1-t/\beta)^B\int_0^t(1-u/\alpha)^{-A-1}(1-u/\beta)^{-B-1}\,du\\ &=2\frac{\lambda+a}{B(\alpha-t)}-\frac{2(\lambda+a)\beta}{B}\left[1+\frac{A+1}{\alpha}\int_0^t(1-u/\alpha)^{-A-2}(1-u/\beta)^{-B}\,du\right]\\ &\quad\cdot(1-t/\alpha)^A(1-t/\beta)^B. \end{aligned} \tag{6.10}$$

For fixed $x\in\mathbb{C}-[-1,1]$ and as $n\to\infty$, Darboux's Method gives

$$P_n^{\lambda}(x)\sim(1-\beta^2)^A\beta^{-n}n^{-B-1}/\Gamma(-B) \tag{6.11}$$

and

$$\begin{aligned} P_n^{*\lambda}(x)&\sim2\frac{\lambda+a}{\Gamma(-B+1)}\beta^{-n+1}n^{-B+1}(1-\beta/\alpha)^A\\ &\quad\cdot\left[1+\frac{A+1}{\alpha}\int_0^{\overline{\beta|}}(1-u/a)^{-A-2}(1-u/\beta)^{-B}\,du\right]. \end{aligned} \tag{6.12}$$

When $\lambda>0$, (6.12) takes the more symmetric form

$$P_n^{*\lambda}(x)\sim2(\lambda+a)(1-\beta/\alpha)^A\beta^{-n}\frac{n^{-B-1}}{\Gamma(-B)}\int_0^{\overline{\beta|}}(1-u/\alpha)^{-A-1}(1-u/\beta)^{-B-1}\,du. \tag{6.13}$$

Therefore

$$\chi_0(x)=-2\frac{(\lambda+a)\beta}{B}\left[1+\frac{A+1}{\alpha}\int_0^{\overline{\beta|}}(1-u\beta)^{-A-2}(1-u\alpha)^{-B}\,du\right] \tag{6.14}$$

or equivalently

$$\chi_0(x)=-2\frac{(\lambda+a)\beta}{B}\left[1+(A+1)\frac{\beta}{\alpha}\int_0^{\overline{1|}}(1-u\beta^2)^{-A-2}(1-u)^{-B}\,du\right], \tag{6.15}$$

and, when $\lambda>0$,

$$\chi_0(x)=2(\lambda+a)\beta\int_0^{1}(1-u\beta^2)^{-A-1}(1-u)^{-B}\,du, \tag{6.16}$$

$$\chi_0(x)=2(\lambda+a)\int_0^{\beta}(1-u\beta)^{-A-1}(1-u\alpha)^{-B-1}\,du. \tag{6.17}$$

As in the case of the continued fraction $\chi^*(x)$ we can show that $\chi_0(z)$ is analytic on Ω^* of (2.36). The series representation

$$\chi_0(x)=-2\frac{\lambda+a}{B}\beta\left\{1-(1-\beta^2)^{-A-1}\sum_{n=1}^{\infty}\frac{(A+1)_n}{n!}\left(\frac{\beta}{\beta-\alpha}\right)^n\frac{n}{n-B}\right\} \tag{6.18}$$

follows from (6.15) and proves that the singularities of $\chi_0(z)$ belong to D^* of (4.17) and are simple poles. Furthermore,

$$\operatorname{Res}(\chi_0, x)=-2\frac{\lambda+a}{B'(x)}\beta(x) \quad \text{if } B(x)=0, \tag{6.19}$$

$$\operatorname{Res}(\chi_0, x)=-2(\lambda+a)\beta^{2n+1}(1-\beta^2)^{2\lambda-1}\frac{(2\lambda)_n}{n!}\frac{n}{B'(x)} \tag{6.20}$$

if $B(x)=n\geqq 1$. Using (4.19), (4.20), we get

$$\operatorname{Res}(\chi_0, x_n)=(\lambda+a)\beta^{2n}(1-\beta^2)^{2\lambda}\frac{(2\lambda)_n[a\sqrt{\Delta_n}-b(n+\lambda)]}{n!\sqrt{\Delta_n}[a^2-(n+\lambda)^2]}, \tag{6.21}$$

and

$$\operatorname{Res}(\chi_0, y_n)=(\lambda+a)\beta^{2n}(1-\beta^2)^{2\lambda}\frac{(2\lambda)_n[a\sqrt{\Delta_n}+b(n+\lambda)]}{n!\sqrt{\Delta_n}[a^2-(n+\lambda)^2]}. \tag{6.22}$$

which hold for $n+\lambda>0$. Here, x_n, y_n are given by (4.5). Furthermore, from (4.28) and (4.29), we obtain

$$\operatorname{Res}(\chi_0, x_0)=-2(\lambda+a)\beta(x_0)\frac{[a\sqrt{\Delta_0}-b\lambda]^2}{\sqrt{\Delta_0}(a^2-y^2)^2} \tag{6.23}$$

and

$$\operatorname{Res}(\chi_0, y_0)=2(\lambda-a)\beta(y_0)\frac{[a\sqrt{\Delta_0}+b\lambda]^2}{\sqrt{\Delta_0}(a^2-\lambda^2)^2} \tag{6.24}$$

when $\lambda<0$, $n=0$, in which case $x_0>1$ (and $\beta>0$) and $y_0<-1$ (with $\beta<0$). Notice that $\lambda+a<0$ in the last two formulas. Again, the last four formulas could be made more explicit by using (4.23), (4.24), (4.34) and (4.35). We have the following theorem, which is nothing but a restatement of Theorems 4.22 and 4.24 for the Pollaczek polynomials.

THEOREM 6.1. *If $a>|b|$ then $D^*=\phi$ when $\lambda>0$. If $\lambda<0$ then $D^*=\{x_0, y_0\}$, and $x_0>1$, $y_0<-1$.*

With the subdivision of the (λ, a) plane shown in Fig. 4.2, Theorem 4.25 in the case of Pollaczek polynomials becomes

THEOREM 6.2. *When $b\geqq 0$ and $a\leqq b$, the set D^* is as follows:*

Region I* (i) *$a<b$. Then $D^*=\{x_n\colon n\geqq 0\}$.*
(ii) *$a=b$. Then $D^*=\varnothing$.*

Region II* (i) $-b \leqq a < b$. *Then* $D^* = \{x_n\colon n \geqq 0\}$.
(ii) $a < -b$. *Then* $D^* = \{x_n\colon n \geqq 0\} \cup \{y_n\colon n \geqq 0\}$.
Region III* (i) $-b < a < b$. *Then* $D^* = \{x_n\colon n \geqq 0\}$, $x_0 > 1$.
(ii) $a = -b \neq 0$. *Then* $D^* = \{x_n\colon n \geqq 1\}$.
(iii) $a < -b$. *Then* $D^* = \{x_n\colon n > 1\} \cup \{y_n\colon n > 1\}$.
(iv) $a = b > 0\ (=0)$. *Then* $D^* = \{x_0\}\ (=\varnothing)$.
Region IV* (i) $-b < a$. *Then* $D^* = \{x_n\colon n \geqq 0\}$, $x_0 > 1$.
(ii) $b = -a$. *Then* $D^* = \{x_n\colon n \geqq 1\}$.
(iii) $a < -b$. *Then* $D^* = \{x_n\colon n \geqq 1\} \cup \{y_n\colon n \geqq 1\}$.

In all the regions $x_n < -1$ *and* $y_n > 1$ *for* $n \geqq 1$. *Also,* $x_0 < -1$ *and* $y_0 > 1$ *if* $\lambda > 0$.

The symmetry relation

$$(-1)^n P_n^\lambda(x; a, b) = P_n^\lambda(-x; a, -b) \tag{6.25}$$

follows from (1.14) and (1.15). It shows that the case $a \leqq -b$, $b \leqq 0$, can be obtained from Theorem 6.2 interchanging x_n and y_n, $n \geqq 0$.

A special case of the results derived in § 5 is the following theorem:

THEOREM 6.3. *The measure* $d\psi$ *the polynomials* $\{P_n^\lambda(x)\}$ *are orthogonal with respect to is absolutely continuous in* $\lfloor -1, 1 \rfloor$ *and its only masses belong to* D^*. *Furthermore,* ψ' *is continuous in* $(-1, 1)$ *and*

$$\begin{aligned}\psi'(\cos\theta) = 2^{2\lambda-1}(\lambda+a)\frac{(\sin\theta)^{2\lambda-1}}{\pi}\,\frac{\Gamma(\lambda + i(a\cot\theta + b\csc\theta))^2}{\Gamma(2\lambda)}\\ \cdot \exp\lfloor (a\cot\theta + b\csc\theta)(2\theta - \pi)\rfloor.\end{aligned} \tag{6.26}$$

The support of the measure $d\psi$ *is*

$$\sigma(\psi) = \lfloor -1, 1 \rfloor\, UD^* \tag{6.27}$$

and the set D^* *is empty if and only if* $a \geqq |b|$ *and* $\lambda > 0$, *a finite set with one point if* $a = b > 0$ *or* $a = -b$, $b < 0$ *and two points if* $a > |b|$, *for* $\lambda < 0$; *and a countable infinite subset of* $(-\infty, -1) \cup (1, \infty)$ *having* -1 *or* 1 *as limit points in the other cases. With the weight function*

$$w(x) = \pi\frac{\Gamma(2\lambda)}{\lambda + a}2^{-2\lambda+1}\psi'(x) \tag{6.28}$$

the orthogonality relation is

$$\int_{-\infty}^{\infty} P_n^\lambda(x)P_m^\lambda(x)w(x)\,dx + \sum_{\xi\in D^*} J_\xi P_n^\lambda(\xi)P_m^\lambda(\xi) = h_n\delta_{mn} \tag{6.29}$$

where

$$h_n = \frac{2\pi\Gamma(n+2\lambda)}{2^{2\lambda}(n+\lambda+a)n!}, \qquad J_\xi = \pi\frac{\Gamma(2\lambda)}{\lambda+a}2^{-2\lambda+1}\,\mathrm{Re}\ s(\chi_0, \xi) \tag{6.30}$$

and Res (χ_0, ξ) *is given by* (6.21), (6.22), (6.23) *and* (6.24).

We now turn to the q-Pollaczek polynomials $\{F_n(x)\}$. The generating functions (3.7) and (3.9) and Darboux's Method establish

$$F_n(x) \sim \beta^{-n}(\beta/\xi; q)_\infty(\beta/\zeta; q)_\infty / \lfloor (q; q)_\infty(\beta^2; q)_\infty \rfloor, \tag{6.31}$$

$$F_n^*(x) \sim 2\beta^{1-n}\frac{(1-U\Delta)}{1-\beta^2}\,{}_2\phi_1\!\left(\begin{matrix}\beta/\xi, \beta/\zeta\\ q\beta^2\end{matrix}; q, q\right), \qquad z \in \mathbb{C} - \lfloor -1, 1 \rfloor, \tag{6.32}$$

where ${}_2\phi_1$ is the basic hypergeometric function

$$ {}_2\phi_1\left(\begin{matrix} a, b \\ c \end{matrix}; q, z\right) = \sum_{n=0}^{\infty} \frac{(a;q)_n(b;q)_n}{(c;q)_n(q;q)_n} z^n. $$

The corresponding continued fraction is

$$ \chi(x) = \frac{2\beta(q;q)_\infty(q\beta^2;q)_\infty(1-\Delta U)}{(\beta/\xi;q)_\infty(\beta/\zeta;q)_\infty} {}_2\phi_1\left(\begin{matrix} \beta/\xi, \beta/\zeta \\ q\beta^2 \end{matrix}; q, q\right). \tag{6.33} $$

It is easy to see that $F(x)$ is single-valued whenever it is defined outside $[-1, 1]$. This shows that the continuous spectrum is $[-1, 1]$ and the discrete spectrum coincides with the closure of the solutions of

$$ \beta = \xi q^n \quad \text{or} \quad \beta = \zeta q^n, \qquad n = 0, 1, \cdots. \tag{6.34} $$

One can also show that $[-1, 1]$ does not intersect the discrete spectrum. The absolutely continuous component of the spectral measure can be obtained from (6.33) via the Perron–Stieltjes Inversion Formula but it is easier to use the following theorem of Nevai [20, pp. 141-143].

THEOREM 6.4. *If* $\sum_1^\infty \{|B_n/A_n| + |\sqrt{C_n/(A_nA_{n-1})} - \frac{1}{2}|\}$ *converges, then the continuous spectrum is* $[-1, 1]$ *and the distribution function* ψ *satisfies*

$$ \limsup_n \{\psi'(x)\sqrt{1-x^2}\, p_n^2(x)/\lambda_n\} = \frac{2}{\pi} \quad \text{a.e. on } [-1, 1]. \tag{6.35} $$

Let $d_\psi = \Psi' \, dx$ on $\lfloor -1, 1 \rfloor$. We now go back to (3.7) and derive

$$ F_n(\cos\theta) \sim \frac{(\alpha/\xi;q)_\infty(\alpha/\zeta;q)_\infty}{(\alpha/\beta;q)_\infty(q;q)_\infty}\alpha^n + \text{conjugate}, \qquad 0 < \theta < \pi, \tag{6.36} $$

since $\alpha = 1/\beta = e^{i\theta}$. The recursion (1.29), and (1.6) imply

$$ \lambda_n = (1 - U\Delta)(\Delta^2; q)_n/(q;q)_n. \tag{6.37} $$

Theorem 6.4 enables us to evaluate $\Psi'(x)$. It is given by

$$ \Psi'(\cos\theta) = \frac{C}{\sin\theta}\left|\frac{(e^{2i\theta};q)_\infty}{(e^{i\theta}/\xi;q)_\infty(e^{i\theta}/\zeta;q)_\infty}\right|^2, \tag{6.38} $$

with

$$ C = \frac{1}{2\pi}(1 - U\Delta)(\Delta^2;q)_\infty(q;q)_\infty. \tag{6.39} $$

Finally, one can show that the discrete spectrum is empty when

$$ q, U, \Delta \in \lfloor 0, 1) \quad \text{and} \quad 1 - U^2 \pm 2V > 0. \tag{6.40} $$

Acknowledgments. Richard Askey read a preliminary version of this paper and made several helpful suggestions. The referees caught several minor errors. We gratefully acknowledge the help of Askey and the referees. We also thank Erna Penta and Marlene Salvato for the patience and care they took in typing this manuscript.

A NOTE ON WILSON POLYNOMIALS*

WILLARD MILLER, JR.†

Abstract. Local symmetry (recurrence relation) techniques are a powerful tool for the efficient derivation of properties associated with families of hypergeometric and basic hypergeometric functions. Here these ideas are applied to the Wilson polynomials, a generalization of the classical orthogonal polynomials, to obtain the orthogonality relations and an elementary evaluation of the norm.

Key words. Wilson polynomials, orthogonal polynomials, q-series, basic hypergeometric functions

AMS(MOS) subject classifications. 33A65, 33A75, 39A10

1. Introduction. In [1] Wilson introduced a family of hypergeometric orthogonal polynomials that included as special or limiting cases the classical polynomials and the 6-j symbols of angular momentum. In the Memoir [2] Askey and Wilson introduced a still more general class of basic hypergeometric orthogonal polynomials, the most extensive generalization of classical orthogonal polynomials known. The orthogonality proofs in these papers, while not unmotivated, are quite technical and rely on Mellin-Barnes contour integrals and several hypergeometric summation formulas that are unfamiliar to most mathematicians. The Askey-Wilson and Wilson polynomials are important and useful; they deserve to be more widely known. Furthermore, the appropriate algebraic and group theoretic setting for these general families is as yet unclear. The elementary algebraic treatment of Wilson polynomials presented here is offered in the hope that it will help to increase the "audience" for the polynomials as well as to shed some light on their structure.

In [3] the author, with Agarwal and Kalnins, introduced symmetry techniques for the study of families of basic hypergeometric functions, in analogy with the local Lie theory techniques for ordinary hypergeometric functions. The fundamental objects in this study are the recurrence relations obeyed by the families, expressed in terms of difference or q-difference equations. Generating functions and identities for each family are characterized in terms of the recurrence relations. These ideas were applied in [4] to obtain a strikingly simple derivation of the orthogonality relations for the Askey-Wilson q-polyomials. The treatment of the Wilson (ordinary hypergeometric) polynomials presented here is very similar to that in [4]. However several minor complications arise, due to the fact that whereas the first order q-difference equation $f(qz)=f(z)$ has only the solution $f(z)\equiv$ constant, the first order difference equation $f(z+1)=f(z)$ is satisfied by any periodic function f with period 1. Thus the treatment presented here is not entirely algebraic: a few simple facts about Fourier series and the gamma function are required.

2. The results. The (unnormalized) Wilson polynomials are:

$$\Phi_n^{(a,b,c,d)}(z^2)={}_4F_3\left(\begin{matrix}-n,\, n+a+b+c+d-1,\, a+z,\, a-z\\ a+b,\, a+c,\, a+d\end{matrix};1\right) \tag{2.1}$$

where $n=0,1,2,\cdots$ and $a, b, c, d>0$. The hypergeometric function ${}_4F_3$ is given by the series

$${}_4F_3\left(\begin{matrix}a_1, a_2, a_3, a_4\\ b_1, b_2, b_3\end{matrix};t\right)=\sum_{m=0}^{\infty}\frac{(a_1)_m(a_2)_m(a_3)_m(a_4)_m}{(b_1)_m(b_2)_m(b_3)_m}\frac{t^m}{m!}$$

* Received by the editors September 22, 1986; accepted for publication December 15, 1986. This work was supported in part by the National Science Foundation under grant DMS-86-00372.

† School of Mathematics, University of Minnesota, Minneapolis, Minnesota 55455.

where

$$(a)_m=\begin{cases}1 & \text{if } m=0,\\ a(a+1)\cdots(a+m-1) & \text{if } m=1,2,\cdots.\end{cases}$$

The functions (2.1) are polynomials of order n in z^2. (In [1] the parameters a, b, c, d are also permitted to become complex, an important extension; but we shall not consider that case here.)

Two fundamental recurrence relations for the Wilson polynomials are:

$$\tau^{(a,b,c,d)}\Phi_n^{(a,b,c,d)}=\frac{n(n+a+b+c+d-1)}{(a+b)(a+c)(a+d)}\Phi_{n-1}^{(a+1/2,b+1/2,c+1/2,d+1/2)}, \tag{2.2a}$$

$$\mu^{(a,b,c,d)}\Phi_n^{(a,b,c,d)}=-(a+b-1)\Phi_n^{(a-1/2,b-1/2,c+1/2,d+1/2)} \tag{2.2b}$$

where

$$\begin{aligned}\tau^{(a,b,c,d)}&=\frac{1}{2z}(E_z^{1/2}-E_z^{-1/2}),\\ \mu^{(a,b,c,d)}&=\frac{1}{2z}\left[-\left(a+z-\frac{1}{2}\right)\left(b+z-\frac{1}{2}\right)E_z^{1/2}+\left(a-z-\frac{1}{2}\right)\left(b-z-\frac{1}{2}\right)E_z^{-1/2}\right]\end{aligned} \tag{2.3}$$

and $E_z^\alpha f(z)=f(z+\alpha)$. Here (2.2a) follows from

$$\tau(a+z)_k(a-z)_k=-k(a+\tfrac{1}{2}+z)_{k-1}(a+\tfrac{1}{2}-z)_{k-1}$$

and (2.2b) follows from

$$\mu(a+z)_k(a-z)_k=-(a+b-k-1)(a-\tfrac{1}{2}+z)_k(a-\tfrac{1}{2}-z)_k.$$

The first relation was discussed by Askey and Wilson [2]; I have not found (2.2b) in the literature.

Relation (2.2b) suggests the existence of an operator μ^* mapping $\Phi_n^{(a-1/2,b-1/2,c+1/2,d+1/2)}$ to $\Phi_n^{(a,b,c,d)}$. We find that

$$\mu^{(c+1/2,d+1/2,a-1/2,b-1/2)}\Phi_n^{(a-1/2,b-1/2,c+1/2,d+1/2)}=\frac{-(n+c+d)(n+a+b-1)}{(a+b-1)}\Phi_n^{(a,b,c,d)}, \tag{2.4}$$

which follows from

$$\begin{aligned}&\mu^{(c+1/2,d+1/2,a-1/2,b-1/2)}(a-\tfrac{1}{2}+z)_k(a-\tfrac{1}{2}-z)_k\\ &\quad=-(k+c+d)(a+z)_k(a-z)_k+k(a+c+k-1)(a+d+k-1)(a+z)_{k-1}(a-z)_{k-1}.\end{aligned}$$

We try to introduce a pre-Hilbert space structure such that $\mu^*\equiv\mu^{(c+1/2,d+1/2,a-1/2,b-1/2)}$ is the adjoint operator to $\mu\equiv\mu^{(a,b,c,d)}$. Let $w_{a,b,c,d}(z)$ be analytic as a function of the complex variable z in a neighborhood of the imaginary axis $z=iy$, $-\infty<y<\infty$, real analytic in the variables a, b, c, d, of exponential decrease as $|y|\to\infty$ and such that $w_{a,b,c,d}(iy)\geqq 0$. Define an inner product:

$$(g_1,g_2)_{a,b,c,d}=\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}g_1(z^2)g_2(z^2)w_{a,b,c,d}(z)\,dz$$

where the contour is a deformation of the imaginary axis and g_1, g_2 are real polynomials in z^2. Let $S_{a,b,c,d}$ be the space of such polynomials with this inner product. We have

$$\mu : S_{a,b,c,d} \to S_{a-1/2,b-1/2,c+1/2,d+1/2},$$

$$\mu^* : S_{a-1/2,b-1/2,c+1/2,d+1/2} \to S_{a,b,c,d}$$

and seek a weight function $w_{a,b,c,d}$ such that

$$(2.5) \qquad (f, \mu g)_{a-1/2,b-1/2,c+1/2,d+1/2} = (\mu^* f, g)_{a,b,c,d}$$

for all polynomials $f \in S_{a-1/2,b-1/2,c+1/2,d+1/2}$ and $g \in S_{a,b,c,d}$. A straightforward computation yields the necessary and sufficient condition

$$\frac{w_{a,b,c,d}(z+1)}{w_{a,b,c,d}(z)} = \frac{(z+1)(a+z)(b+z)(c+z)(d+z)}{z(a-z-1)(b-z-1)(c-z-1)(d-z-1)}$$

with general solution

$$\begin{aligned} w_{a,b,c,d}(z) &= \frac{\Gamma(a+z)\Gamma(a-z)\Gamma(b+z)\Gamma(b-z)\Gamma(c+z)\Gamma(c-z)}{\Gamma(2z)\Gamma(-2z)} \\ &\quad \cdot \Gamma(d+z)\Gamma(d-z)h(a, b, c, d, z) \\ &= \hat{w}_{a,b,c,d}(z)h(a, b, c, d, z) \end{aligned}$$

where h satisfies the periodicity properties

$$\begin{aligned} h(a-\tfrac{1}{2}, b-\tfrac{1}{2}, c+\tfrac{1}{2}, d+\tfrac{1}{2}, z+\tfrac{1}{2}) &= h(a-\tfrac{1}{2}, b-\tfrac{1}{2}, c+\tfrac{1}{2}, d+\tfrac{1}{2}, z-\tfrac{1}{2}) \\ &= h(a, b, c, d, z). \end{aligned}$$

Here $\Gamma(z)$ is the gamma function [5, Chap. XII]. From Stirling's series for the gamma function, $\hat{w}_{a,b,c,d}(z) = (z)^{2(a+b+c+d)-3}O(e^{-2\pi|y|})$ as $|y| \to \infty$, where $z = x+iy$. Thus we must require that $h(z) = o(e^{2\pi|y|})$ as $|y| \to \infty$ in order that $\hat{w}h$ be a suitable weight function. Furthermore, the "integration by parts" formula (2.5) will not be valid unless $h(z)$ is analytic in an open set containing the strip $-\frac{1}{2} \leqq x \leqq \frac{1}{2}$. Since $h(z) = h(z+1)$ it follows that h can be analytically continued to an entire periodic function of z:

$$h(z) = \sum_{m=-\infty}^{\infty} c_m(y)\, e^{2\pi imx}, \qquad c_m(y) = \frac{1}{2\pi i} \int_0^{2\pi} h(z)\, e^{-2\pi inx}\, dx.$$

Using the Cauchy-Riemann conditions for analytic functions we find that $c_m(y) = a_m e^{-2\pi my}$ where a_m is independent of z. Since $h(iy) = o(e^{2\pi|y|})$ we have that $|a_m e^{-2\pi my}| = o(e^{2\pi|y|})$ as $|y| \to \infty$, so $a_m = 0$ for $m \neq 0$. Thus h is independent of z and, without loss of generality, we can set $h \equiv 1$:

$$(2.6) \quad w_{a,b,c,d}(z) = \frac{\Gamma(a+z)\Gamma(a-z)\Gamma(b+z)\Gamma(b-z)\Gamma(c+z)\Gamma(c-z)\Gamma(d+z)\Gamma(d-z)}{\Gamma(2z)\Gamma(-2z)}.$$

Since (2.5) holds, $\mu^*\mu$ is formally selfadjoint:

$$(2.7) \qquad (\mu^*\mu g_1, g_2)_{a,b,c,d} = (g_1, \mu^*\mu g_2)_{a,b,c,d}.$$

From recurrence relations (2.2b) and (2.4) it follows that the Wilson polynomials are eigenfunctions of $\mu^*\mu$:

$$(2.8) \qquad \mu^*\mu\Phi_n^{(a,b,c,d)} = \lambda_n \Phi_n^{(a,b,c,d)}, \qquad \lambda_n = (a+b+n-1)(c+d+n).$$

Note that $\lambda_n = \lambda_m$ iff $n = m$. Since the eigenfunctions corresponding to distinct eigenvalues are orthogonal, we have

$$(\Phi_n^{(a,b,c,d)}, \Phi_m^{(a,b,c,d)})_{a,b,c,d} = 0 \quad \text{if } n \neq m.$$

The operator $\mu^*\mu$ and the weight function are symmetric with respect to the interchange $a \leftrightarrow b$. Thus the polynomials $\{\Phi_n^{(b,a,c,d)}(z^2)\}$ are also orthogonal in $S_{a,b,c,d}$ and are eigenfunctions of $\mu^*\mu$. This means that there exists a constant K_n such that

$$\Phi_n^{(b,a,c,d)}(z^2) = K_n \Phi_n^{(a,b,c,d)}(z^2).$$

Equating coefficients of z^{2n} on both sides of this expression to obtain K_n, we find that

$$\begin{aligned}(2.9)\quad & {}_4F_3\left(\begin{matrix}-n, n+b+a+c+d-1, b+z, b-z \\ b+a, b+c, b+d\end{matrix}; 1\right) \\ & = \frac{(a+c)_n(a+d)_n}{(b+c)_n(b+d)_n} {}_4F_3\left(\begin{matrix}-n, n+a+b+c+d-1, a+z, a-z \\ a+b, a+c, a+d\end{matrix}; 1\right).\end{aligned}$$

This is a transformation formula due to Bailey [6, p. 56] and, as Wilson pointed out [1], it essentially contains the symmetries of the 6-j symbols. It follows from this result that the renormalized polynomials

$$(a+b)_n(a+c)_n(a+d)_n \Phi_n^{(a,b,c,d)}(z^2)$$

are symmetric in all four parameters a, b, c, d.

Setting $f(z^2) = g(z^2) = 1$ in (2.5) and using (2.2b) and (2.1), we obtain the following relationship between the norms on $S_{a-1/2,b-1/2,c+1/2,d+1/2}$ and $S_{a,b,c,d}$:

$$(2.10)\qquad \|1\|^2_{a-1/2,b-1/2,c+1/2,d+1/2} = \frac{c+d}{a+b-1}\|1\|^2_{a,b,c,d}.$$

The symmetry of the weight function in a, b, c, d yields 5 more such relations.

Now consider the recurrence (2.2a):

$$\tau^{(a,b,c,d)}: S_{a,b,c,d} \to S_{a+1/2,b+1/2,c+1/2,d+1/2}.$$

We seek the adjoint τ^* to $\tau \equiv \tau^{(a,b,c,d)}$:

$$(2.11)\qquad (f, \tau g)_{a+1/2,b+1/2,c+1/2,d+1/2} = (\tau^* f, g)_{a,b,c,d}$$

for all $f \in S_{a+1/2,\cdots,d+1/2}$, $g \in S_{a,\cdots,d}$. A simple computation using (2.11) yields

$$\begin{aligned}(2.12)\quad \tau^* & \equiv \tau^{*(a+1/2,b+1/2,c+1/2,d+1/2)} \\ & = \frac{1}{2z}[(a+z)(b+z)(c+z)(d+z)E_z^{1/2} - (a-z)(b-z)(c-z)(d-z)E_x^{-1/2}].\end{aligned}$$

From (2.11) and the orthogonality relations it follows that

$$(2.13)\qquad \tau^*\Phi_{n-1}^{(a+1/2,b+1/2,c+1/2,d+1/2)} = H_n \Phi_n^{(a,b,c,d)}.$$

Comparing coefficients of z^{2n} on both sides of this expression we find that

$$H_n = (a+b)(a+c)(a+d).$$

Thus $\tau^*\tau$ is selfadjoint on $S_{a,b,c,d}$ and the eigenvalue equation is:

$$(2.14)\qquad \tau^*\tau\Phi_n^{(a,b,c,d)} = n(n+a+b+c+d-1)\Phi_n^{(a,b,c,d)}.$$

We also have the Rodrigues formula

$$\Phi_n^{(a,b,c,d)} = J_n \tau^{*(a+1/2,\cdots,d+1/2)}\tau^{*(a+1,\cdots,d+1)}\cdots\tau^{*(a+n/2,\cdots,d+n/2)}(1),$$
$$J_n=(a+b)_n(a+c)_n(a+d)_n. \tag{2.15}$$

Substituting $f=\Phi_{n-1}^{(a+1/2,\cdots,d+1/2)}$, $g=\Phi_n^{(a,\cdots,d)}$ in (2.11), we obtain the recurrence

$$\|\Phi_n^{(a,\cdots,d)}\|_{a,\cdots,d}^2=\frac{n(n+a+b+c+d-1)}{(a+b)^2(a+c)^2(a+d)^2}\|\Phi_{n-1}^{(a+1/2,\cdots,d+1/2)}\|_{a+1/2,\cdots,d+1/2}^2 \tag{2.16}$$

which enables us to compute the norm of any Wilson polynomial once the norm $\|1\|_{a,\cdots,d}^2$ is determined for all $a,\cdots,d>0$. We now turn to this last task.

From the orthogonality relation $(\Phi_1^{(a,\cdots,d)}, \Phi_0^{(a,\cdots,d)})_{a,\cdots,d}=0$ and the explicit expression (2.1) for Wilson polynomials we find that

$$\|1\|_{a,\cdots,d}^2=\frac{(a+b+c+d)}{(a+b)(a+c)(a+d)}\|1\|_{a+1,b,c,d}^2. \tag{2.17}$$

Here we have used the evident relation

$$(g_m^a, 1)_{a,\cdots,d}=\|1\|_{a+m,b,c,d}^2, \qquad g_m^a(z^2)=(a+z)_m(a-z)_m.$$

From (2.10) and (2.17) and the obvious invariance of $\|1\|_{a,\cdots,d}$ with respect to a permutation of a, b, c, d we find:

$$\|1\|_{a,b,c,d}^2=\frac{\Gamma(a+b)\Gamma(a+c)\Gamma(a+d)\Gamma(b+c)\Gamma(b+d)\Gamma(c+d)}{\Gamma(a+b+c+d)}M(a,b,c,d) \tag{2.18}$$

where M satisfies the periodicity properties

$$M(a,b,c,d)=M(a+\tfrac{1}{2}, b+\tfrac{1}{2}, c+\tfrac{1}{2}, d+\tfrac{1}{2})=M(a+1,b,c,d)$$

and is invariant under any permutation of $a,\cdots,d$. Now replace a by $a+k$, k a positive integer, in (2.18) and write this expression in the following form:

$$\begin{aligned}&\frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\frac{\Gamma(a+k+iy)\Gamma(a+k-iy)\Gamma(a+k+b+c+d)}{\Gamma(a+k+b)\Gamma(a+k+c)\Gamma(a+k+d)}\right)\\&\qquad\cdot\left|\frac{\Gamma(b+iy)\Gamma(c+iy)\Gamma(d+iy)}{\Gamma(2iy)}\right|^2dy\\&=\Gamma(b+c)\Gamma(b\ +d)\Gamma(c+d)M(a,b,c,d).\end{aligned} \tag{2.19}$$

From Stirling's series

$$\Gamma(z+k)=\sqrt{2\pi}(k)^{z+k-1/2}e^{-k}\left(1+O\left(\frac{1}{k}\right)\right)$$

as $k\to+\infty$, so

$$\lim_{k\to+\infty}\frac{\Gamma(a+k+iy)\Gamma(a+k-iy)\Gamma(a+k+b+c+d)}{\Gamma(a+k+b)\Gamma(a+k+c)\Gamma(a+k+d)}=1$$

and

$$\frac{1}{2\pi}\int_{-\infty}^{\infty}\left|\frac{\Gamma(b+iy)\Gamma(c+iy)\Gamma(d+iy)}{\Gamma(2iy)}\right|^2dy=\Gamma(b+c)\Gamma(b+d)\Gamma(c+d)M(a,b,c,d). \tag{2.20}$$

(The passage to the limit under the integral sign is easily justified since $|\Gamma(a+iy)||\leqq\Gamma(a)$ for $a>0$.) It is evident from (2.20) that M is independent of a. By symmetry, M is constant. To evaluate the constant we set $b=0$, $c=d=\frac{1}{2}$ in (2.20). Using the multiplication and reflection theorems for the gamma function, we reduce (2.20) to

$$2\int_{-\infty}^{\infty}\frac{dy}{\cosh(\pi y)}=M$$

or $M=2$. Thus

$$\begin{aligned}\|1\|^2_{a,b,c,d}&=\frac{1}{\pi}\int_0^{\infty}\left|\frac{\Gamma(a+iy)\Gamma(b+iy)\Gamma(c+iy)\Gamma(d+iy)}{\Gamma(2iy)}\right|^2dy\\&=\frac{2\Gamma(a+b)\Gamma(a+c)\Gamma(a+d)\Gamma(b+c)\Gamma(b+d)\Gamma(c+d)}{\Gamma(a+b+c+d)}.\end{aligned}\tag{2.21}$$

Note that this integral, and special cases of it, were originally derived by contour integration, evaluation of the residues at the poles of the integrand in the right half plane and use of known summation theorems to sum the resulting infinite series. Wilson [1] used Bailey's Theorem [6, p. 27]

$$\begin{aligned}&{}_5F_4\left(\begin{matrix}2a,\ a+1,\ a+b,\ a+c,\ a+d\\ a,\ a-b+1,\ a-c+1,\ a-d+1\end{matrix};1\right)\\&=\frac{\Gamma(a-b+1)F(a-c+1)\Gamma(a-d+1)\Gamma(-a-b-c-d+1)}{\Gamma(2a+1)\Gamma(-b-c+1)\Gamma(-b-d+1)\Gamma(-c-d+1)}\end{aligned}$$

to compute (2.21). Since we have independently obtained the value of this integral we can consider the usual contour integral technique as a derivation of Bailey's ${}_5F_4$ summation.

For the Racah polynomials (discrete orthogonality), [1], the recurrence relation methods of this paper yield a purely algebraic derivation of the orthogonality, including as a byproduct the terminating version of Bailey's Theorem: $a+b=-N$.

Note added in proof. Recurrence techniques similar to those used in this paper have been employed by Nikiforov, Suslov and Uvarov [7] and Nikiforov and Suslov [8], but these authors have apparently not applied them to the computation of contour integrals and summation formulas.

Acknowledgments. The author thanks Dick Askey, Mourad Ismail and Dennis Stanton for several helpful conversations.

THE BEHAVIOR AT UNIT ARGUMENT OF THE HYPERGEOMETRIC FUNCTION ${}_3F_2$*

WOLFGANG BÜHRING†

Abstract. The behavior at $z=1$ of the generalized hypergeometric function ${}_3F_2(a, b, c; e, f; z)$ is investigated. First the analytic continuation near $z=1$ is obtained for the general case when $s=e+f-a-b-c$ is not equal to an integer. The corresponding continuation formulas for the special cases when s is equal to an integer are then derived by appropriate limiting processes. When $f=c$ or $e=c$, the formulas immediately reduce to the well-known continuation formulas of the Gaussian hypergeometric function.

Key words. special functions, hypergeometric series, hypergeometric functions, continuation formulas, hypergeometric differential equations

AMS(MOS) subject classifications. 33A30, 34A20, 34A30, 30B40

1. Introduction.

The behavior near $z=1$ of the Gaussian hypergeometric function or series

$$(1.1)\qquad {}_2F_1(a, b; e; z)=\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(e)_n n!}z^n$$

is given by a well-known continuation formula which may be written

$$(1.2)\qquad \begin{aligned}\frac{\Gamma(a)\Gamma(b)}{\Gamma(e)}{}_2F_1(a, b; e; z)&=\frac{\Gamma(a)\Gamma(b)\Gamma(s)}{\Gamma(a+s)\Gamma(b+s)}{}_2F_1(a, b; 1-s; 1-z)\\&\quad+\Gamma(-s)(1-z)^s{}_2F_1(a+s, b+s; 1+s; 1-z)\\&\qquad\qquad(|\arg(1-z)|<\pi),\end{aligned}$$

$$(1.3)\qquad s=e-a-b.$$

As it stands, (1.2) is valid if s is not equal to an integer, otherwise it is the starting point from which the relevant formulas may be derived by a limiting process. It is the aim of the present work to obtain a corresponding formula for the generalized hypergeometric function ${}_3F_2(a, b, c; e, f; z)$, including the formulas for the exceptional cases when

$$(1.4)\qquad s=e+f-a-b-c$$

is equal to an integer.

Like the ${}_2F_1$, the ${}_3F_2$ is also a particular solution of a certain linear differential equation, now of the third order, with three regular singular points at $z=0, 1, \infty$. The characteristic exponents 0, 1, s and the local power series solutions of this differential equation relative to the point $z=1$ are known from the detailed investigation by Nørlund [8]. The analytic structure near $z=1$ of the general solution is therefore known and, if s is not equal to an integer, is given by

$$(1.5)\qquad A+B(1-z)+O(\{1-z\}^2)+C(1-z)^s\{1+O(1-z)\}.$$

It is more difficult to obtain the connecting constants A, B, C for the function ${}_3F_2(a, b, c; e, f; z)$. While the value of C (and of K in (1.6) below) can be inferred from

† Physikalisches Institut, Universität Heidelberg, D-6900 Heidelberg, West Germany.

[8], A and B are not known in general. This matter has recently received attention in the special case when $s=0$. Then, as $z\to 1$ in the sector $|\arg(1-z)|<\pi$, we have

$$\begin{aligned}\frac{\Gamma(a)\Gamma(b)\Gamma(c)}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a,b,c\\ e,f\end{matrix}\middle|\, z\right)\\ =L+M(1-z)+O(\{1-z\}^2)+K\ln(1-z)\{1+O(1-z)\}\end{aligned}\tag{1.6}$$

where

$$K=-1\tag{1.7}$$

and, if $\operatorname{Re}(c)>0$,

$$L=2\psi(1)-\psi(a)-\psi(b)+\sum_{m=1}^{\infty}\frac{(e-c)_m(f-c)_m}{m(a)_m(b)_m}.\tag{1.8}$$

Here $\psi(x)$ denotes the logarithmic derivative $\Gamma'(x)/\Gamma(x)$ of the gamma function. The expression (1.8) for L, contained without proof in Ramanujan's note books [9], has recently been proved by Evans and Stanton [3], but, as they state themselves, "because of the inductive nature" of their proofs, their paper "unfortunately sheds little light on how Ramanujan might have made this remarkable discovery." A new proof along different lines is therefore of interest. Also, the third connecting constant M is not known. Its value will be given in (4.9) below.

In the present paper we first consider the general case when s is not equal to an integer and determine the connecting constants A, B, C of (1.5) for the function ${}_3F_2(a,b,c;e,f;z)$. The results for the exceptional case when s is equal to zero or, more generally, equal to any integer are then obtained by a limiting process.

A lemma is provided in § 2. The main theorem for the general case is derived in § 3. The results for the exceptional cases are supplied in § 4.

2. A lemma. In order to avoid inconvenient and unnecessary restrictions of the denominator parameters, we follow Olver [6] and consider $\{\Gamma(e)\Gamma(f)\}^{-1}{}_3F_2(a,b,c;e,f;z)$ rather than ${}_3F_2$ itself, but without explicitly introducing a new symbol for this quantity. As a function of z, it has a finite value at $z=1$ if $\operatorname{Re}(e+f-a-b-c)>0$. Following Wimp [11], [12] we may consider this value as a function of the five parameters. This suggests the following.

Definition 1. For those points of the parameter space which satisfy $\operatorname{Re}(e+f-a-b-c)>0$ let the symbol ${}_3\mathrm{F}_2(a,b,c;e,f)$ be defined by

$$\frac{1}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a,b,c\\ e,f\end{matrix}\right)=\frac{1}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a,b,c\\ e,f\end{matrix}\middle|\, 1\right)\tag{2.1}$$

and let it then be defined for the other points by analytic continuation.

Using this definition we supply for later application the following.

Lemma 1. *With $s=e+f-a-b-c$ there holds*

$$\frac{1}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a,b,c\\ e,f\end{matrix}\right)=\frac{\Gamma(s)}{\Gamma(c)\Gamma(a+s)\Gamma(b+s)}\,{}_3F_2\left(\begin{matrix}e-c,f-c,s\\ a+s,b+s\end{matrix}\right).\tag{2.2}$$

Proof. If $\operatorname{Re}(s)>0$ and $\operatorname{Re}(c)>0$ we have from [2] or [5]

$$\frac{1}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a,b,c\\ e,f\end{matrix}\middle|\, 1\right)=\frac{\Gamma(s)}{\Gamma(c)\Gamma(a+s)\Gamma(b+s)}\,{}_3F_2\left(\begin{matrix}e-c,f-c,s\\ a+s,b+s\end{matrix}\middle|\, 1\right).\tag{2.3}$$

Here the conditions on s and c are needed to ensure the convergence of the hypergeometric series of unit argument on the left- and right-hand side, respectively. By means of Definition 1 and analytic continuation with respect to the parameters we get rid of these restrictions, which completes the proof.

3. Derivation of the main theorem. The generalized hypergeometric function ${}_3F_2(a, b, c; e, f; z)$ is a particular solution of the third order linear differential equation

$$\{D(zD+e-1)(zD+f-1)-(zD+a)(zD+b)(zD+c)\}w(z)=0 \tag{3.1}$$

where $D=d/dz$. Relative to the regular singular point $z=1$ of the differential equation, the Frobenius ansatz

$$w(z)=\sum_{n=0}^{\infty} g_n(r)(1-z)^{r+n}, \tag{3.2}$$

written with powers of $1-z$ rather than $z-1$ for later convenience, yields for the coefficients g_n the recurrence relation

$$\begin{aligned}(r+n)(r+n-1)(r+n+a+b+c-e-f)g_n(r)\\ =(r+n-1)\{(r+n-2)(2r+2n-1-e-f+2a+2b+2c)\\ -ef+ab+bc+ca+a+b+c+1\}g_{n-1}(r)\\ -(r+n-2+a)(r+n-2+b)(r+n-2+c)g_{n-2}(r),\end{aligned} \tag{3.3}$$

valid for $n=0, 1, 2, \cdots$, provided that we have defined $g_{-2}(r)=g_{-1}(r)=0$ while $g_0(0)\neq 0$. The equation for $n=0$ then leads to the indicial equation which determines the characteristic exponents

$$r\in\{0, 1, s\}, \quad s \text{ as in } (1.4). \tag{3.4}$$

We now assume in this section that s is not equal to an integer, so that the exponent $r=s$ yields a solution of the differential equation. Of the two exponents which are integers the larger one always gives a solution, but for the smaller one we have to check if (3.3) is consistent for all the n. Since the difference of the exponents is 1, the equation for $n=1$ is crucial. With (1.4) we have from (3.3)

$$\begin{aligned}(r+1)r(r+1-s)g_1(r)=r\{(r-1)(2r+1-e-f+2a+2b+2c)\\ -ef+ab+bc+ca+a+b+c+1\}g_0(r).\end{aligned} \tag{3.5}$$

For $r=0$ not only the left-hand side vanishes but the right-hand side happens to vanish also, and so (3.5) is consistent irrespective of the value of $g_1(0)$. Therefore $g_1(0)$, besides $g_0(0)$, may be assigned arbitrarily. The exponent $r=0$ in this way yields a solution containing two constants of integration, where changing $g_1(0)$ is equivalent to adding a constant multiple of the solution with the exponent $r=1$ mentioned above. Thus we have shown that

$$\frac{\Gamma(a)\Gamma(b)\Gamma(c)}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a, b, c\\ e, f\end{matrix}\,\middle|\, z\right)=\sum_{n=0}^{\infty} g_n(0)(1-z)^n+(1-z)^s\sum_{n=0}^{\infty} g_n(s)(1-z)^n \tag{3.6}$$

where the connecting constants $g_0(0)$, $g_1(0)$, $g_0(s)$ still have to be determined while the other coefficients $g_n(r)$ are then given by the recurrence relation

$$g_n(r)=\frac{1}{(r-s+n)(r+n)(r+n-1)}$$

$$\begin{aligned}\cdot((r+n-1)\{(r+n-2)(2r-s+2n-1+a+b+c)\\ -ef+ab+bc+ca+a+b+c+1\}g_{n-1}(r)\\ -(r+n-2+a)(r+n-2+b)(r+n-2+c)g_{n-2}(r)),\end{aligned}\tag{3.7}$$

to be used for $r=0$ with $n=2,3,4,\cdots$, or for $r=s$ with $n=1,2,3,\cdots$, and $g_{-1}(s)=0$.

The connecting constant $g_0(s)$, which multiplies the (at $z=1$) singular contribution, can most conveniently be determined by Darboux's method [6] as follows. The left-hand side of (3.6), when written in the form $\sum u_n z^n$, has coefficients

$$u_n=\frac{\Gamma(a+n)\Gamma(b+n)\Gamma(c+n)}{\Gamma(e+n)\Gamma(f+n)\Gamma(1+n)}\tag{3.8}$$

with the asymptotic behavior

$$u_n\sim n^{a+b+c-e-f-1}\left\{1+O\left(\frac{1}{n}\right)\right\}\tag{3.9}$$

as $n\to\infty$, which follows by means of the formula

$$\frac{\Gamma(x+n)}{\Gamma(y+n)}\sim n^{x-y}\left\{1+O\left(\frac{1}{n}\right)\right\}.\tag{3.10}$$

The leading singular term on the right-hand side of (3.6) is $g_0(s)(1-z)^s$, which, when expanded in powers of z by means of the formula

$$(1-z)^s=\sum_{n=0}^{\infty}\frac{(-s)_n}{n!}z^n\tag{3.11}$$

and written in the form $\sum v_n z^n$, has coefficients

$$v_n=\frac{g_0(s)}{\Gamma(-s)}\frac{\Gamma(-s+n)}{\Gamma(1+n)}\tag{3.12}$$

with the asymptotic behavior

$$v_n\sim\frac{g_0(s)}{\Gamma(-s)}n^{-s-1}\left\{1+O\left(\frac{1}{n}\right)\right\}\tag{3.13}$$

as $n\to\infty$. Thus u_n and v_n have, in view of the definition of s according to (1.4), the same n-dependence of the leading asymptotic term, as expected, and comparison of the constant factors in (3.9) and (3.13) yields

$$g_0(s)=\Gamma(-s).\tag{3.14}$$

This result has been obtained in a different way by Nørlund [8]. More recently such connection problems have been treated by Naundorf [7] and by Schäfke and Schmidt [10].

The connecting constants $g_0(0)$ and $g_1(0)$, which appear in the (at $z=1$) regular term, will now be determined. If $\operatorname{Re}(s)>0$, the singular contribution vanishes and (3.6) evaluated at $z=1$ yields

$$g_0(0)=\frac{\Gamma(a)\Gamma(b)\Gamma(c)}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix}a,b,c\\e,f\end{matrix}\middle|\,1\right). \tag{3.15}$$

In a similar way, if $\operatorname{Re}(s)>1$, the derivative with respect to z of (3.6) gives

$$g_1(0)=-\frac{\Gamma(a+1)\Gamma(b+1)\Gamma(c+1)}{\Gamma(e+1)\Gamma(f+1)}\,{}_3F_2\left(\begin{matrix}a+1,b+1,c+1\\e+1,f+1\end{matrix}\middle|\,1\right). \tag{3.16}$$

By analytic continuation with respect to the parameters, Definition 1 and Lemma 1, we then finally obtain

$$g_0(0)=\frac{\Gamma(a)\Gamma(b)\Gamma(s)}{\Gamma(a+s)\Gamma(b+s)}\,{}_3F_2\left(\begin{matrix}e-c,f-c,s\\a+s,b+s\end{matrix}\right), \tag{3.17}$$

$$g_1(0)=-\frac{\Gamma(a+1)\Gamma(b+1)\Gamma(s-1)}{\Gamma(a+s)\Gamma(b+s)}\,{}_3F_2\left(\begin{matrix}e-c,f-c,s-1\\a+s,b+s\end{matrix}\right). \tag{3.18}$$

All the other coefficients $g_n(r)$ appearing in (3.6) are now uniquely defined by the recurrence relation (3.7). On the computer they may efficiently be evaluated in this way, but for analytical work, in particular the investigation of the so far excluded exceptional cases when s is equal to an integer, an explicit representation of all the $g_n(r)$ is desirable.

When $r=0$ we may consider the nth derivative with respect to z of (3.6) and proceed essentially in the same way as above with $g_1(0)$. As a generalization of (3.17), (3.18) we then immediately obtain

$$g_n(0)=(-1)^n\frac{\Gamma(a+n)\Gamma(b+n)\Gamma(s-n)}{\Gamma(a+s)\Gamma(b+s)n!}\,{}_3F_2\left(\begin{matrix}e-c,f-c,s-n\\a+s,b+s\end{matrix}\right). \tag{3.19}$$

When $r=s$ we suspect that the $g_n(s)$ can be represented in a similar form. From (3.7) and (3.14) we have, after rearrangement of the terms,

$$g_1(s)=-\Gamma(-s-1)\{s^2+(a+b)s-ef+ab+c(a+b+s)\}. \tag{3.20}$$

By the definition of s the factor of c is equal to $e+f-c$. Making use of this fact we lose the symmetry with respect to the numerator parameters and obtain

$$\begin{aligned}g_1(s)&=-\Gamma(-s-1)\{(a+s)(b+s)-(e-c)(f-c)\}\\&=-\Gamma(-s-1)(a+s)(b+s)\,{}_3F_2\left(\begin{matrix}e-c,f-c,-1\\a+s,b+s\end{matrix}\middle|\,1\right).\end{aligned} \tag{3.21}$$

To proceed further, it is convenient to get rid of some factors and to consider $y_n(r)$ defined by

$$n!g_n(r)=(-1)^n\Gamma(s-2r-n)y_n(r) \tag{3.22}$$

rather than $g_n(r)$ itself. In view of $r\in\{0,s\}$, the recurrence relation for $y_n(r)$ then reads

$$\begin{aligned}y_n(r)=\{&(r+n-2)(2n-1+2r-s+a+b+c)\\&-ef+ab+bc+ca+a+b+c+1\}y_{n-1}(r)\\&+(s-r-n+1)(a+r+n-2)(b+r+n-2)(c+r+n-2)y_{n-2}(r),\end{aligned} \tag{3.23}$$

and we are interested in its special solution which, according to (3.14), (3.17), (3.18), (3.21), has the starting values

$$y_0(r)=\frac{\Gamma(a+r)\Gamma(b+r)}{\Gamma(a+s)\Gamma(b+s)}{}_3F_2\left(\begin{matrix}e-c, f-c, s-r\\ a+s, b+s\end{matrix}\right), \tag{3.24}$$

$$y_1(r)=\frac{\Gamma(a+r+1)\Gamma(b+r+1)}{\Gamma(a+s)\Gamma(b+s)}{}_3F_2\left(\begin{matrix}e-c, f-c, s-r-1\\ a+s, b+s\end{matrix}\right). \tag{3.25}$$

The factor of $y_{n-1}(r)$ in (3.23) may be rewritten, using the definition of s, as

$$\begin{aligned}&(n-2)(2n-1+4r-s+a+b+c)-(e+r)(f+r)+(a+r)(b+r)\\ &\quad+(b+r)(c+r)+(c+r)(a+r)+a+b+c+3r+1.\end{aligned} \tag{3.26}$$

We then may see that the recurrence relation for $y_n(r)$ can be obtained from that for $y_n(0)$ by the simultaneous substitutions

$$a\to a+r,\quad b\to b+r,\quad c\to c+r,\quad e\to e+r,\quad f\to f+r, \tag{3.27}$$

and as a consequence,

$$s\to s-r. \tag{3.28}$$

The same is true for the starting values (3.24), (3.25). Since we already know from (3.19) that

$$y_n(0)=\frac{\Gamma(a+n)\Gamma(b+n)}{\Gamma(a+s)\Gamma(b+s)}{}_3F_2\left(\begin{matrix}e-c, f-c, s-n\\ a+s, b+s\end{matrix}\right), \tag{3.29}$$

it follows by the substitutions (3.27)-(3.28) that

$$y_n(r)=\frac{\Gamma(a+r+n)\Gamma(b+r+n)}{\Gamma(a+s)\Gamma(b+s)}{}_3F_2\left(\begin{matrix}e-c, f-c, s-r-n\\ a+s, b+s\end{matrix}\right). \tag{3.30}$$

By means of (3.22) we obtain the required explicit representation for $g_n(r)$ which is valid for both $r=0$ and $r=s$ and so we have proved the following.

THEOREM 1. *If $s=e+f-a-b-c$ is not equal to an integer, then the analytic continuation of the ${}_3F_2$-series near $z=1$ in the sector $|\arg(1-z)|<\pi$ is given by the formula*

$$\frac{\Gamma(a)\Gamma(b)\Gamma(c)}{\Gamma(e)\Gamma(f)}{}_3F_2\left(\begin{matrix}a, b, c\\ e, f\end{matrix}\middle| z\right)=\sum_{n=0}^{\infty}g_n(0)(1-z)^n+(1-z)^s\sum_{n=0}^{\infty}g_n(s)(1-z)^n \tag{3.31}$$

where the series on the right-hand side converge inside the circle $|z-1|=1$ and the coefficients $g_n(r)$, with $r\in\{0, s\}$, are

$$g_n(r)=(-1)^n\frac{\Gamma(a+r+n)\Gamma(b+r+n)\Gamma(s-2r-n)}{\Gamma(a+s)\Gamma(b+s)n!}{}_3F_2\left(\begin{matrix}e-c, f-c, s-r-n\\ a+s, b+s\end{matrix}\right). \tag{3.32}$$

We may observe that when $f=c$ or $e=c$ then the ${}_3F_2$ on the right-hand side of (3.32) becomes equal to 1 and the Theorem 1 reduces to the continuation formula for the ${}_2F_1$.

The recurrence (3.7) for the quantities (3.32) can also be deduced from the work of Lewanowicz [4] and is, essentially, a special case of the recursion relation for the Wilson polynomials.

4. The exceptional cases. When s is an integer, the hypergeometric series is called s-balanced. In such a case the continuation formula may be derived from Theorem 1 by an approximate limiting process. For this purpose it is convenient to make the simultaneous substitutions $a \to a-\varepsilon$, $b \to b-\varepsilon$, $c \to c-\varepsilon$, $e \to e-\varepsilon$, $f \to f-\varepsilon$, and as a consequence, $s \to s+\varepsilon$ and then to consider the resulting equations for integral s, separately for $s \geqq 0$ or $s \leqq 0$, respectively. Since the series representation of the ${}_3F_2$ in (3.32) is needed, a restriction of the parameter c now comes in to ensure the convergence. By performing the limit $\varepsilon \to 0$, which is a somewhat lengthy but standard [5] procedure, we may derive the following results.

COROLLARY 1. *If $s = e+f-a-b-c$ is equal to an integer $t \geqq 0$, then the analytic continuation of the ${}_3F_2$-series near $z = 1$ in the sector $|\arg(1-z)| < \pi$ is given by the formula*

$$\tag{4.1} \begin{aligned} &\frac{\Gamma(a)\Gamma(b)\Gamma(c)}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix} a, b, c \\ e, f \end{matrix}\,\middle|\, z\right) \\ &\qquad = \sum_{n=0}^{t-1} k_n(1-z)^n + (1-z)^t \sum_{n=0}^{\infty} \{p_n + q_n \ln(1-z)\}(1-z)^n \end{aligned}$$

where the series on the right-hand side converges inside the circle $|z-1| = 1$ and the coefficients are

$$\tag{4.2} k_n = (-1)^n \frac{\Gamma(a+n)\Gamma(b+n)(t-n-1)!}{\Gamma(a+t)\Gamma(b+t)n!}\,{}_3F_2\left(\begin{matrix} e-c, f-c, t-n \\ a+t, b+t \end{matrix}\right),$$

$$\tag{4.3} \begin{aligned} p_n = \frac{(a+t)_n(b+t)_n}{(t+n)!n!}&\left((-1)^t \sum_{m=0}^{n} \frac{(e-c)_m(f-c)_m(-n)_m}{(a+t)_m(b+t)_m m!}\right. \\ &\cdot\{\psi(1+n-m)+\psi(1+t+n)-\psi(a+t+n)-\psi(b+t+n)\} \\ &\left. +(-1)^{t+n} n! \sum_{m=n+1}^{\infty} \frac{(e-c)_m(f-c)_m(m-n-1)!}{(a+t)_m(b+t)_m m!}\right) \\ &\textit{if } \operatorname{Re}(c) > -t-n, \end{aligned}$$

$$\tag{4.4} q_n = -(-1)^t \frac{(a+t)_n(b+t)_n}{(t+n)!n!}\,{}_3F_2\left(\begin{matrix} e-c, f-c, -n \\ a+t, b+t \end{matrix}\,\middle|\, 1\right).$$

COROLLARY 2. *If $s = e+f-a-b-c$ is equal to an integer $-t \leqq 0$, then the analytic continuation of the ${}_3F_2$-series near $z = 1$ in the sector $|\arg(1-z)| < \pi$ is given by the formula*

$$\tag{4.5} \begin{aligned} &\frac{\Gamma(a)\Gamma(b)\Gamma(c)}{\Gamma(e)\Gamma(f)}\,{}_3F_2\left(\begin{matrix} a, b, c \\ e, f \end{matrix}\,\middle|\, z\right) \\ &\qquad = (1-z)^{-t} \sum_{n=0}^{t-1} h_n(1-z)^n + \sum_{n=0}^{\infty} \{u_n + v_n \ln(1-z)\}(1-z)^n \end{aligned}$$

where the series on the right-hand side converges inside the circle $|z-1| = 1$ and the coefficients are

$$\tag{4.6} h_n = (-1)^n \frac{(a-t)_n(b-t)_n(t-n-1)!}{n!}\,{}_3F_2\left(\begin{matrix} e-c, f-c, -n \\ a-t, b-t \end{matrix}\,\middle|\, 1\right),$$

$$u_n = \frac{(a-t)_{t+n}(b-t)_{t+n}}{n!(t+n)!}$$
$$\tag{4.7} \cdot\Bigg((-1)^t \sum_{m=0}^{t+n} \frac{(e-c)_m(f-c)_m(-t-n)_m}{(a-t)_m(b-t)_m m!} \cdot\{\psi(1+t+n-m)+\psi(1+n)-\psi(a+n)-\psi(b+n)\} + (-1)^n(t+n)! \sum_{m=t+n+1}^{\infty} \frac{(e-c)_m(f-c)_m(m-t-n-1)!}{(a-t)_m(b-t)_m m!}\Bigg)$$

if Re $(c) > -n$,

$$\tag{4.8} v_n = -(-1)^t \frac{(a-t)_{t+n}(b-t)_{t+n}}{(t+n)!n!} {}_3F_2\left(\begin{matrix} e-c, f-c, -t-n \\ a-t, b-t \end{matrix}\middle| 1\right).$$

When $t=0$, the empty sums in (4.1) or (4.5) have to be interpreted as 0.

If $f=c$ or $e=c$, the formulas in Corollaries 1 and 2 immediately reduce to the corresponding formulas for the Gaussian hypergeometric function, which appear, apart from some minor differences of presentation, as (15.3.10)-(15.3.12) in [1], for instance.

Taking the leading terms of (4.1) or (4.5) with $t=0$ we may obtain (1.6) with the constants K and L as expected and the third connecting constant

$$\tag{4.9} M = \{ab-(e-c)(f-c)\}\{2+2\psi(1)-\psi(a+1)-\psi(b+1)\} + (e-c)(f-c) - ab \sum_{m=2}^{\infty} \frac{(e-c)_m(f-c)_m}{(m-1)m(a)_m(b)_m} \quad (\text{Re}\,(c) > -1).$$

FABER EXPANSIONS OF RATIONAL AND ENTIRE FUNCTIONS*

ELGIN H. JOHNSTON†

Abstract. The Faber polynomials for a bounded, simply connected domain D can, under certain circumstances, be used to give series expansions of functions analytic on D [5] and to give good polynomial approximations to such functions [3]. We provide explicit, easily computable formulae for the coefficients of the Faber polynomials and formulae for the Faber coefficients of certain types of rational and analytic functions. Finally, since the study of the properties of an analytic function may require us to look at its derivative, we also provide formulae for the Faber expansions of the derivatives of Faber polynomials.

Key words. Faber polynomials, Faber expansion, rational function, entire function

AMS(MOS) subject classifications. Primary 30B50; secondary 30C99

1. Introduction.

Let

$$g(\xi)=\xi+b_0+\frac{b_1}{\xi}+\frac{b_2}{\xi^2}+\cdots \tag{1}$$

be analytic and univalent in $\Delta=\{\xi: |\xi|>1\}$. Then $E=\mathbf{C}\backslash g(\Delta)$ is a continuum of capacity 1. The Faber polynomials $\{F_n(w)\}_{n=0}^{\infty}$ associated with g (or E) are defined by the generating function relation [4, p. 57]

$$\log\left(\frac{g(\xi)-w}{\xi}\right)=-\sum_{n=1}^{\infty}\frac{1}{n}F_n(w)\xi^{-n}. \tag{2}$$

We define $F_0(w)\equiv 1$. As well as providing a valuable tool in studying properties of univalent functions, the Faber polynomials also provide a means for expressing functions analytic on E or Int E. In fact, if $f(z)$ is such a function then under suitable conditions,

$$f(z)=\sum_{n=0}^{\infty}a_nF_n(z) \qquad (z\in \operatorname{Int} E) \tag{3}$$

where

$$a_n=\frac{1}{2\pi i}\int_{|\xi|=r}\frac{f(g(\xi))}{\xi^{n+1}}\,d\xi. \tag{4}$$

In (4), r is a positive number, usually close to 1, and of course $f(g(\xi))$ must be defined on $|\xi|=r$; this gets back to the "suitable conditions" alluded to above and will be made more precise in later sections. In spite of (4), very little seems to have been done concerning methods for actually obtaining Faber expansions. In this paper we address this and other problems concerning Faber polynomials.

In § 2 we find explicit formulae for the coefficients of the Faber polynomials. Various expressions for the Faber coefficients have been obtained by Todorov [7].

* Received by the editors January 20, 1986; accepted for publication September 17, 1986.

† Department of Mathematics, Iowa State University, Ames, Iowa 50011.

However we consider the coefficients for the expansion about b_0,

$$F_n(w) = \sum_{n=0}^{n} c_k^{(n)}(w-b_0)^n.$$

Such an expression seems natural in view of the recursion relation [4, p. 57]

$$F_{n+1}(w) = (w-b_0)F_n(w) - \sum_{k=1}^{n-1} b_{n-k}F_k(w) - (n+1)b_n. \tag{5}$$

The resulting expressions for the $c_k^{(n)}$, being independent of b_0, seem somewhat simpler than Todorov's expressions.

In § 3 we find explicit formulae for the Faber expansions of the polynomials $(w-b_0)^k$ $(k=0, 1, \cdots)$ and use these to obtain Faber expansions of entire and some analytic functions. As examples, we present some expansions of certain entire functions in terms of Chebyshev polynomials.

In § 4 we find explicit formulae for the Faber expansions of derivatives of the Faber polynomials. Such expressions may prove useful for working with Faber expansions of functions, and also lead to explicit formulae for the Faber expansions of rational functions.

In the remainder of the paper we will encounter many summations which, in certain cases, may be summing over empty sets. Such sums are taken to be 0.

2. Coefficients of Faber polynomials.

THEOREM 1. *For* $n=0, 1, 2, \cdots,$

$$F_n(w) = (w-b_0)^n + \sum_{k=0}^{n-2} c_k^{(n)}(w-b_0)^k \tag{6}$$

where, for $1 \leqq k \leqq n-2$,

$$c_k^{(n)} = \frac{n}{k}\sum (-1)^m \binom{m+k-1}{k-1} b_{r_1-1}\cdots b_{r_m-1} \tag{7}$$

and

$$c_0^{(n)} = \sum_{j=2}^{n-2} jb_{j-1}\left(\sum (-1)^{m+1} b_{r_1-1}\cdots b_{r_m-1}\right) - nb_{n-1}. \tag{8}$$

In (7), *the sum is over all ordered m-tuples* $(r_1, \cdots, r_m)$ $(m=1, 2, \cdots)$ *of integers* $\geqq 2$ *with* $r_1+r_2+\cdots+r_m = n-k$. *In* (8), *the inner sum is over all ordered m-tuples* $(r_1, r_2, \cdots, r_m)$ $(m=1, 2, \cdots,)$ *of integers* $\geqq 2$ *with* $r_1+r_2+\cdots+r_m = n-j$. *In* (6), (7) *and* (8) *all empty sums will be taken to be* 0. *For convenience, we will let* $c_n^{(n)}=1$ *and* $c_{n-1}^{(n)}=0$.

Remark. Todorov [7] found expressions for the coefficients of the Faber polynomials when expanded in powers of w (rather than $w-b_0$). The formulae in [7] involve homogeneous isobaric polynomials [6] and seem to be more complicated than those presented in Theorem 1. However, we have sacrificed, for this simplicity, the convenience of having the polynomials in powers of w.

For the proof of Theorem 1 it is convenient to first find an expression for the reciprocal of a power series. Such expressions have been found previously [2], but we need an alternate form that does not appear to be in a convenient place in the literature.

LEMMA 2. *Let $p(z)=\alpha_0+\alpha_1 z+\alpha_2 z^2+\cdots$ be a formal power series with $\alpha_0\neq 0$. Then the formal power series for $1/p(z)$ is $\beta_0+\beta_1 z+\beta_2 z^2+\cdots$ where $\beta_0=\alpha_0^{-1}$ and*

$$\beta_k=\sum\frac{(-1)^m}{\alpha_0^{m+1}}\alpha_{r_1}\alpha_{r_2}\cdots\alpha_{r_m}\qquad (k=1,2,\cdots). \tag{9}$$

The sum in (9) *is over all m-tuples $(r_1,\cdots,r_m)$ of positive integers with $r_1+r_2+\cdots+r_m=k$.*

Proof. That $\beta_0=\alpha_0^{-1}$ is clear. Assume (9) correct for indices $j\leqq k-1$ ($k\geqq 1$). Since

$$\left(\sum_0^\infty \alpha_k z^k\right)\left(\sum_0^\infty \beta_k z^k\right)\equiv 1,$$

we have $\sum_{j=0}^k \beta_j\alpha_{k-j}=0$. Thus

$$\begin{aligned}\beta_k&=-\frac{1}{\alpha_0}\sum_{j=0}^{k-1}\beta_j\alpha_{k-j}\\ &=-\frac{1}{\alpha_0}\sum_{j=1}^{k-1}\alpha_{k-j}\left(\sum\frac{(-1)^m}{\alpha_0^{m+1}}\alpha_{r_1}\cdots\alpha_{r_m}\right)-\frac{\alpha_k}{\alpha_0}.\end{aligned}\tag{10}$$

The inner sum is over all m-tuples $(r_1,\cdots,r_m)$ of positive integers with $r_1+r_2+\cdots+r_m=j$. The inner sum, combined with the first sum, then gives a sum over all ordered m-tuples ($m\geqq 2$) $(r_1,\cdots,r_m)$ with $r_1+r_2+\cdots+r_m=k$. (The double sum in (10) simply counts all such m-tuples with $k-1$ in the last position, then those with $k-2$ in the last position, etc.). The $-\alpha_k/\alpha_0$ term takes care of the "1-tuple" (k) appearing in (9). Bringing the factor $-1/\alpha_0$ inside the expression (10) thus gives (9) and completes the proof by induction. □

Before using (9) to prove Theorem 1, we first rearrange (9) to group like powers of α_1. We observe that if l 1's appear in the m-tuple $(r_1,r_2,\cdots,r_m)$, then after the 1's are deleted, the remaining $(m-l)$-tuple $(r_1',\cdots,r_{m-l}')$ has coordinates $\geqq 2$ and summing to $k-l$. Now starting from $(r_1',\cdots,r_{m-l}')$ we may insert l 1's in this $(m-l)$-tuple and fill it out to an m-tuple in $\binom{m}{l}$ ways.

Thus

$$\beta_k=\sum_{l=0}^{k-2}\left(\sum\binom{m+l}{l}a_0^{(-1)^{m+l}/(m+l+1)}\alpha_{r_1}\alpha_{r_2}\cdots\alpha_{r_m}\right)\alpha_1^l+\frac{(-1)^k}{\alpha_0}\frac{\alpha_1^k}{\alpha_0}\tag{11}$$

where the inner sum is over all m-tuples $(r_1,\cdots,r_m)$ of integers $\geqq 2$ with $r_1+r_2+\cdots+r_m=k-l$ and empty sums are taken to be 0. We then note that (11) holds for all $k\geqq 0$.

Proof of Theorem 1. Differentiating (2) with respect to w and then multiplying by ξ we get

$$\frac{\xi}{g(\xi)-w}=\sum_{n=0}^\infty\frac{1}{n+1}F_{n+1}'(w)\xi^{-n}.\tag{12}$$

We apply Lemma 2 to $p(z)=[g(1/z)-w]z$, noting that $p(z)=\sum_{k=0}^\infty \alpha_k z^k$ with

$$\alpha_0=1,\quad \alpha_1=b_0-w\quad\text{and}\quad \alpha_k=\beta_{k-1}\quad (k\geqq 2).\tag{13}$$

Replacing z by $1/\xi$ we find that

$$\frac{\xi}{g(\xi)-w}=\sum_{n=0}^\infty\beta_n\xi^{-n}\tag{14}$$

where we may take the β_n's as given by (11). Equating coefficients in (12) and (14), then using (11) and (13) we have, for $n \geqq 1$,

$$\begin{aligned}\frac{1}{n}F'_n(w)&=\beta_{n-1}\\&=(w-b_0)^{n-1}+\sum_{l=0}^{n-3}\left(\sum\binom{m+l}{l}(-1)^m b_{r_1-1}b_{r_2-1}\cdots b_{r_m-1}\right)(w-b_0)^l\end{aligned}\tag{15}$$

where the inner sum in (15) is over the same values as the one in (11) for β_{n-1}. When we integrate both sides of (15) and multiply by n we have that

$$\begin{aligned}F_n(w)&=(w-b_0)^n+n\sum_{l=0}^{n-3}\left(\sum(-1)^m\binom{m+l}{l}b_{r_1-1}\cdots b_{r_m-1}\right)\frac{(w-b_0)^{l+1}}{l+1}+F_n(b_0)\\&=(w-b_0)^n+\sum_{l=1}^{n-2}\frac{n}{l}\left(\sum(-1)^m\binom{m+l-1}{l-1}b_{r_1-1}\cdots b_{r_m-1}\right)(w-b_0)^l+F_n(b_0).\end{aligned}\tag{16}$$

The inner sum in (16) is over all m-tuples $(r_1,\cdots,r_m)$ of integers $\geqq 2$ with $r_1+r_2+\cdots+r_m=n-l$. Thus we have, as defined in the statement of Theorem 1,

$$F_n(w)=(w-b_0)^n+\sum_{k=1}^{n-2}c_k^{(n)}(w-b_0)^k+F_n(b_0).$$

We need only prove that $c_0^{(n)}=F_n(b_0)$ is as claimed.

If we differentiate (5) and let $w=b_0$ we have

$$F_n(b_0)=F'_{n+1}(b_0)+\sum_{k=1}^{n-1}b_{n-k}F'_k(b_0).$$

Substituting (15), with $w=b_0$, into this last expression and noting $F'_1\equiv 1$, we have

$$\begin{aligned}F_n(b_0)&=(n+1)\sum_{\textcircled{1}}(-1)^m b_{r_1-1}\cdots b_{r_m-1}\\&\quad+\sum_{k=2}^{n-1}kb_{n-k}\sum_{\textcircled{2}}(-1)^m b_{r_1-1}\cdots b_{r_m-1}+b_{n-1}\end{aligned}\tag{17}$$

where sum ① (resp. ②) is over all m-tuples $(r_1,\cdots,r_m)$ of integers $\geqq 2$ with $r_1+r_2+\cdots+r_m=n$ (resp. $k-1$). We rearrange the first sum in (17) to group together all of those m-tuples whose last entry is $n-k$ $(0\leqq k\leqq n-2)$. Noting that when $k=2$, $\sum_{\textcircled{2}}$ is 0 we find that

$$\begin{aligned}F_n(b_0)&=(n+1)\sum_{k=2}^{n-2}b_{n-k-1}\left(\sum(-1)^{m+1}b_{r_1-1}\cdots b_{r_m-1}\right)\\&\quad-\sum_{k=2}^{n-2}(k+1)b_{n-k-1}\left(\sum(-1)^{m+1}b_{r_1-1}\cdots b_{r_m-1}\right)-nb_{n-1}\\&=\sum_{k=2}^{n-2}(n-k)b_{n-k-1}\left(\sum(-1)^{m+1}b_{r_1-1}\cdots b_{r_m-1}\right)-nb_{n-1}\end{aligned}\tag{18}$$

where the inner sums in (18) are over m-tuples $(r_1,\cdots,r_m)$ of integers $\geqq 2$ with $r_1+\cdots+r_m=k$. With a change of variable in the first sum $(k\leftrightarrow n-k)$ this is equivalent to (8). □

To conclude this section, we admit that using expressions (7) and (8) to compute a large number of coefficients can be tedious. In this event we should point out that (5) gives rise to an easily proven recursion relation.

LEMMA 3. *With the same notation as Theorem* 1, *and taking* $c_n^{(n)}=1$ $(n=0,1,2,\cdots)$ *and* $c_{n-1}^{(n)}=0$ $(n=1,2,\cdots)$ *we have that*

$$c_k^{(n+1)}=c_{k-1}^{(n)}-\sum_{l=k}^{n-1} b_{n-l}c_k^{(l)} \qquad (n\geqq 0,\ 1\leqq k\leqq n-1)$$

and

$$c_0^{(n+1)}=-\sum_{l=1}^{n-1} b_{n-l}c_0^{(l)}-(n+1)b_n \qquad (n\geqq 1).$$

3. Expansions of analytic functions. In this section we will derive an explicit formula for the Faber expansion of functions that are entire, or at least analytic on an appropriate disk containing E or Int (E). It is known [5, p. 42] that if $f(z)$ is analytic on E or if ∂E is analytic and $f(z)$ is analytic on Int E, then (3) and (4) hold. In the first case, the r in (4) will be >1 while in the second case, will be <1. In either case the series (3) converges uniformly on compact subsets of Int (E). Throughout this section we will assume $f(z)$ and/or E are as discussed above, though more general circumstances under which (3) and (4) hold are known [3].

THEOREM 4. *Let* $k\geqq 0$ *be an integer. Then*

$$(w-b_0)^k=F_k(w)+\sum_{l=0}^{k-1}\gamma_l^{(k)}F_l(w) \tag{19}$$

where

$$\gamma_l^{(k)}=\sum_{s=[(k+l+1)/2]}^{k-1}\binom{k}{s}\sum b_{r_1}\cdots b_{r_{k-s}} \qquad (0\leqq l\leqq k-1) \tag{20}$$

and the inner sum in (20) *is over all* $(k-s)$*-tuples* $(r_1,\cdots,r_{k-s})$ *of positive integers with* $r_1+\cdots+r_{k-s}=s-l$. *We take* $\gamma_k^{(k)}=1$ $(k=0,1,\cdots)$. *In* (20), [ ] *is the greatest integer function.*

Proof. It is clear that the coefficient of F_k is 1. Since $(w-b_0)^k$ is entire, we may use (4) to obtain

$$\begin{aligned}\gamma_l^{(k)}&=\frac{1}{2\pi i}\int_{|\xi|=r}\frac{(g(\xi)-b_0)^k}{\xi^{l+1}}\,d\xi \qquad (0\leqq l\leqq k-1)\\ &=\text{coefficient of } \xi^l \text{ in } (g(\xi)-b_0)^k\\ &=\sum b_{r_1}b_{r_2}\cdots b_{r_k}\end{aligned} \tag{21}$$

where the sum in (21) is over all ordered k-tuples $(r_1, r_2,\cdots,r_k)$ with $r_j\in\{-1\}\cup\mathbf{Z}^+$ $(1\leqq j\leqq k)$, $r_1+r_2+\cdots+r_k=-l$ and where $b_{-1}=1$. If we rearrange (21) to first sum over those r_j's that may be -1, we find that to achieve the sum $-l$, at least $[(k+l+1)/2]$ of the r_j's must be -1. Since $l\leqq k-1$ in (21) and the sum is over k-tuples, we see at most $k-1$ of the r_j's may be -1. Thus

$$\gamma_l^{(k)}=\sum_{s=[(k+l+1)/2]}^{k-1}\binom{k}{s}\sum b_{r_1}\cdots b_{r_{k-s}}$$

where the inner sum is as described in the statement of the theorem. □

We may note that in (20) the sum is empty when $l=k-1$. Thus $\gamma_{k-1}^{(k)}\equiv 0$ $(k=1, 2,\cdots)$. As was the case for the coefficients $c_k^{(n)}$ of Theorem 1, we can also generate the $\gamma_l^{(k)}$'s through a recursion relation.

LEMMA 5. *We have* $\gamma_k^{(k)}=1$ $(k=0, 1, \cdots)$ *and* $\gamma_{k-1}^{(k)}=0$ $(k=1, 2, \cdots)$. *For* $k \geqq 1$,

$$\gamma_l^{(k+1)}=\gamma_{l-1}^{(k)}+\sum_{j=l+1}^{k} \gamma_j^{(k)} b_{j-l} \qquad (1 \leqq l \leqq k-1) \tag{22}$$

and

$$\gamma_0^{(k+1)}=\sum_{j=0}^{k}(j+1)\gamma_j^{(k)} b_j. \tag{23}$$

Proof. By (5) and (19) we have, for $k \geqq 1$,

$$\sum_{l=0}^{k+1} \gamma_l^{(k+1)} F_l(w)=(w-b_0)^{k+1}=(w-b_0)(w-b_0)^k \tag{24}$$

$$=\sum_{j=0}^{k} \gamma_j^{(k)}(w-b_0)F_j(w)$$

$$=\sum_{j=0}^{k} \gamma_j^{(k)}\left[F_{j+1}(w)+\sum_{l=1}^{j-1} b_{j-l}F_l(w)+(j+1)b_j\right]$$

$$=\sum_{j=1}^{k+1} \gamma_{j-1}^{(k)} F_j+\sum_{l=1}^{k-1}\left\{\sum_{j=l+1}^{k} \gamma_j^{(k)} b_{j-l}\right\}F_l+\sum_{j=0}^{k}(j+1)\gamma_j^{(k)} b_j$$

$$=F_{k+1}+\sum_{l=1}^{k-1}\left\{\gamma_{l-1}^{(k)}+\sum_{j=l+1}^{k} \gamma_j^{(k)} b_{j-l}\right\}F_l(w) \tag{25}$$

$$+\sum_{j=0}^{k}(j+1)\gamma_j^{(k)} b_j F_0(w).$$

Equating coefficients of $F_l(w)$ in (24) and (25) we get (22) and (23). □

With Theorem 4 we easily obtain the Faber expansions of entire functions.

THEOREM 6. *Suppose that either*

(i) ∂E *is analytic and* $f(z)$ *is analytic on some disk* $\Delta(b_0, r) \supset \operatorname{Int} E$,

or

(ii) $f(z)$ *is analytic on some disk* $\Delta(b_0, r) \supset E$. *Then if*

$$f(z)=\sum_{j=0}^{\infty} a_j(z-b_0)^j \qquad (|z-b_0|<r),$$

then

$$f(z)=\sum_{l=0}^{\infty} \alpha_l F_l(w) \tag{26}$$

where, for $l \geqq 0$,

$$\alpha_l=\sum_{k=l}^{\infty} a_k \gamma_l^{(k)} \tag{27}$$

and the $\gamma_l^{(k)}$*'s are defined in Theorem* 4. *In case* (i) *series* (26) *converges uniformly on compact subsets of* Int E *while in case* (ii) *series* (26) *converges uniformly on* E.

Proof. Let $S_n(z)=\sum_{j=0}^n a_j(z-b_0)^j$. By Theorem 4,

$$S_n(z)=\sum_{j=0}^n a_j\left\{F_j(z)+\sum_{l=0}^{j-1}\gamma_l^{(j)}F_l(z)\right\}$$

$$=\sum_{l=0}^n\left\{a_l+\sum_{j=l+1}^{n-1}a_j\gamma_l^{(j)}\right\}F_l(z).$$

In case (i), $\{S_n(z)\}_1^\infty$ converges to $f(z)$ uniformly on compact subsets of Int E. In case (ii), $\{S_n(z)\}_1^\infty$ converges to $f(z)$ uniformly on some disk $\Delta(b_0, r')$ where $\Delta(b_0, r)\supset\Delta(b_0, r')\supset E$. In either case, the α_l's are given by (3) and (4) for appropriate p.

$$\alpha_l=\int_{|\xi|=p}\frac{f(g(\xi))}{\xi^{l+1}}\,d\xi$$

$$=\lim_{n\to\infty}\int_{|\xi|=p}\frac{S_n(g(\xi))}{\xi^{l+1}}\,d\xi$$

$$=\lim_{n\to\infty}\left\{a_l+\sum_{j=l+1}^{n-1}a_j\gamma_l^{(j)}\right\}$$

$$=\sum_{j=l}^{\infty}a_j\gamma_l^{(j)}.$$

The uniform convergence of the Faber series follows from [5, p. 42]. □

As an example, we consider the case in which $g(z)=z+b_0+e^{i\theta}/z$ (θ real) and $f(z)=e^z$. In this case g maps Δ onto the complement of the segment

$$\left\{b_0+2e^{i\theta/2}\cos\left(t-\frac{\theta}{2}\right): 0\leqq t\leqq 2\pi\right\}.$$

For this choice of g, the Faber polynomials are translations of the familiar Chebyshev polynomials. In fact, we have that

$$F_n(w)=\frac{1}{2^n}\{[(w-b_0)+\sqrt{(w-b_0)^2-4e^{i\theta}}]^n+[(w-b_0)-\sqrt{(w-b_0)^2-4e^{i\theta}}]^n\}.$$

We may apply Theorem 1 to write $F_n(w)$ in more conventional form. Since $b_1=e^{i\theta}$ and $b_k=0$ ($k\geqq 2$), (7) shows that for $1\leqq k\leqq n-2$

$$c_k^{(n)}=\begin{cases}0 & (n-k\text{ odd}),\\ \dfrac{n}{k}(-1)^{(n-k)/2}\dbinom{(n+k-2)/2}{k-1}e^{((n-k)/2)i\theta} & (n-k\text{ even}),\end{cases}$$

while (8) gives

$$c_0^{(n)}=\begin{cases}0 & (n\text{ odd}),\\ 2(-1)^{n/2}e^{in\theta/2} & (n\text{ even}).\end{cases}$$

Thus

$$F_n(w) = (w-b_0)^n + \frac{(-1)^{n/2} n e^{in\theta/2}}{2} \sum_{k=1}^{(n/2-1)} \frac{(-1)^k}{k} \binom{\frac{1}{2}n+k-1}{2k-1} e^{-ik\theta}(w-b_0)^{2k}$$

$$+2(-1)^{n/2}\, e^{in\theta/2} \quad (n \text{ even})$$

and

$$F_n(w) = (w-b_0)^n + (-1)^{(n+1)/2} n\, e^{((n+1)/2)i\theta}$$

$$\cdot \sum_{k=1}^{(n-1)/2} \frac{(-1)^k}{2k-1} \binom{(n-1)/2+k-1}{2k-2} e^{-ik\theta}(w-b_0)^{2k-1} \quad (n \text{ odd}).$$

If we apply Theorem 4 to this particular $g(z)$, we find that

$$(w-b_0)^k = F_k(w) + \sum_{l=0}^{k-1} \gamma_l^{(k)} F_l(w)$$

where

$$(28) \qquad \gamma_l^{(k)} = \begin{cases} 0 & (l+k \text{ odd}), \\ \dbinom{k}{(l+k)/2} e^{i((k-l)/2)\theta} & (l+k \text{ even}). \end{cases}$$

Thus we find that

$$(w-b_0)^k = F_k(w) + \sum_{l=0}^{k/2-1} \binom{k}{k/2+l} e^{i(k/2-l)\theta} F_{2l}(w) \quad (k \text{ even})$$

and

$$(w-b_0)^k = F_k(w) + \sum_{l=0}^{(k-3)/2} \binom{k}{(k+1)/2+l} e^{(i((k-1)/2)-l)\theta} F_{2l+1}(w) \quad (k \text{ odd}),$$

giving expansions for $(w-b_0)^k$ in terms of Chebyshev polynomials. Finally, taking

$$f(z) = e^z = e^{b_0} \sum_{j=0}^{\infty} \frac{1}{j!}(z-b_0)^j,$$

Theorem 6 says, for $g(z) = z + b_0 + e^{i\theta}/z$,

$$e^z = \sum_{l=0}^{\infty} \alpha_l F_l(z)$$

where

$$\alpha_l = e^b \sum_{k=l}^{\infty} \frac{1}{k!} \gamma_l^{(k)}$$

and the $\gamma_l^{(k)}$'s are, in this case, given by (28). Hence, if l is even,

$$\begin{aligned}\alpha_l &= e^b \sum_{k=l/2}^{\infty} \frac{1}{(2k)!}\binom{2k}{k+l/2} e^{i(k-l/2)\theta} \\ &= e^b \sum_{j=0}^{\infty} \frac{e^{ij\theta}}{j!(j+l)!} \qquad (29)\\ &= e^{b-il\theta/2} J_l(2ie^{i\theta/2}).\end{aligned}$$

If l is odd

$$\begin{aligned}\alpha_l &= e^b \sum_{k=(l+1)/2}^{\infty} \frac{1}{(2k-1)!}\binom{2k-1}{k+(l-1)/2} e^{i(k-((l+1)/2))\theta} \\ &= e^b \sum_{j=0}^{\infty} \frac{e^{ij\theta}}{j!(j+l)!} \qquad (30)\\ &= e^{b-(il\theta/2)} J_l(2ie^{i\theta/2}).\end{aligned}$$

In (29) and (30) $J_l(t)$ is Bessel's function of order l of the first kind [1, p. 175]. Thus, in terms of the Chebyshev polynomials $\{F_n(w)\}$ generated by $z+b_0+e^{i\theta}/z$, we find that

$$e^z = e^b \sum_{l=0}^{\infty} e^{-il\theta/2} J_l(2ie^{i\theta/2}) F_l(z).$$

4. Rational functions and derivatives of Faber polynomials. Let $R(\mathbf{z})$ be a rational function. We may write

$$R(\mathbf{z}) = P(\mathbf{z}) + \sum_{j=1}^{n} \sum_{k=1}^{m_j} \frac{a_{j,k}}{(\mathbf{z}-\rho_j)^k}$$

where $P(\mathbf{z})$ is a polynomial ($P(\mathbf{z}) \equiv 0$ is possible) and $\rho_1, \rho_2, \cdots, \rho_n$ are the finite poles of R. We will assume that R has at least one finite pole and that for $1 \leqq j \leqq n$, R has a pole of order m_j at ρ_j. If none of the poles of R lies in E, then R is analytic on E and (3) and (4) hold with $f(\mathbf{z}) = R(\mathbf{z})$. Thus we may ask for the Faber expansion of R with respect to E.

Since the Faber expansion of a polynomial can be obtained using Theorems 4 and 6, it suffices to consider the Faber expansion for

$$f(\mathbf{z}) = \frac{1}{(\mathbf{z}-\rho)^k} \qquad (k=1,2,\cdots,\rho \in C\backslash E). \tag{31}$$

For future reference, we observe that if ρ is sufficiently large, then the techniques of § 3 can be used to obtain the expansion for (31). In fact, the following result is an easy application of Theorem 6.

THEOREM 7. *Let $\rho \in \mathbf{C}\backslash E$ with $E \subseteq \Delta(b_0, |\rho-b_0|)$. Then for $\mathbf{z} \in E$*

$$\frac{1}{(\mathbf{z}-\rho)^k} = \sum_{l=0}^{\infty} \beta_l F_l(\mathbf{z}) \tag{32}$$

where

$$\beta_l = \frac{1}{(b_0-\rho)^k} \sum_{r=l}^{\infty} \binom{k+r-1}{r} \frac{\gamma_l^{(r)}}{(\rho-b_0)^r} \tag{33}$$

and the $\gamma_l^{(r)}$'s are defined by (20).

Since (32) and (33) are valid whenever $E \subseteq \overline{\Delta(b_0, |\rho-b_0|)}$ and since $E \subseteq \overline{\Delta(b_0, 2)}$ [4, p. 19] it follows that (33) must converge whenever $|\rho-b_0|>2$. This leads to the following estimate on the growth of the $\gamma_l^{(r)}$'s.

COROLLARY 8. *For the coefficients $\gamma_l^{(r)}$ defined in* (20) *we have*

$$\limsup_{r\to\infty} |\gamma_l^{(r)}|^{1/r} \leqq 2. \tag{34}$$

This estimate is best possible in that the constant 2 *in* (34) *cannot be replaced by a smaller number.*

Proof. Applying the root test to (33), we see that for those ρ for which the series converges

$$1 \geqq \limsup_{r\to\infty}\left[\binom{k+r-1}{r}\frac{|\gamma_l^{(r)}|}{|\rho-b_0|^2}\right]^{1/2}$$

$$=\frac{1}{|\rho-b_0|}\limsup_{r\to\infty}|\gamma_l^{(r)}|^{1/r}.$$

Thus $|\rho-b_0|\geqq \limsup_{r\to\infty}|\gamma_l^{(r)}|^{1/r}$ for each ρ for which (33) converges. Since (33) converges for $|\rho-b_0|>2$, the desired inequality follows.

Taking $g(\mathbf{z})=\mathbf{z}+b_0+e^{i\theta}/\mathbf{z}$, the resulting $\gamma_l^{(r)}$'s given in (28) show the estimate is best possible. □

If $\rho\in\mathbf{C}\backslash E$ but $E\not\subseteq\Delta(b_0,|\rho-b_0|)$, then Theorem 7 does not apply. Nonetheless, we can still find the Faber expansion for (31) if we assume $g^{-1}(\rho)=\mathbf{z}_0\in\Delta$ is known. We will need the following lemma.

Lemma 9. *Let n, k be positive integers with* $k\leqq n$. *Then*

$$F_n^{(k)}(w)=k!\binom{n}{k}F_{n-k}(w)+k!\sum_{l=0}^{n-k-2}\eta_l^{(n,k)}F_l(w) \tag{35}$$

where

$$\eta_l^{(n,k)}=\left[\gamma_l^{(n-k)}+\binom{l+k}{k}c_{l+k}^{(n)}+\sum_{t=l}^{n-k-2}\binom{t+k}{k}c_{t+k}^{(n)}\gamma_l^{(t)}\right] \tag{36}$$

$(0\leqq l\leqq n-k-2)$ *and the c's and* γ*'s are defined in* (7), (8) *and* (20).

Proof. By Theorem 1

$$F_n(w)=(w-b_0)^n+\sum_{r=0}^{n-2}c_r^{(n)}(w-b_0)^r$$

where the $c_r^{(n)}$'s are given in (7) and (8). Thus

$$F_n^{(k)}(w)=k!\left\{\binom{n}{k}(w-b_0)^{n-k}+\sum_{t=0}^{n-k-2}c_{t+k}^{(n)}\binom{t+k}{k}(w-b_0)^t\right\}.$$

Where we apply Theorem 4 the last expression becomes

$$F_n^{(k)}(w)=k!\left\{\binom{n}{k}\left[F_{n-k}(w)+\sum_{l=0}^{n-k-1}\gamma_l^{(n-k)}F_l(w)\right]\right.$$
$$\left.+\sum_{t=0}^{n-k-2}c_{t+k}^{(n)}\binom{t+k}{k}\left[F_t(w)+\sum_{l=0}^{t-1}\gamma_l^{(t)}F_l(w)\right]\right\}.$$

Using $\gamma_{s-1}^{(s)}=c_{s-1}^{(s)}=0$ and interchanging the order of summation, we have

$$F_n^{(k)}(w)=k!\left\{\binom{n}{k}F_{n-k}(w)+\sum_{l=0}^{n-k-2}\left[\gamma_l^{(n-k)}+C_{l+k}\binom{l+k}{k}\right.\right.$$
$$\left.\left.+\sum_{t=l}^{n-k-2}C_{t-k}^{(n)}\gamma_l^{(t)}\binom{t+k}{k}\right]F_l(w)\right\}.$$

This completes the proof of the lemma. □

Theorem 10. *Let* $\mathbf{z}_0\in\Delta$ *and set* $\rho=g(\mathbf{z}_0)$. *Then for* $k=1, 2, \cdots,$

$$\frac{1}{(z-\rho)^k}=\sum_{l=0}^{\infty}\beta_lF_l(w) \tag{37}$$

where

$$\beta_l = (-1)^k k \sum_{n=l+k}^{\infty} \frac{\eta_l^{(n,k)}}{n\mathbf{z}_0^n} \tag{38}$$

and the $\eta_l^{(n,k)}$*'s are defined by* (36).

Proof. Let $A_{r_0} = \mathbf{C}\backslash\{g(\xi): |\xi| \geqq |z_0|\}$ $(r_0 = |z_0|)$. Then the series

$$\log\left(\frac{g(\mathbf{z}_0) - w}{\mathbf{z}_0}\right) = -\sum_{n=1}^{\infty} \frac{1}{n} F_n(w)\mathbf{z}_0^{-n}$$

is an analytic function of $w \in A_{r_0}$ and the series on the right converges uniformly (as a function of w) on compact subsets of A_{r_0}. Thus if we differentiate with respect to w, we find

$$\frac{1}{g(\mathbf{z}_0) - w} = \sum_{n=1}^{\infty} \frac{1}{n} F_n'(w)\mathbf{z}_0^{-n} \tag{39}$$

uniformly on compact subsets of A_{r_0}. Letting $g(\mathbf{z}_0) = \rho$ and differentiating (39) $k-1$ times with respect to w, we find

$$\begin{aligned} \frac{1}{(w-p)^k} &= \frac{(-1)^k}{(k-1)!} \frac{d^{(k-1)}}{dw^{(k-1)}}\left(\frac{1}{g(z) - w}\right) \\ &= \frac{(-1)^k}{(k-1)!} \sum_{n=k}^{\infty} \frac{1}{n} F_n^{(k)}(w)\mathbf{z}_0^{-n}. \end{aligned} \tag{40}$$

For $N \geqq k$, let

$$S_N(w) = \frac{(-1)^k}{(k-1)!} \sum_{n=k}^{N} \frac{1}{nz_0^n} F_n^{(k)}(w).$$

Then the sequence $\{S_N(w)\}_{N=k}^{\infty}$ converges to $1/(w-\rho)^k$ uniformly on compact subsets of A_{r_0}. The same is true if we rewrite $S_N(w)$ after substituting expression (35), with $\eta_{n-k}^{(n,k)} = \binom{n}{k}$ and $\eta_{n-k-1}^{(n,k)} = 0$:

$$\begin{aligned} S_N(w) &= (-1)^k k\left(\sum_{n=k}^{N} \frac{1}{n\mathbf{z}_0^n}\left(\sum_{l=0}^{n-k} \eta_l^{(n,k)} F_l(w)\right)\right) \\ &= (-1)^k k \sum_{l=0}^{N-k}\left(\sum_{n=l+k}^{N} \frac{\eta_l^{(n,k)}}{n\mathbf{z}_0^n}\right) F_l(w). \end{aligned}$$

If $r > 1$ is chosen so that $|z_0| > r$, then $1/(w-\rho)^k$ is analytic on $\mathbf{C}\backslash\{g(\xi): |\xi| \geqq r\}$. Thus (4) holds, that is, $f(w) = 1/(w-\rho)^k = \sum_{l=0}^{\infty} \beta_l F_l(w)$ with

$$\begin{aligned} \beta_l &= \frac{1}{2\pi i} \int_{|\xi|=r} \frac{f(g(\xi))}{\xi^{l+1}}\, d\xi \\ &= \lim_{N\to\infty} \frac{1}{2\pi i} \int_{|\xi|=r} \frac{S_N(g(\xi))}{\xi^{l+1}}\, d\xi \end{aligned}$$

$$= \lim_{N\to\infty} (-1)^k k \sum_{n=l+k}^{N} \frac{\eta_l(n,k)}{nz_0^n}$$

$$= (-1)^k k \sum_{n=l+k}^{\infty} \frac{\eta_l^{(n,k)}}{nz_0^n}. \qquad \square$$

5. Remarks and examples.

Remark. Unfortunately, the formula for β_l in Theorem 10 is rather complicated. However this seems unavoidable, even if we disregard the fact that working with coefficients of $(g(\xi)-w)^{-k}$ must lead to complications. In fact, we first note that the formula

$$\beta_l = (-1)^k k \sum_{n=l+k}^{\infty} \frac{\eta_l^{(n,k)}}{n\mathbf{z}_0^n} = (-1)^k k \sum_{n=l+k}^{\infty} \frac{\eta_l^{(n,k)}}{n(g^{-1}(\rho))^n} \tag{41}$$

must be valid for all $|\mathbf{z}_0|>1$ or $\rho \in \mathbf{C}\backslash E$. On the other hand, Theorem 7 shows that if $|\rho - b_0| > 2$, then

$$\beta_l = \frac{1}{(b_0-\rho)^k} \sum_{r=l}^{\infty} \binom{k+r-1}{r} \frac{\gamma_l(r)}{(\rho-b_0)^r}. \tag{42}$$

Since the Faber expansion coefficients for a function are unique, we have

$$\frac{1}{(b_0-\rho)^k} \sum_{r=l}^{\infty} \binom{k+r-1}{r} \frac{\gamma_l(r)}{(\rho-b_0)^r} = (-1)^k k \sum_{n=l+k}^{\infty} \frac{\eta_l^{(n,k)}}{n(g^{-1}(\rho))^n}$$

for $|\rho-b_0|>2$. Thus (41) is an analytic continuation of (42) to $\mathbf{C}\backslash E$. The fact that ∂E may be rather complicated means that this analytic continuation may be rather complicated also.

In spite of the complexity of the $\eta_l^{(n,k)}$'s we can, however, say that since (38) must converge for all $|\mathbf{z}_0|>1$,

$$\limsup_{n\to\infty} |\eta_l^{(n,k)}|^{1/n} \leqq 1. \tag{43}$$

Remark. Other methods for finding the $\eta_l^{(n,k)}$'s and the β_l's are possible, but also lead to complicated expressions. For example, we may first find the series expansion for $1/(g(z_0)-w)$ using Lemma 2, and then the coefficients for $(1/(g(\mathbf{z}_0)-w))^k$ as in the proof of Theorem 4. We chose the method presented in the proof of Lemma 9 and Theorem 10 because it gave access to and used expressions for the derivatives of the Faber polynomials. Such expressions can be valuable in working with Faber expansions.

Example. As an example of the use of formulas (35) and (36), again consider $g(\xi)=\xi+b_0+e^{i\theta}/\xi$. In § 3 we saw that for this choice of g we have that

$$e^z = e^b \sum_{l=0}^{\infty} e^{-il\theta/2} J_l(2ie^{i\theta/2}) F_l(z).$$

Equating e^z to its own derivative and substituting (35) with $k=1$ gives the following:

$$\sum_{l=0}^{\infty} e^{-il\theta/2} J_l(2ie^{i\theta/2}) F_l(z) \tag{44}$$

$$= \sum_{l=1}^{\infty} e^{-il\theta/2} J_l(2ie^{i\theta/2}) \left[lF_{l-1}(z) + \sum_{j=0}^{l-3} \eta_j^{(l,1)} F_j(w) \right]$$

$$(45)\qquad = \sum_{j=0}^{\infty} \left[\sum_{l=j+1}^{\infty} e^{-il\theta/2} \eta_j^{(l,1)} J_l(2ie^{i\theta/2}) \right] F_j(w),$$

where $\eta_j^{(j+1,1)} = j+1$ and $\eta_j^{(j+2,1)} = 0$. Equating coefficients of $F_j(w)$ in (44) and (45) we see that

$$(46)\qquad J_n(2ie^{i\theta/2}) = e^{in\theta/2} \sum_{l=n+1}^{\infty} e^{-il\theta/2} \eta_n^{(l,1)} J_l(2ie^{i\theta/2}).$$

The $\eta_n^{(l,1)}$'s are somewhat complicated even in this simple case. Nonetheless (46) exhibits an interesting relation between Bessel functions of different orders.

A TOPOLOGICAL APPROACH TO NEVANLINNA-PICK INTERPOLATION*

TRYPHON T. GEORGIOU†

Abstract. We study the set of rational solutions of an $(N+1)$-point Nevanlinna-Pick problem, that has degree bounded by N. Based on the invariance of the topological degree of a certain mapping under deformation, we establish that when the $(N+1)$-point Nevanlinna-Pick problem is solvable, then for any dissipation polynomial of degree N or less, there corresponds an interpolating function with dimension at most N. Our results provide a novel topological proof for the sufficiency of Pick's criterion for the solvability of the Nevanlinna-Pick problem, and also give a solution to an extended interpolation problem.

Key words. Nevanlinna-Pick interpolation, bounded degree solution, topological degree theory

AMS(MOS) subject classifications. Primary 46; secondary 30, 55, 93

1. Introduction. The Nevanlinna-Pick interpolation theory has a long history in mathematics. Its origin can be traced back to the beginning of the century in the work of Pick [20] and Nevanlinna [19] and it has reached a high degree of achievement in the recent work of Adamjan, Arov and Krein [1], Sarason [21], Sz.-Nagy and Foias [25] and Ball and Helton [3].

In engineering, it was in a circuit theoretical context where interpolation theory found the first applications (see Belevitch [4] and Wohlers [28]). In recent years, renewal of interest in the Nevanlinna-Pick interpolation problem has been motivated by a multitude of applications to system theoretic problems. These have been in the area of robust control, circuit theory, approximation theory, filtering, and stochastic processes (see Zames and Francis [30], Khargonekar and Tannenbaum [15], Helton [11], Genin and Kung [7], Dewilde, Vieira and Kailath [6] and Delsarte, Genin and Kamp [5]).

This paper addresses certain questions that carry a significant interest from an engineering standpoint.

It is known that whenever an $(N+1)$-point Nevanlinna-Pick problem is solvable, there exist rational solutions of degree at most N. Generically, the solution is nonunique. In this paper we present a study of the solutions of the $(N+1)$-point Nevanlinna-Pick problem that are at most of degree N. We show in Theorem 5.3 that for any dissipation polynomial (for a definition, see § 4) of degree at most N there exists a corresponding solution of degree at most N. This provides a description of the set of degree N solutions. We must point out that the degree of the interpolating function is related to the dimension of a controller in a feedback system, to the dimension of a modeling filter of a stochastic process, or to the McMillan degree of a certain transfer function in a circuit theoretic context. We show the above by exploiting the invariance of the topological degree of a certain mapping under deformation.

This approach also provides an independent topological proof of the sufficiency of Pick's criterion for the solvability of the Nevanlinna-Pick problem.

Our results are applied to tackle the solvability of an extended interpolation problem (see § 5) where, in addition to the $N+1$ interpolating conditions of the

† Department of Electrical and Computer Engineering, Iowa State University, Ames, Iowa 50011.

standard problem, we require that the real part of the function satisfy extra N interpolating conditions on the boundary of the "stability" region. These N interpolating conditions are interpreted as attenuation zeros of an associated transmittance function.

This work follows the lines of an investigation on the Carathéodory problem [8], and a preliminary version was reported in [9].

A variety of different terminologies has appeared in connection with the Nevanlinna-Pick problem. For instance, the reflectance of a passive system is known also as a bounded real function or as a Schur function, etc. We have chosen to use a rather mathematical terminology as it appears in the classical references (e.g. Akhiezer [2]), although occasionally we indicate the "translation" of the various terms in the circuit theoretic or stochastic terminology.

2. Notation and terminology.

$\mathbb{C} = \{\text{complex numbers}\}$.

$\mathbb{R} = \{\text{real numbers}\}$.

$D =$ open unit disc
$= \{z \in \mathbb{C}: |z| < 1\}$.

X^c, X^0, ∂X indicate the closure, the interior and the boundary of a set X, respectively.

$H(D) = \{\text{functions holomorphic in } D\}$.

$C =$ class C (for Carathéodory)
$= \{f(z) \in H(D): \operatorname{Re}\{f(z)\} \geqq 0 \text{ for all } z \text{ in } D\}$.

$S =$ class S (for Schur)
$= \{f(z) \in H(D): |f(z)| \leqq 1 \text{ for all } z \text{ in } D\}$.

$z^* =$ complex conjugate of $z \in \mathbb{C}$.

If $a(z) = a_0 + a_1 z + \cdots + a_n z^n + \cdots \in H(D)$, then
$a(z)_* = a^*(z^{-1})$
$= a_0^* + a_1^* z^{-1} + \cdots + a_n^* z^{-n} + \cdots$ is analytic in $\mathbb{C} - D^c$.

L^2: the space of squarely integrable functions on ∂D.

H^2: the space of L^2-functions that have analytic continuation in D.

3. Nevanlinna-Pick interpolation. Consider two sets of $N+1$ points in $\mathbb{C}$,

$$z = \{z_\kappa: z_\kappa \in D \text{ for } \kappa = 0, 1, \cdots, N\} \quad \text{and} \quad w = \{w_\kappa: w_\kappa \in \mathbb{C} \text{ for } \kappa = 0, 1, \cdots, N\}.$$

For simplicity we will always assume that the points z_κ are all distinct. The Nevanlinna-Pick problem can be stated as follows.

PROBLEM NP (z, w). Construct, if possible, a function $f(z) \in C$ that satisfies the interpolation conditions

$$f(z_\kappa) = w_\kappa \quad \text{for } \kappa = 0, 1, \cdots, N. \tag{3.1}$$

In particular,

(NP$_1$) find necessary and sufficient conditions on the data (z, w) for the existence of a solution $f(z)$, and

(NP$_2$) give a complete description of *the set $C(z, w)$ of all C-functions satisfying* (3.1).

The solvability criterion was derived by Pick and a constructive algorithm was provided by Nevanlinna—we now outline these. For a more detailed exposition see Walsh [27].

Pick criterion. There exists a function $f(z) \in C$ that satisfies (3.1) if and only if the Pick matrix

$$P(z, w) := \left[\frac{w_k + w_l^*}{1 - z_\kappa z_l^*}\right]_{\kappa, l=0}^{N}$$

is nonnegative definite.

A similar interpolation problem can be stated in terms of functions of class S instead of C. Both formulations are equivalent. However, the Nevanlinna recursive scheme is simpler to describe in terms of S-functions. Define

$$\zeta_\kappa(z) := \frac{z - z_\kappa}{1 - z z_\kappa^*} \quad \text{for } \kappa = 0, 1, \cdots, N.$$

Nevanlinna recursive scheme. A function $f(z) \in C$ satisfies the interpolation conditions (3.1) if and only if

$$\text{(3.2a)} \qquad \operatorname{Re} w_0 \geqq 0$$

and

$$\text{(3.2b)} \qquad s_1(z) := \zeta_0(z)^{-1} \frac{f(z) - w_0}{f(z) + w_0^*}$$

belongs to the class S and satisfies the interpolation conditions

$$\text{(3.3)} \qquad s_1(z_\kappa) = v_{1,\kappa} := \zeta_0(z_\kappa)^{-1} \frac{f(z_\kappa) - w_0}{f(z_\kappa) + w_0^*} \quad \text{for } \kappa = 1, 2, \cdots, N.$$

Furthermore, a function $s_l(z) \in S$ such that

$$s_l(z_\kappa) = v_{l,\kappa} \quad \text{for } \kappa = l, l+1, \cdots, N$$

exists if and only if either

$$\text{(3.4a)} \qquad |v_{l,l}| < 1 \quad \text{and} \quad s_{l+1}(z) = \zeta_l(z)^{-1} \frac{s_l(z) - v_{l,l}}{1 - v_{l,l}^* s_l(z)} \text{ belongs to } S,$$

or,

$$\text{(3.4b)} \qquad |v_{l,l}| = 1 \quad \text{and} \quad s_l(z) = v_{l,l} = v_{l,l+1} = \cdots = v_{l,N}.$$

In case (3.4a) holds, $s_{l+1}(z)$ satisfies

$$s_{l+1}(z_\kappa) = v_{l+1,\kappa} := \zeta_\kappa(z_\kappa)^{-1} \frac{v_{l,\kappa}(z_\kappa) - v_{l,l}}{1 - v_{l,l}^* v_{l,\kappa}(z_\kappa)} \quad \text{for } \kappa = l+1, \cdots, N.$$

(For a proof see Walsh [27].)

Notice that at each step of this procedure the number of interpolation conditions is reduced. Thus, it leads to a recursive solution of NP (z, w). This is summarized below.

PROPOSITION 3.5. *The NP problem is solvable if and only if* $\operatorname{Re} w_0 > 0$ *and either*

$$\text{(3.5a)} \qquad |v_{\kappa,\kappa}| < 1 \quad \textit{for } \kappa = 1, \cdots, N$$

or

$$\text{(3.5b)} \qquad |v_{\kappa,\kappa}| < 1 \quad \textit{for } \kappa = 1, \cdots, m-1 \quad \textit{and} \quad |v_{m,m}| = 1, \quad v_{m,m} = \cdots = v_{m,N}.$$

In the later case the solution is unique, whereas in the former case the general solution is obtained using

$$f(z)=j\ \mathrm{Im}\ w_0+\mathrm{Re}\ w_0\frac{1+\zeta_0(z)s_1(z)}{1-\zeta_0(z)s_1(z)} \tag{3.6a}$$

and

$$s_l(z)=\frac{v_{l,l}+\zeta_l(z)s_{l+1}(z)}{1+v_{l,l}^*\zeta_l(z)s_{l+1}(z)} \quad \textit{for } l=n, n-1, \cdots, 1 \tag{3.6b}$$

from $v_{l,l}$, $l=1, \cdots, n$ *and an arbitrary* $s_{l+1}(z)\in S$.

We are interested in the "indeterminate" case when there is more than one solution. A necessary and sufficient condition for the problem to be indeterminate is (3.5a). This condition is equivalent to the positive definiteness of the associated Pick matrix. Hence, from now on, we will assume that *P is positive definite.*

In the indeterminate case, one particular solution of the NP problem is obtained by setting $s_{n+1}(z)=0$ in (3.6). We state some related facts in the following proposition.

PROPOSITION 3.7. *Let the Pick matrix P be positive definite and let* $f_0(z)$ *denote the solution of the NP problem that is obtained by setting* $s_{n+1}(z)\equiv 0$. *Then,* (a) $f_0(z)$ *is a rational function, and* (b) *if* $f_0(z)=\pi_0(z)/\chi_0(z)$ *with* $\pi_0(z)$ *and* $\chi_0(z)$ *coprime polynomials in z, then* $\max\{\deg \pi_0(z), \deg \chi_0(z)\}\leqq n$ *and* $\chi_0(z)\neq 0$ *for all* $z\in D^c$.

Proof of Proposition 3.7. From (3.6) it is easy to see that $f_0(z)$ is a rational function of degree less than or equal to *n*. (The *degree of a rational function* $\pi_0(z)/\chi_0(z)$ is defined to be the maximum of $\{\deg \pi_0(z), \deg \chi_0(z)\}$ where $\pi_0(z)$, $\chi_0(z)$ are polynomials in *z*.) Also using (3.6), one can derive that

$$\pi_0(z)\chi_0(z)_*+\chi_0(z)\pi_0(z)_*=k\prod_{\kappa=0}^{n-1}(z-z_\kappa)(z^{-1}-z_\kappa^*)$$

for some scalar $k>0$. Now, since $|z_\kappa|<1$ for all κ, $\chi_0(z)$ (and for that matter $\pi_0(z)$ also) cannot have a root on ∂D, otherwise, $\chi_{0*}(z)$ would have a root at the same point. This cannot happen because the right-hand side of the above has no root on ∂D. Finally, that $\chi_0(z)$ has no root outside D^c is a consequence of the fact that $f_0(z)$ is a *C*-function (Proposition 3.5). Q.E.D.

4. Rational *C*-functions.

A well-known characterization of rational *C*-functions is given below (see Siljak [24]).

PROPOSITION 4.1. *Let* $\pi(z)$, $\chi(z)$ *be coprime polynomials in z. The rational function* $\pi(z)/\chi(z)$ *belongs to C if and only if*

$$\pi(z)+\chi(z)\neq 0 \quad \textit{for all } z\in D^c \tag{4.1a}$$

and

$$d(z, z^{-1}):=\pi(z)\chi(z)_*+\chi(z)\pi(z)_*\geqq 0 \quad \textit{for all } z\in\partial D. \tag{4.1b}$$

A polynomial $d(z, z^{-1})\in\mathbb{C}[z, z^{-1}]$ that satisfies (4.1b) will be called a *dissipation polynomial* (following Kalman [12]). The degree of the highest power of *z* will be called the *degree of* $d(z, z^{-1})$. (A necessary condition for $d(z, z^{-1})$ to be a dissipation polynomial is that $d(z, z^{-1})_*=d(z, z^{-1})$. Hence $\deg d(z, z^{-1})$ is also equal to the highest power of z^{-1}.)

Allowing the polynomials $\pi(z)$, $\chi(z)$ to have common factors, condition (4.1a) can be somewhat relaxed. The following modification of (4.1) will be utilized in the sequel.

PROPOSITION 4.2. *Let $\pi(z)$, $\chi(z)$ be polynomials in z (not necessarily coprime). If*

(4.2a) $$\pi(z)+\chi(z)\neq 0 \quad \textit{for all } z\in D \ (\textit{and not necessarily in } D^c)$$

and

(4.2b) $$d(z, z^{-1})\geqq 0 \quad \textit{for all } z\in \partial D,$$

then $\pi(z)/\chi(z)$ is a C-function.

Proof. From

$$|\pi(z)+\chi(z)|^2-|\pi(z)-\chi(z)|^2=2d(z, z^{-1})\geqq 0 \quad \text{for } z\in\partial D,$$

it follows that any root of $\pi(z)+\chi(z)$ on ∂D is also a root of $\pi(z)-\chi(z)$ and hence, of both $\pi(z)$ and $\chi(z)$. After extracting all common roots of $\pi(z)$ and $\chi(z)$ that lie on ∂D, we are left with a pair of polynomials $(\tilde{\pi}(z), \tilde{\chi}(z))$ that satisfy (4.1a), (4.1b) and also $\pi(z)/\chi(z)=\tilde{\pi}(z)/\tilde{\chi}(z)$. Therefore, $\pi(z)/\chi(z)$ is in C. Q.E.D.

5. Interpolation with rational *C*-functions of degree *N*: Main results.

PROBLEM 5.1: $I(z, w, \xi)$. Let (z, w) be a set of $N+1$ interpolating conditions, and let $\xi=\{\xi_\kappa: \xi_\kappa\in\partial D, \kappa=1, 2, \cdots, N\}$. Find necessary and sufficient conditions for the existence of a rational function $f(z)=\pi(z)/\chi(z)\in C$ that satisfies the interpolation conditions

(5.1a) $$f(z_\kappa)=w_\kappa \quad \text{for } \kappa=0, 1, \cdots, N,$$

and also

(5.1b) $$\pi(\xi_\kappa)\chi(\xi_\kappa)_*+\chi(\xi_\kappa)\pi(\xi_\kappa)_*=0 \quad \text{for } \kappa=1, \cdots, N.$$

Note that in case $\pi(z)$, $\chi(z)$ have no common factor, conditions (5.1b) can be written as

(5.1c) $$\operatorname{Re} f(\xi_\kappa)=0 \quad \text{for } \kappa=1, \cdots, N$$

(which represent Löwner-type interpolation conditions). In a circuit theoretic context the points $\xi_\kappa\in\partial D$ correspond to attenuation zeros for the corresponding Schur-bounded real transmittance function $s(z)$. That is, if $s(z)=1/z[f(z)-f(0)]/\ [f(z)+f(0)^*]$, then (5.1c) implies that $|s(\xi_\kappa)|=1$ and hence the attenuation $\log|s(\xi_\kappa)|=0$ for $\kappa=1, 2, \cdots, N$.

Although we have two sets of interpolation conditions it turns out that the solvability depends again on the positive definiteness of the Pick matrix.

THEOREM 5.2. *Problem $I(z, w, \xi)$ is solvable if and only if the Pick matrix associated with (z, w) is positive definite. Moreover, in this case, there always exists a solution of degree less than or equal to N.*

Theorem 5.2 is a direct corollary of the following more general one.

MAIN THEOREM 5.3. *Let (z, w) be a set of $N+1$ interpolating conditions such that the associated Pick matrix is positive definite, and also let $d(z, z^{-1})$ be an arbitrary dissipation polynomial of degree at most N. Then, there exists a pair of polynomials $(\pi(z), \chi(z))$ such that*

(5.3a) $$f(z)=\frac{\pi(z)}{\chi(z)}\in C \textit{ and satisfies } f(z_\kappa)=w_\kappa \textit{ for } \kappa=0, 1, \cdots, N,$$

(5.3b) $$\pi(z)\chi(z)_*+\chi(z)\pi(z)_*=k\,d(z, z^{-1}) \quad \textit{for some } k>0,$$

(5.3c) $$\deg f(z)\leqq N.$$

The proof of the above makes use of Topological Degree Theory (see § 6) and thus provides a novel approach to establish the sufficiency of Pick's criterion for the solvability of the NP problem which follows.

COROLLARY. *If the Pick matrix $P(z, w)$ is positive definite, then the* NP (z, w) *problem is solvable.*

Proof. This is a direct consequence of Theorem 5.3. Q.E.D.

Naturally, one would like to know whether NP (z, w) (or $I(z, w, \xi)$) has a solution of degree strictly less than N and for that matter, to determine the minimal degree (see Youla and Saito [29] and Kalman [13]). Unfortunately, this question seems to be tractable only by methods of decision theory. In fact, the problem of finding the minimal degree of a rational solution $f(z)$ when NP (z, w) is solvable, is a decidable one. The reason for that is that both the set of interpolation conditions and the conditions that guarantee that $f(z)$ belongs to C (see Proposition 4.1 and also Siljak [24]) can be phrased in terms of the solvability of a finite set of equations that depend polynomially on the coefficients of $f(z)$. For the existence of a solution the theory of Tarski [26] and Seidenberg [23] can be used. However, using the tools developed for the proof of Theorem 5.2 we obtain the following.

PROPOSITION 5.4. *The set of $N+1$-pairs (z, w) for which NP (z, w) is solvable but has no solution of degree strictly less than N, is open and nonempty for all N.*

Below we demonstrate the implications of our results to a particular case.

Example 5.5. Consider the problem NP (z, w) where $z=\{0, \frac{1}{2}\}$ and $w=\{1, 2\}$. The associated Pick matrix

$$P=\begin{pmatrix} 2 & 3 \\ 3 & 16/3 \end{pmatrix}$$

is positive definite. Consequently, the NP (z, w) is solvable. The general solution is given by

$$f(z)=\frac{1+zs_1(z)}{1-zs_1(z)}$$

where $s_1(z)$ is an S-function that satisfies

$$s_1\left(\frac{1}{2}\right)=-\frac{2}{3}$$

and a general expression for it is given by (3.6b).

Let us restrict our attention to $f(z)$ of degree 1 or less. A rational function $f(z)$ that meets the interpolation data (z, w) is given by

$$f(z)=\frac{1+\alpha z}{1+\beta z} \quad \text{where } \alpha=2(1+\beta). \tag{5.6}$$

In order for $f(z)$ to belong to C it is necessary and sufficient that

$$|\alpha+\beta|+|\alpha-\beta|\leqq 2. \tag{5.7}$$

This follows easily from Proposition 4.1.

Let us now consider solutions of $I(z, w, \xi)$ for various points $\xi=\exp\{j\theta\}\in\partial D$. It can easily be verified that for all $\xi\neq+1$ there exists a degree 1 function $f(z)\in C$ as above, such that

$$\operatorname{Re} f(\xi)=0. \tag{5.8}$$

For instance, if $\xi=-1$, then the required $f(z)$ is

$$f(z)=\frac{1+z}{1-\frac{1}{2}z}.$$

(For all other choices of $\xi, f(z)$ has complex coefficients.) It is straightforward to verify (5.6)-(5.8). However, for $\xi=+1$, the function $f(z)$ sought in Theorem 5.1 is

$$f(z)=\frac{1}{1-z}.$$

This satisfies (5.6), (5.7) and also (5.1b). But $f(z)$ has a pole at $\xi=+1$ and, in this case,

$$\lim_{z\to\xi}\operatorname{Re} f(z)=\tfrac{1}{2}\neq 0.$$

In the general case, similar situations occur with probability zero. In other words, with generic data (z, w, ξ), the solutions to $I(z, w, \xi)$ have no poles on ∂D and in this case (5.1c) is equivalent to (5.1b).

6. Proof of the main results. First we recall certain tools of the geometric-functional theoretic approach of Sarason [21] to the interpolation problem.

Let $B(z)$ denote the finite Blaschke product (all-pass function) with simple zeros at z_κ, $\kappa=0, 1, \cdots, N$; i.e.,

$$B(z)=\prod_{\kappa=0}^{N}\frac{z-z_\kappa}{1-z_\kappa^* z}\cdot\frac{|z_\kappa|}{z_\kappa}$$

(where $|z_\kappa|/z_\kappa$ is replaced by 1 when $z_\kappa=0$). Let K denote the subspace of H^2

$$K:=H^2\ominus B(z)H^2.$$

The orthogonal projection in L^2 with range K is denoted by $[\ ]_K$, whereas $\langle\,,\rangle$ denotes the inner product in L^2.

K is an $(N+1)$-dimensional vector space and a commonly used basis for K is

$$B=\left\{g_\kappa(z)=\frac{1}{1-z_\kappa^* z},\ \kappa=0, 1, \cdots, N\right\}.$$

Note that for all $q(z)$ in H^2, $\langle q(z), g_\kappa(z)\rangle=q(z_\kappa)$.

Any element $q(z)$ in K can be represented as the ratio

$$q(z)=\frac{\chi(z)}{r(z)},$$

where $\chi(z)$ is a polynomial of degree N and

$$r(z):=\prod_{\kappa=0}^{N}(1-z_\kappa^* z).$$

Let $C(z, w)$ *be the set of solutions of* NP (z, w). The Pick matrix is assumed to be positive definite. Consequently, by Proposition 3.7, there exists a solution $f(z)$ in $C(z, w)$ that also belongs to $H(D^c)$. Define the linear operator

$$T: K\to K: q(z)\to[f(z)q(z)]_K.$$

It turns out that T depends only on the interpolation data (z, w) and not on the particular solution $f(z)$ in $C(z, w)$. Moreover, as it will become clear below, T can be defined directly on the basis of (z, w) (and does not require the solvability of NP (z, w)).

LEMMA 6.1. *Let $p(z)=[f(z)q(z)]_K$, where $q(z)\in K$, and $f(z)\in C(z,w)\cap H(D^c)$ as above. Then $p(z)$ is independent of the particular $f(z)$, it depends only on (z,w) and it satisfies*

$$\frac{p(z_\kappa)}{q(z_\kappa)}=w_\kappa,\qquad \kappa=0,1,\cdots,N.$$

Proof. Let $q(z)=\sum_{\kappa=0}^N b_\kappa g_\kappa(z)$ and $p(z)=\sum_{\kappa=0}^N a_\kappa g_\kappa(z)$. Then

$$\begin{aligned}p(z_\kappa)&=\langle p(z),g_\kappa(z)\rangle=\langle [f(z)q(z)]_K,g_\kappa(z)\rangle\\&=w_\kappa q(z_\kappa).\end{aligned}$$

This is a set of $N+1$ equations in the $N+1$ coefficients of $p(z)$:

$$G\begin{bmatrix}a_0\\a_1\\\vdots\\a_N\end{bmatrix}=\begin{bmatrix}w_0q(z_0)\\w_1q(z_1)\\\vdots\\w_Nq(z_N)\end{bmatrix}=\begin{bmatrix}w_0&&&\\&w_1&&\\&&\ddots&\\&&&w_N\end{bmatrix}G\begin{bmatrix}b_0\\b_1\\\vdots\\b_N\end{bmatrix}$$

where G is the Gram matrix

$$G=\lfloor\langle g_k(z),g_l(z)\rangle\rfloor_{\kappa,l=D}^N=\left[\frac{1}{1-z_\kappa z_l^*}\right]_{\kappa,l=0}^N.$$

Since the $g_\kappa(z)$, $\kappa=0,1,\cdots,N$ are linearly independent, G is nonsingular. (This can also be shown directly by computing the determinant of G. G is related in a simple way to the so-called Hilbert matrix and a formula for the determinant of a Hilbert matrix can be found in Knuth [16, p. 36].) Thus, T is the linear transformation specified by $p(z)=Tq(z)$ where

$$\begin{bmatrix}a_0\\a_1\\\vdots\\a_N\end{bmatrix}=G^{-1}\begin{bmatrix}w_0&&&\\&w_1&&\\&&\ddots&\\&&&w_N\end{bmatrix}G\begin{bmatrix}b_0\\b_1\\\vdots\\b_N\end{bmatrix}.\tag{6.1a}$$

Q.E.D.

PROPOSITION 6.2 (Sarason [21]). *The Pick matrix P is the real part of T.*

Proof. Let $q(z)=\sum_{\kappa=0}^N b_\kappa g_\kappa(z)$. Then,

$$\begin{aligned}2\,\mathrm{Re}\,\langle[f(z)q(z)]_K,q(z)\rangle&=\langle[f(z)q(z)]_K,q(z)\rangle+\langle q(z),[f(z)q(z)]_K\rangle\\&=\sum_{\kappa,l=0}^N b_l\frac{w_\kappa+w_l}{1-z_\kappa z_l^*}b_\kappa.\end{aligned}\tag{6.1b}$$

Q.E.D.

Let $f(z)\in C(z,w)\cap H(D^c)$ as before. Define the following linear map:

$$\Psi:K\to K:q(z)\to u(z)=[(1+f(z))q(z)]_K.$$

Since $f(z)\in C$, then $1+f(z)$ has an inverse in $H(D^c)$ and Ψ is invertible. Define

$$\psi:=\Psi^{-1}:K\to K:u(z)\to q(z)=[(1+f(z))^{-1}q(z)]_K.$$

Note that ψ (and also Ψ) depends only on (z,w) and not on our choice of $f(z)\in C(z,w)$. This can be readily established as in Lemma 6.1 and, in point of fact, if $u(z)=\Sigma u_\kappa g_\kappa$, then $\psi[u(z)]=q(z)=\Sigma b_\kappa q_\kappa$ where

$$\begin{bmatrix}b_0\\b_1\\\vdots\\b_N\end{bmatrix}=G^{-1}\begin{bmatrix}1/(1+w_0)&&&\\&1/(1+w_1)&&\\&&\ddots&\\&&&1/(1+w_N)\end{bmatrix}G\begin{bmatrix}u_0\\u_1\\\vdots\\u_N\end{bmatrix}.\tag{6.2a}$$

We also note that if $p(z)=T[q(z)]$ then $u(z)=p(z)+q(z)$. Using these facts we proceed to the proof of Theorem 5.3.

Proof of Theorem 5.3. Given $u(z)\in K$ we can readily obtain a pair $(p(z), q(z))\in K\times K$, by $q(z)=\psi[u(z)]$ and $p(z)=T[q(z)]$ using (6.1a) and (6.2a), such that

$$\frac{p(z)}{q(z)} \text{ is a rational function of degree at most } n,$$

$$\frac{p(z_i)}{q(z_i)}=w_i \qquad \text{(Lemma 6.1)}, \tag{6.2b}$$

$$p(z)+q(z)=u(z).$$

Let $q(z)=\chi(z)/r(z)$ and $p(z)=\pi(z)/r(z)$ where $\pi(z)$, $\chi(z)$ are polynomials of degree n and $r(z)$ is as earlier. Consider the function

$$\begin{aligned} e(z) &:= p(z)q(z)_* + q(z)p(z)_* \\ &= \frac{\pi(z)\chi(z)_* + \chi(z)\pi(z)_*}{r(z)r(z)_*} \\ &= d(z, z^{-1})\rho(z) \quad \text{with } z\in\partial D \end{aligned}$$

where $\rho(z)=(r(z), r(z)_*)^{-1}$ ($e(z)$ can be considered as an L^1-function).

In order for $p(z)/q(z)=\pi(z)/\chi(z)$ to be a C-function it is sufficient (by Proposition 4.2) that

$$u(z)\neq 0 \quad \text{for all } z\in D^c \tag{6.3a}$$

and

$$d(z, z^{-1})\geqq 0 \quad \text{for all } z\in\partial D. \tag{6.3b}$$

We will establish the theorem by studying the correspondence

$$u(z)\to d(z, z^{-1}),$$

and showing that the image of $\{u(z)\colon u(z)\in K$, such that (6.3a) holds$\}$ contains the set of all polynomials $d(z, z^{-1})$ of degree at most n that satisfy (6.3b) (and are properly normalized). We now proceed to consider a normalization of $u(z)$ and $d(z, z^{-1})$ so that their correspondence becomes a continuous map between smooth manifolds.

Both $e(z)$ and $\rho(z)$ can be easily seen to be in L^2. Let e_k (resp., ρ_k) with $\kappa\in Z$ denote the Fourier coefficients of $e(z)$ (resp., $\rho(z)$). The polynomial $d(z, z^{-1})$ is of degree N (in both z and z^{-1}) and it holds that

$$e_0=\sum_{\kappa=-N}^{N} d_\kappa \rho_{-\kappa}.$$

On the other hand, using Proposition 6.2, we have that if $q(z)=\sum_{\kappa=0}^{N} b_\kappa g_\kappa(z)$ then

$$e_0=(b_0^* \cdots b_N^*)P\begin{bmatrix} b_0 \\ \vdots \\ b_N \end{bmatrix}.$$

Since P is positive definite, $e_0\neq 0$ (unless $q(z)\equiv 0$).

We now define the sets:

$$Y := \left\{ \tilde{d}(z, z^{-1}) = \sum_{\kappa=-N}^{N} \tilde{d}_\kappa z^\kappa \text{ such that } \sum_{k=-N}^{N} \tilde{d}_\kappa \rho_{-\kappa} = 1 \right\},$$

$$Y_+ := \{\tilde{d}(z, z^{-1}) \in Y \text{ such that } \tilde{d}(z, z^{-1}) \geqq 0 \text{ for all } z \in \partial D\},$$

$$X := \{u(z) \in K \text{ such that } u(0) = 1\},$$

$$X_+ := \{u(z) \in X \text{ such that } u(z) \neq 0 \text{ for all } z \in D^c\},$$

$$W := \{\text{rational functions } \pi(z)/\chi(z) \text{ of dimension at most } N \text{ that satisfy } \pi(z_k)/\chi(z_\kappa) = w_\kappa \text{ for } \kappa = 0, 1, \cdots, N\}.$$

Also we consider the following mappings:

$$\theta : K - \{0\} \to Y: q(z) \to \tilde{d}(z, z^{-1}) = \frac{1}{e_0} d(z, z^{-1}),$$

where e_0, $d(z, z^{-1})$ and $p(z)$ are computed from $q(z)$ as before, and

$$\omega := \theta \circ \psi|_X : X \to Y : u(z) \to \tilde{d}(z, z^{-1}).$$

Both mappings are completely specified by the interpolation data, and since $0 \in \chi(X)$, it is easy to see that ω is a continuous map. Now, X and Y are (smooth) linear manifolds of real dimension $2N$, and X_1 and Y_1 are compact subsets of X and Y respectively. On the other hand the mapping

$$X \to W : u(z) \to \frac{p(z)}{q(z)} = \frac{\pi(z)}{\chi(z)}$$

where $q(z) = \psi(u(z))$ and $p(z) = T(q(z))$, is clearly surjective. Hence, in order to establish the theorem we only need to show that

$$\omega(X_+^c) \supseteq Y_+.$$

To show this we will exploit the dependence of ω on the interpolation data w.

Consider z being fixed and define the set of w that render $P(z, w)$ positive definite:

$$B := \{w \in \mathbb{C}^{N+1} \text{ such that } P(z, w) \text{ is positive definite}\}.$$

We want to establish that B is a pathwise connected set. This follows immediately from the continuous dependence of w on the parameter $v_{\kappa\kappa}$, $\kappa = 1, 2, \cdots, N$ and the fact that the positive definiteness of P is equivalent to the conditions

$$\operatorname{Re} w_0 > 0 \quad \text{and} \quad |v_{\kappa\kappa}| < 1 \quad \text{for } \kappa = 1, 2, \cdots, N.$$

Now, provided the Pick matrix is positive definite (nonsingular would suffice), ω is a continuous map. Also, ω depends continuously on the parameters w. We shall indicate this by writing ω_w.

Since B is pathwise connected, we can construct a (continuous) homotopy H from $\omega_{w_{in}}$ to ω_w; by following a continuous path from an initial $w_{in} := \{w_\kappa = 1, \kappa = 0, 1, \cdots, N\}$ to any other point w in B, i.e.,

$$H : X \times [0, 1] \to Y,$$

such that $H(u(z), 0) = \omega_{w_{in}}(u(z))$ and $H(u(z), 1) = \omega_w(u(z))$.

We now proceed as follows: we first show that

$$H(X_+^c, t) \supseteq Y_+,$$

for $t=0$, and then that the same property holds for all $t\in[0,1]$; i.e., it remains invariant under the homotopy.

We first note that $f_0(z)\equiv 1\in C(z, w_{in})$. Then, the map $H(\cdot, 0)=\omega_{W_{in}}(\cdot)$ assumes a simple form where

$$q(z)=\tfrac{1}{2}u(z)=p(z).$$

If $q(z)=\chi(z)/r(z)$ as before,

$$\omega_{w_{in}}: X\to Y: \frac{2\chi(z)}{r(z)}\to k\chi(z)\chi(z)_*,$$

where k is a positive scalar making $k\chi(z)\chi(z)_*$ an element of Y. By the Riesz–Fejer Theorem ([10, p. 21]) any element of Y_+ assumes a unique representation

$$\tilde{d}(z, z^{-1})=k\chi(z)\chi(z)_*,$$

with $\chi(z)$ a polynomial in z, devoid of zeros in D.

From the above it readily follows that

$$\omega_{w_{in}}(X_+^c)=Y_+.$$

Moreover, the correspondence

$$\omega_{w_{in}}|_{X_+^c}: X_+^c\to Y_c \quad \text{is bijective.} \tag{6.4}$$

Now let $d(X_+, \omega, \tilde{d})$ denote the *topological degree of the map ω at $\tilde{d}$ relative to the set X_+*. The topological degree is a "measure" of the number of preimages in X_+ of the point $\tilde{d}$ under the mapping ω. In particular (6.4) implies that

$$d(X_+, H(\cdot, 0), \tilde{d})=1 \quad \text{for all } \tilde{d}\in Y_+^0, \tag{6.5}$$

where Y_+^0 indicates the interior of Y_+. For a comprehensive exposition of various aspects of degree theory see Lloyd [17] and Milnor [18].

We now show that

$$d(X_+, H(\cdot, t), \tilde{d})=1 \quad \text{for all } \tilde{d}\in Y_+^0 \text{ and } t\in[0,1]. \tag{6.6}$$

This follows from a very powerful theorem on the invariance of the degree under homotopy (Lloyd [17, p. 23]) after we prove that the image of the boundary of X_+ never intersects the interior of Y_+:

$$H(\partial X_+, t)\cap Y_+^0=\varnothing \quad \text{for all } t\in[0,1] \tag{6.7}$$

(see also Lloyd [17, p. 32], Milnor [18] and Schwartz [22] for the case of continuous deformations of maps between smooth manifolds).

We now prove (6.7). Assume that the above intersection was not empty and let $\tilde{d}(z, z^{-1})=H(u(z), t)\in Y_+^0$, where $u(z)\in\partial X_+$, and $t\in[0,1]$. Hence, $u(a)=p(a)+q(a)=0$ for some value $z=a\in\partial D$. Also

$$\begin{aligned}\tilde{d}(z, z^{-1}) &= k[p(z)q(z)_* + q(z)p(z)_*]\\ &= \frac{k}{2}[|p(z)+q(z)|^2-|p(z)-q(z)|^2]\geqq 0,\end{aligned}$$

for all $z\in\partial D$, while k is a positive scalar. Hence,

$$d(a, a^{-1})=0,$$

and $\tilde{d}(z, z^{-1})$ is not in the interior of Y_+. This is a contradiction.

Consequently, (6.7) is valid. Then, (6.6) follows from (6.5) and (6.7). Finally, (6.6) implies that

$$Y_+^0 \subseteq H(X_+, 1) = \omega_w(X_+),$$

which in turn, due to the compactness of X_+^c and the continuity of $\omega_w(\cdot)$, implies that

$$Y_+ \subseteq \omega_w(X_+^c).$$

This establishes the theorem. Q.E.D.

Proof of Theorem 5.2. From the Pick criterion it follows that $P(z, w)$ being nonnegative definite is a necessary condition for $I(z, w, \xi)$ to be solvable. To show the sufficiency part, let

$$d(z, z^{-1}) = \prod_{\kappa=1}^{N} (z-\xi_\kappa)(z^{-1}-\xi_\kappa^*)$$

and apply Theorem 5.3. Q.E.D.

Proof of Proposition 5.4. Consider the interpolation data (z, w) where

$$w_0 = 1 + a, \quad a \in \mathbb{C} \quad \text{and} \quad w_\kappa = 1 \quad \text{for } \kappa = 1, 2, \cdots, N.$$

The Pick matrix depends continuously on the parameters w and, consequently, it also depends continuously on the parameter a. For $a = 0$ the Pick matrix is positive definite. Hence, for $a \neq 0$ but is sufficiently small, the Pick matrix is still positive definite and NP (z, w) admits a solution. However, there is no rational function of degree *strictly* less than N that interpolates (z, w) unless $a = 0$. To see this, assume that such a function $f(z)$ exists, and let $f(z) = \pi(z)/\chi(z)$, where $\pi(z)$, $\chi(z)$ are polynomials of degree less than N. Then,

$$f(z) - 1 = \frac{\pi(z) - \chi(z)}{\chi(z)} = 0$$

for N different values of z. Therefore, $\pi(z) - \chi(z)$, being of degree at most $N-1$, is identically zero. Hence, $f(z) \equiv 1$, which is a contradiction. This establishes the proposition. Q.E.D.

7. Concluding remarks. Theorems 5.2 and 5.3 provide existence-type results to an inherently nonlinear problem. However, the homotopy used in the derivation can be used to provide an algorithmic way to find the sought solutions. For a study of homotopy methods as they relate to deriving numerical algorithms see the work of Kellogg, Li and Yorke [14].

In this paper we have presented a description of the set of interpolating functions of degree N to the $(N+1)$-point NP problem. However, it is not known at the moment whether the correspondence in Theorem 5.3 represents in fact a parametrization of this set; i.e., whether the correspondence between interpolating functions of degree N and dissipation polynomials as in Theorem 5.3 is in fact bijective.

Finally, a simple criterion to determine whether there exists an $f(z)$ in $C(z, w)$ of degree strictly less than N is still lacking. Such a criterion seems necessary for a thorough understanding of minimal degree solutions to NP (z, w) as considered in Youla and Saito [29] and Kalman [13].

THE CONSTRUCTION AND SMOOTHNESS OF INVARIANT MANIFOLDS BY THE DEFORMATION METHOD*

JERROLD MARSDEN† AND JÜRGEN SCHEURLE‡

Abstract. This paper proves optimal results for the invariant manifold theorems near a fixed point for a mapping (or a differential equation) by using the deformation, or Lie transform, method from singularity theory. The method was inspired by the difficulties encountered by the implicit function theorem technique in the case of the center manifold. The idea here is simply to deform the given system into its linearization and to track this deformation using the flow of a time-dependent vector field. Corresponding to the difficulties with the center manifold encountered by other techniques, we run into a "derivative loss" in this case as well, which is overcome by utilizing estimates on the differentiated equation. A survey of the other methods used in the literature is also presented.

Key words. invariant manifold, deformation method, center manifold, Lie transform

AMS(MOS) subject classification. 58F

1. Introduction. The theory of invariant manifolds is one of the fundamental ingredients in the study of dynamical systems. In this theory one looks for submanifolds of the phase space which are invariant under the flow, i.e., trajectories which start on such a manifold at some time, stay on it.

This problem is not only of interest from a qualitative point of view, but can lead to quantitative results. In fact, by restriction to an invariant manifold, an original system is reduced to a lower-dimensional one which might be relatively simple. In particular, this is the case when the phase space of the original system is infinite-dimensional and one considers finite-dimensional invariant submanifolds. An important example for applications is the center manifold which contains all bounded solutions near a fixed point [3], [15], [16].

The well-known invariant manifold theorems refer to the flow generated by a nonlinear vector field or diffeomorphism defined in a neighborhood of a fixed point [8], [10], [11], [14]. They give sufficient conditions for the existence of an invariant submanifold which contains this fixed point. For example, each component of the spectral decomposition of the phase space corresponding to a linear operator is an invariant subspace for the flow generated by this linear operator. In the general nonlinear theory one begins with such an invariant subspace of the linearized system and shows its persistence as an invariant submanifold for the full system (at least locally) and then one determines the smoothness of the resulting nonlinear manifold ([6]; cf. also [9]).

To construct such invariant manifolds, two different approaches have been used in the literature so far. First, the invariance property of the manifold has been used to derive an equation for a representing map [10], [11], [14]. The manifold is sought as a graph and an iteration scheme is used on the graphs. For diffeomorphisms, this "graph transform method" developed in [11] yields optimal results and even holds for "Lipeomorphisms" (also [18] and [20]). Second, asymptotic properties of the flow on the manifold have been used to derive an equation for the corresponding trajectories [2], [5], [7], [8], [12]. All these trajectories together span the desired manifold and

‡ Department of Mathematics, Colorado State University, Fort Collins, Colorado 80523, and Mathematisches Institut A der Universität Stuttgart, Pfaffenwaldring 57, D-7000 Stuttgart 80, West Germany.

invariance is a consequence. Alternatively, this second approach may be phrased as a fixed point problem for a map representing the manifold by considering the initial values of the trajectories parameterized over the invariant subspace of the linearized system [4], [19]. In both cases in the second approach, the resulting equation may be solved iteratively. For stable and unstable invariant manifolds the equation for the trajectories also has been solved using the classical implicit function theorem [12]. This yields optimal smoothness for C^k vector fields and diffeomorphisms, and even in the analytic case.

Unfortunately, it is not obvious how to apply the classical implicit function theorem for general invariant manifolds, e.g., for center manifolds. In general, the operator underlying the equation for the trajectories is not continuously differentiable in a space of functions which have the right asymptotic behavior (exponential growth). This difficulty always occurs for the equation of a representing map in a space of maps with a certain smoothness. Sacker [17] uses a smoothing technique to overcome this difficulty, but he still loses one order of smoothness for the solution. For unsuccessful attempts to apply the implicit function theorem in the case of center manifolds, see [4] and [13].

In the present paper we solve the equation for a representing map using a different approach, namely the "Lie transform" method of integrating a differential equation which is based on a deformation principle. This method has been used for the Darboux theorem, the Frobenius theorem and the Poincaré lemma [1] and is a common tool in singularity theory. The idea is to consider a one-parameter family of systems connecting the given system with its linearization. Differentiation with respect to the parameter yields a linear equation for a vector field which eventually has to be integrated in order to get the desired map. An initial condition is known from the invariant manifold of the linearized system.

We consider only diffeomorphisms here, although a similar approach for vector fields is possible. Our approach applies for general invariant manifolds; although we shall concentrate on the harder case of center manifolds, we indicate how results about other invariant manifolds can be obtained. Our smoothness results are optimal. We note at the outset that the diffeomorphisms which we are going to consider have to be of class C^3_{Lip} at least. This is the price we pay for our more sophisticated method.

The plan of the paper is as follows. In § 2 we state our main results. Theorem 2.1 is an existence and uniqueness result for a global center stable or center unstable invariant manifold of a C^3_{Lip} map in a Banach space. Corollary 2.2 contains the corresponding smoothness result for C^k ($k \geqq 4$) and C^k_{Lip} ($k \geqq 3$) maps. In Remark 2.3 we list certain modifications and generalizations of these results. Finally, §§ 3 and 4 contain the proofs of Theorem 2.1 and Corollary 2.2.

2. Formulation of the problem and results.

Let X and Y be Banach spaces. The product space is denoted by $X \times Y$ and equipped with the sup-norm. The Banach space of k-linear continuous maps from X to Y equipped with the usual norm induced by the norms of X and Y is denoted by $\mathcal{L}^k(X, Y)$, and we let $\mathcal{L}^k(X, X) = \mathcal{L}^k(X)$.

Also we introduce the Banach space $C^k(V, Y)$ of k-times continuously differentiable maps f from an open subset $V \subset X$ into Y, equipped with the norm

$$\|f\|_k = \sup_{\substack{x \in V \\ 0 \leqq i \leqq k}} \|D^i f(x)\|$$

where $D^i f$ denotes the ith derivative of f. Similar to the above, we set $C^k(X, X) = C^k(X)$. The linear subspace of those elements of $C^k(V, Y)$ for which the kth derivative is Lipschitz continuous in V is denoted by $C^k_{\mathrm{Lip}}(V, Y)$. Furthermore, we introduce the notation $C^k_L(V, Y)$ for the closed subset of elements of $C^k(V, Y)$ which satisfy a Lipschitz condition in V with a particular Lipschitz constant L.

Open balls in Banach spaces are denoted by $B_r(\cdot)$, where r is the radius and the point stands for the center of the ball. The closure of a set V is written as $\mathrm{cl}\,(V)$.

Let us consider a map

$$T: X\times Y\to X\times Y, \qquad (x,y)\mapsto(\phi_1(x,y), \phi_2(x,y))$$

given by

$$\phi_1(x,y)=Ax+f(x,y), \qquad \phi_2(x,y)=By+g(x,y),$$

where $A\in\mathscr{L}(X)$, $B\in\mathscr{L}(Y)$, and f and g are (nonlinear) perturbations. We consider the following hypotheses, for $\delta\in\mathbb{R}^+$ and k an integer:

$(\mathrm{L}1)_k$ $\|B^{-1}\|\,\|A^j\|<1$ for $0\leqq j\leqq k$.

$(\mathrm{L}2)_k$ $\|B\|\,\|A^{-j}\|<1$ for $0\leqq j\leqq k$.

$(\mathrm{N}1)_\delta$ $f\in C^3_{\mathrm{Lip}}(X\times U, X)$, and $g\in C^3_{\mathrm{Lip}}(X\times U, Y)$ where U is some neighborhood of 0 in Y;
$\|f\|_1<\delta$ and $\|g\|_1<\delta$.

(N2) $f(0,0)=0, \qquad g(0,0)=0.$

(N3) $D_xg(0,0)=0.$

Note that $(0,0)$ is a fixed point of T when (N2) holds.

We shall prove the following theorem about a so-called center stable or center unstable manifold.

THEOREM 2.1. *Let the assumption* $(\mathrm{L}1)_4$ *or* $(\mathrm{L}2)_4$, *and* $(\mathrm{N}1)_\delta$ *hold, where* $\delta>0$ *is sufficiently small. Then there is a map* $h\in C^3_{\mathrm{Lip}}(X, Y)$ *with* $\|h\|_1=O(\delta)$ *as* $\delta\to0$, *such that the manifold*

$$M=\{(x,y)\in X\times Y \mid y=h(x)\}$$

is invariant under the iteration of the map T, *i.e.*, $(x,y)\in M$ *implies* $T(x,y)\in M$; *the map* h *is unique in* $C_L(X, Y)$, *where* $L=O(1/\delta)$ *as* $\delta\to0$.

If in addition (N2) (*resp.* (N2) *and* (N3)) *hold, then* $h(0)=0$ (*resp.* $h(0)=0$ *and* $D_xh(0)=0$).

COROLLARY 2.2. *Assume that f and g are of class* C^{k-1}_{Lip} (*resp.* C^k) *for some* $k\geqq4$. *Furthermore, let* $(\mathrm{L}1)_k$ *or* $(\mathrm{L}2)_k$, *and* $(\mathrm{N}1)_\delta$ *hold. Then h is of class* C^{k-1}_{Lip} (*resp.* C^k) *provided that* δ *is sufficiently small.* (*In general* δ *depends on k for given A and B.*)

In the following remark we state some generalizations and modifications of the above results, which are obvious from the proofs in the next sections.

Remarks 2.3. (i) If B decomposes into two parts B_1 and B_2 such that B_1 satisfies $(\mathrm{L}1)_k$ and B_2 satisfies $(\mathrm{L}2)_k$ for some $k\geqq4$, then the above assertions remain true. In this case M is called a center manifold.

(ii) If $\|B^{-1}\|<1$ and $\|A\|<1$ (resp. $\|B\|<1$ and $\|A^{-1}\|<1$), then M is called the stable (resp. unstable) invariant manifold. In this case M is a C^∞ manifold if f and g are of class C^∞. (Here δ does not depend on k.) Moreover, in this case M is even analytic for analytic maps f and g. For the stable manifold this follows by using spaces of complex analytic functions instead of C^1_{Lip} functions in the existence proof. The unstable manifold case is reduced to the stable one just by considering the map T^{-1} instead of T, provided that it exists.

(iii) If the assumptions are only fulfilled when x is restricted to some neighborhood of 0 in X, then one can use a cut-off function $\chi: X \to \mathbb{R}$ to extend f and g to the domain $X \times U$. This is a C^∞ function with the property $\chi(x) = 1$ for $\|x\| \leqq \frac{1}{2}$ and $\chi(x) = 0$ for $\|x\| \geqq 1$. Such a function always exists if X is finite-dimensional. The extensions are given by $\tilde{f}(x, y) = f(\chi(\mu x)x, y)$ and $\tilde{g}(x, y) = g(\chi(\mu x)x, y)$ with an appropriate constant $\mu > 0$. Applying our results for $\tilde{f}$ and $\tilde{g}$ then yields a local invariant manifold for the original map T by restricting h to the ball $\|x\| < \mu^{-1}/2$.

This cut-off procedure destroys uniqueness and analyticity for the local case. On the other hand, we do not need the cut-off procedure for the local theory when $\|A\| < 1$ (or $\|A^{-1}\| < 1$). In that case we can directly work with spaces of maps which are defined only in some ball around $x = 0$. This yields local results for general spaces X and, in particular, analyticity. Hence, local stable (unstable) invariant manifolds are analytic if f and g are analytic. Furthermore, under the additional hypothesis that f and g together with all partial derivatives of g with respect to x up through order $l-1$ vanish at $(0, 0)$, the local results still hold when $\|A\| < 1$ (or $\|A^{-1}\| < 1$) and the inequalities in $(\mathrm{L1})_k$ ($(\mathrm{L2})_k$) only hold for $l \leqq j \leqq k$ for some $l \geqq 1$. In this case one has to work with functions h and $H = D_x h$ which have the properties $\|h(x)\| \leqq C_1\|x\|^l$, $\|Dh(x)\| \leqq C_2\|x\|^{l-1}$, $\|H(x)\| \leqq C_3\|x\|^{l-1}$ and $\|DH(x)\| \leqq C_4\|x\|^{l-2}$ in some ball around $x = 0$ with certain constants C_j. It finally follows that $\|D^j h(x)\| \leqq C_j\|x\|^{l-j}$ for $0 \leqq j \leqq l-1$. Note that strong, stable (or unstable) invariant manifolds, where $l = 1$, and also certain weak stable (or unstable) invariant manifolds are included in this local theory.

(iv) To obtain a smoothness result for M with respect to a parameter $\lambda \in \Lambda$, where Λ is some Banach space, we can consider λ as a component of x by adding the trivial component $\lambda \mapsto \lambda$ to the original map T (cf., [15]).

(v) Theorem 2.1 and Corollary 2.2 remain true if, in the definition of T, the terms Ax and By are replaced by any maps $A(x): X \to X$ and $B(x)y: X \times Y \to Y$ which are as smooth as f and g and satisfy the following assumptions:

$$(\tilde{\mathrm{L}}1)_k \qquad \|B(x)^{-1}\| \, \|DA(x)^j\| < 1 \quad \text{for } 0 \leqq j \leqq k,$$

$$(\tilde{\mathrm{L}}2)_k \qquad \|B(x)\| \, \|DA^{-1}(x)^j\| < 1 \quad \text{for } 0 \leqq j \leqq k.$$

For example, this generalization is relevant when one deals with a suspension of a nonautonomous system in the extended phase space which is the product of the (discrete) time axis and the original phase space.

(vi) Finally, we remark that it suffices to require $\|D_x f\| < \delta$ instead of $\|Df\| < \delta$ to prove the above results.

3. Proof of Theorem 2.1. We begin with the existence part. First we outline the basic ideas of our proof in a more or less formal way. Afterwards we shall justify each step by means of a series of lemmas.

We consider the following one-parameter family of maps:

$$T_\varepsilon: X \times Y \to X \times Y, \qquad (x, y) \mapsto (\phi_1(\varepsilon, x, y), \phi_2(\varepsilon, x, y))$$

given by

$$(3.1) \qquad \phi_1(\varepsilon, x, y) = Ax + \varepsilon f(x, y), \qquad \phi_2(\varepsilon, x, y) = By + \varepsilon g(x, y),$$

for ε a real number. Obviously T_ε defines a homotopy between the linear map

$$T_0: (x, y) \mapsto (Ax, By) \quad \text{and} \quad T_1 = T.$$

For each T_ε we are looking for an invariant manifold M_ε of the form $y = h_\varepsilon(x)$, where the map $h_\varepsilon: X \to Y$ depends smoothly on ε. The invariance property leads to the equation

$$h_\varepsilon(\phi_1(\varepsilon, x, h_\varepsilon(x))) = \phi_2(\varepsilon, x, h_\varepsilon(x)). \tag{3.2}$$

Moreover, we require

$$h_0(x) = 0 \quad \text{for } x \in X, \tag{3.3}$$

since $y = 0$ is an invariant manifold of T_0. Thus, we aim to solve the system of equations (3.2) and (3.3) for $h_\varepsilon(x)$.

The main idea now is to derive a first order differential equation for the function $\varepsilon \mapsto h_\varepsilon$ and to integrate this in the interval $0 \leqq \varepsilon \leqq 1$ with (3.3) as an initial condition. Actually, we shall consider a differential system for the function $\varepsilon \mapsto (h_\varepsilon, H_\varepsilon)$, where

$$H_\varepsilon(x) = D_x h_\varepsilon(x) \in \mathscr{L}(X, Y). \tag{3.4}$$

Thus we get a linear equation for the corresponding vector field which can be solved explicitly. Subsequently the arguments of ϕ_1, ϕ_2 and all their derivatives are $(\varepsilon, \cdot, h_\varepsilon(\cdot))$, if not indicated otherwise. A dot above a symbol for a map denotes the partial derivative with respect to ε.

First we differentiate equation (3.2) with respect to ε, which yields

$$\dot{h}_\varepsilon(\phi_1) - \mathscr{B}\dot{h}_\varepsilon = \mathscr{F}_1, \tag{3.5}$$

where

$$\mathscr{B} = \mathscr{B}(\varepsilon, h_\varepsilon, H_\varepsilon) = D_y\phi_2 - H_\varepsilon(\phi_1)D_y\phi_1$$

is a map from X to $\mathscr{L}(Y)$ and

$$\mathscr{F}_1 = \mathscr{F}_1(\varepsilon, h_\varepsilon, H_\varepsilon) = \dot{\phi}_2 - H_\varepsilon(\phi_1)\dot{\phi}_1$$

is a map from X to Y. An equation for H_ε is obtained by differentiating (3.2) with respect to x. Thus we obtain

$$H_\varepsilon(\phi_1)\mathscr{A} - D_y\phi_2 H_\varepsilon = D_x\phi_2 \tag{3.6}$$

where

$$\mathscr{A} = \mathscr{A}(\varepsilon, h_\varepsilon, H_\varepsilon) = D_x\phi_1 + D_y\phi_1 H_\varepsilon$$

is a map from X to $\mathscr{L}(X, Y)$. Since this equation is still nonlinear, we again differentiate it with respect to ε. Setting

$$G_\varepsilon(x) = D_x H_\varepsilon(x) \in \mathscr{L}^2(X, Y), \tag{3.7}$$

we thus get

$$\dot{H}_\varepsilon(\phi_1)\mathscr{A} - \mathscr{B}\dot{H}_\varepsilon + \mathscr{C}\dot{h}_\varepsilon = \mathscr{F}_2 \tag{3.8}$$

where

$$\begin{aligned} \mathscr{C}\dot{h}_\varepsilon &= \mathscr{C}(\varepsilon, h_\varepsilon, H_\varepsilon, G_\varepsilon)\dot{h}_\varepsilon \\ &= G_\varepsilon(\phi_1)(\mathscr{A}, D_y\phi_1\dot{h}_\varepsilon) + H_\varepsilon(\phi_1)(D^2_{xy}\phi_1\dot{h}_\varepsilon + D^2_{yy}\phi_1(H_\varepsilon, \dot{h}_\varepsilon)) \\ &\quad - D^2_{xy}\phi_2(\cdot, \dot{h}_\varepsilon) - D^2_{yy}\phi_2(H_\varepsilon, \dot{h}_\varepsilon), \end{aligned}$$

$$\begin{aligned}\mathcal{F}_2 &= \mathcal{F}_2(\varepsilon, h_\varepsilon, H_\varepsilon, G_\varepsilon)\\ &= D_x\dot{\phi}_2 + D_y\dot{\phi}_2 H_\varepsilon - G_\varepsilon(\phi_1)(\mathcal{A}, \dot{\phi}_1) - H_\varepsilon(\phi_1)(D_x\dot{\phi}_1 + D_y\dot{\phi}_1 H_\varepsilon)\end{aligned}$$

are maps from X to $\mathcal{L}(X, Y)$. A linear equation for G_ε is obtained by differentiating (3.6) with respect to x and using (3.4) again

$$(3.9) \qquad G_\varepsilon(\phi_1)(\mathcal{A}, \mathcal{A}) - \mathcal{B}G_\varepsilon = \mathcal{F}_3$$

where

$$\begin{aligned}\mathcal{F}_3 = \mathcal{F}_3(\varepsilon, h_\varepsilon, H_\varepsilon) &= D^2_{xx}\phi_2 + 2D^2_{xy}\phi_2(\cdot, H_\varepsilon) + D^2_{yy}\phi_2(H_\varepsilon, H_\varepsilon)\\ &\quad - H_\varepsilon(\phi_1)(D^2_{xx}\phi_1 + 2D^2_{xy}\phi_1(\cdot, H_\varepsilon) + D^2_{yy}\phi_2(H_\varepsilon, H_\varepsilon))\end{aligned}$$

is a map from X to $\mathcal{L}^2(X, Y)$.

Now we proceed as follows. For each fixed real ε and for each fixed pair of maps $h_\varepsilon : X \to Y$ and $H_\varepsilon : X \to \mathcal{L}(X, Y)$, we solve (3.9) for G_ε. The solution is written in the form

$$(3.10) \qquad G_\varepsilon = \mathcal{G}(\varepsilon, h_\varepsilon, H_\varepsilon)$$

where $\mathcal{G}(\varepsilon, h_\varepsilon, H_\varepsilon)$ is a map from X to $\mathcal{L}^2(X, Y)$. Inserting this expression into (3.8), we obtain

$$(3.11) \quad \dot{H}_\varepsilon(\phi_1)\mathcal{A} - \mathcal{B}\dot{H}_\varepsilon + \mathcal{C}(\varepsilon, h_\varepsilon, H_\varepsilon, \mathcal{G}(\varepsilon, h_\varepsilon, H_\varepsilon))\dot{h}_\varepsilon = \mathcal{F}_2(\varepsilon, h_\varepsilon, H_\varepsilon, \mathcal{G}(\varepsilon, h_\varepsilon, H_\varepsilon)).$$

This relation together with (3.5) is linear equation for $(\dot{h}_\varepsilon, \dot{H}_\varepsilon)$, which we write as

$$(3.12) \qquad \begin{pmatrix}\dot{h}_\varepsilon\\ \dot{H}_\varepsilon\end{pmatrix} = \mathcal{H}(\varepsilon, h_\varepsilon, H_\varepsilon)$$

where the right-hand side is a map from X to $Y \times \mathcal{L}(X, Y)$. This is the desired differential equation.

By the derivation of this equation, every two times continuously differentiable function $h_\varepsilon(x)$ which satisfies (3.2), together with its partial derivative $H_\varepsilon(x) = D_x h_\varepsilon(x)$, is a solution. To show that vice versa a solution $(h_\varepsilon(x), H_\varepsilon(x))$ of (3.12) such that (3.3) and

$$(3.13) \qquad H_0(x) = 0 \quad \text{for } x \in X$$

are satisfied yields a solution of (3.2), we show that H_ε is actually the partial derivative of h_ε with respect to x, i.e., (3.4) is satisfied. Inserting (3.4) into (3.5) and integrating with respect to ε, we then get relation (3.2). Here we use the fact that by (3.3), $h_\varepsilon(x)$ solves (3.2) for $\varepsilon = 0$.

To prove (3.4), we differentiate (3.5) and (3.8) with respect to x, which gives

$$(3.14)_j \qquad \begin{aligned}&\dot{p}_j(\phi_1)\mathcal{A}(\varepsilon, h_\varepsilon, p_j) - \mathcal{B}\dot{p}_j = \mathcal{F}_4(\varepsilon, p_j, q_j),\\ &\dot{q}_j(\phi_1)(\mathcal{A}(\varepsilon, h_\varepsilon, p_j), \mathcal{A}) - \mathcal{B}\dot{q}_j + \mathcal{C}\dot{p}_j = \mathcal{F}_5(\varepsilon, p_j, q_j, q_{l(j)}),\end{aligned}$$

for $j = 1$, where

$$l(1) = 2, \quad p_1 = D_x h_\varepsilon, \quad q_1 = D_x H_\varepsilon, \quad q_2 = G_\varepsilon,$$

$$\begin{aligned}\mathcal{F}_4(\varepsilon, p_j, q_j) = {} & D_x\dot{\phi}_2 + D_y\dot{\phi}_2 p_j + D^2_{yx}\phi_2(\dot{h}_\varepsilon, \cdot) + D^2_{yy}\phi_2(p_j, \dot{h}_\varepsilon) \\ & - q_j(\phi_1)(\mathcal{A}(\varepsilon, h_\varepsilon, p_j), (\dot{\phi}_1 + D_y\phi_1\dot{h}_\varepsilon)) \\ & - H_\varepsilon(\phi_1)(D_x\dot{\phi}_1 + D_y\dot{\phi}_1 p_j + D^2_{yx}\phi_1(\dot{h}_\varepsilon, \cdot) + D^2_{yy}\phi_1(\dot{h}_\varepsilon, p_j))\end{aligned}$$

is a map from X to $\mathcal{L}(X, Y)$ and

$$\begin{aligned}\mathcal{F}_5(\varepsilon, p_j, q_j, q_{l(j)}) = {} & D^2_{xx}\dot{\phi}_2 + D^2_{xy}\dot{\phi}_2(\cdot, p_j + H_\varepsilon) + D^3_{xxy}\phi_2(\cdot, \cdot, \dot{h}_\varepsilon) \\ & + D^3_{xyy}\phi_2(\cdot, \dot{h}_\varepsilon, H_\varepsilon + p_j) + D^2_{yy}\dot{\phi}_2(p_j, H_\varepsilon) + D_y\dot{\phi}_2 q_j \\ & + D^3_{yyy}\phi_2(\dot{h}_\varepsilon, H_\varepsilon, p_j) + D^2_{yy}\phi_2(\dot{h}_\varepsilon, q_j) + D^2_{yx}\phi_2(\dot{H}_\varepsilon, \cdot) \\ & + D^2_{yy}\phi_2(\dot{H}_\varepsilon, p_j) \\ & - H_\varepsilon(\phi_1)(D^2_{xx}\phi_1 + D^2_{xy}\phi_1(\cdot, p_j + H_\varepsilon) \\ & + D^2_{yy}\phi_2(H_\varepsilon, p_j) + D_y\phi_1 q_j - D_x G_\varepsilon(\phi_1)(\mathcal{A}(\varepsilon, h_\varepsilon, p_j), \mathcal{A}, \dot{\phi}_1 \\ & \qquad\qquad + D_y\phi_1\dot{h}_\varepsilon) \\ & - G_\varepsilon(\phi_1)(\mathcal{A}, D_x\dot{\phi}_1 + D_y\dot{\phi}_1 p_j + D^2_{yx}\phi_1\dot{h}_\varepsilon + D^2_{yy}\phi_1(\dot{h}_\varepsilon, p_j)) \\ & - q_{l(j)}(\phi_1)(\dot{\phi}_1 + D_y\phi_1\dot{h}_\varepsilon, D^2_{xx}\phi_1 \\ & \qquad\qquad + D^2_{xy}\phi_1(\cdot, p_j + H_\varepsilon) + D^2_{yy}\phi(p_j, H_\varepsilon) + D_y\phi_1 q_j) \\ & - q_j(\phi_1)(\mathcal{A}(\varepsilon, h_\varepsilon, p_j), D_x\dot{\phi}_1 + D^2_{xy}\phi_1(\cdot, \dot{h}_\varepsilon) + D_y\dot{\phi}_1 H_\varepsilon \\ & \qquad\qquad + D^2_{yy}\phi_1(\dot{h}_\varepsilon, H_\varepsilon) + D_y\phi_1\dot{H}_\varepsilon) \\ & - H_\varepsilon(\phi_1)(D^2_{xx}\dot{\phi}_1 + D^2_{xy}\dot{\phi}_1(\cdot, p_j + H_\varepsilon) + D^3_{xxy}\phi_1(\cdot, \cdot, \dot{h}_\varepsilon) \\ & \quad + D^3_{xyy}\phi_1(\cdot, \dot{h}_\varepsilon, p_j + H_\varepsilon) + D^2_{yy}\dot{\phi}_1(p_j, H_\varepsilon) + D_y\dot{\phi}_1 q_j \\ & \quad + D^3_{yyy}\phi_1(p_j, \dot{h}_\varepsilon, H_\varepsilon) + D^2_{yy}\phi_1(\dot{h}_\varepsilon, q_j) + D^2_{yx}\phi_1(\dot{H}_\varepsilon, \cdot) \\ & \qquad\qquad + D^2_{yy}\phi_1(p_j, \dot{H}_\varepsilon))\end{aligned}$$

is a map from X to $\mathcal{L}^2(X, Y)$. Furthermore, taking relation (3.8) as it stands and differentiating (3.9) with respect to ε, we obtain the relations $(3.14)_2$, where

$$l(2) = 1 \quad \text{and} \quad p_2 = H_\varepsilon.$$

Note, that here we need the assumption that f and g are of class C^3.

We shall show that the subspace given by $p_1 = p_2$ and $q_1 = q_2$ is invariant under the flow defined by the system of equations $(3.14)_1$ and $(3.14)_2$ in (p_1, q_1, p_2, q_2)-space. Thus, the identities (3.4) and (3.7) follow, when they are satisfied for $\varepsilon = 0$. But this will be a consequence of the initial conditions (3.3) and (3.13).

To summarize, so far we have argued that the problem (3.2) is formally equivalent to an initial-value problem for the differential equation (3.12). Now we are going to justify this argument step by step and to solve the initial-value problem.

We introduce the following notation:

$$I = [-\varepsilon_0, \varepsilon_0],$$

$$\mathcal{D}(r, L, M) = \{(h, H) \in C^1_L(X, Y) \times C^1_M(X, \mathcal{L}(X, Y)) \mid \|h\|_1 \leqq r, \|H\|_0 \leqq r, \|H\|_1 \leqq L\}$$

where ε_0 is an arbitrary real number greater than one, and r, L, and M are positive constants which are specified later.

LEMMA 3.1. *Assume that the conditions of Theorem* 2.1 *are satisfied and let* $(h_\varepsilon, H_\varepsilon) = (h, H)$ *be any element of* $\mathcal{D}(r, L, M)$ *where* $\operatorname{cl}(B_r(0)) \subset U$. *Then, for any* ε *in* I, *the equation* (3.5) *has a unique solution* $h_\varepsilon = \mathcal{H}_1 = \mathcal{H}_1(\varepsilon, h, H)$ *with the following properties*:

(i) $\mathcal{H}_1 \in C^1_{K_1}(X, Y)$

where the constant K_1 can be chosen independently of L and M. Furthermore $\|\mathcal{H}_1\|_0 \leqq r_1$ *and* $\|\mathcal{H}_1\|_1 \leqq r_2$, *where*

$$r_1 \leqq K_2(\|g\|_0 + \|f\|_0), \qquad r_2 \leqq K_3(\|f\|_1 + \|g\|_1),$$

with some positive constants K_2 and K_3; K_2 does not depend on L and M. Moreover, $\mathcal{H}_1(0)=0$ ($\mathcal{H}_1(0)=0$ *and* $D_x\mathcal{H}_1(0)=0$), *provided that* (N2) *and* $h(0)=0$ ((N2), (N3), $h(0)=0$, $Dh(0)=0$, *and* $H(0)=0$) *hold.*

(ii) *The map* $(\varepsilon, h, H) \mapsto \mathcal{H}_1(\varepsilon, h, H): I \times \mathcal{D}(r, L, M) \to C^1(X, Y)$ *is continuous and satisfies a Lipschitz condition with respect to* (h, H) *with constant* K_4.

Proof. The unique solution of (3.5) is given by

$$\mathcal{H}_1 = -\sum_{j=0}^{\infty} \left(\prod_{i=0}^{j} \mathcal{B}^{-1}(\phi_1^i) \right) \mathcal{F}_1(\phi_1^j) \tag{3.15}$$

if (L1)$_4$ holds, and by

$$\mathcal{H}_1 = \sum_{j=0}^{\infty} \left(\prod_{i=1}^{j} \mathcal{B}(\phi_1^{-i}) \right) \mathcal{F}_1(\phi_1^{-j-1}) \tag{3.16}$$

if (L2)$_4$ holds. Here we use the estimates $\|\mathcal{A}(\varepsilon, h, Dh) - A\|_0 = O(\delta)$ and $\|\mathcal{B} - B\|_0 = O(\delta)$ as $\delta \to 0$. It follows that for sufficiently small $\delta > 0$ the map

$$\mathcal{B}(x): Y \to Y \quad (\text{where } x \in X) \quad (\phi_1(\varepsilon, \cdot, h(\cdot)): X \to X)$$

can be inverted and the estimate $\|\mathcal{B}^{-1} - B^{-1}\|_0 = O(\delta)$ ($\|D_x\phi_1(\varepsilon, \cdot, h(\cdot))^{-1} - A^{-1}\|_0 = O(\delta)$) holds. Hence,

$$\|\mathcal{B}^{-1}\|_0 \|D_x\phi_1(\varepsilon, \cdot, h(\cdot))\|_0^j < 1 \qquad (\|\mathcal{B}\|_0 \|D_x\phi_1(\varepsilon, \cdot, h(\cdot))^{-1}\|_0^j < 1)$$

for all $0 \leqq j \leqq 4$. A straightforward computation shows that the series in (3.15) ((3.16)) converges in $C^1(X, Y)$ and represents a solution of (3.5) for $\dot{h}_\varepsilon$. Uniqueness is easily seen by an a priori C^0 estimate.

The remaining properties of $\mathcal{H}_1$ which are stated in the lemma, are easily seen by inspection of the formulas in (3.15) and (3.16). We simply note that $\|\mathcal{F}_1\|_0 \leqq \tilde{K}_2(\|g\|_0 + r\|f\|_0)$ and $\|D_x\mathcal{F}_1\|_0 \leqq \tilde{K}_3(\|f\|_1 + \|g\|_1)$ holds with some constants $\tilde{K}_2$ and $\tilde{K}_3$, where $\tilde{K}_2$ does not depend on L and M. Moreover, $\mathcal{F}_1(0)=0$ (resp. $\mathcal{F}_1(0)=0$ and $D_x\mathcal{F}_1(0)=0$) provided that (N2) and $h(0)=0$ (resp. (N2), (N3), $h(0)=0$, $Dh(0)=0$, and $H(0)=0$) holds. We also remark that Lipschitz constants can be estimated by the sup-norm of derivatives. Since the Lipschitz constant of $D_x\mathcal{F}_1$ is close to

$$\|D_{xx}^2 g\|_0 + 2\|D_{xy}^2 g\|_0 r + \|D_{yy}^2 g\|_0 r^2 + \|D_{xx}^2 f\|_0 r^2 + 2\|D_{xy}^2 f\|_0 r^2 + \|D_{yy}^2 f\|_0 r^3$$

where δ is sufficiently small, K_1 can be chosen independently of L and M.

To prove continuity of the map in (ii), one uses the fact that each member of the series in (3.15) (resp. (3.16)) has this property and that the convergence is uniform with respect to $(\varepsilon, h, H) \in I \times \mathcal{D}(r, L, M)$. □

LEMMA 3.2. *Suppose that the assumptions of Lemma* 3.1 *are valid. Then* (3.9) *has a unique solution* $G_\varepsilon = \mathcal{G} = \mathcal{G}(\varepsilon, h, H)$ *with the following properties*:

(i) $\mathcal{G} \in C_{K_5}^1(X, \mathcal{L}^2(X, Y))$,

$\|\mathcal{G}\|_0 \leqq K_6$, *and* $\|\mathcal{G}\|_1 \leqq K_7$, *where* K_5, K_6 *and* K_7 *are certain constants*; K_6 *does not depend on L and M. Furthermore,* $\mathcal{G}(0, 0, 0) = 0$.

(ii) *The map* $(\varepsilon, h, H) \mapsto \mathcal{G}(\varepsilon, h, H): I \times \mathcal{D}(r, L, M) \to C^1(X, \mathcal{L}^2(X, Y))$ *is continuous and satisfies a Lipschitz condition with respect to* (h, H) *with constant* K_8. *Moreover, with* $C^0(X, \mathcal{L}^2(X, Y))$ *as range, it is continuously differentiable.*

Proof. As in the previous proof, the unique solution of (3.9) is given by

$$\mathcal{G} = -\sum_{j=0}^{\infty}\left(\prod_{i=0}^{j}\mathcal{B}^{-1}(\phi_1^i)\right)\mathcal{F}_3(\phi_1^j)\left(\prod_{i=j-1}^{0}\mathcal{A}(\phi_1^i),\ \prod_{i=j-1}^{0}\mathcal{A}(\phi_1^i)\right) \tag{3.17}$$

if (L1)$_4$ holds, and by

$$\mathcal{G} = \sum_{j=0}^{\infty}\left(\prod_{i=1}^{j}\mathcal{B}(\phi_1^{-1})\right)\mathcal{F}_3(\phi_1^{-j-1})\left(\prod_{i=j+1}^{1}\mathcal{A}^{-1}(\phi_1^{-i}),\ \prod_{i=j+1}^{1}\mathcal{A}^{-1}(\phi_1^{-i})\right) \tag{3.18}$$

if (L2)$_4$ holds. Again, all properties of $\mathcal{G}$ which are stated easily follow from these formulae. Note that $\mathcal{F}_3(0,0,0)=0$. To see that K_6 does not depend on L and M we note that

$$\begin{aligned}\|\mathcal{F}_3\|_0 \leqq |\varepsilon|(&\|D_{xx}^2 g\|_0 + 2\|D_{xy}^2 g\|_0 r + \|D_{yy}^2 g\|_0 r^2\\ &+ \|D_{xx}^2 f\|_0 r + 2\|D_{xy}^2 f\|_0 r^2 + \|D_{yy}^2 f\|_0 r^3). \qquad \square\end{aligned}$$

LEMMA 3.3. *Suppose that the assumptions of the above lemmas hold. Then* (3.11), *with* $h_\varepsilon = \mathcal{H}_1$ *from Lemma* 3.1 *and* $\mathcal{G}$ *from Lemma* 3.2, *has a unique solution* $H_\varepsilon = \mathcal{H}_2 = \mathcal{H}_2(\varepsilon, h, H)$ *which has the following properties*:

(i) $\mathcal{H}_2 \in C_{K_9}^1(X, \mathcal{L}(X, Y)), \quad \|\mathcal{H}_2\|_0 \leqq r_3, \quad \|\mathcal{H}_2\|_1 \leqq K_{10}$

where $r_3 \leqq K_{11}(\|f\|_1 + \|g\|_1)$ *and* K_9, K_{10}, K_{11} *are certain positive constants*; K_9 *can be chosen independently of* M *and* K_{10} *independently of* L *and* M. *Moreover,* $\mathcal{H}_2(0)=0$ *provided that* (N2), (N3), $h(0)=0$, *and* $H(0)=0$ *hold.*

(ii) *The map* $(\varepsilon, h, H) \mapsto \mathcal{H}_2(\varepsilon, h, H): I \times \mathcal{D}(r, L, M) \to C^1(X, \mathcal{L}(X, Y))$ *is continuous and satisfies a Lipschitz condition with respect to* (h, H) *with some constant* K_{12}.

Proof. Set

$$\mathcal{F}_6 = \mathcal{F}_6(\varepsilon, h, H) = \mathcal{F}_2(\varepsilon, h, H, \mathcal{G}) - \mathcal{C}(\varepsilon, h, H, \mathcal{G})\mathcal{H}_1.$$

Then the equation which is considered in Lemma 3.3 has a unique solution given by

$$\mathcal{H}_2 = \sum_{j=0}^{\infty}\left(\prod_{i=0}^{j}\mathcal{B}^{-1}(\phi^i)\mathcal{F}_6(\phi_1)\prod_{i=j-1}^{0}\mathcal{A}(\phi_1^i)\right) \tag{3.19}$$

if (L1)$_4$ holds, and by

$$\mathcal{H}_2 = \sum_{j=0}^{\infty}\left(\prod_{i=1}^{j}\mathcal{B}(\phi^{-i})\mathcal{F}_6(\phi^{-j-1})\prod_{i=j+1}^{1}\mathcal{A}^{-1}(\phi_1^{-i})\right) \tag{3.20}$$

if (L2)$_4$ holds. To prove its stated properties, we note that

$$\|\mathcal{F}_6\|_0 \leqq \tilde{K}_{11}(\|f\|_1 + \|g\|_1)$$

holds with some constant $\tilde{K}_{11}$. Furthermore,

$$\begin{aligned}\|D_x\mathcal{F}_6\|_0 \leqq &\|D_{xx}^2 g\|_0 + 2\|D_{xy}^2 g\|_0 r + \|D_{yy}^2 g\|_0 r\\ &+ \|D_{xx}^2 f\|_0 r + \|D_{xy}^2 f\|_0 r^2 + \|D_{yy}^2 f\|_0 + O(\delta),\end{aligned}$$

the Lipschitz constant of $D_x\mathcal{F}_6$ with respect to x is smaller than

$$\begin{aligned}&\|D_{xxx}^3 g\|_0 + 3r\|D_{xxy}^3 g\|_0 + 3r^2\|D_{xyy}^3 g\|_0 + r^3\|D_{yyy}^3 g\|_0\\ &+ r(3L + |\varepsilon|K_1)\|D_{yy}^2 g\|_0 + (3L + |\varepsilon|K_1)\|D_{xy}^2 g\|_0 + r\|D_{xxx}^3 f\|_0\\ &+ 3r^2\|D_{xxy}^3 f\|_0 + 3r^3\|D_{xyy}^3 f\|_0 + r^4\|D_{yyy}^3 f\|\end{aligned}$$

$$+r^2(4L+(L+K_6)\|\mathcal{A}(\varepsilon, h, H)\|_0+|\varepsilon|K_1)\|D^2_{yy}f\|_0$$
$$+r(5L+2(L+K_6)\|\mathcal{A}(\varepsilon, h, H)\|_0+|\varepsilon|K_1)\|D^2_{yx}f\|_0$$
$$+(L+(L+K_6)\|\mathcal{A}(\varepsilon, h, H)\|_0)\|D^2_{xx}f\|_0+O(\delta),$$
$$\|D_x\mathcal{A}\|_0\leqq|\varepsilon|(\|D^2_{xx}f\|_0+2\|D^2_{xy}f\|_0r+\|D^2_{yy}f\|_0r^2)+O(\delta)$$

and

$$\|D_x\mathcal{B}\|_0\leqq|\varepsilon|(\|D^2_{xy}g\|_0+\|D^2_{yy}g\|_0r+\|D^2_{xy}f\|_0r+\|D^2_{yy}f\|_0r^2)+O(\delta)\quad \text{as } \delta\to 0.$$

Therefore, K_{10} can be chosen independently of L and M, and K_9 independently of M. Moreover, $\mathcal{F}_6(0)=0$, provided that (N2), (N3), $h(0)=0$ and $H(0)=0$ holds. But this implies $\mathcal{H}_2(0)=0$. The rest of the proof is similar to the previous proofs. □

By Lemma 3.1 and Lemma 3.3, the right-hand side of the differential equation (3.12) is given by

$$\mathcal{H}(\varepsilon, h, H)=\begin{pmatrix}\mathcal{H}_1(\varepsilon, h, H)\\ \mathcal{H}_2(\varepsilon, h, H)\end{pmatrix}.$$

It is uniquely determined by the stated properties. Next we are going to solve this equation with initial values $h=0$ and $H=0$ at $\varepsilon=0$. To this end we select r, L and M such that

(I1) $$\operatorname{cl}(B_r(0))\subset U,\ L\geqq\varepsilon_0\max(K_1, K_{10})\quad\text{and}\quad M\geqq\varepsilon_0K_9(L).$$

We also assume that the conditions

(I2) $$r_i\leqq\frac{r}{\varepsilon_0}\qquad(i=1,2,3)$$

are valid. This is achieved by requiring δ to be sufficiently small since $r_i=O(\delta)$ as $\delta\to 0$. Note that r has been chosen independently of δ. On the other hand we point out that $\operatorname{cl}(B_{\varepsilon_0r_1}(0))\subset U$ has to be true, but not necessarily $\operatorname{cl}(B_r(0))\subset U$. Hence, under certain circumstances one can shrink U to make δ sufficiently small and work with functions h such that $h(x)\in U$ for all $x\in X$.

LEMMA 3.4. *Let the assumptions of Theorem* 2.1 *be true. Furthermore, suppose that the constants r, L, M and δ are chosen such that the conditions* (I1) *and* (I2) *are fulfilled. Then the differential equation* (3.12) *has a unique solution* $\varepsilon\mapsto(h_\varepsilon(x), H_\varepsilon(x))$ *in the interval I, which has the following properties*:

(i) $\varepsilon\mapsto h_\varepsilon\in C^1(I, C^1_L(X, Y))$, $\varepsilon\mapsto H_\varepsilon\in C^1(I, C^1(X, \mathcal{L}(X, Y)))$, *where* $(h_\varepsilon, H_\varepsilon)\in\mathcal{D}(r, L, M)$ *holds for all* ε *in I, and* $h_0(x)=0$, $H_0(x)=0$ *for all* $x\in X$. *Moreover,* $h_\varepsilon(0)=0$ $(h_\varepsilon(0)=0, D_xh_\varepsilon(0)=0$ *and* $H_\varepsilon(0)=0)$ *for all* ε *in I, provided that* (N2) ((N2) *and* (N3)) *holds.*

(ii) $D_xh_\varepsilon=H_\varepsilon$, $D_xH_\varepsilon=G_\varepsilon=\mathcal{G}(\varepsilon, h_\varepsilon, H_\varepsilon)$.

Proof. The proof of part (i) follows the lines of the proof of the usual Picard-Lindelöf theorem for ordinary differential equations. We look for a continuous solution $\varepsilon\mapsto(h_\varepsilon, H_\varepsilon)$ of the integral equation

(3.21) $$\begin{pmatrix}h_\varepsilon\\ H_\varepsilon\end{pmatrix}=\int_0^\varepsilon\mathcal{H}(\sigma, h_\sigma, H_\sigma)\,d\sigma\qquad(\varepsilon\in I).$$

This problem is equivalent to solving the initial-value problem (3.12), (3.3), and (3.13). In particular, a continuous solution of (3.21) is continuously differentiable. According to the previous lemmas, the right-hand side of (3.21) defines a contraction map $\mathscr{T}$ of the metric space

$$S=\{\varepsilon\mapsto(h_\varepsilon, H_\varepsilon)\in C^0(I, C^1_L(X, Y))$$
$$\times C^0(I, C^1_M(X, \mathscr{L}(X, Y)))|(h_\varepsilon, H_\varepsilon)\in\mathscr{D}(r, L, M)\text{ for all }\varepsilon\in I\}$$

into itself, where the metric is given by the norm defined by

$$\sup_{\varepsilon\in I}(e^{\gamma|\varepsilon|}\|h_\varepsilon\|_1, e^{\gamma|\varepsilon|}\|H_\varepsilon\|_1)$$

with

$$\gamma>\max(K_2, K_{12}).$$

Obviously, with this metric S is complete. Therefore $\mathscr{T}$ has a unique fixed point in S, which is the desired solution. Moreover, the set

$$S_0=\{\varepsilon\mapsto(h_\varepsilon, H_\varepsilon)\in S|h_\varepsilon(0)=0\text{ for all }\varepsilon\in I\}$$

or $S_1=\{\varepsilon\mapsto(h_\varepsilon, H_\varepsilon)\in S|h_\varepsilon(0)=0,\ D_xh_\varepsilon(0)=0$ and $H_\varepsilon(0)=0\}$ for all $\varepsilon\in I$ is closed and invariant under the map $\mathscr{T}$, provided that (N2) (resp. (N2) and (N3)) holds. Hence, the unique fixed point of $\mathscr{T}$ in S lies in $S_0(S_1)$. Thus, part (i) is proved.

To prove (ii), let $(h_\varepsilon, H_\varepsilon)$ be given by the solution of (3.21) constructed above and define G_ε to be $\mathscr{G}(\varepsilon, h_\varepsilon, H_\varepsilon)$ for ε in I. Note that $p_1(\varepsilon)=D_xh_\varepsilon$, $q_1(\varepsilon)=D_xH_\varepsilon$, $p_2(\varepsilon)=H_\varepsilon$ and $q_2(\varepsilon)=G_\varepsilon$ defines a solution of the system of equations in $(3.14)_1$ and $(3.14)_2$. These relations are fulfilled in the space $(C^0(I, C^0(X, \mathscr{L}(X, Y)))\times C^0(I, C^0(X, \mathscr{L}^2(X, Y))))^2$. Furthermore, by (3.3), (3.13) and $\mathscr{G}(0,0,0)=0$,

$$p_1(0)=p_2(0)=0,\qquad q_1(0)=q_2(0)=0 \tag{3.22}$$

holds for this solution. Therefore it remains to show that this implies $p_1(\varepsilon)=p_2(\varepsilon)$ and $q_1(\varepsilon)=q_2(\varepsilon)$ for all $\varepsilon\in I$.

Using the formulas (3.19) (resp. (3.20)) and (3.17) (resp. (3.18)), we can rewrite the relations in $(3.14)_j$ $(j=1,2)$ in the form

$$(3.23)_j\qquad \dot p_j(\varepsilon)=\mathscr{H}_3(\varepsilon, p_j(\varepsilon), q_j(\varepsilon)),\qquad q_j(\varepsilon)=\mathscr{H}_4(\varepsilon, p_j(\varepsilon), q_j(\varepsilon), q_{l(j)}(\varepsilon))$$

where the maps $\varepsilon\mapsto\mathscr{H}_3(\varepsilon, p_j(\varepsilon), q_j(\varepsilon)): I\to C^0(X, \mathscr{L}(X, Y))$ and $\varepsilon\to\mathscr{H}_4(\varepsilon, p_j(\varepsilon), q_j(\varepsilon), q_{l(j)}(\varepsilon))$ are continuous, and

$$\|\mathscr{H}_3(\varepsilon, p_1(\varepsilon), q_1(\varepsilon))-\mathscr{H}_3(\varepsilon, p_2(\varepsilon), q_2(\varepsilon))\|_0\leqq K_{13}\alpha(\varepsilon),$$
$$\|\mathscr{H}_4(\varepsilon, p_1(\varepsilon), q_1(\varepsilon), q_2(\varepsilon))-\mathscr{H}_4(\varepsilon, p_2(\varepsilon), q_2(\varepsilon), q_1(\varepsilon))\|_0\leqq K_{13}\alpha(\varepsilon),$$

holds for all ε in I with some positive constant K_{13} and

$$\alpha(\varepsilon)=\sup(\|p_1(\varepsilon)-p_2(\varepsilon)\|_0, \|q_1(\varepsilon)-q_2(\varepsilon)\|_0).$$

Integrating the equations in $(3.23)_j$ from 0 to ε, subtracting the integral relations which are obtained for $j=1$ and $j=2$ and using (3.22), we get the following estimate

$$\alpha(\varepsilon)\leqq\left|\int_0^\varepsilon K_{13}\alpha(\sigma)\,d\sigma\right|\qquad(\varepsilon\in I).$$

Gronwall's lemma yields $\alpha(\varepsilon)=0$ for all ε in I, i.e., $p_1(\varepsilon)=p_2(\varepsilon)$ and $q_1(\varepsilon)=q_2(\varepsilon)$.

Taking the map h_ε which has been constructed in Lemma 3.4 and setting $\varepsilon=1$, the existence part of Theorem 2.1 follows according to the discussion previous to the above lemmas.

The proof also yields uniqueness, but only within the class of families of maps h_ε (where $\varepsilon \in I$) which have the properties stated in Lemma 3.4. To prove the uniqueness assertion of Theorem 2.1 we therefore have to give a different argument. Here we can even weaken our assumptions considerably.

LEMMA 3.5. *Suppose the maps $f \in C^0(X \times U, X)$ and $g \in C^0(X \times U, Y)$ satisfy a Lipschitz condition with respect to y with constant $\delta > 0$. Furthermore, assume that $\|B^{-1}\| < 1$ (resp. $\|B\| < 1$)) holds. Then for each ε in I, (3.2) has at most one solution $h_\varepsilon = h \in C^0_L(X, Y)$ (resp. such that the map $x \mapsto \phi_1(\varepsilon, x, h(x)) : X \to X$ is surjective), where*

$$L < (\|B^{-1}\|^{-1} - 1 - \delta\varepsilon)/(\delta\varepsilon) \qquad (\textit{resp. } L < (1 - \|B\| - \delta\varepsilon)/(\delta\varepsilon)).$$

Proof. Assume that h and $\tilde{h}$ are two such solutions of equation (3.2). Then,

$$h - \tilde{h} = B^{-1}(h(\phi_1) - \tilde{h}(\phi_1) + \tilde{h}(\phi_1) - \tilde{h}(\phi_1(\varepsilon, \cdot, \tilde{h}(\cdot))) + \varepsilon g(\cdot, \tilde{h}(\cdot)) - \varepsilon g(\cdot, h(\cdot)))$$

$$(\text{resp. } h(\phi_1) - \tilde{h}(\phi_1) = B(h - \tilde{h}) + \tilde{h}(\phi_1(\varepsilon, \cdot, \tilde{h}(\cdot))) - \tilde{h}(\phi_1) + \varepsilon g(\cdot, h(\cdot)) - \varepsilon g(\cdot, \tilde{h}(\cdot))),$$

in which we use our standing convention that $\phi_1 = \phi_1(\varepsilon, \cdot, h(\cdot))$. Thus by the assumptions

$$\|h - \tilde{h}\|_0 \leqq \|B^{-1}\|(1 + \delta\varepsilon L + \delta\varepsilon)\|h - \tilde{h}\|_0 < \|h - \tilde{h}\|_0$$

$$(\text{resp. } \|h - \tilde{h}\|_0 \leqq (\|B\| + \delta\varepsilon L + \delta\varepsilon)\|h - \tilde{h}\|_0 < \|h - \tilde{h}\|_0)$$

follows, which implies $h = \tilde{h}$.

Remark 3.6. The initial-value problem (3.12), (3.3) and (3.13) also has a unique solution in a ball around the origin in the space $C^0_L(X, Y) \times C^0_M(X, \mathscr{L}(X, Y))$ with appropriate constants L and M, even under the weaker assumptions that f and g are of class C^2_{Lip} and that $(\text{L}1)_3$ or $(\text{L}2)_3$ holds. However, it is not obvious how to show $D_x h_\varepsilon = H_\varepsilon$, to make sure that the solution actually yields a solution of (3.2).

On the other hand, one can still use the deformation principle to prove existence of a C^2_{Lip} invariant manifold under the weaker assumptions mentioned above. This requires the solution of the nonlinear equation (3.6) for H_ε in some space $C^1_M(X, \mathscr{L}(X, Y))$ as a Lipschitz continuous function of ε in I and $h_\varepsilon \in C^1_L(X, Y)$. Here the identity $D_x h_\varepsilon = H_\varepsilon$ follows from the fact that $D_x h_\varepsilon$ as well as H_ε are solutions of the first equation in $(3.14)_j$ for p_j, if we set $q_j = D_x H_\varepsilon$. In general, one does not have an explicit representation for the solution of (3.6); one can, however, use the contraction mapping principle to solve it. Thus, this method is a combination of the usual fixed point method to construct invariant manifolds [15] and the pure deformation method which we have proposed in the present paper.

4. Proof of Corollary 2.2. Corollary 2.2 is a consequence of Theorem 2.1 together with the following lemma; a bootstrapping argument accomplishes our purpose.

LEMMA 4.1. (a) *Assume that $f \in C^k(X \times U, X)$ and $g \in C^k(X \times U, Y)$ holds for some $k \geqq 3$. Furthermore, let $(\text{L}1)_k$ or $(\text{L}2)_k$, $\|f\|_1 < \delta$, and $\|g\|_1 < \delta$ hold. Suppose that for fixed ε, $h_\varepsilon = h \in C^{k-1}(X, Y)$ is a solution of (3.2). Then $h \in C^k(X, Y)$ if δ is sufficiently small, generally depending on k and $\|h\|_1$ for fixed A and B.*

(b) *If f and g are of class C^k_{Lip} for some $k \geqq 2$ and $(\text{L}1)_{k+1}$ or $(\text{L}2)_{k+1}$, $\|f\|_1 < \delta$, and $\|g\|_1 < \delta$ holds, then any C^k solution of (3.2) is contained in $C^k_{\text{Lip}}(X, Y)$ for sufficiently small $\delta > 0$.*

Proof. Since h is at least of class C^2 and a solution of (3.3), by uniqueness of the solution of (3.9) we have $D^2_{xx}h = \mathscr{G}(\varepsilon, h, D_x h)$ with $\mathscr{G}$ given either by (3.17) or by (3.18). Hence, it remains to show that $h \in C^{k-1}(X, Y)$ implies $\mathscr{G}(\varepsilon, h, D_x h) \in C^{k-2}(X, \mathscr{L}^2(X, Y))$ in case (a), and $h \in C^k(X, Y)$ implies $\mathscr{G}(\varepsilon, h, D_x h) \in C^{k-2}_{\text{Lip}}(X, \mathscr{L}^2(X, Y))$ in case (b).

If f and g are of class C^k and $h \in C^{k-1}(X, Y)$ for some $k \geqq 2$, then the $(k-2)$nd derivative of each term in the series (3.17) (resp. (3.18)) exists and is continuous. It is easily proved by induction with respect to k that these derivatives are of the form $(j = 0, 1, 2, \cdots)$

$$(4.1)\qquad \begin{aligned} &\sum_{\Sigma\alpha = k-2} \left(\prod_{i=0}^{j} D^\alpha_x \mathscr{B}^{-1}(\phi^i_1)\mathscr{P}_{\alpha i} \right) D^\alpha_x \mathscr{F}_3(\phi^j_1)\mathscr{P}_{\alpha j} \\ &\qquad \cdot \left(\prod_{i=j-1}^{0} D^\alpha_x \mathscr{A}(\phi^i_1)\mathscr{P}_{\alpha i}, \prod_{i=j-1}^{0} D^\alpha_x \mathscr{A}(\phi^{-i}_1)\mathscr{P}_{\alpha i} \right) \end{aligned}$$

or

$$(4.2)\qquad \begin{aligned} &\sum_{\Sigma\alpha = k-2} \left(\prod_{i=1}^{j} D^\alpha_x \mathscr{B}(\phi^{-i}_1)\mathscr{P}_{\alpha i} \right) D^\alpha_x \mathscr{F}_3(\phi^{-j-1})\mathscr{P}_{\alpha(j+1)} \\ &\qquad \cdot \left(\prod_{i=j+1}^{1} D^\alpha_x \mathscr{A}^{-1}(\phi^{-i}_1)\mathscr{P}_{\alpha i}, \prod_{i=j+1}^{1} D^\alpha_x \mathscr{A}^{-1}(\phi^{-i}_1)\mathscr{P}_{\alpha i} \right) \end{aligned}$$

where

$$\mathscr{B} = \mathscr{B}(\varepsilon, h, D_x h), \quad \mathscr{F}_3 = \mathscr{F}_3(\varepsilon, h, D_x h), \quad \mathscr{A} = \mathscr{A}(\varepsilon, h, D_x h),$$

and $\mathscr{P}_{\alpha i}$ is an α-tuple of products with i factors of the form

$$D^\alpha_x \mathscr{A}(\phi^n_1)\mathscr{P}_{\alpha n} \quad (0 \leqq n \leqq i-1)$$

$$(\text{resp. } D^\alpha_x \mathscr{A}^{-1}(\phi^{-n}_1)\mathscr{P}_{\alpha n} \quad (1 \leqq n \leqq i)).$$

These sums have less than $\frac{1}{2}k!(j+1)^{k-2}$ terms, each of which is a "product" of less than $(k+1)j+2$ (resp. $(k+1)(j+1)$) factors, with at least $j-k+3$ (resp. $j-k+2$) factors $\mathscr{B}^{-1}$ (resp. $\mathscr{B}$), at most kj(resp. $k(j+1)$) factors $\mathscr{A}$(resp. $\mathscr{A}^{-1}$). Besides these factors there are at most $k-2$ factors which are derivatives of such factors, or of $\mathscr{F}_3$ of order less than or equal to $k-2$. Of course, $\mathscr{F}_3$ is itself a factor if no derivative of it is contained in the product.

Now assume that

$$(4.3)_k \qquad \|\mathscr{B}^{-1}\|_0 \|\mathscr{A}\|^i_0 < q < 1 \quad (\text{resp. } \|\mathscr{B}\|_0 \|\mathscr{A}^{-1}\|^i_0 < q < 1) \quad (0 \leqq i \leqq k)$$

holds, where q is some real number which does not depend on i. Then

$$K_{14}(j+1)^{k-2}q^{j-k+3} \quad (j > k-3) \quad (\text{resp. } K_{14}(j+1)^{k-2}q^{j-k+2}(j > k-2))$$

is an upper bound for the C^0 norm of the sum in (4.1) (resp. (4.2)), where the constant K_{14} depends on k. Consequently, the series of these sums over j converges uniformly with respect to x and represents the $(k-2)$nd derivative of $\mathscr{G}(\varepsilon, h, D_x h)$. But, by $(\text{L}1)_k$ (resp. $(\text{L}2)_k$), $(4.3)_k$ is satisfied for some number q, provided that δ is sufficiently small. Thus, part (a) of Lemma 4.1 follows.

Under the assumptions of part (b) the sum in (4.1) (resp. (4.2)) is contained in $C^0_{\text{Lip}}(X, \mathscr{L}^k(X, Y))$ for each j. Furthermore, if $(4.3)_{k+1}$ holds, by the above information about this sum, its Lipschitz constant L_j can be estimated from above by

$$K_{15}(j+1)^{k-1}q^{j-k+2} \quad (j > k-2) \quad (\text{resp. } K_{15}(j+1)^{k-1}q^{j-k+1}(j > k-1))$$

with some constant K_{15} that depends on k. But by $(\mathrm{L1})_{k+1}$ (resp. $(\mathrm{L2})_{k+1}$), the condition $(4.3)_{k+1}$ is satisfied for sufficiently small $\delta > 0$. It follows that $D_x^{k-2}\mathscr{G}(\varepsilon, h, D_x h) \in C^0_{\mathrm{Lip}}(X, \mathscr{L}^k(X, Y))$, since $\sum_{j=0}^{\infty} L_j < \infty$. Thus, part (b) of Lemma 4.1 holds. □

Remark 4.2. In case of center manifolds, the C^k_{Lip} result, even for $k=0$ and $k=1$, is the usual result which is obtained by a fixed point argument ([15], [18]). For $k=0$ one assumes that $(\mathrm{L1})_1$ or $(\mathrm{L2})_1$ holds and that $\|f\|_0$, $\|g\|_0$, and the Lipschitz constants for f and g are sufficiently small. For $k \geqq 1$ the assumptions are analogous to those of Theorem 2.1. For $k=2$, see also Remark 3.6.

The C^2_{Lip} center-manifold theorem together with Lemma 4.1(a) now yields the center manifold theorem in C^k spaces for any $k \geqq 3$.

Moreover, observe that for fixed h_ε in $C^1(X, Y)$, (3.6) can be solved for H_ε in the space $C^1(X, \mathscr{L}(X, Y))$, provided that f and g are of class C^2, $\|f\|_1$ and $\|g\|_1$ are sufficiently small, and $(\mathrm{L1})_2$ or $(\mathrm{L2})_2$ holds (cf., Remark 3.6). Thus it follows that the C^1_{Lip} center manifold is actually contained in the class C^2 in this case; but this is the C^2 center manifold theorem.

Acknowledgments. We thank Ethan Akin, Marty Golubitsky, Jack Hale, Morris Hirsch, Pat McSwiggen and Charles Pugh for their comments.

GLOBAL APPROXIMATION OF PERTURBED HAMILTONIAN DIFFERENTIAL EQUATIONS WITH SEVERAL TURNING POINTS*

HARRY GINGOLD† AND PO-FANG HSIEH‡

Abstract. Given a perturbed Hamiltonian system (E) $i\varepsilon V' = [H_0(x) + \varepsilon H_1(x, \varepsilon)]V$, where $H_0(x)$ is a Hermitian matrix analytic on an interval I. Any two eigenvalues of $H_0(x)$ are allowed to coalesce finitely many times in the interval I (however, no two of them are identical on I). Assume that $H_1(x, \varepsilon) \in C^1(I \times \bar{S}_c)$ with $S_c = (0, c]$. Let $U(x)$ be the unitary matrix such that $D(x) = U^{-1}(x)H_0(x)U(x)$ is diagonal. Assume that the entries of $U^{-1}H_1U - iU^{-1}U'$ are bounded on $I \times S_c$, absolutely integrable over I. Then, (E) is shown to have a fundamental matrix of the form $V = U(x)Y(I_n + P(x, \varepsilon))$ where Y is the exponential of a diagonal matrix, I_n is the n-dimensional unit matrix and $P(x, \varepsilon) \to 0$ as $\varepsilon \to 0^+$. This result is applied to prove an adiabatic approximation theorem in quantum mechanics and provide a criterion measuring the phenomenon of degeneracy by the orders of coalescing of eigenvalues. Two examples are given.

Key words. global approximation, singularly perturbed Hamiltonian system, several turning points, adiabatic approximation theorem

AMS(MOS) subject classifications. Primary 34E20; secondary 34E15, 81C12

1. Introduction. When dealing with a system of differential equations depending in a singular way on a parameter, it is not usually possible to obtain *one* global asymptotic expression to approximate the solution. This is so for a linear system even though the global existence of its solution is theoretically guaranteed. For example, if we are dealing with a singularly perturbed system $\varepsilon y' = A(x)y$ on an interval $[a, b]$ where all eigenvalues of $A(x)$ are distinct, but for some eigenvalues of $A(x)$, the real part of some of their differences change sign on $[a, b]$, the asymptotic solutions are obtained only for subintervals. In order to investigate the solution on an entire interval $[a, b]$, one needs so-called connection formulas (e.g. see W. Wasow [22], [26]).

However, there are certain singular differential systems for which it is possible to obtain global asymptotic formulas on an entire interval. This is so even if the coefficient matrix possesses eigenvalues which coalesce finitely many times on that interval. Such points are commonly called turning points of the differential equations.

The presence of symmetry properties in a physical system is of interest to a physicist. Given a Hamiltonian system in quantum mechanics, some of its symmetry properties are manifested in certain degeneracies of its energy levels. When the Hamiltonian is time-dependent, the appearance of symmetries can show up as coalescence of certain energy eigenvalues. In other words, this is equivalent to the presence of turning, or transition, points of the system. This is our motivation to study a Hamiltonian system with one or several turning points of any (finite) order. As a matter of fact, we will study systems which are slightly more general than a Hamiltonian system.

Consider the following n-dimensional matrix differential system:

$$i\varepsilon V' = [H_0(x) + \varepsilon H_1(x, \varepsilon)]V, \qquad ' = \frac{d}{dx} \tag{1.1}$$

where $H_0(x)$ is a Hermitian matrix, analytic and no two eigenvalues are identical on $I = [a, b]$, and $H_1(x, \varepsilon)$ is in the class of $C^1(I \times \bar{S}_c)$ with $S_c = (0, c]$. Here a may be

$-\infty$ and b may be $+\infty$. By a theorem of linear algebra due to F. Rellich [17] there exists a unitary matrix $U(x)$, analytic on I such that

$$\begin{aligned} D_1(x) &= U^{-1}(x)H_0(x)U(x) \\ &= \operatorname{diag}\{\lambda_1(x), \lambda_2(x), \cdots, \lambda_n(x)\} \end{aligned} \tag{1.2}$$

where $\{\lambda_j(x) \mid j=1,2,\cdots,n\}$ are the eigenvalues of $H_0(x)$, which are known to be real and analytic on I. Let

$$Y = U^{-1}(x)V. \tag{1.3}$$

Then, the n by n matrix Y satisfies a differential equation

$$i\varepsilon Y' = [D_1(x) + \varepsilon R_1(x, \varepsilon)]Y \tag{1.4}$$

with

$$R_1(x, \varepsilon) = U^{-1}(x)H_1(x, \varepsilon)U(x) - iU^{-1}(x)U'(x). \tag{1.5}$$

Let

$$D(x, \varepsilon) = D_1(x) + \varepsilon \operatorname{diag} R_1(x, \varepsilon), \qquad R(x, \varepsilon) = R_1(x, \varepsilon) - \operatorname{diag} R_1(x, \varepsilon). \tag{1.6}$$

Also, let

$$\begin{aligned} &R_0(x, \varepsilon) = \operatorname{diag} R_1 = \operatorname{diag}\{r_1^0, r_2^0, \cdots, r_n^0\}, \\ &R(x, \varepsilon) = (r_{jk}), \qquad j, k = 1, 2, \cdots, n. \end{aligned} \tag{1.7}$$

Then $r_{jj} \equiv 0$ and (1.4) becomes

$$i\varepsilon Y' = [D(x, \varepsilon) + \varepsilon R(x, \varepsilon)]Y. \tag{1.8}$$

Assume that

$$\lambda_j(x) - \lambda_k(x) \neq 0 \quad \text{for } x \in I \quad (j \neq k; j, k = 1, 2, \cdots, n), \tag{1.9}$$

$$\|H_1(x, \varepsilon)\| \leqq k, \quad x \in I, \varepsilon \in S_c \quad (j, k = 1, 2, \cdots, n) \tag{1.10}$$

where k is a constant independent of (x, ε) and $\| \; \|$ is a suitable norm of a matrix, and that

$$\int_a^b \|H_1(x, \varepsilon)\| \, dx \quad \text{is uniformly bounded for } \varepsilon \in S_c, \tag{1.11}$$

$$\int_a^b \|H_1'(x, \varepsilon)\| \, dx \quad \text{is uniformly bounded for } \varepsilon \in S_c. \tag{1.12}$$

We shall prove the following.

THEOREM 1. *Under the assumptions* (1.9)-(1.12), *the fundamental matrix of* (1.8) *can be expressed as*

$$Y = Z(x, \alpha, \varepsilon)(I_n + P(x, \varepsilon)), \qquad I_n : n \times n \textit{ identity matrix} \tag{1.13}$$

where $Z(x, \alpha, \varepsilon)$ is a fundamental matrix of

$$i\varepsilon Z' = D(x, \varepsilon)Z, \qquad Z(\alpha, \alpha, \varepsilon) = I_n, \tag{1.14}$$

with $\alpha \in I$, and $P(x, \varepsilon)$ is an n by n matrix in the class $C^1(I \times S_{\hat{c}})$, $(0 < \hat{c} \leqq c)$, $\|P(x, \varepsilon)\| = O(\varepsilon^d)$, with $d > 0$, uniformly on I as $\varepsilon \to 0^+$, satisfying $P(\alpha, \varepsilon) = 0$.

If the transformation (1.13) is taken to be $Y = (I_n + P)Z$, then the resulting equation for P is longer and requires more complicated computation to find its solutions.

The points $x_0 \in I$ where $\lambda_j(x_0) = \lambda_k(x_0)$ for certain j, k $(j \neq k; j, k = 1, 2, \cdots, n)$ are called the turning points of (1.8).

An immediate result of Theorem 1 is that the system (1.1) has a fundamental solution

$$V(x, \varepsilon) = U(x) \exp\left\{-i\varepsilon^{-1} \int_\alpha^x D(t, \varepsilon)\, dt\right\}(I_n + P(x, \varepsilon)), \tag{1.15}$$

which is uniformly valid on I. As the interval I contains one or more turning points of the differential equation, i.e., points where some of $\{\lambda_j(x)\}$ coalesce, (1.15) may be considered a central connection formula valid at all turning points of I. (It is called "two point connection formula" by H. Turrittin [20] when there are only two singularities present.) As pointed out by H. Turrittin [20] and J. A. M. McHugh [14], the lateral connection formulas (or sectorial connection formulas in [20]) follow from central connection formulas; thus it is important to have (1.15).

Furthermore, when $a = -\infty$ and/or $b = +\infty$, (1.15) not only gives the asymptotic approximation of the solutions of (1.1) for $\varepsilon \to 0^+$, it also provides the asymptotic approximation of the solutions in terms of x as x tends to $a = -\infty$ and/or $b = +\infty$. In this case $P(-\infty, \varepsilon)$ or $P(\infty, \varepsilon)$ may be chosen to be zero. This is why it is called the *doubly asymptotic* formulas for the solutions of (1.1) (cf. W. Wasow [26]).

Similar to [8], a differential system of the form (1.8) which is taken into (1.14) by (1.13) with a matrix $P(x, \varepsilon)$ satisfying the properties described in Theorem 1 may be called a *globally almost diagonal system.* An entirely different method is used in [8] to prove results similar to Theorem 1 for a system without the factor i in the left-hand side of the equation.

Theorem 1 will be used in § 9 to prove an adiabatic approximation theorem in quantum mechanics for an n-dimensional slowly varying time-dependent Hamiltonian system with degenerate energy levels. This theorem was first proved by M. Born and V. Fock [2] and also studied later in the general setting by T. Kato [10] (also see R. L. Liboff [13] and A. Messiah [15]), even though the case of degenerate energy levels caused by crossing of eigenvalues is not rigorously studied in the general setting. However, a rigorous comprehensive asymptotic decomposition for the solutions of the Hamiltonian system in the presence of multidegenerate energy levels is yet to be derived (cf. W. Wasow [24], [25]). A special degeneracy of a special two-dimensional system was studied by K. O. Friedrich [3], [4]. Recently, H. Gingold [6], [7] provided a comprehensive asymptotic decomposition method for a two-dimensional system with general degeneracy. We will illustrate in this paper that his method can be generalized to an n-dimensional system.

Using the principle of superposition (e.g. see R. L. Liboff [13]) a criterion equivalent to the adiabatic approximation theorem will be established, which enables us to measure *quantitatively* the *qualitative* phenomenon of degeneracy (or symmetry) by the *order of degeneracy* of eigenvalues in a slowly varying time-dependent Hamiltonian system.

In § 10, two examples of Theorem 1 will be given, one for bounded and the other for unbounded I.

The method of taking the system (1.8) into (1.14) is an essential tool in the study of singularly perturbed differential equations. For instance, W. Wasow [23] used it to calculate an adiabatic invariant of a second order equation with a simple turning point and A. Leung and K. Meyer [11] used it to study that for Hamiltonian systems with distinct and purely imaginary eigenvalues.

If $H_0+\varepsilon H_1$ in (1.1) is an infinite (or a general Hamiltonian) matrix, we cannot expect Theorem 1 to hold. However, if the "*orders*" *of all turning points of this infinite system are bounded*, then an analogue of Theorem 1 is expected to hold under fairly general conditions.

The requirement that H_0 is analytic can be relaxed considerably if we apply the methods in H. Gingold [5].

2. Preliminary reduction. From equations (1.8), (1.13) and (1.14), we have

$$iP'=Z^{-1}(x,\alpha,\varepsilon)RZ(x,\alpha,\varepsilon)(I_n+P),\quad P(\alpha,\varepsilon)=0,\quad \alpha\in I. \tag{2.1}$$

Equation (2.1) can be written equivalently as

$$P(x,\varepsilon)=-i\int_\alpha^x Z^{-1}(t,\alpha,\varepsilon)R(t,\varepsilon)Z(t,\alpha,\varepsilon)(I_n+P(t,\varepsilon))\,dt. \tag{2.2}$$

Put

$$LP=-i\int_\alpha^x Z^{-1}RZP\,dt, \tag{2.3}$$

and

$$P_0=LI_n. \tag{2.4}$$

Then, (2.2) is expressible as

$$P=P_0+LP, \tag{2.5}$$

or,

$$P=P_0+LP_0+L^2P=LI_n+L^2I_n+L^2P. \tag{2.6}$$

From (1.14), since $D(x,\varepsilon)$ is diagonal,

$$Z(x,\alpha,\varepsilon)=\exp\left\{-i\varepsilon^{-1}\int_\alpha^x D(t,\varepsilon)\,dt\right\}. \tag{2.7}$$

Thus,

$$\begin{aligned}L^2P=\int_\alpha^x & Z^{-1}(s,\alpha,\varepsilon)R(s,\varepsilon)Z(s,\alpha,\varepsilon)\\ &\cdot\left\{\int_\alpha^s Z^{-1}(t,\alpha,\varepsilon)R(t,\varepsilon)Z(t,\alpha,\varepsilon)P(t,\varepsilon)\,dt\right\}ds,\end{aligned} \tag{2.8}$$

or, by changing the order of integration,

$$\begin{aligned}L^2P=\int_\alpha^x & \left\{\int_t^x Z^{-1}(s,\alpha,\varepsilon)R(s,\varepsilon)Z(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z^{-1}(t,\alpha,\varepsilon)R(t,\varepsilon)Z(t,\alpha,\varepsilon)P(t,\varepsilon)\,dt.\end{aligned} \tag{2.9}$$

Put

$$D(x,\varepsilon)=\operatorname{diag}\{d_1(x,\varepsilon),d_2(x,\varepsilon),\cdots,d_n(x,\varepsilon)\}. \tag{2.10}$$

Then, by (1.6) and (1.7),

$$d_j(x, \varepsilon) = \lambda_j(x) + \varepsilon r_j^0(x, \varepsilon), \qquad j = 1, 2, \cdots, n. \tag{2.11}$$

Put

$$L^2P = (A_{jk}) \quad \text{and} \quad P = (p_{jk}), \quad j, k = 1, 2, \cdots, n. \tag{2.12}$$

By (1.7), (2.7) and (2.10), we have

$$\begin{aligned}&(Z^{-1}(s, \alpha, \varepsilon)R(s, \varepsilon)Z(s, \alpha, \varepsilon))_{jk}\\ &=\begin{cases} r_{jk}(s, \varepsilon) \exp\left\{i\varepsilon^{-1} \int_\alpha^s [d_j(\eta, \varepsilon) - d_k(\eta, \varepsilon)]\, d\eta\right\} & \text{if } j \neq k,\\ 0 \quad \text{if } j = k. \end{cases}\end{aligned} \tag{2.13}$$

Then,

$$\begin{aligned}A_{jk} = \int_\alpha^x \sum_{l=1}^n \Bigg[\sum_{h=1}^n \Bigg(\int_t^x r_{jh}(s, \varepsilon) \exp\left\{i\varepsilon^{-1} \int_\alpha^s (d_j(\eta, \varepsilon) - d_h(\eta, \varepsilon))\, d\eta\right\} ds\Bigg)\\ \cdot r_{hl}(t, \varepsilon) \exp\left\{i\varepsilon^{-1} \int_\alpha^t (d_h(\eta, \varepsilon) - d_l(\eta, \varepsilon))\, d\eta\right\}\Bigg] p_{lk}(t, \varepsilon)\, dt.\end{aligned} \tag{2.14}$$

In order to prove Theorem 1, we have to establish that

$$|||L^2P||| \leqq L(\varepsilon)|||P||| \tag{2.15}$$

for a suitable norm $|||\ \ |||$ of a matrix, where $L(\varepsilon)$ is a quantity which depends only on ε and tends to 0 as $\varepsilon \to 0^+$. We will introduce an alternate stationary phase method for several turning points, in several steps, in §§ 3-7.

The method used in the proof of Theorem 1 is different from those employed by W. A. Harris, Jr. and D. A. Lutz [9], N. Levinson [12], Y. Sibuya [18] and W. Wasow [22], [26]. The integral operator L given by (2.3) depends on the fundamental matrix $Z(x, s, \varepsilon)$ of (1.14), given by (2.7), but (2.6) is linear in P. Thus, it is possible to find $P(x, \varepsilon)$ uniformly valid on I, even though it contains one or more turning points of (1.8). Therefore, the tedious construction of the connection formulas can be avoided.

3. Alternative to stationary phase method. Consider

$$J(a, b, \alpha) = \int_a^b r(s, \varepsilon) \exp\left\{i\varepsilon^{-1} \int_\alpha^s p(\eta, \varepsilon)\, d\eta\right\} ds, \qquad a \leqq \alpha \leqq b \tag{3.1}$$

where $r(x, \varepsilon)$ is in $C^1(I \times \bar{S}_c)$, and $p(x, \varepsilon)$ is real analytic on $I \times \bar{S}_c$. Assume that the following conditions are satisfied:

(i) $p(x, 0)$ vanishes at some points of I, but is not identically zero on I;

(ii) There exists a positive constant g_1 such that

$$|p'(x, \varepsilon)| \leqq g_1 \quad \text{for } x \in I, \quad \varepsilon \in S_c; \tag{3.2}$$

(iii) There exist two positive constants m_1 and m_2 such that

$$|r(x, \varepsilon)| \leqq m_1 \quad \text{for } x \in I, \quad \varepsilon \in S_c, \tag{3.3}$$

$$\int_a^b |r(s, \varepsilon)|\, ds \leqq m_2, \quad \int_a^b |r'(s, \varepsilon)|\, ds \leqq m_2 \quad \text{for } \varepsilon \in S_c. \tag{3.4}$$

The zeros of $p(x, 0)$ are called the "turning points" of the integral $J(a, b, \alpha)$.

First note that, by integration by parts, (3.1) is expressible as

$$\begin{aligned} J(a,b,\alpha)&=\left[-i\varepsilon r(s,\varepsilon)\frac{1}{p(s,\varepsilon)}\exp\left\{i\varepsilon^{-1}\int_\alpha^s p(\eta,\varepsilon)\,d\eta\right\}\right]_a^b \\ &\quad+i\varepsilon\int_a^b \frac{r'(s,\varepsilon)p(s,\varepsilon)-r(s,\varepsilon)p'(s,\varepsilon)}{[p(s,\varepsilon)]^2}\exp\left\{i\varepsilon^{-1}\int_\alpha^s p(\eta,\varepsilon)\,d\eta\right\}ds. \end{aligned} \tag{3.5}$$

We shall use (3.5) to estimate the integral $J(a,b,\alpha)$ as $\varepsilon\to 0^+$ in several steps, each proved as a lemma.

LEMMA 1. *For α, β, $t\in[a,b]$, $J(a,b,\alpha)$ satisfies*

$$J(a,b,\alpha)=J(a,t,\alpha)+J(t,b,\beta)\exp\left\{i\varepsilon^{-1}\int_\alpha^\beta p(\eta,\varepsilon)\,d\eta\right\}. \tag{3.6}$$

Consequently, $|J(a,b,\alpha)|$ is independent of α and

$$|J(a,b,\alpha)|\leqq|J(a,t,\alpha)|+|J(t,b,\beta)|\quad \textit{for all } \alpha,\beta,t\in[a,b]. \tag{3.7}$$

LEMMA 2. *Suppose that a is finite, $p(x,\varepsilon)$ is independent of ε and expressible as*

$$p(x,\varepsilon)\equiv p(x)=(x-a)^{\nu_a}\hat p(x), \tag{3.8}$$

where ν_a is a positive integer, $\hat p(x)$ is real analytic on I and satisfying

$$0<g_2\leqq|\hat p(x)|\quad \textit{for } x\in I, \tag{3.9}$$

with g_2 a positive constant. Assume that the conditions (3.3) *and* (3.4) *hold. Then, there exist three positive constants K_a, l_a and c_a satisfying $0<\nu_a l_a<1$, $0<c_a\leqq c$ such that*

$$|J(a+\varepsilon^{l_a},t,\alpha)|\leqq K_a\varepsilon^{1-\nu_a l_a} \tag{3.10}$$

for $a+\varepsilon^{l_a}\leqq t$, $\alpha\leqq b$, $\varepsilon\in S_{c_a}$.

LEMMA 2A. *Suppose that $a=-\infty$, $p(x,\varepsilon)$ is independent of ε and expressible as*

$$p(x,\varepsilon)\equiv p(x)=x^{-\nu_a}\hat p(x) \tag{3.11}$$

where ν_a is a positive integer, $\hat p(x)$ is real analytic on I and satisfying (3.9). *Assume that* (3.3) *and* (3.4) *hold. Furthermore, assume that $r(x,\varepsilon)$ is expressible as*

$$r(x,\varepsilon)=x^{-2}\hat r(x,\varepsilon) \tag{3.12}$$

for $x\in(-\infty,-q)$, $\varepsilon\in S_c$, where q is a suitable positive constant, and

$$|\hat r(x,\varepsilon)|\leqq m_3 \tag{3.13}$$

for $s\in(-\infty,-q)$ and $\varepsilon\in S_c$ with m_3 a positive constant. Then, there exist three positive constants K_a, d_a, and c_a with $0<d_a<1$, $0<c_a\leqq c$ such that

$$|J(-\infty,t,\alpha)|\leqq K_a\varepsilon^{d_a} \tag{3.14}$$

for $-\infty<t$, $\alpha\leqq b$, $\varepsilon\in S_{c_a}$.

LEMMA 3. *Suppose that b is finite, $p(x,\varepsilon)$ is independent of ε and expressible as*

$$p(x,\varepsilon)\equiv p(x)=(x-b)^{\nu_b}\hat p(x) \tag{3.15}$$

where ν_b is a positive integer, $\hat p(s)$ is real analytic on I and satisfies (3.9). *Under the conditions* (3.3) *and* (3.4), *there exist three positive constants K_b, l_b and c_b satisfying $0<\nu_b l_b<1$ and $0<c_b\leqq c$ such that*

$$|J(t,b-\varepsilon^{l_b},\alpha)|\leqq K_b\varepsilon^{1-\nu_b l_b} \tag{3.16}$$

for $a\leqq t$, $\alpha\leqq b-\varepsilon^{l_b}$, $\varepsilon\in S_{c_b}$.

LEMMA 3A. *Suppose that $b=+\infty$, $p(x,\varepsilon)$ is independent of ε and expressible as*

$$p(x,\varepsilon)\equiv p(x)=x^{-\nu_b}\hat{p}(x) \tag{3.17}$$

where ν_b is a positive integer, $\hat{p}(s)$ is real analytic on I and satisfying (3.9). *Assume that* (3.3) *and* (3.4) *hold. Furthermore, assume that $r(x,\varepsilon)$ is expressible as in* (3.12) *and satisfies* (3.13) *for $x\in(q,+\infty)$, $\varepsilon\in S_c$ where q is a suitable positive constant. Then, there exist three positive constants K_b, d_b, and c_b with $0<d_b<1$, $0<c_b\leqq c$ such that*

$$|J(t,+\infty,\alpha)|\leqq K_b\varepsilon^{d_b} \tag{3.18}$$

for $a\leqq t$, $\alpha<+\infty$, $\varepsilon\in S_{c_b}$.

LEMMA 4. *Suppose that a and b are both finite, $p(x,\varepsilon)$ is independent of ε and expressible in the form*

$$p(x,\varepsilon)\equiv p(x)=(x-a)^{\nu_a}(x-b)^{\nu_b}\hat{p}(x) \tag{3.19}$$

where ν_a and ν_b are positive integers. Under the conditions (3.3), (3.4) *and* (3.9), *there exist five positive constants K_{ab}, l_a, l_b, d_{ab} and c_{ab}, with $0<\nu_a l_a<1$, $0<\nu_b l_b<1$, $0<d_{ab}<1$ and $0<c_{ab}\leqq c$, such that*

$$|J(a+\varepsilon^{l_a},b-\varepsilon^{l_b},\alpha)|\leqq K_{ab}\varepsilon^{d_{ab}} \tag{3.20}$$

for $a\leqq\alpha\leqq b$, $\varepsilon\in S_{c_{ab}}$.

LEMMA 5. *Suppose that $p(x,\varepsilon)$ is independent of ε and expressible in the form*

$$p(x,\varepsilon)\equiv p(x)=\left[\prod_{j=1}^{m}(x-\alpha_j)^{\nu_j}\right]\hat{p}(x) \tag{3.21}$$

where $a\leqq\alpha_1<\alpha_2<\cdots<\alpha_{m-1}<\alpha_m\leqq b$ (equality may hold only when $a\neq-\infty$, $b\neq\infty$), and $\nu_j(j=1,2,\cdots,m)$ are positive constants. Under the assumptions (3.3), (3.4) *and* (3.9), *there exist positive constants K_1, d_1 and c_1 $(0<d_1<1$, $0<c_1\leqq c)$ such that*

$$|J(a,b,\alpha)|\leqq K_1\varepsilon^{d_1}\quad\textit{for } a\leqq\alpha\leqq b,\quad \varepsilon\in S_{c_1}. \tag{3.22}$$

Lemma 1 follows easily from (3.1). As a matter of fact,

$$\begin{aligned}
J(a,t,\alpha)&+J(t,b,\beta)\exp\left\{i\varepsilon^{-1}\int_\alpha^\beta p(\eta,\varepsilon)\,d\eta\right\}\\
&=\int_a^t r(s,\varepsilon)\exp\left\{i\varepsilon^{-1}\int_\alpha^s p(\eta,\varepsilon)\,d\eta\right\}ds\\
&\quad+\int_t^b r(s,\varepsilon)\exp\left\{i\varepsilon^{-1}\left[\int_\beta^s p(\eta,\varepsilon)\,d\eta+\int_\alpha^\beta p(\eta,\varepsilon)\,d\eta\right]\right\}ds\\
&=\left(\int_a^t+\int_t^b\right)r(s,\varepsilon)\exp\left\{i\varepsilon^{-1}\int_\alpha^s p(\eta,\varepsilon)\,d\eta\right\}ds=J(a,b,\alpha).
\end{aligned}$$

Remarks. (1) The points b in Lemmas 2, 2A and 5 may be $+\infty$ and a in Lemma 3, 3A and 5 may be $-\infty$.

(2) If l_a is chosen to be $l_a=(1+\nu_a)^{-1}$, then

$$1-\nu_a l_a=(1+\nu_a)^{-1}=l_a. \tag{3.23}$$

Then (3.10) agrees with the estimate obtained by the traditional stationary phase method (e.g. see F. W. J. Olver [16, p. 101]). The estimate for (3.16) can be treated similarly. Thus, our method contains the traditional stationary phase method as a special case, but *does not need* to utilize the integration in the complex plane.

(3) If $p(x,0)$ is in the form of (3.21), $x=\alpha_j$ $(j=1,2,\cdots,m)$ are called "turning points" of $J(a,b,\alpha)$ of order ν_j, respectively. If $p(x,0)$ is in the form of (3.17), the order of the turning point $x=+\infty$ is

$$\nu_\infty=\nu_b-2. \tag{3.24}$$

Similarly, if $p(x,0)$ is in the form of (3.11), the order of the turning point $x=-\infty$ is

$$\nu_{-\infty}=\nu_a-2. \tag{3.25}$$

(4) For the system (1.8), if $x=x_0$ is a turning point arised in more than one entries of A_{jk} (cf. (2.14)), the highest order is taken to be the order of the system at this turning point.

(5) To avoid cumbersome notation, the subscript h for ν_h, l_h, K_h and d_h, in this paper, is to denote either a point on $[a,b]$ or an index of the points on $[a,b]$. As it is clear from the text, we utilize both notation without warning.

(6) N. Bleistein [1] and F. Ursell [21] studied the asymptotic expansions of $J(a,b,\alpha)$ in fractional powers when several zeros of $p(x,\varepsilon)$ are nearly coincident at $x=0$. Their methods differ from ours as they employ transformations of variables and special functions. Their method is more in the spirit of the method of steepest descent, while ours is a straightforward alternative to the stationary phase method.

4. Proof of Lemmas 2 and 3. Let us prove Lemma 2 and consider first the case when b is finite. By (3.3), (3.8) and (3.9), we have

$$\left|\frac{r(t,\varepsilon)}{p(t)}\right|+\left|\frac{r(a+\varepsilon^{l_a},\varepsilon)}{p(a+\varepsilon^{l_a})}\right|\leqq\frac{2m_1}{g_2}\varepsilon^{-\nu_a l_a} \tag{4.1}$$

for $a+\varepsilon^{l_a}\leqq t\leqq b$.

In order to estimate the second term of (3.5), note that, since $\hat{p}(x)$ is analytic on I, there exists a positive constant g_3 such that

$$|\hat{p}'(x)|\leqq g_3 \quad \text{for } x\in I. \tag{4.2}$$

By (3.4), (3.8) and (3.9), we have

$$\int_{a+\varepsilon^{l_a}}^{t}\left|\frac{r'(s,\varepsilon)}{p(s)}\right|ds\leqq\frac{m_2}{g_2}\varepsilon^{-\nu_a l_a}. \tag{4.3}$$

(i) If $\nu_a>1$, by (3.3) and (3.8), we have

$$\begin{aligned}\int_{a+\varepsilon^{l_a}}^{t}\left|\frac{r(s,\varepsilon)p'(s)}{[p(s)]^2}\right|ds&\leqq m_1\int_{a+\varepsilon^{l_a}}^{t}\left|\frac{\nu_a}{(s-a)^{\nu_a+1}\hat{p}(s)}+\frac{\hat{p}'(s)}{(s-a)^{\nu_a}[\hat{p}(s)]^2}\right|ds\\&\leqq m_1\left\{\frac{\nu_a}{g_2}\int_{a+\varepsilon^{l_a}}^{t}\frac{ds}{(s-a)^{\nu_a+1}}+\frac{g_3}{g_2^2}\int_{a+\varepsilon^{l_a}}^{t}\frac{ds}{(s-a)^{\nu_a}}\right\}\\&\leqq m_1\left\{\frac{\nu_a}{g_2}\left(\frac{1}{\varepsilon^{\nu_a l_a}}-\frac{1}{(t-a)^{\nu_a}}\right)\right.\\&\qquad\left.+\frac{g_3}{g_2^2}\left(\frac{1}{(\nu_a-1)\varepsilon^{(\nu_a-1)l_a}}-\frac{1}{(\nu_a-1)(t-a)^{\nu_a-1}}\right)\right\}\\&\leqq m_1\left\{\frac{\nu_a}{g_2}\frac{1}{\varepsilon^{\nu_a l_a}}+\frac{g_3}{g_2^2}\frac{1}{(\nu_a-1)\varepsilon^{(\nu_a-1)l_a}}\right\}\\&=\frac{m_1}{\varepsilon^{\nu_a l_a}g_2}\left\{\nu_a+\frac{g_3}{g_2(\nu_a-1)}\varepsilon^{l_a}\right\}\\&=K_1\varepsilon^{-\nu_a l_a}\quad\text{for }\varepsilon\in S_{c_a}\end{aligned} \tag{4.4}$$

where $K_1=(m_1/g_2)\{\nu_a+(g_3/(g_2(\nu_a-1)))c_a^{l_a}\}$ with c_a to be specified.

(ii) If $\nu_a=1$, then $p'(s)=\hat{p}(s)+(s-a)\hat{p}'(s)$ and

$$\begin{aligned}\int_{a+\varepsilon^{l_a}}^{t}\left|\frac{r(s,\varepsilon)p'(s)}{[p(s)]^2}\right|ds &\leqq m_1\left\{\int_{a+\varepsilon^{l_a}}^{t}\left|\frac{1}{(s-a)^2\hat{p}(s)}+\frac{\hat{p}'(s)}{(s-a)\hat{p}(s)^2}\right|ds\right\}\\ &\leqq m_1\left\{\frac{1}{g_2}\int_{a+\varepsilon^{l_a}}^{t}\frac{ds}{(s-a)^2}+\frac{g_3}{g_2^2}\int_{a+\varepsilon^{l_a}}^{t}\frac{ds}{(s-a)}\right\}\\ &\leqq m_1\left\{\frac{1}{g_2}\left(\frac{1}{\varepsilon^{l_a}}-\frac{1}{t-a}\right)+\frac{g_3}{g_2^2}(|\log(t-a)|+|\log\varepsilon^{l_a}|)\right\}\\ &\leqq\frac{m_1}{g_2}\left\{\frac{1}{\varepsilon^{l_a}}+\frac{2g_3}{g_2}|\log\varepsilon^{l_a}|\right\}\leqq K_2\varepsilon^{-\nu_a l_a}\end{aligned}\tag{4.5}$$

if $0<\varepsilon<\min\{1,(b-a)^{1/l_a},(b-a)^{-1/l_a}\}$, where

$$K_2=\frac{m_1}{g_2}\left\{1+\frac{2g_3}{eg_2}\right\}.$$

Here we use the fact that $0>x^l\log x>-e^{-1}$ for $0<x<1$ and positive constant l. Thus, in either case, if

$$c_a=\min\{c,1,(b-a)^{1/l_a},(b-a)^{-1/l_a}\},\tag{4.6}$$

there exists a positive constant K_a such that (3.10) is satisfied for $\varepsilon\in S_c$.

If $b=\infty$, and $t\to\infty$, (4.1) and (4.3) hold also. Instead of using (4.4) or (4.5), observe that

$$\begin{aligned}\left|\int_{a+\varepsilon^{l_a}}^{\infty}\frac{r(s,\varepsilon)p'(s)}{[p(s)]^2}ds\right| &\leqq m_1\left|\int_{a+\varepsilon^{l_a}}^{\infty}\frac{p'(s)}{[p(s)]^2}ds\right|\\ &=m_1\left|\left[\frac{1}{p(s)}\right]_{a+\varepsilon^{l_a}}^{\infty}\right|\leqq\frac{m_1}{g_2}\varepsilon^{-\nu_a l_a},\end{aligned}\tag{4.7}$$

for $\varepsilon\in S_{c_a}$ since $p(\infty)=\infty$ in this case. In this case $c_a=\min\{c,1\}$.

Similarly, Lemma 3 is proved for both finite a and $a=-\infty$.

Remark. The condition (4.2) is used, instead of (3.2), when $p(x)$ is in the form of (3.8). The same is true for the situations given in Lemmas 2A-5.

5. Proof of Lemmas 2A and 3A. Let us prove Lemma 2A and consider first the case that b is finite. Let

$$\gamma_a=\begin{cases}-\infty & \text{if } b\geqq 0,\\ b^{-1} & \text{if } b<0,\end{cases}\tag{5.1}$$

and l_a be a positive constant satisfying $0<\nu_a l_a<1$. Note that $|J(a,b,\alpha)|$ is independent of α. Then, by (3.7), we have

$$|J(-\infty,b,\alpha)|\leqq|J(-\infty,-\varepsilon^{-l_a},\alpha)|+|J(-\varepsilon^{-l_a},\gamma_a^{-1},\beta)|+|J(\gamma_a^{-1},b,\gamma)|,\tag{5.2}$$

for $-\infty<\alpha,\ \beta,\ \gamma\leqq b$.

By (3.5), (3.3) and (3.4), as $p(s)$ is analytic, nonzero for $\gamma_a^{-1} \leqq s \leqq b$, there is a nonnegative constant K_1 such that

$$|J(\gamma_a^{-1}, b, \gamma)| \leqq K_1 \varepsilon \quad \text{for } -\infty < \gamma \leqq b, \qquad \varepsilon \in S_c. \tag{5.3}$$

In order to estimate $|J(-\infty, -\varepsilon^{-l_a}, \alpha)|$ and $|J(-\varepsilon^{-l_a}, \gamma_a^{-1}, \beta)|$, put

$$s = z^{-1}. \tag{5.4}$$

Then, by (3.1), (5.4), (3.11), (3.12) and (3.13), we have

$$\begin{aligned} |J(-\infty, -\varepsilon^{-l_a}, \alpha)| &= \left| \int_0^{-\varepsilon^{l_a}} \hat{r}\left(\frac{1}{z}, \varepsilon\right) z^2 \exp\left\{ i\varepsilon^{-1} \int_{\alpha^{-1}}^{z} p\left(\frac{1}{\eta}\right)\left(-\frac{d\eta}{\eta^2}\right)\right\}\left(-\frac{dz}{z^2}\right)\right| \\ &\leqq m_3 \varepsilon^{l_a} \end{aligned} \tag{5.5}$$

for $\varepsilon \in S_{c_a}$, where $-\varepsilon^{l_a} < \alpha^{-1} < 0$ and

$$c_a = \min\{1, c, q^{-1/l_a}, (-b)^{-1/l_a}\}. \tag{5.6}$$

Also, from (3.5), we have

$$\begin{aligned} |J(-\varepsilon^{-l_a}, \gamma_a^{-1}, \beta)| \leqq \varepsilon & \left| \left[r\left(\frac{1}{z}, \varepsilon\right) \frac{1}{z^{\nu_a} \hat{p}(1/z)} \right]_{-\varepsilon^{l_a}}^{\gamma_a} \right| \\ & + \varepsilon \int_{\gamma_a}^{-\varepsilon^{l_a}} \left| \frac{(dr/dz)(1/z, \varepsilon) p(1/z) - r(1/z, \varepsilon)(dp/dz)(1/z)}{[p(1/z)]^2} \right| dz. \end{aligned} \tag{5.7}$$

By (3.3), (3.11) and (5.6)

$$\left| \frac{r(\gamma_a^{-1}, \varepsilon)}{\gamma_a^{\nu_a} \hat{p}(\gamma_a^{-1})} \right| + \left| \frac{r(-\varepsilon^{-l_a}, \varepsilon)}{(-\varepsilon^{l_a})^{\nu_a} \hat{p}(-\varepsilon^{-l_a})} \right| \leqq \frac{2m_1}{g_2} \varepsilon^{-\nu_a l_a} \tag{5.8}$$

for $\varepsilon \in S_{c_a}$. By (3.4), (3.11) and (5.6), we have

$$\int_{\gamma_a}^{-\varepsilon^{l_a}} \left| \frac{(dr/dz)(1/z, \varepsilon)}{z^{\nu_a} \hat{p}(1/z)} \right| dz \leqq \frac{m_2}{\varepsilon^{\nu_a l_a} g_2} \tag{5.9}$$

for $\varepsilon \in S_{c_a}$. Also, similar to (4.4) and (4.5), there exists a positive constant K_4 such that

$$\int_{\gamma_a}^{-\varepsilon^{l_a}} \left| \frac{r(1/z, \varepsilon)(dp/dz)(1/z)}{[p(1/z)]^2} \right| dz \leqq K_4 \varepsilon^{-\nu_a l_a} \tag{5.10}$$

for $\varepsilon \in S_{c_a}$.

Thus, by (5.3), (5.5), (5.7), (5.8), (5.9) and (5.10), we have (3.14) for a suitable positive constant K_a, and

$$d_a = \min\{l_a, 1 - \nu_a l_a\}. \tag{5.11}$$

If $b = +\infty$, then, by (3.7), we can apply

$$|J(-\infty, \infty, \alpha)| \leqq |J(-\infty, \hat{\alpha}, \alpha)| + |J(\hat{\alpha}, \hat{\beta}, \beta)| + |J(\hat{\beta}, \infty, \gamma)| \tag{5.12}$$

for suitable finite constants $\hat{\alpha}$, $\hat{\beta}$, α, β and $\gamma (\hat{\alpha} \leqq \hat{\beta})$. The estimate of the first is shown above, that of the last term can be obtained in a similar fashion, and that of the middle term can be obtained by Lemma 2, or repeatedly using Lemma 2, similar to the proof of Lemma 4, if necessary. Thus, Lemma 2A is proved.

In a similar way, Lemma 3A is proved.

6. Proof of Lemma 4. For $p(x)$ in the form of (3.19), let $0<\nu_a l_a<1$, $0<\nu_b l_b<1$ and

$$c_{ab}=\min\left\{c,1,\left(\frac{b-a}{4}\right)^{1/l_a},\left(\frac{b-a}{4}\right)^{1/l_b},\left(\frac{b-a}{4}\right)^{-1/l_a},\left(\frac{b-a}{4}\right)^{-1/l_b}\right\}. \tag{6.1}$$

Here, a and b are both finite. Then, by Lemma 2 and Lemma 3, there are two positive constants K_{1a} and K_{1b} such that

$$\begin{aligned}\left|J\left(a+\varepsilon^{l_a},\frac{a+b}{2},\alpha\right)\right|&\leqq K_{1a}\varepsilon^{1-\nu_a l_a},\\ \left|J\left(\frac{a+b}{2},b-\varepsilon^{l_b},\beta\right)\right|&\leqq K_{1b}\varepsilon^{1-\nu_b l_b},\end{aligned} \tag{6.2}$$

for α, $\beta\in[a,b]$, $\varepsilon\in S_{c_{ab}}$. Let

$$d_{ab}=\min\{1-\nu_a l_a,1-\nu_b l_b\}. \tag{6.3}$$

Then, by Lemma 2, there exists a suitable positive constant K_{ab} such that

$$|J(a+\varepsilon^{l_a},b-\varepsilon^{l_b},\alpha)|\leqq K_{ab}\varepsilon^{d_{ab}} \tag{6.4}$$

for $\alpha\in[a,b]$, $\varepsilon\in S_{c_{ab}}$. Thus Lemma 4 is proved.

7. Proof of Lemma 5. For $p(x)$ in the form of (3.21) first choose m constants l_1, $l_2,\cdots,l_m$ satisfying

$$0<\nu_j l_j<1,\qquad j=1,2,\cdots,m. \tag{7.1}$$

Let

$$\begin{aligned}\varepsilon_a&=\begin{cases}1 & \text{if } \alpha_1=a,\\ \min\left\{\left(\frac{\alpha_1-a}{2}\right)^{1/l_a},\left(\frac{\alpha_1-a}{2}\right)^{-1/l_a}\right\} & \text{if } a<\alpha_1,\end{cases}\\ \varepsilon_b&=\begin{cases}1 & \text{if } \alpha_m=b,\\ \min\left\{\left(\frac{b-\alpha_m}{2}\right)^{1/l_m},\left(\frac{b-\alpha_m}{2}\right)^{-1/l_m}\right\} & \text{if } \alpha_m<b,\end{cases}\end{aligned} \tag{7.2}$$

and

$$\begin{aligned}c_1=\min\Bigg\{c,1,\varepsilon_a,\varepsilon_b,&\left(\frac{\alpha_{j+1}-\alpha_j}{4}\right)^{1/l_j},\left(\frac{\alpha_{j+1}-\alpha_j}{4}\right)^{-1/l_j},\\ &\left(\frac{\alpha_{j+1}-\alpha_j}{4}\right)^{1/l_{j+1}},\left(\frac{\alpha_{j+1}-\alpha_j}{4}\right)^{-1/l_{j+1}}\Bigg|\ j=1,2,\cdots,m-1\Bigg\}.\end{aligned} \tag{7.3}$$

Also, let

$$\delta_j=\varepsilon^{l_j},\qquad j=1,2,\cdots,m, \tag{7.4}$$

and

$$\delta_a=\begin{cases}0 & \text{if } \alpha_1=a,\\ \delta_1 & \text{if } a<\alpha_1,\end{cases}\qquad \delta_b=\begin{cases}0 & \text{if } \alpha_m=b,\\ \delta_m & \text{if } \alpha_m<b.\end{cases} \tag{7.5}$$

Consider

$$I_1=[\alpha_1-\delta_a,\alpha_1]\cup[\alpha_1,\alpha_1+\delta_1]\left\{\bigcup_{j=2}^{m-1}[\alpha_j-\delta_j,\alpha_j+\delta_j]\right\} \tag{7.6}$$
$$\cup[\alpha_m-\delta_m,\alpha_m]\cup[\alpha_m,\alpha_m+\delta_b]$$

and

$$I_2=[a,b]-\mathrm{Int}\,(I_1). \tag{7.7}$$

By Lemma 1, $|J(a,b,\alpha)|$ is decomposed into

$$|J(a,b,\alpha)|\leqq J_1+J_2 \tag{7.8}$$

where J_1 is the sum of absolute values of the integrals over each subinterval of I_1 and J_2 is the sum of those over each subinterval of I_2.

To estimate each term in J_1, using (3.1) and (3.3), we can find a suitable positive constant $\hat{K}_1$ such that

$$J_1=\int_{I_1}|r(s,\varepsilon)|\,ds\leqq 2m_1\sum_{j=1}^{m}\varepsilon^{l_j}\leqq\hat{K}_1\varepsilon^{\hat{d}} \tag{7.9}$$

for $\varepsilon\in S_{c_1}$, where

$$\hat{d}=\min\{l_1,l_2,\cdots,l_m\}. \tag{7.10}$$

In order to estimate J_2, as $\hat{p}(x)$ satisfies (3.9), let

$$\hat{g}_0=\left(\inf_{a_j\leqq x\leqq\alpha_1}\prod_{j=2}^{m}|x-\alpha_j|^{\nu_j}\right)g_2,$$
$$\hat{g}_m=\left(\inf_{\alpha_m\leqq x\leqq b}\prod_{j=1}^{m-1}|x-\alpha_j|^{\nu_j}\right)g_2, \tag{7.11}$$
$$\hat{g}_j=\left(\inf_{\alpha_j\leqq x\leqq\alpha_{j+1}}\prod\nolimits_j'|x-\alpha_i|^{\nu_i}\right)g_2\qquad(j=1,2,\cdots,m-1)$$

where $\prod_j'$ is the product over all i's satisfying $1\leqq i\leqq j-1$, $j+1\leqq i\leqq m$. Then each $\hat{g}_j$ $(j=0,1,2,\cdots,m)$ is a positive constant. Note that J_2 is the sum

$$J_2=|\hat{J}(a,\alpha_1-\delta_a,\beta_1)|+\sum_{j=1}^{m-1}|J(\alpha_j+\delta_j,\alpha_{j+1}-\delta_{j+1},\beta_j)|+|\hat{J}(\alpha_m+\delta_m,b,\beta_m)| \tag{7.12}$$

where $\beta_1,\beta_2,\cdots,\beta_m\in[a,b]$. By (7.5)

$$\hat{J}(a,\alpha_1-\delta_a,\beta_1)=\begin{cases}0 & \text{if } a=\alpha_1,\\ J(a,\alpha_1-\delta_1,\beta_1) & \text{if } a<\alpha_1,\end{cases} \tag{7.13}$$
$$\hat{J}(\alpha_m+\delta_b,b,\beta_m)=\begin{cases}0 & \text{if } \alpha_m=b,\\ J(\alpha_m+\delta_m,b,\beta_m) & \text{if } \alpha_m<b.\end{cases}$$

By Lemma 3, using $\hat{g}_0$ for g_2 in (3.9), we have

$$|\hat{J}(a,\alpha_1-\delta_a,\beta_1)|\leqq\hat{K}_0\varepsilon^{1-\nu_a l_a}\quad\text{for }\beta_1\in[a,b],\quad\varepsilon\in S_{c_1} \tag{7.14}$$

where $\hat{K}_0$ is zero if $a=\alpha_1$ and positive if $a<\alpha_1$. Similarly, by Lemma 2 and using $\hat{g}_m$ for g_2 in (3.9), we have

$$|\hat{J}(\alpha_m+\delta_b,b,\beta_m)|\leqq\hat{K}_m\varepsilon^{1-\nu_b l_b}\quad\text{for }\beta_m\in[a,b],\quad\varepsilon\in S_{c_1} \tag{7.15}$$

where $\hat{K}_m$ is zero if $\alpha_m=b$, and positive if $\alpha_m<b$.

Also, by Lemma 4, using $\hat{g}_j$ for g_2 in (3.9), we have

$$|J(\alpha_j+\delta_j,\ \alpha_{j+1}-\delta_{j+1},\ \beta_j)| \leqq \hat{K}_j\varepsilon^{\hat{d}_j}, \qquad j=1,2,\cdots,m-1, \tag{7.16}$$

for $\beta_j \in [a, b]$, $\varepsilon \in S_{c_1}$, where $\hat{K}_j$ is a suitable positive constant, and

$$\hat{d}_j = \min(1-\nu_j l_j,\ 1-\nu_{j+1}l_{j+1}), \qquad j=1,2,\cdots,m-1. \tag{7.17}$$

Let

$$d_1 = \min(\hat{d},\ 1-\nu_1 l_1,\ 1-\nu_2 l_2,\cdots,1-\nu_m l_m). \tag{7.18}$$

Then, by (7.8), (7.9), (7.12), (7.14), (7.15) and (7.16), there is a positive constant K_1 such that (3.22) is satisfied. Thus, Lemma 5 is proved.

Remark. The value of d_1 may be actually larger if $r(x, 0)$ vanishes at the same point where $p(x, 0)$ vanishes, namely at the turning points of $J(a, b, \alpha)$.

8. Completion of proof of Theorem 1. Note first that, by the analyticity of H_0, H_1, U and the conditions of (1.10)-(1.12), all the conditions of Lemmas 2-5 are satisfied. For $\alpha \in I$, let

$$\Delta_{jk}(x,\varepsilon) := d_j(x,\varepsilon) - d_k(x,\varepsilon) = q_{jk}(x) + \varepsilon\tilde{q}_{jk}(x,\varepsilon) \tag{8.1}$$

and

$$\begin{aligned} J_{jk}(a,b,\alpha) &:= \int_a^b r_{jk}(s,\varepsilon)\exp\left\{i\varepsilon^{-1}\int_\alpha^s \Delta_{jk}(\eta,\varepsilon)\,d\eta\right\}ds, \\ &= \int_a^b \hat{r}_{jk}(s,\varepsilon)\exp\left\{i\varepsilon^{-1}\int_\alpha^s q_{jk}(\eta)\,d\eta\right\}ds, \end{aligned} \tag{8.2}$$

$$j, k = 1, 2, \cdots, n, \quad j \neq k,$$

where

$$\hat{r}_{jk}(x,\varepsilon) = r_{jk}(x,\varepsilon)\exp\left\{i\int_\alpha^x \tilde{q}_{jk}(s,\varepsilon)\,ds\right\}.$$

By (1.11) and (1.12), $\hat{r}_{jk}(x, \varepsilon)$ satisfies the conditions (3.3) and (3.4). We shall show first that there exists a function $G_{jk}(\varepsilon)$ such that

$$|J_{jk}(a,t,\alpha)| \leqq G_{jk}(\varepsilon) \quad \text{for } t \in I \tag{8.3}$$

where

$$G_{jk}(\varepsilon) \text{ tends to 0 as } \varepsilon \to 0^+. \tag{8.4}$$

(i) If all the turning points of $J_{jk}(a, b, \alpha)$ are finite in order and in number, then $q_{jk}(x)$ is expressible as

$$q_{jk}(x) = \left[\prod_{i=1}^{m_{jk}} (x-\alpha_i^{(jk)})^{\nu_i^{(jk)}}\right]\hat{q}_{jk}(x) \tag{8.5}$$

where m_{jk} and $\nu_i^{(jk)}$ are positive integers, $\alpha_i^{(jk)} \in I (i = 1, 2, \cdots, m_{jk})$, and $\hat{q}_{jk}(x)$ is real analytic on I satisfying

$$0 < g_{jk} \leqq |\hat{q}_{jk}(x)| \tag{8.6}$$

for $x \in I$ with a positive constant g_{jk}. Then, by Lemma 5, there exists $G_{jk}(\varepsilon)$ such that (8.3) and (8.4) are true. It is noteworthy that in this case, a may be $-\infty$ and b may be $+\infty$.

(ii) If $a = -\infty$, b is finite and $a = -\infty$ is a turning point of $J_{jk}(a, b, \alpha)$, then there exists a positive integer $\nu_0^{(jk)}$ and a positive constant ρ_1, $(-\rho_1 \leqq b)$, such that $q_{jk}(x)$ is expressible as

$$q_{jk}(x) = x^{-\nu_0^{(jk)}}\hat{q}_{jk}^0(x) \tag{8.7}$$

for $x \in (-\infty, -\rho_1)$, where $\hat{q}^0_{jk}(x)$ is real analytic and satisfies

$$0 < g^0_{jk} < |\hat{q}^0_{jk}(x)| \tag{8.8}$$

for $x \in (-\infty, -\rho_1)$ with g^0_{jk} a positive constant. Since $U(x)$ is a real analytic unitary matrix on I, and $r_{jk}(x, \varepsilon)$ is an entry of $R_1(x, \varepsilon)$ given by (1.15), it satisfies (3.12) and (3.13) for $x \in (-\infty, -\rho_2)$ with certain positive constant ρ_2 satisfying $-\rho_2 \leqq b$. Let

$$\rho = \max\{\rho_1, \rho_2\}. \tag{8.9}$$

Then, by Lemma 2A, $J_{jk}(-\infty, -\rho, \alpha)$ satisfies (3.14). Combine this with the method of step (i) and by (3.7) we have (8.3).

Similarly, if $b = +\infty$, a is finite and $b = +\infty$ is a turning point of $J_{jk}(a, b, \alpha)$, by Lemma 3A, we have (8.3).

If $a = -\infty$, $b = +\infty$ and both are turning points of $J_{jk}(-\infty, +\infty, \alpha)$, apply above discussion to $J_{jk}(-\infty, -\rho, \alpha)$, $J_{jk}(-\rho, \rho, \alpha)$, $J_{jk}(\rho, +\infty, \alpha)$ and by (3.7), we have (8.3).

Thus, (8.3) is true for all situations.

Now, let $\|P(x, \varepsilon)\|$ be a suitable norm of P and

$$|||P||| = \sup_{x \in I} \|P(x, \varepsilon)\|. \tag{8.10}$$

Then, by (2.14), (1.10), (1.11) and (8.3),

$$\begin{aligned} |A_{jk}| &\leqq \sum_{l=1}^{n} \left[\sum_{h=1}^{n} G_{jh}(\varepsilon) \left| \int_{\alpha}^{x} r_{hl}(t, \varepsilon) \exp\left\{ i\varepsilon^{-1} \int_{\alpha}^{t} \Delta_{hl}(\eta, \varepsilon)\, d\eta \right\} dt \right| \right] |||P||| \\ &\leqq \left[\sum_{l,h=1}^{n} G_{jh}(\varepsilon) \hat{G}_{hl} \right] |||P||| \end{aligned} \tag{8.11}$$

where $\hat{G}_{hl}$ are suitable positive constants. Let

$$L(\varepsilon) = \max_{1 \leqq j \leqq n} \left\{ \sum_{l,h=1}^{n} G_{jh}(\varepsilon) \hat{G}_{hl} \right\}. \tag{8.12}$$

Then, we have

$$|||L^2 P||| \leqq L(\varepsilon) |||P||| \tag{8.13}$$

where $L(\varepsilon)$ tends to 0 as $\varepsilon \to 0^+$.

Similarly, if we let

$$\hat{L}(\varepsilon) = \|\hat{G}_{jk}(\varepsilon)\|, \tag{8.14}$$

then, we have

$$|||P_0||| = |||LI_n||| \leqq \hat{L}(\varepsilon) \tag{8.15}$$

with $\hat{L}(\varepsilon)$ tending to 0 as $\varepsilon \to 0^+$.

Furthermore, if we choose c_3 such that

$$0 < L(\varepsilon) < 1 \tag{8.16}$$

for $\varepsilon \in S_{c_3}$, then (2.6) defines a contraction mapping and

$$\begin{aligned} |||P||| &\leqq |||P_0||| + |||L^2 I_n||| + |||L^2 P||| \\ &\leqq \hat{L}(\varepsilon) + L(\varepsilon)|||I_n||| + L(\varepsilon)|||P|||. \end{aligned} \tag{8.17}$$

Therefore,

$$|||P||| \leqq \frac{\hat{L}(\varepsilon) + L(\varepsilon)|||I_n|||}{1 - L(\varepsilon)} \tag{8.18}$$

for $x \in I$, $\varepsilon \in S_{\hat{c}}$, where $\hat{c} = \min\{c_1, c_2, c_3\}$. Thus, Theorem 1 is proved.

9. Adiabatic approximation theorem. In this section, we shall investigate an adiabatic approximation theorem for an n-dimensional Hamiltonian system with multidegenerate energy levels. This theorem was first proved by M. Born and V. Fock [2] in 1928, and later studied in a general setting by T. Kato [10]. Although some cases of crossing of energy levels were discussed, as pointed out by Wasow [24], [25], the rigorous proof of a general situation as in Theorem 1 was not previously given.

This adiabatic approximation theorem will be shown to be true by observing the asymptotic behavior of the probabilities that eigenstates of the system stay in their original states. A comprehensive study of the *size* of such probabilities for a multidegenerate system has not been done before. This asymptotic analysis also will allow the computing of adiabatic invariants in the presence of several turning points. Although this paper studies the Hamiltonian system of a general degeneracy, the case of most general degeneracy, such as the degeneracy of two identical eigenvalues or of an infinite system, is not yet included here.

Given a slowly varying Hamiltonian operator $H(\varepsilon t)$ which depends on $x=\varepsilon t$ for small but nonvanishing parameter ε, where $t\in[0,\infty]$, $\varepsilon\in[0,c]$; namely $x\in[0,\infty]$. Given a state of the system $v(t,\varepsilon)$, an n-column vector, governed by Schrödinger equation

$$i\frac{dv}{dt}=H(\varepsilon t)v, \tag{9.1}$$

or equivalently

$$i\varepsilon v'=H(x)v, \qquad '=\frac{d}{dx}. \tag{9.2}$$

LEMMA 6. *Assume that $H(x)$ is analytic on $[0,\infty]$ and its eigenvalues coalesce finitely many times on $[0,\infty]$. Then, the fundamental matrix of (9.2) is*

$$V(x,\varepsilon)=U(x)\exp\left\{-i\varepsilon^{-1}\int_0^x D(s,\varepsilon)\,ds\right\}(I_n+P(x,\varepsilon)) \tag{9.3}$$

where $U(x)$ is a unitary matrix, $D(x,\varepsilon)$ is a diagonal matrix such that

$$D(x,0)=\operatorname{diag}\{\lambda_1(x),\lambda_2(x),\cdots,\lambda_n(x)\} \tag{9.4}$$

with $\{\lambda_j(x)\,|\,j=1,2,\cdots,n\}$ eigenvalues of $H(x)$, and $\|P(x,\varepsilon)\|=O(\varepsilon^d)$, $(d>0)$, uniformly on $[0,\infty]$ as $\varepsilon\to0^+$ with $P(0,\varepsilon)=0$.

Before proceeding to prove this lemma, we first compare some terminologies in mathematics and physics. An eigenvalue of H is referred as an energy level of the operator H, while the eigenvector of H is referred as its eigenstate. A solution $v(t,\varepsilon)$ of the time-dependent system (9.1) is referred as a state of the system. The evolution of a state $v(t,\varepsilon)$ is the observation of how is the dependence of v on t.

To show this lemma, let $U(x)$ be the unitary matrix such that

$$D_1(x)=U^{-1}(x)H(x)U(x)=\operatorname{diag}\{\lambda_1(x),\cdots,\lambda_n(x)\}. \tag{9.5}$$

Put

$$y=U^{-1}(x)v. \tag{9.6}$$

Then, (9.2) becomes

$$i\varepsilon y'=[D_1(x)+\varepsilon R_1(x)]y \tag{9.7}$$

where

$$R_1(x) = -iU^{-1}(x)U'(x). \tag{9.8}$$

Let

$$D(x, \varepsilon) = D_1(x) + \varepsilon \operatorname{diag} R_1(x). \tag{9.9}$$

Then, by Theorem 1, Lemma 6 follows immediately.

Now, let

$$U(x) = (u_1(x), u_2(x), \cdots, u_n(x)), \tag{9.10}$$

$$V(x, \varepsilon) = (v_1(x, \varepsilon), v_2(x, \varepsilon), \cdots, v_n(x, \varepsilon)). \tag{9.11}$$

Then, by (9.5), $u_j(x)$ is an eigenstate corresponding to $\lambda_j(x)$, $(j = 1, 2, \cdots, n)$. Let $D(x, \varepsilon)$ given by (9.9) be

$$D(x, \varepsilon) = \operatorname{diag}\{\lambda_j(x) + \varepsilon r_j(x)\}, \tag{9.12}$$

let α in Theorem 1 be 0, and

$$\lambda_j(x, \varepsilon) = \exp\left\{-i\varepsilon^{-1}\int_0^x [\lambda_j(s) + \varepsilon r_j(s)]\, ds\right\}. \tag{9.13}$$

Also, let e_j denote the jth unit vector of the standard basis of R^n. Then, by the notation for $P(x, \varepsilon)$ given by (2.12), we have

$$\begin{aligned} v_j(x, \varepsilon) &= U(x)\exp\left\{-i\varepsilon^{-1}\int_0^x D(s, \varepsilon)\, ds\right\}(I_n + P(x, \varepsilon))e_j \\ &= U(x)\begin{pmatrix} \hat{\lambda}_1 & & & 0 \\ & \hat{\lambda}_2 & & \\ & & \ddots & \\ 0 & & & \hat{\lambda}_n \end{pmatrix}\begin{pmatrix} p_{1j} \\ \vdots \\ p_{j-1,j} \\ 1 + p_{jj} \\ p_{j+1,j} \\ \vdots \\ p_{nj} \end{pmatrix} \\ &= \hat{\lambda}_j(x, \varepsilon)u_j(x) + U(x)\begin{pmatrix} \hat{\lambda}_1 p_{1j} \\ \hat{\lambda}_2 p_{2j} \\ \vdots \\ \hat{\lambda}_n p_{nj} \end{pmatrix} \\ &= \hat{\lambda}_j(x, \varepsilon)u_j(x) + \sum_{k=1}^{n} \hat{\lambda}_k(x, \varepsilon)p_{kj}(x, \varepsilon)u_k(x). \end{aligned} \tag{9.14}$$

Let $q_k^{(j)}$ be the probability of the state $v_j(x, \varepsilon)$ to be in the eigenstate $u_k(x)$. Note that $\hat{\lambda}_j(x, \varepsilon) = 0(1)$, $(j = 1, 2, \cdots, n)$; then, by the superposition principle (e.g. see R. L. Liboff [13, Chap. 5]),

$$q_j^{(j)} = |\hat{\lambda}_j|^2|1 + p_{jj}|^2/\{|\hat{\lambda}_j|^2|1 + p_{jj}|^2 + \sum_{h=1}^{n}{}' |\lambda_n P_{hj}|^2\}, \qquad \textstyle\sum': \text{sum over } h \neq j, \tag{9.15}$$

$$q_k^{(j)} = |\hat{\lambda}_k p_{kj}|^2/\{|\hat{\lambda}_j|^2|1 + p_{jj}|^2 + \sum_{h=1}^{n}{}' |\lambda_n P_{hj}|^2\} \qquad (k \neq j). \tag{9.16}$$

Since $\|P(x, \varepsilon)\| = O(\varepsilon^d)$, $(d > 0)$, *uniformly* on $[0, \infty]$ as $\varepsilon \to 0^+$, we have the following.

LEMMA 7. *The probabilities* $q_j^{(j)}$ *and* $q_k^{(j)}$ $(j,\ k=1,2,3,\cdots,n;\ k\neq j)$ *satisfy*

$$q_j^{(j)}-1=O(\varepsilon^{2d}),\qquad q_k^{(j)}=O(\varepsilon^{2d}),\tag{9.17}$$

uniformly on $[0,\infty]$ *as* $\varepsilon\to 0^+$.

By (9.14), we have

$$v_j(0,\varepsilon)=U(0)e_j=u_j(0),\qquad j=1,2,\cdots,n;\tag{9.18}$$

namely, $v_j(0,\varepsilon)$ is an eigenstate corresponding to the eigenvalue $\lambda_j(0)$. Thus, we have the following adiabatic approximation theorem.

THEOREM 2. *Suppose that the eigenvalues of* $H(\varepsilon t)$, *a slowly varying selfadjoint Hamiltonian operator, coalesce finitely many times for* $x=\varepsilon t$, $t\in[0,\infty]$ *and* $\varepsilon\in(0,c]$ *with* c *a small positive constant. Assume that* $H(x)$ *is analytic for* $x\in[0,\infty]$. *If the system started to evolve at* $t=0$ *such that* $v_j(0,\varepsilon)$ *is an eigenvector (an eigenstate) of* $H(0)$ *corresponding to the eigenvalue (energy level)* $\lambda_j(0)$, *then* $v_j(x,\varepsilon)$, *the evolution of that state is approximately the eigenvector of* $H(\varepsilon t)$ *for* $t\in[0,\infty]$, *corresponding to the eigenvalue* $\lambda_j(\varepsilon t)$, *while* $\varepsilon\to 0^+$ $(j=1,2,\cdots,n)$.

As pointed out in Remark 2 in § 3, if we use the estimate that could be provided by the traditional stationary phase method, then, by the proof of Theorem 1, we have, for each difference of eigenvalues $\lambda_j(x)-\lambda_k(x)$, $(j\neq k)$,

$$d_{jk}=\min\{l_h,l_\infty\}\tag{9.19}$$

where

$$\begin{aligned}&l_h=(\nu_h+1)^{-1},\ \nu_h:\text{ order of finite turning point } x=x_h,\\ &l_\infty=\begin{cases}(\nu_\infty+3)^{-1} & \text{if } x=\infty \text{ is a turning point with order } \nu_\infty,\\ +\infty & \text{if } x=\infty \text{ is not a turning point.}\end{cases}\end{aligned}\tag{9.20}$$

Then, d in (9.17) is given by

$$d=\min\{d_{jk}\,|\,1\leqq j,\ k\leqq n, j\neq k\}.\tag{9.21}$$

From (9.17) we can see that $q_j^{(j)}$ is closer to 1 and $q_k^{(j)}$ $(k\neq j)$ are closer to 0 if d is larger, i.e., ν_h and/or ν_∞ are smaller. Thus, we can measure the *qualitative* phenomenon of degeneracy (or symmetry) *quantitatively* by the *order* of the degeneracy of eigenvalues (energy levels) in a slowly varying time dependent Hamiltonian system.

Therefore, it is tempting to speculate that the following criterion is valid in quantum mechanical systems.

CRITERION. *In a slowly varying time-dependent Hamiltonian system* (9.1), *if a state of the system starts to evolve from an eigenstate, the less the order of degeneracy (symmetry), the closer is (in an asymptotic sense as* $\varepsilon\to 0^+$*) the state to its initial eigenstate.*

10. Examples. To illustrate Theorem 1, consider the following two examples.

Example 1. Given the following three-dimensional system:

$$i\varepsilon Y'=\left[\begin{pmatrix}x^{q+2} & 0 & 0\\ 0 & x^q(2x-1) & 0\\ 0 & 0 & 3x^q(2x-3)\end{pmatrix}+\varepsilon\begin{pmatrix}0 & r_{12} & r_{13}\\ r_{21} & 0 & r_{23}\\ r_{31} & r_{32} & 0\end{pmatrix}\right]Y\tag{10.1}$$

for $x\in[0,5]$, where q is a positive integer, $r_{jk}=r_{jk}(x,\varepsilon)$ $(j,\ k=1,2,3;\ j\neq k)$ satisfy (1.10)-(1.12) for $x\in[0,5]$, $\varepsilon\in S$. Denote

$$\lambda_1(x)=x^{q+2},\quad \lambda_2(x)=x^q(2x-1),\quad \lambda_3(x)=3x^q(2x-3),\tag{10.2}$$

and

$$D_1(x)=\operatorname{diag}\{\lambda_1(x),\lambda_2(x),\lambda_3(x)\}. \tag{10.3}$$

Then,

$$\begin{gathered}\lambda_1(x)-\lambda_2(x)=x^q(x-1)^2,\quad \lambda_1(x)-\lambda_3(x)=x^q(x-3)^2,\\ \lambda_2(x)-\lambda_3(x)=-4x^q(x-2).\end{gathered} \tag{10.4}$$

Thus, $x=0$, $x=1$, $x=2$ and $x=3$ are turning points of orders q, 2, 1 and 2, respectively. By Theorem 1, (10.1) has a fundamental solution

$$Y(x,\varepsilon)=\exp\left\{-i\varepsilon^{-1}\int_\alpha^x D_1(s)\,ds\right\}(I_3+P(x,\varepsilon)) \tag{10.5}$$

with

$$\|P(x,\varepsilon)\|\leqq K\varepsilon^d, \tag{10.6}$$

uniformly on $[0,5]$ for $\varepsilon\in S_{\hat c}$. Here K, d and $\hat c$ are suitable positive constants. As each obtained by the traditional stationary phase method, for $\lambda_1(x)-\lambda_2(x)$, $l_0=1/(1+q)$, $l_1=\frac{1}{3}$; for $\lambda_1(x)-\lambda_3(x)$, $l_0=1/(1+q)$, $l_3=\frac{1}{3}$; and for $\lambda_2(x)-\lambda_3(x)$, $l_0=1/(1+q)$, $l_2=\frac{1}{2}$. Then, by (7.10) and (7.18) $d=\min(1/(1+q),\frac{1}{3},\frac{1}{2})$.

Example 2. Given

$$i\varepsilon Y'=\left[\begin{pmatrix}1 & 0 & 0\\ 0 & 2x/(x^2+1) & 0\\ 0 & 0 & -2x/(x^2+1)\end{pmatrix}+\varepsilon\begin{pmatrix}0 & r_{12} & r_{13}\\ r_{21} & 0 & r_{23}\\ r_{31} & r_{32} & 0\end{pmatrix}\right]Y \tag{10.7}$$

for $x\in(-\infty,\infty)$ where $r_{jk}(x,\varepsilon)$ $(j,k=1,2,3;j\neq k)$ satisfy (1.10)-(1.12) for $x\in(-\infty,\infty)$, $\varepsilon\in S_c$. In this case,

$$\lambda_1(x)-\lambda_2(x)=\frac{(x-1)^2}{x^2+1},\quad \lambda_1(x)-\lambda_3(x)=\frac{(x+1)^2}{x^2+1},\quad \lambda_2(x)-\lambda_3(x)=\frac{4x}{x^2+1}. \tag{10.8}$$

Thus, $x=0$, ±1 are turning points of order 1 and 2, respectively, while $x=\pm\infty$ are turning points of order -2 for $\lambda_1(x)-\lambda_2(x)$ and $\lambda_1(x)-\lambda_3(x)$, and of order -1 for $\lambda_2(x)-\lambda_3(x)$. Then, by Theorem 1 and the estimates obtained in Lemmas 2-5, (10.7) has a fundamental solution (10.5) satisfying (10.6) uniformly on $[-\infty,\infty]$ for $\varepsilon\in S_{\hat c}$, with suitable positive constants K, d and $\hat c$. Then, by (7.10) and (7.18), $d=\frac{1}{3}$.

Acknowledgment. The authors wish to express their sincere gratitude to the referee for valuable suggestions to improve this work.

TIME DEPENDENT NONLINEAR OSCILLATIONS WITH MANY PERIODIC SOLUTIONS*

JAMES DAMON†

Abstract. We investigate the local structure of nonlinear operators defining time dependent nonlinear oscillations. We explicitly describe the local structure of such operators using as models stable mappings between finite-dimensional spaces. This structure theorem allows us to prove the existence of many periodic solutions for such nonlinear oscillations. We determine the maximum number of such periodic solutions occurring near equilibrium. As one consequence we deduce that there exist oscillations with polynomial nonlinear terms of degree $2n$ for which there exist $(n+1)^2$ periodic solutions.

Key words. nonlinear oscillations, periodic solutions, infinitesimal stability, Lyapunov-Schmidt reduction, local algebras, nonlinear Fredholm mappings

AMS(MOS) subject classifications. 34C15, 34C25, 58F22

Introduction. The goal of this paper is to derive results concerning the number of small amplitude periodic solutions of the equation

$$(*) \qquad x''+m^2\lambda^2x+P(x,x',t)=q(t)$$

for $q(t)$ near 0. We assume that P and q are periodic in t of period $\lambda'=2\pi/\lambda$ and that $P(0,0,t)=0$, so that $x(t)\equiv 0$ is an equilibrium solution to $(*)$ when $q=0$. Our method is to explicitly determine the local structure near 0 of the operator

$$(**) \qquad F(x(t))=x''+m^2\lambda^2x+P(x,x',t)$$

where $F: C^2_{\lambda'}\to C^0_{\lambda'}$ and $C^k_{\lambda'}$ denotes the C^k-periodic functions of period $\lambda'=2\pi/\lambda$ defined on $\mathbb{R}$. In this formulation, solutions of $F(x(t))=q(t)$ correspond to small amplitude periodic solutions to $(*)$.

First of all, the results state that for a generic choice of P (in a sense to be made precise) the operator F is infinitesimally stable, and any such infinitesimally stable operator is locally equivalent as a mapping to $f_0\times \mathrm{id}$, for f_0 an infinitesimally stable mapping between finite dimensional spaces (id denotes the identity mapping on a Banach space). Moreover, for any infinitesimally stable $f_0:\mathbb{R}^k, 0\to\mathbb{R}^k, 0$ with $\dim\ker df_0(0)=2$, there is an operator F of the form $(**)$ locally equivalent to $f_0\times\mathrm{id}$. This infinitesimal stability has several main consequences:

(1) Since $\dim\ker(dF(0))=2$, the maximum number of small amplitude periodic solutions to $(*)$ which do occur for some small $q(t)$ is given by the dimension of a certain local algebra associated to F (this follows from the above decomposition together with results in [DG] giving explicitly the maximum number of solutions to $f(x)=y$ near 0 for $f:\mathbb{R}^n, 0\to\mathbb{R}^p, 0$ an infinitesimally stable germ).

(2) The maximum number of small periodic solutions remains constant under small perturbations P (and the periodic solutions themselves persist under small perturbations of P and q).

* Received by the editors October 1, 1985; accepted for publication October 29, 1986. This work was supported in part by a grant from the National Science Foundation.

(3) This maximum number can be determined from a finite part of the Taylor expansion of P.

For the special case of P polynomial in x and x' (with coefficients depending on t), these results imply that there exists such a P of degree $2n$ and an appropriate (open set of) $q(t)$ for which $(*)$ has $(n+1)^2$ periodic solutions.

These results can be contrasted with the results previously obtained for the case where P does not depend on t and $q=0$. Then $(*)$ can be converted to a first-order system and the number of periodic solutions of $(*)$ for P and its perturbations was studied in the context of (degenerate) Hopf bifurcation by Takens [T] and Golubitsky and Langford [GL]. Here periodic solutions are created by perturbation of some basic P. As such the case is treated as a bifurcation problem. In contrast, infinitesimal stability implies that the local structure of the operator does not change under small perturbations. This corresponds to the difference between using the Lyapunov–Schmidt reduction to study the bifurcations of $F^{-1}(0)$ under perturbation by a finite number of external parameters, and using it to determine that all possible deformations of the operator itself already occur along the "internal directions" of the eigenfunctions.

For the polynomial case of $\deg 2n$, the number of periodic solutions we obtain exceeds by a factor of $n+1$ the number obtained by Takens and others, e.g. [CH], [S1] and [LMP]. However, even the number of periodic solutions we give is not generally the best possible for P of degree n. For $n=2$ or 3 the methods of this paper allow us to construct P of degree n with n^2 periodic solutions for $(*)$. Very likely this holds for all n, although technical details have prevented the verification of the more general results. Beyond the examples of degree 2 and 3 which we explicitly give in § 8, we have not been able to explicitly give P of degree $2n-2$ with n^2-periodic solutions. However, we are able to give very explicitly the form of a polynomial P of degree n and a $q(t)$ such that $(*)$ has $2n$-periodic solutions.

It seems likely that the methods used here are applicable to some other nonlinear problems. The main feature of nonlinear oscillations which is used is that the eigenfunctions of the linearized operator form an algebra whose complexification is the algebra of finite Laurent series. Thus, similar results should hold for other nonlinear operators whose linearization is selfadjoint with eigenfunctions forming an algebra possessing appropriate analogous properties.

1. Infinitesimally stable germs and operators.

Since the questions which we shall consider are local, we shall consider two mappings to be equivalent at a point x_0 if they agree in a neighborhood of x_0. Such an equivalence class is referred to as a germ of a mapping. Furthermore, by translation we may assume $x_0=0$ and $f(0)=0$; then $f: E,\ 0\to F,\ 0$ will be used to denote the germ of f at 0. Here, E and F may denote finite- or infinite-dimensional spaces, depending on the circumstances.

For a smooth germ $f:\mathbb{R}^n,\ 0\to\mathbb{R}^p,\ 0$, let $\pi: T\mathbb{R}^p\to\mathbb{R}^p$ denote the projection of the tangent bundle. Then, a germ of a smooth vector field along f is a smooth germ $\zeta:\mathbb{R}^n,\ 0\to T\mathbb{R}^p$ such that $\pi\circ\zeta=f$. Then, f is *infinitesimally* stable (as defined by Mather [M2]) if given ζ, there are smooth germs of vector fields ξ on $\mathbb{R}^n$ and η on $\mathbb{R}^p$ so that $\zeta=\xi(f)+\eta\circ f$ (here $\xi(f)$ denotes the directional derivative of f with respect to ξ). Next, suppose that E and F are Frechet spaces with $E=E_1\oplus G$, $F=F_1\oplus G$ with $\dim_{\mathbb{R}} E_1,\ F_1,\ <\infty$. Suppose $f: E,\ 0\to F,\ 0$ is a smooth germ of the form $f(x,u)=(\bar{f}(x,u),u)$ with $x\in E_1$, $u\in G$. If there is a finite-dimensional subspace $G_1\subset G$ such that the germ $f_1=(f|E_1\oplus G_1): E_1\oplus G_1,\ 0\to F_1\oplus G_1,\ 0$ is infinitesimally stable, then we shall say that *f is infinitesimally stable*. Here and in what follows, "smooth" will mean "smooth in the Gateaux differentiable sense." More generally, a smooth germ

$g: E, 0 \to F, 0$ will be said to be infinitesimally stable if it is *locally equivalent* to an infinitesimally stable f above by $f = \psi \circ g \circ \varphi$ for ψ and φ germs of local diffeomorphisms of E and F.

Ambrosetti and Prodi [AP] and Berger, Church and Timourian [BC], [BCT] have determined the structure of certain nonlinear operators using infinite-dimensional versions of folds and cusps. Quite generally, the local structure of smooth infinitesimally stable germs can be given using a slight modification of Mather's theorem "Infinitesimal stability implies stability." This is given in [D1].

THEOREM 1.1. *With the above notation, if $f: E, 0 \to F, 0$ is infinitesimally stable, then f is locally equivalent to $f_1 \times \mathrm{id}_{G_2}$ (where G_2 is a closed complement to G_1 in G).*

A corollary follows.

COROLLARY 1.2. *Suppose E, F and H are Banach spaces, $f: E, 0 \to F, 0$ is infinitesimally stable, and $h: E \oplus H, 0 \to F \oplus H, 0$ has the form $h(x, u) = (\bar{h}(x, u), u)$ with $\bar{h}(x, 0) = f(x)$ for $x \in E$, $u \in H$. Then, h is locally equivalent to $f \times \mathrm{id}_H$.*

To use these results, we recall several fundamental properties of infinitesimally stable germs due to Mather. If we apply the finite-dimensional analogue of the Lyapunov-Schmidt procedure to a germ $f: \mathbb{R}^n, 0 \to \mathbb{R}^p, 0$, then we may choose local coordinates $(x_1, \cdots, x_s, u_1, \cdots, u_q)$ for $\mathbb{R}^n$ and $(y_1, \cdots, y_t, u_1, \cdots, u_q)$ for $\mathbb{R}^p$ so that f has the form $f(x, u) = (\bar{f}(x, u), u)$, with $\bar{f}(x, 0)$ $(= f_0(x))$ having rank 0 at 0. In the terminology of singularity theory, such an f is called an unfolding of f_0 and the u_i are the unfolding parameters. With f in this form it now becomes a formal calculation to verify infinitesimal stability.

Let $\mathscr{E}_s$ denote the ring of smooth germs $g: \mathbb{R}^s, 0 \to \mathbb{R}$; it has a maximal ideal $\mathscr{m}_s$ consisting of germs vanishing at 0. In $(\mathscr{E}_s)^{(t)} = \mathscr{E}_s \oplus \mathscr{E}_s \cdots \oplus \mathscr{E}_s$ (t copies), which we can view as an $\mathscr{E}_s$-module, we consider the submodule L generated by $\partial f_0/\partial x_1, \cdots, \partial f_0/\partial x_s$, and the submodule $(I(f_0))^{(t)}$ (t-copies of $I(f_0) =$ ideal in $\mathscr{E}_s$ generated by the coordinate functions of f_0, $\{y_i \circ f_0, 1 \leq i \leq t\}$). By $\mathscr{m}_s^k$ we mean the ideal of $\mathscr{E}_s$ generated by monomials of degree $= k$. Then, the quotient $\mathscr{E}_s/\mathscr{m}_s^k$ is a finite-dimensional vector space with basis given by the monomials of degree $< k$. Last, letting $v = (v_1, \cdots, v_q)$, $\partial f/\partial v_i|_{v=0}$ is a germ on $\mathbb{R}^s$, and hence via its coordinate functions can be viewed as an element of $(\mathscr{E}_s)^{(t)}$, in fact, of $(\mathscr{m}_s)^{(t)}$. Then Proposition 1.8 of [M4] can be applied.

THEOREM 1.3 (Verification criterion). *f is infinitesimally stable iff $\partial \bar{f}/\partial v_1|_{v=0}, \cdots, \partial \bar{f}/\partial v_q|_{v=0}$ span the quotient space*

$$N(f_0) = (\mathscr{m}_s)^{(t)}/(L + I(f_0)^{(t)} + (\mathscr{m}_s^{p+1})^{(t)}).$$

As this space is finite-dimensional, this becomes a very computable criterion using part of the Taylor series of f.

An important invariant of a germ is its local algebra. For $f: \mathbb{R}^n, 0 \to \mathbb{R}^p, 0$, we define the local algebra $Q(f) = \mathscr{E}_n/I(f)$, where, just as earlier, $I(f)$ is the ideal generated by the coordinate functions of f. If f is an unfolding of f_0 as above, then $I(f) = I(f_0) + \mathscr{m}_q \cdot \mathscr{E}_n$; hence $Q(f) \xrightarrow{\sim} Q(f_0)$. Furthermore, for infinitesimally stable germs there is the very fundamental classification theorem of Mather [M4, Thm. A].

THEOREM 1.4 (Classification by local algebras). *If $f, g: \mathbb{R}^n, 0 \to \mathbb{R}^p, 0$ are infinitesimally stable germs with isomorphic local algebras then f and g are locally equivalent at 0.*

Furthermore, given an algebra Q satisfying certain conditions it is possible to construct an infinitesimally stable germ f, with $Q(f) \simeq Q$. For example, consider $Q \simeq \mathscr{E}_s/I$ with $I \subset \mathscr{m}_s^2$ generated by $f_{01}, \cdots, f_{0t}$ and suppose for simplicity that $\dim_{\mathbb{R}} Q < \infty$. Then, we use the f_{0i} as coordinate functions to define $f_0: \mathbb{R}^s, 0 \to \mathbb{R}^t, 0$.

Then, $N(f_0)$ is a subspace of a quotient of $(Q)^{(t)} \xrightarrow{\sim} (Q(f_0))^{(t)}$. Hence, there are $\varphi_1, \cdots, \varphi_q \in (m_s)^{(t)}$ which project to a basis for $N(f_0)$. Then, $f: \mathbb{R}^{s+q}, 0 \to \mathbb{R}^{t+q}, 0$ defined by

$$f(x_1, \cdots, x_s, v_1, \cdots, v_q) = \left(f_0(x) + \sum_{i=1}^{q} v_i\varphi_i, v_1, \cdots, v_q\right) \tag{1.5}$$

is infinitesimally stable by Theorem 1.1 and has a local algebra $Q(f) \xrightarrow{\sim} Q(f_0) \xrightarrow{\sim} Q$.

This leads to the third property.

THEOREM 1.6 (Normal form for infinitesimally stable germs). *Given an algebra Q satisfying certain conditions* (*which include the case* $\dim_{\mathbb{R}} Q < \infty$) (*see* [M4, *Thm.* B]), *then there is an infinitesimally stable germ f of the form* (1.5) *with local algebra $Q(f) \xrightarrow{\sim} Q$.*

These three results allow one to begin with an infinitesimally stable germ g, compute its local algebra $Q(g)$, construct a normal form f with local algebra $Q(f) \xrightarrow{\sim} Q(g)$. Then, by the classification theorem, f and g are locally equivalent, so the specifically given germ f can be used instead to study the local structure of g.

One consequence of these results is the following:

If $f: \mathbb{R}^n, 0 \to \mathbb{R}^p, 0$ is infinitesimally stable and $n \leqq p$ then by Mather [M4] $\dim_{\mathbb{R}} Q(f) < \infty$. Let N be the smallest integer so that $m_n^N \cdot Q(f) = 0$.

COROLLARY 1.7. *In the above situation if $h: \mathbb{R}^n, 0 \to \mathbb{R}^p, 0$ with $h = (h_1, \cdots, h_p)$ and $h_j \in m_n^{N+1}$, $1 \leqq j \leqq p$, then $f_1 = f + h$ is locally equivalent to f.*

Proof. By the classification theorem it is sufficient to show that $f + h$ is infinitesimally stable and $Q(f+h) \xrightarrow{\sim} Q(f)$. We may assume that we have chosen coordinates for $\mathbb{R}^n$ and $\mathbb{R}^p$ so that f has the form $f(x, u) = (\bar{f}(x, u), u)$ with $d\bar{f}(0) = 0$. We must further change coordinates to put $f_1 = f + h$ in this form; however, this will only change the coordinate functions of f by terms in m_n^{N+1}. Thus, f_1 has the form $(\bar{f}_1(x, u), u) = (\bar{f}(x, u) + g(x, u), u)$ with $g = (g_1, \cdots, g_t)$ and $g_i \in m_n^{N+1}$. Then, by the conditions on g,

$$I(f) = I(f_1) + m_n^{N+1} \quad \text{or} \quad I(f) = I(f_1) + m_n \cdot I(f).$$

By Nakayama's Lemma, $I(f) = I(f_1)$.

Second, with v_i denoting x_i or u_i,

$$\frac{\partial(\bar{f} + g)}{\partial v_i} \equiv \frac{\partial \bar{f}}{\partial v_i} \operatorname{mod} m_n^N.$$

Thus, in the verification criterion

$$N(\bar{f}(x, 0)) = N(\bar{f}_1(x, 0))$$

and

$$\left.\frac{\partial \bar{f}}{\partial u_i}\right|_{u=0} = \left.\frac{\partial f_1}{\partial u_i}\right|_{u=0} \quad \text{in } N(\bar{f}_1(x, 0)).$$

Thus, f_1 is infinitesimally stable and since $I(f_1) = I(f)$, $Q(f_i) \xrightarrow{\sim} Q(f)$. □

One consequence of the infinitesimal stability of a germ $f: \mathbb{R}^n, 0 \to \mathbb{R}^p, 0$ with $n \leqq p$ occurs when we wish to count solutions x near 0 to the equation $f(x) = y$ for y near 0. We define the *real multiplicity* of f:

$m(f) \overset{\text{def}}{=} \max \{k$: for all sufficiently small open neighborhoods V of 0 in $\mathbb{R}^p$ and U of 0 in $\mathbb{R}^n$, there is a $y \in V$ so that $\operatorname{card}(f^{-1}(y) \cap U) = k\}$.

For infinitesimally stable germs, $m(f)$ has several important properties summarized in the following theorem (see [DG] or [D2]).

THEOREM 1.8. *For infinitesimally stable f*

(1) *$m(f)$ only depends on $Q(f)$, i.e., it will be the same for different infinitesimally stable f between different dimensional spaces as long as they have isomorphic local algebras.*

(2) *In the case that* $\dim_{\mathbb{R}} \ker (df(0)) \leqq 2$ *or $Q(f)$ satisfies other conditions in* [DG] *then*

$$m(f) = \delta(f) \overset{\text{def}}{=} \dim_{\mathbb{R}} Q(f).$$

(3) *Even if f is not infinitesimally stable at* 0 *but $\delta(f) < \infty$, then $m(f) \leqq \delta(f)$ (see* [GG]).

We conclude this section by deducing from Theorem 1.1 and Corollary 1.2 consequences for germs of smooth Fredholm mappings $f: E, 0 \to F, 0$ between Banach spaces E and F. By the Lyapunov-Schmidt procedure, we may assume f has the form $\bar{f}(x, u) = (\bar{f}(x, u), u)$ for $u \in G$, $x \in E_1$ and $E \xrightarrow{\sim} E_1 \oplus G$, $F \xrightarrow{\sim} F_1 \oplus G$. Then, $f_0(x) = \bar{f}(x, 0): E_1, 0 \to F_1, 0$ is a smooth mapping between finite-dimensional spaces and so has a well-defined local algebra $Q(f_0)$.

LEMMA 1.9. *If $Q(f_0)$ is isomorphic to an algebra of an infinitesimally stable germ, then the algebra obtained by carrying out the Lyapunov-Schmidt procedure in a different way is still isomorphic to $Q(f_0)$.*

Thus, the algebra is an invariant of f and so, for such an f, we may denote the algebra by $Q(f)$ and call it the *local algebra of the smooth germ of a Fredholm mapping f.*

Note. In the case that f is Fredholm of index $\leqq 0$, then the condition on $Q(f_0)$ is equivalent to $\dim_{\mathbb{R}} Q(f_0) < \infty$ by another result of Mather [M4].

Proof. There is a germ $g: E \oplus \mathbb{R}^k, 0 \to F \oplus \mathbb{R}^k, 0$ defined by $g(x, u, v) = (\bar{f}(x, u) + \sum_{i=1}^{k} v_i \varphi_i, u, v)$, where $f_1(x, v) = (f_0(x) + \sum_{i=1}^{n} v_i \varphi_i, v)$ is a normal form for an infinitesimally stable germ with algebra $Q(f_0)$. Then, by Theorem 1.1, g is locally equivalent to $f_1 \times \mathrm{id}_G$ by $g = \Psi \circ (f_1 \times \mathrm{id}_G) \circ \Phi$ with Ψ, Φ germs of diffeomorphisms satisfying $\Psi | F_1 \oplus \mathbb{R}^n = \mathrm{id}$, $\Phi | E_1 \oplus \mathbb{R}^n = \mathrm{id}$.

If a Lyapunov-Schmidt procedure were applied using different local coordinates then in place of E_1 and F_1 we would obtain finite-dimensional submanifolds E_1' and F_1' such that $T_0 E_1' = E_1$ and $T_0 F_1' \oplus G = F$. Then, $f_0': E_1', 0 \to F_1', 0$ would be obtained as the restriction of g to E_1'. Hence, if E_1'' and F_1'' denote the images of E_1' and F_1' via Φ^{-1} and Ψ^{-1}, then f_0' is locally equivalent to $f_0'': E_1'', 0 \to F_1'', 0$ with f_0'' the restriction of $f_1 \times \mathrm{id}_G$ to E_1''. By the properties of Φ and Ψ, if p_1 and p_2 denote the linear projections $E \oplus \mathbb{R}^n \to E_1 \oplus \mathbb{R}^n$ and $F \oplus \mathbb{R}^n \to F_1 \oplus \mathbb{R}^n$ then $p_1 | T_0 E_1''$ is an isomorphism with image transverse to $\mathbb{R}^n$ and similarly for $p_2 | T_0 F_1''$. Let $E_1''' = p_1(E_2'')$, $F_1''' = p_2(F_1'')$ and $f_0''' = f_1 \times \mathrm{id} | E_1'''$. Then, $f_1 = p_2 \circ (f_1 \times \mathrm{id}_G)$ is constant on the fibers of p_1 so f_0''' is locally equivalent to f_0''. Finally, as E_1''' and F_1''' are transverse to $\mathbb{R}^n$ at 0, it follows that f_1 can be represented as an unfolding of f_0'''. Hence, $Q(f_0''') \xrightarrow{\sim} Q(f_1) \xrightarrow{\sim} Q(f_0)$. As f_0''' is locally equivalent to f_0', $Q(f_0''') \xrightarrow{\sim} Q(f_0')$ and the result follows. □

We can then summarize the consequences for germs of smooth nonlinear Fredholm maps.

THEOREM 1.10. *Let $f: E, 0 \to F, 0$ be an infinitesimally stable germ of a mapping of Banach spaces. Then*

(1) *f is locally equivalent to an infinitesimally stable germ $g: E, 0 \to F, 0$ iff $Q(f) \xrightarrow{\sim} Q(g)$ and their Fredholm indices are equal.*

(2) *Let $\mathfrak{m}$ denote the maximal ideal of $Q(f)$ and suppose $\mathfrak{m}^N \cdot Q(f) = 0$. If $h: E, 0 \to F, 0$ is a smooth germ such that $\|h\| \leqq O(\|x\|^{N+1})$, then $f + h$ is locally equivalent to f.*

(3) *If $df(0)$ has index $\leqq 0$ (as a Fredholm mapping) then $m(f)$ only depends on $Q(f)$ (i.e. it is the same for any other infinitesimally stable germ $f': E', 0 \to F', 0$ even with a different index $\leqq 0$ as long as $Q(f') \xrightarrow{\sim} Q(f)$).*

(4) *As in (3), and moreover if $\dim_{\mathbb{R}} \ker (df(0)) \leqq 2$ or $Q(f)$ satisfies other conditions in* [DG], *then $m(f) = \delta(f) \overset{\text{def}}{=} \dim_{\mathbb{R}} (Q(f))$.*

(5) *Even if f is not infinitesimally stable, but $Q(f)$ is isomorphic to the local algebra of an infinitesimally stable germ and the Fredholm index of $f \leqq 0$, then $m(f) \leqq \delta(f)$.*

2. Statements of main theorems. We use the notation and terminology of the preceding section to state the main results. We consider solutions to

$$x'' + m^2\lambda^2 x + P(x, x', t) = q(t) \tag{2.1}$$

with P continuous in (x, x', t), smooth in (x, x') but *without* linear terms and periodic of period $2\pi/\lambda$ in t. Associated to (2.1) we have the operator

$$f(x) = x'' + m^2\lambda^2 x + P(x, x', t) \tag{2.2}$$

as an operator $f: C^2_{(2\pi/\lambda)} \to C^0_{(2\pi/\lambda)}$ (recall that $C^k_{(2\pi/\lambda)}$ denotes the space of $2\pi/\lambda$-periodic C^k-functions on $\mathbb{R}$).

Many of the results about solutions of (2.1) for $q(t)$ near 0 follow from results about the operator f.

The first result is a weak form of genericity.

THEOREM 1. *Given $N \geqq 2$ with m and λ fixed, there is an integer r such that we may consider the space of the first r Fourier coefficients of the coefficient functions $a_{ij}(t)$ of terms $x^i x'^j$ of P with $i+j \leqq N$ for operators of the form* (2.2). *Then, for any such operator f, there is an open dense set of the space of such Fourier coefficients such that the operator is infinitesimally stable at* 0. *Thus, as mappings these operators are locally equivalent near* 0 *to mappings of the form $f_0 \times \mathrm{id}$ where $f_0: \mathbb{R}^k, 0 \to \mathbb{R}^k, 0$ is an infinitesimally stable germ* (*and* id *denotes the identity mapping on some Banach space*).

There is also a partial converse.

THEOREM 2. *Given any infinitesimally stable germ $f_0: \mathbb{R}^k, 0 \to \mathbb{R}^k, 0$ with $\dim_{\mathbb{R}} \ker (df(0)) = 2$, then there is an operator f of the form* (2.2) *such that as a mapping f is locally equivalent* (*near* 0) *to $f_0 \times \mathrm{id}$.*

Thus, the entire theory of Σ_2 stable map germs (i.e. mapping germs f with $\dim \ker df(0) = 2$) is needed to describe the possible structure for operators of the form (2.2).

Let f be such an infinitesimally stable operator of the form (2.2) and let Q denote its local algebra with maximal ideal $\mathfrak{m}$ so that $\mathfrak{m}^l \cdot Q = 0$ and $\dim_{\mathbb{R}} Q = \delta(Q)$. Then we may draw the following conclusions.

THEOREM 3. (1) *There are $q(t) \in C^0_{(2\pi/\lambda)}$ such that there are $\delta(Q)$* (*isolated*) *periodic solutions to* (2.1) *of period* $(2\pi/\lambda)$. *For $q(t)$ in a sufficiently small neighborhood of* 0, *this is the maximum number of solutions close to zero which can occur.*

(2) *These periodic solutions persist under deformations in the following sense*:

Let $P(x, x', t, \nu)$ and $Q(t, \nu)$ be continuous functions, smooth in (x, x', ν) (*respectively ν*) *for $\nu \in B_a(0) \subset E$, a Banach space, and periodic of period $(2\pi/\lambda)$ in t, so that $P(x, x', t, 0) = P(x, x', t)$ and $Q(t, 0) = q(t)$* (*as in* 1). *Then there are $\delta(Q)$ families of periodic solutions $x^{(i)}(t, \nu)$ to the equation*

$$x'' + m^2\lambda^2 x + P(x, x', t, \nu) = Q(t, \nu) \tag{2.3}$$

defined for $\|\nu\| < \varepsilon$ for some ε with $0 < \varepsilon < a$.

(3) *If $H(x, x', t)$ is continuous, smooth in (x, x') and periodic in t of period $(2\pi/\lambda)$, so that*

$$|H(x, x', t)| = O(\|(x, x')\|)^{l+1}$$

where $m^l \cdot Q = 0$ by hypothesis, then there still exists $q_H(t)$ so that

$$x'' + m^2\lambda^2 x + P(x, x', t) + H(x, x', t) = q_H(t) \tag{2.4}$$

has $\delta(Q)$ periodic solutions of period $(2\pi/\lambda)$.

As a corollary of this, we have the existence of polynomial P for which (2.1) has a specific number of periodic solutions.

THEOREM 4. *There is a polynomial P of total degree $2n-2$ in x and x' and a $q(t)$ such that* (2.1) *has n^2 periodic solutions.*

A specific example of a polynomial P with a given number of periodic solutions is given by the following.

Let

$$P(x, x', t) = \sin(\lambda t)(x^2 + x'^2) + \sum_{j=3}^{n+1} p_j(t)x^j \tag{2.5}$$

where

$$p_j(t) = a_j \cos((j-1)\lambda t) + b_j \sin((j-1)\lambda t) + c_j \cos(j\lambda t).$$

Then, as a corollary of Theorem 3, we have the following.

THEOREM 5. *For almost all c_j, and then for specific a_j and b_j, f obtained using* (2.5) *is infinitesimally stable with local algebra $\mathbb{R}[[x, y]]/(x^2 + y^2, x^{n+1})$. There is $q(t)$ which has only nonzero Fourier coefficients of degree $\leqq 2n$ so that with the above P,* (2.1) *has $2n+2$ (isolated) periodic solutions of period $(2\pi/\lambda)$.*

3. Outline of the method and some derivative computations. We begin by outlining the method we use and describing the role that subsequent sections play in carrying out the outline. The first step is to apply the Lyapunov-Schmidt procedure to the operator (2.2). For simplicity, we refer to the case $m = \lambda = 1$ so that $f: C^2_{2\pi} \to C^0_{2\pi}$. The form of Lyapunov-Schmidt we use is slightly different from its standard form. For our operator f, $df(0)$ is Fredholm of index 0 with $K = \ker df(0)$ spanned by $\{\cos(t), \sin(t)\}$, which also spans a subspace complementary to image $(df(0))$. Let W (respectively W') denote the L^2-orthogonal complement to K in $C^2_{2\pi}$ (respectively $C^0_{2\pi}$). Then: $df(0): W \xrightarrow{\sim} W'$. We define $\Phi: C^2_{2\pi} \to C^0_{2\pi}$ by $\Phi(x, u) = x + f(x, u)$ for $(x, u) \in K \oplus W$. By the inverse function theorem, Φ^{-1} is defined in a neighborhood U of 0; and $F = f \circ \Phi^{-1}: U \to C^0_{2\pi}$ has the form $F(x, u) = (\bar{F}(x, u), u)$ for $(x, u) \in K \oplus W'$. Then, we shall refer to this procedure of obtaining F from f as the Lyapunov-Schmidt procedure.

Our goal is to apply the verification criterion (1.3) to F to deduce that, under certain circumstances, F is infinitesimally stable. The results needed to apply the criterion will be developed in the remainder of this section and in §§ 4 and 5. The verification criterion requires us to compute certain derivatives of $\bar{F}$ at 0, and establish certain surjectivity properties. By the rule for derivatives of compositions, to do this we must be able to compute the derivatives of f at 0. The remainder of this section will be concerned with computations of such derivatives. Lemmas 3.10 and 3.15 provide the key surjectivity results (while Corollaries 3.12, 3.13 and Lemma 3.14 are mainly used for examples).

Second, the verification criterion is to be applied to the restriction of F to a finite-dimensional subspace V_m spanned by $\{\cos(rt), \sin(rt)\}_{r=0}^{m}$. We wish to know that terms involving eigenfunctions $\cos(st)$ and $\sin(st)$ for s sufficiently large (say $\geqq M$) will not affect the derivative computations after restriction. This is achieved by the noninterference Lemma 4.1 and its Corollary 4.9. They allow us, for example, to restrict our original f to a mapping from V_M to itself and apply Lyapunov-Schmidt to the finite-dimensional mapping. This allows us to use standard techniques for working with finite-dimensional mappings and to inductively establish the verification procedure by successively adding terms without altering the preceding surjectivity conditions.

Last, in § 5 we prove that adding a "model operator" to any operator f produces one satisfying the verification criterion. This gives a "universal model" for establishing infinitesimal stability (Theorem 5.4 and Corollary 5.9).

Once these results are in place, the proofs of the theorems follow very simply by the arguments in § 6. Sections 7 and 8 contain specific examples already referred to. We now proceed to the derivative computations.

We begin by simplifying notation and assuming $\lambda = 1$. Then, we consider derivatives of nonlinear operators from $C^2_{2\pi}$ to $C^0_{2\pi}$ which are sums of terms of the form

$$(a_1 \cos kt + a_2 \sin kt) \cdot x^i (x')^j. \tag{3.1}$$

Although we will be working with real mappings and derivatives, computations are easier to see conceptually using complex notation. Furthermore, in certain steps we will wish to show that certain real forms span a vector space of multilinear forms. It will be easier to show that the forms span the corresponding complex space of multilinear forms.

We use local coordinates (x_1, x_2) for the subspace spanned by $\cos(t)$ and $\sin(t)$. We let $\omega = \cos(t) + i\sin(t)$ with complex conjugate $\bar{\omega}$. Also, we let $z = x_1 + ix_2$ so that $x_1 \cos t + x_2 \sin t = (1/2)(\bar{z}\omega + z\bar{\omega})$. Similarly, for $x = a_1 + ia_2$, $a_1 \cos kt + a_2 \sin kt = (1/2)(\bar{x}\omega^k + x\bar{\omega}^k)$. Since $d/dt(\omega) = i\omega$ and $d/dt(\bar{\omega}) = -i\bar{\omega}$,

$$\frac{d}{dt}\left(\frac{1}{2}(\bar{z}\omega + z\bar{\omega})\right) = \left(\frac{i}{2}\right)(\bar{z}\omega - z\bar{\omega}).$$

Given a polynomial in ω and $\bar{\omega}$, $Q(\omega, \bar{\omega})$, we introduce the function which gives the constant term of Q,

$$\mathrm{Cst}\,(Q(\omega, \bar{\omega})) = Q(0, 0).$$

Then, we can compute the L^2-component of $Q(\omega, \bar{\omega})$ for $\cos(kt)$ or $\sin(kt)$ by taking L^2-inner products with $(1/\pi)\cos(kt)$ or $(1/\pi)\sin(kt)$. This can alternately be computed as

$$\mathrm{Cst}\,((\omega^k + \bar{\omega}^k) \cdot Q(\omega, \bar{\omega})) \quad \text{or} \quad \mathrm{Cst}\,((-i)(\omega^k - \bar{\omega}^k) \cdot Q(\omega, \bar{\omega})). \tag{3.2}$$

More generally, if we let (u_k, v_k) denote coordinates for the subspace $\langle\cos(kt), \sin(kt)\rangle$, and let $w_k = u_k + iv_k$, then from (3.2),

$$w_k = 2 \cdot \mathrm{Cst}\,(\omega^k \cdot Q(\omega, \bar{\omega})). \tag{3.3}$$

Now consider $f: C^2_{2\pi} \to C^0_{2\pi}$ defined by

$$f(x) = (a_1 \cos(rt) + a_2 \sin(rt)) \cdot x^j (x')^k. \tag{3.4}$$

A standard computation yields

$$\frac{1}{m!}d^m f(0)(l_1, \cdots, l_m)$$

(3.5) $$= \begin{cases} 0, & m < j+k, \\ \frac{1}{m!}(a_1 \cos(rt) + a_2 \sin(rt)) \sum l_{\sigma(1)} \cdots l_{\sigma(j)} l'_{\sigma(j+1)} \cdots l'_{\sigma(k)} & \\ \qquad \text{(summed over } \sigma \in S_m) & \text{if } m = j+k. \end{cases}$$

We will consider several special cases of (3.5).

Case 1. If we evaluate (3.5) for $l_i = (1/2)(\bar{z}\omega + z\bar{\omega})$ for all i we obtain

(3.6) $$w_1 = \text{Cst}\,(\omega \cdot (\bar{\alpha}\omega^r + \alpha\bar{\omega}^r) \cdot (1/2)^m \cdot i^k(\bar{z}\omega + z\bar{\omega})^j(\bar{z}\omega - z\bar{\omega})^k).$$

Case 2. If $j = m$, $k = 0$, $l_1 = \cdots = l_{m-1} = (1/2)(\bar{z}\omega + z\bar{\omega})$ and $l_m = (1/2)(\bar{\beta}\omega^s + \beta\bar{\omega}^s)$ with $\beta = b_1 + ib_2$, then for (3.5)

(3.7) $$w_q = \text{Cst}\,(\omega^q \cdot (\bar{\alpha}\omega^r + \alpha\bar{\omega}^r) \cdot (\bar{\beta}\omega^s + \beta\bar{\omega}^s) \cdot (1/2)^m \cdot (\bar{z}\omega + z\bar{\omega})^{m-1}).$$

Case 3. Last, if $k = 1$, $l_1 = \cdots = l_j = (1/2)(\bar{z}\omega + z\bar{\omega})$ (and $m = j+1$) and $l_{j+1} = (1/2)(\bar{\beta}\omega^s + \beta\bar{\omega}^s)$, then for (3.5)

(3.8) $$w_1 = \text{Cst}\,(\omega \cdot (\bar{\alpha}\omega^r + \alpha\bar{\omega}^r) \cdot \Psi)$$

where

(3.9) $$\Psi = (i/j+1)\{j(\bar{\beta}\omega^s + \beta\bar{\omega}^s)(\bar{z}\omega + z\bar{\omega})^{j-1}(\bar{z}\omega - z\bar{\omega}) + s(\bar{\beta}\omega^s - \beta\bar{\omega}^s)(\bar{z}\omega + z\bar{\omega})^j\}.$$

Let (3.6), with α replaced by $\alpha_{jk}^{(r)}$, be denoted by $\Psi_{jk}^{(r)}$. Also, let $S^m(x_1, x_2)$ denote the vector space of real homogeneous polynomials of degree m in (x_1, x_2). Let $S_{\mathbb{C}}^m(x_1, x_2)$ denote the corresponding complex vector space. The $\Psi_{jk}^{(r)}$ are elements of $S^m(x_1, x_2) \times S^m(x_1, x_2)$ with $m = j+k$.

LEMMA 3.10. *$\{\Psi_{jk}^{(r)}: j+k = m, 0 \leqq r \leqq m\}$ span $S^m(x_1, x_2) \times S^m(x_1, x_2)$.*

Proof. We first observe that $S_{\mathbb{C}}^m(x_1, x_2)$ can be identified with $S^m(x_1, x_2) \times S^m(x_1, x_2)$ by $g + ih \mapsto (g, h)$. Via this identification, $\{z^j\bar{z}^k: j+k = m\}$ is a basis over $\mathbb{C}$ (since $x_1 = (1/2)(z + \bar{z})$, $x_2 = (i/2)(z - \bar{z})$ we may expand $x_1^n x_2^l = (1/2)^{n+l}(-i)^l(z+\bar{z})^n(z-\bar{z})^l$ to represent $x_1^n x_2^l$ as a linear combination of $z^j\bar{z}^k$). Thus viewing the elements $\Psi_{jk}^{(r)}$ as elements of $S_{\mathbb{C}}^m(x_1, x_2)$, it is sufficient to represent each $z^j\bar{z}^k$ as a complex linear combination of such elements. Consider

(3.11) $$\begin{aligned} w_1 &= \text{Cst}\,(\omega \cdot (\bar{\alpha}\omega^r + \alpha\bar{\omega}^r) \cdot (z^j\bar{\omega}^j)(\bar{z}^k\omega^k)) \\ &= \text{Cst}\,((\bar{\alpha}\omega^{r+1} + \alpha\bar{\omega}^{r-1})\omega^{k-j}) \cdot z^j\bar{z}^k. \end{aligned}$$

If $k \geqq j$ and $r = 1 + k - j$, then $w_1 = \alpha z^j\bar{z}^k$. If α represents an arbitrary complex number, we obtain the complex subspace spanned by $z^j\bar{z}^k$. If instead $j > k$, we use $r' = j - k - 1$ and obtain $\bar{\alpha}' z^j\bar{z}^k$. Again if α' is an arbitrary complex number then we obtain the subspace spanned by $z^j\bar{z}^k$.

Now, using in (3.11)

$$\bar{z}\omega = (1/2)(\bar{z}\omega + z\bar{\omega}) - i((i/2)(\bar{z}\omega - z\bar{\omega})),$$

$$z\bar{\omega} = (1/2)(\bar{z}\omega + z\bar{\omega}) + i((i/2)(\bar{z}\omega - z\bar{\omega}))$$

and expanding we obtain $z^j\bar{z}^k$ as a complex linear combination of $\{\Psi_{jk}^{(r)}\}$. □

We obtain the following as corollaries of the method.

COROLLARY 3.12. *In* (3.6) *with $r = m-1$, $j = m$, $k = 0$, $w_1 = (1/2)^m\bar{\alpha}z^m$ modulo terms of the form $(z \cdot \bar{z}) \cdot h$.*

COROLLARY 3.13. *For $f(x)=\sin(t)(x^2+x'^2)$, with $l_i=(1/2)(\bar z\omega+z\bar\omega)$ $i=1,2$, the w_1 component of $(1/2!)d^2f(0)(l_1,l_2)$ equals $iz\bar z$. If $l_2=(1/2)(\bar w_3\omega^3+w_3\bar\omega^3)$, it equals*

$$(1/4)(-i)(\bar z w_3)=\tfrac14(v_3x_2-u_3x_1,\ u_3x_2+v_3x_1).$$

For Case 2 we have the following lemma.

LEMMA 3.14. (1) *When $q=1$ and $r+s>m$ expression* (3.7) *equals*

$$\left(\frac12\right)^m\cdot\left\{\binom{m-1}{a}\alpha\bar\beta\bar z^{m-1-a}z^a+\binom{m-1}{a-1}\bar\alpha\beta z^{m-a}\bar z^{a-1}\right\}$$

if $r-s-1=m-1-2a$ and $0\leqq a\leqq m$; otherwise it equals 0.

(2) *When $r>s>q>m-1$, it equals*

$$\left(\frac12\right)^m\cdot\alpha\bar\beta\binom{m-1}{a}\bar z^{m-1-a}z^a$$

if $r-s-q=m-1-2a$ and $0\leqq a\leqq m-1$; otherwise it is 0 (*note by convention* $\binom{m-1}{m}=\binom{m-1}{-1}=0$).

Proof.

$$\omega^q(\bar\alpha\omega^r+\alpha\bar\omega^r)(\bar\beta\omega^s+\beta\bar\omega^s)=\bar\alpha\bar\beta\omega^{r+s+q}+\alpha\beta\bar\omega^{r+s-q}+\bar\alpha\beta\omega^{r-s+q}+\alpha\bar\beta\bar\omega^{r-s-q}.$$

In the first case, only the last two terms can have exponent $\leqq m-1$ in absolute value. In the second case, only the last term is possible. Thus, if $r-s-q=m-1-2a$, then (2) is as stated and we have the extra term if $q=1$. □

LEMMA 3.15. *Expression* (3.8), *with $r>j+1$, $s\geqq0$, is equal to*

$$\left(\frac{i}{j+1}\right)\left[-\bar\alpha\beta\left\{(s-j)\binom{j}{a}+(s+j)\binom{j}{a-1}\right\}\bar z^{j-a}z^a\right.$$
$$\left.+\alpha\bar\beta\left\{(s-j)\binom{j}{a-1}+(s+j)\binom{j}{a-2}\right\}z^{j+1-a}\bar z^{a-1}\right]\tag{3.16}$$

if $s=r+j+1-2a$ and $0\leqq a\leqq j$;

and equals 0 *if $s(\geqq0)$ is not of the above form.*

Proof. We first compute Ψ in (3.8):

$$\Psi=\left(\frac{i}{j+1}\right)(\bar z\omega+z\bar\omega)^{j-1}\{j(\bar\beta\omega^s+\beta\bar\omega^s)(\bar z\omega-z\bar\omega)+s(\bar\beta\omega^s-\beta\bar\omega^s)(\bar z\omega+z\bar\omega)\}.$$

Thus,

$$\omega(\bar\alpha\omega^r+\alpha\bar\omega^r)\cdot\Psi=\left(\frac{i}{j+1}\right)(\bar z\omega+z\bar\omega)^{j-1}\cdot\Psi_1\tag{3.17}$$

where a computation yields

$$\Psi_1=(s+j)(\bar\alpha\bar\beta\bar z\omega^{r+s+2}-\alpha\beta z\bar\omega^{r+s}+\alpha\bar\beta\bar z\omega^{s+2-r}-\beta\bar\alpha z\bar\omega^{s-r})$$
$$+(s-j)(\bar\alpha\bar\beta z\omega^{r+s}-\alpha\beta\bar z\bar\omega^{r+s-2}+\alpha\bar\beta z\omega^{s-r}-\bar\alpha\beta\bar z\bar\omega^{s-r-2}).$$

From (3.17), the formula for Ψ_1 yields, for (3.8) with $s=r+j+1-2a$, the expression

$$-\bar\alpha\beta\left\{(s-j)\binom{j}{a}\bar z\cdot\bar z^{j-1-a}z^a+(s+j)\cdot\binom{j}{a-1}z\bar z^{j-1-(a-1)}\cdot z^{a-1}\right\}$$
$$+\alpha\bar\beta\left\{(s-j)\binom{j}{a-1}\cdot z\cdot z^{j-1-(a-1)}\bar z^{a-1}+(s+j)\binom{j}{a-2}\cdot\bar z\cdot z^{j-1-(a-2)}\bar z^{a-2}\right\}$$

(where $\binom{j}{c}=0$ if $c<0$). This gives the desired formula upon rearrangement. If s is not of this form, then (3.17) is without constant terms and so (3.8) is zero. □

4. A noninterference lemma. We consider an operator f obtained by adding to $x''+x$ a finite number of terms of the form $(a \sin kt + b \cos kt)\cdot x^i(x')^j$ with $i+j>1$ (and say $i+j \leqq n$). Let

$$V_m = \text{vector space spanned by } \{\cos(kt), \sin(kt), 0 \leqq k \leqq m\}.$$

Then, we shall show that given $m>0$, there is an $M>0$ so that the n-jet of the germ obtained by applying the Lyapunov-Schmidt procedure to f and restricting to V_m does not depend on the Fourier coefficients of order $\geqq M$ of the image of the original f. In essence, the higher eigenfunctions do not interfere with the nonlinear behavior of the Lyapunov-Schmidt form of f on V_m.

More specifically, let $\Phi: C^2_{2\pi} \to C^0_{2\pi}$ be defined by $\Phi(x, u) = x + f(x, u)$ for $x \in K = \ker(df(0))$ and u belonging to the L^2-orthogonal complement in $C^2_{2\pi}$. Then, $f\circ\Phi^{-1}: C^0_{2\pi} \to C^0_{2\pi}$ gives the Lyapunov-Schmidt reduction. We let W_m denote the L^2-orthogonal complement to V_m in $C^0_{2\pi}$, and P_m denote the projection onto V_m along W_m. Define $f_2 = P_M \circ f \mid V_M$ (with M to be determined). Also, let $\Phi': V_M \to V_M$ be defined by $\Phi' = P_M \circ \Phi \mid V_M$ so that $\Phi'(x, u') = x + f_2(x, u')$. Then, $f_2 \circ \Phi'^{-1}: V_M \to V_M$ is the Lyapunov-Schmidt reduction for f_2. Finally, we let $f_1 = f_2 \circ \Phi'^{-1} \mid V_m : V_m \to V_m$ (here $m<M$). Note $f_1(V_m) \subseteq V_m$ by Lyapunov-Schmidt. Then, the n-jets of f_1 and $f\circ\Phi^{-1}$ are related by the following lemma.

LEMMA 4.1. *Given $m>0$, there is an integer $M>m$ such that for $1 \leqq j \leqq n$*

$$\text{(i)} \qquad d^j(f\circ\Phi^{-1})(0) \mid V_m \times\cdots\times V_m = d^j f_1(0),$$

$$\text{(ii)} \qquad d^j(P_m \circ f \circ \Phi^{-1})(0) \mid V_m \times\cdots\times V_m \times W_M \equiv 0.$$

Proof. First we prove (i). Let

$$K = \max\{k: \cos(kt) \text{ or } \sin(kt) \text{ appears as a coefficient of a term of } f\}.$$

We inductively define a sequence of integers by $m_1 = m$, and $m_j > (n+1)m_j + K$ for $1 < j \leqq n+1$ and let $M = m_{n+1}$. We claim this M will suffice for (i).

Let Q_j denote the projection onto W_{m_j} along V_{m_j} and let P_{m_j} be denoted just by P_j. Then, we first observe

$$Q_{j+1} \circ d^j f(0) \mid V_{m_j} \times\cdots\times V_{m_j} \equiv 0. \tag{4.2}$$

This follows from (3.5) since to have a component of $\cos(st)$ or $\sin(st)$ for $d^j f(0)$, we must have $s \leqq j\cdot m_j + K < m_{j+1}$ with $j \leqq n$.

Next, temporarily let P_1' denote the projection onto $\langle\cos(t), \sin(t)\rangle$ along its L^2 orthogonal complement in $C^2_{2\pi}$. Then, $\Phi = P_1' + f$ so

$$d^j\Phi(0) = \begin{cases} P_1' + df(0), & j=1, \\ d^j f(0), & j>1. \end{cases}$$

Thus,

$$Q_{j+1}\circ d^j\Phi(0) \mid V_{m_j}\times\cdots\times V_{m_j} = \begin{cases} (Q_{j+1}\circ P_1') + (Q_{j+1}\circ df(0) \mid V_{m_1}), & j=1, \\ Q_{j+1}\circ d^j f(0) \mid V_{m_j}\times\cdots\times V_{m_j}, & j>1 \end{cases}$$

or

$$Q_{j+1}\circ d^j\Phi(0) \mid V_{m_j}\times\cdots\times V_{m_j} = 0, \qquad j \geqq 1.$$

Thus,

$$d^j\Phi(0)\,|\,V_{m_j}\times\cdots\times V_{m_j}=P_{j+1}\circ d^j\Phi(0)\,|\,V_{m_j}\times\cdots\times V_{m_j} \tag{4.3}$$
$$=d^j\Phi'(0)\,|\,V_{m_j}\times\cdots\times V_{m_j},\qquad j\geqq 1$$

and

$$d^j\Phi(0)(V_{m_j}\times\cdots\times V_{m_j})\subset V_{m_{j+1}},\qquad j\leqq n. \tag{4.4}$$

Let L^l denote the l-multilinear operator.

$$L^l\overset{\text{def}}{=}(d\Phi(0))^{-1}\circ d^l\Phi(0).$$

By an expression in L of depth r we mean a term of the form L^l if $r=1$, while for $r>1$ we mean an expression (i.e. a composition) $L^s(L^{j_1},\cdots,L^{j_s})$ where each L^{j_i} is an expression of depth $r-1$. We claim that if $\Psi(L)$ is an expression in L of depth r then

$$\text{Image}\,(\Psi(L)\,|\,V_{m_1}\times\cdots\times V_{m_1})\subset V_{m_r}.$$

This follows by induction using (4.4) and the fact that $d\Phi(0)$ preserves the V_{m_j}. Furthermore, by another induction argument, if we replace L^l by

$$L'^l=(d\Phi'(0))^{-1}\circ d^l\Phi'(0)$$

then

$$\Psi(L)\,|\,V_{m_1}\times\cdots\times V_{m_1}=\Psi(L'). \tag{4.5}$$

Now,

$$d^lf_1(0)=d^l(f_2\circ\Phi'^{-1})(0)\,|\,V_{m_1}\times\cdots\times V_{m_1}$$
$$=P_1\circ d^l(f\circ\ \Phi'^{-1})(0)\,|\,V_{m_1}\times\cdots\times V_{m_1}.$$

We finally claim that

$$d^l(f\circ\Phi'^{-1})(0)\,|\,V_{m_1}\times\cdots\times V_{m_1}=d^l(f\circ\Phi^{-1})(0)\,|\,V_{m_1}\times\cdots\times V_{m_1}. \tag{4.6}$$

Then by the Lyapunov-Schmidt procedure, $Q_2(f\circ\Phi^{-1})=Q_2$; hence we may compose the left-hand side of (4.6) with P_1 and equality remains; the first result will follow. For this final claim we proceed in two steps. First, by the product rule $d^l(f\circ\ \Phi^{-1})(0)$ is a sum of terms of the form

$$d^rf(0)(d^{l_1}\Phi^{-1}(0),\cdots,d^{l_r}\Phi^{-1}(0))$$

with coefficients only depending upon r, $l_1,\cdots,l_r$ (see e.g. [F] or [R]).

Thus, if

$$d^l(\Phi^{-1})(0)\,|\,V_{m_1}\times\cdots\times V_{m_1}=d^l(\Phi'^{-1})(0)\,|\,V_{m_1}\times\cdots\times V_{m_1} \tag{4.7}$$

and both have images in V_{m_l}, then by the product rule and (4.2) we have equality in (4.6).

Lastly, to establish (4.7) we again apply the product rule to

$$\Phi\circ\Phi^{-1}=\text{id}\quad\text{or}\quad\Phi_1\circ\Phi_1^{-1}=\text{id}_{V_{m_{n+1}}}$$

to obtain that $d^l\Phi^{-1}(0)$ is a sum of terms with well-determined coefficients which are expressions in L, as defined above. A similar statement applies to $d^l\Phi'^{-1}(0)$ and L'. Thus by (4.5), (4.7) is valid.

For (ii), we let the M from (i) be denoted by m' and reapply (i) for m' in place of m, obtaining $m'_j > (n+1)m'_{j-1} + K$ and $M' = m'_{n+1}$. This implies $m'_j - (n \cdot m'_1 + K) > m'_{j-1}$. By the product rule, to prove (ii), it is sufficient to prove that the terms

$$P_1 \circ d^r f(0)(d^{l_1}(\Phi^{-1})(0), \cdots, d^{l_r}(\Phi^{-1})(0)) \,|\, V_{m_1} \times \cdots \times V_{m_1} \times W_{M'}$$

are identically zero (recall $P_1 \overset{\text{def}}{=} P_{m_1}$). Since

$$d^l(\Phi^{-1})(0)(V_{m_1} \times \cdots \times V_{m_1}) \subset V_{m_l} \subset V_{m'}, \qquad l \leqq n,$$

it is sufficient to show that

$$(4.8) \qquad d^l(\Phi^{-1})(0)(V_{m'} \times \cdots \times V_{m'} \times W_{M'}) \subset W_{m'_2}$$

since then

$$d^r f(0)(V_{m'} \times \cdots \times V_{m'} \times W_{m'_2}) \subset W_{m'_1}$$

by the above inequality for m'_j. However, as we already mentioned, $d^l(\Phi^{-1})(0)$ is a sum of terms each of which is an expression in L of depth $l \leqq n$. At each stage, the image will be one lower $W_{m'_j}$; hence, each term will be in $W_{m'_2}$. Thus, so will (4.8). □

As a corollary of the method of proof we have the following additional result.

COROLLARY 4.9. *Given f, M, and m as in Lemma* 4.1, *let*

$$g(x, x', t) = \sum b_{ij}(t) x^i x'^j$$

summed for $i + j = k$ (with fixed $k \leqq n$) with $b_{ij}(t) \in W_M$. Let g_1 be obtained from $f + g$ by applying Lyapunov-Schmidt; then

(i) $d^j(f \circ \Phi^{-1})(0) \,|\, V_m \times \cdots \times V_m = d^j g_1(0) \,|\, V_m \times \cdots \times V_m, \qquad 1 \leqq j \leqq k,$

(ii) $P'_1 \circ d^k g(0) \circ d\Phi^{-1}(0) \,|\, V_m \times \cdots \times V_m \times W_M = d^k g_1(0) \,|\, V_m \times \cdots \times V_m \times W_M.$

Remark. In fact, a slightly more careful analysis allows us to conclude (i) for $1 \leqq j \leqq 2k - 2$.

5. A universal model. Consider a family of operators of the form

$$f(x, \nu) = x'' + \lambda^2 x + P(x, x', \nu, t)$$

with $\nu \in E$, and $\|P\| = O(\|x\|^2 + \|x'\|^2)$ (with P continuous, smooth in (x, x', ν), and periodic in t of period $2\pi/\lambda$). We may simultaneously apply Lyapunov-Schmidt and obtain a family which we may further restrict to some V_m.

$$F: U \to V_m \times E, \qquad F(x, u, \nu) = (\bar{F}(x, u, \nu), u, \nu)$$

for U an open neighborhood of 0 in $V_m \times E$ with $x \in \langle \sin(t), \cos(t) \rangle$, and u belonging to the orthogonal complement of $\langle \sin(t), \cos(t) \rangle$ in V_m. Looking at the nth order Taylor expansion of F with respect to x, we have in local coordinates $x = (x_1, x_2)(x^{\boldsymbol{\alpha}} = x_1^{\alpha_1} x_2^{\alpha_2}$ for $\boldsymbol{\alpha} = (\alpha_1, \alpha_2))$

$$\bar{F}(x, u, \nu) = \left(\sum_{1 \leqq |\boldsymbol{\alpha}| \leqq n} v_{\boldsymbol{\alpha}} x^{\boldsymbol{\alpha}}, \sum_{1 \leqq |\boldsymbol{\alpha}| \leqq n} v'_{\boldsymbol{\alpha}} x^{\boldsymbol{\alpha}} \right) + H \quad \text{with } \|H\| = O(\|x\|^{n+1} + \|x'\|^{n+1})$$

and $v_{\boldsymbol{\alpha}}$, $v'_{\boldsymbol{\alpha}}$ functions of (u, ν). If we let

$$\{v_{\boldsymbol{\alpha}}, v'_{\boldsymbol{\alpha}}: 1 \leqq |\boldsymbol{\alpha}| \leqq n\}$$

denote coordinates for a space T, this defines a mapping $v: U' \to T$ sending $(u, \nu) \mapsto (v_{\boldsymbol{\alpha}}(u, \nu), v'_{\boldsymbol{\alpha}}(u, \nu))$: $1 \leqq |\boldsymbol{\alpha}| \leqq n$. Here $U' = U_1 \times U_2$ is a neighborhood of 0 in $\langle \sin(t), \cos(t) \rangle^{\perp} \oplus E$. We let T_1 denote the subspace of T defined by the vanishing of

$\{v_\alpha, v'_\alpha: |\alpha|=1\}$. Given an operator $f_0(x)=x''+\lambda^2x+P(x,x',t)$ we consider a family of operators of the form

$$f(x,\nu)=f_0(x)+G(x,\nu) \tag{5.1}$$

where $G(x,\nu)=G_1+G_2$ with

$$G_1=\sum_{\substack{1\leqq k\leqq i+j\\ 2\leqq i+j\leqq n}}(a_{ij}^{(k)}\cos(kt)+b_{ij}^{(k)}\sin(kt))x^ix'^j \tag{5.2}$$

and

$$G_2=\sum_{i=2}^{n+1}(c_i\sin(r_it)+d_i\cos(r_it)+c'_i\sin(r'_it)+d'_i\cos(r'_it))x^{i-1}x'. \tag{5.3}$$

Let $\nu=(\nu_1,\nu_2)$, where ν_1 denotes the set of all coefficients $\{a_{ij}^{(k)}, b_{ij}^{(k)}\}$ and ν_2 denotes the set of all coefficients $\{c_i, d_i, c'_i, d'_i\}$. Let E_i denote the subspace with local coordinates ν_i and $E=E_1\oplus E_2$.

THEOREM 5.4. *There are integers r_i, r'_i such that for any f_0:*

(i) *For any $\nu_2\in E_2$, $v|(U_2\cap E_1): U_2\cap E_1\to T_1$ is a submersion at* 0.

(ii) *For any $\nu_1\in E_1$ and almost all $\nu_2\in E_2$ $v|U_1: U_1\to T$ is a submersion at* 0.

Proof. We repeatedly apply Lemma 4.1 $2n-1$ times beginning with $m_0=n+1$ and at the jth step increasing $K=m_{j+1}$ to obtain $m_0, m_1, \cdots, m_{2n-1}$. We choose r_i and r'_i so that $|r_i-r'_i|>4(i+1)$ and $m_0<m_1<r_1$, $r'_1<m_2<m_3<r_2$, $r'_2<m_4\cdots<m_{2n-1}<r_{n+1}$, r'_{n+1}. For (i), we first observe that the only derivative of f in which the $a_{ij}^{(k)}$ or $b_{ij}^{(k)}$ appear is the $i+j$th derivative. Thus, for $d^l\bar{F}(0)=P'\circ d^l(f\circ\Phi^{-1})$, we obtain from the formula for the derivative of compositions that the coefficients $a_{ij}^{(k)}$ and $b_{ij}^{(k)}$ do not appear in $d^l\bar{F}(0)$ if $l<i+j$. If $l=i+j$, then they only appear in the term

$$P'\circ d^lf\circ d\Phi^{-1}(=P'\circ d^lf \text{ when restricted to } \langle\sin(t),\cos(t)\rangle)$$

(recall P' denotes projection onto $\langle\sin(t),\cos(t)\rangle$). We remark that they also appear in $df\circ d^l(\Phi^{-1})$; however composing with P' annihilates this term.

Hence, evaluating (3.6) we obtain, with $\alpha_{jk}^{(l)}=a_{jk}^{(l)}+ib_{jk}^{(l)}$, that the $i+j$th-order terms of $\bar{F}$ involving $a_{ij}^{(k)}$ and $b_{ij}^{(k)}$ equal $\Psi_{ij}^{(k)}$, in the notation of Lemma 3.10. Thus, by Lemma 3.10 and the preceding discussion, the derivatives

$$\left.\frac{\partial\bar{F}}{\partial a_{ij}^{(k)}}\right|_{\nu_1=0}, \left.\frac{\partial\bar{F}}{\partial b_{ij}^{(k)}}\right|_{\nu_1=0} : i+j=s, \qquad 1\leqq k\leqq i+j$$

span $S^s(x_1,x_2)\times S^s(x_1,x_2)$ modulo higher order terms. The union of such derivatives for $2\leqq s\leqq n$, span T_1 so (i) holds.

For (ii), we let $\alpha_j=d_j+ic_j$, $\alpha'_j=d'_j+ic'_j$, and $w_s=u_s+iv_s$, where $s=r_j+j+1-2a$, $0\leqq a\leqq j$, or a corresponding formula for s' with r_j replaced by r'_j, $2\leqq j\leqq n$. We also let U_0 denote $U_1\cap V'$, where V' is the subspace spanned by the eigenfunctions $\cos(s''t)$, $\sin(s''t)$ for $s''=s$ or s' satisfying the preceding conditions. Then we shall show that (ii) holds even for the subset U_0. It is sufficient to show that

$$\left.\frac{\partial v}{\partial u_{s''}}\right|_{\langle\sin t,\cos t\rangle}, \quad \left.\frac{\partial v}{\partial v_{s''}}\right|_{\langle\sin t,\cos t\rangle} \tag{5.5}$$

span T for almost all choices of coefficients $\{\alpha_j, \alpha'_j\}$, where we undertand that in (5.5) s'' runs through all allowable values. By the way that the r_j and r'_j were chosen, the w_s and $w_{s'}$ are all distinct as j and a range over the allowable values just given. We first show that the lowest-order terms of the derivatives involving u_s and v_s (or $u_{s'}$, $v_{s'}$)

span T. We apply Lemma 3.15, with α replaced by α_j and α_j' and β replaced by w_s or $w_{s'}$. It is sufficient to show that (3.16) with $\alpha\bar{\beta}$ respectively real and purely imaginary, and for both s and s', spans a 4-dimensional real subspace to obtain both $\bar{z}^{j-a}z^a$ and $z^{j+1-a}\bar{z}^{a-1}$ in both coordinates. By subtracting versions of (3.16) for $\alpha\bar{\beta}$ real and s (respectively s') we obtain a real multiple of

$$(5.6)\qquad i\cdot(s-s')\left\{-\left(\binom{j}{a}+\binom{j}{a-1}\right)\bar{z}^{j-a}z^a+\left(\binom{j}{a-1}+\binom{j}{a-2}\right)z^{j+1-a}\bar{z}^{a-1}\right\}$$

or equivalently,

$$i\cdot(r_j-r_j')\left\{-\binom{j+1}{a}\bar{z}^{j-a}z^a+\binom{j+1}{a-1}z^{j+1-a}\bar{z}^{a-1}\right\}.$$

Subtracting a multiple of (5.6) from (3.16), we obtain a multiple of

$$(5.7)\qquad i\left[-\left\{-\binom{j}{a}+\binom{j}{a-1}\right\}\bar{z}^{j-a}z^a+\left\{-\binom{j}{a-1}+\binom{j}{a-2}\right\}z^{j-1-a}\bar{z}^{a-1}\right].$$

Then, adding and subtracting multiples of (5.6) and (5.7) yields multiples of

$$i\left(\binom{j}{a-1}\bar{z}^{j-a}z^a+\binom{j}{a-2}z^{j+1-a}\bar{z}^{a-1}\right)\quad\text{and}\quad i\left(\binom{j}{a}\bar{z}^{j-a}z^a-\binom{j}{a-1}z^{j+1-a}\bar{z}^{a-1}\right),$$

which are always linearly independent if $a \geqq 1$ (or they give just $i\binom{j}{0}\bar{z}^j$ if $a=0$). For $\alpha\bar{\beta}$ purely imaginary we obtain real multiples instead. This gives the claim. These elements will, in general, generate the four-dimensional subspace for a Zariski open subset of α_j, α_j', which we have just seen is nonempty.

Now we proceed to show inductively that the elements of (5.5) corresponding to r_j, r_j', $2 \leqq j \leqq k-1$ and allowable a, span T modulo the space T_k defined by the vanishing of $\{v_{\boldsymbol{\alpha}}, v_{\boldsymbol{\alpha}}' \colon |\boldsymbol{\alpha}| \leqq k\}$. This is true for T modulo T_1 by the preceding discussion since the elements of (5.5) for r_2 and r_2' map to a basis for T modulo T_1; and so adding fixed linear terms to them will not change this for a generic choice of coefficients c_2, d_2, c_2', d_2'. If now the result is true for $k<l$, then the terms of (5.5) corresponding to r_{l+1} and r_{l+1}' are of the form $\varphi_i+\varphi_i'+\varphi_i''$, where φ_i have zero coefficients $v_{\boldsymbol{\alpha}}$, $v_{\boldsymbol{\alpha}}'$ for $|\boldsymbol{\alpha}| \geqq l$, φ_i' only has nonzero coefficients for $|\boldsymbol{\alpha}|=l$, and $\varphi_i'' \in T_l$. By the earlier discussion the φ_i' span T_{l-1}/T_l. By induction, we may subtract off constant multiples of the terms given by the induction hypothesis to obtain $\varphi_i=0$. Then, in terms of a basis for T_{l-1}/T_l, the φ_i' have the matrix representation

$$(5.8)\qquad B+c_{l+1}A_1+d_{l+1}A_2+c_{l+1}'A_3+d_{l+1}'A_4$$

where B and A_i are fixed with generic sums of the A_i being nonsingular; thus a determinant argument implies (5.8) is nonsingular for almost all choices of c_{l+1}, etc. This completes the induction step. After n steps, we obtain the conclusion for (ii).

As a corollary, we have the following.

COROLLARY 5.9. *Let $P=0$ with the preceding notation. If W is a neighborhood of 0 in E, then there exists a neighborhood V of 0 in T_1 such that for every $h \in V$, there exists $\nu=(\nu_1,\nu_2) \in W$ so that $v(0,\nu)=h$ and $v\,|\,U_1$ is a submersion at 0.*

Proof. We prove the result by induction on n. It is vacuously true if $n=1$. Suppose it is true for $n-1$. We let $v^{(n-1)}$, $E_1^{(n-1)}$, $E_2^{(n-1)}$ denote the corresponding objects for $n-1$. Then, $E_i=E_i^{(n-1)}\oplus E_i'$, where E_i' denotes the subspace corresponding to $\{a_{ij}^{(k)}, b_{ij}^{(k)} \colon i+j=n\}$ if $i=1$ or $\{c_{n+1}, c_{n+1}', d_{n+1}, d_{n+1}'\}$ if $i=2$. Given $W \subset E_1 \oplus E_2$ we may find $W_i \subset E_i$ so that $W_1 \times W_2 \subset W$. We may further assume $W_i = W_i' \times W_i''$ according to the above decompositions for E_i. We also decompose $\nu \in W$, $\nu = (\nu_1, \nu_2)$ with $\nu_i = (\nu_i', \nu_i'')$.

Observe that $v(W_1'')$ is a neighborhood of 0 in T_{n-1} (this follows from the proof of (i) in Theorem 5.4). We choose a neighborhood V_1 of 0 in T_{n-1} so that if $h_1, h_2 \in V_1$, then $h_1 - h_2 \in v(W_1'')$. Then by continuity there exists a neighborhood Z of 0 in E such that the following composition maps into V_1

$$Z \xrightarrow{v} T_1 \xrightarrow{\text{pr}} T_{n-1}$$

(here pr is projection onto the nth derivative, which is well defined since we have fixed coordinates $\mathbf{x}$).

Now, if $Z = Z_1 \times Z_2$ and $Z_i = Z_i' \times Z_i''$ as above, then by the inductive assumption applied to $Z_1' \times Z_2'$, there is a V' satisfying the result. Here $V' \subset T_1/T_{n-1}$. We let $V = V' \times V_1$ (using the splitting of $T_1 = T_1/T_{n-1} \oplus T_{n-1}$ given by the fixed coordinates).

We claim V satisfies the result. Given $h \in V$, $h = h_{n-1} + h_n$ via the splitting. By induction, there exist $\nu_{n-1} \in Z_1' \times Z_2'$ so that $v^{(n-1)}(0, \nu_{n-1}) = h_{n-1}$ and $v^{(n-1)} \mid U_1^{(n-1)}$ is a submersion at 0. Then, $v(0, \nu_{n-1}) = h_{n-1} + w_n$ where $w_n \in V_1$. Thus, $h_n - w_n \in v(W_1'')$; hence, $h_n - w_n = v(\nu_1'')$, for some $\nu_1'' \in W_1''$. Let $\nu_n^{(1)} = (\nu_{n-1}, (\nu_1'', 0))$.

Then, by the proof of (i) in Theorem 5.4,

$$\begin{aligned} v(0, \nu_n^{(1)}) &= v(0, \nu_{n-1}) + v(0, \nu_1'') \\ &= h_{n-1} + w_n + h_{n-1} - w_n = h. \end{aligned}$$

Also, by Corollary 4.9,

$$d^n\bar{F}(x, u, \nu_n^{(1)})(0) \big|_{V_{m_0} \times \cdots \times V_{m_0} \times V_{m_{2n-2}}} = d^n\bar{F}(x, u, \nu_{n-1})(0) \big|_{V_{m_0} \times \cdots \times V_{m_0} \times V_{m_{2n-2}}},$$

and

$$d^j\bar{F}(x, u, \nu_n^{(1)})(0) = d^j\bar{F}(x, u, \nu_{n-1})(0), \qquad 1 \leqq j \leqq n-1.$$

Thus, $v \mid U_1^{(n-1)}$ is still a submersion at 0.

Finally, let $\nu_n = (\nu_{n-1}, (\nu_1'', \nu_2''))$. By the conditions on r_{n+1} and r_{n+1}' and Corollary 4.9, $v(0, \nu_n) = v(0, \nu_n^{(1)}) = h$. Also, by Corollary 4.9,

$$\begin{aligned} d^{n+1}\bar{F}(x, u, \nu_n)(0) \big|_{V_{m_0} \times \cdots \times V_{m_0} \times W_{m_{2n-1}}} &= d^{n+1}\bar{F}(x, 0, \nu_2'')(0) \big|_{V_{m_0} \times \cdots \times W_{m_{2n-1}}}, \\ d^j\bar{F}(x, u, \nu_n)(0) \big|_{V_{m_{2n-2}}} &= d^j\bar{F}(x, u, \nu_n^{(1)})(0) \big|_{V_{m_{2n-2}}}, \qquad 1 \leqq j \leqq n. \end{aligned}$$

Thus, by the proof of (ii) of Theorem 5.4, for almost all ν_2'', $v \mid U_1^{(n)}$ is a submersion at 0. Picking such a $\nu_2'' \in Z_2''$ completes the proof. □

6. Proofs of Theorems 1–4. For Theorem 1, it is sufficient to prove local openness and density near any specific operator f_0. Given N there is an $r > r_i$ given in Theorem 5.4. First we prove density. Consider $f = f_0 + G$ as in that theorem.

We claim that we may choose ν sufficiently small so that (ii) of Theorem 5.4 holds and $\mathfrak{m}^{N+1} \cdot Q(f) = 0$. Then, condition (ii) implies that f is infinitesimally stable by the verification criterion.

To establish the claim, we first apply (ii) of Theorem 5.4 with $\nu_1 = 0$ to obtain that $v \mid U_1$ is a submersion at 0. Now we let our original f_0 be replaced by $f(x, \nu_2)$ and still denote it by f_0. For this new f_0 we apply Theorem 5.4(i) to conclude that $v \mid U_2 \cap E_1$ is a submersion at 0. Thus, all k-jets sufficiently close to $v(0)$ are in the image of v. Furthermore, for small enough ν_1, $v \mid U_1$ remains a submersion at 0. Then, by the classification of algebras in [M6], there are arbitrarily small deformations of f_0 so that $I(\bar{F}(x, 0, \nu_1)) \supset \mathfrak{m}_x^{N+1}$ for $N \geqq 2$. Thus, we may pick a sufficiently small ν_1 to achieve this. For $\nu = (\nu_1, \nu_2)$ we have our result. □

This proof works for $m=1$. However, for $m>1$, we can consider $C^k_{2\pi/m\lambda}\subset C^k_{2\pi/\lambda}$. The argument just given works for $C^k_{2\pi/m\lambda}$. Then, we may consider the operator for $C^k_{2\pi/\lambda}$ as an extension of the operator for $C^k_{2\pi/m\lambda}$, since all coefficient functions constructed using Theorem 5.4 would be periodic of period $2\pi/m\lambda$. Then, the proof of Theorem 5.4 still follows in exactly the same way since ultimately the proof reduces to considering the restriction to $V_{m_1}\subset C^0_{2\pi/m\lambda}$, and the same arguments apply.

For openness, we consider $f=f_0+H$, where

$$H=\sum_{\substack{2\leqq i+j\leqq N\\ 0\leqq k\leqq r}}(a^{(k)}_{ij}\cos(kt)+b^{(k)}_{ij}\sin(kt))x^i x'^j.$$

We apply Lyapunov-Schmidt to

$$F: C^2_{2\pi/\lambda}\times T\to C^0_{2\pi/\lambda}\times T,\qquad (x(t),\nu)\to(f(x,\nu),\nu)$$

where ν denotes the Fourier coefficients $\{a^{(k)}_{ij}, b^{(k)}_{ij}\}_{i,j,k}$.

This gives $F': U\to C^0_{2\pi/\lambda}\times T$ where U is a neighborhood of 0 in $C^0_{2\pi/\lambda}\times T$. We restrict F' to $U\cap(V_{m_1}\times T)$. The coefficients of $x^\alpha u^\beta v^\gamma$ in the expression for F' are smooth functions in the Fourier coefficients. Then, the n-jet of F' will define an infinitesimally stable germ if it belongs to the open subset St^n of the set of all stable n-jets (see [M5]). Thus, the set of Fourier coefficients for which the n-jet of F' defines an infinitesimally stable germ will be the inverse image of this set and hence (locally) open in a neighborhood of 0 in T. The union of such sets for all n is again open. □

For Theorem 2, we use the universal model. To obtain a given infinitesimally stable germ f_0 up to equivalence, it is sufficient to construct one with a local algebra isomorphic to $Q(f_0)$. As f_0 is infinitesimally stable, it is finitely $\mathscr{K}$-determined (see [M4]) hence $\dim_{\mathbb{R}} Q(f_0)<\infty$ [M4]. Thus, if $Q(f_0)$ has maximal ideal $\mathscr{m}$, there is an l with $\mathscr{m}^l\cdot Q(f_0)=0$. It then follows using Nakayama's lemma, that for a germ f_1 to have $Q(f_1)\xrightarrow{\sim}Q(f_0)$ it is sufficient that their l-jets lie in the same $\mathscr{K}^l$-orbit (see [M4]). However, any $\mathscr{K}^l$-orbit contains 0 in its closure. Thus, we may apply Corollary 5.9 to obtain ν yielding an l-jet in the $\mathscr{K}^l$-orbit for which $v\,|\,U_1$ is a submersion at 0. The operator so constructed has local algebra isomorphic to $Q(f_0)$ by the preceding discussion; and furthermore, since $v\,|\,U_1$ is a submersion, the F obtained after Lyapunov-Schmidt satisfies the verification criterion (since $I(\bar{F}(x,0,\nu))\subset\mathscr{m}^l_x$). Thus, F is infinitesimally stable.

Theorem 3 is an immediate consequence of Corollary 1.2 and Theorem 1.10 applied to infinitesimally stable operators of the form (2.2).

Last, Theorem 4 follows because for $N=2n-2$ it is possible to construct an infinitesimally stable operator f with local algebra $\xrightarrow{\sim}\mathbb{R}[[x,y]]/(x^n,y^n)$, which has $\dim=n^2$. Then, Theorem 3 gives the desired result. □

7. Proof of Theorem 5. Again as in earlier proofs we assume $\lambda=1$ to slightly simplify notation. If f denotes the operator (2.2) with $(m=1,\lambda=1)$ P as in (2.5), we wish to examine the restriction $P_{2n}\circ f_1\,|\,V_{2n}$ with P_{2n} denoting projection onto V_{2n} along its L^2-orthogonal complement in $C^0_{2\pi}$, and f_1 denoting f after Lyapunov-Schmidt is applied. By the noninterference lemma, there is an $m>2n$ so that if g denotes $P_{2n}\circ f'_1\,|\,V_{2n}$, where f'_1 is obtained by applying Lyapunov-Schmidt to $P_m\circ f\,|\,V_m$, then g and $P_{2n}\circ f_1\,|\,V_{2n}$ have the same $n+1$th order Taylor expansions. Thus, it is sufficient to replace f by $f'=P_m\circ f\,|\,V_m$.

Thus, we are considering a smooth mapping between finite dimensional subspaces. We use the following notation. We let $\mathscr{C}_{x,w}$ denote the algebra of real-valued smooth germs on V_m at 0 (here recall $x=(x_1,x_2)$ and $w_j=u_j+iv_j$ as in § 3). Also, $\mathscr{C}_x$ denotes the algebra of germs only depending on (x_1, x_2), and $\mathscr{C}_w$ denotes the algebra of germs only depending on $\{(u_j, v_j): 2 \leqq j \leqq m\} \cup \{u_0\}$. These algebras have maximal ideals of germs vanishing at 0, denoted by $\mathfrak{m}_{x,w}$, $\mathfrak{m}_x$, and $\mathfrak{m}_w$. Then, Theorem 5 will follow from two lemmas.

LEMMA 7.1. *The mapping f' is given in local coordinates by*

$$f'(x, u, v) = \left(x_1^2 + x_2^2 + h,\ P_1(x_1) + x_2 P_2(x_1) + \sum_{i=2}^{2n} (c_i u_i \varphi_i + c_i' v_i \varphi_i') + H_0,\ q\right), \tag{7.2}$$
$$q = (q_0, q_3, \cdots, q_{2m})$$

where

(i) $$h = (1/4)(-u_3 x_1 + v_3 x_2) + h_1(x, u, v),$$
$$H_0 = (1/4)(u_3 x_2 + v_3 x_1) + H_0',$$

(ii) *both h_1 and H_0' have terms of degree $\geqq 3$ and h_1 consists of terms at least quadratic in* **x**,

(iii) $$H_0' \in (x_1^2 + x_2^2) \cdot \mathscr{C}_{x,w} + (\mathfrak{m}_w^2 + \mathfrak{m}_x^{n+2}) \cdot \mathscr{C}_{x,w},$$

(iv) $$P_1(x_1) = A x_1^{n+1} + \sum_{i=3}^{n} A_i x_1^i,$$
$$P_2(x_1) = B x_1^n + \sum_{i=2}^{n-1} B_i x_1^i,$$

(v) $$\left.\begin{aligned} q_{2j} &\equiv d_j u_j \\ q_{2j-1} &\equiv d_j v_j \end{aligned}\right. \quad \operatorname{mod} \mathfrak{m}_{x,w}^2 \cdot \mathscr{C}_{x,w},$$
$$d_j = 1 - j^2, \quad j \neq 0 \quad \textit{and} \quad d_0 = 1,$$

(vi) *all monomials of f' which have coefficients involving a_j, b_j or c_j have total degree in (x, u, v) at least equal to j; and A, B, A_i, B_i, C_{2i}, C_{2i}' are fixed nonzero multiples of a_{n+1}, b_{n+1}, a_i, b_i, c_i,*

(vii) *Finally, if $in(\varphi_i)$ denotes the lowest degree nonzero terms in the Taylor expansion of φ_i, then $\{(0, x_1), (0, x_2)\} \cup \{in(\varphi_{2i}), in(\varphi_{2i}')\}_{i=1}^n$ span the quotient space $\mathfrak{m}_x/((x_1^2 + x_2^2) \cdot \mathscr{C}_x + \mathfrak{m}_x^{n+1}$.*

From this lemma we can deduce the next one.

LEMMA 7.3. *For f' of the form in the preceding lemma, the corresponding g obtained after applying Lyapunov-Schmidt is infinitesimally stable at* 0 *and has local algebra*

$$Q(g) \xrightarrow{\sim} \mathbb{R}[[x, y]]/(x^2 + y^2, x^{n+1}).$$

Remark. Of course f' itself is infinitesimally stable with the same local algebra; however, it is much easier to show this for g (after further changing coordinates).

Theorem 5 follows from the lemmas, except for the special condition that $q(t)$ can be chosen to have only nonzero Fourier coefficients of degree $\leqq 2n$. In fact, $q(t)$ may be chosen in V_{2n}. This is because Lyapunov-Schmidt is applied to f by composing with Φ^{-1} so the target space is not changed. Then, the restriction of g to V_{2n} is proven to be infinitesimally stable, so by Theorem 1.8, there are $q(t) \in V_{2n}$ arbitrarily close to zero so that $g^{-1}(q)$ contains $2n+2$ points near 0. Thus, so must f.

Proof of Lemma 7.1. The proof of Lemma 7.1 follows from the derivative computations of § 3. The form of the coordinate for sin (t) follows from Corollary 3.13.

For the second term, we can first use Corollary 3.12 to obtain terms of the form $w_1=(1/2)^m\bar{\alpha}\cdot z^m$, where $\alpha=a_m+ib_m$. This gives, for the coefficient of $\cos(t)$,

$$(1/2)^m(a_m\operatorname{Re}(z^m)-b_m\operatorname{Im}(z^m)).$$

Now, we can modify this by adding terms of the form $h\cdot(x_1^2+x_2^2)=h\cdot z\bar{z}$. For example,

$$\operatorname{Re}(z^m)\equiv\operatorname{Re}(z^m+\bar{z}z^{m-1})\equiv 2x_1z^{m-1}\bmod (x_1^2+x_2^2)\mathscr{C}_x.$$

Continuing in this fashion gives

$$\operatorname{Re}(z^m)\equiv\operatorname{Re}(2^{m-1}x_1^{m-1}z)=2^{m-1}x_1^m\bmod (x_1^2+x_2^2)\cdot\mathscr{C}_x.$$

Similarly, mod $(x_1^2+x_2^2)\cdot\mathscr{C}_x$,

$$\operatorname{Im}(z^m)\equiv\operatorname{Im}(2ix_2z^{m-1})=2x_2\operatorname{Re}(z^{m-1})\equiv 2^{m-1}x_2x_1^{m-1}.$$

This gives the terms $P_1+x_2P_2$. The linear term of H_0 also comes from Corollary 3.13. We obtain the terms $C_iu_i\varphi_i+C_i'v_i\varphi_i'$ by applying Lemma 3.14 with $r=m$ so that the nonzero terms for the coefficient of $\cos(t)$ in the expression for f will be given in the lemma by $s=2a$, $0\leqq a\leqq m$. Thus, there will be no terms in $\cos(t)$ coefficient of f of the form $u_{2m}x_1^{j_1}x_2^{j_2}$ with $j_1+j_2<m$. For the degree m-terms in x, we obtain by the same corollary, for $s=2m$, $\bar{\alpha}\beta\bar{z}^{m-1}$ with $\alpha=c_m$ and $\beta=u_m+iv_m$.

This gives for the $\cos(t)$ term

$$(1/2)^m\cdot c_m\cdot(u_m\operatorname{Re}(\bar{z}^{m-1})-v_m\operatorname{Im}(\bar{z}^{m-1})).$$

By the same reasoning as above, $\operatorname{Re}(\bar{z}^{m-1})$ and $\operatorname{Im}(\bar{z}^{m-1})$ are congruent (modulo $(x_1^2+x_2^2)\cdot\mathscr{C}_x$) to $2^{m-2}\cdot x_2^{m-1}$ and $2^{m-2}x_1^{m-2}x_2$. These will be exactly the lowest order terms in which u_{2m} and v_{2m} can appear linearly; thus they are in (φ_m), in (φ_m'). Hence, (vii) follows. The conditions on the coefficients A_i, B_i, etc. follow from the above discussion. Furthermore since a_i, b_i, c_i only appear in the ith derivative, they will still only appear in derivatives of order $\geqq i$ after we apply Lyapunov-Schmidt. Hence, (vi) follows. Finally, the conditions on the functions q_i just state that the first derivative of f is $x''+x$. □

Proof of Lemma 7.3. The Lyapunov–Schmidt procedure corresponds to changing coordinates via

$$(x_1,x_2,u_0',u_1',\cdots,u_m',v_2',\cdots,v_m')=(x_1,x_2,q_0(x,u,v),\cdots,q_{2m}(x,u,v)).$$

Then

$$(u_i,v_i)=(d_i^{-1}u_i'+q_{2i-1}'(x,u,v),d_i^{-1}v_i'+q_{2i}'(x,u,v))\quad\text{with } q_j'\in\mathscr{m}_{x,w}^2. \tag{7.4}$$

We claim that g can be written in the form

$$\begin{gathered}g(x,u',v')=\left(x_1^2+x_2^2+h',P_1+x_2P_2+\sum_{i=2}^{2n}C_i^{(1)}\cdot u_i\cdot\varphi_i+C_i^{(2)}v_i\varphi_i'+H_1,u',v'\right)\\ \text{with } u'=(u_0',\cdots,u_m'),\quad v'=(v_1',\cdots,v_m')\end{gathered} \tag{7.5}$$

obtained from the change of coordinates. Here,

$$h'=(1/2^5)(u_3'x_1-v_3'x_2)+h_1',\qquad H_1=(1/2^5)(-u_3x_2-v_3x_1)+H_1'$$

with H_1', $h_1'\in\mathscr{m}_{x,w'}^3$ and the terms of h_1' still at least quadratic in x. Also, $C_j^{(1)}=d_{2j}^{-1}C_j$, $C_j^{(2)}=d_{2j}^{-1}C_j$ (recall $d_r=1-r^2$).

Again monomials $x^\alpha u'^\beta v^\gamma$ with coefficients involving a_i, b_i, or c_i still have total degree $\geqq i$. Moreover, we may write

$$H_1'=H_1''+H_1'''\quad\text{with } H_1'''\in(x_1^2+x_2^2)\cdot\mathscr{C}_{x,w'}+(\mathscr{m}_{w'}^2+\mathscr{m}_x^{n+2})\cdot\mathscr{C}_{x,w'}.$$

Also, the monomials $x^\alpha u'^\beta v'^\gamma$ in H_1'' with coefficients involving a_i, b_i, or c_i have total degree $>i$.

To show that this claim is correct, we note that the simplest way to carry out the change of coordinates for the first two coordinate functions is to repeatedly use (7.4) to replace each u_i or v_i that appears in the lowest degree terms. If initially a monomial $x^\alpha u^\beta v^\gamma$ has total degree $=j$, then after substitution and expansion, each term which still contains some u_j or v_j has total degree $>j$, while there will be a term of the form $c \cdot x^\alpha u'^\beta v'^\gamma$. Furthermore, for any term with coefficient involving a_i, b_i or c_i in $q_k'(x, u, v)$, the term has total degree $\geqq i$; hence, after substitution and expansion, it will contribute to terms of total degree $\geqq j-1+i$. As $j \geqq 2$, we may continue inductively.

Next, any term in $(x_1^2+x_2^2) \cdot \mathscr{C}_{x,w}$ will still belong to $(x_1^2+x_2^2) \cdot \mathscr{C}_{x,w'}$ after substitution. A similar remark holds for $\mathfrak{m}_x^{n+2}\mathscr{C}_{x,w}$. On the other hand, a monomial in $\mathfrak{m}_w^2 \cdot \mathscr{C}_{x,w}$ yields after substitution, a term in $\mathfrak{m}_{w'}^2 \cdot \mathscr{C}_{x,w'}$ plus monomials of total degree at least one greater. Thus, g has the form (7.5) as claimed.

We further change coordinates

$$x_1 = x_1' + \Psi_1(x', u', v'), \qquad x_2 = x_2' + \Psi_2(x', u', v') \tag{7.6}$$

so that

$$x_1^2 + x_2^2 + h_1'(x, u', v') = x_1'^2 + x_2'^2.$$

We can show this in two steps by first applying the parametrized Morse lemma to write

$$x_1^2 + x_2^2 + h_1'(x, u', v') = x_1'^2 + x_2'^2 + h_2(x_1', x_2', u', v') \tag{7.7}$$

with h_2 quadratic in x_1' and x_2' with coefficients in $\mathscr{C}_{w'}$. Since elements of $1+\mathfrak{m}_{w'}$ are invertible and have square roots, we can make a second local change of coordinates which is linear with coefficients in $\mathscr{C}_{w'}$ by diagonalizing $x_1'^2 + x_2'^2 + h_2$ viewed as a function of x_1', x_2'. This gives a new (x_1', x_2') with the desired properties.

From the first change of coordinates, we can insure that terms in Ψ_i involving a_j, b_j or c_j have total degree $\geqq j-1$ (this is not altered by the second change). This can be seen either from the explicit form for constructing change of coordinates in the Morse lemma, or by using a result of Mather [M3] for $\mathscr{R}^{(k)}$-equivalence. This latter method concerns change of coordinates with $k-1$-jet = id. Let $h_1'^{(k)}$ denote the terms of h_1' of degree $\leqq k$ (with $k \geqq 3$). Then, Mather's result states that $x_1^2+x_2^2+h_1'^{(k+1)}$ is equivalent to $x_1^2+x_2^2+h_1'^{(k)}$ by a local change of coordinates with $k-1$ jet = id if, for $0 \leqq t_0 \leqq 1$ with $\rho^{(k)} = h_1'^{(k+1)} - h_1'^{(k)}$,

$$\rho^{(k)} \in \mathfrak{m}_x^k \cdot \Delta(x_1^2 + x_2^2 + h_1'^{(k)} + (t_0 + t)\rho^{(k)}) \tag{7.8}$$

(where $\Delta(f_t)$ is the ideal in $\mathscr{C}_{x,w',t}$ generated by $\partial f_t/\partial x_1$, $\partial f_t/\partial x_2$). However, by Nakayama's lemma, the right-hand side of (7.8) equals $\mathfrak{m}_x^{k+1} \cdot \mathscr{C}_{x,w',t}$. Thus, the inclusion holds. Composing coordinate changes for decreasing k, $3 \leqq k \leqq n+1$ gives the result about Ψ_i.

When we change coordinates using (7.6) we obtain

$$\begin{aligned} g(x', u', v') = \Big(& x_1'^2 + x_2'^2 + h_2,\ P_1(x_1') + x_2' P_2(x_1') \\ & + \sum_{j=2}^{2n} (C_j^{(1)} u_j \varphi_j(x') + C_j^{(2)} v_j \varphi_j'(x')) + H_2,\ \mathbf{u}', \mathbf{v}' \Big) \end{aligned} \tag{7.9}$$

where now

$$h_2 = (1/2^5)(u_3'\sigma_1 - v_3'\sigma_2), \quad H_2' = (1/2^5)(-u_3'x_2' - v_3'x_1') \quad \text{for } H_2 = H_2' + H_2'' + H_2'''.$$

$H_2'' \in (x_1'^2 + x_2'^2) \cdot \mathscr{C}_{x',w'} + (m_{w'}^2 + m_{x'}^{n+2}) \cdot \mathscr{C}_{x',w'}$ and H_2''' consists of terms involving a_j, b_j and c_j and of total degree $>j$. Here σ_i denotes x_i as a function of (x', u', v').

For the claim concerning H_2', note that $P_1 + x_2 \cdot P_2$ has terms of degree $\geqq 3$; hence after substitution using (7.6), terms involving a_i, b_i or c_i will increase degree by at least two. A similar remark applies to φ_{2i} or φ_{2i}' since deg $in(\varphi_{2i}) =$ deg $in(\varphi_{2i}') = i$. Last, an element of $(m_{w'}^2 + m_x^{n+2}) \cdot \mathscr{C}_{x,w'}$ will be in $(m_{w'}^2 + m_{x'}^{n+2}) \cdot \mathscr{C}_{x',w'}$ after substitution; while an element of $(x_1^2 + x_2^2) \cdot \mathscr{C}_{x,w'}$ differs from an element of $(x_1'^2 + x_2'^2) \cdot \mathscr{C}_{x',w'}$ by an element of $h_1'(x, u', v') \cdot \mathscr{C}_{x',w'}$, which is at least quadratic in x. Again the degree of terms involving a_i, b_i, or c_i will increase by at least 1.

Thus, we can inductively choose a_i and b_i so that the terms of degree i of $P_1 + xP_2 + H_2$ not involving (u', v') belong to $(x_1'^2 + x_2'^2) \cdot \mathscr{C}_{x',w'}$. Furthermore we may write the remaining terms of H_2 as

$$\sum_{j=1}^{2n+2} l_j(u', v') \cdot \psi_j \bmod m_{x',w'}^{n+2} \quad \text{where } l_j = \sum_{i=2}^{2n} a_{ij} u_i' + b_{ij} v_i'$$

and $\{\psi_j, j = 1, \cdots, 2n+2\}$ denotes $\{in(\varphi_{2i}), in(\varphi_{2i}')\}_{i=1}^n \cup \{(0, x_1'), (0, x_2')\}$ and the coefficient functions of $(0, x_1')$ and $(0, x_2')$ are $(1/2)^5$ times $-v_3'$ and $-u_3'$ respectively. Moreover, the preceding discussion implies that l_j does not involve c_i unless deg $(\psi_j) >$ deg $(in(\varphi_{2i})) =$ deg $(in(\varphi_{2i}'))$. Thus, for generic a_n, b_n, and c_i the coefficients A' of $x_1'^{n+1}$ and B' of $x_2' x_1'^n$ are not zero. We also claim that for generic c_i the elements

$$\left\{ C_{2i}^{(1)} in(\varphi_{2i}) + \sum_{j=1}^{2n} a_{2i,j}\psi_j,\ C_{2i}^{(2)} in(\varphi_{2i}') + \sum_{j=1}^{2n} b_{2i,j}\psi_j \right\}_{i=1}^{n} \tag{7.10}$$

span $D_n = m_{x'}^2 / (m_{x'}^{n+1} + (x_1'^2 + x_2'^2) \cdot \mathscr{C}_{x'})$. This follows by replacing D_n by D_k and proceeding by induction on $k \leqq n$ using the fact that $\{in(\varphi_{2i}), in(\varphi_{2i}')\}_{i=1}^k$ span D_k. In the inductive step, we use that $C_{2i}^{(1)}$ and $C_{2i}^{(2)}$ are fixed multiples of c_i so that we must know that a matrix of the form

$$\begin{pmatrix} at + b_{11} & b_{12} \\ b_{21} & bt + b_{22} \end{pmatrix}$$

with a, $b \neq 0$ is nonsingular for generic t, which it clearly is.

Then, for such generic values for a_n, b_n, c_i and specific values of a_j, b_j, $j < n$,

$$g(x', 0) = (x_1^2 + x_2'^2, A' x_1'^{n+1} + B' x_2' x_1'^n + (x_1'^2 + x_2'^2) \cdot R(x'), 0)$$

and has local algebra

$$\mathbb{R}[[x_1', x_2']]/(x_1'^2 + x_2'^2, A' x_1'^{n+1} + B' x_2' x_1'^n) \xrightarrow{\sim} \mathbb{R}[[x, y]]/(x^2 + y^2, x^{n+1})$$

(by the classification in [M4] provided $A' \neq 0$).

Last, if we write $g(x', u', v') = (\bar{g}(x', u', v'), u', v')$, then

$$\left\{ \left.\frac{\partial \bar{g}}{\partial u_{2i}'}\right|_{u',v'=0}, \left.\frac{\partial \bar{g}}{\partial v_{2i}'}\right|_{u',v'=0} \right\}_{i=1}^{n}$$

are exactly (7.9), while

$$\left.\frac{\partial \bar{g}}{\partial u_3}\right|_{u',v'=0} = (1/2)^5 (\sigma_1(x', 0), -x_2') \quad \text{and} \quad \left.\frac{\partial \bar{g}}{\partial v_3}\right|_{u',v'=0} = (1/2)^5 (-\sigma_2(x', 0), -x_1').$$

By the verification criterion Theorem 1.3, g is infinitesimally stable. □

8. Examples of degree n with n^2-periodic solutions. We earlier referred to examples for $n=2$ and 3 of polynomial P of degree n for which there were $q(t)$ arbitrarily close to 0 for which (2.1) has n^2-periodic solutions. Here we briefly describe the examples.

$n=2$. Let

$$P(x,t)=(a+b\cos(t)+c\sin(t))x^2.$$

Then, a computation similar to those made in §§ 4 and 5 shows that if $a\neq 0$, $(b,c)\neq(0,0)$, the operator f in (2.2) (with $m=\lambda=1$) is infinitesimally stable with local algebra $Q(f)\xrightarrow{\sim}\mathbb{R}[[x,y]]/(x^2+y^2,xy)$. Thus, there are $q(t)$ arbitrarily close to 0 for which (2.1) has $\delta(Q(f))=4$ periodic solutions (more generally see [D1, § 3]). Moreover we may find such a $q(t)$ which has Fourier coefficients equal to zero except for $\sin(rt)$, $\cos(rt)$, $0\leqq r\leqq 2$.

$n=3$. Let

$$P(x,x',t)=(a_1\cos(4t)+a_2\cos(2t))x^3+(b_1(t)x^2+b_2(t)x)\cdot x'$$

where for $i=1,2$

$$b_i(t)=c_i\cos(r_it)+d_i\sin(r_it)+c_i'\cos(r_i't)+d_i'\sin(r_i't).$$

We claim that for generic a_i, c_i, c_i', d_i, d_i' and sufficiently general r_i and r_i', there are $q(t)$ arbitrarily close to 0 for which (2.1) (with $m=\lambda=1$) has 9 periodic solutions close to 0. This time the operator f so obtained may not be infinitesimally stable, so we have to modify our arguments slightly.

First, note that the second term of P is G_2 of (5.3) with $n=3$. However, now we have a much smaller version of G_1 in the first term. This is because the quadratic terms in G_2 can affect at most the cubic terms in x_1 and x_2 (using our earlier notation) for the germ g obtained from f by Lyapunov-Schmidt. The first term will contribute to the cubic terms of g. By a calculation using (3.5), we obtain from the first term of P, the following cubic terms in the $\langle\cos(t),\sin(t)\rangle$ coordinates for g,

$$a_4(\alpha x_1^3-3x_1x_2^2,\ \alpha x_2^3-3x_1^2x_2) \tag{8.1}$$

where $a_4\alpha=a_4+a_2$ (assuming $a_4\neq 0$). By the classification of Mather [M4], pairs of generic cubics in two variables contain one modulus parameter. A computation shows that α is the modulus parameter for $\alpha\neq 0$. Such pairs of generic cubics form a Zariski open subset of the space of pairs of cubics. Hence, for sufficiently small values of the constants c_i, d_i, etc., it follows that α (and hence a_2, for a_4 fixed) is still a modulus when we include the contribution to the cubic terms from G_2. Then, by the verification criterion, the operator

$$\tilde f: C^2_{2\pi}\times\mathbb{R}\to C^0_{2\pi}\times\mathbb{R},\qquad \tilde f(x(t),a_2)\to(f(x(t)),a_2)$$

is infinitesimally stable at $(0,a_2)$ for c_i, d_i, etc. sufficiently small, $a_4\neq 0$, and $a_2\neq -a_4$. Thus, it is so for generic values of c_i, d_i, etc., by the same argument given in § 6. Thus, for generic c_i, $d_i,\cdots,a_2$, $\tilde f$ has real multiplicity at $(0,a_2)$ equal to dimension of the local algebra of $\tilde f$ at $(0,a_2)$, which is 9. Thus, there is $(q(t),a_2')$ arbitrarily close to $(0,a_2)$ for which there are 9 solutions to $\tilde f(x(t),a_2')=(q(t),a_2')$, i.e., 9 periodic solutions to (2.1) for the specific value of a_2'. This does not quite prove what was claimed, since when we pick a point $(q_1(t),a_2'')$ still closer with 9 solutions we have no guarantee that $a_2''=a_2'$. Thus, for a fixed a_2, we do not know that $q(t)$ can be chosen arbitrarily close to 0 so there are still 9 solutions for the given a_2. However, this is true because by [D3, § 9, Thm. 4], for almost all values α (or a_2), the infinitesimally stable germ is topologically a product mapping along the α-direction. This implies the desired result.

This argument does not work in the general case of degree n; however, there is an alternate way to obtain the case $n = 3$ which suggests that the result should be true for general n, provided certain technical points in the computation can be handled.

Acknowledgment. Special gratitude is expressed to Jorge Sotomayor for his valuable comments and suggestions concerning earlier and cruder forms of these results.

THE CONVERSE OF PÓLYA'S MEAN VALUE THEOREM*

JAMES S. MULDOWNEY†

Abstract. Suppose L is a real linear scalar ordinary differential operator of order n with continuous coefficients which is disconjugate on an interval I. Pólya showed that if v is any n times differentiable function on I which has $n+1$ zeros, then $Lv(p)=0$ for some point p intermediate to the zeros of v. It is shown that an operator L has this mean value property with respect to functions v on an interval I if and only if L is disconjugate on the interior of I.

Key words. linear equations, zeros, disconjugacy

AMS(MOS) subject classification. Primary 34C10

1. Introduction. We consider linear differential operators of the form

$$Lu = u^{(n)} + a_1(t)u^{(n-1)} + \cdots + a_n(t)u \tag{1.1}$$

where a_i, $i=1,\cdots,n$ are continuous real valued functions on a fixed open interval J. Such an operator is said to be *disconjugate* on an interval $I \subset J$ if the only solution of $Lu=0$ which, counting multiplicities, has n or more zeros in I is the zero solution.

In the paper [4], Pólya shows that disconjugate operators have the following mean value property. Let v be any real valued function such that $v^{(n)}$ exists on I and v has $n+1$ or more zeros in I. Then, if L is disconjugate on I, there exists a point p intermediate to the zeros of v such that $Lv(p)=0$. The result is a generalization of Rolle's Theorem and, in fact, Pólya's proof is an induction on the order of L based on Rolle's Theorem.

Pólya also shows in [4, Thm. V] that, if v is a function which has n zeros in an interval I on which L is disconjugate and Lv is of one sign, then v satisfies a certain sign restriction on I. This result is often referred to as Čaplygin's Inequality since the case of the n zeros of v all occurring at a single point was investigated by Čaplygin (cf. [1]).

In this paper we consider the question of whether the converses of the Pólya Mean Value Theorem and Čaplygin's Inequality hold. For example, if L has the Pólya mean value property on an interval I, is L necessarily disconjugate on I? We find that this is in fact the case if the interval I is not closed. If I is a closed interval on which L has the Pólya mean value property, we show that L is necessarily disconjugate on the interior of I.

2. Results. The following notation will be used throughout this paper.

DEFINITION 2.1. (a) Let $t_i \in J$, $i=1,\cdots,m$, $t_1 \leqq t_2 \leqq \cdots \leqq t_m$ and consider the m-tuple $\tau = (t_1,\cdots,t_m)$. If $t\in J$, then $\tau^t = (s_1,\cdots,s_{m+1})$ is the $(m+1)$-tuple obtained by inserting an extra entry t in τ in such a way that $s_1 \leqq s_2 \leqq \cdots \leqq s_{m+1}$. If $s \in \tau$, then τ_s denotes the $(m-1)$-tuple obtained by deleting one occurrence of the entry s from τ. In particular τ_s^t denotes the m-tuple obtained from τ by deleting an entry s from τ and adding an entry t in such a way that the ordering is maintained.

* Received by the editors March 18, 1985; accepted for publication May 22, 1986. This work was supported by Natural Sciences and Engineering Research Council of Canada grant 7197.

† Department of Mathematics, University of Alberta, Edmonton, Alberta, Canada T6G 2G1.

(b) A function v has m zeros at $\tau=(t_1,\cdots,t_m)$ if $v(t_i)=v'(t_i)=\cdots=v^{(j-1)}(t_i)=0$ for each distinct entry $t_i\in\tau$, where j is the number of times the entry t_i occurs in τ.

(c) If $u_1,\cdots,u_m$ are real functions on J and τ is as in (a), $\mathcal{W}(u_1,\cdots,u_m)(\tau)$ denotes the determinant of the $m\times m$ matrix whose kth column is $\operatorname{col}(u_k(t_1),\cdots,u_k(t_m))$, $k=1,\cdots,m$, when the entries t_i in τ are all distinct; the terms $u_k(t_i), u_k(t_{i+1}),\cdots,u_k(t_{i+j-1})$ are replaced by $u_k(t_i), u_k'(t_i),\cdots,u_k^{(j-1)}(t_i)$ if the entry t_i occurs j times in τ. In particular, the Wronskian determinant $W(u_1,\cdots,u_m)(t)=\mathcal{W}(u_1,\cdots,u_m)(t,\cdots,t)$.

(d) For τ as in (a) $\operatorname{co}(\tau)=[t_1,t_m]$.

Definition 2.2. Let $I\subset J$ be an interval and let int I, cl I denote the interior and closure in J, respectively, of I.

(a) $C'_{n-1}(I)$ denotes the set of real valued functions v on I such that $v^{(n-1)}$ exists and is continuous on I and $v^{(n)}$ exists on int I.

(b) $\mathcal{D}_n(I)$ is the set of operators L of the form (1.1) which are disconjugate on I as defined in the first paragraph of the introduction.

(c) $\mathcal{P}_n(I)$ is the set of operators L of the form (1.1) with the property that if $v\in C'_{n-1}(I)$ has $n+1$ zeros at $(t_1,\cdots,t_{n+1})$, $t_i\in I$, $t_1\leqq t_2\leqq\cdots\leqq t_{n+1}$, $t_1<t_{n+1}$, then $Lv(p)=0$ for some $p\in(t_1,t_{n+1})$. Thus $\mathcal{P}_n(I)$ is the set of operators with the Pólya mean value property on I.

(d) $\mathcal{Q}_n(I)$ denotes the set of operators L of the form (1.1) with the property that if $t\in I$ and $v\in C'_{n-1}(I)$ has n zeros at $\tau=(t_1,\cdots,t_n)$, $t_i\in I$, $t\neq t_i$ and $Lv\geqq 0$ on int I with $Lv(p)>0$ for some $p\in\operatorname{co}(\tau^t)$, then

$$\prod_{i=1}^{n}(t-t_i)v(t)>0. \tag{2.1}$$

$\mathcal{Q}_n(I)$ is the set of operators for which Čaplygin's inequality holds on I.

We will prove the following theorem:

Theorem 2.3. (a) *For any subinterval I of J,*

$$\mathcal{D}_n(\operatorname{cl} I)\subset\mathcal{D}_n(I),\quad \mathcal{P}_n(\operatorname{cl} I)=\mathcal{P}_n(I),\quad \mathcal{Q}_n(\operatorname{cl} I)=\mathcal{Q}_n(I);$$

(b) *For any subinterval I of J such that I is not closed in* $\mathbf{R}$,

$$\mathcal{D}_n(I)=\mathcal{P}_n(I)=\mathcal{Q}_n(I).$$

It is clear that $\mathcal{D}_n$, $\mathcal{P}_n$, $\mathcal{Q}_n$ are nonincreasing with respect to set inclusion: $I_1\subset I_2$ implies

$$\mathcal{D}_n(I_2)\subset\mathcal{D}_n(I_1),\quad \mathcal{P}_n(I_2)\subset\mathcal{P}_n(I_1),\quad \mathcal{Q}_n(I_2)\subset\mathcal{Q}_n(I_1).$$

In particular,

$$\mathcal{D}_n(\operatorname{cl} I)\subset\mathcal{D}_n(I),\quad \mathcal{P}_n(\operatorname{cl} I)\subset\mathcal{P}_n(I),\quad \mathcal{Q}_n(\operatorname{cl} I)\subset\mathcal{Q}_n(I). \tag{2.2}$$

We will prove Theorem 2.3 by establishing the following three propositions and using (2.2).

Proposition 2.4. *If I is any subinterval of J, then*

$$\mathcal{Q}_n(I)\subset\mathcal{P}_n(I).$$

Proposition 2.5. *If I is any subinterval of J, then*

$$\mathcal{D}_n(I)\subset\mathcal{Q}_n(\operatorname{cl} I).$$

PROPOSITION 2.6. *If I is any subinterval of J such that I is not closed in* $\mathbf{R}$, *then*

$$\mathcal{P}_n(I) \subset \mathcal{D}_n(I).$$

Since Theorem 2.3(a) is trivial if I is closed, we may suppose that I is not closed. Then the three propositions and (2.2) imply

$$\mathcal{Q}_n(\mathrm{cl}\, I) \subset \mathcal{Q}_n(I) \subset \mathcal{P}_n(I) \subset \mathcal{D}_n(I) \subset \mathcal{Q}_n(\mathrm{cl}\, I),$$

$$\mathcal{Q}_n(\mathrm{cl}\, I) \subset \mathcal{P}_n(\mathrm{cl}\, I) \subset \mathcal{P}_n(I) \subset \mathcal{D}_n(I) \subset \mathcal{Q}_n(\mathrm{cl}\, I)$$

which proves Theorem 2.3(a),(b).

Proof of Proposition 2.4. To prove Proposition 2.4, suppose $L \in \mathcal{Q}_n(I)$, $v \in C'_{n-1}(I)$ and v has $n+1$ zeros at $(t_1, \cdots, t_{n+1})$, $t_i \in I$, $t_1 \leqq t_2 \leqq \cdots \leqq t_{n+1}$, $t_1 < t_{n+1}$. If $Lv > 0$ on (t_1, t_{n+1}), then

$$\prod_{i=1}^{n} (t-t_i)v(t) > 0, \qquad \prod_{i=2}^{n+1} (t-t_i)v(t) > 0$$

if $t \in (t_1, t_{n+1})$, $t \neq t_i$, from (2.1), and these two inequalities contradict each other. Similarly, the assumption $Lv < 0$ on (t_1, t_{n+1}) leads to a contradiction. Thus $Lv(p) = 0$ for some $p \in (t_1, t_{n+1})$ and we conclude that $L \in \mathcal{P}_n(I)$, which proves Proposition 2.4.

Pólya's Mean Value Theorem states that $\mathcal{D}_n(I) \subset \mathcal{P}_n(I)$ and Čaplygin's Inequality, which was also first proved in generality by Pólya [4], states that $\mathcal{D}_n(I) \subset \mathcal{Q}_n(I)$ for any interval I. In view of (2.2) and Proposition 2.4, it follows that Proposition 2.5 is a slightly stronger statement than both of these. To prove Proposition 2.5, we shall need the following lemma which is essentially Theorem V of [4] and is Pólya's statement of Čaplygin's inequality. A detailed proof may be found in [3, pp. 376-378].

LEMMA 2.7. *Suppose* $u_1, \cdots, u_{n+1} \in C'_{n-1}(I)$,

$$u_1 > 0, \qquad W(u_1, u_2) > 0, \cdots, W(u_1, \cdots, u_n) > 0 \tag{2.3}$$

and $W(u_1, \cdots, u_{n+1}) \geqq 0$. *Then, if* $\sigma = (t_1, \cdots, t_{n+1})$, $t_i \in I$, $t_1 \leqq t_{n+1}$,

$$\mathcal{W}(u_1, \cdots, u_{n+1})(\sigma) \geqq 0 \tag{2.4}$$

and the inequality (2.4) *is strict if* $W(u_1, \cdots, u_{n+1})(p) > 0$ *for some* $p \in [t_1, t_{n+1}]$.

Proof of Proposition 2.5. We first show that Lemma 2.7 implies Proposition 2.5 for subintervals I of J which are closed relative to J. Suppose $I = \mathrm{cl}\, I$, $L \in \mathcal{D}_n(I)$, $v \in C'_{n-1}(I)$ has n zeros at $\tau = (t_1, \cdots, t_n)$, $t_i \in I$, $Lv \geqq 0$ and $t \in I$ is such that $Lv(p) \geqq 0$ for some $p \in \mathrm{co}\,(\tau^t)$. Since $L \in \mathcal{D}_n(\mathrm{co}\,(\tau^t))$, solutions $u_1, \cdots, u_n$ of $Lu = 0$ may be chosen so that (2.3) is satisfied on $\mathrm{co}\,(\tau^t)$ (cf. [2, p. 94]). Also $Lv = W(u_1, \cdots, u_n, v)/W(u_1, \cdots, u_n)$ so that Lemma 2.7 implies $\mathcal{W}(u_1, \cdots, u_n)(\tau) > 0$, $\mathcal{W}(u_1, \cdots, u_n, v)(\tau^t) > 0$, and therefore

$$\mathcal{W}(u_1, \cdots, u_n, v)(\tau^t)/\mathcal{W}(u_1, \cdots, u_n)(\tau) > 0. \tag{2.5}$$

Now since

$$\mathcal{W}(u_1, \cdots, u_n, v)(\tau^t) = v(t)\mathcal{W}(u_1, \cdots, u_n)(\tau)\ \mathrm{sgn} \prod_{i=1}^{n} (t-t_i), \tag{2.6}$$

we conclude that v satisfies (2.1) and $L \in \mathcal{Q}_n(I)$. Thus Proposition 2.5 holds if $I = \mathrm{cl}\, I$.

The discussion of the preceding paragraph also establishes Proposition 2.5 for subintervals I of J which have at least one endpoint in common with J, since (cf. [2, p. 102])

$$\mathcal{D}_n(I) = \mathcal{D}_n(\text{int } I) \quad \text{if } i \text{ is not closed.} \tag{2.7}$$

Also (2.7) shows that, to complete the proof, it suffices to consider open intervals $I = (a, b)$ which have no endpoint in common with J. It is assumed that L and v satisfy the same conditions as before while the conditions on t_i, $i = 1, \cdots, n$ and t are relaxed to t_i, $t \in \text{cl } I$. The discussion of the preceding paragraph applied to closed subintervals of I and continuity considerations imply that if $Lu_i = 0$, $i = 1, \cdots, n$ and $W(u_1, \cdots, u_n) > 0$, then

$$\mathcal{W}(u_1, \cdots, u_n)(\tau) \geqq 0, \qquad \mathcal{W}(u_1, \cdots, u_n, v)(\tau^t) \geqq 0. \tag{2.8}$$

We assert that the existence of the function v as described implies that both of these inequalities are strict, and the result follows from (2.5), (2.6) as when I is closed.

To prove the last assertion, suppose first that $\mathcal{W}(u_1, \cdots, u_n)(\tau) = 0$. From (2.7), both endpoints a, b of I must occur in τ since $\mathcal{W}(u_1, \cdots, u_n)(\tau) = 0$ implies the existence of a nontrivial solution u of $Lu = 0$ which has n zeros at τ. We suppose further that, of all τ, v satisfying our assumptions, the ones under consideration are such that the number of occurrences of endpoints of I in τ is a minimum. The constant c may be chosen so that $w = v + cu$ has a zero at $s \in I$, $s \notin \tau$. Therefore w has $n+1$ zeros at $\tau^s = (s_1, \cdots, s_{n+1})$ and, in particular, w has n zeros at each of $\sigma = \tau_b^s = (s_1, \cdots, s_n)$, $\rho = \tau_a^s = (s_2, \cdots, s_{n+1})$. The number of occurrences of endpoints of I in each of σ, ρ is one fewer than in τ. Since $Lw = Lv \geqq 0$ and $Lw(p) = Lv(p) > 0$, and from the minimal character of τ with respect to endpoints, we conclude that $\mathcal{W}(u_1, \cdots, u_n)(\sigma) > 0$, $\mathcal{W}(u_1, \cdots, u_n)(\rho) > 0$. The second inequality (2.8) and (2.6) hold with v, τ, τ^t replaced by w, σ, σ^t respectively and by w, ρ, ρ^t, respectively. Therefore

$$\prod_{i=1}^{n} (t - s_i) w(t) \geqq 0, \qquad \prod_{i=2}^{n+1} (t - s_i) w(t) \geqq 0$$

for each $t \in I$, and $w(t) = 0$ for all $t \in I$ contradicting $Lw(p) > 0$; we conclude that either $\mathcal{W}(u_1, \cdots, u_u)(\tau) > 0$ or v satisfying our hypothesis does not exist. It remains to show that $\mathcal{W}(u_1, \cdots, u_n, v)(\tau^t) > 0$ for each $t \in \text{cl } I$; if not then (2.6), (2.8) imply that v has $(n+1)$ zeros at $\tau^s = (r_1, \cdots, r_{n+1})$ for some $s \in \text{cl } I$ and hence v has n zeros at each of $\delta = \tau_a^s$, $\gamma = \tau_b^s$. We have shown that the hypotheses on v imply $\mathcal{W}(u_1, \cdots, u_n)(\delta) > 0$, $\mathcal{W}(u_1, \cdots, u_n)(\gamma) > 0$ and, as before,

$$\prod_{i=1}^{n} (t - r_i) v(t) \geqq 0, \qquad \prod_{i=2}^{n+1} (t - r_i) v(t) \geqq 0$$

implying $v = 0$, which contradicts $Lv(p) > 0$.

Before proving Proposition 2.6 we recall some facts about Green's functions. The function $G(t, s)$, $t, s \in J$ is Green's function associated with the boundary value problem

$$Lv = f, \quad v \text{ has } n \text{ zeros at } \tau, \tag{2.9}$$

if it has the following properties:

(i) For each $s \in J$, $u(t) = G(t, s)$ is a solution of $Lu = 0$ for $t < s$ and $t > s$ and u has n zeros at τ, if $s \notin \tau$.

(ii) For each $s \in J$, $u(t)$ and its first $n-2$ derivatives are continuous at s and $u^{(n-1)}(s+) - u^{(n-1)}(s-) = 1$.

Green's function exists provided $\mathcal{W}(u_1, \cdots, u_n)(\tau) \neq 0$, where $u_1, \cdots, u_n$ is a fundamental solution set for $Lu = 0$ [2, p. 106] and has the property that, if $f \in C(J)$, the solution of (2.9) is

$$v(t)=\int_J f(s)G(t,s)\,ds. \tag{2.10}$$

In the special case that all n points in τ equal t_1, $G(t,s)$ is called the Cauchy function at t_1 for L. Thus the Cauchy function at t_1 is defined by: $G(t,s)=u(t)$ is a solution of $Lu=0$, $u(s)=\cdots=u^{(n-2)}(s)=0$, $u^{(n-1)}(s)=\operatorname{sgn}(t-s)$, if $|s-t_1|\leqq|t-t_1|$ and $G(t,s)=0$ otherwise.

LEMMA 2.8. *Suppose $L\in\mathcal{D}_n[b,c]$ and $G(t,s)$ is the Cauchy function for L at b. Then*

$$\begin{aligned} G(t,s)&=0, \qquad b\leqq t\leqq s\leqq c,\\ G(t,s)&>0, \qquad b\leqq s<t\leqq c. \end{aligned} \tag{2.11}$$

Proof. Since $G(t,s)=0$, $b\leqq t\leqq s$ and $G(t,s)=u(t)$, $b\leqq s\leqq t$, is a solution of $Lu=0$ which has $n-1$ zeros at s, it follows from $L\in\mathcal{D}_n[b,c]$ that u cannot have a zero in $(s,c]$ and thus $u^{(n-1)}(s+)=1$ implies $u(t)>0$, if $t\in(s,c]$.

Proof of Proposition 2.6. Suppose the proposition fails to hold for some interval $I\subset J$. Since I is not closed, it may be assumed that I is open, from (2.7). Our hypothesis implies the existence of $L\in\mathcal{P}_n(I)$, $L\notin\mathcal{D}_n(I)$. Thus I contains a subinterval $[a,b]$ such that b is the first right conjugate point of a with respect to L:

$$L\in\mathcal{D}_n[a,b),\qquad L\notin\mathcal{D}_n[a,b]. \tag{2.12}$$

We will show that this leads to a contradiction. First (2.12) implies that a fundamental solution set $u_1,\cdots,u_n$ of $Lu=0$ satifies $\mathcal{W}(u_1,\cdots,u_n)(\sigma)=0$ for some σ, $\operatorname{co}(\sigma)=[a,b]$ (both endpoints a, b occur in σ). We suppose that σ is such that the number $m+1$, $m\geqq 0$, of occurrences of b in σ is a minimum. There is a nontrivial solution u_m of $Lu=0$ such that u_m has n zeros at σ and there is a neighbourhood of b in which the only zeros of u_m are the $m+1$ zeros at b. Choose $c\in I$ such that $c>b$, u_m has no zeros in $(b,c]$ and

$$L\in\mathcal{D}_n[b,c]. \tag{2.13}$$

Now let $\tau=\sigma_b^a$, the n-tuple obtained by deleting one of the entries b from σ and adding an extra entry a. Note that b occurs $n\geqq 0$ times in τ. From the minimal character of σ with respect to b, it follows that $\mathcal{W}(u_1,\cdots,u_n)(\tau)\neq 0$ and Green's function $G(t,s)$ for (2.9) exists. For $f\in C(J)$, the solution v of (2.9) is given by (2.10). Moreover, if $f>0$, v satisfies (2.1), from (2.12) and Proposition 2.5, since

$$L\in\mathcal{D}_n[a,b)\subset\mathcal{Q}_n[a,b].$$

From (2.1) we conclude that $v^{(m)}(b)\geqq 0$. In fact this inequality is strict since, if $v^{(m)}(b)=0$, v would have at least $n+1$ zeros in $[a,c]\subset I$ and $Lv=f>0$ contradicting $L\in\mathcal{P}_n(I)$. We conclude that, if $f>0$, the solution v of (2.9) satisfies

$$\begin{aligned} &v(b)=\cdots=v^{(m-1)}(b)=0, \qquad v^{(m)}(b)>0 \quad \text{if } m>0,\\ &v(b)>0 \quad \text{if } m=0. \end{aligned} \tag{2.14}$$

Note that if $s>b$ and $t\leqq s$, then $G(t,s)=0$ since $u(t)=G(t,s)$ is a solution of $Lu=0$ with n zeros at τ, which implies $u=0$, because $\mathcal{W}(u_1,\cdots,u_n)(\tau)\neq 0$. Thus, if $s,t\in(b,c)$, $G(t,s)$ is the Cauchy function for L at b and, from (2.13), satisfies (2.11). Similarly $G(t,s)=0$, if $s<a$ and $t>s$.

Consider $K(t, s) = G(t, s) - G(c, s)u_m(t)/u_m(c)$. Observe that $u(t) = K(t, s)$ is a solution of $Lu = 0$ if $t \neq s$, u and its first $n-2$ derivatives are continuous at s, $u^{(n-1)}(s+) - u^{(u-1)}(s-) = 1$ and u has $n-1$ zeros at the points common to τ and σ as well as a zero at c. Thus $K(t, s)$ is Green's function for the problem

$$Lw = f, \quad w \text{ has } n \text{ zeros at } \tau_a^c. \tag{2.15}$$

The point b occurs m times in τ_a^c. Let $t_0 \in (b, c)$ and let $f \in C(J), f > 0$, be chosen so that

$$\left| \int_a^{t_0} f(s)[G(t_0, s) - G(c, s)u_m(t_0)/u_m(c)]\, ds \right| < \int_{t_0}^c f(s)G(c, s)u_m(t_0)/u_m(c)\, ds. \tag{2.16}$$

This may be accomplished by choosing f sufficiently large on (t_0, c) since, as we have seen in the preceding paragraph, (2.11) implies $G(c, s) > 0$ for $s \in (b, c)$ and u_m has no zeros in $(b, c]$.

The solution of (2.15) is

$$w(t) = \int_J f(s)K(t, s)\, ds \tag{2.17}$$

and this function has m zeros at b, with

$$w^{(m)}(b) = \int_J f(s)\frac{\partial^m}{\partial t^m}K(b, s)\, ds = \int_J f(s)\frac{\partial^m}{\partial t^m}G(b, s)\, ds \tag{2.18}$$

since $u^{(m)}(b) = 0$, because u_m has $m+1$ zeros at b. Therefore

$$w^{(m)}(b) = v^{(m)}(b) > 0 \quad \text{from (2.10), (2.14), (2.18),}$$

so that for some $\varepsilon > 0$

$$w(t) > 0, \qquad t \in (b, b+\varepsilon). \tag{2.19}$$

Now from (2.17)

$$\begin{aligned} w(t_0) = \int_J f(s)K(t_0, s) &= \int_J f(s)[G(t_0, s) - G(c, s)u_m(t_0)/u_m(c)]\, ds \\ &= \int_a^{t_0} f(s)[G(t_0, s) - G(c, s)u_m(t_0)/u_m(c)]\, ds \\ &\quad - \int_{t_0}^c f(s)G(c, s)u_m(t_0)/u_m(c)\, ds, \end{aligned}$$

since $G(t_0, s) = G(c, s) = 0$, $s < a$ and $G(t_0, s) = 0$, $s > t_0$ and $G(c, s) = 0$, $s > c$. It follows from (2.16) that $w(t_0) < 0$ which, with (2.19), implies w has a zero in (b, c). Since w has n zeros at τ_a^c and a zero in (b, c), w has $n+1$ zeros in $[a, c] \subset I$. But then $Lw = f > 0$ contradicts $L \in \mathcal{P}_n(I)$.

We have now shown that the assumption $L \in \mathcal{P}_n(I)$, $L \notin \mathcal{D}_n(I)$, where I is a subinterval of J which is not closed, leads to a contradiction. This establishes Proposition 2.6.

SUBSPACES OF STABLE AND UNSTABLE SOLUTIONS OF A FUNCTIONAL DIFFERENTIAL EQUATION IN A FADING MEMORY SPACE: THE CRITICAL CASE*

G. S. JORDAN†, OLOF J. STAFFANS‡ AND ROBERT L. WHEELER§

Abstract. We study the asymptotic behavior of the linear infinite delay, autonomous system of functional differential equations

$$(*)\qquad \begin{aligned} &x'(t)+\mu * x(t)=f(t) \qquad (t\geqq 0),\\ &x(t)=\phi(t) \qquad (t\leqq 0).\end{aligned}$$

Here μ is an n-dimensional matrix-valued measure supported on $[0,\infty)$, finite with respect to a weight function, and f, ϕ and x are $\mathbf{C}^n$-valued continuous or locally integrable functions bounded with respect to a fading memory norm. We find conditions that ensure that the state space of (*) can be written as a direct sum of a stable subspace, which is characterized by the fact that solutions are small at infinity, a finite dimensional central-stable subspace in which solutions are neither small nor large at infinity, and a finite dimensional exponentially unstable subspace consisting of exponentially growing solutions. We give estimates for the rate of decay at infinity of solutions belonging to the stable subspace. Our results extend earlier work of Staffans [10], [11] since we analyze the critical case in which the components of the solutions are not exponentially separated, as well as the noncritical case.

1. Introduction.

We study the asymptotic behavior of the solutions of the linear, infinite delay, autonomous system of functional differential equations

$$(1.1)\qquad \begin{aligned} &x'(t)+\mu * x(t)=f(t), \qquad t\in\mathbf{R}^+,\\ &x(t)=\phi(t), \qquad t\in\mathbf{R}^-.\end{aligned}$$

Here $\mathbf{R}^+=[0,\infty)$, $\mathbf{R}^-=(-\infty,0]$, μ is an n by n matrix-valued measure supported on $\mathbf{R}^+$ which is finite with respect to a weight function, and x, f and ϕ are $\mathbf{C}^n$-valued functions. The initial function ϕ and the forcing function f belong to certain weighted function spaces compatible with the weighted measure space containing μ. As usual, $\mu * x$ denotes the convolution

$$(\mu * x)(t)=\int_{-\infty}^{\infty} d\mu(s)x(t-s).$$

We find conditions that ensure that the solution subspace of (1.1) can be decomposed into a direct sum of a *stable subspace* $\mathcal{S}$, which is characterized by the fact that the solutions in $\mathcal{S}$ are small at infinity, a finite dimensional *central-stable subspace* $\mathcal{C}$ in which solutions do not decay, but also do not grow at exponential rates, and finally a finite dimensional *unstable subspace* $\mathcal{U}$ consisting of exponentially growing solutions.

The question that we consider here has been discussed before in a very similar setting in [10] and [11], and our present results contain those of [10] and [11]. The chief improvement of our results over those in [10] and [11] is that we now treat the critical case in which the growth rates of the components of the solution are not exponentially separated, as well as the noncritical case previously studied.

We do not employ semigroup theory, but one could give a semigroup formulation of our results. In this formulation, the noncritical case is the one where the stable subspace and its complementary subspace correspond to disjoint, separated parts of the spectrum of the generator. This is in contrast to the critical case where the spectrum corresponding to the central subspace lies on the boundary of the spectrum corresponding to the stable subspace.

We also give an estimate for the rate of decay at infinity of solutions belonging to the stable subspace (Corollary 6.1). In the case of systems of integrodifferential equations, a similar decay estimate was obtained by Jordan and Wheeler [5]. For other results on the structure of solutions of systems of integrodifferential equations, see [6] and [8]. A similar structure theorem for an integrodifferential equation in Hilbert space is given in [9].

In order to treat the critical case, we have been forced first to refine the description given in [11] of the null space of the convolution operator appearing on the left side of (1.1), since the description in [11] applies only to the noncritical case. We have separated this part of the theory into the paper [4], and the present paper can be regarded as a continuation of [4]. In [4] we describe the null space of this operator in terms of the Jordan chains at its eigenvalues, and to do this we develop a Smith factorization theorem for locally analytic matrix-valued functions. A similar description of the null space in the case of finite delay equations is given by Kappel and Wimmer [7]. We expect the reader to be familiar with the concepts and results of [4].

2. The functional differential equation. The setting in which we study the functional differential equation (1.1) is very similar to the setting used in § 7 of [11]. It is more general in the sense that the critical case is also included. The equation in [1] is neutral rather than retarded, but to keep the technical details as simple as possible we here require the equation to be retarded.

As we already mentioned above, we expect the reader to be familiar with [4]. In spite of this, let us recall the most basic concepts from [4].

We call a continuous positive function ρ a *dominating function* or a *weight function* if ρ is submultiplicative, i.e., ρ satisfies

$$\rho(s+t) \leqq \rho(s)\rho(t), \qquad s, t \in \mathbf{R}, \tag{2.1}$$

and $\rho(0)=1$. A continuous positive function η is called an *influence function* dominated by ρ if $\eta(0)=1$ and

$$\eta(s+t) \leqq \eta(s)\rho(t), \qquad t, s \in \mathbf{R}. \tag{2.2}$$

It follows from (2.1) and (2.2) that η always satisfies

$$[\rho(-t)]^{-1} \leqq \eta(t) \leqq \rho(t), \qquad t \in \mathbf{R}. \tag{2.3}$$

Throughout this paper we work in weighted spaces, where the weights are either dominating functions or influence functions. For example, if we let the set of n by n matrices be denoted by $\mathbf{C}^{n\times n}$, then $M(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$ is the set of matrix-valued measures μ on $\mathbf{R}$ for which $\int_{\mathbf{R}} \rho(s)\,d|\mu|(s) < \infty$. (In the scalar case $|\mu|$ is the total variation measure of μ, and in the matrix case we use a matrix norm when computing the total variation $|\mu|$ of μ.) The space $L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$ is defined analogously with measures replaced by measurable functions, and $V(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$ is the subspace of measures which one gets by adding point masses at zero to functions in $L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$. When we write $x \in L^p(\mathbf{R}; \mathbf{C}^n; \eta)$, we mean that x is defined on $\mathbf{R}$ with values in $\mathbf{C}^n$, and that ηx belongs to the ordinary nonweighted L^p-space on $\mathbf{R}$. A continuous function x belongs to $BUC(\mathbf{R}; \mathbf{C}^n; \eta)$ if $x \in L^\infty(\mathbf{R}; \mathbf{C}^n; \eta)$, and if $\tau_t x \to x$ in $L^\infty(\mathbf{R}; \mathbf{C}^n; \eta)$ as $t \to 0$, where τ_t is the translation operator $\tau_t x(s) = x(s+t)$, $s, t \in \mathbf{R}$. A special subclass of $BUC(\mathbf{R}; \mathbf{C}^n; \eta)$ is $BC_0(\mathbf{R}; \mathbf{C}^n; \eta)$ which consists of those functions x in $BUC(\mathbf{R}; \mathbf{C}^n; \eta)$ which satisfy $\lim_{|t|\to\infty} \eta(t)x(t) = 0$. We define $W^{m,p}(\mathbf{R}; \mathbf{C}^n; \eta)$, $BUC^m(\mathbf{R}; \mathbf{C}^n; \eta)$ and $BC_0^m(\mathbf{R}; \mathbf{C}^n; \eta)$ to be the set of functions which together with their first m derivatives belong to $L^p(\mathbf{R}; \mathbf{C}^n; \eta)$, $BUC(\mathbf{R}; \mathbf{C}^n; \eta)$ or $BC_0(\mathbf{R}; \mathbf{C}^n; \eta)$, respectively. In the preceding function space notation, when we replace $\mathbf{R}$ by $\mathbf{R}^+$ or $\mathbf{R}^-$, we mean the spaces of functions which one gets by restricting the functions in question to $\mathbf{R}^+$ or $\mathbf{R}^-$.

After these preliminaries, let us return to the original equation. Defining $\mathscr{L}$ to be the operator

$$\mathscr{L}x = x' + \mu * x, \tag{2.4}$$

where x' is the distribution derivative of x, we can write (1.1) in the following form:

$$\begin{aligned} \mathscr{L}x(t) &= f(t), && t \in \mathbf{R}^+, \\ x(t) &= \phi(t), && t \in \mathbf{R}^-. \end{aligned} \tag{2.5}$$

We let ρ be a given weight function on $\mathbf{R}$, and suppose that $\mu \in M(\mathbf{R}+; \mathbf{C}^{n\times n}; \rho)$, i.e., $\mu \in M(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$, and μ is supported on $\mathbf{R}^+$. We let η be an influence function dominated by ρ, let $\mathscr{B}$ be one of the spaces L^p, $1 \leqq p \leqq \infty$, BUC, or BC_0, and let $\mathscr{B}^{m+1}$ be one of the spaces $W^{m,p}$, BUC^m or BC_0^m. The functions ϕ and f in (2.5) are throughout assumed to satisfy $\phi \in \mathscr{B}^{m+1}(\mathbf{R}^-; \mathbf{C}^n; \eta)$ and $f \in \mathscr{B}^m(\mathbf{R}^+; \mathbf{C}^n; \eta)$ for some $m \geqq 0$.

We look for a solution of (2.5) which is locally in $\mathscr{B}^{m+1}$; in particular, we require x to be continuous at zero. A necessary condition for the existence of such a solution is that ϕ and f in (2.5) are compatible in the sense that if we define g by

$$g(t) = \begin{cases} \mathscr{L}\phi(t), & t < 0, \\ f(t), & t \geqq 0, \end{cases} \tag{2.6}$$

then g must belong to $\mathscr{B}^m$. This is true, because the operator $\mathscr{L}$ maps $\mathscr{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta)$ continuously into $\mathscr{B}^m(\mathbf{R}; \mathbf{C}^n; \eta)$. If $\mathscr{B} = L^p$, and $m = 0$, then this extra condition is automatically satisfied. If $\mathscr{B} = L^p$ and $m > 0$, then it is equivalent to

$$\mathscr{L}\phi^{(k)}(0) = f^{(k)}(0), \qquad 0 \leqq k \leqq m-1,$$

and if $\mathscr{B} = BUC$ or $\mathscr{B} = BC_0$, then it is equivalent to

$$\mathscr{L}\phi^{(k)}(0) = f^{(k)}(0), \qquad 0 \leqq k \leqq m.$$

From now on, we shall only consider data (ϕ, f) satisfying this extra condition, and choose our *state space* $\mathscr{D}$ to be

$$\mathscr{D} = \{(\phi, f) \in \mathscr{B}^{m+1}(\mathbf{R}^-; \mathbf{C}^n; \eta) \times \mathscr{B}^m(\mathbf{R}^+; \mathbf{C}^n; \eta) \,|\, \text{the function } g \text{ in (2.6) belongs to } \mathscr{B}^m(\mathbf{R}; \mathbf{C}^n; \eta)\}.$$

This is not the only possible choice. One could also restrict $\mathscr{D}$ further, and get a slightly different set of results. We shall return to that question elsewhere.

For each point $(\phi, f) \in \mathscr{D}$, we denote the solution of (2.5) which corresponds to this pair of functions by $x(\phi, f)$.

Let r be the fundamental solution of (2.5), i.e., the unique right continuous solution of the equation

$$r'+r*\mu=r'+\mu*r=\delta I \tag{2.7}$$

which vanishes on $(-\infty, 0)$. Here r' is the distribution derivative of r, δ is the unit point mass at zero, and I is the identity matrix. This function r is locally absolutely continuous with the exception of a jump discontinuity at zero, and it grows at most exponentially at infinity; see e.g. [10, Thm. 5.2].

The solution $x=x(\phi,f)$ of (2.5) can be written in the form

$$x(\phi,f)(t)=\begin{cases}\phi(t), & t\in\mathbf{R}^-,\\ r(t)\phi(0)+r*(f+M\phi)(t), & t\in\mathbf{R}^+,\end{cases} \tag{2.8}$$

where

$$M\phi(t)=-\int_{(t,\infty)} d\mu(s)\phi(t-s), \qquad t\in\mathbf{R}^+, \tag{2.9}$$

and we interpret f and $M\phi$ to be zero on $(-\infty, 0)$ in the definition of $r*(f+M\phi)$. See e.g. [12].

When one wants to know how the solutions of (2.5) behave asymptotically one has to look at eigenvalues of the formal Laplace transform

$$\hat{L}(z)=zI+\hat{\mu}(z) \tag{2.10}$$

of the operator $\mathscr{L}$ in (2.4). This function is well defined for $\Re z\geqq\omega$, where

$$\omega=-\lim_{t\to\infty} t^{-1}\log\rho(t)$$

is the exponential order of decay of ρ at infinity (cf. [4]). Throughout the sequel we assume that $\omega\leqq 0$, so that $\hat{L}(z)$ is defined in the closed right half plane. The importance of the eigenvalues of $\hat{L}$ becomes obvious once one realizes that the Laplace transform $\hat{r}$ of r in (2.7) is $\hat{r}(z)=[\hat{L}(z)]^{-1}$ for $\Re z$ sufficiently large. Roughly speaking, those eigenvalues of $\hat{L}(z)$ which belong to the open right half plane give rise to exponentially growing solutions of (1.1), and those on the imaginary axis give rise to solutions which neither grow exponentially, nor die out. If $\omega<0$, then it is possible that $\hat{L}(z)$ also has eigenvalues in the open left half plane, but these eigenvalues are less interesting in the sense that the solutions of (1.1) which they produce die out exponentially as $t\to\infty$. Accordingly, we shall more or less ignore the open left half plane, and we classify the eigenvalues of $\hat{L}(z)$ in the closed right half plane as *unstable* or *central* depending on whether they belong to the open right half plane or to the imaginary axis, respectively.

Even though the condition $\omega\leqq 0$ is sufficient to imply that $\hat{L}(z)$ is defined in the closed right half plane, it is not yet sufficient to imply that the solutions of (1.1) behave asymptotically in the way in which we would like. One also needs a growth condition at infinity on f and $M\phi$ in (2.8). To see this one can, e.g., transform (2.8) to get

$$\hat{x}(z)=\hat{r}(z)(\phi(0)+\hat{f}(z)+(M\phi)^{\wedge}(z)). \tag{2.11}$$

It is important to us that $\hat{f}(z)$ and $(M\phi)^{\wedge}(z)$ are analytic in the open right half plane. To insure this we shall impose a growth restriction on ρ at minus infinity, and suppose that $\alpha\leqq 0$, where $\alpha=-\lim_{t\to-\infty} t^{-1}\log\rho(t)$ is the exponential order of decay of ρ at minus infinity. It follows from (2.3) that the condition $\alpha\leqq 0$ will indeed imply that $\hat{f}(z)$ and $(M\phi)^{\wedge}(z)$ are analytic in the open right half plane. It is always true that $\omega\leqq\alpha$; hence the new assumption $\alpha\leqq 0$ implies the earlier one $\omega\leqq 0$.

Above we have divided the eigenvalues of $\hat{L}$ in the closed right half plane into two classes: The set of unstable eigenvalues and the set of central eigenvalues. From a stability point of view, this division is very appropriate, but from a technical point of view, the line $\Re z=0$ is no different from any other vertical line in the complex plane. In [10] and [11] all the decomposition arguments were made with the imaginary axis replaced by an arbitrary vertical line. A more technical division of the eigenvalues of $\hat{L}(z)$, which in spirit is more similar to the approach in [10] and in [11], would be to classify the eigenvalues as critical or noncritical depending on whether they belong to the critical region $\omega \leqq \Re z \leqq \alpha$ or to the noncritical region $\Re z > \alpha$. Roughly speaking, the eigenvalues on the line $\Re z = \omega$ are those which are most difficult to handle (none of $\hat{L}, \hat{f}$ and $(M\phi)^{\wedge}$ is analytic on this line), those in the strip $\omega < \Re z \leqq \alpha$ are somewhat easier to deal with (here $\hat{L}$ is analytic but not $\hat{f}$ and $(M\phi)^{\wedge}$), and eigenvalues in $\Re z > \alpha$ cause virtually no technical difficulties ($\hat{L}, \hat{f}$ and $(M\phi)^{\wedge}$ are all analytic). In [10] and [11] only noncritical eigenvalues are allowed, and the chief improvement here is that we are also able to treat critical eigenvalues. Going back to the original decomposition of the eigenvalues into central and unstable eigenvalues, this means that here we are able to deal with the case when $\alpha=0$ and $\hat{L}(z)$ has central eigenvalues, and even with the case when $\omega=\alpha=0$ and $\hat{L}(z)$ has central eigenvalues.

3. The central-stable and the unstable subspaces. As we observed earlier, the eigenvalues in the closed right half plane of $\hat{L}$ in (2.8) are of crucial importance for the asymptotic behavior of the solutions of (2.5). As $|z|\to\infty$, also $|\det(\hat{L}(z))|\to\infty$, so the set of all eigenvalues of $\hat{L}$ is bounded. Because of the analyticity of $\hat{L}$ in $\Re z>\omega$, the eigenvalues can only accumulate at the line $\Re z=\omega$. Throughout the sequel we shall suppose that the open right half plane contains only finitely many eigenvalues. It follows from the preceding discussion that this assumption is automatically satisfied if $\omega<0$. Later on we shall also assume that there are at most finitely many central eigenvalues, but for the moment this assumption is not needed.

In this section we intend to show that the state space $\mathscr{D}$ can be divided into an unstable subspace $\mathscr{U}$, and a central-stable subspace $\mathscr{CS}$. Here we use the same technique as is used in [10] and [11], and a reader familiar with [10] and [11] should have no difficulty in extending the results presented here to the neutral equation (and to allow infinitely many unstable eigenvalues of the same type as in [10] and [11]).

Let Z_U be the set of all eigenvalues z_l of $\hat{L}$ satisfying $\Re z_l>0$, and suppose that Z_U is a finite (possibly empty) set. If $Z_U=\emptyset$, then define $\lambda=\infty$, $\kappa=0$; otherwise, define

$$\lambda=\min\{\Re z_l | z_l\in Z_U\}, \qquad \kappa=\max\{\Re z_l | z_l \in Z_U\}. \tag{3.1}$$

DEFINITION 3.1. A point (ϕ,f) in $\mathscr{D}$ belongs to the *central-stable subspace* $\mathscr{CS}$, if the solution $x(\phi,f)$ of (2.5) satisfies $x(\phi,f)(t)=o(e^{\lambda t})$ as $t\to\infty$. A point $(\phi,0)$ in $\mathscr{D}$ belongs to the *unstable subspace* $\mathscr{U}$ if $\mathscr{L}\phi(t)=0$ for $t\in\mathbf{R}^-$, and $\phi(t)=O(e^{-|\varepsilon t|})$ as $t\to-\infty$, for some $\varepsilon>0$.

Here we consider the growth condition $x(\phi,f)=o(e^{\lambda t})$ as $t\to\infty$ to be vacuously satisfied if $\lambda=\infty$. Also, $\mathscr{L}\phi(t)$ is defined in the obvious way, namely $\mathscr{L}\phi(t)=\phi'(t)+\mu*\phi(t)$ for $t\in\mathbf{R}^-$ (as μ vanishes on $(-\infty,0)$, this definition makes sense).

As we already mentioned above, we want to show that $\mathscr{D}=\mathscr{CS}\oplus\mathscr{U}$. To do this we proceed as follows. Fix two constants γ and ξ, $0<\gamma<\lambda$, and $\xi>\kappa$. Define three new dominating functions ρ^C, ρ^U and ρ_U and a new influence function η_U by

$$\begin{aligned} &\rho^C(t)=e^{-\gamma t}, && t\in\mathbf{R},\\ &\rho^U(t)=e^{-\xi t}, && t\in\mathbf{R},\\ &\rho_U(t)=\max\{\rho^C(t),\rho^U(t)\}, && t\in\mathbf{R},\\ &\eta_U(t)=\min\{\rho^C(t),\rho^U(t)\}, && t\in\mathbf{R}. \end{aligned} \tag{3.2}$$

By Theorem 5.2 of [10], we have $r \in L^1(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^U)$. It follows from (2.7) and Lemma 2.1 of [10] that $r' - \delta I \in L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho^U)$; therefore $r \in W^{1,1}(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^U)$. By Lemma 3.7 of [10], $r \in BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^U)$. Also, by Theorem 5.1 of [10], there is a unique right continuous function $r_{CS} \in W^{1,1}((-\infty, 0); \mathbf{C}^{n\times n}; \rho^C) \cap W^{1,1}(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^C)$ (the comment above on the smoothness of r also applies here), which satisfies (2.7) with r replaced by r_{CS}. It follows again from Lemma 3.7 of [10] that $r_{CS} \in BC_0((-\infty, 0); \mathbf{C}^{n\times n}; \rho^C) \cap BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^C)$. Define $d_U = r - r_{CS}$. Then $d_U \in BC_0(\mathbf{R}; \mathbf{C}^{n\times n}; \eta_U)$ (the two jump discontinuities of r and r_{CS} at zero cancel each other). (A more explicit description of d_U is given in § 6.)

The function d_U defined above plays a crucial role in our decomposition of $\mathscr{D}$ into $\mathscr{U} \oplus \mathscr{CS}$, and it will be very important that r_{CS} and d_U can be convolved with the function $f + M\phi$ appearing in (2.8). That this is the case one can see as follows: We know that $f + M\phi$ in (2.8) belongs to $\mathscr{B}(\mathbf{R}^+; \mathbf{C}^n; \eta)$ when $\mathscr{B} = L^p$ for some p, $1 \leqq p \leqq \infty$, and to $L^\infty(\mathbf{R}^+; \mathbf{C}^n; \eta)$ when $\mathscr{B} = BUC$ or $\mathscr{B} = BC_0$. As $\gamma > 0 \geqq \alpha$, this implies that $f + M\phi \in L^1(\mathbf{R}^+; \mathbf{C}^n; \rho_U)$. If we define both f and $M\phi$ to vanish on $(-\infty, 0)$ then $f + M\phi \in L^1(\mathbf{R}; \mathbf{C}^n; \rho_U)$. Now, ρ^C and η_U are both influence functions dominated by ρ_U, and therefore, by Lemma A.1 in Appendix A, $r_{CS} * (f + M\phi)$ and $d_U * (f + M\phi)$ are well defined, $r_{CS} * (f + M\phi) \in BC_0(\mathbf{R}; \mathbf{C}^n; \rho^C)$, and $d_U * (f + M\phi) \in BC_0(\mathbf{R}; \mathbf{C}^n; \eta_U)$.

For each point $(\phi, f) \in \mathscr{D}$, we define $y(\phi, f)$ and $z(\phi, f)$ by

$$y(\phi,f)(t) = \begin{cases} \phi(t) + r_{CS}(t)\phi(0) + r_{CS} * (f + M\phi)(t), & t < 0, \\ r_{CS}(t)\phi(0) + r_{CS} * (f + M\phi)(t), & t \geqq 0, \end{cases} \tag{3.3}$$

$$z(\phi,f)(t) = d_U(t)\phi(0) + d_U * (f + M\phi)(t), \qquad t \in \mathbf{R}.$$

Then, by (2.8), $x(\phi, f) = y(\phi, f) + z(\phi, f)$.

THEOREM 3.1. *Given $(\phi, f) \in \mathscr{D}$, define $M\phi$ by (2.9), and $y(\phi, f)$ and $z(\phi, f)$ by (3.3), and let ψ and ζ be the restrictions of $y(\phi, f)$ and $z(\phi, f)$, respectively, to $\mathbf{R}^-$. Let P_{CS} be the operator which maps (ϕ, f) into (ψ, f), and let P_U be the operator which maps (ϕ, f) into $(\zeta, 0)$. Then P_{CS} and P_U are continuous projections in $\mathscr{D}$ with ranges $\mathscr{CS}$ and $\mathscr{U}$, respectively, and $P_{CS} + P_U = I$.*

The proof of Theorem 3.1 depends upon two lemmas. In the first the unstable subspace $\mathscr{U}$ is described in a different and much more explicit way. For each unstable eigenvalue $z_l \in Z_U$, we let $\mathscr{N}_l$ consist of the zero function together with all functions of the form

$$\sum_{i=0}^{p-1} \frac{t^i}{i!} r_{p-1-i}\, e^{z_l t}, \qquad t \in \mathbf{R}, \tag{3.4}$$

where $r_0 \neq 0$ and $r_0, \cdots, r_{p-1}$ is a right Jordan chain of $\hat{L}$ at z_l (see [4, Definition 4.1]).

LEMMA 3.1. *A point $(\phi, 0)$ in $\mathscr{D}$ belongs to $\mathscr{U}$ if and only if ϕ is the restriction to $\mathbf{R}^-$ of a function $x \in \oplus_{z_l \in Z_U} \mathscr{N}_l$, or equivalently, if and only if ϕ is the restriction to $\mathbf{R}^-$ of a function $x \in BUC^1(\mathbf{R}; \mathbf{C}^n; \eta_U)$ satisfying $\mathscr{L}x = 0$. Moreover, $\mathscr{CS} \cap \mathscr{U} = \{(0, 0)\}$.*

Lemma 3.1 has one especially important consequence, namely, it implies that the dimension of $\mathscr{U}$ is finite, and equal to the sum of the algebraic orders of the unstable eigenvalues of $\hat{L}$. This is true because by the discussion in [4, § 4], this is the dimension of $\oplus_{z_l \in Z_U} \mathscr{N}_l$, and because the correspondence between the initial function ϕ and $x(\phi, 0)$ is one to one.

Proof. That a function $x \in BUC^1(\mathbf{R}; \mathbf{C}^n; \eta_U)$ satisfies $\mathscr{L}x = 0$ if and only if $x \in \oplus_{z_l \in Z_U} \mathscr{N}_l$ follows from Theorem 5.1 of [10]. Thus, the two different characterizations of the functions x in Lemma 3.1 are equivalent.

It is clear that if ϕ is of the type mentioned in Lemma 3.1, then $(\phi, 0) \in \mathscr{U}$.

Conversely, suppose that $(\phi, 0) \in \mathscr{U}$. We know that $r \in BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \eta_U)$, that r vanishes on $(-\infty, 0)$, and that $f + M\phi \in L^1(\mathbf{R}; \mathbf{C}^n; \rho_U)$. Hence, by (2.8) and Lemma A.1 in Appendix A, we have $x(\phi, 0) \in BC_0(\mathbf{R}^+; \mathbf{C}^n; \eta_U)$. If we choose γ in (3.2) to be so small that $\phi(t) = O(e^{\varepsilon t})$, $t \to -\infty$, for some $\varepsilon > \gamma$, then $x(\phi, 0) \in BC_0(\mathbf{R}^-; \mathbf{C}^n; \eta_U)$. Thus, since $x(\phi, 0)$ is continuous at zero, $x(\phi, 0) \in BC_0(\mathbf{R}; \mathbf{C}^n; \eta_U)$. Moreover, as $\mathscr{L}\phi(t) = 0$ for $t \in \mathbf{R}^-$, and $x(\phi, 0)$ satisfies (2.5) with $f = 0$, we have $\mathscr{L}x(\phi, 0) = 0$. Explicitly, the condition $\mathscr{L}x(\phi, 0) = 0$ means that $(x(\phi, 0))' = -\mu * (\phi, 0)$, and this together with Lemma 2.1 of [10] gives $(x(\phi, 0))' \in BC_0(\mathbf{R}; \mathbf{C}^n; \eta_U)$. Thus, ϕ is the restriction to $\mathbf{R}^-$ of the function $x(\phi, 0)$, which belongs to $BC_0^1(\mathbf{R}; \mathbf{C}^n; \eta_U)$ and satisfies $\mathscr{L}x(\phi, 0) = 0$.

The fact that $\mathscr{CS} \cap \mathscr{U} = \{(0, 0)\}$ follows immediately from the growth rate at infinity imposed on $x(\phi, f)$ in the case when $(\phi, f) \in \mathscr{CS}$ together with the fact that $x(\phi, 0) \in \oplus_{z_l \in Z_U} \mathscr{N}_l$ when $(\phi, 0) \in \mathscr{U}$. □

LEMMA 3.2. *The range of P_{CS} is contained in $\mathscr{CS}$, and the range of P_U is contained in $\mathscr{U}$.*

Proof. Define ψ and ζ as in Theorem 3.1. We have to show that $(\psi, f) \in \mathscr{CS}$, and that $(\zeta, 0) \in \mathscr{U}$.

Let us begin with the claim that $(\zeta, 0) \in \mathscr{U}$. It follows from the discussion in the paragraph containing (3.2) that $d_U \in BC_0(\mathbf{R}; \mathbf{C}^{n\times n}; \eta_U)$. Moreover, as both r and r_{CS} satisfy (2.7), and $d_U = r - r_{CS}$, we have $\mathscr{L}d_U = 0$. In the same way as in the preceding proof we conclude that $d_U \in BC_0^1(\mathbf{R}; \mathbf{C}^{n\times n}; \eta_U)$. Recall that $f + M\phi \in L^1(\mathbf{R}; \mathbf{C}^n; \rho_U)$, and use (3.3) and Lemma 3.5 of [10] to get

$$\begin{aligned}\mathscr{L}z(\phi, f) &= \mathscr{L}(d_U\phi(0)) + \mathscr{L}(d_U * (f + M\phi)) \\ &= (\mathscr{L}d_U)\phi(0) + (\mathscr{L}d_U) * (f + M\phi) = 0.\end{aligned}$$

It follows from (3.3) and Lemma 3.5 of [10] that $z(\phi, f) \in BC_0^1(\mathbf{R}; \mathbf{C}^n; \eta_U)$. By Lemma 3.1, $(\zeta, 0) \in \mathscr{U}$.

It remains to show that $(\psi, f) \in \mathscr{CS}$. We know from the preceding argument that $z(\phi, f) \in \mathscr{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta_U)$, $\mathscr{L}z(\phi, f) = 0$, and $y(\phi, f) = x(\phi, f) - z(\phi, f)$, so $y(\phi, f)$ belongs locally to $\mathscr{B}^{m+1}$, and $y(\phi, f)$ is the solution of (2.5) with ϕ replaced by ψ (in other words, $y(\phi, f) = x(\psi, f)$). Therefore, to show that $(\psi, f) \in \mathscr{CS}$, it suffices to prove that $y(\phi, f)(t) = o(e^{\lambda t})$ as $t \to \infty$. This, however, follows directly from (3.3), because we already know that $r_{CS} \in BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^C)$ and $r_{CS} * (f + M\phi) \in BC_0(\mathbf{R}^+; \mathbf{C}^n; \rho^C)$; hence, $y(\phi, f)(t) = o(e^{\gamma t})$ as $t \to \infty$, which is a stronger statement than the needed $y(\phi, f)(t) = o(e^{\lambda t})$ as $t \to \infty$. □

Let us formally record the fact which became apparent at the end of the preceding proof:

COROLLARY 3.1. *If $(\phi, f) \in \mathscr{CS}$, then $x(\phi, f)(t) = o(e^{\varepsilon t})$ as $t \to \infty$ for every $\varepsilon > 0$.*

If one strengthens the assumptions on μ, f and ϕ, then this growth estimate can be further improved. See §§ 4 and 6.

Proof of Theorem 3.1. By now the proof of Theorem 3.1 is trivial, i.e., Theorem 3.1 is a direct consequence of Lemmas 3.1 and 3.2 (if $P_{CS} + P_U = I$, the range of P_{CS} is contained in $\mathscr{CS}$, the range of P_U is contained in $\mathscr{U}$, and $\mathscr{CS} \cap \mathscr{U} = \{(0, 0)\}$, then necessarily P_{CS} and P_U are projections, and their ranges are the claimed ones). □

4. The stable and the central subspaces in the noncritical case. In the preceding section we subtracted off an exponentially growing part from the solution, and got a remainder in $\mathscr{CS}$ which grows slower than exponentially as $t \to \infty$. If $\alpha < 0$, then one can use exactly the same technique to subtract off another part of the solution, which neither grows exponentially, nor tends to zero as $t \to \infty$. The new remainder tends to zero exponentially as $t \to \infty$. The technique is exactly the same as in § 3, and therefore we shall state the results, but leave the proofs to the reader.

Throughout this section we assume that $\alpha < 0$ (except in Proposition 4.1). Let Z_S be the (possibly empty, possibly infinite) set of eigenvalues z_l of $\hat{L}$ satisfying $\alpha < \Re z_l < 0$, and let Z_C be the set of eigenvalues of $\hat{L}$ on the imaginary axis. Define λ as in § 3. If $Z_S = \emptyset$, then define $\iota = \alpha$; otherwise define

$$\iota = \max \{\Re z_l | z_l \in Z_S\}. \tag{4.1}$$

Definition 4.1. A point (ϕ, f) in $\mathscr{D}$ belongs to the stable subspace $\mathscr{S}$, if the solution $x(\phi, f)$ of (2.5) satisfies $x(\phi, f)(t) \to 0$ as $t \to \infty$. A point $(\phi, 0)$ in $\mathscr{D}$ belongs to the *central subspace* $\mathscr{C}$ if $\mathscr{L}\phi(t) = 0$ for $t \in \mathbf{R}^-$, $\phi(t) = O(e^{(\iota+\varepsilon)t})$ as $t \to -\infty$, for some $\varepsilon > 0$, and $x(\phi, 0)(t) = o(e^{\lambda t})$ as $t \to \infty$.

Clearly, both $\mathscr{S}$ and $\mathscr{C}$ are subspaces of $\mathscr{C}\mathscr{S}$.

We want to show that $\mathscr{C}\mathscr{S} = \mathscr{S} \oplus \mathscr{C}$. To do this we proceed as in § 3. We fix two constants ν and γ, satisfying $\iota < \nu < 0$ and $0 < \gamma < \lambda$. Define three dominating functions ρ^S, ρ^C and ρ_C, and a new influence function η_C by

$$\begin{aligned} \rho^S(t) &= e^{-\iota t}, && t \in \mathbf{R}, \\ \rho^C(t) &= e^{-\gamma t}, && t \in \mathbf{R}, \\ \rho_C(t) &= \max \{\rho^S(t), \rho^C(t)\}, && t \in \mathbf{R}, \\ \eta_C(t) &= \min \{\rho^S(t), \rho^C(t)\}, && t \in \mathbf{R}. \end{aligned} \tag{4.2}$$

By Theorem 5.1 of [10], we can find a unique right continuous solution $r_S \in W^{1,1}((-\infty, 0); \mathbf{C}^{n \times n}; \rho^S) \cap W^{1,1}(\mathbf{R}^+; \mathbf{C}^{n \times n}; \rho^S)$ to the resolvent equation (2.7). Define $d_C = r_{CS} - r_S$. Then $d_C \in BC_0(\mathbf{R}; \mathbf{C}^{n \times n}; \eta_C)$.

For each point $(\phi, f) \in \mathscr{D}$, we define $v(\phi, f)$ and $w(\phi, f)$ by

$$\begin{aligned} v(\phi, f)(t) &= \begin{cases} \phi(t) + r_S(t)\phi(0) + r_S * (f + M\phi)(t), & t \leqq 0, \\ r_S(t)\phi(0) + r_S * (f + M\phi)(t), & t \geqq 0, \end{cases} \\ w(\phi, f)(t) &= d_C(t)\phi(0) + d_C * (f + M\phi)(t), \qquad t \in \mathbf{R}. \end{aligned} \tag{4.3}$$

Then, by (3.3), $v(\phi, f) + w(\phi, f) = y(\phi, f)$.

Theorem 4.1. *Given $(\phi, f) \in \mathscr{D}$, define $v(\phi, f)$ and $w(\phi, f)$ by* (4.3), *and let θ and χ be the restrictions of $v(\phi, f)$ and $w(\phi, f)$, respectively, to $\mathbf{R}^-$. Let P_S be the operator which maps (ϕ, f) into (θ, f), and let P_C be the operator which maps (ϕ, f) into $(\chi, 0)$. Then P_S and P_C are continuous projections in $\mathscr{D}$ with ranges $\mathscr{S}$ and $\mathscr{C}$, respectively, and $P_S + P_C = P_{CS}$.*

For each $z_l \in Z_C$ we define $\mathscr{N}_l$ in the same way as in the paragraph containing (3.4). Analogously to Lemma 3.1 we have Lemma 4.1.

Lemma 4.1. *A point $(\phi, 0)$ in $\mathscr{D}$ belongs to $\mathscr{C}$ if and only if ϕ is the restriction to $\mathbf{R}^-$ of a function $x \in \oplus_{z_l \in Z_C} \mathscr{N}_l$, or equivalently, if and only if ϕ is the restriction to $\mathbf{R}^-$ of a function $x \in BUC^1(\mathbf{R}; \mathbf{C}^n; \eta_C)$ satisfying $\mathscr{L}x = 0$.*

Corollary 3.1 has the following analogue:

Corollary 4.1. *If $(\phi, f) \in \mathscr{S}$, then $x(\phi, f)(t) = O(e^{(\iota+\varepsilon)t})$ as $t \to \infty$ for every $\varepsilon > 0$.*

If $\alpha < 0$ and $\hat{L}$ has no central eigenvalues, then by Lemma 4.1, $\mathscr{C} = \{(0, 0)\}$, and for every $(\phi, f) \in \mathscr{C}\mathscr{S}$, the solution $x(\phi, f)$ of (2.5) tends exponentially to zero as $t \to \infty$. A similar result is true also when $\alpha = 0$ and $\hat{L}$ has no critical eigenvalues:

Proposition 4.1. *Suppose that $\alpha \leqq 0$ and that $\hat{L}$ has no eigenvalues in the region $\omega \leqq \Re z \leqq 0$. Then, for each $(\phi, f) \in \mathscr{C}\mathscr{S}$, the solution $x(\phi, f)$ of* (2.5) *satisfies $x \in \mathscr{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta)$.*

Proposition 4.1 is essentially contained in Theorems 6.5 and 6.6 of [10]. For completeness we include a proof.

Proof. Fix $\gamma, 0<\gamma<\lambda$, and define

$$\rho_S(t)=\max\{\rho(t), e^{-\gamma t}\}, \qquad t\in \mathbf{R},$$

$$\eta_S(t)=[\rho_S(-t)]^{-1}, \qquad t\in \mathbf{R}.$$

Then η_S is an influence function dominated by ρ_S. It follows from Theorem 5.1 of [10] that $r_{CS}\in L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho_S)$ and $r'_{CS}\in M(\mathbf{R}; \mathbf{C}^{n\times n}; \rho_S)$.

Let $(\phi, f)\in \mathscr{CS}$. Then, by (2.3), (2.5) and Corollary 3.1, $x(\phi, f)\in \mathscr{B}(\mathbf{R}; \mathbf{C}^n; \eta_S)$. Moreover, $x(\phi, f)$ satisfies $\mathscr{L}x(\phi, f)=g$, where $g\in \mathscr{B}^m(\mathbf{R}; \mathbf{C}^n; \eta)$ is the function defined in (2.6). If we write this equation in the form $(x(\phi, f))'=g-\mu * x(\phi, f)$, and use (2.3) and Lemma 2.1 of [10], we get $(x(\phi, f))'\in \mathscr{B}(\mathbf{R}; \mathbf{C}^n; \eta_S)$; i.e., $x\in \mathscr{B}^1(\mathbf{R}; \mathbf{C}^n; \eta_S)$. Convolving the equation $\mathscr{L}x(\phi, f)=g$ with r_{CS}, and using (2.7), we obtain $x(\phi, f)=r_{CS} * g$. Here $r_{CS}\in L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho_S)\subset L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$ and $r'_{CS}\in M(\mathbf{R}; \mathbf{C}^{n\times n}; \rho_S)\subset M(\mathbf{R}; \mathbf{C}^{n\times n}; \rho)$, and $g\in \mathscr{B}^m(\mathbf{R}; \mathbf{C}^n; \eta)$; therefore, by Lemmas 3.5 and 3.6 of [10], $x(\phi, f)\in \mathscr{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta)$. □

5. The singular part expansion. In the critical case, i.e., in the case when $\alpha=0$, the argument in the preceding section must be modified. Two problems arise. First, the method used to construct r_S and d_C is no longer available, unless $\omega<0$. Second, even if $\omega<0$, it need no longer be true that $r_S * (f+M\phi)$ and $d_C * (f+M\phi)$ are well defined.

In the scalar case one can define r_S and d_C by an alternative method which is based on the L^1-remainder theorem for locally analytic functions [3, Thm. 3.6]. The same approach can also be used in the vector case provided that we have an analogue of Theorem 3.6 in [3] for matrix-valued locally analytic functions. We devote this section to the development of such a result.

Our treatment is general in the sense that we assume that ρ is any weight function on $\mathbf{R}$ with exponential orders of growth ω and α at plus and minus infinity, respectively. Throughout this section we assume that the reader has our recent paper [4] at hand. We refer to [4] for the significance of the region $\Pi=\{x|\omega\leqq \Re z\leqq \alpha\}$, the definitions of a zero, a locally analytic zero, smoothness of order m, a local Smith factorization and partial multiplicity, and for the factorization theory for locally analytic matrix functions developed in that paper.

DEFINITION 5.1. Let M be an n by n matrix-valued function, which is locally analytic at $z_0\in\Pi$. If M^{-1} has the form

$$M^{-1}(z)=\sum_{i=1}^{p-1} K_i(z-z_0)^{i-p}+\zeta(z), \qquad z\in U\backslash\{z_0\}, \tag{5.1}$$

where each K_i is an n by n matrix, $K_0\neq 0, \zeta$ is locally analytic at z_0, and U is a neighborhood (relative to Π) of z_0, then we say that M^{-1} has a singular part expansion at z_0 of length p, and call $\sum_{i=1}^{p-1} K_i(z-z_0)^{i-p}$ the singular part of M^{-1}.

As one would expect from the scalar theory, (cf. [3, Thms. 3.4, 3.6]), the property that M^{-1} has a singular part expansion at z_0 is stronger than the property that M has a local Smith factorization at z_0:

PROPOSITION 5.1. *Let the n by n matrix function M be locally analytic at $z_0\in\Pi$, and let M^{-1} have a singular part expansion at z_0 of length p. Then M has a local Smith factorization at z_0, and the maximal partial multiplicity σ of M at z_0 is equal to p.*

Proof. By Theorem 4.4 of [1], one can construct a matrix function T that is analytic at z_0 such that T^{-1} and M^{-1} have the same singular part at z_0. In other words, if M^{-1} satisfies (5.1), then

$$T^{-1}(z)=\sum_{i=0}^{p-1} K_i(z-z_0)^{i-p}+\xi(z), \qquad z\in U\backslash\{z_0\}, \tag{5.2}$$

with ξ analytic at z_0. Clearly,

$$M^{-1}(z)=T^{-1}(z)-\xi(z)+\zeta(z), \qquad z\in U\backslash\{z_0\},$$

so that the equations

$$T^{-1}(z)M(z)=I-(\zeta(z)-\xi(z))M(z)$$

and

$$M^{-1}(z)T(z)=I+(\zeta(z)-\xi(z))T(z)$$

both hold for all $z\in U\backslash\{z_0\}$. The right-hand sides of the last two equalities are locally analytic at z_0, and they are inverses of each other for $z\neq z_0$. Thus, if we define

$$S(z)=I-(\zeta(z)-\xi(z))M(z), \qquad z\in U,$$

then S is locally analytic and invertible at z_0, and

$$M(z)=T(z)S(z), \qquad z\in U. \tag{5.3}$$

By, e.g., Theorem 3.1 of [4], the analytic matrix function T has a left local Smith factorization PDR at z_0, and, since $S(z_0)$ is invertible, $PDRS$ is a left local Smith factorization of M at z_0. The existence of a right local Smith factorization is proved in a completely analogous way.

The claim that $p=\sigma$ follows directly from the corresponding property in the analytic case, the fact that (by the construction of T) T^{-1} and M^{-1} have the same singular part expansion at z_0, and the fact that M and T have the same maximal partial multiplicity at z_0 (by Lemma 3.1 of [4] since S in (5.3) is invertible at z_0). □

Proposition 5.1 tells us that a necessary condition for M^{-1} to have a singular part expansion at z_0 is that M has a local Smith factorization at z_0. If we require the locally analytic factor in this factorization to be sufficiently smooth, then we get a sufficient condition for the existence of a singular part expansion of M^{-1} at z_0.

THEOREM 5.1. *Let the n by n matrix function M have a left local Smith factorization at $z_0\in\Pi$ with maximal partial multiplicity $\sigma>0$. In addition, assume that each factor in this factorization is smooth of order σ at z_0. Then M^{-1} has a singular part expansion at z_0.*

Of course, the analogue of Theorem 5.1 in which left factorization is replaced by right factorization is also valid.

Proof. By the hypothesis, M can be written as $M(z)=P(z)D(z)R(z)$ in a neighborhood of z_0, where P is a unimodular quasipolynomial,

$$D(z)=\operatorname{diag}\left\{\left(\frac{z-z_0}{z-c}\right)^{\kappa_1},\dots,\left(\frac{z-z_0}{z-c}\right)^{\kappa_n}\right\}$$

with $0\leqq\kappa_1\leqq\cdots\leqq\kappa_n=\sigma$, and where R is locally analytic and smooth of order σ at z_0 with $\det R(z_0)\neq 0$. Here c is a fixed constant with $\Re z<\omega$ [4, Definition 2.1]. Since R is smooth of order σ, Lemma 2.1 of [4] yields that R has the form $R(z)=Q(z)+(z-z_0)^\sigma\chi(z)$, where Q is a polynomial of degree at most $\sigma-1$ with $\det Q(z_0)\neq 0$, and χ is locally analytic at z_0. It follows that in some neighborhood U of z_0,

$$\begin{aligned} R^{-1}(z)-Q^{-1}(z)&=-R^{-1}(z)(z-z_0)^\sigma\chi(z)Q^{-1}(z)\\ &=-(z-z_0)^\sigma R^{-1}(z)\chi(z)Q^{-1}(z), \qquad z\in U. \end{aligned}$$

Thus, M^{-1} can be written as

$$\begin{aligned} M^{-1}(z)&=R^{-1}(z)D^{-1}(z)P^{-1}(z)\\ &=Q^{-1}(z)D^{-1}(z)P^{-1}(z)\\ &\quad -R^{-1}(z)\chi(z)Q^{-1}(z)(z-z_0)^\sigma D^{-1}(z)P^{-1}(z), \qquad z\in U. \end{aligned} \tag{5.4}$$

Now PDQ is analytic at z_0, and therefore $Q^{-1}D^{-1}P^{-1}$ has a singular part expansion at z_0 (cf. [1, p. 98]). Since the second term on the right-hand side of (5.4) is clearly locally analytic at z_0, M^{-1} has a singular part expansion at z_0. □

As an immediaate consequence of Theorem 5.1 combined with the factorization Theorem 3.1 of [4] (the localized matrix version of Theorem 3.4 of [3]), we obtain for matrix functions the following localized analogue of the scalar L^1-remainder theorem [3, Thm. 3.6].

COROLLARY 5.1. *Let the n by n matrix function M be locally analytic at* $z_0\in\Pi$, *and assume that* det M *has a zero of integral order* $k\geqq 0$ *at* z_0. *If* $n>1$, *let* $\sigma=\sigma(M)$ *be the smallest nonnegative integer such that every minor* Δ *of M of order* $n-1$ *has a zero of order at least* $k-\sigma$ *at* z_0; *in the scalar case* $n=1$ *set* $\sigma=k$. *If M is smooth of order* 2σ *at* z_0, *then* M^{-1} *has a singular part expansion at* z_0.

Proof. By Theorem 3.1 of [4], M has a (left) local Smith factorization $M=PDR$ in a neighborhood U of z_0 with maximal partial multiplicity equal to σ. Since $R(z)=D^{-1}(z)P^{-1}(z)M(z)$ for $z\in U\backslash\{z_0\}$ and M is smooth of order 2σ, it follows from Lemma 2.2 of [4] that the locally analytic factor R is smooth of order σ at z_0. Corollary 5.1 then follows from Theorem 5.1. □

We remark that the smoothness assumption on M in Corollary 5.1 is not necessary for M^{-1} to have a singular part expansion (compare with the corresponding discussion following the factorization Theorem 3.1 in [4]). For example, let $M(z)=\operatorname{diag}(\phi_1(z),(z-z_0))$, where ϕ_1 is locally analytic at z_0, and $\phi_1(z_0)\neq 0$. Then

$$M^{-1}(z)=\operatorname{diag}(0,(z-z_0)^{-1})+\operatorname{diag}(\phi_1^{-1}(z),0)$$

has a singular part expansion at z_0, but M is not smooth of order 2 at z_0 unless ϕ_1 is smooth of order 2 at z_0.

We conclude this section by showing that the singular part $\sum_{k=0}^{p-1}K_i(z-z_0)^{i-p}$ of M^{-1} is closely related to the left and right Jordan chains of M at z_0. In fact, the sequence $K_0, K_1, \cdots, K_{p-1}$ itself turns out to be both a left and a right Jordan chain of M at z_0 provided we define the notion of a matrix Jordan chain in the obvious way:

DEFINITION 5.2. Let the n by n matrix function M be locally analytic at $z_0\in\Pi$. If $K_0\neq 0$ and $M(z)\sum_{k=0}^{p-1}K_i(z-z_0)^i$ has a zero of order at least p at z_0, then we call $K_0, K_1, \cdots, K_{p-1}$ *a right* (*matrix*) *Jordan chain* of M at z_0. Similarly, if $K_0\neq 0$ and $\sum_{k=0}^{p-1}K_i(z-z_0)^iM(z)$ has a zero of order at least p at z_0, then we call $K_0, K_1, \cdots, K_{p-1}$ *a left* (*matrix*) *Jordan chain* of M at z_0.

Apart from the different setting with matrices instead of vectors, this definition is equivalent to Definition 4.1 in [4].

PROPOSITION 5.2. *Let the n by n matrix function M be locally analytic at* $z_0\in\Pi$, *and suppose that* M^{-1} *has a singular part expansion* $\sum_{k=0}^{p-1}K_i(z-z_0)^{i-p}$ *at* z_0. *Then* $K_0, K_1, \cdots, K_{p-1}$ *is both a left and a right Jordan chain of M at* z_0.

Proof. Define

$$R(z)=\sum_{k=0}^{p-1} K_i(z-z_0)^i.$$

Then, by the hypothesis, M^{-1} has the form

$$M^{-1}(z)=(z-z_0)^{-p}R(z)+\zeta(z), \qquad z\in U\backslash\{z_0\},$$

where U is a neighborhood of z_0, and ζ is locally analytic at z_0. Multiplying this equation from the left by $(z-z_0)^pM(z)$ we get

$$M(z)R(z)=(z-z_0)^p(I-M(z)\zeta(z)), \qquad z\in U.$$

By definition, this means that $K_0, K_1, \cdots, K_{p-1}$ is a right Jordan chain of M at z_0. The proof of the fact that $K_0, K_1, \cdots, K_{p-1}$ is also a left Jordan chain of M is completely analogous. □

6. The stable and central subspaces in the critical case. In this section we decompose the central-stable subspace $\mathscr{C}\mathscr{S}$ into a central subspace $\mathscr{C}$ and a stable subspace $\mathscr{S}$ in the critical case when $\alpha=0$. The crucial properties of the functions r_S and d_C in § 4 are that they have the appropriate growth rates at plus and minus infinity, and that $\mathscr{L}d_C=0$. In § 4 we first construct r_S, and then define d_C to be $r_{CS}-r_S$. Here we proceed in the opposite way, i.e., we first construct d_C, and then define $r_S=r_{CS}-d_C$. Our construction of d_C is based on the singular part expansion of $(\hat{L})^{-1}$ at the central eigenvalues of $\hat{L}$ in (2.7). In addition to being more general than the construction in § 3, it has another advantage, since it gives a much more explicit description of d_C (and also of the function d_U in § 3).

We begin with the following lemma.

LEMMA 6.1. *Let z_0 be an eigenvalue of $\hat{L}$, and suppose that $(\hat{L})^{-1}$ has a singular part expansion with singular part*

$$SP_{z_0}(z)=\sum_{i=0}^{p-1} K_i(z-z_0)^{i-p} \tag{6.1}$$

at z_0, and that

$$\int_{\mathbf{R}^+} t^{p-1}e^{-\gamma t}d|\mu|(t)<\infty, \tag{6.2}$$

where $\gamma=\Re z_0$. Then the function $d_{z_0}(t)$ defined by

$$d_{z_0}(t)=\sum_{i=0}^{p-1}\frac{t^i}{i!}K_{p-1-i}\,e^{z_0t}, \qquad t\in\mathbf{R}, \tag{6.3}$$

satisfies

$$d'_{z_0}+\mu * d_{z_0}=0=d'_{z_0}+d_{z_0}*\mu. \tag{6.4}$$

We remark that assumption (6.2) is automatically satisfied whenever $\gamma>\omega$.

Proof. We prove the left-hand equality; the proof of the right-hand equality is completely analogous.

By Proposition 5.2, $K_0, \cdots, K_{p-1}$ is a right Jordan chain of length p of $\hat{L}$ at z_0. Since (6.2) holds, $\hat{L}(z)$ is smooth of order $p-1$ at z_0 with respect to the dominating function $e^{-\gamma t}$, $t\in\mathbf{R}$, and a standard multiplication of series (cf. [4, (4.2)]) shows that

$$\sum_{i=0}^{j}\frac{\hat{L}^{(i)}(z_0)}{i!}K_{j-i}=0, \qquad 0\leqq j\leqq p-1. \tag{6.5}$$

Next, an elementary calculation that uses the binomial theorem and that is given in the proof of Lemma 5.2 of [4] yields that

$$\mu * d_{z_0}(t) = e^{z_0 t} \sum_{j=0}^{p-1} \frac{t^{p-1-j}}{(p-1-j)!} \sum_{i=0}^{j} \frac{\hat{\mu}^{(i)}(z_0)}{i!} K_{j-i}.$$

This calculation is valid since (6.2) holds. Using the last line and (6.5), we get after another easy calculation that

$$d'_{z_0}(t) + \mu * d_{z_0}(t) = e^{z_0 t} \sum_{j=0}^{p-1} \frac{t^{p-1-j}}{(p-1-j)!} \sum_{i=0}^{j} \frac{\hat{L}^{(i)}(z_0)}{i!} K_{j-i} = 0. \qquad \square$$

We now proceed with our construction of the desired function r_S. We let ρ^S be a positive, continuous, nondecreasing and submultiplicative function on $\mathbf{R}^+$ satisfying $\rho^S(0)=1$ and $\rho^S(t) \leqq \rho(t)$ for $t \in \mathbf{R}^+$ (this function will determine the rate of convergence to zero of the solutions corresponding to initial data in the stable subspace). If we extend ρ^S to all of $\mathbf{R}$ by defining $\rho^S(t)=1$ for $t<0$, then ρ^S is a weight function on $\mathbf{R}$. We assume that $\hat{L}(z)$ has no eigenvalues in $\omega^S \leqq \Re z < 0$, where $\omega^S = -\lim_{t\to\infty} t^{-1} \log \rho^S(t)$ (if $\omega^S = 0$, then this condition is vacuously satisfied). We also assume that $\hat{L}(z)$ has only a finite number of eigenvalues z_l in the closed right half plane, and let the sets

$$Z_C = \{z_l | \Re z_l = 0\}, \qquad Z_U = \{z_l | \Re z_l > 0\},$$

consist of the central and unstable eigenvalues, respectively. Let $Z = Z_C \cup Z_U$. Assume that $\hat{L}(z)$ has a singular part expansion *with respect to* ρ^S with singular part $SP_{z_l}(z) = \sum_{i=0}^{p_l-1} K_{l,i}(z-z_l)^{i-p_l}$ at each eigenvalue $z_l \in Z$. Of course, this assumption is automatically satisfied at all the unstable eigenvalues, and also at all the central eigenvalues if $\omega < 0$. Theorem 5.1 gives sufficient smoothness assumptions on $\hat{L}$ for this hypothesis to hold at central eigenvalues in the case when $\omega = 0$.

For each eigenvalue $z_l \in Z$, set

$$d_{z_l}(t) = \sum_{i=0}^{p_l-1} \frac{t^i}{i!} K_{l,p_l-1-i}\, e^{z_l t}, \qquad t \in \mathbf{R}.$$

Define the matrix-valued functions d_U, d_C and d by

$$d_U(t) = \sum_{z_l \in Z_U} d_{z_l}(t), \qquad d_C(t) = \sum_{z_l \in Z_C} d_{z_l}(t),$$

and $d = d_C + d_U$.

Before proceeding we first observe that the function d_U as defined above is the same as the function d_U previously defined in § 3, and, in the noncritical case, d_C as defined above is the same as the function d_C defined in § 4. The verifications of these two claims are completely similar, so let us only give the argument for d_U. Define ρ^U, r_{CS} and d_U in the same way as in § 3. We know that $r \in W^{1,1}(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^U)$, that r vanishes on $(-\infty, 0)$ and that $\hat{r}(z) = [\hat{L}(z)]^{-1}$ for $\Re z = \xi$. Therefore, for each $t \neq 0$ we can express $r(t)$ as an inverse Laplace integral

$$r(t) = \lim_{T\to\infty} \frac{1}{2\pi i} \int_{\xi-iT}^{\xi+iT} e^{zt} [\hat{L}(z)]^{-1}\, dz.$$

In the same way, one gets for each $t \neq 0$,

$$r_{CS}(t) = \lim_{T\to\infty} \frac{1}{2\pi i} \int_{\gamma-iT}^{\gamma+iT} e^{zt} [\hat{L}(z)]^{-1}\, dz,$$

where γ is the constant used in the definition of ρ^C in (3.2). We defined d_U to be $r-r_{CS}$; hence, for each $t\neq 0$,

$$d_U(t)=\lim_{T\to\infty}\frac{1}{2\pi i}\left(\int_{\xi-iT}^{\xi+iT}-\int_{\gamma-iT}^{\gamma+iT}\right)e^{zt}[\hat{L}(z)]^{-1}\,dz.$$

The function $[\hat{L}(z)]^{-1}$ tends to zero, uniformly in the strip $\gamma\leqq\Re z\leqq\xi$ as $\Im z\to\infty$. Therefore, if we define Γ to be the closed curve in the complex plane which is composed of four straight lines, and joins the points $\gamma-iT$, $\xi-iT$, $\xi+iT$, $\gamma+iT$ in a counterclockwise way, then, for $t\neq 0$,

$$d_U(t)=\lim_{T\to\infty}\frac{1}{2\pi i}\int_\Gamma e^{zt}[\hat{L}(z)]^{-1}\,dz.$$

By the residue theorem, the integral on the right-hand side is the sum of the residues of the meromorphic function inside the integral. Expanding e^{zt} into a power series around each unstable eigenvalue z_l of $\hat{L}$, and using the singular part expansion of $[\hat{L}(z)]^{-1}$ at z_l, one easily gets the desired formula.

Continuing with our construction of r_S, we let $r_{CS}=r-d_U$ (as in §§ 3 and 4), and define $r_S=r-d$. Let

$$\sigma=\max\{p_l|z_l\in Z_C\}$$

be the maximal partial multiplicity of the central eigenvalues of $\hat{L}$. At this stage we assume that $Z_C\neq\varnothing$; the case $Z_C=\varnothing$ will be discussed later.

Fix some constant γ, $0<\gamma<\lambda$, with λ defined as in § 3, and define

$$\begin{aligned}
\rho_S(t)&=\begin{cases}1, & t\in\mathbf{R}^-,\\ (1+t)^{\sigma-1}\rho^S(t), & t\in\mathbf{R}^+,\end{cases}\\
\eta_S(t)&=\begin{cases}(1+|t|)^{1-\sigma}, & t\in\mathbf{R}^-,\\ \rho^S(t), & t\in\mathbf{R}^+,\end{cases}\\
\rho^C(t)&=e^{-\gamma t},\qquad t\in\mathbf{R},\\
\rho_C(t)&=\max\{\rho^C(t),(1+|t|)^{\sigma-1}\},\qquad t\in\mathbf{R},\\
\eta_C(t)&=[\rho_C(-t)]^{-1},\qquad t\in\mathbf{R}.
\end{aligned}\tag{6.6}$$

LEMMA 6.2. *The function r_S satisfies $r_S\in BUC((-\infty,0);\mathbf{C}^{n\times n};\eta_S)\cap BC_0(\mathbf{R}^+;\mathbf{C}^{n\times n};\eta_S)$. In particular, $r_S(t)\to 0$ as $t\to\infty$.*

Proof. For $t<0$ we have $r_S(t)=-d(t)$, and the claim $r_S\in BUC((-\infty,0);\mathbf{C}^{n\times n};\eta_S)$ follows immediately. It remains to show that $r_S\in BC_0(\mathbf{R}^+;\mathbf{C}^{n\times n};\eta_S)$.

Define $d^+(t)=d(t)$ for $t\geqq 0$, $d^+(t)=0$ for $t<0$, and likewise $r_S^+(t)=r_S(t)$ for $t\geqq 0$, $r_S^+(t)=0$ for $t<0$. Then $r_S^+=r-d^+$, and it follows from elementary Laplace transform theory that for $\Re z$ sufficiently large,

$$(r_S^+)\hat{}\,(z)=\hat{r}(z)-(d^+)\hat{}\,(z)=[\hat{L}(z)]^{-1}-\sum_{z_l\in Z}SP_{z_l}(z).\tag{6.7}$$

The expression on the right-hand side is locally analytic with respect to $V(\mathbf{R}^+;\mathbf{C}^{n\times n};\rho^S)$ on $\{z|\Re z\geqq\omega^S)\cup\{\infty\}$ and it vanishes at infinity; hence by Proposition 2.3 of [3], $r_S^+\in L^1(\mathbf{R}^+;\mathbf{C}^{n\times n};\rho^S)$. Multiplying (6.7) by z, we get

$$[(r_S^+)']\hat{}\,(z)=z\left\{[\hat{L}(z)]^{-1}-\sum_{z_l\in Z}SP_{z_l}(z)\right\},\qquad \Re z\geqq\omega^S.$$

Again the expression on the right-hand side is easily seen to be locally analytic with respect to $V(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^S)$ in $\{z|\Re z \geqq \omega^S\} \cup \{\infty\}$; hence, $(r_S^+)' \in V(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^S)$. We conclude that $r_S^+ \in W^{1,1}(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^S)$. By Lemma 3.7 of [10], $r_S^+ \in BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \rho^S)$, or equivently, $r_S \in BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \eta_S)$. □

We decompose $\mathscr{C}\mathscr{S}$ into the two subspaces $\mathscr{S}$ and $\mathscr{C}$ and construct projections of $\mathscr{D}$ onto $\mathscr{S}$ and $\mathscr{C}$ in a manner which parallels our earlier decomposition in § 4. To do this we must now assume that the influence function η is sufficiently small at minus infinity and sufficiently large at plus infinity. More precisely, henceforth we assume that

$$\rho(t) \geqq (1+t)^{\sigma-1}, \qquad t \in \mathbf{R}^+, \tag{6.8}$$

$$BUC(\mathbf{R}^-; \mathbf{C}^n; \eta_S) \subset \mathscr{B}(\mathbf{R}^-; \mathbf{C}^n; \eta), \tag{6.9}$$

$$\mathscr{B}(\mathbf{R}^+; \mathbf{C}^n; \eta) \subset L^1(\mathbf{R}^+; \mathbf{C}^n; \rho_S). \tag{6.10}$$

We discuss assumptions (6.8)-(6.10) after we have stated and proved our results. Note that the closed graph theorem implies that the inclusions in (6.9) and (6.10) are continuous.

DEFINITION 6.1. A point (ϕ, f) in $\mathscr{D}$ belongs to the stable subspace $\mathscr{S}$ if the solution $x(\phi, f)$ of (2.5) satisfies $x(\phi, f)(t) \to 0$ as $t \to \infty$. A point $(\phi, 0)$ in $\mathscr{D}$ belongs to the central subspace $\mathscr{C}$ if $\mathscr{L}\phi(t) = 0$ for $t \in \mathbf{R}^-$, $\phi(t) = O(|t|^{\sigma-1})$ as $t \to -\infty$, and $x(\phi, 0)(t) = o(e^{\lambda t})$ as $t \to \infty$.

THEOREM 6.1. *Assume that* (6.8)-(6.10) *hold. Given* $(\phi, f) \in \mathscr{D}$, *define* $v(\phi, f)$ *and* $w(\phi, f)$ *by* (4.3), *and let* θ *and* χ *be the restrictions of* $v(\phi, f)$ *and* $w(\phi, f)$, *respectively, to* $\mathbf{R}^-$. *Let* P_S *be the operator which maps* (ϕ, f) *into* (θ, f), *and let* P_C *be the operator which maps* (ϕ, f) *into* $(\chi, 0)$. *Then* P_S *and* P_C *are continuous projections in* $\mathscr{D}$ *with ranges* $\mathscr{S}$ *and* $\mathscr{C}$, *respectively, and* $P_S + P_C = P_{CS}$.

As usual, one can reduce the proof of Theorem 6.1 to the proof of the following two lemmas.

LEMMA 6.3. *A point* $(\phi, 0)$ *in* $\mathscr{D}$ *belongs to* $\mathscr{C}$ *if and only if* ϕ *is the restriction to* $\mathbf{R}^-$ *of a function* $x \in \oplus_{z_l \in Z_C} \mathscr{N}_l$, *or equivalently, if and only if* ϕ *is the restriction to* $\mathbf{R}^-$ *of a function* $x \in BUC^1(\mathbf{R}; \mathbf{C}^n; \eta_C)$ *satisfying* $\mathscr{L}x = 0$. *Moreover,* $\mathscr{S} \cap \mathscr{C} = \{(0, 0)\}$.

LEMMA 6.4. *The range of* P_S *is contained in* $\mathscr{S}$, *and the range of* P_C *is contained in* $\mathscr{C}$.

Proof of Lemma 6.3. That the two different characterizations of the functions x in Lemma 3.1 are equivalent follows as usual from Theorem 5.1 of [4]. It is also clear that if ϕ is of the type mentioned in Lemma 6.3, then $(\phi, 0) \in \mathscr{C}$.

Conversely, suppose that $(\phi, 0) \in \mathscr{C}$. Then $(\phi, 0) \in \mathscr{C}\mathscr{S}$; hence, by Corollary 3.1, $x(\phi, 0)(t) = o(e^{\gamma t})$ as $t \to \infty$. Therefore, $x(\phi, 0) \in L^\infty(\mathbf{R}; \mathbf{C}^n; \eta_C)$. As $\mathscr{L}\phi(t) = 0$ for $t \in \mathbf{R}^-$, and $x(\phi, 0)$ satisfies (2.5) with $f = 0$, we have $\mathscr{L}x(\phi, 0) = 0$. As usual, this makes it possible for us first to conclude that $x \in W^{1,\infty}(\mathbf{R}; \mathbf{C}^n; \eta_C)$, so that by Lemma 3.7 of [10], $x \in BUC(\mathbf{R}; \mathbf{C}^n; \eta_C)$, and then to use the fact that $\mathscr{L}x(\phi, 0) = 0$ once more to get $x \in BUC^1(\mathbf{R}; \mathbf{C}^n; \eta_C)$. Thus, ϕ is the restriction to $\mathbf{R}^-$ of the function $x(\phi, 0)$, which belongs to $BUC^1(\mathbf{R}; \mathbf{C}^n; \eta_C)$ and satisfies $\mathscr{L}x(\phi, 0) = 0$.

The fact that $S \cap C = \{(0, 0)\}$ follows immediately from the growth rate at infinity imposed on $x(\phi, f)$ in the case when $(\phi, f) \in \mathscr{S}$ together with the fact that $x(\phi, 0) \in \oplus_{z_l \in Z_C} \mathscr{N}_l$ when $(\phi, 0) \in \mathscr{C}$. □

Proof of Lemma 6.4. Define θ and χ as in Theorem 6.1. We have to show that $(\theta, f) \in \mathscr{S}$, and that $(\chi, 0) \in \mathscr{C}$.

It follows from the way in which d_C was defined that $d_C \in BUC^1(\mathbf{R}; \mathbf{C}^{n\times n}; \eta_C)$. By (6.6) and (6.10), $f + M\phi \in L^1(\mathbf{R}^+; \mathbf{C}^n; \rho_S) \subset L^1(\mathbf{R}^+; \mathbf{C}^n; \rho_C)$. We can now argue exactly in the same way as in the proof of Lemma 3.2 to show that $(\chi, 0) \in \mathscr{C}$.

It remains to show that $(\theta, f) \in \mathcal{S}$. As in the proof of Lemma 3.2 we conclude that $v(\phi, f) = x(\theta, f)$, so it suffices to show that $v(\phi, f)(t) \to 0$ as $t \to \infty$. To prove this, let us first observe that η_S is dominated by ρ_S. To see that this is the case it suffices to note that the influence function which is $(1+|t|)^{1-\sigma}$ for $t \leqq 0$ and 1 for $t > 0$ is dominated by the weight function which is 1 for $t \leqq 0$ and $(1+|t|)^{\sigma-1}$ for $t > 0$, and ρ^S, extended to $\mathbf{R}$ to be 1 on $(-\infty, 0)$, is dominated by itself. It follows trivially from (2.1) and (2.2) that if η_1 is dominated by ρ_1 and η_2 is dominated by ρ_2, then $\eta_1\eta_2$ is dominated by $\rho_1\rho_2$, and therefore our claim that η_S is dominated by ρ_S is correct. By Lemma 6.2, $r_S \in BUC((-\infty, 0); \mathbf{C}^{n\times n}; \eta_S) \cap BC_0(\mathbf{R}^+; \mathbf{C}^{n\times n}; \eta_S)$, and by (6.10), $f + M\phi \in L^1(\mathbf{R}^+; \mathbf{C}^n; \rho_S)$. It follows from (4.3) and Lemma A.1 in Appendix A that $v(\phi, f)(t) \in BC_0(\mathbf{R}^+; \mathbf{C}^n; \eta_S) = BC_0(\mathbf{R}^+; \mathbf{C}^n; \rho^S)$. As $\rho^S(t) \geqq 1$ for $t \in \mathbf{R}^+$ we get $v(\phi, f)(t) \to 0$ as $t \to \infty$. □

Again we observe that we obtained a better convergence rate in the stable subspace than the one used in Definition 6.1:

COROLLARY 6.1. *If* $(\phi, f) \in \mathcal{S}$, *then* $x(\phi, f)(t) = o([\rho^S(t)]^{-1}$ *as* $t \to \infty$.

Above, in the definition of σ, and in the definition of the weight and influence functions in (6.6), we assumed that Z_C is nonempty. If $Z_C = \emptyset$, then one can still proceed in essentially the same way. There is no longer a need to assume (6.8) and (6.9), so these two conditions can be dropped. In this case, since $d_C = 0$ and $r_S = r_{CS}$, we have $r_{CS} \in L^1(\mathbf{R}; \mathbf{C}^{n\times n}; \rho^S)$ and $r'_{CS} \in V(\mathbf{R}; \mathbf{C}^{n\times n}; \rho^S)$. If we still assume (6.10), but with ρ_S replaced by ρ^S, then for every $(\phi, f) \in \mathcal{CS}$, it follows from (3.3) that $y(\phi, f) = x(\phi, f)$, and from Lemma 2.1 of [10] that $x(\phi, f) \in W^{1,1}(\mathbf{R}^+; \mathbf{C}^n; \rho^S)$; hence, by Lemma 3.7 of [10], $x(\phi, f) = o([\rho^S(t)]^{-1})$ as $t \to \infty$. In other words, the conclusion of Corollary 6.1 still holds if we replace $\mathcal{S}$ by $\mathcal{CS}$ and assume (6.10) with ρ_S replaced by ρ^S, but drop (6.8) and (6.9).

One can also obtain a slightly different result in the case when $Z_C = \emptyset$ by appealing to Proposition 4.1 with ρ replaced by ρ^S. For this to be possible we have to replace (6.10) by the assumption that there exists an influence function η^S dominated by ρ^S, and satisfying

$$(6.11) \qquad \eta^S(t) \leqq \eta(t), \qquad t \in \mathbf{R}^+.$$

Clearly, when (6.11) holds, we have $\mathcal{B}(\mathbf{R}^+; \mathbf{C}^n; \eta) \subset \mathcal{B}(\mathbf{R}^+; \mathbf{C}^n; \eta^S)$. If we also knew that

$$(6.12) \qquad \eta^S(t) \leqq \eta(t), \qquad t \in \mathbf{R}^-,$$

then we could apply Proposition 4.1 to conclude that for every $(\phi, f) \in \mathcal{CS}$, $x(\phi, f) \in \mathcal{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta^S)$. However, in general (6.12) will not be satisfied. Still, it turns out that (6.11) alone implies that $x(\phi, f) \in \mathcal{B}^{m+1}(\mathbf{R}^+; \mathbf{C}^n; \eta^S)$ for each $(\phi, f) \in \mathcal{CS}$, a fact one can see as follows. Let ξ be an infinitely many times continuously differentiable "cutoff" function satisfying $\xi(t) = 1$ for $t \leqq -1$ and $\xi(t) = 0$ for $t \geqq 0$. Define $x_1(\phi, f)(t) = \xi(t)x(\phi, f)(t)$ and $x_2(\phi, f)(t) = (1-\xi(t))x(\phi, f)(t)$ for $t \in \mathbf{R}$. Then, if we let f_1 be the restriction of the function $\mathcal{L}x_1$ to $\mathbf{R}^+$ and $f_2 = f - f_1$, we find that $x_1(\phi, f) = x(\phi_1, f_1)$ and $x_2(\phi, f) = x(\phi_2, f_2)$, where $\phi_1(t) = \xi(t)\phi(t)$ and $\phi_2(t) = (1-\xi(t))\phi(t)$ for $t \in \mathbf{R}^-$. As $\mathcal{L}$ maps $\mathcal{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta)$ into $\mathcal{B}^m(\mathbf{R}; \mathbf{C}^n; \eta)$, both f_1 and f_2 belong to $\mathcal{B}^m(\mathbf{R}^+; \mathbf{C}^n; \eta) \subset \mathcal{B}^m(\mathbf{R}^+; \mathbf{C}^n; \eta^S)$. If follows from Definition 3.1 and the fact that $(\phi, f) \in \mathcal{CS}$ that both (ϕ_1, f_1) and (ϕ_2, f_2) belong to $\mathcal{CS}$. We can apply Proposition 4.1 with ρ replaced by ρ^S, η replaced by η^S, and (ϕ, f) replaced by (ϕ_2, f_2) to conclude that $x_2(\phi, f) = x(\phi_2, f_2) \in \mathcal{B}^{m+1}(\mathbf{R}; \mathbf{C}^n; \eta^S)$. But $x(\phi, f)(t) = x_2(\phi, f)(t)$ for $t \in \mathbf{R}^+$, and therefore also $x(\phi, f) \in \mathcal{B}^{m+1}(\mathbf{R}^+; \mathbf{C}^n; \eta^S)$, as claimed.

We conclude this section with a short discussion of the conditions (6.9) and (6.10), and with an example which shows that the decay rate in Corollary 6.1 is optimal.

The conditions (6.9) and (6.10) require that η be small and large at $-\infty$ and ∞, respectively. As one might expect, this essentially implies (6.8), as the following example shows:

Example 6.1. Let $p \geqq 0$, and set $\rho(t)=1$ for $t \leqq 0$, $\rho(t)=(1+t)^p$ for $t>0$. Then ρ is a dominating function with $\omega=\alpha=0$. Let q_- and q_+ be nonnegative. Then the function η defined by

$$\eta(t)=\begin{cases}(1+|t|)^{-q_-}, & t\in \mathbf{R}^-,\\ (1+|t|)^{q_+}, & t\in \mathbf{R}^+,\end{cases}$$

is dominated by ρ if and only if $q_-+q_+\leqq p$.

To show that the condition $p \geqq q_-+q_+$ is sufficient for ρ to dominate η one argues in the same way as in the proof of Lemma 6.4 (take $\rho^S(t)=\eta(t)$ for $t\geqq 0$). That this condition is necessary follows directly from (2.2), which for $s=-t/2$ gives $\rho(t)\geqq \eta(t/2)/\eta(-t/2)$.

That the decay rate in Corollary 6.1 is the best possible one can be shown with the following example.

Example 6.2. Let ρ and η be as in Example 6.1 with $q_->1$, define $\rho^S(t)=\eta(t)$ for $t\geqq 0$, and let $\mathscr{B}=L^1$ and $m=0$. Consider the scalar equation

$$\begin{aligned} x'(t)&=f(t), && t\in\mathbf{R}^+,\\ x(t)&=\phi(t), && t\in\mathbf{R}^-. \end{aligned} \tag{6.13}$$

The characteristic function $\hat{L}(z)=z$ has a simple central eigenvalue at $z=0$. For this example, $\mathscr{U}=\{(0,0)\}$, $\mathscr{C}=\{(k,0)|k\in\mathbf{C}\}$, $\rho_S(t)=\rho^S(t)$ for $t\geqq 0$, and

$$\mathscr{S}=\left\{(\phi,f)\in W^{1,1}(\mathbf{R}^-;\mathbf{C};\eta)\times L^1(\mathbf{R}^+;\mathbf{C};\eta)|\phi(0)+\int_0^\infty f(s)\,ds=0\right\}.$$

The solution x of (6.13) corresponding to $(\phi,f)\in\mathscr{S}$ is given by

$$x(\phi,f)(t)=-\int_t^\infty f(s)\,ds,\qquad t\in\mathbf{R}^+,$$

so $x(t)=o(t^{-q_+})$ as $t\to\infty$. Clearly, this estimate for the rate of decay of $x(t)$ to zero as $t\to\infty$ cannot be improved.

Appendix A. Above we needed the following variant of Lemma 2.3 of [10].

LEMMA A.1. *Let $a\in L^1(\rho)$ and $\phi\in L^\infty(\eta)$, where η is dominated by ρ. Then $a*\phi\in BUC(\eta)$. If, in addition,* $\lim_{t\to\infty}\operatorname{ess\,sup}_{s\geqq t}\eta(t)|\phi(t)|=0$, *then $\eta(t)(a*\phi)(t)\to 0$ as $t\to\infty$, and if* $\lim_{t\to-\infty}\operatorname{ess\,sup}_{s\leqq t}\eta(t)|\phi(t)|=0$, *then $\eta(t)(a*\phi)(t)\to 0$ as $t\to-\infty$.*

As in [10], this follows directly from the fact that the same statement is true when $\rho(t)\equiv\eta(t)\equiv 1$.

LOCAL STABILITY RESULTS FOR THE ELASTIC BEAM EQUATION*

ALESSANDRA LUNARDI†

Abstract. We study classical solutions of a partial differential equation which arise as a model for the transverse deflection of an extensible beam with hinged ends in a viscous medium. In particular, we study the stability properties of all the stationary solutions and of small periodic orbits near stationary solutions.

Key words. stability, Hopf bifurcation, beam equation, abstract parabolic semilinear equations

AMS(MOS) subject classifications. 35K60, 58D25, 73H10

Introduction. In this paper we study the asymptotic behavior of the solutions of a partial differential equation

$$\begin{aligned} &u_{tt}(t,x)+\alpha u_{xxxx}(t,x)-\left(\beta+k\int_0^l (u_x(\xi,t))^2\,d\xi\right),\\ (0.1)\qquad &u_{xx}(t,x)+\gamma u_{xxxxt}(t,x)-\sigma\int_0^l u_x(t,\xi)u_{xt}(t,\xi)\,d\xi,\\ &u_{xx}(t,x)+\delta u_t(t,x)=0,\qquad t\geqq 0,\quad 0\leqq x\leqq l \end{aligned}$$

with initial and boundary conditions

$$(0.2)\qquad u(t,0)=u(t,l)=u_{xx}(t,0)=u_{xx}(t,l)=0,\qquad t\geqq 0,$$

$$(0.3)\qquad \begin{aligned} &u(0,x)=u_0(x),\qquad 0\leqq x\leqq l,\\ &u_t(0,x)=v_0(x),\qquad 0\leqq x\leqq l \end{aligned}$$

for initial data near stationary solutions. In particular, we study stability and instability of the stationary solutions and of small periodic orbits near stationary solutions.

Equation (0.1) arises as a model for the transverse deflection $u(t,x)$ of the centerline of an elastic beam in a viscous medium; the boundary conditions in (0.2) correspond to the case of hinged ends (see [9], [14]). The coefficients are given by

$$(0.4)\qquad \alpha=\frac{EI}{\rho},\quad \beta=\frac{EA\Delta}{\rho},\quad \gamma=\frac{\eta I}{\rho},\quad k=\frac{EA}{2l\rho},\quad \sigma=\frac{A\eta}{l\rho},$$

where E is the Young's modulus, I is the cross-sectional second moment of area, ρ is the mass per unit length, l is the length of the beam at stress-free state, Δ is the stretching, η is the viscosity and δ is the coefficient of external damping. Therefore $\alpha, k, \gamma, \sigma$ are positive whereas the sign of β and δ is unrestricted. The assumption $\gamma>0$ gives a parabolic character to (0.1). For the hyperbolic case $\gamma=0$ we refer to [8] and the references quoted there.

The initial value problem for (0.1) has been studied first in [2] and then in [7], [4], [5], [12], where results of existence in the large, uniqueness and continuous dependence of the solution on u_0 and v_0 in suitable norms are given. Moreover in [2], [4] and [5], sufficient conditions on the parameters are given which guarantee the convergence of the solution to zero or to some other stationary solution for any initial data. In [2] the Galerkin approximation method is used, and in [4], [5] the theory of

† Dipartimento di Matematica, Università di Pisa, Via Buonarroti 2, 56100 Pisa, Italy.

analytic semigroups in Hilbert space is used. In [7], [12] some qualitative methods (in particular, center manifold theory) are suggested for the study of the behavior of the solutions for small u_0 and v_0. All the mentioned authors work in a Hilbert space setting and obtain weak solutions which satisfy (0.1) in the variational sense ([2]), or strong solutions such that $u(t,\cdot)$, $u_t(t,\cdot)$ belong to $H^4(0,l)$, $u_{tt}(t,\cdot)$ belongs to $L^2(0,l)$ ([2], [4], [5]) or such that $u(t,\cdot)+\alpha u_t(t,\cdot)$ belongs to $H^4(0,l)$ and $u_t(t,\cdot)\in H^2(0,l)$, $u_{tt}\in L^2(0,l)$ ([7]).

We are interested here in classical solutions of (0.1) (that is, such that u_{tt}, u_{xxxx}, u_{xxxxt} exist and are continuous with respect to (t,x) up to $t=0$); therefore we consider only initial data belonging to $C^4([0,l])$ and satisfying the necessary compatibility conditions

$$u_0(0)=u_0(l)=u_0''(0)=u_0''(l)=v_0(0)=v_0(l)=v_0''(0)=v''(l)=0,$$
$$\alpha u_0^{iv}(0)+\gamma v_0^{iv}(0)=\alpha u_0^{iv}(l)+\gamma v_0^{iv}(l)=0.$$

Setting

$$E=\{\phi\in C([0,l];\mathbb{R});\ \phi(0)=\phi(l)=0\},$$
$$D=\{\phi\in C^4([0,l];\mathbb{R});\ \phi(0)=\phi(l)=\phi''(0)=\phi''(l)=0\},$$

we transform problem (0.1)–(0.3) into an abstract parabolic initial value problem in the Banach space $X=D\times E$:

$$w(t)=A(t)+g(w(t)),\quad t\geqq 0,\qquad w(0)=w_0, \tag{0.5}$$

where $w(t)=(u(t,\cdot),u_t(t,\cdot))$, $w_0=(u_0,v_0)$. The linear unbounded operator A: $D(A)=\{(\phi,\psi)\in D\times D;\ \alpha\phi^{iv}(0)+\gamma\phi^{iv}(0)=\alpha\phi^{iv}(l)+\gamma\psi^{iv}(l)=0\}\to X$, $A(\phi,\psi)=(\psi,-\alpha\phi^{iv}-\gamma\psi^{iv}+\beta\phi''-\delta\psi)$ generates an analytic semigroup in X, and the nonlinear function g maps $D(A)$ into an interpolation space $D_A(\theta,\infty)$. Now (0.5) is nothing but a semilinear abstract parabolic i.v.p., which is relatively easy to handle. In particular, it is not difficult to show local existence, uniqueness and continuous dependence (in the norm of $D(A)$) on w_0 of the solution and to give results of linearized stability and instability for any stationary solution $\bar{w}$ in the noncritical cases. Even in the cases of instability, we are able to give conditions on w_0 for existence in the large and convergence of the solution to $\bar{w}$ as $t\to+\infty$.

We study also the critical cases of stability, when the operator $L:D(A)\to X$, defined by $Lw=(A+f'(\bar{w}))w$, has some eigenvalues on the imaginary axis, and the remainder of the spectrum has negative real part. In our case, the purely imaginary eigenvalues of L are simple, and their corresponding eigenvectors span a subspace $X^+\subset D(A)$, whose dimension may be 1, 2, or 4. The dimension of X^+ is 1 only when $\bar{w}\equiv 0$ and $\delta\geqq-(\pi^4/l^4)\gamma$, $\beta=-(\pi^2/l^2)\alpha$. In this case, we have $f(D(L))\subset X^-$, where $X^-=(1-P)(X)$ and P is a projection on X^+. Thanks to this property it is not difficult to prove the stability of the null solution of (0.5).

In the other cases, the dimension of X^+ is 2 or 4, and we have $f(X^+)\subset X^+$: that is, X^+ is a center manifold, and it is shown to have the usual attractivity properties of the center manifolds. In particular, to study stability properties of the stationary solution $\bar{w}$ considered, and existence and attractivity of small periodic orbits near $\bar{w}$, we can reduce our problem to a system of ordinary differential equations in $\mathbb{R}^2$ or in $\mathbb{R}^4$.

The well-known techniques of Hopf bifurcation are employed in the two-dimensional system and we give necessary and sufficient conditions on the parameters to get asymptotic stability or instability. The study of the four-dimensional system is much more complicated because the results available in the literature are not as complete as in the two-dimensional case. Moreover, there are no relations between the stability properties of the stationary solutions and the stability properties of the periodic solutions given by Hopf's theorem. However, in our case, a nonresonance condition is satisfied and we find that $\bar{w}$ is asymptotically stable, whereas the periodic orbits are not stable.

The paper is organized as follows: in § 1, problem (0.5) is treated; in § 2, the results of § 1 are applied to problem (0.1)-(0.3) and the noncritical cases of stability are studied. In § 3 the critical cases of stability are considered. At the end of § 3 we give a summary scheme of all the results. Finally, the Appendix contains the proofs of the propositions of § 1.

1. Notation and preliminaries on abstract parabolic equations. Let X be a real Banach space with norm $\|\cdot\|$ and let $\tilde{X}=\{x+iy;\, x, y \in X\}$ be its complexification. If $L\colon D(L)\subset X\to X$ is a linear closed operator, we denote by $\tilde{L}\colon D(\tilde{L})\to\tilde{X}$ its complexification, defined by $\tilde{L}(x+iy)=Lx+iLy$, $x, y\in D(L)$. Throughout the paper we shall assume that $D(L)$ is dense in X and L generates an analytic semigroup e^{tL} in X, that is,

(1.1) there exist $\omega\in\mathbb{R}$, $M>0$, $\theta\in\,]\pi/2, \pi[$ such that the resolvent set $\rho(\tilde{L})$ of $\tilde{L}$ contains a sector $S=\{\lambda\in\mathbb{C};\, \lambda\neq\omega,\, |\arg(\lambda-\omega)|<\theta\}$ and $\|(\lambda-\tilde{L})^{-1}\|_{L(\tilde{X})}\leqq M|\lambda-\omega|^{-1}$ for $\lambda\in S$.

In this case, the interpolation spaces $D_L(\theta,\infty)$ $(0<\theta<1)$ are defined by

$$D_L(\theta,\infty)=\left\{x\in X;\, [x]_\theta=\sup_{0<t\leqq 1}\|t^{1-\theta}L\,e^{tL}x\|<+\infty\right\},\tag{1.2}$$
$$\|x\|_{D_L(\theta,\infty)}=\|x\|+[x]_\theta.$$

Then we have $D(L)\hookrightarrow D_L(\theta,\infty)\hookrightarrow D_L(\alpha,\infty)\hookrightarrow X$ for $0<\alpha<\theta<1$, where $D(L)$ is endowed with the graph norm. For other properties see [21, §§ 1.13, 1.14].

In the next section, problem (0.1), (0.2) will be reduced to an abstract semilinear initial value problem:

$$\dot{w}(t)=Lw(t)+g(w(t)),\quad t\geqq 0,\qquad w(0)=w_0,\tag{1.3}$$

where

$$L \text{ satisfies (1.1), } g \text{ belongs to } C^\infty(D(L);\, D_L(\theta,\infty))\tag{1.4}$$

for some $\theta\in\,]0, 1[$. For such a problem it is not difficult to give results of local existence and uniqueness of the solution, continuous dependence on w_0 and regularity (see the Appendix for a proof).

PROPOSITION 1.1. *Let* (1.4) *hold and let* $w_0\in D(L)$. *Then there exists a maximal time interval* $[0, \tau[(\tau=\tau(w_0)>0)$ *and a unique* $w\in C^1([0, \tau[;\, X)\cap C([0, \tau[;\, D(L))$ *which satisfies* (1.3).

Let $w_{0n}\in D(L)$ $(n\in\mathbb{N})$ *be such that* $\|w_{0n}-w_0\|_{D(L)}\to 0$ *as* $n\to+\infty$, *and denote by* $w_n\colon [0, \tau(w_n)[\to D(L)$ *the solution of* (1.3) *with initial value* w_{0n}. *Then for each* $\tau<\tau(w_0)$ *and* $\varepsilon>0$ *there exists* $\bar{n}$ *such that, for* $n\geqq\bar{n}$, $\tau(w_{0n})\geqq\tau$ *and* $\sup_{0\leqq t\leqq\tau}\|w_n(t)-w(t)\|_{D(L)}\leqq\varepsilon$. *In other words, the mapping* $w_0\to w(t)$ *is a local semiflow on* $D(L)$.

From now on, we shall assume

$$g(0)=0,\qquad g'(0)=0\tag{1.5}$$

and we shall study the stability properties of the null solution of (1.3) and of other invariant sets.

We recall that, if $S: \{(t, w_0);\ w_0 \in Y,\ t \in [0, \tau(w_0)[\} \to Y$ is a semiflow on a Banach space Y, a subset $\Omega \subset Y$ is said to be *invariant* if for each $w_0 \in \Omega$ we have $\tau(w_0) = +\infty$ and $S(t, w_0) \in \Omega$ for all $t \geqq 0$. Ω is said to be *stable* if for any $r > 0$ there exists $\varepsilon > 0$ such that for any $w_0 \in Y$ with $\operatorname{dist}(w_0, \Omega) \leqq \varepsilon$ we have $\tau(w_0) = +\infty$ and $\operatorname{dist}(S(t, w_0), \Omega) \leqq r$ for all $t \geqq 0$. Ω is said to be *asymptotically stable* if it is stable and moreover, for any $\varepsilon > 0$, there are $\delta > 0$, $T > 0$ such that if $w_0 \in Y$ and $\operatorname{dist}(w_0, \Omega) \leqq \delta$, then $\operatorname{dist}(S(t, w_0), \Omega) \leqq \varepsilon$ for all $t \geqq T$. Ω is said to be *unstable* if it is not stable.

Let now $Y = D(L)$, $S(t, w_0) = w(t)$, where w is the solution of (1.3). The null solution of (1.3) is said to be stable (resp. asymptotically stable, unstable) if the set $\Omega = \{0\}$ is stable (resp. asymptotically stable, unstable).

We begin with an exponential asymptotic stability result.

PROPOSITION 1.2. *Assume that*

$$\sup\{\operatorname{Re}\lambda;\ \lambda \in \sigma(L)\} \doteq -\bar{\omega} < 0. \tag{1.6}$$

Then the null solution of (1.3) *is asymptotically stable. In particular, for each* $\eta \in]0, \bar{\omega}[$ *there exists* r, $C > 0$ *such that for any* $w_0 \in D(L)$ *with* $\|w_0\|_{D(L)} < r$ *we have*

$$\begin{aligned} &\tau(w_0) = +\infty, \\ &\|w(t)\|_{D(L)} \leqq C e^{-\eta t} \|w_0\|_{D(L)} \quad \textit{for all } t \geqq 0. \end{aligned} \tag{1.7}$$

Assume now that the spectrum of $\tilde{L}$ has an element with positive real part. Then, if $\sigma^+(L) = \{\lambda \in \sigma(L);\ \operatorname{Re}\lambda > 0\}$ is closed, one can show (arguing as in [6, Thm. 5.1.3]) that the null solution is unstable. But, even in this case, it is often possible to prove the existence of an invariant stable manifold M, such that $0 \in M \subset D(L)$, M is homeomorphic to a ball of some subspace of $D(L)$, and for each $w_0 \in M$ the solution of (1.3) is defined in $[0, +\infty[$ and converges to 0 exponentially as $t \to +\infty$. Analogously, we can show the existence of an invariant unstable manifold W, such that $0 \in W \subset D(L)$, W is homeomorphic to a ball of another subspace of $D(L)$, and for each $w_0 \in W$ there exists a backward solution of (1.3), $w:]-\infty, 0] \to W$, with $\lim_{t \to -\infty} w(t) = 0$. To study critical cases of stability (namely, when $\sup\{\operatorname{Re}\lambda;\ \lambda \in \sigma(\tilde{L})\} = 0$), another invariant manifold—the so-called center manifold—may be introduced. The study of such manifolds and of their properties is, in general, rather lengthy and complicated. For the sake of brevity we do not consider here the most general case, but we assume on L and g some particular hypotheses which are satisfied in a sufficiently large class of equations, including the beam equation (0.1), (0.2). In particular, we set, for $\omega \in \mathbb{R}$:

$$\sigma^+_\omega(L) = \{\lambda \in \sigma(\tilde{L});\ \operatorname{Re}\lambda > \omega\}, \qquad \sigma^-_\omega(L) = \sigma(\tilde{L}) \backslash \sigma^+_\omega(L), \tag{1.8}$$

and we assume that there exists $\omega \in \mathbb{R}$ such that

(1.9) $\sigma^+_\omega(L)$ consists of a finite (nonzero) number of eigenvalues with finite algebraic multiplicity.

Let $\tilde{X}^+$ be the eigenspace of $\tilde{L}$ corresponding to $\sigma^+_\omega(L)$. If $\tilde{X}^+$ is spanned by $x_1 + iy_1, \cdots, x_n + iy_n$ $(n \in \mathbb{N})$, set

$$X^+ = \operatorname{span}_{\mathbb{R}}\{x_1, y_1, \cdots, x_n, y_n\}. \tag{1.10}$$

Let $P^+: X \to X^+$ be a projection that commutes with L, that is

$$\begin{aligned} &P^+ \in L(X), \quad P^+(X) \subset X^+, \quad P^+x = x \quad \forall x \in X^+, \\ &P^+Lx = LP^+x \quad \forall x \in D(L) \end{aligned} \tag{1.11}$$

(such a P^+ exists thanks to (1.9)), and set

$$P^-: X \to X, \quad P^-x = x - P^+x, \quad X^- = P^-(X). \tag{1.12}$$

In the following we shall often assume

$$(1.13) \qquad g(X^+) \subset X^+.$$

Condition (1.13) implies that X^+ is invariant; since, by (1.9), X^+ is finite-dimensional, all the stability results about ordinary differential equations hold for the semiflow in X^+. In particular, we easily get instability results as follows:

(1.14) If $\omega = 0$ satisfies (1.9), and (1.13) holds, then the null solution is unstable. In particular, there is $r > 0$ such that for each $w_0 \in X^+$ with $\|w_0\|_{D(L)} \leqq r$ there exists a backward solution w: $]-\infty, 0[\to X^+$ of (1.3), which converges exponentially to zero as $t \to -\infty$.

Moreover, as a corollary of Proposition 1.2, we get a stability result as follows:

(1.15) If some $\omega < 0$ satisfies (1.9) and $g(D(L) \cap X^-) \subset X^-$, then for each $\eta \in]0, -\sup \sigma_\omega^-(L)[$ there exist $\varepsilon = \varepsilon(\eta) > 0$, $C = C(\eta) > 0$ such that if $w_0 \in D(L) \cap X^-$ and $\|w_0\|_{D(L)} \leqq \varepsilon$, then (1.7) holds.

While (1.14) and (1.15) are quite obvious, the attractivity properties of X^+ stated in the next proposition are not trivial and will be proved in the Appendix.

PROPOSITION 1.3. *Let* (1.4), (1.5) *hold, and assume that* (1.9), (1.13) *are satisfied for some* $\omega < 0$. *Then*

(a) *for each* $\eta \in]0, -\sup \sigma_\omega^-(L)[$ *there exist* $\varepsilon_0 = \varepsilon_0(\eta) > 0$, $C_0 = C_0(\eta) > 0$ *such that if* $w_0 \in D(L)$ *and* $\|w_0\|_{D(L)} \leqq \varepsilon_0$, *then*

$$\|P^- w(t)\|_{D(L)} \leqq C_0 \, e^{-\eta t} \|P^- w_0\|_{D(L)} \quad \textit{for all } t \geqq 0;$$

(b) *there exists* $r > 0$ *such that if* $\Omega \subset X^+$ *is compact and asymptotically stable in* X^+, *and* $\operatorname{diam} \Omega = \max \{\|x\|_{D(L)};\ x \in \Omega\} \leqq r$, *then* Ω *is asymptotically stable in* $D(L)$.

Statement (a) is nothing but a local exponential attractivity property of X^+. Statement (b) gives the possibility of reducing local stability problems in Banach space to finite-dimensional ones; it will be widely used in § 3.

We finally consider a critical case of stability, which happens for some value of the parameters in the beam equation.

PROPOSITION 1.4. *Let* (1.4), (1.5) *hold. Assume that L has a finite number of semisimple eigenvalues on the imaginary axis, and* $\sup \{\operatorname{Re} \lambda;\ \lambda \in \sigma(L), \operatorname{Re} \lambda \neq 0\} < 0$, *so that* (1.9) *is satisfied for suitable* $\omega < 0$. *Assume also* $g(D(L)) \subset X^-$. *Then the zero solution of* (1.13) *is stable but not asymptotically stable.*

2. Reduction to an abstract problem, stability and instability in the noncritical cases. Setting $u_t = v$, problem (0.1)-(0.3) becomes

$$(2.1) \quad \begin{aligned} &\text{(i)} && u_t = v, \\ & && v_t = -\alpha u_{xxxx} + (\beta + k|u_x|^2 + \sigma\langle u, v\rangle) u_{xx} - \gamma v_{xxxx} - \delta v, \\ &\text{(ii)} && u(t, 0) = u(t, l) = u_{xx}(t, 0) = u_{xx}(t, l) = 0, \\ &\text{(iii)} && u(0, x) = u_0(x), \qquad v(0, x) = v_0(x), \end{aligned}$$

with the obvious notation

$$(2.2) \qquad \langle \phi, \psi \rangle = \int_0^l \phi(x)\psi(x)\, dx, \qquad |\phi| = \left(\int_0^l (\phi(x))^2 \, dx \right)^{1/2}.$$

Let E be the Banach space of all continuous functions $\phi:[0,l]\to\mathbb{R}$ such that $\phi(0)=\phi(l)=0$, endowed with the sup norm, and let

$$D=\{\phi\in C^4([0,1]);\ \phi(0)=\phi(l)=\phi''(0)=\phi''(l)=0\} \tag{2.3}$$

be endowed with the C^4-norm. Set

$$X=D\times E,$$

$$D(A)=\{(\phi,\psi)\in D\times D;\ \alpha\phi^{(iv)}(0)+\gamma\psi^{(iv)}(0)=\alpha\phi^{(iv)}(l)+\gamma\psi^{(iv)}(l)=0\} \tag{2.4}$$

(endowed with the product norms),

$$A(\phi,\psi)=(\psi,-\alpha\phi^{(iv)}-\gamma\psi^{(iv)}),\qquad (\phi,\psi)\in D(A). \tag{2.5}$$

Then the following proposition holds.

PROPOSITION 2.1. *$D(A)$ is dense in X and the operator $A: D(A)\subset X\to X$ satisfies* (1.1). *For $\theta\in\,]0,1[$ we have*[1]

$$D_A(\theta,\infty)=\begin{cases} D\times\{\phi\in C^{4\theta}([0,l]),\ \phi(0)=\phi(l)=0\} \\ \qquad\qquad\qquad\qquad \textit{if } 0<\theta<\frac{1}{2},\quad \theta\neq\frac{1}{4}, \\ D\times\{\phi\in C^{4\theta}([0,l]);\ \phi(0)=\phi(l)=\phi''(0)=\phi''(l)=0\} \\ \qquad\qquad\qquad\qquad \textit{if } \frac{1}{2}<\theta<1,\quad \theta\neq\frac{3}{4}, \end{cases} \tag{2.6}$$

with equivalence of the respective norms.

Proof. The density of $D(A)$ in X is obvious. Let $\Lambda: D\to C([0,l])$ be defined by $\Lambda u=-u^{iv}$, $u\in D$. It is easy to see that the spectrum of Λ consists of the simple eigenvalues $-\pi^4n^4/l^4$, $n\in\mathbb{N}$, and that Λ satisfies (1.1). Therefore Λ generates an analytic semigroup in $C([0,l])$ (for analytic semigroups with nondense domain, see [19]).

For $(\phi,\psi)\in\tilde{X}$ and $\lambda\in\mathbb{C}$, the equation $\lambda(u,v)-\tilde{A}(u,v)=(\phi,\psi)$ is equivalent to

$$\begin{gathered}(u,v)\in D(\tilde{A}),\qquad v=\lambda u-\phi,\\ \lambda^2u-(\alpha+\gamma\lambda)\Lambda u=\psi+\lambda\phi-\gamma\Lambda\phi.\end{gathered} \tag{2.7}$$

Hence the spectrum of $\tilde{A}$ consists of the point $\lambda_0=-\alpha/\gamma$ and of the eigenvalues

$$\lambda_n^{\pm}=\frac{\pi^2n^2}{2l^2}\left(-\frac{\pi^2n^2}{l^2}\gamma\pm\sqrt{\frac{\pi^4n^4}{l^4}\gamma^2-4\alpha}\right).$$

Moreover, for $\lambda\in\rho(\tilde{A})$ we have: $u=((\lambda^2/(\alpha+\gamma\lambda)-\Lambda)^{-1}(\psi+\lambda\phi-\gamma\Lambda\phi)/(\alpha+\gamma\lambda))$, so that (1.1) easily follows. Since the graph norm of A is equivalent to the norm of D on $D(A)$, then $D_A(\theta,\infty)=D\times D_\Lambda(\theta,\infty)$, with equivalence of the respective norms. To characterize $D_\Lambda(\theta,\infty)$ it is sufficient to observe that $\Lambda=-\Delta^2$, where Δ: $D(\Delta)\to E$, $D(\Delta)=\{\phi\in C^2([0,l]);\ \phi(0)=\phi(1)=0\}$, $\Delta\phi=\phi''$. Then we have $D_\Lambda(\theta,\infty)=D_\Delta(2\theta,\infty)$ for $\theta\neq\frac{1}{2}$. Theorem 2.10 of [11] implies now

$$D_\Delta(\eta,\infty)=\{\phi\in C^{2\eta}([0,l]),\ \phi(0)=\phi(l)=0\},\qquad 0<\eta<1,\quad \eta\neq\tfrac{1}{2}, \tag{2.8}$$

$$\begin{gathered}D_\Delta(\eta,\infty)=\{\phi\in C^{2\eta}([0,l]);\ \phi(0)=\phi(l)=\phi''(0)=\phi''(l)=0\},\\ 1<\eta<2,\quad \eta\neq\tfrac{3}{2},\end{gathered} \tag{2.9}$$

with equivalence of the respective norms, so that (2.6) follows. The results of general interpolation theory which we have just used (such as $D_{\Delta^2}(\theta,\infty)=D_\Delta(2\theta,\infty)$, etc.) are well known in the dense domain case (see, for instance, [21, §§ 1.13, 1.14]) and may be easily extended to our case (see [11]). □

[1] The cases $\theta=\frac{1}{4}$, $\theta=\frac{1}{2}$, $\theta=\frac{3}{4}$ would require the introduction of the Zygmund classes $\mathscr{C}^{1*}$, $\mathscr{C}^{2*}$, $\mathscr{C}^{3*}$ and will not be considered here.

Now set

$$f(\phi, \psi) = (0, k|\phi'|^2 + \sigma\langle\phi, \psi\rangle)\phi'', \qquad \phi \in C^2([0, l]), \quad \psi \in C^1([0, l]). \tag{2.10}$$

Then it is easy to see that f belongs to $C^\infty(D(A), D_A(\theta, \infty))$ for each $\theta < \frac{1}{2}$ and

$$\begin{aligned} f'(\bar\phi, \bar\psi)(\phi, \psi) = (0, 2k\langle\phi', \bar\psi'\rangle + \sigma\langle\bar\phi', \psi'\rangle + \sigma\langle\phi', \bar\psi'\rangle)\bar\phi'' \\ + (0, k|\bar\phi'|^2 + \sigma\langle\bar\phi', \bar\psi'\rangle)\phi''. \end{aligned} \tag{2.11}$$

Finally, define a linear operator $L: D(L) \to X$ by

$$D(L) = D(A), \quad L(\phi, \psi) = (\psi, -\alpha\phi^{iv} - \gamma\psi^{iv} + \beta\phi'' - \delta\psi), \quad (\phi, \psi) \in D(A). \tag{2.12}$$

Then $L = A + B$, where $B \in L(X)$, $B(\phi, \psi) = (0, \beta\phi'' - \delta\psi)$. Therefore L satisfies (1.1) and $D_L(\theta, \infty) = D_A(\theta, \infty)$ for each $\theta \in]0, 1[$, with equivalence of the norms.

Now, if we set $w = (u, v)$, problem (2.1) may be written in the abstract form (1.3), with

$$w_0 = (u_0, v_0), \qquad g(w) = f(u, v). \tag{2.13}$$

In fact, if $w(t) = (u(t), v(t))$ is a solution of (1.3) in some interval $[0, T]$ with X, $D(L)$, L defined by (2.4) and (2.12), then $(u(t, x) \doteq u(t)(x), v(t, x) \doteq v(t)(x))$ is a classical solution of (2.1), such that each term appearing in (2.1)(i) is continuous in $[0, T] \times [0, l]$. Conversely, if $(u(t, x), v(t, x))$ is a solution of (2.1) such that u, v, u_t, v_t, u_{xxxx}, v_{xxxx} are continuous in $[0, T] \times [0, l]$, then the compatibility conditions $v(t, 0) = v(t, l) = v_{xx}(t, 0) = v_{xx}(t, l) = \alpha u_{xxxx}(t, 0) + \gamma v_{xxxx}(t, 0) = \alpha u_{xxxx}(t, l) + \gamma v_{xxxx}(t, l) = 0$ $(0 \leqq t \leqq T)$ hold. Therefore $(u(t) \doteq u(t, \cdot), v(t) \doteq v(t, \cdot))$ belongs to $D(A)$ for $0 \leqq t \leqq T$ and $w(t) = (u(t), v(t))$ is a solution of (1.3) in $[0, T]$.

Then, applying Proposition 1.1, it is possible to obtain a local existence and uniqueness result for the solution of (2.1), together with continuous dependence on (u_0, v_0). More precisely, for each $u_0, v_0 \in C^4([0, l])$ such that the compatibility conditions

$$\begin{aligned} u_0(0) = u_0(l) = u_0''(0) = u_0''(l) = v_0(0) = v_0(l) \\ = v_0''(0) = v_0''(l) = 0, \\ \alpha u_0^{(iv)}(0) + \gamma v_0^{(iv)}(0) = \alpha u_0^{(iv)}(l) + \gamma v_0^{(iv)}(l) = 0 \end{aligned} \tag{2.14}$$

hold, there exist $\tau > 0$ and a unique solution $u: [0, \tau[\times [0, l] \to \mathbb{R}$ of (0.1) such that each derivative of u appearing in (0.1) is continuous in $[0, \tau[\times [0, l]$. Moreover, the C^4 norms of $u(t, \cdot)$ and $u_t(t, \cdot)$ depend continuously on the C^4 norms of u_0 and v_0 (in the sense of Proposition 1.1).

In fact, one could show existence, uniqueness and C^∞ regularity (for $t > 0$) for less regular initial data (u_0, v_0) and even existence in the large of the solution (that is, $\tau(u_0, v_0) = +\infty$). These are not purposes of the present paper and we shall limit ourselves to consider very regular initial data (u_0, v_0) near $(\bar\phi, 0)$, where $\bar\phi$ is any stationary solution of (0.1), (0.2).

We begin with the stationary solution $\bar\phi \equiv 0$. To apply the results of § 1 we have to compute the spectrum of $\tilde{L}$: it is easy to see that $\sigma(\tilde{L}) = \{-\alpha/\gamma\} \cup \{\lambda_{\pm h}, h \in \mathbb{N}\}$, where the simple eigenvalues $\lambda_{\pm h}$ are given by

$$\lambda_{\pm h} = -\frac{1}{2}\left(\delta + \frac{\pi^4}{l^4}\gamma h^4\right) \pm \frac{1}{2}\left[\left(\delta + \frac{\pi^4}{l^4}\gamma h^4\right)^2 - 4\frac{\pi^2 h^2}{l^2}\left(\beta + \frac{\pi^2}{l^2}\alpha h^2\right)\right]^{1/2}, \qquad h \in \mathbb{N}, \tag{2.15}$$

and the eigenspace corresponding to the eigenvalue $\lambda_{\pm h}$ is spanned by

$$\left(\sin\frac{\pi h}{l}x, \lambda_{\pm h}\sin\frac{\pi h}{l}x\right). \tag{2.16}$$

Using (1.14), (1.15) and Proposition 1.2 gives some results about the stability of the null solution.

THEOREM 2.2. *Let $\lambda_j, j\in\mathbb{Z}$, be defined by* (2.15). *Then*

(a) *If $\delta>-(\pi^4/l^4)\gamma$ and $\beta+(\pi^2/l^2)\alpha>0$, the null solution of* (0.1), (0.2) *is exponentially asymptotically stable in the C^4 norm; more precisely, for each $\eta\in\,]0,\min\{\alpha/\gamma,-\operatorname{Re}\lambda_1\}[$ there exist $r>0$, $C>0$ such that if $u_0, v_0\in C^4([0,l])$ satisfy the compatibility conditions* (2.14) *and $\|u_0\|_{C^4([0,l])}\leqq r$, $\|v_0\|_{C^4([0,l])}\leqq r$, then the solution u of* (0.1)-(0.3) *is defined for all positive t, and*

$$\begin{aligned}\|u(t,\cdot)\|_{C^4([0,l])}&+\|u_t(t,\cdot)\|_{C^4([0,l])}\\ &\leqq C e^{-\eta t}(\|u_0\|_{C^4([0,l])}+\|v_0\|_{C^4([0,l])})\quad \textit{for all } t\geqq 0.\end{aligned}\tag{2.17}$$

(b) *If $\delta<-(\pi^4/l^4)\gamma$ or $\beta+(\pi^2/l^2)\alpha<0$, the null solution is unstable. In particular, if $J\subset\mathbb{Z}$ is such that $\operatorname{Re}\lambda_j>0$ for each $j\in J$, then there exists $r>0$ such that for $a_j, b_j\in\mathbb{R}$, $|a_j|\leqq r$, $|b_j|\leqq r$ $(j\in J)$ and*

$$u_0(x)=\sum_{j\in J}a_j\sin\frac{\pi j}{l}x,\qquad v_0(x)=\sum_{j\in J}b_j\sin\frac{\pi j}{l}x,\quad 0\leqq x\leqq l,\tag{2.18}$$

there exists a backward solution $u:]-\infty,0]\times[0,l]\to\mathbb{R}$ of (0.1), (0.2), *$u(t,x)=\sum_{j\in J}a_j(t)\sin(\pi j/l)x$, and a_j, $\dot a_j$ decay exponentially to* 0 *as $t\to-\infty$.*

On the other hand,

(c) *let $\delta<-(\pi^4/l^4)\gamma$ or $\beta+(\pi^2/l^2)\alpha<0$, and let $J'=\{j\in\mathbb{Z};\operatorname{Re}\lambda_j<0\}$. Then for each $\eta\in\,]0,\min\{\alpha/\gamma,-\sup\{\operatorname{Re}\lambda_j;j\in J'\}\}[$ there exist $r>0$, $c>0$ such that if $u_0\in C^4([0,l])$, $v_0\in C^4([0,l])$ satisfy* (2.14),

$$\|u_0\|_{C^4([0,l])}\leqq r,\qquad \|v_0\|_{C^4([0,l])}\leqq r,$$

and

$$\left\langle u_0,\sin\frac{\pi j}{l}x\right\rangle=\left\langle v_0,\sin\frac{\pi j}{l}x\right\rangle=0\quad\forall j\in\mathbb{Z}\backslash J',\tag{2.19}$$

then the solution of (0.1) *is defined for all positive t and satisfies* (2.17).

The critical cases $\delta=-(\pi^4/l^4)\gamma$ and $\beta+(\pi^2/l^2)\alpha=0$ will be studied in the next section.

Let us consider now the other stationary solutions: it is easy to see that if $\beta+(\pi^2/l^2)\alpha\geqq0$ the unique stationary solution of (0.1), (0.2) is $\bar\phi\equiv0$, whereas if $\beta+(\pi^2n^2/l^2)\alpha<0$ for some $n\in\mathbb{N}$, then (0.1), (0.2) has exactly $2n$ nontrivial stationary solutions $\pm\bar\phi_j, j=1,\cdots,n$, given by

$$\begin{aligned}\bar\phi_j(x)=\frac{1}{\pi j}\left[-\frac{2}{kl}\left(\beta+\frac{\pi^2j^2}{l^2}\alpha\right)\right]^{1/2}\sin\frac{\pi j}{l}x,&\\ 0\leqq x\leqq l,\quad j=1,\cdots,n.&\end{aligned}\tag{2.20}$$

It is easy to see that a function u satisfies (0.1), (0.2) if and only if $-u$ does. Therefore for any $j=1,\cdots,n$, $\bar\phi_j$ and $-\bar\phi_j$ have the same stability properties, and, from now on, we shall consider only the $\bar\phi_j$'s.

To use the results of § 1 for the study of the stability of $\bar\phi_n$ we must define the linear operators $L_n:D(L_n)\to X$ and the functions $g_n:D(L_n)\to D_{L_n}(\theta,\infty)$:

$$D(L_n)=D(A),\qquad L_n(\phi,\psi)=L(\phi,\psi)+f'(\bar\phi_n,0)(\phi,\psi),\qquad(\phi,\psi)\in D(A),\tag{2.21}$$

$$g_n(\phi,\psi)=f(\bar\phi_n+\phi,\psi)-f'(\bar\phi_n,0)(\phi,\psi)-f(\bar\phi_n,0),\qquad(\phi,\psi)\in D(A),\tag{2.22}$$

where L,f,f' are given by (2.12), (2.20), (2.21), respectively.

Then L_n satisfies (1.1), $g_n \in C^\infty(D(L_n), D_{L_n}(\theta, \infty))$ for $\theta < \frac{1}{2}$, $g_n(0) = g_n'(0) = 0$, so that the results of the previous section may be applied to problem

$$\dot{w}_n(t) = L_n w_n(t) + g_n(w(t)), \quad t \geqq 0, \qquad w_n(0) = w_0,$$

with $w(t) = (u(t, \cdot) - \bar{\phi}_n, u_t(t, \cdot))$, $w_0 = (u_0 - \bar{\phi}_n, v_0)$.

The spectrum of $\tilde{L}_n$ consists of the point $\lambda_0 = -\alpha/\gamma$ and of the simple eigenvalues $\lambda_{\pm h}$, $h \in \mathbb{N}$, defined by

$$\lambda_{\pm h} = \begin{cases} -\dfrac{1}{2}\left(\delta + \dfrac{\pi^4}{l^4}\gamma h^4\right) \pm \dfrac{1}{2}\left[\left(\delta + \dfrac{\pi^4}{l^4}\gamma h^4\right)^2 - \dfrac{4\pi^4 h^2}{l^2}(h^2 - n^2)\alpha\right]^{1/2}, & \\ & h \in \mathbb{N}, \quad h \neq n, \\ -\dfrac{1}{2}(\delta + \mu(n)) \pm \dfrac{1}{2}\left[(\delta + \mu(n))^2 + \dfrac{8\pi^2 n^2}{l^2}\left(\beta + \dfrac{\pi^2 n^2}{l^2}\alpha\right)\right]^{1/2}, & h = n, \end{cases} \tag{2.23}$$

with $\mu(n) = (\pi^4 n^4/l^4)\gamma - (\pi^2 n^2/l^2)(\beta + (\pi^2 n^2/l^2)\alpha)\sigma/k$. The corresponding eigenspace is spanned by

$$\left(\sin \frac{\pi h}{l} x, \lambda_{\pm h} \sin \frac{\pi h}{l} x\right), \qquad 0 \leqq x \leqq l. \tag{2.24}$$

Applying (1.14), (1.15) and Proposition 1.2 gives results quite similar to those of Theorem 2.2.

THEOREM 2.3. *Let $\beta + (\pi^2 n^2/l^2)\alpha < 0$ for some $n \in \mathbb{N}$, and let $\bar{\phi}_j, j = 1, \cdots, n$ be defined by* (2.20). *The following are true*:

(a) *If $\delta > \max\{\delta_1, \delta_2\}$, where*

$$\delta_1 = -\frac{\pi^4}{l^4}\gamma + \frac{\pi^2}{l^2}\left(\beta + \frac{\pi^2}{l^2}\alpha\right)\frac{\sigma}{k}, \qquad \delta_2 = -16\frac{\pi^4}{l^4}\gamma, \tag{2.25}$$

then $\bar{\phi}_1$ is exponentially asymptotically stable: for each $n \in]0, \min\{-\alpha/\gamma, \operatorname{Re}\lambda_1, \operatorname{Re}\lambda_2\}[$ ($\lambda_1\lambda_2$ are given by (2.23) *with $n = 1$) there exist $r > 0$, $C > 0$ such that if $u_0, v_0 \in C^4$ ($[0, l]$) satisfy the compatibility conditions* (2.14), *and $\|u_0 - \bar{\phi}_1\|_{C^4([0,l])} \leqq r$, $\|v_0\|_{C^4([0,l])} \leqq r$, then the solution u of* (0.1)-(0.3) *is defined in $[0, +\infty[\times [0, l]$, and*

$$\begin{aligned} &\|u(t, \cdot) - \bar{\phi}_1\|_{C^4([0,l])} + \|u_t(t, \cdot)\|_{C^4([0,l])} \\ &\qquad \leqq C e^{-\eta t}(\|u_0 - \bar{\phi}_1\|_{C^4([0,l])} + \|v_0\|_{C^4([0,l])}) \quad \text{for all } t \geqq 0. \end{aligned} \tag{2.26}$$

(b) *If $\delta < \max\{\delta_1, \delta_2\}$, then $\bar{\phi}_1$ is unstable. In particular, if $J \in \mathbb{Z}$ is such that $\operatorname{Re}\lambda_j > 0$ for each $j \in J$ (the eigenvalues λ_j are defined in* (2.23) *with $n = 1$) then there exists $r > 0$ such that if $a_j, b_j \in \mathbb{R}$, $|a_j| \leqq r$, $|b_j| \leqq r$ for $j \in J$ and*

$$\begin{aligned} u_0(x) &= \bar{\phi}_1(x) + \sum_{j \in J} a_j \sin \frac{\pi j}{l} x, \qquad 0 \leqq x \leqq l, \\ v_0(x) &= \sum_{j \in J} b_j \sin \frac{\pi j}{l} x, \qquad 0 \leqq x \leqq l, \end{aligned} \tag{2.27}$$

then there exists a backward solution $u:]-\infty, 0] \times [0, l] \to \mathbb{R}$ of (0.1)-(0.3), *$u(t, x) = \bar{\phi}_1(x) + \sum_{j \in J} a_j(t) \sin(\pi j/l)x$ and a_j, $\dot{a}_j$ converge to* 0 *exponentially as $t \to -\infty$.*

(c) *The other stationary solutions $\bar{\phi}_2, \cdots, \bar{\phi}_n$ are unstable for each value of δ. The second statement of* (b) *holds for $\bar{\phi}_2, \cdots, \bar{\phi}_n$, with obvious modifications.*

(d) *Let* $\nu \in \{1, \cdots, n\}$ *and let* $\lambda_j, j \in \mathbb{Z}$, *be defined by* (2.23) *with n replaced by* ν. *Assume that* $\operatorname{Re} \lambda_\nu < 0$, *and let* $J^\nu \subset \mathbb{Z}$ *be the set of all integers j such that* $\operatorname{Re} \lambda_j < 0$. *Then for each* $\eta \in]0, \min\{\alpha/\gamma, -\sup\{\operatorname{Re} \lambda_j, j \in J^\nu\}\}[$ *there exist* $r > 0$, $C > 0$ *such that if* $u_0, v_0 \in C^4([0, l])$ *satisfy* (2.24), $\|u_0 - \bar{\phi}_\nu\|_{C^4([0,l])} \leqq r$, $\|v_0\|_{C^4([0,l])} \leqq r$, *and*

$$\left\langle u_0, \sin \frac{\pi j}{l} x \right\rangle = \left\langle v_0, \sin \frac{\pi j}{l} x \right\rangle = 0 \quad \forall j \in \mathbb{Z} \backslash J^\nu, \tag{2.28}$$

the solution u of (0.1)-(0.3) *is defined for all positive t, and*

$$\begin{aligned} &\|u(t, \cdot) - \bar{\phi}_\nu\|_{C^4([0,l])} + \|u_t(t, \cdot)\|_{C^4([0,l])} \\ &\quad \leqq C e^{-\eta t}(\|u_0 - \bar{\phi}_\nu\|_{C^4([0,l])} + \|v_0\|_{C^4([0,l])}) \quad \forall t \geqq 0. \end{aligned} \tag{2.29}$$

The critical case $\delta = \max\{\delta_1, \delta_2\}$ will be treated in the next section.

Let us remark that (d) differs from (c) of Theorem 2.2 because of the additional assumption $\operatorname{Re} \lambda_\nu < 0$. This is due to the fact that now we have (see (2.22))

$$\begin{aligned} g_\nu(\phi, \psi) &= (k|\phi'|^2 + 2k\langle \phi', \bar{\phi}'_\nu \rangle + \sigma\langle \bar{\phi}'; \psi' \rangle)\phi'' \\ &\quad + (k|\phi'|^2 + \sigma\langle \phi', \psi' \rangle)\bar{\phi}''_\nu, \qquad \nu = 1, \cdots, n \end{aligned} \tag{2.30}$$

so that, using the notation of § 1, there exists $\omega < 0$ such that $g_\nu(X^-) \subset X^-$ if and only if $\bar{\phi}_\nu \in X^-$, that is, if and only if $\operatorname{Re} \lambda_\nu < 0$. Then statement (d) follows from (1.15).

3. Critical cases of stability, bifurcation and stability of periodic orbits.

In this section we shall treat the problem of the stability of the stationary solutions $0, \bar{\phi}_1, -\bar{\phi}_1$, for the values of the parameters $\alpha, \beta, \gamma, \delta, k, \sigma$ which we did not consider in § 2: that is, when $\max\{\operatorname{Re} \lambda; \lambda \in \sigma(\tilde{L})\} = 0$ and when $\max\{\operatorname{Re} \lambda; \lambda \in \sigma(\tilde{L}_1)\} = 0$. In these cases, X^+ may be one-, two- or four-dimensional, so that we shall use classical results about ordinary differential equations in $\mathbb{R}^n$ to study the stability of $0, \bar{\phi}_1, -\bar{\phi}_1 \in X^+$ for the restriction of the semiflow to X^+. By Proposition 1.3(b), asymptotic stability of any stationary solution in X^+ implies its asymptotic stability in $D(L)$: therefore our problem is reduced to a finite-dimensional one. Proposition 1.3(b) holds not only for stationary solutions, but also for small compact sets (near stationary solutions): it will be used for studying the stability of periodic orbits which we shall prove to exist for suitable values of the parameters.

We shall use the following notion of stability, which involves not only u but also u_t.

Definition 3.1. A stationary solution $\bar{\phi}$ of (0.1) is said to be stable in $C^4([0, l])$ if

(i) for any $\varepsilon > 0$ there is $\delta_\varepsilon > 0$ such that if $u_0, v_0 \in C^4([0, l])$ satisfy the compatibility conditions (2.14) and $\|u_0 - \bar{\phi}\|_{C^4([0,l])} + \|v_0\|_{C^4([0,l])} \leqq \delta_\varepsilon$, then the solution u of (0.1)-(0.3) satisfies

$$\|u(t, \cdot) - \bar{\phi}\|_{C^4([0,l])} \leqq \varepsilon, \quad \|u_t(t, \cdot)\|_{C^4([0,l])} \leqq \varepsilon \quad \forall t \geqq 0.$$

It is said to be asymptotically stable in $C^4([0, l])$ if (i) holds and

(ii) there is $\bar{\delta} > 0$ such that for any $\varepsilon > 0$ there exists $T_\varepsilon > 0$ such that if $u_0, v_0 \in C^4([0, l])$ satisfy (2.14) and $\|u_0 - \bar{\phi}\|_{C^4([0,l])} + \|v_0\|_{C^4([0,l])} \leqq \bar{\delta}$, then

$$\|u(t, \cdot) - \bar{\phi}\|_{C^4([0,l])} + \|u_t(t, \cdot)\|_{C^4([0,l])} \leqq \varepsilon \quad \forall t \geqq T_\varepsilon.$$

It is said to be unstable if it is not stable. A time periodic solution $\phi(t, x)$ of (0.1) is said to be asymptotically stable in $C^4([0, l])$ if

(i′) for any $\varepsilon > 0$ there is $\delta_\varepsilon > 0$ such that if $u_0, v_0 \in C^4([0, l])$ satisfy (2.14) and

$$\|u_0 - \phi(t_0, \cdot)\|_{C^4([0,l])} + \|v_0 - \phi_t(t_0, \cdot)\|_{C^4([0,l])} \leqq \delta_\varepsilon$$

for some $t_0 \in \mathbb{R}$, then

$$\|u(t,\cdot)-\phi(t_0+t,\cdot)\|_{C^4([0,l])}+\|u_t(t,\cdot)-\phi_t(t_0+t,\cdot)\|_{C^4([0,l])} \leqq \varepsilon \quad \forall t \geqq 0;$$

(ii′) there is $\bar{\delta}>0$ such that for any $\varepsilon>0$ there exists $T_\varepsilon>0$ such that if $u_0, v_0 \in C^4([0, l])$ satisfy (2.14), and $\|u_0-\phi(t_0,\cdot)\|_{C^4([0,l])}+\|v_0-\phi_t(t_0,\cdot)\|_{C^4([0,l])} \leqq \bar{\delta}$ for some $t_0 \in \mathbb{R}$, then

$$\|u(t,\cdot)-\phi(t_0+t,\cdot)\|_{C^4([0,l])}+\|u_t(t,\cdot)-\phi_t(t_0+t,\cdot)\|_{C^4([0,l])} \leqq \varepsilon \quad \forall t \geqq T_\varepsilon.$$

We begin with the stationary solution $\bar{\phi} \equiv 0$.

3.1. Stability of the null solution and of small periodic orbits near 0. By (2.15), there are two possibilities for $\max\{\operatorname{Re}\lambda;\ \lambda \in \sigma(\tilde{L})\}$ to be zero: either $\delta \geqq \delta_0$, where

$$\delta_0 = -\frac{\pi^4}{l^4}\gamma \tag{3.1}$$

and $\beta+(\pi^2/l^2)\alpha=0$, so that the unique element of $\sigma(\tilde{L})$ on the imaginary axis is 0, or $\delta=\delta_0$ and $\beta+(\pi^2/l^2)\alpha>0$, so that $\sigma(\tilde{L})$ has exactly two purely imaginary conjugate eigenvalues.

Let us consider the first case.

PROPOSITION 3.2. *Let $\delta \geqq \delta_0$, $\beta+(\pi^2/l^2)\alpha=0$. Then $\bar{\phi}\equiv 0$ is stable* (*but not asymptotically stable*) *in $C^4([0, l])$. Moreover, for any $\eta \in]0, \min\{\alpha/\gamma, -\operatorname{Re}\lambda_2\}[$* (*the eigenvalues λ_j, $j \in \mathbb{Z}$ are defined in* (2.15)) *there exist r, $C>0$ such that if u_0, $v_0 \in C^4([0, l])$ satisfy the compatibility conditions* (2.14), *$\|u_0\|_{C^4([0,l])} \leqq r$, $\|v_0\|_{C^4([0,l])} \leqq r$, and*

$$\left\langle u_0, \sin\frac{\pi}{l}x\right\rangle = 0, \tag{3.2}$$

then (2.17) *holds.*

Proof. In this case, 0 is a simple eigenvalue of L and the corresponding eigenspace is spanned by $(\sin(\pi/l)x, 0)$; we have also $\max\{\operatorname{Re}\lambda;\ \lambda\in\sigma(\tilde{L}),\ \lambda\neq 0\} = \max\{-\alpha/\gamma, \operatorname{Re}\lambda_2\}$ (see (2.15), (2.16)). Therefore any $\omega \in [\max\{-\alpha/\gamma, \operatorname{Re}\lambda_2\}, 0[$ satisfies (1.10), and the projection

$$P^+(\phi,\psi)=\left(\left\langle \phi, \sin\frac{\pi}{l}x\right\rangle \sin\frac{\pi}{l}x, 0\right)$$

obviously satisfies (1.11). The statements follow now from Proposition 1.4. □

Let us consider now the case $\delta=\delta_0$, $\beta+(\pi^2/l^2)\alpha>0$.

PROPOSITION 3.3. *Let $\delta=\delta_0$, $\beta+(\pi^2/l^2)\alpha>0$. Then $\bar{\phi}\equiv 0$ is asymptotically stable in $C^4([0, l])$. Moreover, for any $\eta \in]0, \min\{\alpha/\gamma, -\operatorname{Re}\lambda_2\}[$ there exist r, $C>0$ such that if u_0, $v_0 \in C^4([0, l])$ satisfy* (2.14), *$\|u_0\|_{C^4([0,l])} \leqq r$, $\|v_0\|_{C^4([0,l])} \leqq r$, and*

$$\left\langle u_0, \sin\frac{\pi}{l}x\right\rangle = \left\langle v_0, \sin\frac{\pi}{l}x\right\rangle = 0, \tag{3.3}$$

then (2.17) *holds.*

By Theorem 2.2, when $\delta<\delta_0$, the null solution is unstable. But, for δ near δ_0, $\delta<\delta_0$, it can be proved that other solutions are stable (in fact, asymptotically stable). In particular, if $\beta+(\pi^2/l^2)\alpha<0$, the stationary solutions $\bar{\phi}_1$ and $-\bar{\phi}_1$ are stable (see further information later in the text), and if $\beta+(\pi^2/l^2)\alpha>0$, there exists a stable small periodic orbit, as the following proposition states.

PROPOSITION 3.4. *Let $\beta+(\pi^2/l^2)\alpha>0$. Then there exists $\varepsilon<0$ such that for each $\delta\in\,]\delta_0-\varepsilon,\delta_0[$, problem* (0.1), (0.2) *has a time periodic solution $\bar{u}_\delta(t,x)=\phi(\delta,t)\sin(\pi/l)x$, which is asymptotically stable in $C^4([0,l])$. Denoting by T_δ the period of $\bar{u}_\delta(\cdot,x)$, we have*

$$
(3.4)\qquad
\begin{aligned}
&\text{(i)}\quad \lim_{\delta\to\delta_0^-} T_\delta = 2l\left(\beta+\frac{\pi^2}{l^2}\alpha\right)^{-1/2},\\
&\text{(ii)}\quad \lim_{\delta\to\delta_0^-} \max\left\{\|\bar{u}_\delta(t,\cdot)\|_{C^4([0,l])}+\left\|\frac{\partial}{\partial t}\bar{u}_\delta(t,\cdot)\right\|_{C^4([0,l])};\ t\in\mathbb{R}\right\}=0.
\end{aligned}
$$

There exists $r_0>0$ such that $\bar{u}_\delta$ is the unique periodic solution (translations apart) of (0.1), (0.2) *in the class of the $u(t,x)$ such that $\|u(t,\cdot)\|_{C^4([0,l])}\leqq r_0$, $\|u_t(t,\cdot)\|_{C^4([0,l])}\leqq r_0$ for all $t\geqq 0$.*

The stability of the zero solution in Proposition 3.3 and the stability of the periodic orbits in Proposition 3.4 are closely related, so that the two propositions above will be proved together.

Proof of Propositions 3.3 *and* 3.4. Let $\eta>0$ be such that for $\delta\in\,]\delta_0-\eta,\delta_0+\eta[$ we have

$$
(3.5)\qquad
\begin{aligned}
&\text{(i)}\quad \operatorname{Re}\lambda_1=\operatorname{Re}\lambda_{-1}=-\tfrac{1}{2}(\delta-\delta_0),\\
&\text{(ii)}\quad -\tfrac{1}{2}(\delta-\delta_0)>\sup\{\operatorname{Re}\lambda;\ \lambda\in\sigma(L),\ \lambda\neq\lambda_{\pm1}\}=\max\{-\alpha/\gamma,\operatorname{Re}\lambda_2\}.
\end{aligned}
$$

Then, by (3.5)(ii), each $\omega\in[\max\{-\alpha/\gamma,\operatorname{Re}\lambda_2\},\operatorname{Re}\lambda_1[$ satisfies (1.9), and X^+ is spanned by $(\sin(\pi/l)x,0)$ and $(0,\sin(\pi/l)x)$. A projection satisfying (1.11) is, for instance,

$$
(3.6)\qquad P^+(\phi,\psi)=\left(\left\langle\phi,\sin\frac{\pi}{l}x\right\rangle\sin\frac{\pi}{l}x,\left\langle\psi,\sin\frac{\pi}{l}x\right\rangle\sin\frac{\pi}{l}x\right).
$$

For $\delta_0-\eta<\delta<\delta_0+\eta$ set

$$
(3.7)\qquad a(\delta)=-\frac{1}{2}(\delta-\delta_0),\qquad b(\delta)=\frac{1}{2}\left[\frac{4\pi^2}{l^2}\left(\beta+\frac{\pi^2}{l^2}\alpha\right)-(\delta-\delta_0)^2\right]^{1/2}.
$$

By (3.5)(ii), $b(\delta)\in\mathbb{R}$ and $\lambda_{\pm1}=a(\delta)\pm ib(\delta)$. Define a basis for X^+, setting

$$
(3.8)\qquad
\begin{aligned}
e_1&=\left(-\sin\frac{\pi}{l}x,-a(\delta)\sin\frac{\pi}{l}x\right),\\
e_2&=\left(0,b(\delta)\sin\frac{\pi}{l}x\right).
\end{aligned}
$$

With this choice of the basis in X^+ the operator $L_{|X^+}:X^+\to X^+$ may be represented with the matrix

$$
(3.9)\qquad A(\delta)=\begin{pmatrix} a(\delta) & -b(\delta)\\ b(\delta) & a(\delta)\end{pmatrix}.
$$

We have seen that if $(u_0,v_0)\in X^+$, then the solution $(u(t),v(t))$ of (2.1) belongs to X^+ for each t belonging to the interval of existence. Set

$$
(3.10)\qquad (u(t),v(t))=x(t)e_1+y(t)e_2
$$

so that

$$\begin{aligned} \dot{x}(t) &= a(\delta)x(t) - b(\delta)y(t), \\ \dot{y}(t) &= b(\delta)x(t) + a(\delta)y(t) + q(\delta, x(t), y(t)), \end{aligned} \tag{3.11}$$

where $q(\delta, x, y) = \langle f(xe_1 + ye_2), e_2\rangle$ is given by

$$q(\delta, x, y) = \frac{\pi^4}{2l^3 b(\delta)}((k + \sigma a(\delta))x^3 - \sigma b(\delta)x^2 y). \tag{3.12}$$

Moreover, by (3.7)

$$a(\delta_0) = 0, \qquad b(\delta_0) > 0, \qquad a'(\delta_0) = -\tfrac{1}{2} < 0 \tag{3.13}$$

so that the classical Hopf bifurcation assumptions are satisfied for system (3.11). Therefore (see for instance [13, Thm. 3.1] or [16, Thm. 2.1]) there exist $\varepsilon > 0$, $c_0 > 0$, a neighborhood U of 0 in $\mathbb{R}^2$ and a continuous function $[0, c_0[\to]\delta_0 - \varepsilon, \delta_0 + \varepsilon[$, $c \to \delta(c)$ (with $\delta(0) = \delta_0$), such that system (3.11) has a nontrivial periodic solution $(x(t), y(t))$ with $(x(t), y(t)) \in U$ for all $t \in \mathbb{R}$ if and only if there exists $c \in]0, c_0[$ with $\delta = \delta(c)$. Moreover any periodic solution $(x(t), y(t))$ of (3.11) with $(x(t), y(t)) \in U$ for all $t \in \mathbb{R}$ is one of the above (translations apart). Since the data are analytic, our periodic orbits have the same stability properties of the null solution of (3.11) for $\delta = \delta_0$: more precisely, exactly one of the following possibilities holds (see [16, Cor. 4.4]):

(3.14) (i) 0 is asymptotically stable for $\delta = \delta_0$, the periodic orbits given by Hopf's Theorem are asymptotically stable and occur only for $\delta < \delta_0$ (that is, $\delta(c) < \delta_0$ for any c).

(ii) 0 is unstable for $\delta = \delta_0$, and for any sufficiently small $(x_0, y_0) \in \mathbb{R}^2$ system (3.11) has a backward solution $(x(t), y(t))$ such that $x(0) = x_0$, $y(0) = y_0$ and $\lim_{t \to -\infty} x(t) = \lim_{t \to -\infty} y(t) = 0$; the periodic orbits are unstable and occur only for $\delta > \delta_0$.

(iii) 0 is stable but not asymptotically stable for $\delta = \delta_0$; the periodic orbits have the same property and occur only for $\delta = \delta_0$ (that is, $\delta(c) \equiv \delta_0$).

To see that, in our case, (3.14)(i) holds, we may, for instance, use the classical Poincaré procedure (see [16, § 3]) which allows us to construct a Lyapunov function for (3.13) when $\delta = \delta_0$. Using this procedure, we find that the polynomial

$$V(x, y) = x^2 + y^2 + \frac{\pi^4 k}{4l^3 b^2(\delta_0)} x^4 - \frac{\pi^4 \sigma}{8l^3 b(\delta_0)} x^3 y + \frac{\pi^4 \sigma}{8l^3 b(\delta_0)} xy^3 \tag{3.15}$$

is such that

$$\begin{aligned} \dot{V}(x, y) &\doteq -b(\delta_0)y \frac{\partial V}{\partial x}(x, y) + (b(\delta_0)x + q(\delta_0, x, y)) \frac{\partial V}{\partial x}(x, y) \\ &= -\frac{\pi^4}{8l^3}\sigma(x^2 + y^2)^2 + \text{higher order terms} \end{aligned} \tag{3.16}$$

so that $\dot{V}$ is negative for (x, y) near $(0, 0)$. Therefore $(0, 0)$ is asymptotically stable when $\delta = \delta_0$, so that (3.4)(i) holds. The statements of Propositions 3.2 and 3.3 now follow from (b) of Proposition 1.3 and (3.14)(i) (except for the second part of Proposition 3.2, which follows from Theorem 2.2(c), and (3.4)(i), which can be deduced from [16, § 2] or [13, Thm. 3.1]). □

Let us consider system (3.11) for $\delta = \delta_0$. Since $V(x, y)$ defined in (3.15) has degree 4, the origin is said to be 3-*asymptotically stable* in the notation of [16] and it is said to be a *vague attractor* in the notation of [13], [17].

Let us finally remark that the procedure above can be used to show the existence of small periodic solutions of (2.1) for δ near $h^4\delta_0$, for each $h \in \mathbb{N}$, $h > 1$.

3.2. Stability of $\bar{\boldsymbol{\phi}}_1$ and of small periodic orbits near $\bar{\boldsymbol{\phi}}_1$. We have seen in § 2 that if

$$\beta + \frac{\pi^2}{l^2}\alpha < 0 \tag{3.17}$$

then problem (0.1), (0.2) has (at least) two nontrivial stationary solutions $\pm\bar{\phi}_1$, given by (2.20). The spectrum of the corresponding linear operator L_1 consists of the point $\lambda_0 = -\alpha/\gamma$ and of the eigenvalues $\lambda_{\pm h}$, $h \in \mathbb{N}$, defined in (2.23) with $n = 1$. Therefore there are three critical cases of stability: namely, $\delta = \delta_1 > \delta_2$, $\delta = \delta_2 > \delta_1$ and $\delta = \delta_1 = \delta_2$, where δ_1 and δ_2 are defined by (2.25). In the first two cases, there are two eigenvalues on the imaginary axis and the situation is very similar to the one of Propositions 3.3 and 3.4, so the proofs of Propositions 3.5 and 3.6 below will be only outlined. Also in this section we shall consider only $\bar{\phi}_1$; all the results hold, with obvious modifications, for $-\bar{\phi}_1$ also.

PROPOSITION 3.5. *Let $\beta + (\pi^2/l^2)\alpha < 0$. Then, for $\delta = \delta_1 > \delta_2$, $\bar{\phi}_1$ is unstable. In particular, for*

$$\begin{aligned} u_0(x) &= \bar{\phi}_1(x) + a \sin\frac{\pi}{l}x, \qquad 0 \leqq x \leqq l, \\ v_0(x) &= b \sin\frac{\pi}{l}x, \qquad 0 \leqq x \leqq l \end{aligned} \tag{3.18}$$

with $a, b \in \mathbb{R}$, a, b sufficiently small, then there exists a backward solution $u:]-\infty, 0] \times [0, l] \to \mathbb{R}$ of (0.1)-(0.3), *$u(t, x) = \bar{\phi}_1(x) + a(t) \sin(\pi/l)x$ such that $\lim_{t\to-\infty} a(t) = \lim_{t\to-\infty} \dot{a}(t) = 0$. If $\delta = \delta_2 > \delta_1$, there $\bar{\phi}_1$ is asymptotically stable. Moreover, for any $n \in]0, \min\{a/\gamma, \operatorname{Re}\lambda_1, \operatorname{Re}\lambda_3\}[$ there exist $r, C > 0$ such that if $u_0, v_0 \in C^4([0, l])$ satisfy* (2.14), *$\|u_0 - \bar{\phi}_1\|_{C^4([0,l])} \leqq r$, $\|v_0\|_{C^4([0,l])} \leqq r$, and*

$$\left\langle u_0, \sin\frac{2\pi}{l}x\right\rangle = \left\langle v_0, \sin\frac{2\pi}{l}x\right\rangle = 0, \tag{3.19}$$

then (2.26) *holds.*

PROPOSITION 3.6. *Let $\beta + (\pi^2/l^2)\alpha < 0$ and $\delta_1 < \delta_2$ (resp. $\delta_1 > \delta_2$). Then there exists $\varepsilon > 0$ such that for any $\delta \in]\delta_2 - \varepsilon, \delta_2[$ (resp. $\delta \in]\delta_1, \delta_1 + \varepsilon[$), problem* (0.1), (0.2) *has a nonconstant time periodic solution $w_\delta(t, x) = \phi(\delta, t) \sin(2\pi/l)x$ (resp. $w_\delta(t, x) = \phi(\delta, t) \sin(\pi/l)x$), which is asymptotically stable (resp. unstable) in $C^4([0, l])$. Denoting by T_δ the period of $\phi(\delta, \cdot)$, we have*

$$\lim_{\delta\to\delta_2^-} T_\delta = \frac{l^2}{\pi}(3\alpha)^{-1/2}\left(\text{resp. } \lim_{\delta\to\delta_1^+} T_\delta = 2l\left[-2\left(\beta + \frac{\pi^2}{l^2}\alpha\right)\right]^{-1/2}\right),$$

$$\lim_{\delta\to\delta_2^-}\left(\text{resp. } \lim_{\delta\to\delta_1^+}\right) \max\left\{\|w_\delta(t, \cdot) - \bar{\phi}\|_{C^4([0,l])} + \left\|\frac{d}{dt}w_\delta(t, \cdot)\right\|_{C^4([0,l])}, \quad t \in \mathbb{R}\right\} = 0.$$

Moreover, there exists $r > 0$ such that w_δ is the unique periodic solution of (0.1), (0.2) *(translations apart) satisfying $\|w_\delta(t, \cdot) - \bar{\phi}_1\|_{C^4([0,l])} + \|(d/dt)w_\delta(t, \cdot)\|_{C^4([0,l])} \leqq r$ for all $t \in \mathbb{R}$.*

Sketch of the proof of Propositions 3.5 *and* 3.6. We have to use the procedure of Propositions 3.3 and 3.4, with obvious changes: δ_0 must be replaced by $\max\{\delta_1, \delta_2\}$, $u(t)$ by $u(t)-\bar{\phi}_1$, L by L_1 (see (2.21)). Now $a(\delta)$ and $b(\delta)$ are defined by

$$\text{(3.20)}\qquad \begin{aligned} a(\delta) &= -\frac{1}{2}(\delta - \max\{\delta_1, \delta_2\}),\\ b(\delta) &= \begin{cases} b_1(\delta) \doteq \dfrac{1}{2}\left[-\dfrac{8\pi^2}{l^2}\left(\beta + \dfrac{\pi^2}{l^2}\alpha\right) - (\delta - \delta_1)^2\right]^{1/2} & \text{if } \delta_1 > \delta_2,\\ b_2(\delta) \doteq \dfrac{1}{2}\left[48\dfrac{\pi^4}{l^4}\alpha - (\delta - \delta_2)^2\right]^{1/2} & \text{if } \delta_1 < \delta_2 \end{cases} \end{aligned}$$

and $q(\delta, x, y)$ in (3.11) is given by

$$\text{(3.21)}\qquad q(\delta, x, y) = \begin{cases} \text{(i)}\ \dfrac{\pi^3}{2l^2 b(\delta)}\left[-\dfrac{2}{kl}\left(\beta + \dfrac{\pi^2}{l^2}\alpha\right)\right]^{1/2} \\ \quad \cdot[(-3k - 2\sigma a(\delta))x^2 + 2\sigma b(\delta)xy] \\ \quad\quad + \dfrac{\pi^4}{2l^3 b(\delta)}[(k + \sigma a(\delta))x^3 - \sigma b(\delta)x^2 y] \\ \quad \doteq Ax^2 + Bxy + Cx^3 + Dx^2 y \quad \text{if } \delta_1 > \delta_2, \\ \text{(ii)}\ \dfrac{8\pi^4}{l^3 b(\delta)}[(k + \sigma a(\delta))x^3 - \sigma b(\delta)x^2 y] \\ \quad \doteq Ex^3 + Fx^2 y \quad \text{if } \delta_1 < \delta_2. \end{cases}$$

Then the polynomials

$$\begin{aligned} V_1(x, y) &= x^2 + y^2 + \frac{1}{b(\delta_1)}\left[\frac{2}{3}Ax^3 - \frac{2}{3}By^3 + \frac{1}{2}Cx^4 + \frac{1}{4}\left(D - \frac{AB}{b(\delta_1)}\right)x^3 y\right.\\ &\qquad\qquad \left. - \frac{1}{4}\left(D - \frac{AB}{b(\delta_1)}\right)xy^3 + \frac{1}{2b(\delta_1)}By^4\right] \quad \text{if } \delta_1 > \delta_2,\\ V_2(x, y) &= x^2 + y^2 + \frac{1}{2b(\delta_1)}\left[Ex^4 + \frac{1}{2}F(x^3 y - xy^3)\right] \quad \text{if } \delta_1 < \delta_2 \end{aligned}$$

(constructed by the Poincaré procedure) satisfy

$$\begin{aligned} \dot{V}_1(x, y) &= \frac{1}{4}\left(D - \frac{AB}{b(\delta_1)}\right)(x^2 + y^2)^2 + \text{higher order terms}\\ &= \frac{\pi^4\sigma}{4l^3}(x^2 + y^2)^2 + \text{h.o.t.},\\ \dot{V}_2(x, y) &= \frac{F}{4}(x^2 + y^2)^2 + \text{h.o.t.} = -\frac{2\pi^4\sigma}{l^3}(x^2 + y^2)^2 + \text{h.o.t.} \end{aligned}$$

Therefore, if $\delta_1 > \delta_2$, then (3.14)(ii) holds and the instability statements of Propositions 3.5 and 3.6 follow easily. If $\delta_1 > \delta_2$, then (3.17)(i) holds and the stability results of Propositions 3.5 and 3.6 follow by (1.15) and Proposition 1.3(b). □

The case $\delta = \delta_1 = \delta_2$ is much more complicated because it requires the study of a four-dimensional system. The problem of the stability (in the critical cases) of the stationary solutions of o.d.e. in $\mathbb{R}^4$ has not yet been completely solved, nor under nonresonance assumptions. However, in our case, we will obtain an equation which can be treated again by the Poincaré procedure, since (0.4) implies the nonresonance condition

$$\delta_1=\delta_2 \Rightarrow b_1(\delta_1)/b_2(\delta_1)\in\mathbb{R}\backslash\mathbb{Q} \tag{3.22}$$

($b_1(\delta)$ and $b_2(\delta)$ are defined in (3.20)).

Proposition 3.7. *Let $\delta=\delta_1=\delta_2$. Then $\bar{\phi}_1$ is asymptotically stable in $C^4([0,l])$. Moreover, for any $\eta\in\,]0,\min\{\alpha/\gamma,-\operatorname{Re}\lambda_3\}[$ (λ_3 is defined in* (2.23) *with $n=1$) there exist $r, C>0$ such that if $u_0, v_0\in C^4([0,l])$ satisfy* (2.14), *$\|u_0-\bar{\phi}_1\|_{C^4([0,l])}\leqq r$, $\|v_0\|_{C^4([0,l])}<r$, and*

$$\left\langle u_0,\sin\frac{\pi}{l}x\right\rangle=\left\langle u_0,\sin\frac{2\pi}{l}x\right\rangle=\left\langle v_0,\sin\frac{\pi}{l}x\right\rangle=\left\langle v_0,\sin\frac{2\pi}{l}x\right\rangle=0,$$

then (2.26) *holds.*

Proof. A procedure similar to the one employed in Propositions 3.4–3.6 gives rise to the system

$$\begin{aligned}
\dot{x}_1(t)&=a(\delta)x_1(t)-b_1(\delta)y_1(t),\\
\dot{y}_1(t)&=b_1(\delta)x_1(t)+a(\delta)y_1(t)+q_1(\delta,x_1(t),y_1(t),x_2(t),y_2(t)),\\
\dot{x}_2(t)&=a(\delta)x_2(t)-b_2(\delta)y_2(t),\\
\dot{y}_2(t)&=b_2(\delta)x_2(t)+a(\delta)y_2(t)+q_2(\delta,x_1(t),y_1(t),x_2(t),y_2(t)),
\end{aligned} \tag{3.23}$$

where a, b_1, b_2 are defined in (3.20), and

$$\begin{aligned}
&q_1(\delta,x_1,y_1,x_2,y_2)\\
&\quad=-\frac{\pi^3}{2l^2b_1(\delta)}\sqrt{\frac{2}{kl}\left(-\beta-\frac{\pi^2}{l^2}\alpha\right)}\\
&\qquad\cdot[3kx_1^2+4kx_2^2-2\sigma x_1(-x_1a(\delta)+y_1b_1(\delta))-4\sigma x_2(-x_2a(\delta)+y_2b_2(\delta))]\\
&\qquad-\frac{\pi^4}{2l^3b_1(\delta)}[-kx_1^3-4kx_1x_2^2+\sigma x_1^2(-x_1a(\delta)+y_1b_1(\delta))\\
&\qquad\qquad+4\sigma x_1x_2(-x_2a(\delta)+y_2b_2(\delta))]\\
&\quad\doteq c(\delta)x_1^2+d(\delta)x_2^2+e(\delta)x_1y_1+f(\delta)x_2y_2+g(\delta)x_1^3\\
&\qquad+h(\delta)x_1x_2^2+l(\delta)x_1^2y_1+m(\delta)x_1x_2y_2,
\end{aligned} \tag{3.24}$$

$$\begin{aligned}
&q_2(\delta,x_1,y_1x_2,y_2)\\
&\quad=-\frac{2\pi^3}{l^2b_2(\delta)}\sqrt{\frac{2}{kl}\left(-\beta-\frac{\pi^2}{l^2}\alpha\right)}\\
&\qquad\cdot[2kx_1x_2-\sigma x_2(-x_1a(\delta)+y_1b_1(\delta))]-\frac{2\pi^4}{l^3b_2(\delta)}\\
&\qquad\cdot[-kx_1^2x_2-4kx_2^3+\sigma x_1x_2(-x_1a(\delta)+y_1b_1(\delta))\\
&\qquad\qquad+4\sigma x_2^2(-x_2a(\delta)+y_2b_2(\delta))]\\
&\quad\doteq p(\delta)x_1x_2+q(\delta)x_2y_1+r(\delta)x_1^2x_2+s(\delta)x_2^3+t(\delta)x_1x_2y_1+u(\delta)x_2^2y_2.
\end{aligned} \tag{3.25}$$

Using the generalization of the Poincaré method described in [18] we construct a Lyapunov function for system (3.23) when $\delta=\delta_1=\delta_2$:

$$\begin{aligned}
V(x_1,y_1,x_2,y_2)&=x_1^2+y_1^2+x_2^2+y_2^2+Ax_1^3+By_1^3+Cx_1x_2^2+Dx_2^2y_1\\
&\quad+Ex_1y_2^2+Fy_1y_2^2+Gx_1x_2y_2+Hx_2y_1y_2,
\end{aligned}$$

where

$$A=\frac{2c(\delta)}{3b_1(\delta)},\qquad B=-\frac{2e(\delta)}{3b_1(\delta)},\qquad C=\frac{b_2(\delta)(2b_1(\delta)p(\delta)-4b_2(\delta)d(\delta))}{b_1(\delta)(4b_2^2(\delta)-b_1^2(\delta))},$$

$$D=\frac{2b_2(\delta)(q(\delta)+f(\delta))}{4b_2^2(\delta)-b_1^2(\delta)},\qquad E=\frac{b_2(\delta)(4b_2(\delta)d(\delta)-2b_1(\delta)p(\delta))}{b_1(\delta)(4b_2^2(\delta)-b_1^2(\delta))},$$

$$F=\frac{-2b_2(\delta)(q(\delta)+f(\delta))}{4b_2^2(\delta)-b_1^2(\delta)},\qquad G=\frac{-2b_1(\delta)(q(\delta)+f(\delta))}{4b_2^2(\delta)-b_1^2(\delta)},$$

$$H=-\frac{4b_2(\delta)d(\delta)-2b_1(\delta)p(\delta)}{4b_2^2(\delta)-b_1^2(\delta)}.$$

Then (see [18, § 3]) $\dot V$ is negative definite near $(0,0,0,0)$ if, setting for $\delta=\delta_1=\delta_2$,

$$H=\frac{2}{7b_1(\delta)}(b_1(\delta)l(\delta)-e(\delta)),$$

$$K=\frac{2}{7}\left(u(\delta)+\frac{b_1(\delta)p(\delta)f(\delta)+2b_2(\delta)q(\delta)d(\delta)}{4b_2^2(\delta)-b_1^2(\delta)}\right),$$

$$S=\frac{b_1(\delta)q(\delta)p(\delta)}{4b_2^2(\delta)-b_1^2(\delta)},$$

$$Q=\frac{1}{2}\left(-\frac{e(\delta)}{b_1(\delta)}-\frac{2b_2(\delta)q(\delta)d(\delta)}{4b_2^2(\delta)-b_1^2(\delta)}-\frac{b_2(\delta)p(\delta)f(\delta)}{4b_2^2(\delta)-b_1^2(\delta)}\right),$$

we have $H<0$, $K<0$ and HQ or $KS\geqq 0$; $\dot V$ is positive definite if H or K is positive and HQ or $KS\geqq 0$. In our case (see (3.24), (3.25)) H is negative, K and S have the same sign of $b_1^2(\delta)-4b_2^2(\delta)$. Therefore the null solution of (3.23) is asymptotically stable if $4b_2^2(\delta)-b_1^2(\delta)=\beta+(25\pi^2/l^2)\alpha$ is positive, and it is unstable if $\beta+(25\pi^2/l^2)\alpha<0$. In our case (see (0.4)) we have $\beta+(25\pi^2/l^2)\alpha=(9\pi^2/l^2)(EI/\rho)>0$. The conclusions follow now from Proposition 1.3(b) and (1.15). □

We have seen before that the problem of existence and stability of small periodic orbits for system (3.11) is closely related to the problem of the stability of the null solution. The same thing does not happen, in general, for higher-dimensional systems. For studying small periodic solutions of (3.23) we shall use the method employed in [15].

PROPOSITION 3.8. *Let $\beta+(\pi^2/l^2)\alpha<0$, $\delta=\delta_1=\delta_2$ and assume* (3.23). *Then there exists $\varepsilon>0$ such that for any $\delta\in\,]\delta_1-\varepsilon,\ \delta_1+\varepsilon[$, $\delta\neq\delta_1$, problem* (0.1), (0.2) *has a nonconstant time periodic solution u_δ, given by $u(t,x)=a_1(\delta,t)\sin(\pi/l)x+a_2(\delta,t)\sin(2\pi/l)x$, $t\in\mathbb{R}$, $x\in[0,l]$, with $a_2(\delta,\cdot)\equiv 0$ for $\delta>\delta_1$. u_δ is unstable in $C^4([0,l])$ and, denoting by T_δ the period of u_δ, we have*

$$\lim_{\delta\to\delta_1^-}T_\delta=\frac{l^2}{\pi}(3\alpha)^{-1/2},\qquad \lim_{\delta\to\delta_1^+}T_\delta=2l\left[-2\left(\beta+\frac{\pi^2}{l^2}\alpha\right)\right]^{-1/2},\tag{3.26}$$

$$\lim_{\delta\to\delta_1}\max\left\{\|u_\delta(t,\cdot)-\bar\phi_1\|_{C^4([0,l])}+\left\|\frac{d}{dt}u_\delta(t,\cdot)\right\|_{C^4([0,l])};\ t\in\mathbb{R}\right\}=0.\tag{3.27}$$

Moreover there exists $r>0$ such that if $v(t,x):\mathbb{R}\times[0,l]\to\mathbb{R}$ is a T-periodic solution of (0.1), (0.2) *with*

$$\sup\left\{\|v(t,\cdot)-\bar\phi\|_{C^4([0,l])}+\left\|\frac{d}{dt}v(t,\cdot)\right\|_{C^4([0,l])}\leqq r\right\}$$

and

$$\left|T-\frac{l}{\pi}(3\alpha)^{-1/2}\right|\leqq r\left(\textit{resp.}\left|T-2l\left[-2\left(\beta+\left(\frac{\pi^2}{l^2}\right)\alpha\right)\right]^{-1/2}\right|\leqq r\right),$$

then $v(t,\cdot)=v_\delta(t+r,\cdot)$ *for some* $\tau\in\mathbb{R}$, $\delta\in\,]\delta_1-\varepsilon,\delta_1[$ (*resp.* $\delta\in\,]\delta_1,\delta_1+\varepsilon[$).

Proof. Let us consider again system (3.23). Existence and uniqueness of small periodic solutions satisfying (3.26) may be proved by applying Hopf's Theorem twice (see [13, Thm. 3.15], since the transversality condition $a'(\delta_1)\neq 0$ holds. We find that the periodic orbits corresponding to the eigenvalues $a(\delta)\pm ib_1(\delta)$ (resp. $a(\delta)\pm ib_2(\delta)$) occur for $\delta>\delta_1$ (resp. $\delta<\delta_1$).

Let us consider first the couple of eigenvalues $a(\delta)\pm ib_1(\delta)$, where $a(\delta)$, $b_1(\delta)$ are defined in (3.20). The manifold $x_2=y_2=0$ is invariant for system (3.23). In particular, setting $x_2=y_2=0$, the (x_1,y_1)-part of (3.23) takes the form

$$x_1=-b_1(\delta)y_1,\qquad y_1=b_1(\delta)x_1+q(\delta,x_1,y_1), \tag{3.28}$$

where $q(\delta,x,y)$ is defined in (3.21)(i). Therefore (see the proof of Proposition 3.6) the small periodic solutions of (3.28) occurring for $\delta>\delta_1$ are unstable. Setting now $u_\delta(t,x)=\bar{x}_1(t)\sin(\pi/l)x$, u_δ satisfies all the statements of Proposition 3.8 (the uniqueness follows from Proposition 1.3(a)).

Let us consider now the second couple of eigenvalues $a(\delta)\pm ib_2(\delta)$. The existence of another invariant manifold $(x_1y_1)=\phi(x_2,y_2)$ (which could allow us to reduce again (3.23) to a two-dimensional system) is not evident. To study the stability properties of the periodic solutions of (3.23) given by Hopf's Theorem we shall use the procedure of [15]. To use the notation of [15], we replace t by $\tau=t/b_2(\delta_1)$. Setting $x(t)=x_2(t/b_2(\delta_1))$, $y(t)=y_2(t/b_2(\delta_1))$, $z_1(t)=x_1(t/b_2(\delta_1))$, $z_2(t)=y_1(t/b_2(\delta_1))$, and taking $\delta=\delta_1$, (3.23) becomes

$$\begin{aligned}\dot{x}&=-y, & \dot{y}&=x+\frac{1}{b_1(\delta_1)}q_2(\delta_1,z_1,z_2,x,y),\\ \dot{z}_1&=-\omega z_2, & \dot{z}_2&=\omega z_1+\frac{1}{b_2(\delta_1)}q_1(\delta_1,z_1,z_2,x,y),\end{aligned} \tag{3.29}$$

where $\omega=b_1(\delta_1)/b_2(\delta_1)$ and q_1, q_2 are defined in (3.24), (3.25). Thanks to the nonresonance condition (3.22), for each $h\in\mathbb{N}$ it is possible to find a polynomial $\Phi^{(h)}:\mathbb{R}^2\to\mathbb{R}^2$ of degree h, such that

$$\frac{d}{dt}(z-\Phi^{(h)}(x,y))|_{z=\Phi^{(h)}(x,y)}=o(x^2+y^2)^{h/2},$$

where d/dt is evaluated along the solutions of (3.29). In particular, for $h=3$, we get

$$\begin{aligned}\Phi^{(3)}(x,y)&=(A_1x^2+B_1xy+C_1y^2,\ A_2x^2+B_2xy+C_2y^2)\\&=(\Phi_1^{(3)}(x,y),\Phi_2^{(3)}(x,y)),\end{aligned}$$

where

$$A_1=\frac{d(\delta_1)}{\omega b_2(\delta_1)}\frac{2-\omega^2}{\omega^2-4},\qquad B_1=-\frac{\omega f(\delta_1)}{b_2(\delta_1)(\omega^2-4)},\qquad C_1=\frac{2d(\delta_1)}{\omega b_2(\delta_1)(\omega^2-4)},$$

$$A_2=\frac{f(\delta_1)}{b_2(\delta_1)(\omega^2-4)},\qquad B_2=-\frac{2d(\delta_1)}{b_2(\delta_1)(\omega^2-4)},\qquad C_2=-\frac{f(\delta_1)}{b_2(\delta_1)(\omega^2-4)}$$

and the functions d, f are defined in (3.24) and (3.25). When we set $z = \Phi^{(3)}(x, y)$ in (3.29), the (x, y)-part becomes

$$\begin{aligned} \dot{x} &= -y, \\ \dot{y} &= x + \frac{p(\delta_1)}{b_2(\delta_1)} x\Phi_1^{(3)}(x, y) + \frac{q(\delta_1)}{b_2(\delta_1)} x\Phi_2^{(3)}(x, y) \\ &\quad + \frac{s(\delta_1)}{b_2(\delta_1)} x^3 + \frac{u(\delta_1)}{b_2(\delta_1)} x^2 y + \frac{r(\delta_1)}{b_2(\delta_1)} (\Phi_1^{(3)}(x, y))^2 \\ &\quad + \frac{t(\delta_1)}{b_2(\delta_1)} \Phi_1^{(3)}(x, y)(\Phi_1^{(3)}(x, y))^2. \end{aligned} \tag{3.30}$$

By the Poincaré procedure we find that the polynomial

$$\begin{aligned} V(x, y) &= x^2 + y^2 + \frac{c(\delta_1)}{2} x^4 + \frac{1}{4}\left(\frac{p(\delta_1)}{b_2(\delta_1)} B_1 + \frac{q(\delta_1)}{b_2(\delta_1)} B_2\right) \\ &\quad \cdot (x^3 y + xy^3) - \frac{e(\delta_1)}{2} y^4 \end{aligned}$$

satisfies

$$\begin{aligned} \dot{V}(x, y) &= \frac{1}{4}\left(\frac{p(\delta_1)}{b_2(\delta_1)} B_1 + \frac{q(\delta_1)}{b_2(\delta_1)} B_2\right)(x^2 + y^2) + \text{h.o.t.} \\ &\doteq G_3(x^2 + y^2)^2 + \text{h.o.t.}, \end{aligned} \tag{3.31}$$

so that V is negative definite for small (x, y) (since $\delta_1 = \delta_2$ implies $\omega^2 - 4 > 0$; see (0.4)). The definiteness of V implies (see [15, Thms. 2.2, 3.1, 4.2]) that the stability properties of the bifurcating orbits may be recognized by studying the auxiliary system (3.30)-(3.32) and its normal form, where

$$\begin{aligned} \dot{\chi}_1 &= -\frac{G_3}{2}(x^2 + y^2)\chi_1 - \omega\chi_2, \\ \dot{\chi}_2 &= \omega\chi_1 - \frac{G_3}{2}(x^2 + y^2)\chi_2 + \frac{1}{b_2(\delta_1)} \\ &\quad \cdot [2c(\delta_1)\Phi_1^{(3)}(x, y) + e(\delta_1)\Phi_1^{(3)}(x, y) + h(\delta_1)x^2 + m(\delta_1)xy]\chi_1 \\ &\quad + \frac{e(\delta_1)}{b_2(\delta_1)} \Phi_1^{(3)}(x, y)\chi_2. \end{aligned} \tag{3.32}$$

The normal form of (3.32) (see [1], [20]) may be obtained by a change of variables $\chi = \xi + L(x, y)\xi$, where $L(x, y)\xi = (\phi_{11}(x, y)\xi_1 + \phi_{12}(x, y)\xi_2,\ \phi_{21}(x, y)\xi_1 + \phi_{22}(x, y)\xi_2)$ and $\phi_{ij}(j = 1, 2)$ are polynomials of degree 3 vanishing at the origin, such that (3.32) becomes

$$\begin{aligned} \dot{\xi}_1 &= P(x^2 + y^2)\xi_1 - (\omega + Q(x^2 + y^2))\xi_2 + \psi_1(x, y)\xi, \\ \dot{\xi}_2 &= (\omega + Q(x^2 + y^2))\xi_1 + P(x^2 + y^2)\xi_2 + \psi_2(x, y)\xi, \end{aligned} \tag{3.33}$$

where $P, Q \in \mathbb{R}$ and $\psi_j(x, y) = o(x^2 + y^2)^{3/2}$. Then ([15, Thm. 4.3]) the bifurcating orbits given by Hopf's Theorem are stable if both G_3 and P are negative (G_3 is given by

(3.31)), they are unstable if one of them is positive. In our case we get

$$P=-\frac{G_3}{2}-\frac{d(\delta_1)}{b_1(\delta_2)}$$

so that the orbits are unstable. Now it is sufficient to set $u_\delta(t,x)=-\bar{x}_1(t)\sin(\pi/l)x-\bar{x}_2(t)\sin(2\pi/l)x$ (where $(\bar{x}_1(\cdot), \bar{y}_1(\cdot), \bar{x}_2(\cdot), \bar{y}_2(\cdot))$ is the periodic solution of (3.32)), and the proof is finished. □

In Tables 1 and 2 we summarize the stability properties of the stationary solutions $0, \bar{\phi}_1, -\bar{\phi}_1$.

TABLE 1

Appendix.

Proofs of the propositions of § 1.

Proof of Proposition 1.1. The proof is straightforward, and it will be only outlined.

Let $\bar{w}\in D(L)$, and let $r>0$ be such that g is Lipschitz continuous on the closed ball centered at $\bar{w}$ with radius r.

Let $0\leqq t_0<t_1$, $w_0\in D(L)$, $\|w_0-\bar{w}\|_{D(L)}\leqq r/2$. Consider the problem

$$\text{(A.1)}\qquad \dot{w}=Lw+g(w),\quad t_0\leqq t\leqq t_1,\qquad w(t_0)=w_0.$$

A function $w\in C^1([t_0,t_1];X)\cap C([t_0,t_1];D(L))$ is a solution of (A.1) if and only if

$$\text{(A.2)}\qquad w(t)=e^{(t-t_0)L}w_0+\int_{t_0}^{t}e^{(t-s)L}g(w(s))\,ds,\qquad t_0\leqq t\leqq t_1.$$

Set

$$Y=\{w\in C([t_0,t_1];D(L));\ \|w(\cdot)-\bar{w}\|_{C([t_0,t_1];D(L))}\leqq r\}$$

$$\Gamma\colon Y\to C([t_0,t_1];D(L)),\qquad \Gamma(w)(t)=e^{(t-t_0)L}w_0+\int_{t_0}^{t}e^{(t-s)L}g(w(s))\,ds.$$

In fact, $\Gamma(Y)\subset C([t_0,t_1];D(L))$ because for each $w\in Y, g(w(\cdot))$ belongs to $C([t_0,t_1];D_L(\theta,\infty))$ and $w_0\in D(L)$, $Lw_0\in X=\overline{D(L)}$ (see [19, Thm. 5.5]). Moreover, using the estimates (see [19, § 1])

$$\|e^{sL}\|_{\mathscr{L}(D(L))}\leqq K,\qquad \|s^{1-\theta}\,e^{sL}\|_{\mathscr{L}(D_L(\theta,\infty);D(L))}\leqq K,\qquad 0\leqq s\leqq t_1-t_0,$$

we can easily see that if t_1-t_0 and r are sufficiently small, then $\Gamma(Y)\subset Y$ and Γ is a contraction with constant $\alpha<1$, not depending on w_0, so that Γ has a unique fixed point w in Y. It is also easy to show that in fact w is the unique solution of (A.1), and that if $w_{0n}\in D(L)(n\in\mathbb{N})$ are such that $\lim_{n\to\infty}\|w_0-w_{0n}\|_{D(L)}=0$, then, denoting by w_n the solution of (A.1) with initial value w_{0n}, we have $\lim_{n\to+\infty}\|w-w_n\|_{C([t_0,\,t_1];D(L))}=0$. Consider again the solution of (A.1): we have $w(t_1)\in D(L)$, so that w can be continued to some interval $[t_1,t_2]$. Set

$$\tau=\sup\{T>0;\ (1.3)\text{ has a solution in }[0,T]\}.$$

Then $[0,\tau[$ is the maximal interval of existence of the solution of (1.3). The last statement may be proved as in [10, Thm. 4.11], with obvious modifications. □

Proof of Proposition 1.2. For $\eta\in]0,\bar{\omega}[$ let $M(\eta)>0$ be such that

$$\|t^{1-\theta}\,e^{tL}\|_{L(D_L(\theta,\infty),D(L))}\leqq M(\eta)\,e^{-\eta t}\quad\text{for all } t>0,$$

$$\|e^{tL}\|_{L(D(L))}\leqq M(\eta)\,e^{-\eta t}\quad\text{for all } t>0.$$

Fix $0<\eta<\eta_1<\bar{\omega}$ and let $R,K>0$ be such that $\|x\|_{D(L)}\leqq R\Rightarrow\|g(x)\|_{D_L(\theta,\infty)}\leqq K\|x\|^2_{D(L)}$. Let $r\leqq R$ be such that $(M(\eta_1)K\Gamma(\theta)/(\eta_1-\eta)^\theta)r^2\leqq r/3$ (Γ denotes the Euler Gamma Function). We shall show that, if $w_0\in D(L)$ and $\|w_0\|_{D(L)}<r/3M(\eta)$, then $\tau(w_0)=+\infty$ and (1.7) holds. Assume by contradiction that $\tau(w_0)<+\infty$. Then, setting

$$T=\sup\{t>0,\ \tau(w_0)>2t,\ \|w(s)\,e^{\eta s}\|_{D(L)}\leqq r, 0\leqq s\leqq t\},$$

we have $T<+\infty$, and $\|w(T)\,e^{\eta T}\|_{D(L)}=r$ because of the continuity of w. Therefore

$$r=\|w(T)\,e^{\eta T}\|_{D(L)}\leqq M(\eta)\|w_0\|_{D(L)}+\left\|\int_0^T e^{(T-s)L}g(w(s))\,ds\right\|_{D(L)}$$

$$\leqq M(\eta)\|w_0\|_{D(L)}+e^{\eta T}M(\eta_1)\int_0^T e^{-\eta_1(T-s)}(T-s)^{\theta-1}Kr^2\,e^{-2\eta s}\,ds$$

$$\leqq\frac{r}{3}+M(\eta_1)Kr^2\int_0^T e^{(-\eta_1+\eta)(T-s)}(T-s)^{\theta-1}\,ds\leqq\frac{2}{3}r.$$

Hence $\tau(w_0)=T=+\infty$, and (1.7) holds with $C(\eta)=(3/2)M(\eta)$. □

Proof of Proposition 1.3. The proof follows the same lines as in [3, Thms. 3.3, 3.4], but is simpler because of the invariance properties of X^+.

(a) Set $\omega_1 = \sup\{\operatorname{Re}\lambda;\, \lambda \in \sigma_\omega^-(L)\}$, $w_2 = \min\{\operatorname{Re}\lambda;\, \lambda \in \sigma_\omega^+(L)\}$, $\omega_3 = \max\{\operatorname{Re}\lambda;\, \lambda \in \sigma_\omega^+(L)\}$, and define the operators:

$$\begin{aligned} &L_1\colon D(L_1) = D(L)\cap X^- \to X^-, \qquad L_1x = Lx,\\ &L_2\colon D(L_2) = X^+ \to X^+, \qquad L_2x = Lx. \end{aligned} \tag{A.3}$$

Then $D_{L_1}(\theta,\infty) = D_L(\theta,\infty)\cap X^-$. For $\eta \in \,]0, -\omega_1[$ let $M_1(\eta) > 0$ be such that

$$\begin{aligned} &\|e^{tL_1}\|_{\mathscr{L}(D(L_1))} \leqq M_1(\eta)\, e^{-\eta t}, \ \|t^{1-\theta}\, e^{tL_1}\|_{\mathscr{L}(D_L(\theta,\infty);D(L_1))}\\ &\qquad \leqq M_1(\eta)\, e^{-\eta t} \quad \forall t > 0 \end{aligned} \tag{A.4}$$

and, for $\varepsilon > 0$, let $M_2(\varepsilon) > 0$ be such that

$$\begin{aligned} &\|e^{tL_2}\|_{\mathscr{L}(X^+)} \leqq M_2(\varepsilon)\, e^{(\omega_2-\varepsilon)t} \quad \forall t \leqq 0,\\ &\|e^{tL_2}\|_{\mathscr{L}(X^+)} \leqq M_3(\varepsilon)\, e^{(\omega_3+\varepsilon)t} \quad \forall t \geqq 0. \end{aligned} \tag{A.5}$$

For $\rho > 0$ (to be chosen later) consider the system

$$\begin{aligned} &\dot{x}(t) = L_1x(t) + g_1(x(t), y(t)), \qquad x(0) = x_0,\\ &\dot{y}(t) = L_2y(t) + g_2(x(t), y(t)), \qquad y(0) = y_0, \end{aligned} \tag{A.6}$$

where

$$\begin{aligned} &x_0 = P^-w_0, \qquad y_0 = P^+w_0,\\ &g_1\colon D(L_1)\times X^+ \to D_{L_1}(\theta,\infty), \qquad g_1(x,y) = P^-g(x + \psi(y/\rho)y),\\ &g_2\colon D(L_1)\times X^+ \to X^+, \qquad g_2(x,y) = P^+g(x+\psi(y/\rho)y) \end{aligned}$$

and $\psi\colon X^+ \to \mathbb{R}$ is a C^∞ function such that

$$\begin{aligned} &0 \leqq \psi(x) \leqq 1 \quad \forall x \in X^+,\\ &\psi(x) = 1 \quad \text{if } \|x\| \leqq \tfrac{1}{2}, \qquad \psi(x) = 0 \quad \text{if } \|x\| \geqq 1. \end{aligned}$$

System (A.6) is equivalent (setting $x(t) = P^-w(t)$, $y(t) = P^+w(t)$) to (3.1) when $\|w(t)\|_{D(L)}$ is sufficiently small. Proposition 1.1 may be applied to system (A.6) to get local existence and uniqueness of the solution. Let

$$\begin{aligned} K(\rho) = \max\Bigg\{ &\left\|\frac{\partial g_1}{\partial x}(x,y)\right\|_{\mathscr{L}(D(L_1),D_{L_1}(\theta,\infty))}, \left\|\frac{\partial g_1}{\partial y}(x,y)\right\|_{\mathscr{L}(X^+,D_{L_1}(\theta,\infty))},\\ &\left\|\frac{\partial g_2}{\partial x}(x,y)\right\|_{\mathscr{L}(D(L_1),X^+)}, \left\|\frac{\partial g_2}{\partial y}(x,y)\right\|_{\mathscr{L}(X^+)},\\ &\qquad\qquad y \in X^+, x \in D(L_1), \|x\|_{D(L_1)} \leqq \rho \Bigg\}. \end{aligned} \tag{A.7}$$

Then $\lim_{\rho\to 0} K(\rho) = 0$.

It is easy to see (arguing as in the proof of Proposition 1.2) that there exist $\bar{\rho}, \bar{c} > 0$ such that for $0 < \rho < \bar{\rho}$ and $\|x_0\|_{D(L_1)} \leqq \bar{c}\rho$ then $\|x(t)\|_{D(L_1)} \leqq \rho$ for each $t \in [0, \tau(x_0, y_0)[$. This a priori estimate implies easily $\tau(x_0, y_0) = +\infty$. Fixed such ρ and x_0, let $t \geqq 0$ and let $z(s,t)(s \in \mathbb{R})$ be the solution of the i.v.p.

$$\dot{z}(s) = L_2z(s) + g_2(0, z(s)), \qquad z(t) = y(t).$$

Then for $0 \leqq s \leqq t$ and $\varepsilon > 0$

$$\|y(s) - z(s, t)\| = \left\| \int_t^s e^{(s-\sigma)L_2}[g_2(x(\sigma), y(\sigma)) - g_2(0, z(\sigma, t))]\, d\sigma \right\|$$

$$\leqq M_2(\varepsilon) \int_s^t e^{(\omega_2 - \varepsilon)(s-\sigma)} K(\rho)(\|x(\sigma)\|_{D(L_1)} + \|y(\sigma) - z(\sigma, t)\|)\, d\sigma.$$

Therefore, by Gronwall's Lemma

$$\|y(s) - z(s, t)\| \leqq M_2(\varepsilon) K(\rho) \int_s^t e^{(-\omega_2 + \varepsilon)(\sigma - s) + M_2(\varepsilon)K(\rho)(t-s)}$$

$$\cdot \|x(\sigma)\|_{D(L_1)}\, d\sigma, \qquad 0 \leqq s \leqq t,$$

so that, since $g_1(0, w(s, t)) = 0$, we have, for $\eta \in]\max\{-\omega_2, 0\}, -\omega_1[$ and $\varepsilon \in]0, \omega_2 + \eta[$:

$$\|e^{\eta s} g_1(x(s), y(s))\|_{D_{L_1}(\theta, \infty)}$$

$$\leqq K(\rho)\|e^{\eta s} x(s)\|_{D(L_1)} + M_2(\varepsilon)(K(\rho))^2 \int_s^t e^{(-\omega_2 + \varepsilon - \eta)(\sigma - s)}\, d\sigma\, e^{M_2(\varepsilon)K(\rho)(t-s)}$$

$$\cdot \sup_{s \leqq \sigma \leqq t} \|x(\sigma)\, e^{\eta\sigma}\|_{D(L_1)}$$

$$\leqq K(\rho)\left(1 + \frac{M_2 K(\rho)}{\omega_2 + \eta - \varepsilon}\right) \sup_{0 \leqq \sigma \leqq t} \|x(\sigma)\, e^{\mu\sigma}\|_{D(L_1)}, \quad 0 \leqq s \leqq t$$

if ρ is so small that $\omega_2 + \eta - \varepsilon > M_2(\varepsilon)K(\rho)$. Then we have (since $\eta < -\omega_1$)

$$\|e^{\eta t} x(t)\|_{D(L_1)} = \|e^{\eta t}\left(e^{tL_1} x_0 + \int_0^t e^{(t-s)L_1} g_1(x(s), y(s))\right) ds\|_{D(L_1)}$$

$$\leqq M_1(\eta)\|x_0\|_{D(L_1)} + M_1\left(\frac{\eta - \omega_1}{2}\right) K(\rho)\left(1 + \frac{M_2 K(\rho)}{\omega_2 + \eta - \varepsilon}\right) \int_0^{+\infty} e^{-(\eta - \omega_1)_s/2}$$

$$\cdot s^{\theta - 1}\, ds \sup_{0 \leqq s \leqq t} \|e^{\eta s} x(s)\|_{D(L_1)}.$$

Choose ρ so small that

$$K(\rho) M_1\left(\frac{\eta - \omega_1}{2}\right)\left(1 + \frac{M_2 K(\rho)}{\eta + \omega_2 - \varepsilon}\right)\left(\frac{2}{\eta - \omega_1}\right)^{\theta} \Gamma(\theta) \leqq \frac{1}{2}.$$

Then $\|x(t)\|_{D(L_1)} = \|P^- w(t)\|_{D(L)} \leqq 2M_1(\eta)\, e^{-\eta t}\|x_0\|_{D(L_1)} = 2M_1(\eta)\, e^{-\eta t}\|P^- w_0\|_{D(L_1)}$ for $t \geqq 0$ and the proof of (a) is finished.

(b) Let $\eta \in]0, -\omega_1[$ and $r \in]0, \varepsilon_0(\eta)/2]$ ($\varepsilon_0(\eta)$ is given in (a)).

Let $\Omega \subset X^+$ be compact and asymptotically stable for the semiflow in X^+, and assume $\operatorname{diam} \Omega \leqq r$. For $\delta > 0$ define $I(\Omega, \delta) = \{y \in X^+;\ \operatorname{dist}(y, \Omega) \leqq \delta\}$. Then, if δ is sufficiently small, say $\delta \leqq \bar{\delta}$, there exists a Lyapunov function $V: I(\Omega, \delta) \to \mathbb{R}$ such that

$$|V(y) - V(\bar{y})| \leqq \|y - \bar{y}\| \quad \text{for any } y, \bar{y} \in I(\Omega, \delta),$$

$$V(w(t)) \leqq e^{-t} V(w(0)) \quad \text{if } w(0) \in I(\Omega, \delta),$$

$$\alpha(\operatorname{dist}(y, \Omega)) \leqq V(y) \leqq \operatorname{dist}(y, \Omega) \quad \text{for any } y \in I(\Omega, \delta),$$

where $\alpha: [0, +\infty[\to [0, +\infty[$ is increasing, continuous and $\alpha(0) = 0$.

Let us define a Lyapunov function for system (A.6):

$$W: D(L_1) \times I(\Omega; \delta) \to [0, +\infty[, \qquad W(x, y) = p\|x\| - V(y),$$

where $p > 1$ will be chosen later. We have

(A.8) $$(\operatorname{dist}((x, y), \{0\} \times \Omega)) \leqq W(x, y) \leqq p \operatorname{dist}((x, y), \{0\} \times \Omega),$$

where $\beta^{-1}(\xi)=\xi+\alpha^{-1}(\xi)$ for $\xi\geqq 0$, and the distance is in the norm $\|(x, y)\|=\|x\|_{D(L_1)}+\|y\|$, $x\in D(L_1)$, $y\in X^+$.

Let $z(t)$ $(t\in\mathbb{R})$ be the solution of

$$z'(t)=L_2 z(t)+g_2(0, z(t)), \qquad z(0)=y_0.$$

Then for $\|x_0\|_{D(L)}\leqq \varepsilon_0(\eta)/2$, $\|y_0\|_{D(L)}\leqq \varepsilon_0(\eta)/2$, $y_0\in I(\bar\delta, \Omega)$ and $\varepsilon>0$, we have (using Proposition 1.3(a) and Gronwall's Lemma)

$$\|z(t)-y(t)\|\leqq c_1\, e^{c_2 t}\|x_0\|_{D(L)} \quad \text{for all } t\geqq 0,$$

where

$$c_1=\frac{K(\rho)M_3(\varepsilon)C_0(\eta)}{\omega_3+\varepsilon+\eta}, \qquad c_2=K(\rho)M_3(\varepsilon)-\eta.$$

Since

$$W(x(t), y(t))=V(z(t))+[V(y(t))-V(z(t))]+p\|x(t)\|_{D(L)}, \qquad t\geqq 0,$$

for $T\geqq 0$ and $T\leqq t\leqq 2T$ we have

$$W(x(t), y(t))\leqq e^{-T}V(y_0)+[c_1\, e^{c_2 t}+C_0(\eta)p\, e^{-\eta T}]\|x_0\|_{D(L)}.$$

Let $T>0$ be such that

$$\text{(A.9)} \qquad e^{-T}\leqq \tfrac{1}{2}, \quad C_0(\eta)\, e^{-T}\leqq \tfrac{1}{4}, \quad \alpha^{-1}(e^{-T}\bar\delta)\leqq\bar\delta$$

and choose p so large that $c_1\, e^{2c_2 T}\leqq p/4$; then $W(x(t), y(t))\leqq\frac{1}{2}W(x_0, y_0)$ for all $t\in[T, 2T]$. Then for

$$\|x_0\|_{D(L)}\leqq\frac{\bar\delta}{2c_1}\, e^{-c_2 T}\wedge\frac{\varepsilon_0(\eta)}{2}$$

and $y_0\in I(\Omega, \bar\delta)$ with $\|y_0\|\leqq\varepsilon_0(\eta)/2$ we have, by (A.9) and Proposition 1.3(a), $\|x(T)\|_{D(L)}\leqq\frac{1}{4}\|x_0\|_{D(L)}$, and

$$\begin{aligned}\operatorname{dist}(y(T), \Omega)&\leqq\|y(T)-z(T)\|+\operatorname{dist}(z(T), \Omega)\\ &\leqq c_1\, e^{c_2 T}\|x_0\|_{D(L)}+\alpha^{-1}(V(z(T)))\\ &\leqq\frac{\bar\delta}{2}+\alpha^{-1}(e^{-T}\bar\delta)\leqq\bar\delta\end{aligned}$$

so that we can repeat the previous argument replacing (x_0, y_0) by $(x(T), y(T))$. We get

$$W(x(t), y(t))\leqq 2^{-n}W(x_0, y_0), \qquad nT\leqq t\leqq(n+1)T, \qquad n\in\mathbb{N}$$

so that $W(x(t), y(t))\leqq 2\, e^{-(t/T)\log 2}W(x_0, y_0)$ for all $t\geqq T$. This implies, together with (A.5), that W is a Lyapunov function for system (A.6) and the conclusion follows. □

Proof of Proposition 1.4. Consider again system (A.6). In our cases we have $g_1\equiv 0$. Since the purely imaginary eigenvalues of L are semisimple, there exists $M_4>0$ such that

$$\|e^{tL_2}\|_{L(X^+)}\leqq M_4 \quad \forall t\in\mathbb{R}.$$

Therefore we have

$$\|y(t)\|_{D(L)}\leqq cM_4\|P^+w_0\|_{D(L)},$$

where $c>0$ is such that $\|y\|_{D(L)}\leqq c\|y\|$ for all $y\in X^+$. For each $\alpha\in\,]0,-\sup\{\operatorname{Re}\lambda;\lambda\in\sigma_\omega^-(L)\}[$ and $t\in\,]0,\tau(w_0)[$ we have, by (A.4),

$$\begin{aligned}\|x(t)\|_{D(L)}&\leqq M_1(\alpha)\|P^-w_0\|_{D(L)}\\&\quad+M_1(\alpha)\frac{\Gamma(\theta)}{\alpha^\theta}\sup_{0\leqq s\leqq t}\|g_1(x(s)+y(s))\|_{D_L(\theta,\infty)}\\&\leqq M_1(\alpha)\|P^-w_0\|_{D(L)}+\frac{M_1(\alpha)\Gamma(\theta)}{\alpha^\theta}\\&\quad\cdot K(\rho)(\sup_{0\leqq s\leqq t}\|x(s)\|_{D(L)}+cM_4\|P^+w_0\|_{D(L)}).\end{aligned}$$

Therefore for $\|w_0\|_{D(L)}\leqq\rho$, where ρ is such that $(M_1(\alpha)\Gamma(\theta)/\alpha^\theta)K(\rho)\leqq\frac{1}{2}$, we have

$$\|x(t)\|_{D(L)}\leqq 2M_1(\alpha)\|P^-w_0\|_{D(L)}+CM_4\|P^+w_0\|_{D(L)},\qquad 0\leqq t<\tau,$$

and the statement follows easily. □

Evaluation of the eigenvalues of $\tilde{L}$. For any $\lambda\in\mathbb{C}$, the equation $\lambda(\phi,\psi)=\tilde{L}(\phi,\psi)$ is equivalent to

$$\text{(A.10)}\qquad\begin{aligned}&\text{(i)}\quad(\phi,\psi)\in D(L),\qquad\text{(ii)}\quad\lambda\phi=\psi,\\&\text{(iii)}\quad(\alpha+\gamma\lambda)\phi^{(iv)}-\beta\phi''+(\lambda^2+\delta\lambda)\phi=0.\end{aligned}$$

Each solution of (A.10) is a couple of C^∞ functions whose even order derivatives vanish at $x=0$, $x=1$. Therefore $\phi(x)=\text{const.}\sin(h\pi/l)x(0\leqq x\leqq l)$ for some $h\in\mathbb{N}$, and

$$\text{(A.11)}\qquad\lambda^2+\lambda\left(\delta+\frac{\gamma h^4\pi^4}{l^4}\right)+\frac{h^2\pi^2}{l^2}\left(\frac{\alpha h^2\pi^2}{l^2}+\beta\right)=0$$

so that the eigenvalues of $\tilde{L}$ are given by (2.15).
