ERGODIC PROPERTIES OF LINEAR DYNAMICAL SYSTEMS*

RUSSELL A. JOHNSON†, KENNETH J. PALMER‡ AND GEORGE R. SELL§

Abstract. The Multiplicative Ergodic theorem, which gives information about the dynamical structure of a cocycle Φ, or a linear skew product flow π, over a suitable base space $\mathbf{M}$, asserts that for every invariant probability measure μ on $\mathbf{M}$ there is a measurable decomposition of the vector bundle over $\mathbf{M}$ into invariant measurable subbundles, and that every solution with initial conditions in any of these subbundles has strong Lyapunov exponents. These exponents depend on the measure μ, and when μ is ergodic, they are constant (almost everywhere) on $\mathbf{M}$ and form a finite set meas $\Sigma(\mu)$. The dynamical spectrum dyn Σ consists of those values $\lambda \in \mathbf{R}$ for which the shifted flow π_λ fails to have an exponential dichotomy over $\mathbf{M}$. The Spectral theorem for linear skew product flows states that when $\mathbf{M}$ is compact and dynamically connected then dyn Σ is the finite union of k disjoint compact intervals and the vector bundle over $\mathbf{M}$ is the sum of k continuous invariant subbundles. We show that

$$\text{Boundary dyn } \Sigma \subseteq \bigcup_{\mu} \text{meas } \Sigma(\mu) \subseteq \text{dyn } \Sigma$$

where the union above is over all ergodic measures μ on $\mathbf{M}$. Also we show that the measurable invariant subbundles which arise in the Multiplicative Ergodic theorem form a refinement of the continuous invariant subbundles described in the Spectral theorem. A new proof of the Multiplicative Ergodic theorem is presented here. This proof is a substantial simplification over other arguments. Applications of the theory of Lyapunov exponents to "spiral" systems, products of "random" matrices, stochastic differential equations, and the almost periodic Schrödinger operator are included.

Key words. ergodic properties, linear dynamical system, Lyapunov exponents

AMS(MOS) subject classifications. 34C35, 58F11, 58F19

1. Introduction. Nearly two decades ago Oseledec (1968) published his proof of the Multiplicative Ergodic theorem. This theorem, which is one of the milestones in the study of ergodic properties of dynamical systems, has had far-reaching applications, including its role in the work of Margulis (1975) on arithmeticity in Lie groups, in the theory of Pesin (1977) on Bernoullian substructures for diffeomorphisms, in the theory of Katok (1980) on entropy and periodic points, in the study of Kotani (1982) on spectral measures for Schrödinger operators, in the work of Constantin and Foias (1983) on attractors in the Navier–Stokes equations, and in the study of Novikov (1975) and Millionscikov (1978) on almost reducible systems with almost periodic coefficients. As a testimony to the importance of this theorem one finds several alternative proofs including the contemporaneous paper of Millionscikov (1968), and those of Raghunathan (1979), Ruelle (1979) and Crauel (1981), as well as the anticipatory paper of Liao (1966).

The Multiplicative Ergodic theorem gives information about the dynamical structure of a cocycle Φ, or a linear skew product flow π, over a suitable base space $\mathbf{M}$. In typical applications the base space $\mathbf{M}$ is either an attractor, a compact invariant set, or the space of coefficients for a diffeomorphism, a differential equation, or a vector field. This theorem asserts that for every invariant probability measure μ on $\mathbf{M}$ there is a measurable decomposition of the vector bundle over $\mathbf{M}$ into invariant measurable

subbundles, and that every solution with initial conditions in any of these subbundles has strong Lyapunov exponents. These exponents, or growth rates, depend on the measure μ, and when μ is ergodic, they are constant (almost everywhere) on $\mathbf{M}$ and form a finite set meas $\Sigma(\mu)$, the measurable (Millionscikov-Oseledec) spectrum.

The main objective in this paper is to study the connection between the measurable spectrum meas $\Sigma(\mu)$ and the dynamical spectrum dyn Σ introduced by Sacker and Sell (1975), (1978), (1980). (Also see Daletskii and Krein (1974), as well as Selgrade (1975).) The dynamical spectrum dyn Σ consists of those values $\lambda \in \mathbf{R}$ for which the shifted flow π_λ fails to have an exponential dichotomy over $\mathbf{M}$. It follows from the Spectral theorem for linear skew-product flows, Sacker and Sell (1978), that the dynamical spectrum is the finite union of disjoint compact intervals when $\mathbf{M}$ is compact and dynamically connected.

The dynamical spectrum and the theory of exponential dichotomies are central concepts in wide-ranging branches of analysis including the perturbation theories for invariant manifolds (see Sacker (1969), Fenichel (1971) and Hirsch, Pugh and Shub (1977), the bifurcation theories of Chenciner and Iooss (1979) and Sell (1979), the characterization of the spectrum of Schrödinger operators in Johnson (1982), linearization theories near invariant manifolds in Sell (1984), the study of transversal homoclinic orbits in Palmer (1984), as well as the study of inertial manifolds for dissipative systems in Foias, Sell and Temam (1985).

It is important therefore to understand the connection between these two spectral concepts. We will show, in § 8, that

$$\text{boundary dyn}\,\Sigma \subseteq \bigcup_{\mu} \text{meas}\,\Sigma(\mu) \subseteq \text{dyn}\,\Sigma, \tag{1.1}$$

where the union above is over all ergodic measures μ on $\mathbf{M}$. We actually derive much more than (1.1). We show that the measurable invariant subbundles which arise in the Multiplicative Ergodic theorem form a refinement of the continuous invariant subbundles described in the Spectral theorem. The relationship (1.1) also leads to good methods for computing the Lyapunov exponents and the continuous spectral bundles (see Perry (1986)).

Another objective is to show that the cocycle Φ, itself, has a strong Lyapunov exponent (almost everywhere) and that this agrees with max meas $\Sigma(\mu)$. Although simple, this fact is very important because it forms the foundation for deriving an approximation theory which leads to the numerical evaluation of the measurable and dynamical spectra. The approximation theory and the related numerical coding is described in the University of Minnesota Ph.D. thesis of David Perry (1986).

While doing this investigation we discovered a new proof of the Multiplicative Ergodic theorem. Since our proof is a substantial simplification over other arguments, we present it here. In addition to this simplification, our proof has some interesting geometrical features which may be useful elsewhere. While our proof of the Multiplicative Ergodic theorem is restricted to cocycles over a compact base space $\mathbf{M}$, we will see that this includes practically every application. Among other things, our theory applies to linear stochastic differential equations with bounded measurable coefficients, as well as to the linearized flow near an attractor in a nonlinear dynamical system.

A final objective of this paper is the presentation of several applications of these spectral theories. One of these theories, the theory of Lyapunov exponents for "spiral" systems, is central to any numerical investigation of Lyapunov exponents. Other applications include products of "random" matrices, stochastic differential equations, and the almost periodic Schrödinger operator.

This paper is organized as follows: In § 2 we present the statements of the main theorems in this paper. Section 3 is concerned with a number of technical details which shall be used in the proofs of our theorems. One may wish to skip this on the first reading. In § 4 we present the basic triangularization method as it applies to linear skew product flows. Section 5 is concerned with a brief review of some basic facts about invariant measures, and in § 6 we present our proof of the Multiplicative Ergodic theorem. The ergodic properties of the induced flow on the projective bundle are presented in § 7. In § 8 we derive (1.1) which describes the connection between the measurable and the dynamical spectra. In § 9 we study the theory of wedge-product flows and show how this can be used to compute the measurable spectrum, and in § 10 we present the applications discussed above. The paper concludes with an Appendix which contains some comments on related geometric properties of linear skew product flows.

2. Statement of main theorems. Let **M** be a compact Hausdorff space and let **T** denote either the integers **Z** or the reals **R**. Assume that $\theta \cdot t$ is a flow on **M**, i.e. the mapping $(\theta, t) \to \theta \cdot t$ of $\mathbf{M} \times \mathbf{T}$ into **M** is continuous and satisfies $\theta \cdot 0 = \theta$, and $\theta \cdot (t+s) = (\theta \cdot t) \cdot s$. The Krylov-Bogoliubov theorem (see Nemytskii and Stepanov (1960)) assures us that there is an invariant probability measure μ on **M**. This means that $\mu(A \cdot t) = \mu(A)$ for all Borel sets $A \subseteq \mathbf{M}$ and all $t \in \mathbf{T}$, where $A \cdot t = \{\theta \cdot t \colon \theta \in A\}$. The invariant measure μ is *ergodic* if $\mu(A \triangle A \cdot t) = 0$ for all $t \in \mathbf{T}$ implies that $\mu(A) = 0$ or $\mu(A) = 1$. Recall that $A \triangle B = (A \backslash B) \cup (B \backslash A)$ is the symmetric difference. For an integer $m \geqq 1$ let $\mathcal{GL}(m)$ denote the group of all isomorphisms on $\mathbf{R}^m$, i.e., the group of nonsingular $(m \times m)$ matrices with entries in **R**. A *cocycle* on **M** is a continuous mapping $\Phi \cdot \mathbf{M} \times \mathbf{T} \to \mathcal{GL}(m)$ that satisfies

$$\Phi(\theta, t+s) = \Phi(\theta \cdot t, s)\Phi(\theta, t) \tag{2.1}$$

for all $\theta \in \mathbf{M}$ and $s, t \in \mathbf{T}$. We note that Φ is a cocycle on **M** if and only if

$$\pi(x, \theta, t) := (\Phi(\theta, t)x, \theta \cdot t) \tag{2.2}$$

is a linear skew product flow on $R^m \times \mathbf{M}$.

If $\mathbf{T} = \mathbf{R}$ we shall say that the flow π is *smooth* provided the mapping

$$A\colon \theta \to \frac{d}{dt}\Phi(\theta, t)|_{t=0}$$

exists and is continuous. In this case the cocycle $\Phi(\theta, t)$ is simply the fundamental matrix solution of

$$x' = A(\theta \cdot t)x \qquad (x \in \mathbf{R}^m) \tag{2.3}$$

that satisfies $\Phi(\theta, 0) = I$. This is the prototypical example of a cocycle.

Let Φ and Ψ be two cocycles on **M** with range in $\mathcal{GL}(m)$. We shall say that Φ and Ψ are *cohomologous* if there is a continuous mapping $F\colon \mathbf{M} \to \mathcal{GL}(m)$ that satisfies

$$\Phi(\theta, t) = F(\theta \cdot t)\Psi(\theta, t)F(\theta)^{-1} \tag{2.4}$$

for all $\theta \in \mathbf{M}$, $t \in \mathbf{T}$, where (-1) denotes the matrix inverse.

Let Φ be a cocycle on $\mathbf{M}$. Let $x \in \mathbf{R}^m$ $(x \neq 0)$ and $\theta \in \mathbf{M}$ and define the four *Lyapunov exponents* $\lambda_i^{\pm}(x, \theta)$, $\lambda_s^{\pm}(x, \theta)$ by

$$\lambda_s^{\pm}(x, \theta) = \limsup_{t \to \pm\infty} \frac{1}{t} \log |\Phi(\theta, t)x|, \qquad \lambda_i^{\pm}(x, \theta) := \liminf_{t \to \pm\infty} \frac{1}{t} \log |\Phi(\theta, t)x|.$$

If it happens that the following two limits exist *and* are equal

$$\lim_{t \to +\infty} \frac{1}{t} \log |\Phi(\theta, t)x| = \lim_{t \to -\infty} \frac{1}{t} \log |\Phi(\theta, t)x|, \tag{2.5}$$

then we shall denote the common value as $\lambda(x, \theta)$. *In the future when we write the symbol* $\lambda(x, \theta)$ *this should be interpreted as an assertion that both limits in* (2.5) *exist and* $\lambda(x, \theta)$ *is the common value.* In this case one says that (x, θ) has a *strong* Lyapunov exponent.

Let Φ and Ψ be two cohomologous cocycles on $\mathbf{M}$ that satisfy (2.4), and let $x = F(\theta)y$. Then one has

$$\limsup_{t \to \pm\infty} \frac{1}{t} \log |\Phi(\theta, t)x| = \limsup_{t \to \pm\infty} \frac{1}{t} \log |\Psi(\theta, t)y|$$

and

$$\lim_{|t| \to \infty} \frac{1}{t} \log |\Phi(\theta, t)x| = \lim_{|t| \to \infty} \frac{1}{t} \log |\Psi(\theta, t)y|.$$

In other words, cohomologous cocycles have the same Lyapunov exponents.

For $0 \leqq k \leqq m$ let $\mathscr{G}(m, k)$ denote the Grassman manifold of k-planes in $\mathbf{R}^m$, and let $\mathscr{G}(m) = \bigcup_{k=0}^m \mathscr{G}(m, k)$ denote the disjoint union of these compact manifolds. For $k \in \{1, \cdots, m\}$ we shall let $N(k)$ denote those vectors $\vec{m} = (m_1, \cdots, m_k)$ with $1 \leqq m_i$ and $m_1 + \cdots + m_k = m$.

The first two theorems are statements of the Multiplicative Ergodic theorem.

THEOREM 2.1. *Let* $\mathbf{M}$ *be a compact Hausdorff space with a flow* $\theta \cdot t$ *and let* μ *be an invariant probability measure on* $\mathbf{M}$. *Let* ϕ *denote a cocycle on* $\mathbf{M}$. *Then there exist*:

(i) *an invariant set* $\mathbf{M}_\mu \subseteq \mathbf{M}$ *with* $\mu(\mathbf{M}_\mu) = 1$;

(ii) *a measurable decomposition* $\mathbf{M}_\mu = \bigcup \mathbf{M}_\mu(p)$ *where each* $\mathbf{M}_\mu(p)$ *is invariant and the union is taken over all pairs* $p = (k, \vec{m})$ *where* $1 \leqq k \leqq m$, *and* $\vec{m} \in N(k)$;

(iii) *measurable mappings* $\lambda_1, \cdots, \lambda_k : \mathbf{M}_\mu(p) \to \mathbf{R}$, *where*

$$\lambda_1(\theta) < \lambda_2(\theta) < \cdots < \lambda_k(\theta)$$

for $\theta \in \mathbf{M}_\mu(p)$; *and*

(iv) *measurable mappings* $\mathscr{W}_i : \mathbf{M}_\mu(p) \to \mathscr{G}(m, m_i)$, $1 \leqq i \leqq k$, *where*

$$\vec{m} = (m_1, \cdots, m_k),$$

such that for $\theta \in \mathbf{M}_\mu(p)$ *one has*:

(v) $\{\mathscr{W}_1(\theta), \cdots, \mathscr{W}_k(\theta)\}$ *is linearly independent*;

(vi) $R^m = \mathscr{W}_1(\theta) + \cdots + \mathscr{W}_k(\theta)$;

(vii) *if* $x \in \mathscr{W}_i(\theta)$, $x \neq 0$, *then* $\lambda(x, \theta) = \lambda_i(\theta)$ *for* $1 \leqq i \leqq k$.

If, in addition, μ *is an ergodic measure, then precisely one* $\mathbf{M}_\mu(p)$ *has positive measure, and the mappings* $\lambda_i : \mathbf{M}_\mu \to \mathbf{R}$ *are constant,* $1 \leqq i \leqq k$.

The results in the last theorem extend readily to linear skew product flows on arbitrary vector bundles, Sacker and Sell (1978).

THEOREM 2.2. *Let $\mathscr{E}$ be a vector bundle over a compact Hausdorff space* $\mathbf{M}$ *and let π be a linear skew product flow on $\mathscr{E}$. Let μ be an invariant probability measure on* $\mathbf{M}$. *Then the conclusions of Theorem* 2.1 *remain valid where $\mathscr{W}_i$, $1 \leqq i \leqq k$, now assume values in the appropriate Grassman bundles over* $\mathbf{M}$.

The *measurable spectrum* meas $\Sigma(\mu)$ is defined to be the collection $\{\lambda_1, \cdots, \lambda_k\}$ when μ is ergodic. The numbers $m_1, \cdots, m_k$ are the *multiplicities* of the spectral values $\lambda_1, \cdots, \lambda_k$. When μ is not ergodic, then the spectrum is meas $\Sigma(\mu, \theta) = \{\lambda_1(\theta), \cdots, \lambda_k(\theta)\}$ and the multiplicities $\{m_1, \cdots, m_k\}$ depend on $\theta \in \mathbf{M}_\mu$ and $\theta \in \mathbf{M}_\mu(p)$. For an ergodic measure μ, the *measurable bundle* associated with a spectral value λ_i, $1 \leqq i \leqq k$ is

$$\mathscr{W}_i = \{(x, \theta) \colon x \in \mathscr{W}_i(\theta), \theta \in \mathbf{M}_\mu\}.$$

If μ is not ergodic, then the measurable bundles are defined similarly on each of the invariant sets $\mathbf{M}_\mu(p)$.

The next theorem compares the measurable spectrum and the measurable bundles with the dynamical (or continuous) spectrum and associated continuous spectral subbundles arising in the theory of exponential dichotomies in linear skew product flows; see Sacker and Sell (1978), (1980).

Let $\pi(x, \theta, t)$ be a linear skew product flow on $\mathbf{R}^m \times \mathbf{M}$, where $\mathbf{M}$ is a compact, connected space, and for $\lambda \in \mathbf{R}$ let

$$\pi_\lambda(x, \theta, t) := (\Phi_\lambda(\theta, t)x, \theta \cdot t) \tag{2.6}$$

be the shifted flow, where $\Phi_\lambda(\theta, t) := e^{-\lambda t}\Phi(\theta, t)$. Recall that π_λ has an *exponential dichotomy over* $\mathbf{M}$ if there is a (continuous) projector $P(x, \theta) = (P(\theta)x, \theta)$ on $\mathbf{R}^m$ and constants $K \geqq 1$, $\alpha > 0$ such that

$$|\Phi_\lambda(\theta, t)P(\theta)\Phi_\lambda^{-1}(\theta, s)| \leqq K e^{-\alpha(t-s)}, \qquad s \leqq t,$$

$$|\Phi_\lambda(\theta, t)[I - P(\theta)]\Phi_\lambda^{-1}(\theta, s)| \leqq K e^{-\alpha(s-t)}, \qquad t \leqq s$$

for all $\theta \in \mathbf{M}$ and $s, t \in \mathbf{T}$. The set $\lambda \in \mathbf{R}$ for which π_λ fails to have an exponential dichotomy over $\mathbf{M}$ is defined to be dyn Σ, the dynamical spectrum. The Spectral theorem (Sacker and Sell (1978)) assures us that dyn $\Sigma = \bigcup_{i=1}^k [a_i, b_i]$ is the union of k-nonoverlapping compact intervals, where $1 \leqq k \leqq m$. Also corresponding to each spectral interval $[a_i, b_i]$ there is an invariant spectral subbundle $\mathscr{V}_i$ of $\mathbf{R}^m \times \mathbf{M}$ with dim $\mathscr{V}_i(\theta) \geqq 1$, where $\mathscr{V}_i(\theta) = \{x \in \mathbf{R}^m \colon (x, \theta) \in V_i\}$, $1 \leqq i \leqq k$, the spaces $\{\mathscr{V}_1(\theta), \cdots, \mathscr{V}_k(\theta)\}$ are linearly independent and $\mathbf{R}^m \times \mathbf{M} = \mathscr{V}_1 + \cdots + \mathscr{V}_k$ (as a Whitney sum). The boundary of dyn Σ is the finite collection of end points $\{a_1, \cdots, a_k, b_1, \cdots, b_k\}$. The next theorem, which describes the connection between the measurable and dynamical spectra, is proved in § 7.

THEOREM 2.3. *Let π be a linear skew product flow on $\mathbf{R}^m \times \mathbf{M}$ where $\mathbf{M}$ is compact and connected, and let* dyn Σ *denote the dynamical spectrum of π. Then one has*

$$\text{boundary dyn}\,\Sigma \subseteq \bigcup_\mu \text{meas}\,\Sigma(\mu) \subseteq \text{dyn}\,\Sigma \tag{2.7}$$

where the union is either over all invariant probability measures μ on $\mathbf{M}$ *or over all ergodic measures on* $\mathbf{M}$. *Let μ be a given invariant probability measure on* $\mathbf{M}$ *and let* meas $\Sigma(\mu, \theta) = \{\lambda_1(\theta), \cdots, \lambda_k(\theta)\}$ *be the measurable spectrum for $\theta \in \mathbf{M}_\mu(p)$. Then for each λ_j there is precisely one spectral interval $[a_i, b_i]$ with $\lambda_j(\theta) \in [a_i, b_i]$ for all $\theta \in \mathbf{M}_\mu(p)$. Also the associated measurable bundle $\mathscr{W}_j(\theta)$ satisfies $\mathscr{W}_j(\theta) \subseteq \mathscr{V}_i(\theta)$ for all $\theta \in \mathbf{M}_\mu(p)$.*

Finally one has $\mathcal{V}_i(\theta)=\sum \mathcal{W}_j(\theta)$ *for all* $\theta\in \mathbf{M}_\mu(p)$ *where the summation is over all j with* $\lambda_j(\theta)\in[a_i, b_i]$.

If $\mathbf{T}=\mathbf{Z}$, then the last theorem is valid when $\mathbf{M}$ is compact and "dynamically connected," where the latter means that $\mathbf{M}$ cannot be written as the union of two disjoint nonempty closed invariant sets. Also, as in the spirit of Theorem 2.2, we note that Theorem 2.3 extends to linear skew product flows on general vector bundles.

Our next theorem is concerned directly with the problem of computing the measurable spectrum meas $\Sigma(\mu, \theta)$. The point is that one is able to do this without computing the basis elements $e_1, \cdots, e_m$. The key idea here is the notion of a wedge product, cf. Matshushima (1972). For $1\leqq k\leqq m$ let $\Lambda^k\mathbf{R}^m$ denote the vector space generated by all k-fold wedge products $x_1\wedge\cdots\wedge x_k$ where $x_i\in\mathbf{R}^m$, $1\leqq i\leqq k$. Recall that the wedge product $x_1\wedge\cdots\wedge x_k$ is linear in each factor and antisymmetric, i.e. $x\wedge y=-y\wedge x$. If $L:\mathbf{R}^m\to\mathbf{R}^m$ is linear, then this induces a linear mapping Λ^kL on $\Lambda^k\mathbf{R}^m$ by the formula

$$\Lambda^kL(x_1\wedge\cdots\wedge x_k):=Lx_1\wedge\cdots\wedge Lx_k.$$

Since one has $\Lambda^k(LM)=(\Lambda^kL)(\Lambda^kM)$, we see that if $\Phi(\theta, t)$ is a cocycle on $\mathbf{M}$ then $\Lambda^k\Phi(\theta, t)$ is also cocycle, for $1\leqq k\leqq m$.

In the statement of the next theorem reference will be made to the notation of Theorem 2.1. In particular for $\theta\in\mathbf{M}_\mu(p)$ the growth rates

$$\lambda_1(\theta)<\lambda_2(\theta)<\cdots<\lambda_k(\theta)$$

with multiplicities $m_1, \cdots, m_k$ will be rewritten in the form

$$\gamma_1(\theta)\leqq\gamma_2(\theta)\leqq\cdots\leqq\gamma_m(\theta) \tag{2.8}$$

where $\lambda_i(\theta)$ is repeated m_i-times in (2.8), $1\leqq i\leqq k$.

THEOREM 2.4. *Let* $\mathbf{M}$ *be a compact Hausdorff space with a flow* $\theta\cdot t$ *and let* μ *be an invariant probability measure on* $\mathbf{M}$. *Let* Φ *denote a cocycle on* $\mathbf{M}$ *and adopt the conclusions and notation of Theorem* 2.1. *Let* $\gamma_1, \cdots, \gamma_m$ *satisfy* (2.8) *for* $\theta\in\mathbf{M}_\mu(p)$. *Then for all* $\theta\in\mathbf{M}_\mu(p)$ *one has*:

(i) $\lim_{t\to+\infty}(1/t)\log|\Phi(\theta, t)|=\gamma_m(\theta)$,

(ii) $\lim_{t\to+\infty}(1/t)\log|\Lambda^k\Phi(\theta, t)|=\gamma_{m+1-k}(\theta)+\cdots+\gamma_m(\theta)$, *for* $2\leqq k\leqq m$,

(iii) $\lim_{t\to-\infty}(1/t)\log|\Phi(\theta, t)|=\gamma_1(\theta)$,

(iv) $\lim_{t\to-\infty}(1/t)\log|\Lambda^k\Phi(\theta, t)|=\gamma_1(\theta)+\cdots+\gamma_k(\theta)$, *for* $2\leqq k\leqq m$.

The last theorem extends to linear skew product flows on a vector bundle $\mathscr{E}$ over a compact Hausdorff space $\mathbf{M}$. In this case the wedge product of vectors $x_1, \cdots, x_k\in\mathscr{E}(\theta)$ forms a new bundle $\Lambda^k\mathscr{E}$, $1\leqq k\leqq m$ over $\mathbf{M}$. Also the flow π on $\mathscr{E}$ induces a flow $\Lambda^k\pi$ on $\Lambda^k\mathscr{E}$. This extension is a direct consequence of the proof of the last theorem together with Lemma 3.4 below. We will omit the details.

Remark 2.1. For simplicity of exposition we have formulated these theorems for cocycles with values in $\mathscr{GL}(m, \mathbf{R})$. The theorems are valid for cocycles with values in $\mathscr{GL}(m, \mathbf{C})$, and the proofs we give below extend with only trivial modifications.

3. Some technicalities. Before we turn our attention to the proofs of the main theorems, we need to dispense with some technical details which will enable us to simplify our arguments. We begin with a proof of the following facts:

1. One can assume, without loss of generality, that the base space $\mathbf{M}$ is a compact metric space instead of a compact Hausdorff space. (This fact simplifies substantially some of the measure theoretic considerations.)

2. If $\mathbf{T}=\mathbf{R}$ one can assume that the cocycle Φ is the fundamental solution matrix of an ordinary differential equation on $\mathbf{M}$ with continuous coefficients. We call such a cocycle *smooth.*

3. A linear skew product flow on an arbitrary vector bundle $\mathscr{E}$ over a compact Hausdorff space $\mathbf{M}$ can be imbedded into a linear skew product flow on $\mathbf{R}^m\times\mathbf{M}$ for some $m\geqq 1$.

The argument in each of these three cases is based on the same principle, viz. one can show that the given flow is cohomologous to the desired flow. The resulting cohomology preserves all the desired properties of our main theorems. In particular if Φ_1 and Φ_2 are two cohomologous cocycles on a compact Hausdorff space $\mathbf{M}$ that satisfy

$$F(\theta\cdot t)\Phi_1(\theta,t)=\Phi_2(\theta,t)F(\theta)$$

where $F:\mathbf{M}\to\mathscr{GL}(m)$ is continuous, then as noted above Φ_1 and Φ_2 have the same collection of Lyapunov exponents. Furthermore (x,θ) has a strong Lyapunov exponent for Φ_1 if and only if $(F(\theta)x,\theta)$ has a strong Lyapunov exponent for Φ_2. Thus F preserves the measurable spectrum meas $\Sigma(\mu,\theta)$ and it maps the measurable bundles of Φ_1 onto those of Φ_2. In addition F preserves the dynamical spectrum, and it sets up a one-to-one correspondence between the continuous spectral subbundles.

The situation is, in fact, more general. Let $\mathbf{M}_1$ and $\mathbf{M}_2$ be two compact Hausdorff spaces and let $f:\mathbf{M}_1\to\mathbf{M}_2$ be a flow epimorphism. Next let Φ_i be a cocycle on $\mathbf{M}_i$ $(i=1,2)$ and let $F:\mathbf{M}_1\to\mathscr{GL}(m)$ satisfy

$$F(\theta_1\cdot t)\Phi_1(\theta_1,t)=\Phi_2(f(\theta_1),t)F(\theta_1).$$

Then Φ_1 and Φ_2 have the same measurable and dynamical spectra and F sets up a one-to-one correspondence between the associated spectral bundles.

Our first step is to show that we can replace a compact Hausdorff base space $\mathbf{M}_1$ with a compact metric space $\mathbf{M}_2$. We use an argument of Ellis (1969).

LEMMA 3.1. *Let Φ_1 be a cocycle over a compact Hausdorff space $\mathbf{M}_1$ with a flow $\theta_1\cdot t$. Then there is* (i) *a compact metric space $\mathbf{M}_2$ with a flow $\theta_2\cdot t$,* (ii) *a flow epimorphism $f:\mathbf{M}_1\to\mathbf{M}_2$ and* (iii) *a cocycle Φ_2 over $\mathbf{M}_2$ such that $\Phi_1(\theta_1,t)=\Phi_2(f(\theta_1),t)$.*

Proof. Let $\{t_n\}$ be a countable dense subset of $\mathbf{T}$. Let $\mathscr{A}$ be the closed subalgebra of $\mathscr{C}(\mathbf{M}_1,\mathbf{R})$ generated by all functions of the form $\{\theta_1\to\phi_{ij}(\theta_1,t_n)\}$ where ϕ_{ij} are the components of Φ. Then $\mathscr{A}$ is a separable subalgebra of $\mathscr{C}(\mathbf{M}_1,\mathbf{R})$. Since $\mathscr{A}$ is closed it contains all mappings $\{\theta_1\to\phi_{ij}(\theta_1,\tau)\}$ where $\tau\in T$; in fact $\mathscr{A}$ is also the closed subalgebra generated by all such mappings for $\tau\in T$. Because of the cocycle identity (2.1) we see that $\mathscr{A}$ is invariant, in the sense that if $g\in\mathscr{A}$ then $g_\tau\in\mathscr{A}$, where $g_\tau(\theta_1)=g(\theta_1\cdot\tau)$. The Stone theorem, cf. Hewitt and Ross (1963, pp. 483-484), says that $\mathscr{A}=\mathscr{C}(\mathbf{M}_2,\mathbf{R})$, where $\mathbf{M}_2$ is the maximal ideal space of $\mathscr{A}$. Since $\mathscr{A}$ is separable, $\mathbf{M}_2$ is a compact metric space. Recall that $\mathbf{M}_2$ can be realized as the space of equivalence classes $[\theta_1]$ where $\theta_1\sim\tilde{\theta}_1$ provided $\phi_{ij}(\theta_1,t_n)=\phi_{ij}(\tilde{\theta}_1,t_n)$ for all i,j and all t_n. Note that if $\theta_1\sim\tilde{\theta}_1$ then $\theta_1\cdot\tau\sim\tilde{\theta}_1\cdot\tau$ for all $\tau\in T$. Consequently a flow on $\mathbf{M}_2$ is given by $[\theta_1]\cdot\tau=[\theta_1\cdot\tau]$. Also the mapping $f(\theta_1):=[\theta_1]$ from $\mathbf{M}_1$ to $\mathbf{M}_2$ is an epimorphism because $\mathscr{A}$ is invariant. Finally we see that for each $t\in\mathbf{T}$ the cocycle $\Phi_1(\theta_1,t)$ depends only on the equivalence class $[\theta_1]$. So we conclude the proof by defining Φ_2 by $\Phi_2([\theta_1],t):=\Phi_1(\theta_1,t)$. Q.E.D.

The following lemma appears in Ellis and Johnson (1982), but we include a proof for completeness of exposition.

LEMMA 3.2. *Let Φ be a cocycle over a compact Hausdorff space $\mathbf{M}$ with $\mathbf{T}=\mathbf{R}$. Then Φ is cohomologous to a smooth cocycle Ψ over $\mathbf{M}$, i.e. $\Psi(\theta,t)$ is a fundamental matrix solution to $x'=A(\theta\cdot\tau)x$ where A is given by* (3.1) *below.*

Proof. Let $V \subseteq \mathcal{GL}(m)$ be a compact convex neighborhood of the identity I and choose $r>0$ so that $\Phi(\theta, t) \in V$ for all $\theta \in \mathbf{M}$ and $0 \leqq t \leqq r$. Define $F(\theta) :=$ $(1/r)\int_0^r \Phi(\theta, s)\, ds$. Then $F(\theta)$ is invertible, and it is easily verified that the cocycle

$$\Psi(\theta, t) := F(\theta \cdot t)\Phi(\theta, t)F(\theta)^{-1} = \frac{1}{r}\int_t^{t+r} \Phi(\theta, s)\, ds\, F(\theta)^{-1},$$

which is cohomologous to Φ, is the fundamental matrix solution to $x' = A(\theta \cdot t)x$ where

$$A(\theta) := \frac{1}{r}[\Phi(\theta, r) - I]F(\theta)^{-1}. \tag{3.1}$$

Q.E.D.

The next lemma will allow us to conclude that the Multiplicative Ergodic theorem 2.2 is valid for linear skew product flows on a vector bundle $\mathscr{E}$ over a compact Hausdorff space $\mathbf{M}$. The same lemma shows that Theorems 2.3 and 2.4 extend to vector bundles as well. Before stating this we need to derive the following general fact concerning smooth approximations to continuous mappings on a compact invariant set.

LEMMA 3.3. *Let* $\mathbf{M}$ *be a compact Hausdorff space with a flow* $\theta \cdot t$ *and let* $f : \mathbf{M} \to \mathbf{N}$ *be a continuous mapping where* $\mathbf{N}$ *is a smooth compact Riemannian manifold. Then for every* $\delta > 0$ *there is a continuous function* $g : \mathbf{M} \to \mathbf{N}$ *with the following properties*:

(i) $\sup\{\operatorname{dist}(f(\theta), g(\theta)) \colon \theta \in \mathbf{M}\} \leqq \delta$,

(ii) *for every* $\theta \in \mathbf{M}$, *the mapping* $\theta \to (d/dt)g(\theta \cdot t)|_{t=0}$ *of* $\mathbf{M}$ *into the tangent bundle* $\mathbf{TN}$ *is a continuous mapping in* θ.

Proof. Let $\delta > 0$ be given. The Tubular Neighborhood theorem, see Guillemin and Pollack (1974), assures us that for a sufficiently large $m \geqq 1$ there is a smooth imbedding $h : \mathbf{N} \to \mathbf{R}^m$, an open set $W \supseteq h(\mathbf{N})$ and a smooth retract $R : W \to h(\mathbf{N})$. Now choose $\eta > 0$ so that if $\phi_1, \phi_2 \in h(\mathbf{N})$ and $|\phi_1 - \phi_2| \leqq \eta$ then $\operatorname{dist}(h^{-1}(\phi_1), h^{-1}(\phi_2)) \leqq \delta$. Next choose $\tau > 0$ so that

$$V(\theta) := \operatorname{Co}\{h(f(\theta \cdot t)) : 0 \leqq t \leqq \tau\} \subseteq W$$

for every $\theta \in \mathbf{M}$, where Co refers to the closed convex hull, and $|h(f(\theta)) - R(y)| \leqq \eta$ for every $\theta \in \mathbf{M}$ and $y \in V(\theta)$. We now define $g : \mathbf{M} \to \mathbf{N}$ by

$$g := h^{-1} \circ R\left(\frac{1}{\tau}\int_0^\tau h \circ f(\theta \cdot s)\, ds\right).$$

Since $1/\tau \int_0^\tau hf(\theta \cdot s)\, ds \in V(\theta)$ we see that $|f(\theta) - g(\theta)| \leqq \delta$ for all $\theta \in \mathbf{M}$. Furthermore it is easy to conclude that g is C^1 along trajectories and the mapping $\theta \to (d/dt)g(\theta \cdot t)|_{t=0}$ is continuous. Q.E.D.

LEMMA 3.4. *Let* $\mathscr{E}$ *be a finite dimensional vector bundle over a compact Hausdorff base space* $\mathbf{M}$ *and let* $\pi(x, \theta, t) = (\Phi(\theta, t)x, \theta \cdot t)$ *be a linear skew product flow on* $\mathscr{E}$. *Then for any* $\lambda \in R$ *there exists an integer* $m \geqq 1$, *a monomorphism* $H : \mathscr{E} \to \mathbf{R}^m \times \mathbf{M}$, *a smooth cocycle* $\Psi : \mathbf{M} \to \mathcal{GL}(m)$ *and an orthogonal invariant resolution of the identity* $Q = (Q_1, Q_2)$ *such that* $H(\mathscr{E}) = \text{Range } Q_1$ *and*

$$Q_1(\theta \cdot t)\Psi(\theta, t) = \Psi(\theta, t)Q_1(\theta), \qquad H(\theta \cdot t)\Phi(\theta, t) = \Psi(\theta, t)H(\theta),$$

$$Q_2(\theta \cdot t)\Psi(\theta, t) = \Psi(\theta, t)Q_2(\theta) = e^{\lambda t}Q_2(\theta).$$

Proof. Since $\dim \mathscr{E}(\theta)$ is constant on the components of $\mathbf{M}$, there is no loss in generality in assuming that $\dim \mathscr{E}(\theta) = k$ for all $\theta \in \mathbf{M}$. The first step is to apply a standard result in the theory of vector bundles, Atiyah (1967, p. 25), which states that there is an integer $m > 0$ and a projector $P_1 : \mathbf{R}^m \times \mathbf{M} \to \mathbf{R}^m \times \mathbf{M}$ such that the vector bundle Range P_1 is isomorphic to $\mathscr{E}$. Let $\hat{H} : \mathscr{E} \to \text{Range } P_1 \subseteq \mathbf{R}^m \times \mathbf{M}$ be the isomorphism. Without any loss of generality we can assume that $P_1(\theta)$ is an orthogonal projection on $\mathbf{R}^m$ for all $\theta \in \mathbf{M}$. Let $P_2 := I - P_1$.

The mapping $\hat{W}_1: \theta \to \text{Range } P_1(\theta)$ defines a continuous mapping of $\mathbf{M}$ into the smooth manifold $\mathscr{G}(m, k)$ of k-planes in $\mathbf{R}^m$. By Lemma 3.3, there is a smooth mapping $W_1: \mathbf{M} \to \mathscr{G}(m, k)$ that is close to $\hat{W}_1$. Define $Q_1(\theta)$ to be the orthogonal projection with $W_1(\theta) = \text{Range } Q_1(\theta)$. Since W_1 is smooth this means that $\theta \to (d/dt)Q_1(\theta \cdot t)|_{t=0}$ is continuous. Also $Q_2(\theta) = I - Q_1(\theta)$ is smooth. Since Q_1 is close to P_1 it follows that $H = Q_1\hat{H}$ is an isomorphism of $\mathscr{E}$ onto Range Q_1.

Next we define a flow on $\mathbf{R}^m \times \mathbf{M}$ under which Q_1 and Q_2 are invariant. Let $S(\theta) = Q_1'(\theta)Q_1(\theta) + Q_2'(\theta)Q_2(\theta)$ and let $\Psi_1(\theta, t)$ be the fundamental matrix solution of $x' = S(\theta \cdot t)x$ satisfying $\Psi_1(\theta, 0) = I$. Then as shown by Daletskii and Krein (1974) one has

$$Q_i(\theta \cdot t)\Psi_1(\theta, t) = \Psi_1(\theta, t)Q_i(\theta)$$

for all $\theta \in \mathbf{M}$, $t \in \mathbf{R}$, and $i = 1, 2$. Define a cocycle Ψ on $\mathbf{M}$ by

$$\Psi(\theta, t)Q_1(\theta) = H(\theta \cdot t)\Phi(\theta, t)H^{-1}(\theta),$$

$$\Psi(\theta, t)Q_2(\theta) = e^{\lambda t}\Psi_1(\theta, t)Q_2(\theta).$$

It is now straightforward to check the remaining details. Lemma 3.2 assures us that Ψ can be chosen to be smooth. Q.E.D.

4. Triangularization of cocycles. We turn next to the theory of the Gram-Schmidt factorization of isomorphisms on $\mathbf{R}^m$, where $\mathbf{R}^m$ has the Euclidean inner product $\langle\ ,\ \rangle$. Let $\mathscr{GL}(m)$ denote the group of all isomorphisms of $\mathbf{R}^m$. Each element $L \in \mathscr{GL}(m)$ is identified with the $(m \times m)$ matrix whose column vectors satisfy $\text{col}_i\, L = Le_i$, $1 \leqq i \leqq m$, where $\{e_1, \cdots, e_m\}$ is a fixed orthonormal basis in $\mathbf{R}^m$. Let $\mathscr{O} = \mathscr{O}(m)$ denote the subgroup of $\mathscr{GL}(m)$ consisting of all orthogonal linear transformations, and let $\mathscr{T}^+(m)$ denote the subcollection of all upper triangular matrices $L \in \mathscr{GL}(m)$ with positive entries on the main diagonal. Then $\mathscr{T}^+(m)$ is also a subgroup of $\mathscr{GL}(m)$ and one has

$$\mathscr{O}(m) \cap \mathscr{T}^+(m) = \{I\}. \tag{4.1}$$

The Gram-Schmidt orthogonalization process assures us that for every $A \in \mathscr{GL}(m)$ there are unique matrices $G(A) \in \mathscr{O}(m)$ and $T(A) \in \mathscr{T}^+(m)$ such that

$$G(A) = AT(A). \tag{4.2}$$

Since the entries in $T(A)$ are algebraic functions of $\langle \text{col}_i\, A, \text{col}_j\, A\rangle$ we see that both $T(A)$ and $G(A)$ are smooth functions of A.

Next we note that one has

$$G(AB) = G(AG(B)), \qquad T(AB) = T(B)T(ABT(B)). \tag{4.3}$$

In order to prove (4.3), we define $U, V \in \mathscr{O}(m)$ by

$$U := G(AB) = ABT(AB), \qquad V := G(AG(B)) = ABT(B)T(ABT(B)),$$

where (4.2) is used above. One then has

$$U^{-1}V = T(AB)^{-1}T(B)T(ABT(B)) \in \mathscr{O}(m) \cap \mathscr{T}^+(m). \tag{4.4}$$

Hence by (4.1) $U^{-1}V = I$, which proves (4.3).

Let $\Phi: \mathbf{M} \to \mathscr{GL}(m)$ be a cocycle on $\mathbf{M}$. Then (4.2) admits the factorization

$$G(\Phi(\theta, t)U) = \Phi(\theta, t)UT(\Phi(\theta, t)U) \tag{4.5}$$

for every $U \in \mathcal{O}(m)$. This permits us to define a new flow on $\mathbf{H} := \mathbf{M} \times \mathcal{O}(m)$ as follows: Let $\phi := (\theta, U) \in \mathbf{M} \times \mathcal{O}(m)$ and define

$$\phi \cdot t := (\theta \cdot t, G(\Phi(\theta, t)U)). \tag{4.6}$$

LEMMA 4.1. *Equation* (4.6) *defines a flow on* $\mathbf{H} = \mathbf{M} \times \mathcal{O}(m)$.

Proof. It suffices to verify the group property

$$G[\Phi(\theta \cdot t, s)G(\Phi(\theta, t)U)] = G(\Phi(\theta, t+s)U).$$

However, this is an immediate consequence of (2.1) and (4.3). Q.E.D.

We noted in § 2 that the cocycle $\Phi(\theta, t)$ on $\mathbf{M}$ defines a linear skew product flow on $\mathbf{R}^m \times \mathbf{M}$ by $\pi(x, \theta, t) = (\Phi(\theta, t)x, \theta \cdot t)$. By using (4.6) we see that π can be lifted to a new flow $\hat{\pi}$ on $\mathbf{R}^m \times \mathbf{H}$ by

$$\hat{\pi}(x, \phi, t) := (\Phi(\theta, t)x, \phi \cdot t)$$

where $\phi = (\theta, U)$. Let $q: \mathbf{M} \times \mathcal{GL}(m) \to \mathcal{GL}(m)$ and $r: \mathbf{M} \times \mathcal{GL}(m) \to \mathbf{M}$, (or $r: \mathbf{H} \to \mathbf{M}$) be the natural projections. Define $\Psi(\phi, t)$ by

$$\Psi(\phi, t) := q(\phi \cdot t)^{-1}\Phi(\theta, t)q(\phi) = G(\Phi(\theta, t)U)^{-1}\Phi(\theta, t)U \tag{4.7}$$

where the (-1) denotes the matrix inverse and $\phi = (\theta, U)$. Since $\phi \cdot t$ is a flow on $\mathbf{H}$, it follows that Ψ is a cocycle on $\mathbf{H}$, and

$$\tilde{\pi}(x, \phi, t) := (\Psi(\phi, t)x, \phi \cdot t) \tag{4.8}$$

is a linear skew product flow on $\mathbf{R}^m \times \mathbf{H}$ which is cohomologous to $\hat{\pi}$. The following lemma is now an immediate consequence of (4.2) and (4.7).

LEMMA 4.2. *Let* Φ *be a cocycle on* $\mathbf{M}$ *and define* $\phi \cdot t$ *and* $\Psi(\phi, t)$ *by* (4.6) *and* (4.7). *Then one has*

$$\Psi(\phi, t) = T(\Phi(\theta, t)U)^{-1} \in \mathcal{T}^+(m) \tag{4.9}$$

for all $\phi = (\theta, U) \in \mathbf{H}$ *and* $t \in \mathbf{T}$.

Remark 4.1. The triangularization method described above is directly related to the familiar technique developed by Lyapunov (1892), Perron (1930) and Diliberto (1950). Let $\mathbf{T} = \mathbf{R}$ and let $\Phi(\theta, t)$ be a smooth cocycle and (therefore) the fundamental solution matrix of a differential equation

$$x' = A(\theta \cdot t)x, \qquad x \in \mathbf{R}^m, \quad \theta \in \mathbf{M}, \tag{4.10}$$

where A is a continuous $(m \times m)$ matrix valued function defined on $\mathbf{M}$. Then $\Psi(\phi, t)$ is the fundamental solution matrix of

$$y' = B(\phi \cdot t)y, \qquad y \in \mathbf{R}^m, \quad \phi \in \mathbf{H}, \tag{4.11}$$

where $\phi = (\theta, U)$, $B = G^{-1}(AG - G')$, $G = G(\Phi(\theta, t)U)$ and $G' = (d/dt)G$. The change of variables which maps solutions of (4.11) onto those of (4.10) is

$$x = P(t)y = G(\Phi(\theta, t)U)y.$$

Also since the fundamental matrix solution of (4.11) is Ψ, an upper triangular matrix, we see that B is also upper triangular.

Remark 4.2. For $\mathbf{T} = \mathbf{Z}$ this is basically the triangularization method described in Oseledec (1968).

5. Invariant measures. In this section we record for reference a number of known results concerning invariant measures associated with the flows on $\mathbf{M}$ and $\mathbf{H}$. Let r be the natural projection of $\mathbf{H}$ onto $\mathbf{M}$. By (4.6) we see that r is a flow epimorphism, i.e. $r(\phi) \cdot t = r(\phi \cdot t)$.

Because of Lemma 3.1 we see that there is no loss in generality in assuming **M** (and therefore **H**) to be compact metric spaces. The Riesz Representation theorem says that for any compact metric space **M** there is an isomorphism between bounded positive linear functionals l on $\mathscr{C}(\mathbf{M}, \mathbf{R})$ satisfying $l(1) = 1$ with the (regular, positive, Borel, probability) measures μ on **M**, and this isomorphism is given by the formula

$$l(f) = \int_M f(\theta)\mu(d\theta).$$

Hereafter we will interchange freely such functionals and the associated measures and write $\mu(f)$ in place of $l(f)$.

The measure μ is invariant for the flow $\theta \cdot t$ if and only if $\mu(f_\tau) = \mu(f)$ for all $f \in \mathscr{C}(\mathbf{M}, \mathbf{R})$ and all $\tau \in \mathbf{T}$ where $f_\tau(\theta) = f(\theta \cdot \tau)$. Also μ is ergodic if and only if for $f \in \mathscr{L}^1(\mathbf{M}, \mathbf{R})$ one has

$$\mu(f_\tau) = \mu(f) \quad \text{for all } \tau \in \mathbf{T} \Leftrightarrow f \equiv \text{constant}.$$

The Krylov-Bogoliubov method, cf. Nemytskii and Stepanov (1960), is a method for constructing invariant measures. Let us review this for the case $\mathbf{T} = \mathbf{R}$. Let μ be a given measure on **M** and define

$$\mu_T(f) := \frac{1}{T} \int_0^T \mu(f_\tau)\, d\tau \tag{5.1}$$

for $T > 0$. Let $T_n \to +\infty$, and suppose (by choosing a subsequence if necessary) that μ_{T_n} converges weakly to a measure $\hat{\mu}$. Then $\hat{\mu}$ is easily seen to be invariant.

If the original measure μ is a δ-measure, i.e. $\mu(f) = \delta_\theta(f) = f(\theta)$, then (5.1) becomes

$$\mu_T(f) := \frac{1}{T} \int_0^T f(\theta \cdot \tau)\, d\tau. \tag{5.2}$$

Notice that if the original measure μ has support in a closed invariant set $\mathbf{M}_0$, then the induced invariant measure $\hat{\mu}$ has support in $\mathbf{M}_0$ as well.

Let μ be a given invariant measure on **M**. Let $I(\mu)$ denote the collection of all invariant measures ν on **H** that cover μ, i.e. $\nu \in I(\mu)$ if it is invariant and $r(\nu) = \mu$. If μ is an ergodic measure on **M** we let $E(\mu)$ denote the ergodic measures $\nu \in I(\mu)$. By using the Krylov-Bogoliubov method we see that $I(\mu)$ is nonempty. Indeed if l is any measure on $\mathcal{O}(m)$, then $\mu \times l$ is a measure on **H**. Now form

$$(\mu \times l)_T(g) = \frac{1}{T} \int_0^T (\mu \times l)(g_\tau)\, d\tau,$$

and let ν be a resulting invariant measure. In order to show that ν covers μ we need to show that $\nu(f) = \mu(f)$ whenever $f = f(\theta)$ depends only on the coordinate $\theta \in \mathbf{M}$. However in this case one has

$$(\mu \times l)(f_\tau) = \mu(f_\tau) = \mu(f) = (\mu \times l)_T(f)$$

since μ is invariant. Hence the limit ν satisfies $\nu(f) = \mu(f)$. Since $I(\mu)$ is nonempty, compact and convex it has extreme points. The extreme points in $I(\mu)$ are ergodic measures ν when μ is ergodic.

6. Proof of the Multiplicative Ergodic theorem. Throughout this section we will adopt without any loss of generality the following Standing Hypotheses which will lead to a proof of Theorems 2.1 and 2.2: Let $\pi(x, \theta, t) = (\Phi(\theta, t)x, \theta \cdot t)$ be a given linear skew-product flow on the trivial (Lemma 3.4) vector bundle $\mathbf{R}^m \times \mathbf{M}$, where $\mathbf{M}$ is a compact metric space (Lemma 3.1). If $\mathbf{T}=\mathbf{R}$ we assume that $\Phi(\theta, t)$ is smooth and is the fundamental solution matrix (Lemma 3.2) of

$$x' = A(\theta \cdot t)x, \qquad x \in \mathbf{R}^m, \quad \theta \in \mathbf{M}. \tag{6.1}$$

Let $\hat{\pi}(x, \phi, t) = (\Psi(\phi, t)x, \phi \cdot t)$ be the cohomologous triangular flow induced on $\mathbf{R}^m \times \mathbf{H}$ (§ 4). If $\mathbf{T}=\mathbf{R}$ then $\Psi(\phi, t)$ is also smooth and is the fundamental solution matrix of

$$y' = B(\phi \cdot t)y, \qquad y \in \mathbf{R}^m, \quad \phi \in \mathbf{H} \tag{6.2}$$

where B is a continuous upper triangular matrix. Let μ be a given invariant measure on $\mathbf{M}$ and let $\nu \in I(\mu)$ be any invariant measure on $\mathbf{H}$ that covers μ. If μ is ergodic we assume that ν is ergodic (§ 5). Also $r: \mathbf{H} \to \mathbf{M}$ is the natural projection.

We shall say that a point $\theta \in \mathbf{M}$ (or $\phi \in \mathbf{H}$) is a *Lyapunov point for* π (or $\hat{\pi}$) if there are real numbers $\gamma_1, \cdots, \gamma_m$ and a basis $e_1, \cdots, e_m$ of $\mathbf{R}^m$ such that

$$\lambda(e_i, \theta) := \lim_{|t| \to \infty} \frac{1}{t} \log |\Phi(\theta, t)e_i| = \gamma_i, \tag{6.3}$$

$$(\text{or } \lambda(e_i, \phi) := \lim_{|t| \to \infty} \frac{1}{t} \log |\Psi(\phi, t)e_i| = \gamma_i) \tag{6.4}$$

for $1 \leqq i \leqq m$.

Roughly speaking, the Multiplicative Ergodic theorem asserts that there are *many* Lyapunov points (i.e. $\mu(\mathbf{M}_\mu) = 1$) and that they fit together in a measurable manner. As we now show this follows from the triangularization technique described in § 4.

LEMMA 6.1. *Let $\phi = (\theta, U) \in \mathbf{H}$ be a Lyapunov point for $\hat{\pi}$. Then $\theta \in \mathbf{M}$ is a Lyapunov point for π.*

Proof. Choose $\gamma_1, \cdots, \gamma_m$ in $\mathbf{R}$ and a basis $e_1, \cdots, e_m$ in $\mathbf{R}^m$ so that (6.4) is satisfied. Define $f_1, \cdots, f_m$ by $f_i = Ue_i$, $1 \leqq i \leqq m$. Equation (4.7) yields

$$G(\Phi(\theta, t)U)\Psi(\phi, t) = \Phi(\theta, t)U. \tag{6.5}$$

Since $G(\Phi(\theta, t)U)$ is an orthogonal matrix one has

$$|\Phi(\theta, t)f_i| = |\Psi(\phi, t)e_i|, \qquad 1 \leqq i \leqq m.$$

It follows that (6.3) is satisfied with the same γ_i when e_i is replaced by f_i, $1 \leqq i \leqq m$. Q.E.D.

The next lemma is the key step in our proof.

LEMMA 6.2. *Let $\phi = (\theta, U) \in \mathbf{H}$ be fixed. Assume that the diagonal entries $\Psi(\phi, t)$ satisfy*

$$\lim_{|t| \to \infty} \frac{1}{t} \log |\psi_{ii}(\phi, t)| = \gamma_i \tag{6.6}$$

for some constants γ_i, $1 \leqq i \leqq m$. Then ϕ is a Lyapunov point for $\hat{\pi}$ where the growth rates $\gamma_1, \cdots, \gamma_m$ are given by (6.6), *and the associated matrix V of basis vectors $\{e_i, \cdots, e_m\}$ is an upper triangular matrix given by* (6.7) *with $v_{ii} = 1$, $1 \leqq i \leqq m$.*

If $\mathbf{T}=\mathbf{R}$, then $\psi_{ii}(\phi, t) = \exp\left(\int_0^t b_{ii}(\phi \cdot s)\, ds\right)$ where b_{ii}, $1 \leqq i \leqq m$, are the diagonal entries of the triangular matrix B in (6.2). In this case (6.6) becomes

$$\lim_{|t| \to \infty} \frac{1}{t} \log |\psi_{ii}(\phi, t)| = \lim_{|t| \to \infty} \frac{1}{t} \int_0^t b_{ii}(\phi \cdot s)\, ds = \gamma_i, \qquad 1 \leqq i \leqq m.$$

Also if $\mathbf{T}=\mathbf{Z}$, then the diagonal elements of ψ satisfy

$$\psi_{ii}(\phi, t)=\prod_{s=0}^{t-1} \psi_{ii}(\phi \cdot s, 1), \qquad t>0$$

with a similar expression valid for $t<0$. For $t>0$ one has

$$\frac{1}{t}\log|\psi_{ii}(\phi, t)|=\frac{1}{t}\sum_{s=0}^{t-1} \log|\psi_{ii}(\phi \cdot s, 1)|.$$

We see then that for both $\mathbf{T}=\mathbf{R}$ and $\mathbf{T}=\mathbf{Z}$, the limits in (6.6) are time-averages of continuous real-valued functions defined on $\mathbf{H}$. This fact will be used later when we apply the Birkhoff Ergodic theorem.

Proof. The argument we now give applies to any triangular cocycle Ψ over any compact metric space $\mathbf{H}$. We will not use the special form of the flow on $\mathbf{H}$.

Let i satisfy $1\leqq i\leqq m$. For any upper triangular $(m\times m)$ matrix T we let T_i denote the lower-right $(k\times k)$-dimensional block where $k=(m-i+1)$. Thus $T_1=T$ and $T_m=(t_{mm})$. For the matrix B given by (6.2) we let β_i denote the $(m-i)$-dimensional row vector that satisfies

$$B_i=\begin{pmatrix} b_{ii} & \beta_i \\ 0 & B_{i+1}\end{pmatrix}$$

for $1\leqq i\leqq m-1$.

The upper triangular matrix V of basis vectors is obtained by constructing the V_i inductively starting with $V_m=(1)$. Suppose $1\leqq i\leqq m-1$ and that V_{i+1} has been constructed with the properties that its diagonal elements are 1 and

$$\lambda(\operatorname{col}_j(V_{i+1}), \phi)=\gamma_j$$

for $i+1\leqq j\leqq m$. To construct V_i with the corresponding properties we first define $v_{ii}=1$. For $1\leqq i\leqq m-1$ and $i+1\leqq j\leqq m$ we define[1]

$$(6.7)\qquad v_{ij}=v_{ij}(\phi):=\int_\tau^0 \psi_{ii}^{-1}(\phi, s)\beta_i(\phi\cdot s)\Psi_{i+1}(\phi, s)\operatorname{col}_j(V_{i+1}(\phi))\,ds$$

$$\operatorname{col}_j(V_i):=\begin{pmatrix} v_{ij} \\ \operatorname{col}_j(V_{i+1})\end{pmatrix}$$

where

$$\tau=\tau_{ij}:=\begin{cases}\infty & \text{if } \gamma_i>\gamma_j,\\ 0 & \text{if } \gamma_i=\gamma_j,\\ -\infty & \text{if } \gamma_i<\gamma_j.\end{cases}$$

Equations (6.4) and (6.6) and the induction hypothesis imply that for every $\varepsilon>0$ there are constants K_1 and K_2 such that for $t\geqq 0$ one has

$$|\psi_{ii}(\theta, t)|\leqq K_2\exp[(\gamma_i+\varepsilon)t], \qquad |\psi_{ii}^{-1}(\theta, t)|\leqq K_2\exp[(-\gamma_i+\varepsilon)t],$$

$$K_1\exp[(\gamma_j-\varepsilon)t]\leqq|\Psi_{i+1}(\phi, t)\operatorname{col}_j(V_{i+1})|\leqq K_2\exp[(\gamma_j+\varepsilon)t]$$

for $i+1\leqq j\leqq m$. Since $|\beta_i|$ is uniformly bounded on $\mathbf{H}$, it follows that the infinite integral in (6.7) is well defined.

[1] We assume for the moment that $\mathbf{T}=\mathbf{R}$. The modification of our argument needed for the case $\mathbf{T}=\mathbf{Z}$ is described in the last paragraph of the proof.

The variation of constants formula for the block-triangular system $u' = B_i(\phi \cdot t)u$ yields

$$(6.8) \qquad \Psi_i(\phi, t)\operatorname{col}_j(V_i) = \begin{pmatrix} \psi_{ii}(\phi, t)\int_\tau^t \psi_{ii}^{-1}(\phi, s)\beta_i(\phi \cdot s)\Psi_{i+1}(\phi, s)\operatorname{col}_j(V_{i+1})\,ds \\ \Psi_{i+1}(\phi, t)\operatorname{col}_j(V_{i+1}) \end{pmatrix}$$

for $i+1 \leqq j \leqq m$ and $\Psi_i(\phi, t)\operatorname{col}_i(V_i) = \operatorname{col}(\psi_{ii}(\theta, t), 0, \cdots, 0)$. Let $v_{ij}(t)$ denote the first entry in (6.8). One then has $\lambda(\operatorname{col}_i(V_i), \phi) = \gamma_i$. While it is known that

$$(6.9) \qquad \lambda(\operatorname{col}_j(V_i), \phi) = \lambda(\operatorname{col}_j(V_{i+1}), \phi) = \gamma_j$$

for $i+1 \leqq j \leqq m$, cf. Millionscikov (1968), we shall include a proof for completeness. Indeed it follows from (6.8) and the inequalities after (6.7) that there is a constant K such that

$$|v_{ij}(t)| \leqq K \exp[(\gamma_j + 3\varepsilon)t]$$

for $i+1 \leqq j \leqq m$ and $t \geqq 0$. Since ε is arbitrary one has

$$(6.10) \qquad \limsup_{t \to +\infty} \frac{1}{|t|} \log |v_{ij}(t)| \leqq \gamma_j, \qquad i+1 \leqq j \leqq m,$$

and therefore by (6.8) we have

$$\gamma_j = \lim_{t \to +\infty} \frac{1}{t} \log |\Psi_{i+1}(\phi, t)\operatorname{col}_j(V_{i+1})| \leqq \liminf_{t \to +\infty} \frac{1}{t} \log |\Psi_i(\phi, t)\operatorname{col}_j(V_i)|$$

$$\leqq \limsup_{t \to +\infty} \frac{1}{t} \log |\Psi_i(\phi, t)\operatorname{col}_j(V_i)| \leqq \limsup_{t \to +\infty} \frac{1}{t} \log |v_{ij}(t)| \leqq \gamma_j.$$

A similar argument applies as $t \to -\infty$. Also (6.10) is valid as $t \to -\infty$.

This completes the argument for $\mathbf{T} = \mathbf{R}$. If $\mathbf{T} = \mathbf{Z}$ the integrals in (6.7)-(6.8) are replaced by sums. For example by the variation of constants formula in Sacker and Sell (1976b), $v_{ij}(t)$ takes the form

$$v_{ij}(t) = \psi_{ii}(\phi, t) \sum_{s=\tau}^{t-1} \psi_{ii}^{-1}(\phi, s+1)\beta_i(\phi \cdot s)\Psi_{i+1}(\phi, s)\operatorname{col}_j(V_{i+1})$$

where $\beta_i = \beta_i(\phi)$ is the $(m-i)$-dimensional row vector that satisfies

$$\Psi_i(\phi, 1) = \begin{pmatrix} \psi_{ii}(\phi, 1) & \beta_i(\phi) \\ 0 & \Psi_{i+1}(\phi, 1) \end{pmatrix}$$

for all $\phi \in \mathbf{H}$. We will omit the details, which are easily verified. Q.E.D.

LEMMA 6.3. *Let $\phi = (\theta, U)$ satisfy the hypotheses of Lemma 6.2 and let V be the matrix of basis vectors constructed above. Then there are upper triangular $(m \times m)$ matrices $S(\phi, t)$ and $D(\phi, t)$ that satisfy*

(i) $\Psi(\phi, t)V = S(\phi, t)D(\phi, t)$,

(ii) $D(\phi, t) = \operatorname{diag}(\psi_{11}(\phi, t), \cdots, \psi_{mm}(\phi, t))$,

(iii) $\limsup_{|t| \to \infty} (1/|t|) \log |S(\phi, t)| \leqq 0$,

(iv) $\limsup_{|t| \to \infty} (1/|t|) \log |S^{-1}(\phi, t)| \leqq 0$.

Proof. S and D are uniquely determined by (i) and (ii) and

$$S(\phi, t) = \begin{pmatrix} 1 & \psi_{22}^{-1}(\phi, t)v_{12}(t) & \cdots & \psi_{mm}^{-1}(\phi, t)v_{1m}(t) \\ 0 & 1 & \cdots & \psi_{mm}^{-1}(\phi, t)v_{2m}(t) \\ \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & \cdots & 1 \end{pmatrix}.$$

It follows from (6.10) that

$$\limsup_{|t|\to+\infty} \frac{1}{|t|} \log |\psi_{jj}^{-1}(\phi, t) v_{ij}(t)| \leqq 0$$

for $1 \leqq i \leqq m-1$ and $i+1 \leqq j \leqq m$. Parts (iii) and (iv) then follow from the last inequality and the fact that the entries in S^{-1} are polynomials in the entries of S. Q.E.D.

Next we apply the Birkhoff Ergodic theorem which assures us that there are a good supply of Lyapunov points in $\mathbf{H}$.

LEMMA 6.4. *There is a Borel measurable invariant set* $\mathbf{H}_\nu \subseteq \mathbf{H}$ *with* $\nu(\mathbf{H}_\nu)=1$ *and such that every point* $\phi \in \mathbf{H}_\nu$ *is a Lyapunov point.*

Proof. As noted above the limits

$$\lim_{|t|\to\infty} \frac{1}{t} \log |\psi_{ii}(\phi, t)|, \qquad 1 \leqq i \leqq m,$$

are time-averages of continuous functions defined on $\mathbf{H}$. The Birkhoff Ergodic theorem, see Nemytskii and Stepanov (1960), asserts that there is a Borel set $\mathbf{H}_\nu \subseteq \mathbf{H}$ with $\nu(\mathbf{H}_\nu)=1$, and there exist bounded Borel measurable invariant functions $\rho_1, \cdots, \rho_m : \mathbf{H}_\nu \to \mathbf{R}$ with the property that

$$\text{(6.11)} \qquad \lim_{|t|\to\infty} \frac{1}{t} \log |\psi_{ii}(\phi, t)| = \rho_i(\phi), \qquad 1 \leqq i \leqq m,$$

for all $\phi \in \mathbf{H}_\nu$. It then follows from Lemma 6.2 that each $\phi \in \mathbf{H}_\nu$ is a Lyapunov point. Q.E.D.

Let $\rho_1, \cdots, \rho_m$ satisfy (6.11). For each integer k, $1 \leqq k \leqq m$, let $N(k)$ denote the collection of vectors $\vec{m} = (m_1, \cdots, m_k)$ with integer entries that satisfy $1 \leqq m_j$, $1 \leqq j \leqq k$, and $m_1 + \cdots + m_k = m$. We will now construct a measurable decomposition of $\mathbf{H}_\nu$. Fix $\phi \in \mathbf{H}_\nu$. We then note that there is an integer k, $1 \leqq k \leqq m$, and an $\vec{m} \in N(k)$ such that the following two properties hold:

(i) There are exactly k distinct values in the collection $\{\rho_1(\phi), \cdots, \rho_m(\phi)\}$, which we rewrite as $\{\lambda_1(\phi), \cdots, \lambda_k(\phi)\}$ where

$$\text{(6.12)} \qquad \lambda_1(\phi) < \lambda_2(\phi) < \cdots < \lambda_k(\phi).$$

(ii) The cardinality of the set $\{i : 1 \leqq i \leqq m \text{ and } \rho_i(\phi) = \lambda_j(\phi)\}$ is m_j for each j, $1 \leqq j \leqq k$.

We denote the ordered pair $(k, \vec{m})$ briefly by p and define $\mathbf{H}_\nu(p)$ to be the set of all $\phi \in \mathbf{H}_\nu$ to which k and $\vec{m}$ correspond as above. The set $\mathbf{H}_\nu(p)$ is Borel measurable since it is the pullback of the closed set

$$\{(x_1, \cdots, x_m) : x_1 = x_2 = \cdots = x_{m_1} < x_{m_1+1} = \cdots = x_{m_2} < \cdots < x_{m_{k-1}+1} = \cdots = x_{m_k}\}$$

by the Borel measurable function that is the composition of the Borel measurable function $\phi \to (\rho_1(\phi), \cdots, \rho_m(\phi))$ with the continuous function σ that maps $(x_1, x_2, \cdots, x_m)$ onto its permutation $(x_1', x_2', \cdots, x_m')$ where $x_1' \leqq x_2' \leqq \cdots \leqq x_m'$.

It is easy to see that $\mathbf{H}_\nu = \bigcup \mathbf{H}_\nu(p)$, where the union is taken over all such points $p = (k, \vec{m})$, is a measurable decomposition of $\mathbf{H}_\nu$. Since each ρ_i is invariant we see that the sets $\mathbf{H}_\nu(p)$ are invariant. If ν is an ergodic measure, then all but one $\mathbf{H}_\nu(p)$ has ν-measure 0. The following result is a consequence of the measurability and invariance of $\rho_1, \cdots, \rho_m$.

LEMMA 6.5. *The functions* $\lambda_1, \cdots, \lambda_k : \mathbf{H}_\nu(p) \to \mathbf{R}$ *are Borel measurable and invariant.*

Let $\phi \in \mathbf{H}_\nu(p)$ and let $\rho_1, \cdots, \rho_m$ and $\lambda_1, \cdots, \lambda_k$ be given as above. Let $e_1, \cdots, e_m$ be the basis in $\mathbf{R}^m$ constructed in Lemma 6.2. Thus one has $\lambda(e_i, \phi) = \rho_i(\phi)$, $1 \leqq i \leqq m$. For $1 \leqq j \leqq k$ define

$$\mathcal{W}_j(\phi) := \text{Span}\,\{e_i \colon \lambda(e_i, \phi) = \lambda_j(\phi)\}.$$

One then has $\dim \mathcal{W}_j(\phi) = m_j$ and $R^m = \mathcal{W}_1(\phi) + \cdots + \mathcal{W}_k(\phi)$.

The next lemma shows that every $y \in \mathcal{W}_j(\phi)$, $y \neq 0$, has $\lambda_j(\phi)$ as a strong Lyapunov exponent.

LEMMA 6.6. *Let $\phi \in \mathbf{H}$ satisfy the hypothesis of Lemma 6.2. Then for all $y \in W_j(\phi)$, $y \neq 0$, one has*

$$\lim_{|t| \to +\infty} \frac{1}{t} \log |\Psi(\phi, t) y| = \lambda_j(\phi), \qquad 1 \leqq j \leqq k. \tag{6.13}$$

Moreover the limit in (6.13) *is uniform for* $|y| = 1$.

Proof. We will use Lemma 6.3. Fix j and let $y \in \mathcal{W}_j(\phi)$, $x \neq 0$. Then

$$y \in \text{Span}\,\{\text{col}_i\,(V) \colon \lambda_i(\phi) = \lambda_j(\phi)\}.$$

If $\{e_1, \cdots, e_m\}$ is the natural basis in $\mathbf{R}^m$ then $z = V^{-1} y$ satisfies

$$z \in \text{Span}\left\{e_i \colon \lim_{|t| \to \infty} \frac{1}{t} \log |\psi_{ii}(\phi, t)| = \lambda_j(\phi)\right\}.$$

Consequently one has

$$\lim_{|t| \to +\infty} \frac{1}{t} \log |D(\phi, t) z| = \lambda_j(\phi),$$

and the last limit is uniform for $|y| = 1$. Since one has

$$|S^{-1}(\phi, t)|^{-1} |D(\phi, t) z| \leqq |\Psi(\phi, t) V z| = |\Psi(\phi, t) y| \leqq |S(\phi, t)|\,|D(\phi, t) z|$$

and

$$\liminf_{t \to +\infty} \frac{1}{t} \log |S^{-1}(\phi, t)|^{-1} = -\limsup_{t \to +\infty} \frac{1}{t} \log |S^{-1}(\phi, t)| \geqq 0$$

(by Lemma 6.3), we get

$$\begin{aligned} \lambda_j(\phi) &\leqq \liminf_{t \to +\infty} \frac{1}{t} \log |S^{-1}(\phi, t)|^{-1} + \liminf_{t \to +\infty} \frac{1}{t} \log |D(\phi, t) z| \\ &\leqq \liminf_{t \to +\infty} \frac{1}{t} \log |\Psi(\phi, t) y| \leqq \limsup_{t \to +\infty} \frac{1}{t} \log |\Psi(\phi, t) y| \\ &\leqq \limsup_{t \to +\infty} \frac{1}{t} \log |S(\phi, t)| + \limsup_{t \to +\infty} \frac{1}{t} \log |D(\phi, t) y| \\ &\leqq \lambda_j(\phi). \end{aligned}$$

A similar argument applies as $t \to -\infty$. Q.E.D.

LEMMA 6.7. *Let $\phi \in \mathbf{H}_\nu(p)$ and let $y \in \mathbf{R}^m$, $y \neq 0$. Assume that $\lambda(y, \phi) = \gamma$. Then there is a j, $1 \leqq j \leqq k$ such that $\lambda(y, \phi) = \lambda_j(\phi)$ and $y \in \mathcal{W}_j(\phi)$.*

Proof. Since $e_1, \cdots, e_m$ is a basis one has

$$y = \alpha_1 e_1 + \cdots + \alpha_m e_m \tag{6.14}$$

where $\alpha_1, \cdots, \alpha_m$ are scalars. It is an easy exercise to see that one has

$$\lim_{t\to\infty} \frac{1}{t} \log |\Psi(\phi, t)y| = \max \{\rho_i(\phi): 1 \leqq i \leqq m \text{ and } \alpha_i \neq 0\},$$

$$\lim_{t\to-\infty} \frac{1}{t} \log |\Psi(\phi, t)y| = \min \{\rho_i(\phi): 1 \leqq i \leqq m \text{ and } \alpha_i \neq 0\}.$$

Therefore if the two-sided limit $\lambda(y, \phi) = \gamma$ exists, the only nonzero α's in (6.14) are coefficients of basis vectors used to define a single $\mathscr{W}_j(\phi)$. Hence $\lambda(y, \phi) = \lambda_j(\phi)$ and $y \in \mathscr{W}_j(\phi)$. Q.E.D.

Let $\phi_1 = (\theta, U_1)$, $\phi_2 = (\theta, U_2)$ be two points in $\mathbf{H}$ with the same θ-coordinate. From (6.5) one has

$$(6.15) \qquad G(\Phi(\theta, t)U_1)\Psi(\phi_1, t)U_1^{-1} = \Phi(\theta, t) = G(\Phi(\theta, t)U_2)\Psi(\phi_2, t)U_2^{-1}.$$

Therefore if $y \in \mathbf{R}^m$ then $|\Psi(\phi_1, t)y| = |\Psi(\phi_2, t)Vy|$ where $V = U_2^{-1}U_1$. We see that

$$(6.16) \qquad \lambda(y, \phi_1) = \gamma \Leftrightarrow \lambda(Vy, \phi_2) = \gamma.$$

Now assume further that $\phi_1 \in \mathbf{H}_\nu$. Then ϕ_1 is a Lyapunov point by Lemma 6.2 and (6.4). Let $\gamma_1, \cdots, \gamma_m$ be the strong Lyapunov exponents and let $e_1, \cdots, e_m$ be a basis with $\lambda(e_i, \phi_1) = \gamma_i$, $1 \leqq i \leqq m$. It follows from (6.16) that $Ve_1, \cdots, Ve_m$ is a basis for which $\lambda(Ve_i, \phi_2) = \gamma_i$, $1 \leqq i \leqq m$. We have just proved the following result:

LEMMA 6.8. *Let $\phi = (\theta, U) \in \mathbf{H}_\nu$, and let $\gamma_1, \cdots, \gamma_m$ be the set of strong Lyapunov exponents given by Lemma 6.2 and (6.4). Then every point $\hat{\phi} = (\theta, \hat{U})$ in the fiber over θ is a Lyapunov point with precisely the same set of strong Lyapunov exponents.*

By combining Lemmas 6.7 and 6.8 and (6.15) we immediately have the following:

LEMMA 6.9. *Let $\phi_1 = (\theta, U_1)$ and $\phi_2 = (\theta, U_2)$ be two points in $\mathbf{H}_\nu$ with the same θ-coordinate. Then ϕ_1 and ϕ_2 lie in the same set $\mathbf{H}_\nu(p)$, and for $1 \leqq j \leqq k$ one has*

$$(6.17) \qquad \lambda_j(\phi_1) = \lambda_j(\phi_2), \qquad U_1\mathscr{W}_j(\phi_1) = U_2\mathscr{W}_j(\phi_2).$$

Hence $\lambda_j(\phi_1)$ and $U_1\mathscr{W}_j(\phi_1)$ depend only on the θ-coordinate.

By using (6.16) together with Lemma 6.6 we see that if $\phi_1 = (\theta, U_1) \in \mathbf{H}_\nu$ then for any $\phi_2 = (\theta, U_2)$, with the same θ-coordinate, we have

$$\lambda(y, \phi_1) = \lambda(Vy, \phi_2) = \lambda_j(\phi_1)$$

for all $y \in \mathscr{W}_j(\phi_1)$, $y \neq 0$, where $V = U_2^{-1}U_1$.

We now use $r: \mathbf{H} \to \mathbf{M}$ to project $\mathbf{H}_\nu$ and $\mathbf{H}_\nu(p)$ to $\mathbf{M}$. Define $\mathbf{M}_\mu$ and $\mathbf{M}_\mu(p)$ by

$$r(\mathbf{H}_\nu) := \mathbf{M}_\mu, \qquad r(\mathbf{H}_\nu(p)) := \mathbf{M}_\mu(p).$$

Note that since $\mathbf{M}$ and $\mathbf{H}$ are compact metric spaces, and $\mathbf{H}_\nu$ and $\mathbf{H}_\nu(p)$ are Borel measurable sets in $\mathbf{H}$, the images $\mathbf{M}_\mu$ and $\mathbf{M}_\mu(p)$ are μ-measurable sets in $\mathbf{M}$, see Federer (1969, Chap. 2). Furthermore one has $\mu(\mathbf{M}_\mu) = 1$. (Strictly speaking, $\mathbf{M}_\mu$ and $\mathbf{M}_\mu(p)$ depend on the choice of $\nu \in I(\mu)$. Since $\mu(r(\mathbf{H}_\nu)) = \nu(\mathbf{H}_\nu) = 1$ we see that any two such sets $\mathbf{M}_\mu$ agree except on a set of μ-measure 0.)

Let $\phi = (\theta, U) \in \mathbf{H}_\nu(p)$. Then $\theta \in \mathbf{M}_\nu(p)$. Next define

$$\lambda_j(\theta) := \lambda_j(\phi), \quad \mathscr{W}_j(\theta) := U\mathscr{W}_j(\phi), \quad 1 \leqq j \leqq k.$$

From Lemma 6.9 we see that $\lambda_j(\theta)$ and $U(\mathscr{W}_j(\phi))$ depend only on the θ-coordinate. Also from Lemmas 6.5 and 6.9 we see that $\lambda_1, \cdots, \lambda_k: \mathbf{M}_\mu(p) \to \mathbf{R}$ are μ-measurable and invariant. For $\theta \in \mathbf{M}_\mu(p)$ we see that the spaces $\mathscr{W}_1(\theta), \cdots, \mathscr{W}_k(\theta)$ satisfy conclusions (v)–(vii) of Theorem 2.1.

The only point that remains to be proven is that the mappings $\mathscr{W}_i:\mathbf{M}_\mu(p)\to\mathscr{G}(m, m_i)$, $1\leqq i\leqq k$, are μ-measurable. Because of Lemma 6.9 it suffices to show that each $\mathscr{W}_i$ is Borel measurable on $\mathbf{H}_\nu(p)$, $1\leqq i\leqq k$. We will do this by noting that the basis matrix $V=\{e_1,\cdots,e_m\}$ constructed in (6.7) is Borel measurable in ϕ since the coefficients in the integral depend continuously in ϕ, and therefore the integral is measurable[2] in ϕ, cf. Federer (1969). This completes the proof of Theorem 2.1.

Theorem 2.2, the Multiplicative Ergodic theorem on a vector bundle $\mathscr{E}$, follows directly from Lemma 3.4 and Theorem 2.1. In Lemma 3.4 one can choose the $\lambda\in\mathbf{R}$ arbitrarily. A good choice for λ is $\lambda\notin\operatorname{dyn}\Sigma(\mathscr{E})$, where $\operatorname{dyn}\Sigma(\mathscr{E})$ is the dynamical spectrum of the linear skew product flow on $\mathscr{E}$. With this choice one knows that the measurable subbundle associated with λ is Range (Q_2) and is disjoint from Range (Q_1). (See Theorem 8.1 below.)

Remark 6.1. The uniformity described in Lemma 6.6 can be strengthened. Let $\phi=(\theta, U)\in\mathbf{H}_\nu(p)$, let $\lambda_1,\cdots,\lambda_k:\mathbf{H}_\nu(p)\to\mathbf{R}$ be the growth rates with $\lambda_1(\phi)<\cdots<\lambda_k(\phi)$, and let

$$\mathbf{R}^m=\mathscr{W}_1(\phi)+\cdots+\mathscr{W}_k(\phi)$$

be the decomposition of $\mathbf{R}^m$ into the measurable bundles. Then every $y\in\mathbf{R}^m$ can be written uniquely as $y=y_1+\cdots+y_k$ where $y_i\in\mathscr{W}_i(\phi)$, $1\leqq i\leqq k$. Furthermore for $y\neq 0$ one has

$$\lim_{t\to+\infty}\frac{1}{t}\log|\Psi(\phi, t)y|=\lambda_b(\phi), \tag{6.18}$$

$$\lim_{t\to-\infty}\frac{1}{t}\log|\Psi(\phi, t)y|=\lambda_a(\phi), \tag{6.19}$$

where $a=\min\{i: y_i\neq 0\}$ and $b=\max\{i: y_i\neq 0\}$. (See Lemma 6.7.) By using the argument of Lemma 6.6, it is easily seen that the limits in (6.18) and (6.19) are uniform on compact sets of the form

$$\{y\in\mathbf{R}^m: 0<\alpha\leqq|y_b|, |y|\leqq\beta\},\qquad \{y\in\mathbf{R}^m: 0<\alpha\leqq|y_a|, |y|\leqq\beta\}.$$

These considerations extend immediately to the cocycle $\Phi(\theta, t)$ over $\mathbf{M}$, where $\mathscr{W}_i(\phi)$ is replaced by $U\mathscr{W}_i(\phi)$, $1\leqq i\leqq k$. (See Lemma 6.9.)

Remark 6.2. As noted by Oseledec (1968) the uniformity condition in Lemma 6.6 implies that the limits

$$\lim_{|t|\to+\infty}\frac{1}{|t|}\log\beta_i(\theta, t),\qquad 1\leqq i\leqq m, \tag{6.20}$$

exist almost everywhere, where $\beta_1\geqq\beta_2\geqq\cdots\geqq\beta_m$ are the eigenvalues of the positive self-adjoint matrix $\Phi^*(\theta, t)\Phi(\theta, t)$.

Remark 6.3. The basis $e_1,\cdots,e_m$, which we construct in Lemma 6.2, is very closely related to Lyapunov's concept of "regularity" or "biregularity", see Lyapunov (1892) and Bylov et al. (1966). Note that if $\theta\in\mathbf{M}_\mu$ then there are real numbers $\gamma_1<\gamma_2<\cdots<\gamma_k$ and a splitting

$$\mathbf{R}^m=W_1+\cdots+W_k$$

such that if $x\in W_i$, $x\neq 0$, then $\lambda(x, \theta)=\gamma_i$, $1\leqq i\leqq k$, and

$$\sum_{i=1}^{k} m_i\gamma_i=\lim_{|t|\to+\infty}\frac{1}{t}\log|\det(\Phi(\theta, t))|, \tag{6.21}$$

[2] Discontinuities in ϕ can arise from the definition of τ in Lemma 6.2.

where $m_i = \dim W_i$, $1 \leqq i \leqq k$. If Φ is a smooth cocycle, i.e. if Φ is a fundamental solution matrix of (6.1), then (6.21) becomes

$$\sum_{i=1}^{k} m_i \gamma_i = \lim_{|t| \to +\infty} \frac{1}{t} \int_0^t \operatorname{tr} A(\theta \cdot s)\, ds.$$

Also see Vinograd (1956).

Remark 6.4. *Other proofs of the Multiplicative Ergodic theorem.* The proof of Oseledec (1968) uses many features of our argument, including the triangularization method described in § 4 and the theory of regularity described above. Some complication in Oseledec's argument seems to be due to the fact that he used neither (6.7) nor the factorization technique described in Lemmas 6.3 and 6.6. Also, Oseledec did not assume the base space **M** to be a compact metric space, and consequently his proof of the measurability (with respect to θ) of the bundles $\mathcal{W}_i(\theta)$ leaves some unanswered questions.

A portion of the Multiplicative Ergodic theorem was derived by Millionscikov (1968) for the case where μ is an ergodic measure. He constructed the measurable spectrum meas $\Sigma(\mu)$ and showed that it was constant almost everywhere. Equation (6.7) was used by Millionscikov; however, he did not derive Lemma 6.6, nor did he address the question of the measurability of the bundles $\mathcal{W}_i(\theta)$.

Raghunathan (1979), Ruelle (1979), Crauel (1981), and Kifer (1985) give alternative proofs of the Multiplicative Ergodic theorem. Their approach is based on either a theorem of Furstenberg and Kesten (1960) (see § 10) or the Subadditive Ergodic theorem, which was proved by Kingman (1968). Ruelle, for example, first shows that the limits in (6.20) exist almost everywhere. By using the eigenspaces of the associated self-adjoint operator $\Phi^*(\theta, t)\Phi(\theta, t)$, he constructs the measurable subbundles $\mathcal{W}_i(\theta)$.

The proof by Ruelle is more general than ours in that it applies to certain linearized semiflows generated by evolutionary equations on an infinite dimensional Hilbert space. Ruelle does not assume the base space **M** to be compact; instead he uses a logarithmic-boundedness condition on the cocycle Φ. This boundedness condition is automatically satisfied when the base space is compact. As we shall see in § 10, the assumption that **M** be compact is not a serious restriction, since this can be satisfied in practically every application.

7. Flow on the projective bundle. In this section we shall study the ergodic properties of the induced flow on the projective bundle, see Johnson (1978), (1980b) and Crauel (1981).

As in § 6, we let $\phi = (\theta, U) \in \mathbf{H}_\nu(p)$ and let $\lambda_1(\phi) < \cdots < \lambda_k(\phi)$ be the growth rates with multiplicity $\vec{m} = (m_1, \cdots, m_k)$, where $m_1 + \cdots + m_k = m$. By Lemma 6.9 we recall that $\lambda_i(\phi)$ depends only on θ, $1 \leqq i \leqq k$. Next define

$$U_i^{\pm}(\phi) = \operatorname{Span}\left\{ y \in \mathbf{R}^m : y \neq 0 \text{ and } \limsup_{t \to \pm\infty} \frac{1}{|t|} \log |\Psi(\phi, t) y| \leqq \lambda_i(\phi) \right\}.$$

Then $\dim U_i^+(\phi) = m_1 + \cdots + m_i$ and $\dim U_i^-(\phi) = m_i + \cdots + m_k$. Also one has $\mathcal{W}_i(\phi) = U_i^+(\phi) \cap U_i^-(\phi)$, $\dim \mathcal{W}_i(\phi) = m_i$ and $\mathbf{R}^m = \mathcal{W}_1(\phi) + \cdots + \mathcal{W}_k(\phi)$. By Lemma 6.9 we see that $\mathcal{W}_i(\theta) := U\mathcal{W}_i(\phi)$ depends only on θ.

Let $\mathbf{P}^{m-1}(\mathbf{R})$ denote the projective space of lines in $\mathbf{R}^m$ containing the origin, with the usual topology. We define the induced flow $\tilde{\pi}$ on the projective bundle $\mathbf{N} = \mathbf{P}^{m-1}(\mathbf{R}) \times \mathbf{M}$ by $(l, \theta) \cdot t = (\Phi(\theta, t)l, \theta \cdot t)$. (Since Φ is linear it maps lines onto lines.)

If $\mathbf{T} = \mathbf{R}$, we define $f : \mathbf{N} \to \mathbf{R}$ by $f(l, \theta) = \langle A(\theta)x, x \rangle$, where A is the matrix function (6.1), $\langle\ ,\ \rangle$ is the Euclidean inner product on $\mathbf{R}^m$, and $x \in l$ satisfies $|x| = 1$. Then for

$|x|=1$ one has

$$\log|\Phi(\theta,t)x|=\int_0^t f((l,\theta)\cdot s)\,ds. \tag{7.1}$$

If $\mathbf{T}=\mathbf{Z}$, we define $f:\mathbf{N}\to\mathbf{R}$ by $f(\theta,l)=\frac{1}{2}\log\langle A^*(\theta)A(\theta)x,x\rangle$, where $A(\theta)=\Phi(\theta,1)$ and $|x|=1$. Then one has

$$\begin{aligned}\log|\Phi(\theta,t)x|&=\sum_{s=0}^{t-1}f((l,\theta)\cdot s), && t\geqq 1,\\ \log|\Phi(\theta,t)x|&=\sum_{s=1}^{|t|}f((l,\theta)\cdot -s), && t<0.\end{aligned} \tag{7.2}$$

Next define the time-averages

$$f^+(l,\theta)=\limsup_{t\to+\infty}\frac{1}{t}\int_0^t f((l,\theta)\cdot s)\,ds,$$

and

$$f^-(l,\theta)=\liminf_{t\to-\infty}\frac{1}{|t|}\int_0^t f((l,\theta)\cdot s)\,ds$$

when $\mathbf{T}=\mathbf{R}$. (For $\mathbf{T}=\mathbf{Z}$, $f^{\pm}$ are defined similarly by using (7.2).) Then by (7.1) and (7.2) $f^+(l,\theta)$ and $f^-(l,\theta)$ are the Lyapunov exponents $\lambda_s^+(x,\theta)$ and $\lambda_i^-(x,\theta)$, respectively, where $x\in l$, $x\neq 0$. Also the functions $f^{\pm}:\mathbf{N}\to\mathbf{R}$ are Borel measurable.

For $\theta\in\mathbf{M}_\mu(p)=r(\mathbf{H}_\nu(p))$ and $1\leqq i\leqq k$ we define

$$u_i^+(\theta)=\{l\in\mathbf{P}^{m-1}(\mathbf{R})|f^+(l,\theta)\leqq\lambda_i(\theta)\},$$

$$u_i^-(\theta)=\{l\in\mathbf{P}^{m-1}(\mathbf{R})|f^-(l,\theta)\leqq-\lambda_i(\theta)\}.$$

For θ fixed, $u_i^{\pm}(\theta)$ are closed subsets of $\mathbf{P}^{m-1}(\mathbf{R})$, and in fact are the "traces" in $\mathbf{P}^{m-1}(\mathbf{R})$ of the vector subspaces $U_i^{\pm}(\theta)$ of $\mathbf{R}^m$ defined above. This leads us to introduce the space $\mathcal{K}$ of closed subsets of $\mathbf{P}^{m-1}(\mathbf{R})$, with the Hausdorff topology. Thus $F_n\to F$ in $\mathcal{K}\Leftrightarrow$ to each $x\in F$, there corresponds a sequence $x_n\in F_n$ so that $x_n\to x$ in $\mathbf{P}^{m-1}(\mathbf{R})$. Observe that the "trace" of $\mathcal{W}_i(\theta)$ in $\mathbf{P}^{m-1}(\mathbf{R})$ is $u_i^+(\theta)\cap u_i^-(\theta)$.

Fix the pair $p=(k,\vec{m})$ and restrict attention to $\mathbf{M}_\mu(p)$. The following proposition is a direct consequence of the measurability of the exponents $\lambda_1,\cdots,\lambda_k$.

LEMMA 7.1. *For every $r>0$, there is a compact set $Z\subseteq\mathbf{M}_\mu(p)$ such that $\mu(\mathbf{M}_\mu(p)\backslash Z)<r$ and the restriction $\lambda_i|_Z$ is continuous, $1\leqq i\leqq k$.*

We will now show that the functions $u_i^{\pm}$ are μ-measurable. (The measurability of $\mathcal{W}_i$ is also a consequence of this fact.) Consider u_i^+ and $\mathbf{T}=\mathbf{R}$. (The arguments for u_i^- and $\mathbf{T}=Z$ are similar and we will omit them.) Define $g_t(l,\theta):=(1/t)\int_0^t f((l,\theta)\cdot s)\,ds$. Then g_t is continuous on $\mathbf{N}$, and $\limsup_{t\to+\infty}g_t(l,\theta_0)=f^+(l,\theta)$ for all $(l,\theta)\in\mathbf{P}^{m-1}(\mathbf{R})\times\mathbf{M}_\mu(p)$. Let $r>0$ be given, and let $Z\subseteq\mathbf{M}_\mu(p)$ be a compact set with $\mu(\mathbf{M}_\mu(p)\backslash Z)<r$, where λ_i is continuous on Z, $1\leqq i\leqq k$. Choose δ so that

$$0<3\delta<|\lambda_i(\theta)-\lambda_j(\theta)| \tag{7.3}$$

for all $i\neq j$ and $\theta\in Z$. Finally define

$$v_t^+(\theta):=\{l\in\mathbf{P}^{m-1}(\mathbf{R})\,|\,g_t(l,\theta)\in(-\infty,\lambda_i(\theta)+\delta]\}.$$

Then $v_t^+(\theta)\in\mathcal{K}$ for $\theta\in Z$. It is not difficult to verify that $v_t^+:Z\to\mathcal{K}$ is a Borel measurable function. (In general it is not continuous.)

We claim that $v_t^+(\theta) \to u_i^+(\theta)$ in $\mathscr{K}$ as $t \to +\infty$, for each $\theta \in Z$. Assume on the contrary that there is a monotone subsequence $t_k \to +\infty$ and an element $Q \in \mathscr{K}$ such that $Q \neq u_i^+(\theta)$ and $v_{t_k}^+(\theta) \to Q$. Then $u_i^+(\theta) \subseteq Q$, since $l \in u_i^+(\theta) \Rightarrow l \in v_t^+(\theta)$ for large t. On the other hand, let $l \in Q \backslash u_i^+(\theta)$. Since $v_{t_k}^+(\theta) \to Q$ in the Hausdorff topology, there is a sequence $l_k \in v_{t_k}^+(\theta)$ with $l_k \to l$. Therefore l_k is eventually in every neighborhood of l in $\mathbf{P}^{m-1}(\mathbf{R})$. By Lemma 7.2 (below) we conclude that $g_{t_k}(l_k, \theta) \geqq \lambda_i(\theta) + 2\delta$, which contradicts the definition of $v_{t_k}^+(\theta)$.

LEMMA 7.2. *Let $l \in \mathbf{P}^{m-1}(\mathbf{R})$ with $l \notin u_i^+(\theta)$ where $\theta \in Z$. Then given any $\delta > 0$ there is a neighborhood $N(l)$ of l and a $\tau \in \mathbf{T}$ such that for all $t \geqq \tau$ one has $g_t(\tilde{l}, \theta) \geqq \lambda_i(\theta) + 2\delta$ for all $l \in N(\tilde{l})$.*

Proof. We will use the notation of Remark 6.1. Let $x \in l$, $x \neq 0$. Since $l \notin u_i^+(\theta)$ one has $i < b$ where

$$\lim_{t \to +\infty} \frac{1}{t} \log |\Phi(\theta, t) x_b| = \lambda_b(\theta)$$

and $|x_b| = 2\alpha > 0$. Let $N(l)$ be those lines $\tilde{l}$ in $\mathbf{P}^{m-1}(\mathbf{R})$ with the property that $\tilde{x} \in \tilde{l}$, $|\tilde{x}| = 1$, satisfies $|\tilde{x}_b| > \alpha$. The uniformity assertion in Remark 6.1 implies that for every $\beta > 0$ there is a $\tau \in \mathbf{T}$ such that

$$g_t(\tilde{l}, \theta) = \frac{1}{t} \log |\Phi(\theta, t) \tilde{x}| \geqq \lambda_b(\theta) - \beta$$

for all $t \geqq \tau$ and all $\tilde{x} \in \tilde{l} \in N(l)$ with $|\tilde{x}| = 1$. Now set $\beta = \delta$, then the lemma follows from (7.3). Q.E.D.

We see then that u_i^+ is the point-wise limit of a sequence of Borel measurable functions on Z. By the Lusin theorem, it follows that u_i^+ is measurable on $\mathbf{M}_\mu(p)$.

8. Comparison with the continuous spectrum. Let Φ be a cocycle on a compact, connected Hausdorff space $\mathbf{M}$. Let $\operatorname{dyn} \Sigma = \bigcup_{i=1}^k [a_i, b_i]$ be the dynamical spectrum with the corresponding Whitney decomposition of $\mathbf{R}^m \times \mathbf{M}$ into continuous spectral subbundles $\mathbf{R}^m \times \mathbf{M} = \mathscr{V}_1 + \cdots + \mathscr{V}_k$. Let $\mathscr{V}_i(\theta)$ denote the fiber of $\mathscr{V}_i$ in $\mathbf{R}^m$, $1 \leqq i \leqq k$. The following result is proved in Sacker and Sell (1978):

THEOREM 8.1. *The spectral subbundles $\mathscr{V}_i$ are characterized by*

$$V_i(\theta) = \operatorname{Span} \{x \in \mathbf{R}^m \colon x \neq 0 \text{ and } \lambda_s^\pm(x, \theta), \lambda_i^\pm(x, \theta) \in [a_i, b_i]\}$$

for $1 \leqq i \leqq k$, where

$$\lambda_s^\pm(x, \theta) = \limsup_{t \to \pm\infty} \frac{1}{t} \log |\Phi(\theta, t) x|, \qquad \lambda_i^\pm(x, \theta) = \liminf_{t \to \pm\infty} \frac{1}{t} \log |\Phi(\theta, t) x|.$$

We will next give a proof of Theorem 2.3. The essence of the argument is to verify (2.7), i.e.

$$\text{boundary dyn } \Sigma \subseteq \bigcup_\mu \text{meas } \Sigma(\mu) \subseteq \text{dyn } \Sigma,$$

and to show that the measurable subbundle decomposition implied by the Multiplication Ergodic theorem leads to a refinement of the continuous decomposition given by the Spectral theorem.

It follows immediately from Theorem 8.1 that for any invariant probability measure μ on $\mathbf{M}$ one has meas $\Sigma(\mu, \theta) \subseteq \operatorname{dyn} \Sigma$ for all $\theta \in \mathbf{M}_\mu$. In particular one has meas $\Sigma(\mu) \subseteq \operatorname{dyn} \Sigma$ for every ergodic measure μ on $\mathbf{M}$. Furthermore the measurable bundles $\mathscr{W}_j(\theta)$ are contained in the associated continuous spectral bundle $\mathscr{V}_i(\theta)$ when $\lambda_j(\theta) \in [a_i, b_i]$, and $\theta \in \mathbf{M}_\mu$. Since the sum of both the $\mathscr{W}_j(\theta)$'s and the $\mathscr{V}_i(\theta)$'s span $\mathbf{R}^m$ for $\theta \in \mathbf{M}_\mu$, it follows that for all $\theta \in \mathbf{M}_\mu$ one has $\mathscr{V}_i(\theta) = \sum \mathscr{W}_j(\theta)$, where the summation is over all j with $\lambda_j(\theta) \in [a_i, b_i]$, $1 \leqq i \leqq k$. (This also follows from applying Theorem 2.2 to the spectral subbundle $\mathscr{V}_i$.)

It remains to show that if $\beta \in$ boundary dyn Σ then $\beta \in$ meas $\Sigma(\mu)$ for some ergodic measure μ. Let β be an endpoint of one of the spectral intervals $[a_i, b_i]$ in dyn Σ. Let $\mathscr{V}_i$ be the continuous spectral subbundle associated with $[a_i, b_i]$. As noted in Lemma 3.1 there is no loss in generality in assuming $\mathbf{M}$ to be a compact metric space. Let X_i be the trace of $\mathscr{V}_i$ in the projective bundle $\mathbf{N} = \mathbf{P}^{m-1}(\mathbf{R}) \times \mathbf{M}$, i.e.

$$X_i = \{(l, \theta) \colon l \text{ is a line in } \mathscr{V}_i(\theta)\}.$$

Since $\mathscr{V}_i$ is invariant under the flow $\pi(x, \theta, t) = (\Phi(\theta, t)x, \theta \cdot t)$, X_i is invariant under the induced flow $\hat{\pi}$ on $\mathbf{N}$. Also X_i is compact. Let $f(l, \theta)$ be given as in § 7. Recall that the time-average of $f(l, \theta)$ along orbits in $\mathbf{N}$ determines the Lyapunov exponents of the solution $\Phi(\theta, t)x$ where x is on the line l, $x \neq 0$.

Let J be the set of all invariant measures η on X_i. We claim that

$$a_i \leqq \int_{X_i} f \, d\eta \leqq b_i \tag{8.1}$$

for all $\eta \in J$. If, on the contrary, (8.1) is false for some $\eta \in J$, then for η-almost all $(l, \theta) \in X_i$ one has

$$\lim_{|t| \to \infty} \frac{1}{t} \log |\Phi(\theta, t)x| = \hat{f}(l, \theta)$$

where f is an invariant function defined on $\mathbf{N}$ with $\int_{X_i} \hat{f} \, d\eta = \int_{X_i} f \, d\eta$, x is on l, $x \neq 0$, and $\int_{X_i} f \, d\eta \notin [a_i, b_i]$. This implies that $\hat{f}(l, \theta) \notin [a_i, b_i]$ on some invariant set of positive η-measure, which contradicts Theorem 8.1.

Next we claim that there is a measure $\eta \in J$ such that $\int_{X_i} f \, d\eta = \beta$. To see this, assume for definiteness that $\beta = b_i$ is the right endpoint of $[a_i, b_i]$. Recall that J is compact, and that the mapping $\eta \to \int_{X_j} f \, d\eta$ is continuous. Therefore if there is no $\eta \in J$ with $\int_{X_i} f \, d\eta = \beta$, then it follows from (8.1) that there is an $\varepsilon > 0$ such that $\int_{X_j} f \, d\eta \leqq \beta - \varepsilon$ for all $\eta \in J$. It follows from the Krylov–Bogoliubov method described in § 5 that for every $(x, \theta) \in \mathscr{V}_i$ with $x \neq 0$ one has

$$\limsup_{t \to \infty} \frac{1}{t} \log |\Phi(\theta, t)x| = \limsup_{t \to \infty} \frac{1}{t} \int_0^t f(\pi(l, \theta, s)) \, ds \leqq \beta - \varepsilon.$$

It then follows from Sacker and Sell (1978, Lemma 4) that $\beta \notin$ dyn Σ, a contradiction. A similar argument works for $\beta = a_i$.

We want to show next that η can be chosen to be an ergodic measure on X_i. Now fix $\eta \in J$ with $\int_{X_j} f \, d\eta = \beta$. Since X_j is a metric space, we can use the Choquet Representation theorem, Phelps (1966), to find a probability measure A_η on the set of *ergodic* measures E in J such that

$$\int_{X_j} g \, d\eta = \int_E \left(\int_{X_j} g \, d\sigma \right) dA_\eta(\sigma)$$

for each $g \in \mathscr{C}(X_i, \mathbf{R})$. In particular for $f = g$ one has

$$\beta = \int_{X_j} f \, d\eta = \int_E \left(\int_{X_j} f \, d\sigma \right) dA_\eta(\sigma).$$

From (8.1) we see that one cannot have $\int_{X_j} f\,d\sigma < \beta = b_i$ for all $\sigma \in E$. It follows then that there is an ergodic measure $\sigma \in E$ with $\int_{X_j} f\,d\sigma = \beta$.

Finally let μ be the projection of σ to $\mathbf{M}$. Then μ is an ergodic measure on $\mathbf{M}$, and from § 6 we see that $\beta \in \operatorname{meas} \Sigma(\mu)$. This completes the proof of Theorem 2.3. Q.E.D.

Remark 8.1. In general, one cannot find a single ergodic measure μ such that $a_i, b_i \in \operatorname{meas} \Sigma(\mu)$ for all endpoints a_i, b_i, even if $\mathbf{M}$ is minimal. Here is a simple example. According to Furstenberg (1961), there is a discrete flow on the 2-torus $\mathbf{M} = \mathbf{T}^2$ with more than one (in fact uncountably many) ergodic measures. Moreover, there is a continuous function g on $\mathbf{M}$ so that $\int_{\mathbf{M}} g\,d\mu_1 \neq \int_{\mathbf{M}} g\,d\mu_2$ for distinct ergodic measures μ_1, μ_2. Define $\Phi: \mathbf{M} \times \mathbf{Z} \to \mathbf{R}$ by $\Phi(y, 1) = \exp g(y)$. The dynamical spectrum of the cocycle Φ is $[a, b]$, where $a = \inf \int_{\mathbf{M}} g\,d\mu$, $b = \sup \int_{\mathbf{M}} g\,d\mu$, and the inf and sup are taken over all ergodic measures on $\mathbf{M}$. However, the measurable spectrum contains just the point $\{\int_{\mathbf{M}} g\,d\mu\}$ for each ergodic measure μ.

Remark 8.2. If there is only one ergodic measure μ on $\mathbf{M}$, for example if the flow $\theta \cdot t$ on $\mathbf{M}$ is almost periodic, then $\operatorname{meas} \Sigma(\mu)$ is a subset of the $\operatorname{dyn} \Sigma$ and *all* endpoints a_i, b_i of $\operatorname{dyn} \Sigma$ are in $\operatorname{meas} \Sigma(\mu)$. For $m = 2$ we conclude that $\operatorname{meas} \Sigma(\mu) = $ boundary $\operatorname{dyn} \Sigma$. An example in Johnson (1986) shows that for $m = 3$, even if $\mathbf{M}$ is almost periodic, the measurable spectrum need not consist entirely of endpoints a_i, b_i.

9. Computation of the measurable spectrum. Wedge product flows. Let $\theta \in \mathbf{M}$ be a Lyapunov point and let $\gamma_1(\theta) \leqq \cdots \leqq \gamma_m(\theta)$ denote the growth rates with associated basis $e_1, \cdots, e_m$. Thus one has $\lambda(e_i, \theta) = \gamma_i(\theta)$, $1 \leqq i \leqq m$. By a standard argument, see Naylor and Sell (1982, p. 268) for example, there is a constant K such that for any vector $x \in \mathbf{R}^m$ one has $x = \alpha_1 e_1 + \cdots + \alpha_m e_m$ and

$$|\Phi(\theta, t)x| \leqq K \max\{|\Phi(\theta, t)e_i| : \alpha_i \neq 0\}|x\} \tag{9.1}$$

for all $t \in \mathbf{T}$. It follows from (9.1) that

$$\limsup_{t \to +\infty} \frac{1}{t} \log |\Phi(\theta, t)| \leqq \gamma_m(\theta).$$

On the other hand one has

$$|\Phi(\theta, t)e_m| \leqq |\Phi(\theta, t)|\,|e_m|,$$

which implies that

$$\gamma_m(\theta) = \lim_{t \to +\infty} \frac{1}{t} \log |\Phi(\theta, t)e_m| \leqq \liminf_{t \to \infty} \frac{1}{t} \log |\Phi(\theta, t)|,$$

and hence one has

$$\lim_{t \to \infty} \frac{1}{t} \log |\Phi(\theta, t)| = \gamma_m(\theta). \tag{9.2}$$

A similar argument yields

$$\lim_{t \to -\infty} \frac{1}{t} \log |\Phi(\theta, t)| = \gamma_1(\theta). \tag{9.3}$$

An early version of (9.2) for stationary stochastic process of $(m \times m)$ matrices appears in Furstenberg and Kesten (1960).

The same considerations extend to the induced wedge product cocycles $\Lambda^k\Phi(\theta, t)$ on $\Lambda^k\mathbf{R}^m$, where $2 \leqq k \leqq m$. If $\Psi(\phi, t)$ satisfies (4.7), then one has

$$\Lambda^k\Psi(\phi, t) = (\Lambda^k q(\phi \cdot t))^{-1}(\Lambda^k\Phi(\theta, t))(\Lambda^k q(\phi)).$$

Hence the cocycles $\Lambda^k\Psi$ and $\Lambda^k\Phi$ are cohomologous. Therefore $\Lambda^k\Psi$ and $\Lambda^k\Phi$ have the same Lyapunov exponents.

For $1 \leqq k \leqq m$ let Ord (k, m) denote the collection of all strictly monotone mappings $\sigma: \{1, \cdots, k\} \to \{1, \cdots, m\}$. We will use the lexicographic ordering on Ord (k, m); thus $\sigma < \tau$, where $\sigma, \tau \in \text{Ord}\,(k, m)$, provided there is a j, $1 \leqq j \leqq k$ such that $\sigma(i) = \tau(i)$ for $1 \leqq i \leqq j-1$ and $\sigma(j) < \tau(j)$. If $\{e_1, \cdots, e_m\}$ is any basis for $\mathbf{R}^m$, then $\{e_\sigma: \sigma \in \text{Ord}\,(k, m)\}$ is a basis for $\Lambda^k\mathbf{R}^m$ where

$$e_\sigma = e_{\sigma(1)} \wedge \cdots \wedge e_{\sigma(k)}. \tag{9.4}$$

Furthermore if T is an upper-triangular $(m \times m)$ matrix (with respect to the basis $\{e_1, \cdots, e_m\}$), then $\Lambda^k T$ is an upper-triangular matrix with respect to the basis e_σ, $\sigma \in \text{Ord}\,(k, m)$. Also the diagonal entry $t_{\sigma\sigma}$ (in the σth position on the diagonal) is given by the product

$$t_{\sigma\sigma} = t_{\sigma(1)\sigma(1)} \cdot \cdots \cdot t_{\sigma(k)\sigma(k)}.$$

If, in addition, one has $t_{ii} > 0$ for $1 \geqq i \geqq m$, then $t_{\sigma\sigma} > 0$ for all $\sigma \in \text{Ord}\,(k, m)$.

Let us return to the triangular cocycle $\Psi(\phi, t)$. It follows from the last paragraph that if $\phi = (\theta, U)$ is fixed and if the diagonal entries of $\Psi(\phi, t)$ satisfy (6.6), then the diagonal entry $\psi_{\sigma\sigma}$ of $\Lambda^k\Psi$ satisfies

$$\lim_{|t|\to\infty} \frac{1}{t} \log |\psi_{\sigma\sigma}(\phi, t)| = \gamma_{\sigma(1)} + \cdots + \gamma_{\sigma(k)}, \tag{9.5}$$

where $\sigma \in \text{Ord}\,(k, m)$ and $2 \leqq k \leqq m$. The collection of numbers given by (9.5), where σ varies over Ord (k, m), represents the Lyapunov exponents of $\Lambda^k\Psi$. This analysis applies for every $\phi \in \mathbf{H}_\nu$, where $\mathbf{H}_\nu$ is given by Lemma 6.4. For $\phi \in \mathbf{H}_\nu(p)$ we shall rewrite the growth rates in the form (2.8) where

$$\gamma_1(\phi) \leqq \gamma_2(\phi) \leqq \cdots \leqq \gamma_m(\phi). \tag{9.6}$$

It then follows from (9.5) that the largest growth rate for $\Lambda^k\Psi$ is

$$\gamma_{m+1-k}(\phi) + \cdots + \gamma_m(\phi)$$

and the smallest is

$$\gamma_1(\phi) + \cdots + \gamma_k(\phi).$$

The argument in the first paragraph in this section now applies to $\Lambda^k\Psi$, which completes the proof of Theorem 2.4.

Remark 9.1. One can give a precise description of the measurable bundles $W_\tau^{(k)}(\phi)$ corresponding to $\Lambda^k\Psi$. Fix $\phi \in \mathbf{H}_\nu(p)$, where the growth rates of Ψ satisfy (9.6), and let $e_1(\phi), \cdots, e_m(\phi)$ be a basis in $\mathbf{R}^m$ that satisfies $\lambda(e_i(\phi), \phi) = \gamma_i(\phi)$, $1 \leqq i \leqq m$. For $\tau \in \text{Ord}\,(k, m)$ we define

$$\gamma_\tau(\phi) = \gamma_{\tau(1)}(\phi) + \cdots + \gamma_{\tau(k)}(\phi).$$

Then one has

$$W_\tau^{(k)}(\phi) = \text{span}\,\{e_\sigma: \lambda(e_\sigma, \phi) = \gamma_\tau(\phi)\}, \tag{9.7}$$

where e_σ is defined by (9.4) for $\sigma \in \text{Ord}\,(k, m)$. We will omit the proof of (9.7), which is a simple application of the techniques developed in § 6.

10. Applications and illustrations. In this section we collect several illustrative examples of the theory described above. Included here is a discussion of spiral systems, products of "random" matrices, conservative second-order Schrödinger equations with almost periodic potentials, and linear stochastic differential equations with bounded measurable coefficients.

(A) *Spiral systems.* The theory above applies to every compact invariant set **N** in **M**. In this case the dynamical spectrum dyn $\Sigma(\mathbf{N})$ depends on **N**. Next we want to study the case where **N** is a single orbit together with its ω-limit set, i.e. a *spiral system.* More precisely let **M** be a compact Hausdorff space with a flow $\theta \cdot t$. Let θ_0 be a given point in **M** and define

$$\mathbf{N} = H^+(\theta_0) = \text{closure}\,\{\theta_0 \cdot t\colon t \geqq 0\}.$$

Then **N** is positively invariant and the ω-limit set $\Omega = \bigcap_{\tau \geqq 0} H^+(\theta_0 \cdot \tau)$ is a compact invariant set. We are interested in the case where $\theta_0 \notin \Omega$. Thus the positive trajectory $\theta_0 \cdot t$ forms a spiral. See Fig. 1.

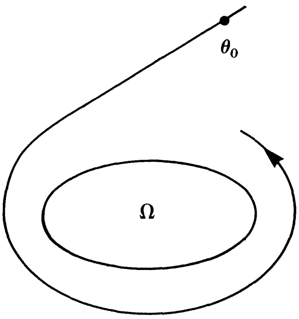

FIG. 1. N: *A spiral system.*

Let $\Phi(\theta, t)$ be a cocycle defined on **M**. Then the theory described above applied directly to the restriction of Φ to the ω-limit set Ω. The problem we wish to study here is the limiting behavior (as $s, \tau \to +\infty$) of the cocycles $\Lambda^k\Phi(\theta_0 \cdot s, t)$, $1 \leqq k \leqq m$, along the spiral trajectory θ_0. In particular we want to show that this limiting behavior can be used to evaluate the measurable spectrum of the ω-limit set Ω.

Before doing the analysis it should be noted that this study addresses a basic question which arises naturally when one is doing a numerical evaluation of the measurable (or dynamical) spectrum. The initial point θ_0 in **M** is determined by the code or program. If by good fortune it happens to lie in the set $\mathbf{M}_\mu$ (Theorem 2.1), then Theorem 2.4 explains how to compute the spectrum. With our present understanding, one does not know whether or not we have had good fortune. However, what is always true is that θ_0 does determine a spiral system.

For $k = 1, \cdots, m$ we define

$$b^k := \limsup_{s,\tau \to +\infty} \frac{1}{\tau} \log |\Lambda^k\Phi(\theta_0 \cdot s, \tau)|.$$

Also let Σ^k denote the dynamical spectrum of the linear skew-product flow $(\Lambda^k\Phi(\theta, t), \theta \cdot t)$ over Ω, and define

$$a^k := \max \Sigma^k.$$

We will now prove the following result:

THEOREM 10.1. *The following statements are valid*:

(A) *For* $k=1,\cdots,m$ *one has* $a^k=b^k$.

(B) *If the flow on* Ω *is uniquely ergodic* (*e.g. almost periodic*) *then* meas $\Sigma=\{\gamma_1,\cdots,\gamma_m\}$ *where* $\gamma_m=b^1$ *and*

$$\gamma_{m-k}=b^{k+1}-(\gamma_m+\cdots+\gamma_{m-k+1}),\qquad 1\leqq k\leqq m-1.$$

Proof. We will give the proof of (A) for $k=1$. The argument for $k\geqq 2$ is the same. Statement (B) is an immediate corollary of part (A) and Theorems 2.1, 2.3 and 2.4.

Let a and b denote a^1 and b^1. For $S\geqq 0$ and $T\geqq 0$ we define

$$\beta(S,T)=\sup_{\substack{S\leqq s\\ T\leqq \tau}}\frac{1}{T}\log|\Phi(\theta_0\cdot s,\tau)|.$$

Then $b=\lim_{S,T\to+\infty}\beta(S,T)$. Fix $\varepsilon>0$ and choose $S\geqq 0$, $T\geqq 0$ so that $\beta(S,T)\leqq b+\varepsilon$. For $t=s+\tau$ one then has

$$|\Phi(\theta_0\cdot s,\tau)|=|\Phi(\theta_0,t)\Phi^{-1}(\theta_0,s)|\leqq K\,e^{(b+\varepsilon)(t-s)},\qquad 0\leqq s\leqq t$$

where $K=\max\{|\Phi(\theta_0\cdot s,\tau)|: 0\leqq s\leqq S,\ 0\leqq\tau\leqq T\}$. It then follows directly, see Sacker and Sell (1974, Thms. 2 and 5) and (1976a, Lemma 4) for example, that $a\leqq b+\varepsilon$ for every $\varepsilon>0$. Hence $a\leqq b$.

If one has $a<b$, then we can replace $\Phi(\theta,t)$ by the shifted flow $e^{\lambda t}\Phi(\theta,t)$ where $3\lambda=2a+b$. This has the effect of shifting a and b to $a-\lambda$ and $b-\lambda$, respectively. Without any loss of generality, therefore, we can assume then that $a<0<b$ and set $b=3\alpha$. Since $a<0$, the linear skew-product flow $(\Phi(\theta,t)x,\theta\cdot t)$ has an exponential dichotomy over Ω with $\mathcal{S}=\mathbf{R}^m\times\Omega$. This means that there is a constant K such that

$$|\Phi(\theta,t)\Phi^{-1}(\theta,s)|\leqq K\,e^{-\sigma(t-s)}$$

for all $\theta\in\Omega$, and $s\leqq t$, $s,t\in\mathbf{T}$. In particular it follows from Sacker and Sell (1974, p. 452) that $\mathcal{B}=\{0\}\times\Omega$, $\mathcal{S}=\mathbf{R}^m\times\Omega$ and $\mathcal{U}=\{0\}\times\Omega$, where $\mathcal{B}$, $\mathcal{S}$ and $\mathcal{U}$ are defined to be those $(x,\theta)\in\mathbf{R}^m\times\Omega$ that satisfy

$$\sup_{t\in\mathbf{T}}|\Phi(\theta,t)x|<\infty,\quad \lim_{t\to+\infty}|\Phi(\theta,t)x|=0\quad\text{and}\quad \lim_{t\to-\infty}|\Phi(\theta,t)x|=0,$$

respectively.

Since $b>0$ there are sequences $s_n\to+\infty$, $\tau_n\to+\infty$ such that

$$|\Phi(\theta_0\cdot s_n,\tau_n)|\geqq e^{\alpha\tau_n}.$$

Let e_n be a vector with $|e_n|=1$ and

$$|\Phi(\theta_0\cdot s_n,\tau_n)e_n|\geqq e^{\alpha\tau_n}.$$

Fix σ_n so that $0\leqq\sigma_n\leqq\tau_n$ and

$$|\Phi(\theta_0\cdot s_n,t)e_n|\leqq|\Phi(\theta_0\cdot s_n,\sigma_n)e_n|,\qquad 0\leqq t\leqq\tau_n.$$

Set $\xi_n=\Phi(\theta_0\cdot s_n,\sigma_n)e_n$. Then $|\xi_n|\geqq e^{\alpha\tau_n}$, and

$$|\xi_n|^{-1}|\Phi(\theta_0\cdot s_n,t)e_n|\leqq 1,\qquad 0\leqq t\leqq\sigma_n.$$

Since $|\xi_n|\to+\infty$ one has $\sigma_n\to+\infty$. Also one has $e_n=\Phi(\theta_n,-\sigma_n)\xi_n$ where $\theta_n=\theta_0\cdot(s_n+\sigma_n)$. By choosing subsequences (if necessary) we can assume that $\theta_n\to\theta\in\Omega$ and $|\xi_n|^{-1}\xi_n\to e$ where $|e|=1$. It follows from Sacker and Sell (1976a, Lemma 4) that $(e,\theta)\in\mathcal{U}$, which contradicts the fact that $\mathcal{U}=\{0\}\times\Omega$. We conclude that $a=b$.

Remark 10.1. The conclusions of Theorem 10.1 can be reformulated in another manner. The numbers a^k represent the "largest possible" Lyapunov exponents for the cocycle $\Lambda^k\Phi(\theta, t)$, where $\theta \in \Omega$ and $1 \leqq k \leqq n$. By the inequality (2.7) and Theorem 2.4 we see that there are ergodic measures μ_k on Ω with the property that a^k is the largest value in the measurable spectrum generated by $\Lambda^k\Phi$, $1 \leqq k \leqq n$. Consequently if μ is any invariant measure on Ω and $\gamma_1(\theta) \leqq \cdots \leqq \gamma_m(\theta)$ are the growth rates satisfying (9.6) for $\theta \in \Omega_\mu$, then one has

$$\gamma_m(\theta) + \cdots + \gamma_{m-k+1}(\theta) \leqq a^k$$

for all $\theta \in \Omega_\mu$.

Remark 10.2. The ergodic measures μ_k referred to in the last paragraph need not be the same. Let Ω be a minimal set in the flow $\theta \cdot t$, and assume that this flow is not uniquely ergodic. Then there are ergodic measures μ_1 and μ_2 on Ω and a continuous real-valued function g that satisfies $\int g\, d\mu_1 \neq \int g\, d\mu_2$. Since g can be replaced by $g + c$ and/or αg, where c and α are constants with $\alpha \neq 0$, we can assume that μ_1, μ_2 and g are chosen to satisfy

$$-1 = \int g\, d\mu_2 \leqq \int g\, d\mu \leqq \int g\, d\mu_1 = 3$$

for every ergodic measure μ. Now set $h = -2g$ and consider the linear skew-product flow on $\mathbf{R}^2 \times \Omega$ generated by

$$x' = \operatorname{diag}(g(\theta \cdot t), h(\theta \cdot t))x.$$

In the notation introduced above one then has $a^1 = 3$, $a^2 = 2$, and $a^i = \max \operatorname{meas} \Sigma(\mu_i)$, $i = 1, 2$.

Remark 10.3. It may happen that all the limits

$$\lim_{t \to +\infty} \frac{1}{t} \log |\Lambda^k\Phi(\theta_0, t)| = c^k, \qquad 1 \leqq k \leqq m,$$

exist. If so, then one has $c^k \leqq a^k$, $1 \leqq k \leqq m$. By using the associated triangular flow and the Krylov-Bogoliubov method described in § 5, one can show that there is an invariant measure μ on Ω with the property that $\operatorname{meas} \Sigma(\mu) = \{\gamma_1, \cdots, \gamma_m\}$ where $\gamma_1 \leqq \cdots \leqq \gamma_m$ and

$$\gamma_{m-k+1} + \cdots + \gamma_m = c^k, \qquad 1 \leqq k \leqq m.$$

Remark 10.4. The conclusions of Theorem 10.1 and the above remarks are related to results of Pelikan (1983) who has analyzed the structure of Bowen-Ruelle invariant measures on certain attractors.

(B) *Products of random matrices.* In this example we show that the theory of products of matrices considered in Furstenberg and Kesten (1960) is often imbeddable in our theory. Let $\mathbf{K}$ denote a fixed compact subset of $\mathscr{GL}(m)$ and let $\{X_1, X_2, \cdots\}$ be a given sequence of $(m \times m)$ matrices with values in $\mathbf{K}$. For $n = 1, 2, \cdots$ form the product

$$Y_n = X_n X_{n-1} \cdots X_1.$$

We wish to study the limiting behavior of

$$\frac{1}{n} \log |Y_n|$$

as $n \to \infty$. This will be done by imbedding this problem into a spiral system, where $Y_n = \Phi(\theta_0, n)$ for an appropriate cocycle Φ, and using Theorem 10.1.

Let $\mathbf{M} := \mathbf{K}^{\mathbf{Z}}$ denote the collection of all two-sided sequences

$$\theta = (\cdots, A_{-2}, A_{-1}; A_0; A_1, A_2, \cdots) \tag{10.1}$$

with entries $A_i \in \mathbf{K}$, $i \in \mathbf{Z}$. (We will use semi-colons to designate the zeroth position of θ.) Then $\mathbf{M}$ is a compact metric space with the shift flow $\theta \cdot n$ where

$$\theta \cdot n = (\cdots, A_{n-2}, A_{n-1}; A_n; A_{n+1}, A_{n+2}, \cdots)$$

for $n \in \mathbf{Z}$. Define $F: \mathbf{M} \to \mathbf{K}$ by $F(\theta) := A_0$ where θ is given by (10.1). Then one constructs a cocycle Φ over $\mathbf{M}$ by defining $\Phi(\theta, 0) = I$

$$\Phi(\theta, n) = F(\theta \cdot (n-1)) \cdots F(\theta), \qquad n \geqq 1,$$

$$\Phi(\theta, n) = [F(\theta \cdot (-1)) \cdots F(\theta \cdot n)]^{-1}, \qquad n \leqq -1.$$

It is not difficult to see that the cocycle identity (2.1) is valid for $t, s \in \mathbf{Z}$.

The distinguished sequence $\{X_1, X_2, \cdots\}$ is imbedded into this flow as a spiral, i.e. let A be a fixed element in $\mathbf{K}$ and set

$$\theta_0 = (\cdots, A, A; X_1; X_2, X_3, \cdots),$$

where every negative entry in θ_0 is A. Then $\theta_0 \in \mathbf{M}$ and $Y_n = \Phi(\theta_0, n)$ for $n \geqq 1$. By Theorem 10.1 we see that

$$\limsup_{m,n \to +\infty} \frac{1}{m} \log |\Phi(\theta \cdot n, m)| = \limsup_{m,n \to +\infty} \frac{1}{m} \log |Y_{m+n} Y_n^{-1}| \tag{10.2}$$

exists and this is the maximum value of the dynamical spectrum over Ω, the ω-limit set of θ_0.

When the distinguished sequence $\{X_1, X_2, \cdots\}$ is a stationary stochastic process, then the expectation satisfies $E(\log^+ |X_1|) < \infty$ since X_1 assumes values in the compact set $\mathbf{K}$. If, in addition, this stochastic process is metrically transitive (i.e. ergodic) then Theorem 2.4 is applicable, and one concludes that

$$\lim_{n \to \infty} \frac{1}{n} \log |Y_n| \tag{10.3}$$

exists with probability 1. Also the limits in (10.2) and (10.3) agree. We refer the reader to Furstenberg and Kesten (1960) for more details.

Remark 10.5. Some interesting applications of products of random matrices to problems in demographics can be found in Cohen (1979).

(C) *Schrödinger equation.* In the study of the Schrödinger equation

$$\mathrm{L}y = \left(-\frac{d^2}{dt^2} + q(t)\right) y = \lambda y,$$

where $q(t)$ is real and Bohr almost periodic, it is of interest to compute the "Lyapunov number" $\beta(\lambda)$ as a function of $\lambda \in R$. $\beta(\lambda)$ is defined as follows: First introduce the *hull* $\mathbf{M}$ of q by

$$\mathbf{M} = \text{closure}\,\{q_\tau \mid \tau \in \mathbf{R}\},$$

where $q_\tau(t) = q(t+\tau)$, and the closure is in the uniform topology. Then $\mathbf{M}$ is a compact metric space with translation flow $\theta \cdot \tau = \theta_\tau$. In fact $\mathbf{M}$ is a compact topological group, and the normalized Haar measure μ is the unique invariant measure on $\mathbf{M}$. Define

$Q(\theta)=\theta(0)$, and consider the operators $L_\theta=-(d^2/dt^2)+Q(\theta\cdot t)$ and the associated equations

$$x'=\begin{pmatrix}0 & 1\\ -\lambda+Q(\theta\cdot t) & 0\end{pmatrix}x,\qquad x=\begin{pmatrix}y\\ y'\end{pmatrix}. \tag{10.4}$$

Since the trace of the coefficient matrix is zero, one obtains from Liouville's formula that

$$\operatorname{meas}\Sigma(\mu)=\{-\beta(\lambda),\beta(\lambda)\}$$

where $\beta(\lambda)\geqq 0$. This defines $\beta(\lambda)$. Also, as noted in Remark 8.2, one has boundary dyn $\Sigma=\operatorname{meas}\Sigma(\mu)$.

Spectral properties of the self-adjoint linear operators L_θ on $L^2(-\infty,\infty)$ are reflected in the dynamics of (10.4). For example, λ is in the resolvent set for L_θ if and only if (10.4) admits an exponential dichotomy, Johnson (1982). Also if $\beta(\lambda)>0$ for all λ in an interval I, then for μ-almost all θ, the (functional analytic) spectrum of L_θ has no absolutely continuous component in I, Pastur (1980), Ishii (1973). Moreover if $\beta(\lambda)=0$ for all λ in I, then I is in the purely absolutely continuous spectrum of L_θ for μ-almost all θ, Kotani (1982).

The numerical computation of $\beta(\lambda)$ when $q(t)=\cos t+\cos\pi t$, for example, is a challenging problem. An investigation of this problem is described in Perry (1986). The basic idea is to use Theorem 2.4 to estimate $\beta(\lambda)$. Also special properties of second order linear equations, as described in Johnson (1980a) and Johnson and Moser (1982), can be exploited to help determine whether or not (10.4) admits an exponential dichotomy for $\lambda=0$. This, in turn, leads to a resolution of the question of whether or not one has dyn $\Sigma=\operatorname{meas}\Sigma(\mu)$.

Another method for computing $\beta(\lambda)$, which was suggested by R. Helleman, is to use the theory of Johnson and Moser (1982). In this setting one extends λ to the complex plane so that for $\operatorname{Im}\lambda>0$, $\beta(\lambda)$ is the real part of a holomorphic function $w(\lambda)$, called the Floquet exponent of (10.4). When $\operatorname{Im}\lambda>0$, (10.4) has an exponential dichotomy. One can compute $\beta(\lambda)$ for real λ by a limiting formula:

$$\beta(\lambda)=\lim\nolimits_{\eta\to 0^+}\beta(\lambda+i\eta).$$

(D) *Linear stochastic differential equations.* An interesting variation of the Schrödinger equation occurs when the potential $q(t)$ is a stochastic variable. More generally consider the m-dimensional case $x'=A(t)x$, $x\in\mathbf{R}^m$, where the entries $a_{ij}(t)$ are stochastic variables in t. We will show how this can be imbedded in a linear skew-product flow on $\mathbf{R}^m\times\mathbf{M}$, where $\mathbf{M}$ is a compact space, under the assumption that the coefficients $a_{ij}(t)$ are bounded and measurable in t, i.e. $a_{ij}\in L^\infty(\mathbf{R})$. (See Kurzweil (1957), Miller and Sell (1970) and Sacker and Sell (1974) for more information.)

The set $\mathbf{M}$ is the hull of A and is defined by

$$\mathbf{M}=\text{closure}\,\{A_\tau\colon \tau\in\mathbf{R}\},$$

where $A_\tau(t)=A(\tau+t)$ and the closure is taken in the "weak L^1-local" topology. That is, a generalized sequence $\{A_n\}$ converges to a limit B if for every $\tau\in\mathbf{R}$ and every $\phi\in L^1[\tau,\tau+1]$ one has

$$\int_\tau^{\tau+1} A_n(t)\phi(t)\,dt\to\int_\tau^{\tau+1} B(t)\phi(t)\,dt.$$

Since $A(t)$ is bounded and measurable, the hull of A is a compact Hausdorff space. If $B\in\mathbf{M}$ we let $\Phi(B, t)$ be the fundamental solution matrix for $x'=B(t)x$. Then $\Phi:\mathbf{M}\times\mathbf{R}\to\mathcal{GL}(m)$ is continuous and the associated linear skew-product flow is

$$\pi(B, x, \tau)=(\Phi(B, \tau)x, B_\tau).$$

When the coefficients a_{ij} are stationary stochastic variables, it is not difficult to show (by using the ideas of § 5) that a given underlying invariant probability measure μ lifts to an invariant measure ν on $\mathbf{M}$. If the coefficients are metrically transitive, i.e. if μ is ergodic, then the lifted measure ν can be chosen to be ergodic.

Appendix. Further geometric properties of cocycles. A *projector* is a continuous mapping $P(x, \theta)=(P(\theta)x, \theta)$ on $\mathbf{R}^m\times\mathbf{M}$ where $\mathbf{M}$ is a compact Hausdorff space and $P(\theta)$ is a linear projection on $\mathbf{R}^m$. A *resolution of the identity* on $\mathbf{R}^m\times\mathbf{M}$ is a k-tuple $P=(P_1,\cdots, P_k)$, $k\geqq 1$, satisfying: (i) each P_i is a projector, (ii) $P_iP_j=\vec{0}$ when $i\neq j$ and (iii) $I=P_1+\cdots+P_k$. (Here we define $\vec{0}(x, \theta):=(0, \theta)$.) Let $P=(P_1,\cdots, P_k)$ be a k-tuple of projectors on $\mathbf{R}^m\times\mathbf{M}$ and define

$$\mathcal{R}_i:=\text{Range}\,(P_i):=\{(x, \theta)\in\mathbf{R}^m\times\mathbf{M}\colon P_i(\theta)x=x\},\qquad 1\leqq i\leqq k.$$

Then P is a resolution of the identity if and only if $\mathbf{R}^m\times\mathbf{M}=\mathcal{R}_1+\cdots+\mathcal{R}_k$ (as a Whitney sum). A resolution of the identity P is said to be *orthogonal* if $\mathcal{R}_i\perp\mathcal{R}_j$ whenever $i\neq j$, i.e. the Euclidean inner product $\langle\cdot,\cdot\rangle$ satisfies $\langle x, y\rangle=0$ for all $(x, \theta)\in\mathcal{R}_i$, $(y, \theta)\in\mathcal{R}_j$ when $i\neq j$. The latter is equivalent to saying that each $P_i(\theta)$ is an orthogonal projection on $\mathbf{R}^m$.

Now let Φ be a cocycle on $\mathbf{R}^m\times\mathbf{M}$ and assume $\mathbf{R}^m\times\mathbf{M}=\mathcal{V}_1+\cdots+\mathcal{V}_k$ as a Whitney sum. Let $P=(P_1,\cdots, P_k)$ be the induced resolution of the identity where Range $(P_i)=\mathcal{V}_i$, $1\leqq i\leqq k$. Then the subbundles $\mathcal{V}_i$ are invariant under the linear skew product flow induced by Φ if and only if one has

$$P_i(\theta\cdot t)\Phi(\theta, t)=\Phi(\theta, t)P_i(\theta),\qquad 1\leqq i\leqq k \tag{A.1}$$

for all $\theta\in\mathbf{M}$ and $t\in\mathbf{T}$. We shall say that a resolution of the identity $P=(P_1,\cdots, P_k)$ is *invariant* if (A.1) is satisfied. It is not always the case that an invariant resolution of the identity is orthogonal; however, the next lemma shows that one can replace Φ with a cohomologous flow in which the new invariant resolution of the identity is orthogonal.

LEMMA A. *Let Φ be a cocycle over a compact Hausdorff space $\mathbf{M}$ and let $P=(P_1,\cdots, P_k)$ be an invariant resolution of the identity. Then there is a continuous self-adjoint mapping $R:\mathbf{M}\to\mathcal{GL}(m)$ with the property that $Q=(Q_1,\cdots, Q_k)$ is an orthogonal resolution of the identity, where*

$$Q_i(\theta)=R(\theta)P_i(\theta)R^{-1}(\theta),\qquad 1\leqq i\leqq k. \tag{A.2}$$

Furthermore Q is invariant under the cocycle

$$\Psi(\theta, t)=R(\theta\cdot t)\Phi(\theta, t)R^{-1}(\theta). \tag{A.3}$$

Proof. Define $S(\theta)$ by

$$S(\theta):=\sum_{i=1}^{k}P_i^*(\theta)P_i(\theta)$$

where P^* denotes the adjoint operation. Then $S(\theta)$ is positive definite and self-adjoint, so it has a unique positive definite, self-adjoint square root $R(\theta)$, i.e. $R^2(\theta)=S(\theta)$. If $Q_i(\theta)$ is defined by (A.2) and Ψ is given by (A.3) it is easy to verify that $Q_i^*(\theta)=Q_i(\theta)$ and $\Psi(\theta, t)Q_i(\theta)=Q_i(\theta\cdot t)\Psi(\theta, t)$, $1\leqq i\leqq k$. Q.E.D.

Lemma 3.4 also gives information about the case where one has a linear skew-product flow on a vector bundle $\mathscr{E}$ over a compact Hausdorff space $\mathbf{M}$ where $\mathscr{E} = \mathscr{V}_1 + \cdots + \mathscr{V}_k$ is a Whitney sum of invariant subbundles. Each of these subbundles $\mathscr{V}_i$ can be separately imbedded in a trivial bundle $\mathbf{R}^{m_i} \times \mathbf{M}$ where $m = m_1 + \cdots + m_k$. The construction of Lemma 3.4 shows that one can construct a cocycle on $\mathbf{R}^m \times \mathbf{M}$ so that the given flow on $\mathscr{E}$ is cohomologous to a flow on a subbundle of $\mathbf{R}^m \times \mathbf{M}$.

If π is a discrete flow on a vector bundle $\mathscr{E}$, i.e. if $\mathbf{T} = \mathbf{Z}$, then Lemma 3.4 can be extended to this case by first suspending the discrete flow to get an equivalent continuous-time flow on a new vector bundle. See Ellis and Johnson (1982) for the suspension construction. One should note that even if the original bundle is trivial, the suspended bundle may be nontrivial.

The triangularization technique can be used to put some cocycles into a block-diagonal, upper-triangular form. Let Φ be a cocycle on $\mathbf{M}$ and let $P = (P_1, \cdots, P_k)$ be an invariant partition of unity of $\mathbf{R}^m \times \mathbf{M}$. Because of Lemma A we can assume P to be orthogonal. For any point $\phi = (\theta, U) \in \mathbf{H}$ we define the P-partition of U to be the partitioning of U into block matrices $U = (U_1, \cdots, U_k)_P$ where the number m_i of column vectors in U_i is $\dim \operatorname{Range} P_i(\theta)$, $1 \leqq i \leqq k$. Let $\mathbf{H}_P$ denote the set of all $\phi = (\theta, U) \in \mathbf{H}$ with the property that the P-partition $U = (U_1, \cdots, U_k)_P$ satisfies

$$P_i(\theta) U_j = \delta_{ij} U_i, \qquad 1 \leqq i, \quad j \leqq k. \tag{A.4}$$

By using Lemma A one can easily verify the following:

LEMMA B. *$\mathbf{H}_P$ is a compact invariant set in $\mathbf{H}$ in the flow $\phi \cdot t$. Furthermore if $\phi = (\theta, U) \in \mathbf{H}_P$ then the column vectors in $\Phi(\theta, t) U_i$ are orthogonal to those in $\Phi(\theta, t) U_j$ when $i \neq j$.*

For $\phi = (\theta, U) \in \mathbf{H}_P$ let $T(\Phi(\theta, t) U)$ be given by (4.5). The P-partition of U prescribes an induced block partition of $T(\Phi(\theta, t) U)$ where the diagonal blocks are square matrices of size $(m_i \times m_i)$, $1 \leqq i \leqq k$. Since the off-diagonal blocks of $T(\Phi(\theta, t) U)$ depend on the inner products of column vectors of $\Phi(\theta, t) U_i$ and $\Phi(\theta, t) U_j$ for $i \neq j$, it follows from Lemma B that these off-diagonal blocks are zero. Hence $\Psi(\phi, t) = T(\Phi(\theta, t) U)^{-1}$ is a block-diagonal, upper-triangular matrix.

The block-diagonalization of Ψ involves an "untwisting" of the spectral subbundles of Φ. A similar untwisting with additional useful structures appears in Ellis and Johnson (1982). Also compare with Coppel (1967), Palmer (1980) and Vinograd et al. (1977).

SIMPLE CRITERIA FOR STABLE BIFURCATING PERIODIC SOLUTIONS OF O.D.E.'s*

G. CICOGNA†

Abstract. We propose a very simple criterion (generalizing classical Hopf theory) ensuring the existence of bifurcating periodic solutions for systems of O.D.E. of order larger than one. We show also that these solutions can be evaluated by means of a practical recursive procedure, and give a direct rule for finding the critical Floquet exponent. Some further generalizations are also considered, mainly based on symmetry properties and stability theory.

Key words. nonlinear systems of O.D.E.'s, Hopf bifurcation, recursive methods, Floquet exponent, equivariant bifurcation problems

AMS(MOS) subject classifications. 34A34, 58E07, 34A45, 34D20

1. Introduction. We will deal in this paper with systems of nonlinear differential equations, for a n-component real variable $x = x(t)$, of order higher than one: our aim is mainly to provide simple and readily applicable criteria concerning the existence of bifurcating periodic solutions (§ 2), and their stability (§ 6). It can be observed, actually, that any system of differential equations of order higher than one could be transformed—in principle—into a system containing only first-order derivatives; however, the price that must be paid is the introduction of a very high number of equations and variables, which are in general not easily handled. In addition, it may happen that the initial system cannot be explicitly transformed into a first-order system, so that the classical Hopf bifurcation theory cannot be applied. Our criteria do not require these transformations; rather they involve only linear algebra in the vector space C^n.

The interest in this type of problem is increasing: we can refer to the books and reviews [2], [4], [8], [9], [11], [12], and to the Proceedings of recent courses [1], [10], [17].

Another relevant point is that our scheme enables us to apply a general recursion procedure (again in an n-dimensional space) for explicitly calculating the periodic solution (cf. [11]): this will be illustrated also by means of an example (§ 4). Another example will be examined in some detail (§ 7), in order to discuss the stability of the bifurcating periodic solution, in terms of Floquet exponents [11]. In § 3, we will compare our results with the classical Hopf bifurcation theory.

In § 5 we discuss some symmetry properties of the problem. It is known that symmetries play an interesting role in bifurcation theory; what concerns us especially is the case of bifurcating periodic solutions (see the paper by Golubitsky and Stewart [7]) where one can find a detailed analysis of this point of view. Symmetries are also treated in § 8, where some generalizations of the method are briefly considered: precisely, the case of multiple critical eigenvectors (Theorem 3), and finally the case when the classical conditions of the Hopf method are not verified, and one has to resort to different arguments based on stability theory (Theorem 4).

2. Existence of bifurcating periodic solutions. Let $x = x(t)$ be a real n-dimensional vector, depending on time t; we shall consider a family, depending on a real parameter

λ, of systems of nonlinear ordinary differential equations of the following type

$$\text{(1a)} \qquad F(\lambda, x) \equiv L(\lambda)x + H(\lambda, x), \qquad \lambda \in R, \quad x \in R^n$$

where L is the linear differential operator

$$\text{(1b)} \qquad L(\lambda) = \sum_{r=0}^{k} A_r(\lambda) \frac{d^r}{dt^r}$$

and $A_r = A_r(\lambda)$ $(r = 0, \cdots, k)$ are given $n \times n$ real matrices, $H: R \times R^n \to R^n$ is the remaining nonlinear higher order part, with $H(\lambda, 0) = 0$; we will assume also for simplicity that $A_r = A_r(\lambda)$ and $H = H(\lambda, x)$ are analytical functions.

Theorem 1 below provides a condition for the existence of a bifurcating nonzero periodic solution of (1): this will be readily obtained introducing first the $n \times n$ auxiliary matrix T defined by

$$\text{(2)} \qquad T = T(\lambda, \omega) = \sum_{r=0}^{k} (i\omega)^r A_r(\lambda)$$

where ω is a new real parameter.

THEOREM 1. *Suppose that when* $\lambda = \lambda_0$ *and* $\omega = \omega_0 > 0$ *the matrix* $T_0 = T(\lambda_0, \omega_0)$ *defined in* (2) *is singular, and that its kernel in* C^n *is one-dimensional. Assume also that the usual "no-resonance" condition is fulfilled, i.e. that, in the case there is some other* $\omega' \neq \omega_0$ *such that* $\det T(\lambda_0, \omega') = 0$, *then* ω'/ω_0 *is not an integer number. Finally, denoting by* ζ *and* ζ' *unit vectors in* C^n *such that*[1]

$$\text{(3)} \qquad T_0\zeta = 0 \quad \textit{and} \quad T_0^+\zeta' = 0$$

assume that the two complex numbers

$$\text{(4)} \qquad \langle T_\lambda \rangle = \left(\frac{\partial T}{\partial \lambda}\zeta, \zeta'\right) \quad \textit{and} \quad \langle T_\omega \rangle = \left(\frac{\partial T}{\partial \omega}\zeta, \zeta'\right)$$

(*where* (,) *is the scalar product in* C^n *and derivatives are evaluated at* $\lambda = \lambda_0$ *and* $\omega = \omega_0$) *are not aligned with the origin of the complex plane. Then, the problem* (1) *possesses a periodic nonzero solution, branching at* $\lambda = \lambda_0$, *with period* $2\pi/\omega$, *which can be parameterized in this form*

$$\text{(5)} \qquad \begin{aligned} x &= x(s, t) = s \operatorname{Re}(\zeta e^{i\omega t}) + w(s, t), \\ \lambda &= \lambda(s), \\ \omega &= \omega(s), \end{aligned}$$

where s is a real parameter, defined in a neighbourhood of zero, and such that

$$\lim_{s \to 0} \lambda(s) = \lambda_0, \quad \lim_{s \to 0} \omega(s) = \omega_0, \quad \lim_{s \to 0} s^{-1} w(s, t) = 0.$$

Proof. Having rescaled the time variable t

$$\text{(6)} \qquad t \to \tau = \omega t$$

(so one has to look for 2π-periodic solutions in τ), let us put

$$\text{(7)} \qquad L(\lambda, \omega) = \sum_{r=0}^{k} \omega^r A_r(\lambda) \frac{d^r}{d\tau^r}$$

[1] The choice of phase factors of ζ and ζ' is irrelevant here and in the following.

and introduce the $L^2((0,2\pi), R^n)$ scalar product

$$(x(\tau), y(\tau))_{L^2} = \frac{1}{\pi}\int_0^{2\pi} (x(\tau), y(\tau))_{R^n}\, d\tau \tag{8}$$

(easily extended, whenever necessary, to $L^2((0,2\pi), C^n)$). Our assumptions imply that the operator $L_0 = L(\lambda_0, \omega_0)$ is a Fredholm operator of index zero, with two-dimensional (in the real sense) kernel V, spanned by

$$\mathrm{Re}\,(\zeta\, e^{i\tau}) \quad \text{and} \quad \mathrm{Im}\,(\zeta\, e^{i\tau}). \tag{9a}$$

Let V' be the kernel, spanned by

$$\mathrm{Re}\,(\zeta'\, e^{i\tau}) \quad \text{and} \quad \mathrm{Im}\,(\zeta'\, e^{i\tau}), \tag{9b}$$

of the formal adjoint

$$L_0^+ = \sum_{r=0}^{k} (-\omega_0)^r A_r(\lambda_0) \frac{d^r}{d\tau^r}$$

and W, W' the orthogonal complementary subspaces in $L^2((0,2\pi), R^n)$ of V, V' respectively. According to the usual Lyapunov-Schmidt technique (see e.g. [4], [8]), introduce the projectors P, P' on V, V', and Q, Q' on W, W'; then, writing $w = Qx$ and $v = Px$, the projection of (1) on W' uniquely fixes w as a function of λ, ω and v; next, the projection on V' gives the bifurcation equation:

$$P'F(\lambda, \omega, v + w(\lambda, \omega, v)) \equiv \Phi(\lambda, \omega, v) \equiv \Psi(\lambda, \omega, v)v = 0 \tag{10}$$

where $\Phi: R^2 \times V \to V'$, and $\Psi(\lambda, \omega, v)$ is a 2×2 real matrix with the property

$$\Psi(\lambda_0, \omega_0, 0) = 0.$$

Let now $\hat{v}$ be any unit vector in V (the choice of $\hat{v}$ is arbitrary, as we shall see more clearly in § 5), and s a real parameter; then (10), written in the one-dimensional subspace $\{s\hat{v}\}$, becomes

$$\Psi(\lambda, \omega, s)\hat{v} = 0$$

($s = 0$ corresponds to the trivial solution $v = w = x = 0$). An application of the implicit function theorem gives that this equation has nonzero solution if

$$\frac{\partial\Psi}{\partial\lambda}(\lambda_0, \omega_0, 0)\hat{v} \quad \text{and} \quad \frac{\partial\Psi}{\partial\omega}(\lambda_0, \omega_0, 0)\hat{v} \tag{11}$$

are two linearly independent vectors (in the real sense: see [4] and also [6, § 6]). If this condition is satisfied, the solution can be put precisely in the explicit form (5). On the other hand, one has

$$\frac{\partial\Psi}{\partial\lambda}(\lambda_0, \omega_0, 0)\hat{v} = \frac{\partial}{\partial\lambda} P'F_x(\lambda_0, \omega_0, 0)\hat{v} = P'\frac{\partial L}{\partial\lambda}(\lambda_0, \omega_0)\hat{v}$$

and similarly for $(\partial\Psi/\partial\omega)\hat{v}$, having taken into account that $w_v(\lambda_0, \omega_0, 0) = 0$, as known from usual bifurcation theory. The projection P' on V' is obtained by evaluating the two scalar products with vectors (9b); using now definition (8), one can observe that, for any real function $y(\tau) \in L^2$,

$$\begin{aligned}(y(\tau), \mathrm{Re}\,(\zeta'\, e^{i\tau}))_{L^2} &= \mathrm{Re}\,(\eta_1, \zeta')_{C^n},\\ (y(\tau), \mathrm{Im}\,(\zeta'\, e^{i\tau}))_{L^2} &= \mathrm{Im}\,(\eta_1, \zeta')_{C^n}\end{aligned} \tag{12}$$

where $\eta_1 \in C^n$ is the vector of the first components of the Fourier series

$$y(\tau) = \sum_{p=0}^{\infty} \frac{1}{2}(\eta_p e^{ip\tau} + \bar{\eta}_p e^{-ip\tau}).$$

Choosing now $\hat{v} = \operatorname{Re}(\zeta e^{i\tau})$, it is immediately seen that the condition given above on the two vectors (11) is equivalent to the assumption on the scalar products (4) as given in the theorem. The other assertions follow from standard results of the Lyapunov-Schmidt procedure.

3. A particular case: the Hopf bifurcation problem. In the particular case of first-order differential systems ($k = 1$), the two quantities (4) become now

$$\langle T_\lambda \rangle = ((i\omega_0 A_{1\lambda} + A_{0\lambda})\zeta, \zeta') \quad \text{and} \quad \langle T_\omega \rangle = i(A_1\zeta, \zeta') \tag{13}$$

where $A_{1\lambda} = \partial A_1/\partial\lambda$ evaluated at $\lambda = \lambda_0$, etc. If, in addition, the matrix $A_1(\lambda)$ is assumed to be invertible, at least near λ_0 (Theorem 1 actually works also without this assumption), the problem is the classical Hopf bifurcation problem:

$$\frac{d}{dt}x = B(\lambda)x + C(\lambda, x) \quad \text{with } B(\lambda) = -A_1^{-1}(\lambda)A_0(\lambda).$$

Observing that

$$B(\lambda_0)\zeta = i\omega_0\zeta,$$
$$B^+(\lambda_0)\zeta'' = -i\omega_0\zeta'' \quad \text{if } \zeta'' = A_1^+(\lambda_0)\zeta',$$

one obtains in this case from (13) (all quantities are evaluated at $\lambda = \lambda_0$)

$$\langle T_\lambda \rangle = -\sigma_\lambda(\zeta, \zeta'') \quad \text{and} \quad \langle T_\omega \rangle = i(\zeta, \zeta'')$$

where $\sigma = \sigma(\lambda)$ is the critical branch of eigenvalues of $B(\lambda)$, with $\sigma(\lambda_0) = i\omega_0$. Our condition on (4) becomes then

$$(\zeta, \zeta'') \neq 0 \quad \text{and} \quad \operatorname{Re}\sigma_\lambda(\lambda_0) \neq 0$$

which is precisely the usual "transversality" assumption [11], [4], together with the condition that the critical eigenvalue $i\omega_0$ of B is semisimple (i.e. algebraically simple). For what concerns this last assertion, note in fact that $(\zeta, \zeta'') = 0$ would imply, using also (8) and (12), that $\operatorname{Re}(\zeta e^{i\tau})$ and $\operatorname{Im}(\zeta e^{i\tau})$ are orthogonal to the kernel of the formal adjoint

$$L_0^+ = -\omega_0\frac{d}{dt} - B^+(\lambda_0),$$

which in turn implies that there exists some vector $\xi \in C^n$ such that $(B(\lambda_0) - i\omega_0)\xi = \zeta$, thus showing the nonsemisimplicity of the eigenvalue $i\omega_0$, and vice versa.

4. The recursive method. First example. We want to show here a very general recursive method (cf. [11]) which, if the hypotheses of Theorem 1 are verified, can be applied for explicitly evaluating solution (5), and which appears to be more convenient—for practical uses—than the Lyapunov-Schmidt procedure.

Let us insert into (1) the following expansion of (5) in powers of the parameter s

$$\begin{aligned} x(s, \tau) &= sx_{(1)}(\tau) + s^2x_{(2)}(\tau) + s^3x_{(3)}(\tau) + \cdots, \\ \lambda(s) &= \lambda_0 + s\lambda_1 + s^2\lambda_2 + \cdots, \\ \omega(s) &= \omega_0 + s\omega_1 + s^2\omega_2 + \cdots. \end{aligned} \tag{14}$$

At the first order one gets

$$L(\lambda_0, \omega_0)x_{(1)}(\tau) = 0$$

which is solved just by all vectors in V. Choose now (the normalization of ζ fixes the scale of s)

$$x_{(1)} = \text{Re}\,(\zeta\, e^{i\tau}).$$

At the order s^2, one has the linear differential problem

$$L_0 x_{(2)}(\tau) = -\left(\lambda_1 \frac{\partial L}{\partial \lambda} + \omega_1 \frac{\partial L}{\partial \omega}\right) x_{(1)}(\tau) + H_2(\tau) \tag{15}$$

where $H_2(\tau)$ is the second order term in the expansion of $H(\lambda, x)$ in powers of s. Classical alternative theorems say that this equation can be solved (in $x_2(\tau)$) if its r.h.s. is orthogonal to V'; imposing this condition by means of (8) and (12) gives an equation for λ_1, ω_1. This equation, in turn, can be satisfied just if assumptions of Theorem 1 (in particular the one concerning quantities (4)) are verified.

The method can be illustrated by means of the following example. This is one of the simplest examples which could have some interest, because of the occurrence of the highest derivatives in just one of the equations. To my knowledge, such cases which are not (or cannot be) transformed into a first order system rarely appear to be considered in the literature. However, there are several problems (e.g. in nonlinear field theories, nonlinear quantum-mechanical systems, etc.: see [1], [2], [9]) which are of this form: our method may then be useful, even if this possibility cannot be considered in this paper. Consider then the system, with $k = 2$, $n = 2$, writing here the two-component vector x in the form $x \equiv (x(t), y(t))$

$$\ddot{x} + x - \ddot{y} - x^2 = 0, \qquad \dot{y} + \lambda x - x^3 = 0 \qquad (\dot{x} = dx/dt, \text{etc.}).$$

It is easily seen that the auxiliary matrix

$$T(\lambda, \omega) = \begin{pmatrix} -\omega^2 + 1 & \omega^2 \\ \lambda & i\omega \end{pmatrix}$$

is singular for $\lambda_0 = 0$ and $\omega_0 = 1$, and that all conditions of Theorem 1 are satisfied with $\langle T_\lambda \rangle / \langle T_\omega \rangle = -i$. The spaces V and V' are spanned by

$$\begin{pmatrix} \cos\tau \\ 0 \end{pmatrix}, \begin{pmatrix} \sin\tau \\ 0 \end{pmatrix} \quad \text{and} \quad \frac{1}{\sqrt{2}}\begin{pmatrix} \cos\tau \\ \sin\tau \end{pmatrix}, \frac{1}{\sqrt{2}}\begin{pmatrix} -\sin\tau \\ \cos\tau \end{pmatrix}$$

respectively. An alternative theorem from (15) requires

$$\lambda_1 \langle T_\lambda \rangle + \omega_1 \langle T_\omega \rangle = 0$$

which gives

$$\lambda_1 = \omega_1 = 0$$

and then (neglecting for simplicity an independent solution with $y = \text{const.}$)

$$x_{(2)}(\tau) = \frac{1}{6}\begin{pmatrix} 3 - \cos 2\tau \\ 0 \end{pmatrix}.$$

At the third step, the solvability condition can be satisfied, as before, by fixing λ_2 and ω_2; we thus obtain, summarizing:

$$x(s,\tau)=\begin{pmatrix} s\cos\tau+\dfrac{s^2}{6}(3-\cos 2\tau)-\dfrac{s^3}{96}(2\cos 3\tau+9\sin 3\tau)+\cdots \\ -\dfrac{s^3}{12}\sin 3\tau+\cdots \end{pmatrix},$$

$$\lambda=-\tfrac{3}{4}s^2+\cdots,\qquad \omega=1+\tfrac{5}{12}s^2+\cdots,\qquad \tau=\omega t.$$

It can be easily seen that the equation for $x_n(\tau)$ obtained at the nth step is not very different from (15). Then one can be easily convinced that our assumptions guarantee that each step can be completed, and that this method works for any other example as well.

5. Symmetry properties. All systems as (1), being "autonomous," exhibit in a natural way a "covariance" with respect to the group SO_2 (isomorphic to the circle group S^1) of the "time translations" $\tau\to\tau+\tau'(\bmod 2\pi)$ [7], [20], [22]. Let us recall that a map $F:R\times X\to X'$, where X, X' are topological vector spaces, is said to be covariant with respect to a topological group G [20]-[22], if there exist two continuous representations D and D' of G, acting on X and X' respectively, such that, for any $\lambda\in R$, $x\in X$ and $g\in G$,

$$F(\lambda, D(g)x)=D'(g)F(\lambda,x). \tag{16}$$

It can be shown [20]-[22], [5] that covariance is inherited by the bifurcation equation (10), and that the kernel V of the linearized map $F_x(\lambda,0)$ is an invariant subspace under the group action. In our cases, this implies that the two-dimensional space V is the basis space of a real irreducible representation of SO_2; therefore, all unit vectors in V are equivalent, in the sense that they belong to the same orbit under SO_2 (changing the choice of $\hat{v}$ corresponds to choose another origin for the time τ).

Another consequence is that, exactly as in Hopf bifurcation [11], λ and ω are *even* functions of s:

$$\lambda(s)=\lambda(-s),\qquad \omega(s)=\omega(-s).$$

In fact, after a time $\tau=\pi$, one has $s\hat{v}\,e^{i\tau}\to -s\hat{v}\,e^{i\tau}$, and then, from covariance of (10)

$$\psi(\lambda,\omega,s)=\psi(\lambda,\omega,-s)$$

which proves the assertion. The same result is confirmed by the iterative method used in the previous section: it suffices to observe that the odd-order coefficients λ_{2m-1}, ω_{2m-1} in the expansion (15) are determined, via solvability condition, by the projection on V' of the terms of order $2m$ in the s-power expansion of the nonlinear part $H(\lambda,x)$, and take into account the computation rule (12).

As a final remark, let us consider the case in which the system (1) contains only even-order derivatives: in this case, both quantities $\langle T_\lambda\rangle$ and $\langle T_\omega\rangle$ are real, and the condition stated in Theorem 1 cannot be satisfied. However, in this case, the covariance of the problem is larger: it is described in fact by the whole group O_2 (i.e., it includes time inversion $\tau\to-\tau$). In this case, by restricting e.g. the problem to the subspace of even functions (with respect to time inversion), one can easily reduce the bifurcation equation, as a consequence of symmetry, to a standard one-dimensional case [4], [7], [20]-[22], [5], and then apply classical arguments [4].

6. Stability of the bifurcating periodic solution. We will give now a readily applicable criterion for finding the "critical" Floquet exponent [11], [19] governing the linearized stability of the periodic bifurcated solution (5). Assuming here that $A_k(\lambda)$ is invertible in a neighbourhood of λ_0, and introducing the vector variables

$$x_1=x,\quad x_2=\frac{dx_1}{dt},\quad \cdots,\quad x_k=\frac{dx_{k-1}}{dt}, \qquad u\equiv(x_1,\cdots,x_k)\in R^{kn}, \tag{17}$$

system (1) becomes equivalent to

$$\frac{du}{dt}=M(\lambda)u+K(\lambda,u) \tag{18}$$

with

$$M(\lambda)=\left(\begin{array}{c|cccc} & I & & & 0\\ 0 & & \ddots & & \\ & 0 & & & I\\ \hline B_0 & B_1 & & \cdots & B_{k-1}\end{array}\right)$$

where I is the unit $n\times n$ matrix, and

$$B_j=B_j(\lambda)=-A_k^{-1}(\lambda)A_j(\lambda)\qquad (j=0,\cdots,k-1),$$

$$K=K(\lambda,u)=\begin{pmatrix}\vdots\\ 0\\ \vdots\\ -A_k^{-1}(\lambda)H(\lambda,x_1)\end{pmatrix}.$$

For the problem (18), the Floquet exponent [11], at the lowest order of the parameter s, is given by

$$\gamma=-s\frac{d\lambda}{ds}\operatorname{Re}\frac{d\rho}{d\lambda}=-2s^2\lambda_2\operatorname{Re}\frac{d\rho}{d\lambda} \tag{19}$$

where $\rho=\rho(\lambda)$ is the critical branch of the eigenvalues of the matrix M, with $\rho(\lambda_0)=i\omega_0$, and derivatives are evaluated at $\lambda=\lambda_0$.

We can now state the following:

THEOREM 2. *The sign of the Floquet exponent governing stability of the bifurcating periodic solution* (5) *of the system* (1) *is equal to the sign of the quantity*

$$\delta=\operatorname{Im}(\langle H_3\rangle\overline{\langle T_\omega\rangle}), \tag{20}$$

$\langle T_\omega\rangle$ *being defined in* (4) *and*

$$\langle H_3\rangle=\frac{1}{\pi}\int_0^{2\pi}(H_{(3)}(\tau),\zeta')\,e^{-i\tau}\,d\tau,$$

where $H_3(\tau)$ is the third-order term in the s-power expansion of the nonlinear part $H(\lambda,x)$, and all other assumptions are as in Theorem 1. *Therefore, $\delta<0$ (>0) corresponds to linearized stability* (*instability*).

Proof. Let us denote by η, $\eta'\in C^{kn}$ the critical eigenvectors of the matrix $M(\lambda_0)$:

$$M(\lambda_0)\eta=i\omega_0\eta,\qquad M^+(\lambda_0)\eta'=-i\omega_0\eta'.$$

One can see that (apart from normalization factors) η and η' are given, in terms of vectors ζ, ζ' (3), by

$$\eta = \begin{pmatrix} \zeta \\ (i\omega_0)\zeta \\ (i\omega_0)^2\zeta \\ \vdots \\ (i\omega_0)^{k-1}\zeta \end{pmatrix}$$

and

$$\eta' = \begin{pmatrix} \dfrac{-1}{(-i\omega_0)} A_0^+\zeta' \\ \dfrac{-1}{(-i\omega_0)^2}[A_0^+ + (-i\omega_0)A_1^+]\zeta' \\ \vdots \\ \dfrac{-1}{(-i\omega_0)^{k-1}}[A_0^+ + (-i\omega_0)A_1^+ + \cdots + (-i\omega_0)^{k-2}A_{k-2}^+]\zeta' \\ A_k^+\zeta' \end{pmatrix}$$

and verify, after some calculations, that

$$(\eta, \eta') = -i\langle T_\omega\rangle, \qquad \left(\frac{\partial M}{\partial\lambda}\eta, \eta'\right) = -\langle T_\lambda\rangle, \qquad \left(\frac{\partial M}{\partial\lambda}\eta, \eta'\right) = \frac{d\rho}{d\lambda}(\eta, \eta');$$

then

$$\text{(21)} \qquad \operatorname{Re}\frac{d\rho}{d\lambda} = \operatorname{Im}\frac{\langle T_\lambda\rangle}{\langle T_\omega\rangle}.$$

Now using methods of § 4, from the solvability condition

$$\lambda_2\langle T_\lambda\rangle + \omega_2\langle T_\omega\rangle + \langle H_3\rangle = 0,$$

one gets

$$\text{(22)} \qquad \lambda_2 = \frac{\operatorname{Im}(\langle H_3\rangle\overline{\langle T_\omega\rangle})}{\operatorname{Im}(\overline{\langle T_\lambda\rangle}\langle T_\omega\rangle)},$$

and finally

$$\gamma = \frac{2s^2}{|\langle T_\omega\rangle|^2}\delta.$$

7. Second example. We will consider here in some detail this second example, writing $x \equiv (x(t), y(t))$:

$$\text{(23)} \qquad \begin{aligned} &\ddot{x} + \dot{y} + 2x + \lambda y - (x+y)(x^2+y^2) = 0, \\ &\ddot{y} - \dot{x} + 2y - \lambda x + (x-y)(x^2+y^2) = 0 \end{aligned}$$

(which, of course, has the special property of being covariant also with respect to an additional rotation group SO_2 (see § 5; cf. also [7], [14], [15]) acting, for each fixed t, on the vectors $(x(t), y(t))$ through its basic representation). One has now $\lambda_0 = 0$, $\omega_0 = 2$, and $\langle T_\omega\rangle/\langle T_\lambda\rangle = -3i$; the periodic solution is given (exactly) by

$$\text{(24)} \qquad x(t) = \frac{1}{\sqrt{2}}\begin{pmatrix}\cos\omega t \\ \sin\omega t\end{pmatrix}, \quad \lambda = \frac{s^2}{2}, \quad \omega = 2 + \frac{1}{2}(\sqrt{9-2s^2} - 3).$$

In view of Theorem 2, one gets

$$H_{(3)}(\tau)=\frac{1}{2\sqrt{2}}\begin{pmatrix}-\cos\tau-\sin\tau\\ \cos\tau-\sin\tau\end{pmatrix}=\frac{1}{2\sqrt{2}}\operatorname{Re}\begin{pmatrix}-1+i\\ 1+i\end{pmatrix}e^{i\tau}$$

and then, using (12) and Theorem 2,

$$\delta=-\frac{3}{2},\qquad \gamma=-\frac{s^2}{3}$$

corresponding to stability of this solution for small variations of s.

It can be interesting to check these conclusions by directly inspecting the equations governing the small "perturbations" of solution (24): precisely, by writing

$$x(t)=\frac{s}{\sqrt{2}}\begin{pmatrix}\cos\omega t\\ \sin\omega t\end{pmatrix}+\begin{pmatrix}\xi(t)\\ \eta(t)\end{pmatrix},\qquad \lambda=\frac{s^2}{2}$$

and introducing for convenience the two functions

$$f(t)=\xi(t)\cos\omega t+\eta(t)\sin\omega t,$$
$$g(t)=\eta(t)\cos\omega t-\xi(t)\sin\omega t,$$

one can see that f and g obey the equations

$$\dddot{f}+3(3-s^2)\dot{f}+s^2(2\omega-1)f=0,$$
$$\ddot{g}=(1-2\omega)\dot{f}-s^2f.$$

This is sufficient to show that $\xi(t)$ and $\eta(t)$ behave typically according to

$$\xi(t),\ \eta(t)\sim e^{\gamma_i t}$$

where γ_i can be directly evaluated for small s to be[2]

$$\gamma_1=-\frac{s^2}{3}\quad\text{and}\quad \gamma_{2,3}=\pm 3i+\frac{s^2}{6},$$

so, γ_1 confirms the above calculation, whereas the two others correspond to displacements toward nonclosed orbits in the R^2-plane "oscillating" around the periodic solution (24). Alternatively, the various aspects of this discussion can be viewed writing (23) in polar coordinates r, θ. In this way one can obtain e.g. that

$$\text{(25a)}\qquad r^2\dot{\theta}-\tfrac{1}{2}r^2=C=\text{const},$$

$$\text{(25b)}\qquad \ddot{r}=-\frac{9}{4}r+r^3+\frac{C^2}{r^3};$$

then the "equilibrium solution" $r=r_0$ of (25b) requires through (25a)

$$\dot{\theta}=\text{const}=\frac{1}{2}+\left(\frac{9}{4}-r_0^2\right)^{1/2}$$

which is just (24) with $\dot{\theta}=\omega$ and $r_0=s/\sqrt{2}$.

8. Some generalizations. One of the hypotheses of Theorem 1 was that the kernel of $T_0=T(\lambda_0,\omega_0)$ is one-dimensional (in C^n). If the system (1) is covariant under some "external" symmetry group G (i.e. a group acting on the vectors $x\in R^n$ for each fixed

[2] Apart from the value $\gamma_0=0$, always present in these cases, as is well known [11].

t, not only through the time translations considered in § 5), this hypothesis is usually not verified; but it can happen that some group-theoretical consideration allows us to restrict the problem to some subspace where the initial hypothesis is recovered. The situation is completely similar to the one considered in full detail in [7] for the case of Hopf bifurcation. Referring for a more complete description of the group-theoretical situation to [7], we briefly state the assumption in this form:

(G) Let system (1) be covariant under a symmetry group G, as in (16), with $D=D'$. Suppose that there is an isotropy subgroup $\tilde{G}$ in G and a two-dimensional (in the real sense) subspace $U \subset R^n$ such that

$$D(\tilde{g})u=u \quad \text{for all } \tilde{g} \in \tilde{G}, \quad u \in U$$

and that no other vector in R^n is left fixed by $D(\tilde{G})$.

The following result needs then no further comment:

THEOREM 3. *Let system* (1) *satisfy assumption* (G); *then the restriction* $T_0|_U$ *maps* U *in itself, and if all other assumptions in Theorem* 1 *are verified by this restriction, the same conclusions are true.*

Another crucial point is the classical Hopf "transversality condition": in particular, it was proved in § 3 that our hypothesis concerning the two scalar products (4) is equivalent—in the case of first-order systems—to this condition. However, even if transversality is *not* satisfied, it is known [1], [3], [13], [16], [18] that suitable assumptions concerning a well defined change in the stability property of the solution $x \equiv 0$ can ensure the existence of a nontrivial bifurcation. Combining these ideas with symmetry properties, we get the following result, which we state for first-order normal systems.

THEOREM 4. *Let system* (1) *be of order* 1, *with*

$$L(\lambda)=\frac{d}{dt}+A_0(\lambda),$$

and satisfy assumption (G). *Denoting by* $\tilde{F}=\tilde{F}(\lambda, u)$ *the restriction of* F *to* $R \times U$, *suppose now that a positively definite (continuously differentiable, for simplicity) Lyapunov function* $V: U \to R$ *can be defined in a neighbourhood of* $u=0$ *in such a way that its time derivative*

$$\frac{dV}{dt}=\partial_u V \cdot \tilde{F}$$

is negatively definite for $\lambda=\lambda_0$, *but when* $\lambda>\lambda_0$ *it becomes positively definite. Suppose finally that* $\tilde{F}(\lambda, u) \neq 0$ *for all* $u \neq 0$ *in a neighbourhood of* $u=0$ *and* $\lambda>\lambda_0$: *then for* $\lambda>\lambda_0$ *there exists a bifurcating invariant set. This set is in general an annular region (possibly reduced to a single periodic cycle) around the origin* $u=0$, *and stable under perturbations belonging to* U.

Proof. By assumption (G), we can restrict the problem to the subspace U. Assumptions on the Lyapunov function V imply that the trivial solution $u=0$ is asymptotically stable for $\lambda=\lambda_0$ and becomes completely unstable for $\lambda>\lambda_0$; then (see [1], [3], [13], [16], [18]) there exists a stable bifurcating set in U. For classical Bendixson theorems, being U a two-dimensional real space and having locally $\tilde{F}$ no critical points other than $u=0$, this bifurcating set has all the mentioned properties.

Just for illustrating the idea, consider the following example. Let $x \in R^m$, $y \in R^m$, with $m=9$, be 4×4 real symmetric traceless matrices; let $G=\mathrm{SO}_4$ act irreducibly on the space R^9 according to the rule (in matrix notation)

$$x \to gxg^t, \qquad g \in G \tag{26}$$

and on the space $R^9 \oplus R^9$ according to the "diagonal" direct sum of the transformation rule (26). Consider the system, covariant with respect to this representation of G

$$\dot{x} = \lambda^3 x - \lambda y + \partial_x(\det x),$$

$$\dot{y} = \lambda x + \lambda^3 x + \partial_y(\det y).$$

The two-dimensional subspace U is generated by the two vectors $\tilde{x}$, $\tilde{y}$ lying along the direction of the diagonal matrix (cf. [5])

$$\tilde{e} = \frac{1}{3\sqrt{2}} \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & -3 \end{pmatrix}.$$

Even if restricted to this subspace, standard Hopf theory cannot be applied (nor Theorem 1, being now $T_0 \equiv 0$); in fact for $\lambda = \lambda_0 = 0$ transversality is not verified and, in addition, $\omega_0 = \operatorname{Im} \sigma(0) = 0$. However, denoting now by $\tilde{x}$, $\tilde{y}$ (instead of the vectors) their projections along the direction $\tilde{e}$, and choosing the Lyapunov function

$$V = \tfrac{1}{2}(\tilde{x}^2 + \tilde{y}^2),$$

which gives

$$\frac{dV}{dt} = \lambda^3(\tilde{x}^2 + \tilde{y}^2) - \frac{1}{48}(\tilde{x}^4 + \tilde{y}^4),$$

all hypotheses of Theorem 4 are verified, and in fact one can see that a periodic solution bifurcates from $\lambda_0 = 0$. Clearly, under the action of the group G, this solution generates orbits of equivalent solutions.

Note of course that, in this example, it is impossible to extend the function V to the whole space in such a way that the required properties of dV/dt are preserved; also in this case, therefore, symmetry plays an important role.

AN EXPLICIT SOLUTION OF THE INVERSE PERIODIC PROBLEM FOR HILL'S EQUATION*

ALLAN FINKEL†, ELI ISAACSON‡ AND EUGENE TRUBOWITZ§

Abstract. Let the periodic spectrum of the Hill's operator $-d^2/dx^2+p(x)$ have n nonzero gaps. We give explicit formulas for the isospectral manifold of operators $-d^2/dx^2+q(x)$ having the same spectrum. This allows us to realize the isospectral manifold explicitly as a torus. What makes this possible is an explicit solution of the flow

$$\frac{d}{dt}q=\frac{d}{dx}\frac{\partial}{\partial q(x)}\Delta(\lambda,q)\bigg|_{\lambda=\mu_n(q)}$$

introduced by McKean and Trubowitz, where Δ is the discriminant and $\mu_n(q)$ is the nth Dirichlet eigenvalue. The general case (in which there are an infinite number of nonzero gaps) is handled by a limiting process.

Key words. inverse eigenvalue problem, Hill's equation, isospectral manifold, flow on manifold

1. Introduction. Let $-d^2/dx^2+q(x)$ be the Hill's operator with[1] $q\in L^2_{\mathbf{R}}(S^1)$. We give a simple explicit formula for the isospectral manifold of all potentials having the same periodic spectrum as q. The formula, which involves only the Floquet solutions and Dirichlet eigenfunctions of q, represents the isospectral manifold explicitly as a torus.

Its and Matveev [4] and Dubrovin, Matveev, and Novikov [3] have given another formula which involves the directional derivative of the theta function for the Jacobi variety associated with q. Our formula involves no algebraic geometry but cannot be used to solve the KdV flow explicitly.

Before stating our results we fix our notation. Let $y_1(x,\lambda,q)$, $y_2(x,\lambda,q)$ be the solutions of

$$-y''+q(x)y=\lambda y \qquad (-\infty<x<\infty)$$

with[2]

$$y_1(0)=y_2'(0)=1,$$
$$y_1'(0)=y_2(0)=0.$$

[1] $L^2_{\mathbf{R}}(S^1)$ is the Hilbert space of real-valued square integrable functions of period 1 with the norm $\|f\|^2=\int_0^1|f(x)|^2\,dx$.

[2] x,λ, or q will often be suppressed.

The discriminant is given by

$$\Delta(\lambda,q)\equiv y_1(1,\lambda,q)+y_2'(1,\lambda,q).$$

The zeros

$$\lambda_0(q)<\lambda_1(q)\leqq\lambda_2(q)<\cdots,$$

of $\Delta^2(\lambda)-4$ are the eigenvalues of $-d^2/dx^2+q(x)$ with eigenfunctions of period 2; equality means that $\lambda_{2n-1}=\lambda_{2n}$ is equivalently a double zero or a double eigenvalue. Moreover, $\Delta(\lambda_0)=+2$ and the corresponding eigenfunction is periodic, while $\Delta(\lambda_{2n-1})=\Delta(\lambda_{2n})=2(-1)^n$ $(n\geqq 1)$ and the corresponding eigenfunctions are periodic when n is even and antiperiodic when n is odd.[3]

The Floquet multipliers and corresponding Floquet solutions are

$$m_\pm(\lambda,q)\equiv\frac{\Delta(\lambda)}{2}\pm\frac{1}{2}(\Delta^2(\lambda)-4)^{1/2}$$

and

$$\begin{aligned}f_\pm(x,\lambda,q)&\equiv y_1(x,\lambda,q)+\left[\frac{m_\pm-y_1(1,\lambda)}{y_2(1,\lambda)}\right]y_2(x,\lambda,q)\\&=y_1(x,\lambda,q)+\left[\frac{y_1'(1,\lambda)}{m_\pm-y_2'(1,\lambda)}\right]y_2(x,\lambda,q),\end{aligned}$$

respectively. We note that

$$f_\pm(x+1,\lambda)=m_\pm(\lambda)f_\pm(x,\lambda)$$

so that $f_\pm(x,\lambda_n)$ is an eigenfunction when it is well defined. Also,[4]

$$\frac{\partial\Delta(\lambda)}{\partial q(x)}=y_2(1,\lambda)f_+(x,\lambda)f_-(x,\lambda).$$

The zeros

$$\mu_1(q)<\mu_2(q)<\cdots$$

of $y_2(1,\lambda,q)$ are the Dirichlet eigenvalues of q; i.e., there is a nontrivial solution of

$$-y''+q(x)y=\mu_n y$$

with $y(0)=y(1)=0$. The normalized Dirichlet eigenfunction corresponding to $\mu_n(q)$ is[5]

$$g_n(x,q)\equiv\frac{y_2(x,\mu_n(q),q)}{(\dot{y}_2(1,\mu_n)y_2'(1,\mu_n))^{1/2}}\qquad(n\geqq 1).$$

[3] The function f is periodic if $f(x+1)=f(x)$ and antiperiodic if $f(x+1)=-f(x)$.

[4] The gradient $\partial\Delta(\lambda,q)/\partial q(x)$ is defined to be the kernel of the directional derivative of $\Delta(\lambda,q)$; i.e.,

$$\frac{d}{d\varepsilon}\Delta(\lambda,q+\varepsilon v)\bigg|_{\varepsilon=0}=\int_0^1\frac{\partial\Delta(\lambda,q)}{\partial q(x)}v(x)\,dx$$

for all $v\in L^2_{\mathbf{R}}(S^1)$.

[5] $\cdot\equiv\partial/\partial\lambda$.

The Dirichlet eigenvalues interlace the periodic eigenvalues: $\lambda_{2n-1} \leqq \mu_n \leqq \lambda_{2n}$ $(n \geqq 1)$. Details can be found in [1], [6].

Fix $p \in L^2_{\mathbf{R}}(S^1)$ and define the isospectral manifold

$$L(p) \equiv \{q \in L^2_{\mathbf{R}}(S^1)\colon \lambda_n(q) = \lambda_n(p),\ n \geqq 0\}.$$

Then $q \in L(p)$ if and only if $\Delta(\lambda, q) = \Delta(\lambda, p)$ for all λ. Furthermore, McKean and Trubowitz [7] have shown that $L(p)$ is a (generically infinite dimensional) torus.

The isospectral manifold is realized as a product of circles as follows (see [7]). The map $q \in L^2_{\mathbf{R}}[0,1] \to (\mu_n(q), y_1(1, \mu_n(q), q); n \geqq 1)$ is one-to-one by a theorem of Borg.[6] However, $y_1(1, \mu_n, q) = \Delta(\mu_n)/2 \pm \frac{1}{2}(\Delta^2(\mu_n) - 4)^{1/2}$ for an appropriate choice of the sign. Since $\Delta(\lambda)$ is the same for each $q \in L(p)$, it follows that the map

$$q \in L(p) \to (\mathbf{p}_n(q), n \geqq 1)$$

is one-to-one where

$$\mathbf{p}_n(q) \equiv (\mu_n(q), \sigma_n(q)) \qquad (n \geqq 1)$$

and $\sigma_n(q) \in \{\pm\}$ is the sign of the radical in $y_1(1, \mu_n(q), q)$. Thus, $L(p)$ is mapped into the product of circles in Fig. 1.

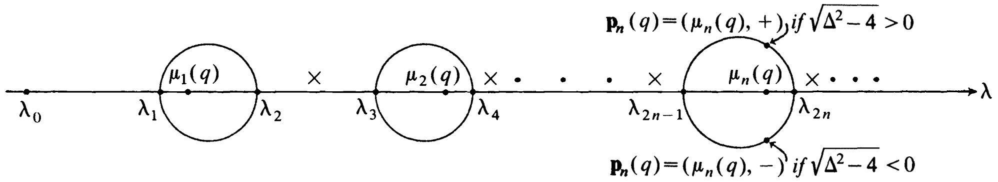

FIG. 1

McKean and Trubowitz show in addition that the map is onto and therefore a homeomorphism. Our main result is a concrete realization of this map. In fact in Theorems 1 and 2 we give a simple explicit construction of $L(p)$ in terms of p and $y_i(x, \lambda, p)$ $(i = 1, 2)$. Theorem 1 covers the case of finitely many gaps, and Theorem 2 covers the general case.

THEOREM 1. *Let* $p \in L^2_{\mathbf{R}}(S^1)$, $\tilde{\mathbf{p}}_i = (\omega_i, s_i) \in [\lambda_{2i-1}, \lambda_{2i}] \times \{\pm\}$ *be a point in the ith circle* $(1 \leqq i \leqq n)$, *and set*

$$\text{(1a)} \qquad q(x, \tilde{\mathbf{p}}_1, \cdots, \tilde{\mathbf{p}}_n) \equiv p(x) - 2\frac{d^2}{dx^2}\log W(f_1, g_1, f_2, g_2, \cdots, f_n, g_n)$$

where $f_i \equiv f_{s_i}(x, \omega_i, p)$, $g_i \equiv g_i(x, p)$, *and W denotes the Wronskian. Then q is the unique point in* $L(p)$ *with*

$$\text{(1b)} \qquad \mathbf{p}_i(q) = \begin{cases} \tilde{\mathbf{p}}_i, & 1 \leqq i \leqq n, \\ \mathbf{p}_i(p), & i > n. \end{cases}$$

In particular, $L(p)$ *is homeomorphic to an n-dimensional torus when p has n nonzero gaps.*

[6] Levinson [5] has shown that the map $q \in L^2_{\mathbf{R}}[0,1] \to (\mu_n(q), y_2'(1, \mu_n(q), q); n \geqq 1)$ is one-to-one, and the equality $y_1(1, \mu_n) = 1/y_2'(1, \mu_n)$ follows from the Wronskian identity.

Remark. The Wronskian is defined by

$$W(f_1,g_1,\cdots,f_n,g_n)\equiv$$

$$\det\begin{vmatrix} f_1 & g_1 & \cdots & f_n & g_n \\ f_1' & g_1' & \cdots & f_n' & g_n' \\ -\omega_1 f_1 & -\mu_1 g_1 & \cdots & -\omega_n f_n & -\mu_n g_n \\ -\omega_1 f_1' & -\mu_1 g_1' & \cdots & -\omega_n f_n' & -\mu_n g_n' \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ (-\omega_1)^{n-1} f_1 & (-\mu_1)^{n-1} g_1 & \cdots & (-\omega_n)^{n-1} f_n & (-\mu_n)^{n-1} g_n \\ (-\omega_1)^{n-1} f_1' & (-\mu_1)^{n-1} g_1' & \cdots & (-\omega_n)^{n-1} f_n' & (-\mu_n)^{n-1} g_n' \end{vmatrix}.$$

The standard definition is not used because p is only in $L^2_{\mathbf{R}}(S^1)$. The definition above can be obtained from the standard definition when p is sufficiently smooth by using the differential equations for f,g to eliminate the higher order derivatives.

The final conclusion of Theorem 1 follows from (1). In fact, $\mathbf{p}_i(q)=\mathbf{p}_i(p)$ whenever $q\in L(p)$ and $\lambda_{2i-1}=\lambda_{2i}$. Therefore, the map $q\in L(p)\to(\mathbf{p}_i(q),i\geqq 1)$, which is one-to-one by Borg's theorem, is onto by formula (1). Consequently, formula (1) gives an explicit construction of all points on $L(p)$.

The remainder of the proof of Theorem 1 is given in §3. The proof depends on the solution of certain flows on $L(p)$ described in §2. Theorem 2 will also be proven in §3.

THEOREM 2. *Let* $p\in L^2_{\mathbf{R}}(S^1)$, *and let* $\tilde{\mathbf{p}}_i=(\omega_i,s_i)\in[\lambda_{2i-1},\lambda_{2i}]\times\{\pm\}$ $(i\geqq 1)$ *be a point on the ith circle. Then the sequence*

$$q_n(x)\equiv p(x)-2\frac{d^2}{dx^2}\log W(f_1,g_1,\cdots,f_n,g_n) \tag{2a}$$

converges strongly in $L^2_{\mathbf{R}}(S^1)$ *to the unique point* $q\in L(p)$ *with*

$$\mathbf{p}_i(q)=\tilde{\mathbf{p}}_i \qquad (i\geqq 1). \tag{2b}$$

This result exhibits every point in $L(p)$ as the (strong) limit of an appropriate sequence constructed explicitly from $y_i(x,\lambda,p)(i=1,2)$ and the parameters on the torus. This gives another proof that the continuous, one-to-one map $q\in L(p)\to(\mathbf{p}_i(q),i\geqq 1)$ is also onto. That is, $L(p)$ is homeomorphic to a torus.

2. Some flows on $L(p)$. In order to obtain formula (1), we find an exact solution of the differential equation

$$\frac{d}{dt}q(x,t)=\frac{d}{dx}\left.\frac{\partial}{\partial q(x)}\Delta(\lambda,q(\cdot,t))\right|_{\lambda=\mu_n(q(\cdot,t))} \tag{3}$$

which was studied in [7]. Theorem 3 shows that this differential equation generates a flow on $L(p)$. In Theorem 4 we solve (3) explicitly, and in Theorem 5 we eliminate the time parameter to obtain a formula for certain points on $L(p)$.

THEOREM 3. *Let* $p\in L^2_{\mathbf{R}}(S^1)$. *Then*

$$Z_n(q)\equiv\frac{d}{dx}\left.\frac{\partial\Delta(\lambda,q)}{\partial q(x)}\right|_{\lambda=\mu_n(q)}$$

is a vector field on $L(p)$. That is, a solution of the differential equation

$$\frac{d}{dt}q(x,t)=\frac{d}{dx}\frac{\partial\Delta(\lambda)}{\partial q(x)}\bigg|_{\lambda=\mu_n(q(\cdot,t))}$$

with initial data in $L(p)$ stays in $L(p)$ for all time.

This flow was described first in [7] where the following geometric picture is given. Under the flow Z_n the point $\mathbf{p}_i(q(\cdot,t))$ $(i\neq n)$ remains fixed on its circle, while the point $\mathbf{p}_n(q(\cdot,t))$ moves clockwise around its circle without pausing. It moves in such a way that

$$\frac{d\mu_n}{dt}=\frac{1}{2}\left(\Delta^2(\mu_n)-4\right)^{1/2},$$

the radical having the sign of $\mathbf{p}_n(q(\cdot,t))$.

Proof of Theorem 3. Let $q(x,t)$ solve the differential equation

$$\frac{d}{dt}q(x,t)=\frac{d}{dx}\frac{\partial\Delta(\mu)}{\partial q(x)}\bigg|_{\mu=\mu_n(q(\cdot,t))}$$

with $q(x,0)\in L(p)$. We show that $\frac{d}{dt}\Delta(\lambda,q(\cdot,t))=0$ so that $\Delta(\lambda,q(\cdot,t))=\Delta(\lambda,q(\cdot,0))$ for all $\lambda\in C$. Indeed,

$$\begin{aligned}\frac{d}{dt}\Delta(\lambda,q(\cdot,t))&=\int_0^1\frac{\partial}{\partial q(x)}\Delta(\lambda,q(\cdot,t))\frac{dq}{dt}\,dx\\&=\int_0^1\frac{\partial\Delta(\lambda)}{\partial q(x)}\frac{d}{dx}\frac{\partial\Delta(\mu)}{\partial q(x)}\bigg|_{\mu=\mu_n(q(\cdot,t))}dx,\end{aligned}$$

and we need only show that

$$\int_0^1\frac{\partial\Delta(\lambda,q)}{\partial q(x)}\frac{d}{dx}\frac{\partial\Delta(\lambda',q)}{\partial q(x)}\,dx=0$$

for all $\lambda,\lambda'\in C$ and all $q\in L^2_{\mathbf{R}}(S^1)$. Now, for $\lambda,\lambda'\neq\mu_i(q)$ $(i\geq 1)$ and $\lambda\neq\lambda'$ we have

$$\begin{aligned}&2\int_0^1\frac{\partial\Delta(\lambda)}{\partial q(x)}\frac{d}{dx}\frac{\partial\Delta(\lambda')}{\partial q(x)}\,dx\\&=2\int_0^1 y_2(1,\lambda)f_+(x,\lambda)f_-(x,\lambda)\frac{d}{dx}\left(y_2(1,\lambda')f_+(x,\lambda')f_-(x,\lambda')\right)dx\\&=y_2(1,\lambda)y_2(1,\lambda')\int_0^1\bigg[f_+(x,\lambda)f_-(x,\lambda)\frac{d}{dx}\left(f_+(x,\lambda')f_-(x,\lambda')\right)\\&\qquad\qquad-f_+(x,\lambda')f_-(x,\lambda')\frac{d}{dx}\left(f_+(x,\lambda)f_-(x,\lambda)\right)\bigg]dx\\&=\frac{y_2(1,\lambda)y_2(1,\lambda')}{\lambda-\lambda'}\int_0^1\frac{d}{dx}\left(W\left(f_+(x,\lambda),f_+(x,\lambda')\right)W\left(f_-(x,\lambda),f_-(x,\lambda')\right)\right)dx\\&=0.\end{aligned}$$

The extension to λ, $\lambda'=\mu_i$ $(i\geq 1)$ and $\lambda=\lambda'$ follows from continuity.

THEOREM 4. *Let $q_0\in L(p)$, and let $\mu_n(t)$ denote the unique solution of*

$$\frac{d}{dt}\mu_n=\frac{1}{2}\left(\Delta^2(\mu_n)-4\right)^{1/2}$$

for which the point $\mathbf{p}_n(t) \equiv (\mu_n(t), \sigma_n(t))$ *starts at* $\mathbf{p}_n(q_0)$ *and moves clockwise around its circle without pausing. Then*

$$q(x,t) = q_0(x) - 2\frac{d^2}{dx^2}\log W\left[f_{\sigma_n(t)}(x,\mu_n(t),q_0), g_n(x,q_0)\right]$$

is the integral curve of Z_n *passing through* q_0.

The sign of the radical in the differential equation is taken to be $\sigma_n(t)$. The requirements on $\mathbf{p}_n(t)$ actually determine $\sigma_n(t)$ in addition to specifying a unique solution.

Proof of Theorem 4. We show first that $\chi(x,\mu) \equiv W(f_+(x,\mu), g_n(x))$ does not vanish for $\lambda_{2n-1} \leqq \mu \leqq \lambda_{2n}$. The proof for f_- is similar. It can be shown that $\chi(x,\mu_n)$, $\chi(0,\mu)$, $\chi(1,\mu)$ are all positive. Therefore, if $\chi(x,\mu)=0$, then there is a μ closest to μ_n for which χ vanishes, say $\chi(x^0,\mu^0)=0$. It follows that $(d/dx)\chi(x^0,\mu^0)$ also vanishes. These two conditions imply that $f_+(x^0,\mu^0)=0$ and $g_n(x^0)=0$. But this is impossible because both $f_+(x+x^0,\mu^0)$ and $g_n(x+x^0)$ would be Dirichlet eigenfunctions for the translated potential $q(x+x^0)$ with corresponding eigenvalues μ^0, μ_n lying in the same gap $[\lambda_{2n-1}, \lambda_{2n}]$.

To complete the proof we show that

$$\frac{dq}{dt}(x,t) = \frac{d}{dx}\frac{\partial}{\partial q(x)}\Delta(\mu, q(\cdot,t))\bigg|_{\mu=\mu_n(t)}.$$

It can be shown that

$$\frac{d}{dt}q(x,t) = -2\frac{d}{dx}\frac{g_n(x)}{W(f_{\sigma_n},g_n)}\left[f_{\sigma_n} + (\mu_n(t)-\mu_n)\frac{g_n(x)}{W(f_{\sigma_n},g_n)}W(f_{\sigma_n},\dot{f}_{\sigma_n})\right]\frac{d\mu_n(t)}{dt},$$

$$y_2(x,\mu_n(t),q(\cdot,t)) = \frac{g_n(x)}{W(f_{\sigma_n},g_n)},$$

and

$$f_{\sigma_n}(x,\mu_n(t),q(\cdot,t)) = f_{\sigma_n}(x,\mu_n(t)) + (\mu_n(t)-\mu_n)\frac{g_n(x)}{W(f_{\sigma_n},g_n)}\;W(f_{\sigma_n},\dot{f}_{\sigma_n})\big|_{q(\cdot,0)}.$$

Therefore

$$\begin{aligned}\frac{d}{dt}q(x,t) &= -2\frac{d}{dx}y_2(x,\mu_n(t))f_{\sigma_n}(x,\mu_n(t))\frac{d\mu_n(t)}{dt}\bigg|_{q(\cdot,t)}\\ &= \frac{d}{dx}\frac{\partial}{\partial q(x)}\Delta(\mu,q(\cdot,t))\bigg|_{\mu=\mu_n(t)}\end{aligned}$$

since

$$\frac{d\mu_n(t)}{dt} = \frac{1}{2}\left(y_1(1,\mu_n(t)) - y_2'(1,\mu_n(t))\right)\bigg|_{q(\cdot,t)},$$

so that in the limit $\mu \to \mu_n(t)$

$$-y_2(x,\mu_n(t))\frac{d\mu_n(t)}{dt} = y_2(1,\mu_n(t))f_{-\sigma_n}(x,\mu_n(t)).$$

THEOREM 5. *Let* $\tilde{\mathbf{p}}_n=(\omega_n,s_n)\in[\lambda_{2n-1},\lambda_{2n}]\times\{\pm\}$ *be a point in the nth circle. Then*

$$q(x,\tilde{\mathbf{p}}_n)\equiv p(x)-2\frac{d^2}{dx^2}\log W\left[f_{s_n}(x,\omega_n,p),g_n(x,p)\right]$$

is the unique point in $L(p)$ *with*

$$\mathbf{p}_i(q(\cdot,\tilde{\mathbf{p}}_n))=\begin{cases}\mathbf{p}_i(p), & i\neq n,\\ \tilde{\mathbf{p}}_n, & i=n.\end{cases}$$

This result is a straightforward corollary of Theorem 4. It removes the dependence on t allowing us to construct points in $L(p)$ using only the parameters in Borg's theorem and information obtained from p.

3. Proofs of Theorems 1 and 2.

Proof of Theorem 1. We use induction and Theorem 5. Suppose the result holds for some $n\geqq 1$, and let q^k denote the potential satisfying

$$\mathbf{p}_i(q^k)=\begin{cases}\tilde{\mathbf{p}}_i, & 1\leqq i\leqq k,\\ \mathbf{p}_i(p), & i>k.\end{cases}$$

Then by Theorem 5,

$$q^{n+1}=q^n-2\frac{d^2}{dx^2}\log W(f^n_{n+1},g^n_{n+1})$$

where f^n_{n+1},g^n_{n+1} are the Floquet solution and Dirichlet eigenfunction of q^n. Thus,

$$q^{n+1}=p-2\frac{d^2}{dx^2}\log W(f_1,g_1,\cdots,f_n,g_n)-2\frac{d^2}{dx^2}\log W(f^n_{n+1},g^n_{n+1}). \tag{4}$$

Direct calculation shows that

$$f^n_{n+1}=\frac{W(f_1,g_1,\cdots,f_n,g_n,f_{n+1})}{W(f_1,g_1,\cdots,f_n,g_n)\Pi^n_{j=1}(\omega_j-\omega_{n+1})}, \tag{5}$$

$$y^n_2(x,\mu_{n+1})=\frac{W(f_1,g_1,\cdots,f_n,g_n,y_2(x,\mu_{n+1}))}{W(f_1,g_1,\cdots,f_n,g_n)\Pi^n_{j=1}(\mu_j-\mu_{n+1})}, \tag{6}$$

$$W(f^n_{n+1},y^n_2)=-(y^n_2)^2\frac{d}{dx}\frac{f^n_{n+1}}{y^n_2}, \tag{7}$$

and (see Deift–Trubowitz [2])

(8)

$$W^2(h_1,\cdots,h_n)\frac{d}{dx}\frac{W(h_1,\cdots,h_{n-1},h_{n+1})}{W(h_1,\cdots,h_n)}=W(h_1,\cdots,h_n,h_{n+1})W(h_1,\cdots,h_{n-1}).$$

Consequently, substituting (5) and (6) into (7) and using (8) gives

$$W(f^n_{n+1},y^n_2)=\frac{W(f_1,g_1,\cdots,f_n,g_n,f_{n+1},g_{n+1})}{W(f_1,g_1,\cdots,f_n,g_n)\Pi^n_{j=1}(\omega_j-\omega_{n+1})(\mu_j-\mu_{n+1})}.$$

Combining this with (4) yields the result.

Proof of Theorem 2. First, $\int_0^1 q^2 dx$ is constant on $L(p)$ (see [7]), and $\Delta(\lambda,q)$ is weakly sequentially continuous. Therefore, every subsequence of $\{q_n\}$ has a weakly convergent subsequence which must converge to the point q with $\mathbf{p}_i(q)=\tilde{\mathbf{p}}_i$ $(i\geqq 1)$. Consequently, the original sequence converges weakly to q. The convergence is actually strong since all points in $L(p)$ have the same norm.

OSCILLATORY SECOND ORDER LINEAR DIFFERENCE EQUATIONS AND RICCATI EQUATIONS*

JOHN W. HOOKER†, MAN KAM KWONG‡ AND WILLIAM T. PATULA†

Abstract. Oscillation criteria are established for the equation $c_nx_{n+1}+c_{n-1}x_{n-1}=b_nx_n$, $c_n>0$, involving asymptotic behavior of the quantity $\alpha_{n,m}=4\Pi_{j=0}^{m}(4q_{n+j})^{-1}$, where $q_n=c_n^2/(b_nb_{n+1})$. We also show that the given equation is oscillatory if $y_{n+1}+y_{n-1}=(q_n^{-1}-1)y_n$ is oscillatory. This result is then employed to obtain several new oscillation criteria. Riccati difference equations are used to prove the basic results.

Key words. oscillation, nonoscillation, linear difference equation, Riccati transformation

AMS(MOS) subject classifications. Primary 39A10, 39A12

1. Introduction and main results. In this paper we continue our investigation begun in [4] and [5] of oscillation criteria for solutions of the second-order linear difference equation

$$c_nx_{n+1}+c_{n-1}x_{n-1}=b_nx_n,\qquad n=1,2,3,\cdots,\tag{1.1}$$

with $c_n>0$ and $b_n>0$ for all $n\geqq 0$, using Riccati transformation methods.

This equation models, for example, the amplitude of oscillation of the weights on a discretely weighted vibrating string [1, pp. 15–17]. It is equivalent to the self-adjoint equation

$$-\Delta(c_{n-1}\Delta x_{n-1})+a_nx_n=0,$$

where $a_n=b_n-c_n-c_{n-1}$ and Δ is the forward difference operator $\Delta u_n=u_{n+1}-u_n$. A nontrivial solution of (1.1) is called oscillatory if for every $N>0$ there exists an $n\geqq N$ such that $x_nx_{n+1}\leqq 0$.

Either all nontrivial solutions of (1.1) are oscillatory or none are (see [2, p. 153]), so (1.1) may be classified as oscillatory or nonoscillatory. The assumption $b_n>0$ is made because if $b_{n_k}\leqq 0$ for some subsequence $n_k\to\infty$, then (1.1) clearly must be oscillatory [6, Lemma 3].

Suppose that (1.1) is nonoscillatory, and let $\{x_n\}$, $n\geqq 0$, be a solution of (1.1) such that $x_n>0$, $n\geqq N$, for some N. The substitutions $r_n=x_{n+1}/x_n$, $z_n=c_nx_{n+1}/x_n$ and $s_n=b_{n+1}x_{n+1}/(c_nx_n)$, $n\geqq N$, lead, respectively, to the difference equations

$$c_nr_n+c_{n-1}/r_{n-1}=b_n,\qquad n>N,\tag{1.2}$$

$$z_n+c_{n-1}^2/z_{n-1}=b_n,\qquad n>N,\tag{1.3}$$

and

$$q_ns_n+1/s_{n-1}=1,\qquad n>N,\tag{1.4}$$

where

$$q_n = \frac{c_n^2}{b_n b_{n+1}}, \qquad n \geqq 1. \tag{1.5}$$

Equations (1.2), (1.3), and (1.4) we call equations of Riccati type, since the substitutions which lead to them are discrete analogues of the Riccati transformation for ordinary differential equations. The above remarks lead immediately to the following theorem.

THEOREM 1.1 [4, Thm. 2]. *The following conditions are equivalent.*

(i) *Equation* (1.1) *is nonoscillatory.*

(ii) *Equation* (1.2) *has a positive solution* $\{r_n\}$, $n \geqq N$, *for some* $N > 0$.

(iii) *Equation* (1.3) *has a positive solution* $\{z_n\}$, $n \geqq N$, *for some* $N > 0$.

(iv) *Equation* (1.4) *has a positive solution* $\{s_n\}$, $n \geqq N$, *for some* $N > 0$.

For convenient reference, and because the quantity $q_n = c_n^2/(b_n b_{n+1})$ defined by (1.5) will play a central role in the results below, we restate here in terms of q_n three more theorems proved in [4].

THEOREM 1.2 [4, Thm. 5]. *If* $q_n \geqq 1/(4-\varepsilon)$ *for some* $\varepsilon > 0$, *for all sufficiently large* n, *then* (1.1) *is oscillatory.*

THEOREM 1.3 [4, Thm. 6]. *If* $q_n \leqq \frac{1}{4}$ *for all sufficiently large* n, *then* (1.1) *is nonoscillatory.*

THEOREM 1.4 [4, Thm. 7]. *If* $q_{n_k} \geqq 1$ *for a sequence* $n_k \to \infty$, *then* (1.1) *is oscillatory.*

In [5], the following necessary condition for nonoscillation of (1.1) is presented.

THEOREM 1.5 [5, Thm. 2.3]. *Suppose* (1.1) *is nonoscillatory. Then there exists* $N > 0$ *such that for any* $n \geqq N$ *and any* $m \geqq 0$,

$$q_n q_{n+1} \cdots q_{n+m} < 4^{-m}. \tag{1.6}$$

We can rewrite condition (1.6) as

$$\alpha_{n,m} > 1, \tag{1.7}$$

where $\alpha_{n,m}$ is defined as

$$\alpha_{n,m} = 4 \prod_{j=0}^{m} (4q_{n+j})^{-1}, \qquad n \geqq 1, \quad m \geqq 0. \tag{1.8}$$

The contrapositive of Theorem 1.5 says that (1.1) is oscillatory if for every $K > 0$ there exists $n \geqq K$ such that $\alpha_{n,m} \leqq 1$ for some $m \geqq 0$. Since this statement involves two variables m and n, one can state corollaries in various forms. For example, we have:

COROLLARY 1.1. *If for some* $M \geqq 0$ *there exists a sequence* $n_k \to \infty$ *such that*

$$\alpha_{n_k,M} \leqq 1,$$

then (1.1) *is oscillatory.*

In particular, for $M = 0$, we have $\alpha_{n_k,0} = 1/q_{n_k}$. Thus Corollary 1.1 implies that if $1/q_{n_k} \leqq 1$ for some sequence $n_k \to \infty$, then (1.1) is oscillatory. This is precisely Theorem 1.4, so Corollary 1.1 generalizes that theorem.

The following theorem is also an immediate corollary of Theorem 1.5.

THEOREM 1.6. *If for every* $K > 0$ *there exists* $N \geqq K$ *such that*

$$\liminf_{m \to \infty} \alpha_{N,m} < 1, \tag{1.9}$$

then (1.1) *is oscillatory.*

On the other hand, if condition (1.9) is not satisfied for arbitrarily large N, then (1.1) may or may not be oscillatory, as the following examples show.

Example 1. Consider the equation

$$x_{n+1}+x_{n-1}=2x_n,$$

which has linearly independent solutions $u_n=1$, $v_n=n$, $n=0,1,2,\cdots$. This nonoscillatory example has $q_n=c_n^2/(b_nb_{n+1})\equiv\frac{1}{4}$, and $\alpha_{n,m}\equiv 4$.

Example 2. Consider (1.1) with $c_n\equiv 1$, $b_{2n}=2^{-1}4^{2-n}$, $b_{2n+1}=4^{n-1}$, $n=1,2,3,\cdots$. Then $q_{2n-1}=\frac{1}{2}$, $q_{2n}=\frac{1}{8}$, and it follows that $\alpha_{N,m}=4$ if m is odd, $\alpha_{N,m}=2$ if N is odd and m is even, while $\alpha_{N,m}=8$ if N and m are both even. Thus $\liminf_{m\to\infty}\alpha_{N,m}$ equals 2 if N is odd and 4 if N is even, so (1.9) fails to hold. It was shown in [5, Ex. 2.1] that (1.1) is oscillatory in this example. Indeed, this follows immediately from our next theorem.

These two examples lead us to ask what additional conditions are sufficient for (1.1) to be oscillatory if condition (1.9) is not satisfied. Theorems 1.7–1.9 address this question.

THEOREM 1.7. *If for some* $N>0$,

$$\liminf_{m\to\infty}\alpha_{N,m}\neq\limsup_{m\to\infty}\alpha_{N,m}, \tag{1.10}$$

then (1.1) *is oscillatory.*

(*Note.* If (1.10) holds for some $N>0$, then it holds for all $N>0$ by definition of $\alpha_{n,m}$.)

Proof. Suppose that (1.1) is nonoscillatory. Then by Theorem 1.1 there is a positive sequence s_n which satisfies the Riccati equation (1.4) $q_js_j+s_{j-1}^{-1}=1$ for all sufficiently large j, say $j\geqq N$. By the note following the statement of the theorem, we may take this to be the same value N as in the hypotheses of the theorem. Multiplying (1.4) by q_j^{-1} yields

$$q_j^{-1}=s_j+(q_js_{j-1})^{-1},\qquad j\geqq N, \tag{1.11}$$

so

$$q_j^{-1}q_{j+1}^{-1}=\left(s_j+(q_js_{j-1})^{-1}\right)\left(s_{j+1}+(q_{j+1}s_j)^{-1}\right). \tag{1.12}$$

From (1.12), we obtain

$$q_j^{-1}=q_{j+1}s_js_{j+1}\left(1+(q_js_js_{j-1})^{-1}\right)\left(1+(q_{j+1}s_{j+1}s_j)^{-1}\right),$$

so

$$\begin{aligned} q_j^{-1}&=\left(1+(q_js_js_{j-1})^{-1}\right)(q_{j+1}s_js_{j+1}+1)\\ &=\left(1+\beta_j^{-1}\right)(1+\beta_{j+1}),\qquad j\geqq N, \end{aligned} \tag{1.13}$$

where we define

$$\beta_j=q_js_js_{j-1}.$$

Note that $\beta_j>0$, $j\geqq N$.

From (1.8) and (1.13) we have

$$\alpha_{N,m}=4\prod_{j=0}^{m}4^{-1}\left(1+\beta_{N+j}^{-1}\right)\left(1+\beta_{N+j+1}\right),\qquad m\geqq 0,$$

$$=4\left(1+\beta_N^{-1}\right)\left(1+\beta_{N+m+1}\right)\prod_{i=1}^{m}4^{-1}\left(1+\beta_{N+i}^{-1}\right)\left(1+\beta_{N+i}\right),$$

from which some elementary algebra leads us to

$$\alpha_{N,m}=4\left(1+\beta_N^{-1}\right)\left(1+\beta_{N+m+1}\right)\prod_{i=1}^{m}\left(1+4^{-1}\beta_{N+i}^{-1}(\beta_{N+i}-1)^2\right),$$

for $m\geqq 0$. We rewrite this as

$$\alpha_{N,m}=4\left(1+\beta_N^{-1}\right)\left(1+\beta_{N+m+1}\right)\prod_{i=1}^{m}(1+A_i),\tag{1.14}$$

where

$$A_i=4^{-1}\beta_{N+i}^{-1}(\beta_{N+i}-1)^2\geqq 0,\qquad i\geqq 1.\tag{1.15}$$

Now from the hypotheses we must have $\liminf_{m\to\infty}\alpha_{N,m}<\infty$. Hence there exists a finite bound B such that

$$\alpha_{N,m_k}\leqq B\tag{1.16}$$

for some sequence of subscripts $m_k\to\infty$. Since $\beta_j>0$ for all j, (1.14) and (1.16) imply that

$$\prod_{i=1}^{m_k}(1+A_i)\text{ is bounded.}$$

Since $m_k\to\infty$ and $A_i\geqq 0$, it follows that

$$\prod_{i=1}^{\infty}(1+A_i)\text{ is bounded,}\tag{1.17}$$

which implies that

$$\sum_{i=1}^{\infty}A_i\text{ is finite.}\tag{1.18}$$

Therefore $A_i\to 0$ as $i\to\infty$. Thus, by (1.15) we have

$$\beta_j\to 1\quad\text{as } j\to\infty.\tag{1.19}$$

That is,

$$q_js_js_{j-1}\to 1\quad\text{as } j\to\infty.\tag{1.20}$$

Since $A_i\geqq 0$, (1.14), (1.17), and (1.19) imply that $\lim_{m\to\infty}\alpha_{N,m}$ exists, a contradiction which proves the theorem.

In the next theorem we refer to l^2, the space of square summable sequences. We remark, as in the note following the statement of Theorem 1.7, that if the hypotheses of Theorems 1.8 and 1.9 hold for some $N>0$, they hold for all $N>0$.

THEOREM 1.8. *If* $\liminf_{n\to\infty}\alpha_{N,m}<\infty$ *for some* $N>0$ *and if the sequence* $\{q_j^{-1}-4\}\notin l^2$, *then* (1.1) *is oscillatory.*

Proof. Assume (1.1) is nonoscillatory. Because of the assumption $\liminf\alpha_{N,m}<\infty$, we can proceed as in the proof of Theorem 1.7 to arrive at (1.18) and (1.19), and thus by (1.15) we have

$$\sum_{j=1}^{\infty}(\beta_j-1)^2/(4\beta_j)<\infty. \tag{1.21}$$

Since $\beta_j\to 1$ as $j\to\infty$, it follows from (1.21) that

$$(\beta_j-1)\in l^2. \tag{1.22}$$

Expanding the right side of (1.13) leads to

$$q_j^{-1}=1+\beta_j^{-1}+\beta_{j+1}+\beta_j^{-1}\beta_{j+1},$$

so

$$\begin{aligned} q_j^{-1}-4&=2\beta_j^{-1}-2+\beta_{j+1}-1+\beta_j^{-1}\beta_{j+1}-\beta_j^{-1}\\ &=2\beta_j^{-1}(1-\beta_j)+(\beta_{j+1}-1)+\beta_j^{-1}(\beta_{j+1}-1). \end{aligned} \tag{1.23}$$

By (1.19) and (1.22), each term on the right in (1.23) is in l^2, so $\{q_j^{-1}-4\}\in l^2$. Therefore, if $\{q_j^{-1}-4\}\notin l^2$, (1.1) must be oscillatory, as claimed.

COROLLARY 1.2. *If* $\liminf_{m\to\infty}\alpha_{N,m}<\infty$ *and* $\lim_{j\to\infty}q_j^{-1}\neq 4$, *then* (1.1) *is oscillatory.*

Proof. The condition $\lim_{j\to\infty}q_j^{-1}\neq 4$ implies that $\{q_j^{-1}-4\}\notin l^2$.

In connection with Theorem 1.8 and Corollary 1.2, we again call attention to Example 1 above, a nonoscillatory example with $\lim_{m\to\infty}\alpha_{N,m}=4$ and $q_n\equiv\frac{1}{4}$.

THEOREM 1.9. *If for some* N *the sequence* $\{\alpha_{N,m}\}$ *is eventually monotone increasing in* m, *then* (1.1) *is nonoscillatory.*

Proof. If $\alpha_{N,m}$ is eventually monotone increasing in m, there exists $M>0$ such that for all $m>M$, $\alpha_{N,m}\geqq\alpha_{N,m-1}$. From (1.8), this implies that $q_{N+m}\leqq\frac{1}{4}$ for all $m\geqq M$. Thus (1.1) is nonoscillatory by Theorem 1.3.

The following example shows that the monotonicity hypothesis of Theorem 1.9 cannot be replaced by the condition that $\alpha_{N,m}\to\infty$ as $m\to\infty$.

Example 3. For (1.1), let $b_n\equiv 1$, $c_{3n}=(4\sqrt{\sqrt{2}})^{-1}$, $c_{3n+1}=(\sqrt{2})^{-1}$ and $c_{3n+2}=(\sqrt{2\sqrt{2}})^{-1}$. Then $q_{3n}=(16\sqrt{2})^{-1}$, $q_{3n+1}=\frac{1}{2}$ and $q_{3n+2}=(2\sqrt{2})^{-1}$, so

$$\begin{aligned} \alpha_{2,3m+1}&=\frac{b_{3m+3}b_{3m+4}}{4c^2_{3m+3}}\cdot\frac{b_{3m+2}b_{3m+3}}{4c^2_{3m+2}}\cdot\frac{b_{3m+1}b_{3m+2}}{4c^2_{3m+1}}\cdot\alpha_{2,3m-2}\\ &=\frac{16\sqrt{2}}{4}\cdot\frac{2\sqrt{2}}{4}\cdot\frac{2}{4}\alpha_{2,3m-2}\\ &=2\alpha_{2,3m-2}. \end{aligned} \tag{1.24}$$

Thus $\alpha_{2,j}\to\infty$ as $j\to\infty$. Also,

$$\begin{aligned} \alpha_{2,3m+2}&=\frac{b_{3m+4}b_{3m+5}}{4c^2_{3m+4}}\cdot\alpha_{2,3m+1}\\ &=\frac{1}{2}\alpha_{2,3m+1}. \end{aligned} \tag{1.25}$$

Thus (1.24) and (1.25) imply that $\alpha_{2,j}\to\infty$ but not monotonically.

Next, define $a_n = b_n - c_n - c_{n-1}$. Then

$$a_{3n} = 1 - \left(4\sqrt{\sqrt{2}}\right)^{-1} - \left(\sqrt{2\sqrt{2}}\right)^{-1},$$

$$a_{3n+1} = 1 - (\sqrt{2})^{-1} - \left(4\sqrt{\sqrt{2}}\right)^{-1},$$

and

$$a_{3n+2} = 1 - (2\sqrt{2})^{-1} - (\sqrt{2})^{-1}.$$

So, for all n,

$$a_{3n} + a_{3n+1} + a_{3n+2} \cong 3 - 3.0238 = -.0238.$$

Therefore $\Sigma^{\infty} a_n = -\infty$. Since the sequence $\{b_n\}$ is bounded, equation (1.1) must be oscillatory by [5, Thm. 3.7] or [3, Thm. 4].

2. An extension theorem for the case $q_n < 1$. In this section we introduce a technique for extending known oscillation criteria for equation (1.1) by making use of the following theorem, where $q_n = c_n^2/(b_n b_{n+1})$, as before. We assume throughout that $q_n < 1$ for all sufficiently large n, since (1.1) must be oscillatory if $q_{n_k} \geqq 1$ for a sequence $n_k \to \infty$, by Theorem 1.4.

THEOREM 2.1. *Given* (1.1), *let* $B_n = q_n^{-1} - 1 > 0$, $n \geqq N$. *If the equation*

$$y_{n+1} + y_{n-1} = B_n y_n \tag{2.1}$$

is oscillatory, then (1.1) *is oscillatory also.*

To prove this theorem we will make use of the following simple comparison lemma.

LEMMA 2.1. *If* $\{u_n\}$, $n \geqq N$, *is a positive solution of*

$$u_n + \frac{1}{u_{n-1}} = \tilde{B}_n, \tag{2.2}$$

and if $B_n \geqq \tilde{B}_n > 0$ *for all* $n > N$, *then*

$$v_n + \frac{1}{v_{n-1}} = B_n \tag{2.3}$$

has a solution, with $v_n \geqq u_n$ *for* $n \geqq N$.

Proof. Given such a sequence u_n, let $v_N = u_N$ and define

$$v_{N+1} = B_{N+1} - \frac{1}{v_N} \geqq \tilde{B}_{N+1} - \frac{1}{u_N} = u_{N+1}.$$

Thus v_n satisfies (2.3) for $n = N+1$, and $v_{N+1} \geqq u_{N+1} > 0$. Proceeding inductively, we construct the required solution v_n.

Proof of Theorem 2.1. Assume (1.1) is nonoscillatory, and let x_n be a solution with $x_n > 0$, $n \geqq N$. Then by Theorem 1.1, $z_n = c_n x_{n+1}/x_n$ is a positive solution of (1.3) for $n > N$. If we take (1.3) for n and for $n+1$, multiply corresponding sides, and divide the result by c_n^2, we obtain

$$\frac{z_n z_{n+1}}{c_n^2} + 1 + \left(\frac{z_n z_{n+1}}{c_n^2}\right) \Big/ \left(\frac{z_{n-1} z_n}{c_{n-1}^2}\right) + \left(\frac{z_{n-1} z_n}{c_{n-1}^2}\right)^{-1} = \frac{1}{q_n}.$$

We write this as

$$r_n + 1 + \frac{r_n}{r_{n-1}} + \frac{1}{r_{n-1}} = \frac{1}{q_n}, \qquad n > N, \tag{2.4}$$

where $r_n = z_n z_{n+1}/c_n^2 > 0$. Thus r_n is a positive solution of

$$r_n + \frac{1}{r_{n-1}} = \frac{1}{q_n} - 1 - \frac{r_n}{r_{n-1}} = B_n - \varepsilon_n \quad \text{for } n > N, \tag{2.5}$$

where $\varepsilon_n = r_n/r_{n-1} > 0$. By applying Lemma 2.1, with $\tilde{B}_n = B_n - \varepsilon_n$, we see that there exists a sequence $v_n \geqq r_n > 0$, $n > N$, satisfying

$$v_n + \frac{1}{v_{n-1}} = B_n.$$

This equation is of the form (1.3) with $c_n \equiv 1$ and with b_n replaced by B_n. Since v_n is a positive solution, we may apply Theorem 1.1 to conclude that (2.1) is nonoscillatory, which completes the proof.

We now apply some known oscillation criteria to (2.1) to obtain new criteria for (1.1).

For example, by [5, Cor. 3.3], if

$$\liminf_{n\to\infty} \sum_{k=1}^{n} (B_k - 2) = -\infty \tag{2.6}$$

then (2.1) is oscillatory. Since $B_k = q_k^{-1} - 1$, we have the following oscillation result for (1.1).

THEOREM 2.2. *Equation* (1.1) *is oscillatory if for some N,*

$$\liminf_{n\to\infty} \sum_{k=N}^{n} \left(q_k^{-1} - 3\right) = -\infty. \tag{2.7}$$

For another result, we apply Theorem 1.4 to (2.1), which tells us that (2.1) is oscillatory if $Q_{n_k} \geqq 1$ for a sequence $n_k \to \infty$, where

$$Q_n = \frac{C_n^2}{B_n B_{n+1}} = \frac{1}{B_n B_{n+1}} = \left(q_n^{-1} - 1\right)^{-1}\left(q_{n+1}^{-1} - 1\right)^{-1}. \tag{2.8}$$

Thus, by Theorem 2.1, (1.1) is oscillatory if $q_n < 1$ and

$$\left(q_{n_k}^{-1} - 1\right)\left(q_{n_k+1}^{-1} - 1\right) \leqq 1, \tag{2.9}$$

for some sequence $n_k \to \infty$. But since $0 < q_n < 1$ for all $n \geqq N$, some simple algebra shows that condition (2.9) is equivalent to

$$q_{n_k} + q_{n_k+1} \geqq 1. \tag{2.10}$$

Thus we have the following refinement of Theorem 1.4.

THEOREM 2.3. *If $q_{n_k} + q_{n_k+1} \geqq 1$ for some sequence $n_k \to \infty$, then* (1.1) *is oscillatory.*

Similarly, Theorem 1.2 leads to the following result.

THEOREM 2.4. *If $q_n < 1$ and $q_n + q_{n+1} + (3-\varepsilon) q_n q_{n+1} \geqq 1$ for all $n \geqq N$, for some $\varepsilon > 0$, then* (1.1) *is oscillatory.*

Any other known oscillation criteria could be applied to (2.1) in this same way to obtain further results like Theorems 2.2–2.4. We leave the details to the interested reader.

3. Extensions of §2. In this section, we will assume that $q_n + q_{n+1} < 1$ for all $n \geqq N$, for some $N > 0$. If this were not the case, (1.1) would be oscillatory by Theorem 2.3.

The method of §2 can be extended in two ways. First, since (2.1) is of the form (1.1) with $C_n \equiv 1$, we can apply Theorem 2.1 to equation (2.1) to obtain the following result.

THEOREM 3.1. *Given* (2.1), *let* $\bar{B}_n = Q_n^{-1} - 1$, $n \geqq N$, *where* $Q_n = (B_n B_{n+1})^{-1}$. *If the equation*

$$(3.1) \qquad u_{n+1} + u_{n-1} = \bar{B}_n u_n$$

is oscillatory, then (2.1) *is oscillatory also.*

(*Note.* Since $\bar{B}_n = Q_n^{-1} - 1$ and $B_n = q_n^{-1} - 1$, our assumption $q_n + q_{n+1} < 1$ implies that $B_n B_{n+1} > 1$, which in turn implies that $\bar{B}_n > 0$.)

As in §2, we can now apply known oscillation criteria to equation (3.1) to obtain new criteria for (2.1) and hence for (1.1). For example, by Theorem 1.4, (3.1) is oscillatory if $\bar{B}_n > 0$ for $n \geqq N$ and

$$(3.2) \qquad \bar{Q}_{n_k} = \left(\bar{B}_{n_k} \bar{B}_{n_k+1}\right)^{-1} \geqq 1 \quad \text{for some sequence } n_k \to \infty.$$

Since $\bar{B}_n = Q_n^{-1} - 1 = B_n B_{n+1} - 1$ and $B_n = q_n^{-1} - 1$, we have

$$(3.3) \qquad \begin{aligned} \bar{Q}_n &= (\bar{B}_n \bar{B}_{n+1})^{-1} = (B_n B_{n+1} - 1)^{-1} (B_{n+1} B_{n+2} - 1)^{-1} \\ &= \left[(q_n^{-1} - 1)(q_{n+1}^{-1} - 1) - 1\right]^{-1} \left[(q_{n+1}^{-1} - 1)(q_{n+2}^{-1} - 1) - 1\right]^{-1}. \end{aligned}$$

Hence, condition (3.2) becomes

$$(3.4) \qquad \left(\frac{1 - q_{n_k} - q_{n_k+1}}{q_{n_k} q_{n_k+1}}\right) \left(\frac{1 - q_{n_k+1} - q_{n_k+2}}{q_{n_k+1} q_{n_k+2}}\right) \leqq 1.$$

Thus, by applying Theorems 2.1 and 3.1, the following criterion is readily verified.

THEOREM 3.2. *If* $q_n + q_{n+1} < 1$ *for* $n \geqq N$ *and* (3.4) *holds for a sequence* $n_k \to \infty$, *then* (1.1) *is oscillatory.*

In general, since $\bar{C}_n \equiv 1$ in (3.1), any oscillation criterion in terms of the coefficients of (3.1) becomes an oscillation criterion for (1.1) given in terms of the expression

$$(3.5) \qquad \bar{B}_n = B_n B_{n+1} - 1 = \frac{1 - q_n - q_{n+1}}{q_n q_{n+1}}.$$

A second way of extending the results of §2 is again to assume that (1.1) is nonoscillatory and proceed as in the proof of Theorem 2.1 to obtain (2.4). However, (2.4) may be written in the form

$$(3.6) \qquad (1 + r_n)\left[1 + \frac{1}{r_{n-1}}\right] = \frac{1}{q_n}, \qquad n > N.$$

From (3.6) we obtain

$$(3.7) \qquad (1 + r_n)\left[1 + \frac{1}{r_{n-1}}\right](1 + r_{n+1})\left[1 + \frac{1}{r_n}\right] = \frac{1}{q_n q_{n+1}}.$$

By the inequality $(1 + a)(1 + a^{-1}) \geqq 4$ for $a > 0$, (3.7) implies

$$(3.8) \qquad 4(1 + r_{n+1})\left[1 + \frac{1}{r_{n-1}}\right] \leqq \frac{1}{q_n q_{n+1}}, \qquad n > N.$$

Then

$$r_{n+1}+\frac{1}{r_{n-1}}\leqq\frac{1}{4q_nq_{n+1}}-1-\frac{r_{n+1}}{r_{n-1}}. \tag{3.9}$$

Thus, r_n is a positive solution of an equation of the form

$$r_{n+1}+\frac{1}{r_{n-1}}=\frac{1}{4q_nq_{n+1}}-1-\delta_n, \qquad n>N, \tag{3.10}$$

where $\delta_n\geqq r_{n+1}/r_{n-1}>0$. We write this second-order nonlinear equation as

$$r_{n+1}+\frac{1}{r_{n-1}}=E_n-\delta_n, \qquad n>N, \tag{3.11}$$

where $E_n=(4q_nq_{n+1})^{-1}-1$, and consider the related first-order equation

$$u_n+\frac{1}{u_{n-1}}=E_{2n}-\delta_{2n}. \tag{3.12}$$

Then the sequence $u_n=r_{2n+1}$ is a positive solution of (3.12) for $n>(N-1)/2$. By Lemma 2.1, the equation

$$v_n+\frac{1}{v_{n-1}}=E_{2n} \tag{3.13}$$

also has a positive solution. We then apply Theorem 1.1 to conclude that

$$y_{n+1}+y_{n-1}=E_{2n}y_n \tag{3.14}$$

is nonoscillatory. Thus if (3.14) is oscillatory, (1.1) must be oscillatory also.

Similarly, $u_n=r_{2n}$ is a positive solution of

$$u_n+\frac{1}{u_{n-1}}=E_{2n-1}-\delta_{2n-1}. \tag{3.15}$$

By Lemma 2.1, the equation

$$v_n+\frac{1}{v_{n-1}}=E_{2n-1}$$

must also have a positive solution v_n. Again, an application of Theorem 2.1 implies that the following equation is nonoscillatory.

$$z_{n+1}+z_{n-1}=E_{2n-1}z_n. \tag{3.16}$$

Thus if (3.16) is oscillatory, so is (1.1).

As in the first part of this section, one can now apply various known oscillation criteria to (3.14) or (3.16) to obtain new criteria for (1.1).

As an example, by [5, Cor. 3.3], if

$$\liminf_{n\to\infty}\sum_{k=N}^{n}(E_{2k}-2)=-\infty, \tag{3.17}$$

then (3.14) is oscillatory. Similarly, if

$$\liminf_{n\to\infty}\sum_{k=N}^{n}(E_{2k-1}-2)=-\infty, \tag{3.18}$$

then (3.16) is oscillatory. However, if (3.14) or (3.16) is oscillatory, so is (1.1). At least one of (3.17) or (3.18) will be true if

$$\liminf_{n\to\infty} \sum_{k=N}^{n} (E_k - 2) = -\infty. \tag{3.19}$$

Thus we have the following theorem.

THEOREM 3.3. *If condition* (3.19) *holds then* (1.1) *is oscillatory, where* $E_k = (4q_kq_{k+1})^{-1} - 1$.

From (1.8), $(4q_kq_{k+1})^{-1} = \alpha_{k,1}$, which means Theorem 3.3 can be restated as follows.

THEOREM 3.4. *If*

$$\liminf_{n\to\infty} \sum_{k=N}^{n} (\alpha_{k,1} - 3) = -\infty,$$

then (1.1) *is oscillatory.*

Using the $\alpha_{n,m}$ notation, observe that Theorem 3.4 is the same as Theorem 2.2, except that Theorem 2.2 has $\alpha_{k,0}$ instead of $\alpha_{k,1}$. We conjecture that Theorem 3.4 is true for $\alpha_{k,m}$ for any $m \geqq 0$.

A more ambitious question is as follows. In essence, Theorem 2.1 says that any known result on the oscillation of (2.1) involving B_n can be rephrased with B_n replaced by $(1/q_n - 1) = (\alpha_{n,0} - 1)$ and then applied to (1.1) to yield sufficient conditions for the oscillation of that equation. Our conjecture is that B_n can be replaced by $(\alpha_{n,m} - 1)$, for any $m \geqq 0$.

ON OSCILLATIONS OF SOME RETARDED DIFFERENTIAL EQUATIONS*

O. ARINO[†], G. LADAS[‡] AND Y. G. SFICAS[§]

Abstract. Consider the delay differential equation

$$y'(t)+py(t-\tau)-qy(t-\sigma)=0 \tag{$*$}$$

where p, q, τ, and σ are positive constants.

THEOREM. *Assume that $\sigma \leqq \tau$, $q<p$, and $q(t-\sigma) \leqq 1$. Then every nonoscillatory solution of $(*)$ tends to zero as $t \to \infty$. Furthermore, assume that $(p-q)\tau e>1$. Then every solution of $(*)$ oscillates.*

The above result was extended to equations with several delays.

Finally we obtained sufficient conditions for the oscillation of delay differential equations with oscillating coefficients.

Key words. oscillation, retarded differential equation, delay differential equation

1. Introduction. Recently, there has been a lot of interest in establishing computable sufficient conditions for the oscillation of all solutions of linear delay differential equations. See, for example [2], [4], [8], [9] and the references cited in [9].

For the most part the literature is devoted to equations of the form

$$x'(t)=-\sum_{i=1}^{n} p_i(t)x(t-\tau_i(t))$$

where all the coefficients p_i are positive. The case where both positive and negative coefficients may be present was recently considered by Ladas and Sficas [5].

The aim of the present paper is to provide a significant extension of the results in [5] and to develop some methods for studying equations with positive and negative coefficients. In particular, we combine the methods used separately in [2] and [5] and utilize more cleverly the integral form introduced in [5, formula 10].

2. Differential inequalities. In this section we study the properties of solutions of certain differential inequalities and obtain some useful results which can be used as tools in the study of oscillation theory.

LEMMA 1. *Let z be a nonnegative solution*[1] *of the delay differential inequality*

$$z'(t)+az(t-\tau) \leqq 0, \qquad t \geqq t_0 \tag{1}$$

where a and τ are positive constants. Then the following statements hold:

(i) $z \in L^1(t_0, \infty)$;

(ii) *$z(t)$ decreases to zero as $t \to \infty$*;

[§] Department of Mathematics, University of Ioannina, Ioannina, Greece.

[1] That is, $z(t) \geqq 0$ and continuous for $t_0-\tau \leqq t \leqq t_0$ and satisfies (1) for $t \geqq t_0$.

(iii) *if* $z(t_0)>0$ *then there exist positive constants* α *and* A *such that*

$$z(t)\geqq Ae^{-\alpha t}, \qquad t\geqq t_0. \tag{2}$$

Proof. As $z'(t)\leqq -az(t-\tau)\leqq 0$ for $t\geqq t_0$, it follows that z is a decreasing function. Integrating (1) from t_1 to t_2 with $t_0\leqq t_1\leqq t_2$, we find that

$$a\int_{t_1}^{t_2} z(s-\tau)\,ds\leqq z(t_1)-z(t_2)\leqq z(t_0) \tag{3}$$

which implies that $z\in L^1(t_0,\infty)$. And since $z(t)$ is also decreasing, it follows that $\lim_{t\to\infty} z(t)$ exists and is equal to zero. Next, we turn to the proof of (iii). Replacing t_1 by t and letting $t_2\to\infty$ in (3), we find

$$z(t)\geqq a\int_t^\infty z(s-\tau)\,ds. \tag{4}$$

Using the decreasing nature of $z(t)$ we obtain,

$$z(t)\geqq a\int_t^\infty z(s-\tau)\,ds\geqq a\int_t^{t+\tau/2} z(s-\tau)\,ds\geqq \frac{a\tau}{2}z\left(t-\frac{\tau}{2}\right)$$

that is,

$$z(t)\geqq Cz\left(t-\frac{\tau}{2}\right), \tag{5}$$

where $C=a\tau/2>0$. Then $z(t_0+\tau/2)\geqq Cz(t_0)>0$. Set

$$I_n=\left[t_0+n\frac{\tau}{2},t_0+(n+1)\frac{\tau}{2}\right], \qquad n=0,1,2,\cdots.$$

Let $t\geqq t_0$ be given. Then $t\in I_n$ for some n. Using the estimate (5) we find by iteration

$$z(t)\geqq C^{n+1}z(t_0).$$

Assume $C>1$. Thus, using the fact that $2(t-t_0)/\tau\leqq n+1$, we have

$$z(t)\geqq e^{(n+1)\ln C}z(t_0)\geqq \exp\left[\frac{2(t-t_0)}{\tau}\ln C\right]z(t_0).$$

On the other hand, if $C\leqq 1$, using the fact that $n\leqq 2(t-t_0)/\tau$, we obtain

$$z(t)\geqq \exp\left[\frac{2(t-t_0)}{\tau}\ln C\right]Cz(t_0).$$

In either case, inequality (2) is valid and the proof of Lemma 1 is complete.

The proof of the following result makes use of the notion of nonautonomous exponents [1], [2].

PROPOSITION 1. *Let* z *be a nonnegative solution of the delay differential inequality* (1). *Assume that*

$$a\tau>\frac{1}{e}. \tag{6}$$

Then $z(t)=0$ *for* $t\geqq t_0$.

Proof. If $z(t_0)=0$ then, as z is nonnegative and decreasing, it follows that $z(t)=0$ for $t\geqq t_0$. Next, assume, for the sake of contradiction, that $z(t_0)>0$. Then, from Lemma 1 (iii), $z(t)>0$ for $t\geqq t_0$. Set

$$z(t)=\exp\left[-\int_0^t \lambda(s)\,ds\right], \qquad t\geqq t_0. \tag{7}$$

Substituting (7) into (1) we find that

$$\lambda(t) \geqq a \exp\left[\int_{t-\tau}^{t} \lambda(s)\,ds\right], \qquad t \geqq t_0. \tag{8}$$

Also from (7), and in view of (2), there is a positive constant β such that

$$\int_0^t \lambda(s)\,ds \leqq \beta t, \qquad t \geqq t_0. \tag{9}$$

In view of (8), it follows by induction that for $n = 1, 2, \cdots$

$$\lambda(t) \geqq b_n, \qquad t \geqq t_0 + (n-1)\tau \tag{10}$$

where $b_0 = 0$ and $b_n = a\exp(b_{n-1}\tau)$. We now claim that the sequence $\{b_n\}$ is increasing and $\lim_{n\to\infty} b_n = +\infty$. In fact, using (6) and the fact that $\exp(x) \geqq ex$ for all x we find

$$b_n = a\exp(bb_{n-1}\tau) \geqq aeb_{n-1}\tau \geqq b_{n-1}$$

that is, $\{b_n\}$ is increasing. If, contrary to the claim, $\{b_n\}$ were bounded, then $b_\infty \equiv \lim_{n\to\infty} b_n > 0$ and

$$b_\infty = a\exp(b_\infty \tau) \geqq aeb_\infty \tau > b_\infty.$$

Thus our claim about $\{b_n\}$ is true and consequently, from (10), $\lim_{t\to\infty}\lambda(t) = \infty$. This contradicts (9) and the proof of the proposition is complete.

Remark 1. The main tools behind the proof of Proposition 1 are the integral form (4) of inequality (1), the exponential representation (7) of z, and the integral estimates (8) and (9). As we will see in the next result, the same tools can be used in the case of delay differential inequalities with several delays. Note also that in the following result the condition (6) of Proposition 1 has been replaced by the general assumption that all solutions of the corresponding equation oscillate. As it is known, in the case of equations with one delay the two statements are equivalent.

PROPOSITION 2. *Let z be a nonnegative solution of the delay differential inequality*

$$z'(t) + \sum_{j=1}^{n} a_j z(t-\tau_j) \leqq 0, \qquad t \geqq t_0 \tag{11}$$

where a_j and τ_j are positive constants for $j = 1, 2, \cdots, n$. Assume that all solutions of the DDE

$$z'(t) + \sum_{j=1}^{n} a_j z(t-\tau_j) = 0, \qquad t \geqq t_0 \tag{12}$$

oscillate. Then, $z(t) = 0$ for $t \geqq t_0$.

Proof. Inequality (11) implies that for each $j = 1, 2, \cdots, n$,

$$z'(t) + a_j z(t-\tau_j) \leqq 0, \qquad t \geqq t_0$$

and therefore the results (i), (ii), and (iii) of Lemma 1 are also true here. In particular, if $z(t_0) > 0$ then $z(t) > 0$ for $t \geqq t_0$. As in Proposition 1, the change of variables (7) yields

$$\lambda(t) \geqq \sum_{j=1}^{n} a_j \exp\left[\int_{t-\tau_j}^{t} \lambda(s)\,ds\right] \tag{8$'$}$$

which inductively leads to a sequence of estimates,

$$\lambda(t) \geqq b_k, \qquad t \geqq t_0+(n-1)\tau$$

where $b_0=0$, $b_k=\sum_{j=1}^{n} a_j \exp(\tau_j b_{k-1})$ for $k=1,2,\cdots,n$, and $\tau=\max_{1 \leqq j \leqq n}\tau_j$. We now claim that the sequence $\{b_n\}$ is increasing. Indeed, the characteristic equation

$$F(\lambda) \equiv \lambda + \sum_{j=1}^{n} a_j e^{-\lambda\tau_j}=0$$

of (12) has no real roots. As $F(0)=\sum_{j=1}^{\infty} a_j > 0$, it follows that $F(\lambda)>0$ for all $\lambda \in R$. In particular

$$F(-b_{k-1}) = -b_{k-1} + \sum_{j=1}^{n} a_j e^{b_{k-1}\tau_j} > 0.$$

Hence,

$$b_k = \sum_{j=1}^{n} a_j e^{b_{k-1}\tau_j} > b_{k-1}$$

which proves our claim. Next, we will show that

$$\lim_{k \to \infty} b_k = \infty. \tag{13}$$

Otherwise, $b_\infty \equiv \lim_{k \to \infty} b_k$ is a finite number and so

$$b_\infty = \sum_{j=1}^{n} a_j \exp(\tau_j b_\infty)$$

which implies that (12) has the nonoscillatory solution $z(t)=\exp(-b_\infty t)$. This contradiction establishes (13). Finally, as in the proof of Proposition 1, (13) implies that $\lim_{t \to \infty} \lambda(t)=\infty$ which contradicts (9). The proof of Proposition 2 is complete.

3. Positive and negative coefficients—autonomous equations. In [5], Ladas and Sficas studied the asymptotic behavior of the nonoscillatory solutions and the oscillation of all solutions of the DDE

$$x'(t)+px(t-\tau)-qx(t-\sigma)=0 \tag{14}$$

where the delays τ and σ and the coefficients p and q satisfy the hypothesis that

(H_1) p, q, τ, and σ are positive constants.

The aim in this section is to sharpen the conditions which were assumed in [5] and to extend the results to equations with more than two delays. It was shown in [5] that the hypothesis

(H_2) $q<p$ and $\sigma \leqq \tau$, is a necessary condition for all solutions of (14) to oscillate.

The following statement improves [5, Thm. 2]:

THEOREM 1. *In addition to the hypotheses* (H_1) *and* (H_2) *assume that*

(H_3) $q(\tau-\sigma) \leqq 1$.

Then every nonoscillatory solution of (14) *tends to zero as* $t \to \infty$.

Proof. It suffices to prove the theorem for the eventually positive solutions of (14). To this end, let $x(t)$ be a solution of (14) which is positive for $t \geqq t_0$. As in [5] we introduce the function

$$z(t)=x(t)-q\int_{t-\tau}^{t-\sigma} x(s)\,ds, \qquad t \geqq t_0+\tau. \tag{15}$$

Then

$$(16)\qquad z'(t)=-(p-q)x(t-\tau)<0,\quad t\geqq t_0+\tau$$

and so $z(t)$ is decreasing. We claim that $z(t)$ is bounded below. Otherwise, $\lim_{t\to\infty}z(t)=-\infty$ which implies that x, itself, is unbounded. But then, there must exist a point $t_1\geqq t_0+\tau$ such that $z(t_1)<0$ and $x(t_1)=\max_{s\leqq t_1}x(s)>0$. From (15) and ($H_3$) we obtain the contradiction that

$$0>z(t_1)=x(t_1)-q\int_{t_1-\tau}^{t_1-\sigma}x(s)\,ds\geqq x(t_1)-qx(t_1)(\tau-\sigma)$$
$$=x(t_1)[1-q(\tau-\sigma)]\geqq 0.$$

Thus $z(t)$ is bounded below and $\lim_{t\to\infty}z(t)\equiv l$ exists and is finite. Now integrating (16) from $t_1=t_0+2\tau$ to t and letting $t\to\infty$ we obtain

$$z(t_1)-l=-(p-q)\int_{t_1}^{\infty}x(s-\tau)\,ds$$

which proves that $x\in L^1(t_1,\infty)$. From (14), it follows that $x'\in L^1(t_1,\infty)$. Hence $\lim_{t\to\infty}x(t)$ exists and it has to be zero because $x\in L^1(t_1,\infty)$. The proof is complete.

Remark 2. (a) In place of (H_3) it was assumed in [5] that the more restrictive condition

$$\tau\leqq\frac{1}{q}-\frac{1}{p}$$

holds.

(b) The hypothesis (H_3) is the "best" one when the coefficients p and q are equal. Indeed, when $p=q$ all constants are solutions and conversely all solutions of (14) are asymptotically constant. In the latter case $\lim_{t\to\infty}x(t)$ is given in terms of the initial data, using the "first integral" $x(t)+p\int_{t-\sigma}^{t-\tau}x(s)\,ds\equiv C$, namely,

$$\lim_{t\to\infty}x(t)=\frac{C}{1-p(\tau-\sigma)}.$$

The following is an improved version of [5, Thm. 3]. Its proof makes use of Theorem 1; otherwise it is identical to the proof given in [5] and will be omitted.

THEOREM 2. *Assume* (H_1), (H_2), (H_3) *and* (H_4) $(p-q)\tau e>1$. *Then every solution of* (14) *oscillates.*

Example 1. The DDE

$$x'(t)+e^4x(t-4)-2e^2x(t-2)=0$$

satisfies the hypotheses (H_1), (H_2) and (H_4), but not (H_3). Therefore it is not surprising that $x(t)=e^t$ is a nonoscillatory solution which does not tend to zero as $t\to\infty$.

Next, we extend Theorems 1 and 2 to equations with several delays.

THEOREM 3. *Consider the delay differential equation*

$$(17)\qquad x'(t)+\sum_{i=1}^{n}p_ix(t-\sigma_i)-\sum_{j=1}^{m}q_jx(t-\tau_j)=0$$

where the coefficients p_i, q_j *and the delays* σ_i, τ_j *are positive constants for* $i=1,2,\cdots,n$ *and* $j=1,2,\cdots,m$. *Assume that the following hypotheses are satisfied.*

(H_5) *There exist a positive number $p \leqq n$ and a partition of $\{1,2,\cdots,m\}$ into p disjoint subsets $J_1, J_2,\cdots, J_p$ such that $j \in J_i$ implies $\tau_j \leqq \sigma_i$ and $\sum_{k\in J_i} q_k < p_i$.*

(H_6) $\sum_{i=1}^{p}\sum_{k\in J_i} q_k(\sigma_i - \tau_k) < 1$.

Then every nonoscillatory solution of (17) *tends to zero as $t \to \infty$. Furthermore, if in addition to the above hypotheses we assume that the equation*

$$z'(t)+\sum_{i=1}^{p}\Big(p_i - \sum_{k\in J_i} q_k\Big) z(t-\sigma_i)=0 \tag{18}$$

has only oscillatory solutions then the same is true with (17).

Proof. As the negative of a solution of (17) is also a solution, we first prove that every eventually positive solution $x(t)$ of (17) tends to zero as $t\to\infty$. The key idea is, once more, the introduction of the function

$$z(t)=x(t)-\sum_{i=1}^{p}\sum_{k\in J_i} q_k \int_{t-\sigma_i}^{t-\tau_k} x(s)\,ds. \tag{19}$$

We have

$$z'(t)=\sum_{i=1}^{p}\Big(\sum_{k\in J_i} q_k - p_i\Big)x(t-\sigma_i) - \sum_{i=p+1}^{n} p_i x(t-\sigma_i) \tag{20}$$

and so eventually, $z'(t)<0$ and $z(t)$ is decreasing. Now, as in the proof of Theorem 1, we can deduce from (H_6) that z is bounded below and integrating (20) we conclude that $x \in L^1(t_0,\infty)$. Then from (17), it follows that $x' \in L^1(t_0,\infty)$, and therefore x tends to a limit as $t\to\infty$. And this limit is necessarily zero because $x\in L^1(t_0,\infty)$.

Next, in addition to (H_5) and (H_6), we assume that every solution of (18) is oscillatory. We should prove that every solution of (17) oscillates. Otherwise, (17) has an eventually positive solution $x(t)$. And, as we have already proved, $\lim_{t\to\infty} x(t)=0$. From (19) and (20), we see that $z(t)$ is decreasing to zero which implies that $z(t)$ is eventually positive. In view of (19), we have, $0<z(t)\leqq x(t)$. Thus, (20) yields

$$z'(t)+\sum_{i=1}^{p}\Big(p_i - \sum_{k\in J_i} q_k\Big) z(t-\sigma_i)\leqq 0. \tag{21}$$

On the basis of our assumptions, Proposition 2 applied to (21) implies that eventually $z(t)=0$. This contradiction completes the proof of Theorem 3.

4. Nonautonomous equations. Consider the DDE

$$x'(t)+p(t)x(t-\tau)=0 \tag{22}$$

where $p(t)$ is continuous on $[0,\infty)$ and $\tau>0$ is a constant. Set

$$p(t)=p^+(t)-p^-(t)$$

where p^+ and p^- are the positive and negative parts of p respectively.

Lemma 2. *Assume that*

$$p^- \in L^1[0,\infty). \tag{H_7}$$

Then every nonoscillatory solution of (22) *tends to a (finite) limit as $t\to\infty$.*

Proof. Choose a $t_0 > t$ such that

$$\int_{t_0}^{\infty} p^-(s)\,ds = \alpha < 1.$$

Now, we will prove that if x is an eventually positive solution of (22), then x is bounded above. Assuming the contrary, we could find a sequence $\{t_n\}$ such that $t_n \geqq t_0$

$$\lim_{n\to\infty} t_n = +\infty, \quad \lim_{n\to\infty} x(t_n) = +\infty, \quad x(t_n) = \max_{t \leqq t_n} x(t).$$

Let $t_1 \geqq t_0$ be so large that $x(t-\tau)>0$ for $t \geqq t_1$. Then from (22) we have

$$x'(t) \leqq p^-(t)x(t-\tau), \qquad t \geqq t_1,$$

and by integration

$$x(t)-x(t_1) \leqq \alpha \max_{s \leqq t} x(s).$$

If we replace t by t_n we find

$$x(t_n) \leqq \frac{x(t_1)}{1-\alpha}$$

which contradicts the asumption that $\lim_{n\to\infty} x(t_n) = +\infty$. Thus x is bounded and so in view of (H_7), $p^-(t)x(t-\tau) \in L^1[t_1,\infty)$. Integrating (22) from t_1 to t_2, with $t_1<t_2$, we get

$$\int_{t_1}^{t_2} p^+(s)x(s-\tau) \leqq \int_{t_0}^{\infty} p^-(s)x(s-\tau) + 2 \sup_{s \geqq t_0} x(s).$$

Therefore, $p^+(t)x(t-\tau) \in L^1[t_1,\infty)$ and so $x' \in L^1[t_1,\infty)$ which implies that x tends to a finite limit as $t \to \infty$.

Example 2. The DDE

$$y'(t) - \frac{\cos t}{2-\cos t} y\left(t-\frac{\pi}{2}\right) = 0$$

has the nonoscillatory solution $y(t) = 2+\sin t$ which does not have a limit as $t \to \infty$. As expected, the hypothesis (H_7) is not satisfied in this example.

LEMMA 3. *Assume* (H_7) *and that*

$$(\mathrm{H}_8) \qquad \int_0^{\infty} p^+(s)\,ds = \infty.$$

Then every solution of (22) *either oscillates or tends to zero as* $t \to \infty$.

Proof. Assume, for the sake of contradiction, that (22) has a positive solution $x(t)$ which does not tend to zero as $t \to \infty$. In view of Lemma 2, $\lim_{t\to\infty} x(t) = x(\infty)$ exists and since it is not zero it follows that

$$(23) \qquad x(\infty) > 0.$$

Then, for t sufficiently large, say $t \geqq t_1$, we have

$$\frac{1}{2}x(\infty) \leqq x(t) \leqq \frac{3}{2}x(\infty).$$

In view of (22) this leads to

$$x'(t) + \frac{1}{2}x(\infty)p^+(t) - \frac{3}{2}x(\infty)p^-(t) \leqq 0$$

for $t \geqq t_1+\tau$. Integrating from $t_1+\tau$ to t we obtain

$$(24) \qquad x(t)-x(t_1+\tau)+\frac{1}{2}x(\infty)\int_{t_1+\tau}^{t} p^+(s)\,ds - \frac{3}{2}x(\infty)\int_{t_1+\tau}^{t} p^-(s)\,ds \leqq 0.$$

Taking limits in (24) as $t\to\infty$ and using the hypotheses (H_7) and (H_8), we find that $y(\infty)=-\infty$ which contradicts (23) and completes the proof.

The following result gives sufficient conditions for all solutions of (22) to oscillate. A similar result was established in [6] under the (strong) assumption that $\lim_{n\to\infty}(v_n-\theta_n)=\infty$.

THEOREM 4. *Assume that the following conditions hold*:

(i) (H_7) *and*

$$(\mathrm{H}_9)\qquad \varliminf_{t\to\infty}\int_{t-\tau}^{t}p^+(s)\,ds>\frac{1}{e}.$$

(ii) *There exist two sequences* $\{\theta_n\}_{n=1}^{\infty}$ *and* $\{v_n\}_{n=1}^{\infty}$ *such that for* $n=1,2,\cdots$,

$$\theta_n<v_n\leqq\theta_{n+1},\quad v_n-\theta_n\geqq\frac{3\tau}{2},\quad \theta_{n+1}-v_n<\frac{\tau}{2}$$

and

$$p(t)\ is\begin{cases}\geqq 0 & for\ t\in\bigcup_{n=1}^{\infty}(\theta_n,v_n),\\ <0 & for\ t\in\bigcup_{n=1}^{\infty}(v_n,\theta_{n+1}).\end{cases}$$

(iii) *There exists a positive constant k such that*

$$\varliminf_{t\to\infty}\int_{t-\tau/2}^{t}p^+(s)\,ds>\frac{1}{k}\quad for\ t\in\bigcup_{n=1}^{\infty}(v_n,\theta_{n+1})$$

and

$$(25)\qquad p^+(t)\geqq kp^-\left(t-\frac{\tau}{2}\right)\quad for\ t\ sufficiently\ large.$$

Then every solution of (22) *oscillates.*

Proof. Otherwise, (22) has a solution $x(t)>0$ for $t\geqq t_0$ where t_0 is sufficiently large. And by Lemma 3 [which holds because condition (H_9) implies (H_8)],

$$(26)\qquad \lim_{t\to\infty}x(t)=0.$$

Let $t\in\bigcup_{n=1}^{\infty}[v_n,\theta_{n+1}]$. Thus from (22) and the fact that $x(t)$ decrease in the interval $[t-3\tau/2,t-\tau/2]$ we find

$$(27)\qquad x\left(t-\frac{\tau}{2}\right)>x\left(t-\frac{\tau}{2}\right)-x(v_n)=\int_{t-\tau/2}^{v_n}p(x)x(s-\tau)\,ds$$
$$=\int_{t-\tau/2}^{t}p^+(s)x(s-\tau)\,ds\geqq x(t-\tau)\int_{t-\tau/2}^{t}p^+(s)\,ds.$$

Now for t sufficiently large, say $t\geqq t_1$ and for $t\in\bigcup_{n=1}^{\infty}[v_n,\theta_{n+1}]$ we find, from (27) and (iii),

$$(28)\qquad x\left(t-\frac{\tau}{2}\right)>\frac{1}{k}x(t-\tau).$$

And for all $t\geqq t_1$ the following inequality holds:

(29)

$$x'(t)+\left[p^+(t)-kp^-\left(t-\frac{\tau}{2}\right)\right]x(t-\tau)+kp^-\left(t-\frac{\tau}{2}\right)x(t-\tau)-kp^-(t)x\left(t-\frac{\tau}{2}\right)\geqq 0.$$

In fact (29) reduces to (22) for $t \in \bigcup_{n=1}^{\infty}(\theta_n, v_n)$ and for $t \in \bigcup_{n=1}^{\infty}(v_n, \theta_{n+1})$ it follows from (22) using (28) and (H_9). Set

$$z(t) = x(t) - k\int_{t-\tau/2}^{t} p^-(s)\,x\left(s-\frac{\tau}{2}\right)ds.$$

Thus from (29) we have for $t \geqq t_1$

$$z(t) \leqq x(t) \tag{30}$$

and

$$z'(t) + \left[p^+(t) - kp^-\left(t-\frac{\tau}{2}\right)\right]x(t-\tau) \leqq 0. \tag{31}$$

From (30) and because of (26) and (H_7), $\lim_{t\to\infty} z(t) = 0$. Hence $z(t) > 0$ and (30), (31), and (iii) yield the inequality

$$z'(t) + \left[p^+(t) - kp^-\left(t-\frac{\tau}{2}\right)\right]z(t-\tau) \leqq 0. \tag{32}$$

Since

$$\varliminf_{t\to\infty}\int_{t-\tau}^{t}\left[p^+(s) - kp^-\left(s-\frac{\tau}{s}\right)\right]ds = \varliminf_{t\to\infty}\int_{t-\tau}^{t} p^+(s)\,ds > \frac{1}{e},$$

it follows from [7] that (32) cannot have an eventually positive solution. But $z(t)$ is positive and this contradiction completes the proof.

Example 3. This is an example of a DDE which satisfies the hypotheses of Theorem 4 and therefore every solution of the equation oscillates. Consider the DDE

$$x'(t) + p(t)x(t-4\pi) = 0, \qquad t \geqq 0$$

where

$$p(t) = \begin{cases} \mu\sin^2 t & \text{for } t \in [10n\pi, 10n\pi + 9\pi), \\ -\mu\dfrac{\sin^2 t}{t^2} & \text{for } t \in [10n\pi + 9\pi, 10(n+1)\pi), \end{cases} \qquad n = 0, 1, 2, \cdots,$$

and μ is a positive constant satisfying the condition

$$\mu\frac{3\pi}{2} > \frac{1}{e}. \tag{33}$$

In this example, $\tau = 4\pi$, $\theta_n = 10n\pi$, $v_n = 10n\pi + 9\pi$, $v_n - \theta_n = 9\pi > 3\tau/2 = 6\pi$ and $\theta_{n+1} - v_n = \pi < \tau/2 = 2\pi$ and so condition (ii) of Theorem 4 is satisfied. Condition (H_7) is clearly satisfied and condition (H_9) is true because of (33). Indeed, examining the value of the integral in (H_9) for the different possible locations of t and $t-\tau$ in the intervals $(\theta_n, v_n]$ and $(v_n, \theta_{n+1}]$ we find that the integral takes its smallest value when $t = \theta_{n+1}$ and in this case, in view of (33),

$$\int_{t-\tau}^{t} p^+(s)\,ds = \int_{10n\pi+6\pi}^{10n\pi+9\pi} \mu\sin^2 ds = \mu\frac{3\pi}{2} > \frac{1}{e}.$$

Inequality (25) is true as can be seen by examining it for the different locations of t and $t-\tau/2$ in the intervals $(\theta_n, v_n]$ and $(v_n, \theta_{n+1}]$. For example, when $t \in (\theta_n, v_n]$ and $t - \tau/2$ in $(v_n, \theta_{n+1}]$,

$$p^+(t) - kp^-\left(t-\frac{\tau}{2}\right) = \sin^2 t - k\frac{\sin^2(t-2\pi)}{(t-2\pi)^2} = \sin^2 t\left[1 - \frac{k}{(t-2\pi)^2}\right] \geqq 0$$

for t sufficiently large and $k>0$. Finally, the first inequality in (iii) of Theorem 4 is satisfied with k any constant greater than $1/\mu\pi$. Indeed, the smallest value of the integral

$$\int_{t-\tau/2}^{t} p^{+}(s)\,ds$$

is obtained when $t=10(n+1)\pi$ and in this case

$$\int_{t-\tau/2}^{t} p^{+}(s)\,ds=\int_{10n\pi+8P\pi}^{10(n+1)\pi} \mu\sin^2 s\,ds=\mu\pi>\frac{1}{k}.$$

AN ABSTRACT DELAY-DIFFERENTIAL EQUATION MODELLING SIZE DEPENDENT CELL GROWTH AND DIVISION*

M. GYLLENBERG† AND H. J. A. M. HEIJMANS‡

Abstract. A two-phase model for the growth of a single cell population structured by size is formulated and analysed. The model takes the form of a delay-differential equation in a Banach space. Using positivity arguments, we describe the spectrum of the infinitesimal generator of the semigroup associated with solutions. Under a certain condition on the growth rate of individual cells the semigroup is compact after finite time. This enables us to determine the ultimate behavior of solutions and prove the existence of a stable size distribution.

Key words. structured populations, cell cycle, first order partial differential equation with delay and transformed argument, delay-differential equation in a Banach space, strongly continuous semigroup, generation expansion, positive operator, Riesz operator, spectral theory, stable size distribution

AMS(MOS) subject classifications. Primary 34K30, 92A15, 35R10

1. Introduction. In this paper we study a mathematical model for the dynamics of a population of single cells which can be distinguished from each other according to their size and the particular cell cycle phase they are in. Models for populations of dividing organisms incorporating size or age-size structure have been formulated, among others, by Bell and Anderson (1967) and Sinko and Streifer (1971) and have recently been investigated by Diekmann, Heijmans and Thieme (1984) and Heijmans (to appear a, b). We refer to the book of Metz and Diekmann (to appear) for a general exposition of the dynamics of physiologically structured populations. There exists a vast literature on models for progress through the cell cycle and its various phases, see for instance the book of Eisen (1979). Tyson and Hannsgen (1984) and Hannsgen and Tyson (1984) have studied cell cycle models which also take the cell size distribution into account.

We consider a model in which we assume that the cell cycle consists of two distinct phases. The first phase is of variable length. The cells in this phase cannot divide—they increase in size and, provided they do not die, they will eventually enter the second phase. This second phase, which is assumed to have constant duration, can be considered as an idealization of the mitotic period. At the conclusion of this phase cells split into two equal parts and the newborn daughter cells start the cycle in the first phase. It is assumed that the cells in the first phase are fully characterized by their size. By this we mean that for instance the growth, death and transition rates are functions of size, and of size only. Moreover, we assume that in the second phase the growth and death rates are functions of size, but the fission rate is a (delta-) function of the time elapsed since entering the second phase.

Our model could be considered as a generalization of the one-phase model studied by Diekmann et al. (1984) since if one formally puts the duration of the second phase equal to zero our fundamental equation (2.1) reduces to the corresponding equation in the above-mentioned paper.

The model could easily be modified (without essentially affecting the results) to allow for more complicated cell cycles and asymmetric division, see Gyllenberg (to appear).

Diekmann et al. (1984) showed that under reasonable hypotheses the population will ultimately grow or decay exponentially and they gave conditions on the individual growth rate under which the size distribution converges towards a so-called stable size distribution. In this paper we shall prove that the two-phase model exhibits a similar asymptotic behavior, if we adapt the condition on the growth rate.

It turns out to be mathematically convenient to write the model as a delay-differential equation in a Banach space. Our main tools will be the theory of strongly continuous semigroups and spectral theory, in particular of positive operators.

The organization of the paper is as follows. In §2 we write down the balance equation for the size distribution of the population of the first phase. This equation, which is a first-order hyperbolic PDE with time delay, transformed argument and singular coefficients, is then reformulated as an abstract linear delay-differential equation in a Banach space. In §3 we prove well-posedness of the abstract problem and associate a strongly continuous semigroup of bounded linear operators with the solution. In §4 we represent the solution as a generation expansion and give conditions under which the semigroup is compact after finite time. In §5 we study the related eigenvalue problem and characterize the spectrum of the infinitesimal generator of the semigroup. In §6 we use the results of the preceding sections to state and prove the main result on the asymptotic behavior of solutions.

2. The model. The starting point of our investigation is the balance equation for the size distribution of cells in the first phase

$$(2.1)\quad \frac{\partial}{\partial t}n(t,x)+\frac{\partial}{\partial x}(g(x)n(t,x))$$
$$=-\mu(x)n(t,x)-b(x)n(t,x)+\frac{2p(y^{-1}(x))b(y^{-1}(x))}{y'(y^{-1}(x))}n(t-r,y^{-1}(x)).$$

Here t denotes time and x denotes size. The unknown n is the size distribution of cells in the first phase, i.e. the integral $\int_{x_1}^{x_2} n(t,x)\,dx$ represents the number of cells in the first phase with size between x_1 and x_2 at time t. The functions g,μ and b (which are assumed to be known) are the rates at which cells of size x grow, die and transit to the second phase, respectively. $r>0$ is the constant duration of the second phase, $y(x)$ is the size of a newborn cell whose mother entered the second phase (exactly r time units before) with size x and $p(x)$ is the fraction of cells who survive the second phase given that they entered it with size x.

The left-hand side of (2.1) is the derivative along characteristic curves and describes an individual's motion in the time-size continuum due to growth. The first term on the right-hand side describes the loss due to deaths and the second the loss due to transition to the second phase. The last term describes the birth of cells from mother cells completing their second phase: of those cells that entered the second phase r time units ago with size $y^{-1}(x)$ a fraction $p(y^{-1}(x))$ will successfully complete the phase and give rise to two new cells of size x. The factor $1/y'(y^{-1}(x))$ may seem strange. It is due to the fact that cells giving birth to daughters in the size interval $(x,x+dx)$ left the first phase with size in the interval

$$\left(y^{-1}(x),y^{-1}(x)+\frac{dx}{y'(y^{-1}(x))}\right).$$

If one formally puts $r=0$, one should take $y(x)=\frac{1}{2}x$ and the last term in (2.1) reduces to the corresponding term in the model of Diekmann et al. (1984), namely $4b(2x)n(t,2x)$.

We assume that cells cannot enter the second phase before they have reached a minimal size x_0 and that $y(x_0)\leqq x_0$. It follows that cells with size less than $\alpha:=y(x_0)$ cannot exist. This fact is expressed by the boundary condition

$$n(t,\alpha)=0 \tag{2.2}$$

which supplements (2.1).

We assume further that each cell in the first phase must either die or transit to the second phase before it reaches a maximal size (normalized to $x=1$) of the first phase. This requires that the integral $\int_\alpha^x [b(s)/g(s)]\,ds$ diverges as $x\uparrow 1$ and that the source term in (2.1) is interpreted as zero for $x\geqq\beta:=y(1)$ where β is assumed to be smaller than 1. We once and for all make the convention that all functions containing $y^{-1}(x)$ as an argument are given the value zero for $x\geqq\beta$. The possible sizes a cell in the first phase can have thus lie in the interval $(\alpha,1)$, which should be chosen as the domain of x in (2.1). In order to obtain a well-posed problem, an initial function ν should be prescribed on $[-r,0]\times[\alpha,1]$:

$$n(t,x)=\nu(t,x), \qquad -r\leqq t\leqq 0, \quad \alpha\leqq x<1. \tag{2.3}$$

Concerning the growth, death and transition rates and the other given functions, we assume (compare Diekmann et al. (1984)):

(H_y) $y\in C^1[x_0,1]$, $y'>0$, $\alpha:=y(x_0)\leqq x_0$ and $\beta:=y(1)<1$.

(H_p) $p\in C[x_0,1]$, $0<p(x)\leqq 1$, $x\in[x_0,1]$.

(H_g) $g\in C[\alpha,1]$, $g(x)>0$, $x\in[\alpha,1]$.

(H_μ) $\mu\in C[\alpha,1]$, $\mu(x)\geqq 0$, $x\in[\alpha,1]$.

(H_b) $b\in C[\alpha,1]$, $b(x)=0$, $x\in[\alpha,x_0]$, $b(x)>0$, $x\in(x_0,1)$,

$$\lim_{x\uparrow 1}\int_{x_0}^x b(s)\,ds=\infty \quad\text{and}\quad \frac{b(x)}{g(x)}E(x)\leqq M<\infty, \qquad x\in[\alpha,1].$$

In the last condition we have used the notation

$$E(x)=\exp\left(-\int_\alpha^x \frac{b(s)+\mu(s)}{g(s)}\,ds\right). \tag{2.4}$$

$E(x)/E(y)$ is the probability that a cell of size y remains in the first phase at least until it reaches size x and $\int_{x_1}^{x_2}(b(s)/g(s))E(s)\,ds$ is the probability that a cell with size x_0 enters the second phase when its size is between x_1 and x_2. By our assumptions the (possibly defective) probability density bE/g is not only an L^1-function but also bounded and continuous.

We point out that some of the assumptions could be weakened at the cost of some minor technical difficulties. For instance, if $y(x_0)>x_0$ we could redefine x_0 in the following way. Let $x_n=y(x_{n-1})$, $n=1,2,\cdots$. Since $y(1)<1$, $x_n\to x_0'$ as $n\to\infty$ where x_0' is the smallest fixed point of y. x_0' could then be taken as the new x_0. A similar procedure has been carried out in Heijmans (to appear, b). Guided by Diekmann et al. (1984) we substitute

$$n(t,x)=\frac{E(x)}{g(x)}u(t,x) \tag{2.5}$$

into (2.1) and obtain

$$\frac{\partial u}{\partial t}(t,x)+g(x)\frac{\partial u}{\partial x}(t,x)=k(x)u(t-r,y^{-1}(x)), \tag{2.6}$$

where

$$k(x)=\begin{cases}2\dfrac{g(x)p(y^{-1}(x))b(y^{-1}(x))}{E(x)y'(y^{-1}(x))g(y^{-1}(x))}E(y^{-1}(x)), & x\in[\alpha,\beta),\\ 0, \quad x\in(\beta,1). \end{cases} \tag{2.7}$$

The boundary condition (2.2) becomes

$$u(t,\alpha)=0 \tag{2.8}$$

and the initial condition (2.3) changes into

$$u(t,x)=\phi(t,x), \qquad t\in[-r,0], \quad x\in[\alpha,1], \tag{2.9}$$

where

$$\phi(t,x)=[g(x)/E(x)]\nu(t,x).$$

We shall look for solutions which are continuous functions of t with values in the Banach space $X=L^1[\alpha,1]$. Therefore we rewrite the problem (2.6), (2.8), (2.9) as the following abstract delay equation:

$$\frac{du(t)}{dt}=Bu(t)+Lu(t-r), \qquad t>0, \tag{2.10}$$

$$u(t)=\phi(t), \qquad t\in[-r,0]. \tag{2.11}$$

Here B is the unbounded closed linear operator defined by $B\psi=-g\psi'$ for all ψ in the domain $\mathscr{D}(B)=\{\psi\in X\,|\,\psi$ is absolutely continuous on $[\alpha,1]$, $\psi(\alpha)=0\}$ and L is the operator defined for all ψ in X by $(L\psi)(x)=k(x)\psi(y^{-1}(x))$. It follows from (H_b) that L is a bounded linear operator on X. ϕ is a given initial function in

$$C=C([-r,0];X).$$

The rest of the paper is devoted to the investigation of so-called mild solutions of the abstract problem (2.10)–(2.11).

3. Existence and uniqueness and the corresponding semigroup. It is obvious that the operator B defined at the end of §2 generates a strongly continuous semigroup $\{S(t)\}_{t\geqq 0}$ of linear operators on X. In fact, let

$$G(x)=\int_\alpha^x \frac{d\xi}{g(\xi)} \tag{3.1}$$

and define

$$X(t,x)=G^{-1}(G(x)+t), \qquad 0\leqq G(x)+t\leqq G(1). \tag{3.2}$$

(Note that G^{-1} is well defined on $[0,G(1)]$ because $g>0$.) Then $S(t)$ is given for every $\psi\in X$, every $t\geqq 0$ and almost every $x\in[\alpha,1]$ by

$$(S(t)\psi)(x)=\begin{cases}\psi(X(-t,x)) & \text{if } G(x)-t>0,\\ 0 & \text{if } G(x)-t\leqq 0.\end{cases} \tag{3.3}$$

Note that $S(t)=0$ for $t \geqq G(1)$. Observe that $X(t,x)$ is the solution of the initial value problem

$$\frac{dX}{dt}=g(X), \qquad X(0,x)=x \tag{3.4}$$

and hence $X(t,x)$ represents the size of a cell at time t which had size x at time zero.

If there exists a continuously differentiable function u satisfying (2.10), (2.11), it satisfies the following integral equation (variation of constants formula)

$$u(t)=S(t)\phi(0)+\int_0^t S(t-s)Lu(s-r)\,ds \tag{3.5}$$

for $t>0$. Any continuous function u which satisfies (3.5), (2.11) is called a *mild solution* of the initial value problem.

Travis and Webb (1974) have investigated existence, uniqueness and semigroup properties of a class of functional differential equations in Banach spaces. Some of their basic results can be applied to the present problem. As a special case of Proposition 2.1 of Travis and Webb (1974) we have

PROPOSITION 3.1. *For each $\phi \in C$ there exits a unique mild solution $u(\phi)$: $[-r,\infty)\to X$ of the initial value problem* (2.10), (2.11).

If u is a continuous function $[-r,\infty)\to X$ we denote by u_s $(s \geqq 0)$ the element of C defined by

$$u_s(\theta)=u(s+\theta), \qquad \theta \in [-r,0].$$

For each $t \geqq 0$ we define $T(t)$: $C \to C$ by $T(t)\phi=u(\phi)_t$, $\phi \in C$, where $u(\phi)$ is the unique mild solution of (2.10), (2.11) given by Proposition 3.1. The results of Travis and Webb (1974, Prop. 3.1.) give us the following:

PROPOSITION 3.2. *$\{T(t)\}_{t \geqq 0}$ is a strongly continuous semigroup of linear operators on C. The infinitesimal generator A of $\{T(t)\}_{t \geqq 0}$ is given by*

$$\mathscr{D}(A)=\{\phi \in C \mid \phi' \in C, \phi(0) \in \mathscr{D}(B), \phi'(0-)=B\phi(0)+L\phi(-r)\},$$
$$(A\phi)(\theta)=\phi'(\theta), \qquad \theta \in [-r,0].$$

One of our main objectives is to describe the large time behavior of mild solutions. Such information can be obtained from spectral properties of $T(t)$. If the semigroup is compact after finite time, then by a well-known spectral mapping theorem (cf. Pazy (1983, Chap. 2)) the spectrum of $T(t)$ is completely determined by the spectrum of its infinitesimal generator A. In the next section we give conditions under which $T(t)$ is indeed compact for t large enough and in §5 we use positivity arguments to give a rather precise characterization of the spectrum of A. It turns out that the same condition which ensures compactness of $T(t)$ guarantees the existence of a strictly dominant real eigenvalue of A. A combination of these results enables us to determine the asymptotic behavior of solutions.

4. Generation expansion and compactness of the semigroup. In the theory of linear autonomous differential-delay equations in finite-dimensional Euclidean spaces $\mathbb{R}^n$ the semigroup associated with the solution acts on the space $C([-r,0];\mathbb{R}^n)$ and it is a relatively easy consequence of Ascoli's theorem that the semigroup is compact for $t \geqq r$ (cf. Hale (1977, Chap. 7)). In our case $\mathbb{R}^n$ is replaced by the infinite-dimensional Banach space X and the proof of Lemma 1.1 of Hale (1977, Chap. 7) does not carry over to this case, simply because the Heine–Borel theorem fails in infinite-dimensional spaces. Neither can we use the compactness results of Travis and Webb (1974) since their results depend heavily on the assumption that the operator B generates a semigroup which which is compact for *all* $t>0$ and this condition is not satisfied in the problem under consideration.

In order to prove compactness of the semigroup corresponding to a related problem (without delay), Diekmann et al. (1984) wrote down a generation expansion for the solution. Here we shall use similar methods. The larger dimensionality of our state space makes the compactness proof a bit more involved than in the above-mentioned paper.

In the problem under consideration where we have to take account of individuals present at negative time, it makes sense to define also the -1st generation. We write

$$u(t;\phi)=\sum_{i=-1}^{\infty} u^i(t;\phi), \tag{4.1}$$

where

$$u^{-1}(t;\phi)=\begin{cases}\phi(t), & -r\leqq t\leqq 0,\\ 0, & t>0,\end{cases} \tag{4.2}$$

$$u^0(t;\phi)=S(t)\phi(0)+\int_0^t S(t-\tau)Lu^{-1}(\tau-r;\phi)\,d\tau, \qquad t\geqq 0 \tag{4.3}$$

and the higher generations are obtained by iteration of the integral operator.

$$u^{i+1}(t;\phi)=\int_0^t S(t-\tau)Lu^i(\tau-r;\phi)\,d\tau, \qquad t\geqq 0, \quad i\geqq 0. \tag{4.4}$$

Let for $i\geqq 0$ and $t\in[r,\infty)$ the operator family $T^i(t)$: $C\to C$ be defined by

$$T^i(t)\phi=u^i(\phi)_t. \tag{4.5}$$

Now let $i\geqq 0$, $t\geqq r$ and $\theta\in[-r,0]$, then

$$\begin{aligned}(T^{i+1}(t)\phi)(\theta)=u^{i+1}(t+\theta;\phi)&=\int_0^{t+\theta} S(t+\theta-\tau)Lu^i(\tau-r;\phi)\,d\tau\\ &=\int_{-\theta}^t S(t-s)Lu^i(s+\theta-r;\phi)\,ds\\ &=\int_{-\theta}^t S(t-s)L(T^i(s-r)\phi)(\theta)\,ds\\ &=\int_r^t S(t-s)L(T^i(s-r)\phi)(\theta)\,ds.\end{aligned}$$

For a bounded operator F: $X\to X$ we define the bounded operator $\tilde{F}$: $C\to C$ by $(\tilde{F}\phi)(\theta)=F(\phi(\theta))$ for all $\phi\in C$. Thus we can write

$$T^{i+1}(t)=\int_r^t \tilde{S}(t-s)\tilde{L}T^i(s-r)\,ds, \qquad t\geqq r, \quad i\geqq 0. \tag{4.6}$$

We note that $T(t)=\sum_{i=0}^{\infty}T^i(t)$, $t\geqq r$. If we can prove that $T^1(t)$ is compact for $t\geqq r$ then it follows from (4.6) that $T^{i+1}(t)$ is compact for $t\geqq r$ and $i\geqq 1$ and this finally yields that $T(t)$ is compact, $t\geqq r+G(1)$, since $T^0(t)=0$ if $t\geqq r+G(1)$. Therefore the rest of this section is concerned with a proof of the compactness of $T^1(t)$, $t\geqq r$.

The following version of Ascoli's theorem can be found in Martin (1976, Thm. II, 3.2.).

LEMMA 4.1. *A set V in C is precompact if the following conditions are satisfied*:

i) *V is bounded.*

ii) *The family V is equicontinuous.*

iii) *For each $\theta \in [-r,0]$ the subset $\{\phi(\theta) \mid \phi \in V\}$ of X is precompact.*

An easy calculation shows that

$$(4.7)\quad u^0(t,x;\phi)=\phi(0,X(-t,x))+\int_0^t k(X(-\tau,x))\phi\big(t-\tau-r,y^{-1}(X(-\tau,x))\big)\,d\tau,$$

$$(4.8)\quad u^1(t,x;\phi)=\int_0^t k(X(-\tau,x))\Big\{\phi\big(0,X(-t+\tau+r,y^{-1}(X(-\tau,x)))\big) + \int_0^{t-\tau-r} k\big(X(-\sigma,y^{-1}(X(-\tau,x)))\big) \cdot\phi\big(t-\sigma-\tau-2r,y^{-1}\big(X(-\sigma,y^{-1}(X(-\tau,x)))\big)\big)\,d\sigma\Big\}\,d\tau.$$

In trying to prove compactness of $T^1(t)$ it becomes clear that we need some relation between g and y. We shall make the following assumption:

Assumption 4.2.

$$g(x)y'(x)<g(y(x)),\qquad x_0\leqq x\leqq 1.$$

Below we shall give an interpretation of this inequality.

THEOREM 4.3. *If Assumption* 4.2 *is satisfied, then the semigroup $T(t)$ is compact for $t\geqq r+G(1)$.*

Proof. We have already explained that it suffices to show that $T^1(t)$ is compact for $t\geqq r$. Instead of (4.8) we can write

$$u^1(t,x;\phi)=u_1^1(t,x;\phi)+u_2^1(t,x;\phi),$$

where

$$u_1^1(t,x;\phi)=\int_0^t k(X(-\tau,x))\cdot\phi\big(0,X(-t+\tau+r,y^{-1}(X(-\tau,x)))\big)\,d\tau,$$

$$u_2^1(t,x;\phi)=\int_0^t k(X(-\tau,x))\Big\{\int_{-r}^{t-\tau-2r} k\big(X(s-t+\tau+2r,y^{-1}(X(-\tau,x)))\big) \cdot\phi\big(s,y^{-1}\big(X(s-t+\tau+2r,y^{-1}(X(-\tau,x)))\big)\big)\,ds\Big\}\,d\tau$$

where in this second expression we have substituted

$$s=t-\sigma-\tau-2r.$$

Let $T_j^1(t)$: $C\to C$ for $t\geqq r$, $j=1,2$ be given by

$$\big(T_j^1(t)\phi\big)(\theta)=u_j^1(t+\theta;\phi),\qquad \theta\in[-r,0].$$

Here we shall prove that $T_2^1(t)$ is compact for $t\geqq r$. The easier proof of compactness of $T_1^1(t)$, $t\geqq r$ is omitted.

Let $t\geqq r$ be fixed and let for $R>0$ the subset C_R of C be given by $C_R=\{\phi\in C \mid \|\phi\|_C\leqq R\}$. We will show that $V=\{T_2^1(t)\phi \mid \phi\in C_R\}$ obeys the conditions of Lemma 4.1. Obviously V is bounded. Now we replace τ by the variable

$$z=y^{-1}\big(X(s-t+\tau+2r,y^{-1}(X(-\tau,x)))\big).$$

Then

$$X(-s+t-\tau-2r,y(z))=y^{-1}(X(-\tau,x))=\xi.$$

Differentiation with respect to τ yields:

$$-g(\xi)+\frac{g(\xi)}{g(y(z))}\cdot y'(z)\frac{dz}{d\tau}=-\frac{g(y(\xi))}{y'(\xi)}.$$

Therefore, if Assumption 4.2 is satisfied, $dz/d\tau$ never becomes zero and replacing τ by z in the expression of u_2^1 one obtains

$$u_2^1(t,x;\phi)=\iint\limits_{\Omega(t,x)} Q(s,z;t,x)\phi(s,z)\,ds\,dz,$$

where $\iint_{\Omega(t,x)}ds\,dz$ is uniformly continuous in t and x in bounded subsets of the (t,x)-plane and $Q(s,z;\ t,x)$ is uniformly continuous in s,z,t and x in bounded subsets of the (s,z,t,x)-plane. At this point the reader will have no difficulty in seeing that V indeed obeys conditions (ii) and (iii) of Lemma 4.1. □

In the case where there is no delay, which has been studied by Diekmann et al. (1984), the function y is given by $y(x)=\frac{1}{2}x$ and Assumption 4.2 reduces to $\frac{1}{2}g(x)<g(\frac{1}{2}x)$, $x_0\leqq x\leqq 1$, and this is indeed the condition imposed in that paper in order to establish compactness of the semigroup.

To see the biological meaning of Assumption 4.2, consider two identical cells in the first phase with size $x>x_0$. Assume that one of the cells immediately enters the second phase. It will divide after r time units. Assume further that the two daughter cells will remain in the first phase for t time units. $t+r$ time units after our initial moment each daughter cell will have size $X(t,y(x))$. The other cell is assumed to behave differently. It first grows for t time units reaching size $X(t,x)$, then enters the second phase and finally at time $t+r$ divides into two daughter cells of size $y(X(t,x))$ each. Assumption 4.2 guarantees that

$$y(X(t,x))<X(t,y(x)). \tag{4.9}$$

This can be seen as follows. Differentiation of $G(x)-G(y(x))$ shows that this expression is increasing in x if Assumption 4.2 is satisfied. Now for $t>0$ and x, $\alpha\leqq x\leqq X(-t,1)$ we have that $x<X(t,x)$ and therefore

$$G(x)-G(y(x))<G(X(t,x))-G(y(X(t,x)))=t+G(x)-G(y(X(t,x)));$$

hence

$$G(y(X(t,x)))<t+G(y(x))$$

which implies (4.9). This thought experiment shows that the combination of growth and division provides a dispersion mechanism for cell size, which is essential for proving compactness and also, as we shall see in the following section, for proving some sort of strong positivity.

If $\beta<x_0$, then every cell has to pass size x_0 in each cycle. If Assumption 4.2 fails for all $x\in[x_0,1]$ (which corresponds to the case where individual cells grow exponentially throughout the cell cycle), then $\tau:=G(x)-G(x_0)+r+G(x_0)-G(y(x))$ is constant. But τ is the time elapsed between the event when the mother cell passes size x_0 and the event when the two daughter cells pass size x_0. Thus τ can be considered as the effective cycle time. In the case of exponential individual growth the cycle time τ is the same for all cells; it does not depend on size; there is no dispersion.

Finally we point out that Assumption 4.2 implies

$$y(x)<x \quad \text{for all } x\in(x_0,1) \tag{4.10}$$

which is a strengthening of (H_y). To see this, let $x\in(x_0,1)$ and take $t>0$ such that $X(t,x_0)=x$. Then (4.9) implies

$$y(x)=y(X(t,x_0))<X(t,y(x_0))\leqq X(t,x_0)=x. \tag{4.11}$$

5. The spectrum of $\boldsymbol{A}$. In this section we combine ideas similar to those of Travis and Webb (1974), Hale (1977, Chap. 7) and Heijmans (to appear, a) to describe the spectrum of the generator A and, in particular, to prove the existence of a strictly dominant, algebraically simple real eigenvalue. Assumption 4.2 is not presupposed unless this is explicitly stated.

Let us first introduce some notation. The norm of a Banach space Z is denoted by $\|\cdot\|_Z$. Z^* stands for the dual space of Z. We let $\langle\Phi,\phi\rangle_Z$ be the duality pairing of $\phi\in Z$, $\Phi\in Z^*$. For an operator T defined on a domain $\mathscr{D}(T)\subset Z$ with values in Z we let $\sigma(T)$, $P\sigma(T)$ and $\rho(T)$ denote the spectrum, point spectrum and resolvent set of T respectively. $r(T)$ is the spectral radius, $\mathscr{N}(T)$ the kernel and $\mathscr{R}(T)$ the range of T.

By definition, $\lambda\in\rho(A)$ if and only if the equation

$$(\lambda I-A)\phi=\psi \tag{5.1}$$

has a unique solution $\phi\in\mathscr{D}(A)$ for all ψ in C and ϕ depends continuously on ψ. By Proposition 3.2 each ϕ in $\mathscr{D}(A)$ is continuously differentiable on $[-r,0]$ and $A\phi=\phi'$. Hence (5.1) can be rewritten as

$$\lambda\phi(\theta)-\phi'(\theta)=\psi(\theta), \qquad \theta\in[-r,0] \tag{5.2}$$

and it follows that every solution ϕ of (5.2) is given by

$$\phi(\theta)=e^{\lambda\theta}\phi(0)+\int_\theta^0 e^{\lambda(\theta-s)}\psi(s)\,ds, \qquad \theta\in[-r,0]. \tag{5.3}$$

In particular,

$$\phi(-r)=e^{-\lambda r}\phi(0)+\int_{-r}^0 e^{-\lambda(r+s)}\psi(s)\,ds. \tag{5.4}$$

On the other hand, Proposition 3.2 also tells us that

$$\phi'(0)=B\phi(0)+L\phi(-r) \tag{5.5}$$

for all $\phi\in\mathscr{D}(A)$. Combining (5.2), (5.4) and (5.5), one obtains

$$\Delta(\lambda)\phi(0)=\psi(0)+H(\lambda)\psi, \tag{5.6}$$

where for each $\lambda\in\mathbf{C}$ the operator $\Delta(\lambda)$ with domain $\mathscr{D}(\Delta(\lambda))=\mathscr{D}(B)$ and values in X is defined by

$$\Delta(\lambda)=\lambda I-B-e^{-\lambda r}L \tag{5.7}$$

and $H(\lambda)$ is defined on all of C by

$$H(\lambda)\psi=L\left(\int_{-r}^{0}e^{-\lambda(r+s)}\psi(s)\,ds\right),\qquad \psi\in C. \tag{5.8}$$

We can now prove the following.

PROPOSITION 5.1. (a) $\lambda\in\sigma(A)$ *if and only if* $0\in\sigma(\Delta(\lambda))$.

(b) $\lambda\in P\sigma(A)$ *if and only if* $0\in P\sigma(\Delta(\lambda))$. *Moreover*, $\dim\mathcal{N}(\lambda I-A)=\dim\mathcal{N}(\Delta(\lambda))$.

Proof. (a) Above we have shown that if $\phi\in\mathcal{D}(A)$ is a solution of (5.1), then $\phi(0)$ satisfies (5.6). Conversely, if $\phi(0)\in X$ satisfies (5.6) then the function ϕ given by (5.3) belongs to $\mathcal{D}(A)$ and is a solution of (5.1). To complete the proof of (a), it suffices to show that the right-hand side of (5.6) covers X as ψ ranges over C. In order to see this, consider $\psi\in C$ given by $\psi(s)=f(s)w$ where $w\in X$ and the scalar function f defined on $[-r,0]$ satisfies (i) $f(0)=1$, (ii) $\int_{-r}^{0}e^{-\lambda s}f(s)\,ds=0$. It is obvious that $\psi(0)+H(\lambda)\psi=w$.

b) Suppose $\lambda\in P\sigma(A)$ and let $\phi\in C$, $\phi\neq0$ satisfy $A\phi=\lambda\phi$. Then $\phi(\theta)=\phi(0)e^{\lambda\theta}$ and $\Delta(\lambda)\phi(0)=0$. From $\phi\neq0$ it follows that $\phi(0)\neq0$ and therefore $0\in P\sigma(\Delta(\lambda))$. Similarly, $0\in P\sigma(\Delta(\lambda)\Rightarrow\lambda\in P\sigma(A)$. The second relation follows immediately. □

Proposition 5.1 characterizes the spectrum and the point spectrum of A acting in the space $C=C([-r,0],X)$ in terms of the operator $\Delta(\lambda)$ acting in the simpler space X. Below we shall investigate the spectral properties of $\Delta(\lambda)$ with the aid of yet another operator and eventually obtain a rather precise description of $\sigma(A)$.

Consider the equation

$$\Delta(\lambda)w=f, \tag{5.9}$$

that is,

$$\lambda w(x)+g(x)w'(x)-e^{-\lambda r}k(x)w(y^{-1}(x))=f(x) \tag{5.10}$$

where $f\in X$. We are looking for solution $w\in\mathcal{D}(\Delta(\lambda))=\mathcal{D}(B)$. Following Heijmans (to appear, a), we transform (5.10) into an integral equation by means of the following substitution:

$$w(x)=e^{-\lambda G(x)}v(x). \tag{5.11}$$

Then (5.10) takes the form

$$v'(x)-k_\lambda(x)v(y^{-1}(x))=\frac{f(x)}{g(x)}e^{\lambda G(x)}, \tag{5.12}$$

where by definition

$$k_\lambda(x)=\begin{cases}\dfrac{k(x)}{g(x)}e^{-\lambda[G(y^{-1}(x))-G(x)+r]}, & x\in[\alpha,\beta),\\ 0, & x\in[\beta,1).\end{cases} \tag{5.13}$$

Since w as a member of $\mathcal{D}(B)$ should be continuous and vanish at $x=\alpha$ the same must be true for v. We therefore look for solutions $v\in Y$ of (5.12) where Y is the Banach space

$$Y=\{v\in C[\alpha,1]\mid v(\alpha)=0\}. \tag{5.14}$$

Integration of (5.12) yields

$$v-K(\lambda)v=U(\lambda)f \tag{5.15}$$

where for $\lambda\in\mathbb{C}$ the operators $K(\lambda)$: $Y\to Y$ and $U(\lambda)$: $X\to X$ are defined by

$$(5.16)\qquad [K(\lambda)v](x)=\int_\alpha^{(x,\beta)^-} k_\lambda(\xi)v(y^{-1}(\xi))\,d\xi,\qquad v\in Y,\quad x\in[\alpha,1],$$

$$(5.17)\qquad [U(\lambda)f](x)=\int_\alpha^x \frac{f(\xi)}{g(\xi)}e^{\lambda G(\xi)}d\xi,\qquad f\in X.$$

The advantage of the formulation using the operators $K(\lambda)$ and $U(\lambda)$ is that these are compact (the proof of this fact is standard) and that $K(\lambda)$ has useful positivity properties. Observe that the range of $U(\lambda)$ lies in Y.

We can now prove the following theorem concerning some relations between the spectra of A, $\Delta(\lambda)$ and $K(\lambda)$.

THEOREM 5.2. *The following conditions are equivalent.*

(a) $\lambda\in\sigma(A)$.

(b) $\lambda\in P\sigma(A)$.

(c) $0\in\sigma(\Delta(\lambda))$.

(d) $0\in P\sigma(\Delta(\lambda))$.

(e) $1\in\sigma(K(\lambda))$.

(f) $1\in P\sigma(K(\lambda))$.

Moreover, if $K(\lambda)v=v$ *for some* $\lambda\in\mathbb{C}$ *and* $v\in Y$, *then* w *given by* (5.11) *belongs to* $\mathscr{D}(B)$ *and satisfies* $\Delta(\lambda)w=0$. *If* $0\notin\sigma(\Delta(\lambda))$, *then* $\Delta(\lambda)^{-1}$ *is compact.*

Proof. In Proposition 5.1 we have already proved (a)⇔(c) and (b)⇔(d).

Putting $f=0$ one observes by comparing (5.9) and (5.15) that (d)⇔(f) and that the eigenvector v belonging to the eigenvalue 1 of $K(\lambda)$ corresponds to the eigenvector w belonging to the eigenvalue 0 of $\Delta(\lambda)$.

(e)⇔(f) follows directly from the compactness of $K(\lambda)$.

Since trivially (b)⇒(a) it remains to show that (c)⇒(e). To this end, suppose that $1\notin\sigma(K(\lambda))$ which means that $I-K(\lambda)$ is invertible. For each $f\in X$ there exists therefore a unique solution $v\in Y$ of (5.15). But then w defined by (5.11) satisfies (5.9). Hence $0\in\sigma(\Delta(\lambda))$.

To prove compactness of $\Delta(\lambda)^{-1}$ for $0\in\rho(\Delta(\lambda))$ observe that since $U(\lambda)$ is compact and $(I-K(\lambda))^{-1}$ is bounded, the mapping $f\to v$ defined by (5.15) is compact. The transformation $v\to w$ defined by (5.11) is obviously bounded, hence $\Delta(\lambda)^{-1}$: $f\to w$ is compact. □

One important consequence of Theorem 5.2 is that the spectrum of A consists solely of eigenvalues ((a)⇔(b)). We emphasize that in order to establish this result we have not used compactness of $T(t)$, which would also imply the equivalence of (a) and (b).

Theorem 5.2 gives two entirely different characterizations of $\sigma(A)$—one in terms of $\Delta(\lambda)$, the other in terms of $K(\lambda)$. These characterizations will also be used for different purposes in the analysis to follow. $\Delta(\lambda)$ will prove to be of great importance in determining the algebraic and analytic properties of the eigenvalues and the resolvent operator of A. $K(\lambda)$ turns out to play a fundamental role in the investigation of the location of the eigenvalues in the complex plane.

We start by writing down an explicit expression for the resolvent operator $R(\lambda,A)$: $C\to C$ of A. It follows from (5.3) and (5.6) that for $\lambda\in\rho(A)(\neq\varnothing$, since by a standard result for semigroups $\lambda\in\rho(A)$ for all λ with $\operatorname{Re}\lambda$ large enough)

$$(5.18)\qquad (R(\lambda,A)\psi)(\theta)=e^{\lambda\theta}\left\{\Delta(\lambda)^{-1}(\psi(0)+H(\lambda)\psi)+\int_\theta^0 e^{-\lambda s}\psi(s)\,ds\right\}.$$

Hence $R(\lambda,A)=R_1(\lambda)+R_2(\lambda)$, where for $\lambda\in\rho(A)$, the bounded operators $R_1(\lambda)$ and $R_2(\lambda)$ are given by

$$(R_1(\lambda)\psi)(\theta)=e^{\lambda\theta}\cdot\Delta(\lambda)^{-1}(\psi(0)+H(\lambda)\psi), \qquad \psi\in C,$$

$$(R_2(\lambda)\psi)(\theta)=\int_\theta^0 e^{\lambda(\theta-s)}\psi(s)\,ds, \qquad \psi\in C.$$

From the boundedness of $H(\lambda)$: $C\to X$ and the compactness of $\Delta(\lambda)^{-1}$ if $\lambda\in\rho(A)$ it follows that $R_1(\lambda)$: $C\to C$ is compact if $\lambda\in\rho(A)$. Furthermore $R_2(\lambda)$ is quasinilpotent, i.e. $r(R_2(\lambda))=0$ if $\lambda\in\mathbb{C}$. This can be shown as follows. Define the norm $\|\cdot\|_\gamma$ on C as follows: $\|\psi\|_\gamma=\sup_{-r\leqq\theta\leqq 0}\|e^{-\gamma\theta}\psi(\theta)\|_X$. (This norm is equivalent to the original norm $\|\cdot\|_C$.) Now let $\gamma\in\mathbb{R}$ be such that $\gamma+\mathrm{Re}\lambda>0$. A straightforward calculation shows that $\|R_2(\lambda)\psi\|_\gamma\leqq(1/(\gamma+\mathrm{Re}\lambda))\|\psi\|_\gamma$. Therefore $r(R_2(\lambda))\leqq 1/(\gamma+\mathrm{Re}\lambda)$ for all $\gamma>-\mathrm{Re}\lambda$ and this yields the result. As a sum of a compact and a quasinilpotent operator $R(\lambda,A)$ is a *Riesz operator* (cf. Dowson (1978)). The following result was proved by Lay (1970, Thm. 4.6).

THEOREM 5.3. *Let Z be an infinite-dimensional Banach space and let T be a closed operator on Z with nonempty resolvent set. Suppose that there exists an $\alpha\in\rho(T)$ such that $R(\alpha,T)$ is a Riesz operator. Then $\sigma(T)$ is a countable set of poles of $R(\lambda,T)$ of finite rank with ∞ the only possible point of accumulation.*

As a consequence we have the following result.

COROLLARY 5.4. *If $\lambda_0\in\sigma(A)$ then λ_0 is a pole of $R(\lambda,A)$ with residue of finite rank.*

Remark 5.5. (a) For all $\lambda_0\in\sigma(A)$ we have that λ_0 is a pole of order p of $(\Delta(\lambda))^{-1}$ iff λ_0 is a pole of order p of $R(\lambda,A)$. This follows easily from (5.18) and the fact that $e^{\lambda\theta}$, the operator $H(\lambda)$ and the operator from C to X given by $\psi\to\int_\theta^0 e^{-\lambda s}\psi(s)\,ds$ define entire functions.

(b) If Assumption 4.2 is satisfied, then the semigroup $T(t)$ is compact after finite time, and therefore the *Browder essential spectrum* (see e.g. Webb (1985) for a definition) $\sigma_{\mathrm{ess}}(T(t))=\{0\}$, $t>0$, and now Corollary 5.4 follows immediately from Proposition 4.13 of Webb (1985) which says among other things

$$\{e^{\lambda t}\,|\,\lambda\in\sigma_{\mathrm{ess}}(A)\}\subset\sigma_{\mathrm{ess}}(T(t)), \qquad t>0.$$

The operator $K(\lambda)$ is very similar to an operator studied by Heijmans (to appear, a). Using essentially the same methods, based on the positivity of $K(\lambda)$ for $\lambda\in\mathbb{R}$, one can prove the following result. For readers consulting the above mentioned reference we mention that $K(\lambda)$ corresponds to T_λ and that $x_0>\alpha$ and $x_0=\alpha$ respectively correspond to the cases $a>0$ and $a=0$ of that paper.

LEMMA 5.6. *There exists a $\lambda_d\in\mathbb{R}$ such that*

i) 1 *is an algebraically simple eigenvalue of* $K(\lambda_d)$.

ii) *The associated eigenvector $v_d\in Y$ is strictly positive on* $(\alpha,1]$.

iii) *All elements $\lambda\in\sigma(A)$ satisfy* $\mathrm{Re}\lambda\leqq\lambda_d$.

Let X_+ be the subset of X consisting of all functions which are nonnegative a.e.; then X_+ defines a cone in X and with the induced ordering X is a Banach lattice (see e.g. Schaefer (1974)). Define C_+ as

$$C_+=\{\phi\in C\,|\,\phi(\theta)\in X_+,\theta\in[-r,0]\}.$$

With the ordering induced by the cone C_+ the space C becomes a Banach lattice as well.

Now we can prove the following important result.

THEOREM 5.7. *The eigenvalue* λ_d *of* A *is algebraically simple. The eigenvector* ϕ_d *satisfies* $\phi_d(\theta,x)=e^{\lambda_d\theta}w_d(x)$ *where* $w_d\in Y$ *and* $w_d(x)>0$, $x\in(\alpha,1]$. *The dual eigenvector* Φ_d, *determined by* $A^*\Phi_d=\lambda_d\Phi_d$ *is strictly positive, i.e.* $\phi\in C_+$, $\phi\neq 0$ *implies that* $\langle\Phi_d,\phi\rangle_c>0$.

Proof. As in Theorem 5.4 of Heijmans (to appear, a) we can show that λ_d is a simple pole of $\Delta(\lambda)^{-1}$ and that the eigenvalue 0 of $\Delta(\lambda_d)$ has geometric multiplicity one. Combined with Proposition 5.1(b) and Remark 5.5(a) this yields the algebraic simplicity of the eigenvalue λ_d of A. Let v_d be given by Lemma 5.6 and w_d by (5.11); then $\Delta(\lambda_d)w_d=0$. Now $\phi_d\in C_+$ given by $\phi_d(\theta)=e^{\lambda_d\theta}w_d$ satisfies indeed the conditions stated in the theorem.

An easy calculation shows that $R(\lambda,A)$ defines a positive operator with respect to the cone C_+ if $\lambda>\lambda_d$. Now let $\lambda_0>\lambda_d$ be fixed. Then $r(R(\lambda_0,A))=1/(\lambda_0-\lambda_d)$ and a standard result from positive operator theory says that $R(\lambda_0,A)^*\Phi_d=(1/(\lambda_0-\lambda_d))\Phi_d$ for some positive functional $\Phi_d\neq 0$. Since $R(\lambda_0,A)^*=R(\lambda_0,A^*)$ (cf. Taylor and Lay (1980)) we obtain that $A^*\Phi_d=\lambda_d\Phi_d$. Now suppose that Φ_d is not strictly positive, i.e., there is a $\psi\in C_+$, $\psi\neq 0$ such that $\langle\Phi_d,\psi\rangle_c=0$. Then $\psi\in\mathcal{N}(\lambda_dI-A^*)^\perp=\mathcal{R}(\lambda_dI-A)$; hence $\lambda_d\phi-A\phi=\psi$ for some $\phi\in C$, hence

$$\Delta(\lambda_d)\phi(0)=\psi(0)+H(\lambda_d)\psi+X_+\backslash\{0\}.$$

A calculation very similar to the one performed in the proof of Theorem 5.4 of Heijmans (to appear, a) shows that

$$\mathcal{R}(\Delta(\lambda_d))\cap X_+=\{0\}$$

and this is a contradiction. Therefore Φ_d is strictly positive. □

An important question is whether or not the eigenvalue λ_d is strictly dominant, i.e. $\mathrm{Re}\lambda<\lambda_d$ if $\lambda\in\sigma(A)$, $\lambda\neq\lambda_d$. If Assumption 4.2 is satisfied, this would immediately imply that there exists a positive ε such that $\mathrm{Re}\lambda<\lambda_d-\varepsilon$ if $\lambda\in\sigma(A)$, $\lambda\neq\lambda_d$, because if this were not true then there would exist a sequence $\lambda_n\in\sigma(A)$ such that $\mathrm{Re}\lambda_n$ is strictly increasing and $\mathrm{Re}\lambda_n\to\lambda_d$, $n\to\infty$. But if $t>0$ is such that $T(t)$ is compact, then $e^{\lambda_nt}\in\sigma(T(t))$ and $|e^{\lambda_nt}|=e^{\mathrm{Re}\lambda_n\cdot t}\to e^{\lambda_dt}$, $n\to\infty$ which implies that $\sigma(T(t))$ has an accumulation point different from zero contradicting the compactness of $T(t)$.

The answer to the question concerning the strict dominance depends strongly on the dependence of the kernel $k_\lambda(x)$ of the operator $K(\lambda)$ on λ. As in Heijmans (to appear, a) we can prove the following result.

THEOREM 5.8. *If Assumption* 4.2 *is satisfied, then there is an* $\varepsilon>0$ *such that* $\mathrm{Re}\lambda<\lambda_d-\varepsilon$ *if* $\lambda\in\sigma(A)\backslash\{\lambda_d\}$.

If Assumption 4.2 is false for every $x\in[x_0,1]$, then

$$G(\gamma^{-1}(\xi))-G(\xi)=c,\qquad \alpha\leqq\xi\leqq\beta,$$

where c is a constant, and we find that

$$K(\lambda)=e^{-\lambda(r+c)}K(0),$$

where the operator $K(0)$ does not depend on λ.

It follows immediately that in this case

$$\lambda\in\sigma(A)\Rightarrow\lambda+k\cdot\frac{2\pi i}{r+c}\in\sigma(A),\qquad k\in\mathbb{Z},$$

and Theorem 5.8 is certainly not true in this case. If Assumption 4.2 is fulfilled on a nonempty subset of $[x_0,1]$ then the situation is more complicated but one can prove that Theorem 5.8 is still true (see Diekmann, Heijmans and Thieme (1985)).

As in Heijmans (to appear, a) it is possible to compute the so-called characteristic equation from which all eigenvalues of A can be calculated in principle. Here we shall only do this for the special case $\beta < x_0$.

Let $\beta < x_0$ and let v be a solution of

$$K(\lambda)v=v.$$

Then $v(x)$ is constant for $\beta \leqq x \leqq 1$ and we may take $v(x)=1$, $\beta \leqq x \leqq 1$. Then

$$v(x)=\int_\alpha^x k_\lambda(\xi)v(y^{-1}(\xi))\,d\xi=\int_\alpha^x k_\lambda(\xi)\,d\xi, \qquad \alpha \leqq x < \beta.$$

Since v has to be continuous in $x=\beta$, we obtain

$$1=\int_\alpha^\beta k_\lambda(\xi)\,d\xi \tag{5.19}$$

and this equation determines the elements of $\sigma(A)$ if $\beta < x_0$.

6. The stable size distribution. Throughout this section we assume that Assumption 4.2 is satisfied. Let λ_d be the strictly dominant eigenvalue of A, and let ϕ_d, Φ_d be given by Theorem 5.7. Since λ_d is a simple pole of $R(\lambda,A)$, we have the following decomposition of the state space C (cf. Taylor and Lay (1980)):

$$C=\mathscr{N}(\lambda_d I-A)\oplus\mathscr{R}(\lambda_d I-A), \tag{6.1}$$

where $\mathscr{N}(\lambda_d I-A)$ is the one-dimensional space spanned by the positive eigenvector ϕ_d. Let P be the orthogonal projection on $\mathscr{N}(\lambda_d I-A)$ according to this decomposition; then P is given by

$$P\phi=\langle\Phi_d,\phi\rangle_c\cdot\phi_d, \tag{6.2}$$

where we have normalized Φ_d, ϕ_d such that $\langle\Phi_d,\phi_d\rangle_c=1$. Let $\tilde{T}(t)$ be the restriction of $T(t)$ to $\mathscr{R}(\lambda_d I-A)$; then $r(\tilde{T}(t))\leqq e^{(\lambda_d-\varepsilon)t}$, $t\geqq 0$, where we have used Theorem 5.8. A standard result from semigroup theory says that for all $0<\eta<\varepsilon$ there exits an $M(\eta)\geqq 1$ such that $\|\tilde{T}(t)\psi\|\leqq M(\eta)e^{(\lambda_d-\eta)t}\|\psi\|$, for all $\psi\in\mathscr{R}(\lambda_d I-A)$. Let $\phi\in C$; then $\phi=P\phi+(I-P)\phi=\langle\Phi_d,\phi\rangle_c\cdot\phi_d+(I-P)\phi$ and therefore

$$T(t)\phi=\langle\Phi_d,\phi\rangle_c\cdot e^{\lambda_d t}\cdot\phi_d+\tilde{T}(t)(I-P)\phi, \qquad t\geqq 0$$

and the following result is obtained.

THEOREM 6.1. *For all $0<\eta<\epsilon$ there is a constant $M(\eta)\geqq 1$ such that for all $\phi\in C$*

$$\left\|T(t)\phi-\langle\Phi_d,\phi\rangle_c\cdot e^{\lambda_d t}\cdot\phi_d\right\|\leqq M(\eta)e^{(\lambda_d-\eta)t}\|\phi\|, \qquad t\geqq 0.$$

For obvious reasons we call ϕ_d the stable size distribution.

Finally we mention that there is an alternative way to reach the main results exploiting the positivity of the semigroup. Using known results from positive semigroup theory (cf. Greiner (1981)), Theorem 5.8 follows immediately. The main problem is now to establish the algebraic simplicity of λ_d. This can be done by showing that the semigroup is not only positive but also irreducible (cf. Schaefer (1974), Greiner (1981)). However, the technical difficulties arising in this approach seem to be greater than in the one we have adopted.

Acknowledgments. We gratefully acknowledge a number of valuable suggestions by Odo Diekmann and some stimulating discussions and correspondence with John Tyson on the biological aspects of the paper.

WEAK SOLUTIONS OF AN INITIAL BOUNDARY VALUE PROBLEM FOR AN INCOMPRESSIBLE VISCOUS FLUID WITH NONNEGATIVE DENSITY*

JONG UHN KIM†

Abstract. The initial boundary value problem associated with the motion of an incompressible viscous fluid with variable density is studied. The lower bound of density is allowed to be zero and the local existence of a weak solution is established.

Key words. local existence, weak solutions, semi-Galerkin method, compactness property

AMS(MOS) subject classifications. Primary 35D05, 35Q10, 76D0

Introduction. In this paper we establish the local existence of weak solutions to the initial boundary value problem associated with the motion of a fluid with nonnegative density. We assume that the fluid is contained in a region Ω of space and that the fluid is nonhomogeneous, incompressible and viscous. Let $u(t,x)$, $\rho(t,x)$ and $p(t,x)$ denote the unknown velocity vector, the density and the pressure of the fluid at point x at time t. Then the governing equations are

$$\rho\frac{\partial u}{\partial t}+(\rho u\cdot\nabla)u-\Delta u=\rho f+\nabla p, \tag{0.1}$$

$$\nabla\cdot u=0, \tag{0.2}$$

$$\frac{\partial\rho}{\partial t}+(u\cdot\nabla)\rho=0, \tag{0.3}$$

where $f(t,x)$ is the known external force. The boundary condition is given by

$$u(t,x)=0 \quad \text{for } t>0,\ x\in\partial\Omega, \tag{0.4}$$

and the initial conditions are expressed by

$$u(0,x)=u_0(x), \qquad \rho(0,x)=\rho_0(x), \tag{0.5}$$

where $u_0(x)$ and $\rho_0(x)$ are given functions. Here Ω is an open bounded subset of R^3 with a smooth boundary. We assume that the coefficient of viscosity is uniformly a constant; it is taken to be 1 for convenience.

Kazhikhov [4] established the existence of weak solutions of (0.1) to (0.5) under the assumption that $0<\alpha\leqq\rho_0(x)\leqq M<\infty$, a.e. in Ω; for the definition of weak solution, see §1. His work was reviewed by Lions [6], who raised the question of existence of solutions in the case $0\leqq\rho_0(x)\leqq M$. In fact, Lions [6] proved the existence of weak solutions to a variant of the above system of equations for a penalized model when $0\leqq\rho_0(x)\leqq M<\infty$, a.e. in Ω. In this paper we show that (0.1) to (0.5) admit a local weak solution if we assume some more regularity on $u_0(x)$ and $f(t,x)$. For the precise statement, see Theorem 2.1 below. Our basic approach to this problem is parallel with

* Received by the editors March 25, 1985, and in final form September 12, 1985.

† Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061.

that of Kazhikhov [4]: we employ the so-called "semi-Galerkin method". We use, however, different energy estimates which are derived capitalizing on the regularity of $u_0(x)$. These estimates are independent of lower bounds of $\rho_0(x)$ and are strong enough to use standard compactness properties of a sequence of approximating solutions. In Kazhikhov [4], energy estimates were obtained under the essential assumption that $0<\alpha\leqq\rho_0(x)\leqq M$, a.e. in Ω and a delicate compactness property was necessary; see Lions [6] for detailed exposition. In §1, we explain our notations and present some mathematical preliminaries. Detailed proof of our result is given in §2.

1. Notation and preliminaries. $x=(x_1,x_2,x_3)$ is the space variable in R^3. For $x,y\in R^3$, $x\cdot y=\sum_{i=1}^3 x_iy_i$. ∇ is the gradient and Δ is the Laplacian. When $f(x)=(f_1(x),f_2(x),f_3(x))$ is an R^3-valued function,

$$\nabla\cdot f=\sum_{i=1}^3\frac{\partial f_i}{\partial x_i},\quad |\nabla f|^2=\sum_{i,j=1}^3\left|\frac{\partial f_i}{\partial x_j}\right|^2,\quad \|f\|_{L^p(\Omega)}=\left(\sum_{i=1}^3\|f_i\|^p_{L^p(\Omega)}\right)^{1/p},$$

$$\|\nabla f\|_{L^p(\Omega)}=\left(\sum_{i,j=1}^3\left\|\frac{\partial f_i}{\partial x_j}\right\|^p_{L^p(\Omega)}\right)^{1/p}.$$

For $s\in R$, $H^s(\Omega)$ denotes the usual Sobolev space as defined in Lions and Magenes [7]. Let $W=\{\phi\in C_0^\infty(\Omega)^3\colon \nabla\cdot\phi=0\}$. Then $H_\sigma^s(\Omega)$ is defined to be the completion of W with respect to the norm of $H^s(\Omega)^3$. When E is a Banach space, $L^p(0,T;E)$ stands for the space of functions g, strongly measurable on $[0,T]$ with range in E such that

$$\|g\|_{L^p(0,T;E)}\overset{\text{def}}{=}\left(\int_0^T\|g(t)\|_E^p dt\right)^{1/p}<\infty,\quad \text{for } 1\leqq p<\infty$$

and

$$\|g\|_{L^\infty(0,T;E)}\overset{\text{def}}{=}\operatorname*{ess\,sup}_{t\in[0,T]}\|g(t)\|_E<\infty,\quad \text{for } p=\infty.$$

$C^k([0,T];E)$ is the space of functions which are k-times continuously differentiable on $[0,T]$ with range in E and when $k=0$, we omit the superscript. The norm is defined in the obvious way. If $E=R$, we denote it by $C^k([0,T])$.

Now we give the definition of weak solution (0.1) to (0.5).

DEFINITION 1.1. A weak solution of (0.1) to (0.5) is a pair of functions $u(t,x)$, $\rho(t,x)$ such that $u(t,x)=(u_1(t,x),u_2(t,x),u_3(t,x))\in L^2(0,T;H_\sigma^1(\Omega))$, $\rho(t,x)\in L^\infty([0,T]\times\Omega)$ and

$$(1.1)\quad -\int_0^T\int_\Omega\rho u\cdot\frac{\partial\Phi}{\partial t}dx\,dt-\sum_{j=1}^3\int_0^T\int_\Omega\rho u_j u\cdot\frac{\partial\Phi}{\partial x_j}dx\,dt+\sum_{j=1}^3\int_0^T\int_\Omega\frac{\partial u}{\partial x_j}\cdot\frac{\partial\Phi}{\partial x_j}dx\,dt$$
$$=\int_0^T\int_\Omega\rho f\cdot\Phi\,dx\,dt+\int_\Omega\rho_0(x)u_0(x)\cdot\Phi(0,x)\,dx,$$

$$(1.2)\quad \int_0^T\int_\Omega\rho\frac{\partial\psi}{\partial t}dx\,dt-\sum_{j=1}^3\int_0^T\int_\Omega\rho u_j\frac{\partial\psi}{\partial x_j}dx\,dt=\int_\Omega\rho_0(x)\psi(0,x)\,dx$$

hold for all $\Phi\in C^1([0,T];H_\sigma^1(\Omega))$ and $\psi\in C^1([0,T];H^1(\Omega))$ satisfying $\Phi(T,x)=0,\psi(T,x)=0$, a.e. in Ω, where $\rho_0(x)\in L^\infty(\Omega)$ and $u_0(x)\in H_\sigma^0(\Omega)$ are given functions.

Next we list some basic facts for later use. Let the operator P be the projection of $L^2(\Omega)^3$ onto $H_\sigma^0(\Omega)$ and consider the eigenvalue problem:

$$P\Delta\phi_k+\lambda_k\phi_k=0 \quad \text{in } \Omega, \qquad \phi_k=0 \quad \text{on } \partial\Omega. \tag{1.3}$$

LEMMA 1.2. *$P\Delta$ is a self-adjoint operator in $H_\sigma^0(\Omega)$ and its inverse is compact. There are countably many eigenvalues $(-\lambda_k)_{k=1}^\infty$ and corresponding eigenfunctions $\{\phi_k\}_{k=1}^\infty$ such that $0<\lambda_1\leqq\lambda_2\leqq\cdots,\lambda_k\to\infty$ as $k\to\infty$ and*

$$\int_\Omega \phi_j\cdot\phi_k\,dx=\delta_{jk}. \tag{1.4}$$

For detailed discussion on the convergence of eigenfunction expansions and the regularity of eigenfunctions, see Ladyzhenskaya [5]. The following lemma is a special case of the result in Aubin [1].

LEMMA 1.3. *Let E_0, E, E_1 be Banach spaces such that $E_0\subset E\subset E_1$, E_0 and E_1 are reflexive, and the injection $E_0\to E$ is compact. Define $\mathscr{F}=\{v\in L^{P_0}(0,T;E_0)$: $dv/dt\in L^{P_1}(0,T;E_1)\}$, where $0<T<\infty$ and $1<P_0, P_1<\infty$. The norm of $\mathscr{F}$ is defined by*

$$\|v\|_{L^{P_0}(0,T;E_0)}+\left\|\frac{dv}{dt}\right\|_{L^{P_1}(0,T;E_1)}.$$

Then the injection $\mathscr{F}\to L^{P_0}(0,T;E)$ is compact.

For the following lemmas, see Lions and Magenes [7].

LEMMA 1.4. *For any $s\in R$ and any $\varepsilon>0$, the injection $H^s(\Omega)\to H^{s-\varepsilon}(\Omega)$ is compact.*

LEMMA 1.5. *Let $f\in H^2(\Omega)\cap H_0^1(\Omega)$. Then it holds that*

$$\|f\|_{H^{1+\theta}(\Omega)}\leqq C_\theta\|\nabla f\|_{L^2(\Omega)}^{1-\theta}\|\Delta f\|_{L^2(\Omega)}^{\theta} \quad \textit{for } 0\leqq\theta\leqq 1 \tag{1.5}$$

where C_θ depends only on θ and Ω.

LEMMA 1.6. *For any $\delta>\frac{3}{2}$, $H^\delta(\Omega)\subset C(\bar\Omega)$ and $(f,g)\to fg$ is a continuous mapping from $H^\delta(\Omega)\times H_0^1(\Omega)$ into $H_0^1(\Omega)$ and from $H^\delta(\Omega)\times H^{-1}(\Omega)$ into $H^{-1}(\Omega)$.*

For $f\in H^\delta(\Omega)$, $g\in H^{-1}(\Omega)$, fg is defined by $\langle fg,\psi\rangle=\langle g,f\psi\rangle$ for all $\psi\in H_0^1(\Omega)$, where $\langle\ ,\ \rangle$ is the duality pairing between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$. This multiplication coincides with the pointwise multiplication for $g\in L^2(\Omega)$.

2. Local existence. In this section we state and prove the main result:

THEOREM 2.1. *Suppose $f(t,x)\in L^\infty(0,T^*;L^2(\Omega)^3)$, $u_0(x)\in H_\sigma^1(\Omega)$, $\rho_0(x)\in L^\infty(\Omega)$ and $0\leqq\rho_0(x)\leqq M<\infty$, a.e. in Ω. Then there is a number $T\in(0,T^*]$ and a weak solution $u(t,x)$, $\rho(t,x)$ of* (0.1) *to* (0.5) *such that $\rho(t,x)\in L^\infty(0,T\times\Omega)$, $u(t,x)\in L^2(0,T;H^2(\Omega)^3)\cap L^\infty(0,T;H_\sigma^1(\Omega))$.*

The proof of this result is divided into several steps. First we consider the initial value problem:

$$\frac{\partial\rho}{\partial t}+(v\cdot\nabla)\rho=0, \qquad \rho(0,x)=\rho_0(x). \tag{2.1}$$

LEMMA 2.2. *Suppose $v(t,x)\in C([0,T];C^1(\bar\Omega)^3)$, $\nabla\cdot v=0$ for all $(t,x)\in[0,T]\times\bar\Omega$, $v=0$ for all $(t,x)\in[0,T]\times\partial\Omega$ and $\rho_0(x)\in C^1(\bar\Omega)$, $\alpha\leqq\rho_0(x)\leqq\beta$ for all $x\in\bar\Omega$, where $\alpha,\beta\in R$. Then* (2.1) *has a unique solution $\rho(t,x)$ in $C^1([0,T]\times\bar\Omega)$. Furthermore, $\alpha\leqq\rho(t,x)\leqq\beta$ holds for all $(t,x)\in[0,T]\times\bar\Omega$.*

LEMMA 2.3. *For each $n=1,2,\cdots$, let $v_n(t,x)\in C([0,T];C^1(\bar\Omega)^3)$, $\nabla\cdot v_n=0$ for all $(t,x)\in[0,T]\times\bar\Omega$ and $v_n=0$ for all $(t,x)\in[0,T]\times\partial\Omega$. Suppose that v_n converges to v in $C([0,T];C^1(\bar\Omega)^3)$, and denote by $\rho_n(t,x)$, $\rho(t,x)$ the unique solution of*

$$\frac{\partial\rho_n}{\partial t}+(v_n\cdot\nabla)\rho_n=0, \qquad \rho_n(0,x)=\rho_0(x) \tag{2.1n}$$

and the unique solution of (2.1), *respectively, where* $\rho_0(x)$ *is the same as in Lemma* 2.2. *Then* $\rho_n(t,x)$ *converges to* $\rho(t,x)$ *in* $C([0,T]\times\bar{\Omega})$.

Proof of Lemma 2.2. We use the classical method of characteristics to construct a solution. Let E be an open ball in R^3 such that $\bar{\Omega}\subset E$. We extend v to $w\in C([0,T];C^1(\bar{E})^3)$ so that $v\equiv w$ for all $(t,x)\in[0,T]\times\bar{\Omega}$. Consider the system:

$$\frac{dx}{dt}=w(t,x),\qquad x(0)=y\in\bar{\Omega}. \tag{2.2}$$

Then there is $0<\tilde{T}\leqq T$ such that (2.2) has a unique solution $x(t,y)$ in $C^1([0,\tilde{T}];C^1(\bar{\Omega})^3)$. If $y\in\partial\Omega$, then $x(t,y)=y$ for all $t\in[0,\tilde{T}]$ since $w(t,x)=v(t,x)=0$ for all $(t,x)\in[0,T]\times\partial\Omega$. If $y\in\Omega$, then $x(t,y)\in\Omega$ for all $t\in[0,\tilde{T}]$ by the uniqueness of solution. Hence, we may take $\tilde{T}=T$ and replace w by v in (2.2). Furthermore, $\det\{\partial x_i/\partial y_j\}=1$ for each $(t,y)\in[0,T]\times\bar{\Omega}$ since $v(t,x)$ is a divergence-free vector field. It is apparent that for each $t\in[0,T]$, the mapping S_t defined by S_t: $y\to x(t,y)$ is C^1-diffeomorphism of $\bar{\Omega}$ onto itself and that $y=S_t^{-1}x=y(t,x)\in C^1([0,T]\times\bar{\Omega})^3$. Now define $\rho(t,x)=\rho_0(y(t,x))$. Then $\rho(t,x)$ is the unique solution in $C^1([0,T]\times\bar{\Omega})$, which can be easily shown by the classical argument.

Proof of Lemma 2.3. Let $x_n(t,y)\in C^1([0,T];C^1(\bar{\Omega})^3)$ be the solution of

$$\frac{dx_n}{dt}=v_n(t,x_n),\qquad x_n(0,y)=y\in\bar{\Omega}. \tag{2.2n}$$

Then $x_n(t,y)$ converges to $x(t,y)$, the solution of (2.2), uniformly in $[0,T]\times\bar{\Omega}$; see Hale [3]. For each $t\in[0,T]$, define $y_n(t,\cdot)$ to be the inverse of the mapping $y\to x_n(t,y)$. Then it is easy to see that all the first order derivatives of $y_n(t,x)$ are uniformly bounded with respect to n and $(t,x)\in[0,T]\times\bar{\Omega}$. By Ascoli's theorem, we derive that $y_n(t,x)$ converges to $y(t,x)$ uniformly in $[0,T]\times\bar{\Omega}$, from which it follows that $\rho_n(t,x)$ converges to $\rho(t,x)$ uniformly in $[0,T]\times\bar{\Omega}$, from which it follows that $\rho_n(t,x)$ converges to $\rho(t,x)$ uniformly in $[0,T]\times\bar{\Omega}$.

Next we choose sequences of functions $\{\rho_{0m}(x)\}_{m=1}^{\infty}$, $\{f_m(t,x)\}_{m=1}^{\infty}$ such that $\rho_{0m}(x)\in C^1(\bar{\Omega})$, $1/m\leqq\rho_{0m}(x)\leqq M+(1/m)$ for all $x\in\bar{\Omega}$, $\rho_{0m}(x)\to\rho_0(x)$ in $L^2(\Omega)$, and $f_m(t,x)\in C([0,T^*];L^2(\Omega)^3)$, $\|f_m(t,x)\|_{L^2(\Omega)^3}\leqq\|f(t,x)\|_{L^\infty(0,T^*;L^2(\Omega)^3)}$ for all $t\in[0,T^*]$, $f_m(t,x)\to f(t,x)$ in $L^2(0,T^*;L^2(\Omega)^3)$ where $\rho_0(x)$ and $f(t,x)$ are given functions in Theorem 2.1. Recalling Lemma 1.2, we set

$$U_m(t,x)=\sum_{k=1}^{m}A_{mk}(t)\phi_k(x) \tag{2.3}$$

and consider the system of equations:

$$\frac{\partial\rho_m}{\partial t}+(U_m\cdot\nabla)\rho_m=0, \tag{2.4}$$

$$\begin{aligned}\sum_{k=1}^{m}b_{jk}^m(t)\frac{d}{dt}A_{mk}(t)+\sum_{k,l=1}^{m}C_{jkl}^m(t)A_{mk}(t)A_{ml}(t)+\lambda_jA_{mj}(t)&\\ =d_j^m(t),\qquad j=1,\cdots,m,&\end{aligned} \tag{2.5}$$

with initial conditions

$$\rho_m(0,x)=\rho_{0m}(x), \tag{2.6}$$

$$A_{mk}(0)=\int_{\Omega}u_0(x)\cdot\phi_k(x)\,dx,\qquad k=1,\cdots,m, \tag{2.7}$$

where $u_0(x)$ is given in Theorem 2.1 and

$$b_{jk}^m(t)=\int_\Omega \rho_m(t,x)\phi_k(x)\cdot\phi_j(x)\,dx, \tag{2.8}$$

$$C_{jkl}^m(t)=\int_\Omega \rho_m(t,x)\{(\phi_k\cdot\nabla)\phi_l\}(x)\cdot\phi_j(x)\,dx, \tag{2.9}$$

$$d_j^m(t)=\int_\Omega \rho_m(t,x)f_m(t,x)\cdot\phi_j(x)\,dx. \tag{2.10}$$

Now we find solutions of (2.4) to (2.7).

PROPOSITION 2.4. *There is a number* $T\in(0,T^*]$ *independent of m such that there are solutions* $\rho_m(t,x)\in C^1([0,T]\times\bar\Omega)$, $A_{mk}(t)\in C^1([0,T])$, $k=1,\cdots,m$ *of* (2.4) *to* (2.7) *satisfying*

$$\left\|\sqrt{\rho_m}\,\frac{\partial U_m}{\partial t}\right\|_{L^2(0,T;\,L^2(\Omega)^3)}\leqq K, \tag{2.11}$$

$$\|U_m\|_{L^2(0,T;\,H^2(\Omega)^3)}\leqq K, \tag{2.12}$$

$$\|U_m\|_{L^\infty(0,T;\,H_\sigma^1(\Omega))}\leqq K, \tag{2.13}$$

$$\left\|\frac{\partial\rho_m}{\partial t}\right\|_{L^\infty(0,T;\,H^{-1}(\Omega))}\leqq K, \tag{2.14}$$

$$\frac{1}{m}\leqq\rho_m(t,x)\leqq M+\frac{1}{m}\quad \textit{for all } (t,x)\in[0,T]\times\bar\Omega, \tag{2.15}$$

where K is a positive constant independent of m.

Proof. First we shall derive a priori estimates. Suppose $\rho_m(t,x)\in C^1([0,T]\times\bar\Omega)$ and $1/m\leqq\rho_m(t,x)\leqq M+1/m$ for all $(t,x)\in[0,T]\times\bar\Omega$, where T is a positive number which will be determined later on. Using this $\rho_m(t,x)$ we define b_{jk}^m, C_{jkl}^m, d^m by (2.8) to (2.10). Suppose $A_{mk}(t)\in C^1([0,T])$, $k=1,\cdots,m$, to be the solution of (2.5). Borrowing a technique from Beirao da Veiga [2], we multiply (2.5) by $(d/dt)A_{mj}(t)$ and $\varepsilon\lambda_jA_{mj}(t)$, $\varepsilon>0$ and sum over $j=1,\cdots,m$:

$$\int_\Omega\rho_m\left|\frac{\partial U_m}{\partial t}\right|^2dx+\int_\Omega\rho_m\{(U_m\cdot\nabla)U_m\}\cdot\frac{\partial U_m}{\partial t}\,dx+\frac{1}{2}\frac{d}{dt}\int_\Omega|\nabla U_m|^2dx$$
$$=\int_\Omega\rho_mf_m\cdot\frac{\partial U_m}{\partial t}\,Dx, \tag{2.16}$$

$$-\varepsilon\int_\Omega\rho_m\frac{\partial U_m}{\partial t}\cdot P\Delta U_m dx-\varepsilon\int_\Omega\rho_m((U_m\cdot\nabla)U_m)\cdot P\Delta U_m dx+\varepsilon\int_\Omega|P\Delta U_m|^2dx$$
$$=-\varepsilon\int_\Omega\rho_mf_m\cdot P\Delta U_m dx. \tag{2.17}$$

We observe that

$$\left|\int_\Omega\rho_m\frac{\partial U_m}{\partial t}\cdot P\Delta U_m dx\right|\leqq\frac{1}{4}\int_\Omega|P\Delta U_m|^2dx+(M+1)\int_\Omega\rho_m\left|\frac{\partial U_m}{\partial t}\right|^2dx, \tag{2.18}$$

(2.19)

$$\left|\int_\Omega \rho_m\{(U_m\cdot\nabla)U_m\}\cdot P\Delta U_m dx\right| \leqq \frac{1}{4}\int_\Omega |P\Delta U_m|^2 dx + (M+1)^2\int_\Omega |U_m|^2|\nabla U_m|^2 dx,$$

(2.20)

$$\left|\int_\Omega \rho_m\{(U_m\cdot\nabla)U_m\}\cdot\frac{\partial U_m}{\partial t} dx\right| \leqq \frac{1}{4}\int_\Omega \rho_m\left|\frac{\partial U_m}{\partial t}\right|^2 dx + (M+1)\int_\Omega |U_m|^2|\nabla U_m|^2 dx,$$

$$\begin{aligned}(2.21)\qquad \int_\Omega |U_m|^2|\nabla U_m|^2 dx &\leqq 3\|U_m\|^2_{L^\infty(\Omega)}\int_\Omega |\nabla U_m|^2 dx\\ &\leqq C_\delta\|\nabla U_m\|^{3-2\delta}_{L^2(\Omega)}\|\Delta U_m\|^{1+2\delta}_{L^2(\Omega)}\\ &\leqq C_\delta\|\nabla U_m\|^{3-2\delta}_{L^2(\Omega)}\|P\Delta U_m\|^{1+2\delta}_{L^2(\Omega)},\end{aligned}$$

where C_δ denotes positive constants depending only on Ω and $0<\delta<\frac{1}{2}$. Here we have used Theorem 2 of Ladyzhenskaya [5, p. 67] and Lemmas 1.5, 1.6. Combining (2.16) to (2.21), we obtain

(2.22)

$$\frac{1}{2}\frac{d}{dt}\int_\Omega |\nabla U_m|^2 dx + \frac{1}{2}\int_\Omega \rho_m\left|\frac{\partial U_m}{\partial t}\right|^2 dx \leqq \int_\Omega \rho_m|f_m|^2 dx + C_\delta(M+1)\|\nabla U_m\|^{3-2\delta}_{L^2(\Omega)}\|P\Delta U_m\|^{1+2\delta}_{L^2(\Omega)},$$

$$(2.23)\quad \frac{1}{4}\varepsilon\int_\Omega |P\Delta U_m|^2 dx \leqq \varepsilon\int_\Omega \rho_m^2|f_m|^2 dx + \varepsilon(M+1)\int_\Omega \rho_m\left|\frac{\partial U_m}{\partial t}\right|^2 dx + \varepsilon(M+1)^2C_\delta\|\nabla U_m\|^{3-2\delta}_{L^2(\Omega)}\|P\Delta U_m\|^{1+2\delta}_{L^2(\Omega)},$$

where C_δ depends only on Ω and $0<\delta<\frac{1}{2}$. Now we fix $\varepsilon\in(0, 1/(4(M+1))]$ and take $\delta=\frac{1}{4}$. Then, (2.22) together with (2.23) implies

$$(2.24)\quad \frac{1}{2}\frac{d}{dt}\int_\Omega |\nabla U_m|^2 dx + \frac{1}{4}\int_\Omega \rho_m\left|\frac{\partial U_m}{\partial t}\right|^2 dx + \frac{1}{8}\varepsilon\int_\Omega |P\Delta U_m|^2 dx \leqq C\int_\Omega |f_m|^2 dx + C\|\nabla U_m\|^{10}_{L^2(\Omega)},$$

where C denotes positive constants depending only on M and Ω. From (2.24), it follows that

$$(2.25)\qquad \frac{d}{dt}\int_\Omega |\nabla U_m|^2 dx \leqq C + C\left(\int_\Omega |\nabla U_m|^2 dx\right)^5,$$

where C denotes positive constants depending only on M, Ω and $\|f\|_{L^\infty(0,T^*;\,L^2(\Omega)^3)}$. By making use of the well-known differential inequality, we conclude that there is a number $T\in(0,T^*]$ and $L>0$ such that

$$(2.26)\qquad \|\nabla U_m\|^2_{L^2(\Omega)} \leqq L \quad \text{for all } t\in[0,T],$$

where T and L depend only on M, Ω, $\|f\|_{L^\infty(0,T^*;L^2(\Omega)^3)}$, $\|u_0(x)\|_{H^1_\sigma(\Omega)}$ and are independent of m. From now on, we fix this T and L. Next we need the following fact.

LEMMA 2.5. *Suppose* $\rho_m(t,x) \in C^1([0,T]\times\overline{\Omega})$ *and* $1/m \leqq \rho_m(t,x) \leqq M+1/m$, *for all* $(t,x)\in[0,T]\times\overline{\Omega}$. *Then, the matrix* $\{b^m_{jk}(t)\}$ *defined by* (2.8) *is nonsingular and each component of its inverse belongs to* $C^1([0,T])$.

Proof. Suppose $\{b^m_{jk}(t_0)\}$ is singular for some $t_0 \in [0,T]$. Then, without loss of generality, we assume that the first row is a linear combination of other rows: $b^m_{1k}(t_0) = C_2 b^m_{2k}(t_0) + \cdots + C_m b^m_{mk}(t_0)$ holds for each $k=1,\cdots,m$, i.e., $\int_\Omega \rho_m(t_0,x)\eta(x)\cdot\phi_k(x)\,dx = 0$ holds for each $k=1,\cdots,m$, where $\eta=\phi_1 - C_2\phi_2 - \cdots - C_m\phi_m$. Therefore, $\int_\Omega \rho_m(t_0,x)|\eta(x)|^2\,dx=0$ holds, which implies $\eta(x)=0$ for all $x\in\Omega$ since $\rho_m(t_0,x)\geqq 1/m$ for all $x\in\Omega$. But this is impossible in view of (1.4). It is obvious that each component of the inverse of $\{b^m_{jk}(t)\}$ is continuously differentiable with respect to the time.

Now we proceed to prove the proposition. Let $\overline{B}_R$ be a closed ball in $C([0,T])^m$ with radius $R \geqq (L/\lambda_1)^{1/2}$, where T and L were fixed above and $-\lambda_1$ is the first eigenvalue of the operator $P\Delta$; see Lemma 1.2. Let $(A_{m1}(t),\cdots,A_{mm}(t))\in\overline{B}_R$ and set $U_m(t,x)=\sum_{k=1}^m A_{mk}(t)\phi_k(x)$. By Lemma 2.2, we find a solution $\rho_m(t,x)$ of (2.4), (2.6) in $C^1([0,T]\times\overline{\Omega})$. Using this $\rho_m(t,x)$, we find a solution $(\tilde{A}_{m1}(t),\cdots,\tilde{A}_{mm}(t))$ of (2.5), (2.7) in $C^1([0,T])^m \cap \overline{B}_R$ with the aid of (2.26) and Lemma 2.5. By means of (2.24), (2.26) and Lemma 2.3, we infer that the mapping $(A_{m1}(t),\cdots,A_{mm}(t)) \to (\tilde{A}_{m1}(t),\cdots,\tilde{A}_{mm}(t))$ is completely continuous from $\overline{B}_R$ into itself; see Hale [3]. Hence, it has a fixed point which, together with $\rho_m(t,x)$, is a solution of (2.4) to (2.7). (2.15) was shown in the proof of Lemma 2.2 and (2.13) follows from (2.26), which, combined with (2.24), also implies (2.11) and (2.12). Since U_m is divergence-free, (2.14) follows from (2.4).

Proof of Theorem 2.1. Thanks to the estimates (2.11) to (2.15), we can extract subsequences $\{U_m\}_{m=1}^\infty$ and $\{\rho_m\}_{m=1}^\infty$ such that $U_m \to u$ weakly in $L^2(0,T;H^2(\Omega)^3)$, $U_m\to u$ weak* in $L^\infty(0,T;H^1_\sigma(\Omega))$, $\rho_m\to\rho$ weak* in $L^\infty([0,T]\times\Omega)$ and $\partial\rho_m/\partial t\to\partial\rho/\partial t$ weak* in $L^\infty(0,T;H^{-1}(\Omega))$. By virtue of Lemmas 1.3, 1.4, $\rho_m\to\rho$ strongly in $L^2(0,T;H^{-1/2}(\Omega))$. Therefore, $\rho_m U_m \to \rho u$ in $\mathscr{D}^*((0,T)\times\Omega)^3$ and thus, $\rho_m U_m\to\rho u$ weak* in $L^\infty(0,T;L^2(\Omega)^3)$. In the meantime, $\{U_m\}_{m=1}^\infty$ is bounded in $L^q(0,T;H^{3/2+\delta}(\Omega)^3)$, $q=4/(1+2\delta)$, $0<\delta<\frac{1}{2}$, by interpolation. Hence, by Lemma 1.6, $\{U_m(\partial\rho_m/\partial t)\}_{m=1}^\infty$ is bounded in $L^2(0,T;H^{-1}(\Omega)^3)$. On the other hand, $\{\rho_m(\partial U_m/\partial t)\}_{m=1}^\infty$ is bounded in $L^2(0,T;L^2(\Omega)^3)$, which is obvious from (2.11). Consequently, $\{\partial(\rho_m U_m)/\partial t\}_{m=1}^\infty$ is bounded in $L^2(0,T;H^{-1}(\Omega)^3)$. Again by Lemmas 1.3, 1.4, $\rho_m U_m \to \rho u$ strongly in $L^2(0,T;H^{-1/2}(\Omega)^3)$. Since $U_m\to u$ weakly in $L^2(0,T;H^2(\Omega)^3)$, $\rho_m U_m U_{mk}\to\rho u v_k$ in $\mathscr{D}^*((0,T)\times\Omega)^3$ for each $k=1,2,3$ where $U_m=(U_{m1},U_{m2},U_{m3})$ and $u=(v_1,v_2,v_3)$. Thus it follows that $\rho_m U_m U_{mk}\to\rho u v_k$ weakly in $L^2(0,T;L^2(\Omega)^3)$, for each $k=1,2,3$. It is easy to see that $(U_m\cdot\nabla)\rho_m\to(u\cdot\nabla)\rho$ weakly in $L^2(0,T;H^{-1}(\Omega))$. Now let us choose arbitrary $\xi_j(t)\in C^1([0,T])$, $\xi_j(T)=0$, $j=1,\cdots,\nu$. Then, by (2.4) and (2.5), it holds that for each $m\geqq\nu$,

$$(2.27)\quad -\int_0^T\int_\Omega \rho_m U_m\cdot\frac{\partial}{\partial t}\left(\sum_{j=1}^{\nu}\xi_j\phi_j\right)dx\,dt - \sum_{k=1}^{3}\int_0^T\int_\Omega \rho_m U_m U_{mk}\cdot\frac{\partial}{\partial x_k}\left(\sum_{j=1}^{\nu}\xi_j\phi_j\right)dx\,dt$$
$$+\sum_{k=1}^{3}\int_0^T\int_\Omega \frac{\partial U_m}{\partial x_k}\cdot\frac{\partial}{\partial x_k}\left(\sum_{j=1}^{\nu}\xi_j\phi_j\right)dx\,dt$$
$$=\int_\Omega \rho_{0m}U_{0m}\cdot\sum_{j=1}^{\nu}\xi_j(0)\phi_j\,dx + \int_0^T\int_\Omega \rho_m f_m\cdot\sum_{j=1}^{\nu}\xi_j\phi_j\,dx\,dt$$

where $U_m=(U_{m1},U_{m2},U_{m3})$ and $U_{0m}=\Sigma_{k=1}^{m}A_{mk}(0)\phi_k(x)$; see (2.6) and (2.7). By passing m to ∞, we obtain

$$\begin{aligned}(2.28)\qquad -\int_0^T\int_\Omega \rho u\cdot\frac{\partial}{\partial t}\left(\sum_{j=1}^{\nu}\xi_j\phi_j\right)dx\,dt-\sum_{k=1}^{3}\int_0^T\int_\Omega \rho u v_k\cdot\frac{\partial}{\partial x_k}\left(\sum_{j=1}^{\nu}\xi_j\phi_j\right)dx\,dt\\ +\sum_{k=1}^{3}\int_0^T\int_\Omega\frac{\partial u}{\partial x_k}\cdot\frac{\partial}{\partial x_k}\left(\sum_{j=1}^{\nu}\xi_j\phi_j\right)dx\,dt\\ =\int_\Omega\rho_0u_0\cdot\sum_{j=1}^{\nu}\xi_j(0)\phi_j\,dx+\int_0^T\int_\Omega\rho f\cdot\sum_{j=1}^{\nu}\xi_j\phi_j\,dx\,dt,\end{aligned}$$

where we used the convergence properties of $\{U_m\}_{m=1}^{\infty}$ and $\{\rho_m\}_{m=1}^{\infty}$ which were derived above; also recall the way we chose $\{\rho_{0m}\}_{m=1}^{\infty}$ and $\{f_m\}_{m=1}^{\infty}$. Noting that $\rho\in L^\infty([0,T]\times\Omega)$, $u\in L^\infty(0,T;H_\sigma^1(\Omega))\cap L^2(0,T;H^2(\Omega))$ and that every $\Psi(t,x)\in C^1([0,T];H_\sigma^1(\Omega))$, $\Psi(T,x)=0$, a.e. in Ω, and be approximated by a sequence $\{\Sigma_{k=1}^{\nu}\xi_{\nu k}\phi_k\colon\ \xi_{\nu k}(t)\in C^1([0,T]),\ \xi_{\nu k}(T)=0\}_{\nu=1}^{\infty}$ in $C^1([0,T];H_\sigma^1(\Omega))$, we conclude that u and ρ satisfy (1.1). By a similar argument, ρ satisfies (1.2). This completes the proof of Theorem 2.1.

ETUDE DES ETATS STATIONNAIRES POUR UNE EQUATION DE SCHRÖDINGER NON LINEAIRE COMPORTANT UN TERME NON AUTONOME*

ALAIN BAMBERGER† AND LAURENCE HALPERN†

Abstract. This paper deals with the steady problem for a nonlinear one-dimensional Schrödinger equation of the following type:

$$i\frac{\partial u}{\partial t}-\frac{\partial^2 u}{\partial x^2}+xu-p|u|^2u=f(x), \qquad x\in\mathbb{R},$$

arising in plasma physics.

We prove the existence of many steady states for large values of the nonlinearity parameter p.

Résumé. Nous étudions le problème stationnaire associé à une équation de Schrödinger non linéaire monodimensionnelle du type suivant:

$$i\frac{\partial u}{\partial t}-\frac{\partial^2 u}{\partial x^2}+xu-p|u|^2u=f(x), \qquad x\in\mathbb{R},$$

intervenant en physique des plasmas.

Nous montrons l'existence d'un grand nombre d'états stationnaires lorsque le paramètre p de non linéarité est grand.

Key words. nonlinear Schrödinger equation

AMS(MOS) subject classification. Primary 35

Introduction. L'étude de l'absorption d'une onde électromagnétique par un plasma inhomogène conduit, avec nombre d'hypothèses simplificatrices, à une équation de Schrödinger monodimensionnelle non linéaire du type suivant:

$$(1) \qquad i\frac{\partial u}{\partial t}-\frac{\partial^2 u}{\partial x^2}+xu-p|u|^2u=f(x); \qquad x\in\mathbb{R}$$

où u est une "onde sortante" en $-\infty$, u tend vers 0 en $+\infty$. La fonction f représente l'amplitude de l'onde magnétique incidente. Son support est "petit", concentré autour de 0 (voir J. C. Adam, A. Gourdin-Servenière et G. Laval [2], G. J. Morales et Y. C. Lee [8]).

Les auteurs de [2] ont testé numériquement la validité de ce modèle. Ils se sont intéressés aux solutions stationnaires, et ont notamment mis en évidence le fait que celles-ci n'étaient pas stables pour de grandes valeurs du paramètre p de non linéarité.

D'autres équations de Schrödinger non linéaires, du type

$$(2) \qquad i\frac{\partial u}{\partial t}+\Delta u+F(u)=0 \quad \text{dans } \mathbb{R}\times\mathbb{R}^n$$

ont été étudiées par les mathématiciens, en particulier pour une non linéarité de la forme $F(u)=|u|^{k-1}u$.

Ainsi J. Ginibre et G. Velo [6] ont démontré l'existence et l'unicité d'une solution locale pour $1<k<(n+2)/(n-2)$ $(n\geqq 3)$. Ils ont montré de plus que, pour $k<1+4/n$,

*Received by the editors September 24, 1984; accepted for publication August 18, 1985.

†Ecole Polytechnique, Centre de Mathématiques Appliquées, 91128 Palaiseau Cedex, France.

toute solution locale est globale, et pour $k<1+4/n$, R. T. Glassey [7] a prouvé qu'il existe des solutions qui explosent en un temps fini. D'autre part V. E. Zakharov et A. B. Shabat [9] ont mis en évidence l'existence de solitons en dimension 1.

Une étude globale de l'existence et du nombre de solitons pour l'équation (2) a été menée par H. Berestycki et P. L. Lions [4]. Ils ont établi l'existence d'une infinité de solutions radiales pour le problème

$$-\Delta u=g(u) \tag{3}$$

où g vérifie certaines hypothèses en 0 et $+\infty$.

En particulier en dimension 1, ils ont prouvé l'existence d'une "solution fondamentale" indéfiniment dérivable, paire, positive, décroissante pour $x>0$, tendant vers zéro à l'infini. Toutes les autres solutions sont obtenues par translation et symétrie par rapport à l'origine. T. Cazenave [5] a étudié la stabilité de ces solitons.

Pour notre part, nous nous intéressons aux solutions stationnaires de l'équation (1). Elle comporte un second membre et un terme "non autonome" xu. Aussi, les études précédentes qui utilisent de façon essentielle l'existence d'une intégrale première, ne semblent pas pouvoir s'appliquer dans cette étude.

Pour connaître l'influence du paramètre p de nonlinéarité sur le nombre de solutions de (1), nous avons introduit un problème simplifié:

Puisque le support de f est petit, nous l'avons concentré autour de 0, et nous avons donc remplacé le second membre par une discontinuité de la partie réelle de la dérivée en 0.

La condition d'onde sortante en $-\infty$ nous a conduits à supposer que le terme non linéaire est petit devant le terme xu pour x négatif. Nous avons donc fait intervenir la non-linéarité uniquement pour $x>0$. Pour ce problème nous avons montré qu'il y a toujours une solution stationnaire, et que le nombre de solutions stationnaires est croissant en fonction de p.

Il ne nous semble pas que ces simplifications changent fondamentalement les résultats.

Les problèmes envisagés et la démarche suivie. Les simplifications énoncées plus haut nous mènent aux deux problèmes suivants, que nous notons $\mathscr{P}_{\alpha,p}$ et $\mathscr{Q}_{\alpha,p}$:

Problème $\mathscr{P}_{\alpha,p}$: Trouver une fonction u qui est, pour $x<0$, solution du problème $\mathscr{P}_c^-$, et, pour $x>0$, solution du problème $\mathscr{P}_c^+$:

$$\mathscr{P}_c^-\begin{cases}(1.1) & u''+u=0;\ x<0,\\ (1.3) & u'+iu\to 0;\ x\to-\infty,\end{cases}\qquad \mathscr{P}_c^+\begin{cases}(1.2) & u''-u+p|u|^2u=0;\ x>0,\\ (1.4) & u\to 0;\ x\to+\infty,\end{cases}$$

et qui vérifie les conditions de transmission à l'origine:

$$u(0_+)-u(0_-)=0, \tag{1.5}$$
$$u'(0_+)-u'(0_-)=\alpha, \qquad \alpha>0. \tag{1.6}$$

Nous avons indexé par C les problèmes $\mathscr{P}_c^-$ et $\mathscr{P}_c^+$ pour signifier que nous cherchons des solutions à valeurs dans $\mathbb{C}$.

Problème $\mathscr{Q}_{\alpha,p}$: Trouver une fonction u qui est, pour $x<0$, solution du problème $\mathscr{Q}_c^-$, et, pour $x>0$, solution du problème $\mathscr{Q}_c^+$:

$$\mathscr{Q}_c^-\begin{cases}(2.1) & u''-xu=0;\ x<0,\\ (2.3) & u'+i(-x)^{1/2}u\to 0;\ x\to-\infty,\end{cases}\qquad \mathscr{Q}_c^+\begin{cases}(2.2) & u''-xu+p|u|^2u=0;\ x>0,\\ (2.4) & xu\to 0;\ x\to+\infty,\end{cases}$$

et qui vérifie les conditions de transmission à l'origine:

(2.5) $$u(0_+)-u(0_-)=0,$$

(2.6) $$u'(0_+)-u'(0_-)=\alpha, \qquad \alpha>0.$$

Rappelons que $u(0_+)$ (resp. $u(0_-)$) désigne la limite à droite (resp. à gauche) de u en 0.

Pour ces deux problèmes, nous avons imposé les mêmes conditions en zéro: continuité de la fonction et discontinuité de la partie réelle de sa dérivée. Les conditions (1.3) et (2.3) correspondent à une condition d'onde sortante en $-\infty$, les conditions (1.4) et (2.4) correspondent à une décroissance vers 0 de la fonction lorsque x tend vers $+\infty$.

Le problème $\mathscr{P}_{\alpha,p}$ est plus simple que le problème $\mathscr{Q}_{\alpha,p}$: le terme xu dans $\mathscr{Q}_{\alpha,p}$ a été remplacé par signe$(x)u$ dans $\mathscr{P}_{\alpha,p}$. Il nous a permis de mettre en évidence l'influence de la nonlinéarité, qui se traduit par l'existence de plusieurs solutions. Les résultats obtenus pour $\mathscr{P}_{\alpha,p}$ nous ont servi de guide pour l'étude de $\mathscr{Q}_{\alpha,p}$.

Nous avons adopté la démarche suivante: nous découplons les problèmes posés sur $\mathbb{R}_-$ et sur $\mathbb{R}_+$, et nous déterminons une relation entre $u(0_-)$ et $u'(0_-)$ (resp. $u(0_+)$ et $u'(0_+)$), condition nécessaire et suffisante pour qu'une solution u de l'équation differentielle posée sur $\mathbb{R}_-$ (resp. $\mathbb{R}_+$) vérifie les conditions à l'infini imposées. La première relation est linéaire: elle est obtenue par la résolution explicite d'une équation differentielle linéaire. La deuxième relation est non linéaire; elle provient d'un calcul explicite pour $\mathscr{P}_{\alpha,p}$, et sera calculée numériquement pour $\mathscr{Q}_{\alpha,p}$.

Ces deux relations, jointes aux conditions de transmission, constituent un système non linéaire complexe de quatre équations à quatre inconnues $u(0_-)$, $u'(0_-)$, $u(0_+)$, $u'(0_+)$. La forme du problème permet de découpler les parties réelles et imaginaires de u pour x positif, et de ramener en fait la discussion sur le nombre de solutions de $\mathscr{P}_{\alpha,p}$ (resp. $\mathscr{Q}_{\alpha,p}$) à la résolution d'un système non linéaire réel de deux équations à deux inconnues: la partie réelle de u et sa dérivée en 0_+. L'une des deux équations dépend du paramètre α^2p.

Nous représentons dans le plan $(u(0_+), u'(0_+))$ les deux équations, pour chacun des deux problèmes.

Pour le problème $\mathscr{P}_{\alpha,p}$, l'une des équations est représentée par une famille de cercles dont de rayon est croissant en fonction de p. Il apparait un seuil: si p est inférieur à ce seuil, $\mathscr{P}_{\alpha,p}$ admet deux solutions, et audelà $\mathscr{P}_{\alpha,p}$ n'a plus de solution. Ce phénomène de seuil est du à la simplification apportée en remplaçant xu par signe$(x)u$ dans $\mathscr{P}_{\alpha,p}$.

Pour le problème $\mathscr{Q}_{\alpha,p}$, l'une des relations est obtenue à partir du problème posé sur $\mathbb{R}_+$, et est représentée par une ellipse. L'autre relation est obtenue numériquement à partir d'un paramètre x_0, et est représentée par une spirale.

Lorsque le paramètre α^2p varie, la première relation entre $u(0_+)$ et $u'(0_+)$ est représentée par une famille d'ellipses, dont les axes croissent en fonction de α^2p: il y a toujours une solution, et plus la non-linéairité est importante, plus $\mathscr{Q}_{\alpha,p}$ admet de solutions.

La première partie de cette étude est consacrée au problème $\mathscr{P}_{\alpha,p}$. Des méthodes d'équations différentielles ordinaires permettent de décrire explicitement les solutions.

Ces méthodes ne sont plus applicables pour le problème $\mathscr{Q}_{\alpha,p}$ et nous serons amenés, dans la deuxième partie, à utiliser à la fois des méthodes mathématiques et des méthodes numériques.

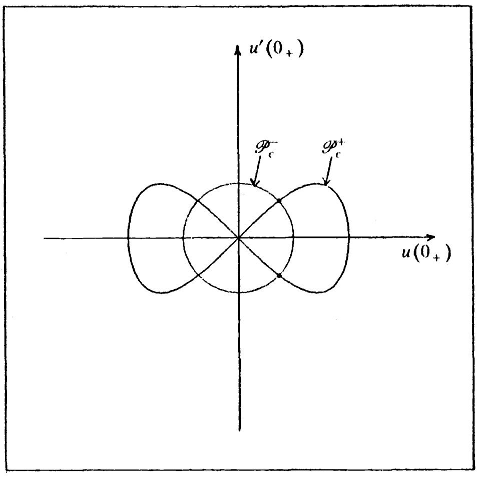

FIG. 1. *Nombre de solutions de $\mathscr{P}_{\alpha,p}$, α et p fixés.*

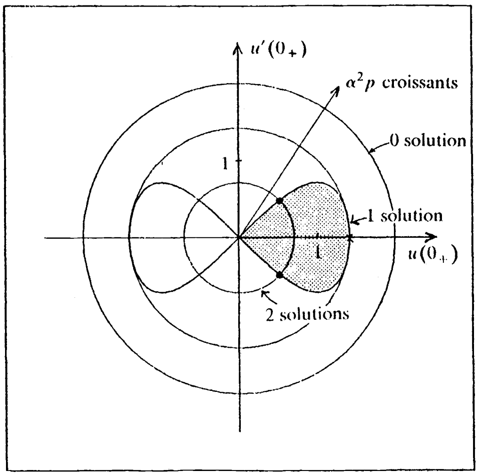

FIG. 2. *Nombre de solutions de $\mathscr{P}_{\alpha,p}$ lorsque α^2p varie.*

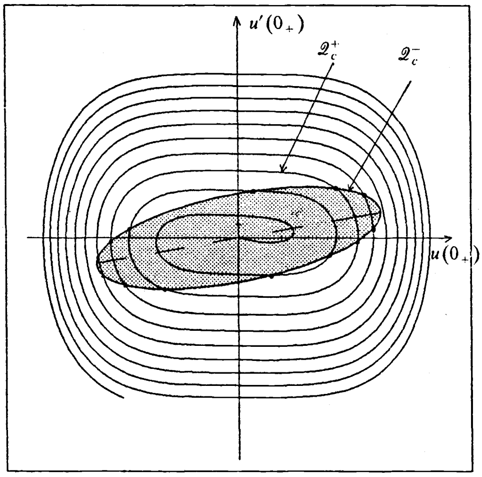

FIG. 3. *Nombre de solutions de $\mathscr{Q}_{\alpha,p}$, α et p fixés.*

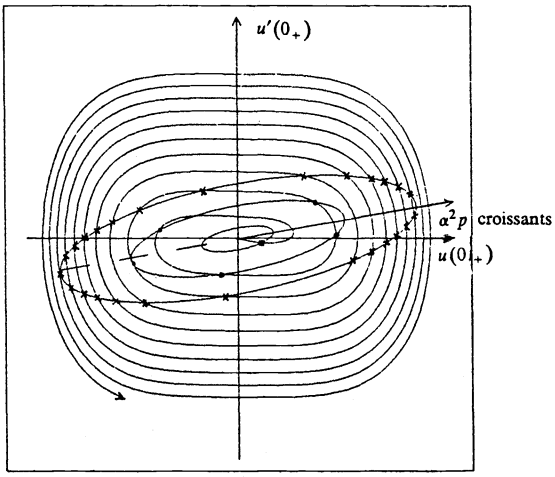

FIG. 4. *Nombre de solutions de $\mathscr{Q}_{\alpha,p}$ lorsque α^2p varie.*

1. Etude du problème $\mathscr{P}_{\alpha,p}$. Nous pouvons pour le problème $\mathscr{P}_{\alpha,p}$ décrire complètement et explicitement l'ensemble des solutions:

PROPOSITION 1.1. *Le problème $\mathscr{P}_{\alpha,p}$ admet, suivant les valeurs de p et α, zéro, une ou deux solutions*:

• $p=0$	*une solution*,
• $0<p<p^*=2/\alpha^2$	*deux solutions*,
• $p=p^*$	*une solution*,
• $p>p^*$	*pas de solution*.

De plus, ces solutions sont C^∞ sauf en $x=0$.

Le cas $p=0$ correspond à une équation linéaire. Le problème $\mathscr{P}_{\alpha,0}$ admet une seule solution, $u^*(0,x)$, donnée par

$$u^*(0,x)=\begin{cases} -\frac{\alpha}{2}(1+i)e^{-ix}, & x\leqq 0,\\ -\frac{\alpha}{2}(1+i)e^{-x}, & x\geqq 0.\end{cases}$$

Nous nous intéressons d'abord à $\mathscr{P}_c^+$, dont nous exprimerons les solutions à partir de celles d'un problème réel $\mathscr{P}_R^+$. Nous étudierons les orbites de l'équation différentielle associée dans le plan des phases. Nous montrerons en particulier qu'il existe une seule orbite non périodique, qui représente l'ensemble des solutions de $\mathscr{P}_R^+$, et nous expliciterons ces solutions.

1.1. Le problème $\mathscr{P}_c^+$. Introduisons le problème réel

$$(1.7)\qquad \mathscr{P}_R^+\begin{cases} -v''+v-v^3=0, & x\geqq 0,\\ v(x)\to 0, & x\to+\infty.\end{cases}$$

Pour passer de $\mathscr{P}_c^+$ à $\mathscr{P}_R^+$, nous aurons besoin d'estimations à priori. Pour l'équation (1.2) on obtient de façon classique la conservation du moment et de l'énergie. On a plus précisément ici le

LEMME 1.1. Estimations à priori. *Toute solution u de $\mathscr{P}_c^+$ appartenant à $\mathscr{C}^1(\mathbb{R}^+,\mathbb{R})$ possède un moment nul*:

$$(1.8)\qquad u'\bar{u}-\bar{u}'u=0,$$

ainsi qu'une énergie nulle:

$$(1.9)\qquad |u'|^2-|u|^2+\frac{p}{2}|u|^4=0.$$

Elle vérifie de plus

$$(1.10)\qquad u'(x)\to 0;\qquad x\to+\infty.$$

Démonstration. Nous multiplions (1.2) par $\bar{u}'$ et nous prenons la partie réelle

$$\frac{d}{dx}\left(|u'|^2-|u|^2+\frac{p}{2}|u|^4\right)=0,\quad \text{d'où}$$

$$(1.11)\qquad |u'|^2-|u|^2+\frac{p}{2}|u|^4=\text{cte}\quad \text{sur } \mathbb{R}_+.$$

D'autre part, nous multiplions (1.2) par $\bar{u}$ et nous prenons la partie imaginaire

$$\frac{d}{dx}(u'\bar{u}-\bar{u}'u)=0, \quad \text{d'où}$$

$$u'\bar{u}-\bar{u}'u=\text{cte} \quad \text{sur } \mathbb{R}_+. \tag{1.12}$$

Par hypothèse u tend vers 0 à l'infini, et on déduit de (1.11) que u' est bornée. La constante dans (1.12) est donc nulle. Montrons maintenant que u' tend vers 0 à l'infini.

D'après (1.8) la partie réelle et la partie imaginaire de u sont proportionnelles, nous pouvons donc raisonner sur $v=\operatorname{Re} u$.

La fonction réelle v est $\mathscr{C}^1$, tend vers 0 à l'infini, et d'après (1.11) v'^2 a une limite à l'infini. La fonction v' a donc une limite l quand x tend vers l'infini. Cette limite doit être nulle.

Nous en déduisons le

LEMME 1.2. Equivalence entre $\mathscr{P}_c^+$ et $\mathscr{P}_R^+$. *La fonction u est solution de $\mathscr{P}_c^+$ si et seulement si il existe un nombre complexe z_0 et une fonction réelle v tels que*

$$u=\frac{z_0}{\sqrt{p}}v, \qquad |z_0|=1, \tag{1.13}$$

v solution de $\mathscr{P}_R^+$.

Démonstration. Soit u une solution de $\mathscr{P}_c^+$. D'après la démonstration précédente, la partie imaginaire de u est proportionnelle à sa partie réelle

$$u=(1+\lambda i)u_1$$

et u_1 est solution de l'équation réelle

$$u_1''-u_1+p(1+\lambda^2)u_1^3=0.$$

La fonction u s'écrit donc sous la forme

$$u=\frac{1+\lambda i}{\sqrt{p(1+\lambda^2)}}v \tag{1.14}$$

où v est solution de $\mathscr{P}_R^+$.

Réciproquement, si v est solution de $\mathscr{P}_R^+$, la fonction u définie par (1.14) est solution de $\mathscr{P}_c^+$.

Nous définissons sur $\mathbb{R}$ le système différentiel

$$-v''+v-v^3=0, \qquad x\in\mathbb{R}. \tag{1.15}$$

Introduisons la fonction U (assimilable à une énergie potentielle), définie par

$$U(v)=-\frac{v^2}{2}+\frac{v^4}{4} \tag{1.16}$$

ainsi que la fonction E définie sur l'ensemble des fonctions C^1 par

$$E(v)=\frac{v'^2}{2}+U(v); \tag{1.17}$$

E est "l'énergie totale."

Nous avons pour ce système l'équivalent du lemme 1.1, c'est-à-dire que le système (1.15) est *conservatif*:

$$\frac{d}{dx}(E(v))=0. \tag{1.18}$$

Pour tracer les orbites du système, c'est-à-dire $\{(v,v');\ E(v)=E\}$, il est commode de tracer la courbe représentant les variations du potentiel U (voir figure 5).

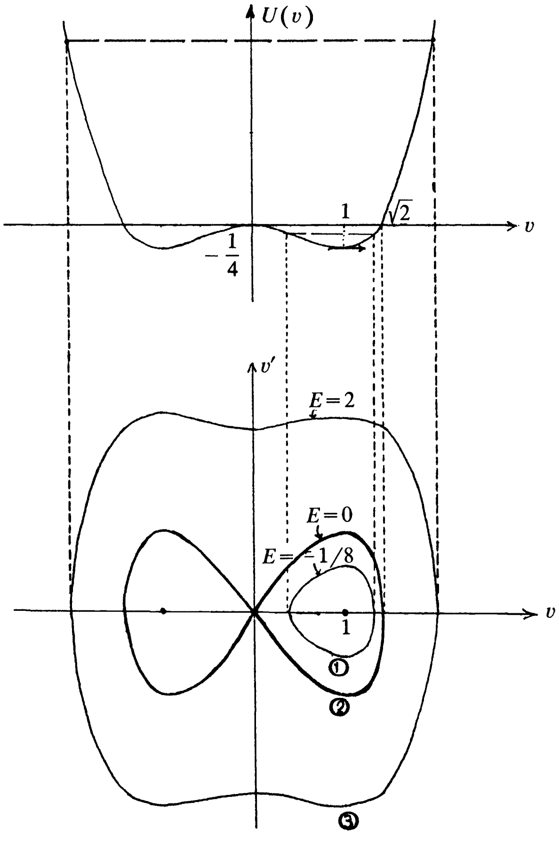

FIG. 5. *Orbites du système* (1.15).

Il y a deux sortes d'orbites périodiques: de type pour une énergie totale négative et de type pour une énergie totale positive. Il y a une orbite non périodique (à une symétrie par rapport à l'origine près), de type, correspondant à une énergie nulle. Un point représentatif situé sur cette orbite atteindra le point zéro sur une distance infinie. L'analyse de ces orbites est résumée dans le lemme 1.3.

LEMME 1.3. Description des solutions du système différentiel. *Le système* (1.15) *admet une infinité de solutions d'énergie E donnée. Elles sont toutes égales, à une translation et une symétrie près, à une fonction* V^E, *paire, telle que*

$$\frac{dV^E}{dx}(0)=0,\quad U(V^E(0))=E,\quad V^E(0)>1. \tag{1.19}$$

Les solutions de (1.15) *d'énergie nulle sont celles qui tendent vers* 0 *en* $+\infty$ *et* $-\infty$.

De plus V^0 est donnée explicitement par

$$V^0(x)=\begin{cases} 2\sqrt{2}\,\dfrac{e^x}{1+e^{2x}}, & x\geqq 0,\\ V^0(-x), & x\leqq 0.\end{cases} \tag{1.20}$$

Remarque. H. Berestycki et P. L. Lions ont montré, dans [3], le même type de résultat pour l'équation

$$-u''=g(u).$$

Leur approche est différente, mais les hypothèses faites sur g permettent d'utiliser la théorie des systèmes conservatifs, et d'assurer l'existence d'une orbite de type (1).

Démonstration du Lemme 1.3. Il ne nous reste qu'à établir l'expression (1.20):

V^0 est solution sur $\mathbb{R}_+$ du problème de Cauchy:

$$\begin{aligned} &-v''+v-v^3=0, \qquad x\geqq 0,\\ &v(0)=\sqrt{2},\\ &v'(0)=0.\end{aligned} \tag{1.21}$$

D'après (1.17) nous avons sur $\mathbb{R}_+$

$$v'^2-v^2+\frac{v^4}{2}=0. \tag{1.22}$$

Posons

$$w=\frac{v'}{v}. \tag{1.23}$$

La fonction w est solution sur $\mathbb{R}_+$ du problème de Cauchy:

$$\begin{aligned} &w'=w^2-1,\\ &w(0)=0.\end{aligned} \tag{1.24}$$

Cette équation de Riccati se résout explicitement sous la forme

$$w=\frac{1-e^{2x}}{1+e^{2x}}. \tag{1.25}$$

Il suffit maintenant d'intégrer (1.23) pour obtenir l'expression de V^0 sur $[0,+\infty[$. V^0 est obtenue alors par symétrisation sur $]-\infty,0]$. □

Nous pouvons maintenant énoncer le théorème d'existence pour $\mathscr{P}_R^+$.

THEOREME 1.1. Condition nécessaire et suffisante d'existence pour $\mathscr{P}_R^+$. *Une fonction v solution de l'équation différentielle* (1.15) *sur* $\mathbb{R}_+$ *est solution du problème* $\mathscr{P}_R^+$ *si et seulement si ses valeurs de Cauchy en* 0: $v_0=v(0)$ *et* $v_0'=v'(0)$ *sont liées par la relation*

$$v_0'^2-v_0^2+\frac{v_0^4}{2}=0. \tag{1.26}$$

Elle est alors donnée explicitement par

$$V(v_0,v_0';\,x)=V^0(x+x_0) \tag{1.27}$$

où x_0 est donné par

$$e^{x_0}=\frac{v_0}{\sqrt{2(1+v_0'/v_0)}}. \tag{1.28}$$ □

A un couple (v_0,v_0') de solutions de (1.26) sont associées quatre solutions de $\mathscr{P}_R^+$: $V(v_0,v_0';\,x)$, $V(v_0,-v_0';\,x)$, $-V(v_0,v_0';\,x)$, et $-V(v_0,-v_0',\,x)$.

Les deux premières sont obtenues à partir de V^0 par translation respectivement de x_0 et $-x_0$. Les deux autres sont ensuite obtenues par symétrie par rapport à l'axe des x. La figure 6 représente les variations de la solution fondamentale V^0 en fonction de x. La figure 7 représente les quatre solutions associées à un couple (v_0,v_0') de nombres positifs solution de (1.26).

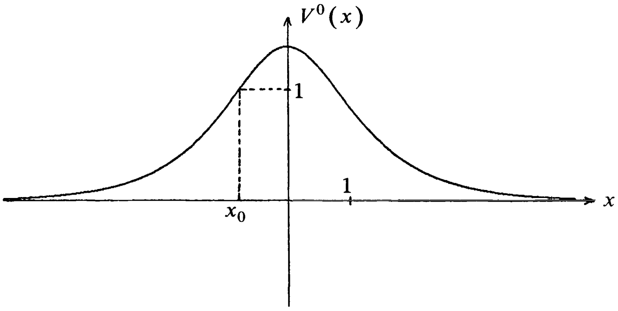

FIG. 6. *Représentation de V^0 sur* $\mathbb{R}$.

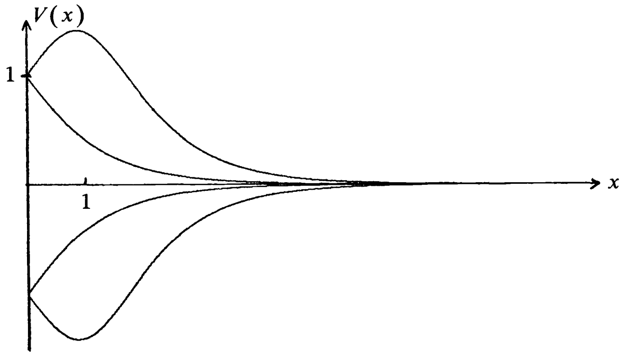

FIG. 7. *Solutions de $\mathscr{P}_R^+$ associées à* $(v_0,v_0')=(1,1/\sqrt{2})$.

Le théorème 1.1 nous donne une relation entre v_0 et v_0', condition nécessaire et suffisante pour que v soit solution de $\mathscr{P}_R^+$. Pour compléter notre étude, nous devons revenir au problème complexe $\mathscr{P}_{\alpha,p}$.

1.2. Le problème $\mathscr{P}_c^-$. L'étude de $\mathscr{P}_c^-$ nous conduira à une relation linéaire entre $u(0_-)$ et $u'(0_-)$. Les conditions de transmission la transformeront en une relation linéaire entre $u(0_+)$ et $u'(0_+)$. Le lemme 1.2 nous permettra d'en déduire une relation entre v_0 et v_0', valeurs de Cauchy de la solution de l'équation différentielle réelle associée à $\mathscr{P}_c^+$. Nous aboutirons ainsi à un système de deux équations réelles à deux inconnues v_0 et v_0'.

1.2.1. Le problème $\mathscr{P}_c^-$. Il peut être résolu explicitement:

LEMME 1.4. *Toutes les solutions u de $\mathscr{P}_c^-$ vérifient*

$$u' + iu = 0 \qquad \forall x \leqq 0, \tag{1.29}$$

$$u = u_0 \exp - ix \qquad \forall x \leqq 0. \tag{1.30}$$

En effet, d'après (1.1), u s'écrit

$$u = A^+ \exp ix + A^- \exp - ix,$$

et la condition d'onde sortante élimine la composante $\exp ix$.

Nous sommes maintenant en mesure d'écrire une caractérisation des solutions de $\mathscr{P}_{\alpha,p}$.

1.2.2. Détermination du système non linéaire reliant v_0 et v_0'. Notons (S) le système non linéaire liant v_0 et v_0':

$$\text{(S)}\begin{cases} v_0'^2 + v_0^2 = \alpha^2 p, \\ v_0'^2 - v_0^2 + \dfrac{v_0^4}{2} = 0, \\ v_0 \geqq 0. \end{cases} \tag{1.31}$$

Nous avons alors le:

THÉORÈME 1.2. Condition nécessaire et suffisante d'existence pour le problème $\mathscr{P}_{\alpha,p}$. *Le problème $\mathscr{P}_{\alpha,p}$ admet une solution u si et seulement si le système* (S) *admet une solution* (v_0, v_0'). *Elle est alors donnée par*:

$$u(x) = \begin{cases} \dfrac{1}{\alpha p}(v_0' - iv_0) V(v_0, v_0'; \, x), & x \geqq 0, \\ \dfrac{1}{\alpha p}(v_0' - iv_0) v_0 \exp - ix; & x \leqq 0. \end{cases} \tag{1.32}$$

Démonstration. Soit u une solution de $\mathscr{P}_{\alpha,p}$. D'après le lemme 1.4, $u'(0_-)$ et $u(0_-)$ sont liés par:

$$u'(0_-) + iu(0_-) = 0.$$

Nous transformons cette relation à l'aide des conditions de transmission:

$$u'(0_+) + iu(0_+) = \alpha. \tag{1.33}$$

D'autre part, d'après le lemme 1.2, u s'écrit pour $x \geqq 0$:

$$u = \frac{z_0}{\sqrt{p}} v$$

où v_0 et v_0' sont liés par

$$v_0'^2 - v_0^2 + \frac{v_0^4}{2} = 0.$$

L'équation (1.33) se traduit alors par une relation entre z_0, v_0 et v_0':

$$\frac{z_0}{\sqrt{p}}\left(v_0'+iv_0\right)=\alpha.$$

Si nous exprimons que z_0 est un nombre complexe de module 1, il vient

$$v_0'^2+v_0^2=\alpha^2 p, \tag{1.34}$$

$$z_0=\frac{1}{\alpha\sqrt{p}}\left(v_0'-iv_0\right). \tag{1.35}$$

Pour x positif, u s'écrit alors

$$u(x)=\frac{1}{\alpha p}\left(v_0'-iv_0\right)V\left(v_0,v_0';\ x\right)$$

où V est la solution du problème réel associé à (v_0,v_0'), et, pour x négatif

$$u(x)=\frac{1}{\alpha p}\left(v_0'-iv_0\right)v_0\exp(-ix).$$

Les considérations de parité sur v développées après le théorème 1.1 permettent enfin de supposer que v_0 est positif.

Réciproquement, si (v_0,v_0') est une solution de (S), la fonction u définie par (1.32) est solution de $\mathscr{P}_{\alpha,p}$.

Pour achever la démonstration de la proposition 1, il nous faut dénombrer les solutions du système (S) de deux équations à deux inconnues. La figure 8 représente les variations des fonctions:

$$Y^2+X^2=\alpha^2 p,$$
$$Y^2-X^2+\frac{X^4}{2}=0.$$

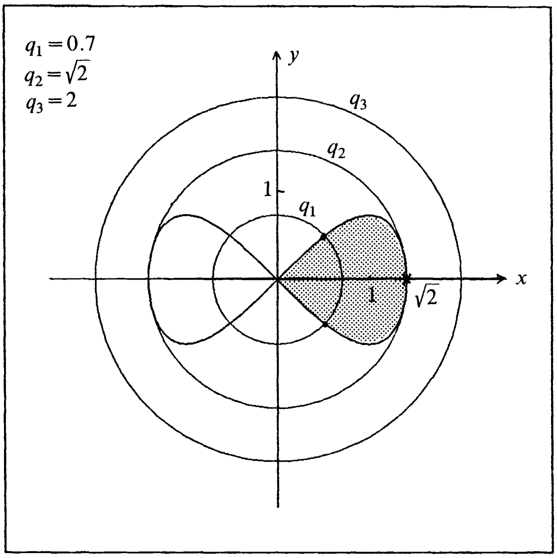

FIG. 8. *Solutions du système* (S) *pour différentes valeurs du paramètre* $q=\sqrt{\alpha^2 p}$.

Les points d'intersection des deux courbes représentatives donnent les solutions du système (S).

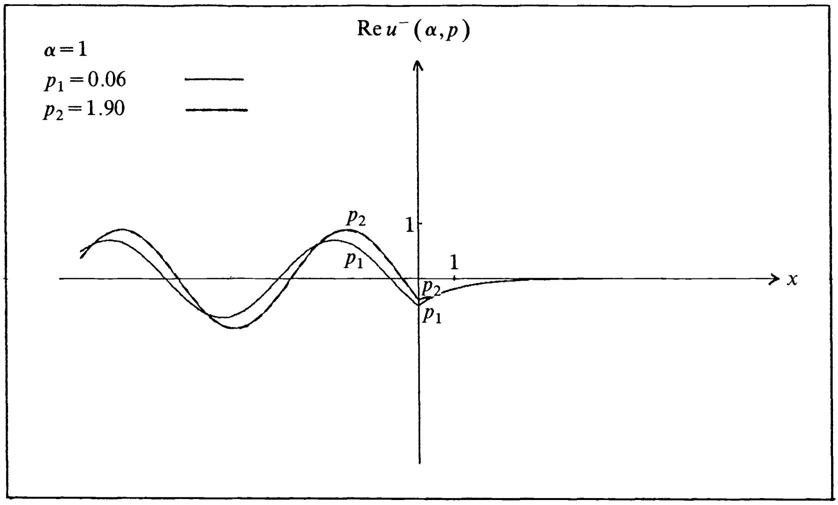
Nous pouvons calculer explicitement les solutions du système (S) en fonction du paramètre $p\alpha^2$.

Notons

$$V_0(p)=\sqrt{2}\left(1-\left(1-\frac{p\alpha^2}{2}\right)^{1/2}\right)^{1/2}, \tag{1.36}$$

$$V_0'(p)=\left(1-\frac{p\alpha^2}{2}\right)^{1/4}V_0(p) \tag{1.37}$$

si $p\alpha^2 \leqq 2$.



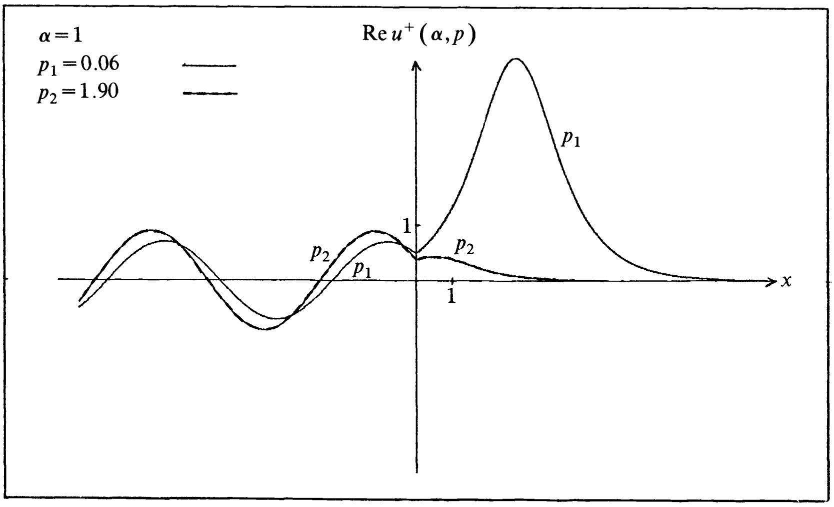


FIG. 9. *Représentation des parties réelles de u^+ et u^-.*

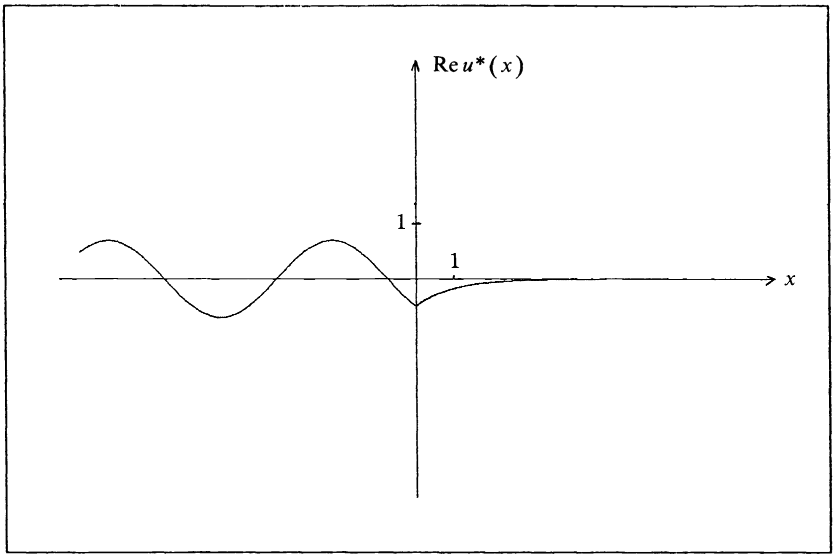

FIG. 10. *Représentation de la partie réelle de u^*, solution du problème linéaire.*

Nous avons alors le:

LEMME 1.5. *Le système* (S) *admet, suivant les valeurs de $p\alpha^2$, zéro, une ou deux solutions*:

$$\begin{array}{ll} 0<p\alpha^2<2, & 2 \text{ solutions} : (V_0(p), V_0'(p)) \text{ et } (V_0(p), -V_0'(p)), \\ p\alpha^2=2, & 1 \text{ solution} : (\sqrt{2}, 0), \\ p\alpha^2>2, & 0 \text{ solution}. \end{array}$$

L'expression des solutions de $\mathscr{P}_{\alpha,p}$ donnée au théorème 1.2 permet de différencier les deux solutions associées au même paramètre $\alpha^2 p$ par le signe de leurs parties réelles.

Nous notons $u^+(\alpha,p)$ la solution de partie réelle positive et $u^-(\alpha,p)$ la solution de partie réelle négative, et nous représentons leurs parties réelles pour $\alpha=1$ et différentes valeurs de p (voir figures 9 et 10).

Remarquons d'abord que la valeur de la fonction pour x négatif varie peu lorsque p est proche de zéro ou de deux.

De même, pour x positif, la partie réelle de u^- dépend peu de p, et lorsque p tend vers 0, $u^-(\alpha,p)$ tend vers la solution u^* du problème linéaire. Par contre, lorsque p devient petit, $u^+(\alpha,p)$ admet un maximum pour x positif qui croit en $1/\sqrt{p}$. La fonction u^- semble donc être la "bonne" solution, et u^+ la solution "parasite."

L'étude de $\mathscr{P}_{\alpha,p}$ fait ainsi apparaître qu'une non-linéarité, même faible, peut modifier totalement la nature de l'équation stationnaire. Nous allons maintenent examiner le problème dérivant directement de (1), en réintroduisant le terme non autonome xu. Nous verrons que l'effet de seuil disparait, mais qu'en revanche le nombre de solutions est croissant avec p.

2. Etude du problème $\mathscr{Q}_{\alpha,p}$. Comme pour le problème $\mathscr{P}_{\alpha,p}$, nous allons écrire un système de deux relations à deux inconnues, reliant les valeurs en zéro d'une fonction v

et de sa dérivée, où v est solution de l'équation réelle associée à $\mathcal{Q}_c^+$:

$$-v'' + xv - v^3 = 0. \tag{2.7}$$

La première relation sera obtenue comme précédemment par l'intégration explicite de $\mathcal{Q}_c^-$ et les conditions de transmission. Par contre la caractérisation des solutions de (2.7) est beaucoup plus complexe, car il nous semble impossible de résoudre explicitement cette équation. Nous ferons intervenir un paramètre x_0, et pour chaque valeur de x_0 nous définissons une fonctionnelle sur $[x_0, +\infty[$. Nous caractérisons ainsi les solutions de (2.7) qui tendent vers zéro à l'infini comme les solutions coincidant sur $[x_0, +\infty[$ avec le minimum de cette fonctionnelle pour un certain x_0. Nous obtiendrons ainsi la deuxième relation entre v_0 et v_0', par l'intermédiaire du paramètre x_0.

2.1. Etude mathématique. Nous commençons par caractériser les solutions du problème linéaire $\mathcal{Q}_c^-$.

2.1.1. Etude du problème $\mathcal{Q}_c^-$. Nous pouvons exprimer la solution u de $\mathcal{Q}_c^-$ à partir de la fonction d'Airy Ai définie dans [1] par:

$$\begin{aligned} &z'' - xz = 0, \qquad x \in \mathbb{R}, \\ &z(0) = 3^{-2/3}/\Gamma(2/3), \\ &z'(0) = -3^{-1/3}/\Gamma(1/3). \end{aligned} \tag{2.8}$$

LEMME 2.1. *Toutes les solutions de $\mathcal{Q}_c^-$ vérifient*

$$\forall v < 0, \quad u(x) = \lambda Ai(xe^{2i\pi/3}), \qquad \lambda \in \mathbb{C}. \tag{2.9}$$

En $x = 0$, u et u' sont liés par la relation

$$u'(0_-) + Ke^{2i\pi/3}u(0_-) = 0 \tag{2.10}$$

où $K = -\mathrm{Ai}'(0)/\mathrm{Ai}(0)$.

Ce lemme est une conséquence immédiate des propriétés de la fonction d'Airy données dans [1].

Nous introduisons maintenant le problème réel:

$$Q_R^+ \begin{cases} -v' + xv - v^3 = 0, & x \in \mathbb{R}_+, \\ xv \to 0, & x \to +\infty, \end{cases} \tag{2.11}$$

et nous cherchons à décrire l'ensemble de ses solutions. Pour celà nous notons que, pour x fixé, l'application:

$$v \to xv - v^3$$

est le gradient d'une fonction convexe sur

$$I_x = \left[-\sqrt{\frac{x}{3}}, +\sqrt{\frac{x}{3}}\right]. \tag{2.12}$$

Pour tout x_0 positif, nous introduisons un problème aux limites sur $]x_0, +\infty[$ tel que, pour tout x, la solution $v(x)$ appartienne à I_x. Nous montrerons que toute solution de $\mathcal{Q}_R^+$ est solution d'un unique problème de ce type, et nous en caractériserons les solutions comme minima d'une fonctionnelle convexe.

Nous la prolongerons ensuite sur $[0, x_0]$ et nous aurons *toutes* les solutions de $\mathcal{Q}_R^+$, paramétrisées par x_0.

2.1.2. Comportement asymptotique des solutions de $\mathscr{Q}_R^+$. Pour tout x_0 positif, nous introduisons le problème

$$(2.13)\qquad \mathscr{Q}_{x_0}\begin{cases} -v''+xv-v^3=0, \\ v(x_0)=\sqrt{\dfrac{x_0}{3}}, \qquad xv(x)\to 0 \quad \text{quand } x\to+\infty, \\ \forall x\geqq x_0, \quad v(x)\in I_x. \end{cases}$$

Avant de décrire ses solutions, nous montrons qu'elles sont les restrictions à $[x_0, +\infty[$ des solutions de $\mathscr{Q}_R^+$ (voir figure 11).

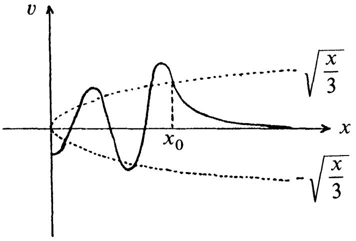

FIG. 11. *Illustration du lemme* 2.2.

LEMME 2.2. *Soit v une solution de $\mathscr{Q}_R^+$. Alors il existe un x_0 positif tel que la restriction de v à $[x_0, +\infty[$ soit solution de $\mathscr{Q}_{x_0}$.*

Démonstration. Comme dans 1, si v est solution de $\mathscr{Q}_R^+$, $v^{(n)}(x)$ tend vers 0 pour tout n lorsque x tend vers $+\infty$. Puisque v est $\mathscr{C}^\infty$, il existe alors un x_0 positif tel que $v^2(x_0)=x_0/3$ et, pour tout x supérieur à x_0, $v^2(x)\leqq x/3$. Alors v est solution de $\mathscr{Q}_{x_0}$.

Le lien entre $\mathscr{Q}_R^+$ et $\mathscr{Q}_{x_0}$ ainsi établi, nous étudions le problème $\mathscr{Q}_{x_0}$, et nous introduisons un problème de minimisation.

Notons:

$$(2.14)\qquad V(x_0)=\{v\in H^1(]x_0,+\infty[),\ \sqrt{x}\,v\in L^2(]x_0,+\infty[)\}.$$

$V(x_0)$ est un espace de Hilbert pour la norme définie par

$$(2.15)\qquad \|v\|^2=|v|_1^2+\|\sqrt{x}v\|_0^2.$$

Soit

$$(2.16)\qquad \mathscr{J}_{x_0}(v)=\frac{1}{2}\int_{x_0}^{+\infty}v'^2(x)\,dx+\frac{1}{2}\int_{x_0}^{+\infty}\left(xv^2(x)-\frac{v^4(x)}{2}\right)dx,$$

une fonctionnelle définie sur $V(x_0)$.

Nous définissons un convexe fermé de $V(x_0)$ par

$$(2.17)\qquad K(x_0)=\left\{v\in V(x_0);\ v(x_0)=\sqrt{\frac{x_0}{3}}\ ;\ v(x)\in I_x, \forall x\geqq x_0\right\}$$

et un problème de minimisation avec contraintes par:

$$(2.18)\qquad \mathscr{M}_{x_0}:\ \inf_{v\in V(x_0)}\mathscr{J}_{x_0}(v).$$

L'introduction de ce problème est justifiée par le

LEMME 2.3. Existence et unicité pour le problème $\mathcal{Q}_{x_0}$. *Le problème* $\mathcal{Q}_{x_0}$ *admet une solution unique* $\mathcal{C}^\infty$. *C'est une fonction positive, décroissante, convexe. De plus c'est la solution du problème de minimisation* $\mathcal{M}_{x_0}$.

Démonstration. La fonctionnelle $\mathcal{J}_{x_0}$ est strictement convexe, différentiable, coercive, sur la convexe fermé $K(x_0)$. Un théorème usuel d'optimisation prouve qu'elle admet un minimum unique sur $K(x_0)$, caractérisé par

$$\forall w \in K(x_0), \quad \mathcal{J}_{x_0}'(v)(w-v) \geqq 0,$$

soit ici

$$(2.19) \qquad \forall w \in K(x_0), \quad \int_{x_0}^{+\infty} (-v''+xv-v^3)(w-v) \geqq 0.$$

D'autre part, $|v|$ est dans $K(x_0)$ et $\mathcal{J}_{x_0}(v)=\mathcal{J}_{x_0}(|v|)$. L'unicité assure alors la positivité de v.

Posons maintenant:

$$(2.20) \qquad \Omega_0 = \left\{ x \in [x_0, +\infty[;\ v(x) = \sqrt{\frac{x}{3}} \right\},$$

$$(2.21) \qquad \Omega_+ = \left\{ x \in]x_0, +\infty[;\ v(x) < \sqrt{\frac{x}{3}} \right\}.$$

Si φ appartient à $\mathcal{D}_+(\,]x_0, +\infty[\,)$, et si ε est un nombre positif assez petit:

$$w = v - \varepsilon\varphi \in K(x_0).$$

Appliquons (2.19) à w:

$$\forall x \in \Omega_+, \quad -v''+xv-v^3=0,$$
$$\forall x \in \Omega_0, \quad -v''+xv-v^3 \leqq 0.$$

Nous en déduisons que v'' est positive, et donc que v' est croissante, sur $[x_0, +\infty[$. Or v' tend vers 0 à l'infini. Donc v' est négative, et v est décroissante sur $]x_0, +\infty[$. Par suite Ω_0 se réduit à x_0, et

$$(2.22) \qquad \forall x \in]x_0, +\infty[, \quad -v''+xv-v^3=0.$$

Ainsi v est dans $H^2(]x_0, +\infty[)$, et donc dans $\mathcal{C}^1(]x_0, +\infty[)$; v est $\mathcal{C}^\infty$ sur $]x_0, +\infty[$ et par continuité (2.22) est valable aussi en x_0. La caractérisation (2.19) montre enfin que toute solution de $\mathcal{Q}_{x_0}$ est solution de $\mathcal{M}_{x_0}$.

Notons maintenant, pour tout x_0:

(2.23) $v(x_0,\gamma;\ x)$ une solution $\mathcal{C}^\infty$ du problème de Cauchy,

$$\begin{cases} -v''+xv-v^3=0 & \text{sur }]x_0, +\infty[, \\ v(x^0) = \sqrt{\dfrac{x_0}{3}}, & v'(x_0)=\gamma, \end{cases}$$

(2.24) $v^*(x_0;\ x)$ la solution du problème de minimisation $\mathcal{M}_{x_0}$,

(2.25) $\gamma^*(x_0)$ sa dérivée en x_0.

Nous pouvons énoncer le

THÉORÈME 2.1. Condition nécessaire d'existence pour le problème $\mathcal{Q}_R^+$. *Soit v une solution du problème $\mathcal{Q}_R^+$. Il existe un x_0 positif tel que*

$$v=v^*(x_0;\ \cdot) \quad ou\ v=-v^*(x_0;\ \cdot)\ sur\ ]x_0,+\infty[.$$

Ce théorème est une conséquence des deux lemmes précédents.

Remarquons que $\gamma^*(x_0)$ n'est pas donné explicitement en fonction de x_0. Par la suite, nous calculerons $u^*(x_0;\ \cdot)$ numériquement, et nous aurons besoin de certaines propriétés de $\gamma^*(x_0)$ que nous établissons maintenant.

2.1.3. Propriétés de $\gamma^*(x_0)$—Comportement asymptotique lorsque x tend vers $+\infty$. Toutes les démonstrations seront basées sur une estimation à priori.

LEMME 2.4. Egalité d'énergie. *Si une fonction v est solution sur $]y,z[$ de l'équation différentielle* (2.7), *on a sur $]y,z[$ la relation*:

$$\frac{d}{dx}\left(v'^2-xv^2+\frac{v^4}{2}\right)=-v^2. \tag{2.26}$$

La démonstration est analogue à celle du lemme 1.1.

Nous établissons maintenant deux propriétés de $v^*(x_0;\ \cdot)$.

LEMME 2.5.

i) *Encadrement de la solution $v^*(x_0;\ \cdot)$ du problème aux limites par des solutions $v(x_0,\gamma;\ \cdot)$ de problèmes de Cauchy.*

●*Si $\gamma_1<\gamma^*(x_0)$ il existe un $x_1>x_0$, tel que $v(x_0,\gamma_1;\ x_1)=0$.*

●*Si $\gamma_1>\gamma^*(x_0)$ il existe un $x_2>x_0$, tel que $v'(x_0,\gamma_2;\ x_2)=0$.*

ii) *Encadrement de $\gamma^*(x_0)$ en fonction de x_0. Pour tout $x_0>0$ on a l'encadrement*

$$-\frac{1}{\sqrt{3}}\left(x_0+\frac{1}{4}x_0^{-1/2}\right)\leqq\gamma^*(x_0)\leqq-\frac{x_0}{3}\sqrt{\frac{5}{2}}. \tag{2.27}$$

En particulier $\gamma^*(x_0)$ tend vers $-\infty$ lorsque x_0 tend vers $+\infty$.

La figure 12 illustre la partie (i) du lemme 2.5.

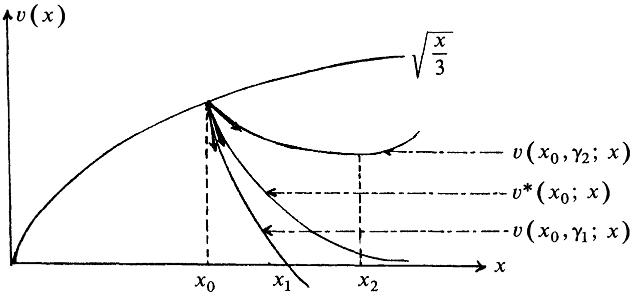

FIG. 12. *Représentation de $v(x_0,\gamma_1;\ \cdot)$, $v^*(x_0;\ \cdot)$, $v(x_0,\gamma_2;\ \cdot)$ pour $\gamma_1<\gamma^*(x_0)<\gamma_2$.*

Démonstration. i) Nous établissons le premier résultat; le deuxième se démontre de même. Soit donc $\gamma_1<\gamma^*(x_0)$, et raisonnons par l'absurde: supposons que $v(x_0,\gamma_1;\ x)$ ne s'annule jamais sur $]x_0,+\infty[$. D'après l'unicité de la solution du problème $\mathcal{Q}_{x_0}$, les deux fonctions $v^*(x_0;\ \cdot)$ et $v(x_0,\gamma_1;\ \cdot)$ prennent la même valeur en un point x' tel que $x'>x_0$ (voir figure 13):

$$v^*(x_0;\ x')=v(x_0,\gamma_1;\ x').$$

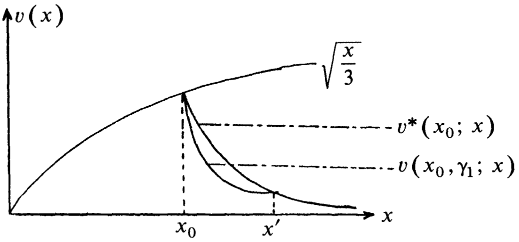

FIG. 13

Posons

$$w(x)=v^*(x_0;\ x)-v(x_0,\gamma_1;\ x).$$

w s'annule en x_0 et x', sa dérivée s'annule donc en un point x'' tel que:

$$x_0<x''<x',\quad w'(x'')=0.$$

Or

$$w''(x)=x\big(v^*(x_0;\ x)-v(x_0,\gamma_1;\ x)\big)-\Big(\big(v^*(x_0;\ x)\big)^3-\big(v(x_0,\gamma_1;\ x)\big)^3\Big).$$

w'' est positive sur $]x_0,x'[$, et $w'(x_0)=\gamma^*(x_0)-\gamma_1>0$. w' est alors strictement positive sur $]x_0,x'[$, et ne peut s'annuler en x''.

ii) La majoration résulte du lemme 2.4. En effet, la fonction

$$x\to\big(v^{*\prime}(x_0;\ x)\big)^2-x\big(v^*(x_0;\ x)\big)^2+\tfrac{1}{2}\big(v^*(x_0;\ x)\big)^4$$

est décroissante et tend vers 0 à l'infini. Elle est donc positive en x_0:

$$\gamma^{*2}(x_0)-\frac{5x_0^2}{18}\geqq 0.$$

La minoration provient de la remarque suivante: la fonction v définie sur $]x_0,+\infty[$ par

$$v(x)=\frac{x_0^{3/4}}{\sqrt{3}}\exp\left(\frac{2}{3}x_0^{3/2}x^{-1/4}\exp\left(-\frac{2}{3}x^{3/2}\right)\right)$$

est une sous-solution. Sa dérivée en x_0 est donc inférieure à $\gamma^*(x_0)$.

Nous pouvons de plus préciser le comportement asymptotique des fonctions $v^*(x_0;\ \cdot)$.

Effectuons un changement d'échelle et une translation; posons pour celà:

$$\text{(2.28)}\qquad \begin{aligned} &v^*(x_0;\ x)=\sqrt{x_0}\,w_{x_0}(y),\\ &y=\sqrt{x_0}\,(x-x_0). \end{aligned}$$

w_{x_0} est une fonction définie sur $[0, +\infty[$, solution du problème aux limites:

$$(2.29)\qquad \begin{aligned} &-w''+\left(1+\frac{y}{x_0^{3/2}}\right)w-w^3=0,\\ &w(0)=\frac{1}{\sqrt{3}},\qquad w(x)\to 0 \quad \text{quand } x\to+\infty. \end{aligned}$$

De plus la pente de w_{x_0} en 0 est déterminée:

$$(2.30)\qquad w'_{x_0}(0)=\frac{\gamma^*(x_0)}{x_0}.$$

Nous avons tracé ci-dessous les représentations de $v^*(x_0;\ \cdot)$ sur $[x_0, x_0+A]$ et de w_{x_0} sur $[0, A]$ pour différentes valeurs de x_0. Il apparait nettement sur la fig. 14 que la pente de v^* en $x_0, \gamma^*(x_0)$ décroit et tend vers $-\infty$ lorsque x_0 croit et tend vers $+\infty$. La figure 15 semble montrer que la famille w_{x_0} est croissante sur $[0, +\infty[$ et converge uniformément lorsque x_0 tend vers $+\infty$. C'est ce résultat que nous allons établir.

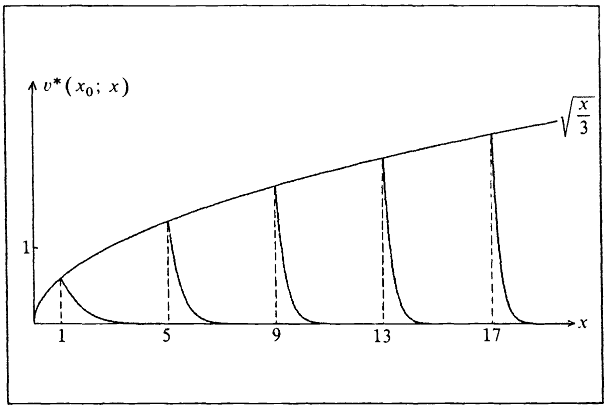

FIG. 14. *Représentation de $v^*(x_0;\ \cdot)$ sur $[x_0,\ +\infty[$ pour différentes valeurs de x_0.*

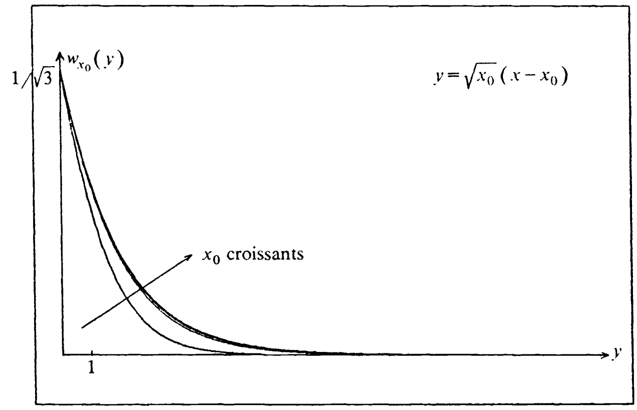

FIG. 15. *Représentation de w_{x_0} sur $[0,\ +\infty[$ pour différentes valeurs de x_0.*

LEMME 2.6. Comportement asymptotique de $v^*(x_0;\ \cdot)$ lorsque x_0 tend vers l'infini. *La famille de fonctions w_{x_0} est croissante avec x_0 et converge uniformément vers $V(\frac{1}{3}, -\frac{1}{3}\sqrt{\frac{5}{2}}\ ;\ \cdot)$ lorsque x_0 tend vers $+\infty$. En particulier*

i) *la fonction $x_0 \to \gamma^*(x_0)/x_0$ est croissante et tend vers $-\frac{1}{3}\sqrt{\frac{5}{2}}$ lorsque x_0 tend vers $+\infty$;*

ii) *sur $]x_0, +\infty[$, $v^*(x_0;\ x) \leqq \lambda\sqrt{x_0}\, e^{-\sqrt{x_0}(x-x_0)}$, où λ est une constante.*

Rappelons que $V(1/\sqrt{3},\ -\frac{1}{3}\sqrt{\frac{5}{2}}\ ;\ \cdot)$ est définie en (1.27) comme la solution du problème:

$$-v''+v-v^3=0, \qquad x \geqq 0,$$
$$v(0)=\frac{1}{\sqrt{3}},$$
$$v'(0)=-\frac{1}{3}\sqrt{\frac{5}{2}}\,.$$

Démonstration. 1. Montrons d'abord que la famille des fonctions w_{x_0} est croissante avec x_0. Soient donc deux réels positifs x_0 et x_1. Nous allons établir l'inégalité:

$$\forall y \geqq 0, \quad \frac{1}{\sqrt{x_0}} v^*\left(x_0;\ x_0+\frac{y}{\sqrt{x_0}}\right) \geqq \frac{1}{\sqrt{x_1}} v^*\left(x_1;\ x_1+\frac{y}{\sqrt{x_1}}\right). \tag{2.31}$$

Notons

$$\mu=\sqrt{\frac{x_1}{x_0}} \tag{2.32}$$

et, pour $x \geqq x_1$,

$$v(x)=\mu v^*(x_0;\ x_0+\mu(x-x_1)) \tag{2.33}$$

μ est supérieur à 1, et la fonction v vérifie

$$v(x_1)=v^*(x_1;\ x_1),$$
$$0 \leqq v(x) \leqq \sqrt{\frac{x}{3}}, \qquad x \geqq x_1,$$
$$-v''+xv-v^3=(1-\mu^3)(x-x_1)v(x) \geqq 0, \qquad x \geqq x_1.$$

v est donc une sur-solution pour le problème de minimisation $\mathscr{M}_{x_1}$, et

$$\forall x \geqq x_1, \quad v(x) \geqq v^*(x_1;\ x);$$

donc,

$$\forall y \geqq 0, \quad v\left(x_1+\frac{y}{\sqrt{x_1}}\right) \geqq v^*\left(x_1;\ x_1+\frac{y}{\sqrt{x_1}}\right).$$

L'inégalité (2.31) est établie.

2. Montrons maintenant que, pour tout x_0, la fonction w_{x_0} est bornée par $V(1/\sqrt{3},\ -\frac{1}{3}\sqrt{\frac{5}{2}}\ ;\ \cdot)$. Il suffit pour celà de prouver que la fonction φ définie sur $[x_0, +\infty[$ par

$$\varphi(x)=\sqrt{x_0}\, V\left(\frac{1}{\sqrt{3}},\ -\frac{1}{3}\sqrt{\frac{5}{2}}\ ;\ \sqrt{x_0}(x-x_0)\right)$$

est une sous-solution pour le problème de minimisation $\mathcal{M}_{x_0}$, ce qui se vérifie immédiatement.

La famille des w_{x_0} est une famille croissante de fonctions monotones, uniformément majorée sur $[0, +\infty[$; elle converge donc presque partout. Pour assurer la convergence uniforme, il suffit de vérifier que $w'_{x_0}(x)$ est uniformément bornée sur $[0, +\infty[$. Or:

$$\forall x \geqq 0, \quad 0 \geqq w'_{x_0}(x) \geqq w'_{x_0}(0) = \frac{\gamma^*(x_0)}{x_0}$$

et d'après le lemme 2.4,

$$\frac{\gamma^*(x_0)}{x_0} \geqq -\frac{1}{\sqrt{3}}\left(1 + \frac{1}{4}x_0^{-3/2}\right) \geqq C \quad \text{pour } x_0 \text{ assez grand.}$$

La famille w_{x_0} converge donc uniformément vers une fonction continue w.

3. Il nous reste à prouver que la limite de w_{x_0} est $V(1/\sqrt{3}, -\frac{1}{3}\sqrt{\frac{5}{2}}\,;\,\cdot)$. Rappelons d'abord que, d'après le théorème 1.1, v est donnée explicitément par

$$V\left(\frac{1}{\sqrt{3}}, -\frac{1}{3}\sqrt{\frac{5}{2}}\,;\,y\right) = 2\sqrt{2}\,\frac{e^{y+X}}{1+e^{(y+X)}}$$

où X est déterminé par

$$e^X = \sqrt{5} + \sqrt{6},$$

d'où

$$\forall y \geqq 0, \quad V\left(\frac{1}{\sqrt{3}}, -\frac{1}{3}\sqrt{\frac{5}{2}}\,;\,y\right) < \lambda e^{-y},$$

et puisque v est un majorant de w_{x_0}

$$\forall x_0 > 0, \forall y \geqq 0, \quad w_{x_0}(y) \leqq \lambda y e^{-y} \leqq C.$$

Nous avons ainsi tous les éléments pour passer à la limite dans l'équation

$$-w'' + \left(1 + \frac{y}{x_0^{3/2}}\right)w - w^3 = 0, \qquad y \geqq 0.$$

La limite w de w_{x_0} vérifie donc

$$\begin{aligned}
&-w'' + w - w^3 = 0,\\
&w(0) = \frac{1}{\sqrt{3}}, \qquad w(y) \to 0 \text{ quand } y \to +\infty,\\
&w'(0) < 0,
\end{aligned}$$

et w est bien égale à $V(1/\sqrt{3}, \frac{1}{3}\sqrt{\frac{5}{2}}\,;\,\cdot)$. En particulier la fonction $x_0 \to \gamma^*(x_0)/x_0$ tend vers $-\frac{1}{3}\sqrt{\frac{5}{2}}$ lorsque x_0 tend vers $+\infty$.

La majoration ii) du lemme provient de la majoration établie plus haut:

$$\forall x_0>0, \forall y \geqq 0, \quad w_{x_0}(y) \leqq \lambda e^{-y}.$$

Ces propriétés asymptotiques étant établies, nous poursuivons notre étude en prolongeant les fonctions $v^*(x_0;\ \cdot)$ sur $[0,x_0]$.

2.1.4. Description des solutions de $\mathscr{D}_R^+$. Nous définissons un problème de Cauchy sur $[0,x_0]$ (en renversant le sens des x), par:

$$-v''+xv-v^3=0, \qquad 0 \leqq x \leqq x_0, \tag{2.34}$$

$$\begin{gathered} v(x_0)=\sqrt{\frac{x_0}{3}}, \\ v'(x_0)=\gamma^*(x_0). \end{gathered} \tag{2.35}$$

L'existence locale d'une solution à ce problème provient simplement des théorèmes usuels d'équations différentielles. L'existence globale sera assurée par des estimations à priori.

LEMME 2.7. *On a pour une solution v de* (2.34), (2.35) *les estimations à priori*:

$$\|v\|_{L^\infty([0,x_0])} \leqq \varphi(x_0) \tag{2.36}$$

$$\|v'\|_{L^\infty([0,x_0])} \leqq \psi(x_0) \tag{2.37}$$

où $\varphi(x_0)$ et $\psi(x_0)$ sont données par:

$$\varphi^2(x_0)=x_0+\left(x_0^2+2\left(\gamma^{*2}(x_0)-\frac{5x_0^2}{18}\right)\right)^{1/2}, \tag{2.38}$$

$$\psi^2(x_0)=2x_0\varphi^2(x_0)+\gamma^{*2}(x_0)-\frac{5x_0^2}{18}. \tag{2.39}$$

Les estimations ne sont pas uniformes en x_0, car $\varphi(x_0)$ et $\psi(x_0)$ tendent vers l'infini avec x_0.

Démonstration. Les estimations seront établies en deux étapes. Nous montrerons d'abord que la suite des extrema locaux est croissante, puis nous majorerons le dernier extremum local, c'est-à dire celui qui est atteint le plus près de x_0.

Rappelons d'abord l'estimation d'énergie:

$$\frac{d}{dx}\left(v'^2-xv^2+\frac{v^4}{2}\right)=-v^2 \quad \text{sur } [0,x_0]. \tag{2.40}$$

La fonction

$$x \to v'^2-xv^2+\frac{v^4}{2}$$

est décroissante. Puisque v est le prolongement de $v^*(x_0,\cdot)$ elle est égale en x_0 à $(\gamma^*(x_0))^2-5x_0^2/18$ qui est positif, et donc

$$\forall x \in [0,x_0], \quad v'^2-xv^2+\frac{v^4}{2} \geqq \gamma^{*2}(x_0)-\frac{5x_0^2}{18}. \tag{2.41}$$

En particulier, en un point où la dérivée s'annule, nous obtenons:

$$\forall x \in [0,x_0], \quad v'(x)=0 \Rightarrow v^2 \geqq 2x. \tag{2.42}$$

Montrons le résultat suivant: *si deux extrema locaux successifs sont atteints en* x_1 *et* x_2, $0 \leqq x_1 < x_2 < x_0$, *alors* $|v(x_1)| < |v(x_2)|$.

Nous raisonnerons par l'absurde: soient x_1 et x_2 deux points tels que

$$0 < x_1 < x_2 < x_0, \qquad |v(x_1)| \geqq |v(x_2)|.$$

Nous sommes par exemple dans le cas de la figure 16.

Par commodité, nous noterons

$$v_1 = v(x_1), \qquad v_2 = v(x_2).$$

Nous intégrons l'égalité d'énergie (2.40) entre x_1 et x_2. Puisque v' s'annule en x_1 et x_2, nous avons:

$$-x_1v_1^2 + \frac{v_1^4}{2} - \left(-x_2v_2^2 + \frac{v_2^4}{2}\right) = \int_{x_1}^{x_2} v^2(x)\,dx.$$

Par hypothèse, nous pouvons majorer v sur $[x_1,x_2]$ par v_1^2. Après simplification, nous obtenons:

$$\frac{v_1^2+v_2^2}{2} \leqq x_2.$$

Mais d'autre part, d'après (2.42),

$$\frac{v_1^2+v_2^2}{2} \geqq v_2^2 \geqq 2x_2,$$

ce qui apporte une contradiction.

Le cas où un extremum local est atteint en zéro se traite de même.

Il nous reste à établir les estimations sur l'extremum le plus proche de x_0. Comme pour la démonstration précédente, deux situations peuvent se présenter: l'extremum est atteint, soit en 0, soit en $x_1 > 0$ (voir figure 17).

Nous traitons le premier cas, le deuxième se résout de même. Nous intégrons l'égalité d'énergie entre 0 et x_0:

$$v'^2 + \frac{v_0^4}{2} - \left(\gamma^{*2}(x_0) - \frac{5x_0^2}{18}\right) = \int_0^{x_0} v^2(x)\,dx.$$

Nous majorons v^2 sur $[0,x_0]$ par v_0^2 et nous obtenons

$$\frac{v_0^4}{2} - x_0v_0^2 - \left(\gamma^{*2}(x_0) - \frac{5x_0^2}{18}\right) \leqq 0,$$

ce qui n'est réalisé que si

$$v_0^2 \leqq x_0 + \left(x_0^2 + \left(\gamma^{*2}(x_0) - \frac{5x_0^2}{18}\right)\right)^{1/2}$$

ce qui constitue l'estimation (2.36).

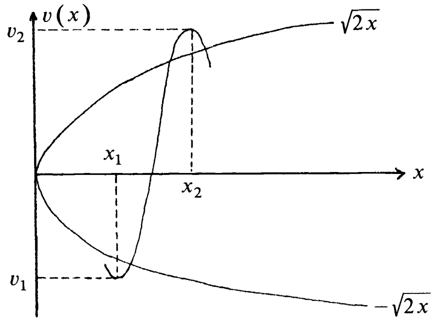

FIG. 16

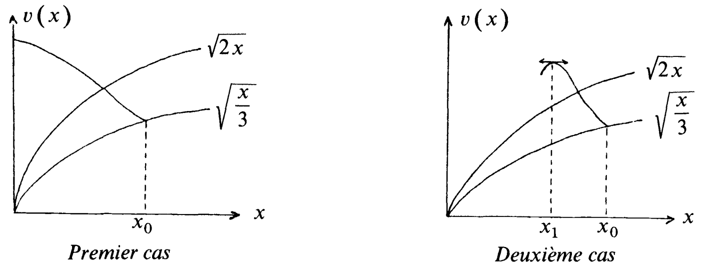


Premier cas

Deuxième cas

FIG. 17

Pour établir l'estimation (2.37), il suffit de remarquer que

$$\forall x \in [0, x_0], \quad 0 \leqq v'^2 - xv^2 + \frac{v^4}{2} \leqq v_0'^2 + \frac{v_0^4}{2}$$

et

$$v_0'^2 + \frac{v_0^4}{2} \leqq \gamma^{*2}(x_0) - \frac{5x_0^2}{18} + x_0\varphi^2(x_0).$$

Nous avons ainsi:

$$\forall x \in [0, x_0], \quad v'^2 \leqq 2x_0\varphi^2(x_0) + \gamma^{*2}(x_0) - \frac{5x_0^2}{18} = \psi^2(x_0).$$

Nous avons ainsi établi les estimations L^∞ sur u et u'.

Le lemme 2.7 nous permet donc de prolonger $v^*(x_0; \cdot)$ sur toute la droite $\mathbb{R}_+$. En particulier, nous pouvons définir sa valeur en zéro ainsi que celle de sa dérivée, et donc une application de $\mathbb{R}_+$ dans $\mathbb{R}^2$ par

$$(2.43) \qquad \sigma(x_0) = \left(v^*(x_0; 0), \frac{dv^*}{dx}(x_0; 0) \right).$$

Nous noterons $\mathcal{S}$ l'image de $\mathbb{R}_+$ par σ:

$$(2.44) \qquad \mathcal{S} = \left\{ (v_0, v_0') \in \mathbb{R}^2, \exists x_0 \in \mathbb{R}_+, (v_0, v_0') = \sigma(x_0) \right\}.$$

Les solutions de $\mathcal{Q}_R^+$ sont les solutions de l'équation différentielle dont les valeurs initiales appartiennent à $\mathcal{S}$.

THÉORÈME 2.2. Caractérisation des solutions de $\mathcal{Q}_R^+$. *L'ensemble des solutions de* $\mathcal{Q}_R^+$ *est l'ensemble des* $v^*(x_0; \cdot)$ *et* $-v^*(x_0; \cdot)$ *lorsque* x_0 *décrit* $\mathbb{R}_+$.

Il ne nous reste plus qu'à relier les caractérisations des solutions des problèmes $\mathscr{Q}_c^-$ et $\mathscr{Q}_R^+$.

2.1.5. Le système d'équations non linéaires vérifié par v_0 et v_0'. Comme pour le problème $\mathscr{P}_{\alpha,p}$, nous pouvons établir une équivalence entre les problèmes réel et complexe sur $\mathbb{R}_+$:

LEMME 2.8. Equivalence entre $\mathscr{Q}_c^+$ et $\mathscr{Q}_R^+$. *La fonction u à valeurs complexes est solution de $\mathscr{Q}_c^+$ si et seulement si il existe un nombre complexe z_0 et une fonction réelle v tels que*

$$(2.45)\qquad u=\frac{z_0}{\sqrt{p}}v, \qquad |z_0|=1, \qquad v \textit{ solution de } \mathscr{Q}_R^+.$$

La démonstration est pratiquement la même que dans le lemme 1.2. Ce qui tient lieu ici d'énergie est la fonction

$$x\to|u'|^2-x|u|^2+\frac{p}{2}|u|^4$$

qui est décroissante, ce qui permet d'affirmer que u' tend vers zéro lorsque x tend vers $+\infty$.

Notons $E_{\alpha,p}$ la famille d'ellipses définie par:

$$(2.46)\qquad E_{\alpha,p}=\left\{(X,Y)\in\mathbb{R}^2, \left(Y-\frac{k}{2}X\right)^2+\frac{3}{4}k^2X^2-\alpha^2p=0\right\}$$

où k est le réel défini dans le lemme 2.1.

Nous pouvons maintenant décrire explicitement les solutions de $\mathscr{Q}_{\alpha,p}$.

PROPOSITION 2.1. Caractérisation des solutions de $\mathscr{Q}_{\alpha,p}$. *Le problème $\mathscr{Q}_{\alpha,p}$ admet une solution u si et seulement si il existe (v_0,v_0') appartenant à $\mathscr{S}\cap E_{\alpha,p}$. Elle s'écrit alors*:

$$(2.47)\qquad u(x)=\begin{cases}\dfrac{1}{\alpha p}\left(v_0'+ke^{-2i\pi/3}v_0\right)v^*(x_0;\ \cdot), & x\geqq 0,\\[2ex] \dfrac{1}{\alpha p}v_0\left(v_0'+ke^{-2i\pi/3}v_0\right)\dfrac{\mathrm{Ai}\left(xe^{2i\pi/3}\right)}{\mathrm{Ai}(0)}, & x\leqq 0,\end{cases}$$

où x_0 est tel que

$$(2.48)\qquad v_0=v^*(x_0;0), \qquad v_0'=\frac{d}{dx}v^*(x_0;0).$$

Démonstration. Soit u une solution de $\mathscr{Q}_{\alpha,p}$. D'après le lemme 2.8, u peut s'exprimer sur $\mathbb{R}_+$ à partir des solutions de $\mathscr{Q}_R^+$, et donc

$$(2.49)\qquad \exists x_0\in\mathbb{R}_+, \exists z_0\in\mathbb{C}, \quad u=\frac{z_0}{\sqrt{p}}v^*(x_0;\ \cdot), \qquad |z_0|=1.$$

Nous utilisons maintenant la caractérisation des solutions de $\mathscr{Q}_c^-$ donnée par le lemme 2.1, et les conditions de transmission

$$\begin{aligned}&u'(0_-)+ke^{2i\pi/3}u(0_-)=0,\\&u(0_-)=u(0_+),\\&u'(0_-)=u'(0_+)-\alpha.\end{aligned}$$

Ce système se traduit par

$$\frac{z_0}{\sqrt{p}}\left(\frac{dv^*}{dx}(x_0;\,0)+ke^{2i\pi/3}v^*(x_0;\,0)\right)=\alpha. \tag{2.50}$$

Notons

$$v_0=v^*(x_0;\,0),\qquad v_0'=\frac{dv^*}{dx}(x_0;\,0).$$

La relation (2.50) se réécrit sous la forme

$$\left|v_0'+ke^{2i\pi/3}v_0\right|^2=\alpha^2p,$$

$$z_0=\frac{1}{\alpha p}\left(v_0'+ke^{-2i\pi/3}v_0\right).$$

(v_0,v_0') appartient donc à $\mathscr{S}\cap E_{\alpha,p}$, et u est donnée par l'expression (2.47).

Réciproquement si (v_0,v_0') appartient à $\mathscr{S}\cap E_{\alpha,p}$, il leur correspond par $\mathscr{s}^{-1}$ un réel x_0 positif tel que $(v_0,v_0')=\mathscr{s}(x_0)$, et la fonction u définie par (2.47) est solution de $\mathscr{Q}_{\alpha,p}$.

Nous sommes donc ramenés à étudier le nombre de solutions du problème

$$(v_0,v_0')\in\mathscr{S}\cap E_{\alpha,p} \tag{2.50}$$

en fonction du paramètre α^2p. C'est un système non linéaire de deux relations à deux inconnues; l'une, $E_{\alpha,p}$, est connue exactement, et nous approcherons $\mathscr{S}$ numériquement.

2.2. Etude numérique du système non linéaire reliant v_0 et v_0'. Nous commençons par étudier l'approximation numérique de $v^*(x_0;\,\cdot)$. Un pas h de discrétisation étant donné, nous approchons $v^*(x_0;\,\cdot)$ par $v_h^*(x_0;\,\cdot)$ définie de la manière suivante:

Nous discrétisons l'équation différentielle $-v''+xv-v^3=0$ sur $[0,\,+\infty[$ par un schéma aux différences finies centré.

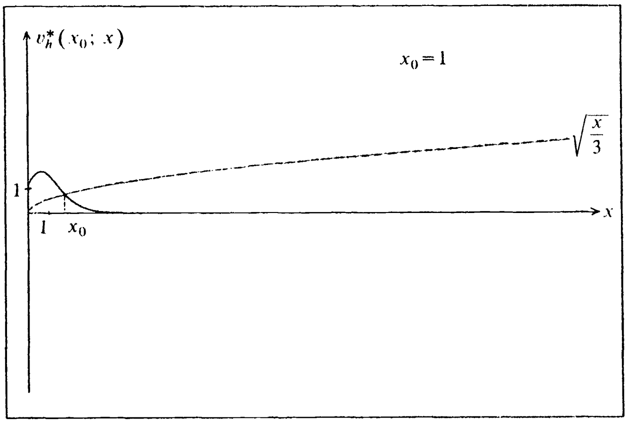
$$\begin{aligned}&-\frac{v_{i+1}-2v_i+v_{i-1}}{h}+x_iv_i-v_i^3=0,\\ &x_i=x_0+\varepsilon ih,\\ &v_i\sim v^*(x_0;\,x_i);\end{aligned} \tag{2.51}$$

ε prend la valeur $+1$ ou -1 selon qu'on se place sur $[0,x_0]$ ou $[x_0,\,+\infty]$.

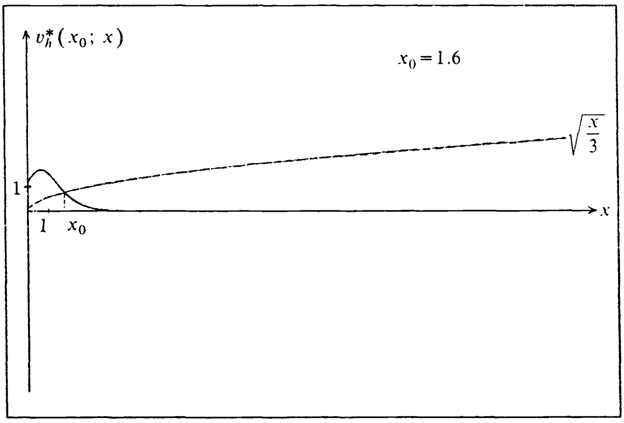
1. D'après le lemme 2.5, nous avons un encadrement de $\gamma^*(x_0)$ et de $v^*(x_0;\,\cdot)$ sur $[x_0,\,+\infty[$. Ces propriétés nous permettent de calculer une approximation $\gamma_h^*(x_0)$ de $\gamma^*(x_0)$ avec toute la précision souhaitée, et $v_h^*(x_0;\,\cdot)$ sur $[x_0,\,x_0+A[$ à l'aide du schéma (2.51).

2. Nous calculons $v_h^*(x_0;\,\cdot)$ sur $[0,x_0]$ comme solution de l'équation (2.51), associée aux valeurs de Cauchy $(v^*(x_0;\,x_0),\,\gamma_h^*(x_0))$.

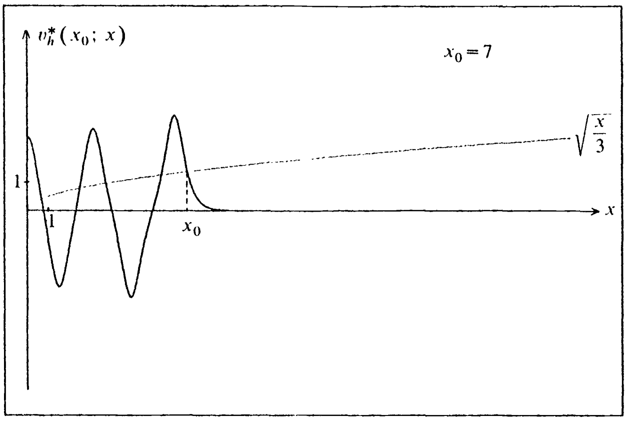
3. Nous traçons les courbes représentant $v_h^*(x_0;\,\cdot)$ pour différentes valeurs du paramètre x_0 (voir figure 18).



$x_0=1$. $v_h^*(x_0;\,\cdot)$ *est strictement décroissante sur* $[0,+\infty[$.

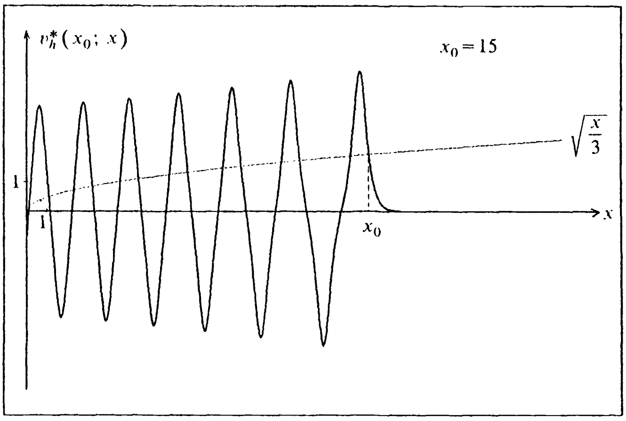


$x_0=1.6$. *Naissance d'une oscillation.*



$x_0=7$. $v_h^*(x_0;\,\cdot)$ *a* 2 *oscillations.*

FIG. 18. *Représentation de la solution approchée de* $\mathscr{Q}_R^+$ *pour différentes valeurs de* x_0, *pour un pas de discrétisation* $h=\frac{1}{100}$.



$x_0 = 15$. *Le nombre d'oscillations croît avec* x_0.

FIG. 18 (*continued*).

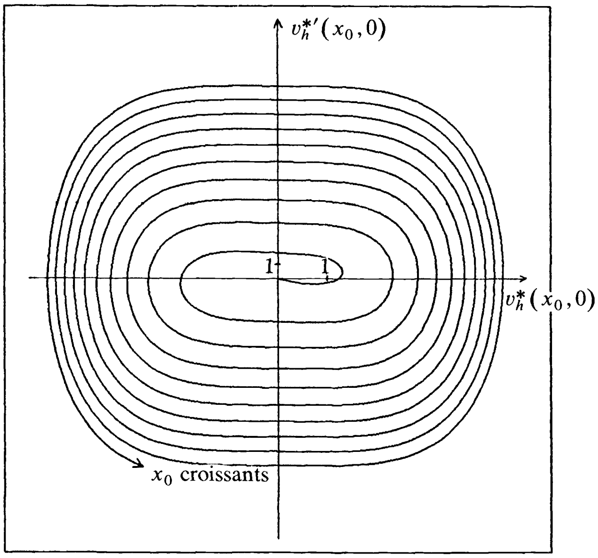


FIG. 19. *Représentation de l'approximation* $\mathcal{S}_h$ *de* $\mathcal{S}$.

Tant que x_0 reste petit, v_h^* est décroissante sur $[0, x_0]$. Pour une valeur de x_0 proche de 1, il apparaît une oscillation. Puis, lorsque x_0 grandit, le nombre d'oscillations de $v_h^*(x_0; \cdot)$ sur $[0, x_0]$ grandit. Pour $x \geqq x_0$, $v_h^*(x_0; \cdot)$ est décroissante et tend vers zéro de plus en plus rapidement lorsque x_0 croit. Tout ceci correspond bien aux résultats démontrés précédemment.

Nous représentons ci-dessous l'image par l'application σ_h du segment $[0, 20]$.

$$\mathcal{S}_h = \left\{ \left(v_h^*(x_0; 0), \frac{dv_h^*}{dx}(x_0; 0) \right); \; x_0 \in [0, 20] \right\};$$

$\sigma_h(x_0)$ a été calculé pour des valeurs de x_0 variant de 0 à 20 par pas de $\frac{1}{100}$ (voir figure 19).

La fonction $|s_h(x_0)|$ croît: $\mathscr{S}_h$ est une spirale qui se déroule;celà est du au fait que lorsque x_0 est grand, $v_h^*(x_0;\ \cdot)$ oscille de plus en plus sur $[0, x_0]$.

Nous n'avons pas d'estimation d'erreur sur $\mathscr{S}_h$, mais nous avons fait le calcul numérique pour différentes valeurs du pas de discrétisation: $h = \frac{1}{100}$, $h = \frac{1}{500}$, $h = \frac{1}{1000}$: les courbes sont strictement superposables: $\mathscr{S}_h$ semble donc constituer, pour x_0 variant entre 0 *et* 20, *une bonne approximation de $\mathscr{S}$.*

Par ailleurs nous n'avons pas pu établir le comportement asymptotique de $\mathscr{S}(x_0)$: la nécessité de prendre un pas de plus en plus petit augmente notablement le volume des calculs et en limite le fiabilité: nous ne savons donc pas s'il existe un cycle limite ou si, au contraire, $|\mathscr{s}_h(x_0)|$ tend vers l'infini avec x_0.

Revenons maintenant au nombre de solutions du problème $\mathscr{Q}_{\alpha,p}$. Il est donné, rappelons le, par le nombre d'éléments (v_0, v_0') dans l'intersection de $\mathscr{S}$ et $E_{\alpha,p}$. Dans la mesure où $\mathscr{S}_h$ est une approximation de $\mathscr{S}$, il est donné par le nombre d'éléments dans $\mathscr{S}_h \cap E_{\alpha,p}$. Nous avons représenté ci-dessous $\mathscr{S}_h$ et les ellipses $E_{\alpha,p}$ pour des valeurs du paramètre $\alpha^2 p$ croissant entre 1 et 5 (voir figure 20).

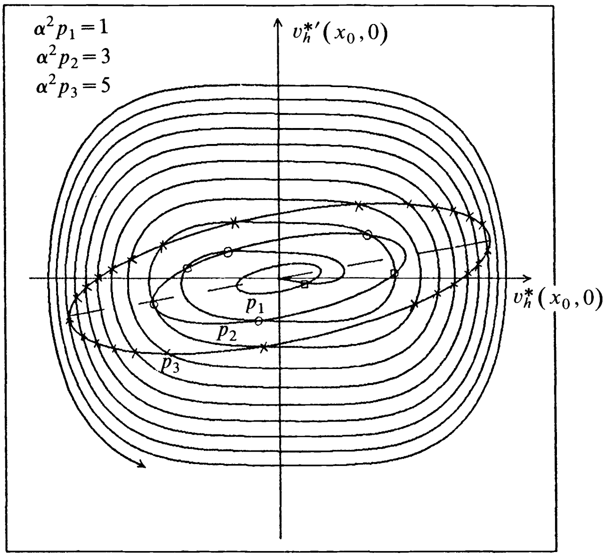

FIG. 20. *Représentation de $\mathscr{S}_h \cap E_{\alpha,p}$ pour $\alpha^2 p = 1, 3, 5$.*

Lorsque $\alpha^2 p$ varie, il y a toujours au moins un élément dans $\mathscr{S}_h \cap E_{\alpha,p}$. Plus $\alpha^2 p$ est grand, plus il y a d'éléments dans l'intersection. Par contre nous ne savons pas s'il existe une valeur limite de $\alpha^2 p$ au-dessus de laquelle $\mathscr{S}_h \cap E_{\alpha,p}$ contient une infinité d'éléments.

Rappelons que nous avons pris toutes les précautions pour que $\mathscr{S}_h$ soit une "bonne" approximation de $\mathscr{S}$. Dans cette mesure, il semble que:

Le problème $\mathscr{Q}_{\alpha,p}$ admet toujours au moins une solution. Lorsque $p\alpha^2$ grandit, le nombre des solutions croit comme le montre la figure 14. *L'ensemble des solutions peut être paramétré par $\{x_i\}_{i=1,I}$ et plus x_i est grand, plus la solution associée oscille.*

SHOCK LAYERS IN PERTURBED SYSTEMS RELATED TO STEADY CONSERVATION LAWS*

F. A. HOWES†

Abstract. Singular perturbation techniques are used to determine the locations of shock layers in steady solutions of a hyperbolic system to which viscosity terms have been added.

Key words. shock layer, jump condition, singular perturbation analysis

AMS(MOS) subject classifications. Primary 34B15, 34D15, 34E15

1. Introduction.

As a prelude to a study of the existence, asymptotic behavior and stability of solutions of initial-boundary value problems for the weakly coupled system

$$\text{(IBVP)}\qquad \underset{\sim}{u}_t+\mathrm{diag}\{f_1(\underset{\sim}{u}),\cdots,f_n(\underset{\sim}{u})\}\underset{\sim}{u}_x=\varepsilon\underset{\sim}{u}_{xx},$$

we consider the associated steady boundary value problem

$$\text{(BVP)}\qquad \begin{aligned}&\varepsilon\underset{\sim}{u}_{xx}=\mathrm{diag}\{f_1(\underset{\sim}{u}),\cdots,f_n(\underset{\sim}{u})\}\underset{\sim}{u}_x, \qquad a<x<b,\\ &\underset{\sim}{u}(a,\varepsilon)=\underset{\sim}{A}, \qquad \underset{\sim}{u}(b,\varepsilon)=\underset{\sim}{B},\end{aligned}$$

as the positive perturbation parameter ε tends to zero. The steady problem is of course much simpler than the time-dependent one, and so it is a natural starting point for the investigation of the structure of solutions of (IBVP), some of which evolve as $t\to\infty$ into solutions of (BVP). Despite its relative simplicity, though, (BVP) has solutions with interesting features, including boundary layers and interior (shock) layers. Shock layers connect different constant equilibrium states, and in a multicomponent system like (BVP), the location of such a layer in one component usually depends on the occurrence or nonoccurrence of interior layers in the other components. Thus the theory for (BVP) is inherently more complicated than the well-known theory for its scalar counterparts $(S_1)\,\varepsilon u_{xx}=f(u)u_x$ or $(S_2)\,\varepsilon u_{xx}=f(x,u)u_x+g(x,u)$.

Before turning to our treatment of (BVP), let us review briefly some of the previous work on (BVP) and (IBVP). The scalar theory for (S_1) and (S_2) is now fairly well in hand; see, for example, [16, Chap. 5], [9, Chap. 2] and [4]. Using some of these results, O'Malley [17], [18], O'Donnell [13], [15] and the author [6], [7] have studied the Dirichlet problem for the more general steady system $\varepsilon\underset{\sim}{u}_{xx}=F(x,\underset{\sim}{u})\underset{\sim}{u}_x+\underset{\sim}{g}(x,\underset{\sim}{u})$, where either $F(x,\underset{\sim}{u})=\mathrm{diag}\{f_1(x,\underset{\sim}{u}),\cdots,f_n(x,\underset{\sim}{u})\}$ or F is an arbitrary $(n\times n)$-matrix-valued function. In the present treatment of (BVP) we make extensive use of many of O'Donnell's ideas, and we generalize his results on the occurrence of shock layers by allowing shocks in different components at the same point. Turning to the time-dependent problem (IBVP), we note that the scalar version has been studied by a number of authors; cf. for example [9, Chap. 4], [20, Part I], [3] and [8] and the references contained therein. Less is known about the general problem (IBVP), but some representative results can be found in [10], [19, Part III], [11] and [6].

2. The componentwise theory. The work of O'Donnell [14], [15] (cf. also [1, Chap. 7]) is concerned, in part, with the Dirichlet problem on (a,b)

$$\text{(DP)}\qquad \begin{gathered} \varepsilon u_i''=f_i(x,u_1,\cdots,u_n)u_i'+g_i(x,u_1,\cdots,u_n),\\ u_i(a,\varepsilon)=A_i,\qquad u_i(b,\varepsilon)=B_i \end{gathered}$$

where $'=d/dx$ and $i=1,\cdots,n$. Under the principal assumption that the reduced system $f_i(x,\underset{\sim}{u})u_i'+g_i(x,\underset{\sim}{u})=0$ has solutions $u_i=U_i(x)$ that satisfy this system in the strong sense that

$$f_i(x,u_1,\cdots,U_i(x),\cdots,u_n)U_i'(x)+g_i(x,u_1,\cdots,U_i(x),\cdots,u_n)=0 \tag{2.1}$$

for all values of u_j $(j\neq i)$ in some domain of interest, he is able to prove the existence of solutions of (DP) as $\varepsilon\to 0$ which are close to certain reduced solutions $\underset{\sim}{U}$ in most of $[a,b]$. In neighborhoods of the boundaries and/or interior points, however, such reduced solutions often must be supplemented with layer terms that allow either a boundary condition to be satisfied (boundary layer term) or a smooth transition from one reduced solution to another to take place (shock layer term).

To be more precise, let us look first for solutions of (DP) that exhibit boundary layer behavior at $x=a$; analogous results for boundary layer behavior at $x=b$ then follow by making the change of variable $x\to b+a-x$. We begin with the assumption that the reduced problem

$$f_i(x,\underset{\sim}{u})u_i'+g_i(x,\underset{\sim}{u})=0,\qquad u_i(b)=B_i,$$

has a solution $\underset{\sim}{U}=(U_1(x),\cdots,U_n(x))$ of class $C^{(2)}([a,b])$, and we define the regions for $i=1,\cdots,n$

$$\mathscr{D}_i=\{u_i\colon |u_i-U_i(x)|\leqq d_i(x)\},$$

where each d_i is a smooth positive function such that $d_i(x)\equiv|A_i-U_i(a)|+\delta$ for x in $[a,a+\delta/2]$ and $d_i(x)\equiv\delta$ for x in $[a+\delta,b]$, with δ a small positive constant. Each of the regions $\mathscr{D}_i$ is thus a δ-tube around $U_i(x)$ that widens near $x=a$ to include a boundary layer of size $|A_i-U_i(a)|+\delta$, since, in general, $U_i(a)\neq A_i$. It is within the region $\mathscr{D}=\prod_{i=1}^n\mathscr{D}_i$ that we look for a solution of (DP) by imposing further conditions on $f_i(x,\underset{\sim}{u})$ in $[a,b]\times\mathscr{D}$. The second assumption is that $\underset{\sim}{U}$ additionally satisfies the reduced system in the stronger sense that (2.1) obtains for all u_j $(j\neq i)$ in $\mathscr{D}_j$. This assumption allows us to decouple the system, and thereby apply the extensive scalar theory to the problem (DP) componentwise. Finally we require $\underset{\sim}{U}$ to be attractive in the sense that there exist positive constants k_i such that for x in $[a,b]$

$$f_i(x,u_1,\cdots,U_i(x),\cdots,u_n)\leqq -k_i<0$$

for all u_j $(j\neq i)$ in $\mathscr{D}_j$. In particular, we must have $f_i(x,\underset{\sim}{U}(x))\leqq -k_i<0$ in $[a,b]$, and so these inequalities imply that $\underset{\sim}{U}$ is necessarily asymptotically stable in the linear approximation. To see this, note that the perturbation $w_i=u_i-U_i$ satisfies approximately the equation $\varepsilon w_i''=f_i(x,\underset{\sim}{U}+\underset{\sim}{w})w_i'$ and the terminal condition $w_i(b,\varepsilon)=0$, since U_i is a solution of the reduced problem; hence, $w_i(x,\varepsilon)=\mathcal{O}(|A_i-U_i(a)|\exp[-k_i(x-a)/\varepsilon])$ for x in $[a,b]$ as $\varepsilon\to 0$. Then under these assumptions it follows from a continuity argument that the problem (DP) has a solution $\underset{\sim}{u}=(u_1,\cdots,u_n)(x,\varepsilon)$ as $\varepsilon\to 0$ which is close to $(U_1(x),\cdots,U_n(x))$ in $[a+\delta,b]$, provided the "boundary layer jumps" $|A_i-U_i(a)|$ are sufficiently small. Estimates for the maximum allowable sizes of these jumps are given by O'Donnell [13] (cf. also [1, Chap. 7]) in the form of the integral conditions: if $U_i(a) \neq A_i$ then

$$(2.2) \qquad (U_i(a)-A_i)\int_{U_i(a)}^{\xi} f_i(a,A_1,\cdots,A_{i-1},s,A_{i+1},\cdots,A_n)\,ds>0$$

for all values of ξ between $U_i(a)$ and A_i, $\xi \neq U_i(a)$. Such conditions generalize the well-known integral condition of Coddington and Levinson [2] (cf. also [4]) for the scalar equation (S_2), and they are the starting point for our investigation in §4 of shock layers in solutions of (BVP). The usefulness of (2.2) is easily seen by examining a scalar problem like $\varepsilon u''=-uu'+u$, $u(0,\varepsilon)=A$, $u(1,\varepsilon)=B$; cf. [4], [9, Chap. 2]. Suppose that $B>1$. Then $U(x)=x+B-1$ is the solution of the reduced problem $uu'=u$, $u(1)=B$, and it is attractive in the sense that $f(U(x)) \leqq -(B-1)<0$ in $[0,1]$ for $f(u)=-u$. Now if $A>0$ then $f(u)<0$ for all values of u between A and $B-1$, and so we know that the solution of this problem has a boundary layer at $x=0$, that is, $(*)\lim_{\varepsilon\to 0}u(x,\varepsilon)=x+B-1$ in $[\delta,1]$. On the other hand, if $A\leqq 0$ then this inequality on f does not obtain for all such values of u, and we might be tempted to conclude that $(*)$ does not obtain. However, we see that $(*)$ *is* valid provided $A>-(B-1)$, since condition (2.2) is satisfied with this restriction on $A\leqq 0$. Thus it is the "integrated" effect of f in the boundary layer, as measured by (2.2), that determines if there is a boundary layer relative to the attractive reduced solution U. The n conditions in (2.2) are an extension of this basic fact to the system (DP).

Let us illustrate O'Donnell's approach by considering next solutions of (DP) in which there is a shock layer in just the kth component. Our basic assumption is that the reduced system has two $C^{(2)}$-solutions $\underset{\sim}{u}_L=(U_1(x),\cdots,U_{k-1}(x),\ U_L(x),\ U_{k+1}(x),\cdots,U_n(x))$ and $\underset{\sim}{u}_R=(U_1(x),\cdots,U_{k-1}(x),\ U_R(x),\ U_{k+1}(x),\cdots,U_n(x))$ which exist in $[a,b]$ and satisfy $U_i(a)=A_i$ and $U_i(b)=B_i$ for $i\neq k$, $U_L<U_R$, $U_L(a)=A_k$ and $U_R(b)=B_k$. In addition, we assume that $\underset{\sim}{u}_L$ and $\underset{\sim}{u}_R$ satisfy the reduced system in the stronger sense that for $i\neq k$ (2.1) obtains in (a,b) for all values of u_j $(j\neq i)$ in $\tilde{\mathscr{D}}_j$. (Here $\tilde{\mathscr{D}}_i=\{u_i\colon |u_i-U_i(x)|\leqq\delta\}$ for $i\neq k$ and $\tilde{\mathscr{D}}_k=\{u_k\colon U_L(x)-\delta\leqq u_k\leqq U_R(x)+\delta\}$.) For $i=k$ we assume that in (a,b)

$$f_k(x,u_1,\cdots,v,\cdots,u_n)v'+g_k(x,u_1,\cdots,v,\cdots,u_n)=0$$

for $v=U_L$ or U_R and for all values of u_j $(j\neq k)$ in $\tilde{\mathscr{D}}_j$. We can guarantee that these solutions are attractive by assuming also that, for $i\neq k$,

$$|f_i(x,u_1,\cdots,U_i(x),\cdots,u_n)|>0,$$

and that there exists a positive constant K for which

$$f_k(x,u_1,\cdots,U_L(x),\cdots,u_n)\geqq K>0, \qquad f_k(x,u_1,\cdots,U_R(x),\cdots,u_n)\leqq -K<0$$

in the regions defined above. Then the theory [13], [6] implies that (DP) has a solution $\underset{\sim}{u}=\underset{\sim}{u}(x,\varepsilon)$ as $\varepsilon\to 0$ such that for $i\neq k$

$$\lim_{\varepsilon\to 0}u_i(x,\varepsilon)=U_i(x) \quad \text{in } [a,b]$$

and

$$\lim_{\varepsilon\to 0}u_k(x,\varepsilon)=\begin{cases} U_L(x) & \text{in } [a,x_0-\delta],\\ U_R(x) & \text{in } [x_0+\delta,b],\end{cases}$$

provided the "shock strength" $|U_L(x_0)-U_R(x_0)|$ is sufficiently small. The location x_0 of the shock layer is determined as a solution $x=x_0$ of the functional equation

$$J[x]=\int_{U_L(x)}^{U_R(x)} f_k(x,U_1(x),\cdots,U_{k-1}(x),s,U_{k+1}(x),\cdots,U_n(x))\,ds=0$$

which also satisfies $J'[x_0]\neq 0$. This result can be extended in an obvious way to cases in which there are shock layers in different components of the solution at distinct points. The example $\varepsilon u''=-uu'+u$, $u(0,\varepsilon)=A$, $u(1,\varepsilon)=B$, again provides us with a good illustration of this result; cf. [4], [9, Chap. 2]. We saw above that if $B>1$ then the function $U_R(x)=x+B-1$ is the solution of the reduced problem $uu'=u$, $u(1)=B$, which satisfies $f(U_R(x))<0$ in $[0,1]$ for $f(u)=-u$. Similarly, if $A<-1$ then the function $U_L(x)=x+A$ is the solution of the left-hand reduced problem $uu'=u$, $u(0)=A$, and by virtue of the restriction on A, $f(U_L(x))>0$ in $[0,1]$. Now if $A<-(B-1)$ then the integral condition (2.2) does not obtain, and if $B>-(A+1)$ then the integral condition corresponding to (2.2) at $x=1$ also does not obtain. Thus if $A<-1$, $B>1$ and $|A+B|<1$ then boundary layer behavior relative to U_L or U_R is impossible; however, for these values of A and B,

$$(\dagger)\qquad J[x]=\int_{x+A}^{x+B-1}(-s)\,ds=0 \quad \text{at } x=x_0=(1-B-A)/2$$

in $(0,1)$ and $J'[x_0]\neq 0$. The solution of the example is therefore a shock layer joining $U_L(x)$ and $U_R(x)$ at the point x_0. This should come as no surprise since the relation $(\dagger)$, that is, $U_L^2(x_0)=U_R^2(x_0)$ or $U_L(x_0)+U_R(x_0)=0$, is nothing more than the Rankine-Hugoniot condition for a stationary shock wave at x_0; cf. [10, §2], [20, Chap. 2].

O'Donnell's shock layer theory does not apply to an autonomous problem like (BVP) since attractive reduced solutions are constants, and the functional J is thereby independent of x. In addition, his theory for (DP) is unable to describe what happens when there is a shock layer in two or more components at the *same* point, because this is no longer a scalar phenomenon. It turns out that we can now provide a shock layer theory for (BVP) which complements O'Donnell's boundary layer theory and which covers the occurrence of a shock layer in several components at the same point. Before doing so we review briefly the scalar theory for (S_1).

3. Shock layer theory for (S_1). The occurrence of shock layers in solutions of the scalar boundary value problem

$$(\mathrm{S}_1)\qquad \begin{aligned} &\varepsilon u''=f(u)u', \qquad 0<x<1,\\ &u(0,\varepsilon)=A, \quad u(1,\varepsilon)=B, \quad A<B, \end{aligned}$$

has been considered in [5] and [12]. (In this and the following sections we replace, without loss of generality, the finite interval $[a,b]$ with $[0,1]$, so as to simplify some of our formulas.) Let us recall briefly the results in [5].

Suppose that the function f is continuous for all u in $[A,B]$ and that the states $U_L\equiv A$ and $U_R\equiv B$ are such that $f(A)>0$ and $f(B)<0$. Then if $F(A)<F(B)$ $[F(A)>F(B)]$, for F an antiderivative of f, there is a boundary layer at $x=1$ $[x=0]$, that is, the solution $u=u(x,\varepsilon)$ of (S_1) satisfies $\lim_{\varepsilon\to 0}u(x,\varepsilon)=A$, $0\leqq x\leqq 1-\delta$ $[\lim_{\varepsilon\to 0}u(x,\varepsilon)=B$, $\delta\leqq x\leqq 1]$ $(0<\delta<1)$. This follows by virtue of the corresponding integral conditions (2.2), expressed now in terms of F. Consequently, if $F(A)=F(B)$ (the Rankine-Hugoniot relation) boundary layer behavior is impossible, and there must be a shock layer in (0, 1) joining A and B; indeed, the solution (S_1) satisfies

$$\lim_{\varepsilon\to 0} u(x,\varepsilon)=\begin{cases} A, & 0\leqq x\leqq x_0-\delta, \\ B, & x_0+\delta\leqq x\leqq 1, \end{cases} \tag{3.1}$$

where $x_0=f(B)/(f(B)-f(A))$ (in (0,1)) is the location of the shock layer. To see this, note that such a solution satisfies $u'(x)>0$ in $[0,1]$, since $u'(x)=(\text{const})\exp[\int^x f(u(s))\,ds]$. Thus (S_1) can be rewritten as $\varepsilon u''/u'=f(u)$, that is, $\varepsilon[\ln u']'=f(u)$. Integrating this equation from $x=0$ to $x=x_0$, and from $x=x_0$ to $x=1$, we obtain the two equations

$$\varepsilon\left[\ln u'(x_0)-\ln u'(0)\right]=\int_0^{x_0} f(u(s))\,ds, \tag{3.2}$$

$$\varepsilon\left[\ln u'(1)-\ln u'(x_0)\right]=\int_{x_0}^{1} f(u(s))\,ds. \tag{3.3}$$

Since $F(A)=F(B)$ it follows by integrating both sides of (S_1) from $x=0$ to $x=1$ and using the boundary conditions that $u'(0)=u'(1)$. Thus, adding (3.2) and (3.3) together, we have that

$$\int_0^{x_0} f(u(s))\,ds+\int_{x_0}^{1} f(u(s))\,ds=0. \tag{3.4}$$

By virtue of (3.1) $u\to A$ on $(0,x_0)$ and $u\to B$ on $(x_0,1)$ as $\varepsilon\to 0$, and so by the continuity of f and the Dominated Convergence Theorem, it follows from (3.4) that $f(A)x_0+f(B)(1-x_0)=0$, that is, $x_0=f(B)/(f(B)-f(A))$.

Simple arguments such as these allow us to study the occurrence of shock layers in the more general problem (BVP), to which we now turn.

4. Shock layer theory for (BVP). Let us consider finally the occurrence of shock layers in solutions of the problem

$$\begin{aligned} &\varepsilon u_i''=f_i(u_1,\cdots,u_n)u_i', && 0<x<1, \\ &u_i(0,\varepsilon)=A_i,\ u_i(1,\varepsilon)=B_i, && A_i<B_i, \end{aligned} \tag{BVP}$$

where the functions f_i are continuous for all $(u_1,\cdots,u_n)$ in $\Pi_{i=1}^n[A_i,B_i]$. Then (BVP) has a solution $\underset{\sim}{u}=(u_1,\cdots,u_n)$ of class $C^{(2)}([0,1])$ for each $\varepsilon>0$ that satisfies $A_i\leqq u_i(x,\varepsilon)\leqq B_i$ and $u_i'(x,\varepsilon)>0$ in $[0,1]$ for $i=1,\cdots,n$, since $\Pi_{i=1}^n[A_i,B_i]$ is an invariant region (cf. [19, Chap. 14]) and $u_x'=(\text{const})\exp[\int^x f_i(u_1(s),\cdots,u_n(s))\,ds]$.

In order to discuss our results in the simplest setting possible, we examine first the two-dimensional system

$$\begin{aligned} &\varepsilon u_1''=f_1(u_1,u_2)u_1', && u_1(0,\varepsilon)=A_1, && u_1(1,\varepsilon)=B_1, \\ &\varepsilon u_2''=f_2(u_1,u_2)u_2', && u_2(0,\varepsilon)=A_2, && u_2(1,\varepsilon)=B_2. \end{aligned} \tag{P}$$

The theory of §2 tells us, for instance, that if B_1, B_2 are such that

$$\begin{aligned} &f_1(B_1,\mu)<0 && \text{for all } \mu \text{ in } [A_2,B_2], \\ &f_2(\lambda,B_2)<0 && \text{for all } \lambda \text{ in } [A_1,B_1], \end{aligned} \tag{4.1}$$

then there is a solution of (P) as $\varepsilon \to 0$ with boundary layers (in both components) at $x=0$, provided

$$\begin{aligned} &\int_{B_1}^{\xi} f_1(s,A_2)\,ds>0 \quad \text{for } \xi \text{ in } [A_1,B_1), \\ &\int_{B_2}^{\eta} f_2(A_1,s)\,ds>0 \quad \text{for } \eta \text{ in } [A_2,B_2). \end{aligned} \tag{4.2}$$

In other words, we have that

$$\lim_{\varepsilon\to 0}(u_1(x,\varepsilon),u_2(x,\varepsilon))=(B_1,B_2) \quad \text{in } [\delta,1].$$

Similarly, if A_1, A_2 are such that

$$f_1(A_1,\mu)>0 \quad \text{and} \quad f_2(\lambda,A_2)>0 \tag{4.3}$$

for the ranges of λ and μ in (4.1), and

$$\begin{aligned} &\int_{A_1}^{\xi} f_1(s,B_2)\,ds>0 \quad \text{for } \xi \text{ in } (A_1,B_1], \\ &\int_{A_2}^{\eta} f_2(B_1,s)\,ds>0 \quad \text{for } \eta \text{ in } (A_2,B_2], \end{aligned} \tag{4.4}$$

then there is a solution of (P) as $\varepsilon\to 0$ with boundary layers (in both components) at $x=1$. In other words, we have that

$$\lim_{\varepsilon\to 0}(u_1(x,\varepsilon),u_2(x,\varepsilon))=(A_1,A_2) \quad \text{in } [0,1-\delta].$$

Finally under the appropriate combination of the integral inequalities there are solutions of (P) as $\varepsilon\to 0$ with a boundary layer at $x=0$ in one component and a boundary layer at $x=1$ in the other.

Suppose now that we look for a solution of (P) whose ith component has only a shock layer at x_i in (0,1), that is,

$$\lim_{\varepsilon\to 0} u_i(x,\varepsilon)=\begin{cases} A_i, & 0\leqq x\leqq x-\delta, \\ B_i, & x_i+\delta\leqq x\leqq 1. \end{cases} \tag{4.5}$$

Our basic result is contained in the following

THEOREM 1. *Assume that the reduced solutions* $\underset{\sim}{U}_L=(A_1,A_2)$ *and* $\underset{\sim}{U}_R=(B_1,B_2)$ *are attractive in the sense that the inequalities* (4.1) *and* (4.3) *obtain for the stated values of* λ *and* μ. *Assume also that*

$$F_1(B_1,A_2)\geqq F_1(A_1,A_2)$$

and

$$F_1(B_1,B_2)\leqq F_1(A_1,B_2),$$

where $F_1(\cdot,A_2$ *or* $B_2)$ *is an antiderivative of* $f_1(\cdot,A_2$ *or* $B_2)$ *and that*

$$F_2(A_1,B_2)\geqq F_2(A_1,A_2)$$

and

$$F_2(B_1,B_2)\leqq F_2(B_1,A_2),$$

where $F_2(A_1$ *or* $B_1,\cdot)$ *is an antiderivative of* $f_2(A_1$ *or* $B_1,\cdot)$*. Then for these boundary values there is a solution* (u_1,u_2) *of* (P) *as* $\varepsilon\to 0$ *whose ith component satisfies the limiting relation* (4.5).

Proof. For this choice of boundary values we know that there is a solution $\underset{\sim}{u}$ of (P) as a consequence of the fact that the rectangle $[A_1,B_1]\times[A_2,B_2]$ is invariant with respect to (P); cf. [19, Chap. 14]. However boundary layer behavior is impossible, since none of the boundary layer inequalities in (4.2) and (4.4) obtains by virtue of the inequalities involving F_1 and F_2. Consequently each component u_i of $\underset{\sim}{u}$ has a shock layer at x_i in $(0,1)$.

It remains for us to determine the locations x_i. We begin by noting that $\varepsilon\{\ln u_i'(1)-\ln u_i'(0)\}\to 0$ as $\varepsilon\to 0$, since $\underset{\sim}{U}_L$ *and* $\underset{\sim}{U}_R$ are constant vectors that satisfy the system (P) in $(0,1)$ and the boundary conditions at $x=0$ and $x=1$, respectively. Suppose, for definiteness, that $x_1\leqq x_2$. Then by arguing as in §3 we see that for $i=1,2$

$$\begin{aligned}(4.6)\qquad 0&\sim\int_0^1 f_i(u_1(s),u_2(s))\,ds\\ &\sim\int_0^{x_1} f_i(A_1,A_2)\,ds+\int_{x_1}^{x_2} f_i(B_1,A_2)\,ds+\int_{x_2}^1 f_i(B_1,B_2)\,dds\\ &=f_i(A_1,A_2)x_1+f_i(B_1,A_2)(x_2-x_1)+f_i(B_1,B_2)(1-x_2).\end{aligned}$$

Suppose we consider first the case when $x_1=x_2=x_0$, that is, both components have a shock layer at the same point. Then (4.6) implies that for $i=1,2$

$$[-f_i(A_1,A_2)+f_i(B_1,B_2)]x_0=f_i(B_1,B_2);$$

whence,

$$\begin{aligned}x_0&=f_1(B_1,B_2)/(f_1(B_1,B_2)-f_1(A_1,A_2))\\ &=f_2(B_1,B_2)/(f_2(B_1,B_2)-f_2(A_1,A_2)),\end{aligned}$$

provided that

$$f_1(A_1,A_2)f_2(B_1,B_2)=f_1(B_1,B_2)f_2(A_1,A_2).$$

The point x_0 lies in $(0,1)$ by virtue of the inequalities (4.1) and (4.3). Thus for such boundary values the problem (P) has a solution as $\varepsilon\to 0$ satisfying the limiting relation (4.5) with $x_1=x_2=x_0$.

Suppose that we consider next the case when there is a shock layer in u_1 at x_1 and a shock layer in u_2 at x_2 for $x_1<x_2$. The points x_1, x_2 are solutions of the linear system (cf. (4.6))

$$(4.7)\qquad [f_i(B_1,A_2)-f_i(A_1,A_2)]x_1+[f_i(B_1,B_2)-f_i(B_1,A_2)]x_2=f_i(B_1,B_2).$$

It follows that if

$$(4.8)\qquad f_1(A_1,A_2)f_2(B_1,B_2)<f_1(B_1,B_2)f_2(A_1,A_2)$$

the determinant of the coefficient matrix of (4.7) is positive by virtue of the inequalities (4.1) and (4.3). Thus (4.7) can be solved uniquely for x_1, x_2, and these values satisfy $0<x_1<x_2<1$. Indeed we have

$$x_1=\Delta^{-1}\det\begin{pmatrix}f_1(B_1,B_2) & f_1(B_1,B_2)-f_1(B_1,A_2)\\ f_2(B_1,B_2) & f_2(B_1,B_2)-f_2(B_1,A_2)\end{pmatrix}$$

and

$$x_2=\Delta^{-1}\det\begin{pmatrix} f_1(B_1,A_2)-f_1(A_1,A_2) & f_1(B_1,B_2) \\ f_2(B_1,A_2)-f_2(A_1,A_2) & f_2(B_1,B_2) \end{pmatrix}$$

for

$$\Delta=[f_1(B_1,A_2)-f_1(A_1,A_2)][f_2(B_1,B_2)-f_2(B_1,A_2)] \\ -[f_1(B_1,B_2)-f_1(B_1,A_2)][f_2(B_1,A_2)-f_2(A_1,A_2)]>0.$$

The remaining case when $x_2<x_1$ can be handled without difficulty, as well as the cases $A_i>B_i$, $i=1,2$, or $A_1>B_1$, $A_2<B_2$ or $A_1<B_1$, $A_2>B_2$ in (P). We turn finally to the general problem $(1\leqq i\leqq n)$

$$\text{(BVP)} \qquad \begin{gathered} \varepsilon u_i''=f_i(u_1,\cdots,u_n)u_i', \qquad 0<x<1, \\ u_i(0,\varepsilon)=A_i, \quad u_i(1,\varepsilon)=B_i, \quad A_i<B_i. \end{gathered}$$

The basic result for (BVP) is contained in the following theorem. It follows by noting that each of the corresponding boundary layer inequalities (cf. (2.2)) is violated and then proceeding as in the proof of Theorem 1.

THEOREM 2. *Assume that* $\underset{\sim}{U}_L=\underset{\sim}{A}=(A_1,\cdots,A_n)$ *and* $\underset{\sim}{U}_R=\underset{\sim}{B}=(B_1,\cdots,B_n)$ *are attractive in the sense that (cf.* §2) *for* $i=1,\cdots,n$

$$f_i(u_1,\cdots,A_i,\cdots,u_n)>0 \quad \textit{and} \quad f_i(u_1,\cdots,B_i,\cdots,u_n)<0$$

for all values of u_j *in* $[A_j,B_j]$ $(j\neq i)$. *Assume also that for* $i=1,\cdots,n$

$$F_i(A_1,\cdots,A_{i-1},A_i,A_{i+1},\cdots,A_n)\leqq F_i(A_1,\cdots,A_{i-1},B_i,A_{i+1},\cdots,A_n)$$

and

$$F_i(B_1,\cdots,B_{i-1},A_i,B_{i+1},\cdots,B_n)\geqq F_i(B_1,\cdots,B_{i-1},B_i,B_{i+1},\cdots,B_n),$$

where $F_i(A_1$ *or* $B_1,\cdots,A_{i-1}$ *or* $B_{i-1},\cdot,A_{i+1}$ *or* $B_{i+1},\cdots,A_n$ *or* $B_n)$ *is an antiderivative of* $f_i(A_1$ *or* $B_1,\cdots,A_{i-1}$ *or* $B_{i-1},\cdot,A_{i+1}$ *or* $B_{i+1},\cdots,A_n$ *or* $B_n)$. *Then there is a solution of* (BVP) *as* $\varepsilon\to 0$ *having a shock layer in each component.*

The simplest situation occurs when each shock layer is located at the same point x_0 in $(0,1)$. By proceeding as before, we see that for $i=1,\cdots,n$

$$0\sim\int_0^1 f_i(\underset{\sim}{u}(s))\,ds\sim\int_0^{x_0} f_i(\underset{\sim}{A})\,ds+\int_{x_0}^1 f_i(\underset{\sim}{B})\,ds,$$

and so

$$x_0=f_i(\underset{\sim}{B})/(f_i(\underset{\sim}{B})-f_i(\underset{\sim}{A})),$$

provided

$$\text{(4.9)} \qquad f_i(\underset{\sim}{B})/(f_i(\underset{\sim}{B})-f_i(\underset{\sim}{A}))=f_j(\underset{\sim}{B})/(f_j(\underset{\sim}{B})-f_j(\underset{\sim}{A}))$$

for all $i,j=1,\cdots,n$. The consistency conditions in (4.9) reduce to $\binom{n}{2}=n(n-1)/2$ equations. Thus it is usually the case that the components of a solution of (BVP) do not all have a shock layer at the same point, but rather different components have shock layers at different points. The locations x_i of the shocks are found as before by solving a linear system of n equations. Unfortunately the prohibitive number of algebraic manipulations prevents us from providing explicit conditions such as (4.8) for the general problem (BVP), although the analysis is straightforward and could be performed numerically.

5. Examples. In this final section we illustrate some of the theory developed above.

Example 1. Consider first the problem

$$\begin{aligned} &\varepsilon u_i''=-u_ig_i(u_1,\cdots,u_{i-1},u_{i+1},\cdots,u_n)u_i', \qquad 0<x<1,\\ &u_i(0,\varepsilon)=A_i,\quad u_i(1,\varepsilon)=B_i,\quad A_i<0,\quad B_i>0, \end{aligned}\tag{E1}$$

where $g_i>0$ for all values of u_j in $[A_j,B_j]$ $(j\neq i)$. We anticipate that each component of the solution behaves very much like the solution of the scalar problem $\varepsilon y''=-yy'$, $y(0,\varepsilon)=A$, $y(1,\varepsilon)=B$ (cf. §3 or [16, Chap. 1] where the exact solution is given). In particular, if $A=-B<0$ then $f(A)>0$, $f(B)<0$ and $F(A)=F(B)$, for $f(y)=-y$ and $F(y)=-y^2/2$. Consequently there is a solution $y=y(x,\varepsilon)$ as $\varepsilon\to 0$ with a shock layer at $x_0=f(B)/(f(B)-f(A))=1/2$ joining $U_L=A(x<x_0)$ and $U_R=B$ $(x>x_0)$. For the problem (E1) we see that

$$f_i(u_1,\cdots,A_i,\cdots,u_n)>0 \quad\text{and}\quad f_i(u_1,\cdots,B_i,\cdots,u_n)<0\tag{5.1}$$

for all values of u_j in $[A_j,B_j]$, since $g_i>0$ there. If we assume that $A_i=-B_i<0$ for $i=1,\cdots,n$, then

$$\begin{aligned} F_i(A_1,\cdots,A_i,\cdots,A_n)&=F_i(A_1,\cdots,B_i,\cdots,A_n),\\ F_i(B_1,\cdots,A_i,\cdots,B_n)&=F_i(B_1,\cdots,B_i,\cdots,B_n), \end{aligned}\tag{5.2}$$

since $F_i(u_1,\cdots,u_{i-1},\gamma,u_{i+1},\cdots,u_n)=-(\gamma^2/2)g_i(u_1,\cdots,u_{i-1},u_{i+1},\cdots,u_n)$. Thus we know that (E1) has a solution with a shock layer in each component. It only remains to locate the position x_i of the ith shock. Suppose first that

$$g_i(A_1,\cdots,A_n)g_j(B_1,\cdots,B_n)=g_i(B_1,\cdots,B_n)g_j(A_1,\cdots,A_n)\tag{5.3}$$

for $i\neq j$. Then it follows that $(x_0=)$ $f_i(\underset{\sim}{B})/(f_i(\underset{\sim}{B})-f_i(\underset{\sim}{A}))=f_j(\underset{\sim}{B})/(f_j(\underset{\sim}{B})-f_j(\underset{\sim}{A}))$ for $i\neq j$, and so there is a shock layer in each component at $x=x_0$ in $(0,1)$ joining A_i $(x<x_0)$ and B_i $(x>x_0)$. However if the $\binom{n}{2}$ equalities in (5.3) do not obtain, then different components of the solution of (E1) have shock layers at different points in $(0,1)$. Rather than discuss this situation in its full generality, we turn to a much simpler special case.

Example 2. Consider then the two-dimensional problem on $(0,1)$

$$\begin{aligned} &\varepsilon u_1''=-u_1(1-u_2)u_1',\quad u_1(0,\varepsilon)=A_1,\quad u_1(1,\varepsilon)=B_1,\\ &\varepsilon u_2''=-u_2(1+u_1)u_2',\quad u_2(0,\varepsilon)=A_2,\quad u_2(1,\varepsilon)=B_2, \end{aligned}\tag{E2}$$

where $A_i=-B_i<0$ and $|A_i|<1$ for $i=1,2$. Under these restrictions on the boundary values the relations (5.1) and (5.2) certainly hold, but $g_1(\underset{\sim}{A})g_2(\underset{\sim}{B})=(1-A_2)(1+B_2)>(1-B_2)(1+A_1)=g_1(\underset{\sim}{B})g_2(\underset{\sim}{A})$, which implies that $f_1(\underset{\sim}{A})f_2(\underset{\sim}{B})<f_2(\underset{\sim}{A})f_1(\underset{\sim}{B})$. Consequently there is a solution (u_1,u_2) of (E2) as $\varepsilon\to 0$ such that u_1 $[u_2]$ has a shock layer at x_1 $[x_2]$ in $(0,1)$ with $x_1<x_2$. Proceeding as in §4 we find that $x_1=2B_1B_2(B_1+1)/\Delta$ and $x_2=2B_1B_2(2B_1+B_2+1)/\Delta$, for $\Delta=4B_1B_2(B_1+B_2+1)$, that is,

$$x_1=(B_1+1)/[2(B_1+B_2+1)]$$

and

$$x_2=(2B_1+B_2+1)/[2(B_1+B_2+1)].$$

SINGULAR PERTURBATIONS FOR NONLINEAR HYPERBOLIC-PARABOLIC PROBLEMS*

AHMED BENAOUDA[†] AND MONIQUE MADAUNE TORT[†]

Abstract. A boundary value problem for a semilinear hyperbolic equation with a small parameter ε and its reduced problem of parabolic type are considered. It is proved that the solution u_ε of the initial problem is approximated for $\varepsilon \to 0$ by the solution u of the reduced problem in Sobolev spaces. Estimates of the difference-norm are given in function of ε and are improved by using boundary layer correctors.

Key words. singular perturbations, semilinear hyperbolic equations, boundary value problems

AMS(MOS) subject classifications. Primary 35B25, 35L20

Introduction. We consider "hyperbolic-parabolic" singular perturbation problems for semi-linear equations of the type:

$$L_2^{(\varepsilon)}u_\varepsilon + L_1 u_\varepsilon + G u_\varepsilon = f, \qquad (t,x) \in]0,T[\times\Omega \tag{0.1}$$

where T is a real, $T > 0$, Ω is a bounded open set in $\mathbf{R}^n$, $\varepsilon > 0$,

$$L_2^{(\varepsilon)}u = \varepsilon\frac{\partial^2 u}{\partial t^2} - \Delta u, \tag{0.2}$$

$$L_1 u = a(t,x)\frac{\partial u}{\partial t} + \sum_{k=1}^{n} b_k(t,x)\frac{\partial u}{\partial x_k}, \tag{0.3}$$

G: $\mathbf{R} \to \mathbf{R}$ is a continuous function which satisfies a monotonicity condition and a growth limitation at ∞ (the precise hypotheses are given in §1). Two examples of such functions G are:

(i) G is a Lipschitzian function,

(ii) $Gu = |u|^\rho u$, $\rho > 0$.

The questions of singular perturbations of "hyperbolic-parabolic" type do not seem to have been much studied. However we may mention the works of Zlamal [20] (1960), Kisynski [4] (1963), Nazarkulova–Pankov [17] (1971), Lenjuk–Fedoruk [6] (1972), Muradov [15] (1978), Muradov–Gasanov [16] (1974), concerning linear problems to which we may add the study of nonlinear problems done in Muradov [14] (1974) and N. A. Lar'kin [5] (1980). In [14] Muradov considers an equation like (0.1) with $\Omega \subset \mathbf{R}$ where $\partial^2 u/\partial x^2$ and $\partial u/\partial x$ may have discontinuous coefficients, and in [5] N. A. Lar'kin studies a hyperbolic regularization of a one-sided problem for the Burgers equation in Sobolev spaces when $\Omega \subset \mathbf{R}$. Moreover two recent papers point out the interest of such problems which model oscillator phenomena in a highly viscous medium similarly to Prandtl's model for ordinary differential equation (Hsiao–Weinacht [2] (1979), [3] (1983)).

Hence the mathematical model:

$$P_\varepsilon \quad \begin{cases} \varepsilon^2 \dfrac{\partial^2 u_\varepsilon}{\partial t^2} - \dfrac{\partial^2 u_\varepsilon}{\partial x^2} + \dfrac{\partial u_\varepsilon}{\partial t} + G u_\varepsilon = 0, & (t,x) \in]0, +\infty[\times \mathbf{R}, \\ u_\varepsilon(0,x) = u_0(x), & \varepsilon \dfrac{\partial u}{\partial t}(0,x) = u_1(x). \end{cases}$$

The study of this problem is given in [3] when G belongs to $C^r(r \geq 8)$ and satisfies $G'(x) > 0$, $\forall x \in \mathbf{R}$. An asymptotic representation of u_ε is given with an explicit calculation of the boundary layer correctors which are computed to all order when the reduced problem has a bounded classical solution on $[0, T] \times \mathbf{R}$.

Here, we study the variational point of view under weak hypotheses when x belongs to an open set of $\mathbf{R}^n$, in order to obtain the convergence in Sovolev spaces of u_ε to u, the solution of a problem relative to the equation:

$$L_2^{(0)} u + L_1 u + G u = f.$$

This paper is an extension of a part of the work [1].

1. Notation–hypotheses. Ω is a bounded open set in $\mathbf{R}^n$, of class $\eta^{(1),1}$ (Nečas [18]), Γ is the boundary of Ω, T is a given real, $T > 0$. We set $Q =]0, T[\times \Omega$, $\Sigma = [0, T] \times \Gamma$. For each real p, $2 \leq p \leq +\infty$, we note $|\ |_p$ (resp. $\|\ \|_p$) the usual norm of $L^p(\Omega)$ (resp. $W^{1,p}(\Omega)$). We represent the inner product in $L^2(\Omega)$ by $(\cdot,\cdot)$; we keep the same notation for the duality between $H^{-1}(\Omega)$, $H_0^1(\Omega)$ and $L^p(\Omega)$, $L^{p'}(\Omega)(1/p + 1/p' = 1)$. $(u, v) \mapsto \alpha(u, v)$ is the bilinear form defined by

$$\alpha(u,v) = \int_\Omega \vec{\nabla} u, \vec{\nabla} v \, dx.$$

The derivatives of u in the sense of vector-valued distributions on $]0, T[$ are represented by u', u'', $\cdots$.

We recall the hyperbolic problem that we consider:

$$P_\varepsilon \quad \begin{cases} L_2^{(\varepsilon)} u_\varepsilon + L_1 u_\varepsilon + G u_\varepsilon = f, & (t,x) \in Q, \\ u_\varepsilon(0,x) = u_0(x), \quad u_\varepsilon'(0,x) = u_1(x), & x \in \Omega, \\ u_\varepsilon|_\Sigma = 0. \end{cases}$$

We are going to study the behavior of u_ε when $\varepsilon \to 0_+$ ($L_2^{(\varepsilon)}$ and L_1 are respectively defined by (0.2) and (0.3)). This work is undertaken when the following hypothesis is satisfied:

$H_{1.1}$ (i) $u_0 \in H_0^1(\Omega)$, $u_1 \in L^2(\Omega)$, $f \in L^2(Q)$,

(ii) $a \in W^{1,\infty}(Q) \cap C^0(\bar{Q})$ and $\inf_{\bar{Q}} a = \delta > 0$, $b_k \in W^{1,\infty}(Q)$, $1 \leq k \leq n$,

(iii) G is a continuous function from $\mathbf{R}$ to $\mathbf{R}$ such that $Gv = Fv + \theta v$ where θ is a real constant and F a function from $\mathbf{R}$ to $\mathbf{R}$ satisfying: $F0 = 0$ and $\exists p \in \mathbf{R}$, $p \geq 2$, $\exists \beta > 0$, $\exists \gamma > 0$ such that:

$$\beta |u - v|^p \leq (Fu - Fv)(u - v) \leq \gamma \left(|u|^{p-2} + |v|^{p-2} \right) |u - v|^2, \tag{1.1}$$

(iv) n and p satisfy the inequality:

$$n \leq 2 + \frac{2}{p-2} \qquad \left(n \in \mathbf{N}^* \text{ if } p = 2 \right).$$

The condition $\mathrm{H}_{1.1}$(iv) implies the algebraic and topological inclusion:

$$(1.2)\qquad H_0^1(\Omega)\hookrightarrow L^q(\Omega)\quad \forall q\in[2,2(p-1)].$$

A comment on hypothesis $\mathrm{H}_{1.1}$(iii) *and examples of functions G satisfying* $\mathrm{H}_{1.1}$(iii): In fact (1.1) implies that the nonlinear part of G, denoted by F, satisfies the condition $F'(z)\geq 0$, $\forall z\in\mathbf{R}$ (instead of $F'(z)>0$, $\forall z\in\mathbf{R}$ as in [3]). So here F' may be equal to zero in a subset of $\mathbf{R}$ and G is not necessary a monotone function as θ may be a nonpositive real.

(1) A first example of such a function is given by every Lipschitzian function G: $\mathbf{R}\to\mathbf{R}$ such that $G0=0$ (for example $Gv=\sin v$). Indeed if we denote by l a Lipschitz constant of G, we may choose $\theta=-l$ and $p=2$.

(2) Another classical example is given by $G(u)=|u|^\rho u$, $\rho\geq 0$. Indeed, $\mathrm{H}_{1.1}$(iii) is verified for $\theta=0$, $F=G$, and $p=\rho+2$; then the existence of a constant β is ensured (see Lions [8, p. 200]).

A result on existence and uniqueness. We associate with the problem P_ε the variational problem:

$$\mathcal{T}_\varepsilon\begin{cases}(1.3)\quad \varepsilon(u_\varepsilon'',v)+\alpha(u_\varepsilon,v)+(L_1u_\varepsilon,v)+(Gu_\varepsilon,v)=(f,v)\\ \qquad\qquad \forall v\in H_0^1(\Omega),\ \text{a.e. } s\in\,]0,T[,\\ (1.4)\quad u_\varepsilon\in L^\infty(0,T;H_0^1(\Omega)),\qquad u_\varepsilon'\in L^\infty(0,T;L^2(\Omega)),\\ (1.5)\quad u_\varepsilon(0,x)=u_0(x),\qquad u_\varepsilon'(0,x)=u_1(x)\end{cases}$$

for which we have the following property:

THEOREM 1.1. *Under the hypothesis* $\mathrm{H}_{1.1}$, *for each* $\varepsilon>0$, *the problem* $\mathcal{T}_\varepsilon$ *has a unique solution.*

The proof of this theorem is founded on Galerkin's method and is similar to the one given in Lions [7, Thm. 1.1] for the case $Gu=|u|^\rho u$ or in Saut [19] for the case of a Lipschitzian function G. We remark that the conditions (1.4) imply thanks to the results of Lions–Magenes [9] that u_ε is continuous from $[0,T]$ to $L^2(\Omega)$ and that u_ε' is continuous from $[0,T]$ to $H^{-1}(\Omega)$, so (1.5) has a sense.

A result of regularity. We introduce the hypothesis:

$\mathrm{H}_{1.2}$: $\mathrm{H}_{1.1}$ with $u_0\in H^2(\Omega)\cap H_0^1(\Omega)$, $u_1\in H_0^1(\Omega)$, $f'\in L^2(Q)$.

Then we have

THEOREM 1.2. *Under the hypothesis* $\mathrm{H}_{1.2}$, *for each* $\varepsilon>0$, *the solution of the problem* $\mathcal{T}_\varepsilon$ *is such that*:

$$u_\varepsilon\in L^\infty(0,T;H^2(\Omega)\cap H_0^1(\Omega)),\quad u_\varepsilon'\in L^\infty(0,T;H_0^1(\Omega)),\quad u_\varepsilon''\in L^\infty(0,T;L^2(\Omega)).$$

The proof of this theorem is analogous to a proof given in Lions [7, Thm. 1.3] or in Saut [19]. The only difficulty is to justify the differentiation of the nonlinear term. Now, the hypothesis $\mathrm{H}_{1.1}$(iii) implies that F is a local Lipschitzian function. Therefore $F'x$ exists almost everywhere on $\mathbf{R}$ (see for example Marcus–Mizel [13]) and verifies thanks to (1.1)

$$0\leq F'x\leq 2\gamma|x|^{p-2}\quad \text{a.e. } x\in\mathbf{R}.$$

Moreover thanks to the results of [13, Thm. 2.1 and property 1.5] we may assert that: for every function $u\in L^\infty(0,T;W_0^{1,2(p-1)}(\Omega))$ such that $u'\in L^\infty(0,T;L^{2(p-1)}(\Omega))$, we have $Fu\in L^\infty(0,T;H_0^1(\Omega))$, $(Fu)'\in L^\infty(0,T;L^2(\Omega))$ and the equalities:

$$\frac{\partial}{\partial x_k}(Fu)=(F'u)\frac{\partial u}{\partial x_k},\quad 1\leq k\leq n,\qquad (Fu)'=(F'u)u'.$$

Scheme of this paper. In the second paragraph we establish a priori estimates on u_ε and its derivatives $\partial u_\varepsilon/\partial x_k$ $(1\le k\le n)$, u'_ε by methods similar to those done in Madaune and Genet [12] and Madaune [10]. These estimates are sufficient to establish the convergence of u_ε when $\varepsilon\to 0_+$, by compactness arguments in the third paragraph; some results of strong convergence and estimates of $(u_\varepsilon-u)$ are also given in this paragraph. Lastly some remarks are gathered in the fourth paragraph in particular when the operator L_1 is nonlinear, Ω being a segment of $\mathbf{R}$.

2. A priori estimates.

THEOREM 2.1. *Under the hypothesis* $\mathrm{H}_{1.1}$, *the solution* u_ε *of the problem* $\mathscr{T}_\varepsilon$ *is such that*:

$$\|u_\varepsilon\|_{L^\infty(0,T;H_0^1(\Omega))}+\sqrt{\varepsilon}\,|u'_\varepsilon|_{L^\infty(0,T;L^2(\Omega))}+|u'_\varepsilon|_{L^2(Q)}\le C.K_1 \tag{2.1}$$

where

$$K_1^2=|f|^2_{L^2(Q)}+\|u_0\|_2^2+|u_0|_p^p+\varepsilon|u_1|_2^2 \tag{2.2}$$

and C is a positive constant independent of f, u_0, u_1 *and* ε.

Proof. We first establish the estimates (2.1) under the hypothesis $\mathrm{H}_{1.2}$; then we use a method of regularization to prove the theorem.

(1) *With assumption* $\mathrm{H}_{1.2}$. We consider the equality (1.3):

$$\varepsilon(u''_\varepsilon,v)+\alpha(u_\varepsilon,v)+(au'_\varepsilon,v)+\left(\sum_{k=1}^{n}b_k\frac{\partial u_\varepsilon}{\partial x_k},v\right)+(Gu_\varepsilon,v)=(f,v)$$

$$\forall v\in H_0^1(\Omega)\quad \text{a.e. } s\in]0,T[.$$

We put $v=2u'_\varepsilon(s)$; that is possible thanks to Theorem 1.2. We obtain

$$\frac{d}{dt}\left[\varepsilon|u'_\varepsilon|_2^2+\alpha(u_\varepsilon,u_\varepsilon)\right]+2|\sqrt{a}\,u'_\varepsilon|_2^2+2(Fu_\varepsilon,u'_\varepsilon) \tag{2.3}$$

$$=2(f,u'_\varepsilon)-2\left(\sum_{k=1}^{n}b_k\frac{\partial u_\varepsilon}{\partial x_k},u'_\varepsilon\right)-2\theta(u_\varepsilon,u'_\varepsilon).$$

Thanks to Hölder's inequality, the second member of (2.3) may be bounded by:

$$\delta|u'_\varepsilon|_2^2+\frac{3}{\delta}|f|_2^2+\frac{3}{\delta}\left(\sum_{k=1}^{n}|b_k|_{L^\infty(Q)}\right)^2\alpha(u_\varepsilon,u_\varepsilon)+\frac{3}{\delta}\theta^2|u_\varepsilon|_2^2.$$

Then, we integrate (2.3) from 0 to t. We denote by $\tilde{F}$ the primitive of F which vanishes at 0; we obtain:

$$\varepsilon|u'_\varepsilon(t)|_2^2+\alpha(u_\varepsilon(t),u_\varepsilon(t))+\delta\int_0^t|u'_\varepsilon(s)|_2^2ds+2\int_\Omega\tilde{F}u_\varepsilon(t)\,dx$$

$$\le\varepsilon|u_1|_2^2+\alpha(u_0,u_0)+2\int_\Omega\tilde{F}u_0\,dx+\frac{3}{\delta}|f|^2_{L^2(Q)}+M\int_0^t\|u_\varepsilon(s)\|_2^2ds$$

where

$$M=\frac{3}{\delta}\max\left(\theta^2,\left(\sum_{k=1}^{n}|b_k|_{L^\infty(Q)}\right)^2\right).$$

As the inequality (1.1) of hypothesis $\mathrm{H}_{1.1}$(iii) implies:

$$\forall v \in \mathbf{R}, \qquad \frac{\beta}{p}|v|^p \leq \tilde{F}v \leq \frac{\gamma}{p}|v|^p, \tag{2.4}$$

it is easy to deduce the estimates (2.1) from Poincare's inequality and Gronwall's lemma.

(2) *With assumption* $\mathrm{H}_{1.1}$. Let $W = L^2(Q) \times H_0^1(\Omega) \times L^2(\Omega)$ provided with the product topology and let $(f, u_0, u_1) \in W$. There is a sequence $(f_\mu; u_{0,\mu}; u_{1,\mu})$ which satisfies $H_{1,2}$ and converges to (f, u_0, u_1) in W. The solution $u_{\varepsilon,\mu}$ of the problem $\mathscr{T}_{\varepsilon,\mu}$ associated with $(f_\mu; u_{0,\mu}; u_{1,\mu})$ satisfies the estimates:

$$|u_{\varepsilon,\mu}|_{L^\infty(0,T;\, H_0^1(\Omega))} + \sqrt{\varepsilon}\,|u'_{\varepsilon,\mu}|_{L^\infty(0,T;\, L^2(\Omega))} + |u'_{\varepsilon,\mu}|_{L^2(Q)} \leq CK_{1,\mu} \tag{2.5}$$

where $K_{1,\mu} = |f_\mu|^2_{L^2(Q)} + \|u_{0,\mu}\|_2^2 + |u_{0,\mu}|_p^p + \varepsilon |u_{1,\mu}|_2^2$ and C is a constant independent of μ, f, u_0, u_1 and ε. Taking into account the convergence properties of the sequence $(f_\mu; u_{0,\mu}; u_{1,\mu})$, $K_{1,\mu}$ may be bounded independently of μ. Then, we can extract from the sequence $\{u_{\varepsilon,\mu}\}_\mu$ a subsequence still written $\{u_{\varepsilon,\mu}\}$ such that:

$$u_{\varepsilon,\mu} \rightharpoonup v_\varepsilon \quad \text{in } L^\infty(0,T; H_0^1(\Omega)) \text{ weak star}, \tag{2.6}$$

$$u'_{\varepsilon,\mu} \rightharpoonup v'_\varepsilon \quad \text{in } L^\infty(0,T; L^2(\Omega)) \text{ weak star}. \tag{2.7}$$

We deduce from (2.6) and (2.7) that $u_{\varepsilon,\mu}$ converges weakly in $H^1(Q)$ to v_ε. Consequently, we may choose the subsequence $\{u_{\varepsilon,\mu}\}$ such that $u_{\varepsilon,\mu}$ converges to v_ε in $L^2(Q)$ and almost everywhere in Q. Then, thanks to the continuity of G and to the condition (1.1), we may assert that $Gu_{\varepsilon,\mu}$ converges weakly to Gv_ε in $L^2(Q)$. Moreover $\varepsilon u''_{\varepsilon,\mu} = f_\mu + \Delta u_{\varepsilon,\mu} - L_1 u_{\varepsilon,\mu} - Gu_{\varepsilon,\mu}$ is bounded in $L^2(0,T; H^{-1}(\Omega))$ thanks to (2.5); so $\varepsilon u''_{\varepsilon,\mu}$ converges weakly in $L^2(0,T; H^{-1}(\Omega))$ to $\varepsilon v''_\varepsilon$. Hence, we can take the limit on μ in the equation satisfied by $u_{\varepsilon,\mu}$ and in the initial conditions. We deduce $v_\varepsilon = u_\varepsilon$ which gives us thanks to (2.5) the estimates of the theorem.

THEOREM 2.2. *Under hypothesis* $\mathrm{H}_{1.2}$, *the solution* u_ε *of the problem* $\mathscr{T}_\varepsilon$ *is such that*:

$$\varepsilon |u''_\varepsilon|_{L^\infty(0,T;\, L^2(\Omega))} + \sqrt{\varepsilon}\,|u''_\varepsilon|_{L^2(Q)} + \sqrt{\varepsilon}\,\|u'_\varepsilon\|_{L^\infty(0,T;\, H_0^1(\Omega))} \leq C \tag{2.8}$$

where C is a constant independent of ε.

Proof. To obtain the estimates (2.8), the idea is to differentiate the equality (1.3) with respect to t and then, to put $v = u''_\varepsilon(s)$. But we are not allowed to do so because u_ε is not smooth enough, even under hypothesis $\mathrm{H}_{1.2}$ (see Theorem 1.2). Therefore, we use a method of difference quotients.

Let h be a positive real, which will tend to 0 and let $s \in]0, T-h[$. We consider the equality (1.3) at times s and $s+h$ and we substract these two equalities. Then if for each function w: $Q \to \mathbf{R}$ we denote by $\tau_h w(s)$ the difference quotient $(1/h)(w(s+h) - w(s))$, we obtain:

(2.9)

$$\varepsilon(\tau_h u''_\varepsilon(s), v) + \alpha(\tau_h u_\varepsilon(s), v) + (a(s+h)\tau_h u'_\varepsilon(s), v) + \left(\sum_{k=1}^{n} b_k(s+h)\left[\tau_h \frac{\partial}{\partial x_k} u_\varepsilon(s)\right], v\right)$$

$$= (\tau_h f(s), v) - ([\tau_h a(s)]\, u'_\varepsilon(s), v) - \left(\sum_{k=1}^{n} [\tau_h b_k(s)] \frac{\partial u_\varepsilon}{\partial x_k}(s), v\right) - (\tau_h G u_\varepsilon(s), v)$$

$$\forall v \in H_0^1(\Omega), \text{ a.e. } s \in]0, T-h[.$$

Thanks to the results of Theorem 1.2, we may put $v=2\tau_h u_\varepsilon'(s)$ in (2.9); we have:

(2.10)

$$\frac{d}{ds}\left[\varepsilon|\tau_h u_\varepsilon'(s)|_2^2+a(\tau_h u_\varepsilon(s),\tau_h u_\varepsilon(s))\right]+2\delta|\tau_h u_\varepsilon'(s)|_2^2$$

$$\leq 2(\tau_h f(s),\tau_h u_\varepsilon'(s))-2([\tau_h a(s)]u_\varepsilon'(s),\tau_h u_\varepsilon'(s))-2\left(\sum_{k=1}^{n}[\tau_h b_k(s)]\frac{\partial u_\varepsilon}{\partial x_k}(s),\tau_h u_\varepsilon'(s)\right)$$

$$-2\left(\sum_{k=1}^{n}b_k(s+h)\left[\tau_h\frac{\partial}{\partial x_k}u_\varepsilon(s)\right],\tau_h u_\varepsilon'(s)\right)-2(\tau_h G u_\varepsilon(s),\tau_h u_\varepsilon'(s))\quad \text{a.e. } s\in\,]0,T-h[.$$

First, we bound the second member of (2.10) as follows (where μ denotes a constant that we will choose later):

$$|2(\tau_h f(s),\tau_h u_\varepsilon'(s))|\leq\mu|\tau_h f(s)|_2^2+\frac{1}{\mu}|\tau_h u_\varepsilon'(s)|_2^2,$$

$$|2([\tau_h a(s)]u_\varepsilon'(s),\tau_h u_\varepsilon'(s))|\leq\mu|a'|_{L^\infty(Q)}^2|u_\varepsilon'(s)|_2^2+\frac{1}{\mu}|\tau_h u_\varepsilon'(s)|_2^2,$$

$$\left|2\left(\sum_{k=1}^{n}[\tau_h b_k(s)]\frac{\partial u_\varepsilon}{\partial x_k}(s),\tau_h u_\varepsilon'(s)\right)\right|\leq\mu\left(\sum_{k=1}^{n}|b_k'|_{L^\infty(Q)}\right)^2\|u_\varepsilon(s)\|_2^2+\frac{1}{\mu}|\tau_h u_\varepsilon'(s)|_2^2,$$

$$\left|2\left(\sum_{k=1}^{n}b_k(s+h)\left[\tau_h\frac{\partial}{\partial x_k}u_\varepsilon(s)\right],\tau_h u_\varepsilon'(s)\right)\right|$$

$$\leq\mu\left(\sum_{k=1}^{n}|b_k|_{L^\infty(Q)}\right)^2\|\tau_h u_\varepsilon(s)\|_2^2+\frac{1}{\mu}|\tau_h u_\varepsilon'(s)|_2^2,$$

and finally, thanks to inequality (1.1), the nonlinear term is bounded by

$$|2(\tau_h G u_\varepsilon(s),\tau_h u_\varepsilon'(s))|\leq 2\gamma\int_\Omega\left(|u_\varepsilon(s+h)|^{p-2}+|u_\varepsilon(s)|^{p-2}\right)|\tau_h u_\varepsilon(s)||\tau_h u_\varepsilon'(s)|\,dx$$

$$+2|\theta||(\tau_h u_\varepsilon(s),\tau_h u_\varepsilon'(s))|;$$

therefore by using Hölder's inequality (with $(p-2)/(2(p-1))+1/(2(p-1))+\frac{1}{2}=1$), Theorem 2.1 and (1.2) we have:

$$|2(\tau_h G u_\varepsilon(s),\tau_h u_\varepsilon'(s))|\leq k_1\|\tau_h u_\varepsilon(s)\|_2^2+\frac{1}{\mu}|\tau_h u_\varepsilon'(s)|_2^2,$$

where k_1 is a positive constant independent of ε and h. Then, we integrate (2.10) from 0 to $t\in\,]0,T-h[$ and we set $\mu=\frac{5}{\delta}$. We obtain, thanks to the estimates (2.1) and hypothesis $H_{1.1}$(ii):

$$\text{(2.11)}\quad \varepsilon|\tau_h u_\varepsilon'(t)|_2^2+\|\tau_h u_\varepsilon(t)\|_2^2+\delta\int_0^t|\tau_h u_\varepsilon'(s)|_2^2ds\leq c_1(h)+c_2+c_3\int_0^t\|\tau_h u_\varepsilon(s)\|_2^2ds$$

where c_2, c_3 are two positive constants independent of ε and h, $c_1(h)$ is equal to:

$$c_1(h)=\frac{5}{\delta}\int_0^t|\tau_h f(s)|_2^2ds+\varepsilon|\tau_h u_\varepsilon'(0)|_2^2+a(\tau_h u_\varepsilon(0),\tau_h u_\varepsilon(0)).$$

It follows from hypothesis $\mathrm{H}_{1.2}$, Theorem 1.2 and equality (0.1) that $\varepsilon c_1(h)$ is bounded independently of h and ε. So, we deduce from (2.11) by Gronwall's lemma, the estimates:

$$\varepsilon|\tau_h u_\varepsilon'|_{L^\infty(0,T;L^2(\Omega))}+\sqrt{\varepsilon}\,|\tau_h u_\varepsilon'|_{L^2(Q)}+\sqrt{\varepsilon}\,\|\tau_h u_\varepsilon\|_{L^\infty(0,T;H_0^1(\Omega))}\leq C,$$

where $C>0$, is independent of h and ε. Therefore, the properties of the difference quotient allow us to take the limit when $h\to 0_+$. So we obtain the estimates (2.8). The theorem is proved.

3. Convergence.

3.1. Convergence under hypothesis $\mathbf{H_{1.1}}$. We assume that hypothesis $\mathrm{H}_{1.1}$ holds. The estimates obtained in the Theorem 2.1 imply the existence of a subsequence of $\{u_\varepsilon\}_{\varepsilon>0}$, again written $\{u_\varepsilon\}$ such that:

$$u_\varepsilon \rightharpoonup u \quad \text{in } L^\infty(0,T;H_0^1(\Omega)) \text{ weak-star,} \tag{3.1}$$

$$u_\varepsilon' \rightharpoonup u' \quad \text{weakly in } L^2(Q). \tag{3.2}$$

Thanks to the compactness of the injection from $H^1(Q)$ to $L^2(Q)$, we have:

$$u_\varepsilon \to u \quad \text{in } L^2(Q) \text{ and a.e. on } Q. \tag{3.3}$$

Then, it results from the continuity of G and from (1.1) that

$$Gu_\varepsilon \rightharpoonup Gu \quad \text{weakly in } L^2(Q). \tag{3.4}$$

Finally, as $\varepsilon u_\varepsilon''$ is bounded in $L^2(0,T;H^{-1}(\Omega))$ thanks to (1.3) and as $\varepsilon u_\varepsilon''$ tends to 0 in the sense of the distributions, we have:

$$\varepsilon u_\varepsilon'' \rightharpoonup 0 \quad \text{weakly in } L^2(0,T;H^{-1}(\Omega)). \tag{3.5}$$

Therefore, we may take the limit in the equality (1.3) as $\varepsilon\to 0_+$. We find that the limit function u verifies:

$$\begin{aligned}&\alpha(u,v)+(L_1u,v)+(Gu,v)=(f,v)\quad \forall v\in H_0^1(\Omega),\text{ a.e. } s\in]0,T[,\\ &u\in L^\infty(0,T;H_0^1(\Omega));\qquad u'\in L^2(Q).\end{aligned}$$

Moreover, it results from (3.1) and (3.2) that u_ε and u are continuous from $[0,T]$ to $L^2(\Omega)$ and then:

$$u_\varepsilon(t)\rightharpoonup u(t) \quad \text{weakly in } L^2(\Omega) \quad \forall t\in[0,T].$$

Therefore the limit function u satisfies the initial condition:

$$u(0,x)=u_0(x) \quad \text{a.e. } x\in\Omega.$$

Then, the limit function u is solution of the parabolic problem

$$\mathscr{T}\begin{cases}\alpha(u,v)+(L_1u,v)+(Gu,v)=(f,v)\quad \forall v\in H_0^1(\Omega),\text{ a.e. } s\in]0,T[,\\ u\in L^\infty(0,T;H_0^1(\Omega)),\qquad u'\in L^2(Q),\\ u(0,x)=u_0(x)\quad \text{a.e. } x\in\Omega.\end{cases} \tag{3.6}$$

Now, such a problem has a unique solution, under hypothesis $\mathrm{H}_{1.1}$. In consequence, we have proved

THEOREM 3.1. *When $\varepsilon \to 0_+$, the solution u_ε of the problem $\mathscr{T}_\varepsilon$ converges to the solution u of the problem $\mathscr{T}$ in the following spaces*:

(i) $u_\varepsilon \rightharpoonup u$ *in* $L^\infty(0,T;H_0^1(\Omega))$ *weak-star and weakly in* $H^1(Q)$,
$Gu_\varepsilon \rightharpoonup Gu$ *weakly in* $L^2(Q)$;

(ii) $u_\varepsilon \to u$ *in* $L^2(Q)$.

Now, we are going to establish an estimate for $u_\varepsilon - u$ in $L^\infty(0,T;L^2(\Omega))$ and also in $L^2(0,T;H_0^1(\Omega))$.

THEOREM 3.2. *The solution u_ε of the problem $\mathscr{T}_\varepsilon$ and the solution u of the problem $\mathscr{T}$ satisfy*:

$$|u_\varepsilon - u|_{L^\infty(0,T;L^2(\Omega))} + \|u_\varepsilon - u\|_{L^2(0,T;H_0^1(\Omega))} \leq C\sqrt{\varepsilon},$$

$$|u_\varepsilon - u|_{L^p(Q)} \leq C(\varepsilon)^{1/p}$$

where $C > 0$, is independent of ε.

Proof. For each $v \in H_0^1(\Omega)$ and for a.e. $s \in]0,T[$, we have, by substracting (1.3) and (3.6):

$$\varepsilon(u_\varepsilon'', v) + \alpha(w_\varepsilon, v) + (aw_\varepsilon', v) + \left(\sum_{k=1}^n b_k \frac{\partial w_\varepsilon}{\partial x_k}, v\right) + (Gu_\varepsilon - Gu, v) = 0 \tag{3.7}$$

where $w_\varepsilon = u_\varepsilon - u$. We can set $v = w_\varepsilon(s)$ in (3.7). We obtain:

$$\varepsilon(u_\varepsilon'', w_\varepsilon) + \alpha(w_\varepsilon, w_\varepsilon) + (aw_\varepsilon', w_\varepsilon) + \left(\sum_{k=1}^n b_k \frac{\partial w_\varepsilon}{\partial x_k}, w_\varepsilon\right) + (Gu_\varepsilon - Gu, w_\varepsilon) = 0.$$

We integrate from 0 to t and we use the condition (1.1). Then we have:

$$2\int_0^t \|w_\varepsilon(s)\|_2^2 ds + \delta|w_\varepsilon(t)|_2^2 + 2\beta\int_0^t |w_\varepsilon(s)|_p^p ds + 2(\theta-1)\int_0^t |w_\varepsilon(s)|_2^2 ds$$

$$\leq -2\varepsilon(u_\varepsilon'(t), w_\varepsilon(t)) + 2\varepsilon\int_0^t (u_\varepsilon', w_\varepsilon') ds + \left|a' + \sum_{k=1}^n \frac{\partial b_k}{\partial x_k}\right|_{L^\infty(Q)} \int_0^t |w_\varepsilon(s)|_2^2 ds.$$

Thanks to the estimates (2.1) and Hölder's inequality, we obtain:

$$2\int_0^t \|w_\varepsilon(s)\|_2^2 ds + \frac{\delta}{2}|w_\varepsilon(t)|_2^2 + 2\beta\int_0^t |w_\varepsilon(s)|_p^p ds \leq k_1\varepsilon + k_2\int_0^t |w_\varepsilon(s)|_2^2 ds$$

where k_1 and k_2 are two positive constants independent of ε. Then, the theorem results from Gronwall's lemma.

3.2. Convergence under hypothesis $\mathbf{H_{1,2}}$. The additional estimates obtained in Theorem 2.2 allow us to complement Theorem 3.2 by the results of

THEOREM 3.3. *For each $\varepsilon > 0$, $u_\varepsilon - u$ where u_ε (resp. u) is the solution of the problem $\mathscr{T}_\varepsilon$ (resp. $\mathscr{T}$) satisfies the additional estimates*:

$$\|u_\varepsilon - u\|_{L^\infty(0,T;H_0^1(\Omega))} + |u_\varepsilon' - u'|_{L^2(Q)} \leq C\sqrt{\varepsilon}$$

where $C > 0$ is independent of ε.

Proof. It results from (3.7) that $w_\varepsilon = u_\varepsilon - u$ satisfies:

$$-\Delta w_\varepsilon + aw_\varepsilon' + \sum_{k=1}^n b_k \frac{\partial w_\varepsilon}{\partial x_k} + Gu_\varepsilon - Gu = -\varepsilon u_\varepsilon'' \quad \text{in } L^2(\Omega), \text{ a.e. } s \in]0,T[. \tag{3.8}$$

We can take the inner product in $L^2(\Omega)$ of the two members of (3.8) with $2w_\varepsilon'(s)$. We do so and we integrate from 0 to t. It follows that:

$$(3.9)\qquad \int_0^t -\left(2\Delta w_\varepsilon, w_\varepsilon'\right)ds + 2\int_0^t \left|\sqrt{a}\,w_\varepsilon'\right|_2^2 ds$$

$$= -2\int_0^t \left[\varepsilon\left(u_\varepsilon'', w_\varepsilon'\right) + \left(\sum_{k=1}^n b_k \frac{\partial w_\varepsilon}{\partial x_k}, w_\varepsilon'\right) + \left(Gu_\varepsilon - Gu, w_\varepsilon'\right)\right]ds.$$

As $w_\varepsilon \in L^\infty(0,T;H_0^1(\Omega)) \cap L^2(0,T;H^2(\Omega))$ and $w_\varepsilon' \in L^2(Q)$, we may write:

$$(3.10)\qquad \int_0^t -\left(2\Delta w_\varepsilon, w_\varepsilon'\right)ds = a\left(w_\varepsilon(t), w_\varepsilon(t)\right).$$

(This result is established for instance in Madaune [11] by a technique of regularization.) Next, in order to bound the three terms of the second member of (3.9), we first use Theorem 2.2, then the properties of the coefficients b_k, and finally for the nonlinear term, the condition (1.1), Hölder's inequality (with $(p-2)/(2(p-1)) + 1/(2(p-1)) + \frac{1}{2} = 1$) and (1.2). We obtain:

$$2\left|\int_0^t \left[\left(\varepsilon u_\varepsilon'', w_\varepsilon'\right) + \left(\sum_{k=1}^n b_k \frac{\partial w_\varepsilon}{\partial x_k}, w_\varepsilon'\right) + \left(Gu_\varepsilon - Gu, w_\varepsilon'\right)\right]ds\right|$$

$$\leq k_1\varepsilon + k_2\int_0^t \|w_\varepsilon\|_2^2 ds + \delta\int_0^t |w_\varepsilon'|_2^2 ds$$

where k_1 and k_2 are two positive constants, independent of ε. Then, we deduce from (3.9) and (3.10), the inequality:

$$\|w_\varepsilon(t)\|_2^2 + \delta\int_0^t |w_\varepsilon'(s)|_2^2 ds \leq c_1\varepsilon + c_2\int_0^t \|w_\varepsilon(s)\|_2^2 ds$$

with c_1 and c_2, two constants independent of ε. Gronwall's lemma gives us the estimate of $(u_\varepsilon - u)$ in $L^\infty(0,T;H_0^1(\Omega))$ and the estimate of $(u_\varepsilon' - u')$ in $L^2(Q)$; the proof is thus achieved.

4. Some remarks. In this section, we collect some remarks. In particular, we introduce the notion of boundary layer corrector which will allow us to improve the estimates on $u_\varepsilon - u$. To do so, we need some regularity properties of u that we can obtain under some additional assumptions on f and u_0. Finally, we end this section by giving some results when the operator L_1 is nonlinear.

4.1. Regularity of *u*. We have the first property:

PROPERTY 4.1. *Under hypothesis* $\mathrm{H}_{1.2}$, *the solution* u *of the problem* $\mathcal{T}$ *is such that*: $u' \in L^2(0,T;H_0^1(\Omega)) \cap L^\infty(0,T;L^2(\Omega))$; $u'' \in L^2(0,T;H^{-1}(\Omega))$.

Proof. To establish the property for u', one may consider a sequence $\{u_m\}$ of approximated solutions of $\mathcal{T}$, constructed by Galerkin's method. It is easy to show, by classical techniques, that the sequence $\{u_m'\}$ is bounded independently of m in $L^2(0,T;H_0^1(\Omega)) \cap L^\infty(0,T;L^2(\Omega))$. So by taking the limit on m one obtains the property for u'. Next to have: $u'' \in L^2(0,T;H^{-1}(\Omega))$, it is enough to differentiate the equality (3.6) with respect to t.

Now we assume the hypothesis

$\mathrm{H}_{1.3}$: $\mathrm{H}_{1.2}$ with $u_0 \in H^3(\Omega)$, $f(0) \in H^1(\Omega)$.

PROPERTY 4.2. *Under hypothesis* $\mathrm{H}_{1.3}$, *the solution* u *of the problem* $\mathcal{T}$ *is such that*:

$$u' \in L^\infty\left(0,T;H_0^1(\Omega)\right), \qquad u'' \in L^2(Q).$$

Proof. Once again, we consider the sequence $\{u_m\}$ of approximated solutions of $\mathscr{T}$. We show that u'_m (resp. u''_m) is bounded independently of m in $L^\infty(0,T;H_0^1(\Omega))$ (resp. in $L^2(Q)$). (The technique we use to do this means formally that we differentiate the equation (3.6) and we choose $v=u''$.) The additional regularity imposed on u_0 and $f(0)$ allows us to bound $u'_m(0)$ in $H^1(\Omega)$, independently of m. Next, we take the limit on m.

Consequence. Under the assumptions of Property 4.2, $u'\in C([0,T];L^2(\Omega))$, so $u'(0,\cdot)$ exists and

$$u'(0,\cdot)=f(0)+\Delta u_0-\sum_{k=1}^{n} b_k(0,\cdot)\frac{\partial u_0}{\partial x_k}-Gu_0. \tag{4.1}$$

4.2. Utilization of boundary layer correctors. We assume the hypothesis $\mathrm{H}_{1.2}$.

4.2.1. Definition of the boundary layer corrector θ_ε. Let be $g_\varepsilon\in L^2(Q)$ such that $|g_\varepsilon|_{L^2(Q)}$ is bounded independently of ε. Then, we consider the problem

$$\Pi_\varepsilon\begin{cases}\varepsilon(\theta''_\varepsilon,v)+\alpha(\theta_\varepsilon,v)+(L_1\theta_\varepsilon,v)+(G(\theta_\varepsilon+u)-Gu,v)=\varepsilon(g_\varepsilon-u'',v)\\ \qquad\qquad\qquad\qquad\forall v\in H_0^1(\Omega),\ \text{a.e. } s\in\,]0,T[,\\ \theta_\varepsilon\in L^\infty(0,T;H_0^1(\Omega)),\qquad \theta'_\varepsilon\in L^\infty(0,T;L^2(\Omega)),\\ \theta_\varepsilon(0,x)=0,\quad \theta'_\varepsilon(0,x)=u_1(x)-u'(0,x)\quad\text{in } H^{-1}(\Omega)\end{cases} \tag{4.2}$$

(we know, from the Property 4.1, that $u''\in L^2(0,T;H^{-1}(\Omega))$). We may assert that the problem Π_ε has a unique solution since $\theta_\varepsilon+u$ satisfies the problem:

$$\begin{cases}\varepsilon((\theta_\varepsilon+u)'',v)+\alpha(\theta_\varepsilon+u,v)+(L_1(\theta_\varepsilon+u),v)+(G(\theta_\varepsilon+u),v)\\ \qquad\qquad=(f+\epsilon g_\varepsilon,v)\quad\forall v\in H_0^1(\Omega),\ \text{a.e. } s\in\,]0,T[,\\ \theta_\varepsilon+u\in L^\infty(0,T;H_0^1(\Omega)),\qquad (\theta_\varepsilon+u)'\in L^\infty(0,T;L^2(\Omega)),\\ (\theta_\varepsilon+u)(0,x)=u_0(x),\qquad (\theta_\varepsilon+u)'(0,x)=u_1(x)\quad\text{a.e. } x\in\Omega\end{cases}$$

which has a solution and only one, thanks to the Theorem 1.1.

PROPERTY 4.3. *Under hypothesis* $\mathrm{H}_{1.2}$, *we have*:

$$\|u_\varepsilon-(\theta_\varepsilon+u)\|_{L^\infty(0,T;H_0^1(\Omega))}+|u'_\varepsilon-(\theta_\varepsilon+u)'|_{L^2(Q)}\le C\varepsilon,$$
$$|u'_\varepsilon-(\theta_\varepsilon+u)'|_{L^\infty(0,T;L^2(\Omega))}\le C\sqrt{\varepsilon},$$

where C is a positive constant independent of ε.

Proof. Let be $z_\varepsilon=u_\varepsilon-(\theta_\varepsilon+u)$; z_ε satisfies

$$\begin{aligned}&\varepsilon z''_\varepsilon-\Delta z_\varepsilon+L_1z_\varepsilon+Gu_\varepsilon-G(\theta_\varepsilon+u)=-\varepsilon g_\varepsilon\quad\text{in } L^2(\Omega)\quad\text{a.e. } s\in\,]0,T[,\\ &z_\varepsilon(0,x)=z'_\varepsilon(0,x)=0.\end{aligned} \tag{4.3}$$

By using a method of regularization as in the proof of the Theorem 2.1 we may suppose that $g'_\varepsilon\in L^2(Q)$. Then, thanks to the Theorem 1.2, we can take the inner product in $L^2(\Omega)$ of the two members of (4.3) with $2z'_\varepsilon(s)$. We do so and we integrate from 0 to t.

By calculations analogous to the ones done in the proof of the Theorem 3.3, we obtain the inequality:

$$\varepsilon|z_\varepsilon'|_2^2+\|z_\varepsilon\|_2^2+\delta\int_0^t|z_\varepsilon'(s)|_2^2ds\le c_1\varepsilon^2+c_2\int_0^t\|z_\varepsilon(s)\|_2^2ds$$

where c_1 and c_2 are two positives constant independent of ε and g_ε. The utilization of Gronwall's lemma gives us the estimates of the Property 4.3.

4.2.2. Example of a boundary layer corrector. We introduce

$$\theta_\varepsilon=\varepsilon\left[u'(0,x)-u_1(x)\right]e^{-a(x,0)(t/\varepsilon)} \tag{4.4}$$

and we shall prove that θ_ε is a boundary layer corrector. Thus, the element θ_ε which is a boundary layer corrector for the case of the linear equation $L_2^{(\varepsilon)}u_\varepsilon+L_1u_\varepsilon=f$ remains a corrector for the case of nonlinearities of the type introduced here. We need some additional properties on f and u_0.

$H_{1.4}$: $H_{1.2}$ with $u_0\in H^4(\Omega)$, $u_1\in H^2(\Omega)$, $f(0)\in H^2(\Omega)$, $Gu_0\in H^2(\Omega)$.

THEOREM 4.4. *Under hypothesis* $H_{1.4}$, θ_ε *defined by* (4.4) *is a boundary layer corrector that is* θ_ε *satisfies the Property* 4.3.

Proof. We first remark that the assumption $H_{1.4}$ implies, thanks to (4.1), that: $u'(0,\cdot)-u_1\in H^2(\Omega)$. We assume, in order to simplify the calculations, that $a\equiv 1$. The result holds in the general case; only the calculations are more complicated. It is easy to prove that θ_ε satisfies the equality (4.2) with

$$g_\varepsilon=u''-\left(\Delta u'(0,\cdot)-\Delta u_1\right)e^{-t/\varepsilon}$$
$$+\sum_{k=1}^n b_k\left(\frac{\partial}{\partial x_k}u'(0,\cdot)-\frac{\partial}{\partial x_k}u_1\right)e^{-t/\varepsilon}+\frac{1}{\varepsilon}\left(G(\theta_\varepsilon+u)-Gu\right)$$

and that $|g_\varepsilon|_{L^2(Q)}$ is bounded independently of ε. So, we can apply results of Property 4.3 to θ_ε defined by (4.4).

4.2.3. Consequence. The corrector θ_ε defined by (4.4) is such that:

$$\|\theta_\varepsilon\|_{L^\infty(0,T;H_0^1(\Omega))}\le C\varepsilon,\qquad\left|\sqrt{t}\,\theta_\varepsilon'\right|_{L^2(Q)}\le C\varepsilon,$$

where C is a positive constant independent of ε. Therefore we obtain

THEOREM 4.5. *Under hypothesis* $H_{1.4}$, *the solution* u_ε *of the problem* $\mathscr{T}_\varepsilon$ *and the solution* u *of the problem* $\mathscr{T}$ *are such that*:

(i) $\|u_\varepsilon-u\|_{L^\infty(0,T;H_0^1(\Omega))}\le C.\varepsilon$; $|\sqrt{t}(u_\varepsilon'-u')|_{L^2(Q)}\le C\varepsilon$,
where C is a positive constant independent of ε,

(ii) *for each* $\tau\in]0,T[$, $|u_\varepsilon'-u'|_{L^\infty(\tau,T;L^2(\Omega))}\le C_1\sqrt{\varepsilon}$,
where C_1 *is a positive constant independent of* ε, *but dependent on* τ.

4.3. A remark when L_1 is nonlinear and $\Omega\subset\mathbf{R}$. When Ω is an interval of $\mathbf{R}$, the results of the Theorems 1.1 and 1.2 remain valid when the operator L_1 is nonlinear:

$$L_1u=a(x,t,u)\frac{\partial u}{\partial t}+b(x,t,u)\frac{\partial u}{\partial x}$$

upon condition of assuming instead of $H_{1.1}$(ii), the condition

$$H_{1.1}'(\mathrm{ii}):\ a,b\in C^1(\overline{Q}\times\mathbf{R}),\ a(x,t,u)\ge\delta>0\text{ on }\overline{Q}\times\mathbf{R},\ b\in L^\infty(Q\times\mathbf{R}).$$

To prove this, it is sufficient to work again with Galerkin's method used when L_1 is a linear operator. Next, it is easy to verify that the solution u_ε of the problem $\mathscr{T}_\varepsilon$ satisfies the estimates of the Theorem 2.1 and the convergence results of the Theorem 3.1. Now, if we assume that the coefficient a is independent of u, we may prove that u_ε satisfies the estimates of the Theorem 2.2 and the convergence properties of the Theorems 3.2 and 3.3. Of course, modifications must be brought on the treatment of the term $b(x,t,u)\partial u/\partial x$; we use in particular the algebraic and topological inclusion: $H^1(\Omega) \hookrightarrow L^\infty(\Omega)$.

THE ONE-DIMENSIONAL NONLINEAR HEAT EQUATION WITH ABSORPTION: REGULARITY OF SOLUTIONS AND INTERFACES*

MIGUEL A. HERRERO[†] AND JUAN L. VÁZQUEZ[‡]

Abstract. We consider the equation $u_t=(u^m)_{xx}-\lambda u^n$ with $m>1$, $\lambda>0$, $n\geqq m$ as a model for heat diffusion with absorption. Hence we assume that $u\geqq 0$ for $x\in\mathbb{R}$, $t\geqq 0$. We study the regularity of the solution to the Cauchy problem for this degenerate parabolic equation. When the initial datum $u_0(x)$ is positive only in a part of the space $\mathbb{R}$, we also study the regularity of the free boundaries that appear. The asymptotic behavior of solutions and free boundaries is also discussed.

Key words. nonlinear diffusion with absorption, regularity, interfaces or free boundaries, waiting time, asymptotic behavior

AMS(MOS) subject classifications. Primary 35Q20, 35K55, 35K65

Introduction. In this paper we study the regularity and propagation properties of the solutions to the following Cauchy problem:

$$u_t=(u^m)_{xx}-\lambda u^n \quad \text{when } (x,t)\in S=\mathbb{R}\times(0,\infty), \tag{0.1}$$

$$u(x,0)=u_0(x) \quad \text{for } x\in\mathbb{R}, \tag{0.2}$$

where λ, m and n are positive constants and u_0 is a nonnegative, continuous and bounded real function.

Equations like (0.1) are used as mathematical models in a number of problems, in particular in describing thermal propagation with absorption; then u stands for the temperature, $(u^m)_{xx}$ is the diffusion term and $-\lambda u^n$ represents the absorption of heat by the medium. We see that in general the thermal conductivity mu^{m-1} and the absorption coefficient λu^{n-1} are temperature-dependent. We refer to Zeldovich and Raizer [ZR] for a detailed account of nonlinear heat conduction problems.

In this paper we consider the case of "slow diffusion" $m>1$ and "weak absorption" $n\geqq m$. The first restriction implies that initial data with compact support propagate with finite velocity, so that two *interfaces* or *free boundaries* arise, $x=\zeta_1(t)$ and $x=\zeta_2(t)$, that bound the support of $u(\cdot,t)$ for every $t>0$; see Oleinik, Kalashnikov and Chzou [OKC] for the case $\lambda=0$ and Kalashnikov [K2] for positive λ. We study here the regularity of the solution u and the free boundaries $\zeta_i(t)$. We obtain the following results.

I) *Regularity.*

i) For a.e. $(x,t)\in S$ we have:

$$|(u^{m-1})_x(x,t)|^2\leqq c\|u_0\|_\infty^{m-1}t^{-1} \tag{0.3}$$

for a positive constant $c=c(m)$ ($\|f\|_p$, $1\leqq p\leqq +\infty$, denotes the L^p-norm of a function f). This is proved in Theorem 1 under the more general assumptions $m>1$, $n>0$, $m+n\geqq 2$.

The fact that $(u^{m-1})_x$ is bounded for $t\geqq\tau>0$ was already proved by Kalashnikov [K3]. From this it follows that u is Hölder continuous in S with respect to x with exponent $\alpha=\min(1,1/m-1)$, and consequently (cf. [G]) with respect to t with exponent $\alpha/2$. It is also proved in [K3] that the result cannot be true in general for $m+n<2$.

ii) u^{m-1} is a semiconvex function of x for every $t>0$ and we have

$$(u^{m-1})_{xx}\geqq -k/t \tag{0.4}$$

with $k=k(n,m)>0$ (Theorem 2). This result is due to Aronson and Bénilan [AB] in the nonabsorption case $\lambda=0$, and has played a prominent role in the theory of that "porous medium" equation. From (0.4) a sharper form of (0.3) follows, see (2.14).

II) *Interfaces*. We use the above results to discuss the regularity of the solution u and the free boundaries. We prove that the $\zeta_i(t)$ are C^1, strictly increasing functions after a possibly positive time t_i^* (Theorem 5) whose occurrence we characterize in terms of u_0 (Theorem 4). The equation satisfied on the free boundary is proved to be the same as in the porous medium case:

$$-\zeta_i'(t)=\lim v_x(x,t) \quad \text{as } x\to\zeta_i(t), \quad x\in(\zeta_1(t),\zeta_2(t)), \tag{0.5}$$

where $v=(m/m-1)u^{m-1}$ (Theorem 3). Note that by (0.3) $|v_x|$ is locally bounded for $t>0$. It now follows from (0.5) that whenever $\zeta_i'(t)\neq 0$ (i.e., for $t>t_i^*$) the function $v_x(x,t)$ cannot be continuous at $(\zeta(t),t)$: we thus obtain the *optimal regularity* for solutions with an interface. This is exactly the situation in the porous medium case (cf. Aronson [A1], Knerr [Kn1]). Of course, if $u>0$ in S then s is smooth everywhere.

It is to be noted that in our study of the free boundary we do not require, as it was customary in the literature ([K2], [Kn1], [Ke1], $\cdots$) that u_0 have compact support, but only that

$$d=\sup\{x\in\mathbb{R}\colon\ u_0(x)>0\}<+\infty. \tag{0.6}$$

This is the natural condition on u_0 in order to have a (right-hand) interface $x=\zeta(t)$, defined by $\zeta(t)=\sup\{x\in\mathbb{R}\colon\ u(x,t)>0\}$, $t\geqq 0$.

III) *Asymptotic behavior*. We use our previous results to describe the behavior as $t\to\infty$ of 1) the solution u of (0.1), (0.2) for general u_0, 2) its interface $\zeta(t)$ if u_0 satisfies (0.6).

Under the hypothesis that u_0 has compact support $I=[a,b]$ (and is positive in (a,b)) Kersner [Ke1] studies the asymptotic behavior for $m>1$, $n\geqq 1$ and distinguishes three regions: $1<n<m$, $m<n<m+2$ and $n>m+2$, with three limit cases: $n=1$, $n=m$ and $n=m+2$. He gives rates for u and ζ as $t\to\infty$ in the different cases. A parallel study is done by Knerr [Kn2]. The set of estimates if then improved by Herrero [H] and completed by Bertsch, Kersner and Peletier [BKP1].

We give simple proofs of some of the difficult estimates above (under our more general conditions) by applying the results in i) and ii). Since we use (0.5) to convert estimates on v_x into estimates on $\zeta'(t)$ this quantity is also controlled. But our main result is to point out a basic difference between the cases $m\leqq n<m+2$ and $n>m+2$ that happens precisely because we consider general initial data: in the first region $m\leqq n<m+2$ the asymptotic behavior of u (and that of ζ if u_0 satisfies (0.6)) is essentially *unique* and its rates are given by the *absorption* (Theorem 8). On the

contrary, if $n>m+2$ solutions corresponding to $u_0\in L^1(\mathbb{R})$ have minimal rates given by the *diffusion* term (Theorem 6; they agree with the ones for the porous medium equation, see Vàzquez [V1]), whereas when $u_0(x)\geqq c>0$ for all $x\ll 0$ and some constant c, the rates are maximal and given by the *absorption* as in the previous case (Theorem 7).

Finally the paper is divided into several sections, according to the following plan:

1. Preliminaries.
2. Regularity of solutions.
3. Proof of Theorem 1.
4. Proof of Theorem 2.
5. Regularity of interfaces.
6. Asymptotic behavior.

1. Preliminaries. It is known that for $\lambda=0$ the problem (0.1), (0.2) does not have classical solutions for initial data u_0 that vanish in some interval, even if they are smooth; this happens because of the degeneracy of the equation at $u=0$. A similar situation occurs for $\lambda>0$ in view of particular explicit solutions and in general because of the regularity results that we shall prove. Therefore a concept of *generalized* solution is needed. A function $u(x,t)$ continuous, nonnegative and bounded in $\bar{S}=\mathbb{R}\times[0,\infty)$ is said to be a generalized solution of (0.1) (0.2) if $u(x,0)=u_0(x)$ and the following equality holds for every function $\phi(x,t)\in C^{2,1}(\bar{S})$ having compact support in $\bar{S}$:

$$(1.1)\qquad I(u,\phi)\equiv\iint_S(u^m\phi_{xx}+u\phi_t-\lambda u^n\phi)\,dx\,dt+\int_{\mathbb{R}}u_0(x)\phi(x,0)\,dx=0.$$

When a function $u(x,t)$ as above satisfies $I(u,\phi)\leqq$ (resp. $I(u,\phi)\geqq 0$) for all nonnegative test functions ϕ as before we say that u is a *supersolution* of (0.1), (0.2) (resp. a *subsolution*).

The existence, uniqueness and properties of generalized solutions have been studied by Kalashnikov [K2], Kersner [Ke2] and Knerr [Kn2]. (Incidentally, they use slightly different but equivalent definitions.) In the sequel we shall use a series of results that we summarize here. We refer to the pertinent literature for some of them and prove for the reader's convenience those for which we could find no proof.

THEOREM 0. *Let $m>1$, $n>0$, $m+n\geqq 2$ and let u_0 be a continuous, nonnegative and bounded real function. Then*:

i) *There exists a unique generalized solution $u(x,t)$ of* (0.1) (0.2).

ii) *u is smooth in the open set $\{(x,t)$: $u(x,t)>0\}$. In particular, if $u_0>0$ everywhere and $n\geqq 1$ then u is smooth in $\bar{S}$.*

iii) *If $\hat{u}$ is a supersolution and $\bar{u}$ a subsolution to* (0.1) *with initial data $\hat{u}_0$ and $\bar{u}_0$ respectively, and $\hat{u}_0\geqq\bar{u}_0$ then $\hat{u}\geqq\bar{u}$ in S.*

iv) *Let $u_j(x,t)$ $(j=1,2\cdots)$ and $u(x,t)$ be solutions to* (0.1) *with initial data $u_{0_j}(x)$, $u_0(x)$ respectively. If $u_{0_j}\to u_0$ uniformly on compacts as $j\to\infty$ then $u_j(x,t)\to u(x,t)$ uniformly on compacts of S as $j\to\infty$.*

Proof. Existence and uniqueness is obtained by Kalashnikov [K2] for the more general equation

$$(1.2)\qquad u_t=(\alpha(u))_{xx}-\psi(u)$$

under assumptions that in our case mean $n\geqq 1$ and u_0^m Lipschitz continuous. The range $0<n<\infty$ is dealt with by Kersner [Ke2], as a particular case of equation (1.2), by using a sequence of approximate problems,

$$(1.3)\qquad \begin{aligned} &u_t=(u^m)_{xx}-\lambda u^n+\lambda\varepsilon^n,\\ &u(x,0)=u_{0_\varepsilon}(x), \end{aligned}\qquad \varepsilon>0$$

where $u_{0_\varepsilon}(x)>u_0(x)$ and $u_{0_\varepsilon}(x)\downarrow u_0(x)$ as $\varepsilon\downarrow 0$. This allows him to avoid the degeneracy of (0.1). He assumes compact support of u_0. His proof of uniqueness (i), smoothness (ii) and comparison (iii) can be repeated in our case (for this last point see also Bertsch [Be]). But let us prove in detail the existence (i) and dependence (iv) parts.

As to the existence, we consider the approximate problems (1.3) with a sequence of smooth, positive functions $u_{0_\varepsilon}(x)\geqq\varepsilon>0$ that converge to u_0 uniformly on compacts and is bounded by a constant $M>0$ independent of ε. It is easy to see that (1.3) has, for each ε, a unique classical solution in S $u_\varepsilon(x,t)$ and $\varepsilon\leqq u_\varepsilon\leqq M$ in S (cf. [Ke2]). Then, using Kalashnikov's result (cf. [K3]), the uniform bound

$$(1.4)\qquad \left|\left(u_\varepsilon^{m-1}\right)_x\right|\leqq C(\tau)\quad \text{for } t\geqq\tau$$

follows and therefore the functions u_ε are Hölder continuous with respect to x uniformly in $\varepsilon>0$, $x\in\mathbb{R}$ and $t\geqq\tau>0$. Hence $\{u_\varepsilon\}$ is also uniformly Hölder continuous in t (see Kruzhkov [Kr], Gilding [G]). Thus, passing to a subsequence (that we label again u_ε), we find that u_ε converges to a continuous function $u(x,t)$ uniformly on compacts on S, and therefore for every $(x,t)\in S$. Since we have

$$(1.5)\qquad I(u_\varepsilon,\phi)=-\lambda\varepsilon^n\iint\phi(x,t)\,dx\,dt$$

in the limit $\varepsilon\downarrow 0$ we get $I(u,\phi)=0$.

We have yet to check that u is continuous down to $t=0$ and that $u(x,0)=u_0(x)$. The classical results for quasilinear parabolic equations, cf. [LSU], do not apply directly because of the degeneracy of the equation.

Consider first a point x_0 where $u_0(x_0)>0$. We construct an explicit lower barrier for u_0 at x_0 as follows: given $0<\delta<u_0(x_0)$ there is an interval $I=[x_0-a,x_0+a]$ where $u_0(x)\geqq u_0(x_0)-\delta\equiv b>0$. We now consider the function

$$(1.6)\qquad \tilde v(x,t)=B-\frac{B}{a^2}(x-x_0)^2-ct,$$

with $B=(m/(m-1))b^{m-1}$ and $c>0$, in the set

$$(1.7)\qquad \Omega=\left\{(x,t)\in S\colon\ B>\frac{B}{a^2}\cdot(x-x_0)+ct\right\}.$$

If $c>2B^2(m-1)/a^2+\mu B^\beta$ for some μ, $\beta\geqq 0$, $\tilde v$ satisfies in Ω

$$(1.8)\qquad L_1\tilde v\equiv\tilde v_t-(m-1)\tilde v\tilde v_{xx}-\tilde v_x^2+\mu\tilde v^\beta<0.$$

We now perform the change of variables $\tilde v=(m/m-1)\tilde u^{m-1}$. Then $\tilde u\in C^\infty(\Omega)$ and satisfies there the inequality

$$(1.9)\qquad L\tilde u\equiv\tilde u_t-(\tilde u^m)_{xx}+\lambda\tilde u^n<0,$$

where $\mu=\lambda m((m-1)/m)^\beta$ and $\beta=(m+n-2)/(m-1)$ (hence we assume $\lambda\geqq 0$, $n+m\geqq 2$). It is easy to see that for ε small the approximations u_ε above to the solution $u(x,t)$ of (0.1) with initial data $u_0(x)$ satisfy: i) $u_\varepsilon\in C^\infty(\Omega)$, ii) $Lu_\varepsilon>0$ in Ω, iii) $u_\varepsilon(x,t)\geqq\tilde u(x,t)$ in $\partial\Omega$. By the maximum principle it follows that $u_\varepsilon(x,t)\geqq\tilde u(x,t)$ in Ω. Letting $\varepsilon\downarrow 0$ we have $u(x,t)\geqq\tilde u(x,t)$ in Ω, hence as $(x,t)\in S\to(x_0,0)$ we get

$$\liminf u(x,t)\geqq\tilde u(x_0,0)=u_0(x)-\delta.$$

Letting $\delta \to 0$ the lower semicontinuity of u at $(x_0, 0)$ follows. The result is obviously true if $u_0(x_0)=0$ since $u \geqq 0$.

The upper semicontinuity at $t=0$ is now easy. For any $\delta > 0$ we can take a smooth function $\hat{u}_1(x)$ such that $\hat{u}_1(x) > \delta$ and $u_0(x) \leqq \hat{u}_1(x) \leqq u_0(x)+\delta$. Let $\hat{u}(x,t)$ be the corresponding solution. By the argument above $\hat{u}(x,t)$ and its approximations $\hat{u}_\varepsilon(x,t)$, ε small, will be uniformly positive in every strip $S_T = \mathbb{R} \times (0, T]$, T small, and the classical theory implies that $\hat{u}$ is continuous at $t=0$. Therefore as $(x,t) \in S \to (x_0, 0)$ we have

$$\limsup u(x,t) \leqq \lim \hat{u}(x,t) = u(x_0) \leqq u_0(x_0) + \delta.$$

To end the proof of the theorem we remark that the dependence result, part iv), can be proved by repeating these same arguments.

2. Regularity results. To motivate the results in this section, we disregard the absorption term in (0.1), thus obtaining the porous medium equation:

$$u_t = (u^m)_{xx}, \qquad m > 1, \tag{2.1}$$

that appears in a variety of situations (see for instance Peletier [P]), in particular as as model for the flow of an isentropic gas through a porous medium. In this case u represents the density of the gas and two other physical magnitudes play a role in describing the flow: the *pressure*, defined by

$$v = \frac{m}{m-1} u^{m-1} \tag{2.2}$$

and the *local velocity*, given by $-v_x$.

Equation (2.1) has been extensively studied and many of its properties are well known by now. In particular, with respect to the regularity Aronson [A1] proved that for every solution of (2.1), (0.2) the velocity is *bounded* in every strip $S_{\tau,\infty} = \mathbb{R} \times (\tau, \infty)$ where $\tau > 0$, and this result is best possible in the sense that v_x can be discontinuous. This gives a regularity threshold for solutions, since $u(x,t)$ is Hölder continuous in x with exponent $\alpha = \min(1, 1/(m-1))$, which is sharp as it can be tested against the explicit similarity solutions obtained by Barenblatt [B]

$$\hat{u}_p(x,t) = t^{-1/(1+m)} \left[p - \frac{m-1}{2m(m+1)} \left(x t^{-1/(1+m)} \right)^2 \right]_+^{1/(m-1)} \tag{2.3}$$

(valid also for $m < 1$) where $p > 0$ is arbitrary. We just note here that this threshold no longer appears when $m < 1$, in which case disturbances from rest propagate with infinite speed (cf. Aronson and Bénilan [AB] and Vâzquez [V2]) and nonnegative solutions are always positive and smooth everywhere.

A second important regularity result is also shown in [AB]; it states that the pressure is a *semiconvex* function with respect to the space variable. More precisely,

$$v_{xx} \geqq -\frac{1}{(m+1)t}, \tag{2.4}$$

where the inequality is to be understood in the sense of distributions in S. Noting from this and the equation $v_t = (m-1) v v_{xx} + v_x^2$ satisfied by v, it easily follows that

$$u_t \geqq -\frac{u}{(m+1)t} \quad \text{in } S.$$

On the other hand Kalashnikov [K3] proved that if we apply the previous definitions of pressure and velocity to equation (0.1) (as we shall do in the sequel), the velocity of solutions to (0.1), (0.2) is bounded in every strip of the form $S_{\tau,\infty}$ with $\tau>0$ if $m+n\geqq 2$, but not in general if $m+n<2$. Though the boundedness of v_x is already an important fact, for some applications we need to know the way in which this bound depends on time. This is included in our first result.

THEOREM 1. *Let $u(x,t)$ be the solution to* (0.1), (0.2) *with n, m as above and $n+m\geqq 2$, $n>0$. Then $v(x,t)$ is Lipschitz continuous in x for each $t>0$ and we have a.e.*:

$$(2.5)\qquad |v_x(x,t)|^2\leqq\frac{2}{m}\|v_0\|_\infty t^{-1}.$$

Moreover, for every t_1, t_2 with $0\leqq t_1<t_2$ one has

$$(2.6)\qquad \sup_{x\in R}|v_x(x,t_2)|<\sup_{x\in R}|v_x(x,t_1)|.$$

The proof of Theorem 1 is postponed to §3. To obtain from the theorem sharper bounds for $|v_x|$ as $t\to\infty$, we remark that there exist two a priori bounds for solutions of the problem under consideration. The first one is valid if $u_0(x)\in L^p(R)$ with $1\leqq p<+\infty$ and asserts that there exists a constant $c=c(m,p)>0$ such that for every solution of (0.1), (0.2) we have in S

$$(2.7)\qquad \dot{u}(x,t)\leqq c\|u_0\|_p^\alpha t^{-\theta},$$

where

$$(2.8)\qquad \alpha=\frac{2p}{2p+m-1},\qquad \theta=\frac{1}{2p+m-1}.$$

This has been proved for the case $\lambda=0$ by Véron [Ve]. Since solutions of (2.1) are supersolutions to (0.1) with the same initial data, the estimate holds for $\lambda>0$. Therefore, using (2.7) in the time interval $[0,t/2]$ and (2.5) in $[t/2,t]$ after displacing the origin of time from 0 to $t/2$, we get the following.

COROLLARY 1. *Let u, u_0,m,n be as above and let also $u_0\in L^p(\mathbb{R})$, $1\leqq p<+\infty$. Then we have in S*

$$(2.9)\qquad |v_x(x,t)|\leqq c_1\|u_0\|_p^\gamma\cdot t^{-\delta},$$

where $c_1=c_1(m,p)>0$, $\gamma=p(m-1)/(2p+m-1)$, $\delta=(p+m-1)/(2p+m-1)$.

The second bound occurs for $n>1$ and is a consequence of the existence of a solution of (0.1) of the form:

$$u^*(x,t)=(\lambda(n-1)t)^{-1/(n-1)}.$$

It then follows by comparison that for every solution of (0.1), (0.2) we have in S

$$(2.10)\qquad u(x,t)\leqq(\lambda(n-1)t)^{-1/(n-1)}.$$

Combining (2.10) and (2.5) as above yields the following.

COROLLARY 2. *Let u, u_0,m as in Theorem 1 and let $n>1$. Then for every $(x,t)\in S$ we have*

$$(2.11)\qquad |v_x(x,t)|^2\leqq c_2\cdot t^{-(m+n-2)/(n-1)}$$

with

$$c_2^2=\frac{2^\sigma}{m-1}\left(\frac{1}{\lambda(n-1)}\right)^{(m-1)/(n-1)},\qquad \sigma=2+\frac{m-1}{n-1}.$$

Our second result consists in establishing a semiconvexity property like (2.4) for (0.1), (0.2) under the restrictions $m>1$, $n\geqq m$.

THEOREM 2. *Let u, v be as above and assume that $n\geqq m$. Then*

$$v_{xx}\geqq-\frac{k}{t}\quad in\ D'(S)\tag{2.12}$$

where

$$k=\frac{1}{m+1}+\left(\frac{2^\sigma(m+n-2)}{m(m^2-1)}\right)^{1/2}.$$

The proof of Theorem 2 fails for $1<n<m$, though it can be adapted to cover the case $n\leqq 1$. When $n=1$ one is easily reduced to the nonabsorption equation (2.1) by means of the change in variables (see Martinson and Pavlov [MP]):

$$\begin{gathered}\tau=\frac{1}{\lambda(m-1)}\left(1-e^{-\lambda(m-1)t}\right),\\ u(x,t)=\hat{u}(x,\tau)e^{-\lambda t}.\end{gathered}\tag{2.13}$$

In proving Theorem 2, essential use is made of estimate (2.5). Conversely, (2.5) is a simple consequence of Theorem 2 and the boundedness of v. In fact a stronger result holds.

COROLLARY 3. *Under the assumptions of Theorem 2, we have for every $(x,t)\in S$:*

$$|v_x(x,t)|\leqq\left(2k\|v(x,t)\|_\infty t^{-1}\right)^{1/2},\tag{2.14}$$

where k is the constant in (2.12).

This result is a consequence of the following Calculus Lemma applied to $v(\cdot,t)$: "Let f be a bounded real function such that $f''(x)\geqq -d>0$. Then f is Lipschitz continuous and

$$|f'(x)|\leqq\left(2\|f\|_\infty d\right)^{1/2}$$

for every $x\in R$."

3. The proof of Theorem 1. We begin by deriving the basic result, that consists in applying Bernstein's method to the pressure v assuming that our solution is smooth. Let us write $S_T=\mathbb{R}\times(0,T]$ with $T>0$. We obtain the following.

LEMMA 3.1. *Let $v(x,t)$ be a smooth, positive and bounded solution of the equation*

$$v_t=(m-1)vv_{xx}+v_x^2-cv^\beta\tag{3.1}$$

in $\bar{S}_T=\mathbb{R}\times[0,T]$ and let c,β be nonnegative constants. Then we have:

$$v_x^2(x,t)\leqq\frac{2}{m}\|v(x,0)\|_\infty t^{-1}\tag{3.2}$$

for every $(x,t)\in S_T$. In addition, for $0\leqq t_1<t_2$

$$\sup_{x\in\mathbb{R}}|v_x(x,t_2)|<\sup_{x\in\mathbb{R}}|v_x(x,t_1)|.\tag{3.3}$$

Proof. We begin as in Aronson's proof for the case $\lambda=0$, [A1, p. 463] (see also [K3]). Let $N=\sup_{x\in\mathbb{R}}v(x,t)$. We choose a C^2 function ϕ: $[0,1]\to[0,N]$ strictly increasing, concave and such that $(\phi''/\phi')'\leqq 0$; further specifications will be given below. We also take a cut-off function $\zeta\in C(\overline{S}_T)\cap C^\infty(S_T)$ such that $0\leqq\zeta\leqq 1$ and $\zeta=0$ for $t=0$ or $|x|\geqq c$, c being some positive constant. Setting $v=\phi(w)$ we obtain from (3.1)

$$w_t=(m-1)\phi w_{xx}+\left[(m-1)\phi\frac{\phi''}{\phi'}+\phi'\right]w_x^2-c\frac{\phi^\beta}{\phi'}.$$

Now we differentiate with respect to x, multiply by $w_x\zeta^2$ and consider a point (x_0,t_0) of S_T where the function (x_0,t_0) of $S_T$where the function $z=\zeta^2w_x^2$ attains a maximum, so that we have $z_t\geqq 0$, $z_x=0$, $z_{xx}\leqq 0$ at (x_0,t_0) and $t_0>0$ (unless $z\equiv 0$, a case we may disregard). It then follows that at such a point:

(3.4)

$$\left[-m\phi''-(m-1)\phi\left(\frac{\phi''}{\phi'}\right)'\right]\zeta^2w_x^4\leqq\left[\zeta\zeta_t+2(m-1)\phi\zeta_x^2-(m-1)\phi\zeta\zeta_{xx}-c\left(\frac{\phi^\beta}{\phi'}\right)'\zeta^2\right]$$
$$\cdot w_x^2-\left[(m+1)\phi'+2(m-1)\phi\frac{\phi''}{\phi'}\right]\zeta\zeta_xw_x^3.$$

Now set

$$a_1=\max|\zeta_t|,\quad a_2=\max|\zeta_x|,\quad a_3=\max|\zeta_{xx}|,$$

and assume that there are positive constants b_i, $i=1,\cdots,4$ such that

$$0<Nb_1\leqq\phi'\leqq Nb_2,\quad \phi''\leqq -Nb_3,\quad |\phi''/\phi'|\leqq b_4. \tag{3.5}$$

Taking also into account that $(\phi^\beta/\phi')'\geqq 0$, we can disregard this term. We then get:

$$\zeta^2w_x^4\leqq c_1w_x^2+c_2\zeta|w_x|^3,$$

where

$$c_1=\frac{1}{Nmb_3}(a_1+N(m-1)a_3+2N(m-1)a_2^2),$$

$$c_2=\frac{a_2}{mb_3}((m+1)b_2+2(m-1)b_4).$$

Since for every $\delta>0$, $c_2\zeta|w_x|^3\leqq\delta\zeta^2w_x^4+c_2^2w_x^2/4\delta$, we get

$$(1-\delta)\zeta^2w_x^4\leqq\left(c_1-\frac{c_2^2}{4\delta}\right)w_x^2.$$

Therefore for every $(x,t)\in S_T$ we have

$$z(x,t)\leqq\max z\leqq\frac{1}{1-\delta}\left(c_1+\frac{c_2^2}{4\delta}\right). \tag{3.6}$$

Since this bound depends on ζ and ϕ, we now fix a point $(x_1,t_1)\in S_T$ and make a suitable selection of these functions. We begin with ζ: we choose

$$\zeta_n(x,t)=\frac{t}{t_1}\psi\left(\frac{x-x_1}{n}\right), \tag{3.7}$$

where $\psi \in C_0^\infty(R)$ satisfies $0 \leqq \psi \leqq 1$, $\psi(x)=1$ if $|x| \leqq 1$, $\psi(x)=0$ if $|x| \geqq 2$. Plugging ζ_n into (3.4) we obtain (3.6) with constants c_{1_n}, c_{2_n} depending on a_{1_n}, a_{3_n}. Now $a_{1_n}=1/t_1$ whereas a_{2_n}, $a_{3_n} \to 0$ as $n \to \infty$. Thus passing to the limit we obtain from (3.6)

$$w_x^2(x_1,t_1)=z(x_1,t_1) \leqq \frac{1}{Nmb_3t_1}$$

and noting that $v_x=\phi'(w)w_x$ and $x_1, t_1>0$ were arbitrary, we arrive at

$$v_x^2(x,t) \leqq \frac{Nb_2^2}{mb_3t} \quad \text{for every } (x,t) \in S_T. \tag{3.8}$$

Now we choose a suitable ϕ. For this purpose we consider the simplest form that satsfies $(\phi''/\phi')' \leqq 0$ as well as (3.5), namely

$$\phi(r)=Nr(a-br), \qquad a,b>0.$$

Then $\phi(1) \geqq N$ if $a \geqq b+1$, ϕ is strictly increasing in $[0,1]$ if $a \geqq 2b$ and we have $b_2=a$, $b_3=2b$. Thus (3.8) becomes

$$v_x^2(x,t)=\frac{Na^2}{2mbt}. \tag{3.9}$$

The second member above is to be minimized with respect to a,b subject to the conditions $a,b>0$, $a \geqq b+1$, $a \geqq 2b$. This happens for $a=2$, $b=1$ for which (3.9) gives (3.2).

To prove (3.3) we may assume that $t_1=0$ and $w \in C(\bar{S}_T)$ by displacing the origin of the times. We then repeat the previous argument taking now

$$\zeta_n(x,t)=\psi\left(\frac{x-x_1}{n}\right)$$

to conclude that at any interior maximum of w_x^2, $w_x=0$ so that the maximum is achieved at $t=0$.

Proof of Theorem 1. Let us consider first the case $n \geqq 1$. Then for every real x and $0 \leqq t_1 \leqq t_2$, $u(x,t_1)>0$ implies $u(x,t_2)>0$ (see [Kn2], [Ke2]). Therefore if we assume that $u_0(x)$ is positive everywhere, so is $u(x,t)$ in S and, as stated in §1, Theorem 0, $u \in C^\infty(S)$. Since the change of variables $v=(m/(m-1))u^{m-1}$ transforms (0.1) into (3.1) with

$$\beta=\frac{m+n-2}{m-1}, \qquad c=\lambda m\left(\frac{m-1}{m}\right)^\beta, \tag{3.10}$$

it then follows that estimates (2.5), (2.6) are a consequence of Lemma 3.1. When $u_0(x)$ is only nonnegative, we just approach it by strictly positive data $u_0(x)$ such that $u_{0j}(x) \to u_0(x)$ as $j \to \infty$ uniformly on compact subsets of $\mathbb{R}$ and use part iv) in Theorem 0 to conclude the result.

When $2-m \leqq n<1$ we no longer can deal with smooth positive solutions of (0.1), (0.2), since solutions may disappear after a finite time (see [K2]). We then start from problems (1.3) with, say, $\varepsilon=1/j$ for $j=1,2,\cdots$. Then the estimates hold true for each $u_j(x,t)$, since in applying Bernstein's technique to the equation for $v_\varepsilon=(m/(m-2))u_\varepsilon^{m-1}$ it happens, as in Lemma 3.1, that the perturbation which appears with respect to the case $\lambda=0$ has the right sign and may be dropped (see for instance [Ke2, pp. 1957–1958] for this detail). Therefore letting $j \to \infty$ (2.5), (2.6) follow.

Remark. Estimate (3.2) does not depend on λ, so that it even applies to the case $\lambda=0$. However the constant in (3.2) is not best possible; for instance when $\lambda=0$ one has

$$v_x^2(x,t)\leqq\frac{2}{m+1}\|v(x,0)\|_\infty t^{-1}, \tag{3.11}$$

(see Vâzquez [V2]), a result which is sharp in view of the explicit solutions (2.3).

4. Semiconvexity of the pressure. This section is devoted to the proof of Theorem 2. To this aim we shall proceed in three steps.

i) The core of the proof lies in the following formal argument. Let $v=(m/(m-1))u^{m-1}$ where u is a smooth positive solution of (0.1) and c, β are given in (3.10). As in Aronson and Bénilan [AB] we set $p=v_{xx}$ and differentiate twice in (3.1) with respect to x to get

$$\begin{aligned} p_t=(m-1)vp_{xx}+2mv_xp_x+(m+1)p^2-c\beta v^{\beta-1}p \\ -c\beta(\beta-1)v^{\beta-2}v_x^2. \end{aligned} \tag{4.1}$$

Let us consider now the differential operator:

$$L\theta=(m-1)v\theta_{xx}+2mv_x\theta_x-c\beta v^{\beta-1}\theta+(m+1)\theta^2-\theta_t. \tag{4.2}$$

It then follows from (4.1) and estimates (2.10), (2.11) that

$$Lp=c\beta(\beta-1)v^{\beta-1}v_x^2\leqq\frac{2^\sigma(m+n-2)}{m(m-1)t^2}.$$

Take now $\hat{p}(x,t)=-k/t$ where $k>0$ is some positive constant to selected later. One then has

$$p\geqq\hat{p} \quad \text{at } t=0 \tag{4.3}$$

and on the other hand

$$L\hat{p}=(m+1)\hat{p}^2-c\beta v^{\beta-1}\hat{p}-\hat{p}_t\geqq(m+1)\frac{k^2}{t^2}-\frac{k}{t^2}.$$

Thus we obtain $L\hat{p}\geqq Lp$ in S if

$$(m+1)k^2\geqq k+\frac{2^\sigma(m+n2)}{m(m-1)}. \tag{4.4}$$

A simple choice for k is, for instance,

$$k=\frac{1}{m+1}+\left(\frac{2^\sigma(m+n-2)}{m(m^2-1)}\right)^{1/2}. \tag{4.5}$$

By the maximum principle it then follows that $p\geqq\hat{p}=-k/t$ in S.

ii) We next show how to justify this argument in the case where v is smooth in S_T, $T>0$, and satisfies there

$$v\leqq\Lambda, \quad |v_x|\leqq\mu, \quad v_{xx}\geqq-\nu \tag{4.6}$$

where Λ, μ, ν are some positive constants. Fix $\tau>0$ such that $\tau<\min(k/\nu, T)$, where k is given in (4.5). Now write $S_{\tau,T}=\mathbb{R}\times(\tau,T\,|$ and define

$$p^*(x,t)=-\frac{k}{t-\tau'}$$

where $0<\tau'<\tau$. Then if L is the differential operator in (4.2) one has upon replacing t by $(t-\tau')$ in estimates (2.10), (2.11)

$$Lp^*\geqq Lp \quad \text{in } S_{\tau,T},$$

whereas, by the choice of τ and the fact that $\tau'<\tau$, one has $p^*(x,t)\leqq p(x,\tau)$. From the maximum principle, cf. [IKO, Thm. 8], it follows that $p^*\leqq p$ in $S_{\tau,T}$ (though the operators in [IKO] are linear, the proof applies unchanged). Then let $\tau\downarrow 0$ to conclude, since $T>0$ is arbitrary.

iii) It only remains to show that under our current assumptions on n,m and u_0, $v(x,t)$ can be approximated by smooth solutions of (3.1) $v_j(x,t)$ $(j=1,2,\cdots)$ satisfying (4.6) with bounds possibly depending on j. To this aim we select a sequence $v_0^j(x)$ as follows:

> For each fixed $j, v_0^j(x)\in C^\infty(\mathbb{R}); v_0^j(x)>1/j$ in $\mathbb{R}$, $v_0^j(x)$, $|v_{0_x}^j(x)|$ and $|v_{0_{xx}}^j(x)|$ are bounded in $\mathbb{R}$ and $v_0^j(x)\rightarrow v_0(x)$ uniformly on compact subsets of $\mathbb{R}$.

We consider the Cauchy problem corresponding to (3.1) (where c,β are given in (3.10)) with initial datum v_0^j. Since the generalized solution $v_j(x,t)$ is such that $v_j(x,t) >(j^{n-1}+\lambda(n-1)t)^{-(1/n-1)}$, the exact solution with initial data $1/j$, the equation is then uniformly parabolic in each strip S_T with $T>0$. Then by classical results [LSU, Chap. V, Thm. 8] $v_j(x,t)$ is smooth and satisfies (4.6). Hence $p_j=v_{jxx}$ satisfies (2.12) and letting $j\rightarrow\infty$ the same is true for p.

Remark. The constant k in (4.5), which is independent of λ, is clearly not the best possible. This is not surprising, in view of our remark in §3, since we use (3.2) to calculate it. When $\lambda=0$, the best constant is $1/(m+1)$, as shown in [AB]. For $\lambda>0$ and $n=m$ one also can check (2.12) against the explicit solutions obtained by Bertsch, Kersner and Peletier [BKP2] which are of the form:

$$(y(x,t))^{m-1}=\frac{1}{f(t)}\left\{\rho-\frac{ch(\alpha x)-1}{g(t)}\right\}_+$$

where $\rho>0$ is arbitrary, $\alpha=\sqrt{\lambda}((m-1)/m)$ and f,g are positive increasing functions which in particular satisfy

$$(fg)'=a(\rho g+1) \quad \text{with } a=\frac{\lambda(m^2-1)}{m}.$$

In the support of y we thus have for $\bar{v}=(m/(m-1))y^{m-1}$

$$\bar{v}_{xx}=-\frac{\lambda(m-1)}{m}\cdot\frac{ch(\alpha x)}{fg}\geqq-\frac{\lambda(m-1)}{m}\frac{\rho g+1}{fg}.$$

Now since $(fg)(t)\geqq a\int(\rho g+1)\,dt\geqq at$ and $\rho/f=\sup y^{m-1}$ one gets, using (2.10),

$$\bar{v}_{xx}\geqq-\frac{k_1}{t} \quad \text{where } k_1=\left(\frac{1}{m+1}+\frac{1}{m}\right),$$

whereas our estimate reads

$$\bar{v}_{xx} \geqq -\frac{k}{t} \quad \text{where } k = \left(\frac{1}{m+1} + \frac{4}{\sqrt{m(m+1)}} \right).$$

5. The free boundary. This section is devoted to the study of the propagation properties of the solutions of problem (0.1), (0.2) under the hypotheses $m>1$, $n \geqq m$, u_0 continuous, nonnegative and bounded, plus the support condition (0.6):

$$\sup\{x:\ u_0(x)>0\} = d < +\infty.$$

Under the stronger hypothesis that u_0 is positive in a finite interval, say $(-d,d)$ with $0<d<+\infty$, and zero otherwise, the set $P=P[u] \equiv \{(x,t) \in S:\ u(x,t)>0\}$ has been studied by several authors: Kalashnikov [K2], Kersner [Ke1], Knerr [Kn2], $\cdots$. They prove that there exist two functions $\zeta_1(t)$, $\zeta_2(t) \in C[0,\infty) \cap C^{0,1}(0,\infty)$ such that $\zeta_1(0) = (-1)^i d$ $(i=1,2)$ and $P(t) \equiv \{x \in \mathbb{R}:\ (x,t) \in P\}$ is the interval $(\zeta_1(t), \zeta_2(t))$. In addition $(-1)^i \zeta_i(t)$ is nondecreasing and $|\zeta_i(t)| \to \infty$ as $t \to \infty$ for $i=1,2$. Actually these properties are true for $n \geqq m$, but not for $n<m$ (cf. [K2], [Ke3]). The curves $x=\zeta_i(t)$ are called *interfaces* or *free boundaries*. The proofs of these results can be easily adapted to our situation; then we obtain the existence of a *right-hand interface* $x=\zeta(t)= \sup\{x:\ u(x,t)>0\}$ with the above properties.

In the nonabsorption case $\lambda=0$ much more is known about the free boundaries: equation satisfied on the interface, C^1 regularity of $\zeta(t)$ (cf. [A1], [Kn1], [CF]). It is possible that the interface remains stationary for t less than or equal to a certain time $t^*[0,\infty)$, called *waiting time*, after which it moves with positive velocity: $\zeta'(t)>0$ if $t>t^*$ [K1], [Kn1]. The existence of a waiting time has been characterized by one of the authors [V3], and the behavior of ζ near t^* is studied in [ACK], [LOT] and [ACV].

It is our purpose to use the regularity results of the preceding chapters to prove similar facts for the absorption case $\lambda>0$. Our first result is the following theorem.

THEOREM 3. *Let u be the solution of* (0.1), (0.2) *under the conditions above, and let $x=\zeta(t)$ be the right-hand free boundary. For every $t>0$ the right-hand derivative $D^+\zeta(t)$ exists and*

$$D^+\zeta(t) = -v_x(\zeta(t),t), \tag{5.1}$$

where $v_x(\zeta(t),t)$ is understood as $\lim v_x(x,t)$ *as $x \to \zeta(t)$, $x<\zeta(t)$.*

Proof. The line of argument parallels that of the nonabsorption case $\lambda=0$, and uses Theorem 2 followed by suitable comparisons.

i) Since $v \leqq C$ and $v_{xx} \geqq -C \cdot t^{-1}$ for some $C>0$, the function $x \mapsto v(x,t)+Cx^2/2t$ is convex in $\mathbb{R}$ for every $t>0$, and hence it has one-sided derivatives at every point. Therefore the limit $v_x(\zeta(t),t)$ appearing in (5.1) exists for each $t>0$.

ii) To prove (5.1) at $t=t_0>0$, we first consider the solution $\hat{u}(x,t)$ of the problem:

$$\begin{aligned} &\hat{u}_t = (\hat{u}^m)_{xx} \quad \text{for } x \in \mathbb{R}, \quad t>t_0, \\ &\hat{u}(x,t_0) = u(x,t_0) \quad \text{for } x \in \mathbb{R}. \end{aligned} \tag{5.2}$$

It is clear (see e.g. [Ke2, Thm. 3]) that $\hat{u}$ is a supersolution for our problem when $t \geqq t_0$, so that by Theorem 0, part iii) $\hat{u}(x,t) \geqq u(x,t)$ for such t. Hence $\hat{\zeta}(t) \geqq \zeta(t)$ if $t>t_0$ and $\hat{\zeta}(t_0) = \zeta(t_0)$, $\hat{\zeta}$ being the interface for $\hat{u}$. Now for problem (5.2) the result holds, $D^+\hat{\zeta}(t_0) = -v_x(\hat{\zeta}(t_0),t_0)$ and therefore

$$\limsup_{h \to 0} \frac{1}{h}(\zeta(t_0+h) - \zeta(t_0)) \leqq -v_x(\hat{\zeta}(t_0),t_0). \tag{5.3}$$

Next we consider the problem:

$$(5.4)\qquad \begin{cases} \bar{u}_t=(\bar{u}^m)_{xx}-\lambda_0\bar{u} & \text{if } x\in\mathbb{R},\ t>t_0,\\ \bar{u}(x,t)=u(x,t_0) & \text{if } x\in\mathbb{R}, \end{cases}$$

where $\lambda_0=((n-1)t_0)^{-1}$, so that by (2.10) $\lambda u^n \leqq \lambda_0 u$. Then $u(x,t)$ is a supersolution for (5.4) for $t\geqq t_0$. On the other hand (5.4) can be converted into a nonabsorption problem by means of (2.13) and it is not difficult to see that $D^+\bar{\zeta}(t_0)=-v_x(\bar{\zeta}(t_0),t_0)$ also holds. Therefore

$$(5.5)\qquad \liminf_{h\to 0}\frac{1}{h}(\zeta(t_0+h)-\zeta(t_0))\geqq D^+\bar{\zeta}(t_0)=-v_x(\zeta(t_0),t_0)$$

and the theorem is proved.

We now extend the characterization of the existence of a positive waiting-time to our absorption case.

THEOREM 4. *Let $u(x,t)$, $u_0(x)$, $\zeta(t)$, m as above and let $n\geqq 1$. Let $t^*=\sup\{t\geqq 0$: $\zeta(t)=d\}$. Then t^* is positive if and only if*

$$(5.6)\qquad \sup_{x<d}\left((d-x)^{-(m+1)/(m-1)}\int_x^d u_0(s)\,ds\right)<+\infty.$$

Proof. If (5.6) holds we consider the solution $\hat{u}$ of (5.2) with $t_0=0$. By the results of [V3] we then have a positive waiting-time $\hat{t}_i^*$ for $\hat{\zeta}$. Since $\hat{u}\geqq u$, we conclude that $t_i^*\geqq \hat{t}_i^*>0$.

Conversely, if u does not satisfy (5.6), the solution of (5.2) with $t_0=0$ has a zero waiting time. By the change of variables (2.13) the same is true for the solution $\hat{u}$ of (5.4) with $t_0=0$ and λ_0 arbitrary. But choosing λ_0 large enough $\bar{u}(x,t)<u(x,t)$ whence $t_i^*<\bar{t}_i^*=0$.

Our next result deals with the behavior of $\zeta(t)$ after a waiting time.

THEOREM 5. *Under the assumptions of Theorem* 3, $\zeta(t)\in C^1(t^*,\infty)$, $\zeta'(t)>0$ *for* $t>t^*$ *and the function*

$$(5.7)\qquad \zeta'(t)\cdot t^{\rho}$$

is nondecreasing when $t>t^*$ for a certain $\rho=\rho(m,n)>0$ (see (5.13)).

Remark. When $\lambda=0$ it has been proved in [V1] that (5.7) holds with $\rho_0=m/(m+1)$ which is sharp. In particular for the Barenblatt solutions (2.3) $\zeta'(t)t^{\rho_0}$ is constant.

Proof of Theorem 5. i) We first prove a weak version of (5.7). At any point $t_1>t^*$ with $D^+\zeta(t_1)>0$ we adapt a subsolution $\bar{u}(x,t)$ to (0.1) in the strip $\mathbb{R}\times(t_1,\infty)$ satisfying $\bar{u}(x,t_1)\leqq u(x,t_1)$ and such that $\bar{u}$ has a good contact with u at $x=\zeta(t_1)$; namely we require that the corresponding interface and pressure, $\bar{\zeta}(t)$ and $\bar{v}(x,t)$, satisfy

$$(5.8)\qquad \begin{aligned} &\bar{\zeta}(t_1)=\zeta(t_1),\\ &\bar{\zeta}'(t_1)=D^+\zeta(t_1) \qquad (\text{i.e. } \bar{v}_x(\zeta(t_1),t_1)=v_x(\zeta(t_1),t_1)),\\ &\bar{v}_{xx}(x,t_1)=-\frac{k}{t_1}, \qquad k \text{ as in } (2.12). \end{aligned}$$

To this aim we start from $\hat{u}(x,t)$ given as in (2.3) by

$$(5.9)\qquad \hat{u}(x,t)=t^{-1/(1+m)}\left[p-\frac{m-1}{2m(m+1)}(x\cdot t^{-1/(1+m)})^2\right]_+^{1/(m-1)}$$

where $\rho > 0$ is to be selected presently. Now for $\lambda_1 > 0$ fixed we consider the solution of $u_t = (u^m)_{xx} - \lambda_1 u$ obtained from (5.9) through transformation (2.13). This reads

$$\bar{u}_{p,\lambda_1}(x,t) = e^{-\lambda_1 t}\left(\frac{1}{\lambda_1(m-1)}\right)^{-1/(m+1)}\left(1-e^{-\lambda_1(m-1)t}\right)^{-1/(m+1)}$$

$$\cdot\left[p - \frac{m-1}{2m(m+1)}\left(\frac{1}{\lambda_1(m-1)}\right)^{-2/(m+1)}\left(1-e^{-\lambda_1(m-1)t}\right)^{-2/(m+1)}x^2\right]_+^{1/(m-1)}.$$

We now set

$$\bar{u}(x,t) = \bar{u}_{p,\lambda_1}(x-x_0, t-\tau) \equiv \bar{u}(x,t;\lambda_1,p,x_0,\tau) \tag{5.10}$$

with

$$\lambda_1 = ((n-1)t_1)^{-1}$$

so that by estimate (2.10) $\lambda_1 \bar{u} \geqq \lambda \bar{u}^n$ and $\bar{u}$ is a subsolution to (0.1). Next we determine x_0, τ, p from (5.8). This last can be done in a unique way. In particular τ is obtained from the third condition in (5.8) which reads

$$\exp\left(\frac{m-1}{n-1}\left(1-\frac{\tau}{t_1}\right)\right) - 1 = \frac{m-1}{k(m+1)(n-1)},$$

whereas x_0, p are determined from

$$\zeta(t_1) - x_0 = \frac{t_1}{k}\cdot D^+\zeta(t_1),$$

$$\frac{t_1}{k}\cdot D^+\zeta(t_1) = \left(\frac{2m(m+1)p}{m-1}\right)^{1/2}\left(\frac{(n-1)t_1}{m+1}\right)^{1/(m+1)}\left(1-\exp\left(\frac{1-m}{n-1}\left(1-\frac{\tau}{t_1}\right)\right)\right)^{1/(m+1)}.$$

It follows easily from (5.8) that $u(x,t_1) \geqq \bar{u}(x,t_1)$. By the choice of λ_1, $u(x,t) \geqq \bar{u}(x,t)$ for $t \geqq t_1$ and therefore $\zeta(t_1+h) \geqq \bar{\zeta}(t_1+h)$ for any $h > 0$. Hence

$$\zeta(t_1+h) - \zeta(t_1) - hD^+\zeta(t_1) \geqq \bar{\zeta}(t_1+h) - \bar{\zeta}(t_1) - h\bar{\zeta}'(t_1). \tag{5.11}$$

On the other hand it follows from (5.10) that

(5.12)

$$\bar{\zeta}(t) = x_0 + \left(\frac{2m(m+1)p}{m-1}\right)^{1/2}\left(\frac{(n-1)t_1}{m+1}\right)^{1/(m+1)}\left(1-\exp\left(\frac{(1-m)(t-\tau)}{(n-1)t_1}\right)\right)^{1/(m+1)}$$

so that $\bar{\zeta}(t)$ is a C^∞-function for $t > \tau$, and the second member in (5.11) can be written as $h^2/2\cdot\bar{\zeta}''(t_1) + O(h^3)$. Besides one easily checks on (5.12) that:

$$\bar{\zeta}''(t_1) = -\rho\frac{\bar{\zeta}'(t_1)}{t_1} \quad \text{with } \rho = \left(\frac{m-1}{n-1} + mk\right). \tag{5.13}$$

We now divide (5.11) by h^2 to obtain

$$F_h(t) = \frac{2}{h^2}\left[\zeta(t+h) - \zeta(t) - hD^+\zeta(t)\right] \geqq -\frac{\rho}{t}D^+\zeta(t) + O(h) \tag{5.14}$$

at any point t_1 where $D^+\zeta(t_1)>0$. It is obvious that (5.14) also holds at t_1 if $D^+\zeta(t_1)=0$ (with $O(h)\equiv 0$ in this case). On the other hand, it follows from (5.12) that $O(h)$ is uniform in t. Therefore letting $h\to 0$ we obtain

$$\zeta''(t) \geqq -\frac{\rho}{t}D^+\zeta(t), \qquad t>0, \tag{5.15}$$

where ζ'' is to be understood in the sense of distributions. Since $\zeta(t)$ is locally Lipschitz continuous in $(0,\infty)$, $D^+\zeta(t)=\zeta'(t)$ a.e. and (5.15) may be rewritten as

$$(\zeta'(t)\cdot t^\rho)' \geqq 0 \quad \text{in } \mathscr{D}'(0,\infty). \tag{5.16}$$

Assume now that $\rho<1$. Then (5.16) means that the function $\eta(\tau)=\zeta(t)$ with $\tau=(1-\rho)^{-1}t^{1-\rho}$ is convex for $0\leqq\tau<\infty$. Therefore the lateral limits $D^+\eta(\tau)$, $D^-\eta(\tau)$ exist for every $\tau>0$, they are nondecreasing functions of τ, and

$$D^+\eta(\tau)\geqq D^-\eta(\tau)\geqq D^+\eta(\tau-h) \quad \text{for } \tau>\tau-h>0.$$

Since $D^{\pm}\eta(\tau)=D^{\pm}\zeta(t)\cdot t^\rho$, we then conclude that

$$\begin{aligned} &D^+\zeta(t)\cdot t^\rho,\ D^-\zeta(t)\cdot t^\rho \quad \text{are nonnegative and nondecreasing,} \\ &D^+\zeta(t)\geqq D^-\zeta(t)\geqq D^+\zeta(t-h)\left(1-\frac{h}{t}\right)^\rho \quad \text{for every } t>t-h>t^*. \end{aligned} \tag{5.17}$$

The same result is obtained if $\rho\geqq 1$, but now we have to take $\tau=\log t$ if $\rho=1$ and $\tau=-(\rho-1)t^{-(\rho-1)}$ if $\rho>1$. Note that (5.17) implies that once the interface starts it never stops.

ii) We have yet to prove that $D^+\zeta(t)=D^-\zeta(t)$ for every $t>t^*$ to obtain that $\zeta\in C^1(t^*,\infty)$ and (5.7) holds. But once the estimates on v_x (2.5) and v_{xx} (2.12) have been established, this can be done by repeating, with some minor modifications, the arguments in [ACK, Thm. B], for the case $\lambda=0$. We just indicate here for completeness an important auxiliary tool that is used in the proof and has some independent interest.

LEMMA 5.1. *Let $v=(m/(m-1))u^{m-1}$, where $u=u(x,t)$ is the solution of* (0.1), (0.2) *under our current hypotheses, and assume that*

$$-v_x(\zeta(t_0),t_0)=\gamma$$

for some $t_0>0$, $\gamma>0$. Then in a neighborhood of $(\zeta(t_0),t_0)$ one has

$$v(x,t)=L_\gamma(x-\zeta(t_0),t-t_0)+o(|x-x_0|+|t-t_0|)$$

where

$$L_\gamma(x,t)=(\gamma^2 t-\gamma x)_+.$$

This result is in [ACK, Prop. 2.3] when $\lambda=0$. The case $\lambda>0$ offers no difficulties.

6. Asymptotic behavior. In this section we study the asymptotic behavior of the solution of (0.1), (0.2) with $1<m\leqq n$. We also study the behavior of the interface $\zeta(t)$ when u_0 satisfies (0.6).

We shall use the following notation: If $f(t)$, $g(t)$ are nonnegative functions defined for all large $t>0$ we write:

i) $f(t)=O(g(t))$ if there exists a constant $C>0$ such that $f(t)\leqq Cg(t)$ for all large enough t.

ii) $f(t)\sim g(t)$ if $f(t)=O(g(t))$ and $g(t)=O(f(t))$.

Our main contribution is the description of different behaviors if $n>m+2$.

6.1. The case $n>m+2$. It follows from (2.10) that $\|u(\cdot,t)\|_\infty=O(t^{-1/(n-1)})$; this bound is due to the effect of the absorption and holds for all initial data. A stronger bound $O(t^{-1/(m+1)})$ holds for all solutions with intial data $u_0\in L^1(\mathbb{R})$, cf (2.7), which coincides with the one obtained in the pure diffusion case $\lambda=0$. We show next that both rates can be exact.

THEOREM 6. *Let $u_0\in L^1(\mathbb{R})$. Then*

$$u(\cdot,t)\sim t^{-1/(m+1)} \tag{6.1}$$

uniformly on sets of the form $|x|\leqq ct^{1/(m+1)}$, with $c>0$ small enough. If (0.6) *holds, one then has*

$$\zeta(t)\sim t^{1/m+1}, \qquad \zeta'(t)=O(t^{-m/(m+1)}). \tag{6.2}$$

Proof. The estimates on u_0 and ζ when u_0 has compact support are due to Kersner [Ke1]. In fact he constructs subsolutions of the form

$$w(x,t)=\sigma(t+\tau)^{-1/(m-1)-\varepsilon}\left(\rho-x^2(t+\tau)^{\varepsilon(m-1)-2/(m+1)}\right)_+^{1/(m-1)}, \tag{6.3}$$

where $\varepsilon>0$ must be small but otherwise arbitrary, and θ,τ,ρ are positive constants that can be selected independently of ε. It is clear by comparison of u with w for suitably chosen θ,τ,ρ that the rates in (6.1), (6.2) serve as lower bounds for every solution.

To obtain the upper bounds we observe that (6.1) comes from (2.7) and that (6.2) is a consequence of estimate (2.9) for v_x with $p=1$ and formula (0.5); we obtain thus $\zeta'(t)=O(t^{-m/(m+1)})$ and by integration the corresponding one for $\zeta(t)$.

We now obtain solutions with maximal rates.

THEOREM 7. *Assume that $u_0(x)\geqq\delta>0$ for all $x<0$, $|x|$ large. Then*

$$\lim_{t\to\infty}\|u(\cdot,t)\|_\infty t^{1/(n-1)}=(\lambda(n-1))^{-1/(n-1)} \tag{6.4}$$

and $u\sim t^{-(1/(n-1))}$ uniformly on sets of the form $x<ct^{n-m/(2(n-1))}$, $c>0$ small. If (0.6) *holds one has*

$$\zeta(t)\sim t^{n-m/(2(n-1))}, \qquad \zeta'(t)=O\left(t^{-\frac{n+m-2}{2(n-1)}}\right). \tag{6.5}$$

Proof. To get the upper bounds we argue as before: using (2.10) and (0.5) we obtain the bound for ζ', and by integration the one for ζ. The corresponding case in (6.4) comes also from (2.10).

For the lower bounds we construct a new subsolution as follows: Let $z=z(x,t)$ be the solution of the porous medium equation $z_t=(z^m)_{xx}$ with initial datum $z_0(x)$ defined by $z_0(x)=a>0$ if $x<0$, $z_0(x)=0$ if $x>0$. It is shown in [V3] that for each a there exists a unique generalized solution of the form

$$z(x,t)=f(x,t^{-1}/2), \tag{6.6}$$

where f: $\mathbb{R}\to\mathbb{R}$ satisfies

$$\begin{aligned}&(f^m)''(\xi)+\frac{1}{2}\xi f'(\xi)=0, \qquad \xi\in\mathbb{R},\\ &f(-\infty)=a, \qquad f(+\infty)=0.\end{aligned} \tag{6.7}$$

Moreover there exists $\xi_0 = \xi_0(a,m) > 0$ such that $0 < f(\xi) < a$ for $x < \xi_0$ and $f(\xi) = 0$ for $x \geqq \xi_0$. Now we set

$$w(x,t) = \sigma(t+\tau)^{-1/(n-1)} f\left((x-x_0)(t+\tau)^{-n-m/(2(n-1))}\right) \tag{6.8}$$

for some constants σ, x_0, τ such that σ, $\tau > 0$. We now impose the condition

$$\begin{aligned} Lw &\equiv w_t - (w8Um)_{xx} + \lambda w^n \\ &= \sigma(t+\tau)^{-(n/(n-1))}\left[-\frac{n-m}{2(n-1)}\eta f'(\eta) - \frac{1}{n-1} f(\eta) \right. \\ &\qquad \left. - \sigma^{m-1}(f^m)''(\eta) + \lambda\sigma^{n-1} f^{n-1}(\eta) \right] \\ &\leqq 0 \end{aligned} \tag{6.9}$$

where $\eta = (x-x_0)(t+\tau)^{-((n-m)/(2(n-1))}$. Now (6.9) is satisfied if we choose

$$\sigma = \left(\frac{n-m}{n-1}\right)^{1/(m-1)}, \qquad a\sigma = ((n-1)\lambda)^{-1/(n-1)}.$$

In order that $w(x,0) \leqq z_0(x)$ we choose appropriately x_0 and τ. It then follows that

$$u(x,t) \geqq w(x,t), \qquad \zeta(t) \geqq \zeta_w(t) = x_0 + \xi_0(t+\tau)^{n-m/2(n-1)} \tag{6.10}$$

where $\zeta_w(t)$ is the interface corresponding to $w(x,t)$. Taking into account that $\|w(x,t)\|_\infty = \sigma a(t+\tau)^{-(1/(n-1))}$ the estimates follow.

Remarks. 1) The subsolution (6.8) can be constructed for $n > m$. Therefore Theorem 7 holds for this range of n's.

2) We have shown the two extreme cases. Results for intermediate classes of initial data are not difficult to obtain in many instances. To point out a simple fact if $u_0 \in L^p(\mathbb{R})$, $1 < p < \infty$, we have by (2.7)

$$u(x,t) = O(t^{-\theta}), \qquad \theta = (2p+m-1)^{-1}, \tag{6.11}$$

uniformly in x. Arguing as above it follows that

$$\zeta'(t) = O(t^{-(p+m-1/(2p+m-1))}), \qquad \zeta(t) = O(t^{+(p/(2p+m-1))}), \tag{6.12}$$

as $t \to \infty$.

3) In the nonabsorption case, $\lambda = 0$, a very detailed description of the asymptotic behavior is available, cf. [V3] and its references.

6.2. Case $m \leqq n < m+2$. In this case there is only one type of asymptotic behavior summarized in the following result that extends Theorem 7 (see Remark 1 above).

THEOREM 8. *Let $m < n < n+2$ (resp. $n = m$) and let u be a solution of* (0.1), (0.2). *Then as $t \to \infty$*

$$u(\cdot,t) \sim t^{-1/n-1} \tag{6.13}$$

uniformly on sets of the form $|x| \leqq ct^{n-m/(2(n-1))}$ (resp. $|x| \leqq c \log t$) for c small. Moreover if u_0 satisfies (0.6) *we have*

$$\zeta'(t) = O(t^{-((m+n-2)/(2(n-1)))}), \qquad \zeta(t) \sim t^{((n-m)/(2(n-1)))} \tag{6.14}$$
$$\times \left(\textit{resp. } \zeta'(t) = O(t^{-1}), \ \zeta(t) \sim \log t\right).$$

Proof. This result was essentially known. Thus in [Ke1], [BKP1], the lower estimates are obtained by means of suitable subsolutions. As to the upper bounds, (6.13) comes from (2.10) and the estimate $\zeta'(t)=O(t^{-((m+n-2)/(2(n-1)))})$ (resp. $\zeta'(t)=O(t^{-1})$) is obtained as in Theorem 6 above. By integration we obtain (6.14).

A related argument to obtain the upper bounds is explained in [H]. For another argument see [BKP1]. In both cases u_0 has compact support.

A VOLTERRA EQUATION WITH L^2-SOLUTIONS*

STIG-OLOF LONDEN†

Abstract. Consider the nonlinear Volterra equation $x'(t)+\int_0^t a(t-s)g(x(s))\,ds=f(t)$ where a is strongly positive and $f\in L^2(R^+)$. We formulate sufficient conditions for bounded solutions to be square integrable on R^+. The result generalizes earlier work by Staffans [Proc. Amer. Math. Soc., 78 (1980), pp. 213–217.]

Key words. Volterra equations, Fourier transforms

AMS(MOS) subject classifications. 45D05, 45G99, 45J05, 45M05

1. Introduction. In this note we consider the asymptotic size of bounded solutions of the (scalar, real) nonlinear Volterra equation

$$x'(t)+\int_0^t g(x(t-s))a(s)\,ds=f(t),\qquad t\in R^+\equiv[0,\infty),\quad x(0)=x_0, \tag{1.1}$$

and prove the following result:

THEOREM 1. *Let $x\in L^\infty(R^+)$ be a solution of* (1.1) *on R^+ satisfying*

$$\sup_{T>0}\int_0^T \varphi(t)(a*\varphi)(t)\,dt<\infty. \tag{1.2}$$

Also assume that

$$a \text{ is strongly positive definite}, \tag{1.3}$$

$$a'\in L^1(R^+), \tag{1.4}$$

$$g\in C(R),\qquad xg(x)>0,\quad x\neq 0,\qquad 0<\liminf_{|x|\downarrow 0}\frac{g(x)}{x}, \tag{1.5}$$

$$f\in L^2(R^+). \tag{1.6}$$

Then

$$x,x'\in L^2(R^+). \tag{1.7}$$

We define $x(t)$ to be a solution of (1.1) on R^+ if x is locally absolutely continuous and satisfies (1.1) almost everywhere on R^+. Above $\varphi(t)\overset{\text{def}}{=}g(x(t))$ and $*$ denotes convolution, thus $(a*\varphi)(t)=\int_0^t a(t-s)\varphi(s)\,ds$. By definition the kernel $a(t)$ satisfies (1.3) if and only if there exists $\varepsilon>0$ such that $a(t)-\varepsilon e^{-t}$ is positive definite. From (1.4) follows that $\hat a(\omega)=\lim_{\sigma\downarrow 0}\tilde a(\sigma+i\omega)=\lim_{\sigma\downarrow 0}\int_0^\infty a(t)e^{-\sigma t-i\omega t}dt$ is well defined for $\omega\neq 0$ and consequently (1.3) amounts to

$$\operatorname{Re}\hat a(\omega)\geqq \varepsilon[1+\omega^2]^{-1},\qquad \omega\neq 0, \text{ and some } \varepsilon>0.$$

The problem concerning the asymptotic size of solutions of (1.1) has earlier been considered by Staffans [3] (where references to prior work can be found) and our

* Received by the editors December 4, 1984; accepted for publication (in revised form) November 5, 1985. This work was done while the author was visiting the Institute of Mathematics of the University of Graz, Austria.

† Institute of Mathematics, Helsinki University of Technology, 02150 Espoo 15, Finland.

theorem extends his result. Thus we show by an elementary proof that the additional assumption

$$a' \in BV(R^+)$$

which is made in [3] to obtain (1.7) is in fact unnecessary.

As in [3] one may slightly extend Theorem 1:

THEOREM 2. *Let x be as in Theorem* 1 *and suppose* (1.2), (1.3), (1.5) *hold. Assume $a = b + c$ where $b \in L^1(R^+)$ and satisfies*

$$|\hat{b}(\omega)|^2 \leqq \beta \operatorname{Re} \hat{b}(\omega), \qquad \omega \in R,$$

for some $\beta \geqq 0$,

$$c \textit{ is positive definite}, \qquad c' \in L^1(R^+).$$

Finally let $f = f_1 + f_2 + f_3$ where $f_1 \in L^2(R^+)$, $f_2 \in BV(R^+)$, $f_3 \in L^\infty(R^+)$, $f_3' \in L^2(R^+)$. Then (1.7) *is satisfied.*

The proof of Theorem 2 closely follows that of Theorem 1 and we only note that by [3, Thm. 1] we may without loss of generality assume $c \not\equiv 0$ and that the integration by parts in (2.9) is performed only with $c(t)$.

To obtain $x \in L^\infty(R^+)$ (which is postulated in Theorem 1) one needs a somewhat different hypothesis. For completeness we state the following result which is a consequence of a result in [2].

THEOREM 3. *Let x be a solution of* (1.1) *on R^+ and assume that* (1.3) *holds. Suppose f, $f' \in L^2(R^+)$ and let $\limsup_{|x| \to \infty} G(x) = \infty$. Then $x \in L^\infty(R^+)$, and* (1.2) *holds.*

Above $G(x) = \int_0^x g(u)\,du$, $x \in R$. To prove Theorem 3 multiply (1.1) by $\varphi(t)$, integrate over $[0, T]$ and use [2, Prop. 4.1].

2. Proof of Theorem 1. Note first that $(d/dt)(a * \varphi)(t) \in L^\infty(R^+)$ from which (use (1.1), $x \in L^\infty(R^+)$ and $f \in L^2(R^+)$) follows $(a * \varphi)(t) \in L^\infty(R^+)$. Consequently x' is the sum of two functions belonging respectively to $L^\infty(R^+)$ and $L^2(R^+)$.

For any $T > 0$ let $y_T \in LAC(R^+)$ satisfy $y_T(t) = 0$, $t \notin (0, T)$ and be such that for $p = 1, 2$ and some c independent of T,

$$\int_0^T |x'(\tau) - y_T'(\tau)|^2 d\tau \leqq c, \qquad \int_0^T |x(\tau) - y_T(\tau)|^p d\tau \leqq c. \tag{2.1}$$

As $x \in L^\infty(R^+)$ and by the above decomposition of x this is possible. (Below c always denotes a constant independent of T. The actual value of c changes from line to line.)

Write $\varphi_T = \chi_{[0,T]}\varphi$. From (1.2) and by Parseval's identity (see e.g. [1, p. 258])

$$\sup_{T>0} \int_R |\hat{\varphi}_T(\omega)|^2 \operatorname{Re} \hat{a}(\omega)\, d\omega < \infty, \tag{2.2}$$

and so, by (1.3),

$$\sup_{T>0} \int_{|\omega| \leqq 1} |\hat{\varphi}_T(\omega)|^2 d\omega < \infty. \tag{2.3}$$

Multiply (1.1) by $y_T'(t)$ and integrate over $[0, T]$ to get

$$(2.4)\qquad \int_0^T |y_T'(\tau)|^2 d\tau = \int_0^T y_T'(\tau) f(\tau)\, d\tau + \int_0^T y_T'(\tau)[y_T'(\tau) - x'(\tau)]\, d\tau$$
$$- \int_0^T y_T'(\tau)(a * \varphi)(\tau)\, d\tau.$$

Thus, recalling (1.6) and (2.1),

$$(2.5)\qquad \|\hat{y}_T'(\omega)\|^2_{L^2(R)} \leqq c\left[1 + \left|\int_R \overline{\hat{y}_T'(\omega)}\hat{a}(\omega)\hat{\varphi}_T(\omega)\, d\omega\right|\right].$$

Obviously $\hat{y}_T'(\omega) = i\omega\hat{y}_T(\omega)$, $\omega \in R$. Also note that as $a' \in L^1(R^+)$ then $\sup_{\omega \in R\setminus\{0\}} |\omega\hat{a}(\omega)| < \infty$. Consequently (2.3) yields

$$(2.6)\qquad \left|\int_{|\omega| \leqq 1} \overline{\hat{y}_T'(\omega)}\hat{a}(\omega)\hat{\varphi}_T(\omega)\, d\omega\right| \leqq \int_{|\omega| \leqq 1} |\omega\hat{a}(\omega)|\,|\hat{y}_T(\omega)|\,|\hat{\varphi}_T(\omega)|\, d\omega$$
$$\leqq c\left(\int_{|\omega| \leqq 1} |\hat{y}_T(\omega)|^2 d\omega\right)^{1/2}.$$

Since $|\hat{a}(\omega)| = O(|\omega|^{-1})$ and a is strongly positive definite there exists $q < \infty$ such that $|\hat{a}(\omega)|^2 \leqq q^2 \operatorname{Re}\hat{a}(\omega)$, $|\omega| \geqq 1$. Therefore by (2.2)

$$(2.7)\qquad \left|\int_{|\omega| \geqq 1} \overline{\hat{y}_T'(\omega)}\hat{a}(\omega)\hat{\varphi}_T(\omega)\, d\omega\right|$$
$$\leqq q\left(\int_{|\omega| \geqq 1} |\hat{y}_T'(\omega)|^2 d\omega\right)^{1/2}\left(\int_{|\omega| \geqq 1} \operatorname{Re}\hat{a}(\omega)|\hat{\varphi}_T(\omega)|^2 d\omega\right)^{1/2}$$
$$\leqq c\left(\int_{|\omega| \geqq 1} |\hat{y}_T'(\omega)|^2 d\omega\right)^{1/2}.$$

The estimates (2.5)–(2.7) imply

$$(2.8)\qquad \int_R |\hat{y}_T'(\omega)|^2 d\omega \leqq c\left[1 + \left(\int_{|\omega| \leqq 1} |\hat{y}_T(\omega)|^2 d\omega\right)^{1/2}\right].$$

Consider the last term on the right side of (2.4). Add and subtract an extra term and integrate parts to get

$$(2.9)\qquad \int_0^T y_T'(\tau)(a * \varphi)(\tau)\, d\tau$$
$$= -a(0)\int_0^T x(\tau)\varphi(\tau)\, d\tau + a(0)\int_0^T [x(\tau) - y_T(\tau)]\varphi(\tau)\, d\tau$$
$$- \int_0^T y_T(\tau)(a' * \varphi)(\tau)\, d\tau.$$

The absolute value of the second term on the right side of (2.9) is obviously uniformly bounded in T. For the third term we have $(d=\int_{R^+}|a'(\tau)|\,d\tau)$

(2.10)

$$\begin{aligned}\left|\int_R \overline{\hat{y}_T(\omega)}\hat{a}'(\omega)\hat{\varphi}_T(\omega)\,d\omega\right| &\leqq d\left(\int_{|\omega|\geqq 1}+\int_{|\omega|\leqq 1}\{|\hat{y}_T(\omega)||\hat{\varphi}_T(\omega)|\}\,d\omega\right)\\ &\leqq d\left(\int_{|\omega|\geqq 1}\omega^2|\hat{y}_T(\omega)|^2\,d\omega\right)^{1/2}\left(\int_{|\omega|\geqq 1}\omega^{-2}|\hat{\varphi}_T(\omega)|^2\,d\omega\right)^{1/2}\\ &\quad +c\left(\int_{|\omega|\leqq 1}|\hat{y}_T(\omega)|^2\,d\omega\right)^{1/2}\\ &\leqq c\left(\int_{|\omega|\geqq 1}|\hat{y}_T'(\omega)|^2\,d\omega\right)^{1/2}+c\left(\int_{|\omega|\leqq 1}|\hat{y}_T(\omega)|^2\,d\omega\right)^{1/2},\end{aligned}$$

where we have used (2.2), (2.3). From (2.4), (2.9), (2.10) follows (note that by positive definiteness $a(0)>0$)

$$\left|\int_0^T x(\tau)\varphi(\tau)\,d\tau\right|\leqq c\left[1+\int_R|\hat{y}_T'(\omega)|^2\,d\omega+\left(\int_{|\omega|\geqq 1}|\hat{y}_T(\omega)|^2\,d\omega\right)^{1/2}\right]$$

and hence by (2.8)

$$\left|\int_0^T x(\tau)\varphi(\tau)\,d\tau\right|\leqq c\left[1+\left(\int_{|\omega|\leqq 1}|\hat{y}_T(\omega)|^2\,d\omega\right)^{1/2}\right].$$

Together with (1.5) this implies $(x_T=\chi_{[0,T]}x)$

$$\int_R|\hat{x}_T(\omega)|^2\,d\omega\leqq c\left[1+\left(\int_R|\hat{y}_T(\omega)|^2\,d\omega\right)^{1/2}\right].$$

With the aid of (2.1) we conclude that $x\in L^2(R^+)$. From (2.1), (2.8) then follows $x'\in L^2(R^+)$.

SOLUTIONS OF A NONLOCAL CONSERVATION LAW ARISING IN COMBUSTION THEORY*

ROBERT GARDNER†

Abstract. We prove a local existence theorem for smooth solutions with Sobolev space data of a nonlinear conservation law which contains a nonlocal operator. In a certain parameter range we also prove that smooth solutions develop shocks in finite time. This gives further confirmation of the validity of the equation as an asymptotic approximation for the prediction of spontaneous Mach stem formation in solutions of the equations of reactive gas dynamics.

Key words. conservation laws, Mach stem, combustion shock formation

AMS(MOS) subject classifications. 35L, 35R

Introduction. This paper is concerned with solutions of the equation

$$(1)\qquad \begin{aligned} &u_t+Ruu_x+(R-1)\left[\int_0^\infty u(x+\beta s)u_x(x+s)\,ds\right]_x=0,\\ &u(x,0)=u_0(x), \end{aligned}$$

where $x\in\mathbb{R}^1$ (we shall suppress the t-dependence of u in the integral term). Equation (1) arises as an asymptotic approximation which governs the growth of multi-dimensional perturbations in planar detonation front solutions of the equations of reactive gas dynamics in two space variables (see Majda and Rosales [5]). In particular, if $\phi_x=u$, then ϕ describes the evolution of a 2-D perturbation in the primary planar front. In this context the formation of shocks in smooth, rapidly decaying solutions of (1) is associated with the onset of spontaneous Mach stem formation in solutions of the original system. The appearance of the additional shock and contact discontinuity at the Mach node is predicted by the first order asymptotics for the fluid components. This, together with the mechanism leading to the presence of the nonlocal term in (1), is discussed in depth in [5].

Conservation laws with nonlocal terms also arise in other contexts (see e.g. Majda and Rosales [7]), and it has been suggested that (1) may serve as an important canonical model in asymptotic approximations to multidimensional shock wave theory (see Majda [4]). It therefore seems desirable to present a framework for this type of problem in which analytical questions can be investigated. The local existence theory presented here generalizes in a straightforward manner to equations with more complicated nonlocal terms, such as those appearing in the general discussion in [5], and perhaps to systems of the type appearing in [7]. However, we shall limit the discussion to equations of the form (1). Our proof follows lines similar to those of the proof of [4, Thm. 2.1], the main difference being that the nonlocal term forces us to work in Sobolev spaces based on L^1 rather than L^2. In regard to the application of (1) to combustion theory, the existence of solutions with integrable decay in x was postulated in [5] and confirmed numerically in [6]. Such solutions were needed to construct suitable matched asymptotic expansions. Our result provides a rigorous proof of the local existence of such solutions.

* Received by the editors July 22, 1985, and in revised form December 9, 1985. This research was supported by the Deutsche Forschungsgemeinschaft and by the National Science Foundation under grant DMS 8320485.

† Department of Mathematics, University of Massachusetts, Amherst, Massachusetts 01003 and Universität Heidelberg, 6900 Heidelberg, Federal Republic of Germany.

We also prove that smooth solutions of (1) develop shocks in finite time. In the application to combustion theory, the relevant parameter range is

$$R>0, \quad R\neq 1, \quad \beta>1;$$

here, R and β depend in a complicated manner on several physical parameters (see [5], [6]). We are not aware of any analytical results on breakdown for this problem; however, there is strong numerical evidence that breakdown does indeed occur (see [6], [7]). Moreover, these numerical results indicate that solutions of (1) exhibit a strikingly rich, parameter dependent variety of phenomena. For example, when $R>1$, solutions with nonnegative data exhibit amplitude growth and oscillation through negative values in the "tail," in marked contrast to solutions of the Burgers equation. Our proof of shock formation is confined to the range $0<R<1$, where the numerics indicate that the mechanism leading to breakdown is somewhat closer to that occurring in the Burgers equation. There is also another requirement for R and β (see (iii) of Theorem 2.1), which we discuss later.

By a *solution* we shall mean a C^1 function which together with its first derivatives is integrable, and which satisfies the equation in the classical sense (actually, we require that u satisfies an equivalent equation, (10b) below, which only involves the first derivatives of u). Since (1) is in conservation form it is also possible to consider weak solutions; however, this is beyond the scope of the present discussion. Natural questions about such solutions, for example, global existence and decay, are probably not routine in character (see Dafermos [1] for a survey of this general area). For example, it does not appear that the equation admits the symmetry of a centered rarefaction wave; since it is not clear how to solve Riemann problems, the Glimm scheme is not immediately available. It may be more appropriate to consider a conservative finite difference approximation of the type used in the numerics in [6]. It would be interesting to investigate the applicability of the method of compensated compactness to the convergence of such approximate solutions (see Tartar [9] for a survey of this area and DiPerna [2] for a recent application to conservation laws). An important ingredient in such an approach is an a priori L^∞ bound for solutions. The numerics suggest that such bounds are available in some parameter ranges but not in others.

1. Local existence of smooth solutions.

A. We will present a local existence theory for smooth solutions of (1) with Sobolev space data. The proof employs an iteration scheme (see e.g. Kato [3], Majda [4]) in which contractiveness is obtained in a low derivative norm while uniform control is maintained over the iterates in a high derivative norm. The new aspect of the present discussion is the presence of the nonlocal operator, which makes it necessary to work in Sobolev spaces based on L^1 rather than L^2. We remark that a proof could also be given based on the Nash-Moser implicit function theorem. However, the above method is simpler and therefore seems preferable.

B. Notation. Let H^s denote the space of functions with s $L^1(\mathbb{R}^1)$ derivatives and with norm

$$\|u\|_s=\sum_{j\leqq s}\int_{-\infty}^{\infty}|\partial_x^j u|\,dx.$$

Also, let $X_{s,T}$ denote the space $L^\infty([0,T]\times H^s)$ with norm

$$\|u\|_{s,T}=\sup_{0\leqq t\leqq T}\|u(\cdot,t)\|_s.$$

If $D \subset \mathbb{R}^1$ and $\Omega \subset \{x \in \mathbb{R}^1, t \geqq 0\}$ define

$$\|u\|_{D,s} = \sum_{j \leqq s} \|\partial_x^j u\|_{L^1(D)}, \qquad \|u\|_{\Omega,s,T} = \sup_{0 \leqq t \leqq T} \|u\|_{\Omega(t),s},$$

where $\Omega(r) = \Omega \cap \{t = r\}$. Finally we will denote the supremum norm by $\|u\|_\infty$; the domain over which the supremum is being taken will be clear from the context.

C. Here are the main results of this section.

THEOREM 1.1. (i) *Suppose that* $u_0 \in H^s$ *with* $s \geqq 2$. *There exists* $T = T(\beta, R, s, \|u_0\|_s, \|u_0^0\|_s) > 0$, *where* u_0^0*is defined in* (8), *below, such that there exists a solution* $u \in X_{s,T}$ *of* (1). *For* $s \geqq 3$, $u \in C^1([0, T_2] \times \mathbb{R}^1)$.

(ii) *Suppose that* $u_0 \in H^s$ *for all* $s \geqq 2$ *and let* T_2 *be the* T *obtained in* (i) *with* $s = 2$. *Then* $u \in C^\infty([0, T_2] \times \mathbb{R}^1)$.

We note that if $u_0 \in H^{s+1}$ then $\|u_0^0\|_s \leqq \|u_0\|_{s+1}$. Thus the precise dependence of T on u_0 can be obtained by sacrificing one derivative.

COROLLARY 1.2. *Let* u *and* v *be solutions of* (1) *such that* $u(x, 0) = v(x, 0)$ *for* $x \geqq \alpha$. *If* $x(t; \alpha)$ *is the solution of* $x_t = u$, $x(0, \alpha) = \alpha$, *define*

$$\Omega = \{(x, t)\colon x \geqq x(t; \alpha),\ u \text{ and } v \text{ are smooth for } t \leqq T\}.$$

Then $u \equiv v$ *in* Ω. *In particular, if* $u \equiv 0$, *then* $v = 0$ *for* $0 \leqq t \leqq T$, $x \geqq x(t; \alpha)$.

Corollary 1.2 implies that signals propagate to the right with finite speed; this plays a crucial role in our proof of breakdown in § 2.

The proofs of Theorem 1.1 and Corollary 1.2 are concluded in §§ G and H, below.

D. L^1 estimates. We first present an L^1 estimate for solutions of local linear equations. Although this is a standard result, we include a proof for completeness.

LEMMA 1.3. (i) *Suppose that* $u_0 \in L^1(\mathbb{R}^1) \cap C^\infty$, $f \in X_{0,T} \cap C^\infty$, *and that* $a(x, t)$, $b(x, t)$ *are smooth bounded functions such that*

$$C = \|a_x\|_\infty + \|b\|_\infty < \infty.$$

If u *is the solution of*

$$u_t + au_x + bu = f, \qquad u(x, 0) = u_0(x), \tag{2}$$

then

$$\|u\|_{0,T} \leqq e^{CT}[\|u_0\|_0 + T\|f\|_{0,T}].$$

(ii) *Let* $x(t; \alpha)$ *be the characteristic curve defined by* $x_t = a(x, t)$, $x(0, \alpha) = \alpha$, *and let*

$$\Omega = \{(x, t)\colon x(t, \alpha) \leqq x \leqq \infty, 0 \leqq t \leqq T\},$$

$$I = \{x\colon x \geqq \alpha\}.$$

Then with notation and hypotheses as in (i), *we have that*

$$\|u\|_{\Omega,0,T} \leqq e^{CT}[\|u_0\|_{I,0} + T\|f\|_{\Omega,0,T}].$$

Proof. (i) First assume that $f = 0$. It suffices to consider data $u_0(x)$ such that the set D where $u_0(x) \neq 0$ consists of a finite number of components, since such functions are dense in L^1. Thus let D be the union of $I_j(0)$, $1 \leqq j \leqq N$, where

$$I_j(0) = (x_j^-(0), x_j^+(0)), \qquad x_j^+(0) \leqq x_{j+1}^-(0).$$

Since $f = 0$, u is of one sign along characteristics of (2). Let $x_j^\pm(t)$ be the solution of

$$\dot{x} = a(x, t), \qquad x(0) = x_j^\pm(0),$$

and let $I_j(t)$ be the interval $(x_i^-(t), x_j^+(t))$. Since $u=0$ on $\partial I_j(t)$ it follows that

$$\partial_t \int_{I_j(t)} u\,dx = \int_{I_j(t)} u_t\,dx.$$

Multiply (2) by the sign of u on I_j, integrate over $I_j(t)$ and sum over j. From the above identity it follows (after integrating au_x by parts) that

$$\partial_t \|u\|_0 \leqq C\|u\|_0, \qquad C = \|a_x\|_\infty + \|b\|_\infty;$$

this proves the lemma when $f=0$.

If $f \neq 0$ but $u_0 = 0$, let $U(x, t; s)$ be the solution of

$$U_t + a(x,t)U_x + b(x,t)U = 0, \qquad U(x,s;s) = f(x,s).$$

Then $u(x,t)$ is a solution of (2), where

$$u(x,t) = \int_0^t U(x,t;s)\,ds,$$

and it follows from the first step that

$$\|u\|_{0,T} \leqq T\|U\|_{0,T} \leqq Te^{CT}\|f\|_{0,T}.$$

If $u_0 \neq 0$, $f \neq 0$, the lemma follows from the above and linearity.

(ii) The proof is virtually the same as (i) and we omit the details.

E. Linear nonlocal equations. In order to define our iteration scheme for (1) it will be necessary to solve equations of the form

$$(3) \qquad u_t + a^2u_x + a^1u + I(u, a^0) = 0, \qquad u(x,0) = u_0(x)$$

where the operator I is defined by

$$(4) \qquad I(u,v) = \int_0^\infty u(x+\beta s)v(x+s)\,ds.$$

LEMMA 1.4. *Suppose that* $s \geqq 2$, $u_0 \in H^s$, $\partial_t^k a^i \in X_{s-k,T}$, $i=1,2$, $k=0,1$. *For every* $T>0$ *there exists a solution* $u \in X_{s,T}$ *of* (3) *which satisfies the estimate*

$$(5) \qquad \|u\|_{s,T} \leqq e^{KT}\|u_0\|_s,$$

where K depends only on s, $\|a^i\|_{s,T}$, $i=1,2$, $(\beta-1)^{-1}\|a^0\|_{s,T}$ *and* R. *If* $s \geqq 3$, *then* $u \in C^1([0,T]\times\mathbb{R}^1)$.

Proof. Define $u^0 \equiv u_0(x)$ and let u^k, $k \geqq 1$ be the solution of

$$u_t^k + a^2u_x^k + a^1u^k = -I(u^{k-1}, a^0), \qquad u^k(x,0) = u_0(x).$$

Let $v^{k+1} = u^{k+1} - u^k$, so that

$$v_t^{k+1} + a^2v_x^{k+1} + a^1v^{k+1} = -I(v^k, a^0), \qquad v^{k+1}(x,0) = 0.$$

Define $w^j = \partial_x^j v^{k+1}$, $\bar{w}^j = \partial_x^j v^k$. For each $r \leqq s$, w^r satisfies

$$(6)_r \qquad w_t^r + a^2w_x^r = -\sum_{j=0}^{r-1}(\partial_x^{j+1}a^2 + \partial_x^j a^1)w^{r-j} - (\partial_x^r a^1)w^0 + \sum_{j=0}^{r}\lambda_j I(\bar{w}^j, \partial_x^{r-j}a^0) \equiv F_r$$

where λ_j depends only on r, and $w^j = 0$ initially. From Lemma 1.3, we have that

$$\|w^r\|_{0,T} \leqq \{Te^{T\|a_x^2\|_\infty}\}\|F_r\|_{0,T}.$$

A simple computation shows that

$$(7) \qquad \|I(u,v)\|_0 \leqq (\beta-1)^{-1}\|u\|_0\|v\|_0.$$

Also, for any $g \in H^1$ it is immediate that $\|g\|_\infty \leqq \|g\|_1$. Using these remarks to estimate F_r in the above we obtain

$$\|w^r\|_{0,T} \leqq \alpha_r T e^{T\|a_x^2\|_\infty}[(\|a^2\|_{r,t} + \|a^1\|_{r,T})\|w^0\|_{r,T} + (\beta-1)^{-1}\|a^0\|_{r,T}\|\bar{w}^0\|_{r,T}],$$

where α_r is a constant depending only on r.

For $s \geqq 2$ we have that $\|a_x^2\|_\infty \leqq \|a^2\|_{s,T}$. Finally, we note that for $r = 0, 1$ we obtain

$$\|w^r\|_{0,T} \leqq \alpha_s T e^{T\|a_x^2\|_\infty}(\|a^2\|_{2,T} + \|a^1\|_{2,T})\|w^0\|_{2,T} + (\beta-1)^{-1}\|a^0\|_{2,T}\|\bar{w}^0\|_{2,T}).$$

Thus we can sum the above for all $r \leqq s$ to obtain

$$\|v^{k+1}\|_{s,T} \leqq \alpha_s T e^{T\|a_x^2\|_\infty}[(\|a^2\|_{s,T} + \|a^1\|_{s,T})\|v^{k+1}\|_{s,T} + (\beta-1)^{-1}\|a^0\|_{s,T}\|v^k\|_{s,T}].$$

It follows that for sufficiently small T, say $T \leqq T^*$, that

$$\|v^{k+1}\|_{s,T^*} \leqq \rho\|v^k\|_{s,T^*}$$

for some $\rho \in (0, 1)$, and so $\{u^k\}$ is Cauchy in X_{s,T^*}. If $u \in X_{s,T^*}$ and $s \geqq 2$ it follows that u and u_x are continuous functions of x, and using the equation, that u is uniformly Lipschitz in t. From the differential equation it also follows that $u_{tx} \in X_{s-1,T^*}$ and so $u_{tt} \in X_{s-1,T^*}$. It then follows that u_t is continuous in x and t also, so that $u \in C^1([0, T^*] \times \mathbb{R}^1)$.

The estimate (5) follows from an estimate similar to the one obtained for v^{k+1}; this clearly allows us to continue the solution globally in T.

F. An iteration scheme for the nonlinear equation. We now use solutions of (3) to define our iteration scheme. It will first be necessary to mollify the data; to this end let $j_\varepsilon(x) = \varepsilon^{-1}j(\varepsilon^{-1}x)$ be a C_0^∞ function with unit mass and let

$$u_0^k(x) = j_{\varepsilon_k} * u_0, \qquad \varepsilon_k = \varepsilon_0 2^{-k}. \tag{8}$$

It is well known that

$$\|J_\varepsilon u - u\|_s \to 0 \qquad \text{as } \varepsilon \to 0, \tag{9a}$$

$$\|J_\varepsilon u - u\|_0 \leqq C\varepsilon\|u\|_1 \quad \text{for } u \in H^1. \tag{9b}$$

Next, note that integration by parts yields two equivalent and useful forms of (1), namely

$$\begin{aligned} &u_t + auu_x + bI(u, u_{xx}) = 0, \\ &a = R - (R-1)\beta^{-1}, \qquad b = (R-1)(1-\beta^{-1}), \end{aligned} \tag{10a}$$

$$u_t + uu_x + BI(u_x, u_x) = 0, \qquad B = (R-1)(1-\beta), \tag{10b}$$

where I is the operator defined in (4).

The approximation scheme is defined by setting $u^0 \equiv u_0^0(x)$, and for $k \geqq 1$, setting u^k to be the solution of

$$0 = u_t^k + au^{k-1}u_x^k + bI(u^k, u_{xx}^{k-1}), \qquad u^k(x, 0) = u_0^k(x), \tag{11a}$$

$$[0 = u_t^k + u^{k-1}u_x^k + BI(u_x^k, u_x^{k-1})]. \tag{11b}$$

From Lemma 1.4 it follows that u^k exists, and since each u_0^k is actually C^∞, that u^k is smooth. Thus u^k also satisfies the equivalent equation (11b).

The main task is to show that $\{u^k\}$ is uniformly bounded in a high derivative norm on some uniform t interval.

LEMMA 1.5. *Suppose that $s \geqq 2$. There exists $T^* > 0$ depending only on s, R, β and $\|u_0\|_{s+1}$ such that for sufficiently small ε_0 in* (8),

$$\|u^k - u_0^0\|_{s,T^*} \leqq 1, \qquad k = 0, 1, 2, \cdots. \tag{12}$$

Proof. The lemma clearly holds when $k=0$; we proceed by induction on k. We shall always view u^k as a solution of (11b).

We again use the notation w^j (resp. $\bar{w}^j$) for $\partial_x^j u^{k+1}$ (resp. $\partial_x^j u^k$). We first establish the following formulas for $j \geqq 1$:

$$\partial_x^{2j} I(w^1, \bar{w}^1) = (2-\beta-\beta^{-1})^j I(w^{j+1}, \bar{w}^{j+1}) + R_j, \tag{13a}$$

$$\partial_x^{2j+1} I(w^1, \bar{w}^1) = (2-\beta-\beta^{-1})^j [I(w^{j+2}, \bar{w}^{j+1}) + I(w^{j+1}, \bar{w}^{j+2})] + \hat{R}_j, \tag{13b}$$

(13c)$_j$ R_j (resp. $\hat{R}_j$) consists of local terms of the form $\lambda w^\alpha \bar{w}^\gamma$, where $1 \leqq \alpha, \gamma \leqq 2j$ (resp. $2j+1$) and $3 \leqq \alpha+\gamma \leqq 2j+1$ (resp. $2j+2$). The coefficients λ depend only on β and j.

We establish (13a) by induction on j; (13b) is obtained by taking ∂_x of (13a). For $j=1$ we have that

$$\begin{aligned}\partial_x^2 I(w^1, \bar{w}^1) &= I(w^3, \bar{w}^1) + 2I(w^2, \bar{w}^2) + I(w^1, \bar{w}^3)\\ &= (2-\beta-\beta^{-1}) I(w^2, \bar{w}^2) - \beta^{-1} w^2 \bar{w}^1 - \beta w^1 \bar{w}^2.\end{aligned}$$

Now assume that (13a) holds for $j \geqq 1$; then

$$\begin{aligned}\partial_x^{2j+2} I(w^1, w^1) &= (2-\beta-\beta^{-1})^j \partial_x^2 I(w^{j+1}, \bar{w}^{j+1}) + \partial_x^2 R_j\\ &= (2-\beta-\beta^{-1})^{j+1} I(w^{j+2}, \bar{w}^{j+2})\\ &\quad -(2-\beta-\beta^{-1})^j [\beta^{-1} w^{j+2} \bar{w}^{j+1} + \beta w^{j+1} \bar{w}^{j+2}] + \partial_x^2 R_j.\end{aligned}$$

If R_j satisfies (13c)$_j$ then $\partial_x^2 R_j$ satisfies (13c)$_{j+1}$; the other local terms satisfy (13c)$_{j+1}$ as well. This establishes (13).

For each j we obtain an equation for w^j by taking ∂_x^j of (11b); using (13) we obtain

$$w_t^j + \bar{w}^0 w_x^j = -\sum_{\alpha,\beta=0}^{j} \lambda_{\alpha,\beta} w^\alpha \bar{w}^\beta + B\tilde{I}_j \equiv F_j, \tag{14a}$$

where $\tilde{I}_j$ is defined by

$$\tilde{I}_j = \begin{cases} I(w^{j/2+1}, \bar{w}^{j/2+1}) & j \text{ even},\\ I(w^{(j+3)/2}, \bar{w}^{(j+1)/2}) + I(w^{(j+1)/2}, \bar{w}^{(j+3)/2}) & j \text{ odd}.\end{cases} \tag{14b}$$

The crucial observation is that for $j \geqq 2$ all terms on the right-hand side of (14a) involve only w^k and $\bar{w}^k$ with $k \leqq j$ (this is false when $j=0, 1$). For example, it follows from (13c) that if $\lambda_{\alpha,\beta} \neq 0$ then at least one of α or β is strictly less than j. It follows from the embedding of H^1 in L^∞ we have that for such α, β,

$$\|w^\alpha \bar{w}^\beta\|_0 \leqq \|w^0\|_j \|\bar{w}^0\|_j. \tag{15a}$$

Similarly, from (7) we have that for all $j \geqq 2$,

$$\|\tilde{I}_j\|_0 \leqq 2(\beta-1)^{-1} \|w^0\|_j \|\bar{w}^0\|_j. \tag{15b}$$

We can now estimate $u^k - u_0^0$. To this end let $U^j = \partial_x^j u_0^0$ and define z^j, $\bar{z}^j$ by

$$w^j = z^j + U^j, \qquad \bar{w}^j = \bar{z}^j + U^j, \qquad 0 \leqq j \leqq s.$$

From (14a) we have for $j \geqq 2$ that z^j satisfies

$$z_t^j + \bar{w}^0 z_x^j = -\bar{w}^0 U^{j+1} + F_j, \tag{16}$$

where from (15), it follows that F_j satisfies the estimate

$$\|F_j\|_0 \leqq C[\|z^0\|_j \|\bar{z}^0\|_j + \|u_0^0\|_j (\|z^0\|_j + \|\bar{z}^0\|_j) + \|u_0^0\|_j^2],$$

where C depends only on j, β and R.

Let $\bar{C} = \|\bar{w}^0\|_{s,T}$ so that for $s \geqq 2$, $\|\bar{w}_x^0\|_\infty \leqq \bar{C}$. For $j \geqq 2$ we obtain from Lemma 1.3 that

$$\|z^j\|_{0,T} \leqq e^{\bar{C}T}[\|u_0^k - u_0^0\|_j + T(\bar{C}\|u_0^0\|_{j+1} + C\|u_0^0\|_j^2) \\ + CT\|z^0\|_{0,T}\|\bar{z}^0\|_{j,T} + \|u_0^0\|_j(\|z^0\|_{j,T} + \|\bar{z}^0\|_{j,T})]. \tag{17$_j$}$$

For $j = 0, 1$ we obtain equations for z^0, z^1, where the right-hand side contains z^j, z^i with $j, i \leqq 2$. This yields an estimate of the form $(17)_j$ with $j = 0, 1$ on the left and $j \leqq 2$ on the right. Finally, sum $(17)_j$ over j, $0 \leqq j \leqq s$ to obtain

$$\|u^k - u_0^0\|_{s,T} \leqq K e^{\bar{C}T}[\|u_0^k - u_0^0\|_s + T(\bar{C}\|u_0^0\|_{s+1} + C\|u_0^0\|_s^2) \\ + CT(\|u^k - u_0^0\|_{s,T}\|u^{k-1} - u_0^0\|_{s,T} \\ + \|u_0^0\|_s(\|u^k - u_0^0\|_{s,T} + \|u^{k-1} - u_0^0\|_{s,T})], \tag{18}$$

where K depends only on s. The induction hypothesis for the $k-1$ step and (9) imply that

$$\bar{C} \leqq 1 + 2\|u_0\|_s \equiv \hat{C} \quad \text{(for small } \varepsilon_0).$$

From (8) and (9) we have for sufficiently small ε_0 that

$$K e^{\hat{C}}\|u_0^k - u_0^0\|_s < \tfrac{1}{3}, \qquad k = 0, 1, 2, \cdots.$$

Now choose $T^* \leqq 1$ so small that

$$T^* K e^{\hat{C}}((\hat{C}+1)\|u_0^0\|_{s+1} + C\|u_0^0\|_s^2) < \tfrac{1}{3}, \qquad T^* K e^{\hat{C}}(C + \|u_0^0\|_s) < \tfrac{1}{2}.$$

For such T^* the induction step will hold at the kth step; this completes the proof.

We remark that if $u_0 \in H^{s+1}$, then $\|u_0^0\|_{s+1} \leqq \|u_0\|_{s+1}$, so that T^* can be chosen uniformly for all small ε_0. If $u_0 \notin H^{s+1}$ the choice of T^* must tend to zero with decreasing ε_0.

Armed with Lemma 1.5, we can now prove contactiveness in the low norm.

LEMMA 1.6. *Suppose that* $\alpha \in (0, 1)$. *There exists* $T^{**} \in (0, T^*]$ *such that*

$$\|u^{k+1} - u^k\|_{0,T^{**}} \leqq \alpha\|u^k - u^{k-1}\|_{0,T^{**}} + \|u_0^k - u_0^0\|_0. \tag{19}$$

T^{**} *depends only on* β, R *and* T^*.

Proof. Let $v^k = u^{k+1} - u^k$, $k = 0, 1, \cdots$. After an integration by parts, it can be seen that v^k satisfies

$$0 = v_t^k + u^k v_x^k - B u_x^k v^k + (1-B)u_x^k v^{k-1} - B[\beta I(u_{xx}^k, v^k) + \beta^{-1} I(v^{k-1}, u_{xx}^k)],$$
$$v^k(x, 0) = u_0^{k+1}(x) - u_0^k(x).$$

By Lemma 1.3, (7), and the embedding of H^1 into L^∞, we obtain

$$\|v^k\|_{0,T} \leqq e^{CT}[CT\|v^{k-1}\|_{0,T} + CT\|v^k\|_{0,T} + \|v^k(\cdot, 0)\|_0],$$

where C depends only on $\|u^k\|_{2,T}$, β and R. This determines a suitable $T^{**} \leqq T^*$ such that (19) holds.

G. Completion of the proof. (i) Lemmas 1.5 and 1.6 imply that for $T \leqq T^{**}$, $\{u^k\}$ converges to a limit $u \in x_{0,T}$. These lemmas, together with a standard interpolation inequality for Sobolev space imply that the convergence occurs in the space $X_{s-1,T}$. The equation implies that u_t^k converges to u_t in $X_{s-2,T}$, so that for $s \geqq 3$ the Sobolev embedding theorem implies that u is $C^1([0, T] \times \mathbb{R}^1)$.

(ii) If $u_0 \in H^s$ for all $s \in \mathbb{Z}_+$, we claim that there exists T independent of s such that $u \in C^\infty([0, T] \times \mathbb{R}^1)$. Pick $T_2 > 0$ such that the existence holds when $s = 2$. If $w = \partial_x^2 u$, then w satisfies

$$(20)\quad w_t + uw_x + [3 - (\beta + \beta^{-1})(R-1)(1-\beta)]u_x w = (2 - \beta - \beta^{-1})(R-1)(1-\beta)I(w, w).$$

From Lemma 1.3 and (7) we see that

$$\partial_t \|w\|_0 \leqq \text{const } \|w\|_0^2;$$

this inequality and $\|u_0''\|_0$ determine the maximal T_2.

For $j > 2$ we let $w^j = \partial_x^j w$. From (13) with $\bar{w}^j = w^j$ it follows that the equation for w^j analogous to (14a) is *linear* in w^j. Thus, given a bound for $\|w^k\|_{0,T}$ for $k < j$ and $T < T_2$ we obtain a bound for $\|w^j\|_{0,T}$ since by Lemma 1 and the previous remark $\|w^j\|_{0,T}$ can grow at most exponentially fast for $T \leqq T_2$. This proves (ii).

H. Proof of Corollary 1.2. Let $w = u - v$; using form (11b) of (1) we have that

$$(21)\qquad 0 = w_t + uw_x + v_x w + BI(w_x, u_x) + BI(v_x, w_x),$$

and after an integration by parts this becomes

$$(22)\qquad 0 = w_t + uw_x + (v_x - \beta^{-1}Bu_x - Bv_x)w - \beta^{-1}BI(w, u_{xx}) - BI(v_{xx}, w).$$

We now use (ii) of Lemma 1.3 with Ω as in the statement of the corollary and (7) to obtain

$$\|w\|_{\Omega,0,T} \leqq CTe^{CT}\|w\|_{\Omega,0,T},$$

where C depends only on $\|u\|_{\Omega,2,T}$, $\|v\|_{\Omega,2,T}$, β and R. Thus for sufficiently small T, $\|w\|_{\Omega,0,T} = 0$. The argument can be repeated to obtain the result in all of Ω.

2. Formation of shocks.

A. We will show that for certain parameter values and rather general data the solution of (1) breaks down in finite time, i.e., there exists $T_b > 0$ such that $u_x(x, t)$ becomes infinite at some $t = \hat{t} \leqq T_b$. The result is not sharp in that $\hat{t}$ may be substantially smaller than T_b, although for solutions with a single positive pulse (such as those studied numerically in [6]) T_b may provide a more accurate estimate for $\hat{t}$.

The analysis of breakdown is facilitated by having a suitable continuation theorem for smooth solutions. For example, for local conservation laws it can be shown that a bound for $\|\nabla u\|_\infty$ implies a bound on the higher derivatives (see [4, Thm. 2.2]). The difficulty in this regard with equation (1) can be seen in equation (20) for $w = \partial_x^2 u$. Even if a uniform bound is postulated for $\|u_x\|_\infty$ the quadratic term $I(w, w)$ could conceivably cause blow-up in the second derivative.

The key to continuation and breakdown is in controlling this term. To this end we consider C_0^∞ data u_0 supported in $\{x \leqq 0\}$ which, together with u_0' and u_0'', satisfy certain sign conditions near $x = 0$. Using maximum principle type arguments it can be shown that these sign conditions persist into a certain region $\Omega \subset \{t > 0, x < 0\}$ as long as the solution remains C^∞. It can then be shown that if $|u_x|$ is uniformly bounded for $t \leqq T_b$, then Ω intersects the line $t = T_b$. This is our continuation principle. Breakdown is obtained from the explicit knowledge of the signs of the derivatives of u in Ω.

In summary, breakdown could occur in two different ways. Either a shock forms from the data in Ω in time of order T_b or a shock forms somewhere to the left of Ω and rapidly moves into Ω.

THEOREM 2.1. *Suppose that $u_0 \in C_0^\infty(x \leqq 0)$ and that u_0, β and R satisfy the conditions*

(i) *There exists $y < 0$ such that $u_0''(x) > 0$ for $y < x < 0$.*

(ii) $0 < R < 1$, $\beta > 1$.

(iii) $\gamma > 0$, *where* $\gamma = 1 - (1-R)(\beta - \beta^{-1})/2$.

Then u_x becomes unbounded at a time $\hat{t} \leqq T_b$, where $T_b = (\gamma |u_0'(y)|)^{-1}$.

We have been unable to determine whether (iii) is a genuine threshold for breakdown, or whether it is an artifact of our techniques. In the two numerical examples reported in [6] with $R < 1$, condition (iii) is satisfied. The second example has $\gamma = 10^{-2}$. However, the authors mention other experiments in the parameter ranges $0.5 \leqq R \leqq 1$, $1 \leqq \beta \leqq 10$ in which they still found evidence of breakdown. It may be that for $\gamma < 0$ breakdown can be inhibited if the data are sufficiently small. Further numerical experiments in this parameter range might provide a better indication of what sort of results to expect.

In the following we will assume that u_x is uniformly bounded for $t \leqq T_b$. A contradiction is obtained in § D, below.

B. An a priori estimate. Given a solution u of (1) we define "characteristic" curves $x(t; \alpha)$ by

$$\frac{dx}{dt} = u(x, t), \qquad x(0, \alpha) = \alpha \quad \text{for } \alpha \in \mathbb{R}^1. \tag{23}$$

The region Ω referred to earlier is defined by setting

$$\begin{aligned} T_0 &= \sup\{T \geqq 0\colon u \text{ is } C^\infty \text{ on } 0 \leqq t \leqq T, x(t; y) \leqq x \leqq 0\}, \\ \Omega &= \{(x, t)\colon 0 < t < T_0, x(t; y) < x < 0\}. \end{aligned} \tag{24}$$

Note that by (ii) of Theorem 1.1, $T_0 > 0$.

THEOREM 2.2. (i) *For all $\hat{t} < T_0$, the set $\Omega \cap \{t = \hat{t}\}$ is an interval of positive length.*

(ii) *The inequalities $u > 0$, $u_x < 0$, and $u_{xx} > 0$ hold for all $(x, t) \in \Omega$.*

Proof. (i) Since u is assumed to be smooth in $\bar{\Omega} \cap \{t \leqq \hat{t}\}$ solution curves of (23) cannot cross in the (x, t) plane, so that the map $\alpha \to x(t; \alpha)$ is a diffeomorphism of $[y, 0]$ onto $[x(t; y), 0]$.

(ii) We will show that $u_{xx} > 0$ in Ω; the other inequalities follow immediately from this.

By hypothesis (i) of Theorem 2.1 and Corollary 1.2, u must decay rapidly near $x = 0$. It is therefore difficult to control the sign of u_{xx} in this region. This problem is overcome by perturbing the equation slightly to

$$u_t^\varepsilon + u^\varepsilon u_x^\varepsilon + (R-1)(1-\beta)I(u_x^\varepsilon, u_x^\varepsilon) = \varepsilon f(x), \qquad u^\varepsilon(x, 0) = u_0(x),$$

where f is specified below. If f decays rapidly at $|x| = \infty$ and is reasonably smooth, the existence theory of § 1 proceeds exactly as before. In particular, the proofs of Lemmas 1.5 and 1.6 are exactly the same. Thus for such f, u^ε will depend continuously on ε in a high derivative norm, and it will exist on some interval $[0, T_1]$ where T_1 is uniform for all small ε. We omit the details.

We now choose $f(x)$ so that $f(x) = 0$ for $x \geqq 0$, f and f' are continuous, and so that $f''(x) = \rho(x)|x|^k$ for $x < 0$, where k is a large positive integer and $\rho(x) \geqq 0$ is C^∞ with $\rho = 0$ for $x < y$ and $\rho = 1$ for $x \geqq y/2$. Clearly $f \in H^{k+2}$ but $f \notin H^{k+1}$.

We next define "characteristic" curves $x^\varepsilon(t; y)$ and a region Ω_ε for the solution u^ε as in (23) and (24). We will show that $u_{xx}^\varepsilon > 0$ in $\Omega_\varepsilon \cap [0, T_1]$ for all $\varepsilon > 0$.

To this end we make the following claim: there exists a (relatively open) border $B_\varepsilon \subset \bar{\Omega}_\varepsilon \cap [0, T_1]$ containing the line segments in $\partial\Omega_\varepsilon$,

$$S = \{t = 0, y \leqq x \leqq 0\} \cup \{x = 0, 0 \leqq t \leqq T_1\},$$

such that $u_{xx}^\varepsilon = w^\varepsilon > 0$ in $B_\varepsilon \cap \Omega_\varepsilon$. We assume the claim for the moment and proceed with the proof.

If the lemma were false there would exist a smallest $t = \hat{t} \leqq T_1$ such that $w^\varepsilon(\hat{x}, \hat{t}) = 0$ for some $\hat{x} \in [x^\varepsilon(\hat{t}; y), 0]$; since $w^\varepsilon > 0$ in B_ε it follows that $\hat{x} < 0$. The equation for w^ε is (see (20))

$$\begin{aligned} &w_t^\varepsilon + u^\varepsilon w_x^\varepsilon + \Gamma u_x^\varepsilon w^\varepsilon = (2 - \beta - \beta^{-1})(R - 1)(\beta - 1)I(w^\varepsilon, w^\varepsilon) + \varepsilon f''(x), \\ &w(x, 0) = u_0''(x), \qquad \Gamma = 3 - (\beta + \beta^{-1})(R - 1)(1 - \beta). \end{aligned} \tag{25}$$

For $\beta > 1$ and $0 < R < 1$ the coefficient of I in the above is positive. Also, by minimality of $\hat{t}$, $w = w_x = 0$ at $(\hat{x}, \hat{t})$. Since $\varepsilon f''$, $w^\varepsilon \geqq 0$ and $w^\varepsilon > 0$ near $x = 0$ it follows that the right-hand side of (25) is positive, whence $w_t(\hat{x}, \hat{t}) > 0$. This contradicts the minimality of $\hat{t}$. Thus $w^\varepsilon > 0$ in $\Omega_\varepsilon \cap [0, T_1]$ for all $\varepsilon > 0$. Since w^ε converges to $w = u_{xx}$ as ε tends to zero in $[0, T_1] \times \mathbb{R}^n$, we have that $w \geqq 0$ in Ω. It follows that $u \geqq 0$ and $u_x \leqq 0$ in Ω. Thus the free boundary of Ω, $x = x(t; y)$, is an increasing function of t. If, for some $(\hat{x}, \hat{t}) \in \Omega$, $w(\hat{x}, \hat{t}) = 0$, then the above argument applied to w at $(\hat{x}, \hat{t})$ shows that w must vanish identically on the segment $x \geqq \hat{x}$, $t = \hat{t}$. Thus u must be a linear function of x for $x \geqq \hat{x}$, $y = \hat{t}$, and since u lies in a Sobolev space, it follows that $u \equiv 0$ on this half line. Now the equation is reversible in time as long as u remains smooth, so that we may apply Corollary 1.2 in backward time to conclude that $u(x, 0) = u_0(x) = 0$ for $x \geqq \hat{x}$. Since our assumption was that $\hat{x} < 0$, we have obtained a contradiction to (ii) of Theorem 2.1. Thus $w > 0$ in $\Omega \cap [0, T_1]$.

Fix $T < T_0$, where T_0 is as in (24); we next extend the result to the region $\Omega \cap [0, T]$. By hypothesis, u is C^∞ in $\bar{\Omega} \cap [0, T]$ so that $\|u(\cdot, t)\|_{\Omega(r),s}$ is uniformly bounded for $r \in [0, T]$ and each s, where $\Omega(r)$ is as in 1.B. We next note that given a bound for $\|u(\cdot, r)\|_{\Omega(r),s}$ we can alter $u(x, r)$ for $x < x(r; y)$ to a (C^∞) function $\tilde{u}(\cdot, r)$ such that $\|\tilde{u}(\cdot, r)\|_s \leqq C\|u(\cdot, r)\|_{\Omega(r),s}$ for some constant C depending only on s. Now fix $s > 2$; for $r \in [0, T]$ we can determine a T_1 as in the beginning of the proof using $\tilde{u}(\cdot, r)$ as "data," and by construction, T_1 will depend only on T. If v is the resulting solution we have that $u \equiv v$ in Ω by Corollary 1.2. Thus the mollification does not affect u in Ω. (Note that such a modification may be necessary since a singularity could form rapidly in the region to the left of Ω.) Proceeding by induction, we assume $u(\cdot, nT_1)$ satisfies (ii) of Theorem 2.1, with y replaced with $x(nT_1, y)$, modify u to $\tilde{u}$ in the manner described above at $t = nT_1$, and apply the argument of the preceding paragraph to conclude that $u_{xx} > 0$ in $\Omega \cap \{t \leqq (n+1)T_1\}$. Since T_1 is independent of n provided that $nT_1 \leqq T$, we obtain the result in $\Omega \cap [0, T]$ for any $T < T_0$.

To complete the proof it only remains to construct the border B_ε. We first claim that there exists $x(\varepsilon) < 0$ such that for $x(\varepsilon) \leqq x \leqq 0$ and $t \leqq T_1$ we have that

$$|(2 - \beta - \beta^{-1})(R - 1)(\beta - 1)I(w^\varepsilon, w^\varepsilon)| < \varepsilon f(x). \tag{26}$$

Since $f \in H^{k+2}$ and $u_0 \in C_0^\infty$ it follows that $u \in X_{k+2,T}$, whence w is C^{k-1} in near $x = 0$ uniformly in t. Since $w(x, t) \equiv 0$ for $x \geqq 0$ it follows that $\partial_x^j w = 0$ for $j \leqq k - 1$, at $x = 0$. Thus by Taylor's theorem $|w(x, t)| \leqq C|x|^{k-1}$ for x near zero, uniformly in t. Thus for x near zero we have that

$$|\text{const } I(w^\varepsilon, w^\varepsilon)| \leqq c|x|^{2k-1}$$

which clearly implies (26) for x close enough to zero (depending on ε) and $k \geqq 2$.

Now let $x^\varepsilon(t;\alpha)$ be the characteristics for u^ε and define

$$p^\varepsilon(t;\alpha)=u^\varepsilon_{xx}(x^\varepsilon(t;\alpha),t),$$
$$q^\varepsilon(t;\alpha)=u^\varepsilon_x(x^\varepsilon(t;\alpha),t).$$

The equation for p^ε is

$$\begin{aligned}&p^\varepsilon_t+\Gamma q^\varepsilon p^\varepsilon=(2-\beta-\beta^{-1})(R-1)(\beta-1)I(w^\varepsilon,w^\varepsilon)+\varepsilon f''(x),\\&p(0;\alpha)=u_0''(\alpha).\end{aligned}\tag{27}$$

From (26) it follows that the terms on the right-hand side are positive provided that α is close enough to zero. Moreover by (ii) of Theorem 2.1, $p^\varepsilon(\alpha,0)>0$ for $\alpha\in(y,0)$. At the smallest $t=\hat t$ where $p^\varepsilon=0$ it would follow from (27) that $p_t(\hat t,\alpha)>0$ for α near zero, contradicting the minimality of $\hat t$. Thus $p^\varepsilon(\hat t;\alpha)>0$ on some region of the form $[0,T]\times[\alpha,0)$ for $|\alpha|$ small enough. Finally, we note that from (i) of this theorem, the intersection of B_ε with each line $t=\text{constant}$ is an interval containing zero in its closure, for $t\leqq T_1$. Thus B_ε has nonempty interior in x for each fixed t.

C. A continuation principle. Given a sign condition on u_{xx} and u_x, it is relatively easy to prove a continuation theorem.

LEMMA 2.3. *Suppose that $|u_x|$ is uniformly bounded for $t\leqq T_b$. Then $T_0\geqq T_b$ where T_0 is as in* (24).

Proof. We need to show that a bound for $|u_x|$ implies that u is C^∞ in Ω. Clearly $\|u\|_{\Omega,1,T_b}$ is finite. Since $u_{xx}>0$ in Ω we also have that

$$\|u_{xx}\|_{\Omega,0,T_b}=\sup_{0\leqq t\leqq T_b}\int_{x(t;y)}^0 u_{xx}(x,t)\,dx=\sup_{0\leqq t\leqq T_b}-u_x(x(t;y),t)<\infty.$$

Thus $\|u\|_{\Omega,2,T_b}<\infty$. Proceeding by induction, suppose that $\|u\|_{\Omega,j,T_b}$ is bounded for $j\geqq 2$. We then use (13) to obtain (14a) with $\partial_x^{j+1}u=w^{j+1}$ and $\bar w^k=w^k$. From (14b) and $(13\text{c})_l$ where $l=[(j+1)/2]$, this equation is linear in w^{j+1} if $j\geqq 2$. Thus we can apply (ii) of Lemma 1.3 to obtain a bound for $\|u\|_{\Omega,j+1,T_b}$. This completes the proof.

D. A proof of breakdown. We finally derive a contradiction to the hypothesis that u_x is uniformly bounded for $t\leqq T_b$.

Let $q(t)=u_x(x(t;y),t)$; then the equation for q is

$$\begin{aligned}q_t&=-q^2+(R-1)(\beta-1)[I(u_{xx},u_x)+I(u_x,u_{xx})]\\&=[-1-(R-1)(\beta-1)]q^2-(R-1)(\beta-1)^2I(u_{xx},u_x).\end{aligned}\tag{28}$$

Since $u_x<0$ and $u_{xx}>0$ in Ω, u_x is monotone, and we have that

$$\begin{aligned}I(u_{xx},u_x)&=\int_0^\infty u_{xx}(x(t;y)+\beta s)u_x(x(t;y)+s)\,ds\\&<\int_0^\infty u_{xx}(x(t;y)+\beta s)u_x(x(t;y)+\beta s)\,ds\\&=\beta^{-1}\int_0^\infty\frac{\partial}{\partial x}[u_x(x(t;y)+\beta s)^2/2]\,ds\\&=-\beta^{-1}q^2/2.\end{aligned}$$

Thus from the above and (28) we obtain

$$q_t<[-1-(R-1)(\beta-1)+(R-1)(\beta-1)^2\beta^{-1}/2]q^2=-\gamma q^2$$

where γ is as in (ii) of Theorem 2.1. Thus $q(t)$ is less than $(-T_b+t)^{-1}$, which completes the proof.

APPLICATION OF TOPOLOGICAL TECHNIQUES TO THE ANALYSIS OF ASYMPTOTIC BEHAVIOR OF NUMERICAL SOLUTIONS OF A REACTION-DIFFUSION EQUATION*

SAT NAM S. KHALSA†

Abstract. The initial boundary value problem for a reaction-diffusion equation

$$(*) \qquad u_t = u_{xx} + f(u), \qquad f(u) = -u(u-b)(u-1), \qquad 0 < b < \tfrac{1}{2},$$

was analysed in [2], [10] by using the Conley index. In this paper we study the asymptotic behavior of solutions of the semidiscrete approximations

$$(**) \qquad \dot{u}_i = (u_{i-1} - 2u_i + u_{i+1})/h^2 + f(u_i), \qquad i = 1, \cdots, n.$$

We show that for large n the spectrum of the linearized discrete steady-state problem is a "good" approximation for the spectrum of the linearized continuous steady-state problem. Using the interpretation of the Conley index as the dimension of an unstable manifold of a steady-state solution, we establish that the properties of solutions of (**) are completely analogous to those of the solutions of (*). The asymptotic, as $t \to \infty$, second order convergence of the approximate solutions is proved.

Key words. reaction-diffusion, finite differences, Conley index

AMS(MOS) subject classifications. 65M20, 65M10, 35K57

1. Introduction. Many phenomena in biology and physiology can be modeled by certain nonlinear reaction-diffusion equations. The asymptotic state of a solution specifies its ultimate behavior while ignoring transient effects. The stable asymptotic states may be represented by solutions which can be perturbed by a uniformly small function without destroying their long-time behavior. These are the solutions generally seen in applied contexts. It is therefore crucial to know that the asymptotic behavior of the approximate solutions mimic those of the exact solution.

The asymptotic behavior of solutions for the problem

$$(1.1a) \qquad u_t = u_{xx} + f(u), \qquad |x| < L, \quad t > 0,$$

$$(1.1b) \qquad u(x, 0) = u^0(x), \qquad |x| < L,$$

$$(1.1c) \qquad u(\pm L, t) = 0, \qquad t > 0,$$

where

$$(1.2) \qquad f(u) = -u(u-b)(u-1), \qquad 0 < b < \tfrac{1}{2},$$

was analysed in [2] and [10] (see Theorem 2.2 below). In particular, it was shown there that for $L > L_0$ the steady-state problem

$$(1.3a) \qquad u'' + f(u) = 0, \qquad |x| < L,$$

$$(1.3b) \qquad u(\pm L) = 0$$

has exactly three solutions: u_0, u_1 and u_2 with $u_0 \equiv 0 < u_1(x) < u_2(x)$, which are nondegenerate (i.e., zero is not in the spectrum of the linearized problem). u_0 and u_2 are attractors for the associated parabolic problem (1.1a-c). By this we mean that if the initial data u^0 is sufficiently close (in C) to either u_0 or u_2, then the corresponding

* Received by the editors May 28, 1985; accepted for publication (in revised form) September 5, 1985.

† Department of Mathematics, Iowa State University, Ames, Iowa 50011.

solution of (1.1a–c) converges (in C) to the corresponding solution of (1.3a–b). Similarly, u_1 is unstable and has a one-dimensional unstable manifold. These results are based on computation of the Conley index (the Morse index of an isolated invariant set) for each of u_0, u_1 and u_2. The Conley index generalizes the classical Morse index of a nondegenerate critical point of a vector field in that the classical index is a nonnegative integer n, where n is the dimension of the unstable manifold to the critical point, and, considered as an isolated invariant set, the homotopy index of the critical point is the homotopy type of a pointed n-sphere.

In this paper we analyse the asymptotic behavior of solutions of semidiscrete approximations

$$\text{(1.4a)} \qquad \dot{u}_i=(u_{i-1}-2u_i+u_{i+1})/h^2+f(u_i), \qquad i=1,\cdots,n, \quad t>0,$$

$$\text{(1.4b)} \qquad u_i(0)=u_{i,0}, \qquad i=1,\cdots,n,$$

$$\text{(1.4c)} \qquad u_0(t)=u_{n+1}(t)=0, \qquad t>0,$$

of (1.1a–c). Here $h=2L/(n+1)$, and $u_i(t)$ is an approximation to $u(x_i,t)$, with an appropriate choice of $u_{i,0}$, say, $u_{i,0}=u^0(x_i)$, $x_i=ih-L$, $i=0,\cdots,n+1$. We first study the approximate steady-state problem

$$\text{(1.5a)} \qquad (u_{i-1}-2u_i+u_{i+1})/h^2+f(u_i)=0, \qquad i=1,\cdots,n,$$

$$\text{(1.5b)} \qquad u_0=u_{n+1}=0.$$

In Theorem 3.1 we prove that for large n (1.5a, b) also has exactly three solutions $\bar{0}=\bar{u}^0<\bar{u}^1<\bar{u}^2$ and establish the second order convergence in the sup-norm of the approximate solutions.

In Theorem 3.2 we show that the properties of solutions of the problem (1.4a–c) are completely analogous to those of (1.1a–c) and establish the asymptotic, as $t\to\infty$, second order convergence of the approximate solutions.

Our approach is based on an (intuitively natural) fact that for large n the spectrum of the linearized operator in the right-hand side of (1.4a) is a "good" approximation of the spectrum of the linearized operator in the right-hand side of (1.1a). This gives existence and convergence of the approximate steady-state solutions, and also implies that the Conley index of a rest point $\bar{u}^k$ of the approximate problem is the same as the one of the corresponding rest point $u_k(x)$, $k=0,1,2$, of the exact problem. The latter implies the existence of orbits connecting the rest points of the approximate problem.

The results of this paper have been extended [7] to the finite element approximation of (1), with interpolation of coefficients for nonlinear terms.

In § 2 we collect the results from [8] and [9] which we need to analyse the approximate steady-state problem and the results from [10] about the continuous problem (1.1a–c).

In § 3 we prove our principal result, Theorem 3.2, which analyses the properties of the approximate problem (1.4a–c) and establishes the asymptotic convergence of the approximate solutions.

Recently, asymptotic convergence of numerical solutions of systems of reaction-diffusion equations to constant and zero rest points was analysed by several authors. In [4], [5] finite difference approximations were shown to converge with a time-independent error bound by imposing a monotonicity condition on the reaction term or under the conditions that the reaction term is "slowly varying." The conditions imposed guarantee the exponential decay of the exact solution together with its derivatives. The results in [4], [5] were obtained for both the Dirichlet and Neumann problems. For the Neumann problem similar results were obtained in [3] and in the linear case, using finite elements, in [6].

2. Background and preliminaries. As we mentioned in the Introduction, in our analysis of the approximate steady-state problem we follow [8]. The approach in [8] is to replace the problem of solving the steady-state problem using finite differences by an equivalent problem: solving the integral equation

$$u(x)+\int_{-L}^{L} G(x,y)f(u(y))\,dy=0 \tag{2.1}$$

using the method of mechanical quadratures

$$u_i+\sum_{j=1}^{n} G(x_i,x_j)f(u_j)=0, \qquad i=1,\cdots,n, \tag{2.2}$$

and then to analyse the latter problem. Here $G(x,y)$ is the Green's function of the operator d^2/dx^2 for the boundary condition (1.3b).

Equation (2.1) can be regarded as an operator equation

$$u+Tu=0, \tag{2.3}$$

where

$$Tu=\int_{-L}^{L} G(x,y)f(u(y))\,dy, \tag{2.4}$$

in the Banach space E of bounded measurable functions $u(x)$ on $[-L, L]$.

From [8, p. 307, proof of Thm. 19.5 and Thm. 19.6] we have

THEOREM 2.1. (i) *The boundary value problem* (1.3a, b) *in* $C^2([-L, L])$ *is equivalent to the integral equation* (2.1) *in* E.

(ii) *Let* $u_*(x)$ *be an isolated solution of the problem* (1.3a, b). *Let also* $f(u)$ *be continuously differentiable in the domain*

$$|u-u_*(x)|\leqq \delta, \qquad \delta=\text{const}>0, \tag{2.5}$$

and set

$$g(x)=f'(u_*(x)). \tag{2.6}$$

Assume that the linearized problem

$$u''+g(x)u=0 \tag{2.7}$$

with the boundary conditions (1.3b) *has no nontrivial solutions.*

Then there exist n_0 *and* δ_0 *such that for* $n\geqq n_0$ *the system* (1.5a, b) *has a unique solution satisfying the inequalities*

$$|u_i-u_*(x_i)|\leqq \delta_0, \qquad i=1,\cdots,n. \tag{2.8}$$

If $f(u_*(x))$ *is twice continuously differentiable, then the rate of convergence is given by*

$$\max_{1\leqq i\leqq n} |u_i-u_*(x_i)|\leqq ch^2, \qquad c=\text{const}. \tag{2.9}$$

Remark. Note that by Theorem 2.2 below all solutions $u_*(x)$ of (1.3a, b) are isolated, and (2.7) has no nontrivial solutions.

Theorem 2.1 together with the argument in [8, p. 302] imply

LEMMA 2.1. *Under the assumptions of Theorem* 2.1, *for any given* δ_0 *there exists* n_0 *such that for* $n \geqq n_0$ *any solution* $\bar{u}^* = (u_0^*, \cdots, u_{n+1}^*)^T$ *of* (1.5a, b) *satisfies*

$$\max_{0 \leqq i \leqq n+1} |u_i^* - u_*(x_i)| \leqq \delta_0, \tag{2.10}$$

for some solution $u_*(x)$ *of* (1.3a, b).

The following lemma is contained in [9, Thm. 6.2] and can also be obtained using [8, Thm. 18.1].

LEMMA 2.2. *Under the assumptions of Theorem* 2.1 *every limit point of any sequence* λ_n *of eigenvalues of equations*

$$(v_{i-1} - 2v_i + v_{i+1})/h^2 + g(x_i)v_i = \lambda v_i, \qquad i = 1, \cdots, n, \tag{2.11}$$

$$v_0 = v_{n+1} = 0, \tag{2.12}$$

is an eigenvalue of the equation

$$v'' + g(x)v = \lambda v, \tag{2.13}$$

$$v(\pm L) = 0. \tag{2.14}$$

We shall use the notation $\bar{u} \equiv \bar{u}_n = (u_0, \cdots, u_{n+1})^T$ for $\bar{u} \in R^{n+2}$ and the notation $\bar{u} < \bar{v}$ when $u_i < v_i$, $i = 1, \cdots, n$; $u_0 \leqq v_0$, $u_{n+1} \leqq v_{n+1}$. With some abuse of notation we shall also write $\bar{u}$ for the vector $(u_1, \cdots, u_n)^T$, in the case that $u_0 = u_{n+1} = 0$.

We shall also need a comparison principle by Kamke in the following form:

LEMMA 2.3 [1]. *Let* $\bar{u}(t)$ *and* $\bar{v}(t)$ *be solutions of* (1.4a, c), *defined for* $a \leqq t \leqq b$. *Then* $\bar{u}(a) < \bar{v}(a)$ *implies* $\bar{u}(b) \leqq \bar{v}(b)$.

A solution $u_*(x)$ of a steady-state problem (1.3a, b) is called an attractor for the associated parabolic problem (1.1a, c) if, for the initial data $u(x, 0)$ sufficiently close (in C) to u_*, the corresponding solution of (1.1a–c) converges (in C) to u_*. We shall use the notation $h(I)$ for the Conley index of an isolated invariant set I, and Σ^k for the pointed k-sphere.

THEOREM 2.2 [10, Thm. 24.13]. *Let* f *be defined by* (1.2), *and let* $L > L_0$. *Then there are exactly three steady-state solutions* $u_k \in C^\infty$, $k = 0, 1, 2$, *of* (1.1a, c): $0 \equiv u_0(x) < u_1(x) < u_2(x) \leqq 1$, $|x| < L$. *They are isolated invariant sets,* $h(u_0) = h(u_2) = \Sigma^0$, *in particular,* u_0 *and* u_2 *are attractors for* (1.1a, c), *and the linearized operators* Q_0 *and* Q_2, *where*

$$Q_k = \frac{d^2}{dx^2} + g_k, \qquad g_k(x) = f'(u_k(x)), \qquad k = 0, 1, 2, \tag{2.15}$$

together with the boundary conditions (1.3b), *have only negative eigenvalues.* $h(u_1) = \Sigma^1$, *in particular* Q_1 *has precisely one positive eigenvalue, and* u_1 *has a one-dimensional unstable manifold which consists of orbits connecting* u_1 *to each of the other rest points. Initial data* $u(x, 0)$ *which satisfies* $u_1(x) < u(x, 0) < u_2(x)$ (*resp.* $0 < u(x, 0) < u_1(x)$) *on* $|x| < L$ *is in the stable manifold of* u_2 (*resp.* 0).

3. Convergence.

THEOREM 3.1. *Let* $u_k(x)$, $k = 0, 1, 2$, *be the solutions of* (1.3a, b). *There exists* n_0 *such that for* $n \geqq n_0$ *the system* (1.5a, b) *has exactly three solutions* $\bar{u}_n^k \equiv \bar{u}^k = (u_0^k, \cdots, u_{n+1}^k)^T$, $k = 0, 1, 2$, *satisfying*

$$\max_{0 \leqq i \leqq n+1} |u_i^k - u_k(x_i)| \leqq ch^2, \qquad c = \text{const}, \quad k = 1, 2, \tag{3.1}$$

$$\bar{0} \equiv \bar{u}^0 < \bar{u}^1 < \bar{u}^2, \tag{3.2}$$

where $\bar{0} = (0, \cdots, 0)^T$.

Proof. By Theorem 2.2, for $u_*(x) = u_k(x)$, $k = 0, 1, 2$, the conditions of Theorem 2.1 are satisfied. This gives the existence of solutions $\bar{u}^k$, $k = 0, 1, 2$, of (1.5a, b), satisfying (3.1). By (2.9) and Lemma 2.1 $\bar{u}^k$, $k = 0, 1, 2$, are the only solutions of (1.5a, b).

By Theorem 2.2 $0 \equiv u_0 < u_1 < u_2$ are isolated solutions of (1.3a, b). Together with (3.1) this implies (3.2) for n_0 sufficiently large. □

Define

$$F(u) = \int_0^u f(t)\,dt, \tag{3.3}$$

$$\Phi(\bar{u}) = \sum_{k=1}^{n} [u_k(u_{k-1} - 2u_k + u_{k+1})/2h^2 + F(u_k)]. \tag{3.4}$$

Then we have

LEMMA 3.1. *The system* (1.4a-c) *is a gradient one with respect to the function* Φ, *i.e.*

$$\dot{u} = \nabla\Phi. \tag{3.5}$$

Let $u_k(x)$ solve (1.3a, b) and $\bar{u}^k$ solve (1.5a, b). For $k = 0, 1, 2$, define the linearized matrix operators $Q_n^k = (q_{ij})$ and $\tilde{Q}_n^k = (\tilde{q}_{ij})$, $i, j = 1, \cdots, n$, by

$$q_{ij} = \begin{cases} -2/h^2 + f'(u_i^k), & i = j, \\ 1/h^2, & |i - j| = 1, \\ 0, & |i - j| > 1, \end{cases} \tag{3.6}$$

$$\tilde{q}_{ij} = \begin{cases} q_{ij} + \gamma_i, & i = j, \\ q_{ij}, & i \neq j, \end{cases} \tag{3.7}$$

where

$$\gamma_i = f'(u_k(x_i)) - f'(u_i^k). \tag{3.8}$$

LEMMA 3.2. *Suppose the assumptions of Theorem* 3.1 *hold. Let* n_0 *be chosen as in Theorem* 3.1. *There exists* $n_0' \geqq n_0$ *such that for* $n \geqq n_0'$ *we have*:

(i) Q_n^0 *and* Q_n^2 *have only negative eigenvalues, and* Q_n^1 *has precisely one positive eigenvalue, and* $\bar{u}_1$ *has a one-dimensional unstable manifold.*

(ii) $\bar{u}^k$, $k = 0, 1, 2$, *are isolated invariant sets of the system* (1.4a, c) *and* $h(\bar{u}^0) = h(\bar{u}^2) = \Sigma^0$, $h(\bar{u}^1) = \Sigma^1$.

Proof. By Lemma 2.2 with $u_*(x) = u_k(x)$, $k = 0, 1, 2$, every limit point of any sequence λ_n of eigenvalues of (2.11)-(2.12) is an eigenvalue of the problem (2.13)-(2.14). Using the notation (2.15) and (3.6)-(3.8), we rewrite (2.11)-(2.12) and (2.13)-(2.14), respectively, as

$$\tilde{Q}_n^k \bar{v} = \lambda \bar{v}, \tag{3.9}$$

$$Q_k^v = \lambda v, \qquad v(\pm L) = 0. \tag{3.10}$$

Let us prove the lemma for $k = 0$. For $k = 1, 2$, the proof is completely analogous.

Let $\tilde{\lambda}_n$ be a sequence of eigenvalues of (3.9). Since by Theorem 2.2 the largest eigenvalue λ of Q_0 is negative, say, $\lambda = -3\varepsilon$, $\varepsilon > 0$, by the above there exists n_0'' such that for $n \geqq n_0''$, $\tilde{\lambda}_n \leqq -2\varepsilon$. To complete the proof of (i) it is sufficient to verify that the eigenvalues λ_n of Q_n^0 satisfy $\lambda_n \leqq -\varepsilon$ for sufficiently large n. For $n \geqq n_0$ from (3.8) and (3.1), using that f'' is bounded on $[-L, L]$, we have

$$|\gamma_i| = \left| \int_{u_i^0}^{u^0(x_i)} f''(t)\,dt \right| \leqq c|u^0(x_i) - u_i^0| \leqq \frac{c}{n^2}. \tag{3.11}$$

From (3.7) and (3.11)

$$\begin{aligned}\lambda_n &= \sup_{\|\bar{v}\|=1} (Q_n^0 \bar{v}, \bar{v}) = \sup_{\|\bar{v}\|=1} \left[(\tilde{Q}_n^0 \bar{v}, \bar{v}) + \sum_{i=1}^{n} \gamma_i v_i^2 \right] \\ &\leqq \sup_{\|\bar{v}\|=1} \left[(\tilde{Q}_n^0 \bar{v}, \bar{v}) + \frac{c}{n^2} \right] = \tilde{\lambda}_n + \frac{c}{n^2}, \qquad c = \text{const},\end{aligned} \tag{3.12}$$

where

$$\|\bar{v}\|^2 = \sum_{i=1}^{n} v_i^2, \qquad (\bar{u}, \bar{v}) = \sum_{i=1}^{n} u_i v_i.$$

Now the above implies that choosing $n_0' \geqq \max\{n_0, n_0'', \sqrt{c/\varepsilon}\}$, we have for $n \geqq n_0'$, $c/n^2 < \varepsilon$, and therefore $\lambda_n < -\varepsilon$.

By (i) $\bar{u}^k$, $k = 0, 1, 2$, are nondegenerate rest points of (1.4a, c). Since from Lemma 3.1 the system (1.4a, c) is a gradient one, then by [10, pp. 151-152] the Morse index of $\bar{u}^k$, which is the number of positive eigenvalues of Q_n^k, is defined and is equal to the Conley index $h(\bar{u}^k)$. Thus by (i) $h(\bar{u}^0) = h(\bar{u}^2) = \Sigma^0$ and $h(\bar{u}^1) = \Sigma^1$. Alternatively, the latter result follows from [10, § 4, pp. 503-504]. By [10, p. 468 and Thm. 23.32] $\bar{u}^k$, $k = 0, 1, 2$, are isolated invariant sets for (1.4a, c). □

LEMMA 3.3. *The rectangle*

$$R = \bigcap_{i=1}^{n} \{\bar{u}: 0 \leqq u_i \leqq 1\} \tag{3.13}$$

is attracting for the problem (1.4a-c), *i.e., all solutions* $\bar{u}(t)$ *of* (1.4a-c) *tend to* R *as* $t \to \infty$.

Proof. Let $R_\tau = \tau R$, $\tau > 1$, be a family of contracting rectangles about R. We say that $\bar{u}(t)$ is in the jth right-hand face on R_τ if $u_j(t) = \tau$, with a similar definition for the jth left-hand face. We shall also use the notations $\bar{f} = \{f(u_1), \cdots, f(u_n)\}^T$ and $\nabla\Phi$ (see (3.5)) for the vector field which is the right-hand side of the system (1.4a).

If now $\bar{u}(T) \in \partial R_\tau$, e.g., $\bar{u}(T)$ is in the jth right-hand face, then from the definition (1.2) of $f(u)$ we have

$$(\bar{f}, \bar{n}(\bar{u})) = f(u_j) < -\eta,$$

where $\bar{n}$ is the outward-pointing normal at $\bar{u}$, $\eta = \text{const} > 0$. And therefore by (1.4a) and Lemma 3.1 there holds

$$(\nabla\Phi, \bar{n}) = (u_{j+1} - 2u_j + u_{i-1})/h^2 + f(u_j) < -\eta. \tag{3.14}$$

Thus (3.14) shows that $\bar{u}(t)$ must lie in a smaller rectangle for $T < t < T + \delta$, for some $\delta > 0$. □

Using Lemmas 3.2 and 3.3 and repeating the proof of [10, Lemma 24.12] with $u_k(x)$ replaced by $\bar{u}^k$ we arrive at the next lemma.

LEMMA 3.4. *Under the assumptions of Lemma* 3.2, *there exist solutions* $\bar{v}^0$ *and* $\bar{v}^2$ *of* (1.4a, c), *which connect* $\bar{u}^1$ *to* $\bar{u}^0$ *and* $\bar{u}^1$ *to* $\bar{u}^2$, *respectively*; *i.e.*,

$$\lim_{t \to -\infty} \bar{v}^0(t) = \bar{u}^1, \qquad \lim_{t \to \infty} \bar{v}^0(t) = u^0,$$

$$\lim_{t \to -\infty} \bar{v}^2(t) = \bar{u}^1, \qquad \lim_{t \to \infty} \bar{v}^2(t) = \bar{u}^2.$$

Combining the above results, we have the following:

THEOREM 3.2. *Let f be defined by* (1.2) *and $L > L_0$. Then there exists n_0 such that for $n \geqq n_0$*

(i) *The steady-state problem* (1.5a, b) *has exactly three solutions*: $\bar{0} \equiv \bar{u}^0 < \bar{u}^1 < \bar{u}^2 \leqq \bar{1}$.

(ii) $\bar{u}^k$, $k = 0, 1, 2$, *are isolated invariant sets for the associated parabolic problem* (1.4a, c). $h(\bar{u}^0) = h(\bar{u}^2) = \Sigma^0$, *in particular, $\bar{u}^0$ and $\bar{u}^2$ are the attractors, and the linearized operators Q_n^0 and Q_n^2, where Q_n^k are defined by* (3.6), *have only negative eigenvalues.* $h(\bar{u}^1) = \Sigma^1$, *in particular, $\bar{u}^1$ has a one-dimensional unstable manifold which consists of orbits connecting $\bar{u}^1$ to each of the other rest points.*

(iii) *Initial data which satisfies $\bar{u}^1 < \bar{u}(0)$ is in the stable manifold of $\bar{u}^2$, and there holds*:

$$\lim_{t \to \infty} \max_{0 \leqq i \leqq n+1} |u_i(t) - u(x_i, t)| \leqq ch^2. \tag{3.15}$$

Initial data which satisfies $\bar{u}(0) < \bar{u}^1$ is in the stable manifold of $\bar{0}$, and there holds:

$$\lim_{t \to \infty} \max_{0 \leqq i \leqq n+1} |u_i(t)| = 0. \tag{3.16}$$

Proof. Condition (i) follows from Theorem 3.1 and Lemma 3.3. Condition (ii) follows from Lemmas 3.2 and 3.4. Condition (iii) follows from (i), (ii) and Lemmas 2.3, 3.4 by repeating the argument in [10, pp. 535-536]. □

ON THE ZEROS OF THE ASKEY-WILSON POLYNOMIALS, WITH APPLICATIONS TO CODING THEORY*

LAURA CHIHARA†

Abstract. In a symmetric association scheme that is (P and Q)-polynomial, the P and Q eigenmatrices are given by balanced ${}_4\phi_3$ Askey-Wilson polynomials. In this paper, the parameters of the Askey-Wilson polynomial are classified so that its zeros are not contained in its spectrum. These results, together with theorems of Biggs and Delsarte, imply the nonexistence of perfect codes and tight designs in the classical association schemes of type A_N, B_N, C_N, D_N and the affine matrix schemes.

Key words. Askey-Wilson polynomials, association schemes, perfect codes, tight designs

AMS(MOS) subject classifications. 5, 33, 94

1. Introduction. In classical coding theory there is a well-known relationship between the existence of perfect codes and the properties of certain orthogonal polynomials. Lloyd's theorem [7, p. 179] states that if a perfect code exists in the Hamming metric, then the Krawtchouk polynomial must have integral zeros. In this paper we consider a very general set of orthogonal polynomials, the Askey-Wilson polynomials [1], and give sufficient conditions on their parameters so that they do not have the corresponding property from Lloyd's theorem. Our main result is Theorem 4.8, which shows that perfect codes do not exist in the families of association schemes [10] defined by Chevalley groups over $GF(q)$. The only possible exceptions are perfect 1-codes for B_N and C_N when $N=2^m-1$. Since B_N and C_N provide q-analogues of N-tuples of 0's and 1's, this is the natural condition for perfect Hamming 1-codes [7, p. 23].

The fact that the Askey-Wilson polynomials are relevant is due to work of Biggs [3], Delsarte [5] and Leonard [6]. Biggs showed that Lloyd's theorem generalized to distance regular graphs, while Delsarte generalized it to metric P-polynomial association schemes. Both theorems stated that related polynomials must have zeros in a very restricted set. Leonard proved that the polynomials for a (P and Q)-polynomial association scheme must be the Askey-Wilson polynomials. The set for the zeros of these polynomials is easily identified. Since the Askey-Wilson polynomials have an explicit formula, it is possible to show that the zeros do not lie in the set. Since the parameters of the association scheme are related to the parameters of the polynomial, this proves nonexistence of perfect codes. A dual theorem of Delsarte [5, p. 76] also proves the nonexistence of tight designs.

Our paper is organized in the following way. In § 2, we give the Askey-Wilson polynomials and identify the generalized Lloyd polynomials in Proposition 2.1 as other Askey-Wilson polynomials. Properties of the zeros are given in § 3. Under the hypothesis that q is integral and a, b, d rational, sufficient conditions on a, b and d are listed in Table 1 so that the zeros do not lie in the spectrum. In § 4, we show how to use the results from § 3 to prove nonexistence of perfect codes and tight designs in the classical association schemes. These results are summarized in Table 2. Finally, in § 5 we show that if a perfect 1-code exists in types B_N and C_N, then $N=2^m-1$. We also give another proof of Proposition 2.1.

2. Preliminaries. In this section, we review the basic facts about (P and Q)-polynomial association schemes and the Askey-Wilson polynomials. References for this material are [1], [2], [5].

A symmetric association scheme X is called P-polynomial, where P is the eigenmatrix of X with (i, k) entry $P_k(i)$, if for a given set of distinct nonnegative real numbers $z_0=0, z_1, \cdots, z_n$ and each integer k, $0 \leqq k \leqq N$, there exists a polynomial $\Phi_k(z)$ over $\mathbb{R}$ of degree k such that

$$\Phi_k(z_i)=P_k(i), \qquad i=0, 1, \cdots, N.$$

A Q-polynomial scheme is defined analogously from the Q eigenmatrix. We denote the corresponding polynomials by Φ_k^*.

If X is a (P and Q)-polynomial association scheme, Leonard showed [6] that for $N \geqq 9$, Φ_k and Φ_k^* are given by Askey-Wilson polynomials, including certain limiting cases. These polynomials $P_k(\theta(x), a, b, c, d; q)$ of degree k in $\theta(x)$ are defined in terms of basic hypergeometric series and have the explicit formula [1]

$$P_k(\theta(x), a, b, c, d; q)=P_k(\theta(x))={}_4\phi_3\left(\begin{matrix} q^{-k}, abq^{k+1}, q^{-x}, cdq^{x+1} \\ aq, bdq, cq \end{matrix} \;\middle|\; q; q\right) \tag{2.1}$$

where

$$\theta(x)=(1-q^{-x})(1-cdq^{x+1}) \tag{2.2}$$

and

$${}_{r+1}\phi_r\left(\begin{matrix} q^{-k}, a_1, \cdots, a_r \\ b_1, \cdots, b_r \end{matrix} \;\middle|\; q; q\right)=\sum_{j=0}^{k} \frac{(q^{-k})_j(a_1)_j \cdots (a_r)_j q^j}{(b_1)_j \cdots (b_r)_j(q)_j} \tag{2.3}$$

with

$$(a)_j=(a; q)_j=\begin{cases} (1-a)(1-aq) \cdots (1-aq^{j-1}), & j=1, 2, \cdots, \\ 1, & j=0. \end{cases} \tag{2.4}$$

Askey and Wilson showed that if aq, bdq or cq is assumed to be q^{-N}, then $\{P_k(\theta(x))\}_{k=0}^N$ are orthogonal polynomials on $\{\theta(0), \cdots, \theta(N)\}$ and have the discrete orthogonality relation

$$\sum_{x=0}^{N} P_n(\theta(x), a, b, c, d; q)P_m(\theta(x), a, b, c, d; q)w(x)=0, \tag{2.5}$$

$$m \neq n, \quad 0 \leqq m, \quad n \leqq N$$

where

$$w(x)=w(x, a, b, c, d; q)=\frac{(cdq)_x(1-cdq^{2x+1})(aq)_x(bdq)_x(cq)_x(abq)^{-x}}{(q)_x(1-cdq)(cda^{-1}q)_x(b^{-1}cq)_x(dq)_x}. \tag{2.6}$$

Leonard's theorem [6] states that for $N \geqq 9$, given a (P and Q)-polynomial association scheme X, there exists parameters a, b, c, d, q such that

$$\Phi_k(\theta(x), a, b, c, d; q)=\Phi_k(\theta(x))=\nu_k P_k(\theta(x), a, b, c, d; q) \tag{2.7}$$

and

$$\Phi_k^*(\theta^*(x), a, b, c, d; q)=\Phi_k^*(\theta^*(x))=\mu_k P_k(\theta^*(x), c, d, a, b; q) \tag{2.8}$$

where $\theta^*(x)=(1-q^{-x})(1-abq^{x+1})$. The nonzero constants ν_k and μ_k are the valencies and multiplicities, respectively, of the association scheme. Moreover, up to a constant, $\nu_k=w(k, c, d, a, b; q)$ and $\mu_k=w(k, a, b, c, d; q)$.

For such an association scheme X, recall that the generalized Lloyd and Wilson polynomials [5, p. 58] are given by

$$\Psi_e(\theta(x))=\sum_{k=0}^{e}\Phi_k(\theta(x)), \tag{2.9}$$

$$\Psi_e^*(\theta^*(x))=\sum_{k=0}^{e}\Phi_k^*(\theta^*(x)) \tag{2.10}$$

where e is a positive integer.

We now state a proposition that identifies $\Psi_e(\theta(x))$ and $\Psi_e^*(\theta^*(x))$ also as Askey-Wilson polynomials.

PROPOSITION 2.1. *Suppose X is a (P and Q)-polynomial association scheme such that* (2.7) *and* (2.8) *hold. Then*

$$\Psi_e(\theta(x))=AP_e(\tilde{\theta}(x-1), aq, b, cq, dq; q), \tag{2.11}$$

$$\Psi_e^*(\theta^*(x))=A^*P_e(\tilde{\theta}^*(x-1), cq, d, aq, bq; q), \tag{2.12}$$

where A and A^* are nonzero constants, $\tilde{\theta}(x-1)=(1-q^{-x+1})(1-cdq^{x+2})$ and $\tilde{\theta}^*(x-1)=(1-q^{-x+1})(1-abq^{x+2})$.

Remark. Recall that for $P_k(\theta(x), a, b, c, d; q)$, we have defined $\theta(x)$ as in (2.2). Thus, for polynomials with shifted parameters, $P_k(\theta(x), aq, b, cq, dq; q)$, we get $\theta(x)=(1-q^{-x})(1-cdq^{x+3})$. From now on, $\theta(x)$ will always stand for the variable in $P_k(\theta(x), a, b, c, d, q)$, and whenever the parameters shift, we will denote the corresponding variable as $\tilde{\theta}(x)$.

Proof of Proposition 2.1. Delsarte shows [5, p. 58] that $\Psi_0(\theta(x)),\cdots,\Psi_{N-1}(\theta(x))$ form an orthogonal set of polynomials on $\{\theta(1),\cdots,\theta(N)\}$ with respect to the weight $\theta(x)w(x)$. From (2.2) and (2.3), we see that

$$\theta(x)w(x, a, b, c, d; q)=\alpha w(x-1, aq, b, cq, dq; q) \tag{2.13}$$

where $\alpha\neq 0$ is a constant. Since $\Psi_e(\theta(x))$ is a polynomial in $\theta(x)$ and orthogonal polynomials are unique with respect to a weight, we have (2.11). Similarly, we get (2.12).

Remark. In § 5, we will present another proof of Proposition 2.1 in which we explicitly determine the constant A.

3. Properties of the roots of the Askey-Wilson polynomials. There is a generalized Lloyd's theorem for perfect e-codes due to Delsarte [5, p. 63] and Biggs [3, p. 294]. It states that if the association scheme X has a perfect e-code, then the Lloyd polynomial of degree e, $\Psi_e(\theta(x))$, must have e distinct roots among $\{\theta(1),\cdots,\theta(N)\}$. A similar result holds for tight t-designs ($t=2e$) and Wilson polynomials [5, p. 76]. By Proposition 2.1, $\Psi_e(\theta(x))$ and $\Psi_e^*(\theta^*(x))$ are explicitly given by an Askey-Wilson polynomial. In this section, we state properties of $P_e(\tilde{\theta}(x-1), aq, b, cq, dq; q)$.

PROPOSITION 3.1. *Let $\theta_1,\cdots,\theta_e$ be the e roots of $P_e(\tilde{\theta}(x-1), aq, b, cq, dq; q)$ as a polynomial in $\theta(x)$. Then*

(i) $\theta_1=\theta(1)+\dfrac{(1-aq^2)(1-bdq^2)(1-cq^2)q^{-1}}{(1-abq^3)}$ *if* $e=1$,

(ii) $\displaystyle\sum_{j=1}^{e}\theta_j=\sum_{j=1}^{e}\theta(j)+\frac{(1-aq^{e+1})(1-bdq^{e+1})(1-cq^{e+1})(1-q^{e-1})(1-q^{e})q^{-e}}{(1-abq^{2e+1})(1-q)}$

if $e\geqq 2$.

Proof. Note that $\tilde{\theta}(x-1)=q\theta(x)+1-q-cdq^2+cdq^3$. Let $F_e(\theta(x))=P_e(\tilde{\theta}(x-1), aq, b, cq, dq; q)$. Then clearly $F_e(\theta(x))=\beta(\theta(x)-\theta_1)\cdots(\theta(x)-\theta_e)$ for some constant $\beta\neq 0$. Thus, to get a formula for the sum of the roots, we need to consider the coefficient of $\theta^{e-1}(x)$ in $F_e(\theta(x))/\beta$. From (2.1) and (2.3), we have

$$F_e(\theta(x))=\sum_{j=0}^{e}\frac{(q^{-e})_j(abq^{e+2})_j(q^{-x+1})_j(cdq^{x+2})_jq^j}{(aq^2)_j(bdq^2)_j(cq^2)_j(q)_j}. \tag{3.1}$$

An explicit computation yields $(1-q^{-x+k})(1-cdq^{x+k+1})=q^k(\theta(x)-\theta(k))$. Hence, for $j\geqq 1$,

$$(q^{-x+1})_j(cdq^{x+2})_j=\prod_{k=1}^{j}(1-q^{-x+k})(1-cdq^{x+k+1})=\prod_{k=1}^{j}q^k(\theta(x)-\theta(k)).$$

Thus,

$$\begin{aligned}F_e(\theta(x))&=1+\sum_{j=1}^{e}\frac{(q^{-e})_j(abq^{e+2})_j[\prod_{k=1}^{j}\theta(x)-\theta(k)]q^{j+j(j+1)/2}}{(aq^2)_j(bdq^2)_j(cq^2)_j(q)_j}\\&=\beta\left\{\frac{1}{\beta}+\sum_{j=1}^{e}\frac{(q^{-e})_j(abq^{e+2})_j[\prod_{k=1}^{j}\theta(x)-\theta(k)]q^{j+j(j+1)/2}}{\beta(aq^2)_j(bdq^2)_j(cq^2)_j(q)_j}\right\},\end{aligned} \tag{3.2}$$

where

$$\beta=\frac{(q^{-e})_e(abq^{e+2})_eq^{e+e(e+1)/2}}{(aq^2)_e(bdq^2)_e(cq^2)_e(q)_e}=\frac{(-1)^eq^e(abq^{e+2})_e}{(aq^2)_e(bdq^2)_e(cq^2)_e}.$$

Thus, the expression between the brackets in (3.2) is now monic in $\theta(x)$. The coefficient of $\theta(x)^{e-1}(e\geqq 2)$ in $F_e(\theta(x))/\beta$ is

$$-\sum_{i=1}^{e}\theta_i=-\sum_{j=1}^{e}\theta(j)-\frac{(1-aq^{e+1})(1-bdq^{e+1})(1-cq^{e+1})(1-q^{e-1})(1-q^e)q^{-e}}{(1-abq^{e+1})(1-q)},$$

where the sum on the right side of the equality is the contribution when $j=e$ in (3.2), and the second is the $j=e-1$ contribution. For $e=1$, $F_1(\theta(x))$ is of degree 1, so solving explicitly for θ_1 yields (i).

PROPOSITION 3.2. *If $\theta_1,\cdots,\theta_e$ are the e roots of $P_e(\tilde{\theta}(x-1), aq, b, cq, dq; q)$ as a polynomial in $\theta(x)$, then*

$$\prod_{i=1}^{e}\theta_i=\frac{(aq^2)_e(bdq^2)_e(cq^2)_e}{(abq^{e+2})_eq^e}\,{}_4\phi_3\left(\begin{matrix}q^{-e}, abq^{e+2}, cdq^2, q\\ aq^2, bdq^2, cq^2\end{matrix}\;\middle|\; q;q\right). \tag{3.3}$$

Proof. Using the same notation as in the proof of Proposition 3.1 we see that we want the constant term in $F_e(\theta(x))/\beta$. From (3.2) we have

$$(-1)^e\prod_{i=1}^{e}\theta_i=\frac{1}{\beta}+\sum_{j=1}^{e}\frac{(q^{-e})_j(abq^{e+2})_j(-1)^j\theta(1)\cdots\theta(j)q^{j+j(j+1)/2}}{\beta(aq^2)_j(bdq^2)(cq^2)_j(q)_j}.$$

Noting that $\theta(k)=-(1-q^k)(1-cdq^{k+1})q^{-k}$ and recalling (2.3) and the definition of β, the result follows.

From now on, we assume $cq=q^{-N}$.

PROPOSITION 3.3. *Suppose $P_e(\tilde{\theta}(x-1), aq, b, cq, dq; q)$ has e roots θ_i such that $\theta_i=\theta(x_i)$ for some x_i, $i=1,2,\cdots,e$. Then*

$$\begin{aligned}-(1-abq^{2e+1})\sum_{i=1}^{e}(dq^{x_i}+q^{N-x_i})&=-(1-abq^{2e+1})(dq+q^{N-e})(1+p'(q))\\&\quad+(1-aq^{e+1})(1-bdq^{e+1})(-1+p(q))\end{aligned} \tag{3.4}$$

where $p'(q)$ and $p(q)$ are polynomials in q with integer coefficients and $p'(q) \equiv 0 \bmod q$ and $p(q) \equiv 0 \bmod q$.

Proof. Recalling $\theta(x) = (1-q^{-x})(1-dq^{-N+x})$, we have

$$\sum_{i=1}^{e} \theta(x_i) = \sum_{i=1}^{e} (1 - dq^{-N+x_i} - q^{-x_i} + dq^{-N})$$
$$= e(1+dq^{-N}) - \sum_{i=1}^{e} (dq^{-N+x_i} + q^{-x_i})$$

and

$$\sum_{j=1}^{e} \theta(j) = e(1+dq^{-N}) - \sum_{j=1}^{e} (dq^{-N+j} + q^{-j})$$
$$= e(1+dq^{-N}) - (dq^{-N} + q^{-e})\frac{(1-q^e)}{(1-q)}$$

where the last equality is obtained by the sum for the geometric progression. Substituting the above expressions into (i) and (ii) of Proposition 3.1 and multiplying the resulting identity by $q^N(1-abq^{2e+1})$ yields the desired result, where

$$1+p'(q) = \begin{cases} 1, & e=1, \\ \dfrac{1-q^e}{1-q}, & e \geqq 2, \end{cases}$$

and

$$-1+p(q) = \begin{cases} -1+q^{N-1}, & e=1, \\ (q^{N-e}-1)(1-q^{e-1})\dfrac{(1-q^e)}{(1-q)}, & e \geqq 2. \end{cases}$$

Remarks. The existence of a perfect e-code in X implies that the e distinct roots of $\Psi_e(\theta(x))$ are contained in $\{\theta(1), \cdots, \theta(N)\}$. In fact, we can eliminate $\theta(1)$ and $\theta(N)$ as possible roots of $\Psi_e(\theta(x))$. From (2.11) and (3.2), we see that $\Psi_e(\theta(1)) = 1 \neq 0$. On the other hand, if we let $x = N$, then

$$\Psi_e(\theta(N)) = {}_3\phi_2\left(\begin{matrix} q^{-e}, abq^{e+2}, dq \\ aq^2, bdq^2 \end{matrix} \,\middle|\, q; q\right) = \frac{(1/bq^e)_e(aq/d)_e}{(aq^2)_e(1/bdq^{e+1})_e}$$

where the last equality was obtained by the ${}_3\phi_2$ evaluation [8, p. 96]

$$(3.5) \qquad {}_3\phi_2\left(\begin{matrix} q^{-e}, A, B \\ C, ABq^{1-e}/C \end{matrix} \,\middle|\, q; q\right) = \frac{(C/A)_e(C/B)_e}{(C)_e(C/AB)_e}.$$

Hence, $\Psi_e(\theta(N)) = 0$ implies that either

$$(3.6) \qquad b = q^{-k}, \quad 1 \leqq k \leqq e \quad \text{or} \quad a/d = q^{-k}, \quad 1 \leqq k \leqq e.$$

However, since the Askey-Wilson polynomials are orthogonal on $\{\theta(1), \cdots, \theta(N)\}$, certain positivity conditions must be satisfied, putting some restrictions on a, b and d [1, p. 1015]. These considerations rule out (3.6). Thus $\Psi_e(\theta(N)) \neq 0$.

We assume that the (P and Q)-polynomial association scheme X has a perfect e-code ($2e+1 \leqq N$). Thus, the generalized Lloyd's theorem and the previous remarks tell us that Ψ_e has all its roots in $\{\theta(2), \cdots, \theta(N-1)\}$. For integral $q \neq 1$ this will imply conditions on the parameters a, b and d. For the known association schemes we will record those values a, b and d and find they do not satisfy these conditions.

The main idea is to assume q integral and a, b and d rational. Then (3.4), upon clearing denominators, is a polynomial identity in q. We get an expression that is $0 \bmod q$ on one side, and not $0 \bmod q$ on the other. This contradiction establishes that $\Psi_e(\theta(x))$ cannot have e distinct roots among $\{\theta(i) | i = 2, \cdots, N-1\}$ and hence X cannot have a perfect e-code. These results are given in Table 1. For simplicity's sake, we only list those parameters for which a contradiction can be obtained without detailed knowledge of the zeros themselves. We give two examples to illustrate the techniques.

We assume q is integral, $q \neq 1$, and e is an integer, $2e+1 \leqq N$. Also, recall $cq = q^{-N}$.

Example 1. Suppose $d = r/s$, $a = m/nq^k$, $b = m'/n'q^l$, where r, s, m, n, k, m', n', l are integers, $r, s, m, n, m', n' \not\equiv 0 \bmod q$, and $k \leqq e$, $l \leqq e$. From (3.4), we get

$$-\left(1-\frac{mm'}{nn'}q^{2e+l-l-k}\right)\sum_{i=1}^{e}\left(\frac{r}{s}q^{x_i}+q^{N-x_i}\right)$$
$$=-\left(1-\frac{mm'}{nn'}q^{2e+1-l-k}\right)\left(\frac{r}{s}q+q^{N-e}\right)(1+p'(q))$$
$$+\left(1-\frac{m}{n}q^{e+1-k}\right)\left(1-\frac{m'r}{n's}q^{e+1-l}\right)(-1+P(q)),$$

or upon clearing fractions,

$$\begin{aligned}&-(nn'-mm'q^{2e+1-l-k})\sum_{i=1}^{e}(rq^{x_i}+sq^{N-x_i})\\ &=-(nn'-mm'q^{2e+1-l-k})(rq+sq^{N-e})(1+p'(q))\\ &+(n-mq^{e+1-k})(n's-m'rq^{e+1-l})(-1+p(q)).\end{aligned}\tag{3.7}$$

Since we have e distinct zeros $\theta(x_i) \in \{\theta(2), \cdots, \theta(N-1)\}$, we let $2 \leqq x_1 < x_2 < \cdots < x_e \leqq N-1$. Noting that all powers of q are positive ($k \leqq e, l \leqq e, 2e+1 \leqq N$), we see that the expression on the left of the equality in (3.6) is $0 \bmod q$. On the right side, the first term is $0 \bmod q$. Thus, we get a contradiction if the second term on the right side is not $0 \bmod q$, or in particular, $nn's \not\equiv 0 \bmod q$. This is listed in Table 1 under 2B(ii).

Example 2. Suppose $a = m/nq^{e+1}$, $b = m'/n'q^{e+1}$, $d = r/s$ where m, n, m', n', r, s are integers not congruent to $0 \bmod q$. Substituting these values into (3.4) and clearing fractions yield

$$-(nn'q-mm')\sum_{i=1}^{e}(rq^{x_i}+sq^{N-x_i}) = -(nn'q-mm')(rq+sq^{N-e})(1+p'(q))$$
$$+q(n-m)(n's-m'r)(-1+p(q)).$$

If we have $N - x_i \geqq 2$ for all i (recall we always have $x_i \geqq 2$), then the expression on the left of the equality is $0 \bmod q^2$, so we get a contradiction if we insist that $mm'r - (n-m)(n's-m'r) \not\equiv 0 \bmod q$. This case is not listed in Table 1 since in general, we do not know if $N - x_i \geqq 2$ for all i.

To consider results on tight t-designs ($t = 2e$) in the known (P and Q) association schemes, the following limiting case is very important. We will see (Corollary 3.5) that knowledge of the x_i's is crucial.

PROPOSITION 3.4. *Suppose the parameters of* $P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)$ *have the following limiting values*: $d = 0$, $a \to 0$, $b \to \infty$, $ab \to u/vq^p$, *where* u, v *and* p *are integers*, $u, v \not\equiv 0 \bmod q$. *Then the* e *roots of* $P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)$ *satisfy*

$$-(v-uq^{2e+1-p})\sum_{i=1}^{e}q^{N-x_i} = -(v-uq^{2e+1-p})q^{N-e}(1+p'(q))+v(-1+p(q)).\tag{3.8}$$

Proof. Using (3.4), the proof is straightforward.

TABLE 1

Parameters such that $P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)$ does not have e distinct zeros in $\{\theta(j) \mid j=2,\cdots,N-1\}$.

d	$a=m/hq^k$ $m, n \not\equiv 0 \bmod q$, k integral	$b=m'/n'q^l$ $m', n' \not\equiv 0 \bmod q$, l integral
1. $d=0$	A. $a \to 0$	(i) b no restriction ($\lvert b\rvert<\infty$)
		(ii) $b\to\infty$, $ab \to u/vq^p$, $u, v \not\equiv 0 \bmod q$ $p \leqq 2e+1$
	B. $k \leqq e$	(i) $b=0$
		(ii) $l \leqq e+1$, $nn' \not\equiv 0 \bmod q$
		(iii) $l>e+1$, $l+k \leqq 2e+1$, $nn' \not\equiv 0 \bmod q$
	C. $k=e+1$	(i) $b=0$, $n-m \not\equiv 0 \bmod q$
		(ii) $l \leqq e$, $n'(n-m) \not\equiv 0 \bmod q$
		(iii) $l \geqq N$, $mm' \not\equiv 0 \bmod q$
	D. $k \geqq e+2$	(i) $b=0$
		(ii) $l \leqq e$, $mn' \not\equiv 0 \bmod q$
		(iii) $l \geqq N$, $mm' \not\equiv 0 \bmod q$
	E. $a \to \infty$	(i) $\lvert b\rvert<\infty$, $b \neq 0$, $l \leqq e$
		(ii) $\lvert b\rvert<\infty$, $l \geqq N$
2. $d=r/s$ $r, s \not\equiv 0 \bmod q$	A. $a=0$	(i) $b=0$
		(ii) $l<e+1$, $n's \not\equiv 0 \bmod q$
		(iii) $l=e+1$, $n's-m'r \not\equiv 0 \bmod q$

COROLLARY 3.5. *Under the hypothesis of Proposition* 3.4, $P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)$ *does not have* e *distinct zeros* $\theta(x_i)$, $x_1<x_2<\cdots<x_e$, *in* $\{\theta(j)\mid j=2,\cdots,N-1\}$ *if*

(i) $p\leqq 2e+1$, *or*

(ii) $p>2e+1$ *and* $N-x_e<\min\{p-2e-1, N-e\}$.

Proof. (i) Since $2\leqq x_i\leqq N-1$, the left side of (3.8) is $0 \bmod q$, whereas on the right, $v\not\equiv 0 \bmod q$ by assumption. This is a contradiction.

(ii) We see that (3.8) is equivalent to

$$-(vq^{p-2e-1}-u)\sum_{i=1}^{e} q^{N-x_i}=-(vq^{p-2e-1}-u)q^{N-e}(1+p'(q))+vq^{p-2e-1}(-1+p(q)).$$

Both sides are now $0 \bmod q$. However, if $N-x_e<\min\{p-2e-1, N-e\}$, then we can divide both sides by q^{N-x_e}. The left side will not be 0 mod q (since $u \not\equiv 0 \bmod q$), but the right side will still be 0 mod q. This is a contradiction.

4. Applications. We shall show that the results of the previous section establish the nonexistence of perfect e-codes and tight e-designs in the classical association schemes of types $A_{v-1}, {}^2A_{2N}, {}^2A_{2N-1}, B_N, C_N, D_N, {}^2D_{N+1}$, and the affine matrix schemes. We refer the reader to [2] for a brief description.

As an example, consider the association scheme of type D_N. The (i, k) entry of the P eigenmatrix is given by

$$P_k(i) = v_k P_k(\theta(i), 0, 0, q^{-N}, -q; q).$$

Hence we have $a=0$, $b=0$, $d=-1$. These parameters lie in Table 1 under 2A(i). We conclude that the Lloyd polynomial does not have e distinct roots in $\{\theta(j) | j=1, \cdots, N\}$ and so there are no perfect e-codes.

The (i, k) entry of the Q eigenmatrix in type D_N is given by

$$Q_k(i) = \mu_k {}_3\phi_2\left(\begin{matrix} q^{-k}, q^{-i}, -q^{-N+k} \\ 0, q^{-N} \end{matrix} \middle| q; q\right).$$

The ${}_3\phi_2$ is derived from (2.1) by considering the limiting case $d=0$, $a \to \infty$, $b \to 0$, $ab \to -q^{-N-1}$. To apply Corollary 3.5, we will need to establish some lemmas giving us more information on the roots of the corresponding Wilson polynomial. (For this reason, Table 1 is inapplicable here.)

LEMMA 4.1. *If $P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, 0; q)$ has e distinct roots $\theta(x_1), \cdots, \theta(x_e)$ in $\{\theta(j) | j=2, \cdots, N-1\}$, $2 \leqq x_1 < \cdots < x_e \leqq N-1$, then $x_e > 2e$ except in the following cases*:

(i) *If $q>0$, $x_1=2$, $x_2=4, \cdots, x_e=2e$.*

(ii) *If $q<0$ and e is even, then either*

$$x_1=2, \quad x_2=3, \quad x_3=6, \quad x_4=7, \cdots, x_{e-1}=2(e-1), \quad x_e=2e-1, \textit{ or}$$

$$x_1=3, \quad x_2=4, \quad x_3=7, \quad x_4=8, \cdots, x_{e-1}=2(e-1)+1, \quad x_e=2e.$$

(iii) *If $q<0$ and e is odd, then*

$$x_1=2, \quad x_2=3, \quad x_3=6, \quad x_4=7, \cdots, x_{e-1}=2(e-1)+1, \quad x_e=2e.$$

Proof. Recall that the open interval between two consecutive zeros of an orthogonal polynomial must contain a point of the spectrum [4, p. 59]. Also, since $d=0$, we have $\theta(x) = 1-q^{-x}$.

(i) If $q>0$, then $\theta(k) < \theta(k+1)$ for all positive integers k. Hence $x_e > 2e$ unless $x_1=2$, $x_2=4, \cdots, x_2=2e$.

(ii) If $q<0$, then for nonnegative integers n and k, we have

$$\theta(2n) < \theta(2n+2), \quad \theta(2n+1) > \theta(2n+3), \quad \theta(2n) < \theta(2k+1).$$

If e is even, then there are only two ways to choose the x_i $(x_1 < x_2 < \cdots < x_e)$ so that $x_e \leqq 2e$. We take $(e/2)$ of the x_i to be even and $(e/2)$ of the x_i to be odd to get either

$$\theta(2) < \theta(6) < \theta(10) < \cdots < \theta(2e-2) < \theta(2e-1) < \theta(2e-5) < \cdots < \theta(7) < \theta(3),$$

or

$$\theta(4) < \theta(8) < \cdots < \theta(2e-4) < \theta(2e) < \theta(2e-1) < \theta(2e-5) < \cdots < \theta(7) < \theta(3).$$

(iii) If $q<0$ and e is odd, we choose $((e+1)/2)$ of the x_i to be even and $((e-1)/2)$ of the x_i to be odd

$$\theta(2)<\theta(6)<\cdots<\theta(2e-4)<\theta(2e)<\theta(2e-1)<\cdots<\theta(7)<\theta(3).$$

LEMMA 4.2. *For the association scheme D_N, $\Psi_e^*(\theta^*(3))\neq 0$ for $e\geqq 1$.*

Proof. If $e\geqq 2$ and $\Psi_e^*(\theta^*(3))=0$, then

$$A^*\sum_{j=0}^{2}\frac{(q^{-e})_j(-q^{-N+e+1})_j(q^{-2})_j q^j}{(q^{-N+1})_j(q)_j}=0.$$

Multiplying the above expression by $(1-q^{-N+1})(1-q^{-N+2})(1-q)(1-q^2)q^{2N-2}$ yields $qf(q)-(q^{N-2}-1)(q^{N-e-1}+1)(q^e-1)(q^2-1)^2=0$ where $f(q)$ is a polynomial in q with integer coefficients. Since $2e+1\leqq N$ and $e\geqq 2$, the second term on the left side of the equality is not 0 mod q. This contradiction implies $\Psi^*(\theta^*(3))\neq 0$. A similar calculation establishes the result for $e=1$.

THEOREM 4.3. *The association scheme of type D_N has no tight t-design of order $e(t=2e)$ unless $2e+1=N$.*

Proof. Since $\Psi_e^*(\theta^*(x))=P_e(\tilde{\theta}(x-1),\infty,0,q^{-N},0;q)$, we apply Corollary 3.5 with $d=0$, $a\to\infty$, $b\to 0$, $ab\to q^{-N-1}$. We take $u=-1$, $v=1$ and $p=N+1$. Since $2e+1\leqq N$, we have $p>2e+1$ and so $\Psi_e^*(\theta^*(x))$ does not have e distinct roots in $\{\theta(j)\,|\,j=2,\cdots,N-1\}$ if $N-x_e>\min\{P-2e-1,N-e\}$, or equivalently $x_e>2e$. By Lemma 4.1 and Lemma 4.2, the only possibility is $x_1=2$, $x_2=4,\cdots,x_e=2e$ if $q>0$. Checking $\Psi_e^*(\theta(2))=0$ yields $e=(N-1)/2$. Tight designs where $N=2e+1$ are known to exist [11, p. 661].

We summarize our results in Table 2. We list the P and Q polynomials for the classical association schemes and affine matrix schemes along with the values of the parameters for the Askey-Wilson polynomials. Finally, we give the references which establish the nonexistence of perfect e-codes and tight t-designs. Note that Table 1 gives the nonexistence of perfect e-codes for all the schemes except types B_N and C_N (these will be done later in this paper). The results for e-designs in types A_{v-1}, ${}^2A_{2N}$, ${}^2A_{2N-1}$, B_N, C_N, D_N and ${}^2D_{N+1}$ follow from Corollary 3.5 and Lemma 4.1, and for ${}^2A_{2N-1}$, B_N and C_N, a calculation similar to Lemma 4.2 showing $\Psi_e^*(\theta^*(2))\neq 0$.

We conclude this section by showing that there are no perfect e-codes for $e\geqq 2$ in the association schemes of types B_N and C_N. The sum of the roots formula for the Lloyd polynomial fails to yield a contradiction in this case, so we will use the product of the roots formula.

The polynomial for this scheme is

$$P_k(i)=v_k p_k(\theta(i),0,0,q^{-N-1},-q^{-1};q).$$

Assuming $\Psi_e(\theta(x))$ has e distinct roots $\theta(x_i)$, $x_1<\cdots<x_e$, in $\{\theta(j)\,|\,j=2,\cdots,N-1\}$, Proposition 3.2 yields

$$\prod_{i=1}^{e}\theta(x_i)=\frac{(q^{-N+1})_e}{q^e}\,{}_3\phi_2\left(\begin{matrix}q^{-e},-q^{-N},q\\ 0,q^{-N+1}\end{matrix}\,\middle|\,q;q\right). \tag{4.1}$$

We shall need a transformation of a terminating ${}_3\phi_2$ [10, p. 101]

$${}_3\phi_2\left(\begin{matrix}q^{-e},A,B\\ C,D\end{matrix}\,\middle|\,q;q\right)=\frac{(C/A)_e A^e}{(C)_e}\,{}_3\phi_2\left(\begin{matrix}q^{-e},A,D/B\\ Aq^{1-e}/C,D\end{matrix}\,\middle|\,q,\frac{Bq}{C}\right).$$

Thus, (4.1) is equivalent to

$$\prod_{i=1}^{e} \theta(x_i) = (q^{-N})_e \sum_{j=0}^{e} \frac{(q^{-e})_j(-1)^j}{(q^{N-e+1})_j}, \tag{4.2}$$

or, upon multiplying by q^{Ne+e},

$$q^{Ne+e} \prod_{i=1}^{e} \theta(x_i) = q^{Ne+e}(q^{-N})_e \sum_{j=0}^{e} \frac{(q^{-e})_j(-1)^j}{(q^{N-e+1})_j}. \tag{4.3}$$

Next, we state without proof, a result from [11, p. 630].

PROPOSITION 4.4. *Let k, y and M be integers, $0 \leqq k, y \leqq M$ and $d \neq 0$. Then*

$$ {}_3\phi_2\left(\begin{matrix} q^{-k}, q^{-y}, -d^{-1}q^{-2M+y-1} \\ 0, q^{-M} \end{matrix} \middle| q; q\right)$$
$$= (-d)^{-k}q^{-k(M+1)} {}_3\phi_2\left(\begin{matrix} q^{-k}, q^{-M+y}, -dq^{M-y+1} \\ 0, q^{-M} \end{matrix} \middle| q; q\right).$$

In particular, setting $k=e$, $y=x-1$, $M=N-1$ and $d=q^{-N}$ in Proposition 4.4 and checking the expression for $\Psi_e(\theta(x))$, we see that $\Psi_e(\theta(x)) = \Psi_e(\theta(N-x+1))$. Hence we record

COROLLARY 4.5. *In types B_N and C_N, $\theta(x)$ is a root of Ψ_e if and only if $\theta(N-x+1)$ is.*

LEMMA 4.6. *Set $f(q) = q^{Ne+e}\prod_{i=1}^{e} \theta(x_i)$. Then $f(q) = (-1)^e + (-1)^{e-1}q^{2x_1} +$ higher ordered terms in q.*

Proof. Suppose e is even. We take the $e/2$ smallest x_i: $x_1 < x_2 < \cdots < x_{e/2}$. Hence, by Corollary 4.5,

$$\begin{aligned} f(q) &= q^{Ne+e} \prod_{i=1}^{e/2} \theta(x_i)\theta(N-x_i+1) \\ &= \prod_{i=1}^{e/2} (q^{2x_i}-1)(q^{2N-2x_i+2}-1) \\ &= 1-(q^{2x_1}+q^{2x_2}+\cdots)+\text{higher order terms in } q. \end{aligned}$$

If e is odd, then Corollary 4.5 implies that $\theta(k) = \theta(N-k+1)$ for some k. Hence $k=(N+1)/2$ and so N must be odd also.

$$\begin{aligned} f(q) &= q^{Ne+e}\theta\left(\frac{N+1}{2}\right) \prod_{i=0}^{(e-1)/2} \theta(x_i)\theta(N-x_i+1) \\ &= (q^{N+1}-1) \prod_{i=0}^{(e-1)/2} (q^{2x_i}-1)(q^{2N-2x_i+2}-1) \\ &= 1-(q^{2x_1}+q^{2x_2}+\cdots)+\text{higher ordered terms in } q. \end{aligned}$$

LEMMA 4.7. *Let*

$$h(q) = q^{Ne+e}(q^{-N})_e \sum_{j=0}^{e} \frac{(q^{-e})_j(-1)^j}{(q^{N-e+1})_j}.$$

Then $h(q) = (-1)^e + (-1)^{e-1}q^2 +$ higher ordered terms in q.

Proof. If $h(q) = \sum_{j=0}^{e} C(j)$, then

$$\begin{aligned} C(e) &= (q^e-1)(q^{e-1}-1)\cdots(q-1) \\ &= (-1)^e + (-1)^{e+1}(q+q^2+\cdots q^e) + \text{terms in } q \text{ of order} \geqq 3, \end{aligned}$$

$$C(e-1)=q(q^N-1)(q^e-1)(q^{e-1}-1)\cdots(q^2-1)$$
$$=(-1)^e q+(-1)^{e-1}(q^3+\cdots+q^{e+1}+q^{N+1})+\text{terms in } q \text{ of order} \geqq 6,$$

and for $0 \leqq j \leqq e-2$, we have

$$C(j)=q^{e(e+1)/2}(q^N-1)(q^{N-1}-1)\cdots(q^{N-e+j-1}-1)(q^{-e})_j$$
$$=(-1)^e \cdot q^{(e+1)e/2-ej+(j-1)j/2}+\text{higher ordered terms in } q.$$

In particular, for $0 \leqq j \leqq e-2$, we have $e(e+1)/2-ej+(j-1)j/2 \geqq 3$ (recall $e \geqq 2$). Thus $h(q)=(-1)^e+(-1)^{e-1}q^2+$higher ordered terms in q.

From (4.3) we have $f(q)=h(q)$ and hence $f(q)-(-1)^e=h(q)-(-1)^e$. But since $x_1 \geqq 2$, we have $f(q)-(-1)^e \equiv 0 \bmod q^3$, whereas $h(q)-(-1)^3 \equiv (-1)^{e-1}q^2 \bmod q^3$. This contradiction shows that for $e \geqq 2$, there are no perfect e-codes in the association schemes of type B_N and C_N.

We summarize our main results:

THEOREM 4.8. (i) *There are no perfect e-codes for $e \geqq 1$ in the dual polar spaces of types A_{v-1}, ${}^2A_{2N}$, ${}^2A_{2N-1}$, D_N, ${}^2D_{N+1}$, and the affine matrix schemes, and no perfect e-codes for $e \geqq 2$ in the spaces B_N and C_N.*

(ii) *There are no tight designs of order e in the spaces of types A_{v-1}, ${}^2A_{2N}$, ${}^2A_{2N-1}$, B_N, C_N, D_N, ${}^2D_{N+1}$, and the affine matrix schemes with the exception of tight designs of order $e=(N-1)/2$ in D_N.*

5. Conclusion. We have determined the nonexistence of perfect e-codes and tight t-designs ($t=2e$) in the classical association schemes and affine matrix schemes for $e \geqq 1$, except in type D_N where tight designs exist if $e=(N-1)/2$ and in types B_N and C_N for $e=1$ where perfect codes are still undetermined. For types B_N and C_N, the sphere packing bound says that if a perfect 1-code exists, then [11, p. 659]

$$\frac{q^{N+1}-1}{q-1} \,\Big|\, (1+q)(1+q^2)\cdots(1+q^N). \tag{5.1}$$

We are grateful to J. Shearer for the following proposition.

PROPOSITION 5.1. *For q integral, $q \neq 1$, (5.1) implies $N+1=2^m$ for some integer m.*

Proof. Suppose (5.1) holds and $N+1$ has an odd prime factor p, then $(q^p-1)/(q-1) \mid (1+q)\cdots(1+q^N)$. Let $r \mid (q^p-1)/(q-1)$ for r prime. Then $r \mid 1+q^s$ for some s (pick s minimal). Hence $q^s \equiv -1 \bmod r$ and thus $q^{2s} \equiv 1 \bmod r$. We also have $q^p \equiv 1 \bmod r$. If $r \neq 2$ then clearly $s<p$ and $p \mid 2s$. Since p is odd, we see that $p \mid s$ which contradicts $p<s$. If $r=2$, then $1+q+\cdots+q^{p-1} \equiv 0 \bmod 2$ which contradicts p being odd.

Thus, if there are perfect 1-codes in types B_N and C_N, then $N+1=2^m$. This is the same condition for perfect 1-codes in the Hamming scheme. Perfect 1-codes are known to exist in C_3 [11, p. 660], [12].

To conclude this paper, we present another proof of Proposition 2.1. We establish that

$$P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)$$
$$=B\sum_{n=0}^{e} w(n, q^{-N-1}, d, a, b)P_n(\theta(x), a, b, q^{-N-1}, d; q) \tag{5.2}$$

for a nonzero constant B (to be determined).

We shall need the following ${}_4\phi_3$ transformation [8, p. 167]

(5.3)
$$
\begin{aligned}
&{}_4\phi_3\left(\begin{matrix} q^{-e}, q^{e-1}ABCD, A/Z, AZ \\ AB, AC, AD \end{matrix}\;\middle|\; q; q\right) \\
&= \frac{(BC)_e(BD)_e(AB^{-1})^e}{(AC)_e(AD)_e}\,{}_4\phi_3\left(\begin{matrix} q^{-e}, q^{e-1}ABCD, B/Z, BZ \\ AB, BC, BD \end{matrix}\;\middle|\; q; q\right).
\end{aligned}
$$

Recalling (2.1), we see that (5.3) implies

(5.4)
$$
\begin{aligned}
&P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q) \\
&= \frac{(aq/d)_e(bq)_e}{(aq^2)_e(bdq^2)_e}(dq)^e P_e(\tilde{\theta}(N-x), b, aq, q^{-N}, 1/dq; q).
\end{aligned}
$$

Note that $(1-q^{x-N+s})(1-d^{-1}q^{-x+s}) = d^{-1}q^s(\theta(x)-\theta(N-s))$, so that $(q^{x-N})_m (d^{-1}q^{-x})_m$ is a polynomial of degree m in $\theta(x)$. Since $\{p_0(\theta(x)), \cdots, p_m(\theta(x))\}$ forms a basis for the vector space of polynomials of degree at most m in $\theta(x)$, we have

(5.5)
$$
(q^{x-N})_m(d^{-1}q^{-x})_m = \sum_{n=0}^{m} A_{m,n}P_n(\theta(x), a, b, q^{-N-1}, d; q)
$$

for constants $A_{m,n}$. Askey and Wilson have calculated $A_{m,n}$[1, p. 1014].

(5.6)
$$
\begin{aligned}
&A_{m,n} \\
&= \frac{(abq)_n(1-abq^{2n+1})(aq)_n(bdq)_n(a^{-1}dq^{-m})_m(b^{-1}q^{-m})_m(q^{-N})_m(q^{-m})_n(ab)^m q^{2\binom{m+1}{2}}}{(q)_n(1-abq)(bq)_n(ad^{-1}q)_n(abq^{m+2})_n(abq^2)_m d^{m+n}}.
\end{aligned}
$$

Thus, from (5.4), (5.5) and (5.6), we clearly have that the coefficient $B_{m,n}$ of $P_n(\theta(x), a, b, q^{-N-1}, d; q)$ in $P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)$ is

$$
\begin{aligned}
&B_{m,n} = \\
&\frac{(aq/d)_e(bq)_e(dq)^e(abq)_n(1-abq^{2n+1})(aq)_n(bdq)_n(q^{-e})_n(q^{e+2}ab)_n(q^{-N})_n q^{n+\binom{n}{2}}(-1)^n}{(aq^2)_e(bdq^2)_e(q)_n(1-abq)(bq)_n(ad^{-1}q)_n(abq^2)_n(q^{n+2}ab)_n(q^{-N+1})_n d^n} \\
&\quad\times {}_3\phi_2\left(\begin{matrix} q^{-e+n}, q^{e+n+2}ab, q^{-N+n} \\ abq^{2n+2}, q^{-N+n+1} \end{matrix}\;\middle|\; q; q\right) \\
&= (dq)^e\frac{(aq/d)_e(bq)_e(q^{-e})_e(abq^{N+2})_e}{(aq^2)_e(bdq^2)_e(q^{N-e})_e(abq^2)_e} w(n, q^{-N-1}, d, a, b)
\end{aligned}
$$

where we have recalled the evaluation (3.5) and the definition of the weights (2.6).

Hence,

$$
\begin{aligned}
P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q) &= (dq)^e\frac{(aq/d)_e(bq)_e(q^{-e})_e(abq^{N+2})_e}{(aq^2)_e(bdq^2)_e(q^{N-e})_e(abq^2)_e} \\
&\quad\times \sum_{n=0}^{e} w(n, q^{-N-1}, d, a, b)P_n(\theta(x), a, b, q^{-N-1}, d; q)
\end{aligned}
$$

and so finally, recalling (2.7) and (2.9), we have

$$
\Psi_e(\theta(x)) = (dq)^{-e}\frac{(aq^2)_e(bdq^2)_e(q^{N-e})_e(abq^2)_e}{(aq/d)_e(bq)_e(q^{-e})_e(abq^{N+2})_e}P_e(\tilde{\theta}(x-1), aq, b, q^{-N}, dq; q)
$$

which establishes (2.11).

Acknowledgment. The author gratefully acknowledges Dennis Stanton for his many helpful comments and suggestions.

TIME TO REACH STATIONARITY IN THE BERNOULLI-LAPLACE DIFFUSION MODEL*

PERSI DIACONIS† AND MEHRDAD SHAHSHAHANI‡

Abstract. Consider two urns, the left containing n red balls, the right containing n black balls. At each time a ball is chosen at random in each urn and the two balls are switched. We show it takes $\frac{1}{4}n \log n + cn$ switches to mix up the urns. The argument involves lifting the urn model to a random walk on the symmetric group and using the Fourier transform (which in turn involves the dual Hahn polynomials). The methods apply to other "nearest neighbor" walks on two-point homogeneous spaces.

Key words. Markov chains, eigenvalues, Gelfand pairs, Hahn polynomials

1. Introduction. Daniel Bernoulli and Laplace introduced a simple model to study diffusion. Consider two urns, the left containing n red balls, the right containing n black balls. A ball is chosen at random in each urn and the two balls are switched. It is intuitively clear that after many such switches the urns will be well mixed, about half red and half black. The process is completely determined by the number of red balls in one of the urns. The stationary distribution may be described as the law of the composition of n balls drawn without replacement from n red and n black balls

$$\pi_n(j)=\binom{n}{j}\binom{n}{n-j}\bigg/\binom{2n}{n}, \quad 0 \leqq j \leqq n. \tag{1.1}$$

The main question addressed here is the rate of convergence to the stationary distribution. Let P_k be the law of the process after k steps. Distance to stationarity will be measured by variation distance

$$\|P_k-\pi_n\| = \frac{1}{2}\sum_j |P_k(j)-\pi_n(j)|. \tag{1.2}$$

THEOREM 1. *Let P_k be the probability distribution of the number of red balls in one urn of the Bernoulli-Laplace diffusion model based on n of each color.*

(1.3) *Let $k=\frac{1}{4}n\log n+cn$ for $c \geqq 0$. Then for a universal constant a, $\|P_k-\pi_n\| \leqq ae^{-2c}$.*

(1.4) *With k as above, and arbitrary negative c in $[-\frac{1}{4}\log n, 0]$ there is a universal positive b such that $\|P_k-\pi_n\| \geqq 1-be^{4c}$.*

Remarks. Theorem 1 gives a sharp sense in which $\frac{1}{4}n \log n$ switches are needed: for somewhat fewer switches, the variation distance is essentially at its maximum value of 1. For somewhat more switches, the distance tends to zero exponentially fast. There is a fairly sharp cut-off at $\frac{1}{4}n \log n$.

A somewhat stronger result, starting with r red balls and $n-r$ black balls is proved in §§3 and 4 of this paper. The argument uses Fourier analysis on the symmetric group S_n and the homogeneous space $S_n/S_r \times S_{n-r}$. This last space is a "Gelfand pair" so the Fourier analysis is essentially commutative, involving spherical functions that turn out to be the dual Hahn polynomials. Section 2 develops the needed background material. Section 5 describes how essentially the same argument applies to nearest neighbor random walks on two-point homogeneous spaces. These include the Ehrenfest's model of diffusion (random walk on the "cube" Z_2^n) and random walk on the k dimensional subspaces of a vector space over a finite field.

The Bernoulli-Laplace process is discussed by Feller (1968, p. 423) who gives historical references. See also Johnson and Kotz (1977, pp. 205-207). We conclude this section by listing several "real world" problems where the model appears.

1) *r sets of an n set.* Let X be the set of r element subsets of $\{1, 2, \cdots, n\}$ so $|X| = \binom{n}{r}$. A random walk can be constructed on X as follows. Begin at $\{1, 2, \cdots, r\}$. Each time, pick an element from the present set and an element from its complement, and switch the two elements. This is a nearest neighbor walk using the metric: $d(x, y) = r - |x \cap y|$. The stationary distribution is the uniform distribution over X. Professor Laurel Smith points out that when $n = r = 2$, this becomes nearest neighbor random walk on the vertices of an octahedron. The rate of convergence to stationarity is the same as the rate for the Bernoulli-Laplace model with r red and $n-r$ black balls as shown in Lemma 1 below.

Walks of this type are an essential ingredient of the currently fashionable approach to combinatorial optimization called simulated annealing. Given a function $f: X \rightarrow \mathbb{R}$ annealing algorithms perform a stochastic search for the minimum of f based on the walk. Kirkpatrick et al. (1983) or Aragon et al. (1984) give further details.

2) *Moran's model in mathematical genetics.* Moran (1958) introduced a simple process to model the stochastic behavior of gene frequencies in a finite population. In one version, there is a population of n individuals each of whom is either of type A_1 or A_2. At each time, an individual is chosen at random to reproduce. After reproduction, an individual is chosen at random to die. The model allows mutation of the newborn (from A_1 to A_2 at rate u, from A_2 to A_1 at rate v). If $u = v = 1$, the transition mechanism of Moran's model becomes precisely the transition mechanism of the Bernoulli-Laplace diffusion. A clear discussion of Moran's model is in Ewens (1979, §3.3).

Ewens gives numerous references to eigenvalue-eigenvector analysis of this Markov chain. We will use part of this literature as an ingredient of our analysis.

3) *Piaget's randomization board.* In investigating children's ability to comprehend randomness, Piaget and Inhelder (1975, pp. 1-25) worked extensively with the physical device shown in Fig. 1. The left side of the box contains 8 red balls, the right side contains 8 white balls. When the box is tipped about an axis through its center (like a child's see-saw) the balls roll across to the other side. Usually one or two balls "change sides"—a red moving into the blacks or vice versa.

Piaget asked children of varying ages questions such as "how long will we have to wait until the balls are mixed up?" Answer: 5-10 switches for 8 reds. He also asked "how long will we have to wait until the balls return to the way they started?" Piaget offered an answer to the second problem for 10 reds and 10 blacks: about 185,000 moves are needed! Naturally, children (and most adults) do not guess it takes such a long time.

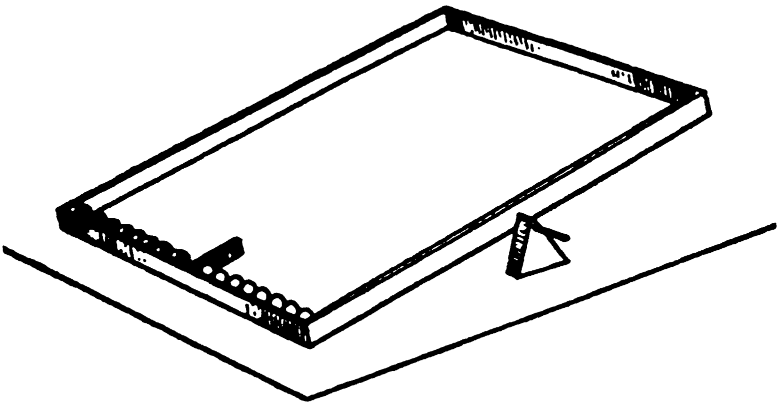

FIG. 1

One natural reaction for a mathematician is "how on earth does he know?" We began work on this paper by considering the Bernoulli–Laplace model (ignorant of its origins). Theorem 1 shows the random walk is "rapidly mixing," to use terminology of Aldous (1983). That is, the time to reach stationarity is of the order of the log of the number of states. Aldous (1983) shows that for rapidly mixing walks, the time to return to the original state has approximately the same distribution as a random walk with independent uniform steps.

If there are $|X|$ states, and W is the first time to return, then for large $|X|$,

$$P\left\{\frac{W}{|X|}>t\right\}\doteq e^{-t}.$$

For 8 red and 8 black balls, $|X| = \binom{16}{8} = 12{,}870$, so the median return time is about 9,000. For 10 red and 10 black balls $|X| = 184{,}756$; the median return time is about 128,000.

A referee points out that the associated Markov chain is doubly stochastic, irreducible, and aperiodic. Standard Markov chain theory shows that the expected number of steps to return to the starting state is $|X|$.

As explained in Diaconis and Shahshahani (1981), the analysis presented for this problem yields all the eigenvalues and eigenvectors of the associated Markov chain. Using these, it is straightforward to derive a closed form expression for the generating function of W as in Flatto, Odlyzko and Wales (1985). This can be used to get sharper asymptotic estimates for Piaget's problem.

2. Group theoretic preliminaries. One natural way to analyze the Bernoulli–Laplace process is by lifting to a random walk on the symmetric group. For integers r and b with $r + b = n$, let S_n be the symmetric group on n letters. Let $S_r \times S_b$ be the subgroup of permutations that permute the first r elements among themselves and the last b elements among themselves. Then $X = S_n/S_r \times S_b$ may be identified with the set of all $\binom{n}{r}$ r-element subsets. The random walk on X moves from x to y by choosing an element in the set x at random and an element of the complement of x at random and switching the two elements to form a new subset y. Choose a metric $d(x, y) = r - |x \cap y|$ on X. The walk is thus a nearest neighbor random walk on X. It is easy to see that the Bernoulli–Laplace process corresponds to the distance process of this walk on subsets.

It is useful to work in more generality: let G be a group and K a subgroup. Let $X = G/K$ be the associated space of cosets. Choose $x_0 = \text{id}, x_1, \cdots, x_m$ as fixed coset representatives, so $G = x_0K \cup x_1K \cdots \cup x_mK$. We will often identify X and $\{x_i\}$. Let Q be a K bi-invariant probability on G, so $Q(k_1gk_2) = Q(g)$ for all $k_1, k_2 \in K$, $g \in G$. The probability Q induces a random walk (more precisely a Markov chain) on X by the following recipe

$$Q(x, y) \overset{d}{=} Q(x^{-1}yK). \tag{2.1}$$

In (2.1), $Q(x, y)$ is the probability of going from x to y in one step. The definition comes from the following considerations: think of x_0 as the origin. Each time choose $g \in G$ from Q and move from x_0 to gx_0. This motion is then translated to motion around x via $y = xgx_0$. Thus, the chance of moving from x to y is $Q(x^{-1}yK)$.

Note that $Q(x, y)$ is well defined and satisfies

$$Q(x, y) = Q(gx, gy) \quad \text{for any} \quad g \in G. \tag{2.2}$$

Philippe Bougerol has pointed out a converse. If $Q(x, y)$ is a Markov chain on $X = G/K$ satisfying (2.2), then Q is induced by a bi-invariant probability defined by

$$Q(A) = Q(x_0, Ax_0) \quad \text{for} \quad A \subset G.$$

Alternatively, write a generic element of G as xk, then $Q(xk) = Q(x_0, x)/|K|$. This measure is K bi-invariant and $Q(x^{-1}yK) = |K|Q(x^{-1}y) = Q(x_0, x^{-1}y) = Q(x, y)$ as required. The following elementary lemma gives further connections between the random walk and Markov chain.

LEMMA 1. *Let $Q(x, y) = Q(gx, gy)$. For any $k \geqq 1$, the k step transition matrix of the Markov chain $Q(x, y)$ is induced by the kth convolution of the associated bi-invariant probability Q. The variation distance to the stationary distribution equals the variation distance to the uniform distribution.*

Because of Lemma 1, Fourier analysis on G can be used to approximate the convolution powers. We briefly review what we need from representation theory. Serre (1977) or Diaconis (1982) contain the details. Recall that a representation of G is a homomorphism $\rho: G \rightarrow GL(V)$ from G into invertible matrices on a vector space V. The dimension d_ρ of ρ is defined as the dimension of V. A representation ρ is irreducible if there are no nontrivial invariant subspaces of V. For Q a probability and ρ a representation, the Fourier transform of Q at ρ is defined by

$$\hat{Q}(\rho) = \Sigma\rho(g)Q(g).$$

The Fourier transform takes convolution into products through $P * Q(\rho) = \hat{Q}(\rho)\hat{P}(\rho)$. The uniform distribution of G: $U(g) = 1/|G|$, has $\hat{U}(\rho) = 0$ for every nontrivial irreducible representation ρ. For $X = G/K$, the set of all complex functions on X is denoted $L(X)$. The group acts on X and so $L(X)$ can be thought of as a representation as well.

The variation distance can be approximated by the following

LEMMA 2. *Let Q be a K bi-invariant probability on a finite group G*

$$\|Q - U\|^2 \leqq \tfrac{1}{4}\Sigma_\rho^* d_\rho \operatorname{Tr}(\hat{Q}(\rho)\hat{Q}(\rho)^*)$$

where the sum is over all nontrivial representations that occur in the decomposition of $L(X)$.

Proof.

$$\|Q-U\|^2=\tfrac{1}{4}\{\Sigma|Q(g)-U(g)|\}^2\leqq\tfrac{1}{4}|G|\,\Sigma|Q(g)-U(g)|^2$$
$$=\tfrac{1}{4}\Sigma_\rho^* d_\rho \operatorname{Tr}(\hat{Q}(\rho)\hat{Q}(\rho^*)).$$

Here, the Cauchy-Schwarz inequality was used and then the Plancherel theorem as in Serre (1977, p. 49) applied to $Q(g) - U(g)$. Terms corresponding to representations ρ that do not appear in the decomposition of $L(X)$ have zero Fourier transform because of Frobenius reciprocity (Serre (1977, p. 56)): this implies that a representation ρ occurs in $L(X)$ with multiplicity corresponding to the dimension of the space of K fixed vectors of ρ. Thus if ρ does not occur, then the restriction of ρ to K does not contain the trivial representation. Thus $\hat{Q}(\rho) = \Sigma_x Q(x)\rho(x)\Sigma_k \rho(k)$. The inner sum is zero because of the orthogonality of the matrix entries of the irreducible representations (Serre (1977, p. 14)). □

The Fourier transform can simplify a great deal further. Indeed, for the cases treated here the matrix $\hat{Q}(\rho)$ has only one nonzero entry in a suitable basis. The simplification in general is discussed in Volume 6 of Dieudonné (1978).

DEFINITION. The pair (G, K) is called a *Gelfand pair* if each irreducible representation of G appears in $L(X)$ with multiplicity at most 1.

Remarks. Probability theory for bi-invariant probabilities on a Gelfand pair has an extensive literature. Readable overviews appear in Letac (1981), Bougerol (1983), or Dieudonné (1978). The Bernoulli-Laplace model can be treated directly in this framework. However, the more general framework developed here is needed if one is to attack more general problems such as the natural extension to three urns where $L(X)$ has multiplicity.

For a Gelfand pair, let

$$L(X) = V_0 \oplus V_1 \oplus \cdots \oplus V_\lambda \tag{2.3}$$

be the decomposition into distinct irreducibles. Frobenius reciprocity implies that each V_j has a one-dimensional subspace of K invariant functions. Let $s_j(x)$ be a K invariant function in V_j normed so that $s_j(x_0) = 1$. This is called the jth spherical function. The spherical functions have been explicitly computed for many Gelfand pairs.

LEMMA 3. *If (G, K) is a Gelfand pair and Q is a K bi-invariant probability, then*

$$\|Q-U\|^2\leqq\frac{1}{4}\sum_{j=0}^{\lambda} d_j|\hat{Q}(j)|^2,$$

where the sum is over the nontrivial irreducible representations occurring in (2.3) *and*

$$\hat{Q}(j)=\Sigma_g Q(g)s_j(g).$$

Proof. Fix i, and consider the vector space V_i of (2.3) as a representation ρ_i of G. Complete s_i to a basis for V_i, taking s_i as the first basis vector. With respect to this basis, the Fourier transform of any K bi-invariant function f on G becomes

$$\hat{f}(\rho)=\Sigma_g f(g)\rho_i(g)=\Sigma_x f(x)\rho_i(x)\Sigma_k \rho_i(k).$$

But the Schur orthogonality relations imply

$$\Sigma_k \rho_{ij}(k)=\begin{cases}|K| & \text{if } i=j=1,\\ 0 & \text{otherwise.}\end{cases}$$

Thus

$$\hat{f}(\rho)=\begin{pmatrix} a & & 0 \\ 0 & 0 & \\ 0 & & 0 \end{pmatrix} \quad \text{with } a=|K|\Sigma f(x)s_\rho(x).$$

Since the trace norm is invariant under unitary changes of basis, the result follows from Lemma 2. □

Remark. In the description above, the random walk associated to a bi-invariant probability Q can be represented somewhat curiously as a *right* action of G on X. Thus if the basic random elements chosen from Q on G are $g_1, g_2, g_3, \cdots$, and the walk starts at x, the successive steps have the representation $x, xg_1, xg_1g_2, xg_1g_2g_3, \cdots$, where xg denotes the coset containing xg. This is well defined for Q bi-invariant.

There is another natural way to associate a Markov chain to a probability Q, using the natural left action: $x, g_1x, g_2g_1x, g_3g_2g_1x, \cdots$. This process does not correspond to a nearest neighbor walk. It yields a Markov chain with transition matrix $\tilde{Q}(x, y) = Q(yKx^{-1})$. Chains defined in this way satisfy $\tilde{Q}(k_1x, k_2y) = \tilde{Q}(x, y)$ but we do not know a necessary and sufficient condition for a chain to lift to the left action of a bi-invariant Q. Of course, if a lifting can be found, the Fourier analysis is precisely as above, all the bounds and lemmas holding without essential change.

3. The upper bound. Let r and $n - r$ be positive integers. The stationary distribution for the Bernoulli-Laplace model based on two urns, one containing r red balls initially, the second containing $n - r$ black balls may be described as the distribution of the number of red balls in a random sample of size r from the total population of n

$$\pi_r^n(j)=\binom{r}{j}\binom{n-r}{r-j}\Big/\binom{n}{r}, \qquad 0 \leqq j \leqq r.$$

Let P_k be the probability distribution of the number of red balls in the urn containing r balls after k switches have been made.

THEOREM 2. *If*

$$k=\frac{r}{2}\left(1-\frac{r}{n}\right)[\log n+c] \quad \textit{for } c \geqq 0,$$

then, for a universal constant a,

$$\|P_k-\pi_r^n\| \leqq ae^{-c/2}.$$

Proof. Without loss, take $r \leqq n/2$. The decomposition of the space $L(X)$ is a standard result in the representation theory of the symmetric group. James (1978, p. 52) proves that $L(X) = V_0 \oplus V_1 \oplus \cdots \oplus V_r$ where V_i are distinct irreducible representations of the symmetric group corresponding to the partition $(n - i, i)$. In particular, the pair S_n, $S_r \times S_{n-r}$ is a Gelfand pair. Since this result holds for all $r \leqq n/2$, induction gives $\dim(V_i) = \binom{n}{i} - \binom{n}{i-1}$.

The spherical functions have essentially been determined by Karlin and McGregor (1961). Stanton (1984) contains this result in modern language. The spherical functions turn out to be classically studied orthogonal functions called the dual Hahn polynomials. As a function on X, the function $s_i(x)$ only depends on the distance $d(x, x_0)$ and is a polynomial in d given by

$$s_i(d)=\sum_{m=0}^{i}\frac{(-i)_m(i-n-1)_m(-d)_m}{(r-n)_m(-r)_m m!},\qquad 0\leqq i\leqq r, \tag{3.1}$$

where $(j)_m=j(j+1)\cdots(j+m-1)$. Thus

$$\begin{aligned} &s_0(d)=1, \qquad s_1(d)=1-\frac{dn}{r(n-r)},\\ &s_2(d)=1-\frac{2d(n-1)}{r(n-r)}+\frac{(n-1)(n-2)d(d-1)}{(n-r)(n-r-1)r(r-1)}. \end{aligned} \tag{3.2}$$

The basic probability Q for this problem may be regarded as the uniform distribution on the $r(n-r)$ sets of distance one from the set $\{1, \cdots, r\}$. Thus, the Fourier transform of Q at the ith spherical function is

$$\hat{Q}(i)=s_i(1)=1-\frac{i(n-i+1)}{r(n-r)},\qquad 0\leqq i\leqq r.$$

Using this information in the upper bound lemma (Lemma 3) yields

$$\|P_k-\pi_r^n\|^2\leqq\frac{1}{4}\sum_{i=1}^{r}\left\{\binom{n}{i}-\binom{n}{i-1}\right\}\left(1-\frac{i(n-i+1)}{r(n-r)}\right)^{2k}. \tag{3.3}$$

To bound the sum, consider first the term for $i=1$

$$(n-1)\left(1-\frac{n}{r(n-r)}\right)^{2k}.$$

This is smaller than

$$\exp\left(-\frac{2kn}{r(n-r)}+\log n\right).$$

Thus k must be at least

$$\frac{r}{2}\left(1-\frac{r}{n}\right)[\log n+c]$$

to drive this term to zero. With k of this form, the problem is reduced to bounding

$$\sum_{i=1}^{r} e^{a(i)+b(i)}$$

where

$$a(i)=ci\left(\frac{(i-1)}{n}-1\right),\qquad b(i)=\frac{i(i-1)\log n}{n}-\log(i!).$$

Calculus shows that $a(i)\leqq a(1)=-c$ for all $i=[2, n/2]$. Thus, to prove Theorem 1 it suffices to prove

$$\sum_{i=1}^{n/2} e^{b(i)}\leqq B \quad \text{independently of } n.$$

Clearly, the sum of $e^{b(i)}$ over $1\leqq i\leqq 21$ is uniformly bounded. For the remaining range, upper bound $b(i)$ by $i^2(\log n/n)-i\log i+i$. It will be argued that

$i^2(\log n/n) - i\log i + i < -i$ for $21 \leqq i \leqq n/2$, equivalently, $\log n/n < (\log i - 2)/i$. Now if $f(x) = (\log x - 2)/x$, $f'(x) = (3 - \log x)/x^2$. This is negative for $x > e^3$, so for $i > 21 > e^3$,

$$\frac{\log i - 2}{i} > \frac{\log(n/2) - 2}{n/2}.$$

This last is greater than $\log n/n$ for $n \geqq e^{4+2\log 2}$. Thus,

$$\sum_{i=22}^{n/2} e^{b(i)} \leqq \sum_{i=22}^{\infty} e^{-i} < B \quad \text{uniformly in } n. \qquad \square$$

Remarks. Change n to $2n$ and take $r = n$. The result becomes $(n/4)\log n + (c/2)n$ which gives (1.3) of Theorem 1. If $r = o(n)$, the result becomes $(r/2)\log n + (c/2)r$. As usual with approximations, some precision has been lost to get a clean statement. When $r = 1$, for example, there is only one term: $(n-1)(1/(n-1))^{2k}$. For $k = 1$ this gives $\frac{1}{2}(1/\sqrt{n-1})$ as an upper bound for the variation distance. Elementary considerations show that for this case the correct answer is $1/n$. Thus, the upper bound lemma gives the right answer for the number of steps required (namely, 1) but an over estimate for the distance.

4. The lower bound. A lower bound for the variation distance will be found by using the easily derived relation

$$\|P - Q\| = \sup_A |P(A) - Q(A)|. \tag{4.1}$$

Any specific set A thus provides a lower bound. Intuitively, if the number of steps k is too small, there will tend to be too many of the original color in the urn. The argument below gives a sharp form of this. For ease of exposition, we only prove the result for $r = n - r$ (for example (1.4)) but the proof works in the general case.

The idea of the proof is to again use spherical functions, but this time as random variables, not transforms. Thus for any Gelfand pair (G, K) with $X = G/K$, consider $s_j\colon X \to \mathbb{R}$ as a random variable. If Z is a point chosen uniformly in X, the orthogonality relations (as in Stanton (1984, eq. (2.9))) give

$$E\{s_j(Z)\} = \delta_{0j}, \qquad \operatorname{Var}(s_j(Z)) = \frac{1}{\dim(V_j)}. \tag{4.2}$$

If Z_k denotes an X valued random variable with distribution P^{*k} for P a bi-invariant probability on X the basic convolution property of spherical functions becomes

$$E\{s_j(Z_k)\} = E\{s_j(Z_1)\}^k. \tag{4.3}$$

On $S_{2n}/S_n \times S_n$ the first three spherical functions, as functions of the distance d are given (from (3.1)) as

$$s_0(d) = 1, \qquad s_1(d) = 1 - \frac{2d}{n},$$

$$s_2(d) = 1 - \frac{2(2n-1)d}{n^2} + \frac{(2n-1)(2n-2)d(d-1)}{[n(n-1)]^2}.$$

Since these are polynomials in d, it follows that for some a, b, c, $s_1^2 = a + bs_1 + cs_2$. After a computation

$$s_1^2 = \frac{1}{2n-1} + \frac{2n-2}{2n-1} s_2. \tag{4.4}$$

Remark. When working with general r, $n-r$ values the term s_1 appears in the expression for s_1^2.

To lower bound the variation distance, consider the normalized spherical function $f(x) \overset{d}{=} \sqrt{n-1}\, s_1(x)$. Now (4.2) implies for Z uniform on x,

$$E\{f(Z)\} = 0, \qquad \mathrm{Var}\,\{f(Z)\} = 1.$$

Under the convolution measure

$$E\{f(Z_k)\} = \sqrt{n-1}\left(1-\frac{2}{n}\right)^k, \tag{4.5}$$

$$\mathrm{Var}\{f(Z_k)\} = \frac{n-1}{2n-1} + \frac{(n-1)(2n-2)}{(2n-1)}\left(1-\frac{2(2n-1)}{n^2}\right)^k - (n-1)\left(1-\frac{2}{n}\right)^{2k}. \tag{4.6}$$

For k of the form $\frac{1}{4}n\log n - cn$, the mean becomes

$$E\{f(Z_k)\} = \exp\left(2c + O\left(\frac{\log n}{n}\right) + O\left(\frac{c}{n}\right)\right), \tag{4.7}$$

where $c > 0$, and all error terms are uniform in both n and c. Thus, for c large, the mean is large. Similarly

$$\begin{aligned}\mathrm{Var}\{f(Z_k)\} &= \frac{1}{2} + O\left(\frac{1}{n}\right) + \exp\left(4c + O\left(\frac{\log n}{n}\right) + O\left(\frac{c}{n}\right)\right)\\ &\quad - \exp\left(4c + O\left(\frac{\log n}{n}\right) + O\left(\frac{c}{n}\right)\right)\\ &= \frac{1}{2} + e^{4c}\left\{O\left(\frac{\log n}{n}\right) + O\left(\frac{c}{n}\right)\right\}.\end{aligned}$$

Thus, the variance is uniformly bounded for $O \leqq c \leqq \frac{1}{4}\log n$. Now use Chebyshev's inequality: if $A_\alpha = \{x\colon |f(x)| \leqq \alpha\}$, $\pi_n(A_\alpha) \geqq 1 - 1/\alpha^2$ while $P_k(A_\alpha) < B/(e^{2c} - \alpha)^2$ where B is uniformly bounded for $c \leqq \frac{1}{4}\log n$. Thus, for any fixed α and c, for all sufficiently large n,

$$\|P_k - \pi_n\| \geqq 1 - \frac{1}{\alpha^2} - \frac{B}{(e^{2c}-\alpha)^2}.$$

This completes the proof of (1.4), choosing $\alpha = e^{2c}/2$, for example. □

Remark. From the definition of s_1, the set A_α can be interpreted as the event

$$\left|\#\,\mathrm{reds} - \frac{n}{2}\right| \Big/ \sqrt{n} \geqq \alpha.$$

5. Other nearest neighbor walks. A class of problems that can be treated by following the steps above involves a connected graph with vertex set X and an edge set E. Define a metric on X as

$$d(x, y) = \text{length of shortest path from } x \text{ to } y.$$

We want to analyze nearest neighbor walks on this graph. An automorphism of the graph is a 1–1 mapping from X to X which preserves the edge set. Let G be the group of automorphisms of X. Call the graph *2-point homogeneous* if $d(x, y) = d(x', y')$ implies there is a $g \in G$ such that $gx = x'$, $gy = y'$. Taking $x = y$, $x' = y'$ shows G operates transitively on X, so $X \cong G/K$ where $K = \{g \in G: gx_0 = x_0\}$ for some fixed point x_0. Stanton (1984) shows

THEOREM. *For a 2-point homogeneous graph, (G, K) form a Gelfand pair and the spherical functions are orthogonal polynomials.*

This means that in principle the analysis above can be carried out for such examples. Here is a list of some of the examples in Stanton:

Example 1. $X = Z_2^n$, $d(x, y)$ = number of coordinates where x and y differ. Here the random walk becomes nearest neighbor walk on the n cube. This is a well studied problem equivalent to the well-known model of diffusion known as the Ehrenfest urn model. A wonderful discussion of this model is in Kac (1945). Further references are in Letac and Takacs (1979). The straightforward random walk never converges because of parity—after an even number of steps the walk is at a point at an even distance from 0. One simple way to get convergence is to stay fixed with probability $1/(n+1)$ and move to a vertex 1 away with probability $1/(n+1)$. For this process, the analysis can be carried out just as in §§3 and 4 to show $\frac{1}{4}n \log n + cn$ steps suffice and that this many steps are needed.

THEOREM 3. *Let $X = Z_2^n$. Let $P(00 \cdots 0) = P(10 \cdots 0) = \cdots = P(00 \cdots 1) = 1/(n+1)$. Let U be the uniform distribution on X. Suppose $k = \frac{1}{4}(n+1)\log n + c(n+1)$ for $c > 0$. Then*

$$\|P^{*k} - U\|^2 \leqq \tfrac{1}{2}(e^{e^{-4c}} - 1).$$

Conversely, for $k = \frac{1}{4}(n+1)\log n - c(n+1)$, for $c > 0$, the variation distance does not tend to zero as n tends to infinity: $\underline{\lim}\ \|P^{*k} - U\| \geqq (1 - 8e^{-c})$.

Remark. It is curious that the critical rate is precisely the same $\frac{1}{4}n \log n$, for the cube and n sets of a $2n$ set.

Example 2. Let F_q be a finite field with q elements. Let V be a vector space of dimension n over F_q. Let X be the set of k-dimensional subspaces of V, with metric $d(x, y) = k - \dim(x \cap y)$. Here, $G = GL_n(q)$ operates transitively on X. Stanton (1984) gives all the ingredients needed to carry out the analysis.

Example 3. Let X be the set of $(n-r) \times r$ matrices over F_q with metric $d(x, y) = \operatorname{rank}(x - y)$. Here, $GL_{n-r} \times GL_r$ operates transitively on X. Again a complete analysis seems in reach using results given by Stanton.

Example 4. For q odd, let X be the set of skew-symmetric matrices over F_{q^2} with metric $\frac{1}{2}\operatorname{rank}(x - y)$. Here $G = GL_n$ acts on X by $x \to A^T x A$. Again Stanton gives enough information about spherical functions and dimensions to allow a complete analysis.

Stanton also gives results for orthogonal, hermitian, and symplectic matrices over finite fields. He also gives results for a variety of less familiar combinatorial objects. Combinatorialists have also studied such objects: see Biggs (1974, Chaps. 20, 21). Further surveys and examples of Gelfand pairs are given by Heyer (1983) and Sloane (1982).

Finally, there are Gelfand pairs that do not arise from two point homogeneous graphs. An example is the set X of all partitions of $\{1, 2, \cdots, 2n\}$ into n two-element subsets. In graph theoretic language this is the set of all "matchings" of a $2n$ set. The symmetric group S_{2n} acts transitively on X and yields a Gelfand pair. A natural random walk involves picking two elements at random and switching them to form a new partition. This gives an algorithm that converges to a random matching. The spherical functions are "zonal polynomials." It can be shown that $\frac{1}{2}n \log n$ switches suffice.

REAL SINGULARITIES OF SINGULAR STURM–LIOUVILLE EXPANSIONS*

GILBERT G. WALTER[†] AND AHMED J. ZAYED[‡]

Abstract. Elliptic equations in polar coordinates lead to singular Sturm–Liouville problems on $(0, \infty)$ with equations of the form $y''+(\lambda-q)y=0$. Let $\phi(x,\lambda)$ be solutions to the problem satisfying the condition $\phi(0,\lambda)=\sin\beta$, $\phi'(0,\lambda)=-\cos\beta$. The associated generalized Fourier transform $F(\lambda)=\int_0^\infty f(x)\phi(x,\lambda)\,dx$ is extended to cases where $F(\lambda)$ is a function of polynomial growth. This enables us to study the location of singularities of the analytic representation $\hat{f}$ of the generalized function $f(x)=\int_{-\infty}^\infty F(\lambda)\phi(x,\lambda)\,d\rho(\lambda)$. We do so by comparing them to the location of the singularities of the analytic representation $\hat{g}$ of the tempered distribution g which is the Fourier transform of $F(s^2)$.

Key words. generalized functions, analytic representations, Fourier transforms

AMS(MOS) subject classifications. Primary 34B25; secondary 35B50

1. Introduction. In this paper we extend the results of [7] on singularities of Sturm–Liouville expansions to include cases in which the location of the singular points lies on the real axis. This includes many cases of interest in which the function to be expanded is not holomorphic on all of $(0, \infty)$.

Indeed most convergence theorems for Sturm–Liouville expansions involve only real derivatives of the functions to be expanded, or as in the case of L^1 or L^2, no derivatives at all. Nonetheless they may be locally holomorphic and it is of interest in some applications to find the location of those real singular points [4].

In order to develop a theory encompassing such points we first introduce a space of generalized functions which will include most ordinary functions of interest. Each element in this space will have a convergent Sturm–Liouville expansion and an analytic representation obtained from a dual system of eigenfunctions. The singular points of these analytic representations are then compared to those of an associated Laplace transform of a tempered distribution [1]. The results obtained are similar to those in [7] whose terminology and results we shall also use.

A similar theory had been developed in [6] for regular Sturm–Liouville series. This in turn was an extension of the results found in [3] to the case of real singularities.

2. Preliminaries. We consider singular Sturm–Liouville problems of the form

$$y''+(\lambda-q(x))y=0, \tag{2.1}$$

with boundary conditions

$$\begin{aligned} &y(0)\cos\alpha+y'(0)\sin\alpha=0,\\ &|y(\infty)|<\infty. \end{aligned} \tag{2.2}$$

*Received by the editors August 7, 1984, and in final revised form August 20, 1985.

[‡] Department of Mathematics, California Polytechnic State University, San Luis Obispo, California 93407.

Let $\phi(x,\lambda)$ be a solution of (2.1) such that

$$\phi(0,\lambda)=\sin\alpha, \qquad \phi'(0,\lambda)=-\cos\alpha.$$

We shall suppose that $q(x)\in L^1(0,\infty)$ and is holomorphic in the right half plane. Hence the negative portion of the spectrum of the problem (2.1), (2.2) is discrete and bounded below, and can be ignored for most of what we shall do.

We shall be interested in Sturm–Liouville expansions of the form

$$f(x)\sim\int_{-\infty}^{\infty}F(\lambda)\phi(x,\lambda)\,d\rho(\lambda) \tag{2.3}$$

where $F(\lambda)$ is a continuous function of polynomial growth and where $\rho(\lambda)$ is the spectral measure. In this case the integral in (2.3) does not exist in the usual sense but must be interpreted as a generalized inverse Fourier transform of a generalized function. Similarly $f(x)$ will not necessarily be an ordinary function but rather a generalized function belonging to a particular space.

2.1. A space of generalized functions. Let A_0 denote $L^2(0,\infty)$ and let A_1 be the space of those functions $\phi\in L^2(0,\infty)$ whose derivative is absolutely continuous such that

$$\phi''-q\phi\in L^2(0,\infty), \qquad \phi(0)\cos\alpha+\phi'(0)\sin\alpha=0$$

and successively,

$$A_{n+1}=\{\phi\in L^2(0,\infty)|\phi^{(2n+1)} \text{ is absolutely continuous,}$$
$$(D^2-q)\phi\in A_n,\ \phi(0)\cos\alpha+\phi'(0)\sin\alpha=0\}.$$

Then

$$A=\bigcap_{n=0}^{\infty}A_n$$

is a linear space contained in $L^2(0,\infty)$ topologized by the countable family of seminorms given by

$$\rho_k(\phi)=\left\|(D^2-q)^k\phi\right\|_2.$$

PROPOSITION 2.1. *Let ψ be in A and let $\Psi(\lambda)$ be its generalized Fourier transform*

$$\Psi(\lambda)=\underset{N\to\infty}{\text{l.i.m.}}\int_0^N\psi(x)\phi(x,\lambda)\,dx; \tag{2.4}$$

then the eigenfunction expansion of ψ

$$\int_{-\infty}^{\infty}\Psi(\lambda)\phi(x,\lambda)\,d\rho(\lambda) \tag{2.5}$$

converges to ψ in the sense of A. Furthermore

$$\lambda^p\Psi(\lambda)\in L^2(\rho), \qquad p>0.$$

Proof. Let ψ_N be given by

$$\psi_N(x)=\int_{-N}^{N}\Psi(\lambda)\phi(x,\lambda)\,d\rho(\lambda).$$

Then $\psi_N \in L^2(0,\infty)$ ([5, p. 131]) as is $(D^2-q)^k\psi_N$ for each integer $k \geqq 0$, since $\lambda^k\Psi(\lambda)\chi_{[-N,N]}$, (where $\chi_{[-N,N]}$ is the characteristic function of $[-N,N]$) is also in $L^2(\rho)$. By the expansion theorem for Sturm–Liouville problems ([5, p. 130])

$$(D^2-q)^k\psi_N \to (D^2-q)^k\psi \qquad (L^2).$$

Hence $\psi_N \to \psi$ in the sense of A. The second conclusion follows similarly.

We now consider the dual space A' of A. Clearly $L^2(0,\infty) \subset A'$ and A contains $S(0,\infty)$, the space of all C^∞-functions with support in a closed half line in $(0,\infty)$ and which with their derivatives are rapidly decreasing at ∞. Since convergence in S implies convergence in A, S' contains A'. That is, the elements of A' are tempered distributions on $(0,\infty)$. Similarly A' contains E'_+ the space of distributions of compact support on $(0,\infty)$.

Proposition 2.2. *Let $f \in E'_+$ and let $F(\lambda)$ be its generalized Fourier transform*

$$F(\lambda) = \langle f, \phi(\cdot,\lambda)\rangle; \tag{2.6}$$

then the restriction of F to $(0,\infty)$ is a continuous function of polynomial growth.

Proof. Since $f \in A'$, it must belong to the dual space A'_k of one of the A_k's ([2, p. 11]). Hence $f=(D^2-q)^kG$ for some $G \in L^2$ since $\langle f,\varphi\rangle = \langle G,(D^2-q)^kG\rangle$ and $G \in A'_0 = L^2$. Since f has compact support, G satisfies

$$(D^2-q)^kG=0$$

in $(0,a)\cup(b,\infty)$ for some $0<a<b$. Let χ be the characteristic function of $(a/2,\ 2b)$. Then we have

$$\begin{aligned} f &= (D^2-q)^kG = (D^2-q)^k[G\chi] + (D^2-q)^k[G(1-\chi)] \\ &= (D^2-q)^kG_1 + (D^2-q)^{k-1}[((D^2-q)G)(1-\chi) + 2DGD(1-\chi) + GD^2(1-\chi)] \\ &= (D^2-q)^kG_1 + \sum_{i=0}^{2k-1} \left(c_i\delta_{a/2}^{(i)} + d_i\delta_{2b}^{(i)}\right)(-1)^i, \end{aligned}$$

where $G_1 = G\chi$ has compact support and $\delta_\alpha^{(i)}(x) = \delta^{(i)}(x-\alpha)$. Therefore we have

$$\begin{aligned} F(\lambda) &= \langle (D^2-q)^kG_1,\ \phi(\cdot,\lambda)\rangle + \sum_{i=0}^{2k-1} c_i\phi^{(i)}\left(\frac{a}{2},\ \lambda\right) + d_i\phi^{(i)}(2b,\lambda) \\ &= \langle G_1,\ (D^2-q)^k\phi(\cdot,\lambda)\rangle + O(\lambda^{k-1/2}) \\ &= (-\lambda)^k\langle G_1,\ \phi(\cdot,\lambda)\rangle + O(\lambda^{k-1/2}) \end{aligned}$$

by the asymptotic formula for ϕ [5, p. 206]. Thus the conclusion follows.

For f in A' we cannot use (2.6) as the definition of the generalized Fourier transform since $\phi(x,\lambda) \notin A$. However we can use another property which is consistent with Parseval's relation.

Definition 2.1. Let $f=(D^2-q)^kG$ be an element of A' where $G \in L^2(0,\infty)$. Then the generalized Fourier transform F of f is given by

$$F(\lambda) = (-\lambda)^k \operatorname*{l.i.m.}_{M\to\infty} \int_0^M G(x)\phi(x,\lambda)\,dx. \tag{2.7}$$

If $G \in L^1(0,\infty)$ as well, then f is called admissible.

PROPOSITION 2.3. *Let $f \in A'$ and let $F_1(\lambda)$ be the restriction of its generalized Fourier transform to positive values of λ. Then*

(i) *for admissible f $F_1(\lambda)$ is a continuous function of polynomial growth*;

(ii) *the eigenfunction expansion of f converges to f in the sense of A'.*

Proof. Since $\phi(x,\lambda)$ is bounded for $x \in (0,\infty)$, $F(\lambda)$ is at most of polynomial growth by (2.7). The continuity follows from the expression ([5, p. 206])

$$\phi(x,\lambda) = \sin\alpha\cos\sqrt{\lambda}\,x - \cos\alpha\frac{\sin\sqrt{\lambda}\,x}{\sqrt{\lambda}} + \frac{1}{\sqrt{\lambda}}\int_0^x \sin\sqrt{\lambda}\,(x-t)q(t)\phi(t,\lambda)\,dt. \tag{2.8}$$

Now we let $F(\lambda)$ be a continuous function of polynomial growth; then f_N given by

$$f_N(t) = \int_{-N}^{N} F(\lambda)\phi(t,\lambda)\,d\rho(\lambda) = \int_{-\infty}^{\infty} F_N(\lambda)\phi(t,\lambda)\,d\rho(\lambda)$$

belongs to $L^2(0,\infty)$ and hence A'. Furthermore

$$\langle f_N, \phi\rangle = \int_{-\infty}^{\infty} F_N(\lambda)\Phi(\lambda)\,d\rho(\lambda) \to \int_{-\infty}^{\infty} F(\lambda)\Phi(\lambda)\,d\rho(\lambda) \tag{2.9}$$

where the integral converges by Proposition 2.1. But this is just the eigenfunction expansion of f if $F(\lambda)$ is as in (2.7).

2.2. Analytic representations. The analytic representation of a function $h \in L^2(-\infty,\infty)$ is given by

$$\hat{h}(z) = \frac{1}{2\pi i}\int_{-\infty}^{\infty} \frac{h(x)}{x-z}\,dx, \qquad \operatorname{Im} z \neq 0. \tag{2.10}$$

This can be extended to S' by using the inverse Fourier transform $\mathscr{F}^{-1}$

$$\hat{h}(z) = \begin{cases} \displaystyle\int_0^{\infty} e^{izs}(\mathscr{F}^{-1}h)(s)\,ds, & \operatorname{Im} z > 0, \\ \displaystyle\int_{-\infty}^{0} e^{izs}(\mathscr{F}^{-1}h)(s)\,ds, & \operatorname{Im} z < 0. \end{cases}$$

(See [1].) In our case we have, for $\lambda = s^2$,

$$\hat{g}(z) = \begin{cases} \displaystyle\int_0^{\infty} e^{izs}F(s^2)\,ds, & \operatorname{Im} > 0, \\ 0, & \operatorname{Im} z < 0. \end{cases} \tag{2.11}$$

This $\hat{g}$ is the analytic representation of a tempered distribution $g \in S'$. It is related to the element $f \in A'$ through its Fourier transform F which is the same as the generalized Fourier transform of f, i.e. $\mathscr{F}(g) = F(s^2)$ and $F(s^2) = \langle f, \phi(\cdot, s^2)\rangle$.

In order to construct an analytic representation of f we use another solution to (2.1), namely

$$\psi^{\pm}(z,\lambda) = \phi(z,\lambda)\int_{\pm i\infty}^{z} \frac{d(\lambda)}{\phi^2(z',\lambda)}\,dz'$$

where $+i\infty$ is used for $\operatorname{Im} z>0$, $-i\infty$ for $\operatorname{Im} z<0$, and $d(\lambda)$ is a constant to be determined. We shall assume that the behavior of $\phi(z,\lambda)$ is similar to its upper bound off the real axis.

Assumption 1.

$$|\phi(z,s^2)|\sim e^{|\operatorname{Im} zs|}, \quad s \text{ real} \quad (\text{see [5]}).$$

Then $|\psi^+(z,s^2)|\leqq Ae^{-s\operatorname{Im} z}$, s real, $\operatorname{Im} z>0$. Since q is assumed holomorphic in the right half plane, $\psi^\pm$ is also holomorphic there. The function $\psi^+(x)-\psi^-(x)$ is also a solution to (2.1) on the real axis. It is related to ϕ by

$$\psi^+(x,\lambda)-\psi^-(x,\lambda)=\phi(x,\lambda)\left\{\int_{i\infty}^{x}\frac{c(\lambda)}{\phi^2(x,z)}\,dz-\int_{-i\infty}^{x}\frac{c(\lambda)}{\phi^2(x,z)}\,dz\right\}$$
$$=\phi(x,\lambda)$$

provided

$$c^{-1}(\lambda)=\int_{+i\infty}^{-i\infty}\frac{1}{\phi^2(z,\lambda)}\,dz.$$

This is independent of the contour since the Wronskian of $\psi^+-\psi^-$ with ϕ is zero. Thus we may take $\psi^+(\psi^-)$ to be the analytic representation of $\phi(x,\lambda)$ in the upper (lower) half plane respectively.

The usual analytic representation of ϕ given by (2.10) exists as well provided the integral is l.i.m.

From this we get an analytic representation for $f\in A'$ given by

$$\hat{f}^{\pm}(z)=\int_{-\infty}^{\infty}F(\lambda)\psi^{\pm}(z,\lambda)\,d\rho(\lambda)$$

which converges for $|\operatorname{Im} z|$ sufficiently large.

3. Associated kernels. It was shown in [7] that the kernels

$$K(t,z)=\int_0^\infty\phi(t,s^2)e^{-isz}\,d\rho(s^2),\qquad \operatorname{Im} z<0,\quad 0<t \tag{3.1a}$$

and

$$L(t,z)=\int_0^\infty\phi(t,s^2)e^{isz}\,ds,\qquad \operatorname{Im} z>0,\quad 0<t \tag{3.1b}$$

are holomorphic in the lower (resp. upper) half plane and may be continued to the real axis except possibly at the point $z=\pm t$. The analytic representations of each, $\hat{K}$ and $\hat{L}$, may be shown to be singular at most at the same values as well. Indeed $K(t,z)\in L^2(0,\infty)$ for $\operatorname{Im} z<0$ as a function of t and

$$\hat{K}(w,z)=\frac{1}{2\pi i}\int_0^\infty\frac{K(t,z)}{t-w}\,dt \tag{3.2}$$

is holomorphic for $\operatorname{Im} z<0$, $\operatorname{Im} w\neq 0$. It may be continued for w fixed in the upper half plane to any value of z except possibly $z=\pm w$ by deforming the contour of integration.

The same is true for $\hat{L}(w,z)$. Hence both are holomorphic in C^2 except possibly on $w=0$ and $z=\pm w$.

Another analytic representation of these kernels is obtained by using $\psi^{\pm}$ in place of ϕ. We have

$$\hat{K}^{\pm}(w,z)=\int_0^{\infty}\psi^{\pm}(w,s^2)e^{-isz}d\rho(s^2)$$

which differs from $\hat{K}$ by a function holomorphic in $\{(w,z)|\operatorname{Re} w>0\}$ and similarly for $\hat{L}^{\pm}(w,z)$.

4. Relation between ***f*** **and** ***g*** **and their analytic representations.** For the same coefficient function $F(\lambda)$ we have on the one hand, formally,

$$f(t)=\int_{-\infty}^{\infty}\phi(t,\lambda)F(\lambda)\,d\rho(\lambda) \tag{4.1}$$

where $f\in A'$, and on the other

$$g(x)=\int_0^{\infty}e^{ixs}F(s^2)\,ds \tag{4.2}$$

where $g\in S'$. Both integrals must be interpreted as the limits in an appropriate sense, (namely A' and S') of the functions obtained by truncating F to its value on bounded intervals. But $F(\lambda)$ may be obtained from f by using the fact that $f=((D^2-q)^2+1)^pG$ where $G\in L^2$ is given by

$$G(t)=\int_{-\infty}^{\infty}\phi(t,\lambda)\frac{F(\lambda)}{(\lambda^2+1)^p}\,d\rho(\lambda).$$

If p is chosen sufficiently large, $F(\lambda)/(\lambda^2+1)^p\in L^2(\rho)$ and hence $G(t)\in L^2$ and the usual inversion theorem holds

$$\frac{F(\lambda)}{(\lambda^2+1)^p}=\underset{N\to\infty}{\text{l.i.m.}}\int_0^N\phi(t,\lambda)G(t)\,dt. \tag{4.3}$$

The analytic representation of $g(x)$ is also given by (4.2) with x replaced by the complex variable z. We now replace F by the expression (4.3)

$$\hat{g}(z)=\int_0^{\infty}e^{isz}(s^4+1)^p\int_0^{\infty}\phi(t,s^2)G(t)\,dt\,ds.$$

For $\operatorname{Im} z>0$, $e^{isz}(s^4+1)^p\in L^2$ and hence this integral exists. It may also be given by

$$\begin{aligned}\hat{g}(z)&=(D_z^4+1)^p\int_0^{\infty}\int_0^{\infty}e^{isz}\phi(t,s^2)\,ds\,G(t)\,dt \\ &=(D_z^4+1)^p\int_0^{\infty}L(t,z)G(t)\,dt \\ &=(D_z^4+1)^p\int_0^{\infty}L(t,z)(\hat{G}(t+i0)-\hat{G}(t-i0))\,dt \\ &=(D_z^4+1)^p\left(\int_{c^+}-\int_{c^-}\right)L(w,z)\hat{G}(w)\,dw, \qquad \operatorname{Im} z>0\end{aligned} \tag{4.4}$$

where $\hat{G}$ is the usual analytic representation of G and c^+, c^- are contours from 0 to ∞ lying respectively in the upper and lower half plane.

To go in the other direction we first use the fact that

$$\hat{f}(z)=\int_0^{\infty}\psi^{\pm}(z,s^2)F(s^2)\,d\rho(s^2). \tag{4.5}$$

Since

$$F(s^2)=\frac{1}{2\pi}\int_{-\infty}^{\infty}g(x)e^{-ixs}\,dx$$

we have by interchanging the order of integration

$$\begin{aligned}\hat{f}(z)&=\frac{1}{2\pi}\int_{-\infty}^{\infty}g(x)\int_0^{\infty}\psi^{\pm}(z,s^2)e^{-ixs}\,d\rho(s^2)\,dx \\ &=\frac{1}{2\pi}\langle g,\,\hat{K}^{\pm}(z,\cdot)\rangle \\ &=\frac{1}{2\pi}\int_{c^+}\hat{K}^{\pm}(z,w)\hat{g}(w)\,dw\end{aligned} \tag{4.6}$$

where c^+ is a contour in the upper half plane.

5. The singularity theorem. The main result can now be given.

THEOREM. *Let $f\in A'$ and admissible, let $F(\lambda)$ be the generalized Fourier transform of f; then the analytic representation of f is singular at $t=\alpha>0$ if and only if $\hat{g}(z)$ given by*

$$\hat{g}(z)=\int_0^{\infty}e^{isz}F(s^2)\,ds$$

is singular at α or $-\alpha$.

Proof. For $f\in A'$ we have

$$f(t)=\underset{N\to\infty}{\text{l.i.m.}}\int_{-N}^{N}F(\lambda)\phi(t,\lambda)\,d\rho(\lambda)$$

where the limit is in the sense of A'. Since the negative part of the spectrum is discrete and bounded below, we may express f as

$$\begin{aligned}f(t)&=\int_{-\infty}^{0}F(\lambda)\phi(t,\lambda)\,d\rho(\lambda)+\int_0^{\infty}F(\lambda)\phi(t,\lambda)\,d\rho(\lambda) \\ &=m(t)+f_1(t)\end{aligned} \tag{5.1}$$

where m is holomorphic for $\operatorname{Re}t>0$ and $f_1\in A'$.

Clearly $\hat{f}(z)$ and $\hat{f}_1(z)$ the analytic representations of f and f_1 respectively, are singular at the same points in $\operatorname{Re}z>0$.

Let us suppose that $\hat{f}$ has an isolated singularity at $z=\alpha$ on the positive real axis. Then either $\hat{G}(\alpha+i0)$ or $\hat{G}(\alpha-i0)$ of (4.4) is singular there as well, say $\hat{G}(\alpha+i0)$. Then

$$\int_{c^+}L(w,z)\hat{G}(w)\,dw \tag{5.2}$$

is holomorphic for $\operatorname{Im}z>0$. It may be continued to Real z for all values except the singularities of $\hat{G}$ or their negatives (since $L(w,z)$ has singularities at most at $z=\pm w$) by deforming the contour c^+. The same is true for c^-. Hence the only possible singular point of $\hat{g}(z)$ is at $z=\pm\alpha$. Since $\hat{g}(z)=0$ for $\operatorname{Im}z<0$, no possible singularities arise there.

Now suppose $\hat{g}(w)$ has an isolated singularity at $\beta\neq 0$. Then by (4.6) for $\operatorname{Im} z<0$, $\hat{f}(z)$ may be continued to the entire real axis since $\hat{K}^{-}(z,w)$ has singularities only at $w=\pm z$, and the contour lies above the x-axis. For $\operatorname{Im} z>0$, $\hat{f}(z)$ may be continued to the real axis by again deforming the contour except at whichever of β or $-\beta$ is positive.

Hence if $\hat{f}$ is singular at $t=\alpha$, $\hat{g}$ must be singular at least at $-\alpha$ and α since if it were not, $\hat{f}$ would not be singular at $t=\alpha$

Example 1. $q(x)=0$.

a) $\alpha=\pi/2$, $\phi(x,s)=\cos xs$, $d\rho(\lambda)=ds$.

For $F(s^2)=e^{ias}s^{\nu-1}$, $a,s>0$, $\operatorname{Re}\nu>0$, we have $f\in A'$ given by

$$f(x)=\int_0^\infty e^{ias}s^{\nu-1}\cos xs\,ds$$

where the integral converges in the sense of A'. The integral converges locally as well to the function

$$f(x)=\frac{\Gamma(\nu)}{2(-1)^\nu}\{(x-a)^{-\nu}+(x+a)^{-\nu}\}.$$

The analytic representation $\hat{f}$ of f has a singularity on $[0,\infty)$ at most at $x=a$. Since $\psi^{\pm}(z,s)$ can be calculated explicitly in this case,

$$\psi^{\pm}(z,s)=\pm\frac{e^{\pm isz}}{2},$$

we can also find $\hat{f}$ explicitly:

$$\hat{f}^{\pm}(z)=\pm\frac{\Gamma(\nu)}{2(-1)^\nu}(a\pm z)^{-\nu}$$

with + or − corresponding to $\operatorname{Im} z>0$ or $\operatorname{Im} z<0$. The corresponding $\hat{g}$ is

$$\hat{g}(z)=\int_0^\infty e^{ias}s^{\nu-1}e^{isz}\,ds=\begin{cases}\dfrac{\Gamma(\nu)}{(-1)^\nu}(z+a)^{-\nu}, & \operatorname{Im} z>0,\\ 0, & \operatorname{Im} z<0,\end{cases}$$

which agrees with the theorem of §5.

b) $0\neq\alpha\neq\pi/2$, $\phi(x,s)=\sin\alpha\cos xs-(\cos\alpha/s)\sin xs$, $d\rho(\lambda)=2s\rho'(s)\,ds=(1/\pi)\{2s^2/(\cos^2\alpha+s^2\sin^2\alpha)\}\,ds$.

For $F(s^2)=\pi(\cos^2\alpha+s^2\sin^2\alpha)s^\mu$, $\operatorname{Re}\mu>-2$, we have $f\in A'$ given locally by

$$\begin{aligned}f(x)&=\frac{1}{\pi}\int_0^\infty F(s^2)\phi(x,s)2s\rho'(s)\,ds\\&=2\int_0^\infty \sin\alpha\cos xs\,s^{\mu+2}\,ds\\&\quad-2\cos\alpha\int_0^\infty \sin xs\,s^{\mu+1}\,ds\\&=2\sin\alpha\Gamma(\nu+3)\cos\frac{((\nu+3)\pi)}{2}x^{-\mu-3}\\&\quad-2\cos\alpha\Gamma(\nu+2)\sin\frac{((\nu+2)\pi)}{2}x^{-\mu-2}.\end{aligned}$$

Thus $\hat{f}^{\pm}(z)$ has singularities at most $z=0$. Similarly $\hat{g}(z)$ can be found to be

$$\hat{g}(z)=\cos^2\alpha\frac{\Gamma(\mu+1)}{(-1)^{\mu+1}}z^{-\mu-1}+\sin^2\alpha\frac{\Gamma(\mu+3)}{(-1)^{\mu+3}}z^{-\mu-3}$$

for $\operatorname{Im} z>0$.

Example 2. $q(x)=(\nu^2-1/4)/x^2$, $\nu>1$, $\phi(x,s)=\sqrt{x}\,J_\nu(xs)$, $d\rho(\lambda)=s\,ds$.

a) $F(s^2)=s^{\mu-2}$, $\operatorname{Re}(\mu+\nu)-1>0$, $\mu>1$.

Then $f\in A'$ is given locally by

$$f(x)=\int_0^\infty s^{\mu-1}\sqrt{x}\,J_\nu(xs)\,ds=\frac{\Gamma((\mu+\nu)/2)2^{\mu-1}}{\Gamma((\nu-\mu)/2+1)x^{\mu-1/2}},$$

while

$$\hat{g}(z)=\begin{cases}\dfrac{\Gamma(\mu-1)}{(-1)^{\mu-1}}z^{1-\mu}, & \operatorname{Im} z>0,\\ 0, & \operatorname{Im} z<0.\end{cases}$$

b) $F(s^2)=s^{\nu-1}\sin as$.

Then

$$f(x)=\int_0^\infty s^{\nu-1/2}\sin as\sqrt{sx}\,J_\nu(sx)\,ds$$

$$=\frac{\sqrt{\pi}\,2^\nu x^{\nu+1/2}}{\Gamma(1/2\nu)(a^2-x^2)^{\nu+1/2}}\chi_{[0,a)}(x)$$

where $\chi_{[0,a)}$ is the characteristic function of $[0,a)$. Now

$$\hat{g}(z)=\begin{cases}\dfrac{|z+a|^{-\nu}-|z-a|^{-\nu}\operatorname{sgn}(z-a)}{4\Gamma(1-\nu)\cos(\nu\pi/2)}+i\dfrac{|z-a|^{-\nu}|z+a|^{-\nu}}{4\Gamma(1-\nu)\sin(\nu\pi/2)}, & \operatorname{Im} z>0,\\ 0, & \operatorname{Im} z<0.\end{cases}$$

q-POLLACZEK POLYNOMIALS AND A CONJECTURE OF ANDREWS AND ASKEY*

W. A. AL-SALAM[†] AND T. S. CHIHARA[‡]

Abstract. The q-Pollaczek polynomials are orthogonal polynomials having a generating function of the form $A(t)\prod_{k=0}^{\infty}F(x,tq^k)=\sum_{n=0}^{\infty}P_n(x)t^n$, where $F(x,t)=[1-xH(t)]/[1-xK(t)]$ and $A(t)$, $H(t)$ and $K(t)$ are formal power series with $H(0)=K(0)=0$, $A(0)H'(0)K'(0)\neq 0$. We determine all orthogonal polynomials having generating functions of this form. We find that in addition to the q-Pollaczek polynomials, there are two other sets that are closely related to the q-Pollaczek polynomials.

Key words. q-Pollaczek polynomials, orthogonal polynomials

AMS(MOS) subject classification. Primary 33A65

1. Introduction. In the characterization of a class of orthogonal polynomials having a certain "convolution structure" [2], we were led to generating functions of the form

$$\prod_{k=0}^{\infty}\frac{1-atq^k+bt^2q^{2k}}{1-xtq^k+ct^2q^{2k}}=\sum_{n=0}^{\infty}P_n(x)t^n \tag{1.1}$$

in which the $P_n(x)$ are orthogonal polynomials. These polynomials are special cases of certain orthogonal ${}_4\phi_3$ polynomials ("q-Askey–Wilson polynomials") studied by Askey and Wilson and the orthogonality relations for $|q|<1$ can be obtained from those given in [6]. These relations are rederived by Askey and Ismail in [5] and the orthogonality relations are also given for $|q|>1$ in those cases where the associated Hamburger moment problem is determined. Andrews and Askey [4] have recently conjectured that the only generating functions of the form

$$A(t)\prod_{k=0}^{\infty}\left[1-xK(tq^k)\right]^{-1}=\sum_{n=0}^{\infty}P_n(x)t^n \tag{1.2}$$

in which $\{P_n(x)\}$ is a sequence of orthogonal polynomials are (after change of variables and renormalization) the ones we found in [2].

Independently, in a private communication, Askey suggested to one of us that it would be interesting to characterize those orthogonal polynomials that have generating functions of the form

$$A(t)\prod_{k=0}^{\infty}\left[1-xH(tq^k)\right]=\sum_{n=0}^{\infty}P_n(x)t^n. \tag{1.3}$$

Al-Salam was able to find all orthogonal polynomials of the latter class and this suggested to him the further characterization problem of finding all orthogonal polynomials having generating functions of the form

$$(1.4)\qquad A(t)\prod_{m=0}^{\infty}\frac{1-\delta xH(q^m t)}{1-\theta xK(q^m t)}=\sum_{n=0}^{\infty}P_n(x)t^n.$$

When apprised of the latter, Askey noted that the q-Pollaczek polynomials have a generating function of this type. He pointed out that the q-Pollaczek polynomials can be defined (after a scale change of the independent variable: $x\to x/2$) by the recurrence relation

$$(1.5)\qquad (1-q^{n+1})P_{n+1}(x)=[(1-aq^n)x+bq^n]P_n(x)-(1-cq^{n-1})P_{n-1}(x),$$

$P_n(x)=P_n(x;a,b,c)$. They have the generating function

$$(1.6)\qquad F(x;q;a,b,c;t)=\prod_{k=0}^{\infty}\frac{1-(ax+b)tq^k+ct^2q^{2k}}{1-xtq^k+t^2q^{2k}}=\sum_{n=0}^{\infty}P_n(x)t^n.$$

This can be written in the form (1.4) with

$$A(t)=\prod_{k=0}^{\infty}\frac{1-btq^k+ct^2q^{2k}}{1+t^2q^{2k}},$$
$$H(t)=(1-bt+ct^2)^{-1},$$
$$K(t)=(1+t^2)^{-1}.$$

Askey suggested that these were essentially the only orthogonal polynomials having such generating functions. These polynomials were initially studied by Askey and Ismail and the orthogonality measures have now been found in most cases. The special case of the symmetric polynomials ($b=0$) is discussed thoroughly for $0<q<1$ by Askey and Ismail in their memoir [5]. For the general case, weight functions have been obtained for all cases where the spectrum is continuous by Charris and Ismail [8]. These authors also discuss a sieved version of the Pollaczek polynomials which can be obtained from the q-Pollaczek polynomials by letting $q\to$ a root of unity.

In this paper, we will investigate Askey's suggestion by looking for all cases where (1.4) generates orthogonal polynomials. We will show that the initial conjecture of Andrews and Askey concerning (1.2) is correct and that in the general case (1.4) with $\delta\theta\neq 0$, Askey's conjecture is nearly right. However there are two exceptional cases closely related to the q-Pollaczek polynomials. We mention that the different but related generating function

$$A(t)\prod_{n=0}^{\infty}[1-xK(t)q^n]^{-1}=\sum_{n=0}^{\infty}P_n(x)t^n$$

was studied by Ismail [11] who found all cases where the $P_n(x)$ are orthogonal polynomials.

2. General necessary conditions. We study the polynomial generating function

$$(2.1)\qquad G(x,t)=A(t)\prod_{k=0}^{\infty}\frac{1-\delta xH(tq^k)}{1-\theta xK(tq^k)}=\sum_{n=0}^{\infty}Q_n(x)t^n$$

where $0<|q|<1$, $|\delta|+|\theta|>0$, and

$$A(t)=\sum_{m=0}^{\infty} a_m t^m, \tag{2.2}$$

$$H(t)=\sum_{m=1}^{\infty} h_m t^m,$$

$$K(t)=\sum_{m=1}^{\infty} k_m t^m$$

and we assume that $\{Q_n(x)\}$ is a sequence of orthogonal polynomials. In particular, $Q_n(x)$ must be of precise degree n and there is no loss of generality if we take

$$a_0=1, \qquad h_1=k_1=1, \tag{2.3}$$

and for convenience we also write

$$h_0=k_0=0. \tag{2.4}$$

Now considering (2.1), replace x by x^{-1}, t by xt. Upon letting $x\to 0$, we obtain

$$A(0)\prod_{m=0}^{\infty}\frac{1-\delta q^m t}{1-\theta q^m t}\sum_{n=0}^{\infty} b_n t^n$$

where b_n denotes the leading coefficient of $Q_n(x)$. This yields

$$b_n=\frac{(\delta/\theta;q)_n\theta^n}{(q;q)_n}. \tag{2.5}$$

Here we use the usual notation,

$$(a;q)_0=1, \qquad (a;q)_n=(1-a)(1-aq)\cdots(1-aq^{n-1}) \quad \text{for } n>0.$$

It then follows that the three-term recurrence relation for these polynomials has the form

$$(1-q^{n+1})Q_{n+1}(x)=[(\theta-\delta q^n)x+\beta_n]Q_n(x)-\gamma_n Q_{n-1}(x). \tag{2.6}$$

From (2.1), we have that $Q_n(0)=a_n$ so

$$(1-q^{n+1})a_{n+1}=\beta_n a_n-\gamma_n a_{n-1}, \qquad n\geqq 1. \tag{2.7}$$

Next we set

$$\mathscr{A}(t)=\frac{A(qt)}{A(t)}=\sum_{n=0}^{\infty}\alpha_n t^n.$$

We then have

$$G(x,qt)=\mathscr{A}(t)\frac{1-\theta xK(t)}{1-\delta xH(t)}G(x,t)$$

from which we obtain

$$[1-\theta xK(t)]\sum_{m=0}^{\infty}\alpha_m t^m\sum_{n=0}^{\infty}Q_n(x)t^n=[1-\delta xH(t)]\sum_{n=0}^{\infty}Q_n(x)q^nt^n.$$

This can be expanded to

$$\sum_{n=0}^{\infty}\sum_{j=0}^{n}\alpha_jQ_{n-j}(x)t^n-\sum_{n=0}^{\infty}Q_n(x)q^nt^n$$
$$=x\left[\theta K(t)\sum_{n=0}^{\infty}\sum_{j=0}^{n}\alpha_jQ_{n-j}(x)t^n-\delta H(t)\sum_{n=0}^{\infty}Q_n(x)q^nt^n\right]$$

and this yields for $n>0$

$$(2.8)\quad q^nQ_n(x)-\sum_{j=0}^{n}\alpha_jQ_{n-j}(x)$$
$$=x\left[\delta\sum_{m=0}^{n-1}h_{m+1}Q_{n-m-1}(x)q^{n-m-1}-\theta\sum_{m=0}^{n-1}k_{m+1}\sum_{j=0}^{n-m-1}\alpha_jQ_{n-m-j-1}(x)\right].$$

We use the recurrence formula (2.6) to eliminate $\delta xq^sQ_s(x)$ from the right side of (2.8). The result is

$$q^nQ_n(x)-\sum_{j=0}^{n}\alpha_jQ_{n-j}(x)$$
$$=\sum_{i=0}^{n-1}h_{i+1}\left[\beta_{n-i-1}Q_{n-i-1}(x)-\gamma_{n-i-1}Q_{n-i-2}(x)-(1-q^{n-i})Q_{n-i}(x)\right]$$
$$-\theta x\sum_{r=0}^{n-1}\left[k_{r+1}\sum_{j=0}^{n-r-1}\alpha_jQ_{n-r-j-1}(x)-h_{r+1}Q_{n-r-1}(x)\right]$$

which in turn yields

$$(2.9)\quad \sum_{i=0}^{n}\alpha_iQ_{n-i}(x)=\theta x\sum_{i=0}^{n-1}F_{n,i}(x)-\beta_{n-1}Q_{n-1}(x)+(1-q^{n-1})h_2Q_{n-1}(x)$$
$$-\sum_{j=0}^{n}\left[h_j\beta_{n-j}-h_{j-1}\gamma_{n-j+1}-h_{j+1}(1-q^{n-j})\right]Q_{n-j}(x)$$

where

$$F_{n,i}(x)=k_{i+1}\sum_{j=0}^{n-i-1}\alpha_jQ_{n-i-j-1}(x)-h_{i+1}Q_{n-i-1}(x).$$

Once again using (2.8), we eliminate the $xQ_s(x)$ terms from $xF_{n,i}(x)$ and obtain

(2.10)

$$\begin{aligned} xF_{n,i}(x) &= \frac{k_{i+1}-h_{i+1}}{\theta-\delta q^{n-i-1}}(1-q^{n-i})Q_{n-i}(x) \\ &+ \left[\frac{\alpha_1 k_{i+1}(1-q^{n-i-1})}{\theta-\delta q^{n-i-2}} - \frac{k_{i+1}-h_{i+1}}{\theta-\delta q^{n-i-1}}\beta_{n-i-1}\right]Q_{n-i-1}(x) \\ &+ \left[\frac{\alpha_2 k_{i+1}(1-q^{n-i-2})}{\theta-\delta q^{n-i-3}} - \frac{\alpha_1 k_{i+1}\beta_{n-i-2}}{\theta-\delta q^{n-i-2}} + \frac{k_{i+1}-h_{i+1}}{\theta-\delta q^{n-i-1}}\gamma_{n-i-1}\right]Q_{n-i-2}(x) \\ &+ k_{i+1}\sum_{s=3}^{n-i} D_s(n,i)Q_{n-i-s}(x) \end{aligned}$$

where

$$D_s(n,i) = \frac{\alpha_s(1-q^{n-i-s})}{\theta-\delta q^{n-i-s-1}} - \frac{\alpha_{s-1}\gamma_{n-i-s}}{\theta-\delta q^{n-i-+s}} + \frac{\alpha_{s-2}\gamma_{n-i-s+1}}{\theta-\delta q^{n-i-s+1}}.$$

We next compare the coefficients of $Q_{n-1}(x)$ in (2.9) with the aid of (2.10) and find

$$\alpha_1 = \frac{\theta(\alpha_1+k_2-h_2)(1-q^{n-1})}{\theta-\delta q^{n-2}} - \beta_{n-1} + (1-q^{n-1})h_2, \qquad n \geqq 1,$$

so that

$$\beta_n = \frac{\theta(\alpha_1+k_2)-\delta h_2 q^{n-1}}{\theta-\delta q^{n-1}}(1-q^n) - \alpha_1, \qquad n \geqq 0. \tag{2.11}$$

Similarly, comparison of the coefficients of $Q_{n-2}(x)$ yields

$$\begin{aligned} \gamma_n &= \frac{\theta(\alpha_1+k_2)-\delta h_2 q^{n-1}}{\theta-\delta q^{n-1}}\beta_{n-1} \\ &- \frac{\theta(\alpha_2+\alpha_1 k_2+k_3)-\delta h_3 q^{n-2}}{\theta-\delta q^{n-2}}(1-q^{n-1}) + \alpha_2, \qquad n \geqq 1. \end{aligned} \tag{2.12}$$

As derived, (2.12) does not necessarily hold for $n=1$ but (2.7) can be used to obtain

$$\gamma_1 = -\frac{\alpha_1(\beta_1+\alpha_1)}{(1-q)} + \alpha_2$$

and if (2.11) is used to eliminate β_1, this reduces to (2.12) for $n=1$. Finally, we equate coefficients of $Q_{n-s}(x)$ and obtain

$$\begin{aligned} \alpha_s &= \left\{\theta\sum_{i=0}^{s}\alpha_i k_{s-i+1} - \delta h_{s+1}q^{n-s-1}\right\}\frac{1-q^{n-s}}{\theta-\delta q^{n-s-1}} \\ &- \left\{\theta\sum_{i=0}^{s-1}\alpha_i k_{s-i} - \delta h_s q^{n-s}\right\}\frac{\beta_{n-s}}{\theta-\delta q^{n-s}} \\ &+ \left\{\theta\sum_{i=0}^{s-2}\alpha_i k_{s-i-1} - \delta h_{s-1}q^{n-s+1}\right\}\frac{\gamma_{n-s+1}}{\theta-\delta q^{n-s+1}}. \end{aligned} \tag{2.13}$$

One can verify directly that (2.13) remains valid for $n \geqq 1$ provided we interpret an empty sum as 0.

3. The special cases where $\delta\theta = 0$. We first take up the case $\delta = 0$. We can then set $\theta = 1$ without loss of generality so that (2.11) and (2.12) can be written

$$\beta_n = \beta - bq^n, \qquad \gamma_n = \gamma - cq^{n-1} \tag{3.1}$$

where

$$\beta = k_2, \quad \gamma = k_2^2 - k_3, \quad b = \alpha_1 + k_2, \quad c = \alpha_1^2 + \alpha_1 k_2 - \alpha_2 - k_3.$$

Setting $Q_n^*(x) = (q;q)_n Q_n(x-\beta)$, we can write the recurrence formula (2.6) as

$$Q_{n+1}^*(x) = (x - bq^n) Q_n^*(x) - (\gamma - cq^{n-1}) Q_{n-1}^*(x). \tag{3.2}$$

Thus the $Q_n^*(x)$ are the polynomials found by us in [2], the ones whose orthogonality relations were first found by Askey and Wilson (see the introduction). If $\gamma \neq 0$, these polynomials are special cases of the q-Pollaczek polynomials. If $\gamma = 0$, these polynomials are the Al-Salam and Carlitz q-polynomials $U_n^{(a)}(x)$ (see [1], [8, p. 196]). The generating function given in [2] is

$$\phi(x,t) = \prod_{k=0}^{\infty} \frac{1 - btq^k + ct^2q^{2k}}{1 - xtq^k + t^2q^{2k}} = \sum_{n=0}^{\infty} Q_n(x-\beta)t^n \tag{3.3}$$

which is one of the right form.

It remains to show that the product representation in (3.3) is the only one of the form (2.1). We let $n \to \infty$ in (2.13) and obtain

$$\alpha_s = \sum_{i=0}^{s} \alpha_i k_{s-i+1} - \beta \sum_{i=0}^{s-1} \alpha_i k_{s-i} + \gamma \sum_{i=0}^{s-2} \alpha_i k_{s-i-1},$$

$$\sum_{i=0}^{s-1} \alpha_i (k_{s-i+1} + \beta k_{s-i} - \gamma k_{s-i-1}) = 0, \qquad s \geqq 1.$$

Since $\alpha_0 \neq 0$, it follows that

$$k_{s+1} - \beta k_s + \gamma k_{s-1} = 0, \qquad s \geqq 1.$$

Together with the initial conditions $k_0 = 0$, $k_1 = 1$, this yields

$$K(t) = \frac{t}{1 - \beta t + \gamma t^2}. \tag{3.4}$$

Thus

$$1 - xK(t) = \frac{1 - (x+\beta)t + \gamma t^2}{1 - \beta t + \gamma t^2}$$

and this shows that the generating function (2.1) must be (3.3).

Next we let $\theta = 0$ and take $\delta = 1$. Now (2.11) and (2.12) reduce to

$$\beta_n = \beta - bq^n, \qquad \gamma_n = \gamma - cq^{n-1} \tag{3.5}$$

where

$$b=h_2,\quad c=h_2^2-h_3,\quad \beta=h_2-\alpha_1,\quad \gamma=h_2^2-h_3-\alpha_1h_2+\alpha_2.$$

Now (2.13) reads

$$\alpha_s=-(1-q^{n-s})[h_{s+1}-bh_s+ch_{s-1}]-\alpha_1(h_s-bh_{s-1})-\alpha_2h_{s-1},$$

from which we conclude

$$(3.6)\qquad h_{s+1}-bh_s+ch_{s-1}=0,\qquad s\geqq 1,$$

$$(3.7)\qquad \alpha_s=-\alpha_1h_s+(b\alpha_1-\alpha_2)h_{s-1},\qquad s\geqq 1.$$

For $s=1$ and 2, (3.6) yields $\alpha_1=\alpha_2=0$; hence $\alpha_s=0$ for all $s\geqq 1$. Thus $A(t)=1$ and from (3.7) we find,

$$(3.8)\qquad H(t)=\frac{t}{1-bt+ct^2}.$$

The recurrence formula (2.6) becomes

$$(3.9)\qquad (1-q^{n+1})Q_{n+1}(x)=[-xq^n+\beta-bq^n]Q_n(x)-(\gamma-cq^{n-1})Q_{n-1}(x).$$

Comparing (3.9) with the recurrence formula (3.68) in Askey and Ismail's memoir [5], we see that (using their notation)

$$(3.10)\qquad Q_n(x)=v_n(x+b;q;\beta,\gamma,c).$$

For $\gamma\neq 0$ these polynomials are special cases of the q-Pollaczek polynomials. For $\gamma=0$, they can be transformed to the Al-Salam and Carlitz polynomials $V_n^{(a)}(x)$ ([1], [8, p. 196]). The generating function (2.1) determined by (3.8) is the one given by Askey and Ismail.

4. The case $\delta\theta\neq 0$.

Turning now to the case $\delta\theta\neq 0$, we take $\theta=1$ without loss of generality.

Referring to (2.11) and (2.12), we first note the limits

$$(4.1)\qquad \beta\equiv\lim_{n\to\infty}\beta_n=k_2,$$

$$(4.2)\qquad \gamma\equiv\lim_{n\to\infty}\gamma_n=k_2^2-k_3.$$

We let $n\to\infty$ in (2.13) and get exactly as we did in §3

$$(4.3)\qquad K(t)=\frac{t}{1-\beta t+\gamma t^2}.$$

Next we note that if we write $x=q^n$, (2.13) can be rewritten as

$$(4.4)\qquad \begin{aligned}\alpha_s=&\left(A_s-\delta q^{-s-1}h_{s+1}x\right)\frac{1-xq^{-s}}{1-\delta q^{-s-1}x}\\&-\left(B_s-\delta q^{-s}h_sx\right)\frac{\beta(x)}{1-\delta q^{-s}x}\\&+\left(C_s-\delta q^{-s+1}h_{s-1}x\right)\frac{\gamma(x)}{1-\delta q^{-s+1}x}\end{aligned}$$

where A_s, B_s, and C_s are independent of x, $\beta(x)$ is obtained from (2.11):

$$\beta(x)=\frac{(\alpha_1+k_2-\delta h_2 q^{-s-1}x)(1-q^{-s}x)}{1-\delta q^{-s-1}x}-\alpha_1 \tag{4.5}$$

and $\gamma(x)$ is similarly obtained from (2.12). Since $|q|\neq 0,1$, (4.4) is valid for infinitely many values of x and hence it must be an identity in x. We therefore multiply both sides of (4.4) by x^{-1} and let $x\to\infty$. We have

$$\lim_{x\to\infty}\frac{\beta(x)}{1-\delta q^{-s}x}=\frac{h_2}{\delta},\qquad \lim_{x\to\infty}\frac{\gamma(x)}{1-\delta q^{-s+1}x}=\frac{h_2^2-h_3}{q^2}$$

so (4.4) gives

$$0=h_{s+1}-h_2h_s+(h_2^2-h_3)h_{s-1},\qquad s\geqq 1.$$

Letting

$$b=h_2,\qquad c=h_2^2-h_3, \tag{4.6}$$

we conclude

$$H(t)=\frac{t}{1-bt+ct^2}. \tag{4.7}$$

The generating function (2.1) thus has the form

$$G(x,t)=D(t)\prod_{k=0}^{\infty}\frac{1-(\delta x+b)tq^k+ct^2q^{2k}}{1-(x+\beta)tq^k+\gamma t^2q^{2k}} \tag{4.8}$$

where

$$D(t)=A(t)\prod_{k=0}^{\infty}\frac{1-\beta tq^k+\gamma t^2q^{2i}k}{1-btq^k+ct^2q^{2k}}=\sum_{n=0}^{\infty}d_nt^n.$$

At this point we can see that there will be no loss of generality if we assume henceforth that $\beta=0$ and $\gamma=1$ since this amounts to a translation in x and a scale change in t. With this convention adopted, comparison of (4.8) with (1.6) shows that we have

$$Q_n(x)=\sum_{k=0}^{n}d_kP_{n-k}(x;q;a,b,c)\qquad(a=\delta,d_0=1). \tag{4.9}$$

We will complete the characterization problem by determining all sequences $\{d_n\}$ such that the $Q_n(x)$ determined by (4.9) will be orthogonal polynomials. To this end, we recall the recurrence formula (2.6) which now reads

$$(1-q^{n+1})Q_{n+1}(x)=[(1-aq^n)x+\beta_n]Q_n(x)-\gamma_nQ_{n-1}(x). \tag{4.10}$$

Now we use (4.9) to eliminate $Q_k(x)$ from (4.10). We also use the recurrence relation (1.5) to linearize the $xP_k(x)$ terms. The result is

$$\begin{aligned}&(1-q^{n+1})\sum_{k=0}^{n+1}d_kP_{n+1-k}(x)\\&\quad=\beta_n\sum_{k=0}^{n}d_kP_{n-k}(x)-\gamma_n\sum_{k=0}^{n-1}d_kP_{n-k-1}(x)\\&\qquad+(1-aq^n)\sum_{k=0}^{n}\frac{d_k}{1-aq^{n-k}}\big[(1-q^{n-k+1})P_{n+1-k}(x)-bq^{n-k}P_{n-k}(x)\\&\qquad\qquad+(1-cq^{n-k-1})P_{n-k-1}(x)\big].\end{aligned}$$

Note that (4.10) shows that a is restricted by the condition that

$$1-aq^n\neq 0, \qquad n\geqq 0. \tag{4.11}$$

Equating coefficients of $P_{n-k}(x)$ now yields

$$(1-q^{n+1})d_{k+1}=d_k\beta_n-d_{k-1}\gamma_n+\frac{(1-aq^n)(1-q^{n-k})}{1-aq^{n-k-1}}d_{k+1}$$
$$-\frac{bq^{n-k}(1-aq^n)}{1-aq^{n-k}}d_k+\frac{(1-aq^n)(1-cq^{n-k})}{1-aq^{n-k+1}}d_{k-1}$$

and this can be written

$$\frac{q^{n-k-1}(1-q^{k+1})(q-a)}{1-aq^{n-k-1}}d_{k+1}=\left\{\beta_n-\frac{bq^{n-k}(1-aq^n)}{1-aq^{n-k}}\right\}d_k$$
$$+\left\{\frac{(1-aq^n)(1-cq^{n-k})}{1-aq^{n-k+1}}-\gamma_n\right\}d_{k-1}. \tag{4.12}$$

Setting $k=0$ and $k=1$ yields, respectively,

$$\beta_n=bq^n+\frac{d_1q^{n-1}(1-q)(q-a)}{1-aq^{n-1}}, \tag{4.13}$$

(4.14)

$$\gamma_n=1-cq^{n-1}-\frac{d_1b(1-q)q^{n-1}}{1-aq^{n-1}}+\frac{d_1^2(1-q)(q-a)q^{n-1}}{1-aq^{n-1}}-\frac{d_2(1-q^2)(q-a)q^{n-2}}{1-aq^{n-2}}.$$

Because of (4.10), (4.13) and (4.14) are valid for $n\geqq 0$ and $n\geqq 1$, respectively, except in the special case $a=q$. In the latter case, (4.13) need not hold for $n=0$ and (4.14) need not hold for $n=1$.

Using (4.13) and (4.14) in (4.10) now gives

(4.15)

$$\frac{(1-q^{k+1})(q-a)}{1-aq^{n-k-1}}d_{k+1}+\left\{\frac{bq(1-q^k)}{1-aq^{n-k}}-\frac{d_1(1-q)(q-a)q^k}{1-aq^{n-1}}\right\}d_k$$
$$+\left\{\frac{q(c-aq)(1-q^{k-1})}{1-aq^{n-k+1}}-\frac{d_1b(1-q)q^k}{1-aq^{n-1}}\right.$$
$$\left.+\frac{d_1^2(1-q)(q-a)q^k}{1-aq^{n-1}}-\frac{d_2(1-q^2)(q-a)q^{k-1}}{1-aq^{n-2}}\right\}d_{k-1}=0.$$

5. The case $\delta\theta\neq 0$ continued. Referring to (4.15), we note as before that we can formally replace q^n by x and observe that the result must be an identity involving a rational function with poles at $x=a^{-1}q^s$, $s=1,2,k-1,k,k+1$. Taking $k\geqq 2$, the residue at $x=a^{-1}q^{k+1}$ gives us the condition

$$(q-a)d_k=0, \qquad k\geqq 3. \tag{5.1}$$

Let us first consider the case $a \neq q$. In this case, $d_m = 0$ for $m \geqq 3$. Now take $k=2$ and look at the residue at $x = a^{-1}q^2$. We find

$$d_2[a-(q-a)d_1]=0.$$

If $d_2 \neq 0$, then

$$d_1 = \frac{a}{q-a}. \tag{5.2}$$

Then let $k=3$ and consider the pole $x=a^{-1}q^2$. We find

$$[q(1-q^2(c-aq)-d_2q^2(1-q^2)(q-a))]\,d_2=0 \tag{5.3}$$

so that

$$d_2 = \frac{c-aq}{q(q-a)}. \tag{5.4}$$

Thus for the case $a \neq q$, $c \neq aq$, we will have

$$Q_n(x) = P_n(x) + \frac{a}{q-a}P_{n-1}(x) + \frac{c-aq}{q(q-a)}P_{n-2}(x) \tag{5.5}$$

and the corresponding recurrence formula will read

$$(1-q^{n+1})Q_{n+1}(x) = \left\{(1-aq^n)x + \frac{b(1-aq^n)q^{n-1}}{1-aq^{n-1}}\right\}Q_n(x) - \frac{(1-cq^{n-3})(1-aq^n)}{1-aq^{n-2}}Q_{n-1}(x). \tag{5.6}$$

If we set

$$Q_n^{\#}(x) + \frac{1-aq^{-1}}{1-aq^{n-1}}Q_n(x),$$

it is easily seen from (5.6) that $Q_n^{\#}(x)$ satisfies the Pollaczek recurrence (1.5) with parameters aq^{-1}, bq^{-1}, cq^{-2}. Thus

$$Q_n(x) = \frac{1-aq^{n-1}}{1-aq^{-1}}P_n(x;q;aq^{-1},bq^{-1},cq^{-2}), \qquad a \neq q, \quad c \neq aq. \tag{5.7}$$

Still keeping $a \neq q$, suppose next that $d_2 = 0$ so that

$$Q_n(x) = P_n(x) + d_1 P_{n-1}(x). \tag{5.8}$$

We then take $k=2$ in (4.15) and consider $x=a^{-1}q$. This time we get

$$q(q-a)d_1^2 - bqd_1 + c - aq = 0 \tag{5.9}$$

as the condition determining the value of d_1. The coefficients for the recurrence formula can be written

$$\begin{aligned} \beta_n &= bq^n + \frac{d_1(1-q)(q-a)q^{n-1}}{1-aq^{n-1}}, \\ \gamma_n &= \frac{(1-cq^{n-2})(1-aq^n)}{1-aq^{n-1}}. \end{aligned} \tag{5.10}$$

We will identify these polynomials in terms of their orthogonality relations in the next section. Here we turn to the remaining cases which occur when $a=q$. When $a=q$, (4.15) reduces to

$$\text{(5.11)}\qquad \frac{bq(1-q^k)}{1-q^{n-k+1}}d_k+\left\{\frac{q(c-q^2)(1-q^{k-1})}{1-q^{n-k+2}}-\frac{d_1b(1-q)q^k}{1-q^n}\right\}d_{k-1}=0.$$

If $b=0$, (5.11) yields the condition

$$(c-q^2)d_n=0,\qquad n\geqq 1.$$

Thus if $c\neq q^2$, we have $d_k=0$ for $k\geqq 1$. Therefore when $a=q$, $b=0$, $c\neq q^2$,

$$\text{(5.12)}\qquad Q_n(x)=P_n(x;q;q,0,c).$$

If, however, $c=q^2$, the recursion coefficients (4.13), (4.14) become

$$\beta_n=0,\quad n\geqq 1,\qquad \gamma_n=1-q^{n+1},\quad n\geqq 2.$$

Thus the recurrence relation reduces to

$$\text{(5.13)}\qquad \begin{aligned} &Q_{n+1}(x)=xQ_n(x)-Q_{n-1}(x),\qquad n\geqq 2.\\ &Q_2(x)=xQ_1(x)-\gamma Q_0(x),\\ &Q_1(x)=x+\beta,\qquad Q_0(x)=1.\end{aligned}$$

It follows that for the case $a=q$, $b=0$, $c=q^2$, the generating function is

$$\text{(5.14)}\qquad \frac{1+\beta t+\gamma t^2}{1-xt+t^2}=\sum_{n=0}^{\infty}Q_n(x)t^n$$

where β and $\gamma>0$ are arbitrary. The polynomials are

$$\text{(5.15)}\qquad Q_n(x)=U_n(x/2)+\beta U_{n-1}(x/2)+\gamma U_{n-2}(x/2),$$

where $U_n(x)=P_n(2x;q;q,0,q^2)$ are the Chebyshev polynomials of the second kind (with $U_{-2}(x)=U_{-1}(x)=0$). The orthogonality of these polynomials is included in studies of a more general situation by Geronimus (see [10, p. 52]). The distribution functions (including any isolated mass points that occur) are given explicitly for all cases by Allaway [3]. (Note that $Q_n^*(x)=\gamma^{-1}Q_n(x)$ satisfies (5.13) for $n>1$.) They can also be found in [6] where Askey and Wilson have given a further extension of Allaway's work.

The remaining cases occur when $a=q$, $b\neq 0$. To handle this case, first take $k\geqq 2$ in (5.11). The residue at $x=q^{k-1}$ then tells us that $d_k=0$ for $k\geqq 2$. When $k=2$, (5.11) then yields the condition

$$(c-q^2-bqd_1)d_1=0.$$

If $d_1=0$, we have $Q_n(x)=P_n(x;q;q,b,c)$ $(b\neq 0)$ so take $d_1\neq 0$. Then

$$\text{(5.16)}\qquad d_1=\frac{c-q^2}{bq},\qquad c\neq q^2.$$

The recursion coefficients now become

$$\text{(5.17)}\qquad \beta_n=bq^n,\qquad \gamma_n=\frac{(1-cq^{n-2})(1-q^{n+1})}{1-q^n},\qquad n\geqq 1.$$

According to the remarks made following (4.14), the formula for γ_n is valid for $n \geqq 2$ but it can be verified directly that (5.17) gives γ_1 correctly also. Also, it is easy to verify directly that

$$\beta_0 = b + d_1(1-q). \tag{5.18}$$

When these formulas are compared with (5.9) and (5.10), we see that this case is included in (5.8) as the limiting case $a=q$, $b \neq 0$, $c \neq q^2$. Thus (5.8) with d_1 determined by (5.9) remains the only case for which orthogonality relations are not known.

6. Orthogonality relations. We will now find orthogonality relations for the polynomials given by (5.8) and (5.9) with $P_n(x) = P_n(x; q; a, b, c)$ and with $a=q$ now allowed. We set

$$\sigma = d_1 + \frac{1}{d_1}, \tag{6.1}$$

translate: $x \to x - \sigma$, and then consider the monic polynomials

$$\hat{Q}_n(x) = \frac{(q;q)_n}{(a;q)_n} Q_n(x-\sigma). \tag{6.2}$$

With reference to (5.10), we find these polynomials satisfy

$$\hat{Q}_n(x) = (x - c_n)\hat{Q}_{n-1}(x) - \lambda_n \hat{Q}_{n-2}(x), \qquad n \geqq 1, \tag{6.3}$$

$$c_n = \sigma - \frac{bq^{n-1}}{1-aq^{n-1}} - \frac{d_1(1-q)(q-a)q^{n-2}}{(1-aq^{n-2})(1-aq^{n-1})}, \tag{6.4}$$

$$\lambda_{n+1} = \frac{(1-cq^{n-2})(1-q^n)}{(1-aq^{n-1})^2}. \tag{6.5}$$

Note that when $a=q$, $c_1 = d_1^{-1} - b/(1-q)$.

Now define

$$\Gamma_{2n+1} = \frac{(1-q^n)d_1}{1-aq^{n-1}}, \quad \Gamma_{2n+2} = \frac{1-cq^{n-1}}{(1-aq^n)d_1}, \quad n \geqq 0. \tag{6.6}$$

With the aid of (5.9), one can now verify directly (but tediously) that

$$c_n = \Gamma_{2n-1} + \Gamma_{2n}, \quad \lambda_{n+1} = \Gamma_{2n}\Gamma_{2n+1}, \qquad n \geqq 1. \tag{6.7}$$

On the other hand, the corresponding monic q-Pollaczek polynomials,

$$\hat{P}_n(x) = [(q;q)_n/(a;q)_n]\, P_n(x-\sigma; q; a, b, c),$$

satisfy

$$\hat{P}_n(x) = (x - d_n)\hat{P}_{n-1}(x) - \nu_n \hat{P}_{n-2}(x), \qquad n \geqq 1, \tag{6.8}$$

$$d_n = \sigma - \frac{bq^{n-1}}{1-aq^{n-1}}, \qquad \nu_{n+1} = \frac{(1-cq^{n-1})(1-q^n)}{(1-aq^{n-1})(1-aq^n)}. \tag{6.9}$$

Now one can verify that

$$(6.10) \qquad d_n = \Gamma_{2n} + \Gamma_{2n+1}, \quad \nu_{n+1} = \Gamma_{2n+1}\Gamma_{2n+2}, \qquad n \geqq 1.$$

It follows from (6.6) and (6.10) that the $\hat{P}_n(x)$ are kernel polynomials (with K-parameter 0) corresponding to $\hat{Q}_n(x)$. That is, if $\{\hat{Q}_n(x)\}$ is an orthogonal polynomial sequence (OPS) with respect to a measure $d\mu(x)$, then the existence of Γ_n such that (6.6) and (6.10) hold is necessary and sufficient for $\{P_n(x)\}$ to be the OPS with respect to $x d\mu(x)$ (see [9, p. 46]). Therefore, if $d\varphi(x)$ denotes the measure with respect to which the q-Pollaczek polynomials are orthogonal, then the polynomials given by (5.8) are orthogonal with respect to the measure given by

$$(6.11) \qquad d\psi(x) = (x+\sigma)^{-1} d\varphi(x+\sigma),$$

together with a possible positive mass at $x = -\sigma$. All of this is subject to restricting the parameters a, b, c and d_1 so that the Γ_n are positive for $n \geqq 2$. If they are not all positive but are all nonzero, then corresponding relations still hold formally with integrals replaced by moment functionals (see [9]). We will here assume we have the positive definite case:

$$\begin{aligned} d_1 > 0 \text{ and either} \quad &\text{(i)} \quad 0<q<1, \quad a<1, \quad c<q; \\ \text{or} \quad &\text{(ii)} \quad -1<q<0, \quad q^{-1}<a<1, \quad 0<c<1. \end{aligned}$$

We will complete the analysis by determining the cases where $d\psi$ has positive mass at $x = -\sigma$.

First note that we have not lost any generality by the assumption that $|q|<1$ since the case $|q|>1$ can be handled by setting $q = p^{-1}$, $|p|<1$. The resulting recurrence formula written in terms of p can be reduced after a linear change of variable to the original form and the generating function would remain of the same type. Now in any case, the coefficients in the recurrence formula are bounded so the corresponding Hamburger moment problem is determined. We consider the corresponding orthonormal polynomials

$$(6.12) \qquad \hat{q}_n(x) = (\lambda_1\lambda_2 \cdots \lambda_{n+1})^{-1/2} \hat{Q}_n(x),$$

where λ_1 denotes the total mass of the measure $d\psi$. Now $[\hat{q}_n(0)]^2 = (\Gamma_2 \cdots \Gamma_{2n})/(\lambda_1\Gamma_3 \cdots \Gamma_{2n+1})$ (see [9, p. 49]). Hence we have

$$(6.13) \qquad [\hat{q}_n(0)]^2 = \frac{(cq^{-1};q)_n}{\lambda_1 (q;q)_n d_1^{2n}} \sim d_1^{-2n}.$$

Now it is a classical result from the problem of moments [12] that when the Hamburger moment problem is determined, the mass at x is $\rho(x) = \{\Sigma[\hat{q}_n(x)]^2\}^{-1}$. Thus when $d_1 > 1$, at the point $x = -\sigma$, $d\psi(x)$ will have the mass $\rho(0) = \lambda_1 J$, where

$$(6.14) \qquad J = \{{}_1\phi_0(cq^{-1}; -; r)\}^{-1} = \prod_{n=0}^{\infty} \frac{1-rq^n}{(1-rcq^{n-1})}, \qquad r = d_1^{-1}$$

and ψ will be continuous at σ in all other cases.

Finally, we note that the total mass of $d\psi(x)$ is given by

$$(6.15) \qquad \lambda_1 = (1-J)^{-1} \int_{-\infty}^{\infty} \frac{d\varphi(x+\sigma)}{x+\sigma}.$$

In those cases where the q-Pollaczek polynomials have a continuous spectrum, the measure $d\varphi(x)$ is given by Charris and Ismail [8, §6]. They denote the q-Pollaczek polynomial by $F_n(x;u,v,w;q)$ where

$$F_n(x;u,v,w;q)=P_n(2x;q;uw,2v,w^2). \tag{6.16}$$

7. Summary and remarks. For the special case $\delta=0$ of (2.1), the Andrews–Askey conjecture is verified: the only OPS generated are the so-called Al-Salam–Chihara polynomials (apart from trivial changes of variable and renormalizations). When $\theta=0$, the only OPS generated are the "q-duals" $v_n(x)$ which correspond to the formal replacement of q by q^{-1} in the first set.

In the general case $\delta\theta\neq 0$, the OPS generated are the q-Pollaczek polynomials together with two closely related classes. The first consists of the most general orthogonal solutions of the Chebyshev recurrence (coefficients independent of n), and the second is the class of "inverse kernel" polynomials discussed in §6. An interesting near exception is provided by the polynomials given by (5.5). According to (5.7), these polynomials are also q-Pollaczek polynomials which satisfy the interesting identity (5.5). Additionally these results say that if $\alpha\neq 1$, $\gamma\neq\alpha$, then $P_n(x;q;\alpha,\beta,\gamma)$ and $(1-\alpha q^n)P_n(x;q;\alpha,\beta,\gamma)$ are each generated by different generating functions having the general form (2.1).

The relations involving Γ_n obtained in §6 are quite general and provide a number of formal identities involving q-Pollaczek polynomials. In particular, we obtain the symmetric OPS $\{S_n(x)\}$ defined by

$$S_{2n}(x)=\hat{Q}_n(x^2),\qquad S_{2n+1}(x)=x\hat{P}_n(x^2). \tag{7.1}$$

In the positive-definite case, these are the polynomials orthogonal with respect to the symmetrization of the measure $d\psi(x)$ (6.11).

Finally, we observe that the q-Pollaczek polynomials enjoy a convolution property. Using here the normalization of Askey and Ismail [5, p. 17], consider the generating function for the Al-Salam–Chihara polynomials $Q_n(x)=Q_n(x;q;a,b,c)$:

$$Q(xq;a,b,cc;t)=\prod_{k=0}^{\infty}\frac{1-atq^k+bt^2q^{2k}}{1-xtq^k+ct^2q^{2k}}=\sum_{n=0}^{\infty}Q_n(x)t^n$$

and for their q-duals, $v_n(x)=v_n(x;q;\alpha,\beta,\gamma)$:

$$V(x;q;\alpha,\beta,\gamma;t)=\prod_{k=0}^{\infty}\frac{1-xtq^k+\gamma t^2q^{2k}}{1-\alpha tq^k+\beta t^2q^{2k}}=\sum_{n=0}^{\infty}v_n(x)t^n.$$

Referring to (1.6), we see that

$$Q(x;q;\alpha,\beta,1;t)V(ax+b;q;\alpha,\beta,c;t)=G(x;q;a,b,c;t).$$

Thus we have the convolution formula

$$P_n(x;q;a,b,c)=\sum_{k=0}^{n}Q_k(x;q;\alpha,\beta,1)v_{n-k}(ax+b;q;\alpha,\beta,c). \tag{7.2}$$

Note that $P_n(x)$ is independent of α and β.

Thus the polynomials of one orthogonal sequence are expressed as the convolution of polynomials from two other orthogonal sequences in the same independent variable. Other examples of this phenomenon are given by setting $y=x$ in all examples found by us in our characterization problem [2] while another class of examples is furnished by the associated Legendre polynomials which are expressible as a convolution of ordinary Legendre polynomials [7]. These include the Chebyshev polynomials of the second kind as a limiting case. All of this of course suggests a characterization problem. Indeed, it was this characterization problem we originally considered before we followed Polya's dictum and looked for an "easier problem we couldn't solve" (which eventually led to [2]). We suspect that the solution of the more difficult characterization problem with only one independent variable would lead to the discovery of new, important classes of orthogonal polynomials.

ON THE GENERALIZED CHEBYSHEV POLYNOMIALS*

MOURAD E. H. ISMAIL† AND FUAD S. MULLA‡

Abstract. We study the spectrum of the Jacobi matrix $(\delta_{m,n+1}+\delta_{m,n-1}+aq^n\delta_{m,n})$, $m,n=0,1,\cdots$ and the corresponding orthogonal polynomials. The spectral measure is computed when $q\in(-1,1)$ and sufficient conditions are given to guarantee the absolute continuity of the spectral measure. When $q>1$ or <-1 the measure is purely discrete. The case $q=-1$ leads to a set of polynomials orthogonal on the union of two disjoint intervals. When $q=1$, the polynomials are essentially the Chebyshev polynomials $\{U_n(x)\}$.

Key words. Chebyshev polynomials, asymptotics, continued fractions

AMS(MOS) subject classifications. Primary 33A65, 42C05

1. Introduction. The Chebyshev polynomials $U_n(x):=\sin[(n+1)\theta]/\sin\theta$, $x=\cos\theta$, satisfy the three term recursion formula

$$xp_n(x)=\frac{1}{2}p_{n+1}(x)+\frac{1}{2}p_{n-1}(x),\qquad n>0,\tag{1.1}$$

and the initial conditions $p_0(x)=1$, $p_1(x)=2x$. The associated Jacobi matrix is

$$A=\frac{1}{2}(\delta_{m,n+1}+\delta_{m+1,n}),\qquad m,n=0,1,2,\cdots.\tag{1.2}$$

The spectrum of A is $[-1,1]$. Avron and Simon [5] considered the doubly infinite Jacobi matrix

$$B=\frac{1}{2}(\delta_{m,n+1}+\delta_{m+1,n})+(\lambda\cos(2\pi n\alpha+\varepsilon)\delta_{m,n}),\qquad m,n=0,\pm1,\cdots,\tag{1.3}$$

where α is an irrational number belonging to $(0,1)$ and $\varepsilon>0$. They conjectured that the spectrum of B is a Cantor set when $\lambda>1$. The spectrum of the semi-infinite Jacobi matrix

$$B_+=\frac{1}{2}(\delta_{m,n+1}+\delta_{m+1,n})+(\lambda\cos(2\pi n\alpha+\varepsilon)\delta_{m,n}),\qquad m,n=0,1,\cdots,\tag{1.4}$$

where α and ε are as before, is not known but is also very likely to be a Cantor set when $\lambda>1$. The orthogonal polynomials associated with B_+ are generated by

$$\begin{aligned}&2xp_n(x)=p_{n+1}(x)+p_{n-1}(x)+2\lambda\cos(2\pi n\alpha+\varepsilon)p_n(x),\qquad n>0,\\&p_0(x)=1,\qquad p_1(x)=2x-2\lambda\cos\varepsilon,\end{aligned}\tag{1.5}$$

and are very interesting. The limiting distribution of their zeros coincides with the spectrum of B_+. Even the special case $\varepsilon=0$ is very interesting. When $\varepsilon=0$ the term $2\lambda\cos(2\pi\alpha n)$ is $\lambda(q^n+q^{-n})$, where q now lies on the unit circle and $\arg q$ is not a rational multiple of π. This problem, or rather our inability to solve it, motivated us to

*Received by the editors February 14, 1983, and in final revised form June 12, 1985.

‡Department of Mathematics, Kuwait University, P. O. Box 5969, Kuwait.

study the polynomials $\theta_n^{(a)}(x;\ q)$ generated by

$$(1.6)\qquad 2x\theta_n^{(a)}(x;\ q)=\theta_{n+1}^{(a)}(x;\ q)+\theta_{n-1}^{(a)}(x;\ q)+aq^n\theta_n^{(a)}(x;\ q),\qquad n>0$$

with

$$(1.7)\qquad \theta_0^{(a)}(x;\ q)=1,\qquad \theta_1^{(a)}(x;\ q)=2x-a.$$

When $a=0$ the θ_n's reduce to the Chebyshev polynomials $U_n(\cos\theta)=\sin[(n+1)\theta]/\sin\theta$. Since the θ_n's generalize the Chebyshev polynomials it is appropriate to call them the generalized Chebyshev polynomials. The associated Jacobi matrix is

$$(1.8)\qquad J=A+D,$$

where D is the diagonal matrix

$$(1.9)\qquad D=\frac{1}{2}(aq^n\delta_{m,n}),\qquad m,n=0,1,2,\cdots,$$

and A is as in (1.2). When $-1<q<1$, J is the sum of the self-adjoint operator A and the compact operator D; hence the essential spectra of J and A are identical, i.e. the essential spectrum of J is $[-1,1]$ since $2A$ is the forward shift plus the backward shift. When $q>1$ or $q<-1$ the matrix operator A is unbounded (on l^2).

In §2 we treat the case $-1<q<1$. We derive a generating function for the θ_n's and apply Darboux's method to the generating function in order to determine the asymptotic behavior of $\theta_n^{(a)}(x;\ q)$ for fixed x and large n. This asymptotic result is then used to compute the resolvent of the operator J in the case $-1<q<1$. The resolvent and some recent results of P. Nevai [12] are used in §3 to compute the absolutely continuous component of the spectral measure of J explicitly. In the rest of §3 and all of §4 we give some necessary and some sufficient conditions for the absence of a discrete singular component of the spectral measure. In §5 an explicit representation of $\theta_n^{(a)}(x;\ q)$ is derived and the sign of the linearization coefficients is determined. Section 6 contains an analysis of the spectrum for $q>1$ and $q<-1$. We show that the continuous spectrum is empty, hence the spectral measure is purely singular. In §7, we treat the case $q=-1$.

The present work is a sequel to Askey and Ismail's work [4] and uses their approach which is originally due to Pollaczek [14].

The following well-known theorem will be used in the text.

THEOREM 1.1. *Let $\{P_n(x)\}$ be a sequence of monic polynomials generated by*

$$(1.10)\qquad P_0(x)=1,\qquad P_1(x)=x-c_1,$$

$$(1.11)\qquad P_n(x)=(x-c_n)P_{n-1}(x)-\lambda_nP_{n-2}(x),\qquad n>1.$$

The positivity condition $\lambda_n>0$ is satisfied if and only if there exists a nondecreasing function $\sigma(x)$ of bounded variation on $(-\infty,\infty)$ such that

$$(1.12)\qquad \int_{-\infty}^{\infty}P_n(x)P_m(x)\,d\sigma(x)=\lambda_1\lambda_2\lambda_3\cdots\lambda_{n+1}\delta_{m,n},$$

where σ is normalized by

$$\lambda_1:=\int_{-\infty}^{\infty}d\sigma(x)=1.$$

For a proof, see Chihara [8, pp. 16–22 and 56–58]. Akhiezer [1] gives an account of the role played by orthogonal polynomials in the spectral theory of Jacobi matrices.

2. The resolvent when $-1<q<1$. We first establish the generating function

$$\sum_{n=0}^{\infty} \theta_n^{(a)}(x;\ q)t^n=\sum_{n=0}^{\infty} \frac{(-at)^k q^{k(k-1)/2}}{(t/A;\ q)_{k+1}(t/B;\ q)_{k+1}}, \tag{2.1}$$

where A and B are roots of $1-2xt+t^2=0$ and the q-shifted factorial $(\sigma;\ q)_n$ is

$$(\sigma;\ q)_0=1,\quad (\sigma;\ q)_n=\prod_{j=1}^{n}(1-\sigma q^{j-1}),\quad n=1,2,\cdots. \tag{2.2}$$

The case $n=\infty$ is also allowed in (2.2) since the infinite product converges for $q\in(-1,1)$. To fix the notation we set

$$A,B=x\pm\sqrt{x^2-1},\qquad |B|\leq|A|. \tag{2.3}$$

Proof of (2.1). Denote the left side of (2.1) by $H(x,t)$. Multiplying (1.6) by t^{n+1} and adding the resulting equalities for $n=1,2,\cdots$, we see that $H(x,t)$ satisfies the functional equation

$$H(x,t)=(1-2xt+t^2)^{-1}[1-atH(x,qt)]. \tag{2.4}$$

We also used the initial conditions (1.7). Iterating (2.4) formally leads to (2.1). This formal argument can be justified. Observe that the right side of (2.1) is analytic in t in a neighborhood of $t=0$ and it satisfies (2.4). Let $\Sigma_0^\infty w_n t^n$ be its Taylor series about $t=0$. It is easily verified that w_j and $\theta_j^{(a)}(x;\ q)$ agree when $j=0,1$ and that w_n satisfies (1.6). This identifies w_n as $\theta_n^{(a)}(x;\ q)$ since both satisfy the same three term recurrence relation and the same initial conditions. This completes the proof of (2.1).

The polynomials of the second kind $\phi_n^{(a)}(x;\ q)$ satisfy the recursion (1.6) and the initial conditions

$$\phi_0^{(a)}(x;\ q)=0,\qquad \phi_1^{(a)}(x;\ q)=2. \tag{2.5}$$

It is not difficult to identify the ϕ_n's as

$$\phi_n^{(a)}(x;\ q)=2\theta_{n-1}^{(aq)}(x;\ q),\quad n>0,\quad \phi_0^{(a)}(x;\ q)=0. \tag{2.6}$$

We now investigate the asymptotic behavior of $\theta_n^{(a)}(x;\ q)$ and $\phi_n^{(a)}(x;\ q)$ for large n and fixed x. The reason is that if $d\psi$ is the *spectral measure* of $A+D$ then the θ_n's are orthogonal with respect to $d\psi^{(a)}(t;\ q)$ and $d\psi^{(a)}(t;\ q)$, normalized by

$$\int_{-\infty}^{\infty} d\psi^{(a)}(t;\ q)=1,$$

satisfies

$$\lim_{n\to\infty}\frac{\phi_n^{(a)}(x;\ q)}{\theta_n^{(a)}(x;\ q)}=\int_{-\infty}^{\infty}\frac{d\psi^{(a)}(t;\ q)}{x-t},\qquad \operatorname{Im} x\neq 0, \tag{2.7}$$

see [4, Thm. 2.4]. The relationships (2.6) and (2.7) identify the resolvent

$$\int_{-\infty}^{\infty}(d\psi^{(a)}(t;\ q)/(x-t))$$

in terms of the asymptotic behavior of $\theta_n^{(a)}(x;\ q)$.

THEOREM 2.1. *The asymptotic behavior of* $\theta_n^{(a)}(x;\, q)$ *is given by*

$$\theta_n^{(a)}(x;\, q) \sim A^n \sum_0^\infty \frac{(-aB)^k q^{k(k-1)/2}}{(B/A;\, q)_{k+1}(q;\, q)_k}, \qquad x \notin [-1,1], \tag{2.8}$$

$$\theta_n^{(a)}(x;\, q) \sim A^n \sum_0^\infty \frac{(-aB)^k q^{k(k-1)/2}}{(B/A;\, q)_{k+1}(q;\, q)_k} + \textit{conjugate}, \qquad x \in (-1,1), \tag{2.9}$$

$$\theta_n^{(a)}(1;\, q) \sim (n+1) \sum_0^\infty \frac{(-a)^k q^{k(k-1)/2}}{(q;\, q)_k^2}, \tag{2.10}$$

$$\theta_n^{(a)}(-1, q) \sim (-1)^n (n+1) \sum_0^\infty \frac{a^k q^{k(k-1)/2}}{(q;\, q)_k^2}. \tag{2.11}$$

Note that A and B are complex conjugates when x belongs to $[-1,1]$. An essential tool in proving (2.8)–(2.11) is the following asymptotic method of Darboux.

THEOREM 2.2 (Darboux's method). *Assume that* $f(z)=\sum_0^\infty f_n z^n$ *is analytic in* $|z|<r$ *and has a finite number of algebraic singularities on* $|z|=r$. *Let* $g(z)=\sum_0^\infty g_n z^n$ *be a comparison function, that is g is also analytic in* $|z|<r$, *has a finite number of algebraic singularities on* $|z|=r$ *and* $f-g$ *is continuous on* $|z|=r$. *Then* $f_n=g_n+o(r^{-n})$.

Olver [13] used the Riemann–Lebesgue lemma to prove Theorem 2.2, see also Szegö [18].

Proof of Theorem 2.1. Apply Darboux's method with the comparison functions

$$(1-t/B)^{-1} \sum_{k=0}^\infty \frac{(-aB)^k q^{k(k-1)/2}}{(B/A;\, q)_{k+1}(q;\, q)_k} \quad \text{if } x \notin [-1,1],$$

$$(1-t/B)^{-1} \sum_{k=0}^\infty \frac{(-aB)^k q^{k(k-1)/2}}{(B/A;\, q)_{k+1}(q;\, q)_k} + (1-t/A)^{-1} \sum_{k=0}^\infty \frac{(-aA)^k q^{k(k-1)/2}}{(A/B;\, q)_{k+1}(q;\, q)_k} \quad \text{if } x \in (-1,1),$$

$$(1 \pm t)^{-2} \sum_0^\infty \frac{(\pm a)^k q^{k(k-1)/2}}{(q;\, q)_k^2} \quad \text{if } x = \mp 1.$$

The details are straightforward and will be omitted.

THEOREM 2.3. *The polynomials* $\{\theta_n^{(a)}(x;\, q)\}$ *satisfy the orthogonality relation*

$$\int_{-\infty}^\infty \theta_n^{(a)}(x;\, q)\theta_m^{(a)}(x;\, q)\, d\psi^{(a)}(x;\, q) = \delta_{m,n}, \tag{2.12}$$

where $d\psi$ *is a positive measure with bounded support. Furthermore the Stieltjes transform of* $d\psi$ *is given by*

$$\int_{-\infty}^\infty \frac{d\psi^{(a)}(t;\, q)}{x-t} = 2BF_{aq}(x)/F_a(x), \tag{2.13}$$

when $\operatorname{Im} x \neq 0$, *where*

$$F_a(x) := \sum_{k=0}^\infty \frac{(-aB)^k q^{k(k-1)/2}}{(B^2;\, q)_{k+1}(q;\, q)_k}. \tag{2.14}$$

Proof. The monic polynomials associated with the θ_n's are

$$p_n(x) := 2^{-n}\theta_n^{(a)}(x;\, q). \tag{2.15}$$

The p's satisfy

$$p_{n+1}(x)=\left(x-\frac{1}{2}aq^n\right)p_n(x)-\frac{1}{4}p_{n-1}(x), \tag{2.16}$$

so the coefficients in Chihara's notation [8, see Thm. 1.1] are given by

$$c_n=\frac{1}{2}aq^{n-1}, \quad n\geqq 1, \qquad \lambda_n=\frac{1}{4} \quad \text{for } n>1. \tag{2.17}$$

Combining Theorems 4.2 (p. 19) and 4.4 (p. 21) in Chihara [8], we establish (2.12). The boundedness of the support of $d\psi^{(a)}$ follows from Theorem 2.2 in [8, p. 109]. Now Markoff's theorem [8, pp. 89–90] implies (2.7) which when combined with (2.6) and the asymptotic formula (2.8) establishes (2.13). This completes the proof.

Note that (2.13) actually holds for x off the support of $d\psi^{(a)}$.

3. Absolutely continuous component of the spectral measure. We first compute the absolutely continuous component of $d\psi$. If $\{p_n(x)\}$ is a sequence of orthonormal polynomials,

$$\gamma_n := \text{coefficient of } x^n \text{ in } p_n(x),$$

then $\{p_n(x)\}$ satisfies a three term recursion of the type

$$xp_n(x)=\frac{\gamma_n}{\gamma_{n+1}}p_{n+1}(x)+\alpha_n p_n(x)+\frac{\gamma_{n-1}}{\gamma_n}p_{n-1}(x). \tag{3.1}$$

Combining Corollaries 36 (p. 141) and 40 (p. 143) in Nevai [12], we get

THEOREM 3.1 (Nevai). *If*

$$\sum_{k=1}^{\infty}\left\{|\alpha_k|+\left|\frac{\gamma_{k-1}}{\gamma_k}-\frac{1}{2}\right|\right\}<\infty \tag{3.2}$$

then

$$d\psi(t)=\psi'(t)\,dt+d\psi_j(t),$$

where ψ' is continuous and positive in $(-1,1)$, $\operatorname{supp}\psi'=[-1,1]$ *and ψ_j is a step function constant on $(-1,1)$. Furthermore*

$$\limsup_n \psi'(x)\sqrt{1-x^2}\,p_n^2(x)=\frac{2}{\pi}, \tag{3.3}$$

holds for almost every $x\in$ $\operatorname{supp} d\psi$.

In the case of the θ_n's, $\gamma_n=2^n$, $\alpha_n=\frac{1}{2}aq^n$, so (3.2) is satisfied. The θ's are orthonormal. The asymptotic formula (2.9) can be written in the form

$$\theta_n(\cos\theta;\, q)\sim 2\left|\sum_0^{\infty}\frac{\left(-ae^{i\theta}\right)^k q^{k(k-1)/2}}{\left(e^{2i\theta};\, q\right)_{k+1}(q;\, q)_k}\right|\cos(n\theta+\varphi), \tag{3.4}$$

holding for $0<\theta<\pi$, where

$$\varphi=\arg\left(\sum_{k=0}^{\infty}\frac{\left(-ae^{-i\theta}\right)^k q^{k(k-1)/2}}{\left(e^{-2i\theta};\, q\right)_{k+1}(q;\, q)_k}\right). \tag{3.5}$$

This analysis and Nevai's theorem establish the following.

THEOREM 3.2. *We have*

$$(3.6)\qquad \psi'(x)=\frac{2}{\pi}\sqrt{1-x^2}\left|\sum_{0}^{\infty}\frac{\left(-ae^{i\theta}\right)^k q^{k(k-1)/2}}{\left(qe^{2i\theta};\,q\right)_k(q;\,q)_k}\right|^{-2},\qquad x=\cos\theta,$$

holding for $q\in(-1,1)$.

We now analyse the discrete measure $d\psi_j$. Recall that

$$(3.7)\qquad F_a(x):=\sum_{j=0}^{\infty}\frac{(-aB)^j q^{j(j-1)/2}}{\left(B^2;\,q\right)_{j+1}(q;\,q)_j},$$

where A, B are as in (2.13). These functions, as functions of a, are essentially basic Bessel functions, see Al-Salam and Ismail [2] and Ismail [10]. Furthermore $F_a(x)$ and $F_{aq}(x)$ have no common zeros. A jump J in $\psi(t)$ at $t=\xi$ contributes $J(x-\xi)^{-1}$ to the left side of (2.13). Hence the location of the discrete masses coincides with the poles of the right side of (2.13), i.e. $F_{aq}(x)/F_a(x)$. These poles are the zeros of $F_a(x)$. Since computing the zeros of the transcendental function $F_a(x)$ seems impossible, we will make additional assumptions on a and q to guarantee that $F_a(x)$ does not vanish. Theorem 3.1 ensures the nonvanishing of $F_a(x)$ for $-1<x<1$. The zeros, if any, of $F_a(x)$ are all real since for x, y real, $y\neq 0$,

$$\left|\int_{-\infty}^{\infty}\frac{d\psi^{(a)}(t;\,q)}{x+iy-t}\right|\leqq\frac{1}{|y|}\int_{-\infty}^{\infty}d\psi^{(a)}(t;\,q)<\infty.$$

When x is real and lies outside $[-1,1]$ the quantities A, B will take real values and $0<B/A<1$ since $AB=1$. Observe that (3.7) implies the positivity of $F_a(x)$ if $a<0$ and $x>1$, $q>0$ because in this case

$$B=x-\sqrt{x^2-1}>0.$$

On the other hand when $a>0$ and $x<-1$ with q still positive B is $x+\sqrt{x^2-1}$, which is negative, and $F_a(x)$ is strictly positive. This means that when $q>0$ the zeros of $F_a(x)$, if any, are to the right of $[-1,1]$ if $a>0$ and to the left of $[-1,1]$ if $a<0$. In general for fixed real $x\notin[-1,1]$ and $q>0$ the function $F_a(x)$ as a function of a, has infinitely many zeros and all the zeros are real and simple, [2], [10]. So, without restricting a discrete masses will appear. In fact for every prescribed value of $x_0>1$ (<-1) of x and $q>0$ there are infinitely many values of $a>0$ (<0) that will make $F_a(x)$ vanish at $x=x_0$ and, of course, $F_{aq}(x_0)\neq 0$.

THEOREM 3.3 (Chihara [9]). *In order that* $d\psi_j\equiv 0$, *outside* $[-1,1]$, *for* $-1<q<1$ *it is necessary that*

$$(3.8)\qquad -2<a<2.$$

Proof. In Chihara's notation [8, p. 18] the recursion (1.6) is

$$(3.9)\qquad P_{n+1}(x)=\left(x-\frac{a}{2}q^n\right)P_n(x)-\frac{1}{4}P_{n-1}(x)$$

where

$$(3.10)\qquad P_n(x):=2^{-n}\theta_n^{(a)}(x;\,q),$$

so

$$(3.11)\qquad C_n=\frac{a}{2}q^{n-1},\qquad \lambda_{n+1}=\frac{1}{4}\qquad (n\geqq 1).$$

By Theorem 4.1 in [8, p. 122], we see that $\sigma=-1$, $\tau=1$, that is the zeros of $P_n(x)$ are dense in $(-1,1)$ confirming our earlier result that $\operatorname{supp}\psi'(t)=[-1,1]$. Thus, the true interval of orthogonality is $[\xi_1,\eta_1]\supset[-1,1]$. Theorem 2.1 and Corollary 1 in [8, p. 108] imply that if $[\xi_1,\eta_1]=[-1,1]$, i.e. ψ_j is constant outside $[-1,1]$, then $-1<c_n<1$ $(n\geqq 1)$. Clearly $-1<c_n<1$ is equivalent to (3.8). This completes the proof.

In particular there will be mass points <1 (>-1) if $a\leqq -2$ $(\geqq 2)$.

The results presented so far are valid for $-1<q<1$. In the rest of this section we shall restrict ourselves to the case

$$1>q>0. \tag{3.12}$$

The cases $q=0,1$ are essentially the Chebyshev polynomials.

We now prove the following.

THEOREM 3.4. *The points $t=\pm 1$ are not mass points when $1>q>0$ and $|a|\leqq(1-q)^2$.*

Proof. From the theory of moment problems [15, pp. 45–46] we know that ξ is a mass point if and only if

$$\sum_0^\infty\left[\theta_n^{(a)}(\xi;\ q)\right]^2<\infty, \tag{3.13}$$

since the θ's are orthonormal. The asymptotic formulas (2.10) and (2.11) imply that the above series diverged at $\xi=\pm 1$ if

$$\sum_0^\infty\frac{(-|a|)^k q^{k(k-1)/2}}{(q;\ q)_k^2}\neq 0. \tag{3.14}$$

We rewrite (3.14) in the form

$$\sum_0^\infty\frac{a^{2k}q^{k(2k-1)}}{(q;\ q)_{2k+1}^2}\left\{\left(1-q^{2k+1}\right)^2-|a|q^{2k}\right\}$$

which will be positive if $(1-q^{2k+1})^2-|a|q^{2k}$ is positive. Let w be q^{2k}, so $w\in[0,1]$. The function $(1-wq)^2-|a|w$ is positive when $w=0,1$ and its global minimum (on $(-\infty,\infty)$) is at $w=\frac{1}{2}(2q+|a|)q^{-2}$ which lies outside $[-1,1]$. This establishes the positivity of the series (3.14) when $|a|\leqq(1-q)^2$ and completes the proof.

For completeness we include the definition of a chain sequence.

DEFINITION. A sequence $\{a_n\}_1^\infty$, is a chain sequence if there is a parameter sequence $\{g_n\}$ such that $0\leqq g_0<1$, $0<g_n<1$, $(n\geqq 1)$ and $a_n=g_n(1-g_{n-1})$ $(n\geqq 1)$.

Chihara kindly communicated the following theorem and its proof to us.

THEOREM 3.5 (Chihara [9]). *A necessary condition for $\psi^{(a)}(t;\ q)$ to be continuous outside $[-1,1]$ is*

$$|a|<\left(1+q-\sqrt{1+q^2}\right)q^{-1}, \tag{3.15}$$

when $q\in(0,1)$.

Proof. Recall the notation (3.9), (3.10), (3.11). Theorem 2.1 and Corollary 1 in [8, p. 108] characterize the true interval of orthogonality to be $[-1,1]$ if and only if $-1<c_n<1$ and $\{\alpha_n(-1)\}$ and $\{\alpha_n(1)\}$ are both chain sequences, where

$$\alpha_n(x)=\lambda_{n+1}\left[(c_n-x)(c_{n+1}-x)\right]^{-1},$$

c_n, λ_n are as in (3.11). As we saw in Theorem 3.3, $-1<c_n<1$ is equivalent to (3.8). It is clear from (1.6) that

$$\theta_n^{(-a)}(-x;\ q)=(-1)^n\theta_n^{(a)}(x;\ q), \tag{3.16}$$

so in the rest of the proof we shall assume $0<a<2$, from (3.8). Clearly,

$$\alpha_n(-1)=\left[(2+aq^{n-1})(2+aq^n)\right]^{-1}\in\left(0,\frac{1}{4}\right),$$

so $\{\alpha_n(-1)\}$ is a chain sequence because it is dominated by the chain sequence $\{\frac{1}{4},\frac{1}{4},\cdots\}$, see [8, pp. 91, 97]. This implies that there are no mass points to the left of -1. Clearly $q>0$ implies

$$\alpha_n(1)=\frac{1}{(2-aq^{n-1})(2-aq^n)}>\frac{1}{4}.$$

Now $\{\frac{1}{2},\frac{1}{4},\frac{1}{4},\cdots\}$ is a chain sequence that determines its parameters uniquely, see [8, Exercise 5.1, p. 99], so no chain sequence can dominate it [8, p. 97]. Thus $\alpha_1(1)<\frac{1}{2}$ is necessary for $\psi^{(a)}(t;\, q)$ to be continuous to the right of 1. The condition $\alpha_1(1)<\frac{1}{2}$ is

$$qa^2-2(1+q)a+2>0,$$

which is equivalent to (3.15) and the proof is complete.

4. The singular component of the spectral measure. The purpose of the present section is to define conditions sufficient for the absence of the point spectrum, that is $\psi^{(a)}(x;\, q)$ is constant outside $[-1,1]$. Since the point spectrum coincides with the zeros of $F_a(x)$ we now study the function $F_a(x)$.

THEOREM 4.1. *When* $0<q<1$ *and*

$$|a|\leqq(1-q)^2, \tag{4.1}$$

the function $F_a(x)$ will have no zeros and the discrete spectrum will be empty.

Proof. We know that the zeros of $F_a(x)$, if any, are real and lie outside $(-1,1)$. The definition (3.7) of $F_a(x)$ clearly implies the positivity of F_a when $aB<0$, so we shall concentrate on the case $aB>0$. We express $F_a(x)$ in the form

$$F_a(x)=\sum_{j=0}^{\infty}\frac{(aB)^{2j}q^{j(2j-1)}}{(B^2;\, q)_{2j+2}(q;\, q)_{2j+1}} \cdot\left[(1-B^2q^{2j+1})(1-q^{2j+1})-aBq^{2j}\right]. \tag{4.2}$$

Observe that the positivity of $F_a(x)$ will follow from (4.2) if

$$(1-B^2q^{2j+1})(1-q^{2j+1})-aBq^{2j}\geqq 0,\qquad j=0,1,\cdots, \tag{4.3}$$

holds with strict inequality for at least one j. The cases $x\geqq 1$ and $x\leqq -1$ will be considered separately.

Case (i). $x\geqq 1$. In this case $B=x-\sqrt{x^2-1}\in(0,1]$ for finite $x\geqq 1$, and we need only to consider the case $a>0$. Clearly we have

$$1-B^2q^{2j+1}\geqq 1-q^{2j+1}; \tag{4.4}$$

hence (4.3) will hold if

$$(1-qy)^2-ay\geqq 0,\qquad 0\leqq y\leqq 1, \tag{4.5}$$

where $y=q^{2j}$. The polynomial on the left side of (4.5) has a local minimum at

$$y=\frac{1}{q}+\frac{a}{2q^2}$$

which is outside [0, 1]. Thus $(1-qy)^2-ay$ is monotone on [0, 1] and takes the value 1 at $y=0$. Therefore (4.5) holds for $y\in[0,1]$ if and only if it holds at $y=1$, that is

$$(1-q)^2-a\geqq 0,$$

which is (4.1).

Case (ii). $x\leqq -1$. Now B is $x+\sqrt{x^2-1}$, so $0>B\geqq -1$ and we need only to consider the case $a<0$. The analysis in case i goes through until (4.3). In (4.3) we replace aB by $|aB|$ then use $|B|\leqq 1$ and the rest will follow in the same way but a is now replaced by $|a|$.

THEOREM 4.2. *The function $F_a(x)$ does not vanish for x real when $0<q<1$ and*

$$|B|\leqq(1-q)^2/|a|. \tag{4.6}$$

Proof. The proof is similar to our proof of Theorem 4.1. In Case (i) we use (4.4) to replace (4.3) by

$$(1-qy)^2-aBy\geqq 0, \qquad y\in[0,1]. \tag{4.7}$$

In the proof of Theorem 4.1 we used $0<B\leqq 1$ to essentially replace (4.7) by the stronger condition (4.5). Repeating the same argument we establish (4.3) from (4.6). Case (ii) can be handled in a similar fashion.

COROLLARY 4.3. *If $|a|>(1-q)^2$, $0<q<1$ and $F_a(\xi)$ vanishes then*

$$|\xi|<\frac{d^2+1}{2d}, \tag{4.8}$$

where

$$d:=(1-q)^2/|a|. \tag{4.9}$$

Proof. If $\xi>0$ then $\xi>1$ and $B=\xi-\sqrt{\xi^2-1}>0$. The inequality (4.6) should be violated at ξ, so

$$\xi-\sqrt{\xi^2-1}>d.$$

Thus $\xi-d>\sqrt{\xi^2-1}$ which is equivalent to (4.8) because $\xi-d>0$ due to the fact $d<1<\xi$. The case $\xi<0$ can be treated similarly.

Observe that (4.8) provides a bound for the spectrum in general. We now treat the case $-1<q<0$. Define Q by

$$Q:=\frac{q^{-1}}{2}\left[1-q^2-\sqrt{(1-q^2)^2-4q}\right], \qquad 0>q>-1. \tag{4.10}$$

It is easy to see that $Q>0$.

THEOREM 4.4. *Let $0>q>-1$. The zeros, if any, of $F_a(x)$ lie outside the region*

$$|B|\leqq(1-q^2)Q/|a|. \tag{4.11}$$

In particular if

$$|a|\leqq(1-q^2)Q, \tag{4.12}$$

then $F_a(x)$ has no zeros and the discrete spectrum is empty.

Proof. There is no loss of generality in assuming $a > 0$ because

$$\theta_n^{(-a)}(-x;\, q) = (-1)^n \theta_n^{(a)}(x;\, q),$$

see (3.16), and the θ_n's reduce to Chebyshev polynomials when $a = 0$.

We express the series (3.7) defining $F_a(x)$ as the sum of four series according to whether the summation index k is $\equiv 0, 1, 2$ or $3 \pmod 4$. We then regroup the series in the form

$$F_a(x) = \sum_{j=0}^{\infty} \frac{(aB)^{4j} q^{2j(4j-1)} H_j}{(B^2;\, q)_{4j+4} (q;\, q)_{4j+3}}, \tag{4.13}$$

where

$$\begin{aligned} H_j := {} & \prod_{l=1}^{3} (1 - q^{4j+l})(1 - B^2 q^{4j+l}) \\ & - aBq^{4j} \prod_{l=2}^{3} (1 - q^{4j+l})(1 - B^2 q^{4j+l}) \\ & + a^2 B^2 q^{8j+1} (1 - q^{4j+3})(1 - B^2 q^{4j+3}) - a^3 B^3 q^{12j+3}. \end{aligned} \tag{4.14}$$

The cases $x \geqq 1$ and $x \leqq -1$ require separate treatment.

Case (i). $x \geqq 1$. Now $B = x - \sqrt{x^2 - 1} \in (0, 1]$, so $aB > 0$ and the last term in H_j is positive. From (4.14) we get

$$H_j > (1 - q^3)(1 - B^2 q^3) \varphi(q^{4j}), \tag{4.15}$$

if $\varphi(q^{4j}) > 0$, where

$$\varphi(y) = (1 - q^2)^2 - aB(1 - q^2)^2 y + a^2 B^2 q y^2. \tag{4.16}$$

The quadratic polynomial $\varphi(y)$ has a local maximum at the point

$$y = (2aBq)^{-1} (1 - q^2)^2 < 0,$$

and $\varphi(0) = (1 - q^2)^2 > 0$, hence $\varphi(y)$ is monotone on $(0, 1)$ and (4.13) and (4.15) will imply the positivity of $F_a(x)$ if we show that $\varphi(1) \geqq 0$. It is not difficult to see that $\varphi(1) \geqq 0$ is equivalent to (4.11).

Case (ii). $x \leqq -1$. In this case $B = x + \sqrt{x^2 - 1} \in [-1, 0)$ and $aB < 0$, so the first and second terms in H_j are positive while the third and fourth terms are negative. The sum of the first and third terms is bounded below by

$$(1 - q^{4j+3})(1 - B^2 q^{4j+3}) \left[(1 - q^2)^2 + a^2 B^2 q \right]$$

which is nonnegative if

$$-aB \leqq (1 - q^2)/\sqrt{-q}\,. \tag{4.17}$$

Similarly we prove that (4.17) implies the nonnegativity of the sum of the second and fourth terms in H_j. Finally observe that the condition (4.17) is weaker than (4.11), so (4.11) implies the positivity of $F_a(x)$ in all cases.

COROLLARY 4.5. *If* $|a|>(1-q^2)Q$, $0>q>-1$ *and* $F(\xi)=0$ *then*

$$|\xi|<\frac{c^2+1}{2c}, \tag{4.18}$$

and

$$c=(1-q^2)Q/|a|. \tag{4.19}$$

The proof of Corollary 4.5 is very similar to the proof of Corollary 4.3 and will be omitted.

5. Explicit representation and linearization of products. The present section contains two additional results concerning the θ_n's. The first is the following explicit representation for $\theta_n^{(a)}(\cos\theta;\,q)$ as a trigonometric polynomial of degree n.

THEOREM 5.1. *We have*

(5.1)
$$\theta_n^{(a)}(\cos\theta;\,q)=\sum_{\substack{j,k\geqq 0\\ j+k\leqq n}}\frac{q^{k(k-1)/2}(q;\,q)_{n-j}(q;\,q)_{j+k}}{(q;\,q)_k^2(q;\,q)_j(q;\,q)_{n-k-j}}(-a)^k\cos[(n-k-2j)\theta].$$

Proof. We use the q-binomial theorem

$$\frac{(az;\,q)_\infty}{(z;\,q)_\infty}=\sum_0^\infty\frac{(a;\,q)_n}{(q;\,q)_n}z^n$$

(Slater [16, p. 92]) to expand $(t/A;\,q)_{k+1}^{-1}$ and $(t/B;\,q)_{k+1}^{-1}$ in the generating function (2.1) in the form

$$(t/c;\,q)_{k+1}^{-1}=(q^{k+1}t/c;\,q)_\infty/(t/c;\,q)_\infty=\sum_{j=0}^\infty\frac{(q^{k+1};\,q)_j}{(q;\,q)_j}t^jc^{-j}$$

$$=\sum_{j=0}^\infty\frac{(q;\,q)_{k+j}}{(q;\,q)_k(q;\,q)_j}t^jc^{-j}.$$

This identity, the substitutions $A=e^{i\theta}$, $B=e^{-i\theta}$ and some simple manipulations establish (5.1) and the proof is complete.

In the process of proving Theorem 5.1, we essentially proved the following.

COROLLARY 5.2. *The* θ_n*'s have the explicit representation*

$$\theta_n^{(a)}(x;\,q)=\sum_{\substack{k,l,m\geqq 0\\ k+l+m=n}}\frac{(-a)^kq^{k/(k-1)/2}(q;\,q)_{k+l}(q;\,q)_{k+m}}{(q;\,q)_k^2(q;\,q)_l(q;\,q)_m}A^{-l}B^{-m}, \tag{5.2}$$

where A and B are as in (2.3).

The second result in this section concerns coefficients in the linearization of a product of two θ_n's as a sum of θ_n's. We shall show that these linearization coefficients are nonnegative. Our proof of the nonnegativity of the linearization coefficients depends on the following key lemma of Askey [3].

LEMMA 5.3. *Let* $\{P_n(x)\}$ *be a sequence of monic polynomials, that is*

$$P_n(x)=x^n+\text{a polynomial of degree at most } n-1,$$

that satisfies

$$P_1(x)P_n(x)=P_{n+1}(x)+a_nP_n(x)+b_nP_{n-1}(x). \tag{5.3}$$

If $a_n \geqq 0$, $b_n > 0$ *and* $a_{n+1} \geqq a_n$, $b_{n+1} \geqq b_n$, *then*

$$P_n(x)P_m(x) = \sum_{k=|m-n|}^{m+n} \alpha_k P_k(x) \tag{5.4}$$

with $\alpha_k \geqq 0$.

THEOREM 5.4. *The coefficients* $\alpha(k,m,n)$ *in*

$$\theta_m^{(a)}(x;\ q)\theta_n^{(a)}(x;\ q) = \sum_{k=|m-n|}^{m+n} \alpha(k,m,n)\theta_k^{(a)}(x;\ q)$$

are nonnegative for $a \leqq 0$.

Proof. The associated monic set is $P_n(x) := 2^{-n}\theta_n^{(a)}(x;\ q)$. Hence $P_1(x) = x - \frac{1}{2}a$. Therefore

$$P_1(x)P_n(x) = P_{n+1}(x) + \frac{1}{4}P_{n-1}(x) - \frac{a}{2}(1-q^n)P_n(x),$$

since the P's satisfies (3.9), i.e. $b_n = \frac{1}{4}$, $a_n = -\frac{a}{2}(1-q^n)$. If $a \leqq 0$ then $a_n \geqq 0$ and $a_{n+1} \geqq a_n$, so by Lemma 5.3 we establish the nonnegativity of the linearization coefficients in this case.

COROLLARY 5.5. *If* $a > 0$ *then* $(-1)^{k+m+n}\alpha(k,m,n) \geqq 0$.

Proof. This follows from

$$(-1)^n\theta_n^{(a)}(-x;\ q) = \theta_n^{(a)}(x;\ q),$$

see (3.16).

6. The case $|q| > 1$. In this case the generating function (2.1) no longer holds but the explicit formula (5.2) remains valid because both sides of (5.2) are well defined for $q > 1$ or $q < -1$ and computing any θ_n involves only a finite number of steps. We now determine the asymptotic behavior of θ_n for large n and fixed x. We set

$$p := 1/q. \tag{6.1}$$

THEOREM 6.1. *The following asymptotic formula*

$$\theta_n^{(a)}(x;\ q) \sim (-a)^n q^{n(n-1)/2}\left(\frac{A}{a};\ p\right)_\infty \sum_{k=0}^{\infty} \frac{p^{k(k-1)/2}(-B/a)^k}{(p;\ p)_k(A/a;\ p)_k}, \tag{6.2}$$

holds for x *off the support of* $d\psi^{(a)}$.

Proof. We replace q in (5.2) by $1/p$, use the observation

$$(q;\ q)_l = (-1)^l q^{l(l+1)/2}(p;\ p)_l,$$

and replace the summation index k in (5.2) by $n-k$ to obtain

(6.3)

$$(-a)^{-n}q^{-n(n-1)/2}\theta_n^{(a)} = \sum_{0\leqq l\leqq k\leqq n} \frac{p^{k(k-1)/2}(-a)^{-k}(p;\ p)_{n+l-k}(p;\ p)_{n-l}A^{-l}B^{l-k}}{(p;\ p)_l(p;\ p)_{k-l}(p;\ p)_{n-k}^2}.$$

We now apply Tannery's theorem, a discrete and earlier version of the Lebesgue dominated convergence theorem, see Bromwich [6], to the right side of (6.3). The pointwise limit exists and since the infinite product $(p;\ p)_\infty$ exists the right side of (6.3) is bounded by a constant multiple of

$$\sum_{k,l=0}^{\infty} \frac{p^{(k+l)(k+l-1)/2}|A|^{-l}|B|^{-k}|a|^{-k-l}}{(p;\ p)_k(p;\ p)_l}$$

which is a convergent double series. Thus

$$\lim_{n\to\infty}(-a)^{-n}p^{n(n-1)/2}\theta_n^{(a)}(x;\ a)=\sum_{l=0}^{\infty}\frac{(-aA)^{-l}p^{l(l-1)/2}}{(p;\ p)_l}\sum_{k=0}^{\infty}\frac{p^{k(k-1)/2}(-aBp^{-l})^{-k}}{(p;\ p)_k}.$$

The inner sum can be evaluated by Euler's formula

$$\sum_{0}^{\infty}\frac{(-x)^n q^{n(n-1)/2}}{(q;\ q)_n}=(x;\ q)_\infty,$$

Slater [16, p. 93], and we get

$$(-a)^{-n}p^{n(n-1)/2}\theta_n^{(a)}(x;\ q)\sim\sum_{l=0}^{\infty}\frac{(-aA)^{-l}p^{l(l-1)/2}}{(p;\ p)_l}\left(\frac{p^l}{aB};\ p\right)_\infty,$$

which can be easily reduced to (6.2) since $AB=1$ and $(\sigma p^l;\ p)_\infty$ is nothing but $(\sigma;\ p)_\infty/(\sigma;\ p)_l$. This completes the proof.

We define

$$G(r,s):=(s;\ p)_\infty\sum_{k=0}^{\infty}\frac{p^{k(k-1)/2}r^k}{(p;\ p)_k(s;\ p)_k}. \tag{6.4}$$

THEOREM 6.2. *There exists a unique measure $d\psi^{(a)}(x;\ q)$ such that*

$$\int_{-\infty}^{\infty}\theta_n^{(a)}(x;\ q)\theta_m^{(a)}(x;\ q)\,d\psi^{(a)}(x;\ q)=\delta_{mn}. \tag{6.5}$$

The support of $d\psi^{(a)}$ is unbounded and the Stieltjes transform of $d\psi^{(a)}$ is given by

$$\int_{-\infty}^{\infty}\frac{d\psi^{(a)}(t;\ q)}{x-t}=-2a^{-1}G\left(-\frac{B}{a}q,\ \frac{A}{a}\right)\Big/G\left(-\frac{B}{a},\ \frac{A}{a}\right), \tag{6.6}$$

valid for $x\notin\operatorname{supp}\{d\psi^{(a)}\}$. Furthermore $d\psi^{(a)}$ is singular with respect to the Lebesgue measure, that is its absolutely continuous component vanishes almost everywhere.

Proof. The existence of $d\psi^{(a)}$ follows from Theorem 1.1 because the positivity condition $\lambda_n>0$, (2.15) and (2.17) remain valid when $|q|>1$. In the terminology of the moment problem, [15], the uniqueness of $d\psi^{(a)}$ is called the determinacy of the moment problem. Theorem 2.9 in Shohat and Tamarkin [15, p. 50] insures the uniqueness of $d\psi^{(a)}$ if the series

$$\sum_{0}^{\infty}\left|\theta_n^{(a)}(x;\ q)\right|^2 \tag{6.7}$$

diverges at one point x, real or complex. The existence of an x that makes the series (6.7) diverge when $a\neq 0$ is clear from (6.2) because $G(-B/a,\ A/a)$ does not vanish identically and $|q|>1$. This proves (6.5). The polynomials of the second kind are $\{\theta_{n-1}^{(aq)}(x;\ q)\}_1^\infty$, so the continued fraction

$$\frac{2|}{|2x-a}-\frac{2|}{|2x-aq}-\cdots-\frac{2|}{|2x-aq^n}-\cdots \tag{6.8}$$

converges to the left side of (6.6), see the discussion in [15, p. 46]. On the other hand the continued fraction (6.8) is

$$\lim_{n\to\infty} \theta_{n-1}^{(aq)}(x,q)/\theta_n^{(a)}(x;\,q)$$

which, in view of (6.2), is the right side of (6.6). It only remains to show that $d\psi^{(a)}$ is singular. Recall that (Stone [17])

$$F(z)=\int_{-\infty}^{\infty}\frac{d\mu(t)}{z-t},\qquad z\notin\{\operatorname{supp} d\mu\} \tag{6.9}$$

if and only if

$$\mu(t_2)-\mu(t_1)=\lim_{\varepsilon\to0^+}\frac{1}{2\pi i}\int_{t_1}^{t_2}\{F(t-i\varepsilon)-F(t+i\varepsilon)\}\,dt, \tag{6.10}$$

where μ is normalized by $\mu(-\infty)=0$, $\mu(t)=\frac{1}{2}\{\mu(t+)+\mu(t-)\}$. Therefore the absolutely continuous component of $d\mu$ is

$$\mu'(t)=\frac{1}{2\pi i}\{F(t-i0)-F(t+i0)\}\quad \text{a.e.} \tag{6.11}$$

so if $F(z)$ is single-valued across the x-axis μ' will vanish almost everywhere. The functions $G(-B/a,\ A/a)$ appearing in the right side of (6.6) is

$$\sum_{k,l=0}^{\infty}\frac{p^{(k+l)(k+l-1)/2}}{(p;\,p)_k(p;\,p)_l}\left(-\frac{B}{a}\right)^l\left(-\frac{A}{a}\right)^k,$$

hence both $G(-B/a,\ A/a)$ and $G(-Bp/a,\ A/a)$ are uniform limits of polynomials symmetric in A, B. We now show that the polynomials symmetric in A and B are single-valued functions of x. Any such polynomial is a sum of terms of the type

$$a_{mn}\{A^mB^n+B^mA^n\},\qquad m\geqq n.$$

But

$$A^mB^n+B^mA^n=(AB)^n(A^{m-n}+B^{m-n})=A^{m-n}+B^{m-n},$$

since $AB=1$. Therefore

$$\begin{aligned}A^mB^n+B^mA^n&=(A+B)^{m-n}-\sum_{j=1}^{m-n-1}\binom{m-n}{j}A^jB^{m-n-j}\\&=(A+B)^{m-n}-\sum_{j=1}^{m-n-1}\binom{m-n}{j}A^{j-1}B^{m-n-j-1},\end{aligned}$$

where we used $AB=1$. Recall that $A+B=2x$. The above relationship expresses $B^mA^n+B^nA^m$ as $(2x)^{m-n}$ plus some symmetric lower degree polynomial. Repeating this process shows that $A^mB^n+B^mA^n$ is a polynomial in x of degree $m-n$; hence is single-valued. Therefore both $G(-B/a,\ A/a)$ and $G(-Bq/a,\ A/a)$ are entire functions of x, hence single-valued across the x-axis. This completes the proof.

The idea of using Tannery's theorem to derive asymptotic expansions for certain polynomials has been used successfully in other cases, see [2], [10] and [11].

7. The case $q=-1$. When $q=-1$ the generating function

$$G(x,t):=\sum_{0}^{\infty}t^n\theta_n^{(a)}(x;\ -1), \tag{7.1}$$

satisfies the functional equation, see (2.4),

$$(1-2xt+t^2)G(x,t)=1-at\,G(x,-t). \tag{7.2}$$

We now iterate (7.2), that is replace t by $-t$, then use the result and (7.2) to eliminate $G(x,-t)$. The result is

$$\sum_{0}^{\infty}t^n\theta_n^{(a)}(x;\ -1)=\{1+(2x-a)t+t^2\}\{(1+t^2)^2+(a^2-4x^2)t^2\}^{-1}. \tag{7.3}$$

THEOREM 7.1. *For fixed x, let α, β be the roots of*

$$(1+u)^2+(a^2-4x^2)u=0 \quad \textit{with } |\beta|\leqq|\alpha|. \tag{7.4}$$

The polynomials $\{\theta_n^{(a)}(x;\ -1)\}$ can be expressed explicitly as

$$\begin{aligned}\theta_{2n}^{(a)}(x;\ -1)&=(\alpha-\alpha)^{-1}[(\alpha+\beta)\alpha^n-(\beta+1)\beta^n],\\ \theta_{2n+1}^{(a)}(x;\ -1)&=(2x-a)(\alpha-\beta)^{-1}(\alpha^{n+1}-\beta^{n+1}),\end{aligned}\qquad n=0,1,2,\cdots. \tag{7.5}$$

Proof. Rewrite the right side of (7.3) in the form

$$\frac{1}{\alpha-\beta}\left[\frac{\alpha+1}{1-t^2\alpha}-\frac{\beta+1}{1-t^2\beta}+(2x-a)t\left(\frac{\alpha}{1-t^2\alpha}-\frac{\beta}{1-t^2\beta}\right)\right],$$

then expand $(1-t^2\alpha^{-1})$ and $(1-t^2\beta^{-1})$ in powers of t^2 and equate coefficients of like powers of t. A simple calculation yields (7.5) and the proof is complete.

THEOREM 7.2. *The polynomial $\{\theta_n^{(a)}(x;\ -1)\}$ satisfies the orthogonality relation*

$$\int_E\left[\frac{2x+a}{2x-a}\left(1+\frac{a^2}{4}-x^2\right)\right]^{1/2}\theta_n^{(a)}(x;\ -1)\theta_m^{(a)}(x;\ -1)\,dx=\pi\delta_{m,n}, \tag{7.6}$$

where E is given by

$$E=\left[-\frac{1}{2}\sqrt{4+a^2},\ -\frac{|a|}{2}\right]\cup\left[\frac{|a|}{2},\ \frac{1}{2}\sqrt{a^2+4}\right]. \tag{7.7}$$

Proof. The corresponding continued fraction $\chi(x)$ is periodic and satisfies

$$\chi(x)=\frac{1}{2x-a-1/(2x+a-\frac{1}{2}\chi(x))}.$$

Therefore

$$\chi(x)=\int_{-\infty}^{\infty}\frac{d\psi^{(a)}(t,-1)}{x-t}=2(\beta+1)(2x-a)^{-1}. \tag{7.8}$$

We now invert (7.8) to compute $d\psi^{(a)}$. It is clear from (7.8) that $d\psi^{(a)}$ is absolutely continuous because $\beta=-1$ when $x=\frac{1}{2}a$. We now apply (6.9), (6.10) and (6.11) to get

$$\frac{d}{dx}\psi^{(a)}(x,-1)=\lim_{\varepsilon\to0^+}2(\beta_1-\beta_2)\frac{(2\pi i)^{-1}}{2x-a}, \tag{7.9}$$

where β_1 and β_2 are the values of β when $x = x - i0$ and $x = x + i0$, respectively. It is not difficult to see from (7.8) and (7.4) that $\psi^{(a)}$ is constant outside E and

$$(7.10) \quad \frac{d}{dx}\psi^{(a)}(x, -1) = \left\{4 - (2 + a^2 - 4x^2)^2\right\}^{1/2}\left\{\pi(2x - a)\right\}^{-1}, \qquad x \in E,$$

which implies the orthogonality relation (7.6) because $\psi^{(a)}$ is normalized by

$$\int_{-\infty}^{\infty} d\psi^{(a)}(x; -1) = 1.$$

Remark 7.3. The fact that $d/dx\psi^{(a)}(x; -1)$ vanishes outside E is predicted in Chihara [8, Thm. 4.1, p. 122].

Observe that as $a \to 0$ the orthogonality relation (7.6) reduces to the orthogonality relation for $\{U_n(x)\}$. The results obtained here also follow from Chihara's work [7].

GENERALIZED FEJÉR AND LANCZOS KERNELS*

M. CLUTTON-BROCK[†]

Abstract. On a circle, the Fejér kernel is nonnegative and is useful for approximating positive densities, and the Lanczos kernel is an approximate identity and gives rapid convergence when applied to discontinuous functions. These kernels are easy to construct from trigonometric functions because the Dirichlet kernel is invariant under translations. This paper uses the invariance under rotations of the Dirichlet kernel constructed from spherical harmonics to construct Fejér and Lanczos kernels on a sphere. On a $(q+2)$-dimensional sphere, the kth order Lanczos kernel is an approximate identity for $q<2k$. The corresponding Fejér and Lanczos kernels in Euclidean space can be constructed by a simple mapping.

Key words. kernels, approximate identity, convergence

AMS(MOS) subject classifications. Primary 41, 33

1. Introduction. One sometimes wants to approximate a function which is everywhere nonnegative. For example, Smoothed Particle Hydrodynamics [5] fits a mass density to discrete masses at points $x_1..x_J$, and in statistical estimation the kernel method [12] fits a frequency density to a sample $x_1..x_J$. These methods generally use something like a Gaussian for a nonnegative kernel, but a more economic representation is obtained if the kernel is constructed from a set $\{\phi_n\}$ of orthonormal functions:

$$K_N(x,y)=\sum_{n=0}^{N}\sigma_n\phi_n(x)\phi_n(y). \tag{1.1}$$

The problem is, how do we choose the sigma factors σ_n so that the kernel (1.1) is everywhere nonnegative?

The best known nonnegative kernel is the Fejér kernel $F_N(x,y)$ constructed from trigonometric functions with

$$\sigma_n=1-n(N+1). \tag{1.2}$$

It can be derived from the Dirichlet kernel either as the $(C,1)$ mean or by squaring the Dirichlet kernel of order $N/2$ and normalizing. These methods work essentially because the trigonometric functions are invariant under translation so that the Dirichlet kernel $D_N(x,y)$ is a function of $x-y$ only. Now spherical harmonics are invariant under rotations, so the Dirichlet kernel $D_N(A,B)$ on a sphere is a function only of the angle $\widehat{AB}$. Because of this it is possible to construct a Fejér kernel on the sphere, as we see in §3. How to do this using Cesàro means is already known: the $(C,q+1)$ mean of the Dirichlet kernel on a $(q+2)$-dimensional sphere is everywhere nonnegative (Kogbetlianz [9], Askey and Pollard [3]). For even N, however, the $(C,q+1)$ mean is everywhere greater than zero and is not the sharpest possible kernel. It may therefore be better for even N to use the kernel obtained by squaring the Dirichlet kernel of order $N/2$ and normalizing, and in §3 we derive the corresponding sigma factors.

In practical problems we more often want kernels in Euclidean space. It is easy, however, to map Euclidean space E_{q+1} onto the surface S_{q+1} of a $(q+2)$-dimensional sphere; we discuss this briefly in §6. The case $q=2$ is especially important because it

*Received by the editors June 4, 1982, and in final revised form May 15, 1985. This work was supported in part by the Natural Sciences and Engineering Research Council of Canada.

[†] Department of Mathematics and Astronomy, University of Manitoba, Winnipeg R3T 2N2, Canada.

corresponds to 3-dimensional Euclidean space, and fortunately the ultraspherical polynomials from which the Dirichlet kernel on a 4-dimensional sphere is constructed are especially simple.

The Fejér kernel has many desirable properties apart from being nonnegative: it captures all continuous functions, and it avoids the notorious Gibbs oscillations. The Gibbs oscillations induced when the Dirichlet kernel is applied to a discontinuous function get worse as the number of dimensions increases, and in 3 dimensions they can be very serious indeed. Of course, if the function we are approximating is smooth enough, there is no trouble, and the Dirichlet kernel will converge rapidly. But in practical problems functions are not always smooth; compressible flows develop discontinuities, and in particle methods of simulating fluids and plasmas the data is noisy. In these circumstances some form of smoothing is essential.

The Fejér kernel, however, may provide too much smoothing. The Nth order Fejér kernel is about as sharp as the Dirichlet kernel of order $N/2$, and in 3 dimensions the Fejér kernel needs about 8 times as many terms to achieve the same sharpness as the Dirichlet kernel. We therefore want a kernel which is better behaved than the Dirichlet kernel but is sharper than the Fejér kernel.

Lanczos [10], [11] showed how to construct a kernel for trigonometric functions that gives rapid convergence when applied to a discontinuous function. The Lanczos kernel $L_N(x,y)$ is obtained from the Dirichlet kernel $D_N(x,z)$ by integrating over a window in z:

$$L_N(x,y)=\frac{1}{\Delta}\int_{y-\Delta/2}^{y+\Delta/2} D_N(x,z)\,dz. \tag{1.3}$$

In other words, the Lanczos kernel is a moving average of the Dirichlet kernel. This provides the same amount of smoothing for all x because the Dirichlet kernel is a function of $x-z$ only. Because the Dirichlet kernel $D_N(A,B)$ on a sphere is a function of the angle $\widehat{AB}$ only, we can also construct a Lanczos kernel on the sphere, and we derive the Lanczos sigma factors in §4.

The Lanczos kernel constructed from trigonometric functions is well behaved because it is an approximate identity, that is, it fulfills the following conditions:

$$\int_{\text{all } y} L_N(x,y)\,dy=1, \tag{1.4}$$

$$\sup_N \int_{\text{all } y} |L_N(x,y)|\,dy<\infty, \tag{1.5}$$

$$\lim_{N\to\infty} \int_{|x-y|>\varepsilon} |L_N(x,y)|\,dy=0. \tag{1.6}$$

An approximate identity captures all continuous functions and avoids Gibbs oscillations. Many of the troubles of the Dirichlet kernel stem from the fact that it is not an approximate kernel. On a $(q+2)$-dimensional sphere, for example, we have

$$\int_{\text{all } B} |D_N(A,B)|\,d\Omega(B)=\begin{cases} O(\ln N) & \text{for } q=0 \text{ (a circle)},\\ O(N^{q/2}) & \text{for } q>0, \end{cases} \tag{1.7}$$

which shows how a Dirichlet kernel gets worse behaved and farther from being an approximate identity as the number of dimensions increases.

In §5 we show that the Lanczos kernel is an approximate identity for $q=1$ (the 2-dimensional surface of a 3-dimensional sphere), but not for $q=2$. To obtain an approximate identity for $q \geq 2$, we must use higher order Lanczos kernels, which are obtained by repeated Lanczos averaging, that is, by repeated integration over the window. The second order Lanczos kernel is an approximate identity for $q=2$ or 3, and the kth order Lanczos kernel is an approximate identity for $q<2k$.

For ease of reference and to define the notation §2 gives the most important formulae involving spherical harmonics in $(q+2)$-dimensions. An excellent account is given by Hochstadt [6].

2. Notation and useful formulae for spherical harmonics. In terms of the angular coordinates $(\theta_0, \theta_1 \cdots \theta_q)$ the element of area of a $(q+2)$-dimensional sphere can be written

$$d\Omega_q = (\sin\theta_0)^q d_0 \times (\sin\theta_1)^{q-1} d\theta_1 \times \cdots \times d\theta_q. \tag{2.1}$$

This suggests representing a $(q+2)$-dimensional spherical harmonic in terms of ultraspherical polynomials $C(\begin{smallmatrix}\lambda\\ n\end{smallmatrix}|\cos\theta)$ orthogonal under the weight function $(\sin\theta)^{2\lambda}$

$$\begin{aligned} &Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|\theta_0\theta_1..\theta_q\right) \\ &= \left\{H\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\right)\right\}^{-1} C\left(\begin{matrix}k_1+q/2\\ n-k_1\end{matrix}\middle|\cos\theta_0\right)(\sin\theta_0)^{k_1} \times C\left(\begin{matrix}k_2+(q-1)/2\\ k_1-k_2\end{matrix}\middle|\cos\theta_1\right)(\sin\theta_1)^{k_2} \\ &\qquad \times \cdots \times C\left(\begin{matrix}|k_q|+1/2\\ k_{q-1}-|k_q|\end{matrix}\middle|\cos\theta_{q-1}\right)(\sin\theta_{q-1})^{|k_q|} \times \exp(ik_q\theta_q), \end{aligned} \tag{2.2}$$

where H is the normalizing integral

$$H\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\right) = h\left(\begin{matrix}k_1+q/2\\ n-k_1\end{matrix}\right) \times h\left(\begin{matrix}k_2+(q-1)/2\\ k_1-k_2\end{matrix}\right) \times \cdots \times h\left(\begin{matrix}|k_q|+1/2\\ k_{q-1}-|k_q|\end{matrix}\right) \times 2\pi, \tag{2.3}$$

and h is the normalizing integral for ultraspherical polynomials

$$h\left(\begin{matrix}\lambda\\ n\end{matrix}\right) = \int_0^\pi \left\{C\left(\begin{matrix}\lambda\\ n\end{matrix}\middle|\cos\theta\right)\right\}^2 (\sin\theta)^{2\lambda} d\theta = \frac{C\left(\begin{matrix}\lambda\\ n\end{matrix}\middle|1\right)}{(1+n/\lambda)} h\left(\begin{matrix}\lambda\\ 0\end{matrix}\right) \tag{2.4}$$

with

$$h\left(\begin{matrix}\lambda\\ 0\end{matrix}\right) = \frac{\pi 2^{1-2\lambda}\Gamma(2\lambda)}{\lambda\{\Gamma(\lambda)\}^2}, \tag{2.5}$$

and the ultraspherical polynomials are standardised so that

$$C\left(\begin{matrix}\lambda\\ n\end{matrix}\middle|1\right) = \left(\begin{matrix}n+2\lambda-1\\ n\end{matrix}\right). \tag{2.6}$$

The Dirichlet kernel on a sphere is

$$D_N(A,B) = \sum_{n=0}^{N} \sum_{k_1 \cdots k_q} Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|A\right) Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|B\right). \tag{2.7}$$

The sum over $k_1..k_q$ is invariant under rotations [6], and on rotating B to the pole $(0,0..0)$ and A to the point $(\widehat{AB},0..0)$, all terms vanish except those with $k_1..k_q=0$. We therefore obtain the addition formula

(2.8)
$$\sum_{k_1\cdots k_q} Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|A\right)Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|B\right)=Y\left(\begin{matrix}0..0\\ n\end{matrix}\middle|\widehat{AB},0..0\right)Y\left(\begin{matrix}0..0\\ n\end{matrix}\middle|0,0..0\right)$$
$$=\left\{H\begin{pmatrix}0..0\\ n\end{pmatrix}\right\}^{-1}C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|1\right)C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\widehat{AB}\right).$$

Recalling (2.3) and (2.4), we have

$$H\begin{pmatrix}0..0\\ n\end{pmatrix}=\Omega_q C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|1\right)\Big/(1+2n/q), \tag{2.9}$$

where

$$\Omega_q=h\begin{pmatrix}q/2\\ 0\end{pmatrix}\times h\begin{pmatrix}(q-1)/2\\ 0\end{pmatrix}\times\cdots\times h\begin{pmatrix}1/2\\ 0\end{pmatrix}\times 2\pi \tag{2.10}$$

is the surface area of a $(q+2)$-dimensional sphere. The Dirichlet kernel is therefore

$$D_N(A,B)=\Omega_q^{-1}\sum_{n=0}^{N}(1+2n/q)C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\widehat{AB}\right). \tag{2.11}$$

Our task is now to find the sigma factors in the Fejér and Lanczos kernels which take the form

$$K_N(A,B)=\sum_{n=0}^{N}\sigma_n\sum_{k_1..k_q}Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|A\right)Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|B\right) \tag{2.12}$$
$$=\Omega_q^{-1}\sum_{n=0}^{N}\sigma_n(1+2n/q)C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\widehat{AB}\right).$$

3. The Fejér sigma factors. The simplest way to obtain a nonnegative kernel is to use Cesàro means. Recall that the (C,β) mean of Σt_n is

$$S_N(C,\beta;\,t)=\sum_{n=0}^{N}\frac{[N]_n}{[N+\beta]_n}t_n \tag{3.1}$$

where $[\alpha]_n$ is the nth descending factorial of α. Kogbetlianz [9] first stated that the $(C,2\lambda+1)$ means of

$$\sum_n(1+n/\lambda)C\left(\begin{matrix}\lambda\\ n\end{matrix}\middle|x\right) \tag{3.2}$$

are nonnegative. Askey and Pollard [3] gave a simple proof, which is also outlined in Askey's book [1]. Now (3.2) is simply proportional to the Dirichlet kernel (2.11) with $q=2\lambda$, so it is clear that the $(C,q+1)$ means of the Dirichlet kernel should be nonnegative. The corresponding Fejér sigma factors are

$$\sigma_n=\frac{[N]_n}{[N+q+1]_n}. \tag{3.3}$$

It is desirable that the Fejér kernel should be as sharp as possible consistent with being nonnegative. The smallest value of β which will make the (C,β) mean of the Dirichlet kernel nonnegative is $q+1$ for odd N, but less than $q+1$ for even N. For example, with $q=2$, $N=6$, the (C,β) mean of the Dirichlet kernel is positive for

$$\beta=2.28<q+1=3. \tag{3.4}$$

Thus, for even N the optimum value of β which will give the sharpest nonnegative Fejér kernel is less than $q+1$. I would like to be able to find the optimum value of β by using the elegant methods in Chapters 8 and 9 of Askey's book [1], or perhaps to extend Askey's results [2] for positive radial functions on a sphere, but I am not clever enough.

For even N we can obtain another nonnegative kernel by squaring the Dirichlet kernel of order $N/2$ and normalizing. The square of the Dirichlet kernel (2.11) is

$$\begin{aligned}\{D_{N/2}(A,B)\}^2=\Omega_q^{-2}\sum_{n,m=0}^{N/2}&(1+2n/q)(1+2m/q)\\ &\times C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\widehat{AB}\right)C\left(\begin{matrix}q/2\\ m\end{matrix}\middle|\cos\widehat{AB}\right).\end{aligned}\tag{3.5}$$

The product of two ultraspherical polynomials can be linearized:

$$C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|x\right)C\left(\begin{matrix}q/2\\ m\end{matrix}\middle|x\right)=\sum_l \Pi(n,m;\ l)C\left(\begin{matrix}q/2\\ l\end{matrix}\middle|x\right).\tag{3.6}$$

The product linearization coefficients are given by the explicit formula

$$\begin{aligned}\Pi(n,m;\ n+m-2k)=&\frac{(m+n+q/2-2k)}{(m+n+q/2-k)}\\ &\times\frac{(q/2)_k(q/2)_{m-k}(q/2)_{n-k}(q)_{m+n-k}(m+n-2k)!}{k!(m-k)!(n-k)!(q/2)_{m+n-k}(q)_{m+n-2k}},\end{aligned}\tag{3.7}$$

where $(\alpha)_n$ is the nth ascending factorial of α. This result was first stated by Dougall [4] and proved by Hsü [7]; see also Askey's book. We can see from (3.7) that all the coefficients are nonnegative, and the only nonzero coefficients in (3.6) are those for which $n+m+l$ is even and $|n-m|\leqq l\leqq n+n$.

When many product linearizations are needed, it is easier to generate them using a recurrence relation such as the one found by Hyllaraas [8] or, more simply still, using the one found directly from the recurrence relation for the ultraspherical polynomials:

$$a_n\Pi(n+1,m;\ l)+b_n\Pi(n-1,m;\ l)=a_{l-1}\Pi(n,m;\ l-1)+b_{l+1}\Pi(n,m;\ l+1)\tag{3.8}$$

where

$$a_n=(n+1)/(2n+q)\quad\text{and}\quad b_n=(n+q-1)/(2n+q)\tag{3.9}$$

are the coefficients in the recurrence relation

$$xC\left(\begin{matrix}q/2\\ n\end{matrix}\middle|x\right)=a_nC\left(\begin{matrix}q/2\\ n+1\end{matrix}\middle|x\right)+b_nC\left(\begin{matrix}q/2\\ n-1\end{matrix}\middle|x\right).\tag{3.10}$$

Linearizing the square (3.5) of the Dirichlet kernel gives

$$\text{(3.11)}\quad \{D_{N/2}(A,B)\}^2=\Omega_q^{-2}\sum_{m,n=0}^{N/2}(1+2n/q)(1+2m/q)$$
$$\times\sum_{\left\{\substack{|n-m|\leqq l\leqq n+m\\ n+m+l\text{ even}}\right\}}\Pi(n,m;\,l)C\left(\begin{matrix}q/2\\ l\end{matrix}\middle|\cos\widehat{AB}\right).$$

The Fejér kernel has the form

$$\text{(3.12)}\quad F_N(A,B)=\Omega_q^{-1}\sum_{l=0}^{N}\sigma_l(1+2l/q)C\left(\begin{matrix}q/2\\ l\end{matrix}\middle|\cos\widehat{AB}\right)$$

with $\sigma_0=1$ for proper normalization. Comparing (3.11) and (3.12), we see that the Fejér sigma factors are

$$\text{(3.13)}\quad \sigma_l=\frac{S_l/S_0}{(1+2l/q)}$$

where

$$\text{(3.14)}\quad S_l=\sum_{\left\{\substack{0\leqq n,m\leqq N/2\\ |n-m|\leqq l\leqq n+m\\ n+m+l\text{ even}}\right\}}(1+2n/q)(1+2m/q)\Pi(n,m;\,l).$$

For even N, the Fejér kernel with sigma factors (3.13) should be sharper than the Fejér kernel with sigma factors (3.3). The sigma factors (3.3) are easier to obtain, and of course there may be some purposes for which the resulting kernel is actually better. For the important case $q=2$ the sigma factors (3.13) are, however, easy to obtain.

For $q=2$ the ultraspherical polynomials are Chebyshev polynomials of the second kind, and all the nonzero product linearization coefficients are unity, as may be seen directly from the explicit formula (3.7). Then (3.14) becomes

$$\text{(3.15)}\quad S_l=\sum_{\left\{\substack{0\leqq n,m\leqq N/2\\ |n-m|\leqq l\leqq n+m\\ n+m+l\text{ even}}\right\}}(1+n)(1+m).$$

On evaluating these sums we obtain

$$\text{(3.16)}\quad S_{2l}=\left(\frac{2l+1}{6}N-\frac{2l^2-1}{2}\right)(N/2+1)(N/2+2)$$
$$+\left(\frac{l(l+2)}{3}-\frac{2l+1}{6}\right)l(l+1),$$

$$\text{(3.17)}\quad S_{2l+1}=\frac{l+1}{3}\left[(N-3l)(N/2+1)(N/2+2)+l(l+1)(l+2)\right].$$

In particular

$$\text{(3.18)}\quad S_0=(N/6+1/2)(N/2+1)(N/2+2),\qquad S_{N+1}=0.$$

4. The Lanczos sigma factors. The Lanczos kernel on a sphere is obtained by integrating the Dirichlet kernel $D_N(A,C)$ over a window in C centered at B with radius Δ:

$$L_N(A,B)=\int_{\overset{\frown}{CB}\leqq\Delta} D_N(A,C)\,d\Omega(C)\Big/\int_{\overset{\frown}{CB}\leqq\Delta} d\Omega(C). \tag{4.1}$$

The second order Lanczos kernel is formed by integrating again over the window:

$$L_N^{(2)}(A,B)=\int_{\overset{\frown}{CB}\leqq\Delta} L_N(A,C)\,d\Omega(C)\Big/\int_{\overset{\frown}{CB}\leqq\Delta} d\Omega(C). \tag{4.2}$$

Higher order Lanczos kernels are obtained similarly by integrating repeatedly over the window.

To obtain the Lanczos sigma factors, we expand the Dirichlet kernel in spherical harmonics as in (2.7), so that

(4.3)

$$\int_{\overset{\frown}{CB}\leqq\Delta} D_N(A,C)\,d\Omega(C)=\sum_{n=0}^{N}\sum_{k_1\cdots k_q} Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|A\right)\int_{\overset{\frown}{CB}\leqq\Delta} Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|C\right)d\Omega(C).$$

We put B at the pole $(0,0..0)$, A at $(\overset{\frown}{AB},0..0)$, and give to C coordinates $(\gamma_0,\gamma_1..\gamma_q)$ where $\gamma_0=\overset{\frown}{CB}$. In the representation (2.7) all spherical harmonics vanish at A unless $k_2..k_q=0$. The integral over the window $\gamma_0=\overset{\frown}{CB}\leqq\Delta$ then vanishes unless $k_1=0$, because the part of the spherical harmonic which depends on γ_1 is

$$\left(\begin{matrix}k_1,0..0\\ n\end{matrix}\middle|C\right)\propto C\left(\begin{matrix}(q-1)/2\\ k_1\end{matrix}\middle|\cos\gamma_1\right), \tag{4.4}$$

and the integral over the window is proportional to

$$\int_0^{\pi} C\left(\begin{matrix}(q-1)/2\\ k_1\end{matrix}\middle|\cos\gamma_1\right)(\sin\gamma_1)^{q-1}d\gamma_1=0 \quad \text{if } k_1\neq 0. \tag{4.5}$$

The integral (4.3) of the Dirichlet kernel then becomes

$$\begin{aligned}(4.6)\quad &\int_{\overset{\frown}{CB}\leqq\Delta} D_N(A,C)\,d\Omega(C)\\ &=\sum_{n=0}^{N} Y\left(\begin{matrix}0..0\\ n\end{matrix}\middle|A\right)\int Y\left(\begin{matrix}0..0\\ n\end{matrix}\middle|C\right)d\Omega(C)\\ &=\sum_{n=0}^{N}\left\{H\left(\begin{matrix}0..0\\ n\end{matrix}\right)\right\}^{-1} C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\overset{\frown}{AB}\right)\times\Omega_{q-1}\int_0^{\Delta} C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\gamma_0\right)(\sin\gamma_0)^q d\gamma_0.\end{aligned}$$

Since

$$\int_{\overset{\frown}{CB}\leqq\Delta} d\Omega(C)=\Omega_{q-1}\int_0^{\Delta}(\sin\gamma_0)^q d\gamma_0 \tag{4.7}$$

we find, using (2.9) for H, that the Lanczos kernel becomes

$$L_N(A,B)=\Omega_q^{-1}\sum_{n=0}^{N}\sigma_n(1+2n/q)C\left(\begin{matrix}q/2\\ n\end{matrix}\middle|\cos\overset{\frown}{AB}\right) \tag{4.8}$$

with

$$\sigma_n = \frac{\int_0^\Delta C\left(\begin{smallmatrix} q/2 \\ n \end{smallmatrix} \middle| \cos\gamma_0\right)(\sin\gamma_0)^q\,d\gamma_0}{C\left(\begin{smallmatrix} q/2 \\ n \end{smallmatrix} \middle| 1\right)\int_0^\Delta (\sin\gamma_0)^q\,d\gamma_0}. \tag{4.9}$$

From the Rodrigues formula

$$C\left(\begin{matrix} q/2 \\ n \end{matrix} \,\middle|\, \cos\theta\right) = \frac{A_n^q}{(\sin\theta)^{q-1}}\left(\frac{1}{\sin\theta}\frac{d}{d\theta}\right)^n (\sin\theta)^{2n+q-1}, \tag{4.10}$$

with

$$A_n^q = \frac{\Gamma((q+1)/2)\Gamma(n+q)}{2^n n!\Gamma(n+(q+1)/2)\Gamma(q)}, \tag{4.11}$$

we find for $n>0$ that

$$\int_0^\Delta C\left(\begin{matrix} q/2 \\ n \end{matrix} \,\middle|\, \cos\gamma_0\right)(\sin\gamma_0)^q\,d\gamma_0 = \frac{q(\sin\Delta)^{q+1}}{n(q+n)}\,C\left(\begin{matrix} q/2+1 \\ n-1 \end{matrix} \,\middle|\, \cos\Delta\right). \tag{4.12}$$

Since

$$C\left(\begin{matrix} q/2 \\ n \end{matrix} \,\middle|\, 1\right) = \binom{n+q-1}{n} = \frac{q(q+1)}{n(q+n)}\,C\left(\begin{matrix} q/2+1 \\ n-1 \end{matrix} \,\middle|\, 1\right), \tag{4.13}$$

we have for $n>0$

$$\sigma_n = \frac{(\sin\Delta)^{q+1}/(q+1)}{\int_0^\Delta (\sin\gamma_0)^q\,d\gamma_0} \times \frac{C\left(\begin{matrix} q/2+1 \\ n-1 \end{matrix} \,\middle|\, \cos\Delta\right)}{C\left(\begin{matrix} q/2+1 \\ n-1 \end{matrix} \,\middle|\, 1\right)}. \tag{4.14}$$

We shall fix Δ by the requirement that

$$\sigma_{N+1} = 0, \tag{4.15}$$

or

$$C\left(\begin{matrix} q/2+1 \\ N \end{matrix} \,\middle|\, \cos\Delta\right) = 0. \tag{4.16}$$

For the important case $q=2$, the ultraspherical polynomials are Chebyshev polynomials of the second kind, $U_n(\cos\theta) = \sin((n+1)\theta)/\sin\theta$. It is then easiest to obtain the sigma factors by direct integration of (4.9):

$$\begin{aligned} \sigma_n &= \frac{\int_0^\Delta \sin((n+1)\gamma_0)(\sin\gamma_0)\,d\gamma_0}{(n+1)\int_0^\Delta (\sin\gamma_0)^2\,d\gamma_0} \\ &= \frac{1}{(n+1)}\left[\frac{\sin(n\Delta)}{n} - \frac{\sin((n+2)\Delta)}{(n+2)}\right]\bigg/(\Delta - \sin(2\Delta)/2). \end{aligned} \tag{4.17}$$

The condition $\sigma_{N+1} = 0$ gives

$$\tan((N+2)\Delta) - (N+2)\tan\Delta = 0 \tag{4.18}$$

which is easily solved by the iteration

$$\Delta = \frac{\pi + \arctan((N+2)\tan\Delta)}{(N+2)} \tag{4.19}$$

with the starting value

$$\Delta = \frac{Z}{N+2} \tag{4.20}$$

where $Z = 4.4934$ is the solution of

$$Z = \pi + \arctan(Z) \quad \text{or} \quad J_{3/2}(Z) = 0 \tag{4.21}$$

with $\pi < Z < 3\pi/2$.

On integrating again over the window, each spherical harmonic in the expansion (2.7) is simply multiplied by another factor of σ_n, so that the mth order Lanczos kernel is

$$L_N^{(m)}(A,B) = \sum_{n=0}^{N} \sigma_n^m \sum_{k_1..k_q} Y\left(\begin{matrix} k_1..k_q \\ n \end{matrix} \middle| A \right) Y\left(\begin{matrix} k_1..k_q \\ n \end{matrix} \middle| B \right). \tag{4.22}$$

5. The Lanczos kernel as an approximate identity. To show that the Lanczos kernel $L_N(A,B) = L_N(\cos\widehat{AB})$ is an approximate identity it is sufficient to show that

$$\int_{\text{all } B} \left| L_N(\cos\widehat{AB}) \right| d\Omega(B) = O(1), \tag{5.1}$$

$$\int_{\widehat{AB} \geqq \varepsilon} \left| L_N(\cos\widehat{AB}) \right| d\Omega(B) = O(N^{-\alpha}) \quad \text{with } \alpha > 0. \tag{5.2}$$

Over most of the interval $0 \leqq \widehat{AB} \leqq \pi$ the Lanczos kernel for large N oscillates rapidly, but to get the asymptotic behavior of the integrals (5.1) and (5.2) we need only concern ourselves with the amplitude of the oscillations. We get this amplitude from the integral

$$L_N(\cos\widehat{AB}) = \int_{\widehat{CB} \leqq \Delta} D_N(\cos\widehat{AC})\, d\Omega(C) \Big/ \int_{\widehat{CB} \leqq \Delta} d\Omega(C) \tag{5.3}$$

by substituting the asymptotic form of the Dirichlet kernel.

The angle $\widehat{AC}$ is

$$\cos\widehat{AC} = \cos\widehat{AB}\cos\widehat{CB} + \sin\widehat{AB}\sin\widehat{CB}\cos\widehat{ABC}. \tag{5.4}$$

As before we put B at $(0,0..0)$, A at $(\theta,0..0)$ where $\theta = \widehat{AB}$, and C at $(\gamma_0, \gamma_1 .. \gamma_q)$ where $\gamma_0 = \widehat{CB}$ and $\gamma_1 = \widehat{ABC}$. Then

$$\begin{aligned} \cos\widehat{AC} &= \cos(\theta - \delta) = \cos\theta\cos\delta + \sin\theta\sin\delta \\ &= \cos\theta\cos\gamma_0 + \sin\theta\sin\gamma_0\cos\gamma_1. \end{aligned} \tag{5.5}$$

Now $\gamma_0 = \widehat{CB} \leqq \Delta$ in the integral (5.3), and we saw in the last section that Δ is $O(N^{-1})$, so γ_0 is $O(N^{-1})$ also. Then

$$\begin{aligned} \delta &= \tan\theta - \left[(\tan\theta)^2 + \gamma_0^2 - 2\gamma_0\tan\theta\cos\gamma_1 \right]^{1/2} + O(N^{-3}) \\ &= \gamma_0\cos\gamma_1 - \tfrac{1}{2}\gamma_0^2\cot\theta(\sin\gamma_1)^2 + O\left(N^{-3}(\cot\theta)^2\right). \end{aligned} \tag{5.6}$$

We have to include factors of $\cot\theta$ when θ is near 0 or π. To accuracy $O(N^{-2})$, we can replace $\sin\gamma_0$ by γ_0, and (5.3) becomes

$$L_N(\cos\theta)=\frac{O(1)}{\Delta^{q+1}}\int_0^\Delta\gamma_0^q d\gamma_0\int_0^\pi(\sin\gamma_1)^{q-1}d\gamma_1 D_N(\cos(\theta-\delta)). \tag{5.7}$$

We can obtain the asymptotic forms for the Dirichlet kernel by starting with a simple closed expression in terms of Jacobi polynomials (Szegö [14, 4.5.3]):

$$D_N(\cos\theta)=O(N^{(q+1)/2})P\left(\begin{matrix}(q+1)/2,(q-1)/2\\N\end{matrix}\middle|\cos\theta\right). \tag{5.8}$$

For the interval $c/N\leqq\theta\leqq\pi-c/N$ with fixed c, the Jacobi polynomials have the following asymptotic form (Szegö [14, 8.21.12 and 8.21.18]; see also [15]):

$$\begin{aligned}P\left(\begin{matrix}\alpha,\beta\\N\end{matrix}\middle|\cos\theta\right)&=O(N^{-1/2})(\sin\theta/2)^{-\alpha-1/2}(\cos\theta/2)^{-\beta-1/2}\\&\quad\times\left\{\cos(N_0\theta-\phi_0)+\frac{O(N^{-1})}{\sin\theta}\cos(N_1\theta-\phi_1)+\cdots\right\},\end{aligned} \tag{5.9}$$

with $N_0,N_1=N+O(1)$ and $\phi_0,\phi_1=O(1)$. For the interval $0\leqq\theta\leqq c/N$ we have (Szegö [14, 8.21.17]):

$$P\left(\begin{matrix}\alpha,\beta\\N\end{matrix}\middle|\cos\theta\right)=O(1)\theta^{-\alpha}J_\alpha(N_0\theta)+\theta^2O(N^\alpha). \tag{5.10}$$

We will consider first the interval $c/N\leqq\theta\leqq\pi-c/N$. Combining (5.8) with (5.9), we have

$$\begin{aligned}D_N(\cos\theta)&=O(N^{q/2})(\sin\theta/2)^{-q/2-1}(\cos\theta/2)^{-q/2}\\&\quad\times\left\{\cos(N_0\theta-\phi_0)+\frac{O(N^{-1})}{\sin\theta}\cos(N_1\theta-\phi_1)+\cdots\right\}.\end{aligned} \tag{5.11}$$

When we substitute the asymptotic form (5.11) into the Lanczos kernel (5.7), we find the Lanczos kernel contains the integral

$$\begin{aligned}&\int_0^\pi(\sin\gamma_1)^{q-1}d\gamma_1\cos(N_0(\theta-\delta)-\phi_0)\\&=\cos(N_0\theta-\phi_0)\int_0^\pi(\sin\gamma_1)^{q-1}d\gamma_1\cos\left[N_0\gamma_0\cos\gamma_1+O(N^{-1})\cot\theta(\sin\gamma_1)^2\right]\\&\quad+\sin(N_0\theta-\phi_0)\int_0^\pi(\sin\gamma_1)^{q-1}d\gamma_1\sin\left[N_0\gamma_0\cos\gamma_1+O(N^{-1})\cot\theta(\sin\gamma_1)^2\right].\end{aligned} \tag{5.12}$$

Now we use the integral representation for Bessel functions

$$J_\nu(z)=O(1)z^\nu\int_0^\pi\cos(z\cos\gamma)(\sin\gamma)^{2\nu}d\gamma, \tag{5.13}$$

together with the fact that

$$\int_0^\pi\sin(z\cos\gamma)(\sin\gamma)^{2\nu}d\gamma=0, \tag{5.14}$$

and we find that (5.12) becomes

$$(5.15)\quad \int_0^{\pi}(\sin\gamma_1)^{q-1}d\gamma_1\cos(N_0(\theta-\delta)-\phi_0)$$

$$=\cos(N_0\theta-\phi_0)\times\left\{O(1)(N_0\gamma_0)^{-(q-1)/2}J_{(q-1)/2}(N_0\gamma_0)+O(N^{-2})(\cot\theta)^2\right\}$$

$$+\sin(N_0\theta-\phi_0)\times O(N^{-1})\cot\theta.$$

The integral over γ_0 becomes

$$(5.16)\quad \frac{1}{\Delta^{q+1}}\int_0^{\Delta}\gamma_0^q d\gamma_0\int_0^{\pi}(\sin\gamma_1)^{q-1}d\gamma_1\cos(N_0(\theta-\delta)-\phi_0)$$

$$=\cos(N_0\theta-\phi_0)\times\frac{O(1)}{(N_0\Delta)^{q+1}}\int_0^{N_0\Delta}x^{(q+1)/2}J_{(q-1)/2}(x)\,dx$$

$$+\sin(N_0\theta-\phi_0)\times O(N^{-1})\,\cot\theta.$$

From the ascending series for Bessel functions, it is easy to see that

$$(5.17)\qquad \int_0^{N_0\Delta}x^{(q+1)/2}J_{(q-1)/2}(x)\,dx=(N_0\Delta)^{(q+1)/2}J_{(q+1)/2}(N_0\Delta).$$

We shall now see that this vanishes to order $O(N^{-1})$ if Δ is fixed by

$$(4.16)\qquad C\left(\begin{matrix}q/2+1\\ N\end{matrix}\middle|\cos\Delta\right)=0.$$

The asymptotic form of the ultraspherical polynomial is obtained from (5.10) and $\Delta=O(N^{-1})$ as

$$(5.18)\quad C\left(\begin{matrix}q/2+1\\ N\end{matrix}\middle|\cos\Delta\right)=O(1)P\left(\begin{matrix}(q+1)/2,\,(q+1)/2\\ N\end{matrix}\middle|\cos\Delta\right)$$

$$=O(N^{(q+1)/2})\left\{J_{(q+1)/2}(N\Delta)+O(N^{-2})\right\}.$$

Since $N_0=N+O(1)$, (4.16) and (5.18) together imply that

$$(5.19)\qquad J_{(q+1)/2}(N\Delta)=O(N^{-2})\quad\text{and}\quad J_{(q+1)/2}(N_0\Delta)=O(N^{-1}).$$

Thus the Lanczos kernel becomes, for $c/N\leqq\theta\leqq\pi-c/N$,

$$(5.20)\quad L_N(\cos\theta)=O(N^{q/2})(\sin\theta/2)^{-q/2-1}(\cos\theta/2)^{-q/2}$$

$$\times\left\{O(N^{-1})\,\cos(N_0\theta-\phi_0)+O(N^{-1})\,\cot\theta\sin(N_0\theta-\phi_0)\right.$$

$$\left.+\frac{O(N^{-2})}{\sin\theta}\cos(N_1\theta-\phi_1)+\frac{O(N^{-2})}{\sin\theta}\cot\theta\sin(N_1\theta-\phi_1)+\cdots\right\}.$$

We see that the effect of Lanczos averaging is to reduce the amplitude of the kernel in the interval $c/N\leqq\theta\leqq\pi-c/N$ by a factor $O(N^{-1})$ $\cot\theta$. The amplitude will be reduced by the same factor every time the averaging is carried out, so the amplitude of the kth order Lanczos kernel in this interval will be less than the amplitude of the Dirichlet kernel by a factor of $O(N^{-k})(\cot\theta)^k$.

In the interval $\varepsilon \leqq \theta \leqq \pi - \varepsilon$ for fixed ε, $\cot\theta$ is $O(1)$, so

$$(5.21)\qquad \int_{\varepsilon}^{\pi-\varepsilon} |L_N^{(k)}(\cos\theta)|(\sin\theta)^q d\theta = O(N^{q/2-k}).$$

Over the interval $c/N \leqq \theta \leqq \varepsilon$ we can replace $\cot\theta$ by θ^{-1}, $\sin\theta/2$ by $\theta/2$, and $\cos\theta/2$ is $O(1)$, so

$$(5.22)\qquad \int_{c/N}^{\varepsilon} |L_N^{(k)}(\cos\theta)|\,(\sin\theta)^q d\theta = O(N^{q/2-k})\int_{c/N}^{\varepsilon} \theta^{-q/2-1}\theta^{-k}\theta^q d\theta$$

$$= \begin{cases} O(1) & \text{for } q/2 < k, \\ O(\ln N) & \text{for } q/2 = k, \\ O(N^{q/2-k}) & \text{for } q/2 > k. \end{cases}$$

Over the interval $\pi - \varepsilon \leqq \theta \leqq \pi - c/N$, $\sin\theta/2$ is $O(1)$ and we can replace $\cos\theta/2$ by $(\pi-\theta)/2$, so

$$(5.23)\qquad \int_{\pi-\varepsilon}^{\pi-c/N} |L_N(\cos\theta)|\,(\sin\theta)^q d\theta = O(N^{q/2-k})\int_{c/N}^{\varepsilon} \theta^{-q/2}\theta^{-k}\theta^q d\theta$$

$$= \begin{cases} O(N^{-1}) & \text{for } q/2 \leqq k-1, \\ O(N^{q/2-k}) & \text{for } q/2 > k-1. \end{cases}$$

In the intervals $0 \leqq \theta \leqq c/N$ and $\pi - c/N \leqq \theta \leqq \pi$, Lanczos averaging does not produce any effective cancellation, and the Lanczos kernel is of the same order of magnitude as the Dirichlet kernel. (5.8) together with the asymptotic form (5.10) gives, for $0 \leqq \theta \leqq c/N$

$$(5.24)\qquad D_N(\cos\theta) = O(N^{(q+1)/2})\theta^{-(q+1)/2}J_{(q+1)/2}(N_0\theta) + \theta^2 O(N^{(q+1)/2}),$$

so that

$$(5.25)\qquad \int_0^{c/N} |L_N(\cos\theta)|(\sin\theta)^q d\theta = O(1)\int_0^{c/N} |D_N(\cos\theta)|\,(\sin\theta)^q d\theta$$

$$= O(N^{(q+1)/2})\int_0^{c/N} \theta^{-(q+1)/2}\theta^q d\theta$$

$$= O(1) \quad \text{for all } q.$$

Recalling that

$$(5.26)\qquad P\left(\begin{matrix}\alpha,\beta \\ N\end{matrix}\middle|\cos\theta\right) = (-)^N P\left(\begin{matrix}\beta,\alpha \\ N\end{matrix}\middle|\cos(\pi-\theta)\right),$$

we obtain from (5.8) and (5.10)

$$(5.27)\qquad D_N(\cos(\pi-\theta)) = O(N^{q/2+1})\theta^{-(q-1)/2}J_{(q-1)/2}(N_0\theta) + \theta^2 O(N^{(q-1)/2}),$$

so that

$$(5.28)\qquad \int_{\pi-c/N}^{\pi} |L_n(\cos\theta)|(\sin\theta)^q d\theta = O(1)\int_0^{c/N} |D_N(\cos(\pi-\theta))|(\sin\theta)^q d\theta$$

$$= O(N^{(q+1)/2})\int_0^{c/N} \theta^{-(q-1)/2}\theta^q d\theta$$

$$= O(N^{-1}) \quad \text{for all } q.$$

Combining (5.21) through (5.23), (5.25) and (5.28), we have

$$(5.29)\qquad \int_{\text{all }B} |L_N^{(k)}(A,B)|\,d\Omega(B) = \int_0^\pi |L_N^{(k)}(\cos\theta)|(\sin\theta)^q d\theta$$

$$= \begin{cases} O(1) & \text{for } q/2<k, \\ O(\ln N) & \text{for } q/2=k, \\ O(N^{q/2-k}) & \text{for } q/2>k, \end{cases}$$

and

$$(5.30)\qquad \int_{\overline{AB}\geqq\varepsilon} |L_N^{(k)}(A,B)|\,d\Omega(B) = \int_\varepsilon^\pi |L_N^{(k)}(\cos\theta)|(\sin\theta)^q d\theta$$

$$= \begin{cases} O(N^{-1}) & \text{for } q/2\leqq k-1, \\ O(N^{q/2-k}) & \text{for } q/2>k-1. \end{cases}$$

Thus the kth order Lanczos kernel is an approximate identity if $q<2k$. In particular, the first order Lanczos kernel is an approximate identity for $q=0$ or 1, the second order Lanczos kernel is an approximate identity for $q=2$ or 3, and so on.

6. Fejér and Lanczos kernels in Euclidean space. We can obtain kernels $K_V(x,y)$ in E_{q+1} from the corresponding kernels $K_\Omega(A,B)$ on the surface S_{q+1} of a $(q+2)$-dimensional sphere by a mapping $f: x\to A$ such that

$$(6.1)\qquad f:(r,\theta_1..\theta_q)\to(\theta_0(r),\theta_1..\theta_q).$$

A simple form for $\theta_0(r)$ which maps E_{q+1} onto the whole of S_{q+1} is

$$(6.2)\qquad \theta_0=2\arctan(r/a).$$

This maps widely separated points at large r in E_{q+1} onto points near the pole $\theta_0=\pi$ of S_{q+1}. This will not matter if the function we are approximating either vanishes rapidly or tends to a constant as $r\to\infty$. If however the function varies significantly with $\theta_1..\theta_q$ as $r\to\infty$, it is better to map E_{q+1} onto the half sphere $0\leqq\theta\leqq\pi/2$ by a transformation such as

$$(6.3)\qquad \theta_0=\arctan(r/a),$$

which maps points at large r with different $\theta_1..\theta_q$ onto well separated points on the sphere. Functions such as a radiating wave which oscillate at constant $\theta_1..\theta_q$ even at large r need special treatment.

The kernel $K_\Omega(A,B)$ is normalized over the full sphere; if we wish to use (6.3), we need a kernel normalized over the half sphere. Such a kernel is

$$(6.4)\qquad K_H(A,B)=K_\Omega(RA,B)+K_\Omega(A,B)$$

where R is the reflection operator

$$(6.5)\qquad R:(\theta_0,\theta_1..\theta_1)\to(\pi-\theta_0,\theta_1..\theta_q).$$

Now the part of the spherical harmonic Y which depends on θ_0 is

$$(6.6)\qquad Y\left(\begin{matrix} k_1..k_q \\ n \end{matrix}\middle|\,\theta_0,\theta_1..\theta_q\right)\propto C\left(\begin{matrix} k_1+q/2 \\ n-k_1 \end{matrix}\middle|\,\cos\theta_0\right).$$

Terms in $K_\Omega(A,B)$ which are odd functions of $\theta_0-\pi/2$ will cancel in the sum (6.4) of K_H, so only those terms for which $n-k_1$ is even will survive in the kernel K_H. The expansion of K_H is therefore

$$K_H(A,B)=2\sum_{n=0}^{N}\sigma_n\sum_{\left\{\substack{k_1..k_q\\ n-k_1\ \text{even}}\right\}}Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|A\right)Y\left(\begin{matrix}k_1..k_q\\ n\end{matrix}\middle|B\right). \tag{6.7}$$

The kernels $K_V(x,y)$ obtained from $K_\Omega(A,B)$ by a mapping of the type (5.1) are not normalized over the volume element dV_q of E_{q+1} but over the element $d\Omega_q$ of S_{q+1}. Consequently the normalization is not

$$\int K_V(x,y)\,dV(y)=1 \quad\text{or}\quad \int dV(x)K_V(x,y)=1, \tag{6.8}$$

but is instead

$$\int K_V(x,y)W(y)\,dV(y)=1 \quad\text{or}\quad \int dV(x)W(x)K_V(x,y)=1, \tag{6.9}$$

where

$$W=\frac{d\Omega_q}{dV_q}=\left(\frac{\sin\theta_0}{r}\right)^q\frac{d\theta_0}{dr} \tag{6.10}$$

is the appropriate weighting function.

ON THE ASYMPTOTIC EXPANSION OF MELLIN TRANSFORMS*

C. L. FRENZEN†

Abstract. The asymptotic behavior of the Mellin transform $M[f;\ x]$ is studied as $x \to +\infty$, and it is shown that the Mellin transform of a certain class of asymptotic sequences $\{\phi_n(t)\}$ $(t \to \infty)$ yields another asymptotic sequence $\{M[\phi_n;\ x]\}$ $(x \to \infty)$. An analogue of Watson's lemma is also established; i.e., under certain circumstances, the asymptotic expansion of $f(t)$ $(t \to \infty)$ induces an asymptotic expansion of $M[f;\ x]$ $(x \to \infty)$.

Key words. asymptotic expansion, Mellin transform

AMS(MOS) subject classifications. Primary 41A60; secondary 44A15

1. Introduction. Recently A. Sidi [7] studied the asymptotic behavior of the Mellin transform

$$M[f;\ x] = \int_0^\infty t^{x-1} f(t)\, dt \tag{1.1}$$

as $x \to +\infty$. This transform and its associated convolution have played an important role in recent developments in the asymptotic expansion of integrals; see Wong [9], and Handelsman and Lew [3]. Sidi, however, was interested in establishing a Mellin transform analogue of Watson's lemma—a result which would say that, under certain circumstances, an asymptotic expansion of $f(t)$ induces an asymptotic expansion of the Mellin transform of $f(t)$, $M[f;\ x]$. Until Sidi's work, this problem had received little attention, although Doetsch [1] and Handelsman and Lew [3] had considered the problem of analytic continuation of the Mellin transform, Riekstins [6] had considered the asymptotic expansion of the inverse Mellin transform and Wagner [8] had obtained some Tauberian theorems for Mellin transforms.

By giving several specific examples, Sidi established some evidence to support the following: under certain circumstances, (1) the dominant contribution to the Mellin transform $M[f;\ x]$ as $x \to +\infty$ comes from the large t-behavior of $f(t)$; (2) the Mellin transform of an asymptotic sequence (for $t \to \infty$) yields an asymptotic sequence (for $x \to +\infty$); (3) the Mellin transform of an asymptotic expansion (for $t \to \infty$) yields an asymptotic expansion (for $x \to +\infty$). In this note we show that (1), (2) and (3) hold for a general class of functions, sequences, and asymptotic expansions, respectively. In particular we dispense with Sidi's assumption that the Mellin transform of a specific asymptotic sequence is again an asymptotic sequence by showing that (2) holds for a general class of asymptotic sequences.

Suppose that a function $f(t)$ is locally integrable for $0 < t < \infty$, such that for some real constant σ, $t^{\sigma-1} f(t)$ is absolutely integrable in any finite interval of the form $[0, a]$, and $f(t) = o(t^{-\mu})$ as $t \to \infty$ for any $\mu > 0$. It follows that $M[f;\ z]$ exists for all sufficiently large $\operatorname{Re} z = x$. We shall say that a function $f(t)$ is in the class M (or in M) if $M[f;\ z]$ exists for all $\operatorname{Re} z = x > x_0$, where x_0 may depend on f. It is well known that

*Received by the editors February 20, 1985, and in revised form July 25, 1985.

† Department of Mathematics, Southern Methodist University, Dallas, Texas 75275.

if $f(t)$ is in M, then $M[f;\, z]$ converges absolutely and is holomorphic for all $\operatorname{Re} z = x > x_0$. Here we show that (1) holds for all real nonnegative functions in M which are strictly positive beyond some (perhaps large) value of their argument. For (2) to hold, each individual function of the asymptotic sequence must satisfy the above requirements for (1). Finally in (3) we make use of generalized asymptotic expansions. We require that the function itself and each of the functions in its generalized asymptotic expansion be in M, and that the asymptotic sequence or scale be equivalent to another asymptotic sequence which satisfies the requirements for (2).

In many ways this paper is the Mellin transform analogue of A. Erdélyi's [2] fundamental paper on generalized asymptotic expansions of Laplace integrals. However there are some differences. Erdélyi considered a one-sided Laplace integral:

$$L[g;\, x] = \int_0^\infty e^{-xu} g(u)\, du. \tag{1.2}$$

As $x \to +\infty$, the kernel e^{-xu} decreases for each fixed positive u, but decreases least rapidly for small u. Consequently the *small-u* behavior of $g(u)$ most influences the large-x behavior of $L[g;\, x]$. If $t = e^u$ and $f(t) = g(u)$ then the Mellin transform becomes a *two*-sided Laplace integral:

$$M[f;\, x] = \int_0^\infty t^{x-1} f(t)\, dt = \int_{-\infty}^\infty e^{xu} g(u)\, du. \tag{1.3}$$

The constant $\int_{-\infty}^0 |g(u)|\, du$ bounds the part $\int_{-\infty}^0 e^{xu} g(u)\, du$, which is a standard one-sided Laplace integral. In the remaining part, $\int_0^\infty e^{xu} g(u)\, du$, as $x \to \infty$ the kernel e^{xu} increases for each fixed positive u, and increases most rapidly for large u. Hence it is the *large-t* behavior of $f(t)$ which most influences the large-x behavior of $M[f;\, x]$.

Since the Mellin transform of a function in M converges in the complex half plane $x > x_0$, it is also natural to ask, in an attempt to extend the validity of (2), whether it is possible for an asymptotic sequence $\{\phi_n(t)\}$ for $t \to \infty$ to induce an asymptotic sequence $\{M[\phi_n;\, z]\}$ as z tends to infinity in some region of the complex plane. By means of a simple example we show that limited results in this direction are possible.

2. A basic inequality. Throughout this paper t is a real variable, z is a complex variable, and we always write $z = x + iy$. The Mellin transform analogue of Watson's lemma will follow from a result relating the relative behavior of two functions at $t = \infty$ to the relative behavior of their Mellin transforms at $x = \infty$. Let the two functions be denoted by $g(t)$ and $h(t)$, and their Mellin transforms by $M[g;\, x]$ and $M[h;\, x]$. The result below is the Mellin transform analogue of Lemma 1 in [2].

LEMMA 1. *Suppose g and h are in M, $h(t) \geqq 0$, and $h(t) > 0$ for $t_1 < t < \infty$ for some $t_1 > 0$. Then*

$$\limsup_{z \to \infty} \frac{|M[g;\, z]|}{M[h;\, x]} \leqq \operatorname{ess\,lim\,sup}_{t \to \infty} \frac{|g(t)|}{h(t)} \tag{2.1}$$

when $z \to \infty$ in such a manner that $x \to +\infty$.

Proof. If g and h are in M, they possess Mellin transforms for $x > x_0$ for some x_0, so that $M[g;\, z]$ and $M[h;\, x]$ exist and $M[h;\, x] > 0$ whenever $x > x_0$. Let $x_1 > x_0$, and assume $\operatorname{Re} z = x \geqq x_1$. For some fixed T, $t_1 < T < \infty$, we write $M[g;\, z] = I_1 + I_2$ where

$$I_1 = \int_0^T t^{z-1} g(t)\, dt, \tag{2.2}$$

and

$$I_2=\int_T^\infty t^{z-1}g(t)\,dt. \tag{2.3}$$

From (2.2) we have

$$|I_1|\leqq\int_0^T t^{x_1-1}|g(t)|t^{x-x_1}\,dt\leqq B(T,x_1)T^{x-x_1}, \tag{2.4}$$

where $B(T,x_1)$ is a constant depending only on T and x_1. This result follows from the absolute convergence of $M[g;\ x]$ for $x\geqq x_1>x_0$.

We set

$$U_T=\operatorname{ess\,sup}\left[\frac{|g(t)|}{h(t)}:T<t<\infty\right] \tag{2.5}$$

and assume that $U_T<\infty$ for some T. (Otherwise the right-hand side of (2.1) is equal to $+\infty$ and there is nothing to prove.) Then $|g(t)|\leqq U_T h(t)$ for almost all $t>T$, and so

$$|I_2|\leqq\int_T^\infty t^{x-1}U_T h(t)\,dt\leqq U_T M[h;\ x]. \tag{2.6}$$

Consequently, for any $t_1<T<\infty$, we have

$$\frac{|M[g;\ z]|}{M[h;\ x]}\leqq U_T+\frac{B(T,x_1)T^{x-x_1}}{M[h;\ x]}. \tag{2.7}$$

Now by the conditions imposed on $h(t)$, for every $\varepsilon>0$ we have

$$M[h;\ x]\geqq\int_{e^\varepsilon T}^\infty t^{x_1-1}h(t)t^{x-x_1}\,dt\geqq e^{\varepsilon(x-x_1)}T^{x-x_1}\int_{e^\varepsilon T}^\infty t^{x_1-1}h(t)\,dt, \tag{2.8}$$

where the last integral in (2.8) is a constant $D(\varepsilon,T,x_1)$ depending only on ε, T and x_1 and is bounded away from zero as $\varepsilon\to 0$. Using (2.8) in (2.7) gives

$$\frac{|M[g;\ z]|}{M[h;\ x]}\leqq U_T+\frac{B(T,x_1)}{D(\varepsilon,T,x_1)}e^{-\varepsilon(x-x_1)}. \tag{2.9}$$

Now let $z\to\infty$ in a manner satisfying the last condition of the lemma, i.e. so that $x\to+\infty$ as well. The second term on the right-hand side of (2.9) then approaches zero and

$$\limsup_{z\to\infty}\frac{|M[g;\ z]|}{M[h;\ x]}\leqq U_T. \tag{2.10}$$

Since the left-hand side of (2.10) is independent of T, and the right-hand side tends to the right hand of (2.1) as $T\to\infty$, this proves the lemma. □

Note that the last condition in the lemma is satisfied if z tends to infinity in the sector $S_\Delta:|\arg z|\leqq\pi/2-\Delta$, $\Delta>0$.

We now show that under certain circumstances (1) holds—that the dominant contribution to $M[h;\ x]$ for $x\to\infty$ comes from the large t-behavior of $h(t)$. This is suggested by Lemma 1, in which only large values of t are important. Specifically, suppose that h_1 and h_2 are in M and $h_1(t)=h_2(t)>0$ for $t_2<t<\infty$ for some $t_2>0$. Then

$$M[h_1;\ x]-M[h_2;\ x]=\int_0^{t_2}t^{x-1}[h_1(t)-h_2(t)]\,dt=O(t_2^x) \tag{2.11}$$

as $x\to\infty$ by an argument similar to that leading to (2.4). Without loss of generality, we shall assume $t_2>1$. Then $\log t_2>0$ and from (2.11) we have for $\log t_2<\delta<\infty$

$$(2.12)\qquad e^{3\delta x/2}(M[h_1;\, x]-M[h_2;\, x])\to 0 \qquad (x\to\infty).$$

Now by the conditions on h_1 and h_2, for $x\geqq x_1>x_0$

$$(2.13)\quad M[h_1;\, x]\geqq -\int_0^{t_2} t^{x_1-1}|h_1(t)|t^{x-x_1}\,dt+\int_{e^{2\delta}t_2}^{\infty} t^{x_1-1}h_1(t)t^{x-x_1}\,dt$$

$$\geqq -t_2^{x-x_1}\int_0^{t_2} t^{x_1-1}|h_1(t)|\,dt+t_2^{x-x_1}e^{2\delta(x-x_1)}\int_{e^{2\delta}t_2}^{\infty} t^{x_1-1}h_1(t)\,dt.$$

From (2.13) it follows that

$$(2.14)\qquad e^{-3\delta x/2}M[h_1;\, x]\to\infty \qquad (x\to\infty),$$

and a similar argument holds for $e^{-3\delta x/2}M[h_2;\, x]$. This result together with (2.12) implies that

$$(2.15)\qquad \frac{M[h_1;\, x]}{M[h_2;\, x]}\to 1 \qquad (x\to\infty).$$

Since t_2 was arbitrary, (2.15) shows that the dominant contribution to $M[h;\, x]$ as $x\to\infty$ for $h(t)>0$ beyond some value of t comes from the large t-behavior of $h(t)$.

3. Asymptotic sequences. The results of the preceding section may be used to show that under certain circumstances the Mellin transforms $\{M[\phi_n;\, x]\}$ of an asymptotic sequence $\{\phi_n(t)\}$ form an asymptotic sequence.

THEOREM 1. (i) *Suppose that $\{\phi_n(t)\}$ is an asymptotic sequence for $t\to\infty$ and for each n, $\phi_n(t)$ is in M, $\phi_n(t)\geqq 0$ and $\phi_n(t)>0$ for $t_n<t<\infty$. Then $\{M[\phi_n;\, x]\}$ is an asymptotic sequence as $x\to\infty$.*

(ii) *If, in addition, there is an unbounded set R in the complex plane such that $x\to\infty$ whenever $z\to\infty$ in R, and if for each n,*

$$(3.1)\qquad M[\phi_n;\, x]=O(M[\phi_n;\, z])$$

as $z\to\infty$ in R, then $\{M[\phi_n;\, z]\}$ is also an asymptotic sequence as $z\to\infty$ in R.

Proof. (i) From Lemma 1, we have

$$(3.2)\qquad \limsup_{x\to+\infty}\frac{M[\phi_{n+1};\, x]}{M[\phi_n;\, x]}\leqq \operatorname{ess}\limsup_{t\to\infty}\frac{\phi_{n+1}(t)}{\phi_n(t)}$$

and the right-hand side is zero since $\{\phi_n(t)\}$ is an asymptotic sequence. Hence $M[\phi_{n+1};\, x]=o(M[\phi_n;\, x])$ as $x\to\infty$, and this proves the first half of the theorem.

(ii) Since $\phi_n(t)\geqq 0$, we have

$$(3.3)\qquad |M[\phi_n;\, z]|\leqq\int_0^\infty t^{x-1}\phi_n(t)\,dt=M[\phi_n;\, x]$$

so that $M[\phi_n;\, z]=O(M[\phi_n;\, x])$ as $z\to\infty$ in R. Since by (3.1) we also have $M[\phi_n;\, x]=O(M[\phi_n;\, z])$, it follows that the two sequences $\{M[\phi_n;\, x]\}$ and $\{M[\phi_n;\, z]\}$ are equivalent as $z\to\infty$ in R. Since by part (i) the first sequence is asymptotic, the second must also be asymptotic. □

Example 1. Consider the sequence $\{\phi_n(t)\}$ with $\phi_n(t)=t^{-\lambda_n}\exp(-\alpha_n t^{\beta_n})$, where λ_n, α_n and β_n are real. The sequence $\{\phi_n(t)\}$ is an asymptotic sequence as $t\to\infty$ in any one of the following cases: for $n > m$

(a) $\beta_n > \beta_m > 0$, and $\alpha_k > 0$, $k = 1,2,3 \cdots$.

(b) $\beta_n \geqq \beta_m > 0$ and $\alpha_k > 0$, $k = 1,2,3 \cdots$; when $\beta_m = \beta_n$, then $\alpha_n > \alpha_m > 0$.

(c) $\beta_n \geqq \beta_m > 0$ and $\alpha_k > 0$, $k = 1,2,3 \cdots$; when $\beta_m = \beta_n$, then $\alpha_n > \alpha_m > 0$; when $\beta_m = \beta_n$ and $\alpha_m = \alpha_n > 0$, then $\lambda_n > \lambda_m$.

Note that each $\phi_n(t)$ is in M if $x > \lambda_n$. The sequence $\{\phi_n(t)\}$ satisfies the conditions of Theorem 1(i), and hence, as is easily checked, the sequence $\{M[\phi_n;\ x]\}$ where

$$(3.4) \qquad M[\phi_n;\ x] = \frac{1}{\beta_n} \alpha_n^{-(x-\lambda_n)/\beta_n} \Gamma\left(\frac{x-\lambda_n}{\beta_n}\right) \qquad (x > \lambda_n)$$

is an asymptotic sequence as $x \to \infty$ under any of the conditions (a), (b), (c). In this example one can also allow α_n to be complex. The sequence $\{\phi_n(t)\}$ then becomes complex valued and Theorem 1 (i) is no longer applicable, but the path of integration in $M[\phi_n;\ x]$ may be rotated and further conditions placed on the sequences $\{|\alpha_n|\}$ and $\{\operatorname{Re} \alpha_n\}$ so that the sequence $\{M[\phi_n;\ x]\}$ is again asymptotic. This particular example was treated by Sidi [7, Thm. 2.1].

The next example illustrates that in certain cases the domain R in Theorem 1 (ii) in which $M[\phi_n;\ x]$ and $M[\phi_n;\ z]$ are equivalent asymptotic sequences may not be the largest domain in the complex plane in which $M[\phi_n;\ z]$ is an asymptotic sequence.

Example 2. Consider the sequence $\{\phi_n(t)\}$ where $\phi_n(t) = e^{-\alpha_n t}$ and $\alpha_{n+1} > \alpha_n > 0$. As $t \to \infty$, $\{\phi_n(t)\}$ is an asymptotic sequence and each $\phi_n(t)$ is in M. Since $M[\phi_n;\ z] = \alpha_n^{-z}\Gamma(z)$, $\operatorname{Re} z > 0$, we have

$$(3.5) \qquad \frac{|M[\phi_n;\ z]|}{M[\phi_n;\ x]} = \frac{|\alpha_n^{-z}\Gamma(z)|}{\alpha_n^{-x}\Gamma(x)} = \frac{|\Gamma(z)|}{\Gamma(x)} \leqq 1 \qquad (\operatorname{Re} z = x > 0);$$

see, for example [5, p. 38]. Therefore $M[\phi_n;\ z] = O(\mathrm{M}[\phi_n;\ x])$, and to apply Theorem 1 (ii), we need to exhibit an unbounded set R with $x \to \infty$ whenever $z \to \infty$ in R, such that, for each n, $M[\phi_n;\ x] = O(M[\phi_n;\ z])$ as $z \to \infty$ in R. Since

$$(3.6) \qquad I = \left(\frac{\Gamma(x)}{|\Gamma(z)|}\right)^2 = \prod_{n=0}^{\infty}\left(1 + \frac{y^2}{(x+n)^2}\right)$$

(see [5, p. 38], for example) this means finding an R such that as $z \to \infty$ in R, $x \to \infty$ and the right-hand side of (3.6) is bounded. From the latter, we have

$$(3.7) \qquad \log I = \sum_{n=0}^{\infty} \log\left(1 + \frac{y^2}{(x+n)^2}\right) = \sum_{n=0}^{\infty}\left(\frac{y^2}{(x+n)^2} + O\left(\frac{y^4}{(x+n)^4}\right)\right)$$
$$= y^2\zeta(2,x) + O(y^4\zeta(4,x))$$

where $\zeta(m,x) = \sum_{n=0}^{\infty}(1/(x+n)^m)$ is the generalized zeta function. For fixed m and large positive x, $\zeta(m,x) = 1/(m-1)x^{1-m} + O(x^{-m})$ (see [4, p. 25]), and using this in (3.7) gives

$$(3.8) \qquad \log I = \frac{y^2}{x} + O\left(\frac{y^2}{x^2}\right).$$

Thus $\log I$, and consequently I, is bounded as $z \to \infty$ in R if R consists of a region of the complex plane in which

$$(3.9) \qquad (\operatorname{Im} z)^2 = O(\operatorname{Re} z) \qquad (z \to \infty, \operatorname{Re} z = x > 0).$$

In this region $x \to \infty$ as $z \to \infty$ and $M[\phi_n; x] = O(M[\phi_n; z])$, so that by Theorem 1 (ii) $\{M[\phi_n; z]\}$ is an asymptotic sequence as $z \to \infty$ in R, defined in (3.9). However,

$$\frac{|M[\phi_{n+1}; z]|}{|M[\phi_n; z]|} = \left(\frac{\alpha_n}{\alpha_{n+1}}\right)^x, \tag{3.10}$$

and the right-hand side of (3.10) tends to zero as $x \to \infty$. Consequently, for example, $M[\phi_n; z]$ is an asymptotic sequence as $z \to \infty$ in the sector $S_\Delta = \{z : |\arg z| \leqq \pi/2 - \Delta, \Delta > 0\}$, a larger region than that in (3.9), which was determined from Theorem 1 (ii).

Example 3. Consider the sequence $\{\phi_n(t)\}$ where

$$\phi_n(t) = \begin{cases} 0, & t < c, \\ (\log t)^{a_n} e^{-b_n t}, & t \geqq c \end{cases} \tag{3.11}$$

where $c > 1$ and $b_n > 0$ for all n. As $t \to \infty$, the sequence $\{\phi_n(t)\}$ is an asymptotic sequence under either of the conditions

(a′) $b_{n+1} > b_n > 0$,

(b′) $b_{n+1} \geqq b_n > 0$; if $b_{n+1} = b_n$ then $a_{n+1} < a_n$.

By Theorem 1, $M[\phi_n; x]$ will be an asymptotic sequence under (a′) or (b′) as $x \to +\infty$. We now confirm this. Note that if a_n is a positive integer, the asymptotic behavior of

$$M[\phi_n; x] = \int_c^\infty t^{x-1} (\log t)^{a_n} e^{-b_n t} dt \tag{3.12}$$

may be obtained by considering the derivative of the incomplete gamma function.

Now write (3.12) as

$$M[\phi_n; x] = I_1 + I_2 + I_3 \tag{3.13}$$

where

$$I_1 = \int_c^{x^{1-\delta}} t^{x-1} (\log t)^{a_n} e^{-b_n t} dt, \tag{3.14}$$

$$I_2 = x^x (\log x)^{a_n} \int_{x^{-\delta}}^{x^\delta} y^{x-1} \left(1 + \frac{\log y}{\log x}\right)^{a_n} e^{-b_n x y} dy \tag{3.15}$$

and

$$I_3 = \int_{x^{1+\delta}}^\infty t^{x-1} (\log t)^{a_n} e^{-b_n t} dt, \tag{3.16}$$

with δ a positive number satisfying $0 < \delta < 1$. We estimate I_1 as follows:

$$I_1 \leqq e^{-b_n c} \left((1-\delta)^{|a_n|} (\log x)^{|a_n|}\right) \int_c^{x^{1-\delta}} t^{x-1} dt. \tag{3.17}$$

Equation (3.17) implies

$$I_1 = O\left((\log x)^{|a_n|} x^x x^{-\delta x - 1}\right) \qquad (x \to +\infty). \tag{3.18}$$

To estimate I_3, note that for any a_n there exists a constant A_n such that

$$(\log t)^{|a_n|} \leqq A_n t, \qquad x^{1+\delta} \leqq t < \infty,$$

and since $b_n t/2x < \exp(b_n t/2x)$ it follows that $t^x < (2x/b_n)^x \exp(b_n t/2)$ for $x^{1+\delta} \leqq t < \infty$. Consequently

$$I_3 \leqq A_n \left(\frac{2x}{b_n}\right)^x \int_{x^{1+\delta}}^\infty e^{-b_n t/2} dt \tag{3.19}$$

or

$$I_3 = O\left(e^{-b_n x^{\delta/2}/2}\right) \qquad (x \to \infty). \tag{3.20}$$

To evaluate I_2, note from (3.15) that within its range of integration $|\log y/\log x| \leqq \delta < 1$, and so using the finite binomial expansion gives

$$\left(1 + \frac{\log y}{\log x}\right)^{a_n} = \sum_{j=0}^{N} \binom{a_n}{j}\left(\frac{\log y}{\log x}\right)^j + R_N, \tag{3.21}$$

where N is a positive integer and

$$|R_N| \leqq K \left|\left(\frac{\log y}{\log x}\right)^{N+1}\right| \tag{3.22}$$

for some fixed $K > 0$. Substituting (3.21) into (3.15) gives

$$I_2 = x^x (\log x)^{a_n} \sum_{j=0}^{N} \binom{a_n}{j} (\log x)^{-j} B_j(x) + r_N(x) \tag{3.23}$$

where

$$B_j(x) = \int_{x^{-\delta}}^{x^{\delta}} e^{-x(b_n y - \log y)} \frac{(\log y)^j}{y}\, dy \tag{3.24}$$

and

$$|r_N(x)| \leqq K x^x (\log x)^{a_n - N - 1} \int_{x^{-\delta}}^{x^{\delta}} y^{x-1} |\log y|^{N+1} e^{-b_n x y}\, dy. \tag{3.25}$$

Since

$$B_j(x) \sim \int_0^\infty e^{-x(b_n y - \log y)} \frac{(\log y)^j}{y}\, dy \tag{3.26}$$

as $x \to +\infty$, by (a modification of) the method of Laplace (see [5]),

$$B_j(x) \sim \sqrt{\frac{2\pi}{x}}\, e^{-x} b_n^{-x} (-\log b_n)^j \qquad (x \to \infty). \tag{3.27}$$

A similar estimate in (3.25) coupled with (3.27) and (3.23) then shows that

$$I_2 \sim x^x (\log x)^{a_n} e^{-x} b_n^{-x} \sqrt{\frac{2\pi}{x}} \qquad (x \to \infty) \tag{3.28}$$

and from (3.13), (3.18) and (3.20) it follows that

$$M[\phi_n;\, x] \sim x^x (\log x)^{a_n} e^{-x} b_n^{-x} \sqrt{\frac{2\pi}{x}} \qquad (x \to \infty). \tag{3.29}$$

Thus, the sequence $\{M[\phi_n;\, x]\}$ is indeed an asymptotic sequence under either conditions (a′) or (b′), in agreement with Theorem 1.

4. Asymptotic expansions. We will now use the previous results to deduce asymptotic expansions of Mellin transforms. Let $\{\psi_n(t)\}$ be an asymptotic sequence as $t \to \infty$ and $f(t)$, $f_k(t)$, $k = 0, 1, \cdots$, functions such that for each nonnegative integer n

$$f(t) = \sum_{k=0}^{n} f_k(t) + o(\psi_n(t)) \qquad (t \to \infty). \tag{4.1}$$

Then we say that $\Sigma f_k(t)$ is a *generalized asymptotic expansion of $f(t)$ with respect to the asymptotic sequence* $\{\psi_n(t)\}$ and write

$$f(t) \sim \sum_{k=0}^{\infty} f_k(t), \qquad \{\psi_k(t)\} \qquad (t \to \infty). \tag{4.2}$$

Our main result is the following analogue of Watson's lemma for Mellin transforms.

THEOREM 2. *Let $\{\psi_n(t)\}$ be an asymptotic sequence for $t \to \infty$ which is equivalent to a sequence $\{\psi_n(t)\}$ satisfying the conditions of Theorem 1. Let R be an unbounded region of the complex plane such that $x \to +\infty$ as $z \to \infty$ in R, and let $\{X_n(z)\}$ be a sequence equivalent to $\{M[\phi_n;\, x]\}$ as $z \to \infty$ in R. If, under these circumstances,*

$$f(t) \sim \sum_{k=0}^{\infty} f_k(t), \qquad \{\psi_k(t)\} \qquad (t \to \infty) \tag{4.3}$$

where $f(t)$ and all the $f_k(t)$ are in M, then

$$M[f, z] \sim \sum_{k=0}^{\infty} M[f_k;\, z], \qquad \{X_k(z)\} \tag{4.4}$$

as $z \to \infty$ in R.

Proof. Fix n and set

$$g(t) = f(t) - \sum_{k=0}^{n} f_k(t), \qquad h(t) = \phi_n(t). \tag{4.5}$$

Then $g(t)$ and $h(t)$ are in M, $\phi_n(t) \geqq 0$ and $\phi_n(t) > 0$ for $t_n < t < \infty$. Since by (4.3) and (4.5), $g(t) = o(\psi_n(t))$ as $t \to \infty$ and $\{\psi_n(t)\}$ and $\{\phi_n(t)\}$ are equivalent asymptotic sequences, we also have $g(t) = o(\phi_n(t))$ as $t \to \infty$. Applying Lemma 1 to $g(t)$ and $h(t)$, it follows that

$$M[g;\, z] = o(M[\phi_n;\, x]) \tag{4.6}$$

as $z \to \infty$ in R. However since $\{M[\phi_n;\, x]\}$ and $\{X_n(z)\}$ are equivalent asymptotic sequences as $z \to \infty$ in R, it is also true that

$$M[g;\, z] = o(X_n(z)) \tag{4.7}$$

as $z \to \infty$ in R, or

$$M[f;\, z] - \sum_{k=0}^{n} M[f_k;\, z] = o(X_n(z)) \tag{4.8}$$

as $z \to \infty$ in R. Since (4.8) holds for each n, we have the conclusion of the theorem. □

Note that in the real case $z = x$ and one may take $X_n(z) = M[\phi_n;\, x]$. Theorem 2 extends Sidi's Theorem 2.1 [7] to a wide class of asymptotic sequences and, in view of a remark following (3.4), covers some of the examples in [7] too.

Example 4. Consider the integral

$$I(x) = \int_0^{\infty} t^{x-1}(1+t)^{-1/2}\left(1 + b\exp\left(a(1+t)^{1/2}\right)\right)^{-\nu} dt \tag{4.9}$$

where a, b and ν are fixed positive constants. The asymptotic expansion of $I(x)$ is not easily obtained from Sidi's theory. However the function

$$f(t)=(1+t)^{-1/2}\left(1+b\exp\left(a(1+t)^{1/2}\right)\right)^{-\nu} \tag{4.10}$$

in the integrand of (4.9) is in M, and

$$f(t)\sim\sum_{k=0}^{\infty}f_k(t),\qquad\{\psi_k(t)\}\qquad(t\to\infty), \tag{4.11}$$

where

$$f_k(t)=(1+t)^{-1/2}\binom{-\nu}{k}b^{-(\nu+k)}\exp\left(-a(k+\nu)(1+t)^{1/2}\right) \tag{4.12}$$

and

$$\psi_k(t)=(1+t)^{-1/2}\exp\left(-a(k+\nu)(1+t)^{1/2}\right) \tag{4.13}$$

both satisfy the requirements of Theorem 2. Consequently, since $I(x)=M[f;\ x]$,

$$I(x)\sim\sum_{k=0}^{\infty}M[f_k;\ x],\qquad\{M[\psi_k;\ x]\} \tag{4.14}$$

as $x\to\infty$. From [5, p. 254], for example, we have

$$M[\psi_k;\ x]=\frac{2}{\pi^{1/2}}\frac{\Gamma(x)K_{x-1/2}(a(k+\nu))}{(a(k+\nu)/2)^{x-1/2}}. \tag{4.15}$$

Note that the asymptotic behavior of $K_x(a)$ for fixed argument and large order is

$$K_x(a)\sim\left(\frac{\pi}{2x}\right)^{1/2}\left(\frac{2x}{ea}\right)^{x}\qquad(a\text{ fixed, }x\to+\infty); \tag{4.16}$$

see, for example [5, p. 328]. Combining the above results and applying Theorem 2, we obtain

(4.17)

$$I(x)\sim\frac{2\Gamma(x)}{\pi^{1/2}}\sum_{k=0}^{\infty}\binom{-\nu}{k}b^{-(\nu+k)}\frac{K_{x-1/2}(a(k+\nu))}{(a(k+\nu)/2)^{x-1/2}},\qquad\left\{\frac{\Gamma(x)K_{x-1/2}(a(k+\nu))}{(a(k+\nu)/2)^{x-1/2}}\right\}$$

as $x\to+\infty$.

Acknowledgments. The author would like to thank Professor R. Wong for informing him about this problem, for his comments on an earlier version of this paper and for his hospitality during the summer of 1984. Also to be thanked are Professors B. Seymour and L. Mysak of the University of British Columbia Institute of Applied Mathematics where this work initially began. Lastly, thanks are due to the referee and Professor F. W. J. Olver, whose comments and suggestions helped to improve this paper.

POSITIVE SOLUTION OF A PROBLEM OF EMDEN–FOWLER TYPE WITH A FREE BOUNDARY*

GEORGES IFFLAND†

Abstract. A sufficient condition is given for the existence of a solution for a generalized Emden–Fowler problem with a free end point. In the special case of the Emden–Fowler equation, this condition is also necessary; and moreover, a monotone iteration scheme holds for the approximation of a positive solution.

Key words. Emden–Fowler equation, nonlinear boundary value problem, free boundary problem, monotone iteration method

AMS(MOS) subject classifications. 34B15, 34A45

1. Introduction. We are interested in the question of existence of a solution of the following free end point problem. Find $T>0$ and $y\in C[0,T]\cap C^1[0,T)\cap C^2(0,T)$ such that

$$\begin{aligned}&y''(t)+q(t)y(t)^\gamma=0, \qquad t\in(0,T),\\ &y(0)=y(T)=0, \qquad y'(0)=\alpha, \qquad (1.1)\\ &y(t)>0, \qquad t\in(0,T),\end{aligned}$$

where $\gamma\geqq 1$, $\alpha>0$ and q, a positive function, are given. With $q(t):=t^\beta$, (1.1) gives the Emden–Fowler equation [10]. Its origin lies in theories concerning gaseous dynamics in astrophysics around the turn of the century [2]; see [10] for more recent applications. In this special case, (1.1) can be written

$$\begin{aligned}&y''(t)+t^\beta y(t)^\gamma=0, \qquad t\in(0,T),\\ &y(0)=y(T)=0, \qquad y'(0)=\alpha, \qquad (1.2)\\ &y(t)>0, \qquad t\in(0,T).\end{aligned}$$

The question of existence of a solution of (1.1) is related to that of existence of oscillatory solutions of the differential equation

$$y''(t)+q(t)y(t)^\gamma=0. \qquad (1.3)$$

This problem has been profusely studied; see for example [4], [10] or [3]. In this case, γ is supposed to be the quotient of odd, positive integers. For $\gamma:=2n-1$, where $n=2,3,\cdots$, a result of Atkinson [1] allows one to show the existence of a solution of (1.1) if $\int^\infty tq(t)\,dt=\infty$; for problem (1.2), this condition becomes $\beta>-2$. Owing to a theorem of Hinton [5], we are able to give a more general (sufficient) condition for the existence of a solution of (1.1). Moreover, this condition is necessary and sufficient if $q(t):=t^\beta$; it then becomes $\gamma+2\beta+3>0$.

Problem (1.2) can be set in the form of an eigenvalue problem of the following type

$$\begin{aligned}&x''(\tau)+\lambda a(\tau)x(\tau)^\gamma=0, \qquad \tau\in(0,1),\\ &x(0)=x(1)=0, \qquad x'(0)=1, \qquad (1.4)\\ &x(\tau)>0, \qquad \tau\in(0,1).\end{aligned}$$

* Received by the editors December 21, 1984, and in revised form May 15, 1985.

† Département de mathématiques, Ecole polytechnique fédérale, CH-1015 Lausanne, Switzerland.

A monotone iteration method has been proposed by Luning and Perry [7], in order to establish the existence of a solution of (1.4). Their proof needs the assumption $a \in L^1(0, 1)$; for problem (1.2) it becomes $\beta > -1$. Without such a restriction, we show first the convergence of the iterative method to a solution of (1.4), if the existence of a solution is presupposed. The method can then be applied to the Emden–Fowler problem, that is for $a(\tau) := \tau^\beta$, with $\gamma + 2\beta + 3 > 0$.

Let us further point out a problem related to (1.1). We introduce the following initial value problem

$$\begin{aligned} &y''(t) + q(t)y(t)^\gamma = 0, \qquad t \in (0, \infty), \\ &y(0) = 0, \qquad y'(0) = \alpha, \\ &y(t) > 0, \qquad t \in (0, \infty). \end{aligned} \tag{1.5}$$

Under quite general assumptions, (1.3) has a positive solution satisfying the initial condition $y(0) = 0$, $y'(0) = \alpha$. Moreover, y may be chosen such that the following alternative holds: either y is solution of (1.5), or there exists a $T > 0$ such that (T, y) is a solution of (1.1).

Notation and definitions. Let y_1 and y_2 be functions defined on the same interval I (bounded or not). Then $y_1 \leqq y_2$ iff $\forall t \in I$: $y_1(t) \leqq y_2(t)$; $y_1 < y_2$ iff $y_1 \leqq y_2$ and $y_1 \neq y_2$. A function y is *positive* if $y > 0$. A sequence (y_n) of functions is *increasing* iff $y_n \leqq y_{n+1}$ for all $n \in \mathbb{N}$; it is *decreasing* iff $(-y_n)$ is increasing.

2. Existence result for (1.1). Let us introduce the following conditions:

(H1) $\alpha > 0$, $\gamma \geqq 1$.

(H2) $q \in C^2(0, \infty)$, $\forall t > 0$: $q(t) > 0$, $t \mapsto t^\gamma q(t)$ belongs to $L^1(0, 1)$.

(H3) $\eta\eta'' \in L^1(1, \infty)$, where $\eta \in C^2(0, \infty)$ is the function defined by $\eta(t) := [q(t)]^{-1/(\gamma+3)}$.

(H4) $\int_1^\infty [\eta(t)]^{-2}\, dt = \infty$.

(H5) If $\gamma > 1$: $\lim_{t \downarrow 0} t^{-1}\eta(t)[\int_t^\infty \eta(s)|\eta''(s)|\, ds]^{2/(\gamma-1)} = 0$.

The main result is contained in Theorem 2.1; its proof partly reproduces Hinton's [5] and will be given later.

THEOREM 2.1. *Let assumptions* (H1)-(H5) *be satisfied. Then problem* (1.1) *has a unique solution* (T, y), *with* $y \in C[0, T] \cap C^1[0, T) \cap C^2(0, T)$.

LEMMA 2.2. *Let assumptions* (H1) *and* (H2) *be satisfied. Then problem*

$$\begin{aligned} &y''(t) + q(t)y(t)^\gamma = 0, \\ &y(0) = 0, \qquad y'(0) = \alpha \end{aligned} \tag{2.1}$$

has a positive (*local*) *solution.*

Proof. One establishes the existence of a solution by an alternating iteration method, like the one used for example by Stuart [8]. Let us introduce the following iteration scheme

$$y_{n+1}(t) := \alpha t - \int_0^t (t-s)q(s)y_n(s)^\gamma\, ds. \tag{2.2}$$

Set $y_0 := 0$; by (2.2) define y_1: $t \mapsto \alpha t$. Then

$$y_2\colon \quad t \mapsto \alpha t\left(1 - \alpha^{\gamma-1} \int_0^t \left(1 - \frac{s}{t}\right) q(s)s^\gamma\, ds\right).$$

By assumption (H2), a $t^*>0$ can be chosen such that y_2 remains positive on $(0, t^*)$. By means of formula (2.2), an alternating sequence is defined:

$$0=y_0 \leqq y_2 \leqq y_{2n} \leqq y_{2n+1} \leqq y_3 \leqq y_1=\alpha t, \quad \text{on } [0, t^*].$$

Differentiating (2.2):

$$\alpha \geqq y_{n+1}'(t)=\alpha-\int_0^t q(s) y_n(s)^\gamma \, ds \geqq \alpha-\alpha^\gamma \int_0^{t^*} q(s) s^\gamma \, ds, \qquad t \in [0, t^*].$$

The sequence (y_n') being uniformly bounded, the Arzelà-Ascoli theorem implies the existence of a convergent subsequence of (y_n). The subsequence (y_{2n}), increasing and containing a convergent subsequence, is convergent itself to a function $\bar{y}$, uniformly on $[0, t^*]$. Likewise, the decreasing subsequence (y_{2n+1}) converges to a function $\hat{y}$. Moreover

$$\begin{aligned} \bar{y}(t) &= \alpha t-\int_0^t (t-s) q(s) \hat{y}(s)^\gamma \, ds \\ &\leqq \alpha t-\int_0^t (t-s) q(s) \bar{y}(s)^\gamma \, ds=\hat{y}(t), \qquad t \in [0, t^*]. \end{aligned} \tag{2.3}$$

Define $w:=\hat{y}-\bar{y}$. The following inequality holds:

$$\forall t \in [0, t^*]: \quad 0 \leqq \hat{y}(t)^\gamma-\bar{y}(t)^\gamma \leqq \gamma y_1(t)^{\gamma-1} w(t) \leqq C w(t) \tag{2.4}$$

where $C>0$ is a constant. Introduce (2.4) into (2.3):

$$0 \leqq w(t) \leqq C \int_0^t (t^*-s) q(s) w(s) \, ds, \qquad t \in [0, t^*].$$

By Gronwall's lemma, $w=0$. The function $y:=\bar{y}=\hat{y}$ satisfies

$$y(t)=\alpha t-\int_0^t (t-s) q(s) y(s)^\gamma \, ds, \qquad t \in [0, t^*]$$

and is a solution of (2.1) on $[0, t^*]$. □

LEMMA 2.3. *Every positive solution of* (2.1) *may be extended to a function* $\tilde{y}$ *for which the following alternative holds*:

(i) $\tilde{y}$ *is a solution of* (1.5);

(ii) *there exists a* $T>0$ *such that* $(T, \tilde{y})$ *is a solution of* (1.1).

Proof. Let y be a positive solution of (2.1) and $\tilde{y}$ be the maximal positive extension of y. If $\tilde{y}$ is defined for each $t>0$, we are in case (i) and $\tilde{y}(t)>0$ on $(0, \infty)$. Assume now that y is only defined on a bounded interval I. As $\tilde{y}$ is positive and concave, I must be closed; write $I=[0, T]$. If $\tilde{y}(T)>0$, Peano's existence theorem would allow one to extend $\tilde{y}$ at the the right side of I; but it is in contradiction with the definition of $\tilde{y}$. Hence $\tilde{y}(T)=0$. □

LEMMA 2.4. *Suppose* $\gamma>1$. *Assume conditions* (H2), (H3) *and* (H5) *to be satisfied. Let* y *be a positive,* C^1 *function, such that* $y(0)=0$ *and* $y'(0)>0$. *Then for every* $\chi>0$ *there exists a* $t_0>0$ *such that*

$$y(t_0)>\chi \eta(t_0)\left[\int_{t_0}^\infty \eta(s)|\eta''(s)| \, ds\right]^{2/(\gamma-1)}. \tag{2.5}$$

Proof. By contradiction, assume the existence of a $C>0$, such that for every t, in a neighbourhood of zero, the following inequality holds:

$$y(t) \leqq C \eta(t)\left[\int_t^\infty \eta(s)|\eta''(s)| \, ds\right]^{2/(\gamma-1)}.$$

Dividing by t and letting t tend to zero, we get

$$0 < y'(0) \leqq C \lim_{t \downarrow 0} t^{-1}\eta(t)\left[\int_t^\infty \eta(s)|\eta''(s)|\,ds\right]^{2/(\gamma-1)},$$

in contradiction with assumption (H5). □

Proof of Theorem 2.1. (i) Uniqueness is easily established by using an inequality of (2.4) type and Gronwall's lemma. Then owing to Lemmas 2.2 and 2.3, it is sufficient to show the nonexistence of a solution of (1.5). In order to do that, suppose, by way of contradiction, that y is a solution of (1.5). If $\gamma = 1$, choose an arbitrary $t_0 > 0$. If $\gamma > 1$, set $\chi := [2(\gamma+1)]^{1/(\gamma-1)}$; then, by Lemma 2.4, a $t_0 > 0$ can be chosen such that

$$y(t_0) > [2(\gamma+1)K^2]^{1/(\gamma-1)}\eta(t_0) \tag{2.6}$$

where $K := \int_{t_0}^\infty \eta(\tau)|\eta''(\tau)|\,d\tau < \infty$, by (H3).

Define

$$h:\quad t \mapsto \int_{t_0}^t [\eta(\tau)]^{-2}\,d\tau, \qquad t \in [t_0, \infty)$$

and

$$x:\quad s \mapsto (y/\eta)(h^{-1}(s)), \qquad s \in [0, \infty)$$

where h^{-1} is the inverse function of h. Since y is a positive solution of (1.3), x cannot vanish on $(0, \infty)$ and satisfies the following differential equation

$$x''(s) + (\eta^3\eta'')(h^{-1}(s))x(s) + x(s)^\gamma = 0, \qquad s \in (0, \infty). \tag{2.7}$$

Define a function z by

$$z(s) := \frac{1}{2}(x'(s))^2 + \frac{1}{\gamma+1}(x(s))^{\gamma+1}, \qquad s \in [0, \infty). \tag{2.8}$$

(ii) We show that z is bounded on $[0, \infty)$. If not, there exists an increasing sequence $s_1 < s_2 < \cdots$ for which $\lim_{i\to\infty} z(s_i) = \infty$; without loss of generality, the sequence can be taken such that

$$z(s_i) > 1 \quad \text{and} \quad z(s_i) = \max\{z(s);\, 0 \leqq s \leqq s_i\}, \quad i = 1, 2, \cdots. \tag{2.9}$$

By (2.7) and (2.8)

$$\forall s \in (0, \infty), \quad z'(s) = -(\eta^3\eta'')(h^{-1}(s))x(s)x'(s). \tag{2.10}$$

From (2.8) we deduce that

$$\forall s \in [0, \infty), \quad x(s) \leqq [(\gamma+1)z(s)]^{1/(\gamma+1)} \quad \text{and} \quad |x'(s)| \leqq [2z(s)]^{1/2}. \tag{2.11}$$

By assumption (H3), a $t_1 > t_0$ can be chosen such that

$$\sqrt{2}(\gamma+1)^{1/(\gamma+1)} \int_{t_1}^\infty \eta(\tau)|\eta''(\tau)|\,d\tau \leqq \frac{1}{2}. \tag{2.12}$$

Consider the s_i such that $s_i > h(t_1)$ and integrate (2.10)

$$z(s_i) - z(h(t_1)) = -\int_{h(t_1)}^{s_i} (\eta^3\eta'')(h^{-1}(\sigma))x(\sigma)x'(\sigma)\,d\sigma.$$

Taking into account (2.9), (2.11) and (2.12), it follows that

$$\begin{aligned}0&\leqq z(s_i)-z(h(t_1))\\&\leqq\sqrt{2}(\gamma+1)^{1/(\gamma+1)}z(s_i)^{1/2+1/(\gamma+1)}\int_{h(t_1)}^{s_i}|(\eta^3\eta'')(h^{-1}(\sigma))|\,d\sigma\\&\leqq\sqrt{2}(\gamma+1)^{1/(\gamma+1)}z(s_i)\int_{t_1}^{\infty}\eta(\tau)|\eta''(\tau)|\,d\tau\leqq\frac{1}{2}z(s_i).\end{aligned}$$

Whence $z(s_i)\leqq 2z(h(t_1))$, and this is in contradiction to the assumption that $z(s_i)\to\infty$ as $i\to\infty$.

(iii) Let us show that z tends to a limit L as $s\to\infty$. Since z is bounded, we define a constant

$$C:=\sqrt{2}(\gamma+1)^{1/(\gamma+1)}\sup\{z(s)^{1/2+1/(\gamma+1)};\ s\in(0,\infty)\}.$$

Let $\varepsilon>0$ be arbitrary. By assumption (H3), a $t_2>t_0$ can be chosen such that

$$\int_{t_2}^{\infty}\eta(\tau)|\eta''(\tau)|\,d\tau<\frac{\varepsilon}{C}.$$

Integrate (2.10) with $s\geqq h(t_2)$

$$\begin{aligned}|z(s)-z(h(t_2))|&\leqq\int_{h(t_2)}^{s}|(\eta^3\eta'')(h^{-1}(\sigma))|x(\sigma)|x'(\sigma)|\,d\sigma\\&\leqq C\int_{h(t_2)}^{s}|(\eta^3\eta'')(h^{-1}(\sigma))|\,d\sigma<\varepsilon.\end{aligned}$$

The existence of the limit L follows.

(iv) Let us show that $L>0$. Consider first the case $\gamma=1$. From (2.10)

$$\frac{d}{ds}(\ln z(s))=-(\eta^3\eta'')(h^{-1}(s))x(s)x'(s)(z(s))^{-1},\qquad s\in(0,\infty).$$

Using estimates (2.11)

$$|\ln z(s)-\ln z(0)|\leqq 2\int_{t_0}^{\infty}\eta(\tau)|\eta''(\tau)|\,d\tau=2K<\infty.$$

Thus $\ln z(s)$ is bounded for $s\in[0,\infty)$; hence $L>0$. Consider now the case $\gamma>1$ and, by way of contradiction, suppose $L=0$. The function z being bounded, one can define

$$L_1:=\sup\{|x'(s)|;\ s\in[0,\infty)\}\quad\text{and}\quad L_2:=\sup\{x(s);\ s\in[0,\infty)\}.$$

Putting this in (2.10)

$$z(s)=\int_{s}^{\infty}(\eta^3\eta'')(h^{-1}(\sigma))x(\sigma)x'(\sigma)\,d\sigma\leqq KL_1L_2.$$

From (2.11) we obtain

$$L_2^{\gamma}\leqq(\gamma+1)KL_1\quad\text{and}\quad L_1\leqq 2KL_2.$$

Whence $L_2^{\gamma-1}\leqq 2(\gamma+1)K^2$ and

$$y(t_0)=\eta(t_0)x(0)\leqq\eta(t_0)L_2\leqq\eta(t_0)[2(\gamma+1)K^2]^{1/(\gamma-1)},$$

in contradiction to (2.6).

(v) Since $L>0$, one can find an s_0 such that $z(s) \geqq \frac{1}{2}L$ for all $s \geqq s_0$. First case: x' has an infinite number of zeros $s_1 < s_2 < \cdots$ on $[s_0, \infty)$. On every interval $[s_1, s_i]$, the minimum of x is achieved at a zero s_k of x' and

$$\frac{L}{2} \leqq z(s_k) \leqq \frac{1}{\gamma+1}(x(s_k))^{\gamma+1}.$$

Hence

$$x(s) \geqq x(s_k) \geqq (\tfrac{1}{2}(\gamma+1)L)^{1/(\gamma+1)}, \qquad s \in [s_1, \infty).$$

By (2.7), the following holds on $[s_1, \infty)$:

$$|x'(s)| = \left| \int_{s_1}^{s} x''(\sigma)\, d\sigma \right| \geqq \int_{s_1}^{s} x(\sigma)^\gamma \, d\sigma - \left| \int_{s_1}^{s} (\eta^3 \eta'')(h^{-1}(\sigma)) x(\sigma)\, d\sigma \right|$$
$$\geqq \left(\frac{1}{2}(\gamma+1)L \right)^{\gamma/(\gamma+1)} (s - s_1) - KL_2.$$

It follows that x' is unbounded and therefore we have a contradiction. Second case: x' is monotone on some interval $[s_0, \infty)$. Since x is bounded, $x(s) \to M$ as $s \to \infty$. M cannot be zero, for in this case $|x'(s)| \to \sqrt{2L}$ and x would be unbounded. So assume $M>0$. An s_1 can be found such that $x(s) \geqq M/2$ for all $s \geqq s_1$. As in the first case, we establish

$$|x'(s) - x'(s_1)| \geqq \left(\frac{M}{2} \right)^\gamma (s - s_1) - KL_2, \qquad s \in [s_1, \infty).$$

A contradiction follows again, since x' must be bounded. We conclude that x must vanish, and so must y. □

3. Existence result for (1.5). Let us introduce two additional conditions:

(H6) $\lim_{t \downarrow 0} t^{\gamma+2} q(t) = 0$.

(H7) $\forall t > 0$: $(\gamma+3)q(t) + 2tq'(t) \leqq 0$.

We show first the nonexistence of a solution of (1.1); by Lemmas 2.2 and 2.3, the existence of a (unique) solution of (1.5) follows.

LEMMA 3.1. *Let assumptions* (H1), (H2), (H6) *and* (H7) *be satisfied. Then* (1.1) *has no solution.*

Proof. Every solution of the differential equation (1.3) must satisfy the following identity

$$\frac{d}{dt}\left[t(y'(t))^2 - y(t)y'(t) + \frac{2}{\gamma+1} tq(t) y(t)^{\gamma+1} \right]$$
$$= \frac{1}{\gamma+1}[(\gamma+3)q(t) + 2tq'(t)] y(t)^{\gamma+1}. \tag{3.1}$$

By contradiction, assume (T, y) to be a solution of (1.1). Integrate (3.1) between 0 and T; according to the boundary conditions and hypothesis (H6):

$$T(y'(T))^2 = \frac{1}{\gamma+1} \int_0^T ((\gamma+3)y(\tau) + 2\tau q'(\tau)) y(\tau)^{\gamma+1}\, d\tau.$$

This is in contradiction to the hypothesis (H7), since $y'(T) > 0$. □

THEOREM 3.2. *Let assumptions* (H1), (H2), (H6) *and* (H7) *be satisfied. Then problem* (1.5) *has a solution.*

4. A monotone iteration method. We now develop some results given by Luning and Perry [7]. They apply to the eigenvalue problem (1.4). The relation with the problem (1.2) will be shown in the next section. We admit here any nonnegative value for γ. The following condition is prescribed for the function a:

(H8) $a \in C(0,1), \forall \tau \in (0,1)$: $a(\tau) > 0$, $\tau \mapsto \tau^\gamma(1-\tau)a(\tau)$ belongs to $L^1(0,1)$. Introduce the following iteration scheme for $n = 0, 1, \cdots$:

$$\lambda_n := \left[\int_0^1 (1-\theta)a(\theta)x_n(\theta)^\gamma\,d\theta\right]^{-1},$$

$$x''_{n+1}(\tau) = -\lambda_n a(\tau)x_n(\tau)^\gamma, \qquad \tau \in (0,1), \tag{4.1}$$

$$x_{n+1}(0) = x_{n+1}(1) = 0.$$

Suppose that $\gamma \geqq 0$ and assume (H8) to hold. Setting x_0: $\tau \mapsto \tau$, $\tau \in [0,1]$, one defines by (4.1) two sequences (λ_n) and (x_n); and for each n: $x'_n(0) = 1$. Let us recall a result drawn from [7].

LEMMA 4.1. *Suppose $\gamma \geqq 0$ and let a satisfy the condition* (H8). *Then the sequence (λ_n) defined above is increasing, and the sequence (x_n) is decreasing; moreover, $\forall n \in \mathbf{N}$ and $\forall \tau \in (0,1)$: $0 < x_{n+1}(\tau) < x_n(\tau)$.*

The following theorem and its corollary are drawn from [6].

THEOREM 4.2. *Suppose that $\gamma \geqq 0$ and let a satisfy* (H8). *Let (λ_n) and (x_n) be the sequences defined as above. Assume the existence of a solution (λ, x) of* (1.4). *Then the sequence (λ_n) tends to a limit $\bar\lambda$, the sequence (x_n) converges uniformly on $[0,1]$ to a function $\hat x$; $(\bar\lambda, \hat x)$ is a solution of* (1.4), *and $\bar\lambda \leqq \lambda$, $\hat x \geqq x$.*

Proof. (i) Let us show that $\forall n \in \mathbf{N}$: $\lambda_n < \lambda$ and $x_n \geqq x$. Of course $x_0 > x$; moreover for each $\mu \in (0,1)$ there exists a unique $\tau_0(\mu) \in (0,1)$ such that $\mu x_0(\tau_0) = x(\tau_0)$. Make the following inductive hypothesis: $x_n > x$ and for each $\mu \in (0,1)$ there exists at most one $\tau_n(\mu) \in (0,1)$ such that $\mu x_n(\tau_n) = x(\tau_n)$. If this is true, an obvious first consequence is that $\lambda_n < \lambda$. Secondly: $x_{n+1} > x_n$. To show this, set $\mu := (\lambda_n/\lambda)^{1/\gamma} < 1$ and $w := x - x_{n+1}$. Since $x_n(0) = x(0)$ and $x'_n(0) = x'(0) = 1$, there exists a $\delta > 0$ such that

$$w''(\tau) = a(\tau)[\lambda_n x_n(\tau)^\gamma - \lambda x(\tau)^\gamma] = \lambda a(\tau)[\mu^\gamma x_n(\tau)^\gamma - x(\tau)^\gamma] < 0$$

if $\tau \in (0,\delta)$. We obtain $w(0) = w'(0) = w(1) = 0$ and $w''(\tau) < 0$ for $\tau \in (0,\delta)$; by the inductive hypothesis, w'' changes sign at most once in $(0,1)$. We conclude that $w(\tau) < 0$ for $\tau \in (0,1)$. Third consequence: for each $\mu \in (0,1)$, there exists at most one $\tau_{n+1}(\mu) \in (0,1)$ such that $\mu x_{n+1}(\tau_{n+1}) = x(\tau_{n+1})$. Indeed, set $\nu := (\mu\lambda_n/\lambda)^{1/\gamma} < 1$ and $v := x - \mu x_{n+1}$. Since $x_n(0) = x(0)$ and $x'_n(0) = x'(0) = 1$, there exists a $\delta > 0$ such that

$$v''(\tau) = a(\tau)[\mu\lambda_n x_n(\tau)^\gamma - \lambda x(\tau)^\gamma] = \lambda a(\tau)[\nu^\gamma x_n(\tau)^\gamma - x(\tau)^\gamma] < 0$$

if $\tau \in (0,\delta)$. We have $v(0) = v(1) = 0$, $v'(0) = 1 - \mu > 0$ and $v''(\tau) < 0$ for $\tau \in (0,\delta)$; by the inductive hypothesis, v'' vanishes at most once in $(0,1)$. Therefore v cannot vanish more than once in $(0,1)$.

(ii) The sequence (λ_n), being increasing and bounded by λ, tends to a limit $\bar\lambda \leqq \lambda$. The sequence (x_n) is decreasing, and $x_n \geqq x$. For $\tau \in [0,1]$, we get from (4.1)

$$|x'_{n+1}(\tau)| \leqq 1 + \lambda_n \int_0^\tau a(\theta)x_n(\theta)^\gamma\,d\theta$$

$$\leqq 1 + \bar\lambda \int_0^1 a(\theta)x_0(\theta)^\gamma\,d\theta < 1 + \bar\lambda \int_0^1 a(\theta)\theta^\gamma\,d\theta < \infty.$$

By the Arzelà-Ascoli theorem, the decreasing sequence (x_n) converges to a function $\hat{x} \geqq x$ (since it contains a convergent subsequence). From (4.1) again, one has

$$x_{n+1}(\tau) = \tau - \lambda_n \int_0^\tau (\tau - \theta) a(\theta) x_n(\theta)^\gamma \, d\theta, \qquad \tau \in [0, 1].$$

Making n tend to infinity

$$\hat{x}(\tau) = \tau - \bar{\lambda} \int_0^\tau (\tau - \theta) a(\theta) \hat{x}(\theta)^\gamma \, d\theta.$$

It is easily checked that $(\bar{\lambda}, \hat{x})$ is a solution of (1.4). □

COROLLARY 4.3. *Let (λ_n) and (x_n) be the two sequences defined as above. Then the following alternatives hold:*

(i) *The sequence (λ_n) is unbounded. In this case, problem* (1.4) *has no solution and the sequence (x_n) tends to the zero function.*

(ii) *The sequence (λ_n) converges. In this case, problem* (1.4) *has a solution $(\bar{\lambda}, \hat{x})$, such that $\lambda_n \to \bar{\lambda}$ and x_n converges uniformly to $\hat{x}$. If (λ, x) is another solution of* (1.4), *then $\lambda > \bar{\lambda}$ and $x < \hat{x}$.*

5. Emden–Fowler problem (1.2). Consider now the problem (1.2), which corresponds to the special case of (1.1) when $q(t) := t^\beta$.

THEOREM 5.1. *Let $\gamma \geqq 1$ and β be real numbers. Then problem* (1.2) *has a solution if and only if $\gamma + 2\beta + 3 > 0$.*

Proof. (i) Suppose that $\gamma + 2\beta + 3 > 0$. Then $\gamma + \beta + 1 > 0$ (for $\beta \leqq -2$: $\gamma + \beta + 1 = (\gamma + 2\beta + 3) - (\beta + 2) > 0$ and for $\beta > -2$: $\gamma + \beta + 1 = (\gamma - 1) + (\beta + 2) > 0$). Hypothesis (H2) is satisfied iff $\gamma + \beta + 1 > 0$. Conditions (H3) and (H5) hold iff $\gamma + 2\beta + 3 > 0$, and (H4) iff $\gamma + 2\beta + 3 \geqq 0$. Thus Theorem 2.1 applies and (1.2) has a unique solution (T, y), with $y \in C[0, T] \cap C^1[0, T) \cap C^2(0, T)$.

(ii) Notice that if $y \in C^1[0, T)$ satisfies (1.2), then $\gamma + \beta + 1 > 0$. Indeed, for any $t_0 \in (0, \varepsilon)$

$$y'(\varepsilon) = y'(t_0) - \int_{t_0}^{\varepsilon} \tau^\beta y(\tau)^\gamma \, d\tau.$$

By continuity at the origin

$$\int_0^\varepsilon \tau^\beta y(\tau)^\gamma \, d\tau = \alpha - y'(\varepsilon).$$

Therefore $t \mapsto t^\beta y(t)^\gamma$ belongs to $L^1(0, \varepsilon)$. Taking ε small enough and a $\bar{t} \in (0, \varepsilon)$, we have

$$t^\beta y(t)^\gamma = t^{\beta+\gamma} y'(\bar{t})^\gamma \geqq \left(\frac{\alpha}{2}\right)^\gamma t^{\beta+\gamma}, \qquad t \in (0, \varepsilon).$$

Thus $t \mapsto t^{\beta+\gamma}$ is integrable.

(iii) Suppose now that $\gamma + 2\beta + 3 \leqq 0$ and, by way of contradiction, that (T, y) is a solution of (1.2). According to the preceding notice: $\gamma + \beta + 1 > 0$; thus condition (H6) is satisfied. On the other hand, (H7) holds iff $\gamma + 2\beta + 3 \leqq 0$. Therefore (1.2) has no solution, by Lemma 3.1. □

Suppose that $\gamma + 2\beta + 3 > 0$. We establish now the relation between problems (1.2) and (1.4). Let (T, y) be the solution of (1.2) and define $\tau := t/T$, $x : \tau \mapsto (\alpha T)^{-1} y(T\tau)$, for $\tau \in [0, 1]$, and $\lambda := \alpha^{\gamma-1}T^{\gamma+\beta+1}$. Then (λ, x) satisfies

$$\begin{aligned} &x''(\tau)+\lambda\tau^{\beta}x(\tau)^{\gamma}=0, \qquad \tau\in(0,1),\\ &x(0)=x(1)=0, \qquad x'(0)=1, \\ &x(\tau)>0, \qquad \tau\in(0,1). \end{aligned} \tag{5.1}$$

Reciprocally let (λ, x) be a solution of (5.1). Define $T := \lambda^{1/(\gamma+\beta+1)}\alpha^{(\gamma-1)/(\gamma+\beta+1)}$ (note that $\gamma+\beta+1>0$), $t := T\tau$ and $y : t \mapsto \alpha T x(t/T)$, for $t \in [0, T]$. Then (T, y) is a solution of (1.2). One thus gets the uniqueness of the solution of (5.1); this solution may be approximated by the monotone iteration method of the preceding section. Define $x_0(\tau) := \tau$, for $\tau \in [0, 1]$, and

$$\begin{aligned} &\lambda_n := \left[\int_0^1 (1-\theta)\theta^{\beta}x_n(\theta)^{\gamma}\,d\theta\right]^{-1}, \\ &x''_{n+1}(\tau) = -\lambda_n\tau^{\beta}x_n(\tau)^{\gamma}, \qquad \tau\in(0,1), \\ &x_{n+1}(0)=x_{n+1}(1)=0 \quad \text{for } n=0,1,\cdots. \end{aligned} \tag{5.2}$$

The existence of the solution of (1.2), by Theorem 5.1, involves the existence of the solution of (5.1). The condition (H8) being satisfied, Theorem 4.2 yields the convergence of the method (5.2). The sequence (λ_n) converges to λ, the sequence (x_n) converges uniformly to x, and (λ, x) is a solution of (5.1). With the inverse transformation, one gets the solution (T, y) of (1.2).

6. Remarks. (i) In this paper, a sufficient condition for the existence of a solution of (1.1) has been obtained. We do not know any necessary and sufficient condition, except in the special case (1.2).

(ii) The eigenvalue problem (1.4) has a solution if the function a belongs to $L^1(0, 1)$ and satisfies (H8); see [7]. This condition is not optimal, since if $a(\tau) := \tau^{\beta}$, the necessary and sufficient condition for existence is $\gamma+2\beta+3>0$ (thus a is not necessarily integrable).

(iii) For $\gamma<1$, the study of problems (1.1) and (1.4) requires other methods. Let us mention a paper of Taliaferro [9], which is devoted to problem (1.4), with $\gamma<0$. In [7], Luning and Perry studied (1.4) with $\gamma>-1$ and $a\in L^1(0, 1)$.

(iv) More generally, one can consider a differential equation of the type

$$(p(s)u'(s))' + r(s)u(s)^{\gamma} = 0 \tag{6.1}$$

with $p \in C^1(0, \infty)$ and $p(s)>0$ for all $s>0$. Moreover, suppose that $1/p \in L^1_{\text{loc}}(0, \infty)$ or $1/p \in L^1(1, \infty)$; we then introduce one of the following transformations:

If $1/p \in L^1(0, 1)$ and $1/p \notin L^1(1, \infty)$, set

$$t := \int_0^s \frac{d\sigma}{p(\sigma)} \quad \text{and} \quad y(t) := u(s).$$

If $1/p \notin L^1(0, 1)$ and $1/p \in L^1(1, \infty)$, set

$$t := \left[\int_s^{\infty} \frac{d\sigma}{p(\sigma)}\right]^{-1} \quad \text{and} \quad y(t) := tu(s).$$

If $1/p \in L^1(0, \infty)$, set

$$t_0 := \left[\int_0^{\infty} \frac{d\sigma}{p(\sigma)}\right]^{-1}, \quad t := \left[\int_s^{\infty} \frac{d\sigma}{p(\sigma)}\right]^{-1} - t_0 \quad \text{and} \quad y(t) := (t+t_0)u(s).$$

In each case: $0 \leqq t < \infty$ if $0 \leqq s < \infty$, and y is a solution of (1.3) if u is a solution of (6.1).

Acknowledgments. The author wishes to thank Dr. P. Bader, Dr. C. Khanmy, Professor C. Stuart and Professor B. Zwahlen for their kind interest.

BEST INTERVAL LENGTHS FOR BOUNDARY VALUE PROBLEMS FOR THIRD ORDER LIPSCHITZ EQUATIONS*

JOHNNY HENDERSON†

Abstract. For the third order differential equation $y''' = f(t, y, y', y'')$, where $|f(t, y_1, y_2, y_3) - f(t, z_1, z_2, z_3)| \leqq \sum_{i=1}^{3} k_i |y_i - z_i|$ on $(a, b) \times \mathbf{R}^3$, subintervals (α, β) of (a, b) of maximal length are characterized, in terms of the Lipschitz coefficients k_i, $i = 1, 2, 3$, for the existence of unique solutions of certain two-point and three-point boundary value problems. The techniques for establishing best interval length involve applications of the Pontryagin Maximum Principle coupled with uniqueness implies existence arguments. For the case $k_i = 1$, $i = 1, 2, 3$, comparisons are made with interval lengths obtained via standard applications of the Contraction Mapping Principle.

Key words. boundary value problem, Lipschitz equation, Pontryagin Maximum Principle, optimal length interval

1. Introduction.

We shall be concerned with solutions of boundary value problems for the third order differential equation

$$y''' = f(t, y, y', y'') \tag{1}$$

where we assume throughout that

(A) $f(t, y_1, y_2, y_3)$: $(a, b) \times \mathbf{R}^3 \to \mathbf{R}$ is continuous, and

(B) f satisfies the Lipschitz condition

$$|f(t, y_1, y_2, y_3) - f(t, z_1, z_2, z_3)| \leqq \sum_{i=1}^{3} k_i |y_i - z_i|$$

for each (t, y_1, y_2, y_3), $(t, z_1, z_2, z_3) \in (a, b) \times \mathbf{R}^3$.

In particular, we will address the question concerning interval length bounds on subintervals of (a, b), in terms of the Lipschitz coefficients k_i, $i = 1, 2, 3$, on which certain two-point and three-point boundary value problems for (1) have unique solutions. Such questions have been commonly resolved by various applications of the Contraction Mapping Principle; for example, see [1]-[7], [15], [20]. A limitation of the methods using the Contraction Mapping Principle is the fact that often unique solutions of the boundary value problems exist on longer subintervals of (a, b). Recently, for two types of the boundary value problems for (1) that we consider here, Aftabizadeh and Wiener [1] sharpened some of the previous bounds by using the Contraction Mapping Principle, after having transformed their problems into boundary value problems for a second order integro-differential equation. We further mention that in [4], a weight function technique previously used by Collatz was employed in obtaining best possible subinterval lengths in the cases (with one exception) where (1) is independent of y'' or independent of both y' and y''.

The purpose of this paper will be to characterize in terms of the Lipschitz coefficients k_i, $i = 1, 2, 3$, the subintervals (α, β) of (a, b) of *maximal length* for the existence and uniqueness of solutions of certain boundary value problems for (1). We accomplish this by applying techniques from optimal control theory that are motivated

by works of Melentsova and Mil'shtein [18] and Melentsova [19], and most notably by the two works of Jackson [12], [13].

Jackson's [12], [13] papers dealt with the cases of conjugate type boundary value problems and right focal type boundary value problems for nth order Lipschitz equations. In terms of the third order equation (1), his results concerned solutions of the conjugate problems,

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y(t_3)=y_3,\qquad a<t_1=t_2<t_3<b, \tag{2}$$

$$y(t_1)=y_1,\quad y(t_2)=y_2,\quad y'(t_3)=y_3,\qquad a<t_1<t_2=t_3<b, \tag{3}$$

$$y(t_1)=y_1,\quad y(t_2)=y_2,\quad y(t_3)=y_3,\qquad a<t_1<t_2<t_3<b, \tag{4}$$

and solutions of the right focal problems,

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y''(t_3)=y_3,\qquad a<t_1=t_2<t_3<b, \tag{5}$$

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y''(t_3)=y_3,\qquad a<t_1<t_2=t_3<b, \tag{6}$$

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y''(t_3)=y_3,\qquad a<t_1<t_2<t_3<b. \tag{7}$$

In [13], Jackson proved the first two theorems we present here.

THEOREM 1.1. *Let $h>0$ be the smallest positive number such that there is a solution $x(t)$ of the boundary value problem*

$$x'''=-k_1x-k_2|x'|-k_3|x''|,$$
$$x(0)=x'(0)=x(h)=0,$$

with $x(t)>0$ on $(0,h)$, or $h=+\infty$ if no such solution exists. Then boundary value problems for (1) *satisfying* (2), (3), *or* (4) *have unique solutions, for any assignment of $y_1, y_2, y_3\in\mathbf{R}$, provided $t_3-t_1<h$. Furthermore, this result is best possible for the class of all differential equations that satisfy the Lipschitz condition* (B).

The use made by Jackson of optimal control was via an application of the Pontryagin Maximum Principle in establishing the uniqueness of solutions of boundary value problems, when solutions exist. In the case of conjugate problems, uniqueness implies existence (see [9], [14]), thus, the existence statement of Theorem 1.1. For right focal problems, the second theorem of Jackson's that we state is a uniqueness result.

THEOREM 1.2. *Let $h=\min\{h_1,h_2\}$, where $h_1>0$ is the smallest positive number such that there is a solution $x(t)$ of the boundary value problem*

$$x'''=-k_1x-k_2|x'|-k_3|x''|,$$
$$x(0)=x'(0)=x''(h_1)=0,$$

with $x(t)>0$ on $(0,h_1]$, or $h_1=+\infty$ if no such solution exists, and where $h_2>0$ is the smallest positive number such that there is a solution $y(t)$ of the boundary value problem

$$x'''=-k_1x-k_2|x'|-k_3|x''|,$$
$$x'(0)=x''(0)=x(h_2)=0,$$

with $y(t)>0$ on $[0,h_2)$, or $h_2=+\infty$ if no such solution exists. Then boundary value problems for (1) *satisfying* (5), (6), *or* (7) *have at most one solution, provided $t_3-t_1<h$, and again, this result is best possible.*

Recently, Henderson [10] proved that uniqueness implies existence for solutions of right focal problems. Thus, we can state an analogue of Theorem 1.1.

THEOREM 1.3. *Let $h>0$ be as in Theorem* 1.2. *Then boundary value problems for* (1) *satisfying* (5), (6), *or* (7) *have unique solutions, for any assignment of* $y_1, y_2, y_3 \in \mathbf{R}$, *provided* $t_3-t_1<h$, *and this result is best possible for the class of all differential equations satisfying* (B).

For our purposes here, we shall consider, (as in [8], [11]), boundary value problems for (1) that are "in between" those of the conjugate type and the right focal type. More specifically, we shall be interested in solutions of (1) satisfying

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y'(t_3)=y_3,\qquad a<t_1=t_2<t_3<b, \tag{8}$$

$$y(t_1)=y_1,\quad y(t_2)=y_2,\quad y'(t_3)=y_3,\qquad a<t_1<t_2=t_3<b, \tag{9}$$

$$y(t_1)=y_1,\quad y(t_2)=y_2,\quad y'(t_3)=y_3,\qquad a<t_1<t_2<t_3<b, \tag{10}$$

and in solutions of (1) satisfying

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y'(y_3)=y_3,\qquad a<t_1=t_2<t_3<b, \tag{11}$$

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y''(t_3)=y_3,\qquad a<t_1<t_2=t_3<b, \tag{12}$$

$$y(t_1)=y_1,\quad y'(t_2)=y_2,\quad y'(t_3)=y_3,\qquad a<t_1<t_2<t_3<b, \tag{13}$$

and finally, in solutions of (1) satisfying,

$$y(t_1)=y_1,\quad y''(t_2)=y_2,\quad y'(t_3)=y_3,\qquad a<t_1=t_2<t_3<b. \tag{14}$$

In order that this presentation be self-contained, we will briefly state in § 2 the basics involved in applying the Pontryagin Maximum Principle to each of the families of boundary value problems for (1). That discussion is taken from [13]. In §§ 3 and 4, we then apply the Pontryagin Maximum Principle and determine maximal length subintervals on which solutions for each family of "in between" boundary value problems for (1) are unique, when solutions exist. Then, for each case, we will either reference theorems or prove uniqueness implies existence theorems for these boundary value problems. Finally, in § 5, we consider the case where $k_i=1$, $i=1, 2, 3$, and we compute the corresponding best subinterval lengths for subintervals of (a, b), on which there exist unique solutions, for the cases of the conjugate, the right focal, and the "in between" boundary value problems for (1). In some of the cases, we compare the best interval lengths with those obtained by standard applications of the Contraction Mapping Principle; in a couple of cases, we compare the best interval lengths with those obtained by the methods developed in [1].

2. The Pontryagin Maximum Principle. In this section, we will give a brief presentation on the manner in which the Pontryagin Maximum Principle can be applied. Our discussion is taken from Jackson [13]. We formulate this application in terms of nth order differential equations.

Let $k_i>0$, $1\leqq i\leqq n$, be fixed and let

$$U=\{(u_1(t),\cdots,u_n(t))\,|\,u_i(t) \text{ is Lebesgue measurable on } (a,b), \text{and } |u_i(t)|\leqq k_i,\ 1\leqq i\leqq n, \text{ on } (a,b)\}.$$

Let I, J be nonempty subsets of $\{1,\cdots,n\}$ such that $\operatorname{card}(I)+\operatorname{card}(J)=n$, and let I^c, J^c denote the respective complements of I, J in $\{1,\cdots,n\}$.

For fixed sets I, J, consider the boundary value problems

$$x^{(n)}=\sum_{i=1}^{n} u_i(t)x^{(i-1)}, \tag{15}$$

$$x^{(i-1)}(t_1)=0,\qquad i\in I, \tag{16}$$

$$x^{(i-1)}(t_2)=0,\qquad i\in J, \tag{17}$$

where $a < t_1 < t_2 < b$ and $u = (u_1(t), \cdots, u_n(t)) \in U$. Since the $u_i(t)$ are bounded measurable functions, we define here what is meant by a *solution* of (15).

DEFINITION. $x(t)$ is a *solution* of (15), for a control vector $u \in U$, if $x(t)$ is of class $C^{(n-1)}(a, b)$, $x^{(n-1)}(t)$ is absolutely continuous on (a, b), and $x(t)$ satisfies (15) for almost all $t \in (a, b)$.

We assume similar definitions for *solutions* of other differential equations which appear in this paper and which involve the control vectors $u \in U$.

Now, if (15)-(17) has a nontrivial solution for some $t_1 < t_2$ and some $u \in U$, then it follows that there is a boundary value problem in the collection which has a nontrivial optimal solution, (see Lee and Markus [16, Thm. 1, p. 30 or Thm. 4, p. 259]); that is, there exists at least one nontrivial $u^* \in U$ and $t_1 \leqq c < d \leqq t_2$ such that

$$x^{(n)} = \sum_{i=1}^{n} u_i^*(t) x^{(i-1)},$$

$$x^{(i-1)}(c) = 0, \qquad i \in I,$$

$$x^{(i-1)}(d) = 0, \qquad i \in J,$$

has a nontrivial solution $x(t)$ and $d - c$ is a minimum over all such solutions. For this time optimal solution, if $z(t) = (x(t), x'(t), \cdots, x^{(n-1)}(t))^T$, then $z(t)$ is a solution of the corresponding first order system

$$z' = A[u^*(t)]z.$$

By the Pontryagin Maximum Principle [16, Cor. 1, p. 314], the adjoint system

$$\psi' = -A^T[u^*(t)]\psi$$

has a nontrivial solution $\psi(t) = (\psi_1(t), \cdots, \psi_n(t))^T$ such that

(i) $\sum_{i=1}^{n} x^{(i)}(t)\psi_i(t) = \langle z'(t), \psi(t)\rangle = \operatorname*{Max}_{u \in U} \{\langle A[u(t)]z(t), \psi(t)\rangle\}$,
for almost all $t \in [c, d]$, ($\langle \cdot, \cdot \rangle$ denotes inner product);

(ii) $\langle z'(t), \psi(t)\rangle$ is a nonnegative constant for almost all $t \in [c, d]$; and

(iii) $\psi_i(c) = 0, \qquad i \in I^c,$

$\psi_i(d) = 0, \qquad i \in J^c.$

As shown in [13], the maximum condition in (i) can be rewritten as

$$\psi_n(t) \sum_{i=1}^{n} u_i^*(t) x^{(i-1)}(t) = \operatorname*{Max}_{u \in U} \left\{ \psi_n(t) \sum_{i=1}^{n} u_i(t) x^{(i-1)}(t) \right\}, \tag{18}$$

for almost all $t \in [c, d]$, whence it follows that if $\psi_n(t)$ has no zeros on (c, d) and if $x(t) > 0$ on (c, d), then (18) can be used to determine an optimal control $u^*(t)$ for almost all $t \in [c, d]$, (conceivably some derivative of $x(t)$ might be zero at some points).

In particular, if $x(t) > 0$ and $\psi_n(t) < 0$ on (c, d), then the time optimal solution $x(t)$ is a solution of

$$x^{(n)} = -\left[k_1 x + \sum_{i=1}^{n} k_i |x^{(i-1)}| \right], \tag{19}$$

on $[c, d]$. On the other hand, if $x(t) > 0$ and $\psi_n(t) > 0$ on (c, d), then the time optimal solution $x(t)$ is a solution of

$$x^{(n)} = k_1 x + \sum_{i=1}^{n} k_i |x^{(i-1)}|, \tag{20}$$

on $[c, d]$.

In subsequent sections, converse statements concerning the adjoint equation play a major role. If $u \in U$ is such that the boundary value prolem (15)-(17) has a nontrivial solution, then

$$\psi' = -A^T[u(t)]\psi, \tag{21}$$

$$\psi_i(t_1) = 0, \qquad i \in I^c, \tag{22}$$

$$\psi_i(t_2) = 0, \qquad i \in J^c, \tag{23}$$

also has a nontrivial solution; thus, the converse is also true. As a consequence of that, the Pontryagin Maximum Principle associates with a time optimal solution of (15)-(17), a time optimal solution of (21)-(23), and conversely.

In applying our statements in this section to nonlinear equations, consider the nth order differential equation

$$y^{(n)} = f(t, y, y', \cdots, y^{(n-1)}), \tag{24}$$

where f is continuous and satisfies the Lipschitz condition

$$|f(t, y_1, \cdots, y_n) - f(t, z_1, \cdots, z_n)| \leqq \sum_{i=1}^{n} k_i |y_i - z_i| \tag{25}$$

on $(a, b) \times R^n$.

If $y(t)$ and $z(t)$ are distinct solutions of (24) on (a, b), and if $u_i(t)$, $1 \leqq i \leqq n$, is defined by

$$u_i(t) = \begin{cases} \dfrac{f(t, z(t), \cdots, z^{(i-2)}(t), y^{(i-1)}(t), \cdots, y^{(n-1)}(t))}{y^{(i-1)}(t) - z^{(i-1)}(t)} \\ \quad - \dfrac{f(t, z(t), \cdots, z^{(i-1)}(t), y^{(i)}(t), \cdots, y^{(n-1)}(t))}{y^{(i-1)}(t) - z^{(i-1)}(t)} & \text{for } y^{(i-1)}(t) \neq z^{(i-1)}(t), \\ -k_i \quad \text{for } y^{(i-1)}(t) = z^{(i-1)}(t), \end{cases}$$

then $u_i(t)$ is measurable on (a, b) and $|u_i(t)| \leqq k_i$. Let $x(t) = y(t) - z(t)$. Now if $t \in (a, b)$ is such that $y^{(i-1)}(t) = z^{(i-1)}(t)$, $i \in H \subset \{1, \cdots, n\}$, and if $K = H^C$, then invoking the two parts defining $u_i(t)$,

$$x^{(n)}(t) = \sum_{i \in K} u_i(t) x^{(i-1)}(t) + \sum_{i \in H} -k_i(0) = \sum_{i=1}^{n} u_i(t) x^{(i-1)}(t),$$

and consequently, $x(t) = y(t) - z(t)$ is a solution of the linear equation (15).

3. Intervals of existence, I. In this section we will be concerned with determining best possible interval lengths in terms of k_i, $i = 1, 2, 3$, of subintervals of (a, b) on which boundary value problems for the third order equation (1) satisfying (8), (9), or (10) all have unique solutions. First, we will use the results of the preceding section to determine optimal length subintervals on which solutions of each of the above boundary value problems are unique, when solutions exist. We then appeal to uniqueness implies existence theorems for this family of problems.

As we noted in § 2, if a time optimal solution of (15)-(17) and a corresponding solution of the adjoint equation satisfy certain sign conditions, then the time optimal solution is a solution of either (19) or (20). For this section and those that follow (since $n=3$), equations (15), (19), and (20) take the respective forms

$$x'''=u_1(t)x+u_2(t)x'+u_3(t)x'', \tag{26}$$

$$x'''=-k_1x-k_2|x'|-k_3|x''|, \tag{27}$$

$$x'''=k_1x+k_2|x'|+k_3|x''|. \tag{28}$$

THEOREM 3.1. *If there is a vector $u\in U$ such that the corresponding equation* (26) *has a nontrivial solution satisfying*

$$y(t_1)=y'(t_1)=y'(t_2)=0, \qquad a<t_1<t_2<b$$

and if $x(t)$ is a time optimal solution with

$$x(c)=x'(c)=x'(d)=0$$

and with $d-c$ a minimum, then $x(t)$ is a solution of (27) *on* $[c, d]$.

Proof. By the time optimality, it follows that $x'(t)\neq 0$ on (c, d), and thus $x(t)\neq 0$ on $(c, d]$. Without loss of generality we may assume $x''(c)>0$, so that $x(t)>0$ on $(c, d]$.

Now, if $\psi(t)$ is a solution of the adjoint system associated with $x(t)$ by the Pontryagin Maximum Principle, then

$$\psi_3(c)=\psi_1(d)=\psi_3(d)=0,$$

and by its own time optimality, $\psi_3(t)\neq 0$ on (c, d). Hence, $x(t)$ is a solution of (27) or (28) on $[c, d]$. From the nature of these two equations, $x''(t)$ is strictly monotone on $[c, d]$, and since $x'(c)=x'(d)=0$, while $x''(c)>0$, it follows that $x''(d)<0$.

Moreover, from the Maximum Principle, there exists $K\geqq 0$ such that

$$K=\sum_{i=1}^{3} x^{(i)}(t)\psi_i(t)=x''(d)\psi_2(d)=x''(c)\psi_2(c)$$

on $[c, d]$. We conclude $\psi_2(d)<0$, and from the adjoint system

$$\psi_3'(d)=-\psi_2(d)-u_3^*(d)\psi_3(d)=-\psi_2(d)>0.$$

Consequently, $\psi_3(t)<0$ on (c, d), and $x(t)$ is a solution of (27).

The following two theorems concerning uniqueness of solutions and uniqueness implies existence of solutions for (1), (8), (9) and (10) are proven in [8], [11].

THEOREM 3.2. *The boundary value problem* (1), (10) *has at most one solution on* (a, b), *if and only if each of the boundary value problems* (1), (8), *and* (1), (9) *has at most one solution on* (a, b).

THEOREM 3.3. *If* (1), (10) *has at most one solution on* (a, b), *then boundary value problems for* (1) *satisfying* (8), (9), *or* (10) *all have unique solutions on* (a, b).

We can now state the result concerning maximal length subintervals of (a, b) on which the boundary value problems of this section have unique solutions.

THEOREM 3.4. *Let $h>0$ be the smallest positive number such that there is a solution $x(t)$ of the boundary value problem for* (27) *satisfying*

$$x(0)=x'(0)=x'(h)=0,$$

with $x(t)>0$ on $(0, h]$, or $h=+\infty$ if no such solution exists. Then each of the boundary value problems for (1) *satisfying* (8), (9), *or* (10) *has a unique solution, provided $t_3-t_1<h$. Moreover, this result is best possible for the class of all differential equations satisfying the Lipschitz condition* (B).

Proof. We first note that since (27) is autonomous, in applying Theorem 3.1, rather than specifying boundary conditions at $a<c<d<b$, it suffices to consider conditions at 0 and h.

We show that solutions of (1) satisfying (8) or (9) are unique, when they exist, on any subinterval of (a, b) of length less than h. Assume that $y(t)$ and $z(t)$ are distinct solutions of (1) satisfying either (8) or (9) with $t_3-t_1<h$. Then $w(t)=y(t)-z(t)$ is a nontrivial solution of the linear equation (26) for suitable $u=(u_1(t), u_2(t), u_3(t))\in U$, and satisfies either

(i) $w(t_1)=w'(t_1)=w'(t_3)=0$, or

(ii) $w(t_1)=w(t_3)=w'(t_3)=0$.

Case (i) leads to a contradiction of Theorem 3.1. For case (ii), it is shown in Jackson [12, Cor. to Thm. 8] that there is a nontrivial solution $x(t)$ of (28) satisfying $x(0)=x'(0)=x(-k)=0$, for some $0<k<h$. If $v(t)=x(-t)$, then $v(t)$ is a nontrivial solution of (27) and satisfies $v(0)=v'(0)=v(k)=0$. By Rolle's theorem, there exists $0<\eta<k$ such that

$$v(0)=v'(0)=v'(\eta)=0,$$

which again contradicts Theorem 3.1.

Therefore, solutions of boundary value problems for (1) satisfying (8) or (9) are unique, when they exist. That unique solutions of (1) satisfying (8), (9), or (10) exist, provided $t_3-t_1<h$, is immediate from Theorems 3.2 and 3.3. Since (27) is a Lipschitz equation satisfying (B), it also follows that this result is best possible.

4. Intervals of existence, II. We now consider interval lengths of subintervals of (a, b) on which there exist unique solutions of boundary value problems for (1) satisfying (11), (12), or (13) (note that (11) is the same as (8)). By further restricting our subinterval length for the above three problems, we will also consider existence and uniqueness for problems studied by Aftabizadeh and Wiener [1] satisfying (1), (14).

THEOREM 4.1. *Assume that for all vectors $u\in U$, the corresponding linear equation* (26) *has only the trivial solution satisfying*

$$x(t_1)=x'(t_1)=x'(t_2)=0, \qquad a<t_1<t_2<b.$$

If there is a control vector $u\in U$ such that the corresponding equation (26) *has a nontrivial solution satisfying*

$$y(t_1)=y'(t_2)=y''(t_2)=0, \qquad a<t_1<t_2<b$$

and if $x(t)$ is a time optimal solution with

$$x(c)=x'(d)=x''(d)=0$$

and with $d-c$ a minimum, then $x(t)$ is a solution of (28) *on* $[c, d]$.

Proof. By the time optimality of $x(t)$ and uniqueness of solutions of initial value problems, $x(t)\neq 0$ on $(c, d]$. Also, we may assume that $x'(c)>0$ so that $x(t)>0$ on $(c, d]$.

If $\psi(t)$ is a solution of the adjoint system associated with $x(t)$ by the Maximum Principle, then

$$\psi_2(c)=\psi_3(c)=\psi_1(d)=0$$

and $\psi_1(t)\neq 0$ on $[c, d)$.

In order to apply the results of § 2, we need to show that $\psi_3(t)\neq 0$ on (c, d). To this end, let $y(t)=(y_1(t), y_2(t), y_3(t))^T$, where $y_1(t)=\psi_3(t)$, $y_2(t)=\psi_2(t)$, and $y_3(t)=\psi_1(t)$, so that $y(t)$ is a solution of

$$y'=B[u^*(t)]y \tag{29}$$

where

$$B[u(t)] = \begin{bmatrix} -u_3(t) & -1 & 0 \\ -u_2(t) & 0 & -1 \\ -u_1(t) & 0 & 0 \end{bmatrix}$$

and $y_1(c) = y_2(c) = y_3(d) = 0$. Our argument will now be concerned with showing $y_1(t) = \psi_3(t) \neq 0$ on (c, d).

We remark that from the optimality of $x(t)$ and $\psi(t)$ and from the hypotheses, $\psi_3(d) = y_1(d) \neq 0$. For $j = 1, 2, 3$, let

$$y^j(t) = (y_1^j(t), y_2^j(t), y_3^j(t))^T$$

denote the solution of the initial value problem for (29) satisfying

$$y_i^j(d) = \delta_{ij}, \qquad i = 1, 2, 3.$$

It follows that

$$y(t) = C_1 y^1(t) + C_2 y^2(t),$$

for some C_1, C_2. Moreover, since $y_1(d) \neq 0$, we have $C_1 \neq 0$.

Now, it is also the case that $y_1^2(t) \neq 0$ on (a, d). To see this, asume there exists $\tau \in (a, d)$ so that $y_1^2(\tau) = 0$. Since $y^2(t)$ is a solution of (29), it follows that the adjoint system $\psi' = -A[u^*(t)]\psi$ has a solution $\eta(t) = (\eta_1(t), \eta_2(t), \eta_3(t))^T$, where $\eta_1 = y_3^2$, $\eta_2 = y_2^2$, $\eta_3 = y_1^2$, satisfying

$$\eta_3(\tau) = \eta_1(d) = \eta_3(d) = 0.$$

This, in turn, implies there exists an optimal such solution to the adjoint equation, for some $u^{**} \in U$, and then by the Pontryagin Maximum Principle, there is an optimal solution $v(t)$ of (26), for $u^{**} \in U$, such that

$$v(\tau_1) = v'(\tau_1) = v'(\tau_2) = 0,$$

where $\tau \leqq \tau_1 < \tau_2 \leqq d$; this is a contradiction to the hypotheses of the theorem. Thus, $y_1^2(t) \neq 0$ on (a, d).

Now, if $y_1(t_0) = \psi_3(t_0) = 0$, for some $t_0 \in (c, d)$, since

$$-W(y^2(t), y(t)) = [y_1^2(t)]^2 (y_1(t)/y_1^2(t))',$$

(where $W(\cdot, \cdot)$ denotes the Wronskian), and since $y_1(c) = 0$ and $y_1^2(c) \neq 0$, it follows from Rolle's theorem that $W(y^2(t_1), y(t_1)) = 0$, for some $c < t_1 < t_0$. But $W(y^2(t_1), y(t_1)) = C_1 W(y^1(t_1), y^2(t_1))$, and since $C_1 \neq 0$, there are constants r_1, r_2 such that the solution

$$w(t) \equiv r_1 y^1(t) + r_2 y^2(t)$$

of (29) satisfies $w_1(t_1) = w_2(t_1) = w_3(d) = 0$. This implies the adjoint system has a solution $\beta(t)$ such that $\beta_2(t_1) = \beta_3(t_1) = \beta_1(d) = 0$, where $c < t_1 < d$. This contradicts the optimality of $d - c$. Therefore $y_1(t) = \psi_3(t) \neq 0$ on (c, d).

From our assumption that $x(t) > 0$, it follows that $x(t)$ is a solution of (27) or (28) on $[c, d]$. It follows, in turn, from the constancy in sign of $x'''(t)$ on $[c, d]$ and from the boundary conditions $x(c) = x'(d) = x''(d) = 0$, that $x'''(t) > 0$ on $[c, d]$, so that $x(t)$ is a solution of (28) on $[c, d]$.

For our remaining existence considerations, we appeal to results much like those in the previous section. The next two theorems are proven in [8], [11].

THEOREM 4.2. *If there is at most one solution of the boundary value problem* (1), (13) *on* (a, b), *then each of the boundary value problems* (1), (11), *and* (1), (12) *has at most one solution on* (a, b).

THEOREM 4.3. *If* (1), (13) *has at most one solution on* (a, b), *then boundary value problems for* (1) *satisfying* (11), (12), *or* (13) *all have unique solutions on* (a, b).

Although Theorem 4.2 is not the analogue of Theorem 3.2, the converse of Theorem 4.2 is true for linear equations.

LEMMA. *Let Ly be a linear third order differential operator on an interval I. If the only solution of $Ly = 0$ satisfying either*

$$y(t_1) = y'(t_2) = y'(t_3) = 0, \qquad t_1 = t_2 < t_3,$$

or

$$y(t_1) = y'(t_2) = y''(t_3) = 0, \qquad t_1 < t_2 = t_3$$

is the trivial solution, then the only solution of $Ly = 0$ satisfying

$$y(t_1) = y'(t_2) = y'(t_3) = 0, \qquad t_1 < t_2 < t_3$$

is $y(t) = 0$.

Proof. Assume to the contrary that there is a nontrivial solution $y(t)$ of $Ly = 0$ satisfying $y(t_1) = y'(t_2) = y'(t_3) = 0$, for some $t_1 < t_2 < t_3$ belonging to I. By the hypotheses, $y'(t_1), y''(t_2), y''(t_3) \neq 0$.

Now, by the hypotheses, there exists a unique solution $z(t)$ of $Ly = 0$ satisfying $z(t_1) = z'(t_1) = 0$ and $z'(t_2) = +1$. Moreover, $z'(t) \neq 0$, for all $t \in [t_2, t_3]$. It follows that for some nonzero $\alpha \in \mathbf{R}$ and $\tau \in (t_2, t_3)$, the solution $w(t) \equiv y(t) + \alpha z(t)$ of $Ly = 0$ satisfies $w(t_1) = w'(\tau) = w''(\tau) = 0$; see [17]. This contradicts the hypotheses of the lemma, and we conclude no such nontrivial solution $y(t)$ exists.

For the case of boundary value problems (1), (11), (12), and (13), we can now determine our optimal length subintervals on which all have unique solutions.

THEOREM 4.4. *Let $k = \min\{h, r\}$, where h is the number obtained in Theorem* 3.4, *and $r > 0$ is the smallest positive number such that there is a solution $x(t)$ of the boundary value problem for* (28) *satisfying*

$$x(0) = x'(r) = x''(r) = 0,$$

with $x(t) > 0$ on $(0, r]$, or $r = +\infty$ if no such solution exists. Then each of the boundary value problems for (1) *satisfying* (11), (12), *or* (13) *has a unique solution, provided $t_3 - t_1 < k$. Again, this result is best possible.*

Proof. We will show that solutions for (1), (13) are unique, when they exist. For the purpose of contradiction, assume there are distinct solutions $y(t)$ and $z(t)$ of (1), (13), where $t_3 - t_1 < k$. Then $w(t) = y(t) - z(t)$ is a nontrivial solution of linear equation (26), for a suitable $u^0 \in U$, and satisfies $w(t_1) = w'(t_2) = w'(t_3) = 0$. The above lemma coupled with Theorem 4.2 implies (26), for $u^0 \in U$, has a solution $\beta(t)$ satisfying either

(i) $\beta(\tau_1) = \beta'(\tau_1) = \beta'(\tau_2) = 0$, or

(ii) $\beta(\tau_1) = \beta'(\tau_2) = \beta''(\tau_2) = 0$

where $t_1 \leqq \tau_1 < \tau_2 \leqq t_3$; consequently, there is a nontrivial optimal solution $x(t)$ satisfying either (27) or (28) and boundary conditions of the type respectively given in (i) or (ii). Since $t_3 - t_1 < k$, this is a contradiction.

Therefore, solutions of (1), (13) are unique, when they exist, and the conclusion follows from Theorem 4.3.

We conclude this section by further restricting our above subinterval length k and obtaining, in addition, subintervals on which there unique solutions of (1), (14). Such a problem was considered in [1], by first transforming the problem into a boundary value problem for a second order integro-differential equation. Then successive approximations were used in obtaining length bounds on intervals for existence of unique solutions; these bounds were somewhat better than those obtained using standard Contraction Mapping arguments. However, we will determine best length subintervals for the existence of unique solutions of (1), (14), when the problems (1), (11), (12), and (13) all have unique solutions.

THEOREM 4.5. *Assume that for all vectors $u \in U$, the corresponding linear equation* (26) *has only the trivial solution satisfying*

$$x(t_1)=x'(t_1)=x'(t_2)=0, \qquad a<t_1<t_2<b.$$

If there is a control vector $u \in U$ such that the corresponding equation (26) *has a nontrivial solution satisfying*

$$y(t_1)=y''(t_1)=y'(t_2)=0, \qquad a<t_1<t_2<b$$

and if $x(t)$ is a time optimal solution with

$$x(c)=x''(c)=x'(d)=0$$

and with $d-c$ a minimum, then $x(t)$ is a solution of (27) *on* $[c, d]$.

Proof. The proof proceeds much like those before. By optimality $x'(t)\neq 0$ on $[c, d)$, and thus by Rolle's theorem, $x(t)\neq 0$ on $(c, d]$. We may assume $x(t)>0$ on $(c, d]$. Now if $\psi(t)$ is the corresponding optimal solution of the adjoint system, then

$$\psi_2(c)=\psi_1(d)=\psi_3(d)=0.$$

Now, if $\psi_3(t_0)=0$, for some $t_0\in[c, d)$, since $\psi_1(d)=\psi_3(d)=0$, there is an optimal solution $z(t)$ of (26) satisfying

$$z(\tau_1)=z'(\tau_1)=z'(\tau_2)=0,$$

for some $t_0\leqq \tau_1<\tau_2\leqq d$, a contradiction. Therefore, $\psi_3(t)\neq 0$ on $[c, d)$, and $x(t)$ is a solution of (27) or (28).

Since $x'''(t)$ is of constant sign on [c, d], from the conditions $x(c)=x''(c)=x'(d)=0$, we conclude $x'''(t)<0$ on $[c, d]$, and $x(t)$ is a solution of (27) on $[c, d]$.

For uniqueness implies existence we have the following.

LEMMA. *Assume that solutions of* (1), (13), *and* (1), (14) *are unique, when they exist on* (a, b). *Then boundary value problems for* (1) *satisfying* (11), (12), (13), *or* (14) *all have unique solutions on* (a, b).

Proof. In light of Theorem 4.3, we need only prove the statement for (1), (14). For this, let $a<t_1<t_2<b$ and $y_1, y_2, y_3\in \mathbf{R}$ be given, and let $y(t)$ be the solution of the initial value problem for (1) satisfying

$$y(t_1)=y_1, \quad y'(t_1)=0, \quad y''(t_1)=y_2.$$

Now define

$$S\equiv\{z'(t_2)\,|\,z(t) \text{ is a solution of (1) and } z(t_1)=y(t_1),\ z''(t_1)=y''(t_1)\}.$$

Using continuous dependence and the fact that solutions of (1), (11) and (1), (12) exist, it can be shown by fairly standard arguments that $S=\mathbf{R}$; see [10]. Thus, by choosing $y_3\in S$, the corresponding solution $z(t)$ of (1) satisfies (14).

THEOREM 4.6. *Let $l=\min\{k, s\}$, where k is the number obtained in Theorem* 4.4, *and $s>0$ is the smallest positive number such that there is a solution $x(t)$ of the boundary problem for* (27) *satisfying*

$$x(0)=x''(0)=x'(s)=0,$$

with $x(t)>0$ *on* $(0, s]$, *or* $s=+\infty$ *if no such solution exists. Then each of the boundary value problems for* (1) *satisfying* (11), (12), (13), *or* (14) *has a unique solution, provided* $t_3-t_1<l$. *Again, this is best possible.*

Proof. The proof is immediate from the last lemma and Theorem 4.4.

5. Best interval lengths for $k_1=k_2=k_3=1$. In this section, we employ the results of the previous sections in computing the best possible interval lengths of subintervals of (a, b) on which the boundary value problems for (1) have unique solutions for the case where the Lipschitz coefficients satisfy $k_1=k_2=k_3=1$. For some of the problems, we compare our results with interval length bounds obtained by standard Contraction Mapping methods. In a couple of cases, we will also compare our results with those obtained in [1].

For each of the following cases, we let $k_1=k_3=k_3=1$.

(i) For our first case, we are concerned with solutions of conjugate boundary value problems for (1); that is, conditions (2), (3), and (4). As a corollary to Theorem 1.1, Jackson [12] showed that the boundary value problems for (1) satisfying (2), (3), or (4) all have unique solutions on any open subinterval of length less than h, where $x(t)$ is the solution of (27) satisfying the initial conditions

$$x(0)=x'(0)=0, \qquad x''(0)=1$$

and $h>0$ is the first positive number such that $x(h)=0$. In this case, Jackson obtained the best possible result to be $h=2.7353$. On the other hand, from Contraction Mapping bounds, interval lengths of only 1.1284 result.

(ii) In this case, we are concerned with right focal boundary value problems for (1) satisfying conditions (5), (6), and (7). From Theorem 1.3, boundary value problems for (1) satisfying (5), (6), or (7) all have unique solutions on open subintervals of (a, b) of length less than $k=\min\{r_1, r_2\}$, where $x(t)$ is the solution of (27) satisfying the initial conditions

$$x(0)=x'(0)=0, \qquad x''(0)=1$$

and $r_1>0$ is the first positive number such that $x''(r_1)=0$, and $y(t)$ is the solution of (27) satisfying

$$y(0)=1, \qquad y'(0)=y''(0)=0$$

and $r_2>0$ is the first positive number such that $y(r_2)=0$. For this case, we obtain the best subinterval length as $k=r_1=1.03842$. For comparison, using Contraction Mapping, interval lengths are bounded by .672496, whereas Aftabizadeh and Wiener's techniques yielded lengths of .896861.

(iii) For this case, we consider the problems of § 3. From Theorem 3.4, boundary value problems for (1) satisfying (8), (9), or (10) have unique solutions on open subintervals of (a, b) of length less than η, where $x(t)$ is the solution of (27) and satisfies

$$x(0)=x'(0)=0, \qquad x''(0)=1,$$

and $\eta>0$ is the first positive number such that $x'(\eta)=0$. We find here that best subinterval lengths are $\eta=1.923239$. Aftabizadeh and Wiener's techniques yield interval lengths bounded by 1.59542.

(iv) For this case, we are concerned with subinterval lengths for the problems of § 4. For the case of problems (1)-(11), (12), or (13), all have unique solutions on subintervals of (a, b) of length less than $l=\min\{l_1, l_2\}$, where $x(t)$ is the solution (27) satisfying

$$x(0)=x'(0)=0, \qquad x''(0)=1$$

and $l_1 > 0$ is the first number such that $x(l_1) = 0$, and $y(t)$ is the solution of (27) satisfying

$$y(0) = 1, \qquad y'(0) = y''(0) = 0$$

and $l_2 > 0$ is the first positive number such that $y(l_2) = 0$ (to see this is the appropriate initial value problem for l_2, replace the solution $x(t)$ in Theorem 4.4 by $x(-t+r)$). We note that $l_1 = \eta$ from (iii) and $l_2 = r_2$ from (ii), and it follows that the best subinterval length is $l = l_2 = 1.52374$.

As we proved in Theorem 4.6, by restricting the subinterval lengths further, (1), (14) also has a unique solution. In fact, for this special case of Lipschitz coefficients, we have unique solutions of (1), (14) on intervals of length less than m, where $x(t)$ is the solution of (27) satisfying

$$x(0) = x''(0) = 0, \qquad x'(0) = 1$$

and $m > 0$ is the first number such that $x'(m) = 0$. For the best possible interval length, $m = 1.10647$.

Remark. For the calculations discussed in (ii)-(iv), Runge-Kutta methods were used. However, in some cases, such as (ii), it is elementary to explicitly solve the specified initial value problem; then applying Newton's method to the appropriate derivative of the solution, the optimal interval length can be determined.

ON THE RATE OF CONVERGENCE OF VISCOSITY SOLUTIONS FOR BOUNDARY VALUE PROBLEMS*

JENS LORENZ† AND RICHARD SANDERS‡

Abstract. A class of singularly perturbed boundary value problems is considered for viscosity tending to zero. From compactness arguments it is known that the solutions converge to a limit function characterized by an entropy inequality. We formulate an approximate entropy inequality (AEI) and use it to obtain the order of convergence. The AEI is also used to obtain the order of convergence for monotone difference schemes.

Key words. singular perturbations, entropy inequality, bounded variation functions

AMS(MOS) subject classifications. Primary 34E99, 65L10

1. Introduction. In this paper we establish a minimal rate of convergence theorem for solutions to the singularly perturbed boundary value problem

$$\begin{aligned} &-\varepsilon \frac{d^2}{dx^2} u_\varepsilon + \frac{d}{dx} f(x, u_\varepsilon) + b(x, u_\varepsilon) = 0, \\ &u_\varepsilon(0) = \gamma_0, \qquad u_\varepsilon(0) = \gamma_1, \end{aligned} \tag{1.1}$$

as the parameter $\varepsilon > 0$ tends to zero. Throughout we impose no special conditions on $f(x, u)$ or $b(x, u)$ other than that they are smooth and satisfy

$$\frac{\partial}{\partial u} b(x, u) - \left| \frac{\partial^2}{\partial u \partial x} f(x, u) \right| \geqq \mu > 0 \tag{1.2}$$

for all $(x, u) \in [0, 1] \times I$ where I is an a priori interval determined from the maximum principle.[1]

It is well known that for positive ε, condition (1.2) implies that the boundary value problem (1.1) has a unique smooth solution; see [8], [9] for results in this direction.

As ε tends to zero, solutions to (1.1) need not converge to a continuous function. Therefore, it is natural to seek a rate of convergence result in an integral sense. Below we show that there exists a function $\bar{u} \in BV$ such that for sufficiently small ε

$$\int_0^1 |u_\varepsilon - \bar{u}| \, dx \leqq \frac{C_\gamma}{\mu} \sqrt{\varepsilon}, \tag{1.3}$$

where the constant C_γ depends on the boundary data γ_0 and γ_1. In general the rate above is not valid *unless* condition (1.2) is imposed. That is to say there are examples

[1] The interested reader can greatly relax the smoothness assumption we make on the coefficients of (1.1). We consider these details uninteresting however, and we take $f(x, u)$ and $b(x, u)$ as smooth as the specified number of derivatives indicate.

of boundary value problems of the form (1.1) that violate (1.2) (they must satisfy an estimate like (1.2) with $\mu = 0$) and satisfy

$$\int_0^1 |u_\varepsilon - \bar{u}|\, dx \geqq \text{const. } \varepsilon^q$$

for any $\frac{1}{2} \geqq q > 0$. Moreover, given that condition (1.2) *is* satisfied, the L^1 rate result (1.3) cannot be improved unless further conditions are imposed. That is, there are examples that satisfy condition (1.2) and satisfy

$$\int_0^1 |u_\varepsilon - \bar{u}|\, dx \geqq \text{const.} \sqrt{\varepsilon}.$$

Some examples that demonstrate the sharpness of our rate result are presented at the end of this section.

The main contribution of this paper is to extend the techniques developed in [6], [13] to include problems with Dirichlet boundary conditions. The notion of an "approximate entropy inequality (AEI)," first introduced in the study of single conservation laws, is suitably modified to include boundary value problems of the type studied here. Specifically, what we show is that if a parameterized family of functions, say $\{v_h\}_{h>0}$, satisfies the uniform estimate

$$\text{var}\,(v_h) \leqq \text{const.},$$

together with an h-dependent AEI, then v_h satisfies (1.3) with h taking the place of ε. We have intentionally been vague about the precise definition of the family $\{v_h\}_{h>0}$ since it is shown below that besides representing the family of solutions to (1.1) it can also represent a family of certain numerical approximations. In the application to numerical approximations v_h denotes an interpolation of grid values generated by a finite difference scheme, and h denotes a measure of grid refinement.

In § 2 the characterizing "entropy inequality" for the limit of solutions to (1.1) is stated; see [2], [3], [5], [14] for a thorough development of these ideas. The "approximate entropy inequality" is also defined in this section, and solutions of (1.1) are shown to satisfy it. The abstract rate of convergence theorem implied by the AEI is also stated in § 2. In § 3 the abstract rate of convergence theorem, stated in § 2, is proved. Finally in § 4 the rate of convergence theorem is applied to numerical approximations generated by certain types of finite difference schemes.

We should mention that most of the results of this paper can be routinely extended to quasilinear Dirichlet problems in many space dimensions. This will be the topic of future work; see [12], where somewhat parallel techniques are applied to nonlinear problems with boundary conditions of Neumann type.

We conclude this section by constructing some nontrivial examples of the type mentioned above. First we show that if (1.2) is violated then an arbitrarily slow L^1 rate of convergence is possible. To this end, consider the boundary value problem

$$\begin{gathered} -\varepsilon \frac{d^2}{dx^2} u_\varepsilon + \frac{d}{dx}(\gamma - u_\varepsilon)^{2p} = 0, \\ u_\varepsilon(0) = 0, \qquad u_\varepsilon(1) = \gamma > 0, \end{gathered} \tag{1.4}$$

where we take $p > 1$. Clearly (1.4) violates (1.2). By [8, Thm. 4] the solutions of (1.4) tend uniformly to γ on any interval $[\delta, 1]$, $1 > \delta > 0$, as ε tends to zero. Therefore, we wish to examine

$$\int_0^1 |u_\varepsilon - \gamma|\, dx. \tag{1.5}$$

With this end in mind we first consider

$$-\varepsilon\frac{d^2}{dx^2}v_\varepsilon+\frac{d}{dx}(\gamma-v_\varepsilon)^{2p}=0, \tag{1.6}$$
$$v_\varepsilon(0)=0, \qquad v_\varepsilon(\infty)=\gamma,$$

which can be integrated exactly, giving

$$v_\varepsilon(x)=\Phi^{-1}(x/\varepsilon), \tag{1.7}$$

where

$$\Phi(w)=\int_0^w (\gamma-s)^{-2p}\,ds.$$

Since $v_\varepsilon(x)+\gamma-v_\varepsilon(1)$ is an upper solution for (1.4), it follows that this function is $\geqq u_\varepsilon(x)$; thus

$$\gamma-u_\varepsilon(x)\geqq v_\varepsilon(1)-v_\varepsilon(x)\geqq 0,$$

which implies

$$\int_0^1 |u_\varepsilon-\gamma|\,dx\geqq\int_0^1 (v_\varepsilon(1)-v_\varepsilon(x))\,dx. \tag{1.8}$$

Interchanging the order of integration and using (1.7), we have that the right-hand side of (1.8) is given by

$$\varepsilon\int_0^{v_\varepsilon(1)}\Phi(w)\,dw.$$

Finally, a simple calculation will reveal that

$$\varepsilon\int_0^{v_\varepsilon(1)}\Phi(w)\,dw=\frac{1}{2p-2}\left(\frac{\varepsilon}{2p-1}\right)^{1/2p-1}+O(\varepsilon),$$

which therefore shows that

$$\int_0^1 |u_\varepsilon-\gamma|\,dx\geqq C_p(\varepsilon^{1/2p-1}),$$

as ε tends to zero.

To establish the fact, given only condition (1.2), our rate result (1.3) is the best possible, we note that the trivial example

$$-\varepsilon\frac{d^2}{dx^2}u_\varepsilon+u_\varepsilon=0,$$
$$u_\varepsilon(0)=0, \qquad u_\varepsilon(1)=1,$$

satisfies the $\sqrt{\varepsilon}L^1$ rate of convergence exactly. A less trivial example is given by

$$-\varepsilon\frac{d^2}{dx^2}u_\varepsilon+\frac{d}{dx}((1-x)u_\varepsilon)+2u_\varepsilon=0, \tag{1.9}$$
$$u_\varepsilon(0)=0, \qquad u_\varepsilon(1)=1.$$

To obtain the sharp $\sqrt{\varepsilon}$ rate for example (1.9) we apply the "shooting method." (Although this method is less general than the techniques we present in the following sections, it takes into account specific properties of $f(x, u)$ and often leads to sharper results than ours; see [4] for applications of differential inequalities.) From our results below, we expect that $\lim_{\varepsilon\downarrow 0} u_\varepsilon = 0$. The maximum principle together with integrating (1.9) gives us that

$$\int_0^1 |u_\varepsilon - 0|\, dx = \frac{\varepsilon}{2}\left[\frac{d}{dx}u_\varepsilon(1) - \frac{d}{dx}u_\varepsilon(0)\right]. \tag{1.10}$$

By applying the shooting method, it is easy to conclude that for all $\varepsilon > 0$ sufficiently small, we have

$$\frac{1}{2\sqrt{\varepsilon}} \leqq \frac{d}{dx}u_\varepsilon(1) \leqq \frac{3}{\sqrt{\varepsilon}},$$

and

$$0 \leqq \frac{d}{dx}u_\varepsilon(0) \leqq 1.$$

Inserting these inequalities into (1.10) we finally get

$$\frac{\sqrt{\varepsilon}}{4} - O(\varepsilon) \leqq \int_0^1 |u_\varepsilon - 0|\, dx \leqq \frac{3}{2}\sqrt{\varepsilon},$$

which establishes our L^1 rate for example (1.9).

2. The approximate entropy inequality. Throughout this paper the following notation is used:

(i) BV denotes the space of functions $u: [0, 1] \to \mathbb{R}$ of bounded variation.

(ii) $\operatorname{var}(u)$ is the total variation of $u \in BV$.

(iii) C_+^∞ denotes the space of functions $\phi: \mathbb{R} \to \mathbb{R}$ which are infinitely differentiable and nonnegative.

The sign-function is defined by

$$\operatorname{sgn}(u) = \begin{cases} -1 & \text{if } u < 0, \\ 0 & \text{if } u = 0, \\ 1 & \text{if } u > 0, \end{cases}$$

and

$$\operatorname{sgn}_\delta(u) = \begin{cases} u/|u| & \text{for } |u| \geqq \delta, \\ u/\delta & \text{for } |u| < \delta \end{cases}$$

denotes a Lipschitz continuous approximation to $\operatorname{sgn}(u)$ for $\delta > 0$. We furthermore use

$$\|u\|_\infty = \sup\{|u(x)|: 0 \leqq x \leqq 1\} \quad \text{for } u \in L^\infty[0, 1],$$

$$\|u\|_1 = \int_0^1 |u(x)|\, dx \quad \text{for } u \in L^1[0, 1].$$

For simplicity we assume that $f(x, u) \in C^2([0, 1] \times \mathbb{R})$ and $b(x, u) \in C^1([0, 1] \times \mathbb{R})$ although we recognize that weaker conditions are sufficient. The essential assumption is nevertheless condition (1.2), and it will be assumed throughout.

In the next proposition we state some known results concerning the second order boundary value problem (1.1); see [2], [9]. These facts are relevant in what follows.

PROPOSITION 2.1. *For all $\varepsilon > 0$, (1.1) has a unique smooth solution u_ε. Moreover, there exists a constant c, not depending on ε, such that*

$$\|u_\varepsilon\|_\infty + \operatorname{var}(u_\varepsilon) \leqq c.$$

Finally, there exists a unique (a.e.) function $\bar{u} \in BV$ such that

$$\|u_\varepsilon - \bar{u}\|_1 \to 0,$$

as $\varepsilon \downarrow 0$.

It is known that the limit $\bar{u} \in BV$ is the only (a.e.) BV function satisfying the following so-called "entropy inequality":

For all $k \in \mathbb{R}$ and all $\phi \in C_+^\infty$

$$\begin{aligned}\int_0^1 \operatorname{sgn}(\bar{u}-k)\left\{-(f(x,\bar{u})-f(x,k))\phi_x + \left(b(x,\bar{u}) + \frac{\partial}{\partial x} f(x,k)\right)\phi\right\} dx \\ + \operatorname{sgn}(\gamma_1 - k)\{f(1,\bar{u}(1-)) - f(1,k)\}\phi(1) \\ - \operatorname{sgn}(\gamma_0 - k)\{f(0,\bar{u}(0+)) - f(0,k)\}\phi(0) \leqq 0.\end{aligned}$$

We now state what we call the "approximate entropy inequality" (or AEI) for a parameterized family of BV functions $\{v_h\}_{0<h\leqq h_0}$. Below the family of solutions to (1.1) are shown to satisfy the AEI, and in § 4 certain numerical approximations are shown to satisfy the AEI as well.

DEFINITION 2.1. A family of BV functions $\{v_h\}_{0<h\leqq h_0}$ is said to satisfy the AEI if there exists nonnegative functions

$$R_h^0, \quad R_h^1, \quad R_h^2 \in BV, \qquad 0 < h \leqq h_0,$$

with the properties that

A. There exists a constant c independent of $0 < h \leqq h_0$ and $0 \leqq \delta \leqq 1$ such that

A0. $$\int_0^\delta R_h^0(s)\, ds \leqq c(h + \delta^2),$$

A1. $$\int_{1-\delta}^1 R_h^1(s)\, ds \leqq c(h + \delta^2),$$

A2. $$\int_0^1 R_h^2(s)\, ds \leqq ch;$$

B. For all $k \in \mathbb{R}$, all $\phi \in C_+^\infty$ and almost every $\alpha, \beta \in (0,1)$ we have

$$\begin{aligned}\int_0^1 \operatorname{sgn}(v_h - k)\left\{-(f(x,v_h) - f(x,k))\phi_x + \left(b(x,v_h) + \frac{\partial}{\partial x} f(x,k)\right)\phi\right\} dx \\ + \operatorname{sgn}(\gamma_1 - k)\{f(\beta, v_h(\beta)) - f(1,k)\}\phi(1) \\ - \operatorname{sgn}(\gamma_0 - k)\{f(\alpha, v_h(\alpha)) - f(0,k)\}\phi(0) \\ \leqq R_h^1(\beta)\phi(1) + R_h^0(\alpha)\phi(0) + \int_0^1 R_h^2 |\phi_x|\, dx.\end{aligned}$$

In § 3 we prove the following theorem.

THEOREM 2.1. *Let $\{v_h\}$ satisfy the AEI and assume that there exists a constant C_1 independent of $0 < h \leqq h_0$ such that $\|v_h\|_\infty + \operatorname{var}(v_h) \leqq C_1$. Then, there exists a constant C_2 independent of $0 < h \leqq h_0$ such that*

$$\|v_h - \bar{u}\|_1 \leqq C_2\sqrt{h},$$

where $\bar{u} = \lim_{\varepsilon\downarrow 0} u_\varepsilon$.

The result of Theorem 2.1 applies directly to the family of solutions to (1.1).

COROLLARY. *The family* $\{u_\varepsilon\}_{\varepsilon>0}$ *of solutions to* (1.1) *satisfies the AEI*; *consequently we have the estimate*

$$\|u_\varepsilon - \bar{u}\| \leqq C\sqrt{\varepsilon}.$$

Proof. Multiply the identity

$$0 = -\varepsilon \frac{d^2}{dx^2} u_\varepsilon + \frac{d}{dx}(f(x, u_\varepsilon) - f(x, k)) + \left(b(x, u_\varepsilon) + \frac{\partial}{\partial x} f(x, k) \right)$$

by $\operatorname{sgn}_\delta (u_\varepsilon - k)\phi$, $\phi \in C_+^\infty$, integrate over $0 \leqq x \leqq 1$, apply integration by parts, use the estimate

$$\int_0^1 \left(\frac{d}{dx} \operatorname{sgn}_\delta (u_\varepsilon - k) \frac{d}{dx} u_\varepsilon \right) \phi \, dx \geqq 0$$

and let $\delta \downarrow 0$ to find with Lebesgue's dominated convergence theorem that

$$\begin{aligned} \int_0^1 \operatorname{sgn}(u_\varepsilon - k) &\left\{ -(f(x, u_\varepsilon) - f(x, k))\phi_x + \left(b(x, u_\varepsilon) + \frac{\partial}{\partial x} f(x, k) \right) \phi \right\} dx \\ &+ \operatorname{sgn}(\gamma_1 - k) \left\{ f(1, \gamma_1) - f(1, k) - \varepsilon \frac{d}{dx} u_\varepsilon(1) \right\} \phi(1) \\ &- \operatorname{sgn}(\gamma_0 - k) \left\{ f(0, \gamma_0) - f(0, k) - \varepsilon \frac{d}{dx} u_\varepsilon(0) \right\} \phi(0) \\ \leqq -\varepsilon &\int_0^1 \operatorname{sgn}(u_\varepsilon - k) \left(\frac{d}{dx} u_\varepsilon \right) \phi_x \, dx. \end{aligned}$$

Integrating the differential equation (1.1) we make it evident that the boundary terms above can be written as

$$\operatorname{sgn}(\gamma_1 - k) \left\{ (f(\beta, u_\varepsilon(\beta)) - f(1, k)) - \varepsilon \frac{du_\varepsilon}{dx}(\beta) - \int_\beta^1 b(x, u_\varepsilon) \, dx \right\} \phi(1),$$

and

$$\operatorname{sgn}(\gamma_0 - k) \left\{ (f(\alpha, u_\varepsilon(\alpha)) - f(0, k)) - \varepsilon \frac{du_\varepsilon}{dx}(\alpha) + \int_0^\alpha b(x, u_\varepsilon) \, dx \right\} \phi(0).$$

Inserting these identities into the inequality above we easily find that u_ε satisfies the AEI with

$$R_\varepsilon^0(\alpha) = \varepsilon \left| \frac{d}{dx} u_\varepsilon(\alpha) \right| + \int_0^\alpha |b(x, u_\varepsilon)| \, dx,$$

$$R_\varepsilon^1(\beta) = \varepsilon \left| \frac{d}{dx} u_\varepsilon(\beta) \right| + \int_\beta^1 |b(x, u_\varepsilon)| \, dx,$$

$$R_\varepsilon^2(x) = \varepsilon \left| \frac{d}{dx} u_\varepsilon(x) \right|.$$

Using the result of Proposition 2.1 we finally conclude that R_ε^0, R_ε^1 and R_ε^2 above satisfy properties A0, A1 and A2 of Definition 2.1 with ε taking the role of h.

3. Proof of Theorem 2.1. Let $\{u_\varepsilon\}_{\varepsilon>0}$ denote the family of solutions to (1.1), and let $\{v_h\}_{h>0}$ denote a family of functions which have uniformly bounded variation and which satisfy the AEI. Moreover, let R^j_ε, (resp. R^j_h), with $j=0,1,2$, represent the estimating functions of the AEI of Definition 2.1 for $\{u_\varepsilon\}_{\varepsilon>0}$, (resp. $\{v_h\}_{h>0}$). The proof of Theorem 2.1 is essentially a test function argument with a particular family of test functions ϕ_δ of the form

$$\phi_\delta(x)=\frac{1}{\delta}\phi\left(\frac{x}{\delta}\right),$$

where $\phi\in C^\infty_+$ is symmetric, $\int_{-\infty}^{\infty}\phi(x)\,dx=1$ and supp $(\phi)\subset(-1,1)$. Now consider the AEI of Definition 2.1 applied to $u_\varepsilon(x)$ with $k=v_h(y)$ and the test function ϕ replaced by $\phi(x)=\phi_\delta(x-y)$ and with $\alpha=\beta=y$ in R^j_h, $j=0,1$. Integrate the resulting inequality from $y=0$ to $y=1$. Since v_h also satisfies the AEI, the same procedure can be done as above with the roles of v_h and u_ε reversed. Adding both resulting inequalities together we obtain

$$\begin{aligned}\int_0^1\int_0^1 &\operatorname{sgn}(u_\varepsilon(x)-v_h(y))\Big\{(b(x,u_\varepsilon(x))-b(y,v_h(y)))\\ &\qquad+\left(\frac{\partial}{\partial x}f(x,v_h(y))-\frac{\partial}{\partial y}f(y,u_\varepsilon(x))\right)\Big\}\phi_\delta(x-y)\,dx\,dy\\ &\qquad+\int_0^1\int_0^1\operatorname{sgn}((u_\varepsilon(x)-v_h(y))\{(f(x,v_h(y))-f(y,v_h(y)))\\ &\qquad+(f(y,u_\varepsilon(x))-f(x,u_\varepsilon(x)))\}\frac{d}{dx}\phi_\delta(x-y)\,dx\,dy+T_1(\varepsilon,h,\delta)-T_0(\varepsilon,h,\delta)\\ &\leqq P^0_h(\delta)+P^1_h(\delta)+P^2_h(\delta)+P^0_\varepsilon(\delta)+P^1_\varepsilon(\delta)+P^2_\varepsilon(\delta),\end{aligned}\tag{3.1}$$

where

$$\begin{aligned}T_1(\varepsilon,h,\delta)=&\int_0^1\operatorname{sgn}(\gamma_1-v_h(y))\{f(y,u_\varepsilon(y))-f(1,v_h(y))\}\phi_\delta(1-y)\,dy\\ &+\int_0^1\operatorname{sgn}(\gamma_1-u_\varepsilon(x))\{f(x,v_h(x))-f(1,u_\varepsilon(x))\}\phi_\delta(1-x)\,dx,\end{aligned}\tag{3.2}$$

$$\begin{aligned}T_0(\varepsilon,h,\delta)=&\int_0^1\operatorname{sgn}(\gamma_0-v_h(y))\{f(y,u_\varepsilon(y))-f(0,v_h(y))\}\phi_\delta(y)\,dy\\ &+\int_0^1\operatorname{sgn}(\gamma_0-u_\varepsilon(x))\{f(x,v_h(x))-f(0,u_\varepsilon(x))\}\phi_\delta(x)\,dx,\end{aligned}\tag{3.3}$$

and

$$P^0_h(\delta)=\int_0^1 R^0_h(x)\phi_\delta(x)\,dx,\tag{3.4}$$

$$P^1_h(\delta)=\int_0^1 R^1_h(x)\phi_\delta(1-x)\,dx,\tag{3.5}$$

$$P^2_h(\delta)=\int_0^1\int_0^1 R^2_h(y)\left|\frac{d}{dx}\phi_\delta(x-y)\right|\,dx\,dy,\tag{3.6}$$

and a similar expression for $P^j_\varepsilon(\delta)$. The proof is divided into basically the following four lemmas.

LEMMA 3.1. *There is a constant c independent of $\varepsilon > 0$, $h > 0$, and $\delta > 0$ such that we have*

$$r.h.s. \leqq c\left(\frac{\varepsilon}{\delta}+\frac{h}{\delta}+\delta\right),$$

where r.h.s. is the right-hand side of (3.1).

LEMMA 3.2. *There is another constant c as above such that we have*

$$T_0(\varepsilon, h, \delta) \leqq c\left(\frac{\varepsilon}{\delta}+\frac{h}{\delta}+\delta\right), \qquad -T_1(\varepsilon, h, \delta) \leqq c\left(\frac{\varepsilon}{\delta}+\frac{h}{\delta}+\delta\right),$$

where T_0 and T_1 are defined in (3.2), (3.3).

LEMMA 3.3. *There is a constant c independent of positive ε, h and δ such that*

$$\left|\int_0^1 \int_0^1 \operatorname{sgn}(u_\varepsilon(x) - v_h(y))\{(f(x, v_h(y)) - f(y, v_h(y))) + (f(y, u_\varepsilon(x)) - f(x, u_\varepsilon(x)))\} \frac{d}{dx}\phi_\delta(x-y)\, dx\, dy\right| \leqq c\delta.$$

LEMMA 3.4. *There is a constant c independent of positive ε, h, $\delta \leqq 1/2$ such that*

$$\begin{aligned}\int_0^1 &\left|\left(b(x, u_\varepsilon(x)) - \frac{\partial}{\partial x} f(x, u_\varepsilon(x))\right) - \left(b(x, v_h(x)) - \frac{\partial}{\partial x} f(x, v_h(x))\right)\right| dx \\ &\leqq 2\int_0^1\int_0^1 \operatorname{sgn}(u_\varepsilon(x) - v_h(y))\left\{(b(x, u_\varepsilon(x)) - b(y, v_h(y))) \right.\\ &\qquad \left. + \left(\frac{\partial}{\partial x} f(x, v_h(y)) - \frac{\partial}{\partial y} f(y, u_\varepsilon(x))\right)\right\} \phi_\delta(x-y)\, dx\, dy + c\delta.\end{aligned}$$

Given the results above, the final result follows by first noting that, along with condition (1.2), they imply

$$\begin{aligned}\mu &\int_0^1 |u_\varepsilon(x) - v_h(x)|\, dx \\ &\leqq \int_0^1 \left|\left(b(x, u_\varepsilon(x)) - \frac{\partial}{\partial x} f(x, u_\varepsilon(x))\right) - \left(b(x, v_h(x)) - \frac{\partial}{\partial x} f(x, v_h(x))\right)\right| dx \\ &\leqq \hat{c}\left(\frac{\varepsilon}{\delta}+\frac{h}{\delta}+\delta\right),\end{aligned}$$

with $\hat{c}$ independent of positive ε, h and $\delta \leqq \frac{1}{2}$. Sending ε to zero, we conclude that

$$\|\bar{u} - v_h\|_1 \leqq \frac{\hat{c}}{\mu}\left(\frac{h}{\delta}+\delta\right),$$

and choosing $\delta = \sqrt{h}$ proves the theorem.

Proof of Lemma 3.1. The terms to be estimated are given in (3.4)-(3.6). Note that

$$P_h^0(\delta) = \int_0^\delta R_h^0(x)\phi_\delta(x)\, dx \leqq \frac{C}{\delta}(h+\delta^2)$$

and

$$P_h^2(\delta) = \int_0^1 R_h^2(y)\left\{\int_0^1 \left|\frac{d}{dx}\phi_\delta(y-x)\right| dx\right\} dy \leqq C\frac{h}{\delta},$$

where the first inequality above follows from the definition $R_h^0(x)$ and $\phi_\delta(x)$, and the second follows from the definition of $R_h^2(y)$ and the fact that

$$\int_0^1 \left|\frac{d}{dx}\phi_\delta(y-x)\right| dx \leqq \frac{1}{\delta^2}\int_{-\infty}^{\infty} \left|\phi'\left(\frac{z}{\delta}\right)\right| dz \leqq C/\delta.$$

Similar estimates hold for the remaining terms on the right-hand side of (3.1).

Proof of Lemma 3.2. We only estimate T_0 since $-T_1$ can be treated similarly. Note that T_0 can be written as

$$\begin{aligned} T_0(\varepsilon, h, \delta) = \int_0^1 & \{\operatorname{sgn}(\gamma_0 - v_h) - \operatorname{sgn}(\gamma_0 - u_\varepsilon)\} \\ & \cdot \{(f(x, u_\varepsilon) - f(x, \gamma_0)) + (f(x, \gamma_0) - f(x, v_h))\}\phi_\delta(x)\, dx \\ & + \int_0^1 \operatorname{sgn}(\gamma_0 - v_h)\{f(x, v_h) - f(0, v_h)\}\phi_\delta(x)\, dx \\ & + \int_0^1 \operatorname{sgn}(\gamma_0 - u_\varepsilon)\{f(x, u_\varepsilon) - f(0, u_\varepsilon)\}\phi_\delta(x)\, dx. \end{aligned}$$

Clearly, the second two terms above can be bounded above by $C\delta$. The first term above is bounded above by

$$\begin{aligned} & \int_0^1 [|f(x, u_\varepsilon) - f(x, \gamma_0)| + \operatorname{sgn}(u_\varepsilon - \gamma_0)(f(x, u_\varepsilon) - f(x, \gamma_0))]\phi_\delta(x)\, dx \\ & \quad + \int_0^1 [|f(x, v_h) - f(x, \gamma_0)| + \operatorname{sgn}(v_h - \gamma_0)(f(x, v_h) - f(x, \gamma_0))]\phi_\delta(x)\, dx. \end{aligned} \tag{3.7}$$

We estimate the first integral above only since the second integral can be estimated similarly. Return now to the AEI applied to u_ε, and set $k = \gamma_0$ and suppose there we replace the test function $\phi(x)$ with a test function approaching

$$H(x - x_0) = \begin{cases} 1, & x < x_0, \\ 0, & x \geqq x_0. \end{cases}$$

Doing so we find that for almost every $x_0 \in (0, 1)$ the AEI implies that

$$\begin{aligned} \operatorname{sgn}(u_\varepsilon(x_0) - \gamma_0)\{f(x_0, u_\varepsilon(x_0)) - f(x_0, \gamma_0)\} & \leqq R_\varepsilon^0(x_0) + R_\varepsilon^2(x_0) + cx_0 \\ & \equiv e_\varepsilon(x_0). \end{aligned} \tag{3.8}$$

To find an estimate for the integral in question, we note the obvious implication: If $Q \leqq e$ then $|Q| + Q \leqq 2e$. Therefore, applying (3.8) (and the analogous estimate for v_h) to (3.7) shows that (3.7) is bounded above by

$$2\int_0^1 [e_\varepsilon(x) + e_h(x)]\phi_\delta(x)\, dx.$$

Finally, applying the simple estimates of the previous lemma completes the proof of the present lemma.

The proof of Lemma 3.3 is routine and is left to the reader.

Proof of Lemma 3.4. The proof of this lemma can be given for fixed $\varepsilon > 0$, $h > 0$, using only condition (1.2) and the uniform estimate

$$\|u_\varepsilon\|_\infty + \int_0^1 \left|\frac{d}{dx}u_\varepsilon\right| dx \leqq C_0.$$

For convenience we omit the subscripts ε and h. Condition (1.2) and a simple rearrangement gives us that

$$\begin{aligned}\left|(b(y,u(y))-\frac{\partial}{\partial y}f(y,u(y)))-\left(b(y,v(y))-\frac{\partial}{\partial y}f(y,v(y))\right)\right|&\\ \leqq \operatorname{sgn}(u(x)-v(y))\Big\{(b(x,u(x))-b(y,v(y)))&\\ +\left(\frac{\partial}{\partial x}f(x,v(y))-\frac{\partial}{\partial y}f(y,u(x))\right)\Big\}&\\ +L_1|x-y|+L_2|u(x)-u(y)|,&\end{aligned}$$

where

$$L_1=\max\left\{\left|\frac{\partial}{\partial x}b(x,u)\right|+\left|\frac{\partial^2}{\partial x^2}f(x,u)\right|, u\in I, x\in[0,1]\right\},$$

$$L_2=\max\left\{\left|\frac{\partial}{\partial u}b(x,u)\right|+\left|\frac{\partial^2}{\partial x\partial u}f(x,u)\right|, u\in I, x\in[0,1]\right\}.$$

Furthermore, it is obvious that for all $0\leqq y\leqq 1$ and all $\frac{1}{2}\geqq\delta>0$

$$\int_0^1 \phi_\delta(x-y)\,dx\geqq\tfrac{1}{2}.$$

Therefore

$$\begin{aligned}&\int_0^1\left|\left(b(y,u(y))-\frac{\partial}{\partial y}f(y,u(y))\right)-\left(b(y,v(y))-\frac{\partial}{\partial y}f(y,v(y))\right)\right|dy\\ &\leqq 2L_1\int_0^1\int_0^1|x-y|\phi_\delta(x-y)\,dx\,dy+2L_2\int_0^1\int_0^1|u(x)-u(y)|\phi_\delta(x-y)\,dx\,dy\\ &+2\int_0^1\int_0^1\operatorname{sgn}(u(x)-v(y))\\ &\cdot\left\{(b(x,u(x))-b(y,v(y)))+\left(\frac{\partial}{\partial x}f(x,v(y))-\frac{\partial}{\partial y}f(y,u(x))\right)\right\}\phi_\delta(x-y)\,dx\,dy.\end{aligned}$$

To complete the proof we need only estimate the second term on the right-hand side above since the other terms have been dealt with already. To see that

$$\int_0^1\int_0^1|u(x)-u(y)|\phi_\delta(x-y)\,dx\,dy\leqq C\delta,$$

extend the smooth function $u(x)$ to the whole real line by $u(x)=u(0)$ for $x<0$ and $u(x)=u(1)$ for $x>1$. Then for each $0\leqq y\leqq 1$ we have

$$\begin{aligned}\int_0^1|u(x)-u(y)|\phi_\delta(x-y)\,dx&\leqq\int_{y-\delta}^{y+\delta}\int_{y-\delta}^{y+\delta}|u'(s)|\phi_\delta(x-y)\,dx\,ds\\ &=\int_{-\delta}^{\delta}|u'(y+s)|\,ds.\end{aligned}$$

Integrating this inequality with respect to y and interchanging the order of integration makes the desired result obvious.

4. Application to difference schemes. In this section we give another application of the AEI. We show that certain finite difference schemes yield approximations that satisfy the AEI; hence, according to Theorem 2.1, they satisfy the $\sqrt{h}L^1$ rate of convergence. We begin with a few preliminaries.

Partition the interval $[0, 1]$ into subintervals $I_j=[x_j, x_{j+1}]$, $0\leqq j\leqq J-1$, with $x_0=0$ and $x_J=1$, and define $\Delta x_j=(x_{j+1}-x_j)$. Define the approximate solution v_h by

$$v_h(x)=\sum_{j=0}^{J-1} u_j\chi_{I_j}(x),$$

where χ_{I_j} is the characteristic function of the interval I_j. We shall consider a class of finite difference schemes of the form

$$\begin{aligned}&\Delta^+F(x_j, u_j, u_{j-1})+\Delta x_jB(x_j, x_{j+1}, u_j)=0, \qquad 0\leqq j\leqq J-1,\\ &u_{-1}=\gamma_0, \qquad u_J=\gamma_1,\end{aligned} \tag{4.1}$$

where the forward difference operator Δ^+ is defined by $\Delta^+\alpha_j=\alpha_{j+1}-\alpha_j$ and $B(x_j, x_{j+1}, u_j)$ is given by

$$B(x_j, x_{j+1}, u)=b(x_j, u)+\frac{\partial}{\partial x}f(x_j, u)-\frac{1}{\Delta x_j}(f(x_{j+1}, u)-f(x_j, u)). \tag{4.2}$$

The numerical flux function $F(\cdot,\cdot,\cdot)$ of (4.1) is assumed throughout to satisfy the following properties:

F1. $F(x, u, u)=f(x, u)$.
F2a. $u\to F(x, u, v)$ is nonincreasing for all $x\in[0, 1]$, $v, u\in\mathbb{R}$.
F2b. $v\to F(x, u, v)$ is nondecreasing for all $x\in[0, 1]$, $u, v\in\mathbb{R}$.
F3. $F(x, u, v)$ is Lipschitz continuous in x, u, v.[2]

We now give three examples of numerical flux functions that satisfy the properties above.

1) Lax-Friedrichs [7]:

$$F(x, u, v)=\tfrac{1}{2}\{f(x, u)+f(x, v)-\lambda(u-v)\},$$

where $\lambda\geqq\|(\partial/\partial u)f(x, u)\|_\infty$.

2) Godunov [10]:

$$F(x, u, v)=\begin{cases}\max\limits_{u\leqq s\leqq v} f(x, s) & \text{if } u\leqq v,\\ \min\limits_{v\leqq s\leqq u} f(x, s) & \text{if } v\leqq u.\end{cases}$$

3) Engquist-Osher [1], [11].

$$F(x, u, v)=\int_0^u \min\left(\frac{\partial}{\partial s}f(x, s), 0\right) ds+\int_0^v \max\left(\frac{\partial}{\partial s}f(x, s), 0\right) ds+f(x, 0).$$

The following theorem is a straightforward extension of known results [1], [8].

[2] Assumption F3 need only be valid in the a priori interval determined by the maximum principle.

THEOREM 4.1. *Under properties* F1, F2, *and* F3, *and condition* (1.2) *of* § 1, *the difference scheme* (4.1) *has a unique solution for every grid. Moreover, there exists a constant c independent of the grid such that*

$$\|v_h\|_\infty + \operatorname{var}(v_h) \leqq c.$$

By using the results of Theorem 4.1 we next prove the following.

THEOREM 4.2. *Under the conditions of the previous theorem, the family of approximations* $\{v_h\}$ *satisfy the AEI; consequently by Theorem* 2.1 *they satisfy the rate of convergence*

$$\|v_h - \bar{u}\|_1 \leqq c\sqrt{h},$$

where $h = \max \Delta x_j$, $\bar{u} = \lim_{\varepsilon \downarrow 0} u_\varepsilon$ *and for some constant c which does not depend on h.*

Proof of Theorem 4.2. For arbitrary $k \in \mathbb{R}$, $\phi \in C_+^\infty$ and $0 \leqq \alpha$, $\beta \leqq 1$, we estimate the quantity

$$\begin{aligned}&\int_0^1 \operatorname{sgn}(v_h - k)\left\{-(f(x, v_h) - f(x, k))\phi_x + (b(x, v_h) + \frac{\partial}{\partial x} f(x, k))\phi\right\} dx \\ &\quad + \operatorname{sgn}(\gamma_1 - k)\{f(\beta, v_h(\beta)) - f(1, k)\}\phi(1) \\ &\quad - \operatorname{sgn}(\gamma_0 - k)\{f(\alpha, v_h(\alpha)) - f(0, k)\}\phi(0),\end{aligned} \tag{4.3}$$

where v_h is the piecewise constant interpolation of grid values generated by (4.1). Using the explicit form of v_h and integration by parts we find that the integral term in (4.3) is given by

$$\begin{aligned}\sum_{j=0}^{J-1} \operatorname{sgn}(u_j - k)\Big\{&-(f(x_{j+1}, u_j) - f(x_{j+1}, k))\phi(x_{j+1}) + (f(x_j, u_j) - f(x_j, k))\phi(x_j) \\ &+ \int_{x_j}^{x_{j+1}} \left(\frac{\partial}{\partial x} f(x, u_j) + b(x, u_j)\right)\phi(x)\, dx\Big\}.\end{aligned} \tag{4.4}$$

Rearranging terms and then adding and subtracting $F(x_{j+1}, u_{j+1}, u_j)$ and $F(x_j, u_j, u_{j-1})$ into this result we get that (4.4) equals

$$\begin{aligned}&\sum_{j=1}^{J} \operatorname{sgn}(u_{j-1} - k)[-(F(x_j, u_j, u_{j-1}) - f(x_j, k))]\phi(x_j) \\ &\quad + \sum_{j=0}^{J-1} \operatorname{sgn}(u_j - k)[(F(x_j, u_j, u_{j-1}) - f(x_j, k))]\phi(x_j) \\ &\quad + \sum_{j=0}^{J-1} \operatorname{sgn}(u_j - k)[(F(x_{j+1}, u_{j+1}, u_j) - f(x_{j+1}, u_j))]\phi(x_{j+1}) \\ &\quad + \sum_{j=0}^{J-1} \operatorname{sgn}(u_j - k)[-(F(x_j, u_j, u_{j-1}) - f(x_j, u_j))]\phi(x_j) \\ &\quad + \sum_{j=0}^{J-1} \operatorname{sgn}(u_j - k) \int_{x_j}^{x_{j+1}} \left(\frac{\partial}{\partial x} f(x, u_j) + b(x, u_j)\right)\phi(x)\, dx \\ &\quad = \mathrm{I} + \mathrm{II} + \mathrm{III} + \mathrm{IV} + \mathrm{V}.\end{aligned} \tag{4.5}$$

Before proceeding we give two simple lemmas.

LEMMA 4.1. *For any three numbers a, b,* $k \in \mathbb{R}$ *and* $x \in [0, 1]$ *we have*

$$\{\operatorname{sgn}(b - k) - \operatorname{sgn}(a - k)\}\{F(x, b, a) - f(x, k)\} \leqq 0.$$

Proof. The quantity above can be written as

$$\{\cdots\}\{F(x, b, a) - F(x, b, k)\} + \{\cdots\}\{F(x, b, k) - F(x, k, k)\},$$

where $\{\cdots\}=\{\operatorname{sgn}(b-k)-\operatorname{sgn}(a-k)\}$ and where we have used property F1 to write $f(x,k)=F(x,k,k)$. We can now bound this above by

$$|F(x,b,a)-F(x,b,k)|-\operatorname{sgn}(a-k)\{F(x,b,a)-F(x,b,k)\}$$
$$+\operatorname{sgn}(b-k)\{F(x,b,k)-F(x,k,k)\}+|F(x,b,k)-F(x,k,k)|.$$

Finally, using properties F2a and F2b shows us that this quantity is equal to zero.

LEMMA 4.2. *If $H(x)\in C^1$, $\phi(x)\in C^1$, then*

$$\left|\int_{x_j}^{x_{j+1}} H(x)\phi(x)\,dx-\Delta x_j H(x_j)\phi(x_j)\right|$$
$$\leqq \Delta x_j\left[\left\|\frac{d}{dx}H\right\|_\infty \int_{x_j}^{x_{j+1}}|\phi(s)|\,ds+\|H\|_\infty\int_{x_j}^{x_{j+1}}\left|\frac{d}{ds}\phi(s)\right|\,ds\right].$$

Proof. The left-hand side of the inequality above can be written as

$$\left|\int_{x_j}^{x_{j+1}}[(H(x)-H(x_j))\phi(x)+H(x_j)(\phi(x)-\phi(x_j))]\,dx\right|,$$

which is bounded above by

$$\Delta x_j\left\|\frac{d}{dx}H\right\|_\infty\int_{x_j}^{x_{j+1}}|\phi(x)|\,dx+\|H\|_\infty\left|\int_{x_j}^{x_{j+1}}\int_{x_j}^{x}\frac{d}{ds}\phi(s)\,ds\,dx\right|.$$

The final estimate is now obvious.

Continuing the proof of the theorem, it is clear with the result of Lemma 4.1 that the sums of terms I and II of (4.5) is bounded above by

$$\mathrm{I}+\mathrm{II}\leqq -\operatorname{sgn}(u_{J-1}-k)\{F(1,\gamma_1,u_{J-1})-f(1,k)\}\phi(1)$$
$$+\operatorname{sgn}(u_0-k)\{F(0,u_0,\gamma_0)-f(0,k)\}\phi(0).$$

Moreover, the sum of III and IV can be rewritten as

$$\sum_{j=0}^{J-1}\operatorname{sgn}(u_j-k)\{F(x_{j+1},u_{j+1},u_j)-f(x_{j+1},u_j)\}(\phi(x_{j+1})-\phi(x_j))$$
$$+\sum_{j=0}^{J-1}\operatorname{sgn}(u_j-k)\{(F(x_{j+1},u_{j+1},u_j)-F(x_j,u_j,u_{j-1}))$$
$$-(f(x_{j+1},u_j)-f(x_j,u_j))\}\phi(x_j),$$

and using Lemma 4.2 we see that term V of (4.5) can be bounded above by

$$\sum_{j=0}^{J-1}\operatorname{sgn}(u_j-k)\left\{\left(\frac{\partial}{\partial x}f(x_j,u_j)+b(x_j,u_j)\right)\Delta x_j\right\}$$
$$+h\left(\left\|\frac{d}{dx}H(x,v_h)\right\|_\infty+\|H(x,v_h)\|_\infty\right)\int_0^1\left(|\phi(x)|+\left|\frac{d}{dx}\phi(x)\right|\right)dx,$$

where $H(x,u)=(\partial/\partial x)f(x,u)+b(x,u)$ and $h=\max\Delta x_j$. Combining these estimates and using the difference scheme (4.1) we conclude that

$$\int_0^1\operatorname{sgn}(v_h-k)\left\{-(f(x,v_h)-f(x,k))\phi_x+(b(x,v_h)+\frac{\partial}{\partial x}f(x,k))\phi\right\}dx$$
$$\leqq -\operatorname{sgn}(u_{J-1}-k)\{F(1,\gamma_1,u_{J-1})-f(1,k)\}\phi(1)$$
$$+\operatorname{sgn}(u_0-k)\{F(0,u_0,\gamma_0)-f(0,k)\}\phi(0) \tag{4.6}$$
$$+\sum_{j=0}^{J-1}L|u_{j+1}-u_j|\int_{x_j}^{x_{j+1}}|\phi_x|\,dx+h\text{ const.}\left\{\int_0^1(|\phi|+|\phi_x|)\,dx\right\},$$

where L is the Lipschitz constant, given by

$$L=\sup\left\{\frac{|F(x,u,v)-F(x,v,v)|}{|u-v|},\ u,v\in I,\ x\in[0,1]\right\}.$$

Next we include the boundary terms of the AEI into the inequality above. Using the fact that Lemma 4.1 implies that

$$-\operatorname{sgn}(u_{J-1}-k)\{F(1,\gamma_1,u_{J-1})-f(1,k)\}\leqq-\operatorname{sgn}(\gamma_1-k)\{F(1,\gamma_1,u_{J-1})-f(1,k)\}$$

and

$$\operatorname{sgn}(u_0-k)\{F(0,u_0,\gamma_0)-f(0,k)\}\leqq\operatorname{sgn}(\gamma_0-k)\{F(0,u_0,\gamma_0)-f(0,k)\},$$

we find that for $\alpha,\beta\in(0,1)$

$$\begin{aligned}(4.7)\qquad &\int_0^1\operatorname{sgn}(v_h-k)\left\{-(f(x,v_h)-f(x,k))\phi_x+\left(b(x,v_h)+\frac{\partial}{\partial x}f(x,k)\right)\phi\right\}dx\\&+\operatorname{sgn}(\gamma_1-k)\{f(\beta,v_h(\beta))-f(1,k)\}\phi(1)\\&-\operatorname{sgn}(\gamma_0-k)\{f(\alpha,v_h(\alpha))-f(0,k)\}\phi(0)\end{aligned}$$

is bounded above by

$$\begin{aligned}(4.8)\qquad &\operatorname{sgn}(\gamma_1-k)\{f(\beta,v_h(\beta))-F(1,\gamma_1,u_{J-1})\}\phi(1)\\&-\operatorname{sgn}(\gamma_0-k)\{f(\alpha,v_h(\alpha))-F(0,u_0,\gamma_0)\}\phi(0)\\&+L\sum_{j=0}^{J-1}|u_{j+1}-u_j|\int_{x_j}^{x_{j+1}}|\phi_x|\,dx+h\text{ const.}\left\{\int_0^1(|\phi|+|\phi_x|)\,dx\right\}.\end{aligned}$$

We estimate the first boundary term above only since the second can be estimated in a similar way. Sum (4.1) from $j=j_1$ to $J-1$ where j_1 is chosen so that $x_{j_1}\leqq\beta<x_{j_1+1}$. Doing so, we substitute the result into the first term of (4.8) and find that

$$\begin{aligned}&\operatorname{sgn}(\gamma_1-k)\{f(\beta,v_h(\beta))-F(1,\gamma_1,u_{J-1})\}\\&\qquad\leqq L|u_{j_1}-u_{j_1-1}|+\left\|\frac{\partial}{\partial x}f(x,u)\right\|_\infty|\beta-x_{j_1}|+\sum_{j=j_1}^{j-1}|B(x_j,x_{j+1},u_j)|\Delta x_j\\&\qquad\leqq L|u_{j_1}-u_{j_1-1}|+\text{const.}\,(h+1-\beta).\end{aligned}$$

Now define

$$H_h(x)=\sum_{j=0}^{J-1}\frac{|u_{j+1}-u_j|}{\Delta x_j}\chi_{I_j}(x),$$

and note that

$$\int_0^1H_h(x)\,dx=\sum_{j=0}^{J-1}|u_{j+1}-u_j|\leqq\operatorname{var}(v_h).$$

Inserting this and the estimate above into (4.8) we have that (4.7) is bounded above by

$$\text{const.}\left\{(hH_h(\beta)+1-\beta+h)\phi(1)+(hH_h(\alpha)+\alpha+h)\phi(0)+h\int_0^1(H_h(x)+1)|\phi_x|\,dx\right\}.$$

Note that above we have used the fact that

$$\int_0^1|\phi(x)|\,dx\leqq\int_0^1|\phi_x(x)|\,dx+\phi(0).$$

Reading off the terms $R_h^0(\alpha)$, $R_h^1(\beta)$ and $R_h^2(x)$ from above one easily establishes that they satisfy properties A0, A1 and A2 of Definition 2.1. Therefore the families of approximate solutions generated by finite difference schemes of the form (4.1) satisfy the AEI of Definition 2.1. This completes the proof of Theorem 4.2.

NONMONOTONE INTERIOR LAYER THEORY FOR SOME SINGULARLY PERTURBED QUASILINEAR BOUNDARY VALUE PROBLEMS WITH TURNING POINTS*

ALBERT J. DESANTI†

Abstract. The quasilinear singular perturbation problem $\varepsilon y''=f(x,y)y'+g(x,y)$, $y(-1,\varepsilon)=A$, $y(1,\varepsilon)=B$ is studied under the principal assumption that $f(0,y)=0$ for all y, i.e., that $x=0$ is a turning point for the function f. Under explicit conditions on f, g, A and B, solutions are shown to exhibit one of two types of nonmonotone interior layer behavior: (i) spike layer behavior or (ii) nonmonotone transition layer behavior. The results are obtained using a method based on the theory of differential inequalities. Applications and examples are discussed in detail.

Key words. singular perturbation, quasilinear boundary value problems, turning points, differential inequalities, spike layer behavior, nonmonotone transition layer behavior

AMS(MOS) subject classifications. 34E20, 34A40

1. Introduction. In this paper we study the asymptotic behavior (as $\varepsilon\to 0$) of solutions of the singularly perturbed quasilinear boundary value problem

$$(\mathrm{P}_1)\qquad \begin{aligned}&\varepsilon y''=f(x,y)y'+g(x,y), \qquad -1<x<1,\\ &y(-1,\varepsilon)=A, \qquad y(1,\varepsilon)=B\end{aligned}$$

where ε is a small parameter, f and g are smooth functions, $f(0,y)=0$ for all y (i.e., $x=0$ is a turning point), and A and B are prescribed. In particular, we are interested in establishing the existence, for ε sufficiently small, of a solution of problem (P_1) which exhibits spike layer behavior and a solution which exhibits nonmonotone transition layer behavior at $x=0$. We say that a solution $y=y(x,\varepsilon)$ of problem (P_1) exhibits spike layer behavior at $x=0$ if

$$\lim_{\varepsilon\to 0} y(x,\varepsilon)=\begin{cases} u_L(x) & \text{for } -1<x<0,\ 0<x<1,\\ s & \text{for } x=0\end{cases}$$

where $u_L=u_L(x)$ is a certain solution of the reduced problem

$$\begin{aligned}&0=f(x,u)u'+g(x,u), \qquad -1<x<1,\\ &u(-1)=A \qquad (\text{or } u(1)=B),\end{aligned}$$

and $s\neq u_L(0)$. Similarly, we say that $y(x,\varepsilon)$ exhibits nonmonotone transition layer behavior if

$$\lim_{\varepsilon\to 0} y(x,\varepsilon)=\begin{cases} u_L(x) & \text{for } -1<x<0,\\ s & \text{for } x=0,\\ u_R(x) & \text{for } 0<x<1\end{cases}$$

where u_L and u_R are certain solutions of the reduced problems

$$\begin{aligned}&0=f(x,u)u'+g(x,u), \qquad u(-1)=A,\\ &0=f(x,u)u'+g(x,u), \qquad u(1)=B,\end{aligned}$$

respectively, and s is such that $s>\max\{u_L(0),u_R(0)\}$ or $s<\min\{u_L(0),u_R(0)\}$.

An example of a function exhibiting spike layer behavior is $y_1(x, \varepsilon) = \operatorname{sech}^2(x/\varepsilon)$. We note that $y_1(x, \varepsilon) \to 0$ for $x \neq 0$ and $y_1(0, \varepsilon) = 1$. The function y_1 is sketched in Fig. 1.

Interior nonmonotone transition layer behavior is exemplified by the function $y_2(x, \varepsilon) = \frac{1}{2}\tanh(x/\varepsilon) + \operatorname{sech}^2(x/\varepsilon)$. We note that $y_2(x, \varepsilon) \to -\frac{1}{2}$ for $x < 0$, $y_2(x, \varepsilon) \to \frac{1}{2}$ for $x > 0$, and $y_2(0, \varepsilon) = 1$. The function y_2 is sketched in Fig. 2.

The existence of a solution of problem (P_1) exhibiting interior layer behavior depends upon the behavior of the function f near the turning point $x = 0$. In other words, interior layer behavior is possible only if the function f changes its algebraic sign in passing through zero. Howes [8] showed that this is true for shock layer behavior, and we shall show that this is true for spike and nonmonotone transition layer behavior. If f does not change sign across zero, then Howes has shown that problem (P_1) admits only solutions which exhibit boundary layer behavior at one or both of the endpoints.

Physically, problem (P_1) may be interpreted as a model for a one-dimensional, steady-state, reaction-diffusion-convection system. In this connection, ε is a measure of the diffusivity of the medium, the function f is a measure of convection, and the

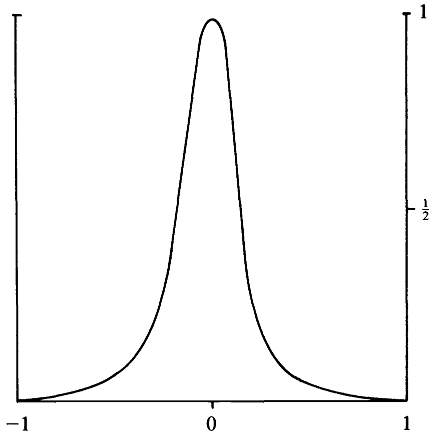

FIG. 1. *Graph of* $y_1(x) = \operatorname{sech}^2(x/\varepsilon)$.

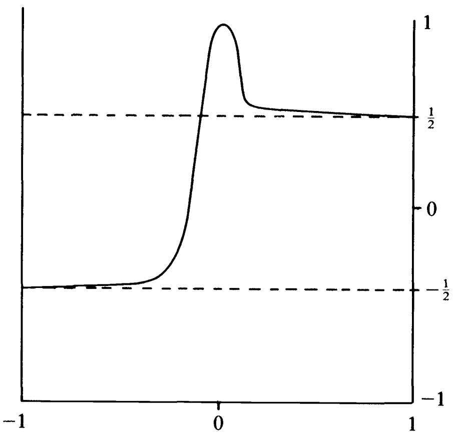

FIG. 2. *Graph of* $y_2(x) = \frac{1}{2}\tanh(x/\varepsilon) + \operatorname{sech}^2(x/\varepsilon)$.

function g is a measure of the effect of reaction and of sources in the medium. Under this interpretation, spike layer solutions of problem (P_1) are reasonable. Since the convection term is zero at $x=0$, the dominant mechanism of transport of substance or heat away from $x=0$ is diffusion, which is a slow process since the diffusivity of the medium is small. Hence, if there is a source or a reaction at $x=0$, a buildup of substance or of heat is likely.

Problem (P_1) may also be interpreted as a model for a nonlinear mass-spring system, or, more generally, simply as a formulation of Newton's Second Law of Motion. In this connection, x is time, ε is the mass of the object, f is a measure of the damping effect of the medium and g is a nonlinear restoring force.

Nonmonotone transition layer behavior has been observed in some problems arising in gas dynamics. Indeed, Zel'dovich and Raizer [16] have observed such behavior in their studies of entropy changes across shock fronts in gases. Majda [12] has also found such behavior in solutions of a quasilinear equation modeling dynamic combustion in gases.

A number of authors have studied problem (P_1) under various assumptions. O'Malley [14] and Ackerberg and O'Malley [1] have provided a theory for the boundary and shock layer behavior of solutions of problem (P_1) for the case in which f is independent of y and g is a linear function of y. Dorr [6] has extended the results of the linear theory to quasilinear equations of the form

$$\varepsilon y''=x^nF(x,y)y', \qquad -1<x<1,$$

where $n\geqq 1$. Most recently, Howes [8], [9] has provided a theory for the boundary and shock layer behavior of solutions of the full quasilinear problem (P_1).

The only published studies of the spike and nonmonotone transition layer behavior of solutions of problem (P_1) concern the case $f(x,y)\equiv 0$ for all x in $[-1,1]$ and for all y. In particular, O'Malley [15] has studied the autonomous problem

$$\varepsilon y''=g(y), \qquad y(-1,\varepsilon)=A, \quad y(1,\varepsilon)=B,$$

using a phase-plane argument. In his work, O'Malley made the astonishing discovery that this problem has solutions that exhibit spike layer behavior at each rational point in $(-1,1)$. DeSanti [5] has generalized the results of O'Malley to the nonautonomous case, i.e., $g=g(x,y)$, and has given a method for determining the location of the spike layer as well as the height of the spike. We make extensive use of these results in this paper.

To study the asymptotic behavior of solutions of problem (P_1), we use a method based on the theory of differential inequalities. This theory is due originally to Nagumo [13] and Brish [3], but most recently has been described by Jackson [11] and Bernfeld and Lakshmikantham [2]. We describe the method in the next section.

2. Mathematical preliminaries. Throughout the paper we use standard asymptotic terminology. We say that the function $h(x,\varepsilon)$ is $O(\varepsilon^n)$ if $\lim_{\varepsilon\to 0} h(x,\varepsilon)/\varepsilon^n$ exists. In other words, $h(x,\varepsilon)$ is $O(\varepsilon^n)$ if h behaves like ε^n as $\varepsilon\to 0$. We say that the function $h(x,\varepsilon)$ is transcendentally small if $h(x,\varepsilon)$ is $O(\varepsilon^n)$ for every n. Thus a transcendentally small term (abbreviated T.S.T.) behaves like $\exp(-k/\varepsilon^\nu)$ for some $k,\nu>0$ as $\varepsilon\to 0$. Finally, we say that a function $h(x,\varepsilon)$ approaches zero exponentially as $\varepsilon\to 0$ if $|h(x,\varepsilon)|<M\exp(-\eta(x,\varepsilon))$ where M is a positive constant and $\lim_{\varepsilon\to 0}\eta(x,\varepsilon)=+\infty$. In a region in which η is bounded away from zero, a term that decays exponentially to zero as $\varepsilon\to 0$ is also a transcendentally small term.

The basic mathematical tool we use in our study of problem (P$_1$) is a theorem due to Nagumo [13] concerning the boundary value problem

$$(\mathrm{P}_2)\qquad \begin{aligned} &y''=f(x,y)y'+g(x,y), \quad a<x<b,\\ &y(a)=A, \qquad y(b)=B, \end{aligned}$$

and generalizations of this problem.

THEOREM 2.1 (Nagumo [13]). *Let f and g be of class $C^{(1)}$ on $(-1,1)\times R$. Suppose that there exist functions $\alpha=\alpha(x)$ and $\beta=\beta(x)$ of class $C^{(2)}$ on (a,b) such that*

$$\begin{aligned} &\alpha''\geqq f(x,\alpha)\alpha'+g(x,\alpha), \qquad a<x<b,\\ &\alpha(a)\leqq A, \qquad \alpha(b)\leqq B,\\ &\beta''\leqq f(x,\beta)\beta'+g(x,\beta), \qquad a<x<b,\\ &\beta(a)\geqq A, \qquad \beta(b)\geqq B,\\ &\alpha(x)\leqq\beta(x), \qquad a\leqq x\leqq b. \end{aligned}$$

Then there exists a solution $y=y(x)$ of (P$_2$) *such that $\alpha(x)\leqq y(x)\leqq\beta(x)$ for $a\leqq x\leqq b$.*

Theorem 2.1 is valid if α and β are not differentiable at a finite number of points in (a,b), provided that α and β behave appropriately near these points. The behavior required at a point x_0 of nondifferentiability is that the inequalities $D_l\alpha(x_0)\leqq D_r\alpha(x_0)$ and $D_l\beta(x_0)\geqq D_r\beta(x_0)$ are satisfied, where D_l and D_r denote differentiation on the left and right, respectively. It is this stronger version of Nagumo's Theorem, proved in Jackson [11] and in Bernfeld and Lakshmikantham [2], that we use in the following sections.

3. Spike layer theory. In this section we use the method of differential inequalities described in the previous section to deduce the existence of a spike layer solution of the problem

$$(\mathrm{P}_1)\qquad \begin{aligned} &\varepsilon y''=f(x,y)y'+g(x,y),\\ &y(-1,\varepsilon)=A, \qquad y(1,\varepsilon)=B \end{aligned}$$

when f has a certain type of turning point at $x=0$. Our method allows the asymptotic determination of the spike height as well as the construction of $O(\varepsilon)$—approximate solutions that serve as upper and lower bounds on the exact solutions of problem (P$_1$). The principal result is the following.

THEOREM 3.1. *Assume*

(a) *the functions f and g are of class $C^{(1)}$ on $[-1,1]\times R$, and $f(0,y)\equiv 0$ for all y*;

(b) *there exists a function $u_L=u_L(x)$ of class $C^{(2)}$ on $[-1,1]$ satisfying the reduced problem*

$$\begin{aligned} &0=f(x,u)u'+g(x,u),\\ &u(-1)=A, \qquad u(-1)>B; \end{aligned}$$

(c) $f_y(x,u_L(x))u_L'(x)+g_y(x,u_L(x))>K_1>0$ *for some* $K_1>0$ *and for all x in* $(-1,1)$;

(d) $g(0,u_L(0))=0$;

(e) *there exists a number $s\neq u_L(0)$ such that $[s-u_L(0)]g(0,s)<0$, $J_L(s)=0$ and $[s-u_L(0)]J_L(z)>0$ for $u_L(0)<z<s$ or $s<z<u_L(0)$, where $J_L(z)=\int_{u_L(0)}^z g(0,u)\,du$*;

(f) $f_y(1,y)u_L'(1)+g_y(1,y)>K_2$ *for some* $K_2>0$ *and for* $B\leqq y\leqq u_L(1)$;

(g) $f_x(0,y)<0$ *for* $u_L(0)\leqq y\leqq s$ *or* $s\leqq y\leqq u_L(0)$;

(h) $f(1,y)<0$ *for* $B\leqq y\leqq u_L(1)$.

Then, there exists a solution $y=y(x,\varepsilon)$ of problem (P_1) *for ε sufficiently small, say $0<\varepsilon\leqq\varepsilon_1$, that exhibits spike layer behavior at $x=0$. More precisely, $y(x,\varepsilon)\to u_L(x)$ for x in $(-1,1)-\{0\}$ as $\varepsilon\to 0$ and $y(0,\varepsilon)\to s$ as $\varepsilon\to 0$.*

Proof. We consider only the case $u_L(0)<s$. The proof for the case $u_L(0)>s$ is similar.

To prove the theorem, we construct lower and upper solutions α and β, respectively, as in Theorem 2.1. These functions are taken to be straightforward modifications of the solution u_L of the reduced problem.

We define α and β as follows:

$$\alpha(x,\varepsilon)=u_L(x)+v_1(x,\varepsilon)+v_b(x,\varepsilon)-\gamma\varepsilon,$$
$$\beta(x,\varepsilon)=u_L(x)+v_2(x,\varepsilon)+\gamma\varepsilon,$$

where γ is such that $\gamma\min\{K_1,K_2\}>\max_{-1\leqq x\leqq 1}|u_L''(x)|$, and where v_1, v_2 and v_b satisfy, respectively,

$$(\mathrm{C}_1)\quad\begin{cases}\varepsilon v_1''>g(0,u_L(0)+v_1)\text{ in }(-1,1),\\ v_1(0,\varepsilon)=s-u_L(0),\\ v_1>0\text{ for all }x\text{ in }(-1,1),\\ v_1'(0,\varepsilon)=0,\\ v_1'>0\text{ for }x<0,\ v_1'<0\text{ for }x>0,\\ v_1'(x,\varepsilon)=(x/\sqrt{\varepsilon})p(x,\varepsilon),\text{ where }p\to 0\text{ exponentially as }\varepsilon\to 0\text{ for }x\neq 0,\\ v_1\to 0\text{ exponentially as }\varepsilon\to 0\text{ for }x\neq 0,\end{cases}$$

$$(\mathrm{C}_2)\quad\begin{cases}\varepsilon v_2''<g(0,u_L(0)+v_2)\text{ in }(-1,1)-\{0\},\\ v_2(0,\varepsilon)=s-u_L(0),\\ v_2>0\text{ for all }x\text{ in }(-1,1),\\ v_2'>0\text{ for }x<0,\ v_2'<0\text{ for }x>0,\\ v_2\to 0\text{ exponentially as }\varepsilon\to 0\text{ for }x\neq 0,\end{cases}$$

$$(\mathrm{C}_b)\quad\begin{cases}\varepsilon v_b''>f(1,u_L(1)+v_b)v_b'\text{ in }(-1,1),\\ v_b(1,\varepsilon)=B-u_L(1),\\ v_b<0\text{ for all }x\text{ in }(-1,1),\\ v_b'<0\text{ for }x<1,\\ v_b\to 0\text{ exponentially as }\varepsilon\to 0\text{ for }x\neq 1.\end{cases}$$

The existence of a function v_1 satisfying conditions (C_1) has been proved by DeSanti [5] under hypotheses (d) and (e). The existence of a piece-wise smooth function v_2 satisfying conditions (C_2) has been established by Fife [7]. Finally, the existence of a function v_b satisfying conditions (C_b) has been proved by Howes [10] using a result of Coddington and Levinson [4] and hypothesis (h). The functions α and β are sketched in Fig. 3.

We consider first the proof that α is a lower solution on the interval $(-1,1)$. The proof is divided into three stages. First we verify that α is a lower solution for x near 1, then for x near 0, and finally for x bounded away from 0 and 1.

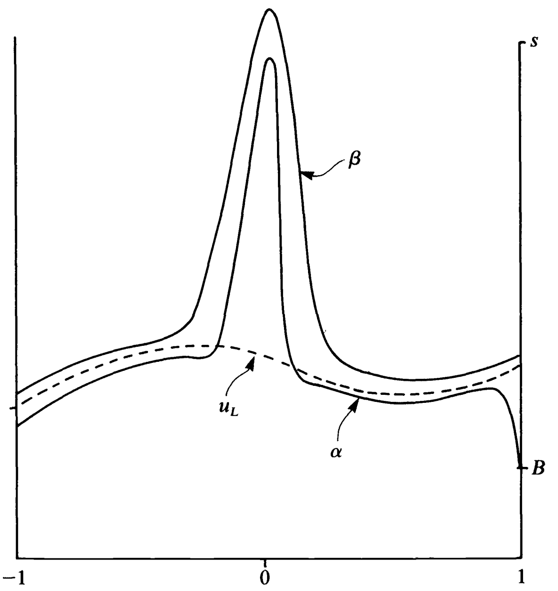

FIG. 3. *Graphs of the lower solution α and the upper solution β.*

Let us first examine the behavior of α in the vicinity of $x=1$. From the Mean Value theorem we have

$$(*)\qquad \begin{aligned} \varepsilon\alpha''-f(x,\alpha)\alpha'-g(x,\alpha)&=\varepsilon v_b''-f(x,u_L(x)+v_b+\gamma\varepsilon)\\ &\quad-[f_y(x,u_L(x)+\theta_1(x))u_L'+g_y(x,u_L(x)+\theta_2(x))]v_b \end{aligned}$$

where $u_L(x)\leqq\theta_1$, $\theta_2<v_b(x,\varepsilon)+\gamma\varepsilon$. From conditions C_b and hypotheses (c) and (f), we see that for x near 1, say in the interval $(1-\rho,1)$, where ρ is a sufficiently small positive number, the right-hand side of equation $(*)$ is positive for ε sufficiently small. Thus, α is a lower solution on the interval $(1-\rho,1)$.

We turn now to an examination of α in the vicinity of $x=0$. Let $S(\varepsilon)$ denote the set

$$\{x\colon x=\delta\varepsilon^{\nu}, \text{for all } \delta \text{ such that } -1\leqq\delta\leqq1, \text{ and for some } \nu, \tfrac{1}{4}<\nu<\tfrac{1}{2}\}.$$

The set $S(\varepsilon)$ is an $O(\varepsilon^{\nu})$-neighborhood of $x=0$. Taylor expanding about $x=0$, and making use of the fact that $v_1'=(x/\sqrt{\varepsilon})p(x,\varepsilon)$, where $p\to0$ exponentially as $\varepsilon\to0$, we have, for x in $S(\varepsilon)$,

$$\varepsilon\alpha''-f(x,\alpha)\alpha'-g(x,\alpha)=\varepsilon v_1''-g(0,u_L(0)+v_1)+O(\varepsilon^{2\nu-1/2}).$$

By virtue of the nature of v_1, the right-hand side of this equation is positive for ε sufficiently small. Thus, α is a lower solution for x in $S(\varepsilon)$.

Let us finally consider the region

$$I^0=(-1,1)-S(\varepsilon)-(1-\rho,1).$$

In this region, v_1 and v_b are both transcendentally small terms (T.S.T.). Thus, for x in I^0, we have

$$\begin{aligned} &\varepsilon\alpha''-f(x,\alpha)\alpha'-g(x,\alpha)\\ &\qquad=\varepsilon[u_L''(x)+\gamma(f_y(x,u_L(x))u_L'(x)+g_y(x,u_L(x))]+\text{T.S.T.}\\ &\qquad\geqq\varepsilon[u_L''+\gamma K_1]. \end{aligned}$$

For ε sufficiently small the right-hand side of this inequality is positive by virtue of the definition of γ. Thus, α is a lower solution for x in the region I°. We conclude that α is a lower solution in the sense of Theorem 2.1 on all of the interval $(-1, 1)$.

We consider now the proof that β is an upper solution on the interval $(-1, 1)$. We note first of all that β is not differentiable at $x=0$. However, since $v_2(0, \varepsilon) = s - u_L(0)$, $v_2' > 0$ for $x<0$ and $v_2'<0$ for $x>0$, and since $v_2 \to 0$ exponentially as $\varepsilon \to 0$ for $x \neq 0$, it follows that

$$\lim_{\varepsilon\to 0} D_l v_2(0, \varepsilon) = +\infty \quad \text{and} \quad \lim_{\varepsilon\to 0} D_r v_2(0, \varepsilon) = -\infty.$$

Thus, for ε sufficiently small we must have

$$D_l\beta(0, \varepsilon) = u_L'(0) + D_l v_2(0, \varepsilon) \geqq D_r\beta(0, \varepsilon) = u_L'(0) + D_r v_2(0, \varepsilon).$$

We see that the behavior of β at $x=0$ is correct in view of the extended version of Theorem 2.1.

Let us now consider the verification that β is an upper solution in the vicinity of $x=0$. Recalling that $\varepsilon v_2'' < g(0, u_L(0)+v_2)$, it follows that $\varepsilon\beta'' < g(x, u_L(x)+v_2+\gamma\varepsilon) \equiv g(x, \beta)$ for ε sufficiently small and for x sufficiently close to zero, say x in the interval $(-d, d)$ for some $d>0$. Thus, we have, for x in $(-d, d)$,

$$\begin{aligned} &\varepsilon\beta'' - f(x, \beta)\beta' - g(x, \beta) \\ (**) \qquad &= \varepsilon\beta'' - g(x, \beta) - f(x, \beta)u_L'(x) - f(x, \beta)v_2' + O(\varepsilon) \\ &= \varepsilon\beta'' - g(x, \beta) - f(x, \beta)v_2' + O(d) \end{aligned}$$

where we have made use of the fact that $f(0, y) = 0$ for all y to assert that the term $f(x, \beta)u_L'(x)$ is $O(d)$ for x in $(-d, d)$. Since $f(x, y)>0$ for $x<0$ and $f(x, y)<0$ for $x>0$, and since $v_2'>0$ for $x<0$ and $v_2'<0$ for $x>0$, it follows that $f(x, \beta)v_2' \geqq 0$ for all x near zero. Hence, the right-hand side of equation (**) is negative for ε and d sufficiently small. We conclude that β is an upper solution on the interval $(-d, d)$.

In the region $(-1, 1)-(-d, d)$, the verification that β is an upper solution proceeds much like the verification that α is a lower solution. In this region, v_2 and v_b are both transcendentally small terms (T.S.T.), so that

$$\begin{aligned} \varepsilon\beta'' - f(x, \beta)\beta' - g(x, \beta) &= \varepsilon[u_L'' - \gamma(f_y(x, u_L)u_L' + g_y(x, u_L))] + \text{T.S.T.} \\ &\leqq \varepsilon[u_L'' - \gamma K_1]. \end{aligned}$$

The right-hand side of this inequality is negative by virtue of the definition of γ. Thus, β is an upper solution for x in the region $(-1, 1)-(-d, d)$. Putting everything together, we see that β is an upper solution in the sense of Theorem 2.1 on all of the interval $(-1, 1)$.

We have thus far shown that α and β satisfy the appropriate differential inequalities of Theorem 2.1. Since v_1 and v_2 are transcendentally small terms for $x=-1$ and $x=1$, and since $v_b>0$, it follows that for ε sufficiently small we have $\alpha(-1, \varepsilon) \leqq A \leqq \beta(1, \varepsilon)$ and $\alpha(1, \varepsilon) \leqq \beta \leqq \beta(1, \varepsilon)$. Furthermore, since $\alpha(0, \varepsilon) < \beta(0, \varepsilon)$ and since v_1 and v_2 both converge to zero exponentially (meaning that v_1 and v_2 are transcendentally small terms for x away from zero), it follows that $\alpha(x, \varepsilon) \leqq \beta(x, \varepsilon)$ on all of $(-1, 1)$. Thus we see that α and β satisfy all the conditions of Theorem 2.1. We conclude, therefore, that there is a solution $y = y(x, \varepsilon)$ of problem (P_1) such that $\alpha(x, \varepsilon) \leqq y(x, \varepsilon) \leqq \beta(x, \varepsilon)$ for all x in $[-1, 1]$. Since α and β both converge to u_L for x in $(-1, 1)-\{0\}$ and to s for $x=0$, the solution $y(x, \varepsilon)$ must behave in the same way. This completes the proof of Theorem 3.1.

Remark 3.1.1. The conclusion of Theorem 3.1 obviously remains valid if f, g, A and B are allowed to depend smoothly on ε.

Remark 3.1.2. The reduced solution u_L of condition (b) could be replaced by the solution u_R of the problem

$$0=f(x,u)u'+g(x,u), \qquad u(1)=B.$$

In this case we would require $u(-1)>A$ and $f(-1,y)>0$ for $A\leqq y\leqq u_R(-1)$. All other conditions of the theorem remain unchanged.

4. Nonmonotone transition layer theory. In this section we again consider the singularly perturbed boundary value problem

$$(\mathrm{P}_1) \qquad \begin{gathered} \varepsilon y''=f(x,y)y'+g(x,y), \\ y(-1,\varepsilon)=A, \qquad y(1,\varepsilon)=B. \end{gathered}$$

Our principal goal is to deduce the existence of a solution of (P_1) that exhibits interior nonmonotone transition layer behavior at the turning point $x=0$. We make extensive use of the results of the previous sections. Our principal result is the following:

THEOREM 4.1. *Assume*

(a) *the functions f and g are of class $C^{(1)}$ on $[-1,1]\times R$, and $f(0,y)\equiv 0$ for all y*;

(b) *there exist functions $u_L=u_L(x)$ and $u_R=u_R(x)$ of class $C^{(2)}$ on $[-1,1]$ satisfying, respectively, the reduced problems*

$$0=f(x,u)u'+g(x,u), \qquad u(-1)=A,$$

$$0=f(x,u)u'+g(x,u), \qquad u(1)=B;$$

(c) *$f_y(x,u)u'+g_y(x,u)>K$ for some $K>0$, for $u=u_L$, u_R, and for all x in $(-1,1)$*;

(d) *$g(0,u_L(0))=0$*;

(e) *$u_L(0)<u_R(0)$ and either*

(i) *there exists a number $s>u_R(0)$ such that $g(0,s)<0$, $J_L(s)=0$, $J_L(z)>0$ for $u_L(0)\leqq z<s$, and $J_R(z)>0$ for $u_R(0)<z\leqq s$, or*

(ii) *there exists a number $s<u_L(0)$ such that $g(0,s)>0$, $J_L(s)=0$, $J_R(z)<0$ for $s<z<u_R(0)$, and $J_L(z)<0$ for $s\leqq z<u_R(0)$, where $J_L(z)=\int_{u_{L(0)}}^{z} g(0,u)\,du$ and $J_R(z)=\int_{u_{R(0)}}^{z} g(0,u)\,du$*;

(f) *$f_x(0,y)<0$ for $u_L(0)\leqq y\leqq s$ or $s\leqq y\leqq u_R(0)$.*

Then, there exists a solution $y=y(x,\varepsilon)$ of (P_1) for ε sufficiently small, say $0<\varepsilon\leqq\varepsilon_2$, that exhibits interior nonmonotone transition layer behavior at $x=0$. More precisely, $y(x,\varepsilon)\to u_L(x)$ for x in $(-1,0)$, $y(x,\varepsilon)\to u_R(x)$ for x in $(0,1)$, and $y(0,\varepsilon)\to s$ as $\varepsilon\to 0$.

Proof. We consider only the case $s>u_R(0)$. The proof for the remaining case is similar.

As in the proof of Theorem 3.1, the proof of this theorem inolves the construction of lower and upper solutions which satisfy the conditions of Theorem 2.1. In this construction, we make extensive use of the lower and upper solutions α and β constructed in the previous section.

We define new lower and upper solutions $\bar{\alpha}$ and $\bar{\beta}$ as follows:

$$\bar{\alpha}(x,\varepsilon)=\begin{cases} \alpha(x,\varepsilon) & \text{for } x \text{ in } [-1,0], \\ \max\{\alpha(x,\varepsilon),u_R(x)-\lambda\varepsilon\} & \text{for } x \text{ in } (0,1]. \end{cases}$$

$$\bar{\beta}(x,\varepsilon)=\begin{cases} \beta(x,\varepsilon) & \text{for } x \text{ in } [-1,0], \\ u_R(x)+\bar{v}(x,\varepsilon)+\lambda\varepsilon & \text{for } x \text{ in } (0,1], \end{cases}$$

where λ is such that $\lambda K \max_{-1 \leqq x \leqq 1} |u_R''(x)|$, and where the function $\bar{v}$ satisfies

$$(\bar{\mathrm{C}}) \qquad \begin{aligned} &\varepsilon \bar{v}'' < g(0, u_R(0) + \bar{v}), \\ &\bar{v} > 0,\ \bar{v}' < 0 \text{ for } x \text{ in } [0, 1], \\ &\bar{v}(0, \varepsilon) = s - u_R(0), \\ &\bar{v} \to 0 \text{ exponentially as } \varepsilon \to 0^+ \text{ for } x \neq 0. \end{aligned}$$

The existence of a function $\bar{v}$ satisfying conditions ($\bar{\mathrm{C}}$) follows from hypotheses (d) and (e) and Lemma 2.1 of Fife [7]. The functions $\bar{\alpha}$ and $\bar{\beta}$ are sketched in Fig. 4.

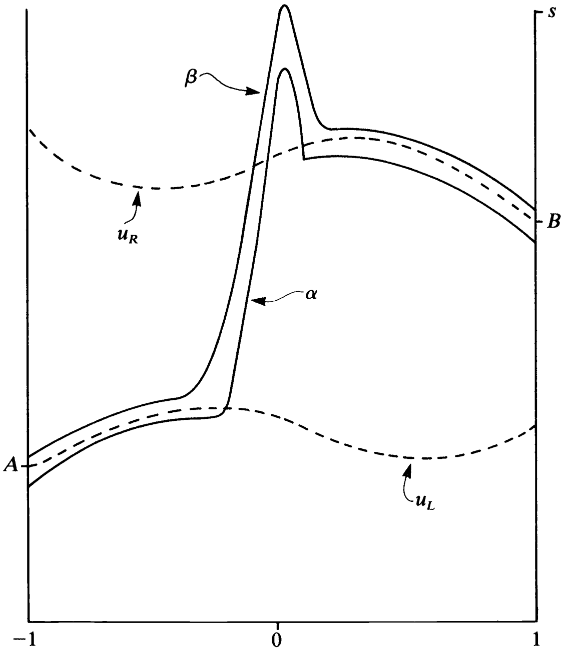

FIG. 4. *Graphs of the lower solution $\bar{\alpha}$ and the upper solution $\bar{\beta}$.*

That $\bar{\alpha}$ and $\bar{\beta}$ are lower and upper solutions, respectively, on the interval $[-1, 0]$ is a consequence of the proof of Theorem 3.1. Moreover, if we simply replace u_L with u_R in the proof of Theorem 3.1, then it is clear that $u_R(x) - \lambda\varepsilon$ is a lower solution on $(0, 1]$ and that $\bar{\beta}(x, \varepsilon) = u_R(x) + \bar{v}(x, \varepsilon) + \lambda\varepsilon$ is a lower solution on $(0, 1]$. At the point of intersection $\bar{x}$ of $\alpha(x, \varepsilon)$ and $u_R(x) - \lambda\varepsilon$, the function $\bar{\alpha}$ is not differentiable. However, since $\lim_{\varepsilon \to 0} v_1'(\bar{x}, \varepsilon) = -\infty$ we have

$$D_l \bar{\alpha}(\bar{x}, \varepsilon) = \alpha'(\bar{x}, \varepsilon) = u_L'(\bar{x}) + v_1'(\bar{x}, \varepsilon) \leqq D_r \bar{\alpha}(\bar{x}, \varepsilon) = u_R'(\bar{x})$$

for ε sufficiently small. Thus, $\bar{\alpha}$ and $\bar{\beta}$ satisfy all the appropriate differential inequalities in the extended version of Theorem 2.1.

From the construction of $\bar{\alpha}$ and $\bar{\beta}$ it is clear that $\bar{\alpha}(-1, \varepsilon) \leqq A \leqq \bar{\beta}(-1, \varepsilon)$ and $\bar{\alpha}(1, \varepsilon) \leqq \beta \leqq \bar{\beta}(1, \varepsilon)$. Moreover, since $\alpha(x, \varepsilon) \leqq \beta(1, \varepsilon)$ and $\bar{v}(x, \varepsilon) > 0$, we have $\bar{\alpha}(x, \varepsilon) \leqq \bar{\beta}(x, \varepsilon)$ for all x in $[-1, 1]$. Thus, $\bar{\alpha}$ and $\bar{\beta}$ satisfy all the conditions of the extended version of Theorem 2.1. We conclude, therefore, that there exists a solution $y(x, \varepsilon)$ of problem (P_1) such that $\bar{\alpha}(x, \varepsilon) \leqq y(x, \varepsilon) \leqq \bar{\beta}(x, \varepsilon)$. Since $\bar{\alpha}$ and $\bar{\beta}$ both converge to u_L for x in $(-1, 0)$, to u_R for x in $(0, 1)$, and to s for $x = 0$ as $\varepsilon \to 0$, the function y must behave in the same way. This completes the proof of Theorem 4.1.

Remark 4.1.1. In condition (e) of Theorem 4.1 we could have $u_L(0) > u_R(0)$. In this case, Theorem 4.1 remains valid with u_L replaced by u_R and J_L by J_R.

Remark 4.1.2. As in Theorem 3.1, Theorem 4.1 remains valid if f, g, A and B are allowed to depend smoothly on ε.

Remark 4.1.3. Majda [12] has considered a time-dependent version of problem (P_1) as a model for dynamic combustion in gases. A simplified version of this combustion model is

$$(P_3) \qquad \mu(\varepsilon)u_t = \varepsilon u_{xx} - f(x, t, u)u_x - g(x, t, u),$$

where ε is a lumped parameter representing the effects of diffusion and heat conduction, and where μ is a measure of combustion speed. This simplified model is appropriate for the case in which the mass fraction of unburnt gas in the system is constant, or is at least a slowly varying function of time.

The nonmonotone interior layer Theorem 4.1 is applicable to problem (P_3) provided that $\mu(\varepsilon) \to 0$ as $\varepsilon \to 0$. Let $\bar{\alpha} = \bar{\alpha}(x, t, \varepsilon)$ and $\bar{\beta} = \bar{\beta}(x, t, \varepsilon)$ be functions analogous to those given in the proof of Theorem 4.1; i.e., suppose that

$$\varepsilon\bar{\alpha}_{xx} > f(x, t, \bar{\alpha})\bar{\alpha}_x + g(x, t, \bar{\alpha}),$$

and

$$\varepsilon\bar{\beta}_{xx} < f(x, t, \bar{\beta})\bar{\beta}_x + g(x, t, \bar{\beta}),$$

where f and g satisfy the conditions of Theorem 4.1 with t considered to be a parameter. Then, because the inequalities are sharp, they hold if the terms $\mu\bar{\alpha}_t$ and $\mu\bar{\beta}_t$ are added to the appropriate sides of the inequalities, provided that ε is sufficiently small. Thus, in agreement with the qualitative theory of Majda, nonmonotone interior layer behavior is possible for solutions of problem (P_3).

5. Examples. In this section we give some examples of the application of Theorems 3.1 and 4.1.

Example 5.1. Consider the problem

$$(E_1) \qquad \begin{aligned} &\varepsilon y'' = -xy' + y(1-y), \qquad x \text{ in } (-1, 1),\\ &y(-1, \varepsilon) = 0, \qquad y(1, \varepsilon) = -1. \end{aligned}$$

The reduced problem is

$$0 = -xu' + u(1-u), \qquad u(-1) = 0.$$

This reduced problem has the solution $u_L(x) = 0$. Now, $f_y(x, u_L)u'_L + g_y(x, u_L) = -u_L^2 - u_L + 1 = 1 > 0$ and $f_y(1, y)u'_L + g_y(1, y) = -y^2 - y + 1 > 0$ for $-1 \leqq y \leqq 0$ since $\min_{-1 \leqq y \leqq 0}[-y^2 - y + 1] = 1$. Moreover, $J_L(z) = z^2(\frac{1}{2} - \frac{1}{3}z)$. The unique positive zero of J_L is $s = \frac{3}{2} > u_L(0) = 0$. We note that $g(0, \frac{3}{2}) < 0$ and $z^2(\frac{1}{2} - \frac{1}{3}z) > 0$ for $0 \leqq z \leqq s$. Finally, we have $f_x(0, y) = -1 < 0$ and $f(1, y) = -1 < 0$. Thus, all the conditions of Theorem 3.1 are satisfied. We conclude that the boundary value problem (E_1) has a solution $y = y(x, \varepsilon)$, for ε sufficiently small, such that $y(x, \varepsilon) \to u_L(x) \equiv 0$ for x in $(-1, 1) - \{0\}$ and $y(0, \varepsilon) \to s = \frac{3}{2}$ as $\varepsilon \to 0$.

Example 5.2. Consider now the problem

$$(E_2) \qquad \begin{aligned} &\varepsilon y'' = -xy' - y(y^2 - 1)(2 - y), \qquad x \text{ in } (-1, 1),\\ &y(-1, \varepsilon) = -1, \qquad y(1, \varepsilon) = 1. \end{aligned}$$

The reduced problems are

$$\begin{aligned} 0 &= -xu' - u(u^2 - 1)(2 - u), \qquad u(-1) = -1,\\ 0 &= -xu' - u(u^2 - 1)(2 - u), \qquad u(1) = 1. \end{aligned}$$

These problems have the solutions $u_L(x)\equiv -1$ and $u_R(x)\equiv 1$ respectively. We have $u_L(0)<u_R(0)$, $f_y(x, u_L)u'_L+g_y(x, u_L)=6>0$ and $f_y(x, u_R)u'_R+g_y(x, u_R)=2>0$. Furthermore, we have $J_L(z)=\frac{1}{60}[-12z^5+15z^4+20z^3-60z^2+53]$ and $J_R(z)=\frac{1}{60}[-12z^5+15z^4+20z^3-60z^2+77]$. The polynomial $J_L(z)$ has a unique zero at a point $s>1$ in the interval $(-1, 2)$. Moreover, $J_R(z)>0$ for $u_R(0)=1<z<s$. Finally, we note that $g(0, s)<0$ since $s>1$ and $f_x(0, y)=-1<0$ for all y. Thus, all conditions of Theorem 4.1 are satisfied. We conclude that (E_2) has a solution $y=y(x, \varepsilon)$, for ε sufficiently small, such that $y(x, \varepsilon)\to u_L(x)=-1$ for x in $(-1, 0)$, $y(x, \varepsilon)\to u_R(x)=1$ for x in $(0, 1)$, and $y(0, \varepsilon)\to s>1$ as $\varepsilon\to 0$, where, again, s is the unique root of the polynomial equation $J_L(z)=0$ in the interval $-1<z<2$.

Acknowledgment. The author would like to thank the referee for pointing out the work of A. Majda.

THE EXISTENCE OF BOUNDED SOLUTIONS OF A SEMILINEAR HEAT EQUATION*

WILLIAM C. TROY†

Abstract. We investigate the existence of bounded solutions of $\Delta w - y \cdot \nabla w/2 - (1/(p-1))w + |w|^{p-1}w = 0$, $y \in R^N$, for $N > 2$ and $p > (N+2)/(N-2)$. We show that if $N = 3$ and $6 \leqq p \leqq 12$ then there are infinitely many positive, bounded, radially symmetric solutions $w(r)$, $r = |y|$, such that $\lim_{r\to\infty} w(r) = 0$.

Key words. backward self-similar solutions, radially symmetric solutions, globally bounded solutions

Introduction. We investigate the existence of nonconstant, bounded solutions of the equation

$$\Delta w - y \cdot \nabla w/2 + |w|^{p-1}w - w/(p-1) = 0 \tag{1}$$

in R^N, $N > 2$, where $p > (N+2)/(N-2)$, and $y \cdot \nabla \equiv \sum_{j=1}^N y_j \cdot \partial/\partial y_j$. Equation (1) is derived from the semilinear heat equation

$$u_t - \Delta u - |u|^{p-1}u = 0. \tag{2}$$

Weissler [7] has shown that (2) has solutions which blow up at $(x, t) = (0, 0)$. Giga and Kohn [5] prove that the asymptotic behavior near the blow up time is described by special solutions of (2) called "backward self-similar solutions," i.e., solutions of the form

$$u(x, t) = (-t)^{1/(1-p)} w(y) \tag{3}$$

where $y = x/(-t)^{1/2}$ and $t < 0$. Substitution of (3) into (2) yields (1). Their analysis demonstrates that (1) has no globally bounded solution for $N = 1$ and 2, nor for $N > 2$ and $p \leqq (N+2)/(N-2)$. However, Giga [4] has recently shown that (1) does have radially symmetric, bounded solutions if the term $w/(p-1)$ is replaced by αw, $\alpha > 1/p - 1$, $N > 2$ and $p < (N+2)/(N-2)$. In addition, he shows that if $\alpha \leqq 1/(p-1)$ and $p < (N+2)/(N-2)$ then there are no radially symmetric solutions.

In this paper we consider the parameter range $N > 2$ and $p > (N+2)/(N-2)$, and investigate (1) for the existence of nonconstant, globally bounded solutions. For simplicity we restrict our attention to the case $N = 3$ and therefore $p > 5$. We look for radially symmetric solutions $w = w(r)$, $r = |y|$ so (1) becomes

$$w'' + \left(\frac{2}{r} - \frac{r}{2}\right)w' + |w|^{p-1}w - \frac{w}{(p-1)} = 0. \tag{4}$$

A bounded solution of (4) must satisfy

$$w(0) = \alpha \in R, \qquad w'(0) = 0. \tag{5}$$

We can assume throughout that on each compact interval $[0, L] \subseteq [0, \infty]$, the solution of (4)-(5) exists, is unique and depends continuously on initial values (see, for example, Haraux and Weissler [6, Thm. 1]). Our main result is:

* Received by the editors January 27, 1986; accepted for publication (in revised form) June 3, 1986. This work was supported in part by National Science Foundation grant MCS-83-01085.

† Department of Mathematics and Statistics, University of Pittsburgh, Pittsburgh, Pennsylvania 15260.

THEOREM. *Let $N=3$ and $6 \leqq p \leqq 12$. There is an unbounded, increasing, positive sequence $\{\alpha_L\}_{L \geqq N}$ such that for each L, if $w(0)=\alpha_L$ and $w'(0)=0$ then $w(r)>0$ for every $r>0$ and $\lim_{r\to\infty} w(r)=0$. Furthermore, $0<w(r)<[(2p-6)/(p-1)^2]^{1/(p-1)}r^{-2/(p-1)}$ for all large r.*

Remarks. 1) It will become clear during the course of our proof that the theorem can be extended to a larger range of parameters than $N=3$ and $6 \leqq p \leqq 12$. However, the details become more complicated. Thus, for the sake of simplicity we restrict our attention to the values given.

2) Results similar to those stated above have recently been given for a combustion model similar to (2), namely

$$u_t - \Delta u - e^u = 0.$$

Solutions of this equation also blow up at $(x,t)=(0,0)$. Again, a similarity form of solution and the assumption of radial symmetry lead to an equation like (4),

$$w'' + \left(\frac{N-1}{r} - \frac{r}{2}\right)w' + e^w - 1 = 0. \tag{6}$$

The appropriate boundary conditions are

$$w(0) \in R, \quad w'(0)=0 \quad \text{and} \quad \lim_{r\to\infty} \frac{w}{2\ln(r)} = -1. \tag{7}$$

For $N=1$ Bebernes and Troy [1] have shown that there are no solutions of (6)-(7). Subsequently, Eberly [2] proved that (6)-(7) has no solution if $N=2$. However, if $N \in (2,9)$, Eberly and Troy [3] proved that the problem (6)-(7) has an infinite number of solutions.

Outline of Proof. The proof of our theorem uses a shooting argument. First, we note that (4) has two particular solutions. One of these is the constant solution $w=\beta^\beta$ where $\beta = 1/(p-1)$. The other, a nonconstant solution, is given by

$$w_0(r) = [(2p-6)/(p-1)^2]^{1/(p-1)} r^{-2/(p-1)}.$$

Define the auxiliary function $h = w - w_0$ where w solves (4)-(5). We prove that if $\alpha - \beta^\beta > 0$ is small then h has at most two zeros before $w=0$. Also, for any given integer $L \geqq 1$, if α is sufficiently large then h has at least $2L+2$ zeros before $w=0$. This leads us to define the set

$$A_{2L} = \{\alpha > \beta^\beta \mid h \text{ has at least } 2L+2 \text{ zeros before } w=0\}. \tag{8}$$

We show that for each $L \geqq 0$, the set A_{2L} is open, nonempty and unbounded above. The remainder of the proof is devoted to showing that there exists $\alpha_L \in (\beta^\beta, \inf A_{2L}]$ such that if $w(0)=\alpha_L$ and $w'(0)=0$ then h has exactly $2L$ zeros and $w(r)>0$ on $(0,\infty)$, with $\lim_{r\to\infty} w(r)=0$.

Proof of Theorem. We assume that $\alpha>0$. Thus, for $r>0$, as long as $w>0$ we observe that w satisfies

$$w'' + \left(\frac{2}{r} - \frac{r}{2}\right)w' + w^p - \frac{w}{(p-1)} = 0 \tag{9}$$

with initial values

$$w(0)=\alpha, \qquad w'(0)=0. \tag{10}$$

The first step of our proof is to show that h has at most two zeros before $w=0$ if $\alpha-\beta^{\beta}>0$ is sufficiently small. This is done in Lemma 3. However, we first need two technical lemmas before proceeding with the proof of Lemma 3.

LEMMA 1. *For each $p>5$, $w''<0$ for $r>0$ as long as $w(r)\leqq w_0(r)$.*

Proof. If there is a first $\bar{r}>0$ for which $w''(\bar{r})=0$ then

$$w'''(\bar{r})\geqq 0. \tag{11}$$

Suppose that $w(\bar{r})<w_0(\bar{r})$. Then (9) and the definition of $w_0(r)$ lead to $w'''(\bar{r})<w'(\bar{r})(2p+2)/(p-1)^2\bar{r}^2<0$, contradicting (11).

Next, recall that $h=w-w_0$.

LEMMA 2. *For each $\alpha>\beta^{\beta}$ there is a first $r_1=r_1(\alpha)>0$ for which $h(r_1)=0$, and*

$$0<r_1(\alpha)<[(2p-6)/(p-1)^2]^{1/2}[(p+1)/(\alpha(p-1))]^{(p-1)/2}. \tag{12}$$

Proof. If there were an $\alpha>\beta^{\beta}$ for which $r_1(\alpha)$ does not exist, then, by Lemma 1, $w''<0$ and $w'<0$ until $w(a)=\beta^{\beta}$ at some $a\in(0,((2p-6)/(p-1))^{1/2})$. But then it follows from (9) that $w''(a)>0$, a contradiction. Thus $r_1(\alpha)$ exists for every $\alpha>\beta^{\beta}$. Further, from Lemma 1, $w''<0$ on $[0,r_1(\alpha)]$ and therefore $w_0'(r_1)<\Delta w/\Delta r=(w_0(r_1)-\alpha)/r_1$. Since $w_0'(r_1)=-2w_0(r_1)/(p-1)r_1$ this becomes $(-2/(p-1))\times(w_0(r_1)/r_1)<(w_0(r_1)-\alpha)/r_1$ and (12) follows.

LEMMA 3. *If $\alpha-\beta^{\beta}>0$ is sufficiently small then h has at most two zeros before $w=0$.*

Proof. The function h satisfies

$$h''=\left(\frac{r}{2}-\frac{2}{r}\right)h'+h\left(\frac{1}{(p-1)}-g(r)\right) \tag{13}$$

where

$$g(r)\equiv w^{p-1}+w^{p-2}w_0+w^{p-3}w_0^2+\cdots+w_0^{p-1}. \tag{14}$$

We observe that

$$\frac{1}{p-1}-pw_0^{(p-1)}>0 \quad \text{for } r>r_p\equiv\left(\frac{p(2p-6)}{p-1}\right)^{1/2}. \tag{15}$$

Since $w\equiv\beta^{\beta}$ satisfies (9) it follows from continuity that if $\alpha-\beta^{\beta}>0$ is sufficiently small then $r_1(\alpha)$ is the only zero of h on $(0,r_p+1)$, and $w(r_p+1)>w_0(r_p+1)$. If h has another zero, $r_2(\alpha)$, on (r_p+1,∞) then $h'(r_2)<0$ and $h''(r_2)<0$. For $r>r_2$, as long as $0<w<w_0$ then $g(r)<pw_0^{p-1}$ and it follows from (13) and (15) that $h''<0$ and $h'<0$ at least until $w\leqq 0$. This completes the proof of Lemma 3.

The following lemma plays a key role in our shooting method.

LEMMA 4. *Let $L\geqq 1$. Then A_{2L} is nonempty, open and unbounded.*

Proof. Continuity and uniqueness imply that A_{2L} is open. To prove that $A_{2L}\neq\varnothing$ we use a comparison method. First, let $v=hre^{-r^2/8}$. Then (13) becomes

$$v''+f(r)v=0 \tag{16}$$

where

$$f(r)\equiv g(r)+\frac{3}{4}-\frac{1}{p-1}-\frac{r^2}{16}. \tag{17}$$

Next, consider the auxiliary equation

$$u''+\frac{.26u}{r^2}=0 \tag{18a}$$

and define

$$R=\min\left((2(p-5)/(p-1))^{1/2},(2p-6)/(p-1)^3)^{1/2},4(\tfrac{3}{4}-1/(p-1))^{1/2}\right).$$

It is well known that (18a) has a solution $u_0(r)$ which has an infinite number of zeros accumulating at $r=0$. Since $\lim_{\alpha\to\infty} r_1(\alpha)=0$, we choose $\alpha^*>\bar{\alpha}$ such that for all $\alpha>\alpha^*$, $u_0(r)$ has at least $2L+4$ zeros in $(r_1(\alpha), R)$. With $\alpha>\alpha^*$, it follows from the Sturm Comparison Theorem (see Simmons [3]) that if $f(r)\geqq .26/r^2$ on $(r_1(\alpha), R)$, then $v(r)$ and $h(r)$ have at least $2L+2$ zeros in $(r_1(\alpha), R)$. Since $\frac{3}{4}-(1/(p-1))-(r^2/16)>0$ for all $p\geqq 5$ and $r\in[0, R]$, it suffices to show that $g(r)\geqq .26/r^2$ on $[r_1(\alpha), R]$ for each $\alpha\geqq\alpha^*$. We note that $w(r)\geqq w_0(r)$ whenever $h(r)\geqq 0$ and therefore $g(r)\geqq 2p(p-3)/(r^2(p-1)^2)\geqq 1/r^2$, $p\geqq 5$. Thus it remains to determine a lower bound on $g(r)$ when $h<0$. For this we make the transformation $w=sw_0$ and $z=\ln(r)$. Then (9) becomes

$$\ddot{s}+\left(\frac{p-5}{p-1}-\frac{e^{2z}}{2}\right)\dot{s}+\frac{(2p-6)}{(p-1)^2}(s^p-s)=0 \tag{18b}$$

where $\dot{s}\equiv ds/dz$. Let $z_1=\ln(r_1)$ and $z_R=\ln(R)$. The definition of R implies that

$$\frac{p-5}{p-1}-\frac{e^{2z}}{2}>0 \quad \forall z\in(z_1, z_R). \tag{19}$$

Further, it follows from Lemma 1 that $w'(r_1)<0$; hence $h'(r_1)\leqq -w_0'(r_1)=2w_0(r_1)/(p-1)r_1$. Therefore

$$\dot{s}(z_1)\leqq\frac{2}{p-1}. \tag{20}$$

Next, we multiply both sides of (18b) by $\dot{s}$, integrate and obtain

$$\frac{(\dot{s})^2}{2}\leqq\frac{2}{(p-1)^2}+\frac{(2p-6)}{(p-1)^2}\left(\frac{1}{p+1}-\frac{1}{2}+\frac{s^2}{2}-\frac{s^{p+1}}{p+1}\right), \tag{21}$$

$z\in[z_1, z_R]$. It follows from (21) that the right-hand side of (21) is negative if

$$6\leqq p\leqq 7 \quad\text{and}\quad s\leqq .21 \tag{22}$$

or

$$7\leqq p\leqq 13.8 \quad\text{and}\quad s\leqq\tfrac{1}{2}. \tag{23}$$

Thus, $s>.2$ on $[z_1, z_R]$ for $6\leqq p\leqq 7$, and $s>.5$ on $[z_1, z_R]$ if $7\leqq p\leqq 13.8$. Consequently, if $6\leqq p\leqq 7$ then it follows that

$$g(r)\geqq\left(\frac{1-.2^p}{.80}\right)\left(\frac{2p-6}{(p-1)^2}\right)\frac{1}{r^2}\geqq\frac{.27}{t^2}\quad\text{for all } r\in[r_1, R].$$

Similarly, from (23), $g(r)\geqq .26/r^2$ for all $r\in[r_1, R]$ if $7\leqq p\leqq 12.6$. Thus, from this analysis and the Sturm Comparison Theorem it follows that $w>0$ on $[r_1, R]$, and h has at least $2L+2$ zeros on $[r_1, R]$.

Remark. It is clear from the proof that we can vastly expand the range of values of p for which the appropriate estimates hold. For the sake of brevity and simplicity we have chosen not to do so.

For each $L\geqq 1$ it follows from Lemmas 3 and 4 that the set A_{2L} is bounded below with

$$\gamma_L\equiv\inf A_{2L}>\beta^\beta. \tag{24}$$

We fix $L \geqq 1$ and consider the solution of (9) with $w(0) = \gamma_L$ and $w'(0) = 0$. If $h = w - w_0$ has exactly $2L$ zeros and $w > 0$ on $(0, \infty)$ with $\lim_{r\to\infty} w(r) = 0$ then $\alpha_L \equiv \gamma_L$ and the proof of the theorem is complete. Otherwise there are several cases to consider:

(i) h has at least $2L+2$ zeros before $w = 0$. Then continuity implies the same is true if $\gamma_L - \alpha > 0$ is sufficiently small, contradicting the definition of γ_L. Therefore h has at most $2L+1$ zeros before $w = 0$;

(ii) h has at most $2L+1$ zeros followed by a finite value of r for which $h = 0$. Again, continuity implies the same is true if $\alpha - \gamma_L > 0$ is sufficiently small, contradicting the definition of γ_L;

(iii) h has less than $2L$ zeros and $w > 0$ on $(0, \infty)$. Continuity implies that if $\alpha - \gamma_L > 0$ is sufficiently small then h has at most $2L-1$ zeros on $(0, r_p+1)$ as well as at least three more, say at a_1, a_2, a_3 on (r_p+1, ∞) before $w = 0$. Thus, either $h'(a_1) < 0$ or $h'(a_2) < 0$. It suffices to consider the case that $h'(a_1) < 0$. Then $h''(a_1) < 0$ since $a_1 > r_p$ and it follows as in the proof of Lemma 3 that $h'' < 0$ for $r > a_2$ until $w = 0$ at some finite value of r. This contradicts the assumption that h has at least $2L+2$ zeros before $w = 0$ for $\alpha - \gamma_L > 0$ sufficiently small. We conclude from (i)-(iii) that h has at least $2L$ zeros and $w > 0$ for every $r > 0$. If h has exactly $2L$ zeros then $0 < w < w_0$ for all $r > r_{2L}$; hence $\lim_{r\to\infty} w(r) = 0$ and the theorem is proved for $\alpha_L = \gamma_L$. It remains to consider the possibility that h has exactly $2L+1$ zeros with $w > 0$ for every $r > 0$. We define the set $B_{2L+1} = \{\hat{\alpha} < \gamma_L |$ if $\hat{\alpha} < \alpha < \gamma_L$ then h has exactly $2L+1$ zeros. If $\gamma_L - \alpha > 0$ is sufficiently small then continuity and the definition of γ_L imply that h has exactly $2L+1$ zeros. Thus, by Lemma 3, B_{2L+1} is bounded below with $\gamma_{2L+1} \equiv \inf B_{2L+1} > \beta^\beta$. We consider the solution with $w(0) = \gamma_{2L+1}$, $w'(0) = 0$. There are several possibilities;

(iv) h has $2L+1$ zeros before $w = 0$, or

(v) h has at most $2L$ zeros followed by a finite value of r where $h = 0$, or

(vi) h has fewer than $2L$ zeros and $w > 0$ on $(0, \infty)$. These three possibilities are eliminated in the same way as in (i)-(iii) above. We conclude that h has exactly $2L$ zeros and $w > 0$ on $0 < r < \infty$. This implies that $0 < w < w_0$ for every $r > r_{2L}$ and $\lim_{r\to\infty} w(r) = 0$. Thus $\alpha_L \equiv \gamma_{2L+1}$ and the theorem is proved.

THE DRAWING AND WHIRLING OF STRINGS: SINGULAR GLOBAL MULTIPARAMETER BIFURCATION PROBLEMS*

STUART S. ANTMAN† AND MICHAEL REEKEN‡

Abstract. This paper treats the steady motion under gravity of both inextensible and elastic strings that are simultaneously whirled and drawn. The motion is governed by a quasilinear system of singular ordinary differential equations that depend on the two parameters ω and γ, which are the rates of whirling and drawing. The singular nonlinear problem is approximated by a sequence of regular problems to which global multiparameter bifurcation theory is applied. It is then shown that the sequence of solution sheets for the approximating problems converges to solution sheets of the actual problem. All these solution sheets, infinite in number, are shown to bifurcate from the ω- and γ-axes, which form the boundaries of the continuous spectra for the problem linearized about the trivial solution. (These linearized problems have no eigenvalues.) Nevertheless, each bifurcating sheet is characterized by a novel and distinctive nodal pattern. The nature of steady shocks in elastic strings is briefly discussed.

Key words. steady motions of strings, global multiparameter bifurcation theory, singular differential equations, nodal properties, steady shocks

AMS(MOS) subject classifications. 33A40, 34B15, 35L67, 47H12, 58E07, 73G99, 73H99, 73K03

1. Introduction. Global studies of the steady whirling of strings began with the work of Kolodner [17]. Such problems have stimulated many advances in global bifurcation theory. (A comprehensive bibliography is given by Alexander, Antman and Deng [3].) Of special relevance for our present investigation is the work of Stuart [28]. His model for a process by which fibers are spun is that of an inextensible string having a fixed configuration in a vertical plane rotating with constant angular speed about the vertical axis. The string is subjected to unusual boundary conditions. Stuart's beautiful analysis represents the first application of the global bifurcation theory of Crandall and Rabinowitz [10], [11] and Rabinowitz [23], [24] to a concrete problem from physics.

Although he described the manufacturing process as one in which fibers are both whirled and drawn, Stuart in fact ignored the longitudinal motion. As we shall show, the presence of both longitudinal and rotational motions results in a Coriolis acceleration, which prevents the fiber from remaining in a rotating plane, as Stuart required. Moreover, shocks can form in an elastic string that is being drawn. Thus the more realistic model we shall present introduces several qualitatively new and interesting phenomena.

The actual formulation of our problem, carried out in § 2, requires care because the material particles forming the fiber under study change with time. The problem has two basic parameters: the speed of drawing γ and the angular rotation speed ω.

In § 3 we work out the full bifurcation analysis for a special elastic string for which the boundary value problem admits a closed-form solution. This example shows that bifurcating sheets of solutions exhibit remarkable nodal properties characteristic

‡ Mathematik, Bergische Universität, Gesamthochschule Wuppertal, 5600 Wuppertal 1, West Germany. This author conducted some of his work during visits to the University of Maryland, College Park, Maryland 20742, and Stanford University, Stanford, California 94305, in 1982–1983.

of solution sets for all kinds of strings. Other features of its solutions are not typical, however, as we show in the subsequent analysis.

In § 4 we carry out an analysis of the regularity of solutions, which enables us to reformulate the problem in a more tractable form. In § 5 we give a careful formulation of the equations for inextensible strings. This formulation supports the global bifurcation analysis of § 6, the heart of the paper. Here we employ a delicate regularization procedure to handle the troublesome singularities of the governing equations. We ultimately obtain the remarkable bifurcation diagram of Fig. 6.63. It shows that all bifurcating sheets of solutions bifurcate from the ω and γ axes (which are the boundaries of the continuous spectra for the linearization). Associated with each bifurcating sheet is a distinctive nodal pattern. This nodal pattern obviously cannot be inherited from that of the linearized problem, because the solutions of the linearized problem have no nodal pattern. In § 7 we examine some aspects of the behavior of elastic strings.

We denote ordinary derivatives by primes and partial derivatives by subscripts. Thus the partial derivative of $(\alpha, \beta, t) \mapsto f(\alpha, \beta, t)$ with respect to t at (α, β, t) is denoted $f_t(\alpha, \beta, t)$. The partial derivative of $(\alpha, t) \mapsto f(\alpha, b(t), t)$ with respect to t at (α, t) is denoted $(\partial/\partial t)f(\alpha, b(t), t) = f_\beta(\alpha, b(t), t)b'(t) + f_t(\alpha, b(t), t)$. We occasionally use the summation convention for twice repeated Latin indices ranging over 1, 2, 3.

2. Formulation of the governing equations. Let $\{\mathbf{i}, \mathbf{j}, \mathbf{k}\}$ represent a fixed right-handed orthonormal basis for Euclidean 3-space $\mathbb{E}^3$. Let $a \geqq 0$. We study the whirling motion under gravity of that part of a string lying between $\mathbf{0}$ and $a\mathbf{k}$ when it is being fed through an *inlet* at $\mathbf{0}$ and is being withdrawn through an *outlet* at $a\mathbf{k}$. Gravity is taken to act in either the $\mathbf{k}$ or $-\mathbf{k}$ direction.

Let ζ parametrize an unstressed reference configuration of the string. ζ identifies a typical material point of the string. Let $\xi(\tau)$ and $\eta(\tau)$ be the material points of the string that respectively pass through $\mathbf{0}$ and $a\mathbf{k}$ at time τ. Let $\mathbf{p}(\zeta, t)$ be the position of material point ζ at time t. Then by definition of ξ and η we have

$$(2.1) \qquad \mathbf{p}(\xi(t), t) = \mathbf{0}, \qquad \mathbf{p}(\eta(t), t) = a\mathbf{k}.$$

We assume that $\mathbf{p}(\cdot, t)$ is absolutely continuous so that it has a derivative almost everywhere and has a well defined length. The *stretch* at (ζ, t), which is the local ratio of deformed to reference length at (ζ, t), is

$$(2.2) \qquad \delta(\zeta, t) \equiv |\mathbf{p}_\zeta(\zeta, t)|.$$

The string is *inextensible* if δ is constrained to equal 1, no matter what system of forces acts on the string. The arc length of the curve $\mathbf{p}(\cdot, t)$ between $\mathbf{p}(\alpha, t)$ and $\mathbf{p}(\beta, t)$ is

$$(2.3) \qquad \sigma(\alpha, \beta, t) = \int_\alpha^\beta \delta(\zeta, t)\, d\zeta.$$

From (2.1) we find that the arc length of $\mathbf{p}(\cdot, t)$ between $\mathbf{0}$ and $\mathbf{p}(\xi(\tau), t)$ is $\sigma(\xi(t), \xi(\tau), t)$.

We now seek steady motions of the string in which it is fed in at $\mathbf{0}$ and withdrawn at $a\mathbf{k}$ at a constant rate and in which the configuration of the *active part* of the string, i.e., the part between $\mathbf{0}$ and $a\mathbf{k}$, occupies a rigid space curve that is rotating about the $\mathbf{k}$-axis with a constant angular velocity ω. We now translate these requirements into precise analytic forms. We assume that

$$(2.4) \qquad \xi'(\tau) = \eta'(\tau) = -\gamma < 0$$

so that

$$\xi(\tau)=\xi(0)-\gamma\tau, \qquad \eta(\tau)=\eta(0)-\gamma\tau. \tag{2.5}$$

Thus

$$l\equiv\eta(\tau)-\xi(\tau)=\eta(0)-\xi(0) \tag{2.6}$$

is independent of τ. (The prescription of l for uniform strings, which are defined below, is equivalent to the prescription of the amount of material in the active part of the string.) Let us set

$$s=\gamma(t-\tau)=\xi(\tau)-\xi(t). \tag{2.7}$$

Note that if $\xi(t)\leqq\xi(\tau)\leqq\eta(t)$, then $s\in[0, l]$. We require that the string lie on a rotating rigid space curve $\mathbf{r}(\cdot, t)$, which (without loss of generality) must have the form

$$\mathbf{r}(s, t)=x_m(s)\mathbf{e}_m(t) \quad \text{for } s\in[0, l], \tag{2.8}$$

$$\mathbf{e}_1(t)\equiv\cos\omega t\mathbf{i}+\sin\omega t\mathbf{j}, \quad \mathbf{e}_2(t)\equiv\mathbf{k}\times\mathbf{e}_1(t), \quad \mathbf{e}_3(t)\equiv\mathbf{k}, \tag{2.9}$$

by setting

$$\mathbf{p}(\xi(\tau), t)\equiv\mathbf{p}(\xi(t)+s, t)=\mathbf{r}(s, t)\equiv\mathbf{r}(\gamma(t-\tau), t). \tag{2.10}$$

The absolute continuity of $\mathbf{p}(\cdot, t)$ ensures that of $\mathbf{r}(\cdot, t)$. We are actually requiring that the motion of the string be a travelling wave with s representing the fixed phase.

Under these conditions we have

$$\mathbf{p}_\xi(\xi(\tau), t)=\mathbf{r}_s(s, t), \tag{2.11a}$$

so that (2.2) and (2.10) imply that

$$\delta(\xi(\tau), t)=|\mathbf{r}_s(s, t)|\equiv\nu(s) \tag{2.11b}$$

since $|\mathbf{r}_s(s, t)|$ does not depend explicitly on t. Moreover, the equality of the extremes of (2.10) implies that

$$\mathbf{p}_t(\xi(\tau), t)=\gamma\mathbf{r}_s(s, t)+\omega\mathbf{k}\times\mathbf{r}(s, t), \tag{2.12}$$

$$\mathbf{p}_{tt}(\xi(\tau), t)=\gamma^2\mathbf{r}_{ss}(s, t)+2\omega\gamma\mathbf{k}\times\mathbf{r}_s-\omega^2[x_1(s)\mathbf{e}_1(t)+x_2(s)\mathbf{e}_2(t)] \tag{2.13}$$

whenever $\mathbf{r}(\cdot, t)$ is twice continuously differentiable. Note that the speeds at $\mathbf{0}$ and $a\mathbf{k}$ of the material points occupying them are

$$|\mathbf{p}_t(\xi(t), t)|=\gamma\nu(0), \qquad |\mathbf{p}_t(\eta(t), t)|=\gamma\nu(l). \tag{2.14}$$

These are not necessarily equal. For a uniform string, (2.4) can be interpreted as a requirement that the mass fluxes at $\mathbf{0}$ and $a\mathbf{k}$ be equal. This requirement, rather than the equality of the entrance and exit speeds (given by (2.14)), is essential for steady motions.

We could have alternatively chosen to parametrize $\mathbf{r}$ by the arc length $\sigma(\xi(t), \xi(\tau), t)$ from $\mathbf{0}$ to $\mathbf{p}(\xi(\tau), t)$. We should then have to require that

$$\sigma(\xi(t+\lambda), \xi(\tau+\lambda), t+\lambda)=\sigma(\xi(t), \xi(\tau), t) \quad \forall\lambda. \tag{2.15a}$$

We would therefore obtain from (2.5) and (2.15a) that

$$\sigma_t(\xi(t), \xi(\tau), t)=\gamma[\delta(\xi(\tau), t)-\delta(\xi(t), t)]. \tag{2.15b}$$

In this case the resulting equations would be cluttered with δ's.

Having described the kinematics of the steady motion of our string, we now turn to the mechanics. To ensure that the string admits motion (2.10) solely under the action of gravity, we require that the string be *uniform*, i.e., that its mass density ρA per unit natural length be a positive constant and that its constitutive functions be independent of ζ. Otherwise (2.10) would represent a constraint, which would have to be maintained by artificial (time-varying) constraint forces. Since ρA is constant, equation (2.6) implies that the total mass of the active part of the string is independent of t.

Let $\mathbf{n}(\zeta, t)$ be the resultant contact force exerted by the material of $\{\chi: \chi > \zeta\}$ on that of $\{\chi: \chi \leqq \zeta\}$ at time t. The defining property of a string is that $\mathbf{n}(\zeta, t)$ be tangent to the curve $\mathbf{p}(\cdot, t)$ at $\mathbf{p}(\zeta, t)$, i.e., that $\mathbf{n}$ have the form

$$\mathbf{n}(\zeta, t) = \tilde{n}(\zeta, t)\mathbf{p}_\zeta(\zeta, t)/\delta(\zeta, t). \tag{2.16}$$

$\tilde{n}(\zeta, t)$ is the *tension* at (ζ, t). The string is *in tension* at (ζ, t) if $\tilde{n}(\zeta, t) > 0$ and *in compression* at (ζ, t) if $\tilde{n}(\zeta, t) < 0$.

The string is *elastic* (and *uniform*) if there is a function $(0, \infty) \ni \nu \mapsto N(\nu) \in \mathbb{R}$ such that

$$\tilde{n}(\zeta, t) = N(\delta(\zeta, t)). \tag{2.17}$$

We assume that N is continuously differentiable and that

$$N'(\nu) > 0, \quad N(1) = 0, \quad N(\nu) \to \infty \quad \text{as } \nu \to \infty, \quad N(\nu) \to -\infty \quad \text{as } \nu \to 0. \tag{2.18}$$

For the steady motions we study, we set

$$\tilde{n}(\xi(\tau), t) = \tilde{n}(s + \xi(0) - \gamma t, t) \equiv n(s, t) \tag{2.19}$$

(cf. (2.5), (2.7)). In this case (2.11) implies that (2.17) reduces to

$$n(s, t) = N(\nu(s)) \tag{2.20}$$

so that n is independent of t for elastic strings. We henceforth drop the argument t of n.

The string is *inextensible* if

$$\nu(s) = 1 \quad \forall s \in [0, l] \tag{2.21}$$

no matter what tension field is acting. For an inextensible string, the constraint force n is retained as a fundamental unknown of the problem. (It is the Lagrange multiplier maintaining the constraint of inextensibility.) We shall seek solutions for which n is locally integrable. As part of our definition of steady motion for such strings we require that n be independent of t.

Since we expect that the string might sustain shocks we formulate its equations of motion in the weakest possible form as impulse-momentum laws (cf. [5]). Let g denote the acceleration of gravity. If the only forces acting on the active part of the string executing the motion described above are its weight acting in the $\mathbf{k}$ or $-\mathbf{k}$ direction and the forces acting on its ends, then the impulse-momentum law for each material segment $(\xi(\tau_1), \xi(\tau_2))$ in $(\xi(t), \eta(t))$ and for each time interval (t_1, t_2) is

$$\begin{aligned} &\int_{t_1}^{t_2} \frac{\tilde{n}(\zeta, t)\mathbf{p}_\zeta(\zeta, t)}{\delta(\zeta, t)}\bigg|_{\zeta=\xi(\tau_1)}^{\zeta=\xi(\tau_2)} dt + \varepsilon\rho A g[\xi(\tau_2) - \xi(\tau_1)](t_2 - t_1)\mathbf{k} \\ &\quad = \rho A \int_{\xi(\tau_1)}^{\xi(\tau_2)} \mathbf{p}_t(\zeta, t)\bigg|_{t=t_1}^{t=t_2} d\zeta \end{aligned} \tag{2.22a}$$

where $\varepsilon = \pm 1$. We now use (2.5), (2.7), (2.11), (2.12) to convert (2.22a) to the following form

$$\int_{t_1}^{t_2} \frac{n(\gamma(t-\tau))\mathbf{r}_s(\gamma(t-\tau), t)}{\rho A\nu(\gamma(t-\tau))}\bigg|_{\tau=\tau_1}^{\tau=\tau_2} dt - \varepsilon g\gamma(\tau_2-\tau_1)(t_2-t_1)\mathbf{k}$$

$$\text{(2.22b)} \qquad = \int_{\xi(\tau_1)}^{\xi(\tau_2)} [\gamma\mathbf{r}_s(\zeta-\xi(0)+\gamma t, t)+\omega\mathbf{k}\times\mathbf{r}(\zeta-\xi(0)+\gamma t, t)]\bigg|_{t=t_1}^{t=t_2} d\zeta$$

$$= \int_{\gamma(t_2-\tau_1)}^{\gamma(t_2-\tau_2)} [\gamma\mathbf{r}_s(s, t_2)+\omega\mathbf{k}\times\mathbf{r}(s, t_2)]\, ds$$

$$- \int_{\gamma(t_1-\tau_1)}^{\gamma(t_1-\tau_2)} [\gamma\mathbf{r}_s(s, t_1)+\omega\mathbf{k}\times\mathbf{r}(s, t_1)]\, ds.$$

Since $\mathbf{r}(\cdot, t)$ is absolutely continuous and since $\mathbf{r}(s, \cdot)$ is analytic, we can differentiate (2.22) with respect to t_2 almost everywhere, obtaining

$$\text{(2.23)} \qquad \begin{aligned} &\left[\frac{n(s)}{\rho A\nu(s)}-\gamma^2\right]\mathbf{r}_s(s, t)\bigg|_{s_1}^{s_2} + \varepsilon g(s_2-s_1)k \\ &\qquad = 2\omega\gamma\mathbf{k}\times\mathbf{r}(s, t)\bigg|_{s_1}^{s_2} + \omega^2\int_{s_1}^{s_2} \mathbf{k}\times[\mathbf{k}\times\mathbf{r}(s, t)]\, ds \end{aligned}$$

where we have set $s_2 = \gamma(t_2-\tau_2)$, $s_1 = \gamma(t_2-\tau_1)$ and have replaced t_2 by t.

Let us now set

$$\text{(2.24a)} \qquad m(s, \gamma) = \frac{n(s)}{\rho A\nu(s)}-\gamma^2, \qquad M(\nu, \gamma) = \frac{N(\nu)}{\rho A\nu}-\gamma^2$$

(so that

$$\text{(2.24b)} \qquad m(s, \gamma) = M(\nu(s), \gamma)$$

for elastic strings),

$$\text{(2.25a)} \qquad u(s) = x_1(s)+ix_2(s), \qquad z(s) = x_3(s)$$

where i is the imaginary unit. Thus

$$\text{(2.25b)} \qquad \nu^2 = |u'|^2+(z')^2.$$

Then we can write (2.23) and the boundary conditions corresponding to (2.4) as

$$\text{(2.26)} \qquad m(y, \gamma)u'(y)\bigg|_c^s = 2i\omega\gamma u(y)\bigg|_c^s - \omega^2\int_c^s u(y)\, dy,$$

$$\text{(2.27)} \qquad u(0) = 0 = u(l),$$

$$\text{(2.28)} \qquad m(s, \gamma)z'(s) = \varepsilon g(b-s),$$

where b is a constant of integration,

$$\text{(2.29)} \qquad z(0) = 0, \qquad z(l) = a.$$

Equations (2.26) and (2.28) are to hold for all $[c, s]\subset[0, l]$.

If (2.26)-(2.29) has a solution with u absolutely continuous, then mu' is absolutely continuous and mz' is an affine function of s. We can therefore differentiate (2.26) and (2.28) with respect to s almost everywhere to obtain

$$\text{(2.30)} \qquad (mu')'-2i\omega\gamma u'+\omega^2 u = 0,$$

$$\text{(2.31)} \qquad (mz')'+\varepsilon g = 0.$$

If the configuration of the string is confined to a vertical plane through **k** rotating about **k** with angular velocity ω, then we can always take u to be real. In this case (2.26) and (2.27) imply that $\omega\gamma u=0$. If $\gamma>0$, then either the solution is trivial: $u=0$, or else $\omega=0$. In the latter case (2.26) implies that

$$mu'=\mathscr{C}\text{ (real const.).}\tag{2.32}$$

Now (2.28) and (2.32) imply that $m^2\nu^2=\mathscr{C}^2+g^2(b-s)^2$. We require that $\nu>0$. Thus if m should vanish on $[0,l]$, it could do so only at $s=b$ provided $b\in[0,l]$. In this case (2.32) would imply that $\mathscr{C}=0$ and therefore $u'=0$. Conditions (2.27) would then imply that $u=0$. If m vanishes nowhere, then (2.32) and (2.37) imply that $\mathscr{C}=0$. Thus *if* $\gamma>0$, *then the only planar solution of boundary value problem* (2.26)-(2.29) *is the trivial solution.*

The equations for an elastic string are obtained by supplementing (2.26)-(2.29) with the constitutive equation (2.24b). The equations for an inextensible string are obtained by retaining n or m as a fundamental variable in (2.23) and by setting $\nu=1$, so that

$$(z')^2=1-|u'|^2.\tag{2.33}$$

In principle, we can determine m from (2.28), (2.29), (2.33) in terms of $|u'|^2$. (Note that m does not now depend on the u' or z' through a composition of M with ν.) Solutions for m can be substituted into (2.26) to obtain a system for u alone. We shall discuss the details of this procedure in § 5.

3. Example. If $\nu_0>1$, then a conceivable form for the restriction of N to $[\nu_0,\infty)$ is

$$N(\nu)=\alpha^2\rho A\nu\quad\text{for }\nu\geqq\nu_0\tag{3.1}$$

where α^2 is a positive constant. The substitution of (3.1) into (2.30), (2.27)-(2.29) reduces them to

$$(\alpha^2-\gamma^2)u''-2i\omega\gamma u'+\omega^2u=0,\qquad u(0)=0=u(l),\tag{3.2}$$

$$(\alpha^2-\gamma^2)z'=\varepsilon g(b-s),\qquad z(0)=0,\quad z(l)=a.\tag{3.3}$$

γ^2 cannot equal α^2 if (3.3) is to have a solution. If $\gamma^2\neq\alpha^2$, then the solution of (3.3) is

$$z=\frac{\varepsilon gs(b-s/2)}{\alpha^2-\gamma^2}=\frac{as}{l}+\frac{\varepsilon gs(l-s)}{2(\alpha^2-\gamma^2)}\tag{3.4a}$$

with

$$b=\frac{l}{2}+\frac{\varepsilon(\alpha^2-\gamma^2)a}{gl}.\tag{3.4b}$$

Problem (3.2) has a nontrivial solution if and only if

$$\omega=\frac{k\pi}{\alpha l}(\alpha^2-\gamma^2),\qquad k=\pm1,\pm2,\cdots.\tag{3.5}$$

If l is fixed, (3.5) defines a countable family of parabolic eigencurves in the (ω,γ)-plane. If l is variable, then (3.5) defines a countable family of eigensurfaces in (ω,γ,l)-space. Corresponding to (3.5) are the nontrivial solutions

$$u^k=B\sin\frac{k\pi s}{l}\exp i\left(\frac{k\pi\gamma s}{\alpha l}\right).\tag{3.6}$$

Let us now check that $\nu \geqq \nu_0$. From (3.4) and (3.6) we obtain

$$(3.7) \qquad \nu^2 = \left(\frac{a}{l} + \frac{\varepsilon g(l-2s)}{2(\alpha^2-\gamma^2)}\right)^2 + \left(B\frac{k\pi}{l}\right)^2 \left(\cos^2\left(\frac{k\pi s}{l}\right) + \left(\frac{\gamma}{\alpha}\right)^2 \sin^2\left(\frac{k\pi s}{l}\right)\right).$$

We can ensure that $\nu \geqq \nu_0$ for all B by taking

$$(3.8) \qquad \frac{a}{l} + \frac{\varepsilon g(l-2s)}{2(\alpha^2-\gamma^2)} \geqq \nu_0,$$

i.e., by taking

$$(3.9) \qquad \frac{a}{l} - \frac{gl}{2|\alpha^2-\gamma^2|} \geqq \nu_0 \quad \text{or equivalently } |\gamma^2-\alpha^2| \geqq \frac{gl}{2(a-\nu_0 l)}.$$

Since $\nu_0 > 1$, the first form of (3.9) requires that $a/l > \nu_0 > 1$. This means that the distance a between inlet and outlet exceeds the natural length l of the string. When (3.9) holds, (3.4b) yields

$$(3.10) \qquad \left|b - \frac{l}{2}\right| \geqq \frac{l}{2}\left(\frac{a}{a-\nu_0 l}\right) > \frac{l}{2}.$$

Thus $b \notin [0, l]$ so that (3.3) implies that z is strictly increasing along the length of the curve.

In the space of (ω, γ, u) the solution pairs are represented by cylindrical surfaces above the eigencurves (3.5) with the points at which $\nu \leqq \nu_0$ excluded. (Thus the planes $\gamma = \pm\alpha$ are excluded.) We sketch the curves (3.5) in Fig. 3.11. On the kth sheet $|u^k|$ has exactly $(k-1)$ interior zeros (which are simple), but the number of zeros of x_1^k and x_2^k varies markedly with γ along the sheet. The shape of the string for $k=3$ and $\gamma/\alpha = 6$ is sketched in Fig. 3.12. (The virtues of (3.1) for other "nonlinear" problems for strings were recognized by Keller [16].)

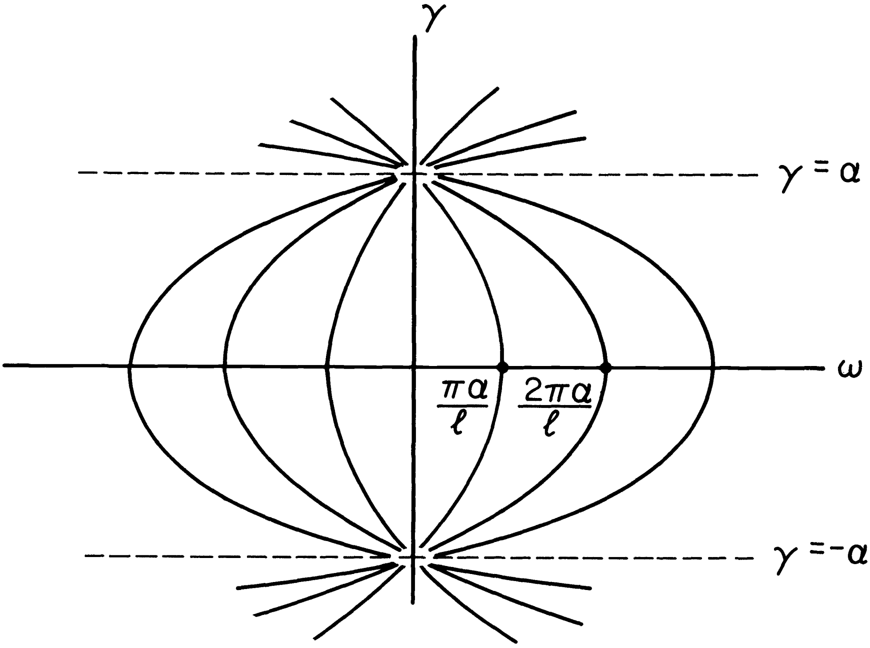

FIG. 3.11

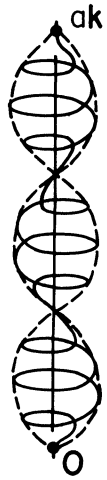

FIG. 3.12

Our goal in the remainder of this paper is to determine which properties of this example are typical of all materials.

4. Regularity of solutions. A solution of the boundary value problem (2.26)-(2.29) is *trivial* if $u=0$ and *nontrivial* otherwise. We seek nontrivial solutions of our boundary value problem for which u and z are absolutely continuous. Throughout this section we suppose that (2.26)-(2.29) has such solutions. Our results apply to them. Below we show that such solutions actually exist.

Equations (2.26) and (2.28) imply that mu' and mz' are absolutely continuous. Thus $|m\nu|$ is absolutely continuous. But this fact does not imply that $m\nu$ itself is continuous. It can be shown that if $m\nu$ is allowed to be discontinuous, then the governing equations admit an uncountable collection of pathological solutions. (Indeed, the methods of Reeken [25], [26] show that for an elastic string there are solutions of (2.26)-(2.29) with $m\nu$ nowhere negative on an arbitrarily prescribed measurable subset of $[0, l]$ and negative on its complement.) Such kinky solutions correspond to certain kinds of travelling shocks. These cannot exist when the string has some bending stiffness. But the presence of bending stiffness would also exclude other effects that are quite reasonable for our model. (For example, a stiff string supported at two nearby points on the same vertical line could not have a folded; pendant equilibrium configuration confined to the line beneath the supports. Such a configuration is a reasonable approximation to the actual one.) To avoid discussions on the physical admissibility of kinky solutions, we choose to preclude them from consideration by seeking solutions for which $m\nu$ is continuous.

Note that the continuity of $|m\nu|$ and the properties of N given in (2.18) ensure that ν has a positive lower bound for any solution of the boundary value problem for elastic strings. For inextensible strings ν is constrained to be 1.

If the string is inextensible, the requirement that $m\nu$ be continuous reduces to the requirement that m be continuous. If we compute m^2 from (2.26), (2.28) we find that m could only vanish on $[0, l]$ at b, provided $b \in [0, l]$. It then follows from (2.26) and (2.28) that u and z are continuously differentiable on $[0, l]\backslash\{b\}$.

The corresponding results for elastic strings are more delicate. Set

$$\gamma_0^2 = \inf_\nu \frac{N'(\nu)}{\rho A}. \tag{4.1}$$

Then (2.18) implies that if $\gamma^2 < \gamma_0^2$, then $\nu \mapsto M(\nu, \gamma)\nu$ is strictly increasing on $(0, \infty)$ and has a continuously differentiable inverse. The continuity of $s \mapsto M(\nu(s), \gamma)\nu(s)$ then implies that of ν when $\gamma^2 < \gamma_0^2$. For $\gamma^2 \geqq \gamma_0^2$ we cannot in general exclude the possibility of discontinuities in ν (density shocks). (γ_0 is the smallest longitudinal wave speed. For special N's, however, a priori estimates could restrict ν to an interval on which $s \mapsto M(\nu(s), \gamma)\nu(s)$ is invertible so that ν would be continuous.) The continuity of ν implies that u' and z' are bounded. It follows from (2.28) that m could have at most one zero on $[0, l]$, at b, provided $b \in [0, l]$. From (2.26) and (2.28) we then find that u and z are continuously differentiable on $[0, l] \backslash \{b\}$ when $\gamma^2 < \gamma_0^2$, or more generally, when the parameters are such that ν is continuous. Henceforth, without further comment, we shall restrict our attention to parameter ranges for elastic strings for which ν is continuous.

Equation (2.26) now implies that $s \mapsto m(s, \gamma)u'(s)$ is continuously differentiable on $[0, l] \backslash \{b\}$ so that (2.30) and (2.31) hold on this set in the classical sense. This fact does not, by itself, imply that u is twice continuously differentiable here. But if we compute $m^2\nu^2$ as before, we find that it is continuously differentiable on $[0, l] \backslash \{b\}$. Thus $m\nu$ is continuously differentiable because it cannot vanish here. For the inextensible string, m itself is continuously differentiable and does not vanish on $[0, l] \backslash \{b\}$. From (2.26) and (2.28) we find that u' and z' are continuously differentiable here. For elastic strings we proceed as before to show that ν is continuously differentiable (where it is continuous). Since ν does not vanish, m itself is continuously differentiable on $[0, l] \backslash \{b\}$ and we again find that u and $z \in C^2([0, l] \backslash \{b\})$. Now suppose that the complex-valued function u has a double zero at a point $s_0 \in [0, l] \backslash \{b\}$. Since m does not vanish on $[0, l] \backslash \{b\}$, the initial value problem for (2.30) on the connected component of $[0, l] \backslash \{b\}$ containing s_0 with initial conditions $u(s_0) = 0 = u'(s_0)$ has the unique solution $u = 0$ on this connected component. Thus we conclude that on each connected component of $[0, l] \backslash \{b\}$ either $u = 0$ or else all the zeros of u are simple. By the same token we find that if u is not the zero function on $[0, b]$ with $b \in (0, l]$, then the only place its zeros on $[0, b]$ could accumulate is at b. An analogous result holds for u nonzero on $[b, l]$.

Let u be a nontrivial solution and let

$$(4.2) \qquad E = \{s \in (0, l) \backslash \{b\}: u(s) \neq 0\}, \qquad F = \begin{cases} [0, b] & \text{if } u(s) = 0 \quad \text{for } s \in [0, b], \\ [b, l] & \text{if } u(s) = 0 \quad \text{for } s \in [b, l]. \end{cases}$$

Since u is continuous, E is open and can therefore be expressed as a countable union of disjoint open intervals. We now define real-valued functions v and ϕ on $E \cup F$ such that

$$(4.3) \qquad u(s) = v(s)e^{i\phi(s)}.$$

We do not require v to be positive. Clearly $v(s) = \pm|u(s)|$. On each component open interval of E, ϕ is determined by (4.3) to within an integral multiple of π. Representation (4.3) does not restrict ϕ on F.

Suppose that $b > 0$ and that u is not the zero function on $[0, b]$. Since the zeros of u could accumulate only at b, we can number the intervals of E starting with that having 0 as an end point. Let $0 \equiv s_0 < s_1 < s_2 < \cdots$ denote the zeros of u that are less than b. On (s_k, s_{k+1}) we set $v = (-1)^k|u|$, $k = 0, 1, \cdots$. Since u is twice continuously differentiable on $[0, b]$, it follows that v is Lipschitz continuous on $[0, b)$ and twice continuously differentiable on each interval (s_k, s_{k+1}). On $[0, s_1)$, we take

$$(4.4) \qquad \phi(s) = \arg u'(0) + \int_0^s \frac{[x_1(\sigma)x_2'(\sigma) - x_2(\sigma)x_1'(\sigma)]}{|u(\sigma)|^2} \, d\sigma$$

where arg $u'(0)$ is well defined by the requirement that it lie in $[0, 2\pi)$ (since $u'(0) \neq 0$). We now show that ϕ is defined at s_1. Since $u \in C^2([0, b))$, we have

$$(4.5) \qquad u(s) = (s - s_1)u'(s_1) + o(s - s_1), \qquad u'(s) = u'(s_1) + o(s - s_1).$$

The use of (4.5) in (4.4) shows not only that the integral converges when the upper limit is s_1, but also that $\phi'(s_1) = 0$. We can extend this argument to all the component open intervals of $[0, b)$. Thus (4.4) defines a continuously differentiable function on $[0, b)$ that is twice continuously differentiable on $E \cap [0, b)$. If $b \geqq l$, then v and ϕ are completely defined. If $b \in (0, l)$, then we use a similar process to define v and ϕ on $(b, l]$ when u is not identically zero here. If u is identically zero here, then we set $v = 0$ here. The remaining cases are treated similarly. We now substitute (4.3) into (2.30) to obtain

$$(4.6a) \qquad (mv')' - mv(\phi')^2 + 2\omega\gamma v\phi' + \omega^2 v = 0,$$

$$(4.6b) \qquad (m\phi')'v + 2m\phi'v' - 2\omega\gamma v' = 0,$$

which hold in the classical sense on each component open interval of E. We multiply (4.6b) by v and integrate the resulting expression to obtain

$$(4.7) \qquad m\phi'v^2 = \omega v^2 + c_n \quad \text{on } E_n$$

where E_n is a component open interval of E and c_n is a constant. But since $v(s) \to 0$ as s approaches an end point of E_n (which is not b), the constant c_n must be 0 (since $m\phi'$ is continuous on $\bar{E} \backslash \{b\}$). Since $v(s) \neq 0$ for $s \in E$, we obtain from (4.7) that

$$(4.8) \qquad m\phi' = \omega\gamma$$

on E. Since $m\phi'$ is continuous on $\bar{E} \backslash \{b\}$ it follows that (4.8) holds on $\bar{E} \backslash \{b\}$, the superposed bar denoting the closure. We now substitute (4.8) into (4.6a) and use (2.24a) to obtain

$$(4.9) \qquad (mv')' + \omega^2 m^{-1}(m + \gamma^2)v = 0$$

on $\bar{E} \backslash \{b\}$. (Note that $m + \gamma^2 = n/\rho A\nu$.)

There are still a few loose ends to tie up. We shall show that if u has a double zero on $[0, l]$, then $u = 0$. This result would imply that (4.9) holds on all of $[0, l]$. To prove these results we first obtain a proposition of some intrinsic interest.

PROPOSITION 4.10. *Let m and ν be continuous and let (u, z) be a nontrivial absolutely continuous solution of* (2.26)-(2.29) *for $\omega\gamma \neq 0$. If $b \in [0, l]$, then $m(b, \gamma) \neq 0$.*

Proof. We restrict our attention to independent variables s lying in $\bar{E} \backslash \{b\}$. From (2.25b) and (4.3) we obtain

$$(4.11) \qquad \nu^2 = (v')^2 + v^2(\phi')^2 + (z')^2.$$

Thus

$$(4.12) \qquad m^2\nu^2 \geqq m^2(v')^2 \geqq 0.$$

From (4.11) and (4.8) we get

$$(4.13) \qquad m^2\nu^2 \geqq \omega^2\gamma^2 v^2 \geqq 0.$$

From (4.11) and (2.28) we get

$$(4.14) \qquad |m(s, \gamma)|^{-1} \leqq g^{-1}|b - s|^{-1}\nu(s) \quad \text{for } s \neq b.$$

Let us assume for contradiction that $m(b, \gamma) = 0$. Since ν is continuous on $[0, l]$, (4.13) implies that

$$(4.15) \qquad v(b) = 0$$

and since mv' is continuous on $\bar{E}\backslash\{b\}$, (4.12) implies that

$$m(s,\gamma)v'(s)\to 0 \quad \text{as } s\to b. \tag{4.16}$$

The integration of (4.9) from b to s and the use of (4.16) yields

$$m(s,\gamma)v'(s)=-\omega^2\int_b^s [1+\gamma^2 m(\sigma,\gamma)^{-1}]v(\sigma)\,d\sigma. \tag{4.17}$$

We now multiply (4.17) by $m(s,\gamma)^{-1}v(s)$, integrate the resulting expression from b to s, and use (4.15) to get

$$\frac{v(s)^2}{2}=-\omega^2\int_b^s \frac{v(\sigma)}{m(\sigma,\gamma)}\int_b^\sigma\left[1+\frac{\gamma^2}{m(\tau,\gamma)}\right]v(\tau)\,d\tau\,d\sigma. \tag{4.18}$$

Next we divide (4.18) by $m(s)^2$ and integrate the resulting expression from b to s to get

$$\frac{1}{2}\int_b^s \frac{v(\sigma)^2}{m(\sigma,\gamma)^2}\,d\sigma=-\omega^2\int_b^s \frac{1}{m(\sigma,\gamma)^2}\int_b^\sigma \frac{v(\tau)}{m(\tau,\gamma)}\int_b^\tau\left[1+\frac{\gamma^2}{m(\chi,\gamma)}\right]v(\chi)\,d\chi\,d\tau\,d\sigma. \tag{4.19}$$

The integral on the left of (4.19) converges despite the singularity of $m(\sigma,\gamma)^{-1}$ at $\sigma=b$ because (4.13) implies that $|vm^{-1}|\leqq \nu|\omega\gamma|^{-1}$. This same inequality also implies that the double integral with respect to χ and τ on the right side of (4.19) behaves like $(\sigma-b)^2$. Thus (4.14) implies that the entire integral on the right side of (4.19) also converges.

Let us set $w=vm^{-1}$ and observe that

$$2\int_b^\sigma w(\tau)\int_b^\tau w(\chi)\,d\chi\,d\tau=\left[\int_b^\sigma w(\tau)\,d\tau\right]^2. \tag{4.20}$$

It then follows from (4.19) that

$$\begin{aligned}
\frac{1}{2}\int_b^s w(\sigma)^2\,d\sigma &\leqq -\omega^2\int_b^s m(\sigma,\gamma)^{-2}\int_b^\sigma w(\tau)\int_b^\tau m(\chi,\gamma)w(\chi)\,d\chi\,d\tau\,d\sigma\\
&\leqq \omega^2\left|\int_b^s m(\sigma,\gamma)^{-2}\int_b^\sigma w(\tau)\,d\tau\left[\int_b^\sigma m(\chi,\gamma)^2\,d\chi\right]^{1/2}\left[\int_b^s w(\chi)^2\,d\chi\right]^{1/2} d\sigma\right| \qquad (4.21)\\
&\leqq \omega^2\left[\int_b^s w(\sigma)^2\,d\sigma\right]M(s,b),
\end{aligned}$$

$$M(s,b)\equiv\left|\int_b^s m(\sigma,\gamma)^{-2}|\sigma-b|^{1/2}\left|\int_b^\sigma m(\chi,\gamma)^2\,d\chi\right|^{1/2} d\sigma\right|, \tag{4.22}$$

the last two inequalities of (4.21) coming from two applications of the Cauchy-Bunyakovskii-Schwarz inequality.

We now show that w must vanish near b by showing that $M(s,b)$ can be made arbitrarily small by taking $|s-b|$ sufficiently small. Thus we must show that the integrand of (4.22) is integrable.

Let us define the set

$$A\equiv\left\{\alpha>0:\left|\int_b^{s_0}|\sigma-b|^{-2\alpha}m(\sigma,\gamma)^2\,d\sigma\right|<\infty\right\} \tag{4.23}$$

where $s_0\neq b$ is some fixed number (in $\bar{E}\backslash\{b\}$). Since m is continuous, $(0,\frac{1}{2})\subset A$. Since ν has a positive lower bound, (4.14) implies that $[\frac{3}{2},\infty)\subset A^c$, the complement of A.

Let $\beta = \sup A$. Thus $\frac{1}{2} \leqq \beta \leqq \frac{3}{2}$ and

$$\left| \int_b^{s_0} |\sigma - b|^{-2(\beta-\varepsilon)} m(\sigma, \gamma)^2 \, d\sigma \right| < \infty, \tag{4.24}$$

$$\left| \int_b^{s_0} |\sigma - b|^{-2(\beta+\varepsilon)} m(\sigma, \gamma)^2 \, d\sigma \right| = \infty \tag{4.25}$$

for all $\varepsilon > 0$. Condition (4.25) implies that the reciprocal of its integrand is bounded:

$$m(s, \gamma)^{-2} \leqq C|s-b|^{-2(\beta+\varepsilon)} \quad \text{for } s \text{ between } b \text{ and } s_0. \tag{4.26}$$

Here and below C denotes a positive constant.

Combining (4.26) with (4.14) we have

$$m(s, \gamma)^{-2} \leqq C|s-b|^{-\mu} \quad \text{where } \mu \equiv \begin{cases} 2 & \text{if } \beta \geqq 1, \\ 2(\beta+\varepsilon) & \text{if } \beta < 1, \end{cases} \tag{4.27}$$

for s between b and s_0. Using (4.27) and the inequality

$$\left| \int_b^{\sigma} m(\chi, \gamma)^2 \, d\chi \right| \leqq |\sigma - b|^{2\alpha} \left| \int_b^{\sigma} \frac{m(\chi, \gamma)^2}{|\chi - b|^{2\alpha}} \, d\chi \right| \tag{4.28}$$

with $\alpha = b - \varepsilon$, we obtain

$$\begin{aligned} M(s, b) &\leqq \left| \int_b^s |\sigma - b|^{(1/2)-\mu+\beta-\varepsilon} \left| \int_b^{\sigma} \frac{m(\chi, \gamma)^2}{|\chi - b|^{2(\beta-\varepsilon)}} \, d\chi \right|^{1/2} d\sigma \right| \\ &\leqq C \int_b^s |\sigma - b|^{(1/2)-\mu+\beta-\varepsilon} \, d\sigma. \end{aligned} \tag{4.29}$$

The definition of μ in (4.27) shows that for sufficiently small ε, the exponent $\frac{1}{2} - \mu + \beta - \varepsilon$, appearing in (4.29), exceeds -1. Thus (4.21) implies that w and therefore v and u must vanish on a neighborhood of b. By the argument preceding (4.2) this fact ensures that $u = 0$ on $[0, l]$. □

By reproducing our earlier arguments we immediately obtain the following.

COROLLARY 4.30. *Let m and ν be continuous. Then absolutely continuous solutions* (u, z) *of* (2.26)-(2.29) *with $\omega\gamma \neq 0$ are continuously differentiable on* $[0, l]$ *and therefore twice continuously differentiable solutions of* (2.30), (2.31).

COROLLARY 4.31. *Let m and ν be continuous. If* (u, z) *is a nontrivial absolutely continuous solution of* (2.26)-(2.29) *with $\omega\gamma \neq 0$, then all the zeros of u are simple. Moreover, ϕ is continuously differentiable on* $[0, l]$ *and v is a twice continuously differentiable solution of* (4.9) *on* $[0, l]$.

5. Inextensible strings. We begin our study of inextensible strings, for which ν is constrained to equal 1, by examining the consequences of (2.28), (2.29), (2.33). Throughout this and the following section we tacitly consider only solutions for which (u, z) is absolutely continuous and m is continuous.

CASE 1. If z' has but one sign on $[0, l]$, which must be positive to accommodate (2.29), then

$$z' = \sqrt{1 - |u'|^2}, \quad \int_0^l \sqrt{1 - |u'|^2} \, ds = a, \quad m = \frac{\varepsilon g(b-s)}{\sqrt{1 - |u'|^2}}. \tag{5.1a, b, c}$$

CASE 2. If $b \in (0, l)$ and $z' > 0$ on $[0, b)$, $z' < 0$ on $(b, l]$, then

$$z'(s) = \operatorname{sign}(b-s)\sqrt{1-|u'|^2}, \tag{5.2a, b, c}$$
$$\int_0^l \operatorname{sign}(b-s)\sqrt{1-|u'|^2}\,ds = a, \qquad m = \frac{\varepsilon g|b-s|}{\sqrt{1-|u'|^2}}.$$

CASE 3. If $b \in (0, l)$ and $z' < 0$ on $[0, b)$, $z' > 0$ on $(b, l]$, then

$$z' = -\operatorname{sign}(b-s)\sqrt{1-|u'|^2}, \tag{5.3a, b, c}$$
$$-\int_0^l \operatorname{sign}(b-s)\sqrt{1-|u'|^2}\,ds = a, \qquad m = \frac{-\varepsilon g|b-s|}{\sqrt{1-|u'|^2}}.$$

For inextensible strings we necessarily restrict our attention to problems in which $(0 \leqq)\ a \leqq l$. If $a = l$, then (5.2b) and (5.3b) cannot be satisfied, while (5.1b) implies that the solution is trivial. Unless there is a statement to the contrary we assume throughout this section that $a < l$. For similar reasons we also assume that $\omega\gamma \neq 0$.

Using (4.3) and (4.8) we obtain from (5.1c), (5.2c), (5.3c) that

$$m^2 = \frac{g^2|b-s|^2 + \omega^2\gamma^2 v^2}{1-(v')^2} \tag{5.4}$$

from which we can get explicit forms for m in each case. Now we convert (4.9) into a system by setting

$$y = \omega\gamma v, \qquad \omega\gamma w = y'm \tag{5.5a, b}$$

so that (5.4) yields

$$\omega^2\gamma^2 w^2 = (y')^2 m^2 = (y')^2[g^2|b-s|^2 + y^2 + w^2]. \tag{5.5c}$$

In Cases 1, 2 and 3, we then have

$$m(s) = \varepsilon \operatorname{sign}(b-s)|m(s)|, \quad m = \varepsilon|m|, \quad m = -\varepsilon|m|, \tag{5.6a}$$

respectively. Here we take

$$|m(s)| = \sqrt{g^2|b-s|^2 + y(s)^2 + w(s)^2}. \tag{5.6b}$$

Then (4.9) reduces to each of the equivalent systems:

$$v' = \frac{w}{m}, \qquad w' = -\omega^2(1+\gamma^2/m)v, \tag{5.7a}$$

$$y' = \frac{\omega\gamma w}{m}, \qquad w' = \frac{-\omega}{\gamma}(1+\gamma^2/m)y. \tag{5.7b}$$

In (5.7b) m has the form (5.6) and, in (5.7a), m has the same form, but with y expressed in terms of v by (5.5a). In (5.7b) m does not depend upon the eigenvalue parameters ω and γ, but the value of $\gamma = 0$ is singular. This formulation is useful for comparison theorems, but the problem in which $\gamma = 0$ cannot be readily treated in this setting. In (5.7a), the right sides of the equations are regular in the parameters, but the dependence is complicated because m also depends on $\omega\gamma$. In view of (4.3), equation (5.7) has the boundary conditions

$$y(0) = 0 = y(l). \tag{5.8}$$

Note that Proposition 4.10 and (5.1c) imply that if there is a nontrivial solution corresponding to Case 1, then $b \notin [0, l]$. We can now consolidate the nontrivial cases of our problem. Let

$$\eta \equiv \begin{cases} 1 & \text{in Case 1 when } b \geqq l \quad \text{and} \quad \text{in Case 2,} \\ -1 & \text{in Case 1 when } b \leqq 0 \quad \text{and} \quad \text{in Case 3.} \end{cases} \tag{5.9}$$

Then (5.6) reduces to

$$m = \varepsilon\eta|m| \tag{5.10}$$

while (5.1a), (5.2a), (5.3a) yield

$$z'(s) = \eta \operatorname{sign}(b-s)\sqrt{1-|u'(s)|^2} = \eta g(b-s)/|m|. \tag{5.11}$$

Let us set

$$r = \sqrt{y^2+w^2}. \tag{5.12}$$

Thus (5.1b), (5.2b), (5.3b) have the form

$$A[b, r] \equiv g\int_0^l [(b-s)/|m|]\, ds = \eta a. \tag{5.13}$$

For $r \neq 0$, we readily find that

$$A[b, r] \to \pm l \quad \text{as } b \to \pm\infty, \qquad A_b[b, r] = g\int_0^l r^2|m|^{-3}\, ds. \tag{5.14}$$

This means that if $a < l$, we can solve (5.18) uniquely for b in terms of r and ηa whenever $r \neq 0$. We denote the solution as $b = \beta[r]$. The classical implicit function theorem in Banach space implies that β is continuously differentiable on $C^0\backslash\{0\}$. For trivial solutions, we find that $2b = 2\beta[0] = l + \eta a$ if $a < l$, but that b is not defined if $a = l$, in which case b can assume any value in $\mathbb{R}\backslash(0, l)$. In this case, however, $z' = 1$ and the configuration is well defined, but

$$m(s) = \varepsilon\eta g|b-s|. \tag{5.15}$$

Thus there is a whole family of compatible tensions when $a = l$. For $a < l$, m is uniquely determined from b by (5.15).

At this stage it is convenient to obtain some estimates for $A[b, r]$. Suppose that R is a positive number with $R \geqq r$. We have the following inequalities:

If $b \leqq 0$,

$$\begin{aligned} -l = A[b, 0] &\leqq A[b, r] \leqq A[b, R] \\ &= \sqrt{b^2+R^2/g^2} - \sqrt{(l-b)^2+R^2/g^2}, \end{aligned} \tag{5.16a}$$

if $b \in (0, l)$,

$$\begin{aligned} \sqrt{b^2+R^2/g^2} - R/g - (l-b) &= g\int_0^b \frac{(b-s)\, ds}{\sqrt{g^2(b-s)^2+R^2}} - g\int_b^l \frac{|b-s|\, ds}{\sqrt{g^2|b-s|^2}} \\ &\leqq g\int_0^l \frac{(b-s)\, ds}{\sqrt{g^2(b-s)^2+r^2}} \\ &\equiv A[b, r] \leqq b - g\int_b^l \frac{|b-s|\, ds}{\sqrt{g^2|b-s|^2+R^2}} \\ &= b + R/g - \sqrt{(l-b)^2+R^2/g^2}, \end{aligned} \tag{5.16b}$$

if $b \geqq l$,

$$\sqrt{b^2+R^2/g^2}-\sqrt{(b-l)^2+R^2/g^2}=A[b,R]\leqq A[b,r]\leqq A[b,0]=l. \tag{5.16c}$$

We consolidate these inequalities into

$$A^-(b,R)\leqq A[b,r]\leqq A^+(b,R) \tag{5.16d}$$

where $A^-(b, R)$ is defined by the leftmost terms of (5.16a, b, c) and $A^+(b, R)$ by the rightmost terms. We illustrate (5.16) in Fig. 5.17.

Equation (5.10) allows us to write (5.7a) as

$$v'=\frac{\varepsilon\eta w}{|m|}, \qquad w'=-\omega^2(1+\varepsilon\eta\gamma^2/|m|)v \tag{5.18}$$

where $|m|$ is given by (5.6b) with $b=\beta[r]$, $r^2=\omega^2\gamma^2v^2+w^2$. Equation (5.18) is equivalent to

$$(|m|v')'+\omega^2[\varepsilon\eta+\gamma^2/|m|]v=0. \tag{5.19}$$

The conversion of (5.7b) is analogous. Indeed, v satisfies (5.19) with the appropriate form of $|m|$.

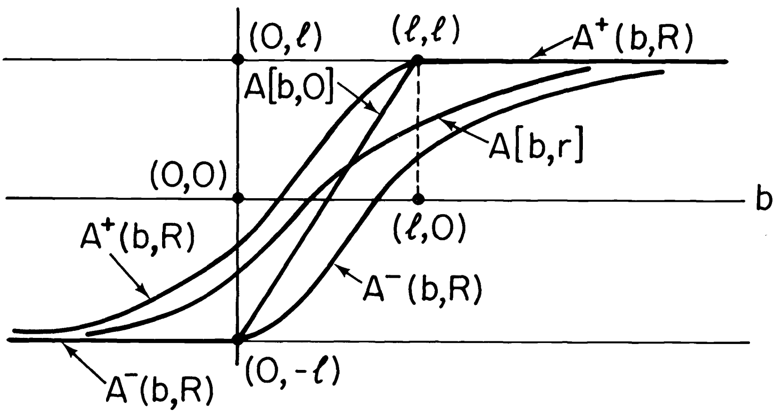

FIG. 5.17

The formal linearization of (5.19) is obtained by replacing $|m|$ in (5.10) with $g|s-(l+\eta a)/2|$. In this case (5.19) reduces to the singular Sturm-Liouville equation

$$g(|s-(l+\eta a)/2|v')'+\omega^2[\varepsilon y+\gamma^2g^{-1}|s-(l+\eta a)/2|^{-1}]v=0. \tag{5.20}$$

Independent solutions of (5.20) on either of the intervals $(0, (l+\eta a)/2)$ or $((l+\eta a)/2, l)$ are the Bessel functions

$$J_{\pm 2i\omega\gamma/g}(2[\varepsilon\eta\omega^2g^{-1}|s-(l+\eta a)/2|]^{1/2}). \tag{5.21}$$

The power series

$$J_\nu(z)=\sum_{m=0}^{\infty}\frac{(-1)^m(z/2)^{\nu+2m}}{m!\Gamma(\nu+m+1)} \tag{5.22}$$

shows that (5.21) is bounded near $s=(l+\eta a)/2$. Indeed, when $\varepsilon\eta=1$, the leading term of (5.21) about this point is

$$\begin{aligned}\Gamma(1\pm 2i\omega\gamma/g)^{-1}\Big\{&\cos\Big\{\frac{\omega\gamma}{g}\ln\Big[\frac{\omega^2}{g}\Big|s-\frac{(l+\eta a)}{2}\Big|\Big]\Big\}\\ &\pm i\sin\Big\{\frac{\omega\gamma}{g}\ln\Big[\frac{\omega^2}{g}\Big|s-\frac{(l+\eta a)}{2}\Big|\Big]\Big\}\Big\},\end{aligned} \tag{5.23}$$

which is discontinuous at $s=(l+\eta a)/2$. Analogous results hold for $\varepsilon\eta=-1$. Since the solutions of (5.20), (5.8) must be real combinations of the functions of (5.21), this problem can have no nontrivial *continuous* solutions. This disturbing observation is a manifestation of the failure of the integral operator corresponding to (5.18), (5.8), say, to be Fréchet differentiable on all of $C^0\times C^0$.

Remarks. (i) That solutions of our boundary value problems should be continuous is a consequence of the underlying physics. The problem (5.20), (5.8) can be given a very complete spectral analysis in weighted L_2-spaces by the Weyl theory and its refinements (cf. Coddington and Levinson [8], Dunford and Schwartz [13] and Naimark [22]). But the results of such an analysis are largely irrelevant for our problem. One inkling of the difficulty we face is that nontrivial solutions of (5.20), (5.8) in the appropriate Hilbert space have no discernible nodal structure.

(ii) Tabulations of the properties of Bessel functions of complex order are sparse (apparently because they were once wrongly deemed to be of little use in applications). The following references, kindly provided to us by F. W. J. Olver, may be consulted: Buckens [7], Luke and Weissman [20], Morgan [21].

(iii) For $\gamma=0$, independent solutions of (5.20) are the Bessel functions J_0 and N_0 of the argument shown in (5.21). Since N_0 is singular when its argument vanishes, its coefficient in the general solution must vanish. The remaining coefficient is generally insufficient to handle the two boundary conditions. A strategy for obtaining physically meaningful results in this case, which relies on the introduction of a or b as a second bifurcation parameter, is described in [3].

6. Global bifurcation theory for inextensible strings. To circumvent the difficulties portended by the singularities of (5.20), we let k denote a positive integer and replace (5.13) with the regularized problem

$$A_k[b,r]\equiv A[b,\sqrt{r^2+k^{-2}}]\equiv g\int_0^l \frac{(b-s)\,ds}{\sqrt{g^2|b-s|^2+r(s)^2+k^{-2}}}=\eta a. \tag{6.1}$$

For each k, considerations like those discussed in the treatment of (5.13) show that (6.1) has a unique solution for b, which we denote by $b=\beta_k[r]$. The functional β_k is continuously Fréchet differentiable on C^0. Next we set

$$m_k(s)=\varepsilon\eta\sqrt{g^2|\beta_k[r]-s|^2+r(s)^2+k^{-2}}. \tag{6.2}$$

We now study the regularized version of (5.18), (5.8)

$$v'=w/m_k,\quad w'=-\omega^2(1+\gamma^2/m_k)v,\quad v(0)=0=v(l) \tag{6.3}$$

and the associated integral equations

$$v(s)=\int_0^s m_k(t)^{-1}w(t)\,dt, \tag{6.4}$$

$$w(s)=\omega^2\Big[\int_0^l m_k(t)^{-1}\,dt\Big]^{-1}\int_0^l m_k(t)^{-1}\int_0^t[1+\gamma^2 m_k(\tau)^{-1}]v(\tau)\,d\tau\,dt \tag{6.5}$$

$$-\omega^2\int_0^s [1+\gamma^2 m_k(t)^{-1}]v(t)\,dt.$$

We abbreviate (6.4), (6.5) as

$$(v, w)=T_k(\omega, \gamma, v, w). \tag{6.6}$$

Since the right sides of (6.4) and (6.5) are innocuous, a simple application of the Ascoli-Arzelà theorem shows that T_k is a compact and continuous mapping from $\mathbb{R}\times[\mathbb{R}\backslash\{0\}]\times C^0\times C^0$ to $C^0\times C^0$. The linearization of (6.6) about the trivial solution, which we denote by

$$(v, w)=L_k(\omega, \gamma)(v, w), \tag{6.7}$$

corresponds to integral equations obtained by replacing m_k in (6.4), (6.5) with

$$m_k^0(s)=\varepsilon\eta\sqrt{g^2|\beta_k[0]-s|+k^{-2}} \tag{6.8}$$

where

$$2\beta_k[0]=2\beta[k^{-1}]=l+\eta a\sqrt{1+4[k^2g^2(l^2-a^2)]^{-1}}. \tag{6.9}$$

These integral equations in turn correspond to the regular Sturm-Liouville problem (5.19), (5.8) with $m(s)$ replaced by (6.8). In the formal limit as $k\to\infty$, these regularized problems reduce to the actual problems of § 5. Our goal is to justify this limit process.

Remark. Had we replaced the radical of (6.1) with $\sqrt{g^2|b-s|^2+r(s)^2+k^{-1}}$ and made analogous changes elsewhere, then we would not have obtained the resulting solution $b=\beta_k[0]$ of the equation $A_k[b, 0]=a$ in closed form. On the other hand, the boundary value problem corresponding to (6.7) could be solved explicitly in terms of Bessel functions of imaginary order.

To carry out the analysis we shall require the following results from the Sturmian theory for the boundary value problem

$$[p(s, \lambda)u']'+q(s, \lambda)u=0, \qquad u(0)=0=u(l). \tag{6.10}$$

The Prüfer transformation

$$u=\rho\sin\theta, \qquad pu'=\rho\cos\theta \tag{6.11}$$

takes (6.10) into the system

$$\rho'=\rho[p(s, \lambda)^{-1}-q(s, \lambda)]\sin\theta\cos\theta, \tag{6.12}$$

$$\theta'=p(s, \lambda)^{-1}\cos^2\theta+q(s, \lambda)\sin^2\theta, \tag{6.13}$$

$$\theta(0)=0, \qquad \theta(l)=(j+1)\pi \tag{6.14a, b}$$

where j is an integer. (Note that (6.13) can be solved in closed form when p and q are independent of s.)

THEOREM 6.15. *Let q be continuous and let p be continuous and positive on* $[0, l]\times[0, \infty)$. *Let the solution of* (6.13), (6.14a) (*known to exist on* $[0, l]$ *for each* $\lambda\in[0, \infty)$) *be denoted by* $\theta(\cdot, \lambda)$. *If*

$$\theta(l, 0)\leqq\pi \quad \text{and} \quad \theta(l, \lambda)\to\infty \quad \text{as } \lambda\to\infty, \tag{6.16}$$

then (6.10) *has a countable infinity of collections* e_j, $j=0, 1, \cdots$, *of eigenvalues with the following properties*: e_j *is a compact subset of* $(0, \infty)$,

$$0<\min e_0<\min e_1<\cdots,$$

$$0<\max e_0<\max e_1<\cdots,$$

$$\min e_j\to\infty \quad \text{as } j\to\infty,$$

the eigenspace corresponding to any eigenvalue is one-dimensional, an eigenfunction corresponding to any eigenvalue in e_j has exactly $j+2$ zeros on $[0, l]$ each of which is simple. If

$$\theta(l, \lambda) \text{ strictly increases to } \infty \quad \text{as } \lambda \to \infty, \tag{6.17}$$

then each e_j consists of but a single eigenvalue λ_j.

Let P and Q be continuous on $[0, l] \times [0, \infty)$ and satisfy

$$p(s, \lambda) \leqq P(s, \lambda), \qquad q(s, \lambda) \geqq Q(s, \lambda). \tag{6.18}$$

Let $\Theta(\cdot, \lambda)$ denote the solution of the modification of (6.13), (6.14a) *obtained by replacing p and q by P and Q. (Then $\Theta(s, \lambda) \leqq \theta(s, \lambda)$.) Let $\theta(\cdot, \lambda)$ and $\Theta(\cdot, \lambda)$ each satisfy* (6.16). *Let $\{E_j\}$ represent the collections of eigenvalues for the problem with P and Q. Then*

$$\min e_j \leqq \min E_j, \quad \max e_j \leqq \max E_j, \quad j = 0, 1, \cdots. \tag{6.19}$$

THEOREM 6.20. *Let $p(s, \lambda) = p(s)$, $q(s, \lambda) = \lambda h(s) - k(s)$ where p, h, k are continuous on $[0, l]$, p is positive on $[0, l]$, and h and k are positive on $(0, l)$. (In this case θ satisfies* (6.16) *and* (6.17).) *Then the eigenvalues λ_j of* (6.10) *are characterized by*

$$\lambda_j = \max_{E_j \in S_j} \min_{u \in E_j^\perp} \frac{\int_0^l [p(v')^2 + kv^2]\, ds}{\int_0^l hv^2\, ds} \tag{6.21}$$

where S_j is the class of all j-dimensional subspaces of the Sobolev space H_0^1 and $E_j^\perp$ is the orthogonal complement of E_j with respect to the inner product $(v_1, v_2) \mapsto \int_0^l hv_1v_2\, ds$. λ_j and its suitably normalized eigenfunction depend analytically on p, h, k in the topology of $C^0 \times C^0 \times C^0$.

Theorem 6.15 is a generalized version of standard results. Its proof relies on the simple observation that $\lambda \in e_j$ if and only if $\theta(b, \lambda) = (j+1)\pi$. (Cf. (6.14b).) Since it is a straightforward exercise (cf. Hille [14], e.g.) to verify that (6.16) and (6.17) hold for our problems, we shall not pause to give the details. Equation (6.21) is derived in [9, Chap. VI], e.g., it has various generalizations. When the hypotheses of Theorem 6.20 hold, the specialization of (6.19) is readily proved by means of (6.21). The last statement of Theorem 6.20 is based on Kato [15, Thm. II.5.16 and § IV.3.57].

We set

$$\chi = ((\omega^2, \gamma^2), (v, w)). \tag{6.22}$$

We define the norm $\|\cdot\|$ on $C^0 \times C^0$ by

$$\|(v, w)\| = \max_{s \in [0,l]} \sqrt{v(s)^2 + w(s)^2}. \tag{6.23}$$

We are now ready to use Theorems 6.15 and 6.20 to study (6.7). Our analysis is based on the observation that if χ satisfies (6.7), then (ω^2, γ^2, v) satisfies (5.19), (5.8) with $m(s)$ replaced by (6.8).

THEOREM 6.24. *Let $\varepsilon\eta = 1$. Then* (6.7) *has a countable infinity of analytic eigencurves $G_j^k \equiv \{(\omega^2, \gamma^2) \in [0, \infty] \times [0, \infty]: \omega^2 = \Omega_j^k(\gamma^2)\}$, $j = 0, 1, 2, \cdots$, such that*

$$0 < \Omega_0^k(\gamma^2) < \Omega_1^k(\gamma^2) < \cdots, \tag{6.25}$$

$$\Omega_j^k(\gamma^2) \to \infty \quad \text{as } j \to \infty, \tag{6.26}$$

$$\Omega_j^k(\gamma^2) = \max_{E_j \in S_j} \min_{v \in E_j^\perp} \frac{\int_0^l |m_k^0|(v')^2\, ds}{\int_0^l (\varepsilon\eta + \gamma^2/|m_k^0|)v^2\, ds}, \qquad \varepsilon\eta = 1, \tag{6.27}$$

$$\Omega_j^k(\gamma^2) \searrow 0 \quad \text{as } \gamma^2 \to \infty, \tag{6.28}$$

$$\Omega_j^k(\gamma^2) \searrow 0 \quad \text{as } k \to \infty. \tag{6.29}$$

(S_j is defined as in (6.21).) *The eigenfunction $V_j^k(\cdot, \gamma^2)$ corresponding to the eigenvalue $(\Omega_j^k(\gamma^2), \gamma^2)$ on G_j^k has exactly $j+2$ zeros on* $[0, l]$, *each of which is simple. V_j^k depends analytically on γ^2.*

Proof. All the statements of this theorem save (6.28) and (6.29) follow immediately from Theorems 6.15 and 6.20. Limits (6.28) and (6.29) are consequences of (6.27), the proof of the latter requiring the observation that if v does not vanish near $(l+\eta a)/2$ then the denominator of the Rayleigh quotient in (6.27) becomes infinite with k. (For k sufficiently large, (6.9) implies that $\beta_k[0]\in(0, l)$.) These results can also be established on the basis of (6.19) by means of a suitable comparison problem. □

In a similar way we obtain the following.

THEOREM 6.30. *Let $\varepsilon\eta=-1$. Then* (6.7) *has a countable infinity of analytic eigencurves $G_j^k\equiv\{(\omega^2, \gamma^2)\in[0,\infty)\times[0,\infty): \gamma^2=\Gamma_j^k(\omega^2)\}$, $j=0, 1, 2, \cdots$ such that*

$$(6.31)\qquad 0<\Gamma_0^k(\omega^2)<\Gamma_1^k(\omega^2)<\cdots,$$

$$(6.32)\qquad \Gamma_j^k(\omega^2)\to\infty \quad as\, j\to\infty,$$

$$(6.33)\qquad \Gamma_j^k(\omega^2)=\max_{E_j\in S_j}\min_{v\in E_j^\perp}\frac{\int_0^l[\omega^{-2}|m_k^0|(v')^2+v^2]\,ds}{\int_0^l|m_k^0|^{-1}v^2\,ds},$$

$$(6.34)\qquad \Gamma_j^k(\omega^2)\nearrow\infty \quad as\, \omega^2\searrow 0,$$

$$(6.35)\qquad \Gamma_j^k(\omega^2)\searrow 0 \quad as\, k\to\infty.$$

Suppose now that $\varepsilon\eta=-1$ and that γ^2 is a fixed positive number. The coefficient of $\omega^2 v$ in the second-order version of (6.7) is

$$(6.36)\qquad -1+\gamma^2[g^2|\beta_k[0]-s|^2+k^{-2}]^{-1/2}.$$

For k sufficiently large there is a neighborhood around $\beta_k[0]$, in fact, around $(l+\eta a)/2$, on which (6.36) is positive. In this case we can conclude from Theorem 6.15 that (6.7) has a countable infinity of eigenvalues $\Omega_j^k(\gamma^2)$ satisfying (6.25) and (6.26). In particular, if

$$(6.37)\qquad \gamma^4\geqq g^2l^2+1,$$

then (6.36) is nonnegative on $[0, l]$, whence it follows that (6.27)-(6.29) also hold. On the other hand, if

$$(6.38)\qquad \gamma^2<g(l+a)/2,$$

then (6.36) is negative on an open subset of $(0, l)$. In this case (6.7) also has a countable infinity of negative eigenvalues ω^2, which we ignore because ω^2 is confined to $[0,\infty)$ on physical grounds.

All these considerations show that the eigencurves of (6.7) have the forms shown in Fig. 6.39. When $\varepsilon\eta=-1$ we take Ω_j^k to be the inverse of Γ_j^k.

The simplicity of the eigenvalues, the nodal properties of the corresponding eigenfunctions, the Fréchet differentiability of T_k, and the compactness and continuity of T_k and L_k enable us to apply the global multiparameter bifurcation theory of Alexander and Antman [2] to conclude the following.

THEOREM 6.40. *Bifurcating from each eigencurve G_j^k of* (6.7) *is a connected family K_j^k of nontrivial solution pairs χ of* (6.6), *each point of which has Lebesgue dimension at least* 2. *The intersection of K_j^k with a plane of the form $\gamma^2=\gamma_0^2$ has at least one of the following properties*: (i) *K_j^k is unbounded in* $(0,\infty)\times(0,\infty)\times C^0\times C^0$, (ii) *there is an $i\neq j$ such that K_j^k connects* $((\Omega_j^k(\gamma^2), \gamma^2), (0, 0))$ *to* $((\Omega_i^k(\gamma^2), \gamma^2), (0, 0))$. *Moreover, if $\chi\in K_j^k$ and if $\|(v, w)\|$ is sufficiently small, then v has exactly $j+2$ zeros on* $[0, l]$, *each of which is simple.*

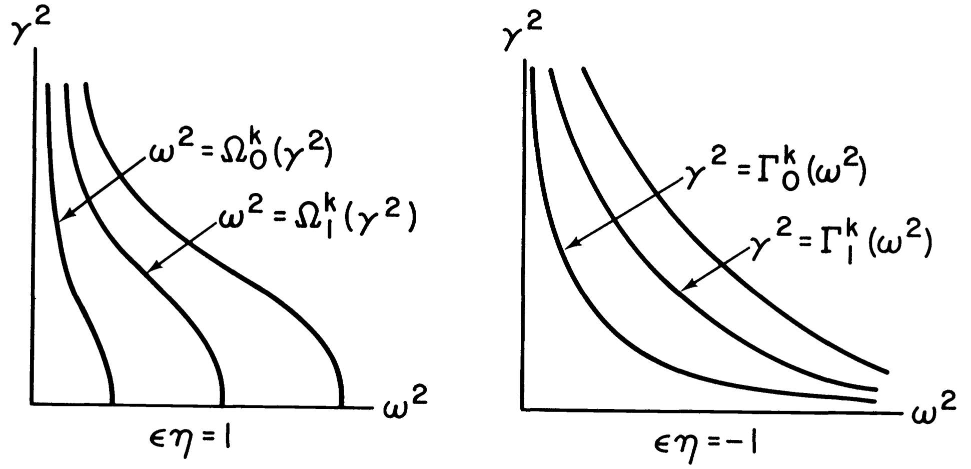

FIG. 6.39. *Eigencurves of* (6.7).

Corollaries 4.30 and 4.31 for our regularized problem and the last statement of Theorem 6.40 allow us to imitate a now standard argument of Crandall and Rabinowitz [10] (cf. e.g. [23], [3]) to deduce the following.

THEOREM 6.41. *Everywhere on K_j^k, v has exactly $j+2$ zeros, each of which is simple. For each γ_0^2, $K_j^k \cap \{\chi: \gamma^2 = \gamma_0^2\}$ is unbounded in* $(0, \infty) \times (0, \infty) \times C^0 \times C^0$, *does not satisfy property* (ii) *of Theorem* 6.40, *and does not meet K_i^k for $i \neq j$.*

We now study the behavior of K_j^k as $k \to \infty$. For this purpose we need estimates, such as those of Proposition 6.51, that are uniform in k. Unless there is a statement to the contrary, we assume that $\omega\gamma \neq 0$. Now (5.18) implies that $|v'| \leqq 1$. From this inequality and from (2.29), or more simply from the underlying geometry, we find that

$$4v^2 \leqq l^2 - a^2. \tag{6.42a}$$

If we use this inequality together with the inequality $|\omega\gamma v/m_k| \leqq 1$ in (6.5) we obtain

$$|w|^2 \leqq 2l^2\omega^2[\omega^2(l^2-a^2)/4+\gamma^2], \tag{6.42b}$$

whence

$$r^2 \leqq \omega^2\{[\gamma^2+2l^2\omega^2](l^2-a^2)/4+2l^2\gamma^2\}. \tag{6.42c}$$

Thus v and w are bounded when ω and γ are bounded.

We now construct related bounds, which are sharper for small $\|(v, w)\|$. Set

$$B(R) = \{(v, w): \|(v, w)\| \leqq R\}. \tag{6.43a}$$

If

$$\chi \in \{[0, \infty) \times [0, \infty) \times B(R)\} \cap K_j^k, \tag{6.43b}$$

then

$$r^2 \leqq (\omega^2\gamma^2+1)R^2 \equiv \delta^2 - 1 \tag{6.44}$$

and

$$A^-(b, \delta) \leqq A_k[b, r] \equiv A[b, \sqrt{r^2+k^{-2}}] \leqq A^+(b, \delta). \tag{6.45}$$

It follows from Fig. 5.17 that

$$\beta^-(\delta, \eta a) \leqq \beta_k[r] \leqq \beta^+(\delta, \eta a) \tag{6.46}$$

where $b = \beta^{\mp}(\delta, \eta a)$ is the solution of $A^{\pm}(b, \delta) = \eta a$. Indeed, we find from (5.16) that

$$\text{(6.47a)} \qquad \begin{aligned} &2\beta^{+}(\delta, \eta a) = (l+\eta a)\frac{[l+\eta a+2\delta/g]}{[l+\eta a+\delta/g]} \in (0, l) \\ &\text{when } 2\eta\delta < g(l^2-a^2)/a, \end{aligned}$$

$$\text{(6.47b)} \qquad \begin{aligned} &2\beta^{+}(\delta, \eta a) = l+\eta a\sqrt{1+4\delta^2 g^{-2}(l^2-a^2)^{-1}} \in [l, \infty) \\ &\text{when } \eta = 1, \qquad 2\delta \geqq g(l^2-a^2)/a. \end{aligned}$$

Now from Fig. 5.17 we find that

$$\text{(6.48a)} \qquad 0 < \beta^{-}(\delta, a) < \beta^{+}(\delta, a),$$

$$\text{(6.48b)} \qquad |\beta^{-}(\delta, a)| \leqq \beta^{+}(\delta, a).$$

Thus (6.46)-(6.48) imply that

$$\text{(6.49)} \qquad 2|\beta_k[r]| \leqq l + a\sqrt{1+\frac{4\delta^2}{g^2(l^2-a^2)}}.$$

Inequalities (6.44) and (6.49) imply that

$$\text{(6.50a)} \qquad |m_k|^2 \leqq 2g^2(|\beta_k|^2+l^2)+r^2 \leqq g^2(3l^2+a^2)+\frac{(3a^2-l^2)}{l^2-a^2}\delta^2-1,$$

$$\text{(6.50b)} \qquad |m_k| \leqq g\sqrt{3l^2+a^2}+\sqrt{\frac{3a^2+l^2}{l^2-a^2}}[\omega\gamma R+\sqrt{R^2+1}] \equiv \omega\gamma R\xi+\psi(R).$$

We now study the case in which $\varepsilon\eta = 1$. Since (6.43) is still in force, χ is a solution pair of the regularized version of (5.19), which we regard as a linear equation for v with coefficients known. We can compare the eigenvalues ω^2 of this nonlinear equation with those of the linear equation obtained by replacing the coefficient $|m_k|$ of v' with the right side of (6.50b) and replacing the coefficient $\omega^2[1+\gamma^2/|m_k|]$ with ω^2. Since the resulting comparison problem has constant coefficients, we find from Theorem 6.15 the following result.

PROPOSITION 6.51. *Let* $\varepsilon\eta = 1$ *and let* (6.44) *hold. Then*

$$\text{(6.52a)} \qquad 0 < \omega_j^2 \leqq \Omega_j^{+}(\gamma^2, R)$$

where

$$\text{(6.52b)} \qquad 2l^2\sqrt{\Omega_j^{+}(\gamma^2, R)} \equiv j^2\pi^2\xi\gamma R+[(j^2\pi^2\xi\gamma R)^2+4l^2j^2\pi^2\psi(R)]^{1/2}.$$

(The comparison problem has two eigenvalues ω for each j. We called the larger $\sqrt{(\Omega_j^{+}(\gamma^2, R))}^{1/2}$ because its square is also the larger, in consonance with Theorem 6.15.)

From Theorem 6.41, inequalities (6.42), and Proposition 6.51, we deduce the following.

THEOREM 6.53. *Let* $\varepsilon\eta = 1$ *and let* γ^2 *be fixed. Then* w *is unbounded and* ω^2 *is positive and unbounded on* K_j^k.

We now fix j, fix a number $\Gamma > 0$, and set

$$\text{(6.54)} \qquad \Delta_j(\Gamma) \equiv \{\chi \in [0, \infty) \times [0, \Gamma] \times C^0 \times C^0 \colon \omega^2 \leqq \Omega_j^{+}(\gamma^2, \|(v, w)\|)\} \cup \{\infty\}.$$

We define the topology of Δ_j (which is like a one-point compactification) by taking a neighborhood basis of ∞ to be

$$\text{(6.55)} \qquad \{\chi \colon \|(v, w)\| \geqq h, h = 1, 2, \cdots\}.$$

Let

$$H_j(\Gamma) \equiv \{\chi: v = 0 = w\} \cap \Delta_j(\Gamma), \tag{6.56}$$

$$\bar{K}_j^k(\Gamma) \equiv [K_j^k \cup H_j(\Gamma) \cup \{\infty\}] \cap \Delta_j(\Gamma). \tag{6.57}$$

Then $\bar{K}_j^k(\Gamma)$ is compact in $\Delta_j(\Gamma)$ and Theorem 6.53 says that $H_j(\Gamma)$ is not separated from $\{\infty\}$ in $\bar{K}_j^k(\Gamma)$. We define

$$K_j(\Gamma) \equiv \{\chi \in \Delta_j(\Gamma): \chi \text{ satisfies (6.6); } v \text{ has exactly } j+2 \text{ zeros on } [0, l], \text{ which are simple}\}, \tag{6.58}$$

$$\bar{K}_j(\Gamma) \equiv K_j(\Gamma) \cup H_j(\Gamma) \cup \{\infty\}. \tag{6.59}$$

It is conceivable that $K_j(\Gamma)$ is empty. Our basic result, which among other things asserts that it is not, is the following.

THEOREM 6.60. *Let $\varepsilon\eta = 1$. (i) $H_j(\Gamma)$ and $\{\infty\}$ are not separated in $\bar{K}_j(\Gamma)$. Thus $K_j(\Gamma)$ contains a connected subset $C_j(\Gamma)$ bifurcating from the jth eigencurve $\{((\omega^2, \gamma^2), (0, 0)): \omega^2 = \Omega_j(\gamma^2), \gamma^2 \in [0, \Gamma]\}$ and containing solution pairs with $\|w\|$ and ω^2 unbounded. (ii) $K_j(\Gamma) \cap K_i(\Gamma) = \varnothing$ for $i \neq j$. (iii) $C_j(\Gamma)$ has Lebesgue dimension at least 2 at each of its points.*

Proof. We hold j fixed. Property (ii) is a consequence of Corollary 4.31. To prove property (i) we appeal to Alexander's [1] generalization and unification of connectivity results of the sort treated by Kuratowski [18, Chap. V] and Whyburn [30, Chap. I]. The theory of Alexander shows that the following two properties suffice to establish property (i): (a) Let $\{k\}$ be any subsequence of the positive integers. If $\chi_j^k \in \bar{K}_j^k(\Gamma)$, then $\{\chi_j^k\}$ has a subsequence converging in the topology of $\Delta_j(\Gamma)$. (b) If $\chi_j^k \in \bar{K}_j^k(\Gamma)$ and if $\chi_j^k \to \chi_j$ in $\Delta_j(\Gamma)$ as $k \to \infty$, then $\chi_j \in \bar{K}_j(\Gamma)$. We first prove (a). If an infinite number of the points χ_j^k equal ∞, or if $\|w_j^k\|$ is unbounded, then $\{\chi_j^k\}$ has a subsequence converging to ∞ and (a) holds. If an infinite number of χ_j^k lie in $H_j(\Gamma)$, then the Bolzano-Weierstrass theorem ensures that (a) holds. Otherwise we may suppose that there is an $R > 0$ such that $(0, 0) \neq (v, w)_j^k \in B(R)$. Since elements of $K_j^k(\Gamma) \cap [\mathbb{R}^2 \times B(R)]$ are nontrivial solution pairs χ_j^k of (6.6) with $(\gamma^2)_j^k \in [0, \Gamma]$ and $(\omega^2)_j^k$ satisfying (6.52a), it suffices to show that $\bigcup_k T_k(\Delta_j(\Gamma) \cap \{\mathbb{R}^2 \times B(R)\}) \equiv D(\Gamma, R)$ is precompact. But the inequalities $|wm_k^{-1}|, |ym_k^{-1}| \leqq 1$ allow us to deduce from (6.4), (6.5) that $D(\Gamma, R)$ is uniformly bounded and equicontinuous, and, by virtue of the Ascoli-Arzelà theorem, is precompact.

We now prove (b), assuming that its hypotheses hold. As before, we can restrict our attention to the case that $R^{-1} \leqq \|w_j^k\| \leqq R$ with $R > 1$. Since χ_j^k satisfies (6.6) (i.e., (6.4) and (6.5)), we let $k \to \infty$. The Lebesgue Dominated Convergence theorem allows us to interchange the order of limit and integration to show that χ_j is a nontrivial solution pair of the limiting form of (6.6), which is equivalent to the boundary value problem posed in § 5. We need only show that v_j has exactly $j+2$ zeros on $[0, l]$, which are simple. If not, $(v, w)_j$ would be approximated in $C^0 \times C^0$ by functions $(v, w)_j^k$ with this nodal pattern. Thus $(v, w)_j$ would vanish at some point in $[0, l]$, whence $(v, w)_j = 0$ by Corollary 4.31, a contradiction. Thus (b) also holds, so that property (i) holds.

To prove property (iii) we observe that the statement that each point of $K_j^k(\Gamma)$ has Lebesgue dimension at least 2 is proved by computing Čech cohomology (cf. [2]). But Čech cohomology is continuous under the limit processes we have just carried out (cf. [1]). Thus the dimensionality properties of $K_j(\Gamma)$ are inherited from those of $K_j^k(\Gamma)$. □

We now study the behavior of K_j or C_j as $\|(v, w)\| \to 0$. We assume that (ω^2, γ^2) lies in a compact subset Σ of $[0, \infty) \times (0, \infty)$. Then (5.6) implies that

$$|m(s)| \leqq \sqrt{g^2|\beta[r] - s|^2 + \zeta^2\|r\|^2} \quad \text{where } \zeta^2 = \max\{\omega^2\gamma^2 + 1: (\omega^2, \gamma^2) \in \Sigma\}. \tag{6.61}$$

Now the analysis supporting Fig. 5.17 shows that $\beta[r] \in (0, l)$ if $\|r\|$ is sufficiently small. Thus we can imitate the proof leading to (6.29) to obtain

THEOREM 6.62 *Let $\varepsilon\eta = 1$. Let $\chi_j \in K_j \cap [\Sigma \times \{(v, w) \colon \|(v, w)\| \leqq \rho\}]$. Then $\omega_j^2 \to 0$ as $\rho \to 0$.*

We do not pause to refine our picture of C_j by the use of Theorems 6.15 and 6.20 buttressed by sharper estimates. We illustrate the appearance of C_j in Figs. 6.63 and 6.64. For fixed $\gamma^2 > 0$, a countable infinity of nontrivial solution branches bifurcate from $\omega^2 = 0 = (v, w)$. $\omega^2 = 0$ is the boundary of the continuous spectrum of the linearized problem. All the sheets of solutions we have treated bifurcate from the lines $\omega^2 = 0$ and $\gamma^2 = 0$.

The treatment of the problem for $\varepsilon\eta = -1$ is much easier than that for $\varepsilon\eta = 1$, paradoxically because the singular behavior as $\gamma^2 \to 0$ of the former is worse than that of the latter. One manifestation of this singular behavior is that the eigencurves of the regularized problem with $\varepsilon\eta = -1$, which are shown in Fig. 6.39, do not intersect the ω^2-axis. The presence of such intersections for $\varepsilon\eta = 1$ meant that we had to treat the behavior for small γ^2 with great care in the analysis beginning with (6.42). Since no such phenomena occur for $\varepsilon\eta = -1$, no such care is required. Consequently we can formulate the problem for $\varepsilon\eta = -1$ in terms of the variables y and w (cf. (5.5), (5.7)).

The integral equations for (y, w) corresponding to (6.4)-(6.6) are singular for $\gamma^2 = 0$, as is evident from (5.7). We set

$$\tilde{\chi} \equiv ((\omega^2, \gamma^2), (y, w)), \tag{6.65}$$

$$\tilde{K}_j^k = \{\tilde{\chi} \colon \chi \in K_j^k\} \tag{6.66}$$

where y is related to v by (5.5a). Then clearly Theorem 6.40 holds with χ and K_j^k

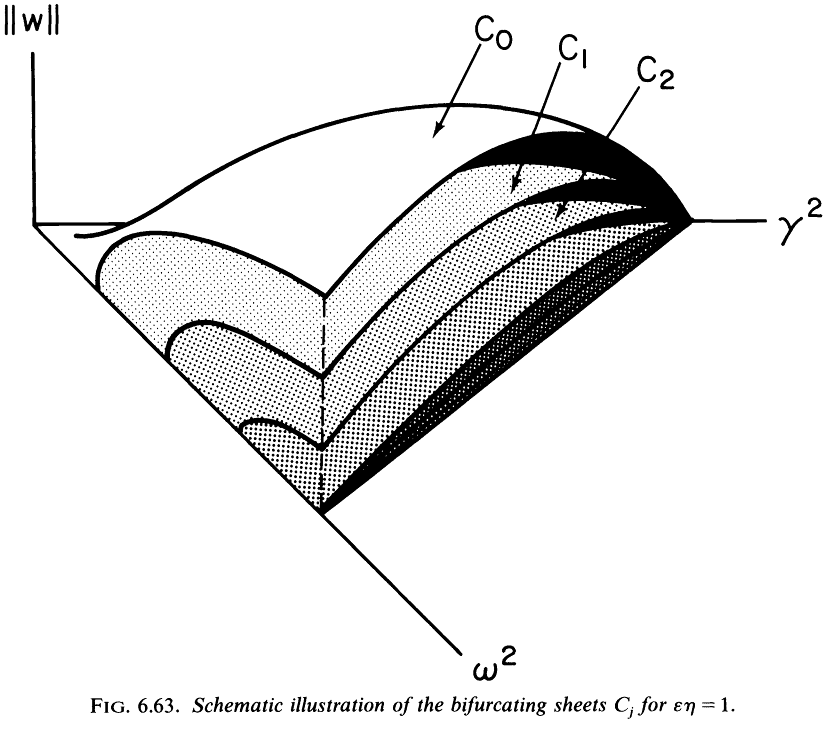

FIG. 6.63. *Schematic illustration of the bifurcating sheets C_j for $\varepsilon\eta = 1$.*

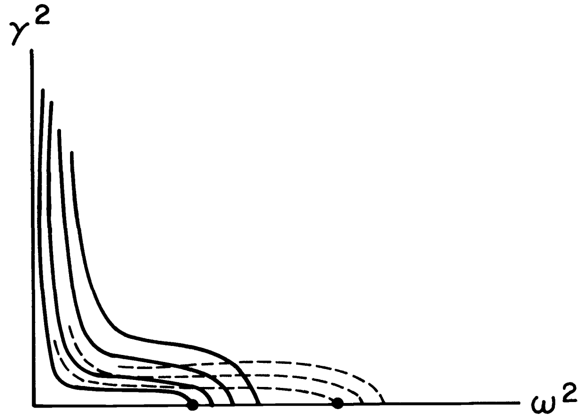

FIG. 6.64. *Schematic diagram of the level surfaces* $C_j \cap \{\chi: \|(v, w)\| = \rho\}$ *for different values of* ρ. *The solid lines correspond to* C_0 *and the dashed lines to* C_1.

replaced with $\tilde{\chi}$ and $\tilde{K}_j^k$ and with (6.6) interpreted as the equivalent equation for $\tilde{\chi}$. Theorem 6.41 holds with these substitutions together with the replacement of v by y.

Next we set

$$\tilde{B}(R) = \{(y, w): \|(y, w)\| \leqq R\}. \tag{6.67}$$

If

$$\tilde{\chi} \in \{[0, \infty) \times (0, \infty) \times \tilde{B}(R)\} \cap \tilde{K}_j^k, \tag{6.68}$$

then

$$r^2 \leqq R^2, \tag{6.69}$$

which is a great simplication over (6.44). It follows that (6.45)-(6.50) hold with

$$\delta^2 = R^2 + 1. \tag{6.70}$$

In analogy with Proposition 6.51 we have the following.

PROPOSITION 6.71. *Let* $\varepsilon\eta = -1$ *and let* (6.68) *hold. Then*

$$0 < \gamma^2 \leqq \Gamma_j^+(\omega^2, R) \equiv |\mu| + \frac{\mu^2}{\omega^2}\left(\frac{j\pi}{l}\right)^2 \tag{6.72}$$

where $\mu^2 \equiv 10g^2l^2 + \alpha^2(R^2+1)$.

(The estimates leading to (6.72) are painless.)

We now fix j, fix a number $\Omega > 1$ and set

$$\tilde{\Delta}_j(\Omega) \equiv \{\tilde{\chi}: \omega^2 \in [\Omega^{-1}, \Omega],\ \gamma^2 \leqq \Gamma_j^+(\omega^2, \|(y, w)\|)\} \cup \{\infty\}, \tag{6.73}$$

defining its topology just as we did for $\Delta_j(\Gamma)$. We set

$$\begin{aligned}\tilde{K}_j(\Omega) \equiv \{\tilde{\chi} \in \tilde{\Delta}_j(\Omega)&: \tilde{\chi} \text{ satisfies its equivalent version of (6.6)},\\ &y \text{ has exactly } j+2 \text{ zeros on } [0, l], \text{ which are simple.}\}\end{aligned} \tag{6.74}$$

Then we can duplicate the proof of Theorem 6.60 to obtain the following.

THEOREM 6.75. *Let* $\varepsilon\eta = -1$. *Then* $\tilde{K}_j(\Omega)$ *contains a connected subset* $\tilde{C}_j(\Omega)$ *bifurcating from the jth eigencurve* $\{((\omega^2, \gamma^2), (0, 0)): \gamma^2 = \Gamma_j(\omega^2), \omega^2 \in [\Omega^{-1}, \Omega]\}$ *and containing solution pairs with* $\|(y, w)\|$ *unbounded.* $\tilde{K}_j(\Omega) \cap \tilde{K}_i(\Omega) = \varnothing$ *for* $i \neq j$. $\tilde{C}_j(\Omega)$ *has Lebesgue dimension at least two at each of its points.*

Further analysis shows that the level curves on which $\|(y, w)\| = R$ resemble hyperbolas and that the bifurcation diagram corresponding to Fig. 6.63 looks like a quarter of a saddle surface. All the solution sheets bifurcate from the lines $\omega^2 = 0$, $\gamma^2 = 0$. (Incidentally, the use of (6.65) promotes the further analysis of the problem for which $\varepsilon\eta = 1$.)

From (4.8) we see that ϕ' depends on $\omega\gamma$. Hence the number of zeros of x_1 and x_2, although not the number of zeros of v, on any sheet changes with ω and γ. To study this dependence, we use (6.50a) with $\delta^2 - 1$ taken to be the right side of (6.42c). We thus obtain

$$|\phi'| \geqq \frac{\omega\gamma}{A\omega^2 + B\omega\gamma + C} \tag{6.76}$$

where A, B, C are positive constants that depend on l and a. Contrast this behavior with that of § 3. The Prüfer transformation $\omega = r \cos \theta$, $\gamma = r \sin \theta$ converts (5.7b) to a system for which

$$r(s) = r(s_0) \exp\left[-\frac{\omega}{\gamma} \int_{s_0}^{s} \sin \theta(t) \cos \theta(t)\, dt\right], \qquad s_0 \in [0, l]. \tag{6.77}$$

From (6.77), (4.8), (5.6b), (5.12) we then get

$$r(s) \geqq r(s_0) e^{-\omega l/\gamma}, \tag{6.78}$$

$$|\phi'| \leqq \frac{|\omega\gamma| e^{\omega l/\gamma}}{\sqrt{\omega^2 \gamma^2 v(s_0)^2 + w(s_0)^2}}. \tag{6.79}$$

We finally observe that when $r^2 > 0$, the differential equation (5.18) involves only analytic functions. For one-parameter bifurcation problems of the form $f(x, \lambda) = 0$ where x is in a Banach space, λ is real, and f is real-analytic, Dancer [12] has shown that where the set of solution pairs is compact, it consists of a locally finite union of finite-dimensional analytic manifolds. That λ is a scalar is irrelevant to Dancer's proof. Thus his theorem is applicable to our problem away from the bifurcation points. Moreover, the theorem of Alexander and Antman [2] shows that the set of nontrivial solution pairs contains a minimal set each point of which has dimension at least two. The combination of these two results shows that the set of nontrivial solution pairs for our problem contains a locally finite union of analytic manifolds of dimension at least two.

Several authors ([3], [4], [27], [29]) have developed methods to handle lack of compactness in one-parameter problems. See [29] for an extensive bibliography on this matter.

7. Elastic strings. Here we indicate the extent to which our results for inextensible strings are typical of those for elastic strings. We begin by observing that the bifurcation diagram (Fig. 6.63) bears absolutely no resemblance to that corresponding to Fig. 3.11, because the singularities arising in the problem for the inextensible string reflect the fact that the trivial state must be folded at $b \in (0, l)$ for the problem to have meaning. The conditions under which Fig. 3.11 is valid ensure that $b \notin [0, l]$ so that the trivial state is not folded and so that $z' > 0$ for any steady state. Solutions for elastic strings can be expected to exhibit the properties of those for inextensible strings when $l > a$. But there are other pathologies that can arise. We now examine the simplest manifestation of these.

We seek a trivial solution of the problem for elastic strings, i.e., we seek an absolutely continuous function z and a real number b satisfying (2.28), (2.29):

$$(7.1)\qquad N(|z'(s)|)-\gamma^2\rho A|z'(s)|=\varepsilon\rho Ag(b-s)\operatorname{sign} z'(s),\quad z(0)=0,\quad z(l)=a.$$

To be specific let us assume that $\varepsilon=1$, that γ is given, and that N is concave. Then $\nu\mapsto N(\nu)-\gamma^2\rho A\nu$ has the form shown in Fig. 7.2. $\mu(\gamma)$ denotes the maximum value of this function. (It decreases with increasing $|\gamma|$.)

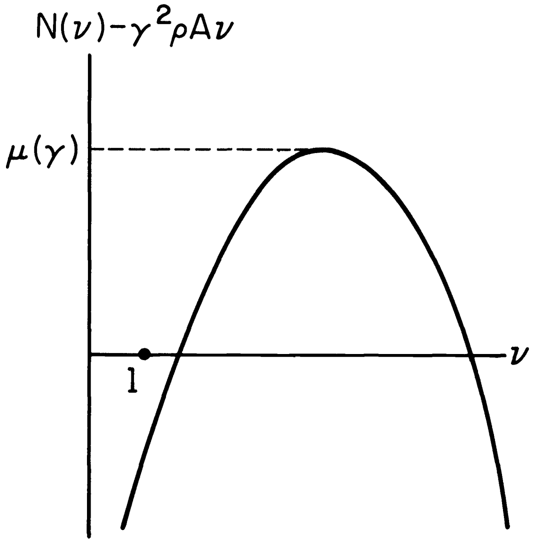

FIG. 7.2

We examine whether (7.1) admits a solution with z' continuous and positive. In this case (7.1) reduces to

$$(7.3\text{a, b, c})\qquad N(z'(s))-\gamma^2\rho Az'(s)=\rho Ag(b-s)\quad\text{for } s\in[0,l],\quad z(0)=0,\quad z(l)=a.$$

Equation (7.3a) has no solutions for z' if there is an s in $[0,l]$ such that $\rho Ag(b-s)>\mu(\gamma)$ and hence no solutions if $\rho Agb>\mu(\gamma)$. Equation (7.3a) has two continuous solutions for z' if $\rho Ag(b-s)\leqq\mu(\gamma)$ for all $s\in[0,l]$, i.e., if $\rho Agb\leqq\mu(\gamma)$. We denote the two continuous functions whose graphs form the inverse of that of Fig. 7.2 by $\nu^-(\cdot,\gamma)$ and $\nu^+(\cdot,\gamma)$ with $\nu^-(\xi,\gamma)<\nu^+(\xi,\gamma)$ for $\xi<\mu(\gamma)$. We set

$$(7.4)\qquad \Phi^\pm(g\rho Ab,\gamma)\equiv\int_0^l \nu^\pm(g\rho A(b-s),\gamma)\,ds\quad\text{when } g\rho Ab\leqq\mu(\gamma).$$

$\Phi^-(\cdot,\gamma)$ strictly increases from 0 at $b=-\infty$ to $\int_0^l \nu^-(\mu(\gamma)-g\rho As,\gamma)\,ds$ at $g\rho Ab=\mu(\gamma)$ while $\Phi^+(\cdot,\gamma)$ strictly decreases from ∞ at $b=-\infty$ to $\int_0^l \nu^+(\mu(\gamma)-g\rho As,\gamma)\,ds$ at $g\rho Ab=\mu(\gamma)$. Hence $\Phi^+(\mu(\gamma),\gamma)>\Phi^-(\mu(\gamma),\gamma)$. The graphs of $\Phi^\pm$ are shown in Fig. 7.5.

From Fig. 7.5 we immediately see that (7.3) has a continuous solution with $z'=\nu^\pm(\rho Ag(b-s))$ when $a\notin(\Phi^-(\mu(\gamma),\gamma),\Phi^+(\mu(\gamma),\gamma))$, for then one of the equations $\Phi^\pm(g\rho Ab,\gamma)=a$ has a unique solution for b in terms of a, these equations corresponding to the condition that $z(l)-z(0)=a$.

We do not get a solution with z' continuous if $a\in(\Phi^-(\mu(\gamma),\gamma),\Phi^+(\mu(\gamma),\gamma))$. In this case we can construct a discontinuous z' (nonuniquely) to satisfy (7.3). Now,

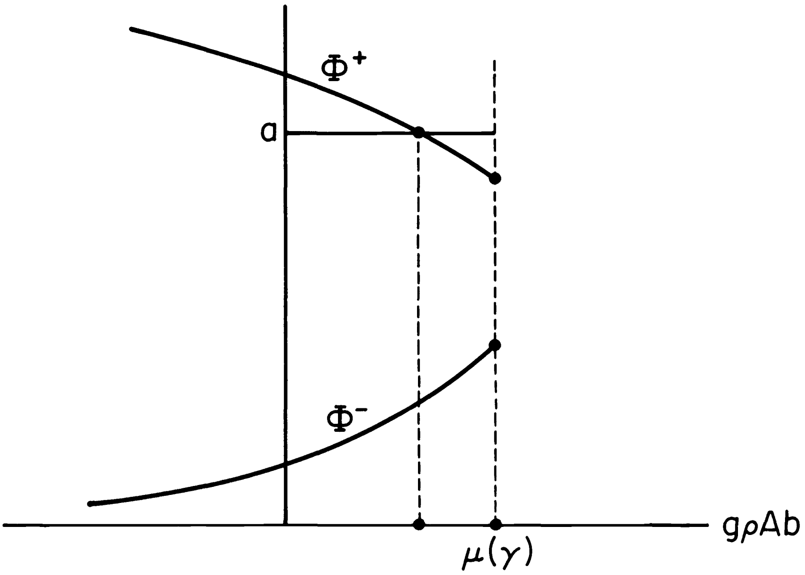

FIG. 7.5

since $N(\nu)\to\infty$ as $\nu\to\infty$, we can make $\mu(\gamma)$ as large as we like by taking $|\gamma|$ small enough. Suppose that $\mu(\gamma)\geqq g\rho Al$. Then $\Phi^-(\mu(\gamma),\gamma)>l\nu^-(\mu-g\rho Al)\geqq l$. Thus we fail to get a continuous solution for a range of a's exceeding l. In this range the average stretch a/l of the string exceeds one, yet the only possible steady motion is a standing shock.

We can similarly treat other cases under the requirement, introduced at the end of § 4, that $m\nu$ be continuous. Since the left side of (7.1) is just $m\nu$ for the class of trivial solutions under consideration, the continuity of $m\nu$ requires that z' could only change sign in $(0, l)$ at b, when $b\in(0, l)$.

The same difficulties arise for the full problem. Figure 7.2 represents a typical graph for $m\nu$. Other such graphs may have several local maxima and minima with $m\nu$ approaching ∞ as $\nu\to\infty$ if N is asymptotically superlinear and approaching $-\infty$ as $\nu\to\infty$ if N is asymptotically sublinear. The requirement that $m\nu$ be continuous allows many possible jumps in ν. An entropy condition is needed to eliminate solutions that are not physically realistic. Unfortunately the concept of being physically realistic is not mathematically precise. Admissibility conditions such as those of Liu [19] are based on the interpretation of the original hyperbolic system as a singular limit of a parabolic system with a mechanism for viscous dissipation. Such mechanisms are appropriate for treating shocks in fluids, but their suitability for solids is not so well established (cf. [6]). For our problem the jump conditions they provide are incompatible with those based on criteria such as Maxwell's equal area rule, which has a more purely thermodynamical motivation. Neither kind of jump condition can be relied upon to pick out a unique system of shocks for the steady motions we study. Our preliminary studies of shock conditions also show that they are very sensitive to an interpretation of the equations of motion for strings as singular limits of those for rods, which have flexural and torsional stiffness.

Even if we could confidently adopt an entropy condition as realistic, we have no assurance that the resulting operator equations admit a global bifurcation theory. (If they do, then a proof of that fact would likely require an analysis based on a regularization argument like that of § 6.) Nevertheless, we can still get useful global information about nontrivial solutions for elastic strings by exploiting the techniques of § 6 when $b \in (0, l)$ and by less drastic techniques otherwise:

THEOREM 7.6. *The number of (necessarily simple) zeros of v on $[0, l]$ is constant on any connected set of nontrivial shock-free solution pairs. (The topology of solution-parameter space is that of § 6.) Let D be a region of (ω^2, γ^2)-space for which the trivial solutions are shock-free. If the b for the trivial state lies outside $[0, l]$ for all $(\omega^2, \gamma^2) \in D$, then there is a neighborhood of D in solution-parameter space in which the bifurcation diagram resembles that corresponding to Fig. 3.11 with the bifurcating sheets inheriting their nodal properties from those of the eigenfunctions of the linearized problem. Let $D \subset \{(\omega^2, \gamma^2): \omega^2 \neq 0, \gamma^2 \neq 0\}$ and let $D \neq \emptyset$. If the b for the trivial state lies inside $(0, l)$ for all $(\omega^2, \gamma^2) \in D$, then there is a neighborhood of D in solution-parameter space in which the bifurcation diagram resembles those of § 6.*

Note that all these conclusions hold for $\gamma^2 < \gamma_0^2$, where γ_0^2 is defined in (4.1).

Finally we may comment briefly on the limit as an elastic string becomes inextensible. Let ν^* be the inverse of N and let $n = N(\nu)$. Then (2.24) yields

$$n = \rho A(m + \gamma^2)\nu^*(n). \tag{7.7}$$

If ν^* is sufficiently "flat," e.g., if ν^* is concave on $(0, \infty)$, then (7.7) has a unique solution $n = \hat{n}(m, \gamma)$ for n in terms of m. In the limit that the string becomes inextensible, i.e., as $\nu^*(n) \to 1$ for all n, this solution is obviously $\hat{n}(m, \gamma) = \rho A(m + \gamma^2)$. We now replace (2.33) with

$$(z')^2 = \nu^*(\hat{n}(m, \gamma))^2 - |u'|^2. \tag{7.8}$$

We may then follow the approach of §§ 5 and 6, observing than an equation such as (5.1c) becomes an implicit equation for m. It appears from our preliminary analysis of this question that the resulting bifurcation diagrams for slightly extensible strings converge nonuniformly to those for inextensible strings, the nonuniformity occurring for large values of γ^2. Note that the special material used in § 3 does not admit a natural limit process allowing the extensibility to go to zero.

Acknowledgments. We are indebted to J. C. Alexander, E. N. Dancer, and F. W. J. Olver for their very helpful comments on parts of this paper.

CONVOLUTION OPERATORS IN A FADING MEMORY SPACE: THE CRITICAL CASE*

G. S. JORDAN†, OLOF J. STAFFANS‡ AND ROBERT L. WHEELER§

Abstract. We study the linear system of convolution equations

$$\mathscr{L}x(t) \equiv x'(t) + \mu * x(t) = f(t), \qquad t \in (-\infty, \infty),$$

where x, f are n-dimensional column vectors and μ is an $n \times n$ matrix-valued measure which is finite with respect to a suitable weight function. We describe the null space and the range of the operator $\mathscr{L}$ in a fading memory space. Our results include the previously untreated critical case when there may be a finite number of eigenvalues of the Laplace transform $\hat{L}(z) = zI + \hat{\mu}(z)$ of $\mathscr{L}$ on the boundary of the strip of convergence of $\hat{\mu}$. Our description is given in terms of the Jordan chains at the eigenvalues of the locally analytic matrix-valued function $\hat{L}(z)$. We prove a new Smith factorization theorem for locally analytic matrix functions. At the eigenvalues on the boundary of the strip of convergence, sufficient conditions for the existence of such a factorization are given in terms of the Banach algebra concept of the order of smoothness of a locally analytic matrix function and the structure of the Smith factorization. The authors have previously developed such Banach algebra methods to analyze scalar locally analytic functions.

Key words. convolution equation, locally analytic matrix function, Smith factorization, null space, range, fading memory

1. Introduction.

We study the linear system of convolution equations

$$\mathscr{L}x(t) \equiv x'(t) + \mu * x(t) = f(t), \qquad t \in R \equiv (-\infty, \infty), \tag{1.1}$$

where x, f are n-dimensional column vectors and μ is an $n \times n$ matrix-valued measure which is finite with respect to a suitable weight function. As usual $\mu * x$ denotes the convolution

$$\mu * x(t) \equiv \int_{-\infty}^{\infty} d\mu(s) x(t-s).$$

We describe the null space and the range of the operator $\mathscr{L}$ in a fading memory space in the critical case when there may be a finite number of eigenvalues of the Laplace transform $\hat{L}(z) = zI + \hat{\mu}(z)$ of $\mathscr{L}$ (that is, zeros of the determinant of $\hat{L}(z)$) on the boundary of the strip of convergence of $\hat{\mu}$. Our descriptions are in terms of Jordan chains of vectors at the eigenvalues of the Laplace transform $\hat{L}$ of $\mathscr{L}$, and they depend on a Smith factorization theorem which we prove for locally analytic matrix functions.

Conditions sufficient to guarantee the existence of local and global Smith factorizations of locally analytic matrix functions are given in §3. These results are central to the subsequent analysis and are the most difficult theorems of the paper. The global Smith factorization theorem, Theorem 3.2, is the matrix analogue of the L^1-quotient theorem for scalar locally analytic functions [7, Thm. 3.4]. Since we are primarily concerned with permitting eigenvalues on the boundary of the strip of convergence of

locally analytic matrix functions, the development of these theorems is, of necessity, rather technical. For eigenvalues on the boundary of this strip, these theorems require that the components of the locally analytic matrix function satisfy certain smoothness hypotheses with the required order of smoothness being determined by the maximal partial multiplicity of the factored matrix. In the interior of the strip of convergence, the locally analytic matrix function is analytic and these smoothness assumptions hold automatically.

In § 2 we describe the weighted measure spaces in which we work, and review the concepts of local analyticity and smoothness of scalar locally analytic functions as developed in [7]. We remark that in [7, Lemma 4.3] we gave conditions on the components of the measure $\mu(t)$ that are necessary and sufficient to guarantee that the components of $\hat{\mu}(z)$, and hence of $\hat{L}(z)$, are smooth of a prescribed order. We conclude § 2 with a discussion of the fading memory spaces on which the operator $\mathscr{L}$ in (1.1) acts.

We describe the null space and the range of the operator $\mathscr{L}$ in (1.1) in §§ 5 and 6, respectively. The results established here are in the same spirit as those of [12]. However, they are more general because the eigenvalues of $\hat{L}(z)$ are not restricted to the interior of the strip of convergence of $\hat{\mu}$ as was the case in [12]. The results here also sharpen those in [12] since, roughly, our descriptions take account of polynomial rates of growth (or decay), whereas the descriptions in [12] only distinguish growth (or decay) rates that are exponentially separated. The methods of proof in [12] do not apply in the present situation; instead we must use the factorization theorems that we develop in § 3. Our description relates the null space and range of $\mathscr{L}$ to the Jordan chains of $\hat{L}(z)$. The notion of Jordan chains of vectors at the eigenvalues of a locally analytic matrix function and some of their elementary properties are described in § 4.

The principal application which motivates the results given here is the same as in [12] and [11], i.e., a study of the asymptotic behavior of the linear, infinite delay, autonomous system of functional differential equations

$$\begin{aligned} &x'(t)+\mu * x(t)=f(t), \qquad t\in R^+\equiv[0,\infty),\\ &x(t)=\phi(t), \qquad t\in R^-\equiv(-\infty,0], \end{aligned} \tag{1.2}$$

where $\mu(t)$ is supported on R^+. We analyze (1.2) in the sequel paper [8]. Again the results in [8] improve those in [12] and [11] since in [8] we study the critical case where the components of the solution of (1.2) are not exponentially separated as well as the noncritical case studied in [12] and [11].

In addition to the description of the null and range spaces of the Fredholm convolution operator (1.1) given in §§ 5 and 6, the analysis of the functional differential equation (1.2) in [8] requires us to study the singular part expansion of the inverse of a locally analytic matrix function at its eigenvalues. Conditions necessary to ensure the existence of such a singular part expansion follow from the Smith factorization theorems proved here. Since this expansion is not used in our study of (1.1), we postpone its development to [8]. Kappel and Wimmer [9] have used similar factorization and singular part expansions to decompose the null space of a system of linear functional differential equations with finite delay. However, in the case of finite delay equations, the characteristic equation $zI+\hat{\mu}(z)$ is entire, so the analytic difficulties that we encounter at the boundary of the strip of convergence do not arise.

Finally, we remark that the scalar L^1-quotient theorem as well as less precise results concerning singular part expansions have been used to study the asymptotic behavior of both scalar and system versions of Volterra integrodifferential equations of convolution type whose eigenvalues lie on the boundary of the half-plane of convergence of the Laplace transform of the kernel [7, Props. 5.1, 5.2, 5.3], [4], [5], [6], [10] (both in weighted and nonweighted L^1-spaces). The Smith factorization theorem for locally analytic matrix functions obtained here as well as the related results concerning singular part expansions given in [8] can be applied to sharpen and extend these earlier results for systems of integrodifferential equations.

2. Weighted measures and fading memory spaces. Let us begin with a short presentation of weighted L^1-spaces and locally analytic functions. For more details see, e.g., [7], [11] and [12].

We call the function ρ a *weight function*, if ρ is a Borel measurable, strictly positive function on R, ρ and ρ^{-1} are locally bounded, and ρ is submultiplicative, i.e.,

$$\rho(s+t) \leqq \rho(s)\rho(t), \qquad s, t \in R.$$

Without loss of generality one may always take $\rho(0)=1$. A typical weight function to keep in mind is

$$\rho(t)=\begin{cases} e^{-at}(1+|t|)^{\delta}, & t \in R^-, \\ e^{-bt}(1+t)^{\gamma}, & t \in R^+, \end{cases}$$

where $\delta, \gamma \geqq 0$ and $-\infty < b \leqq a < \infty$.

The space $L^1(C; \rho)$ consists of all complex measurable functions x on R for which

$$\|x\| \equiv \int_R |x(t)|\rho(t)\, dt < \infty.$$

For $x, y \in L^1(C; \rho)$, define the convolution of x and y by

$$x * y(t) = \int_R x(t-s)y(s)\, ds.$$

Then $L^1(C; \rho)$ becomes a commutative normed ring with convolution multiplication. We let $V(C; \rho)$ denote the ring one obtains from $L^1(C; \rho)$ by adjoining a unit.

Both $L^1(C; \rho)$ and $V(C; \rho)$ are closed subrings of $M(C; \rho)$, the space of locally finite complex Borel measures μ on R satisfying

$$\|\mu\| \equiv \int_R \rho(t)\, d|\mu|(t) < \infty,$$

where $|\mu|$ is the total variation measure of μ. The convolution of $a \in L^1(C; \rho)$ and $\mu \in M(C; \rho)$ is defined by

$$\mu * a(t) = a * \mu(t) = \int_R a(t-s)\, d\mu(s).$$

Define

$$\alpha = -\sup_{t<0} \frac{\log \rho(t)}{t} = -\lim_{t\to-\infty} \frac{\log \rho(t)}{t}, \tag{2.1}$$
$$\omega = -\inf_{t>0} \frac{\log \rho(t)}{t} = -\lim_{t\to\infty} \frac{\log \rho(t)}{t}$$

(in [7] these numbers were denoted by ρ^* and ρ_*, respectively). Then $-\infty < \omega \leqq \alpha < \infty$, and the maximal ideal space of $V(C; \rho)$ can be identified with $\bar{\Pi} = \Pi \cup \{\infty\}$, where

$$\Pi \equiv \{z \in C \mid \omega \leqq \operatorname{Re} z \leqq \alpha\}.$$

For the example of a weight function given earlier, $\omega = b$ and $\alpha = a$. We note that for the special case $\rho(t) \equiv 1$, $\omega = \alpha = 0$ and Π is the imaginary axis.

The bilateral Laplace transforms defined by

$$\hat{a}(z) = \int_R e^{-zt} a(t)\, dt, \qquad a \in L^1(C; \rho),$$

$$\hat{\mu}(z) = \int_R e^{-zt}\, d\mu(t), \qquad \mu \in M(C; \rho)$$

converge absolutely for $z \in \Pi$.

We let $C^{n \times n}$ stand for the space of $n \times n$ complex-valued matrices, and define $L^1(C^{n\times n}; \rho)$, $V(C^{n\times n}; \rho)$ and $M(C^{n\times n}; \rho)$ as above, but with complex-valued functions and measures replaced by $C^{n\times n}$-valued functions and measures. Also these are normed rings, if one defines the convolutions componentwise in the obvious way, but they are no longer commutative due to the fact that matrix multiplication is not commutative. One can define the bilateral Laplace transforms $\hat{a}(z)$ and $\hat{\mu}(z)$ of a function $a \in L^1(C^{n\times n}; \rho)$ and a measure $\mu \in M(C^{n\times n}; \rho)$, e.g., componentwise, and these too converge for all $z \in \Pi$.

We use the same concept of "local analyticity" as in [7], and call a complex function ϕ *locally analytic at a point* $z_0 \in \Pi$, if there exist measures $\mu_0, \cdots, \mu_k$ in $M(C; \rho)$ and a function $\psi(z, \xi_1, \cdots, \xi_k)$ analytic at $(z_0, \hat{\mu}_1(z_0), \cdots, \hat{\mu}_k(z_0))$ such that

$$\phi(z) = \psi(z, \hat{\mu}_1(z), \cdots, \hat{\mu}_k(z))$$

in a neighborhood of z_0. We say that ϕ is *locally analytic at infinity* if there exist functions $a_1, \cdots, a_m$ in $L^1(C; \rho)$, measures $\mu_1, \cdots, \mu_k$ in $M(C; \rho)$, and a function $\psi(z, \eta_1, \cdots, \eta_m, \xi_1, \cdots, \xi_k)$ analytic at $(0, 0, \cdots, 0)$ such that

$$\phi(z) = \psi(z^{-1}, \hat{a}_1(z), \cdots, \hat{a}_m(z), \hat{\mu}_1(z)/z, \cdots, \hat{\mu}_k(z)/z)$$

in a neighborhood of infinity. Throughout, the word "neighborhood" means an open subset of $\bar{\Pi}$ rather than an open subset of the compactified plane. Finally, we call ϕ *locally analytic* if it is locally analytic at each point of $\bar{\Pi}$.

The "smoothness" concept which we use is also the same as in [7]. We say that a complex function ϕ has a *zero of order at least m* at $z_0 \in \Pi$ if

$$\limsup_{z \to z_0,\, z \in \Pi} |(z - z_0)^{-m} \phi(z)| < \infty.$$

The point $z_0 \in \Pi$ is a *zero of order m* of ϕ if $\lim_{z \to z_0} (z - z_0)^{-m} \phi(z)$ exists and is nonzero. A very important subclass of zeros consists of those which are locally analytic; specifically, z_0 is a *locally analytic zero of order* (*at least*) *m* of ϕ if it is a zero of order (at least) m and $(z - z_0)^{-m} \phi(z)$ is locally analytic at z_0. Finally, we define a complex locally analytic function to be *smooth of order m* at z_0 [7, Def. 3.5] if $\phi(z) = \psi(z) + \zeta(z)$ near z_0 where ψ is analytic at z_0 and ζ is locally analytic at z_0 with a locally analytic zero of order at least m at z_0. Observe that a complex locally analytic function ϕ has a locally analytic zero of order (at least) m at z_0 if and only if it has a zero of order (at least) m at z_0 and is smooth of order m at z_0.

The scalar concepts listed above carry over to vector and matrix functions in an obvious way. We say that a vector or matrix function is locally analytic (at a point), has a zero of order at least m, has a locally analytic zero of order at least m, or is smooth of order m, if each component has the same scalar property.

In the following lemmas we list some elementary properties of the preceding definitions. They apply to scalar, vector and matrix functions, except when stated otherwise.

LEMMA 2.1. *A function ϕ is smooth of order m at z_0 if and only if it is of the form $\phi = p + \zeta$, where p is a polynomial of degree at most $m-1$, and ζ has a locally analytic zero of order at least m at z_0. The functions p and ζ in this decomposition are uniquely determined.*

Proof. Clearly, if $\phi = p + \zeta$, with p and ζ as above, then ϕ is smooth of order m at z_0. Also, if we have two decompositions $\phi = p_1 + \zeta_1 = p_2 + \zeta_2$, then $p_1 - p_2$ has a zero of order at least m at z_0; hence it vanishes identically. This proves the uniqueness of the decomposition.

To prove the existence of the decomposition, one first writes ϕ in the form $\phi = \psi + \zeta_1$, where ψ is analytic at z_0 and ζ_1 has a zero of order at least m at z_0, and then uses the Taylor series for ψ at z_0 to get

$$\phi = p + \zeta_1 + \zeta_2,$$

where p is a polynomial of degree at most $m-1$, ζ_2 is the remainder of order m in the Taylor series, and $\zeta_1 + \zeta_2$ has a zero of order at least m at z_0. □

If ϕ is smooth of order m at z_0, then we can define the *generalized derivatives* $\phi'(z_0), \cdots, \phi^{(m-1)}(z_0)$ of ϕ at the point z_0 to be

$$\phi^{(i)}(z_0) = p^{(i)}(z_0) = i!\,p_i, \qquad 1 \leqq i \leqq m-1$$

where

$$p(z) = \sum_{i=0}^{m-1} p_i (z - z_0)^i,$$

is the polynomial in the decomposition in Lemma 2.1. The generalized derivative $\phi^{(m)}(z_0)$ can be defined analogously by

$$\phi^{(m)}(z_0) = \lim_{z \to z_0,\, z \in \Pi} (z - z_0)^{-m} \eta(z),$$

where η is the remainder in the decomposition in Lemma 2.1. If ζ is m times continuously differentiable, then the generalized derivatives defined above coincide with the ordinary derivatives of ϕ at z_0. If both ϕ and ψ are smooth of order m at z_0, then so is $\phi\psi$ (cf. Lemma 2.2 below), and the generalized derivatives $(\phi\psi)^{(j)}(z_0)$, $0 \leqq j \leqq m$, of $\phi\psi$ at z_0 satisfy the same conditions as ordinary derivatives do, i.e.,

$$(\phi\psi)^{(j)}(z_0) = \sum_{i=0}^{j} \binom{j}{i} \phi^{(i)}(z_0) \psi^{(j-i)}(z_0). \tag{2.2}$$

DEFINITION 2.1. A scalar, vector or matrix quasipolynomial is an expression of the form $\sum_{k=0}^{m} A_k (z-c)^{-k}$, where the A_k are scalars, vectors or $n \times n$ matrices. Here $c < \omega$ is a fixed real number.

Note that a quasipolynomial may be expressed in the alternative form $\sum_{k=0}^{m} B_k((z - z_0)/(z-c))^k$ where $z_0 \neq c$ can be chosen arbitrarily, and each B_k is a scalar, vector or $n \times n$ matrix.

LEMMA 2.2. *Let ϕ and ψ be functions which are locally analytic at z_0.*

(i) *If both ϕ and ψ are smooth of order l at z_0, then each of $\phi \pm \psi$ is smooth of order l at z_0.*

(ii) *If ϕ has a zero of order at least m and is smooth of order $l \geqq m$ at z_0, and if ψ is smooth of order $l-m$ and has a zero of order at least $r \leqq l-m$ at z_0, then $\phi\psi$ and $\psi\phi$ are smooth of order l and have a zero of order at least $m+r$ at z_0.*

(iii) *If ϕ has a zero of order at least r at z_0, ψ is scalar-valued and has a zero of order m at z_0 and ϕ and ψ are smooth of order l at z_0, where $m \leqq r \leqq l$, then ϕ/ψ is* *smooth of order $l-m$ and has a zero of order at least $r-m$ at z_0. Moreover, there is a quasipolynomial p such that $\phi - p\psi$ has a zero of order at least l at z_0.*

Proof. The proofs of (i) and (ii) are obvious and will not be given. To prove (iii), first express ϕ and ψ in the form $\phi(z)=(z-z_0)^r\tilde{\phi}(z)$ and $\psi(z)=(z-z_0)^m\tilde{\psi}(z)$, where $\tilde{\phi}$ and $\tilde{\psi}$ are smooth of order $l-r$ and $l-m$, respectively. Since $\tilde{\psi}(z_0)\neq 0, 1/\tilde{\psi}$ is smooth of order $l-m$ at z_0 by [7, Lemma 4.2]. Now (ii) implies $\tilde{\phi}/\tilde{\psi}$ is smooth of order $l-r$, and thus $\phi(z)/\psi(z)=(z-z_0)^{r-m}\tilde{\phi}(z)/\tilde{\psi}(z)$ is smooth of order $l-m$, and has a zero of order at least $r-m$ at z_0.

As ϕ/ψ is smooth of order $l-m$, we can use Lemma 2.1 to write $\phi/\psi = p_1+\zeta_1$ where p_1 is a polynomial of degree at most $l-m-1$ and ζ_1 has a zero of order at least $l-m$ at z_0. If p is a quasipolynomial whose Taylor series expansion at z_0 up to order $l-m-1$ equals p_1, then also $\zeta=\phi/\psi-p=p_1-p+\zeta_1$ has a zero of order at least $l-m$ at z_0. By Lemma 2.2(ii), $\phi-\psi p=\zeta\psi$ has a zero of order at least l at z_0. □

Every measure $\mu\in M(C^{n\times n};\rho)$ induces a continuous operator μ^* on certain spaces of (fading) memory type. These spaces are defined as follows (for more details, see [11] or [12]).

We call η an *influence function dominated* by ρ if η is Borel measurable, strictly positive, $\eta(0)=1$, and

$$\eta(s+t)\leqq \eta(s)\rho(t), \qquad s,t\in R$$

(in [12] both ρ and η were supposed to be continuous, but that assumption was not important). In particular, ρ is an influence function dominated by itself. For each influence function η we define the *adjoint influence function* $\tilde{\eta}$ by

$$\tilde{\eta}(t)=[\eta(-t)]^{-1}, \qquad t\in R. \tag{2.3}$$

If η is dominated by ρ, then so is $\tilde{\eta}$. Moreover, every influence function dominated by ρ must satisfy

$$\tilde{\rho}(t)\leqq \eta(t)\leqq \rho(t), \qquad t\in R, \tag{2.4}$$

so $\tilde{\rho}$ and ρ, respectively, are the smallest and largest influence functions dominated by ρ. We point out, however, that not every η satisfying (2.4) is an influence function dominated by ρ. For example, if $\rho(t)=(1+|t|)^p$ and

$$\eta(t)=\begin{cases}(1+|t|)^{-q_-}, & t\in R^-,\\ (1+t)^{q_+}, & t\in R^+,\end{cases}$$

with p, q_- and q_+ nonnegative, then it is easy to check that η is dominated by ρ if and only if $q_-+q_+\leqq p$.

Every influence η induces a number of (fading) memory spaces. We let $L^p(C^n;\eta)$, $1\leqq p\leqq\infty$, be the space of measurable functions x: $R\to C^n$, with norm

$$\|x\|=\begin{cases}\left\{\int_R [\eta(t)\|x(t)\|]^p\,dt\right\}^{1/p}, & 1\leqq p<\infty,\\ \operatorname*{ess\,sup}_{t\in R}\eta(t)\|x(t)\|, & p=\infty.\end{cases}$$

We let the space $BUC(C^n;\eta)$ consist of those continuous functions $x\in L^\infty(C^n;\eta)$ which satisfy $\|\tau_t x-x\|\to 0$ as $t\to 0$, where τ_t is the translation operator $\tau_t x(s)=x(t+s)$, $s,t\in R$. An important subclass of $BUC(C^n;\eta)$ is $BC_0(C^n;\eta)$, which is made up of those functions x in $BUC(C^n;\eta)$ which satisfy

$$\lim_{t\to\infty}\operatorname*{ess\,sup}_{|s|\geqq t}\eta(t)\|x(t)\|=0.$$

We use the notation $\mathscr{B}(C^n; \eta)$ to represent any one of the preceding spaces, i.e., all results which are formulated in terms of $\mathscr{B}(C^n; \eta)$ remain true when $\mathscr{B}(C^n; \eta)$ is replaced by $L^p(C^n; \eta)$, $1 \leqq p \leqq \infty$, $BUC(C^n; \eta)$, and $BC_0(C^n; \eta)$. Finally, we define $\mathscr{B}^m(C^n; \eta)$ to be the space of all functions $x \in \mathscr{B}(C^n; \eta)$ whose distribution derivatives up to order m also belong to $\mathscr{B}(C^n; \eta)$. In particular, $\mathscr{B}^0(C^n; \eta)$ is the same as $\mathscr{B}(C^n; \eta)$.

The convolution of a measure $\mu \in M(C^{n\times n}; \rho)$ and a function $x \in \mathscr{B}^m(C^n; \eta)$ is defined by

$$\mu * x(t) = \int_R d\mu(s)x(t-s).$$

In the case when $m=0$ and $\mathscr{B}^m(C^n; \eta) = L^p(C^n; \eta)$ this convolution is well defined only a.e., but in the other cases it is defined for all $t \in R$. The convolution operator $\mu*$ maps each $\mathscr{B}^m(C^n; \eta)$, $m \geqq 0$, continuously back into itself [11, Lemma 2.1].

3. Factorization of locally analytic matrix functions. In this section we obtain local and global Smith factorizations for locally analytic matrix functions. Theorem 3.2, giving the global Smith factorization, is the matrix analogue of [7, Thm. 3.4]. Our development relies on the theory for matrix polynomials as developed in [2] (see also [3] for the Smith form for analytic matrix functions).

DEFINITION 3.1. Let the matrix function M be locally analytic at $z_0 \in \Pi$. We say that M has a local Smith factorization at z_0 if it has a right local Smith factorization

$$M(z) = R_1(z)D_1(z)P_1(z) \tag{3.1}$$

and a left local Smith factorization

$$M(z) = P_2(z)D_2(z)R_2(z) \tag{3.2}$$

in a neighborhood of z_0. Here P_i are unimodular (determinant identically one) quasipolynomials, R_1 and R_2 are locally analytic at z_0 with $\det R_1(z_0) \neq 0 \neq \det R_2(z_0)$, and D_1 and D_2 are diagonal quasipolynomials with diagonal entries of the form $((z-z_0)/(z-c))^k$, where the exponents are nonnegative integers which are nondecreasing as one moves down the diagonal of each of D_1 and D_2.

Trivially, if $M(z_0)$ is invertible, then M has a local Smith factorization at z_0 (take $D_1(z) \equiv P_1(z) \equiv D_2(z) \equiv P_2(z) \equiv I$). The interesting case is when $M(z_0)$ is not invertible. In this case we follow [2] and [3] and call z_0 an eigenvalue of M at z_0. (In our terminology, the constant function $M(z) \equiv A$, where A is invertible, has no eigenvalues. To get the "ordinary" eigenvalues of A, one has to study the analytic function $zI - A$ instead of the function $M(z) \equiv A$.)

The following lemma implies that the two diagonal matrices D_1 and D_2 in Definition 3.1 must be the same:

LEMMA 3.1. *Let* $z_0 \in \Pi$, *and let the matrix functions A and B be locally analytic at* z_0 *with* $\det A(z_0) \neq 0 \neq \det B(z_0)$. *If* D_1 *and* D_2 *are diagonal quasipolynomials having the structure of the diagonal quasipolynomials of Definition* 3.1, *and if*

$$D_2(z) = A(z)D_1(z)B(z) \tag{3.3}$$

in a neighborhood of z_0, *then* $D_1 = D_2$.

It follows immediately from Lemma 3.1 that if M has a local Smith factorization at z_0, then the diagonal quasipolynomials D_1 and D_2 occurring in the left and right local Smith factorizations of M are uniquely determined and equal. We denote this diagonal quasipolynomial by D. Also, the nonnegative integral powers $k_1 \leqq k_2 \leqq \cdots \leqq k_n$ which occur in D are called the *partial multiplicities* of M at z_0. The partial multiplicity k_n is called the *maximal partial multiplicity* of M at z_0, and the sum $k=\sum_{i=1}^n k_i$ is called the *algebraic order* of M at z_0 (z_0 is an eigenvalue of M if and only if the algebraic order of M at z_0 is positive). Alternative characterizations of k_n and k will be given in Theorem 3.1.

Proof of Lemma 3.1. For $i=1,2$ we have

$$D_i(z)=\operatorname{diag}\left(\left(\frac{z-z_0}{z-c}\right)^{k_{1i}},\cdots,\left(\frac{z-z_0}{z-c}\right)^{k_{ni}}\right),$$

where the nonnegative integers k_{ji} satisfy $k_{1i}\leqq k_{2i}\leqq\cdots\leqq k_{ni}$, $i=1,2$. Since the entries a_{ij} and b_{ij} of A and B are continuous at z_0 (in the relative topology of Π), a standard argument (see [1, Vol. I, § VI 3]), which uses the Binet-Cauchy formula to expand the right-hand side of (3.3), yields that

$$k_{12}+\cdots+k_{j2}\geqq k_{11}+\cdots+k_{j1},\qquad 1\leqq j\leqq n.$$

The reverse inequality is obtained by applying the same argument to $D_1=A^{-1}D_2B^{-1}$, and Lemma 3.1 follows immediately. □

We continue with another preliminary lemma:

LEMMA 3.2. *Suppose M is a locally analytic matrix function which is smooth of order l at $z_0\in\Pi$,* det *M has a zero of integral order $k\geqq 0$ at z_0, and all minors Δ of M of order $n-1$ satisfy*

$$\Delta(z)=O((z-z_0)^{k-l}),\quad z\to z_0,\quad z\in\Pi. \tag{3.4}$$

Then in each row and each column of M there is at least one element which has a locally analytic zero of integral order at most l at z_0.

Proof. We prove the result for rows only, since the proof for columns is completely analogous.

Develop det M along an arbitrary row i to obtain

$$\det M=\sum_{j=1}^{n}(-1)^{i+j}m_{ij}\Delta_{ij}, \tag{3.5}$$

where m_{ij} is the (i,j)-element of M and Δ_{ij} is the corresponding minor of M of order $n-1$. If each m_{ij}, $1\leqq j\leqq n$, satisfies $m_{ij}(z)=o((z-z_0)^l)$, $z\to z_0$, $z\in\Pi$, then by (3.4), (3.5) $\det M(z)=o((z-z_0)^k)$, $z\to z_0$, $z\in\Pi$. This estimate contradicts the assumption that det M has a zero of order exactly k at z_0. Thus, some element m_{ij} does not satisfy $m_{ij}(z)=o((z-z_0)^l)$, $z\to z_0$, $z\in\Pi$, and, being smooth of order l, it must have a locally analytic zero of order $q\leqq l$, q being an integer, possibly zero. □

We now can establish a sufficient condition for a matrix to have a local Smith factorization at z_0.

THEOREM 3.1. *Let the $n\times n$ matrix function $M=(m_{ij})$ be locally analytic at $z_0\in\Pi$ and assume that* det *M has a zero of integral order $k\geqq 0$ at z_0. If $n>1$, let $\sigma=\sigma(M)$ be the smallest nonnegative integer such that every minor Δ of M of order $n-1$ has a zero of order at least $k-\sigma$ at z_0; in the scalar case $n=1$ set $\sigma=k$. If M is smooth of order σ at z_0, then M has a local Smith factorization at z_0. In addition, the maximal partial multiplicity of M at z_0 equals σ, and the algebraic order of M at z_0 equals k.*

Note that z_0 is not assumed to be a *locally analytic* zero of order k of det M. That this is, in fact, the case follows from the conclusion of Theorem 3.1 since M satisfies (3.1) and (3.2) with

$$D_1(z)=D_2(z)=\operatorname{diag}\left(\left(\frac{z-z_0}{z-c}\right)^{k_1},\cdots,\left(\frac{z-z_0}{z-c}\right)^{k_n}\right)$$

and $k_1+k_2+\cdots+k_n=k$.

The smoothness assumption on M in Theorem 3.1 is far from necessary for M to have a local Smith factorization at z_0. For example, if ϕ_1 and ϕ_2 are scalar locally analytic functions with $\phi_1(z_0)\neq 0\neq \phi_2(z_0)$, then the matrix function $\operatorname{diag}[\phi_1(z),(z-z_0)\phi_2(z)]$ has a Smith factorization at z_0 with maximal partial multiplicity one, but it is not smooth of order one unless ϕ_1 is smooth of order one at z_0. It is also evident from the proof given below that not all the elements of M need be smooth of order σ for the construction to go through.

Proof of Theorem 3.1. We construct only a right local Smith factorization for M since the construction of a left local Smith factorization is completely analogous.

By multiplying M from the left and from the right by (unimodular) permutation matrices (i.e., $n\times n$ matrices $Q=(q_{st})$ which for some distinct i and j, $1\leqq i,j\leqq n$, satisfy $q_{st}=1$ if $s=t\neq i,j$, $q_{ij}=q_{ji}=1$, $q_{st}=0$, otherwise), we may assume that the order $k_1\geqq 0$ of the zero at z_0 of the element in the position (1, 1) is the minimum of the orders of the zeros at z_0 of all elements of M. Let us denote this rearranged matrix by $\tilde{M}=(\tilde{m}_{ij})$. It follows from Lemma 3.2 that $k_1\leqq\sigma$. By Lemma 2.2(iii), the quotients $\tilde{m}_{i1}/\tilde{m}_{11}$, $1\leqq i\leqq n$, are locally analytic and smooth of order $\sigma-k_1$. This means that we may successively left-multiply $\tilde{M}$ by unimodular locally analytic matrices to add the product of $-\tilde{m}_{i1}/\tilde{m}_{11}$ and the first row of $\tilde{M}$ to the ith row of $\tilde{M}$, where $2\leqq i\leqq n$; for fixed i, $2\leqq i\leqq n$, the required matrix has the form $R=(r_{st})$, where $r_{ss}=1$, $1\leqq s\leqq n$, $r_{i1}=-\tilde{m}_{i1}/\tilde{m}_{11}$ and $r_{st}=0$, otherwise. The result of these multiplications is a matrix $M_1=(m_{ij}^{(1)})$, where $m_{i1}^{(1)}\equiv 0$ for $2\leqq i\leqq n$. As our elimination matrices are smooth of order $\sigma-k_1$, and each of the elements of M has a zero of order at least k_1, it follows from Lemma 2.2 that each element of M_1 is smooth of order σ, and has a zero of order at least k_1. Also, the Binet–Cauchy formula shows that $\sigma(M_1)$, defined analogously to $\sigma(M)$, satisfies $\sigma(M_1)=\sigma(M)=\sigma$.

The first stage of the construction of a right local Smith factorization for M is now complete. In the next stage a similar sequence of steps will be used to place in the (2, 2) position an element with a zero at z_0 satisfying a certain minimality condition, and to assure that all off-diagonal elements in the second column vanish. Attaining the latter property requires an additional step to treat the elements above the diagonal; we begin with this step.

By Lemma 2.2(iii), there is a quasipolynomial p_{1j} for each j, $2\leqq j\leqq n$, such that $m_{1j}^{(1)}-p_{1j}m_{11}^{(1)}$ has a zero of order at least σ at z_0. Thus, we may successively right-multiply M_1 by unimodular quasipolynomial matrices to add the product of $-p_{1j}$ and the first column of M_1 to the jth column of M_1, where $2\leqq j\leqq n$; for fixed j, $2\leqq j\leqq n$, the required matrix has the form $U=(u_{st})$ where $u_{ss}=1$, $1\leqq s\leqq n$, $u_{1j}=-p_{1j}$ and $u_{st}=0$, otherwise. The effect of these multiplications is to replace each element $m_{1j}^{(1)}$, $j\geqq 2$, of M_1 with a locally analytic function which has a zero of order at least σ at z_0. Let us denote the new matrix by $\bar{M}_1=(\bar{m}_{ij}^{(1)})$.

Now left- and right-multiply $\bar{M}_1$ by permutation matrices to rearrange the $(n-1)\times(n-1)$ submatrix $(\bar{m}_{ij}^{(1)})$, $2\leqq i,j\leqq n$, so that its element which minimizes the order of the zero at z_0 is in its upper left-hand corner; by Lemma 3.2, if k_2 is the order of the zero at z_0 of the minimizing element, then $k_1\leqq k_2\leqq\sigma$. Observe that even after the permutations, all the elements in the first column except for the first vanish, and all the elements in the top row except for the first have a zero of order at least σ. As before, we may left-multiply the resulting matrix by unimodular locally analytic matrices to replace all the off-diagonal elements in the second column with identically zero functions. We get a matrix $M_2=(m_{ij}^{(2)})$ with the following properties: Each element of M_2 is smooth of order σ, $m_{i1}^{(2)}\equiv 0$, $i\neq 1$, $m_{i2}^{(2)}\equiv 0$, $i\neq 2$, $m_{11}^{(2)}=m_{11}^{(1)}$ has a zero at z_0 of order $k_1\geqq 0$, $m_{22}^{(2)}$ has a zero at z_0 of order k_2 with $k_1\leqq k_2\leqq\sigma$, each element $m_{1k}^{(2)}$,

$3 \leqq k \leqq n$, has a zero at z_0 of order at least σ, and each element $m_{ij}^{(2)}$, $2 \leqq i, j \leqq n$, has a zero at z_0 of order at least k_2. Moreover, $\sigma(M_2) = \sigma(M_1) = \sigma(M) = \sigma$.

Continue this process of right-multiplying by unimodular quasipolynomial matrices, multiplying by permutation matrices and then left-multiplying by unimodular locally analytic matrices to construct, successively, matrices $M_3, M_4, \cdots, M_n$ such that the elements $m_{ij}^{(l)}$ of M_l are smooth of order σ, $m_{ij}^{(l)} \equiv 0$ for $1 \leqq i, j \leqq l$, $i \neq j$, $m_{ii}^{(l)}$ has a zero at z_0 of order k_i, $1 \leqq i \leqq l$, with $0 \leqq k_1 \leqq k_2 \leqq \cdots \leqq k_l \leqq \sigma$, and, if $l < n$, each element $m_{ij}^{(l)}$ for $1 \leqq i \leqq l-1$, $l+1 \leqq j \leqq n$, has a zero at z_0 of order at least σ and each element $m_{ij}^{(l)}$ for $l \leqq i \leqq n$, $l+1 \leqq j \leqq n$ has a zero at z_0 of order at least k_l. In addition, $\sigma(M_l) = \sigma$, $1 \leqq l \leqq n$.

Clearly, each element $m_{ii}^{(n)}$, $1 \leqq i \leqq n$, of the diagonal matrix M_n may be written in the form

$$m_{ii}^{(n)}(z) = \left(\frac{z - z_0}{z - c}\right)^{k_i} \tilde{m}_{ii}^{(n)},$$

where $\tilde{m}_{ii}^{(n)}$ is locally analytic at z_0 and $\tilde{m}_{ii}^{(n)}(z_0) \neq 0$. Thus, we may left-multiply M_n by the invertible locally analytic matrix diag $(1/\tilde{m}_{11}^{(1)}, \cdots, 1/\tilde{m}_{nn}^{(n)})$ to obtain the diagonal matrix

$$D(z) = \operatorname{diag}\left(\left(\frac{z - z_0}{z - c}\right)^{k_1}, \cdots, \left(\frac{z - z_0}{z - c}\right)^{k_n}\right).$$

To complete the right local Smith factorization we now simply invert all the different left-factors which we have obtained and combine them into one locally analytic factor R_1 with det $R_1(z_0) \neq 0$, and likewise we invert all the different right-factors and combine them into one unimodular quasipolynomial factor P_1.

Finally, it was observed earlier that $\sum_{i=1}^{n} k_i = k$, i.e., that the algebraic order of M at z_0 equals k. We also note that because of the nature of the diagonal elements of M_n and because $\sigma(M_n) = \sigma$, we have $k - \sigma = \sum_{i=1}^{n-1} k_i$. Thus, the maximal partial multiplicity k_n of M at z_0 is given by $k_n = \sigma$. This completes the proof of Theorem 3.1. □

As an immediate consequence of Theorem 3.1 we have the following.

COROLLARY 3.1. *Let M have a local Smith factorization at $z_0 \in \Pi$ with diagonal quasipolynomial D and with maximal partial multiplicity σ. Suppose that the locally analytic matrix function Q is smooth of order σ at z_0, and that* det $Q(z_0) \neq 0$. *Then MQ and QM have local Smith factorizations at z_0 with the same diagonal quasipolynomial D.*

Proof. We prove the result for MQ; the proof for QM is completely analogous. The left factorization of MQ clearly holds with R_2 from (3.2) replaced by R_2Q. To obtain the right factorization from (3.1) we must rewrite DP_1Q. By Theorem 3.1 we may rewrite this expression as $DP_1Q = \tilde{R}DP$, where $\tilde{R}$ is locally analytic at z_0 with det $\tilde{R}(z_0) \neq 0$ and P is a unimodular quasipolynomial matrix. By Lemma 3.1 we still have the same diagonal quasipolynomial D on the right-hand side; thus, substituting this new expression for DP_1Q into (3.1) one gets the desired result for MQ. □

We conclude this section by giving conditions which ensure the existence of a "global Smith factorization" on $\bar{\Pi}$ of a locally analytic matrix function M that has only a finite number of eigenvalues, each of which is in Π and admits a local Smith factorization. This result is the matrix analogue of the scalar L^1-quotient theorem [7, Thm. 3.4].

THEOREM 3.2. *Let the n-by-n matrix function M be locally analytic on $\bar{\Pi}$, assume that* det $M(z) \neq 0$ *except on a finite set $Z = \{z_1, \cdots, z_N\} \subset \Pi$, and let M have a local Smith factorization at each $z_l \in Z$. Then M has a global Smith factorization on $\bar{\Pi}$, i.e., a* *right global Smith factorization*

$$M(z)=R_1(z)D(z)P_1(z), \qquad z\in\bar{\Pi}, \tag{3.6}$$

and a left global Smith factorization

$$M(z)=P_2(z)D(z)R_2(z), \qquad z\in\bar{\Pi}. \tag{3.7}$$

Here P_1 *and* P_2 *are unimodular quasipolynomials,* R_1 *and* R_2 *are locally analytic on* $\bar{\Pi}$ *with* $\det R_i(z)\neq 0$, $i=1,2$, *for all* $z\in\Pi$, *and* D *is the diagonal quasipolynomial*

$$D=\prod_{l=1}^{N} D_l, \tag{3.8}$$

where, for $1\leqq l\leqq N$, D_l *is the diagonal quasipolynomial occurring in the local Smith factorization of* M *at* z_l.

Proof. Once again we construct only the right factorization since the construction of the left one is completely analogous.

The matrix M has the local Smith factorization

$$M(z)=R_{11}(z)D_1(z)P_{11}(z) \tag{3.9}$$

in a neighborhood of z_1. Since D_1 and P_{11} have analytic inverses in $\bar{\Pi}\backslash\{z_1\}$, we may solve (3.9) for R_{11} in a neighborhood of z_1 and extend R_{11} to a locally analytic matrix defined on all of $\bar{\Pi}$ in such a way that (3.9) holds on $\bar{\Pi}$. By Corollary 3.1, this extended R_{11} has a right local Smith factorization $R_{11}(z)=R_{21}(z)D(z)P_{21}(z)$ at z_2 with D_2 being the diagonal quasipolynomial in the factorization of M at z_2. Substituting this expression for R_{11} in (3.9), one gets a factorization for M in a neighborhood of z_2.

Clearly, we may solve for R_{21} in a neighborhood of z_2 and then extend its domain to all of $\bar{\Pi}$ in the same way that the domain of R_{11} was extended. Continuing the argument above and then repeating it until all the eigenvalues $z_1,\cdots,z_N$ are included, one arrives at a decomposition of M on $\bar{\Pi}$ of the form

$$M=R_{N1}D_NP_{N1}D_{N-1}P_{N-1,1}\cdots D_1P_{11}. \tag{3.10}$$

Here $R_{l1}=R_{l+1,1}D_{l+1}P_{l+1,1}$, $1\leqq l\leqq N-1$, and each D_l is the diagonal quasipolynomial from the local Smith factorization of M at z_l.

The product $Q\equiv D_NP_{N1}D_{N-1}P_{N-1,1}\cdots D_1P_{11}$ is a quasipolynomial, i.e., a polynomial in $w\equiv(z-c)^{-1}$; hence, by [2, Thm. S1.1], Q has a global Smith factorization $Q=RDP_1$ where P_1 is a unimodular quasipolynomial, R is a quasipolynomial with constant nonzero determinant, $D=\operatorname{diag}(d_1,\cdots,d_n)$ and each d_i is a monic scalar quasipolynomial. Because of the form of Q it is easy to express the minors of Q in terms of the minors of the factors of Q (cf. [1, p. 12]) and then to use [2, Thms. S1.2 and S1.4] to determine the d_i and to establish (3.8). Thus, substituting the global Smith factorization of Q in (3.10) and letting $R_1=R_{N1}R$, we obtain the right global Smith factorization (3.6). □

4. Jordan chains. In order to describe the null space and the range of the convolution operator $\mathscr{L}$ defined in the introduction we have to introduce the concept of Jordan chains of a locally analytic matrix function with a Smith factorization. The easiest way to do this seems to be via the concept of root functions.

DEFINITION 4.1. Let q be a positive integer, and let the matrix function M be locally analytic at $z_0\in\Pi$. We say that a (column) vector-valued function r is a right root function of M of order at least q at z_0 if r is locally analytic and smooth of order q at z_0, $r(z_0)\neq 0$, and Mr has a zero of order at least q at z_0. Define

$$r_i=\frac{1}{i!}r^{(i)}(z_0), \qquad 0\leqq i\leqq q-1, \tag{4.1}$$

where $r^{(i)}(z_0)$ is the generalized derivative of order i of r at z_0. For any $p, 0 \leqq p \leqq q-1$, we call the vector sequence $r_0, \cdots, r_p$ a right Jordan chain of length $p+1$ of M at z_0; the vector $r(z_0)=r_0$ is said to be a right eigenvector corresponding to the eigenvalue z_0.

If M is smooth of order p at z_0, then so is Mr, and it follows from (2.2) and (4.1) that

$$\sum_{i=0}^{j} \frac{1}{i!} M^{(i)}(z_0) r_{j-i} = 0, \qquad 0 \leqq j \leqq p, \tag{4.2}$$

where $M^{(i)}(z_0)$ is the generalized derivative of order i of M at z_0. This means that our definition of a right Jordan chain of length $p+1$ agrees with, e.g., the definition given in [3, p. 91]. Observe that $r_0, r_1, \cdots, r_p$ is a right Jordan chain of M at z_0 if and only if the polynomial $\sum_{i=0}^{p} r_i(z-z_0)^i$ is a right root function of order at least $p+1$ of M at z_0.

LEMMA 4.1. *Let M and T be $n \times n$ matrix functions that are locally analytic at $z_0 \in \Pi$, and assume that* det $T(z_0) \neq 0$. *Then r is a right root function of M of order at least q at z_0 if and only if r is a right root function of TM of order at least q at z_0. In particular, if M has a local Smith factorization $R_1 D P_1$ at z_0, then the right root functions and right Jordan chains of M are identical with those of the right factor DP_1 at z_0.*

Proof. If r is a right root function of M of order at least q at z_0, then

$$\limsup_{z \to z_0,\, z \in \Pi} |(z-z_0)^{-q} T(z) M(z) r(z)| \leqq |T(z_0)| \limsup_{z \to z_0,\, z \in \Pi} |(z-z_0)^{-q} M(z) r(z)| < \infty.$$

Conversely, if r is a right root function of TM of order at least q at z_0, it follows that

$$\limsup_{z \to z_0,\, z \in \Pi} |(z-z_0)^{-q} M(z) r(z)| \leqq |T(z_0)^{-1}| \limsup_{z \to z_0,\, z \in \Pi} |(z-z_0)^{-q} T(z) M(z) r(z)| < \infty,$$

and Lemma 4.1 is proved. □

We emphasize that the right root functions and right Jordan chains of a locally analytic matrix function M having a local Smith factorization at z_0 do not depend on the particular factorization chosen; moreover, since they are determined by the quasipolynomial right factor DP_1 at z_0, the theory of right root functions and right Jordan chains for analytic matrix functions as developed in [3] (see also [2]) can be directly applied in this setting. In particular, the length of a right Jordan chain at a point cannot exceed the maximal partial multiplicity of M at that point.

If we multiply a matrix function M from the right by a sufficiently smooth matrix with nonvanishing determinant, then the right Jordan chains change in the same way as in the analytic case:

LEMMA 4.2. *Let the matrix function M have a local Smith factorization at $z_0 \in \bar{\Pi}$ with maximal partial multiplicity σ, and let the matrix function T be smooth of order σ at z_0, and satisfy* det $T(z_0) \neq 0$. *Then $r_0, \cdots, r_p$ is a right Jordan chain of length $p+1$ of MT at z_0 if and only if*

$$s_j = \sum_{i=0}^{j} \frac{1}{i!} T^{(i)}(z_0) r_{j-i}, \qquad 0 \leqq j \leqq p \tag{4.3}$$

is a right Jordan chain of M at z_0.

The proof is essentially the same as the proof of, e.g., [3, p. 93] and [2, Prop. 1.11]. It is a consequence of the fact that the polynomial $r(z)=\sum_{i=0}^{p} r_i(z-z_0)^i$ is a right root function of MT of order at least $p+1$ at z_0 if and only if Tr is a right root function of M of order at least $p+1$ at z_0, and that the polynomial part of Tr in the decomposition in Lemma 2.1 equals $\sum_{i=0}^{p} s_i(z-z_0)^i$.

Lemma 4.1 allows us to immediately transfer the concept of a canonical set of right Jordan chains as developed for matrix analytic functions [3] (see also [2, p. 32]) to the present setting.

DEFINITION 4.2. Let the $n \times n$ matrix function M be locally analytic and have a local Smith factorization at $z_0 \in \Pi$, and assume that $\det M$ has a zero of positive integer order k at z_0. Let $k_1 \leqq \cdots \leqq k_s$, $s \leqq n$, be positive integers, and let

$$r_{i0}, \cdots, r_{i,k_i-1}, \qquad 1 \leqq i \leqq s, \tag{4.4}$$

be a set of right Jordan chains of M at z_0. The set of sequences (4.4) is said to be a canonical set of right Jordan chains of M at z_0 if the vectors $r_{10}, \cdots, r_{s0}$, are linearly independent, and $k_1 + \cdots + k_s = k$.

We note that since the right Jordan chains of $M = R_1 D P_1$ are determined by the quasipolynomial right factor DP_1, the existence of a canonical set of right Jordan chains of M at z_0 is guaranteed by [3, pp. 92–93], and the properties of canonical sets of right Jordan chains are exactly those for analytic matrices as developed in [3]. In particular, the positive integers k_j, $1 \leqq j \leqq s$, are exactly the nonzero partial multiplicities $k_{n-s+1} \leqq \cdots \leqq k_n$ of M at z_0 [3]. The number s in Definition 4.2 equals the dimension of the null space (eigenspace) of $M(z_0)$, and it is often called the *geometric order* of M at z_0.

The importance of a canonical set of right Jordan chains of M at z_0 derives from the fact that its elements can be used to generate a basis for the set of all right Jordan chains of M at z_0. More precisely, let σ be the maximal partial multiplicity of the zero of M at z_0, and let $\mathcal{N}$ be the subspace of $C^{n \times \sigma}$ consisting of all sequences of the form $(0, 0, \cdots, 0, r_0, \cdots, r_p)$, where $r_0, \cdots, r_p$ is a right Jordan chain of M at z_0, and the total number of vectors is σ. Then it follows [2, Prop. 1.15] that the set of sequences (4.4) is a canonical set of right Jordan chains of M at z_0 if and only if the set of sequences

$$\gamma_{jp} = (0, \cdots, 0, r_{j0}, \cdots, r_{jp}), \qquad 0 \leqq p \leqq k_j - 1, \quad 1 \leqq j \leqq s,$$

where the number of zero vectors preceding r_{j0} in γ_{jp} is $\sigma - (p+1)$, forms a basis for $\mathcal{N}$. Observe that the total number of sequences γ_{jp} above equals the algebraic order of the zero of M at z_0. In other words, the dimension of $\mathcal{N}$ is the same as the algebraic order of M at z_0.

The notions of left root function and left Jordan chain of a locally analytic matrix M are defined analogously to the corresponding notions of right root function and right Jordan chain except that column vectors are replaced by row vectors and left multiplications are replaced by right multiplications throughout. The results concerning left root functions and left Jordan chains are completely analogous to the corresponding results for right root functions and right Jordan chains. In particular, if M has a left global Smith factorization $P_2 D R_2$, then the left root functions and left Jordan chains of M at z_0 are identical with those of the left factor $P_2 D$. A canonical set of left Jordan chains is defined analogously to a canonical set of right Jordan chains.

5. The null space of $\mathcal{L}$. In this section we describe the null space of the convolution operator

$$\mathcal{L}x(t) \equiv x'(t) + \mu * x(t) \tag{5.1}$$

in a space of fading memory type. Here $\mu \in M(C^{n \times n}; \rho)$. A similar description has been given in [12], but that one is not as general as the one given here (in [12] it is assumed that all the critical points belong to the interior of Π), and also is less precise (no connection between the null space of $\mathscr{L}$ and the right Jordan chains of $\hat{L}$ is made in [12]).

Formally, the Laplace transform of $\mathscr{L}$ is the function

$$\hat{L}(z) \equiv z + \hat{\mu}(z), \qquad z \in \Pi, \tag{5.2}$$

which is locally analytic in Π. We assume that $\hat{L}$ has only a finite set $Z = \{z_1, \cdots, z_N\}$ of eigenvalues. Moreover, we assume that $\hat{L}$ has a local Smith factorization at each point z_l of Z. Of course, this assumption is automatically satisfied at points of Z in the interior of Π. The function $\hat{L}$ is unbounded at infinity, and cannot therefore be locally analytic there. However, if we define

$$M(z) \equiv (z-c)^{-1}\hat{L}(z) = (z-c)^{-1}(z + \hat{\mu}(z)), \qquad z \in \bar{\Pi}, \tag{5.3}$$

where as before $c < \omega$, then M is locally analytic on all of $\bar{\Pi}$. It also has a local Smith factorization at each point z_l of Z. By Theorem 3.2, M has a right global Smith factorization

$$M(z) = R_1(z)D(z)P_1(z), \qquad z \in \bar{\Pi}. \tag{5.4}$$

Substituting this factorization into (5.2), we get the factorization

$$\hat{L}(z) = (z-c)R_1(z)D(z)P_1(z), \qquad z \in \Pi, \tag{5.5}$$

for $\hat{L}$ itself. This factorization is the main tool which we use to determine the nullspace of $\mathscr{L}$ in $\mathscr{B}^{m+1}(C^n; \eta)$.

To see how the factorization (5.5) can be used, note that since $\det R_1(z) \neq 0$, $z \in \bar{\Pi}$, the locally analytic matrix function R_1 is the transform of an invertible element $\xi_1 \in V(C^{n\times n}; \rho)$. Also the quasipolynomial $Q_1(z) \equiv D(z)P_1(z) = \sum_{i=0}^{q} A_i(z-c)^{-i}$, A_0 invertible, is the transform of the element $\nu_1 = \sum_{i=0}^{q} A_i e^{i*}$ in $V(C^{n\times n}; \rho)$. Here

$$e(t) = \exp(ct)I, \quad t \geqq 0, \qquad e(t) = 0, \quad t < 0,$$

$e^{0*} = \delta I$ with I the unit point mass at zero, and e^{i*}, $i = 1, 2, \cdots$, denotes the i-fold convolution $e * e * \cdots * e$.

LEMMA 5.1. *The operator* $\mathscr{L}$: $\mathscr{B}^{m+1}(C^n; \eta) \to \mathscr{B}^m(C^n; \eta)$ *has the same null space as the operator* $\mathscr{Q}_1 : \mathscr{B}^{m+1}(C^n; \eta) \to \mathscr{B}^{m+1}(C^n; \eta)$ *defined by*

$$\mathscr{Q}_1 x \equiv \nu_1 * x. \tag{5.6}$$

Proof. Since ξ_1 is invertible in $V(C^{n\times n}; \rho)$, Lemma 5.1 of [12] gives that the operator $(d/dt - c)\xi_1 *$maps $\mathscr{B}^{m+1}(C^n; \eta)$ one-to-one and onto $\mathscr{B}^m(C^n; \eta)$. Thus, since $\mathscr{Q}_1$ maps $\mathscr{B}^{m+1}(C^n; \eta)$ into $\mathscr{B}^{m+1}(C^n; \eta)$ and $\mathscr{L}x = (d/dt - c)\xi_1 * (\mathscr{Q}_1 x)$, the proof of Lemma 5.1 is complete. □

The null space of $\mathscr{Q}_1$ in $\mathscr{B}^{m+1}(C^n; \eta)$ is easy to compute. To do this, we follow the procedure in [11] and for $a \geqq b$ let $\rho_{a,b}$ denote the weight function

$$\rho_{a,b}(t) = \begin{cases} e^{-at}, & t \leqq 0, \\ e^{-bt}, & t > 0. \end{cases}$$

Choose α_1 and ω_1 so that $c < \omega_1 < \omega \leqq \alpha < \alpha_1 < \infty$. Then $\nu_1 \in V(C^{n\times n}; \rho_{\alpha_1,\omega_1})$. Also, by (2.1), (2.3) and (2.4), there exists a $T > 0$ such that

$$\tilde{\rho}_{\alpha_1,\omega_1}(t) \leqq \tilde{\rho}(t) \leqq \eta(t), \qquad |t| \geqq T;$$

hence, $\mathscr{B}^{m+1}(C^n; \eta) \subset \mathscr{B}^{m+1}(C^n; \tilde{\rho}_{\alpha_1,\omega_1})$.

Now when $\operatorname{Re} z=\alpha_1$ or $\operatorname{Re} z=\omega_1$, $\det Q_1(z)\neq 0$, so Lemmas 4.1 and 4.3 of [12] tell us that all solutions of

$$\left(\frac{d}{dt}-c\right)\mathscr{Q}_1 x(t)=0$$

in $\mathscr{B}^{m+1}(C^n;\tilde{\rho}_{\alpha_1,\omega_1})$ are of the form

$$x(t)=\sum_{l=1}^{N} p_l(t)\,e^{z_l t}, \tag{5.7}$$

where the p_l are (column) vector polynomials in t of degree at most one less than the order of the zero of $\det Q_1$ at z_l. Since $(d/dt-c)$ maps $\mathscr{B}^{m+1}(C^n;\tilde{\rho}_{\alpha_1,\omega_1})$ one-to-one onto $\mathscr{B}^{m}(C^n;\tilde{\rho}_{\alpha_1,\omega_1})$ (use [12, Lemma 3.1]), formula (5.7) characterizes the form of all functions x in the null space of $\mathscr{Q}_1$ in $\mathscr{B}^{m+1}(C^n;\tilde{\rho}_{\alpha_1,\omega_1})$. As $\mathscr{B}^{m+1}(C^n;\eta)\subset\mathscr{B}^{m+1}(C^n;\tilde{\rho}_{\alpha_1,\omega_1})$, it also characterizes the form of all functions x in the null space of $\mathscr{Q}_1$ in $\mathscr{B}^{m+1}(C^n;\eta)$, and by Lemma 5.1, the form of all functions x in the null space of $\mathscr{L}$ in $\mathscr{B}^{m+1}(C^n;\eta)$.

Formula (5.7) gives the form of all functions in the null space of $\mathscr{Q}_1$, but not all functions of the form (5.7) actually do belong to the null space. To identify exactly the null space of $\mathscr{Q}_1$ in $\mathscr{B}^{m+1}(C^n;\tilde{\rho}_{\alpha_1,\omega_1})$, we need the notion of right Jordan chains, developed in § 4.

LEMMA 5.2. *Let $\nu\in M(C^{n\times n};\rho_{\alpha_1,\omega_1})$, and let x be of the form*

$$x(t)=\sum_{i=0}^{p}\frac{t^i}{i!}r_{p-i}\,e^{z_0 t}, \tag{5.8}$$

with $r_0\neq 0$ and $\alpha_1<\operatorname{Re} z_0<\omega_1$. Then $\nu*x=0$ if and only if $r_0, r_1,\cdots, r_p$ is a right Jordan chain of $\hat{\nu}$ at z_0.

Proof. First use the binomial theorem, then interchange the order of the summation, and finally make a change of summation variables to get

$$\begin{aligned}\nu*x(t)&=\sum_{i=0}^{p}\int_R d\nu(s)\frac{(t-s)^i}{i!}r_{p-i}\,e^{z_0(t-s)}\\&=e^{z_0 t}\sum_{j=0}^{p}\frac{t^{p-j}}{(p-j)!}\sum_{i=0}^{j}\frac{1}{i!}\left\{\int_R(-s)^i e^{-z_0 s}\,d\nu(s)\right\}r_{j-i}.\end{aligned}$$

By elementary Laplace transform theory,

$$\int_R(-s)^i e^{-z_0 s}\,d\nu(s)=\hat{\nu}^{(i)}(z_0),$$

so we have

$$\nu*x(t)=e^{z_0 t}\sum_{j=0}^{p}\frac{t^{p-j}}{(p-j)!}\sum_{i=0}^{j}\frac{1}{i!}\hat{\nu}^{(i)}(z_0)r_{j-i}.$$

Clearly, this implies that $\nu*x=0$ if and only if

$$\sum_{i=0}^{j}\frac{1}{i!}\hat{\nu}^{(i)}(z_0)r_{j-i}=0,\qquad 0\leqq j\leqq p,$$

and since $\hat{\nu}$ is analytic at z_0 this condition is equivalent to $r_0, r_1, \cdots, r_p$ being a right Jordan chain of $\hat{\nu}$ at z_0. □

Combining Lemmas 5.1 and 5.2 with Lemma 4.1, we get the following.

COROLLARY 5.1. *A function $x \in \mathscr{B}^{m+1}(C^n; \eta)$ of the form* (5.8) *with $r_0 \neq 0$ and $z_0 \in \Pi$ belongs to the null space of $\mathscr{L}$ if and only if $r_0, r_1, \cdots, r_p$ is a right Jordan chain of $\hat{L}$ at z_0.*

Observe in particular the requirement that $x \in \mathscr{B}^{m+1}(C^n; \eta)$. This may or may not restrict the growth of x in (5.8) at plus or minus infinity in such a way that only those right Jordan chains whose length does not exceed a fixed number generate functions in the null space of $\mathscr{L}$. In the two settings discussed in [12, §§ 5 and 6], either all right Jordan chains at z_0 generate functions in the null space of $\mathscr{L}$, or none of them does.

By combining Corollary 5.1 with the discussion preceding Lemma 5.2, we can give a complete description of the null space $\eta(\mathscr{L})$ of $\mathscr{L}$ in $\mathscr{B}^{m+1}(C^n; \eta)$.

THEOREM 5.1. *Let $\mathscr{L}$ be the operator in* (5.1) *acting on $\mathscr{B}^{m+1}(C^n; \eta)$. Assume that $\hat{L}$ has only a finite set $Z = \{z_1, \cdots, z_N\}$ of eigenvalues, and that $\hat{L}$ has a local Smith factorization at each point of Z. Then the null space $\mathscr{N}(\mathscr{L})$ is the direct sum*

$$\mathscr{N}(\mathscr{L}) = \mathscr{N}_1 \oplus \cdots \oplus \mathscr{N}_N, \tag{5.9}$$

where each $\mathscr{N}_l$ is the set of functions $x \in \mathscr{N}(\mathscr{L})$ in Corollary 5.1 *with z_0 replaced by $z_l \in Z$, plus the zero function.*

6. The range of $\mathscr{L}$. Here we describe the range of the convolution operator $\mathscr{L}$ defined in (5.1) as a mapping from $\mathscr{B}^{m+1}(C^n; \eta)$ into $\mathscr{B}^m(C^n; \eta)$. The setting is exactly the same as in § 5. Namely, $\hat{L}$ defined in (5.2) has only a finite set $Z = \{z_1, \cdots, z_N\}$ of eigenvalues, and $\hat{L}$ has a local Smith factorization at each point z_l of Z. By Theorem 3.2, the locally analytic matrix M defined in (5.3) has a left global Smith factorization; substituting this factorization into (5.2), we get the factorization

$$\hat{L}(z) = (z - c)P_2(z)D(z)R_2(z), \qquad z \in \Pi. \tag{6.1}$$

This factorization is the tool which we use to determine the image of $\mathscr{L}$ in $\mathscr{B}^m(C^n; \eta)$.

In analogy with § 5, we use the fact that $\det R_2(z) \neq 0$, $z \in \bar{\Pi}$, to see that R_2 is the transform of an invertible element $\xi_2 \in V(C^{n \times n}; \rho)$. Also, the quasipolynomial $Q_2 = P_2 D$ is the transform of the element

$$\nu_2 \equiv Q_2(e) = \sum_{i=0}^{q} B_i e^{i*}$$

in $V(C^{n \times n}; \rho)$.

LEMMA 6.1. *The operator $\mathscr{L}$: $\mathscr{B}^{m+1}(C^n; \eta) \to \mathscr{B}^m(C^n; \eta)$ has the same range as the operator $\mathscr{Q}_2 : \mathscr{B}^m(C^n; \eta) \to \mathscr{B}^m(C^n; \eta)$ defined by*

$$\mathscr{Q}_2 x \equiv \nu_2 * x. \tag{6.2}$$

Proof. Using Lemma 3.5 of [11], we get

$$\mathscr{L}x = \left(\frac{d}{dt} - c\right) \mathscr{Q}_2(\xi_2 * x) = \mathscr{Q}_2\left[\left(\frac{d}{dt} - c\right) \xi_2 * x\right]$$

when $x \in \mathscr{B}^{m+1}(C^n; \eta)$. Now as in the proof of Lemma 5.1, we use the fact that $(d/dt - c)\xi_2 *$ maps $\mathscr{B}^{m+1}(C^n; \eta)$ one-to-one onto $\mathscr{B}^m(C^n; \eta)$ to complete the proof of Lemma 6.1. □

Our description of the range of $\mathscr{L}$ is given in terms of the left Jordan chains of $\hat{L}$ (which, by the analogue of Lemma 4.1 for left Jordan chains, are the same as the left Jordan chains of P_2D), and the concept of (left) Jordan chains of functions in $\mathscr{B}^m(C^n; \eta)$, which can be defined in the following way:

DEFINITION 6.1. The row vectors $v_0, \cdots, v_p$ with $v_0 \neq 0$ form a Jordan chain of length $p+1$ of $f \in \mathscr{B}^m(C^n; \eta)$ at $z_0 \in \Pi$ if there exist scalar functions $F_1, \cdots, F_{p+1} \in \mathscr{B}^{m+1}(C; \eta)$ satisfying

$$\left(\frac{d}{dt} - z_0\right) F_1 = v_0 f, \quad \left(\frac{d}{dt} - z_0\right) F_{j+1} = F_j + v_j f, \quad 1 \leqq j \leqq p. \tag{6.3}$$

In the case when $\eta = \rho$ and $\mathscr{B} = L^1$ one could also use an obvious modification of Definition 4.1 and define the notion of a left Jordan chain of $\hat{f}$ at a point $z_0 \in \Pi$. The connection between these two types of Jordan chains is very simple; the vectors $v_0, \cdots, v_p$ form a left Jordan chain of $\hat{f}$ at z_0 if and only if they form a Jordan chain of f at z_0 in the sense of Definition 6.1 (a proof of one direction of this claim is contained in the proof of Lemma 6.2 below; see, in particular, (6.4)). In other words, one should regard the notion of a Jordan chain of a function $f \in \mathscr{B}^m(C^n; \eta)$ defined above as a generalization of the notion of a left Jordan chain of $\hat{f}$ (Definition 6.1 makes sense even when $\hat{f}$ does not exist).

THEOREM 6.1. *Let $\mathscr{L}$ be the operator* (5.1) *acting on $\mathscr{B}^{m+1}(C^n; \eta)$. Assume that $\hat{L}$ has only a finite set $Z = \{z_1, \cdots, z_N\}$ of eigenvalues, and that $\hat{L}$ has a local Smith factorization at each point of Z. Then f in $\mathscr{B}^m(C^n; \eta)$ belongs to the range of $\mathscr{L}$ if and only if, for every $z_l \in Z$, every left Jordan chain of $\hat{L}$ at z_l is also a Jordan chain of f at z_l.*

In a way this result is very natural. Thinking of the interpretation of a Jordan chain of f as a left Jordan chain of $\hat{f}$, one could interpret Theorem 6.1 as a factorization result. It generalizes the statement that $\hat{L}$ is a left divisor of $\hat{f}$ if and only if every left Jordan chain of $\hat{L}$ is also a left Jordan chain of $\hat{f}$. In the setting of analytic matrix-valued functions this is a well-known result (see e.g., [3, Thm. 1.4]).

In [12] the range of $\mathscr{L}$ was characterized in two different cases. In [12, § 5] the influence function η is "small" at infinity, and $\mathscr{L}$ is a surjection, i.e., the range of $\mathscr{L}$ is all of $\mathscr{B}^m(C^n; \eta)$. The same result can be deduced from Theorem 6.1 because it is not difficult to show that, under the assumption in [12, § 5], for every $f \in \mathscr{B}^m(C^n; \eta)$, every sequence $v_0, \cdots, v_p$ of vectors with $v_0 \neq 0$ is a Jordan chain of f at those points z_l allowed in [12]. On the other hand, in [12, § 6], the influence function is "large" at infinity, and that forces the Laplace transform of f to converge and be analytic in a neighborhood of every eigenvalue z_l allowed in [12]. In that situation one could equally well work with the notion of Jordan chains of $\hat{f}$ mentioned above. Much more can be said about the significance of Theorem 6.1, and we shall discuss this question in a forthcoming paper.

We begin the proof of Theorem 6.1 by first proving the necessity of the Jordan chain condition in Theorem 6.1:

LEMMA 6.2. *Let $\nu \in M(C^{n \times n}; \rho)$, let $z_0 \in \Pi$ be an eigenvalue of $\hat{\nu}$, and assume that $\hat{\nu}$ is smooth of order q at z_0. Suppose that $f = \nu * x$, where $x \in \mathscr{B}^m(C^n; \eta)$. If $0 \leqq p \leqq q-1$, then every left Jordan chain of length $p+1$ of $\hat{\nu}$ at z_0 is also a Jordan chain of f at z_0.*

We remark that Lemma 6.2 gives a necessary condition for f to belong to the range of $\mathscr{L}$ even in the case when $\hat{L}$ has an infinite number of eigenvalues. This is true because the factorization (6.1) is not used to prove the necessity of the condition in Theorem 6.1; all that is required is that $\hat{L}$ be suitably smooth at each of its eigenvalues. We also remark that we can apply Lemma 6.2 to the measure $\nu_2 = Q_2(e)$ obtained from the factorization (6.1) since $\hat{\nu}_2$ is analytic on all of Π.

Proof of Lemma 6.2. Let $v_0, \cdots, v_p$, with $v_0 \neq 0$, be a left Jordan chain of $\hat{\nu}$ at z_0, where $0 \leqq p \leqq q-1$. Define

$$v(z) = \sum_{i=0}^{p} v_i (z-z_0)^i,$$

and note that

$$v(z)\hat{\nu}(z) = \sum_{i=0}^{p} v_i \hat{\nu}(z)(z-z_0)^i$$

has a locally analytic zero of order at least $p+1$ at z_0. In particular, the partial sum

$$\sum_{i=0}^{j} v_i \hat{\nu}(z)(z-z_0)^i$$

has a locally analytic zero of order at least $j+1$ at z_0 for each j, $0 \leqq j \leqq p$. Hence, if we define $\hat{a}_j$, $1 \leqq j \leqq p+1$, inductively by

$$(z-z_0)\hat{a}_1(z) = v_0\hat{\nu}(z), \qquad (z-z_0)\hat{a}_{j+1}(z) = \hat{a}_j(z) + v_j\hat{\nu}(z), \qquad 1 \leqq j \leqq p,$$

then each $\hat{a}_j$ is the Laplace transform of a function $a_j \in L^1(C^n; \rho)$ (see [7, Prop. 2.3]). Using Lemma 3.1 of [11], we find that the functions a_j satisfy $a_j' \in M(C^n; \rho)$ (where prime denotes a distribution derivative), and

$$a_1' - z_0 a_1 = v_0 \nu, \quad a_{j+1}' - z_0 a_{j+1} = a_j + v_j \nu, \quad 1 \leqq j \leqq p. \tag{6.4}$$

Define $F_j = a_j * x$ for $1 \leqq j \leqq p+1$. Then by [11, Lemma 3.6], $F_j' = a_j' = a_j' * x$, so $F_j \in \mathscr{B}^{m+1}(C; \eta)$. Moreover, by (6.4),

$$\left(\frac{d}{dt} - z_0\right) F_1 = v_0 \nu * x = v_0 f,$$

and

$$\left(\frac{d}{dt} - z_0\right) F_{j+1} = a_j * x + v_j \nu * x = F_j + v_j f$$

for $1 \leqq j \leqq p$. Hence $v_0, \cdots, v_p$ is a Jordan chain of f at z_0. □

By Lemma 6.1, f is in the range of $\mathscr{L}$ if and only if it is in the range of the operator $\mathscr{Q}_2$ corresponding to the quasipolynomial left factor $P_2 D$. The next lemma describes the action of the invertible operator corresponding to the unitary quasipolynomial P_2, and thereby further reduces the problem to an examination of the range of the operator corresponding to the diagonal quasipolynomial D.

LEMMA 6.3. *Let ν and ν^{-1} both belong to $M(C^{n \times n}; \rho_{\alpha_1, \omega_1})$ and let z_0 satisfy $\alpha_1 < \operatorname{Re} z_0 < \omega_1$. If $f \in \mathscr{B}^m(C^n; \eta)$, then $v_0, \cdots, v_p$ is a Jordan chain of $\nu * f$ at z_0 if and only if*

$$w_j = \sum_{i=0}^{j} \frac{1}{i!} v_{j-i} \hat{\nu}^{(i)}(z_0), \qquad 0 \leqq j \leqq p, \tag{6.5}$$

is a Jordan chain of f at z_0.

The proof given below is very similar to the proof of Lemma 6.2.

Proof. First, observe that it suffices to prove Lemma 6.3 in one direction only since if $g = \nu * f$, then $f = \nu^{-1} * g$, and, by a Taylor series argument (cf. Lemma 4.2), (6.5) is equivalent to

$$v_j = \sum_{i=0}^{j} \frac{1}{i!} w_{j-i} (\nu^{-1})^{\wedge(i)}(z_0), \qquad 0 \leqq j \leqq p.$$

Also observe that $w_0 \neq 0$ if and only if $v_0 \neq 0$.

Suppose that $w_0, \cdots, w_p$ is a Jordan chain of f at z_0, and let $F_1, \cdots, F_{p+1}$ in $\mathcal{B}^{m+1}(C;\eta)$ satisfy relation (6.3) with all the v_j's replaced by w_j's. By (6.5) and the fact that $\hat{\nu}$ is analytic at z_0, we find that, for $0 \leqq j < p$, the partial sum

$$\psi_{j+1}(z) \equiv \sum_{i=0}^{j} (v_i\hat{\nu}(z) - w_i)(z-z_0)^i$$

has an analytic zero of order at least $j+1$ at z_0. Hence, for $1 \leqq j \leqq p+1$, there exist functions $a_j \in L^1(C^n; \rho_{\alpha_1,\omega_1})$ so that

$$\hat{a}_j(z) = (z-z_0)^{-j}\psi_j(z), \qquad z \in \Pi.$$

From this formula and Lemma 3.1 of [11] we see that the distribution derivatives a_j' satisfy

$$\text{(6.6)} \qquad a_1' - z_0 a_1(z) = v_0\nu - w_0\delta, \quad a_{j+1}' - z_0 a_{j+1} = a_j + v_j\nu - w_j\delta, \quad 1 \leqq j \leqq p,$$

where δ is the unit point mass at zero.

Define $G_j \in \mathcal{B}^{m+1}(C;\eta)$ by

$$G_j = F_j + a_j * f, \qquad 1 \leqq j \leqq p+1.$$

Then by (6.6), [11, Lemma 3.6] and (6.3), we get

$$\left(\frac{d}{dt} - z_0\right) G_1 = w_0 f + v_0\nu * f - w_0 f = v_0 \nu * f,$$

$$\left(\frac{d}{dt} - z_0\right) G_{j+1} = F_j + w_j f + a_j * f + v_j \nu * f - w_j f = G_j + v_j \nu * f, \qquad 1 \leqq j \leqq p.$$

Thus, $v_0, \cdots, v_p$ is a Jordan chain of $\nu * f$ at z_0. □

Finally, to complete our proof that the Jordan chain condition in Theorem 6.1 is sufficient for f to belong to the range of $\mathcal{L}$, we have the following lemma for scalar quasipolynomials:

LEMMA 6.4. *Let $z_1, \cdots, z_l$ be distinct points satisfying* $\operatorname{Re} z_l > c$, *and let $p_1, \cdots, p_N$ be positive integers. Define the operator d on $\mathcal{B}^m(C;\eta)$ by*

$$\text{(6.7)} \qquad dx \equiv d * x \equiv \prod_{l=1}^{N} * (\delta - (z_l - c)e)^{p_l *} * x, \qquad x \in \mathcal{B}^m(C;\eta).$$

Let $f \in \mathcal{B}^m(C;\eta)$, and assume that for each l, $1 \leqq l \leqq N$, the sequence $1, 0, \cdots, 0$ *is a Jordan chain of length p_l of f at z_l. Then f belongs to the range of d.*

Here the notation $\prod_{l=1}^{N} * d_l$ denotes the convolution product $d_1 * d_2 * \cdots * d_N$ when $N \geqq 2$, and d_1 when $N = 1$.

Proof. The Laplace transform of the measure d in (6.7) is given by

$$\hat{d}(z) = \prod_{l=1}^{N} \left(\frac{z-z_l}{z-c}\right)^{p_l}.$$

Write

$$\text{(6.8)} \qquad \prod_{l=1}^{N} \left(\frac{z-z_l}{z-c}\right)^{p_l} = \sum_{l=1}^{N} \sum_{j=0}^{p_l} a_{lj}(z-z_l)^{-j}$$

for appropriate constants a_{lj}. Define d_{lj} by

$$d_{lj}(t) = \left(\frac{d}{dt} - z_l\right)^{p_l - j} e^{p_l *}(t)$$

for $1 \leqq l \leqq N$, $0 \leqq j \leqq p_l$. It is easy to check that, for $1 \leqq l \leqq N$, $d_{lj} \in L^1(C; \rho)$ for $0 \leqq j \leqq p_l - 1$ and $d_{lp_l} \in V(C; \rho)$. Observe that

$$\hat{d}_{lj}(z) = (z + z_l)^{p_l - j}(z - c)^{-p_l},$$

so d is given by

$$d = \prod_{l=1}^{N} * \, d_{l0}.$$

Moreover, it follows from (6.8) that

$$\sum_{l=1}^{N} \sum_{j=0}^{p_l} a_{lj} \prod_{\substack{i=1 \\ i \neq l}}^{N} * \, d_{i0} * d_{lj} = \delta. \tag{6.9}$$

Set $F_{l0} = f$ for $1 \leqq l \leqq N$, and let $F_{l1}, \cdots, F_{lp_l}$ be the functions in Definition 6.1 corresponding to the Jordan chains $v_{l0} = 1, v_{l1} = \cdots = v_{l,p_l - 1} = 0$ of f at z_l. Note in particular that, due to the special structure of these Jordan chains, $F_{lj} \in \mathscr{B}^{m+j}(C; \eta)$, and that the repeated application of Lemma 3.5 of [11] yields

$$d_{l0} * F_{lj} = d_{lj} * f \tag{6.10}$$

for $1 \leqq l \leqq N, 0 \leqq j \leqq p_l$.

Define $x \in \mathscr{B}^m(C; \eta)$ by

$$x(t) = \sum_{l=1}^{N} \sum_{j=0}^{p_l} a_{lj} F_{lj}.$$

It follows from the commutativity of convolution, (6.9) and (6.10) that

$$\begin{aligned} dx &= \prod_{i=1}^{N} * \, d_{i0} * \sum_{l=1}^{N} \sum_{j=0}^{p_l} a_{lj} F_{lj} \\ &= \sum_{l=1}^{N} \sum_{j=0}^{p_l} a_{lj} \prod_{\substack{i=1 \\ i \neq l}}^{N} * \, d_{i0} * d_{lj} * f = f, \end{aligned}$$

so f belongs to the range of d. □

Proof of Theorem 6.1. As stated above, the necessity of the condition in Theorem 6.1 for f in $\mathscr{B}^m(C^n; \eta)$ to belong to the range of $\mathscr{L}$ is an immediate consequence of Lemmas 6.1 and 6.2, and the fact that the left Jordan chains of $\hat{L}$ are identical with those of the left factor $\hat{\nu}_2 = P_2 D$ in (6.1).

Conversely, suppose that $f \in \mathscr{B}^m(C^n; \eta)$ and, for every $z_l \in Z$, every left Jordan chain of $\hat{L}$ at z_l is also a Jordan chain of f at z_l. By Lemma 6.1 and Lemma 4.1 for left Jordan chains it suffices to prove that f belongs to the range of the operator $\mathscr{Q}_2$. Let $\nu_3 = P_2(e)$ and $\nu_4 = D(e)$ be the measures whose transforms are the factors P_2 and D in (6.1), respectively. If α_1 and ω_1 satisfy $c < \omega_1 < \omega \leqq \alpha < \alpha_1$, then ν_3, ν_3^{-1} and ν_4 all belong to $V(C^{n \times n}; \rho_{\alpha_1, \omega_1})$. Since $\nu_2 = \nu_3 * \nu_4$, the function f belongs to the range of $\mathscr{Q}_2$ if and only if $g \equiv \nu_3^{-1} * f$ belongs to the range of the diagonal operator $\mathscr{D}x \equiv \nu_4 * x$. Thus, by Lemma 6.3 and the analogue of Lemma 4.2 for left Jordan chains, it suffices to show that g in $\mathscr{B}^m(C^n; \eta)$ belongs to the range of $\mathscr{D}$ whenever, for each eigenvalue $z_l \in Z$, every left Jordan chain of $\hat{D}$ is also a Jordan chain of g. But $D = \operatorname{diag}[d_1, \cdots, d_n]$, where each d_i is the monic scalar quasiopolynmial

$$d_i(z) = \prod_{l=1}^{N} \left(\frac{z - z_l}{z - c} \right)^{k_{il}}.$$

Here $k_{il} \geqq 0$ is the ith partial multiplicity of D at z_l. For each l with $k_{il} > 0$, the vectors $v_{i0} = (0, 0, \cdots, 1, 0, \cdots, 0)$ with the one in the ith coordinate, and $v_{i1} = \cdots = v_{i, k_{il}-1} = 0$ form a left Jordan chain of length k_{il} of D at z_l; hence, by assumption, $v_{i0}, \cdots, v_{i,k_{il}-1}$ is a Jordan chain of g at z_l. Lemma 6.4 shows that the ith component of g belongs to the range of the scalar operator d_i corresponding to d_i. Thus, g belongs to the range of $\mathscr{D}$. □

NONLINEAR EVOLUTION EQUATIONS WITH ALMOST PERIODIC TIME DEPENDENCE*

GEORGE SEIFERT†

Abstract. We give conditions under which solutions of the equation $u'(t) = Au(t)+f(t)$ are asymptotically almost periodic; here $u(t)$ and $f(t)$ are functions on the reals with values in a real Banach space X, $f(t)$ is almost periodic in the sense of Bohr and A is a function on a subset $D(A)$ of X, to X. We apply the result to a nonlinear one-dimensional heat equation with an almost periodic time-dependent heat supply.

Key words. nonlinear evolution equation, almost periodic function, asymptotically almost periodic function

AMS(MOS) subject classification. 34G20

1. Introduction. Let $\{X, |\ |\}$ denote a real Banach space. Let A denote a function on $D(A) \subset X$ to X, and f a function on R to X; R the set of reals. If we assume that f is almost periodic (a.p.) in the usual sense of Bohr, it is the purpose of this paper to give conditions on A so that strong solutions of

$$u' = Au + f(t) \tag{1}$$

on $[s, \infty)$ for some fixed $s \in R$ are asymptotically almost periodic (a.a.p.) and approach an a.p. generalized solution of (1) as $t \to \infty$.

As an application, we obtain a result for the nonlinear one-dimensional heat equation with a.p. time-dependent heat supply:

$$\begin{aligned} &u_t(t, \xi) = (\sigma(u_\xi))_\xi + r(t, \xi), \quad t \in R, \quad 0 < \xi < 1, \\ &u(t, 0) = u(t, 1) = 0 \quad \text{for } t \in R, \end{aligned} \tag{2}$$

where $r(t, \xi)$ is a.p. in t. Our result for (2) is in terms of almost periodicity in t for $L^2[0, 1]$-valued functions in terms of the $L^2[0, 1]$ norm; it is the purpose of a future investigation to find additional conditions under which almost periodicity with respect to the usual real valued norm is obtained.

Our methods are based on some results in [1]. The case where f is periodic is treated in [1] where a monotonicity condition on A, similar to the one we use, is imposed.

We assume without loss of generality that $A0 = 0$, the zero in X, since the conditions we impose on f also hold for $f(t) + x_0$, x_0 any element in X.

2. Definitions and preliminary results. We say that the function $u : [s, \infty) \to X$ is asymptotically almost periodic (a.a.p. for short) if it is continuous and if there exists an a.p. function $v : R \to X$ such that $u(t) - v(t) \to 0$ as $t \to \infty$.

We will use the following results, which can easily be established by following the proofs for the corresponding finite-dimensional results given in, for example, the book by Fink [2]; it is important to observe that the range of any a.p. function is contained in a compact subset of X (cf. [3]).

PROPOSITION 1. *The continuous function $u : [s, \infty) \to X$ is a.a.p. if and only if given a sequence $\{t'_n\}$, $t'_n \geqq s$, $t'_n \to \infty$ as $n \to \infty$, there exists a subsequence $\{t_n\}$ such that $\{u(t + t_n)\}$ converges uniformly for $t \geqq s$.*

* Received by the editors March 25, 1985; accepted for publication April 7, 1986.

† Department of Mathematics, Iowa State University, Ames, Iowa 50011.

PROPOSITION 2. *If $v:R\to X$ is a.p. there exists a sequence $\{t_n\}$, $t_n\to\infty$ as $n\to\infty$, such that $v(t+t_n)-v(t)\to 0$ as $n\to\infty$ uniformly for $t\in R$.*

The next results are basically in [1] and are concerned with solutions of (1). We define $u:[s,\infty)\to X$ to be a strong solution of (1) if $u(t)$ is continuous, is absolutely continuous on each compact interval of $[s,\infty)$, is differentiable almost everywhere on (s,∞) and satisfies (2) almost everywhere on (s,∞). If $u(s)=x$, x is called the initial value of $u(t)$. We shall henceforth refer to a strong solution of (1) as simply a solution of (1).

For each (t,s) in a subset of $R\times R$ of the form $a\leqq s\leqq t\leqq b$, a function $U(t,s):X\to X$ is called an evolution operator on X if

(i) $U(s,s)x=x$ for each $x\in X$;

(ii) $U(t,s)U(s,r)=U(t,r)$ for $a\leqq r\leqq s\leqq t\leqq b$;

(iii) $U(t,s)x$ is continuous in (t,s) for each $x\in X$.

Here and henceforth we always suppose $a\leqq s\leqq t\leqq b$ with $a=-\infty$ and $b=\infty$ possible.

We say that $U(t,s)$ is an evolution operator for (1) if for each solution $u:[s,b)\to X$ of (1), $u(t)=U(t,s)u(s)$.

If $U(t,s)$ is an evolution operator for (1) and $x\in X$ is arbitrary, we call $U(t,s)x$ a generalized solution of (1) on $[s,b)$. If $a=-\infty$ and $b=\infty$, we say that $U(t,s)x$ is a generalized solution on R.

We note that if there exists an evolution operator for (1) any solution $u:[s,b)\to X$, $a<s<b$, is unique, and similarly, if there exists such a solution u of (1), any evolution operator for (1) is unique. If $A:D(A)\to X$, we say that $A\in\mathscr{A}(\omega)$, $\omega\in R$, if

$$|x-y|-|x-y-\lambda(Ax-Ay)|\leqq\lambda\omega|x-y| \tag{3}$$

for $x,y\in D(A)$ and $\lambda>0$ with $\lambda\omega<1$ (cf. [1, § 1]).

It is not difficult to show that fixed x and y,

$$\lambda^{-1}(|x-y|-|x-y-\lambda(Ax-Ay)|)$$

is a nonincreasing function of λ for $\lambda>0$ (cf. [4, Lemma 5.1, p. 37]). Thus if (3) holds for some $\lambda_0>0$, it holds for all $\lambda>\lambda_0$.

PROPOSITION 3. *Let $A:D(A)\to X$ and $A\in\mathscr{A}(0)$. Let $\overline{D(A)}=X$ where $\overline{D(A)}$ is the closure of $D(A)$. Let $f:R\to X$ be continuous. Let $(I-\lambda_0A)D(A)=X$ for some $\lambda_0>0$; here and henceforth I denotes the identity operator on X. Then there exists an evolution operator $U(t,s)$ for (1) for $t\geqq s$.*

For a proof we may use Theorem 5.1 in [1]; we also use the well-known fact that if $A\in\mathscr{A}(0)$ and $(I-\lambda_0A)D(A)=X$, then $(I-\lambda A)D(A)=X$ for any $\lambda>0$.

PROPOSITION 4. *Let $A\in\mathscr{A}(\omega)$ and $\overline{D(A)}=X$ and f and g be continuous on R to X. Let $U_f(t,s)$ and $U_g(t,s)$ be evolution operators for (1) and an equation like (1) with f replaced by g. Then*

$$|U_f(t,s)x-U_g(t,s)x|\leqq\int_s^t|f(\tau)-g(\tau)|\exp\omega(t-\tau)\,d\tau\quad \textit{for}\ x\in X,\quad t\geqq s. \tag{4}$$

This is essentially Lemma 5.2 in [1].

PROPOSITION 5. *Let A satisfy the hypotheses of Proposition 4 and f be continuous on R to X. Let $U(t,s)$ be an evolution operator for (1). Then*

$$|U(t,s)x-U(t,s)y|\leqq|x-y|\exp\omega(t-s),\qquad t\geqq s\quad \textit{and}\quad x,y\in X. \tag{5}$$

For a proof, cf. Theorem 2.1 in [1] where actually weaker conditions on A are used.

3. Main results.

THEOREM 1. *Let A and f be functions as given in the introduction with $A \in \mathscr{A}(\omega)$ for some $\omega < 0$, and f a.p. Let $\overline{D(A)} = X$, and suppose there exists a $\lambda_0 > 0$ such that $(I - \lambda_0 A)D(A) = X$. Then each solution of* (1) *on* $[0, \infty)$ *is a.a.p. and there exists a unique generalized a.p. solution $\bar{u}(t)$ of* (1) *on R such that if $u(t)$ is any solution of* (1), *$u(t) - \bar{u}(t) \to 0$ as $t \to \infty$.*

Proof. Since $\omega < 0$, we have $A \in \mathscr{A}(0)$, and so the hypotheses of Proposition 3 hold. Let $\{t'_n\}$ be a sequence with $t'_n > 0$, $t'_n \to \infty$ as $n \to \infty$. Since f is a.p. there exists a subsequence $\{t_n\}$ of $\{t'_n\}$ and an a.p. function $g: R \to X$ such that

$$f(t + t_n) - g(t) \to 0 \quad \text{as } n \to \infty \tag{6}$$

uniformly for $t \in R$. We may clearly suppose $t_{n+1} > t_n$, $n = 1, 2, 3, \cdots$.

Let $U_f(t, s)$ be the evolution operator for (1) and $u(t)$ be a solution of (1) on $[0, \infty)$; let $u(0) = x$. Then

$$U_f(t + t_n, 0)x = u_n(t) \text{ is a solution of}$$

$$u' = Au + f_n(t) \tag{2n}$$

for $t \geqq -t_n$; here $f_n(t) = f(t + t_n)$. Let $U_{f_n}(t, s)$ be the evolution operator for (2n); then

$$U_f(t + t_n, 0)x = U_{f_n}(t, -t_n)x, \qquad t \geqq -t_n.$$

Since g is continuous on R, there exists an evolution operator $U_g(t, s)$ for $u' = Au + g(t)$ and a generalized solution

$$v_n(t) = U_g(t, -t_n)x, \qquad t \geqq -t_n$$

for this equation. Fix $t \geqq 0$ and m and n such that $m > n$. Then

$$|u_n(t) - u_m(t)| \leqq |u_n(t) - v_n(t)| + |v_n(t) - v_m(t)| + |v_m(t) - u_m(t)|. \tag{7}$$

By Proposition 4 with (6) and the condition $\omega < 0$, we have given $\varepsilon > 0$, there exists an N_ε so that $n > N_\varepsilon$ implies

$$|u_n(t) - v_n(t)| \leqq \int_{-t_n}^{t} |f_n(\tau) - g(\tau)| \exp \omega(t - \tau)\, d\tau \leqq \varepsilon, \tag{8}$$

and a similar result with n replaced by m.

Using Proposition 5, we have

$$\begin{aligned} |v_n(t) - v_m(t)| &\leqq |v_n(-t_n) - v_m(-t_n)| \exp \omega(t + t_n) \\ &\leqq |x - U_g(-t_n, -t_m)x| \exp \omega t_n. \end{aligned} \tag{9}$$

Using Proposition 4 again with $U_0(t, s)$ the evolution operator for $u' = Au$, we have

$$|U_g(-t_n, -t_m)x - U_0(-t_n, -t_m)x| \leqq B_1 \tag{10}$$

for some constant B_1; this follows since g is a.p. and hence bounded on R. By Proposition 5 and the fact that $u = 0$ is a solution of $u' = Au$ on R, we get

$$|U_0(-t_n, -t_m)x| \leqq |x|. \tag{11}$$

Using (10) and (11) in (9) yields

$$|v_n(t) - v_m(t)| \leqq (2|x| + B_1) \exp \omega t_n$$

and using this with (8) in (7) shows that for N_ε sufficiently large $n > N_\varepsilon$ and $m > n$ imply $|u_n(t) - u_m(t)| \leqq 3\varepsilon$. Thus $\{u_n(t)\}$ is Cauchy uniformly on $[0, \infty)$ and so converges uniformly on that interval. By Proposition 1 we conclude that $u(t)$ is a.a.p. and so by definition $u(t) - w(t) \to 0$ as $t \to \infty$ for some $w: R \to X$, w a.p.

Since f is a.p. there exists by Proposition 2 a sequence $\{\tau_n\}$, $\tau_n > 0$, $\tau_n \to \infty$ as $n \to \infty$, such that $f(t+\tau_n) - f(t) \to 0$ as $n \to \infty$; since w is also a.p., we may suppose $w(t+\tau_n) \to \bar{u}(t)$ as $n \to \infty$ uniformly for $t \in R$, where $\bar{u}(t)$ is a.p.

We show that $\bar{u}(t)$ is a generalized solution of (1). Let $t \in R$ be given and fix $t_0 \leqq t$. We have for n sufficiently large

$$|U_f(t, t_0)\bar{u}(t_0) - \bar{u}(t)| \leqq |U_f(t, t_0)\bar{u}(t_0) - u(t+\tau_n)| + |u(t+\tau_n) - \bar{u}(t)|. \tag{12}$$

Since $u(t+\tau_n) = U_{f_n}(t, -\tau_n)u(0)$ where $f_n(t) = f(t+\tau_n)$ and $U_{f_n}(t, -\tau_n) = U_{f_n}(t, t_0)U_{f_n}(t_0, -\tau_n)$ for n sufficiently large, we have

$$\begin{aligned} |U_f(t, t_0)\bar{u}(t_0) - u(t+\tau_n)| &\leqq |U_f(t, t_0)\bar{u}(t_0) - U_f(t, t_0)U_{f_n}(t_0, -\tau_n)u(0)| \\ &\quad + |U_f(t, t_0)U_{f_n}(t_0, -\tau_n)u(0) - U_{f_n}(t, t_0)U_{f_n}(t_0, -\tau_n)u(0)| \\ &\leqq |\bar{u}(t_0) - u(t_0+\tau_n)| + \sup\{|f_n(t) - f(t)|/|\omega| : t \in R\}; \end{aligned} \tag{13}$$

here we have used $\omega < 0$ and Propositions 4 and 5. Since

$$|\bar{u}(t_0) - u(t_0+\tau_n)| \leqq |\bar{u}(t_0) - w(t_0+\tau_n)| + |w(t_0+\tau_n) - u(t_0+\tau_n)| \tag{14}$$

and since $f_n(t) - f(t) \to 0$ as $n \to \infty$ uniformly on R, (13) shows that the first term on the right in (12) tends to zero as $n \to \infty$. But by (14) with t_0 replaced by t, we see that the second term on the right in (12) also approaches zero as $n \to \infty$. Thus $U_f(t, t_0)\bar{u}(t_0) = \bar{u}(t)$, $t \in R$; i.e., $\bar{u}$ is a generalized solution of (1) on R.

The uniqueness of $\bar{u}$ follows easily from Proposition 5; if $u_1(t)$ and $u_2(t)$ are distinct generalized a.p. solutions of (1) then $h(t) = u_1(t) - u_2(t)$ would be a.p. with $h(t_1) \neq 0$ for some $t_1 \in R$. But $h(t) \to 0$ as $t \to \infty$ by Proposition 5; since this is impossible, the uniqueness of $\bar{u}$ follows and our proof is complete.

THEOREM 2. *Let A and f be as in Theorem* 1, *and suppose X is reflexive and f is of bounded variation on each compact interval in R. Then for each $x \in D(A)$, there exists a solution $u(t)$ of* (1) *on* $[0, \infty)$ *such that $u(0) = x$ which is a.a.p. and approaches a unique generalized a.p. solution of* (1) *as $t \to \infty$.*

A proof of this theorem is an easy consequence of our Theorem 1 and Theorem 5.1(iv) in [1]; our hypotheses imply $\hat{D}(A) = D(A)$, where $\hat{D}(A)$ is defined in [1]. To show that we also have that A is closed, let $x_n \to x_0$ and $Ax_n \to y_0$ as $n \to \infty$, where $x_n \in D(A)$. Since $(I - \lambda A)^{-1}$ is defined and continuous on X (cf. [1, p. 9]) for any $\lambda > 0$,

$$(I - \lambda A)^{-1}(I - \lambda A)x_n \to (I - \lambda A)^{-1}(x_0 - \lambda y_0) \quad \text{as } n \to \infty.$$

So $(I - \lambda A)^{-1}(x_0 - \lambda y_0) = x_0$, and hence $Ax_0 = y_0$; i.e., A is closed.

It is clear that in Theorems 1 and 2, the solution $u(t)$ of (1) may be on any interval $[t_0, \infty)$ rather than on $[0, \infty)$; the latter was chosen to simplify the notation only.

We also have as a consequence of Proposition 5 that under our hypotheses, all generalized solutions of (1) are a.a.p. We stated Theorem 1 for strong solutions mainly to emphasize the fact that the definition of $U(t, s)$ as evolution operator for (1) involves strong solutions of (1).

4. An application. We consider the boundary value problem (2) stated in the introduction. We take $X = L^2[0, 1] = L^2$, the set of Lebesgue square integrable real-valued functions on $[0, 1]$ with the usual norm $|u| = \langle u, u\rangle^{1/2}$ in terms of the inner product:

$$\langle u, v\rangle = \int_0^1 u(\xi)v(\xi)\, d\xi, \qquad u, v \in L^2.$$

Since $\{L^2, \langle\ ,\ \rangle\}$ is a Hilbert space, X is now reflexive.

Let $\sigma: R \to R$ be continuously differentiable, $\sigma(0)=0$, and suppose there exist constant m and M such that $0<m \leqq \sigma'(u) \leqq M<\infty$ for $u \in R$. Let $r(t, \xi): R \times [0,1] \to R$ be in L^2 for each t and L^2-a.p.; i.e., a.p. in t in the L^2 norm.

We apply Theorems 1 and 2 of the previous section. Take $Au = (\sigma(u_\xi))_\xi$ with $D(A) = \{u \in L^2$: $u(0)=u(1)=0$, with $u(\xi)$ and $u'(\xi)$ absolutely continuous on $[0,1]$, $u''(\xi) \in L^2\}$.

It is well known that $L^2 = \overline{D(A)}$.

We next show that $A \in \mathscr{A}(\omega)$ for some $\omega < 0$. By direct calculations we find that for $u \neq v$, $u, v \in D(A)$,

$$\begin{aligned} &\lim_{\lambda \to 0+} (|u-v| - |u-v-\lambda(Au-Av)|)/\lambda|u-v| \\ &\quad = \langle u-v, Au-Av\rangle/|u-v|^2 \\ (15) \qquad &\quad = -\int_0^1 (u'(\xi)-v'(\xi))(\sigma(u'(\xi))-\sigma(v'(\xi)))\,d\xi \Big/ \int_0^1 (u(\xi)-v(\xi))^2\,d\xi \\ &\quad \leqq -m \int_0^1 (u'(\xi)-v'(\xi))^2\,d\xi \Big/ \int_0^1 (u(\xi)-v(\xi))^2\,d\xi \\ &\quad \leqq -m\pi; \end{aligned}$$

the last estimate follows from a result in [5, p. 182]; we can also easily get this with π replaced by 2 by using the Cauchy-Schwartz inequality. From (15) and the remark preceding the statement of Proposition 3, we have that $A \in \mathscr{A}(-m\pi)$.

We next show that there exists a $\lambda > 0$ such that $(I-\lambda A)D(A) = L^2$. Let $f \in L^2$ be given. Let $\{C, \|\ \|\}$ be the Banach space of real valued functions continuous on $[0,1]$ with norm $\|u\| = \sup\{|u(\xi)|: 0 \leqq \xi \leqq 1\}$. For fixed $\lambda > 0$ define $T_\lambda: C \to C$ as follows:

$$(T_\lambda u)(\xi) = \int_0^\xi \sigma^{-1}\left[\lambda^{-1}\int_0^\eta (u(s)-f(s))\,ds + c_u\right] d\eta, \qquad 0 \leqq \xi \leqq 1,$$

where c_u is the unique constant such that

$$(16) \qquad \int_0^1 \sigma^{-1}\left[\lambda^{-1}\int_0^\eta (u(s)-f(s))\,ds + c_u\right] d\eta = 0$$

and σ^{-1} denotes the inverse of σ. The fact that there exists a unique constant c_u follows since

$$(17) \qquad M^{-1} \leqq \sigma^{-1\prime}(u) \leqq m^{-1} \quad \text{for } u \in R.$$

From (16) we may also easily verify that

$$(18) \qquad |c_u - c_v| \leqq (M/m\lambda)\|u-v\|, \qquad u, v \in C;$$

we omit the details. Using (18) and (16), we see that for $\lambda > 0$ sufficiently large, T_λ is a contraction on C; let $\bar{u}$ be the unique fixed point of T_λ. It is easy to verify that $\bar{u} \in D(A)$ and satisfies $\lambda(\sigma(u'))' = u - f$. We have therefore $(I-\lambda A)D(A) = L^2$, as asserted. We have essentially proved the following theorem.

THEOREM 3. *Suppose $\sigma: R \to R$ is differentiable, $\sigma(0)=0$, and its derivative σ' satisfies $0<m \leqq \sigma'(u) \leqq M < \infty$ on R. Let $r(t,\cdot): R \to L^2$ be a.p. in t with respect to the L^2 norm. Then each solution $u(t,\xi)$ of* (2) *such that $u(t,\cdot) \in L^2$ for $t \geqq 0$ is a.a.p. and approaches a unique generalized solution of* (2) *which is L^2-a.p. as $t \to \infty$. If $r(t,\cdot)$ is of bounded variation for t in each compact interval of R, then for each $u_0 \in L^2$ with $u_0(0) = u_1(0) = 0$, u_0 and u_0' absolutely continuous on* $[0,1]$, *and $u_0'' \in L^2$, there exists a solution*

$u(t, \xi)$ of (2) *such that $u(0, \xi) = u_0(\xi)$, $0 \leqq \xi \leqq 1$, and $u(t, \xi)$ is a.a.p. and approaches a unique generalized a.p. solution of* (2).

The concept of generalized solution of (2) is in terms of the general definition given in § 2. It is not immediately clear that the generalized a.p. solution is a strong solution of (2) in the sense as defined in § 2. It is the purpose of future investigations to determine whether conditions exist sufficient for the existence of strong a.p. solutions of (1) as well as (2).

APPLICATION OF ACCRETIVE OPERATORS THEORY TO THE RADIATIVE TRANSFER EQUATIONS*

B. MERCIER†

Abstract. Under some restrictive assumptions about opacities, we show that the radiative transfer equations have the form $(du/dt)+\mathscr{A}u+\mathscr{B}u=0$, where $\mathscr{A}$ is m-accretive and $\mathscr{B}$ is Lipschitz. Mathematically, this gives existence and uniqueness of the solution. We also show that the maximum principle applies. Assuming that opacities are decreasing with respect to temperature, we are able to prove that $\mathscr{B}$ itself is accretive. Finally, we derive from this analysis an algorithm for solving the radiative transfer equations which has some nice properties.

Key words. nonlinear operators, accretive operators, contraction semi-groups, radiative transfer, splitting algorithms, transport equation

AMS(MOS) subject classifications. 47, 47H06, 47H20, 85, 85A30

1. Nonlinear accretive operators theory. Let us assume we are given a real Banach space Y, which may not be reflexive. We denote by Y^* the dual space and by $\langle \cdot, \cdot \rangle$ the duality pairing between Y and Y^*. Let $\|\cdot\|$ and $\|\cdot\|_*$ denote the norms of Y and Y^*, respectively. We shall use the sets

$$s(u)=\{f\in Y^*: \|f\|_*=1, \langle u,f\rangle=\|u\|\},$$

for all $u\in Y$ such that $\|u\|\neq 0$. Let $\mathscr{A}$ denote a mapping from a nonempty subset $D(\mathscr{A})\in Y$ into Y. We shall say that $\mathscr{A}$ is an *accretive operator* if for each u_1, $u_2\in D(\mathscr{A})$ there exists an $f\in s(u_2-u_1)$ such that

$$\langle \mathscr{A}u_2-\mathscr{A}u_1, f\rangle \geqq 0.$$

In particular, if there exists a mapping $s_0: Y\rightarrow Y^*$ such that

$$s_0(u)\in s(u)$$

for all $u\in Y$, and such that

$$\langle \mathscr{A}u_2-\mathscr{A}u_1, s_0(u_2-u_1)\rangle \geqq 0 \tag{1}$$

for all u_1, $u_2\in D(\mathscr{A})$, then $\mathscr{A}$ is accretive. Furthermore, if, for some $\lambda>0$, the range of operator $\mathscr{T}+\lambda\mathscr{A}$ is equal to Y, where $\mathscr{T}$ denotes the identity of Y, we shall say that $\mathscr{A}$ is *m-accretive.* In such a case, operator $(\mathscr{T}+\lambda\mathscr{A})^{-1}$ is a contraction mapping from Y into Y (see [7]).

We now turn to the following abstract differential equation:

$$\begin{aligned}&\frac{du}{dt}+\mathscr{A}u=0\\ &u(0)=u_0\end{aligned}\qquad \text{where } u_0\in Y \text{ is given.} \tag{2}$$

* Received by the editors November 8, 1984; accepted for publication (in revised form) January 7, 1986.

† Commissariat à l'Energie Atomique, Centre d'Etudes de Limeil-Valenton, B.P. 27, 94190 Villeneuve-Saint-Georges, France.

The key idea for solving such an initial value problem is to introduce the following backward difference scheme:

$$(3)\qquad \begin{aligned} &\frac{u^{n,k+1}-u^{n,k}}{\lambda_n}+\mathscr{A}u^{n,k+1}=0,\\ &u^{n,0}=u_0 \end{aligned}$$

where $\lambda_n>0$ is a time-step that tends to zero as $n\to\infty$.

A fundamental result, due to Crandall and Liggett (see [6]), states that if $u_0\in\overline{D(\mathscr{A})}$ and $\mathscr{A}$ is m-accretive then the sequence of piecewise constant functions $u^n(t)$ defined by

$$u^n(t)=u^{n,k}\quad \text{for } k\lambda_n\leqq t<(k+1)\lambda_n$$

converges uniformly on $[0, T]$ to a limit function $u\in C^0([0, T]; Y)$, which may be considered as a *generalised solution* to problem (2). (It is actually called a mild solution (see [5]).) In particular, if problem (2) has a solution $v\in C^1$ $(0, T; X)$ such that $v(t)\in D(\mathscr{A})$ for a.e.t., then $u\equiv v$ (see [3]).

On the other hand, the mapping

$$S(t): u_0\to u(t)$$

is a contraction from $\overline{D(\mathscr{A})}$ into $\overline{D(\mathscr{A})}$ and the family $(S(t))_{t>0}$ is called the *semi-group* generated by $\mathscr{A}$.

Let us denote by F the (assumed nonempty) set of equilibrium points of $\mathscr{A}$, that is of elements $p\in\overline{D(\mathscr{A})}$ such that

$$(4)\qquad S(t)p=p$$

for all $t>0$. We have the following property:

$$(5)\qquad \|u(t)-p\|\searrow \text{ as } t\nearrow,$$

which means that the distance between the solution at time t and any equilibrium point decreases. In particular, the existence of equilibrium points ensures that the solution is bounded as time goes to infinity.

In many applications, $Y=L^1(X)$, where X is a closed subset of $\mathbb{R}^d$. In such a case, the set $s(u)$ is found to be the set of all functions $f\in L^\infty(X)$ such that

$$\begin{aligned} f(x)&=1 && \text{when } u(x)>0,\\ f(x)&=-1 && \text{when } u(x)<0,\\ |f(x)|&\leqq 1 && \text{when } u(x)=0. \end{aligned}$$

It is usually convenient to choose s_0 such that

$$(6)\qquad (s_0(u))(x)=\begin{cases} 1 & \text{when } u(x)>0,\\ -1 & \text{when } u(x)<0,\\ 0 & \text{when } u(x)=0. \end{cases}$$

We note that the sum $\mathscr{A}+\mathscr{B}$ of two accretive operators need not be accretive (see [5]). However, this is the case (see [5]) in the case where one of the operators, say $\mathscr{B}$, is continuous. This is also the case, obviously, when both operators satisfy condition (1) with the *same* s_0.

About the sum $\mathscr{A}+\mathscr{B}$ of two m-accretive operators, we shall need a result which states that if $\mathscr{A}$ is m-accretive and $\mathscr{B}$ is Lipschitz, i.e. there exists $\omega > 0$ such that

$$\|\mathscr{B}u_2-\mathscr{B}u_1\| \leqq \omega\|u_2-u_1\|$$

for all u_1, $u_2 \in Y$, then $\mathscr{A}+\mathscr{B}$ is m-accretive. This result is standard and has a simple proof; as $\mathscr{A}+\mathscr{B}$ is accretive, we need only prove that

$$u+\lambda\mathscr{A}u+\lambda\mathscr{B}u=f$$

has a solution for any $f \in X$. For this we note that

$$u \rightarrow (I+\lambda\mathscr{A})^{-1}(f-\lambda\mathscr{B}u)$$

is a strictly contractive mapping from X into itself for $\lambda > 0$ small enough.

Remark 1. When $\mathscr{B}$ is Lipschitz but not accretive, then the Crandall-Liggett result still applies. However semigroup $S(t)$ generated by $\mathscr{A}+\mathscr{B}$ is of type ω, that is

$$\|S(t)u_2-S(t)u_1\| \leqq e^{\omega t}\|u_2-u_1\|$$

where ω is the Lipschitz constant of $\mathscr{B}$.

2. Problem to be solved. Let us consider a continuous medium, assumed to be a motionless gas, in a subdomain $X \subset \mathbb{R}^3$, with boundary ∂X. In the following, we shall denote by x a generic point in the domain X and Ω a generic direction on the unit sphere S^2.

The interaction of the gas with radiation is described by the energy equation

$$\frac{\partial \varepsilon}{\partial t}+\int_0^\infty K(\nu, \varepsilon)\, d\nu \int_{S^2} (B(\nu, \varepsilon)-I)\, d\Omega=0 \tag{7}$$

where

$K \equiv K(\nu, \varepsilon)$ denotes the opacity,

$B \equiv B(\nu, \varepsilon)$ is Planck's function,

$I \equiv I(x, \Omega, \nu, t)$ is the specific intensity of radiation at frequency ν in direction Ω.

The radiation is assumed to be travelling at the speed of light c so that I satisfies the following transfer equation

$$\frac{1}{c}\frac{\partial I}{\partial t}+\Omega \cdot \frac{\partial I}{\partial x}+K(I-B)=\mathscr{D}I \tag{8}$$

where $\mathscr{D}$ denotes an integral operator defined to take into account Thomson scattering: we have

$$(\mathscr{D}I)(x, \Omega, \nu)=\int_{S^2} (K_d(\Omega', \Omega)I(x, \Omega', \nu)-K_d(\Omega, \Omega')I(x, \Omega, \nu))\, d\Omega' \tag{9}$$

where $K_d((\Omega', \Omega) \geqq 0$ denotes the scattering cross section assumed to be independent of ε and ν.

The unknown function I is subject to a *boundary condition*:

$$I(x, \Omega, \nu, t)=h(x, \Omega, \nu, t) \tag{10}$$

for $x \in \partial X$, $\nu > 0$, $t > 0$ and $\Omega \in S^2$ such that $\Omega \cdot n(x) < 0$, where $n(x)$ denotes the unit normal vector to X, directed outward. The meaning of boundary condition (10) is that the inflow specific intensity h is assumed to be known.

Finally, we supplement the system (7), (8), (10) with some *initial conditions*

$$\begin{aligned} &I(x,\Omega,\nu,0)=I_0(x,\Omega,\nu), \quad x\in X, \quad \Omega\in S^2, \quad \nu>0,\\ &\varepsilon(x,0)=\varepsilon_0(x), \qquad x\in X, \end{aligned} \tag{11}$$

where I_0 and ε_0 are given functions.

3. Choice of a functional framework. We shall introduce a Banach space Y for the couple of unknown functions

$$u(t)=\{\varepsilon(t), I(t)\}.$$

We choose

$$Y=L^1(X)\times L^1(X\times S^2\times(0,\infty)) \tag{12}$$

with

$$\|u\|\equiv\|\varepsilon\|_1+\|I\|_1 \quad \text{whenever } u\equiv\{\varepsilon, I\}. \tag{13}$$

We denote by $\|\cdot\|_1$ either the norm of $L^1(X)$ defined as

$$\|\varepsilon\|_1\equiv\int_X |\varepsilon(x)|\,dx$$

or the norm of $L^1(X\times S^2\times(0,\infty))$ defined by

$$\|I\|_1\equiv\int_X\int_{S^2}\int_0^\infty |I(x,\Omega,\nu)|\,dx\,d\Omega\,d\nu.$$

The choice (13) for the norm $\|\cdot\|$ is a natural one. Indeed, if (as they should) both $\varepsilon(t)$ and $I(t)$ are positive, then $\|u(t)\|$ is the total energy (material + radiation).

Next we shall introduce some operators $\mathscr{A}$ and $\mathscr{B}$ on space Y so that problem (7)-(11) is equivalent to

$$\frac{du}{dt}+\mathscr{A}u+\mathscr{B}u=0, \qquad u(0)=u_0 \tag{14}$$

where $u_0=\{\varepsilon_0, I_0\}$. First we define operator $\mathscr{A}$ as follows:

$$\begin{aligned} &\mathscr{A}\{\varepsilon, I\}=\left\{0, \Omega\cdot\frac{\partial I}{\partial x}-\mathscr{D}I\right\},\\ &D(\mathscr{A})=\left\{u\in X\colon u=\{\varepsilon, I\}, \Omega\cdot\frac{\partial u}{\partial x}\in L^1, I \text{ satisfies } (10)\right\}. \end{aligned} \tag{15}$$

Note that we need a trace theorem, which is proved in [4], to give meaning to the boundary condition (10). We shall assume that the inflow specific intensity (h) does not depend on t, so that $\mathscr{A}$ is independent of t. We note that $\mathscr{A}$ is unbounded.

Next, we define operator $\mathscr{B}$ as follows: for $u\in X$, $u=\{\varepsilon, I\}$, we let

$$\mathscr{B}u=\left\{-\int_0^\infty d\nu\int_{S^2} q\,d\Omega, q\right\} \tag{16}$$

where

$$q\equiv q(x,\Omega,\nu)=K(\nu,\varepsilon(x))(\varphi(\nu, I(x,\Omega,\nu))-B(\nu,\varepsilon(x)) \tag{17}$$

and

$$\varphi(\nu, I) = \max(0, \min(I, B(\nu, M))); \tag{18}$$

finally, M is a given constant.

With such a definition of operator $\mathscr{B}$, we note first that (14) coincides with the original problem (7)-(11) whenever

$$0 \leqq I(x, \Omega, \nu, t) \leqq B(\nu, M) \tag{19}$$

for $\nu > 0$, $x \in X$, $\Omega \in S^2$ and $t > 0$.

We shall prove in § 5 that the maximum principle applies to system (7)-(11) so that (19) holds for some $M > 0$ together with

$$0 \leqq \varepsilon(x, t) \leqq M. \tag{20}$$

The function $\varphi(\nu, I)$ defined in (18) is obtained from I with an appropriate truncation; if we require $\mathscr{B}$ to be Lipschitzian, then we need φ to be bounded, and if we want $\mathscr{B}$ to be accretive, we need φ to be positive, as we shall see in § 6.

4. Properties of operators $\mathscr{A}$ and $\mathscr{B}$. Let us first recall some facts about operator $\mathscr{A}$. We note that $D(\mathscr{A})$ is dense in Y (see [2]). To prove that $\mathscr{A}$ is accretive we shall need the following lemmas.

LEMMA 1. *Let W denote the space of functions I in L^1 ($\equiv L^1(X \times S^2 \times (0, \infty))$) such that $\Omega \cdot \nabla I \in L^1$. Let $\beta : \mathbb{R} \to \mathbb{R}$ be a C^1 function such that $\beta(0) = 0$ and $\beta' \in L^\infty(\mathbb{R})$. Then, for any $I \in W$, $\beta(I) \in W$ and*

$$\Omega \cdot \frac{\partial}{\partial x} \beta(I) = \beta'(I)\left(\Omega \cdot \frac{\partial I}{\partial x}\right) \quad \text{in } L^1. \tag{21}$$

To prove the result, one introduces a sequence $(I_n)_n$ of smooth functions converging to $I \in W$ (the existence of such a sequence relies on a density result; see [4]). For a given smooth I_n (21) obviously holds. The Lebesgue dominated convergence theorem is used to prove that (21) holds in the limit, after extraction of a suitable subsequence. The details are left to the reader.

LEMMA 2. *For any $I \in W$, then $|I| \in W$ and*

$$\Omega \cdot \frac{\partial}{\partial x} |I| = s_0(I)\Omega \cdot \frac{\partial I}{\partial x}.$$

Proof. For given $n \in \mathbb{N}$ we introduce the function $\beta_n : \mathbb{R} \to \mathbb{R}$ defined by

$$\beta_n(\xi) = \begin{cases} n\dfrac{\xi^2}{2} & \text{if } |\xi| \leqq \dfrac{1}{n}, \\ |\xi| - \dfrac{1}{2n} & \text{otherwise.} \end{cases}$$

We check that

$$\begin{aligned} &\text{(i)} \quad \beta_n(\xi) \to |\xi|; \\ &\text{(ii)} \quad \beta_n'(\xi) \to s_0(\xi) \end{aligned} \tag{22}$$

for all $\xi \in \mathbb{R}$ when $n \to \infty$ and that

$$|\beta_n'(\xi)| \leqq 1 \tag{23}$$

for all $\xi \in \mathbb{R}$.

Let $I \in W$ be given. From Lemma 1 we know that $\beta_n(I) \in W$ and that

$$f_n \equiv \Omega \cdot \frac{\partial}{\partial x} \beta_n(I) = \beta_n'(I)\left(\Omega \cdot \frac{\partial I}{\partial x}\right).$$

From (22)(ii) and (23) we see with Lebesgue's theorem that

$$f_n \to f \equiv s_0(I)\left(\Omega \cdot \frac{\partial I}{\partial x}\right) \quad \text{in } L^1.$$

On the other hand, using Lebesgue's theorem once again, from (22)(i) and (23) we prove that

$$\beta_n(I) \to |I| \quad \text{in } L^1.$$

If $\varphi \in C_0^\infty$ $(X \times S^2 \times (0, \infty))$ from the definition of the derivative in the distribution sense, we know that

$$\langle f_n, \varphi \rangle = -\left\langle \beta_n(I), \Omega \cdot \frac{\partial \varphi}{\partial x} \right\rangle.$$

In the limit $n \to \infty$, we get that

$$\langle f, \varphi \rangle = -\left\langle |I|, \Omega \cdot \frac{\partial \varphi}{\partial x} \right\rangle.$$

Therefore $\Omega \cdot (\partial/\partial x)|I| \in L^1$ and $f = \Omega \cdot (\partial/\partial x)|I|$ in L^1. QED

PROPOSITION 1. *Operator $\mathscr{A}$ is m-accretive.*

Proof. To show that $\mathscr{A}$ is accretive, we shall choose

$$s_0(u) = \{s_0(\varepsilon), s_0(I)\}$$

where $s_0(\varepsilon) \in L^\infty$ (X) is defined as in (6), and $s_0(I) \in L^\infty$ $(X \times S^2 \times (0, \infty))$ is defined in an analogous way.

Let $u_\alpha = \{\varepsilon_\alpha, I_\alpha\} \in D(\mathscr{A})$, $\alpha = 1, 2$. We have

$$\langle \mathscr{A}u_2 - \mathscr{A}u_1, s_0(u_2 - u_1) \rangle = \left\langle \Omega \cdot \frac{\partial}{\partial x}(I_2 - I_1) - \mathscr{D}(I_2 - I_1), s_0(I_2 - I_1) \right\rangle.$$

To prove that $\mathscr{A}$ is accretive, it suffices to prove separately that the advection operator

$$\mathscr{L} \equiv \Omega \cdot \frac{\partial}{\partial x}$$

with domain

$$D(\mathscr{L}) = \left\{ I \in L^1 : \Omega \cdot \frac{\partial I}{\partial x} \in L^1, I \text{ satisfies } (10) \right\}$$

and operator $(-\mathscr{D})$ are accretive.

To prove that $\mathscr{L}$ is accretive, we notice that from Lemma 2

$$\left[\Omega \cdot \frac{\partial}{\partial x}(I_2 - I_1)\right] s_0(I_2 - I_1) = \Omega \cdot \frac{\partial}{\partial x}|I_2 - I_1| \quad \text{in } L^1$$

provided that I_1 and $I_2 \in D(\mathscr{L})$ and that function $I \equiv |I_2 - I_1|$ satisfies

$$\Omega \cdot \frac{\partial I}{\partial x} \in L^1$$

and vanishes on the inflow boundary $\Gamma_- \times (0,\infty)$ (where $\Gamma_\pm$ denotes the subset of $\partial X \times S^2$ made with those couples $\{x, \Omega\}$ such that $\Omega \cdot n(x) \gtrless 0$).

Applying Green's formula (see [4] for a justification)

$$\int_0^\infty d\nu \int_{X\times S^2} \Omega \cdot \frac{\partial}{\partial x} I \, dx \, d\Omega = \int_0^\infty d\nu \int_{\Gamma_+} (\Omega \cdot n) I \, d\Gamma_+$$

to $I = |I_2 - I_1|$, we see that

$$\left\langle \Omega \cdot \frac{\partial}{\partial x}(I_2 - I_1), s_0(I_2 - I_1) \right\rangle \geqq 0 \text{ so that } \mathcal{L} \text{ is accretive.}$$

Since operator $\mathcal{D}$ is linear, it is sufficient to prove that

$$\langle \mathcal{D} I, s_0(I) \rangle \leqq 0. \tag{24}$$

We have

$$\int_{S^2} \left(\int_{S^2} (K_d(\Omega', \Omega) I(\Omega') - K_d(\Omega, \Omega') I(\Omega)) \, d\Omega' \right) s_0(I(\Omega)) \, d\Omega$$

$$\leqq \int_{S^2} \int_{S^2} (K_d(\Omega', \Omega) |I(\Omega')| - K_d(\Omega, \Omega') |I(\Omega)|) \, d\Omega' \, d\Omega = 0.$$

Hence from (9) we get (24).

Finally, since the problem

$$I + \lambda \Omega \cdot \frac{\partial I}{\partial x} = f,$$

with I subject to boundary condition (9), can be solved for any $f \in L^1(X)$, provided h satisfies

$$\int_0^\infty d\nu \int_{\Gamma_-} (\Omega \cdot n) h \, d\Gamma_- < +\infty,$$

which we shall assume (see [4]), operator $\mathcal{L}$ is m-accretive.

As $\mathcal{D}$ is Lipschitz, we have that $\mathcal{L} - \mathcal{D}$ is m-accretive. QED

We now turn to operator $\mathcal{B}$. To get Lipschitz continuity of $\mathcal{B}$, we shall require some regularity on the functions

$$\varepsilon \to K(\nu, \varepsilon), \qquad \varepsilon \to B(\nu, \varepsilon).$$

Actually, we know that $\varepsilon = \varepsilon(T)$ depends on the temperature T through an *equation of state* ($\varepsilon = \rho c_v T$ in the case of a perfect gas), and that

$$B(\nu, \varepsilon(T)) = \frac{2h\nu^3}{c^2} (e^{h\nu/kT} - 1)^{-1} \tag{25}$$

where h is Planck's constant, and k Boltzmann's constant. Then the function $\varepsilon \to B(\nu, \varepsilon)$ is regular provided that the equation of state $T \to \varepsilon(T)$ is regular.

More precisely, we shall assume that there exists a constant C positive such that

$$|K(\nu, \varepsilon_1) - K(\nu, \varepsilon_2)| \leqq C |\varepsilon_1 - \varepsilon_2| \quad \textit{for all } \nu > 0, \quad \varepsilon_1, \varepsilon_2 \in \mathbb{R}, \tag{H1}$$

$$0 \leqq K(\nu, \varepsilon) \leqq C \quad \textit{for all } \nu > 0, \quad \varepsilon \in \mathbb{R} \tag{H2}$$

and that there exists $\beta_0, \beta_1 > 0$ such that

$$0 < \beta_0 \leqq \frac{d\varepsilon}{dT} \leqq \beta_1. \tag{H3}$$

Furthermore, for technical reasons we shall modify function B for $\varepsilon > M$ (this is without consequence if we prove that (20) holds).

Let T_M be such that $\varepsilon(T_M) = M$, for $\varepsilon > M$ we choose

$$B(\nu, \varepsilon) = B(\nu, \varepsilon(T_M)).$$

We check that, with such a modification, we have

$$\int_0^\infty B(\nu, \varepsilon(T))\, d\nu = a \min (T^4, T_M^4) \tag{26}$$

where a is some constant.

PROPOSITION 2. *Assume* (H1) (H2) (H3); *then operator* $\mathcal{B}$ *defined in* (16)-(18) *is Lipschitzian.*

Proof. Let $u_\alpha = \{\varepsilon_\alpha, I_\alpha\} \in Y$, $\alpha = 1, 2$ be given, and

$$q_\alpha \equiv K(\nu, \varepsilon_\alpha)(\varphi(\nu, I_\alpha) - B(\nu, \varepsilon_\alpha)).$$

As

$$\mathcal{B}u_\alpha \equiv \left\{ -\int_0^\infty d\nu \int_{S^2} q_\alpha\, d\Omega, q_\alpha \right\}$$

for $\alpha = 1, 2$, we have

$$\|\mathcal{B}u_2 - \mathcal{B}u_1\| \leqq 2 \int_X dx \int_0^\infty d\nu \int_{S^2} |q_2 - q_1|\, d\Omega.$$

We notice that

$$\begin{aligned} q_2 - q_1 &= K(\varepsilon_2)(\varphi(I_2) - B(\varepsilon_2)) - K(\varepsilon_1)(\varphi(I_1) - B(\varepsilon_1)) \\ &= K(\varepsilon_2)(\varphi(I_2) - \varphi(I_1)) + (K(\varepsilon_2) - K(\varepsilon_1))\varphi(I_1) + K(\varepsilon_2)(B(\varepsilon_1) - B(\varepsilon_2)) \\ &\quad + (K(\varepsilon_1) - K(\varepsilon_2))B(\varepsilon_1). \end{aligned}$$

From (H2) and (H1) we get

$$|q_1 - q_2| \leqq C|I_2 - I_1| + C(B(M) + B(\varepsilon_1))|\varepsilon_2 - \varepsilon_1| + C|B(\varepsilon_1) - B(\varepsilon_2)|. \tag{27}$$

Applying (26) we get

$$\begin{aligned} \int_0^\infty |B(\nu, \varepsilon(T_1)) - B(\nu, \varepsilon(T_2))|\, d\nu &= a[\min (T_1^4, T_M^4) - \min (T_2^4, T_M^4)] \\ &\leqq 4aT_M^3(T_1 - T_2) \leqq C'(\varepsilon(T_1) - \varepsilon(T_2)) \end{aligned}$$

where $C' = 4aT_M^3/\beta_0$.

Finally, when we integrate (27) for $x \in X$, $\Omega \in S^2$, $\nu > 0$, we obtain

$$\|\mathcal{B}u_2 - \mathcal{B}u_1\| \leqq 2C\|I_2 - I_1\|_1 + 16\pi C\left(\int_0^\infty B(M)\, d\nu\right)\|\varepsilon_2 - \varepsilon_1\|_1 + 8\pi CC'\|\varepsilon_1 - \varepsilon_2\|_1.$$

QED

Applying the Crandall-Liggett Theorem (see Remark 1), we obtain the following existence result.

COROLLARY 1. *If assumptions* (H1) (H2) (H3) *hold, then for any given* $t_0 > 0$ *problem* (14) *has a unique solution*

$$u \in C^0([0, t_0]; Y).$$

About the asymptotic behavior of solution $u(t)$ as time $t\to\infty$, we have no information as yet. Note that in the general case of an m-accretive $\mathcal{A}$ perturbed by a Lipschitz $\mathcal{B}$, the solution $u(t)$ might grow exponentially as $t\to\infty$.

Remark 2. According to inequalities (19), (20) we can restrict ourselves to an energy interval $[0, M]$. Then assumptions (H1) and (H2) need to hold only for ε_1, ε_2, $\varepsilon\in[0, M]$.

Indeed, outside this interval we can modify opacity $K(\nu, \varepsilon)$ in order to get the desired assumptions.

5. Maximum principle. To solve the original problem ((7)-(11)), we have introduced an operator $\mathcal{B}$ which involves $\varphi(I)$ instead of I, where $\varphi(I)$ is a truncation of I defined in (18). We needed such a truncation to get a Lipschitz $\mathcal{B}$. However we have yet to prove that the solution u of (14) is also a solution of the original problem. We proceed in the following way.

Assume that the initial energy ε^0 satisfies

$$N'\leqq\varepsilon^0(x)\leqq N \tag{28}$$

for all $x\in X$, with $0\leqq N'\leqq N\leqq M$. We also assume that

$$B(\nu, N')\leqq I^0(x, \Omega, \nu)\leqq B(\nu, N) \tag{29}$$

and

$$B(\nu, N')\leqq h(x, \Omega, \nu)\leqq B(\nu, N) \tag{30}$$

for all $x\in X$, $\Omega\in S^2$, $\nu>0$. Then, we prove that the solution $u=\{\varepsilon, I\}$ of (14) satisfies

$$N'\leqq\varepsilon(x, t)\leqq N \tag{31}$$

for almost every $x\in X$, $t>0$ and

$$B(\nu, N')\leqq I(x, \Omega, \nu, t)\leqq B(\nu, N) \tag{32}$$

for almost every $x\in X$, $\Omega\in S^2$, $\nu>0$ and $t>0$. In such a case, we have $\varphi(I)=I$ so that $u=\{\varepsilon, I\}$ is also a solution of the original problem.

To prove (31), (32) we shall require K_d (appearing in definition (9) of operator $\mathcal{D}$) to be symmetric:

$$K_d(\Omega, \Omega')=K_d(\Omega', \Omega)\quad\text{for all }\Omega,\quad \Omega'\in S^2. \tag{33}$$

LEMMA 3. *Let $v=\{e, J\}\in Y$ be such that*

$$N'\leqq e(x)\leqq N$$

for (almost) every $x\in X$, and

$$B(\nu, N')\leqq J(x, \Omega, \nu)\leqq B(\nu, N)$$

for (almost) every $x\in X$, $\Omega\in S^2$, $\nu>0$. Let $u=\{\varepsilon, I\}$ denote the solution of

$$u+\lambda(\mathcal{A}u+\mathcal{B}u)=v.$$

Then, one has

$$N'\leqq\varepsilon(x)\leqq N,$$

$$B(\nu, N')\leqq I(x, \Omega, \nu)\leqq B(\nu, N)$$

for (almost) every $x\in X$, $\Omega\in S^2$, $\nu>0$.

Proof. We shall use operator $s_+: L^1(X)\to L^\infty(X)$ defined as follows, if $\varepsilon\in L^1(\mathbb{R})$, $s_+(\varepsilon)$ denotes the function equal to one where $\varepsilon>0$, and equal to zero where $\varepsilon\leqq0$.

We note that ε and I satisfy

$$(34)\quad \varepsilon - N + \lambda \int_0^\infty K(\varepsilon) \int_{S^2} ((B(\varepsilon) - B(N)) - (\varphi(I) - B(N)))\, d\Omega\, d\nu = e - N,$$

$$(35)\quad \begin{aligned} I - B(N) + \lambda\Omega \cdot \frac{\partial}{\partial x}(I - B(N)) + \lambda K(\varepsilon)(\varphi(I) - B(N)) - (B(\varepsilon) - B(N)) \\ = \lambda\mathcal{D}(I - B(N)) + J - B(N), \end{aligned}$$

since

$$\frac{\partial}{\partial x} B(N) = 0$$

and, by virtue of (33)

$$\mathcal{D}(B(N)) = B(N) \int_{S^2} (K_d(\Omega', \Omega) - K_d(\Omega, \Omega'))\, d\Omega' = 0.$$

We multiply (34) by $v \equiv s_+(\varepsilon - N)$ and integrate for $x \in X$.

On the other hand, we multiply (35) by $w = s_+(I - B(N))$ and integrate for $x \in X$, $\Omega \in S^2$ and $\nu \in (0, \infty)$.

We note that

$$(\varepsilon - N)s_+(\varepsilon - N) = (\varepsilon - N)_+$$

and since $\varepsilon \to B(\nu, \varepsilon)$ is increasing (see (25) and (H3))

$$(B(\varepsilon) - B(N))s_+(\varepsilon - N) = (B(\varepsilon) - B(N))_+.$$

On the other hand,

$$(I - B(N))s_+(I - B(N)) = (I - B(N))_+$$

and (since $M \geqq N$)

$$(\varphi(I) - B(N))s_+(I - B(N)).$$

We obtain by addition

$$\begin{aligned} &\|(\varepsilon - N)_+\|_1 + \|(I - B(N))_+\|_1 + \lambda\left\langle \Omega \cdot \frac{\partial}{\partial x}(I - B(N)), w \right\rangle \\ &+ \lambda \int_X \int_0^\infty K(\varepsilon) \int_{S^2} ((B(\varepsilon) - B(N))_+ - w(B(\varepsilon) - B(N)))\, d\Omega\, d\nu\, dx \\ &+ \lambda \int_X dx \int_0^\infty K(\varepsilon) \int_{S^2} [(\varphi(I) - B(N))_+ - v(\varphi(I) - B(N))]\, d\Omega\, d\nu \\ &= \lambda\langle \mathcal{D}(I - B(N)), w\rangle + \langle e - N, v\rangle + \langle J - B(N), w\rangle. \end{aligned}$$

We note that

$$(B(\varepsilon) - B(N))_+ - w(B(\varepsilon) - B(N)) = (1 - w)(B(\varepsilon) - B(N))_+ + w(B(\varepsilon) - B(N))_- \geqq 0$$

since $0 \leqq w \leqq 1$. Similarly,

$$(\varphi(I) - B(N))_+ - v(\varphi(I) - B(N)) = (1 - v)(\varphi(I) - B(N))_+ + v(\varphi(I) - B(N))_- \geqq 0$$

since $0 \leqq v \leqq 1$.

On the other hand, we have (using a result similar to the one proved in Lemma 2)

$$\Omega\cdot\frac{\partial}{\partial x}(I-B(N))s_+(I-B(N))=\Omega\cdot\frac{\partial}{\partial x}(I-B(N))_+;$$

therefore, by integration by parts, we obtain

$$\int_X dx\int_{S^2}\Omega\cdot\frac{\partial}{\partial x}(I-B(N))_+\,d\Omega=\int_{\Gamma_+}(\Omega\cdot n)(I-B(N))_+\,d\Gamma_+\geqq 0$$

(note that $(I-B(N))_+$ vanishes on Γ_- by assumption (see (30)).

Let $\tilde I\equiv I-B(N)$. Then we have

$$\int_{S^2}\left(\int_{S^2}(K_d(\Omega',\Omega)\tilde I(\Omega')-K_d(\Omega,\Omega')\tilde I(\Omega))\,d\Omega'\right)s_+(\tilde I(\Omega))\,d\Omega$$

$$=\int_{S^2\times S^2}K_d(\Omega',\Omega)(\tilde I_+(\Omega')-\tilde I_-(\Omega'))s_+(\tilde I(\Omega))\,d\Omega'\,d\Omega$$

$$-\int_{S^2\times S^2}K_d(\Omega,\Omega')\tilde I_+(\Omega)\,d\Omega\,d\Omega'$$

$$\leqq-\int_{S^2\times S^2}K_d(\Omega',\Omega)\tilde I_-(\Omega')\,d\Omega'\,d\Omega\leqq 0;$$

hence $\langle\mathcal{D}\tilde I, s_+(\tilde I)\rangle\leqq 0$.

Finally, we have

$$\|(\varepsilon-N)_+\|_1+\|(I-B(N))_+\|_1\leqq 0,$$

which proves that

$$\varepsilon(x)\leqq N\quad\text{for a.e. } x\in X,$$

$$I(x,\Omega,\nu)\leqq B(\nu,N)\quad\text{for a.e. } x\in X,\quad \Omega\in S^2,\quad \nu>0.$$

In an analogous way, we could prove that

$$\|(\varepsilon-N')_-\|_1+\|(I-B(N'))_-\|_1\leqq 0.$$ QED

We are now able to prove the main result.

THEOREM 1. *Assume that initial solution* $u_0=\{\varepsilon_0,I_0\}$ *satisfies* (28), (29) *and that boundary condition h satisfies* (30). *Then the solution* $u(t)=\{\varepsilon(t),I(t)\}$ *of problem* (14) *satisfies* (31), (32). *Furthermore, it is also the solution of the original problem* (7)-(11).

Proof. From the Crandall-Liggett Theorem (see § 1) we know that solution $u(t)$ is the uniform limit as $n\to\infty$ of the piecewise constant functions $u^n(t)$ defined by

$$u^n(t)=u^{n,k}\quad\text{for } k\lambda_n\leqq t\leqq(k+1)\lambda_n$$

where $u^{n,k}$ is defined inductively by

$$\frac{u^{n,k+1}-u^{n,k}}{\lambda_n}+\mathcal{A}u^{n,k+1}+\mathcal{B}u^{n,k+1}=0.$$

Let $u^{n,k}\equiv\{\varepsilon^{n,k},I^{n,k}\}$. If we have

(36) $$N'\leqq\varepsilon^{n,k}(x)\leqq N$$

for (almost every) $x\in X$, and

(37) $$B(\nu,N')\leqq I^{n,k}(x,\Omega,\nu)\leqq B(\nu,N)$$

for (almost every) $x \in X$, $\Omega \in S^2$, $\nu > 0$, then, applying Lemma 3 with $v = u^{n,k}$, $u = u^{n,k+1}$ and $\lambda = \lambda_n$, we have (36), (37) at index $k+1$. Since (36) and (37) hold for $k = 0$, then they hold for all $k > 0$. Since they also hold for all $n > 0$, making $n \to \infty$, we get (31) and (32). As noticed above, since $0 \leqq N' \leqq N \leqq M$, $u(t)$ is also a solution of (7) to (11). QED

The maximum principle we just proved has 3 applications:

(a) It shows that solution $u(t)$ of (14) is actually a solution of the original problem;

(b) It shows that solution $u(t)$ remains bounded in L^∞ as $t \to \infty$;

(c) It shows that $u(t)$ is positive.

Remark 3. Assume that $u + \lambda(\mathscr{A}u + \mathscr{B}u) = v$ with $v = \{e, J\}$ and $u = \{\varepsilon, I\}$ as in Lemma 3. We easily prove that, if $h = 0$,

$$\int_X \varepsilon\, dx + \int_X dx \int_0^\infty d\nu \int_{S^2} I\, d\Omega \leqq \int_X e\, dx + \int_X dx \int_0^\infty d\nu \int_{S^2} J\, d\Omega.$$

Using an argument similar to the one used for Theorem 1, we have

$$\int_X \varepsilon(t)\, dx + \int_X dx \int_0^\infty d\nu \int_{S^2} I(t)\, d\Omega \leqq \|u_0\|,$$

which shows that the energy is decreasing (or conserved if $X = \mathbb{R}^3$).

Remark 4. In a way similar to Remark 2, we note that assumptions (H1) and (H2) need to hold only for ε_1, ε_2, $\varepsilon \in [N', N]$. If opacities are infinite for $\varepsilon = 0$, as they should be, then our existence result applies only for $N' > 0$.

6. Accretiveness of operator $\mathscr{B}$. We shall now prove that operator $\mathscr{B}$ itself is accretive under some new assumptions (see (H4) and (H5) below). Actually, the accretiveness of $\mathscr{B}$ is not very useful information if we assume (H1) and (H2) since we already have existence, uniqueness, and uniform L^∞ bounds for $t \to \infty$. However, besides mathematical curiosity, the accretiveness of $\mathscr{B}$ is of fundamental importance for the case where $K(\nu, \varepsilon)$ is infinite either for $\nu = 0$ (see [10]) or for $\varepsilon = 0$, for which we refer to Golse and Perthame [8].

We assume the following:

(H4) for all $\nu > 0$, function $\varepsilon \to K(\nu, \varepsilon)$ is decreasing,

(H5) for all $\nu > 0$, function $\varepsilon \to K(\nu, \varepsilon)B(\nu, \varepsilon)$ is increasing.

Assumptions (H4) and (H5) should hold for all $\varepsilon \in \mathbb{R}$; however, as noticed in Remark 4, they need only be satisfied in some interval $[N', N]$ related to the initial and boundary data.

Remark 5. To understand the significance of assumptions (H4) and (H5) we note that if I is given, and is independent of t, then (7) is just an autonomous ordinary differential equation depending on a parameter $x \in X$.

Let

$$\psi(\varepsilon) \equiv 4\pi \int_0^\infty K(\nu, \varepsilon)(B(\nu, \varepsilon) - E(\nu))\, d\nu$$

where

$$E \equiv \frac{1}{4\pi} \int_{S^2} I\, d\Omega.$$

Then (7) can be written as

$$\frac{d\varepsilon}{dt} + \psi(\varepsilon) = 0$$

(for given $x \in X$). If we assume that ψ is increasing then $\psi(\varepsilon^*) = 0$ has a unique solution, and $\varepsilon(t) \to \varepsilon^*$, as $t \to \infty$, whatever ε_0. If assumptions (H4) or (H5) were violated, then limit ε^* of $\varepsilon(t)$ as $t \to \infty$ could depend on the initial value at $t = 0$, or $\varepsilon(t)$ could even diverge as $t \to \infty$.

The case where I is given is a special case, but corresponds physically to the case of an optically thin medium submitted to a constant inflow intensity h (see (10)). As opacity $K(\varepsilon)$ is small, the relaxation time of the gas is large compared to the propagation time connected with speed of light c. In other words, we get $I = h$ everywhere before $\varepsilon(t)$ has significantly changed from its starting value ε_0.

We prove the following lemma.

LEMMA 4. *If assumptions* (H4) *and* (H5) *hold, then operator* $\mathcal{B}$ *defined in* (16) *is accretive.*

Proof. We shall first prove that

$$\langle \mathcal{B}u_2 - \mathcal{B}u_1, s_+(u_2 - u_1) \rangle \geqq 0 \tag{38}$$

for all $u_1, u_2 \in Y$ where $s_+ : Y \to Y^*$ is defined by

$$s_+(u) = \{s_+(\varepsilon), s_+(I)\}$$

for all $u = \{\varepsilon, I\} \in Y$ and where s_+ is defined as before.

Let

$$q_\alpha \equiv K(\varepsilon_\alpha)(\varphi(I_\alpha) - B(\varepsilon_\alpha)), \qquad \alpha = 1, 2$$

where $\{\varepsilon_\alpha, I_\alpha\} = u_\alpha$, $\alpha = 1, 2$. We have

$$\mathcal{B}u_2 - \mathcal{B}u_1 = \left\{ \int_0^\infty d\nu \int_{S^2} (q_1 - q_2)\, d\Omega, q_2 - q_1 \right\}.$$

Then

$$\langle \mathcal{B}u_2 - \mathcal{B}u_1, s_+(u_2 - u_1) \rangle = \int_X dx \int_0^\infty d\nu \int_{S^2} (v - w)(q_1 - q_2)\, d\Omega$$

where $v \equiv s_+(\varepsilon_2 - \varepsilon_1)$ and $w \equiv s_+(I_2 - I_1)$. Thus

$$\begin{aligned} &\langle \mathcal{B}u_2 - \mathcal{B}u_1, s_+(u_2 - u_1) \rangle \\ &= \int_X dx \int_0^\infty d\nu \int_{S^2} (v - w)(K(\varepsilon_2)B(\varepsilon_2) - K(\varepsilon_1)B(\varepsilon_1))\, d\Omega \\ &+ \int_X dx \int_0^\infty d\nu \int_{S^2} (w - v)(K(\varepsilon_2)\varphi(I_2) - K(\varepsilon_1)\varphi(I_1))\, d\Omega. \end{aligned} \tag{39}$$

Let

$$A \equiv K(\varepsilon_2)B(\varepsilon_2) - K(\varepsilon_1)B(\varepsilon_1).$$

From (H5) and the definition of v, we get $vA = (A)_+$.

On the other hand, writing $A = A_+ - A_-$ we have $(v - w)A = (1 - w)A_+ + wA_-$. As function $w = s_+(I_2 - I_1)$ satisfies $0 \leqq w \leqq 1$ a.e. for $x \in X$, $\nu > 0$, $\Omega \in S^2$, we obtain $(v - w)A \geqq 0$ which shows that the first term in the right-hand side of (39) is positive. Let us show that the second term is also positive.

Let $y \equiv w - v$ and $z \equiv K(\varepsilon_2)\varphi(I_2) - K(\varepsilon_1)\varphi(I_1)$. We notice that

$$y(x, \Omega, \nu) = \begin{cases} 1 & \text{if } I_2(x, \Omega, \nu) > I_1(x, \Omega, \nu) \text{ and } \varepsilon_2(x) \leqq \varepsilon_1(x), \\ -1 & \text{if } \varepsilon_2(x) > \varepsilon_1(x) \text{ and } I_2(x, \Omega, \nu) \leqq I_1(x, \Omega, \nu), \\ 0 & \text{otherwise.} \end{cases}$$

In case $y=1$, we check that $z \geqq 0$, since, from (H4), $K(\varepsilon_2) \geqq K(\varepsilon_1)$ and $\varphi(I_2) \geqq \varphi(I_1)$. In case $y=-1$, we check that $z \leqq 0$, since (from (H4)) $K(\varepsilon_1) \leqq K(\varepsilon_2)$ and $\varphi(I_2) \leqq \varphi(I_1)$.

Finally, we have proved that $yz \geqq 0$ for all $x \in X$, $\Omega \in S^2$, $\nu > 0$, which suffices to prove that the second term in the right-hand side of (39) is positive, and proves (38).

Permuting indices 1 and 2, we also get

$$\langle \mathscr{B}u_1 - \mathscr{B}u_2, s_+(u_1-u_2)\rangle \geqq 0. \tag{40}$$

As

$$s_0(u_2-u_1) = s_+(u_2-u_1) - s_+(u_1-u_2)$$

we obtain

$$\langle \mathscr{B}u_2 - \mathscr{B}u_1, s_0(u_2-u_1)\rangle \geqq 0$$

by summation of (38) and (40). QED

Applying a result proved at the end of § 1, we obtain the following.

COROLLARY 2. *If assumptions* (H1) *to* (H5) *hold, then operator* $\mathscr{A}+\mathscr{B}$ *is m-accretive.*

As a consequence of Corollary 2, we learn that the distance between $u(t)$ and any equilibrium point u is decreasing in the energy norm.

We refer the reader to [8] and [10] for more useful applications of the accretiveness of $\mathscr{B}$.

7. Operator splitting algorithms for solving the radiative transfer equations. Each time one has to solve a problem of the form

$$\begin{aligned} &\frac{du}{dt} + \mathscr{A}u + \mathscr{B}u = 0, \\ &u(0) = u_0, \end{aligned} \tag{41}$$

one can use operator splitting methods like

$$\begin{aligned} &\text{(i)} \quad \frac{u^{n+1/2} - u^n}{\Delta t} + \mathscr{A}u^{n+1/2} = 0, \\ &\text{(ii)} \quad \frac{u^{n+1} - u^{n+1/2}}{\Delta t} + \mathscr{B}u^{n+1} = 0 \end{aligned} \tag{42}$$

or

$$\begin{aligned} &\text{(i)} \quad u^{n+1/2} = S_{\mathscr{A}}(\Delta t)u^n, \\ &\text{(ii)} \quad u^{n+1} = S_{\mathscr{B}}(\Delta t)u^{n+1/2} \end{aligned} \tag{43}$$

where $S_{\mathscr{A}}(t)$ and $S_{\mathscr{B}}(t)$ denote the semigroups generated by operators $\mathscr{A}$ and $\mathscr{B}$, respectively.

If $\mathscr{A}$ and $\mathscr{B}$ are m-accretive, then each one of these algorithms is unconditionally stable, since, in such a case, the operators

$$(\mathscr{T}+\Delta t\mathscr{A})^{-1}, \quad (\mathscr{T}+\Delta t\mathscr{B})^{-1}, \quad S_{\mathscr{A}}(\Delta t), \quad S_{\mathscr{B}}(\Delta t)$$

are contractions for all $\Delta t > 0$.

We refer the reader to [9] for convergence of such algorithms, as $\Delta t \to 0$, in the case where Y is a Hilbert space.

In the case where $\mathscr{A}$ and $\mathscr{B}$ are defined as in § 2, we see that operator splitting methods introduce a decomposition of time step Δt into two so-called "fractionary steps." The first half-step corresponds to *linear transport* of specific intensity I at speed c, coupled with Thomson diffusion. The second half-step corresponds to local *relaxation of radiation* with material energy. We note that the first half-step is global but linear, whereas the second half-step is nonlinear but local.

Practically, for solving the linear transport part, one has a choice between Monte Carlo methods, or finite element methods. Usually, such methods give a piecewise constant estimate of specific intensity I on some spatial mesh of the domain; material energy ε is chosen piecewise constant on the same mesh.

We note that solving (42)(ii) or (43)(ii) can be performed cell by cell since x is only a parameter for operator $\mathscr{B}$.

Let Q denote some cell of the given mesh: solving (42)(ii) on cell Q amounts to solving

$$(44)\quad \begin{aligned} &\text{(i)} && \varepsilon_Q^{n+1}+\Delta t\int_0^\infty d\nu\int_{S^2} K(\varepsilon_Q^{n+1})(B(\varepsilon_Q^{n+1})-I_Q^{n+1})\,d\Omega=\varepsilon_Q^n,\\ &\text{(ii)} && I_Q^{n+1}+\Delta t K(\varepsilon_Q^{n+1})(I_Q^{n+1}-B(\varepsilon_Q^{n+1}))=I_Q^n. \end{aligned}$$

From (34)(ii) (which is linear w.r.t. I_Q^{n+1}) we get

$$I_Q^{n+1}=\frac{I_Q^n+\Delta t(KB)(\varepsilon_Q^{n+1})}{1+\Delta t K(\varepsilon_Q^{n+1})},$$

which can be substituted in (44)(i). The result is a scalar nonlinear equation of the following type:

$$(45)\qquad f(\varepsilon_Q^{n+1})=\varepsilon_Q^n.$$

It can be seen that, if (H4) and (H5) hold, then f is monotone increasing and (45) has a unique solution; otherwise, for Δt large enough, f may not be monotone, so that (45) may have more than one solution. In such a case, it is not clear which one we should select. Then, from a numerical point of view, assumptions (H4) and (H5), which imply accretiveness, have some useful properties.

In the case where the discrete ordinate method is used to discretize both Ω and ν, (43)(ii) is a system of ordinary differential equations that is more difficult to solve than (42)(ii).

On the other hand, when the Monte Carlo method is used, it is *not* more difficult to solve (43)(i) than (42)(i).

This is why we prefer the following mixed algorithm:

$$(46)\quad \begin{aligned} &\text{(i)} && u^{n+1/2}=S_{\mathscr{A}}(\Delta t)u^n,\\ &\text{(ii)} && u^{n+1}=(\mathscr{T}+\Delta t\mathscr{B})^{-1}u^{n+1/2}. \end{aligned}$$

Note that each one of these algorithms is at most first order accurate with respect to Δt. It is also possible to use second order accurate algorithms (see [9]). However, these operator splitting algorithms, which are very well suited to optically thin media, are fairly inefficient when applied to optically thick media. In fact, in the latter case, radiation and material are strongly coupled since $K(\varepsilon)$ is large, which requires very small time steps Δt.

Acknowledgment. The author would like to thank the referee for many appropriate remarks which have been helpful with respect to mathematical rigor.

ESTIMATES FOR CONSERVATION LAWS WITH LITTLE VISCOSITY*

CONSTANTINE M. DAFERMOS†

Abstract. We consider the parabolic system that is generated by adding "artificial viscosity" to the equations of one-dimensional nonlinear elasticity. We construct families of entropies that induce a priori bounds on solutions, independent of the viscosity. The entropies have exponential growth in the case of strain hardening and polynomial growth in the case of strain softening. In particular, we recover the standard theory of invariant regions.

Key words. vanishing viscosity, Riemann invariants, entropy

AMS (MOS) subject classification. 35L65

1. Introduction.

Consider the family of parabolic equations

$$\begin{aligned} &\partial_t u - \partial_x v + f(u, v) = \nu \partial_x^2 u, \\ &\partial_t v - \partial_x \sigma(u) + g(u, v) = \nu \partial_x^2 v, \end{aligned} \tag{1.1}$$

where $\sigma(u)$ is a given smooth, strongly monotone function on $(-\infty, \infty)$,

$$\sigma'(u) = a^2(u), \quad a(u) > 0, \quad -\infty < u < \infty. \tag{1.2}$$

$f(u, v)$ and $g(u, v)$ are given smooth functions on $(-\infty, \infty) \times (-\infty, \infty)$, and ν is a positive parameter that measures the "viscosity."

We view (1.1) as a singular perturbation of the strictly hyperbolic system

$$\begin{aligned} &\partial_t u - \partial_x v + f(u, v) = 0, \\ &\partial_t v - \partial_x \sigma(u) + g(u, v) = 0. \end{aligned} \tag{1.3}$$

The method of *vanishing viscosity* seeks to identify and construct admissible discontinuous solutions of the Cauchy problem for (1.3) as limits of solutions $\{u(x, t), v(x, t)\}$ of the Cauchy problem for (1.1), with $\nu \downarrow 0$. To carry this program out, one needs a priori bounds on $\{u(x, t), v(x, t)\}$, independent of ν, sufficiently strong to induce sequences that are convergent almost everywhere. A bound on the total variation of $\{u(x, t), v(x, t)\}$ would be ideal for that purpose, but no estimates of this type are presently available. A weaker, L^∞, estimate for $\{u(x, t), v(x, t)\}$ would induce sequences convergent in L^∞ weak $*$ but this would not suffice, in itself, to guarantee that the limit is a solution of (1.3). Nevertheless, the theory of compensated compactness yields (DiPerna [2], Rascle [6]) that when $\sigma(u)$ has isolated inflection points, any sequence of solutions of (1.1) converging in L^∞ weak $*$ converges necessarily almost everywhere.

The standard vehicle for establishing uniform L^∞ bounds for solutions of (1.1) is the method of Chueh, Conley and Smoller [1], which applies if and only if $\sigma(u)$ has a single inflection point, say at u_0, being convex on (u_0, ∞) and concave on $(-\infty, u_0)$,

and

$$[\operatorname{sgn}(u-u_0)]a(u)f(u,v)+[\operatorname{sgn} v]g(u,v)\geqq 0 \tag{1.4}$$

holds for $|u|$, $|v|$ sufficiently large. Under these conditions, the level curves of the *Riemann invariants*

$$r(u,v):=v+\int_{u_0}^{u} a(w)\,dw, \qquad s(u,v):=v-\int_{u_0}^{u} a(w)\,dw \tag{1.5}$$

confine a nested family of open, bounded, positively invariant regions for (1.1) whose union covers the entire u-v plane. (In fact, (1.4) simply states that the vector field $\{f(u,v), g(u,v)\}$ points towards the exterior of these regions.) Then the range of the solution of the Cauchy problem for (1.1) is trapped inside one of these invariant regions, determined solely by the initial data.

It is not to be expected that solutions $\{u(x,t), v(x,t)\}$ of the Cauchy problem for (1.1) will be bounded in L^∞, uniformly in ν, for arbitrary $\sigma(u)$. For instance, considering that, in the isentropic flow of an ideal gas (the flow is described by equations of the form (1.3)), vacuum may develop over regions of space-time, one should anticipate that $u(x,t)$ will not stay bounded from above, uniformly in ν, when $\sigma(u)$ is concave for u large. Still one hopes that (perhaps weaker than L^∞) bounds for $\{u(x,t), v(x,t)\}$ hold under assumptions less stringent than those required for the existence of invariant regions. For example, in the homogeneous case $f(u,v)\equiv g(u,v)\equiv 0$, it is reasonable to expect strong bounds when $\sigma(u)$ is convex for u large and concave for u small, irrespectively of the number of inflection points in between. In fact it is plausible that estimates of a certain type apply, even when $\sigma(u)$ is concave for u large and/or convex for u small, provided $\sigma''(u)$ decays to zero, sufficiently fast, as $u\uparrow\infty$ and/or $u\downarrow-\infty$. These estimates should extend to the nonhomogeneous case, so long as the growth of $f(u,v)$ and $g(u,v)$, as $|u|$ and $|v|$ tend to infinity, is properly restricted.

The aim of this paper is to establish estimates on solutions of the Cauchy problem for (1.1), under various assumptions on $\sigma(u)$. Our approach rests on the construction of appropriate entropies for (1.3) (cf. Lax [4]). For interesting, recent, related results see Serre [7] and Venttsel' [8].

A smooth, convex function $\eta(u,v)$ on $(-\infty,\infty)\times(-\infty,\infty)$ is an *entropy* for (1.3), with *entropy flux* $q(u,v)$, if

$$\begin{aligned} q_u(u,v)&=-\sigma'(u)\eta_v(u,v),\\ q_v(u,v)&=-\eta_u(u,v) \end{aligned} \tag{1.6}$$

hold on $(-\infty,\infty)\times(-\infty,\infty)$. By eliminating $q(u,v)$ between the two equations in (1.6) and using (1.2), we deduce that $\eta(u,v)$ is an entropy for (1.3) if and only if it is a convex solution of the linear wave equation

$$\eta_{uu}(u,v)=a^2(u)\eta_{vv}(u,v), \tag{1.7}$$

on $(-\infty,\infty)\times(-\infty,\infty)$.

Assume $\eta(u,v)$ is an entropy for (1.3), with entropy flux $q(u,v)$, and let $\{u(x,t), v(x,t)\}$ be a solution of the Cauchy problem for (1.1), which tends, as $|x|\to\infty$, to a constant state $\{\bar u,\bar v\}$, for any $t\in[0,\infty)$. Upon setting

$$\begin{aligned} \bar\eta(u,v)&:=\eta(u,v)-\eta(\bar u,\bar v)-\eta_u(\bar u,\bar v)(u-\bar u)-\eta_v(\bar u,\bar v)(v-\bar v),\\ \bar q(u,v)&:=q(u,v)-q(\bar u,\bar v)+\eta_u(\bar u,\bar v)(u-\bar u)+\eta_v(\bar u,\bar v)[\sigma(u)-\sigma(\bar u)], \end{aligned} \tag{1.8}$$

we verify easily the familiar identity

$$\begin{aligned}(1.9)\qquad &\partial_t\bar{\eta}(u,v)+\partial_x\bar{q}(u,v)+\bar{\eta}_u(u,v)f(u,v)+\bar{\eta}_v(u,v)g(u,v)\\ &\quad=\nu\partial_x^2\bar{\eta}(u,v)-\nu\{\eta_{uu}(u,v)(\partial_x u)^2+2\eta_{uv}(u,v)(\partial_x u)(\partial_x v)+\eta_{vv}(u,v)(\partial_x v)^2\},\end{aligned}$$

which induces, by virtue of the convexity of $\eta(u, v)$, the inequality

$$\begin{aligned}(1.10)\qquad &\int_{-\infty}^{\infty}\bar{\eta}(u(x,t),v(x,t))\,dx+\int_0^t\int_{-\infty}^{\infty}\{\bar{\eta}_u(u,v)f(u,v)+\bar{\eta}_v(u,v)g(u,v)\}\,dx\,d\tau\\ &\quad\leqq\int_{-\infty}^{\infty}\bar{\eta}(u(x,0),v(x,0))\,dx.\end{aligned}$$

We observe that, since $\eta(u, v)$ is convex, $\bar{\eta}(u, v)$, as defined by $(1.8)_1$, is nonnegative on $(-\infty,\infty)\times(-\infty,\infty)$ and vanishes at $(\bar{u},\bar{v})$, to quadratic order.

The simplest choice of an entropy-entropy flux pair is

$$\begin{aligned}(1.11)\qquad &\eta(u,v)=\frac{1}{2}v^2+\int_0^u\sigma(w)\,dw,\\ &q(u,v)=-v\sigma(u).\end{aligned}$$

This is valid for arbitrary nondecreasing $\sigma(u)$ and yields the standard energy estimate. Our aim, however, is to derive sharper bounds and for that purpose we have to impose restrictions on $\sigma(u)$. In the homogeneous case $f(u,v)\equiv g(u,v)\equiv 0$, equations (1.3) govern, in Lagrangian coordinates, the motion of one-dimensional, nonlinear, elastic media. We need estimates that cover both the case of strain hardening and the case of strain softening.

In § 2 we assume $\sigma(u)$ is convex for u large and concave for u small (strain hardening) and construct entropies for (1.3) which grow exponentially in u and v. They induce a priori estimates on solutions of the Cauchy problem for (1.1). As a byproduct of our analysis, we get an alternative derivation of invariant regions for (1.1) and a new proof of a recent result of Roytburd and Slemrod [5]. Special entropies with exponential growth were constructed by Lax [4] and by DiPerna [3].

In § 3 we consider $\sigma(u)$ which are concave when u is large and/or convex when u is small (strain softening) and construct entropies that grow like powers of u and v. The maximal power depends on how fast $\sigma''(u)$ decays to zero, as $u\uparrow\infty$ and/or $u\downarrow-\infty$. These entropies induce L^p estimates, independent of ν, on solutions of the Cauchy problem for (1.1) with initial data in $L^p(-\infty,\infty)\cap L^2(-\infty,\infty)$.

2. Entropies with exponential growth.

In this section we assume $\sigma(u)$ is convex for u large and concave for u small, i.e., there are numbers $-\infty<u_-\leqq u_+<\infty$ such that

$$\begin{aligned}(2.1)\qquad &a'(u)\leqq 0,\qquad -\infty<u<u_-,\\ &a'(u)\geqq 0,\qquad u_+<u<\infty,\end{aligned}$$

and construct entropies for (1.3) of the form

$$(2.2)\qquad \eta(u,v)=Y(u)\cosh(kv),$$

where k is a positive constant. By virtue of (1.7), $Y(u)$ must satisfy the linear differential equation

$$(2.3)\qquad Y''(u)=k^2a^2(u)Y(u),\qquad -\infty<u<\infty.$$

For reasons to become apparent shortly, we determine $Y(u)$ as the solution of (2.3) with initial conditions

$$(2.4) \qquad Y(u_0)=1, \qquad Y'(u_0)=0,$$

where u_0 is a point at which $a(u)$ attains its maximum in the interval $[u_-, u_+]$. In particular, $Y'(u)\leqq 0$ on $(-\infty, u_0)$, $Y'(u)\geqq 0$ on (u_0, ∞) and

$$(2.5) \qquad Y(u)\geqq \cosh[k\bar{a}(u-u_0)], \qquad -\infty<u<\infty,$$

where $\bar{a}$ is the minimum of $a(u)$ over $(-\infty, \infty)$.

A simple calculation shows that $\eta(u, v)$, as defined by (2.2) with $Y(u)$ satisfying (2.3), (2.4), will be strictly convex on $(-\infty, \infty)\times(-\infty, \infty)$ if and only if

$$(2.6) \qquad |Y'(u)|\leqq ka(u)Y(u), \qquad -\infty<u<\infty.$$

As long as (2.6) holds,

$$(2.7) \qquad Y(u)\leqq \exp\left\{k\left|\int_{u_0}^{u} a(w)\,dw\right|\right\}, \qquad -\infty<u<\infty.$$

We shall test (2.6) only for $u\geqq u_0$, because the discussion for the case $u\leqq u_0$ would be completely symmetrical. We define

$$(2.8) \qquad \chi(u):=ka(u)Y(u)-Y'(u), \qquad u_0\leqq u<\infty,$$

and note that, by account of (2.3), (2.4), $\chi(u)$ is the solution of the initial value problem

$$(2.9) \qquad \chi'(u)+ka(u)\chi(u)=ka'(u)Y(u), \qquad u_0\leqq u<\infty,$$

$$(2.10) \qquad \chi(u_0)=ka(u_0).$$

It is clear that when $a'(u)\geqq 0$ on $[u_0, \infty)$, then $\chi(u)>0$ for all u in $[u_0, \infty)$. We have thus shown the following.

PROPOSITION 2.1. *If for some u_0 in $(-\infty, \infty)$*

$$(2.11) \qquad (u-u_0)a'(u)\geqq 0, \qquad -\infty<u<\infty,$$

then the function $\eta(u, v)$, defined through (2.2), (2.3), (2.4), *for any $k>0$, is a strictly convex entropy of* (1.3).

By contrast, when $a'(u)<0$ on some interval (u_0, u_1), a crude estimation using (2.9), (2.10), (2.5) shows that, for k very large, $\chi(u)<0$ on an interval $u_0<\hat{u}<u<u_1$. However, we have the following.

PROPOSITION 2.2. *Assume* (2.1) *holds. Then there is $k_0>0$ such that the function $\eta(u, v)$, defined through* (2.2), (2.3), (2.4), *for any $0<k\leqq k_0$, is a strictly convex entropy of* (1.3).

Proof. We integrate (2.9), (2.10) to get

$$(2.12) \qquad \exp\left\{k\int_{u_0}^{u} a(w)\,dw\right\}\chi(u)=ka(u_0)+k\int_{u_0}^{u} a'(w)Y(w)\exp\left\{k\int_{u_0}^{w} a(s)\,ds\right\}dw.$$

The right-hand side of (2.12) attains its minimum over $[u_0, \infty)$ at a point $u_1\in[u_0, u_+]$. We recall that u_0 is a point at which $a(u)$ attains its maximum on the interval $[u_-, u_+]$. Combining this with the observation that the function

$$Y(w)\exp\left\{k\int_{u_0}^{w} a(s)\,ds\right\}$$

is increasing on $[u_0, \infty)$, we infer that

$$\begin{aligned}\int_{u_0}^{u} a'(w)Y(w)\exp\left\{k\int_{u_0}^{w} a(s)\,ds\right\}dw \\ \geqq -\{a(u_0)-a(u_1)\}Y(u_1)\exp\left\{k\int_{u_0}^{u_1} a(s)\,ds\right\},\end{aligned} \tag{2.13}$$

for any u in $[u_0, \infty)$. From (2.12), (2.13) and (2.7) it follows that so long as χ is nonnegative on the interval (u_0, u),

$$\frac{1}{k}\exp\left\{k\int_{u_0}^{u} a(w)\,dw\right\}\chi(u) \geqq a(u_0)-\{a(u_0)-a(u_1)\}\exp\left\{2k\int_{u_0}^{u_1} a(s)\,ds\right\}. \tag{2.14}$$

Therefore, if

$$k \leqq \frac{1}{2}\left\{\int_{u_0}^{u_1} a(s)\,ds\right\}^{-1}\log\frac{a(u_0)}{a(u_0)-a(u_1)}, \tag{2.15}$$

then $\chi(u) > 0$ for all u in $[u_0, \infty)$. This completes the proof. □

We proceed to demonstrate how the entropies constructed above may induce a priori estimates on solutions $\{u(x, t), v(x, t)\}$ of the Cauchy problem for (1.1). Let us assume that, for $t \in [0, \infty)$, $\{u(x, t), v(x, t)\}$ decays, as $|x| \to \infty$, to a constant state $(\bar{u}, \bar{v})$ which is a critical point of the vector field $\{f(u, v), g(u, v)\}$, i.e.,

$$f(\bar{u}, \bar{v}) = g(\bar{u}, \bar{v}) = 0. \tag{2.16}$$

The entropy (2.2) generates, through $(1.8)_1$, a new entropy $\bar{\eta}(u, v)$, which is nonnegative on $(-\infty, \infty) \times (-\infty, \infty)$ and vanishes at $(\bar{u}, \bar{v})$ to quadratic order. We shall estimate the solution by monitoring, with the help of (1.10), the evolution of

$$\int_{-\infty}^{\infty} \bar{\eta}(u(x, t), v(x, t))\,dx.$$

As a consequence of $(1.8)_1$ and (2.16),

$$\bar{\eta}_u(u, v)f(u, v) + \bar{\eta}_v(u, v)g(u, v)$$

vanishes to quadratic order at $(\bar{u}, \bar{v})$. Furthermore, (2.2) and (2.6) yield

$$\begin{aligned}|\eta_u(u, v)| &\leqq ka(u)\eta(u, v), \\ |\eta_v(u, v)| &\leqq k\eta(u, v).\end{aligned} \tag{2.17}$$

First we consider any $a(u)$ that satisfies (2.1) and we assume

$$a(u)|f(u, v)| + |g(u, v)| \leqq L, \quad -\infty < u < \infty, \quad -\infty < v < \infty. \tag{2.18}$$

Then there is a positive constant C such that

$$|\bar{\eta}_u(u, v)f(u, v) + \bar{\eta}_v(u, v)g(u, v)| \leqq CkL\bar{\eta}(u, v). \tag{2.19}$$

From (1.10), (2.19) and Gronwall's inequality we derive the estimate

$$\int_{-\infty}^{\infty} \bar{\eta}(u(x, t), v(x, t))\,dx \leqq e^{CkLt}\int_{-\infty}^{\infty} \bar{\eta}(u(x, 0), v(x, 0))\,dx. \tag{2.20}$$

Next we turn to the special case of $a(u)$ that satisfies (2.11) and establish L^∞ estimates on $\{u(x, t), v(x, t)\}$ assuming that $\{u(x, 0), v(x, 0)\} \in L^\infty(-\infty, \infty)$ and

$$a(u)|f(u, v)| + |g(u, v)| \leqq L(|u| + |v| + 1), \quad -\infty < u < \infty, \quad -\infty < v < \infty. \tag{2.21}$$

Under this hypothesis and so long as $k \geqq \delta > 0$, we have

$$(2.22)\qquad |\bar\eta_u(u,v)f(u,v)+\bar\eta_v(u,v)g(u,v)| \leqq CkL(|u|+|v|+1)\bar\eta(u,v),$$

on $(-\infty,\infty)\times(-\infty,\infty)$, where C is a positive constant that may depend on δ but is otherwise independent of k. Upon setting

$$(2.23)\qquad W(t) := \max_x \,(|u(x,t)|+|v(x,t)|+1),$$

(1.10), (2.22) and Gronwall's inequality yield

$$(2.24)\qquad \int_{-\infty}^{\infty} \bar\eta(u(x,t),v(x,t))\,dx \leqq \exp\left\{CkL\int_0^t W(\tau)\,d\tau\right\}\int_{-\infty}^{\infty}\bar\eta(u(x,0),v(x,0))\,dx.$$

We raise both sides of (2.24) to the power $1/k$ and we pass to the limit, as $k\uparrow\infty$, taking account of (2.2), (2.5) and (2.7). In the resulting inequality we take the logarithm of both sides, thus obtaining

$$(2.25)\qquad W(t) \leqq A + CL\int_0^t W(\tau)\,d\tau, \qquad 0\leqq t<\infty,$$

where A depends solely upon the L^∞ norm of $\{u(x,0), v(x,0)\}$. Therefore, Gronwall's inequality implies that $W(t)$, and thereby also $\{u(x,t), v(x,t)\}$, are bounded, on compact time intervals, uniformly in $\nu>0$. In particular, in the homogeneous case $f(u,v)\equiv g(u,v)\equiv 0$, $\{u(x,t), v(x,t)\}$ is bounded on $(-\infty,\infty)\times[0,\infty)$, uniformly in ν.

Staying with the case of $a(u)$ that satisfies (2.11), we indicate briefly how the standard invariant regions [1] may be identified by studying the asymptotics of solutions of (2.3), as $k\uparrow\infty$. To this end, we introduce new variables:

$$(2.26)\qquad \xi := \int_{u_0}^{u} a(w)\,dw,$$

$$(2.27)\qquad Z := a(u)^{1/2}Y.$$

A straightforward calculation, using (2.3), yields

$$(2.28)\qquad \frac{d^2Z}{d\xi^2} = k^2Z - a^{-3/2}(a^{-1/2})''Z.$$

For u confined in bounded intervals, the variation of constants formula applied on (2.28) yields that, as $k\uparrow\infty$,

$$(2.29)\qquad Z(\xi) = \left[A + O\left(\frac{1}{k}\right)\right]e^{k|\xi|},$$

$$(2.30)\qquad \begin{aligned} &\frac{dZ}{d\xi}+kZ = O(1)\,e^{-k\xi}, &&\xi<0,\\ &\frac{dZ}{d\xi}-kZ = O(1)\,e^{k\xi}, &&\xi>0.\end{aligned}$$

Therefore, using (2.2), (2.27), (2.29), (2.26), (1.5) and (2.30), we obtain

$$(2.31)\qquad \lim_{k\to\infty}\eta(u,v)^{1/k} = \begin{cases} \exp[r(u,v)] & \text{if } u>u_0,\quad v>0,\\ \exp[s(u,v)] & \text{if } u<u_0,\quad v>0,\\ \exp[-s(u,v)] & \text{if } u>u_0,\quad v<0,\\ \exp[-r(u,v)] & \text{if } u<u_0,\quad v<0,\end{cases}$$

$$\frac{\eta_u(u,v)}{\eta(u,v)}=k[\operatorname{sgn}(u-u_0)]a(u)+O(1), \tag{2.32}$$
$$\frac{\eta_v(u,v)}{\eta(u,v)}=k\operatorname{sgn} v+O(1).$$

It follows from (2.32) that when k is large and (1.4) holds as a strict inequality, then the second term on the left-hand side of (1.10) is nonnegative. Hence, raising both sides of (1.10) to the power $1/k$, letting $k\uparrow\infty$, and using (2.31) we conclude that the level curves of the Riemann invariants (1.5) confine positively invariant regions for solutions of (1.1). A derivation of invariant regions that is similar in spirit to the above is given in [4].

The approach to invariant regions presented here may have some advantage over the traditional one [1] when dealing with solutions of (1.1) that are not C^2 smooth. A relevant example, arising in the theory of phase transitions, was discussed recently by Roytburd and Slemrod [5]: Assume $a(u)$ is smooth and strictly decreasing on $(-\infty,\alpha)$, it vanishes identically on the interval (α,β), and it is smooth and strictly increasing on (β,∞). Let $a(u)$ jump from a negative value to zero at $u=\alpha$ and from zero to a positive value at $u=\beta$. Thus $\sigma(u)$ is merely Lipschitz continuous on $(-\infty,\infty)$ and (1.1) does not generally have classical solutions. It is shown in [5] that, under the above hypotheses, the Cauchy problem for (1.1) has a mild solution $\{u(x,t),v(x,t)\}$ in the class of continuous functions. The standard theory of the (linear) equation of heat conduction and a straightforward "bootstrapping" argument yield that $\partial_x u$, $\partial_x v$, $\partial_t u$, $\partial_t v$, $\partial_x^2 u$, $\partial_x^2 v$ are all in $L^2((-\infty,\infty)\times(0,T))$, for any $T>0$. In particular, (1.10) is still valid under the current conditions. We may thus apply our argument, using entropies (2.2) with $k\uparrow\infty$, to infer that the level curves of the Riemann invariants (1.5) still confine positively invariant regions for solutions of (1.1). The original derivation of this result in [5] employs a mollification of $\sigma(u)$ and requires a rather lengthy argument in order to pass to the limit.

3. Entropies with polynomial growth. Here we construct entropies $\eta(u,v)$ on $(-\infty,\infty)\times(-\infty,\infty)$, which grow at infinity like the pth power of u and v and thus induce L^p estimates on solutions of the Cauchy problem for (1.1). Throughout this section we will be assuming

$$a(u)\geqq\bar{a}>0,\qquad -\infty<u<\infty, \tag{3.1}$$

but we do not impose, as yet, any conditions of convexity on $\sigma(u)$.

We shall seek convex solutions of (1.7) on $(-\infty,\infty)\times(-\infty,\infty)$ with initial conditions

$$\eta(0,v)=H(v),\quad \eta_u(0,v)=0,\quad -\infty<v<\infty, \tag{3.2}$$

where $H(v)$ is a positive, even, convex function on $(-\infty,\infty)$.

If $\eta(u,v)$ is the solution of (1.7), (3.2), we set

$$\Phi(u,v):=a(u)\eta_{vv}(u,v)-\eta_{uv}(u,v), \tag{3.3}$$
$$\Psi(u,v):=a(u)\eta_{vv}(u,v)+\eta_{uv}(u,v).$$

It follows from (1.7), (3.3) that

$$\eta_{vv}(u,v)=\frac{1}{2a(u)}\{\Phi(u,v)+\Psi(u,v)\}, \tag{3.4}$$

$$\eta_{uu}(u,v)\eta_{vv}(u,v)-\eta_{uv}^2(u,v)=\Phi(u,v)\Psi(u,v), \tag{3.5}$$

and so $\eta(u, v)$ is strictly convex on $(-\infty, \infty)\times(-\infty, \infty)$ if and only if

$$\Phi(u, v)>0, \quad \Psi(u, v)>0, \quad -\infty<u<\infty, \quad -\infty<v<\infty. \tag{3.6}$$

Combining (3.3), (3.4) and (1.7) we get

$$\begin{aligned} \Phi_u(u, v)+a(u)\Phi_v(u, v)&=\frac{a'(u)}{2a(u)}\{\Phi(u, v)+\Psi(u, v)\}, \\ \Psi_u(u, v)-a(u)\Psi_v(u, v)&=\frac{a'(u)}{2a(u)}\{\Phi(u, v)+\Psi(u, v)\}. \end{aligned} \tag{3.7}$$

$$\Phi(0, v)=\Psi(0, v)=R(v), \qquad -\infty<v<\infty, \tag{3.8}$$

where $R(v)=H_{vv}(v)$. In particular, $R(v)$ is a nonnegative even function,

$$R(-v)=R(v), \qquad -\infty<v<\infty. \tag{3.9}$$

From (3.7), (3.8) and (3.9) it follows that

$$\Psi(u, v)=\Phi(u, -v), \quad -\infty<u<\infty, \quad -\infty<v<\infty. \tag{3.10}$$

Every positive solution of (3.7) on $(-\infty, \infty)\times(-\infty, \infty)$ induces, via (3.3) and (1.7), a strictly convex entropy for (1.3). If $ua'(u)\geqq 0$ on $(-\infty, \infty)$, then the solution of (3.7), (3.8) with any positive $R(v)$ is automatically positive on $(-\infty, \infty)\times(-\infty, \infty)$. Thus, when $\sigma(u)$ is concave on $(-\infty, 0]$ and convex on $[0, \infty)$ it is easy to construct strictly convex entropies with arbitrarily prescribed growth. Our current objective, however, is to determine entropies for the case where $\sigma(u)$ may be concave for u large and/or convex for u small.

We consider solutions of (3.7), (3.8) with

$$R(v)=a(0)|v|^{\gamma}, \qquad -\infty<v<\infty, \tag{3.11}$$

where $\gamma\geqq 0$. When γ is an even integer, say $\gamma=2m$, the solution of (3.7), (3.8), (3.11) is of the form

$$\begin{aligned} \Phi(u, v)&=\sum_{k=0}^{m} A_k(u)a(u)v^{2k}+\sum_{k=0}^{m-1} B_k(u)v^{2k+1}, \\ \Psi(u, v)&=\sum_{k=0}^{m} A_k(u)a(u)v^{2k}-\sum_{k=0}^{m-1} B_k(u)v^{2k+1} \end{aligned} \tag{3.12}$$

where

$$A_m(u)=1, \qquad -\infty<u<\infty, \tag{3.13}$$

and $B_k(u)$, $A_k(u)$, $k=0, \cdots, m-1$, are determined by the recursion relations

$$\begin{aligned} B_k'(u)&=-(2k+2)a^2(u)A_{k+1}(u), \\ A_k'(u)&=-(2k+1)B_k(u), \end{aligned} \qquad k=0, \cdots, m-1, \tag{3.14}$$

$$B_k(0)=A_k(0)=0, \qquad k=0, \cdots, m-1. \tag{3.15}$$

When $m=0$, (3.12) reduces to

$$\Phi(u, v)=\Psi(u, v)=a(u), \quad -\infty<u<\infty, \quad -\infty<v<\infty. \tag{3.16}$$

This solution is uniformly positive on $(-\infty, \infty)\times(-\infty, \infty)$, by virtue of (3.1), and induces the entropy $(1.11)_1$.

When $m=1$, (3.14), (3.15), (3.13) and (1.2) yield

$$B_0(u)=-2[\sigma(u)-\sigma(0)],\qquad A_0(u)=2\int_0^u[\sigma(w)-\sigma(0)]\,dw. \tag{3.17}$$

Inserting these values into (3.12) and after an integration by parts we obtain

$$\begin{aligned}\Phi(u,v)&=a(u)\left\{v-\frac{\sigma(u)-\sigma(0)}{a(u)}\right\}^2-a(u)\int_0^u[\sigma(w)-\sigma(0)]^2[a^{-2}(w)]'\,dw,\\ \Psi(u,v)&=a(u)\left\{v+\frac{\sigma(u)-\sigma(0)}{a(u)}\right\}^2-a(u)\int_0^u[\sigma(w)-\sigma(0)]^2[a^{-2}(w)]'\,dw.\end{aligned} \tag{3.18}$$

If

$$\int_0^u[\sigma(w)-\sigma(0)]^2[a^{-2}(w)]'\,dw<K<\infty,\qquad -\infty<u<\infty, \tag{3.19}$$

then we can generate positive solutions of (3.7) with quadratic growth on $(-\infty,\infty)\times(-\infty,\infty)$ by adding to solution (3.18) K times the solution (3.16). For the case of interest, namely $ua'(u)\leqq 0$ on $(-\infty,\infty)$, and by account of (3.1), (3.19) is equivalent to

$$\int_{-\infty}^{\infty}w^2|a'(w)|\,dw<\infty. \tag{3.20}$$

Though in principle one may proceed with the study of explicit solutions (3.12) for $m=2,3,\cdots$, the calculations get so complicated that a more qualitative approach becomes necessary. We discretize the problem by the following procedure: We fix $\tau>0$, set $a_n:=a(n\tau)$, $n=0,\pm1,\pm2,\cdots$, and define the step function $\hat{a}(u)$ on $(-\infty,\infty)$ by

$$\hat{a}(u)=\begin{cases}a_n, & n\tau\leqq u<(n+1)\tau,\quad n=0,1,2,\cdots,\\ a_n, & (n-1)\tau<u\leqq n\tau,\quad n=0,-1,-2,\cdots.\end{cases} \tag{3.21}$$

We will determine the solution of (1.7), (3.2) on $(-\infty,\infty)\times(-\infty,\infty)$ by first solving

$$\hat{\eta}_{uu}(u,v)=\hat{a}^2(u)\hat{\eta}_{vv}(u,v), \tag{3.22}$$

with the same initial data, and then passing to the limit $\tau\downarrow 0$.

The solution of (3.22), (3.2) is a C^1 function with continuous second derivatives $\hat{\eta}_{uv}(u,v)$ and $\hat{\eta}_{vv}(u,v)$. By contrast, $\hat{\eta}_{uu}(u,v)$ experiences jump discontinuities across the lines $u=\pm\tau,\pm2\tau,\cdots$. The functions

$$\begin{aligned}\hat{\Phi}(u,v)&:=\hat{a}(u)\hat{\eta}_{vv}(u,v)-\hat{\eta}_{uv}(u,v),\\ \hat{\Psi}(u,v)&:=\hat{a}(u)\hat{\eta}_{vv}(u,v)+\hat{\eta}_{uv}(u,v),\end{aligned} \tag{3.23}$$

also experience jump discontinuities across the lines $u=\pm\tau,\pm2\tau,\cdots$ but are continuous, with respect to u, from the right on $[0,\infty)$ and from the left on $(-\infty,0]$.

In the sequel, we restrict attention to the upper half-plane, $0\leqq u<\infty$, $-\infty<v<\infty$, because the discussion for the lower half-plane would be entirely symmetrical. Since $a(u)$ is constant on the interval $[n\tau,(n+1)\tau)$, it follows easily from (3.23), (3.22) that

$$\begin{aligned}\hat{\Phi}_u(u,v)+a_n\hat{\Phi}_v(u,v)&=0,\\ \hat{\Psi}_u(u,v)-a_n\hat{\Psi}_v(u,v)&=0,\end{aligned}\qquad n\tau<u<(n+1)\tau. \tag{3.24}$$

Combining (3.23), (3.21) and (3.24) we deduce

$$
\tag{3.25}
\begin{aligned}
\hat{\Phi}((n+1)\tau, v) &= \frac{a_{n+1}+a_n}{2a_n}\hat{\Phi}(n\tau, v-a_n\tau)+\frac{a_{n+1}-a_n}{2a_n}\hat{\Psi}(n\tau, v+a_n\tau),\\
\hat{\Psi}((n+1)\tau, v) &= \frac{a_{n+1}-a_n}{2a_n}\hat{\Phi}(n\tau, v-a_n\tau)+\frac{a_{n+1}+a_n}{2a_n}\hat{\Psi}(n\tau, v+a_n\tau),
\end{aligned}
$$

which are the discrete analogues of (3.7).

For simple initial data it is possible to determine explicitly $\hat{\Phi}(u, v)$ and $\hat{\Psi}(u, v)$ by solving (3.25) and then using (3.24). For instance, the solution of (3.25) under initial data (3.8), (3.11), with $\gamma=0$, is

$$
\tag{3.26}
\hat{\Phi}(n\tau, v)=\hat{\Psi}(n\tau, v)=a_n, \qquad n=0,1,2,\cdots.
$$

Similarly, it is straightforward to verify by induction that the solution of (3.25) under initial data (3.8), (3.11), with $\gamma=2$, is

$$
\tag{3.27}
\begin{aligned}
\frac{1}{a_n}\hat{\Phi}(n\tau, v) &= \left\{v-\frac{a_0^2+\cdots+a_{n-1}^2}{a_n}\tau\right\}^2+\sum_{k=0}^{n-1}\{a_0^2+\cdots+a_k^2\}\{a_k^{-2}-a_{k+1}^{-2}\},\\
\frac{1}{a_n}\hat{\Psi}(n\tau, v) &= \left\{v+\frac{a_0^2+\cdots+a_{n-1}^2}{a_n}\tau\right\}^2+\sum_{k=0}^{n-1}\{a_0^2+\cdots+a_k^2\}\{a_k^{-2}-a_{k+1}^{-2}\}.
\end{aligned}
$$

As was to be expected, the above solution converges to (3.18), as $\tau \downarrow 0$.

Turning now to general initial data (3.8), (3.9), we apply (3.25) recursively, thus arriving at equations of the form

$$
\tag{3.28}
\begin{aligned}
\hat{\Phi}(n\tau, v) &= \sum_{(\varepsilon_0,\cdots,\varepsilon_{n-1})}\beta_n(\varepsilon_0,\cdots,\varepsilon_{n-1})R\left(v+\sum_{i=0}^{n-1}\varepsilon_i a_i\tau\right),\\
\hat{\Psi}(n\tau, v) &= \sum_{(\varepsilon_0,\cdots,\varepsilon_{n-1})}\beta_n(\varepsilon_0,\cdots,\varepsilon_{n-1})R\left(v-\sum_{i=0}^{n-1}\varepsilon_i a_i\tau\right).
\end{aligned}
$$

In (3.28) the ε_i take values ± 1 so the summation contains 2^n terms. The coefficients $\beta_n(\varepsilon_0,\cdots,\varepsilon_{n-1})$ are determined through the recurrence relations

$$
\tag{3.29}
\beta_0=1,
$$

$$
\tag{3.30}
\begin{aligned}
\beta_{n+1}(\varepsilon_0,\cdots,\varepsilon_{n-1},-1) &= \frac{a_{n+1}+a_n}{2a_n}\beta_n(\varepsilon_0,\cdots,\varepsilon_{n-1}),\\
\beta_{n+1}(\varepsilon_0,\cdots,\varepsilon_{n-1},1) &= \frac{a_{n+1}-a_n}{2a_n}\beta_n(\varepsilon_0,\cdots,\varepsilon_{n-1})
\end{aligned}
$$

for $n=0,1,2,\cdots$.

When $a'(u)\geqq 0$ on $[0,\infty)$, in which case the sequence $\{a_n\}$ is nondecreasing, all β_n are positive and so any positive $R(v)$ yields positive $\hat{\Phi}(u, v)$ and $\hat{\Psi}(u, v)$. Here, however, we are interested in $\sigma(u)$ that are concave on $[0,\infty)$ and convex on $(-\infty, 0]$. The main result of this section is the following proposition.

PROPOSITION 3.1. *Assume* (3.1) *holds and*

$$
\tag{3.31}
ua'(u)\leqq 0, \qquad -\infty<u<\infty.
$$

Furthermore, let

$$
\tag{3.32}
\int_{-\infty}^{\infty}|u|^{p-2}|a'(u)|\,du<\infty
$$

for some $p \geqq 2$. *Then there exists a strictly convex entropy* $\eta(u, v)$ *for* (1.3) *which satisfies the following growth conditions on* $(-\infty, \infty) \times (-\infty, \infty)$:

$$\mu(|u|^p + |v|^p) \leqq \eta(u, v) \leqq M(|u|^p + |v|^p + 1), \tag{3.33}$$

$$|\eta_u(u, v)| + |\eta_v(u, v)| \leqq L(|u|^{p-1} + |v|^{p-1} + 1), \tag{3.34}$$

with μ, M *and* L *positive constants.*

Proof. Let us estimate $\hat{\Phi}(n\tau, v)$, as computed via $(3.28)_1$, with $R(v)$ given by (3.11) for $\gamma = p - 2$. We limit our attention to $n = 0, 1, 2, \cdots$ since the discussion of the case $n = -1, -2, \cdots$ would be completely symmetrical.

Under our assumption (3.31), the sequence $\{a_n\}$ is nonincreasing and so, as it may be seen from (3.30), some of the values of β_n will be positive while others will be negative. In fact it follows easily, by induction, that

$$\begin{aligned} &\beta_n(-1, \varepsilon_1, \cdots, \varepsilon_{n-1}) \geqq 0 \quad \text{for all } (\varepsilon_1, \cdots, \varepsilon_{n-1}), \\ &\beta_n(1, \varepsilon_1, \cdots, \varepsilon_{n-1}) \leqq 0 \quad \text{for all } (\varepsilon_1, \cdots, \varepsilon_{n-1}). \end{aligned} \tag{3.35}$$

Therefore, the sign of $\hat{\Phi}(n\tau, v)$ will depend on the outcome of the competition between terms with positive coefficients and terms with negative coefficients, in the summation (3.28). Using (3.30) we can show by induction that

$$\begin{aligned} &\sum_{(\varepsilon_1, \cdots, \varepsilon_{n-1})} \beta_n(-1, \varepsilon_1, \cdots, \varepsilon_{n-1}) = \frac{a_n + a_0}{2a_0}, \\ &\sum_{(\varepsilon_1, \cdots, \varepsilon_{n-1})} \beta_n(1, \varepsilon_1, \cdots, \varepsilon_{n-1}) = \frac{a_n - a_0}{2a_0}, \end{aligned} \tag{3.36}$$

and so the gross effect of positive coefficients dominates the gross effect of negative coefficients. From (3.36) it follows that

$$\sum_{(\varepsilon_0, \cdots, \varepsilon_{n-1})} \beta_n(\varepsilon_0, \cdots, \varepsilon_{n-1}) = \frac{a_n}{a_0}, \tag{3.37}$$

$$\sum_{(\varepsilon_0, \cdots, \varepsilon_{n-1})} |\beta_n(\varepsilon_0, \cdots, \varepsilon_{n-1})| = 1. \tag{3.38}$$

We write down $(3.28)_1$, with $R(v)$ given by (3.11), and we separate terms with positive and negative coefficients:

$$\begin{aligned} \hat{\Phi}(n\tau, v) = &\sum_{(\varepsilon_1, \cdots, \varepsilon_{n-1})} a_0 \beta_n(-1, \varepsilon_1, \cdots, \varepsilon_{n-1}) \left| v - \sum_{i=0}^{n-1} a_i\tau + \sum_{i=0}^{n-1} (1 + \varepsilon_i) a_i \tau \right|^\gamma \\ &+ \sum_{(\varepsilon_1, \cdots, \varepsilon_{n-1})} a_0 \beta_n(1, \varepsilon_1, \cdots, \varepsilon_{n-1}) \left| v - \sum_{i=0}^{n-1} a_i\tau + \sum_{i=0}^{n-1} (1 + \varepsilon_i) a_i \tau \right|^\gamma . \end{aligned} \tag{3.39}$$

We fix $\delta > 0$ so small that

$$\begin{aligned} &(1+\delta)^{-\gamma}(a_n + a_0) + (1+\delta)^\gamma(a_n - a_0) \geqq a_n, \\ &(1+\delta)^\gamma(a_n + a_0) + (1+\delta)^{-\gamma}(a_n - a_0) \leqq 3a_n, \end{aligned} \qquad n = 1, 2, \cdots . \tag{3.40}$$

Noting the elementary inequalities

$$(1+\delta)^{-\gamma} A^\gamma - (1+\delta^{-1})^\gamma B^\gamma \leqq (A+B)^\gamma \leqq (1+\delta)^\gamma A^\gamma + (1+\delta^{-1})^\gamma B^\gamma, \tag{3.41}$$

which hold for any positive numbers A, B, and using (3.36), we obtain from (3.39)

$$\begin{aligned}\hat{\Phi}(n\tau, v) \leqq \frac{3}{2} a_n \left| v - \sum_{i=0}^{n-1} a_i\tau \right|^{\gamma} \\ + (1+\delta^{-1})^{\gamma} a_0 \sum_{(\varepsilon_0,\cdots,\varepsilon_{n-1})} |\beta_n(\varepsilon_0, \cdots, \varepsilon_{n-1})| \left[\sum_{i=0}^{n-1} (1+\varepsilon_i) a_i\tau \right]^{\gamma},\end{aligned} \tag{3.42}$$

$$\begin{aligned}\hat{\Phi}(n\tau, v) \geqq \frac{1}{2} a_n \left| v - \sum_{i=0}^{n-1} a_i\tau \right|^{\gamma} \\ - (1+\delta^{-1})^{\gamma} a_0 \sum_{(\varepsilon_0,\cdots,\varepsilon_{n-1})} |\beta_n(\varepsilon_0, \cdots, \varepsilon_{n-1})| \left[\sum_{i=0}^{n-1} (1+\varepsilon_i) a_i\tau \right]^{\gamma}.\end{aligned} \tag{3.43}$$

We estimate the last term on the right-hand side of (3.42) and (3.43) by rearranging the terms in the summation and using (3.30), (3.38):

$$\begin{aligned}&\sum_{(\varepsilon_0,\cdots,\varepsilon_{n-1})} |\beta_n(\varepsilon_0, \cdots, \varepsilon_{n-1})| \left[\sum_{i=0}^{n-1} (1+\varepsilon_i) a_i\tau \right]^{\gamma} \\ &= \sum_{k=0}^{n-1} \sum_{(\varepsilon_0,\cdots,\varepsilon_{k-1},1,-1,\cdots,-1)} |\beta_n(\varepsilon_0, \cdots, \varepsilon_{n-1})| \left[\sum_{i=0}^{n-1} (1+\varepsilon_i) a_i\tau \right]^{\gamma} \\ &= \sum_{k=0}^{n-1} \left\{ \left[\prod_{j=k+1}^{n-1} \frac{a_{j+1}+a_j}{2a_j} \right] \frac{a_k - a_{k+1}}{2a_k} \right. \\ &\qquad \left. \times \sum_{(\varepsilon_0,\cdots,\varepsilon_{k-1})} |\beta_k(\varepsilon_0, \cdots, \varepsilon_{k-1})| \left[\sum_{i=0}^{k} (1+\varepsilon_i) a_i\tau \right]^{\gamma} \right\} \\ &\leqq 2^{\gamma} \sum_{k=0}^{n-1} \left[\sum_{i=0}^{k} a_i\tau \right]^{\gamma} \frac{a_k - a_{k+1}}{2a_k}.\end{aligned} \tag{3.44}$$

The right-hand side of (3.44) is a priori bounded, independently of n, by virtue of (3.32) and (3.1) (recall $\gamma = p-2$). We have thus shown that there is a constant K such that

$$\hat{\Phi}(n\tau, v) \leqq \frac{3}{2} a_n \left| v - \sum_{i=0}^{n-1} a_i\tau \right|^{\gamma} + Ka_n, \qquad n = 1, 2, \cdots, \tag{3.45}$$

$$\hat{\Phi}(n\tau, v) \geqq \frac{1}{2} a_n \left| v - \sum_{i=0}^{n-1} a_i\tau \right|^{\gamma} - Ka_n, \qquad n = 1, 2, \cdots. \tag{3.46}$$

Since $\hat{\Psi}(n\tau, v) = \hat{\Phi}(n\tau, -v)$, (3.45), (3.46) yield

$$\hat{\Psi}(n\tau, v) \leqq \frac{3}{2} a_n \left| v + \sum_{i=0}^{n-1} a_i\tau \right|^{\gamma} + Ka_n, \qquad n = 1, 2, \cdots, \tag{3.47}$$

$$\hat{\Psi}(n\tau, v) \geqq \frac{1}{2} a_n \left| v + \sum_{i=0}^{n-1} a_i\tau \right|^{\gamma} - Ka_n, \qquad n = 1, 2, \cdots. \tag{3.48}$$

Letting $\tau \downarrow 0$, $\hat{\Phi}(u, v)$, $\hat{\Psi}(u, v)$ converge to the solution $\Phi(u, v)$, $\Psi(u, v)$ of (3.7), (3.8), (3.11). Hence

$$\begin{aligned}\Phi(u, v) &\leqq \frac{3}{2} a(u) \left| v - \int_0^u a(w)\, dw \right|^{\gamma} + Ka(u), \\ \Psi(u, v) &\leqq \frac{3}{2} a(u) \left| v + \int_0^u a(w)\, dw \right|^{\gamma} + Ka(u),\end{aligned} \tag{3.49}$$

$$\begin{aligned}\Phi(u,v) &\geqq \frac{1}{2}a(u)\left|v-\int_0^u a(w)\,dw\right|^\gamma - Ka(u),\\ \Psi(u,v) &\geqq \frac{1}{2}a(u)\left|v+\int_0^u a(w)\,dw\right|^\gamma - Ka(u)\end{aligned} \tag{3.50}$$

on $(-\infty,\infty)\times(-\infty,\infty)$. Upon adding to the above solution $K+1$ times the special solution (3.16), we end up with a new solution of (3.7) which is positive on $(-\infty,\infty)\times(-\infty,\infty)$. This induces, via (3.3), (3.7) and (1.7), a strictly convex entropy $\eta(u,v)$ for (1.3), which satisfies the growth conditions (3.33), (3.34) (recall $p=\gamma+2$). This completes the proof of the proposition. □

When $p=4$, (3.32) reduces to condition (3.20), which, as we have seen, is both necessary and sufficient for the existence of positive $\Phi(u,v)$, $\Psi(u,v)$ with quadratic growth rates. Thus (3.32) appears to be sharp.

Let $(\bar{u},\bar{v})$ be any constant state and let $\bar{\eta}(u,v)$ be the positive entropy induced by $\eta(u,v)$ via (1.8). It then follows from (3.33), (3.34) that if $\{f(u,v), g(u,v)\}$ satisfies

$$f(\bar{u},\bar{v})=g(\bar{u},\bar{v})=0, \tag{3.51}$$

$$|f(u,v)|+|g(u,v)|\leqq A(|u|+|v|+1), \quad -\infty<u<\infty, \quad -\infty<v<\infty, \tag{3.52}$$

then there is a positive constant C with

$$|\bar{\eta}_u(u,v)f(u,v)+\bar{\eta}_v(u,v)g(u,v)|\leqq CA\bar{\eta}(u,v), \tag{3.53}$$

for $-\infty<u<\infty$, $-\infty<v<\infty$. Therefore, applying Gronwall's inequality to (1.10) yields

$$\int_{-\infty}^{\infty}\bar{\eta}(u(x,t),v(x,t))\,dx\leqq e^{CAt}\int_{-\infty}^{\infty}\bar{\eta}(u(x,0),v(x,0))\,dx. \tag{3.54}$$

By virtue of (3.33) and (1.8), (3.54) induces L^p bounds, independent of ν, on solutions of the Cauchy problem for (1.1) with initial data in $L^p(-\infty,\infty)\cap L^2(-\infty,\infty)$.

OSCILLATING SOLUTIONS OF THE FALKNER-SKAN EQUATION FOR NEGATIVE β*

S. P. HASTINGS† AND W. C. TROY†

Abstract. The Falkner-Skan equation results from an appropriate similarity substitution in the Prandtl boundary layer equations. New solutions are found analytically, including a periodic solution and many solutions which oscillate a finite number of times and then tend to a limit.

Key words. boundary layer theory, similarity solutions

AMS(MOS) subject classifications. 76D10, 34B15, 76D30

1. Introduction. The boundary layer technique of Prandtl [13] has become one of the cornerstones of modern fluid dynamics and aerodynamics. One aspect of the method consists of finding particular solutions of approximations to the Navier-Stokes equations by assuming that a solution within the boundary layer has a "similarity" form. Using these solutions as first approximations, one then employs the method of matched asymptotic expansions to solve the boundary layer equations more generally. General references to these techniques include [2], [12], [15] and [16].

Among the first to look for similarity solutions were Blasius [1] and Falkner and Skan [3]. These authors considered laminar incompressible boundary layer flow past a flat plane or a wedge. They began with the steady-state Prandtl boundary layer equations, which we write as follows:

$$u_x + v_y = 0, \qquad uu_x + vu_y = UU_x + \gamma u_{yy}. \tag{1}$$

Here (x, y) are orthogonal coordinates in the boundary layer, with x representing arc length along the wall and y the perpendicular distance from the wall, u and v are the corresponding velocity components, and γ is the kinematic viscosity. Also, $U = U(x)$ is the assigned exterior stream velocity. The appropriate boundary conditions are

$$u = v = 0 \quad \text{when } y = 0, \qquad u \to U(x) \quad \text{as } y \to \infty. \tag{2}$$

Their investigations led to a classical fluid dynamical model which can be written in the form

$$f''' + ff'' + \beta(1 - f'^2) = 0. \tag{3}$$

Here f is proportional to the stream function and $f' = u/U$. For our purposes a similarity assumption proposed by Spalding [17] and studied extensively by Evans [2] is convenient in deriving (3) from the Prandtl equations. They assume that U satisfies the equation

$$\frac{dU}{dx} = CU^{2(\beta-1)/\beta}, \tag{4}$$

where x is the coordinate in the direction of the stream as measured along the bounding surface and C is a constant. Thus β measures the pressure gradient in the stream direction. With this interpretation negative values of β less than -0.5 and all $\beta > -0.199$ are found by Evans [2] to be of physical interest. This is to be contrasted to the original

derivation of Falkner and Skan, in which U was assumed to be proportional to x^m, producing (3) with $\beta = 2m/(m+1)$. In this original setting only $0 \leqq \beta < 2$ was found to be significant. We study solutions with $\beta > 0$ in a companion paper ([9]; see also [8]).

Small negative values of β, between the "separation" value of -0.199 and 0, were introduced, with physical justification, by Hartree [6] and later by Stewartson [18]. Here we are interested primarily in values of $\beta < -1$, which is included in the range of physical interest as described by Evans. In this range there are two sets of boundary conditions for (3) which have been been considered [2], [6], [18]. These are

$$f(0) = f'(0) = 0, \qquad f'(\infty) = 1, \tag{5}$$

and

$$f(0) = f'(0) = 0, \qquad f'(\infty) = -1. \tag{6}$$

In most known applications f' is restricted to lie between -1 and $+1$, and then solutions to (3)-(5) only exist in a small range of negative β [5], [7]. However it has been suggested that physically interesting solutions may be possible in which f' exhibits "overshoot," by rising above 1, and recently some interesting numerical studies have been done of solutions of this kind [10], [11], [14].

An initial analytical investigation of solutions with overshoot, for large negative β, was done by Troy [19]. In this paper we prove the existence of many new solutions of (3), satisfying either (5) or (6). The existence of these new solutions depends on showing that (3) has a periodic solution if $\beta < -1$. This was first suggested by some numerical computations in [14].

Our method for proving the existence of these solutions is "shooting." That is, we consider an initial value problem for (3), such as

$$f(0) = f'(0) = 0, \qquad f''(0) = \gamma, \tag{7}$$

and vary γ to satisfy the desired condition at ∞. It turns out that a more fundamental initial value problem is (3) coupled with the initial conditions

$$f(0) = f''(0) = 0, \qquad f'(0) = \alpha, \tag{8}$$

with $-1 < \alpha < 0$. We denote the unique solution to (3), (8) by f_α, and will show that if $\beta < -1$, then α can be chosen so that f_α is periodic. From this we will obtain solutions of (3), (8) with either $f'(\infty) = 1$ or $f'(\infty) = -1$. Each of these conditions is of physical interest [16]. Using these solutions, we then study the initial value problem (3), (7), and again find solutions with $f'(\infty) = 1$ or $f'(\infty) = -1$. In this case, we find a solution which is not periodic but which oscillates infinitely often.

2. Statement of results. The first four results refer to the initial value problem (3), (8). They make it clear that there is a complicated bifurcation "from infinity in phase space" as β crosses -1 from above.

THEOREM 1. *For any $\beta < -1$ there is an $\bar{\alpha}$ in $(-1, 0)$ such that $f_{\bar{\alpha}}$ is periodic with some period P and $f'_{\bar{\alpha}}$ has exactly one local maximum in $(0, P)$. If $-1 \leqq \beta \leqq 0$ then there is no periodic solution of (3) except $f \equiv 0$.*

THEOREM 2. *If $\beta < -1$, then there is a sequence $\{\alpha_j\} \subset (-1, \bar{\alpha})$, $j \geqq 0$, tending to $\bar{\alpha}$ from below, such that $f'_{\alpha_j}(\eta)$ tends to -1 as η tends to infinity, and f'_{α_j} has exactly j local maxima in $0 < \eta < \infty$.*

The next result discusses solutions such that f' tends to $+1$. It is more complicated to state, because branches of solutions of (3), (5) (plotted in the β-f'' plane) move into the region $f'' > 0$, according to the numerical computations in [10] and [14], as β decreases from -1. It is convenient to begin with a result in which β is varied and the fixed initial conditions $f(0)=f'(0)=f''(0)=0$ are considered. In accordance with previous notation, we denote the corresponding solution by f_0.

THEOREM 3. *For each $j \geqq 0$, let $S_j = \{\beta \mid f'_0$ tends to $+1$ with exactly j relative maxima and minima$\}$. Then every negative β lies in some S_j, each S_j is bounded below, and there is a decreasing sequence $\{\beta_j\}$ tending to $-\infty$ such that β_j is contained in the interior of S_j.*

We then have a second result about solutions with f' tending to $+1$.

THEOREM 4. *Suppose that $\beta \in S_j$. Let $\bar{\alpha}$ be as defined in Theorem 1. Then there is a decreasing sequence α_k^*, $k \geqq j$, with $\alpha_0^* = 0$ and $\alpha_j^* \geqq \bar{\alpha}$, such that if $\alpha = \alpha_k^*$, then f' has exactly k relative maxima and minima (f'' vanishes exactly k times), and then tends to* 1 *at an exponential rate.*

It should be observed that we have not proved that the α_j^* necessarily tend to $\bar{\alpha}$.

We now consider solutions satisfying the initial conditions (7). We denote the unique solution to (3), (7) by F_γ. The results here parallel to some extent those for the initial conditions (8), except that there does not appear to be a periodic solution.

THEOREM 5. *For each $\beta < -1$ there is a $\bar{\gamma} < 0$ such that $F_{\bar{\gamma}}$, $F'_{\bar{\gamma}}$, and $F''_{\bar{\gamma}}$ all vanish infinitely often on $(0, \infty)$ and do not tend to a limit.*

THEOREM 6. *There is an increasing sequence γ_j, $j \geqq 0$, contained in $(-\infty, \bar{\gamma})$ such that F''_{γ_j} vanishes exactly $2j$ times and then $(F'_{\gamma_j}, F''_{\gamma_j})$ tends to $(-1, 0)$. Thus F_{γ_j} solves* (3), (6).

THEOREM 7. *Suppose $\beta \in S$. Then there is a decreasing sequence γ_k^*, $k \geqq j$, in $(\bar{\gamma}, 0)$ such that if $\gamma = \gamma_k^*$, then $F = F'_\gamma$ has exactly k relative maxima and minima (F'' vanishes k times) and then F' tends to* 1 *exponentially fast. Thus F_{γ_j} solves* (3), (5).

3. Proofs.

Proof of Theorem 1. We first verify that there are no periodic solutions if $-1 \leqq \beta \leqq 0$. (We are not considering any particular initial conditions at this point.) Suppose that for some β in this range there is a periodic solution, with period $P > 0$. We may assume that $f'(0) = 0$. An integration of (3) shows that

$$f'' + ff' = -\beta\eta + (\beta+1)\int_0^\eta (f'(s))^2\, ds + f''(0). \tag{9}$$

At $\eta = P$, under the restriction on β, this a contradiction, since we obtain $f''(P) > f''(0)$.

Henceforth we assume that $\beta < -1$. Let f_α be the solution of (3), (8). We try to choose $\bar{\alpha}$ so that for some $Q > 0$,

$$f(Q) = f''(Q) = 0, \tag{10}$$

where $f = f_{\bar{\alpha}}$. This implies that $f(Q+\eta) = -f(Q-\eta)$, and therefore f is periodic with period $2Q$.

The existence of $\bar{\alpha}$ is proved by shooting. Suppose first that $\alpha = 0$. Then, from (3), f, f' and f'' all are positive on some interval $(0, \varepsilon)$. Therefore for small negative α, while f is initially negative, $f = 0$ before $f'' = 0$. That is, there is an η_0 such that $f'' > 0$ on $(0, \eta_0]$ while $f(\eta_0) = 0$.

From now on we consider only values of α in $(-1, 0)$. Solutions of (3), (8) are continuous in α. Since f is negative and decreasing as long as f' is negative, it follows that f'' is positive up to the first zero of f, if this exists, and at this zero, f' is positive. Also, at the first zero of f'', f''' must be nonzero, for if f'' and and f''' vanish simultaneously, then $1 - f'^2 = 0$ and f'' is identically zero. Therefore, the set of α such that $f_\alpha = 0$ before $f''_\alpha = 0$ is open in the interval $(-1, 0)$, as well as nonempty. Similarly, the set of α such that $f'' = 0$ before $f = 0$ is also open. To obtain condition (10) for some α and $Q > 0$, we must prove that the latter set is nonempty. This follows from the following lemma.

LEMMA 1. *If α is sufficiently close to -1, then f'' becomes zero at least as soon as f.*

Proof. Suppose, instead, that for all α in $(-1, 0)$ there is a $p > 0$ such that $ff'' < 0$ on $(0, p)$ and $f(p) = 0$. Then (9) becomes

$$f''(p) = \lambda p - (\lambda - 1) \int_0^p [f'(\mu)]^2 \, d\mu \tag{11}$$

where $\lambda = -\beta > 1$. A contradiction will be obtained by showing that the right side of (11) is negative for α close to -1. For this we use the following two technical lemmas.

LEMMA 2. *Choose a fixed δ in $(0, 1)$ and assume that $\alpha < -1 + \delta$. Then there is a first $a > 0$ such that $f'(a) = -1 + \delta$ and a first $b > a$ such that $f'(b) = 0$. Further, a and $f''(a)$ tend to infinity as α tends to -1, and $b - a \leqq (1 - \delta)/\delta a$.*

Proof. The existence of a and b is assured since f_α''' is positive as long as $f' < 1$. On $(0, a)$, $\alpha < f' - 1 + \delta$. Therefore, using (9) with $\beta < -1$, we find that $f''(a) \geqq \delta a$. Also, since $f' \equiv -1$ solves (3), it is clear that $a \to \infty$ as $\alpha \to -1+$. To complete the lemma, we observe that $f'' \geqq \delta a$ on (a, b), since $f''' > 0$ there. Therefore

$$1 - \delta = f'(b) - f'(a) \geqq \delta a(b - a)$$

as desired.

In the remainder of the paper we consider a number M such that

$$M > 200\lambda/(\lambda - 1)(1 - \delta). \tag{12}$$

(This inequality is used in the proof of Theorem 2, but for Theorem 1 we only need $M > 6\lambda/(\lambda - 1)(1 - \delta)$.)

LEMMA 3. *If α is sufficiently close to -1, then there is a first $c > a$ such that $f'(c) = M$, and $c - a \to 0$ as $\alpha \to -1+$.*

Proof. Suppose that $f' < M$ on the interval $(b, b + 1)$ for all small values of $1 + \alpha$. Then (3) and Lemma 2 imply that on this interval, $f'' \geqq e^{-M}\delta a/2 - \lambda(M^2 - 1)/M$. Since a tends to infinity as α tends to -1, we see that for sufficiently small $(1 + \alpha)$,

$$f'' \geqq e^{-M}\delta a/2 > M. \tag{13}$$

But this implies that $f'(b + 1) > M$, a contradiction. Therefore for α close to -1 there is a c in $(b, b + 1)$ such that $f'(c) = M$, and (13) holds over (b, c). This implies that $c - b \leqq 2Me^M/\delta a$, and this with Lemma 2 completes the proof of Lemma 3.

We now continue with the proof of Lemma 1. We see that f is negative in $[b, c]$, so $p > c$ and $f'(p) > M$ for α close to -1. On $(0, a)$,

$$\alpha a \leqq \int_0^a f'(s) \, ds \leqq (-1 + \delta)a. \tag{14}$$

Also, $0 = \int_0^p f'(s) \, ds = \int_0^a f'(s) \, ds + \int_a^c f'(s) \, ds + \int_c^p f'(s) \, ds$. Using Lemma 2, we obtain

$$-\alpha a \geqq \int_c^p f'(s) \, ds + o(1) \geqq (1 - \delta)a \tag{15}$$

as $\alpha \to -1+$. Further, $f' > M$ on (c, p), so

$$\int_0^p f'(s)^2 \, ds \geqq M \int_c^p f'(s) \, ds \geqq M(1 - \delta)a/2 \tag{16}$$

for α close enough to -1.

Next we obtain an upper bound on p. From (15) it follows that $-\alpha a \geqq M(p - c) + o(1)$ as $\alpha \to -1+$. We also know that $c - a \to 0$ as $\alpha \to -1+$. Therefore for α sufficiently close to -1,

$$p \leqq 2a - \alpha a/M. \tag{17}$$

To complete the proof of Lemma 1 and Theorem 1, we use (11), (12), (16) and (17) to obtain

$$f''(p) \leqq 2a\lambda + \lambda a/M - (\lambda - 1)(1-\delta)aM/2 < 0.$$

Proof of Theorem 2. Let $\bar{\alpha}$ be a point chosen as above so that $f_{\bar{\alpha}}$ is periodic. (We do not claim that $\bar{\alpha}$ is unique.) Define a set W_1 as follows.

$$W_1 = \{\alpha \text{ in } (-1, 0) \text{ such that if } -1 < f'(0) < \alpha, \text{ then } f'(\bar{\eta}) = -1$$
$$\text{for some first } \bar{\eta} > 0, f''(\bar{\eta}) < 0, \text{ and } f'' = 0 \text{ exactly once in } (0, \bar{\eta})\}.$$

LEMMA 4. *The set W_1 is nonempty and open.*

Proof of Lemma 4. Since f'' and f''' cannot vanish simultaneously, unless $f'' \equiv 0$, W_1 is easily seen to be open. Let η_0 be the first zero of f''. We have shown that if $\alpha + 1$ is small, then $f'(\eta_0) > M$. In addition, define a number K by

$$K = -3\lambda + (\lambda - 1)(1-\delta)M/2.$$

Finally, choose α so close to -1 that

$$a > \max\{e^M(8\lambda + 16M)/\delta, (8\lambda + M)/K\} \tag{18}$$

where a and δ are as in the proof of Lemma 1.

We now observe that if, as previously, p is the first positive zero of f, then

$$f''(p) < -Ka. \tag{19}$$

This is seen from (9), with $\eta = p$, (16) and (17).

We now let η_1 denote the first point beyond $\eta = \eta_0$ where $f' = M$. There are now two cases to consider:

(i) $$f < 0 \quad \text{on } (\eta_0, \eta_1),$$

and

(ii) $$f(p) = 0 \quad \text{at some } p \text{ in } (\eta_0, \eta_1).$$

In considering case (i) we introduce the fundamental "energy" function

$$H = \tfrac{1}{2}f''^2 + \beta(f' - f'^3/3),$$

and we see that $H' = -ff''^2$. Therefore H is increasing in $(0, \eta_1)$, and in particular, $H(\eta_1) > H(c)$, where, as before, $f'(c) = M$. Because $M > 1$, this implies that

$$f''(\eta_1) \leqq -f''(c) \leqq -\bar{\delta}a,$$

where $\bar{\delta} = \frac{1}{2}\delta\, e^{-M}$. If $f' > 0$ on $(\eta_1, \eta_1 + 1)$, then (9) and (18) imply that $f'' < -\bar{\delta}a/2$ on this interval. Then (18) implies that, in fact, f' must equal zero for some η_2 in $(\eta_1, \eta_1 + 1)$.

Similarly, again using (9) and (18), we show that if $f' > -1$ on $(\eta_2, \eta_2 + 1)$, then on this interval

$$f'' \leqq -\bar{\delta}a/4,$$

which again leads to a contradiction. It is apparent from these inequalities that $f'' < 0$ past η_0 until $f' = -1$, and this shows W_1 is nonempty if case (i) holds.

To deal with case (ii), we use (9), (12) and (19) to show that

$$f''(\eta) \leqq -Ka \tag{20}$$

in the interval (p, η_1). This, with (18), leads to

$$f'' \leqq -Ka + \lambda \leqq -Ka/2 \leqq -M \tag{21}$$

on (η_1, η_1+1), if $f'>0$ on this interval. Since $f'(\eta_1)=M$, it is seen that $f'=0$ at some next $\eta_2<\eta_1+1$.

We now want to show that $f'=-1$ before $\eta=\eta_2+1$. This is more complicated than previously, and requires that we find a bound on $f(\eta_2)$. It will also use (12).

Integrate (9) once to give

$$f'+f^2/2 \leqq \lambda\eta^2/2.$$

This inequality, with $\eta=p$ and then with $\eta=\eta_2$, shows that

$$f'(p) \leqq \lambda p^2/2 \tag{22}$$

and

$$f(\eta_2) \leqq \lambda^{1/2}\eta_2. \tag{23}$$

But (21) holds in (p, η_2), so we find that

$$\eta_2 \leqq p+2f'(p)/Ka. \tag{24}$$

From (17), (23), and (24), and the definitions of K and M we conclude that

$$f(\eta_2) \leqq 12\lambda^{1/2}a. \tag{25}$$

Proceeding in a similar way, we can show that if $-1<f'<0$ in (η_2, η_2+1), then in that interval

$$f'' \leqq (12\lambda^{1/2}-K/4)a+\lambda \leqq -1,$$

which leads to a contradiction and so completes the proof of Lemma 4.

Continuing with the proof of Theorem 2, recall that $\bar{\alpha}$ was chosen so that $f_{\bar{\alpha}}$ is periodic, and furthermore, $f'_{\bar{\alpha}}>-1$ everywhere. Therefore if α is sufficiently close to $\bar{\alpha}$, then f'' must vanish at least twice before $f'=-1$. Hence $\alpha_1=\sup W_1$ is in the interval $(-1, \bar{\alpha})$. We wish to show that the solution f_{α_1} has the properties ascribed to it in the statement of Theorem 2. We need the following key result, which is also used later.

LEMMA 5. *Let E denote the set*

$$E=\{(f,f',f'')\,|\,f>0,\ 0\leqq f'\leqq 3^{1/2},\ (f'')^2\leqq -2\beta(f'-\tfrac{1}{3}f'^3)\}.$$

Then E is positively invariant for the natural first order system equivalent to (3), *and if f is a solution such that (f,f',f'') enters E, then $(f',f'')\to(1,0)$ as $\eta\to\infty$.*

Proof. Positive invariance follows because $H=0$ and $H'>0$ on the part of the boundary of E where $f>0$, and since $f'\geqq 0$ in E. The other part of the result is also clear, because H decreases in E and the minimum of H, and its only stationary point in E, is at $(1,0)$.

Now let $f=f_{\alpha_1}$. From the definition of α_1, and the fact that f'' and f''' cannot vanish simultaneously, we see that f'' cannot vanish more than once. On the other hand, suppose that f'' does not vanish at all. If f' becomes larger than 1, then (3) leads to a contradiction. One can therefore show that $(f',f'')\to(1,0)$, which implies that (f,f',f'') enters E. However then nearby solutions also enter E, which again contradicts the definition of α_1. Therefore f'' vanishes exactly once. However f' cannot fall below -1, and it follows easily that when $\alpha=\alpha_1$, $(f',f'')\to(-1,0)$, as desired.

Now there may be other values of α, between α_1 and $\bar{\alpha}$, such that f_α behaves in the same way. However we have seen that for α close enough to $\bar{\alpha}$, f'' must vanish more than once. Therefore the set

$$V_1=\{\alpha \text{ in } (\alpha_1,\bar{\alpha})\,|\,f'' \text{ vanishes once in } (0,\infty), \text{ and } (f',f'')\to(-1,0)\}$$

has a supremum, say $\bar{\alpha}_1$, in $[\alpha_1,\bar{\alpha})$. Let

$$W_2=\{\alpha \text{ in } (\bar{\alpha}_1,\bar{\alpha})\,|\,f'' \text{ vanish twice, after which } f' \text{ falls below } -1\}.$$

Arguing as above, we find the solution f_{α_2} of Theorem 2, and a routine induction completes the proof of this result.

Proof of Theorem 3. We first consider the solution f_0 when $\beta=-1$. A number of papers have been devoted to just this case. A recent paper contains the result we want.

LEMMA 6 [4]. *If $\beta=-1$ and $f(0)=f'(0)=f''(0)=0$, then f' increases to above* 1 *and then decreases to* 1, *while f'' has only one positive zero. Furthermore, $f'\to 1$ at an algebraic rate.*

Next we observe that for any negative β, the vector (f_0,f_0',f_0'') immediately (after $\eta=0$) enters and remains in the set E. By Lemma 5, f_0' tends to 1.

Now let

$$\bar{\beta}_1=\inf\{\beta^*\,|\,\text{if } \beta^*<\beta<-1 \text{ then } f_0'\to 1 \text{ with exactly one local maximum and no local minima}\}.$$

Since f'' and f''' cannot vanish simultaneously, we see that $\bar{\beta}_1$ lies in S_1. Furthermore, the methods of Troy in [19] show that for this value of β, $f'\to 1$ at an exponential rate.

LEMMA 7. *For β just below $\bar{\beta}_1$, f_0'' has exactly one* max *and one* min *before $f_0'\to 1$.*

Proof. Because f_0 is continuous in β, we see that for any $\varepsilon>0$, there is a $\delta>0$ such that if $0<\bar{\beta}_1-\beta<\delta$, then $|f'-1|<\varepsilon$ and $f>1/\varepsilon$ before f_0' crosses 1 for the second time. In a neighborhood of $f'=1$ solutions of (3) behave like (translates of) solutions of Weber's equation

$$y''+\eta y'+2\lambda y=0, \tag{26}$$

where $y\approx f'-1$. It is known that there is a $B>0$, depending on λ, such that no solution of (26) can have two successive zeros in the region $\eta>B$. This implies that f' cannot vanish twice in any region where $f>B$. From this we see that if $\bar{\beta}_1-\beta$ is sufficiently small, then f_0 can have no more than two crossings of $f'=1$. This proves Lemma 7.

In a similar manner one inductively completes the proof of Theorem 3.

Proof of Theorem 4. This proceeds in the same way as Theorem 3. Consider a fixed β in S_j. If $\alpha=0$, then f' tends to 1 with j relative maxima and minima. Let

$$\alpha_j=\inf\{\alpha\,|\,f_\alpha' \text{ tends to 1 after exactly } j \text{ relative maxima and minima}\}.$$

Then just as in the proof of Theorem 3 we show that f_{α_j} has the desired properties, and starting just to the left of α_j we construct α_{j+1}. We know that as $\alpha\to\bar{\alpha}$, $f_\alpha'-1$ acquires more and more zeros, and the result easily follows.

We now turn to the results which concern the initial conditions $f=f'=0$. As before, the solution to this problem, with $f''(0)=\gamma$, will be denoted by F_γ. For the sake of brevity we merely outline the proofs of Theorems 5-7.

We first consider *a* fixed β, which need only be negative.

LEMMA 8. *If $-\gamma$ is sufficiently large, then F_γ' decreases monotonically to below* -1.

This is proved by easy estimates which we omit. Let $\gamma_0=\sup\{\gamma\,|\,F_\gamma'$ decreases monotonically to below $-1\}$. Since we know $F_0'=f_0'$ and tends to $+1$, it is clear that $\gamma_0=0$. Further, F_{γ_0}'' cannot have a zero, since then F_γ'' would have a zero for γ close to γ_0. It easily follows that F_{γ_0}' tends monotonically to -1.

LEMMA 9. *F_{γ_0} is in fact the only solution to* (3), (7) *such that F' tends monotonically to* -1.

Proof. Suppose that F and G are two such solutions, and assume that $F'(0) < G'(0) < 0$. Then $F'''(0) < G'''(0)$, so initially, $F'' < G''$. Suppose that at some η, $F'' = G''$. It is easily seen that then $F''' < G'''$, a contradiction.

It is now clear that if γ is close to, but larger than, γ_0, then F'_γ comes close to, but does not cross, -1. (Otherwise there would be a second solution with the properties of F_{γ_0}.) As in the proof of Lemma 4 it then follows that for such γ, F' first has a negative local minimum, then a positive local maximum, and then falls monotonically below -1. It this way we obtain γ_1, γ_2, etc. as in the proof of Theorem 2. That is, we complete the proof of Theorem 6.

Theorem 7 is obtained in a similar manner. Finally we can obtain Theorem 5 by letting γ be the supremum of the γ_j of Theorem 6 or the infinimum of the γ_j^* of Theorem 7. Note that we cannot prove that these give the same value of γ.

SOLUTION, GRADIENT, AND LAPLACIAN BOUNDS IN SOME NONLINEAR FOURTH ORDER ELLIPTIC EQUATIONS*

PHILIP W. SCHAEFER†

Abstract. In order to obtain bounds of the type in the title, a suitable function is defined on the solutions to a certain class of semilinear fourth order elliptic partial differential equations. The subharmonicity of this function under appropriate conditions on the coefficients and nonlinear terms leads one immediately to the desired bounds.

Key words. elliptic equations, maximum principles, pointwise bounds

AMS(MOS) subject classifications. 35B45, 35B50

1. Introduction. The technique of defining a function on the solution of a differential equation and deducing results about the solution of the equation by means of the auxiliary function is well known. In [4], Payne used this idea to deduce gradient bounds on the solution in the torsion problem. There he utilized the Hopf maximum principles [9] to establish that the maximum of the auxiliary function occurred at a critical point of the solution in the domain of definition. Payne and several other authors [5], [7], [8], [10], [11] and references therein have extended his idea to the determination of bounds on the gradient of the solution to more general second order elliptic partial differential equations which are subject to boundary conditions of various kinds. One can find an exposition of some of these extensions, generalizations, and applications of Payne's method in Sperb's book [13].

The aforementioned technique has also been used in the study of fourth order elliptic partial differential equations. Dunninger [2] showed that, although there is no maximum principle for the solution of fourth order elliptic equations, any nontrivial solution of

$$\Delta^2 u + cu = 0, \qquad c > 0 \quad \text{in } D \subset R^n,$$

for which $\Delta u = 0$ on ∂D, satisfies the inequality

$$|u(x)| < |u(x_0)|, \qquad x \in D,$$

where x_0 is some point on the boundary ∂D of the bounded domain D. This was accomplished by showing that a suitably defined auxiliary function was a nonconstant subharmonic function. The result was extended to allow a variable coefficient in place of c and to deduce a related result in the case of metaharmonic equations in [1].

One can give any of a number of other illustrations of this technique. Here we shall employ this method in the study of nonlinear fourth order equations of the form

$$\Delta^2 u - q(x) g(\Delta u) + p(x) f(u) = 0. \tag{1.1}$$

By means of an appropriately defined auxiliary function defined on solutions of the equation, we shall develop maximum principles and deduce bounds on the solution, gradient of the solution, and the Laplacian of the solution. The principles are presented in § 2 and some immediate applications are obtained in § 3.

* Received by the editors April 22, 1985, and in revised form July 11, 1985.

† Department of Mathematics, University of Tennessee, Knoxville, Tennessee 37996-1300.

2. Principles. In [6] Payne obtained some specialized results from the subharmonicity of certain auxiliary functions defined on the solutions of the equation

$$\Delta^2 u = f(u),$$

where Δ is the Laplace operator and Δ^2 is the iterated Laplacian. Here we introduce an auxiliary function for a more general equation which allows us to deduce other bounds of importance in applications.

Let D be a bounded domain in Euclidean n-space and let $u \in C^4$ be a solution of the equation

$$\Delta^2 u - q(x)g(\Delta u) + cf(u) = 0, \tag{2.1}$$

in D, where we initially assume the coefficients satisfy

$$q(x) \geqq 0, \quad c > 0, \quad c \text{ constant}, \tag{2.2}$$

and the nonlinear functions satisfy the requirements

$$sg(s) \geqq 0, \qquad f'(u) \geqq \beta > 0, \tag{2.3}$$

where the prime indicates differentiation with respect to u.

We define the function

$$V(x) = u_{,i}u_{,i} + \gamma(\Delta u)^2 + 2\gamma c F(u), \tag{2.4}$$

where γ is a positive constant to be chosen and $F(u)$ is a primitive of the function f, i.e.,

$$F(u) = \int_0^u f(t)\, dt.$$

In (2.4) we have used the comma notation to indicate partial differentiation with respect to x_i and the summation convention, i.e., repeated indices in a term signifies summation from 1 to n.

By a straightforward calculation, we have

$$\begin{aligned}\Delta V = {} & 2u_{,ij}u_{,ij} + 2u_{,i}(\Delta u)_{,i} + 2\gamma(\Delta u)(\Delta^2 u) + 2\gamma(\Delta u)_{,i}(\Delta u)_{,i} \\ & + 2\gamma cf(u)\Delta u + 2\gamma cf'(u)u_{,i}u_{,i}.\end{aligned}$$

Now by (2.1) and the addition and subtraction of $u_{,i}u_{,i}$ and $(\Delta u)_{,i}(\Delta u)_{,i}$ we can write

$$\begin{aligned}\Delta V = {} & 2u_{,ij}u_{,ij} + |(\Delta u)_{,i} + u_{,i}|^2 + 2\gamma q(x)(\Delta u)g(\Delta u) \\ & + (2\gamma - 1)(\Delta u)_{,i}(\Delta u)_{,i} + (2\gamma cf'(u) - 1)u_{,i}u_{,i},\end{aligned} \tag{2.5}$$

from which it is clear that V is subharmonic in D for $\gamma = \max\{\frac{1}{2}, \frac{1}{2c\beta}\}$.

We summarize this result in

THEOREM 1. *Let $u \in C^4(D)$ be a solution of* (2.1), *where $q(x) \geqq 0$ and $c > 0$. If $f \in C^1(R)$ satisfies $f'(u) \geqq \beta > 0$ and g satisfies* $\mathrm{sg}(s) \geqq 0$, *then for $\gamma \geqq \max\{\frac{1}{2}, \frac{1}{2c\beta}\}$ the function*

$$V(x) = u_{,i}u_{,i} + \gamma(\Delta u)^2 + 2\gamma c\int_0^{u(x)} f(t)\, dt$$

takes its maximum value on the boundary of D.

If instead of (2.1), we consider

$$\Delta^2 u - q(x)g(\Delta u) + p(x)u = 0, \tag{2.6}$$

where $q(x) \geqq 0$ and $p(x) \geqq p_0 > 0$, and define

$$W(x) = u_{,i}u_{,i} + \gamma(\Delta u)^2 + \gamma p(x)u^2, \tag{2.7}$$

then in a manner similar to the derivation of (2.5), one obtains

$$\begin{aligned}\Delta W = {}& 2u_{,ij}u_{,ij} + |(\Delta u)_{,i} + u_{,i}|^2 + 2\gamma q(x)(\Delta u)g(\Delta u) + (2\gamma - 1)(\Delta u)_{,i}(\Delta u)_{,i} \\ & + (\gamma p - 1)u_{,i}u_{,i} + \gamma p|u_{,i} + 2p^{-1}up_{,i}|^2 + \gamma u^2[\Delta p - 4p^{-1}|\nabla p|^2].\end{aligned}$$

Consequently, we deduce the following.

THEOREM 2. *Let $u \in C^4(D)$ be a solution of* (2.6), *where $q(x) \geqq 0$ and $p \in C^2(D)$ satisfies $p(x) \geqq p_0 > 0$ and $p\Delta p - 4|\nabla p|^2 \geqq 0$. If g satisfies the condition* $\operatorname{sg}(s) \geqq 0$, *then for $\gamma \geqq \max\{\frac{1}{2}, \frac{1}{p_0}\}$ the function*

$$W(x) = u_{,i}u_{,i} + \gamma(\Delta u)^2 + \gamma p(x)u^2$$

takes its maximum value on the boundary of D.

If $q(x) = 0$ in (2.1) and (2.6), then we can introduce alternative auxiliary functions defined on the solutions of the respective equations.

THEOREM 3. *If $u \in C^4(D)$ is a solution of*

$$\Delta^2 u + cf(u) = 0, \qquad c > 0, \tag{2.8}$$

where $f \in C^1$ satisfies $f'(u) \geqq \beta > 0$ and $f(0) = 0$, then for

$$\gamma \geqq \max\left\{1, \frac{1}{(n-1)^2 c\beta}\right\}$$

the function

$$T(x) = nu_{,i}u_{,i} - u\Delta u + \gamma(n-1)^2\left[\frac{1}{2}(\Delta u)^2 + c\int_0^u f(t)\,dt\right]$$

takes its maximum value on the boundary of D.

Proof. Using a straightforward calculation of the Laplacian, (2.8), and a completion of the square, one obtains the identity

$$\begin{aligned}\Delta T = {}& 2nu_{,ij}u_{,ij} - (\Delta u)^2 + cuf(u) + |(n-1)(\Delta u)_{,i} + u_{,i}|^2 \\ & + (n-1)^2(\gamma - 1)(\Delta u)_{,i}(\Delta u)_{,i} + [(n-1)^2\gamma cf' - 1]u_{,i}u_{,i}.\end{aligned}$$

Since $nu_{,ij}u_{,ij} \geqq (\Delta u)^2$, we conclude that T is subharmonic in D under the conditions cited in the theorem.

In our next special case we omit the parameter γ but encounter a fixed lower bound on $p(x)$.

THEOREM 4. *If $u \in C^4(D)$ is a solution of*

$$\Delta^2 u + p(x)u = 0, \tag{2.9}$$

where $p(x) \geqq \frac{1}{3}$ and $\Delta(p^{-1}) \leqq 0$, then

$$S(x) = \frac{1}{2}(\Delta u - 2u)^2 + \frac{(2n-1)^2}{2}(\Delta u)^2 + 4nu_{,i}u_{,i} + (2n^2 - 2n + 1)pu^2$$

takes its maximum value on the boundary of D.

Proof. Computing the Laplacian and using (2.9), we have

$$\begin{aligned}\Delta S = {}& 2pu^2 - 2(\Delta u)^2 + 4u\Delta u + (4n^2 - 4n + 2)(\Delta u)_{,i}(\Delta u)_{,i} + 4(2n-1)u_{,i}(\Delta u)_{,i} \\ & + 4u_{,i}u_{,i} + 8nu_{,ij}u_{,ij} + \tau u^2\Delta p + 2\tau pu_{,i}u_{,i} + 4\tau uu_{,i}p_{,i},\end{aligned} \tag{2.10}$$

where $\tau=\tau(n)=2n^2-2n+1$. We use the arithmetic-geometric mean inequality on the fifth term of (2.10) to deduce that

$$(4n^2-4n+2)(\Delta u)_{,i}(\Delta u)_{,i}+4(2n-1)u_{,i}(\Delta u)_{,i}+4u_{,i}u_{,i} \geqq (\Delta u)_{,i}(\Delta u)_{,i}$$

and is thus nonnegative. Moreover, using the same inequality on the last term in (2.10), we have

$$\tau u^2\Delta p+2\tau p u_{,i}u_{,i}+4\tau u u_{,i}p_{,i} \geqq \tau u^2\left[\Delta p-\frac{2|\nabla p|^2}{p}\right]$$

and hence the sum is nonnegative when the bracket is nonnegative. Consequently, from (2.10) we have

$$\Delta S \geqq 2pu^2-2(\Delta u)^2+4u\Delta u+8nu_{,ij}u_{,ij}.$$

Now since $nu_{,ij}u_{,ij} \geqq (\Delta u)^2$ and

$$4u\Delta u \geqq -\tfrac{2}{3}u^2-6(\Delta u)^2,$$

we conclude that $\Delta S \geqq 2(p-\frac{1}{3})u^2$ and S is subharmonic in D.

In our final principle we require p to be harmonic.

THEOREM 5. *Let $u \in C^4(D)$ be a solution of* (1.1), *where $q(x) \geqq 0$ and $p(x)$ is a positive harmonic function bounded below by p_0. If $f \in C^1$ is a bounded function satisfying $f'(u) \geqq \beta > 0$ and g satisfies the requirement* $\mathrm{sg}\,(s) \geqq 0$, *then for $\gamma \geqq \max\{\frac{1}{2p_0}, \frac{1}{\beta}\}$ and $\alpha=\max\,(2\gamma^2 f^2/p_0)$ the function*

$$R(x)=\frac{u_{,i}u_{,i}}{p(x)}+\gamma\frac{(\Delta u)^2}{p(x)}+2\gamma\int_0^u f(t)\,dt+\alpha p(x)$$

takes its maximum value on the boundary of D.

Proof. We calculate

$$\begin{aligned}
R_{,j} &= 2p^{-1}u_{,i}u_{,ij}-p^{-2}u_{,i}u_{,i}p_{,j}+2p^{-1}\gamma(\Delta u)(\Delta u)_{,j}\\
&\qquad -\gamma p^{-2}(\Delta u)^2p_{,j}+2\gamma f u_{,j}+\alpha p_{,j},\\
\Delta R &= 2p^{-1}u_{,ij}u_{,ij}+2p^{-1}u_{,i}(\Delta u)_{,i}-4p^{-2}u_{,i}u_{,ij}p_{,j}\\
&\qquad +2p^{-3}|\nabla u|^2|\nabla p|^2+2\gamma p^{-1}q(\Delta u)g(\Delta u)+2\gamma p^{-1}(\Delta u)_{,j}(\Delta u)_{,j}\\
&\qquad -4\gamma p^{-2}(\Delta u)(\Delta u)_{,j}p_{,j}+2\gamma p^{-3}(\Delta u)^2|\nabla p|^2+2\gamma f'u_{,j}u_{,j},
\end{aligned}$$

and then form

$$\begin{aligned}
\Delta R+2p^{-1}p_{,j}R_{,j} &= 2p^{-1}u_{,ij}u_{,ij}+2p^{-1}u_{,i}(\Delta u)_{,i}+2\gamma p^{-1}q(\Delta u)g(\Delta u)\\
&\qquad +2\gamma p^{-1}(\Delta u)_{,j}(\Delta u)_{,j}+4\gamma p^{-1}fp_{,j}u_{,j}+2\gamma f'u_{,j}u_{,j}+2\alpha p^{-1}|\nabla p|^2.
\end{aligned} \tag{2.11}$$

The need for $p(x)$ to be harmonic arises in ΔR where Δp appears with both a positive and negative coefficient. Now if we use the arithmetic-geometric mean inequality on the second and fifth terms on the right side of (2.11), we can write

$$\begin{aligned}
\Delta R+2p^{-1}p_{,j}R_{,j} &\geqq 2p^{-1}u_{,ij}u_{,ij}+(2\gamma p-1)p^{-2}(\Delta u)_{,i}(\Delta u)_{,i}\\
&\qquad +2(\gamma f'-1)u_{,i}u_{,i}+[2\alpha p-(2\gamma f)^2]p^{-2}|\nabla p|^2,
\end{aligned}$$

from which the result follows.

3. Bounds. In Theorem 1 the subharmonic function $V(x)$ attains its maximum at some point, say x_0, on the boundary of D. Thus it follows that one can obtain bounds for the gradient of the solution, the Laplacian of the solution, and (perhaps implicitly) for the solution of (2.1). For example, as a consequence of Theorem 1, we have

$$|\nabla u(x)|^2 \leqq |\nabla u(x_0)|^2 + \gamma[\Delta u(x_0)]^2 + 2\gamma c \int_{u(x)}^{u(x_0)} f(t)\,dt$$

for x in D. If in Theorem 1 we also have $f(0)=0$, such as when $f(u)=u^3+u$, then we can obtain an estimate for the gradient that does not depend on the value of the solution at the point in question, i.e.,

$$|\nabla u(x)|^2 \leqq |\nabla u(x_0)|^2 + \gamma[\Delta u(x_0)]^2 + 2\gamma c \int_{0}^{u(x_0)} f(t)\,dt.$$

If, in addition to u being a solution of (2.1), one imposes homogeneous boundary conditions on u, then it may be possible to obtain maximum principles on the gradient or the Laplacian of u. For example, if u satisfies (2.1) in D and $u=0=\partial u/\partial n$ on ∂D, then it follows from Theorem 1 when $f(0)=0$ that

$$|\Delta u(x)| \leqq |\Delta u(x_0)|, \qquad x \in \bar{D}$$

for some $x_0 \in \partial D$. However, one must be concerned with the existence question in a problem of this type as is evident from [3] and [12]. In [3] it was shown that if u is a solution of (2.1) in D, where $f'(u) \geqq 0$ and $f(0)=0$, and is subject to boundary conditions of the form $u=0=\Delta u$, then $u \equiv 0$.

We have only briefly indicated how Theorem 1 in § 2 can be utilized to obtain pointwise bounds. Many other applications of the principles in § 2 are possible.

Acknowledgment. This work was accomplished while the author was a Visiting Guest Professor in the Mathematisches Institut I at the Universität Karlsruhe, West Germany. This opportunity was made possible by a University of Tennessee Faculty Development Leave.

HOMOGENIZATION LIMITS OF THE EQUATIONS OF ELASTICITY IN THIN DOMAINS*

A. DAMLAMIAN† AND M. VOGELIUS‡

Abstract. We study pure bending of a flat, linearly elastic three-dimensional plate with rapidly varying composition. Under appropriate coercivity—and boundedness—assumptions, it is shown that all limiting vertical displacement, coming from the equations of three-dimensional elasticity with plate thickness approaching 0, must necessarily satisfy a fourth order, two-dimensional "plate" equation. This analysis does *not* require any special structure of the composition, such as periodicity or quasiperiodicity.

Key words. elasticity, homogenization, plates

AMS(MOS) subject classifications. 73K10, 73K20, 35B30

Introduction. We study pure bending of a flat, linearly elastic three-dimensional plate with rapidly varying composition. A uniform coercivity-condition and a uniform boundedness-condition are placed on the constitutive elastic law, but we require no special structure in composition, such as periodicity or quasiperiodicity. It is shown that all limiting vertical displacements, coming from the equations of 3-D elasticity with plate-thickness approaching 0, must necessarily satisfy a fourth order equation of the form

$$\partial_{\alpha\beta}(M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta}w)=\mathcal{F} \tag{1}$$

on the (plate-) midplane Ω. The existence of a limiting equation of the form (1) is well known for plates with slowly varying composition [3], [14], [16]; recently Caillerie has studied plates with rapidly varying periodic composition [2]. The analysis presented here extends those results to plates with arbitrary variation in composition. For the periodic case there is an (essentially) unique limiting rigidity tensor $M_{\alpha\beta\gamma\delta}$. In addition to the particular form of the local variation it only depends on the limiting ratio of the thickness and the length scale of variation. The tensor $M_{\alpha\beta\gamma\delta}$ may be expressed in terms of energies of certain periodic cell problems.

Without structure assumptions about the local composition it is no longer possible to give explicit formulas for the $M_{\alpha\beta\gamma\delta}$. We believe that in interesting cases it may be possible to find upper and lower bounds for its eigenvalues much in the same way as has been (at least partially) done for certain composites [5], [12], [13], [19].

The problem studied here is also closely related to the problem of plates with rapidly varying periodic thickness considered in [7]-[10]. If voids are thought of as occupied by a material of zero strength, then a plate with rapidly varying thickness may in principle be thought of as a flat plate with rapidly varying composition. Due to our coercivity-condition, voids are not permitted in the flat plates considered here; they represent an added difficulty which we, at this point, technically do not know

how to handle without extra assumptions about the local structure of the composition. Some of the ideas of Γ-convergence may be relevant to this problem, since they have successfully been applied to study limits of noncoercive functionals in other circumstances [1].

Plates with rapidly varying composition are of interest in structural optimization; in certain design contexts they are known to be stronger than plates with only slow variation in composition. We refer the reader to [10] for a more detailed discussion of the relation between an optimal design problem and plates with rapidly varying composition.

The approach taken here is a variation of the method of H-convergence introduced by Murat [15] and Tartar [17]. One major difference is that in this case both the dimension of the domain in which the limiting equation is satisfied as well as the order of the limiting equation differs from that associated to the equations with rapid variations. In the analysis this difference is probably most apparent in the construction of the isomorphism from $H^{-2}(\Omega)$ to $\overset{\circ}{H}{}^2(\Omega)$, which is the candidate for the resolvent of our limiting operator.

The organization of this paper is as follows. In the first section we briefly provide some preliminaries concerning the equations of 3-D elasticity, and in addition we give a precise statement of the convergence result to be proven later. It is very convenient to rescale the thickness variable of the plate to the interval $(-1, 1)$; the three-dimensional equations are now all in the same domain—but they become singularly perturbed as the old thickness parameter approaches zero. In § 2 we apply Korn's and Poincare's inequalities to the solutions of the rescaled equations, and this leads directly to estimates of various expressions and then to statements about weakly convergent subsequences and the structure of their limits. A major part of any convergence argument, using the method of H-convergence, is to construct the isomorphism which is the candidate for the resolvent of the limit operator. In this case such an operator must necessarily map $H^{-2}(\Omega)$ onto $\overset{\circ}{H}{}^2(\Omega)$ and it turns out that it may be constructed from the three-dimensional equations by restricting attention to external loads that are uniform throughout the thickness. Section 4 contains the final step of the convergence argument, namely the verification of the right constitutive relationship between curvature and bending moments. This is accomplished by integration by parts of the energy bilinear form. The trial-functions are the solutions to the three-dimensional elastic problem with the prescribed loads, and the test functions are picked so that they satisfy the three-dimensional elastic equations with an external load which is uniform throughout the thickness, and so that they furthermore have constant curvatures in the limit as the thickness approaches zero. It is possible to select such test functions because of the aforementioned isomorphism. This last part of the proof is a variation of Murat and Tartar's div-curl lemma, which again is a special case of the so-called method of compensated compactness [18].

1. Preliminaries and statement of the main result. We shall write $\underset{\sim}{x} = (x_1, x_2, x_3)$ for vectors in $\mathbb{R}^3$ and $\underset{\approx}{x} = (x_1, x_2)$ for vectors in $\mathbb{R}^2$. Latin indices will usually range from 1 to 3, and Greek ones from 1 to 2; the summation convention applies whenever indices are repeated. We write $\partial_i = \partial/\partial x_i$ and $\partial_{ij} = \partial^2/\partial x_i\, \partial x_j$. The three-dimensional flat plate of thickness 2ε is given by

$$R(\varepsilon) = \{\underset{\sim}{x} \colon \underset{\approx}{x} \in \Omega, |x_3| < \varepsilon\}$$

where Ω is a smooth bounded domain in $\mathbb{R}^2$ and ε denotes a small parameter, with say $0 < \varepsilon \leqq 1$. We shall denote by $\partial_+ R(\varepsilon)$ and $\partial_- R(\varepsilon)$ the upper and lower faces of the plate

$$\partial_\pm R(\varepsilon)=\{\underset{\sim}{x}\colon \underset{\sim}{x}\in\Omega,\ x_3=\pm\varepsilon\}$$

and by $\partial_0 R(\varepsilon)$ we denote the outer edge of the plate

$$\partial_0 R(\varepsilon)=\{\underset{\sim}{x}\colon \underset{\sim}{x}\in\partial\Omega,\ |x_3|<\varepsilon\}.$$

Associated with any displacement $\underline{u}=(u_1, u_2, u_3)$ of $R(\varepsilon)$ is its strain tensor

$$e_{ij}(\underline{u})=\tfrac{1}{2}(\partial_i u_j+\partial_j u_i)$$

and the corresponding stress tensor

$$\sigma^\varepsilon_{ij}(\underline{u})=b^\varepsilon_{ijkl}e_{kl}(\underline{u}).$$

We are concerned with spatially inhomogeneous materials and so the components b^ε_{ijkl} of the elastic tensor are bounded measurable functions in $\underset{\sim}{x}$. These functions are permitted to change with the thickness parameter ε, and (except for certain symmetries) they will only be restricted by the following two requirements:

$$b^\varepsilon_{ijkl}(\underset{\sim}{x})e_{ij}e_{kl}\geqq c_1\sum_{i,j}|e_{ij}|^2, \tag{2}$$

$$\left(\sum_{i,j}|b^\varepsilon_{ijkl}(\underset{\sim}{x})e_{kl}|^2\right)^{1/2}\leqq C_2\left(\sum_{i,j}|e_{ij}|^2\right)^{1/2}, \tag{3}$$

a.e. in $R(\varepsilon)$ for any symmetric 2 tensor e, with constants $c_1>0$ and C_2 that are independent of ε. Note: throughout this paper c_1 and C_2 always refer to these same constants whereas the letters c and C will denote generic positive constants (independent of ε).

Remark 1. One simple example of rapid variation in composition, which falls within the framework of our study and which has received quite a bit of attention, is the case

$$b^\varepsilon_{ijkl}(\underset{\sim}{x})=b^1_{ijkl}(\underset{\sim}{x}/\varepsilon),$$

where $b^1_{ijkl}(\underset{\sim}{y})$ is periodic in $\underset{\sim}{y}$ and satisfies (2), (3) (cf. [2]). We also mention the work in [7]-[10] about plates with rapidly varying periodic thickness

$$\tilde{R}(\varepsilon)=\{\underset{\sim}{x}\colon \underset{\sim}{x}\in\Omega,\ |x_3|<\varepsilon h(\underset{\sim}{x}/\varepsilon^a)\},\qquad 0<a<\infty.$$

If we denote $h_{\max}=\max h$ then formally, at least, such a plate corresponds to an inhomogeneous material

$$b^\varepsilon_{ijkl}(\underset{\sim}{x})=b^1_{ijkl}(\underset{\sim}{x}/\varepsilon^a, x_3/\varepsilon)$$

with

$$b^1_{ijkl}(\underline{y})=\begin{cases} c_{ijkl}, & |y_3|<h(\underset{\sim}{y}),\\ 0, & |y_3|\geqq h(\underset{\sim}{y}),\end{cases}$$

occupying the flat domain

$$\{\underset{\sim}{x}\colon \underset{\sim}{x}\in\Omega,\ |x_3|<\varepsilon h_{\max}\}.$$

The possibility that b^ε_{ijkl} may vanish on $R(\varepsilon)$ is technically a significant extra difficulty which we shall not include in our analysis of arbitrary, rapidly varying composition. □

We always assume that the elastic tensor obeys the symmetries

$$b^\varepsilon_{ijkl}=b^\varepsilon_{jikl}=b^\varepsilon_{ijlk}=b^\varepsilon_{klij} \tag{4}$$

and that the horizontal planes are planes of elastic symmetry, which means (cf. [11])

$$(5)\qquad b^\varepsilon_{\alpha\beta\gamma 3}=0,\qquad b^\varepsilon_{\alpha 333}=0.$$

Finally we assume that b^ε is even with respect to x_3:

$$(6)\qquad b^\varepsilon_{ijkl}(\underset{\sim}{x}, x_3)=b^\varepsilon_{ijkl}(\underset{\sim}{x}, -x_3).$$

The equations of elastostatic equilibrium for the clamped, vertically loaded, three-dimensional plate $R(\varepsilon)$ are

$$(7)\qquad \begin{aligned} &-\partial_j[\sigma^\varepsilon_{ij}(\underline{u}^\varepsilon)]=\begin{cases}0, & i=1,2\\ \varepsilon^2F^\varepsilon, & i=3\end{cases}\quad \text{in } R(\varepsilon),\\ &\sigma^\varepsilon_{ij}(\underline{u}^\varepsilon)\nu_j=\begin{cases}0, & i=1,2\\ \varepsilon^3 f^\varepsilon_\pm, & i=3\end{cases}\quad \text{on } \partial_\pm R(\varepsilon),\\ &\underline{u}^\varepsilon=0\quad \text{on } \partial_0R(\varepsilon),\end{aligned}$$

where $\underline{\nu}=(0,0,\pm1)$ denotes the outward normal to $\partial_\pm R(\varepsilon)$. The loads are scaled in order to insure that $\underline{u}^\varepsilon$ stays bounded as ε goes to zero. For convenience we shall assume that F^ε is even in x_3 and that $f^\varepsilon_+(\underset{\sim}{x})=f^\varepsilon_-(\underset{\sim}{x})$; the common boundary load is denoted $f^\varepsilon(\underset{\sim}{x})$. Because of the linearity of the problem, this represents no loss of generality in the limit $\varepsilon\to0$, as the energy corresponding to odd loading is negligible compared with that of even loading for an elastic law with the symmetries (5) and (6) (cf. [8]). Notice that from the assumptions about the loads and (5), (6) it follows that

$$u^\varepsilon_1, u^\varepsilon_2 \text{ are odd},\quad u^\varepsilon_3 \text{ is even},$$

$$\sigma^\varepsilon_{\alpha\beta}, \sigma^\varepsilon_{33} \text{ are odd},\quad \sigma^\varepsilon_{\alpha 3} \text{ is even},$$

with respect to x_3; X_ε will denote the space of all admissible displacements that obey these symmetries:

$$X_\varepsilon=\{\underline{u}\in H^1(R(\varepsilon)) \colon \underline{u}|_{\partial_0R(\varepsilon)}=0,\ u_1,\ u_2 \text{ are odd and } u_3 \text{ is even in } x_3\},$$

where $H^1(R(\varepsilon))$ is the space of (vector-valued) functions with square integrable first derivatives. The problem (7) now has the following variational formulation:

$$(8)\qquad \underline{u}^\varepsilon\in X_\varepsilon,\qquad \int_{R(\varepsilon)}\sigma^\varepsilon_{ij}(\underline{u}^\varepsilon)e_{ij}(\underline{v})\,d\underline{x}=\varepsilon^2\int_{R(\varepsilon)}F^\varepsilon v_3\,d\underline{x}+2\varepsilon^3\int_{\partial_+R(\varepsilon)}f^\varepsilon v_3\,d\underset{\sim}{x}$$

for any $\underline{v}\in X_\varepsilon$. Unless explicitly stated otherwise we shall always assume that

$$(9)\qquad F^\varepsilon\in L^2(R(\varepsilon)),\qquad f^\varepsilon\in L^2(\Omega)$$

with

$$(10)\qquad \begin{aligned}&F^\varepsilon(\underset{\sim}{x}, \varepsilon y)\to F^0(\underset{\sim}{x}, y)\quad \text{in } L^2(\Omega\times(-1,1)),\\ &f^\varepsilon(\underset{\sim}{x})\to f^0(\underset{\sim}{x})\quad \text{in } L^2(\Omega),\end{aligned}$$

as $\varepsilon\to0$ (the regularity assumptions on the loads can be somewhat relaxed, see Remark 4, but we do not feel that this serves any purpose in the present context).

Since we are not imposing any requirements on the structure of the rapid variation in the b^ε_{ijkl}, we will not in general obtain convergence of $\underline{u}^\varepsilon$ as ε approaches zero. Instead our main result concerns convergent subsequences (which corresponds to the compactness property in the theory of Γ-convergence, cf. [4]).

THEOREM. *Let $\{\varepsilon_k\}_{k=1}^{\infty}$ be any given sequence converging to zero. There exist a subsequence $\{\varepsilon_{k(l)}\}_{l=1}^{\infty}$, for simplicity denoted $\{\varepsilon_l\}_{l=1}^{\infty}$, and a tensor-valued function $M_{\alpha\beta\gamma\delta}(\underset{\sim}{x})$ such that*

(i) $M_{\alpha\beta\gamma\delta}=M_{\beta\alpha\gamma\delta}=M_{\alpha\beta\delta\gamma}=M_{\gamma\delta\alpha\beta}$,

(ii) *$M_{\alpha\beta\gamma\delta}$ lies in $L^{\infty}(\Omega)$ with*

$$M_{\alpha\beta\gamma\delta}(\underset{\sim}{x})t_{\alpha\beta}t_{\gamma\delta}\geqq\frac{2}{3}c_1\sum_{\alpha,\beta}|t_{\alpha\beta}|^2,$$

$$\left(\sum_{\alpha,\beta}|M_{\alpha\beta\gamma\delta}(\underset{\sim}{x})t_{\gamma\delta}|^2\right)^{1/2}\leqq\frac{2}{3}C_2\left(\sum_{\alpha,\beta}|t_{\alpha\beta}|^2\right)^{1/2},$$

a.e. in Ω, for any symmetric 2 tensor t;

(iii) *for any even external load F^{ε_l} and any boundary loads $f_+^{\varepsilon_l}=f_-^{\varepsilon_l}=f^{\varepsilon_l}$, satisfying* (9) *and* (10), *the solution to the problem* (7), *$\underset{\sim}{u}^{\varepsilon_l}$, as ε_l approaches zero, converges to*

$$(-x_3\partial_1 w(\underset{\sim}{x}),\ -x_3\partial_2 w(\underset{\sim}{x}),\ w(\underset{\sim}{x})),$$

where $w\in H^2(\Omega)$ solves the problem

$$\partial_{\alpha\beta}(M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta}w)=\mathscr{F}^0\quad in\ \Omega,$$

$$w=\frac{\partial w}{\partial n}=0\quad on\ \partial\Omega.$$

The effective load $\mathscr{F}^0(\underset{\sim}{x})$ is given by

$$\mathscr{F}^0(\underset{\sim}{x})=\int_{-1}^{1}F^0(\underset{\sim}{x},y)\,dy+2f^0(\underset{\sim}{x}),$$

where F^0 and f^0 are the limits from (10). *The convergence is in the weak topologies*

$$u_3^{\varepsilon_l}(\underset{\sim}{x},\varepsilon_l y)\rightharpoonup w(\underset{\sim}{x})\quad in\ H^1(\Omega\times(-1,1)),$$

$$\frac{1}{\varepsilon_l}u_\alpha^{\varepsilon_l}(\underset{\sim}{x},\varepsilon_l y)\rightharpoonup -y\partial_\alpha w(\underset{\sim}{x})\quad in\ H^1(\Omega\times(-1,1)).$$

Remark 2. It is possible to prove a similar theorem without the symmetry requirement that $b_{ijkl}^{\varepsilon}=b_{klij}^{\varepsilon}$ (i.e., without assuming that b_{ijkl}^{ε} is a symmetric operator on 2 tensors). Of course, the resulting tensor $M_{\alpha\beta\gamma\delta}$ will not possess this symmetry either. The coercivity estimate stays the same, but the operator norm estimate for $M_{\alpha\beta\gamma\delta}$, $\frac{2}{3}C_2$, is replaced by $\frac{2}{3}((C_2)^2/c_1)$. We consider the symmetric case, since it is the only physically interesting one in the context of elastostatics.

Remark 3. It follows immediately from the statement of our theorem that

$$\frac{1}{2\varepsilon_l}\int_{-\varepsilon_l}^{\varepsilon_l}u_3^{\varepsilon_l}\,dx_3\rightharpoonup w(\underset{\sim}{x})\quad\text{in }\mathring{H}^1(\Omega);$$

it is actually shown in the proof of the theorem that $1/(2\varepsilon_l)\int_{-\varepsilon_l}^{\varepsilon_l}u_3^{\varepsilon_l}\,dx_3$ converges strongly towards w in $\mathring{H}^1(\Omega)$.

Remark 4. As stated earlier, the assumptions (10) on the loads are not the weakest possible. For the solution of (7) (or rather of (8)) to make sense it is necessary and sufficient that the functional

$$v\to\varepsilon^2\int_{R(\varepsilon)}F^{\varepsilon}v\,d\underset{\sim}{x}+2\varepsilon^3\int_{\partial_+R(\varepsilon)}f^{\varepsilon}v\,d\underset{\sim}{x}$$

be in the dual of $\{v \in H^1(R(\varepsilon)) \colon v|_{\partial_0 R(\varepsilon)} = 0,\ v$ is even in $x_3\}$, with the integrals representing appropriate duality pairings.

Define a rescaled functional $\mathscr{F}^\varepsilon$ as follows:

$$\langle \mathscr{F}^\varepsilon, v\rangle = \varepsilon^{-1} \int_{R(\varepsilon)} F^\varepsilon v(\underset{\sim}{x}, x_3/\varepsilon)\, d\underset{\sim}{x} + 2 \int_{\partial_+ R(\varepsilon)} f^\varepsilon v(\underset{\sim}{x}, x_3/\varepsilon)\, d\underset{\sim}{x}.$$

$\mathscr{F}^\varepsilon$ is then an element of the dual of $\{v \in H^1(R(1)) \colon v|_{\partial_0 R(1)} = 0,\ v$ is even in $x_3\}$ and our theorem still holds provided $\mathscr{F}^\varepsilon$ converge strongly in this dual space. The effective load $\mathscr{F}^0$ is given by the functional

$$\langle \mathscr{F}^0, w\rangle = \langle \lim_{\varepsilon \to 0} \mathscr{F}^\varepsilon, w\rangle,$$

where the function $w(\underset{\sim}{x})$ in the second expression is interpreted as a function of all three variables $(x_1, x_2, x_3) = (\underset{\sim}{x}, x_3)$ (only independent of x_3). We note that it is not possible to obtain all elements of the dual of $\overset{\circ}{H}{}^2(\Omega)$ as effective loads by this construction. The solution to the limit problem

$$\partial_{\alpha\beta}(M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta} w) = \mathscr{F}^0 \quad \text{in } \Omega,$$
$$w = \frac{\partial w}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

may be defined variationally for any $\mathscr{F}^0$ in the dual of $\overset{\circ}{H}{}^2(\Omega)$, but for certain (very unsmooth) $\mathscr{F}^0$, w is not related to solutions of the 3-D equations of elasticity through the limiting process discussed in this paper.

2. The rescaled problem—a priori estimates and limit behaviour. In this paragraph we study a rescaling of the problem (7) to the fixed domain $R(1) = \Omega \times (-1, 1)$. Independent variables in $R(1)$ will be denoted $(\underset{\sim}{x}, y)$ and we define the new dependent variables as follows:

$$U^\varepsilon_\alpha(\underset{\sim}{x}, y) = \frac{1}{\varepsilon} u^\varepsilon_\alpha(\underset{\sim}{x}, \varepsilon y), \qquad U^\varepsilon_3(\underset{\sim}{x}, y) = u^\varepsilon_3(\underset{\sim}{x}, \varepsilon y),$$

$$E^\varepsilon_{ij}(\underset{\sim}{x}, y) = \frac{1}{\varepsilon} e_{ij}(\underline{u}^\varepsilon)(\underset{\sim}{x}, \varepsilon y), \qquad \Sigma^\varepsilon_{ij}(\underset{\sim}{x}, y) = \frac{1}{\varepsilon} \sigma^\varepsilon_{ij}(\underline{u}^\varepsilon)(\underset{\sim}{x}, \varepsilon y).$$

The strain tensor of $\underline{U}^\varepsilon$ respective to the variables $(\underset{\sim}{x}, y)$ is given by

$$\left(\begin{array}{c|c} E^\varepsilon_{\alpha\beta} & \varepsilon E^\varepsilon_{\alpha 3} \\ \hline \varepsilon E^\varepsilon_{3\beta} & \varepsilon^2 E^\varepsilon_{33} \end{array}\right), \tag{11}$$

and from an application of Korn's inequality in the domain $R(1)$ (cf. [6]), it now follows that

$$\|\underline{U}^\varepsilon\|_{H^1(R(1))} \leqq C\left(\sum_{\alpha,\beta} \|E^\varepsilon_{\alpha\beta}\|^2_{L^2(R(1))} + \varepsilon^2 \sum_{\alpha} \|E^\varepsilon_{\alpha 3}\|^2_{L^2(R(1))} + \varepsilon^4 \|E^\varepsilon_{33}\|^2_{L^2(R(1))}\right)^{1/2} \tag{12}$$

(remember $\underline{U}^\varepsilon$ vanishes on $\partial_0 R(1)$). By rescaling the system (7) we see that

$$\begin{gathered} -\partial_\beta \Sigma^\varepsilon_{\alpha\beta} + \frac{1}{\varepsilon} \frac{\partial}{\partial y} \Sigma^\varepsilon_{\alpha 3} = 0, \\ -\frac{1}{\varepsilon} \partial_\beta \Sigma^\varepsilon_{3\beta} - \frac{1}{\varepsilon^2} \frac{\partial}{\partial y} \Sigma^\varepsilon_{33} = F^\varepsilon(\underset{\sim}{x}, \varepsilon y) \quad \text{in } R(1), \\ \Sigma^\varepsilon_{\alpha 3} = 0, \quad \frac{1}{\varepsilon^2} \Sigma^\varepsilon_{33} = \pm f^\varepsilon(\underset{\sim}{x}) \quad \text{on } \partial_\pm R(1), \end{gathered} \tag{13}$$

or in a variational form

$$\begin{aligned}(14)\qquad &\int_{R(1)}\left[\Sigma^\varepsilon_{\alpha\beta}e_{\alpha\beta}(\underline{V})+\frac{2}{\varepsilon}\Sigma^\varepsilon_{\alpha3}e_{\alpha3}(\underline{V})+\frac{1}{\varepsilon^2}\Sigma^\varepsilon_{33}e_{33}(\underline{V})\right]d\underset{\sim}{x}\,dy\\ &=\int_{R(1)}F^\varepsilon(\underset{\sim}{x},\varepsilon y)V_3\,d\underset{\sim}{x}\,dy+2\int_{\partial_+R(1)}f^\varepsilon V_3\,d\underset{\sim}{x}\end{aligned}$$

for any $\underline{V}\in X_1=\{\underline{V}\in H^1(R(1))\colon \underline{V}|_{\partial_0R(1)}=0,\ V_1,\ V_2$ are odd and V_3 is even in $y\}$. Here we have used the notation $e(\underline{V})$ for the strain of the displacement field $\underline{V}(\underset{\sim}{x},y)$ relative to the variables $(\underset{\sim}{x},y)$.

LEMMA 1. *The norms* $\|\underline{U}^\varepsilon\|_{H^1(R(1))}$, $\|E^\varepsilon_{ij}\|_{L^2(R(1))}$, *and* $\|\Sigma^\varepsilon_{ij}\|_{L^2(R(1))}$ *are all bounded by* $C(\|F^\varepsilon(\underset{\sim}{x},\varepsilon y)\|_{L^2(R(1))}+\|f^\varepsilon\|_{L^2(\Omega)})$.

Proof. Inserting $\underline{V}=\underline{U}^\varepsilon$ into (14) and using the formula (11) for $e(\underline{U}^\varepsilon)$ we get

$$(15)\qquad \int_{R(1)}\Sigma^\varepsilon_{ij}E^\varepsilon_{ij}\,d\underset{\sim}{x}\,dy=\int_{R(1)}F^\varepsilon(\underset{\sim}{x},\varepsilon y)U^\varepsilon_3\,d\underset{\sim}{x}\,dy+2\int_{\partial_+R(1)}f^\varepsilon U^\varepsilon_3\,d\underset{\sim}{x}.$$

The coercivity of the elastic tensor and the estimate (12) now leads to

$$\begin{aligned}c_1\sum_{i,j}\|E^\varepsilon_{ij}\|^2_{L^2(R(1))}&\leqq C(\|F^\varepsilon(\underset{\sim}{x},\varepsilon y)\|_{L^2(R(1))}+\|f^\varepsilon\|_{L^2(\Omega)})\|\underline{U}^\varepsilon\|_{H^1(R(1))}\\ &\leqq C(\|F^\varepsilon(x,\varepsilon y)\|_{L^2(R(1))}+\|f^\varepsilon\|_{L^2(\Omega)})\left(\sum_{i,j}\|E^\varepsilon_{ij}\|^2_{L^2(R(1))}\right)^{1/2}\end{aligned}$$

so that

$$(16)\qquad \left(\sum_{i,j}\|E^\varepsilon_{ij}\|^2\right)^{1/2}\leqq C(\|F^\varepsilon(\underset{\sim}{x},\varepsilon y)\|_{L^2(R(1))}+\|f^\varepsilon\|_{L^2(\Omega)}).$$

The desired estimates follow directly from (16) in combination with (3) and (12). □

Remark 5. Based on Lemma 1 and the formulas for $E^\varepsilon_{\alpha3}$ and E^ε_{33} we get that

$$(17)\qquad \left\|\frac{\partial}{\partial y}U^\varepsilon_\alpha+\partial_\alpha U^\varepsilon_3\right\|_{L^2(R(1))}\leqq C\varepsilon(\|F^\varepsilon(\underset{\sim}{x},\varepsilon y)\|_{L^2(R(1))}+\|f^\varepsilon\|_{L^2(\Omega)}),$$

$$(18)\qquad \left\|\frac{\partial}{\partial y}U^\varepsilon_3\right\|_{L^2(R(1))}\leqq C\varepsilon^2(\|F^\varepsilon(\underset{\sim}{x},\varepsilon y)\|_{L^2(R(1))}+\|f^\varepsilon\|_{L^2(\Omega)}).$$

According to our assumption (10) $F^\varepsilon(\underset{\sim}{x},\varepsilon y)$ converges in $L^2(R(1))$ and f^ε in $L^2(\Omega)$; Lemma 1 now gives that $\|\underline{U}^\varepsilon\|_{H^1(R(1))}$, $\|E^\varepsilon_{ij}\|_{L^2(R(1))}$ and $\|\Sigma^\varepsilon_{ij}\|_{L^2(R(1))}$ are bounded independently of ε. From any sequence $\{\varepsilon_k\}^\infty_{k=1}$ converging to zero it is thus possible to extract a subsequence $\{\varepsilon_l\}^\infty_{l=1}$ such that

$$(19)\qquad \underline{U}^{\varepsilon_l}\rightharpoonup\underline{U}^0\quad\text{in } H^1(R(1)),$$

$$(20)\qquad E^{\varepsilon_l}_{ij}\rightharpoonup E^0_{ij}\quad\text{in } L^2(R(1)),$$

$$(21)\qquad \Sigma^{\varepsilon_l}_{ij}\rightharpoonup\Sigma^0_{ij}\quad\text{in } L^2(R(1)),$$

as ε_l approaches zero.

LEMMA 2. *The third component of* $\underline{U}^0$, U^0_3, *is independent of* y *and belongs to* $\overset{\circ}{H}{}^2(\Omega)$. *Furthermore*

$$U^0_\alpha=-y\partial_\alpha U^0_3,\qquad E^0_{\alpha\beta}=-y\partial_{\alpha\beta}U^0_3.$$

Proof. From (18) we get that $(\partial/\partial y)U^0_3=0$, U^0_3 is therefore independent of y. From (17) we get $(\partial/\partial y)U^0_\alpha=-\partial_\alpha U^0_3$ and since U^0_α is odd with respect to y, $U^0_\alpha=-y\partial_\alpha U^0_3$.

$E^{\varepsilon_l}_{\alpha\beta}=e_{\alpha\beta}(\underset{\sim}{U}^{\varepsilon_l})=\frac{1}{2}(\partial_\alpha U^{\varepsilon_l}_\beta+\partial_\beta U^{\varepsilon_l}_\alpha)$ converges as a distribution towards $\frac{1}{2}(\partial_\alpha U^0_\beta+\partial_\beta U^0_\alpha)=-y\partial_{\alpha\beta}U^0_3$; on the other hand, it also converges towards $E^0_{\alpha\beta}$, and consequently $E^0_{\alpha\beta}=-y\partial_{\alpha\beta}U^0_3$. We already know that $U^0_3\in H^1(\Omega)$ with $U^0_3=0$ on $\partial\Omega$. From the fact that $-y\,\partial_\alpha U^0_3=U^0_\alpha\in H^1(R(1))$ we conclude that $U^0_3\in H^2(\Omega)\cap\mathring{H}^1(\Omega)$. It only remains to prove that $(\partial/\partial n)U^0_3=0$ on $\partial\Omega$, where $\partial/\partial n$ is the outward normal derivative.

Since $U^{\varepsilon_l}_\alpha=0$ on $\partial_0R(1)=\partial\Omega\times(-1,1)$ and $U^{\varepsilon_l}_\alpha$ converges weakly towards U^0_α in $H^1(R(1))$, it follows that $-y\partial_\alpha U^0_3=U^0_\alpha=0$ on $\partial\Omega\times(-1,1)$. This necessarily implies that $\partial_\alpha U^0_3=0$ on $\partial\Omega$, and so $(\partial/\partial n)U^0_3=n_\alpha\partial_\alpha U^0_3=0$ on $\partial\Omega$. □

If $v(\underset{\sim}{x},y)$ is a function on $R(1)$ then we define

$$\bar{v}(\underset{\sim}{x})=\frac{1}{2}\int_{-1}^{1}v(\underset{\sim}{x},y)\,dy.$$

From (19) and the fact that U^0_3 is independent of y it follows that $\bar{U}^{\varepsilon_l}_3\rightharpoonup U^0_3$ in $H^1(\Omega)$; this result may be slightly improved.

LEMMA 3. *$\bar{U}^{\varepsilon_l}_3$ converges strongly towards U^0_3 in $\mathring{H}^1(\Omega)$ as ε_l approaches zero.*

Proof. We may write

$$\begin{aligned}\partial_\alpha\bar{U}^\varepsilon_3(\underset{\sim}{x})&=\frac{1}{2}\int_{-1}^{1}\partial_\alpha U^\varepsilon_3(\underset{\sim}{x},y)\,dy\\&=\frac{1}{2}\int_{-1}^{1}\left(\varepsilon E^\varepsilon_{\alpha3}(\underset{\sim}{x},y)-\frac{\partial}{\partial y}U^\varepsilon_\alpha(\underset{\sim}{x},y)\right)dy\\&=\varepsilon\bar{E}^\varepsilon_{\alpha3}(\underset{\sim}{x})-\frac{1}{2}(U^\varepsilon_\alpha(\underset{\sim}{x},1)-U^\varepsilon_\alpha(\underset{\sim}{x},-1)).\end{aligned}$$

From the estimate of $\|E^\varepsilon_{\alpha3}\|_{L^2(R(1))}$ in Lemma 1 it therefore follows that

$$\partial_\alpha\bar{U}^\varepsilon_3(\underset{\sim}{x})+\tfrac{1}{2}(U^\varepsilon_\alpha(\underset{\sim}{x},1)-U^\varepsilon_\alpha(\underset{\sim}{x},-1))\to0\quad\text{in } L^2(\Omega)\quad\text{as }\varepsilon\to0. \tag{22}$$

We also know that $U^{\varepsilon_l}_\alpha\rightharpoonup U^0_\alpha$ in $H^1(R(1))$, and this implies that $U^{\varepsilon_l}_\alpha(\underset{\sim}{x},\pm1)$ converges weakly in $H^{1/2}(\Omega)$, and thus strongly in $L^2(\Omega)$, towards $U^0_\alpha(\underset{\sim}{x},\pm1)=\mp\partial_\alpha U^0_3(\underset{\sim}{x})$. It follows immediately from (22) that

$$\partial_\alpha(\bar{U}^{\varepsilon_l}_3-U^0_3)\to0\quad\text{in } L^2(\Omega),$$

which shows that $\bar{U}^{\varepsilon_l}_3$ converges strongly towards U^0_3 in $\mathring{H}^1(\Omega)$, as ε_l approaches zero. □

Integration in y on both sides of (21) gives $\int_{-1}^{1}\Sigma^{\varepsilon_l}_{\alpha3}\,dy\rightharpoonup\int_{-1}^{1}\Sigma^0_{\alpha3}\,dy$ in $L^2(\Omega)$. It turns out that $\int_{-1}^{1}\Sigma^0_{\alpha3}\,dy=0$, and furthermore that it is possible to find the weak limit of $(1/\varepsilon_l)\int_{-1}^{1}\Sigma^{\varepsilon_l}_{\alpha3}\,dy$ in $H^{-1}(\Omega)$ (our notation for the dual of $\mathring{H}^1(\Omega)$).

LEMMA 4. *$(1/\varepsilon_l)\int_{-1}^{1}\Sigma^{\varepsilon_l}_{\alpha3}\,dy$ converges weakly in $H^{-1}(\Omega)$ towards $\partial_\beta\int_{-1}^{1}y\Sigma^0_{\alpha\beta}\,dy$ as ε_l approaches zero.*

Proof. Performing an integration by parts and using the first and third equation in (13) we obtain

$$\frac{1}{\varepsilon}\int_{-1}^{1}\Sigma^\varepsilon_{\alpha3}\,dy=-\frac{1}{\varepsilon}\int_{-1}^{1}y\frac{\partial}{\partial y}\Sigma^\varepsilon_{\alpha3}\,dy=\int_{-1}^{1}y\partial_\beta\Sigma^\varepsilon_{\alpha\beta}\,dy=\partial_\beta\int_{-1}^{1}y\Sigma^\varepsilon_{\alpha\beta}\,dy. \tag{23}$$

Since $\Sigma^{\varepsilon_l}_{\alpha\beta}\rightharpoonup\Sigma^0_{\alpha\beta}$ in $L^2(R(1))$ we know that

$$\int_{-1}^{1}y\Sigma^{\varepsilon_l}_{\alpha\beta}\,dy\rightharpoonup\int_{-1}^{1}y\Sigma^0_{\alpha\beta}\,dy\quad\text{in } L^2(\Omega)$$

and therefore

$$\frac{1}{\varepsilon_l}\int_{-1}^{1}\Sigma^{\varepsilon_l}_{\alpha3}\,dy\rightharpoonup\partial_\beta\int_{-1}^{1}y\Sigma^0_{\alpha\beta}\,dy\quad\text{in } H^{-1}(\Omega).$$

□

The tensor $-\int_{-1}^{1} y\Sigma_{\alpha\beta}^0\, dy$ will play a significant role in the construction of the tensor $M_{\alpha\beta\gamma\delta}$; it eventually turns out that

$$-\int_{-1}^{1} y\Sigma_{\alpha\beta}^0\, dy = M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta}U_3^0.$$

At this point we only observe that

$$-\partial_{\alpha\beta}\int_{-1}^{1} y\Sigma_{\alpha\beta}^0\, dy = \int_{-1}^{1} F^0(\underset{\sim}{x}, y)\, dy + 2f^0(\underset{\sim}{x}) \quad \text{in } \Omega, \tag{24}$$

where F^0 and f^0 are the limits of $F^\varepsilon(\underset{\sim}{x}, \varepsilon y)$ and f^ε, respectively (cf. (10)). To get (24) one uses (23) and the second and fourth identities in (13) to write

$$\begin{aligned} -\partial_{\alpha\beta}\int_{-1}^{1} y\Sigma_{\alpha\beta}^\varepsilon\, dy &= -\frac{1}{\varepsilon}\partial_\alpha \int_{-1}^{1} \Sigma_{\alpha 3}^\varepsilon\, dy \\ &= \frac{1}{\varepsilon^2}\int_{-1}^{1} \frac{\partial}{\partial y}\Sigma_{33}^\varepsilon\, dy + \int_{-1}^{1} F^\varepsilon(\underset{\sim}{x}, \varepsilon y)\, dy \\ &= 2f^\varepsilon(\underset{\sim}{x}) + \int_{-1}^{1} F^\varepsilon(\underset{\sim}{x}, \varepsilon y)\, dy. \end{aligned} \tag{25}$$

Passing to the limits in this identity as ε approaches zero along the sequence $\{\varepsilon_l\}_{l=1}^\infty$ we are led to (24).

Remark 6. So far we have obtained a number of convergence results for subsequences $\underline{U}^{\varepsilon_l}$, $E_{ij}^{\varepsilon_l}$ and $\Sigma_{ij}^{\varepsilon_l}$ corresponding to a specific set of loads $(F^\varepsilon, f^\varepsilon)$ converging to (F^0, f^0). Since the appropriate norms of the differences between the U^ε's, the E^ε's and the Σ^ε's corresponding to different loads $(F^\varepsilon, f^\varepsilon)$ and $(G^\varepsilon, g^\varepsilon)$ are bounded by $C(\|(F^\varepsilon - G^\varepsilon)(\underset{\sim}{x}, \varepsilon y)\|_{L^2(R(1))} + \|f^\varepsilon - g^\varepsilon\|_{L^2(\Omega)})$ (Lemma 1), it follows that we may pick the same index sequence $\{\varepsilon_l\}_{l=1}^\infty$ for *any* loads $(F^\varepsilon, f^\varepsilon)$ that converge to this (F^0, f^0) in the sense of (10).

$L^2(R(1)) \times L^2(\Omega)$ is a separable Hilbert space; let $\{(F_N^0, f_N^0)\}_{N=1}^\infty$ be a basis. Following the previous argument we may for each N find a subsequence

$$\{\varepsilon_l^N\}_{l=1}^\infty \subseteq \{\varepsilon_l^{N-1}\}_{l=1}^\infty \subseteq \cdots \subseteq \{\varepsilon_l^1\}_{l=1}^\infty \subseteq \{\varepsilon_k\}_{k=1}^\infty$$

so that the convergence results listed above hold for solutions to the problem (7) for any $(F^\varepsilon, f^\varepsilon)$ converging to (F_N^0, f_N^0). By taking the diagonal subsequence of all the $\{\varepsilon_l^N\}_{l=1}^\infty$ we obtain a subsequence $\{\varepsilon_l\}_{l=1}^\infty$ for which the convergence results hold simultaneously for all N. Since linear combinations of the $\{(F_N^0, g_N^0)\}_{N=1}^\infty$ are dense in $L^2(R(1)) \times L^2(\Omega)$, and since appropriate norms of the differences between the U^{ε_l}'s, the E^{ε_l}'s and the Σ^{ε_l}'s, in the limit, are bounded by the norm of the difference between the limits of the loads in $L^2(R(1)) \times L^2(\Omega)$ (Lemma 1), it follows that the *convergence results of this section hold for the fixed subsequence* $\{\varepsilon_l\}_{l=1}^\infty$ *for any loads* $(F^\varepsilon, f^\varepsilon)$ *that converge in the sense of* (10).

3. An auxiliary isomorphism. If the homogenized limit operator is to have the form $\partial_{\alpha\beta}(M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta})$ then it must necessarily be an isomorphism between $\mathring{H}^2(\Omega)$ and $H^{-2}(\Omega)$ (our notation for the dual of $\mathring{H}^2(\Omega)$). We shall now study in more detail a particular case of the boundary value problem (7), where the exterior load is independent of x_3 and ε and where the boundary loads vanish. We show that, in the limit as ε_l approaches 0, this naturally leads to an isomorphism between $\mathring{H}^2(\Omega)$ and $H^{-2}(\Omega)$. We owe the initial suggestion, that it might be easier to obtain an isomorphism using vanishing boundary loads, to L. Tartar. For the remainder of this paper $\{\varepsilon_l\}_{l=1}^\infty$ always refers to the "universal" subsequence of $\{\varepsilon_k\}_{k=1}^{\infty}$ selected by the diagonalization process discussed in Remark 6.

Let G be in $L^2(\Omega)$ and let $\underline{v}^\varepsilon \in X_\varepsilon$ be the solution to

$$
\begin{aligned}
&-\partial_j[\sigma_{ij}^\varepsilon(\underline{v}^\varepsilon)] = \begin{cases} 0, & i=1,2 \\ \varepsilon^2 G(\underset{\sim}{x}), & i=3 \end{cases} \quad \text{in } R(\varepsilon), \\
&\sigma_{ij}^\varepsilon(\underline{v}^\varepsilon)\nu_j = 0, \qquad i=1,2,3 \quad \text{on } \partial_\pm R(\varepsilon), \\
&\underline{v}^\varepsilon = 0 \quad \text{on } \partial_0 R(\varepsilon).
\end{aligned} \tag{26}
$$

As before we introduce rescaled variables

$$
V_\alpha^\varepsilon(\underset{\sim}{x}, y) = \frac{1}{\varepsilon} v_\alpha^\varepsilon(\underset{\sim}{x}, \varepsilon y), \qquad V_3^\varepsilon(\underset{\sim}{x}, y) = v_3^\varepsilon(\underset{\sim}{x}, \varepsilon y),
$$

$$
\tilde{E}_{ij}^\varepsilon = \frac{1}{\varepsilon} e_{ij}(\underline{v}^\varepsilon)(\underset{\sim}{x}, \varepsilon y), \qquad \tilde{\Sigma}_{ij}^\varepsilon = \frac{1}{\varepsilon} \sigma_{ij}^\varepsilon(\underline{v}^\varepsilon)(\underset{\sim}{x}, \varepsilon y).
$$

From the analysis in the previous section we know among other things that

$$
\bar{V}_3^{\varepsilon_l} \to V_3^0 \quad \text{in } H^1(\Omega)
$$

as ε_l approaches zero. We furthermore know that $V_3^0 \in \mathring{H}^2(\Omega)$.

LEMMA 5. *For any* $G \in L^2(\Omega)$,

$$
\|V_3^0\|_{\mathring{H}^2(\Omega)}^2 \leqq C \int_\Omega G V_3^0 \, d\underset{\sim}{x}, \qquad \|G\|_{H^{-2}(\Omega)}^2 \leqq C \int_\Omega G V_3^0 \, d\underset{\sim}{x}.
$$

Proof. The identity corresponding to (15) in this case ($F^\varepsilon(\underset{\sim}{x}, \varepsilon y) = G(\underset{\sim}{x})$, $f^\varepsilon = 0$) reads

$$
\int_{R(1)} \tilde{\Sigma}_{ij}^\varepsilon \tilde{E}_{ij}^\varepsilon \, d\underset{\sim}{x}\, dy = \int_{R(1)} G V_3^\varepsilon \, d\underset{\sim}{x}\, dy;
$$

because of the coercivity assumption (2) and the fact that G is independent of y it follows that

$$
c_1 \sum_{\alpha,\beta} \|\tilde{E}_{\alpha\beta}^\varepsilon\|_{L^2(R(1))}^2 \leqq c_1 \sum_{i,j} \|\tilde{E}_{ij}^\varepsilon\|_{L^2(R(1))}^2 \leqq 2 \int_\Omega G \bar{V}_3^\varepsilon \, d\underset{\sim}{x}. \tag{27}
$$

From Lemma 2 we know

$$
\tilde{E}_{\alpha\beta}^{\varepsilon_l} \rightharpoonup -y \partial_{\alpha\beta} V_3^0 \quad \text{in } L^2(R(1)).
$$

Passing to the limit in (27) along the sequence $\{\varepsilon_l\}$, and using the weak lower semicontinuity of the norm, we thus obtain

$$
\frac{2}{3} c_1 \sum_{\alpha,\beta} \|\partial_{\alpha\beta} V_3^0\|_{L^2(\Omega)}^2 = c_1 \sum_{\alpha,\beta} \|y \partial_{\alpha\beta} V_3^0\|_{L^2(R(1))}^2 \leqq 2 \int_\Omega G V_3^0 \, d\underset{\sim}{x}.
$$

This proves the first inequality of our statement, since

$$
\left(\sum_{\alpha,\beta} \|\partial_{\alpha\beta} \cdot \|_{L^2(\Omega)}^2 \right)^{1/2}
$$

is one of the equivalent norms on $\mathring{H}^2(\Omega)$.

The identity corresponding to (25) in the present situation reads

$$\partial_{\alpha\beta}\int_{-1}^{1} y\tilde{\Sigma}^{\varepsilon}_{\alpha\beta}\,dy=-2G(\underset{\sim}{x}).$$

Consequently,

$$\|G\|^2_{H^{-2}(\Omega)}\leqq C\sum_{\alpha,\beta}\left\|\int_{-1}^{1} y\tilde{\Sigma}^{\varepsilon}_{\alpha\beta}\,dy\right\|^2_{L^2(\Omega)}\leqq C\sum_{\alpha,\beta}\|\tilde{\Sigma}^{\varepsilon}_{\alpha\beta}\|^2_{L^2(R(1))}. \tag{28}$$

The $\tilde{E}^{\varepsilon}_{ij}$ and $\tilde{\Sigma}^{\varepsilon}_{ij}$ are related by

$$\tilde{\Sigma}^{\varepsilon}_{ij}=b^{\varepsilon}_{ijkl}(\underset{\sim}{x},\varepsilon y)\tilde{E}^{\varepsilon}_{kl},$$

and this in combination with (3) and (28) leads to

$$\|G\|^2_{H^{-2}(\Omega)}\leqq C\sum_{i,j}\|\tilde{E}^{\varepsilon}_{ij}\|^2_{L^2(R(1))}.$$

The last inequality of (27) then gives

$$\|G\|^2_{H^{-2}(\Omega)}\leqq C\int_{\Omega} G\bar{V}^{\varepsilon}_3\,d\underset{\sim}{x},$$

which in the limit as ε approaches zero along the sequence $\{\varepsilon_l\}_{l=1}^{\infty}$ yields the desired second inequality. □

We define an operator from $L^2(\Omega)$ into $\mathring{H}^2(\Omega)$ by $G\to V^0_3$. It follows directly from the two inequalities in Lemma 5 that

$$c\|G\|_{H^{-2}(\Omega)}\leqq\|V^0_3\|_{\mathring{H}^2(\Omega)}\leqq C\|G\|_{H^{-2}(\Omega)},$$

i.e., the above operator may be extended as an injective and bounded linear operator $\mathcal{S}$: $H^{-2}(\Omega)\to\mathring{H}^2(\Omega)$. From the second inequality in Lemma 5 it now follows, using the Lax-Milgram lemma, that $\mathcal{S}$ maps $H^{-2}(\Omega)$ onto $\mathring{H}^2(\Omega)$. In summary

(29) The operator $G\to V^0_3$ may be extended as an isomorphism $\mathcal{S}$ between $H^{-2}(\Omega)$ and $\mathring{H}^2(\Omega)$.

Let G_i, $i=1,2$, be two elements of $L^2(\Omega)$, and let $\underset{\sim}{v}^{\varepsilon}_{(i)}$ denote the solution of (26), corresponding to $G=G_i$, $i=1,2$. According to the variational formulation (8) and the symmetry of the elastic tensor b^{ε}_{ijkl}

$$\begin{aligned}\varepsilon^2\int_{R(\varepsilon)} G_1v^{\varepsilon}_{(2),3}\,d\underset{\sim}{x}&=\int_{R(\varepsilon)}\sigma^{\varepsilon}_{ij}(\underset{\sim}{v}^{\varepsilon}_{(1)})e_{ij}(\underset{\sim}{v}^{\varepsilon}_{(2)})\,d\underset{\sim}{x}\\&=\int_{R(\varepsilon)}\sigma^{\varepsilon}_{ij}(\underset{\sim}{v}^{\varepsilon}_{(2)})e_{ij}(\underset{\sim}{v}^{\varepsilon}_{(1)})\,d\underset{\sim}{x}=\varepsilon^2\int_{R(\varepsilon)} G_2v^{\varepsilon}_{(1),3}\,d\underset{\sim}{x}.\end{aligned}$$

From this we immediately conclude that

$$\int_{\Omega} G_1\bar{V}^{\varepsilon}_{(2),3}\,d\underset{\sim}{x}=\int_{\Omega} G_2\bar{V}^{\varepsilon}_{(1),3}\,d\underset{\sim}{x},$$

and thus in the limit, as ε approaches zero along the sequence $\{\varepsilon_l\}_{l=1}^{\infty}$, we obtain

$$\int_{\Omega} G_1\mathcal{S}(G_2)\,d\underset{\sim}{x}=\int_{\Omega} G_2\mathcal{S}(G_1)\,d\underset{\sim}{x}. \tag{30}$$

By continuity the identity (30) is satisfied for any $G_i\in H^{-2}(\Omega)$, i.e., we have shown that $\mathcal{S}$ is selfadjoint.

Finally let us consider the operator that takes $G \in L^2(\Omega)$ to the tensor $-\int_{-1}^{1} y\tilde{\Sigma}^0_{\alpha\beta}\, dy \in L^2(\Omega)$. The $\tilde{E}^\varepsilon_{ij}$ and $\tilde{\Sigma}^\varepsilon_{ij}$ are related by

$$\tilde{\Sigma}^\varepsilon_{ij} = b^\varepsilon_{ijkl}(x, \varepsilon y)\tilde{E}^\varepsilon_{kl},$$

and using (3) and the last inequality in (27), we thus get

$$\begin{aligned} \sum_{\alpha,\beta} \left\| \int_{-1}^{1} y\tilde{\Sigma}^\varepsilon_{\alpha\beta}\, dy \right\|^2_{L^2(\Omega)} &\leqq C \sum_{\alpha,\beta} \|\tilde{\Sigma}^\varepsilon_{\alpha\beta}\|^2_{L^2(R(1))} \\ &\leqq C \sum_{i,j} \|\tilde{E}^\varepsilon_{ij}\|^2_{L^2(R(1))} \leqq C \int_\Omega G\bar{V}^\varepsilon_3\, dx. \end{aligned} \tag{31}$$

Because of the weak lower semicontinuity of the norm it follows, by passing to the limit in (31) along the sequence $\{\varepsilon_l\}_{l=1}^\infty$, that

$$\sum_{\alpha,\beta} \left\| \int_{-1}^{1} y\tilde{\Sigma}^0_{\alpha\beta}\, dy \right\|^2_{L^2(\Omega)} \leqq C \int_\Omega GV^0_3\, dx. \tag{32}$$

We just proved that $\|V^0_3\|_{\mathring{H}^2(\Omega)} \leqq C\|G\|_{H^{-2}(\Omega)}$ and from (32) we therefore get

$$\sum_{\alpha,\beta} \left\| \int_{-1}^{1} y\tilde{\Sigma}^0_{\alpha\beta}\, dy \right\|^2_{L^2(\Omega)} \leqq C\|G\|^2_{H^{-2}(\Omega)},$$

or

(33) The operator $G \to -\int_{-1}^{1} y\tilde{\Sigma}^0_{\alpha\beta}\, dy$ may be extended as a bounded linear operator from $H^{-2}(\Omega)$ into $L^2(\Omega)$.

We shall refer to this extension as $\mathcal{T}_{\alpha\beta}$.

4. The proof of the main result. We already proved that the rescaled displacements

$$U^{\varepsilon_l} = \left(\frac{1}{\varepsilon} u_1^{\varepsilon_l}(x, \varepsilon_l y), \frac{1}{\varepsilon} u_2^{\varepsilon_l}(x, \varepsilon_l y), u_3^{\varepsilon_l}(x, \varepsilon_l y)\right)$$

converge weakly towards

$$(-y\partial_1 U^0_3(x), -y\partial_2 U^0_3(x), U^0_3(x))$$

in $H^1(R(1))$, with $U^0_3 \in \mathring{H}^2(\Omega)$.

In this section we verify that there exists a tensor $M_{\alpha\beta\gamma\delta}$ (independent of the loads $F^\varepsilon, f^\varepsilon$), with the properties (i) and (ii) listed in our theorem, for which

$$-\int_{-1}^{1} y\Sigma^0_{\alpha\beta}\, dy = M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta}U^0_3. \tag{34}$$

From (24) we know that

$$-\partial_{\alpha\beta} \int_{-1}^{1} y\Sigma^0_{\alpha\beta}\, dy = \int_{-1}^{1} F^0(x, y)\, dy + 2f^0(x),$$

and by combining with (34) we therefore get that U^0_3 satisfies

$$\partial_{\alpha\beta}(M_{\alpha\beta\gamma\delta}\partial_{\gamma\delta}U^0_3) = \int_{-1}^{1} F^0(x, y)\, dy + 2f^0(x) \quad \text{in } \Omega,$$

with

$$U^0_3 = \frac{\partial}{\partial n} U^0_3 = 0 \quad \text{in } \partial\Omega.$$

Except for a change of notation (replace U_3^0 by the simpler w) this will complete the proof of our theorem.

Our verification of the existence of the tensor $M_{\alpha\beta\gamma\delta}$ proceeds by the method of compensated compactness (cf. [18]); specifically we adapt the so-called div-curl lemma of Murat and Tartar to the present problem. $\underline{u}^\varepsilon$ as previously denotes the solution of (7) (or (8)) with loads $F^\varepsilon \in L^2(R(\varepsilon))$ and $f_+^\varepsilon = f_-^\varepsilon = f^\varepsilon \in L^2(\Omega)$, and $\underline{v}^\varepsilon$ denotes the solution of (26) with $G \in L^2(\Omega)$. $\underline{U}^\varepsilon$, E_{ij}^ε, Σ_{ij}^ε and $\underline{V}^\varepsilon$, $\tilde{E}_{ij}^\varepsilon$, $\tilde{\Sigma}_{ij}^\varepsilon$ denote the rescaled variables corresponding to $\underline{u}^\varepsilon$ and $\underline{v}^\varepsilon$, respectively. Letting ϕ be an arbitrary but fixed function in $\mathscr{D}(\Omega)$, we shall then compute the limit of

$$\int_{R(1)} \Sigma_{ij}^\varepsilon \tilde{E}_{ij}^\varepsilon \phi \, d\underset{\sim}{x} \, dy = \int_{R(1)} \tilde{\Sigma}_{ij}^\varepsilon E_{ij}^\varepsilon \phi \, d\underset{\sim}{x} \, dy$$

in two different ways as ε goes to zero along the sequence $\{\varepsilon_l\}_{l=1}^\infty$.

Inserting the test field $\phi \underline{V}^\varepsilon$ into (14), and using the fact that $e(\underline{V}^\varepsilon)$ has the form (11), with E^ε replaced by $\tilde{E}^\varepsilon$, we get

$$\begin{aligned}\int_{R(1)} \Sigma_{ij}^\varepsilon \tilde{E}_{ij}^\varepsilon \phi \, d\underset{\sim}{x} \, dy &= \int_{R(1)} F^\varepsilon(\underset{\sim}{x}, \varepsilon y) V_3^\varepsilon \phi \, d\underset{\sim}{x} \, dy + 2 \int_{\partial_+ R(1)} f^\varepsilon V_3^\varepsilon \phi \, d\underset{\sim}{x} \\ &\quad - \int_{R(1)} \Sigma_{\gamma\delta}^\varepsilon V_\gamma^\varepsilon \partial_\delta \phi \, d\underset{\sim}{x} \, dy - \frac{1}{\varepsilon} \int_{R(1)} \Sigma_{\gamma 3}^\varepsilon V_3^\varepsilon \partial_\gamma \phi \, d\underset{\sim}{x} \, dy \end{aligned} \tag{35}$$

(other terms vanish because ϕ is independent of y). From (19), compactness and Lemma 2 we get that

$$\begin{aligned} &V_3^{\varepsilon_l} \phi \to V_3^0 \phi \quad \text{in } L^2(R(1)), \\ &V_3^{\varepsilon_l}(\underset{\sim}{x}, 1) \phi \to V_3^0 \phi \quad \text{in } L^2(\Omega), \\ &V_\gamma^{\varepsilon_l} \partial_\delta \phi \to -y \partial_\gamma V_3^0 \partial_\delta \phi \quad \text{in } L^2(R(1)); \end{aligned}$$

at the same time F^{ε_l}, f^{ε_l} and $\Sigma_{\alpha\beta}^{\varepsilon_l}$ are all weakly convergent in L^2 (indeed the first two converge strongly). We therefore conclude that as ε approaches 0 along the sequence $\{\varepsilon_l\}_{l=1}^\infty$, the first three terms on the right-hand side of (35) approach

$$\int_\Omega \left(\int_{-1}^1 F^0(\underset{\sim}{x}, y) \, dy + 2 f^0(\underset{\sim}{x}) \right) V_3^0 \phi \, d\underset{\sim}{x} + \int_\Omega \int_{-1}^1 y \Sigma_{\gamma\delta}^0 \, dy \, \partial_\gamma V_3^0 \partial_\delta \phi \, d\underset{\sim}{x}. \tag{36}$$

The last term $-1/\varepsilon \int_{R(1)} \Sigma_{\gamma 3}^\varepsilon V_3^\varepsilon \partial_\gamma \phi \, d\underset{\sim}{x} \, dy$ requires special attention. Using Poincaré's inequality on vertical lines and the fact that $(\partial/\partial y) V_3^\varepsilon = \varepsilon^2 \tilde{E}_{33}^\varepsilon$ (cf. (11)) we get

$$\begin{aligned} \left| \frac{1}{\varepsilon} \int_{R(1)} \Sigma_{\gamma 3}^\varepsilon (V_3^\varepsilon - \bar{V}_3^\varepsilon) \partial_\gamma \phi \, d\underset{\sim}{x} \, dy \right| &\leqq C \frac{1}{\varepsilon} \| \Sigma_{\gamma 3}^\varepsilon \|_{L^2(R(1))} \| V_3^\varepsilon - \bar{V}_3^\varepsilon \|_{L^2(R(1))} \\ &\leqq C \frac{1}{\varepsilon} \| \Sigma_{\gamma 3}^\varepsilon \|_{L^2(R(1))} \left\| \frac{\partial}{\partial y} V_3^\varepsilon \right\|_{L^2(R(1))} \\ &= C \varepsilon \| \Sigma_{\gamma 3}^\varepsilon \|_{L^2(R(1))} \| \tilde{E}_{33}^\varepsilon \|_{L^2(R(1))}, \end{aligned}$$

and since both $\|\Sigma_{\gamma 3}^\varepsilon\|_{L^2(R(1))}$ and $\|\tilde{E}_{33}^\varepsilon\|_{L^2(R(1))}$ are bounded this last term is of order ε. It thus suffices to study the limiting behavior of

$$-\frac{1}{\varepsilon} \int_{R(1)} \Sigma_{\gamma 3}^\varepsilon \bar{V}_3^\varepsilon \partial_\gamma \phi \, d\underset{\sim}{x} \, dy = \int_\Omega \left(-\frac{1}{\varepsilon} \int_{-1}^1 \Sigma_{\gamma 3}^\varepsilon \, dy \right) \bar{V}_3^\varepsilon \partial_\gamma \phi \, d\underset{\sim}{x}.$$

According to Lemma 3, $\bar{V}_3^{\varepsilon_l}$ converges strongly in $\mathring{H}^1(\Omega)$ and according to Lemma 4 $(1/\varepsilon_l)\int_{-1}^1 \Sigma_{\gamma 3}^{\varepsilon_l}\,dy$ converges weakly in $H^{-1}(\Omega)$ towards $\partial_\delta \int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy$, hence

$$\int_\Omega \left(-\frac{1}{\varepsilon_l}\int_{-1}^1 \Sigma_{\gamma 3}^{\varepsilon_l}\,dy\right)\bar{V}_3^{\varepsilon_l}\partial_\gamma\phi\,d\underset{\sim}{x}$$

converges to

$$-\int_\Omega \partial_\delta \Bigg(\Bigg(\int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy\Bigg) V_3^0\partial_\gamma\phi\,d\underset{\sim}{x} \tag{37}$$

as ε_l approaches 0. Collecting the terms in (36) and (37) we get

$$\begin{aligned}\lim_{\varepsilon_l\to 0}\int_{R(1)} \Sigma_{ij}^{\varepsilon_l}\tilde{E}_{ij}^{\varepsilon_l}\phi\,d\underset{\sim}{x}\,dy = \int_\Omega \mathscr{F}^0 V_3^0\phi\,d\underset{\sim}{x} + \int_\Omega \Bigg(\Bigg(\int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy\Bigg)\partial_\gamma V_3^0\partial_\delta\phi\,d\underset{\sim}{x}\\ -\int_\Omega \partial_\delta\Bigg(\Bigg(\int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy\Bigg) V_3^0\partial_\gamma\phi\,d\underset{\sim}{x}.\end{aligned}$$

We integrate the last two terms in the right-hand side by parts to remove derivatives from ϕ. Using the fact that ϕ vanishes on $\partial\Omega$ and the identity (24) we thus obtain

$$\lim_{\varepsilon_l\to 0}\int_{R(1)} \Sigma_{ij}^{\varepsilon_l}\tilde{E}_{ij}^{\varepsilon_l}\phi\,d\underset{\sim}{x}\,dy = -\int_\Omega \Bigg(\Bigg(\int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy\Bigg)\partial_{\gamma\delta}V_3^0\phi\,d\underset{\sim}{x}. \tag{38}$$

Exchanging the roles of $\underset{\sim}{U}^\varepsilon$ and $\underset{\sim}{V}^\varepsilon$ in the above argument we would similarly obtain

$$\lim_{\varepsilon_l\to 0}\int_{R(1)} \tilde{\Sigma}_{ij}^{\varepsilon_l}E_{ij}^{\varepsilon_l}\phi\,d\underset{\sim}{x}\,dy = -\int_\Omega \Bigg(\Bigg(\int_{-1}^1 y\tilde{\Sigma}^0_{\gamma\delta}\,dy\Bigg)\partial_{\gamma\delta}U_3^0\phi\,d\underset{\sim}{x}. \tag{39}$$

Because of the symmetry of the elastic law

$$\int_{R(1)} \Sigma_{ij}^{\varepsilon}\tilde{E}_{ij}^{\varepsilon}\phi\,d\underset{\sim}{x}\,dy = \int_{R(1)} \tilde{\Sigma}_{ij}^{\varepsilon}E_{ij}^{\varepsilon}\phi\,d\underset{\sim}{x}\,dy,$$

and it then follows from (38) and (39) that

$$\int_\Omega \left(-\int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy\right)\partial_{\gamma\delta}V_3^0\phi\,d\underset{\sim}{x} = \int_\Omega \left(-\int_{-1}^1 y\tilde{\Sigma}^0_{\gamma\delta}\,dy\right)\partial_{\gamma\delta}U_3^0\phi\,d\underset{\sim}{x}.$$

In terms of the operators $\mathscr{S}$ and $\mathscr{T}$ defined in the previous section, this may be stated

$$\int_\Omega \left(-\int_{-1}^1 y\Sigma^0_{\gamma\delta}\,dy\right)\partial_{\gamma\delta}\mathscr{S}(G)\phi\,d\underset{\sim}{x} = \int_\Omega \mathscr{T}_{\gamma\delta}(G)\partial_{\gamma\delta}U_3^0\phi\,d\underset{\sim}{x}. \tag{40}$$

The identity (40) has so far only been verified for G in $L^2(\Omega)$ (and any $\phi\in\mathscr{D}(\Omega)$), but because of the continuity of the operators $\mathscr{S}$ and $\mathscr{T}_{\gamma\delta}$ (cf. (29), (33)) it follows immediately that (40) holds for any G in $H^{-2}(\Omega)$. Let $\Omega'\subset\subset\Omega$ and pick $\psi\in\mathscr{D}(\Omega)$ with $\psi\equiv 1$ in Ω'. $\mathscr{S}$ is an isomorphism between $H^{-2}(\Omega)$ and $\mathring{H}^2(\Omega)$ (cf. (29)); insertion of $G=\mathscr{S}^{-1}(\frac{1}{2}x_\alpha x_\beta\psi)$ into (40) yields

$$\int_\Omega \left(-\int_{-1}^1 y\Sigma^0_{\alpha\beta}\,dy\right)\phi\,d\underset{\sim}{x} = \int_\Omega \mathscr{T}_{\gamma\delta}(\mathscr{S}^{-1}(\tfrac{1}{2}x_\alpha x_\beta\psi))\partial_{\gamma\delta}U_3^0\phi\,d\underset{\sim}{x} \tag{41}$$

for all ϕ in $\mathscr{D}(\Omega')$ (here we use that $\psi\equiv 1$ on supp (ϕ), $\phi\in\mathscr{D}(\Omega')$). Since $\Omega'\subset\subset\Omega$ is arbitrary we conclude from (41) that there exists $M_{\alpha\beta\gamma\delta}(\underset{\sim}{x})$ with

$$-\int_{-1}^1 y\Sigma^0_{\alpha\beta}\,dy = M_{\alpha\beta\gamma\delta}(\underset{\sim}{x})\partial_{\gamma\delta}U_3^0,$$

as stated in (34). $M_{\alpha\beta\gamma\delta}$ is given by

$$M_{\alpha\beta\gamma\delta} = \mathscr{T}_{\gamma\delta}(\mathscr{S}^{-1}(\tfrac{1}{2}x_\alpha x_\beta\psi)) \quad \text{in } \Omega', \tag{42}$$

where ψ is any element of $\mathcal{D}(\Omega)$, $\psi\equiv 1$ in Ω'. It is clear from the formula (42) for $M_{\alpha\beta\gamma\delta}$ that it obeys the symmetries

$$M_{\alpha\beta\gamma\delta}=M_{\beta\alpha\gamma\delta}=M_{\alpha\beta\delta\gamma}.$$

By taking the U_3^0 (and $\Sigma_{\gamma\delta}^0$), that correspond to loads $F^\varepsilon=F(\underset{\sim}{x})\in L^2(\Omega)$, $f^\varepsilon=0$ and inserting in (40) we obtain

$$\int_\Omega \mathcal{T}_{\gamma\delta}(F)\partial_{\gamma\delta}\mathcal{S}(G)\phi\,d\underset{\sim}{x}=\int_\Omega \mathcal{T}_{\gamma\delta}(G)\partial_{\gamma\delta}\mathcal{S}(F)\phi\,d\underset{\sim}{x}. \tag{43}$$

Because of continuity (43) holds for all F, $G\in H^{-2}(\Omega)$. Pick $F=\mathcal{S}^{-1}(\frac{1}{2}x_\alpha x_\beta\psi)$ and $G=\mathcal{S}^{-1}(\frac{1}{2}x_\rho x_\sigma\psi)$ with $\psi\equiv 1$ in Ω', it then follows from (42) and (43) that

$$M_{\alpha\beta\rho\sigma}=\mathcal{T}_{\rho\sigma}(\mathcal{S}^{-1}(\tfrac{1}{2}x_\alpha x_\beta\psi))=\mathcal{T}_{\alpha\beta}(\mathcal{S}^{-1}(\tfrac{1}{2}x_\rho x_\sigma\psi))=M_{\rho\sigma\alpha\beta}$$

in Ω'. Since Ω' is arbitrary this verifies the last symmetry of $M_{\alpha\beta\gamma\delta}$.

At this point we only know that $M_{\alpha\beta\gamma\delta}\in L^2_{\mathrm{loc}}(\Omega)$; we now verify that the $M_{\alpha\beta\gamma\delta}$ are indeed L^∞-functions. Consider the identity (38) corresponding to $F^\varepsilon=G(\underset{\sim}{x})$ and $f^\varepsilon=0$, and replace ϕ by ϕ^2:

$$\lim_{\varepsilon_l\to 0}\int_{R(1)}\tilde{\Sigma}^{\varepsilon_l}_{ij}\tilde{E}^{\varepsilon_l}_{ij}\phi^2\,d\underset{\sim}{x}\,dy=-\int_\Omega\left(\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right)\partial_{\alpha\beta}V_3^0\phi^2\,d\underset{\sim}{x}. \tag{44}$$

It follows directly from (3) and the fact that b^ε_{ijkl} is symmetric that

$$C_2^{-1}\sum_{i,j}|\tilde{\Sigma}^\varepsilon_{ij}|^2\leqq\tilde{\Sigma}^\varepsilon_{ij}\tilde{E}^\varepsilon_{ij},$$

consequently,

$$C_2^{-1}\int_{R(1)}\sum_{i,j}|\tilde{\Sigma}^\varepsilon_{ij}|^2\phi^2\,d\underset{\sim}{x}\,dy\leqq\int_{R(1)}\tilde{\Sigma}^\varepsilon_{ij}\tilde{E}^\varepsilon_{ij}\phi^2\,d\underset{\sim}{x}\,dy.$$

Because of the weak lower semicontinuity of the norm, (44) now yields

$$C_2^{-1}\int_{R(1)}\sum_{i,j}|\tilde{\Sigma}^0_{ij}|^2\phi^2\,d\underset{\sim}{x}\,dy\leqq-\int_\Omega\left(\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right)\partial_{\alpha\beta}V_3^0\phi^2\,d\underset{\sim}{x}. \tag{45}$$

Hölder's inequality gives

$$\int_\Omega\sum_{\alpha,\beta}\left|\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right|^2\phi^2\,d\underset{\sim}{x}\leqq\frac{2}{3}\int_{R(1)}\sum_{\alpha,\beta}|\tilde{\Sigma}^0_{\alpha\beta}|^2\phi^2\,d\underset{\sim}{x}\,dy,$$

and therefore in combination with (45) it gives

$$\begin{aligned}\frac{3}{2}C_2^{-1}\int_\Omega\sum_{\alpha,\beta}\left|\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right|^2\phi^2\,d\underset{\sim}{x}&\leqq-\int_\Omega\left(\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right)\partial_{\alpha\beta}V_3^0\phi^2\,d\underset{\sim}{x}\\&\leqq\left(\int_\Omega\sum_{\alpha,\beta}\left|\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right|^2\phi^2\,d\underset{\sim}{x}\right)^{1/2}\\&\quad\cdot\left(\int_\Omega\sum_{\alpha,\beta}|\partial_{\alpha\beta}V_3^0|^2\phi^2\,d\underset{\sim}{x}\right)^{1/2}.\end{aligned}$$

From this we conclude that

$$\int_\Omega\sum_{\alpha,\beta}\left|\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right|^2\phi^2\,d\underset{\sim}{x}\leqq\left(\frac{2}{3}C_2\right)^2\int_\Omega\sum_{\alpha,\beta}|\partial_{\alpha\beta}V_3^0|^2\phi^2\,d\underset{\sim}{x},$$

or in terms of the operators $\mathcal{S}$ and $\mathcal{T}$

$$\int_\Omega\sum_{\alpha,\beta}|\mathcal{T}_{\alpha\beta}(G)|^2\phi^2\,d\underset{\sim}{x}\leqq\left(\frac{2}{3}C_2\right)^2\int_\Omega\sum_{\alpha,\beta}|\partial_{\alpha\beta}\mathcal{S}(G)|^2\phi^2\,d\underset{\sim}{x}. \tag{46}$$

If we pick $G=\mathcal{S}^{-1}(\frac{1}{2}x_\gamma x_\delta t_{\gamma\delta}\psi)$ for some constant symmetric 2 tensor t and some $\psi\in\mathcal{D}(\Omega)$, $\psi\equiv 1$ in $\Omega'\subset\subset\Omega$, then

$$\mathcal{T}_{\alpha\beta}(\mathcal{S}^{-1}(\tfrac{1}{2}x_\gamma x_\delta t_{\gamma\delta}\psi))=\mathcal{T}_{\alpha\beta}(\mathcal{S}^{-1}(\tfrac{1}{2}x_\gamma x_\delta\psi))t_{\gamma\delta}=M_{\alpha\beta\gamma\delta}t_{\gamma\delta}$$

in Ω'. Inserting in (46) we get for any $\phi\in\mathcal{D}(\Omega')$

$$(47)\qquad \int_{\Omega'}\sum_{\alpha,\beta}|M_{\alpha\beta\gamma\delta}t_{\gamma\delta}|^2\phi^2\,d\underset{\sim}{x}\leqq\left(\frac{2}{3}C_2\right)^2\int_{\Omega'}\sum_{\alpha,\beta}|t_{\alpha\beta}|^2\phi^2\,d\underset{\sim}{x}$$

(since $\mathcal{S}(G)=\frac{1}{2}x_\gamma x_\delta t_{\gamma\delta}\psi$). Equation (47) says that $(\sum_{\alpha,\beta}|M_{\alpha\beta\gamma\delta}t_{\gamma\delta}|^2)^{1/2}$ is an L^2 multiplier of norm $\leqq\frac{2}{3}C_2(\sum_{\alpha,\beta}|t_{\alpha\beta}|^2)^{1/2}$, consequently, $(\sum_{\alpha,\beta}|M_{\alpha\beta\gamma\delta}t_{\gamma\delta}|^2)^{1/2}$ is in $L^\infty(\Omega')$ and

$$\left(\sum_{\alpha,\beta}|M_{\alpha\beta\gamma\delta}t_{\gamma\delta}|^2\right)^{1/2}\leqq\frac{2}{3}C_2\left(\sum_{\alpha,\beta}|t_{\alpha\beta}|^2\right)^{1/2}$$

a.e. in Ω'. Since $\Omega'\subset\subset\Omega$ is arbitrary this proves that $M_{\alpha\beta\gamma\delta}\in L^\infty(\Omega)$ and it also verifies the second inequality in (ii). It remains to show that $M_{\alpha\beta\gamma\delta}$ is coercive. Due to the coercivity of b^ε_{ijkl} (cf. (2))

$$c_1\sum_{i,j}|\tilde{E}^\varepsilon_{ij}|^2\leqq\tilde{\Sigma}^\varepsilon_{ij}\tilde{E}^\varepsilon_{ij},$$

so

$$c_1\int_{R(1)}\sum_{i,j}|\tilde{E}^\varepsilon_{ij}|^2\phi^2\,d\underset{\sim}{x}\,dy\leqq\int_{R(1)}\tilde{\Sigma}^\varepsilon_{ij}\tilde{E}^\varepsilon_{ij}\phi^2\,d\underset{\sim}{x}\,dy.$$

Passing to the limit in ε along the sequence $\{\varepsilon_l\}_{l=1}^\infty$, using the relation $\tilde{E}^0_{\alpha\beta}=-y\partial_{\alpha\beta}V^0_3$ (Lemma 2), the identity (44) and the weak lower semicontinuity of the norm, we get

$$\begin{aligned}c_1\int_{R(1)}y^2\sum_{\alpha,\beta}|\partial_{\alpha\beta}V^0_3|^2\phi^2\,d\underset{\sim}{x}\,dy&\leqq c_1\int_{R(1)}\sum_{i,j}|\tilde{E}^0_{ij}|^2\phi^2\,d\underset{\sim}{x}\,dy\\&\leqq-\int_\Omega\left(\int_{-1}^1 y\tilde{\Sigma}^0_{\alpha\beta}\,dy\right)\partial_{\alpha\beta}V^0_3\phi^2\,d\underset{\sim}{x}.\end{aligned}$$

Because of the constitutive relation (34) (which has already been verified) this yields

$$\frac{2}{3}c_1\int_\Omega\sum_{\alpha,\beta}|\partial_{\alpha\beta}V^0_3|^2\phi^2\,d\underset{\sim}{x}\leqq\int_\Omega M_{\alpha\beta\gamma\delta}\partial_{\alpha\beta}V^0_3\partial_{\gamma\delta}V^0_3\phi^2\,d\underset{\sim}{x},$$

or in terms of the operator $\mathcal{S}$

$$(48)\qquad \frac{2}{3}c_1\int_\Omega\sum_{\alpha,\beta}|\partial_{\alpha\beta}\mathcal{S}(G)|^2\phi^2\,d\underset{\sim}{x}\leqq\int_\Omega M_{\alpha\beta\gamma\delta}\partial_{\alpha\beta}\mathcal{S}(G)\partial_{\gamma\delta}\mathcal{S}(G)\phi^2\,d\underset{\sim}{x}.$$

If we pick $G=\mathcal{S}^{-1}(\frac{1}{2}x_\gamma x_\delta t_{\gamma\delta}\psi)$ for some constant symmetric 2 tensor t and some ψ in $\mathcal{D}(\Omega)$, $\psi\equiv 1$ in $\Omega'\subset\subset\Omega$ then

$$\partial_{\alpha\beta}\mathcal{S}(G)=t_{\alpha\beta}$$

in Ω'. Inserting in (48) we get for any $\phi\in\mathcal{D}(\Omega')$

$$\frac{2}{3}c_1\int_{\Omega'}\sum_{\alpha,\beta}|t_{\alpha\beta}|^2\phi^2\,d\underset{\sim}{x}\leqq\int_{\Omega'}M_{\alpha\beta\gamma\delta}t_{\alpha\beta}t_{\gamma\delta}\phi^2\,d\underset{\sim}{x},$$

from which it immediately follows that

$$\frac{2}{3}c_1\sum_{\alpha,\beta}|t_{\alpha\beta}|^2\leqq M_{\alpha\beta\gamma\delta}t_{\alpha\beta}t_{\gamma\delta}$$

a.e. in Ω'. Since $\Omega' \subset\subset \Omega$ is arbitrary this establishes the first inequality in (ii). We have thus completed the proof of our theorem.

LINEAR RECURSIVE SCHEMES ASSOCIATED WITH SOME NONLINEAR PARTIAL DIFFERENTIAL EQUATIONS IN ONE DIMENSION AND THE TAU METHOD*

E. L. ORTIZ† AND A. PHAM NGOC DINH‡

Abstract. Standard compactness arguments for Volterra's equation are used to prove the existence of the solution of some nonlinear partial differential equations in one dimension by associating them to linear recursive schemes. Sufficient conditions for the quadratic convergence of hyperbolic and parabolic types are given in this paper. By using a best approximation perturbation technique—the Tau Method—we show that these recursive schemes lead to accurate numerical approximations in concrete problems.

Key words. Tau Method, nonlinear PDE, hyperbolic equations, parabolic equations, singular perturbation of PDE

AMS(MOS) subject classifications. A07, 35J60, 35K55, B25, 45D05, 65M99

1. Introduction. Kalaba has shown in [4] that the solutions of certain classes of *nonlinear* ordinary and partial differential equations may be represented in terms of maximal operations applied to the solution of associated *linear* equations. The technique of quasilinearization was introduced by Bellman [2], who used it successfully in the analysis of the initial value problem associated with Riccati's equation.

The nonlinear partial differential equations considered in this paper are of the form

$$L(u)=\varepsilon f(t, u(x,t)), \tag{0}$$

where u is an unknown function defined on a domain D and $\varepsilon: 0<\varepsilon\leqq 1$ is a small parameter. The linear differential operators L considered here are the wave and heat operators in one dimension. The function $f(t,u)$ is assumed to be continuous in (t,u) and to satisfy a Lipschitz condition in u.

In the hyperbolic case this paper can be regarded as a generalization of Pham Ngoc Dinh [13], where stronger assumptions on f are required. We associate with our problem $L(u)=\varepsilon f$ a linear recursive scheme for which the existence of solution is proved by using standard compactness arguments related to Volterra's equation. If $f(t,u)$ is twice differentiable in u, quadratic convergence is shown for the case of a parabolic operator; this result extends a previous result of Kalaba [4]. A similar result is proved for the hyperbolic case. Both results are local in time.

The linear recursive schemes developed in this paper enabled us to use a perturbation technique based on the ideas of best uniform approximation, which extends very considerably the classical Tau Method of Lanczos, and which has attracted considerable attention in the last few years. We give examples in which by using the recursive formulation of the Tau Method of Ortiz [8] we are able to construct very accurate numerical approximations to two nonlinear partial differential equations: one of hyperbolic and one of parabolic type.

2. A weakly nonlinear hyperbolic problem in one dimension. In this section we are concerned with the solution of the nonhomogeneous one-dimensional wave equation with a right-hand side depending on the unknown function $u(x,t)$.

Let us consider the problem of finding a function $u(x, t)$ satisfying the equation:

$$\frac{\partial^2 u}{\partial t^2}-\frac{\partial^2 u}{\partial x^2}=\varepsilon f(t, u) \quad \text{for } 0<x<1, \quad 0<t<T, \tag{1}$$

and such that

$$\begin{aligned} &u(0, t)=u(1, t)=0, \qquad u(x, 0)=\tilde{u}_0(x), \\ &\frac{\partial u}{\partial t}(x, 0)=\tilde{u}_1(x) \quad \text{for } 0<x<1, \quad 0<t<T. \end{aligned} \tag{2}$$

We make the following assumptions on the function f in (1):

(3) (i) f is locally Lipschitz with respect to u, i.e. for each $T>0$, there exist $A(t)$ such that $|f(t, u_1)-f(t, u_2)| \leqq A(t)|u_1-u_2|$ for each $t \in]0, T[$ and with $A(t) \in L^2(0, T)$.

(ii) $f(t, u)$ is a continuous function with respect to the two variables t and u.

(3′) $\tilde{u}_0(x)$ is given in $H_0^1(\Omega)$ and $\tilde{u}_1(x)$ in $L^2(\Omega)$, where $\Omega =]0, 1[$, ε is a small parameter $(0<\varepsilon \leqq 1)$.

We write $f(u) := f(t, u)$; $u(t) := u(x, t)$; $\dot{u}(t) := \partial u/\partial t$.

2.1. Definition of a bounded sequence $u_n(t)$. Let us introduce the sequence of functions $\{u_n(t)\}$, $u_n(t) := u_n(x, t)$, defined by the linear recursive relations:

$$\begin{aligned} &\frac{\partial^2 u_1}{\partial t^2}-\frac{\partial^2 u_1}{\partial x^2}=\varepsilon f(u_0), \\ &u_1(0, t)=u_1(1, t)=0, \\ &u_1(x, 0)=\tilde{u}_0(x); \qquad \dot{u}_1(x, 0)=\tilde{u}_1(x). \end{aligned} \tag{4}$$

$$\begin{aligned} &\frac{\partial^2 u_{n+1}}{\partial t^2}-\frac{\partial^2 u_{n+1}}{\partial x^2}=\varepsilon f(u_n), \\ &u_{n+1}(0, t)=u_{n+1}(1, t)=0, \\ &u_{n+1}(x, 0)=\tilde{u}_0(x); \qquad \dot{u}_{n+1}(x, 0)=\tilde{u}_1(x); \end{aligned} \tag{5}$$

the first function $u_0(t)$ will be determined for

$$u_0(t) \in L^\infty(0, T; H_0^1(\Omega)), \qquad \dot{u}_0(t) \in L^\infty(0, T; L^2(\Omega)).$$

LEMMA 1. *The solution $u_{n+1}(t)$ of* (5) *exists and belongs to a bounded set of $L^\infty(0, T; H_0^1(\Omega))$, and $\dot{u}_{n+1}(t)$ belongs to a bounded set of $L^\infty(0, T; L^2(\Omega))$; these sets are bounded independently of n and ε.*

Proof. Let us suppose that u_n is in a bounded set of $L^\infty(0, T; H_0^1(\Omega))$ and that $\dot{u}_n$ is in a bounded set of $L^\infty(0, T; L^2(\Omega))$, i.e.:

Let M be a constant independent of n and ε such that

$$\|u_n\|_{H_0^1(\Omega)} \leqq M, \quad \|\dot{u}_n\|_{L^2(\Omega)} \leqq M, \quad \text{a.e. } t \in [0, T]. \tag{6}$$

Then, let us show that $u_{n+1}(t)$ and $\dot{u}_{n+1}(t)$ are in the same bounded sets of $L^\infty(0, T; H_0^1(\Omega)$ (and $L^\infty(0, T; L^2(\Omega))$ respectively.

Equation (5) is equivalent to the following variational formulation:

$$\begin{aligned} &a(u_{n+1}, v)+\frac{d}{dt}\langle \dot{u}_{n+1}, v\rangle_{L^2(\Omega)}=\varepsilon\langle f(u_n), v\rangle_{L^2(\Omega)} \quad \text{for all } v \in H_0^1(\Omega), \\ &u_{n+1}(0)=\tilde{u}_0, \qquad \dot{u}_{n+1}(0)=\tilde{u}_1 \end{aligned} \tag{7}$$

where $a(u, v) = \int_0^1 (\partial u/\partial x) \cdot (\partial v/\partial x)\, dx$ and $\langle u, v\rangle_{L^2(\Omega)}$ is the scalar product in $L^2(\Omega)$. Let $u^j_{n+1}(t)$ be the sequence defined by:

$$u^j_{n+1}(t) = \sum_{k=1}^{j} \xi^{n+1}_{k,j}(t) \cdot v_k(x) \tag{8}$$

($\{v_k(x)\}$ is a "basis" of $H^1_0(\Omega)$ i.e. a countable and everywhere dense subset of $H^1_0(\Omega)$; the $\{v_k(x)\}$ can be the eigenfunctions of $\partial^2/\partial x^2$), which is the solution of

$$\begin{aligned} &a(u^j_{n+1}, v_p) + \frac{d}{dt}\langle \dot{u}^j_{n+1}, v_p\rangle_{L^2(\Omega)} = \varepsilon\langle f(u_n), v_p\rangle_{L^2(\Omega)}, \\ &u^j_{n+1}(0) = \tilde{u}_{0j}, \qquad \dot{u}^j_{n+1}(0) = \tilde{u}_{1j}, \end{aligned} \tag{9}$$

where

$$\tilde{u}_{0j}(x) = \sum_{k=1}^{j} \eta_{kj} \cdot v_k(x) \to \tilde{u}_0(x) \quad \text{in } H^1_0(\Omega) \text{ strongly,}$$

$$\tilde{u}_{1j}(x) = \sum_{k=1}^{j} \gamma_{kj} \cdot v_k(x) \to \tilde{u}_1(x) \quad \text{in } L^2(\Omega) \text{ strongly.}$$

The coefficients $\xi^{n+1}_{kj}(\mathrm{t})$ verify the linear differential equation of second order [3]:

$$\begin{aligned} &\ddot{\xi}^{n+1}_{k,j}(t) + k^2\pi^2\xi^{n+1}_{k,j}(t) = 2\varepsilon\langle f(u_n), v\rangle_{L^2(\Omega)}, \\ &\xi^{n+1}_{k,j}(0) = \eta_{k,j}, \qquad \dot{\xi}^{n+1}_{k,j}(0) = \gamma_{kj}, \quad 1 \leqq k \leqq j. \end{aligned} \tag{10}$$

Let us multiply (9) by $\dot{\xi}^{n+1}_{k,j}(t)$ and sum up with respect to the index k,

$$\frac{1}{2}\frac{d}{dt}\|u^j_{n+1}\|^2_{H^1_0(\Omega)} + \frac{1}{2}\frac{d}{dt}\|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)} = \varepsilon\langle f(u_n), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}.$$

Therefore by integration we obtain

$$\|u^j_{n+1}\|^2_{H^1_0(\Omega)} + \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)} = \|\tilde{u}_{0j}\|^2_{H^1_0(\Omega)} + \|\tilde{u}_{1j}\|^2_{L^2(\Omega)} + 2\varepsilon\int_0^t \langle f(u_n), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta. \tag{11}$$

Since $\tilde{u}_{0j}$ and $\tilde{u}_{1j}$ converge to $\tilde{u}_0$ and $\tilde{u}_1$ in $H^1_0(\Omega)$ and $L^2(\Omega)$ respectively, there exists a constant C_1 independent of n and j such that:

$$\|\tilde{u}_{0j}\|^2_{H^1_0(\Omega)} + \|\tilde{u}_{1j}\|^2_{L^2(\Omega)} \leqq C_1. \tag{12}$$

On the other hand:

$$\left|2\varepsilon\int_0^t \langle f(u_n), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta\right| \leqq \int_0^t \|f(u_n)\|^2_{L^2(\Omega)}\, d\theta + \int_0^t \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}\, d\theta.$$

But in one dimension the imbedding of $H^1(\Omega) = \{u \mid u, \partial u/\partial x \in L^2(\Omega)\}$, Sobolev space of order 1, in $\mathscr{C}^0(\bar{\Omega})$ space of continuous functions defined in $\bar{\Omega}$, is continuous [1]. Hence

$$|u_n(t)| \leqq \|u_n\|_{\mathscr{C}^0(\bar{\Omega})} \leqq \sqrt{2}\|u_n\|_{H^1_0(\Omega)} \leqq \sqrt{2M}. \tag{13}$$

Therefore

$|f(u_n)| \leqq C_2$, where C_2 is a constant independent of n, ε

on account of the continuity of the function f on a compact set.

Let us consider:

$$S^j_{n+1}(t) = \|u^j_{n+1}\|^2_{H^1_0(\Omega)} + \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}. \tag{14}$$

From (11), (12) and (13):

$$S^j_{n+1}(t) \leqq C_1 + \int_0^t (C_2^2 + \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)})\, d\theta.$$

Hence

$$S^j_{n+1}(t) \leqq C_1 + \int_0^t (C_2^2 + S^j_{n+1}(\theta))\, d\theta. \tag{15}$$

The theory of Volterra integral equations [5] implies that

$$S^j_{n+1}(t) \leqq S(t) \quad \text{a.e. } t \in [0, \bar{T}[, \quad \bar{T} \leqq T \tag{16}$$

where $S(t)$ is the maximal solution of Volterra's equation:

$$S(t) = C_1 + \int_0^t (C_2^2 + S(\theta))\, d\theta,$$

and the solution is defined in $[0, \bar{T}[$. Hence

$$S^j_{n+1}(t) \leqq S(t) \quad \text{in } [0, \hat{T}] \quad \text{with } \hat{T} < \bar{T} \leqq T. \tag{17}$$

Let us then choose the bound M of (6) such that

$$2C_1 < M^2 \qquad (C_1 \text{ given by (12)}). \tag{18}$$

But $S(0) = C_1$; $S(t)$ being a continuous function, there exists an interval $[0, \hat{\hat{T}}]$($\hat{\hat{T}} \leqq \hat{T}$) such that

$$S(t) \leqq M^2 \quad \text{for each } t \in [0, T] \qquad (\hat{\hat{T}} \text{ will now be called } T). \tag{19}$$

From (17) and (19)

$$\|u^j_{n+1}\|_{H_0^1(\Omega)} \leqq M; \qquad \|\dot{u}^j_{n+1}\|_{L^2(\Omega)} \leqq M \quad \text{a.e. } t \in [0, T], \tag{20}$$

that is

$$\begin{aligned} &u^j_{n+1} \text{ is in a bounded set of } L^\infty(0, T; H_0^1(\Omega)),\\ &\dot{u}^j_{n+1} \text{ is in a bounded set of } L^\infty(0, T; L^2(\Omega)),\\ &\text{sets bounded independently of } j, n, \varepsilon. \end{aligned} \tag{21}$$

From (21) we can extract a subsequence, still denoted by $\{u^j_{n+1}\}$, such that

$$\begin{aligned} &\text{(i)} \quad u^j_{n+1} \to u_{n+1} \quad \text{in } L^\infty(0, T, H_0^1(\Omega)) \text{ weakly} * \text{ when } j \to \infty,\\ &\text{(ii)} \quad \dot{u}^j_{n+1} \to \dot{u}_{n+1} \quad \text{in } L^\infty(0, T; L^2(\Omega)) \text{ weakly} * \text{ when } j \to \infty. \end{aligned} \tag{22}$$

We can easily check from (9) and (22) that u_{n+1} satisfies (7) in $L^\infty(0, T)$ weakly $*$. From (20) we deduce that

(23) the solution $u_{n+1}(t)$ of (7) remains in a bounded set of $L^\infty(0, T; H_0^1(\Omega))$ and $\dot{u}_{n+1}(t)$ in a bounded set of $L^\infty(0, T; L^2(\Omega))$.

2.2. Solution of the initial problem.

1. *Existence of the solution of* (1)-(2). We shall show that $\{u_n(t)\}$ is a Cauchy sequence in $L^\infty(0, T; L^2(\Omega))$. Let d_{n+1} be $d_{n+1} = u_{n+1} - u_n$ with $d_{n+1}(0) = \dot{d}_{n+1}(0) = 0$. d_{n+1} satisfies the equation

$$\begin{aligned} &\ddot{d}_{n+1} - \frac{\partial^2}{\partial x^2}(d_{n+1}) = \varepsilon[f(u_n) - f(u_{n-1})],\\ &d_{n+1}(0) = \dot{d}_{n+1}(0) = 0, \quad d_{n+1} \in L^\infty(0, T; H_0^1(\Omega)), \quad \dot{d}_{n+1} \in L^\infty(0, T; L^2(\Omega)). \end{aligned} \tag{24}$$

Let us consider $s \in]0, T[$ and define $\psi_{n+1}(t)$ [6] by

$$(25) \qquad \psi_{n+1}(t) = \begin{cases} -\int_t^s d_{n+1}(\sigma)\,d\sigma, & s \geqq t, \\ 0, & s < t. \end{cases}$$

Let us set

$$(25') \qquad w_{n+1}(t) = \int_0^t d_{n+1}(\sigma)\,d\sigma.$$

Multiplying (24) by $\psi_{n+1}(t)$, we obtain, after integrating by parts

$$\|d_{n+1}(s)\|^2_{L^2(\Omega)} + \|w_{n+1}(s)\|^2_{H_0^1(\Omega)} = -2\varepsilon \int_0^s \langle [f(u_n) - f(u_{n-1})], \psi_{n+1}\rangle_{L^2(\Omega)}\,dt.$$

Using the assumption (3)(i) it follows that

$$(26) \qquad \|d_{n+1}(s)\|^2_{L^2(\Omega)} + \|w_{n+1}(s)\|^2_{H_0^1(\Omega)} \leqq 2\varepsilon \int_0^s A(t)\|d_n\|_{L^2(\Omega)} \cdot \|\psi_{n+1}\|_{L^2(\Omega)}\,dt.$$

But

$$(27) \qquad \|\psi_{n+1}\|^2_{L^2(\Omega)} = \int_0^1 \left|\int_t^s d_{n+1}(\sigma)\right|^2 dx \leqq T^2\|d_{n+1}\|^2_{L^\infty(0,T;L^2(\Omega))}.$$

Finally, due to (26) and (27):

$$(28) \qquad \|d_{n+1}\|_{L^\infty(0,T;L^2(\Omega))} \leqq \left(2\varepsilon T \int_0^T A(t)\,dt\right)\|d_n\|_{L^\infty(0,T;L^2(\Omega))}.$$

Let

$$k = 2\varepsilon T \int_0^T A(t)\,dt < 1$$

(a condition which is always satisfied by taking a sufficiently small ε or a suitable T).

Therefore

(29) $\{u_n(t)\}$ is a Cauchy sequence in $L^\infty(0, T; L^2(\Omega))$;
hence in $L^2(0, T; L^2(\Omega)) = L^2(Q)$ where $Q =]0, T[\times]0, 1[$.

From (23) it is possible to extract from $\{u_n(t)\}$ a subsequence, still denoted by $\{u_n(t)\}$, such that

$$u_{n+1} \to u \quad \text{in } L^\infty(0, T; H_0^1(\Omega)) \text{ weakly} * \text{ when } n \to \infty,$$
$$\dot{u}_{n+1} \to \dot{u} \quad \text{in } L^\infty(0, T; L^2(\Omega)) \text{ weakly} * \text{ when } n \to \infty.$$

From (20) we can deduce that

(30) the limit u of the subsequence $\{u_n\}$ is such that
$u_n \to u$ (a.e. in Q).

From (30) we can show, by using a lemma on weak convergence [7], that

$$\langle f(t, u_n), v_p\rangle_{L^2(\Omega)} \to \langle f(t, u), v_p\rangle_{L^2(\Omega)} \quad \text{in } L^\infty(0, T) \text{ weakly} *.$$

Then we can take limits in (7) and find that u satisfies the equation

$$\begin{aligned} &a(u, v)+(d/dt)\langle \dot{u}, v\rangle_{L^2(\Omega)} = \varepsilon\langle f(u), v\rangle_{L^2(\Omega)} \quad \text{for each } v \in H_0^1(\Omega), \\ &u(0) = \tilde{u}_0, \qquad u(0) = \tilde{u}_1. \end{aligned} \tag{31}$$

Expression (31) is the variational formulation of (1)-(2).

By using the same argument as in § 2.1 we obtain

$$\|u_{n+1} - u\|_{L^\infty(0,T,L^2(\Omega))} \leqq k\|u_n - u\|_{L^\infty(0,T;L^2(\Omega))} \qquad (k<1).$$

Remark 1. By using the function $\psi_{n+1}(t)$ defined in (25) we can show the uniqueness of the problem (7).

2. *Uniqueness of the solution of the problem* (1)-(2). Let u and b be two solutions of (1)-(2); if we set $w = u - v$, then w verifies the following equation:

$$\begin{aligned} &\ddot{w} - \frac{\partial^2 w}{\partial x^2} = \varepsilon[f(t, u) - f(t, v)], \\ &w(0) = \dot{w}(0) = 0, \quad w \in L^\infty(0, T; H_0^1(\Omega)), \quad \dot{w} \in L^\infty(0, T; L^2(\Omega)). \end{aligned} \tag{32}$$

As before let us introduce the function $\psi(t)$ defined by

$$\psi(t) = \begin{cases} -\displaystyle\int_t^s w(\sigma)\, d\sigma, & s \geqq t, \\ 0, & s < t. \end{cases}$$

Multiplying (32) by $\psi(t)$, and after integrating by parts we find that

$$\|w(s)\|^2_{L^2(\Omega)} + \|w_1(s)\|^2_{H_0^1(\Omega)} = -2\varepsilon \int_0^s \langle [f(t, u) - f(t, v)], \psi \rangle_{L^2(\Omega)}\, dt,$$

where $w_1(t) = \int_0^t w(\sigma)\, d\sigma$. If we set

$$\sigma(s) = \|w(s)\|^2_{L^2(\Omega)} + \|w_1(s)\|^2_{H_0^1(\Omega)},$$

we obtain, by using hypothesis (3)(i) and the inequality $2ab \leqq (1/\alpha)a^2 + \alpha b^2$ for each $\alpha > 0$, that

$$\sigma(s) \leqq 2\varepsilon \max\left(\alpha, \frac{1}{\alpha} + \frac{1}{\alpha'}\right) \int_0^s A(t)\sigma(t)\, dt + \varepsilon\alpha' \|w_1(s)\|^2_{H_0^1(\Omega)} \int_0^s A(t)\, dt \tag{33}$$

for each α, $\alpha' > 0$.

Then let us choose α' such that $\varepsilon\alpha' \int_0^T A(t)\, dt < 1$. Therefore we obtain finally

$$\sigma(s) \leqq C(T)\left(\int_0^T A^2(t)\, dt\right)^{1/2} \left(\int_0^s \sigma^2(t)\, dt\right)^{1/2}, \tag{34}$$

where $C(T)$ is a constant only depending on T. By using Gronwall's lemma we have:

$$\sigma(s) = 0 \quad \text{i.e.} \quad u = v.$$

Hence, we have the following.

THEOREM 1. *The problem* (1)-(2) *under the assumptions* (3)(i), (ii) *and* (3') *has one and only one solution* $u \in L^\infty(0, T; H_0^1(\Omega))$ *and such that* $\dot{u} \in L^\infty(0, T; L^2(\Omega))$.

Remark 2. From the uniqueness of the solution of the problem (1)-(2) it follows that the total sequence $\{u_n(t)\}$ converges to the solution $u(t)$.

3) *Limit when ε approaches* 0. Let us denote u_ε the solution of (1)-(2). On account of (21) u_ε and $\dot{u}_\varepsilon$ are in a bounded set of $L^\infty(0, T; H_0^1(\Omega))$ and $L^\infty(0, T; L^2(\Omega))$ respectively; therefore we can prove as before the following result:

THEOREM 2. *When $\varepsilon \to 0$, $u_\varepsilon \to \bar{u}$ unique solution of*

$$(35)\qquad \begin{aligned} &a(u, v)+\frac{d}{dt}\langle \dot{u}, v\rangle_{L^2(\Omega)}=0,\\ &u(0)=\tilde{u}_0, \quad \dot{u}(0)=\tilde{u}_1 \quad \textit{in } L^2(Q) \textit{ strongly.}\end{aligned}$$

3. A weakly nonlinear parabolic problem in one dimension. In this section we consider the partial differential equation

$$(36)\qquad \begin{aligned} &\frac{\partial u}{\partial t}-\frac{\partial^2 u}{\partial x^2}=\varepsilon f(u), \qquad 0<x<1, \quad 0<t<T,\\ &u(0, t)=u(1, t)=0,\\ &u(x, 0)=\tilde{u}_0(x).\end{aligned}$$

3.1. Case of simple convergence. Let us assume the f satisfies hypothesis (3)(i), (ii). Let us define the sequence of functions $\{u_n(t)\}$ by the linear recursive expression

$$(37)\qquad \begin{aligned} &\frac{\partial u_{n+1}}{\partial t}-\frac{\partial^2 u_{n+1}}{\partial x^2}=\varepsilon f(u_n), \quad n\geqq 0, \quad 0<x<1, \quad 0<t<T,\\ &u_{n+1}(0, t)=u_{n+1}(1, t)=0,\\ &u_{n+1}(x, 0)=\tilde{u}_0(x)\in H_0^1(\Omega),\end{aligned}$$

with $u_0(t)\in L^\infty(0, T; H_0^1(\Omega))$ and such that $\dot{u}_0(t)\in L^2(0, T; L^2(\Omega))$.

By using the same arguments as in § 2 it is possible to show that

LEMMA 2. *The solution $u_{n+1}(t)$ of the equation* (37) *exists, is unique, belongs to a bounded set of $L^\infty(0, T; H_0^1(\Omega))$ and $\dot{u}_{n+1}(t)$ is in a bounded set of $L^2(0, T; L^2(\Omega))$; the sets are bounded independently of n and ε.*

THEOREM 3. *The problem* (36) *under the assumptions* (3)(i), (ii) *has one and only one solution $u\in L^\infty(0, T; H_0^1(\Omega))$ and is such that $\dot{u}\in L^2(0, T; L^2(\Omega))$. We also have*

$$\lim_{n\to\infty} \|u_{n+1}-u\|_{L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;H_0^1(\Omega))}=0,$$

where $u_{n+1}(t)$ is the solution of (37).

Let us denote $u_\varepsilon(t)$ the solution of (36). Then, we have the following.

THEOREM 4. *When $\varepsilon\to 0$, $u_\varepsilon\to\bar{u}$, unique solution of*:

$$\begin{aligned} &a(u, v)+\langle \dot{u}, v\rangle_{L^2(\Omega)}=0 \quad \textit{for all } v\in H_0^1(\Omega),\\ &u(0)=\tilde{u}_0 \quad \textit{in } L^2(0, T; H_0^1(\Omega)) \textit{ strongly.}\end{aligned}$$

3.2. Case of quadratic convergence. Let us assume that f satisfies the conditions 3(i), (ii) and also that

(38) the first and second derivatives f'_u and f''_{u^2} with respect to u exist
and are continuous with respect to (t, u).

Let $\dot{u}$ stand for the partial derivative of u with respect to t. As before, we will associate with (36) a sequence of functions $\{u_n(t)\}$ defined now by the linear recursive scheme

$$(39)\qquad \begin{aligned} &\frac{\partial u_{n+1}}{\partial t}-\frac{\partial^2 u_{n+1}}{\partial x^2}=\varepsilon[f(u_n)+(u_{n+1}-u_n)f'(u_n)], \qquad n\geqq 0,\\ &u_{n+1}(0, t)=u_{n+1}(1, t)=0,\\ &u_{n+1}(x, 0)=\tilde{u}_0(x).\end{aligned}$$

Let us set

$$F_n(t, u)=f(u_n)+(u-u_n)f'(u_n).$$

LEMMA 3. *The solution $u_{n+1}(t)$ of* (39) *exists, is unique and belongs to a bounded set of $L^\infty(0, T; H_0^1(\Omega))$, and $\dot{u}_{n+1}(t)$ is in a bounded set of $L^2(0, T; L^2(\Omega))$.*

Proof. Let us suppose that u_n and $\dot{u}_n$ are in bounded sets of $L^\infty(0, T; H_0^1(\Omega))$ and $L^2(0, T; L^2(\Omega))$ respectively,

$$\text{(40)} \qquad \begin{aligned} &\|u_n\|_{H_0^1(\Omega)} \leqq M \quad \text{a.e. } t\in[0, T], \\ &\int_0^T \|\dot{u}_n\|^2_{L^2(\Omega)}\, d\theta \leqq M^2, \end{aligned}$$

where M is a constant independent of n and ε. Let $u^j_{n+1}(t)$ be the sequence defined by

$$\text{(41)} \qquad u^j_{n+1}(t)=\sum_{k=1}^{j} \xi^{n+1}_{k,j}(t)\cdot v_k(x) \qquad (\{v_k(x)\} \text{ is a “basis” of } H_0^1(\Omega)),$$

solution of the equation

$$\text{(42)} \qquad \begin{aligned} &a(u^j_{n+1}, v_p)+\langle \dot{u}^j_{n+1}, v_p\rangle_{L^2(\Omega)}=\varepsilon\langle F_n(t, u^j_{n+1}), v_p\rangle_{L^2(\Omega)}, \\ &u^j_{n+1}(0)=\tilde{u}_{0j}, \end{aligned}$$

where $\tilde{u}_{0j}=\sum_{k=1}^{j} \eta_{kj}\cdot v_k(x)\rightarrow \tilde{u}_0(x)$ in $H_0^1(\Omega)$ strongly. The coefficients $\xi^{n+1}_{k,j}$ satisfy the following first order linear differential equation

$$\text{(43)} \qquad \begin{aligned} &\dot{\xi}^{n+1}_{k,j}(t)+(k^2\pi^2-\varepsilon f'(u_n))\xi^{n+1}_{k,j}(t)=2\varepsilon\langle[f(u_n)-u_nf'(u_n)], v_k\rangle_{L^2(\Omega)}, \\ &\xi^{n+1}_{k,j}(0)=\eta_{kj}, \qquad 1\leqq k\leqq j. \end{aligned}$$

Let us multiply (42) by $\dot{\xi}^{n+1}_{k,j}$ and sum with respect to the index k:

$$\text{(44)} \quad \|u^j_{n+1}\|^2_{H_0^1(\Omega)}+2\int_0^t \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}\, d\theta=2\varepsilon\int_0^t \langle F_n(\theta, u^j_{n+1}), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta+\|\tilde{u}_{0j}\|^2_{H_0^1(\Omega)}$$

with

$$\text{(45)} \qquad \begin{aligned} &2\varepsilon\int_0^t \langle F(\theta, u^j_{n+1}), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta \\ &\quad=2\varepsilon\int_0^t \langle u^j_{n+1}f'(u_n), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta+2\varepsilon\int_0^t \langle f(u_n), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta \\ &\quad-2\varepsilon\int_0^t \langle u_nf'(u_n), \dot{u}^j_{n+1}\rangle_{L^2(\Omega)}\, d\theta. \end{aligned}$$

By using the hypothesis of recurrence (40), assumption (38) and the inequality $2ab\leqq a^2/\alpha+\alpha b^2$ for each $\alpha>0$ we obtain

$$\text{(46)} \qquad \begin{aligned} &\|u^j_{n+1}\|^2_{H_0^1(\Omega)}+2\int_0^t \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}\, d\theta \\ &\quad\leqq C_1+\int_0^t [C_2+(\alpha+\beta+\gamma)\|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}+C_3\|u^j_{n+1}\|^2_{L^2(\Omega)}]\, d\theta \end{aligned}$$

for each α, β, $\gamma>0$ and where C_1 (C_1 such that $\|\tilde{u}_{0j}\|^2_{H_0^1(\Omega)}\leqq C_1$), C_2 and C_3 are constants independent of n and ε.

Let us set

$$S^j_{n+1}(t) = \|u^j_{n+1}\|^2_{H^1_0(\Omega)} + \int_0^t \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}\, d\theta \tag{47}$$

and let us choose $\alpha = \beta = \gamma = \frac{1}{3}$. Then we finally obtain

$$S^j_{n+1}(t) \leqq C_1 + \int_0^t (C_2 + C_3 S^j_{n+1}(\theta))\, d\theta. \tag{48}$$

As in § 2, if we choose, for instance, M such that $M^2 > 2C_1$ we can deduce that there exists an interval $[0, T]$ such that

$$\begin{aligned} &\|u^j_{n+1}(t)\|_{H^1_0(\Omega)} \leqq M \qquad \text{a.e. } t \in [0, T], \\ &\int_0^T \|\dot{u}^j_{n+1}\|^2_{L^2(\Omega)}\, d\theta \leqq M^2. \end{aligned} \tag{49}$$

From (49) and if we take limits in equation (42), we find that there exists one and only one $u_{n+1}(t)$ which solves

$$\begin{aligned} &a(u_{n+1}, v) + (\dot{u}_{n+1}, v)_{L^2(\Omega)} = \varepsilon\langle F_n(t, u_{n+1}), v\rangle_{L^2(\Omega)} \quad \text{for all } v \in H^1_0(\Omega), \\ &u_{n+1}(0) = \tilde{u}_0. \end{aligned} \tag{50}$$

Quadratic convergence. Let us show now that $\{u_n(t)\}$ is a Cauchy sequence in $L^\infty(0, T; L^2(\Omega))$. Let d_{n+1} be such that $d_{n+1} = u_{n+1} - u_n$, with $d_{n+1}(0) = 0$. $d_{n+1}(t)$ satisfies the equation

$$a(d_{n+1}, v) + \langle \dot{d}_{n+1}, v\rangle_{L^2(\Omega)} = \varepsilon\langle [F_n(u_{n+1}) - F_{n-1}(u_n)], v\rangle_{L^2(\Omega)} \quad \text{for all } v \in H^1_0(\Omega) \tag{51}$$

with

$$\begin{aligned} F_n(u_{n+1}) - F_{n-1}(u_n) &= \varepsilon[f(u_n) + (u_{n+1} - u_n)f'(u_n) - f(u_{n-1}) - (u_n - u_{n-1})f'(u_{n-1})] \\ &= \varepsilon\left[\frac{d_n^2}{2} f''(q_n) + d_{n+1} \cdot f'(u_n)\right] \end{aligned} \tag{52}$$

and where $q_n = \lambda u_n + (1-\lambda)u_{n-1} (0 < \lambda < 1)$. By using a lemma on regularity [7] we obtain from (51)

$$\begin{aligned} &2\int_0^t \|d_{n+1}\|^2_{H^1_0(\Omega)}\, d\theta + \|d_{n+1}\|^2_{L^2(\Omega)} \\ &\qquad = 2\varepsilon \int_0^t \left\langle \frac{d_n^2}{2} f''(q_n) + f'(u_n) \cdot d_{n+1}, d_{n+1}\right\rangle_{L^2(\Omega)} d\theta. \end{aligned} \tag{53}$$

The continuous imbedding of $H^1_0(\Omega)$ in $\mathscr{C}^0(\bar{\Omega})$ enables us to show that

$$\left|\left\langle \frac{d_n^2}{2} f''(q_n), d_{n+1}\right\rangle_{L^2(\Omega)}\right| \leqq \frac{\alpha c^2}{16}\|d_{n+1}\|^2_{H^1_0(\Omega)} + \frac{1}{\alpha}\|d_n\|^4_{L^2(\Omega)} \quad \text{for all } \alpha > 0 \tag{54}$$

where C is a constant independent of n and ε.

If we choose α and T sufficiently small, we can deduce that there exist two constants β and $\gamma > 0$ such that:

$$\beta \int_0^T \{\|d_{n+1}\|^2_{H^1_0(\Omega)} + \gamma\|d_{n+1}\|^2_{L^\infty(0,T;L^2(\Omega))}\}\, d\theta \leqq \frac{2\varepsilon T}{\alpha}\|d_n\|^4_{L^\infty(0,T;L^2(\Omega))}.$$

Finally

$$\|d_{n+1}\|_{L^\infty(0,T;L^2(\Omega))} \leqq k_T^{(0)}\|d_n\|^2_{L^\infty(0,T;L^2(\Omega))} \tag{55}$$

with $(k_T^{(0)})^2=2\varepsilon T/\alpha$. Therefore, for a suitable value of T, $\{u_n\}$ is a Cauchy sequence in $L^\infty(0, T; L^2(\Omega))$ (ε is not necessarily small).

Taking limits in (50), we find that the limit u is the solution of:

$$\tag{56} \begin{aligned} &a(u, v)+\langle \dot u, v\rangle_{L^2(\Omega)}=\varepsilon\langle f(u), v\rangle_{L^2(\Omega)} \qquad \text{for all } v\in H_0^1(\Omega).\\ &u(0)=\tilde u_0. \end{aligned}$$

Equation (56) is the variational formulation of (36).

The convergence of $\{u_n\}$ to u is such that

$$\tag{57} \|u_{n+1}-u\|_{L^\infty(0,T;L^2(\Omega))}\leqq k_T^{(0)}\|u_n-u\|^2_{L^\infty(0,T;L^2(\Omega))}.$$

Hence, we have the following:

THEOREM 5. *Problem* (36), *with assumptions* (3)(ii) *and* (38), *has one and only one solution* $u\in L^\infty(0, T; H_0^1(\Omega))$. *The sequence* $\{u_n\}$ *defined by* (37) *converges quadratically to it in the meaning defined by* (57).

Remark 3. Let us go back to the hyperbolic case. If the function $f(t, u)$ satisfies the assumptions (3)(ii) and (38), we can show that there exists an inequality similar to (55): let us consider the sequence $\{u_n\}$ defined by

$$\tag{58} \frac{\partial^2 u_{n+1}}{\partial t^2}-\frac{\partial^2 u_{n+1}}{\partial x^2}=\varepsilon F_n(t, u_{n+1})$$

with $F_n(t, u)=f(u_n)+(u-u_n)f'(u_n)$, where $u_{n+1}(t)$ satisfies condition (2). As in the parabolic case we show that the sequences $\{u_n\}$ and $\{\dot u_n\}$ are in bounded sets of $L^\infty(0, T; H_0^1(\Omega))$ and $L^\infty(0, T; L^2(\Omega))$ respectively.

Let $d_{n+1}=u_{n+1}-u_n$. $d_{n+1}(t)$ satisfy the equation

$$\tag{59} \begin{aligned} &\ddot d_{n+1}(t)-\frac{\partial^2}{\partial x^2}d_{n+1}=\varepsilon[F_n(t, u_{n+1})-F_{n-1}(t, u_n)],\\ &d_{n+1}(0)=\dot d_{n+1}(0)=0. \end{aligned}$$

Let us introduce the functions $\psi_{n+1}(t)$ and $w_{n+1}(t)$ defined by (25) and (25'). We have

$$\tag{60} \begin{aligned} &\|d_{n+1}(s)\|^2_{L^2(\Omega)}+\|w_{n+1}(s)\|^2_{H_0^1(\Omega)}\\ &\quad=-2\varepsilon\int_0^s\langle[F_n(t, u_{n+1})-F_{n-1}(t, u_n)], \psi_{n+1}\rangle_{L^2(\Omega)}\,dt\\ &\quad=-2\varepsilon\int_0^s\left\langle\frac{d_n^2}{2}f''(q_n)+f'(u_n)d_{n+1}, \psi_{n+1}\right\rangle_{L^2(\Omega)}dt \end{aligned}$$

where $q_n=\lambda u_n+(1-\lambda)u_{n-1}$ $(0<\lambda<1)$.

But using the continuous imbedding of $H_0^1(\Omega)$ in $\mathscr{C}^0(\bar\Omega)$ and (27), we have

$$\tag{61} \left|2\varepsilon\int_0^s\langle d_{n+1}f'(u_n), \psi_{n+1}\rangle_{L^2(\Omega)}\right|\leqq 2\varepsilon T^2C_1\|d_{n+1}\|^2_{L^\infty(0,T;L^2(\Omega))}$$

where C_1 is a constant independent of n and ε.

Writing $\psi_{n+1}(t)=w_{n+1}(t)-w_{n+1}(s)$, we have

$$\tag{62} |\psi_{n+1}(t)|\leqq|w_{n+1}(t)|+|w_{n+1}(s)| \qquad (t\leqq s).$$

This enables us to evaluate

$$\left|-2\varepsilon\int_0^s\left\langle\frac{d_n^2}{2}f''(q_n), \psi_{n+1}\right\rangle_{L^2(\Omega)}dt\right|.$$

On account of the continuous imbedding of $H_0^1(\Omega)$ in $\mathscr{C}^0(\bar{\Omega})$:

$$\left|-2\varepsilon\int_0^s\left\langle\frac{d_n^2}{2}f''(q_n),\,\psi_{n+1}\right\rangle_{L^2(\Omega)}dt\right|\leqq 2\varepsilon C_2T\|w_{n+1}\|_{L^\infty(0,T;H_0^1(\Omega))}\|d_n\|^2_{L^\infty(0,T;L^2(\Omega))}\tag{63}$$

where C_2 is a constant independent of n and ε.

Finally by (60), (61) and (63) we can find for a suitable $T>0$ a number $\alpha>0$ such that

$$\begin{aligned}\alpha^2\|d_{n+1}\|^2_{L^\infty(0,T;L^2(\Omega))}&+\|w_{n+1}\|^2_{L^\infty(0,T;H_0^1(\Omega))}\\&\leqq 2T\varepsilon C_2\|w_{n+1}\|_{L^\infty(0,T;H_0^1(\Omega))}\|d_n\|^2_{L^\infty(0,T;L^2(\Omega))}.\end{aligned}\tag{64}$$

But the inequality $2ab\leqq a^2+b^2$ implies that

$$\|d_{n+1}\|_{L^\infty(0,T;L^2(\Omega))}\leqq k_T^{(1)}\|d_n\|^2_{L^\infty(0,T;L^2(\Omega))}\tag{65}$$

with $k_T^{(1)}=TC_2\varepsilon/\alpha$.

Therefore, for a suitable $T>0$, the convergence is quadratic even if ε is not necessarily small. We then have the following result:

THEOREM 6. *Problem* (1)-(2) *with assumptions* (3)(ii), (3') *and* (38) *has one and only one solution* $u\in L^\infty(0,T;H_0^1(\Omega))$. *The sequence* $\{u_n\}$ *defined by* (58) *converges quadratically to it.*

4. An application to the numerical solution of nonlinear partial differential equations. The Tau Method is a perturbation technique based on the ideas of best uniform approximation by polynomials. Given a linear differential equation with polynomial coefficients, or with coefficients approximated by polynomials to a sufficient degree of accuracy,

$$L(u)=F(x,t),\tag{66}$$

we attempt to solve a slightly perturbed form of the original problem, defined by the so-called *Tau problem*

$$L(u_{rs})=F(x,t)+\tau H_{rs}(x,t),\tag{67}$$

where $H_{rs}(x,t)$ is the product (or linear combination of products) of best uniform approximations of zero, of degrees r and s respectively, on a given domain D. The parameter (or vector parameter) τ is chosen for $u_{rs}(x,t)$ to be a bivariate polynomial which satisfies the initial or boundary conditions given for u.

The theory of the Tau Method, originally proposed by Lanczos in the late thirties, has been developed by Ortiz [8] and computational procedures for the numerical treatment of linear and nonlinear partial differential equations have been discussed by Ortiz and Samara [10] and Ortiz and Pun [11], [12] in very recent papers and in references given there.

Ortiz and Pham Ngoc Dinh have discussed aspects of the error analysis of the Tau Method in connection with nonlinear ordinary differential equations in [9]. Their approach is, essentially, to reduce the nonlinear problem to a sequence of linear problems for equations with variable coefficients.

In this section we shall discuss the numerical solution of two types of nonlinear partial differential equations by making use of the linear recursion schemes proposed in the early parts of this paper. As we shall see, results of a very remarkable accuracy are obtained.

Problem 1. Let us consider the nonlinear hyperbolic problem

$$\begin{aligned}&\frac{\partial^2 u}{\partial t^2}-\frac{\partial^2 u}{\partial x^2}=u^2(x,t)+F(x,t), \qquad (x,t)\in D,\\ &u(x,0)=\left.\frac{\partial u(x,t)}{\partial t}\right|_{t=0}=g(x), \qquad 0\leqq x\leqq 1,\\ &u(0,t)=u(1,t)=h(t), \qquad 0\leqq t\leqq 1,\end{aligned} \tag{68}$$

where

$$F(x,t)=\exp(t)(1+\pi^2-\exp(t)\sin\pi x)\sin\pi x;$$

$$g(x)=\sin\pi x, \qquad h(t)\equiv 0,$$

and the domain $D=\{(x,t)\in\mathbb{R}^2\colon 0\leqq t, x\leqq 1\}$.

The exact solution of (68) is $u(x,t)=\exp(t)\sin\pi x$. We use the linear recursive scheme defined by

$$\frac{\partial^2 u_{n+1}}{\partial t^2}-\frac{\partial^2 u_{n+1}}{\partial x^2}-2u_n u_{n+1}=-u_n^2+F, \tag{69}$$

with $u_0=(1+t)\sin\pi x$, and u_{n+1} satisfying the conditions given in (68), but for the fact that functions F and g have been replaced by tight polynomial approximations. After 3 iterations the uniform norm of the error of approximation over the domain D becomes stable for $r=s=6$, 8 and 10. It is equal to 0.1×10^{-3}, 0.9×10^{-6} and 0.4×10^{-8} respectively.

Problem 2. Let us consider the nonlinear parabolic problem

$$\begin{aligned}&\frac{\partial u}{\partial t}-\frac{\partial^2 u}{\partial x^2}=u^2(x,t)+F(x,t), \qquad (x,t)\in D,\\ &u(x,0)=g(x), \quad 0\leqq x\leqq 1, \qquad u(0,t)=u(1,t)=h(t), \quad 0\leqq t\leqq 1,\end{aligned} \tag{70}$$

where F, g, and h are the same functions as in Problem 1. The domain D is also the same and the exact solution of (70) is identical to that of (68). We asssociate with (70) the linear recursive scheme defined by

$$\frac{\partial u_{n+1}}{\partial t}-\frac{\partial^2 u_{n+1}}{\partial x^2}-2u_n u_{n+1}=-u_n^2+F, \tag{71}$$

with $u_0=\sin\pi x$, and u_{n+1} satisfying the same conditions as (70), but with F and g approximated by polynomials. Applying the Tau Method to the numerical solution of the problems defined by the linear recursive scheme (71), we find that for $r=s=6$ and 8 the uniform norm of the error of approximation over D becomes stable after 3 iterations, the error being equal to 0.7×10^{-4} and 0.8×10^{-6} respectively. For $r=s=10$ the error becomes stable after four iterations, when it reaches 0.4×10^{-8}.

Acknowledgment. The authors wish to thank the referee of this paper for his constructive and useful remarks.

RECURSION RELATIONS FOR SOLUTIONS TO THE SCHRÖDINGER EQUATION*

MICHAEL REACH†

Abstract. We will consider the general eigenfunction for a second-order differential operator in one variable. For many well-known elementary functions, we can also find a three-term recursion relation in the eigenvalue parameter. For practical computation, this is a very desirable property. Examples include Legendre functions, Bessel functions, etc.

In [Math. Z., 29 (1929), pp. 730-736], Bochner showed that the only polynomial solutions to this problem were the well-known ones. This paper will look for solutions that may not be polynomials.

It will be shown that, unfortunately, for the simple recursion relation considered here, no really new examples exist.

Key words. recursion relations, Bochner, elementary functions

AMS(MOS) subject classifications. 34, 39

1. Notation. Let L be a second-order differential operator in one variable x,

$$L\phi(x) \equiv g_1(x)\frac{d^2\phi}{dx^2} + g_2(x)\frac{d\phi}{dx} + g_3(x)\phi, \tag{1}$$

and let B be a second-order difference operator in k, acting on a sequence $\{l_k\}$ by

$$(Bl)_k \equiv a_k l_{k+1} + b_k l_k + c_k l_{k-1}. \tag{2}$$

For later convenience, subscripts like k will range over $\mathbf{Z}+c$ for some fixed $c \in \mathbf{C}$; that is, over all complex numbers differing from a given one by an integer. Constants will normally be complex; functions will be: $\mathbf{C} \to \mathbf{C}$ and as smooth as necessary.

2. Basic problem. We seek a sequence of functions $\{\phi_k(x)\}$ s.t.

$$L\phi_k(x) = \lambda_k \phi_k(x) \tag*{(3)$_k$}$$

and

$$(B\phi(x))_k = a_k\phi_{k+1}(x) + b_k\phi_k(x) + c_k\phi_{k-1}(x) = \theta(x)\phi_k(x) \tag*{(4)$_k$}$$

for all $k \in \mathbf{Z}+c$ and some L, $\{a_k, b_k, c_k\}$, $\{\lambda_k\}$, $\theta(x)$. Of course, we really seek the whole sextuple $(L, B, \lambda, \theta, \phi, c)$.

We can allow some (not all) of the ϕ_k's to be zero. This will enable us to include the classical orthogonal polynomials. We will see in § 5, though, that all ϕ_k's must be nonzero, either for each k big enough, or else for each k small enough. $\theta(x)$ should be nonconstant in x, and λ_k nonconstant in k. Note that L and θ are independent of k, and that B and λ are independent of x. This will allow us to commute them in several formulas.

3. Symmetries. Given a solution to our Basic Problem, many obvious changes yield new sextuples which will also be solutions. Nine of these changes will be listed,

* Received by the editors December 17, 1984, and in revised form August 30, 1985. This work was supported in part by the Applied Mathematical Sciences subprogram of the Office of Energy Research, U.S. Department of Energy under contract DE-AC03-76SF00098.

† Department of Mathematics and Lawrence Berkeley Laboratory, University of California, Berkeley, California 94720.

to be used extensively later. Assume, then, that $c' \in \mathbf{C}$ is an arbitrary constant, and that $(L, B, \lambda, \theta, \phi, c)$ solves the Basic Problem. The following is a list of new solution sextuples:

(a)

(S1) $$(c'L, B, c'\lambda, \theta, \phi, c).$$

This scales L by a constant. Since $(3)_k$ implies $(c'L)\phi_k = (c'\lambda_k)\phi_k$, (S1) is also a solution.

(b)

(S2) $$(L, B, \lambda, \theta, c'\phi, c).$$

ϕ is scaled by a constant here. (S2) clearly follows from multiplying $(3)_k$ and $(4)_k$ by c'.

(c)

(S3) $$(L+c', B, \lambda+c', \theta, \phi, c).$$

(S3) transfers a constant between L and λ_k. We see it by modifying $(3)_k$ to be $(L+c')\phi_k = (\lambda_k + c')\phi_k$.

(d)

(S4) $$(L, B, \lambda, \theta, \phi, c-c').$$

This new solution just has a shifted subscript. The $(3)_k$ corresponding to it is now $L\phi_{k+c'} = \lambda_{k+c'}\phi_{k+c'}$ for $k \in \mathbf{Z} + c - c'$ and the new $(4)_k$ is similar.

(e)

(S5) $$(L, c'B, \lambda, c'\theta, \phi, c).$$

(S5) scales the recursion relation by a constant. The new $(4)_k$ will be $((c'B)\phi)_k = (c'\theta(x))\phi_k$.

(f)

(S6) $$(L, B+c', \lambda, \theta+c', \phi, c).$$

In (S6), a constant is transferred between B and θ, so that $(4)_k$ is now $(B\phi)_k + c'\phi_k = (\theta(x)+c')\phi_k$.

(g) Symmetry seven is under the change of independent variable x, say by $x = x(x')$. If L' is the new differential operator resulting from the variable change, we derive the new solution (S7):

(S7) $$(L', B, \lambda, \theta(x(x')), \phi(x(x')), c).$$

Equations $(3)_k$ and $(4)_k$ change in the obvious ways. We will use this transformation most commonly for the simple shift $x = x' + c'$.

(h) Let $\phi_k(x) = f(x)\psi_k(x)$, for some function $f(x)$ and all k. Then

(S8) $$(f^{-1}Lf, B, \lambda, \theta, \psi(x), c)$$

is a solution allowing us to multiply ϕ by an arbitrary function of x. Equation $(4)_k$ will look similar, with ψ in place of ϕ, and $(3)_k$ will be $(f^{-1}Lf)\psi_k(x) = \lambda_k\psi_k(x)$.

(i) Let $\phi_k(x) = f_k\psi_k(x)$, for all k and for f_k independent of x. This multiplication of ϕ_k by an arbitrary constant depending only on k gives the new solution

(S9) $$(L, f^{-1}Bf, \lambda, \theta, \psi(x), c).$$

Here $(3)_k$ will be similar, and $(4)_k$ becomes $f_k^{-1}(B(f\psi))_k = \theta(x)\psi_k(x)$.

We will be using these to transfer to simpler-looking solutions, and eventually to reduce to a few fundamental ones. Clearly, the space of possible variations of these fundamental solutions will be extremely large.

4. Commutation relations. L is second order, and we can think of the operator of multiplying by $\theta(x)$ as zeroth order. Then

$$\begin{aligned} &[\theta, L] \equiv \theta L - L\theta && \text{is first order,}\\ &[\theta, [\theta, L]] && \text{is zeroth order,}\\ &[\theta, [\theta, [\theta, L]]] && = 0. \end{aligned}$$

Thus

$$[\theta, [\theta, [\theta, L]]]\phi_k = 0.$$

A typical term of this last expression is

$$\begin{aligned} -3\theta\theta L\theta\phi_k &= -3\theta\theta L(B\phi)_k && \text{by } (4)_k,\\ &= -3\theta\theta(B(L\phi))_k && \text{as } L \text{ and } B \text{ commute,}\\ &= -3\theta\theta(B(\lambda\phi))_k && \text{by } (3)_k,\\ &= -3(B\lambda\theta\theta\phi)_k && \text{since } B \text{ and } \theta \text{ also commute,}\\ &= -3(B\lambda BB\phi)_k && \text{once again using } (4)_k. \end{aligned}$$

Continuing in this way, we soon see that

$$0 = [\theta, [\theta, [\theta, L]]]\phi_k = ([B, [B, [B, \lambda]]]\phi)_k.$$

This last expression is a linear combination of seven terms, multiplying $\phi_{k-3}, \phi_{k-2}, \cdots, \phi_{k+3}$, respectively. If we assume the ϕ_k's linearly independent for different k's (as, for example, if $\lambda_k \neq \lambda_{k'}$, for $k \neq k'$), each of the seven terms must vanish. In particular, let us examine the terms containing ϕ_{k+3} and ϕ_{k-3}, which each must be zero. The term with ϕ_{k+3} is $a_{k+2}a_{k+1}a_k(\lambda_{k+3} - 3\lambda_{k+2} + 3\lambda_{k+1} - \lambda_k)\phi_{k+3}$. The term with ϕ_{k-3} is $c_kc_{k-1}c_{k-2}(\lambda_k - 3\lambda_{k-1} + 3\lambda_{k-2} - \lambda_{k-3})\phi_{k-3}$. These must be zero for all $k \in \mathbf{Z} + c$. Thus, for a given k,

$$(5) \qquad \begin{aligned} &\text{either} && (a_ka_{k+1}a_{k+2}\phi_{k+3} = c_{k+1}c_{k+2}c_{k+3}\phi_k = 0),\\ &\text{or} && \lambda_k - 3\lambda_{k+1} + 3\lambda_{k+2} - \lambda_{k+3} = 0. \end{aligned}$$

5. Pinning down λ.

THEOREM. *At least one of the following statements is true:*

(6)
(1) $c_k \neq 0$ *and* $\phi_k \neq 0$ *for all k sufficiently large negative, or*
(2) $a_k \neq 0$ *and* $\phi_k \neq 0$ *for all k sufficiently large positive.*

(*Recall that the a's and c's are the coefficients in* (4).)

Proof. Pick some $\phi_l \neq 0$. If, for all $k < l$, c_k and $\phi_k \neq 0$, the theorem is proven. Otherwise, there is some largest $m \leqq l$ such that

$$c_m \cdot \phi_{m-1} = 0.$$

Since this m is maximal, $\phi_m \neq 0$. Then $(4)_m$ becomes

$$0 + (b_m - \theta(x))\phi_m + a_m\phi_{m+1} = 0.$$

Thus $a_m\phi_{m+1} \neq 0$ and $\phi_{m+1} = \phi_m \cdot$ (polynomial in $\theta(x)$, degree 1). Now $(4)_{m+1}$ implies

$$\phi_m \cdot (\text{polynomial in } \theta(x), \text{degree } 2) + a_{m+1}\phi_{m+2} = 0.$$

Therefore $a_{m+1}\phi_{m+2} \neq 0$ and $\phi_{m+2} = \phi_m \cdot$ (polynomial in θ, degree 2). We continue this way to generate the ϕ_k's for $k > m$. Since θ is not constant, the nth degree polynomial in θ at the nth step cannot be zero. At the nth step we'll get $a_{m+n}\phi_{m+n+1} \neq 0$, so that we've shown $a_n \neq 0$ and $\phi_{n+1} \neq 0$ for all $n \geqq k$.

We will write $k \in K$ as a synonym for "k sufficiently large negative" or "k sufficiently large positive," respectively. It will turn out in § 7 that all we shall need is that the theorem be true for many contiguous k's. This explains why we can be so ambiguous about the finite end-point of K.

From this theorem and (5) we get that

$$\lambda_k - 3\lambda_{k+1} + 3\lambda_{k+2} - \lambda_{k+3} = 0 \quad \text{for } k \in K.$$

Therefore, $\lambda_k = r_1 k^2 + r_2 k + r_3$ for $k \in K$; r_1, r_2, r_3 fixed. $\lambda_k \neq$ constant, so $r_1 \neq 0$ or $r_2 \neq 0$.

If $r_1 \neq 0$, use (S1) to scale λ_k so that the leading coefficient is 1. Then (S4) can shift k and kill the linear term. Finally, (S3) transfers the constant term into L, yielding $\lambda_k = k^2$.

If $r_1 = 0$, $r_2 \neq 0$, (S1) can be used to scale the leading coefficient of λ_k to be 1. (S4) will kill the constant term by shifting k, giving $\lambda_k = k$. We can keep (S3) in reserve this time for possible need later.

We have reduced to either of two cases

$$\lambda_k = k \quad \text{or} \quad \lambda_k = k^2 \quad \text{for } k \in K. \tag{7}$$

6. Some convenient formulas.

LEMMA.

$$(L - \lambda_k)^n(\theta\phi_k) = \underbrace{[L, [L, \cdots, [L, \theta]] \cdots]}_{\leftarrow n\ L'\ s \rightarrow}\phi_k, \qquad n \geqq 0. \tag{8}$$

Proof. For $n = 1$, the proof is

$$(L - \lambda_k)\theta\phi_k = (L\theta - \theta\lambda_k)\phi_k = (L\theta - \theta L)\phi_k.$$

Larger n's can be shown similarly by induction.

LEMMA.

$$(L - \lambda_{k+1})(L - \lambda_k)(L - \lambda_{k-1})(\theta\phi_k) = 0.$$

Proof. $\theta\phi_k = (B\phi)_k =$ a linear combination of ϕ_{k-1}, ϕ_k, ϕ_{k+1}. Call $\Delta_k \equiv \lambda_k - \lambda_{k+1}$, $\nabla_k \equiv \lambda_k - \lambda_{k-1}$. Then from the previous lemma,

$$\begin{aligned} 0 &= (L - \lambda_{k+1})(L - \lambda_k)(L - \lambda_{k-1})(\theta\phi_k) \\ &= (L - \lambda_k + \Delta_k)(L - \lambda_k)(L - \lambda_k + \nabla_k)(\theta\phi_k) \\ &= ((L - \lambda_k)^3 + (\Delta_k + \nabla_k)(L - \lambda_k)^2 + \Delta_k\nabla_k(L - \lambda_k))(\theta\phi_k). \\ \text{By (8),} \quad &= ([L, [L, [L, \theta]]] + (\Delta_k + \nabla_k)[L, [L, \theta]] + \Delta_k\nabla_k[L, \theta])\phi_k = 0. \end{aligned}$$

Call

$$A_n \equiv \text{the operator } \underbrace{[L, [L, \cdots [L, \theta]] \cdots]}_{\longleftarrow n\ L'\ s \longrightarrow}.$$

Then

$$A_3\phi_k + (\Delta_k + \nabla_k)A_2\phi_k + (\Delta_k\nabla_k)A_1\phi_k = 0 \tag{9}$$

which is often a convenient form.

In [3], Grünbaum and Duistermaat attack the problem of finding a differential equation (instead of a recursion relation) in the spectral parameter, and arrive at a simpler but similar formula.

7. Finding possible potentials. We need not work with the general second-order operator for L. Using (S7) to set the leading coefficient to 1, and (S8) to kill the d/dx term, we can use

$$L=\frac{d^2}{dx^2}+V(x), \quad \text{without loss of generality.}$$

Hand calculations show (use $D=d/dx$)

$$A_1=2\theta'D+\theta'', \qquad A_2=4\theta''D^2+4\theta'''D+\theta''''-2\theta'V',$$

$$A_3=8\theta'''D^3+12\theta''''D^2+(6\theta^{(5)}-4\theta'V''-12\theta''V')D+(\theta^{(6)}-6\theta'''V'-8\theta''V''-2\theta'V''').$$

Case I. $\lambda_k=k$, $k\in K$ (from (7)). Here $\Delta_k=-1$, $\nabla_k=+1$. Then by (9)

$$(A_3-A_1)\phi_k=0 \quad \text{for } k\in K.$$

Since the finite order operator A_3-A_1 has here infinitely many independent solutions (by the theorem, $\phi_k\neq 0$ for all $k\in K$), it must be identically zero:

$$A_3-A_1\equiv 0. \tag{10}$$

We will use this argument again. Since we only need an infinite number of solutions, the sloppy definition of K in § 5 is sufficient. Take (10), and equate to zero each coefficient of a power of D.

D^3: $8\theta'''=0\Rightarrow\theta=r_1x^2+r_2x+r_3$ for some fixed r_1, r_2, r_3.

D^2: $12\theta''''=0\Rightarrow$nothing new.

D^1: $6\theta^{(5)}-4\theta'V''-12\theta''V'=2\theta'$. Using the D^1 equation$\Rightarrow -4(2r_1x+r_2)V''-24r_1V'=2(2r_1x+r_2)$.

D^0: nothing new.

There are now two subcases.

(a) $r_1=0$, so $-4r_2V''=2r_2$. $\theta\neq$ constant, so r_2 cannot be zero. Then

$$V=-\tfrac{1}{4}x^2+q_1x+q_2 \quad \text{for some fixed } q_1, q_2,$$

$$\theta=r_2x+r_3.$$

Use (S7) to shift $x\to x+2q_1$, and (S3) + (S4) to move a constant into λ_k, giving $V=-\frac{1}{4}x^2-\frac{1}{2}$ ($-\frac{1}{2}$ for later convenience). Use (S5), (S6) giving $\theta=x$.

(b) $r_1\neq 0$. Using (S7), (S5), (S6) yields $\theta=x^2$ and $-8r_1V''-24r_1V'=4r_1x$ for our two equations. The second one can be easily solved:

$$2xV''+6V'=-x, \quad (2x^3V')'=-x^3, \quad 2x^3V'=-\tfrac{1}{4}x^4-s_1,$$

$$V'=-\tfrac{1}{8}x-(s_1/2x^3), \qquad V=-\tfrac{1}{16}x^2+(s_1/x^2)+s_2.$$

Here s_1, s_2 are arbitrary constants. Thus Case I, $\lambda_k=k$, has two possible kinds of solution:

(a) $\theta=x$, $V=-\frac{1}{4}x^2-\frac{1}{2}$,

(b) $\theta=x^2$, $V=-\frac{1}{16}x^2+s_1/x^2+s_2$.

Solution to Case I. If $R_n(x)$ solves $y''-2xy'+2ny=0$ (Hermite equation), then $R_n((1/\sqrt{2})ix)\,e^{x^2/4}$ is an eigenfunction for (a).

For (b), pick an m s.t. $\frac{1}{4}-m^2=s_1$. Using (S3) and (S4) to move a constant into λ_k, we can get $V=-\frac{1}{16}x^2+(1-4m^2)/4x^2-(m+1)/2$. Then if $L_n^{(m)}(x)$ solves

$$xy''+(m+1-x)y'+ny=0 \tag{11}$$

(the Generalized Laguerre equation), one can check that $L_n^{(m)}(-x^2/4)\,e^{x^2/8}x^{m+1/2}$ is an eigenfunction for (b), eigenvalue n.

For the sake of completeness, the recursion relations for Hermite and Laguerre solutions are included (see [1, pp. 252, 241]): If R_n is a solution to the Hermite equation, then

$$R_{n+1}-2xR_n+2nR_{n-1}=0.$$

If $L_n^{(m)}$ solves the Generalized Laguerre equation, then

$$(n+1)L_{n+1}^{(m)}=(2n+m+1-x)L_n^{(m)}-(n+m)L_{n-1}^{(m)}.$$

These relations are well known. They do not work only for the orthogonal polynomials. Instead, for any element of the solution space for a given n, one can find elements of the solutions spaces for $n-1$ and $n+1$ such that the recursion relation will hold.

Case II. $\lambda_k=k^2$ for $k\in K$ (from (7)). In this case $\Delta_k=-2k-1$, $\nabla_k=2k-1$. Then by (9)

$$(A_3-2A_2+(1-4k^2)A_1)\phi_k=0 \quad \text{for } k\in K.$$

Here $k^2\phi_k=\lambda_k\phi_k=L\phi_k$, so $(A_3-2A_2+A_1(1-4L))\phi_k=0$ for $k\in K$. Again, since this operator has too many solutions,

$$A_3-2A_2+A_1(1-4L)=0.$$

We shall use $L=D^2+V(x)$ again, and set coefficients to zero. Only the D^3 and D^1 coefficients give new data.

D^3: $8\theta'''-8\theta'=0\Rightarrow\theta=r_1e^x+r_2e^{-x}+r_3$, r_1, r_2, r_3 constant.

Using (S7) to shift x, and (S6), (S5), we get to

$$\theta=e^x \quad \text{or} \quad \theta=\cosh x. \tag{12}$$

D^1: $6\theta^{(5)}-12\theta''V'-4\theta'V''-8\theta'''+2\theta'-8\theta'V=0$.

From (12), we can replace θ'' by θ, so

$$-12\theta V'-4\theta'V''-8\theta'V'=0.$$

Now a little algebra:

$$(\theta'V'+2\theta V)'=0,$$

$$(\theta'V'+2\theta V)=s_1,$$

$$((\theta')^2V)'=s_1\theta',$$

$$(\theta')^2V=s_1\theta+s_2,$$

$$V=\frac{s_1\theta+s_2}{(\theta')^2}. \tag{13}$$

We can list the possible solutions to (12) and (13):

(a) $\theta=e^x$, $V=e^{-2x}$ ($s_1=0$, use (S7) to shift x),

(b) $\theta=e^x$, $V=e^{-x}$ ($s_2=0$, use (S7) to shift x),

(c) $\theta = e^{x}$, $V = -\nu\omega\, e^{-x} - \omega^{2}\, e^{-2x}$ $(s_1 = -\nu\omega,\ s_2 = -\omega^{2})$,

(d) $\theta = \cosh x$, $V = \dfrac{(\beta^{2} - \alpha^{2}) \cosh x + (1 - 4\alpha^{2})/16}{\sinh^{2} x}$

$$(s_1 = \beta^{2} - \alpha^{2},\ s_2 = \tfrac{1}{16}(1 - 4\alpha^{2}))$$

where we have set the constants for later convenience.

Solutions to Case II.

(a) For $V = e^{-2x}$: If $C_n(x)$ solves

$$x^{2}y'' + y' + (x^{2} - n^{2})y = 0 \quad \text{(Bessel equation)}$$

then $C_n(e^{-x})$ is an eigenfunction for (a), eigenvalue n^{2}.

(b) $V = e^{-x}$: $C_{2n}(2e^{-x/2})$ is eigenfunction, eigenvalue n^{2}.

(c) $V = -\nu\omega\, e^{-x} - \omega^{2}\, e^{-2x}$. If $L_n^{(m)}(x)$ is a solution of (11), the generalized Laguerre equation, for given n and m, then

$$z^{n}\, e^{-z/2} L^{(2n)}_{-(v+1)/2-n}(z) \qquad (\text{with } z = 2\omega\, e^{-x})$$

is an eigenfunction to (c) with eigenvalue n^{2}.

(d) $$V = \frac{(\beta^{2} - \alpha^{2}) \cosh x + (1 - 4\alpha^{2})/16}{\sinh^{2} x}, \qquad \alpha, \beta \text{ constants.}$$

If $P_n^{\alpha\beta}(x)$ solves

$$(1 - x^{2})(P_n^{\alpha\beta})'' + [\beta - \alpha - (\alpha + \beta + 2)x](P_n^{\alpha\beta})' + n(\alpha + \beta + n + 1)P_n^{\alpha\beta} = 0$$

(Jacobi equation) then

$$\left(\sinh \frac{x}{2}\right)^{\alpha+1/2} \left(\cosh \frac{x}{2}\right)^{\beta+1/2} P^{\alpha\beta}_{n-(\alpha+\beta+1)/2}(\cosh x)$$

is an eigenfunction to (d) with eigenvalue n^{2}. (See [1, p. 214].)

For Bessel functions $C_n(x)$, the recursion relation is (see [1, p. 67]):

$$C_{n-1} + C_{n+1} = \frac{2n}{x} C_n.$$

This relation can be used to derive a recursion relation also for the Bessel functions that solve (b). For the recursion relation for the Jacobi functions P, see [1, p. 213]. The relation for the Generalized Laguerre function in (c) is not obvious. However, the following relation

$$\frac{(n+1)(n-m)}{(m+1)(m+2)} L^{(m)}_{n-m}(y) + \left(\frac{2n - m + 1}{(m+1)(m+3)} - \frac{1}{y}\right) y L^{(m+2)}_{n-m-1}(y)$$
$$+ \frac{1}{(m+2)(m+3)} y^{2} L^{(m+4)}_{n-m-2}(y) = 0$$

is sufficient, and can be derived by repeated use of

$$L_n^{(m)} = L_n^{(m+1)} - L_{n-1}^{(m+1)}$$

and

$$yL_{n-2}^{(m+2)} - (m + 1 - y)L_{n-1}^{(m+1)} + nL_n^{(m)} = 0$$

found in [1, pp. 241-2]. Here we use the standard normalizations for the $L_n^{(m)}$'s.

8. Conclusion. All the possible solutions found correspond to shifts, using the symmetries from § 3, of well-known functions; i.e., solutions to the Bessel, generalized Laguerre, Hermite and Jacobi differential equations. Note again that those solutions need not be the standard orthogonal polynomials, but can come from the full solution spaces. Since these functions are already well known, no attempt was made to catalogue them precisely: Some are special cases of others.

9. Final note. Though the results given here are hardly surprising, hardly anything is known about cases with higher-order L's or B's. For instance, the problem of finding the functions satisfying both a Schrödinger equation and also a *five* term recurrence, is, I think, completely uncharted territory. Some of the only nontrivial examples I have seen of this kind are given by Grünbaum in [4]. The examples he gives are of soliton-like functions. Though certain steps may be harder, many of these techniques should work for higher-order L's or B's.

INFINITE SUMS IN THE THEORY OF DISPERSION OF CHEMICALLY REACTIVE SOLUTE*

A. E. DEGANCE† AND L. E. JOHNS‡

Abstract. We use the Cauchy partial fraction expansion to derive formulae for infinite sums arising in dispersion theory; the method is general. If $\{\lambda_j\}$ is the sequence of zeros of $f(\lambda)=0$ and if for some $g(\lambda)$

$$\frac{g(\lambda)}{f(\lambda)}=\sum_j \frac{1}{(\lambda-\lambda_j)}\frac{g(\lambda_j)}{f'(\lambda_j)},$$

then

$$\left.\frac{d^n}{d\lambda^n}\frac{\lambda-\lambda_k}{f(\lambda)}g(\lambda)\right|_{\lambda=\lambda_k}=(-1)^n n!\sum_{j\neq k}\frac{1}{(\lambda_k-\lambda_j)^n}\frac{g(\lambda_j)}{f'(\lambda_j)}.$$

Key words. infinite sums, Cauchy partial fraction expansion, dispersion theory

AMS(MOS) subject classifications. Primary 40C15; secondary 30B50

1. The problem. In our study of the dispersion of a chemically reactive solute in a cylinder of circular cross section we turn up infinite sums. The physical process is this: a cloud of solute is released into a solvent, which is in rectilinear flow inside a cylinder on which a chemical rearrangement of the solute takes place. The flow, being nonuniform over the cross section of the cylinder, distorts the cloud in the longitudinal direction; transverse diffusion opposes this; surface reaction moderates the influence of the streamlines near the cylinder. As time passes, the dispersion process is increasingly accurately represented by a constant coefficient dispersion equation in which the dispersion coefficients $X_{2\infty}$, $X_{3\infty}, \cdots$ turn out to be infinite sums, viz.

$$X_{2\infty}=D+\sum_{j\neq 1}\frac{\langle\psi_1, v\psi_j\rangle\langle\psi_j, v\psi_1\rangle}{\lambda_j^2-\lambda_1^2},$$

$$X_{3\infty}=\sum_{j\neq 1}\sum_{k\neq 1}\frac{\langle\psi_1, v\psi_j\rangle\langle\psi_j, v\psi_k\rangle\langle\psi_k, v\psi_1\rangle}{(\lambda_j^2-\lambda_1^2)(\lambda_k^2-\lambda_1^2)}$$

$$\cdots$$

(cf. DeGance and Johns [5]). The eigenfunctions, ψ_j, and the eigenvalues, $-\lambda_j^2$, satisfy

$$D\nabla^2\psi_j=-\lambda_j^2\psi_j,\quad (x,y)\in A,\quad D>0,$$

$$-D\mathbf{n}\cdot\nabla\psi_j+K\psi_j=0,\quad (x,y)\in\partial A,\quad K\leqq 0$$

where A is the cross section of the cylinder, ∂A is its boundary and $\langle,\rangle$ denotes the plain vanilla inner product. Aris [2] reviews the literature of this problem.

For a cylinder of circular cross section, $X_{2\infty}$ simplifies to

$$X_{2\infty}=1+16N_{pe}^2\frac{\lambda_1^2}{\lambda_1^2+\beta^2}\sum_{j\neq 1}\frac{\lambda_j^2}{\lambda_j^2+\beta^2}\frac{(\lambda_j^2+\lambda_1^2+2\beta^2)^2}{(\lambda_j^2-\lambda_1^2)^5}$$

where $\beta=-K/D\geqq 0$. The sum on the right-hand side can be written

$$S_0^{3,1}(\beta)+4(\lambda_1^2+\beta^2)S_0^{4,1}(\beta)+4(\lambda_1^2+\beta^2)^2S_0^{5,1}(\beta)$$

and the problem then is to sum

$$S_0^{m,k}(\beta)=\sum_{j\neq k}\frac{1}{(\lambda_j^2-\lambda_k^2)^m}\frac{\lambda_j^2}{\lambda_j^2+\beta^2}\qquad \forall\beta\geqq 0,\quad m=1,2,\cdots$$

where $0\leqq\lambda_1<\lambda_2<\cdots$ satisfy

$$\lambda_jJ_1(\lambda_j)-\beta J_0(\lambda_j)=0.$$

We derive formulae that express $S_0^{m,k}(\beta)$ as a rational function of β and λ_k^2.

Both Euler and Rayleigh worked on the problem of establishing formulae for certain sums (cf. Watson [8, pp. 500-502]). Indeed, Rayleigh [7] evaluated the sums[1]

$$S_0^{m,1}(0)=\sum_{j\neq 1}\frac{1}{\lambda_j^{2m}},\qquad \beta=0,\quad m=1,2,\cdots$$

where $0=\lambda_1<\lambda_2<\cdots$ satisfy $J_1(\lambda_j)=0$. Much later, Ahmed and Muldoon [1] showed how to evaluate the sums

$$S^{m,k}(\beta)=\sum_{j\neq k}\frac{1}{(\lambda_j^2-\lambda_k^2)^m}\qquad \forall\beta\geqq 0,\quad m=1,2,\cdots$$

using the logarithmic derivative and its Cauchy partial fraction expansion. What we do is not unlike what Rayleigh does nor what Ahmed and Muldoon do; but it is not limited to the expansion of the logarithmic derivative. Indeed, various partial fraction expansions are required to do various classes of sums, but the justification of each partial fraction expansion requires some analysis and while it is general in form it is specific in detail. The general idea then is the use of the Cauchy partial fraction expansion to deduce formulae for certain infinite sums; we illustrate this in two concrete problems of interest to us: the dispersion of a single solute in circular tubes, cf. §§ 2 and 3, and in narrow slits, cf. § 5.

In § 3 we evaluate $S_0^{m,k}(\beta)$ and its companion $S_1^{m,k}(\beta)$ where

$$S_1^{m,k}(\beta)=\sum_{j\neq k}\frac{1}{(\lambda_j^2-\lambda_k^2)^m}\frac{1}{\lambda_j^2+\beta^2}.$$

Now because $\lambda_jJ_1(\lambda_j)-\beta J_0(\lambda_j)=0$ implies

$$\frac{d}{d\beta}\lambda_j^2=\frac{2\lambda_j^2}{\lambda_j^2+\beta^2},$$

$S_0^{m,k}(\beta)$ and $S_1^{m,k}(\beta)$ $m=2,\cdots$ can be deduced from the expansion of the logarithmic derivative, e.g.,

$$S_0^{m+1,k}(\beta)=\frac{\lambda_k^2}{\lambda_k^2+\beta^2}S^{m+1,k}(\beta)-\frac{1}{2m}\frac{d}{d\beta}S^{m,k}(\beta),\qquad m=1,2,\cdots.$$

Thus, to show that various partial fraction expansions are required to do various classes of sums, we investigate

$$\sum_{j\neq k}\frac{1}{(\lambda_j^2-\lambda_k^2)^m}\frac{\lambda_j^2}{\lambda_j^2+\beta^2}\frac{J_0(\alpha\lambda_j)}{J_0(\lambda_j)},\qquad 0\leqq\alpha\leqq 1,$$

[1] In fact Rayleigh evaluated $\sum(1/\lambda_j^{2m})$ where $\{\lambda_j\}$ is the sequence of positive roots of $J_\nu(\lambda)=0$, $\nu=0,1,\cdots$.

and

$$\sum_{j\neq k} \frac{1}{(\lambda_j^2-\lambda_k^2)^m} \frac{1}{\lambda_j^2+\beta^2} \frac{J_1(\alpha\lambda_j)}{J_1(\lambda_j)}, \qquad 0 \leqq \alpha \leqq 1,$$

which, like similar sums that arise in multisolute dispersion (cf. DeGance and Johns [6]) cannot be deduced from the expansion of the logarithmic derivative.

2. The Cauchy partial fraction expansion. For $\beta \geqq 0$, the zeros of $f(\lambda) = \lambda J_1(\lambda) - \beta J_0(\lambda)$ are real (cf. Lommel's theorem (Watson [8, p. 482])). We let λ_j, $j = 1, \cdots$, denote the nonnegative zeros ordered so that $\lambda_j < \lambda_{j+1}$; for $\beta = 0$, $\lambda_1 = 0$ is a double root and $\lambda_j > 0, j = 2, \cdots$ is a simple root; for $\beta > 0$, λ_j is a simple root. Then $f(\lambda)$ vanishes for $\lambda = \pm\lambda_j$ and nowhere else.

The residues of $g(\lambda)/f(\lambda)$ at $\pm\lambda_j$ for $g(\lambda) = f'(\lambda)$, $g(\lambda) = J_0(\lambda)$ and $g(\lambda) = J_1(\lambda)$ are 1, $\pm\lambda_j/(\lambda_j^2+\beta^2)$ and $\beta/(\lambda_j^2+\beta^2)$. Neither $J_0(\pm\lambda_j)$ nor $J_1(\pm\lambda_j)$ survives the calculation of the second and third residues. Their cancellation results because

$$\frac{d}{d\lambda}(\lambda J_1(\lambda) - \beta J_0(\lambda)) = \lambda J_0(\lambda) + \beta J_1(\lambda) \quad \text{and} \quad \pm\lambda_j J_1(\pm\lambda_j) = \beta J_0(\pm\lambda_j).$$

We find, using the Cauchy partial fraction expansion (cf. Copson [4]),

$$\frac{d/d\lambda(\lambda J_1(\lambda) - \beta J_0(\lambda))}{\lambda J_1(\lambda) - \beta J_0(\lambda)} = \sum_{j=1} \frac{2\lambda}{\lambda^2 - \lambda_j^2},$$

$$\frac{J_0(\lambda)}{\lambda J_1(\lambda) - \beta J_0(\lambda)} = \sum_{j=1} \frac{2\lambda_j^2}{(\lambda^2-\lambda_j^2)(\lambda_j^2+\beta^2)}$$

and

$$\frac{J_1(\lambda)}{\lambda J_1(\lambda) - \beta J_0(\lambda)} = \sum_{j=1} \frac{2\beta\lambda}{(\lambda^2-\lambda_j^2)(\lambda_j^2+\beta^2)}.$$

The first form of Cauchy's theorem implies the second and third expansions; the second form implies the first expansion (cf. Copson [4, pp. 144–148]).

We show that the four hypotheses of the first form of Cauchy's theorem are satisfied so that the second and third expansions obtain. Condition (i) is satisfied because $g(\lambda)/f(\lambda)$ is regular save for the zeros of $f(\lambda)$. If C_j denotes a square contour on the Argand diagram with vertices at $(\pm j\pi, \pm j\pi)$ then the sequence of contours, $\{C_j\}$, satisfies Condition (ii). Indeed Dixon's theorem (cf. Watson [8, p. 480]), implies that the zeros of $\lambda J_1(\lambda) - \beta J_0(\lambda)$ fall between the zeros of $J_1(\lambda)$ and $J_0(\lambda)$, i.e., $\lambda_j(0) < \lambda_j(\beta) < \lambda_j(\infty)$, $\forall \beta \in (0, \infty)$; this and Schafheitlin's result (cf. Watson [8, pp. 490–492]), viz.,

$$\lambda_j(0) \in (j\pi - \tfrac{7}{8}\pi, j\pi - \tfrac{3}{4}\pi), \qquad j = 2, \cdots$$

and

$$\lambda_j(\infty) \in (j\pi - \tfrac{1}{4}\pi, j\pi - \tfrac{1}{8}\pi), \qquad j = 1, \cdots$$

imply that $\lambda_j(\beta) \notin C_k$ $\forall j$, k and β. To see that Conditions (iii) and (iv) are also satisfied, we note the asymptotic formula $J_1(\lambda)/J_0(\lambda) \to \tan(\lambda - \frac{1}{4}\pi) + 1/(2\lambda)$ in the right half-plane (cf. Watson [8, p. 496]); this implies that in the left half-plane

$$\frac{J_1(\lambda)}{J_0(\lambda)} \to -\tan\left(-\lambda - \frac{1}{4}\pi\right) + \frac{1}{2\lambda} = -\cot\left(\lambda - \frac{1}{4}\pi\right) + \frac{1}{2\lambda}.$$

Then, because

$$\left|\tan\left(\lambda-\frac{1}{4}\pi\right)\right|^2=\frac{\cosh(2\operatorname{Im}\lambda)-\sin(2\operatorname{Re}\lambda)}{\cosh(2\operatorname{Im}\lambda)+\sin(2\operatorname{Re}\lambda)}$$

we find that on the horizontal sides of C_j, $\tanh(j\pi)\leqq|\tan(\lambda-\frac{1}{4}\pi)|\leqq\coth(j\pi)$, whereas on the vertical sides, $|\tan(\lambda-\frac{1}{4}\pi)|=1$. We conclude that $|J_1(\lambda)/J_0(\lambda)|\to 1$ on C_j as $j\to\infty$. This implies that

$$\left|\frac{J_0(\lambda)}{\lambda J_1(\lambda)-\beta J_0(\lambda)}\right| \quad\text{and}\quad \left|\frac{J_1(\lambda)}{\lambda J_1(\lambda)-\beta J_0(\lambda)}\right|$$

are bounded by $(|\lambda|-\beta)^{-1}\leqq(j\pi-\beta)^{-1}$ on C_j as $j\to\infty$ and hence vanish uniformly as $j\to\infty$. This establishes the second and third expansions. Likewise, we conclude that the first expansion obtains, inasmuch as $[(d/d\lambda)(\lambda J_1(\lambda)-\beta J_0(\lambda))]/(\lambda J_1(\lambda)-\beta J_0(\lambda))$ satisfies the hypotheses of the second form of Cauchy's theorem.

The first expansion leads to the infinite product expansion of $f(\lambda)$ and thence to $S^{m,k}(\beta)$, Ahmed and Muldoon's sum; the second and third lead to $S_0^{m,k}(\beta)$ and $S_1^{m,k}(\beta)$. Thus, if we let $F(z;\beta)=\sqrt{z}J_1(\sqrt{z})-\beta J_0(\sqrt{z})$ and write $F(z;\beta)=(z-\lambda_k^2)F_k(z;\beta)$, then the second expansion implies that

$$R_{0k}(z;\beta)\equiv\frac{J_0(\sqrt{z})}{F_k(z,\beta)}=\frac{2\lambda_k^2}{\lambda_k^2+\beta^2}+(z-\lambda_k^2)\sum_{j\neq k}\frac{2\lambda_j^2}{(z-\lambda_j^2)(\lambda_j^2+\beta^2)}$$

and hence that

$$\frac{d^n}{dz^n}R_{0k}=(-1)^{n-1}n!\sum_{j\neq k}\frac{2\lambda_j^2}{(z-\lambda_j^2)^n(\lambda_j^2+\beta^2)}$$

$$+(-1)^n n!(z-\lambda_k^2)\sum_{j\neq k}\frac{2\lambda_j^2}{(z-\lambda_j^2)^{n+1}(\lambda_j^2+\beta^2)},\qquad n=1,2,\cdots.$$

On setting $z=\lambda_k^2$ we find that

$$R_{0k}^{(n)}(\lambda_k^2;\beta)=(-1)^{n-1}n!\sum_{j\neq k}\frac{2\lambda_j^2}{(\lambda_k^2-\lambda_j^2)^n(\lambda_j^2+\beta^2)}$$

and hence that $S_0^{m,k}(\beta)=-R_{0k}^{(m)}(\lambda_k^2;\beta)/(2m!)$ so that the evaluation of $S_0^{m,k}(\beta)$ reduces to the evaluation of $R_{0k}^{(m)}(\lambda_k^2;\beta)$.

Likewise, the third expansion implies that

$$R_{1k}(z;\beta)\equiv\frac{J_1(\sqrt{z})}{\sqrt{z}F_k(z;\beta)}=\frac{2\beta}{\lambda_k^2+\beta^2}+(z-\lambda_k^2)\sum_{j\neq k}\frac{2\beta}{(z-\lambda_j^2)(\lambda_j^2+\beta^2)};$$

hence a calculation shows that $S_1^{m,k}(\beta)=-R_{1k}^{(m)}(\lambda_k^2;\beta)/(2\beta m!)$ so that the evaluation of $S_1^{m,k}(\beta)$ reduces to the evaluation of $R_{1k}^{(m)}(\lambda_k^2;\beta)$.

3. The evaluation of $R_{0k}^{(m)}(\lambda_k^2;\beta)$. We observe that

$$R_{0k}^{(1)}(z;\beta)=\frac{(d/dz)J_0(\sqrt{z})}{F_k(z;\beta)}-\frac{J_0(\sqrt{z})(d/dz)F_k(z;\beta)}{F_k^2(z;\beta)},$$

$$R_{0k}^{(2)}(z;\beta)=\frac{(d^2/dz^2)J_0(\sqrt{z})}{F_k(z;\beta)}-2\frac{[(d/dz)J_0(\sqrt{z})][(d/dz)F_k(z;\beta)]}{F_k^2(z;\beta)}$$

$$+2\frac{J_0(\sqrt{z})[(d/dz)F_k(z;\beta)]^2}{F_k^3(z;\beta)}-\frac{J_0(\sqrt{z})(d^2/dz^2)F_k(z;\beta)}{F_k^2(z;\beta)},$$

etc., so that the evaluation of $R_{0k}^{(m)}(z;\beta)$ requires the evaluation of $(d^n/dz^n)J_0(\sqrt{z})$ and $(d^n/dz^n)F_k(z;\beta)$, $n=0,1,\cdots,m$. Because $F(z;\beta)=(z-\lambda_k^2)F_k(z;\beta)$ we find that

$$\frac{d^n}{dz^n}F(z;\beta)=n\frac{d^{n-1}}{dz^{n-1}}F_k(z;\beta)+(z-\lambda_k^2)\frac{d^n}{dz^n}F_k(z;\beta),$$

and hence in $R_{0k}^{(m)}(\lambda_k^2;\beta)$ we can replace $F_k^{(n)}(\lambda_k^2;\beta)$ by $F^{(n+1)}(\lambda_k^2;\beta)/(n+1)$, $n=0,1,\cdots,m$.

Now the formulaе

$$\frac{d}{dz}J_0(\sqrt{z})=-\frac{1}{2z}\sqrt{z}J_1(\sqrt{z})$$

and

$$\frac{d}{dz}\sqrt{z}J_1(\sqrt{z})=\frac{1}{2}J_0(\sqrt{z})$$

imply that $(d^n/dz^n)F(z;\beta)$, as well as $(d^n/dz^n)J_0(\sqrt{z})$, is a sum of two terms, each a rational polynomial in z and β times $J_0(\sqrt{z})$ or $\sqrt{z}J_1(\sqrt{z})$. But $F(\lambda_k^2;\beta)=\lambda_kJ_1(\lambda_k)-\beta J_0(\lambda_k)=0$ hence neither $J_0(\lambda_k)$ nor $J_1(\lambda_k)$ appears in $R_{0k}^{(m)}(\lambda_k^2;\beta)$. It follows that $R_{0k}^{(m)}(\lambda_k^2;\beta)$ is a rational polynomial in λ_k^2 and β and so also therefore is $S_0^{m,k}(\beta)$. The calculation of $S_0^{1,k}(\beta)$ and $S_0^{2,k}(\beta)$ illustrates this:

$$\frac{d}{dz}J_0(\sqrt{z})=-\frac{1}{2z}\sqrt{z}J_1(\sqrt{z})$$

and

$$\frac{d^2}{dz^2}J_0(\sqrt{z})=-\frac{1}{4z}J_0(\sqrt{z})+\frac{1}{2z^2}\sqrt{z}J_1(\sqrt{z})$$

imply

$$\left.\frac{d}{dz}J_0(\sqrt{z})\right|_{z=\lambda_k^2}=-\frac{\beta}{2\lambda_k^2}J_0(\lambda_k)$$

and

$$\left.\frac{d^2}{dz^2}J_0(\sqrt{z})\right|_{z=\lambda_k^2}=\left[-\frac{1}{4\lambda_k^2}+\frac{\beta}{2\lambda_k^4}\right]J_0(\lambda_k);$$

whereas

$$\frac{d}{dz}F(z;\beta)=\frac{1}{2}J_0(\sqrt{z})+\frac{\beta}{2z}\sqrt{z}J_1(\sqrt{z}),$$

$$\frac{d^2}{dz^2}F(z;\beta)=\left[-\frac{1}{4z}-\frac{\beta}{2z^2}\right]\sqrt{z}J_1(\sqrt{z})+\frac{\beta}{4z}J_0(\sqrt{z})$$

and

$$\frac{d^3}{dz^3}F(z;\beta)=\left[-\frac{1}{8z}-\frac{\beta}{2z^2}\right]J_0(\sqrt{z})+\left[\frac{1}{4z^2}+\frac{\beta}{z^3}-\frac{\beta}{8z^2}\right]\sqrt{z}J_1(\sqrt{z})$$

imply

$$F_k(\lambda_k^2;\beta)=\left[\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}\right]J_0(\lambda_k),$$

$$2F_k^{(1)}(\lambda_k^2;\beta)=\left[-\frac{1}{4\lambda_k^2}-\frac{\beta}{2\lambda_k^4}\right]\beta J_0(\lambda_k)+\frac{\beta}{4\lambda_k^2}J_0(\lambda_k)$$

and

$$3F_k^{(2)}(\lambda_k^2;\beta)=\left[-\frac{1}{8\lambda_k^2}-\frac{\beta}{2\lambda_k^4}\right]J_0(\lambda_k)+\left[\frac{1}{4\lambda_k^4}+\frac{\beta}{\lambda_k^6}-\frac{\beta}{8\lambda_k^4}\right]\beta J_0(\lambda_k).$$

Thus we have

$$R_{0k}^{(1)}(\lambda_k^2;\beta)=\frac{-\beta}{2\lambda_k^2\left[\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}\right]}-\frac{\frac{\beta}{8\lambda_k^2}+\frac{\beta}{2}\left[\frac{-1}{4\lambda_k^2}-\frac{\beta}{2\lambda_k^4}\right]}{\left[\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}\right]^2},$$

$$\begin{aligned}R_{0k}^{(2)}(\lambda_k^2;\beta)=&\frac{\frac{-1}{4\lambda_k^2}+\frac{\beta}{2\lambda_k^4}}{\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}}+\frac{\frac{\beta}{\lambda_k^2}\left[\frac{\beta}{8\lambda_k^2}+\frac{\beta}{2}\left[\frac{-1}{4\lambda_k^2}-\frac{\beta}{2\lambda_k^4}\right]\right]}{\left[\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}\right]^2}\\&+\frac{\frac{1}{24\lambda_k^2}+\frac{\beta}{6\lambda_k^4}-\frac{\beta}{3}\left[\frac{1}{4\lambda_k^4}-\frac{\beta}{8\lambda_k^4}+\frac{\beta}{\lambda_k^6}\right]}{\left[\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}\right]^2}+\frac{2\left[\frac{\beta}{8\lambda_k^2}+\frac{\beta}{2}\left[\frac{-1}{4\lambda_k^2}-\frac{\beta}{2\lambda_k^4}\right]\right]^2}{\left[\frac{1}{2}+\frac{\beta^2}{2\lambda_k^2}\right]^3}.\end{aligned}$$

The formulae for $S_0^{m,k}(\beta)$, $m=1,2,\cdots,5$, are recorded in Table 1; these are sufficient for $X_{2\infty}$. For $m=1,2,3$ the work can be done by hand; for higher values of m it

TABLE 1

3	$\frac{1}{4!}\left[-3\lambda_k^2+12\beta-2\beta^2+\frac{-12\beta^2+2\beta^3+\beta^4}{\lambda_k^2}+\frac{4\beta^4}{\lambda_k^4}\right]-\frac{\beta^6}{4\lambda_k^4(\lambda_k^2+\beta^2)}$
4	$\frac{1}{3\cdot 5!}\left[\lambda_k^4+(36+4\beta+3\beta^2)\lambda_k^2-144\beta+15\beta^2+8\beta^3+3\beta^4+\frac{144\beta^2-68\beta^3-28\beta^4+4\beta^5+\beta^6}{\lambda_k^2}+\frac{28\beta^4-14\beta^5-7\beta^6}{\lambda_k^4}+\frac{64\beta^6}{\lambda_k^6}\right]-\frac{\beta^8}{8\lambda_k^6(\lambda_k^2+\beta^2)}$
5	$\frac{1}{2\cdot 6!}\left[-5\lambda_k^4-(120+30\beta+16\beta^2)\lambda_k^2+480\beta-36\beta^2-64\beta^3-18\beta^4+\frac{-480\beta^2+424\beta^3+155\beta^4-38\beta^5-8\beta^6}{\lambda_k^2}+\frac{-384\beta^4+188\beta^5+88\beta^6-4\beta^7-\beta^8}{\lambda_k^4}+\frac{-348\beta^6+34\beta^7+17\beta^8}{\lambda_k^6}+\frac{36\beta^8}{\lambda_k^8}\right]-\frac{\beta^{10}}{16\lambda_k^8(\lambda_k^2+\beta^2)}$

cannot. The Symbolic Manipulation Program[2] (SMP) is indispensable for $m > 3$. The formulae for $S_1^{m,k}(\beta)$, $m = 1, 2, \cdots, 5$, are recorded in Table 2.

The dispersion coefficient $X_{2\infty}$ is then

$$X_{2\infty} = 1 + N_{pe}^2\left[\frac{-2\beta^6(1+\beta)^2}{9\lambda_1^6(\lambda_1^2+\beta^2)^3} + \frac{2\beta^4(1+\beta)^2(4+\beta)}{9\lambda_1^6(\lambda_1^2+\beta^2)^2} - \frac{2\beta^2(42+35\beta+25\beta^2+5\beta^3)}{45\lambda_1^6(\lambda_1^2+\beta^2)} \right.$$
$$\left. - \frac{(21+14\beta+\beta^2)}{45\lambda_1^2(\lambda_1^2+\beta^2)} + \frac{\beta(84+57\beta+10\beta^2)}{45\lambda_1^4(\lambda_1^2+\beta^2)} - \frac{1}{45(\lambda_1^2+\beta^2)}\right]$$

where it remains only to establish λ_1^2 as a function of β.[3] For $\beta \cong 0$, the following is useful:

$$\lambda_1^2 = 2\beta - \frac{1}{2}\beta^2 + \frac{1}{12}\beta^3 - \frac{1}{192}\beta^4 - \frac{1}{640}\beta^5 + \frac{31}{69120}\beta^6 + \frac{1}{387072}\beta^7 - \frac{3221}{123863040}\beta^8 + \cdots,$$

which was derived from $(d/d\beta)\lambda_1^2 = 2\lambda_1^2/(\lambda_1^2+\beta^2)$ by the method of Frobenius.

What we achieve, then, in the calculation of $X_{2\infty}$ is this: we need only estimate λ_1^2 vs. β; we need not estimate the summand, viz., λ_j^2 vs. β, $j = 2, 3, \cdots$, nor the sum itself. More generally we note that only λ_k^2 vs. β is required in order to get $S_0^{m,k}(\beta)$

TABLE 2
The sums $S_1^{m,k}(\beta)$.

2	$\dfrac{1}{3!}\left[6\beta + \beta^2 + \dfrac{-12\beta^2+2\beta^3+\beta^4}{\lambda_k^2} - \dfrac{2\beta^4}{\lambda_k^4}\right] - \dfrac{\beta^6}{2\lambda_k^4(\lambda_k^2+\beta^2)}$
3	$\dfrac{1}{4!}\left[-24\beta - 7\beta^2 + \dfrac{48\beta^2-20\beta^3-10\beta^4}{\lambda_k^2} + \dfrac{44\beta^4-6\beta^5-3\beta^6}{\lambda_k^4} + \dfrac{24\beta^6}{\lambda_k^6}\right] - \dfrac{\beta^8}{4\lambda_k^6(\lambda_k^2+\beta^2)}$
4	$\dfrac{1}{3\cdot 5!}\left[\beta^2\lambda_k^2 + 360\beta + 141\beta^2 + 4\beta^3 + 3\beta^4 + \dfrac{-720\beta^2+516\beta^3+270\beta^4+8\beta^5+3\beta^6}{\lambda_k^2}\right.$ $\left. + \dfrac{-1236\beta^4+322\beta^5+167\beta^6+4\beta^7+\beta^8}{\lambda_k^4} + \dfrac{-992\beta^6+76\beta^7+38\beta^8}{\lambda_k^6} - \dfrac{206\beta^8}{\lambda_k^8}\right]$ $- \dfrac{\beta^{10}}{8\lambda_k^8(\lambda_k^2+\beta^2)}$
5	$\dfrac{1}{2\cdot 6!}\left[-9\beta^2\lambda_k^2 - 1440\beta - 684\beta^2 - 46\beta^3 - 32\beta^4\right.$ $+ \dfrac{2880\beta^2-3024\beta^3-1680\beta^4-112\beta^5-42\beta^6}{\lambda_k^2} + \dfrac{7344\beta^4-2928\beta^5-1593\beta^6-86\beta^7-24\beta^8}{\lambda_k^4}$ $\left. + \dfrac{8528\beta^6-1404\beta^7-732\beta^8-20\beta^9-5\beta^{10}}{\lambda_k^6} + \dfrac{4444\beta^8-270\beta^9-135\beta^{10}}{\lambda_k^8} + 1040\dfrac{\beta^{10}}{\lambda_k^{10}}\right]$ $- \dfrac{\beta^{12}}{16\lambda_k^{10}(\lambda_k^2+\beta^2)}$

[2] SMP Reference Manual, Inference Corporation, Los Angeles, California, 1983.

[3] SMP is useful in combining the formulae of Table 1 into a simple formula for $X_{2\infty}$. The results are correct; in particular they agree with all that we can do by hand, viz., small m, small β, etc., and when evaluated they agree with earlier estimates of $X_{2\infty}$.

for the formula we derive is a rational polynomial in λ_k^2 and β; yet we offer this caveat: to get[4] $\lim_{\beta\to 0} S_0^{m,1}(\beta)$ requires that λ_1^2 be accurate to order m, at least, in β. This is what is necessary to reproduce Rayleigh's results. Thus, approximations to λ_1^2 lead to lower order approximations to $S_0^{m,1}(\beta)$ so that crude approximations to λ_1^2 lead to nonsense.

4. Other sums. The partial fraction expansions

$$\frac{J_0(\alpha\lambda)}{\lambda J_1(\lambda)-\beta J_0(\lambda)}=\sum_{j=1}\frac{1}{\lambda^2-\lambda_j^2}\frac{2\lambda_j^2}{\lambda_j^2+\beta^2}\frac{J_0(\alpha\lambda_j)}{J_0(\lambda_j)},\qquad 0\leqq\alpha\leqq 1,$$

and

$$\frac{J_1(\alpha\lambda)}{\lambda J_1(\lambda)-\beta J_0(\lambda)}=\sum_{j=1}\frac{\lambda\beta}{\lambda^2-\lambda_j^2}\frac{2}{\lambda_j^2+\beta^2}\frac{J_1(\alpha\lambda_j)}{J_1(\lambda_j)},\qquad 0\leqq\alpha\leqq 1,$$

are of interest. Their justification rests on obtaining useful bounds for $J_0(\alpha\lambda)/J_0(\lambda)$ and $J_1(\alpha\lambda)/J_1(\lambda)$ on C_j.

Retaining the sequence of contours C_j in § 2 we find that Conditions (i) and (ii) are satisfied; to show that Conditions (iii) and (iv) are satisfied we use

$$J_0(\lambda)\sim\frac{\sqrt{2}}{\sqrt{\pi\lambda}}\left[\cos\left(\lambda-\frac{\pi}{4}\right)\left(1+O\left(\frac{1}{\lambda^2}\right)\right)-\sin\left(\lambda-\frac{\pi}{4}\right)\left(\frac{-1}{8\lambda}+O\left(\frac{1}{\lambda^3}\right)\right)\right],\qquad \operatorname{Re}\lambda\geqq 0$$

(cf. Watson [8, p. 199]) so that

$$\frac{J_0(\alpha\lambda)}{J_0(\lambda)}\to\frac{1}{\sqrt{\alpha}}\frac{\cos(\alpha\lambda)(1-1/(8\alpha\lambda))+\sin(\alpha\lambda)(1+1/(8\alpha\lambda))}{\cos(\lambda)(1-1(8\lambda))+\sin(\lambda)(1-1/(8\lambda))},\qquad \alpha>0.$$

We conclude for large λ that $|J_0(\alpha\lambda)/J_0(\lambda)|^2$ is bounded by $(1/\alpha)(\cosh(2\alpha\operatorname{Im}\lambda)+\sin(2\alpha\operatorname{Re}\lambda))/(\cosh(2\operatorname{Im}\lambda)+\sin(2\operatorname{Re}\lambda))$; but this is less than $2/\alpha$ on the vertical sides of C_j and is less than $(1/\alpha)\coth^2(\pi j)$ on the horizontal sides of C_j for $\alpha\in(0,1)$. It follows that $|J_0(\alpha\lambda)/J_0(\lambda)|$ is bounded by $2^{1/2}/\alpha^{1/2}$ on C_j as $j\to\infty$ and hence that the first expansion is justified for $\alpha\in(0,1]$. For $\alpha=0$, we find that $|J_0(\lambda)|^{-2}$ is bounded by $\pi|\lambda|/(\cosh(2\operatorname{Im}\lambda)+\sin(2\operatorname{Re}\lambda))$, and thus by $\pi\cdot\pi j$ on the vertical sides of C_j and by $\pi\cdot\sqrt{2}\pi j/\sinh(2\pi j)$ on the horizontal sides of C_j. It follows that $|J_0(\lambda)|^{-1}$ is bounded by $\pi\sqrt{j}$ on C_j as $j\to\infty$, and hence that the first expansion is justified for $\alpha=0$ inasmuch as $\pi\sqrt{j}/(\pi j-\beta)$ vanishes as $j\to\infty$. In a similar way we can show that $|J_1(\alpha\lambda)/J_1(\lambda)|$ is uniformly bounded on C_j by $2^{1/2}/\alpha^{1/2}$ so that Conditions (iii) and (iv) obtain therein, and hence that the second expansion is justified for $\alpha\in(0,1)$. The first expansion implies that

$$R_{0k}(z;\alpha,\beta)\equiv\frac{J_0(\alpha\sqrt{z})}{F_k(z:\beta)}=\frac{2\lambda_k^2}{\lambda_k^2+\beta^2}\frac{J_0(\alpha\lambda_k)}{J_0(\lambda_k)}+(z-\lambda_k^2)\sum_{j\neq k}\frac{2\lambda_j^2}{(z-\lambda_j^2)(\lambda_j^2+\beta^2)}\frac{J_0(\alpha\lambda_j)}{J_0(\lambda_j)}$$

and hence that

$$R_{0k}^{(n)}(\lambda_k^2;\alpha,\beta)=(-1)^{n-1}n!\sum_{j\neq k}\frac{2\lambda_j^2}{(\lambda_k^2-\lambda_j^2)^n(\lambda_j^2+\beta^2)}\frac{J_0(\alpha\lambda_j)}{J_0(\lambda_j)},$$

so that the evaluation of the infinite sum reduces to the evaluation of $R_{0k}^{(n)}(\lambda_k^2;\alpha,\beta)$.

[4] We became interested in this not only to check the results but because constant coefficient dispersion models are most useful for small values of β.

For example, because

$$R_{0k}^{(1)}(z;\alpha=0,\beta)=-\frac{(d/dz)F_k(z;\beta)}{F_k^2(z;\beta)}$$

and

$$R_{0k}^{(2)}(z;\alpha=0,\beta)=2\frac{[(d/dz)F_k(z;\beta)]^2}{F_k^3(z;\beta)}-\frac{(d^2/dz^2)F_k(z;\beta)}{F_k^2(z;\beta)},$$

we find at $\beta=0$ that

$$\frac{J_1(\lambda_k)}{2\lambda_k J_0^2(\lambda_k)}=\sum_{j\neq k}\frac{2}{\lambda_k^2-\lambda_j^2}\frac{1}{J_0(\lambda_k)}$$

and

$$\frac{1}{4\lambda_k^2}\frac{J_1^2(\lambda_k)}{J_0^3(\lambda_k)}+\frac{1}{3\lambda_k^2}\frac{1}{J_0(\lambda_k)}\left[\frac{1}{2}-\frac{J_1(\lambda_k)}{\lambda_k J_0(\lambda_k)}\right]=-2\sum_{j\neq k}\frac{2}{(\lambda_k^2-\lambda_j^2)^2}\frac{1}{J_0(\lambda_j)}.$$

Because

$$J_0(\lambda)=1-\frac{1}{4}\lambda^2+\cdots \quad\text{and}\quad \frac{J_1(\lambda)}{\lambda J_0(\lambda)}=\frac{1}{2}+\frac{1}{16}\lambda^2+\frac{1}{96}\lambda^4+\cdots$$

as $\lambda\to 0$ and $\lambda_1=0$, it follows for $k=1$ that

$$-\frac{1}{8}=\sum_{j=2}\frac{1}{\lambda_j^2}\frac{1}{J_0(\lambda_j)},\qquad -\frac{1}{96}=\sum_{j=2}\frac{1}{\lambda_j^4}\frac{1}{J_0(\lambda_j)};$$

because λ_k satisfies $J_1(\lambda_k)=0$, it follows for $k>1$ that

$$0=\sum_{j\neq k}\frac{1}{\lambda_k^2-\lambda_j^2}\frac{1}{J_0(\lambda_j)},\qquad -\frac{1}{24}\frac{1}{\lambda_k^2 J_0(\lambda_k)}=\sum_{j\neq k}\frac{1}{(\lambda_k^2-\lambda_j^2)^2}\frac{1}{J_0(\lambda_j)}.$$

The sum, $\sum_{j=2}1/(\lambda_j^4 J_0(\lambda_j))$, appears in the work of Bhattacharya and Gupta [3]; its summation, $-1/96$, was conjectured but not rigorously justified.

There are values of z other than $z=\lambda_k^2$ at which the expansion of $R_{0k}(z;\alpha,\beta)$, or more simply

$$R_0(z;\alpha=1,\beta)=\frac{J_0(\sqrt{z})}{\sqrt{z}J_1(\sqrt{z})-\beta J_0(\sqrt{z})}=\sum_{j=1}\frac{2\lambda_j^2}{(z-\lambda_j^2)(\lambda_j^2+\beta^2)},$$

yields useful information. For instance, on setting $z=0$ we find a generalization of Rayleigh's sum, viz., for $m=0,1,\cdots$

$$R_0(0;\alpha=1,\beta)=-m!\sum_{j=1}\frac{2}{\lambda_j^{2m}(\lambda_j^2+\beta^2)}$$

implies

$$\frac{1}{\beta}=\sum_{j=1}\frac{2}{\lambda_j^2+\beta^2},$$

$$\frac{1}{2\beta^2}=\sum_{j=1}\frac{2}{\lambda_j^2(\lambda_j^2+\beta^2)}.$$

More generally $z=\lambda_k^2(0)$ and $z=\lambda_k^2(\infty)$ are interesting: J_1 vanishes at the former, J_0 at the latter.

5. Sums for the parallel plane geometry. There are other applications of the Cauchy partial fraction expansion in dispersion calculations. For instance in the parallel plane geometry (a limiting cylinder) the coefficient $X_{2\infty}$ becomes

$$X_{2\infty}=1+16N_{pe}^2\frac{\lambda_1^2}{\lambda_1^2+\beta+\beta^2}\sum_{j\neq 1}\frac{\lambda_j^2}{(\lambda_j^2+\beta+\beta^2)}\frac{(\lambda_j^2+\lambda_1^2+2\beta+2\beta^2)^2}{(\lambda_j^2-\lambda_1^2)^5}$$

where $\lambda_1<\lambda_2<\cdots$ denotes the increasing sequence of nonnegative zeros of

$$\lambda_j\sin(\lambda_j)-\beta\cos(\lambda_j)=0, \qquad \beta\geqq 0.$$

The infinite sum can be rewritten

$$S_c^{3,1}(\beta)+4(\lambda_1^2+\beta+\beta^2)\ S_c^{4,1}(\beta)+4(\lambda_1^2+\beta+\beta^2)^2S_c^{5,1}(\beta)$$

where

$$S_c^{m,k}(\beta)=\sum_{j\neq k}\frac{1}{(\lambda_j^2-\lambda_k^2)^m}\frac{\lambda_j^2}{(\lambda_j^2+\beta+\beta^2)}.$$

In Tables 3 and 4 we record the SMP derived formulae for $S_c^{m,k}(\beta)$ and $S_s^{m,k}(\beta)$, $m=1,2,\cdots,5$, where

$$S_s^{m,k}(\beta)=\sum_{j\neq k}\frac{1}{(\lambda_j^2-\lambda_k^2)^m}\frac{1}{(\lambda_j^2+\beta+\beta^2)}.$$

TABLE 3

The sums $S_c^{m,k}(\beta)$.

m	$2(\lambda_k^2+\beta+\beta^2)^mS_c^{m,k}(\beta)$
1	$\frac{1}{2}+\beta^2-\frac{\beta(1+\beta)}{\lambda_k^2+\beta+\beta^2}$

TABLE 4
The sums $S_s^{m,k}(\beta)$.

m	$2\beta(\lambda_k^2+\beta+\beta^2)^m S_s^{m,k}(\beta)$
1	$\frac{3}{2}\frac{\beta}{\lambda_k^2}-1-\frac{\beta^2(1+\beta)}{\lambda_k^2(\lambda_k^2+\beta+\beta^2)}$
2	$\frac{1}{3!}\left[(6+\beta)+\frac{\beta(-21+12\beta+4\beta^2)}{4\lambda_k^2}+\frac{3\beta^2(1+\beta)}{4\lambda_k^4}\right]-\frac{\beta^3(1+\beta)^2}{2\lambda_k^4(\lambda_k^2+\beta+\beta^2)}$
3	$\frac{1}{4!}\left[-(24+7\beta)-\frac{\beta(-9+60\beta+20\beta^2)}{2\lambda_k^2}-\frac{3\beta^2(1+\beta)(-3+3\beta+\beta^2)}{\lambda_k^4}+\frac{27\beta^3(1+\beta)^2}{2\lambda_k^6}\right]-\frac{\beta^4(1+\beta)^3}{4\lambda_k^6(\lambda_k^2+\beta+\beta^2)}$
4	$\frac{1}{5!}\left[\frac{1}{6}(720+285\beta+2\beta\lambda_k^2+14\beta^2+6\beta^3)+\frac{\beta(3105+12600\beta+4536\beta^2+224\beta^3+48\beta^4)}{48\lambda_k^2}+\frac{\beta^2(1+\beta)(-2205+7800\beta+2760\beta^2+96\beta^3+16\beta^4)}{48\lambda_k^4}+\frac{5\beta^3(1+\beta)^2(-363+120\beta+40\beta^2)}{16\lambda_k^6}\right]-\frac{19\beta^4(1+\beta)^3}{128\lambda_k^8}-\frac{\beta^5(1+\beta)^4}{8\lambda_k^8(\lambda_k^2+\beta+\beta^2)}$
5	$\frac{1}{6!}\left[\frac{-1}{8}(5760+2805\beta+312\beta^2+128\beta^3+36\beta\lambda_k^2)-\frac{\beta(14895+37800\beta+14952\beta^2+1568\beta^3+336\beta^4)}{16\lambda_k^2}-\frac{\beta^2(1+\beta)(495+9000\beta+3435\beta^2+268\beta^3+48\beta^4)}{4\lambda_k^4}-\frac{5\beta^3(1+\beta)^2(-729+840\beta+300\beta^2+12\beta^3+2\beta^4)}{4\lambda_k^6}-\frac{15\beta^4(1+\beta)^3(-354+105\beta+35\beta^2)}{8\lambda_k^8}\right]+\frac{79\beta^5(1+\beta)^4}{256\lambda_k^{10}}-\frac{\beta^6(1+\beta)^5}{16\lambda_k^{10}(\lambda_k^2+\beta+\beta^2)}$

Here the Cauchy partial fraction expansions

$$\frac{\cos(\lambda)}{\lambda\sin(\lambda)-\beta\cos(\lambda)}=\sum_{j=1}\frac{2\lambda_j^2}{(\lambda^2-\lambda_j^2)(\lambda_j^2+\beta+\beta^2)}$$

and

$$\frac{\sin(\lambda)}{\lambda\sin(\lambda)-\beta\cos(\lambda)}=\sum_{j=1}\frac{2\lambda\beta}{(\lambda^2-\lambda_j^2)(\lambda_j^2+\beta+\beta^2)}$$

lead to useful representations of

$$(z-\lambda_k^2)\frac{\cos(\sqrt{z})}{\sqrt{z}(\sqrt{z}\sin(\sqrt{z})-\beta\cos(\sqrt{z}))}$$

and

$$(z-\lambda_k^2)\frac{\sin(\sqrt{z})}{\sqrt{z}(\sqrt{z}\sin(\sqrt{z})-\beta\cos(\sqrt{z}))}$$

and thence of $S_c^{m,k}(\beta)$ and $S_s^{m,k}(\beta)$.

The four conditions of the first form of Cauchy's theorem are satisfied for $f(\lambda)=\lambda\sin(\lambda)-\beta\cos(\lambda)$, $g(\lambda)=\cos(\lambda)$ and $g(\lambda)=\sin(\lambda)$. In particular, Condition (i) is satisfied because $g(\lambda)/f(\lambda)$ is regular save for the zeros of $f(\lambda)$. If C_j denotes the square contour on the Argand diagram with vertices at $(\pm(j+\frac{3}{4})\pi, \pm(j+\frac{3}{4})\pi)$ then the sequence $\{C_j\}$ satisfies Condition (ii). Indeed the zeros of $f(\lambda)$ are real; the proof parallels Lommel's proof for $\lambda J_1(\lambda)-\beta J_0(\lambda)$. And the zeros of $f(\lambda)$ lie on the interval $(j\pi, j\pi+\frac{1}{2}\pi)$; viz., $(d/d\lambda)\lambda\tan(\lambda)\geqq 0$ on the interval $(j\pi-\frac{1}{2}\pi,\ j\pi+\frac{1}{2}\pi)$ and $j\pi\tan(j\pi)=0$. To see that Conditions (iii) and (iv) are satisfied we note that $|\tan(\lambda)|^2=(\cosh(2\operatorname{Im}\lambda)-\cos(2\operatorname{Re}\lambda))/(\cosh(2\operatorname{Im}\lambda)+\cos(2\operatorname{Re}\lambda))$ implies that on the horizontal sides of C_j $\tanh(j+\frac{3}{4})\pi\leqq|\tan(\lambda)|\leqq\coth(j+\frac{3}{4})\pi$, and that on the vertical sides of C_j $|\tanh(\lambda)|=1$. Thus $|\tan(\lambda)|\to 1$ on C_j as $j\to\infty$. It follows that $|g(\lambda)/f(\lambda)|$ is bounded by $(|\lambda|-\beta)^{-1}\leqq((j+\frac{3}{4})\pi-\beta)^{-1}$ on C_j as $j\to\infty$ and hence vanishes uniformly as $j\to\infty$.

The dispersion coefficient $X_{2\infty}$ is then

$$X_{2\infty}=1+N_{pe}^2\frac{1}{(\lambda_1^2+\beta+\beta^2)^3}$$
$$\cdot\left[-\frac{7}{8}\frac{\beta^3(1+\beta)^3}{\lambda_1^6}-\frac{\beta(1+\beta)(-225-1230\beta-330\beta^2+48\beta^3+8\beta^4)}{360\lambda_1^2}\right.$$
$$+\frac{\beta^2(1+\beta)^2(-33+30\beta+10\beta^2)}{24\lambda_1^4}+\frac{585+810\beta-78\beta^2-192\beta^3-24\beta^4-8\lambda_1^4}{360}$$
$$\left.-\lambda_1^2\left[\frac{7}{12}+\frac{17\beta}{45}+\frac{\beta^2}{15}\right]\right];$$

for $\beta\cong 0$, the following is useful:

$$\lambda_1^2=\beta-\frac{1}{3}\beta^2+\frac{4}{45}\beta^3-\frac{16}{945}\beta^4+\frac{16}{14175}\beta^5+\frac{64}{93555}\beta^6-\frac{69248}{212837625}\beta^7+\frac{512}{8292375}\beta^8+\cdots$$

which was derived from $(d/d\beta)\lambda_1^2=2\lambda_1^2/(\lambda_1^2+\beta+\beta^2)$ by the method of Frobenius.

6. Conclusion. The foregoing analysis turns on two items. Firstly, the existence of the Cauchy partial fraction expansion for $g(\lambda)/f(\lambda)$. This is justified if Conditions (i), (ii), (iii) and (iv) of Cauchy's theorem (cf. Copson [4, pp. 144-148]), are satisfied. Secondly, the evaluation of

$$\frac{d^n}{d\lambda^n}\frac{\lambda-\lambda_k}{f(\lambda)}g(\lambda)|_{\lambda=\lambda_k}.$$

This can be done because $\lambda-\lambda_k$ is an unrepeated factor of $f(\lambda)$ so that if $f(\lambda)$ is regular then $f_k(\lambda)=f(\lambda)/(\lambda-\lambda_k)$ is regular; hence $f_k^{(n)}(\lambda_k)=f^{(n+1)}(\lambda_k)/(n+1)$.

AN ELEMENTARY INEQUALITY FOR WHICH EQUALITY HOLDS IN AN INFINITE-DIMENSIONAL SET*

RAY REDHEFFER† AND ALEXANDER VOIGT‡

Abstract. An inequality involving an infinite series of geometric means has the curious property that the set for which equality holds is of infinite dimension.

Key words. inequality, infinite set

AMS(MOS) subject classifications. 26-01, 26A86, 26D15

1. Introduction. Throughout this note $n \in N = \{1, 2, 3, \cdots\}$ and $\{a_n\}$ for $n \in N$ is a sequence of positive real numbers. The geometric mean of the first n of these numbers is denoted by

$$G_n = (a_1 a_2 \cdots a_n)^{1/n}.$$

Our principal objective is to establish the following.

THEOREM 1. *Let* $a_1 + a_3 + a_5 + \cdots < \infty$. *Then*

$$G_1 - 2G_2 + 3G_3 - 4G_4 + \cdots \leqq a_1 + a_3 + a_5 + \cdots \tag{1}$$

whenever the left-hand side converges. If $a_{2j-1} \neq o(1/j)$ *the inequality is strict, but if* $a_{2j-1} = o(1/j)$ *there is exactly one choice of* $\{a_{2j}\}$ *for which equality holds.*

The condition $a_{2j-1} = o(1/j)$ allows an infinite-dimensional subset of the Hilbert space l_2, and if we had $O(1/j)$ instead of $o(1/j)$, the subset would be isomorphic to the Hilbert cube. We know of no other inequality that exhibits behavior such as this.

In the course of proving Theorem 1 we review some significant classical inequalities from our own point of view. We also supplement the theorem by an inequality in the opposite direction and discuss the difficult problem of convergence.

2. Inequalities of Bernoulli, Rado and Maclaurin. Let us start from Bernoulli's inequality

$$(1+y)^n > 1 + ny, \quad n \geqq 2, \quad y > -1, \quad y \neq 0 \tag{2}$$

for which an inductive proof can be given with ease. Setting $x = 1 + y$ we get the equivalent inequality

$$x^n > nx - (n-1), \quad n \geqq 2, \quad x > 0, \quad x \neq 1. \tag{3}$$

If we choose $x = G_n / G_{n-1}$ in (3) and multiply by G_{n-1} the result is

$$a_n \geqq nG_n - (n-1)G_{n-1}, \qquad n \geqq 2, \tag{4}$$

with strict inequality unless $G_n = G_{n-1}$. The arithmetic mean

$$A_n = \frac{a_1 + a_2 + \cdots + a_n}{n}$$

satisfies $a_n = nA_n - (n-1)A_{n-1}$ and (4) becomes

$$n(A_n - G_n) \geqq (n-1)(A_{n-1} - G_{n-1}), \tag{5}$$

which is one form of Rado's inequality. As indicated in [2], the latter provides the basis for an inductive proof of Maclaurin's inequality $G_n \leqq A_n$, with full control of the cases of equality. Addition of the results (4) gives the following, which is also known as Rado's inequality:

$$\sum_{m+1}^{n} a_k \geqq nG_n - mG_m, \qquad n > m \geqq 1.$$

It is seen below that (4) leads to Theorem 1 and that is the reason why these familiar results have been reviewed above. Of course, (3) can be obtained by noting that the function $f(x) = x^n - nx$ satisfies $f''(x) \geqq 0, f'(1) = 0$, and hence $f(x) \leqq f(1)$. The proof based on Bernoulli's inequality has been preferred here because of its historical interest.

3. Proof of Theorem 1. When the series converge we set

$$E = a_2 + a_4 + a_6 + \cdots, \quad U = a_1 + a_3 + a_5 + \cdots, \quad G = G_1 - 2G_2 + 3G_3 - 4G_4 + \cdots,$$

and we denote the partial sums by $E(m)$, $U(m)$ and $G(m)$, respectively, where the summation stops at index m. Hence m is even, odd, and indifferent for E, U, G, respectively. By (4)

$$a_3 \geqq 3G_3 - 2G_2, \quad a_5 \geqq 5G_5 - 4G_4, \quad a_7 \geqq 7G_7 - 6G_6,$$

and so on. Upon recalling that $a_1 = G_1$ and adding, we get $U(m) \geqq G(m)$ for all odd integers m. By § 2 we have equality if, and only if,

$$G_3 = G_2, \quad G_5 = G_4, \quad G_7 = G_6,$$

and so on. The equation $G_{2k+1} = G_{2k}$ is equivalent to

$$(6) \qquad (a_{2k+1})^{2k} = a_1 a_2 \cdots a_{2k}.$$

Hence, we can prescribe the a_{2k} arbitrarily and the a_{2k+1} are then determined uniquely.

Equation (6) gives $G_{2k} = a_{2k+1}$ and the series G when $G_{2k} = G_{2k+1}$ reduces to the following *without parentheses*:

$$a_1 + (-2a_3 + 3a_3) + (-4a_5 + 5a_5) + \cdots.$$

The series *with parentheses* converges by hypothesis, and the parentheses can be dropped if, and only if, $(2k+1)a_{2k+1} \to 0$. This gives Theorem 1.

4. A two-sided inequality. Adding (4) for even values of m gives $-E(m) \leqq G(m)$ for m even, and equality is equivalent to

$$(a_{2k})^{2k-1} = a_1 a_2 \cdots a_{2k-1}, \qquad k = 1, 2, \cdots, m/2.$$

Here we can prescribe a_{2k-1} arbitrarily and the a_{2k} are then uniquely determined. The equality $-E = G$ is possible if, and only if, $a_{2j} = o(1/j)$. Letting $m \to \infty$ and ignoring the cases of equality, we are led to the following theorem:

THEOREM 2. *Let $a_1 + a_2 + a_3 + \cdots < \infty$. Then the series G is convergent and satisfies $-E \leqq G \leqq U$.*

The only remaining problem is to establish the convergence. To this end let $\varepsilon > 0$ be given and choose m so large that

$$a_m + a_{m+1} + a_{m+2} + \cdots < \varepsilon.$$

With m fixed, let

$$P = P_n = a_{m+1} a_{m+2} \cdots a_n, \qquad n > m.$$

By Maclaurin's inequality between arithmetic and geometric means

$$P<\left(\frac{\varepsilon}{n-m}\right)^{n-m}.$$

Raising both sides to power $1/n$ we get an inequality which implies

$$\limsup_{n\to\infty} nP^{1/n} \leqq \varepsilon.$$

This gives $\limsup nG_n \leqq \varepsilon$ and hence $nG_n \to 0$ as $n\to\infty$. If we use this fact, and apply the method of § 3 to a segment

$$a_{m+1}+a_{m+2}+\cdots+a_n,$$

we find that the series G satisfies the Cauchy criterion, hence converges.

The proof of Theorem 2 shows that the simultaneous equalities $G(2n)=-E(2n)$, $G(2n+1)=U(2n+1)$ are possible only if all a_j are equal.

5. The problem of convergence. That G may converge without convergence of E or U is shown by the following remark, whose proof is left to the reader: Let S be an infinite subset of N and let $a_j>0$ be arbitrarily prescribed for $j\in N-S$. Then we can determine $a_j>0$ with $j\in S$ in such a way that the series G converges. Although convergence of both E and U ensures convergence of G, as seen in Theorem 2, difficulties remain when convergence of E or U alone is postulated. Here we give a sufficient condition which is related to Theorem 1:

THEOREM 3. *Let the series U be convergent, and suppose there are positive constants m, M such that*

$$ma_{2k+1}\leqq G_{2k}\leqq Ma_{2k+1}, \qquad k\in N.$$

Then G converges if, and only if, $a_{2k+1}=o(1/k)$.

The special case $m=M=1$ reduces to the case of equality in Theorem 1.

If G converges then $kG_{2k+1}\to 0$ and the condition $ka_{2k+1}\to 0$ follows from

$$ka_{2k+1}=kG_{2k+1}(a_{2k+1}/G_{2k})^{2k/(2k+1)}\leqq kG_{2k+1}m^{-2k/(2k+1)}.$$

The main difficulty is in the converse.

Suppose, then, that $a_{2k+1}=o(1/k)$. We define b_{2k+1} by

$$a_{2k+1}b_{2k+1}=-2kG_{2k}+(2k+1)G_{2k+1} \tag{7}$$

and note that (4) gives $b_{2k+1}\leqq 1$. A lower bound can be obtained from the identity

$$b_{2k+1}=(G_{2k}/a_{2k+1})^{2k/(2k+1)}(2k+1-2k(G_{2k}/a_{2k+1})^{1/(2k+1)})$$

together with $0<G_{2k}/a_{2k+1}\leqq M$ and the limit

$$\lim_{k\to\infty}(2k+1-2kM^{1/(2k+1)})=1-\log M,$$

whose verification is left to the reader. Hence, there is a constant C such that $|b_{2k+1}|\leqq C$. Referring to (7) we see that

$$\sum_{k=1}^{\infty}|-2kG_{2k}+(2k+1)G_{2k+1}|$$

converges by the comparison test. This establishes existence of $\lim G(2n-1)$ as $n\to\infty$. The convergence of G now follows from

$$nG_{2n}\leqq Mna_{2n+1}\to 0, \qquad n\to\infty.$$

In a similar fashion, if E converges, and

$$ma_{2k} \leqq G_{2k-1} \leqq Ma_{2k}$$

for positive constants m, M, then G converges if, and only if, $a_{2k} = o(1/k)$.

6. Historical note. The inequality $G_n \leqq A_n$ is attributed by Hardy, Littlewood and Pólya [2] to Maclaurin and we have followed this attribution here. By a somewhat different procedure Rado's inequality (5) is also derived in [2] and is used to give an inductive proof of $G_n \leqq A_n$. Another derivation of Rado's inequality was given by Jacobsthal [3] in 1951, which is to say, 17 years after the appearance of the first edition [2]. Here the starting point is the identity

$$A_n = \frac{G_{n-1}}{n}\left((n-1)\frac{A_{n-1}}{G_{n-1}} + \left(\frac{G_n}{G_{n-1}}\right)^n\right)$$

and (5) follows by the choice $x = G_n/G_{n-1}$ in (3). This is the choice we made to get the equivalent equation (4), though the latter is not mentioned in [1], [2], [3]. We believe that the particular sequence of events in § 2 may have some advantage over other treatments but, because of overlap with [1], [2], [3], this part of our paper should be regarded as expository.

Theorem 2 is deduced in [5] from a general inequality, of which $-E \leqq G$ and $G \leqq U$ are extremely special cases. The proof of convergence following Theorem 2 was outlined in [4], but so briefly that the argument caused difficulty for some readers. The missing details have been supplied here. We have not come across any prior statement of Theorems 1 or 3.

NEW INEQUALITIES OF MARKOV TYPE*

P. DÖRFLER†

Abstract. For any polynomial f with complex coefficients we define

$$\|f\|:=\left\{\int_a^b |f(t)|^2 w(t)\,dt\right\}^{1/2},$$

where $w:(a,b)\to R$ is a positive and integrable function with all moments finite. It is well known that there exists a constant γ_n, not depending on f, such that $\|f'\|\leqq \gamma_n\|f\|$ for all f, $\deg f\leqq n$. In the present paper we consider the analogous inequality for derivatives of higher order and compute the best possible γ_n. This constant turns out to be the largest singular value of a certain matrix. Two examples are given.

Key words. Markov inequality, orthogonal polynomials, matrix norm

AMS(MOS) subject classifications. 33A65, 41A17, 41A44

1. Let $-\infty\leqq a<b\leqq\infty$ and denote by $w:(a,b)\to R$ a positive and integrable function with all moments

$$\int_a^b t^n w(t)\,dt, \qquad n\geqq 0$$

finite. For any polynomial f with complex coefficients we define

$$\|f\|:=\left\{\int_a^b |f(t)|^2 w(t)\,dt\right\}^{1/2}. \tag{1}$$

In [3] Mirsky showed that there exists a constant γ_n, not depending on f, such that

$$\|f'\|\leqq \gamma_n\|f\| \tag{2}$$

for every polynomial f, $\deg f\leqq n$.

In this paper we show that the best possible value for γ_n is the largest singular value of a certain matrix. Moreover, (2) will be generalized to derivatives of higher order. Finally, the method which yields the best possible γ_n will be illustrated by two examples.

2. First of all we introduce orthogonal polynomials with reference to the papers of Bellman [1] and Mirsky [3]. Under the above-mentioned assumptions there exists, according to [6], a sequence of real orthonormal polynomials p_n, $n\geqq 0$, associated with the weight function $w(t)$, i.e.,

$$\int_a^b p_n p_m w\,dt=\delta_{nm}, \qquad n,m\geqq 0. \tag{3}$$

If (2) is valid for real polynomials, the same is true for complex ones since $f=g+ih$, g, h real, implies $\|f\|^2=\|g\|^2+\|h\|^2$. Therefore, let f be a real polynomial of degree n. The (unique) representations

$$f(t)=\sum_{k=0}^{n} c_k p_k(t), \quad f^{(r)}(t)=\sum_{m=0}^{n-r} d_m p_m(t), \quad 0\leqq r\leqq n,$$

imply

$$\|f\|^2=\sum_{k=0}^{n} c_k^2, \qquad \|f^{(r)}\|^2=\sum_{m=0}^{n-r} d_m^2 \tag{4}$$

* Received by the editors February 5, 1985, and in revised form November 25, 1985.

† Institut für Mathematik und Angewandte Geometrie, Montanuniversität Leoben, A-8700 Leoben, Austria.

because of (3). On the other hand,

$$\sum_{k=0}^{n} c_k p_k^{(r)}(t) = \sum_{m=0}^{n-r} d_m p_m(t)$$

yields

$$(5) \qquad \sum_{k=0}^{n} c_k e_{kj}^{(r)} = d_j, \qquad 0 \leqq j \leqq n-r,$$

where

$$e_{kj}^{(r)} := \int_a^b p_k^{(r)} p_j w \, dt.$$

Let $c^t := (c_0, \cdots, c_n) \in R^{n+1}$, $d^t := (d_0, \cdots, d_{n-r}) \in R^{n-r+1}$ and

$$(6) \qquad A_n^{(r)} := \begin{pmatrix} e_{00}^{(r)} & \cdots & e_{n0}^{(r)} \\ \vdots & & \vdots \\ e_{0n-r}^{(r)} & \cdots & e_{nn-r}^{(r)} \end{pmatrix}.$$

According to these definitions, (5) can be interpreted as the linear transformation

$$A_n^{(r)} c = d.$$

Since $\|f\| = |c|$ and $\|f^{(r)}\| = |d|$, where $|c|$, $|d|$ are the Euclidean vector norms in R^{n+1} and R^{n-r+1}, respectively (cf. (4)), we have the following problem:

Which is the best possible constant $\gamma_n^{(r)}$ such that

$$|A_n^{(r)} c| \leqq \gamma_n^{(r)} |c| \quad \forall c \in R^{n+1} \, ?$$

Obviously, this constant is the best possible in

$$\|f^{(r)}\| \leqq \gamma_n^{(r)} \|f\|.$$

The answer to this question is well known [5]:

$\gamma_n^{(r)}$ is the 2-norm of $A_n^{(r)}$. This norm is the largest singular value of $A_n^{(r)}$, which is the square root of the largest eigenvalue of $(A_n^{(r)})^t A_n^{(r)}$.

Let $A = (a_{ik}) \in R^{m \times n}$ be any real matrix. Then the Frobenius norm

$$(7) \qquad \|A\|_F := \left\{ \sum_{i=1}^{m} \sum_{k=1}^{n} a_{ik}^2 \right\}^{1/2}$$

provides an upper bound for the 2-norm of A [5]. Consequently we obtain an upper bound for $\gamma_n^{(r)}$ in this way which, moreover, can be expressed easily in terms of the p_j. Since

$$p_n^{(r)} = \sum_{m=0}^{n-r} e_{nm}^{(r)} p_m, \qquad n \geqq 0,$$

it follows that

$$\|A_n^{(r)}\|_F^2 = \sum_{j=0}^{n} \|p_j^{(r)}\|^2.$$

Together with the trivial lower bound for $\gamma_n^{(r)}$,

$$\max_{0\leqq j\leqq n} \|p_j^{(r)}\| \leqq \gamma_n^{(r)},$$

this gives the estimation

$$\max_{0\leqq j\leqq n} \|p_j^{(r)}\| \leqq \gamma_n^{(r)} \leqq \left\{ \sum_{j=0}^{n} \|p_j^{(r)}\|^2 \right\}^{1/2} \tag{8}$$

which, restricted to $r=1$, is better than that given in [3]. Let us sum up now the results.

THEOREM 1. *Let* $\|f\|$, p_j, $A_n^{(r)}$ *be defined as in* (1), (3) *and* (6), *and let* f *be any polynomial with complex coefficients,* $\deg f \leqq n$, $n\geqq 0$. *Then the best possible constant* $\gamma_n^{(r)}$ *such that*

$$\|f^{(r)}\| \leqq \gamma_n^{(r)}\|f\|, \tag{9}$$

is the largest singular value of $A_n^{(r)}$. *Moreover, estimation* (8) *holds.*

Example 1. We consider the case $a=-\infty$, $b=\infty$, $w(t)=e^{-t^2}$. A corresponding system of orthonormal polynomials is

$$p_n(t)=\{\pi^{1/2}2^n n!\}^{-1/2}H_n(t), \qquad n\geqq 0,$$

where $H_n(t)$ denotes the nth Hermite polynomial [6]. Since $H_n'=2nH_{n-1}$, $n\geqq 1$, it is easy to prove by induction that

$$p_n^{(r)}=\left\{2^r r!\binom{n}{r}\right\}^{1/2} p_{n-r} \tag{10}$$

holds for $0\leqq r\leqq n$. Consequently,

$$e_{kj}^{(r)}=\begin{cases} 0 & \text{if } k\neq r+j,\\ \left\{2^r r!\binom{k}{r}\right\}^{1/2} & \text{if } k=r+j. \end{cases}$$

Obviously, the largest eigenvalue of $(A_n^{(r)})^t A_n^{(r)}$ is $2^r r!\binom{n}{r}$ and therefore, by Theorem 1

$$\gamma_n^{(r)}=\left\{2^r r!\binom{n}{r}\right\}^{1/2}.$$

By (10) we have $\|p_n^{(r)}\|=\gamma_n^{(r)}$. Thus, in (8) the equality sign holds on the left-hand side. Moreover, (9) becomes an equality for the polynomials $p_n(t)$ themselves.

These results, as far as they concern the case $r=1$, were also proved by Mirsky [3] by a straightforward computation.

3. We want to give a further application of Theorem 1 which, however, requires some additional considerations. We need the following lemma.

LEMMA. *Let* $A=(a_{ik})\in R^{m\times n}$ *be any real matrix with column sums* $s_k := \sum_{i=1}^m a_{ik}$ *and row sums* $z_i := \sum_{k=1}^n a_{ik}$. *Then*

$$\sigma_A^2 \geqq \max\left\{\frac{1}{n}\sum_{i=1}^m z_i^2, \frac{1}{m}\sum_{k=1}^n s_k^2\right\},$$

where σ_A *denotes the largest singular value of* A.

Proof. σ_A^2 is the largest eigenvalue of $M := A^tA$. Since M is normal the following estimation holds [4]:

$$\sigma_A^2 \geqq \frac{1}{l}\max|S_l|,$$

where S_l is the sum of the elements in any $l\times l$ principal submatrix of M. The representation $m_{ik}=\sum_{j=1}^{m} a_{ji}a_{jk}$ of the elements of M yields

$$S_n=\sum_{i,k=1}^{n} m_{ik}=\sum_{i,k=1}^{n}\sum_{j=1}^{m} a_{ji}a_{jk}=\sum_{j=1}^{m}\sum_{i,k=1}^{n} a_{ji}a_{jk}=\sum_{j=1}^{m} z_j^2.$$

Thus, for the special choice $l=n$, we have obtained the estimation

$$\sigma_A^2\geqq\frac{1}{n}S_n=\frac{1}{n}\sum_{j=1}^{m} z_j^2.$$

Since σ_A is the 2-norm of A, which is invariant under transposition, the assertion is proved. □

Example 2. Put $w(t)=e^{-t}t^{\alpha}$, $\alpha\in R$, $\alpha>-1$, $a=0$, $b=\infty$. A corresponding system of orthonormal polynomials is

$$p_n(t)=\left\{\frac{n!}{\Gamma(n+\alpha+1)}\right\}^{1/2} L_n^{\alpha}(t),\qquad n\geqq 0,$$

where $L_n^{\alpha}(t)$ denotes the nth Laguerre polynomial [6]. As one can prove easily, the recurrence formula [2, p. 109]

$$\frac{d}{dt}L_n^{\alpha}-\frac{d}{dt}L_{n-1}^{\alpha}+L_{n-1}^{\alpha}=0,\qquad n\geqq 1$$

leads to

$$p_n'=c(p_{n-1}'-p_{n-1}),\quad n\geqq 1,\quad c:=(1+\alpha/n)^{-1/2}. \tag{11}$$

Hence, for $k\geqq 1$, $j\geqq 0$,

$$e_{kj}^{(1)}=\begin{cases}-c & \text{if } k=j+1,\\ ce_{k-1j}^{(1)} & \text{if } k\neq j+1,\end{cases}$$

and so

$$A_n:=-A_n^{(1)}=\begin{pmatrix} 0 & c & c^2 & \cdots & c^n\\ \vdots & \ddots & c & \cdots & c^{n-1}\\ \vdots & & \ddots & \ddots & \vdots\\ \vdots & & & \ddots & \vdots\\ 0 & \cdots & \cdots & 0 & c\end{pmatrix}.$$

An upper bound for $\gamma_n^{(1)}$ is $\|A_n^{(1)}\|_F=\|A_n\|_F$ (cf. (7)). A short calculation yields

$$(\gamma_n^{(1)})^2\leqq\|A_n\|_F^2=\frac{c^2}{c^2-1}\left(c^2\frac{c^{2n}-1}{c^2-1}-n\right). \tag{12}$$

Substituting for c in (12) and observing that $(1+\alpha/n)^n\geqq 1+\alpha$, we obtain the "nicer" estimation

$$\gamma_n^{(1)}\leqq\|A_n\|_F\leqq(1+\alpha)^{-1/2}n,$$

which, moreover, implies that $\gamma_n^{(1)}=O(n)$.

Next we present a lower bound for $\gamma_n^{(1)}$ by applying the above lemma to A_n. Let s_j, $0\leqq j\leqq n$, denote the column sums of A_n. Then, by a short calculation,

$$(\gamma_n^{(1)})^2\geqq\frac{1}{n}\sum_{j=1}^{n} s_j^2=\frac{c^2}{n(c-1)^3}\left[c^2\frac{c^{2n}-1}{c+1}-2c(c^n-1)+n(c-1)\right]. \tag{13}$$

Finally we show that $\gamma_n^{(1)}/n > K$ for some positive constant K as $n \to \infty$. We divide the right-hand side of (13) by n^2, substitute for c and take the limit as $n \to \infty$. This yields

$$g(\alpha) := 4(4e^{-\alpha/2} - e^{-\alpha} + \alpha - 3)/\alpha^3,$$

which obviously is positive for all $\alpha > -1$. (If $\alpha = 0$, then $g(0) = \lim_{\alpha \to 0} g(\alpha) = \frac{1}{3}$.) With respect to Theorem 1 we thus have proved the following.

THEOREM 2. *Let f be any polynomial with complex coefficients,* $\deg f \leqq n$, $n \geqq 0$. *Let* $\|f\|$ *be defined by* (1) *with* $a = 0$, $b = \infty$, $w(t) = e^{-t}t^\alpha$, $\alpha \in R$, $\alpha > -1$. *Then we have*

$$\|f'\| \leqq (1+\alpha)^{-1/2} n \|f\|.$$

The exponent of n in this inequality cannot be replaced by a smaller one for arbitrary n.

In Example 2 it is difficult to compute the exact value of $\gamma_n^{(r)}$ for arbitrary n and r. The estimates (12) and (13) for $\gamma_n^{(1)}$, however, are sharp enough to give the right order as $n \to \infty$. In the case $\alpha = 0$ the bounds obtained by taking the limits in (12) and (13) as $\alpha \to 0$ have the form

$$\left\{\frac{(2n+1)(n+1)}{6}\right\}^{1/2} \leqq \gamma_n^{(1)} \leqq \left\{\frac{n(n+1)}{2}\right\}^{1/2}.$$

A WHIPPLE'S TRANSFORMATION FOR HYPERGEOMETRIC SERIES IN $U(n)$ AND MULTIVARIABLE HYPERGEOMETRIC ORTHOGONAL POLYNOMIALS*

R. A. GUSTAFSON†

Abstract. A generalization of the terminating form of Whipple's transformation is given for hypergeometric series in $U(n)$. This is proved by explicit evaluation of a generalized Biedenharn-Elliott identity for multiplicity-free $U(n)$ Racah coefficients. As a corollary, a Dougall's theorem is obtained for hypergeometric series in $U(n)$. A family of summation theorems for classical ordinary and basic hypergeometric series is also proved. Finally, a family of orthogonal polynomials on the discrete set $x_1+\cdots+x_n=N$, where the x_i and N are nonnegative integers, is defined which generalizes the (discrete) Racah polynomials of Wilson. We prove a recurrence relation, duality theorem and an identity similar to an addition theorem for these generalized Racah polynomials.

Key words. hypergeometric series in $U(n)$, multivariable orthogonal polynomials, representation theory of $U(n)$, Whipple's transformation, Dougall's transformation

AMS(MOS) subject classification. 33A75

Introduction. In 1976, Holman, Biedenharn and Louck [15] defined a multivariable generalization of classical well-poised hypergeometric series which they called "well-poised in $SU(n)$", $n\geqq 2$. These new special functions were closely connected to the multiplicity-free Racah and Wigner coefficients for $SU(n)$ (see §§ 1 and 2 below). They showed that the hypergeometric series well-poised in $SU(n)$ satisfied a generalization of the terminating ${}_4F_3(-1)$ summation theorem and gave an $SU(3)$ analogue of Whipple's theorem [4, eq. (4.3.4)]. In 1980, Holman [14] defined a general "hypergeometric series in $U(n)$" and proved generalizations of the Saalschütz summation theorem, a Vandermonde (or Gauss) summation theorem and the terminating form of the ${}_5F_4(1)$ summation theorem. These results were proved by explicitly computing identities involving multiplicity-free Racah and Wigner coefficients for $U(n)$ (or $SU(n)$). However, it remained an outstanding problem to find a true generalization of Whipple's theorem to hypergeometric series in $U(n)$.

The importance of finding such a generalized Whipple's theorem had been noted by Andrews [3] and Milne [20]. They hoped that if there were such a generalized Whipple's theorem, then there would also be a q-analogue of it. In the classical case, Watson's q-analogue of Whipple's theorem [24] had been used to prove several partition identities including the Rogers-Ramanujan identities (Watson [24]). We remark that in a different direction Andrews [3] has given a generalization of Watson's q-analogue of Whipple's theorem.

In this paper we prove a generalization of Whipple's theorem for hypergeometric series in $U(n)$. We first prove in § 1 (Prop. 1.50) a generalization of the Biedenharn-Elliottt (B-E) identity for certain multiplicity-free $U(n)$ Racah coefficients. Generalizations of the B-E identity have been previously stated and proved by more than one author [10], [19]. In § 2 we explicitly compute a degenerate case of this B-E identity and obtain a generalization of Whipple's theorem (Thm. 2.24). For the classical case $n=2$ this proof is already given in [15].

As corollaries of Theorem 2.24, we obtain in § 3 several other summation and transformation theorems for hypergeometric series in $U(n)$. In particular we obtain generalizations of Dougall's theorem (Cor. 3.1), an analogue of Dougall's theorem (Cor. 3.4) and a terminating form of Whipple's ${}_6F_5(-1)$ transformation (Cor. 3.8 and 3.10). Finally, we prove a family of summation theorems for classical terminating ${}_{n+1}F_n(1)$ (Thm 3.13) and their q-analogues, ${}_{n+1}\varphi_n(1)$ (Thm. 3.18), for $n \geqq 1$.

In § 4 we define a family of orthogonal polynomials in several variables (Prop. 4.5) which are orthogonal on the discrete set $x_1 + \cdots + x_n = N$, where the x_i, $1 \leqq i \leqq n$, and N are nonnegative integers and $n \geqq 2$. In §§ 5, 6 and 7 a recurrence relation, duality theorem and an identity similar to an addition theorem are proved for these generalized Racah polynomials.

Finally, in the appendix we prove the key technical Proposition A.16 which is needed in the explicit computation of the special case of the B-E identity used in the proof of Theorem 2.24.

The approach we have taken in this paper relies on the algebraic properties of the Racah coefficients or the "Racah-Wigner algebra of tensor operators" (see [8]). In fact, the key B-E identity is a consequence of the associativity law in the Racah-Wigner algebra [8], [19].

Another complementary approach to the transformation identities for hypergeometric series in $U(n)$ is by means of difference equations. By this method Milne [20] gave an elementary proof of Holman's ${}_5F_4(1)$ summation theorem.

The results in this paper involve only the multiplicity-free Racah coefficients for $U(n)$. A better understanding of the nonmultiplicity-free Racah coefficients should lead to further generalizations of the transformation identities discussed here and to new orthogonality relations.

1. Vector coupling coefficients, recoupling coefficients and the Biedenharn–Elliott identity. We shall recall some facts about Wigner coefficients for $U(n)$, $n \geqq 1$, which are expounded in greater length in [6]. The irreducible representations of $U(n)$ are in one-to-one correspondence with the set of n-tuples of integers $m = [m] = [m]_n = [m_{1n}, m_{2n}, \cdots, m_{nn}]$ satisfying

$$m_{1n} \geqq m_{2n} \geqq \cdots \geqq m_{nn}. \tag{1.1}$$

m is the highest weight of the irreducible representation π_m of $U(n)$ acting on the representation space V_m. The Gelfand-Zetlin basis (over $\mathbb{C}$) of V_m is defined in [17] or [6]. A Gelfand pattern $(m) = (m)_n$ is an array of integers $m_{k,l}$, $1 \leqq k \leqq l \leqq n$, satisfying the "betweenness" conditions

$$m_{k,l+1} \leqq m_{k,l} \leqq m_{k+1,l+1} \tag{1.2}$$

for $1 \leqq k \leqq l \leqq n-1$. The first row of the Gelfand pattern (m) is $m = [m_{1n}, \cdots, m_{nn}]$. To each Gelfand pattern (m) is associated an orthonormal basis vector in V_m, which is also denoted by (m). The vector (m) is called a "Gelfand state" and the set of all Gelfand states (m) with first row m is an orthonormal basis of V_m.

The weight $\Delta(m) = [\Delta_1, \cdots, \Delta_n] = [\Delta]$ of a Gelfand state (m) is given by

$$\Delta_l = \sum_{k=1}^{l} m_{kl} - \sum_{k=1}^{l-1} m_{kl-1} \tag{1.3}$$

for $2 \leqq l \leqq n$ and $\Delta_1 = m_{11}$. The set of weights satisfies a natural partial ordering:

$$\Delta \geqq \Delta' \quad \text{if and only if } \sum_{i=1}^{l} \Delta_i \geqq \sum_{i=1}^{l} \Delta'_i \tag{1.4}$$

for all l, $1 \leqq l \leqq n$. There are unique states in V_m of highest weight $[m_{1n}, \cdots, m_{nn}]$ and lowest weight $[m_{nn}, m_{nn-1}, \cdots, m_{1n}]$.

We are interested in the explicit decomposition of tensor products of the form $V_m \otimes V_{m'}$ or $V_{m''} \otimes V_m \otimes V_{m'}$ where m is an arbitrary n-tuple of integers satisfying (1.1) and m', m'' are of the form $[p', 0, \cdots, 0]$ and $[p'', 0, \cdots, 0]$ respectively, where p' and p'' are nonnegative integers.

We have

$$V_m \otimes V_{m'} \approx \oplus V_\mu \tag{1.5}$$

where the sum is over all n-tuples of integers $\mu = [\mu_{1n}, \cdots, \mu_{nn}]$ satisfying

$$\mu_{1n} \geqq m_{1n} \geqq \mu_{2n} \geqq m_{2n} \geqq \cdots \geqq \mu_{nn} \geqq m_{nn} \tag{1.6a}$$

and

$$\sum_{i=1}^{n} (\mu_{in} - m_{in}) = p'. \tag{1.6b}$$

A space V_μ on the left-hand side of (1.5) is said to *occur* in $V_m \otimes V_{m'}$.

The set of all pairs $(m) \otimes (m')$ where (m), (m') are Gelfand states of V_m and $V_{m'}$ respectively forms an orthonormal basis, called the Gelfand-Zetlin basis, of $V_m \otimes V_{m'}$. Similarly the set of all triples $(m'') \otimes (m) \otimes (m')$ forms an orthonormal basis (Gelfand-Zetlin basis) for $V_{m''} \otimes V_m \otimes V_{m'}$ where (m''), (m), (m') are Gelfand states of $V_{m''}$, V_m and $V_{m'}$. We shall call these vectors Gelfand states of $V_m \otimes V_{m'}$ and $V_{m''} \otimes V_m \otimes V_{m'}$ respectively.

For each highest weight μ satisfying (1.6a and b) let T_μ be a nontrivial intertwining map

$$T_\mu : V_m \otimes V_{m'} \to V_\mu. \tag{1.7}$$

The map T_μ is determined up to scalar multiples. We shall assume that the restriction of T_μ to the orthogonal complement of the kernel is unitary and also that T_μ has real matrix coefficients with respect to the Gelfand-Zetlin bases of $V_m \otimes V_{m'}$ and V_μ (see [6, § 2]). Under these conditions T_μ is determined up to a scalar factor (phase factor) of ±1. This phase factor is then fixed by convention.

We choose the following phase convention. Let

$$(m) = \begin{pmatrix} [m]_n \\ (m)_{n-1} \end{pmatrix}$$

be a Gelfand state of V_m of highest weight $\Delta(m) = [m_{1n}, \cdots, m_{nn}] = m$. The first row of (m) is $[m]_n = m$ and the last $n-1$ rows of (m) are $(m)_{n-1}$, which is a Gelfand pattern for $U(n-1)$. Similarly let

$$(\mu) = \begin{pmatrix} [\mu]_n \\ (m)_{n-1} \end{pmatrix}$$

be a state of V_μ whose first row is $[\mu]_n = \mu$ and last $n-1$ rows are identical to the last $n-1$ rows of (m). Since the first row of $(m)_{n-1}$ is $[m_{1n}, m_{2n}, \cdots, m_{n-1n}]$, then it follows from (1.6a) that (μ) satisfies the betweenness conditions (1.2). Finally let

$$(m') = \begin{pmatrix} [p', 0, \cdots, 0] \\ (0)_{n-1} \end{pmatrix}$$

be the state of lowest weight in $V_{m'}$. Then we require that

$$\langle(\mu), T_\mu(m \otimes (m'))\rangle > 0, \tag{1.8}$$

where $\langle , \rangle$ is the Hermitian inner product on V_μ for which the Gelfand-Zetlin basis is orthonormal. That the inner product (1.8) is nonzero is a consequence of [14, eq. (6)]. This phase convention agrees with that of Chacón, Ciftan and Biedenharn [9] and also Arišaukas, Jucys and Jucys [1] (see also [14]).

Remark 1.9. For the sake of simplicity the dependence on the highest weights m and m' in T_μ will not be denoted, but understood. Thus two distinct operators whose domains are different spaces $V_m \otimes V_{m'}$ but whose images are the same space V_μ will both be denoted by T_μ. Also under essentially the same conditions as above and with the same notation, we construct the $U(n)$ intertwining map:

$$T_\mu : V_{m'} \otimes V_m \to V_\mu. \tag{1.10}$$

Definition 1.11. Let notation be as in (1.5). For arbitrary (m), (m') and (μ) in the representation spaces V_m, $V_{m'}$ and V_μ respectively, the inner product

$$\langle (\mu), T_\mu((m) \otimes (m')) \rangle \tag{1.12}$$

is called a *vector-coupling, Wigner* or *Clebsch-Gordan* coefficient of $U(n)$. These coefficients are simply the matrix coefficients of the intertwining map T_μ.

As a consequence of the definition of the maps T_μ and as discussed in [6, eqs. (2.8a and b)] (with different notation), we have the following orthogonality relations satisfied by the Wigner coefficients:

Proposition 1.13. *With notation as above, let (m), $(\bar{m})$ be fixed states of V_m and (m'), $(\bar{m}')$ be fixed states of $V_{m'}$; then*

$$\sum_{(\mu)} \langle (\mu), T_\mu((m) \otimes (m')) \rangle \langle (\mu), T_\mu((\bar{m}) \otimes (\bar{m}')) \rangle = \begin{cases} 1 & \text{if } (m) = (\bar{m}) \quad \text{and} \quad (m') = (\bar{m}'), \\ 0 & \text{otherwise,} \end{cases} \tag{1.14a}$$

where the sum is over all states (μ) of all distinct V_μ occurring in $V_m \otimes V_{m'}$ (as in (1.5)). Similarly if (μ), (μ') are fixed states of V_μ and $V_{\mu'}$, respectively, occurring in $V_m \otimes V_{m'}$, then

$$\sum_{(m) \otimes (m')} \langle (\mu), T_\mu((m) \otimes (m')) \rangle \langle (\mu'), T_{\mu'}((m) \otimes (m')) \rangle = \begin{cases} 1 & \text{if } \mu = \mu' \quad \text{and} \quad (\mu) = (\mu'), \\ 0 & \text{otherwise,} \end{cases} \tag{1.14b}$$

where the sum is over all Gelfand states $(m) \otimes (m')$ of $V_m \otimes V_{m'}$.

We now consider decompositions of the triple tensor product $V_{m''} \otimes V_m \otimes V_{m'}$ with m an arbitrary $U(n)$ highest weight and m', m'' of the form $[p', 0, \cdots, 0]$ and $[p'', 0, \cdots, 0]$ respectively, with p' and p'' nonnegative integers. We first construct $U(n)$ intertwining maps of the form

$$1 \otimes T_\mu : V_{m''} \otimes (V_m \otimes V_{m'}) \to V_{m''} \otimes V_\mu \tag{1.15a}$$

where V_μ occurs in $V_m \otimes V_{m'}$ (as in (1.5)) and T_μ is defined as in (1.7); and also

$$T_\nu : V_{m''} \otimes V_\mu \to V_\nu \tag{1.15b}$$

where V_ν occurs in $V_{m''} \otimes V_\mu$ and T_ν is defined as above.

Proposition 1.16. *For a fixed highest weight ν such that V_ν occurs in $V_{m''} \otimes V_m \otimes V_{m'}$ (i.e.* $\mathrm{Hom}_{U(n)}(V_{m''} \otimes V_m \otimes V_{m'}, V_\nu) \neq 0$), *then a basis over* $\mathbb{C}$ *for* $\mathrm{Hom}_{U(n)}(V_{m''} \otimes V_m \otimes V_{m'}, V_\nu)$ *is given by the set I of all $U(n)$ intertwining maps of the form*

$$T_\nu(1 \otimes T_\mu) : V_{m''} \otimes V_m \otimes V_{m'} \to V_\nu \tag{1.17}$$

for all highest weights μ such that V_μ occurs in $V_m \otimes V_{m'}$ and V_ν occurs in $V_{m''} \otimes V_m$.

Proof. One checks that the dimension over $\mathbb{C}$ of Hom $(V_{m''}\otimes V_m\otimes V_{m'}, V_\nu)$ equals the order of I. This can be done for example by a $U(n)$ character computation. Second, we show that the elements of I are linearly independent over $\mathbb{C}$. Let N and M be integers such that there exists states $(m'')_l\in V_{m''}$, $(m)_{k,l}\in V_m$ and $(m')_{k,l}\in V_{m'}$ for $k=1,\cdots,N$ and $l=1,\cdots,M$ such that

$$(1.18a)\qquad \sum_{k=1}^{N}(m)_{k,l}\otimes(m')_{k,l}\in V_\mu \quad \text{component of } V_m\otimes V_{m'}$$

for all l, $1\leqq l\leqq M$, and

$$(1.18b)\qquad v=\sum_{l=1}^{M}\sum_{k=1}^{M}(m'')_l\otimes(m)_{k,l}\otimes(m')_{k,l}\in V_\nu \quad \text{component of } V_{m''}\otimes V_m\otimes V_{m'}.$$

It follows that $T_\nu(1\otimes T_\mu)(v)\neq 0$ and $T(v)=0$ for all $T\in I$ such that $T\neq T_\nu(1\otimes T_\mu)$. This implies that the elements of I are linearly independent over $\mathbb{C}$.

Now with m, m', m'' as in (1.15a and b) and μ' and ν are $U(n)$ highest weights such that V_μ occurs in $V_{m''}\otimes V_m$ and V_ν occurs in $V_{\mu'}\otimes V_{m'}$, then we construct the $U(n)$ intertwining maps

$$(1.19a)\qquad T_{\mu'}\otimes 1:(V_{m''}\otimes V_m)\otimes V_{m'}\to V_{\mu'}\otimes V_{m'}$$

and

$$(1.19b)\qquad T_\nu: V_{\mu'}\otimes V_{m'}\to V_\nu.$$

As above, a basis over $\mathbb{C}$ for Hom $(V_{m''}\otimes V_m\otimes V_{m'}, V_\nu)$, if nonzero, is given by the set of all $U(n)$ intertwining maps of the form:

$$(1.20)\qquad T_\nu(T_{\mu'}\otimes 1): V_{m''}\otimes V_m\otimes V_{m'}\to V_\nu$$

for all highest weights μ' such that $V_{\mu'}$ occurs in $V_{m''}\otimes V_m$ and V_ν occurs in $V_{\mu'}\otimes V_{m'}$.

We thus obtain two different bases over $\mathbb{C}$ for Hom $(V_{m''}\otimes V_m\otimes V_{m'}, V_\nu)$: One basis consisting of maps of the form (1.17) and another basis consisting of maps of the form (1.20). The entries of the change of basis matrices between these two are called *recoupling* or (multiplicity-free) *Racah coefficients.*

DEFINITION 1.21. Let assumptions be as in (1.15a and b). Define the (multiplicity-free) Racah coefficients

$$\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix}\in\mathbb{R}$$

by the following identity:

$$(1.22)\qquad T_\nu(1\otimes T_\mu)=\sum_{\mu'}\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix}T_\nu(T_{\mu'}\otimes 1)$$

where the sum is over all highest weights μ' such that $V_{\mu'}$ occurs in $V_{m''}\otimes V_m$ and V_ν occurs in $V_{\mu'}\otimes V_{m'}$.

Remark 1.23. In Definition 1.21 we can vary the assumptions on the highest weights m, m' and m''. Let m'' be an arbitrary $U(n)$ highest weight and m, m' be of the form $[p,0,\cdots,0]$, $[p',0,\cdots,0]$ respectively, where p, p' are nonnegative integers. If $\mu=m+m'=[p+p',0,\cdots,0]$ then the intertwining map $T_\nu(1\otimes T_\mu)$ is defined similarly to (1.15a and b). For all highest weights μ' such that $V_{\mu'}$ occurs in $V_{m''}\otimes V_m$, the maps $T_\nu(T_{\mu'}\otimes 1)$ are defined similarly to (1.19a and b). They still form a basis of Hom $(V_{m''}\otimes V_m\otimes V_{m'}, V_\nu)$. We therefore define $\left[\begin{smallmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{smallmatrix}\right]$ by the same expression (1.22).

Remark 1.24. The notation in Definition 1.21 for the multiplicity-free Racah coefficients above differs from the standard notation of Biedenharn et al. [17]. The standard notation for a general Racah coefficient of $U(n)$ is much more complicated and, in the case above, would have a number of redundancies. The notation of Definition 1.21 is similar to that of the 6-j symbols for $SU(2)$ [7], [12] or more general groups [10], [29]. However, the Racah coefficients are not identical to the 6-j symbols but differ by a product of dimension factors and a sign factor [29]. The 6-j symbols themselves for $U(n)$, $n>2$, are not completely satisfactory as different authors choose different sign factors (see [28]). Since we will not need these complicated sign factors in this paper, we avoid them.

We now state the orthogonality relations satisfied by the Racah coefficients above.

PROPOSITION 1.25. *With notation as in Definition* 1.21 *let the highest weights μ, ν, m, m', m'' satisfy the assumptions of* (1.15a *and* b) *and also with μ replaced by the highest weight $\bar{\mu}$. Similarly let μ', ν, m, m', m'' satisfy the corresponding assumptions for* (1.19a *and* b) *and also with $\bar{\mu}'$ in place of μ'. Then we have*

$$\sum_{\mu'} \begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} \begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \bar{\mu} \end{bmatrix} = \begin{cases} 1 & \textit{if } \mu=\bar{\mu}, \\ 0 & \textit{otherwise}, \end{cases} \tag{1.26a}$$

where the sum is over all highest weights μ' such that $V_{\mu'}$ occurs in $V_{m''}\otimes V_m$ and V_ν occurs in $V_{\mu'}\otimes V_{m'}$. Also

$$\sum_{\mu} \begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} \begin{bmatrix} m'' & m & \bar{\mu}' \\ m' & \nu & \mu \end{bmatrix} = \begin{cases} 1 & \textit{if } \mu'=\bar{\mu}', \\ 0 & \textit{otherwise}, \end{cases} \tag{1.26b}$$

where the sum is over all highest weights μ such that V_μ occurs in $V_m\otimes V_{m'}$ and V_ν occurs in $V_{m''}\otimes V_\mu$.

Proof. Assume that μ, $\bar{\mu}$ are highest weights of irreducible representations occurring in $V_m\otimes V_{m'}$ and also that ν and $\bar{\nu}$ are highest weights of irreducible representations occurring in $V_{m''}\otimes V_\mu$ and $V_{m''}\otimes V_{\bar{\mu}}$ respectively. Let (ν) be a fixed state of V_ν and $(\bar{\nu})$ of $V_{\bar{\nu}}$. We first prove the following identity:

$$\begin{aligned} &\sum_{(m'')\otimes(m)\otimes(m')} \langle(\nu), T_\nu(1\otimes T_\mu)((m'')\otimes(m)\otimes(m'))\rangle \\ &\qquad\cdot\langle(\bar{\nu}), T_{\bar{\nu}}(1\otimes T_{\bar{\mu}})((m'')\otimes(m)\otimes(m'))\rangle \\ &= \begin{cases} 1 & \text{if } \mu=\bar{\mu},\ \nu=\bar{\nu} \text{ and } (\nu)=(\bar{\nu}), \\ 0 & \text{otherwise}, \end{cases} \end{aligned} \tag{1.27}$$

where the sum is over all states $(m'')\otimes(m)\otimes(m')$ of $V_{m''}\otimes V_m\otimes V_{m'}$.

By the definition (1.7) of T_ν, $T_{\bar{\nu}}$, T_μ and $T_{\bar{\mu}}$ the left-hand side of (1.27) equals

$$\begin{aligned} &\sum_{(m'')\otimes(m)\otimes(m')} \Big\{\sum_{(\mu)} \langle(\nu), T_\nu((m'')\otimes(\mu))\rangle \\ &\qquad\cdot\langle(m'')\otimes(\mu), (1\otimes T_\mu)((m'')\otimes(m)\otimes(m'))\rangle\Big\} \\ &\quad\cdot\Big\{\sum_{(\bar{\mu})} \langle(\bar{\nu}), T_{\bar{\nu}}((m'')\otimes(\bar{\mu}))\rangle\langle(m'')\otimes(\bar{\mu}), (1\otimes T_{\bar{\mu}})((m'')\otimes(m)\times(m'))\rangle\Big\} \end{aligned} \tag{1.28a}$$

$$\begin{aligned} &= \sum_{(m'')\otimes(m)\otimes(m')} \Big\{\sum_{(\mu)} \langle(\nu), T_\nu((m'')\otimes(\mu))\rangle\langle(\mu), T_\mu((m)\otimes(m'))\rangle\Big\} \\ &\quad\cdot\Big\{\sum_{(\bar{\mu})} \langle(\bar{\nu}), T_{\bar{\nu}}((m'')\otimes(\bar{\mu}))\rangle\langle(\bar{\mu}), T_{\bar{\mu}}((m)\otimes(m'))\rangle\Big\} \end{aligned} \tag{1.28b}$$

where the outer sum in (1.28a and b) is the same as in (1.27) and the inner sums are over all states (μ), $(\bar{\mu})$ of V_μ and $V_{\bar{\mu}}$ respectively. By interchanging the order of summation in (1.28b) we find that (1.28b) and the left-hand side of (1.27) equal

$$\sum_{(m''),(\mu),(\bar{\mu})} \langle(\nu), T_\nu((m'')\otimes(\mu))\rangle\langle(\bar{\nu}), T_{\bar{\nu}}((m'')\otimes(\bar{\mu}))\rangle \tag{1.29}$$
$$\cdot\left\{\sum_{(m)\otimes(m')} \langle(\mu), T_\mu((m)\otimes(m'))\rangle\langle(\bar{\mu}), T_{\bar{\mu}}((m)\otimes(m'))\rangle\right\}$$

where the outer sum is over all states (m''), (μ), $(\bar{\mu})$ of $V_{m''}$, V_μ and $V_{\bar{\mu}}$ respectively and the inner sum is over all states $(m)\otimes(m')$ of $V_m\otimes V_{m'}$. By identity (1.14b) the inner sum in (1.29) equals 1 if $\mu=\bar{\mu}$ and $(\mu)=(\bar{\mu})$ and equals 0 otherwise. Hence if $\mu\neq\bar{\mu}$, then (1.29) and the left-hand side of (1.27) equals 0. If $\mu=\bar{\mu}$, then (1.29) equals

$$\sum_{(m'')\otimes(\mu)} \langle(\nu), T_\nu((m'')\otimes(\mu))\rangle\langle(\bar{\nu}), T_{\bar{\nu}}((m'')\otimes(\mu))\rangle \tag{1.30}$$

where the sum is over all states of $V_{m''}\otimes V_\mu$. By equation (1.14b) the expression (1.30) and hence the left-hand side of (1.27) equals 1 if $\nu=\bar{\nu}$ and $(\nu)=(\bar{\nu})$, otherwise it equals 0. This completes the proof of (1.27).

With assumptions similar to that in (1.27) and with a similar proof we have

$$\sum_{(m'')\otimes(m)\otimes(m')} \langle(\nu), T_\nu\otimes(T_{\mu'}\otimes 1)((m'')\otimes(m)\otimes(m'))\rangle \tag{1.31}$$
$$\cdot\langle(\nu), T_{\bar{\nu}}\otimes(T_{\bar{\mu}'}\otimes 1)((m'')\otimes(m)\otimes(m'))\rangle$$
$$=\begin{cases}1 & \text{if } \mu'=\bar{\mu}', \quad \nu=\bar{\nu} \quad \text{and } (\nu)=(\bar{\nu}),\\ 0 & \text{otherwise,}\end{cases}$$

where the sum is over all states in $V_{m''}\otimes V_m\otimes V_{m'}$.

Applying (1.22), we obtain the following:

$$\sum_{(m'')\otimes(m)\otimes(m')} \langle(\nu), T_\nu(1\otimes T_\mu)((m'')\otimes(m)\otimes(m'))\rangle \tag{1.32}$$
$$\cdot\langle(\nu), T_\nu(1\otimes T_{\bar{\mu}})((m'')\otimes(m)\otimes(m'))\rangle$$
$$=\sum_{\mu',\bar{\mu}'}\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu\end{bmatrix}\begin{bmatrix} m'' & m & \bar{\mu}' \\ m' & \nu & \bar{\mu}\end{bmatrix}$$
$$\cdot\left\{\sum_{(m'')\otimes(m)\otimes(m')} \langle(\nu), T_\nu\otimes(T_{\mu'}\otimes 1)((m'')\otimes(m)\otimes(m'))\rangle\right.$$
$$\left.\cdot\langle(\nu), T_\nu\otimes(T_{\bar{\mu}'}\otimes 1)((m'')\otimes(m)\otimes(m'))\rangle\right\}$$

where the sum on the left-hand side and the corresponding sum on the right-hand side is over all states of $V_{m''}\otimes V_m\otimes V_{m'}$ and the outer sum on the right-hand side is over all highest weights μ', $\bar{\mu}'$ of irreducible representations occurring in $V_{m''}\otimes V_m$ such that V_ν occurs in $V_{\mu'}\otimes V_{m'}$ and $V_{\bar{\mu}'}\otimes V_{m'}$. From (1.31) the inner sum on the right-hand side of (1.32) equals 1 if $\mu'=\bar{\mu}'$ and 0 otherwise. Thus the right-hand side of (1.32) reduces to the following expression:

$$\sum_{\mu'}\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu\end{bmatrix}\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \bar{\mu}\end{bmatrix}. \tag{1.33}$$

By identity (1.27) the left-hand side of (1.32) equals 1 if $\mu=\bar{\mu}$ and 0 otherwise. This completes the proof of equation (1.26a).

Fix highest weights m, m' and m'' satisfying the assumptions of (1.15a and b) and ν such that V_ν occurs in $V_{m''}\otimes V_m \otimes V_{m'}$. Observe that the number of highest weights μ and the number of μ' for which $\left[\begin{smallmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{smallmatrix}\right]$ is defined are both equal to $\dim_{\mathbb{C}} (\operatorname{Hom}(V_{m''}\otimes V_m \otimes V_{m'}, V_\nu))$. Thus equation (1.26a) implies that the Racah coefficients $\left[\begin{smallmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{smallmatrix}\right]$ are the entries of a real orthogonal matrix with rows indexed by the highest weights μ' and columns indexed by the μ. Equation (1.26b) is a consequence of the orthogonality of this matrix. This completes the proof of Proposition 1.25.

COROLLARY 1.34. *With assumptions as in Proposition* 1.25 *we have*

$$\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} = \begin{bmatrix} m' & m & \mu \\ m'' & \nu & \mu' \end{bmatrix}. \tag{1.35}$$

Proof. Let $i: V_{m''}\otimes V_m \otimes V_{m'} \to V_{m'}\otimes V_m \otimes V_{m''}$ be the isomorphism mapping the state $(m'')\otimes(m)\otimes(m')$ of $V_{m''}\otimes V_m \otimes V_{m'}$ to the state $(m')\otimes(m)\otimes(m'')$ of $V_{m'}\otimes V_m \otimes V_{m''}$. By Remark 1.9 we see that $T_\nu(1\otimes T_\mu) = T_\nu(T_\mu \otimes 1)i$ and $T_\nu(T_{\mu'}\otimes 1) = T_\nu(1\otimes T_{\mu'})i$. It follows that

$$T_\nu(T_\mu \otimes 1) = \sum_{\mu'} \begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} T_\nu(1\otimes T_{\mu'}), \tag{1.36}$$

where the sum is over all highest weights μ' such that $V_{\mu'}$ occurs in $V_m \otimes V_{m''}$ and V_ν occurs in $V_{m'}\otimes V_{\mu'}$. If we now interchange the labels m'' and m' and interchange μ and μ', we obtain

$$T_\nu(T_{\mu'} \otimes 1) = \sum_{\mu} \begin{bmatrix} m' & m & \mu \\ m'' & \nu & \mu' \end{bmatrix} T_\nu(1\otimes T_{\mu}) \tag{1.37}$$

where the sum is over all highest weights μ such that V_μ occurs in $V_m\otimes V_{m'}$ and V_ν occurs in $V_{m''}\otimes V_\mu$.

Multiplying both sides of (1.22) by $\left[\begin{smallmatrix} m'' & m & \bar{\mu}' \\ m' & \nu & \mu \end{smallmatrix}\right]$ and summing over μ, we obtain

$$\begin{aligned} \sum_\mu \begin{bmatrix} m'' & m & \bar{\mu}' \\ m' & \nu & \mu \end{bmatrix} T_\nu(1\otimes T_\mu) &= \sum_{\mu,\mu'} \begin{bmatrix} m'' & m & \bar{\mu}' \\ m' & \nu & \mu \end{bmatrix}\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} T_\nu(T_{\mu'}\otimes 1) \\ &= T_\nu(T_{\bar{\mu}'}\otimes 1) \end{aligned} \tag{1.38}$$

by (1.26a) with summations over μ and μ' as in (1.26a and b). Setting $\bar{\mu}' = \mu'$ and equating the coefficients of $T_\nu(1\otimes T_\mu)$ in identities (1.37) and (1.38), we obtain (1.35).

We now prove a generalization of the Biedenharn-Elliott identity for the multiplicity free Racah coefficients above. For $SU(2)$, the original statement and proofs are due to Biedenharn [5] and Elliott [13] independently. For a more complete exposition of the $SU(2)$ Biedenharn-Elliott identity see [12] and [7]. A generalization of this identity to arbitrary groups for general Racah coefficients was given by Derome and Sharp [10]. Louck and Biedenharn [19] give an alternative proof for the $U(n)$ generalization of this identity. All these proofs consider general (nonmultiplicity-free) Racah coefficients. The proof given below for multiplicity-free Racah coefficients is a simple generalization of the $SU(2)$ proof involving recoupling coefficients for four-fold tensor products (see [12]).

Let m_1 be the highest weight for an arbitrary irreducible representation of $U(n)$. Let m_2, m_3 and m_4 be $U(n)$ highest weights of the form $m_j = [p_j, 0, \cdots, 0]$ where p_j is a nonnegative integer for $j = 2, 3, 4$. Let V_m be an irreducible representation space occurring in $\bigotimes_{i=1}^4 V_{m_i}$. A basis for $\operatorname{Hom}_{U(n)}(\bigotimes_{i=1}^4 V_{m_i}, V_m)$ is given by the following intertwining maps:

$$T_m(T_{m_{123}}\otimes 1)(\cdot T_{m_{12}}\otimes 1\otimes 1):\bigotimes_{i=1}^{4} V_{m_i}\to V_m \tag{1.39}$$

where

$$T_{m_{12}}: V_{m_1}\otimes V_{m_2}\to V_{m_{12}},\quad T_{m_{123}}: V_{m_{12}}\otimes V_{m_3}\to V_{m_{123}},\quad T_m: V_{m_{123}}\otimes V_{m_4}\to V_m, \tag{1.40}$$

as m_{12}, m_{123} vary over all highest weights of irreducible representations occurring in $V_{m_1}\otimes V_{m_2}$, $V_{m_{12}}\otimes V_{m_3}$ respectively and such that V_m occurs in $V_{m_{123}}\otimes V_{m_4}$.

Let m_{23} be the highest weight $[p_2+p_3, 0, \cdots, 0]=m_2+m_3$ and m_{14} be the highest weight of some irreducible representation occurring in $V_{m_1}\otimes V_{m_4}$. If V_m occurs in $V_{m_{23}}\otimes V_{m_{14}}$, then consider the intertwining map:

$$T_m(T_{m_{23}}\otimes T_{m_{14}}):\bigotimes_{i=1}^{4} V_{m_i}\to V_m \tag{1.41}$$

where

$$T_{m_{23}}: V_{m_2}\otimes V_{m_3}\to V_{m_{23}},\quad T_{m_{14}}: V_{m_1}\otimes V_{m_4}\to V_{m_{14}},\quad T_m: V_{m_{23}}\otimes V_{m_{14}}\to V_m. \tag{1.42}$$

We now express the intertwining map (1.41) in terms of the basis (1.39):

$$T_m(T_{m_{23}}\otimes T_{m_{14}})=\sum_{m_{12},m_{123}} C_{m_{12},m_{123}}T_m(T_{m_{123}}\otimes 1)(T_{m_{12}}\otimes 1\otimes 1) \tag{1.43}$$

where $C_{m_{12},m_{123}}\in\mathbb{C}$ are constants. We will compute $C_{m_{12},m_{123}}$ in two different ways.

We have

$$\begin{aligned} T_m(T_{m_{23}}\otimes T_{m_{14}})&=T_m(1\otimes T_{m_{14}})(T_{n_{23}}\otimes 1\otimes 1)\\ &=\sum_{\bar m_{123}}\begin{bmatrix} m_{23} & m_1 & \bar m_{123}\\ m_4 & m & m_{14}\end{bmatrix}T_m(T_{\bar m_{123}}\otimes 1)(T_{m_{23}}\otimes 1\otimes 1),\end{aligned} \tag{1.44}$$

where the sum is over all highest weights $\bar m_{123}$ such that $V_{\bar m_{123}}$ occurs in $V_{m_1}\otimes V_{m_{23}}$ and V_m occurs in $V_{\bar m_{123}}\otimes V_{m_4}$. Also we have

$$T_m(T_{\bar m_{123}}\otimes 1)(T_{m_{23}}\otimes 1\otimes 1)=\sum_{\bar m_{12}}\begin{bmatrix} m_1 & m_2 & \bar m_{12}\\ m_2 & \bar m_{123} & m_{23}\end{bmatrix}T_m(T_{\bar m_{123}}\otimes 1)(T_{\bar m_{12}}\otimes 1\otimes 1), \tag{1.45}$$

where the sum is over all highest weights $\bar m_{12}$ such that $V_{\bar m_{12}}$ occurs in $V_{m_1}\otimes V_{m_2}$ and $V_{\bar m_{123}}$ occurs in $V_{\bar m_{12}}\otimes V_{m_3}$.

From (1.44) and (1.45) it follows that

$$C_{m_{12},m_{123}}=\begin{bmatrix} m_1 & m_2 & m_{12}\\ m_3 & m_{123} & m_{23}\end{bmatrix}\begin{bmatrix} m_{23} & m_1 & m_{123}\\ m_4 & m & m_{14}\end{bmatrix}. \tag{1.46}$$

On the other hand, we have

$$\begin{aligned} T_m(T_{m_{23}}\otimes T_{m_{14}})&=T_m(T_{m_{23}}\otimes 1)(1\otimes 1\otimes Tm_{14})\\ &=\sum_{m_{124}}\begin{bmatrix} m_{14} & m_2 & m_{124}\\ m_3 & m & m_{23}\end{bmatrix}T_m(1\otimes T_{m_{124}})(1\otimes 1\otimes T_{m_{14}})\end{aligned} \tag{1.47}$$

where the sum is over all highest weights m_{124} such that $V_{m_{124}}$ occurs in $V_{m_{14}}\otimes V_{m_2}$ and V_m occurs in $V_{m_{124}}\otimes V_{m_3}$. Similarly,

$$T_m(1\otimes T_{m_{124}})(1\otimes 1\otimes T_{m_{14}})=\sum_{\bar m_{12}}\begin{bmatrix} m_2 & m_1 & \bar m_{12}\\ m_4 & m_{124} & m_{14}\end{bmatrix}T_m(1\otimes T_{m_{124}})(1\otimes 1\otimes T_{\bar m_{12}}) \tag{1.48}$$

and

$$(1.49)\quad T_m(1\otimes T_{m_{124}})(1\otimes 1\otimes T_{\bar{m}_{12}}) = \sum_{\bar{m}_{123}} \begin{bmatrix} m_3 & \bar{m}_{12} & \bar{m}_{123} \\ m_4 & m & m_{124} \end{bmatrix} T_m(T_{\bar{m}_{123}}\otimes 1)(T_{\bar{m}_{12}}\otimes 1\otimes 1),$$

with the sums in (1.48) and (1.49) satisfying conditions similar to that in (1.45).

Equations (1.43) and (1.46)-(1.49) imply the following:

Proposition 1.50 (Generalization of Biedenharn-Elliott Identity). *Let m_1 be an arbitrary $U(n)$ highest weight and m_2, m_3, m_4 be of the form $[p_j, 0, \cdots, 0]$ with p_j a nonnegative integer for $j=2$, 3 4. Let the conditions in* (1.40)-(1.42) *be satisfied, then*

$$(1.51)\quad \begin{aligned} &\begin{bmatrix} m_1 & m_2 & m_{12} \\ m_3 & m_{123} & m_{23} \end{bmatrix}\begin{bmatrix} m_{23} & m_1 & m_{123} \\ m_4 & m & m_{14} \end{bmatrix} \\ &= \sum_{m_{124}} \begin{bmatrix} m_3 & m_{12} & m_{123} \\ m_4 & m & m_{124} \end{bmatrix}\begin{bmatrix} m_2 & m_1 & m_{12} \\ m_4 & m_{124} & m_{14} \end{bmatrix}\begin{bmatrix} m_{14} & m_2 & m_{124} \\ m_3 & m & m_{23} \end{bmatrix}, \end{aligned}$$

where the sum is over all highest weights m_{124} such that $V_{m_{124}}$ occurs in $V_{m_{14}}\otimes V_{m_2}$ and $V_{m_{12}}\otimes V_{m_4}$ and V_m occurs in $V_{m_{124}}\otimes V_{m_3}$.

2. A generalization of Whipple's transformation. In this section we will explicitly compute a special case of the generalized Biedenharn-Elliott identity (1.51). We will then obtain a transformation relating a homogeneous Holman hypergeometric series $W^{(n)}$, "well-poised in $SU(n)$," to a product of gamma functions times a nonhomogeneous Holman hypergeometric series $F^{(n-1)}$ in $U(n-1)$. For $n=2$ this result reduces to a terminating form of the classical Whipple's transformation between a balanced ${}_4F_3$ and a well-poised ${}_7F_6$ hypergeometric series [25, eq. (7.7)].

We begin by writing explicit expressions for the Racah coefficients in identity (1.51). These multiplicity-free Racah coefficients have been (essentially) computed by Ališaukas, Jucys and Jucys [1] (see also [2], [14]) and also by Wong [28], [29].

We start with the following definition.

Definition 2.1. If $\lambda=[\lambda_1, \cdots, \lambda_n]$ is a $U(n)$ highest weight with $\lambda_i \geqq 0$ for $i=1, \cdots, n$ then define

$$(2.2)\qquad \mathcal{M}(\lambda)=\frac{(\lambda_1+n-1)!(\lambda_2+n-2)!\cdots(\lambda_n)!}{\prod_{1\leqq i<j\leqq n}(\lambda_i-\lambda_j+j-i)}.$$

We now express the multiplicity-free Racah coefficient in Definition 1.21 as a product of $\mathcal{M}(\lambda)$ factors times a $U(n+1):U(n)$ reduced Wigner coefficient (see [6] and [9]). This result is given in Wong [29] and Holman [14] except for simple factors due to slightly different definitions. We note that there is a simple typographical error in formula (1.9) of Wong [28] which is corrected in formula (1.13) of [28] and also in formula (3.4) of [29] which is corrected in Holman [14]. In proving the (corrected) formula (1.9) of [28] one uses identity (2.25b) of [18].

Proposition 2.3. *Let $n \geqq 2$. Suppose that the $U(n)$ highest weights m, m', m'', ν, μ, μ' are partitions* (*i.e. all components are nonnegative integers*) *and satisfy the assumptions of Proposition* 1.25, *then*

$$(2.4)\quad \begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} = \left[\frac{\mathcal{M}(\nu)\mathcal{M}(m)}{\mathcal{M}(\mu')\mathcal{M}(\mu)}\right]^{1/2}\left\langle\begin{pmatrix} [\nu,0]_{n+1} \\ \mu \end{pmatrix}\middle|\begin{bmatrix} [m',0]_{n+1} \\ m' \end{bmatrix}\middle|\begin{pmatrix} [\mu',0]_{n+1} \\ m \end{pmatrix}\right\rangle$$

where

$$\left\langle\begin{pmatrix} [\nu,0]_{n+1} \\ \mu \end{pmatrix}\middle|\begin{bmatrix} [m',0]_{n+1} \\ m' \end{bmatrix}\middle|\begin{pmatrix} [\mu',0]_{n+1} \\ m \end{pmatrix}\right\rangle$$

is a $U(n+1):U(n)$ *reduced Wigner coefficient* [6], [9] *and if* $\lambda=[\lambda_1,\cdots,\lambda_n]$ *is a partition, then* $[\lambda,0]_{n+1}$ *is the partition* $[\lambda_1,\cdots,\lambda_n,0]$.

Similarly we obtain from [29, formula (3.3)] the following:

PROPOSITION 2.5. *Let* $n\geqq 2$. *Suppose that the* $U(n)$ *highest weights* m, m', m'', ν, μ, μ' *are partitions and satisfy the assumptions of Remark* 1.23; *then we have*

$$\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix}=\left[\frac{\mathcal{M}(\nu)\mathcal{M}(m)}{\mathcal{M}(\mu')\mathcal{M}(\mu)}\right]^{1/2}\left\langle\begin{pmatrix}[\nu,0]_{n+1}\\ m''\end{pmatrix}\middle|\begin{bmatrix}[m',0]_{n+1}\\ [0,\cdots,0]_n\end{bmatrix}\middle|\begin{pmatrix}[\mu,0]_{n+1}\\ m''\end{pmatrix}\right\rangle \tag{2.6}$$

with notation as in Proposition 2.3.

We now describe the formula for the $U(n+1):U(n)$ reduced Wigner coefficients appearing in (2.4) and (2.6). We first establish our notation.

DEFINITION 2.7. If $h=[h_1,\cdots,h_l]$ is a $U(l)$ highest weight and $q=[q_1,\cdots,q_m]$ is a $U(m)$ highest weight where l and m are positive integers, $l\geqq m$ and

$$h_1\geqq q_1\geqq\cdots\geqq h_m\geqq q_m\geqq h_{m+1}\geqq\cdots\geqq h_l, \tag{2.8}$$

then

$$S_{lm}(h;q)=\left[\frac{\prod_{k=1}^{m}\prod_{s=1}^{k}\Gamma(h_s-q_k+k-s+1)}{\prod_{k=1}^{l-1}\prod_{s=k+1}^{l}\Gamma(q_k-h_s+s-k)}\right]^{1/2}. \tag{2.9a}$$

We also denote the omission of all factors containing q_i for some i, $1\leqq i\leqq m$, in the following manner:

$$S_{l\underset{i}{m}}(h;q)=\left[\frac{\prod_{s=i+1}^{l}\Gamma(q_i-h_s+s-i)}{\prod_{s=1}^{i}\Gamma(h_s-q_i+i-s+1)}\right]^{1/2}S_{lm}(h;q); \tag{2.9b}$$

and similarly for some i, $1\leqq i\leqq l$,

$$S_{\underset{i}{l}m}(h;q)=\left[\frac{\prod_{k=1}^{i-1}\Gamma(q_k-h_i+i-k)}{\prod_{k=1}^{m}\Gamma(h_i-q_k+k-i+1)}\right]^{1/2}S_{lm}(h;q), \tag{2.9c}$$

$$S_{\underset{i}{l}\underset{i}{m}}(h;q)=\left[\frac{\prod_{k=1}^{i-1}\Gamma(q_k-h_i+i-k)}{\prod_{k=i+1}^{m}\Gamma(h_i-q_k+k-i+1)}\right]^{1/2}S_{l\underset{i}{m}}(h;q). \tag{2.9d}$$

In terms of these quantities we can express the reduced $U(n+1):U(n)$ Wigner coefficients in two different ways. Let h, h' be $U(n+1)$ highest weights such that

$$h_1\geqq h_1'\geqq h_2\geqq h_2'\geqq\cdots\geqq h_{n+1}\geqq h_{n+1}' \tag{2.10a}$$

and

$$\sum_{i=1}^{n+1}(h_i-h_i')=p \tag{2.10b}$$

for some nonnegative integer p. Similarly let q, q' be $U(n)$ highest weights such that

$$q_1\geqq q_1'\geqq\cdots\geqq q_n\geqq q_n' \tag{2.11a}$$

and

$$\sum_{i=1}^{n}(q_i-q_i')=p' \tag{2.11b}$$

for some nonnegative integer p', $p'\leqq p$. We also assume h and q satisfy the betweenness condition:

$$h_1\geqq q_1\geqq h_2\geqq q_2\geqq\cdots\geqq q_n\geqq h_{n+1} \tag{2.12}$$

and similarly for h' and q'. From the calculation of Chacón, Ciftan and Biedenharn [9] (see also [14]) we have

$$\tag{2.13}\begin{aligned}\left\langle\begin{pmatrix}h\\q\end{pmatrix}\middle|\begin{bmatrix}[p,0,\cdots,0]_{n+1}\\ [p',0,\cdots,0]_n\end{bmatrix}\middle|\begin{pmatrix}h'\\q'\end{pmatrix}\right\rangle &= \sqrt{(p-p')!}\,\frac{S_{n+1\,n+1}(h;h)S_{n+1\,n}(h';q')S_{nn}(q;q')}{S_{n+1\,n+1}(h;h')S_{n+1\,n}(h;q)}\\ &\cdot S_{nn}(q';q')\sum_{\rho_1,\cdots,\rho_n}(-1)^{\rho_1+\cdots+\rho_n}\\ &\cdot\left[\frac{S_{nn}(\bar q;\bar q)}{S_{n+1\,n}(h';\bar q)S_{nn}(q;\bar q)}\right]^2\cdot\left[\frac{S_{n+1\,n}(h;\bar q)}{S_{nn}(\bar q;q')}\right]^2\end{aligned}$$

where $\bar q_i = q'_i+\rho_i$, ρ_i is a nonnegative integer for $i=1,\cdots,n$ and $\bar q$ is restricted so that all factors on the right-hand side of (2.13) are defined and finite.

From the calculation of Ališaukas, Jucys and Jucys [1] we find

$$\tag{2.14}\begin{aligned}&\left\langle\begin{pmatrix}h\\q\end{pmatrix}\middle|\begin{matrix}[p,0,\cdots,0]_{n+1}\\ [p',0,\cdots,0]_n\end{matrix}\middle|\begin{pmatrix}h'\\q'\end{pmatrix}\right\rangle\\ &\quad=\frac{1}{\sqrt{(p-p')!}}\,\frac{S_{n+1\,n+1}(h;h)S_{nn}(q';q')S_{n+1\,n+1}(h;h')}{S_{nn}(q;q')S_{n+1n}(h';q')}\\ &\quad\cdot S_{n+1\,n}(h;q)\sum_{[r_2,\cdots,r_{n+1}]}(-1)^{\varphi}\\ &\quad\cdot[S_{\substack{n+1\\1}\,\substack{n+1\\1}}(r;r)]^2\left[\frac{S_{\substack{n+1\\1}\,n}(r;q')}{S_{n+1\,\substack{n+1\\1}}(h;r)S_{\substack{n+1\\1}\,n+1}(r;h')S_{\substack{n+1\\1}n}(r;q)}\right]^2\end{aligned}$$

where $\varphi=\sum_{i=2}^{n}(h_i-r_i)$ and the sum is over all $U(n)$ highest weights $r=[r_2,\cdots,r_{n+1}]$ such that right-hand side of (2.14) is defined and finite. Note there is an "understood" r_1 component of r which does not appear in the expression (2.14).

Recall the generalized Biedenharn-Elliott identity (1.51). With notation as in (1.51) and $n\geqq 2$ we now compute a special case of identity (1.51) by setting

$$\tag{2.15} m_{23}=m_2+m_3,\quad m_{123}=m_{12}+m_3,\quad m_{12}=m_1-m_2^*,$$

where if $\lambda=[\lambda_1,\cdots,\lambda_n]$ is a highest weight of a $U(n)$ representation, then

$$\tag{2.16}\lambda^*=\bar\lambda=[-\lambda_n,\cdots,-\lambda_1]$$

is the highest weight of the contragredient $U(n)$ representation. For simplicity we shall further assume that m_1 is a partition, i.e. all the components are nonnegative integers.

Applying Propositions 2.3, 2.5 and Corollary 1.34, we have

$$\tag{2.17a}\begin{aligned}\begin{bmatrix}m_1 & m_2 & m_{12}\\ m_3 & m_{123} & m_{23}\end{bmatrix}&=\left[\frac{\mathcal{M}(m_{123})\mathcal{M}(m_2)}{\mathcal{M}(m_{23})\mathcal{M}(m_{12})}\right]^{1/2}\\ &\cdot\left\langle\begin{pmatrix}[m_{123},0]_{n+1}\\ m_1\end{pmatrix}\middle|\begin{bmatrix}[m_3,0]_{n+1}\\ [0,\cdots,0]_n\end{bmatrix}\middle|\begin{pmatrix}[m_{12},0]_{n+1}\\ m_1\end{pmatrix}\right\rangle,\end{aligned}$$

$$\tag{2.17b}\begin{aligned}\begin{bmatrix}m_{23} & m_1 & m_{123}\\ m_4 & m & m_{14}\end{bmatrix}&=\left[\frac{\mathcal{M}(m)\mathcal{M}(m_1)}{\mathcal{M}(m_{123})\mathcal{M}(m_{14})}\right]^{1/2}\\ &\cdot\left\langle\begin{pmatrix}[m,0]\\ m_{14}\end{pmatrix}\middle|\begin{bmatrix}[m_4,0]\\ m_4\end{bmatrix}\middle|\begin{pmatrix}[m_{123},0]\\ m_1\end{pmatrix}\right\rangle,\end{aligned}$$

$$\begin{bmatrix} m_3 & m_{12} & m_{123} \\ m_4 & m & m_{124} \end{bmatrix} = \left[\frac{\mathcal{M}(m_{12})\mathcal{M}(m)}{\mathcal{M}(m_{123})\mathcal{M}(m_{124})}\right]^{1/2} \cdot \left\langle \begin{pmatrix} [m,0] \\ m_4 \end{pmatrix} \middle| \begin{bmatrix} [m_3,0] \\ [0,\cdots,0]_n \end{bmatrix} \middle| \begin{pmatrix} [m_{124},0] \\ m_4 \end{pmatrix} \right\rangle, \tag{2.17c}$$

$$\begin{bmatrix} m_2 & m_1 & m_{12} \\ m_4 & m_{124} & m_{14} \end{bmatrix} = \left[\frac{\mathcal{M}(m_{124})\mathcal{M}(m_1)}{\mathcal{M}(m_{12})\mathcal{M}(m_{14})}\right]^{1/2} \cdot \left\langle \begin{pmatrix} [m_{124},0] \\ m_{12} \end{pmatrix} \middle| \begin{bmatrix} [m_2,0] \\ m_2 \end{bmatrix} \middle| \begin{pmatrix} [m_{14},0] \\ m_1 \end{pmatrix} \right\rangle, \tag{2.17d}$$

and

$$\begin{bmatrix} m_{14} & m_2 & m_{124} \\ m_3 & m & m_{23} \end{bmatrix} = \left[\frac{\mathcal{M}(m)\mathcal{M}(m_2)}{\mathcal{M}(m_{124})\mathcal{M}(m_{23})}\right]^{1/2} \cdot \left\langle \begin{pmatrix} [m,0] \\ m_{14} \end{pmatrix} \middle| \begin{bmatrix} [m_3,0] \\ [0,\cdots,0]_n \end{bmatrix} \middle| \begin{pmatrix} [m_{124},0] \\ m_{14} \end{pmatrix} \right\rangle, \tag{2.17e}$$

where $[m,0]=[m,0]_{n+1}$, etc. in the notation of Proposition 2.3.

For a $U(n)$ highest weight $\lambda=[\lambda_1,\cdots,\lambda_n]$ (similarly for a $U(n+1)$ highest weight) define

$$d(\lambda) = \text{dimension of } V_\lambda = \frac{\prod_{1\leqq i<j\leqq n}(p_{in}-p_{jn})}{\prod_{i=1}^{n-1} i!} \tag{2.18}$$

where $p_{in}=\lambda_i+n-i$ for $1\leqq i\leqq n$. Now recalling the definition (2.16) of the contragredient highest weight $\bar{\lambda}=\lambda^*$ and applying identity (A.17) from Appendix A, we have in place of (2.17d)

$$\begin{bmatrix} m_2 & m_1 & m_{12} \\ m_4 & m_{124} & m_{14} \end{bmatrix} = (-1)^{p_2}\left[\frac{\mathcal{M}(m_{124})\mathcal{M}(m_1)}{\mathcal{M}(m_{12})\mathcal{M}(m_{14})}\right]^{1/2} \cdot \left(\frac{d([m_{124},0]_{n+1})d(m_1)}{d(m_{12})d([m_{14},0]_{n+1})}\right)^{1/2} \cdot \left\langle \begin{pmatrix} \overline{[m_{14},0]_{n+1}} \\ \bar{m}_1 \end{pmatrix} \middle| \begin{bmatrix} [m_2,0] \\ m_2 \end{bmatrix} \middle| \begin{pmatrix} \overline{[m_{124},0]_{n+1}} \\ \overline{m_{12}} \end{pmatrix} \right\rangle \tag{2.19}$$

where $m_2=[p_2,0,\cdots,0]_n$ as in Proposition 1.50.

To compute the reduced Wigner coefficients appearing in (2.17a), (2.17c) and (2.17e), we use the Chacón, Ciftan and Biedenharn computation (2.13) and to compute the reduced Wigner coefficient in (2.17b) we use the Ališaukas, Jucys and Jucys computation (2.14). Finally to compute the reduced Wigner coefficient in (2.19), we use (2.13) and a summation theorem of Ališaukas, Jucys and Jucys given in identity (14) of [1] and described in [14, eq. (30)].

To describe the final result of this explicit calculation of the generalized Biedenharn-Elliott identity, we need to introduce Holman's "hypergeometric series in $U(n)$" [14], [15].

Definition 2.20. Let $n\geqq 2$. We define

$$W_q^{(n)}\left(\begin{array}{cccc|ccc|ccc|c} A_{12} & & & & a_{11} & \ldots & a_{1k} & b_{11} & \ldots & b_{1j} & z_1 \\ A_{13} & A_{23} & & & \vdots & & \vdots & \vdots & & \vdots & \vdots \\ \vdots & \vdots & \ddots & & & & & & & & \\ A_{1n} & A_{2n} & \cdots & A_{n-1,\,n} & a_{n1} & \cdots & a_{nk} & b_{n1} & \cdots & b_{nj} & z_n \end{array}\right)$$

$$\text{(2.21)}\quad \equiv q! \sum_{y_1+\cdots+y_n=q} \left(\prod_{i=1}^{n-1}\prod_{j=i+1}^{n} \frac{(A_{ij}+y_i-y_j)}{A_{ij}}\right)\left(\prod_{i=1}^{k}\prod_{l=1}^{n}(a_{li})_{y_l}\right)$$
$$\cdot\left(\prod_{i=1}^{j}\prod_{l=1}^{n}(b_{li})_{y_l}\right)^{-1}\left(\prod_{i=1}^{n} z_i^{y_i}\right),$$

where q is a nonnegative integer and the sum is over all n-tuples $(y_1,\cdots,y_n)$ of nonnegative integers such that $y_1+\cdots+y_n=q$. The symbol $(a)_m$ denotes the rising factorial $(a)(a+1)\cdots(a+m-1)$ for $m\geqq 1$ and $a_0=1$.

The series (2.21) is called *well-poised in* $SU(n)$, $n\geqq 2$, if $j\geqq n$,

$$\text{(2.22)}\quad \begin{array}{ll} A_{ir}-A_{is}=A_{sr}, & \text{for } s<r, \\ a_{ir}-a_{sr}=A_{is}, & \text{for } i<s, \\ b_{ir}-b_{sr}=A_{is}, & \text{for } i<s, \\ b_{ii}=1, & 1\leqq i\leqq n. \end{array}$$

If we denote the series (2.21), *whether or not well-poised*, by $W_q^{(n)}((A)|(a)|(b)|(z))$, then for $n\geqq 2$ define

$$\text{(2.23a)}\quad F^{(n)}((A)|(a)|(b)|(z))=\sum_{q=0}^{\infty}\frac{1}{q!}W_q^{(n)}((A)|(a)|(b)|(z)).$$

For $n=1$ define

$$\text{(2.23b)}\quad F^{(1)}((A)|(a)|(b)|(z))=\sum_{q=0}^{\infty}\frac{(a_{11})_q\cdots(a_{1k})_q}{(b_{11})_q\cdots(b_{1j})_q}z_1^q,$$

which is a classical ${}_kF_{j-1}$ hypergeometric series.

We now state a generalization of Whipple's transformation (see [25] and [4, eq. (4.3.4)]).

THEOREM 2.24. *Let q be a nonnegative integer and let $z_1,\cdots,z_n$, $w_1,\cdots,w_n$, a, $b\in\mathbb{C}$ such that w_i-z_i is a nonnegative integer for $i=1,2,\cdots,n-1$. We also set $s=\sum_{k=1}^{n}(w_k-z_k)$. For $n\geqq 2$ we have*

$$W_q^{(n)}\left(\begin{array}{llll} z_1-z_2+1 & & & \\ z_1-z_3+2 & z_2-z_3+1 & & \\ \vdots & \vdots & & \\ z_1-z_n+n-1 & z_2-z_n+n-2 & \cdots & z_{n-1}-z_n+1 \end{array}\right.$$

$$\left|\begin{array}{ccccc} z_1-w_1 & z_1-w_2+1 & \cdots & z_1-w_n+n-1 & z_1+s-q-a \\ z_2-w_1-1 & z_2-w_2 & \cdots & z_2-w_n+n-2 & z_2+s-q-a-1 \\ \vdots & \vdots & & \vdots & \vdots \\ z_n-w_1-n+1 & z_n-w_2-n+2 & \cdots & z_n-w_n & z_n+s-q-a-n+1 \end{array}\right.$$

$$\left|\begin{array}{ccccc} 1 & z_1-z_2+2 & \cdots & z_1-z_n+n & z_1-b \\ z_2-z_1 & 1 & \cdots & z_2-z_n+n-1 & z_2-b-1 \\ \vdots & \vdots & & \vdots & \vdots \\ z_n-z_1-n+2 & z_n-z_2-n+3 & \cdots & 1 & z_n-b-n+1 \end{array}\right|\left.\begin{array}{c} -1 \\ -1 \\ \vdots \\ -1 \end{array}\right)$$

$$\text{(2.25)}\quad =\frac{\Gamma(w_n-z_n+1)}{\Gamma(1+s-q)}\prod_{l=1}^{n-1}\left[\frac{\Gamma(w_l-z_n+n-l+1)\Gamma(a-z_l+l)}{\Gamma(z_l-z_n+n-l+1)\Gamma(a-w_l+l)}\right]$$

$$\cdot\frac{\Gamma(a-s+q-z_n+n)\Gamma(b-z_n+n-q)}{\Gamma(a-w_n+n)\Gamma(b-z_n+n)}$$

$$\cdot F^{(n-1)}\left(\begin{array}{llll} z_1-z_2+1 & & & \\ z_1-z_3+2 & z_2-z_3+1 & & \\ \vdots & \vdots & & \\ z_1-z_{n-1}+n-2 & z_2-z_{n-1}+n-3 & \cdots & z_{n-2}-z_{n-1}+1 \end{array}\right.$$

$$\left|\begin{array}{lll} z_1-w_1 & z_1-w_2+1 & \cdots \\ z_2-w_1-1 & z_2-w_2 & \cdots \\ \vdots & \vdots & \\ z_{n-1}-w_1-n+2 & z_{n-1}-w_2-n+3 & \cdots \end{array}\right.$$

$$\begin{array}{lll} z_1-w_n+n-1 & z_1+s-q-a & z_1+q-b \\ z_2-w_n+n-2 & z_2+s-q-a-1 & z_2+q-b-1 \\ \vdots & \vdots & \vdots \\ z_{n-1}-w_n+1 & z_{n-1}+s-q-a-n+2 & z_{n-1}+q-b-n+2 \end{array}$$

$$\left|\begin{array}{lll} 1 & z_1-z_2+2 & z_1-z_n+n \\ z_2-z_1 & 1 & z_2-z_n+n-1 \\ \vdots & \vdots & \vdots \\ z_{n-1}-z_1-n+3 & z_{n-1}-z_2-n+4 & z_{n-1}-z_n+2 \end{array}\right.$$

$$\left.\begin{array}{ll|l} z_1-a & z_1-b & 1 \\ z_2-a-1 & z_2-b-1 & 1 \\ \vdots & \vdots & \vdots \\ z_{n-1}-a-n+2 & z_{n-1}-b-n+2 & 1 \end{array}\right).$$

Proof. If λ is a $U(n)$ highest weight, let $(\lambda)_k$ denote the kth component of λ, i.e. $\lambda=[(\lambda)_1,\cdots,(\lambda)_k,\cdots,(\lambda)_n]$. Together with the notation and assumptions of Proposition 1.50 and equations (2.15), we will also assume that

$$\begin{aligned}(m_1)_1>(m_1)_2+(p_2+p_3+p_4)>(m_1)_3\\ +2(p_2+p_3+p_4)>\cdots>(m_1)_n+(n-1)(p_2+p_3+p_4).\end{aligned}\tag{2.26}$$

After a lengthy explicit calculation of identity (1.51) using formulas (2.17a–e) and (2.19) as described above, we find

$$\begin{aligned}\sum_{y_1+y_2+\cdots+y_n=p_3}\Bigg\{\prod_{1\leqq r<s\leqq n}\left(\frac{A_{rs}+y_r-y_s}{A_{rs}}\right)\prod_{l=1}^{n}\Bigg[\frac{(p_2+(m_1)_n-(m)_l+l-n)_{y_l}}{((m_1)_1-(m)_l+l-1)_{y_l}}\\ \cdot\prod_{k=1}^{n}\frac{((m_{14})_k-(m)_l+l-k)_{y_l}}{((m)_k-(m)_l+l-k+1)_{y_l}}\Bigg]\Bigg\}\\ =\frac{(-1)^{p_3}}{(p_3)!}\prod_{l=2}^{n}\left[\frac{\Gamma((m)_1-(m_{14})_l+l)}{\Gamma((m)_1-(m)_l+l)}\frac{\Gamma((m)_l-(m_1)_n+n-l+1)}{\Gamma((m_{14})_l-(m_1)_n+n-l+1)}\right]\\ \cdot\frac{\Gamma((m)_1-(m_{14})_1+1)}{(p_2)!}\frac{\Gamma((m)_1-(m_1)_n-p_2+n)}{\Gamma((m_{14})_1-(m_1)_n+n)}\frac{\Gamma((m)_1-(m_1)_1-p_3+1)}{\Gamma((m)_1-(m_1)_1+1)}\\ \cdot\sum_{\substack{y_l\geqq 0\\ 2\leqq l\leqq n}}\prod_{2\leqq r<s\leqq n}\left(\frac{A_{rs}+y_r-y_s}{A_{rs}}\right)\end{aligned}\tag{2.27}$$

$$\cdot \prod_{l=2}^{n} \left[\frac{(p_3+(m_1)_1-(m)_l+l-1)_{y_l}}{((m_1)_1-(m)_l+l-1)_{y_l}} \right.$$

$$\left. \cdot \frac{(p_2+(m_1)_n-(m)_l+l-n)_{y_l}}{((m_1)_n-(m)_l+l-n)_{y_l}} \prod_{k=1}^{n} \frac{((m_{14})_k-(m)_l+l-k)_{y_l}}{((m)_k-(m)_l+l+k+1)_{y_l}} \right]$$

where on both sides $A_{rs}=(m)_s-(m)_r+r-s$ and the y_i are nonnegative integers ($1 \leqq i \leqq n$ on the left-hand side, $2 \leqq i \leqq n$ on the right-hand side). On the left-hand side $y_i=(m)_i-(m_{124})_i$, $1 \leqq i \leqq n$, and on the right-hand side $y_i=(m)_i-r_i$, $2 \leqq i \leqq n$, where the r_i are indices of summation in the Ališaukas, Jucys and Jucys form (2.14) for the reduced Wigner coefficient in (2.17b).

Two remarks should be made. The first is that condition (2.26) implies that the only restriction on the left-hand sum in (2.27) is that $\sum_{i=1}^{n} y_i = p_3$. Also the sum on the right-hand side of (2.27) terminates at $y_i=(m)_i-(m_{14})_i$ for $2 \leqq i \leqq n$ (or possibly smaller values of y_2 and y_n).

Now fix $(m)_i-(m_{14})_i$ for $2 \leqq i \leqq n$ and fix p_3 but let m_1, m_{14}, $(m)_1$, p_2 and p_4 vary subject to the condition (2.26) and also that

$$(2.28) \qquad \sum_{i=1}^{n} [(m_{14})_i-(m_1)_i]=p_4, \qquad \sum_{i=1}^{n} [(m)_i-(m_{14})_i]=p_2+p_3.$$

The identity (2.27) is valid for all nonnegative integers $(m)_1$, $(m_1)_i$, $(m_{14})_i$ for $1 \leqq i \leqq n$ satisfying some condition:

$$(2.29) \quad (m)_1>(m_{14})_1+C_1>(m_1)_1+C_2>(m_{14})_2+C_3>(m_1)_2+C_4>\cdots>(m_1)_n+C_{2n}$$

for some constants $C_1, \cdots, C_{2n}>0$. For simplicity we shall also assume $(m)_1-(m_{14})_1>p_2$.

Note that the factors in front of the summation sign on the right-hand side of (2.27) may be written as

$$(2.30) \qquad \frac{(-1)^{p_3}}{(p_3)!} \prod_{l=2}^{n} \left[\frac{((m)_1-(m)_l+l)_{((m)_l-(m_{14})_l)}}{((m_{14})_l-(m_1)_n+n-l+1)_{((m)_l-(m_{14})_l)}} \right] \cdot \frac{(p_2+1)_{((m)_1-(m_{14})_1-p_2)} \cdot ((m_{14})_1-(m_1)_n+n)_{((m)_1-(m_{14})_1-p_2)}}{((m)_1-(m_1)_1-p_3+1)_{p_3}}.$$

We would have a similar formula if we assume $(m)_1-(m_{14}) \leqq p_2$. Also note that $(m)_1-(m_{14})_1-p_2=p_3-\sum_{i=2}^{n}((m)_i-(m_{14})_i)$ by condition (2.28), so all the subscripts of the rising factorials in (2.30) are constants.

By substituting (2.30) and clearing denominators, the identity (2.27) becomes a polynomial identity of fixed degree in the variables $(m)_1$, $(m_1)_i$, $(m_{14})_i$ for $1 \leqq i \leqq n$. It follows from (2.29) that (2.27) is true for all values of $(m)_1, (m_1)_i, (m_{14})_i \in \mathbb{C}$, $1 \leqq i \leqq n$, such that both sides of (2.27) are defined.

Now substitute $q=p_3$, $a=-(m_1)_n$, $b=-(m_1)_1-(n-1)$, $z_l=-(m)_{n-l+1}$ and $w_l=-(m_{14})_{n-l+1}$ for $1 \leqq l \leqq n$. We then obtain identity (2.25). Q.E.D.

Remark 2.31. For $n=2$ one uses formula (2.5) of [15] to translate Theorem 2.24 above into the classical terminating form of Whipple's transformation [4, eq. (4.3.4)] between a well-poised ${}_7F_6$ and a balanced ${}_4F_3$ hypergeometric series. In this form the parameter q is no longer restricted to be a nonnegative integer, but may take on arbitrary complex values (subject to the usual condition that denominators do not vanish).

Remark 2.32. On the left-hand side of identity (2.25) the $W^{(n)}$ series satisfies Holman's "well-poised in $SU(n)$" conditions (2.22) (also [15, eqs. (3.2)]. On the right-hand side the $F^{(n-1)}$ series satisfies a generalization of the "balanced" or "Saalschützian" condition. With notation as in (2.21) and (2.23a and b) this balanced condition is

$$\sum_{l=1}^{n-1} a_{il}+n=\sum_{l=1}^{n-1} b_{il}, \tag{2.33}$$

for each i, $1 \leqq i \leqq n-1$. Note that the $F^{(n)}$ series in Holman's generalization of the Saalschütz summation theorem [14, Thm. 3] is "balanced" in this sense just as in the classical case.

3. Corollaries of Theorem 2.24. In this section we will discuss a generalization of Dougall's theorem [11], an analogue of Dougall's theorem, limiting cases of Theorem 2.24 and new summation theorems for classical hypergeometric series and basic hypergeometric series.

If we set $q=b-a$ in identity (2.25), then the right-hand side of (2.25) can be summed by means of Holman's generalization of the Saalschütz summation theorem [14]. By continuation we may drop the assumption that w_i-z_i are integers, $1 \leqq i \leqq n-1$. We obtain a generalization of Dougall's theorem [14, eq. (4.3.5)].

COROLLARY 3.1. *With notation as in Theorem* 2.24 *let q be a nonnegative integer and set $s=\sum_{k=1}^{n}(w_k-z_k)$. For $n \geqq 2$ we have*

$$W_q^{(n)}\left(\begin{array}{c}
\begin{array}{llll}
z_1-z_2+1 & & & \\
z_1-z_3+2 & z_2-z_3+1 & & \\
\vdots & \vdots & & \\
z_1-z_n+n-1 & z_2-z_n+n-2 & \cdots & z_{n-1}-z_n+1
\end{array}\\
\left|\begin{array}{ccccc}
z_1-w_1 & z_1-w_2+1 & \cdots & z_1-w_n+n-1 & z_1+s-b\\
z_2-w_1-1 & z_2-w_2 & \cdots & z_2-w_n+n-2 & z_2+s-b-1\\
\vdots & \vdots & & \vdots & \vdots\\
z_n-w_1-n+1 & z_n-w_2-n+2 & \cdots & z_n-w_n & z_n+s-b-n+1
\end{array}\right.\\
\left|\begin{array}{ccccc|c}
1 & z_1-z_2+2 & \cdots & z_1-z_n+n & z_1-b & -1\\
z_2-z_1 & 1 & \cdots & z_2-z_n+n-1 & z_2-b-1 & -1\\
\vdots & \vdots & & \vdots & \vdots & \vdots\\
z_n-z_1-n+2 & z_n-z_2-n+3 & \cdots & 1 & z_n-b-n+1 & -1
\end{array}\right.
\end{array}\right) \tag{3.2}$$

$$=\frac{\Gamma(1+s)\Gamma(b-z_n+n-q)\Gamma(z_n-n+1-b+s)\Gamma(b-z_n+n-s)}{\Gamma(1+s-q)\Gamma(b-z_n+n)\Gamma(w_n-n+1-b)\Gamma(b-w_n+n-q)}$$
$$\cdot\prod_{l=1}^{n-1}\left[\frac{\Gamma(w_l+q-b-l+1)\Gamma(b-w_l+l)}{\Gamma(z_l+q-b-l+1)\Gamma(b-z_l+l)}\right].$$

Proof. We have used

$$\begin{aligned}
&\prod_{l=1}^{n-1}\left[\frac{\Gamma(w_l-z_n+n-l+1)\Gamma(z_n-w_l+l-n)\Gamma(b-z_l+l-q)}{\Gamma(z_l-z_n+n-l+1)\Gamma(z_n-z_l+l-n)\Gamma(b-w_l+l-q)}\right]\\
&\quad=\prod_{l=1}^{n-1}\left[\frac{\Gamma(w_l+q-b-l+1)}{\Gamma(z_l+q-b-l+1)}\right],
\end{aligned} \tag{3.3}$$

where we assume z_i-z_j is not an integer for $1 \leqq i \neq j \leqq n-1$.

An analogue of Dougall's theorem is obtained if we set $q=s=\sum_{k=1}^{n}(w_k-z_k)$.

Corollary 3.4. *With notation as in Theorem* 2.24 *let q and $w_i - z_i$ for $i = 1, \cdots, n-1$ be nonnegative integers and let $q = s = \sum_{K=1}^{n} (w_k - z_k)$. For $n \geqq 2$ we have*

$$\begin{array}{l}
W_q^{(n)}\left(\begin{array}{llll}
z_1-z_2+1 & & & \\
z_1-z_3+2 & z_2-z_3+1 & & \\
\vdots & \vdots & \ddots & \\
z_1-z_n+n-1 & z_2-z_n+n-2 & \cdots & z_{n-1}-z_n+1
\end{array}\right. \\
\qquad\left|\begin{array}{ccccc}
z_1-w_1 & z_1-w_2+1 & \cdots & z_1-w_n+n-1 & z_1-a \\
z_2-w_1-1 & z_2-w_2 & \cdots & z_2-w_n+n-2 & z_2-a-1 \\
\vdots & \vdots & & \vdots & \vdots \\
z_n-w_1-n+1 & z_n-w_2-n+2 & \cdots & z_n-w_n & z_n-a-n+1
\end{array}\right. \\
\qquad\left|\begin{array}{ccccc|c}
1 & z_1-z_2+2 & \cdots & z_1-z_n+n & z_1-b & -1 \\
z_2-z_1 & 1 & \cdots & z_2-z_n+n-1 & z_2-b-1 & -1 \\
\vdots & \vdots & & \vdots & \vdots & \vdots \\
z_n-z_1-n+2 & z_n-z_2-n+3 & \cdots & 1 & z_n-b-n+1 & -1
\end{array}\right) \\
\quad = q! \prod_{l=1}^{n} \left[\dfrac{\Gamma(a-z_l+l)\Gamma(b-w_l+l)}{\Gamma(a-w_l+l)\Gamma(b-z_l+l)}\right].
\end{array} \tag{3.5}$$

Proof. With $q = s$ we can apply Holman's Saalschütz theorem to the right-hand side of (2.25). We then obtain (3.5) after using the following identity:

$$\begin{aligned}
&\frac{\Gamma(z_n-n+1+q-b)}{\Gamma(w_n-n+1-b)} \prod_{l=1}^{n-1} \left[\frac{\Gamma(w_l-z_n+n-l+1)\Gamma(z_n-w_l+l-n)}{\Gamma(z_l-z_n+n-l+1)\Gamma(z_n-z_l+l-n)}\right] \\
&\quad = \frac{\Gamma(b-w_n+n)}{\Gamma(b-z_n+n-q)},
\end{aligned} \tag{3.6}$$

where we assume $z_i - z_j$ is not an integer for $1 \leqq i \neq j \leqq n-1$.

Remark 3.7. For $n = 2$, Corollary 3.1 reduces to the classical Dougall's theorem when the $W_q^{(2)}$ series is replaced by the corresponding well-poised ${}_7F_6$ hypergeometric series by means of formula (2.5) of [15]. In this classical form q is no longer restricted to be a nonnegative integer, but may take on arbitrary complex values (if $z_1 - w_1$ is a negative integer).

In Corollary 3.4 for $n = 2$, the well-poised ${}_7F_6$ series corresponding to the $W_q^{(2)}$ series is in general not defined because the integer $z_1 - w_1 + 1 \leqq 1$ is a denominator parameter in the ${}_7F_6$ series. Hence Corollary 3.4 is not a generalization of a classical result, but rather an analogue of Dougall's theorem.

Limiting cases of identity (2.25) also yield transformation formulas for hypergeometric series in $U(n)$. For example, taking the limit $w_n \to \infty$ in (2.25) gives a form of Holman's generalization of the terminating ${}_5F_4(1)$ summation theorem ([14, Thm. 4] and see also [20]). By taking the limits $a \to \infty$ or $b \to \infty$ we obtain generalizations of the terminating form of Whipple's ${}_6F_5(-1)$ transformation theorem ([4, eq. (4.4.2)] and [25]).

Taking the limit $a \to \infty$ in (2.25), we find

Corollary 3.8. *With notation and assumptions as in Theorem* 2.24, *we have*

$$W_q^{(n)}\left(\begin{array}{llll}
z_1-z_2+1 & & & \\
z_1-z_3+2 & z_2-z_3+1 & & \\
\vdots & \vdots & \ddots & \\
z_1-z_n+n-1 & z_2-z_n+n-2 & \cdots & z_{n-1}-z_n+1
\end{array}\right.$$

$$\left|\begin{array}{cccc} z_1-w_1 & z_1-w_2+1 & \cdots & z_1-w_n+n-1 \\ z_2-w_1-1 & z_2-w_2 & \cdots & z_2-w_n+n-2 \\ \vdots & \vdots & & \vdots \\ z_n-w_1-n+1 & z_n-w_2-n+2 & \cdots & z_n-w_n \end{array}\right.$$

$$\left|\begin{array}{ccccc|c} 1 & z_1-z_2+2 & \cdots & z_1-z_n+n & z_1-b & 1 \\ z_2-z_1 & 1 & \cdots & z_2-z_n+n-1 & z_2-b-1 & 1 \\ \vdots & \vdots & & \vdots & \vdots & \vdots \\ z_n-z_1-n+2 & z_n-z_2-n+3 & \cdots & 1 & z_n-b-n+1 & 1 \end{array}\right)$$

$$(3.9)\qquad =\frac{\Gamma(w_n-z_n+1)}{\Gamma(1+s-q)}\,\frac{\Gamma(b-z_n+n-q)}{\Gamma(b-z_n+n)}\prod_{l=1}^{n-1}\left[\frac{\Gamma(w_l-z_n+n-l+1)}{\Gamma(z_l-z_n+n-l+1)}\right]$$

$$\cdot F^{(n-1)}\left(\begin{array}{cccc} z_1-z_2+1 & & & \\ z_1-z_3+2 & z_2-z_3+1 & & \\ \vdots & \vdots & & \\ z_1-z_{n-1}+n-2 & z_2-z_{n-1}+n-3 & \cdots & z_{n-2}-z_{n-1}+1 \end{array}\right.$$

$$\left|\begin{array}{ccccc} z_1-w_1 & z_1-w_2+1 & \cdots & z_1-w_n+n-1 & z_1+q-b \\ z_2-w_1-1 & z_2-w_2 & \cdots & z_2-w_n+n-2 & z_2+q-b-1 \\ \vdots & \vdots & & \vdots & \vdots \\ z_{n-1}-w_1-n+2 & z_{n-1}-w_2-n+3 & \cdots & z_{n-1}-w_n+1 & z_{n-1}+q-b-n+2 \end{array}\right.$$

$$\left|\begin{array}{ccccc|c} 1 & z_1-z_2+2 & \cdots & z_1-z_n+n & z_1-b & 1 \\ z_2-z_1 & 1 & \cdots & z_2-z_n+n-1 & z_2-b-1 & 1 \\ \vdots & \vdots & & \vdots & \vdots & \vdots \\ z_{n-1}-z_1-n+3 & z_{n-1}-z_2-n+4 & \cdots & z_{n-1}-z_n+2 & z_{n-1}-b-n+2 & 1 \end{array}\right).$$

Now taking the limit $b\to\infty$ in (2.25), we find

Corollary 3.10. *With notation and assumptions as in Theorem* 2.24, *we have*

$$W_q^{(n)}\left(\textit{as above}\left|\begin{array}{cccc} z_1-w_1 & \cdots & z_1-w_n+n-1 & z_1+s-q-a \\ \vdots & & \vdots & \vdots \\ z_n-w_1-n+1 & \cdots & z_n-w_n & z_n+s-q-a-n+1 \end{array}\right.\right.$$

$$\left|\begin{array}{ccc|c} 1 & \cdots & z_1-z_n+n & 1 \\ \vdots & & \vdots & \vdots \\ z_n-z_1-n+2 & \cdots & 1 & 1 \end{array}\right)$$

(3.11)

$$=\frac{\Gamma(a-s+q-z_n+n)\Gamma(w_n-z_n+1)}{\Gamma(a-w_n+n)\Gamma(1+s-q)}\prod_{l=1}^{n}\left[\frac{\Gamma(w_l-z_n+n-l+1)\Gamma(a-z_l+l)}{\Gamma(z_l-z_n+n-l+1)\Gamma(a-w_l+l)}\right]$$

$$\cdot F^{(n-1)}\left(\textit{as above}\left|\begin{array}{cccc} z_1-w_1 & \cdots & z_1-w_n+n-1 & z_1+s-q-a \\ \vdots & & \vdots & \vdots \\ z_{n-1}-w_1-n+2 & \cdots & z_{n-1}-w_n+1 & z_{n-1}+s-q-a-n-2 \end{array}\right.\right.$$

$$\left|\begin{array}{cccc|c} 1 & \cdots & z_1-z_n+n & z_1-a & 1 \\ \vdots & & \vdots & \vdots & \vdots \\ z_{n-1}-z_1-n+3 & \cdots & z_{n-1}-z_n+2 & z_{n-1}-a-n+2 & 1 \end{array}\right).$$

Remark 3.12. We also obtain interesting summation theorems on taking the limit $a \to \infty$ in identity (3.5) or the limit $b \to \infty$ in identities (3.5) and (3.2). After dividing by $q!$, if we sum with respect to q both sides of the limit of identity (3.2) we obtain a generalization of the binomial theorem (see also Milne [21]).

Now divide both sides of identity (3.2) by $q!$ and sum over $q \geqq 0$. The left-hand side becomes a terminating $F^{(n)}$ series which is summable by Holman's generalization of the terminating form of the Gauss summation theorem [14, Thm. 1]. The right-hand side becomes a classical ${}_{n+1}F_n(1)$ series such that the sum of the numerator parameters equals the sum of the denominator parameters. This is for $n \geqq 2$. For $n=1$ we obtain the same result by Vandermonde's theorem or by the classical Gauss summation theorem [4]. Thus we have

THEOREM 3.13. *For $n \geqq 1$, let $b_l \in \mathbb{C}$ and K_l be a nonnegative integer for $l=1, 2, \cdots, n$. We assume that b_l is not a negative integer or zero for $1 \leqq l \leqq n$. Setting $c=\sum_{l=1}^n K_l$, we have*

$$(3.14) \qquad {}_{n+1}F_n\left(\begin{matrix} -c, b_1+K_1, b_2+K_2, \cdots, b_n+K_n; \\ b_1, b_2, \cdots, b_n; \end{matrix} \; 1\right) = (-1)^c c! \prod_{l=1}^{n} \frac{1}{(b_l)_{K_l}}.$$

We also prove a "q-analogue" of Theorem 3.13. First, we give a definition.

DEFINITION 3.15. Define the basic hypergeometric series

$$(3.16) \qquad {}_{r+1}\varphi_r\left(\begin{matrix} a_1, \cdots, a_{r+1} \\ b_1, \cdots, b_r \end{matrix} ; q, x\right) = \sum_{n=0}^{\infty} \frac{(a_1; q)_n \cdots (a_{r+1}; q)_n x^n}{(b_1; q)_n \cdots (b_r; q)_n (q; q)_n}$$

with

$$(3.17) \qquad (a; q)_n = \begin{cases} 1, & n=0, \\ (1-a)(1-aq)\cdots(1-aq^{n-1}), & n=1, 2, \cdots. \end{cases}$$

THEOREM 3.18. *For $n \geqq 1$, let $\beta_l \in \mathbb{C}$ and $\gamma_l = q^{K_l}$ for $1 \leqq l \leqq n$, where K_l is a nonnegative integer and β_l is not a negative power of q or 1. Setting $\sigma = \prod_{l=1}^n \gamma_l = q^c$ where $c = \sum_{l=1}^n K_l$, we have*

$$(3.19) \qquad {}_{n+1}\phi_n\left(\begin{matrix} \sigma^{-1}, \beta_1\gamma_1, \beta_2\gamma_2, \cdots, \beta_n\gamma_n; \\ \beta_1, \beta_2, \cdots, \beta_n; \end{matrix} \; q, 1\right) = \frac{(\sigma^{-1}; q)_c}{\prod_{l=1}^n (\beta_l; q)_{K_l}}.$$

Proof. We first prove the following identity:

$$(3.20) \qquad {}_1\phi_0(\sigma^{-1}; q, q^r) = \sum_{j=0}^{c} \frac{(\sigma^{-1}; q)_j}{(q; q)_j} q^{rj} = \begin{cases} 0, & 0 < r \leqq c, \\ (\sigma^{-1}; q)_c, & r=0. \end{cases}$$

From the q-binomial theorem [4, eq. (8.2.4)], we have

$$(3.21) \qquad {}_1\phi_0(a; q, z) = \prod_{j=0}^{\infty} \frac{(1-aq^j z)}{(1-q^j z)}.$$

Hence ${}_1\phi_0(\sigma^{-1}; q, q^r) = 0$ if $0 < r \leqq c$. We also have [4, p. 66]

$$(3.22) \qquad {}_1\phi_0(a; q, z) - a\, {}_1\phi_0(a; q, qz) = (1-a)\, {}_1\phi_0(aq; q, z).$$

Setting $a=\sigma^{-1}$ and $z=1$ in (3.22), we find

$$(3.23)\qquad {}_1\phi_0(q^{-c};q,1)=(1-q^c)\,{}_1\phi_0(q^{-c+1};q,1)$$

and by induction

$$(3.24)\qquad {}_1\phi_0(q^{-c};q,1)=(1-q^{-c})(1-q^{-c+1})\cdots(1-q^{-1})\,{}_1\phi_0(1;q,1)$$

where ${}_1\phi_0(1;q,1)=1$. This completes the proof of identity (3.20).

Using the identity

$$(3.25)\qquad \frac{(\beta_l\gamma_l;q)_j}{(\beta_l;q)_j}(\beta_l;q)_{K_l}=(\beta_lq^j;q)_{K_l},$$

for $1\leqq l\leqq n$ and $j\geqq 0$, we rewrite (3.19) as

$$(3.26)\qquad \sum_{j=0}^{c}\frac{(\sigma^{-1};q)_j}{(q;q)_j}(\beta_1q^j;q)_{K_1}\cdots(\beta_nq^j;q)_{K_n}=(\sigma^{-1};q)_c.$$

Now if we expand $\prod_{l=1}^n(\beta_lq^j;q)_{K_l}$ in powers of q^j, we find

$$(3.27)\qquad \prod_{l=1}^{n}(\beta_lq^j;q)_{K_l}=1+\text{higher order terms in }q^j,$$

with highest order q^{jc}. An application of identity (3.20) completes the proof of Theorem 3.18.

Remark 3.28. There is a similar proof of Theorem 3.13 relying on a classical (ordinary) analogue of (3.20), which can be proved by induction from the ordinary binomial theorem. This classical analogue of (3.20) is given in an equivalent form by Project Ališaukas, Jucys and Jucys [1].

We also mention that Milne had discussed how a generalization of Dougall's theorem might lead to an identity similar to (3.14), just as in fact occurred. His conjectured identities are different than (3.14) [22].

4. Orthogonal polynomials in several variables. In this section we define a family of orthogonal polynomials in several variables which generalize the Racah polynomials of Wilson [26], [27]. These polynomials are orthogonal on a discrete set $\{(x_1,\cdots,x_n)\in\mathbb{Z}^n\,|\,x_i\geqq 0$ for $1\leqq i\leqq n$ and $\sum_{i=1}^n x_i=N\}$ for some nonnegative integer N and for $n\geqq 2$.

Recall the orthogonality relations (1.26a and b) satisfied by the multiplicity-free Racah coefficients above. Let notation be as in Proposition 1.25 and let $n\geqq 2$. We will denote $\lambda=[\lambda_1,\cdots,\lambda_n]$ for the highest weight λ of any irreducible representation space V_λ. Set $z_i=\mu_i'-m_i$ and $h_i=\nu_i-\mu_i$ for $1\leqq i\leqq n$ and denote $N=p''=\sum_{i=1}^n z_i=\sum_{i=1}^n h_i$. Finally we assume that $\nu_i>N+m_i$ and $m_i>N+\nu_{(i+1)}$ for $1\leqq i\leqq n$ and with $\nu_{(n+1)}=0$.

When we substitute the explicit form (2.4) and (2.14) of the Racah coefficients into identity (1.26a), we obtain

$$(4.1)\qquad \sum_{z_1+\cdots+z_n=N}\phi_\mu(\nu,m,m',m''|\mu')\phi_{\bar\mu}(\nu,m,m',m''|\mu')w(z)=\delta_{\bar\mu,\mu}M_\mu$$

where

$$\delta_{\bar\mu,\mu}=\begin{cases}1 & \text{if }\mu=\bar\mu,\\ 0 & \text{otherwise,}\end{cases}$$

and

$$
\begin{aligned}
w(z)=&\prod_{1\leqq k<l\leqq n}(z_k+m_k-(z_l+m_l)+l-k)\\
&\cdot\prod_{1\leqq k<l\leqq n}\left[\frac{(m_k-\nu_l+l-k)_{z_k}}{(m_k-m_l+l-k+1)_{z_k}(m_l-m_k+k-l)_{(z_l+1)}}\right]\\
&\cdot\prod_{2\leqq k\leqq l\leqq n}(m_l-\nu_k+k-l)_{z_l}\cdot\prod_{l=1}^{n}\frac{1}{(m_l-\nu_1+1-l)_{z_l}(z_l)!},
\end{aligned}\tag{4.2}
$$

and

$$
\begin{aligned}
M_\mu=&\prod_{1\leqq k<l\leqq n}((\nu_k-h_k)-(\nu_l-h_l)+l-k)^{-1}\cdot\frac{1}{(h_1)!}\\
&\cdot\prod_{l=2}^{n}\left[\frac{(\nu_l-\nu_1+1-l)_{(h_1+1)}(h_l)!}{(\nu_1-\nu_l+l)_{h_l}}\right]\cdot\prod_{1\leqq k<l\leqq n}\frac{1}{(m_k-\nu_l+l-k)_{h_l}}\\
&\cdot\prod_{1\leqq k\leqq l\leqq n}\frac{1}{(m_l-\nu_k+k-l)_{h_l}}\\
&\cdot\prod_{2\leqq k<l\leqq n}(\nu_k-\nu_l+l-k+1)_{h_l}(\nu_l-\nu_k+k-l)_{(h_k+1)},
\end{aligned}\tag{4.3}
$$

and

$$
\begin{aligned}
\phi_\mu(\nu,m,m',m''|\mu')=&\sum_{\substack{y_l\geqq 0\\ 2\leqq l\leqq n}}\left\{\prod_{2\leqq \nu<s\leqq n}\left(\frac{\nu_s-\nu_r+r-s+y_r-y_s}{\nu_s-\nu_r+r-s}\right)\right.\\
&\left.\cdot\prod_{l=2}^{n}\prod_{k=1}^{n}\left[\frac{(\mu_k-\nu_l+l-k)_{y_l}(\mu'_k-\nu_l+l-k)_{y_l}}{(\nu_k-\nu_l+l-k+1)_{y_l}(m_k-\nu_l+l-k)_{y_l}}\right]\right\},
\end{aligned}\tag{4.4}
$$

with a similar formula for $\phi_{\bar{\mu}}$.

Similarly to the argument in the proof of Theorem 2.24 it follows that identity (4.1) is true for all ν, $m\in\mathbb{C}^n$ with the restriction that the denominators in (4.2)-(4.4) should not vanish.

We now rewrite (4.1) and set $\alpha_k=-m_{n-k+1}-k$, $\beta_k=-\nu_{n-k+1}-k$, $x_k=z_{n-k+1}$, $t_k=h_{n-k+1}$ for $1\leqq k\leqq n$.

PROPOSITION 4.5. *Let $n\geqq 2$ and N be a nonnegative integer. With notation as above and $\alpha,\beta\in\mathbb{C}^n$, then for $t=(t_1,\cdots,t_n)\in\mathbb{Z}^n$ such that $\sum_{i=1}^n t_i=N$ and $t_i\geqq 0$ for $1\leqq i\leqq n$, and similarly for $t'\in\mathbb{Z}^n$, we have*

$$
\sum_{x_1+\cdots+x_n=N}P_t(x;\alpha,\beta,N)P_{t'}(x;\alpha,\beta,N)w(x)=\delta_{t,t'}M_t\tag{4.6}
$$

where x_i is a nonnegative integer for $1\leqq i\leqq n$ and

$$
\delta_{t,t'}=\begin{cases}1 & \textit{if } t=t',\\ 0 & \textit{otherwise},\end{cases}
$$

and

$$
\begin{aligned}
w(x)=&\prod_{1\leqq k<l\leqq n}((\alpha_k-x_k)-(\alpha_l-x_l))\\
&\cdot\prod_{1\leqq k<l\leqq n}\left[\frac{(\beta_k-\alpha_l)_{x_l}}{(\alpha_k-\alpha_l+1)_{x_l}(\alpha_l-\alpha_k)_{(x_k+1)}}\right]\\
&\cdot\prod_{1\leqq k\leqq l\leqq n-1}(\beta_l-\alpha_k)_{x_k}\cdot\prod_{l=1}^{n}\frac{1}{(\beta_n-\alpha_l)_{x_l}(x_l)!}N!(\beta_n-\alpha_1)_N
\end{aligned}\tag{4.7}
$$

and

$$\begin{aligned} M_t = & \prod_{1\leqq k<l\leqq n} ((t_k+\beta_k)-(t_l+\beta_l))^{-1} \\ & \cdot \prod_{1\leqq k<l\leqq n} \left[\frac{(\beta_k-\beta_l+1)_{t_k}(\beta_l-\beta_k)_{(t_l+1)}}{(\beta_k-\alpha_l)_{t_k}}\right] \\ & \cdot \prod_{2\leqq k\leqq l\leqq n} \frac{1}{(\beta_l-\alpha_k)_{t_l}} \cdot \prod_{l=1}^{n} (\beta_l-\alpha_1)_{t_l}(t_l)! \frac{1}{N!(\beta_n-\alpha_1)_N} \end{aligned} \tag{4.8}$$

and

$$\begin{aligned} P_t(x;\alpha,\beta,N) = & \frac{\prod_{l=1}^{n}(\beta_l-\beta_n+1)_{t_l}(\beta_l-\alpha_1)_{t_l}}{N!(\beta_n-\alpha_1)_N} \\ & \cdot F^{(n-1)}\left(\begin{array}{l} \begin{array}{cccc} \beta_1-\beta_2 & & & \\ \beta_1-\beta_3 & \beta_2-\beta_3 & & \\ \vdots & \vdots & & \\ \beta_1-\beta_{n-1} & \beta_2-\beta_{n-1} & \cdots & \beta_{n-2}-\beta_{n-1} \end{array} \\ \left|\begin{array}{cccccc} -t_1 & \cdots & -t_n-\beta_n+\beta_1 & x_1-\alpha_1+\beta_1 & \cdots & x_n-\alpha_n+\beta_1 \\ -t_1-\beta_1+\beta_2 & \cdots & -t_n-\beta_n+\beta_2 & x_1-\alpha_1+\beta_2 & \cdots & x_n-\alpha_n+\beta_2 \\ \vdots & & \vdots & \vdots & & \vdots \\ -t_1-\beta_1+\beta_{n-1} & \cdots & -t_n-\beta_n+\beta_{n-1} & x_1-\alpha_1+\beta_{n-1} & \cdots & x_n-\alpha_n+\beta_{n-1} \end{array}\right. \\ \left|\begin{array}{cccccc|c} 1 & \cdots & 1-\beta_n+\beta_1 & -\alpha_1+\beta_1 & \cdots & -\alpha_n+\beta_1 & 1 \\ 1-\beta_1+\beta_2 & \cdots & 1-\beta_n+\beta_2 & -\alpha_1+\beta_2 & \cdots & -\alpha_n+\beta_2 & 1 \\ \vdots & & \vdots & \vdots & & \vdots & \vdots \\ 1-\beta_1+\beta_{n-1} & \cdots & 1-\beta_n+\beta_{n-1} & -\alpha_1+\beta_{n-1} & \cdots & -\alpha_n+\beta_{n-1} & 1 \end{array}\right. \end{array}\right) \end{aligned} \tag{4.9}$$

and similarly for $P_{t'}(x;\alpha,\beta,N)$.

Note that $P_t(x;\alpha,\beta,N)$ is a symmetric polynomial in the variables $x_1-\alpha_1$, $x_2-\alpha_2,\cdots,x_n-\alpha_n$. Hence $P_t(x;\alpha,\beta,N)$ may be expressed as a polynomial in the elementary symmetric functions $e_i(x_1-\alpha_1,\cdots,x_n-\alpha_n)$, $1\leqq i\leqq n$. Recall that for a set of variables $u_1,\cdots,u_n$ and $1\leqq i\leqq n$, one defines

$$e_i(u_1,\cdots,u_n)=\sum_{1\leqq j_1<j_2<\cdots<j_i\leqq n} u_{j_1}u_{j_2}\cdots u_{j_i}, \tag{4.10}$$

where the sum is over all subsets $\{j_1,\cdots,j_i\}\subseteq\{1,\cdots,n\}$ of cardinality i.

We will abbreviate $e_i(x_1-\alpha_1,\cdots,x_n-\alpha_n)$ by $e_i(x-\alpha)$ for $1\leqq i\leqq n$ and also abbreviate the set of nonconstant polynomials $\{e_2(x-\alpha),\cdots,e_n(x-\alpha)\}$ by $e(x-\alpha)$. Note that $e_1(x-\alpha)=\sum_{i=1}^n x_i-\alpha_i=N-\sum_{i=1}^n \alpha_i$.

DEFINITION 4.11. With α, β, x, t and t' as in Proposition 4.5 we define the Racah polynomial in the variables $e(x-\alpha)=\{e_2(x-\alpha),\cdots. e_n(x-\alpha)\}$ by

$$R_t(e(x-\alpha);\alpha,\beta,N)\equiv P_t(x;\alpha,\beta,N) \tag{4.12}$$

and the inner product

$$\begin{aligned} & \langle R_t(e(x-\alpha);\alpha,\beta,N), R_{t'}(e(x-\alpha);\alpha,\beta,N)\rangle \\ & \equiv \sum_{x_1+\cdots+x_n=N} R_t(e(x-\alpha);\alpha,\beta,N)R_{t'}(e(x-\alpha);\alpha,\beta,N)w(x). \end{aligned} \tag{4.13}$$

Remark 4.14. For $n=2$ we obtain up to a scalar factor the orthogonal polynomials defined in (4.1) and (4.2) of Wilson [27] by substituting $m_1=\gamma$, $m_2=-\delta-N$, $\mu_1=\beta+n-N-1$, $\mu_2=-n$, $\mu_1'=x+\gamma$, $\mu_2'=-x-\delta$, $\nu_1=\beta-1$, $\nu_2=0$ and $N=-(\alpha+1)$ in the notation of equations (4.1)-(4.3) here and with α, β, γ, δ defined as in [27]. (Use transformation (1.2) of [27].)

We also remark that for $n=2$, the R_t polynomials contain the Hahn polynomials as a limiting case (see [27]). However, for $n>2$, the Hahn polynomials in several variables defined by Karlin and McGregor [16] have a weight function (see [16, eq. (5.13)]) which in general does not appear to be the limit of the weight function $w(x)$ in (4.8) here. It is also not known what relation, if any, there is between the R_t polynomials in two variables and the orthogonal polynomials defined by Suslov [30].

Two important questions need to be answered about the R_t polynomials. First, are there polynomials in several variables orthogonal with respect to a continuous measure generalizing the Wilson polynomials [27], [32] just as the R_t polynomials generalize the discrete Racah polynomials in one variable? Second, are there q-analogues of the R_t polynomials (see [31], [32])?

5. Recurrence relation for the Racah polynomials. Let $t=(t_1,\cdots,t_n)\in\mathbb{Z}^n$ such that $t_i\geqq 0$ for all i, $1\leqq i\leqq n$ and $\sum_{i=1}^n t_i=N$ for some nonnegative integer N. We fix below α, $\beta\in\mathbb{C}^n$ and N, and abbreviate $R_t(e(x-\alpha);\alpha,\beta,N)$ by R_t. R_t is a polynomial of degree $N-t_n$ in the variables $e_2(x-\alpha),\cdots,e_n(x-\alpha)$ where $x=(x_1,\cdots,x_n)\in\mathbb{Z}^n$, $x_i\geqq 0$ and $\sum_{i=1}^n x_i=N$.

DEFINITION 5.1. Let ε_j be the n-tuple $(0,\cdots,0,1,0,\cdots,0)$ with 1 in the jth entry and 0 elsewhere. Then $t+\varepsilon_j-\varepsilon_n$ is the n-tuple obtained by adding 1 to the jth entry and subtracting 1 from the nth entry.

If $t_n>0$, then for all k, $1\leqq k\leqq n-1$, we will show that R_t satisfies the following recurrence relation

$$\begin{aligned}R_{t+\varepsilon_k-\varepsilon_n}&=\sum_{j=1}^{n-1}A_{kj}^{(t)}e_{j+1}(x-\alpha)R_t+A_{kn}^{(t)}R_t+\sum_{m=1}^{n-1}B_{km}^{(t)}R_{t-\varepsilon_m+\varepsilon_k}\\&\quad+\sum_{h=1}^{n-1}B_{kh}'^{(t)}R_{t-\varepsilon_k+\varepsilon_h}+C_k^{(t)}R_{t-\varepsilon_k+\varepsilon_n}\end{aligned}\tag{5.2}$$

where $A_{kj}^{(t)}$, $B_{km}^{(t)}$, $B_{kh}'^{(t)}$,$C_k^{(t)}$ are defined in (5.10), (5.12)-(5.14) and (5.19) below and are independent of x. We also set $R_{t-\varepsilon_j}\equiv 0$ if $t_j=0$, $1\leqq j\leqq n$.

We begin the proof of (5.2) with the following well-known lemma describing those polynomials which can appear nontrivially in a recurrence relation for R_t.

LEMMA 5.3. *If* $t_n>0$ *and* $2\leqq l\leqq n$, *then*

$$e_l(x-\alpha)R_t=\sum a_{t'}R_{t'}\tag{5.4}$$

as polynomials in the variables $e_2(x-\alpha),\cdots,e_n(x-\alpha)$, *where* $a_{t'}\in\mathbb{C}$ *and the sum is over all* $t'=(t_1',\cdots,t_n')\in\mathbb{Z}^n$, $t_i'\geqq 0$ *and* $\sum_{i=1}^n t_i=N$ *such that* $t_n+1\geqq t_n'\geqq t_n-1$.

Proof. We can write

$$e_l(x-\alpha)R_t=\sum a_{t'}R_{t'}$$

where $a_{t'}\in\mathbb{C}$ and the sum is over all $t'\in\mathbb{Z}^n$, $t_i'\geqq 0$ and $\sum_{i=1}^n t_i=N$. We need to show that if $a_{t'}\neq 0$, then $t_n+1\geqq t_n'\geqq t_n-1$. We have

$$a_{t'}=\langle e_l(x-\alpha)R_t,R_{t'}\rangle(M_{t'})^{-1}.\tag{5.5}$$

If $a_{t'}\neq 0$, then $\deg(e_l(x-\alpha)R_t)\geqq\deg R_{t'}$ in the variables $e_2(x-\alpha),\cdots,e_n(x-\alpha)$, equivalently $t'_n \geqq t_n - 1$. Similarly

$$a_{t'} = \langle R_t,\, e_l(x-\alpha)R_{t'}\rangle (M_{t'})^{-1}. \tag{5.6}$$

It follows that if $a_{t'} \neq 0$, then $\deg R_t \leqq \deg R_{t'} + 1$ or equivalently $t_n + 1 \geqq t'_n$. Q.E.D.

Proof of the recurrence relation (5.2). The leading term (L.T.) in the series for R_t is

$$\begin{aligned} &\frac{(t_n)!(\beta_n-\alpha_1)_{t_n}}{N!(\beta_n-\alpha_1)_N} \prod_{1\leqq i<j\leqq n-1} \frac{(\beta_i-\beta_j+t_i-t_j)}{(\beta_i-\beta_j)} \\ &\cdot \prod_{i=1}^{n-1} \left[\prod_{l=1}^{n} (\beta_i - t_l - \beta_l)_{t_i} (\beta_i + x_l - \alpha_l)_{t_i} \prod_{l=1}^{n-1} \frac{1}{(\beta_i-\beta_l+1)_{t_i}} \prod_{l=2}^{n} \frac{1}{(\beta_i-\alpha_l)_{t_i}} \right]. \end{aligned} \tag{5.7}$$

Assume $t_n \neq 0$ and consider $R_{t+\varepsilon_k-\varepsilon_n}$ for some integer k, $1 \leqq k \leqq n-1$. After comparing the leading terms of $R_{t+\varepsilon_k-\varepsilon_n}$ and R_t we obtain

$$\begin{aligned} R_{t+\varepsilon_k-\varepsilon_n} = &\prod_{l=1}^{n-1} \left[\frac{(\beta_n+t_n)-(\beta_l+t_l)}{(\beta_n+t_n-\beta_l)} \right] \prod_{l=2}^{n} \frac{1}{(\beta_k+t_k-\alpha_l)} \\ &\cdot \frac{(\beta_n+t_n-(\beta_k+t_k)-1)}{t_n(\beta_n+t_n-\alpha_1-1)} \left\{ \sum_{m=0}^{n} (\beta_k+t_k)^{n-m} e_m(x-\alpha) R_t \right\} \\ &+ \text{terms of degree less than } N - t_n + 1 \\ &\quad \text{in the variables } e_2(x-\alpha), \cdots, e_n(x-\alpha). \end{aligned} \tag{5.8}$$

To compute lower degree terms in the recurrence relation (5.2), we must consider the next to leading terms in R_t:

$$\begin{aligned} &\frac{(t_n)!(\beta_n-\alpha_1)_{t_n}}{N!(\beta_n-\alpha_1)_N} \sum_{m=1}^{n-1} \Bigg\{ \prod_{\substack{1\leqq i<j\leqq n-1 \\ i,j\neq m}} (\beta_i-\beta_j+t_i-t_j) \prod_{i=1}^{m-1} (\beta_i-\beta_m+t_i-t_m+1) \\ &\qquad \cdot \prod_{j=m+1}^{n-1} (\beta_m-\beta_j+t_m-1-t_j) \prod_{1\leqq i<j\leqq n-1} (\beta_i-\beta_j)^{-1} \\ &\qquad \cdot \prod_{\substack{i=1 \\ i\neq m}}^{n-1} \Bigg[\prod_{l=1}^{n} (\beta_i-t_l-\beta_l)_{t_i} (\beta_i+x_l-\alpha_l)_{t_i} \\ &\qquad\qquad \cdot \prod_{l=1}^{n-1} \frac{1}{(\beta_i-\beta_l+1)_{t_i}} \prod_{l=2}^{n} \frac{1}{(\beta_i-\alpha_l)_{t_i}} \Bigg] \\ &\qquad \cdot \prod_{l=1}^{n} (\beta_m-t_l-\beta_l)_{t_m-1} (\beta_m+x_l-\alpha_l)_{t_m-1} \\ &\qquad \cdot \prod_{l=1}^{n-1} \frac{1}{(\beta_m-\beta_l+1)_{t_m-1}} \prod_{l=2}^{n} \frac{1}{(\beta_m-\alpha_l)_{t_m-1}} \\ &\qquad\qquad \cdot (\beta_m-\beta_n+t_m)(\beta_m-\alpha_1+t_m-1) \Bigg\} \\ &= \sum_{m=1}^{n-1} \Bigg\{ \frac{t_m}{(t_n+1)(\beta_n+t_n-\alpha_1)} \prod_{\substack{i=1 \\ i\neq m}}^{n-1} \left[\frac{(\beta_i-(\beta_m+t_m))}{(\beta_i+t_i-(\beta_m+t_m))} \frac{(\beta_i+t_i-(\beta_n+t_n)-1)}{(\beta_i-(\beta_n+t_n)-1)} \right] \end{aligned} \tag{5.9}$$

$$\cdot \frac{(\beta_m + t_m - (\beta_n + t_n) - 2)}{(\beta_m - (\beta_n + t_n) - 1)} (\beta_m + t_m - \beta_n)$$

$$\left. \cdot (\beta_m + t_m - \alpha_1 - 1) \cdot (\text{L.T. of } R_{t-\varepsilon_m+\varepsilon_n}) \right\}.$$

Now let $(A_{ij}^{(t)})$ be the $n \times n$ matrix with

$$A_{nj}^{(t)} = \begin{cases} 1 & \text{if } j = n, \\ 0 & \text{otherwise} \end{cases} \tag{5.10a}$$

and

$$\begin{aligned} A_{ij}^{(t)} = \prod_{l=1}^{n-1} \left[\frac{(\beta_n + t_n) - (\beta_l + t_l)}{(\beta_n + t_n - \beta_l)} \prod_{l=2}^{n} \frac{1}{(\beta_i + t_i - \alpha_l)} \frac{(\beta + t_n - (\beta_i + t_i) - 1)}{t_n(\beta_n + t_n - \alpha_1 - 1)} \right. \\ \cdot \begin{cases} (\beta_i + t_i)^n + (\beta_i + t_i)^{n-1} e_1(x - \alpha) & \text{if } i < n \text{ and } j = n, \\ (\beta_i + t_i)^{n-j-1} & \text{if } i < n \text{ and } j < n. \end{cases} \end{aligned} \tag{5.10b}$$

It follows that if $t_n > 0$ and $1 \leqq k \leqq n - 1$, then

$$R_{t+\varepsilon_k-\varepsilon_n} - \sum_{j=1}^{n-1} A_{kj}^{(t)} e_{j+1}(x - \alpha) R_t - A_{kn}^{(t)} R_t$$

$$= \sum_{\substack{m=1 \\ m \neq k}}^{n-1} \left\{ \frac{t_m}{t_n(\beta_n + t_n - \alpha_1 - 1)} \prod_{\substack{i=1 \\ i \neq m,k}}^{n-1} \left[\frac{(\beta_i - (\beta_m + t_m))}{(\beta_i + t_i - (\beta_m + t_m))} \frac{(\beta_i + t_i - (\beta_n + t_n))}{(\beta_i - (\beta_n + t_n))} \right] \right.$$

$$\cdot \frac{(\beta_k - (\beta_m + t_m))(\beta_k + t_k - (\beta_n + t_n) + 1)}{(\beta_k + t_k - (\beta_m + t_m) + 1)(\beta_k - (\beta_n + t_n))}$$

$$\left. \cdot \frac{(\beta_m + t_m - (\beta_n + t_n) - 1)}{(\beta_m - (\beta_n + t_n))} (\beta_m + t_m - \beta_n)(\beta_m + t_m - \alpha_1 - 1) R_{t-\varepsilon_m+\varepsilon_k} \right\}$$

$$+ \frac{(t_k + 1)}{t_n(\beta_n + t_n - \alpha_1 - 1)} \prod_{\substack{i=1 \\ i \neq k}}^{n-1} \left[\frac{(\beta_i - (\beta_k + t_k) - 1)}{(\beta_i + t_i - (\beta_k + t_k) - 1)} \frac{(\beta_i + t_i - (\beta_n + t_n))}{(\beta_i - (\beta_n + t_n))} \right] \tag{5.11}$$

$$\cdot \frac{(\beta_k + t_k - (\beta_n + t_n))}{(\beta_k - (\beta_n + t_n))} (\beta_k + t_k - \beta_n + 1)(\beta_k + t_k - \alpha_1) R_t$$

$$+ \sum_{h,j,m=1}^{n-1} \left\{ \frac{-t_m}{(t_n + 1)(\beta_n + t_n - \alpha_1)} \prod_{\substack{i=1 \\ i \neq m}}^{n-1} \left[\frac{(\beta_i - (\beta_m + t_m))}{(\beta_i + t_i - (\beta_m + t_m))} \frac{(\beta_i + t_i - (\beta_n + t_n) - 1)}{(\beta_i - (\beta_n + t_n) - 1)} \right] \right.$$

$$\cdot \frac{(\beta_m + t_m - (\beta_n + t_n) - 2)}{(\beta_m - (\beta_n + t_n) - 1)} (\beta_m + t_m - \beta_n)(\beta_m + t_m - \alpha_1 - 1)$$

$$\left. \cdot A_{kj}^{(t)} (A^{(t-\varepsilon_m+\varepsilon_n)})_{jh}^{-1} R_{t-\varepsilon_m+\varepsilon_h} \right\}$$

$+$ terms of degree less than $N - t_n$

in the variables $e_2(x - \alpha), \cdots, e_n(x - \alpha)$,

where $(A^{(t-\varepsilon_m+\varepsilon_n)})_{jh}^{-1}$ is the (j, h) entry of the matrix inverse of $A^{(t-\varepsilon_m+\varepsilon_n)}$.

Now observe that if $t_m > 0$, then

(5.12)

$$\sum_{j=1}^{n-1} A_{kj}^{(t)}(A^{(t-\varepsilon_m+\varepsilon_n)})_{jh}^{-1}$$

$$= \prod_{l=1}^{n-1}\left[\frac{(\beta_n+t_n-(\beta_l+t_l))(\beta_n+t_n-\beta_l+1)}{(\beta_n+t_n-\beta_l)}\right]$$

$$\cdot \prod_{\substack{l=1\\ l\neq m}}^{n-1}\left[\frac{1}{((\beta_n+t_n)-(\beta_l+t_l)+1)}\right]\frac{1}{((\beta_n+t_n)-(\beta_m+t_m)+2)}\frac{(t_n+1)}{t_n}\frac{(\beta_n+t_n-\alpha_1)}{(\beta_n+t_n-\alpha_1-1)}$$

$$\cdot\begin{cases} 0 \quad \text{if } k\neq m \text{ and } h\neq k, \\[2mm] \dfrac{(\beta_n+t_n-(\beta_k+t_k)-1)}{(\beta_n+t_n-(\beta_k+t_k))} \quad \text{if } k\neq m \text{ and } h=k, \\[2mm] \dfrac{(\beta_n+t_n-(\beta_k+t_k)-1)}{(\beta_n+t_n-(\beta_k+t_k)+1)}\displaystyle\prod_{l=2}^{n}\frac{(\beta_k+t_k-\alpha_l+1)}{(\beta_k+t_k-\alpha_l)}\prod_{\substack{l=1\\ l\neq k}}^{n-1}\frac{(\beta_k+t_k-(\beta_l+t_l))}{(\beta_k+t_k-(\beta_l+t_l)-1)} \\ \hfill \text{if } k=m \text{ and } h=k, \\[2mm] \dfrac{(\beta_n+t_n-(\beta_k+t_k)-1)}{(\beta_n+t_n-(\beta_h+t_h))}\displaystyle\prod_{l=2}^{n}\frac{(\beta_h+t_h-\alpha_l)}{(\beta_k+t_k-\alpha_l)}\prod_{\substack{l=1\\ l\neq k,h}}^{n-1}\frac{(\beta_k+t_k)-(\beta_l+t_l)}{(\beta_h+t_h)-(\beta_l+t_l)} \\ \quad\cdot\dfrac{1}{(\beta_n+t_n-(\beta_k+t_k)+1)} \quad \text{if } k=m \text{ and } h\neq k, \end{cases}$$

where we have used the fact that, except for their nth rows and columns, both matrices $A^{(t)}$ and $A^{(t-\varepsilon_m+\varepsilon_n)}$ are the products of diagonal matrix and a Vandermonde matrix.

For $1\leqq k$, $m\leqq n-1$and $k\neq m$, we set

$$B_{km}^{(t)} = \frac{t_m}{t_n(\beta_n+t_n-\alpha_1-1)}\prod_{\substack{i=1\\ i\neq m,k}}^{n-1}\frac{(\beta_i-(\beta_m+t_m))(\beta_i+t_i-(\beta_n+t_n))}{(\beta_i+t_i-(\beta_m+t_m))(\beta_i-(\beta_n+t_n))}$$

$$\cdot\frac{(\beta_k-(\beta_m+t_m))(\beta_k+t_k-(\beta_n+t_n)+1)(\beta_m+t_m-(\beta_n+t_n)-1)}{(\beta_k+t_k-(\beta_m+t_m)+1)(\beta_k-(\beta_n+t_n))(\beta_m-(\beta_n+t_n))}$$

$$\text{(5.13a)} \qquad \cdot(\beta_m+t_m-\beta_n)(\beta_m+t_m-\alpha_1-1)-\frac{t_m}{(t_n+1)(\beta_n+t_n-\alpha_1)}$$

$$\cdot\prod_{\substack{i=1\\ i\neq m}}^{n-1}\left[\frac{(\beta_i-(\beta_m+t_m))}{(\beta_i+t_i-(\beta_m+t_m))}\frac{(\beta_i+t_i-(\beta_n+t_n)-1)}{(\beta_i-(\beta_n+t_n)-1)}\right]$$

$$\cdot\frac{(\beta_m+t_m-(\beta_n+t_n)-2)}{(\beta_m-(\beta_n+t_n)-1)}(\beta_m+t_m-\beta_n)$$

$$\cdot\frac{(\beta_m+t_m-\alpha_1-1)}{(\beta_n+t_n-(\beta_k+t_k))}(\beta_n+t_n-(\beta_k+t_k)-1).$$

If $1\leqq k\leqq n-1$, then set

$$B_{kk}^{(t)} = \frac{(t_k+1)}{t_n(\beta_n+t_n-\alpha_1-1)}\prod_{\substack{i=1\\ i\neq k}}^{n-1}\left[\frac{(\beta_i-(\beta_k+t_k)-1)}{(\beta_i+t_i-(\beta_k+t_k)-1)}\frac{(\beta_i+t_i-(\beta_n+t_n))}{(\beta_i-(\beta_n+t_n))}\right]$$

$$\text{(5.13b)} \qquad \cdot\frac{(\beta_k+t_k-(\beta_n+t_n))}{(\beta_k-(\beta_n+t_n))}(\beta_k+t_k-\beta_n+1)(\beta_k+t_k-\alpha_1).$$

Similarly for $1 \leqq k,\ h \leqq n-1$ and $k = m$, we set

$$B'^{(t)}_{kh} = \frac{-t_k}{(t_n+1)(\beta_n+t_n-\alpha_1)} \prod_{\substack{i=1 \\ i \neq k}}^{n-1} \left[\frac{(\beta_i-(\beta_k+t_k))}{(\beta_i+t_i-(\beta_k+t_k))} \frac{(\beta_i+t_i-(\beta_n+t_n)-1)}{(\beta_i-(\beta_n+t_n)-1)} \right]$$

$$\cdot \frac{(\beta_k+t_k-(\beta_n+t_n)-2)}{(\beta_k-(\beta_n+t_n)-1)} (\beta_k+t_k-\alpha_1-1) \left(\sum_{j=1}^{n-1} A^{(t)}_{kj} (A^{(t-\varepsilon_k+\varepsilon_n)})^{-1}_{jh} \right). \tag{5.14}$$

Now let $t' = (t'_1, \cdots, t'_n) \in \mathbb{Z}^n$ where $t'_i \geqq 0$ for all $1 \leqq i \leqq n$, $\sum_{i=1}^n t'_i = N$ and $t'_n = t_n + 1$. Then

$$\left\langle R_{t'}, R_{t+\varepsilon_k-\varepsilon_n} - \sum_{j=1}^{n-1} A^{(t)}_{kj} e_{j+1}(x-\alpha) R_t - A^{(t)}_{kn} R_t - \sum_{m=1}^{n-1} B^{(t)}_{km} R_{t-\varepsilon_m+\varepsilon_k} - \sum_{h=1}^{n-1} B'^{(t)}_{kh} R_{t-\varepsilon_k+\varepsilon_h} \right\rangle$$

$$= -\sum_{j=1}^{n-1} \langle R_{t'}, A^{(t)}_{kj} e_{j+1}(x-\alpha) R_t \rangle \tag{5.15}$$

$$= -\sum_{j=1}^{n-1} A^{(t)}_{kj} \langle e_{j+1}(x-\alpha) R_{t'}, R_t \rangle \tag{5.16}$$

$$= -\sum_{j,h=1}^{n-1} A^{(t)}_{kj} (A^{(t')})^{-1}_{jh} \langle R_{t'+\varepsilon_h-\varepsilon_n}, R_t \rangle. \tag{5.17}$$

From (5.12) it follows that $t' = t - \varepsilon_k + \varepsilon_n$ and expression (5.17)

$$= -\sum_{j=1}^{n-1} A^{(t)}_{kj} (A^{(t-\varepsilon_k+\varepsilon_n)})^{-1}_{jk} M_t, \tag{5.18}$$

where $\sum_{j=1}^{n-1} A^{(t)}_{kj} (A^{(t-\varepsilon_k+\varepsilon_n)})^{-1}_{jk}$ is computed in (5.12) and M_t in (4.8).

For $1 \leqq k \leqq n-1$ and $t_k \neq 0$ we set

$$C^{(t)}_k = -M_t (M_{t-\varepsilon_k+\varepsilon_n})^{-1} \sum_{j=1}^{n-1} A^{(t)}_{kj} (A^{(t-\varepsilon_k+\varepsilon_n)})^{-1}_{jk}. \tag{5.19}$$

If $t_k = 0$, set $C^{(t)}_k \equiv 0$.

Applying Lemma 5.3, this completes the proof of the recurrence relation (5.2).

6. Duality for Racah polynomials. The main result in this section is

PROPOSITION 6.1. *With notation as in Proposition* 4.5 *and where* $\bar{\beta} = (-\beta_n, -\beta_{n-1}, \cdots, -\beta_1)$ *and similarly for* $\bar{\alpha}$, $\bar{x}$ *and* $\bar{t}$, *then we have*

$$P_t(x; \alpha, \beta, N) = P_{-\bar{x}}(-\bar{t}; \bar{\beta}, \bar{\alpha}, N). \tag{6.2}$$

The proof of Proposition 6.1 is a consequence of the following

LEMMA 6.3. *With assumptions as in Proposition* 1.25 *we have*

$$\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} = \begin{bmatrix} m'' & \bar{\nu} & \bar{\mu} \\ m' & \bar{m} & \bar{\mu}' \end{bmatrix}. \tag{6.4}$$

Proof. Applying identities (1.22) and (1.31), we obtain

$$\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} = \sum_{(m'')\otimes(m)\otimes(m')} \langle (\nu), T_\nu(1 \otimes T_\mu)((m'')\otimes(m)\otimes(m')) \rangle$$

$$\cdot \langle (\nu), T_\nu(T_{\mu'} \otimes 1)((m'')\otimes(m)\otimes(m')) \rangle \tag{6.5}$$

with the sum over all Gelfand states $(m'')\otimes(m)\otimes(m')$ of $V_{m''} \otimes V_m \otimes V_{m'}$ and (ν) is any state in V_ν.

$$(6.6)\qquad \begin{aligned} &= \sum_{\substack{(\mu),(\mu'),(m''),\\ (m),(m')}} \langle(\nu),\, T_\nu((m'')\otimes(\mu))\rangle\langle(\mu),\, T_\mu((m)\otimes(m'))\rangle \\ &\qquad \cdot \langle(\nu),\, T_\nu((\mu')\otimes(m'))\rangle\langle(\mu'),\, T_{\mu'}((m'')\otimes(m))\rangle \end{aligned}$$

where the sum is over all states (μ') of $V_{\mu'}$, etc.

Let $m''=[p'',0,\cdots,0]$ and

$$(m'')=\begin{pmatrix}[p'',0,\cdots,0]\\ (m'')_{n-1}\end{pmatrix};$$

then in the notation of Proposition A.6 we have

$$(6.7)\qquad \langle(\nu),\, T_\nu((m'')\otimes(\mu))\rangle = \left\langle (\nu) \middle| \left\langle \begin{matrix}(\Gamma)_{n-1}\\ [p'',0,\cdots,0]\\ (m'')_{n-1}\end{matrix}\right\rangle \middle| (\mu)\right\rangle$$

where (Γ) is the unique operator pattern (see [17]) such that $[\nu]_n=\Delta(\Gamma)+[\mu]_n$. From Proposition A.6 it follows that

$$(6.8)\quad \langle(\nu),\, T_\nu((m'')\otimes(\mu))\rangle=(-1)^{p''+\varphi(\mu)+\varphi(\nu)}\left[\frac{d(\nu)}{d(\mu)}\right]^{1/2}\langle(\bar\mu),\, T_{\bar\mu}((m'')\otimes(\bar\nu))\rangle,$$

where $\varphi(\mu)$ and $\varphi(\nu)$ are defined in Definition A.3 and $d(\nu)$, $d(\mu)$ in (2.18).

From (6.6) and (6.8) we find

$$(6.9)\qquad \begin{aligned} d(\nu)\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} &= \sum_{\substack{(\nu),(\mu),(\mu')\\ (m''),(m),(m')}} \langle(\nu),\, T_\nu((m'')\otimes(\mu))\rangle \\ &\qquad \cdot\langle(\mu),\, T_\mu((m)\otimes(m'))\rangle\langle(\nu),\, T_\nu((\mu')\otimes(m'))\rangle \\ &\qquad \cdot\langle(\mu'),\, T_{\mu'}((m'')\otimes(m))\rangle \\ &= \frac{d(\nu)}{d(m)}\sum_{\substack{(\bar\nu),(\bar\mu),(\bar\mu')\\ (m''),(\bar m),(m')}} \langle(\bar\mu),\, T_{\bar\mu}((m'')\otimes(\bar\nu))\rangle \\ &\qquad \cdot\langle(\bar m),\, T_{\bar m}((m')\otimes(\bar\mu))\rangle\langle(\bar\mu'),\, T_{\bar\mu'}((m')\otimes(\bar\nu))\rangle \\ &\qquad \cdot\langle(m),\, T_{\bar m}((m'')\otimes(\bar\mu'))\rangle = d(\nu)\begin{bmatrix} m'' & \bar\nu & \bar\mu \\ m' & \bar m & \bar\mu' \end{bmatrix} \end{aligned}$$

where the sum is over all states $(\nu)\in V_\nu$, etc. This completes the proof of Lemma 6.3.

In order to apply identity (2.4) to (6.4) above, we shall need the following definition and lemma.

Definition 6.10. If $\lambda=(\lambda_1,\cdots,\lambda_n)\in\mathbb{Z}^n$ then $\lambda+k^n=(\lambda_1+k,\lambda_2+k,\cdots,\lambda_n+k)$ for any integer k. If (λ) is a Gelfand pattern, i.e. an array λ_{ij} for $1\leqq i\leqq j\leqq n$, then $(\lambda+k^n)$ is the Gelfand pattern whose (i,j) entry, $1\leqq i\leqq j\leqq n$, is $\lambda_{ij}+k$.

Lemma 6.11. *With notation as in Lemma* 6.3 *we have*

$$(6.12)\qquad \begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix}=\begin{bmatrix} m'' & m+k^n & \mu'+k^n \\ m' & \nu+k^n & \mu+k^n \end{bmatrix}$$

for any integer k.

Proof. In the notation of expression (6.7) and Definition 6.10 it follows from [6, Lemma 2.29] that

$$(6.13)\quad \left\langle (\nu) \middle| \left\langle \begin{matrix}(\Gamma)_{n-1}\\ [p'',0,\cdots,0]\\ (m'')_{n-1}\end{matrix}\right\rangle \middle| (\mu)\right\rangle = \pm\left\langle (\nu+k^n) \middle| \left\langle \begin{matrix}(\Gamma)_{n-1}\\ [p'',0,\cdots,0]\\ (m'')_{n-1}\end{matrix}\right\rangle \middle| (\mu+k^n)\right\rangle,$$

where the sign in (6.13) is always positive or always negative for all choices of Gelfand states (ν), (m'') and (μ) in V_ν, $V_{m''}$ and V_μ (assuming both sides of (6.13) do not vanish).

The phase convention (1.8) guarantees that for at least one choice of such (ν), (m'') and (μ) the sign in (6.13) is positive. Hence the sign is positive for all choices of (ν), (m'') and (μ). Now identity (6.12) follows from (6.6), (6.7) and (6.13).

Proof of Proposition 6.1. With assumptions on m'', m', m, ν, μ, μ' as in (4.1), we have by Lemmas 6.3 and 6.11 the equality

$$\begin{bmatrix} m'' & m & \mu' \\ m' & \nu & \mu \end{bmatrix} = \begin{bmatrix} m'' & \bar{\nu}+k^n & \bar{\mu}'+k^n \\ m' & \bar{m}+k^n & \bar{\mu}+k^n \end{bmatrix} \tag{6.14}$$

where $k=\nu_1$. After substituting the explicit form (2.4) and (2.14) of the Racah coefficients in (6.14) above, then by an elementary computation one obtains the identity

$$P_t(x;\alpha,\beta,N) = P_{-\bar{x}}(-\bar{t};\bar{\beta}-k^n,\bar{\alpha}-k^n,N) \tag{6.15}$$

where $\alpha_l=-m_{n-l+1}-l$, $\beta_l=-\nu_{n-l+1}-l$, $x_l=\mu'_{n-l+1}-m_{n-l+1}$ and $t_l=\nu_{n+l+1}-\mu_{n+l+1}$ for $1\leqq l\leqq n$. Observing that

$$P_{-\bar{x}}(-\bar{t};\bar{\beta}-k^n,\bar{\alpha}-k^n,N) = P_{-\bar{x}}(-\bar{t};\bar{\beta};\bar{\alpha},N), \tag{6.16}$$

then identity (6.2) follows for all $\alpha,\beta\in\mathbb{C}^n$ (such that both sides of (6.2) are defined) by an argument similar to that in the proof of Theorem 2.24.

Remark 6.17. Lemma 6.3 is a well-known symmetry relation for multiplicity free Racah coefficients (see [12] and [29]).

7. An identity for Racah polynomials. The generalized Biedenharn–Elliott identity, Proposition 1.50, implies an identity for Racah polynomials which is similar to an addition theorem. In the notation of formula (1.51) we set $\delta=(n,n-1,\cdots,1)$, $\bar{m}_1-\delta=\alpha$, $\bar{m}-\delta=\beta$, $\bar{m}_1-\bar{m}_{123}=x+y$, $\bar{m}_{12}-\bar{m}_{123}=x$, $\bar{m}_1-\bar{m}_{12}=y$, $\bar{m}_{14}-\bar{m}=t$, $\bar{m}_{14}-\bar{m}_{124}=t-u$, $\bar{m}_{124}-\bar{m}=u$, $\sum_{i=1}^n(m-m_{14})_i=N$, $\sum_{i=1}^n(m_{124}-m_{14})_i=N-N'$, $\sum_{i=1}^n(m-m_{124})_i=N'$, where for λ, $\lambda'\in\mathbb{C}^n$, then $(\lambda+\lambda')_i=\lambda_i+\lambda'_i$, $1\leqq i\leqq n$.

Applying identities (2.4), (2.13), (2.14), (2.17a) and (2.17e) to (1.51) and continuing for $\alpha,\beta\in\mathbb{C}^n$, one obtains the following:

PROPOSITION 7.1. *With notation as in Proposition* 4.5, *let* $\alpha,\beta\in\mathbb{C}^n$, $N\geqq N'\geqq 0$ *be integers and* $x,y,t\in\mathbb{Z}^n$ *such that* $\sum_{i=1}^n t_i=N$, $\sum_{i=1}^n x_i=N'$, $\sum_{i=1}^n y_i=N-N'$, *where* x_i, y_i, $t_i\geqq 0$ *for* $1\leqq i\leqq n$. *We have* (*when both sides are defined*)

$$P_t(x+y;\alpha,\beta,N) = \sum_{t_i\geqq u_i} f(y,\alpha,\beta,t,u)P_u(x;\alpha-y,\beta,N')P_{t-u}(y;\alpha,\beta+u,N-N') \tag{7.2}$$

where the sum is over all $u\in\mathbb{Z}^n$ *such that* $t_i\geqq u_i\geqq 0$ *for* $1\leqq i\leqq n$ *and* $\sum_{i=1}^n u_i=N'$ *and where*

$$\begin{aligned} f(y,\alpha,\beta,t,u) &= \binom{N}{N'}^{-1}\frac{((\beta+u)_n-\alpha_1)_{N-N'}}{((\beta+u)_n-\alpha_1)_{N-u_n}} \\ &\quad\cdot((\beta+u)_n-(\alpha-y)_1)_{N'-u_n}\prod_{l=1}^n\binom{t_l}{u_l}\prod_{2\leqq k\leqq l\leqq n-1}\frac{(\beta_l-(\alpha-y)_k)_{u_l}}{(\beta_l-\alpha_k)_{u_l}} \\ &\quad\cdot\prod_{1\leqq k<l\leqq n}\left[\frac{(\beta_k-(\alpha-y)_l)_{u_k}(\beta_k-(\beta+t)_l)_{u_k}(\beta_l-(\beta+t)_k)_{(t-u)_k}}{(\beta_k-\alpha_l)_{u_k}(\beta_k-(\beta+u)_l)_{u_k}((\beta+u)_l-(\beta+t)_k)_{(t-u)_k}}\right]. \end{aligned} \tag{7.3}$$

Appendix A. Let $m=[m_1,\cdots,m_n]$ be a $U(n)$ highest weight and define

$$\bar{m}=m^*=[-m_n,\cdots,-m_1]. \tag{A.1}$$

If (m) is a Gelfand state of V_m define $(\bar{m})$ to be the Gelfand state of $V_{\bar{m}}$ with Gelfand pattern

$$\text{(A.2)} \qquad \bar{m}_{ij} = -m_{j-i+1,j}, \qquad 1 \leqq i \leqq j \leqq n.$$

It is important to note that $(\bar{m})$ is in general *not* the dual basis vector to (m) with respect to the Gelfand-Zetlin basis of V_m.

Now let

$$(m) = \begin{pmatrix} [m]_n \\ (m)_{n-1} \end{pmatrix}, \qquad (m') = \begin{pmatrix} [m]_n \\ (m')_{n-1} \end{pmatrix}$$

be Gelfand states of V_m and assume that the highest weight m is a partition. In [17] and in [6, eq. (1.10)] the "boson polynomial"

$$B\begin{pmatrix} (m')_{n-1} \\ [m]_n \\ [m]_{n-1} \end{pmatrix}$$

is defined. Also in [6, eq. (1.14)] a "dual boson polynomial"

$$B\begin{pmatrix} (\bar{m}')_{n-1} \\ [\bar{m}]_n \\ (\bar{m})_{n-1} \end{pmatrix} = \overline{B\begin{pmatrix} (m') \\ [m]_n \\ (m)_{n-1} \end{pmatrix}}$$

is defined. This notation for the dual boson polynomial is not consistent with Louck [17] or with definition (A.2) above, because in [6] we set $(\bar{m}) \in V_{\bar{m}}$ to be the dual basis vector to the state (m) with respect to the Gelfand-Zetlin basis of V_m. However the dual basis for $V_{\bar{m}}$ is not actually the Gelfand-Zetlin basis for $V_{\bar{m}}$ as given by applying the lowering operators of Nagel and Moshinsky [23] to the highest weight state of $V_{\bar{m}}$. For a similar reason

$$\overline{B\begin{pmatrix} (m')_{n-1} \\ [m]_n \\ (m)_{n-1} \end{pmatrix}} = \mathcal{M}(m)^{1/2} \overline{\Phi\begin{pmatrix} [m']_{n-1} \\ [m]_n \\ (m)_{n-1} \end{pmatrix}} \in \mathcal{A}$$

is not a Gelfand-Zetlin state vector for the $U(n) \times U(n)$ representation acting on $V_{\bar{m}} \otimes V_{\bar{m}} \subseteq \mathcal{A}$, where

$$\overline{\Phi\begin{pmatrix} (m')_{n-1} \\ [m]_n \\ (m)_{n-1} \end{pmatrix}} \in \mathcal{A}$$

is the dual basis vector to

$$\Phi\begin{pmatrix} (m')_{n-1} \\ [m]_n \\ (m)_{n-1} \end{pmatrix} \in \mathcal{C}$$

in the pairing of the algebras $\mathcal{C}$ and $\mathcal{A}$ of creation and annihilation operators as described in [6, § 1]. We desire that

$$\Phi\begin{pmatrix} (\bar{m}')_{n-1} \\ [\bar{m}]_n \\ (\bar{m})_{n-1} \end{pmatrix}$$

should be a $U(n) \times U(n)$ Gelfand-Zetlin state vector in $V_{\bar{m}} \otimes V_{\bar{m}}$.

DEFINITION A.3. Let $n \geqq 2$. With notation as above we define

$$B\begin{pmatrix}(\bar{m}')_{n-1}\\ [\bar{m}]_n\\ (\bar{m})_{n-1}\end{pmatrix} \equiv (-1)^{\varphi(m')-\varphi(m)} B\overline{\begin{pmatrix}(m')_{n-1}\\ [m]_n\\ (m)_{n-1}\end{pmatrix}}, \tag{A.4}$$

where if (m) is a $U(n)$ Gelfand pattern then

$$\varphi(m) = \sum_{j=1}^{n} \sum_{i=1}^{j} m_{ij}.$$

LEMMA A.5. *With $n \geqq 2$ and notation as above*

$$\Phi\begin{pmatrix}(\bar{m}')_{n-1}\\ [\bar{m}]\\ (\bar{m})_{n-1}\end{pmatrix} = \mathcal{M}(m)^{-1/2} B\begin{pmatrix}(\bar{m}')_{n-1}\\ [\bar{m}]_n\\ (\bar{m})_{n-1}\end{pmatrix} \in \mathcal{A}$$

is a Gelfand-Zetlin state vector in $V_{\bar{m}} \otimes V_{\bar{m}}$.

Proof. After applying (1.10), (1.14), (2.17) and (1.17a and b) of [6] (recalling the different notation in [6]), this is essentially identity (2.112) of Louck [17]. The proof of identity (2.112) is as follows. Identity (2.112) is certainly true when $(m') = (m)$ are highest weight states of V_m. Then applying lowering operations as in (2.98) and (2.99) of [17] and using (2.114) of [17], one proves (2.112) by induction for arbitrary Gelfand states (m') and (m) of V_m.

We have the following proposition.

PROPOSITION A.6. *Let p be a nonnegative integer and*

$$(p) = \begin{pmatrix}[p, 0, \cdots, 0]_n\\ (p)_{n-1}\end{pmatrix}$$

be a Gelfand state of $V_{[p,0,\cdots,0]_n}$. Let $[m]_n$ and $[M]_n$ be $U(n)$ highest weights and assume that $[m]_n$ and $[M]_n$ are partitions. Let (m) and (M) be states in $V_{[m]_n}$ and $V_{[M]_n}$ respectively. Let $V_{[M]_n}$ occur in $V_{[p,0,\cdots,0]_n} \otimes V_{[m]_n}$ and let

$$(\Gamma) = \begin{pmatrix}(\Gamma)_{n-1}\\ [p, 0, \cdots, 0]_n\end{pmatrix}$$

be the unique operator pattern (see [17] or [6]) such that $[M]_n = \Delta(\Gamma) + [M]_n$. For $n \geqq 2$ and with notation as above, we have

$$\begin{aligned}&\left\langle (M) \middle| \left\langle \begin{matrix}(\Gamma)_{n-1}\\ [p, 0, \cdots, 0]_n\\ (p)_{n-1}\end{matrix} \right\rangle \middle| (m) \right\rangle\\ &= (-1)^{p+\varphi(M)-\varphi(m)} \left[\frac{d([M]_n)}{d([m]_n)}\right]^{1/2} \left\langle (\bar{m}) \middle| \left\langle \begin{matrix}(\Gamma_{n-1}\\ [p, 0, \cdots, 0]_n\\ (p)_{n-1}\end{matrix} \right\rangle \middle| (\bar{M}) \right\rangle\end{aligned} \tag{A.7}$$

where, for any $U(n)$ highest weight $\lambda = [\lambda_1, \cdots, \lambda_n]$,

$$d(\lambda) = \frac{\prod_{1 \leqq i < j \leqq n} (p_{in} - p_{jn})}{\prod_{i=1}^{n-1} i!} \tag{A.8}$$

and $p_{in} = \lambda_i + n - i$ for $1 \leqq i \leqq n$.

Proof. Let

$$(m') = \begin{pmatrix}[m]_n\\ (m')_{n-1}\end{pmatrix}$$

be the highest weight state in $V_{[m]_n}$ and

$$\begin{pmatrix}[p,0,\cdots,0]_n\\ (0)_{n-1}\end{pmatrix}$$

be the lowest weight state in $V_{[p,0,\cdots,0]_n}$. With notation as in [6] we have

$$(\mathcal{M}([M]_n)\mathcal{M}([m]_n))^{1/2}\left\langle\begin{pmatrix}(m')_{n-1}\\ [M]_n\\ (M)_{n-1}\end{pmatrix}\middle| B\begin{pmatrix}(0)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{pmatrix}(A)\middle|\begin{pmatrix}(m')_{n-1}\\ [m]_n\\ (m)_{n-1}\end{pmatrix}\right\rangle$$

$$=\left\langle B\begin{pmatrix}(m')_{n-1}\\ [M]_n\\ (M)_{n-1}\end{pmatrix}(A), B\begin{pmatrix}(0)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{pmatrix}(A)B\begin{pmatrix}(m')_{n-1}\\ [m]_n\\ (m)_{n-1}\end{pmatrix}(A)\right\rangle \tag{A.9}$$

$$=\left\langle \overline{B\begin{pmatrix}(0)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{pmatrix}(A)}\,\overline{B\begin{pmatrix}(m')_{n-1}\\ [m]_n\\ (m)_{n-1}\end{pmatrix}(A)}, \overline{B\begin{pmatrix}(m')_{n-1}\\ [M]_n\\ (M)_{n-1}\end{pmatrix}(A)}\right\rangle \tag{A.10}$$

$$=(-1)^{p+\varphi(M)-\varphi(m)}\left\langle \overline{B\begin{pmatrix}(0)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{pmatrix}(A)} \cdot B\begin{pmatrix}(\bar m')_{n-1}\\ [\bar m]_n\\ (\bar m)_{n-1}\end{pmatrix}(\bar A), B\begin{pmatrix}(\bar m')_{n-1}\\ [\bar M]_n\\ (\bar M)_{n-1}\end{pmatrix}(\bar A)\right\rangle \tag{A.11}$$

by Definition A.3 and Lemma A.5, and

$$=(-1)^{p+\varphi(M)-\varphi(m)}\frac{d([M]_n)\mathcal{M}([M]_n)}{d([m]_n)} \cdot\left\langle\begin{pmatrix}[\bar m]_n\\ (\bar m)_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[\bar M]_n\\ (\bar M)_{n-1}\end{pmatrix}\right\rangle \cdot\left\langle\begin{pmatrix}[\bar m]_n\\ (\bar m')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\ (0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[\bar M]_n\\ (\bar m')_{n-1}\end{pmatrix}\right\rangle \tag{A.12}$$

by [6, eq. (2.24)].

From [6, eq. (2.12)] we also have

$$(\mathcal{M}([M]_n)\mathcal{M}([m]_n))^{1/2}\left\langle\begin{pmatrix}(m')_{n-1}\\ [M]_n\\ (M)_{n-1}\end{pmatrix}\middle| B\begin{pmatrix}(0)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{pmatrix}(A)\middle|\begin{pmatrix}(m')_{n-1}\\ [m]_n\\ (m)_{n-1}\end{pmatrix}\right\rangle$$

$$=\mathcal{M}([M]_n)\left\langle\begin{pmatrix}[M]_n\\ (M)_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\ (p)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[m]_n\\ (m)_{n-1}\end{pmatrix}\right\rangle \cdot\left\langle\begin{pmatrix}[M]_n\\ (m')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\ (0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[m]_n\\ (m)_{n-1}\end{pmatrix}\right\rangle. \tag{A.13}$$

If we set $(p)_{n-1}=(0)_{n-1}$ and $(M)_{n-1}=(m)_{n-1}=(m')_{n-1}$ and equate (A.12) and (A.13), we obtain

$$\begin{aligned}&\frac{d([M]_n)}{d([m]_n)}\left\langle\begin{pmatrix}[\bar m]_n\\(\bar m')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\(0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[\bar M]_n\\(\bar m')_{n-1}\end{pmatrix}\right\rangle^2\\ &=\left\langle\begin{pmatrix}[M]_n\\(m')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\(0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[m]_n\\(m)_{n-1}\end{pmatrix}\right\rangle^2.\end{aligned}\tag{A.14}$$

From formula (2.13) above for reduced Wigner coefficients and formula (3.8) of [6] which expresses a $U(n)$ Wigner coefficient in terms of reduced Wigner coefficients, one checks that both Wigner coefficients appearing in (A.14) are postive real numbers. It follows that

$$\begin{aligned}&\left[\frac{d([M]_n)}{d([m]_n)}\right]^{1/2}\left\langle\begin{pmatrix}[\bar m]_n\\(\bar m')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\(0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[\bar M]_n\\(\bar m')_{n-1}\end{pmatrix}\right\rangle\\ &=\left\langle\begin{pmatrix}[M]_n\\(m')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_{n-1}\\ [p,0,\cdots,0]_n\\(0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}[m]_n\\(m')_{n-1}\end{pmatrix}\right\rangle>0.\end{aligned}\tag{A.15}$$

After equating (A.12) and (A.13) and applying (A.15), we obtain identity (A.7). Q.E.D.

PROPOSITION A.16. *Let $n\geqq 2$. With notation as in equations* (2.10)-(2.14) *above, where h, h' are $U(n+1)$ highest weights and q, q' are $U(n)$ highest weights, we have*

$$\begin{aligned}\left\langle\begin{pmatrix}h\\q\end{pmatrix}\middle|\begin{bmatrix}[p,0,\cdots,0]_{n+1}\\ [p',0,\cdots,0]_n\end{bmatrix}\middle|\begin{pmatrix}h'\\q'\end{pmatrix}\right\rangle&=(-1)^{p'}\left[\frac{d(h)\,d(q')}{d(h')\,d(q)}\right]^{1/2}\\ &\cdot\left\langle\begin{pmatrix}\bar h'\\ \bar q'\end{pmatrix}\middle|\begin{bmatrix}[p,0,\cdots,0]_{n+1}\\ [p',0,\cdots,0]_n\end{bmatrix}\middle|\begin{pmatrix}\bar h\\ \bar q\end{pmatrix}\right\rangle\end{aligned}\tag{A.17}$$

where $d(h)$, $d(h')$ are defined by formula (A.8) (*as dimensions of $U(n+1)$ representations*) *and similarly for $d(q)$, $d(q')$* (*as dimensions of $U(n)$ representations*).

Proof. Consider the Wigner coefficient:

$$\left\langle\begin{pmatrix}h\\q\\(q'')_{n-1}\end{pmatrix}\middle|\left\langle\begin{matrix}(\Gamma)_n\\ [p,0,\cdots,0]_{n+1}\\ [p',0,\cdots,0]_n\\(0)_{n-1}\end{matrix}\right\rangle\middle|\begin{pmatrix}h'\\q'\\(q'')_{n-1}\end{pmatrix}\right\rangle\tag{A.18}$$

where

$$(\Gamma)_{n+1}=\begin{pmatrix}[p,0,\cdots,0]_{n+1}\\(\Gamma)_n\end{pmatrix}$$

is the unique operator pattern such that

$$\Delta(\Gamma)_{n+1}+h'=h\quad\text{and}\quad\begin{pmatrix}q'\\(q'')_{n-1}\end{pmatrix}$$

is a $U(n)$ highest weight state in $V_{q'}$.

Applying formula (3.8) of [6], we find

$$\left\langle\!\!\left\langle \begin{pmatrix} h \\ q \\ (q'')_{n-1} \end{pmatrix} \right| \left\langle \begin{matrix} (\Gamma)_n \\ [p,0,\cdots,0]_{n+1} \\ [p',0,\cdots,0]_n \\ (0)_{n-1} \end{matrix} \right\rangle \left| \begin{pmatrix} h' \\ q' \\ (q'')_{n-1} \end{pmatrix} \right\rangle\!\!\right\rangle$$

$$\text{(A.19)} \qquad = \left\langle \begin{pmatrix} h \\ q \end{pmatrix} \right\| \begin{bmatrix} [p,0,\cdots,0]_{n+1} \\ [p',0,\cdots,0]_n \end{bmatrix} \left\| \begin{pmatrix} h' \\ q' \end{pmatrix} \right\rangle$$

$$\cdot \left\langle \begin{pmatrix} q \\ (q'')_{n-1} \end{pmatrix} \right| \left\langle \begin{matrix} (\gamma)_{n-1} \\ [p',0,\cdots,0]_n \\ (0)_{n-1} \end{matrix} \right\rangle \left| \begin{pmatrix} q' \\ (q'')_{n-1} \end{pmatrix} \right\rangle$$

where

$$(\gamma)_n = \begin{pmatrix} [p',0,\cdots,0]_n \\ (\gamma)_{n-1} \end{pmatrix}$$

is the unique operator pattern such that $q' + \Delta(\gamma)_n = q$. Similarly we have

$$\left\langle\!\!\left\langle \begin{pmatrix} \bar{h}' \\ \bar{q}' \\ (\bar{q}'')_{n-1} \end{pmatrix} \right| \left\langle \begin{matrix} (\Gamma)_n \\ [p,0,\cdots,0]_{n+1} \\ [p',0,\cdots,0]_n \\ (0)_{n-1} \end{matrix} \right\rangle \left| \begin{pmatrix} \bar{h} \\ \bar{q} \\ (\bar{q}'')_{n-1} \end{pmatrix} \right\rangle\!\!\right\rangle$$

$$\text{(A.20)} \qquad = \left\langle \begin{pmatrix} \bar{h}' \\ \bar{q}' \end{pmatrix} \right\| \begin{bmatrix} [p,0,\cdots,0]_{n+1} \\ [p',0,\cdots,0]_n \end{bmatrix} \left\| \begin{pmatrix} \bar{h} \\ \bar{q} \end{pmatrix} \right\rangle$$

$$\cdot \left\langle \begin{pmatrix} \bar{q}' \\ (\bar{q}'')_{n-1} \end{pmatrix} \right| \left\langle \begin{matrix} (\gamma)_{n-1} \\ [p',0,\cdots,0]_n \\ (0)_{n-1} \end{matrix} \right\rangle \left| \begin{pmatrix} \bar{q} \\ (\bar{q}'')_{n-1} \end{pmatrix} \right\rangle .$$

Now applying Proposition A.6 to relate the $U(n+1)$ and $U(n)$ Wigner coefficients appearing in (A.19) and (A.20) and using that

$$\text{(A.21)} \qquad \left\langle \begin{pmatrix} q \\ (q'')_{n-1} \end{pmatrix} \right| \left\langle \begin{matrix} (\gamma)_{n-1} \\ [p',0,\cdots,0]_n \\ (0)_{n-1} \end{matrix} \right\rangle \left| \begin{pmatrix} q' \\ (q'')_{n-1} \end{pmatrix} \right\rangle \neq 0$$

as in (A.15), we obtain identity (A.17).

QUADRATURE SUMS INVOLVING *p*TH POWERS OF POLYNOMIALS*

D. S. LUBINSKY†, A. MATɇ AND P. NEVAI§

Abstract. R. Askey's problem of estimating quadrature sums involving pth powers of polynomials $(0<p<\infty)$ in terms of integrals, is solved. In its simplest form, the method can extend the large sieve of number theory to sums involving pth powers, rather than just squares, of trigonometric polynomials. Further, the method yields estimates whenever the abscissas in the quadrature have a suitable spacing and the weights have suitable bounds. In particular, it may be applied to generalized Jacobi weights and to Freud weights.

Key words. quadrature sums, pth powers, orthogonal polynomials, Freud weights, the large sieve, generalized Jacobi weights

AMS(MOS) subject classifications. Primary 41A55; secondary 42C05

1. Introduction. The large sieve of number theory is an inequality for trigonometric polynomials of degree at most n,

$$S_n(\tau)=\sum_{k=-n}^{n} a_k e^{ik\tau}, \qquad \tau\in[0,2\pi],$$

which states that

$$\sum_{j=1}^{m}|S_n(\tau_j)|^2\leqq\{2n+\delta^{-1}\}(2\pi)^{-1}\int_0^{2\pi}|S_n(\tau)|^2\,d\tau, \tag{1.1}$$

whenever $0\leqq\tau_1<\tau_2<\cdots<\tau_M\leqq 2\pi$ and

$$\delta=\min\{\tau_2-\tau_1,\tau_3-\tau_2,\cdots,\tau_m-\tau_{m-1},2\pi-(\tau_m-\tau_1)\}>0. \tag{1.2}$$

See Montgomery [16, p. 548 and p. 559, Thm. 3], but note the different notation.

It is the purpose of this paper to extend (1.1) to sums of the form $\sum_{j=1}^{n}|S_n(\tau_j)|^p$, $p>0$, and to show how such sums may be estimated using L_2 techniques. While such sums have been considered by Davenport and Halberstam [4] and Forti and Viola [5], their estimates did not include the case $0<p<1$, and the upper bounds involved terms such as $\sum_{k=0}^{n-1}|a_k|^p(k+2)^{p-2}$, rather than $\int_0^{2\pi}|S_n(\tau)|^p\,d\tau$. In this paper, we shall also solve a problem of Askey [2] on quadrature sums involving pth powers of polynomials. Before discussing the latter, we first illustrate the method in the case of trigonometric polynomials. Let

$$D_n(\tau)=\sum_{k=-n}^{n} e^{ik\tau}, \qquad \tau\in[0,2\pi). \tag{1.3}$$

Applying (1.1) to $D_n(x-\tau)$, and noting that

$$\int_0^{2\pi} |D_n(\tau)|^2\,d\tau = 2\pi(2n+1), \tag{1.4}$$

we obtain for any $x \in [0, 2\pi)$,

$$\sum_{j=1}^{m} |D_n(x-\tau_j)|^2 \leqq \{2n+\delta^{-1}\}(2n+1). \tag{1.5}$$

We remark that it is unnecessary to use the large sieve to derive an inequality of the form (1.5), and we pause in our exposition to outline the proof of such an inequality. First, note the straightforward bound

$$|D_n(\tau)| \leqq \min\{2n+1, \pi/|\tau|\}, \qquad |\tau| \leqq \pi.$$

Let $\varepsilon = (2n+1)^{-1}+\delta$ and assume (as we may) that all $x-\tau_j$ $(j=1,2,\cdots,m)$ lie in $[-\pi,\pi]$. Then

$$\begin{aligned}\sum_{j=1}^{m} |D_n(x-\tau_j)|^2 &\leqq \sum_{|x-\tau_j|\geqq\varepsilon} (\pi/|x-\tau_j|)^2 + \sum_{|x-\tau_j|<\varepsilon} (2n+1)^2\\ &\leqq 2(2n+1)^2 + 2\sum_{j\delta\geqq\varepsilon} (\pi/(j\delta))^2 + 2\sum_{j\delta<\varepsilon} (2n+1)^2.\end{aligned}$$

Here we have used the fact that in each interval of length δ, there is at most one point of the form $x-\tau_j$. Then, using the definition of ε,

$$\begin{aligned}\sum_{j=1}^{m} |D_n(x-\tau_j)|^2 &\leqq 2(2n+1)^2 + 2(\pi/\delta)^2 \sum_{j\geqq((2n+1)\delta)^{-1}+1} j^{-2} + 2(2n+1)^2\{\varepsilon/\delta+1\}\\ &\leqq 2(\pi/\delta)^2((2n+1)\delta) + 2(2n+1)^2\{2+((2n+1)\delta)^{-1}\}\\ &\leqq 22(2n+1)\{n+\delta^{-1}\}.\end{aligned}$$

This establishes (1.5) except for a factor of 22.

We now return to our main theme. Let $p>0$. Theorem 6 in Maté and Nevai [14] shows that for any trigonometric polynomial $S_n(\tau)$ as above,

$$|S_n(\tau)|^p \leqq (2+2np)e(8\pi)^{-1} \int_0^{2\pi} |S_n(u)|^p\,du, \qquad \tau \in [0, 2\pi]. \tag{1.6}$$

Let k denote the smallest positive integer such that $kp \geqq 2$. Applying (1.6) to $S_n(\tau)D_n^k(x-\tau)$ with x fixed, we obtain

$$|S_n(\tau)D_n^k(x-\tau)|^p \leqq (2+2n(k+1)p)e(8\pi)^{-1} \int_0^{2\pi} |S_n(u)D_n^k(x-u)|^p\,du.$$

Now setting $\tau = x$, and noting that $kp = \{kp-2\}+2$, and

$$|D_n(x-u)| \leqq 2n+1 = D_n(0),$$

we obtain

$$|S_n(x)|^p \leqq (2+2n(k+1)p)e(8\pi)^{-1}(2n+1)^{-2} \int_0^{2\pi} |S_n(u)|^p D_n^2(x-u)\,du. \tag{1.7}$$

Next, $(k-1)p<2$, so that

$$2+2n(k+1)p < 2+2n(2p+2) < (2n+1)2(p+1)$$

and hence

$$|S_n(x)|^p \leqq (p+1)e(4\pi)^{-1}(2n+1)^{-1} \int_0^{2\pi} |S_n(u)|^p D_n^2(x-u)\,du. \tag{1.8}$$

Applying Jensen's inequality (Zygmund [24, p. 24]) to (1.8), and noting (1.4), we obtain the following proposition.

THEOREM 1. *Let* $0<p<\infty$. *Let* $\psi(t)$ *be convex, nonnegative and nondecreasing in* $[0,\infty)$. *For any trigonometric polynomial* $S_n(t)$ *of degree at most n,*

$$\psi(|S_n(x)|^p)\leqq(2\pi)^{-1}(2n+1)^{-1}\int_0^{2\pi}\psi(|S_n(u)|^p(p+1)e/2)D_n^2(x-u)\,du, \tag{1.9}$$
$$x\in[0,2\pi].$$

If $0<p<1$, t^p is concave, rather than convex, and so it is meaningful to include the pth power in (1.9). Applying (1.5) to (1.9), we obtain

THEOREM 2. *Assuming the notation of* (1.2) *and Theorem* 1,

$$\sum_{j=1}^{m}\psi(|S_n(\tau_j)|^p)\leqq(2n+\delta^{-1})(2\pi)^{-1}\int_0^{2\pi}\psi(|S_n(u)|^p(p+1)e/2)\,du. \tag{1.10}$$

Theorems 1 and 2 are useful in trigonometric interpolation and approximation.

In 1969, Askey [2, p. 553] posed the following problem: Let $P_{n-1}(x)$ be any polynomial of degree at most $n-1$. Let $\{x_{nk}\}_{k=1}^{n}$ be the zeros of the polynomials orthogonal with respect to $d\alpha(x)$, a positive measure on $[-1,1]$, and let $\{\lambda_{nk}\}_{k=1}^{n}$ be the corresponding Christoffel numbers. When is

$$\sum_{k=1}^{n}\lambda_{nk}|P_{n-1}(x_{nk})|^p\leqq C\int_{-1}^{1}|P_{n-1}(x)|^p\,d\alpha(x), \tag{1.11}$$

where C is independent of P_{n-1} and n? Such inequalities are essential in various problems in approximation theory, and in particular, in investigating mean convergence of Lagrange interpolation (Askey [1], Bonan [3], Knopfmacher and Lubinsky [9], Nevai [18], [19], [20], [22], [23]).

For $p=2$, the Gauss quadrature formula establishes (1.11) with $C=1$ and with equality of both sides. Askey proved (1.11) for certain Jacobi weights for $p\geqq1$. Subsequently, Nevai [20, pp. 167-168] proved inequalities generalizing (1.11) for $p\geqq1$ and for generalized Jacobi weights on $[-1,1]$. For the Hermite weight, estimates such as (1.11) appear in Nevai [20] with the range of summation suitably restricted. Similar estimates for generalized Hermite weights appear in Bonan [3] and for Freud weights in Knopfmacher and Lubinsky [9].

To date, no one has succeeded in dealing with the case $0<p<1$. We shall fill this gap, using much the same method as that used to prove Theorems 1 and 2. Furthermore, we can treat general quadrature sums with suitably spaced abscissas, rather than just Gauss quadrature sums. As before, estimation of sums involving pth powers is reduced to estimation of a sum involving an even integer power of a specific polynomial. The specific polynomial (which is the analogue of $D_n(x-t)$ above) is

$$K_n(v,x,t)=\sum_{j=0}^{n-1}p_j(v,x)p_j(v,t), \tag{1.12}$$

the kernel function associated with the Chebyshev weight

$$v(t)=\begin{cases}(1-t^2)^{-1/2}, & t\in(-1,1),\\ 0, & t\notin(-1,1).\end{cases} \tag{1.13}$$

Here $p_j(v,x)$, $j=0,1,2,\cdots$, are the orthonormal Chebyshev polynomials associated with v. Finally, the sum involving $K_n(v,x,t)$ may be estimated using the large sieve or using methods of Nevai [20, p. 167].

Before stating the results for weights on $[-1,1]$, we need the definition of the generalized Jacobi weights (GJ), studied in [20], [21], [23]. Throughout, $C, C_1, C_2, \cdots$, denote positive constants independent of n and x, and of all polynomials P of degree at most n, or at most a positive constant times n. Further, we use, o, O as in [20]. Thus, for example, $f(x) \sim g(x)$, if there exist C_1 and C_2 such that $C_1 \leqq f(x)/g(x) \leqq C_2$ for all relevant x.

DEFINITION 3. Let $-1 = t_1 > t_2 > \cdots > t_N = 1$ and $\Gamma_k > -1$, $k = 1, 2, \cdots, N$. Let $w(t) = 0$, $t \notin [-1, 1]$ and

$$w(t) \sim \prod_{k=1}^{N} |t - t_k|^{\Gamma_k}, \qquad t \notin [-1, 1]. \tag{1.14}$$

Then we say that w is a generalized Jacobi weight and write $w \in \mathrm{GJ}$. The following quantities are associated with w:

$$\bar{w}_n(t) = (\sqrt{1-t} + 1/n)^{2\Gamma_1 + 1} \left\{ \prod_{k=2}^{N-1} (|t - t_k| + 1/n)^{\Gamma_k} \right\} (\sqrt{1+t} + 1/n),^{2\Gamma_n + 1}, \tag{1.15}$$
$$t \in [-1, 1], \qquad n = 1, 2, \cdots,$$

and $\bar{w}_n(t) = 0$, $t \notin [-1, 1]$. Further for $0 < p < \infty$ and $n = 1, 2, 3, \cdots$,

$$\lambda_n(w, p, x) = \inf \int_{-1}^{1} \frac{|P(u)|^p w(u)\, du}{|P(x)|^p}, \qquad x \in [-1, 1], \tag{1.16}$$

where the inf is over all polynomials P of degree at most $n-1$. In particular,

$$\lambda_n(w, x) = \lambda_n(w, 2, x), \qquad x \in [-1, 1].$$

THEOREM 4. *Let $w \in GJ$, $0 < p$, $L < \infty$ and l be a positive integer. Further, let $\psi(t)$ be convex, nonnegative and nondecreasing in $[0, \infty)$. Then for all polynomials $P(x)$ of degree at most ln,*

$$\psi(|P(x)|^p) \bar{w}_n(x) \leqq C_1 n^{-L+1} \int_{-1}^{1} \psi(C_2 |P(u)|^p) |K_n(v, x, u)|^L w(u)\, du, \tag{1.17}$$
$$x \in [-1, 1].$$

THEOREM 5. *Let $w \in GJ$, $0 < p < \infty$ and let l be a positive integer. Further, let $\psi(t)$ be convex, nonnegative and nondecreasing in $[0, \infty)$. Given*

$$-1 \leqq y_m < y_{m-1} < \cdots < y_1 \leqq 1,$$

write

$$\theta_j = \arccos(y_j) \in [0, \pi], \qquad j = 1, 2, \cdots, m$$

and let

$$\delta = \min\{\theta_2 - \theta_1, \theta_3 - \theta_2, \cdots, \theta_m - \theta_{m-1}\} > 0. \tag{1.18}$$

Then for all polynomials $P(x)$ of degree at most ln,

$$\sum_{j=1}^{m} \bar{w}_n(y_j) \psi(|P(y_j)|^p) \leqq C_1 \{n + \delta^{-1}\} \int_{-1}^{1} \psi(C_2 |P(u)|^p) w(u)\, du, \tag{1.19}$$

and

$$\sum_{j=1}^{m} \lambda_n(w, y_j) \psi(|P(y_j)|^p) \leqq C_3 \{1 + (n\delta)^{-1}\} \int_{-1}^{1} \psi(C_2 |P(u)|^p) w(u)\, du. \tag{1.20}$$

The constants C_1, C_2 and C_3 are independent of m, $y_1, y_2, \cdots, y_m$, δ, n and P.

COROLLARY 6. *Let $\{x_{nj}\}$ and $\{\lambda_{nj}\}$ denote the abscissas and Christoffel numbers in the Gauss quadrature for the weight $w \in GJ$. With the notation of the previous theorem,*

$$\sum_{j=1}^{n} \lambda_{nj}\psi(|P(x_{nj})|^p) \leqq C_1 \int_{-1}^{1} \psi(C_2|P(u)|^p)w(u)\,du, \tag{1.21}$$

for all polynomials P of degree at most ln.

In the case $\psi(t)=t$ and $p \geqq 1$, Corollary 6 is implied by Nevai [20, Thm. 9.25, p. 168]. Further for $\psi(t)=t$, Corollary 6 ensures that Nevai [23, (24), p. 675] is correct as stated, even for $0<p<1$.

Finally, we state the analogues of the above results for weights with the whole real line as support. First, however, we need a definition of $\mathscr{F}$, a suitable class of Freud weights:

DEFINITION 7. Let $W(x)=\exp(-Q(x))$, $x \in \mathbb{R}$, where Q is even and continuous in $\mathbb{R}$, and $Q''(x)$ is continuous and nonnegative for large positive x. Then we say W is a Freud weight and write $W \in \mathscr{F}$ if either

(1.22) I. $Q''(x)$ is positive and nondecreasing for large positive x, or

II. There exists $\alpha \in (1,2)$ and C and C_1 such that

$$xQ''(x)/Q'(x) \leqq C, \qquad x \in (C_1, \infty), \tag{1.23}$$

and

$$\lim_{x\to\infty} xQ'(x)/Q(x) = \alpha. \tag{1.24}$$

Associated with W are the following quantities: For large enough n, q_n denotes the positive root of the equation

$$q_nQ'(q_n) = n. \tag{1.25}$$

Further, given a nonnegative integer j, $0<p\leqq\infty$ and $n=j+1, j+2, \cdots$, we define the generalized Christoffel functions

$$\lambda_{n,p}(W,j,x) = \inf \|PW\|_{L_p(\mathbb{R})}/|P^{(j)}(x)|, \qquad x \in \mathbb{R}, \tag{1.26}$$

where the inf is over all polynomials P of degree at most n. We also define the classical Christoffel functions

$$\lambda_n(W^2,x) = \lambda_{n,2}^2(W,0,x) = \inf \int_{-\infty}^{\infty} \frac{(PW(u))^2\,du}{P^2(x)}, \qquad n=1,2,\cdots, \quad x \in \mathbb{R}. \tag{1.27}$$

The essential feature of $W \in \mathscr{F}$ is the following: Lower bounds are available for the generalized Christoffel functions (Freud [6], [8], Lubinsky [13], Levin and Lubinsky [10], [11] and inequalities are available which connect the L_p norms of weighted polynomials over finite and infinite ranges (Nevai [17], Mhaskar and Saff [15], Lubinsky [12], [13]). As concrete examples of weights $W \in \mathscr{F}$ satisfying I, we mention $\exp(-|x|^\alpha(\log|x|)^\beta)$, $\alpha \geqq 2$, $\beta \geqq 0$, and $\exp(-\exp(|x|^\alpha))$, $\alpha>0$, suitably modified for small $|x|$. As examples of weights $W \in \mathscr{F}$ satisfying II, we mention $\exp(-|x|^\alpha(\log|x|)^\beta)$, $1<\alpha<2$, $\beta \in \mathbb{R}$, suitably modified for small $|x|$.

THEOREM 8. *Let $W \in \mathscr{F}$, $0<p<\infty$, and let l be a positive integer. Let ψ be convex, nonnegative and nondecreasing in $[0,\infty)$. There exists a positive constant C^* with the following property: Let*

$$-C^*q_n \leqq y_m < y_{m-1} < \cdots < y_1 \leqq C^*q_n,$$

and

$$\delta = \min\{y_j - y_{j-1}: j=2,3,\cdots,m\} > 0. \tag{1.28}$$

Then for all polynomials P of degree at most ln,

$$(1.29)\qquad \sum_{j=1}^{m} \psi(|PW|^p(y_j)) \leqq C_1\{n/q_n+\delta^{-1}\} \int_{-\infty}^{\infty} \psi(C_2|PW|^p(u))\,du.$$

The constants C_1 and C_2 are independent of m, δ, $\{y_j\}$, n and P. If in addition (1.23) *holds, then we may take C^* arbitrarily large, but C_1 and C_2 will depend on C^*.*

We shall prove Theorem 8 using the kernel function for the Chebyshev weight. By using the kernel function for the weight W^2, we can also estimate sums of the form

$$\sum_{j=1}^{m} \psi(|P(y_j)|^p)\,W^2(y_j),$$

but we omit the more complicated proof.

For the Hermite weight, the following corollary is related to results in Nevai [22] and for generalized Hermite weights to results in Bonan [3]. For Freud weights, a similar result appears in Knopfmacher and Lubinsky [9], but for all cases, the following corollary is new when $0<p<1$.

COROLLARY 9. *Let $\{x_{nj}\}$ and $\{\lambda_{nj}\}$ denote the abscissas and Christoffel numbers in the Gauss quadrature for the weight W^2, where $W\in\mathcal{F}$. Let $-\infty<r<2$. With the notation of the previous theorem, there exists C^* such that*

$$(1.30)\qquad \sum_{|x_{nj}|\leqq C^*q_n} \lambda_{nj}|P(x_{nj})|^p W^{-r}(x_{nj}) \leqq C_1 \int_{-\infty}^{\infty} |P(u)|^p W^{2-r}(u)\,du,$$

for all polynomials P of degree at most ln.

Note that even when (1.23) holds, we could not prove (1.30) for the full sum extended over $j=1,2,\cdots,n$. The reason for this is that upper bounds for the Christoffel functions are not available near x_{n1} and x_{nn}.

The paper is organized as follows: In § 2, we prove the results for the finite interval, namely Theorems 4 and 5 and Corollary 6, and in § 3, we prove Theorem 8 and Corollary 9 for weights on the infinite interval.

2. Weights on [−1, 1]. The proof of Theorems 4 and 5 and Corollary 6 will use estimates on the L_p Christoffel functions:

LEMMA 2.1. *Let $w\in GJ$ and $0<p<\infty$. Then for $n=1,2,3,\cdots$,*

$$(2.1)\qquad \lambda_n(w,p,x)\sim\lambda_n(w,x)\sim n^{-1}\bar{w}_n(x),\qquad x\in[-1,1].$$

Proof. See Nevai [20, Thm. 6.3.28, p. 120], and note that if $w\in GJ$ and $w_1\in GJ$ and $w\sim w_1$, in $[-1,1]$, then $\lambda_n(w,p,x)\sim\lambda_n(w,x)$ in $[-1,1]$. □

We can now prove Theorem 4 in a special case:

Proof of Theorem 4 *when $\psi(t)=t$ and L is a positive even integer.* Let L be a fixed positive even integer. By definition of the Christoffel functions, we have for all polynomials P of degree at most ln, and for $|t|\leqq 1$,

$$(2.2)\qquad \begin{aligned} |P(t)|^p &\leqq \lambda_{ln}^{-1}(w,p,t)\int_{-1}^{1}|P(u)|^p w(u)\,du\\ &\leqq Cn\bar{w}_n^{-1}(t)\int_{-1}^{1}|P(u)|^p w(u)\,du, \end{aligned}$$

by Lemma 2.1, and as $\bar{w}_{ln}(x)\sim\bar{w}_n(x)$, $|x|\leqq 1$. Let k be the smallest integer such that

$kp \geqq L$. Applying (2.2) to the polynomial $P(t)K_n^k(v, x, t)$ with x fixed, we obtain

$$(2.3) \qquad |P(t)|^p |K_n(v, x, t)|^{kp} \leqq Cn\bar{w}_n^{-1}(t) \int_{-1}^{1} |P(u)|^p |K_n(v, x, u)|^{kp} w(u)\, du, \qquad x, t \in [-1, 1].$$

Next, we note that

$$(2.4) \qquad |K_n(v, x, t)| \leqq C_1 n, \qquad |x|, |t| \leqq 1,$$

and

$$(2.5) \qquad K_n(v, x, x) \sim n, \qquad |x| \leqq 1$$

(Nevai [20, p. 79, p. 108]). Setting $t = x$ in (2.3), and using (2.4) and (2.5) and $kp = L + \{kp - L\}$ with $kp - L \geqq 0$, we obtain for $|x| \leqq 1$,

$$(2.6) \qquad |P(x)|^p \leqq Cn^{-L+1}\bar{w}_n^{-1}(x) \int_{-1}^{1} |P(u)|^p K_n^L(v, x, u) w(u)\, du,$$

which is Theorem 4 in the special case mentioned. □

In order to complete the proof of Theorem 4, we must apply Jensen's inequality to (2.6). For this to be possible, we must obtain upper bounds for $\int_{-1}^{1} K_n^L(v, x, u) w(u)\, du$:

THEOREM 2.2. *Let $w \in GJ$. Let L be a positive even integer such that*

$$(2.7) \qquad L > 1 + \max\{2\Gamma_1 + 1, \Gamma_2, \Gamma_3, \cdots, \Gamma_{N-1}, 2\Gamma_N + 1\}.$$

Then with the notation of (1.12) *to* (1.16),

$$(2.8) \qquad \int_{-1}^{1} \{K_n(v, x, u)/K_n(v, x, x)\}^L w(u)\, du \sim n^{-1}\bar{w}_n(x), \qquad x \in [-1, 1].$$

Proof. In the special case $N = 2$, so that w is a Jacobi weight, this is Theorem 6.3.10 in Nevai [20, p. 109]. Let

$$I_n(x) = \int_{-1}^{1} \{K_n(v, x, u)/K_n(v, x, x)\}^L w(u)\, du, \qquad |x| \leqq 1, \quad n = 1, 2, \cdots.$$

By Lemma 2.1,

$$I_n(x) \geqq Cn^{-1}\bar{w}_n(x), \qquad |x| \leqq 1.$$

Thus we must prove

$$(2.9) \qquad I_n(x) \leqq C_1 n^{-1}\bar{w}_n(x), \qquad |x| \leqq 1.$$

First, note from (1.15) and (2.7) that

$$(2.10) \qquad \bar{w}_n(t) \geqq C_2(1/n)^{L-1}, \qquad |t| \leqq 1.$$

Let $\varepsilon = (1/4)\min_{i \neq j} |t_i - t_j|$, so that for $|x| \leqq 1$, the interval $(x - \varepsilon, x + \varepsilon)$ contains at most one of $\{t_1, t_2, \cdots, t_N\}$. Given $|x| \leqq 1$, we let t_c denote the element of $\{t_1, t_2, \cdots, t_N\}$ that is closest to x. If this does not uniquely define t_c, we take t_c to be the closest element from the left of x. We have

$$(2.11) \qquad w(u) \sim |u - t_c|^{\Gamma_c}, \qquad u \in (x - \varepsilon, x + \varepsilon) \cap [-1, 1],$$

with the constants in $\sim$ independent of $x\in[-1,1]$. Next, it follows from Lemma 6.3.8 in Nevai [20, p. 108] that

$$|K_n(v,x,u)|\leqq C/\{|x-u|+1/n\},\qquad |x|,|u|\leqq 1. \tag{2.12}$$

By (2.5), (2.11) and (2.12),

$$I_n(x)\leqq n^{-L}\int_{|x-u|\geqq\varepsilon}(C/\varepsilon)^L w(u)\,du \tag{2.13}$$

$$+C_3 n^{-L}\int_{|x-u|<\varepsilon}|u-t_c|^{\Gamma_c}(|x-u|+1/n)^{-L}\,du$$

$$\leqq C_4 n^{-1}\bar{w}_n(x)+C_3 n^{-L}J_n(x), \tag{2.14}$$

by (2.10) and where $L_n(x)$ denotes the second integral in (2.13), so that

$$J_n(x)=\int_{-\varepsilon}^{\varepsilon}|(x-t_c)-t|^{\Gamma_c}/(|t|+1/n)^L\,dt. \tag{2.15}$$

Suppose first that $2\leqq c\leqq N-1$, so that $t_c\in(-1,1)$. Let $z=x-t_c$. We consider two cases:

Case I. $|z|\geqq 1/n$. Let $\sigma=\operatorname{sign}(z)$. We see from (2.15) that

$$J_n(x)\leqq\left\{\int_{|t|\geqq|z|/2}+\int_{|t|\leqq|z|/2}\right\}|z-t|^{\Gamma_c}/(|t|+1/n)^L\,dt$$

$$\leqq|z|^{\Gamma_c+1}\int_{|u|\geqq 1/2}|\sigma-u|^{\Gamma_c}/(|uz|+1/n)^L\,du+C|z|^{\Gamma_c}\int_{|t|\leqq|z|/2}(|t|+1/n)^{-L}\,dt,$$

by the substitution $t=|z|u$ in the first integral, and as $|z-t|\sim|z|$ for t in the second integral. Then we see that

$$J_n(x)\leqq|z|^{\Gamma_c+1-L}\int_{|u|\geqq 1/2}|\sigma-u|^{\Gamma_c}|u|^{-L}\,du+|z|^{\Gamma_c}2C\int_{1/n}^{2}u^{-L}\,du$$

$$\leqq C|z|^{\Gamma_c}n^{L-1}, \tag{2.16}$$

as $L>1+\Gamma_c$ and $|z|\geqq 1/n$. Finally, we note that as $|z|=|x-t_c|\geqq 1/n$,

$$\bar{w}_n(x)\sim(|x-t_c|+1/n)^{\Gamma_c}\sim|z|^{\Gamma_c}$$

and hence (2.14) and (2.16) yield (2.9).

Case II. $|z|<1/n$. Making the substitution $t=u/n$ in (2.15), we see that

$$J_n(x)=n^{L-1-\Gamma_c}\int_{-n\varepsilon}^{n\varepsilon}|nz-u|^{\Gamma_c}/(|u|+1)^L\,du$$

$$\leqq n^{L-1-\Gamma_c}\max\left\{\int_{-\infty}^{\infty}|s-u|^{\Gamma_c}/(|u|+1)^L\,du\colon |s|\leqq 1\right\}$$

$$\leqq Cn^{L-1}\bar{w}_n(x),$$

as $|z|=|x-t_c|<1/n$ implies that

$$\bar{w}_n(x)\sim(|x-t_c|+1/n)^{\Gamma_c}\sim n^{-\Gamma_c}.$$

Then (2.14) again yields (2.9).

Finally, we must show that (2.9) holds when $t_c\in\{t_1,t_N\}$. Proceeding as at (2.13) and (2.14), we see

$$I_n(x)\leqq Cn^{-1}\bar{w}_n(x)+C\int_{|x-u|<\varepsilon}\{K_n(v,x,u)/K_n(v,x,x)\}^L|u-t_c|^{\Gamma_c}\,du.$$

$$\leqq Cn^{-1}\bar{w}_n(x)+Cn^{-1}(|x-t_c|^{1/2}+1/n)^{2\Gamma_c+1}$$

by Theorem 6.3.10 in Nevai [20, p. 109] as $t_c = \pm 1$, and (2.9) again follows. □

We can now complete the proof of Theorem 4:

Proof of Theorem 4 *in the general case.* Let L be a positive even integer satisfying (2.7). By (2.5) and (2.8), we may rewrite (2.6) as

$$|P(x)|^p \leqq C \int_{-1}^{1} |P(u)|^p K_n^L(v, x, u) w(u)\, du \Big/ \int_{-1}^{1} K_n^L(v, x, u) w(u)\, du,$$

for all polynomials P of degree at most ln. Applying Jensen's inequality (Zygmund [24, p. 24]), and then using (2.8), we obtain (1.17) for all sufficiently large positive even integers L. It then follows that (1.17) holds for all $L > 0$, since if $0 < L' < L$,

$$|K_n(v, x, u)|^L \leqq C n^{L-L'} |K_n(v, x, u)|^{L'}, \qquad |x|, |u| \leqq 1. \qquad \square$$

We shall need the full generality of the following lemma in the next section.

LEMMA 2.3. *Let* $-\infty < y_1 < y_2 < \cdots < y_m < \infty$ *and* $Y \geqq \max_j |y_j|$. *Let*

$$\theta_j = \arccos(y_j/Y) \in [0, \pi], \qquad j = 1, 2, \cdots, m, \tag{2.17}$$

and let

$$\delta = \min\{\theta_{j+1} - \theta_j : 1 \leqq j \leqq m-1\}. \tag{2.18}$$

Then for $|u| \leqq Y$,

$$\sum_{j=1}^{m} K_n^2(v, y_j/Y, u/Y) \leqq (8/\pi^2) n\{n + \delta^{-1}\}, \tag{2.19}$$

where $K_n(v, x, t)$ *and* v *are as in* (1.12) *and* (1.13).

Proof. Note that

$$p_0(v, x) = \pi^{-1/2} \quad \text{and} \quad p_j(v, x) = (2/\pi)^{1/2} \cos(j \arccos x),$$

$j = 1, 2, 3, \cdots, x \in [-1, 1]$. Let $\eta, \theta \in [0, \pi]$. If $'$ denotes that the first term in the sum is multiplied by $\frac{1}{2}$,

$$\begin{aligned} K_n(v, \cos\theta, \cos\eta) &= \frac{2}{\pi} \sum_{j=0}^{n-1}{}' \cos(j\theta) \cos(j\eta) \\ &= \frac{1}{\pi} \sum_{j=0}^{n-1}{}' \{\cos j(\eta + \theta) + (-1)^j \cos j(\eta - \theta + \pi)\} \\ &= \operatorname{Re}\{S_n(\eta + \theta) + S_n^*(\eta - \theta + \pi)\}, \end{aligned} \tag{2.20}$$

where

$$S_n(t) = \frac{1}{\pi} \sum_{j=0}^{n-1}{}' e^{ijt} \quad \text{and} \quad S_n^*(t) = \frac{1}{\pi} \sum_{j=0}^{n-1}{}' (-1)^j e^{ijt}.$$

Now let $|u| \leqq Y$ and write $\eta = \arccos(u/Y) \in [0, \pi]$. We see from (2.17) and (2.20) that

$$\sum_{j=1}^{m} K_n^2(v, y_j/Y, u/Y) \leqq 2 \sum_{j=1}^{m} \{|S_n(\eta + \theta_j)|^2 + |S_n^*(\eta - \theta_j + \pi)|^2\}.$$

Note that $\theta_j + \eta \in [0, 2\pi]$ and $\eta - \theta_j + \pi \in [0, 2\pi]$, $j = 1, 2, \cdots, m$, and further that the numbers $\theta_j + \eta$, $j = 1, 2, \cdots, m$ lie in an interval of length at most π, as do the numbers $\eta - \theta_j + \pi$, $j = 1, 2, \cdots, m$. We may thus apply the large sieve, namely (1.1), to S_n and S_n^* to deduce

$$\begin{aligned} \sum_{j=1}^{m} K_n^2(v, y_j/Y, u/Y) &\leqq 2\{2n + \delta^{-1}\} \frac{1}{2\pi} \int_0^{2\pi} \{|S_n(t)|^2 + |S_n^*(t)|^2\}\, dt \\ &\leqq 4n\pi^{-2}(2n + \delta^{-1}). \end{aligned} \qquad \square$$

An alternative proof of Lemma 2.3 may be based on the method in [20, pp. 167-168].

Proof of Theorem 5. First, (1.19) follows easily from Theorem 4 and Lemma 2.3 with $Y=1$, while (1.20) follows from (1.19) and Lemma 2.1.

Proof of Corollary 6. Let $\theta_{nj}=\arccos(x_{nj})\in(0,\pi), j=1,2,\cdots,n$, and assume the zeros x_{nj} are ordered so that $\theta_{nj}>\theta_{n,j-1}, j=2,3,\cdots,n$. By Theorem 9.22 in Nevai [20, p. 167],

$$\theta_{nj}-\theta_{n,j-1}\sim 1/n, \qquad j=1,2,3,\cdots,n.$$

Hence (1.21) follows directly from (1.20). □

3. Weights on ℝ. First, we need some properties of q_n, defined by (1.25).

LEMMA 3.1. *Let $W\in\mathcal{F}$.*

(i) *For large enough n,*

$$1\leqq q_{2n}/q_n\leqq 2.$$

(ii) *If* (1.23) *holds, then there exists $C>1$ such that*

$$q_{2n}/q_n\geqq C>1, \quad \textit{for } n \textit{ large enough.}$$

(iii) *Suppose Q'' satisfies* (1.22). *Let ξ_n denote the positive root of the equation*

$$\xi_n^2 Q''(\xi_n)=n, \tag{3.1}$$

for n large enough. Then

$$q_n\sim\xi_n, \quad \textit{for } n \textit{ large enough.} \tag{3.2}$$

Proof. (i), (ii). These follow exactly as in Freud [8, p. 22].

(iii). By monotonicity of Q'', for n large enough,

$$\begin{aligned} q_nQ'(q_n)=n=\xi_n^2Q''(\xi_n)&\leqq\xi_n\int_{\xi_n}^{2\xi_n}Q''(u)\,du\\ &=\xi_n(Q'(2\xi_n)-Q'(\xi_n))\leqq\xi_nQ'(2\xi_n),\end{aligned}$$

for n large, by (1.22). As $uQ'(u)$ is nondecreasing for large u, we deduce that $q_n\leqq 2\xi_n$. Further for some large enough A,

$$\begin{aligned} q_nQ'(q_n)=n=\xi_n^2Q''(\xi_n)&\geqq\xi_n\int_A^{\xi_n}Q''(u)\,du\\ &=\xi_n(Q'(\xi_n)-Q'(A^+))\\ &\geqq\xi_nQ'(\xi_n)/2, \quad \text{for } n \text{ large enough.}\end{aligned}$$

We deduce that $q_n\geqq\xi_n/2$, for n large enough, as $Q'(u)$ and $uQ'(u)$ are nondecreasing for large enough u. □

LEMMA 3.2 (infinite-finite range inequality). *Let $W\in\mathcal{F}$. Let $0<p\leqq\infty$. There exists a constant C and a positive integer n_0 such that for $n\geqq n_0$ and all polynomials P of degree at most n,*

$$\|PW\|_{L_p(\mathbb{R})}\leqq C\|PW\|_{L_p(-22q_n,22q_n)}. \tag{3.3}$$

Proof. Take $g=1$ in [12, Thm. A, p. 264] and note that $11q_{2n}\leqq 22qn$ by Lemma 3.1(i). □

Next, we need estimates of the Christoffel functions:

LEMMA 3.3. *Let $W\in\mathcal{F}$. Let $0<p\leqq\infty$, and let j be a nonnegative integer. There exists a constant C^* such that*

$$\lambda_{n,p}(W,j,x)\sim(q_n/n)^{j+1/p}W(x), \qquad |x|\leqq C^*q_n. \tag{3.4}$$

If (1.23) *also holds, then*

$$(3.5) \qquad \lambda_{n,p}(W, j, x) \geqq C(q_n/n)^{j+1/p} W(x), \qquad x \in \mathbb{R}.$$

Proof of Theorem 5. First, (1.19) follows easily from Theorem 4 and Lemma 2.3 this follows from Levin and Lubinsky [11, Thm. 3.5]. Suppose now that W satisfies I in Definition 7, so that $Q''(x)$ is positive and nondecreasing for large enough x. Then Lemma 3.1(iii) and Theorem 3.1 in Lubinsky [13] show that there exists C^* such that for $|x| \leqq C^* q_n$,

$$(3.6) \qquad \lambda_{n,p}(W, j, x) \geqq C_1(q_n/n)^{j+1/p} W(x), \qquad |x| \leqq C^* q_n.$$

To prove the upper bounds to match the lower bounds in (3.6), we apply Theorem 3.4 in Lubinsky [13]. Noting that $Q'(x)$ is positive and increasing for large x, we must show the following:

Given $\eta > 0$, there exists $\varepsilon > 0$ and $C > 0$ such that

$$(3.7) \qquad Q'(\varepsilon\xi)/Q'(\xi) < \eta, \qquad \xi > C.$$

There exist $C_1 > 0$ and $C_2 > 0$ such that for $\xi \geqq C_1$,

$$(3.8) \qquad 3\xi Q'(\xi)(\log(|x|/\xi))/Q(x) < 1, \qquad |x| \geqq C_2\xi.$$

The condition [13, (3.10)] holds trivially as $Q'' \geqq 0$. To prove (3.7), we note that if $0 < \varepsilon < 1$, and A is large enough,

$$\begin{aligned} Q'(\varepsilon\xi)/Q'(\xi) &= \left(\int_A^{\varepsilon\xi} Q''(u)\,du + Q'(A+)\right)\Big/\left(\int_A^{\xi} Q''(u)\,du + Q'(A+)\right) \\ &\leqq (\varepsilon\xi Q''(\varepsilon\xi) + Q'(A+))/((\xi - \varepsilon\xi)Q''(\varepsilon\xi) + Q'(A+)) \\ &\to \varepsilon/(1-\varepsilon), \qquad \xi \to \infty. \end{aligned}$$

Next, if $x \geqq 30\xi > C_3$,

$$\begin{aligned} Q(x) &= \int_\xi^x Q'(u)\,du + Q(\xi) > Q'(\xi)(x - \xi) \\ &= \xi Q'(\xi)(29/30)(x/\xi) \geqq 3\xi Q'(\xi)\log(x/\xi), \end{aligned}$$

as $\log u \leqq u/6$ if $u \geqq 30$. Thus (3.8) holds. Then Theorem 3.4 in [13] shows that (3.6) holds with $\geqq$ replaced by $\leqq$, and then (3.4) follows.

Suppose now that (1.23) holds. By Lemma 3.1(ii), we can choose a fixed positive integer k such that $C^* q_{nk} \geqq 22 q_n$, for n large enough. Then (3.6) shows that for $|x| \leqq 22 q_n$,

$$\lambda_{n,p}(W, j, x) \geqq \lambda_{kn,p}(W, j, x) \geqq C_1(q_{kn}/(kn))^{j+1/p} W(x) \geqq C_2(q_n/n)^{j+1/p} W(x).$$

Using the definition (1.26) of $\lambda_{n,p}(W, j, x)$, we see that this last inequality may be rewritten in the following equivalent form: For all polynomials P of degree at most n,

$$\|P^{(j)} W\|_{L_\infty(-22q_n, 22q_n)} \leqq C_1(n/q_n)^{j+1/p} \|PW\|_{L_p(\mathbb{R})}.$$

Then Lemma 3.2 yields

$$\|P^{(j)} W\|_{L_\infty(\mathbb{R})} \leqq C_2(n/q_n)^{j+1/p} \|PW\|_{L_p(\mathbb{R})},$$

and (3.5) follows. □

The following lemma is an analogue of Theorem 4:

LEMMA 3.4. *Let $W \in \mathscr{F}$, $0<p<\infty$ and let l be a positive integer. Further, let $\psi(t)$ be convex, nonnegative and nondecreasing in $[0,\infty)$. There exist C_1, C_2, B and C^* such that*

$$\psi(|PW|^p(x)) \leqq C_1(q_n n)^{-1} \int_{-Bq_n}^{Bq_n} \psi(C_2|PW|^p(u))K_n^2(v, x/(Bq_n), u/(Bq_n))\,du, \tag{3.9}$$

for all $|x| \leqq C^* q_n$ and all polynomials P of degree at most ln. If (1.23) *holds, we may take C^* arbitrarily large, but C, C_1 and C_2 will depend on C^*.*

Proof. Let k be the smallest positive integer such that $kp \geqq 4$. Let

$$B = 44(l+k).$$

It follows easily from $q_{2n} \leqq 2q_n$ (Lemma 3.1(i)) that for any positive integer j, we have

$$q_{jn} \leqq 2jq_n, \quad n \text{ large enough.}$$

Hence

$$22q_{(l+k)n} \leqq Bq_n, \quad n \text{ large enough.} \tag{3.10}$$

Let P have degree at most ln. For each fixed x, $P(t)K_n^k(v, x/(Bq_n), t/(Aq_n))$ has degree less than $(l+k)n$ in t, and Lemma 3.3 shows that there exists C^* such that for $|t| \leqq C^* q_n$,

$$\begin{aligned}
&|PW|^p(t)|K_n^k(v, x/(Bq_n), t/(Bq_n))|^p \\
&\leqq C_2(n/q_n) \int_{-\infty}^{\infty} |PW|^p(u)|K_n(v, x/(Bq_n), u/(Bq_n))|^{kp}\,du \\
&\leqq C_3(n/q_n) \int_{-Bq_n}^{Bq_n} |PW|^p(u)|K_n(v, x/(Bq_n), u/(Bq_n))|^{kp}\,du,
\end{aligned}$$

by Lemma 3.2 and (3.10). As the constants are independent of x, we can set $t = x$, and use (2.4) and (2.5) (as in the proof of Theorem 4—see (2.3) to (2.6)) to deduce that

$$|PW|^p(x) \leqq C_4(n^3 q_n)^{-1} \int_{-Bq_n}^{Bq_n} |PW|^p(u)K_n^4(v, x/(Bq_n), u/(Bq_n))\,du, \tag{3.11}$$

for $|x| \leqq C^* q_n$. To obtain (3.9) from (3.11), we must apply Jensen's inequality. First note that

$$\int_{-Bq_n}^{Bq_n} K_n^4(v, x/(Bq_n), u/(Bq_n))\,du = Bq_n \int_{-1}^{1} K_n^4(v, x/(Bq_n), t)\,dt \sim n^3 q_n, \tag{3.12}$$

for $|x| \leqq Bq_n/2$, by Theorem 2.2 with $w(u) \equiv 1$. We may then use Jensen's inequality and (3.11) and (3.12), in the same way as in the proof of Theorem 4, to deduce (3.9). If (1.23) holds, Lemma 3.3 ensures that lower bounds for $\lambda_{n,p}(W, j, x)$ hold for all $x \in \mathbb{R}$, as obvious modifications of the above argument yield the stronger stated result. □

Proof of Theorem 8. In view of (3.9), it suffices to show that

$$(q_n n)^{-1} \sum_{j=1}^{m} K_n^2(v, y_j/(Bq_n), u/(Bq_n)) \leqq C_3\{n/q_n + \delta^{-1}\}, \tag{3.13}$$

for all $|u| \leqq Bq_n$, with C_3 independent of m, $\{y_j\}$, n, δ and u, provided

$$-C^* q_n \leqq y_m < y_{m-1} < \cdots < y_1 \leqq C^* q_n$$

with C^* small enough and with δ as in (1.28). We can assume that $C^* \leqq B/2$, so that $|y_j/(Bq_n)| \leqq 1/2$, $j = 1, 2, \cdots, m$. Then as d/dx (arc cos $(x)) \sim -1$ for $|x| \leqq 1/2$, we see that

$$\arccos(y_j/(Bq_n)) - \arccos(y_{j-1}/(Bq_n)) \geqq C_4(y_{j-1} - y_j)/q_n \geqq C_4\delta/q_n,$$

by (1.21). Then Lemma 2.3 with $Y = Bq_n$ shows that (3.13) is true. □

Before proving Corollary 9, we need a result on the spacing of the zeros or orthogonal polynomials. Let $p_n(W^2; x)$, $n = 0, 1, 2, \cdots$, denote the orthonormal polynomials for the weight W^2.

LEMMA 3.5. *Let $W \in \mathcal{F}$. There exists C^* such that*

$$x_{n,j-1} - x_{n,j} \sim q_n/n, \qquad |x_{nj}| \leqq C^* q_n.$$

Proof. The proof of the upper bounds on $x_{n,j-1} - x_{n,j}$ in Freud [7, pp. 293-294] requires only suitable upper bounds for $\lambda_n(W^2, x)$ and convexity of Q. The proof of the lower bounds for $x_{n,j-1} - x_{n,j}$ in Freud [8, p 36] uses only suitable upper and lower bounds for $K_n(W^2, x, x)$ and suitable upper bounds for

$$\sum_{j=0}^{n-1} (p_j'(W^2, x))^2 = 1/\{\lambda_{n,2}(W, 1, x)\}^2,$$

as well as the monotonicity of Q'. As Lemma 3.3 yields the desired upper and lower bounds for $\lambda_{n,p}(W, j, x)$ and $\lambda_n(W^2, x)$, the result follows. □

Proof of Corollary 9. If C^* is small enough, Lemma 3.3 shows that

$$\begin{aligned}\sum_{|x_{nj}| \leqq C^* q_n} \lambda_{nj} |P(x_{nj})|^p W^{-r}(x_{nj}) &\leqq C_1(q_n/n) \sum_{|x_{nj}| \leqq C^* q_n} |P(x_{nj})|^p W^{2-r}(x_{nj}) \\ &= C_1(q_n/n) \sum_{|x_{nj}| \leqq C^* q_n} |PW^*(x_{nj})|^p\end{aligned}$$

where $W^*(x) = \exp(-Q^*(x))$ and $Q^*(x) = ((2-r)/p)Q(x)$. If q_n^* denotes the root of the equation $q_n^* Q^{*\prime}(q_n) = n$ for large enough, Lemma 3.1(i) shows $q_n \sim q_n^*$. If $\delta_n = \max\{x_{n,j-1} - x_{n,j}: |x_{nj}| \leqq C^* q_n\}$, Theorem 8 shows that

$$\sum_{|x_{nj}| \leqq C^* q_n} \lambda_{nj} |P(x_{nj})|^p W^{-r}(x_{nj}) \leqq C_2\{1 + (\delta_n n/q_n)^{-1}\} \int_{-\infty}^{\infty} |PW^*(u)|^p \, du$$

and then Lemma 3.5 yields the result. □

JACOBI POLYNOMIALS ASSOCIATED WITH SELBERG INTEGRALS*

K. AOMOTO†

Abstract. An extension of Selberg's beta integral is evaluated and used to obtain a new integral representation for Jacobi polynomials.

Key words. Jacobi polynomials, Selberg integrals

In his work with Y. Kanie on the Fock space representation of the Virasoro algebra, Prof. A. Tsuchiya mentioned the importance of computing the following integral $J_\chi = J_\chi^{(N)}(\lambda, \lambda', \lambda'')$:

$$J_\chi = \int_G \chi(x_3, \cdots, x_N) \prod_{j=3}^{N} x_j^{\lambda'}(1-x_j)^{\lambda''} \prod_{3 \leqq i<j \leqq N} |x_i - x_j|^\lambda \, dx_3 \wedge \cdots \wedge dx_N. \tag{1}$$

The integral is taken over the $(N-2)$-dimensional domain G: $0 \leqq x_j \leqq 1$, $3 \leqq j \leqq N$, where we put $x_1 = 0$ and $x_2 = 1$, and $\chi(x_3, \cdots, x_N)$ is an arbitrary symmetric polynomial. For convergence take $\lambda' > -1$, $\lambda'' > -1$ and for simplicity $\lambda > 0$ (see (Ts)). The one dimensionality of the twisted de Rham cohomology associated with J_χ implies that J_χ / J_1 is equal to a product of certain rational functions of λ, λ', and λ'' (see [Al, p. 177]). However, it seems to be rather difficult to get explicit formulae. J_1 is known, since it is A. Selberg's celebrated formula. See [Se], [Ma], [Mo]. Conjectured q-extensions of J_1 are stated in [As], [Ma], [Mo], [Ra].

In this note we want to show that if $\chi = \prod_{j=3}^N (x_j - t)$, then J_χ / J_1 is equal to

$$P_{N-2}^{(\alpha,\beta)}(1-2t) \frac{(N-2)!}{\prod_{j=3}^N (\alpha + \beta + N + j - 4)} \tag{2}$$

for $\alpha = -1 + 2(\lambda' + 1)/\lambda$, $\beta = -1 + 2(\lambda'' + 1)/\lambda$, where $P_n^{(\alpha,\beta)}(x)$ denotes the Jacobi polynomial of degree n. In the case $\lambda = 2$, this formula reduces to a standard one for orthogonal polynomials; see [Sz, (2.2.10) and § 4.2].

We denote by Φ the function $\prod_{j=3}^N x_j^{\lambda'}(1-x_j)^{\lambda''} \prod_{3 \leqq i<j \leqq N} |x_i - x_j|^\lambda$, by $d\tau$ the $(N-2)$-form $dx_3 \wedge \cdots \wedge dx_N$ and abbreviate by (i, j) the difference $x_i - x_j$. Recall that $x_1 = 0$ and $x_2 = 1$. We start by proving the following.

LEMMA 1.

$$\int_G \Phi \frac{(3,1)(4,1) \cdots (j,1)}{(k,3)} d\tau \tag{3}$$

$$= 0 \quad \textit{for } 4 \leqq k \leqq j \tag{3a}$$

$$= -\frac{1}{2} \int_G \Phi(4,1) \cdots (j,1) \, d\tau \quad \textit{for } j+1 \leqq k \leqq N. \tag{3b}$$

Proof. The domain of integration, is invariant under an arbitrary permutation of the arguments $(3, 4, \cdots, N)$. When $4 \leqq k \leqq j$, the integrand changes sign when 3 and k are transposed. This shows that (3a) holds.

* Received by the editors August 14, 1985; accepted for publication January 7, 1986.

† Department of Mathematics, Nagoya University, Chikusa-ku, Nagoya 464, Japan.

On the other hand, when $j+1\leqq k\leqq N$ the same transposition transforms as follows

$$\frac{(3,1)}{(k,3)}\to\frac{(k,1)}{(3,k)}=-1-\frac{(3,1)}{(k,3)},\tag{4}$$

so the left-hand side of (3) is equal to

$$-\int_G \Phi(4,1)\cdots(j,1)\,d\tau-\int_G \Phi\frac{(3,1)(4,1)\cdots(j,1)}{(k,3)}\,d\tau,\tag{5}$$

and this completes the proof of (3b).

LEMMA 2.

$$\int_G \Phi\frac{(3,1)^2(4,1)\cdots(j,1)}{(k,3)}\,d\tau\tag{6}$$

$$=-\frac{1}{2}\int_G \Phi(3,1)\cdots(j,1)\,d\tau\quad \textit{for } 4\leqq k\leqq j\tag{6a}$$

$$=-\int_G \Phi(3,1)\cdots(j,1)\,d\tau\quad \textit{for } j+1\leqq k\leqq N.\tag{6b}$$

Proof. Transposition of 3 and k transforms

$$\frac{(3,1)^2(k,1)}{(k,3)}\to\frac{(k,1)^2(3,1)}{(3,k)}=-(3,1)(k,1)-\frac{(3,1)^2(k,1)}{(k,3)}\quad\text{for } 4\leqq k\leqq j,\tag{7}$$

while

$$\frac{(3,1)^2}{(k,3)}=-(3,1)+\frac{(3,1)(k,1)}{(k,3)}\quad\text{for } j+1\leqq k\leqq N.\tag{8}$$

The last term changes sign under the transposition of 3 and k, so this integral vanishes. These equalities imply Lemma 2.

LEMMA 3. *For* $3\leqq j\leqq N$

$$-(2,1)\lambda''\int_G \Phi\frac{(4,1)\cdots(j,1)}{(3,2)}\,d\tau=\left(\lambda'+\lambda''+1+\frac{1}{2}(N-j)\lambda\right)\times\int_G \Phi(4,1)\cdots(j,1)\,d\tau.\tag{9}$$

Proof. By Stokes' formula

$$\begin{aligned}O&=\int_G d\{\Phi(3,1)\cdots(j,1)\,dx_4\wedge\cdots\wedge dx_N\}\\&=(\lambda'+1)\int_G \Phi(4,1)\cdots(j,1)\,d\tau\\&\quad+\lambda''\int_G \Phi\frac{(3,1)\cdots(j,1)}{(3,2)}\,d\tau\\&\quad-\lambda\sum_{k=4}^{N}\int_G \Phi\frac{(3,1)\cdots(j,1)}{(k,3)}\,d\tau.\end{aligned}\tag{10}$$

In view of Lemma 1, this is equal to

$$\begin{aligned}\lambda''\int_G \Phi\frac{(2,1)(4,1)\cdots(j,1)}{(3,2)}\,d\tau\\ +\left(\lambda'+\lambda''+1+\frac{1}{2}(N-j)\lambda\right)\int_G \Phi(4,1)\cdots(j,1)\,d\tau\end{aligned}\tag{11}$$

which implies Lemma 3.

LEMMA 4 (Recurrence formula). *For* $3\leqq j\leqq N$,

$$\begin{aligned}\left(\lambda'+\lambda''+2+\frac{1}{2}(j-3)\lambda+(N-j)\lambda\right)\int_G \Phi(3,1)\cdots(j,1)\,d\tau\\ =(2,1)\left(\lambda'+1+\frac{1}{2}(N-j)\lambda\right)\int_G \Phi(4,1)\cdots(j,1)\,d\tau.\end{aligned}\tag{12}$$

Proof. By Stokes' formula again,

$$\begin{aligned}O&=\int_G d\{\Phi(3,1)^2(4,1)\cdots(j,1)\,dx_4\wedge\cdots\wedge dx_N\}\\ &=(\lambda'+2)\int_G \Phi(3,1)\cdots(j,1)\,d\tau\\ &\quad+\lambda''\int_G \Phi\frac{(3,1)^2(4,1)\cdots(j,1)}{(3,2)}\,d\tau\\ &\quad-\lambda\sum_{k=4}^{N}\int_G \Phi\frac{(3,1)^2(4,1)\cdots(j,1)}{(k,3)}\,d\tau.\end{aligned}\tag{13}$$

In view of Lemmas 2 and 3, and seeing that

$$\frac{(3,1)^2}{(3,2)}=(3,1)+(2,1)+\frac{(2,1)^2}{(3,2)}\tag{14}$$

we get

$$\begin{aligned}O&=\left[\lambda'+\lambda''+2+\frac{1}{2}(j-3)\lambda+(N-j)\lambda\right]\int_G \Phi(3,1)\cdots(j,1)\,d\tau\\ &\quad+\lambda''(2,1)\int_G \Phi(4,1)\cdots(j,1)\,d\tau\\ &\quad+\lambda''(2,1)^2\int_G \Phi\frac{(4,1)\cdots(j,1)}{(3,2)}\,d\tau\\ &=\left[\lambda'+\lambda''+2+\frac{1}{2}(j-3)\lambda+(N-j)\lambda\right]\int \Phi(3,1)\cdots(j,1)\,d\tau\\ &\quad-(2,1)\left(\lambda'+1+\frac{1}{2}(N-j)\lambda\right)\int_G \Phi(4,1)\cdots(j,1)\,d\tau\end{aligned}\tag{15}$$

which implies Lemma 4.

Successive applications of Lemma 4 lead to the following theorem.

THEOREM 1.

$$\text{(16)} \qquad \int_G \Phi(3,1)\cdots(j,1)\,d\tau = \int_G \Phi\,d\tau \prod_{i=3}^{j} \frac{\left(\lambda'+1+\frac{1}{2}(N-i)\lambda\right)}{\left(\lambda'+\lambda''+2+\lambda\left(N-\frac{i}{2}-\frac{3}{2}\right)\right)}.$$

This identity and the symmetry of Φ give the following.

THEOREM 2.

$$\text{(17)} \qquad \begin{aligned} \int_G \Phi \prod_{j=3}^{N} (x_j-t)\,d\tau &= \sum_{r=2}^{N} (-t)^{N-r}\binom{N-2}{r-2}\prod_{j=3}^{r} \frac{\left[\lambda'+1+\frac{1}{2}(N-j)\lambda\right]}{\left[\lambda'+\lambda''+2+\lambda\left(N-\frac{j}{2}-\frac{3}{2}\right)\right]} \\ &= \frac{(N-2)!}{\prod_{j=3}^{N}(\alpha+\beta+N-4+j)} P_{N-2}^{(\alpha,\beta)}(1-2t) \end{aligned}$$

for $\alpha=(2(\lambda'+1)/\lambda)-1$ *and* $\beta=(2(\lambda''+1)/\lambda)-1$, *where* $P_n^{(\alpha,\beta)}(x)$ *denotes the Jacobi polynomial of degree n defined by*

$$\text{(18)} \qquad \begin{aligned} P_n^{(\alpha,\beta)}(x) &= \frac{1}{n!}\sum_{\nu=0}^{n}\binom{n}{\nu}(n+\alpha+\beta+1)\cdots(n+\alpha+\beta+\nu), \\ &(\alpha+\nu+1)\cdots(\alpha+n)\left(\frac{x-1}{2}\right)^{\nu}. \end{aligned}$$

It has been remarked by Prof. R. Askey that if we take $\chi=\prod_{i=3}^{r}(x_i-t)$, then the quotient J_χ/J_1 is also equal to a constant multiple of $P_{r-2}^{(N-r+\alpha,N-r+\beta)}(1-2t)$. This easily follows from (16).

He also pointed out the following: If λ, λ', λ'' are all nonnegative integers, then (16) implies the following recurrence relation:

$$J_1^{(N)}(\lambda,\lambda',\lambda'') = \frac{\prod_{k=1}^{\lambda'}\prod_{j=3}^{N}\left\{k+\frac{1}{2}(N-j)\lambda\right\}\prod_{k=1}^{\lambda''}\prod_{j=3}^{N}\left\{k+\frac{1}{2}(N-j)\lambda\right\}}{\prod_{k=1}^{\lambda'+\lambda''}\prod_{j=3}^{N}\left\{k+1+\lambda\left(N-\frac{j}{2}-\frac{3}{2}\right)\right\}} J_1^{(N)}(\lambda,0,0).$$

This equality is nothing else than the key formula (5) in [Se]. By the change of variables $x_j=x_3t_j$ for $j\geqq 4$, we have

$$J_1^{(N)}(\lambda,0,0) = \frac{1}{(N-2)\left(1+\frac{N-3}{2}\lambda\right)} J_1^{(N-1)}(\lambda,0,\lambda).$$

The proof of Selberg's formula can then be completed along the same line as in [Se] using Carlson's theorem.

Note added in proof. K. W. J. Kadell has recently proved a conjecture of Askey for a q-analogue of Selberg's integral.

DIRICHLET AVERAGES OF $x^t \log x$*

B. C. CARLSON†

Abstract. A neglected class of special functions may be described as Dirichlet averages of $x^t \log x$ or equivalently as derivatives of hypergeometric R-functions with respect to the degree of homogeneity. Special cases include the derivative of a Legendre function with respect to the degree and the derivative of Gauss's hypergeometric function with respect to a numerator parameter. There are connections with the logarithmic derivative of the gamma function, with Euler's dilogarithm, and with ${}_3F_2$; some special cases of ${}_3F_2$ are thereby evaluated. Applications include a two-point boundary-value problem, mean values, series expansions of elliptic integrals, integral tables, and several physics problems. The discussion of various properties emphasizes series expansions, quadratic transformations, inequalities, and evaluation of special cases, including certain cases of the derivative of a Legendre function with respect to the degree.

Key words. Dirichlet averages, logarithms, hypergeometric functions, R-functions, elliptic integrals, Legendre functions

AMS (MOS) subject classifications. Primary 33A30; secondary 33A25, 33A45

1. Introduction. A class of special functions that seems not to have been discussed systematically arises in the asymptotic expansion of elliptic integrals and in various other problems. The prototype of this class is the derivative of a Legendre function P_ν with respect to the degree ν. The general case is the derivative of the multivariate hypergeometric function R_t with respect to the degree t of homogeneity. It can equivalently be thought of as a Dirichlet average of $\partial x^t/\partial t = x^t \log x$. After defining this average, denoted by L_t, we shall list some places where it occurs.

We recall first the definition of the R-function [3, (5.9-1)]. Let b and z be k-tuples with components in the open right-half complex plane, $\mathbb{C}_>$. The Dirichlet average of x^t, $t \in \mathbb{C}$, is defined for $k \geqq 2$ by

$$(1.1) \qquad R_t(b, z) = \int (u \cdot z)^t \, d\mu_b(u),$$

where $u \cdot z = \sum_{i=1}^k u_i z_i$ is a convex combination of the variables $z_1, \cdots, z_k$ and μ_b is a Dirichlet measure (i.e. a multivariate beta distribution with possibly complex parameters $b_1, \cdots, b_k$). The integration extends over all nonnegative weights $u_1, \cdots, u_k$ whose sum is unity. If $k = 1$ we define $R_t(b, z) = z^t$. The analytic continuation [3, Sec. 6.8] of $R_t(b, z)/\Gamma(c)$, $c = \sum_{i=1}^k b_i$, is entire in t and b and holomorphic in z on $\mathbb{C}_0^k$, where $\mathbb{C}_0$ is the complex plane slit along the nonpositive real axis.

The subject of this paper is the function L_t defined by

$$(1.2) \qquad L_t(b, z) = \frac{\partial}{\partial t} R_t(b, z).$$

If b, $z \in \mathbb{C}_>^k$, $k \geqq 2$, we see from (1.1) that

$$(1.3) \qquad L_t(b, z) = \int (u \cdot z)^t \log (u \cdot z) \, d\mu_b(u).$$

† Ames Laboratory and Department of Mathematics, Iowa State University, Ames, Iowa 50011.

That is, L_t is a Dirichlet average of $x^t \log x$. The case $t=0$ is discussed briefly in [3, Ex. 5.9-12 and p. 305]. If $k=1$ we define $L_t(b, z)=z^t \log z$. We shall often display the components of b and z by writing $L_t(b_1, \cdots, b_k; z_1, \cdots, z_k)$. If $k=2$, $b=(\beta, \beta')$ and $z=(x, y)$, (1.3) becomes

$$L_t(\beta, \beta'; x, y)=\frac{\Gamma(\beta+\beta')}{\Gamma(\beta)\Gamma(\beta')}\int_0^1 [ux+(1-u)y]^t \log[ux+(1-u)y] \cdot u^{\beta-1}(1-u)^{\beta'-1}\,du, \tag{1.4}$$

where β, β', x, y have positive real parts and t is unrestricted. The case in which x or y is 0 will be discussed in § 4.

We list some examples to show that L_t is worth studying.

Example 1. The difference between two values of the logarithmic derivative of the gamma function is

$$\psi(\beta)-\psi(\gamma)=L_0(\beta, \gamma-\beta; 1, 0), \quad \operatorname{Re}\beta>0, \quad \gamma\neq 0, -1, -2, \cdots. \tag{1.5}$$

Example 2. The derivative of Gauss' hypergeometric function with respect to a numerator parameter is

$$\frac{\partial}{\partial\alpha}\,{}_2F_1(\alpha, \beta; \gamma; z)=-L_{-\alpha}(\beta, \gamma-\beta; 1-z, 1). \tag{1.6}$$

If α is a negative integer, the ${}_2F_1$-function is a polynomial; if α is close to a negative integer, the function can be approximated to first order with the help of the derivative. Equation (1.6) can easily be generalized from ${}_2F_1$ to Appell's F_1 or Lauricella's F_D by expressing these functions in terms of R_t (e.g. see [3, Ex. 6.3-5]).

Example 3. The derivative of an associated Legendre function with respect to its degree is

$$\frac{\partial}{\partial\nu}P_\nu^{-\mu}(\cos\theta)=\frac{\sin^\mu\theta}{2^\mu\Gamma(1+\mu)}L_{\nu-\mu}(\mu+1/2, \mu+1/2; e^{i\theta}, e^{-i\theta}). \tag{1.7}$$

This derivative is useful in antenna theory [13, pp. 114–115]. Special cases are evaluated in closed form in (6.14) and (6.19).

Example 4. For any real t and positive x, a, b, the solution of the two-point boundary-value problem $y''=x^t \log x$, $y(a)=y(b)=0$, is

$$y(x)=\tfrac{1}{2}(x-a)(x-b)L_t(1, 1, 1; x, a, b). \tag{1.8}$$

Closed formulas are given in (8.10), (8.12), and (8.14).

Example 5. Let $x_1, \cdots, x_k$ be positive numbers and $w_1, \cdots, w_k$ positive weights with $\sum w_i=1$. Then $\exp L_0(cw_1, \cdots, cw_k; x_1, \cdots, x_k)$, $c>0$, is a homogeneous mean value of the x_i that increases strictly with c unless the x_i are all equal. It tends to the weighted geometric mean $\prod x_i^{w_i}$ as $c\to 0+$ and the weighted arithmetic mean $\sum w_i x_i$ as $c\to+\infty$.

Example 6. Series expansions of elliptic integrals and some other R-functions [6], [5] near their singularities involve L_t. For example [6, (1.20)],

$$\begin{aligned}(zw)^{1/2}\int_0^\infty [(t+x)(t+y)(t+z)(t+w)]^{-1/2}\,dt &= \sum_{n=0}^\infty [-L_n(1/2, 1/2; x, y)R_n(1/2, 1/2; z^{-1}, w^{-1}) \\ &\qquad - R_n(1/2, 1/2; x, y)L_n(1/2, 1/2; z^{-1}, w^{-1})]\end{aligned} \tag{1.9}$$

where x and y are nonnegative, z and w are positive, and $0<\max\{x,y\}/\min\{z,w\}<1$. Convergence is fast near the logarithmic singularity at $x=y=0$. A closed formula for $L_n(1/2, 1/2; x, y)$, which was not known when [6] was written, is given in (6.13).

Example 7. Integrals with a logarithm in the integrand are met in various applied problems and can sometimes be put in the form (1.4). Two such integrals occurring in diffusion problems associated with crystal growth [14, (17), (36)] [11, (A4)] are constant multiples of $L_0(1/2, 1/2+1/n; z^2-1, z^2)$ and $L_0(1+a, 1-a; z-1, z+1)$, where n is a positive integer and a is an angle in units of π. In connection with the first example, Seeger [14, p. 6] remarks that he "did not succeed in expressing [the concentration] in terms of well-investigated functions." A more complicated integral (not found in tables) containing a logarithm and a Bessel function is

$$\begin{aligned}\int_0^\infty e^{-pt}\log(t)t^\nu J_\nu(xt)\,dt &= \pi^{-1/2}\Gamma(\nu+1/2)(2x)^\nu(p^2+x^2)^{-\nu-1/2}\\ &\quad\cdot[\psi(2\nu+1)-\log(p^2+x^2)+\tfrac{1}{2}L_0(\nu+1/2, 1/2; p^2, p^2+x^2)],\end{aligned}\tag{1.10}$$

where p, x, and $\nu+1/2$ are positive. An example with an integrand not containing a logarithm is

$$\int_0^1 u^{-1}(1-u)^{a-1}[{}_2F_1(a, b; c; ux)-1]\,du = -L_0(b, c-b; 1-x, 1),\tag{1.11}$$

where Re $a>0$, $|\arg(1-x)|<\pi$, and $c\neq 0, -1, -2, \cdots$. The case $a=b=\frac{1}{2}$, $c=1$ occurs in the theory of neutron stars [8, Appendix B].

Equation (1.5) is a special case of (4.4). Equations (1.6) and (1.7) follow, respectively, from differentiating [3, (5.9-12) and (6.8-19)]. It can be verified that (1.8) satisfies the differential equation by using [3, (5.6-5), (5.6-10), (6.3-3)] to prove a more general result for $y''=f(x)$. Example 5 comes from Theorem 7.2 or from [1, (2.6) and Thm. 1] and [7, Thm. 4]. Equation (1.9) is taken from [6, (1.18), (3.17)]. Equation (1.10) is proved by differentiating [3, Ex. 5.10-3] with respect to λ and using [3, (5.9-23)] and Equations (2.11), (6.4), and (2.3) of this paper. Equation (1.11) is derived by integrating the ${}_2F_1$-series term by term and comparing with (5.13).

This paper does not discuss higher derivatives of R_t with respect to t nor double Dirichlet averages of $x^t\log x$, although the latter occur in some problems such as the two-dimensional Ising model.

2. General properties.

Several important properties of L_t follow immediately from the theory of Dirichlet averages or from properties of R_t:

(2.1) $L_t(b, z)/\Gamma(c)$, $c=\sum_{i=1}^k b_i$, is entire in t and b and holomorphic in z on $\mathbb{C}_0^k$. See (1.2).

(2.2) $L_t(b_1, \cdots, b_k; z_1, \cdots, z_k)$ is symmetric in the indices $1, \cdots, k$ [3, Thm. 5.2-3].

(2.3) A vanishing parameter b_i can be omitted along with the corresponding variable z_i [3, (6.3-3)].

(2.4) Equal variables can be replaced by a single variable if the corresponding parameters are replaced by their sum [3, (5.2.-3)].

In particular, if all variables are equal, then

$$L_t(b_1, \cdots, b_k; x, \cdots, x) = L_t(c, x) = x^t\log x.$$

From (1.3) we obtain

$$
\begin{aligned}
L_t(b, \lambda z) &= \lambda^t L_t(b, z) + \lambda^t R_t(b, z) \log \lambda \\
&= \lambda^t L_t(b, z) + R_t(b, \lambda z) \log \lambda, \\
L_0(b, \lambda z) &= L_0(b, z) + \log \lambda.
\end{aligned} \tag{2.5}
$$

Differentiation of [3, (6.8-15)] gives

$$L_t(b, z) = -\left(\prod_{i=1}^{k} z_i^{-b_i}\right) L_{-c-t}(b, z^{-1}), \tag{2.6}$$

where $c = \sum_{i=1}^{k} b_i \neq 0, -1, -2, \cdots$; $z \in \mathbb{C}_0^k$; and $z^{-1} = (z_1^{-1}, \cdots, z_k^{-1})$.

Since L_t is a Dirichlet average, it satisfies a system of Euler-Poisson equations [3, (5.4-2)],

$$[(z_i - z_j) D_i D_j + b_i D_j - b_j D_i] L_t(b, z) = 0, \qquad i, j = 1, 2, \cdots, k, \tag{2.7}$$

where $D_i = \partial/\partial z_i$. Differentiating [3, (5.9-2)] with respect to t, we find also the inhomogeneous differential equation

$$\sum_{i=1}^{k} z_i D_i L_t = t L_t + R_t \tag{2.8}$$

and the differential-difference equation

$$\sum_{i=1}^{k} D_i L_t = t L_{t-1} + R_{t-1}. \tag{2.9}$$

If we define $x + z = (x + z_1, \cdots, x + z_k)$, where z is independent of x, then (2.9) implies

$$\frac{d}{dx} L_t(b, x + z) = t L_{t-1}(b, x + z) + R_{t-1}(b, x + z). \tag{2.10}$$

Some useful relations are peculiar to the case of two variables:

$$L_t(\beta, \beta'; x, y) = \log(xy) R_t(\beta, \beta'; x, y) - x^{t+\beta'} y^{t+\beta} L_{-\beta-\beta'-t}(\beta', \beta; x, y), \tag{2.11}$$

where $x, y \in \mathbb{C}_0$ and $\beta + \beta' \neq 0, -1, -2, \cdots$. This follows from (2.6) and (2.5) or alternatively from [3, (5.9-21)].

$$
\begin{aligned}
\frac{\partial}{\partial t} R_{-a}(u + t, v - t; x, y) &= x^{-a} L_{t-v}(u + v - a, a; 1, y/x) \\
&= -y^{-a} L_{-u-t}(a, u + v - a; x/y, 1),
\end{aligned} \tag{2.12}
$$

where $x, y \in \mathbb{C}_0$ and $u + v \neq 0, -1, -2, \cdots$. On the left side use homogeneity to arrive at arguments 1 and y/x and then apply [3, (5.9-20)]. The second member equals the third by (2.6) and (2.2). We shall use (2.12) to derive (6.4) and (6.5).

In addition to the representation of L_t by the multiple integral (1.3), a representation by a single integral is obtained by differentiating the corresponding representation [3, (6.8-6), Ex. 6.8-8] of R_t:

$$
\begin{aligned}
B(a, a')\{L_{-a}(b, z) &+ [\psi(a') - \psi(a)] R_{-a}(b, z)\} \\
&= \int_0^{\infty} t^{a'-1} \log(t) \prod_{i=1}^{k} (t + z_i)^{-b_i}\, dt \\
&= -\int_0^{\infty} t^{a-1} \log(t) \prod_{i=1}^{k} (1 + t z_i)^{-b_i}\, dt,
\end{aligned} \tag{2.13}
$$

where B is the beta function, $a+a'=\sum_{i=1}^k b_i$, a and a' have positive real parts, and $z\in\mathbb{C}_0^k$. For integrals with finite limits of integration, we find by differentiating [3, (8.1-2)] with respect to a that

$$\begin{aligned}\int_x^y (t-x)^{a-1}(y-t)^{a'-1}\log\left(\frac{y-t}{t-x}\right)\prod_{i=1}^k (z_i+w_it)^{-b_i}\,dt \\ =B(a,a')(y-x)^{a+a'-1}\prod_{i=1}^k (z_i+w_ix)^{-b_i} \\ \cdot\left\{L_{-a}\left(b,\frac{z+wy}{z+wx}\right)+[\psi(a')-\psi(a)]R_{-a}\left(b,\frac{z+wy}{z+wx}\right)\right\} \\ =B(a,a')(y-x)^{a+a'-1}\prod_{i=1}^k (z_i+w_iy)^{-b_i} \\ \cdot\left\{-L_{-a'}\left(b,\frac{z+wx}{z+wy}\right)+[\psi(a')-\psi(a)]R_{-a'}\left(b,\frac{z+wx}{z+wy}\right)\right\}\end{aligned} \tag{2.14}$$

where the conditions on the parameters are the same as for (2.13), $y>x$, $(z+wy)/(z+wx)$ denotes the k-tuple with ith component $(z_i+w_iy)/(z_i+w_ix)$, and $z_i+w_it\in\mathbb{C}_0$ for every $t\in[x,y]$ and every $i=1,\cdots,k$. The equality $a+a'=\sum_{i=1}^k b_i$ can always be satisfied by choice of b_k if we put $z_k=1$ and $w_k=0$.

An integral containing the confluent hypergeometric function S (the Dirichlet average of e^x) can be evaluated by differentiating [3, (5.10-11)] with respect to a:

$$\int_0^\infty t^{a-1}\log(t)S(b,-tz)\,dt=\Gamma'(a)R_{-a}(b,z)-\Gamma(a)L_{-a}(b,z), \tag{2.15}$$

where a and all components of z have positive real parts and $\sum_{i=1}^k b_i\neq 0,-1,-2,\cdots$. The functions of Kummer, Bessel and Whittaker are expressed in terms of S by [3, (5.8-7), (5.8-23), (5.12-20 to 27)].

3. Relations between associated functions. Two or more L-functions of k variables are said to be associated if the parameters $t, b_1,\cdots,b_k$ of each function differ by integers from the corresponding parameters of the other functions.

THEOREM 3.1. *Between any $k+1$ associated L-functions of k variables there exists a linear (possibly inhomogeneous) relation with coefficients that are polynomials in the variables and parameters. The inhomogeneous term, if any, is a linear combination of R-functions with polynomial coefficients.*

Proof. There is a linear homogeneous relation between any $k+1$ associated R-functions [3, Thm. 8.4-3] in which the coefficients are polynomials in the parameters as well as the variables. By (1.2), differentiation with respect to t produces a linear relation of the kind described between the corresponding L-functions.

Let $w_i=b_i/c$, $c=\sum_{i=1}^k b_i$, and let e_i be a k-tuple with unity in the ith place and zeros elsewhere. We list first some homogeneous relations:

$$L_t(b,z)=\sum_{i=1}^k w_iL_t(b+e_i,z), \tag{3.1}$$

$$L_{t+1}(b,z)=\sum_{i=1}^k w_iz_iL_t(b+e_i,z), \tag{3.2}$$

$$(z_i-z_j)L_t(b-e_h,z)+(z_j-z_h)L_t(b-e_i,z)+(z_h-z_i)L_t(b-e_j,z)=0. \tag{3.3}$$

The first and third are special cases of [3, (5.6-4), (5.6-11)], while the second comes from differentiating [3, (5.9-6)].

Differentiation of [3, (5.9-8), (5.9-9), (5.9-10)] yields, for $i=1,2,\cdots,k$,

$$(c-1)L_t(b-e_i,z)=(c+t-1)L_t(b,z)-tz_iL_{t-1}(b,z)+R_t(b,z)-z_iR_{t-1}(b,z), \tag{3.4}$$

$$D_iL_t(b,z)=w_itL_{t-1}(b+e_i,z)+w_iR_{t-1}(b+e_i,z), \tag{3.5}$$

$$(z_iD_i+b_i)L_t(b,z)=w_i(c+t)L_t(b+e_i,z)+w_iR_t(b+e_i,z). \tag{3.6}$$

From [3, Ex. 5.9-6] we see that

$$t(z_i-z_j)L_{t-1}(b,z)+(c-1)[L_t(b-e_i,z)-L_t(b-e_j,z)]+(z_i-z_j)R_{t-1}(b,z)=0, \tag{3.7}$$

$$\begin{aligned}(c+t-1)(z_i-z_j)L_t(b,z)+(c-1)[z_jL_t(b-e_i,z)-z_iL_t(b-e_j,z)]\\ +(z_i-z_j)R_t(b,z)=0.\end{aligned} \tag{3.8}$$

In the case of two variables, differentiation of [3, (5.9-24), (5.9-25)] gives

$$w_i(z_j-z_i)L_t(b+e_i,z)=z_jL_t(b,z)-L_{t+1}(b,z), \qquad j=3-i, \quad i=1,2, \tag{3.9}$$

$$\begin{aligned}(c+t)L_{t+1}(b,z)-\sum_{i=1}^{2}(b_i+t)z_iL_t(b,z)+tz_1z_2L_{t-1}(b,z)\\ =-R_{t+1}(b,z)+(z_1+z_2)R_t(b,z)-z_1z_2R_{t-1}(b,z)\\ =\frac{b_1b_2}{c(c+1)}(z_1-z_2)^2R_{t-1}(b+e_1+e_2,z)\\ =\frac{(z_1-z_2)^2}{t(t+1)}D_1D_2R_{t+1}(b,z).\end{aligned} \tag{3.10}$$

In (3.10), where $c=b_1+b_2$, the second and third equalities come from two applications of [3, (5.9-24)] and [3, (5.9-9)], respectively. The case with t a nonnegative integer and $b=(1/2,1/2)$ was quoted in [6, (2.24)], where it was used to show that the quantity $\lambda_n(1/2,1/2;x,y)$ defined by [6, (1.13)] is a homogeneous polynomial of degree $2n$ in $x^{1/2}$ and $y^{1/2}$ containing $(x^{1/2}-y^{1/2})^2$ as a factor. That conclusion is confirmed by (6.13) of the present paper, which yields the formula

$$\begin{aligned}\lambda_n(1/2,1/2;x,y)=2\sum_{s=1}^{n}\binom{n}{s}\binom{n+s}{s}[\psi(n+1+s)-\psi(n+1)]\\ \cdot\left(\frac{x^{1/2}-y^{1/2}}{2}\right)^{2s}(xy)^{(n-s)/2}.\end{aligned} \tag{3.11}$$

4. The case of a zero argument. If all components of z except one, say z_k, are fixed, both R_t and L_t have a branch point at $z_k=0$. (In the exceptional case where b_k is a nonpositive integer, L_t is a polynomial in z_k, for b_k can be raised to 0 by successive applications of (3.4) and then omitted by (2.3). Equation (5.17) is an example. Similar remarks apply to R_t.) If $\operatorname{Re}(b_1+\cdots+b_{k-1}+t)>0$, R_t and L_t have finite limits as $z_k\to 0$ in $\mathbb{C}_0$ with $|\arg z_k|$ bounded away from π, and we define the value of the function at $z_k=0$ to be this limit. By an extension [3, (8.3-4)] of Gauss' theorem for a hypergeometric function with unit argument,

$$\begin{aligned}R_t(b_1,\cdots,b_k;z_1,\cdots,z_{k-1},0)\\ =\frac{\Gamma(c)\Gamma(c-b_k+t)}{\Gamma(c+t)\Gamma(c-b_k)}R_t(b_1,\cdots,b_{k-1};z_1,\cdots,z_{k-1}),\end{aligned} \tag{4.1}$$

where $c=b_1+\cdots+b_k \neq 0, -1, -2, \cdots$; $\operatorname{Re}(c-b_k+t)>0$; and $z_1, \cdots, z_{k-1} \in \mathbb{C}_0$. Logarithmic differentiation with respect to t shows that

$$\begin{aligned}&\frac{L_t(b_1, \cdots, b_k; z_1, \cdots, z_{k-1}, 0)}{R_t(b_1, \cdots, b_k; z_1, \cdots, z_{k-1}, 0)}\\ &\quad=\psi(c-b_k+t)-\psi(c+t)+\frac{L_t(b_1, \cdots, b_{k-1}; z_1, \cdots, z_{k-1})}{R_t(b_1, \cdots, b_{k-1}; z_1, \cdots, z_{k-1})},\end{aligned} \tag{4.2}$$

with the further conditions that $c+t$, $c-b_k \neq 0, -1, -2, \cdots$. Although (4.2) will be used in the remark following Theorem 7.1, a better form for other purposes is obtained by ordinary differentiation of (4.1):

(4.3)

$$\begin{aligned}&L_t(b_1, \cdots, b_k; z_1, \cdots, z_{k-1}, 0)\\ &\quad=\frac{\Gamma(c)\Gamma(c-b_k+t)}{\Gamma(c+t)\Gamma(c-b_k)}\{L_t(b_1, \cdots, b_{k-1}; z_1, \cdots, z_{k-1})\\ &\qquad\qquad+[\psi(c-b_k+t)-\psi(c+t)]R_t(b_1, \cdots, b_{k-1}; z_1, \cdots, z_{k-1})\},\end{aligned}$$

with the same conditions of validity as for (4.1). If $k=2$ this reduces to

$$L_t(\beta, \gamma-\beta; x, 0)=\frac{\Gamma(\gamma)\Gamma(\beta+t)}{\Gamma(\gamma+t)\Gamma(\beta)}x^t[\psi(\beta+t)-\psi(\gamma+t)+\log x], \tag{4.4}$$

where β, γ, $\gamma+t\neq 0$, -1, $-2, \cdots$ and $\operatorname{Re}(\beta+t)>0$. The elliptic integral (1.9) is equivalent to Legendre's first integral if $w=\infty$, and its series expansion then contains the special case of (4.4) with $\beta=\frac{1}{2}$, $\gamma=1$, and t a nonnegative integer. This case was quoted in [6, (1.10)], with the difference of ψ-functions given by [6, (1.11)] or [3, (8.3-15)]. Other special cases of (4.4) are (1.5) and

$$L_0(1, m; x, 0)=\log x-(1+1/2+1/3+\cdots+1/m), \tag{4.5}$$

where m is a positive integer. If $x=m$, this tends to the negative of the Euler-Mascheroni constant as $m\to\infty$.

5. Series expansions. Let all parameters and variables be complex, define $1-z=(1-z_1, \cdots, 1-z_k)$ and $|1-z|=\max_i |1-z_i|$, and assume $|1-z|<1$ and $b_1+\cdots+b_k\neq 0$, -1, $-2, \cdots$. The series expansion [3, (5.9-4)]

$$R_t(b, z)=\sum_{s=0}^{\infty}\frac{(-t)_s}{s!}R_s(b, 1-z) \tag{5.1}$$

is the Dirichlet average of the binomial series

$$x^t=\sum_{s=0}^{\infty}\frac{(-t)_s}{s!}(1-x)^s, \qquad |1-x|<1, \tag{5.2}$$

where $(-t)_0=1$ and $(-t)_s=(-t)(-t+1)(-t+2)\cdots(-t+s-1)$, $s=1, 2, 3, \cdots$. Differentiation with respect to t is essentially the same for both series. By [3, proof of Cor. 6.3-4] both converge uniformly for $|t|<T$, where T may be arbitrarily large, and so the series may be differentiated term by term. Since $(-t)_0=1$ we assume s to be a positive integer and find

$$\begin{aligned}(d/dt)(-t)_s&=(-1)(-t+1)(-t+2)\cdots(-t+s-1)\\ &\quad+(-t)(-1)(-t+2)\cdots(-t+s-1)+\cdots\\ &\quad+(-t)(-t+1)\cdots(-t+s-2)(-1).\end{aligned} \tag{5.3}$$

If $(-t)_s \neq 0$ we can rewrite this as

$$(5.4)\qquad \begin{aligned}(d/dt)(-t)_s &= (-t)_s\left(\frac{1}{t}+\frac{1}{t-1}+\cdots+\frac{1}{t+1-s}\right)\\ &= (-t)_s[\psi(t+1)-\psi(t+1-s)].\end{aligned}$$

If $t=n$ where $n=0,1,\cdots,s-1$, then (5.4) is indeterminate, but all terms on the right side of (5.3) vanish except one, leaving

$$(5.5)\qquad [(d/dt)(-t)_s]_{t=n} = (-1)^{n+1}n!(s-n-1)!, \qquad n=0,1,\cdots,s-1.$$

Therefore, if $t\neq 0,1,2,\cdots$, differentiation of (5.1) yields

$$(5.6)\qquad L_t(b,z)=\sum_{s=1}^{\infty}\frac{(-t)_s}{s!}[\psi(t+1)-\psi(t+1-s)]R_s(b,1-z), \qquad |1-z|<1.$$

On the other hand, if $n=0,1,2,\cdots$, we find

$$(5.7)\qquad \begin{aligned}L_n(b,z) &= \sum_{s=1}^{n}\frac{(-n)_s}{s!}[\psi(n+1)-\psi(n+1-s)]R_s(b,1-z)\\ &\quad +(-1)^{n+1}n!\sum_{s=n+1}^{\infty}\frac{(s-n-1)!}{s!}R_s(b,1-z), \qquad |1-z|<1.\end{aligned}$$

The first sum is empty if $n=0$, whence

$$(5.8)\qquad L_0(b,z)=-\sum_{s=1}^{\infty}\frac{1}{s}R_s(b,1-z), \qquad |1-z|<1,$$

while

$$(5.9)\qquad \begin{aligned}L_1(b,z) &= -R_1(b,1-z)+\sum_{s=2}^{\infty}\frac{1}{s(s-1)}R_s(b,1-z)\\ &= L_0(b,z)+\sum_{s=2}^{\infty}\frac{1}{s-1}R_s(b,1-z), \qquad |1-z|<1.\end{aligned}$$

The second equality in (5.9) is generalized by

$$(5.10)\qquad \sum_{s=1}^{\infty}\frac{1}{s}R_{N+s}(b,z)=\sum_{n=0}^{N}(-1)^{n+1}\binom{N}{n}L_n(b,1-z),$$

where $|z|<1$ and $N=0,1,2,\cdots$. This equation is proved by taking the Dirichlet average of the case in which all components of z are equal.

If all components of z are equal, (5.7) reduces to

$$(5.11)\qquad \begin{aligned}&x^n\log x-\sum_{s=1}^{n}\frac{(-n)_s}{s!}[\psi(n+1)-\psi(n+1-s)](1-x)^s\\ &\quad =(-1)^{n+1}n!\sum_{s=n+1}^{\infty}\frac{(s-n-1)!}{s!}(1-x)^s, \qquad |1-x|<1,\\ &\quad =\frac{(x-1)^{n+1}}{n+1}\,{}_2F_1(1,1;n+2;1-x)\\ &\quad =\frac{(x-1)^{n+1}}{n+1}R_{-1}(1,n+1;x,1), \qquad |\arg x|<\pi.\end{aligned}$$

We shall use (5.11) to prove (5.15).

An explicit formula [3, (6.2-1)] and a recurrence relation [4, (A.6)] are available for computing the polynomials R_s in (5.6) and (5.7). Moreover we may use (2.5) to make one component of z equal to unity; then R_s has one vanishing component that can be eliminated by [3, (6.2-5), (6.2-6)]. If $k=2$ this leaves a power series in one variable:

$$L_t(\beta, \gamma-\beta; 1-x, 1)=\sum_{s=1}^{\infty}\frac{(-t)_s(\beta)_s}{(\gamma)_s s!}[\psi(t+1)-\psi(t+1-s)]x^s, \tag{5.12}$$

where $|x|<1$, $\gamma\neq 0, -1, -2, \cdots$, and $t\neq 0, 1, 2, \cdots$. From (5.7) we obtain similarly, for $n=0, 1, 2, \cdots$ and $\gamma\neq 0, -1, -2, \cdots$,

$$\begin{aligned} &L_n(\beta, \gamma-\beta; 1-x, 1)-\sum_{s=1}^{n}\frac{(-n)_s(\beta)_s}{(\gamma)_s s!}[\psi(n+1)-\psi(n+1-s)]x^s \\ &=(-1)^{n+1}n!\sum_{s=n+1}^{\infty}\frac{(s-n-1)!(\beta)_s}{(\gamma)_s s!}x^s, \qquad |x|<1, \\ &=\frac{(\beta)_{n+1}(-x)^{n+1}}{(\gamma)_{n+1}(n+1)}\,{}_3F_2(1, 1, \beta+n+1; n+2, \gamma+n+1; x), \qquad |\arg(1-x)|<\pi, \end{aligned} \tag{5.13}$$

which reduces to (5.11) if $\beta=\gamma$. An important case of (5.13) is

$$\begin{aligned} &L_n(1, \gamma-1; x, 1)-\sum_{s=1}^{n}\frac{(-n)_s}{(\gamma)_s}[\psi(n+1)-\psi(n+1-s)](1-x)^s \\ &=\frac{n!}{(\gamma)_{n+1}}(x-1)^{n+1}\,{}_2F_1(1, 1; \gamma+n+1; 1-x) \\ &=\frac{n!}{(\gamma)_{n+1}}(x-1)^{n+1}R_{-1}(1, \gamma+n; x, 1), \end{aligned} \tag{5.14}$$

where n is a nonnegative integer and $|\arg x|<\pi$. If γ is a positive integer, say $\gamma=1+m$, we can sum the ${}_2F_1$-series by (5.11) to get

$$\begin{aligned} L_n(1, m; x, 1)&=\sum_{s=1}^{n}\frac{(-n)_s}{(m+1)_s}[\psi(n+1)-\psi(n+1-s)](1-x)^s+\frac{n!m!}{(n+m)!}(x-1)^{-m} \\ &\cdot\left\{x^{n+m}\log x-\sum_{s=1}^{n+m}\frac{(-n-m)_s}{s!}[\psi(n+m+1)-\psi(n+m+1-s)](1-x)^s\right\}, \end{aligned} \tag{5.15}$$

where n and m are nonnegative integers, $|\arg x|<\pi$, and $x\neq 1$. If $n=0$ the first sum is empty and a change of index in the second sum gives, with the help of (2.5),

$$\begin{aligned} L_0(1, m; x, y)&=\log y+\left(\frac{x}{x-y}\right)^m\log\frac{x}{y} \\ &+\sum_{s=0}^{m-1}\binom{m}{s}[\psi(1+s)-\psi(1+m)]\left(\frac{y}{x-y}\right)^s, \end{aligned} \tag{5.16}$$

where m is a nonnegative integer, $x, y\in\mathbb{C}_0$, and $x\neq y$. This result generalizes (4.5) and will be used to prove (6.18).

The series in (5.12) terminates if β is a nonpositive integer, and the conditions of validity may then be relaxed:

$$L_t(-n, \gamma+n; x, 1)=\sum_{s=1}^{n}\frac{(-n)_s(-t)_s}{(\gamma)_s s!}[\psi(t+1)-\psi(t+1-s)](1-x)^s, \tag{5.17}$$

where x is unrestricted, n is a nonnegative integer, $(\gamma)_n \neq 0$, and $(-t)_n \neq 0$. The last condition is required because (5.4) was used to prove (5.12). This result will be used to prove (6.12).

6. Quadratic transformations. The R-function of two variables has exactly two independent quadratic transformations [3, (6.9-7), (6.10-1)],

$$R_{2t}(\beta, \beta; x, y) = R_t(\beta + t, 1/2 - t; A, G), \tag{6.1}$$

$$R_t(\beta, \beta; x^2, y^2) = R_t(2\beta + t, 1/2 - \beta - t; A, G), \tag{6.2}$$

where A and G denote the squared arithmetic and geometric means of x and y,

$$A = \left(\frac{x+y}{2}\right)^2, \qquad G = xy, \tag{6.3}$$

and where x and y have positive real parts and $\beta + 1/2 \neq 0, -1, -2, \cdots$. When the right-hand sides of (6.1) and (6.2) are differentiated with respect to t, one term arises from the subscript and a second term from the t-dependence of the b-parameters. Using (1.2) and (2.12) we find, with the same conditions of validity,

$$2L_{2t}(\beta, \beta; x, y) = L_t(\beta + t, 1/2 - t; A, G) - G^t L_{-t-\beta}(-t, \beta + 1/2 + t; A/G, 1), \tag{6.4}$$

$$L_t(\beta, \beta; x^2, y^2) = C + D, \tag{6.5}$$

where, for convenience in applications, we give several forms for C and D that are connected by (2.5), (2.11), (6.2), and [3, (5.9-19)]:

$$\begin{aligned} C &= L_t(2\beta + t, 1/2 - \beta - t; A, G) \\ &= \log(G) R_t(\beta, \beta; x^2, y^2) + G^t L_t(2\beta + t, 1/2 - \beta - t; A/G, 1) \\ &= \log(A) R_t(\beta, \beta; x^2, y^2) \\ &\quad - A^{1/2-\beta} G^{t+\beta-1/2} L_{-t-\beta-1/2}(1/2 - \beta - t, 2\beta + t; A/G, 1) \\ &= \log(AG) R_t(\beta, \beta; x^2, y^2) \\ &\quad - A^{1/2-\beta} G^{2t+2\beta} L_{-t-\beta-1/2}(1/2 - \beta - t, 2\beta + t; A, G), \end{aligned} \tag{6.6}$$

$$\begin{aligned} D &= -G^t L_{-t-2\beta}(-t, \beta + 1/2 + t; A/G, 1) \\ &= \log(G) R_t(\beta, \beta; x^2, y^2) - G^{2t+2\beta} L_{-t-2\beta}(-t, \beta + 1/2 + t; A, G) \\ &= -\log(A) R_t(\beta, \beta; x^2, y^2) + A^{1/2-\beta} L_{t+\beta-1/2}(\beta + 1/2 + t, -t; A, G) \\ &= -\log(A/G) R_t(\beta, \beta; x^2, y^2) \\ &\quad + A^{1/2-\beta} G^{t+\beta-1/2} L_{t+\beta-1/2}(\beta + 1/2 + t, -t; A/G, 1). \end{aligned} \tag{6.7}$$

If $t = 0$ the second term in both (6.4) and (6.5) vanishes by (2.3):

$$\begin{aligned} &2L_0(\beta, \beta; x, y) = L_0(\beta, 1/2; A, G), \\ &L_0(\beta, \beta; x^2, y^2) = L_0(2\beta, 1/2 - \beta; A, G), \\ &L_0(1/2, 1/2; x^2, y^2) = \log A = 2 \log \frac{x+y}{2}. \end{aligned} \tag{6.8}$$

Putting $t = -\beta$ and using the first form of C and the second form of D, we find

$$L_{-\beta}(\beta, \beta; x^2, y^2) = \log(xy) R_{-\beta}(\beta, \beta; x^2, y^2). \tag{6.9}$$

If $t=1/2-\beta$ the second term in the third form of C vanishes by (2.3), and the third form of D then gives

$$L_{1/2-\beta}(\beta,\beta;x^2,y^2)=\left(\frac{x+y}{2}\right)^{1-2\beta}L_0\left(1,\beta-1/2;\left(\frac{x+y}{2}\right)^2,xy\right). \tag{6.10}$$

From $L_{1/2-\beta}$ we can obtain $L_{-1/2-\beta}$ in terms of L_0 by (2.11) and [3, Ex. 6.10-12]. We shall use (6.10) to prove (6.18).

From the third form of C and the first form of D, we find

$$\begin{aligned}L_n(1/2+m,1/2+m;x^2,y^2)&=\log(A)R_n(1/2+m,1/2+m;x^2,y^2)\\&\quad-A^{-m}G^{n+m}L_{-n-m-1}(-n-m,n+2m+1;A/G,1)\\&\quad-G^nL_{-n-2m-1}(-n,n+m+1;A/G,1).\end{aligned} \tag{6.11}$$

If m and n are nonnegative integers, the last two terms (which are equal if $m=0$) have terminating series expansions (5.17). The result is

$$\begin{aligned}&L_n(1/2+m,1/2+m;x^2,y^2)\\&\quad=2\log\left(\frac{x+y}{2}\right)R_n(1/2+m,1/2+m;x^2,y^2)\\&\quad+\left(\frac{x+y}{2}\right)^{-2m}\sum_{s=1}^{n+m}\binom{n+m}{s}\frac{(n+m+1)_s}{(m+1)_s}\\&\quad\cdot[\psi(n+m+1+s)-\psi(n+m+1)]\left(\frac{x-y}{2}\right)^{2s}(xy)^{n+m-s}\\&\quad+\sum_{s=1}^{n}\binom{n}{s}\frac{(n+2m+1)_s}{(m+1)_s}[\psi(n+2m+1+s)-\psi(n+2m+1)]\left(\frac{x-y}{2}\right)^{2s}(xy)^{n-s}.\end{aligned} \tag{6.12}$$

By (6.2) and [3, (5.9-11)] the term in R_n can be omitted if, in the last sum, $2\log[(x+y)/2]$ is added to the terms in square brackets and the lower limit of summation is changed from 1 to 0. For example, the case $m=0$ is

$$\begin{aligned}&L_n(1/2,1/2;x^2,y^2)\\&\quad=2\sum_{s=0}^{n}\binom{n}{s}\binom{n+s}{s}\left[\psi(n+1+s)-\psi(n+1)+\log\frac{x+y}{2}\right]\left(\frac{x-y}{2}\right)^{2s}(xy)^{n-s},\end{aligned} \tag{6.13}$$

which generalizes the third equation in (6.8). This formula is useful for calculating the terms of the series (1.9). The polynomial $R_n(1/2,1/2;x^2,y^2)$ occurring in that series is the coefficient of $2\log[(x+y)/2]$ in (6.13).

Comparison of (6.12) and (1.7) gives

$$\begin{aligned}\left[\frac{\partial}{\partial\nu}P_\nu^{-m}(x)\right]_{\nu=n}&=\log\left(\frac{1+x}{2}\right)P_n^{-m}(x)\\&\quad+\left(\frac{1-x^2}{4}\right)^{m/2}\sum_{s=1}^{n-m}\frac{(m-n)_s(n+m+1)_s}{s!(m+s)!}\\&\quad\cdot[\psi(n+m+1+s)-\psi(n+m+1)]\left(\frac{1-x}{2}\right)^s\\&\quad+\left(\frac{1-x}{1+x}\right)^{m/2}\sum_{s=1}^{n}\frac{(-n)_s(n+1)_s}{s!(m+s)!}[\psi(n+1+s)-\psi(n+1)]\left(\frac{1-x}{2}\right)^s,\end{aligned} \tag{6.14}$$

where m and $n-m$ are nonnegative integers and $-1<x\leqq 1$. The logarithmic term can be incorporated in the second sum by adding $\log[(1+x)/2]$ to the terms in square brackets and beginning the sum at $s=0$. Equation (6.14) generalizes a formula due to Schelkunoff [13, (114)], [12, p. 173] for the case $m=0$, in which the two sums are equal. Schelkunoff used his formula in the theory of conical antennas. If m is an integer, differentiation of

$$\frac{P_\nu^m(x)}{\Gamma(\nu+m+1)}=(-1)^m\frac{P_\nu^{-m}(x)}{\Gamma(\nu-m+1)},\qquad -1\leqq x\leqq 1 \tag{6.15}$$

gives

$$\begin{aligned}\left[\frac{\partial}{\partial\nu}P_\nu^m(x)\right]_{\nu=n}&=(-1)^m\frac{(n+m)!}{(n-m)!}\left[\frac{\partial}{\partial\nu}P_\nu^{-m}(x)\right]_{\nu=n}\\&\quad+[\psi(n+m+1)-\psi(n-m+1)]P_n^m(x),\qquad n\geqq m.\end{aligned} \tag{6.16}$$

If m is even, there is no branch point at $x=1$, and the last three equations then hold for $|\arg(1+x)|<\pi$.

Equation (6.14) requires $n\geqq m$, but a known formula [9, 8.762(2)] for the case $n=0$, $m=1$ can be generalized by putting $\beta=1/2+m$ in (6.10) to get

$$L_{-m}(1/2+m,1/2+m;x^2,y^2)=\left(\frac{x+y}{2}\right)^{-2m}L_0\left(1,m;\left(\frac{x+y}{2}\right)^2,xy\right). \tag{6.17}$$

If m is a nonnegative integer, the L_0 function has a terminating series given by (5.16). The result is

$$\begin{aligned}&L_{-m}(1/2+m,1/2+m;x^2,y^2)\\&=\left(\frac{2}{x-y}\right)^{2m}\log\frac{(x+y)^2}{4xy}+\left(\frac{2}{x+y}\right)^{2m}\\&\quad\cdot\left\{\log(xy)+\sum_{s=0}^{m-1}\binom{m}{s}[\psi(1+s)-\psi(1+m)]\left(\frac{2}{x-y}\right)^{2s}(xy)^s\right\},\end{aligned} \tag{6.18}$$

where x and y have positive real parts, $x\neq y$, and $m=0,1,2,\cdots$. From L_{-m} we can obtain also L_{-m-1} by using (2.11) and [3, Ex. 6.10-12]. Comparison of (6.18) and (1.7) shows that

$$\begin{aligned}m!\left[\frac{\partial}{\partial\nu}P_\nu^{-m}(x)\right]_{\nu=0}&=(-1)^m\left(\frac{1+x}{1-x}\right)^{m/2}\log\frac{1+x}{2}\\&\quad+\left(\frac{1-x}{1+x}\right)^{m/2}\sum_{s=0}^{m-1}\binom{m}{s}[\psi(1+s)-\psi(1+m)]\left(\frac{2}{x-1}\right)^s,\end{aligned} \tag{6.19}$$

where $-1<x<1$ and $m=0,1,2,\cdots$. The limit as $x\to 1$ is 0. If m is even, the condition $-1<x<1$ can be replaced by $|\arg(x+1)|<\pi$ and $x\neq 1$.

The infinite series given in [9, (8.761)] can be reproduced by using (1.7), (6.5) with the third form of both C and D, and (5.12). The second equality in (5.4) is used also. It suffices to assume $\mu\neq -1,-2,-3,\cdots$ instead of $\operatorname{Re}\mu>-1$.

7. Inequalities. We assume t real and b_i and x_i strictly positive for $i=1,\cdots,k$. The largest and smallest of the x_i are denoted by $x_{\max}$ and $x_{\min}$, respectively, and we assume $x_{\max}>x_{\min}$ to exclude trivialities. Writing L_t for $L_t(b,x)$ and R_t for $R_t(b,x)$, we see at once from (1.1) and (1.3) that

$$R_t\log x_{\min}<L_t<R_t\log x_{\max}. \tag{7.1}$$

Chebyshev's inequality for integrals [10, Thm. 236] implies

$$L_t > R_t L_0, \qquad t > 0, \tag{7.2}$$

with reversed inequality for $t < 0$. Since $R_0 = 1$, (7.1) and (7.2) are subsumed in the following theorem, which is used in [6, (3.33)].

THEOREM 7.1. *Both L_t and L_t/R_t are strictly increasing functions of t. The limit of L_t/R_t is* $\log x_{\max}$ *as $t \to +\infty$ and* $\log x_{\min}$ *as $t \to -\infty$.*

Proof. Since the integrand of (1.1) is log-convex in t, R_t is strictly log-convex in t by [3, Ap. B.6] or [1, Thm. 4]. Hence its derivative and logarithmic derivative are strictly increasing, which proves the first part of the theorem. To prove the second part we use [1, Thm. 3]:

$$\lim_{t \to +\infty} (R_t)^{1/t} = x_{\max}, \tag{7.3}$$

which implies that $R_t \to \infty$ if $x_{\max} > 1$ and $R_t \to 0$ if $x_{\max} < 1$. If $x_{\max} = 1$ then $x_i < 1$ for some i (since $x_{\max} > x_{\min}$), and $u \cdot x$ in (1.1) is less than unity except on the set of measure zero where $u_i = 0$. Hence $(u \cdot x)^t \to 0$ almost everywhere as $t \to +\infty$, and so $R_t \to 0$. Thus $|\log R_t| \to \infty$ in all cases, and we may use L'Hôpital's rule to conclude from (7.3) that

$$\log x_{\max} = \lim_{t \to +\infty} \frac{\log R_t}{t} = \lim_{t \to +\infty} \frac{L_t}{R_t}.$$

The proof for $t \to -\infty$ is similar.

Remark. If the assumptions of Theorem 7.1 are changed so that exactly one of the variables, say x_k, is 0, then R_t and L_t are well defined for $t > -b_1 - \cdots - b_{k-1}$. In this region L_t/R_t increases strictly with t and has limit $\log x_{\max}$ as $t \to +\infty$. This follows from (4.2) and two well-known facts: $\psi''(x) < 0$ for $x > 0$, implying $\psi'(c - b_k + t) - \psi'(c + t) > 0$; and $\psi(x) = \log x + O(1/x)$ as $x \to +\infty$, implying $\psi(c - b_k + t) - \psi(c + t) \to 0$ as $t \to +\infty$.

THEOREM 7.2. *Let t be real and $x_{\max} > x_{\min} > 0$. Let $cw = (cw_1, \cdots, cw_k)$, where $c > 0$ and the w's are positive weights with $\sum w_i = 1$. Then the limit of $L_t(cw, x)$ is $\sum w_i x_i^t \log x_i$ as $c \to 0+$ and $(\sum w_i x_i)^t \log (\sum w_i x_i)$ as $c \to +\infty$. Also, $L_0(cw, x)$ is strictly increasing and strictly concave in c, and $L_1(cw, x)$ is strictly decreasing and strictly convex in c.*

Proof. We assume for the moment that $x_{\max} < 1$, so that the series expansions (5.6) and (5.7) converge. The proof of the first part of the theorem is entirely similar to the proof of [1, Thm. 1], in which L is the L_0 of the present paper. The second part of the theorem follows from (5.8), (5.9), and [7, Thm. 5]. The case $x_{\max} \geqq 1$ reduces to the case $x_{\max} < 1$ by use of (2.5) and [1, Thm. 1].

Remark. Example 5 in § 1 is contained in Theorem 7.2. The underlying reason why L_0 and L_1 are exceptionally simple is that $x^t \log x$ is concave in x for all $x > 0$ only if $t = 0$ and convex for all $x > 0$ only if $t = 1$.

8. Special cases. Several cases of L_t with restrictions on the parameters have been evaluated in finite terms in (4.6), (5.15), (5.16), (5.17), (6.12), (6.13) and (6.18). Further cases can be evaluated from these by (2.11) and the relations between associated functions in § 3. In (5.15) and (5.17) the apparent restriction of a unit variable can be removed by (2.5). We mention here some other cases, starting with

$$L_0(\beta, 1 - 2\beta; 1, 0) = \psi(\beta) - \psi(1 - \beta) = -\pi \cot (\pi\beta), \tag{8.1}$$

where β is not an integer and $\operatorname{Re}\beta > 0$, and

$$(8.2)\qquad \begin{aligned} L_{2t}(\beta, \beta; x, -x) &= \frac{\pi^{1/2}\Gamma(\beta+1/2)}{2\Gamma(1/2-t)\Gamma(\beta+1/2+t)}(-x^2)^t \\ &\quad\cdot [\psi(1/2-t) - \psi(\beta+1/2+t) + \log(-x^2)], \end{aligned}$$

where $|\arg(\pm x)| < \pi$, $|\arg(-x^2)| < \pi$, and $\beta + 1/2 \neq 0, -1, -2, \cdots$. Equation (8.1) comes from (1.5) or (4.5), and (8.2) comes from differentiating the formula in [3, Ex. 8.3-9].

To evaluate an R-function or L-function of two variables with positive integral b-parameters, we raise the b-parameters from unity by successive differentiations using [3, (5.9-9)]:

$$(8.3)\qquad \begin{aligned} R_{t-1}(m, m'; x, y) &= \frac{(m+m'-1)!}{(m-1)!(m'-1)!(t)_{m+m'-2}} \\ &\quad\cdot D_x^{m-1} D_y^{m'-1} R_{t+m+m'-3}(1, 1; x, y). \end{aligned}$$

Use of [3, Ex. 5.9-13] and two applications of Leibnitz' rule lead to

$$(8.4)\qquad \begin{aligned} R_{t-1}(m, m'; x, y) &= (m)_{m'} x^{t-1} \sum_{s=0}^{m-1} \frac{(1-m)_s (m')_s}{(t)_{m'+s} s!} \left(\frac{x}{x-y}\right)^{m'+s} \\ &\quad + (m')_m y^{t-1} \sum_{s=0}^{m'-1} \frac{(1-m')_s (m)_s}{(t)_{m+s} s!} \left(\frac{y}{y-x}\right)^{m+s}, \end{aligned}$$

where m and m' are positive integers, $x, y \in \mathbb{C}_0$, $x \neq y$, and $(t)_{m+m'-1} \neq 0$. With the same conditions, differentiation with respect to t gives

$$(8.5)\qquad \begin{aligned} L_{t-1}(m, m'; x, y) &= (m)_{m'} x^{t-1} \sum_{s=0}^{m-1} \frac{(1-m)_s (m')_s}{(t)_{m'+s} s!} \\ &\quad\cdot [\psi(t) - \psi(t+m'+s) + \log x]\left(\frac{x}{x-y}\right)^{m'+s} \\ &\quad + (m')_m y^{t-1} \sum_{s=0}^{m'-1} \frac{(1-m')_s (m)_s}{(t)_{m+s} s!} \\ &\quad\cdot [\psi(t) - \psi(t+m+s) + \log y]\left(\frac{y}{y-x}\right)^{m+s}. \end{aligned}$$

Agreement with the special case (5.16) can be shown by a binomial expansion of $[1 + y/(x-y)]^m$.

Putting $n = 0$ and $\gamma = 1$ in (5.13), dividing by β, and letting $\beta \to 0$, we find a relation between L_0 and Euler's dilogarithm:

$$(8.6)\qquad -\lim_{\beta \to 0} \beta^{-1} L_0(\beta, 1-\beta; 1-x, 1) = x\,{}_3F_2(1, 1, 1; 2, 2; x) = \sum_{n=1}^{\infty} \frac{x^n}{n^2}.$$

By (2.3) the limit of the same quantity as β tends to 1 is

$$(8.7)\qquad -\lim_{\beta \to 1} \beta^{-1} L_0(\beta, 1-\beta; 1-x, 1) = -\log(1-x) = \sum_{n=1}^{\infty} \frac{x^n}{n}.$$

The conditions of validity for (8.5) exclude the function

$$(8.8)\qquad L_{-1}(1, 1; x, y) = \frac{(\log x)^2 - (\log y)^2}{2(x-y)}, \qquad x \neq y,$$

which is evaluated by putting $f(x)=(\log x)^2$ in [3, (5.5-3)]. Similarly putting $f(x)=x^t$ in [3, Ex. 5.5-1], we find

$$R_{t-2}(1,1,1;x,y,z)=\frac{2}{t(t-1)}\sum_{\text{cyc}}\frac{x^t}{(x-y)(x-z)}, \tag{8.9}$$

where $t\neq 0$, 1 and the sum extends over cyclic permutations of the distinct complex numbers x, y, z. We shall refrain from raising the b-parameters by differentiation with respect to x, y, z as in (8.3). Differentiation with respect to t gives

$$L_{t-2}(1,1,1;x,y,z)=\frac{2}{t(t-1)}\sum_{\text{cyc}}\frac{x^t}{(x-y)(x-z)}\left(\log x-\frac{1}{t}-\frac{1}{t-1}\right), \tag{8.10}$$

with the same conditions of validity as for (8.9). This is the function that occurs in (1.8). The exceptional cases with $t=0$ or 1 are evaluated by successively putting $f(x)=\log x$, $(\log x)^2$, $x\log x$, and $x(\log x)^2$ in [3, Ex. 5.5-1]:

$$R_{-2}(1,1,1;x,y,z)=-2\sum_{\text{cyc}}\frac{\log x}{(x-y)(x-z)}, \tag{8.11}$$

$$L_{-2}(1,1,1;x,y,z)=-\sum_{\text{cyc}}\frac{(\log x)^2+2\log x}{(x-y)(x-z)}, \tag{8.12}$$

$$R_{-1}(1,1,1;x,y,z)=2\sum_{\text{cyc}}\frac{x\log x}{(x-y)(x-z)}, \tag{8.13}$$

$$L_{-1}(1,1,1;x,y,z)=\sum_{\text{cyc}}\frac{x[(\log x)^2-2\log x]}{(x-y)(x-z)}. \tag{8.14}$$

Values for special cases of the L-function permit evaluation of some special cases of ${}_3F_2$ by using (5.13). For example,

$${}_3F_2(1,1,m+n+3/2;n+2,2m+n+2;x)$$

can be found from (5.13) and (6.12) if m and n are nonnegative integers. The case $n=0$ is

$$\begin{aligned}{}_3F_2(1,1,m+3/2;2,2m+2;x)&=(-4/x)\log y-(2/x)y^{-2m}\sum_{s=1}^{m}\binom{m}{s}\\&\quad\cdot[\psi(m+1+s)-\psi(m+1)](y-1)^{2s}(1-x)^{(m-s)/2},\end{aligned} \tag{8.15}$$

where $2y=1+(1-x)^{1/2}$, $|\arg(1-x)|<\pi$, and $m=0,1,2,\cdots$.

SCHUR-OSTROWSKI THEOREMS FOR FUNCTIONALS ON $L_1(0, 1)$*

WAI CHAN†, FRANK PROSCHAN†‡ AND JAYARAM SETHURAMAN†§

Abstract. Hardy, Littlewood and Pólya [5] introduced the partial ordering of majorization among n-dimensional real vectors. Many well-known inequalities can be recast as the statement that certain functions are increasing with respect to this ordering. Such functions are said to be Schur-convex. An important result in the theory of majorization is the Schur-Ostrowski theorem, which characterizes Schur-convex functions. The concept of majorization has been extended to elements of $L_1(0, 1)$ by Ryff [10]. A functional on $L_1(0, 1)$ that is increasing with respect to the ordering of majorization is said to be Schur-convex. In this paper, we prove an analogue of the Schur-Ostrowski condition that characterizes Schur-convex functionals in terms of their Gâteaux differentials. We also introduce another partial ordering in $L_1(0, 1)$ called unrestricted majorization. This partial ordering is similar to majorization but does not involve the use of decreasing rearrangements. We establish a characterization of nondecreasing functionals on $L_1(0, 1)$ with respect to the partial ordering of unrestricted majorization through another analogue of the Schur-Ostrowski condition.

AMS(MOS) subject classifications. 26D10, 60E15

1. Introduction. Hardy, Littlewood and Pólya [5] introduced the following partial order in n-dimensional Euclidean spaces: an n-vector $\mathbf{x}=(x_1, \cdots, x_n)$ majorizes $\mathbf{y}=(y_1, \cdots, y_n)$, ($\mathbf{x} \geqq^m \mathbf{y}$ in symbols), whenever

$$\sum_1^k x_i^* \geqq \sum_1^k y_i^*, \qquad k=1, \cdots, n-1$$

and

$$\sum_1^n x_i = \sum_1^n y_i,$$

where $\mathbf{x}^*$, $\mathbf{y}^*$ are the vectors obtained from $\mathbf{x}$ and $\mathbf{y}$ by rearranging their components in decreasing order.

This partial order has been extended to elements of $L_1(0, 1)$ by Ryff [10] and is given in Definition 1.2 below. Before giving this definition, we develop some notation to be used in defining a decreasing rearrangement of a function. Let x be a measurable, real valued function on (0, 1) and m be the Lebesgue measure. For each x, one can associate a function d_x on $(-\infty, \infty)$ defined by

$$d_x(s) = m(\{t: x(t) > s\}), \qquad -\infty < s < \infty.$$

This function d_x, called the distribution function of x, is nonincreasing and right continuous. Two functions x and y are said to be equivalent in distribution if $d_x = d_y$. The right continuous inverse of d_x, denoted x^*, is defined by

$$x^*(t) = \inf \{s: d_x(s) \leqq t\}.$$

§ The work of this author was supported by the U.S. Army Research Office under grant DAAG 29-82-K-0168.

The function x^*, which is nonincreasing, right continuous and has the same distribution function as x, is called the decreasing rearrangement of x. The functions x and x^* are simultaneously integrable (or nonintegrable), and their integrals are related by

$$\int_0^s x^*(t)\,dt \geqq \int_0^s x(t)\,dt, \qquad 0 \leqq s < 1$$

and

$$\int_0^1 x^*(t)\,dt = \int_0^1 x(t)\,dt.$$

The following theorem due to Ryff [12] shows that, by composing the decreasing rearrangement of a function with a measure preserving transformation, one can recover the original function.

THEOREM 1.1. *To each* $x \in L_1(0, 1)$, *there corresponds a measure preserving transformation* $\sigma: (0, 1) \to (0, 1)$ *such that* $x(t) = x^*[\sigma(t)]$, *where* σ *is defined by*

$$\sigma(s) = m\{t: x(t) > x(s)\} + m\{t \leqq s: x(t) = x(s)\}.$$

The definition of the partial ordering of majorization of elements in $L_1(0, 1)$, due to Ryff [10], is given below.

DEFINITION 1.2. Let $x, y \in L_1(0, 1)$. We say that x majorizes y, ($x \geqq^m y$ in symbols) if

$$\int_0^s x^*(t)\,dt \geqq \int_0^s y^*(t)\,dt, \qquad 0 \leqq s < 1,$$

and

$$\int_0^1 x(t)\,dt = \int_0^1 y(t)\,dt,$$

where x^* and y^* are the decreasing rearrangements of x and y, respectively.

Several authors (see, e.g., Day [4], Chong [3]) have obtained interesting results using this partial ordering. It is also related to the variability ordering of Ross [9].

By removing the rearrangement requirement in Definition 1.2, we obtain a different ordering called unrestricted majorization, as defined below.

DEFINITION 1.3. Let $x, y \in L_1(0, 1)$. We say that x dominates y in the ordering of unrestricted majorization, ($x \geqq^u y$ in symbols), if

$$\int_0^s x(t)\,dt \geqq \int_0^s y(t)\,dt, \qquad 0 \leqq s < 1,$$

and

$$\int_0^1 x(t)\,dt = \int_0^1 y(t)\,dt.$$

The ordering of unrestricted majorization as applied to the class of density functions leads to the usual stochastic ordering as seen below.

Let X and Y be random variables on $(0, 1)$ with densities f and g, respectively. If $f \geqq^u g$, then $\int_0^s f \geqq \int_0^s g$ for all $0 < s < 1$, or $P(X \leqq s) \geqq P(Y \leqq s)$. Thus the condition $X \leqq^{st} Y$ is equivalent to $f \geqq^u g$.

Many inequalities that arise from majorization in the finite dimensional case can be extended for elements of $L_p(0, 1)$. Ryff [11] proved the following analogue of Muirhead's inequality.

THEOREM 1.4. *Let x and y be bounded measurable functions on* $(0, 1)$. *If $x \geqq^m y$ and u is a positive function such that $u \in L_p(0, 1)$ for all p, $-\infty < p < \infty$, then*

$$\int_0^1 \log\left[\int_0^1 u(t)^{x(s)}\,dt\right] ds \geqq \int_0^1 \log\left[\int_0^1 u(t)^{y(s)}\,dt\right] ds.$$

Conversely, if the inequality holds for all such u, then $x \geqq^m y$.

In the discrete case, Muirhead's inequality can be reformulated by identifying an appropriate function which preserves the ordering of majorization. Such functions are said to be Schur-convex. Schur [13] and Ostrowski [7] gave necessary and sufficient conditions for a function to be Schur-convex in terms of their partial derivatives. We quote from Marshall and Olkin [6] about the importance of this result, "it is difficult to overemphasize the usefulness of the (Schur–Ostrowski) condition . . . , many or even most of the theorems giving Schur-convexity were first discovered by checking (the Schur–Ostrowski condition)." In the next section, we will present an analogue of this result for Schur-convex functionals on $L_\infty(0, 1)$. This result, given in Theorem 2.9, is then used to characterize Schur-convex functionals on $L_1(0, 1)$. We also characterize nondecreasing functionals on $L_1(0, 1)$ with respect to the partial ordering of unrestricted majorization through another analogue of the Schur–Ostrowski condition. These results will be used to prove the generalized Muirhead's theorem (Proschan and Sethuraman [8]) in § 3. An application to peakedness comparisons of distributions is discussed in § 3.

2. Main theorems. We first proceed with some definitions.

DEFINITION 2.1. A functional ϕ defined on a set $\mathscr{A} \subseteqq L_1(0, 1)$ is said to be Schur-convex on $\mathscr{A}$ if $y_1, y_2 \in \mathscr{A}$ and $y_1 \geqq^m y_2$ imply that $\phi(y_1) \geqq \phi(y_2)$.

A Schur-convex functional is necessarily constant over functions that are equivalent in distribution. Thus for a Schur-convex functional ϕ, the value $\phi(x)$ depends only on the distribution function of x. A set $\mathscr{A}$ is said to be invariant if $x \in \mathscr{A}$ and x and y are equivalent in distribution implying that $y \in \mathscr{A}$. Henceforth, we shall only consider Schur-convex functionals on an invariant set.

For a characterization of Schur-convex functionals, we need the following notion of directional derivative.

DEFINITION 2.2. Let ϕ be a functional defined on a convex set $\mathscr{A} \subseteqq L_1(0, 1)$. Let $y \in \mathscr{A}$ and h be such that $y + \theta h \in \mathscr{A}$ for all sufficiently small θ. The Gâteaux differential of ϕ at y in the direction of h is defined to be

$$\frac{\partial\phi}{\partial h}(y) = \lim_{\theta\to 0} \frac{\phi(y+\theta h) - \phi(y)}{\theta}$$

if the limit exists.

Note that $\partial\phi/\partial h(y)$ is simply the derivative, at $\theta = 0$, of the real valued function on $[0, 1]$ defined by $\psi(\theta) = \phi(y + \theta h)$.

Let $\mathscr{D}_1$ be the class of decreasing functions in $L_1(0, 1)$, let $\mathscr{D}_\infty$ be the class of decreasing functions in $L_\infty(0, 1)$. Let $\mathscr{T} = \{h\colon h = \lambda_1 I_{(a,b)} + \lambda_2 I_{(c,d)}$, where $0 \leqq a < b < c < d \leqq 1$, $\lambda_1 \geqq 0 \geqq \lambda_2$, $\lambda_1(b-a) + \lambda_2(d-c) = 0\}$. The class $\mathscr{T}$ consists of step functions h which take at most two nonzero values, are decreasing on their support and satisfy $\int_0^1 h(t)\,dt = 0$. Note that $h \in \mathscr{T}$ implies $h \geqq^m 0$.

Let $y \in \mathscr{D}_1$ and $h \in \mathscr{T}$. Then $y + h$ need not be decreasing. However, we have $y + h \geqq^m y$, as given in the next lemma.

LEMMA 2.3. *Let $y \in \mathscr{D}_1$ and $h \in \mathscr{T}$; then $y + h \geqq^m y$.*

Proof. Note that

$$\begin{aligned}\int_0^s (y+h)^* &\geqq \int_0^s (y+h)\\ &= \int_0^s y^* + \int_0^s h\\ &\geqq \int_0^s y^*, \qquad 0 \leqq s < 1\end{aligned}$$

and

$$\int_0^1 (y+h) = \int_0^1 y + \int_0^1 h = \int_0^1 y.$$

Hence, $y+h \geqq^m y$. □

In the following theorem, we give a necessary condition for functionals increasing in the ordering of unrestricted majorization.

THEOREM 2.4. *Let $\mathscr{A}$ be an open subset of $L_1(0,1)$. Let ϕ be a functional defined on $\mathscr{A}$ such that ϕ is nondecreasing with respect to the ordering of unrestricted majorization. Let $y \in \mathscr{A}$ and $h \in \mathscr{T}$. Suppose that the Gâteaux differential $\partial\phi/\partial h(y)$ exists. Then $\partial\phi/\partial h(y) \geqq 0$.*

Proof. Since $\mathscr{A}$ is open, $y+\theta h \in \mathscr{A}$ for all sufficiently small θ. Thus for all sufficiently small positive θ, $y+\theta h$ and y are elements of $\mathscr{A}$ and $y+\theta h \geqq^u y$. This implies that

$$\phi(y+\theta h) \geqq \phi(y)$$

and

$$\begin{aligned}\frac{\partial\phi}{\partial h}(y) &= \lim_{\theta\downarrow 0} \frac{1}{\theta}[\phi(y+\theta h) - \phi(y)]\\ &\geqq 0.\end{aligned}$$ □

Next, we consider Schur-convex functionals defined on an invariant set $\mathscr{A}$.

THEOREM 2.5. *Let $\mathscr{A}$ be an open invariant subset of $L_1(0,1)$. Let ϕ be a Schur-convex functional defined on $\mathscr{A}$. Let $y \in \mathscr{D}_\infty \cap \mathscr{A}$ and $h \in \mathscr{T}$. Suppose that the Gâteaux differential $\partial\phi/\partial h(y)$ exists. Then $\partial\phi/\partial h(y) \geqq 0$.*

Proof. Since $\mathscr{A}$ is open, $y+\theta h \in \mathscr{A}$ for all sufficiently small θ. Furthermore, for sufficiently small positive θ, $y+\theta h \geqq^m y$ from Lemma 2.3. Hence $\phi(y+\theta h) \geqq \phi(y)$ and

$$\begin{aligned}\frac{\partial\phi}{\partial h}(y) &= \lim_{\theta\downarrow 0} \frac{1}{\theta}[\phi(y+\theta h) - \phi(y)]\\ &\geqq 0.\end{aligned}$$ □

To show that this condition is also sufficient, which is the content of the main theorem, Theorem 2.10 of this section, we need the following lemmas.

LEMMA 2.6. *Let $\mathscr{A}$ be a convex subset of $L_1(0,1)$. Let ϕ be a functional defined on an open set containing $\mathscr{A}$. Let $\partial\phi/\partial h(y) \geqq 0$ for $y \in \mathscr{A}$ and $h \in \mathscr{T}$. Then $y_1, y_2 \in \mathscr{A}$ and $y_2 - y_1 \in \mathscr{T}$ imply that $\phi(y_2) \geqq \phi(y_1)$.*

Proof. Let $h = y_2 - y_1 \in \mathscr{T}$. For $\theta \in [0,1]$, define

$$y_\theta = y_1 + \theta(y_2 - y_1) = \theta y_2 + (1-\theta) y_1$$

and

$$\psi(\theta)=\phi(y_\theta).$$

Note that y_θ is in $\mathscr{A}$. Now,

$$\begin{aligned}\frac{d}{d\theta}\psi(\theta)&=\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}[\psi(\theta+\varepsilon)-\psi(\theta)]\\&=\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}[\phi(y_\theta+\varepsilon h)-\phi(y_\theta)]\\&=\frac{\partial\phi}{\partial h}(y_\theta)\geqq 0\quad\text{for } 0\leqq\theta\leqq 1.\end{aligned}$$

Hence,

$$\begin{aligned}\phi(y_2)-\phi(y_1)&\geqq\int_0^1\frac{d}{d\theta}\psi(\theta)\,d\theta\\&=\int_0^1\frac{\partial\phi}{\partial h}(y_\theta)\,d\theta\geqq 0.\end{aligned}$$ □

In the next lemma, we show that if y_1, y_2 are step functions such that $y_2\geqq^u y_1$, then y_2-y_1 can be written as the sum of functions in $\mathscr{T}$.

LEMMA 2.7. *Let y_1, y_2 be step functions on $(0,1)$ such that $y_2\geqq^u y_1$. Then there exist $h_1,\cdots,h_N$ in $\mathscr{T}$ such that*

$$y_2=y_1+\sum_{i=1}^N h_i. \tag{2.1}$$

Proof. There is nothing to prove if $y_1=y_2$.

Let $y_1\neq y_2$. Since y_1 and y_2 are step functions, there is an integer $n\geqq 2$, such that

$$y_2(t)-y_1(t)=\sum_{i=1}^n a_i I_{(c_i,d_i)}(t)\quad\text{where } a_i\neq 0,$$

(c_i,d_i) are disjoint intervals and $0\leqq c_1<d_1<\cdots<c_n<d_n\leqq 1$. Note that $y_2\geqq^u y_1$ implies that $a_1>0$ and $a_n<0$. We will prove that (2.1) holds with $N\leqq n-1$, by an induction on n.

Note that the lemma is immediate when $n=2$. Assume that the lemma is true for $n=2,\cdots,k-1$. We will now prove that the lemma holds for $n=k$. Let a_j be the first negative term such that either $a_{j+1}>0$ or $j=k$. Define a function in $\mathscr{T}$ by

$$h=a_1 I_{(c_1,c_1')}+a_j I_{(d_j',d_j)},$$

where $c_1'\leqq d_1$ and $d_j'\geqq c_j$ are chosen so that $a_1(c_1'-c_1)+a_j(d_j=d_j')=0$ and one of the following holds:

1) $c_1'=d_1$ and $d_j'=c_j$ if $a_1(d_1-c_1)+a_j(d_j-c_j)=0$,
2) $c_1'<d_1$ and $d_j'=c_j$ if $a_1(d_1-c_1)+a_j(d_j-c_j)>0$,
3) $c_1'=d_1$ and $d_j'>c_j$ if $a_1(d_1-c_1)+a_j(d_j-c_j)<0$.

We will now establish that $y_2\geqq^u y_1+h$ by showing that $\int_0^s(y_2-y_1-h)\geqq 0$ for all $0<s\leqq 1$. Note that $h=0$ on the interval $(d_j,1)$.

Let $s>d_j$, then $\int_0^s h=\int_0^1 h=0$. Thus,

$$\int_0^s(y_2-y_1-h)=\int_0^s(y_2-y_1)\geqq 0.$$

Let $0 < s \leqq d_j$. Then either $y_2(t) - y_1(t) \geqq 0$ for all $0 < t < s$ or $y_2(t) - y_1(t) \leqq 0$ for all $s < t \leqq d_j$, since there is only one sign change among $a_1, \cdots, a_j$ and the sign changes from positive to negative. Note that h agrees with $y_2 - y_1$ on the intervals (c_1, c_1') and (d_j', d_j), and that h is identically zero outside these intervals.

If $y_2(t) - y_1(t) \geqq 0$ for all $0 < t < s$, then $y_2 - y_1 \geqq h \geqq 0$ on the interval $(0, s)$. This implies that

$$\int_0^s (y_2 - y_1 - h) \geqq 0.$$

If $y_2(t) - y_1(t) \leqq 0$ for all $s < t < d_j$, then $y_2 - y_1 \leqq h \leqq 0$ on the interval (s, d_j). This implies that

$$\begin{aligned}\int_0^s (y_2 - y_1 - h) &\leqq \int_0^{d_j} (y_2 - y_1 - h)\\ &= \int_0^{d_j} (y_2 - y_1)\\ &\geqq 0.\end{aligned}$$

Hence we have $y_2 \geqq^u y_1 + h$. Since $y_2 - y_1 - h$ is a step function which takes at most $k-1$ nonzero values, it follows from the induction hypothesis that $y_2 - y_1 - h = \sum_{i=1}^N h_i'$ where $h_i' \in \mathcal{T}$ for $i = 1, \cdots, N$, and $N \leqq k-2$. This completes the proof. □

In Lemma 2.7, if we assume that y_1, y_2 are decreasing step functions, then the condition $y_2 \geqq^u y_1$ is equivalent to $y_2 \geqq^m y_1$. In addition, we can choose $y_1 + h_1, y_1 + h_1 + h_2, \cdots, y_1 + \sum_{i=1}^{N-1} h_i$ to be decreasing functions as shown in the following lemma.

LEMMA 2.8. *Let y_1, y_2 be decreasing step functions on $(0, 1)$ such that $y_2 \geqq^m y_1$. Then there exist $h_1, \cdots, h_N$ in $\mathcal{T}$ such that*

(i) $y_2 = y_1 + \sum_{i=1}^{N} h_i$, *and*

(ii) $y_1 + h_1, \cdots, y_1 + \sum_{i=1}^{N-1} h_i$ *are decreasing functions.*

Proof. Define $h = a_1 I_{(c_1, c_1')} + a_j I_{(d_j', d_j)}$ as in the proof of Lemma 2.7. We need to show that $y_1 + h$ is decreasing. Note that

$$y_1(t) + h(t) = \begin{cases} y_2(t) & \text{if } 0 < t < c_1', \\ y_1(t) & \text{if } c_1' \leqq t \leqq d_j', \\ y_2(t) & \text{if } d_j' < t \leqq d_j, \\ y_1(t) & \text{if } d_j \leqq t < 1. \end{cases}$$

Since $a_1 > 0$, $y_1 + h$ is decreasing on a neighborhood of c_1'. Similarly, $a_j < 0$ implies that $y_1 + h$ is decreasing on a neighborhood of d_j'. Suppose that $d_j < 1$, then the choice of a_j indicates that for $\varepsilon > 0$ sufficiently small, $y_2 - y_1 \geqq 0$ on $(d_j, d_j + \varepsilon)$. Since $y_1 + h = y_2$ on $(d_j', d_j]$, it follows that $y_1 + h$ is decreasing on the interval $(d_j', d_j + \varepsilon)$. Thus $y_1 + h$ is decreasing on the interval $(0, 1)$.

Note that $h \in \mathcal{T}$ implies $y_1 + h \geqq^u y_1$. Since $y_1 + h$, y_1 are decreasing functions, this is equivalent to $y_1 + h \geqq^m y_1$. Following the same induction argument as in Lemma 2.7, we conclude that there exist $h_1, \cdots, h_N$ in $\mathcal{T}$ such that $y_2 = y_1 + h + \sum_{i=1}^N h_i$ and that $y_1 + h + h_1, \cdots, y_1 + h + \sum_{i=1}^{N-1} h_i$ are decreasing functions. This proves the lemma. □

In the next theorem, we give a sufficient condition for a functional of $L_\infty(0,1)$ to be Schur-convex.

THEOREM 2.9. *Let $\mathcal{A}$ be an invariant open convex subset of $L_\infty(0,1)$. Let ϕ be a continuous functional defined on $\mathcal{A}$ such that ϕ is constant over functions that are equivalent in distribution. If the Gâteaux differential $\partial\phi/\partial h(y) \geqq 0$ for each $y \in \mathcal{D}_\infty \cap \mathcal{A}$ and $h \in \mathcal{T}$, then ϕ is Schur-convex on $\mathcal{A}$.*

Proof. Since ϕ is constant over functions that are equivalent in distribution, it suffices to prove that ϕ is Schur-convex on $\mathcal{D}_\infty \cap \mathcal{A}$.

Let $y_1, y_2 \in \mathcal{D}_\infty \cap \mathcal{A}$ be right continuous and $y_2 \geqq^m y_1$. Let $\varepsilon > 0$ be arbitrary. Then for $i = 1, 2$, the sets $\{t: y_i(t^-) - y_i(t) > \varepsilon\}$ are finite, where $y_i(t_0^-) = \inf_{t<t_0} y_i(t)$. Hence there exists a partition $0 < a_1 < \cdots < a_n < 1$ such that

$$y_i(a_k) - y_i(a_{k+1}^-) < \varepsilon, \quad i = 1, 2; \quad k = 1, \cdots, n-1.$$

Define

$$y_{i\varepsilon}(t) = \frac{1}{a_1}\left[\int_0^{a_1} y_i(s)\,ds\right] I_{(0,a_1)}(t) + \sum_{k=1}^{n-1} \frac{1}{a_{k+1}-a_k}\left[\int_{a_k}^{a_{k+1}} y_i(s)\,ds\right] I_{[a_k,a_{k+1})}(t)$$
$$+ \frac{1}{1-a_n}\left[\int_{a_n}^{1} y_i(s)\,ds\right] I_{[a_n,1)}(t), \qquad i = 1, 2.$$

Then $y_{1\varepsilon}$, $y_{2\varepsilon}$ are decreasing step functions satisfying $\int_0^{a_k} y_{i\varepsilon}(s)\,ds = \int_0^{a_k} y_i(s)\,ds$ for $k = 1, \cdots, n$. This implies $y_{2\varepsilon} \geqq^m y_{1\varepsilon}$. Since $\mathcal{A}$ is open and $\|y_i - y_{i\varepsilon}\|_\infty < \varepsilon$, for sufficiently small positive ε, $y_{1\varepsilon}$, $y_{2\varepsilon}$ are in $\mathcal{A}$.

By Lemma 2.8, $y_{2\varepsilon} - y_{1\varepsilon} = \sum_{i=1}^N h_i$ for some $\{h_1, \cdots, h_N\} \subseteq \mathcal{T}$, where $y_{1\varepsilon} + h_1, \cdots, y_{1\varepsilon} + \sum_{i=1}^{N-1} h_i$ are decreasing functions. The functions $y_{1\varepsilon} + h_1, \cdots, y_{1\varepsilon} + \sum_{i=1}^{N-1} h_i$ need not be elements of $\mathcal{A}$. Since $\mathcal{A}$ is open, for sufficiently small positive θ, $y_{1\varepsilon} + \theta h_1, \ldots, y_{1\varepsilon} + \theta \sum_{i=1}^N h_i$ are decreasing functions in $\mathcal{A}$ satisfying

$$y_{1\varepsilon} + \theta \sum_{i=1}^N h_i \geqq^m y_{1\varepsilon} + \theta \sum_{i=1}^{N-1} h_i \geqq^m \cdots \geqq^m y_{1\varepsilon}.$$

It now follows from Lemma 2.6 that

$$\phi\left(y_{1\varepsilon} + \theta \sum_{i=1}^N h_i\right) \geqq \phi\left(y_{1\varepsilon} + \theta \sum_{i=1}^{N-1} h_i\right) \geqq \cdots \geqq \phi(y_{1\varepsilon}).$$

Next, we shall show that this implies $\phi(y_{2\varepsilon}) \geqq \phi(y_{1\varepsilon})$. Note that we have just demonstrated that the set

$$\Theta = \left\{0 \leqq \theta \leqq 1: \phi\left(y_{1\varepsilon} + \theta \sum_{i=1}^N h_i\right) \geqq \phi(y_{1\varepsilon})\right\}$$

is nonempty. Let $\theta_0 = \sup\{\theta: \theta \in \Theta\}$. Since ϕ is continuous, we have $\phi(y_{1\varepsilon} + \theta_0 \sum_{i=1}^N h_i) \geqq \phi(y_{1\varepsilon})$, which shows that $\theta_0 \in \Theta$. Now suppose $\theta_0 < 1$. The preceding arguments show that for sufficiently small positive r,

$$y_{1\varepsilon} + \theta_0 \sum_{i=1}^N h_i + rh_1, \cdots, y_{1\varepsilon} + \theta_0 \sum_{i=1}^N h_1 + r \sum_{i=1}^N h_i$$

are decreasing functions in $\mathcal{A}$ and satisfy

$$\phi\left(y_{1\varepsilon} + \theta_0 \sum_{i=1}^N h_i\right) \leqq \phi\left(y_{1\varepsilon} + \theta_0 \sum_{i=1}^N h_i + rh_1\right) \leqq \cdots \leqq \phi\left(y_{1\varepsilon} + \theta_0 \sum_{i=1}^N h_i + r \sum_{i=1}^N h_i\right).$$

Thus $\theta_0 + r \in \Theta$, which provides a contradiction to the assumption that $\theta_0 < 1$. We therefore conclude that $\theta_0 = 1$ and thus, $\phi(y_{2\varepsilon}) \geqq \phi(y_{1\varepsilon})$.

Since the functional is continuous with respect to L_∞-norm, we conclude that $\phi(y_2) \geqq \phi(y_1)$ by letting $\varepsilon \to 0$. □

We now use this theorem to establish a sufficient condition for Schur-convex functional of $L_1(0, 1)$.

THEOREM 2.10. *Let $\mathcal{A}$ be an invariant open convex subset of $L_1(0, 1)$. Let ϕ be a continuous functional defined on $\mathcal{A}$ such that ϕ is constant over functions that are equivalent in distribution. If the Gâteaux differential $\partial\phi/\partial h(y) \geqq 0$ for each $y \in \mathcal{D}_\infty \cap \mathcal{A}$ and $h \in \mathcal{T}$, then ϕ is Schur-convex on $\mathcal{A}$.*

Proof. Since ϕ is constant over functions that are equivalent in distribution, it suffices to prove that ϕ is Schur-convex on $\mathcal{D}_1 \cap \mathcal{A}$.

Let $y_1, y_2 \in \mathcal{D}_1 \cap \mathcal{A}$ be right continuous and $y_2 \geqq^m y_1$. Let $\varepsilon > 0$ be arbitrary, then there exists $\delta > 0$ such that

$$\int_0^\delta |y_i(t)|\, dt < \frac{\varepsilon}{4} \quad \text{and} \quad \int_{1-\delta}^1 |y_i(t)|\, dt < \frac{\varepsilon}{4}, \quad i = 1, 2.$$

Since the y_i's are in $\mathcal{D}_1$, they are bounded on the interval $[\delta, 1-\delta]$. Define

$$y_{i\varepsilon}(t) = \frac{1}{\delta}\left[\int_0^\delta y_i(s)\, ds\right] I_{(0,\delta)}(t) + y_i(t) I_{[\delta, 1-\delta]}(t)$$

$$+ \frac{1}{\delta}\left[\int_{1-\delta}^1 y_i(s)\, ds\right] I_{(1-\delta,1)}(t), \qquad i = 1, 2.$$

Then $y_{i\varepsilon} \in \mathcal{D}_\infty$, $i = 1$, 2 and $y_{2\varepsilon} \geqq^m y_{1\varepsilon}$. We also have

$$\|y_{i\varepsilon} - y_i\|_1 = \int_0^\delta |y_{i\varepsilon} - y_i| + \int_{1-\delta}^1 |y_{i\varepsilon} - y_i| \leqq \varepsilon, \qquad i = 1, 2.$$

Hence, for sufficiently small ε, $y_{i\varepsilon} \in \mathcal{D}_\infty \cap \mathcal{A}$. Since ϕ is also L_∞-continuous on $\mathcal{A} \cap L_\infty(0, 1)$, it now follows from Theorem 2.9 that $\phi(y_{2\varepsilon}) \geqq \phi(y_{1\varepsilon})$. Since ϕ is a continuous functional, we obtain that $\phi(y_2) \geqq \phi(y_1)$ by letting $\varepsilon \to 0$. This completes the proof. □

The following lemma is used to prove Theorem 2.12, which is an analogue of Theorem 2.10 for functionals on $L_1(0, 1)$ which are nondecreasing with respect to the ordering of unrestricted majorization.

LEMMA 2.11. *Let $y_1, y_2 \in L_1(0, 1)$ such that $y_2 \geqq^u y_1$. For each $\varepsilon > 0$, there exists a partition $0 < a_1 < \cdots < a_n < 1$ such that the step functions defined by*

$$y_{i\varepsilon}(t) = \frac{1}{a_1}\int_0^{a_1} [y_i(s)\, ds] I_{(0,a_1)}(t) + \sum_{k=1}^{n-1} \frac{1}{a_{k+1} - a_k}\left[\int_{a_k}^{a_{k+1}} y_i(s)\, ds\right] I_{[a_k, a_{k+1})}(t)$$

$$+ \frac{1}{1-a_n}\left[\int_{a_n}^1 y_i(s)\, ds\right] I_{[a_n, 1)}(t), \qquad i = 1, 2,$$

satisfy the following:

(i) $\|y_{i\varepsilon} - y_i\|_1 < \varepsilon$, $i = 1, 2$, *and*

(ii) $y_{2\varepsilon} \geqq^u y_{1\varepsilon}$.

Proof. Note that if y_1, y_2 are continuous functions on the interval $[0, 1]$, then (i) follows from the uniform continuity of y_1 and y_2. If y_i's are not continuous on $[0, 1]$, we first approximate y_i's by continuous functions x_i on $[0, 1]$ such that $\|y_i - x_i\|_1 < \varepsilon/3$,

$i=1, 2$. Next, we find a partition $0<a_1<\cdots<a_n<1$ such that the step functions defined by

$$x_{i\varepsilon}(t)=\frac{1}{a_1}\left[\int_0^{a_1} x_i(s)\,ds\right]I_{(0,a_1)}(t)+\sum_{k=1}^{n-1}\frac{1}{a_{k+1}-a_k}\left[\int_{a_k}^{a_{k+1}} x_i(s)\,ds\right]I_{[a_k,a_{k+1})}(t)$$
$$+\frac{1}{1-a_n}\left[\int_{a_n}^{1} x_i(s)\,ds\right]I_{[a_n,1)}(t), \qquad i=1,2$$

satisfy $\|x_{i\varepsilon}-x_i\|_1<\varepsilon/3$.

Now, define the step functions $y_{1\varepsilon}$, $y_{2\varepsilon}$ by

$$y_{i\varepsilon}(t)=\frac{1}{a_1}\left[\int_0^{a_1} y_i(s)\,ds\right]I_{(0,a_1)}(t)+\sum_{k=1}^{n-1}\frac{1}{a_{k+1}-a_k}\left[\int_{a_k}^{a_{k+1}} y_i(s)\,ds\right]I_{[a_k,a_{k+1})}(t)$$
$$+\frac{1}{1-a_n}\left[\int_{a_n}^{1} y_i(s)\,ds\right]I_{[a_n,1)}(t), \qquad i=1,2.$$

Then

$$\|y_{i\varepsilon}-x_{i\varepsilon}\|_1=\left|\int_0^{a_1}[y_i(s)-x_i(s)]\,ds\right|+\sum_{k=1}^{n-1}\left|\int_{a_k}^{a_{k+1}}[y_i(s)-x_i(s)]\,ds\right|$$
$$+\left|\int_{a_n}^{1}[y_i(s)-x_i(s)]\,ds\right|$$
$$\leqq \|x_i-y_i\|_1, \qquad i=1,2.$$

Thus

$$\|y_i-y_{i\varepsilon}\|_1\leqq\|y_i-x_i\|_1+\|x_i-x_{i\varepsilon}\|_I+\|x_{i\varepsilon}-y_{i\varepsilon}\|_1$$
$$\leqq\frac{\varepsilon}{3}+\frac{\varepsilon}{3}+\frac{\varepsilon}{3}=\varepsilon, \qquad i=1,2.$$

This proves the first part of the lemma.

Let $y_2\geqq^u y_1$. Then for any partition $0<a_1<\cdots<a_n<1$, the step functions $y_{i\varepsilon}$, $y_{2\varepsilon}$ satisfy that $y_{2\varepsilon}\geqq^u y_{1\varepsilon}$. This proves (ii). □

THEOREM 2.12. *Let $\mathscr{A}$ be an open convex subset of $L_1(0,1)$ and let ϕ be a continuous functional on $\mathscr{A}$ such that the Gâteaux differentials $\partial\phi/\partial h(y)\geqq 0$ for $y\in\mathscr{A}$ and $h\in\mathscr{T}$. Then $y_1, y_2\in\mathscr{A}$ and $y_2\geqq^u y_1$ imply that $\phi(y_2)\geqq\phi(y_1)$.*

Proof. We shall first prove the theorem for step functions. Let y_1, y_2 be step functions in $\mathscr{A}$ and $y_2\geqq^u y_1$. Then by Lemma 2.7, $y_2-y_1=\sum_{i=1}^N h_i$ for some $\{h_1,\cdots,h_N\}\subseteq\mathscr{T}$. Since $\mathscr{A}$ is open, for sufficiently small positive θ, $y_1+\theta h_1,\cdots,y_1+\theta\sum_{i=1}^N h_i$ are functions in $\mathscr{A}$ and satisfy

$$y_1+\theta\sum_{i=1}^N h_i\overset{u}{\geqq} y_1+\theta\sum_{i=1}^{N-1} h_i\overset{u}{\geqq}\cdots\overset{u}{\geqq} y_1+\theta h_1\geqq y_1.$$

It now follows from Lemma 2.6 that $\phi(y_1+\theta\sum_{i=1}^N h_i)\geqq\cdots\geqq\phi(y_1+\theta h_1)\geqq\phi(y_1)$. Define $\Theta=\{0\leqq\theta\leqq 1\colon \phi(y_1+\theta\sum_{i=1}^N h_i)\geqq\phi(y_i)\}$ and $\theta_0=\sup\{\theta\colon\theta\in\Theta\}$. Following the same argument as in the proof of Theorem 2.9, we can show that $\theta_0=1$. Hence,

$$\phi(y_2)=\phi\left(y_1+\sum_{i=1}^N h_i\right)\geqq\phi(y_1).$$

In general, let $y_1, y_2 \in L_1(0,1)$ and $y_2 \geqq^u y_1$. Let $\varepsilon > 0$. By Lemma 2.11 there exist step functions $y_{1\varepsilon}$, $y_{2\varepsilon}$ such that $\|y_{i\varepsilon} - y_i\|_1 < \varepsilon$ for $i = 1, 2$ and $y_{2\varepsilon} \geqq^u y_{1\varepsilon}$. Since $\mathscr{A}$ is open, for sufficiently small ε, $y_{1\varepsilon}$, $y_{2\varepsilon}$ are functions in $\mathscr{A}$. Thus $\phi(y_{2\varepsilon}) \geqq \phi(y_{1\varepsilon})$. Since ϕ is continuous, we conclude that $\phi(y_2) \geqq \phi(y_1)$ by letting $\varepsilon \to 0$. □

3. Applications. The inequality given in Theorem 1.4 can be reformulated as the statement that the functional defined by

$$\phi(x) = \int_0^1 \log \left[\int_0^1 u(t)^{x(s)}\, dt \right] ds$$

is Schur-convex. By Theorem 2.10, this is equivalent to the condition $\partial\phi/\partial h(x) \geqq 0$ for all $x \in \mathscr{D}_\infty$, $\forall h \in \mathscr{T}$. This condition can be verified as follows.

Using Holder's inequality, we note that the function $M(\alpha) = \log \|u\|_\alpha^\alpha$ is convex in α, and thus

$$M'(\alpha) = \frac{\int_0^1 u(t)^\alpha \log u(t)\, dt}{\int_0^1 u(t)^\alpha\, dt}$$

is increasing in α. Let $x \in \mathscr{D}_\infty$ and $h \in \mathscr{T}$; then both x and h are functions decreasing on their supports, and $\int_0^1 h(t)\, dt = 0$. This implies that

$$\frac{\partial\phi}{\partial h}(x) = \int_0^1 \left[\frac{\int_0^1 u(t)^{x(s)} \log u(t)\, dt}{\int_0^1 u(t)^{x(s)}\, dt} \right] h(s)\, ds \geqq 0.$$

More generally, we can replace the function $u(t)^{x(s)}$ by functions of the form $\psi(t, z)$ which are log convex in z for fixed t. This is the result of Proschan and Sethuraman [8], which we will state below.

THEOREM 3.1. *Let the function* $\psi(t, z)$ *on* $(0,1) \times (-\infty, \infty)$ *be a log convex function in* z *for fixed* t, *and the partial derivative* $\psi_2(t, z) = \partial/\partial z \psi(t, z)$ *exists. Also let* $\sup_{|z| \leqq k} \psi(t, z)$ *belong to* $L_1(0,1)$ *for each* $k < \infty$. *For any bounded measurable function* x *on* $(0,1)$, *define*

$$M_\psi(x) = \int_0^1 \log \left[\int_0^1 \psi(t, x(s))\, dt \right] ds.$$

Then M_ψ *is Schur-convex.*

Proof. It follows from Artin's theorem [1] that the positive linear combination $\int_0^1 \psi(t, z)\, dt$ is log convex in z. Let $x \in \mathscr{D}_\infty$ and $h \in \mathscr{T}$, then

$$\frac{\partial M_\psi}{\partial h}(x) = \int_0^1 \left[\frac{\int_0^1 \psi_2(t, x(s))\, dt}{\int_0^1 \psi(t, x(s))\, dt} \right] h(s)\, ds \geqq 0,$$

which implies that M_ψ is Schur-convex. □

Next, we shall study an application of unrestricted majorization to peakedness ordering of symmetric distributions.

Let X and Y be random variables possessing densities symmetric about zero. According to the definition of peakedness given by Birnbaum [2], X is more peaked than Y, ($X \geqq^p Y$ in symbols), if $P(X \leqq t) \geqq P(Y \leqq t)$ for all $t \geqq 0$. Let f and g be the densities of X and Y respectively. Then the condition $X \geqq^p Y$ is equivalent to $f >^u g$ on the interval $(0, \infty)$.

Birnbaum [2] showed that under appropriate conditions, $X_1 \geqq^p Y_1$ and $X_2 \geqq^P Y_2$ imply that $X_1 + X_2 \geqq^P Y_1 + Y_2$. This result can be obtained by considering certain order preserving functionals. We first introduce some simplifying notations.

For $s > 0$, define

$$\chi_s(x) = I(|x| < s)$$

and, for a symmetric function h, define

$$\begin{aligned} h(s, x) &= (h * \chi_s)(x) \\ &= \int h(x-y)\chi_s(y)\,dy \end{aligned}$$

and

$$\begin{aligned} h(s, 0) &= \int h(-y)\chi_s(y)\,dy \\ &= \int h(y)\chi_s(y)\,dy. \end{aligned}$$

Note that

$$h(s, x) = \begin{cases} \frac{1}{2}[h(x+s, 0) - h(x-s, 0)] & \text{if } s < x, \\ \frac{1}{2}[h(x+s, 0) + h(-x+s, 0)] & \text{if } -s \leqq x \leqq s, \\ \frac{1}{2}[h(-x+s, 0) - h(-x-s, 0)] & \text{if } x < -s. \end{cases}$$

We need the following lemma.

LEMMA 3.2. *Let $\mathscr{C} = \{h\colon h$ symmetric and $h(s, 0) \geqq 0$ for all $s > 0\}$. Let g be symmetric and decreasing on $(0, \infty)$. Then $h * g \in \mathscr{C}$ for all $h \in \mathscr{C}$, i.e., $(h * g * \chi_s)(0) \geqq 0$ for $h \in \mathscr{C}$ and $s > 0$.*

Proof. Let $h \in \mathscr{C}$ and $s > 0$. Then

$$\begin{aligned} (h * g * \chi_s)(0) &= \int (h * \chi_s)(x) g(-x)\,dx \\ &= \int h(s, x) g(-x)\,dx \\ &= \frac{1}{2}\left\{\int_{x>s} [h(x+s, 0) - h(x-s, 0)] g(x)\,dx \right. \\ &\qquad + \int_{-s\leqq x\leqq s} [h(x+s, 0) - h(-x+s, 0)] g(x)\,dx \\ &\qquad \left. + \int_{x<-s} [h(-x+s, 0) - h(-x-s, 0)] g(x)\,dx \right\} \\ &= \frac{1}{2}\left[\int_{x>-s} h(x+s, 0) g(x)\,dx + \int_{x<s} h(-x+s, 0) g(x)\,dx \right. \\ &\qquad \left. - \int_{x<-s} h(-x-s, 0) g(x)\,dx - \int_{x>s} h(x-s, 0) g(x)\,dx \right]. \end{aligned}$$

Let $y = x + s$ in the first integral, $y = -x + s$ in the second integral, $y = -x - s$ in the third integral and $y = x - s$ in the fourth integral. We get

$$\begin{aligned} (h * g * \chi_s)(0) = \frac{1}{2}\left[\int_{y>0} h(y, 0) g(y-s)\,dy + \int_{y>0} h(y, 0) g(-y+s)\,dy \right. \\ \left. - \int_{y>0} h(y, 0) g(-y-s)\,dy - \int_{y>0} h(y, 0) g(y+s)\,dy \right]. \end{aligned}$$

By the symmetry of g,

$$(h * g * \chi_s)(0) = \int_{y>0} h(y, 0)[g(y-s) - g(y+s)]\, dy.$$

Since $h(y, 0) \geqq 0$ for all $y > 0$, and $g(y-s) - g(y+s) \geqq 0$ for $y > 0$ and $s > 0$, we conclude that $(h * g * \chi_s)(0) \geqq 0$. □

We may now obtain the following result.

THEOREM 3.3. *Let* X_1, X_2, Y_1, Y_2 *be independent symmetric random variables on* $(-1, 1)$ *with densities* f_1, f_2, g_1, g_2, *respectively. Let* f_1, g_2 *be nonincreasing on* $(0, 1)$. *Let* $X_i \geqq^P Y_i$ *for* $i = 1, 2$. *Then* $X_1 + X_2 \geqq^P Y_1 + Y_2$.

Proof. We will first establish that $X_1 + X_2 \geqq^P X_1 + Y_2$.

Fix f_1. For each $f \in L_1(0, 1)$, let f_S be the symmetric function on $(-1, 1)$ defined by

$$f_S(t) = f(|t|).$$

For each $s > 0$, define a functional on $L_1(0, 1)$ by

$$\phi_s(f) = \iint I(|x_1 + x_2| \leqq s) f_1(x_1) f_S(x_2)\, dx_1\, dx_2.$$

Let $T(0, 1)$ be the class of nonnegative functions u on $(0, 1)$ with $\int_0^1 u(t)\, dt = \frac{1}{2}$. Note that for $f \in T(0, 1)$,

$$\phi_s(f) = P(|X_1 + Z| \leqq s),$$

where X_1, Z are independent random variables with densities f_1, f_S respectively.

We shall show that for each $s > 0$, ϕ_s is nondecreasing with respect to the ordering of unrestricted majorization on $T(0, 1)$. Let $s > 0$. Let $f \in T(0, 1)$ and $h \in \mathscr{T}$. Then,

$$\begin{aligned}\frac{\partial \phi_s}{\partial h}(f) &= \lim_{\theta \to 0} \frac{1}{\theta} \iint I(|x_1 + x_2| \leqq s) \\ &\quad \cdot \{f_1(x_1)[f_S(x_2) + \theta h_S(x_2)] - f_1(x_1) f_S(x_2)\}\, dx_1\, dx_2 \\ &= \iint I(|x_1 + x_2| \leqq s) f_1(x_1) h_S(x_2)\, dx_1\, dx_2 \\ &= (f_1 * h_S * \chi_s)(0).\end{aligned}$$

Since $h \in \mathscr{T}$, $h_S(t, 0) \geqq 0$ for all $t > 0$. By Lemma 3.2, $(f_1 * h_S * \chi_s)(0) \geqq 0$. It now follows from Theorem 2.12 that ϕ_s is nondecreasing with respect to the ordering of unrestricted majorization on $T(0, 1)$.

Note that $X_2 \geqq^P Y_2$ implies that $f_2 \geqq^u g_2$ when these are considered as elements of $T(0, 1)$. We now have

$$\begin{aligned}P(|X_1 + X_2| \leqq s) &= \phi_s(f_2) \\ &\geqq \phi_s(g_2) \\ &= P(|X_1 + Y_2| \leqq s) \quad \text{for all } s > 0.\end{aligned}$$

Thus $X_1 + X_2 \geqq^P X_1 + Y_2$. Similarly, we can establish that $X_1 + Y_2 \geqq^P Y_1 + Y_2$. Hence $X_1 + X_2 \geqq^P Y_1 + Y_2$. □

NONRESONANT BIFURCATIONS WITH SYMMETRY*

JACK CARR†, JAN A. SANDERS‡ AND STEPHAN A. VAN GILS‡

Abstract. We prove uniqueness of the limit cycle for generic perturbations of a planar integrable vectorfield which arises in the unfolding of a system of two linear uncoupled nonresonant oscillators.

Key words. Abelian integrals, limit cycle, planar vectorfields

AMS(MOS) subject classifications. 34C05, 34C25, 34C29

1. Introduction. Consider a system of ordinary differential equations in $\mathbb{R}^n$, $n \geqq 2$, and suppose that the origin is a nonhyperbolic equilibrium. If the linear part of the vectorfield is doubly degenerate then, after reduction to a center manifold, it takes one of the forms [2], [6], [8]

$$A_1=\begin{pmatrix}0&1\\0&0\end{pmatrix},\quad A_2=\begin{pmatrix}0&1&0\\-1&0&0\\0&0&0\end{pmatrix},\quad A_3=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&\omega\\0&0&-\omega&0\end{pmatrix}.$$

The unfolding of A_1 has been given by Arnold [1], Bogdanov [3] and Takens [12]. The unfoldings of A_2 and A_3 are still far from complete. Partial results have been obtained by Langford [10] and Iooss and Langford [9]. Their methods are restricted to the analysis of planar vectorfields. In these planar vectorfields a global Hopf bifurcation occurs (see Guckenheimer and Holmes [8]). The main mathematical difficulty is to prove the uniqueness of the limit cycle for generic perturbations.

In the case of the singularity A_2 this has been done by Carr, Chow and Hale [5], Sanders and Cushman [11] and Zholondek [13]. Only the last paper solves the problem without any restriction.

The singularity A_3 leads to the study of generic perturbations of the planar Hamiltonian vectorfield with Hamiltonian function $H(x, y)=x^p y^q(1-x-y)$. Most important, one wants to prove the uniqueness of limit cycles for these perturbed vectorfields.

The method of proof was taken from Carr, Chow and Hale [5]; the proof in this paper may seem to be rather ad hoc at first sight, but we have extended it in a more general setting, which as a bonus has produced a sharper result in the original problem [7].

On the one hand, our method seems to work only in the case $p=q$ where the family of curves is hyperelliptic. On the other hand, at least part of this work depends only on that fact and consequently will be useful in other bifurcation problems, for instance in problems with more than one parameter, too.

Zholondek [14] proves the uniqueness of limit cycles by a priori estimates without restriction on p and q.

We will not attempt to relate the results to the behaviour of the original four-dimensional system, because the expected homoclinic phenomenon leads to quite complex behaviour (see [4]).

In § 2 we show how to obtain the relevant equations in the plane and we discuss the unperturbed vectorfield in the symmetric case. The proof of the uniqueness of periodic orbits reduces to proving monotonicity of a certain function, which is the ratio of two Abelian integrals. In this section we also give a sketch of the proof of the uniqueness result.

In § 4 we give all the details of the proof.

2. Formulation of the problem. Consider a singularity of type A_3. In order to classify the behaviour of nearby vectorfields we look at the vectorfield in $\mathbb{R}^4$ given by

$$\dot{v} = \tilde{A}v + G(v), \tag{2.1}$$

where

$$\tilde{A} = \begin{pmatrix} \alpha & 1 & 0 & 0 \\ -1 & \alpha & 0 & 0 \\ 0 & 0 & \beta & \omega \\ 0 & 0 & -\omega & \beta \end{pmatrix},$$

$\alpha, \beta \in \mathbb{R}$ are small parameters, $\omega \in \mathbb{R}$, G is smooth and of higher order in v. We will assume the nonresonance condition: $\omega \neq 0, \pm 1, \pm 2, \pm 3$. If one introduces polar coordinates

$$v_1 = r_1 \cos \theta_1, \qquad v_3 = r_2 \cos \theta_2,$$

$$v_2 = -r_1 \sin \theta_1, \qquad v_4 = -r_2 \sin \theta_2,$$

then (2.1) is equivalent to

$$\begin{aligned} \dot{r}_1 &= \alpha r_1 + R_1(\theta_1, \theta_2, r_1, r_2), \\ \dot{r}_2 &= \beta r_2 + R_2(\theta_1, \theta_2, r_2, r_2), \\ \dot{\theta}_1 &= 1 + \Theta_1(\theta_1, \theta_2, r_1, r_2), \\ \dot{\theta}_2 &= \omega + \Theta_2(\theta_1, \theta_2, r_1, r_2) \end{aligned} \tag{2.2}$$

where each function is 2π-periodic in θ_1 and θ_2. After third order averaging one obtains the vectorfield

$$\begin{aligned} \dot{r}_1 &= r_1(\alpha + cr_1^2 + dr_2^2) + \cdots, \\ \dot{r}_2 &= r_2(\beta + er_1^2 + fr_2^2) + \cdots, \\ \dot{\theta}_1 &= 1 + \cdots, \\ \dot{\theta}_2 &= \omega + \cdots, \end{aligned} \tag{2.3}$$

where the dots indicate higher order terms and c, d, e, f are real constants. We will ignore the higher order terms and analyze the planar autonomous system

$$\dot{r}_1 = r_1(\alpha + cr_1^2 + dr_2^2), \qquad \dot{r}_2 = r_2(\beta + er_1^2 + fr_2^2). \tag{2.4}$$

Substituting $r_1^2 = x$ and $r_2^2 = y$ and rescaling time we obtain the polynomial vectorfield

$$\dot{x} = x(\alpha + cx + dy), \qquad \dot{y} = y(\beta + ex + fy). \tag{2.5}$$

First we look for those values of the constants for which the system becomes integrable. More precisely, if we use the rescalings

$$t=\bar{t}p/\beta,\quad y=-\beta/f\bar{y},\quad x=\frac{-\beta(p+1)}{ep}\bar{x},$$

and we replace $\bar{t}, \bar{y}, \bar{x}$ by t, y, x, respectively, then (2.5) becomes

$$\dot{x}=px(\tilde{a}+\tilde{c}x+\tilde{d}y),\qquad \dot{y}=py\left(1-\frac{p+1}{p}x-y\right),\tag{2.6}$$

for some constants $\tilde{a}$, $\tilde{c}$ and $\tilde{d}$. If we use the integration factor $|x|^{p-1}|y|^{q-1}$, (2.6) is integrable with first integral

$$H=|x|^p|y|^q(1-x-y),\tag{2.7}$$

provided we choose

$$\tilde{a}=-\frac{q}{p},\quad \tilde{c}=\frac{q}{p},\quad \tilde{d}=\frac{q+1}{p}.$$

In all of what follows we will assume (for purely technical reasons) that $p=q$. Under this symmetry hypothesis the integrable system (2.6) becomes

$$X_p:\quad \begin{aligned}\dot{x}&=px\left(-1+x+\frac{p+1}{p}y\right),\\ \dot{y}&=py\left(1-\frac{p+1}{p}x-y\right).\end{aligned}\tag{2.8}$$

Figure 1 gives the various phase portraits of the one-parameter family of vectorfields X_p depending on the value of p.

For $p\in(-\frac{1}{2},\infty)\backslash\{0\}$ we see that X_p has periodic orbits.

For computational convenience we introduce new coordinates u and v defined by

$$x=u+v,\qquad y=u-v.$$

The induced Hamiltonian vectorfield X_H is

$$\dot{u}=pv(-1+2u),\qquad \dot{v}=pu\left(-1+\frac{2p+1}{p}u\right)-v^2\tag{2.9}$$

with Hamiltonian function

$$H=(u^2-v^2)^p(1-2u).\tag{2.10}$$

For ε_1, ε_2 small, consider the vectorfield Y_ε, given by

$$\dot{u}=pv(-1+2u),\qquad \dot{v}=pu\left(-1+\frac{2p+1}{p}u\right)-v^2+\varepsilon_1v+\varepsilon_2u^2v,\tag{2.11}$$

which is a non-Hamiltonian perturbation of X_H. Any other cubic perturbation can by partial integration be shown to lead to a fractional linear transformation of the quotient $\tilde{Q}$ (to be defined in the sequel) and therefore preserves monotonicity results. The derivative of H along the integral curves of Y_ε is

$$\begin{aligned}\dot{H}=\frac{\partial H}{\partial u}\dot{u}+\frac{\partial H}{\partial v}\dot{v}&=2((\varepsilon_1v+\varepsilon_2u^2v-\dot{v})\dot{u}+\dot{u}\dot{v})(u^2-v^2)^{p-1}\\ &=2(\varepsilon_1v+\varepsilon_2u^2v)(u^2-v^2)^{p-1}\dot{u}.\end{aligned}$$

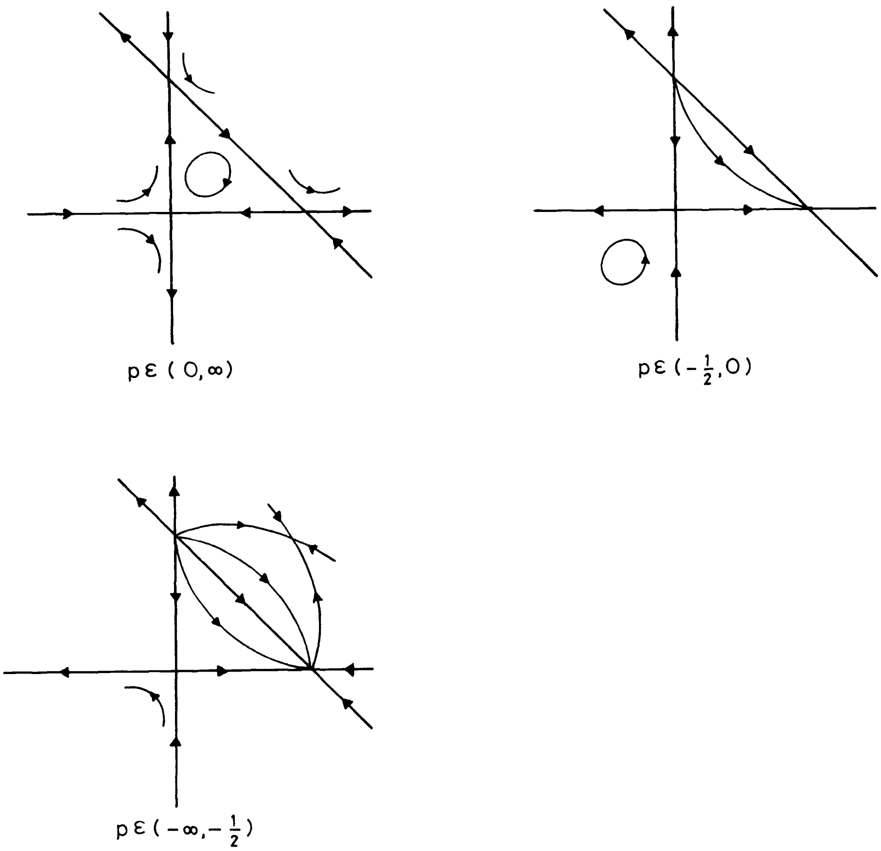

FIG. 1. *Phase portraits of* X_p.

It is not difficult to show (Carr, Chow and Hale [5], Chow and Hale [6]) that a necessary and sufficient condition for an orbit $\Gamma(\varepsilon_1, \varepsilon_2)$ of (2.11) to be periodic is that

$$\int_\Gamma \dot{H}\, dt = 0;$$

in other words

$$\varepsilon_1 \int_\Gamma v(u^2 - v^2)^{p-1}\, du + \varepsilon_2 \int_\Gamma u^2 v(u^2 - v^2)^{p-1}\, du = 0.$$

Next it is shown that if $\varepsilon_1/\varepsilon_2$ is in the range of the strictly monotone function $\tilde{Q}(h)$, (2.11) has, for ε_1, ε_2 small enough, precisely one periodic orbit, where

$$\tilde{Q}(h) = \frac{\int_{\gamma(h)} u^2 v(u^2 - v^2)^{p-1}\, du}{\int_{\gamma(h)} v(u^2 - v^2)^{p-1}\, du}. \tag{2.12}$$

Here $\gamma(h)$ is a periodic orbit of the unperturbed vectorfield. More precisely $\gamma(h)$ is a smooth compact connected component of the level set $H^{-1}(h)$. When $p > 0$, h takes values in the set $(0, h_H)$ and when $-\frac{1}{2} < p < 0$, h takes values in the set (h_H, ∞) where

$$h_H = \left[\left(\frac{p}{2p+1}\right)^2\right]^p \frac{1}{2p+1}. \tag{2.13}$$

In other words, h_H is the value of H where the periodic orbit arises from the center. $\gamma(h)$ is sketched in Fig. 2.

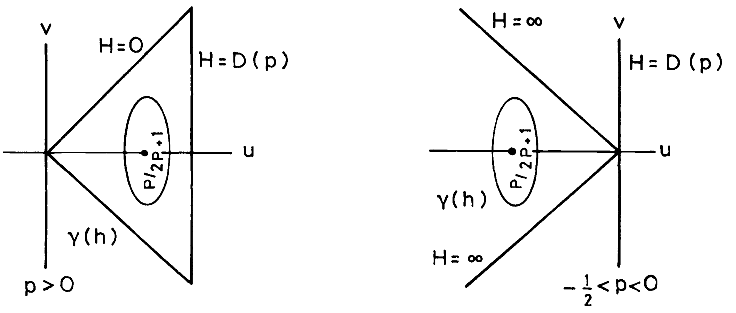

FIG. 2. *Sketch of the level sets of* $H^{-1}(h)$.

In § 4 we will prove the monotonicity of $\tilde{Q}(h)$. This result is a first step in verifying the bifurcation diagrams given in Guckenheimer and Holmes [8].

DEFINITION 2.1. For $-\frac{1}{2}<p<0$ ($p>0$) let I_p denote the interval $[h_H, \infty)$ ($[0, h_H]$).

The following result is the main theorem of this paper.

THEOREM 2.1. *For* $p\in(-\frac{1}{2},\infty)\backslash\{0\}$, $\tilde{Q}(h)$ *is strictly monotone.*

Sketch of the proof. For $n\in\mathbb{N}\cup\{0\}$ and $m\in\mathbb{N}\cup\{-1,0\}$ let

$$\delta^n_m(h)=\int_{\gamma(h)}\frac{u^n v^m}{(1-2u)^{p-1/p}}\,du.$$

It is clear from (2.10), (2.12) that

$$\tilde{Q}(h)=\delta^2_1/\delta^0_1.$$

In Lemma 4.3 we show that δ^0_1 and δ^1_1 are related by $\delta^1_1=p/(2p+1)\delta^0_1$. Therefore in place of $\tilde{Q}$ we may equally well consider

$$Q(h)=\delta^2_1/\delta^1_1=\frac{2p+1}{p}\tilde{Q}(h).$$

Lemma 4.4 states that δ^2_1, δ^1_1 satisfy an inhomogeneous nonautonomous linear differential equation:

$$2ph\dot{\delta}^1_1=\delta^1_1-\delta^3_{-1},\qquad 2ph\dot{\delta}^2_1=-\frac{2p}{2p+1}\delta^1_1+\frac{6p+2}{2p+1}\delta^2_1-\frac{p}{2p+1}\delta^3_{-1}.$$

These equations fit into the framework of the next section. We can apply Theorem 2.1 for $p\in(-\frac{1}{3},\infty)\backslash\{0\}$ directly to obtain a priori bounds for $Q(h)$. For $-\frac{1}{2}<p\leqq-\frac{1}{3}$ we will have to add some more arguments to obtain:

$$\left.\begin{matrix}p\in(0,\infty)\\ h\in[0,h_H]\end{matrix}\right\}\Rightarrow\frac{3p}{6p+2}=Q(0)\geqq Q(h)\geqq Q(h_H)=\frac{p}{2p+1},$$

$$\left.\begin{matrix}p\in(-\frac{1}{3},0)\\ h\in[h_H,\infty)\end{matrix}\right\}\Rightarrow\frac{p}{2p+1}=Q(h_H)\geqq Q(h)\geqq\frac{3p}{6p+2}=Q(\infty),$$

$$\left.\begin{matrix}p\in(-\frac{1}{2},-\frac{1}{3}]\\ h\in[h_H,\infty)\end{matrix}\right\}\Rightarrow\frac{p}{2p+1}=Q(h_H)\geqq Q(h)>-\infty=Q(\infty).$$

Using these bounds on Q we prove that the second derivative of Q is of one sign at critical points of Q. More precisely, in Theorem 3.3 we prove that $\dot{Q}=0$ implies that

$$\frac{h\delta^1_1}{p/(2p+1)-Q}\bar{Q}=h\bar{\delta}^1_1+\left(1-\frac{h\dot{\delta}^1_1}{\delta^1_1}\right)\dot{\delta}^1_1.$$

The hardest part of the argument is Lemma 4.6, where we prove the inequality $\operatorname{sign}(p)\{h\ddot{\delta}_1^1+(1-(h\dot{\delta}_1^1/\delta_1^1))\dot{\delta}_1^1\}<0$ at critical points. Consequently, $\operatorname{sign}(p)\ddot{Q}>0$ at points where $\dot{Q}$ vanishes. This shows that Q is monotone. □

3. A useful framework. In this section we explain some of the structure behind the computations in the paper of Carr, Chow and Hale [5]. We formulate two theorems which apply to both the problem considered in [5] as well as to ours.

Assume that α_0, α_1, q and R are real valued smooth functions, defined on $I=[h_0, h_1)$, $h_0\in\mathbb{R}$, $h_0<h_1\leqq\infty$. Furthermore suppose that on I the differential equations

$$q\dot{\alpha}_0=a\alpha_0+b\alpha_1+eR, \qquad q\dot{\alpha}_1=c\alpha_0+d\alpha_1+fR \tag{3.1}$$

where

$$a, b, c, d, e, f\in\mathbb{R}$$

hold. Let

$$Q=\alpha_1/\alpha_0, \quad \Delta_1=af-ec, \quad \Delta_2=ed-bf, \quad \Delta_3=ad-bc.$$

Then we have

THEOREM 3.1. *Suppose that the following conditions hold*:

(i) $\quad e\neq 0, \quad \Delta_2\neq 0, \quad \dfrac{f}{e}-\dfrac{\Delta_1}{\Delta_2}\neq 0, \quad R(h_0)\neq 0,$

(ii) $\quad \alpha_1(h_0)=\alpha_0(h_0)=0,$

(iii) $\quad \lim\limits_{h\to h_1} Q(h)=\Delta_1/\Delta_2,$

(iv) $\quad \operatorname{sign}\left\{q(h)\dfrac{\dot{\alpha}_0(h)}{\alpha_0(h)}\right\}\neq\operatorname{sign}\dfrac{\Delta_2}{e}$ *on* I,

(v) $\quad Q(h)$ *is bounded on* I,

then,

(α) $\quad Q(h_0)=f/e,$

(β) $\quad \forall h\in I\colon \ \min(f/e), \Delta_1/\Delta_2)\leqq Q(h)\leqq\max(f/e, \Delta_1/\Delta_2).$

Proof. To prove (α) observe that

$$Q(h_0)=\frac{\alpha_1(h_0)}{\alpha_0(h_0)}=\frac{\dot{\alpha}_1(h_0)}{\dot{\alpha}_0(h_0)}=\frac{q(h_0)\dot{\alpha}_1(h_0)}{q(h_0)\dot{\alpha}_0(h_0)}=\frac{f}{e}.$$

Suppose that for some $\bar{h}\in I$, $\dot{Q}(\bar{h})=0$. Then at $h=\bar{h}$

$$q\frac{\dot{\alpha}_0}{\alpha_0}\left(Q-\frac{f}{e}\right)=\frac{\Delta_2}{e}\left(Q-\frac{\Delta_1}{\Delta_2}\right), \tag{3.2}$$

which follows from

$$q\frac{\dot{\alpha}_0}{\alpha_0}Q=q\frac{\dot{\alpha}_1}{\alpha_0}=c+dQ+\frac{f}{e}\left(q\frac{\dot{\alpha}_0}{\alpha_0}-a-bQ\right).$$

Combining (3.2) with (iii) – (v) gives (β). □

Remark. The third hypothesis in the theorem is equivalent to

$$\lim_{h\to h_1} q(h)\dot{\alpha}_i(h)=0, \qquad i=1,2.$$

It will be useful to have an expression for $\dot{Q}(h_0)$ in terms of the coefficients in the right-hand side of (3.1). This is given in the next lemma. We omit the proof.

LEMMA 3.2. *Suppose that $q(h_0) \neq 0$, $e \neq 0$, then*

$$2q(h_0)\dot{Q}(h_0) = -b\left(\frac{f}{e}\right)^2 + (d-a)\frac{f}{e} + c.$$

The next theorem gives an expression for the second derivative of Q at a critical point of Q.

THEOREM 3.3. *Suppose that for some $\bar{h} \in I$, $\dot{Q}(\bar{h}) = 0$. Furthermore suppose that $e \neq 0, f/e \neq \Delta_1/\Delta_2$. Then at $h = \bar{h}$:*

$$\frac{q\alpha_0}{f/e - Q}\ddot{Q} = q\ddot{\alpha}_0 + \left(\dot{q} - \frac{q\dot{\alpha}_0}{\alpha_0}\right)\dot{\alpha}_0.$$

Proof. We will assume that all relations given above are evaluated at $h = \bar{h}$. To keep the notation simple we will suppress the argument $\bar{h}$. From (3.1) we infer that

$$q\ddot{\alpha}_0 = (a - \dot{q})\dot{\alpha}_0 + \dot{b}\alpha_1 + e\dot{R}, \qquad q\ddot{\alpha}_1 = c\dot{\alpha}_0 + (d - \dot{q})\dot{\alpha}_1 + f\dot{R}.$$

Thus after eliminating $\dot{R}$ we obtain

$$q\ddot{\alpha}_1 = c\dot{\alpha}_0 + (d - \dot{q})\dot{\alpha}_1 + \frac{f}{e}(q\ddot{\alpha}_0 - (a - \dot{q})\dot{\alpha}_0 - b\dot{\alpha}_1).$$

Because $\dot{Q} = 0$ both the relations

$$\dot{\alpha}_0 Q = \dot{\alpha}_1, \qquad \ddot{\alpha}_0 Q + \alpha_0 \ddot{Q} = \ddot{\alpha}_1,$$

hold. Straightforward calculation gives:

$$\begin{aligned} q\alpha_0\ddot{Q} &= -q\ddot{\alpha}_0 Q + q\ddot{\alpha}_1 \\ &= -q\ddot{\alpha}_0 Q + c\dot{\alpha}_0 + (d - \dot{q})\dot{\alpha}_0 Q + \frac{f}{e}q\ddot{\alpha}_0 - \frac{af}{e}\dot{\alpha}_0 + \frac{f}{e}\dot{q}\dot{\alpha}_0 - \frac{bf}{e}\dot{\alpha}_0 Q \\ &= q\left(\frac{f}{e} - Q\right)\ddot{\alpha}_0 + \frac{\dot{\alpha}_0}{e}(-\Delta_1 + f\dot{q} + (\Delta_2 - \dot{q}e)Q). \end{aligned}$$

Dividing by $f/e - Q$ gives

$$\frac{q\alpha_0}{f/e - Q}\ddot{Q} = q\ddot{\alpha}_0 + \dot{\alpha}_0\left\{\frac{f\dot{q} - \Delta_1 + (\Delta_2 - \dot{q}e)Q}{f/e - Q}\right\}. \tag{3.3}$$

If we define $\beta = q\dot{\alpha}_0/\alpha_0$ then (3.2) reads $Q(e\beta - \Delta_2) = \beta f - \Delta_1$. Plugging this relation into the right-hand side of (3.3) gives the desired result. □

4. Monotonicity. In this section we will fill in the details of the sketch of the proof of Theorem 2.1. To do this we derive a differential equation for δ_1^2, δ_1^1 which fits into the framework of the previous section.

For $n \in \mathbb{N} \cup \{0\}$ and $m \in \mathbb{N} \cup \{-1, 0\}$ let

$$\delta_m^n(h) = \int_{\gamma(h)} \frac{u^n v^m}{(1-2u)^{p-1/p}}\,du, \tag{4.1}$$

where $\gamma(h)$ is as in (2.12). From (2.10) and (2.12) we have

$$\tilde{Q}(h) = \delta_1^2/\delta_1^0. \tag{4.2}$$

The next two lemmas give a recursion relation and a differential equation which are satisfied by the functions δ_m^n.

LEMMA 4.1. *Let* $(m+3)/2 \in \mathbb{N}$ *and* $n \in \mathbb{N} \cup \{0\}$, *then*

$$R(m,n): \quad m(2p+1)\delta_{m-2}^{n+2} = mp\delta_{m-2}^{n+1} + (m-2pn-2)\delta_m^n + pn\delta_m^{n-1}.$$

Proof. Differentiate (2.10) with respect to u to obtain

$$0 = pu - (2p+1)u^2 + v^2 - pv\frac{\partial v}{\partial u}(1-2u). \tag{4.3}$$

Multiplying this identity with $u^n v^{m-2}/(1-2u)^{p-1/p}$ and integrating along $\gamma(h)$ yields

$$0 = p\delta_{m-2}^{n+1} - (2p+1)\delta_{m-2}^{n+2} + \delta_m^n - p\int (1-2u)^{1/p} u^n v^{m-1}\, dv.$$

Integrating the last integral by parts gives

$$\begin{aligned}
-\frac{p}{m}\int (1-2u)^{1/p}u^n\, dv^m &= \frac{p}{m}\int \frac{d}{du}\{(1-2u)^{1/p}u^n\}v^m\, du \\
&= -\frac{2}{m}\int (1-2u)^{1/p-1}u^n v^m\, du + \frac{pn}{m}\int (1-2u)^{1/p}u^{n-1}v^m\, du \\
&= -\frac{2}{m}\int \frac{u^n v^m}{(1-2u)^{p-1/p}}\, du + \frac{pn}{m}\int \frac{(1-2u)u^{n-1}v^m}{(1-2u)^{p-1/p}}\, du.
\end{aligned}$$

Therefore, by definition of δ_m^n

$$0 = p\delta_{m-2}^{n+1} - (2p+1)\delta_{m-2}^{n+2} + \delta_m^n - \frac{2}{m}\,\delta_m^n + \frac{pn}{m}\,\delta_m^{n-1}.$$

Multiplying this result by m gives the desired result. □

LEMMA 4.2. *Let* $m, n \in \mathbb{N} \cup \{0\}$, *then*

$$2ph\frac{d}{dh}\,\delta_m^n = m(\delta_m^n - \delta_{m-2}^{n+2}).$$

Proof. Introducing the value of H in (2.10) as a variable and differentiating (2.10) with respect to h gives

$$\frac{\partial v}{\partial h} = \frac{v^2 - u^2}{2pvh}. \tag{4.4}$$

Therefore

$$\begin{aligned}
\frac{d}{dh}\,\delta_m^n &= \frac{d}{dh}\int_{\gamma(h)} \frac{u^n v^m}{(1-2u)^{p-1/p}}\, du \\
&= m\int_{\gamma(h)} \frac{u^n v^{m-1}}{(1-2u)^{p-1/p}}\frac{\partial v}{\partial h}\, du = \frac{m}{2ph}\int_{\gamma(h)} \frac{u^n v^{m-2}}{(1-2u)^{p-1/p}}(v^2-u^2)\, du \\
&= \frac{m}{2ph}(\delta_m^n - \delta_{m-2}^{n+2}).
\end{aligned}$$

□

LEMMA 4.3. $p/(2p+1)\delta_1^0 = \delta_1^1$.

Proof. Combining Lemma 4.2 with $R(1,1)$ gives

$$2ph\frac{d}{dh}\delta_1^0=\delta_1^0-\delta_{-1}^2,$$

$$2ph\frac{d}{dh}\delta_1^1=-\frac{p}{2p+1}\,\delta_1^0+2\delta_1^1-\frac{p}{2p+1}\,\delta_{-1}^2.$$

Therefore,

$$2ph\frac{d}{dh}\left(\frac{p}{2p+1}\,\delta_1^0-\delta_1^1\right)=2\left(\frac{p}{2p+1}\delta_1^0-\delta_1^1\right).$$

At $h=h_H$ both δ_1^0 and δ_1^1 vanish. This implies the result. □

LEMMA 4.4. *Let $R=R(h)=-\delta_{-1}^3$. Then*

$$(4.5)\qquad \begin{aligned}2ph\frac{d}{dh}\,\delta_1^1&=\delta_1^1+R,\\ 2ph\frac{d}{dh}\,\delta_1^2&=-\frac{2p}{2p+1}\,\delta_1^1+\frac{6p+2}{2p+1}\,\delta_1^2+\frac{p}{2p+1}\,R.\end{aligned}$$

Proof. Combine Lemma 4.2 with $R(2,1)$, $R(1,1)$. □

To simplify notation we will write

$$\alpha_0=\delta_1^1,\qquad \alpha_1=\delta_1^2.$$

Note that the differential equation (4.5), which α_0, α_1 satisfy, fits into the framework of the previous section with $q(h)=2ph$. As in § 2 the quotient of α_1 and α_0 will be denoted by Q.

The next lemma gives some useful properties of α_0 and Q.

LEMMA 4.5. (See Definition 2.1 for I_p).

(i) *For $h\in I_p$, $\operatorname{sign}(p)\alpha_0(h)\geqq 0$;*

(ii) *for $h\in I_p$, $\dot\alpha_0(h)\leqq 0$;*

(iii) $\operatorname{sign}(p)\dfrac{d}{dh}Q(h_H)>0$;

(iv) *for each $p\in(0,\infty)$ and $h\in[0,h_H]$:*

$$\frac{3p}{6p+2}=Q(0)\geqq Q(h)\geqq Q(h_H)=\frac{p}{2p+1};$$

(v) *for each $p\in(-\frac{1}{3},0)$ and $h\in[h_H,\infty)$:*

$$\frac{p}{2p+1}=Q(h_H)\geqq Q(h)\geqq\frac{3p}{6p+2}=Q(\infty);$$

(vi) *for each $p\in(-\frac{1}{2},-\frac{1}{3}]$ and $h\in[h_H,\infty)$:*

$$\frac{p}{2p+1}=Q(h_H)\geqq Q(h)\geqq-\infty=Q(\infty);$$

(vii) *suppose that $\dot Q(\bar h)=0$ for some $\bar h\in I_p$, then at $h=\bar h$:*

$$(4.6)\qquad \frac{\bar h\alpha_0}{(p/2p+1)-Q}\,\ddot Q=\bar h\ddot\alpha_0+\left(1-\frac{\bar h\dot\alpha_0}{\alpha_0}\right)\dot\alpha_0.$$

Proof. Recall the definition of α_0:

$$\alpha_0 = \int_{\gamma(h)} \frac{uv}{(1-2u)^{p-1/p}}\, du,$$

where $\gamma(h)$ is the level curve $H^{-1}(h), h \in I_p$ (see Fig. 2). Observe that $\operatorname{sign}(u) = \operatorname{sign}(p), 1-2u \geqq 0$. This gives (i). By Lemma 4.2

$$2ph\dot{\alpha}_0(h) = \int_{\gamma(h)} \frac{u(v^2-u^2)}{v(1-2u)^{p-1/p}}\, du.$$

On $\gamma(h)$, $v^2-u^2 \leqq 0$. This gives (ii). Combining Lemma 3.2 with Lemma 4.4 gives (iii).

When $p>0$,

$$\delta_1^n(0) = 2\int_0^{1/2} \frac{u^{n+1}}{(1-2u)^{p-1/p}}\, du = \left(\frac{1}{2}\right)^{n+1} \int_0^1 u^{n+1} \frac{1}{(1-u)^{p-1/p}}\, du$$
$$= \left(\frac{1}{2}\right)^{n+1} B(n+2, 1/p).$$

Therefore $Q(0) = 3p/(6p+2) = \Delta_1/\Delta_2$. The fact that the value of Q at the Hopf point h_H equals $p/(2p+1)$ is a consequence of Stokes' theorem. Consequently when $p>0$ all the hypotheses of Theorem 3.1 are satisfied and therefore (iv) holds.

Suppose that $-\frac{1}{2}<p<0$ and let $u_\pm(h)$ be the two real roots of the equation $u^2(1-2u)^{1/p} = h^{1/p}$. Then

$$\delta_1^n(h) = 2\int_{u_-(h)}^{u_+(h)} \frac{u^n\sqrt{u^2-(h^{1/p}/(1-2u)^{1/p})}}{(1-2u)^{p-1/p}}\, du.$$

Observe that $\int_{-\infty}^0 u^n(1-2u)^{1/p} = (\frac{1}{2})^{n+1}(-1)^n B(n+1), -1/p-n-1)$, which is convergent for $-1/p > n+1 > 0$. Furthermore, $u_-(h)$, $u_+(h)$ goes to $-\infty, 0$, respectively, as h goes to infinity. Thus we conclude that

$$\lim_{h\to\infty} Q(h) = \begin{cases} -\infty, & -\frac{1}{2}<p\leqq -\frac{1}{3}, \\ \dfrac{3p}{6p+2} = \dfrac{\Delta_1}{\Delta_2}, & -\frac{1}{3}<p<0. \end{cases}$$

So (v) is a consequence of Theorem 3.1. For the values of p between $-\frac{1}{2}$ and $-\frac{1}{3}$ we cannot directly apply Theorem 3.1. In this case we argue as follows. For $-\frac{1}{2}<p<-\frac{1}{3}$ we know that $\dot{Q}(h)=0$ implies that (compare (3.2))

$$(*) \qquad (Q-p/2p+1) = \frac{6p+2}{2p+1}\frac{\alpha_0}{2ph\dot{\alpha}_0}\left(Q-\frac{3p}{6p+2}\right)$$

where $((6p+2)/(2p+1))(\alpha_0/2ph\dot{\alpha}_0) > 0$. Suppose that $Q(\bar{h}) > p/2p+1$ for some $\bar{h} > h_H$. Then as $Q(\infty) = -\infty$ and $Q \leqq 0$ there exists a $\bar{h} > h_H$ such that $0 \geqq Q(\bar{h}) \geqq p/2p+1$ and $\dot{Q}(\bar{h}) = 0$. But this contradicts $(*)$. If $p = -\frac{1}{3}$ then (3.2) reads: $\dot{Q}(\bar{h}) = 0$ implies that

$$(Q-p/2p+1) = -\frac{\alpha_0}{2ph\dot{\alpha}_0}\frac{3p}{2p+1}.$$

Thus the same reasoning as above leads to the desired result. This completes (vi). The last assertion is a direct consequence of Theorem 3.3. □

It is our goal to show that the right-hand side of (4.6) is sign definite. To reach this goal we introduce a function $J(h)$ which serves a twofold purpose. First, $J(h)$ gives an h-dependent estimate of the quotient $h\dot{\alpha}_0/\alpha_0$; and second, $J(h)$ gives rise to an integral representation for $\ddot{\alpha}_0$.

LEMMA 4.6. *Suppose that* $\dot{Q}(\bar{h})=0$ *for some* $\bar{h}\in I$. *Then, at* $h=\bar{h}$, $\operatorname{sign}(p)\{\bar{h}\ddot{\alpha}_0+(1-(\bar{h}\dot{\alpha}_0/\alpha_0))\dot{\alpha}_0\}<0$.

COROLLARY 4.7. *Suppose that* $\bar{h}$ *is defined as in the lemma. Then*

$$\operatorname{sign}(p)\ddot{Q}(\bar{h})>0.$$

Proof of the corollary. Combine Lemma 4.6 with (4.6). □

Therefore, when Lemma 4.6 is proved, all the details in the proof of Theorem 2.1 have been given. Only very interested readers will appreciate the lengthy argument needed to establish Lemma 4.6.

Proof of Lemma 4.6.

Step 1. Let

$$J(h)=\int_{\gamma(h)}\{v^2(1-2u)^{1/p}-X(h)\}\frac{uv}{(1-2u)^{p-1/p}}\,du, \tag{4.7}$$

where

$$X(h)=\max_{\gamma(h)} v^2(1-2u)^{1/p}. \tag{4.8}$$

J has some useful properties.

(i) $\operatorname{sign}(p)J(h)\leqq 0,$

(ii) $\dot{J}(h)\geqq 0,$

(iii) $\dot{J}(h)=-(h^{1/p}/2ph)\alpha_0-X(h)\dot{\alpha}_0.$

(i) is clear from the definition of J. By construction of J the factor inside the curly brackets is independent of h. More precisely, from (2.10) and (4.8) it follows that

$$v^2(1-2u)^{1/p}-X(h)=u^2(1-2u)^{1/p}-C(p) \tag{4.9}$$

where

$$C(p)=\left(\frac{p}{2p+1}\right)^2\left(\frac{1}{2p+1}\right)^{1/p}=\max_{u\in\gamma(h)} u^2(1-2u)^{1/p}. \tag{4.10}$$

Therefore the derivative of J is

$$\dot{J}=\frac{1}{2ph}\int_{\gamma(h)}\{v^2(1-2u)^{1/p}-X(h)\}\frac{u(v^2-u^2)}{v(1-2u)^{p-1/p}}\,du, \tag{4.11}$$

and so (ii) is clear. To obtain (iii) we replace $(v^2-u^2)(1-2u)^{1/p}$ by $-h^{1/p}$ in the first term of the right-hand side of (4.11). As a consequence we get

$$\operatorname{sign}(p)\left\{h\ddot{\alpha}_0+\left(1-\frac{h\dot{\alpha}_0}{\alpha_0}\right)\dot{\alpha}_0\right\}\leqq\operatorname{sign}(p)\left\{h\ddot{\alpha}_0+\left(1+\frac{h^{1/p}}{2pX(h)}\right)\dot{\alpha}_0\right\}. \tag{4.12}$$

Step 2. Before we compute the second derivative of J to obtain an integral representation for $\ddot{\alpha}_0$ we integrate J by parts as follows: From (4.3), (4.7) and (4.9) we may write

$$J=\int\frac{u^2(1-2u)^{1/p}-C}{((2p+1)u^2-pu)(1-2u)^{p-1/p}}\,uv^2\left(v-pv\frac{\partial v}{\partial u}(1-2u)\right)du. \tag{4.13}$$

Let

$$\varphi(u)=\frac{u^2(1-2u)^{1/p}-C}{((2p+1)u-pu)(1-2u)^{p-1/p}}.$$

Then integrating (4.13) by parts gives

$$J=\int \mathcal{F}(u)v^3\,du, \tag{4.14}$$

where

$$\mathcal{F}(u)=(1-2p/3)\varphi(u)+p/3\dot\varphi(u)(1-2u). \tag{4.15}$$

The integral representation (4.14) differs in an essential way from the one given by (4.7). Because v is raised to the power three in (4.14), we may differentiate J twice without running into troubles with divergent integrals.

Step 3. We will prove that

$$\begin{aligned} h\ddot\alpha_0+\left(1+\frac{h^{1/p}}{2pX(h)}\right)\dot\alpha_0=\frac{1}{4p^2hX(h)}&\left\{\int_{\gamma(h)}\frac{(v^2-u^2)u}{v(1-2u)((2p+1)u^2-pu)^2}\right\}\\ &\cdot\left[2Cu^2(1-2u)^{1/p}((2p+1)u-p)^2\right.\\ &\left.+3h^{1/p}\frac{\mathcal{F}(u)}{u}((2p+1)u^2-pu)^2(1-2u)^{p-1/p}\right]du. \end{aligned} \tag{4.16}$$

From the definition of J we obtain

$$2phX(h)\ddot\alpha_0=(1-1/p)\frac{h^{1/p}}{h}\alpha_0+h^{1/p}\dot\alpha_0-2ph\ddot J.$$

Consequently,

$$\begin{aligned} h\ddot\alpha_0+\left(1+\frac{h^{1/p}}{2pX(h)}\right)\dot\alpha_0&=\frac{1}{2pX(h)}\left\{(1-1/p)\frac{h^{1/p}}{h}\alpha_0+(2pX(h)+2h^{1/p})\dot\alpha_0-2ph\ddot J\right\}\\ &=\frac{1}{2pX(h)}\{(2X(h)+2h^{1/p})\dot\alpha_0+2\dot J-2p\dot J-2ph\ddot J\}. \end{aligned}$$

In the last step we have expressed α_0 in terms of $\dot\alpha_0$ and $\dot J$ using property (iii) of J (Step 1). Differentiating (4.13) twice and inserting the result in the above identity gives (4.16). This completes Step 3.

Step 4. We will prove that the integrand in (4.16) is sign definite. Let

$$P_3(u)=((2p+1)u-p)^2,\quad W(u)=(1-2u)^{1/p},\quad V(u)=u^2W, \tag{4.17}$$

and let

$$I=2CVP_3+3h^{1/p}\mathcal{F}(u)uP_3W^{p-1}; \tag{4.18}$$

then (4.16) reads

$$h\ddot\alpha_0+\left(1+\frac{h^{1/p}}{2pX(h)}\right)\dot\alpha_0=\frac{1}{4p^2X(h)}\int_{\gamma(h)}\frac{(v^2-u^2)u}{v(1-2u)((2p+1)u^2-pu)^2}I(u)\,du. \tag{4.19}$$

Observe that on $\gamma(h)$

$$\operatorname{sign}\left\{\frac{(v^2-u^2)u}{v(1-2u)((2p+1)u^2-pu)^2}\right\}=-\operatorname{sign}(p). \tag{4.20}$$

If we let

$$P_1(u) = (-2p-1)u^2 + (2p^2+p)u - p^2,$$
$$P_2(u) = (-8p^2-6p-1)u^2 + (6p^2-3p)u - p^2,$$

then by a straightforward computation it follows that

$$3\mathscr{F}(u)uP_3W^{p-1} = VP_1 + CP_2.$$

Consequently we may rewrite (4.18) as

$$I = 2CVP_3 + h^{1/p}VP_1 + h^{1/p}CP_2.$$

We can still simplify this expression by observing that the relation $P_1 + P_2 = -2P_3$ holds, which enables us to rewrite I as

$$I = 2CP_3(V - h^{1/p}) + h^{1/p}P_1(V - C(p)). \tag{4.21}$$

This relation is nice because on $\gamma(h)$ both $V - h^{1/p}$ and $C - V$ are positive (see (2.10), (4.10)). We will finish the last step by proving:

PROPOSITION. *For $p > -\frac{1}{2}$ and $u \in (-\infty, \frac{1}{2}]$, $P_1(u) \leqq 0$.*

Recall that

$$P_1(u) = (-2p-1)u^2 + (2p^2+p)u - p^2.$$

Thus for $p > -\frac{1}{2}, p_1$ has a global maximum at $u = p/2$, and $P_1(p/2) = (p^2/4(2p+1))(p+\frac{1}{2})(4p-6)$. Therefore, for $p \in (-\frac{1}{2}, \frac{2}{3})$, P_1 is nonpositive on $\mathbb{R}$. $P_1(\frac{1}{2}) = -\frac{1}{4}$ and for $p > \frac{2}{3}$ the maximum of P_1 lies to the right of $\frac{1}{2}$. This proves the proposition.

Combining this with (4.21) finishes the last step. □

Note. After the completion of this manuscript, the authors received a paper of Zholondek [14] which deals with the same problem. His methods differ completely from ours and he solves the problem without any restriction.

PERIODIC ORBITS IN SLOWLY VARYING OSCILLATORS*

STEPHEN WIGGINS† AND PHILIP HOLMES‡

Abstract. We develop a global perturbation technique for the study of periodic orbits in three-dimensional, time dependent and independent, perturbations of planar Hamiltonian differential equations. We give existence, stability and bifurcation theorems and illustrate our results with examples that exhibit saddle-node and Hopf bifurcations of periodic orbits.

Key words. bifurcation, Hamiltonian system, periodic orbit, Melnikov method, perturbation theory

AMS(MOS) classification numbers. 34CXX, 58F14, 70KXX

1. Introduction. In this and the following paper we develop tools for the study of periodic and homoclinic orbits occurring in a class of third order systems that arise in mechanical and other applications. We call these systems *slowly varying oscillators*; they take the general form

$$\left.\begin{aligned} \dot{x} &= f_1(x, y, z) + \varepsilon g_1(x, y, z, t; \boldsymbol{\mu}) \\ \dot{y} &= f_2(x, y, z) + \varepsilon g_2(x, y, z, t; \boldsymbol{\mu}) \\ \dot{z} &= \varepsilon g_3(x, y, z, t; \boldsymbol{\mu}) \end{aligned}\right\} \quad \text{or} \quad \dot{\mathbf{q}} = \mathbf{f}(\mathbf{q}) + \varepsilon \mathbf{g}_{\boldsymbol{\mu}}(\mathbf{q}, t) \tag{1.1}$$

where the g_i are T-periodic in t and depend upon parameter(s) $\boldsymbol{\mu} \in \mathbb{R}^k$. Additional structural assumptions on the unperturbed and perturbed phase spaces are given in § 2.

Earlier work on systems with slowly varying parameters includes that of Baker et al. [1971] and Marzec and Spiegel [1980], who pointed out that "strange attractors" similar to the Hénon attractor (Hénon [1976]) apparently arise from the Poincaré maps of such systems. In particular, Marzec and Spiegel [1980] studied two systems with fourth order potentials, similar to (1.2), below. Robinson [1983] and Robbins [1979] also worked on three-dimensional systems with a slow dependent variable; in fact the famous Lorenz model (Lorenz [1963]) can be put into such a form for high Rayleigh numbers (also see Sparrow [1982]). However, our immediate reason for studying such systems is that they occur as models of simple nonlinear elastic structures subject to feedback control when there is a nonnegligible time constant in the control process. (In a "rigid" control system the parameter ε would be very large, so that a singularly perturbed system would result.) See Sparrow [1981], Holmes [1983], [1985], and Moon and Rand [1984] for examples.

An example of such a system is the Duffing equation with slowly varying stiffness and weak linear dissipation:

$$\begin{aligned} \dot{x} &= y, \\ \dot{y} &= x - x^3 - z - \varepsilon\delta y, \\ \dot{z} &= \varepsilon(-\alpha z + g(x, y)), \end{aligned} \tag{1.2}$$

where g is a feedback control function. F. Moon's numerical integration of a fifth order system similar in form to (1.2) revealed chaotic solutions that appear to wind back and forth among a set of unstable periodic orbits, the shapes of which approximate those of certain orbits of the corresponding unperturbed Hamiltonian system. Baker et al. [1971] had made similar observations considerably earlier.

Our main analytical tool is a three-dimensional generalization of the computational method of Melnikov [1963]. The method utilizes the integrable structure of the unperturbed phase space as a framework on which to construct tools for the analysis of the perturbed phase space. See Greenspan and Holmes [1983] and Guckenheimer and Holmes [1983, Chap. 4] for details of the two-dimensional theory. Generalizations to $2n$-dimensional Hamiltonian systems have been made (Holmes and Marsden [1982a], [1982b], [1983]), as well as to homoclinic orbits for general n-dimensional systems (Gruendler [1985]).

The paper is organized as follows: in § 2 we describe the geometrical structure of the phase space and thus motivate our construction of the Melnikov functions. In § 3 we show that zeros of Melnikov functions imply the existence of periodic orbits; in §§ 4 and 5 we give stability and bifurcation results. In § 6 we illustrate our results with two examples. In the companion paper (Wiggins and Holmes [1987]) we consider the related problem of homoclinic orbits in slowly varying oscillators. Although, for simplicity, we restrict ourselves to three-dimensional systems in these papers, our methods generalize to arbitrary perturbations of $2n$-dimensional slowing varying Hamiltonian systems (Wiggins [1986]).

2. The phase space of slowly varying oscillators. We consider systems of the form

$$\left.\begin{aligned} \dot{x} &= f_1(x, y, z) + \varepsilon g_1(x, y, z, t; \boldsymbol{\mu}) \\ \dot{y} &= f_2(x, y, z) + \varepsilon g_2(x, y, z, t; \boldsymbol{\mu}) \\ \dot{z} &= \varepsilon g_3(x, y, z, t; \boldsymbol{\mu}) \end{aligned}\right\} \quad \text{or} \quad \dot{\mathbf{q}} = \mathbf{f}(\mathbf{q}) + \varepsilon \mathbf{g}(\mathbf{q}, t; \boldsymbol{\mu}), \tag{2.1}$$

with $0 < \varepsilon \ll 1$, $\mathbf{f}$ and $\mathbf{g}$ sufficiently smooth (C^r, $r \geqq 4$), $\mathbf{g}$ periodic in t with period T and $\boldsymbol{\mu} \in R^k$ a vector of parameters. We write $\mathbf{g}(\mathbf{q}, t; \boldsymbol{\mu}) = \mathbf{g}_{\boldsymbol{\mu}}(\mathbf{q}, t)$ and frequently drop the explicit dependence on $\boldsymbol{\mu}$. We make the following assumptions on the unperturbed system.

(A1) For $\varepsilon = 0$, (2.1) reduces to a one parameter family of planar Hamiltonian systems with Hamiltonian $H(x, y; z)$,

$$\begin{aligned} \dot{x} &= f_1(x, y, z) = \frac{\partial H}{\partial y}, \\ \dot{y} &= f_2(x, y, z) = -\frac{\partial H}{\partial x}, \\ &(\dot{z} = 0). \end{aligned} \tag{2.2}$$

(A2) For each value of z in some open interval $J \subset \mathbb{R}$ the "planar" system (2.2) possesses a one parameter family of periodic orbits, $q^{\alpha,z}(t-\theta)$, $\alpha \in L(z)$, where $L(z)$ is an open interval in $\mathbb{R}$ and θ denotes the "phase" or starting point of the orbit. We denote the period of $q^{\alpha,z}(t-\theta)$ by $T(\alpha, z)$ and assume that it is a differentiable function of α and z. Thus, when viewed in the full x, y, z phase, system (2.2) possesses a smooth family of invariant cylinders. (See Fig. 1.)

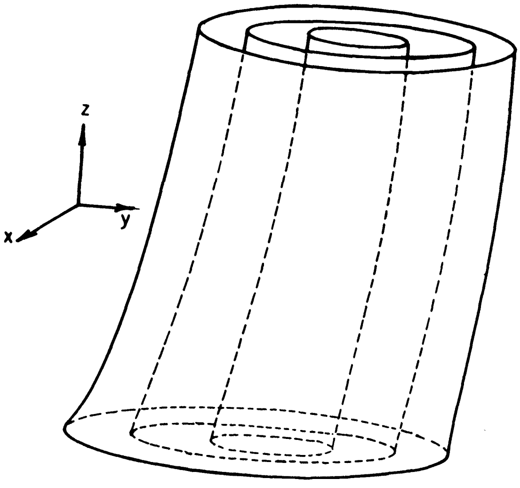

FIG. 1. *Structure of the unperturbed phase space.*

It will be convenient to think of (2.1) as an autonomous differential equation. This is accomplished by defining the function $\phi(t)=t$, mod T; by T-periodicity of the g_i we then have

$$
\begin{aligned}
&\dot{x}=f_1(x, y, z)+\varepsilon g_1(x, y, z, \phi), \\
&\dot{y}=f_2(x, y, z)+\varepsilon g_2(x, y, z, \phi), \qquad (x, y, z, \phi)\in R^3\times S^1, \\
&\dot{z}=\varepsilon g_3(x, y, z, \phi), \\
&\dot{\phi}=1.
\end{aligned} \tag{2.3}
$$

We remark that this suspension makes sense even when the g_i are independent of ϕ, although it then becomes trivial. The main point to note is that all the results developed below in the context of ϕ-dependent perturbations also hold good for ϕ-independent (i.e., autonomous) perturbations, although there are sometimes differences in interpretation.

The following perturbation results will be useful. Consider a subset of the two parameter family of periodic orbits whose period is uniformly bounded above. Let $\tilde{L}(z)\subset L(z)$ denote the set of α such that on a fixed $z=\text{constant}$ plane the periods $T(\alpha, z)$ of the periodic orbits are uniformly bounded above, say by a constant K.

PROPOSITION 2.1. *Let $\mathbf{q}_0^{\alpha,z}(t-\theta_0)$ be a periodic orbit of the unperturbed system with period $T(\alpha, z)<K$. Then there exists a perturbed orbit $\mathbf{q}_\varepsilon^{\alpha,z}(t, \theta)$, not necessarily periodic, which can be expressed as*

$$\mathbf{q}_\varepsilon^{\alpha,z}(t, \theta)=\mathbf{q}_0^{\alpha,z}(t-\theta)+\varepsilon\mathbf{q}_1^{\alpha,z}(t, \theta)+\mathcal{O}(\varepsilon^2) \tag{2.4}$$

uniformly in $t\in[t_0, t_0+T(\alpha, z)]$ for ε sufficiently small and all $\alpha\in\tilde{L}(z)$.

Remarks. This result follows directly from regular perturbation theory and Gronwall estimates (e.g., Hartman [1964]). The restriction to $\tilde{L}(z)$ avoids problems that arise when periodic orbits limit on homoclinic orbits and the period becomes unbounded. Furthermore, $\mathbf{q}_0^{\alpha,z}(t, \theta)$ may be found by solving the first variational equation

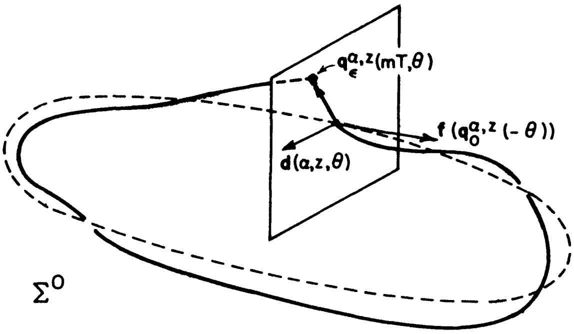
$$\dot{\mathbf{q}}_1^{\alpha,z}=\mathbf{Df}(\mathbf{q}_0^{\alpha,z})\mathbf{q}_1^{\alpha,z}+\mathbf{g}(\mathbf{q}_0^{\alpha,z}, t). \tag{2.5}$$

The main question which we ask is the following: Do any of the two parameter family of periodic orbits in the unperturbed system remain in the perturbed system? In order to answer this question we will reduce the study of the four-dimensional problem (2.3) to a three-dimensional Poincaré map. We define a global cross section transverse to the vector field (2, 3)

$$\Sigma^0 = \{(x, y, z, \phi) | \phi = 0\}$$

and define a mapping of Σ^0 into itself by letting orbits which start on Σ^0 evolve for time T until they return to Σ^0. Thus fixed points of the map correspond to periodic orbits of the vector field. (Note: the construction of the cross section and associated Poincaré map is different when the perturbation is autonomous, for then the problem is three-, not four-dimensional. However, we will see that formally the calculations are identical in both cases.) Although our Poincaré map is three-dimensional we will see that extending an idea due to Melnikov [1963] enables us to eliminate one component.

We now describe the geometric and intuitive notions which motivate the construction of the Melnikov functions. The structure of the unperturbed phase space will form the framework for the analysis of the system. Since the unperturbed system is autonomous, on each cross section, Σ^0, we have identical copies of the unperturbed phase space. In addition, the system possesses two constants of the motion, $H(x, y; z)$ and z itself. These constants are used to construct a moving system of "orbit coordinates" along the unperturbed orbits on the cross section Σ^0. Taking the gradient of the two constants of the motion we obtain the vectors $(\partial H/\partial x, \partial H/\partial y, 0)$ and $(0, 0, 1)$, which span a plane, Π. These vectors are evaluated on the unperturbed orbits on the cross section Σ^0, denoted $\mathbf{q}_0^{\alpha,z}(-\theta)$. Thus varying θ moves our two-dimensional plane Π around the unperturbed orbits on the cross section Σ^0 (see Fig. 2).



$q_\varepsilon^{\alpha,z}(mT,\theta)$
$f(q_0^{\alpha,z}(-\theta))$
$d(\alpha,z,\theta)$
Σ^0

FIG. 2. *The orbit coordinate system on* Σ^0.

In order to study periodic orbits in resonance with a time-periodic perturbation, we introduce the following two component vector valued function:

$$\mathbf{d}(\alpha, \theta, z) = \frac{\left([q_\varepsilon^{\alpha,z}(mT, \theta) - q_\varepsilon^{\alpha;z}(0, \theta)] \cdot \left(\frac{\partial H}{\partial x}, \frac{\partial H}{\partial y}, 0\right), [q_\varepsilon^{\alpha,z}(mT, \theta) - q_\varepsilon^{\alpha,z}(mT, \theta)] \cdot (0, 0, 1)\right)}{\|f(q_0^{\alpha,z}(-\theta))\|}$$

$$(2.6) \qquad = \frac{\varepsilon\left([q_1^{\alpha,z}(mT, \theta) - q_1^{\alpha,z}(0, \theta)] \cdot \left(\frac{\partial H}{\partial x}, \frac{\partial H}{\partial y}, 0\right), [q_1^{\alpha,z}(mT, \theta) - q_1^{\alpha,z}(mT, \theta)] \cdot (0, 0, 1)\right)}{\|f(q_0^{\alpha,z}(-\theta))\|} + \mathcal{O}(\varepsilon^2)$$

$$\overset{\text{def}}{=} \varepsilon \mathbf{M}^{m/n}(\alpha, \theta, z) + \mathcal{O}(\varepsilon^2),$$

where $\mathbf{M}^{m/n}(\alpha, \theta, z) \equiv (M_1^{m/n}(\alpha, \theta, z), M_3^{m/n}(\alpha, \theta, z))$ is defined to be the *subharmonic Melnikov function*, "$\| \ \|$" denotes the Euclidean norm, "$\cdot$" is the vector dot product, and $mT = nT(\alpha, z)$, where $T(\alpha, z)$ is the period of the unperturbed periodic orbit $\mathbf{q}_0^{\alpha,z}(t-\theta)$ and m, n are relatively prime integers.

The intuition behind the definition of $\mathbf{d}(\alpha, \theta, z)$ is the following: on the cross section Σ^0 we have the plane Π normal to the vector $\mathbf{f}(\mathbf{q}_0^{\alpha,z}(-\theta))$ at the point $\mathbf{q}_0^{\alpha,z}(-\theta)$. If a perturbed orbit has its initial value on this plane and evolves for time mT, after which it has returned to within $\mathcal{O}(\varepsilon)$ of the plane Π, $M^{m/n}$ is a measure of the "push" or "shear" the orbit undergoes due to the perturbation in directions transverse to the unperturbed vector field. Thus we expect that if the "push" is zero at some point, an orbit of period mT/n will be preserved in the perturbed flow. These heuristic notions are made precise in § 3, where we show that nondegenerate zeros of $\mathbf{M}^{m/n}$ correspond to isolated fixed points of a Poincaré mapping of $\Sigma^0 \to \Sigma^0$. Another important consequence of the definition of $\mathbf{M}^{m/n}$ is the fact that an explicit, computable expression may be obtained for $\mathbf{M}^{m/n}$.

$$\mathbf{M}^{m/n}(\alpha, \theta, z) = \frac{1}{\|\mathbf{f}(\mathbf{q}_0^{\alpha,z}(-\theta))\|} \left[\int_0^{mT} \left(\frac{\partial H}{\partial x} g_1 + \frac{\partial H}{\partial y} g_2 + \frac{\partial H}{\partial z} g_3 \right) (\mathbf{q}_0^{\alpha,z}(t), t+\theta) \, dt \right.$$

$$(2.7) \qquad - \frac{\partial H}{\partial z} \left(\mathbf{q}_0^{\alpha,z} \left(\frac{mT}{2} \right) \right) \int_0^{mT} g_3(\mathbf{q}_0^{\alpha,z}(t), t+\theta) \, dt,$$

$$\left. \int_0^{mT} g_3(\mathbf{q}_0^{\alpha,z}(t), t+\theta) \, dt \right],$$

where $q_0^{\alpha,z}(t-\theta)$ is an unperturbed periodic orbit of period $T(\alpha, z) = mT/n$. In the next section we derive this expression.

3. Periodic orbits. Here we study the two parameter family of periodic orbits and show how the subharmonic Melnikov function constructed in § 2 is related to a Poincaré map constructed from the perturbed vector field. We will restrict ourselves to a region where the periods are uniformly bounded above by a constant K (so Proposition 2.1 applies). This allows us to use the Hamiltonian structure of the unperturbed system to transform system (2.3) to action-angle variables (see Goldstein [1980] or Arnold [1978]):

$$(x(I, \theta), y(I, \theta), z) \to (I(x, y, z), \theta(x, y, z), z).$$

Under the transformation, (2.3) becomes

$$\begin{aligned}
\dot{I} &= \varepsilon \left(\frac{\partial I}{\partial x} g_1 + \frac{\partial I}{\partial y} g_2 + \frac{\partial I}{\partial z} g_3 \right) \equiv \varepsilon F(I, \theta, z, \phi), \\
\dot{\theta} &= \Omega(I, z) + \varepsilon \left(\frac{\partial \theta}{\partial x} g_1 + \frac{\partial \theta}{\partial y} g_2 + \frac{\partial \theta}{\partial z} g_3 \right) \equiv \Omega(I, z) + \varepsilon G(I, \theta, z), \\
\dot{z} &= \varepsilon g_3, \\
\dot{\phi} &= 1,
\end{aligned} \qquad (3.1)$$

with F, G, g_3 T-periodic in ϕ and where $\Omega(I, z) \equiv \partial H / \partial I$ is the angular frequency of the closed orbit in the unperturbed system on the $z = \text{constant}$ plane with action I and energy $H(I, z)$. So in the action-angle coordinate system the action I plays the role of the parameter α in our more general notation. We note that for $\varepsilon=0$ the solution to (3.1) is given by

$$\begin{aligned} I&=I_0,\\ \theta&=\Omega(I_0,z_0)(t-t_0)+\theta_0,\\ z&=z_0. \end{aligned}\tag{3.2}$$

Now we will construct an approximation to the Poincaré map associated with system (3.1). The cross section to the flow defined by (3.1) is

$$\Sigma^0=\{(I,\theta,z,\phi)\,|\,\phi=0\},\tag{3.3}$$

and the mth iterate of the Poincaré map, P_ε^m, is

$$\begin{aligned} P_\varepsilon^m\colon\ &(I_\varepsilon(0,0,I_0,\theta_0,z_0),\theta_\varepsilon(0,0,I_0,\theta_0,z_0),z_\varepsilon(0,0,I_0,\theta_0,z_0))\\ &\to(I_\varepsilon(mT,0,I_0,\theta_0,z_0),\theta_\varepsilon(mT,0,I_0,\theta_0,z_0),z_\varepsilon(mT,0,I_0,\theta_0,z_0)), \end{aligned}\tag{3.4}$$

where the initial conditions are chosen such that

$$\begin{aligned} I_\varepsilon(0,0,I_0,\theta_0,z_0)&=I_0,\\ \theta_\varepsilon(0,0,I_0,\theta_0,z_0)&=\theta_0,\\ z_\varepsilon(0,0,I_0,\theta_0,z_0)&=z_0. \end{aligned}\tag{3.5}$$

Using Proposition 2.1 and the solutions to the unperturbed problem given by (3.2), we can approximate the Poincaré map using regular perturbation theory.

The solution of (3.1) can be written as

$$\begin{aligned} P_\varepsilon^m\colon\ &(I_0,\theta_0,z_0)\to(I_0,\theta_0,z_0)+(0,mT\Omega(I_0,z_0),0)\\ &+\varepsilon(I_1(mT,0,I_0,\theta_0,z_0),\theta_1(mT,0,I_0,\theta_0,z_0),z_1(mT,0,I_0,\theta_0,z_0))+\mathcal{O}(\varepsilon^2). \end{aligned}\tag{3.6}$$

Recall that this approximation is uniformly valid for one period of an unperturbed orbit, $T(I,z)=mT$. For the case of ultrasubharmonics, $T(I,z)=mT/n$, $n\geqq 2$, m, n relatively prime, the approximation is not uniformly valid since ε must shrink to zero as n increases.

We now compute I_1, θ_1, and z_1 by solving the first variational equation. Using (3.2) we obtain

$$\begin{pmatrix}\dot I_1\\ \dot\theta_1\\ \dot z_1\end{pmatrix}=\begin{pmatrix}0&0&0\\ \partial\Omega/\partial I_0|_{(I_0,z_0)}&0&\partial\Omega/\partial z_0|_{(I_0,z_0)}\\ 0&0&0\end{pmatrix}\begin{pmatrix}I_1\\ \theta_1\\ z_1\end{pmatrix}+\begin{pmatrix}F(I_0,\Omega(I_0,z_0)t+\theta_0,z_0,t)\\ G(I_0,\Omega(I_0,z_0)t+\theta_0,z_0,t)\\ g_3(I_0,\Omega(I_0,z_0)t+\theta_0,z_0,t)\end{pmatrix},\tag{3.7}$$

and consequently

$$I_1(mT,0,I_0,\theta_0,z_0)=\int_0^{mT}F(I_0,\Omega(I_0,z_0)t+\theta_0,z_0,t)\,dt\equiv\bar M_1^{m/n}(I_0,\theta_0,z_0),$$

$$\begin{aligned} \theta_1(mT,0,I_0,\theta_0,z_0)=&\left.\frac{\partial\Omega}{\partial I_0}\right|_{(I_0,z_0)}\int_0^{mT}\int_0^t F(I_0,\Omega(I_0,z_0)\xi+\theta_0,z_0,\xi)\,d\xi\,dt\\ &+\int_0^{mT}G(I_0,\Omega(I_0,z_0)t+\theta_0,z_0,t)\,dt\\ &+\left.\frac{\partial\Omega}{\partial z_0}\right|_{(I_0,z_0)}\int_0^{mT}\int_0^t g_3(I_0,\Omega(I_0,z_0)\xi+\theta_0,z_0,\xi)\,d\xi\,dt\\ \equiv&\ \bar M_2^{m/n}(I_0,\theta_0,z_0), \end{aligned}\tag{3.8}$$

$$z_1(mT, 0, I_0, \theta_0, z_0) = \int_0^{mT} g_3(I_0, \Omega(I_0, z_0)t + \theta_0, t)\, dt \equiv \bar{M}_3^{m/n}(I_0, \theta_0, z_0).$$

The Poincaré map P_ε^m becomes

$$\begin{aligned} P_\varepsilon^m\colon (I_0, \theta_0, z_0) &\to (I_0, \theta_0, z_0) + (0, \Omega(I_0, z_0)mT, 0) \\ &\quad + \varepsilon(\bar{M}_1^{m/n}(I_0, \theta_0, z_0), \bar{M}_2^{m/n}(I_0, \theta_0, z_0), \bar{M}_3^{m/n}(I_0, \theta_0, z_0)) + \mathcal{O}(\varepsilon^2). \end{aligned} \tag{3.9}$$

We will subsequently show that the first and third components of the $\mathcal{O}(\varepsilon)$ part of the Poincaré map make up the subharmonic Melnikov function which we defined in § 2, i.e., $\bar{M}_i^{m/n} = M_i^{m/n}$, $i = 1, 3$.

We define the vector $\bar{\mathbf{M}}^{m/n}$ as

$$\bar{\mathbf{M}}^{m/n}(I_0, \theta_0, z_0) = (\bar{M}_1^{m/n}(I_0, \theta_0, z_0), \bar{M}_2^{m/n}(I_0, \theta_0, z_0), \bar{M}_3^{m/n}(I_0, \theta_0, z_0)). \tag{3.10}$$

We remark that the superscript m/n denotes our search for periodic orbits (which we will frequently omit) which satisfy the resonance relation $T(I, z) = mT/n$, m, n relatively prime integers.

We now state our main theorem.

THEOREM 3.1. *Suppose* $(I_0^*, \theta_0^*, z_0^*)$ *is a point where* $T(I_0^*, z_0^*) = mT/n$ *and the following condition is satisfied*:

$$\left.\frac{\partial \Omega}{\partial I_0}\right|_{(I_0^*, z_0^*)} \neq 0 \quad \text{or} \quad \left.\frac{\partial \Omega}{\partial z_0}\right|_{(I_0^*, z_0^*)} \neq 0,$$

$$\left.\left[\frac{\partial \Omega}{\partial I_0}\left(\frac{\partial \bar{M}_1}{\partial \theta_0}\frac{\partial \bar{M}_3}{\partial z_0} - \frac{\partial \bar{M}_1}{\partial z_0}\frac{\partial \bar{M}_3}{\partial \theta_0}\right) + \frac{\partial \Omega}{\partial z_0}\left(\frac{\partial \bar{M}_1}{\partial I_0}\frac{\partial \bar{M}_3}{\partial \theta_0} - \frac{\partial \bar{M}_1}{\partial \theta_0}\frac{\partial \bar{M}_3}{\partial I_0}\right)\right]\right|_{(I_0^*, \theta_0^*, z_0^*)} \neq 0$$

and

$$\bar{M}_1(I_0^*, \theta_0^*, z_0^*) = \bar{M}_3(I_0^*, \theta_0^*, z_0^*) = 0.$$

Then for $0 < \varepsilon \leqq \varepsilon(n)$ *the Poincaré map*, P_ε^m, *has a fixed point of period m. If* $n = 1$ *the result is uniformly valid in* $0 < \varepsilon \leqq \varepsilon(1)$.

We remark that the conditions

$$\frac{\partial \Omega}{\partial I_0}\left(\frac{\partial \bar{M}_1}{\partial \theta_0}\frac{\partial \bar{M}_3}{\partial z_0} - \frac{\partial \bar{M}_1}{\partial z_0}\frac{\partial \bar{M}_3}{\partial \theta_0}\right) + \frac{\partial \Omega}{\partial z_0}\left(\frac{\partial \bar{M}_1}{\partial I_0}\frac{\partial \bar{M}_3}{\partial \theta_0} - \frac{\partial \bar{M}_1}{\partial \theta_0}\frac{\partial \bar{M}_3}{\partial I_0}\right) \neq 0$$

is a sufficient condition for the Poincaré map minus the identity map to be invertible in each case and for the fixed point to be isolated. We also call attention to the fact that no knowledge of $\bar{M}_2^{m/n}$ is needed. Thus evaluation of the double integrals of (3.8) is unnecessary.

Proof. We note that by hypothesis the resonance relation, $T(I_0, z_0) = mT/n$, is satisfied so that $mT\Omega(I_0^*, z_0^*) = 2\pi n = 0$ since $mT\Omega$ is an angular variable. For definiteness we assume $\partial\Omega/\partial z_0|_{(I_0^*, z_0^*)} \neq 0$ (the case with $\partial\Omega/\partial I_0|_{(I_0^*, z_0^*)} \neq 0$ is proved similarly). Let us perturb the point $(I_0^*, \theta_0^*, z_0^*)$ to $(I_0^*, \theta_0^*, z_0^* + \Delta z)$. Then at this point the Poincaré map takes the form

$$\begin{aligned} &\mathbf{P}_\varepsilon^m(I_0^*, \theta_0^*, z_0^* + \Delta z) - (I_0^*, \theta_0^*, z_0^* + \Delta z) \\ &\quad = \left(0, mT\left.\frac{\partial \Omega}{\partial z_0}\right|_{(I_0^*, z_0)} \Delta z + \varepsilon \bar{M}_2(I_0^*, \theta_0^*, z_0^*) + \mathcal{O}(\Delta z^2) + \mathcal{O}(\Delta z \varepsilon), 0\right) + \mathcal{O}(\varepsilon^2). \end{aligned}$$

Now if we choose

$$\Delta z = -\varepsilon \frac{\bar{M}_2(I_0^*, \theta_0^*, z_0^*)}{mT\left.\dfrac{\partial \Omega}{\partial z_0}\right|_{(I_0^*, z_0^*)}},$$

we have

$$\mathbf{P}_\varepsilon^m(I_0^*, \theta_0^*, z_0^*+\Delta z) - (I_0^*, \theta_0^*, z_0^*+\Delta z) = \mathcal{O}(\varepsilon^2),$$

$$\det |\mathbf{DP}_\varepsilon^m - \mathbf{id}|\bigg|_{(I_0^*,\, \theta_0^*,\, z_0^*+\Delta z)} = \varepsilon^2 \left[\frac{\partial \Omega}{\partial I_0}\left(\frac{\partial \bar{M}_1}{\partial \theta_0}\frac{\partial \bar{M}_3}{\partial z_0} - \frac{\partial \bar{M}_1}{\partial z_0}\frac{\partial \bar{M}_3}{\partial \theta_0}\right) + \frac{\partial \Omega}{\partial z_0}\left(\frac{\partial \bar{M}_1}{\partial I_0}\frac{\partial \bar{M}_3}{\partial \theta_0} - \frac{\partial \bar{M}_1}{\partial \theta_0}\frac{\partial \bar{M}_3}{\partial I_0}\right)\right]\bigg|_{(I_0^*,\, \theta_0^*,\, z_0^*)} + \mathcal{O}(\varepsilon^3) \neq 0 \text{ by hypothesis.}$$

Thus, since $\|\mathbf{DP}_\varepsilon^m - \mathbf{id}\| = \mathcal{O}(1)$, the implicit function theorem allows us to conclude that the Poincaré map has a fixed point near $(I_0^*, \theta_0^*, z_0^*+\Delta z)$ and thus that the differential equation has an isolated periodic orbit of period mT/n near this point. □

We make the following remarks:

(1) Although P_ε^m is a diffeomorphism of $\mathbb{R}^3$, in order to determine whether or not it has fixed points we need only check the first and third components of the map. This is a result of the nonzero twist condition ($\partial\Omega/\partial I_0$ or $\partial\Omega/\partial z_0 \neq 0$), which insures locally that we return to the correct section after time mT.

(2) The advantage of using action-angle variables is that they enable us to explicitly relate the subharmonic Melnikov function to a Poincaré map by allowing us to easily solve the first variational equation (3.7), which might otherwise be intractable analytically. In §§ 4 and 5 this relationship is exploited by utilizing existing theorems concerning stability and bifurcations of maps in order to get similar theorems expressed entirely in terms of the subharmonic Melnikov function.

(3) Theorem 3.1 does not apply to the case of autonomous vector fields. In such cases it suffices to study a diffeomorphism of R^2 obtained by fixing $\theta = \theta_0$ and allowing the I and z variables with initial values at $\theta = \theta_0$ to evolve in time until they return to $\theta = \theta_0$. Hereafter we will delete the subscript 0 on I, θ, and z when there is no possibility of confusion. We have the following theorem.

THEOREM 3.2. *Suppose there exists a point* (I^*, z^*) *such that*

(a) $\bar{M}_1(I^*, z^*) = \bar{M}_3(I^*, z^*) = 0,$

(b) $\dfrac{\partial(\bar{M}_1, \bar{M}_3)}{\partial(I, z)}\bigg|_{(I^*, z^*)} \neq 0.$

Then $(I^*, z^*) + \mathcal{O}(\varepsilon)$ *is an isolated fixed point for the Poincaré map that corresponds to an isolated periodic orbit for the three-dimensional flow.*

We remark that M_1 and M_3 are defined exactly as in the nonautonomous case except that the limits of integration now become $0 \to T(I, z)$; hence we drop the superscript m/n.

Proof. The proof is very similar to that of Theorem 3.1. The details can be found in Wiggins [1985]. □

Finally we want to show that the subharmonic Melnikov function derived in this section using action-angle variables is identical to the expression that we gave in § 2 for an arbitrary coordinate system. We can easily see that $\bar{M}_3^{m/n}$ derived in action-angle variables is identical to the corresponding $M_3^{m/n}$ of § 2 derived using the orbit coordinate system, since the functions under the integrand are the same and both are evaluated on an unperturbed periodic orbit. It makes no difference whether or not the unperturbed orbit is expressed in (I, θ, z) coordinates or (x, y, z) coordinates, since the Jacobian of the transformation between the two coordinate systems is identically one and hence does not affect the integral. The fact that the $M_1^{m/n}$ are the same is not as obvious, but is nevertheless true. In action angle variables $M_1^{m/n}$ is defined as

$$\bar{M}_1^{m/n}(I,\theta,z)=\int_0^{mT}\left(\frac{\partial I}{\partial x}g_1+\frac{\partial I}{\partial y}g_2+\frac{\partial I}{\partial z}g_3\right)dt, \tag{3.11}$$

where the integrand is evaluated on an unperturbed periodic orbit expressed in action-angle variables. (Note: By $\partial I/\partial x$ we mean the partial derivative of I with y and z held fixed; we denote this by $\partial I/\partial x|_{y,z}$, similarly for $\partial I/\partial y$ and $\partial I/\partial z$. This will be important in the following.) Now using the action angle transformation we can write

$$H=H(I,z), \tag{3.12}$$

and since we have assumed that we are in a region where $\partial H/\partial I|_z$ is nonzero we can invert (3.12) to obtain

$$I=I(H,z). \tag{3.13}$$

Differentiating (3.13) we obtain

$$\begin{aligned}\left.\frac{\partial I}{\partial x}\right|_{y,z}&=\left.\frac{\partial I}{\partial H}\right|_z\left.\frac{\partial I}{\partial H}\right|_{y,z},\\ \left.\frac{\partial I}{\partial y}\right|_{x,z}&=\left.\frac{\partial I}{\partial H}\right|_z\left.\frac{\partial H}{\partial y}\right|_{x,z},\\ \left.\frac{\partial I}{\partial z}\right|_{x,y}&=\left.\frac{\partial I}{\partial H}\right|_z\left.\frac{\partial H}{\partial z}\right|_{x,y}+\left.\frac{\partial I}{\partial z}\right|_H,\end{aligned} \tag{3.14}$$

and by definition of the action-angle transformation we have

$$\left.\frac{\partial H}{\partial I}\right|_z=\Omega(I,z). \tag{3.15}$$

Substituting (3.14) and (3.15) into (3.11) we get

$$\bar{M}_1^{m/n}=\frac{1}{\Omega(I,z)}\int_0^{mT}\left(\frac{\partial H}{\partial x}g_1+\frac{\partial H}{\partial y}g_2+\frac{\partial H}{\partial z}g_3\right)dt+\left.\frac{\partial I}{\partial z}\right|_H\int_0^{mT}g_3\,dt, \tag{3.16}$$

where we have pulled the $\partial I/\partial z|_H$ term out of the integrand since it is constant on unperturbed periodic orbits. Recall that on an unperturbed periodic orbit we have

$$I=I(H,z)=\text{constant}. \tag{3.17}$$

So differentiating along this orbit we get

$$0=\left.\frac{\partial I}{\partial H}\right|_z\left.\frac{\partial H}{\partial z}\right|_I+\left.\frac{\partial I}{\partial z}\right|_H. \tag{3.18}$$

Using (3.18), (3.16) becomes

$$\bar{M}_1^{m/n}(I,\theta,z)=\frac{1}{\Omega(I,z)}\left[\int_0^{mT}\left(\frac{\partial H}{\partial x}g_1+\frac{\partial H}{\partial y}g_2+\frac{\partial H}{\partial y}g_3\right)dt-\left.\frac{\partial H}{\partial z}\right|_I\int_0^{mT}g_3\,dt\right], \tag{3.19}$$

where the integrand is evaluated on an unperturbed periodic orbit (note: as in the case of $M_3^{m/n}$, it does not matter whether this periodic orbit is expressed in (I,θ,z) coordinates or (x,y,z) coordinates). Finally, we note that in the action-angle coordinate system (see (3.1)) $\|\mathbf{f}(\mathbf{q}_0^{\alpha,z}(-\theta))\|=\Omega(I,z)$, so we see that the expression which we have derived here in action-angle coordinates (i.e., in a region where the periods of the unperturbed orbits are uniformly bounded) is identical to that obtained from orbit coordinates in § 2, so hereafter we will drop the overbars on $\bar{M}$, and $\bar{M}_3$.

4. Stability. We have shown that the study of system (2.1) can be reduced to the study of a three-dimensional Poincaré map in the nonautonomous case

$$P_\varepsilon^m(q)=q+(0, mT\Omega(I, z), 0)+\varepsilon(M_1^{m/n}(q), \bar{M}_2^{m/n}(q), M_3^{m/n}(q))+\mathcal{O}(\varepsilon^2), \quad q=(I, \theta, z) \tag{4.1}$$

and a two-dimensional Poincaré map in the autonomous case

$$P_\varepsilon^m(q)=q+\varepsilon(M_1(q), M_3(q))+\mathcal{O}(\varepsilon^2), \qquad q=(I, z), \tag{4.2}$$

and that nondegenerate fixed points of these maps correspond to isolated periodic orbits in the ordinary differential equations. We can compute the stability of these fixed points in the obvious way, namely linearize the map about the fixed point and examine the eigenvalues. After some computation, we find that the eigenvalues of (4.1) (the nonautonomous case) are given by the following cases.

Case 1. $\Delta_2\neq 0, \Delta_4\neq 0$.

$$\begin{aligned}\lambda_{1,2}&=1\pm\varepsilon^{1/2}\sqrt{\Delta_2}+\varepsilon/2\left(\Delta_1-\frac{\Delta_4}{\Delta_2}\right)+\mathcal{O}(\varepsilon^{3/2}),\\ \lambda_3&=1+\varepsilon\frac{\Delta_4}{\Delta_2}+\mathcal{O}(\varepsilon^2).\end{aligned} \tag{4.3}$$

Case 2. $\Delta_2=0, \Delta_4\neq 0$.

$$\begin{aligned}\lambda_1&=1+\varepsilon^{2/3}(-\Delta_4)^{1/3}+\varepsilon\frac{\Delta_1}{3}+\frac{\varepsilon^{4/3}}{(-\Delta_4)^{1/3}}\left[\frac{5}{9}\Delta_1^2-\Delta_3\right]+\mathcal{O}(\varepsilon^{5/3}),\\ \lambda_2&=1+\varepsilon^{2/3}e^{4\pi i/3}(-\Delta_4)^{1/3}+\varepsilon\frac{\Delta_1}{3}+\frac{\varepsilon^{4/3}e^{4\pi i/3}}{(-\Delta_4)^{1/3}}\left[\frac{5}{9}\Delta_1^2-\Delta_3\right]+\mathcal{O}(\varepsilon^{5/3}),\\ \lambda_3&=1+\varepsilon^{2/3}e^{8\pi i/3}(-\Delta_4)^{1/3}+\frac{\varepsilon\Delta_1}{3}+\frac{\varepsilon^{4/3}e^{8\pi i/3}}{(-\Delta_4)^{1/3}}\left[\frac{5}{9}\Delta_1^2-\Delta_3\right]+\mathcal{O}(\varepsilon^{5/3}),\end{aligned} \tag{4.4}$$

where

$$\begin{aligned}\Delta_1&=\frac{\partial M_1}{\partial I}+\frac{\partial \bar{M}_2}{\partial \theta}+\frac{\partial M_3}{\partial z}=\text{trace}\,[\mathbf{DM}],\\ \Delta_2&=mT\frac{\partial\Omega}{\partial I}\frac{\partial M_1}{\partial\theta}+mT\frac{\partial\Omega}{\partial z}\frac{\partial M_3}{\partial\theta},\\ \Delta_3&=\frac{\partial(M_1, \bar{M}_2)}{\partial(I, \theta)}+\frac{\partial(M_1, M_3)}{\partial(I, z)}+\frac{\partial(\bar{M}_2, M_3)}{\partial(\theta, z)},\\ \Delta_4&=mT\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\theta, z)}+mT\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(I, \theta)},\\ \Delta_5&=\frac{\partial\bar{M}_2}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\theta, z)}+\frac{\partial\bar{M}_2}{\partial\theta}\frac{\partial(M_1, M_3)}{\partial(z, I)}+\frac{\partial\bar{M}_2}{\partial z}\frac{\partial(M_1, M_3)}{\partial(I, \theta)}=-\det\,[\mathbf{DM}].\end{aligned} \tag{4.5}$$

Here all partial derivatives are evaluated at the zero of M_1, M_3, and

$$\frac{\partial(M_1, \bar{M}_2)}{\partial(I, \theta)}=\frac{\partial M_1}{\partial I}\frac{\partial\bar{M}_2}{\partial\theta}-\frac{\partial M_1}{\partial\theta}\frac{\partial\bar{M}_2}{\partial I}, \text{ etc.}$$

denote Jacobian determinants. These two cases give all possible forms for the eigenvalues for the Poincaré map with $\partial\Omega/\partial I \neq 0$ or $\partial\Omega/\partial z \neq 0$. If $\Delta_1 = 0$, the eigenvalues still maintain the above forms and if $\Delta_4 = 0$ our existence theorem cannot be applied (we are at a bifurcation point). (Note: the computation of these expressions for the eigenvalues are not trivial; they involve some results from algebraic function theory along with the use of Newton diagrams (for complete details see Wiggins [1985]).) Finally, note that the eigenvalues are completely determined by M_1 and M_3 at the lowest order in ε (this is a consequence of the nonzero twist condition).

In the autonomous case the situation is simpler, the eigenvalues of (4.2) are given by

$$\lambda_{1,2} = 1 + \frac{\varepsilon}{2}\operatorname{tr} DM \pm \frac{\varepsilon}{2}\sqrt{(\operatorname{tr} DM)^2 - 4\det DM} + \theta(\varepsilon^2) \tag{4.6}$$

where

$$\operatorname{tr} DM = \frac{\partial M_1}{\partial I} + \frac{\partial M_3}{\partial z}, \qquad \det DM = \frac{\partial M_1}{\partial I}\frac{\partial M_3}{\partial z} - \frac{\partial M_1}{\partial z}\frac{\partial M_3}{\partial I}$$

and the partial derivatives are evaluated at a zero of (M_1, M_3).

Once the eigenvalues are in hand, stability follows from the standard linearization theory.

5. Bifurcations. We now address the question of bifurcations for parameterized families of systems and restrict ourselves to codimension one bifurcations (Guckenheimer and Holmes [1983], Arnold [1982]). Thus, if the parameter is multidimensional, we fix all but one component and vary that alone. We begin with a theorem concerning saddle-node bifurcations.

THEOREM 5.1. *Consider the parametrized Poincaré map with the parameter $\mu \in \mathbb{R}$. Suppose there exists a point $(I^*, \theta^*, z^*, \mu^*) = \mathbf{q}^*$ such that $mT\Omega(I^*, z^*) = 2\pi n$ and*

$$M_1^{m/n}(\mathbf{q}^*) = M_3^{m/n}(\mathbf{q}^*) = 0, \qquad \left[\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(z, \theta)} + \frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta, I)}\right]\Bigg|_{\mathbf{q}^*} = 0,$$

and one of the following holds:

(a) $$\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta, \mu)}\Bigg|_{\mathbf{q}^*} \neq 0, \qquad \frac{d}{dI}\left[\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(z, \theta)} + \frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta, I)}\right]\Bigg|_{\mathbf{q}^*} \neq 0;$$

(b) $$\left[\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\mu, z)} + \frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(I, \mu)}\right]\Bigg|_{\mathbf{q}^*} \neq 0,$$

$$\frac{d}{d\theta}\left[\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(z, \theta)} + \frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta, I)}\right]\Bigg|_{\mathbf{q}^*} \neq 0;$$

(c) $$\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\mu, \theta)}\Bigg|_{\mathbf{q}^*} \neq 0, \qquad \frac{d}{dz}\left[\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(z, \theta)} + \frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta, I)}\right]\Bigg|_{\mathbf{q}^*} \neq 0.$$

Then near $\mathbf{q}^*$ there is a bifurcation point at which saddle-nodes of periodic orbits occur.

Proof. The equations

$$\begin{aligned} &M_1(I, \theta, z, \mu) + \mathcal{O}(\varepsilon) = 0, \\ &mT\Omega(I, z) - 2\pi n + \varepsilon\bar{M}_2(I, \theta, z, \mu) + \mathcal{O}(\varepsilon^2) = 0, \\ &M_3(I, \theta, z, \mu) + \mathcal{O}(\varepsilon) = 0 \end{aligned} \tag{5.1}$$

represent a curve in (I, θ, z, μ) space corresponding to fixed points of the Poincaré map P_ε^m. The tangent to this curve can be computed:

$$\begin{aligned}\mathbf{T}=\Bigg(&\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta,\mu)}+\mathcal{O}(\varepsilon), \frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(I,\mu)}+\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\mu,z)}+\mathcal{O}(\varepsilon),\\ &\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\mu,\theta)}+\mathcal{O}(\varepsilon), \frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(z,\theta)}+\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta,I)}+\mathcal{O}(\varepsilon)\Bigg)^T.\end{aligned}\tag{5.2}$$

We must show that there exists a point near $\mathbf{q}^*=(I^*, \theta^*, z^*, \mu^*)$ such that

$$\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(z,\theta)}+\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta,I)}+\mathcal{O}(\varepsilon)=0$$

at this point and the rate of change of the μ component of the tangent to the curve at this point is nonzero. This will show that the curve of fixed points is locally parabolic in the μ direction about this point and takes one of two possible forms for nondegenerate saddle-node bifurcations (Fig. 3).

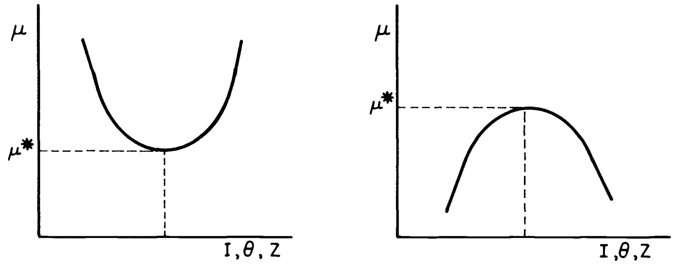


FIG. 3. *Locally parabolic bifurcation curves.*

Let us suppose condition (a) of FP1 holds. Then since $(\partial\Omega/\partial z)(\partial(M_1, M_3)/\partial(\theta, \mu))$ is nonzero at $\mathbf{q}^*$, the I component of the tangent to the curve is nonzero at this point. So by the implicit function theorem we can parametrize the curve of equilibria locally in terms of I. To show that there exists a nearby point such that

$$\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\theta,\mu)}+\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta,I)}+\mathcal{O}(\varepsilon)=0$$

we need only show that

$$\frac{d}{dI}\left(\frac{\partial\Omega}{\partial I}\frac{\partial(M_1, M_3)}{\partial(\theta,\mu)}+\frac{\partial\Omega}{\partial z}\frac{\partial(M_1, M_3)}{\partial(\theta,I)}\right)\Bigg|_{\mathbf{q}^*}\neq 0.$$

This follows by hypothesis and also implies that the rate of change of the μ component of the tangent to the curve of fixed points is nonzero at this point. This completes the proof of case (a). Cases (b) and (c) follow from similar arguments. □

The corresponding result for the autonomous case is the following.

THEOREM 5.2. *Consider the parametrized Poincaré map* (3.1) *with the parameter* $\mu\in\mathbb{R}^1$. *Suppose that there exists a point* $q^*=(I^*, z^*, \mu^*)$ *such that*

$$\mathbf{M}(\mathbf{q}^*)=0,\quad \det \mathbf{DM}|_{\mathbf{q}^*}=\frac{\partial(M_1, M_3)}{\partial(I,z)}\bigg|_{\mathbf{q}^*}=0,\quad \operatorname{tr}\mathbf{DM}|_{\mathbf{q}^*}\neq 0,$$

with at least one of the following conditions satisfied

$$(1)\qquad \left.\frac{\partial(M_1, M_3)}{\partial(I, \mu)}\right|_{\mathbf{q}^*} \neq 0, \qquad \frac{d}{dz}(\det \mathbf{DM})|_{\mathbf{q}^*} \neq 0;$$

$$(2)\qquad \left.\frac{\partial(M_1, M_3)}{\partial(z, \mu)}\right|_{\mathbf{q}^*} \neq 0, \qquad \frac{d}{dI}(\det \mathbf{DM})|_{\mathbf{q}^*} \neq 0.$$

Then $\mathbf{q} = \mathbf{q}^* + \mathcal{O}(\varepsilon)$ *is a bifurcation point at which saddle-nodes of periodic orbits occur.*

Proof. The proof is very similar to the proof of Theorem 5.1. □

We next prove a theorem concerning Hopf bifurcations for the Poincaré map. We utilize the notation given in (3.17).

THEOREM 5.3. *Let* $\mathbf{q}(\mu)$ *be a smooth curve of fixed points for the Poincaré map,* $\mu \in K$, *where* K *is some open interval in* $\mathbb{R}$. *Suppose there exists a* $\mu_0 \in K$ *such that*

$$\left.\frac{\partial \Omega}{\partial I}\right|_{\mathbf{q}(\mu_0)} \neq 0 \quad \mathit{or} \quad \left.\frac{\partial \Omega}{\partial z}\right|_{\mathbf{q}(\mu_0)} \neq 0$$

and

$$(1)\qquad \Delta_2(\mathbf{q}(\mu_0)) < 0,$$

$$(2)\qquad \left.\left(\Delta_1 - \frac{\Delta_4}{\Delta_2} - \Delta_2\right)\right|_{\mathbf{q}(\mu_0)} = 0,$$

$$(3)\qquad \left.\frac{d}{d\mu}\left(\Delta_1 - \frac{\Delta_4}{\Delta_2} - \Delta_2\right)\right|_{\mathbf{q}(\mu_0)} \neq 0,$$

$$(4)\qquad \Delta_4(\mathbf{q}(\mu_0)) \neq 0.$$

Then near μ_0 *there is a bifurcation value for the Poincaré map* (4.1) *at which invariant circles occur.*

Proof. The proof consists of showing that the hypotheses of this theorem imply the hypotheses of the Hopf bifurcation theorem for diffeomorphisms (see Iooss [1979] or Marsden and McCracken [1976]). It is a routine calculation using the expressions for the eigenvalues given in (4.3). □

The analogous theorem in the autonomous case is the following.

THEOREM 5.4. *Let* $\mathbf{q}(\mu)$ *be a smooth curve of zeros for* $\mathbf{M}$, $\mu \in I$, *where* I *is an open interval in* $\mathbb{R}$. *Suppose there exists* $\mu_0 \in I$ *such that*

$$(1)\qquad \operatorname{tr} \mathbf{DM}|_{\mathbf{q}(\mu_0)} = 0,$$

$$(2)\qquad \frac{d}{d\mu}(\operatorname{tr} \mathbf{DM}|_{\mathbf{q}(\mu_0)}) \neq 0,$$

$$(3)\qquad \det \mathbf{DM}|_{\mathbf{q}(\mu_0)} > 0.$$

(*We assume these three quantities to be* $O(1)$.) *Then, for* ε *sufficiently small* (*but not zero*), $\hat{\mu} = \mu_0 + O(\varepsilon)$ *is a bifurcation value for the Poincaré map* (3.1) *at which invariant circles occur.*

Proof. Again a routine calculation using the eigenvalues of (4.6) enables one to verify the hypotheses of the (two-dimensional) Hopf bifurcation theorem. □

The stability of the invariant circles (and direction of bifurcation) can be determined by computation of the quantity

$$\begin{aligned} a = &-\frac{\varepsilon}{32\sqrt{\det \mathbf{DM}}}\{(\bar{f}_{uu}+\bar{f}_{vv})(g_{uu}-g_{vv}+2\bar{f}_{uv})+(g_{uu}+g_{vv})(\bar{f}_{uu}-\bar{f}_{vv}-2g_{uv})\} \\ &+\frac{\varepsilon}{16}\{g_{uuu}+g_{uvv}+\bar{f}_{uuv}+\bar{f}_{vvv}\}, \end{aligned} \tag{5.3}$$

where $\bar{f}=\frac{1}{\sqrt{\det \mathbf{DM}}}[M_{1,I}g-M_{3,I}f]$ and f and g are given by

$$\begin{aligned} f(h, k) &= \tfrac{1}{2}[M_{1,II}h^2+2M_{1,Iz}h^2k+M_{1,zz}k^2] \\ &\quad +\tfrac{1}{6}[M_{1,III}h^3+3M_{1,IIz}h^2k+3M_{1,Izz}hk^2+M_{1,zzz}k^3]+O(4), \\ g(h, k) &= \tfrac{1}{2}[M_{3,II}h^2+2M_{3,Iz}hk+M_{3,zz}k^2] \\ &\quad +\tfrac{1}{6}[M_{3,III}h^3+3M_{3,IIz}h^2k+3M_{3,Izz}hk^2+M_{3,zzz}k^3]+O(4), \end{aligned}$$

where all partial derivatives are evaluated at $\mathbf{q}(\mu_0)$. Here h and k are related to u and v via

$$\begin{pmatrix} h \\ k \end{pmatrix} = \begin{pmatrix} \dfrac{M_{1,I}}{M_{3,I}} & -\dfrac{\sqrt{\det \mathbf{DM}}}{M_{3,I}} \\ 1 & 0 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix}.$$

If $a>0$ (resp. <0) bifurcating circles are unstable (resp. stable). These dreadful formulae follow from application of the standard stability formula of Iooss [1979] or Guckenheimer and Holmes [1983, § 3.5].

6. Examples. In this section we give two examples, the first illustrating the autonomous case and the second illustrating the nonautonomous case.

Our first example not only illustrates how the Hopf and saddle-node bifurcations for diffeomorphisms can interact, but also how the periodic orbits detected by Melnikov theory can be connected to those created in sub- and supercritical Hopf bifurcation from an equilibrium point for the three-dimensional flow. Thus we are able to demonstrate the relationship between the global bifurcation results developed here and conventional local bifurcation methods.

We consider a modification of the van der Pol equation:

$$\begin{aligned} \dot{x} &= y, \\ \dot{y} &= -x+z+\varepsilon(x^2y-\delta y), \\ \dot{z} &= \varepsilon(\gamma-z+y^2), \end{aligned} \tag{6.1}$$

with parameters $(\gamma, \delta)\in\mathbb{R}^2$. For $\varepsilon=0$, the system is Hamiltonian with energy

$$H(x, y; z)=\frac{y^2}{2}+\frac{x^2}{2}-zx=h. \tag{6.2}$$

The family of unperturbed periodic orbits in action angle variables is given by:

$$\begin{aligned} x &= z+\sqrt{2I}\sin\theta, \\ y &= \sqrt{2I}\cos\theta, \\ z &= z. \end{aligned} \tag{6.3}$$

Computation of the Melnikov functions by substitution into (2.7) yields

$$\mathbf{M}=\begin{pmatrix} M_1 \\ M_3 \end{pmatrix}=2\pi\begin{bmatrix} I(z^2+I/2-\delta) \\ \gamma-z+I \end{bmatrix}. \tag{6.4}$$

We now have the following.

THEOREM 6.1. *For $\varepsilon>0$ sufficiently small the bifurcation set of* (6.1) *is as in Fig.* 4; *i.e., there exists a parabola $\gamma=\delta^2$ on which Hopf bifurcations to periodic orbits from the unique fixed point $(\gamma, 0, \gamma)$ occur, yielding stable orbits in the region* COAD *and unstable orbits in* DAE, *and there exists two curves within $O(\varepsilon)$ of* AOB $(16\delta=-(1+8\gamma)$; $\gamma<-1/4)$ *and* CO$(\delta=1+(\gamma+2)^2$; $\gamma<-9/4)$ *on which saddle-nodes of periodic orbits and Hopf bifurcations to unstable invariant tori occur. The tori exist above and near* CO (*in* COF). AOB *and* CO *are tangent at* $O(-9/4, 17/16)$ *and* AOB *and* DAE *are tangent at* A $(-1/4, 1/16)$.

Proof. The behavior of the periodic orbits is derived by verification of the hypotheses of Theorems 5.2 and 5.4, using the Melnikov function (6.4), and computation of the stability coefficient a of (5.3). The local Hopf bifurcations from $(\gamma, 0, \gamma)$ follow from elementary linear computations and conventional center manifold and Hopf bifurcation analysis for flows, as in Carr [1981] or Guckenheimer and Holmes [1983, Chap. 3]. We remark that the parabola $\gamma=\delta^2$ also emerges from a study of the Melnikov function, the zeros of which are given by

$$\begin{aligned} I&=\tfrac{1}{2}\{-(2\gamma+\tfrac{1}{2})\pm\sqrt{2\gamma+\tfrac{1}{4}+4\delta}], \\ z&=I+\gamma. \end{aligned} \tag{6.5}$$

For $\delta>\gamma^2$ $\mathbf{M}$ has only one zero in $I>0$ while for $\delta<\gamma^2$, $\gamma<-1/4$ and $16\delta>-(1+8\gamma)$ $\mathbf{M}$ has two such zeros. □

In Fig. 5 the results of numerical integrations of (6.1) are shown for parameter values in various regions of Fig. 4. These results clearly illustrate the periodic orbits and the invariant torus for the flow predicted by the Melnikov analysis.

To illustrate the nonautonomous theory we consider the equation governing a pendulum subject to weak damping and variable torque. The torque is supplied by a servo-motor or some other device, the dynamics of which is modeled by a first order

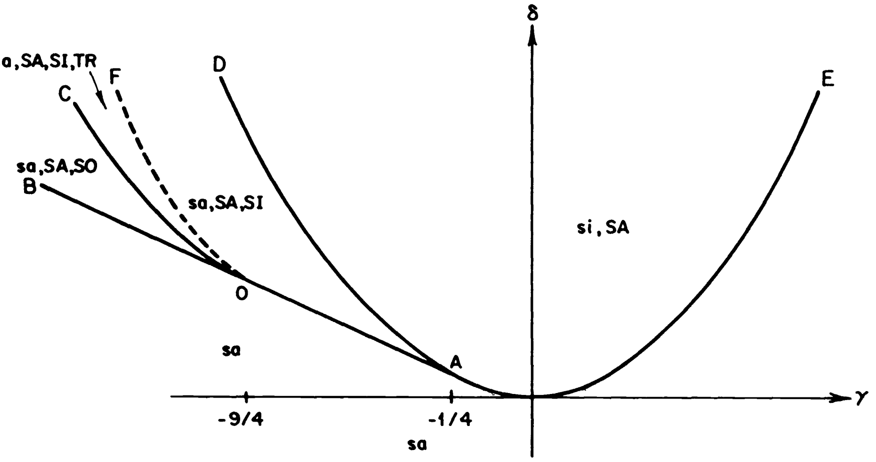

FIG. 4. *The bifurcation set for* (6.1): si = *sink*, sa = *saddle*; SA = *saddle type periodic orbit*; SI = *attracting periodic orbit*; SO = *repelling periodic orbit*; TR = *repelling invariant torus.*

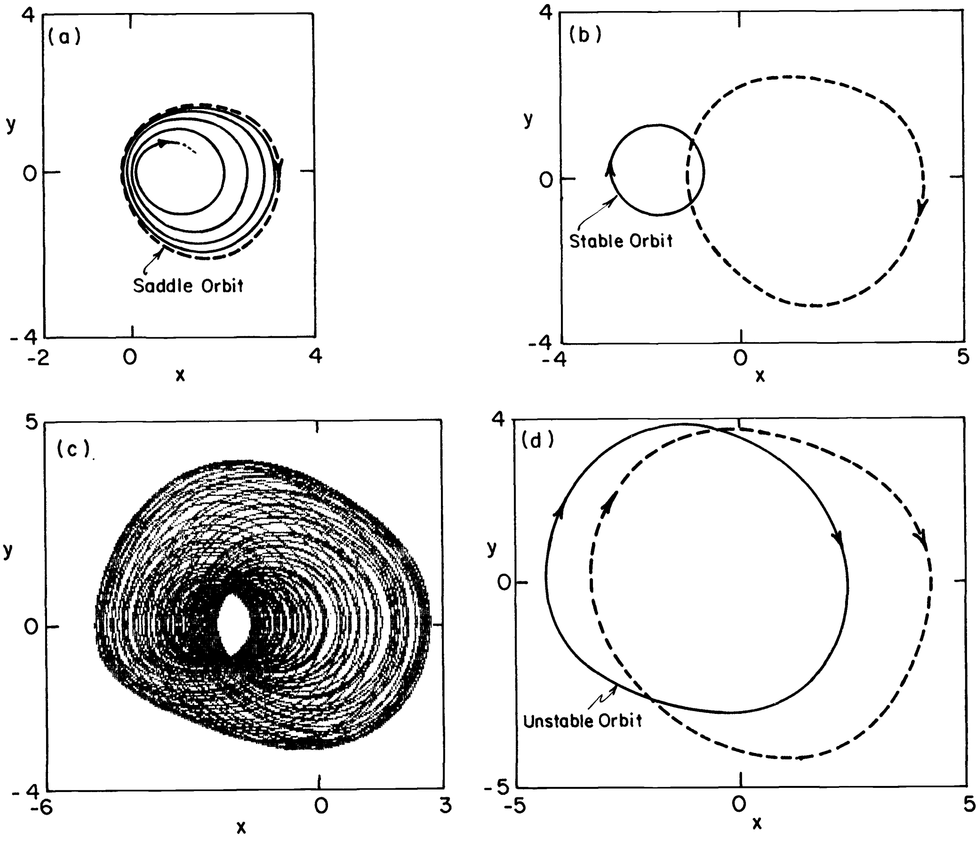

FIG. 5. *Numerical integrations of* (6.1).

equation. The servo-motor is also driven by an external periodic perturbation. The equations of motion are

$$\dot{x} = y,$$
$$\dot{y} = -\sin x + \varepsilon(z - \delta y), \tag{6.6}$$
$$\dot{z} = \varepsilon(-\gamma z + y \cos t),$$

so that the unperturbed system is Hamiltonian with energy

$$H(x, y) = \frac{y^2}{2} + (1 - \cos x). \tag{6.7}$$

We will consider the effect of the perturbation on rotational orbits (overswinging of the pendulum). Note that here H does not depend on z and so the unperturbed system is identical on each $z = z_0$ constant slice. This is unimportant in what follows but does simplify the computations somewhat. The unperturbed orbits are given by

$$x(t) = 2 \sin^{-1}\left(\text{sn}\left[\frac{K(k)}{\pi}(t + t_0)\right]\right),$$
$$y(t) = \frac{2}{k}\,\text{dn}\left[\frac{K(k)}{\pi}(t + t_0)\right], \qquad k \in (0, 1), \tag{6.8}$$
$$z(t) = z_0,$$

where sn and dn are the Jacobi elliptic functions and K is the complete elliptic integral of the first kind with modulus k. The resonance relation is given by

$$T(I)=T(k)=\frac{2\pi m}{n}=\frac{2\pi}{\Omega(I)}=2kK(k), \tag{6.9}$$

where $2kK(k)$ is the period of the unperturbed orbit and 2π the period of the forcing function. Note that the modulus k plays essentially the same role as the action I or energy H, since $I(k)$ and $H(k)$ are both monotonic functions (see below).

Using the remark at the end of § 3, we now compute the Melnikov functions $M_1^{m/n}$ and $M_3^{m/n}$. Dropping the superscripts, we have

$$M_1=\frac{1}{\Omega(I)}\int_0^{2\pi m}(yz-\delta y^2)\,dt, \tag{6.10a}$$

$$M_3=\int_0^{2\pi m}(-\gamma z+y\cos t)\,dt, \tag{6.10b}$$

where $\Omega(I)$ and y depend implicitly on k, which is selected to satisfy the resonance relation (6.9). The computations are lengthy and make use of Fourier expansions of the elliptic function dn (cf. Byrd and Friedman [1971]). For the case $n=1$ we obtain

$$\begin{aligned} M_1&=2m\left[\pi z_0-\frac{4\delta E(k)}{k}\right],\\ M_3&=\pi m\left[-2\gamma z_0+\frac{1}{k}\operatorname{sech}\left(\frac{\pi m K'(k)}{K(k)}\right)\cos m\theta_0\right], \end{aligned} \tag{6.11}$$

where $E(k)$ is the complete elliptic integral of the second kind and $K'(k)=K(\sqrt{1-k^2})$ is the complementary complete elliptic integral of the first kind. In transforming from the initial starting time $t_0\in[0,2\pi m/n]$, which appears in (6.8), to the phase θ_0 we use the relationship $t_0=m\theta_0/n$. When $n\neq 1$ we obtain

$$M_3=-2\pi m\gamma z_0 \tag{6.12}$$

and M_1 remains as in (6.10a). Thus, at first order, only "pure" $m/1$ subharmonics are excited (cf. Greenspan and Holmes [1983], [1984]). Henceforth we drop the subscript "0."

Since the frequency of the unperturbed orbits is

$$\Omega(k)=\frac{2\pi}{T(k)}=\frac{\pi}{kK(k)}, \tag{6.13}$$

we have $\partial\Omega/\partial z\equiv 0$ and

$$\frac{\partial\Omega}{\partial I}=\frac{\partial\Omega}{\partial k}\frac{\partial k}{\partial I}=\left(\frac{-\pi E(k)}{k^2(1-k)^2K(k)}\right)\left(\frac{-\pi k^2}{4K(k)}\right)=\frac{\pi^2E(k)}{4(1-k)^2K^2(k)}>0\quad\text{for } k\in(0,1), \tag{6.14}$$

where we have used the fact that the action $I(k)$ is given by the monotonic function

$$I(k)=\frac{4}{\pi k}E(k). \tag{6.15}$$

We remark that the limits $k=0$ and 1 correspond to the Hamiltonian energies $H=\infty$ and $H=2$, the latter being the energy of the homoclinic loop (separatrix) of the unperturbed system. Thus the frequency increases monotonically with action I in the range $I\in(4/\pi,\infty)(k\in(1,0))$.

We now apply Theorem 3.1 to the example. For $n=1$, the resonance relation (6.9) becomes $\pi m = kK(k)$, which, given $m \in Z^+$, determines k uniquely since $kK(k)$ is monotone. Then, from (6.11), for a zero of M_1 we require

$$z = \frac{4\delta E(k)}{\pi k}, \tag{6.16}$$

which determines z, and for a zero of M_3

$$\frac{8\gamma\delta E(k)}{\pi k} = \frac{1}{k}\operatorname{sech}\left(\frac{\pi m K'(k)}{K(k)}\right)\cos m\theta, \tag{6.17}$$

which determines precisely $2m$ values of θ in the range $[0, 2\pi)$, provided that

$$\operatorname{sech}\left(\frac{\pi m K'(k)}{K(k)}\right) > \left|\frac{8\gamma\delta E(k)}{\pi}\right|. \tag{6.18}$$

We leave it to the reader to verify that the nondegeneracy condition of the theorem also holds.

When (6.18) is an equality we have bifurcation (the $2m$ simple zeros degenerate into m multiple roots). To verify that nondegenerate saddle-node bifurcations occur, we fix $\delta > 0$ and vary γ, thus converting the problem to a one parameter system. Applying Theorem 5.1, we require a zero of M_1, M_2 at which, in addition,

$$\frac{\partial \Omega}{\partial I}\left(\frac{\partial(M_1, M_3)}{\partial(z, \theta)}\right) = 0 \quad \text{and thus} \quad \frac{\partial(M_1, M_3)}{\partial(z, \theta)} = 0 \tag{6.19}$$

(since $\partial\Omega/\partial z \equiv 0$ and $\partial\Omega/\partial I \neq 0$ here). This implies that

$$\begin{aligned} &[2m\pi]\cdot\left[\frac{\pi m^2}{k}\operatorname{sech}\left(\frac{\pi m K'(k)}{K(k)}\right)\sin m\theta\right] = 0 \\ &\Rightarrow m\theta = 0, \pi, \cdots \Rightarrow \theta = \frac{l\pi}{m}, \qquad l = 0, \cdots, 2m-1. \end{aligned} \tag{6.20}$$

Note that $\sin m\theta = 0$, $\cos m\theta = \pm 1$, which occurs precisely where (6.18) becomes an equality. Finally, nondegeneracy condition (b) of Theorem 5.1 holds, since $\partial\Omega/\partial z \equiv 0$ and $\partial\Omega/\partial I \neq 0$ and

$$\frac{\partial(M_1, M_3)}{\partial(\gamma, z)} = [0]\cdot[-2\pi m\gamma] - [2m\pi]\cdot[-2\pi m z] = 4\pi^2 m^2 z \neq 0,$$

when $z \neq 0$, and

$$\begin{aligned} \frac{d}{d\theta}\left(\frac{\partial(M_1, M_3)}{\partial(z, \theta)}\right) &= \frac{d}{d\theta}\left\{[2\pi m]\cdot\left[\frac{\pi m^2}{k}\operatorname{sech}\left(\frac{\pi m K'(k)}{K(k)}\right)\sin m\theta\right] - [0]\cdot[-2\pi m\gamma]\right\} \\ &= -\frac{2\pi^2 m^4}{k}\operatorname{sech}\left[\frac{\pi m K'(k)}{K(k)}\right]\cos m\theta \neq 0, \end{aligned} \tag{6.21}$$

when $\cos m\theta (= \pm 1) \neq 0$. (Since $\gamma, \delta > 0$ we only obtain the $\cos m\theta = +1$ case). Summarizing our results, we have the following.

THEOREM 6.2. *There exists a countable set of bifurcation curves in* (γ, δ)*-space given by*

$$\gamma\delta = \frac{\pi}{8E(k)}\operatorname{sech}\left(\frac{\pi m K'(k)}{K(k)}\right), \quad kK(k) = \pi m, \quad m = 1, 2, \cdots, \tag{6.22}$$

near which, for ε sufficiently small (depending on m), saddle-node bifurcations to pairs of $2\pi m$-periodic orbits occur for the Poincaré map of (6.6).

Eigenvalue computations as outlined in § 4 reveal that each pair of subharmonics consists of a stable sink and a saddle. The requirement that $M_1 = 0$ (see (6.16)) together with the monotonicity of $kK(k)$ shows that these periodic points all lie near a bowl-like surface of revolution in (θ, I, z) (or (x, y, z)) space. Figure 6 gives our impression of the situation. Note how the periodic points accumulate near $z = 4\delta/\pi$ ($k = 1$; $H = 2$). In this connection, we note that the curves (6.22) accumulate on the curve $\gamma\delta = \pi/8 \operatorname{sech}(\pi/2)$ as $k \to 1^-(H \to 2^+)$. We plan to study questions relating to the resulting chaotic invariant sets in a subsequent paper.

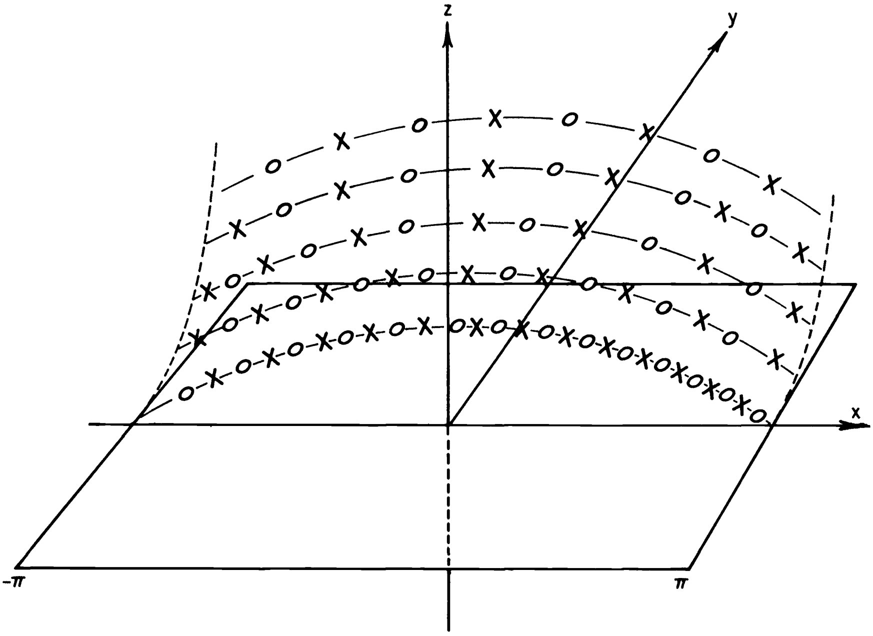

FIG. 6. *Subharmonics for the perturbed pendulum.*

We end our discussion of this example by remarking that since M_3 has no zeros (other than $z = 0$) unless $n = 1$ or $\gamma = 0$, no other periodic orbits exist near the unperturbed rotational solutions for $\delta, \gamma > 0$. We also note that the "bowl" of $m/1$ subharmonics created in (x, y, z) space (Fig. 6) has a similar structure to the unfolding of a Hopf bifurcation for diffeomorphisms of $\mathbb{R}^2$ recently studied by Chenciner [1983], [1985a], [1985b].

HOMOCLINIC ORBITS IN SLOWLY VARYING OSCILLATORS*

STEPHEN WIGGINS† AND PHILIP HOLMES‡

Abstract. We obtain existence and bifurcation theorems for homoclinic orbits in three-dimensional flows that are perturbations of families of planar Hamiltonian systems. The perturbations may or may not depend explicitly on time. We show how the results on periodic orbits of the preceding paper are related to the present homoclinic results, and apply them to a periodically forced Duffing equation with weak feedback.

Key words. bifurcation, Hamiltonian system, homoclinic orbit, perturbation theory, Melnikov method

AMS(MOS) subject classifications. 34CXX, 58F14, 70KXX

1. Introduction. In the preceding paper we developed perturbation methods based on ideas of Melnikov [1963] that permit us to approximate Poincaré maps for autonomous and periodically forced slowly varying oscillators, the flows of which are close to those of families of planar Hamiltonian systems. We obtained existence, stability and bifurcation results for periodic orbits in such systems. In the present paper we extend these results to deal with homoclinic orbits and show how the periodic results are related to them.

In § 2 we outline the geometry of the phase space and we describe basic perturbation results. The computational tools and existence and bifurcation theorems are developed in §§ 3 and 4, and the relationship between periodic and homoclinic orbits is discussed in § 5. The example and conclusions follow in §§ 6 and 7.

2. Structure of the phase space. As in Wiggins and Holmes [1987] we will consider systems of the form

$$\left.\begin{aligned} \dot{x} &= f_1(x, y, z) + \varepsilon g_1(x, y, z, t, \boldsymbol{\mu}) \\ \dot{y} &= f_2(x, y, z) + \varepsilon g_2(x, y, z, t; \boldsymbol{\mu}) \\ \dot{z} &= \varepsilon g_3(x, y, z, t; \boldsymbol{\mu}) \end{aligned}\right\} \quad \text{or} \quad \dot{\mathbf{q}} = \mathbf{f}(\mathbf{q}) + \varepsilon \mathbf{g}_{\mu}(\mathbf{q}, t), \tag{2.1}$$

with $0 < \varepsilon \ll 1$, **f** and **g** sufficiently smooth ($C^r, r \geqq 2$), **g** periodic in t with period T and $\boldsymbol{\mu} \in R^k$ a vector of parameters. We will write $\mathbf{g}(\mathbf{q}, t; \boldsymbol{\mu}) = \mathbf{g}_{\mu}(\mathbf{q}, t)$ and frequently drop the explicit dependence on $\boldsymbol{\mu}$. We make the following assumptions on the unperturbed system:

(A1) For $\varepsilon = 0$, (2.1) reduces to a one-parameter family of planar Hamiltonian systems with Hamiltonian $H(x, y, z)$:

$$\begin{aligned} \dot{x} &= f_1(x, y, z) = \frac{\partial H}{\partial y}, \\ \dot{y} &= f_2(x, y, z) = -\frac{\partial H}{\partial x}, \\ \dot{z} &= 0. \end{aligned} \tag{2.2}$$

(A2) For each value of z in some open interval $J \subseteq \mathbb{R}$ the "planar" system (2.2) possesses a homoclinic orbit to a hyperbolic saddle point. Thus, when viewed in the full three-dimensional phase space, system (2.2) possesses a normally hyperbolic invariant one-dimensional manifold, $\mathcal{N}$, given by the union of saddle points of the one-parameter family of planar systems. $\mathcal{N}$ has two-dimensional stable and unstable manifolds (denoted by $W^s(\mathcal{N})$, $W^u(\mathcal{N})$, respectively), such that their intersection $W^s(\mathcal{N}) \cap W^u(\mathcal{N}) \overset{\text{def}}{=} \Gamma$ is made up of the union of the homoclinic orbits of the one-parameter family of planar systems. Henceforth we assume that $\mathcal{N}$ is connected; if not, the theory is applied separately to each connected component of $\mathcal{N}$.

(A3) The interior of Γ contains a two-parameter family of periodic orbits, which we denote by $\mathbf{q}_0^{\alpha,z}(t-\theta)$ for $z \in J$ and $\alpha \in L(z)$, where for each $z \in J$, $L(z)$ is an open interval in R. We denote $L(z)$ by $(\alpha(z), \alpha_0(z))$ and assume that $\lim_{\alpha \to \alpha_0} T(\alpha, z) = \infty$, where $T(\alpha, z)$ denotes the period of $\mathbf{q}_0^{\alpha,z}(t-\theta)$ and that $T(\alpha, z)$ is a differentiable function of α and z with $dT(\alpha, z)/d\alpha \neq 0$ for $(\alpha, z) \in (L(z), J)$.

Note that the assumptions of Wiggins and Holmes [1987] are included in the above. As before we suspend (2.1) over the space $R^3 \times S^1$ where $S^1 = R/T$ is the circle of length T by defining the function $\phi(t) = t$, mod T and then by T-periodicity of the g_i we have

$$\begin{aligned} \dot{x} &= f_1(x, y, z) + \varepsilon g_1(x, y, z, \phi; \boldsymbol{\mu}), \\ \dot{y} &= f_2(x, y, z) + \varepsilon g_2(x, y, z, \phi; \boldsymbol{\mu}), \\ \dot{z} &= \varepsilon g_3(x, y, z, \phi; \boldsymbol{\mu}), \\ \dot{\phi} &= 1. \end{aligned} \qquad (x, y, z, \phi) \in R^3 \times S^1, \tag{2.3}$$

Again we note that this suspension makes sense even when the g_i are independent of ϕ. At $\varepsilon = 0$, for the suspended system we denote the normally hyperbolic invariant set by $\mathcal{M} \equiv (\mathcal{N}, \phi) = \mathcal{N} \times S^1$. See Fig. 1.

For computations it is convenient to have $\mathcal{M}$ in an explicit form. Recall from assumption (A2) that $\mathcal{N}$ is a one-manifold of equilibrium points for the unperturbed system such that on each $z =$ constant plane the equilibrium point of the associated planar system is hyperbolic. Since we have assumed that the unperturbed vector field is Hamiltonian, a simple computation of the eigenvalues of the linearized vector field at this point shows that $\partial(f_1, f_2)/\partial(x, y) < 0$. Thus, by the implicit function theorem,

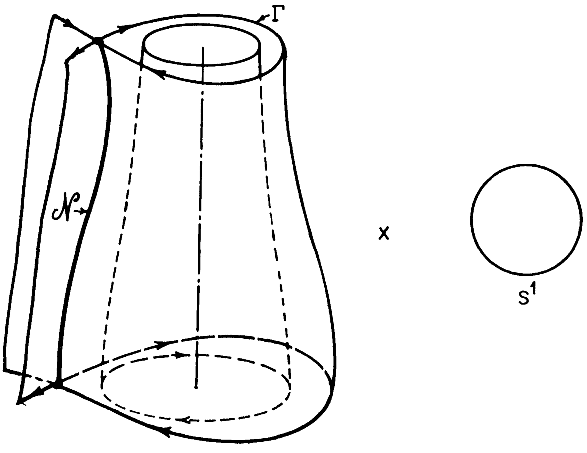

FIG. 1. *The unperturbed phase space.*

$\mathcal{M}$ can be represented as a graph over the z variables:

$$\mathcal{M}=\left\{(\gamma(z),\phi)\;\middle|\;\gamma(z)=(x(z),y(z),z), f_1(x,y,z)=f_2(x,y,z)=0,\ \left.\frac{\partial(f_1,f_2)}{\partial(x,y)}\right|_{\gamma(z)}<0,\ \phi\in S^1,\ z\in J\right\}. \tag{2.4}$$

The following results give us information about the perturbed phase space.

Proposition 2.1. *There exists $\varepsilon_0>0$ such that for $0<\varepsilon<\varepsilon_0\ll 1$ there exists a normally hyperbolic invariant one-manifold*

$$\mathcal{M}_\varepsilon=\{(\gamma(z,\phi;\varepsilon),\phi)=(\gamma(z)+\mathcal{O}(\varepsilon),\phi)\,|\,\phi\in S^1, z\in J\}, \tag{2.5}$$

where $\gamma(z,\phi;\varepsilon)$ is a C^r function of z and ε. Moreover, $\mathcal{M}_\varepsilon$ has local stable and unstable manifolds. $W^s_{\text{loc}}(\mathcal{M}_\varepsilon)$, $W^u_{\text{loc}}(\mathcal{M}_\varepsilon)$, which are C^r-close to the local stable and unstable manifolds of $\mathcal{M}$, denoted by $W^s_{\text{loc}}(\mathcal{M})$ and $W^u_{\text{loc}}(\mathcal{M})$, respectively.

Remark. $\mathcal{M}_\varepsilon$ is an invariant manifold in the weaker sense in that solutions may leave $\mathcal{M}_\varepsilon$ by virtue of their z values crossing the boundary of J. This will occur on a time scale $\mathcal{O}(1/\varepsilon)$ since motion along $\mathcal{M}_\varepsilon$ has a speed $\mathcal{O}(\varepsilon)$.

Proof. The existence of $\mathcal{M}_\varepsilon$, $W^s_{\text{loc}}(\mathcal{M}_\varepsilon)$, and $W^u_{\text{loc}}(\mathcal{M}_\varepsilon)$ follows from the persistence of normally hyperbolic invariant sets and their stable and unstable manifolds (see Hirsch, Pugh and Shub [1977] or Fenichel [1971]), with some slight technical modifications. The usual theorem requires $\mathcal{M}$ to be compact and boundaryless. However, there are two ways to get around these requirements. One, due to Robinson [1983], involves mapping $\mathcal{M}$ into a compact space (e.g. a sphere) and smoothly extending the vector field to a neighborhood of $\mathcal{M}$ via the use of bump functions, the conclusions then follow from the Hirsch, Pugh and Shub [1977] theory. The second method is due to Kopell [1985] and involves the use of the invariant manifold theory of Fenichel [1971]. Briefly, the vector field on the boundary of $\mathcal{M}$ is zero, $\mathcal{M}$ is then perturbed in a neighborhood of its boundary via a bump function in such a manner that it becomes "overflowing" (resp. "underflowing") invariant (see Fenichel [1971] for precise definitions). The existence of the perturbed manifold and its local unstable (resp. stable) manifold then follows from the Fenichel invariant manifold theorem. Furthermore, the modification of the vector field near the boundary of $\mathcal{M}$ does not affect the dynamics of our original system in the sense that, although now $\mathcal{M}_\varepsilon$ and $W^{s,u}_{\text{loc}}(\mathcal{M}_\varepsilon)$ may depend on the specific modification, asymptotic expansions of these manifolds agree to all orders for arbitrary modifications (Kopell [1985]). (Note: the situation is the same as that which arises in applications of center manifold theory, where the nonuniqueness of the center manifold does not effect recurrent motions.) □

On $\mathcal{M}$ all points are fixed, there is no motion. However, on $\mathcal{M}_\varepsilon$ this need not be the case. The following result gives us information concerning the flow on $\mathcal{M}_\varepsilon$.

Proposition 2.2. *Let $\overline{g_3(\gamma(z))}=1/T\int_0^T g_3(\gamma(z),\phi)\,d\phi$ and suppose there exists $z_0\in J$ such that $\overline{g_3(\gamma(z_0))}=0$, $(d/dz)\overline{g_3(\gamma(z_0))}\neq 0$. Then $(\gamma(z_0,\phi,\varepsilon),\phi)=(\gamma(z_0)+\mathcal{O}(\varepsilon),\phi)$ is a hyperbolic periodic orbit on $\mathcal{M}_\varepsilon$ with period T.*

Proof. This is a straightforward application of the averaging theorem (see Hale [1969] or Guckenheimer and Holmes [1983]) restricted to $\mathcal{M}_\varepsilon$. □

Remark. If g_3 is not explicitly time dependent, then $g_3\equiv\overline{g_3}$ and averaging is unnecessary, so the proof goes through without appeal to the averaging theorem.

In order to visualize the situation we take the following cross section to the flow induced by (2.3):

$$\Sigma^{t_0}=\{(x,y,z,\phi)\in R^3\times S^1\,|\,\phi=t_0\in[0,T)\}. \tag{2.6}$$

If there exists a hyperbolic periodic orbit on $\mathcal{M}_\varepsilon$ there are two possible situations (see Fig. 2).

In these pictures the solid lines are to be interpreted as initial conditions for solutions of the perturbed equation, while the dotted lines can be thought of as actual solutions of the unperturbed equation, since the unperturbed equation is autonomous.

FIG. 2. *The perturbed manifolds.* (a) $\gamma(z_0)+\mathcal{O}(\varepsilon)$ *has* 1-*d unstable and* 2-*d stable manifolds.* (b) $\gamma(z_0)+\mathcal{O}(\varepsilon)$ *has* 1-*d stable and* 2-*d unstable manifolds.*

The following perturbation results allows us to approximate certain solutions in the stable and unstable manifolds of $(\gamma(z_0)+\mathcal{O}(\varepsilon), \phi)$ for arbitrarily long time intervals. This is necessary since we wish to find homoclinic, rather than periodic, orbits.

PROPOSITION 2.3. *Suppose there exists* $z_0 \in J$ *such that* $(\gamma(z_0, \phi; \varepsilon), \phi) = (\gamma(z_0)+\mathcal{O}(\varepsilon), \phi)$ *is a hyperbolic periodic orbit on* $\mathcal{M}_\varepsilon$. *Then, for each* ε *sufficiently small, there exists* $C>0$, $K=\{z\colon z_0 - C\varepsilon < z < z_0 + C\varepsilon\}$ *and solutions* $\mathbf{q}_\varepsilon^s(t, \theta)$, $\mathbf{q}_\varepsilon^u(t, \theta)$ *lying in the stable and unstable manifolds of* $(\gamma(z_0, \phi; \varepsilon), \phi)$ *with the following representations valid in the indicated time intervals*:

Case (a) dim $W^s[(\gamma(z_0, \phi; \varepsilon), \phi)] = 3$, dim $W^u[(\gamma(z_0, \phi; \varepsilon), \phi)] = 2$:

$$\mathbf{q}_\varepsilon^s(t, \theta) = \mathbf{q}_0(t-\theta) + \varepsilon \mathbf{q}_1^s(t, \theta) + \mathcal{O}(\varepsilon^2), \qquad z_\varepsilon^s(t_0, \theta) \in K, \quad t \in [t_0, \infty).$$

$$\mathbf{q}_\varepsilon^u(t, \theta) = \mathbf{q}_0(t-\theta) + \varepsilon \mathbf{q}_1^u(t, \theta) + \mathcal{O}(\varepsilon^2), \qquad t \in (-\infty, t_0];$$

Case (b) dim $W^s[(\gamma(z_0, \phi; \varepsilon), \phi)] = 2$, dim $W^u[(\gamma(z_0, \phi; \varepsilon), \phi)] = 3$:

$$\mathbf{q}_\varepsilon^s(t, \theta) = \mathbf{q}_0(t-\theta) + \varepsilon \mathbf{q}_1^s(t, \theta) + \mathcal{O}(\varepsilon^2), \qquad t \in [t_0, \infty),$$

$$\mathbf{q}_\varepsilon^u(t, \theta) = \mathbf{q}_0(t-\theta) + \varepsilon \mathbf{q}_1^u(t, \theta) + \mathcal{O}(\varepsilon^2), \qquad z_\varepsilon^u(t_0, \theta) \in K, \quad t \in (-\infty, t_0],$$

where $\mathbf{q}_0(t-\theta)$ *is the solution of the unperturbed equation that connects the point* $\gamma(z_0)$ *on* $\mathcal{M}$ *to itself, i.e., the homoclinic orbit on the* $z = z_0$ *plane.*

Proof. See Wiggins [1985]. □

Remarks. (1) $\mathbf{q}_1^s(t, \theta)$ and $\mathbf{q}_1^u(t, \theta)$ may be obtained by solving the first variational equations

$$\dot{\mathbf{q}}_1^s = \mathbf{Df}(\mathbf{q}_0)\mathbf{q}_1^s + \mathbf{g}(\mathbf{q}_0, t), \qquad t \in [t_0, \infty),$$

$$\dot{\mathbf{q}}_1^u = \mathbf{Df}(\mathbf{q}_0)\mathbf{q}_1^u + \mathbf{g}(\mathbf{q}_0, t), \qquad t \in (-\infty, t_0].$$

(2) We note that in the (suspended) unperturbed system, dim $W^s[\gamma(z_0), \phi] =$ dim $W^u[(\gamma(z_0), \phi)] = 2$ and that for the perturbed system the dimensions of $W^s[(\gamma(z_0)+\mathcal{O}(\varepsilon), \phi)]$ or $W^u[(\gamma(z_0)+\mathcal{O}(\varepsilon), \phi)]$ may increase by one (Cases (a) and (b)). So in order to uniformly approximate solutions in the unperturbed manifolds by

solutions in the unperturbed manifolds for arbitrarily long time intervals, these solutions must initially start out close together. This is the reason for the requirements $z_\varepsilon^{s,u}(t_0, \theta) \in K$ in Cases (a) and (b).

(3) For the stable manifold in Case (a) and the unstable manifold in Case (b), the theorem does not tell us explicitly which solution in the manifolds we are on, only that all solutions with initial z values in K are approximated uniformly by a corresponding solution to the unperturbed equation. Consequently we are no longer able to follow individual solutions in these manifolds during their time evolutions.

In § 5 we will be concerned with periodic orbits limiting on Γ. In this situation we need to approximate perturbed solutions arbitrarily close to Γ by unperturbed periodic orbits so we need some kind of control on the flow on $\mathcal{M}_\varepsilon$.

PROPOSITION 2.4. *Let* $(\gamma(z_0) + \mathcal{O}(\varepsilon), \phi)$ *be a hyperbolic periodic orbit on* $\mathcal{M}_\varepsilon$ *and let* $\mathbf{q}^{\alpha,z_0}(t-\theta)$ *be a periodic orbit of the unperturbed system with period* $T(\alpha, z_0)$. *Then there exists a perturbed orbit* $\mathbf{q}_\varepsilon^{\alpha,z_0}(t, \theta)$, *not necessarily periodic, which can be expressed as*

$$\mathbf{q}_\varepsilon^{\alpha,z_0}(t, \theta) = \mathbf{q}_0^{\alpha,z_0}(t-\theta) + \varepsilon \mathbf{q}_1^{\alpha,z_0}(t, \theta) + \mathcal{O}(\varepsilon^2)$$

uniformly in $t \in [t_0, t_0 + T(\alpha, z_0)]$, *for* ε *sufficiently small and all* $\alpha \in L(z_0)$.

Proof. See Wiggins [1985]. □

We will remark that Proposition 2.4 only allows us to approximate perturbed orbits by unperturbed orbits for one passage through a neighborhood of $\mathcal{M}_\varepsilon$. This is due to the fact that orbits take arbitrarily long to pass through the neighborhood and therefore the slightest error may be magnified greatly over the long time of passage. Consequently for periodic orbits near Γ we are limited to the study of resonant orbits satisfying $mT = nT(\alpha, z_0)$, $n = 1$. However, since we can pick $T(\alpha, z_0)$ at will, and by (A3) $T \to \infty$ as $\alpha \to \alpha_0$, m can be arbitrarily large.

3. Existence of homoclinic orbits. We now turn our attention to the homoclinic manifold Γ. By Proposition 2.3, in order to approximate to $\mathcal{O}(\varepsilon)$ orbits in the stable and unstable manifolds of $\mathcal{M}_\varepsilon$ by orbits in the stable and unstable manifolds of $\mathcal{M}$ it is necessary that there exist a point $z_0 \in J$ such that $(\gamma(z_0, \phi; \varepsilon), \phi)$ is a hyperbolic periodic orbit on $\mathcal{M}_\varepsilon$. Now a hyperbolic periodic orbit on $\mathcal{M}_\varepsilon$ will have either a three-dimensional stable manifold and a two-dimensional unstable manifold or vice versa. Thus in the four-dimensional phase space we expect the intersection to be generically one-dimensional. In measuring distances between manifolds of solutions in phase space it is only necessary to explore the directions transverse to the manifolds, so the number of measurements necessary in order to determine whether or not the manifolds intersect should be equal to the minimum codimension of the manifolds. In our case that number is one and we expect a single (scalar) measurement to suffice.

Now on the cross section Σ^0 the hyperbolic periodic orbit for the flow, $(\gamma(z_0, \phi; \varepsilon), \phi)$, corresponds to a hyperbolic fixed point, $\gamma(z_0) + \mathcal{O}(\varepsilon)$, for the Poincaré map P_ε, which has either a two-dimensional stable manifold and a one-dimensional unstable manifold (Case (a) of Proposition 2.3) or a one-dimensional stable manifold and a two-dimensional unstable manifold (Case (b) of Proposition 2.3). For definiteness, in the following we assume that Case (a) holds, since the argument and conclusions for Case (b) are identical.

We develop a measure for the distance between the stable manifold $W^s(\gamma(z_0) + \mathcal{O}(\varepsilon))$ and the unstable manifold $W^u(\gamma(z_0) + \mathcal{O}(\varepsilon))$ on the cross-section Σ^0. Let $\alpha_0 = \alpha(z_0)$ denote the value of α on the $z = z_0$ level that corresponds to the unperturbed homoclinic orbit on that z-level, and denote this orbit $\mathbf{q}_0(t-\theta)$, where we have dropped the explicit (α, z) dependence for ease of notation.

At the point $\mathbf{q}_0(-\theta)$ on the cross-section Σ^0 we consider the plane Π normal to the vector $\mathbf{f}(\mathbf{q}_0(-\theta))$. There exists a unique point $\mathbf{q}^u_\varepsilon(-\theta)$ in $W^u(\gamma(z_0)+\mathcal{O}(\varepsilon))\cap\Pi$ which is "closest" to $\gamma(z_0)+\mathcal{O}(\varepsilon)$ in the sense of elapsed time for a solution leaving the neighborhood of $\gamma(z_0)+\mathcal{O}(\varepsilon)$. Similarly, there exists a curve on the plane Π, namely the intersection $W^s(\gamma(z_0)+\mathcal{O}(\varepsilon))\cap\Pi$, which is closest to $\gamma(z_0)+\mathcal{O}(\varepsilon)$ in the sense of elapsed time. We choose the unique point $\mathbf{q}^s_\varepsilon(0,\theta)$ on this curve such that $\mathbf{q}^u_\varepsilon(0,\theta)-\mathbf{q}^s_\varepsilon(0,\theta)$ is parallel to $(-f_2(\mathbf{q}_0(-\theta)), f_1(\mathbf{q}_0(-\theta)), 0)$. Thus we require $z^s_1(0,\theta)=z^u_1(0,\theta)$. We are guaranteed that such a choice of points can be made for each θ by Proposition 2.3 which says that the local perturbed manifolds are C^r ε-close to the local unperturbed manifolds in a neighborhood of $(\gamma(z_0)+O(\varepsilon), \phi)$. Thus their tangent spaces are ε-close. Outside of this neighborhood, solutions remain ε-close to unperturbed solutions for finite times, hence their maximum movement in the z-direction is $\mathcal{O}(\varepsilon)$. See Fig. 3.

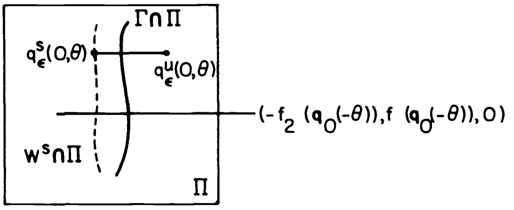

FIG. 3. *Intersections of the stable and unstable manifolds with* Π.

Clearly $|\mathbf{q}^u_\varepsilon(0,\theta)-\mathbf{q}^s_\varepsilon(0,\theta)|$ is a measure of the distance between $W^s(\gamma(z_0)+\mathcal{O}(\varepsilon))$ and $W^u(\gamma(z_0)+\mathcal{O}(\varepsilon))$. However, for easier computation and in order to account for the relative orientations between $W^s(\gamma(z_0)+\mathcal{O}(\varepsilon))$ and $W^u(\gamma(z_0)+\mathcal{O}(\varepsilon))$, we prefer to use the following distance measurement:

$$\begin{aligned} d(\alpha_0,\theta,z_0) &= \frac{(\partial H/\partial x(\mathbf{q}_0(-\theta)), \partial H/\partial y(\mathbf{q}_0(-\theta)), 0)\cdot(\mathbf{q}^u_\varepsilon(0,\theta)-\mathbf{q}^s_\varepsilon(0,\theta))}{\|\mathbf{f}(\mathbf{q}_0(-\theta))\|} \\ &= \frac{\varepsilon[(\partial H/\partial x(\mathbf{q}_0(-\theta)), \partial H/\partial y(\mathbf{q}_0(-\theta)), 0)\cdot(\mathbf{q}^u_1(0,\theta)-\mathbf{q}^s_1(0,\theta))]}{\|\mathbf{f}(\mathbf{q}_0(-\theta))\|}+\mathcal{O}(\varepsilon^2) \qquad (3.1) \\ &\overset{\text{def}}{=} \varepsilon\frac{M(\theta)}{\|\mathbf{f}(\mathbf{q}_0(-\theta))\|}+\mathcal{O}(\varepsilon^2) \end{aligned}$$

where "$\cdot$" is the usual vector dot product, $\|\cdot\|$ is the Euclidean norm, and $M(\theta)$ is defined to be the homoclinic *Melnikov function.*

We now develop a computable expression for $M(\theta)$. Recall that geometrically $M(\theta)$ is the lowest order term in an asymptotic expansion for the distance between the stable and unstable manifolds of a hyperbolic fixed point of a Poincaré map. We shall derive and solve a simple differential equation for a time dependent version of M, as in the standard planar Melnikov calculation.

Letting

$$\begin{aligned} \Delta(t,\theta) &= f_1(\mathbf{q}_0(-\theta))(y^u_1(t,\theta)-y^s_1(t,\theta))-f_2(\mathbf{q}_0(t-\theta))(x^u_1(t,\theta)-x^s_1(t,\theta)) \qquad (3.2) \\ &\overset{\text{def}}{=} \Delta^u(t,\theta)-\Delta^s(t,\theta) \end{aligned}$$

we compute

$$
\begin{aligned}
\dot{\Delta}^u(t,\theta) &= \left(\frac{\partial f_1}{\partial x}(\mathbf{q}_0(t-\theta)) + \frac{\partial f_2}{\partial y}(\mathbf{q}_0(t-\theta))\right)\Delta^u(t,\theta) \\
&\quad + f_1(\mathbf{q}_0(t-\theta))g_2(\mathbf{q}_0(t-\theta,t)) - f_2(\mathbf{q}_0(t-\theta))g_1(\mathbf{q}_0(t-\theta,t)) \\
&\quad + \left[f_1(\mathbf{q}_0(t-\theta))\frac{\partial f_2}{\partial z}(\mathbf{q}_0(t-\theta)) \right. \\
&\qquad \left. - f_2(\mathbf{q}_0(t-\theta))\frac{\partial f_1}{\partial z}(\mathbf{q}_0(t-\theta)) \right] z_1^u(t,\theta).
\end{aligned} \tag{3.3}
$$

Henceforth we suppress the arguments of the f_i, g_i and their partial derivatives. We have assumed the unperturbed vector field to be Hamiltonian, so that $(\partial f_1/\partial x) + (\partial f_2/\partial y) = 0$, and (3.3) becomes

$$
\dot{\Delta}^u(t,\theta) = f_1 g_2 - f_2 g_1 + \left(f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z}\right) z_1^u(t,\theta), \tag{3.4}
$$

where $z_1^u(t,\theta)$ is obtained by solving the z component of the first variational equation:

$$
\dot{z}_1^u(t,\theta) = g_3(\mathbf{q}_0(t-\theta),t), \qquad t \in (-\infty, 0]. \tag{3.5}
$$

Equation (3.4) can be integrated immediately to give

$$
\Delta^u(0,\theta) - \Delta^u(-\infty,0) = \int_{-\infty}^{0} \left[f_1 g_2 - f_2 g_1 + \left(f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z}\right) z_1^u(t,\theta)\right] dt. \tag{3.6}
$$

Similarly, we obtain an expression for $\dot{\Delta}^s(t,\theta)$, which leads to

$$
\Delta^s(\infty,\theta) - \Delta^s(0,\theta) = \int_{0}^{\infty} \left[(f_1 g_2 - f_2 g_1) + \left(f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z}\right) z_1^s(t,\theta)\right] dt. \tag{3.7}
$$

Now $\Delta^s(\infty,\theta)$ and $\Delta^u(-\infty,\theta)$ are both zero since $\mathbf{q}_1^{u,s}(t,\theta)$ is bounded for all time (Proposition 2.3) and the unperturbed vector field goes to zero exponentially fast as $\gamma(z_0)$ is approached. Similarly, the improper integrals converge and we have

$$
\begin{aligned}
M(\theta) &= \int_{-\infty}^{-\infty} (f_1 g_2 - f_2 g_1)\, dt + \int_{-\infty}^{0} \left(f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z}\right) z_1^u(t,\theta)\, dt \\
&\quad + \int_{0}^{\infty} \left(f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z}\right) z_1^s(t,\theta)\, dt.
\end{aligned} \tag{3.8}
$$

Since we assume that the unperturbed vector field is Hamiltonian, the reader can easily verify that

$$
f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z} = \frac{\partial H}{\partial y}\frac{\partial^2 H}{\partial x\,\partial z} + \frac{\partial H}{\partial x}\frac{\partial^2 H}{\partial y\,\partial x} = -\frac{d}{dt}\left(\frac{\partial H}{\partial z}\right) + \frac{\partial^2 H}{\partial z^2}\dot{z}, \tag{3.9}
$$

and that

$$
\left(f_1 \frac{\partial f_2}{\partial z} - f_2 \frac{\partial f_1}{\partial z}\right)(\mathbf{q}_0(t-\theta)) = -\frac{d}{dt}\left(\frac{\partial H}{\partial z}(\mathbf{q}_0(t-\theta))\right), \tag{3.10}
$$

since $z = \text{constant}$ on an unperturbed orbit. Using this fact and integrating by parts once, we find

$$\int_{-\infty}^{0}\left(f_1\frac{\partial f_2}{\partial z}-f_2\frac{\partial f_1}{\partial z}\right)(\mathbf{q}_0(t-\theta),t)z_1^u(t,\theta)\,dt$$

$$(3.11)\qquad =\frac{\partial H}{\partial z}(\mathbf{q}_0(-\infty))z_1^u(-\infty,\theta)-\frac{\partial H}{\partial z}(\mathbf{q}_0(-\theta))z_1^u(0,\theta)$$

$$+\int_{-\infty}^{0}\frac{\partial H}{\partial z}(\mathbf{q}_0(t-\theta))g_3(\mathbf{q}_0(t-\theta),t)\,dt,$$

and similarly

$$\int_{0}^{\infty}\left(f_1\frac{\partial f_2}{\partial z}-f_2\frac{\partial f_1}{\partial z}\right)(\mathbf{q}_0(t-\theta))z_1^s(t,\theta)\,dt$$

$$(3.12)\qquad =\frac{\partial H}{\partial z}(\mathbf{q}_0(-\theta))z_1^s(0,\theta)-\frac{\partial H}{\partial z}(\mathbf{q}_0(\infty))z_1^s(\infty,\theta)$$

$$+\int_{0}^{\infty}\frac{\partial H}{\partial z}(\mathbf{q}_0(t-\theta))g_3(\mathbf{q}_0(t-\theta),t),\,dt.$$

Thus we have

$$(3.13)\qquad \begin{aligned} M(\theta)=&\int_{-\infty}^{+\infty}\left(f_1g_2-f_2g_1+\frac{\partial H}{\partial z}g_3\right)(\mathbf{q}_0(t-\theta),t)\,dt+\frac{\partial H}{\partial z}(\mathbf{q}_0(-\infty))z_1^u(-\infty,\theta)\\ &-\frac{\partial H}{\partial z}(\mathbf{q}_0(\infty))z_1^s(\infty,\theta)+\frac{\partial H}{\partial z}(\mathbf{q}_0(-\theta))(z_1^s(0,\theta)-z_1^u(0,\theta)).\end{aligned}$$

We note that $(\partial H/\partial z)(\mathbf{q}_0(-\infty))=(\partial H/\partial z)(\mathbf{q}_0(\infty))$, since the unperturbed orbit approaches $\gamma(z_0)$ for $t\to\pm\infty$, and that $z_1^u(-\infty,\theta)$ and $z_1^s(\infty,\theta)$ converge to the saddle point on the section Σ^0. See Robinson [1985] or Wiggins [1985] for a discussion of this limit process. It follows that

$$(3.14)\qquad \frac{\partial H}{\partial z}(q(-\infty))z_1^u(-\infty,\theta)-\frac{\partial H}{\partial z}(q(\infty))z_1^s(\infty,\theta)=0,$$

and by our original choice of $q_\varepsilon^s(0,\theta)$ and $q_\varepsilon^u(0,\theta)$ we have $z_1^s(0,\theta)-z_1^u(0,\theta)=0$; thus we arrive at an expression for the Melnikov function:

$$(3.15)\qquad M(\theta)=\int_{-\infty}^{\infty}\left(f_1g_2-f_2g_1+\frac{\partial H}{\partial z}g_3\right)(\mathbf{q}_0(t-\theta),t)\,dt.$$

Finally, using $f_1=\partial H/\partial y$, $f_2=-\partial H/\partial x$, and transforming $t\to t+\theta$, (3.15) can be rewritten in the compact form

$$(3.16)\qquad M(\theta)=\int_{-\infty}^{\infty}(\nabla H\cdot g)(\mathbf{q}_0(t),t+\theta)\,dt.$$

Now on the cross-section Σ^0, the distance between the stable and unstable manifolds of $\gamma(z_0)+\mathcal{O}(\varepsilon)$ is measured by $d(\theta)=\varepsilon(M(\theta)/\|f(\mathbf{q}_0(-\theta))\|)+\mathcal{O}(\varepsilon^2)$, so if $M(\theta)$ has a simple zero at $\hat\theta$ $(M(\hat\theta)=0,\ (dM/d\theta)(\hat\theta)\neq 0)$, then by the implicit function theorem, $d(\theta)$ also has a zero near $\hat\theta$. We have now proved the following.

THEOREM 3.1. *Suppose $M(\theta)$ has at least one simple zero; then for ε sufficiently small, near this point $W^s(\gamma(z_0)+\mathcal{O}(\varepsilon))$ and $W^u(\gamma(z_0)+\mathcal{O}(\varepsilon))$ intersect transversely. On the other hand, if $M(\theta)$ is bounded away from zero for all θ then $W^s(\gamma(z_0)+\mathcal{O}(\varepsilon))\cap W^u(\gamma(z_0)+\mathcal{O}(\varepsilon))=\varnothing$.*

This result is important since it allows us to test for transverse homoclinic points in the Poincaré map of specific differential equations. Thus, by the Smale–Birkhoff homoclinic theorem, we know that some iterate of the Poincaré map, $(P_\varepsilon)^N$, has an invariant hyperbolic set near such a point; i.e., a Smale horseshoe with its attendant chaotic dynamics (Guckenheimer and Holmes [1983, Chapter 5]).

Remark. In the formulation (3.14) $f_1g_2-f_2g_1 \overset{\text{def}}{=} (f\wedge g)_{1,2}$ is the usual planar Melnikov function, while $(\partial H/\partial z)g_3$ is the additional contribution due to the slow variation of z. We note that analogous expressions involving such extra terms occur in multidegree of freedom Hamiltonian examples, of Koiller [1984], Holmes and Marsden [1983] and Holmes [1986]. Also see Robinson [1983] and Gruendler [1985]. We remark that, if g is a time-independent perturbation, then, as formulation (3.16) makes clear, $M=\int_{-\infty}^{\infty}(\nabla H\cdot g)(\mathbf{q}_0(t))\,dt$ is θ-independent and thus simple zeros cannot occur and transversal intersections cannot be found. This is not surprising, since in that case we have an *autonomous* three-dimensional vector field and $\gamma(z_0)+\mathcal{O}(\varepsilon)$ is a fixed point with a one-dimensional unstable manifold and a two-dimensional stable manifold (or vice versa). If such manifolds intersect, they necessarily do so along a solution curve and thus the intersection cannot be transversal (cf. Guckenheimer and Holmes [1983, § 1.8]). However, if g depends upon parameters, then such "autonomous" homoclinic orbits can occur naturally as a parameter varies (see Theorem 4.2 below).

4. Bifurcations. In this section we give two theorems relevant to the case where the slowly varying oscillator depends upon a parameter $\mu\in R$.

THEOREM 4.1. (*Nonautonomous*). *Consider system* (2.1) *depending on a scalar parameter $\mu\in K$, where K is some open interval in R. Suppose there exists a point* (θ_0,μ_0) *such that*

(a) $M(\theta_0,\mu_0)=0,$

(b) $\left.\dfrac{\partial M}{\partial\theta}\right|_{(\theta_0,\mu_0)}=0.$

(c) $\left.\dfrac{\partial^2 M}{\partial\theta^2}\right|_{(\theta_0,\mu_0)}\neq 0,$

(d) $\left.\dfrac{\partial M}{\partial\mu}\right|_{(\theta_0,\mu_0)}\neq 0.$

Then, for $\varepsilon\neq 0$ sufficiently small, near μ_0 there is a bifurcation value $\hat{\mu}$ at which quadratic homoclinic tangencies occur.

As we have noted, if g is time-independent then M is necessarily θ-independent. Hence hypothesis (c) of Theorem 4.1 cannot be satisfied, and Theorem 3.1 cannot be applied. However, in this case we have the following.

THEOREM 4.2. (*Autonomous*). *Consider system* (2.1), *where* $\mathbf{g}(\mathbf{q};\mu)$ *is time independent but depends on a scalar parameter $\mu\in K\subseteq\mathbb{R}$. Suppose there exists a point $\mu_0\in K$ such that*

(a) $M(\mu_0)=0,$

(b) $\left.\dfrac{\partial M}{\partial\mu}\right|_{\mu=\mu_0}\neq 0.$

Then, for $\varepsilon\neq 0$ sufficiently small, near μ_0 there is a bifurcation value μ at which (*nontransverse*) *homoclinic orbits occur.*

Proofs. These two results are proved by straightforward Taylor series expansion of M about the point (θ_0, μ_0) (resp. μ_0) and application of the implicit function theorem. See Guckenheimer and Holmes [1983, § 4.5]. □

We remark that in the autonomous case it does not immediately follow that homoclinic orbits imply horseshoes, although that conclusion does follow for certain types of saddle-point with complex eigenvalues and in some cases with real eigenvalues (Silnikov [1965], [1967], [1970], Devaney [1976], Holmes [1980], Sparrow [1982]).

5. Interaction of periodic and homoclinic orbits. In the preceding paper (Wiggins and Holmes [1987]) we studied the two parameter family of periodic orbits inside Γ which remain bounded away from Γ, i.e., their periods were uniformly bounded above by some constant.

Now we will relate the periodic Melnikov theory to the homoclinic results of the present paper. From Wiggins and Holmes [1987, (2.7) and (3.11)-(3.19)], we have, omitting the arguments $\mathbf{q}_0^{\alpha,z}(t)$

$$\begin{aligned}\mathbf{M}^{m/n}(I, \theta, z) &= \left[\frac{1}{\Omega(1, Z)}\left\{\int_0^{mT} (\nabla H \cdot \mathbf{g})\, dt - \frac{\partial H}{\partial z}\bigg|_I \int_0^{mT} g_3\, dt\right\}, \int_0^{mT} g_3\, dt\right] \\ &\overset{\text{def}}{=} (M_1^{m/n}, M_3^{m/n}).\end{aligned} \tag{5.1}$$

In that paper (5.1) was obtained by a computation involving action angle variables; however, a cartesian (x, y, z) computation analogous to that of § 3 above yields precisely the same expression. To see this, refer to (3.13) of the present paper, use periodicity of $\mathbf{q}_0^{\alpha,z}(t)$, change the limits of integration to $-mT/2 \to mT/2$ and observe that $\Omega(I, z) = \|\mathbf{f}(\mathbf{q}_0^{\alpha,z}(-\theta))\|$. Finally, in dealing with periodic orbits the term $(\partial H/\partial z)(\mathbf{q}_0(-\infty))z_1^u(-\infty, \theta) - (\partial H/\partial z)(\mathbf{q}_0(\infty))z_1^s(\infty, \theta)$ becomes

$$\frac{\partial H}{\partial z}\bigg|_{I=\text{const}}\left(z_1\left(\frac{-mT}{2}, \theta\right) - z_1\left(\frac{mT}{2}, \theta\right)\right)\bigg| = \frac{-\partial H}{\partial z}\bigg|_I \int_{-mT/2}^{mT/2} g_3\, dt,$$

as required, and the other boundary term of (3.13) vanishes.

We now show that the limit of $\mathbf{M}^{m/1}$ exists on the homoclinic manifold and give an interpretation of that limit in terms of the dynamics of the slowly varying oscillators. It is clear that the homoclinic manifold cannot be approached in an arbitrary manner, since not all solutions in the perturbed manifolds can be uniformly approximated by solutions in the unperturbed manifolds for arbitrarily long time intervals: by Propositions 2.3 and 2.4 this can be done only for perturbed solutions with initial z values in $O(\varepsilon)$ neighborhood of a point $z_0 \in J$ such that $(\gamma(z_0) + O(\varepsilon), \phi)$ is a hyperbolic periodic orbit (or fixed point in the autonomous case) on M_ε. However, we have the following result.

PROPOSITION 5.1. *Suppose that there exists a point* $z_0 \in J$ *such that* $(\gamma(z_0) + \mathcal{O}(\varepsilon), \phi)$ *is a hyperbolic periodic orbit on* $\mathcal{M}_\varepsilon$. *Then*

(1) $$\lim_{\substack{m\to\infty \\ z\to z_0}} M_3^{m/1} = \int_{-\infty}^{\infty} g_3(q_0(t), t+\theta)\, dt = 0,$$

(2) $$\lim_{\substack{m\to\infty \\ z\to z_0}} M_1^{m/1} = \frac{1}{\|\mathbf{f}(\mathbf{q}_0(-\theta))\|}\int_{-\infty}^{\infty} (\nabla H \cdot \mathbf{g})(\mathbf{q}_0(t), t+\theta)\, dt = M(\theta),$$

where the integrands are evaluated on the unperturbed homoclinic orbit with $z = z_0$.

Proof. The proof of (1) follows by integrating the z_1 component of the first variational equation and examining the limiting behavior as $t \to \pm\infty$.

The proof of (2) involves a straightforward modification of arguments given in Theorem 4.6.4 of Guckenheimer and Holmes [1983]. □

This proposition shows that the periodic Melnikov functions have a meaning on the homoclinic manifold, although the dynamical interpretations are very different. Inside the homoclinic manifold, a simple zero of $(M_1^{m/1}, M_3^{m/1})$ implies the existence of an isolated periodic orbit of period mT. On the homoclinic manifold, a simple zero of M_3 implies a hyperbolic periodic orbit, $(\gamma(z_0)+\mathcal{O}(\varepsilon), \phi)$, on $\mathcal{M}_\varepsilon$ and a simple zero of M_1 implies a transversal intersection between the stable and unstable manifolds of $(\gamma(z_0)+\mathcal{O}(\varepsilon), \phi)$. However, note that Proposition 5.1 allows us to think of M_1 and M_3 as functions of (α, z, θ) with $\theta \in R$, $z \in J$ and $\alpha \in L(z)=[\alpha(z), \alpha_0(z)]$, where $\alpha_0(z)$ is the value of α which gives an orbit on the homoclinic manifold for that particular z-value.

We end this section by remarking on the case where the system (2.1) is autonomous. In this case the limits of integration for the subharmonic Melnikov vector are $-T(\alpha, z)/2 \rightarrow T(\alpha, z)/2$ where $T(\alpha, z)$ is the period of an unperturbed orbit. In showing that the subharmonic Melnikov vector has a meaning on the homoclinic manifold in this case we take limits as $\alpha \rightarrow \alpha_0$, $z \rightarrow z_0$, where α_0 is the value of α on the homoclinic manifold and z_0 is a z value such that $\gamma(z_0)+\mathcal{O}(\varepsilon)$ is a hyperbolic fixed point on $\mathcal{M}_\varepsilon$.

Now we will show that the hypotheses of the homoclinic bifurcation Theorems 4.1 and 4.2 also imply the existence of nearby families of periodic orbits, which converge to the homoclinic orbits as $\mu \rightarrow \hat{\mu}$.

$M^{m/1}(I, z, \mu)$ and $M^{m/1}(I, \theta, z, \mu)$ denote the autonomous and nonautonomous subharmonic Melnikov vectors respectively (we will drop the superscript $m/1$ for notational convenience), unless $(I(\theta), z)$ belongs to the homoclinic orbit, in which case they denote the homoclinic Melnikov functions of Proposition 5.1. In that case, the requirement of a hyperbolic set in $\mathcal{M}_\varepsilon$ fixes $z=z_0$ (via $\bar{g}_3(\gamma(z_0)=0)$ and $I=I_0$ is fixed by the unperturbed homoclinic orbit on the plane $z=z_0$. Thus, in § 4 we merely wrote $M(\mu)$ for $M_1(I_0, z_0, \mu)$ and $M(\theta, \mu)$ for $M_1(I_0, \theta, z_0, \mu)$.

We remark that we have replaced the parameter α with I, the action. This is convenient since we are interested in periodic orbits limiting on homoclinic orbits and is justifiable by Proposition 5.1 and the fact that I represents the *area* bounded by an orbit on a fixed z plane, and this area is defined even for the homoclinic orbit.

Our two main results are the following.

THEOREM 5.2 (*Autonomous*). *Consider the parametrized Melnikov functions* $\mathbf{M}(I, z, \mu)$ *for a parameter* $\mu \in R$. *Suppose there exists* $z_0=z_0(\mu) \in J$ *such that* $\gamma(z_0(\mu), \mu)+\mathcal{O}(\varepsilon)$ *is a hyperbolic fixed point on* $\mathcal{M}_\varepsilon$ *for each* μ *in an open interval* K *containing a value* μ_0 *and let* $I=I_0$ *be the value of the action corresponding to the homoclinic orbit on the* $z=z_0(\mu)$ *level at which*

(a) $M_1(I_0, z_0, \mu_0)=0,$

(b) $\dfrac{\partial M_1}{\partial \mu}(I_0, z_0, \mu_0) \neq 0,$

(c) $\dfrac{\partial g_1}{\partial x}(\gamma(z_0, \mu_0))+\dfrac{\partial g_2}{\partial y}(\gamma(z_0, \mu_0)) \neq 0,$

(d) $\dfrac{\partial g_3}{\partial z}(\gamma(z_0, \mu_0)) \neq 0.$

Then for $\varepsilon \neq 0$ *sufficiently small the solutions of* (2.1) *contain a family* $\Lambda(\mu)$, *of periodic orbits* $(\mu \in K)$, *which converge on the homoclinic orbit with periods approaching infinity as* $\mu \rightarrow \hat{\mu}=\mu_0+\mathcal{O}(\varepsilon)$, *where* $\hat{\mu}$ *is the homoclinic bifurcation value.*

THEOREM 5.3 (*Nonautonomous*). *Consider the parametrized Melnikov functions* $\mathbf{M}(I, \theta, z, \mu)$ *for a parameter* $\mu \in R$. *Suppose there exists* $z_0 = z_0(\mu) \in J$ *such that* $(\gamma(z_0(\mu), \mu) + \mathcal{O}(\varepsilon), \phi)$ *is a hyperbolic periodic orbit on* $\mathcal{M}_\varepsilon$ *for each* μ *in an open interval* K *containing a value* μ_0, *and let* $I = I_0$ *be the value of the action corresponding to the homoclinic orbit on the* $z = z_0(\mu)$ *level such that at the point* $(I_0, \theta_0, z_0(\mu_0), \mu_0)$ *we have*

$$\text{(a)}\qquad M_1(I_1, \theta_0, z_0(\mu_0), \mu_0) = 0,$$

$$\text{(b)}\qquad \frac{\partial M_1}{\partial \theta}(I_1, \theta_0, z_0(\mu_0), \mu_0) = 0,$$

$$\text{(c)}\qquad \frac{\partial^2 M_1}{\partial \theta^2}(I_1, \theta_0, z_0(\mu_0), \mu_0) \neq 0,$$

$$\text{(d)}\qquad \frac{\partial M_1}{\partial \mu}(I_1, \theta_0, z_0(\mu_0), \mu_0) \neq 0,$$

$$\text{(e)}\qquad \frac{\partial \bar{g}_3}{\partial z}(\gamma(z_0(\mu_0), \mu_0)) \neq 0.$$

Then, for $\varepsilon \neq 0$ *sufficiently small, the homoclinic bifurcation is a countable limit of subharmonic saddle-node bifurcations to higher and higher periods.*

Proofs. The proofs of Theorems 5.2 and 5.3 involve straightforward, though tedious, calculations with the Melnikov functions. The interested reader is referred to Wiggins [1985] for the details. These results generalize the autonomous planar homoclinic bifurcation theorems of Andronov et al. [1971] and the nonautonomous planar Melnikov [1963] methods of Greenspan and Holmes [1983]. We remark that the theorems can also be proved using the more "geometric" arguments of Silnikov [1965], [1967], [1970], in which a local analysis near the hyperbolic set γ is combined with a near identity global return map (cf. Guckenheimer and Holmes [1983, § 6.5]). □

6. An example. In this section we apply the theory developed above to the equation

$$\begin{aligned} \dot{x} &= y, \\ \dot{y} &= x - x^3 - z - \varepsilon\delta y, \qquad (6.1) \\ \dot{z} &= \varepsilon(\gamma x - \alpha z + \beta \cos t), \end{aligned}$$

which models a single degree of freedom nonlinear oscillator subject to weak linear damping and weak feedback control (Holmes and Moon [1983], Holmes [1983], [1985]). If $\beta = 0$, the system is autonomous and, for sufficiently strong damping ($\varepsilon\delta$) and feedback ($\varepsilon\gamma$) the feedback stabilizes the equilibrium position $(0, 0, 0)$, which is a saddle-point for small $\varepsilon\gamma$. In Holmes [1985] local bifurcation results were obtained for a slight variant of this system and in Holmes [1983] an ad hoc perturbation method was used to argue that transverse homoclinic orbits would occur in the nonautonomous ($\beta \neq 0$) case. (The term $\beta \cos t$ represents a desired response characteristic, which is relayed to the system via the feedback loop). This example therefore illustrates both the autonomous and nonautonomous theories developed above.

The unperturbed Hamiltonian corresponding to (6.1) is

$$H(x, y; z) = \frac{y^2}{2} - \frac{x^2}{2} + \frac{x^4}{4} + xz, \qquad (6.2)$$

and straightforward analysis reveals the unperturbed phase space structure sketched in Fig. 4. A hyperbolic manifold $\mathcal{N}$, given by $x=\bar{x}(z)$, $y=0$, where $\bar{x}$ is the intermediate size root of

$$x^3-x+z=0, \tag{6.3}$$

exists for $-2/3\sqrt{3}<z<2/3\sqrt{3}$. For each $z=z_0$ in this range, the Hamiltonian system $H(x, y; z_0)$ restricted to $z=z_0$ has a hyperbolic saddle-point $(\bar{x}(z_0), 0)$ with a "figure 8" double homoclinic loop enclosing two elliptic fixed points (the other two roots of (6.3)). For $|z|>2/3\sqrt{3}$ (6.3) has a single root and H has a single elliptic fixed point.

First we apply Propositions 2.1 and 2.2 to this system, and seek periodic orbits for the perturbed flow in the manifold $\mathcal{M}_\varepsilon=(\mathcal{N}, \phi)+\mathcal{O}(\varepsilon)$. This necessitates computation of

$$\begin{aligned}\overline{g_3(\gamma(z))}&=\frac{1}{2\pi}\int_0^{2\pi}(\gamma\bar{x}(z)-\alpha z+\beta\cos t)\,dt\\&=\gamma\bar{x}(z)-\alpha z.\end{aligned} \tag{6.4}$$

We note that the same result obtains for $\beta=0$ or $\beta\neq 0$. We also check that

$$\frac{\partial(f_1, f_2)}{\partial(x, y)}=3x^2-1 \tag{6.5}$$

is strictly negative on $\mathcal{N}$, since the middle root of (6.3) lies in the range $(-1/\sqrt{3}, 1/\sqrt{3})$ for $-2/3\sqrt{3}<z<2/3\sqrt{3}$.

From (6.4), for a zero of $\bar{g}_3$ we require $z=\gamma\bar{x}(z)/\alpha$, and thus, using (6.3), we must solve

$$x^3+\left(\frac{\gamma}{\alpha}-1\right)x=0, \qquad \Rightarrow x=0 \quad\text{or}\quad x=\pm\sqrt{1-\frac{\gamma}{\alpha}}, \qquad \frac{\gamma}{\alpha}<1. \tag{6.6}$$

Also, note that the derivative

$$\frac{d}{dz}\bar{g}_3=\gamma\bar{x}'-\alpha=\frac{\gamma}{1-3\bar{x}^2}-\alpha, \tag{6.7}$$

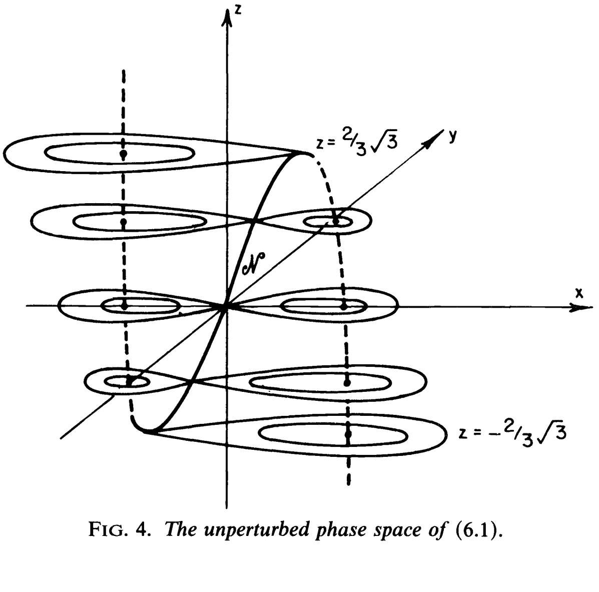

FIG. 4. *The unperturbed phase space of* (6.1).

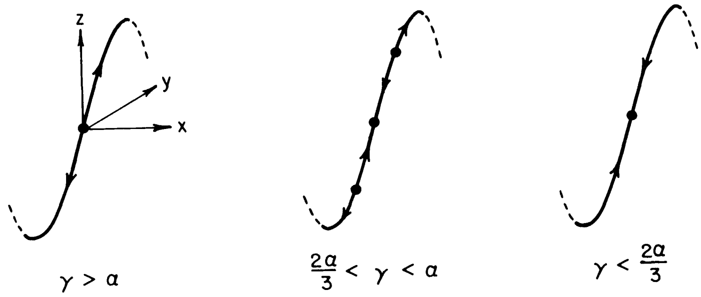
takes the values $\gamma-\alpha$ for $x=0$ and $2\alpha(\alpha-\gamma)/(3\gamma-2\alpha)$ for $x=\pm\sqrt{1-\gamma/\alpha}$. Thus, for simple zeros we require $\gamma\neq\alpha$ at $x=0$ and $2\alpha/3<\gamma<\alpha$ at $x=\pm\sqrt{1-\gamma/\alpha}$. If these conditions are met, then Proposition 2.2 guarantees that the perturbed Poincaré map has hyperbolic fixed points near $(0,0,0)$ and $(\pm\sqrt{1-\gamma/\alpha},\ 0,\ \pm(\gamma/\alpha)\sqrt{1-\gamma/\alpha})$. Examination of the sign of $d\bar{g}_3/dz$ shows that the dynamics on $\mathcal{M}_\varepsilon$ is as sketched in Fig. 5.



z
y
x
$\gamma > \alpha$
$\frac{2\alpha}{3} < \gamma < \alpha$
$\gamma < \frac{2\alpha}{3}$

FIG. 5. *Dynamics on* $\mathcal{M}_\varepsilon$, $\varepsilon\neq 0$.

We next apply the perturbation theory of § 3, computing the Melnikov functions for $z=0$ and $z=\pm(\gamma/\alpha)\sqrt{1-\gamma/\alpha}$. The unperturbed solutions on these z-planes are given by

$$\mathbf{q}_0(t)=(x,y,z)(t)=(\pm\sqrt{2}\operatorname{sech} t,\ \mp\sqrt{2}\operatorname{sech} t\tanh t,\ 0),\tag{6.8}$$

$$\mathbf{q}_0^+(t)=\left(\frac{2cS+ab}{2bS-a},\frac{-2ad^3ST}{(2bS-a)^2},\frac{\gamma}{\alpha}\sqrt{1-\frac{\gamma}{\alpha}}\right)\tag{6.9a}$$

and

$$\mathbf{q}_0^-(t)=\left(\frac{2cS-ab}{2bS+a},\frac{2ad^3ST}{(2bS+a)^2},\frac{\gamma}{\alpha}\sqrt{1-\frac{\gamma}{\alpha}}\right),\tag{6.9b}$$

on the plane $z=\gamma\sqrt{1-\gamma/\alpha}/\alpha$. Here we define

$$\begin{gathered}a=\sqrt{\frac{2\gamma}{\alpha}},\quad b=\sqrt{1-\frac{\gamma}{\alpha}},\quad c=1-\frac{2\gamma}{\alpha},\quad d=\sqrt{\frac{3\gamma}{\alpha}-2},\\ S=\operatorname{sech}(dt)\quad\text{and}\quad T=\tanh(dt).\end{gathered}\tag{6.10}$$

On $z=-\gamma\sqrt{1-\gamma/\alpha}/\alpha$ we have $\bar{\mathbf{q}}_0^+=-\mathbf{q}_0^+$ and $\bar{\mathbf{q}}_0^-=-\mathbf{q}_0^-$. Note that, as $\gamma/\alpha\to 1$, (6.9a, b) → (6.8).

The Melnikov integral is

$$\int_{-\infty}^{\infty}(\nabla H\cdot g)(\mathbf{q}_0(t),t+\theta)\,dt=\int_{-\infty}^{\infty}(-\delta y^2+\gamma x^2-\alpha xz+\beta x\cos(t+\theta))\,dt.\tag{6.11}$$

In the first case this yields

$$\begin{aligned}M&=\int_{-\infty}^{\infty}(-2\delta\operatorname{sech}^2 t\tanh^2 t+2\gamma\operatorname{sech}^2 t\pm\sqrt{2}\beta\operatorname{sech} t\cos(t+\theta))\,dt\\&=-\frac{4\delta}{3}+4\gamma\pm\sqrt{2}\beta\pi\operatorname{sech}\left(\frac{\pi}{2}\right)\cos\theta.\end{aligned}\tag{6.12}$$

In the second case, on the plane $z=(\gamma/\alpha)\sqrt{(1-(\gamma/\alpha))}$, we obtain the expressions

$$\begin{aligned}M=-4\delta\left[\frac{d^4}{3}+b^2d^2+\frac{\gamma bd}{\sqrt{2}\alpha}\left(\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}b\pm\frac{\pi}{2}\right)\right]\\ +2\gamma\left[2d+\sqrt{2}b\left(\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}b\pm\frac{\pi}{2}\right)\right]\mp 2\sqrt{2}\pi\beta\frac{\sinh(1/d\sin^{-1}\sqrt{d\alpha/\gamma})}{\sinh(\pi/d)}\cos\theta,\end{aligned}\tag{6.13}$$

where the upper choice of sign refers to the larger homoclinic loop q_0^+ and the lower choice to the smaller loop, q_0^- (cf. Fig. 5). On $z=-(\gamma/\alpha)\sqrt{1-(\gamma/\alpha)}$, we find

$$\begin{aligned}M=-4\delta\left[\frac{d^4}{3}+b^2d^2+\frac{\gamma bd}{\sqrt{2}\alpha}\left(\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}b\pm\frac{\pi}{2}\right)\right]\\ +2\gamma\Bigl[2d+\sqrt{2}b\Bigl[\Bigl(\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}b\pm\frac{\pi}{2}\Bigr)\Bigr]\pm 2\sqrt{2}\pi\beta\frac{\sinh(1/d\sin^{-1}\sqrt{d\alpha/\gamma})}{\sinh(\pi/d)}\cos\theta.\end{aligned}\tag{6.14}$$

In all four cases the principal value $0\leqq\sin^{-1}(\cdot)\leqq\pi/2$ is to be taken. We note that, when $\gamma/\alpha=1$, so that $b=0$ and $d=1$, both (6.13) and (6.14) reduce to (6.12).

We present the bifurcation results that follow from these computations and Theorem 4.2, for the autonomous case, ($\beta=0$) in Fig. 6(a), where we show the bifurcation sets $M(\delta,\gamma)=0$ for fixed $\alpha=1$ computed from (6.12)-(6.14) using the definitions of a, b, c, d in (6.10). The linear set (6.12) $\delta=3\gamma$ and the two curves from $(6.13)^\pm$ are indicated on the figure. For $\beta=0$ $(6.14)^\pm$ gives curves coincident with those of $(6.13)^\pm$. Note that as $\gamma/\alpha\to 1^-$ (where the three fixed points on M_ε coalesce) all three curves meet, and also that the curves for the homoclinic orbits near $z=\pm(\gamma/\alpha)(1-(\gamma/\alpha))^{1/2}$ go to infinity as $\gamma\to 2/3^+$ (where the two nontrivial fixed points reach the boundary of M_ε). We remark that a branch of the curve labeled $(6.13)^-$ and $(6.14)^-$ has not been shown in Fig. 6(a) since it assumes δ values outside the range of our graph for γ values of physical interest. Figure 7 gives schematic phase portraits corresponding to parameter values labeled in Fig. 6(a).

In the nonautonomous case ($\beta\neq 0$) we see that the effect of the nonautonomous perturbation β cost is to open each of these curves into a band of width $\mathcal{O}(\beta)$ (see Fig. 6(b)). By Theorem 4.1 we conclude that quadratic homoclinic tangencies occur

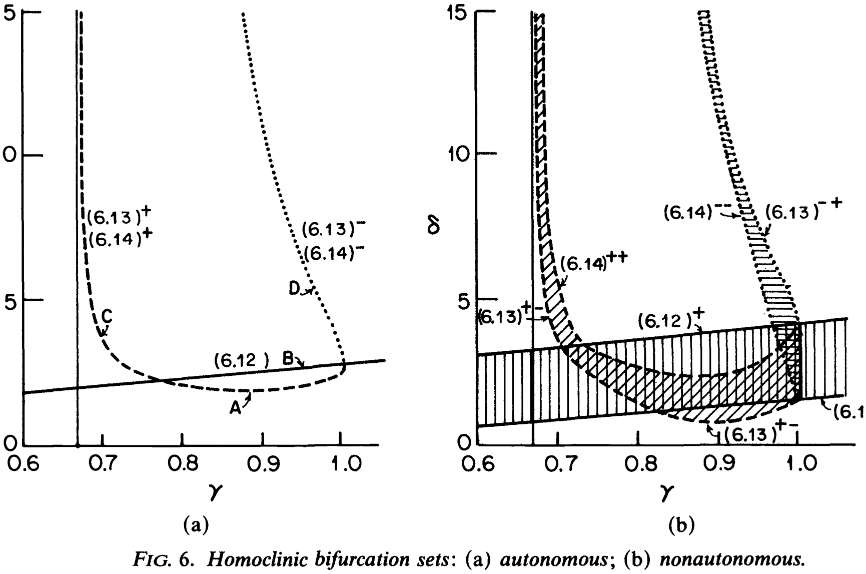


FIG. 6. *Homoclinic bifurcation sets*: (a) *autonomous*; (b) *nonautonomous*.

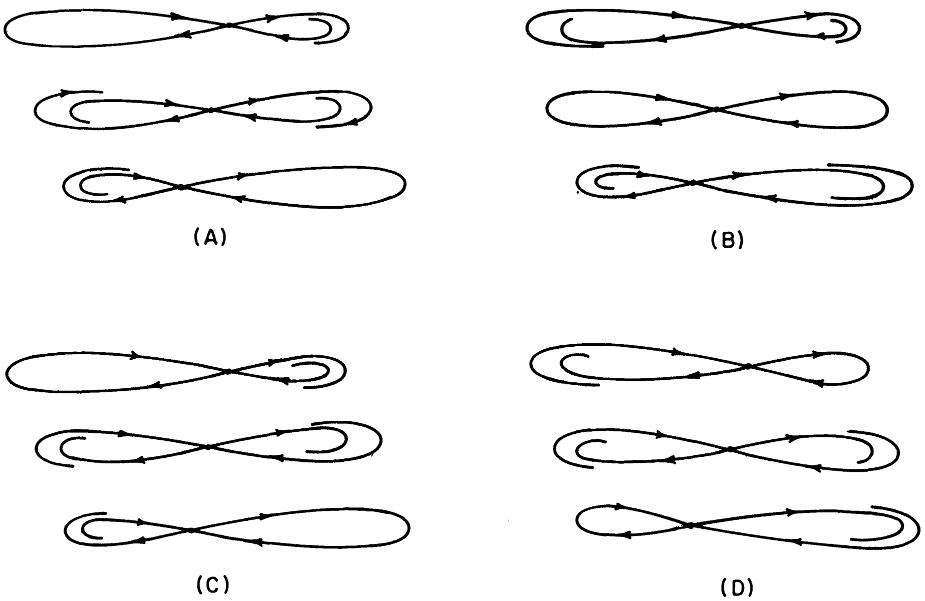

FIG. 7. *Phase portraits at points* A, B, C, D of *Fig.* 6(a).

on the boundaries of these bands with transversal intersections inside. Therefore, from Theorem 5.3 we know that the points on the boundaries of these bands are countable limits of saddle-node bifurcation points of periodic orbits to higher and higher periods. In this case, then, we have deterministic chaos for parameter values in the bands indicated in Fig. 6(b).

We conclude this section by remarking on the situation that occurs when the gain, γ, goes to zero. From (6.1) we see that the z component of the vector field decouples from the x and y components. Thus z can be solved for as an explicit function of time which is asymptotically periodic ($z \sim \varepsilon\beta \sin t + O(\varepsilon^2)$ as $t \to \infty$), and this solution can be substituted into the x and y components, resulting in an equation for a planar forced oscillator. Then one would expect to recover the usual Melnikov function for the equation

$$\dot{x} = y, \qquad \dot{y} = x - x^3 - \varepsilon[\beta \sin t + \delta y] + O(\varepsilon^2)$$

as studied by Greenspan and Holmes [1983], and inspection of (6.12) shows that this is indeed the case. In this respect, we note that the gain γ acts as a destabilizing influence resulting in the effective damping $((4\delta/3) - 4\gamma)$ in (6.12) in comparison with the term $4\delta/3$ in the uncoupled "planar" Duffing equation. Consequently the critical force level for the appearance of transverse homoclinic orbits and chaos is

$$\beta_{\text{crit}} = \frac{((4\delta/3) - 4\gamma)}{\sqrt{2}\pi} \cosh\left(\frac{\pi}{2}\right)$$

rather than

$$\beta_{\text{crit}} = \frac{4\delta}{3\sqrt{2}\pi} \cosh\left(\frac{\pi}{2}\right).$$

These results go some way in explaining the destabilizing effect of gain observed in numerical integrations of this and similar systems by Moon (see Holmes and Moon [1983]).

7. Conclusions. In this and the preceding paper we have developed a global perturbation theory for slowly varying oscillators that collapse to one parameter families of Hamiltonian systems in the limit $\varepsilon = 0$. As such, they typically possess two parameter (α, z) families of periodic orbits and one parameter (z) families of homoclinic orbits to hyperbolic manifolds of equilibria. The perturbation theory we have developed uses these highly degenerate structures to seek isolated periodic and homoclinic orbits for $\varepsilon \neq 0$, small. We have given existence, stability and codimension one bifurcation theorems for periodic orbits in resonance with an external forcing and an existence theorem for transverse homoclinic orbits in the nonautonomous case and homoclinic bifurcation theorems for both cases. The hypotheses of the theorems can be checked explicitly in examples by computations involving integration around the unperturbed closed orbits. We have illustrated such computations with examples of a nonlinear oscillator subject to weak feedback control and external forcing.

In the interests of providing detailed results and specific applications, we have chosen to limit our analyses to three-dimensional systems, but we remark that the methods generalize in a natural way to systems in which x and y are each n-dimensional and z is m-dimensional: i.e., slowly varying perturbations of m-parameter families of n-degree of freedom Hamiltonians (see Wiggins [1986]).

TOPOLOGICAL TRANSVERSALITY: APPLICATIONS TO THIRD ORDER BOUNDARY VALUE PROBLEMS*

DANIEL J. O'REGAN†

Abstract. In this paper we use topological transversality to obtain existence theorems for certain classes of third order boundary value problems. Our analysis is based on the notions of an essential map and on a priori bounds on solutions.

Key words. topological transverality, third order boundary value problems, higher order equations

AMS(MOS) subject classifications. 34B10, 34B15

1. Introduction. In this paper we study the existence of solutions to third order boundary value problems of the form

$$(1.1) \qquad y'''=f(t,y,y',y''), \qquad t\in[0,1], y\in B$$

where $f:[0,1]\times R^3\to R$ is continuous. Here B denotes suitable boundary conditions.

In §2 results of Granas, Guenther and Lee [4], [5] on second order boundary value problems are extended so that existence theorems can be obtained for a certain class of third order boundary value problems. The existence theorems obtained in § 2, however, are rather specialized. In § 3 by placing different types of monotonicity and growth conditions on the nonlinearity f, we obtain new and interesting existence theorems for a wide class of problems.

2. The Bernstein theory of the equation $y'''=f(t,y,y',y'')$. In this section we extend the Bernstein theory and results of Granas, Guenther and Lee [4] to discuss problems of the form (1.1). Fix a point c in $[0,1]$. Let B denote either the boundary conditions

$$\text{(i)} \qquad y(c)=0, \quad y'(0)=0, \quad y'(1)=0,$$

$$\text{(ii)} \qquad y(c)=0, \quad y''(0)=0, \quad y''(1)=0$$

or

$$\text{(iii)} \qquad \begin{aligned} &sy(c)+dy'(c)=0, && s\neq 0,\\ &-\alpha y'(0)+\beta y''(0)=0, && \alpha,\beta>0,\\ &ay'(1)+by''(1)=0, && a,b>0.\end{aligned}$$

Theorem 2.1 of [5] was proved for two point boundary value problems; however, no change in the proof is necessary if we consider multipoint boundary value problems. Hence, specializing Theorem 2.1 of [5] for the case $n=3$ we obtain the following.

THEOREM 2.1. *Let $f:[0,1]\times R^3\to R$ be continuous and $0\leqq\lambda\leqq 1$. Suppose there is a constant K independent of λ such that $\|y\|_3\leqq K$ for each solution $y(t)$ to*

$$(2.1)_\lambda \qquad y'''-y'=\lambda[f(t,y,y',y'')-y'], \qquad t\in[0,1], \quad y\in B.$$

Then the boundary value problem (1.1) *has at least one solution in* $C^3[0,1]$.

Suppose $y(t)$ is a solution to (1.1) and $[y'(t)]^2$ has a maximum at $t_0\in(0,1)$. Then

$$(2.2) \qquad y''(t_0)=0 \quad \text{and} \quad y'(t_0)f(t_0,y(t_0),y'(t_0),0)\leqq 0.$$

* Received by the editors October 20, 1985; accepted for publication (in revised form) April 22, 1986.

† Department of Mathematics and Applied Statistics, University of Idaho, Moscow, Idaho 83843.

THEOREM 2.2. *Suppose there is a constant $M \geqq 0$ such that*

$$pf(t, u, p, 0) > 0 \quad \text{for } |p| > M,$$

and (t, u) in $[0, 1] \times R$.

Then any solution y to (1.1) *satisfies*

$$|y'(t)| \leqq M \quad \text{for } t \in [0, 1].$$

Furthermore, there exists a constant $M_1 \equiv M[1 + |d/s|]$ such that

$$|y(t)| \leqq M_1 \quad \text{for } t \in [0, 1].$$

Proof. Suppose first $|y'|$ achieves a maximum at $t_0 \in (0, 1)$. Assume $|y'(t_0)| > M$. Then $y'(t_0)f(t_0, y(t_0), y'(t_0), 0) > 0$, which contradicts (2.2). Thus $|y'(t_0)| \leqq M_0$.

Now if y satisfies (i) or (iii), an easy argument shows $|y'|$ cannot have a nontrivial maximum at 0 or 1.

Finally, if y is a solution to (ii) and if $|y'|$ assumes its maximum at $t_0 = 0$ or $t_0 = 1$, then $|y'(t_0)| \leqq M$. To see this suppose $|y'(0)|$ is the maximum value of $|y'|$. If we assume $|y'(0)| > M$, then $y'(0)y'''(0) > 0$. Now if $y'(0) > 0$, then $y'''(0) > 0$, so $y''(t) = \int_0^t y'''(z)\, dz$ is strictly increasing near $t = 0$. We then have $y''(t) > y''(0) = 0$ for $t > 0$ and near zero and so $|y'(0)| = y'(0)$ is not the maximum of $|y'|$ on $[0, 1]$, a contradiction. We obtain a similar contradiction if we assume $y'(0) < 0$. Hence $|y'(t)| \leqq M$ for $t \in [0, 1]$. Finally, integration yields the stated bounds on $|y|$ immediately.

We couple the monotonicity condition in Theorem 2.2 with the analogue of the Bernstein growth condition to obtain our basic existence theorem.

THEOREM 2.3. *Let $f: [0, 1] \times R^3 \to R$ be continuous.*

(a) *Suppose there is a constant $M \geqq 0$ such that*

$$pf(t, u, p, 0) > 0 \quad \text{for } |p| > M$$

and $(t, u) \in [0, 1] \times R$.

(b) *Suppose that*

$$|f(t, u, p, q)| \leqq A(t, u, p)q^2 + B(t, u, p)$$

where $A(t, u, p)$, $B(t, u, p) \geqq 0$ are functions bounded on bounded (t, u, p) sets.

Then the boundary value problem (1.1) *has at least one solution in $C^3[0, 1]$.*

Proof. Existence follows immediately from Theorem 2.1 once a priori bounds are established for solutions y to $(2.1)_\lambda$. If $\lambda = 0$, $y \equiv 0$. Otherwise for $0 < \lambda \leqq 1$, $pf(t, u, p, 0) > 0$ for $|p| > M$ implies $\lambda pf(t, u, p, 0) + (1 - \lambda)p^2 > 0$ for $|p| > M$. Thus Theorem 2.2 yields a priori bounds M, M_1 for $|y'|$ and $|y|$ respectively. Finally we obtain a priori bounds on y'' and y'''. Now each of the boundary conditions (i), (ii), or (iii) implies that y'' vanishes at least once on $[0, 1]$. We also have

$$|f(t, u, p, q)| \leqq Aq^2 + B$$

where A and B denote upper bounds of $A(t, u, p)$, $B(t, u, p)$ respectively for $(t, u, p) \in [0, 1] \times [-M_1, M_1] \times [-M, M]$. Now each point $t \in [0, 1]$ for which $y''(t) \neq 0$ belongs to an interval $[\mu, v]$ such that y'' maintains a fixed sign on $[\mu, v]$ and $y''(\mu)$ and/or $y''(v)$ is zero. Assume that $y''(\mu) = 0$ and $y'' \geqq 0$ on $[\mu, v]$. Now with $A_0 = A$, $B_0 = B + M$ the differential equation yields

$$\frac{2A_0 y'' y'''}{A_0(y'')^2 + B_0} \leqq 2A_0 y''.$$

Integrating from μ to t we obtain

$$|y''(t)| \leqq \left[\frac{B_0}{A_0}(e^{4A_0M} - 1)\right]^{1/2} \equiv M_2.$$

The other cases are treated similarly and the same bound is obtained. With these bounds the differential equation yields a priori bounds independent of λ for $|y'''|$.

COROLLARY 2.4. *Let* $f:[0,1]\times R^3\to R$ *be continuous.*

(a) *Suppose there is a constant* $M\geqq 0$ *such that*

$$pf(t,u,p,0)\geqq 0 \quad \text{for } |p|>M$$

and (t,u) *in* $[0,1]\times R$.

(b) *Suppose* (b) *of Theorem* 2.3 *holds.*

Then the boundary value problem (1.1) *has at least one solution in* $C^3[0,1]$.

Proof. Consider

$$y'''=f_n(t,y,y',y''),\qquad t\in[0,1],\quad y\in B \tag{2.3}$$

where $f_n=f+y'/n$, n an integer. Apply Theorem 2.3 to (2.3) to obtain solutions y_n to (2.3) for $n=1,2,\cdots$. Now a simple compactness argument implies that a subsequence of $\{y_n\}$ converges to a solution of $y'''=f(t,y,y',y'')$, $y\in B$ and the proof is complete. □

To conclude this section we examine the inhomogeneous boundary value problems

$$y'''=f(t,y,y',y''),\qquad t\in[0,1],\quad y\in\tilde B \tag{2.4}$$

where $\tilde B$ denotes either the boundary conditions

$$y(c)=r,\quad y'(0)=l,\quad y'(1)=T \tag{iv}$$

or

$$\begin{aligned} &sy(c)+dy'(c)=r, && s\neq 0,\\ &-\alpha y'(0)+\beta y''(0)=l, && \alpha,\beta>0,\\ &ay'(1)+by''(1)=T, && a,b>0. \end{aligned} \tag{v}$$

Here c is a fixed point of $[0,1]$.

THEOREM 2.5. *Let* $f:[0,1]\times R^3\to R$ *be continuous. Suppose* (a) *and* (b) *of Corollary* 2.4 *are also satisfied. Then the boundary value problem* (2.4) *has at least one solution in* $C^3[0,1]$.

Proof. Consider the family of problems

$$y'''=\lambda f(t,y,y',y''),\qquad 0\leqq\lambda\leqq 1,\quad y\in\tilde B. \tag{2.4$_\lambda$}$$

The existence of a solution in $C^3[0,1]$ follows immediately from Theorem 5.1 of [7] once a priori bounds independent of λ are established for solutions y to $(2.4)_\lambda$. We assume at first that $pf(t,u,p,0)>0$ for $|p|>M$ and (t,u) in $[0,1]\times R$. Now if $\lambda=0$ we have a unique solution, and thus $|y'(t)|\leqq L$ for some constant $L<\infty$. Otherwise for $0<\lambda\leqq 1$, it follows immediately from Theorem 2.2 that $|y'|\leqq M_0=\max\{M,|l|,|T|\}$, if y satisfies (iv) and $|y'|\leqq M_1=\max\{M,|l/\alpha|,|T/a|\}$ if y satisfies (v). As an example suppose y satisfies (v) and $|y'(t)|$ assumes its maximum at $t=0$. Then $y'(0)y''(0)\leqq 0$ so

$$0\geqq y'(0)\beta y''(0)=\alpha[y'(0)]^2\left[\frac{l}{\alpha y'(0)}+1\right]$$

and consequently $|y'(0)|\leqq|l/\alpha|$. Hence a priori bounds for $|y'|$ and $|y|$ are immediate. A priori bounds for y'' and y''' follow exactly as in the proof of Theorem 2.3 once we observe that

$$|y''(\mu)|\leqq K,$$

$K\geqq 0$ a fixed constant independent of λ, for some point $\mu\in[0,1]$.

Now assume $pf(t,u,p,0)\geqq 0$ for $|p|>M$ and (t,u) in $[0,1]\times R$. The existence of a solution in this case follows by an argument similar to Corollary 2.4.

Example 1. (Sandwich beam). Beams formed by a few lamina of different materials are known as sandwich beams. In the analysis of such beams Krajcinovic [9] found that the distribution of shear deformation ψ is governed by the differential equation

$$\psi''' - k^2(x, \psi)\psi' + a(x, \psi) = 0.$$

Here $k^2 \neq 0$. For further information on k^2 and a see Krajcinovic [9].

For the case of free ends, the condition of zero shear bimoment at both ends leads to the boundary condition $\psi'(0) = \psi'(1) = 0$. Also symmetry considerations yields $\psi(1/2) = 0$. Thus we are interested in solving the boundary value problem

$$\text{(2.5)} \qquad \begin{aligned} &\psi''' = k^2(x, \psi)\psi' - a(x, \psi), \qquad x \in [0, 1], \\ &\psi'(0) = \psi'(1) = \psi(1/2) = 0. \end{aligned}$$

Now we make the following assumptions on k and a.

Suppose $k^2(x, \omega)$ and $a(x, \psi)$ are continuous functions on $[0, 1] \times R$. In addition, suppose there exists a constant $L < \infty$ such that

$$\left| \frac{a(x, \psi)}{k^2(x, \psi)} \right| \leqq L \quad \text{for } (x, \psi) \in [0, 1] \times R.$$

Then $\psi' f(x, \psi, \psi', 0) = \psi'(k^2\psi' - a) > 0$ for $|\psi'| > L$ and $(x, \psi) \in [0, 1] \times R$, and so Theorem 2.3 implies that (2.5) has at least one solution in $C^3[0, 1]$.

3. Another approach to third order boundary value problems. In this section we place essentially different types of monotonicity and growth conditions on the nonlinearity f to obtain existence theorems for a wide class of third order problems. We consider problems of the form

$$\text{(3.1)} \qquad y''' = f(t, y, y', y''), \qquad t \in [0, 1], y \in B_0$$

where $f: [0, 1] \times R^3 \to R$ is continuous. Here B_0 denotes either the boundary conditions

$$\text{(vi)} \qquad y(0) = 0, \quad y(1) = 0, \quad y'(0) = 0,$$

$$\text{(vii)} \qquad y(0) = 0, \quad y'(0) = 0, \quad y'(1) = 0,$$

or

$$\text{(viii)} \qquad \begin{aligned} &-\alpha y(0) + \beta y'(0) = 0, \quad \alpha, \beta > 0, \\ &ay(1) + by'(1) = 0, \quad a, b > 0, \\ &y''(0) = 0. \end{aligned}$$

Remark. It should be noted here that many of the boundary conditions in § 2 will also be considered in this section. The behaviour of the nonlinearity f will determine which existence theorem to use.

The following theorem, although not the main result in this section, is a powerful existence theorem in its own right.

THEOREM 3.1. *Let* $f: [0, 1] \times R^3 \to R$ *be continuous and* $0 \leqq \lambda \leqq 1$. *Suppose*

$$|f(t, u, p, q)| \leqq [A(t, u)|p| + B(t, u)][C(t, u)|q| + D(t, u)]$$

where $A(t, u)$, $B(t, u)$, $C(t, u)$, $D(t, u) \geqq 0$ are functions bounded on bounded (t, u) sets. Finally, we assume that there is a constant M such that

$$|y(t)| \leqq M, \qquad t \in [0, 1]$$

for each solution $y(t)$ to

$$(3.1)_\lambda \qquad y''' = \lambda f(t, y, y', y''), \qquad t \in [0, 1], \quad y \in B_0.$$

Then the boundary value problem (3.1) *has at least one solution in* $C^3[0, 1]$.

Proof. To prove existence of a solution in $C^3[0, 1]$ we apply Theorem 2.1 of [5]. To establish a priori bounds for $(3.1)_\lambda$, let $y(t)$ be a solution to $(3.1)_\lambda$. All that remains is to obtain a priori bounds for y', y'' and y'''. We first observe that boundary conditions (vi), (vii) or (viii) imply that y'' vanishes at least once on $[0, 1]$. We also have

$$|f(t, u, p, q)| \leqq [A|p| + B][C|q| + D]$$

where A, B, C and D denote upper bounds of $A(t, u)$, $B(t, u)$, $C(t, u)$, $D(t, u)$ respectively for $(t, u) \in [0, 1] \times [-M, M]$, and so

$$|\lambda f(t, y, y', y'')| \leqq (A|y'| + B)(C|y''| + D).$$

Now each point $t \in [0, 1]$ for which $y''(t) \neq 0$ belongs to an interval $[\mu, v]$ such that y'' maintains a fixed sign on $[\mu, v]$ and $y''(\mu)$ and/or $y''(v)$ is zero. Assume $y''(\mu) = 0$ and $y'' \geqq 0$ on $[\mu, v]$. Then the differential equation yields

$$(3.2) \qquad \frac{y'''}{Cy'' + D} \leqq A|y'| + B.$$

Also since $y'' \geqq 0$ on $[\mu, v]$ we have y' increasing on $[\mu, v]$, so in particular $y'(s) \geqq y'(\mu)$ for $s \in [\mu, v]$. At this stage of the proof the argument breaks up into two cases, $y'(\mu) \geqq 0$ and $y'(\mu) < 0$. Assume at first $y'(\mu) \geqq 0$, and so $y'(s) \geqq 0$ for $s \in [\mu, v]$. It follows from (3.2) that

$$\frac{Cy'''}{Cy'' + D} \leqq ACy' + BC,$$

and so integrating from μ to t we obtain

$$|y''(t)| \leqq \frac{D}{C}[\exp(2ACM + BC) - 1] \equiv M_0.$$

On the other hand assume $y'(\mu) < 0$. Again the argument breaks up into two subcases, $y'(s) \leqq 0$ for $s \in [\mu, t]$ or there exists $\zeta \in (\mu, t)$ such that $y'(\zeta) = 0$ and $y'(s) > 0$ for $s \in (\zeta, v]$. Suppose at first $y'(s) \leqq 0$ for $s \in [\mu, t]$; then (3.2) implies

$$\frac{Cy'''}{Cy'' + D} \leqq -ACy' + BC,$$

and so integrating from μ to t yields

$$|y''(t)| \leqq M_0,$$

as before. Finally suppose there exists $\zeta \in (\mu, t)$ such that $y'(\zeta) = 0$ and $y'(s) > 0$ for $s \in (\zeta, v]$; then for $\eta \in [\mu, \zeta]$, (3.2) implies

$$\frac{Cy'''}{Cy'' + D} \leqq -ACy' + BC,$$

which yields $|y''(\zeta)| \leqq M_0$. So for $s \in [\zeta, v]$, (3.2) again implies

$$\frac{Cy'''}{Cy''+D} \leqq ACy' + BC,$$

and thus

$$|y''(t)| \leqq \frac{[CM_0 + D] \exp(2ACM + BC) - D}{C} \equiv M_1.$$

Thus $|y''(t)| \leqq M_1$. The other cases are treated similarly and the same bound $M_1 = \max\{M_0, M_1\}$ is obtained. Thus $|y''| \leqq M_1$ for each solution y to $(3.1)_\lambda$. Now if y satisfies (vi) then

$$|y'(t)| = \left| \int_0^t y''(z)\, dz \right| \leqq M_1,$$

while if y satisfies (vii)

$$|y'(t)| = \left| \int_t^1 y''(z)\, dz \right| \leqq M_1.$$

Finally if y satisfies (viii)

$$|y'(t)| \leqq \left| \int_0^t y''(z)\, dz \right| + |y'(0)| \leqq M_1 + \frac{\alpha M}{\beta} \equiv M_2.$$

Thus $|y'| \leqq M_2$ for each solution y to $(3.1)_\lambda$. With these bounds the differential equation yields a priori bounds independent of λ for $|y'''|$ i.e. $|y'''| \leqq \max\{|f(t, u, p, q)|\} \equiv M_3$ where the maximum is computed over $[0, 1] \times [-M, M] \times [-M_2, M_2] \times [-M_1, M_1]$. Thus $|y|_3 \leqq K = \max\{M, M_1, M_2, M_3\}$ and the existence of a solution to (3.1) is established.

For notational purposes, let $(3.1)_{(\mathrm{vi})}$ denote the boundary value problem $y''' = f(t, y, y', y'')$, $t \in [0, 1]$, with y satisfying (vi). Similarly, define $(3.1)_{(\mathrm{vii})}$ and $(3.1)_{(\mathrm{viii})}$. Next sufficient conditions on f are given which imply a priori bounds on any solution $y(t)$ to $(3.1)_{(\mathrm{vi})}$, $(3.1)_{(\mathrm{vii})}$ or $(3.1)_{(\mathrm{viii})}$. Suppose $y(t)$ is a solution to (3.1) and $[y(t)]^2$ has a maximum at $t_0 \in (0, 1)$. Then $y'(t_0) = 0$ and $y(t_0)y''(t_0) \leqq 0$.

THEOREM 3.2. *Suppose there is a constant $M \geqq 0$ such that*

$$\int_0^t u'(z)[f(z, u(z), u'(z), u''(z)) + L(u'(z))^n u''(z)]\, dz > 0$$

for $|u(t)| > M$, where L and $n > -2$ are constants, with $u \in C^2[0, 1]$ and $u'(0) = 0$.

Then any solution y to $(3.1)_{(\mathrm{vi})}$ or $(3.1)_{(\mathrm{vii})}$ satisfies

$$|y(t)| \leqq M \quad \textit{for } t \in [0, 1].$$

Proof. Suppose $|y|$ achieves a positive maximum at $t_0 \in (0, 1)$, then $y'(t_0) = 0$. Assume $|y(t_0)| > M$, and so

$$\int_0^{t_0} [y'(z)y'''(z) + L(y'(z))^{n+1} y''(z)]\, dz > 0.$$

Integration by parts together with $y'(t_0) = 0$ yields

$$-\int_0^{t_0} (y''(z))^2\, dz > 0,$$

a contradiction. Thus, $|y(t_0)| \leqq M$.

At this stage we divide the proof into two cases. Suppose first y is a solution to $(3.1)_{(\mathrm{vi})}$. If $|y|$ assumes its maximum value at either $t=0$ or $t=1$ then trivially $|y(t)| \leqq M$ for $t \in [0,1]$. So the conclusion of the theorem follows for $(3.1)_{(\mathrm{vi})}$. Now suppose y is a solution to $(3.1)_{(\mathrm{vii})}$. If y assumes its maximum value at $t=0$ then trivially $|y(t)| \leqq M$ for $t \in [0,1]$. On the other hand, suppose $|y|$ achieves its maximum value at $t=1$. Suppose $|y(1)|>M$; if so,

$$\int_0^1 [y'(z)y'''(z)+L(y'(z))^{n+1}y''(z)]\,dz>0,$$

which yields

$$-\int_0^1 [y''(z)]^2\,dz>0,$$

a contradiction. Thus $|y(1)| \leqq M$ and the conclusion of the theorem follows for $(3.1)_{(\mathrm{vii})}$.

Remark. M is independent of L in Theorem 3.2.

An analogous theorem holds for $(3.1)_{(\mathrm{viii})}$.

THEOREM 3.3. *Suppose there is a constant $M \geqq 0$ such that*

$$\int_0^t u'(z)[f(z,u(z),u'(z),u''(z))+L(u'(z))^n u''(z)]\,dz>0$$

for $|u(t)|>M$, where n is an even integer greater than or equal to zero and $L \geqq 0$ is a constant, with $u \in C^2[0,1]$ and $u''(0)=0$.

Then any solution y to $(3.1)_{(\mathrm{viii})}$ satisfies

$$|y(t)| \leqq M \quad \text{for } t \in [0,1].$$

Proof. Suppose $|y|$ achieves a positive maximum at $t_0 \in (0,1)$ and assume $|y(t_0)|>M$. Then $y'(t_0)=0$ and

$$\int_0^{t_0} [y'(z)y'''(z)+L(y'(z))^{n+1}y''(z)]\,dz>0$$

yield

$$-\int_0^{t_0} [y''(z)]^2\,dz - L\frac{(y'(0))^{n+2}}{n+2}>0,$$

a contradiction. Thus $|y(t_0)| \leqq M$.

On the other hand $|y|$ cannot have a nontrivial maximum at 0 or 1. For suppose the maximum of $|y|$ occurs at 0. Then $y(0)y'(0) \leqq 0$. However, from (viii), $y(0)y'(0)=(\beta/\alpha)[y(0)]^2>0$, a contradiction. A similar argument works for the case $t=1$. Thus

$$|y(t)| \leqq M \quad \text{for } t \in [0,1].$$

We are now in a position to prove our main existence theorems for this section.

THEOREM 3.4. *Let $f:[0,1]\times R^3 \to R$ be continuous.*

(a) *Suppose there is a constant $M \geqq 0$ such that*

$$\int_0^t u'(z)[f(z,u(z),u'(z),u''(z))+L(u'(z))^n u''(z)]\,dz>0$$

for $|u(t)|>M$, where L and $n>-2$ are constants, with $u \in C^2[0,1]$ and $u'(0)=0$.

(b) *Suppose*

$$|f(t,u,p,q)| \leqq [A(t,u)|p|+B(t,u)][C(t,u)|q|+D(t,u)]$$

where $A(t,u)$, $B(t,u)$, $C(t,u)$, $D(t,u) \geqq 0$ are functions bounded on bounded (t,u) sets.

Then the boundary value problem $(3.1)_{(\mathrm{vi})}$ *and* $(3.1)_{(\mathrm{vii})}$ *have at least one solution in* $C^3[0,1]$.

Proof. To prove existence of a solution in $C^3[0,1]$ we apply Theorem 3.1. We need to establish a priori bounds for any solution $y(t)$ to $(3.1)_\lambda$. Now if $\lambda=0$ we have the unique solution $y\equiv 0$. Otherwise for $0<\lambda\leqq 1$

$$\int_0^t u'(z)[f(z,u(z),u'(z),u''(z))+L(u'(z))^n u''(z)]\,dz>0,$$

for $|u(t)|>M$ implies

$$\int_0^t u'(z)[\lambda f(z,u(z),u'(z),u''(z))+\lambda L(u'(z))^n u''(z)]\,dz>0$$

for $|u(t)|>M$. So Theorem 3.2 together with its remark implies $|y|\leqq M$ for any solution y to $(3.1)_\lambda$. Hence the existence of a solution to $(3.1)_{(\mathrm{vi})}$ and $(3.1)_{(\mathrm{vii})}$ is established.

COROLLARY 3.5. *Let* $f:[0,1]\times R^3\to R$ *be continuous.*

(a) *Suppose there is a constant* $M\geqq 0$ *such that*

$$\int_0^t u'(z)[f(z,u(z),u'(z),u''(z))+L[u'(z)]^n u''(z)]\,dz\geqq 0$$

for $|u(t)|>M$, *where L and* $n>-2$ *are constants, with* $u\in C^2[0,1]$ *and* $u'(0)=0$.

(b) *Suppose*

$$|f(t,u,p,q)|\leqq[A(t,u)|p|+B(t,u)][C(t,u)|q|+D(t,u)]$$

where $A(t,u)$, $B(t,u)$, $C(t,u)$, $D(t,u)\geqq 0$ *are functions bounded on bounded* (t,u) *sets.*

Then the boundary value problem $(3.1)_{(\mathrm{vi})}$ *and* $(3.1)_{(\mathrm{vii})}$ *have at least one solution in* $C^3[0,1]$.

Proof. Let us consider

$$(3.3)\qquad \begin{gathered} y'''=f_n(t,y,y',y''),\\ y\in(\mathrm{vi})\text{ or }(\mathrm{vii})\end{gathered}$$

where $f_n(t,y,y',y'')=f(t,y,y',y'')+(y/n)$ for $n=1,2,\cdots$. Clearly

$$\begin{aligned}&\int_0^t y'(z)[f_n(z,y(z),y'(z),y''(z))+L(y'(z))^n y''(z)]\,dz\\ &=\int_0^t y'(z)[f(z,y(z),y'(z),y''(z))+L(y'(z))^n y''(z)]\,dz+\frac{1}{n}\frac{y^2(t)}{2}\\ &>0\end{aligned}$$

for $|y(t)|>M$ since $y(0)=0$.

Thus Theorem 3.2 implies $|y_n|\leqq M$ for any solution y_n to (3.3) and $n=1,2,\cdots$. Also

$$|f_n(t,y,y',y'')|\leqq[A(t,y)|y'|+B(t,y)][C(t,y)|y''|+D(t,y)]+M.$$

Now we can apply Theorem 3.4 to (3.3): If y_n is a solution to (3.3) for $n=1,2,\cdots$ we have $|y_n|_3\leqq K$ for some constant K independent of n. By the Arzela-Ascoli Theorem there is a subset N of the natural numbers and a function $y\in C^2[0,1]$ so that $|y_n-y|_2\to 0$ as $n\to\infty$ in N. If $G(t,z)$ is the Green's function for (L,B_0) where $Ly=y'''$ and B_0 denotes the boundary conditions (vi) or (vii) then

$$y_n(t)=\int_0^1 G(t,z)f_n(z,y_n(z),y_n'(z),y_n''(z))\,dz.$$

Let $n \to \infty$ through N to obtain

$$y(t) = \int_0^1 G(t, z) f(z, y(z), y'(z), y''(z))\, dz.$$

Thus $y \in C^3_{B_0}$ and y satisfies $y''' = f(t, y, y', y'')$.

We can obtain a similar result to Theorem 3.4 for $(3.1)_{(\mathrm{viii})}$.

THEOREM 3.6. *Let $f: [0, 1] \times R^3 \to R$ be continuous.*

(a) *Suppose there is a constant $M \geqq 0$ such that*

$$\int_0^t u'(z)[f(z, u(z), u'(z), u''(z)) + L(u'(z))^n u''(z)]\, dz > 0$$

for $|u(t)| > M$, where n is an even integer greater than or equal to zero and $L \geqq 0$ is a constant, with $u \in C^2[0, 1]$ and $u''(0) = 0$.

(b) *Suppose*

$$|f(t, u, p, q)| \leqq [A(t, u)|p| + B(t, u)][C(t, u)|q| + D(t, u)]$$

where $A(t, u)$, $B(t, u)$, $C(t, u)$, $D(t, u) \geqq 0$ are functions bounded on bounded (t, u) sets.

Then the boundary value problem $(3.1)_{(\mathrm{viii})}$ has at least one solution in $C^3[0, 1]$.

Remark. We can obtain similar results to those in Theorems 3.4 and 3.6 if the boundary conditions (vi), (vii) or (viii) are replaced by any of the following:

$$\begin{array}{ll}
(\mathrm{ix}) & y(0) = 0, \quad y(1) = 0, \quad y''(0) = 0, \\
(\mathrm{x}) & y(0) = 0, \quad y'(1) = 0, \quad y''(0) = 0, \\
(\mathrm{xi}) & y(1) = 0, \quad y'(0) = 0, \quad y'(0) = 0, \\
(\mathrm{xii}) & y(0) = 0, \quad y(1) = 0, \quad y'(1) = 0, \\
(\mathrm{xiii}) & y(0) = 0, \quad y(1) = 0, \quad y''(1) = 0, \\
(\mathrm{xiv}) & y(1) = 0, \quad y'(0) = 0, \quad y''(1) = 0,
\end{array}$$

or

$$\begin{array}{lll}
(\mathrm{xv}) & -\alpha y(0) + \beta y'(0) = 0, & \alpha, \beta > 0, \\
 & ay(1) + by'(1) = 0, & a, b > 0, \\
 & y''(1) = 0. &
\end{array}$$

An example of this is the following theorem.

THEOREM 3.7. *Let $f: [0, 1] \times R^3 \to R$ be continuous.*

(a) *Suppose there is a constant $M \geqq 0$ such that*

$$\int_t^1 u'(z)[f(z, u(z), u'(z), u''(z)) + L(u'(z))^n u''(z)]\, dz > 0$$

for $|u(t)| > M$, where n is an even integer greater than or equal to zero and $L \leqq 0$ is a constant, with $u \in C^2[0, 1]$ and $u''(1) = 0$.

(b) *Suppose*

$$|f(t, u, p, q)| \leqq [A(t, u)|p| + B(t, u)][C(t, u)|q| + D(t, u)]$$

where $A(t, u)$, $B(t, u)$, $C(t, u)$, $D(t, u) \geqq 0$ are functions bounded on bounded (t, u) sets.

Then the boundary value problem

$$y''' = f(t, y, y', y''), \qquad t \in [0, 1], \quad y \in (xv)$$

has at least one solution in $C^3[0, 1]$.

The following example illustrates the ideas and results of this section.

Example 2. Consider the boundary value problem

$$\text{(BVP)}\quad \begin{aligned} &y'''(t)=A_0+B_0[y(t)]^p+C_0[y(t)]^m y'(t)+D_0y''(t)+E_0y'(t)y''(t), \qquad t\in[0,1],\\ &y(0)=y(1)=y'(0)=0 \end{aligned}$$

where A_0, $B_0>0$, $C_0\geqq 0$, D_0, E_0 are constants with $m\geqq 0$ even and $p>0$ odd.

We will now show that (BVP) has a solution in $C^3[0,1]$ via Theorem 3.4. Now if $f(t,y,y',y'')=A_0+B_0y^p+C_0y^my'+D_0y''+E_0y'y''$ and $L=-E_0$, $n=1$, $\tilde{L}=-D_0$, $\tilde{n}=0$ we have

$$\begin{aligned} &\int_0^t y'(z)[f(z,y(z),y',y'')+L(y'(z))^n y''(z)+\tilde{L}(y'(z))^{\tilde{n}}y''(z)]\,dz\\ &\qquad=\int_0^t (A_0y'(z)+B_0[y(z)]^p y'(z)+C_0[y(z)]^m[y'(z)]^2)\,dz\\ &\qquad\geqq\int_0^t [A_0y'(z)+B_0(y(z))^p y'(z)]\,dz\\ &\qquad=y(t)\left(A_0+\frac{B_0}{p+1}[y(t)]^p\right)\quad \text{since } y(0)=0\\ &\qquad>0\quad \text{for } |y(t)|>\left[\left|\frac{-(p+1)A_0}{B_0}\right|\right]^{1/p}. \end{aligned}$$

Finally it is clear that we can find constants A, B, C, D such that

$$|f(t,y,y',y'')|\leqq(A|y'|+B)(C|y''|+D)$$

for (t,y) in a bounded set.

Hence all conditions in Theorem 3.4 are satisfied, so (BVP) has at least one solution in $C^3[0,1]$. □

To conclude this section we examine the inhomogeneous boundary value problem

$$\text{(3.4)}\quad \begin{aligned} &y'''=f(t,y,y',y''), \qquad t\in[0,1],\\ &y(0)=r,\quad y(1)=s,\quad y'(0)=l, \end{aligned}$$

or

$$\text{(3.5)}\quad \begin{aligned} &y'''=f(t,y,y',y''), \qquad t\in[0,1],\\ &y(0)=r,\quad y(1)=s,\quad y''(0)=l, \end{aligned}$$

and establish the existence of a solution to (3.4), (3.5) in $C^3[0,1]$ under essentially the same hypothesis on f used in Theorem 3.4.

THEOREM 3.8. *Let $f:[0,1]\times R^3\to R$ be continuous.*

(a) *Suppose there is a constant $M\geqq 0$ such that*

$$\int_0^t u'(z)[f(z,u(z)+lz,u'(z)+l,u''(z))+L(u'(z))^n u''(z)]\,dz>0$$

for $|u(t)|>M$, where L and $n>-2$ are constants with $u\in C^2[0,1]$ and $u'(0)=0$.

(b) *Suppose*

$$|f(t,u,p,q)|\leqq[A(t,u)|p|+B(t,u)][C(t,u)|q|+D(t,u)]$$

where $A(t,u)$, $B(t,u)$, $C(t,u)$, $D(t,u)\geqq 0$ are functions bounded on bounded (t,u) sets.

Then the boundary value problem (3.4) *has at least one solution in* $C^3[0, 1]$.

Proof. Consider the family of problems

$$(3.4)_\lambda \qquad \begin{aligned} &y''' = \lambda f(t, y, y', y''), \qquad 0 \leqq \lambda \leqq 1, \\ &y(0) = r, \quad y(1) = s, \quad y'(0) = l. \end{aligned}$$

The existence of a solution in $C^3[0, 1]$ follows immediately from Theorem 5.1 of [7] once a priori bounds independent of λ are established for solutions y to $(3.4)_\lambda$. To establish a priori bounds for $(3.4)_\lambda$, let $y(t)$ be a solution to $(3.4)_\lambda$. Now if $\lambda = 0$ we have a unique solution and thus $|y(t)| \leqq M_0$, for some constant M_0. Otherwise for $0 < \lambda \leqq 1$, let $w = y - lt$, so $w(0) = r$, $w(1) = s - l$ and $w'(0) = 0$. Now

$$\int_0^t w'(z)[f(z, w(z) + lz, w'(z) + l, w''(z)) + L(w'(z))^n w''(z)]\, dz > 0$$

for $|w(t)| > M$ implies

$$\int_0^t w'(z)[\lambda f(z, w(z) + lz, w'(z) + l, w''(z)) + \lambda L(w'(z))^n w''(z)]\, dz > 0$$

for $|w(t)| > M$. It follows from Theorem 3.2 and its remark that

$$|w(t)| \leqq \max\{M, |r|, |s - l|\} = \tilde{K} \quad \text{for } t \in [0, 1].$$

Thus $|y(t)| \leqq M_1 \equiv \max\{\tilde{K} + |l|, M_0\}$ for any solution y to $(3.4)_\lambda$, $0 \leqq \lambda \leqq 1$. A priori bounds independent of λ for y', y'', y''' will follow from a slight modification of the proof in Theorem 3.1 once we observe that $|y''(\mu)| \leqq K$, $K \geqq 0$ a fixed constant independent of λ, for some $\mu \in [0, 1]$. We accomplish this by letting $v(t) = y(t) - (1 - t^2)r - t^2 s + lt^2$ and noticing that $v(0) = 0$, $v(1) = l$, $v'(0) = l$. Hence by the Mean Value Theorem there exists $\mu \in (0, 1)$ such that $v''(\mu) = 0$, i.e. $y''(\mu) = 2s - 2l - 2r$. The existence of a solution to (3.4) follows from Theorem 5.1 of [7].

We can obtain a corresponding existence theorem for (3.5).

THEOREM 3.9. *Let* $f: [0, 1] \times R^3 \to R$ *be continuous.*

(a) *Suppose there is a constant* $M \geqq 0$ *such that*

$$\int_0^t u'(z)[f(z, u(z) + \frac{lz^2}{z}, u'(z) + lz, u''(z) + l)) + L(u'(z))^n u''(z)]\, dz > 0$$

for $|u(t)| > M$, *where n is an even integer greater than or equal to zero and* $L \geqq 0$ *is a constant, with* $u \in C^2[0, 1]$ *and* $u''(0) = 0$.

(b) *Suppose*

$$|f(t, u, p, q)| \leqq [A(t, u)|p| + B(t, u)][C(t, u)|q| + D(t, u)]$$

where $A(t, u)$, $B(t, u)$, $C(t, u)$, $D(t, u) \geqq 0$ *are functions bounded on bounded* (t, u) *sets.*

Then the boundary value problem (3.5) *has at least one solution in* $C^3[0, 1]$.

STRICTLY COOPERATIVE SYSTEMS WITH A FIRST INTEGRAL*

JANUSZ MIERCZYŃSKI†

Abstract. We consider systems of differential equations $dx_i/dt = F_i(x_1, \cdots, x_n)$ in the nonnegative orthant in the n-space satisfying the following hypotheses: i) $F(0) = 0$; ii) if $x_i < y_i$ and $x_j = y_j$ for $j \neq i$ then $F_k(x) < F_k(y)$ for $k \neq i$; iii) F possesses a first integral with positive gradient. We prove that every solution to such a system either converges to an equilibrium or eventually leaves any compact set.

Key words. equilibrium, first integral, Lyapunov function, ω-limit set, nonnegative orthant, order preserving, strictly cooperative system

AMS(MOS) subject classification. Primary 34C05

1. Introduction. The purpose of the present paper is to study the limiting behavior of solutions of systems of ordinary differential equations possessing a first integral, where the right sides of equations as well as the first integrals are subject to some monotonicity conditions. We prove that any solution to such a system either converges to an equilibrium or eventually leaves any compact set.

Particular classes of systems of differential equations $\dot{x} = F(x)$, $x \in U \subset \mathbb{R}^n$, satisfying conditions $\partial F_i/\partial x_j \geqq 0$ for $i \neq j$, were studied by many authors (see references in [1]; see also [3, Chap. III]). Recently, in [1] and [2], M. W. Hirsch initiated investigation of systems of that type (which he calls cooperative systems), using ideas taken from the dynamical systems theory. Such systems may describe, for instance, competition between biological species or chemical reactions. In cooperative systems it is natural to expect convergence of bounded solutions to an equilibrium or to a closed orbit. A decisive step toward answering this conjecture was made by M. W. Hirsch, who in [2] proved that, for systems that are cooperative and irreducible (that is, the matrices $[(\partial F_i/\partial x_j)(p)]$ are irreducible), almost all (with respect to the Lebesgue measure) points whose forward orbits are bounded approach the equilibrium set. In [11] J. Smillie has found a class of cooperative irreducible systems for which the following holds: every solution either converges to an equilibrium or eventually leaves any compact set.

To our knowledge, a general class of first integrals for cooperative systems was considered only in [2, Thm. 4.7]. However, that result is negative: if the set of equilibria is countable then every continuous invariant function is constant. On the other side, many authors (e.g. [5], [6], [7], [9], [10]) considered cooperative (or related) systems on the nonnegative orthant $\mathbb{R}^n_+$ having $\sum_i x_i$ as a first integral. For such systems it was proved that every solution converges to an equilibrium. In [9] and [10] these results were extended to the case of nonautonomous cooperative systems periodic (resp. almost periodic) in t.

The results contained in the present paper are a generalization of the theorems mentioned above to the case of not necessarily linear first integral. Methods used here are geometric, and the only nonelementary tool made use of is the Brouwer fixed-point theorem. The exposition is independent of any other work on this subject; however, the idea of a Lyapunov function L is taken from the author's previous work [8].

2. Definitions and preliminary lemmas. We define $\mathbb{R}^n_+ = \{x \in \mathbb{R}^n : x_i \geqq 0\}$, $\partial\mathbb{R}^n_+ = \{x \in \mathbb{R}^n_+ : x_i = 0 \text{ for some } i\}$, $\operatorname{Int}\mathbb{R}^n_+ = \mathbb{R}^n_+ \backslash \partial\mathbb{R}^n_+$. Moreover, we denote $e_i = (0, \cdots, 0, {}_i1, 0, \cdots, 0)$—the ith vector of the standard base in $\mathbb{R}^n$, $B = \{x \in \mathbb{R}^n : 0 \leqq x_i \leqq 1$

* Received by the editors February 25, 1985; accepted for publication (in revised form) January 13, 1986.

† Institute of Mathematics, Technical University of Wrocław, PL-50-370 Wrocław, Wybrzeże Wyspiańskiego 27, Poland.

for each $i\}$, $B_+ = \{x \in B \colon x_i = 1$ for some $i\}$, $x < y$ if $x_i < y_i$ for each i, and $x <_i y$ if $x_i < y_i$ and $x_j = y_j$ for $j \neq i$. $\langle \cdot, \cdot \rangle$ will denote the usual inner product in $\mathbb{R}^n$, $\|\cdot\|$—the corresponding norm.

Let $H \colon \mathbb{R}^n_+ \to \mathbb{R}$ be a C^1 function. By a gradient of H at p we mean the vector $((\partial H/\partial x_1)(p), \cdots, (\partial H/\partial x_n)(p))$ (written grad $H(p)$).

Let $F \colon \mathbb{R}^n_+ \to \mathbb{R}^n$ be a vector field. By a *first integral* for F we understand a function $H \colon \mathbb{R}^n_+ \to \mathbb{R}_+$, of class C^1, such that $\operatorname{grad} H(p) \neq 0$ at each $p \in \mathbb{R}^n_+$ and $\langle \operatorname{grad} H(p), F(p) \rangle = 0$.

A point $p \in \mathbb{R}^n_+$ for which $F(p) = 0$ is called an *equilibrium.*

Let $x \colon [0, T) \to \mathbb{R}^n_+$ be a nonextendible solution to the initial value problem $dx/dt = F(x)$, $x(0) = x$. We say the set $\{x(t) \colon 0 \leqq t < T\}$ is a *forward orbit* of x.

The set $\omega(x)$ consists of those points $y \in \mathbb{R}^n_+$ for which there exists a sequence $t_k \to T$ such that $x(t_k) \to y$. This set is called an *ω-limit set* of x. The following facts are well known.

THEOREM 2.1. *If $\omega(x) = \{y\}$ then the solution x is defined on $[0, +\infty)$ and converges to an equilibrium y.*

THEOREM 2.2. *If $\omega(x) = \varnothing$ then $x(\cdot)$ eventually leaves any compact set.*

The set $A \subset \mathbb{R}^n_+$ is called *positively invariant* if for each $a \in A$ its forward orbit is contained in A.

We consider a system of ordinary differential equations in $\mathbb{R}^n_+$ defined by a C^1 vector field $F \colon \mathbb{R}^n_+ \to \mathbb{R}^n$,

$$(2.1) \qquad \frac{dx_i}{dt} = F_i(x_1, \cdots, x_n) = F_i(x), \quad x \in \mathbb{R}^n_+, \qquad F = (F_1, \cdots, F_n),$$

satisfying:

(A1) $F(0) = 0$;

(A2) If $x <_i y$ then $F_j(x) < F_j(y)$ for $j \neq i$;

(A3) There exists a first integral H for F such that $\operatorname{grad} H(x) > 0$ for $x \in \mathbb{R}^n_+$ and (for convenience) $H(0) = 0$. Systems satisfying (A2) will be called *strictly cooperative.*

Let M denote the least upper bound of the values of H. From (A3) it follows that H is onto $[0, M)$, where $0 < M \leqq +\infty$.

By $\operatorname{Int} H^{-1}(h)$ we denote the set $\{x \in \operatorname{Int} \mathbb{R}^n_+ \colon H(x) = h\}$.

LEMMA 2.1. *Let c be an equilibrium. Then $c + \mathbb{R}^n_+$ is positively invariant. Moreover, c is a unique equilibrium on $c + \partial\mathbb{R}^n_+$.*

Proof. By performing, if necessary, the change of coordinates $\tilde{x}_i = x_i - c_i$, we reduce a general case to the case $c = 0$. Let $x \in \mathbb{R}^n_+$. Then let I denote the subset of $\{1, \cdots, n\}$ such that $x_i = 0$ exactly for $i \in I$. If $x \neq 0$ then $x_j > 0$ for indices j belonging to some nonvoid subset J of $\{1, \cdots, n\}$. For convenience assume $I = \{1, \cdots, k\}$, $J = \{k+1, \cdots, n\}$. By (A2) we obtain

$$F_i(0, \cdots, 0, x_{k+1}, \cdots, x_n) > F_i(0, \cdots, 0, x_{k+2}, \cdots, x_n) > \cdots > F_i(0) = 0 \quad \text{for } i \in I.$$

Therefore on the boundary of $\mathbb{R}^n_+$ (except 0) the vector field F is directed inward, which in a standard way implies that $\mathbb{R}^n_+$ is positively invariant. Q.E.D.

LEMMA 2.2. *Let c be an equilibrium. Then for every $\varepsilon > 0$ there exists $\delta > 0$ such that for each $h \in [H(c) - \delta, H(c) + \delta] \cap [0, M)$ there exists an equilibrium c_h such that $H(c_h) = h$, $c_h > c$ for $h > H(c)$ (resp. $c_h < c$ for $h < H(c)$) and $\|c_h - c\| \leqq \varepsilon$.*

Proof. We consider the case $h > H(c)$. From (A3) it follows that $H(c + n^{-1/2}e_i) > H(c)$. Set $\delta = \min_i H(c + n^{-1/2}e_i) - H(c)$. For $x \in c + n^{-1/2}B_+$ we have $H(x) \geqq H(c) + \delta$. Let for a moment $h \in (H(c), H(c) + \delta)$ be fixed. By $\ell(x)$ we denote the straight line passing through c and x. Let the mapping $K \colon (c + n^{-1/2}B_+) \to H^{-1}(h) \cap (c + \mathbb{R}^n_+)$ be defined in the following way: $K(x)$ is the unique point on $\ell(x)$ at which $H(K(x))=h$. The existence and uniqueness of this point follow from (A3). Having in mind our choice of h, we infer that K is in fact onto $H^{-1}(h)\cap(c+n^{-1/2}B)=H^{-1}(h)\cap(c+\mathbb{R}_+^n)$. The definition of K implies that K is one-to-one. Moreover, K^{-1} is continuous as a "central projection" onto $(c+n^{-1/2}B_+)$. Therefore, from the compactness of the domain of K, K is a homeomorphism. Thus $H^{-1}(h)\cap(c+\mathbb{R}_+^n)$ is homeomorphic to the $(n-1)$-dimensional disk. This set, as an intersection of positively invariant sets, is positively invariant. The Brouwer fixed-point theorem tells us that there is an equilibrium $c_h\in H^{-1}(h)\cap(c+\mathbb{R}_+^n)$. From Lemma 2.1 it follows that $(c_h)_i>c_i$. Moreover, for every $y\in c+n^{-1/2}B$ we have $\|y-c\|\leqq\varepsilon$, so $\|c_h-c\|\leqq\varepsilon$. The case $h<H(c)$ is treated in an analogous way. Q.E.D.

PROPOSITION 2.1. *The set S of equilibria is linearly ordered by* $<$.

Proof. Suppose there exist $c, d\in S$ such that $c_i=d_i$ for $i\in I$, $c_j<d_j$ for $j\in J$, $c_l>d_l$ for $l\in L$ and at least two of these sets are nonempty. Consider the point z, $z_k=\max\{c_k, d_k\}$ for $1\leqq k\leqq n$. Proceeding as in the proof of Lemma 2.1 we obtain $F_i(z)>F_i(d)=0$ for $i\in I$, $F_j(z)>F_j(d)=0$ for $j\in J$ and $F_l(z)>F_l(c)=0$ for $l\in L$. But from this it follows that $\langle F(z), \operatorname{grad} H(z)\rangle>0$, a contradiction. Q.E.D.

COROLLARY. *For each $h\in[0, M)$ there is at most one equilibrium on $H^{-1}(h)$.*

PROPOSITION 2.2. *There exists U, $0<U\leqq M$, such that there is an order-preserving homeomorphism between $[0, U)$ and the set S of equilibria of F.*

Proof. The function $H|S$ is continuous. From the corollary and Proposition 2.1 it follows that $H|S$ is one-to-one, so Z, the function inverse to $H|S$, exists. Lemma 2.2 implies that Z is continuous and preserves order. Therefore Z is a homeomorphism. The statement on the domain of Z also follows from Lemma 2.2. Q.E.D.

Let Z denote, as in the above proof, the function inverse to $H|S$. We define the function $L\colon \mathbb{R}_+^n\to\mathbb{R}_+$, $L(x)=\min\{Z_i^{-1}(x_i)\colon Z_i^{-1}(x_i) \text{ is defined}\}$, where Z_i^{-1} denotes the function inverse to the ith coordinate of Z.

LEMMA 2.3. *L is well defined and continuous.*

Proof. Suppose that for each i, $Z_i(h)\to a_i$ as $h\to U$. Then $a=(a_1,\cdots,a_n)$ would be an equilibrium, and $H(a)=U$. But by Lemma 2.2 there would exist an equilibrium $b>a$ and $H(b)>U$. Thus for some i, $Z_i(h)\to\infty$ as $h\to U$, so L is well defined.

In order to prove the continuity of L notice that, by Lemma 2.2, the image of Z_i is a right-open interval. Therefore if in the definition of $L(x)$ the minimum is realized exactly by indices $i\in I$ then for y belonging to some sufficiently small neighborhood of x the minimum is realized by indices from some subset of I. The minimum of a finite family of continuous functions is continuous, so we have obtained the desired result. Q.E.D.

Remark. As we have said in the Introduction, L has a simple geometric interpretation. Namely, the level surface corresponding to h is equal to the set $Z(h)+\partial\mathbb{R}_+^n$.

LEMMA 2.4. *For $h\in[0, U)$, $\sup\{L(x)\colon x\in H^{-1}(h)\}$ is attained only at $Z(h)$. For $h\in[U, M)$, $\sup\{L(x)\colon x\in H^{-1}(h)\}$ is attained nowhere.*

Proof. First assume $h\in[0, U)$. It is easy to check out that $L(Z(h))=h$. Suppose that for some $x\neq Z(h)$, $x\in H^{-1}(h)$, we have $L(x)\geqq h$. From the definition of L it follows that $x_i\geqq Z_i(h)$ for every i. But for some j, $x_j\neq Z_j(h)$. (A3) implies that $H(x)>h$, a contradiction.

Now we assume $h\in[U, M)$. Let x be any point of $H^{-1}(h)$. Denote $L(x)$ by g. This means that $x\in Z(g)+\partial\mathbb{R}_+^n$ (of course $g<h$). Let I stand for the set of indices i for which $x_i=Z_i(g)$. Define the point $\tilde{x}$ in the following way: $\tilde{x}_i=x_i+1$ for $i\in I$, $\tilde{x}_j=x_j$ for $j\notin I$. From (A3) it follows that $H(\tilde{x})>h$. Considering, as in the proof of Lemma 2.2, the straight line passing through $Z(g)$ and x, we can find a point $y\in Z(g)+\operatorname{Int}\mathbb{R}_+^n$

such that $H(y)=h$. But the fact that $y \in Z(g)+\operatorname{Int}\mathbb{R}_+^n$ means that $H(y)>h$, a contradiction. Q.E.D.

3. The main result.

THEOREM 3.1. *For $x \in \mathbb{R}_+^n$ we have either $\omega(x)=\{Z(H(x))\}$ or $\omega(x)=\varnothing$.*

Proof. Let I denote the set of indices realizing the minimum in the definition of $L(x(t))$. Analogously, as in the proof of Lemma 2.1 we can show that $\dot{x}_i(t)>0$ for $i \in I$. Hence L is strictly increasing along the forward orbits of (2.1), except for the constant solutions. Let $x \in \mathbb{R}_+^n$ be fixed, and let E denote the set $H^{-1}(H(x))$. H is a first integral, so the forward orbit of x is contained in E. Furthermore, from the closedness of E it follows that $\omega(x) \subset E$. Now it suffices to show that $\omega(x) \subset \{y \in E: L(y)=\sup_{z\in E} L(z)\}$. Suppose not. Then there exists $y \in \omega(x)$ such that $L(y)<\sup_{z\in E} L(z)$. From Lemma 2.4, y is not an equilibrium, so L strictly increases along the orbit of y. Let v be any point·on the forward orbit of y, distinct from y. Obviously $L(v)>L(y)$. Choose neighborhoods V of v, Y of y, such that $\inf_{z\in V} L(z)>\sup_{z\in Y} L(z)$. From the very definition of the ω-limit set we can find moments $t_1<t_2$ such that $x(t_1)\in V$, $x(t_2)\in Y$. From this we deduce that $L(x(t_1))<L(x(t_2))$, which contradicts our choice of V and Y. Q.E.D.

The following example shows that the case $\omega(x)=\varnothing$ is possible.

Example. Consider the nonnegative quadrant $\mathbb{R}_+^2$. As a first integral choose a function $H(x_1,x_2)=G_1(x_1)+G_2(x_2)$, where $G_2(x_2)=x_2$, and $G_1: \mathbb{R}_+ \to \mathbb{R}_+$ is a function of class C^2 such that $G_1(0)=0$, G_1' is positive and $\lim_{x_1\to\infty} G_1(x_1)=1$. Let $W: \mathbb{R}_+ \to \mathbb{R}_+$ be a function of class C^1 such that $W(0)=0$, W' is positive and $\lim_{x\to\infty} W(x)=1$. As the equilibrium set S we choose the graph of W, i.e., $S=\{(x_1,x_2): x_2=W(x_1), x_1 \in \mathbb{R}_+\}$. We define

$$F_2(x_1,x_2)=W(x_1)-x_2,\ F_1(x_1,x_2)=-(F_2(x_1,x_2))/(G_1'(x_1))=(x_2-W(x_1))/(G_1'(x_1)).$$

It is easy to check out that F is C^1 and that H is a first integral for our system. Moreover

$$(\partial F_2/\partial x_1)(x_1,x_2)=W'(x_1)>0, \qquad (\partial F_1/\partial x_2)(x_1,x_2)=[G_1'(x_1)]^{-1}>0,$$

so that the system is strictly cooperative. From the choice of W it follows that $\sup_{x\in S} H(x)=2$. Hence the level surface $H^{-1}(3)$ does not intersect S, so for each $x\in H^{-1}(3)$, $\omega(x)=\varnothing$.

Remark. Professor Morris W. Hirsch has informed the author that he obtained the same result under slightly different hypotheses [4].

Acknowledgments. The author would like to thank Professor M. W. Hirsch for sending him a preprint of the paper [2]. He is also indebted to Professor G. R. Sell for calling his attention to [9] and [10].

ON THE ASYMPTOTIC BEHAVIOR OF SOLUTIONS OF A REACTING-DIFFUSING SYSTEM: A TWO PREDATORS-ONE PREY MODEL*

L. HSIAO†, Y. SU† AND Z. P. XIN‡

Abstract. We discuss a predator-prey system consisting of two predator species and a single prey species which obeys Michaelis-Menten dynamics. We establish global existence for different initial-boundary conditions by either the semigroup approach or the comparison method. Furthermore, we investigate the asymptotic properties of the solutions.

Key words. predator, prey, reaction, diffusion, sectorial operator, fractional power, linearization, spectrum, monotonicity

AMS(MOS) subject classifications. 35, 92

1. Introduction. Evolution equations of reaction-diffusion type enter a wide number of phenomena in ecology, biology, biochemistry, chemistry and physics. An important and interesting problem about these systems is the time evolution of the various density distributions and their relations to the corresponding stationary distributions. This kind of problem has been discussed quite a lot in various fields for a single reaction-diffusion equation. In recent years, attention has been given to coupled reaction-diffusion equations from various fields of applied sciences, but mostly to two equations. For instance, the question as to whether one prey can support two predators is an intriguing one in ecology. But very little theoretical work has been done on such systems, although competition between species exploiting a common prey population is of frequent occurrence in nature.

The present paper discusses a predator-prey system consisting of two predator species, V_1 and V_2, and a single prey species, S. We assume that the predator species compete purely exploitatively, with no interference between rivals. Both species have access to the prey and compete only by lowering the population of shared prey. For death rates it is assumed that the number dying is proportional to the number currently alive. We also assume that there are no significant time lags in the system, that growth rates are logistic in the prey species in the absence of predation, and that the predators' functional response obeys the Holling "nonlearning" curve (for an ecological problem) [5], [6], or Michaelis-Menten Dynamics (for enzyme reactions). The model is given by

$(1.3)_{\mathrm{I}}$ Dirichlet conditions $(S, V_1, V_2)=(0,0,0)$ on $\partial\Omega\times\mathbb{R}^+$, or

$(1.3)_{\mathrm{II}}$ Neumann conditions $\left(\frac{\partial S}{\partial n}, \frac{\partial V_1}{\partial n}, \frac{\partial V_2}{\partial n}\right)=(0,0,0)$ on $\partial\Omega\times\mathbb{R}^+$,

where γ is the growth rate and K the carrying capacity for the prey s, while y_i, M_i, D_i, a_i are the yield constants, the intrinsic growth rate, the death rate and the Michaelis-Menten constant, respectively, for the ith predator V_i, $i=1,2$. k_1, k_2, k_3 are nonnegative diffusion coefficients, respectively, for S, V_1 and V_2. Ω is an open bounded set of R^3 with boundary $\partial\Omega$.

When the effect of diffusion is not considered, namely, $(k_1, k_2, k_3)=(0,0,0)$, this system (1.1) becomes an ordinary differential equation. Hsu, Hubbell and Waltman [7], [8] and Butler and Waltmann [1] analyzed the behavior of solutions of this system of ordinary differential equations in order to answer the biological question: Under what conditions would neither, one, or both species of predator survive? If only one predator survives, how do we determine the limiting behavior of the surviving predator and its prey?

In this paper we analyze the behavior of solutions of system (1.1) with (1.2), $(1.3)_{\mathrm{I}}$ (Case I) or (1.2), $(1.3)_{\mathrm{II}}$ (Case II). In § 2 we deal with Case I. As for the existence and positivity properties of the solutions of (1.1)-$(1.3)_{\mathrm{I}}$ we shall prove Theorems 2.1 and 2.2 by a semigroup approach. Our results on the asymptotic stability of the equilibrium solutions are summarized in Theorems 2.3-2.6. In § 3 we consider Case II. By employing a monotonicity argument we establish existence-comparison Theorems 3.1 and 3.2. We investigate the asymptotic properties of the solution in Theorems 3.3-3.8.

2. The case of Dirichlet conditions. We are interested in the nonnegative solution of problem (1.1), (1.2), $(1.3)_{\mathrm{I}}$. In view of the special form of the reaction terms in (1.1), it is easy to know that [12] (1.1) has the following invariant region Σ:

$$\Sigma=\{(S, V_1, V_2)\colon S\geqq 0,\ V_1\geqq 0,\ V_2\geqq 0\}. \tag{2.1}$$

We change the form of (1.1) into

$$\begin{aligned}\frac{\partial S}{\partial t}&=(k_1\Delta S+\gamma S)+\left(-\frac{\gamma}{K}S^2-\frac{M_1V_1S}{y_1(a_1+S)}-\frac{M_2V_2S}{y_2(a_2+S)}\right),\\ \frac{\partial V_1}{\partial t}&=(k_2\Delta V_1+\beta_1V_1)+\left(-\frac{a_1M_1V_1}{a_1+S}\right),\\ \frac{\partial V_2}{\partial t}&=(k_3\Delta V_2+\beta_2V_2)+\left(-\frac{a_2M_2V_2}{a_2+S}\right),\end{aligned} \tag{2.2}$$

where $\beta_i=M_i-D_i$, $i=1,2$.

It will be convenient to think of system (2.2) as an evolution equation for the unknown $U(t)=(S(t), V_1(t), V_2(t))$ in a Banach space X.

Define $X=(L_2(\Omega))^3$ with norm $\|U\|=(\|S\|_2^2+\|V_1\|_2^2+\|V_2\|_2^2)^{1/2}$ for any $U=(S, V_1, V_2)\in X$, where $\|\cdot\|_2$ denotes the usual norm in $L_2(\Omega)$. Clearly, X is a Banach space.

If one chooses the above Banach space X to work with, system (2.2) can be rewritten as follows.

Let $S(t)=S(\cdot,t)$, $V_1(t)=V_1(\cdot,t)$, $V_2(t)=V_2(\cdot,t)$, $U(t)=(S(t), V_1(t), V_2(t))$. Then (2.2), (1.2), $(1.3)_{\mathrm{I}}$ is changed into the form

$$\frac{dU}{dt}=AU+F(U), \qquad U(0)=U_0 \tag{2.3}$$

where

$$A=\begin{pmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{pmatrix}=\begin{pmatrix} k_1\Delta+\gamma & 0 & 0 \\ 0 & k_2\Delta+\beta_1 & 0 \\ 0 & 0 & k_3\Delta+\beta_2 \end{pmatrix}, \tag{2.4}$$

$$D(A_i)=\{u\in L^2(\Omega), u|_{\partial\Omega}=0, A_iu\in L^2(\Omega)\},$$

$$F(U)=\begin{pmatrix} -\dfrac{r}{K}S^2-\dfrac{M_1V_1S}{y_1(a_1+S)}-\dfrac{M_2V_2S}{y_2(a_2+S)} \\ -\dfrac{M_1a_1V_1}{a_1+S} \\ -\dfrac{M_2a_2V_2}{a_2+S} \end{pmatrix}. \tag{2.5}$$

It is well known that $D(A_i)\subseteq H_0^1(\Omega)$ and is dense in $L^2(\Omega)$.

Suppose Y, Z are Banach spaces; we shall denote the norm of a linear bounded operator $T\colon Y\to Z$ by $\|T\|_{Y,Z}$. For a closed operator T, the spectrum, resolvent set and resolvent operator will be denoted by the usual symbols $\sigma(T)$, $\rho(T)$ and $R(\mu,t)=(T-\mu)^{-1}$.

LEMMA 2.1. *A generates an analytic semigroup e^{At} on λ.*

Before we prove the lemma, let us recall the following definition and Theorem [4], which is written down as a proposition.

DEFINITION 2.1. We call a linear operator A in a Banach space X a sectorial operator if it is a closed densely defined operator such that, for some θ in $(0,(\pi/2))$ and some $M\geqq 1$ and real a, the sector

$$S_{a,\theta}=\{\mu|\theta\leqq|\arg(\mu-a)|\leqq\pi, \mu\neq a\}$$

is in the resolvent set of A and

$$\|R(\mu,A)\|\leqq\frac{M}{|\mu-a|} \quad \text{for all } \mu\in S_{a,\theta}.$$

PROPOSITION 2.1. *If A is a sectorial operator, then $-A$ is the infinitesimal generator of an analytic semigroup $\{e^{-tA}\}_{t\geqq 0}$, where*

$$e^{-tA}=\frac{1}{2\pi i}\int_\Gamma(\mu+A)^{-1}e^{\mu t}\,d\mu,$$

and Γ is a contour in $\rho(-A)$ with $\arg\mu\to\pm\theta$ *as $|\mu|\to\infty$ for some θ in $((\pi/2),\pi)$.*

Furthermore, e^{-At} can be continued analytically into a sector $\{t\neq 0\colon |\arg t|<\varepsilon\}$ containing the positive real axis, and if $\operatorname{Re}\sigma(A)>a$; *i.e., if* $\operatorname{Re}\lambda>a$ *whenever $\lambda\in\sigma(A)$, then for $t>0$*

$$\|e^{-At}\|\leqq c\,e^{-at}, \qquad \|A\,e^{-At}\|\leqq\frac{c}{t}e^{-at}$$

for some constant c.

Finally

$$\frac{d}{dt} e^{-At} = -A\, e^{-At} \quad \textit{for } t > 0.$$

The proof of Lemma 2.1. Due to the above proposition, it suffices to prove that $-A$ is a sectorial operator. In view of $D(A_i) = H^2(\Omega) \cap H_0^1(\Omega)$, where $H^i(\Omega) = W^{i,2}(\Omega)$, $i \geqq 0$; $H_0^i(\Omega) = W_0^{i,2}(\Omega)$, it follows that $D(A) = (H^2(\Omega) \cap H_0^1(\Omega))^3$, which implies $-A$ is a closed densely defined operator on X. Since $-A_i$ is a self-adjoint densely defined operator in $L_2(\Omega)$ and is bounded below, it is easy to show that $-A_i$ is a sectorial operator on X_i. Namely, there exist $M_i \geqq 1$, a_i and θ_i satisfying $0 < \theta_i < \pi/2$ such that

$$\rho(-A_i) \supset S_{a_i,\theta_i} = \{\mu \,|\, \theta_i \leqq |\arg(\mu - a_i)| \leqq \pi\}$$

and

$$\|R(\mu, -A_i)\|_{L^2;L^2} \leqq \frac{M_i}{|\mu - a_i|} \quad \forall \mu \in S_{a_i,\theta_i}, \quad i = 1, 2, 3.$$

Clearly, a_i can be taken as the smallest eigenvalue λ_0^i of $(-A_i)$ [14]. ($-\lambda_0^i$ is the largest eigenvalue of A_i.)

Define $\gamma_0 = \min\{\lambda_0^1, \lambda_0^2, \lambda_0^3\}$, $\theta = \max\{\theta_1, \theta_2, \theta_3\}$. It is easy to show, by the form (2.4) of A, that

$$R(\mu, -A) = \begin{pmatrix} R(\mu, -A_1) & 0 & 0 \\ 0 & R(\mu, -A_2) & 0 \\ 0 & 0 & R(\mu, -A_3) \end{pmatrix} \quad \forall \mu \in \rho(A). \tag{2.6}$$

Therefore, it can be claimed that

$$\rho(-A) \supset S_{\gamma_0,\theta}$$

and there exists $M_0 \geqq 1$ such that

$$\|R(\mu, -A)\| \leqq \frac{M_0}{|\mu - \gamma_0|} \quad \forall \mu \in S_{\gamma_0,\theta}.$$

This means $-A$ is a sectorial operator on X, so that by Proposition 2.1, it follows that A generates an analytic semigroup e^{At} on X and satisfies

$$\|e^{At}\| \leqq M\, e^{-\gamma_0 t} \tag{2.7}$$

where M denotes a suitable constant.

In order to investigate the existence and asymptotic properties of the solution to (1.1), (1.2), $(1.3)_{\text{I}}$, we recall the concepts of fractional powers of operators and some results concerned with them [4].

Definition 2.2. Suppose T is a sectorial operator and $\operatorname{Re} \sigma(T) > 0$, then for any $\alpha > 0$

$$T^{-\alpha} = \frac{1}{\Gamma(\alpha)} \int_0^\infty t^{\alpha-1} e^{-Tt}\, dt.$$

Definition 2.3. With T as above, define T^α = inverse of $T^{-\alpha}$ ($\alpha > 0$), $D(T^\alpha) = R(T^{-\alpha})$; T^0 = identity on X.

DEFINITION 2.4. If T is a sectorial operator in a Banach space X, define for each $\alpha \geqq 0$,

$$X^{\alpha} = D(T_1^{\alpha}) \quad \text{with the graph norm}$$

$$\|X\|_{\alpha} = \|T_1^{\alpha}x\|, \quad x \in X^{\alpha},$$

where $T_1 = T + aI$ with a chosen so Re $\sigma(T_1) > 0$. It can be shown that different choices of a give equivalent norms on X^{α}, so we suppress the dependence on the choice of a.

PROPOSITION 2.2. *If T is sectorial in a Banach space X, then X^{α} is a Banach space in the norm $\|\cdot\|_{\alpha}$ for $\alpha \geqq 0$, $X^0 = X$, and for $\alpha \geqq \beta \geqq 0$, X^{α} is a dense subspace of X^{β} with continuous inclusion.*

DEFINITION 2.5. Suppose there is an extension map $E: C_c^m(\bar{\Omega}) \to C_c^m(\mathbb{R}^n)$, so $E(\phi)$ restricted to $\bar{\Omega}$ is ϕ, such that for the norms of any of the spaces C^{ν} or $W^{k,q}$ $(0 \leqq \nu$, $k \leqq m$ and $1 \leqq q < \infty)$ there is a constant $B > 0$ with

$$B^{-1}\|\phi\|_{\Omega} \leqq \|E(\phi)\|_{\mathbb{R}^n} \leqq B\|\phi\|_{\Omega}.$$

When such an extension map exists, we say Ω has the C^m-extension property.

PROPOSITION 2.3. *Suppose $\Omega \subset \mathbb{R}^n$ is an open set having the C^m extension property, $1 \leqq p < \infty$, and T is a sectorial operator in $X = L_p(\Omega)$ with $D(T) = X^1 \subset W^{m,p}(\Omega)$ for some $m \geqq 1$. Then for $0 \leqq \alpha \leqq 1$.*

$$X^{\alpha} \subset W^{k,q}(\Omega) \quad \textit{when } k - \frac{n}{q} < m\alpha < \frac{n}{p}, \quad q \geqq p$$

$$X^{\alpha} \subset C^{\nu}(\Omega) \quad \textit{when } 0 \leqq \nu < m\alpha - \frac{n}{p}.$$

Furthermore, these are continuous inclusions, provided $\alpha > \theta$, where θ is the number in Nirenberg-Gagliardo inequalities.

Remark. Such an extension map is easily constructed if Ω is bounded and $\partial\Omega$ is a C^m hypersurface separating Ω from $\mathbb{R}^n \backslash \Omega$ [3], and a more complicated construction shows $\partial\Omega$ needs only to be Lipschitzian [13].

LEMMA 2.2. *Let $0 \leqq \alpha \leqq 1$. Suppose X^{α} is a Banach space defined as Definition 2.4 with $T = -A$. Assume $\alpha = \alpha_0 > \frac{3}{4}$. Then*

$$X^{\alpha_0} \subset (L^{\infty}(\Omega) \cap W^{1,2}(\Omega))^3,$$

continuously.

Proof. In view of the form of A_i, it is easy to see that $D(A_i) = W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)$, $i = 1, 2, 3$. By using Proposition 2.3 for $T = -A_i$ with $m = 2$, $p = 2$, $n = 3$, it follows, for $\alpha_0 > \frac{3}{4}$ that

$$X_i^{\alpha_0} \subset C^{\nu}(\Omega) \quad \text{when } 0 \leqq \nu \leqq \frac{4\alpha_0 - 3}{2}.$$

Furthermore, taking $k = 1$, $q = 2$ in Proposition 2.3, it turns out that

$$X_i^{\alpha} \subset W^{1,2}(\Omega).$$

Thus,

$$X_i^{\alpha_0} \subset L^{\infty}(\Omega) \cap W^{1,2}(\Omega), \quad i = 1, 2, 3.$$

The continuity is easily checked. Then, by the special form of A, we obtain Lemma 2.2.

Define

$$\mathscr{D}=\mathbb{R}^+\times\left\{(S,V_1,V_2)\in\bar{X}^{\alpha_0},\ S>-\frac{\min(a_1,a_2)}{2}\right\}.$$

LEMMA 2.3. *The nonlinear operator F is locally Lipschitz continuous on $\mathscr{D}$.*

Proof. Since F does not depend on t explicitly, it suffices to prove that for any $U_i=\{S^{(i)},V_1^{(i)},V_2^{(i)}\}$ with

$$S^i\geqq-\frac{\min(a_1,a_2)}{2}\quad\text{and}\quad\|U_i\|_{\alpha_0}\leqq R^*,\quad R^*>0,\quad i=1,2,$$

$$\|F(U_1)-F(U_2)\|\leqq C\|U_1-U_2\|_{\alpha_0} \tag{2.8}$$

where C depends only on R^* and the parameters in F.

Set

$$F(U)=\begin{pmatrix}f_1(U)\\ f_2(U)\\ f_3(U)\end{pmatrix},$$

$$F(U_1)-F(U_2)=\begin{pmatrix}f_1(U_1)-f_1(U_2)\\ f_2(U_1)-f_2(U_2)\\ f_3(U_1)-f_3(U_2)\end{pmatrix}.$$

By Lemma 2.2, there exists R_1 depending on R^* such that

$$|U_i|_\infty\leqq R_1.$$

From (2.5),

$$\begin{aligned}|f_1(U_1)-f_1(U_2)|\leqq{}&\frac{M_1}{y_1}|V_1^{(1)}-V_1^{(2)}|+\frac{M_2}{y_2}|V_2^{(1)}-V_2^{(2)}|+\frac{\gamma}{K}|S^{(1)}+S^{(2)}||S^{(1)}-S^{(2)}|\\&+\frac{M_1a_1}{y_1}\left|\frac{V_1^{(1)}}{a_1+S^{(1)}}-\frac{V_1^{(2)}}{a_1+S^{(2)}}\right|+\frac{M_2a_2}{y_2}\left|\frac{V_2^{(1)}}{a_2+S^{(1)}}-\frac{V_2^{(2)}}{a_2+S^{(2)}}\right|.\end{aligned}$$

Since

$$\left|\frac{V_1^{(1)}}{a_1+S^{(1)}}-\frac{V_1^{(2)}}{a_1+S^{(2)}}\right|\leqq\frac{2}{a_1}|V_1^{(1)}-V_1^{(2)}|+\frac{4R_1}{a_1^2}|S^{(1)}-S^{(2)}|,$$

$$\left|\frac{V_2^{(1)}}{a_2+S^{(1)}}-\frac{V_2^{(2)}}{a_2+S^{(2)}}\right|\leqq\frac{2}{a_2}|V_2^{(1)}-V_2^{(2)}|+\frac{4R_1}{a_2^2}|S^{(1)}-S^{(2)}|,$$

it follows that

$$\begin{aligned}|f_1(U_1)-f_1(U_2)|\leqq{}&\frac{3M_1}{y_1}\{|V_1^{(1)}-V_1^{(2)}|+|V_2^{(1)}-V_2^{(2)}|\}\\&+R_1\left(\frac{2\gamma}{K}+\frac{4M_1}{a_1}+\frac{4M_2}{a_2}\right)|S^{(1)}-S^{(2)}|.\end{aligned}$$

Similarly,

$$|f_2(U_1)-f_2(U_2)|\leqq 2M_1|V_1^{(1)}-V_1^{(2)}|+\frac{4M_1K_1}{a_1}|S^{(1)}-S^{(2)}|,$$

$$|f_3(U_1)-f_3(U_2)|\leqq 2M_2|V_2^{(1)}-V_2^{(2)}|+\frac{4M_2R_1}{a_2}|S^{(1)}-S^{(2)}|.$$

Then, $\|F(U_1)-F(U_2)\|^2 \leqq C\|U_1-U_2\|^2$ which, together with Proposition 2.3, implies (2.8). Therefore, $F:\mathcal{D}\to X$ is locally Lipschitz continuous.

By Lemmas 2.1 and 2.3, the local existence result follows.

LEMMA 2.4. *For any $U_0=(S_0(x), V_{10}(x), V_{20}(x))\in X^{\alpha_0}$, there exists $T>0$ such that a unique classical solution $t\to U(t)=(S(t), V_1(t), V_2(t))$ of* (2.3) *exists in* $[0, T)$.

Proof. In view of Lemmas 2.1 and 2.3, it can be proved, by local contraction arguments (cf. [4, Thm. 3.3.3]) that for any $(t_0, U_0)\in\mathcal{D}$ there exists $T(t_0, U_0)>0$ such that (2.3) has a unique solution $U(t)$ on (t_0, t_0+T) with initial value $U(t_0)=U_0$, where $t_0=0$. Namely, $U(t)$ is a continuous function: $(0, T)\to X$ such that $U(0)=U_0$, and on $(0, T)$ we have $(t, U(t))\in\mathcal{D}$, $U(t)\in D(A)$. $(dU(t)/dt)$ exists, $t\to F(U(t))$ is locally Hölder continuous, and $\int_0^\rho \|F(U(t))\|\,dt<+\infty$ for some $\rho>0$, the differential equation (2.3) is satisfied on $(0, T)$. In addition $U(t)$ can be expressed as

$$U(t)=\exp(At)U_0+\int_0^t \exp(A(t-s))F(U(s))\,ds. \tag{2.9}$$

But, in fact; when $t>0$, $t\to(dU(t)/dt)\in X^{\alpha_0}$ is locally Hölder continuous due to Lemmas 2.1 and 2.3 (cf. [4, Thm. 3.5.2]), so $(t,x)\to U(t,x)$, $(\partial U/\partial t)(t,x)$ are also continuous on $0<t<T$ and $x\in\bar{\Omega}$. Since $U(t)\in D(A)$ implies $U(t)\in(W^{2,2}(\Omega)\cap W_0^{1,2}(\Omega))^3$, it can be shown, by the embedding theorem, that there exists $\nu>0$ such that $U(t)\in(C^\nu(\Omega))^3$. Then, $F(U(t))\in(C^\nu(\Omega))^3$ follows easily. Therefore we obtain that $U(x,t)\in C^{2+\nu}(\Omega)$. Thus, for $t>0$, $(t,x)\to U(t,x)$ is continuously differentiable in t, twice continuously differentiable in x and we have a classical solution.

Now, we are ready to prove the following.

THEOREM 2.1. *For any $U_0\in X^{\alpha_0}$, $U_0\geqq 0$, the corresponding solution exists globally and is nonnegative for any $t\geqq 0$.*

Proof. Due to $U_0\geqq 0$ and (2.1), it follows that

$$U(t)\geqq 0, \qquad 0\leqq t<T.$$

In addition, since $-R(\mu, A_i)$ maps nonnegative elements of X_i into themselves for real $\mu\in\rho(A_i)$, $-R(\mu, A)$ does the same for real $\mu\in\rho(A)$. On the other hand, for any $t>0$

$$e^{At}x=\lim_{n\to\infty}\left(I-\frac{t}{n}A\right)^{-n}x. \tag{2.10}$$

In view of $-A$ being a sectorial operator, it can be shown that for any fixed $t>0$, $n/t\in\rho(A)$ if n is sufficiently large. Then $e^{At}\cdot U\geqq 0$, $t>0$, if $U\geqq 0$ by (2.10). This, combined with the fact of $F(U)\leqq 0$ for $U\geqq 0$, implies the estimate

$$U(t)\leqq\exp(At)U_0 \quad \text{for all } t\in(0, T).$$

Therefore, by (2.7), we have

$$\|U(t)\|\leqq Me^{-\gamma_0 t}\|U_0\| \quad \text{for all } t\in(0, T), \tag{2.11}$$

which provides an a priori estimate for $U(t)$, whence the global existence of $U(t)$ and its nonnegativity follow in a standard way, together with the validity of (2.11) on $\mathbb{R}^+$.

Next, we prove an existence theorem for nonnegative and bounded solutions of (1.1), (1.2), $(1.3)_{\mathrm{I}}$.

Let λ_0 denote the principal eigenvalue of Laplace operator Δ on $\Omega\in\mathbb{R}^2$ with homogeneous Dirichlet boundary condition. Then $\lambda_0<0$. Set $\Lambda=\max\{k_1\lambda_0+\gamma, k_2\lambda_0+\beta_1, k_3\lambda_0+\beta_2\}$.

THEOREM 2.2. *Suppose* $\Lambda<0$. *Then, for any* $U_0\in X^{\alpha_0}$, $U_0\geqq 0$, *there exists globally a unique classical solution to* (1.1), (1.2), $(1.3)_{\mathrm{I}}$ *that is nonnegative and bounded in the sense of* L_∞.

Proof. Recalling the special form of A and the property of the spectrum for the operator A_i which is strongly elliptic, we may take Λ as $-\gamma_0$ in (2.7), i.e., $-\gamma_0=\Lambda<0$.

From the proof of Theorem 2.1, we read off the estimate

$$0\leqq U(t)\leqq \exp(At)U_0,$$

which implies that

$$|U(t)|_{(L_\infty)^3}\leqq|\exp(At)U_0|_{(L_\infty)^3}.$$

For $U_0\in X^{\alpha_0}$, it has been shown that $\exp(At)U_0\in X^{\alpha_0}$ and $U(t)\in X^{\alpha_0}$. By Lemma 2.2, $X^{\alpha_0}\hookrightarrow(L_\infty(\Omega))^3$ continuously. Therefore, by a known estimate with fractional powers of operators (cf. [4, Thm. 1.4.3]),

$$\begin{aligned}|U(t)|_{(L_\infty)^3}&\leqq C\|\exp(At)U_0\|_{\alpha_0}\leqq C\|(-A)^{\alpha_0}e^{At}\|\,\|U_0\|\\&\leqq C_\alpha t^{-\alpha_0}e^{-\gamma_0 t}\quad\text{for } t>0.\end{aligned}\tag{2.12}$$

Thus, the theorem is proved.

It is easily seen that the state $(0,0,0)$ is an equilibrium solution for (1.1)-$(1.3)_{\mathrm{I}}$. Now, we will discuss the stability of the solution.

THEOREM 2.3. *Suppose* $\Lambda<0$. *Then the unique equilibrium solution* $(0,0,0)$ *of* (1.1)-$(1.3)_{\mathrm{I}}$ *is globally stable. Namely, for any* $U_0\in X^{\alpha_0}$, $U_0\geqq 0$, *assume* $U(t)$ *is the corresponding solution of* (1.1), (1.2), $(1.3)_{\mathrm{I}}$ *as investigated in Theorem* 2.2; *then* $\lim_{t\to\infty}U(t)=0$ *in the sense of* L_∞, *uniformly for* x.

Proof. Since $-\gamma_0=\Lambda<0$, (2.12) gives the result.

Next, we analyze the possibility of relaxing the assumption $\Lambda<0$.

LEMMA 2.5. *Assume* $k_1\lambda_0+\gamma<0$; *then there exists a unique nonnegative equilibrium solution for* (1.1)-$(1.3)_{\mathrm{I}}$ *that is* $(0,0,0)$.

Proof. Let $U^*=(s^*(x),V_1^*(x),V_2^*(x))$ be another nonnegative equilibrium solution. Namely,

$$\left.\begin{aligned}&k_1\Delta S^*+S^*\left(\gamma-\frac{\gamma}{K}S^*-\frac{M_1V_1^*}{y_1(a_1+S^*)}-\frac{M_2V_2^*}{y_2(a_2+S^*)}\right)=0,\\&k_2\Delta V_1^*+k_1\Delta V_1^*+V_1^*\left(\frac{M_1S^*}{a_1+S^*}-D_1\right)=0,\\&k_3\Delta V_2^*+V_2^*\left(\frac{M_2S^*}{a_2+S^*}-D_2\right)=0,\end{aligned}\right\}\quad x\in\Omega,\tag{2.13}$$

$$S^*(x)=V_1^*(x)=V_2^*(x)=0,\qquad x\in\partial\Omega,\tag{2.14}$$

which means $S^*(x)$ is a nonnegative solution of the following linear problem

$$\begin{aligned}&k_1\Delta S+a(x)S=0,\qquad x\in\Omega,\\&S|_{\partial\Omega}=0\end{aligned}$$

where

$$a(x)=\gamma-\frac{\gamma}{K}S^*-\frac{M_1V_1^*}{y_1(a_1+S^*)}-\frac{M_2V_2^*}{y_2(a_2+S^*)}.$$

Due to $S^*(x)\geqq 0$, $V_1^*(x)\geqq 0$, $V_2^*(x)\geqq 0$, it follows that

$$a(x)\leqq \gamma,$$

which, combining with $k_1\lambda_0+\gamma<0$, implies

$$-\lambda_0> a(x)/k_1.$$

Therefore, it can be shown that $S^*(x)=0$, $x\in\bar{\Omega}$. Then it turns out that $V_i^*(x)=0$, $x\in\Omega$, $i=1,2$.

THEOREM 2.4. *Assume* $k_1\lambda_0+\gamma<0$. *Then the unique nonnegative equilibrium state* $(0,0,0)$ *is globally stable in* X; *namely, for any* $U_0\in X^{\alpha_0}$, $U_0\geqq 0$, *suppose* $U(t)$ *is the corresponding solution for* (1.1)-$(1.3)_{\mathrm{I}}$, *then*

$$\lim_{t\to\infty}\|U(t)\|=0.$$

Proof. In view of $k_1\lambda_0+\gamma<0$ and the fact $U(t)\geqq 0$, it is easily proved that

$$\lim_{t\to\infty} S(t)=0 \quad \text{in } L_\infty(\Omega). \tag{2.15}$$

Define a Lyapunov functional as

$$\mathscr{L}(t)=L(V_1,V_2)=\frac{1}{2}\int_\Omega [V_1^2(x,t)+V_2^2(x,t)]\,dx.$$

Then

$$\frac{d\mathscr{L}(t)}{dt}=\int_\Omega\left[V_1\frac{\partial V_1}{\partial t}+V_2\frac{\partial V_2}{\partial t}\right]dx.$$

Noticing the following

$$\frac{\partial V_1}{\partial t}=k_2\Delta V_1+V_1\left(\frac{M_1S}{a_1+S}-D_1\right),$$
$$\frac{\partial V_2}{\partial t}=k_3\Delta V_2+V_2\left(\frac{M_2S}{a_2+S}-D_2\right),$$
$$V_1(0)=V_{10}(x),\qquad V_2(0)=V_{20}(x),$$
$$V_1(t)=V_2(t)\quad\text{on }\partial\Omega,$$

we find that

$$\frac{d\mathscr{L}(t)}{dt}=\int_\Omega\left[k_2V_1\Delta V_1+V_1^2\left(\frac{M_1S}{a_1+S}\right)-D_1V_1^2\right]dx$$
$$+\int_\Omega\left[k_3V_2\Delta V_2+V_2^2\left(\frac{M_2S}{a_2+S}\right)-D_2V_2^2\right]dx.$$

For the first term, we have, by using the Poincaré inequality

$$\int_\Omega\left[k_2V_1\Delta V_1+V_1^2\left(\frac{M_1S}{a_1+S}\right)-D_1V_1^2\right]dx$$
$$=k_2V_1\frac{\partial V_1}{\partial n}\bigg|_{\partial\Omega}-k_2\int_\Omega(\nabla V_1)^2\,dx-D_1\int_\Omega V_1^2\,dx+\int_\Omega V_1^2\left(\frac{M_1S}{a_1+S}\right)dx$$
$$\leqq -k_2\int_\Omega(\nabla V_1)^2-D_1\int_\Omega V_1^2\,dx+\frac{M_1}{a_1}|S|_{L_\infty}\int_\Omega V_1^2\,dx$$
$$\leqq\left(k_2\lambda_0-D_1+\frac{M_1}{a_1}|S(t)|_{L_\infty}\right)\int_\Omega|V_1|^2\,dx.$$

Similarly,

$$\int_\Omega \left[k_3 V_2 \Delta V_2 + V_2^2\left(\frac{M_2 S}{a_2+S}\right) - D_2 V_2^2\right] dx \leqq \left(k_3\lambda_0 - D_2 + \frac{M_2}{a_2}\cdot |S|_{L_\infty}\right)\int_\Omega V_1^2\,dx.$$

In view of $\lim_{t\to\infty} S(t) = 0$ (in the sense of $L_\infty(\Omega)$), it is known that there exists $t_0 > 0$, $\sigma > 0$ such that

$$\max\left\{\left(k_2\lambda_0 - D_1 + \frac{M_1}{a_1}|S|_{L_\infty}\right), \left(k_3\lambda_0 - D_2 + \frac{M_2}{a_2}|S|_{L_\infty}\right)\right\} \leqq -\sigma \quad \text{for } t \geqq t_0.$$

Thus,

$$\frac{d\mathscr{L}(t)}{dt} \leqq -2\sigma\mathscr{L}(t) \quad \text{for } t \geqq t_0.$$

This implies that

$$\mathscr{L}(t) \leqq \mathscr{L}(t_0)\, e^{-2\sigma(t-t_0)}, \qquad t \geqq t_0,$$

so

$$\lim_{t\to\infty} \mathscr{L}(t) = \lim_{t\to\infty} L(V_1, V_2) = 0,$$

which with (2.15) gives the result.

We will show that the theorem is not true, if the assumption $k_1\lambda_0 + \gamma < 0$ does not hold.

THEOREM 2.5. *Assume* $k_1\lambda_0 + \gamma \geqq 0$. *Then there exist at least two nonnegative equilibrium solutions for* (1.1)–(1.3)$_{\text{I}}$. *Therefore it is impossible for the solution* (0, 0, 0) *to be globally stable.*

Proof. It suffices to prove that there exists a nontrivial nonnegative solution for the following problem:

$$\begin{aligned} &k_1\Delta S + S\left(\gamma - \frac{\gamma}{K}S - \frac{M_1 V_1}{y_1(a_1+S)} - \frac{M_2 V_2}{y_2(a_2+S)}\right) = 0, \\ &k_2\Delta V_1 + V_1\left(\frac{M_1 S}{a_1+S} - D_1\right) = 0, \qquad x \in \Omega, \\ &k_3\Delta V_2 + V_2\left(\frac{M_2 S}{a_2+S} - D_2\right) = 0, \\ &S(x) = V_1(x) = V_2(x) = 0 \quad \text{on } \partial\Omega. \end{aligned}$$

In fact, we may take $V_i(x)$ as $V_i(x) \equiv 0$, $i = 1, 2$, and $S(x)$ as the nonnegative solution of the following problem:

$$\begin{aligned} &k_1\Delta S + S\left(\gamma - \frac{\gamma}{K}S\right) = 0, \qquad x \in \Omega, \\ &S|_{\partial\Omega} = 0, \end{aligned}$$

i.e.

$$\begin{aligned} &-\Delta S = \frac{\gamma}{k_1}S\left(1 - \frac{S}{K}\right), \\ &S|_{\partial\Omega} = 0. \end{aligned} \tag{2.16}$$

Due to $k_1\lambda_0+\gamma \geqq 0$ it can be shown, by comparison theorems and monotonicity methods, (cf. [12]) that there exists a unique solution $S^*(x)$ for (2.16) such that $0 < S^*(x) \leqq K$, $x \in \Omega$. Thus, $(S^*(x), 0, 0)$ is a nontrivial solution for (1.1)-(1.3)$_{\mathrm{I}}$ which is nonnegative. Therefore, $(0, 0, 0)$ cannot be globally stable.

We discuss the stability of $U^* = (S^*(x), 0, 0)$ now. We adopt a standard "linearization procedure" relative to the nontrivial equilibrium solution U^*. In doing so, we take the linear expansion of F at U^*, i.e., $F(U^*+U) = F(U^*) + BU + g(U)$ and make a careful analysis of the spectrum of $\mathcal{U} = A + B$.

Consider

$$F(U^*+U) = \begin{pmatrix} f_1(U^*+U) \\ f_2(U^*+U) \\ f_3(U^*+U) \end{pmatrix}$$

where

$$\begin{aligned} f_1(U^*+U) &= -\frac{M_1V_1}{y_1} - \frac{M_2V_2}{y_2} - \frac{\gamma}{K}(S+S^*)^2 + \frac{M_1V_1a_1}{y_1(a_1+S+S^*)} + \frac{M_2V_2a_2}{y_2(a_2+S+S^*)} \\ &= -\frac{M_1V_1}{y_1} - \frac{M_2V_2}{y_2} - \frac{\gamma}{K}S^2 - \frac{2\gamma}{K}S^*S - \frac{\gamma}{K}S^* + \frac{M_1a_1}{y_1(a_1+S^*)}V_1 \\ &\quad - \frac{M_1a_1}{y_1(a_1+S^*)(a_1+S+S^*)}V_1S + \frac{M_2a_2}{y_2(a_2+S^*)}V_2 \\ &\quad - \frac{M_2a_2}{y_2(a_2+S^*)(a_2+S+S^*)}V_2S \\ &= f_1(U^*) - \frac{S^*M_1V_1}{y_1(a_1+S^*)} - \frac{S^*M_2V_2}{y_2(a_2+S^*)} - \frac{2\gamma}{K}S^*S \\ &\quad - \frac{\gamma}{K}S^2 - \frac{M_1a_1V_1S}{y_1(a_1+S^*)(a_1+S^*+S)} - \frac{M_2a_2V_2S}{y_2(a_2+S^*)(a_2+S^*+S)}, \\ f_2(U^*+U) &= -\frac{M_1a_1V_1}{a_1+S+S^*} = -\frac{M_1a_1}{a_1+S^*}V_1 + \frac{M_1a_1}{(a_1+S^*)(a_1+S^*+S)}V_1S, \\ f_3(U^*+U) &= -\frac{M_2a_2V_2}{a_2+S+S^*} = -\frac{M_2a_2}{a_2+S^*}V_2 + \frac{M_2a_2}{(a_2+S^*)(a_2+S^*+S)}V_2S. \end{aligned}$$

Thus

$$B = \begin{bmatrix} -\dfrac{2\gamma}{K}S^* & -\dfrac{M_1S^*}{y_1(a_1+S^*)} & -\dfrac{M_2S^*}{y_2(a_2+S^*)} \\ 0 & -\dfrac{M_1a_1}{a_1+S^*} & 0 \\ 0 & 0 & -\dfrac{M_2a_2}{a_2+S^*} \end{bmatrix}, \tag{2.17}$$

$$g(U) = \begin{pmatrix} -\dfrac{M_1a_1V_1S}{y_1(a_1+S^*)(a_1+S^*+S)} - \dfrac{M_2a_2V_2S}{y_2(a_2+S^*)(a_2+S^*+S)} - \dfrac{\gamma}{K}S^2 \\ \dfrac{M_1a_1V_1S}{(a_1+S^*)(a_1+S^*+S)} \\ \dfrac{M_2a_2V_2S}{(a_2+S^*)(a_2+S^*+S)} \end{pmatrix}. \tag{2.18}$$

Let us recall a theorem about stability by the linear approximation [4].

Let A be a sectorial linear operator in a Banach space X, and let $f: U \to X$ where U is a cylindrical neighborhood in $\mathbb{R} \times X^\alpha$ (for some $\alpha < 1$) of $(\tau, \infty) \times \{x_0\}$. We say x_0 is an equilibrium point if $x(t) \equiv x_0$ is a solution of $(dx/dt) + Ax = f(t, x)$, $t > t_0$, i.e. if $x_0 \in D(A)$ and $Ax_0 = f(t, x_0)$ for all $t > t_0$.

A solution $\bar{x}(\cdot)$ on $[t_0, \infty)$ is stable (in X^α) if, for any $\varepsilon > 0$, there exists $\delta > 0$ such that any solution x with $\|x(t_0) - \bar{x}(t_0)\|_\alpha < \delta$ exists on $[t_0, \infty)$ and satisfies $\|x(t) - \bar{x}(t)\|_\alpha < \varepsilon$ for all $t \geqq t_0$; that is, if $x_0 \mapsto x(t; t_0, x_0)$ is continuous (in X^α) at $x_0 = \bar{x}(t_0)$, uniformly in $t \geqq t_0$. The solution $\bar{x}$ is uniformly stable if $x_1 \mapsto x(t; t_1, x_1)$ is continuous as $x_1 \mapsto \bar{x}(t_1)$, uniformly in $t \geqq t_1$ and $t_1 \geqq t_0$.

The solution $\bar{x}(\cdot)$ is uniformly asymptotically stable if it is uniformly stable and $\|x(t; t_1, x_1) - \bar{x}(t)\| \to 0$ as $|t - t_1| \to +\infty$, uniformly in $t_1 \geqq t_0$ and $\|x_1 - \bar{x}(t_1)\|_\alpha < \delta$ for some constant $\delta > 0$.

PROPOSITION 2.4 (cf. [4, Thm. 5.1.1]). *Let A, f be as above and let x_0 be an equilibrium point. Suppose*

$$f(t, x_0 + z) = f(t, x_0) + Bz + g(t, z)$$

where B is a bounded linear map from X^α to X and $\|g(t, z)\| = O(\|z\|_\alpha)$ as $\|z\|_\alpha \to 0$, uniformly in $t > \tau$, and $f(t, x)$ is locally Hölder continuous in t, locally Lipschitzian in x, on U.

If the spectrum of $A-B$ lies in $\{\operatorname{Re} \lambda > \beta\}$ for some $\beta > 0$, or equivalently if the linearization

$$\frac{dz}{dt} + Az = Bz$$

is uniformly asymptotically stable, then the original equation has the solution x_0 uniformly asymptotically stable in X^α. More precisely, there exist $\rho > 0$, $M \geqq 1$ such that if $t_0 > \tau$ and $\|x_1 - x_0\|_\alpha \leqq \rho/2M$, then there exists a unique solution of

$$\frac{dx}{dt} + Ax = f(t, x), \quad t > t_0, \quad x(t_0) = x_1$$

existing on $t_0 \leqq t < \infty$ and satisfying for $t \geqq t_0$

$$\|x(t; t_0, x_1) - x_0\|_\alpha \leqq 2M e^{-\beta(t - t_0)} \|x_1 - x_0\|_\alpha.$$

From (2.17), (2.18), it is easy to check the validity of Proposition 2.4 for our case. Then, in order to investigate the stability property of U^*, it suffices to analyze the spectrum of $\mathcal{U} = A + B$.

Let us write down the resolvent equation for $\mathcal{U}$:

$$(A + B - \mu I) U = V, \quad \mu \in \mathbb{C}, \quad V \in X,$$

where

$$U = (u_1, u_2, u_3), \qquad V = (V_1, V_2, V_3).$$

Namely,

$$\begin{aligned} &\left(A_1 - \frac{2\gamma}{K} S^* - \mu\right) u_1 - \frac{M_1 S^*}{y_1(a_1 + S^*)} u_2 - \frac{M_2 S^*}{y_2(a_2 + S^*)} u_3 = V_1, \\ &\left(A_2 - \frac{M_1 a_1}{a_1 + S^*} - \mu\right) u_2 = V_2, \\ &\left(A_3 - \frac{M_2 a_2}{a_2 + S^*} - \mu\right) u_3 = V_3. \end{aligned} \tag{2.19}$$

As

$$\mu \in \rho\left(A_2 - \frac{M_1 a_1}{a_1 + S^*}\right) \cap \rho\left(A_3 - \frac{M_2 a_2}{a_2 + S^*}\right),$$

the system (2.19) can be written as

$$\left(A_1 - \frac{2\gamma}{K} S^* - \mu\right) u_1 = V_1 + \frac{M_1 S^*}{y_1(a_1 + S^*)} R\left(\mu, A_2 - \frac{a_1 M_1}{a_1 + S^*}\right) V_2 + \frac{M_2 S^*}{y_2(a_2 + S^*)} R\left(\mu, A_3 - \frac{a_2 M_2}{a_2 + S^*}\right) V_3,$$

$$u_2 = R\left(\mu, A_2 - \frac{M_1 a_1}{a_1 + S^*}\right) V_2,$$

$$u_3 = R\left(\mu, A_3 - \frac{M_2 a_2}{a_2 + S^*}\right) V_3.$$

Denote

$$\bar{A}_1 = A_1 - \frac{2\gamma}{K} S^* - \mu, \qquad \bar{A}_2 = A_2 - \frac{M_1 a_1}{a_1 + S^*}, \qquad \bar{A}_3 = A_3 - \frac{M_2 a_2}{a_2 + S^*}.$$

Set $\mathcal{B} = \{\mu \colon \mu \in \rho(\bar{A}_2) \cap \rho(\bar{A}_3),\ \bar{A}_1(\mu) \text{ is invertible in } L^2(\Omega)\}$. The following lemma is easily proved.

LEMMA 2.6. *$\rho(\mathcal{U}) \supset \mathcal{B}$ and $R(\mu, \mathcal{U})$ is given by*

$$R(\mu, \mathcal{U}) = \begin{bmatrix} \bar{A}_1^{-1}(\mu) & \bar{A}_1^{-1} \dfrac{M_1 S^*}{y_1(a_1 + S^*)} R(\mu, \bar{A}_2) & \bar{A}_1^{-1} \dfrac{M_2 S^*}{y_2(a_2 + S^*)} R(\mu, \bar{A}_3) \\ 0 & R(\mu, \bar{A}_2) & 0 \\ 0 & 0 & R(\mu, \bar{A}_3) \end{bmatrix} \quad \textit{for } \mu \in \rho(\mathcal{U}).$$

Thus, in order to analyze the spectrum of $\mathcal{U}$, we have to discuss the invertibility of $\bar{A}_1(\mu)$. Clearly, the following lemma can be obtained.

LEMMA 2.7. *The operator $\bar{A}_1(\mu)$, $\mu \in \rho(\bar{A}_2) \cap \rho(\bar{A}_3)$ is invertible in $L^2(\Omega)$ if and only if zero is not an eigenvalue of $\bar{A}_1(\mu)$.*

Set $K^* = \max\{\operatorname{Re} \lambda,\ \lambda \in \sigma(\bar{A}_2) \cup \sigma(\bar{A}_3)\}$.

LEMMA 2.8. *Assume $K^* < 0$; then there exist $\theta^* \in (0, (\pi/2))$ and $\gamma^* > 0$ such that (see Fig. 1)*

$$\mathcal{B} \supset S^* = \left\{\mu \,\middle|\, |\arg(\mu + \gamma^*)| \leq \frac{\pi}{2} + \theta^*\right\}.$$

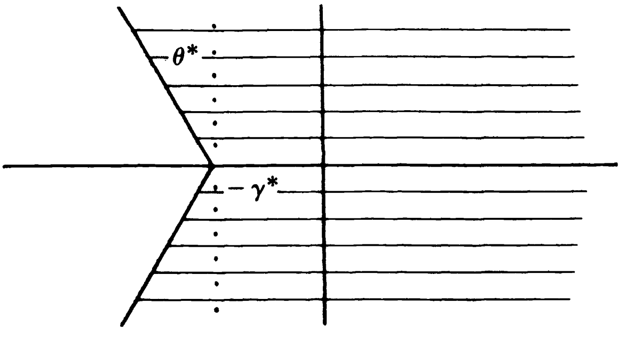

FIG. 1

Proof. Due to Lemma 2.7, it suffices to show that there exist $\theta^* \in (0, (\pi/2))$ and $\gamma^* > 0$ such that $\bar{A}_1(\mu)$ does not have zero as an eigenvalue whenever μ belongs to S^*.

Denote an arbitrary eigenvalue of $\bar{A}_1(\mu)$ by $\zeta(\mu)$ and any eigenfunction belonging to the corresponding eigenspace $\bar{W}_\mu$ by $W(\mu)$, normalized to 1 in the L^2-norm. Let us put $\mu_1 = \operatorname{Re} \mu$, $u_2 = I_m\mu$, $\zeta_1(\mu_1, \mu_2) = \operatorname{Re} \zeta(\mu)$, $\zeta_2(\mu_1, \mu_2) = \operatorname{Im} \zeta(\mu)$. Due to

$$\bar{A}_1(\mu) W(\mu) = \zeta(\mu) W(\mu),$$
$$\langle \bar{A}_1(\mu) W(\mu), W(\mu) \rangle = \zeta(\mu),$$
$$\langle \bar{A}_1(\mu) W(\mu), W(\mu) \rangle = \left\langle \left(A_1 - \frac{\gamma}{K} S^* \right) W(\mu), W(\mu) \right\rangle + \left\langle -\frac{\gamma}{K} S^* W(\mu), W(\mu) \right\rangle - \mu,$$

it turns out that

$$\zeta_1(\mu_1, \mu_2) = \left\langle \left(A_1 - \frac{\gamma}{K} S^* \right) W(\mu), W(\mu) \right\rangle + \left\langle -\frac{\gamma}{K} S^* W(\mu), W(\mu) \right\rangle - \mu_1,$$
$$\xi_2(\mu_1, \mu_2) = -\mu_2.$$

Since $S^*(x) > 0$, $x \in \Omega$ satisfying $(A_1 - (\gamma/K) S^*) S^* = 0$, $S^*|_{\partial\Omega} = 0$, which means that the second order elliptic operator $A_1 - (\gamma/K) S^*$ has $S^* \in H_0^1(\Omega)$ as positive eigenfunction with zero eigenvalue, it follows that the pure point spectrum of $A_1 - (\gamma/K) S^*$ is localized on the nonpositive half-axis, and

$$\left\langle \left(A_1 - \frac{\gamma}{K} S^* \right) u, u \right\rangle \leqq 0 \quad \text{for any } u \in H_0^1(\Omega).$$

Therefore, $\zeta_1(\mu_1, \mu_2) \leqq -\mu_1 - \langle (\gamma/K) S^* W(\mu), W(\mu) \rangle < 0$ for any $\mu_1 \geqq 0$. In view of the inequality $\zeta_1(0, \mu_2) < 0$ and the continuous dependence of $\zeta(\mu)$ on μ, it turns out that there exist $c > 0$, $\alpha > 0$, $-\alpha \in (k^*, 0)$ such that

$$\zeta_1(\mu_1, \mu_2) < 0 \quad \text{for any } \mu \in \rho(\bar{A}_2) \cap \rho(\bar{A}_3) \quad \text{with } \mu_1 \in (-\alpha, 0),$$

$|\mu_2| \leqq C$, while $|\zeta_2(\mu_1, \mu_2)| = |\mu_2| > C > 0$ when $|\mu_2| > C$. These facts show that $\bar{A}_1(\mu)$, $\mu \in \rho(\bar{A}_2) \cap \rho(\bar{A}_3)$ has possibly zero as an eigenvalue only for such kind of μ belonging to the subset $\{\mu \in \rho(\bar{A}_2) \cap \rho(\bar{A}_3)$ with $\operatorname{Re} \mu < -\alpha$, $|\operatorname{Im} \mu| < C\}$. Then the lemma is proved for any $\theta^*(0, \operatorname{arctg}(\alpha - \gamma^*/C))$, $\gamma^* \in (0, \alpha)$. (See Fig. 2.)

It is easily seen from Lemmas 2.6–2.8, that [10]

LEMMA 2.9.

$$\sigma(\mathcal{U}) \subset \{\lambda \in \mathbb{C}, \operatorname{Re} \lambda < -\gamma^*\}.$$

This implies, by Proposition 2.4, the next theorem.

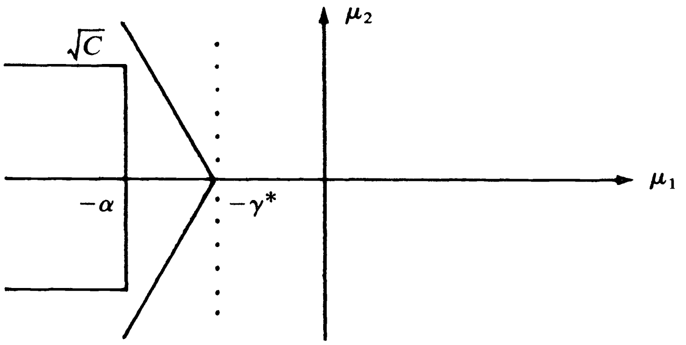

FIG. 2

THEOREM 2.6. *Assume $k_1\lambda_0+\gamma\geqq 0$ and $k^*<0$. Then the equilibrium solution $U^*=(S^*(x),0,0)$ is uniformly asymptotically stable in X^{α_0}. Namely, there exist $\rho>0$, $M\geqq 1$ such that if $\|U_0-U^*\|_{\alpha_0}\leqq \rho/2M$, $U_0\geqq 0$, then there exists a unique solution $U(t)$ of (2.3) on $0\leqq t<+\infty$ satisfying*

$$\|U(t)-U^*\|_{\alpha_0}\leqq 2Me^{-\gamma^*t}\|U_0-U^*\|_{\alpha_0}\to 0 \quad as\ t\to+\infty.$$

3. The case of Neumann conditions. We deal with problems (1.1), (1.2) and $(1.3)_{\text{II}}$ in this section. First, consider the following general form.

$$\begin{aligned} &u_{1t}-k_1\Delta u_1=f_1(u_1,u_2,u_3),\\ &u_{2t}-k_2\Delta u_2=f_2(u_1,u_2), \qquad \text{in } R^+\times\Omega,\\ &u_{3t}-k_3\Delta u_3=f_3(u_1,u_3), \end{aligned} \tag{3.1}$$

together with the boundary and initial conditions

$$B_i[u_i]\equiv\alpha_i(x)\frac{\partial u_i}{\partial n}+\beta_i(x)u_i=0 \quad \text{on } \partial\Omega\times R^+, \tag{3.2}$$

$$u_i(0,x)=u_{0i}(x) \quad \text{on } \Omega \tag{3.3}$$

where Ω is a bounded domain in R^n $(n=1,2,\cdots)$, $\partial\Omega$ is the boundary of Ω, $\alpha_i\geqq 0$, $\beta_i\geqq 0$ with $\alpha_i+\beta_i>0$ on $\partial\Omega$, $i=1,2,3$. $\partial/\partial n$ represents the outward normal derivative at the boundary.

Assume that α_i, β_i, u_{0i} are smooth nonnegative functions with $u_{0i}\not\equiv 0$, f_1 is continuously differentiable in $R^+\times R^+\times R^+$ and f_2, f_3 is continuously differentiable in $R^+\times R^+$. Ω is smooth, $\partial\Omega$ belongs to $C^{1+\alpha}$ $(\alpha>0)$. In addition, in order to employ the monotone argument to establish an existence-comparison theorem in terms of upper and lower solutions for (3.1)-(3.3), we assume

$$\begin{aligned} &\frac{\partial f_1}{\partial u_2}(u_1,u_2,u_3)\leqq 0, \qquad \frac{\partial f_1}{\partial u_3}(u_1,u_2,u_3)\leqq 0,\\ &\frac{\partial f_2}{\partial u_1}\geqq 0, \quad \frac{\partial f_3}{\partial u_1}\geqq 0 \quad \text{for } u_i\geqq 0, \quad i=1,2,3. \end{aligned} \tag{H}$$

Obviously, the reaction terms in our model (1.1) satisfy (H). The precise definition of upper and lower solutions are given as follows.

DEFINITION 3.1. Let $\bar U=(\bar u_1,\bar u_2,\bar u_3)$, $\underline{U}=(\underline{u}_1,\underline{u}_2,\underline{u}_3)$ be an ordered pair of smooth functions in D_T satisfying the following inequalities (3.4), (3.5), (3.6). Then $\bar U$, $\underline{U}$ are called upper and lower solutions of (3.1)-(3.3), respectively.

$$\begin{aligned} &\bar u_{1t}-k_1\Delta\bar u_1\geqq f_1(\bar u_1,\underline{u}_2,\underline{u}_3),\\ &\bar u_{2t}-k_2\Delta\bar u_2\geqq f_2(\bar u_1,\bar u_2), \qquad (t,x)\in D_T,\\ &\bar u_{3t}-k_3\Delta\bar u_3\geqq f_3(\bar u_1,\bar u_3), \end{aligned} \tag{3.4}$$

$$\begin{aligned} &\underline{u}_{1t}-k_1\Delta\underline{u}_1\leqq f_1(\underline{u}_1,\bar u_2,\bar u_3),\\ &\underline{u}_{2t}-k_2\Delta\underline{u}_2\leqq f_2(\underline{u}_1,\underline{u}_2), \qquad (t,x)\in D_T,\\ &\underline{u}_{3t}-k_3\Delta\underline{u}_3\leqq f_3(\underline{u}_1,\underline{u}_3), \end{aligned} \tag{3.5}$$

$$(3.6)\qquad \begin{aligned} &B_i[\bar{u}_i] \geqq 0 \geqq B_i[\underline{u}_i], \quad (t,x)\in S_T,\\ &\bar{u}_i(0,x) \geqq u_{i0}(x) \geqq \underline{u}_i(0,x), \quad x\in\Omega, \quad i=1,2,3, \end{aligned}$$

where $D_T=(0,T]\times\Omega$, $S_T=(0,T]\times\partial\Omega$, $T<\infty$ but can be arbitrarily large.

Suppose that for given reaction functions f_1, f_2, f_3 satisfying the above assumptions there exists an ordered pair of upper and lower solutions $\bar{U}=(\bar{u}_1,\bar{u}_2,\bar{u}_3)$, $\underline{U}=(\underline{u}_1,\underline{u}_2,\underline{u}_3)$. Define

$$\mathscr{L}(D_T)=\{(u_1,u_2,u_3)\colon u_i\in C(\bar{D}_T),\ \underline{u}_i\leqq u_i\leqq\bar{u}_i \text{ on } \bar{D}_T,\ i=1,2,3\}$$

and set

$$(3.7)\qquad l_i=\sup_{(u_1,u_2,u_3)\in\mathscr{L}(D_T)}\left\{\left|\frac{\partial f_i}{\partial u_i}\right|\right\}.$$

To establish an existence-comparison theorem we consider the sequence $\{U^{(k)}\}=\{u_1^{(k)}, u_2^{(k)}, u_3^{(k)}\}$ obtained from the linear problem.

$$(3.8)\qquad (u_i^{(k)})_+ - k_i\Delta u_i^{(k)} + l_i u_i^{(k)} = l_i u_i^{(k-1)} + f_i(u_1^{(k-1)}, u_2^{(k-1)}, u_3^{(k-1)}), \quad (t,x)\in D_T,$$

$$(3.9)\qquad B_i[u_i^{(k)}]=0, \quad (t,x)\in S_T,$$

$$(3.10)\qquad u_i^{(k)}(0,x)=u_{i0}(x), \quad x\in\Omega$$

where $i=1,2,3$ and $k=1,2,\cdots$.

For each k, the above system consists of three linear uncoupled initial-boundary value problems. Therefore the existence of $\{u_1^{(k)}, u_2^{(k)}, u_3^{(k)}\}$ follows from the standard existence theorem for scalar systems. To ensure that $\{u_1^{(k)}, u_2^{(k)}, u_3^{(k)}\}$ is a monotone sequence and converges to a unique solution of (3.1)-(3.3) we use the initial iteration $(\bar{u}_1^{(0)}, \underline{u}_2^{(0)}, \underline{u}_3^{(0)})=(\bar{u}_1, \underline{u}_2, \underline{u}_3)$ to construct the sequence $\{\bar{u}_1^{(k)}, \underline{u}_2^{(k)}, \underline{u}_3^{(k)}\}$ from the equations

$$(3.11)\qquad \begin{aligned} &\bar{u}_{1t}^{(k)} - k_1\Delta\bar{u}_1^{(k)} + l_1\bar{u}_1^{(k)} = l_1\bar{u}_1^{(k-1)} + f_1(\bar{u}_1^{(k-1)}, \underline{u}_2^{(k-1)}, \underline{u}_3^{(k-1)}),\\ &\underline{u}_{2t}^{(k)} - k_2\Delta\underline{u}_2^{(k)} + l_2\underline{u}_2^{(k)} = l_2\underline{u}_2^{(k-1)} + f_2(\underline{u}_1^{(k-1)}, \underline{u}_2^{(k-1)}),\\ &\underline{u}_{3t}^{(k)} - k_3\Delta\underline{u}_3^{(k)} + l_3\underline{u}_3^{(k)} = l_3\underline{u}_3^{(k-1)} + f_3(\underline{u}_1^{(k-1)}, \underline{u}_3^{(k-1)}), \end{aligned}$$

while the sequence $\{\underline{u}_1^{(k)}, \bar{u}_2^{(k)}, \bar{u}_3^{(k)}\}$ with $(\underline{u}_1^{(0)}, \bar{u}_2^{(0)}, \bar{u}_3^{(0)})=(\underline{u}_1, \bar{u}_2, \bar{u}_3)$ is determined from the equations

$$(3.12)\qquad \begin{aligned} &\underline{u}_{1t}^{(k)} - k_1\Delta\underline{u}_1^{(k)} + l_1\underline{u}_1^{(k)} = l_1\underline{u}_1^{(k-1)} + f_1(\underline{u}_1^{(k-1)}, \bar{u}_2^{(k-1)}, \bar{u}_3^{(k-1)}),\\ &\bar{u}_{2t}^{(k)} - k_2\Delta\bar{u}_2^{(k)} + l_2\bar{u}_2^{(k)} = l_2\bar{u}_2^{(k-1)} + f_2(\bar{u}_1^{(k-1)}, \bar{u}_2^{(k-1)}),\\ &\bar{u}_{3t}^{(k)} - k_3\Delta\bar{u}_3^{(k)} + l_3\bar{u}_3^{(k)} = l_3\bar{u}_3^{(k-1)} + f_3(\bar{u}_1^{(k-1)}, \bar{u}_3^{(k-1)}). \end{aligned}$$

In each system, the boundary and initial conditions are (3.9), (3.10). These two systems are interrelated. With this construction we prove our existence-comparison theorem.

THEOREM 3.1. *Suppose the pair of upper and lower solution* $(\bar{u}_1, \bar{u}_2, \bar{u}_3)$, $(\underline{u}_1, \underline{u}_2, \underline{u}_3)$ *can be chosen. Then the sequences*

$$\{\bar{U}^{(k)}\}=\{\bar{u}_1^{(k)}, \bar{u}_2^{(k)}, \bar{u}_3^{(k)}\}, \qquad \{\underline{U}^{(k)}\}=\{\underline{u}_1^{(k)}, \underline{u}_2^{(k)}, \underline{u}_3^{(k)}\}$$

obtained from (3.11), (3.12), (3.9) *and* (3.10) *converge monotonically from above and below, respectively, to a unique solution* $\{u_1, u_2, u_3\}$ *of* (3.1)-(3.3) *such that*

$$\underline{u}_i(t,x)\leqq u_i(t,x)\leqq\bar{u}_i(t,x), \quad (t,x)\in\bar{D}_T, \quad i=1,2,3.$$

Proof. Let $u_1^* = \bar{u}_1 - \bar{u}_1^{(1)}$, $u_2^* = \underline{u}_2^{(1)} - \underline{u}_2$, $u_3^* = \underline{u}_3^{(1)} - \underline{u}_3$. Then by (3.4), (3.5), (3.6), (3.11) and (3.12), it follows that

$$u_{it}^* - k_i \Delta u_i^* + l_i u_i^* \geqq 0, \tag{3.13}$$

$$B_i[u_i^*] \geqq 0, \tag{3.14}$$

$$u_i^*(0, x) \geqq 0, \qquad i = 1, 2, 3. \tag{3.15}$$

By the maximum principle, the above inequalities imply that $u_i^* \geqq 0$ on D_T, $i = 1, 2, 3$; namely, $\bar{u}_1 \geqq \bar{u}_1^{(1)}$, $\underline{u}_2 \leqq \underline{u}_2^{(1)}$, $\underline{u}_3 \leqq \underline{u}_3^{(1)}$. Similarly, it can be shown that $\underline{u}_1 \leqq \underline{u}_1^{(1)}$, $\bar{u}_2 \geqq \bar{u}_2^{(1)}$, $\bar{u}_3 \geqq \bar{u}_3^{(1)}$.

Now let $u_i^* = \bar{u}_i^{(1)} - \underline{u}_i^{(1)}$; then the assumptions (H), (3.7) and the relations in (3.11) and (3.12) imply that

$$u_{it}^* - k_i \Delta u_i^* + l_i u_i^* \geqq 0, \qquad i = 1, 2, 3.$$

Since $B_i[u_i^*] = 0$, $u_i^*(0, x) = 0$ by using the maximum principle we obtain $u_i^* \geqq 0$, i.e., $\underline{u}_i^{(1)} \leqq \bar{u}_i^{(1)}$, $i = 1, 2, 3$. The above conclusions lead to the relation

$$\underline{u}_i = \underline{u}_i^{(0)} \leqq \underline{u}_i^{(1)} \leqq \bar{u}_i^{(1)} \leqq \bar{u}_i^{(0)} = \bar{u}_i, \qquad i = 1, 2, 3.$$

Then, by induction, it is not difficult to show that

$$\underline{u}_i^{(k-1)} \leqq \underline{u}_i^{(k)} \leqq \bar{u}_i^{(k)} \leqq \bar{u}_i^{(k-1)}, \quad i = 1, 2, 3, \quad k = 1, 2, \cdots.$$

It follows from this monotone property that the pointwise limits $\lim_{k\to\infty} \bar{u}_i^{(k)}(t, x) = \tilde{u}_i(t, x)$, $\lim_{k\to\infty} \underline{u}_i^{(k)}(t, x) = \underset{\sim}{u}_i(t, x)$, $i = 1, 2, 3$, exist and $\underset{\sim}{u}_i \leqq \tilde{u}_i$ on $\bar{D}_T$.

By a standard regularity argument and the similar approach used by Pao in [11], it can be shown that $(\underset{\sim}{u}_1, \underset{\sim}{u}_2, \underset{\sim}{u}_3) = (\tilde{u}_1, \tilde{u}_2, \tilde{u}_3) = (u_1, u_2, u_3)$ is the unique solution of (3.1)-(3.3). Obviously, the solution (u_1, u_2, u_3) satisfies $\underline{u}_i \leqq u_i \leqq \bar{u}_i$, $i = 1, 2, 3$. Theorem 3.1 is proved.

For our problem (1.1)-(1.3)$_{\text{II}}$, we choose the pair of upper and lower solution as follows:

Set

$$\hat{S} = \sup_{\bar{\Omega}} S_0(x), \qquad \hat{V}_i = \sup_{\bar{\Omega}} V_{i0}(x), \qquad i = 1, 2.$$

Then solving the following problem:

$$\begin{aligned} &\dot{S}(t) = \gamma S - \frac{\gamma}{K} S^2, && S(0) = \hat{s}, \\ &\dot{V}_1(t) = \left(\frac{M_1 S}{a_1 + S} - D_1\right) V_1, && V_1(0) = \hat{V}_1, \\ &\dot{V}_2(t) = \left(\frac{M_2 S}{a_2 + S} - D_2\right) V_2, && V_2(0) = \hat{V}_2, \end{aligned} \tag{3.16}$$

we obtain

$$\begin{aligned} &S(t) = \frac{K}{1 + \left(\dfrac{K - \hat{s}}{\hat{s}}\right) e^{-\gamma t}}, \\ &V_i(t) = \hat{V}_i \exp\left[\int_0^t \left(\frac{M_i S(\eta)}{a_i + S(\eta)} - D_i\right) d\eta\right], \qquad i = 1, 2. \end{aligned} \tag{3.17}$$

Clearly, $(0,0,0)$ and $(S(t), V_1(t), V_2(t))$ are a pair of lower and upper solutions of (1.1)-$(1.3)_{\text{II}}$. Thus, Theorem 3.1 implies the following.

THEOREM 3.2. *There exists a unique solution of* (1.1)-$(1.3)_{\text{II}}$ *for* $(t,x)\in R^+\times\Omega$, *such that*

$$\begin{aligned} &0\leqq S(t,x)\leqq K\left[1+\frac{K-\hat{s}}{\hat{s}}\exp(-\gamma t)\right]^{-1}=S(t),\\ &0\leqq V_i(t,x)\leqq \hat{V}_i\exp[B_i(t)] \end{aligned}\tag{3.18}$$

where

$$B_i(t)=\int_0^t\left[\frac{M_iS(\eta)}{a_i+S(\eta)}-D_i\right]d\eta,\qquad i=1,2.$$

We next investigate the asymptotic properties of the solution.

From (3.16), (3.17) it is easy to see that $S(t)$ is increasing with $S(t)<K$ and $S(t)\to K$ as $t\to+\infty$ if $\hat{s}<K$, while $S(t)$ is decreasing with $S(t)>K$ and $S(t)\to K$ as $t\to+\infty$ if $\hat{s}>K$.

We consider the case $\hat{s}\leqq K$ first.

THEOREM 3.3. *Let* $M_iK/(a_i+K)<D_i$ $(i=1,2)$ *and* $0<S_0(x)\leqq K$ *for* $x\in\bar{\Omega}$. *Then the unique global solution* (S, V_1, V_2) *to the Neumann problem* (1.1)-$(1.3)_{\text{II}}$ *satisfies*

$$\lim_{t\to\infty}S(t,x)=K,\quad \lim_{t\to\infty}V_i(t,x)=0,\quad i=1,2.\tag{3.19}$$

Proof. Instead of (3.16) we consider

$$\begin{aligned} &\dot{S}(t)=0, \qquad S(0)=K,\\ &\dot{\bar{V}}_i(t)=\left(\frac{M_iK}{a_i+K}-D_i\right)\bar{V}_i,\quad \bar{V}_i(0)=\hat{V}_i,\quad i=1,2. \end{aligned}\tag{3.20}$$

In view of $S_0(x)\leqq k$, the solution $\{K, \bar{V}_1(t), \bar{V}_2(t)\}$ of (3.20) is also an upper solution of (1.1), (1.2), $(1.3)_{\text{II}}$. This implies

$$\lim_{t\to\infty}V_i(t,x)=0,\qquad i=1,2.$$

Let $\underline{S}_0=\inf_{\bar{\Omega}}S_0(x)>0$ and define $\underline{S}(t)$ as follows

$$\begin{aligned} &\frac{d\underline{S}(t)}{dt}=\gamma\underline{S}-\frac{\gamma}{K}\underline{S}^2-\frac{M_1}{y_1}\frac{\bar{V}_1(t)\underline{S}}{a_1+\underline{S}}-\frac{M_2}{y_2}\frac{\bar{V}_2(t)\underline{S}}{a_2+\underline{S}},\\ &\underline{S}(0)=\underline{S}_0 \end{aligned}\tag{3.21}$$

where $\bar{V}_1(t)$ and $\bar{V}_2(t)$ are determined by (3.20).

To show the first relation in (3.19) we recall the following definition and a theorem of Markus [9].

DEFINITION (Markus). Let A: $x_i'=f_i(x,t)$ and A_∞: $x_i'=f_i(x)$ $(i=1,2,\cdots,n)$ be a first order system of ordinary differential equations. The real-valued functions $f_i(x,t)$ and $f_i(x)$ are continuous in (x,t) for $x\in G$, where G is an open subset of $\mathbb{R}^n$, and for $t>t_0$ and they satisfy a local Lipschitz condition in x. A is said to be asymptotic to $A_\infty(A\to A_\infty)$ in G if for each compact set $K\subset G$ and for each $\varepsilon>0$, there is a $T=T(k,\varepsilon)>t_0$ such that $|f_i(x,t)-f_i(x)|<\varepsilon$ for all $i=1,2,\cdots,n$, all $x\in K$, and all $t>T$.

THEOREM (Markus). *Let* $A\to A_\infty$ *in* G *and let* p *be an asymptotically stable critical point of* A_∞. *Then there is a neighborhood* N *of* p *and a time* T *such that the omega limit set for every solution* $x(t)$ *of* A *which intersects* N *at a time later than* T *is equal to* p.

Now let us turn to (3.21). Since $\bar{V}_i(t)\to 0$ as $t\to\infty$, $(i=1,2)$ and $S\equiv K$ is an asymptotically stable solution of

$$\frac{dS}{dt}=\gamma S-\frac{\gamma}{K}S^2, \tag{3.22}$$

regarding the equations in (3.21) and (3.22) as A and A_∞ in Markus theorem respectively, it follows that $\underline{S}(t)\to K$ as $t\to+\infty$. On the other hand, it can be shown that $(\underline{S}(t), 0, 0)$ is a lower solution, which, together with the upper solution $(K, \bar{V}_1(t), \bar{V}_2(t))$, leads to

$$\lim_{t\to\infty} S(t, x)=K.$$

Now we consider the general case without the restriction $\hat{S}\leqq K$.

THEOREM 3.4. *Let* $M_iK/(a_i+K)<D_i$ $(i=1,2)$ *and* $\inf_{\bar{\Omega}} s_0(x)>0$. *Then the solution of* (S, V_1, V_2) *to the Neumann problem* (1.1), (1.2) *and* $(1.3)_{\text{II}}$ *satisfies* $\lim_{t\to\infty} S(x, t)=K$, $\lim_{t\to\infty} V_i(x, t)=0$.

Proof. Take a lower solution $(\underline{S}(t), 0, 0)$ and the upper solution $(\bar{S}(t), V_1(t), V_2(t))$ as follows:

$$\tag{3.23}\begin{aligned}
&\frac{d\bar{S}}{dt}=\gamma\bar{S}-\frac{\gamma}{K}\bar{S}^2, && \bar{S}(0)=\hat{S},\\
&\frac{d\underline{S}}{dt}=\gamma\underline{S}-\frac{\gamma}{K}\underline{S}^2-\frac{M_1}{y_1}\frac{V_1\underline{S}}{(a_1+\underline{S})}-\frac{M_2}{y_2}\frac{V_2\underline{S}}{(a_2+\underline{S})}, && \underline{S}(0)=\underline{S}_0,\\
&\frac{dV_1}{dt}=\left(\frac{M_2\bar{S}}{a_1+\bar{S}}-D_1\right)V_1, && V_1(0)=\hat{V}_1,\\
&\frac{dV_2}{dt}=\left(\frac{M_2\bar{S}}{a_2+\bar{S}}-D_2\right)V_2, && V_2(0)=\hat{V}_2
\end{aligned}$$

where the definitions of $\hat{s}$, $\underline{s}_0$, $\hat{V}_i$ are the same as before. Namely

$$\hat{S}=\sup_{\bar{\Omega}} S_0(x)<+\infty,\quad \underline{S}_0=\inf_{\bar{\Omega}} S_0(x)>0,\quad \hat{V}_i=\sup_{\bar{\Omega}} V_{i0}(x)>0,\quad i=1,2.$$

Since $M_iK/(a_i+K)<D_i$, there exists $\varepsilon>0$ such that

$$\frac{M_i(K+\varepsilon)}{a_i+(K+\varepsilon)}<D_i,\qquad i=1,2. \tag{3.24}$$

On the other hand, in view of the property of the solution of $(3.23)_1$, there exists $T_0>0$ such that

$$\bar{S}(t)<k+\varepsilon\quad\text{for } t>T_0. \tag{3.25}$$

Denote

$$\exp\left\{\int_0^{T_0}\left[\frac{M_i\bar{S}(\eta)}{a_i+\bar{S}(\eta)}-D_i\right]d\eta\right\}\text{ by } A(T_0),$$

it follows by (3.24) and (3.25) that

$$V_i(t)\leqq V_i(0)A(T_0)\exp\left[\frac{M_i(K+\varepsilon)}{a_i+(K+\varepsilon)}-D_i\right](t-T_0)\quad\text{for } t>T_0.$$

Hence, $V_i(t)\to 0$ as $t\to+\infty$. Then, the theorem of Markus leads to $\lim_{t\to\infty}\underline{S}(t)=k$. By Theorem 3.1, it is known that

$$0\leqq V_i(t, x)\leqq V_i(t),\qquad \underline{S}(t)\leqq S(t, x)\leqq\bar{S}(t).$$

Therefore

$$\lim_{t\to+\infty} S(t,x)=K, \quad \lim_{t\to+\infty} V_i(t,x)=0 \quad (i=1,2) \text{ uniformly for } x\in\Omega.$$

Next, we consider the case when one of the assumptions $M_iK/(a_i+K)<D_i$ does not hold, namely, either

$$\frac{M_1K}{a_1+K}\geqq D_1, \quad \frac{M_2K}{a_2+K}<D_2 \tag{3.26}$$

or

$$\frac{M_1K}{a_1+K}<D_1, \quad \frac{M_2K}{a_2+K}\geqq D_2. \tag{3.27}$$

For (3.26), the same argument used in the proof of Theorem 3.4 shows that $V_2(x; t)\to 0$ as $t\to+\infty$. Then it is natural to investigate the stability of $(\lambda_1, V_1^*, 0)$, which is a solution of (1.1), $(1.3)_{\text{II}}$. Where $\lambda_1=a_1D_1/(M_1-D_1)>0$ (this is guaranteed by $M_1K/(a_1+K)\geqq D_1$), $V_1^*=(y_1\gamma/M_1)(1-\lambda_1/K)(a_1+\lambda_1)\geqq 0$, which becomes equality if and only if $K=\lambda_1$, i.e. $M_1K/(a_1+K)=D_1$.

To analyze the stability of $(\lambda_1, V_1^*, 0)$, we recall linearized stability.

Consider the Neumann type initial-boundary problem

$$\begin{aligned} &\frac{\partial u}{\partial t}=DAu+F(u) && \text{in } R^+\times\Omega,\\ &\frac{\partial u}{\partial n}=0 && \text{on } R^+\times\partial\Omega,\\ &u(0,x)=u_0(x), && x\in\Omega. \end{aligned} \tag{3.28}$$

Suppose $u=\varphi(x)$ is a stationary solution of (3.28), namely,

$$\begin{aligned} &-D\Delta\varphi(x)=F(\varphi) \quad \text{in } \Omega,\\ &\left.\frac{\partial\varphi}{\partial n}\right|_{\partial\Omega}=0. \end{aligned} \tag{3.29}$$

Let S denote the differential operator obtained by formally linearizing the right-hand side of (3.28) about the given solution φ:

$$S(\bar u)\equiv D\Delta\bar u+\frac{\partial F}{\partial u}(\varphi(x))\bar u$$

where $\partial F/\partial u$ denotes the Jacobian matrix.

We consider S as an operator on the space $C^0(\bar\Omega)$ of bounded vector functions, continuous on $\bar\Omega$, with domain consisting of functions in $C^2(\bar\Omega)$ and satisfying the given Neumann boundary conditions. Let $\sigma(S)$ denote the spectrum of S.

Definition 3.2. φ is stable according to the linearized criterion (l.c.) or called linearly stable if $\sigma(S)$ is in the negative half-plane and is bounded away from the imaginary axis. Namely, there exists a negative number $\alpha<0$ such that $\operatorname{Re} z\leqq\alpha$ for any $z\in\sigma(S)$. φ is marginally stable (l.c.) if $\operatorname{Re} z\leqq 0$ for any $z\in\sigma(S)$ and there exists a z_0 such that $\operatorname{Re} z_0=0$. φ is unstable (l.c.) if $\sigma(S)$ contains a point in the right open half-plane.

DEFINITION 3.3. Let $\bar{u}$ be a solution of (3.29). Then $\bar{u}$ is stable if there is a neighborhood N of $\bar{u}$ and positive numbers C, α such that if u is a solution of (3.28) with $u(0)\in N$, then u exists for all $t>0$ and

$$\|u(t)-\bar{u}\|\leqq Ce^{-\alpha t}\|u(0,x)-\bar{u}\|, \qquad t>0$$

where $\|\cdot\|$ denotes the usual L_2-norm on $C(\bar{\Omega})$.

It is known that (cf. Smoller [12]) if $\bar{u}$ is a linearly stable solution of (3.28), then $\bar{u}$ is stable.

Now we analyze the stability of $(\lambda_1, V_1^*, 0)$. Let T be the linearization of the right-hand side of (1.1) about $(\lambda_1, V_1^*, 0)$.

$$T\begin{pmatrix} S \\ V_1 \\ V_2 \end{pmatrix}=\begin{bmatrix} k_1\Delta+\gamma-\frac{\gamma}{K}2\lambda_1-\frac{M_1a_1V_1^*}{y_1(a_1+\lambda_1)^2} & -\frac{D_1}{y_1} & -\frac{M_2\lambda_1}{y_2(a_2+\lambda_1)} \\ \frac{M_1a_1V_1^*}{(a_1+\lambda_1)^2} & k_2\Delta & 0 \\ 0 & 0 & k_3\Delta-D_2+\frac{M_2\lambda_1}{a_2+\lambda_1} \end{bmatrix}\begin{pmatrix} S \\ V_1 \\ V_2 \end{pmatrix}.$$

We need to investigate the spectrum $\sigma(T)$. Let $\sigma(\Delta)$ denote the spectrum of the Laplace operator as acting on $C^0(\bar{\Omega})$ with domain consisting of functions in $C^2(\bar{\Omega})$ and satisfying no-flux boundary conditions.

It is well known that $0\in\sigma(\Delta)$ and $\sigma(\Delta)$ consists of an infinite but discrete set of simple real eigenvalues, bounded from above, namely, $\cdots<\tau_n<\cdots<\tau_2<\tau_1<\tau_0=0$. Define

$$C=\frac{M_1a_1V_1^*}{(a_1+\lambda_1)^2}, \qquad E=\gamma-\frac{\gamma}{K}2\lambda_1-\frac{C}{y_1},$$

$$P(\xi,\mu)=P_1(\xi,\mu)\cdot P_2(\xi,\mu),$$

$$P_1(\xi,\mu)=\left(k_3\mu-D_2+\frac{M_2\lambda_1}{a_2+\lambda_1}-\xi\right),$$

$$P_2(\xi,\mu)=\xi^2-(k_1\mu+k_2\mu+E)\xi+\frac{D_1}{y_1}C+(k_1\mu+E)k_2\mu,$$

and

$$\Lambda=\{\eta\colon P(\eta,\mu)=0 \text{ for some } \mu\in\sigma(\Delta)\}.$$

Our first result is that

$$\sigma(T)\subset\Lambda. \tag{3.30}$$

To prove this, suppose that $\eta\notin\Lambda$. Then $P(\eta,\mu)\neq 0$ for all $\mu\in\sigma(\Delta)$, so $0\notin p(\eta,\sigma(\Delta))$. Now consider the sixth order differential operator $p(\eta,\Delta)$. It is known that for such polynomials p, $\sigma(p(\Delta))=p(\sigma(\Delta))$ [2], so that in our case we deduce $0\notin\sigma(p(\eta,\Delta))$. Therefore $p(\eta,\Delta)^{-1}$ exists as a bounded operator on $C^0(\bar{\Omega})$, which implies that both $p_1(\eta,\Delta)^{-1}$ and $p_2(\eta,\Delta)^{-1}$ exist as bounded operators on $C^0(\bar{\Omega})$. For any given f, g, $h\in C^0(\bar{\Omega})$, we can solve the equations

$$(T-\eta I)\begin{pmatrix} S \\ V_1 \\ V_2 \end{pmatrix}=\begin{pmatrix} f \\ g \\ h \end{pmatrix}$$

explicitly as follows:

$$S=\frac{D_1}{y_1}p_2(\eta,\Delta)^{-1}g+(k_2\Delta-\eta)p_2(\eta,\Delta)^{-1}\left[\frac{M_2\lambda_1}{y_2(a_2+\lambda_1)}p_1(\eta,\Delta)^{-1}h+f\right],$$

$$V_1=(k_1\Delta+E-\eta)p_2(\eta,\Delta)^{-1}g-Cp_2(\eta,\Delta)^{-1}\left[\frac{M_2\lambda_1}{y_2(a_2+\lambda_1)}p_1(\eta,\Delta)^{-1}h+f\right],$$

$$V_2=p_1(\eta,\Delta)^{-1}h.$$

This shows that $\eta\notin\sigma(T)$, and this conclusion in turn proves (3.30).

Our problem has been reduced to analyzing the property of Λ. Suppose $\eta\in\Lambda$; then there exists $\mu\in\sigma(\Delta)$ such that

$$\left(k_3\mu-D_2-\frac{M_2\lambda_1}{a_2+\lambda_1}-\eta\right)\left[\eta^2-(k_1\mu+k_2\mu+E)\eta+\frac{D_1}{y_1}C+(k_1\mu+E)k_2\mu\right]=0.$$

Let η_i $(i=1,2,3)$ denote the roots of the above equation. Clearly,

$$\eta_1=k_3\mu-D_2+\frac{M_2\lambda_1}{a_2+\lambda_1},$$

$$\eta_{2,3}=\frac{k_1\mu+k_2\mu+E}{2}\mp\frac{1}{2}\left[(k_1\mu+k_2\mu+E)^2-4\left(\frac{D_1C}{y_1}+(k_1\mu+E)k_2\mu\right)\right]^{1/2}.$$

Due to $M_1K/(a_1+K)\geqq D_1$, $M_2K/(a_2+K)<D_2$, it can be shown that $-D_2+((M_2\lambda_1)/(a_2+\lambda_1))<0$, which implies, since $\mu\leqq 0$, that $\eta_1<0$.

Assume $K<a_1+2\lambda_1$, which shows $E<0$; then it turns out that Re $\eta_{2,3}<0$. Thus, it ends up that $(\lambda_1, V_1^*, 0)$ is a linearly stable solution of (1.1)-(1.3)$_{\rm II}$. We obtain the asymptotic property of the solution (s, v_1, v_2) in this case as follows.

THEOREM 3.5. *Suppose* $M_1K/(a_1+K)\geqq D_1$, $M_2K/(a_2+K)<D_2$ *and* $K<a_1+2\lambda_1$ (*namely,* $a_1D_1/(M_1-D_1)\leqq K<(a_1D_1+a_1M_1)/(M_1-D_1)$). *Then there exists* $\varepsilon>0$ *such that*

$$\lim_{t\to\infty}\|S(t,x)-\lambda_1\|=0,\qquad \lim_{t\to\infty}\|V_1(t,x)-V_1^*\|=0,$$

if $\|S_0(x)-\lambda_1\|<\varepsilon$, $\|V_{10}(x)-V_1^*\|<\varepsilon$. *Moreover,* $\lim_{t\to\infty}V_2(t,x)=0$, *uniformly for* $x\in\Omega$.

Similarly, we obtain the following result for case (3.27).

THEOREM 3.6. *Suppose* $M_1K/(a_1+K)<D_1$, $M_2K/(a_2+K)\geqq D_2$ *and* $K<a_2+2\lambda_2$ (*namely,* $a_2D_2/(M_2-D_2)\leqq K<(a_2D_2+a_2M_2)/(M_2-D_2)$). *Then there exists* $\varepsilon>0$ *such that*

$$\lim_{t\to\infty}\|S(t,x)-\lambda_2\|=0,\qquad \lim_{t\to\infty}\|V_2(t,x)-V_2^*\|=0$$

if $\|S_0(x)-\lambda_2\|<\varepsilon$, $\|V_{20}(x)-V_2^*\|<\varepsilon$. *Moreover,* $\lim_{t\to\infty}V_1(t,x)=0$, *uniformly for* $x\in\Omega$, *where* $(\lambda_2, 0, V_2^*)$ *is a solution of* (1.1), (1.3)$_{\rm II}$, $\lambda_2=a_2D_2/(M_2-D_2)>0$, $V_2^*=(y_2\gamma/M_2)(1-\lambda_2/K)(a_2+\lambda_2)\geqq 0$ *which becomes equality if and only if* $K=\lambda_2$, *i.e.,* $M_2K/(a_2+K)=D_2$.

Finally, we consider the case when both of the assumptions $M_iK/(a_i+K)<D_i$ do not hold, namely,

$$\frac{M_iK}{a_i+K}\geqq D_i,\qquad i=1,2. \tag{3.31}$$

Clearly, (3.31) is equivalent to $0<\lambda_i\leqq K$, $i=1,2$. By the same argument as used before, we obtain the following results.

THEOREM 3.7. *Suppose* $0<\lambda_1<\lambda_2<K<a_1+2\lambda_1$; *then there exists* $\varepsilon>0$ *such that*

$$\lim_{t\to\infty}\|S(t,x)-\lambda_1\|=0,\quad \lim_{t\to\infty}\|V_1(t,x)-V_1^*\|=0,\quad \lim_{t\to\infty}\|V_2(t,x)\|=0$$

if $\|S_0(x)-\lambda_1\|<\varepsilon$, $\|V_{10}(x)-V_1^*\|<\varepsilon$, $\|V_{20}(x)\|<\varepsilon$.

The last theorem is similar.

THEOREM 3.8. *Suppose* $0<\lambda_2<\lambda_1<K<a_2+2\lambda_2$; *then there exists* $\varepsilon>0$ *such that*

$$\lim_{t\to\infty}\|S(t,x)-\lambda_2\|=0,\quad \lim_{t\to\infty}\|V_1(t,x)\|=0,\quad \lim_{t\to\infty}\|V_2(t,x)-V_2^*\|=0$$

if $\|S_0(x)-\lambda_2\|<\varepsilon$, $\|V_{10}(x)\|<\varepsilon$, $\|V_{20}(x)-V_2^*\|<\varepsilon$, *where* λ_1, V_1^* *and* λ_2, V_2^* *are the same as in Theorems* 3.5 *and* 3.6, *respectively.*

PERSISTENCE AND SMOOTHNESS OF HYPERBOLIC INVARIANT MANIFOLDS FOR FUNCTIONAL DIFFERENTIAL EQUATIONS*

LUIS T. MAGALHÃES†

Abstract. The persistence and smoothness of hyperbolic invariant manifolds is established for small perturbations of retarded functional differential equations. Properties of exponential dichotomies and of spectra of invariant manifolds, which are established here for semiflows, form the basis for proving the results. The analysis uses a moving system of coordinates, around the original hyperbolic invariant manifold, consisting of coordinates along the tangential, unstable and stable manifolds of the linearized equation along solutions of the unperturbed equation which lie on the original hyperbolic manifold.

Key words. invariant sets, hyperbolicity, functional differential equations

AMS(MOS) subject classifications. 34K05, 34K15, 58F10

1. Introduction. The study of invariant sets is of fundamental importance in the geometric theory of dynamical systems. Since, in general, these sets can have a wild topological structure, it is of interest to identify situations where they have the particularly simple structure of differentiable manifolds. Especially important in this context are those manifolds that persist under small perturbations, a situation that leads naturally to the study of hyperbolic invariant manifolds.

There is an extensive literature on hyperbolic invariant manifolds for ordinary differential equations, cf. [1]-[3], [6], [8], [9], [13], [14]. In the context of infinite-dimensional dynamical systems, the study of hyperbolic invariant manifolds was pursued for certain parabolic partial differential equations [7] and for particular cases of functional differential equations [10]-[12].

The studies of Kurzweil [10], [11] on hyperbolic invariant manifolds for functional differential equations (FDE) rely on establishing fixed points for maps which correspond to discrete dynamical systems obtained by discretization of the semiflow induced by the equations. The approach in this paper is, in contrast, based directly on the semiflow and uses techniques of exponential dichotomies for obtaining bounded solutions, following the work of Hale, cf. [3], for hyperbolic invariant manifolds of ordinary differential equations (ODE). It is believed that this approach is simpler than methods based on discretization.

The paper begins by establishing the concept of exponential dichotomies in the context of skew-product semiflows in Banach vector bundles, and the concept of hyperbolicity using the notion of spectrum of an invariant manifold, developed by Sacker and Sell for flows [15]-[19]. Here, the numerous discussions with George Sell, while this work was in progress, played an important role, in particular in connection to work of his in collaboration with Sacker [18]. A short reference is then made to FDEs on manifolds, based on the work of Oliva, cf. [5], referring the reduction of the general situation to the case of FDEs on euclidean space R^q. These are basically the contents of §§ 2, 3 and 4.

This research was partially supported by the Institute for Mathematics and Its Applications (IMA) at the University of Minnesota, by the Centro de Matematica e Aplicações Fundamentais (CMAF) of the Instituto Nacional de Investigação Cientifica (INIC) at Lisbon, Portugal, and by the Fundação Calouste Gulbenkian at Lisbon, Portugal.

The main difficulty in establishing the persistence and properties of hyperbolic manifolds for FDEs is related to the impossibility of extending backwards in time all the solutions. It is useful to linearize the equation around the original invariant manifold and to consider the corresponding tangential, unstable and stable manifolds, which are themselves invariant under the linearized semiflow. As it turns out, one only needs to extend the solutions backwards in time along the tangential and unstable directions. That involves no difficulties because both the tangential and unstable manifolds are finite-dimensional and, therefore, the semiflow for the linearized equation can be extended on them to a flow of an ODE. This leaves out only the evolution on the stable manifold to be considered as an FDE, but we do not need to extend the solutions backwards there. These ideas are pursued in § 5 by the introduction of a moving system of coordinates centered at solutions of the unperturbed equation lying on the original invariant manifold. The perturbed equation in these coordinates is given by a family of systems of two perturbed ODEs describing the evolution of the tangential and unstable variables, and an FDE for the stable variable. These systems are written as perturbations of the linear variational equation around the given hyperbolic manifold, using the variation of constants formula introduced by Hale for FDEs, cf. [4]. The analysis is actually based on the existence of exponential dichotomies for the linear variational equation which split the solutions with initial conditions in the tangential, unstable, or stable spaces.

In § 6, we study the persistence and the smoothness of integral manifolds for FDEs of the form obtained by application of the system of coordinates around the original invariant manifold, and we also study the structure of the semiflow around the integral manifolds, under general assumptions of global Lipschitzian nonlinearities with sufficiently small Lipschitz constants. The persistence of the integral manifolds is established using techniques of exponential dichotomies for the determination of bounded solutions, following an approach introduced by Hale, cf. [3], and also applied by Sell [19] in the context of ODEs. The smoothness properties of the integral manifolds are established by a modification of the method developed by Fenichel [2] also in the context of ODEs.

Finally, the results obtained for systems in coordinate form are applied, in § 7, to prove the persistence and smoothness of hyperbolic invariant manifolds for FDEs, and to study the local geometric structure of the orbits around them. Using "cut off" functions around the original invariant manifold, in a similar way as it is usually done for center manifold theory, one can get a system that agrees with the original system inside a neighborhood of the invariant manifold, and whose nonlinear terms satisfy the global Lipschitz conditions assumed in § 6. Thus, finding an invariant manifold for the perturbed equation, in such a neighborhood of the original manifold, amounts to finding an invariant manifold for the auxiliary system which is obtained through the application of the "cut off" functions mentioned above. The results obtained for systems in coordinate form are only good to get patches of the invariant manifolds which occur under perturbations. These pieces have to be patched up in order to obtain the perturbed manifold, but this can be easily done using the uniqueness properties established in § 6 for the integral manifolds of systems in coordinate form.

The system of coordinates which is introduced in this paper, around the original hyperbolic invariant manifold, is redundant, in the sense that each point close to the manifold can be represented by infinitely many combinations of the coordinates. In fact, the system of coordinates is centered at points of the invariant manifold, which therefore account for some of the coordinates used, and also involves coordinates along the tangential, unstable and stable spaces of the linearized equation around the manifold. The redundancy comes from the fact that the coordinates giving the point on the manifold where the coordinate frame is centered and the tangential coordinates eventually play against each other when describing neighborhoods of a particular point on the manifold. This situation is not different from many other cases where moving systems of coordinates have been used with the intent of simplifying the analysis, as for instance in certain situations describing the movement of bodies in the context of Newtonian mechanics. It is, of course, true that a nonredundant system of coordinates could be introduced leaving out the tangential components. However, the use of the redundant coordinates described above simplifies the analysis for two reasons: (i) it allows the separation of the dynamics of the linearized equations around the original manifold from the dynamics on the manifold itself, in particular the tangent bundle is invariant under the linearized equation, and (ii) it avoids the introduction of abstract equations to describe the evolution of the different coordinates, because, in this way, they can be given by FDEs in euclidean space.

Some of the ideas introduced in this paper are new and useful even in the case of ODEs. In particular, the use of the redundant system of coordinates described above, although most useful in the case of FDEs, is also natural in the context of ODEs since it simplifies the description of the linearized equation around the original invariant manifold and considerably simplifies the analysis.

2. Spectrum of a linear skew-product semiflow. Let W be a topological space. A *flow* on W is a continuous mapping $\pi: R\times W\to W$ such that $\pi(0,w)=w$ and $\pi(t,\pi(s,w))=\pi(t+s,w)$ for all $w\in W$ and $t,s\in R$. A *semiflow* on W is a continuous mapping $\pi:[0,\infty)\times W\to W$ satisfying the preceding conditions for $t,s\geqq 0$.

Let X be a smooth Banach manifold without boundary and let E be a Banach vector bundle over X with fiber projection $p: E\to X$, i.e., E is a vector bundle over X with each fiber $E(x)=p^{-1}(x)$, $x\in X$, being a Banach space. Points in E can be represented by ordered pairs (x,z) with $x\in X$, and z a vector in the fiber $E(x)$. A semiflow π on E is said to be a *skew-product semiflow* on E if there is a flow ϕ on X such that the fiber projection p commutes with π and ϕ, i.e., π can be represented as

$$\pi(t,x,z)=(\phi(t,x),\psi(t,x,z)),\qquad t\geqq 0$$

and $\psi(t,x,z)$ is in the fiber $E(\phi(t,x))$. Such a skew-product semiflow π is a *linear skew-product semiflow* if the mapping $z\to\Psi(t,x)z=\psi(t,x,z)$ is a linear mapping from the fiber $E(x)$ to the fiber $E(\phi(t,x))$. One defines analogously *skew-product flow* and *linear skew-product flow*. When π is a semiflow on E, $\pi(t,x,z)$, $\psi(t,x,z)$ and $\Psi(t,x)$ are only defined for $t\geqq 0$. However, they can be extended for $t\leqq 0$ at those points (x,z) through which there is a backwards continuation defined for all $t\leqq 0$. Let us define the set B by

$B=\{(x,z)\in E$: there is exactly one continuous function $(u,v):(-\infty,0]\to E$
such that $u(0)=x$, $v(0)=z$ and $\pi(t,u(s),v(s))=(u(t+s),v(t+s))$
for all $s\leqq 0$ and all $t\in[0,-s]\}$.

The set

$$S=\{(x,z)\in E: |\psi(t,x,z)|\to 0 \text{ as } t\to+\infty\}$$

is called the *stable set* of X under π, and the set

$$U=\{(x,z)\in B: |\psi(t,x,z)|\to 0 \text{ as } t\to-\infty, \text{for the continuation of } \psi(t,x,z) \text{ for } t\leqq 0\}$$

is called the *unstable set* of X under π. A set $I\subset E$ is said to be *positively invariant* under π if $\pi(t,x,z)\in I$ for all $t\geqq 0$ and $(x,z)\in I$, and I is said to be *invariant* under

π if $I \subset B$ and the preceding condition holds for all $t \in R$, for the continuation of $\pi(t, x, z)$. The sets S and U are both positively invariant under π, and the sets B, $S \cap B$ and U are all invariant under π. It is easy to see thai these sets are vector subbundles of E.

The linear skew-product semiflow $\pi = (\phi, \psi)$ on E is said to admit an *exponential dichotomy* on X if there exist linear projections $P(x)$ defined on $E(x)$ and depending continuously on $x \in X$, and there exist constants $K, \alpha > 0$ such that

(i) $N(P) = \{(x, z) \in E: P(x)z = 0\} \subset B$,

(ii) $|\Psi(t, x)P(x)| \leqq K e^{-\alpha t}, \quad t \geqq 0, \quad x \in X$,

(iii) $|\Psi(t, x)[I - P(x)]| \leqq K e^{+\alpha t}, \quad t \leqq 0$,
for the continuation of $\Psi(t, x)z$ for $t \leqq 0$ with $(x, z) \in B$.

We note that condition (iii) makes sense because (i) implies that the range of the mapping $(x, z) \to (x, [I - P(x)]z)$ is contained in B. Whenever π admits an exponential dichotomy on X we have $U = N(P) = \{(x, z) \in E: P(x)z = 0\}$ and $S = R(P) = \{(x, z) \in E: z = P(x)z'$ for some $z' \in E(x)\}$. Then, the stable and unstable sets are complementary subbundles of E.

Given a linear skew-product semiflow $\pi = (\phi, \psi)$ on a vector bundle E, and a real number λ, we define a mapping π_λ by

$$\pi_\lambda(t, x, z) = (\phi(t, x), e^{-\lambda t}\psi(t, x, z)).$$

It is easily seen that π_λ is also a linear skew-product semiflow on E and that the invariant sets under π and under π_λ agree for all $\lambda \in R$. We also define

$$\Psi_\lambda(t, x)z = e^{-\lambda t}\psi(t, x, z) = e^{-\lambda t}\Psi(t, x)z.$$

The stable and the unstable sets of X under π_λ are denoted by S_λ and U_λ, respectively. Clearly, if $\mu < \lambda$ then $S_\mu \subset S_\lambda$ and $U_\mu \supset U_\lambda$. The set of all $\lambda \in R$ for which π_λ admits an exponential dichotomy on X is called the *resolvent set* of π on E and is denoted by $\rho(E, \pi)$. The complement of the resolvent set on R is called the *spectrum* of π on E and is denoted by $\Sigma(E, \pi)$.

A skew-product semiflow $\pi = (\phi, \psi)$ on the vector bundle E is said to be *uniformly completely continuous* if for each $x \in X$ there is a neighborhood V_x of x in X and a real number $r_x \geqq 0$ such that, for all $t \geqq r_x$, the mapping $(y, z) \to \pi(t, y, z)$ maps bounded subsets of $E_{V_x} = \{(y, z) \in E: y \in V_x\}$ into relatively compact subsets of E.

The following theorem contains the properties of the spectrum $\Sigma(E, \pi)$ which are used in this paper.

THEOREM 2.1. *Let $\pi = (\phi, \psi)$ be a uniformly completely continuous linear skew-product semiflow on a Banach vector bundle E defined over a compact, connected, smooth Banach manifold X. Then the spectrum $\Sigma(E, \pi)$ is a closed set of real numbers which is bounded above, and, consequently, it is a union of closed intervals, the spectral intervals (an interval $[a, b]$ is allowed to degenerate to a point when $a = b$).*

Associated with each spectral interval there is a spectral subbundle V of E, which satisfies the following properties:

(1) *If $\mu, \lambda \in \rho(E, \pi)$ and $(\mu, \lambda) \cap \Sigma(E, \pi) = [a, b]$, then the spectral subbundle V associated with $[a, b]$ has finite dimension, satisfies $V = U_\mu \cap S_\lambda$, and is invariant under π;*

(2) *If $\lambda \in \rho(E, \pi)$ and $(-\infty, \lambda) \cap \Sigma(E, \pi) = (-\infty, b]$, then the spectral subbundle V associated with $(-\infty, b]$ satisfies $V = S_\lambda$ and is positively invariant under π.*

Moreover, if $\lambda \in \rho(E, \pi)$, then the number of spectral intervals included in $(\lambda, +\infty)$ is finite.

Proof. Let $\lambda \in \rho(E, \pi)$. Then π_λ admits an exponential dichotomy on X. There exist a linear projection $P_\lambda(x)$ on $E(x)$ and constants $K, \alpha > 0$ such that $N(P_\lambda) \subset B$, and

$$|\Psi_\lambda(t, x)P_\lambda(x)| \leqq K e^{-\alpha t}, \qquad t \geqq 0, \quad x \in X,$$

$$|\Psi_\lambda(t, x)[I - P_\lambda(x)]| \leqq K e^{+\alpha t}, \qquad t \leqq 0, \quad x \in X,$$

where the last inequality holds for some backwards extension of $\Psi_\lambda(t, x)$. If μ satisfies $|\lambda - \mu| < \beta = \alpha/2$, then

$$|\Psi_\mu(t, x)P_\lambda(x)| \leqq K e^{-\beta t}, \qquad t \geqq 0, \quad x \in X,$$

$$|\Psi_\mu(t, x)[I - P_\lambda(x)]| \leqq K e^{+\beta t}, \qquad t \leqq 0, \quad x \in X.$$

Therefore, with $P_\mu = P_\lambda$, π_μ admits an exponential dichotomy on X. It follows that $\mu \in \rho(E, \pi)$, $U_\mu = U_\lambda$ and $S_\mu = S_\lambda$, for all μ such that $|\lambda - \mu| < \alpha/2$. This implies that $\rho(E, \pi)$ and $\{\mu \in R\colon U_\mu = U_\lambda, S_\mu = S_\lambda\}$, for any $\lambda \in \rho(E, \pi)$, are open sets. Thus $\Sigma(E, \pi)$ is a closed set.

The fact that $\Sigma(E, \pi)$ is bounded above results from the compactness of X and the semigroup property of π. In fact, let $k = \sup\{|\Psi(t, x)|\colon x \in X \text{ and } 0 \leqq t \leqq 1\}$. Since Ψ is continuous and the supremum is taken over a compact set, the constant k is finite. Fix $t \geqq 0$ and let m be the largest integer smaller or equal to t. Then, with $x_i = \phi(i, x)$, we have

$$\Psi(t, x) = \Psi(t - m, x_m)\Psi(1, x_{m-1}) \cdots \Psi(1, x)$$

and, consequently,

$$|\Psi(t, x)| \leqq k^{m+1} \leqq kk^t = k\, e^{at}, \qquad t \geqq 0,$$

where $a = \log k$. Therefore, π_λ admits an exponential dichotomy on X for $\lambda > a$, with $\alpha = \lambda - a$ and $P_\lambda(x)$ equal to the identity on $E(x)$. This proves that $(a, +\infty) \subset \rho(E, \pi)$ and $\Sigma(E, \pi) \subset (-\infty, a]$.

Since $\Sigma(E, \pi)$ is a closed set of real numbers which is bounded above, it is a union of compact intervals with, possibly an interval of the form $(-\infty, b]$. Let $\mu < \lambda$ be real numbers in $\rho(E, \pi)$ which separate one of the closed intervals that make up $\rho(E, \pi)$ from the others, i.e., the intersection of the interval (μ, λ) with $\rho(E, \pi)$ is precisely one spectral interval $[a, b]$. With this spectral interval we can associate the spectral bundle $V = U_\mu \cap S_\lambda$. In order to prove the properties (1) and (2) we need to show that V is independent of the points μ, λ, provided they satisfy the properties indicated. More precisely, we need to show that for $\mu, \lambda \in \rho(E, \pi)$ with $\mu < \lambda$ we have $U_\mu = U_\lambda$ and $S_\mu = S_\lambda$ if and only if $(\mu, \lambda) \subset \rho(E, \pi)$. Assume that $U_\mu \neq U_\lambda$ or $S_\mu \neq S_\lambda$, with $(\mu, \lambda) \subset \rho(E, \pi)$, and define $\bar{\sigma} = \sup\{\sigma \in \rho(E, \pi)\colon U_\sigma = U_\mu, S_\sigma = S_\mu\}$. Because the set $\{\mu \in R\colon U_\mu = U_\lambda, S_\mu = S_\lambda\}$, for any $\lambda \in \rho(E, \pi)$, is an open set, and because U_σ depends monotonically on σ, we get a contradiction. This shows that $U_\mu = U_\lambda$ and $S_\mu = S_\lambda$. To prove the converse, let $\mu, \lambda \in \rho(E, \pi)$ and assume that $U_\mu = U_\lambda$ and $S_\mu = S_\lambda$. Then π_μ and π_λ admit exponential dichotomies on X, with projections P_μ, P_λ and constants K_μ, K_λ and α_μ, α_λ, respectively. Let $K = \max\{K_\mu, K_\lambda\}$ and $\alpha = \min\{\alpha_\mu, \alpha_\lambda\}$. For either $\sigma = \mu$ or $\sigma = \lambda$, we have

$$|\Psi_\sigma(t, x)P_\sigma(x)| \leqq K e^{-\alpha t}, \qquad t \geqq 0, \quad x \in X,$$

$$|\Psi_\sigma(t, x)[I - P_\sigma(x)]| \leqq K e^{+\alpha t}, \qquad t \leqq 0, \quad x \in X.$$

Since $U_\mu = U_\lambda$ and $S_\mu = S_\lambda$, we have $P_\mu = P_\lambda = P$. Consequently

$$e^{-\sigma t}|\Psi(t,x)P(x)| \leqq K e^{-\alpha t}, \qquad t \geqq 0, \quad x \in X,$$
$$e^{-\sigma t}|\Psi(t,x)[I - P(x)]| \leqq K e^{+\alpha t}, \qquad t \leqq 0, \quad x \in X,$$

for σ equal to either μ or λ. This implies that these inequalities must also hold for all $\sigma \in [\mu, \lambda]$, proving that each one of the π_σ, for $\sigma \in [\mu, \lambda]$, admits an exponential dichotomy, and, therefore, $[\mu, \lambda] \subset \rho(E, \pi)$.

The invariance properties of the spectral subbundles follow from the positive invariance of the S_λ and the invariance of the U_λ and $S_\lambda \cap B$, for every $\lambda \in \rho(E, \pi)$.

It remains to prove that the spectral bundles associated with compact spectral intervals have finite dimension. For this we use the complete continuity of the semiflow. The semiflow π_λ is uniformly completely continuous for each $\lambda \in \rho(E, \pi)$. Thus, for each $x \in X$ there is a neighborhood V_x of x in X and a real number $r_x \geqq 0$ such that, for $t \geqq r_x$, the mapping $(x, z) \to \pi(t, x, z)$ maps bounded subsets of $E_{V_x} = \{(y, z) \in E: y \in V_x\}$ into relatively compact subsets of E. Since X is compact, we can extract a finite subcovering V_{x_i} of X and define $r = \max\{r_{x_i}\}$. Then, for all $x \in X$, $t \geqq r$, the mapping $z \to \Psi_\lambda(t, x)z$ maps bounded subsets of $E(x)$ into relatively compact subsets of $E(\phi(t, x))$. Since $\lambda \in \rho(E, \pi)$, π_λ admits an exponential dichotomy on X with projection P and constants $K, \alpha > 0$. Then $U_\lambda(x) = N(P(x))$ is a closed linear subspace of $E(x)$. Let us denote $S = \{z \in U_\lambda(x): |z| \leqq 1\}$. For each $z \in S$, the mapping $\Psi_\lambda(t, x)z$ has one backwards extension defined for all $t \leqq 0$ and such that

$$|\Psi_\lambda(t, x)z| \leqq K e^{+\alpha t}, \qquad t \leqq 0.$$

For each $z \in S$, define the set $S' = \{z' \in E(\phi(-r, z)): z' = \Psi_\lambda(-r, x)z \text{ with } z \in S\}$. For each $z' \in S'$ we have $|z'| \leqq K e^{-\alpha r}$ and, consequently, the set S' is bounded. Therefore, the mapping $z' \to \Psi_\lambda(r, \phi(-r, x))z'$ maps S' into a compact subset of $E(x)$. Since S is the image of S' under this map, it follows that S is a compact subset of the Banach space $U_\lambda(x)$. The only Banach spaces which have the closed unit ball compact, are the finite dimensional spaces. Consequently, $\dim U_\lambda(x) < \infty$. Clearly, if $\mu, \lambda \in \rho(E, \pi)$ then $V(x) = U_\mu(x) \cap S_\lambda(x)$ is also finite dimensional and, because X is connected, the dimensions of all fibers $V(x)$, for $x \in X$, are the same.

Finally, if $\lambda \in \rho(E, \pi)$, then $\dim U_\lambda$ is finite and the preceding properties of U_λ, S_λ, with the monotone dependence of S_λ on λ, imply that the union of the spectral subbundles associated with spectral intervals contained in the interval $(\lambda, +\infty)$ is equal to U_λ and, consequently, the number of such spectral intervals is finite. QED

The evolution on the spectral subbundles associated with compact spectral intervals can be given by ordinary differential equations (ODE).

PROPOSITION 2.2. *Let π be a skew-product semiflow on a Banach vector bundle E defined over a connected, smooth Banach manifold X. If V is a finite-dimensional subbundle of E which is invariant under π, then the restriction of π to V can be extended to a flow on V.*

Moreover, if the mapping $t \to \pi(t, x, z)$ is differentiable at $t = 0$, for every $(x, z) \in V$, and its derivative at $t = 0$ is locally Lipschitzian in $(x, z) \in V$, then the flow of π on V can be given by an ODE.

Proof. Since V is invariant under π, through every point of V there is one backwards continuation of π. Consequently, $\pi(t, x, z)$ is well defined and belongs to V, for all $t \in R$, $(x, z) \in V$. It is clear from the definition of backwards continuation that π is a flow on V.

If the mapping $t \to \pi(t, x, z)$ is differentiable at $t = 0$ with the derivative being locally Lipschitzian in $(x, z) \in V$, then we can define a vector field on V by assigning to each point $(x, z) \in V$ the derivative $\partial\pi(t, x, z)/\partial t|_{t=0}$. Initial value problems for the ODE defined by this vector field have unique solutions and define a flow which coincides with π. QED

3. Hyperbolic invariant manifolds. Let X be a smooth Banach manifold without boundary and let ϕ be a continuously differentiable semiflow on X. Let Y be a smooth, compact, connected submanifold of X and assume that Y is positively invariant under the semiflow ϕ. Denote by E the subset of the tangent bundle TX defined by $E = \bigcup_{y \in Y} T_yX$ and suppose that there exists a subbundle N of E which is complementary to the tangent bundle $T = TY$. Then E, T and N are vector bundles over Y. Since ϕ is continuously differentiable, we can define

$$\psi(t, y, z) = \Psi(t, y)z = D_2\phi(t, \phi(t, y))z, \qquad t \geqq 0$$

for all $y \in Y$ and $z \in E(y)$, and

$$\pi(t, y, z) = (\phi(t, y), \psi(t, y, z)), \qquad t \geqq 0.$$

Then π is a linear skew-product semiflow on E. It is called the *linearized skew-product semiflow around Y induced by the semiflow ϕ*. The vector bundle T is positively invariant under the semiflow $\pi = (\phi, \psi)$. The semiflow π induces, by restriction, a semiflow on T which is denoted by π^T and is called the *tangential flow induced by π* on T

$$\pi^T(t, y, z) = (\phi(t, y), \psi^T(t, y, z)), \qquad t \geqq 0$$

defined for $(y, z) \in T$. Analogously, π induces a semiflow π^N on N. In fact, if $P(y)$ denote projections on $E(y)$ which depend continuously on y and are such that $T(y) =$ null space of $P(y)$ and $N(y) =$ range space of $P(y)$, we can set for $(y, z) \in N$

$$\pi^N(t, y, z) = (\phi(t, y), P(\phi(t, y))\psi(t, y, z)), \qquad t \geqq 0.$$

Since T is a positively invariant set for π, the mapping π^N is a linear skew-product semiflow on N. It is called the *normal flow induced by π* on N. Let $\Sigma(E, \pi)$, $\Sigma(T, \pi^T)$ and $\Sigma(N, \pi^N)$ denote the spectra of the semiflows π, π^T and π^N on the vector bundles E, T and N, respectively. We say that Y is a *k-hyperbolic invariant manifold* under ϕ if there exists an $\alpha > 0$ such that $\Sigma(T, \pi^T) \subset (-\alpha, \alpha)$ and $\Sigma(N, \pi^N) \cap (-k\alpha, k\alpha) = \emptyset$. A *hyperbolic invariant manifold* under ϕ is simply a 1-hyperbolic invariant manifold.

THEOREM 3.1. *Let X be a smooth Banach manifold without boundary and let ϕ be a continuously differentiable semiflow on X. If $Y \subset X$ is a connected k-hyperbolic invariant manifold under ϕ and $\pi = (\phi, \psi)$ is the linearized skew-product semiflow around Y induced by the semiflow ϕ, then the tangent bundle of Y, $T = TY$, the unstable set U and the stable set S of Y under π decompose the tangent bundle of X as a Whitney sum $TX = T + U + S$, and the restrictions of π to U, of π to T and of ϕ to Y can be extended to flows on U, T and Y, respectively. Furthermore, if $\pi^U = (\phi, \psi^U)$, $\pi^T = (\phi, \psi^T)$ denote the skew-product flows on U, T obtained by extension of the restrictions of π to U, T, respectively, and if $\pi^S = (\phi, \psi^S)$ denotes the restriction of π to S, then there exist $K, \alpha > 0$ such that*

$$\begin{aligned} &|\psi^U(t, x, z)| \leqq K e^{k\alpha t}|z|, && t \leqq 0, \quad (x, z) \in U, \\ &|\psi^S(t, x, z)| \leqq K e^{-k\alpha t}|z|, && t \geqq 0, \quad (x, z) \in S, \\ &|\psi^T(t, x, z)| \leqq K e^{\alpha|t|}|z|, && t \in R, \quad (x, z) \in T. \end{aligned} \tag{3.1}$$

Proof. We can write

$$\pi(t, y, z) = (\phi(t, y), \psi(t, y, P(y)z)) + (\phi(t, y), \psi(t, y, [I - P(y)]z)).$$

Consequently, if $\psi(t, y, z) = \Psi(t, y)z$, $\psi^T(t, y, z) = \Psi^T(t, y)z$ and $\psi^N(t, y, z) = \Psi^N(t, y)z$, we have

$$\Psi(t, y)z = \Psi^N(t, y)P(y)z + \Psi^T(t, y)[I - P(y)]z.$$

Since $\Sigma(N, \pi^N) \cap \Sigma(T, \pi^T) = \varnothing$, it follows directly from the definitions of spectrum and dichotomy that

$$\Sigma(E, \pi) = \Sigma(N, \pi^N) \cup \Sigma(T, \pi^T).$$

If we denote $V_0 = U_{-\alpha} \cap S_\alpha$, $V_+ = U_{k\alpha}$ and $V_- = S_{-k\alpha}$ it follows from Theorem 2.1 that V_0 and V_+ are unions of a finite number of compact spectral subbundles and V_- is a countable union of spectral subbundles such that $TX = V_0 + V_- + V_+$, as a Whitney sum. Since $\Sigma(T, \pi^T) \subset (-\alpha, \alpha)$, we have $V_0 = T$, and it is also clear that $V_- = S$ and $V_+ = U$. Thus, T and U are finite-dimensional, and Proposition 2.2 implies that the restrictions of π to T and U can be extended to flows on T and U, respectively. It is clear that $\Sigma(U, \pi^U) \subset (k\alpha, +\infty)$, $\Sigma(T, \pi^T) \subset (-\alpha, \alpha)$, $\Sigma(S, \pi^S) \subset (-\infty, -k\alpha)$, and, therefore, the inequalities (3.1) are valid.

The dimensions of Y and $TY = T$ are the same. Consequently, Y is a finite-dimensional manifold invariant under ϕ. It follows that the restriction of ϕ to Y can be extended to a flow on Y. QED

4. Functional differential equations on manifolds. Let M be a separable smooth finite-dimensional connected manifold without boundary, and let TM be the tangent bundle of M, that is, TM is the union of the tangent spaces $T_yM = TM(y)$ of points $y \in M$, with $p_M : TM \to M$ denoting the projection that maps each $TM(y)$ onto the base point y. If I denotes the closed interval $I = [-r, 0]$ for $r > 0$, $C^0(I, M)$ denotes the set of continuous functions from I to M and $\rho : C^0(I, M) \to M$ is the evaluation map $\rho(\phi) = \phi(0)$, then a *retarded functional differential equation* (RFDE) *on* M is a continuous function $F: C^0(I, M) \to TM$ such that $p_M \circ F = \rho$.

The tangent bundle TM can be identified with $M \times R^m$ where $m = \dim M$. Then, for any RFDE F, there exists a function $f: C^0(I, M) \to R^m$, such that $F(\phi)$ can be identified with $(\xi(0), f(\xi))$, for all $\xi \in C^0(I, M)$. The RFDE (F) is frequently represented as $(x(t), \dot{x}(t)) = F(x_t) = (x(t), f(x_t))$ or, simply, $\dot{x}(t) = f(x_t)$, where, given a function x of a real variable and with values in the manifold M, we denote $x_t(\theta) = x(t+\theta)$, $\theta \in I$, whenever the right-hand side is defined.

Given a locally Lipschitzian RFDE (F) on M, its maximal solution $x(t)$ satisfying the initial condition ξ at $t = t_0$ (which necessarily exists and is unique) is sometimes denoted by $x(t; t_0, \xi, F)$ and x_t is denoted $x_t(t_0, \xi, F)$. The *solution map* or *semiflow* of F is then defined by $\phi(t, \xi) = x_t(0, \xi, F)$. The arguments ξ, F are dropped when confusion may not arise, and t_0 is dropped when it is equal to zero. If F is bounded and has bounded continuous derivative, then the solution map is a smoothing operator, in the sense that if it is uniformly bounded for t in compact sets of $[0, \infty)$, then for $t \geqq r$, the function $\phi(t, \cdot): C^0(I, M) \to C^0(I, M)$ maps bounded sets into relatively compact sets.

We denote by BC^k the set of bounded continuous functions from $C^0(I, M)$ into TM which have bounded continuous derivatives up to order $k \geqq 1$. The RFDEs on M we consider in the sequel will always be taken from BC^k for $k \geqq 1$. Each such RFDE (F) induces, by linearization, another RFDE (L) on the tangent bundle TM, which is called the *linear variational equation*. Being an RFDE on TM, the linear variational equation is a map $L: C^0(I, TM) \to T^2M$. The double tangent bundle T^2M can be identified with $M \times R^m \times R^m \times R^m$, and, therefore, if the given RFDE (F) on M is represented as $\dot{x}(t) = f(x_t)$, as done before, then the linear variational equation of F

can be represented, in an analogous fashion, as $(x(t), y(t), \dot{x}(t), \dot{y}(t)) = L(x_t, y_t) = (x(t), y(t), f(x_t), Df(x_t)y_t)$ or, simply, as a system of the two equations $\dot{x}(t) = f(x_t)$ and $\dot{y}(t) = Df(x_t)y_t$, where Df denotes the derivative of f. The solution maps ϕ of F and λ of the linear variational equation L are then related by $\lambda(t, \cdot) = D\phi(t, \cdot)$.

It is clear from the preceding discussion that we can, without loss of generality, restrict the study of the persistence of hyperbolic invariant manifolds, under small perturbations of RFDEs on a manifold M, to the particular case where the manifold is euclidean, i.e., $M = R^q$, for some integer q.

5. System of coordinates around hyperbolic invariant manifolds for FDEs. For a fixed real number $r > 0$, let $C = C([-r, 0]; R^q)$ denote the Banach space of continuous functions from the interval $[-r, 0]$ to R^q, taken with the uniform norm. Given a Banach space B and positive integers k, p, the set

$$BC^k(B; R^p) = \{f: B \to R^p, f \text{ is continuously differentiable and has bounded derivatives up to order } k\},$$

taken with the usual addition and multiplication by scalars and the uniform C^k-norm, is a Banach space. By uniform C^k-norm we mean

$$\|f\|_k = \sup\{|D^i f(\xi)|: i = 1, \cdots, k \text{ and } \xi \in B\}.$$

We are interested in discussing functional differential equations (FDE) defined by functions $f \in BC^k(C; R^n)$ with $k \geqq 1$, as

$$\dot{u}(t) = f(u_t), \tag{5.1}$$

where u_t denotes the segment of the function u defined over the interval $[t - r, t]$, i.e., $u_t(\theta) = u(t + \theta)$ for $\theta \in [-r, 0]$. The solutions of (5.1) define a semiflow $(t, \xi) \to u_t(\xi)$ on C, with $u_0 = \xi$. The mapping $u_t(\cdot): C \to C$ is C^k for all $t \geqq 0$ and is completely continuous for $t \geqq r$.

Let $M \subset C$ be a compact, connected, C^k-manifold which is k-hyperbolic under the semiflow defined by the solutions of (5.1). The vector bundle $E = \bigcup_{\omega \in M} T_\omega C$ can be identified with $M \times C$, since C is infinite-dimensional and M is a finite-dimensional manifold.

We will also consider the *linear variational equation* around M

$$\dot{v}(t) = Df(u_t(\omega))v_t \tag{5.2}$$

for each $\omega \in M$. The linearized semiflow around M which is induced by (5.1) is the linear skew-product semiflow defined, for $(\omega, \xi) \in E$, by

$$\pi(t, \omega, \xi) = (u_t(\omega), v_t(\omega, \xi)), \qquad t \geqq 0,$$

where $v_t(\omega, \xi) \in C$ denotes points in the orbit of (5.2), which passes through the point ξ at $t = 0$.

Because M is a k-hyperbolic manifold under (5.1), the vector bundle TM is invariant under the skew-product semiflow π, and TM has a complementary subbundle N of E, i.e., $E = TM + N$. Let U, S denote, respectively, the unstable and stable subbundles of N. The fibers $T_\omega = T_\omega M$, U_ω and S_ω can be identified with linear subspaces of C, and one can write $C = T_\omega + U_\omega + S_\omega$. Because M is connected, the dimensions of these fibers are independent of $\omega \in M$, and because M is hyperbolic and the semiflow π is completely continuous for $t \geqq r$, it follows that both T_ω and U_ω are finite-dimensional, with dimensions that we denote $d_T = \dim T_\omega$ and $d_U = \dim U_\omega$. We can choose bases for T_ω and U_ω consisting of vectors of unit length that depend on ω in a C^k fashion. These bases are arranged as columns of $q \times d_T$ matrices Φ_ω^T and

$q\times d_U$ matrices Φ^U_ω. To each point $(\omega, \xi)\in E$, we can associate coordinates $x\in R^{d_T}$, $y\in R^{d_U}$, $\zeta\in C$ by the relations $\xi=\xi^T_\omega+\xi^U_\omega+\xi^S_\omega$ where $\xi^T_\omega\in T_\omega$, $\xi^U_\omega\in U_\omega$, $\xi^S_\omega\in S_\omega$, $\xi^T=\Phi^T_\omega x$, $\xi^U_\omega=\Phi^U_\omega y$ and $\zeta=\xi^S_\omega$. These relations associate a unique quadruple $(\omega, x, y, \zeta)\in M\times R^{d_T}\times R^{d_U}\times C$ to each point $(\omega, \xi)\in E$. This system of coordinates (ω, x, y, ζ) around the hyperbolic invariant manifold M is redundant. In fact, the same point in a neighborhood of M can be represented in several ways in these coordinates, according to which point $\omega\in M$ is taken as origin of the coordinate system. In spite of this redundancy, the use of these coordinates facilitates the study of the persistence of hyperbolic invariant manifolds under perturbations.

Given a FDE

$$\dot{w}(t)=f(w_t)+g(w_t), \tag{5.3}$$

where $g\in BC^k$, and defining $v(t)=w(t)-u(t)$, we can write it as a perturbation of the linear variational equation (5.2) in the form

$$\dot{v}(t)=Df(u_t(\omega))v_t+G(u_t(\omega), v_t), \tag{5.4}$$

with $\omega\in M$, by defining

$$G(\phi, \psi)=f(\phi+\psi)-Df(\phi)\psi-f(\phi)+g(\phi+\psi).$$

Equation (5.4) defines a skew-product semiflow on E by

$$\tilde{\pi}(t, \omega, \xi)=(u_t(\omega), v_t(\omega, \xi)),$$

where $v_t(\omega, \xi)$ denotes points on the orbit of (5.4), which satisfies the initial condition $v_0=\xi$. The variation of constants formula for (5.4) can be written (see [4]) as

$$v_t=T_\omega(t, s)v_\sigma+\int_\sigma^t T_\omega(t, s)X_0G(u_s(\omega), v_s)\,ds, \qquad t\geqq\sigma, \tag{5.5}$$

where $T_\omega(t, \sigma)$ denotes the solution operator of the linear variational equation (5.2) and $X_0(\theta)$ is defined to be the identity I_q at $\theta=0$ and to be zero for $\theta\in[-r, 0]$ (notice that the columns of X_0 do not belong to C, but the formula still makes sense if interpreted as suggested by Hale in [4]).

As M is an hyperbolic compact manifold under the semiflow defined by (5.1), which is completely continuous for $t\geqq r$, it follows that (5.1) defines an ODE on M. The points $v_t(\omega)$, which must satisfy (5.5), can be represented in the system of coordinates introduced above as $(u_t(\omega), x(t), y(t), z_t)$, where $x(t)$, $y(t)$, z_t satisfy the variation of constants formulas obtained by projecting both sides of (5.5) along the "coordinate directions." More precisely, we have the following result.

THEOREM 5.1. *Let $f\in BC^k(C, R^q)$, $k\geqq 1$, and assume $M\subset C$ is a compact connected C^k-manifold that is k-hyperbolic under the semiflow defined by the solutions of*

$$\dot{u}(t)=f(u_t). \tag{5.6}$$

Then there exists a system of local coordinates around M, $(\omega, x, y, \zeta)\in M\times R^{d_T}\times R^{d_U}\times C$, where $d_T=\dim M$ and d_U is the dimension of the unstable bundle associated with the linear variational equation (5.2), *such that, for each $\omega\in M$, there exist two matrix-valued functions $\Psi^T_\omega(t, \sigma)$ and $\Psi^U_\omega(t, \sigma)$, which are continuously differentiable in $t, \sigma\in R$, a linear subspace L of C with codimension d_T+d_U, a linear operator $T^S_\omega(t, \sigma)$ acting on L which is continuously differentiable in $t\geqq\sigma$, a $q\times q$ matrix-valued function $X_0^{S,\omega,T}$ defined* *on* $[-r, 0]$ *which is continuous on* τ, *and functions* n, u, s *defined from* $M \times R^{d_T} \times R^{d_U} \times C \times BC^k(C, R)$ *into, respectively,* R^{d_T}, R^{d_U}, R^q *which are bounded and, for each fixed* $\omega \in M$, *are of class* BC^k *in the remaining variables, such that*

(i) $\Psi^T_\omega(t, t) = I_{d_T}$, $\Psi^U_\omega(t, t) = I_{d_U}$, $T^S_\omega(t, t) = I_L$ *for all* $t \in R$;

(ii) *there exist* K, α, $\alpha_0 > 0$ *with* $\alpha > k\alpha_0$ *such that*

$$e^{-\alpha_0|t|}|\Psi^T_\omega(t, \tau)| \to 0 \quad \text{as } |t| \to \infty \quad \text{for all } \tau \in R,$$
$$|\Psi^U_\omega(t, \tau)| \leqq K e^{\alpha(t-\tau)}, \qquad t \leqq \tau,$$
$$|T_\omega(t, \tau)\phi| \leqq K e^{-\alpha(t-\tau)}|\phi|, \qquad t \geqq \tau, \quad \phi \in S_{u_0(\omega)},$$

where S *denotes the stable bundle associated with the linear variational equation of* (5.6) *around* M;

(iii) $|X_0^{S,\omega,\tau}| \leqq 1$, $\omega \in M$, $\tau \in R$;

(iv) *the functions* n, u, s *and their partial derivatives relative to* x, y, ζ *vanish at the points* $(\omega, 0, 0, 0, 0) \in M \times R^{d_T} \times R^{d_U} \times L \times BC^k(C; R^q)$, *and each one of them assumes related values at all points* (ω, x, y, ζ) *that represent the same point of* C;

(v) *for each* $g \in BC^k(C; R^q)$, *the perturbed equation*

$$\dot{w}(t) = f(w_t) + g(w_t) \tag{5.7}$$

is, in the new coordinates and for $t \geqq \sigma$, *equivalent to the system*

$$\begin{aligned} x(t) &= \Psi^T_\omega(t, \sigma)x(\sigma) + \int_\sigma^t \Psi^T_\omega(t, \tau)n(u_\tau(\omega), x(\tau), y(\tau), z_\tau, g)\, d\tau, \\ y(t) &= \Psi^U_\omega(t, \sigma)y(\sigma) + \int_\sigma^t \Psi^U_\omega(t, \tau)u(u_\tau(\omega), x(\tau), y(\tau), z_\tau, g)\, d\tau, \\ z_t &= T^S_\omega(t, \sigma)z_\sigma + \int_\sigma^t T^S_\omega(t, \tau)X_0^{S,\omega,\tau}s(u_\tau(\omega), x(\tau), y(\tau), z_\tau, g)\, d\tau. \end{aligned} \tag{5.8}$$

Proof. We need to project both sides of the variation of constants formula (5.5) in the tangential, unstable and stable directions along the points $u_t(\omega) \in M$, as indicated in the discussion preceding the theorem. Forgetting, for the moment, the differentiability properties of the functions involved, and recalling that T and U are invariant under the skew-product semiflow associated with the linear variational equation, we see that the introduction of bases for the finite-dimensional fibers $T_{u_t(\omega)}$ and $U_{u_t(\omega)}$ and the representation of the projected equations in terms of these bases lead to the first two equations in system (5.8).

The linear spaces $S_{u_t(\omega)}$ have codimension $d_T + d_U$ in C and can be one-to-one mapped onto a fixed subspace L of C of the same codimension. Projecting (5.5) onto S and representing this projection in the subspace L, we obtain an equation of the form of the last equation in system (5.8). The term $T_\omega(t, \tau)X_0^{S,\omega,\tau}$ needs some explanation. First, we notice that $T_\omega(\tau + r, \tau)X_0$ is a matrix with columns in C because of the smoothing action of $T_\omega(t, \tau)$. In fact, though $X_0(\theta)$ is a matrix valued function defined for $\theta \in [-r, 0]$ and discontinuous at $\theta = 0$, the solutions of the FDE with initial conditions equal to each one of the columns of X_0 are continuous for $t \geqq 0$ and, consequently, after $t = r$ units of time all the segment of the solution from $t - r$ to t is continuous, showing that the columns of $T_\omega(\tau + r, \tau)$ do, indeed, belong to C. This matrix can be projected onto $T_{u_{\tau+r}(\omega)}$ and $U_{u_{\tau+r}(\omega)}$ to give components $[T_\omega(\tau + r, \tau)X_0]^T_{u_{\tau+r}(\omega)}$ and $[T_\omega(\tau + r, \tau)X_0]^U_{u_{\tau+r}(\omega)}$, respectively. Since $T_\omega(\tau + r, \tau)$ is a homeomorphism from $T_{u_\tau(\omega)}$ to $T_{u_{\tau+r}(\omega)}$ and from $U_{u_\tau(\omega)}$ to $U_{u_{\tau+r}(\omega)}$, because T and U are invariant under the semiflow, it follows that there exist unique matrix-valued functions

$X_0^{T,\omega,\tau}$ and $X_0^{U,\omega,\tau}$ whose columns belong to $T_{u_\tau(\omega)}$ and $U_{u_\tau(\omega)}$, respectively, and are such that

$$T_\omega(\tau+r,\tau)X_0^{T,\omega,\tau}=[T_\omega(\tau+r,\tau)X_0]^T_{u_{\tau+r}(\omega)},$$
$$T_\omega(\tau+r,\tau)X_0^{U,\omega,\tau}=[T_\omega(\tau+r,\tau)X_0]^U_{u_{\tau+r}(\omega)}.$$

Now, we can define $X_0^{S,\omega,\tau}=X_0-X_0^{T,\omega,\tau}-X_0^{U,\omega,\tau}$, and it becomes clear that the last equation in system (5.8) is correct, provided $T^S_\omega(t,\tau)X_0^{S,\omega,\tau}$ is understood in the same sense as $T_\omega(t,\tau)X_0$ was (notice the $X_0^{S,\omega,\tau}$ does not belong to L, as X_0 does not belong to C; for an explanation of this notation refer to [4]).

Properties (i) and (iii) are easy to verify, property (ii) is a consequence of the hyperbolicity of M through Theorem 3.1, and property (iv) results from the positive invariance of T, U, L under the skew-product semiflow associated with the linear variational equation around M and the invariance of M under (5.6).

It remains to establish the smoothness properties of the functions n, u, s. For this we need to show that the normal bundle N, the projections associated with the decomposition $C=T_{u_t(\omega)}+U_{u_t(\omega)}+S_{u_t(\omega)}$, the vectors forming the bases for $T_{u_t(\omega)}$ and $U_{u_t(\omega)}$ and the one-to-one mapping from $S_{u_t(\omega)}$ onto L can all be chosen to be C^k-smooth in t. The possibility of choosing a C^k-smooth normal bundle N can be proved by a slight modification of the proof given by Whitney [20] for the case when the manifold M is modeled in a finite-dimensional euclidean space. In fact, a "natural" choice of the normal bundle would only be C^{k-1} smooth, but the procedure introduced by Whitney in the cited paper can be used to smooth it to be of class C^k. It follows that the projections associated with the decomposition $C=T_{u_t(\omega)}+U_{u_t(\omega)}+L_{u_t(\omega)}$ are of class C^k in t, provided $U_{u_t(\omega)}$ and $S_{u_t(\omega)}$ are C^k in t. These are defined in terms of the null space and the range, respectively, of the linear projections $P(u_t(\omega))$, defined on $N_{u_t(\omega)}$, which are associated with the dichotomy of the linearized skew-product semiflow around M induced by the given equation. Although these projections are, at the outset, only required to depend continuously on the points in the manifold M, they are in fact of class C^k in t because their null spaces are related, forwards and backwards in time, by a semiflow of class C^k. More precisely, the null space of $P(\omega)$ is mapped onto the null space of $P(u_t(\omega))$ by the map $\xi\to v_t(\omega,\xi)$ given by the solutions of equation (5.2). Since this map is of class C^k in t, due to the general results on smoothness of solutions of FDEs (see [4]), and N is a C^k vector bundle, it follows that $P(u_t(\omega))$ is C^k in t. The possibility of choosing the one-to-one mapping from $S_{u_t(\omega)}$ onto L to be C^k-smooth in t is a direct consequence of the C^k-smoothness of $P(u_t(\omega))$. In order to get the C^k-smoothness in t for the bases taken for $T_{u_t(\omega)}$ and $U_{u_t(\omega)}$, we only need to choose them to be mapped one to each other by the flows on these bundles, since these flows are of class C^k in t. QED

6. Functional differential equations in coordinate form. Under certain general conditions discussed in the preceding section, the linearization of a given FDE around a hyperbolic compact manifold M, and the introduction of local coordinates around the manifold lead to a family of systems parametrized by $\omega\in M$ and of the form

$$\dot x(t)=N(t)x(t)+n(t,x(t),y(t),z_t,\lambda), \tag{6.1}$$

$$y(t)=\Psi(t,\sigma)y(\sigma)+\int_\sigma^t \Psi(t,\tau)u(\tau,x(\tau),y(\tau),z_\tau,\lambda)\,d\tau, \tag{6.2}$$

$$z_t=T(t,\sigma)z_\sigma+\int_\sigma^t T(t,\tau)X_0^{s,\tau}s(\tau,x(\tau),y(\tau),z_\tau,\lambda)\,d\tau, \tag{6.3}$$

where λ is a parameter in a Banach space Λ, $x(t)\in R^{d_N}$, $y(t)\in R^{d_U}$, $z_t\in L$, L is a linear subspace of $C = C([-r, 0]; R^q)$ of codimension $(d_N + d_U)$, d_N, d_U, q are nonnegative integers with $d_N \geqq 1$, $X_0^{S,\tau}$ is a $q \times q$ matrix-valued function defined on $[-r, 0]$ and continuous in τ with its columns belonging to L and satisfying $|X_0^{S,\tau}| \leqq 1$ for all $\tau \in R$, $N(t)$ and $\Psi(t, \tau)$ are matrix-valued functions defined for $t, \tau \in R$, $T(t, \tau)$ are linear operators acting on L for $t \geqq \tau$, and the following hypotheses are satisfied:

(H_1) The function N of t is bounded and continuous for all $t \in R$;

(H_2) The functions n, u, s of $(t, x, y, \zeta, \lambda)$ are bounded, continuously differentiable in x, y, ζ and their partial derivatives relative to x, y, ζ as well as the functions n, u, x themselves are all bounded by some $B(\mu, \varepsilon) > 0$ over the region $t \in R$, $|x|, |y|, |\zeta| \leqq \mu \leqq \mu_0$, $|\lambda| \leqq \varepsilon \leqq \varepsilon_0$, with the function $B(\mu, \varepsilon)$ being nondecreasing in μ and ε, and approaching zero as $\mu, \varepsilon \to 0$;

(H_3) The matrix-valued function $\Psi(t, \tau)$ is continuously differentiable in $t, \tau \in R$, satisfies $\Psi(t, \tau)\Psi(\tau, \sigma) = \Psi(t, \sigma)$ for all $t, \tau, \sigma \in R$ and $\Psi(t, t)$ is the identity matrix for all $t \in R$. The linear operators $T(t, \tau)$ defined on L are continuously differentiable in t, τ such that $t \geqq \tau$, satisfy $T(t, \tau)T(\tau, \sigma) = T(t, \sigma)$ for all $t \geqq \tau \geqq \sigma$, and $T(t, t)$ is the identity operator on L for all $t \in R$;

(H_4) There exist $K \geqq 1$ and $\alpha > \alpha_0 > 0$, such that

$$|\Psi(t, \tau)| \leqq K e^{\alpha(t-\tau)}, \qquad t \leqq \tau,$$

$$|T(t, \tau)\phi| \leqq K e^{-\alpha(t-\tau)}|\phi|, \qquad t \geqq \tau, \quad \phi \in L$$

and the principal matrix solution $\Phi(t, \tau)$ of $\dot{x} = N(t)x$ satisfies

$$|\Phi(t, \tau)| \leqq K e^{\alpha_0|t-\tau|} \quad \text{for all } t, \tau \in R.$$

In this section we consider a more restricted situation, which will be used later on to establish the general result on the persistence of hyperbolic manifolds. More precisely, the hypothesis (H_2) is replaced by

(H_2') The functions n, u, s of $(t, x, y, \zeta, \lambda)$ are bounded and continuous, vanish at all points where x, y, ζ are simultaneously zero, and are globally Lipschitzian in the coordinates x, y, ζ, in the sense that there exists a $D > 0$ such that

$$|n(t, x, y, \zeta, \lambda) - n(\theta, \bar{x}, \bar{y}, \bar{\zeta}, \lambda)| \leqq D(|x - \bar{x}| + |y - \bar{y}| + |\zeta - \bar{\zeta}|)$$

for all $t \in R$, $x, \bar{x} \in R^{d_N}$, $y, \bar{y} \in R^{d_U}$, $\zeta, \bar{\zeta} \in L$, $\lambda \in \Lambda$, and similarly for u and s.

In the proofs of the results of this section on the persistence of hyperbolic invariant manifolds for system (6.1)-(6.3) with $|\lambda|$ small, we use the following property of solutions $(x(t), y(t), z_t)$, $t \in R$, which have $y(t)$ and z_t bounded.

LEMMA 6.1. *Assume the hypotheses* (H_1)-(H_4) *hold. Then* $(x(t), y(t), z_t)$, $t \in R$, *is a solution of the system* (6.1)-(6.3) *with* $y(t)$ *and* z_t *bounded if and only if for some* γ *belonging to the interval* (α_0, α) *the function*

$$w(t, x(0)) = e^{-\gamma|t|}(x(t), y(t), z_t), \qquad t \in R \tag{6.4}$$

agrees, when $x(0) = b \in R^{d_N}$, *with a fixed point of the transformation* T *defined on the set of bounded continuous functions* $w: R \times R^{d_N} \to R^{d_N} \times R^{d_U} \times L$ *by*

$$\begin{aligned} Tw(t, b) = \Big(& e^{-\gamma|t|}\Phi(t, 0)b + e^{-\gamma|t|} \int_0^t \Phi(t, \tau)n(\tau, e^{\gamma|\tau|}w(\tau, b), \lambda)\, d\tau, \\ & e^{-\gamma|t|} \int_{+\infty}^t \Psi(t, \tau)u(\tau, e^{\gamma|\tau|}w(\tau, b), \lambda)\, d\tau, \\ & e^{-\gamma|t|} \int_{-\infty}^t T(t, \tau)X_0^{S,\tau}s(\tau, e^{\gamma|\tau|}w(\tau, b), \lambda)\, d\tau \Big). \end{aligned} \tag{6.5}$$

If (H_2) *is replaced by* (H_2') *the same holds.*

Proof. If $(x(t), y(t), z_t)$ is a solution of (6.1)–(6.3) which is defined for all $t \in R$ and has $y(t)$ bounded, it follows from hypothesis (H_4) that for $\sigma \geqq t$

$$\left| y(t) - \int_\sigma^t \Psi(t, \tau) u(\tau, x(\tau), y(\tau), z_\tau, \lambda)\, d\tau \right| = |\Psi(t, \sigma) y(\sigma)| \leqq K e^{\alpha(t-\sigma)} |y(\sigma)|$$

and, letting $\sigma \to +\infty$, we get

$$y(t) = \int_{+\infty}^t \Psi(t, \tau) u(\tau, x(\tau), y(\tau), z_\tau, \lambda)\, d\tau, \tag{6.6}$$

where the improper integral converges because u is bounded and Ψ satisfies the exponential estimates in assumption (H_4). Analogously, if $(x(t), y(t), z_t)$, $t \in R$, is a solution of (6.1)–(6.3) with z_t bounded, then

$$z_t = \int_{-\infty}^t T(t, \tau) X_0^{S,\tau} s(\tau, x(\tau), y(\tau), z_\tau, \lambda)\, d\tau. \tag{6.7}$$

Conversely, if $(x(t), y(t), z_t)$, $t \in R$, is a given continuous function satisfying equation (6.1) and (6.6)–(6.7) then it is a solution of the system (6.1)–(6.3), with $y(t)$ and z_t bounded, because of hypotheses (H_1) and (H_4).

The variation of constants formula for (6.1) gives

$$x(t) = \Phi(t, 0) x(0) + \int_0^t \Phi(t, \tau) n(\tau, x(\tau), y(\tau), z_\tau, \lambda)\, d\tau. \tag{6.8}$$

From hypothesis (H_2) or (H_2') there exists $B > 0$ which bounds n, and from hypothesis (H_4) we get

$$|x(t)| \leqq K e^{\alpha_0 |t|} |x(0)| + B \left| \int_0^t K e^{\alpha_0 |t-\tau|}\, d\tau \right| \leqq \left(|x(0)| + \frac{B}{\alpha_0} \right) K e^{\alpha_0 |t|}.$$

Consequently (6.1) is equivalent to (6.8) and $e^{-\gamma |t|} |x(t)|$, $t \in R$, is bounded. This finishes the proof of the statement. QED

THEOREM 6.2. *If the hypotheses* (H_1), (H_2'), (H_3), (H_4) *are satisfied and the constants* α_0, α, K *of hypothesis* (H_4) *and* D *of hypothesis* (H_2') *satisfy the inequality*

$$DK(K+1) \left[\frac{1}{\gamma - \alpha_0} + \frac{2}{\alpha - \gamma} + \frac{1}{\alpha + \gamma} \right] < 1 \tag{6.9}$$

for some γ *in the interval* (α_0, α), *then there exist continuous functions* h_1, h_2 *defined on* $R \times R^{d_N} \times \Lambda$ *and with values in* R^{d_U} *and* L, *respectively, which are bounded and such that the function* $x \to (h_1(t, x, \lambda), h_2(t, x, \lambda))$ *is Lipschitzian with Lipschitz constant* $(K+1)$ *and with* $h_1(t, 0, 0) = 0$, $h_2(t, 0, 0) = 0$ *for all* $t \in R$, $x \in R^{d_N}$, $\lambda \in \Lambda$, *such that the set*

$$M_\lambda = \{(t, x, y, \zeta) \in R \times R^{d_N} \times R^{d_U} \times L \colon y = h_1(t, x, \lambda), \zeta = h_2(t, x, \lambda)\}$$

is an integral manifold for system (6.1)–(6.3), *in the sense that if* $(t_0, x(t_0), y(t_0), z_{t_0}) \in M_\lambda$ *then the solution of* (6.1)–(6.3) *with this initial data stays in* M_λ *for all time.*

Furthermore, M_λ *is the maximal integral manifold for system* (6.1)–(6.3) *contained in* $R \times R^{d_N} \times V$, *for any bounded neighborhood of zero* $V \subset R^{d_U} \times L$.

Proof. The preceding lemma indicates that finding integral manifolds M_λ for (6.1)–(6.3), which belong to $R \times R^{d_N} \times V$ for some neighborhood of zero $V \subset R^{d_U} \times L$, amounts to finding fixed points of the mapping T in the lemma. These fixed points are studied, in the present proof, by an application of the contraction mapping principle to a specific set of continuous functions $w \colon R \times R^{d_N} \to R^{d_N} \times R^{d_U} \times L$ taken with a metric generated by a suitable family of pseudonorms.

Let us denote by W the set of bounded continuous functions $w: R\times R^{d_N}\to R^{d_N}\times R^{d_U}\times L$ that satisfy

$$|w(t,b)-w(t,\bar{b})|\leqq (K+1)|b-\bar{b}| \quad \text{for all } b,\ \bar{b}\in R^{d_N},\quad t\in R,$$

where $K\geqq 1$ is the constant in the hypothesis (H$_4$). The set W is a complete metric space with the topology generated by the family of pseudonorms

$$\text{(6.10)}\qquad \|w\|_n=\sup\{|w(t,b)|: t\in R, |b|\leqq n\},\quad n=1,2,\cdots.$$

It is clear that, for each $w\in W$, Tw is a continuous function from $R\times R^{d_N}$ into $R^{d_N}\times R^{d_U}\times L$. Using the hypotheses (H$_2'$) and (H$_4$) we get

$$\begin{aligned}|Tw(t,b)|\leqq \Bigg[& e^{-\gamma|t|}\, e^{\alpha_0|t|}K|b|+e^{-\gamma|t|}\int_0^t K\, e^{\alpha_0|t-\tau|}D\, e^{\gamma|\tau|}\,d\tau \\ & +e^{-\gamma|t|}\int_t^{+\infty} K\, e^{\alpha(t-\tau)}D\, e^{\gamma|\tau|}\,d\tau \\ & +e^{-\gamma|t|}\int_{-\infty}^{t} K\, e^{-\alpha(t-\tau)}D\, e^{\gamma|\tau|}\,d\tau\Bigg]\sup_{\tau\in R}|w(\tau,b)|.\end{aligned}$$

Consequently, as $\gamma\in(\alpha_0,\alpha)$, we obtain

$$|Tw(t,b)|\leqq K|b|+DK\left[\frac{1}{\gamma-\alpha_0}+\frac{2}{\alpha-\gamma}+\frac{1}{\alpha+\gamma}\right]\sup_{\tau\in R}|w(\tau,b)|.$$

This shows that Tw is bounded for each $w\in W$. In a similar way, and using (6.9), one obtains

$$\begin{aligned}|Tw(t,b)-Tw(t,\bar{b})| & \leqq K|b-\bar{b}|+DK\left[\frac{1}{\gamma-\alpha_0}+\frac{2}{\alpha-\gamma}+\frac{1}{\alpha+\gamma}\right]\sup_{\tau\in R}|w(\tau,\bar{b})-w(\tau,\bar{b})| \\ & <(K+1)|b-\bar{b}|.\end{aligned}$$

On the other hand, if w, $\bar{w}\in W$, we have

$$|Tw(t,b)-T\bar{w}(t,b)|\leqq DK\left[\frac{1}{\gamma-\alpha_0}+\frac{2}{\alpha-\gamma}+\frac{1}{\alpha+\gamma}\right]\sup_{\tau\in R}|w(\tau,b)-\bar{w}(\tau,b)|,$$

which implies that

$$\|Tw-T\bar{w}\|_n\leqq DK\left[\frac{1}{\gamma-\alpha_0}+\frac{2}{\alpha-\gamma}+\frac{1}{\alpha+\gamma}\right]\|w-\bar{w}\|_n.$$

Since Condition (6.9) is satisfied, then T is a uniform contraction from W into itself, in the given family of pseudonorms. The contraction mapping principle implies that there exists a unique fixed point of T in the set W and that this fixed point depends continuously on λ.

Let $w^*=Tw^*$ be the fixed point of T in W and define the functions h_1 and h_2 by

$$(b, h_1(t,b,\lambda), h_2(t,b,\lambda))=w^*(t,b).$$

It is clear that h_1, h_2 are defined for $t\in R$, $b\in R^{d_N}$, $\lambda\in\Lambda$, that they are continuous bounded functions which are Lipschitzian in the variable b with Lipschitz constant $(K+1)$ and that they vanish at the points $(t,0,0)$.

Suppose $(x(t), y(t), z_t)$, $t\in R$, is any solution of (6.1)-(6.3) with $y(t)$ and z_t bounded, and denote $b=x(0)$. Lemma 6.1 implies that $w(t)=e^{-\gamma|t|}(x(t),y(t),z_t)$ is a fixed point of the map T_b defined on the set $B(R)$ of the continuous bounded functions $w: R\to R^{d_N}\times R^{d_U}\times L$ by the same formula (6.5) as in the definition of T, but replacing

$w(t, b)$ by $w(t)$. The argument used above for T also shows that T_b maps $B(R)$ into itself and is a contraction in the supremum norm on $B(R)$. Therefore T_b has a unique fixed point in $B(R)$ which must satisfy $w(t) = w^*(t, b)$. It follows that M_λ is the maximal integral manifold in $R \times R^{d_N} \times V$, for any $V \subset R^{d_U} \times L$ which is a bounded neighborhood of zero. QED

Remark. The functions h_1, h_2 of the previous theorem do not depend on the particular value of $\gamma \in (\alpha_0, \alpha)$, provided it satisfies (6.9). In fact, if $\alpha_0 < \gamma_1 < \gamma_2 < \alpha$ and the function $w_1(t, x(0))$ is bounded and given as in (6.4) with $\gamma = \gamma_1$, then the function $w_2(t, x(0))$ also given as in (6.4) but with $\gamma = \gamma_2$ is also bounded. The uniqueness of the fixed point of the mapping T implies that $w_1 = w_2$.

The structure of the solutions around M_λ is preserved under small perturbations, as is illustrated by the following result.

THEOREM 6.3. *Assume the same hypotheses as for Theorem* 6.2. *Then the manifold* M_λ *is the intersection of two manifolds* S_λ, $U_\lambda \subset R \times R^{d_N} \times R^{d_U} \times L$ *which are positive integral manifolds for* (6.1)-(6.3), *and are such that solutions with initial data in* S_λ *approach* M_λ *as* $t \to +\infty$ *and solutions with initial data in* U_λ *are globally defined and approach* M_λ *as* $t \to -\infty$. *Moreover* S_λ, U_λ *are homeomorphic to* $R \times L$, $R \times R^{d_U}$, *respectively, and have the forms*

$$S_\lambda = \{(t, x, y, \zeta) \in R \times R^{d_N} \times R^{d_U} \times L \colon y = h^S(t, x, \zeta, \lambda)\}$$

and

$$U_\lambda = \{(t, x, y, \zeta) \in R \times R^{d_N} \times R^{d_U} \times L \colon \zeta = h^U(t, x, y, \lambda)\},$$

where the functions $(x, \zeta) \to h^S(t, x, \zeta, \lambda)$ *and* $(x, y) \to h^U(t, x, y, \lambda)$ *are Lipschitzian homeomorphisms from, respectively,* $R^{d_N} \times L$ *to* S_λ *and* $R^{d_N} \times R^{d_U}$ *to* U_λ, *with Lipschitz constant* $(K+1)$ *and satisfy* $h^S(t, x, \zeta, 0) = 0$, $h^U(t, x, y, 0) = 0$. *In addition, there exist* σ, $C > 0$ *such that, if* $(x(t), y(t), z_t)$ *is a solution of* (6.1)-(6.3) *with initial condition in* S_λ, *then*

$$|(x(t), y(t), z_t)| \leqq C(|x(0)| + |z_0|)\, e^{\sigma t}, \qquad t \geqq 0$$

and, if $(x(t), y(t), z_t)$ *is a solution of* (6.1)-(6.3) *with initial condition in* U_λ, *then*

$$|(x(t), y(t), z_t)| \leqq C(|x(0)| + |y(0)|)\, e^{-\sigma t}, \qquad t \leqq 0,$$

where $\sigma \in (\alpha_0, \gamma)$.

Proof. If $(x(t), y(t), z_t)$ is an arbitrary solution of (6.1)-(6.3) which is defined for all $t \geqq 0$ and has $y(t)$ bounded for $t \geqq 0$, we find, as in the proof of Lemma 6.1, that

$$y(t) = \int_{+\infty}^{t} \Psi(t, \tau) u(\tau, x(\tau), y(\tau), z_\tau, \lambda)\, d\tau.$$

Consequently, based on the discussion in Lemma 6.1 and Theorem 6.2, we expect that looking for the set S_λ will amount to finding fixed points of the transformation T^S defined on the set of bounded continuous functions $w \colon R^+ \times R^{d_N} \times L \to R^{d_N} \times R^{d_U} \times L$, by

$$\begin{aligned} T^S w(t, b, \zeta) = \Big(& e^{-\gamma t}\Phi(t, 0) b + e^{-\gamma t} \int_0^t \Phi(t, \tau) n(\tau, e^{\gamma \tau} w(\tau, b, \zeta), \lambda)\, d\tau, \\ & e^{-\gamma t} \int_{+\infty}^{t} \Psi(t, \tau) u(\tau, e^{\gamma\tau} w(\tau, b, \zeta), \lambda)\, d\tau, \qquad (6.11) \\ & e^{-\gamma t} T(t, 0)\zeta + e^{-\gamma t} \int_0^t T(t, \tau) X_0^{S,\tau} s(\tau, e^{\gamma\tau} w(\tau, b, \zeta), \lambda)\, d\tau \Big), \end{aligned}$$

where $\gamma \in (\alpha_0, \alpha)$.

We denote by W^S the set of bounded continuous function $w: R^+ \times R^{d_U} \times L \to R^{d_N} \times R^{d_U} \times L$ which satisfy

$$|w(t, b, \zeta) - w(t, \bar{b}, \bar{\zeta})| \leqq (K+1)(|b-\bar{b}| + |\zeta - \bar{\zeta}|)$$

for all $b, \bar{b} \in R^{d_N}$, $\zeta, \bar{\zeta} \in L$, $t \in R^+$, where $K \geqq 1$ is the constant in the hypothesis (H_4). The set W^S is a complete metric space with the topology generated by the family of pseudonorms

$$\|w\|_n = \sup \{|w(t, b, \zeta)| : t \in R^+, |b| \leqq n, |\zeta| \leqq n\}, \qquad n = 1, 2, \cdots.$$

Similar to what was done in the proof of Theorem 6.2 for the mapping T on W, it can be shown that T^S is a uniform contraction on W^S and, therefore, there exists a unique fixed point of T^S in W^S and it depends continuously on λ.

If we let $W^S = T^S w^S$ be the fixed point of T^S on W^S and define the function h^S by

$$(b, h^S(t, b, \zeta, \lambda), \zeta) = w^S(t, b, \zeta),$$

it is clear that the set S_λ, defined as in the statement of the theorem, is a positive integral manifold for system (6.1)-(6.3) and is homeomorphic to $R^{d_N} \times L$.

Next, we will show that $|w^S(t, b, \zeta)| \to 0$ as $t \to +\infty$. Let $\mu = \limsup_{t \to +\infty} |w^S(t, b, \zeta)|$. Because of (6.9), we can choose $\delta > 1$ so that

$$KD\left[\frac{1}{\gamma - \alpha_0} + \frac{1}{\gamma - \alpha} + \frac{1}{\gamma + \alpha}\right]\delta < 1.$$

If $\mu > 0$, then there is a $\sigma > 0$ so that $|w^S(t, b, \zeta)| \leqq \mu\delta$ for $t \geqq \sigma$. Then, using formula (6.11) and the estimates available for its terms, we get for $t \geqq \sigma$

$$\begin{aligned} |w^S(t, b, \zeta)| = |T^S w^S(t, b, \zeta)| &\leqq K e^{-(\gamma - \alpha_0)t}|b| + K e^{-(\alpha+\gamma)t}|\zeta| \\ &\quad + KD\left[\frac{e^{-(\gamma-\alpha_0)(t-\sigma)}}{\gamma - \alpha_0} + \frac{e^{-(\gamma+\alpha)(t-\sigma)}}{\gamma+\alpha}\right] \sup_{t \geqq 0} |w^S(\tau, b, \zeta)| \\ &\quad + KD\left[\frac{1}{\gamma-\alpha_0} + \frac{1}{\gamma-\alpha} + \frac{1}{\gamma+\alpha}\right]\mu\delta. \end{aligned}$$

Letting $t \to +\infty$, we get

$$\mu \leqq KD\left[\frac{1}{\gamma-\alpha_0} + \frac{1}{\gamma-\alpha} + \frac{1}{\gamma+\alpha}\right]\delta\mu < \mu,$$

which is a contradiction. Hence $\mu = 0$. This proves that $|w^S(t, b, \zeta)| \to 0$ as $t \to +\infty$.

Now we derive the exponential rate of decay of w^S as $t \to +\infty$. Let $v(t, b, \zeta) = \sup_{\tau \geqq t} |w^S(\tau, b, \zeta)|$. Since $|w^S(\tau, b, \zeta)| \to 0$ as $\tau \to +\infty$, for every $t \geqq 0$ there is a $\sigma \geqq t$ such that

$$v(\tau, b, \zeta) = v(\sigma, b, \zeta) = |w^S(\sigma, b, \zeta)|, \qquad t \leqq \tau \leqq \sigma.$$

On the other hand, estimates using formula (6.11) give

$$\begin{aligned} |w^S(t, b, \zeta)| \leqq K e^{-(\gamma-\alpha_0)t}|b| + K e^{-(\gamma+\alpha)t}|\zeta| &+ \int_0^t K e^{-(\gamma-\alpha_0)(t-\tau)} D |w^S(\tau, b, \zeta)|\, d\tau \\ &+ \int_t^{+\infty} K e^{-(\gamma-\alpha)(t-\tau)} D |w^S(\tau, b, \zeta)|\, d\tau \\ &+ \int_0^t K e^{-(\gamma+\alpha)(t-\tau)} D |w^S(\tau, b, \zeta)|\, d\tau. \end{aligned}$$

Consequently,

$$\begin{aligned} v(t, b, \zeta) = v(\sigma, b, \zeta) \leqq K e^{-(\gamma-\alpha_0)t}|b| + K e^{-(\gamma+\alpha)t}|\zeta| + \int_0^t K e^{-(\gamma-\alpha_0)(t-\tau)} Dv(\tau, b, \zeta) \\ + \int_t^\sigma K e^{-(\gamma-\alpha_0)(\sigma-\tau)} Dv(\tau, b, \zeta)\, d\tau \\ + \int_t^{-\infty} K e^{(\alpha-\gamma)(t-\tau)} Dv(\tau, b, \zeta)\, d\tau \\ + \int_0^t K e^{-(\gamma+\alpha)(t-\tau)} Dv(\tau, b, \zeta)\, d\tau \\ + \int_t^\sigma K e^{-(\gamma+\alpha)(\sigma-\tau)} Dv(\tau, b, \zeta)\, d\tau \end{aligned}$$

and, therefore,

$$\begin{aligned} v(t, b, \zeta) \leqq K e^{-(\gamma-\alpha_0)t}(|b| + |\zeta|) + \int_0^t K e^{-(\gamma-\alpha_0)(t-\tau)} Dv(\tau, b, \zeta)\, d\tau \\ + KD\left(\frac{1}{\gamma-\alpha_0} + \frac{1}{\alpha-\gamma} + \frac{1}{\gamma+\alpha}\right) v(t, b, \zeta). \end{aligned}$$

Due to (6.9), we can write

$$\begin{aligned} e^{(\gamma-\alpha_0)t} v(t, b, \zeta) \leqq \left[1 - KD\left(\frac{1}{\gamma-\alpha_0} + \frac{1}{\alpha-\gamma} + \frac{1}{\gamma+\alpha}\right)\right]^{-1} \\ \cdot K\left[|b| + |\zeta| + \int_0^t D e^{(\gamma-\alpha_0)\tau} v(\tau, b, \zeta)\, d\tau\right]. \end{aligned}$$

Applying the Gronwall inequality we obtain

$$|v(t, b, \zeta)| \leqq C(|b| + |\zeta|)\, e^{-Bt},$$

where

$$C = K \Big/ \left[1 - KD\left(\frac{1}{\gamma-\alpha_0} + \frac{1}{\alpha-\gamma} + \frac{1}{\alpha+\gamma}\right)\right] \quad \text{and} \quad B = \gamma - \alpha_0 - CD.$$

From (6.9), noting that $K \geqq 1$, it is easy to verify that C, B are positive. It follows that there exist $C, B > 0$ such that

$$|(x(t), y(t), z_t)| \leqq C(|x(0)| + |z_0|)\, e^{(\gamma-B)t}, \qquad t \geqq 0 \tag{6.12}$$

for every solution $(x(t), y(t), z_t)$ of (6.1)-(6.3) which has initial data on S_λ.

In a similar way, we obtain the manifold U_λ. Now, we look for fixed points of the mapping defined on the set of bounded continuous functions $w: R^- \times R^{d_N} \times R^{d_U} \to R^{d_N} \times R^{d_U} \times L$ by

$$T^U w(t, b, c) = \Big(e^{\gamma t}\Phi(t, 0)b + e^{\gamma t} \int_0^t \Phi(t, \tau) n(\tau, e^{-\gamma\tau} w(\tau, b, c), \lambda)\, d\tau,$$

$$e^{\gamma t}\Psi(t,0)c+e^{\gamma t}\int_0^t \Psi(t,\tau)u(\tau,e^{-\gamma\tau}w(\tau,b,c),\lambda)\,d\tau,$$

$$e^{\gamma t}\int_{-\infty}^t T(t,\tau)X_0^{S,\tau}s(\tau,e^{-\gamma\tau}w(\tau,b,c),\lambda)\,d\tau\Big).$$

Similarly, we obtain for some constants $C, B>0$

$$|(x(t),y(t),z_t)|\leqq C(|x(0)|+|y(0)|)\,e^{-(\gamma-B)t},\qquad t\leqq 0 \tag{6.13}$$

for every solution $(x(t),y(t),z_t)$ of system (6.1)-(6.3) which has initial data on U_λ.

It is clear, from the above construction and the proofs of Lemma 6.1 and Theorem 6.2, that $M_\lambda=S_\lambda\cap U_\lambda$ and the trajectory of any solution $(x(t),y(t),z_t)$ for which $e^{-\gamma|t|}|(x(t),y(t),z_t)|$ is bounded for $t\in R$ lies necessarily on M_λ. Consequently, (6.12) and (6.13) imply the exponential estimates in the statement of the theorem. QED

The following result establishes the smoothness properties of M_λ, S_λ and U_λ.

THEOREM 6.4. *If the hypotheses* (H_1), (H_2'), (H_3), (H_4) *are satisfied, the functions n, u, s are continuously differentiable with bounded derivatives up to order $k\geqq 1$, relative to x, y, ζ, and the constants α_0, α, K of hypothesis* (H_4), *and D of hypothesis* (H_2') *satisfy the inequalities*

$$\alpha>k\alpha_0 \tag{6.14}$$

and

$$DK(K+1)\left[\frac{1}{\gamma-\alpha_0}+\frac{2}{\gamma-\alpha}+\frac{1}{\gamma+\alpha}\right]<1 \tag{6.15}$$

for some γ in the interval $(k\alpha_0,\alpha)$, then the function $x\to(h_1(t,x,\lambda),h_2(t,x,\lambda))$, defined as in Theorem 6.2, *is of class C^k, and the same is true for the functions $(x,\zeta)\to h^S(t,x,\zeta,\lambda)$ and $(x,y)\to h^U(t,x,y,\lambda)$ of Theorem* 6.3.

Proof. We recall from the proof of Theorem 6.2 that h_1, h_2 were defined in terms of the fixed point of the transformation T in the set W. Consequently, if w denotes this fixed point, in order to prove that $h_1(t,x,\lambda)$, $h_2(t,x,\lambda)$ are C^k functions of x, we only need to show that the function $b\to w(t,b)$ is of class C^k. This will be done by induction.

Let us assume the hypothesis of the theorem is satisfied for $k=1$. If the derivative $\partial w(t,b)/\partial b$ exists, it must satisfy the equation obtained by formally differentiating $w=Tw$ relative to b. In particular, $\partial w/\partial b$ must be a fixed point of the mapping F defined for functions taking $R\times R^{d_N}$ to linear transformations of R^{d_N} into $R^{d_N}\times R^{d_U}\times L$

$$Fv(t,b)=\Big(e^{-\gamma|t|}\Phi(t,0)+e^{-\gamma|t|}\int_0^t\Phi(t,\tau)\frac{\partial n}{\partial w}(\tau,e^{\gamma|\tau|}w(\tau,b),\lambda)\,e^{\gamma|\tau|}v(\tau,b)\,d\tau,$$

$$e^{-\gamma|t|}\int_{+\infty}^t\Psi(t,\tau)\frac{\partial u}{\partial w}(\tau,e^{\gamma|\tau|}w(\tau,b),\lambda)\,e^{\gamma|\tau|}v(\tau,b)\,d\tau, \tag{6.16}$$

$$e^{-\gamma|t|}\int_{-\infty}^t T(t,\tau)X_0^{s,\tau}\frac{\partial s}{\partial w}(\tau,e^{\gamma|\tau|}w(\tau,b),\lambda)\,e^{\gamma|\tau|}v(\tau,b)\,d\tau\Big).$$

We remark that the improper integrals converge because of hypothesis (H_4), the boundedness of the partial derivatives of u, s and the assumption $\alpha>\alpha_0$. Let Z denote the set of all functions continuously differentiable in the second argument and defined from $R \times R^{d_N}$ to the set of all linear transformations of R^{d_N} into $R^{d_N} \times R^{d_U} \times L$ which satisfy $|v(t, b)| \leqq K+1$, for all $t \in R$, $b \in R^{d_N}$. If $v \in Z$ then

$$\begin{aligned} |Fv(t, b)| &\leqq K e^{-(\gamma-\alpha_0)|t|} + e^{-\gamma|t|} \left| \int_0^t K e^{\alpha_0|t-\tau|} D e^{\gamma|\tau|}(K+1)\, d\tau \right| \\ &\quad + e^{-\gamma|\tau|} \int_t^{+\infty} K e^{\alpha(t-\tau)} D e^{\gamma|\tau|}(K+1)\, d\tau \\ &\quad + e^{-\gamma|\tau|} \int_{-\infty}^t K e^{-\alpha(t-\tau)} D e^{\gamma|\tau|}(K+1)\, d\tau \\ &\leqq K + DK(K+1)\left[\frac{1}{\gamma-\alpha_0} + \frac{2}{\alpha-\gamma} + \frac{1}{\alpha+\gamma}\right] < K+1. \end{aligned} \tag{6.17}$$

Therefore, F maps the set Z into itself. Let us consider the sequence $\{v_i\}$ of functions, taking $R \times R^{d_N}$ into the linear transformations of R^{d_N} into $R^{d_N} \times R^{d_U} \times L$ which is defined recursively by

$$v_1 = 0 \quad \text{and} \quad v_{i+1} = F(v_i), \qquad i \geqq 1.$$

Since F maps Z into itself, we have $\{v_i\} \subset Z$. The set Z with the metric inherited from the usual uniform norm is a complete metric space. As in (6.17), we get

$$\|v_{i+1} - v_i\| = \|Fv_i - Fv_{i-1}\| \leqq DK\left[\frac{1}{\gamma-\alpha_0} + \frac{2}{\alpha-\gamma} + \frac{1}{\alpha+\gamma}\right] \|v_i - v_{i-1}\|. \tag{6.18}$$

It follows from (6.9) that $\{v_i\}$ is a Cauchy sequence in Z and, consequently, converges to some $v \in Z$ as $i \to \infty$. Clearly v is a fixed point of F.

Now, we can prove that v is, indeed, the derivative $\partial w/\partial b$. Fix $t \in R$, $b \in R^{d_N}$ and let σ be a function defined for small values of $\varepsilon > 0$ by

$$\sigma(\varepsilon) = \sup_{\substack{t \in R \\ |h| \leqq \varepsilon}} \frac{|w(t, b+h) - w(t, b) - v(t, b)h|}{|h|}. \tag{6.19}$$

In order to prove that $\partial w/\partial b$ exists and is equal to v we need to show that $\sigma(\varepsilon) \to 0$ as $\varepsilon \to 0$. From formulas (6.5) and (6.16), using the first order Taylor expansion and hypotheses (H_2') and (H_4) in a similar way as for inequalities (6.17) and (6.18), we get

$$\begin{aligned} &|w(t, b+h) - w(t, b) - v(t, b)h| \\ &\quad \leqq DK\left[\frac{1}{\gamma-\alpha_0} + \frac{2}{\alpha-\gamma} + \frac{1}{\alpha+\gamma}\right] \\ &\qquad \cdot \sup_{\tau \in R} [|w(\tau, b+h) - w(\tau, b) - v(\tau, b)h| + o(|w(\tau, b+h) - w(\tau, b)|)]. \end{aligned}$$

Recalling from Theorem 6.2 that $w(t, b)$ is Lipschitzian in b with Lipschitz constant equal to $(K+1)$, we get

$$\sigma(\varepsilon) \leqq DK\left[\frac{1}{\gamma-\alpha_0} + \frac{2}{\alpha-\gamma} + \frac{1}{\alpha+\gamma}\right] \sigma(\varepsilon) + o(\varepsilon)$$

as $\varepsilon \to 0$. Applying (6.9) we get $\sigma(\varepsilon) = o(\varepsilon)$, proving that $w(t, b)$ is differentiable in b and the derivative $\partial w(t, b)/\partial b$ is the continuous function v defined above. The preceding reasoning shows that the function $b \to w(t, b)$ is continuously differentiable and, consequently, also $b \to (h_1(t, b, \lambda), h_2(t, b, \lambda))$ is.

Now, let us assume that $b \to w(t, b)$ is of class C^j for a certain $j \geqq 1$ and the hypothesis of the theorem is satisfied for $k = j+1$. Let $v = \partial w^j/\partial b^j$. Differentiating j times both sides of equation $w = Tw$, we get

$$
\begin{aligned}
v(t, b) = \Bigg(& e^{-\gamma|t|} \int_0^t \Phi(t, \tau) \frac{\partial n}{\partial w}(\tau, e^{\gamma|\tau|} w(\tau, b), \lambda)\, e^{\gamma|\tau|} v(\tau, b)\, d\tau, \\
& e^{-\gamma|t|} \int_{+\infty}^t \Psi(t, \tau) \frac{\partial u}{\partial w}(\tau, e^{\gamma|\tau|} w(\tau, b), \lambda)\, e^{\gamma|\tau|} v(\tau, b)\, d\tau, \\
& e^{-\gamma|t|} \int_{-\infty}^t T(t, \tau) X_0^{S,\tau} \frac{\partial s}{\partial w}(\tau, e^{\gamma|\tau|} w(\tau, b), \lambda)\, e^{\gamma|\tau|} v(\tau, b)\, d\tau \Bigg) \\
& + (\text{terms not involving } v).
\end{aligned} \tag{6.20}
$$

The terms not involving v contain derivatives of n, u, s relative to w up to order j, derivatives of w up to order $j-1$ and exponential factors of the form $e^{i\gamma|\tau|}$ for $i = 1, 2, \cdots, j$. The improper integrals in these terms converge because of hypothesis (H_4), the boundedness of all the partial derivatives of n, u, s up to order j, and the assumption $\alpha > k\alpha_0$. We can let T be the mapping transforming v to the function $T(v)$ of (t, b) according to the right-hand side of (6.20) and define recursively the sequence $\{v_i\}$ by

$$v_i = 0 \quad \text{and} \quad v_{i+1} = T(v_i) \quad \text{for } i \geqq 1.$$

As in the first part of the proof we have that $\{v_i\}$ is a Cauchy sequence and, consequently, it converges to a fixed point of T which must be $v = \partial^j w/\partial b^j$. Clearly, the functions $v_i(t, b)$ are differentiable in b, and $\partial v_{i+1}/\partial b$ is given by the right-hand side of (6.20) with v replaced by $\partial v_i/\partial b$. Proceeding as for (6.18), we get

$$\left\| \frac{\partial v_{i+1}}{\partial b} - \frac{\partial v_i}{\partial b} \right\| \leqq DK \left[\frac{1}{\gamma - \alpha_0} + \frac{2}{\alpha - \gamma} + \frac{1}{\alpha + \gamma} \right] \left\| \frac{\partial v_i}{\partial b} - \frac{\partial v_{i-1}}{\partial b} \right\|.$$

From (6.9), we get that $\{\partial v_i/\partial b\}$ is a Cauchy sequence. Arguing as in the first part of the proof, where the first derivative was handled, we can show that $\partial v/\partial b = \partial w^{j+1}/\partial b^{j+1}$ exists and is equal to the limit of $\{\partial v_i/\partial b\}$ as $i \to \infty$. This completes the induction.

The smoothness of h^U and h^S can be handled in a similar way. QED

7. Functional differential equations with hyperbolic invariant manifolds. As before, consider $r > 0$ and let $C = C([-r, 0]; R^q)$ denote the Banach space of continuous functions from the interval $[-r, 0]$ into R^q, where q is a positive integer and C is taken with the uniform norm. Let us consider a FDE

$$\dot{u}(t) = f(u_t), \tag{7.1}$$

where $f \in BC^k(C, R^n)$ with $k \geqq 1$, and suppose that $M \subset C$ is a compact, connected, C^k-manifold which is k-hyperbolic under the semiflow defined by the solutions of (7.1). It is known from § 5 that the equation can be linearized around the manifold M and a system of coordinates can be introduced around M so that the equation becomes of the form discussed in § 6. The aim of the present section is to show how the results on the persistence and smoothness of integral manifolds for systems in coordinate form, as presented in the previous section, can be applied to (7.1), yielding the persistence of an hyperbolic invariant manifold close to M, under small perturbations of (7.1).

THEOREM 7.1. *Let $f \in BC^k(C, R^q)$, $k \geqq 1$, and assume that $M_0 \subset C$ is a compact, connected, C^k-manifold which is k-hyperbolic under the semiflow defined by the solutions of the equation*

$$\dot{u}(t) = f(u_t). \tag{7.2}$$

If $g \in BC^k(C, R^q)$ and $\|g\|_1 = \sup\{|g(\phi)|, \|g'(\phi)\|: \phi \in C\}$ is sufficiently small, then there exists a C^k-manifold $M_g \subset C$ that is invariant under the perturbed equation

$$\dot{u}(t) = f(u_t) + g(u_t). \tag{7.3}$$

There exists a neighborhood $O \subset C$ of M_0 such that, for $\|g\|_1$ sufficiently small, the manifold M_g is the maximal invariant set for (7.3) *which is contained in O. The manifold M_g depends continuously in g, in the sense that M_g can be made arbitrarily close to M_0 in the Hausdorff metric by choosing $\|g\|_1$ sufficiently close to zero. Furthermore, there exist C^k-manifolds U_g, S_g with $U_g \cap O$ negatively invariant and $S_g \cap O$ positively invariant under* (7.3) *such that $M_g = S_g \cap U_g \cap O$ and*

$$|u_t(\phi, g)| \leqq C|\phi|\, e^{\sigma t}, \qquad t \geqq 0, \quad \text{for } \phi \in (S_g \cap O),$$
$$|u_t(\phi, g)| \leqq C|\phi|\, e^{-\sigma t}, \qquad t \leqq 0, \quad \text{for } \phi \in (U_g \cap O)$$

for some constants C, $\sigma > 0$.

Proof. First, we introduce a system of coordinates around M_0 as indicated in § 5. For each fixed $\omega \in M_0$, the system in coordinate form (5.8) can be written as an equation (6.1)-(6.3), where we take for Λ the Banach space of bounded continuously differentiable functions from C into R^q which have bounded first derivative, taken with the uniform C^1-norm and take $\lambda = g$. As a consequence of Theorem 5.1, the hypotheses (H_1) to (H_4) of § 6 are all satisfied with $\alpha > k\alpha_0$. The only hypothesis which is necessary for applicability of the results in § 6 and is not necessarily fulfilled is that contained in (H_2'), namely that the functions n, u, s of $(t, x, y, \zeta, \lambda)$ are globally Lipschitzian in x, y, ζ, and the requirement that they admit a Lipschitz constant D satisfying (6.9). Consequently these functions have to be "cut-off" and replaced by functions $\bar{n}$, $\bar{u}$, $\bar{s}$ which agree with n, u, s for $|x|$, $|y|$, $|\zeta|$ sufficiently small and are globally Lipschitzian in x, y, ζ with a Lipschitz constant satisfying (6.9).

Let α_0, α, K be as in Theorem 5.1 and let $D > 0$ be chosen to satisfy (6.9). Assume $0 < \mu \leqq \mu_0$, $0 < \varepsilon \leqq \varepsilon_0$ and $B(\mu, \varepsilon)$ is as in hypothesis (H_2) of § 6. Let us consider a C^∞ function $\nu: R^+ \to [0, 1]$ such that

$$\nu(\rho) \in \begin{cases} \{1\} & \text{if } \rho/[\mu^2(2+r)] \leqq 1/4, \\ (0,1) & \text{if } \frac{1}{4} < \rho/[\mu^2(2+r)] < 1, \\ \{0\} & \text{if } 1 \leqq \rho/[\mu^2(2+r)] \end{cases}$$

and $0 \leqq -\nu'(\rho) \leqq 2/[\mu^2(2+r)]$ for $\rho \geqq 0$, and a C^∞ function $.R^+ \to [0, 1]$ such that

$$\sigma(\rho) \in \begin{cases} \{1\} & \text{if } \rho \leqq \varepsilon/2, \\ (0,1) & \text{if } \varepsilon/2 < \rho < \varepsilon, \\ \{0\} & \text{if } \varepsilon \leqq \rho. \end{cases}$$

We define the function $\bar{n}$: $R \times R^{d_N} \times R^{d_U} \times L \times \{\lambda \in \Lambda: \|\lambda\| \leqq \varepsilon_0\}$ so that it satisfies

$$\bar{n}(t, x, y, \zeta, \lambda) = \sigma(\varepsilon)\nu\left(|x|^2 + |y|^2 + \int_{-r}^{0} |\zeta(\tau)|^2\, d\tau\right) n(t, x, y, \zeta, \lambda)$$

for $t \in R$, $|x|$, $|y|$, $|\zeta| \leqq \mu$, $\|\lambda\| \leqq \varepsilon$, vanishing outside this region, and define $\bar{u}$, $\bar{s}$ in a similar way. Then, over the region $t \in R$, $|x|$, $|y|$, $|\zeta| \leqq \mu/2$, $\|\lambda\| \leqq \varepsilon/2$, we have $\bar{n} = n$,

$\bar{u}=u$, $\bar{s}=s$. It remains to show that $\bar{n}$, $\bar{u}$, $\bar{s}$ are globally Lipschitzian in x, y, ζ with Lipschitz constant D.

Let $t\in R$, $\|\lambda\|\leqq \varepsilon$ and $V=\{(x,y,\zeta)\in R^{d_N}\times R^{d_U}\times L\colon |x|,|y|,|\zeta|\leqq \mu\}$. If (x,y,ζ), $(\bar{x},\bar{y},\bar{\zeta})\in V$, then

$$\begin{aligned}
&|\bar{n}(t,x,y,\zeta,\lambda)-\bar{n}(t,\bar{x},\bar{y},\bar{\zeta},\lambda)|\\
&\leqq\left|\nu\left(|x|^2+|y|^2+\int_{-r}^{0}|\zeta(\tau)|^2\,d\tau\right)-\nu\left(|\bar{x}|^2+|\bar{y}|^2+\int_{-r}^{0}|\bar{\zeta}(\tau)|^2\,d\tau\right)\right||n(t,x,y,\zeta,\lambda)|\\
&\qquad+\nu\left(|\bar{x}|^2+|\bar{y}|^2+\int_{-r}^{0}|\bar{\zeta}(\tau)|^2\,d\tau\right)|n(t,x,y,\zeta,\lambda)-n(t,\bar{x},\bar{y},\bar{\zeta},\lambda)|\\
&\leqq\frac{2}{\mu^2(2+r)}2\mu(2+r)(|x-\bar{x}|+|y-\bar{y}|+|\zeta-\bar{\zeta}|)B(\mu,\varepsilon)3\mu\\
&\qquad+B(\mu,\varepsilon)(|x-\bar{x}|+|y-\bar{y}|+|\zeta-\bar{\zeta}|)\\
&=13B(\mu,\varepsilon)(|x-\bar{x}|+|y-\bar{y}|+|\zeta-\bar{\zeta}|).
\end{aligned}$$

If $(x,y,\zeta)\in V$ and $(\bar{x},\bar{y},\bar{\zeta})\notin V$ then there exists a point (x^*,y^*,ζ^*) lying in the intersection of the boundary of V and the straight line joining the points (x,y,ζ) and $(\bar{x},\bar{y},\bar{\zeta})$. Thus $\bar{n}(t,\bar{x},\bar{y},\bar{\zeta},\lambda)=\bar{n}(t,x^*,y^*,\zeta^*,\lambda)=0$ and

$$\begin{aligned}
|\bar{n}(t,x,y,\zeta,\lambda)-\bar{n}(t,\bar{x},\bar{y},\bar{\zeta},\lambda)|&=|\bar{n}(t,x,y,\zeta,\lambda)-\bar{n}(t,x^*,y^*,\zeta^*,\lambda)|\\
&\leqq 13B(\mu,\varepsilon)(|x-\bar{x}|+|y-\bar{y}|+|\zeta-\bar{\zeta}|).
\end{aligned}$$

If $(x,y,\zeta)\notin V$ and $(\bar{x},\bar{y},\bar{\zeta})\notin V$, then $\bar{n}(t,x,y,\zeta,\lambda)=\bar{n}(t,\bar{x},\bar{y},\bar{\zeta},\lambda)=0$. It follows that $\bar{n}$ is globally Lipschitzian in x, y, ζ with Lipschitz constant D, provided μ and ε are taken so small that $13B(\mu,\varepsilon)<D$.

The preceding reasoning also applies to $\bar{u}$, $\bar{s}$. Consequently, the functions $\bar{n}$, $\bar{u}$, $\bar{s}$ satisfy the hypothesis (H_2') of § 6 with a global Lipschitz constant D which satisfies (6.9). We are now in a situation where the theorems of § 6 can be applied to the system in coordinate form, with n, u, s replaced by $\bar{n}$, $\bar{u}$, $\bar{s}$. It remains to see what these theorems imply for the system (7.3) in the phase space C. For this we need to take into account the redundancy built into the system of coordinates introduced around the manifold M_0.

Each point of C lying close to M_0 is represented, in the system of coordinates around M_0 which was introduced in § 5, by a set of points (ω,x,y,ζ) which contains exactly one element with the second coordinate equal to zero. Because the integral manifold introduced in Theorem 6.2,

$$M_\lambda=\{(t,x,y,\zeta)\in R\times R^{d_N}\times R^{d_U}\times L\colon y=h_1(t,x,\lambda),\ \zeta=h_2(t,x,\lambda)\},$$

is, for the system in coordinate form, the maximal integral manifold contained in sets with the y, ζ-coordinates bounded, and because the functions n, u, s and $\bar{n}$, $\bar{u}$, $\bar{s}$ agree for x, y, ζ sufficiently small, it follows that there exists a neighborhood of zero $V\subset R\times R^{d_N}\times R^{d_U}\times L$ such that $M_\lambda\cap V$ is the maximal integral manifold contained in V. Therefore $M_\lambda\cap V$ represents in coordinate form a patch of a submanifold M_g of C which is invariant under (7.3). We recall that the system (7.3) is represented in coordinate form by a family of systems of the form (6.1)-(6.3), one for each $\omega\in M$ which is taken as initial condition for the solution of $\dot{u}(t)=f(u_t)$ used as center of the moving coordinate system. Based on this and on the redundancy built in the system of coordinates used, we can consider a function H defined from $M_0\times\{g\in BC^k(C;R^n)\colon \|g\|\leqq\varepsilon\}$ into C so that $H(\omega,g)$ is the point of C represented in coordinate form by $(\omega, 0, h_1^\omega(0,0,g), h_2^\omega(0,0,g))$ where $h_1 = h_1^\omega$, $h_2 = h_2^\omega$ are the functions considered above for M_λ for the particular system in coordinate form which corresponds to take the moving coordinate system centered on the solution of $\dot{u}(t) = f(u_t)$, $u_0 = \omega$. Then $M_g = \{H(\omega, g)\colon \omega \in M_0\}$, and its properties stated in the theorem follow directly from the theorems of § 6 about the properties of the functions h_1, h_2, if we recall the redundancy built in the system of coordinates, namely that changes of $h_1^\omega(0,0,g)$, $h_2^\omega(0,0,g)$ with ω can be identified with changes of $h_1(0,x,g)$, $h_2(0,x,g)$ with ω fixed and x changing.

The manifolds U_g and S_g can be treated in a similar way. QED

Remark. The persistence of hyperbolic invariant manifolds for FDEs was studied above for the case of retarded FDEs on euclidean space R^q. As indicated in § 4, the same result for retarded FDEs on a smooth, finite dimensional, separable and connected manifold follows from the result in euclidean space.

Acknowledgment. I wish to thank Professor George Sell for his helpful remarks and criticisms while this work was in progress.

ON PERIODIC SOLUTIONS OF A THERMOSTAT EQUATION*

GUSTAF GRIPENBERG†

Abstract. An equation describing the regulation of, for example, temperature with the aid of a thermostat is studied with emphasis on the question whether there are periodic solutions and if there can be several solutions with different periods.

Key words. thermostat, periodic solutions, Volterra equation

AMS(MOS) subject classifications. 93C10, 45D05

1. Introduction. The purpose of this paper is to study periodic solutions of equations describing, for example, temperature regulation by a thermostat. Therefore one considers a situation where a heater is turned ON if the temperature at some fixed point drops to a level θ_{low} and is turned OFF if the temperature rises to a level θ_{high} where one has $\theta_{\text{low}} < \theta_{\text{high}}$. Thus it will be a basic assumption in this paper that the control-function can only take two values. We will not go into further details about how the heating process affects the temperature since one can show that under quite reasonable assumptions one obtains an equation of the form

$$y(t) = \int_{-\infty}^{t} a(t-s)u(s)\,ds, \qquad t \in \mathbf{R} \tag{1}$$

where $y(t)$ is the normalized temperature at the thermostat at time t, $u(t)=1$ if the heater is turned ON at time t; otherwise $u(t)=0$ and a is an integrable real function on $\mathbf{R}^+ = [0, \infty)$ so that $\int_{\mathbf{R}^+} a(t)\,dt = 1$. The temperature has here been normalized in such a way that without heating it approaches 0 and with uninterrupted heating it approaches one. If one considers the heating process known for time $t<0$ and also allows some additive external influence on the temperature, then (1) becomes

$$y(t) = \int_0^t a(t-s)u(s)\,ds + f(t), \qquad t \in \mathbf{R}^+, \quad u(0) = u_0 \in \{0, 1\}. \tag{2}$$

For some derivations of equations like (1) and (2) where diffusion and other effects are taken into account, see e.g. [1] and [2].

The equations (1) and (2) do not involve the crucial part of the formulation of the problem, i.e., the thermostat control or the dependence of u on y. In this paper the relation is taken to be the following one: If $u(t)=1$ and y reaches the value θ_{high} at time t, then $u(t+)=0$ and conversely at the lower limit. Below we will also use a weaker formulation of this condition.

Concerning the question of existence of solutions we take a much more straightforward approach than the one used in [1] and [2], since here we avoid multivalued functions completely. The main problem addressed is therefore whether there exist periodic solutions and if there can be periodic solutions with different periods. Concerning the first question it is intuitively clear that periodic solutions should exist and concerning the second one a reasonable guess (that turns out to be correct) is that it all depends on the function a. The question of existence of periodic solutions is also considered in [3] but there much stronger assumptions are made on the function a and the limits θ_{high} and θ_{low}. It should, however, be pointed out that here only the

* Received by the editors October 31, 1985; accepted for publication (in revised form) May 13, 1986.

† Helsinki University of Technology, Institute of Mathematics, SF-02150 Espoo 15, Finland.

existence of so-called weak solutions (to be defined below) is established in the general case.

The stability of the periodic solutions will not be studied in this paper.

2. Statements of results. First we define the concepts related to the thermostat regulation.

DEFINITION 1. If $I \subset \mathbf{R}$ is an interval and $y: I \to \mathbf{R}$ is a continuous function, then a function $u: I \to \{0, 1\}$ is *weakly thermostat controlled* by y with respect to the higher limit θ_{high} and the lower limit θ_{low} on the interval I provided that u is left-continuous with right-hand limits on I, and for each $t \in I$ the following conditions hold:

(i) $u(t) = 1$ if $y(t) < \theta_{\text{low}}$,

(ii) $u(t) = 0$ if $y(t) > \theta_{\text{high}}$,

(iii) if $u(t) - u(t+) = 1$, then $\theta_{\text{high}} \in \{y(s) \mid s \in I, s \leqq t \text{ and } u(r) = 1 \text{ for all } r \in (s, t]\}$,

and

(iv) if $u(t) - u(t+) = -1$, then $\theta_{\text{low}} \in \{y(s) \mid s \in I, s \leqq t \text{ and } u(r) = 0 \text{ for all } r \in (s, t]\}$.

The function $u: I \to \{0, 1\}$ is *strictly thermostat controlled* by y with respect to the limits θ_{high} and θ_{low} if it is weakly thermostat controlled by y with respect to these limits and in addition for every $t \in I$ the following conditions hold:

(iii′) If $y(t) = \theta_{\text{high}}$ and $u(t) = 1$, then $u(t+) = 0$, and

(iv′) if $y(t) = \theta_{\text{low}}$ and $u(t) = 0$, then $u(t+) = 1$.

From this definition one sees that if u is weakly but not strictly thermostat controlled by y, then y must at some time have a local maximum equal to θ_{high} (or minimum equal to θ_{low}).

The reason for introducing the concept of a weakly thermostat controlled function is that in the general case we only obtain the existence of periodic solutions where u is weakly controlled by y. But this seems to be more of a mathematical than a real-world problem.

For convenience we define exactly what we mean by solutions.

DEFINITION 2. A pair (y, u) is a strict/weak thermostat controlled solution of (1) with respect to the limits θ_{high} and θ_{low} if $y \in C(\mathbf{R}; \mathbf{R})$, u is strictly/weakly thermostat controlled by y on $\mathbf{R}$ with respect to these limits and (1) holds. Similarly a pair (y, u) is a *strict/weak thermostat controlled solution* of (2) with respect to θ_{high} and θ_{low} if $y \in C(\mathbf{R}^+; \mathbf{R}^+)$, u is strictly/weakly thermostat controlled by y on $\mathbf{R}^+$ with respect to these limits and (2) holds.

Now we can give our basic existence result formulated for (2).

THEOREM 1. *Assume that $\theta_{\text{low}} < \theta_{\text{high}}$ are real numbers, $a \in L^1_{\text{loc}}(\mathbf{R}^+; \mathbf{R})$, $f \in C(\mathbf{R}^+; \mathbf{R})$ and let $u_0 \in \{0, 1\}$ be such that $u_0 = 1$ if $f(0) < \theta_{\text{low}}$ and $u_0 = 0$ if $f(0) > \theta_{\text{high}}$. Then there exists unique functions $y \in C(\mathbf{R}^+; \mathbf{R})$ and $u: \mathbf{R}^+ \to \{0, 1\}$ such that (y, u) is a strict thermostat solution of (2) with respect to the limits θ_{high} and θ_{low}.*

Observe that the theorem says nothing about the uniqueness of weakly thermostat controlled solutions; in fact it is easy to see that if there exists such a solution that is not thermostat controlled in the strict sense, then this solution cannot be unique.

Next we consider the question of existence of periodic solutions and here we use the further normalization that the $0 < \theta_{\text{low}} < \theta_{\text{high}} < 1$ and that $\int_{\mathbf{R}^+} a(s)\, ds = 1$.

THEOREM 2. *Assume that $0 < \theta_{\text{low}} < \theta_{\text{high}} < 1$ and that $a \in L^1(\mathbf{R}^+; \mathbf{R})$ satisfies $\int_{\mathbf{R}^+} a(s)\, ds = 1$. Then there exists periodic functions $y \in C(\mathbf{R}; \mathbf{R})$ and $u: \mathbf{R} \to \{0, 1\}$ (having the same period) so that (y, u) is a weak thermostat controlled solution of (1) with respect to the limits θ_{high} and θ_{low}.*

Next we investigate further some simple cases where we can prove that the periodic function u is strictly controlled by y. Note, however, that we in each case claim that every weak solution is in fact a strict one (which is not true in general), and not that there always exists a strict thermostat controlled solution (which one would expect to be the case for all kernels a).

THEOREM 3. *Let the assumptions of Theorem 2 hold. Assume in addition that a is nonincreasing on $(0, \infty)$ and not equal to a nonzero constant on any open interval. Then every periodic weak solution (y, u) of equation (1) is a strict solution.*

The previous result is quite trivial. The next one is slightly harder to prove. Recall that a function c is completely monotone if it is infinitely many times differentiable and $(-1)^j c^{(j)}(t) \geqq 0$ for all $j \geqq 0$.

THEOREM 4. *Let the assumptions of Theorem 2 hold. Assume in addition that $a(t) = \int_0^t a_1(t-s)a_2(s)\,ds$, $t > 0$ where a_1 and a_2 are locally integrable on $\mathbf{R}^+$, and completely monotone on $(0, \infty)$. Then every periodic weak solution (y, u) of (1) is a strict solution.*

Unfortunately, the assumption above on the function a is apparently not satisfied in the example given in [2], but if in that example the thermostat measures the temperature at an endpoint of the rod studied there, then it will be satisfied.

Finally we consider the question of existence of several periodic solutions with different minimal periods. This will be done only in the symmetric case $1-\theta_{\text{high}} = \theta_{\text{low}}$ and for the very special kernels $a_m(t) = (1/m!)t^m e^{-t}$ but these results can of course be slightly extended with the aid of perturbation arguments. ($\lfloor t \rfloor$ is the largest integer $\leqq t$.)

THEOREM 5. *Let $m \geqq 0$ and $a(t) = (1/m!)t^m e^{-t}$, $t \geqq 0$. Then there exist numbers $\alpha > 0$ such that (1) has $\lfloor m/4 \rfloor + 1$ different strict periodic thermostat controlled solutions (y, u) with respect to the limits $\frac{1}{2} + \alpha$ and $\frac{1}{2} - \alpha$.*

3. Proof of Theorem 1. We take $u(0) = u_0$, $y(0) = f(0)$. Next we define two sequences of numbers $\{\alpha_j\}_{j=0}^{\infty}$ and $\{t_j\}_{j=0}^{\infty}$ as follows: If $y(0) = \theta_{\text{high}}$ then $\alpha_0 = 0$ and if $y(0) = \theta_{\text{low}}$, then $\alpha_0 = 1$ and else $\alpha_0 = u_0$. Let $t_0 = 0$ and assume that we have already defined the numbers α_j and t_j for $j = 0, 1, \cdots, k$. As one would expect, we define

$$u(t) = \alpha_j \qquad t \in (t_j, t_{j+1}], \quad j \geqq 0.$$

Now let the function v_k be defined by

$$v_k(t) = \begin{cases} \int_0^t a(t-s)u(s)\,ds + f(t) & \text{when } t \in [0, t_k]; \\ \int_0^{t_k} a(t-s)u(s)\,ds + \int_{t_k}^t a(t-s)\alpha_k\,ds + f(t) & \text{when } t > t_k. \end{cases}$$

We see that v_k is a continuous function and we define t_{k+1} by

$$t_{k+1} \overset{\text{def}}{=} \inf\{t > t_k \mid \alpha_k(v_k(t) - \theta_{\text{high}}) + (1-\alpha_k)(v_k(t) - \theta_{\text{low}}) = 0\}.$$

Thus t_{k+1} is the first time $v_k(t)$ reaches θ_{high} if $\alpha_k = 1$ and otherwise the first time $v(t)$ reaches θ_{low}. Finally we define $\alpha_{k+1} = 1 - \alpha_k$. If $t_{k+1} = \infty$, then we do not have to choose any further points.

We define y to be equal to the right-hand side of (2) and we immediately see that u is strictly thermostat controlled by y on its domain of definition. It remains to prove that $\lim_{j\to\infty} t_j = \infty$. To see this we observe that when $j > 1$, then $|v_{j-1}(t_j) - v_{j-1}(t_{j-1})| = \theta_{\text{high}} - \theta_{\text{low}}$. Furthermore, since f is continuous, a is locally integrable and u only takes the values 1 and 0 we see that on each bounded interval the functions $\{v_j\}_{j=1}^{\infty}$ are equicontinuous and as $\theta_{\text{high}} > \theta_{\text{low}}$ this implies that $\inf_{t_j < T, j > 1}(t_j - t_{j-1}) > 0$. Therefore $\lim_{j\to\infty} t_j = \infty$. This completes the proof. □

We remark that one can have another notion of strict solution if one defines the switching times to be the last time before the temperature rises above the upper limit if the heater is ON or drops below the lower limit if the heater is OFF, that is, one would define the numbers $\{t_j\}$ by

$$t_{k+1} \overset{\text{def}}{=} \inf\{t > t_k \mid \alpha_k(v_k(t) - \theta_{\text{high}}) + (1-\alpha_k)(\theta_{\text{low}} - v_k(t)) > 0\}.$$

4. Proof of Theorem 2. The proof will be based on the following idea: Assume that u is given on $\mathbf{R}^-$ so that it is periodic with period $T+S$, $u(t)=0$ when $t \in (-S, 0]$ and $u(t)=1$ when $t \in (-T-S, -S]$. Now take $u(0+)=1$ and solve equation (1) with u as given on $\mathbf{R}^-$. At some T' the function y reaches θ_{high}, and the value of u is switched to zero. At some later time $T'+S'$ the function reaches θ_{low} again. If we can find a fixed-point of the mapping $(S, T) \mapsto (S', T')$, then we have also found a periodic solution. Now the problem is that this mapping could conceivably be discontinuous and therefore an approximation argument must be used.

Let us for the moment assume that

$$a \in C^1(\mathbf{R}^+; \mathbf{R}) \quad \text{and} \quad a' \in L^1(\mathbf{R}^+; \mathbf{R}). \tag{3}$$

For each pair of nonnegative numbers T and S, define the set $E_{T,S}$ as follows:

$$E_{T,S} = \bigcup_{m=-\infty}^{\infty} (m(S+T), m(S+T)+T] \tag{4}$$

so that $\chi_{E_{T,S}}$ is a function that is zero on intervals of length S and one on intervals of length T. Now define the function $\psi_{T,S}$ by

$$\psi_{T,S}(t) = \int_{-\infty}^{0} a(t-s)\chi_{E_{T,S}}(s)\, ds, \qquad t \in \mathbf{R}^+.$$

It follows from (3) that $\psi_{T,S}$ is Lipschitz-continuous. In fact the Lipschitz-constant will always be less than the number $c \overset{\text{def}}{=} \int_{\mathbf{R}^+} |a'(s)|\, ds + 1$.

Let ε be a number so that $0 < \varepsilon < \frac{1}{2}(\theta_{\text{high}} - \theta_{\text{low}})$ and define

$$f_h(\varepsilon, s) = c \max\left\{0, 1 - \frac{\theta_{\text{high}} - s}{\varepsilon}\right\};$$

$$f_l(\varepsilon, s) = c \min\left\{0, -1 - \frac{\theta_{\text{low}} - s}{\varepsilon}\right\}.$$

Now let v_ε be the solution of the equation

$$v_\varepsilon(t) = \int_0^t f_h(\varepsilon, v_\varepsilon(s))\, ds + \int_0^t a(s)\, ds + \psi_{T,S}(t), \qquad t \in \mathbf{R}^+.$$

It follows from standard results that this equation has a unique solution. If $v_\varepsilon(0) \geqq \theta_{\text{high}}$ then we define $T'=0$; otherwise we let

$$T' \overset{\text{det}}{=} \inf\{t > 0 \mid v_\varepsilon(t) = \theta_{\text{high}}\}.$$

To see that we always have $T' < \infty$ we have only to recall that $\psi_{T,S}(t) \to 0$ as $t \to \infty$, $f_h(\varepsilon, v_\varepsilon(s)) \geqq 0$ and that $\int_{\mathbf{R}^+} a(s)\, ds = 1 > \theta_{\text{high}}$.

To obtain S' we let w_ε be the solution of the equation

$$w_\varepsilon(t) = \int_{T'}^t f_l(\varepsilon, w_\varepsilon(s))\, ds + \int_0^{T'} a(t-s)\, ds + \psi_{T,S}(t), \qquad t \geqq T'$$

and define $S'=0$ if $w_\varepsilon(T')\leqq\theta_{\text{low}}$ and otherwise

$$S'\overset{\text{def}}{=}\inf\{t>T'\,|\,w_\varepsilon(t)=\theta_{\text{low}}\}-T'.$$

Again we conclude that the number S' must be finite.

Now we have constructed a mapping $G_\varepsilon:(T,S)\mapsto(T',S')$. To see that the mapping G_ε is continuous we have only to check that $\psi_{T,S}(t)$ depends continuously on T and S for each t, use a standard result about the continuous dependence of solutions of ordinary differential equations upon data and finally note that it follows from our definition of the functions f_h and f_l that $v_\varepsilon'(T')\geqq 1$ and $w_\varepsilon'(S')\leqq -1$.

We claim that there exist positive numbers δ and τ (independent of ε) such that G_ε maps the set $\{(T,S)\,|\,0\leqq T, S\leqq\tau, T+S\geqq\delta\}$ into itself. Clearly it is sufficient to choose τ so large that $\int_\tau^\infty|a(s)|\,ds<\min\{1-\theta_{\text{high}},\theta_{\text{low}}\}$. Furthermore we always have

$$\operatorname{var}\left(\psi_{T,S}(t)+\int_0^t a(s)\,ds;[0,T']\right)$$
$$+\operatorname{var}\left(\psi_{T,S}(t)+\int_0^{T'} a(t-s)\,ds;[T',T'+S']\right)\geqq\theta_{\text{high}}-\theta_{\text{low}}-2\varepsilon,$$

and hence we can see that we can choose $\delta\leqq(\theta_{\text{high}}-\theta_{\text{low}}-2\varepsilon)/\int_{\mathbf{R}^+}|a'(s)|\,ds$.

Now it follows from Brouwer's Fixed-Point theorem that the mapping $G_\varepsilon:(T,S)\mapsto(T',S')$ has a fixed point that we call $(T_\varepsilon,S_\varepsilon)$. It is easy to check that neither of these numbers can be zero.

We define the function u_ε to be the characteristic function of the set $E_{T_\varepsilon,S_\varepsilon}$ and let y_ε be defined by

$$y_\varepsilon(t)=\int_{-\infty}^t a(t-s)u_\varepsilon(s)\,ds,\qquad t\in\mathbf{R}.$$

Observe that u_ε is not thermostat controlled by y_ε. We do however know that

$$(5)\qquad \begin{aligned} &u_\varepsilon(t)<\theta_{\text{high}}, && t\in[0,T_\varepsilon],\\ &y_\varepsilon(t)>\theta_{\text{low}}, && t\in[S_\varepsilon,S_\varepsilon+T_\varepsilon],\end{aligned}$$

as one can easily see from the definition of the mapping $(T,S)\mapsto(T',S')$ and the fact that S_ε and T_ε are positive.

Next we let $\varepsilon\downarrow 0$ and observe that due to the compactness we may choose a subsequence $\{\varepsilon_j\}$ such that the numbers T_{ε_j} and S_{ε_j} converge towards some positive numbers T^* and S^*. We define the function u by

$$u(t)=\chi_{E_{T^*,S^*}}(t),\qquad t\in\mathbf{R},$$

and

$$y(t)=\int_{-\infty}^t a(t-s)u(s)\,ds,\qquad t\in\mathbf{R}.$$
